AVERAGES OVER SPHERES FOR KINETIC TRANSPORT EQUATIONS WITH VELOCITY DERIVATIVES IN THE RIGHT-HAND SIDE*

NIKOLAOS BOURNAVEAS† AND SUSANA GUTIÉRREZ‡

Abstract. We prove estimates in hyperbolic Sobolev spaces $H^{s,\delta}(R^{1+d})$, $d \geq 3$, for velocity averages over spheres of solutions to the kinetic transport equation $\partial_t f + v \cdot \nabla_x f = \Omega_v^{i,j} g$, where $\Omega_v^{i,j} g$ are tangential velocity derivatives of g. Our results extend to all dimensions earlier results of Bournaveas and Perthame in dimension two [*J. Math. Pures Appl.*, 9 (2001), pp. 517–534]. We construct counterexamples to test the optimality of our results.

Key words. velocity-averaging lemmas, kinetic transport equation, hyperbolic Sobolev spaces

1. Introduction.

Consider the kinetic transport equation

$$\partial_t f + v \cdot \nabla_x f = g,$$

where $f, g : R_t \times R_x^d \times R_v^d \to R$. It is well known that averaging with respect to the velocity variable v has a smoothing effect which can be measured in classical Sobolev spaces. For example, in all dimensions, the average over the unit ball

$$\rho_{_B}(t,x) = \int_{|v|\leq 1} f(t,x,v)dv$$

is smoother than f by $1/2$ derivatives in L^2, and we have the estimate

$$\|\rho_{_B}\|_{H^{1/2}(R^{1+d})} \leq C\left(\|f\|_{L^2(R^{1+2d})} + \|g\|_{L^2(R^{1+2d})}\right).$$

Results of this type are known as averaging lemmas. They were first discovered in [24, 23] and developed further by many authors [4, 5, 9, 11, 12, 13, 14, 15, 17, 19, 20, 21, 25, 26, 27, 28, 29, 33, 34, 37]. We refer the reader to [3, 35] for a review and an extensive bibliography.

Averages over spheres

$$\rho_{_S}(t,x) = \int_{S^{d-1}} f(t,x,v)\, d\sigma(v)$$

were first studied in [7] and later in [8]. These averages appear in the equation of radiative transfer, a phenomenon that describes the scattering of photons in a hot medium [1, 2, 10, 22, 36]. They also appear in certain kinetic models of chemotaxis when the velocity of the cells is normalized to $|v| = 1$ [16]. It turns out that in

dimensions $d \geq 3$ averages over spheres gain $1/2$ derivatives in L^2 [7, Theorem 1] and we have the estimate

$$\|\rho_S\|_{H^{1/2}(R^{1+d})} \leq C\left(\|f\|_{L^2(R\times R^d\times S^{d-1})} + \|g\|_{L^2(R\times R^d\times S^{d-1})}\right). \tag{1.1}$$

Thus, if $d \geq 3$, ρ_S gains the same amount of regularity as averages over balls, although it is an average over a lower-dimensional set. Moreover, the estimate for spheres implies the estimate for balls (see Remark 1 in [7]).

In dimension $d = 2$ averages over spheres gain only $1/4$ derivatives, but the "missing" regularity can be recovered in the so-called hyperbolic Sobolev spaces $H^{s,\delta}(R^{1+d})$ [6, 30, 31, 32, 38]. More precisely [7, Theorem 2],

$$\|\rho_S\|_{H^{1/4,1/4}(R^{1+2})} \leq C\left(\|f\|_{L^2(R\times R^2\times S^1)} + \|g\|_{L^2(R\times R^2\times S^1)}\right),$$

where

$$\|F\|_{H^{s,\delta}(R^{1+d})} = \left\|w_+(\tau,\xi)^s w_-(\tau,\xi)^\delta \widehat{F}(\tau,\xi)\right\|_{L^2(R_\tau\times R^d_\xi)}, \tag{1.2}$$

$w_\pm(\tau,\xi) = 1 + ||\tau| \pm |\xi||$, and $\widehat{F}$ is the space-time Fourier transform of F.

In [8] these spaces were used to further improve estimate (1.1). We have [8, Theorem 1], when $d \geq 3$, $d \neq 7$,

$$\|\rho_S\|_{H^{s,\delta}(R^{1+d})} \leq C\,\|f\|_{L^2(R\times R^d\times S^{d-1})} + C\,\|g\|_{L^2(R\times R^d\times S^{d-1})}, \tag{1.3a}$$

provided that

$$s + \delta \leq 1/2,\ s \leq \min\left\{\frac{d-1}{4}, 1\right\}. \tag{1.3b}$$

This allows us to take s larger than the classical $1/2$, provided that we compensate by using a negative δ. Moreover, in regions where $||\tau| - |\xi||$ is small (near the cone $|\tau| = |\xi|$) we have $w_+^s w_-^\delta \simeq w_+^s$, and we gain $s \geq 1/2$ derivatives. When $d = 7$ we have the same estimate but with a logarithmic loss:

$$\|\rho_S\|_{H^{s,\delta}_{\log}(R^{1+d})} \leq C\left(\|f\|_{L^2(R\times R^d\times S^{d-1})} + \|g\|_{L^2(R\times R^d\times S^{d-1})}\right), \quad d = 7,$$

where

$$\|F\|_{H^{s,\delta}_{\log}(R^{1+d})} = \left\|\frac{w_+(\tau,\xi)^s w_-(\tau,\xi)^\delta}{\left(1 + \log\frac{w_+(\tau,\xi)}{w_-(\tau,\xi)}\right)^{1/2}}\widehat{F}(\tau,\xi)\right\|_{L^2(R_\tau\times R^d_\xi)}.$$

Now we turn our attention to equations with right-hand sides containing derivatives with respect to the velocity variable:

$$\partial_t f + v\cdot\nabla_x f = \partial_v^m g.$$

This case is of great interest in applications. For example, the Vlasov part of the Vlasov–Maxwell system has this structure with $m = 1$. It is well known (see [24, 23]) that in this case averages of the form $\int_{R^d} f(t,x,v)\phi(v)dv$, where $\phi(v)$ is a smooth cut-off function, gain $\frac{1}{2(m+1)}$ derivatives in L^2. In particular, if $m = 1$, then the gain is $1/4$ derivatives. The proof of these results uses an integration by parts which removes the velocity derivatives from the function g.

Consider now the case of spheres. In order to be able to integrate by parts on spheres we are forced to restrict ourselves to equations with tangential v-derivatives in the right-hand side:

$$\partial_t f + v \cdot \nabla_x f = \Omega_v^{i,j} g, \tag{1.4}$$

where

$$\Omega_v^{i,j} g = v_i \frac{\partial g}{\partial v_j} - v_j \frac{\partial g}{\partial v_i}, \quad 1 \le i, j \le d.$$

In this case, if $d \ge 3$, the optimal gain is $1/4$ derivatives (the same gain as for balls) [7, Theorem 3]. In view of the discussion above, one would expect the gain in $d = 2$ dimensions to be $1/8$ derivatives. However, the tangential derivatives introduce a special structure (see, for example, (2.3) below and the discussion in [8]) reminiscent of the Klainerman null forms structure for the wave equation [30, 31, 32], which allows for better estimates. By using this observation the expected classical gain of $1/8$ derivatives was improved in [7] to $1/7$ derivatives and further improved in [8] to $1/6$ derivatives, and it was also shown that this result is optimal.

If one considers the hyperbolic Sobolev spaces, it is also possible to prove estimates with a total of $s + \delta = 1/4$ derivatives. In this setting, the two-dimensional case has been previously considered in [7, 8]. More precisely, in [7] it was shown that $\rho_{_S} \in H^{1/16,3/16}(R^{1+2})$. This was improved in [8] to $\rho_{_S} \in H^{1/8,1/8}(R^{1+2})$, and it was also shown that this is optimal.

In this paper we study the regularity of velocity averages over spheres for solutions of (1.4) in hyperbolic Sobolev spaces in dimensions $d \ge 3$. Recall first the following result from [7].

Let $d \ge 3$, and let $f \in L^2(R_t \times R_x^d \times \ S_v^{d-1})$ be a solution of (1.4) with $g \in L^2(R_t \times R_x^d \times \ S_v^{d-1})$. Then the velocity average over the unit sphere $\rho_{_S}(t,x) = \int_{S^{d-1}} f(t,x,v) d\sigma(v)$ satisfies

$$\|\rho_{_S}\|_{H^{1/4}(R\times R^d)} \le C \left[\|f\|_{L^2(R\times R^d\times \ S^{d-1})} + C \|g\|_{L^2(R\times R^d\times \ S^{d-1})} \right]. \tag{1.5}$$

We shall improve this result by showing that $\rho_{_S} \in H^{s,\delta}$ for certain choices of (s,δ) depending on the dimension d. More precisely we have the following.

THEOREM 1.1. *Let $d \ge 3$, and let $f \in L^2(R_t \times R_x^d \times \ S_v^{d-1})$ be a solution of* (1.4) *with $g \in L^2(R_t \times R_x^d \times \ S_v^{d-1})$. Define*

$$\begin{aligned} (s,\delta) &= \left(\frac{d-1}{6}, -\frac{2d-5}{12} \right) \quad if\ d \in \{3,4,5\}, \\ (s,\delta) &= \left(\frac{4}{5}, -\frac{11}{20} \right) \quad if\ d = 6, \\ (s,\delta) &= \left(1, -\frac{3}{4} \right), \quad if\ d \ge 7. \end{aligned} \tag{1.6}$$

Then the velocity average $\rho_{_S}(t,x) = \int_{S^{d-1}} f(t,x,v) d\sigma(v)$ satisfies

$$\|\rho_{_S}\|_{H^{s,\delta}(R^{1+d})} \le C \|f\|_{L^2(R\times R^d\times \ S^{d-1})} + C \|g\|_{L^2(R\times R^d\times \ S^{d-1})}, \ d \ne 5, 7, \tag{1.7a}$$

$$\|\rho_{_S}\|_{H^{s,\delta}_{\log}(R^{1+d})} \le C \|f\|_{L^2(R\times R^d\times \ S^{d-1})} + C \|g\|_{L^2(R\times R^d\times \ S^{d-1})}, \ d = 5, 7. \tag{1.7b}$$

Notice that in all cases we have $s+\delta = 1/4$, with $s > 1/4$ and $\delta < 0$. By comparing this result to the classical estimate (1.5) we see that it is possible to improve on the

"good derivative" w_+, provided that we make a sacrifice in the derivative w_-. Observe also that since $\delta = 1/4 - s$ and $s > 1/4$ we have

$$w_+^s w_-^\delta = w_+^{\frac{1}{4}} \left(\frac{w_+}{w_-}\right)^{s-\frac{1}{4}} \geq w_+^{\frac{1}{4}},$$

and therefore estimate (1.7) implies estimate (1.5). Moreover, near the cone $|\tau| = |\xi|$ we have $w_+^s w_-^\delta \simeq w_+^s$, because $w_- \simeq 1$, and therefore our estimate says that we gain $s > 1/4$ derivatives in this region. Notice also that, in contrast to (1.3), we gain even in $d = 3$ dimensions. This is due to the fact that we have not only the usual averaging smoothing effect and the flexibility of the $H^{s,\delta}$-spaces but also the special structure of the tangential derivatives.

It is possible to extend the validity of estimate (1.7) to a whole region of pairs (s, δ). We have the following.

THEOREM 1.2. *Let $d \geq 3$, and let $f \in L^2(R_t \times R_x^d \times S_v^{d-1})$ be a solution of* (1.4) *with $g \in L^2(R_t \times R_x^d \times S_v^{d-1})$. Let $s, \delta \in R$ be such that*

$$s + \delta \leq \frac{1}{4}, \tag{1.8a}$$

$$s \leq \frac{d-1}{6} \quad if\ d \in \{3,4,5\}, \tag{1.8b}$$

$$s \leq \frac{4}{5} \quad if\ d = 6, \tag{1.8c}$$

$$s \leq 1 \quad if\ d \geq 7. \tag{1.8d}$$

Then estimates (1.7) *are true.*

In the region $\{|\tau| > |\xi|\}$ in phase space the symbol of the operator $\partial_t + v \cdot \nabla_x$ satisfies $|\tau + v \cdot \xi| \geq |\tau| - |\xi| > 0$, and therefore it is reasonable to expect better estimates. Indeed, improved estimates in this region are contained in [7, 8]. We shall establish the following improvements to the results of Theorem 1.1. First, estimates (1.7) are valid in $\{|\tau| > |\xi|\}$ with the same s and with $\delta = 0$ (instead of a negative δ).

THEOREM 1.3. *Let $d \geq 3$, and let $f \in L^2(R_t \times R_x^d \times S_v^{d-1})$ be a solution of* (1.4) *with $g \in L^2(R_t \times R_x^d \times S_v^{d-1})$. Define*

$$s = \frac{d-1}{6} \quad if\ d \in \{3,4,5\}, \tag{1.9a}$$

$$s = \frac{4}{5} \quad if\ d = 6, \tag{1.9b}$$

$$s = 1 \quad if\ d \geq 7. \tag{1.9c}$$

Then the velocity average $\rho_s(t,x) = \int_{S^{d-1}} f(t,x,v) d\sigma(v)$ satisfies the following estimates in the classical Sobolev spaces $H^s(\{|\tau| > |\xi|\})$.

If $d \neq 5, 7$,

$$\|w_+(\tau,\xi)^s \widehat{\rho_s}(\tau,\xi)\|_{L^2(\{|\tau|>|\xi|\})} \tag{1.10a}$$

$$\leq C\left(\|f\|_{L^2(R\times R^d\times S^{d-1})} + \|g\|_{L^2(R\times R^d\times S^{d-1})}\right). \tag{1.10b}$$

If $d = 5, 7$,

$$\left\| w_+(\tau,\xi)^s \left[1 + \log \frac{w_+(\tau,\xi)}{w_-(\tau,\xi)}\right]^{-1/2} \widehat{\rho_s}(\tau,\xi) \right\|_{L^2(\{|\tau|>|\xi|\})} \tag{1.10c}$$

$$\leq C\|f\|_{L^2(R\times R^d\times S^{d-1})} + C\|g\|_{L^2(R\times R^d\times S^{d-1})}. \tag{1.10d}$$

Moreover, it is possible to prove $H^{s,\delta}$-estimates in all dimensions $d \geq 3$ with $s+\delta = 1$ and $s, \delta \geq 0$. Precisely, we have the following.

THEOREM 1.4. *Under the same assumptions and notation as in Theorem* 1.3 *and with*

$$(s,\delta) = \left(\frac{d-3}{4}, \frac{7-d}{4}\right) \quad if\ d \in \{3,4,5\}, \tag{1.11a}$$

$$(s,\delta) = \left(\frac{3}{4}, \frac{1}{4}\right) \quad if\ d = 6, \tag{1.11b}$$

$$(s,\delta) = (1,0) \quad if\ d \geq 7, \tag{1.11c}$$

we have

$$\left\| w_+(\tau,\xi)^s w_-(\tau,\xi)^\delta \widehat{\rho_S}(\tau,\xi) \right\|_{L^2(\{|\tau|>|\xi|\})} \tag{1.12a}$$

$$\leq C\|f\|_{L^2(R\times R^d\times\ S^{d-1})} + C\|g\|_{L^2(R\times R^d\times\ S^{d-1})}\ \ if\ d \neq 5,7; \tag{1.12b}$$

$$\left\| w_+(\tau,\xi)^s w_-(\tau,\xi)^\delta \left[1+\log\frac{w_+(\tau,\xi)}{w_-(\tau,\xi)}\right]^{-1/2} \widehat{\rho_S}(\tau,\xi) \right\|_{L^2(\{|\tau|>|\xi|\})} \tag{1.12c}$$

$$\leq C\|f\|_{L^2(R\times R^d\times\ S^{d-1})} + C\|g\|_{L^2(R\times R^d\times\ S^{d-1})} \quad if\ d = 5,7. \tag{1.12d}$$

Remark. Regarding the optimality of the conditions on s and δ we will show in the last section that all of the upper bounds for s and $s+\delta$ are optimal with the possible exception of the bound $s \leq 4/5$ in dimension $d = 6$. In some cases it is possible to have improved estimates if we allow weights of the form $w_+^{s_1} w_-^{\delta_1} + w_+^{s_2} w_-^{\delta_2}$; see page 664 for details. The logarithmic divergence in some of the estimates is due to the logarithmic divergence in Lemmas 3.2 and 3.3 in [8].

Notation. We define the weights $w_\pm$ by $w_\pm(\tau,\xi) = 1 + ||\tau| \pm |\xi||$. We denote the classical Sobolev spaces by H^s and the hyperbolic Sobolev spaces (see (1.2)) by $H^{s,\delta}$. We use $\widehat{\ }$ for the Fourier transform in space-time denoting the dual variables by (τ,ξ). We will always average the solution f over the unit sphere S^{d-1} in R^d and denote the average by ρ_s.

2. Proofs of Theorems 1.1 and 1.2. In this section we prove Theorems 1.1 and 1.2. We need the following result from [8].

PROPOSITION 2.1. *Let $m > -1$, $l > 1/2$, and define*

$$J_l^m(\tau,\xi) = \int_0^\pi \frac{(\sin\theta)^m}{[1+(\tau+|\xi|\cos\theta)^2]^l}\, d\theta, \qquad \tau \in R,\ \xi \in R^d. \tag{2.1}$$

Let $\alpha = \min\left\{\frac{m+1-4l}{2}, 0\right\}$. Then the integrals $J_l^m(\tau,\xi)$ satisfy the following pointwise estimates:

$$J_l^m(\tau,\xi) \leq C\frac{w_-(\tau,\xi)^{2l-1+\alpha}}{w_+(\tau,\xi)^{2l+\alpha}}\ \ if\ m+1 \neq 4l,$$

$$J_l^m(\tau,\xi) \leq C\frac{w_-(\tau,\xi)^{2l-1}}{w_+(\tau,\xi)^{2l}}\left(1+\log\frac{w_+(\tau,\xi)}{w_-(\tau,\xi)}\right)\ \ if\ m+1 = 4l.$$

Proof of Theorem 1.1. By taking the space-time Fourier transform of (1.4) and adding $\lambda\widehat{f}(\tau,\xi,v)$ to both sides, where $\lambda = \lambda(\tau,\xi) > 0$ will be determined later,

we get

$$\widehat{f}(\tau,\xi,v)=\frac{\Omega_v^{i,j}\widehat{g}(\tau,\xi,v)}{\lambda+i\,(\tau+v\cdot\xi)}+\lambda\frac{\widehat{f}(\tau,\xi,v)}{\lambda+i\,(\tau+v\cdot\xi)}.$$

By averaging in v and integrating by parts we obtain

$$\begin{aligned}\widehat{\rho}(\tau,\xi)&=\int_{S^{d-1}}\frac{\Omega_v^{i,j}\widehat{g}(\tau,\xi,v)}{\lambda+i\,(\tau+v\cdot\xi)}\,d\sigma(v)+\ \lambda\int_{S^{d-1}}\frac{\widehat{f}(\tau,\xi,v)}{\lambda+i\,(\tau+v\cdot\xi)}\,d\sigma(v)\\&=i\int_{S^{d-1}}\frac{v_i\xi_j-v_j\xi_i}{\left[\lambda+i\,(\tau+v\cdot\xi)\right]^2}\widehat{g}(\tau,\xi,v)d\sigma(v)+\ \lambda\int_{S^{d-1}}\frac{\widehat{f}(\tau,\xi,v)d\sigma(v)}{\lambda+i\,(\tau+v\cdot\xi)}.\end{aligned}$$

By using the Cauchy–Schwarz inequality we get

$$\begin{aligned}|\widehat{\rho}(\tau,\xi)|\ &\leq\left(\int_{S^{d-1}}|\widehat{g}(\tau,\xi,v)|^2\,d\sigma(v)\right)^{1/2}\cdot K(\tau,\xi)\\&\quad+\left(\int_{S^{d-1}}\left|\widehat{f}(\tau,\xi,v)\right|^2\,d\sigma(v)\right)^{1/2}\cdot L(\tau,\xi),\end{aligned}\tag{2.2}$$

where

$$\begin{aligned}K(\tau,\xi)&=\left(\int_{S^{d-1}}\frac{|v_i\xi_j-v_j\xi_i|^2}{|\lambda+i\,(\tau+v\cdot\xi)|^4}\,d\sigma(v)\right)^{1/2},\\L(\tau,\xi)&=\left(\lambda^2\int_{S^{d-1}}\frac{d\sigma(v)}{|\lambda+i\,(\tau+v\cdot\xi)|^2}\right)^{1/2}.\end{aligned}\tag{2.3}$$

We estimate $K(\tau,\xi)$ and $L(\tau,\xi)$ as follows. Set $\tau'=\frac{\tau}{\lambda},\ \xi'=\frac{\xi}{\lambda}$, and let θ be the angle between ξ and v. Then

$$\begin{aligned}K(\tau,\xi)&=\left(\int_{S^{d-1}}\frac{|v_i\xi_j-v_j\xi_i|^2}{|\lambda+i\,(\tau+v\cdot\xi)|^4}\,d\sigma(v)\right)^{1/2}\\&=\left(\int_{S^{d-1}}\frac{|v_i\xi_j-v_j\xi_i|^2}{\left|\lambda^2+(\tau+v\cdot\xi)^2\right|^2}\,d\sigma(v)\right)^{1/2}\\&=\frac{|\xi|}{\lambda^2}\left(\int_{S^{d-1}}\frac{\left|v_i\frac{\xi_j}{|\xi|}-v_j\frac{\xi_i}{|\xi|}\right|^2}{\left|1+(\tau'+v\cdot\xi')^2\right|^2}\,d\sigma(v)\right)^{1/2}\\&\simeq\frac{|\xi|}{\lambda^2}\left(\int_0^\pi\frac{(\sin\theta)^2\,(\sin\theta)^{d-2}}{\left|1+(\tau'+|\xi'|\cos\theta)^2\right|^2}\,d\theta\right)^{1/2}\\&=\frac{|\xi|}{\lambda^2}J_2^d(\tau',\xi')^{1/2},\end{aligned}\tag{2.4}$$

and

$$
\begin{aligned}
L(\tau,\xi) &= \left(\lambda^2 \int_{S^{d-1}} \frac{d\sigma(v)}{\lambda^2 + (\tau + v\cdot\xi)^2} \right)^{1/2} \\
&= \left(\int_{S^{d-1}} \frac{d\sigma(v)}{1 + (\tau' + v\cdot\xi')^2} \right)^{1/2} \\
&\simeq \left(\int_0^\pi \frac{(\sin\theta)^{d-2}}{1 + (\tau' + |\xi'|\cos\theta)^2} d\theta \right)^{1/2} \\
&= J_1^{d-2}(\tau',\xi')^{1/2}. \qquad (2.5)
\end{aligned}
$$

We start with the case $d \in \{3,4,5\}$. From (2.4) we have $K(\tau,\xi) \le C\frac{|\xi|}{\lambda^2} J_2^d(\tau',\xi')^{1/2}$. Proposition 2.1 with $m = d$, $l = 2$ gives

$$
\begin{aligned}
K(\tau,\xi) &\le C \frac{|\xi|}{\lambda^2} \frac{(1 + ||\tau'| - |\xi'||)^{\frac{d-1}{4}}}{(1 + |\tau'| + |\xi'|)^{\frac{d+1}{4}}} \\
&= C \frac{|\xi|}{\lambda^{\frac{3}{2}}} \frac{(\lambda + ||\tau| - |\xi||)^{\frac{d-1}{4}}}{(\lambda + |\tau| + |\xi|)^{\frac{d+1}{4}}} \\
&\le C \frac{(\lambda + ||\tau| - |\xi||)^{\frac{d-1}{4}}}{\lambda^{\frac{3}{2}} (\lambda + |\tau| + |\xi|)^{\frac{d-3}{4}}} \\
&\le C \frac{(\lambda + w_-)^{\frac{d-1}{4}}}{\lambda^{\frac{3}{2}} (w_+)^{\frac{d-3}{4}}},
\end{aligned}
$$

where we have set $w_\pm = 1 + ||\tau| \pm |\xi||$ and we have used the fact that $\lambda > 1$ (this will be guaranteed by the choice of λ; see (2.9)).

Next we deal with $L(\tau,\xi)$. From estimate (2.5) we have $L(\tau,\xi) \le J_1^{d-2}(\tau',\xi')^{1/2}$, and we now apply Proposition 2.1 with $m = d-2$ and $l = 1$. Notice that $m + 1 = 4l$ when $d = 5$, and hence there is an extra logarithmic term in this case. For $d \in \{3,4\}$ we get

$$
\begin{aligned}
L(\tau,\xi) &\le C \frac{(1 + ||\tau'| - |\xi'||)^{\frac{d-3}{4}}}{(1 + |\tau'| + |\xi'|)^{\frac{d-1}{4}}} \\
&= C \frac{\lambda^{1/2} (\lambda + ||\tau| - |\xi||)^{\frac{d-3}{4}}}{(\lambda + |\tau| + |\xi|)^{\frac{d-1}{4}}} \\
&\le C \frac{\lambda^{1/2} (\lambda + w_-)^{\frac{d-3}{4}}}{(w_+)^{\frac{d-1}{4}}}, \qquad (2.6a)
\end{aligned}
$$

and for $d = 5$ we get

$$
L(\tau,\xi) \le C \frac{\lambda^{1/2} (\lambda + w_-)^{\frac{d-3}{4}}}{(w_+)^{\frac{d-1}{4}}} \left(1 + \log \frac{\lambda + |\tau| + |\xi|}{\lambda + ||\tau| - |\xi||} \right)^{1/2}. \qquad (2.6b)
$$

We choose $\lambda = \lambda(\tau,\xi)$ such that

$$
\frac{(\lambda + w_-)^{\frac{d-1}{4}}}{\lambda^{\frac{3}{2}} (w_+)^{\frac{d-3}{4}}} = \frac{\lambda^{1/2} (\lambda + w_-)^{\frac{d-3}{4}}}{(w_+)^{\frac{d-1}{4}}} \qquad (2.7)
$$

or, equivalently,

$$\lambda^4 - w_+\lambda - w_+w_- = 0. \tag{2.8}$$

We need to know that such a λ exists, and we also need an estimate of λ in terms of the weights $1 + ||\tau| \pm |\xi||$.

Consider the function $f(\lambda) := \lambda^4 - w_+\lambda - w_+w_-$. Clearly, $f(1) < 0$. On the other hand,

$$\begin{aligned} f\left(2w_+^{1/3}w_-^{1/6}\right) &= 16w_+^{4/3}w_-^{2/3} - 2w_+^{4/3}w_-^{1/6} - w_+w_- \\ &= \left(8w_+^{4/3}w_-^{2/3} - 2w_+^{4/3}w_-^{1/6}\right) + \left(8w_+^{4/3}w_-^{2/3} - w_+w_-\right) \\ &= 2w_+^{4/3}w_-^{1/6}\left(4w_-^{1/2} - 1\right) + w_+w_-^{2/3}\left(8w_+^{1/3} - w_-^{1/3}\right) \\ &> 0. \end{aligned}$$

It follows that there exists a λ with

$$1 < \lambda < 2w_+^{1/3}w_-^{1/6} \tag{2.9}$$

such that (2.7) and (2.8) are satisfied. From (2.8) we have $\lambda + w_- = \frac{\lambda^4}{w_+}$; therefore

$$\lambda + w_- < \frac{\left(2w_+^{1/3}w_-^{1/6}\right)^4}{w_+} \leq Cw_+^{1/3}w_-^{2/3}. \tag{2.10}$$

It follows that the right-hand side of (2.7) is bounded by

$$\frac{\left(2w_+^{1/3}w_-^{1/6}\right)^{1/2}\left(w_+^{1/3}w_-^{2/3}\right)^{\frac{d-3}{4}}}{(w_+)^{\frac{d-1}{4}}} \leq Cw_+^{-\frac{d-1}{6}}w_-^{\frac{2d-5}{12}}.$$

Moreover $1 < \lambda \leq Cw_+$, and therefore in (2.6b)

$$1 + \log\frac{\lambda + |\tau| + |\xi|}{\lambda + ||\tau| - |\xi||} \leq C\left(1 + \log\frac{w_+}{w_-}\right).$$

We conclude that $K(\tau,\xi)$ satisfies

$$K(\tau,\xi) \leq Cw_+^{-\frac{d-1}{6}}w_-^{\frac{2d-5}{12}}, \quad d \in \{3,4,5\},$$

while $L(\tau,\xi)$ satisfies

$$L(\tau,\xi) \leq Cw_+^{-\frac{d-1}{6}}w_-^{\frac{2d-5}{12}}, \quad d \in \{3,4\},$$

and

$$L(\tau,\xi) \leq Cw_+^{-\frac{d-1}{6}}w_-^{\frac{2d-5}{12}}\left(1 + \log\frac{w_+}{w_-}\right)^{1/2}, \quad d = 5.$$

Next we deal with all dimensions $d \geq 7$. From estimate (2.4) we have $K(\tau,\xi) \leq C\frac{|\xi|}{\lambda^2}J_2^d(\tau',\xi')^{1/2}$. Proposition 2.1 with $m = d$ and $l = 2$ now gives

$$\alpha = \min\left\{\frac{m+1-4l}{2}, 0\right\} = \min\left\{\frac{d-7}{2}, 0\right\} = 0.$$

Notice, however, that $m+1=4l$ when $d=7$, and therefore there is a logarithmic loss in this case. We get

$$\begin{aligned} K(\tau,\xi) &\le C\frac{|\xi|}{\lambda^2}\left(\frac{\left(1+||\tau'|-|\xi'||\right)^3}{\left(1+|\xi'|+|\tau'|\right)^4}\right)^{1/2} \\ &= C\frac{|\xi|}{\lambda^2}\cdot\frac{\lambda^2\ \left(\lambda+||\tau|-|\xi||\right)^{3/2}}{\lambda^{3/2}\ \left(\lambda+|\tau|+|\xi|\right)^2} \\ &\le C\frac{\left(\lambda+||\tau|-|\xi||\right)^{3/2}}{\lambda^{3/2}\ \left(\lambda+|\tau|+|\xi|\right)} \qquad \text{if } d>7 \end{aligned}$$

and

$$K(\tau,\xi)\le C\frac{\left(\lambda+||\tau|-|\xi||\right)^{3/2}}{\lambda^{3/2}\ \left(\lambda+|\tau|+|\xi|\right)}\left(1+\log\frac{\lambda+|\tau|+|\xi|}{\lambda+||\tau|-|\xi||}\right)^{1/2} \quad \text{if } d=7.$$

From (2.5) we have $L(\tau,\xi)\le CJ_1^{d-2}(\tau',\xi')^{1/2}$. By applying Proposition 2.1, this time with $m=d-2$, $l=1$, and $\alpha=\min\left\{\frac{m+1-4l}{2},0\right\}=0$ (notice that $m+1\neq 4l$, so there is no logarithmic loss for L), we get

$$\begin{aligned} L(\tau,\xi) &\le C\left(\frac{1+||\tau'|-|\xi'||}{\left(1+|\tau'|+|\xi'|\right)^2}\right)^{1/2} \\ &= C\frac{\lambda^{1/2}\ \left(\lambda+||\tau|-|\xi||\right)^{1/2}}{\left(\lambda+|\tau|+|\xi|\right)}. \end{aligned}$$

We need to choose λ such that

$$\frac{\left(\lambda+||\tau|-|\xi||\right)^{3/2}}{\lambda^{3/2}\ \left(\lambda+|\tau|+|\xi|\right)}=\frac{\lambda^{1/2}\ \left(\lambda+||\tau|-|\xi||\right)^{1/2}}{\left(\lambda+|\tau|+|\xi|\right)} \tag{2.11}$$

or, equivalently, $\lambda^2-\lambda-||\tau|-|\xi||=0$. We choose $\lambda=\frac{1+\sqrt{1+4||\tau|-|\xi||}}{2}$. Notice that $\lambda\ge 1$ and that $\lambda\le C(+\sqrt{||\tau|-|\xi||})$, and therefore

$$\lambda+||\tau|-|\xi||\le C\left(1+\sqrt{||\tau|-|\xi||}+||\tau|-|\xi||\right)\simeq 1+||\tau|-|\xi||\,.$$

Therefore the right-hand side of (2.11) is bounded by

$$\frac{\left(1+\sqrt{||\tau|-|\xi||}\right)^{1/2}\left(1+||\tau|-|\xi||\right)^{1/2}}{1+|\tau|+|\xi|}\le C\frac{\left(1+||\tau|-|\xi||\right)^{3/4}}{1+|\tau|+|\xi|}. \tag{2.12}$$

Moreover, since $1<\lambda\le C\left(1+|\tau|+|\xi|\right)$, we have

$$\log\frac{\lambda+|\tau|+|\xi|}{\lambda+||\tau|-|\xi||}\le C\log\frac{1+|\tau|+|\xi|}{1+||\tau|-|\xi||}. \tag{2.13}$$

By putting everything together we conclude that

$$\begin{aligned} &K(\tau,\xi)\le C\frac{\left(1+||\tau|-|\xi||\right)^{3/4}}{1+|\tau|+|\xi|} && \text{if } d>7, \\ &K(\tau,\xi)\le C\frac{\left(1+||\tau|-|\xi||\right)^{3/4}}{1+|\tau|+|\xi|}\left(1+\log\frac{1+|\tau|+|\xi|}{1+||\tau|-|\xi||}\right)^{1/2}, && \text{if } d=7, \end{aligned}$$

and

$$L(\tau,\xi) \leq C\frac{(1+||\tau|-|\xi||)^{3/4}}{1+|\tau|+|\xi|},\ d\geq 7.$$

This completes the proof in the case $d \geq 7$.

It remains to deal with the intermediate case $d = 6$. In this case we have the extra difficulty that K still behaves as in the lower-dimensional case but L behaves as in the higher-dimensional case. Indeed, we have $K(\tau,\xi) \leq C\frac{|\xi|}{\lambda^2}J_2^d(\tau',\xi')^{1/2}$, and Proposition 2.1 gives $\alpha = \min\left\{\frac{d-7}{2},0\right\} = -\frac{1}{2}$; therefore

$$\begin{aligned} K(\tau,\xi) &\leq C\frac{|\xi|}{\lambda^2}\cdot\frac{(1+||\tau'|-|\xi'||)^{5/4}}{(1+|\tau'|+|\xi'|)^{7/4}} \\ &= \frac{|\xi|}{\lambda^2}\cdot\frac{\lambda^{7/4}(\lambda+||\tau|-|\xi||)^{5/4}}{\lambda^{5/4}(\lambda+|\tau|+|\xi|)^{7/4}} \\ &\leq C\frac{(\lambda+||\tau|-|\xi||)^{5/4}}{\lambda^{3/2}(\lambda+|\tau|+|\xi|)^{3/4}}. \end{aligned}$$

For $L(\tau,\xi)$ we have $L(\tau,\xi) \leq CJ_1^{d-2}(\tau',\xi')^{1/2}$, and Proposition 2.1 now gives $\alpha = \min\left\{\frac{d-5}{2},0\right\} = 0$. We get

$$\begin{aligned} L(\tau,\xi) &\leq C\frac{(1+||\tau'|-|\xi'||)^{1/2}}{1+|\tau'|+|\xi'|} \\ &= C\frac{\lambda^{1/2}\,(\lambda+||\tau|-|\xi||)^{1/2}}{\lambda+|\tau|+|\xi|}. \end{aligned}$$

We need to choose λ so that

$$\frac{(\lambda+||\tau|-|\xi||)^{5/4}}{\lambda^{3/2}(\lambda+|\tau|+|\xi|)^{3/4}} = \frac{\lambda^{1/2}\,(\lambda+||\tau|-|\xi||)^{1/2}}{\lambda+|\tau|+|\xi|} \tag{2.14}$$

or, equivalently,

$$\lambda^8 - (\lambda+||\tau|-|\xi||)^3\,(\lambda+|\tau|+|\xi|) = 0. \tag{2.15}$$

To see that such a λ exists and to obtain estimates for it, consider the function

$$f:[1,\infty)\to R,\quad f(\lambda) = \lambda^8 - (\lambda+||\tau|-|\xi||)^3(\lambda+|\tau|+|\xi|).$$

Then, on the one hand, $f(1) \leq 0$ and, on the other hand, with $w_\pm = 1+||\tau|\pm|\xi||$, we have

$$f\left(2w_-^{4/5}w_+^{1/5}\right) = 2^8 w_-^{32/5}w_+^{8/5} \tag{2.16}$$

$$-\left(2w_-^{4/5}w_+^{1/5}+||\tau|-|\xi||\right)^3\left(2w_-^{4/5}w_+^{1/5}+|\tau|+|\xi|\right). \tag{2.17}$$

We have

$$2w_-^{4/5}w_+^{1/5}+|\xi|-|\tau| \leq 2w_-^{4/5}w_+^{1/5}+w_- \leq 3w_-^{4/5}w_+^{1/5}$$

and

$$2w_-^{4/5}w_+^{1/5}+|\xi|+|\tau| \leq 3w_+,$$

and therefore

$$\begin{aligned} f\left(2w_-^{4/5}w_+^{1/5}\right) &\geq 2^8 w_-^{32/5}w_+^{8/5} - \left(3w_-^{4/5}w_+^{1/5}\right)^3 \cdot 3w_+ \\ &= 2^8 w_-^{32/5}w_+^{8/5} - 3^4 w_-^{12/5}w_+^{8/5} \\ &= w_+^{8/5}\left(2^8 w_-^{32/5} - 3^4 w_-^{12/5}\right) \\ &> 0. \end{aligned}$$

It follows that there exists a λ with $1 \leq \lambda \leq 2w_-^{4/5}w_+^{1/5}$ such that both (2.14) and (2.15) are satisfied. Notice that for this λ we have

$$\lambda + ||\tau| - |\xi|| \leq 2w_-^{4/5}w_+^{1/5} + w_- \leq 3w_-^{4/5}w_+^{1/5}. \tag{2.18}$$

Moreover, from (2.15) we get

$$\lambda = \left(\lambda + ||\tau| - |\xi||\right)^{3/8}\left(\lambda + |\tau| + |\xi|\right)^{1/8}. \tag{2.19}$$

By using first (2.19) we find that the right-hand side of (2.14) is bounded by

$$\begin{aligned} &\frac{\left((\lambda + ||\tau| - |\xi||)^{3/8}(\lambda + |\tau| + |\xi|)^{1/8}\right)^{1/2}(\lambda + ||\tau| - |\xi||)^{1/2}}{\lambda + |\tau| + |\xi|} \\ &= \frac{(\lambda + ||\tau| - |\xi||)^{11/16}}{(\lambda + |\tau| + |\xi|)^{15/16}}. \end{aligned}$$

Next we use (2.18) for the numerator and $\lambda \geq 1$ for the denominator to get

$$\cdots \leq C\frac{\left(w_-^{4/5}w_+^{1/5}\right)^{11/16}}{w_+^{15/16}} = C\frac{w_-^{11/20}}{w_+^{4/5}}.$$

We conclude that

$$K(\tau,\xi) \leq C\frac{w_-^{11/20}}{w_+^{4/5}}, \quad L(\tau,\xi) \leq C\frac{w_-^{11/20}}{w_+^{4/5}}.$$

This completes the proof of Theorem 1.1. □

Proof of Theorem 1.2. Let (s_0, δ_0) be defined by

$$(s_0,\delta_0) = \left(\frac{d-1}{6}, -\frac{2d-5}{12}\right) \quad \text{if } d \in \{3,4,5\}, \tag{2.20a}$$

$$(s_0,\delta_0) = \left(\frac{4}{5}, -\frac{11}{20}\right) \quad \text{if } d = 6, \tag{2.20b}$$

$$(s_0,\delta_0) = \left(1, -\frac{3}{4}\right) \quad \text{if } d \geq 7. \tag{2.20c}$$

Notice that in all cases we have $s_0 + \delta_0 = \frac{1}{4}$. Then the conditions (1.8) in Theorem 1.2 amount to $s + \delta \leq \frac{1}{4}$ and $s \leq s_0$. We have

$$w_+^s w_-^\delta \leq w_+^s w_-^{1/4-s} = w_+^{s_0}w_-^{\delta_0}\frac{w_-^{1/4-\delta_0-s}}{w_+^{s_0-s}} = w_+^{s_0}w_-^{\delta_0}\left(\frac{w_-}{w_+}\right)^{s_0-s} \leq w_+^{s_0}w_-^{\delta_0}.$$

The result then follows from Theorem 1.1. □

Remark. It is possible to improve the estimates in this section if we allow weights of the form $w_+^{s_1} w_-^{\delta_1} + w_+^{s_2} w_-^{\delta_2}$. Consider, for example, the case $d \in \{3,4,5\}$. In the proof of Theorem 1.1 we bounded both K and L by

$$B := \frac{\lambda^{\frac{1}{2}} (\lambda + w_-)^{\frac{d-3}{4}}}{w_+^{\frac{d-1}{4}}},$$

with a logarithmic loss if $d = 5$. From (2.8), $\lambda = (\lambda + w_-)^{1/4} w_+^{1/4}$, and hence

$$B \leq C \frac{(\lambda + w_-)^{\frac{2d-5}{8}}}{w_+^{\frac{2d-3}{8}}}.$$

By using $(\lambda + w_-)^{2d-5} \leq C\lambda^{2d-5} + w_-^{2d-5}$ and $\lambda \leq C w_-^{1/6} w_+^{1/3}$ (see (2.9)) we get

$$B \leq C \frac{w_-^{\frac{2d-5}{48}}}{w_+^{\frac{d-1}{6}}} + \frac{w_-^{\frac{2d-5}{8}}}{w_+^{\frac{2d-3}{8}}}.$$

Each of these fractions is smaller than

$$\frac{w_-^{\frac{2d-5}{12}}}{w_+^{\frac{d-1}{6}}}.$$

3. Improved estimates in the region $\{|\tau| > |\xi|\}$. In this section we prove Theorems 1.3 and 1.4.

Proof of Theorems 1.3 and 1.4. By arguing, and using the same notation, as in the proof of Theorem 1.1, we have (see (2.2)–(2.5))

$$\begin{aligned} |\widehat{\rho}(\tau,\xi)| \leq & \left(\int_{S^{d-1}} |\widehat{g}(\tau,\xi,v)|^2 \, d\sigma(v) \right)^{1/2} \cdot K(\tau,\xi) \\ & + \left(\int_{S^{d-1}} \left| \widehat{f}(\tau,\xi,v) \right|^2 \, d\sigma(v) \right)^{1/2} \cdot L(\tau,\xi), \end{aligned} \tag{3.1}$$

where

$$K(\tau,\xi) \simeq \frac{|\xi|}{\lambda^2} J_2^d(\tau',\xi')^{1/2}, \qquad L(\tau,\xi) \simeq J_1^{d-2}(\tau',\xi')^{1/2},$$

with $\tau' = \tau/\lambda$ and $\xi' = \xi/\lambda$.

In what follows we will reduce to proving pointwise estimates for $K(\tau,\xi)$ and $L(\tau,\xi)$. As in the proof of Theorem 1.1, the estimates announced in Theorems 1.3 and 1.4 are a direct consequence of these estimates and (3.1), so we will omit the details here.

Recall from [8] that, when $|\tau| > |\xi|$, the integrals $J_l^m(\tau,\xi)$ defined in (2.1) satisfy

$$J_l^m(\tau,\xi) \simeq \frac{(1 + |\tau| - |\xi|)^\alpha}{(1 + |\tau| + |\xi|)^{2l+\alpha}} \quad \text{if} \quad m + 1 \neq 4l,$$

$$J_l^m(\tau,\xi) \simeq \frac{1}{(1 + |\tau| + |\xi|)^{2l}} \left(1 + \log \frac{1 + |\tau| + |\xi|}{1 + |\tau| - |\xi|} \right) \quad \text{if} \quad m + 1 = 4l,$$

where $\alpha = \min((m+1-4l)/2, 0)$.

We may assume that $|\tau| \geq 1$. First, observe that if $|\tau| \geq 2|\xi|$, then

$$J_l^m(\tau,\xi) \simeq \frac{(1+|\tau|-|\xi|)^\alpha}{(1+|\tau|+|\xi|)^{2l+\alpha}} \simeq \frac{1}{|\tau|^{2l}}$$

and $1+\log\frac{1+|\tau|+|\xi|}{1+|\tau|-|\xi|} \simeq 1$; therefore in all dimensions (use $\lambda = 1$) we have

$$K(\tau,\xi) \simeq |\xi| J_2^d(\tau,\xi)^{1/2} \simeq \frac{|\xi|}{|\tau|^2} \leq C\frac{1}{|\tau|}$$

and

$$L(\tau,\xi) \simeq J_1^{d-2}(\tau,\xi)^{1/2} \leq C\frac{1}{|\tau|}$$

which is stronger than all estimates in (1.10) and (1.12). Thus we may assume that $|\xi| < |\tau| < 2|\xi|$, in which case $1+|\tau|+|\xi| \simeq |\xi|$.

Suppose that $d \in \{3,4,5\}$. Then we have

$$K(\tau,\xi) \simeq \frac{|\xi|}{\lambda^2} J_2^d(\tau',\xi')^{1/2} \leq C\frac{1}{(\lambda+|\tau|-|\xi|)^{\frac{7-d}{4}}|\xi|^{\frac{d-3}{4}}}.$$

Similarly,

$$L(\tau,\xi) \simeq J_1^{d-2}(\tau',\xi')^{1/2} \leq C\frac{\lambda}{(\lambda+|\tau|-|\xi|)^{\frac{5-d}{4}}|\xi|^{\frac{d-1}{4}}} \qquad \text{if} \quad d=3,4,$$

and the same estimate with a logarithmic loss if $d=5$. Choose $\lambda = 1$ to get the estimates in Theorem 1.4. On the other hand, there exists a λ such that

$$\frac{1}{(\lambda+|\tau|-|\xi|)^{\frac{7-d}{4}}|\xi|^{\frac{d-3}{4}}} = \frac{\lambda}{(\lambda+|\tau|-|\xi|)^{\frac{5-d}{4}}|\xi|^{\frac{d-1}{4}}}. \tag{3.2}$$

Indeed, this is equivalent to

$$\lambda\,(\lambda+|\tau|-|\xi|)^{\frac{1}{2}} = |\xi|^{\frac{1}{2}}, \tag{3.3}$$

i.e., $\varphi(\lambda) = 0$, where $\varphi(\lambda) = \lambda^3 + (|\tau|-|\xi|)\lambda^2 - |\xi|$. We have $\varphi(0) = -|\xi| < 0$ and $\varphi(|\xi|^{1/3}) = (|\tau|-|\xi|)|\xi|^{2/3} > 0$, and therefore there exists a $\lambda \in (0, |\xi|^{1/3})$ such that (3.2) is satisfied. For this λ, (3.3) gives $\lambda + |\tau| - |\xi| = \frac{|\xi|}{\lambda^2} \geq |\xi|^{1/3}$, and therefore the left-hand side of (3.2) is no greater than

$$\frac{1}{|\xi|^{\frac{1}{3}\cdot\frac{7-d}{4}}|\xi|^{\frac{d-3}{4}}} = \frac{1}{|\xi|^{\frac{d-1}{6}}}.$$

This gives the estimates in Theorem 1.3.

Consider next $d = 6$. By working as above we get

$$K(\tau,\xi) \le C\frac{1}{(\lambda+|\tau|-|\xi|)^{1/4}|\xi|^{3/4}} \qquad \text{and} \qquad L(\tau,\xi) \le C\frac{\lambda}{|\xi|}.$$

Use $\lambda = 1$ to get the estimates of Theorem 1.4. Alternatively, find $\lambda \in \left(0, |\xi|^{1/5}\right)$ such that

$$\frac{1}{(\lambda+|\tau|-|\xi|)^{1/4}|\xi|^{3/4}} = \frac{\lambda}{|\xi|},$$

and work as above to get the estimates in Theorem 1.3. In the case $d \ge 7$ we are already covered by (1.9c). ∎

Remark. We can obtain more estimates in $H^{s,\delta}$-spaces by interpolating between (1.9) and (1.11). For example, if $d \in \{3,4,5\}$, we have that for all $\alpha \in [0,1]$ estimates (1.10) hold true with $s = \alpha\frac{d-1}{6} + (1-\alpha)\frac{d-3}{4}$ and $\delta = (1-\alpha)\frac{7-d}{4}$, with similar results in all other dimensions.

4. Counterexamples. In this section we discuss the optimality of our results. We use the following notation: We fix $i, j \in \{1,\dots,d\}$, with $i \ne j$. Given a vector $\xi \in R^d$, we denote by $\xi' \in R^{d-2}$ the vector resulting from ξ if the ith and jth coordinates are removed, i.e., $\xi' = (\xi_i,\dots,\xi_{i-1},\xi_{i+1},\dots,\xi_{j-1},\xi_{j+1},\dots,\xi_n)$. We denote by μ the Lebesgue measure in R^d and by σ the corresponding surface measure on S^{d-1}.

PROPOSITION 4.1. *The condition $s+\delta \le 1/4$ in Theorem 1.2 is necessary.*

Proof. Fix $N >> 1$, and define

$$A = \left\{(\tau,\xi) : 5 \le \tau \le 10,\ -2N^{1/2} \le \xi_i \le -N^{1/2},\ N/2 \le \xi_j \le N, |\xi'| \le 1\right\}.$$

Let $\phi : S^{d-1} \to R$ be defined by $\phi(v) = \phi_i(v_i)\phi_j(v_j)$, where $\phi_i, \phi_j : R \to [0,1]$ are smooth cutoff functions such that

$$\begin{aligned}
\phi_i(v_i) = 1 \ \text{ for } \ -\frac{9}{10} \le v_i \le -\frac{3}{5},\\
\phi_i(v_i) = 0 \ \text{ for } \ v_i \ge -\frac{1}{2},\\
\phi_j(v_j) = 1 \ \text{ for } \ \frac{1}{10N^{1/2}} \le v_j \le \frac{3}{20N^{1/2}},\\
\phi_j(v_j) = 0 \ \text{ for } \ v_j \le 0 \quad \text{or} \quad v_j \ge \frac{1}{4N^{1/2}}.
\end{aligned}$$

In particular

$$\operatorname{supp}\phi_i \subseteq [-1,-1/2], \quad \operatorname{supp}\phi_j \subseteq [0,1/4N^{1/2}].$$

For $(\tau,\xi) \in A$ and $u \in \operatorname{supp}\phi$ we have

$$\begin{aligned}
\tau + v\cdot\xi = \tau + v_i\xi_i + v_j\xi_j + v'\cdot\xi' \le 10 + \frac{18}{10N^{1/2}} + \frac{3}{20N^{1/2}}N + 1 \le 11 + 2N^{1/2},\\
\tau + v\cdot\xi = \tau + v_i\xi_i + v_j\xi_j + v'\cdot\xi' \ge 5 + \frac{3N^{1/2}}{5} + 0 - 1 = 4 + \frac{3N^{1/2}}{5},
\end{aligned}$$

and therefore

$$\tau + v\cdot\xi \simeq N^{1/2}. \tag{4.1}$$

Also,

$$v_j\xi_i - v_i\xi_j \le 0 + \frac{9N}{10} \le N,$$
$$v_j\xi_i - v_i\xi_j \ge -\frac{6}{20} + \frac{3N}{10} = \frac{3(N-1)}{10},$$

and therefore

$$v_j\xi_i - v_i\xi_j \simeq N. \tag{4.2}$$

On the other hand,

$$\left|\frac{\Omega_v^{i,j}\phi(v)}{\tau + v\cdot\xi}\right| \le \frac{|v_i|\,|\phi_i|\left|\frac{\partial\phi_j}{\partial v_j}\right| + |v_j|\,|\phi_j|\left|\frac{\partial\phi_i}{\partial v_i}\right|}{|\tau + v\cdot\xi|} \le C\frac{N^{1/2} + N^{-1/2}}{N^{1/2}} \le C. \tag{4.3}$$

We define $f(t,x,v)$ and $g(t,x,v) \in L^2(R\times R^d\times S^{d-1})$ by

$$\widehat{f}(\tau,\xi,v) = \frac{\Omega_v^{i,j}\widehat{g}(\tau,\xi,v)}{i(\tau + v\cdot\xi)} \qquad \text{and} \qquad \widehat{g}(\tau,\xi,v) = \chi_A(\tau,\xi)\phi(v).$$

Then f and g are well defined (recall (4.1)) and $\partial_t f + v\cdot\nabla_x f = \Omega_v^{i,j} g$. The definition of f and integration by parts yield

$$\begin{aligned}\widehat{\rho_S}(\tau,\xi) &= \int_{S^{d-1}} \widehat{f}(\tau,\xi,v)d\sigma v \\ &= -i\chi_A(\tau,\xi)\int_{S^{d-1}} \frac{\Omega_v^{i,j}\phi(v)}{\tau + v\cdot\xi}d\sigma v \\ &= i\chi_A(\tau,\xi)\int_{S^{d-1}} \frac{v_j\xi_i - v_i\xi_j}{(\tau + v\cdot\xi)^2}\phi(v)d\sigma(v).\end{aligned}$$

Since $\phi \ge 0$ and $v_j\xi_i - v_i\xi_j \ge 0$ we have

$$|\widehat{\rho_S}(\tau,\xi)| = \chi_A(\tau,\xi)\int_{S^{d-1}} \frac{v_j\xi_i - v_i\xi_j}{(\tau + v\cdot\xi)^2}\phi(v)d\sigma(v)$$

and, by using (4.1) and (4.2),

$$|\widehat{\rho_S}(\tau,\xi)| \simeq \chi_A(\tau,\xi)\int_{S^{d-1}} \phi(v)d\sigma(v) \ge c\chi_A(\tau,\xi)\frac{1}{N^{1/2}}.$$

For $(\tau,\xi)\in A$ we have $1 + ||\tau| \pm |\xi|| \simeq N$, and therefore

$$\begin{aligned}\|\rho_S\|_{H^{s,\delta}} &= \left\|(1+|\tau|+|\xi|)^s(1+||\tau|-|\xi||)^\delta\widehat{\rho_S}(\tau,\xi)\right\|_{L^2} \\ &\ge cN^{s+\delta-1/2}\mu(A)^{1/2}.\end{aligned} \tag{4.4}$$

On the other hand, by using (4.3),

$$\begin{aligned}\|f\|_{L^2(R\times R^d\times S^{d-1})} &= \left(\int_{R^{1+d}}\int_{S^{d-1}}\left|\frac{\chi_A(\tau,\xi)\Omega_v^{i,j}\phi(v)}{i(\tau + v\cdot\xi)}\right|^2 d\sigma(v)d\tau d\xi\right)^{1/2} \\ &\le C\mu(A)^{1/2}\sigma(\operatorname{supp}\phi)^{1/2} \\ &\le C\mu(A)^{1/2}\frac{1}{N^{1/4}}.\end{aligned} \tag{4.5}$$

Finally,

$$\begin{aligned}\|g\|_{L^2(R\times R^d\times S^{d-1})} &= \left(\int_{R^{1+d}}\int_{S^{d-1}} \chi_A(\tau,\xi)^2\phi(v)^2 d\sigma(v)d\tau d\xi\right)^{1/2}\\ &\leq C\mu(A)^{1/2}\sigma(\operatorname{supp}\phi)^{1/2}\\ &\leq C\mu(A)^{1/2}\frac{1}{N^{1/4}}. \qquad (4.6)\end{aligned}$$

If for some (s,δ) we have $\|\rho_S\|_{H^{s,\delta}} \leq C\left(\|f\|_{L^2}+\|g\|_{L^2}\right)$, then (4.4)–(4.6) imply that $N^{s+\delta-1/2}\leq CN^{-1/4}$, and therefore $s+\delta\leq 1/4$ as required. We get exactly the same result if we have $H^{s,\delta}_{\log}$ instead of $H^{s,\delta}$. □

PROPOSITION 4.2. *The condition $s\leq 1$ in Theorem 1.2 is necessary.*

Proof. Fix $N >> 1$. Define

$$A=\left\{(\tau,\xi): N\leq\xi_i\leq 2N,\ -1\leq\xi_j\leq 0,\ |\xi'|\leq 1,\ |\xi|\leq\tau\leq|\xi|+1\right\}.$$

Let $\phi: R\to R$ be a smooth cutoff function, with $0\leq\phi\leq 1$ and $\phi=1$ on $[1/20,1/10]$ and $\phi=0$ outside $[1/21,1/9]$. Define

$$\widehat{g}(\tau,\xi,v)=\chi_A(\tau,\xi)\phi(v_i)\phi(v_j),\ \widehat{f}(\tau,\xi,v)=\frac{\Omega^{i,j}_v\widehat{g}(\tau,\xi,v)}{i(\tau+v\cdot\xi)}.$$

Notice that for $(\tau,\xi)\in A$ and $v\in S^{d-1}$ such that $v_i,v_j\in\operatorname{supp}\phi$ we have

$$\tau+v\cdot\xi\leq|\tau|+|\xi|\leq CN$$

and, since $v_i\xi_i\geq 0$ and $v_j\xi_j\geq -1$,

$$\tau+v\cdot\xi=\tau+v_i\xi_i+v_j\xi_j+v'\cdot\xi'\geq N+0-1-1\geq cN.$$

Therefore $\tau+v\cdot\xi>0$ and

$$\tau+v\cdot\xi\simeq N.$$

It follows that f is well defined and, moreover,

$$\begin{aligned}\left|\widehat{f}(\tau,\xi,v)\right| &\leq \frac{\chi_A(\tau,\xi)\left[\,|v_i|\phi(v_i)\,|\phi'(v_j)|+|v_j|\,|\phi'(v_i)|\,\phi(v_j)\,\right]}{|\tau+v\cdot\xi|}\\ &\leq C\frac{\chi_A(\tau,\xi)}{N};\end{aligned}$$

therefore

$$\|f\|_{L^2}\leq C\frac{\mu(A)^{1/2}}{N}.$$

Also,

$$\|g\|_{L^2}\leq C\mu(A)^{1/2},$$

and therefore

$$\|f\|_{L^2}+\|g\|_{L^2}\leq C\mu(A)^{1/2}. \qquad (4.7)$$

On the other hand, by using integration by parts we find

$$\widehat{\rho_{_S}}(\tau,\xi) = i\chi_A(\tau,\xi)\int_{S^{d-1}} \frac{v_j\xi_i - v_i\xi_j}{(\tau + v\cdot\xi)^2}\phi(v_i)\phi(v_j)d\sigma(v).$$

Since $v_i \geq 0$ and $\xi_j \leq 0$ we have $v_j\xi_i - v_i\xi_j \geq v_j\xi_i \geq \frac{N}{21} \geq cN$, and therefore

$$\begin{aligned}|\widehat{\rho_{_S}}(\tau,\xi)| &= \chi_A(\tau,\xi)\int_{S^{d-1}} \frac{v_j\xi_i - v_i\xi_j}{(\tau + v\cdot\xi)^2}\phi(v_i)\phi(v_j)d\sigma(v)\\ &\geq c\chi_A(\tau,\xi)\frac{N}{N^2}\int_{S^{d-1}}\phi(v_i)\phi(v_j)d\sigma(v)\\ &\geq c\frac{\chi_A(\tau,\xi)}{N}.\end{aligned}$$

Moreover, for $(\tau,\xi)\in A$, $1+|\tau|+|\xi| \simeq N$ and $1+||\tau|-|\xi|| \simeq 1$; therefore

$$\begin{aligned}&\left\|(1+|\tau|+|\xi|)^s(1+||\tau|-|\xi||)^\delta\,|\widehat{\rho_{_S}}(\tau,\xi)|\right\|_{L^2}\\ &\qquad\geq cN^s\frac{\mu(A)^{1/2}}{N} = N^{s-1}\mu(A)^{1/2}.\end{aligned} \tag{4.8}$$

If $\|\rho_{_S}\|_{H^{s,\delta}} \leq C\left(\|f\|_{L^2} + \|g\|_{L^2}\right)$ is satisfied, then (4.7) and (4.8) imply that $N^{s-1} \leq C$; therefore $s \leq 1$. We get exactly the same result if we have $H^{s,\delta}_{\log}$ instead of $H^{s,\delta}$. □

PROPOSITION 4.3. *The condition $s \leq \frac{d-1}{6}$ in Theorem 1.2 is necessary.*

Proof. For simplicity of notation we use $i = 1$ and $j = d$. Then $\xi' = (\xi_2,\dots,\xi_{d-1})$. Fix $N >> 1$, and define

$$A = \left\{(\tau,\xi) : 1 \leq \tau - |\xi| \leq 2,\ 0 \leq \xi_1 \leq 1,\ -2N \leq \xi_d \leq -N,\ |\xi'| \leq 1\right\}. \tag{4.9}$$

Notice that if $(\tau,\xi)\in A$, then

$$1 + ||\tau| - |\xi|| \simeq 1, \tag{4.10}$$

$$1 + |\tau| + |\xi| \simeq N, \tag{4.11}$$

$$\frac{1}{2} \leq \frac{-\xi_d}{|\xi|} \leq 1.$$

Let $\phi : R \to [0,1]$ be a smooth cutoff function, with $\operatorname{supp}\phi \subseteq [N^{-\frac{1}{3}}, 2N^{-\frac{1}{3}}]$ and $\phi \equiv 1$ on $[\frac{5}{4}N^{-\frac{1}{3}}, \frac{3}{2}N^{-\frac{1}{3}}]$. Let $\psi : R \to [0,1]$ be a smooth cutoff function, with $\operatorname{supp}\psi \subseteq [1-4N^{-\frac{2}{3}}, 1-N^{-\frac{2}{3}}]$ and $\psi \equiv 1$ on $[1-3N^{-\frac{2}{3}}, 1-2N^{-\frac{2}{3}}]$. Define

$$B = \left\{v \in S^{d-1} : v_1 \in \operatorname{supp}\phi,\ v_d \in \operatorname{supp}\psi\right\}. \tag{4.12}$$

For $(\tau,\xi)\in A$ and $v \in B$ we then have $v_d, \xi_1 \geq 0$ and $\xi_d \leq 0$; therefore

$$v_d\xi_1 - v_1\xi_d \geq 0 + v_1\,|\xi_d| \geq N^{\frac{2}{3}}. \tag{4.13}$$

Also

$$\tau + v\cdot\xi = \tau - |\xi| + |\xi|\left(1 + v_d\frac{\xi_d}{|\xi|}\right) + \sum_{i=1}^{d-1} v_i\xi_i. \tag{4.14}$$

We have $\tau - |\xi| \simeq 1$ and $|\sum_{i=1}^{d-1} v_i \xi_i| \leq C1$. Moreover,

$$1 + v_d \frac{\xi_d}{|\xi|} = \left(1 + \frac{\xi_d}{|\xi|}\right) + (1 - v_d)\frac{-\xi_d}{|\xi|} \geq 0 + N^{-\frac{2}{3}} \cdot \frac{1}{2} \geq cN^{-\frac{2}{3}},$$

and therefore

$$|\xi| \left(1 + v_d \frac{\xi_d}{|\xi|}\right) \geq cN^{\frac{1}{3}}.$$

As a consequence,

$$\tau + v \cdot \xi \geq cN^{\frac{1}{3}}.$$

Notice also that

$$|\xi| \left(1 + v_d \frac{\xi_d}{|\xi|}\right) = (|\xi| + \xi_d) + (1 - v_d) \cdot (-\xi_d),$$

with

$$(1 - v_d) \cdot (-\xi_d) \leq 4N^{-\frac{2}{3}} \cdot 2N \leq CN^{\frac{1}{3}}$$

and

$$|\xi| + \xi_d = \frac{|\xi|^2 - \xi_d^2}{|\xi| - \xi_d} = \frac{\sum_{k=1}^{d-1} \xi_k^2}{|\xi| + |\xi_d|} \leq C\frac{1}{N} \leq C.$$

Thus

$$|\xi| \left(1 + v_d \frac{\xi_d}{|\xi|}\right) \leq CN^{\frac{1}{3}}.$$

By using this in (4.14) we get

$$\tau + v \cdot \xi \leq CN^{\frac{1}{3}}.$$

We have shown that, for $(\tau, \xi) \in A$ and $v \in B$,

$$\tau + v \cdot \xi \simeq N^{\frac{1}{3}}. \tag{4.15}$$

Next define f and $g \in L^2(R_t \times R_x^d \times S_v^{d-1})$ by

$$\widehat{f}(\tau, \xi, v) = \frac{\Omega_v^{1,d} \widehat{g}(\tau, \xi, v)}{i(\tau + v \cdot \xi)} \qquad \text{and} \qquad \widehat{g}(\tau, \xi, v) = \chi_A(\tau, \xi)\phi(v_1)\psi(v_d).$$

We have

$$\|g\|_{L^2(R_t \times R_x^d \times S_v^{d-1})} \leq \mu(A)^{1/2}\sigma(B)^{1/2}. \tag{4.16}$$

Also

$$\begin{aligned}
\left|\widehat{f}(\tau, \xi, v)\right| &\leq \frac{\chi_A(\tau, \xi)}{|\tau + v \cdot \xi|} \left[v_1 \phi(v_1) \left|\psi'(v_d)\right| + v_d \left|\phi'(v_1)\right| \psi(v_d)\right] \\
&\leq C\frac{\chi_A(\tau, \xi)\chi_B(v)}{N^{\frac{1}{3}}} \left[N^{-\frac{1}{3}} \cdot 1 \cdot N^{\frac{2}{3}} + 1 \cdot N^{\frac{1}{3}} \cdot 1\right] \\
&\leq C\chi_A(\tau, \xi)\chi_B(v),
\end{aligned}$$

so that

$$\|f\|_{L^2(R_t\times R_x^d\times S_v^{d-1})}\le C\mu(A)^{1/2}\sigma(B)^{1/2}. \tag{4.17}$$

Now observe that B is contained in the set $\{v\in S^{d-1}: 1-4N^{-\frac{2}{3}}\le v_d\le 1\}$, which is a "cap" centered at the North pole of the sphere. It is easy to check that its area is $\le CN^{-\frac{d-1}{3}}$, and therefore $\sigma(B)\le CN^{-\frac{d-1}{3}}$. Then, from (4.16), (4.17), and previous observation, we get

$$\|f\|_{L^2(R_t\times R_x^d\times S_v^{d-1})}+\|g\|_{L^2(R_t\times R_x^d\times S_v^{d-1})}\le C\mu(A)^{1/2}N^{-(d-1)/6}. \tag{4.18}$$

For $\rho_{_S}$ we integrate by parts to get

$$\begin{aligned}\widehat{\rho_{_S}}(\tau,\xi)&=\int_{S^{d-1}}\frac{\Omega_v^{1,d}\widehat{g}(\tau,\xi,v)}{i(\tau+v\cdot\xi)}\,d\sigma(v)\\&=i\chi_A(\tau,\xi)\int_{S^{d-1}}\frac{v_d\xi_1-v_1\xi_d}{(\tau+v\cdot\xi)^2}\phi(v_1)\psi(v_d)\,d\sigma(v).\end{aligned}$$

Since $\phi,\psi\ge 0$ and $v_d\xi_1-v_1\xi_d\ge 0$ we have

$$|\widehat{\rho_{_S}}(\tau,\xi)|=\chi_A(\tau,\xi)\int_{S^{d-1}}\frac{v_d\xi_1-v_1\xi_d}{(\tau+v\cdot\xi)^2}\phi(v_1)\psi(v_d)\,d\sigma(v),$$

and therefore, by using (4.13) and (4.15),

$$|\widehat{\rho_{_S}}(\tau,\xi)|\ge c\chi_A(\tau,\xi)\int_{S^{d-1}}\phi(v_1)\psi(v_d)\,d\sigma(v), \tag{4.19}$$

we claim that

$$\int_{S^{d-1}}\phi(v_1)\psi(v_d)d\sigma(v)\ge cN^{-(d-1)/3}. \tag{4.20}$$

We have (recall that v' denotes the vector $(v_2,\dots,v_{d-1})\in R^{d-2}$)

$$\begin{aligned}&\int_{S^{d-1}}\phi(v_1)\psi(v_d)d\sigma(v)\\&=c\int_{v_1^2+|v'|^2\le 1}\phi(v_1)\psi\left(\sqrt{1-v_1^2-|v'|^2}\right)dv_1dv'\\&\ge c\int_X\phi(v_1)\psi\left(\sqrt{1-v_1^2-|v'|^2}\right)dv_1dv',\end{aligned} \tag{4.21}$$

where $X=\{\frac{5}{4}N^{-1/3}\le v_1\le\frac{3}{2}N^{-1/3},\ \frac{\sqrt{39}}{4}N^{-1/3}\le|v'|\le\frac{3}{2}N^{-1/3}\}$. Clearly, in the domain of integration in (4.21) we have $\phi(v_1)=1$. We claim that we also have $\psi(\sqrt{1-v_1^2-|v'|^2})=1$. Indeed,

$$1-\sqrt{1-v_1^2-|v'|^2}=\frac{v_1^2+|v'|^2}{1+\sqrt{1-v_1^2-|v'|^2}}\le\frac{\frac{9}{4}N^{-2/3}+\frac{9}{4}N^{-2/3}}{\frac{3}{2}}=3N^{-2/3},$$

and therefore

$$1-3N^{-2/3}\le\sqrt{1-v_1^2-|v'|^2}.$$

Moreover,

$$1-\sqrt{1-v_1^2-|v'|^2}=\frac{v_1^2+|v'|^2}{1+\sqrt{1-v_1^2-|v'|^2}}\geq\frac{\frac{25}{16}N^{-2/3}+\frac{39}{16}N^{-2/3}}{2}=2N^{-2/3},$$

and therefore

$$\sqrt{1-v_1^2-|v'|^2}\leq 1-2N^{-2/3}.$$

It follows that

$$\int_{S^{d-1}}\phi(v_1)\psi(v_d)d\sigma(v)\geq c\int_X\ 1\ dv_1dv'\geq cN^{-(d-1)/3}.$$

This proves (4.20). By using (4.20) in (4.19) we get

$$|\widehat{\rho_S}(\tau,\xi)|\geq c\chi_A(\tau,\xi)N^{-\frac{d-1}{3}},$$

and therefore, by using (4.10) and (4.11),

$$\left\|w_+(\tau,\xi)^s w_-(\tau,\xi)^\delta\widehat{\rho_S}(\tau,\xi)\right\|_{L^2(R\times R^d)}\geq\mu(A)^{1/2}N^{s-\frac{d-1}{3}}. \tag{4.22}$$

If the estimate

$$\begin{aligned}&\left\|w_+(\tau,\xi)^s w_-(\tau,\xi)^\delta\widehat{\rho_S}(\tau,\xi)\right\|_{L^2(R\times R^d)}\\&\quad\leq C\left(\|f\|_{L^2(R_t\times R^d_x\times S^{d-1}_v)}+\|g\|_{L^2(R_t\times R^d_x\times S^{d-1}_v)}\right)\end{aligned}$$

is valid, then it follows from (4.22) and (4.18) that

$$N^{s-(d-1)/3}\leq CN^{-(d-1)/6}$$

for $N\gg 1$ which gives

$$s\leq\frac{d-1}{6}.$$

We have exactly the same bound for s if $H^{s,\delta}$ is replaced by $H^{s,\delta}_{\log}$. □

STABILITY OF EQUILIBRIA FOR THE STEFAN PROBLEM WITH SURFACE TENSION*

JAN PRÜSS† AND GIERI SIMONETT‡

Abstract. We characterize the equilibrium states for the two-phase Stefan problem with surface tension and with or without kinetic undercooling, and we analyze their stability in terms of dependence on physical and geometric quantities.

Key words. free boundary problem, phase transitions, surface tension, kinetic undercooling, stability, bifurcation

AMS subject classifications. 35R55, 35B55, 35K55, 80A22

DOI. 10.1137/070700632

1. Introduction.

The Stefan problem is a model for phase transitions in solid-liquid systems. In this paper, we consider the two-phase Stefan problem with the modified Gibbs–Thomson law

$$u = \sigma H + \delta V \quad \text{on} \quad \Gamma(t), \quad \sigma > 0, \quad \delta \geq 0, \tag{1.1}$$

and the kinetic condition

$$[d\partial_\nu u] = (\ell - [\kappa]u)V \quad \text{on} \quad \Gamma(t). \tag{1.2}$$

Here $\Gamma(t)$ denotes the unknown moving hypersurface that separates the liquid from the solid phase, u is the temperature, H the mean curvature of $\Gamma(t)$, σ the surface tension coefficient, δ the coefficient of kinetic undercooling, V the normal velocity of $\Gamma(t)$, ℓ the latent heat, $[\kappa]$ the jump of the heat capacities across $\Gamma(t)$, and $[d\partial_\nu u]$ the jump of the heat fluxes across $\Gamma(t)$. Note that in case $\sigma = \delta = 0$, i.e., for the classical Stefan problem, we have $u = 0$ at the interface, and then the kinetic condition becomes the classical Stefan condition.

Under appropriate boundary conditions we will show that spheres (together with constant temperature distributions) are the only equilibrium states for this system, and we will characterize the stability of these equilibria in terms of dependence on physical and geometric quantities.

In order to formulate the Stefan problem we introduce the following notation. Let Ω be a smooth bounded domain in $\mathbb{R}^n$ whose boundary $\partial\Omega$ consists of two disjoint components, an "interior" part J_1 and an "exterior" part J_2. We think of Ω as a homogeneous medium which is occupied by a liquid and a solid phase, say water and ice, that initially occupy the regions Ω_0^1 and Ω_0^2, and that are separated by a sharp interface Γ_0. More precisely, we assume that $\Gamma_0 \subset \Omega$ is a compact closed hypersurface, and that Ω_0^1 and Ω_0^2 are disjoint open sets such that $\overline{\Omega} = \overline{\Omega_0^1} \cup \overline{\Omega_0^2}$, and such that $\partial\Omega_0^i = J_i \cup \Gamma_0$ for $i = 1, 2$. For the sake of definiteness we consider the open set Ω_0^1 as

the region occupied by the liquid phase. Consequently, the component J_1 is in contact with the liquid phase, and J_2 is in contact with the solid phase. The boundaries J_1 and J_2, corresponding for instance to the walls of a container, are fixed, whereas Γ_0 will change as time evolves, due to solidification or liquidation of the two different phases.

Given $t \geq 0$, let $\Gamma(t)$ be the position of Γ_0 at time t, and let $V(\cdot,t)$ and $H(\cdot,t)$ be the normal velocity and the mean curvature of $\Gamma(t)$. Moreover, let $\Omega_1(t)$ and $\Omega_2(t)$ be the two regions in Ω separated by $\Gamma(t)$. According to our assumption, $\Omega_1(t)$ is the region occupied by the liquid phase, and $\Gamma(t)$ is a sharp interface which separates the liquid from the solid phase. Let $\nu(\cdot,t)$ be the outer unit normal field on $\Gamma(t)$ with respect to $\Omega_1(t)$. We shall use the convention that the normal velocity is positive if $\Omega_1(t)$ is expanding, and that the mean curvature is positive if the intersection of $\Omega_1(t)$ with a small ball centered at $\Gamma(t)$ is convex. Consequently, the normal velocity is positive if the liquid region is growing, ν points into the solid phase, and H is positive for a water ball surrounded by ice, and negative for an ice ball surrounded by water.

Here we concentrate on the case $J_1 = \emptyset$. Let Γ_0 and $u_0^i : \Omega_0^i \to \mathbb{R}$ be given, where u_0^1 and u_0^2 denote the initial temperatures of the liquid and solid phase, respectively. The strong formulation of the *two-phase Stefan problem with surface tension and kinetic undercooling* consists of finding a family $\Gamma := \{\Gamma(t)\,;\, t \geq 0\}$ of hypersurfaces and functions $u_i : \cup_{t\geq 0}\,(\Omega_i(t) \times \{t\}) \to \mathbb{R}$, satisfying

$$
\left\{
\begin{aligned}
\kappa_i \partial_t u_i - d_i \Delta u_i &= 0 && \text{in} \quad \Omega_i(t),\\
\partial_\nu u_2 &= 0 && \text{on} \quad J_2,\\
u_i &= \sigma H_\Gamma + \delta V && \text{on} \quad \Gamma(t),\\
[d\partial_\nu u] &= (\ell - [\kappa]u)V && \text{on} \quad \Gamma(t),\\
u_i(0) &= u_0^i && \text{in} \quad \Omega_0^i,\\
\Gamma(0) &= \Gamma_0\,, &&
\end{aligned}
\right. \tag{1.3}
$$

where $\kappa_i \geq 0$ is the heat capacity of phase i, d_i is its thermal conductivity coefficient, $\ell > 0$ is the latent heat per unit mass absorbed or released for melting or solidifying, $\sigma > 0$ is the surface tension, and $\delta \geq 0$ is the speed of kinetic undercooling. Moreover,

$$
\begin{aligned}
[\kappa] &:= \kappa_2 - \kappa_1,\\
[d\partial_\nu u] &:= d_2 \partial_\nu u_2 - d_1 \partial_\nu u_1
\end{aligned}
$$

denote the jump of the heat capacities and the heat fluxes, respectively, across the interface $\Gamma(t)$. Note that $[\kappa] = \kappa_2 - \kappa_1 < 0$ is physically reasonable since in the liquid phase there are more degrees of freedom than in the solid phase; hence, the liquid phase can absorb more energy per unit mass. However, we do not assume $[\kappa] < 0$ in what follows. The condition $u_i = \sigma H_\Gamma$ on the free interface is usually called the Gibbs–Thomson law, and $u_i = \sigma H_\Gamma + \delta V$ the modified Gibbs–Thomson law, or the Gibbs–Thomson law with kinetic undercooling; see [2, 3, 16, 17, 19, 21, 24, 25, 32] for more information.

We refer to [12, 13, 14, 22, 23, 28, 29] for existence and regularity results for the Stefan problem with the Gibbs–Thomson law $u_i = \sigma H_\Gamma$ in case $\kappa_1 = \kappa_2$. The Stefan problem with surface tension and kinetic undercooling in case $\kappa_1 = \kappa_2$ has been studied in [5, 28, 29, 31]; see also [20] for the one-phase case.

It will be shown in [26] that the Stefan problem (1.3) has a unique local solution which is analytic in space and time, provided that the well-posedness condition

$$
\ell - \sigma[\kappa] H_{\Gamma_0} > 0 \quad \text{in case} \quad \delta = 0 \tag{1.4}
$$

is satisfied. On the other hand, if $\delta = 0$ and $\kappa_1 > \kappa_2$, problem (1.3) is not well-posed if H_{Γ_0} is too negative, that is, in case the solid region sharply protrudes into the liquid. Associated to the Stefan problem (1.3) is the energy functional

$$E(u(t),\Gamma(t)) := \int_\Omega \kappa u\,dx + \ell\,|\Omega_1(t)| = \int_{\Omega_1(t)} \kappa_1 u_1\,dx + \int_{\Omega_2(t)} \kappa_1 u_2\,dx + \ell\,|\Omega_1(t)|, \tag{1.5}$$

where $|\Omega_1(t)|$ is the volume of the region $\Omega_1(t)$. If (u,Γ) is a sufficiently smooth solution of (1.3), then we obtain

$$\begin{aligned}\frac{d}{dt}E(u(t),\Gamma(t)) &= \int_{\Omega_1(t)} \kappa_1\partial_t u_1\,dx + \int_{\Omega_2(t)} \kappa_1\partial_t u_2\,dx - [\kappa]\int_{\Gamma(t)} uV\,ds + \ell\int_{\Gamma(t)} V\,ds\\ &= \int_{\Gamma(t)} \Big(- [d\partial_\nu u] - [\kappa]uV + \ell V\Big)\,ds = 0,\end{aligned} \tag{1.6}$$

thus showing that energy is conserved.

If $\kappa_1 = \kappa_2 = 0$ and $\delta = 0$, then the resulting problem is the quasi-stationary Stefan problem with surface tension, which has also been termed the Mullins–Sekerka model (or the Hele–Shaw model with surface tension). Existence, uniqueness, regularity, and global existence of solutions for the quasi-stationary approximation have been investigated in [1, 4, 6, 8, 9, 10, 11, 15]. Existence and global existence of classical solutions for the quasi-stationary approximation with $\sigma > 0$ and $\delta > 0$ have been studied in [33, 20].

A major difficulty in the mathematical treatment of the Stefan problem (1.3) is due to fact that the boundary $\Gamma(t)$, and thus the geometry, is unknown and ever changing. A widely used method to overcome this inherent difficulty is to choose a fixed reference surface Σ and then represent the moving surface $\Gamma(t)$ as the graph of a function (which we will denote by $\rho = \rho(s,t)$) in normal direction of Σ. In this way, one obtains a time-dependent (unknown) diffeomorphism from Σ onto $\Gamma(t)$, and in the next step this diffeomorphism is extended to a diffeomorphism of fixed reference regions D^i onto the unknown domains $\Omega_i(t)$. The treatment of the moving boundary problem (1.3) then proceeds by transforming the equations into a new system of equations defined on the fixed domain $D_1 \cup D_2$ from which both the solution and the parameterizing function ρ have to be determined. In the context of the Stefan problem this approach has first been used by Hanzawa [18].

The same approach has also been used in [10, 11] for the quasi-stationary approximation of the Stefan problem with surface tension, and in [26] for the Stefan problem with surface tension. Once the transformed system has been obtained, one can study the mapping properties of the nonlinearities involved, and in particular, one can determine their linearizations; see [26] for more details.

In this paper, we assume that $\Gamma(t)$ does not touch the fixed boundary $J_2 = \partial\Omega$. Under this assumption, we will characterize all of the equilibrium states (u_1, u_2, Σ) of (1.3). In fact, it is easy to see that the equilibria are precisely given by

$$\Sigma = \bigcup_{j=1}^m S_R(x_j), \quad u_1 = u_2 = \sigma/R,$$

where $S_R(x_j)$ denotes disjoint spheres of the same radius R and centers x_j. This can be seen by the following arguments: the equilibria (u_1, u_2, Σ) of the Stefan problem (1.3)

are given by the system of equations

$$\begin{cases} -d_i\Delta u_i = 0 & \text{in} \quad \Omega_i, \\ \partial_\nu u_2 = 0 & \text{on} \quad \partial\Omega, \\ u_i = \sigma H_\Sigma & \text{on} \quad \Sigma, \\ [d\partial_\nu u] = 0 & \text{on} \quad \Sigma. \end{cases} \tag{1.7}$$

Taking the inner product of $(1.7)_1$ with u_i, the divergence theorem and condition $(1.7)_4$ yield

$$\int_{\Omega_i} |\nabla u_i|^2 \, dx = 0;$$

hence u_i is constant on Ω_i. Equation $(1.7)_3$, in turn, shows that $u_1 = u_2$ and also that $H = u/\sigma$ is constant on Σ. But then, since Ω is bounded, Σ must be a sphere $S_R(x_0)$ centered at some point $x_0 \in \Omega$ with radius $R > 0$, if the phases are connected. Otherwise, again due to the boundedness of Ω, Σ is the union of finitely many spheres of the same radius $R > 0$. Here we concentrate on the case of connected phases. Thus there is an $(n+1)$-parameter family of equilibria, the parameters being the n coordinates of the center x_0 and the radius R.

We want to discuss the stability of those equilibria. The linearized problem (associated to the transformed equations) at such an equilibrium state is given by

$$\begin{cases} \kappa\partial_t v - d\Delta v = f & \text{in} \quad (\Omega \setminus \Sigma) \times \mathbb{R}_+, \\ \partial_\nu v = 0 & \text{on} \quad \partial\Omega \times \mathbb{R}_+, \\ v = \sigma\mathcal{A}_\Sigma\rho + \delta\partial_t\rho + g & \text{on} \quad \Sigma \times \mathbb{R}_+, \\ l\partial_t\rho - [d\partial_\nu v] = h & \text{on} \quad \Sigma \times \mathbb{R}_+, \\ v(0) = v_0 & \text{in} \quad \Omega \setminus \Sigma, \\ \rho(0) = \rho_0 & \text{on} \quad \Sigma; \end{cases} \tag{1.8}$$

see [26]. Here, $l = \ell - [\kappa]\sigma/R$, and the operator $\mathcal{A}_\Sigma$ is given by

$$\mathcal{A}_\Sigma = -\frac{1}{n-1}\left(\frac{n-1}{R^2} + \Delta_\Sigma\right),$$

where Δ_Σ denotes the Laplace–Beltrami operator on Σ. This is the linearization of the mean curvature $H'(0)$ at the sphere Σ; cf., e.g., Escher and Simonett [11]. Here we use the notation $v = v_1\chi_{\Omega_1} + v_2\chi_{\Omega_2}$, where χ_G denotes the characteristic function of a set G, and similarly $\kappa = \kappa_1\chi_{\Omega_1} + \kappa_2\chi_{\Omega_2}$ and $d = d_1\chi_{\Omega_1} + d_2\chi_{\Omega_2}$. Associated to the linearization (1.8) is the following eigenvalue problem:

$$\begin{cases} \lambda\kappa v - d\Delta v = 0 & \text{in} \quad \Omega \setminus \Sigma, \\ \partial_\nu v = 0 & \text{on} \quad \partial\Omega, \\ v = \sigma\mathcal{A}_\Sigma\rho + \lambda\delta\rho & \text{on} \quad \Sigma, \\ \lambda l\rho - [d\partial_\nu v] = 0 & \text{on} \quad \Sigma, \end{cases} \tag{1.9}$$

where as before $l = \ell - [\kappa]\sigma/R$. We will now state the main results of this paper. We will formulate our results for a domain in $\mathbb{R}^n$ for $n \in \mathbb{N}$, $n > 1$, although the physically relevant dimensions, naturally, are $n = 2, 3$.

THEOREM 1.1. *Suppose that the phases in the Stefan problem are connected. Then the following assertions hold:*

(a) *The equilibrium states (without boundary contact) for problem* (1.3) *are given by*

$$(u, \Sigma), \quad \textit{where} \quad \Sigma = S_R(x_0) \quad \textit{and} \quad u = \sigma/R,$$

with $S_R(x_0) \subset \Omega$ being the sphere with radius R and center x_0.

(b) *For $l > 0$, the eigenvalue problem* (1.9) *has countably many real eigenvalues of finite algebraic multiplicity.*

(c) *0 is an eigenvalue of* (1.9) *with geometric multiplicity $(n+1)$. The (geometric) eigenspace is spanned by*

$$(-1, Y_0), (0, Y_1), \ldots, (0, Y_n),$$

where $Y_0 = R^2/\sigma$, and where Y_j, $1 \le j \le n$, are the spherical harmonics of degree 1 (normalized by the orthogonality condition $(Y_i|Y_j)_\Sigma = \delta_{ij}$).

(d) *If $\sigma(\kappa|1)_\Omega \le l|\Sigma|R^2$, then* (1.9) *has no positive eigenvalues.*

(e) *If $\sigma(\kappa|1)_\Omega > l|\Sigma|R^2 > 0$, then* (1.9) *has exactly one positive, algebraically simple eigenvalue.*

(f) *If $l < 0$ and $\delta > 0$, then* (1.9) *has at least one positive eigenvalue.*

(g) *If $l < 0$ and $\delta = 0$, then the linearized problem* (1.8) *is not well-posed.*

Proof. The assertion in (a) has been proved above. We refer to Theorem 2.1 for a proof of assertions (b)–(e), and for additional information about the eigenvalue problem (1.9), for the case $l > 0$. The proof of (f) is given at the end of section 5, and (g) follows from [7]. □

Remark 1.2. (a) If $l < 0$, then all equilibrium states are linearly unstable (and the linearized problem (1.8) is not even well-posed in case $\delta = 0$). Therefore we mainly concentrate on the case $l > 0$. Define then

$$\zeta := \frac{\sigma(\kappa|1)_\Omega}{l|\Sigma|R^2}, \quad \text{where} \quad l = \ell - \frac{\sigma[\kappa]}{R}, \quad (\kappa|1)_\Omega := \int_\Omega \kappa \, dx.$$

According to Theorem 1.1.(d)–(e), we know that all eigenvalues of (1.9) are non-positive if $\zeta \le 1$, and that there exists exactly one positive simple eigenvalue if $\zeta > 1$. We will refer to the case $\zeta \le 1$ as a *stability condition.*

Observe that neither the thermal conductivity coefficients d_i nor the kinetic coefficient δ enters this stability condition, as it depends only on the heat capacities κ_i, the latent heat ℓ, the surface tension σ, and on the geometry. In particular, decreasing the size of a ball decreases its stability, as does increasing surface tension; see also Remark 1.5(a). We also mention that the stability condition $\zeta \le 1$ is always valid in the quasi-stationary case $\kappa_i = 0$, i.e., for the Mullins–Sekerka problem.

(b) It will be shown in the forthcoming paper [27] that solutions for the Stefan problem (1.3) that start out close to an equilibrium (u, Σ) exist globally and converge towards an equilibrium state (u', Σ') as time goes to infinity, provided that $l > 0$ and $\zeta < 1$. This gives justice to the wording *stability condition* for the case $\zeta < 1$. We note again that $\zeta = 0$ if the heat capacities κ_i are zero, that is, in the quasi-stationary case. In this case, global existence and convergence to equilibria were obtained in [11, 20] by using a center-manifold analysis; see also [15] for a different approach in the one-phase case.

(c) If the Gibbs–Thomson condition on the free interface $\Gamma(t)$ is replaced by $u_i = 0$, then (1.3) is called the *(classical) Stefan model.* It should be observed that,

in contrast to the problem with surface tension, the classical Stefan problem does not admit nontrivial equilibrium states.

For $l > 0$, the results in Theorem 1.1 suggest that one eigenvalue, λ_*, crosses the imaginary axis at 0 as the quantity ζ increases and exceeds 1. According to part (c) of Theorem 1.1, 0 is always an eigenvalue with geometric multiplicity $(n+1)$. This suggests that as the eigenvalue λ_* crosses through 0, the algebraic multiplicity of 0 raises by one, and then drops again as soon as the eigenvalue has crossed. This is exactly what happens, as will be proved in Theorem 2.1.

Another way to view and understand this situation can be gained from considering the following parameter-dependent eigenvalue problem:

$$\begin{cases} \lambda_* s\kappa v - d\Delta v = 0 & \text{in} \quad \Omega \setminus \Sigma, \\ \partial_\nu v = 0 & \text{on} \quad \partial\Omega, \\ v = \sigma \mathcal{A}_\Sigma \rho + \lambda_* \delta \rho & \text{on} \quad \Sigma, \\ \lambda_* l\rho - [d\partial_\nu v] = 0 & \text{on} \quad \Sigma. \end{cases} \tag{1.10}$$

The following result will be proved in section 6.

THEOREM 1.3. *Let $l > 0$ and set $s_0 := l|\Sigma|R^2/\sigma(\kappa|1)_\Omega$. Then the following hold:*

(a) *The eigenvalue problem* (1.10) *has an analytic curve of solutions*

$$[s \mapsto (\lambda_*(s), v(s), \rho(s))], \quad s \in (s_0 - \varepsilon_0, \infty),$$

such that $\lambda_*(s) > 0$ iff $s > s_0$, where ε_0 is an appropriate positive number.

(b) *$\lambda_*(s)$ crosses the imaginary axis with positive speed at $s = s_0$.*

(c) *$[s \mapsto \lambda_*(s)]$ is strictly increasing.*

(d) *If $\delta > 0$, then $\lambda_*(s)$ is bounded above by $\sigma/\delta R^2$.*

(e) *If $\delta = 0$, then $\lambda_*(s) \to \infty$ as $s \to \infty$.*

Clearly, the eigenvalues of the modified problem (1.10) coincide with the eigenvalues of (1.9) if $s = 1$. In case $\zeta > 1$ we have $s_0 < 1$ and see that $\lambda = \lambda_*(1)$ is a (the only) positive eigenvalue of (1.9).

According to (1.5) an equilibrium state $(\sigma/R, S_R(x_0))$ for the Stefan problem (1.3) has energy

$$\begin{aligned} \phi(R) :&= E\left(\frac{\sigma}{R}, S_R(x_0)\right) = \frac{\sigma}{R}(\kappa|1)_\Omega + \ell\,|\Omega_1| \\ &= \frac{\sigma}{R}\big(\kappa_1|\Omega_1| + \kappa_2|\Omega_2|\big) + \ell\,|\Omega_1|, \end{aligned} \tag{1.11}$$

where $|\Omega_1| = R^n|B|$ and $|\Omega_2| = |\Omega| - R^n|B|$, with $|B|$ the volume of the unit ball. A straightforward computation shows that the function ϕ has a unique minimum. It is attained at the point R_*, where R_* is the unique solution of

$$\frac{\sigma(\kappa|1)_\Omega}{R^2} = \left(\ell - \frac{\sigma[\kappa]}{R}\right)|S_R|, \tag{1.12}$$

with $|S_R| = |S_R(x_0)|$ being the area of the sphere $S_R(x_0)$.

In the following, we denote by R_* the point where ϕ attains its (unique) minimum and by R^* the largest number R such that $\overline{B}_R(x_0) \subset \overline{\Omega}$, and we suppose that $R_* < R^*$. Then we have the following result; see also the stability diagram in Figure 1.

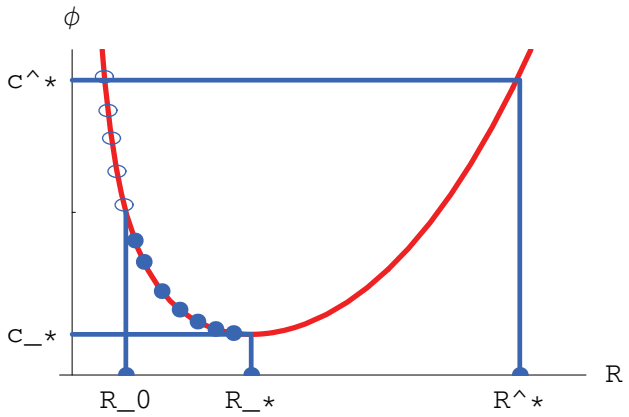

FIG. 1. *Stability diagram for $\kappa_1 < \kappa_2$ and $\delta = 0$; circled: ill-posed, dotted: unstable.*

COROLLARY 1.4. *Let $c_* = \phi(R_*)$ be the minimum value of ϕ, and let $c^* = \phi(R^*)$. Moreover, let $c_0 = E(u_0, \Gamma_0) = \phi(R)$ be a given energy level.*

(a) *If $c_0 < c_*$, then problem* (1.3) *does not admit equilibrium states.*

(b) *If $c_* < c_0 < c^*$, then* (1.3) *admits two branches of equilibrium states. The branch of equilibria $(\sigma/R, S_R(x_0))$ with $0 < R < R_*$ is linearly unstable, whereas the branch with $R_* < R < R^*$ is linearly stable.*

(d) *In case $c_0 = c_*$ or $c_0 > c^*$, the Stefan problem* (1.3) *admits one family of equilibrium states. All equilibria $(\sigma/R, S_R(x_0))$ with $\phi(R) > c^*$ are linearly unstable.*

(e) *If $R_0 := [\kappa]\sigma/\ell > 0$ and $\delta = 0$, then the linearized problem is ill-posed for $R < R_0$.*

Proof. This follows from Remark 1.2(a), (1.12), and the fact that $\phi'(R)$ is negative for $R < R_*$ and positive for $R_* < R < R^*$. □

Remark 1.5. (a) We can show that R_* is increasing with respect to σ (and, for that matter, also with respect to $[\kappa]$). In order to see this, let $R_*(\sigma)$ denote the unique solution of (1.12). Then we have $R_*'(\sigma) > 0$. For this we note that (1.12) can be written as

$$n\ell|B|R_*^{n+1}(\sigma) - \sigma\big(\kappa_2|\Omega| + (n-1)[\kappa]|B|R_*^n(\sigma)\big) = 0. \tag{1.13}$$

Taking the derivative of this equation with respect to σ yields

$$n(n+1)\ell|B|R_*^{n-1}\left(R_* - \frac{(n-1)}{(n+1)}\frac{\sigma[\kappa]}{\ell}\right)R_*'(\sigma)$$
$$= \kappa_2|\Omega| + (n-1)[\kappa]|B|R_*^n = (\ell/\sigma)n|B|R_*^{n+1}(\sigma) > 0.$$

Note that we have used (1.13) for the last equality. It remains to be observed that the parenthetical expression in front of $R_*'(\sigma)$ is always positive. This is clear in case $[\kappa] \le 0$ and follows from the fact that R_* is always greater than $R_0 = \sigma[\kappa]/l$ in case $[\kappa] > 0$. We therefore see that increasing σ increases $R_*(\sigma)$, showing that spheres with a fixed radius R can lose stability as σ increases.

(b) If one considers the case where the domain Ω_1 is occupied by the solid phase, and Ω_2 by the fluid phase, then the third and fourth lines in (1.3) must be replaced

by

$$\begin{aligned} u_i &= -\sigma H_\Gamma - \delta V \qquad \text{on} \quad \Gamma(t), \\ -[d\partial_\nu u] &= (\ell + [\kappa]u)V \qquad \text{on} \quad \Gamma(t), \end{aligned} \tag{1.14}$$

and the energy functional by

$$E(u(t),\Gamma(t)) := \int_\Omega \kappa u\,dx + \ell\,|\Omega_2(t)| = \int_{\Omega_1(t)} \kappa_1 u_1\,dx + \int_{\Omega_2(t)} \kappa_1 u_2\,dx + \ell\,|\Omega_2(t)|,$$

while all other conventions are left unchanged. Thus, one formally has to switch signs in the normal ν and in ℓ and $[\kappa]$. Then all of the results and assertions stated in this paper remain valid for the equilibrium states $(-\sigma/R, S_R(x_0))$.

The plan of this paper is the following. In section 2 we will state a more general and concise version of Theorem 1.1; its proof will be given in sections 3–5. Finally, in section 6 we will prove Theorem 1.3.

2. Main theorem. In this section we will introduce an appropriate functional analytic setting to study the eigenvalue problem (1.9). We always assume $l > 0$ except when proving (f) of Theorem 1.1.

For the case $\delta = 0$ we define the operator L_0 on $E_0 := L_p(\Omega) \times W_p^{2-2/p}(\Sigma)$ by means of

$$\begin{aligned} D(L_0) :=& \big\{(v,\rho) \in W_p^2(\Omega\setminus\Sigma) \times W_p^{4-1/p}(\Sigma) : [d\partial_\nu v] \in W_p^{2-2/p}(\Sigma), \\ &\partial_\nu v = 0 \text{ on } \partial\Omega,\ [v] = 0 \text{ on } \Sigma,\ \ v = \sigma\mathcal{A}_\Sigma\rho \text{ on } \Sigma\big\}, \\ L_0(v,\rho) :=& \big((d/\kappa)\Delta v, [(d/l)\partial_\nu v]\big), \quad (v,\rho) \in D(L_0). \end{aligned}$$

In case $\delta > 0$, we instead set $E_\delta := L_p(\Omega) \times W_p^{1-1/p}(\Sigma)$, and we define L_δ by

$$\begin{aligned} D(L_\delta) :=& \big\{(v,\rho) \in W_p^2(\Omega\setminus\Sigma) \times W_p^{3-1/p}(\Sigma) : \\ &\partial_\nu v = 0 \text{ on } \partial\Omega,\ [v] = 0 \text{ on } \Sigma,\ v - (\delta/l)[d\partial_\nu v] = \sigma\mathcal{A}_\Sigma\rho \text{ on } \Sigma\big\}, \\ L_\delta(v,\rho) :=& \big((d/\kappa)\Delta v, [(d/l)\partial_\nu v]\big), \quad (v,\rho) \in D(L_\delta). \end{aligned}$$

We remark that L_0 and L_δ differ only by their respective domains of definition. It will be shown in [7] that the operators L_δ generate an analytic semigroup on E_δ. This property, in conjunction with the spectral information contained in the next theorem, will be crucial in proving global existence and convergence of solutions for problem (1.3) that start out close to an equilibrium, which will be provided in [27]; see also Remark 1.2(c).

THEOREM 2.1. *Suppose $1 < p < \infty$, and let $l > 0$. For $\delta \geq 0$ let L_δ be defined as above.*

(a) *The spectrum of L_δ consists of countably many real eigenvalues of finite algebraic multiplicity and is independent of p.*

(b) *0 is an eigenvalue of L_δ with geometric multiplicity $(n+1)$. The null space of L_δ is spanned by*

$$(-1, Y_0), (0, Y_1), \ldots, (0, Y_n), \tag{2.1}$$

where $Y_0 = R^2/\sigma$, and where Y_j, $1 \leq j \leq n$, are the spherical harmonics of degree 1 (normalized by the orthogonality condition $(Y_i|Y_j)_\Sigma = \delta_{ij}$).

(c) *Suppose that the degeneracy condition*

$$(\kappa|1)_\Omega := \kappa_1|\Omega_1| + \kappa_2|\Omega_2| = l|\Sigma|R^2/\sigma \tag{2.2}$$

holds. Then the eigenvalue 0 *has algebraic multiplicity* $(n+2)$.

(d) *If the degeneracy condition* (2.2) *does not hold, then* 0 *is semi-simple; that is,* $N(L_\delta^2) = N(L_\delta)$.

(e) *If* $\sigma(\kappa|1)_\Omega \le l|\Sigma|R^2$, *then* L_δ *has no positive eigenvalues.*

(f) *If* $\sigma(\kappa|1)_\Omega > l|\Sigma|R^2$, *then* L_δ *has exactly one positive simple eigenvalue.*

Proof. (a) By the compact embeddings $D(L_\delta) \hookrightarrow E_\delta$, the spectrum of L_δ consists of eigenvalues of finite algebraic multiplicity. The assertion that all eigenvalues are real will be proved in section 4.

Let $1 < p < \infty$ be fixed, and suppose that λ is an eigenvalue of L_δ with a corresponding eigenfunction (v, ρ). Then $v \in W_p^2(\Omega \setminus \Sigma)$, and v solves the elliptic transmission problem

$$\begin{cases} \kappa\lambda v - d\Delta v = 0 & \text{in} \quad \Omega \setminus \Sigma, \\ \partial_\nu v = 0 & \text{on} \quad \partial\Omega, \\ [v] = 0 & \text{on} \quad \Sigma, \\ -[d\partial_\nu v] = -\lambda l\rho & \text{on} \quad \Sigma, \end{cases}$$

with $\rho \in W_p^{4-\mathrm{sign}(\delta)-1/p}(\Sigma)$, where $\mathrm{sign}(\delta) = 1$ if $\delta > 0$, and $\mathrm{sign}(\delta) = 0$ if $\delta = 0$. Due to Sobolev's imbedding theorem we have that $\rho \in W_{p_1}^{1-1/p_1}(\Sigma)$, where $p_1 \in (p, \infty)$ is appropriately chosen. Proposition 5.1 then yields $v \in W_{p_1}^2(\Omega \setminus \Sigma)$. Next, we recall that ρ satisfies

$$\sigma\mathcal{A}_\Sigma\rho = v - (\delta/l)[d\partial_\nu v] =: h \quad \text{on} \quad \Sigma.$$

Since $v \in W_{p_1}^2(\Omega \setminus \Sigma)$ we see that $h \in W_{p_1}^{2-\mathrm{sign}(\delta)-1/p_1}(\Sigma)$, and we obtain from the properties of the elliptic differential operator $\mathcal{A}_\Sigma$ that $\rho \in W_{p_1}^{4-\mathrm{sign}(\delta)-1/p_1}(\Sigma)$. The arguments given above can now be iterated a finite number of times to show that

$$(v, \rho) \in W_q^2(\Omega \setminus \Sigma) \times W_q^{4-\mathrm{sign}(\delta)-1/q}(\Sigma)$$

for any fixed $q > p$. Clearly, this is also true for any $q < p$. We have, thus, shown that the spectrum of L_δ is independent of p. The properties listed in (b)–(d) are proved in section 3, and assertion (e) is shown in section 4 while (f) is established in section 5. ∎

PROPOSITION 2.2. *Let* $1 < p < \infty$. *Suppose that* $(\lambda, v, \rho) \in \mathbb{R} \times W_p^2(\Omega\setminus\Sigma) \times W_p^2(\Sigma)$ *solves the eigenvalue problem* (1.9). *Then the functions* (v, ρ) *are smooth; that is,*

$$v|_{\Omega_i} \in C^\infty(\bar\Omega_i), \quad \rho \in C^\infty(\Sigma).$$

Proof. This follows from a similar bootstrapping argument as in the proof of Theorem 2.1(a), based on regularity properties of the elliptic transmission problems (3.4) and (5.2), and regularity properties of the differential operator $\mathcal{A}_\Sigma$. ∎

Due to Theorem 2.1 and Proposition 2.2 we may restrict our attention to the eigenvalue problem (1.9) in the Hilbert space setting of $L_2(\Omega) \times L_2(\Sigma)$. In the following, we use the notation $(\cdot|\cdot)_\Omega$ and $\|\cdot\|_\Omega$ for the inner product and the norm in $L_2(\Omega)$, respectively, and similarly for $L_2(\Sigma)$.

3. The trivial eigenvalue. Let us first look at the eigenvalue problem (1.9) with $\lambda = 0$. Obviously, here $l \in \mathbb{R}$ can be arbitrary, and also $\delta \in \mathbb{R}$. For this purpose we recall some properties of the operator $\mathcal{A}_\Sigma$.

PROPOSITION 3.1. *Let $\Sigma = S_R(x_0) \subset \mathbb{R}^n$ be a sphere of radius R and center x_0, and let*

$$A_\Sigma = -\frac{1}{n-1}\left(\frac{n-1}{R^2} + \Delta_\Sigma\right)$$

be defined on $L_2(\Sigma)$ with domain $W_2^2(\Sigma)$. Then the following assertions hold:

(a) *A_Σ is self-adjoint. Its spectrum consists of countably many eigenvalues $\lambda_k = \frac{1}{(n-1)R^2}\big(k(k+n-2) - (n-1)\big)$ with $k \geq 0$. The eigenfunctions are given by the spherical harmonics of degree k.*

(b) *The kernel of A_Σ is given by $N(A_\Sigma) = \operatorname{span}\{Y_1, \ldots, Y_n\}$, where Y_j denotes the spherical harmonics of degree 1 on Σ, normalized by $(Y_i|Y_j)_\Sigma = \delta_{ij}$.*

(c) *The range of A_Σ, $R(A_\Sigma)$ is closed, and we have $L_2(\Sigma) = N(A_\Sigma) \oplus R(A_\Sigma)$.*

(d) *There is precisely one negative eigenvalue, namely $-1/R^2$, with eigenfunction 1, which is simple.*

(e) *A_Σ is positive semi-definite on $L_{2,0}(\Sigma) = \{\rho \in L_2(\Sigma) : (\rho|1)_\Sigma = 0\}$ and positive definite on*

$$L_{2,0}(\Sigma) \cap R(A_\Sigma) = \{\rho \in L_2(\Sigma) : (\rho|1)_\Sigma = (\rho|Y_j)_\Sigma = 0,\ j = 1, \ldots, n\}.$$

Proof. We can assume, without loss of generality, that $\Sigma = S_R(0) = R\,\mathbb{S}^{n-1}$, where $\mathbb{S}^{n-1}$ denotes the standard unit sphere in $\mathbb{R}^n$. Let $\Phi : \Sigma \to \mathbb{S}^{n-1}$ be defined by $p \mapsto (1/R)p$. Then Φ is a smooth diffeomorphism of Σ into $\mathbb{S}^{n-1}$, and one readily verifies that

$$(g|h)_{L_2(\Sigma)} = R^{n-1}(\Phi_* g|\Phi_* h)_{L_2(\mathbb{S}^{n-1})}, \quad \Delta_\Sigma = (1/R^2)\,\Phi^* \Delta_{\mathbb{S}^{n-1}}\,\Phi_*, \tag{3.1}$$

where Φ^* and Φ_* are the pull-back and push-forward operators, respectively. We then have

$$(\lambda - A_\Sigma)\rho = 0 \iff \left(\lambda + \frac{1}{(n-1)R^2}\big((n-1) + \Delta_{\mathbb{S}^{n-1}}\big)\right)\Phi_*\rho = 0, \tag{3.2}$$

which shows that λ is an eigenvalue of A_Σ iff

$$\lambda = \frac{1}{(n-1)R^2}\big(\mu - (n-1)\big) \tag{3.3}$$

with μ an eigenvalue of $-\Delta_{\mathbb{S}^{n-1}}$. The assertions in (a)–(b) and (d)–(e) follow now from (3.1)–(3.3) and well-known results for the Laplace–Beltrami operator on $\mathbb{S}^{n-1}$; see, for instance, [30, section 31]. Since A_Σ has compact resolvent we conclude that $R(A_\Sigma)$ is closed, and the fact that A_Σ is self-adjoint then implies the remaining assertion in (c). ∎

Before we proceed we need the following result on the elliptic transmission problem:

$$\begin{cases} -d\Delta v = f & \text{in} \quad \Omega \setminus \Sigma, \\ \partial_\nu v = 0 & \text{on} \quad \partial\Omega, \\ [v] = 0 & \text{on} \quad \Sigma, \\ -[d\partial_\nu v] = g & \text{on} \quad \Sigma. \end{cases} \tag{3.4}$$

PROPOSITION 3.2. *Let $1 < p < \infty$. Then the following hold:*

(a) *The transmission problem* (3.4) *has a solution $v \in W_p^2(\Omega \setminus \Sigma)$ if and only if $(f, g) \in L_p(\Omega) \times W_p^{1-1/p}(\Sigma)$ and the compatibility condition*

$$(f|1)_\Omega + (g|1)_\Sigma = 0$$

is satisfied. The solution is unique with the normalization $(\kappa|v)_\Omega = 0$.

(b) *Let $v = T_0 g$ be the unique solution of* (3.4) *with $f = 0$, $(g|1)_\Sigma = 0$, and $(\kappa|v)_\Omega = 0$. Then T_0 is self-adjoint and positive definite on $L_2(\Sigma)$; that is, there exists a positive constant $c = c(d_i, \Omega_i)$ such that*

$$(T_0 g|g)_{L_2(\Sigma)} \geq c \, \|g\|^2_{L_2(\Sigma)}, \qquad g \in W_2^{1/2}(\Sigma).$$

Proof. (a) This proof follows from known results in elliptic theory since the Lopatinskii–Shapiro conditions are satisfied.

(b) Let $g, h \in W_2^{1/2}(\Sigma)$ be given. Then we have

$$\begin{aligned}(T_0 g|h)_\Sigma = (T_0 g|[-d\partial_\nu T_0 h])_\Sigma &= (d\,\nabla T_0 g|\nabla T_0 h)_\Omega \\ &= (-[d\partial_\nu T_0 g]|T_0 h)_\Sigma = (g|T_0 h)_\Sigma,\end{aligned}$$

thus showing that T_0 is symmetric. For $v := T_0 g$ the computation above yields

$$(T_0 g|g)_\Sigma = (d\,\nabla v|\nabla v)_\Omega.$$

On the other hand, setting $v_i = v|_{\Omega_i}$ we obtain

$$\begin{aligned}\|g\|_{L_2(\Sigma)} &= \|d_1 \partial_\nu v_1 - d_2 \partial_\nu v_2\|_{L_2(\Sigma)} \leq c\big(\|v_1\|_{W_2^2(\Omega_1)} + \|v_2\|_{W_2^2(\Omega_2)}\big) \\ &\leq c\big(\|v_1\|_{L_2(\Omega_1)} + \|\Delta v_1\|_{L_2(\Omega_1)} + \|v_2\|_{L_2(\Omega_2)} + \|\Delta v_2\|_{L_2(\Omega_2)}\big) \\ &= c\|v\|_{L_2(\Omega)} \leq c\|v\|_{W_2^1(\Omega)} \leq c\|\nabla v\|_{L_2(\Omega)} \leq c(T_0 g|g)_\Sigma^{1/2}.\end{aligned}$$

Here we used the fact that

$$v = T_0 g \in W_2^1(\Omega) \cap W_2^2(\Omega \setminus \Sigma).$$

Moreover, we used that $\big(\|\cdot\|_{L_2(\Omega_i)} + \|\Delta \cdot\|_{L_2(\Omega_i)}\big)$ defines an equivalent norm on $W_2^2(\Omega_i)$, and also that $\|\nabla u\|_{L_2(\Omega)}$ defines an equivalent norm on $W_2^1(\Omega)$ for all functions $u \in W_2^1(\Omega)$ with $(\kappa|u)_\Omega = 0$. This completes the proof of Proposition 3.2. □

We are now ready to establish the assertions (b)–(d) of Theorem 2.1.

(b) Suppose that (v, ρ) is a solution of (1.9) with $\lambda = 0$. Then, taking the inner product of $(1.9)_1$ with v, the divergence theorem and $(1.9)_{2,4}$ show that v is constant on $\Omega \setminus \Sigma$; hence, v is constant on Ω and $v = \sigma \mathcal{A}_\Sigma \rho$ due to $(1.9)_3$. A special solution of this problem is $\rho_0 = -R^2 v/\sigma$, and the solutions of the corresponding homogeneous equation are the spherical harmonics Y_j on Σ for $j = 1, \ldots, n$. Thus we obtain an $(n+1)$-dimensional null space spanned by(2.1), which proves Theorem 2.1(b).

This null space is tangent to the (n+1)-dimensional manifold of equilibria, where $(0, Y_j)$ corresponds to the center x_0, and $(-1, Y_0)$ corresponds to the radius R. Note that the null spaces of L_0 and L_δ, $\delta > 0$, coincide.

(c) Suppose that (2.2) holds. Then there exists a pair $(v^*, \rho^*) \in N(L_\delta^2) \setminus N(L_\delta)$. Indeed, this can be seen as follows: we first solve (3.4) with $(f, g) = (-\kappa, lR^2/\sigma)$. According to Proposition 3.2, this problem has a unique solution v_0 with $(\kappa|v_0)_\Omega = 0$ since the necessary compatibility condition is precisely (2.2).

Set $v^* = v_0 + l\sum_{j=1}^n \alpha_j T_0 Y_j$. Then v^* satisfies

$$\begin{cases} -(d/\kappa)\Delta v^* = -1 & \text{in} \quad \Omega\setminus\Sigma, \\ \partial_\nu v^* = 0 & \text{on} \quad \partial\Omega, \\ [v^*] = 0 & \text{on} \quad \Sigma, \\ -[(d/l)\partial_\nu v^*] = R^2/\sigma + \Sigma_{j=1}^n \alpha_j Y_j & \text{on} \quad \Sigma. \end{cases} \tag{3.5}$$

We now want to solve $v^* = \sigma A_\Sigma \rho + (\delta/l)[d\partial_\nu v^*]$ in terms of ρ; that is, we consider the problem

$$\sigma A_\Sigma \rho = v^* - (\delta/l)[d\partial_\nu v^*] =: h.$$

According to Proposition 3.1(b)–(c) this problem has a solution ρ^* iff $(h|Y_i)_\Sigma = 0$ for $i = 1,\dots,n$. The conditions $(h|Y_i)_\Sigma = 0$ will then be employed to determine the coefficients α_j. A short computation yields

$$(h|Y_i)_\Sigma = 0 \quad \Leftrightarrow \quad \delta\alpha_i + \sum_{j=1}^n l(T_0 Y_j|Y_i)_\Sigma\, \alpha_j = -(v_0|Y_i)_\Sigma, \quad i = 1,\dots,n.$$

Since T_0 is self-adjoint and positive definite on $L_2(\Sigma)$, there exists a unique solution of this system, as we shall see in (6.7). Due to $\sigma A_\Sigma(R^2/\sigma + \sum_{j=1}^n \alpha_j Y_j) = -1$ (see Proposition 3.1), we conclude that $(v^*,\rho^*) \in D(L_\delta^2)$. It is then easy to see that $L_\delta(v^*,\rho^*) \neq (0,0)$ and $L_\delta^2(v^*,\rho^*) = (0,0)$. These facts in combination with part (b) show that

$$N(L_\delta^2) = N(L_\delta) \oplus \operatorname{span}\{(v^*,\rho^*)\}, \tag{3.6}$$

in the degenerate case where (2.2) holds.

Next we show, still in the degenerate case (2.2), that $N(L_\delta^3) = N(L_\delta^2)$. In fact, if $(v,\rho) \in N(L_\delta^3)$, then $L_\delta(v,\rho) = (v_N,\rho_N) + \beta(v^*,\rho^*)$ for some $(v_N,\rho_N) \in N(L_\delta)$ and some scalar β. For solvability of this equation, the compatibility condition

$$\big(\kappa(v_N + \beta v^*)|1\big)_\Omega + l\big(\rho_N + \beta\rho^*|1\big)_\Sigma = 0$$

must be valid. Due to the degeneracy condition we have $(\kappa v_N|1)_\Omega + l(\rho_N|1)_\Sigma = 0$, and the compatibility condition is reduced to $\beta\big\{(\kappa v^*)|1)_\Omega + l(\rho^*|1)_\Sigma\big\} = 0$. Using the property that $-(d/\kappa)\Delta v^* = -1$ (see (3.5)), we obtain

$$\begin{aligned} -\big\{(\kappa v^*|1)_\Omega + l(\rho^*|1)_\Sigma\big\} &= -(d\Delta v^*|v^*)_\Omega - l(\rho^*|1)_\Sigma \\ &= \|\sqrt{d}\,\nabla v^*\|_\Omega^2 + ([d\partial_\nu v^*]|v^*)_\Sigma - l(\rho^*|1)_\Sigma \\ &= \|\sqrt{d}\,\nabla v^*\|_\Omega^2 - l\left(R^2/\sigma + \sum_{j=1}^n \alpha_j Y_j|\sigma A_\Sigma\rho^*\right)_\Sigma + (\delta/l)\|[d\partial_\nu v^*]\|_\Sigma^2 - l(\rho^*|1)_\Sigma \\ &= \|\sqrt{d}\,\nabla v^*\|_\Omega^2 + (\delta/l)\|[d\partial_\nu v^*]\|_\Sigma^2 \end{aligned}$$

since A_Σ is self-adjoint on $L_2(\Sigma)$ and $\sigma A_\Sigma(R^2/\sigma + \sum_{j=1}^n \alpha_j Y_j) = -1$; see Proposition 3.1. This implies $\beta = 0$, i.e., $(v,\rho) \in N(L_\delta^2)$, thus establishing Theorem 2.1(c).

(d) Let us examine when the eigenvalue $\lambda_0 = 0$ of L_δ is semi-simple. Assume that $(v,\rho) \in D(L_\delta^2)$ is such that $L_\delta^2(v,\rho) = 0$. Then

$$L_\delta(v,\rho) = \alpha_0(-1,Y_0) + \sum_{j=1}^n \alpha_j(0,Y_j).$$

This implies that

$$\begin{cases} -(d/\kappa)\Delta v = \alpha_0 & \text{in} \quad \Omega \setminus \Sigma, \\ \partial_\nu v = 0 & \text{on} \quad \partial\Omega, \\ [v] = 0 & \text{on} \quad \Sigma, \\ -[(d/l)\partial_\nu v] = -\sum_{j=0}^{n} \alpha_j Y_j & \text{on} \quad \Sigma, \\ v = \sigma \mathcal{A}_\Sigma \rho + (\delta/l)[d\partial_\nu v] & \text{on} \quad \Sigma. \end{cases}$$

According to Proposition 3.2 we necessarily have

$$\alpha_0(\kappa_1|\Omega_1| + \kappa_2|\Omega_2|) = l\sum_{j=0}^{n} \alpha_j (Y_j|1)_\Sigma = l\alpha_0|\Sigma|R^2/\sigma,$$

since the mean value of Y_j over Σ is zero for $j \geq 1$. Assuming the nondegeneracy condition

$$(\kappa|1)_\Omega := \kappa_1|\Omega_1| + \kappa_2|\Omega_2| \neq l|\Sigma|R^2/\sigma, \tag{3.7}$$

we conclude that $\alpha_0 = 0$. But then

$$0 = -\int_\Omega d\Delta v v \, dx = \int_\Omega d|\nabla v|^2 \, dx + \int_\Sigma [d\partial_\nu v] v \, ds,$$

which further yields

$$0 = \|\sqrt{d}\,\nabla v\|_\Omega^2 + l\sigma \sum_{j=1}^{n} \alpha_j (Y_j|\mathcal{A}_\Sigma \rho)_\Sigma + (\delta/l)\|[d\partial_\nu v]\|_\Sigma^2 = \|\sqrt{d}\,\nabla v\|_\Omega^2 + (\delta/l)\|[d\partial_\nu v]\|_\Sigma^2$$

since $\mathcal{A}_\Sigma$ is self-adjoint on $L_2(\Sigma)$ and $A_\Sigma Y_j = 0$ for $j \geq 1$. We conclude that v is constant in Ω and that $0 = [d\partial_\nu v] = l\sum_{j=1}^{n} \alpha_j Y_j$; hence, $\alpha_j = 0$ for all j. This shows that $\lambda_0 = 0$ is a semi-simple eigenvalue of L_δ, that is, $N(L_\delta^2) = N(L_\delta)$ for $\delta \geq 0$, provided the nondegeneracy condition (3.7) is valid, and this proves the assertion of Theorem 2.1(d).

4. Nontrivial eigenvalues. Now we consider the eigenvalue problem (1.9) for $\lambda \in \mathbb{C}$, $\lambda \neq 0$, in case $l > 0$. Suppose that $\lambda \neq 0$ is an eigenvalue with nontrivial eigenfunction (v, ρ). Taking the inner product in $L_2(\Omega)$ of the first equation in (1.9) with v and using the divergence theorem, we get

$$\begin{aligned} \lambda\|\sqrt{\kappa} v\|_\Omega^2 = (d\Delta v|v)_\Omega &= -\|\sqrt{d}\,\nabla v\|_\Omega^2 - ([d\partial_\nu v]|v)_\Sigma \\ &= -\|\sqrt{d}\,\nabla v\|_\Omega^2 - (\delta/l)\|[d\partial_\nu v]\|_\Sigma^2 - \lambda l\sigma(\rho|A_\Sigma \rho)_\Sigma; \end{aligned}$$

hence, we obtain the identity

$$\lambda\Big(\|\sqrt{\kappa} v\|_\Omega^2 + l\sigma(\rho|A_\Sigma\rho)_\Sigma\Big) + \|\sqrt{d}\,\nabla v\|_\Omega^2 + (\delta/l)\|[d\partial_\nu v]\|_\Sigma^2 = 0. \tag{4.1}$$

If $\operatorname{Im}\lambda \neq 0$, then $\|\sqrt{\kappa} v\|_\Omega^2 + l\sigma(\rho|A_\Sigma\rho)_\Sigma = 0$; hence, $\|\sqrt{d}\,\nabla v\|_\Omega^2 + (\delta/l)\|[d\partial_\nu]\|_\Sigma^2 = 0$. We conclude that v is constant and $(1.9)_{1,4}$ now implies that $(v, \rho) = (0, 0)$ since

$\lambda \neq 0$. Therefore the eigenvalues and eigenfunctions are real, thus establishing Theorem 2.1(a).

Using $\lambda l\rho = [d\partial_\nu v]$ and the fact that λ is real, we may rewrite (4.1) as

$$\lambda\Big(\|\sqrt{\kappa}v\|_\Omega^2 + l\sigma(\rho|A_\Sigma\rho)_\Sigma + \lambda l\delta\|\rho\|_\Sigma^2\Big) + \|\sqrt{d}\,\nabla v\|_\Omega^2 = 0. \tag{4.2}$$

Integrating the eigenvalue equation (1.9) we obtain

$$\lambda(v|\kappa)_\Omega = (d\Delta v|1)_\Omega = -([d\partial_\nu v]|1)_\Sigma = -\lambda l(\rho|1)_\Sigma;$$

hence, dividing by λ,

$$(v|\kappa)_\Omega + l(\rho|1)_\Sigma = 0. \tag{4.3}$$

Splitting $\rho = \rho_0 + \bar\rho$ and $v = v_0 + \bar v$, where $(\rho_0|1)_\Sigma = (v_0|\kappa)_\Omega = 0$, from (4.2) and (4.3) we derive an identity equivalent to (4.2), namely,

$$\begin{aligned}\lambda\Big(\|\sqrt{\kappa}v_0\|_\Omega^2 + l\sigma(\rho_0|A_\Sigma\rho_0)_\Sigma + \lambda l\delta\|\rho_0\|_\Sigma^2\Big) + \|\sqrt{d}\,\nabla v\|_\Omega^2 \\ + \lambda\Big(\lambda\delta + \frac{l|\Sigma|}{(\kappa|1)_\Omega} - \frac{\sigma}{R^2}\Big) l|\Sigma|\bar\rho^2 = 0.\end{aligned} \tag{4.4}$$

Since A_Σ is positive semi-definite on $L_{2,0}(\Sigma)$, the L_2-functions with mean zero, we see that in case $\lambda > 0$, (4.4) implies $v =$ constant, and hence $(v,\rho) = (0,0)$, provided that

$$(\kappa|1)_\Omega \leq l|\Sigma|R^2/\sigma. \tag{4.5}$$

Consequently, (1.9) cannot have positive eigenvalues if the stability condition (4.5) is satisfied, thus proving the assertion of Theorem 2.1(e).

5. The unstable eigenvalue. As far as we know, for $l > 0$ and

$$\zeta := \frac{\sigma(\kappa|1)_\Omega}{l|\Sigma|R^2} \leq 1 \tag{5.1}$$

there are no positive eigenvalues; however, the algebraic eigenspace of L_δ rises in dimension by one when ζ becomes 1. This indicates that for $\zeta > 1$ there is exactly one algebraically simple eigenvalue $\lambda_* > 0$. We want to prove that this is indeed the case. In order to do so, we consider the following transmission problem:

$$\begin{cases} \lambda\kappa v - d\Delta v = f & \text{in} \quad \Omega\setminus\Sigma, \\ \partial_\nu v = 0 & \text{on} \quad \partial\Omega, \\ [v] = 0 & \text{on} \quad \Sigma, \\ -[d\partial_\nu v] = g & \text{on} \quad \Sigma. \end{cases} \tag{5.2}$$

Then the following result holds.

PROPOSITION 5.1. *Let $1 < p < \infty$ and $\operatorname{Re}\lambda > 0$. Then the following hold:*

(a) *Problem (5.2) has precisely one solution $v \in W_p^1(\Omega) \cap W_p^2(\Omega\setminus\Sigma)$ iff $(f,g) \in L_p(\Omega) \times W_p^{1-1/p}(\Sigma)$.*

(b) *Let T_λ be the solution operator for (5.2) with $f = 0$. Given any number $\theta \in (0,\pi)$, there exist positive numbers $\lambda_0 = \lambda_0(\theta, d_i, \kappa_i, \Omega_i)$ and $M_0 = M_0(\theta, d_i, \kappa_i, \Omega_i)$ such that*

$$\|T_\lambda g\|_{L_p(\Sigma)} \leq M_0|\lambda|^{-1/2}\|g\|_{L_p(\Sigma)}$$

for $g \in W_p^{1-1/p}(\Sigma)$, whenever $|\lambda| \geq \lambda_0$ and $|\arg\lambda| \leq \theta$.

(c) *For $\lambda > 0$, T_λ is positive definite on $L_2(\Sigma)$; that is, there exists a positive constant $\beta = \beta(d_i, \kappa_i, \Omega_i)$ such that*

$$(T_\lambda g|g)_{L_2(\Sigma)} \geq \beta \frac{\sqrt{\lambda}}{1+\lambda} \|g\|^2_{L_2(\Sigma)}, \qquad g \in W_2^{1/2}(\Sigma).$$

Proof. (a) This proof follows from known results in elliptic theory.

(b) Suppose that $\Omega_1 = \mathbb{R}^n_-$ and $\Omega_2 = \mathbb{R}^n_+$, with $\mathbb{R}^n_\pm = \{(x', x_n) \in \mathbb{R}^n : \pm x_n < 0\}$. Then one readily obtains that

$$T_\lambda g|_{\mathbb{R}^{n-1}\times\{0\}} = \mathcal{F}^{-1}\left(m_\lambda \mathcal{F} g\right),$$

where $\mathcal{F}$ denotes the Fourier transform in the tangential variables, and where

$$m_\lambda(\xi) = \frac{1}{\sqrt{d_1}\sqrt{\kappa_1\lambda + d_1|\xi|^2} + \sqrt{d_2}\sqrt{\kappa_2\lambda + d_2|\xi|^2}}\,.$$

The assertion then follows from Mikhlin's multiplier theorem. The general case can be obtained by the usual procedure of localization.

(c) Let $g, h \in W_2^{1/2}(\Sigma)$ be given. Then we have

$$\begin{aligned}(T_\lambda g|h)_\Sigma = (T_\lambda g|[-d\partial_\nu T_{\bar\lambda} h])_\Sigma &= \lambda(\kappa\, T_\lambda g|T_{\bar\lambda} h)_\Omega + (d\,\nabla T_\lambda g|\nabla T_{\bar\lambda} h)_\Omega \\ &= (-[d\partial_\nu T_\lambda g]|T_{\bar\lambda} h)_\Sigma = (g|T_{\bar\lambda} h)_\Sigma,\end{aligned}$$

showing that $T_\lambda^* = T_{\bar\lambda}$, in particular, that T_λ is symmetric for $\lambda > 0$. For $v := T_\lambda g$, $\lambda > 0$, the computation above yields

$$(T_\lambda g|g)_\Sigma = \lambda(\kappa v|v)_\Omega + (d\,\nabla v|\nabla v)_\Omega. \tag{5.3}$$

Setting $v_i = v|_{\Omega_i}$ we conclude similarly as in the proof of Proposition 3.2 that

$$\begin{aligned}\|g\|_{L_2(\Sigma)} = \|d_1\partial_\nu v_1 - d_2\partial_\nu v_2\|_{L_2(\Sigma)} &\leq c\big(\|d_1 v_1\|_{W_2^2(\Omega_1)} + \|d_2 v_2\|_{W_2^2(\Omega_2)}\big) \\ &\leq c\big(\|d_1 v_1\|_{L_2(\Omega_1)} + \|d_1\Delta v_1\|_{L_2(\Omega_1)} + \|d_2 v_2\|_{L_2(\Omega_2)} + \|d_2\Delta v_2\|_{L_2(\Omega_2)}\big) \\ &= c\big(\|d_1 v_1\|_{L_2(\Omega_1)} + \lambda\|\kappa_1 v_1\|_{L_2(\Omega_1)} + \|d_2 v_2\|_{L_2(\Omega_2)} + \lambda\|\kappa_2 v_2\|_{L_2(\Omega_2)}\big) \\ &\leq c_\lambda\sqrt{\lambda}\|v\|_{L_2(\Omega)} \leq c_\lambda\big(\sqrt{\lambda}\|v\|_{L_2(\Omega)} + \|\nabla v\|_{L_2(\Omega)}\big) \leq c_\lambda\,(T_\lambda g|g)_\Sigma^{1/2},\end{aligned}$$

where $c_\lambda = c(d_i, \kappa_i, \Omega_i)(1+\lambda)/\sqrt{\lambda}$. In the estimates above we have used that $v = T_\lambda g \in W_2^1(\Omega) \cap W_2^2(\Omega\setminus\Sigma)$, and that $\big(\|\cdot\|_{L_2(\Omega_i)} + \|\Delta\cdot\|_{L_2(\Omega_i)}\big)$ defines an equivalent norm on $W_2^2(\Omega_i)$ and, lastly, we employed (5.3). This completes the proof of Proposition 5.1. □

We assume now that $\lambda > 0$ is a fixed number. For given $\rho \in W_2^{1/2}(\Sigma)$, let v be the solution of the transmission problem

$$\begin{cases} \lambda\kappa v - d\Delta v = 0 & \text{in} \quad \Omega\setminus\Sigma, \\ \partial_\nu v = 0 & \text{on} \quad \partial\Omega, \\ [v] = 0 & \text{on} \quad \Sigma, \\ -[d\partial_\nu v] = -\lambda l\rho & \text{on} \quad \Sigma. \end{cases} \tag{5.4}$$

Then $v = T_\lambda(-\lambda l\rho) = -\lambda l T_\lambda\rho$ with T_λ being the solution operator introduced above. By inserting this representation of v into the equation $v = \sigma A_\Sigma\rho + \lambda\delta\rho$, we obtain the problem

$$\lambda\delta\rho + \lambda l T_\lambda\rho + \sigma A_\Sigma\rho = 0, \tag{5.5}$$

which is equivalent to the eigenvalue problem.
Setting $B_\lambda(s) := \lambda\delta I + \lambda l T_\lambda + s\sigma A_\Sigma$ for $s > 0$ and employing Proposition 5.1(c), we obtain the estimate

$$\begin{aligned}(B_\lambda(s)\rho|\rho)_\Sigma &\geq \lambda(\delta+\gamma l)\|\rho\|_\Sigma^2 + s\sigma(A_\Sigma\rho|\rho)_\Sigma \\ &= \lambda(\delta+\gamma l)\|\rho_0\|_\Sigma^2 + s\sigma(A_\Sigma\rho_0|\rho_0)_\Sigma + \big\{\lambda(\delta+\gamma l) - s\sigma/R^2\big\}|\Sigma|\bar\rho^2,\end{aligned}$$

where $\gamma = \beta\sqrt{\lambda}/(1+\lambda)$ and $\rho = \rho_0 + \bar\rho$ with $(\rho_0|1)_\Sigma = 0$. Since $(A_\Sigma\rho_0|\rho_0)_\Sigma \geq 0$ we see that all of the terms in the previous line are nonnegative, provided $\lambda(\delta+\gamma l) \geq s\sigma/R^2$, i.e., for small s. Hence, for small $s > 0$, the operator $B_\lambda(s)$ is positive definite, which means that λ cannot be an eigenvalue of (1.9), where in the third line of (1.9) σ is replaced by $s\sigma$. On the other hand, choosing $\rho = 1$ we have

$$(B_\lambda(s)1|1)_\Sigma = \lambda\delta|\Sigma| + \lambda l(T_\lambda 1|1)_\Sigma - s\sigma|\Sigma|/R^2 < 0$$

if s becomes large. Now we set

$$s_* := s_*(\lambda) := \sup\{s > 0 :\ B_\lambda(s) \text{ is positive definite}\}.$$

Then $B_\lambda(s_*)$ is still semi-definite, but not definite, and hence, by compactness of the resolvent, has a nontrivial kernel. Therefore, for a given $\lambda > 0$ there is an $s_* = s_*(\lambda)$ such that λ is an eigenvalue of (1.9), where σA_Σ is replaced by $s_*\sigma A_\Sigma$ in the third line.

Next, we show that positive eigenvalues are simple. Rewrite (5.5) as

$$\lambda\delta\rho_0 + \lambda l T_\lambda\rho_0 + \sigma A_\Sigma\rho_0 = -\big\{\lambda\delta + \lambda l T_\lambda 1 - \sigma/R^2\big\}\bar\rho.$$

Since B_λ is positive definite on $L_{2,0}(\Sigma)$, this equation has precisely one solution for given $\bar\rho$, which shows that the eigenspace $N(\lambda - L_\delta)$ is at most one-dimensional for any given $\lambda > 0$.

To show that nontrivial eigenvalues are semi-simple, suppose that

$$(\lambda - L_\delta)(v,\rho) = (v_1,\rho_1), \quad (\lambda - L_\delta)(v_1,\rho_1) = 0.$$

Then by Green's formula

$$\begin{aligned}\|\sqrt{\kappa}v_1\|_\Omega^2 &= (\lambda\kappa v - d\Delta v|v_1)_\Omega \\ &= (v|\lambda\kappa v_1 - d\Delta v_1)_\Omega + ([d\partial_\nu v]|v_1)_\Sigma - (v|[d\partial_\nu v_1])_\Sigma \\ &= (\delta/l)([d\partial_\nu v]|[d\partial_\nu v_1])_\Sigma + l\sigma(\lambda\rho - \rho_1|A_\Sigma\rho_1)_\Sigma \\ &\quad - (\delta/l)([d\partial_\nu v]|[d\partial_\nu v_1])_\Sigma - \lambda l\sigma(A_\Sigma\rho|\rho_1)_\Sigma \\ &= -l\sigma(\rho_1|A_\Sigma\rho_1),\end{aligned}$$

which yields

$$\|\sqrt{\kappa}v_1\|_\Omega^2 + l\sigma(\rho_1|A_\Sigma\rho_1).$$

It follows now from (4.1) that v_1 is constant on $\Omega\setminus\Sigma$. Since $\lambda \neq 0$, we then obtain from (1.9) that $(v_1,\rho_1) = (0,0)$. Thus any nontrivial eigenvalue is semi-simple, and, in particular, positive eigenvalues are algebraically simple.

We want to show that for $\zeta > 1$ there is precisely one positive eigenvalue $\lambda_* > 0$. For this purpose we fix the parameters d, l, σ, δ as well as R, but replace κ by $s\kappa$

in the first line of (1.9). Fixing $\mu = \lambda s$ and scaling $\rho \mapsto \rho/s$, we obtain the scaling $\sigma \mapsto s\sigma$. The argument given previously then shows that there is $s_* > 0$ such that μ is a simple eigenvalue of the scaled problem; hence, $\lambda_* = \mu/s_* > 0$ is a simple positive eigenvalue for (1.9) with κ replaced by $s_*\kappa$ in the first line. Since $\lambda_* = \lambda_*(s_*)$ is simple, the eigenvalue problem

$$\begin{cases} \lambda_* s\kappa v - d\Delta v = 0 & \text{in} \quad \Omega \setminus \Sigma, \\ \partial_\nu v = 0 & \text{on} \quad \partial\Omega, \\ v = \sigma \mathcal{A}_\Sigma \rho + \lambda_* \delta\rho & \text{on} \quad \Sigma, \\ \lambda_* l\rho - [d\partial_\nu v] = 0 & \text{on} \quad \Sigma \end{cases} \tag{5.6}$$

has a smooth (analytic) family $[s \mapsto (\lambda_*(s), v(s), \rho(s))]$ of solutions, which exists as long as $\lambda_*(s)$ remains a simple eigenvalue. As $\zeta(s) := s\sigma(\kappa|1)_\Omega/l|\Sigma|R^2$ approaches the value $\zeta = 1$ from above, we must have $\lambda_*(s) \to 0$ from the right. This means that at the value

$$s = s_0 := \frac{l|\Sigma|R^2}{\sigma(\kappa|1)_\Omega} \tag{5.7}$$

the eigenvalue $\lambda_*(s)$ passes through the origin, in accordance with the jump of the algebraic multiplicity by 1 of the eigenvalue 0 for L_δ at $\zeta = 1 = \zeta(s_0)$. This shows that there can be only one positive eigenvalue for (5.6), independently of the values of the parameters, and there is precisely one iff $\zeta > 1$.

If $\zeta = \sigma(\kappa|1)\Omega/l|\Sigma|R^2 > 1$, then we have that $s_0 < 1$. The argument given above shows that the modified eigenvalue problem (5.6) has for each $s > s_0$ exactly one simple eigenvalue. This is, in particular, true for $s = 1$, thus establishing Theorem 2.1(f).

Now we turn our attention to the case $l < 0$. As before, we conclude that the operator L_δ has countably many eigenvalues. We note that the argument given in section 4 also applies to the case $l < 0$ and $\delta = 0$, showing that all eigenvalues of (1.9) are real in this case.

In the following, we assume that $l < 0$ and $\delta > 0$. In order to show Theorem 1.1(f), we consider the operators $B_\lambda := \lambda\delta I + \lambda l T_\lambda + \sigma A_\Sigma$ for $\lambda > 0$. By Proposition 5.1 we have

$$(B_\lambda\rho|\rho)_\Sigma \geq \big(\delta\lambda - |l|M_0\lambda^{1/2} - \sigma/R^2\big)\|\rho\|_\Sigma^2 \geq \|\rho\|_\Sigma^2$$

provided that $\lambda \geq \mu_0$, for some $\mu_0 \geq \lambda_0$. Hence, B_λ is positive definite for large $\lambda > 0$. On the other hand we have

$$(B_\lambda 1|1)_\Sigma = \lambda\delta|\Sigma| - \lambda|l|(T_\lambda 1|1)_\Sigma - \sigma|\Sigma|/R^2 \leq \lambda\delta|\Sigma| - \sigma|\Sigma|/R^2.$$

Thus for λ small we see that B_λ is not positive. Let

$$\lambda_* := \inf\{\lambda > 0 : B_\mu \text{ is positive definite for all } \mu \geq \lambda\}.$$

Then B_{λ_*} is still semi-definite, but not definite, and hence, by compactness of the resolvent, has a nontrivial kernel. This shows that λ_* is an eigenvalue of (1.9), proving Theorem 1.1(f).

Remark 5.2. Suppose $l < 0$ and $\delta > 0$.

(a) While it is still true that all nontrivial eigenvalues of (1.9) are semi-simple, we cannot conclude that positive eigenvalues are simple.

(b) We do not know whether all eigenvalues of (1.9) are real if $l < 0$ and $\delta > 0$. We can, however, prove that every sector $[|\arg\lambda| \le \theta]$ can only contain finitely many eigenvalues for a fixed $\theta \in (0, \pi)$. This can be shown as follows. Let $\theta \in (\pi/2, \pi)$ be fixed, and suppose that $|\arg\lambda| \le \theta$. Moreover, let $\alpha \in (0, \pi/2)$ be an arbitrary fixed number. Then one verifies that

$$|\lambda + \mu| \ge \min\{\sin\alpha, \sin(\pi - \theta)\}|\lambda|, \quad \text{whenever } \mu \in \mathbb{R},\ \alpha \le |\arg\lambda| \le \theta,$$

and this shows that there exists a constant $c > 0$ such that

$$|\lambda\delta + \sigma(A_\Sigma\rho|\rho)_\Sigma| \ge c|\lambda|, \quad \alpha \le |\arg\lambda| \le \theta. \tag{5.8}$$

Using that $\sigma(A_\Sigma\rho|\rho) \ge -\sigma/R^2\|\rho\|_\Sigma^2$, we see that

$$|\lambda\delta + \sigma(A_\Sigma\rho|\rho)_\Sigma| \ge (\delta/2)|\lambda|, \quad \|\rho\|_\Sigma = 1, \quad \operatorname{Re}\lambda \ge 2\sigma/\delta R^2. \tag{5.9}$$

Combining (5.8)–(5.9) yields

$$|\lambda\delta(\rho|\rho)_\Sigma + \sigma(A_\Sigma\rho|\rho)_\Sigma| \ge k|\lambda|, \quad \|\rho\|_\Sigma = 1, \quad |\arg\lambda| \le \theta, \quad |\lambda| \ge \eta, \tag{5.10}$$

where $k = \min\{c, \delta/2\}$ and $\eta = (2\sigma/\delta R^2)(1/\cos\alpha)$. Let λ_0 and M_0 be as in Proposition 5.1. Suppose that $\lambda \in \mathbb{C} \setminus \{0\}$ with $|\arg\lambda| \le \theta$ is an eigenvalue of (1.9) with eigenfunction (v, ρ). Then we have

$$\lambda\delta\rho + \sigma A_\Sigma\rho = \lambda|l|T_\lambda\rho \tag{5.11}$$

and we can assume, without loss of generality, that $\|\rho\|_\Sigma = 1$. If $|\lambda| \ge \max\{\lambda_0, \eta\}$, then we conclude from (5.10)–(5.11) and Proposition 5.1 that

$$k|\lambda| \le M_0|l||\lambda|^{1/2}$$

and so $|\lambda|$ is bounded by $(M_0 l/k)^2$. Clearly, if $|\lambda| \le \max\{\lambda_0, \eta\}$, we have a trivial bound. This shows that all possible eigenvalues in the sector $[|\arg\lambda| \le \theta]$ are bounded. Since eigenvalues cannot accumulate in a bounded set, we see that (1.9) can only have finitely many eigenvalues in the sector $[|\arg\lambda| \le \theta]$.

6. Analysis of the unstable eigenvalue. In this section we analyze the properties of the unstable eigenvalue λ_* of problem (5.6) in case $l > 0$ in more detail. In particular, we study the behavior of $\lambda_*(s)$ and the corresponding eigenfunctions near the critical value 1 of $\zeta(s)$, i.e., for s near s_0; see (5.7).

Proof Theorem 1.3. (a) We will first analyze the behavior of $(\lambda_*(s), v(s), \rho(s))$ for s near s_0. In order to do so we use the following ansatz:

$$\begin{aligned}
\lambda_*(s) &= (s - s_0)\lambda_1(s),\\
v(s) &= -1 + (s - s_0)\lambda_1(s)v_1(s),\\
\rho(s) &= \rho_0 + (s - s_0)\eta + (s - s_0)\lambda_1(s)\big(\rho_1(s) + \vec{\beta}(s)\cdot\vec{y}\,\big),\\
(v_1(s)|\kappa)_\Omega = 0, &\quad (\rho_1(s)|1)_\Sigma = (\rho_1(s)|Y_j) = 0,\ 1 \le j \le n,
\end{aligned} \tag{6.1}$$

with

$$\rho_0 := R^2/\sigma + \vec{\alpha}\cdot\vec{y}\,, \qquad \eta := (\kappa|1)_\Omega/l\Sigma\,, \tag{6.2}$$

where $\vec{\alpha}$, $\vec{\beta}(s) \in \mathbb{R}^n$ and $\vec{y} = (Y_1, \dots, Y_n)$. Setting $r = s - s_0$ and inserting this ansatz into the eigenvalue problem (5.6), we obtain the following system of equations:

$$
\left\{
\begin{aligned}
-d\Delta v_1 &= s_0\kappa + r\kappa(1 - s\lambda_1 v_1) && \text{in} \quad \Omega \setminus \Sigma,\\
\partial_\nu v_1 &= 0 && \text{on} \quad \partial\Omega,\\
[v_1] &= 0 && \text{on} \quad \Sigma,\\
-[d\partial_\nu v_1] &= -l\rho_0 - rl\eta - r\lambda_1 l(\rho_1 + \vec{\beta}\cdot\vec{y}) && \text{on} \quad \Sigma,\\
\sigma A_\Sigma \rho_1 &= \frac{\sigma\eta}{R^2\lambda_1} - \delta\rho_0 + v_1 - r\delta\eta - r\lambda_1\delta(\rho_1 + \vec{\beta}\cdot\vec{y}) && \text{on} \quad \Sigma.
\end{aligned}
\right. \tag{6.3}
$$

We first observe that due to (5.7), $(6.1)_4$, (6.2), and the fact that $(Y_i|1)_\Sigma = 0$, the compatibility condition

$$
\big(1|s_0\kappa + r\kappa(1 - s\lambda_1 v_1)\big)_\Omega - l\big(1|\rho_0 + r\eta + r\lambda_1(\rho_1 + \vec{\beta}\cdot\vec{y})\big)_\Sigma = 0 \tag{6.4}
$$

holds. It is our intention to apply the implicit function theorem to find a smooth (analytic) curve of solutions

$$
[s \mapsto (\lambda_1(s), v_1(s), \rho_1(s), \vec{\beta}(s))]
$$

of (6.3) for s near s_0. The idea is to use the $(n+1)$ orthogonality conditions

$$
(A_\Sigma\rho_1|1) = (A_\Sigma\rho_1|Y_j) = 0, \quad 1 \le j \le n,
$$

to determine the $(n+1)$ scalar functions λ_1 and β_j. In order to do so, we will first derive an expression for $\vec{\alpha}$ and $\vec{\beta}$. Taking the inner product of $(6.3)_5$ with Y_j yields

$$
0 = -\delta\,\vec{\alpha} + (v_1|\,\vec{y}\,)_\Sigma - r\delta\lambda_1\,\vec{\beta}, \tag{6.5}
$$

where $(v_1|\,\vec{y}\,)_\Sigma$ denotes the vector in $\mathbb{R}^n$ with components $(v_1|Y_j)_\Sigma$, $1 \le j \le n$. Due to Proposition 3.2 we have

$$
\begin{aligned}
(v_1|Y_j)_\Sigma &= (v_1| - [d\partial_\nu T_0 Y_j])_\Sigma = \int_\Omega d\,\mathrm{div}(v_1 T_0 Y_j)\,dx\\
&= (d\,\nabla v_1|\nabla T_0 Y_j)_\Omega = (-d\Delta v_1|T_0 Y_j)_\Omega + (-[d\partial_\nu v_1]|T_0 Y_j)_\Sigma\\
&= (s_0\kappa + r\kappa(1 - s\lambda_1 v_1)|T_0 Y_j)_\Omega - l(\rho_0 + r\eta + r\lambda_1(\rho_1 + \vec{\beta}\cdot\vec{y})|T_0 Y_j)_\Sigma.\\
&= -rs\lambda_1(\kappa v_1|T_0 Y_j)_\Omega - l(\rho_0 + r\eta + r\lambda_1(\rho_1 + \vec{\beta}\cdot\vec{y})|T_0 Y_j)_\Sigma
\end{aligned}
$$

for $j = 1, \dots, n$. Setting first $r = 0$ yields an equation for $\vec{\alpha}$, namely,

$$
0 = -\delta\,\vec{\alpha} - (lR^2/\sigma)(1|T_0\,\vec{y}\,)_\Sigma - l(T_0\,\vec{y}\,|\,\vec{y}\,)_\Sigma\,\vec{\alpha},
$$

i.e.,

$$
\vec{\alpha} = -\big(\delta I + l(T_0\,\vec{y}\,|\,\vec{y}\,)_\Sigma\big)^{-1}(lR^2/\sigma)(1|T_0\,\vec{y}\,)_\Sigma, \tag{6.6}
$$

where $(T_0\,\vec{y}\,|\,\vec{y}\,)_\Sigma$ denotes the symmetric matrix with entries $[(T_0 Y_i|Y_j)_\Sigma]_{1\le i,j\le n}$. Here we remind the reader that

$$
\langle (T_0\,\vec{y}\,|\,\vec{y}\,)_\Sigma\xi|\xi\rangle = \sum_{i,j=1}^n \xi_i\xi_j(T_0 Y_i|Y_j)_\Sigma = (T_0(\xi\cdot\vec{y})|(\xi\cdot\vec{y}))_\Sigma \ge c\|\xi\|^2 \tag{6.7}
$$

for $\xi \in \mathbb{R}^n$, where $\langle\cdot|\cdot\rangle$ denotes the Euclidean inner product on $\mathbb{R}^n$. This shows that the matrix $(T_0\,\vec{y}\,|\,\vec{y}\,)_\Sigma$ is positive definite, and hence $\delta I + l(T_0\,\vec{y}\,|\,\vec{y}\,)_\Sigma$ is invertible for any $\delta \geq 0$. Next, we obtain for $\vec{\beta}$ that

$$\vec{\beta} = -\big(\delta I + l(T_0\,\vec{y}\,|\,\vec{y}\,)_\Sigma\big)^{-1}\big\{s\big(\kappa v_1|T_0\,\vec{y}\,\big)_\Omega + l\big(\eta/\lambda_1 + \rho_1|T_0\,\vec{y}\,\big)_\Sigma\big\}. \tag{6.8}$$

Thus we have a function $\vec{\beta} = \vec{\beta}(\lambda_1, v_1, \rho_1, s)$. Finally, we obtain an equation for λ_1 by taking the inner product of $(6.3)_5$ with 1:

$$0 = \sigma\eta|\Sigma|/R^2\lambda_1 - \delta R^2|\Sigma|/\sigma + (v_1|1)_\Sigma - r\delta|\Sigma|\eta. \tag{6.9}$$

Employing the relation $(\kappa|v_1)_\Omega = 0$ and $(6.3)_{1,4}$ as well as (6.5) yields

$$\begin{aligned}
-rs\lambda_1(\kappa v_1|v_1)_\Omega &= (s_0\kappa + r\kappa(1 - s\lambda_1 v_1)|v_1)_\Omega \\
&= (-d\Delta v_1|v_1)_\Omega = \|\sqrt{d}\,\nabla v_1\|_\Omega^2 + ([d\partial_\nu v_1]|v_1)_\Sigma \\
&= \|\sqrt{d}\,\nabla v_1\|_\Omega^2 + (l\rho_0 + rl\eta + r\lambda_1 l(\rho_1 + \vec{\beta}\cdot\vec{y}\,)|v_1)_\Sigma \\
&= \|\sqrt{d}\,\nabla v_1\|_\Omega^2 + \big\{lR^2/\sigma + rl\eta\big\}(v_1|1)_\Sigma + l\delta\big|\,\vec{\alpha} + r\lambda_1\,\vec{\beta}\big|^2 + r\lambda_1 l(\rho_1|v_1)_\Sigma.
\end{aligned}$$

This leads to

$$\begin{aligned}
0 = \|\sqrt{d}\,\nabla v_1\|_\Omega^2 &- \big\{lR^2/\sigma + rl\eta\big\}\big\{(\sigma|\Sigma|\eta/R^2\lambda_1) - \delta R^2|\Sigma|/\sigma - r\delta|\Sigma|\eta\big\} \\
&+ l\delta\big|\,\vec{\alpha} + r\lambda_1\,\vec{\beta}\big|^2 + r\lambda_1\big\{l(\rho_1|v_1)_\Sigma + s(\kappa v_1|v_1)_\Omega\big\},
\end{aligned} \tag{6.10}$$

where we used (6.9).

Suppose now that v_1 solves the first four equations of (6.3). Then one easily verifies that (6.5) is equivalent to (6.6) and (6.8). Moreover, assuming once again that v_1 satisfies the first four equations of (6.3), and that $\vec{\alpha}$ and $\vec{\beta}$ satisfy (6.6) and (6.8), one verifies that

$$(6.9) \iff (6.10). \tag{6.11}$$

For $r = 0$, that is, for $s = s_0$, we obtain from (6.10)

$$\lambda_1(s_0) = l\Sigma\eta/\big\{\|\sqrt{d}\,\nabla v_1(s_0)\|_\Omega^2 + l\delta\big(|\,\vec{\alpha}|^2 + R^4|\Sigma|/\sigma^2\big)\big\}, \tag{6.12}$$

where $v_1(s_0)$ is the unique solution of problem (3.4) with $(f, g) = (s_0\kappa, -l\rho_0)$ and $(\kappa|v_1(s_0))_\Omega = 0$; see Proposition 3.2. This shows that $\lambda_1(s_0)$ is uniquely defined and strictly positive. Moreover, we also know from (6.11) that

$$0 = (\sigma\eta|\Sigma|/R^2\lambda_1(s_0)) - \delta R^2|\Sigma|/\sigma + (v_1(s_0)|1)_\Sigma - r\delta|\Sigma|\eta.$$

We obtain $\rho_1(s_0)$ by solving

$$\sigma A_\Sigma\rho_1 = \sigma\eta/R^2\lambda_1(s_0) - \delta\rho_0 + v_1(s_0)$$

for ρ_1, which is possible since we chose $\lambda_1(s_0)$ and $\vec{\alpha}$ in such a way that the necessary orthogonality conditions of Proposition 3.1(d) hold. Equation (6.8) shows that the mapping

$$\begin{aligned}
&I \times \Big\{v \in W_2^2(\Omega\setminus\Sigma) : [v] = 0 \text{ on } \Sigma\Big\} \times W_2^2(\Sigma) \times \mathbb{R} \to \mathbb{R}^n, \\
&[(\lambda_1, v_1, \rho_1, s) \mapsto \vec{\beta}(\lambda_1, v_1, \rho_1, s)]
\end{aligned} \tag{6.13}$$

is analytic where $I \subset \mathbb{R}$ is an open interval that contains $\lambda_1(s_0)$ but does not contain 0.

We are now in a position to apply the implicit function theorem at the point $(v_1(s_0), \rho_1(s_0), s_0)$ to solve the first four equations in (6.3) and (6.9) for (λ_1, v_1) in terms of (ρ_1, s). We choose the functional analytic setting

$$\begin{aligned}
X_1 &:= \big\{v \in W_2^2(\Omega \setminus \Sigma) :\ \partial_\nu v = 0 \text{ on } \partial\Omega,\ [v] = 0 \text{ on } \Sigma,\ (\kappa|v)_\Omega = 0\big\},\\
X_2 &:= \big\{\rho \in W_2^2(\Sigma) :\ (\rho|1)_\Sigma = (\rho|Y_j)_\Sigma = 0,\ 1 \le j \le n\big\},\\
X &:= \mathbb{R} \times X_1 \times X_2 \times \mathbb{R},\\
Y &:= \mathbb{R} \times \big\{(f,g) \in L_2(\Omega) \times W_2^{1/2}(\Sigma) :\ (f|1)_\Omega + (g|1)_\Sigma = 0\big\}
\end{aligned}$$

and we define $F : V \subset X \to Y$ by means of

$$F(\lambda_1, v_1, \rho_1, s) := \begin{pmatrix} \sigma\eta|\Sigma|/R^2\lambda_1 - \delta R^2|\Sigma|/\sigma + (v_1|1)_\Sigma - r\delta|\Sigma|\eta \\ -\,d\Delta v_1 - s_0\kappa - r\kappa(1 - s\lambda_1 v_1) \\ -\,[d\partial_\nu v_1] + l(\rho_0 + r\eta + r\lambda_1(\rho_1 + \vec{\beta}\cdot\vec{y}\,)) \end{pmatrix},$$

where $V := I \times X_1 \times X_2 \times \mathbb{R}$.

Equation (6.4) implies that F maps V into Y, and (6.13) and the definition of F show that

$$[(\lambda_1, v_1, \rho_1, s) \mapsto F(\lambda_1, v_1, \rho_1, s)] \in C^\omega(V, Y).$$

Clearly, the first four equations of (6.3) together with (6.9) are equivalent to $F(\lambda_1, v_1, \rho_1, s) = (0,0,0)$. Since we already know that

$$F(\lambda_1(s_0), v_1(s_0), \rho_1(s_0), s_0) = (0,0,0),$$

we are left with verifying that the derivative of F at the point $(v_1(s_0), \rho_1(s_0), s_0)$ w.r.t. (ρ_1, v_1) is an isomorphism, i.e.,

$$\mathbb{D}_1 F(\lambda_1(s_0), v_1(s_0), \rho_1(s_0), s_0) \in \mathrm{Isom}(\mathbb{R} \times X_1, Y).$$

It follows from Proposition 3.2(a) that the problem

$$\mathbb{D}_1 F(\lambda_1(s_0), v_1(s_0), \rho_1(s_0), s_0)(\lambda, w) = (\mu, f, g)$$

has for each $(\mu, f, g) \in Y$ a unique solution $(\lambda, w) \in \mathbb{R} \times X_1$, namely,

$$w = R_0(f,g), \quad \lambda = \frac{R^2\lambda_1^2(s_0)}{\sigma\eta|\Sigma|}\big((R_0(f,g)|1)_\Sigma - \mu\big),$$

where $w = R_0(f,g)$ is the unique solution of (3.4) with $(\kappa|w)_\Omega = 0$.

The implicit function theorem then yields a neighborhood U of $(\rho_1(s_0), s_0)$ in $X_2 \times \mathbb{R}$ such that

$$\begin{aligned}
&[(\rho_1, s) \mapsto (\lambda_1(\rho_1, s), v_1(\rho_1, s))] \in C^\omega(U, \mathbb{R} \times X_1)\\
&F(\lambda_1(\rho_1, s) v_1(\rho_1, s), \rho_1, s) = (0,0,0), \quad (\rho_1, s) \in U.
\end{aligned} \tag{6.14}$$

Combining all of the above results, we conclude that

$$[(\rho_1, s) \mapsto (\lambda_1(\rho_1, s), v_1(\rho_1, s), \vec{\beta}(\rho_1, s))] \in C^\omega(U, \mathbb{R} \times X_1 \times \mathbb{R}^n) \tag{6.15}$$

and that the functions $(\lambda_1(\rho_1,s), v_1(\rho_1,s), \vec{\alpha}, \vec{\beta}(\rho_1,s))$ satisfy the first four equations of (6.3) as well as (6.5) and (6.9). We now insert these functions into the equation for ρ_1 which gives an equation of the form

$$G(\rho_1,s) := \sigma A_\Sigma \rho_1 - \sigma\eta/R^2\lambda_1(s_0) + \delta\rho_0 - v_1(s_0) - (s-s_0)R(\rho_1,s) = 0,$$

where $[(\rho_1,s) \mapsto R(\rho_1,s)] \in C^\omega(U, L_2(\Sigma))$. By (6.5) and (6.9) we know that

$$G : X_2 \times \mathbb{R} \to Z := \big\{ g \in L_2(\Sigma) : \ (g|1)_\Sigma = (g|Y_j) = 0, \ 1 \le j \le n \big\}.$$

Moreover, we also know that $G(\rho_1(s_0), s_0) = 0$. The derivative of G with respect to ρ_1 at $(\rho_1(s_0), s_0)$ is σA_Σ, and Proposition 3.1(d) and the implicit function theorem then yield an analytic curve

$$[s \mapsto \rho_1(s)] \in C^\omega((s_0-\varepsilon_0, s_0+\varepsilon_0), X_2)$$

such that $G(\rho_1(s), s) = 0$.

Combining all of the results, we obtain an analytic curve of solutions

$$[s \mapsto (\lambda_*(s), v(s), \rho(s))]$$

of (5.6) for $s \in (s_0-\varepsilon_0, s_0+\varepsilon_0)$. If $s > s_0$, then the statement in (a) follows from the considerations in section 5.

(b) The proof of part (a) shows that the eigenvalue curve $[s \mapsto \lambda_*(s)]$ is analytic near the critical value $s = s_0$ and crosses the imaginary axis at $s = s_0$ with positive speed $\lambda_1(s_0)$; see (6.12).

(c) We show that $\lambda_*(s)$ is strictly increasing. To see this, we differentiate (5.6) w.r.t. s and form the inner product of the resulting equation in Ω with $v = v(s)$. This yields with Green's formula

$$\begin{aligned}
-(s\lambda_*(s))'\|\sqrt{\kappa}v\|_\Omega^2 &= s\lambda_*(\kappa v'|v)_\Omega - (d\Delta v'|v)_\Omega \\
&= (v'|s\lambda_*\kappa v - d\Delta v)_\Omega + ([d\partial_\nu v']|v)_\Sigma - (v'|[d\partial_\nu v])_\Sigma \\
&= (\delta/l)([d\partial_\nu v']|[d\partial_\nu v])_\Sigma + (\lambda_* l\rho' + \lambda_*' l\rho|\sigma A_\Sigma\rho)_\Sigma \\
&\quad - (\delta/l)([d\partial_\nu v]|[d\partial_\nu v'])_\Sigma - (\lambda_* l\rho|\sigma A_\Sigma\rho')_\Sigma \\
&= \lambda_*' l\sigma(A_\Sigma\rho|\rho)_\Sigma;
\end{aligned}$$

hence

$$\lambda_*\|\sqrt{\kappa}v\|_\Omega^2 + \lambda_*'\big\{\|\sqrt{s\kappa}\, v\|_\Omega^2 + l\sigma(A_\Sigma\rho|\rho)_\Sigma\big\} = 0.$$

Employing (4.1) once more (with κ replaced by $s\kappa$), we obtain

$$\lambda_*'(s) = \lambda_*^2(s)\|\sqrt{\kappa}v\|_\Omega^2 / \big\{\|\sqrt{d}\,\nabla v\|_\Omega^2 + (\delta/l)\|[d\partial_\nu v]\|_\Sigma^2\big\},$$

which yields $\lambda_*'(s) > 0$ for $s \ne s_0$. If $s = s_0$, then we have already established in (b) that $\lambda_*'(s_0) > 0$, and this shows the assertion of Theorem 1.3(c).

(d) If the stability condition (5.1) is violated, then we can conclude from the identity (4.4), where κ is now replaced with $s\kappa$ and λ is replaced with λ_*, that

$$\Big(\lambda_*(s) l\delta|\Sigma| + \frac{l^2|\Sigma|^2}{s(\kappa|1)_\Omega} - \frac{l\sigma|\Sigma|}{R^2}\Big) \le 0,$$

which shows that $\lambda_*(s) \le \frac{\sigma}{\delta R^2}\big(1 - 1/\zeta(s)\big)$ provided that $\delta > 0$, i.e., if kinetic undercooling is present.

(e) To show that $\lambda_*(s) \to \infty$ as $s \to \infty$ in case $\delta = 0$, we employ the estimate in Proposition 5.1(b). We first observe that due to the fact that $\lambda_*(s)$ is increasing in s, there exists a number $s_1 > s_0$ such that $s\lambda_*(s) \ge \lambda_0$ for $s \ge s_1$, where λ_0 is the number occurring in Proposition 5.1(b). It then follows from the relation $\lambda_* T_{s\lambda_*}\rho + \sigma A_\Sigma \rho = 0$ that

$$\begin{aligned}\sigma^2\|A_\Sigma\rho\|_\Sigma^2 = \sigma^2\|A_\Sigma\rho_0\|_\Sigma^2 + (\sigma^2|\Sigma|/R^2)\bar\rho^2 &= \lambda_*^2\|T_{s\lambda_*}\rho\|_\Sigma^2 \\ &\le M_1\|\rho\|_\Sigma^2\,\lambda_*(s)/s, \quad s \ge s_1,\end{aligned} \tag{6.16}$$

where we write $\rho = \rho_0 + \bar\rho$ with $(\rho_0|1)_\Sigma = 0$. Multiplying the eigenvalue problem (5.6) with $(s\lambda_* v - (d/\kappa)\Delta v)$ and using the divergence theorem and (6.16), we get

$$\begin{aligned}(s\lambda_*)^2\,\|\sqrt{\kappa}v\|_\Omega^2 + 2s\lambda_*\,\|\sqrt{d}\nabla v\|_\Omega^2 + \|(d/\sqrt{\kappa})\Delta v\|_\Omega^2 + 2s\lambda_*^2 l\sigma(\rho_0|A_\Sigma\rho_0)_\Sigma \\ = \big(2s\lambda_*^2 l\sigma|\Sigma|/R^2\big)\bar\rho^2 \le M_2\|\rho\|_\Sigma^2\,\lambda_*^3, \quad s \ge s_1.\end{aligned}$$

The relation $\lambda_* l\rho = [d\partial_\nu v]$ and the inequality above yield

$$\begin{aligned}\lambda_*^2\|\rho\|_\Sigma^2 = (1/l)^2\|[d\partial_\nu v]\|_\Sigma^2 &\le C\|v\|^2_{W_2^{3/2+\varepsilon}(\Omega\setminus\Sigma)} \le C\|v\|_\Omega^{(1/2-\varepsilon)}\|v\|^{3/2+\varepsilon}_{W_2^2(\Omega\setminus\Sigma)} \\ &\le C\Big\{\|v\|_\Omega^2 + \|v\|_\Omega^{(1/2-\varepsilon)}\|\Delta v\|_\Omega^{3/2+\varepsilon}\Big\} \le C\|\rho\|_\Sigma^2\,\lambda_*^3\left\{\frac{1}{(s\lambda_*)^2} + \frac{1}{(s\lambda_*)^{1/2-\varepsilon}}\right\} \\ &\le C\|\rho\|_\Sigma^2\,\lambda_*^3/(s\lambda_*)^{1/2-\varepsilon} = C\|\rho\|_\Sigma^2\,\lambda_*^{5/2+\varepsilon}/s^{1/2-\varepsilon}\end{aligned}$$

for $s \ge s_1$, where C is a generic constant that may change from line to line. Dividing by λ_*^2 and by $\|\rho\|_\Sigma^2$ implies

$$\lambda_*(s) \ge cs^{(1-2\varepsilon)/(1+2\varepsilon)}, \quad s \ge s_1.$$

Thus we can conclude that $\liminf_{s\to\infty}\lambda_*(s)/s^\theta = \infty$ for each $\theta < 1$. ∎

KHOKHLOV–ZABOLOTSKAYA–KUZNETSOV-TYPE EQUATION: NONLINEAR ACOUSTICS IN HETEROGENEOUS MEDIA*

I. KOSTIN† AND G. PANASENKO†

Abstract. The Khokhlov–Zabolotskaya–Kuznetsov model is a PDE describing the wave profile of an acoustic beam in a nonlinear medium. The paper treats the existence and uniqueness questions for this equation in the case of nonconstant coefficients. For the case of rapidly oscillating coefficients the asymptotic behavior of the solution is studied.

Key words. acoustics, nonlinear, homogenization

1. Introduction.

The so-called Khokhlov–Zabolotskaya–Kuznetsov (KZK) equation [8, 13] belongs to the set of nonlinear acoustics models, such as the well-known Riemann wave equation (or the nonlinear transfer equation), the Burgers equation, the Korteweg–de Vries equation, the Khokhlov–Zabolotskaya equation (see [2, 8, 10, 11, 14]), the Zakharov–Kuznetsov equation [5, 6], and the Rudenko–Sukhorukov equation [7, 9, 12]. These models are derived from the linear or nonlinear wave equation for the acoustic pressure, usually under the hypothesis of small variations of this pressure. More precisely the KZK equation has the form

$$\alpha u_{z\tau} = (f(u_\tau))_\tau + \beta u_{\tau\tau\tau} + \gamma u_\tau + \Delta_x u, \tag{1.1}$$

where $u_\tau = u_\tau(z, x, \tau)$ is the acoustic pressure, $(z, x) \in \mathbb{R} \times \mathbb{R}^d$, $d = 1, 2$, are space variables, and τ is the retarded time.

The nonlinear function f in the KZK equation is quadratic, i.e., $f(s) = \theta s^2$, although for the description of space-limited beams subject to the diffraction and self-action effects it can be taken as cubic: $f(s) = \theta s^3$ (see [13]).

In the real physical setting, f may have a more complicated shape. On the other hand, all of these models are derived under the assumption of small oscillations of the pressure, and so one can always consider f as quadratic for $|s| \le s^*$ and anything different for $|s| > s^*$ with some finite s^*. If $|u_\tau|$ is smaller than s^*, then the two models (with $f(s) = \theta s^2$ $\forall s$ and $f(s) = \theta s^2$ for $|s| \le s^*$) coincide. The advantage of this modified shape of f is that (as it will be proved below) we can get the global existence theorem as soon as f has a bounded derivative.

These arguments motivate us to consider the "KZK-type equation," that is, (1.1) with a nonlinearity f admitting a bounded derivative. Let us emphasize that this shape gives a more convenient physical description than the classical quadratic shape.

Another particularity of the model we consider in the present paper is that the coefficients are rapidly oscillating functions of z. This corresponds to the heterogeneous (stratified in the direction of the axis z) acoustic media. In this case (1.1) takes

†Laboratory of Mathematics of the University of Saint-Etienne (LaMUSE), Université Jean Monnet, 23 rue P. Michelon, 42023 Saint-Etienne, France (kostin@free.fr, grigory.panasenko@univ-st-etienne.fr).

the form

$$u_{zt} = r(z, z/\epsilon)(\phi(u_\tau))_\tau + b(z, z/\epsilon)u_{\tau\tau\tau} + g(z, z/\epsilon)u_\tau + \Delta_x u,$$

where ϵ is a small parameter representing the ratio between the microscale and the macroscale, while the coefficients r, b, g are oscillating with respect to the second variable. In particular, they may be 1-periodic functions of this variable. This feature complicates the problem, although it allows us to apply the homogenization method (see [1]) to obtain the homogenized model. Its solution is close to the one of the initial problem.

It seems that so far there was not any publication on the existence and uniqueness of the solution for the KZK (or KZK-type) equation, although the authors discovered that independently and simultaneously these questions (as well as the derivation of the KZK equation form the Navier–Stokes model) in the case of constant coefficients were studied by Bardos and Rozanova [3, 4]. They consider the KZK equation in the whole space ($x \in \mathbb{R}^d$) in the case of constant coefficients. In the present study we shall consider the varying (and even rapidly oscillating) coefficients of the KZK-type equation set for $x \in \omega$, where $\omega \subset \mathbb{R}^d$ is a bounded domain. The boundedness of f' will ensure the global existence, while in [3, 4] it is proved for small initial data only. In the case of stratified media we homogenize the KZK-type equation and prove the closeness of the solutions of the homogenized and initial models.

The main results of the present paper were announced by the authors in [15].

2. Problem setting. Let ω be a bounded open domain in $\mathbb{R}^d$ with a smooth boundary $\partial\omega$. For a real function $u = u(z, x, \tau)$ of the variables $z \in [0, Z]$, $\tau \in \mathbb{R}$, and $x \in \omega$, consider the following PDE:

$$\alpha u_{z\tau} = (f(u_\tau))_\tau + \beta u_{\tau\tau\tau} + \gamma u_\tau + \Delta u, \tag{2.1}$$

where the Laplace operator Δ (as well as ∇ below) derives with respect to the variable $x \in \omega$. The positive coefficients α, β, and γ are functions of z and x. The nonlinearity f may depend on z and x as well, but neither depends on τ.

In the mathematical setting, the variable z is considered as the evolutionary variable, while x and τ shall be called space variables. Let us impose the following boundary conditions on u:

$$u \text{ is } 2\pi\text{-periodic with respect to } \tau, \tag{2.2}$$

$$\nu \cdot \nabla u = 0 \qquad \text{on } \partial\omega, \tag{2.3}$$

where ν denotes the unit normal vector of ω. It is clear that these conditions are not sufficient to ensure the uniqueness. Indeed, if the coefficients are constant, then any function u depending only on z solves (2.1)–(2.3). This liberty is eliminated by the additional orthogonality condition

$$\int_0^{2\pi} u(z, x, \tau)\, d\tau = 0 \qquad \forall x, \forall z. \tag{2.4}$$

Finally, the evolutionary problem (2.1)–(2.4) requires an initial condition

$$u(0, x, \tau) = u_0(x, \tau). \tag{2.5}$$

To avoid heavy notation, in the estimates below we shall denote by M any large positive constant depending only on ω, f, α, β, γ, and Z. By "large" we mean that the estimate stays true with M replaced by any larger value.

Here is the list of assumptions under which the existence and uniqueness result for problem (2.1)–(2.5) will be established.

(ω) $\omega \subset \mathbb{R}^d$ is an open bounded set. Its boundary $\partial\omega$ is twice continuously differentiable.

($f1$) $f(s) = f(s,z,x)$ is continuously differentiable with respect to s, and its partial derivative $f' \equiv f_s(s,z,x)$ is uniformly bounded on $\mathbb{R} \times \mathbb{R}_+ \times \omega$.

($f2$) $f(0,z,x) = 0$ for all $z \in \mathbb{R}_+$ and $x \in \omega$. As is easy to see, this is not a constraint (otherwise, one can always replace $f(s,z,x)$ by $f(s,z,x) - f(0,z,x)$, leaving the equation intact). Together with the previous assumption this one implies that $|f(s,z,x)| \le M|s|$. Moreover, we assume that f is continuously differentiable with respect to z and its derivative f_z satisfies $|f_z(s,z,x)| \le M|s|$.

($f3$) Denote by F the primitive of f with respect to the first argument such that $F(0,z,x) = 0$. Clearly, $|F(s,z,x)| \le M|s|^2$. We shall assume that F is differentiable with respect to z and $|F_z(v,z,x)| \le M|v|^2$.

($\alpha\beta\gamma$) $\alpha = \alpha(z,x)$, $\beta = \beta(z,x)$, $\gamma = \gamma(z,x)$ are bounded functions defined on $\mathbb{R}_+ \times \omega$. The functions α and β are positive and uniformly bounded away from zero. The derivatives α_z, α_x, β_z, and β_x are assumed to be bounded functions.

These conditions are assumed to hold throughout sections 2–5.

The above list has to be completed by an assumption concerning the regularity of u_0. It will be given along with the definition of a solution.

3. Notation and preliminaries. Let us introduce some functional spaces. First consider the spaces of functions of the variables x and τ. Set $\Omega = \omega \times (0, 2\pi)$. The scalar product and the norm in $L_2(\Omega)$ are denoted by $\langle \cdot, \cdot \rangle$ and $\| \cdot \|$, respectively.

Let D_Ω be the set of infinitely smooth real functions $v = v(x,\tau)$ defined on $\bar\Omega$ and satisfying

$$\int_0^{2\pi} v(x,\tau)\, d\tau = 0 \quad \forall x \in \bar\omega \qquad \text{(orthogonality)}, \tag{3.1}$$

$$\frac{\partial^k}{\partial\tau^k} v(x,0) = \frac{\partial^k}{\partial\tau^k} v(x,2\pi) \quad \forall x \in \bar\omega, \quad \forall k = 0,1,\dots \qquad \text{(periodicity)}, \tag{3.2}$$

$$\nu(x) \cdot \nabla v(x,\tau) = 0 \quad \forall x \in \partial\omega, \quad \forall \tau \in [0,2\pi] \qquad \text{(Neumann condition)}. \tag{3.3}$$

Denote by X_0 the closure of D_Ω in the $L_2(\Omega)$-norm. Given a function $v \in X_0$, we shall denote by $\tilde v$ its (unique in X_0) primitive with respect to τ, that is,

$$\tilde v_\tau = v \qquad \text{and} \qquad \int_0^{2\pi} \tilde v\, d\tau = 0.$$

The Poincaré inequality yields

$$\|\tilde v\| \le \|v\| \le \|v_\tau\| \le \|v_{\tau\tau}\|$$

for all $v \in D_\Omega$. Note also that the mappings $v \mapsto v_\tau$ and $v \mapsto \tilde v$ are both antisymmetric, that is,

$$\langle v, v_\tau \rangle = 0 \qquad \text{and} \qquad \langle v, \tilde v \rangle = 0$$

for all v in X_0 for which these expressions make sense.

The closures of D_Ω with respect to the norms

$$\|v\|_1^2 = \|v_\tau\|^2 + \|\nabla v\|^2,$$
$$\|v\|_2^2 = \|v_{\tau\tau}\|^2 + \|\Delta \tilde v\|^2$$

are denoted by X_1 and X_2, respectively. Recall that, as well as the Laplace operator, the gradient is assumed to derive only with respect to $x \in \omega$. The continuous embeddings $X_2 \subset X_1 \subset X_0$ take place, the first one following from the estimate

$$2\|\nabla v\|^2 = 2\langle v_\tau, \Delta\tilde{v}\rangle \le \|v_\tau\|^2 + \|\Delta\tilde{v}\|^2 \le \|v\|_2^2,$$

while the second is the classical Poincaré inequality. Moreover, by the Rellich theorem, the embedding $X_1 \subset X_0$ is compact, and therefore the embedding $X_2 \subset X_0$ is also compact.

Now let us consider spaces of functions of three variables. For a given positive Z, set $Q = (0, Z) \times \omega \times (0, 2\pi)$. We shall use the triple bars to denote the $L_2(Q)$-norm:

$$|||u|||^2 = \int_0^Z \|u(z, \cdot\,, \cdot\,)\|^2\, dz.$$

Let D_Q be the set of infinitely smooth real functions $u = u(z, x, \tau)$ defined on $\bar{Q}$ such that $u(z, \cdot\,, \cdot\,) \in D_\Omega$ for all $z \in [0, Z]$. The closure of D_Q in $L_2(Q)$ is denoted U_0.

We shall seek for weak solutions of problem (2.1)–(2.5) in the space U_1, which is defined as the closure of D_Q in the norm

$$|||u|||_1^2 = |||u_{\tau\tau}|||^2 + |||\nabla u_\tau|||^2,$$

while U_2 stands for the space of strong solutions and is defined as the closure of D_Q with respect to the norm

$$|||u|||_2^2 = |||u_{z\tau}|||^2 + |||u_{\tau\tau\tau}|||^2 + |||\Delta u|||^2.$$

The continuous embedding $U_2 \subset U_1$ is proved similarly to the case of $X_2 \subset X_1$ and implies the inequality

$$|||u_{z\tau}|||^2 + |||u_{\tau\tau}|||^2 + |||\nabla u_\tau|||^2 \le 2|||u|||_2^2, \tag{3.4}$$

which we shall need in what follows.

4. Strong solutions: Definition and existence. If $u \in U_2$, then (2.1) writes down for u as an equality of functions in U_0. Note also that the functions of U_2 belong to $C([0, Z], X_0)$, so that the initial condition $u(0, \cdot\,, \cdot\,) = u_0$ can be understood as an identity in X_0. These two observations justify the following definition.

DEFINITION 4.1. *For given $u_0 \in X_2$ and $Z > 0$, a function $u \in U_2$ is called a strong solution to problem* (2.1)–(2.5) *on* $[0, Z]$ *if* (2.1) *holds almost everywhere in Q and $u(0, \cdot\,, \cdot\,) = u_0$ almost everywhere in Ω.*

From now on we shall consider the real functions of $(z, x, \tau) \in Q$ as X_0-valued functions of the variable z and write $u(z)$ instead of $u(z, x, \tau)$.

PROPOSITION 4.2. *For any $u_0 \in X_2$ and any $Z > 0$, problem* (2.1)–(2.5) *admits a strong solution u satisfying*

$$\sup_z \Big[\|u_{\tau\tau}\|^2 + \|u_z\|^2\Big] + |||u_{\tau\tau\tau}|||^2 + |||u_{z\tau}|||^2 + |||\Delta u|||^2 \le M\|u_{0\tau\tau}\|^2 + M\|\Delta\tilde{u}_0\|^2.$$

Proof. Denote by ψ_k the eigenfunctions of the following spectral problem:

$$-\psi_{\tau\tau} - \Delta\psi = \lambda\psi, \qquad \psi \in X_2.$$

The functions ψ_k form an orthogonal basis in X_0 as well as in X_1 and X_2. Let P_m stand for the orthogonal projection onto the subspace of X_0 spanned by $\psi_1, \dots, \psi_m$. The above spectral problem can be solved by the separation of variables, so that P_m commutes not only with $-\partial^2/\partial\tau^2 - \Delta$ but also with $-\partial^2/\partial\tau^2$ and $-\Delta$. The Galerkin approximations for problem (2.1)–(2.5) are defined as continuously differentiable functions $u^m : [0, Z] \to P_m X_0$ satisfying

$$P_m \alpha u^m_{z\tau} = P_m(f(u^m_\tau))_\tau + P_m \beta u^m_{\tau\tau\tau} + P_m \gamma u^m_\tau + \Delta u^m, \tag{4.1}$$

$$u^m(0) = P_m u_0, \tag{4.2}$$

which is equivalent to a Cauchy problem for a system of m ODEs.

First let us prove that the sequence u^m is bounded in U_2. Multiply (4.1) by $u^m_{\tau\tau\tau}$, and observe that $\langle \Delta u^m, u^m_{\tau\tau\tau}\rangle = \langle \nabla u^m_\tau, \nabla u^m_{\tau\tau}\rangle = 0$ to obtain

$$-\langle \alpha u^m_{z\tau\tau}, u^m_{\tau\tau}\rangle = \langle f'(u^m_\tau) u^m_{\tau\tau}, u^m_{\tau\tau\tau}\rangle + \langle \beta u^m_{\tau\tau\tau}, u^m_{\tau\tau\tau}\rangle - \langle \gamma u^m_{\tau\tau}, u^m_{\tau\tau}\rangle.$$

After some obvious transformations using assumptions $(f1)$, $(f2)$, and $(\alpha\beta\gamma)$ as well as the Cauchy–Young inequality, the latter relation becomes

$$\frac{d}{dz}\langle \alpha u^m_{\tau\tau}, u^m_{\tau\tau}\rangle + M^{-1}\|u^m_{\tau\tau\tau}\|^2 \le M\|u^m_{\tau\tau}\|^2,$$

and therefore the Gronwall lemma along with the equivalence of the norms $\langle \alpha u^m_{\tau\tau}, u^m_{\tau\tau}\rangle$ and $\|u^m_{\tau\tau}\|^2$ implies that

$$\sup_z \|u^m_{\tau\tau}\|^2 + \|\!|u^m_{\tau\tau\tau}|\!\|^2 \le M\|u^m_{\tau\tau}(0)\|^2 \le M\|u_{0\tau\tau}\|^2. \tag{4.3}$$

In particular, estimate (4.3) guarantees the existence of the functions u^m satisfying (4.1)–(4.2).

In order to obtain a bound on $\|\!|u^m_{z\tau}|\!\|$, take the primitive of (4.1) with respect to τ, and then derive the result in z. This yields the relation

$$\begin{aligned} &P_m \alpha_z u^m_z + P_m \alpha u^m_{zz} \\ &= P_m(f(u^m_\tau))_z + P_m \beta_z u^m_{\tau\tau} + P_m \beta u^m_{z\tau\tau} + P_m \gamma_z u^m + P_m \gamma u^m_z + \Delta \tilde{u}^m_z + c, \end{aligned} \tag{4.4}$$

where the integration constant c may depend on z and x but not on τ. Let us see now what happens when this identity is multiplied by u^m_z. The last two terms on the right will disappear. On the left, keep the second term and half of the first one:

$$\frac{1}{2}\langle \alpha_z u^m_z, u^m_z\rangle + \langle \alpha u^m_{zz}, u^m_z\rangle = \frac{1}{2}\frac{d}{dz}\langle \alpha u^m_z, u^m_z\rangle.$$

The other half of $\langle \alpha_z u^m_z, u^m_z\rangle$ goes to the right and is estimated by $\|u^m_z\|^2$. The third term on the right goes to the left and, after the integration by parts, admits the following lower bound:

$$-\langle \beta u^m_{z\tau\tau}, u^m_z\rangle = \langle \beta u^m_{z\tau}, u^m_{z\tau}\rangle \ge M^{-1}\|u^m_{z\tau}\|^2.$$

As for the first term on the right of (4.4), use the Cauchy–Young inequality and assumption $(f2)$ to obtain the estimate

$$\begin{aligned} \langle (f(u^m_\tau))_z, u^m_z\rangle &= \langle f'(u^m_\tau) u^m_{z\tau}, u^m_z\rangle + \langle f_z(u^m_\tau), u^m_z\rangle \\ &\le \delta\|u^m_{z\tau}\|^2 + \frac{M}{\delta}\|u^m_z\|^2 + \|u^m_z\|^2 + M\|u^m_\tau\|^2, \end{aligned}$$

which is valid for any positive δ. Quite similarly, for the second term on the right, we have

$$\langle \beta_z u^m_{\tau\tau}, u^m_z\rangle = -\langle \beta_z u^m_\tau, u^m_{z\tau}\rangle \le \delta\|u^m_{z\tau}\|^2 + \frac{M}{\delta}\|u^m_\tau\|^2.$$

The treatment of the remaining terms of (4.4) is evident. By putting the pieces together and choosing δ sufficiently small, we finally arrive at

$$\frac{d}{dz}\langle \alpha u^m_z, u^m_z\rangle + M^{-1}\|u^m_{z\tau}\|^2 \le M\|u^m_z\|^2 + M\|u^m_\tau\|^2.$$

As in the case of estimate (4.3), apply the Gronwall lemma to obtain

$$\sup_z \|u^m_z\|^2 + \|\!|u^m_{z\tau}|\!\|^2 \le M\|u^m_z(0)\|^2 + M\|\!|u^m_\tau|\!\|^2. \tag{4.5}$$

On the other hand, the multiplication of (4.1) by $-\tilde u^m_z$, after the appropriate integration by parts, yields

$$\langle \alpha u^m_z, u^m_z\rangle = \langle f(u^m_\tau), u^m_z\rangle + \langle \beta u^m_{\tau\tau}, u^m_z\rangle + \langle \gamma u^m, u^m_z\rangle + \langle \Delta\tilde u^m, u^m_z\rangle.$$

By applying the Cauchy–Young inequality in each of the terms on the right, we have

$$\|u^m_z\|^2 \le M\|u^m_{\tau\tau}\|^2 + M\|\Delta\tilde u^m\|^2,$$

which allows us to eliminate $\|u^m_z(0)\|^2$ from the right-hand side of (4.5). By taking (4.3) into account, we can rewrite estimate (4.5) as

$$\sup_z \|u^m_z\|^2 + \|\!|u^m_{z\tau}|\!\|^2 \le M\|u_{0\tau\tau}\|^2 + M\|\Delta\tilde u_0\|^2. \tag{4.6}$$

The missing bound on $\|\!|\Delta u^m|\!\|$ can be obtained directly from (4.1) with the help of estimates (4.3) and (4.6):

$$\begin{aligned}\|\!|\Delta u^m|\!\|^2 &\le M\|\!|u^m_{z\tau}|\!\|^2 + M\|\!|u^m_{\tau\tau\tau}|\!\|^2 + M\|\!|u^m_{\tau\tau}|\!\|^2 + M\|\!|u^m_\tau|\!\|^2\\ &\le M\|u_{0\tau\tau}\|^2 + M\|\Delta\tilde u_0\|^2.\end{aligned} \tag{4.7}$$

Note that, according to the convention of section 3, we use the symbol M to denote *any* constant, although it is clear that the values of M in the first and in the second line of (4.7) cannot be the same.

By putting together the estimates (4.3), (4.6), and (4.7) we obtain

$$\begin{aligned}\sup_z \left[\|u^m_{\tau\tau}\|^2 + \|u^m_z\|^2\right] + \|\!|u^m_{\tau\tau\tau}|\!\|^2 + \|\!|u^m_{z\tau}|\!\|^2 + \|\!|\Delta u^m|\!\|^2\\ \le M\|u_{0\tau\tau}\|^2 + M\|\Delta\tilde u_0\|^2.\end{aligned} \tag{4.8}$$

Thus the sequence u^m is bounded in U_2 and therefore contains a subsequence u^{m_j} such that

$$u^{m_j}_{\tau\tau\tau} \xrightarrow{U_0} u_{\tau\tau\tau}, \qquad u^{m_j}_\tau \xrightarrow{U_0} u_\tau, \qquad u^{m_j}_{z\tau} \xrightarrow{U_0} u_{z\tau}, \qquad \Delta u^{m_j} \xrightarrow{U_0} \Delta u,$$

where $u \in U_2$. In order to show the convergence in the nonlinear term, notice that by (3.4) the sequence u^m_τ is bounded in $H^1(Q)$, and hence $u^{m_j}_\tau \to u_\tau$ strongly in U_0.

By the Lipschitzness of f we also have that $f(u_\tau^{m_j}) \to f(u_\tau)$ in $L_2(Q)$. Moreover, the sequence $(f(u_\tau^{m_j}))_\tau = f'(u_\tau^{m_j})u_{\tau\tau}^{m_j}$ is bounded in U_0, and therefore

$$(f(u_\tau^{m_j}))_\tau \xrightarrow{U_0} (f(u_\tau))_\tau.$$

Thus we can pass to the U_0-weak limit in (4.1) and obtain

$$\alpha u_{z\tau} = (f(u_\tau))_\tau + \beta u_{\tau\tau\tau} + \gamma u_\tau + \Delta u$$

as an identity in U_0. The compact embedding $U_2 \subset C([0,Z],X_0)$ implies the convergence $u^{m_j}(z) \to u(z)$ in X_0 for each z. In particular, $u(0) = u_0$. Finally, pass to the limit as $m \to \infty$ in estimate (4.8) to complete the proof. □

5. Strong solutions: Further properties. The next two statements establish further properties of strong solutions and prepare the proof of the existence result for the weak solutions.

PROPOSITION 5.1. *Each strong solution u of problem* (2.1)–(2.5) *satisfies*

$$\sup_z \Big[\|u_\tau\|^2 + \|\nabla u\|^2\Big] + \|\!|u_{\tau\tau}|\!\|^2 + \|\!|\nabla u_\tau|\!\|^2 \le M\Big[\|u_{0\tau}\|^2 + \|\nabla u_0\|^2\Big]. \tag{5.1}$$

Proof. Multiply the equation

$$\alpha u_{z\tau} = (f(u_\tau))_\tau + \beta u_{\tau\tau\tau} + \gamma u_\tau + \Delta u$$

by u_τ, and integrate the result over Ω. The first and the last terms on the right will disappear. After obvious transformations in the remaining terms we obtain for almost all $z \in (0,Z)$ the inequality

$$\frac{d}{dz}\langle \alpha u_\tau, u_\tau\rangle + M^{-1}\|u_{\tau\tau}\|^2 \le M\|u_\tau\|^2. \tag{5.2}$$

The multiplication of the equation by $-u_z$ suppresses the left-hand side and thus yields

$$0 = \langle f(u_\tau), u_{z\tau}\rangle + \langle \beta u_{\tau\tau}, u_{z\tau}\rangle - \langle \gamma u_\tau, u_z\rangle + \frac{1}{2}\frac{d}{dz}\|\nabla u\|^2. \tag{5.3}$$

The first term on the right of (5.3) can be transformed as follows:

$$\langle f(u_\tau), u_{z\tau}\rangle = \frac{d}{dz}\langle F(u_\tau), 1\rangle - \langle F_z(u_\tau), 1\rangle \ge \frac{d}{dz}\langle F(u_\tau), 1\rangle - M\|u_\tau\|^2 \tag{5.4}$$

(here we have used assumption $(f3)$). In order to eliminate the term $\langle \beta u_{\tau\tau}, u_{z\tau}\rangle$ from relation (5.3), multiply the equation by $\alpha^{-1}\beta u_{\tau\tau}$. This time the second and the third terms on the right vanish, and thus we have

$$\begin{aligned} \langle \beta u_{\tau\tau}, u_{z\tau}\rangle &= \langle \alpha^{-1}\beta f'(u_\tau)u_{\tau\tau}, u_{\tau\tau}\rangle + \langle \nabla(\alpha^{-1}\beta u_\tau), \nabla u_\tau\rangle \\ &\ge -M\|u_{\tau\tau}\|^2 + M^{-1}\|\nabla u_\tau\|^2 - M\|\nabla u_\tau\|\|u_\tau\| \\ &\ge -M\|u_{\tau\tau}\|^2 + M^{-1}\|\nabla u_\tau\|^2. \end{aligned} \tag{5.5}$$

Recall that, according to the convention about the use of M, its value may change from line to line.

Similarly, to get rid of $\langle \gamma u_\tau, u_z\rangle$ in (5.3), the proper multiplier is $\alpha^{-1}\gamma u$. It follows that

$$\begin{aligned} -\langle \gamma u_\tau, u_z\rangle &= -\langle \alpha^{-1}\gamma f(u_\tau), u_\tau\rangle - \langle \nabla(\alpha^{-1}\gamma u), \nabla u\rangle \\ &\geq -M\|u_\tau\|^2 - M\|\nabla u\|^2. \end{aligned} \tag{5.6}$$

By summing up relations (5.3)–(5.6), we arrive at

$$\frac{d}{dz}\Big[\|\nabla u\|^2 + 2\langle F(u_\tau), 1\rangle\Big] + M^{-1}\|\nabla u_\tau\|^2 \leq M\|u_{\tau\tau}\|^2 + M\|\nabla u\|^2. \tag{5.7}$$

Choose a positive μ sufficiently large so that (5.2) and (5.7) imply that

$$\begin{aligned} \frac{d}{dz}\Big[\mu\langle \alpha u_\tau, u_\tau\rangle + \|\nabla u\|^2 + 2\langle F(u_\tau), 1\rangle\Big] + M^{-1}\|u_{\tau\tau}\|^2 + M^{-1}\|\nabla u_\tau\|^2 \\ \leq M\|u_\tau\|^2 + M\|\nabla u\|^2. \end{aligned} \tag{5.8}$$

Make μ even larger, if necessary, to ensure that

$$\mu\langle \alpha u_\tau, u_\tau\rangle + 2\langle F(u_\tau), 1\rangle \geq \|u_\tau\|^2.$$

Now the Gronwall lemma applied to (5.8) yields the desired estimate (5.1). □

PROPOSITION 5.2. *Let u^1 and u^2 be two strong solutions of problem* (2.1)–(2.5) *corresponding to the initial conditions $u^1(0) = u_0^1$ and $u^2(0) = u_0^2$, respectively. Then*

$$\sup_z \|u_\tau^1 - u_\tau^2\|^2 + \|\!|u_{\tau\tau}^1 - u_{\tau\tau}^2|\!\|^2 \leq M\|u_{0\tau}^1 - u_{0\tau}^2\|^2. \tag{5.9}$$

In particular, this estimate proves the uniqueness of the strong solution.

Proof. The difference $w = u^1 - u^2$ satisfies the equation

$$\alpha w_{z\tau} = (\bar f w_\tau)_\tau + \beta w_{\tau\tau\tau} + \gamma w_\tau + \Delta w, \tag{5.10}$$

where $\bar f = (f(u_\tau^1) - f(u_\tau^2))/(u_\tau^1 - u_\tau^2)$ is a bounded function. Multiply it by w_τ, and integrate the result over Ω. The last term on the right of (5.10) disappears, and we obtain

$$\begin{aligned} \frac{1}{2}\frac{d}{dz}\langle \alpha w_\tau, w_\tau\rangle + \langle \beta w_{\tau\tau}, w_{\tau\tau}\rangle &= \frac{1}{2}\langle \alpha_z w_\tau, w_\tau\rangle - \langle \bar f w_\tau, w_{\tau\tau}\rangle + \langle \gamma w_\tau, w_\tau\rangle \\ &\leq M\|w_\tau\|\|w_{\tau\tau}\| + M\|w_\tau\|^2 \\ &\leq \frac{1}{2}\langle \beta w_{\tau\tau}, w_{\tau\tau}\rangle + M\|w_\tau\|^2. \end{aligned}$$

Apply the Gronwall lemma to complete the proof. □

Remark. Inequality (5.9) is obtained from (5.10) with the help of an argument similar to the one used in the first step of the proof of Proposition 5.1 (estimate (5.2)). However, the equivalent of (5.1) does not appear to be possible for (5.10) because of the special treatment required for the nonlinear term (see (5.4)).

6. Weak solutions. We have already qualified U_1 as the space of weak solutions. In order to introduce the weak solutions we also need the space of test functions. Let $\hat Y$ be the closure of D_Q with respect to the $H^1(Q)$-norm. Denote by Y the set of all functions $\eta \in \hat Y$ such that $\eta(Z) = 0$. The latter condition makes sense because of the continuous (and even compact) embedding $\hat Y \subset C([0, Z], X_0)$.

DEFINITION 6.1. *For a given $u_0 \in X_1$, a function $u \in U_1$ is called a weak solution of problem* (2.1)–(2.5) *if the identity*

$$\begin{aligned} &-\langle \alpha(0)u_{0\tau}, \eta(0)\rangle - \int_0^Z \langle u_\tau, (\alpha\eta)_z\rangle\, dz \\ &= \int_0^Z \Big[-\langle f(u_\tau), \eta_\tau\rangle - \langle \beta u_{\tau\tau}, \eta_\tau\rangle + \langle \gamma u_\tau, \eta\rangle - \langle \nabla u, \nabla\eta\rangle \Big]\, dz \end{aligned} \tag{6.1}$$

holds for any $\eta \in Y$.

By multiplying (2.1) by η and integrating by parts where necessary, one easily shows that each strong solution is also a weak one.

PROPOSITION 6.2. *For any $u_0 \in X_1$ problem* (2.1)–(2.5) *admits a weak solution u satisfying*

$$\sup_z \Big[\|u_\tau\|^2 + \|\nabla u\|^2 \Big] + \|\!| u_{\tau\tau} |\!\|^2 + \|\!| \nabla u_\tau |\!\|^2 \le M \Big[\|u_{0\tau}\|^2 + \|\nabla u_0\|^2 \Big]. \tag{6.2}$$

Proof. Let u_0^m, $m = 1, 2, \dots$, be a sequence in X_2 such that $u_0^m \to u_0$ in X_1 as $m \to \infty$. For each m denote by u^m the strong solution corresponding to the initial condition $u^m(0) = u_0^m$. It is also a weak solution, that is,

$$\begin{aligned} &-\langle \alpha(0)u_{0\tau}^m, \eta(0)\rangle - \int_0^Z \langle u_\tau^m, (\alpha\eta)_z\rangle\, dz \\ &= \int_0^Z \Big[-\langle f(u_\tau^m), \eta_\tau\rangle - \langle \beta u_{\tau\tau}^m, \eta_\tau\rangle + \langle \gamma u_\tau^m, \eta\rangle - \langle \nabla u^m, \nabla\eta\rangle \Big]\, dz \end{aligned} \tag{6.3}$$

for any $\eta \in Y$. By Proposition 5.2,

$$\|\!| u_{\tau\tau}^m - u_{\tau\tau}^n |\!\|^2 \le M \|u_{0\tau}^m - u_{0\tau}^n\|^2 \underset{m,\, n \to \infty}{\longrightarrow} 0,$$

so that there exists an element $u \in U_0$ such that $u_{\tau\tau} \in U_0$ and $u_{\tau\tau}^m \to u_{\tau\tau}$ in U_0 as $m \to \infty$. This also implies that $u_\tau^m \to u_\tau$ in U_0 and therefore $f(u_\tau^m) \to f(u_\tau)$ in $L_2(Q)$ as well. Finally notice that, by Proposition 5.1,

$$\sup_z \Big[\|u_\tau^m\|^2 + \|\nabla u^m\|^2 \Big] + \|\!| u_{\tau\tau}^m |\!\|^2 + \|\!| \nabla u_\tau^m |\!\|^2 \le M \Big[\|u_{0\tau}^m\|^2 + \|\nabla u_0^m\|^2 \Big], \tag{6.4}$$

so that the sequence ∇u^m is bounded in U_0, and therefore ∇u^m converges to ∇u weakly in U_0. Thus we can pass to the limit in (6.3) to obtain (6.1).

In order to establish estimate (6.2), first observe that the sequence ∇u_τ^m is bounded in U_0 and therefore contains a subsequence weakly convergent to ∇u_τ in U_0. Similarly, the sequences u_τ^m and ∇u^m contain subsequences $*$-weakly convergent, respectively, to u_τ and ∇u in $L_\infty([0, Z], X_0)$. One can therefore justify the limit as $m \to \infty$ in (6.4) and thus obtain (6.2). □

PROPOSITION 6.3. *The weak solution is unique.*

Proof. Let u^1 and u^2 be two weak solutions corresponding to the same initial condition $u^1(0) = u^2(0) = u_0 \in X_1$. Their difference $w = u^1 - u^2$ satisfies the identity

$$\begin{aligned} &-\int_0^Z \langle w_\tau, (\alpha\eta)_z\rangle\, dz \\ &= \int_0^Z \Big[-\langle \bar{f} w_\tau, \eta_\tau\rangle - \langle \beta w_{\tau\tau}, \eta_\tau\rangle + \langle \gamma w_\tau, \eta\rangle - \langle \nabla w, \nabla\eta\rangle \Big]\, dz \end{aligned} \tag{6.5}$$

for any $\eta \in Y$. As well as in the proof of Proposition 5.2, here $\bar{f}$ stands for the bounded function $(f(u_\tau^1) - f(u_\tau^2))/(u_\tau^1 - u_\tau^2)$.

Formally, the estimate we are going to obtain for w is quite simple and resembles much the one of Proposition 5.2. However, the direct approach of the proof of Proposition 5.2 is not valid any more since it requires the manipulation of objects which no longer exist in the case of the weak solutions. In particular, the weak solutions have no derivatives with respect to z.

Let the functions ψ_k and the projections P_m be those defined in the proof of Proposition 4.2. Given a function $\phi \in C_0^\infty([0, Z])$, set $\eta = \alpha^{-1}\phi\tilde{\psi}_k$ in (6.5). After some obvious transformations this yields

$$\left| \int_0^Z \phi_z \langle w, \psi_k \rangle \, dz \right| \le C \int_0^Z |\phi| \, dz \qquad \forall \phi \in C_0^\infty([0, Z]),$$

with some positive C depending on w and k but independent of ϕ. By the Riesz theorem, this proves the existence of a function $\theta \in L_\infty([0, Z])$ such that

$$\int_0^Z \phi_z \langle w, \psi_k \rangle \, dz = -\int_0^Z \phi\theta \, dz \qquad \forall \phi \in C_0^\infty([0, Z]),$$

and thus the function $\langle w, \psi_k \rangle$ admits a derivative $\langle w, \psi_k \rangle_z \in L_\infty([0, Z])$ understood in the sense of distributions. Therefore, for any m, the function $w^m \equiv P_m w$ also admits a bounded derivative with respect to z.

Fix positive numbers $s < Z$, $\delta < s$, and set

$$\sigma(z) = \begin{cases} 1 & \text{if } z \le s - \delta, \\ (s - z)/\delta & \text{if } s - \delta < z \le s, \\ 0 & \text{if } z > s. \end{cases}$$

By taking into account the existence of a bounded derivative w_z^m, it is easy to see that the function $\sigma\alpha^{-1}P_m(\alpha w_\tau^m)$ belongs to the class Y. Inject it in (6.5) instead of η. The integrand at the left becomes

$$\begin{aligned} -\langle w_\tau, (\alpha\eta)_z \rangle &= -\langle w_\tau, P_m(\sigma\alpha w_\tau^m)_z \rangle = -\langle w_\tau^m, (\sigma\alpha w_\tau^m)_z \rangle \\ &= -\frac{1}{2}\sigma_z \langle \alpha w_\tau^m, w_\tau^m \rangle - \frac{\sigma}{2}\langle \alpha_z w_\tau^m, w_\tau^m \rangle - \frac{1}{2}\frac{d}{dz}\big[\sigma\langle \alpha w_\tau^m, w_\tau^m \rangle\big]. \end{aligned}$$

By integrating over $[0, Z]$ and recalling the definition of σ, one obtains for the left-hand side of (6.5) the following lower bound:

$$\begin{aligned} &-\int_0^Z \langle w_\tau, (\alpha\eta)_z \rangle \, dz \\ &\ge \frac{1}{2\delta}\int_{s-\delta}^s \langle \alpha w_\tau^m, w_\tau^m \rangle \, dz - M\int_0^s \|w_\tau^m\|^2 \, dz + \frac{1}{2}\langle \alpha(0) w_\tau^m(0), w_\tau^m(0) \rangle \\ &\ge \frac{1}{2\delta}\int_{s-\delta}^s \langle \alpha w_\tau^m, w_\tau^m \rangle \, dz - M\int_0^s \|w_\tau^m\|^2 \, dz. \end{aligned}$$

As for the right-hand side of (6.5), the first and the third terms of the integrand admit the estimate

$$-\langle \bar{f} w_\tau, \eta_\tau \rangle + \langle \gamma w_\tau, \eta \rangle \le \sigma M \|w_\tau\| \|w_{\tau\tau}^m\|,$$

while the other two terms will be kept intact for the moment. By summing up and passing to the limit as $\delta \to \infty$, we have

$$\frac{1}{2}\langle \alpha(s) w_\tau^m(s), w_\tau^m(s)\rangle \le \int_0^s \Big[M\|w_\tau\|\|w_{\tau\tau}^m\| - \langle \beta w_{\tau\tau}, \alpha^{-1} P_m(\alpha w_{\tau\tau}^m)\rangle - \langle \nabla w, \nabla \alpha^{-1} P_m(\alpha w_\tau^m)\rangle \Big]\, dz.$$

The left-hand side of this relation admits no limit as $m \to \infty$, so first let us integrate it once more with respect to s:

$$\frac{1}{2}\int_0^\xi \langle \alpha(s) w_\tau^m(s), w_\tau^m(s)\rangle\, ds \le \int_0^\xi \int_0^s \Big[M\|w_\tau\|\|w_{\tau\tau}^m\| - \langle \beta w_{\tau\tau}, \alpha^{-1} P_m(\alpha w_{\tau\tau}^m)\rangle - \langle \nabla w, \nabla \alpha^{-1} P_m(\alpha w_\tau^m)\rangle \Big]\, dz\, ds.$$

Recall that $w \in U_1$ and therefore $w^m \to w$ in U_1. Thus one can pass to the limit as $m \to \infty$ in all terms to obtain

$$\frac{1}{2}\int_0^\xi \langle \alpha(s) w_\tau(s), w_\tau(s)\rangle\, ds \le \int_0^\xi \int_0^s \Big[M\|w_\tau\|\|w_{\tau\tau}\| - \langle \beta w_{\tau\tau}, w_{\tau\tau}\rangle \Big]\, dz\, ds.$$

With the help of the Cauchy–Young inequality this can be rewritten as

$$\int_0^\xi \langle \alpha w_\tau, w_\tau\rangle\, dz \le M \int_0^\xi \int_0^s \langle \alpha w_\tau, w_\tau\rangle\, dz\, ds.$$

It remains to apply the Gronwall lemma to obtain $w = 0$. □

7. Stratified media. The present section is devoted to the study of the asymptotic behavior of the solutions to problem (2.1)–(2.5) as its coefficients rapidly oscillate. This study will be undertaken under the following additional assumptions:

($\beta\gamma$) The coefficients α, β, and γ depend only on z. It is clear that in this case the replacement of z by the new variable $\tilde{z} = \int_0^z \alpha(s)\, ds$ will bring the equation to the form with $\alpha = 1$. Thus we assume that $\alpha = 1$ throughout the section. The regularity of β and γ is the same as above; that is, β, β_z, and γ are bounded, while β is also positive and bounded away from zero.

($f4$) The nonlinear function f is of the form $f(s, z, x) = \rho(z)\phi(s)$, where ρ is bounded with a bounded derivative, while ϕ satisfies the same assumptions as f in ($f1$)–($f3$), that is, ϕ admits a bounded continuous derivative and $\phi(0) = 0$. We shall denote by Φ the primitive of ϕ satisfying $\Phi(0) = 0$.

Thus the equation we study takes the form

$$u_{z\tau} = \rho(\phi(u_\tau))_\tau + \beta u_{\tau\tau\tau} + \gamma u_\tau + \Delta u. \tag{7.1}$$

The existence and uniqueness results of sections 4–6 remain valid.

In order to introduce the oscillating character of the coefficients, let us assume that they are of the form

$$\rho(z) = r(z, z/\epsilon), \qquad \beta(z) = b(z, z/\epsilon), \qquad \gamma(z) = g(z, z/\epsilon),$$

where $\epsilon < 1$ is a small parameter. The last assumption we introduce is the following.

($\rho\beta\gamma$) The functions $r(z,\zeta)$, $b(z,\zeta)$, and $g(z,\zeta)$ are bounded as well as the derivatives r_z, r_ζ, b_z, and b_ζ. The function b is positive and bounded away from zero. Finally, the functions $r(z,z/\epsilon)$, $b(z,z/\epsilon)$, and $g(z,z/\epsilon)$ admit limits as $\epsilon \to 0$ in the following weak sense: There exists $q > 1/2$ such that for any $Z > 0$ we have

$$\int_0^Z (r(z,z/\epsilon) - \bar\rho(z))\,dz = O(\epsilon^q),$$
$$\int_0^Z (b(z,z/\epsilon) - \bar\beta(z))\,dz = O(\epsilon^q),$$
$$\int_0^Z (g(z,z/\epsilon) - \bar\gamma(z))\,dz = O(\epsilon^q),$$

where the functions $\bar\rho(z)$, $\bar\beta(z)$, and $\bar\gamma(z)$ as well as the derivatives $\bar\rho_z(z)$, and $\bar\beta_z(z)$ are bounded, while $\bar\rho(z)$ are $\bar\beta(z)$ are also positive and bounded away from zero.

Note that if r, b, and g are Lipschitzian with respect to the first argument and periodic with respect to the second one, then the above convergence conditions hold with $q = 1$ (see [1, 7, 9]).

The asymptotic study of the solutions to (7.1) as $\epsilon \to 0$ require a few estimates. The convention concerning the use of the symbol M introduced in section 2 is still valid with the following remark: the constants M are independent of ϵ.

The first estimate we need is similar to the one of Proposition 5.1.

PROPOSITION 7.1. *Let u be the strong solution of* (7.1) *corresponding to the initial condition $u(0) = u_0 \in X_2$. Then*

$$\sup_z \|\nabla u\|^2 + \frac{1}{\epsilon}\sup_z \|u_\tau\|^2 + M^{-1}\int_0^Z \|u_{\tau\tau}\|^2 dz + M^{-1}\int_0^Z \|\nabla u_\tau\|^2 dz \le M\|\nabla u_0\|^2 + \frac{M}{\epsilon}\|u_{0\tau}\|^2.$$

Proof. Multiply (7.1) by u_τ to obtain

$$\frac{1}{2}\frac{d}{dz}\|u_\tau\|^2 = -\langle \beta u_{\tau\tau}, u_{\tau\tau}\rangle + \langle \gamma u_\tau, u_\tau\rangle \le -M^{-1}\|u_{\tau\tau}\|^2 + M\|u_\tau\|^2. \tag{7.2}$$

The multiplication of (7.1) by u_z yields

$$\begin{aligned}\frac{1}{2}\frac{d}{dz}\|\nabla u\|^2 + \frac{d}{dz}\langle \rho\Phi(u_\tau), 1\rangle &= -\langle \beta u_{\tau\tau}, u_{\tau z}\rangle + \langle \rho_z\Phi(u_\tau), 1\rangle + \langle \gamma u_\tau, u_z\rangle \\ &\le -\langle \beta u_{\tau\tau}, u_{\tau z}\rangle + M\epsilon^{-1}\|u_\tau\|^2 + \langle \gamma u_\tau, u_z\rangle.\end{aligned} \tag{7.3}$$

In order to eliminate the first term on the right-hand side of (7.3), multiply (7.1) by $\beta u_{\tau\tau}$:

$$\begin{aligned}\langle \beta u_{\tau\tau}, u_{\tau z}\rangle &= \langle \rho\beta\phi'(u_\tau)u_{\tau\tau}, u_{\tau\tau}\rangle + \langle \beta\nabla u_\tau, \nabla u_\tau\rangle \\ &\ge -M\|u_{\tau\tau}\|^2 + M^{-1}\|\nabla u_\tau\|^2.\end{aligned} \tag{7.4}$$

Similarly, after the multiplication of (7.1) by γu, we have

$$\langle \gamma u_\tau, u_z\rangle \le M\|u_\tau\|^2 + M\|\nabla u\|^2. \tag{7.5}$$

By combining (7.3)–(7.5), we have

$$\begin{aligned}\frac{1}{2}\frac{d}{dz}\|\nabla u\|^2 + \frac{d}{dz}\langle\rho\Phi(u_\tau),1\rangle + M^{-1}\|\nabla u_\tau\|^2 \\ \le M\|u_{\tau\tau}\|^2 + M\|\nabla u\|^2 + M\epsilon^{-1}\|u_\tau\|^2.\end{aligned} \tag{7.6}$$

For a given positive μ, set

$$E = \frac{1}{2}\|\nabla u\|^2 + \langle\rho\Phi(u_\tau),1\rangle + \frac{\mu}{\epsilon}\|u_\tau\|^2.$$

If the parameter μ is sufficiently large, then

$$E \ge \frac{1}{2}\|\nabla u\|^2 + \frac{\mu}{2\epsilon}\|u_\tau\|^2.$$

Fix μ even larger, if necessary, so that the inequalities (7.2) and (7.6) imply that

$$\frac{dE}{dz} + M^{-1}\|u_{\tau\tau}\|^2 + M^{-1}\|\nabla u_\tau\|^2 \le ME.$$

It remains to apply the Gronwall lemma to obtain the claimed estimate. ∎

The next estimate requires some new notation. The operator $I - \Delta : L_2(\omega) \to L_2(\omega)$ defined on $H^2(\omega)$ with the Neumann boundary conditions is self-adjoint and positive definite. Denote it by A^2. Thus A is its square root, which is also positive definite. Clearly, we have $M^{-1}\|A^{-1}u\| \le \|u\| \le M\|Au\|$. Note also that

$$\|Au\|^2 = \langle A^2u, u\rangle = \langle u - \Delta u, u\rangle = \|u\|^2 + \|\nabla u\|^2.$$

On X_1, the norm $\|Au\|$ is equivalent to $\|\nabla u\|$.

PROPOSITION 7.2. *Let u be the strong solution of* (7.1) *corresponding to the initial condition $u(0) = u_0 \in X_2$. Then*

$$\sup_z \|A^{-1}u_{\tau\tau}\|^2 + \int_0^Z \|A^{-1}u_{z\tau}\|^2\,dz \le M\|\nabla u_0\|^2 + \frac{M}{\epsilon}\|u_{0\tau}\|^2 + \|A^{-1}u_{0\tau\tau}\|^2. \tag{7.7}$$

Proof. The multiplication of (7.1) by $A^{-2}u_{z\tau}$ yields

$$\begin{aligned}\|A^{-1}u_{z\tau}\|^2 + \beta\frac{d}{dz}\|A^{-1}u_{\tau\tau}\|^2 \\ \le M\|u_{\tau\tau}\|\|A^{-2}u_{z\tau}\| + M\|u_\tau\|\|A^{-2}u_{z\tau}\| + M\|A^{-1}\Delta u\|\|A^{-1}u_{z\tau}\| \\ \le M\|u_{\tau\tau}\|\|A^{-1}u_{z\tau}\| + M\|\nabla u\|\|A^{-1}u_{z\tau}\|,\end{aligned}$$

which implies, after the division by β, that

$$\beta^{-1}\|A^{-1}u_{z\tau}\|^2 + \frac{d}{dz}\|A^{-1}u_{\tau\tau}\|^2 \le M\|u_{\tau\tau}\|^2 + M\|\nabla u\|^2.$$

Integrate with respect to z to obtain

$$\sup_z \|A^{-1}u_{\tau\tau}\|^2 + \int_0^Z \|A^{-1}u_{z\tau}\|^2\,dz \le M\int_0^Z \left[\|u_{\tau\tau}\|^2 + \|\nabla u\|^2\right]dz + \|A^{-1}u_{0\tau\tau}\|^2.$$

Finally, make use of Proposition 7.1 to complete the proof. ∎

We can now state and prove the main result of this section.

THEOREM 7.3. *Let u be the strong solution of (7.1) corresponding to the initial condition $u(0) = u_0 \in X_2$. Denote by v the strong solution of the equation*

$$v_{z\tau} = \bar{\rho}(\phi(v_\tau))_\tau + \bar{\beta} v_{\tau\tau\tau} + \bar{\gamma} v_\tau + \Delta v \tag{7.8}$$

satisfying the same initial condition as u. Then

$$\sup_z \|u - v\|^2 \le M\epsilon^{q-1/2}\Big[\|u_{0\tau\tau}\|^2 + \|\Delta\tilde{u}_0\|^2\Big].$$

Proof. It is clear that v is subject to the same type of estimates as u but with the coefficients independent of ϵ. In particular,

$$\begin{aligned}\sup_z \|\nabla v\|^2 + \sup_z \|v_\tau\|^2 + M^{-1}\int_0^Z \|v_{\tau\tau}\|^2 dz + M^{-1}\int_0^Z \|\nabla v_\tau\|^2 dz \\ \le M\|\nabla u_0\|^2 + M\|u_{0\tau}\|^2.\end{aligned} \tag{7.9}$$

The difference $w = u - v$ satisfies the relation

$$\begin{aligned}w_{z\tau} = \rho[\phi(u_\tau) - \phi(v_\tau)]_\tau + \beta w_{\tau\tau\tau} + \gamma w_\tau + \Delta w \\ - (\bar{\rho} - \rho)(\phi(v_\tau))_\tau + (\bar{\beta} - \beta)v_{\tau\tau\tau} + (\bar{\gamma} - \gamma)v_\tau.\end{aligned} \tag{7.10}$$

Multiply it by $-\tilde{w}$ to obtain

$$\begin{aligned}\frac{1}{2}\frac{d}{dz}\|w\|^2 = \langle\rho[\phi(u_\tau) - \phi(v_\tau)], w\rangle - \langle\beta w_\tau, w_\tau\rangle + \langle\gamma w, w\rangle \\ + (\bar{\rho} - \rho)P + (\bar{\beta} - \beta)Q + (\bar{\gamma} - \gamma)R \\ \le M\|w\|^2 + (\bar{\rho} - \rho)P + (\bar{\beta} - \beta)Q + (\bar{\gamma} - \gamma)R,\end{aligned} \tag{7.11}$$

where P, Q, and R stand for the residual terms:

$$P = \langle\phi(v_\tau), u - v\rangle, \qquad Q = \langle v_{\tau\tau}, u - v\rangle, \qquad R = \langle v, u - v\rangle.$$

The integration of (7.11) over $z \in [0, s]$ yields

$$\frac{1}{2}\|w(s)\|^2 \le M\int_0^s \|w\|^2\, dz + \int_0^s \left[(\bar{\alpha} - \alpha)P + (\bar{\beta} - \beta)Q + (\bar{\gamma} - \gamma)R\right] dz.$$

By integrating by parts in the second term on the right and making use of assumption $(\rho\beta\gamma)$, we arrive at

$$\frac{1}{2}\|w(s)\|^2 \le M\int_0^s \|w\|^2\, dz + M\epsilon^q \int_0^s (|P_z| + |Q_z| + |R_z|)\, dz. \tag{7.12}$$

The expressions P_z, Q_z, and R_z need to be estimated separately. The most difficult estimate is required by the term $|\langle v_{\tau\tau}, u_z\rangle|$ appearing in $|Q_z|$. We have

$$\begin{aligned}|\langle v_{\tau\tau}, u_z\rangle| = |\langle(I - \Delta)v_\tau, A^{-2}u_{z\tau}\rangle| \\ \le |\langle v_\tau, A^{-2}u_{z\tau}\rangle| + |\langle\nabla v_\tau, \nabla A^{-2}u_{z\tau}\rangle| \\ \le \|A^{-1}v_\tau\|\|A^{-1}u_{z\tau}\| + \|\nabla v_\tau\|\|\nabla A^{-2}u_{z\tau}\|.\end{aligned} \tag{7.13}$$

On the other hand,

$$\begin{aligned}\|\nabla A^{-2}u_{z\tau}\|^2 = -\langle\Delta A^{-2}u_{z\tau}, A^{-2}u_{z\tau}\rangle = \langle(A^2 - I)A^{-2}u_{z\tau}, A^{-2}u_{z\tau}\rangle \\ = \langle A^{-1}u_{z\tau}, A^{-1}u_{z\tau}\rangle - \langle A^{-2}u_{z\tau}, A^{-2}u_{z\tau}\rangle \le \|A^{-1}u_{z\tau}\|^2.\end{aligned}$$

Thus (7.13) becomes

$$|\langle v_{\tau\tau}, u_z\rangle| \le (\|v_\tau\| + \|\nabla v_\tau\|)\|A^{-1}u_{z\tau}\|.$$

Now with the help of (7.7) and (7.9) we obtain

$$\begin{aligned}\int_0^s |\langle v_{\tau\tau}, u_z\rangle|\,dz &\le M\left[\int_0^s (\|v_\tau\|^2 + \|\nabla v_\tau\|^2)\,dz\right]^{1/2}\left[\int_0^s \|A^{-1}u_{z\tau}\|^2\,dz\right]^{1/2}\\ &\le M\Big[\|\nabla u_0\|^2 + \|u_{0\tau}\|^2\Big]^{1/2}\left[\|\nabla u_0\|^2 + \frac{1}{\epsilon}\|u_{0\tau}\|^2 + \|A^{-1}u_{0\tau\tau}\|^2\right]^{1/2}\\ &\le M\epsilon^{-1/2}\Big[\|u_{0\tau\tau}\|^2 + \|\Delta\tilde{u}_0\|^2\Big].\end{aligned} \tag{7.14}$$

The latter inequality follows from the boundedness of the operator A^{-1} and the fact that $\|\nabla u_0\|^2 = \langle \nabla u_0, \nabla u_0\rangle = -\langle \nabla\tilde{u}_0, \nabla u_{0\tau}\rangle = \langle \Delta\tilde{u}_0, u_{0\tau}\rangle \le \frac{1}{2}(\|\Delta\tilde{u}_0\|^2 + \|u_{0\tau}\|^2)$. Quite similarly to (7.14) one establishes the same upper bound on the term $|\langle v_{\tau\tau}, v_z\rangle|$, and therefore

$$\int_0^s |\langle v_{\tau\tau}, u_z - v_z\rangle|\,dz \le M\epsilon^{-1/2}\Big[\|u_{0\tau\tau}\|^2 + \|\Delta\tilde{u}_0\|^2\Big].$$

Now let us note that

$$\begin{aligned}\int_0^s |Q_z|\,dz &\le \int_0^s |\langle v_{\tau\tau}, u - v\rangle_z|\,dz\\ &\le \int_0^s |\langle v_{\tau\tau}, u_z - v_z\rangle|\,dz + \int_0^s |\langle v_z, u_{\tau\tau}\rangle|\,dz + \int_0^s |\langle v_z, v_{\tau\tau}\rangle|\,dz.\end{aligned} \tag{7.15}$$

The term involving u_z having already been estimated, let us treat the second term on the right of (7.15). Recall that v is a strong solution to (7.8) whose coefficients are independent of ϵ. Therefore, by Proposition 4.2,

$$\sup_z \Big[\|v_{\tau\tau}\|^2 + \|v_z\|^2\Big] + \|\!|v_{\tau\tau\tau}|\!\|^2 + \|\!|v_{z\tau}|\!\|^2 + \|\!|\Delta v|\!\|^2 \le M\|u_{0\tau\tau}\|^2 + M\|\Delta\tilde{u}_0\|^2. \tag{7.16}$$

Along with Proposition 7.1 the latter inequality implies that

$$\begin{aligned}\int_0^s |\langle v_z, u_{\tau\tau}\rangle|\,dz &\le \left[\int_0^s \|v_z\|^2 dz\right]^{1/2}\left[\int_0^s \|u_{\tau\tau}\|^2 dz\right]^{1/2}\\ &\le M\big[\|u_{0\tau\tau}\|^2 + \|\Delta\tilde{u}_0\|^2\big]^{1/2} \times \epsilon^{-1/2}\big[\|\nabla u_0\|^2 + \|u_{0\tau}\|^2\big]^{1/2}.\end{aligned}$$

As has been mentioned above, $\|\nabla u_0\|^2 \le \frac{1}{2}(\|\Delta\tilde{u}_0\|^2 + \|u_{0\tau}\|^2)$ and $\|u_{0\tau}\|^2 \le \|u_{0\tau\tau}\|^2$. So we obtain

$$\int_0^s |\langle v_z, u_{\tau\tau}\rangle|\,dz \le M\epsilon^{-1/2}(\|u_{0\tau\tau}\|^2 + \|\Delta\tilde{u}_0\|^2).$$

The last term on the right of (7.15) admits the same estimate, and we finally obtain

$$\int_0^s |Q_z|\,dz \le M\epsilon^{-1/2}(\|u_{0\tau\tau}\|^2 + \|\Delta\tilde{u}_0\|^2).$$

The estimate on $|P_z|$ is simpler. We have

$$P_z = \langle \phi'(v_\tau) v_{z\tau}, u - v \rangle + \langle \phi(v_\tau), u_z - v_z \rangle.$$

Estimate (7.16) together with Proposition 7.1 yields

$$\int_0^s |P_z|\, dz \le M\epsilon^{-1/2} \Big[\|u_{0\tau\tau}\|^2 + \|\Delta \tilde{u}_0\|^2 \Big] + \int_0^s |\langle \phi(v_\tau), u_z \rangle|\, dz. \tag{7.17}$$

The last term on the right should be treated with the help of Proposition 7.2. First note that

$$\begin{aligned} |\langle \phi(v_\tau), u_z \rangle| &= |\langle A\phi(v_\tau), A^{-1} u_z \rangle| \le \|A\phi(v_\tau)\| \|A^{-1} u_z\| \\ &\le M \|\nabla \phi(v_\tau)\| \|A^{-1} u_z\| = M \|\phi'(v_\tau) \nabla v_\tau\| \|A^{-1} u_z\| \\ &\le M \|\nabla v_\tau\| \|A^{-1} u_z\| \le M \Big[\|\Delta v\|^2 + \|v_{\tau\tau}\|^2 \Big]^{1/2} \|A^{-1} u_z\|. \end{aligned}$$

Now the integration over $z \in [0, s]$ and the use of Proposition 7.2 along with estimate (7.16) yield

$$\int_0^s |\langle \phi(v_\tau), u_z \rangle|\, dz \le M\epsilon^{-1/2} \Big[\|u_{0\tau\tau}\|^2 + \|\Delta \tilde{u}_0\|^2 \Big].$$

We omit the details concerning the treatment of the term involving R_z in the second integral on the right of (7.12). It is quite similar to the case of Q_z since $v = \tilde{\tilde{v}}_{\tau\tau}$. Thus we finally obtain

$$\frac{1}{2} \|w(s)\|^2 \le M \int_0^s \|w\|^2\, dz + M\epsilon^{q-1/2} \Big[\|u_{0\tau\tau}\|^2 + \|\Delta \tilde{u}_0\|^2 \Big]. \tag{7.18}$$

By the Gronwall lemma we have

$$\int_0^s \|w\|^2\, dz \le M\epsilon^{q-1/2} \Big[\|u_{0\tau\tau}\|^2 + \|\Delta \tilde{u}_0\|^2 \Big].$$

Reinject the latter inequality into (7.18) to complete the proof. □

8. Concluding remarks. The obtained global existence and uniqueness results for (2.1) for the case of nonlinearity f with bounded derivative show that this formulation may have some mathematical advantages in comparison with the classical KZK equation (see [3, 4]), although for small variations of the acoustic pressure (which is one of the assumptions of the physical model used to derive the equation) these two models coincide.

The introduction of the varying coefficients allows us to model the acoustic beam propagation in a stratified heterogeneous media (for example, in the atmosphere), while the asymptotic analysis by means of the homogenization techniques simplifies reducing it to the case of constant coefficients, when in some situations an analytical solution is possible.

EXISTENCE OF WEAK SOLUTIONS FOR THE UNSTEADY INTERACTION OF A VISCOUS FLUID WITH AN ELASTIC PLATE*

CÉLINE GRANDMONT†

Abstract. We consider a three-dimensional viscous incompressible fluid governed by the Navier–Stokes equations, interacting with an elastic plate located on one part of the fluid boundary. We do not neglect the deformation of the fluid domain which consequently depends on the displacement of the structure. The purpose of this work is to study the solutions of this unsteady fluid-structure interaction problem, as the coefficient modeling the viscoelasticity (resp., the rotatory inertia) of the plate tends to zero. As a consequence, we obtain the existence of at least one weak solution for the limit problem (Navier–Stokes equation coupled with a plate in flexion) as long as the structure does not touch the bottom of the fluid cavity.

Key words. fluid-structure interaction, weak solutions, plate equations

1. Introduction. Many physical phenomena deal with a fluid interacting with a moving or deformable structure. These kinds of problems have a lot of important applications, for instance, in areolasticity, biomechanics, hydroelasticity, sedimentation, etc. From the mathematical point of view they have been studied extensivelly over the past few years. Here we consider a viscous incompressible three-dimensional (3D) fluid described by the Navier–Stokes equations interacting with a two-dimensional elastic plate in flexion.

One already knows that if a viscous term or the rotatory inertia are taken into account in the plate equations, there exists at least one weak solution to this problem (see [4]). From the mechanical point of view, adding a viscous term is a way to introduce dissipation in the plate model, and, from the mathematical point of view, this is a way to regularize the structure velocity. Here the dissipation coming from the fluid enables us to control the space high frequencies of the structure velocity and to pass to the limit in the coupled system as the additional viscous plate coefficient tends to zero and, thus, obtain the existence of weak solutions of the limit problem. This limit system can also be obtained as the limit of the plate-Navier–Stokes system (with a regularized initial plate velocity) as the coefficient of the rotatory inertia tends to zero. In most of the previous studies the structure velocity is quite regular because of the model or because of the presence of a regularization operator in the equations. The existing results are concerned mainly with rigid body motions [5], [10], [11], [13], [16], [17], [18], [21], [22], [24], [25] or with the motion of a structure described by a finite number of modal functions [12] or a structure with additional "viscous" terms [2], [4], [8]. Recently, a significant breakthrough has been made by Coutand and Shkoller. In [6], [7] they prove the existence, locally in time, of a unique regular solution (assuming that the data are smooth enough and satisfy suitable compatibility conditions) for the Navier–Stokes equations coupled with linearized elasticity or quasi-linear elasticity. These are the only existence results where the full 3D elasticity is

†REO project, INRIA Rocquencourt, B.P. 105, 78153 Le Chesnay Cedex, France (celine.grandmont@inria.fr).

considered and that don't require additional viscous terms. Nevertheless, despite these new important results, the case of fluid-plate or fluid-shell interaction problems is not, as far as we know, solved. Here, by assuming that the in-plane motions can be neglected and taking advantage of the transverse-only motions of the plate and of the fact that the plate equations enable some regularity of the boundary of the fluid domain, we prove the existence of weak solutions for a fluid-plate interaction problem. Note that the same proof does not apply for general plate or shell models. Yet, even if we consider here a rather simple structure model, this is, to our knowledge, the first existence result of weak solutions in this direction. Note, moreover, that no compatibility assumptions are required and the existence result holds as long as the plate does not touch the bottom of the fluid cavity. Finally, the same results hold for a 2D viscous flow interacting with a one-dimensional membrane.

In the first section we give the equations of the fluid-structure problem for which we derive a priori energy estimates. Next, definitions and properties of the energy spaces are detailed, and the weak formulation of the problem is given. In particular, we build suitable extensions of the fluid test functions and liftings of the structure test functions. In the second section, we state our main results, the third section being devoted to the derivation of compactness properties that enable us to pass to the limit in the equations as the "viscous" plate coefficient tends to zero (section 4).

1.1. Presentation of the problem. We assume that the fluid fills a three-dimensional cavity and interacts with a thin elastic structure, located on a part of the boundary of the fluid, the other part being rigid. For the sake of simplicity, we assume that, in the reference state, the elastic part of the fluid boundary is $\omega \times \{1\}$, where ω denotes a Lipschitz domain in $\mathbb{R}^2$. In the initial state the fluid occupies the domain Ω_{η_I}:

$$\Omega_{\eta_I} = \left\{(x,y,z) \in \mathbb{R}^3,\, (x,y) \in \omega, 0 < z < 1 + \eta_I(x,y)\right\},$$

where η_I is a given initial displacement of the elastic part. The rigid part of $\partial\Omega_{\eta_I}$ is denoted by Γ_0. Note that we could also have considered the case of a fluid between two elastic plates or the case where $\omega \times \{1\}$ is a part of a smooth fluid domain boundary and obtained the same kind of results. We model the deformable part of the boundary by the classical linear plate theory for tranverse motions. We take its edge to be clamped. Note that the equations describing the tranverse motion and the in-plane motions of a plate are decoupled. Here we ignore in-plane motions. From a mechanical point of view, this assumption is justified (at least for small enough deformations) since the membrane stiffness of a plate is much larger than its flexion stiffness. We denote by $\eta_\varepsilon(t,x,y)$ the vertical displacement with respect to the rest configuration. The subscript ε underlines the dependence of the solution with respect to the parameter $\varepsilon \geq 0$, which measures the "viscosity" of the plate (or the rotatory inertia). Then the equations describing the evolution of the transversal displacement η_ε ($\eta_\varepsilon = \eta_\varepsilon(t,x,y) \in \mathbb{R}$) are

$$\left\{\begin{array}{l} \partial_{tt}\eta_\varepsilon + \Delta^2\eta_\varepsilon + \varepsilon\Delta^2\partial_t\eta_\varepsilon = g + (T_f^\varepsilon)_3 \text{ in } \omega, \\ \eta_\varepsilon = \dfrac{\partial\eta_\varepsilon}{\partial n} = 0 \text{ on } \partial\omega, \\ \eta_\varepsilon(0) = \eta_I,\ \partial_t\eta_\varepsilon(0) = \dot\eta_I, \end{array}\right. \tag{1}$$

where g denotes the given body force on the plate and T_f^ε the surface force exerted by the fluid on the structure. The definition of T_f^ε will be made precise later on. Instead

of the additional viscosity term, we could have added $-\varepsilon\Delta\partial_{tt}\eta_\varepsilon$, which models the inertia of rotation. The domain occupied by the fluid at time t is denoted by $\Omega_{\eta_\varepsilon}(t)$:

$$\Omega_{\eta_\varepsilon}(t) = \left\{(x,y,z) \in \mathbb{R}^3\ ,\ (x,y) \in \omega,\ 0 < z < 1 + \eta_\varepsilon(t,x,y)\right\}. \tag{2}$$

The classical forms of the governing equations for the fluid are

$$\begin{cases} \partial_t \mathbf{u}_\varepsilon + (\mathbf{u}_\varepsilon \cdot \nabla)\mathbf{u}_\varepsilon - \nu\Delta\mathbf{u}_\varepsilon + \nabla p_\varepsilon = \mathbf{f} & \text{in } \Omega_{\eta_\varepsilon}(t), \\ \operatorname{div} \mathbf{u}_\varepsilon = 0 & \text{in } \Omega_{\eta_\varepsilon}(t), \\ \mathbf{u}_\varepsilon(t,\cdot) = \mathbf{0} & \text{on } \Gamma_0, \\ \mathbf{u}_\varepsilon(0,\cdot) = \mathbf{u}_I & \text{in } \Omega_{\eta_I}, \end{cases} \tag{3}$$

where $\mathbf{u}_\varepsilon$ denotes the fluid velocity and p_ε the pressure field. The body force $\mathbf{f}$ and the initial velocity $\mathbf{u}_I$ are given.

Since the fluid is viscous, it adheres to the plate, and thus the velocities coincide (in a sense to be defined) at the interface. This is written, since we assume that the plate motion is vertical:

$$\mathbf{u}_\varepsilon(t,x,y,1+\eta_\varepsilon(t,x,y)) = (0,0,\partial_t\eta_\varepsilon(t,x,y))^T, \quad (x,y) \in \omega. \tag{4}$$

This condition, together with the incompressibility of the fluid, leads to

$$\int_\omega \partial_t \eta_\varepsilon = 0. \tag{5}$$

Condition (5) states that the global volume of the cavity is preserved. The surface force T_f exerted by the fluid on the plate can be defined by

$$\int_\omega T_f^\varepsilon \cdot \bar{\mathbf{v}} = \int_{\partial\Omega_{\eta_\varepsilon}(t)\setminus\Gamma_0} (-2\nu D(\mathbf{u}_\varepsilon)\cdot\mathbf{n}_t^\varepsilon + p_\varepsilon \mathbf{n}_t^\varepsilon)\cdot\mathbf{v} \qquad \forall \mathbf{v}, \tag{6}$$

where $D(\mathbf{u}_\varepsilon) = (\nabla\mathbf{u}_\varepsilon + (\nabla\mathbf{u}_\varepsilon)^T)/2$ is the strain tensor, $\mathbf{n}_t^\varepsilon$ denotes the outer unit normal at $\partial\Omega_{\eta_\varepsilon}(t)\setminus\Gamma_0$ ($\mathbf{n}_t^\varepsilon = \frac{1}{\sqrt{1+(\partial_x\eta_\varepsilon)^2+(\partial_y\eta_\varepsilon)^2}}(-\partial_x\eta_\varepsilon, -\partial_y\eta_\varepsilon, 1)^T$), and $\bar{\mathbf{v}}(t,x,y) = \mathbf{v}(t,x,y,1+\eta_\varepsilon(t,x,y))\ \forall (x,y)\in\omega$. Note here that the pressure p_ε is not defined up to a constant but is uniquely defined. Its average value ensures the global volume conservation of the fluid cavity. This average is in fact the Lagrange multiplier associated with the compatibility condition (5). Note that if Neumann boundary conditions had been imposed on Γ_0, then the plate displacement should not verify an additional "volume-preserving" constraint. As noted in [4], the third component of T_f^ε can be rewritten thanks to

$$2(D(\mathbf{u}_\varepsilon)\cdot\mathbf{n}_t^\varepsilon)_3 = (\nabla\mathbf{u}_\varepsilon\cdot\mathbf{n}_t^\varepsilon)_3.$$

This simplification comes from the fact that the displacement at the fluid-structure interface is only transverse and from the incompressibility of the fluid.

Thus $\forall \mathbf{v},$ such that $v_i(t,x,1+\eta_\varepsilon(t,x,y)) = 0,\ i = 1,2,\ (t,x,y) \in (0,T)\times\omega$, we have

$$\int_\omega T_f^\varepsilon \cdot \hat{\mathbf{v}} = \int_{\Gamma_{\eta_\varepsilon}(t)} (-\nu\nabla\mathbf{u}_\varepsilon\cdot\mathbf{n}_t^\varepsilon + p_\varepsilon\mathbf{n}_t^\varepsilon)_3\ v_3. \tag{7}$$

Note moreover that the two first components of T_f^ε correspond to the Lagrange multiplier associated to the vertical velocity constrain that the fluid has to verify at the interface.

1.2. A priori estimates. In this subsection we recall the a priori estimates satisfied by any solution, assuming that it is smooth enough. We multiply the Navier–Stokes equations by $\mathbf{u}_\varepsilon$ and integrate over $\Omega_{\eta_\varepsilon}(t)$, and we multiply the plate equations by $\partial_t\eta_\varepsilon$, integrate over ω, and add these two contributions. After integrations by parts and taking into account the coupling conditions (equality of the velocities (4) and the definition of T_f^ε (7)), we obtain the following energy equality:

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\Omega_{\eta_\varepsilon}(t)}|\mathbf{u}_\varepsilon|^2+2\nu\int_{\Omega_{\eta_\varepsilon}(t)}|\nabla(\mathbf{u}_\varepsilon)|^2\\&+\frac{1}{2}\frac{d}{dt}\int_\omega(\partial_t\eta_\varepsilon)^2+\frac{1}{2}\frac{d}{dt}\int_\omega(\Delta\eta_\varepsilon)^2+\varepsilon\int_\omega(\Delta\partial_t\eta_\varepsilon)^2\\&=\int_{\Omega_{\eta_\varepsilon}(t)}\mathbf{f}\cdot\mathbf{u}_\varepsilon+\int_\omega g\,\partial_t\eta_\varepsilon.\end{aligned}\tag{8}$$

Hence, using Cauchy–Schwarz and Young's inequalities and Gronwall's lemma:

$$\begin{aligned}&\frac{1}{2}\|\mathbf{u}_\varepsilon(t,\cdot)\|^2_{L^2(\Omega_{\eta_\varepsilon}(t))}+2\nu\int_0^t\|\nabla(\mathbf{u}_\varepsilon)(s,\cdot)\|^2_{L^2(\Omega_{\eta_\varepsilon}(s))}ds\\&+\frac{1}{2}\|\partial_t\eta_\varepsilon(t,\cdot)\|^2_{L^2(\omega)}+\frac{1}{2}\|\Delta\eta_\varepsilon(t,\cdot)\|^2_{L^2(\omega)}+\varepsilon\int_0^t\|\Delta\partial_t\eta_\varepsilon(s,\cdot)\|^2_{L^2(\omega)}ds\\&\le e^t\left(\frac{1}{2}\|\mathbf{u}_I\|^2_{L^2(\Omega_{\eta_I})}+\frac{1}{2}\|\dot\eta_I\|^2_{L^2(\omega)}+\frac{1}{2}\|\Delta\eta_I\|^2_{L^2(\omega)}\right)\\&+\frac{1}{2}\int_0^t\exp(t-s)\left(\|\mathbf{f}(s,\cdot)\|^2_{L^2(\Omega_{\eta_\varepsilon}(s))}+\|g(s,\cdot)\|^2_{L^2(\omega)}\right)ds.\end{aligned}\tag{9}$$

Thus, assuming that $\mathbf{f}\in L^2(0,T;L^2(\mathbb{R}^3))$, $g\in L^2(0,T;L^2(\omega))$, $\mathbf{u}_I\in L^2(\Omega_{\eta_I})$, $\eta_I\in H_0^2(\omega)$, and $\dot\eta_I\in L^2(\omega)$,

$$\mathbf{u}_\varepsilon \text{ is bounded, uniformly in } \varepsilon, \text{ in } L^\infty(0,T;L^2(\Omega_{\eta_\varepsilon}(t))),\tag{10}$$

$$\nabla\mathbf{u}_\varepsilon \text{ is bounded, uniformly in } \varepsilon, \text{ in } L^2(0,T;L^2(\Omega_{\eta_\varepsilon}(t))),\tag{11}$$

and

$$\eta_\varepsilon \text{ is bounded, uniformly in } \varepsilon, \text{ in } W^{1,\infty}(0,T;L^2(\omega))\cap L^\infty(0,T;H_0^2.(\omega)).\tag{12}$$

Moreover, if $\varepsilon>0$,

$$\partial_t\eta_\varepsilon\in L^2(0,T;H_0^2(\omega)).$$

Consequently the spaces $L^p(0,T;L^2(\Omega_\gamma(t)))$, $L^2(0,T;H^1(\Omega_\gamma(t)))$ need to be defined for γ belonging to $W^{1,\infty}(0,T;L^2(\omega))\cap L^\infty(0,T;H_0^2(\omega))$. Note that the following continuous injection holds:

$$W^{1,\infty}(0,T;L^2(\omega))\cap L^\infty(0,T;H^2(\omega))\hookrightarrow C^{0,1-\theta}([0,T];H^{2\theta}(\omega))$$

for all $0<\theta<1$. In particular,

$$W^{1,\infty}(0,T;L^2(\omega))\cap L^\infty(0,T;H^2(\omega))\hookrightarrow C^{0,\mu}([0,T];C^{0,1/2-\mu}(\overline{\omega}))\tag{13}$$

for all $0 < \mu < 1/2$. The proof of the first injection relies on standard Hilbertian interpolation inequalities (see [20]). The other is deduced from the first one and from Sobolev injections in dimension two (see [3]). Consequently, this displacement regularity does not imply that the fluid domain boundary is Lipschitz, and we have to pay a special attention to the definitions of the functional spaces. We have also to give a sense to the equality of the velocities. Thus we are going to give some technical lemmas, definitions, and properties, most of which can be found in [4].

1.3. Preliminary definitions and properties. We now turn to the definition of some functional spaces. These definitions can be found in [4], but for the sake of completness we recall them here. Let $T > 0$ and δ belong to $C^0([0,T] \times \overline{\omega})$ such that, for some positive M and α, $M \geq 1 + \delta(t,x,y) \geq \alpha > 0$ for all $(t,x,y) \in [0,T] \times \overline{\omega}$ and such that $\delta = 0$ on $\partial\omega$. The set $\Omega_\delta(t)$ defined by

$$\Omega_\delta(t) = \left\{(x,y,z) \in \mathbb{R}^3,\ (x,y) \in \omega,\ 0 < z < 1 + \delta(t,x,y)\right\}$$

is an open subset of $\mathbb{R}^3$ for every $t \in [0,T]$ which is included in $\mathcal{C}_M = \omega \times (0,M)$. Let $\widehat{\Omega}_\delta$ be the open domain of $\mathbb{R}^4$ defined by

$$\widehat{\Omega}_\delta = \bigcup_{t \in (0,T)} \{t\} \times \Omega_\delta(t).$$

We set $\widehat{\mathcal{C}_M} = (0,T) \times \mathcal{C}_M$. One can define in a standard way the spaces $L^p(\Omega_\delta(t))$, $H^1(\Omega_\delta(t))$, $H^1_0(\Omega_\delta(t))$, for every t, and $L^p(\widehat{\Omega}_\delta)$, $H^1(\widehat{\Omega}_\delta)$, $L^p(\widehat{\mathcal{C}_M})$, and $H^1(\widehat{\mathcal{C}_M})$. The space $H^1_{0,\Gamma_0}(\Omega_\delta(t))$ will denote the subspace of $H^1_{0,\Gamma_0}(\Omega_\delta(t))$ of functions of zero trace on $\Gamma_0 = \omega \times \{0\} \cup \partial\omega \times (0,1)$. We then define:

$$L^2(0,T;H^1(\Omega_\delta(t))) = \left\{v \in L^2(\widehat{\Omega}_\delta),\ \nabla v \in L^2(\widehat{\Omega}_\delta)\right\},$$

$$L^2(0,T;H^1_0(\Omega_\delta(t))) = \overline{\mathcal{D}(\widehat{\Omega}_\delta)}^{L^2(0,T;H^1(\Omega_\delta(t)))},$$

$$\mathcal{V}_\delta = \left\{\mathbf{v} \in C^1\left(\overline{\widehat{\Omega}_\delta}\right),\ \operatorname{div}\mathbf{v} = 0,\ \mathbf{v} = \mathbf{0} \text{ on } (0,T) \times \Gamma_0\right\},$$

$$V_\delta = \overline{\mathcal{V}_\delta}^{L^2(0,T;H^1(\Omega_\delta(t)))},$$

and

$$L^\infty(0,T;L^2(\Omega_\delta(t))) = \left\{v \in L^2(\widehat{\Omega}_\delta),\ \operatorname{sup\,ess}_{t\in(0,T)}\|v\|_{L^2(\Omega_\delta(t))} < +\infty\right\}.$$

Moreover we define

$$V = \left\{\mathbf{v} \in L^2(0,T;H^1(\mathcal{C}_M)),\ \operatorname{div}\mathbf{v} = 0,\ \mathbf{v} = \mathbf{0} \text{ on } (0,T) \times (\Gamma_0 \cup \Gamma_1)\right\},$$

where $\Gamma_1 = \partial\omega \times (1,M)$.

The space V_δ can be characterized as follows:

$$V_\delta = \left\{\mathbf{v} \in L^2(0,T;H^1(\Omega_\delta(t))),\ \operatorname{div}\mathbf{v} = 0,\ \mathbf{v} = \mathbf{0} \text{ on } (0,T) \times \Gamma_0\right\}.$$

In the case of a Lipschitz or a star-shaped domain independent of time, this follows from standard arguments (see [26] or [15]). In our case it can be proved by using the fact that the domain $\Omega_\delta(t)$ is locally a subgraph. This property will be extensively used in all that follows.

Next we recall various lemmas that explain how the trace on $\partial\Omega_\delta(t) \setminus \Gamma_0$ makes sense, define extension and lifting operators, and explore some properties of the spaces defined above. We omit the proofs whenever they can be found in [4]. Note that these results take advantage of the fact that the fluid domain is a subgraph because the displacement of the interface is only transverse. Let us consider the linear mapping $\gamma_{\delta(t)}\colon\ v \mapsto v(x,y,1+\delta(t,x,y))$ defined for $v \in C^0(\overline{\Omega}_\delta(t))$.

LEMMA 1. *For every $t \in [0,T]$, the mapping $\gamma_{\delta(t)}$ from $C^1(\overline{\mathcal{C}_M})$ (resp., $C^1(\overline{\Omega}_\delta(t))$) in $C^0(\overline{\omega})$ can be extended by continuity to a linear mapping from $H^1(\mathcal{C}_M)$ (resp., $H^1(\Omega_\delta(t))$) into $L^2(\omega)$.*

COROLLARY 1. *If $v \in L^2(0,T;H^1(\Omega_\delta(t)))$, then $\gamma_{\delta(t)}(v) \in L^2(0,T;L^2(\omega))$.*

Thus, the trace of $v(x,y,1+\delta(t,x,y))$ on ω makes sense at least in $L^2(\omega)$. The following lemma makes precise the regularity of $\gamma_{\delta(t)}(v)$ when assuming moreover that δ belongs to $L^\infty(0,T;H_0^2(\omega))$. This additional regularity will play a crucial role in our asymptotic study and will enable us to control the space high frequencies of the structure velocity.

LEMMA 2. *Assuming that $\delta \in C^0([0,T];C^0(\overline{\omega})) \cap L^\infty(0,T;H_0^2(\omega))$, then, for any $v \in H^1(\Omega_\delta(t))$, $\gamma_{\delta(t)}(v) \in W^{1-1/p,p}(\omega)$, $\forall 1 < p < 2$ and for $\frac{3}{2} \le p < 2$, $\gamma_{\delta(t)}(v) \in H^{\frac{3p-2}{p}}(\omega)$, for a.e. t. Moreover, if $v \in L^2(0,T;H^1(\Omega_\delta(t)))$, then $\gamma_{\delta(t)}(v) \in L^2(0,T;W^{1-1/p,p}(\omega))$ $\forall 1 < p < 2$ and $\gamma_{\delta(t)}(v) \in L^2(0,T;H^{\frac{3p-2}{p}}(\omega))$ $\forall \frac{3}{2} \le p < 2$.*

Proof. Let us define an auxilary function by

$$w(t,x,y,s) = v(x,y,1+\delta(t,x,y)-s),\ 0 \le s \le \alpha.$$

It is clear that w belongs to $L^2(\mathcal{C}_\alpha)$ $\forall t$. Moreover

$$\nabla w(t,x,y,s) = \begin{pmatrix} \partial_x v(x,y,1+\delta(t,x,y)-s) + \partial_x\delta(t,x,y)\partial_z v(x,y,1+\delta(t,x,y)-s) \\ \partial_y v(x,y,1+\delta(t,x,y)-s) + \partial_y\delta(x,y)\partial_z v(x,y,1+\delta(t,x,y)-s) \\ -\partial_z v(x,y,1+\delta(t,x,y)-s) \end{pmatrix}.$$

Since $H^1(\omega)$ is continuously imbedded in $L^q(\omega)$ $\forall q < \infty$ and $\partial_i v(x,y,1+\delta(t,x,y)-s) \in L^2(\mathcal{C}_\alpha)$ $\forall t$, we deduce that $\nabla w \in L^p(\mathcal{C}_\alpha)$ for all $1 < p < 2$, for a.e. t. Thus $w \in W^{1,p}(\mathcal{C}_\alpha)$, and $\gamma_{\delta(t)}(v) = w|_{s=0} \in W^{1-1/p,p}(\omega)$ $\forall 1 < p < 2$ for a.e. t. Moreover, for a.e. t,

$$\|\gamma_{\delta(t)}(v)\|_{W^{1-1/p,p}(\omega)} \le C(\|\delta\|_{C^0([0,T];C^0(\overline{\omega}))\cap L^\infty(0,T;H_0^2(\omega))}, \|v\|_{H^1(\Omega_\delta(t))}).$$

Furthermore, from Sobolev injections (see [1, Thm. 7.58, p. 218]), we deduce that, for $2 > p \ge \frac{3}{2}$, $\gamma_{\delta(t)}(v) \in H^{\frac{3p-2}{p}}(\omega)$ and

$$\|\gamma_{\delta(t)}(v)\|_{H^{\frac{3p-2}{p}}(\omega)} \le C(\|\delta\|_{C^0([0,T];C^0(\overline{\omega}))\cap L^\infty(0,T;H_0^2(\omega))}, \|v\|_{H^1(\Omega_\delta(t))}). \tag{14}$$

∎

Now we are going to give a characterization of $H_0^1(\Omega_\delta(t))$ with the help of the mapping $\gamma_{\delta(t)}$. An additional assumption on the boundary displacement δ is needed: δ is assumed to belong to $C^0([0,T];H^1(\omega))$ (this is not an optimal assumption). ∎

LEMMA 3. *Assuming that $\delta \in C^0([0,T];C^0(\overline{\omega}) \cap H^1(\omega))$, then*

$$H_0^1(\Omega_\delta(t)) = \left\{ v \in H^1_{0,\Gamma_0}(\Omega_\delta(t)),\ \gamma_{\delta(t)}(v) = 0 \right\}.$$

COROLLARY 2. *If $v \in L^2(0,T;H^1_{0,\Gamma_0}(\Omega_\delta(t)))$ and $\gamma_{\delta(t)}(v) = 0$, for a.e. t, then $v \in L^2(0,T;H_0^1(\Omega_\delta(t)))$, and the converse is also true.*

We now state a lemma that enables us to extend a function $\mathbf{v} \in V_\delta$ such that $\gamma_{\delta(t)}(\mathbf{v}) = (0,0,b)^T,\ b \in L^2(0,T;H^1(\omega))$, the extension belonging to V.

LEMMA 4. *We assume that $\delta \in C^0([0,T];C^0(\overline{\omega}) \cap H_0^1(\omega))$. Let $\mathbf{v} \in V_\delta$ such that, for a.e. $t, \gamma_{\delta(t)}(\mathbf{v}) = (0,0,b)^T, b \in L^2(0,T;H_0^1(\omega))$. The function defined by*

$$\overline{\mathbf{v}} = \left| \begin{array}{l} \mathbf{v} \text{ in } \widehat{\Omega}_\delta \\ (0,0,b)^T \text{ in } \widehat{\mathcal{C}_M} \setminus \widehat{\Omega}_\delta \end{array} \right. \tag{15}$$

belongs to V, and

$$\|\overline{\mathbf{v}}\|_V \leq C(\|\mathbf{v}\|_{V_\delta} + \|b\|_{L^2(0,T;H^1(\omega))}),$$

where C depends only on M.

Remark 1. If $\mathbf{v} \in L^\infty(0,T;L^2(\Omega_\delta(t)))$ and $b \in L^\infty(0,T;L^2(\omega))$, then $\overline{\mathbf{v}} \in L^\infty(0,T;L^2(\mathcal{C}_M))$.

Next we build different lifting operators.

LEMMA 5. *For every $\phi \in H_0^1(\omega)$ there exists $w \in H^1_{0,\Gamma_0}(\Omega_\delta(t))$ such that*

$$\gamma_{\delta(t)}(w) = \phi \quad \text{and} \quad \|w\|_{H^1(\Omega_\delta(t))} \leq C_\alpha \|\phi\|_{H^1(\omega)}.$$

For every $b \in H_0^1(\omega)$ such that $\int_\omega b = 0$ there exists $\mathbf{v}$ such that $\gamma_{\delta(t)}(\mathbf{v}) = (0,0,b)^T$, $\operatorname{div}(\mathbf{v}) = 0$, and

$$\|\mathbf{v}\|_{H^1_{0,\Gamma_0}(\Omega_\delta(t))} \leq C_\alpha \|b\|_{H_0^1(\omega)}.$$

Proof. Indeed

$$w = \left| \begin{array}{l} \phi \text{ in } \Omega_\delta(t) \setminus \mathcal{C}_\alpha, \\ \mathcal{R}(\frac{z}{\alpha}\phi) \text{ in } \mathcal{C}_\alpha\ , \end{array} \right.$$

where $\mathcal{R}$ is a continuous lifting operator from $H^{1/2}(\partial\mathcal{C}_\alpha)$ into $H^1(\mathcal{C}_\alpha)$ and $\mathcal{C}_\alpha = \omega \times (0,\alpha)$ verifies the desired properties. Moreover, if we consider $b \in H_0^1(\omega)$ such that $\int_\omega b = 0$, then $\tilde{\mathcal{R}}$ is a continuous lifting operator from $H^{1/2}(\partial\mathcal{C}_\alpha)$ into $H^1(\mathcal{C}_\alpha)$ such that $\operatorname{div}(\tilde{\mathcal{R}}\mathbf{v}) = 0$,

$$\mathbf{v} = \left| \begin{array}{l} (0,0,b)^T \text{ in } \Omega_\delta(t) \setminus \mathcal{C}_\alpha, \\ \tilde{\mathcal{R}}(0,0,\frac{z}{\alpha}b)^T \text{ in } \mathcal{C}_\alpha\ , \end{array} \right. \tag{16}$$

is divergence-free and belongs to $H^1_{0,\Gamma_0}(\Omega_\delta(t))$. Furthermore, we have for a.e. t

$$\|\mathbf{v}\|_{H^1_{0,\Gamma_0}(\Omega_\delta(t))} \leq C_\alpha \|b\|_{H_0^1(\omega)}.$$

Consequently (16) defines a continuous linear lifting from $\{b \in H_0^1(\omega)$, such that (s.t.) $\int_\omega b = 0\}$ into $\{\mathbf{v} \in H^1_{0,\Gamma_0}(\Omega_\delta(t))$, s.t. $\operatorname{div}(\tilde{\mathcal{R}}\mathbf{v}) = 0\}$. ∎

Remark 2. Thanks to the previous lemma the space

$$\left\{\mathbf{v} \in V_\delta, \gamma_{\delta(t)}(\mathbf{v}) = (0,0,b)^T \text{ for a.e. } t,\ b \in L^2(0,T;H_0^1(\omega))\right\}$$

is equal to the sum of the two following spaces:

$$\overline{\left\{\mathbf{v} \in \mathcal{D}(\widehat{\Omega}_\delta),\ \operatorname{div}\mathbf{v} = 0\right\}}^{L^2(0,T;H^1(\Omega_\delta(t)))}$$

and

$$\left\{\mathbf{v},\ \mathbf{v}=\left|\begin{array}{l}(0,0,b)^T \text{ in } \Omega_\delta(t)\setminus\mathcal{C}_\alpha\\ \tilde{\mathcal{R}}(0,0,\frac{z}{\alpha}b)^T \text{ in } \mathcal{C}_\alpha\end{array}\right. \text{ for a.e. } t,\ b\in L^2(0,T;H^1_0(\omega)),\int_\omega b=0\right\}.$$

We also need to build a "lifting" operator of $(0,0,b)^T$ for any b that belongs only to $H^s(\omega), 0\le s<\frac{1}{2}$ since the structure velocity $\partial_t\eta_\varepsilon$ will be bounded, uniformly in ε, only in $L^2(0,T;H^s(\omega))\ \forall 0\le s<\frac{1}{2}$ and not in $L^2(0,T;H^1_0(\omega))$ (see Lemma 2).

LEMMA 6. *For all $b\in L^2(0,T;H^s(\omega)),\ 0\le s<\frac{1}{2}$ such that $\int_\omega b=0$, there exists a lifting operator $\mathcal{R}_\alpha$ satisfying $\gamma_{\delta(t)}(\mathcal{R}_\alpha(b))=(0,0,b)^T$ and $\operatorname{div}(\mathcal{R}_\alpha(b))=0$ and for a.e. t*

$$\|\mathcal{R}_\alpha(b)\|_{H^s(\mathcal{C}_M)}\le C\|b\|_{H^s(\omega)}\ \forall 0\le s<\frac{1}{2}. \tag{17}$$

Proof. A rather naive construction will satisfy the desired properties. Let us define $\mathcal{R}_\alpha$ by

$$\mathcal{R}_\alpha(b)=\left|\begin{array}{ll}(0,0,b)^T \text{ for } z\ge\alpha & \\ (0,0,\frac{z}{\alpha}b)^T+\mathbf{w}_\alpha \text{ in } \mathcal{C}_\alpha & \text{for a.e. } t,\end{array}\right. \tag{18}$$

where $\mathbf{w}_\alpha$ is such that $\operatorname{div}(\mathbf{w}_\alpha)=b$ and $\mathbf{w}_\alpha\in H^1_0(\mathcal{C}_\alpha)$, $\|\mathbf{w}_\alpha\|_{H^1_0(\mathcal{C}_\alpha)}\le C\|b\|_{L^2(\omega)}$, for a.e. t. Such a function exists (see, for instance, [14]). It is easy to see that $\mathcal{R}_\alpha(b)$ is divergence-free. Moreover, $\mathcal{R}_\alpha$ is linear continuous from $L^2(0,T,L^2(\omega))$ (resp., $L^2(0,T,H^1_0(\omega))$) into $L^2(0,T,L^2(\mathcal{C}_M))$ (resp., $L^2(0,T,H^1_{0,\Gamma_0}(\mathcal{C}_M))$), and thus, by interpolation (see [19]), $\mathcal{R}_\alpha$ is linear continuous from $L^2(0,T,H^s(\omega)))$ into $L^2(0,T,H^s(\mathcal{C}_M))\ \forall 0\le s<\frac{1}{2}$. Consequently, (17) holds true. ∎

Remark 3. The trace $\gamma_{\delta(t)}(\mathcal{R}_\alpha(b))$ makes sense for any $b\in L^2(\omega)$ since $\mathcal{R}_\alpha(b)$ is regular enough with respect to z.

We end this section by mentioning that Korn's and Poincaré's inequalities hold in the considered spaces.

LEMMA 7. *For all $\mathbf{u}$ and $\mathbf{v}$ in*

$$\left\{\mathbf{v}\in V_\delta,\ \exists\, b\in L^2(0,T;H^1_0(\omega)),\ \gamma_{\delta(t)}(\mathbf{v})=(0,0,b)^T \text{ for a.e. } t\right\},$$

we have

$$2\int_{\Omega_\delta(t)}D(\mathbf{u}):D(\mathbf{v})=\int_{\Omega_\delta(t)}\nabla\mathbf{u}:\nabla\mathbf{v}\ \text{ for a.e. } t, \tag{19}$$

and consequently the following Korn's "equality" holds:

$$\sqrt{2}\|D(\mathbf{u})\|_{L^2(\Omega_{\delta(t)})}=\|\nabla\mathbf{u}\|_{L^2(\Omega_{\delta(t)})} \text{ for a.e. } t. \tag{20}$$

LEMMA 8. *Let $v\in H^1_{0,\Gamma_0}(\Omega_\delta(t))$, and then*

$$\|v\|_{L^2(\Omega_\delta(t))}\le M\|\nabla v\|_{L^2(\Omega_\delta(t))}.$$

1.4. Weak formulation. Let $\eta_I\in H^2_0(\omega)$, $(\mathbf{u}_I,\dot\eta_I)\in L^2(\Omega_{\eta_I})\times L^2(\omega)$, such that

$$\begin{aligned}&\min_{\overline{\omega}}(1+\eta_I)>0,\\ &\operatorname{div}\mathbf{u}_I=0 \text{ in } \Omega_{\eta_I},\\ &\mathbf{u}_I\cdot\mathbf{n}=0 \text{ on } \Gamma_0,\\ &\mathbf{u}_I(x,y,1+\eta_I(x,y))\cdot\mathbf{n}_0=(0,0,\dot\eta_I(x,y))^T\cdot\mathbf{n}_0 \text{ on } \omega,\\ &\int_\omega\dot\eta_I(x,y)=0,\end{aligned} \tag{21}$$

where $\mathbf{n}_0$ denotes the unit normal to the initial position of the plate. We refer to [4], where one proves that the normal trace $\mathbf{u}_I(x,y,1+\eta_I(x,y))\cdot\mathbf{n}_0, (x,y)\in\omega$ makes sense for $\mathbf{u}_I\in L^2(\Omega_{\eta_I})$, with $\eta_I\in H_0^2(\omega)$. We shall say that $(\mathbf{u}_\varepsilon,\eta_\varepsilon)$ is a weak solution of the considered model on $(0,T)$ if it satisfies the following problem that will be denoted $(\mathcal{P}_\varepsilon)$:

- $\mathbf{u}_\varepsilon\in V_{\eta_\varepsilon}\cap L^\infty(0,T;L^2(\Omega_{\eta_\varepsilon}(t)))$, $\eta_\varepsilon\in W^{1,\infty}(0,T;L^2(\omega))\cap L^\infty(0,T;H_0^2(\omega))$,
- for $\varepsilon>0$, $\partial_t\eta_\varepsilon\in L^2(0,T;H_0^2(\omega))$,
- $\mathbf{u}_\varepsilon(t,x,y,1+\eta_\varepsilon(t,x,y))=(0,0,\partial_t\eta_\varepsilon(t,x,y))^T$ for a.e. $(t,x,y)\in(0,T)\times\omega$,
- for all $(\ \ ,b)\in(V_{\eta_\varepsilon}\cap H^1(\widehat{\Omega}_{\eta_\varepsilon}))\times(L^2(0,T;H_0^2(\omega))\times H^1(0,T;L^2(\omega)))$ such that $(t,x,y,1+\eta_\varepsilon(t,x,y))=(0,0,b(t,x,y))^T$, for a.e. $(t,x,y)\in(0,T)\times\omega$, we have for a.e. t

$$
\begin{aligned}
(22)\quad &\int_{\Omega_{\eta_\varepsilon}(t)}\mathbf{u}_\varepsilon(t)\cdot\ \ (t)-\int_0^t\int_{\Omega_{\eta_\varepsilon}(s)}\mathbf{u}_\varepsilon\cdot\partial_t\ \ +\nu\int_0^t\int_{\Omega_{\eta_\varepsilon}(s)}\nabla\mathbf{u}_\varepsilon:\nabla\\
&\quad+\int_0^t\int_{\Omega_{\eta_\varepsilon}(s)}(\mathbf{u}_\varepsilon\cdot\nabla)\mathbf{u}_\varepsilon\cdot\ \ -\int_0^t\int_\omega(\partial_t\eta_\varepsilon)^2b+\int_\omega\partial_t\eta_\varepsilon(t)\,b(t)\\
&\quad-\int_0^t\int_\omega\partial_t\eta_\varepsilon\,\partial_tb+\int_0^t\int_\omega\Delta\eta_\varepsilon\,\Delta b+\varepsilon\int_0^t\int_\omega\Delta\partial_t\eta_\varepsilon\,\Delta b\\
&\quad=\int_0^t\int_{\Omega_{\eta_\varepsilon}(t)}\mathbf{f}\cdot\ \ +\int_0^t\int_\omega g\ b+\int_{\Omega_{\eta_I}}\mathbf{u}_I\cdot\ \ (0)+\int_\omega\dot\eta_Ib(0).
\end{aligned}
$$

In what follows, a solution of $(\mathcal{P}_0)$ will be denoted by $(\mathbf{u},\eta)$ (instead of $(\mathbf{u}_0,\eta_0)$).

Remark 4. The test functions depends on the solution and thus, for $\varepsilon>0$, on ε.

Remark 5. The trace at time $t=0$ of $\ \in H^1(\widehat{\Omega}_{\eta_\varepsilon})$ such that $(t,x,y,1+\eta_\varepsilon(t,x,y))=(0,0,b(t,x,y))^T$ for a.e. $(t,x,y)\in(0,T)\times\omega$, with $b\in H^1((0,T)\times\omega)$, is well-defined and makes sense at least in $L^2(\Omega_{\eta_I})$. Indeed we can prove by density arguments ($C^1(\overline{\widehat{\Omega}_{\eta_\varepsilon}})$ is dense in $H^1(\widehat{\Omega}_{\eta_\varepsilon})$ since the domain is a continuous subgraph; see, for instance, [1, Thm. 2, p. 54]) that

$$
-\int_{\Omega_{\eta_\varepsilon(0)}}|\ \ (0)|^2=2\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}\psi\ \ \partial_t\ \ +\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}|\ \ |^2\partial_t\psi+\int_0^T\int_\omega|b|^2\psi\partial_t\eta_\varepsilon,
$$

where ψ belongs to $\mathcal{D}([0,T))$ and satisfies $\psi(0)=1$. The right-hand side of this equality makes sense for any $\ \in H^1(\widehat{\Omega}_{\eta_\varepsilon})$ such that $(t,x,y,1+\eta_\varepsilon(t,x,y))=(0,0,b(t,x,y))^T$ for a.e. $(t,x,y)\in(0,T)\times\omega$, with $b\in H^1((0,T)\times\omega)$, since $\partial_t\eta_\varepsilon\in L^\infty(0,T;L^2(\omega))$ and $b\in L^4((0,T)\times\omega)$.

2. Main result. We make the following hypotheses on the data (bulk forces and initial data):

$$
\begin{aligned}
(23)\qquad &\mathbf{f}\in L^2_{loc}((0,+\infty)\times\mathbb{R}^2),\ g\in L^2_{loc}((0,+\infty)\times\omega),\\
&\mathbf{u}_I\in L^2(\Omega_{\eta_I}),\ \dot\eta_I\in L^2(\omega),\ \eta_I\in H_0^2(\omega),
\end{aligned}
$$

and we assume moreover that conditions (21) are satisfied.

First we recall that, for $\varepsilon>0$, there exists at least one weak solution provided that the plate does not touch the bottom of the fluid cavity, in other words, as long as $\min_{(x,y)\in\overline{\omega}}(1+\eta_\varepsilon(t,x,y))>0$. The proof of the following theorem can be found in [4].

THEOREM 1. *Let ε be strictly positive. Under assumptions* (21) *and* (23) *and if* $\min_{(x,y)\in\overline{\omega}}1+\eta_I(x,y)>0$, *there exist* $T_\varepsilon^*\in(0,+\infty]$ *and a weak solution* $(\mathbf{u}_\varepsilon,\eta_\varepsilon)$ *of*

$(\mathcal{P}_\varepsilon)$ on $[0,T]$, $T < T_\varepsilon^*$. This solution satisfies an energy estimate for all $T < T_\varepsilon^*$:

$$\begin{aligned}&\|\mathbf{u}_\varepsilon\|_{L^\infty(0,T;L^2(\Omega_{\eta_\varepsilon}(t)))} + \|\nabla \mathbf{u}_\varepsilon\|_{L^2(0,T;L^2(\Omega_{\eta_\varepsilon}(t)))}\\ &+ \|\partial_t \eta_\varepsilon\|_{L^\infty(0,T;L^2(\omega))} + \|\Delta \eta_\varepsilon\|_{L^\infty(0,T;L^2(\omega))} + \sqrt{\varepsilon}\|\Delta \partial_t \eta_\varepsilon\|_{L^2(0,T;L^2(\omega))}\\ &\quad \le C(T, \|\mathbf{u}_I\|_{L^2(\Omega_{\eta_I})}, \|\mathbf{f}\|_{L^2((0,T)\times\mathbb{R}^2)}, \|g\|_{L^2((0,T)\times\omega)}, \|\eta_I\|_{H_0^2(\omega)}, \|\dot\eta_I\|_{L^2(\omega)}),\end{aligned}$$

where $C > 0$ is nondecreasing with respect to its arguments. Moreover, we have the following alternative:

- *either $T_\varepsilon^* = +\infty$*
- *or $\lim_{t\to T_\varepsilon^*} \min_{\overline{\omega}}(1+\eta_\varepsilon) = 0$.*

Since $\mathbf{u}_\varepsilon$ is bounded in $L^2(0,T;H^1(\Omega_{\eta_\varepsilon}(t)))$ uniformly in ε and thanks to the regularity of the moving elastic boundary, the trace $\gamma_{\eta_\varepsilon(t)}(\mathbf{u}_\varepsilon)$ is bounded in $L^2(0,T;W^{1-1/p,p}(\omega))$ $\forall 1 < p < 2$ and in $L^2(0,T;H^s(\omega))$ $\forall 0 \le s < \frac{1}{2}$ uniformly in ε (see Lemma 2 and (14)). Thus, thanks to the equality of the velocities (4),

$$\partial_t \eta_\varepsilon \text{ is bounded, uniformly in } \varepsilon, \text{ in } L^2(0,T;W^{1-1/p,p}(\omega)) \ \forall 1 < p < 2, \tag{24}$$

and

$$\partial_t \eta_\varepsilon \text{ is bounded, uniformly in } \varepsilon, \text{ in } L^2(0,T;H^s(\omega)) \ \forall 0 \le s < \frac{1}{2}. \tag{25}$$

This will be one of the key arguments for the derivation of the compactness properties of the sequence $(\mathbf{u}_\varepsilon, \eta_\varepsilon)$. In particular thanks to (25) we can control, uniformly in ε, the space high frequencies of $\partial_t \eta_\varepsilon$ in $L^2(0,T;L^2(\omega))$.

In all that follows, the characteristic function of $\widehat{\Omega}_{\eta_\varepsilon}$ will be denoted by ρ_ε, and $\rho_\varepsilon v$ will denote the function equal to v in $\widehat{\Omega}_{\eta_\varepsilon}$ and zero elsewhere. Moreover, we choose M large enough such that, for all $\varepsilon > 0$, $1 + \eta_\varepsilon(t,x,y) \le M$ $\forall (t,x,y) \in [0,T]\times\overline{\omega}$, which is made possible by (12) and (13). We set

$$\overline{\mathbf{u}}_\varepsilon = \begin{cases} \mathbf{u}_\varepsilon & \text{in } \widehat{\Omega}_{\eta_\varepsilon},\\ (0,0,\partial_t\eta_\varepsilon)^T & \text{in } \widehat{\mathcal{C}_M} \setminus \overline{\widehat{\Omega}}_{\eta_\varepsilon}. \end{cases}$$

In all that follows, for any $\mathbf{v}$ in $L^2(0,T;H^1_{0,\Gamma_0}(\Omega_{\eta_\varepsilon}(t)))$ such that $\gamma_{\delta(t)}(\mathbf{v}) = (0,0,b)^T$, $b \in L^2(0,T;H_0^1(\omega))$, $\overline{\mathbf{v}}$ is defined by (15).

The main results of the present paper are the following.

PROPOSITION 1. *The sequence $(T_\varepsilon^*)_{\varepsilon>0}$ is bounded from below away from zero, and the following convergences (up to the extractions of subsequences) hold as ε goes to zero:*

$$\begin{array}{llll} \eta_\varepsilon \to \eta & \textit{strongly in} & C^0([0,T];C^0(\overline{\omega})),\\ \eta_\varepsilon \rightharpoonup \eta & \textit{weakly in} & L^2(0,T;H_0^2(\omega)),\\ \partial_t\eta_\varepsilon \to \partial_t\eta & \textit{strongly in} & L^2(0,T;L^2(\omega)),\\ \rho_\varepsilon \mathbf{u}_\varepsilon \to \rho\mathbf{u} & \textit{strongly in} & L^2(0,T;L^2(\mathcal{C}_M)),\\ \overline{\mathbf{u}}_\varepsilon \to \overline{\mathbf{u}} & \textit{strongly in} & L^2(0,T;L^2(\mathcal{C}_M)),\\ \rho_\varepsilon \nabla\mathbf{u}_\varepsilon \rightharpoonup \rho\nabla\mathbf{u} & \textit{weakly in} & L^2(0,T;L^2(\mathcal{C}_M)), \end{array} \tag{26}$$

where $T > 0$ is a lower bound of T_ε^* independent of ε. Moreover

$$\gamma_{\eta(t)}(\mathbf{u}) = (0,0,\partial_t\eta)^T.$$

This enables us to pass to the limit in (22) as ε tends to zero and thus obtain the following theorem.

THEOREM 2. *Under assumptions* (21) *and* (23) *and if* $\min_{(x,y)\in\overline{\omega}} 1+\eta_I(x,y) > 0$, *there exist* $T^* \in (0,+\infty]$ *and a weak solution* $(\mathbf{u},\eta)$ *of* $(\mathcal{P}_0)$ *on* $[0,T]$, $T < T^*$. *This solution satisfies energy estimates for all* $T < T^*$:

$$\begin{aligned}(27)\qquad &\|\mathbf{u}\|_{L^\infty(0,T;L^2(\Omega_\eta(t)))} + \|\nabla\mathbf{u}\|_{L^2(0,T;L^2(\Omega_\eta(t)))}\\ &\quad + \|\partial_t\eta\|_{L^\infty(0,T;L^2(\omega))} + \|\eta\|_{L^\infty(0,T;H_0^2\omega)}\\ &\le C(T, \|\mathbf{u}_I\|_{L^2(\Omega_{\eta_I})}, \|\mathbf{f}\|_{L^2((0,T)\times\mathbb{R}^2)}, \|g\|_{L^2((0,T)\times\omega)}, \|\eta_I\|_{H_0^2(\omega)}, \|\dot\eta_I\|_{L^2(\omega)}),\end{aligned}$$

where $C > 0$ *is nondecreasing with respect to its arguments. The following alternatives are satisfied:*

- *either* $T^* = +\infty$
- *or* $\lim_{t\to T^*} \min_{\overline{\omega}}(1+\eta) = 0$.

3. Proof of Proposition 1. First we prove that Proposition 1 holds true. We have to verify that T_ε^* is bounded from below independently of ε and obtain compactness properties on $(\mathbf{u}_\varepsilon, \partial_t\eta_\varepsilon)$ in order to prove the desired strong convergences that will enable us to pass to the limit in $(\mathcal{P}_\varepsilon)$ as ε goes to zero.

Lower bound of T_ε^*. For $\varepsilon > 0$ the solution η_ε is bounded uniformly in ε in $L^\infty(0,T;H_0^2(\omega)) \cap W^{1,\infty}(0,T;L^2(\omega))$ for all $T < T_\varepsilon^*$. Thus from (13), η_ε is bounded uniformly in ε in $C^{0,\mu}([0,T];C^0(\overline{\omega}))$, $0 < \mu < \frac{1}{2}$. Consequently

$$1 + \eta_\varepsilon(t,x,y) \ge (1+\eta_I(x,y)) - Ct^\mu \quad \forall (t,x,y) \in [0,T_\varepsilon^*) \times \overline{\omega},$$

where C depends only on the data of the problem. Thus T_ε^* is bounded from below by a time independent of ε. Let T be such that

$$\forall \varepsilon > 0, \min_{(t,x,y)\in[0,T]\times\overline{\omega}} (1+\eta_\varepsilon(t,x,y)) \ge \alpha > 0,$$

where α is chosen such that $\min_{(x,y)\in\overline{\omega}}(1+\eta_I(x,y)) \ge 2\alpha > 0$.

Convergences of the sequence $(\mathbf{u}_\varepsilon, \eta_\varepsilon)$. From (12) and the compact injection (13) we deduce easily the first two convergences announced in Proposition 1. Next we prove strong convergence properties for the fluid and the structure velocities. The solution $(\mathbf{u}_\varepsilon, \eta_\varepsilon)_{\varepsilon>0}$ we build verifies estimate (9) and (25). Furthermore, since $\mathbf{u}_\varepsilon$ is bounded uniformly in ε in $L^2(0,T;H^1(\Omega_{\eta_\varepsilon}(t)))$, it is easy to verify that $\mathbf{w}_\varepsilon$, defined by $\mathbf{w}_\varepsilon(t,x,y,z) = \mathbf{u}_\varepsilon(t,x,y,z(1+\eta_\varepsilon(t,x,y)))$, is bounded uniformly in ε in $L^2(0,T;W^{1,p}(\mathcal{C}_1))$ $\forall 1 < p < 2$. This implies, thanks to Sobolev injections (see [1, Thm. 7.58, p. 218]) that $\mathbf{w}_\varepsilon$ is uniformly bounded in $L^2(0,T;H^\theta(\mathcal{C}_1))$ for any $\theta < 1$. Moreover $\partial_t\eta_\varepsilon$ is uniformly bounded in $L^2(0,T;H^s(\omega))$ $\forall 0 \le s < \frac{1}{2}$. Consequently, $\mathbf{w}_\varepsilon - \mathcal{R}_\alpha(\partial_t\eta_\varepsilon)$ is uniformly bounded in $L^2(0,T;H^s(\mathcal{C}_1))$ for any $0 \le s < \frac{1}{2}$ and its extension by zero for $z \ge 1$ is uniformly bounded in $L^2(0,T;H^s(\mathcal{C}_L))$ for any $s < \frac{1}{2}$, $L \ge 1$ (see [19]). Thus if we extend $\mathbf{w}_\varepsilon$ by $(0,0,\partial_t\eta_\varepsilon)^T$ for $z \ge 1$, this extension is uniformly bounded in $L^2(0,T;H^s(\mathcal{C}_L))$ $\forall 0 \le s < \frac{1}{2}, L \ge 1$. Consequently, since the change of variables $\phi_\varepsilon(t,x,y,z) = (x,y,z(1+\eta_\varepsilon(t,x,y))^T$ is in $L^\infty(0,T;C^{0,\beta}(\mathcal{C}_L))$ $\forall \beta < 1$ as well as its inverse, it is easy to verify that

$$(28)\qquad \overline{\mathbf{u}}_\varepsilon \text{ is bounded, uniformly in } \varepsilon, \text{ in } L^2(0,T;H^{s'}(\mathcal{C}_M))\ \forall 0 \le s' < s, \forall s < \frac{1}{2}.$$

Moreover thanks to the Sobolev injections, $\mathbf{w}_\varepsilon$ is bounded uniformly in ε in $L^2(0,T;L^q(\mathcal{C}_1))$ $\forall q < 6$ and $\partial_t\eta_\varepsilon$ is uniformly bounded in $L^2(0,T;L^r(\omega))$ $\forall r < 4$; thus

$$(29)\qquad \overline{\mathbf{u}}_\varepsilon \text{ is bounded, uniformly in } \varepsilon, \text{ in } L^2(0,T;L^r(\mathcal{C}_M))\ \forall r < 4.$$

Nevertheless, these bounds are not sufficient to obtain the desired strong convergences. We are going to use the following lemma that characterizes the compact sets of $L^p(0,T;X)$, where X is a Banach space (see [23]).

LEMMA 9. *Let X be a Banach space and $F \hookrightarrow L^q(0,T;X)$, with $1 \leq q < \infty$. Then F is a relatively compact set of $L^q(0,T;X)$ if and only if*

(i) $\{\int_{t_1}^{t_2} f(t)dt, f \in F\}$ *is relatively compact in X $\forall < t_1 < t_2 < T$;*

(ii) $\|f(t+h) - f(t)\|_{L^q(0,T;X)} \longrightarrow 0$ *as h goes to zero, uniformly with respect to f in F.*

We are going to apply Lemma 9 to $F = (\overline{\mathbf{u}}_\varepsilon, \partial_t \eta_\varepsilon)_{\varepsilon>0}$, $q = 2$, and $X = L^2(\mathcal{C}_M) \times L^2(\omega)$. The first point (i) is clearly satisfied thanks to (25) and (28), and we have to verify the second point. Given any $h > 0$, we denote that $g^-(t,\cdot) = g(t-h,\cdot)$ and $g^+(t,\cdot) = g(t+h,\cdot)$. The assertion (ii) is a consequence of the following lemma.

LEMMA 10. *Let $T > 0$ such that $\min_{[0,T]\times\overline{\omega}}(1+\eta_\varepsilon) \geq \alpha > 0$. We have $\forall \beta > 0$, $\exists h_0 > 0$, s.t. $\forall \varepsilon > 0$, $\forall h \leq h_0$*

$$\int_0^T \int_{\mathcal{C}_M} \rho_\varepsilon |\overline{\mathbf{u}}_\varepsilon - \overline{\mathbf{u}}_\varepsilon^-|^2 + \int_0^T \int_\omega (\partial_t \eta_\varepsilon - \partial_t \eta_\varepsilon^-)^2 \leq \beta \tag{30}$$

and

$$\int_0^T \int_{\mathcal{C}_M} |\rho_\varepsilon \overline{\mathbf{u}}_\varepsilon - \rho_\varepsilon^- \overline{\mathbf{u}}_\varepsilon^-|^2 \leq \beta, \tag{31}$$

with η_ε extended by η_I for $t < 0$ and $\overline{\mathbf{u}}_\varepsilon$ and $\partial_t \eta_\varepsilon$ extended by 0 for $t < 0$ and where ρ_ε denotes the characteristic function of $\widehat{\Omega}_{\eta_\varepsilon}$.

Proof. We first show that (30) implies (31). Indeed:

$$|\rho_\varepsilon \overline{\mathbf{u}}_\varepsilon - \rho_\varepsilon^- \overline{\mathbf{u}}_\varepsilon^-|^2 \leq C\left(\rho_\varepsilon |\overline{\mathbf{u}}_\varepsilon - \overline{\mathbf{u}}_\varepsilon^-|^2 + |\rho_\varepsilon - \rho_\varepsilon^-||\overline{\mathbf{u}}_\varepsilon^-|^2\right).$$

The estimate of the first contribution comes from (30). For the second contribution we use the fact that $\overline{\mathbf{u}}_\varepsilon$ is bounded uniformly in ε in $L^2(0,T;L^3(\mathcal{C}_M))$ (see (29)):

$$\left|\int_0^T \int_{\mathcal{C}_M} |\rho_\varepsilon - \rho_\varepsilon^-||\overline{\mathbf{u}}_\varepsilon|^2\right| \leq \int_0^T \|\rho_\varepsilon - \rho_\varepsilon^-\|_{L^3(\mathcal{C}_M)} \|\overline{\mathbf{u}}_\varepsilon\|^2_{L^3(\mathcal{C}_M)} \leq C \int_0^T \|\rho_\varepsilon - \rho_\varepsilon^-\|_{L^3(\mathcal{C}_M)}.$$

Remember now that $\partial_t \eta_\varepsilon$ is bounded in $L^\infty(0,T;L^2(\omega))$ uniformly in ε, and thus

$$\begin{aligned}
\int_{\mathcal{C}_M} |\rho_\varepsilon - \rho_\varepsilon^-|^3 &= \int_\omega |\eta_\varepsilon - (\eta_\varepsilon)^-| \\
&= \int_\omega \left|\int_{t-h}^t \partial_t \eta_\varepsilon(s) ds\right| \\
&\leq \int_\omega \int_{t-h}^t |\partial_t \eta_\varepsilon(s)| ds \\
&\leq Ch.
\end{aligned}$$

It leads to

$$\left|\int_0^T \int_{\mathcal{C}_M} (\rho_\varepsilon - \rho_\varepsilon^-)|\overline{\mathbf{u}}_\varepsilon|^2\right| \leq Ch^{\frac{1}{3}}. \tag{32}$$

This shows that (30) implies (31).

To prove (30) we are going to make a suitable choice for the test functions in the weak formulation satisfied by $\mathbf{u}_\varepsilon$ and η_ε:

$$
\begin{aligned}
(33)\quad & \int_{\Omega_{\eta_\varepsilon}(T)} \mathbf{u}_\varepsilon(T)\cdot \quad (T) - \int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} \mathbf{u}_\varepsilon \cdot \partial_t \quad + \nu \int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} \nabla \mathbf{u}_\varepsilon : \nabla \\
& + \int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} (\mathbf{u}_\varepsilon \cdot \nabla)\mathbf{u}_\varepsilon \cdot \quad - \int_0^T \int_\omega (\partial_t \eta_\varepsilon)^2 b + \int_\omega \partial_t \eta_\varepsilon(T)\, b(T) \\
& - \int_0^T \int_\omega \partial_t \eta_\varepsilon\, \partial_t b + \int_0^T \int_\omega \Delta \eta_\varepsilon\, \Delta b + \varepsilon \int_0^T \int_\omega \Delta \partial_t \eta_\varepsilon\, \Delta b \\
& = \int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} \mathbf{f}\cdot \quad + \int_0^T \int_\omega g\ b + \int_{\Omega_{\eta_I}} \mathbf{u}_I \cdot \quad (0) + \int_\omega \dot{\eta}_I b(0), \\
& \text{for all } (\quad, b) \in (V_{\eta_\varepsilon} \cap H^1(\widehat{\Omega}_{\eta_\varepsilon})) \times (L^2(0,T;H_0^2(\omega)) \cap H^1(0,T;L^2(\omega))), \\
& \text{s.t.} \quad (t,x,y,1+\eta_\varepsilon(t,x,y)) = (0,0,b(t,x,y))^T \text{ for a.e. } (t,x,y) \in (0,T)\times\omega.
\end{aligned}
$$

We are going to study separately the low frequencies and the high frequencies of $\partial_t \eta_\varepsilon$ and take advantage of the fact that $\partial_t \eta_\varepsilon$ is bounded in $L^2(0,T;H^s(\omega))\ \forall\ 0 \le s < \frac{1}{2}$ uniformly in ε (see (25)). This implies that we can control, uniformly in ε, the space high frequencies of $\partial_t \eta_\varepsilon$ in $L^2(0,T;L^2(\omega))$.

Definition of admissible test functions. First we introduce a basis of $H_0^2(\omega) \cap L_0^2(\omega)$ by taking eigenfunctions $(\xi_i)_{i\in\mathbb{N}}$ defined by:

$$
\begin{cases}
\displaystyle\int_\omega \Delta\xi_i \Delta b = \lambda_i \int_\omega \xi_i b \quad \forall b \in H_0^2(\omega) \text{ s.t.} \quad \int_\omega b = 0, \\
\xi_i \in H_0^2(\omega), \displaystyle\int_\omega \xi_i = 0,
\end{cases}
$$

with $(\lambda_i)_{i\in\mathbb{N}}$ the sequence of increasing eigenvalues: $\lambda_i > 0,\ \lambda_i \to +\infty$. We choose $(\xi_i)_{i\in\mathbb{N}}$ orthonormal in $L^2(\omega)$. We denote by d^{N_0} the L^2-projection on the finite-dimensional space $\mathrm{span}(\xi_i)_{0\le i\le N_0}$ of any function d and by d^{hf,N_0} the difference $d - d^{N_0}$. Thanks to the choice of the ξ_i, the L^2-projection on the finite-dimensional space $\mathrm{span}(\xi_i)_{0\le i\le N_0}$ is stable in the L^2-norm as well as in the H_0^2-norm. In what follows, we will use the fact that the following property, obtained by Hilbertian interpolation, holds true:

$$
(34)\qquad \forall d \in H^s(\omega), 0 \le s < \frac{1}{2}, \quad \|d^{hf,N_0}\|_{L^2(\omega)} \le \lambda_{N_0}^{-\frac{s}{2}} \|d\|_{H^s(\omega)}.
$$

Next, for $\sigma > 1$ we define $\mathbf{v}_\sigma$ by

$$
\mathbf{v}_\sigma(x,y,z) = (\sigma v_1(x,y,\sigma z), \sigma v_2(x,y,\sigma z), v_3(x,y,\sigma z)).
$$

If $\mathbf{v}$ is divergence-free, $\mathbf{v}_\sigma$ is also divergence-free.

We want now to define admissible test functions. We set

$$
b_\varepsilon = \int_{t-h}^t \partial_t \eta_\varepsilon^{N_0}(s) ds
$$

and

$$
{}_\varepsilon = \int_{t-h}^t \left(\overline{(\mathbf{u}_\varepsilon - \mathcal{R}_\alpha(\partial_t \eta_\varepsilon))^\lambda} \right)_\sigma (s) ds + \int_{t-h}^t \overline{\mathcal{R}_\alpha(\partial_t \eta_\varepsilon^{N_0})}(s) ds,
$$

where the extension $\mathbf{v} \mapsto \overline{\mathbf{v}}$ is defined by (15) and where $\mathcal{R}_\alpha$ is the lifting operator defined at Lemma 6. Moreover a space regularization of $\mathbf{v}_\varepsilon = \mathbf{u}_\varepsilon - \mathcal{R}_\alpha(\partial_t \eta_\varepsilon)$, denoted by $\mathbf{v}_\varepsilon^\lambda$, has been introduced in order to have $\quad_\varepsilon$ uniformly bounded in $H^1(0,T;H^1(\mathcal{C}_M))$. It verifies $\operatorname{div}(\mathbf{v}_\varepsilon^\lambda) = 0$, $\mathbf{v}_\varepsilon^\lambda \in L^2(0,T;H_0^1(\Omega_{\eta_\varepsilon}(t)))$, and

$$\begin{array}{l} \|\mathbf{v}_\varepsilon - \mathbf{v}_\varepsilon^\lambda\|_{L^2(0,T;L^2(\Omega_{\eta_\varepsilon}(t)))} \longrightarrow 0, \text{ uniformly in } \varepsilon, \text{ as } \lambda \text{ goes to zero,} \\ \|\mathbf{v}_\varepsilon^\lambda\|_{L^2(0,T;H^1(\Omega_{\eta_\varepsilon}(t)))} \leq C_\lambda. \end{array} \tag{35}$$

Note that the construction of $\mathbf{v}_\varepsilon^\lambda$ relies on the fact that η_ε converges uniformly to η and that the plate does not touch the bottom of the fluid cavity. Moreover, the uniform convergence of $(\mathbf{v}_\varepsilon^\lambda)_\lambda$ as $\lambda \longrightarrow 0$ in $L^2(0,T;L^2(\Omega_{\eta_\varepsilon}(t)))$ is made possible since $\overline{\mathbf{v}}_\varepsilon$ is uniformly bounded in $L^2(0,T;H^{s'}(\mathcal{C}_M)), 0 < s' < 1/2$ thanks to (17), (25), and (28). Note that, with this choice,

$$\begin{gathered} \|\partial_t \eta_\varepsilon^{N_0}\|_{L^\infty(0,T;L^2(\omega))} \leq C, \quad \|\partial_t \eta_\varepsilon^{N_0}\|_{L^2(0,T;H^s(\omega))} \leq C, \\ \|b_\varepsilon\|_{W^{1,\infty}(0,T;L^2(\omega))} \leq C, \quad \|b_\varepsilon\|_{H^1(0,T;H^s(\omega))} \leq C, \\ \|\overline{\mathbf{v}_\varepsilon^\lambda}\|_{L^\infty(0,T;L^2(\mathcal{C}_M))} \leq C, \|\overline{\mathbf{v}_\varepsilon^\lambda}\|_{L^2(0,T;H^{s'}((\mathcal{C}_M))} \leq C \ \forall s' < s < 1/2, \end{gathered}$$

and

$$\|\partial_t \eta_\varepsilon^{N_0}\|_{L^\infty(0,T;H^2(\omega))} \leq C_{N_0}, \|b_\varepsilon\|_{W^{1,\infty}(0,T;H^2(\omega))} \leq C_{N_0}, \|\overline{\mathbf{v}_\varepsilon^\lambda}\|_{L^2(0,T;H^1(\mathcal{C}_M))} \leq C_\lambda,$$

where C denotes and will denote in all that follows a strictly positive constant that depends only on the data and not on ε and N_0, and C_{N_0} (resp., C_λ) denotes and will denote a strictly positive constant that depends on the data and not on ε but may depend on N_0 (resp., λ). The integer N_0 (resp., the real λ) will be fixed later on and will be large enough (resp., small enough). Then for well chosen σ, $(\ _\varepsilon, b_\varepsilon)$ are admissible tests functions. Indeed, $\ _\varepsilon$ is divergence-free thanks to the definitions of the lifting operator $\mathcal{R}_\alpha$, the extension operator $\mathbf{v} \mapsto \overline{\mathbf{v}}$, the operator $\mathbf{v} \mapsto \mathbf{v}_\sigma$, and the regularization $\mathbf{v} \mapsto \mathbf{v}^\lambda$. Moreover $\ _\varepsilon$ belongs to $H^1(0,T;H^1(\mathcal{C}_M))$. The function b_ε belongs to $H^1(0,T;H_0^2(\omega))$. Both of them are bounded in the previous spaces independently of ε but not of N_0 and λ. Moreover since

$$\|\eta_\varepsilon\|_{L^\infty(0,T;H_0^2(\omega)) \cap W^{1,\infty}(0,T;L^2(\omega))} \leq C,$$

and remembering the imbedding (13), we have

$$\|\eta_\varepsilon - \eta_\varepsilon^-\|_{C^0([0,T]\times\overline{\omega})} \leq C h^\mu, \quad 0 < \mu < \frac{1}{2}.$$

Thus if σ is such that $\sigma \geq 1 + \frac{2C}{\alpha} h^\mu$, we have

$$_\varepsilon(t,x,y,1+\eta_\varepsilon(t,x,y)) = \left(0, \int_{t-h}^t \partial_t \eta_\varepsilon^{N_0}(s,x,y)ds\right)^T \text{ on } \omega.$$

In what follows we choose $\sigma = 1 + \frac{2C}{\alpha} h^\mu$, $0 < \mu < \frac{1}{2}$. Hence, with the choice of test

functions that we made, (33) is written:

$$
\begin{aligned}
(36)\quad & -\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)} \mathbf{u}_\varepsilon\cdot((\overline{\mathbf{v}_\varepsilon^\lambda})_\sigma-(\overline{\mathbf{v}_\varepsilon^\lambda})_\sigma^-)\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}\mathbf{u}_\varepsilon\cdot(\overline{\mathcal{R}_\alpha(\partial_t\eta_\varepsilon^{N_0})}-\overline{\mathcal{R}_\alpha(\partial_t\eta_\varepsilon^{N_0})}^-)\\
&\qquad+\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}(\mathbf{u}_\varepsilon\cdot\nabla)\mathbf{u}_\varepsilon\cdot\ {}_\varepsilon+\nu\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}\nabla\mathbf{u}_\varepsilon:\nabla\ {}_\varepsilon\\
&\qquad+\int_{\Omega_{\eta_\varepsilon}(T)}\mathbf{u}_\varepsilon(T)\cdot\ {}_\varepsilon(T)-\int_0^T\int_\omega\partial_t\eta_\varepsilon\partial_t(\eta_\varepsilon^{N_0}-(\eta_\varepsilon^{N_0})^-)\\
&\quad-\int_0^T\int_\omega(\partial_t\eta_\varepsilon)^2(\eta_\varepsilon^{N_0}-(\eta_\varepsilon^{N_0})^-)+\int_0^T\int_\omega\Delta\eta_\varepsilon\Delta(\eta_\varepsilon^{N_0}-(\eta_\varepsilon^{N_0})^-)\\
&+\varepsilon\int_0^T\int_\omega\Delta\partial_t\eta_\varepsilon\Delta(\eta_\varepsilon^{N_0}-(\eta_\varepsilon^{N_0})^-)+\int_\omega\partial_t\eta_\varepsilon(T)(\eta_\varepsilon^{N_0}(T)-\eta_\varepsilon^{N_0}(T-h))\\
&\qquad=\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}\mathbf{f}\cdot\ {}_\varepsilon+\int_0^T\int_\omega g(\eta_\varepsilon^{N_0}-(\eta_\varepsilon^{N_0})^-).
\end{aligned}
$$

The two first terms can be written:

(37)

$$
\begin{aligned}
&-\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}\mathbf{u}_\varepsilon\cdot((\overline{\mathbf{v}_\varepsilon^\lambda})_\sigma-(\overline{\mathbf{v}_\varepsilon^\lambda})_\sigma^-)-\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}\mathbf{u}_\varepsilon\cdot\Big((\overline{\mathcal{R}_\alpha(\partial_t\eta_\varepsilon^{N_0})}-\overline{\mathcal{R}_\alpha(\partial_t\eta_\varepsilon^{N_0})}^-\Big)\\
&=-\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}\mathbf{u}_\varepsilon\cdot(\overline{\mathbf{u}}_\varepsilon-\overline{\mathbf{u}}_\varepsilon^-)-\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}\mathbf{u}_\varepsilon\cdot(\overline{\mathcal{R}_\alpha(\partial_t\eta_\varepsilon^{hf,N_0})}-\overline{\mathcal{R}_\alpha(\partial_t\eta_\varepsilon^{hf,N_0})}^-)\\
&\qquad-\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}\mathbf{u}_\varepsilon\cdot(((\overline{\mathbf{v}_\varepsilon^\lambda})_\sigma-\overline{\mathbf{v}_\varepsilon^\lambda})-((\overline{\mathbf{v}_\varepsilon^\lambda})_\sigma^--(\overline{\mathbf{v}_\varepsilon^\lambda})^-))\\
&\qquad-\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}\mathbf{u}_\varepsilon\cdot(((\overline{\mathbf{v}_\varepsilon^\lambda})-\overline{\mathbf{v}}_\varepsilon)-((\overline{\mathbf{v}_\varepsilon^\lambda})^--(\overline{\mathbf{v}}_\varepsilon)^-)).
\end{aligned}
$$

We set $I_1=\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}\mathbf{u}_\varepsilon\cdot(\overline{\mathbf{u}}_\varepsilon-\overline{\mathbf{u}}_\varepsilon^-)$.

$$
\begin{aligned}
I_1&=-\frac12\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}|\mathbf{u}_\varepsilon|^2+\frac12\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}|\overline{\mathbf{u}}_\varepsilon^-|^2-\frac12\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}|\overline{\mathbf{u}}_\varepsilon-\overline{\mathbf{u}}_\varepsilon^-|^2\\
&=-\frac12\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}|\mathbf{u}_\varepsilon|^2+\frac12\int_0^{T-h}\int_{\Omega_{\eta_\varepsilon}(t+h)}|\overline{\mathbf{u}}_\varepsilon|^2-\frac12\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}|\overline{\mathbf{u}}_\varepsilon-\overline{\mathbf{u}}_\varepsilon^-|^2\\
&=\frac12\int_0^{T-h}\int_{\mathcal{C}_M}(\rho_\varepsilon^+-\rho_\varepsilon)|\overline{\mathbf{u}}_\varepsilon|^2-\frac12\int_{T-h}^T\int_{\Omega_{\eta_\varepsilon}(t)}|\mathbf{u}_\varepsilon|^2-\frac12\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}|\overline{\mathbf{u}}_\varepsilon-\overline{\mathbf{u}}_\varepsilon^-|^2.
\end{aligned}
$$

The same argument we use to prove (32) leads to

$$\int_0^T\int_{\mathcal{C}_M}|\rho_\varepsilon^+-\rho_\varepsilon||\overline{\mathbf{u}}_\varepsilon|^2\le Ch^{\frac13}.$$

This yields

$$I_1\le Ch^{\frac13}-\frac12\int_0^T\int_{\Omega_{\eta_\varepsilon}(t)}|\overline{\mathbf{u}}_\varepsilon-\overline{\mathbf{u}}_\varepsilon^-|^2.\tag{38}$$

For the second term of (37) $\int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} \mathbf{u}_\varepsilon \cdot (\overline{\mathcal{R}_\alpha(\partial_t \eta_\varepsilon^{hf,N_0})} - \overline{\mathcal{R}_\alpha(\partial_t \eta_\varepsilon^{hf,N_0})^-})$ we have, by taking into account the energy estimate (9),

$$\begin{aligned}
&\left| \int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} \mathbf{u}_\varepsilon \cdot (\overline{\mathcal{R}_\alpha(\partial_t \eta_\varepsilon^{hf,N_0})} - \overline{\mathcal{R}_\alpha(\partial_t \eta_\varepsilon^{hf,N_0})^-}) \right| \\
&\qquad \le C \|\mathbf{u}_\varepsilon\|_{L^2(0,T;L^2(\Omega_{\eta_\varepsilon}(t)))} \|\overline{\mathcal{R}_\alpha(\partial_t \eta_\varepsilon^{hf,N_0})}\|_{L^2(0,T;L^2(\mathcal{C}_M))} \\
&\qquad \le C(\|\mathcal{R}_\alpha(\partial_t \eta_\varepsilon^{hf,N_0})\|_{L^2(0,T;L^2(\mathcal{C}_\alpha))} + \|\partial_t \eta_\varepsilon^{hf,N_0}\|_{L^2(0,T;L^2(\omega))}).
\end{aligned}$$

Thanks to the properties satisfied by $\mathcal{R}_\alpha$ and in particular (17) for $s = 0$ we have

$$\|\mathcal{R}_\alpha(\partial_t \eta_\varepsilon^{hf,N_0})\|_{L^2(0,T;L^2(\mathcal{C}_\alpha))} \le C \|\partial_t \eta_\varepsilon^{hf,N_0}\|_{L^2(0,T;L^2(\omega))}, \tag{39}$$

and thus we obtain

$$\left| \int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} \mathbf{u}_\varepsilon \cdot (\overline{\mathcal{R}_\alpha(\partial_t \eta_\varepsilon^{hf,N_0})} - \overline{\mathcal{R}_\alpha(\partial_t \eta_\varepsilon^{hf,N_0})^-}) \right| \le C \|\partial_t \eta_\varepsilon^{hf,N_0}\|_{L^2(0,T;L^2(\omega))}.$$

The definition of $\partial_t \eta_\varepsilon^{hf,N_0}$ and the fact that $\partial_t \eta_\varepsilon$ is bounded in $L^2(0,T;H^s(\omega))$, $s < 1/2$ independently of ε, imply, remembering (34), that

$$\left| \int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} \mathbf{u}_\varepsilon \cdot (\overline{\mathcal{R}_\alpha(\partial_t \eta_\varepsilon^{hf,N_0})} - \overline{\mathcal{R}_\alpha(\partial_t \eta_\varepsilon^{hf,N_0})^-}) \right| \le C \|\partial_t \eta_\varepsilon^{hf,N_0}\|_{L^2(0,T;L^2(\omega))} \le C \lambda_{N_0}^{-\frac{s}{2}}. \tag{40}$$

We have also for the third term of (37):

$$\begin{aligned}
&\left| \int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} \mathbf{u}_\varepsilon \cdot (((\overline{\mathbf{v}_\varepsilon^\lambda})_\sigma - \overline{\mathbf{v}_\varepsilon^\lambda}) - ((\overline{\mathbf{v}_\varepsilon^\lambda})_\sigma^- - (\overline{\mathbf{v}_\varepsilon^\lambda})^-) \right| \\
&\qquad \le 2 \|\mathbf{u}_\varepsilon\|_{L^2(0,T;L^2(\Omega_{\eta_\varepsilon}(t)))} \|(\overline{\mathbf{v}_\varepsilon^\lambda})_\sigma - \overline{\mathbf{v}_\varepsilon^\lambda})\|_{L^2(0,T;L^2(\Omega_{\eta_\varepsilon}(t)))} \\
&\qquad\qquad \le (\sigma - 1) \|\overline{\mathbf{v}_\varepsilon^\lambda}\|_{L^2(0,T;H^1(\Omega_{\eta_\varepsilon}(t)))} \\
&\qquad\qquad\qquad \le C_\lambda (\sigma - 1) \le C_\lambda h^\mu, \quad 0 < \mu < \frac{1}{2}.
\end{aligned} \tag{41}$$

Finally, due to the properties of the space regularization $\mathbf{v} \mapsto \mathbf{v}^\lambda$, the last term of the right-hand side of (37) goes to zero, uniformly in ε, as λ goes to zero. That is written: $\forall \beta > 0$ there exists $\lambda_0 > 0$ such that $\forall \lambda < \lambda_0$

$$\left| \int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} \mathbf{u}_\varepsilon \cdot (((\overline{\mathbf{v}_\varepsilon^\lambda}) - \overline{\mathbf{v}}_\varepsilon) - ((\overline{\mathbf{v}_\varepsilon^\lambda})^- - (\overline{\mathbf{v}}_\varepsilon)^-)) \right| \le C\beta \qquad \forall \varepsilon. \tag{42}$$

Now we take care of the convective term

$$I_2 = \int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} (\mathbf{u}_\varepsilon \cdot \nabla) \mathbf{u}_\varepsilon \cdot \left(\int_{t-h}^t \quad _\varepsilon \right),$$

with $\quad_\varepsilon = (\overline{\mathbf{v}_\varepsilon^\lambda})_\sigma + \overline{\mathcal{R}_\alpha(\partial_t \eta_\varepsilon^{N_0})}$. We have

$$
\begin{aligned}
|I_2| &\le \frac{1}{2}\int_0^T \|\mathbf{u}_\varepsilon\|_{L^4(\Omega_{\eta_\varepsilon}(t))}\|\nabla \mathbf{u}_\varepsilon\|_{L^2(\Omega_{\eta_\varepsilon}(t))}\int_{t-h}^t \|\quad_\varepsilon\|_{L^4(\Omega_{\eta_\varepsilon}(t))}\\
&\le \frac{\sqrt{h}}{2}\int_0^T \|\mathbf{u}_\varepsilon\|_{L^4(\Omega_{\eta_\varepsilon}(t))}\|\nabla \mathbf{u}_\varepsilon\|_{L^2(\Omega_{\eta_\varepsilon}(t))}\left(\int_{t-h}^t \|\quad_\varepsilon\|^2_{L^4(\Omega_{\eta_\varepsilon}(t))}\right)^{\frac{1}{2}} \qquad (43)\\
&\le C_{N_0,\lambda}\sqrt{h}.
\end{aligned}
$$

The next term to consider is $I_3 = \nu\int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} \nabla \mathbf{u}_\varepsilon : \nabla(\int_{t-h}^t \quad_\varepsilon)$.

$$
\begin{aligned}
|I_3| &\le \nu\int_0^T \|\nabla \mathbf{u}_\varepsilon\|_{L^2(\Omega_{\eta_\varepsilon}(t))}\int_{t-h}^t \|\nabla \quad_\varepsilon\|_{L^2(\Omega_{\eta_\varepsilon}(t))}\\
&\le \nu\sqrt{h}\int_0^T \|\nabla \mathbf{u}_\varepsilon\|_{L^2(\Omega_{\eta_\varepsilon}(t))}\left(\int_{t-h}^t \|\nabla \quad_\varepsilon\|^2_{L^2(\Omega_{\eta_\varepsilon}(t))}\right)^{\frac{1}{2}} \qquad (44)\\
&\le C_{N_0,\lambda}\sqrt{h}.
\end{aligned}
$$

The term $I_4 = \int_{\Omega_{\eta_\varepsilon}(T)} \mathbf{u}_\varepsilon(T)\cdot(\int_{T-h}^T \quad_\varepsilon)$ can be estimated as follows:

$$
\begin{aligned}
|I_4| &\le \|\mathbf{u}_\varepsilon(T)\|_{L^2(\Omega_{\eta_\varepsilon}(T))}\int_{T-h}^T \|\quad_\varepsilon\|_{L^2(\Omega_{\eta_\varepsilon}(T))}\\
&\le \sqrt{h}\|\mathbf{u}_\varepsilon(T)\|_{L^2(\Omega_{\eta_\varepsilon}(T))}\left(\int_{T-h}^T \|\quad_\varepsilon\|^2_{L^2(\Omega_{\eta_\varepsilon}(T))}\right)^{\frac{1}{2}} \qquad (45)\\
&\le C\sqrt{h}.
\end{aligned}
$$

We set $I_5 = -\int_0^T \int_\omega \partial_t\eta_\varepsilon \partial_t(\eta_\varepsilon^{N_0} - (\eta_\varepsilon^{N_0})^-)$.

We have thanks to the definition of $\eta_\varepsilon^{N_0}$

$$
\begin{aligned}
I_5 &= -\frac{1}{2}\int_0^T\int_\omega (\partial_t\eta_\varepsilon^{N_0})^2 + \frac{1}{2}\int_0^T\int_\omega ((\partial_t\eta_\varepsilon^{N_0})^-)^2 - \frac{1}{2}\int_0^T\int_\omega (\partial_t\eta_\varepsilon^{N_0} - (\partial_t\eta_\varepsilon^{N_0})^-)^2 \qquad (46)\\
&= -\frac{1}{2}\int_{T-h}^T\int_\omega (\partial_t\eta_\varepsilon^{N_0})^2 - \frac{1}{2}\int_0^T\int_\omega (\partial_t\eta_\varepsilon^{N_0} - (\partial_t\eta_\varepsilon^{N_0})^-)^2\\
&\le -\frac{1}{2}\int_0^T\int_\omega (\partial_t\eta_\varepsilon^{N_0} - (\partial_t\eta_\varepsilon^{N_0})^-)^2.
\end{aligned}
$$

For the next term we have

$$
\begin{aligned}
|I_6| &= \left|\frac{1}{2}\int_0^T\int_\omega (\partial_t\eta_\varepsilon^{N_0})^2(\eta_\varepsilon^{N_0} - (\eta_\varepsilon^{N_0})^-)\right|\\
&\le \frac{1}{2}\int_0^T \|\partial_t\eta_\varepsilon^{N_0}\|^2_{L^3(\omega)}\|\eta_\varepsilon^{N_0} - (\eta_\varepsilon^{N_0})^-\|_{L^3(\omega)},
\end{aligned}
$$

but, taking into account the continuous imbedding of $H^s(\omega), 0 \le s < 1/2$, in $L^3(\omega)$ and the fact that $\partial_t\eta_\varepsilon^{N_0}$ is bounded uniformly in ε in $L^2(0,T,H^s(\omega))\ \forall 0 \le s < 1/2$,

$$
\|\eta_\varepsilon^{N_0} - (\eta_\varepsilon^{N_0})^-\|_{L^3(\omega)} \le \int_{t-h}^t \|\partial_t\eta_\varepsilon^{N_0}\|_{L^3(\omega)} \le C\sqrt{h}.
$$

Consequently

$$|I_6| \leq C\sqrt{h}. \tag{47}$$

The next term to consider is $I_7 = \int_0^T \int_\omega \Delta\eta_\varepsilon^{N_0} \Delta(\eta_\varepsilon^{N_0} - (\eta_\varepsilon^{N_0})^-)$. It can be estimated as follows:

$$\begin{aligned} |I_7| &\leq \int_0^T \|\Delta\eta_\varepsilon^{N_0}\|_{L^2(\omega)} \int_{t-h}^t \|\Delta\partial_t\eta_\varepsilon^{N_0}\|_{L^2(\omega)} \\ &\leq \sqrt{h} \int_0^T \|\Delta\eta_\varepsilon^{N_0}\|_{L^2(\omega)} \left(\int_{t-h}^t \|\Delta\partial_t\eta_\varepsilon^{N_0}\|_{L^2(\omega)}^2 \right)^{\frac{1}{2}} \\ &\leq C_{N_0}\sqrt{h}. \end{aligned} \tag{48}$$

The additional viscous term gives for $\varepsilon \leq 1$:

$$\begin{aligned} |I_8| &= \varepsilon \left| \int_0^T \int_\omega \Delta\partial_t\eta_\varepsilon^{N_0} \Delta(\eta_\varepsilon^{N_0} - (\eta_\varepsilon^{N_0})^-) \right| \\ &\leq \int_0^T \|\Delta\partial_t\eta_\varepsilon^{N_0}\|_{L^2(\omega)} \int_{t-h}^t \|\Delta\partial_t\eta_\varepsilon^{N_0}\|_{L^2(\omega)} \\ &\leq \sqrt{h} \int_0^T \|\Delta\partial_t\eta_\varepsilon^{N_0}\|_{L^2(\omega)} \left(\int_{t-h}^t \|\Delta\partial_t\eta_\varepsilon^{N_0}\|_{L^2(\omega)}^2 \right)^{\frac{1}{2}} \\ &\leq C_{N_0}\sqrt{h}. \end{aligned} \tag{49}$$

We set $I_9 = \int_\omega \partial_t\eta_\varepsilon^{N_0}(T)(\eta_\varepsilon(T) - \eta_\varepsilon^{N_0}(T-h))$.

$$\begin{aligned} |I_9| &= \|\partial_t\eta_\varepsilon(T)\|_{L^2(\omega)} \int_{T-h}^T \|\partial_t\eta_\varepsilon^{N_0}\|_{L^2(\omega)} \\ &\leq Ch. \end{aligned} \tag{50}$$

Next $I_{10} = \int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} \mathbf{f} \cdot (\int_{t-h}^t \quad _\varepsilon)$ and $I_{11} = \int_0^T \int_\omega g(\eta_\varepsilon^{N_0} - (\eta_\varepsilon^{N_0})^-)$ can be estimated respectively by $C\sqrt{h}$ and Ch.

These last two estimates and estimates (38)–(50) yield, for all $\beta > 0$, for λ small enough

$$\int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} |\mathbf{u}_\varepsilon - \overline{\mathbf{u}}_\varepsilon^-|^2 + \int_0^T \int_\omega (\partial_t\eta_\varepsilon^{N_0} - (\partial_t\eta_\varepsilon^{N_0})^-)^2 \leq C_{N_0,\lambda} h^{\frac{1}{3}} + C\lambda_{N_0}^{-\frac{s}{2}} + C\beta \ \forall \varepsilon < \varepsilon_0,$$

with $s < \frac{1}{2}$. Moreover,

$$\int_0^T \int_\omega (\partial_t\eta_\varepsilon^{hf,N_0} - (\partial_t\eta_\varepsilon^{hf,N_0})^-)^2 \leq C\lambda_{N_0}^{-\frac{s}{2}}.$$

Then for all $\beta > 0$, if λ is chosen small enough, we have

$$\int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} |\mathbf{u}_\varepsilon - \overline{\mathbf{u}}_\varepsilon^-|^2 + \int_0^T \int_\omega (\partial_t\eta_\varepsilon - (\partial_t\eta_\varepsilon)^-)^2 \leq C_{N_0,\lambda} h^{\frac{1}{3}} + C\lambda_{N_0}^{-\frac{s}{2}} + C\beta \quad \forall \varepsilon < \varepsilon_0.$$

Thus, by choosing N_0 large enough and λ small enough, we obtain that $\exists h_0 > 0$ such that $\forall h \leq h_0$

$$\int_0^T \int_{\Omega_{\eta_\varepsilon}(t)} |\mathbf{u}_\varepsilon - \overline{\mathbf{u}}_\varepsilon^-|^2 + \int_0^T \int_\omega (\partial_t \eta_\varepsilon - (\partial_t \eta_\varepsilon)^-)^2 \leq C\beta \quad \forall \varepsilon < \varepsilon_0.$$

This proves Lemma 10. □

Thanks to Lemma 9, we obtain that $\partial_t \eta_\varepsilon$ is compact in $L^2(0,T;L^2(\omega))$ and that $\overline{\mathbf{u}}_\varepsilon$ is compact in $L^2(0,T;L^2(\mathcal{C}_M))$.

We now want to verify the convergences announced in Proposition 1 and to verify that the equality between the structure velocity and the fluid velocity at the interface holds in the limit.

Let $T > 0$ such that $\inf_\varepsilon \min_{[0,T]\times\overline{\omega}}(1+\eta_\varepsilon) \geq \alpha > 0$. We will denote any subsequence of $(\eta_\varepsilon, \overline{\mathbf{u}}_\varepsilon)$ by $(\eta_\varepsilon, \overline{\mathbf{u}}_\varepsilon)$. Thanks to the energy estimate and to the compactness properties that have just been derived, we have, denoting by $(\eta, \underline{\mathbf{u}})$ the limit of a subsequence of $(\eta_\varepsilon, \overline{\mathbf{u}}_\varepsilon)$, the following convergences as ε goes to zero:

$$\begin{array}{llll}
\eta_\varepsilon & \to & \eta & \text{uniformly in} \quad C^0([0,T];C^0(\overline{\omega})), \\
\eta_\varepsilon & \rightharpoonup & \eta & \text{weakly in} \quad L^2(0,T;H_0^2(\omega)), \\
\partial_t \eta_\varepsilon & \to & \partial_t \eta & \text{strongly in} \quad L^2(0,T;L^2(\omega)), \\
\partial_t \eta_\varepsilon & \to & \partial_t \eta & \text{weakly in} \quad L^2(0,T;W^{1-1/p,p}(\omega)) \ \forall\ 1 < p < 2, \\
\partial_t \eta_\varepsilon & \to & \partial_t \eta & \text{weakly in} \quad L^2(0,T;H^s(\omega)) \ \forall\ 0 \leq s < 1/2, \\
\overline{\mathbf{u}}_\varepsilon & \to & \underline{\mathbf{u}} & \text{strongly in} \quad L^2(0,T;L^2(\mathcal{C}_M)), \\
\rho_\varepsilon \mathbf{u}_\varepsilon & \to & \rho\underline{\mathbf{u}} & \text{strongly in} \quad L^2(0,T;L^2(\mathcal{C}_M)).
\end{array}$$

Moreover $\rho_\varepsilon \nabla \mathbf{u}_\varepsilon$ tends to some $\mathbf{z}$ weakly in $L^2(0,T;L^2(\mathcal{C}_M))$ as ε goes to zero. It is easy to verify, since $\eta_\varepsilon \to \eta$ in $C^0([0,T]\times\overline{\omega})$, that $\mathbf{z} = 0$ in $\widehat{\mathcal{C}_M}\backslash\widehat{\Omega}_\eta$ and $\mathbf{z}|_{\widehat{\Omega}_\eta} = \nabla(\underline{\mathbf{u}}|_{\widehat{\Omega}_\eta})$. Thus

$$\rho_\varepsilon \nabla \mathbf{u}_\varepsilon \rightharpoonup \rho \nabla(\underline{\mathbf{u}}|_{\widehat{\Omega}_\eta}) \ \text{ in } \ L^2(0,T;L^2(\mathcal{C}_M)). \tag{51}$$

Note also that $\underline{\mathbf{u}} = (0,0,\partial_t\eta)^T$ in $\widehat{\mathcal{C}_M} \setminus \widehat{\Omega}_\eta$, and thus $\underline{\mathbf{u}} = \overline{\mathbf{u}}$ by setting $\mathbf{u} = \underline{\mathbf{u}}|_{\widehat{\Omega}_\eta}$.

Next we take care of the equality

$$\mathbf{u}_\varepsilon(t,x,y,1+\eta_\varepsilon(t,x,y)) = (0,0,\partial_t\eta_\varepsilon(t,x,y))^T$$

on $(0,T)\times\omega$. The right-hand side converges to $(0,0,\partial_t\eta)^T$ strongly in $L^2(0,T;L^2(\omega))$. The left-hand side is the trace of the function $\mathbf{w}_\varepsilon(t,x,y,z) = \mathbf{u}_\varepsilon(t,x,,y,z(1+\eta_\varepsilon(t,x,y))$ on $z=1$, and $\mathbf{w}_\varepsilon$ converges strongly in $L^2(0,T;L^2(\mathcal{C}_1))$ and weakly in $L^2(0,T;W^{1,p}(\mathcal{C}_1))$ $\forall\ 1 < p < 2$ to $\mathbf{u}(t,x,,y,z(1+\eta(t,x,y))$. Hence by the continuity of the trace mapping on $z=1$, we have, for a.e. t,

$$\mathbf{u}(t,x,y,1+\eta(t,x,y)) = (0,0,\partial_t\eta(t,x,y))^T \text{ on } \omega.$$

This ends the proof of Proposition 1.

4. Passage to the limit—Proof of Theorem 2. Next we pass to the limit in the weak formulation:

$$\begin{aligned}\int_{\Omega_{\eta_\varepsilon}(t)} \mathbf{u}_\varepsilon(t)\cdot\ {}_\varepsilon(t) - \int_0^t\int_{\Omega_{\eta_\varepsilon}(s)} \mathbf{u}_\varepsilon\cdot\partial_t\ {}_\varepsilon + \nu\int_0^t\int_{\Omega_{\eta_\varepsilon}(s)} \nabla\mathbf{u}_\varepsilon : \nabla\ {}_\varepsilon \\ + \int_0^t\int_{\Omega_{\eta_\varepsilon}(s)} (\mathbf{u}_\varepsilon\cdot\nabla)\mathbf{u}_\varepsilon\cdot\ {}_\varepsilon - \int_0^t\int_\omega (\partial_t\eta_\varepsilon)^2 b + \int_\omega \partial_t\eta_\varepsilon(t)\, b(t) \\ - \int_0^t\int_\omega \partial_t\eta_\varepsilon\,\partial_t b + \varepsilon\int_0^t\int_\omega \Delta\partial_t\eta_\varepsilon\,\Delta b + \int_0^t\int_\omega \Delta\eta_\varepsilon\,\Delta b \\ = \int_0^t\int_{\Omega_{\eta_\varepsilon}(t)} \mathbf{f}\cdot\ {}_\varepsilon + \int_0^t\int_\omega g\ b + \int_{\Omega(0)} \mathbf{u}_I\cdot\ {}_\varepsilon(0) + \int_\omega \dot\eta_I b(0)\end{aligned}$$

for a.e. t and for all $({}_\varepsilon, b) \in (V_{\eta_\varepsilon}\cap H^1(\widehat{\Omega}_{\eta_\varepsilon}))\times(L^2(0,T;H_0^2(\omega))\times H^1(0,T;L^2(\omega)))$ such that ${}_\varepsilon(t,x,y,1+\eta_\varepsilon(t,x,y)) = (0,0,b(t,x,y))^T$, $(t,x,y)\in[0,T]\times\omega$.

The fluid test functions should depend on ε. However, it is sufficient to consider a dense family of test functions, and it can be chosen independent of ε and admissible for any ε small enough.

First we consider test functions of the form $({}^0, 0)$ such that ^{0} belongs to $\mathcal{D}(\cup_{t\in[0,T]}\{t\}\times\Omega_\eta(t))$ and $\operatorname{div}\ {}^0 = 0$. These test functions satisfy the property that ${}^0(t,\cdot)\in\mathcal{D}(\Omega_\eta(t))\ \forall t$. For ε small enough, since η_ε converges uniformly to η, ${}^0\in\mathcal{D}(\cup_{t\in[0,T]}\{t\}\times\Omega_{\eta_\varepsilon}(t))$.

The second pair of test functions we consider is $({}^1, b)$, where b belongs to $L^2(0,T;H_0^2(\omega))\cap H^1(0,T;L^2(\omega))$, with $\int_\omega b = 0$ and for a.e. t

$${}^1 = \left|\begin{array}{l}(0,0,b)^T \text{ in } \widehat{\mathcal{C}_M}\setminus\overline{\widehat{C}}_\alpha,\\ \mathcal{R}(0,0,\frac{z}{\alpha}b)^T \text{ in } \widehat{C}_\alpha,\end{array}\right.$$

where $\widehat{C}_\alpha = (0,T)\times\mathcal{C}_\alpha$ and $\mathcal{R}$ is a linear lifting operator from $\{\mathbf{w}\in H^{\frac12}(\partial C_\alpha); \int_{\partial C_\alpha}\mathbf{w}\cdot\mathbf{n} = 0\}$ onto $\{\mathbf{v}\in H^1(C_\alpha); \operatorname{div}(\mathbf{v}) = 0\}$. We have easily that ^{1} belongs to $L^2(0,T;H^1(\mathcal{C}_M))$ and $\operatorname{div}({}^1) = 0$. Moreover since $\min_{[0,T]\times\overline{\omega}}(1+\eta_\varepsilon)\ge\alpha$, ${}^1(t,x,y,1+\eta_\varepsilon(t,x,y)) = (0,0,b(t,x,y))^T$ on $(0,T)\times(\omega)\ \forall\varepsilon$. Furthermore we can choose the linear operator $\mathcal{R}$ such that

$$\left\|\mathcal{R}\left(0,0,\frac{zb}{\alpha}\right)^T\right\|_{L^2(\omega\times(0,\alpha))} \le C\|b\|_{L^2(\omega)}. \tag{52}$$

It can be done by solving a Stokes problem in $\omega\times(0,\alpha)$. Indeed this type of inequality can be obtained thanks to a transposition argument and relies on a $H^2\times H^1$ regularity result for the Stokes problem, which is true here since $\omega\times(0,\alpha)$ is a convex set (see [9] for the regularity result for the Stokes problem). Thus if $\mathcal{R}$ is chosen such that (52) holds, we deduce that, for a.e. $t\in I\subset\subset(0,T)$, and for h small enough

$$\left\|\mathcal{R}\left(0,0,\frac{zb}{\alpha}\right)^T(t) - \mathcal{R}\left(0,0,\frac{zb}{\alpha}\right)^T(t+h)\right\|_{L^2(\omega\times(0,\alpha))} \le C\|b(t)-b(t+h)\|_{L^2(\omega)}.$$

Since $\partial_t b\in L^2(0,T;L^2(\omega))$ this implies that $\partial_t\mathcal{R}(0,0,\frac{zb}{\alpha})^T\in L^2(0,T;L^2(\mathcal{C}_\alpha))$ and that $\partial_t\ {}^1\in L^2(0,T;L^2(\mathcal{C}_M))$. Consequently $({}^1, b)$ is a pair of admissible test functions for all ε.

With both types of test functions, it is easy to pass to the limit in the weak formulation as ε goes to zero. Since the considered family of test functions is dense in the set of functions $(\ \ ,b) \in (V_\eta \cap H^1(\widehat{\Omega}_\eta)) \times (L^2(0,T;H_0^2(\omega)) \times H^1(0,T;L^2(\omega)))$ such that $(t,x,y,1+\eta(t,x,y)) = (0,0,b(t,x,y))^T$, $(t,x,y) \in [0,T] \times \omega$, we obtain the existence of one weak solution on $(0,T)$ of (22) that moreover satisfies the energy estimate (27) by passing to the limit as ε tends to zero in (9).

Eventually, we show that we can extend the solution, as long as we have $\min_{[0,T]\times\overline{\omega}}(1+\eta) > 0$. We do exactly as in [4], but for the sake of completness we reproduce the proof here. We build an increasing sequence of times $(T_k)_{k\geq 1}$ as follows. First we choose a time $T_1 > 0$ such that there exists a weak solution up to T_1, with $m_1 = \min_{[0,T_1]\times\overline{\omega}}(1+\eta) > 0$. Possibly changing slightly T_1, we may moreover assume that $\eta(T_1) \in H_0^2(\omega)$, $\partial_t\eta(T_1) \in L^2(\omega)$, and $\mathbf{u}(T_1) \in L^2(\Omega_\eta(T_1))$ (since this is true for almost each time).

Now let $k \geq 1$, and assume that we have built a solution up to some time T_k, with $m_k = \min_{[0,T_k]\times\overline{\omega}}(1+\eta) > 0$. Our construction allows us to build an extension of our solution on some time interval starting from T_k. Thanks to the energy estimate (27) (see also (9)), we have for $s \geq T_k$ for any $0 < \lambda < \frac{3}{4}$

$$1+\eta(s) \geq 1+\eta(T_k) - (s-T_k)^\lambda C(T_k,s) \geq m_k - (s-T_k)^\lambda C(T_k,s)\,, \tag{53}$$

with

$$C(T_k,s) = \tilde{C}\Big(\|\mathbf{u}(T_k)\|_{L^2(\Omega_{\eta_I})}, \|\eta(T_k)\|_{H_0^2(\omega)}, \|\partial_t\eta(T_k)\|_{L_0^2(\omega)}, \int_{T_k}^s \exp(s-u)(\|\mathbf{f}\|_{L^2(\Omega_\eta(u))}(u) + \|g\|_{L^2(\omega)}(u))du\Big),$$

where $\tilde{C}$ is positive and nondecreasing with respect to its arguments, and $C(T_k,s) \leq C(0,s)$. This a priori estimate shows that if we let

$$\tau_k = \min\{1, (m_k/2C(T_k,T_k+1))^{\frac{1}{\lambda}}\},$$

we can build a solution starting from $\mathbf{u}(T_k)$ and $\eta(T_k)$, $\partial_t\eta(T_k)$ up to the time $T_k+\tau_k$ (this corresponds to choosing $\alpha = m_k/2$ in the construction of the solution). The time T_{k+1} is chosen close to $T_k+\tau_k$ (in $[T_k+\tau_k/2, T_k+\tau_k]$), in order to have also $\eta(T_k) \in H_0^2(\omega)$, $\partial_t\eta(T_{k+1}) \in L^2(\omega)$, and $\mathbf{u}(T_{k+1}) \in L^2(\Omega_\eta(T_{k+1}))$.

If the sequence $(T_k)_{k\geq 1}$ is infinite, we let $T^* = \sup_k T_k$. If $T < +\infty$, it must be that $m = \min_{[0,T^*]\times\overline{\omega}}(1+\eta) = 0$. Otherwise, we have $m_k \geq m$ for all k, and hence $\tau_k \geq \min\{1, (m/2C(0,T^*))^{\frac{1}{\lambda}}\} > 0$. But $T_{k+1} - T_k \geq \tau_k/2$ and goes to zero, a contradiction. This achieves the proof of the theorem.

5. Conclusion. We have proved the existence of at least one weak solution for a three-dimensional fluid-plate interaction problem without any (artificial) viscosity of the structure.

TRANSMISSION EIGENVALUES*

LASSI PÄIVÄRINTA† AND JOHN SYLVESTER‡

Abstract. The scattering of a time-harmonic plane wave in an inhomogeneous medium is modeled by the scattering problem for the Helmholtz equation. A transmission eigenvalue is a wavenumber at which the scattering operator has a nontrivial kernel or cokernel. Because many sampling methods for locating scatterers succeed only at wavenumbers that are not transmission eigenvalues, they have been studied for some time. Nevertheless, the existence of transmission eigenvalues has previously been proved only for radial scatterers. In this paper, we prove existence for scatterers without radial symmetry.

Key words. inverse scattering, Helmholtz equation, inverse problems, transmission eigenvalues

1. Introduction.

The scattering of a time-harmonic plane wave in an inhomogeneous medium is modeled by the scattering problem for the Helmholtz equation. The *total wave* u satisfies the perturbed Helmholtz equation

$$\left(\Delta + k^2(1+m)\right) u = 0 \quad \text{in } \mathbb{R}^n. \tag{1.1}$$

The function $m(x)$ denotes the perturbation of the index of refraction from the constant background medium; i.e., $n^2(x) = 1 + m(x)$. We insist that $-1 < m(x)$ be compactly supported and bounded. The relative (far field) scattering operator, s^+, compares the asymptotics of solutions of the free Helmholtz equation to those of (1.1). Both the linear sampling method and the factorization method use the range of this operator to find the support of the scatterer m. These methods are known to succeed at wavenumbers k for which the range of that operator is dense among all far field patterns (i.e., dense in $L^2(S^{n-1})$). If there exists a bounded domain D that contains the support of $m(x)$, and the wavenumber k is not a *transmission eigenvalue* as defined below, then the range of the scattering operator is dense [5].

DEFINITION 1. *A wavenumber k is called a transmission eigenvalue if there exists a nontrivial pair (v, w) solving*

$$\Delta w + k^2 n^2(x) w = 0 \quad \textit{in} \quad D, \tag{1.2}$$

$$\Delta v + k^2 v = 0 \quad \textit{in} \quad D, \tag{1.3}$$

$$w = v, \ \frac{\partial w}{\partial \nu} = \frac{\partial v}{\partial \nu} \quad \textit{on} \quad \partial D. \tag{1.4}$$

If D is not smooth enough, we replace (1.4) with the condition that $u - v \in H_0^2(D)$. Under the conditions that $m > 0$ or $m < 0$ on its support, it has been shown that the set of *transmission eigenvalues* is at most discrete [4], [12], but existence has

been established only for m, which depends only on the radius [6]. Under certain conditions, knowledge of the transmission eigenvalues uniquely determines a radial scatterer [9], [10]. For nonradial scatterers, transmission eigenvalues have also been used to infer simple properties of the scatterer [3].

Under the hypothesis that the infimum of $|m|$ is large enough, we prove existence of transmission eigenvalues, as well as upper and lower bounds on the first transmission eigenvalue. The existence and upper bounds are new; the lower bounds are results from [7] and [3].

In [7], we showed that the following three conditions were equivalent. Notice that (1.5) differs from (1.3) in that the condition below requires that v solve the free Helmholtz equation in all or $\mathbb{R}^n$ rather than just in D. Such v which can be represented as superpositions of plane waves with L^2 densities are called Herglotz wave-functions.

1. There exists a nontrivial pair (v, w) solving

$$\begin{aligned} \Delta w + k^2 n^2(x) w = 0 \quad &\text{in} \quad D, \\ \Delta v + k^2 v = 0 \quad &\text{in} \quad \mathbb{R}^n, \\ w = v,\ \frac{\partial w}{\partial \nu} = \frac{\partial v}{\partial \nu} \quad &\text{on} \quad \partial D. \end{aligned} \tag{1.5}$$

2. There exists a nontrivial $\mu^0 \in \ker\ s^+$.
3. There exists a nontrivial $\mu^0 \in \text{coker}\ \ s^+$.

In the case that v is a Herglotz wave-function, its asymptotic expansion (its far field) belongs to both the kernel and the cokernel of the far field scattering operator. We will show below that, for scatterers supported in a compact set D, the far field scattering operator has a natural extension, and that *transmission eigenvalues* are exactly the wavenumbers for which this natural extension has a kernel or cokernel.

2. The Helmholtz equation and the scattering operator. The scattering operator relates the solutions of (1.1) to solutions of the free Helmholtz equation in all of $\mathbb{R}^n$:

$$\left(\Delta + k^2\right) u^0 = 0 \quad \text{in } \mathbb{R}^n. \tag{2.1}$$

We refer to solutions of (2.1) with finite B^*-norm, defined by

$$||u^0||_{B^*} = \sup_{R>0} \frac{1}{\sqrt{R}} ||u^0||_{L^2(B_R)},$$

as *incident waves* or *free waves*. An *outgoing wave* is a solution to the Helmholtz equation with a compactly supported source f

$$\left(\Delta + k^2\right) v^+ = f \quad \text{in } \mathbb{R}^n \tag{2.2}$$

that satisfies the Sommerfeld radiation condition

$$\lim_{r\to\infty} r^{\frac{n-1}{2}} \left(\frac{\partial v^+}{\partial r} - ikv^+ \right) = 0 \tag{2.3}$$

or, equivalently (for $k > 0$), a *limiting absorption principle*

$$v^+ = \lim_{\varepsilon \downarrow 0} v_\varepsilon^+, \tag{2.4}$$

where v_ε^+ is the unique solution to (2.2) with $k^2 \in \mathbb{R}$ replaced by $k^2 + i\varepsilon$ (see, e.g., section 4 of [1]). We could also define an outgoing wave as a solution to

$$\left(\Delta + k^2(1+m)\right) w^+ = g \tag{2.5}$$

with a compactly supported g, and satisfying (2.3) or (2.4). Because m is compactly supported, the definition based on (2.5) and that based on (2.2) coincide. That is, an outgoing solution v^+ to (2.2) is also an outgoing solution w^+ to (2.5) with $g = f - mv^+$.

Existence and uniqueness of outgoing solutions to (2.5) were proved by Agmon in weighted L^2 spaces[1] [1]. Theorem 2 below is a special case of results in [2], and parts of Theorems 3 and 4 are special cases of results in [2] and section 14 of [8].

Define B to be the completion of $C_0^\infty(\mathbb{R}^n)$ in the B-norm

$$||f||_B = ||f||_{L^2(|x|\in[0,1])} + \sum_{j=1}^{\infty} \frac{1}{\sqrt{2^j}} ||f||_{L^2(|x|\in[2^j,2^{j+1}])}.$$

THEOREM 2. *For every compactly supported g, there exists a unique outgoing solution to* (2.5)*, with*

$$||w^+||_{B^*} \leq C||g||_B,$$

where the constant C depends on m and k.

Because compactly supported functions are dense in B, the correspondence in Theorem 2 defines a bounded map

$$G_m^+ : B \longrightarrow B^*$$

mapping $g \in B$ to w^+. In the rest of the paper, whenever we refer to waves, we mean subspaces of B^*:

1. B^0 is the subspace of incident waves, i.e., solutions to (2.1).
2. B^m is the subspace of total waves, i.e., solutions to (1.1).
3. B^+ is the subspace of outgoing waves, the range of G_0^+.[2]

Both B^0 and B^m are closed in the B^* topology. One way to see this is to note that B^* convergence implies convergence in the sense of tempered distributions so that any u in the closure of B^0 or B^m must satisfy (2.1) or (1.1), respectively, in the sense of distributions. As Schwartz class functions are dense in B, the equations are satisfied in the B^* sense as well. The plane waves, $e^{ik\Theta\cdot x}$, are not in B^0. We shall note in Theorem 4 below that B^0 consists of the Herglotz wave-functions, solutions to (2.1) which have square integrable far fields. The far fields of the plane waves are Dirac deltas. The subspace B^+ is not closed in the B^* topology. In particular, every function in B^+ is in $H^2_{loc}(\mathbb{R}^n)$ and satisfies the radiation condition (2.3), and every compactly supported function in $H^2_{loc}(\mathbb{R}^n)$ belongs to B^+. Because we have defined B^+ as the range of G_0^+, which is injective, B^+ is a Banach space with norm $||G_0^+ f||_{B^+} := ||f||_B$.

A straightforward consequence of Theorem 2 is the correspondence between incident and total waves.

---

[1] $||f||_{L^2_\delta} = ||(1+|x|^2)^{\frac{\delta}{2}} f||_{L^2}$.

[2] This is also the range of G_m^+ for any bounded compactly supported m.

THEOREM 3. *Every total wave has a unique decomposition into an incident wave plus a scattered wave, and every incident wave has a unique decomposition as a total wave minus a scattered wave:*

$$v^m = v^0 + v^+, \tag{2.6}$$

$$u^0 = u^m - u^+. \tag{2.7}$$

Moreover, the scattering map $\mathcal{S}$, defined as $u^0 \mapsto u^m$, is an isomorphism from B^0 onto B^m.

Proof. We prove the second assertion first. Any u_0 that solves (2.1) also solves

$$\left(\Delta + k^2(1+m)\right) u^0 = k^2 m u^0.$$

Let u^+ be the unique outgoing solution to (2.5) with $g = -k^2 m u^0$. Note that

$$||u^+||_{B^*} \leq C_1 ||g||_B \leq k^2 C_1 ||m u^0||_B \leq k^2 C_2 ||u^0||_{B^*},$$

where both constants depend on an upper bound for m and the size of its support.

Defining $u^m = u^0 + u^+$ and noting that it satisfies (1.1) gives decomposition (2.7) and the estimate

$$||u^m||_{B^*} \leq C_3 ||u^0||_{B^*}. \tag{2.8}$$

If $u^0 = w^m - w^+$ is another such decomposition, then w^+ must also satisfy (2.5) with $g = -k^2 m u^0$, but (2.5) has a unique outgoing solution, so $w^+ = u^+$ and $w^m = u^m$.

Similarly, any v^m solving (1.1) is a solution to

$$\left(\Delta + k^2\right) v^m = -k^2 m v^m.$$

Let v^+ be the unique outgoing solution to (2.2) with $f = -k^2 m u^m$, and set $v^0 = v^m - v^+$. Uniqueness follows as in the paragraph above, as does the estimate

$$||u^0||_{B^*} \leq C_3 ||u^m||_{B^*}. \tag{2.9}$$

The existence and uniqueness of the two decompositions (2.6) and (2.7) along with the estimates (2.8) and (2.9) justify the last statement in the theorem—that the scattering map is an isomorphism. □

In order to see the relationship between the *scattering operator* we have defined above and the scattering operator defined on far fields, we need to discuss asymptotics.

THEOREM 4. *Let $u^0 \in B^0$, $u^+ \in B^+$, and $u^m \in B^m$; then, in spherical coordinates $x = r\Theta$ for large r,*

$$u^0 \sim \mu^0(\Theta) \frac{e^{ikr}}{(ikr)^{\frac{n-1}{2}}} + \mu^0(-\Theta) \frac{e^{-ikr}}{(-ikr)^{\frac{n-1}{2}}}, \tag{2.10}$$

$$u^+ \sim \mu^+(\Theta) \frac{e^{ikr}}{(ikr)^{\frac{n-1}{2}}}, \tag{2.11}$$

$$u^m \sim \left(\mu^m(\Theta) + \gamma(\Theta)\right) \frac{e^{ikr}}{(ikr)^{\frac{n-1}{2}}} + \mu^m(-\Theta) \frac{e^{-ikr}}{(-ikr)^{\frac{n-1}{2}}}. \tag{2.12}$$

Moreover, the mappings

$$b^0 : B^0 \longrightarrow L^2(S^{n-1}),$$
$$b^m : B^m \longrightarrow L^2(S^{n-1})$$

defined by $u^0 \mapsto \mu^0$ *and by* $u^m \mapsto \mu^m$ *are isomorphisms. The mapping*

$$b^+ : B^+ \longrightarrow L^2(S^{n-1})$$

defined by $u^+ \mapsto \mu^+$ *is surjective.*[3] *Every compactly supported function in* $H^2(\mathbb{R}^n)$ *belongs to its kernel and any function in its kernel is compactly supported (Rellich's lemma).*

Sketch of proof. The operator $(b^0)^{-1}$is known as the Herglotz operator. We can start with any $\mu_0 \in L^2(S^{n-1})$ and define

$$u^0 = \mathcal{H}\mu^0 = \int_{S^{n-1}} e^{ik\Theta\cdot x}\mu^0(\Theta)dS_\Theta.$$

Noting that any $u^0 \in B^0$ is the inverse Fourier transform of a distribution supported on the sphere $|\xi|^2 - k^2 = 0$ shows that u^0 must have this form, but it requires an estimate [2] to see that $\mu^0 \in L^2$. A stationary phase calculation shows that $\mathcal{H}\mu^0$ has the asymptotics (2.10) when μ^0 is smooth. Again we refer the reader to [2] for the estimate that $||u||_{B^*} \leq C||\mu^0||_{L^2(S^{n-1})}$.

A similar Fourier transform calculation combined with the limiting absorption principle, or a calculation of the asymptotics of the outgoing Green's function, gives (2.11). Alternatively, we may note that $u^+(x,k) - u^+(x,-k)$ belongs to B^0 and deduce (2.11) from (2.10).[4] The surjectivity of b^+ then follows from the surjectivity of b^0.

Because of the decomposition $u^m = u^0 + u^+$ in Theorem 3, (2.12) follows from (2.10) and (2.11). Rellich's lemma and unique continuation imply that b^0 and b^m are injective, as well as the final statement in the theorem. □

We refer to the large r asymptotics as the *far fields* of the corresponding waves; e.g., the far field of u^0 is μ^0, the far field of u^+ is μ^+, and the far field of u^m is μ^m. We use (2.12) to define the far field (relative scattering) operator

$$s^+ : L^2(S^{n-1}) \longrightarrow L^2(S^{n-1})$$

by

$$\mu^m \;\mapsto\; \gamma. \tag{2.13}$$

The wave scattering operator $\mathcal{S}$ and the far field operator s^+ are closely related.

LEMMA 5. *Let* u^0 *and* w^0 *belong to* B^0*, with far fields* μ^0 *and* ω^0*, respectively. Then*

$$\int_{\mathbb{R}^n} \overline{u^0} m\mathcal{S}w^0 = \frac{-2i}{k^n}\int_{S^{n-1}} \overline{\mu^0}s^+\omega^0.$$

[3]The surjectivity of b^+, b^0, and b^m is perhaps the main reason for replacing the L^2_δ spaces in [1] with the Besov spaces, B and B^*, of [2].

[4]Changing the sign of k reverses the sign of ϵ in the limiting absorption principle and changes the sign of the second term in the Sommerfeld radiation condition, thus specifying the unique *incoming*, rather than the *outgoing*, solution.

Proof.

$$\int_{\mathbb{R}^n} \overline{u^0} k^2 m \mathcal{S} w^0 = \int_{\mathbb{R}^n} \overline{u^0} k^2 m w^m,$$

where $w^m = w^0 + w^+$, as in (2.6),

$$\begin{aligned} &= -\int_{\mathbb{R}^n} \overline{u^0} \left(\Delta + k^2\right) w^m \\ &= -\int_{\mathbb{R}^n} \overline{u^0} \left(\Delta + k^2\right) w^+ \\ &= -\lim_{R\to\infty} \int_{|x|<R} \overline{u^0} \left(\Delta + k^2\right) w^+ \\ &= \lim_{R\to\infty} \int_{|x|=R} \frac{\partial \overline{u^0}}{\partial \nu} w^+ - \overline{u^0} \frac{\partial w^+}{\partial \nu}. \end{aligned} \tag{2.14}$$

Making use of the asymptotics in (2.11) and (2.12) gives

$$= \frac{-2i}{k^{n-2}} \int_{S^{n-1}} \overline{\mu^0} \omega^+, \tag{2.15}$$

where ω^+ denotes the far field of w^+,

$$= \frac{-2i}{k^{n-2}} \int_{S^{n-1}} \overline{\mu^0} s^+ \omega^0. \qquad \square$$

A consequence of Lemma 5 is a natural definition of the relative scattering operator, which does not explicitly use asymptotics.

THEOREM 6. *If we define*

$$\mathcal{S}^+ : B^0 \longrightarrow B^{0*}$$

by

$$w^0 \overset{\mathcal{S}^+}{\longmapsto} \frac{-k^n}{2i} \left\langle m \mathcal{S} w^0, \cdot \right\rangle, \tag{2.16}$$

then

$$s^+ \;=\; \mathcal{H}^* \mathcal{S}^+ \mathcal{H}. \tag{2.17}$$

Proof.

$$\begin{aligned} &\langle \mathcal{H}^* \mathcal{S}^+ \mathcal{H} \omega^0, \overline{\mu^0} \rangle \\ &\qquad = \langle \mathcal{S}^+ \mathcal{H} \omega^0, \overline{\mathcal{H} \mu^0} \rangle \\ &\qquad = \frac{-k^n}{2i} \int_{\mathbb{R}^n} \overline{\mathcal{H} \mu^0} m \mathcal{S} \mathcal{H} \omega^0 \\ &\qquad = \frac{-k^n}{2i} \int_{\mathbb{R}^n} \overline{u^0} m \mathcal{S} w^0 \\ &\qquad = \int_{S^{n-1}} \overline{\mu^0} s^+ \omega^0 \\ &\qquad = \langle s^+ \omega^0, \overline{\mu^0} \rangle. \qquad \square \end{aligned}$$

Remark 7. Because $B^0 \subset L^2_{-\delta}$ for any $\delta > \frac{1}{2}$, any $l \in {B^0}^*$ has a (nonunique) extension to an element of $L^2_\delta = {L^2_{-\delta}}^*$, so elements of ${B^0}^*$ can be represented as functions (and called sources).

3. A generalized scattering operator. We describe an incident wave $\mathcal{H}\alpha$ as illuminating the scatterer m. If we use the far field operator s^+, the illumination must always come from the *sphere at infinity*. Many useful sources of illumination are generated by sources outside the scatterer. The waves generated by such sources are never incident waves, although they can be approximated by incident waves on certain compact sets. Solutions to the transmission eigenvalue problem (1.2)–(1.4) are not incident waves, so they do not have a direct interpretation in terms of the far field scattering operator. They do, however, span exactly the kernel of the scattering operator we will define below.

If $m \in L^\infty$ is supported in a bounded domain D, Theorem 2 tells us that we can find a unique $u^+ \in B^+$ solving

$$\left(\Delta + k^2(1+m)\right) u^+ = k^2 m u^0$$

for any $u^0 \in L^2(D)$. It follows that $u^m = u^0 + u^+ \in L^2(D)$. Thus the scattering operator $\mathcal{S}$ has a natural extension,

$$\mathcal{S}_D : B^0_D \longrightarrow B^m_D,$$

where we use the definitions

$$B^0_D = \left\{ w \in L^2(D) \middle| \left(\Delta + k^2\right) w = 0 \text{ in } D \right\},$$
$$B^m_D = \left\{ w \in L^2(D) \middle| \left(\Delta + k^2(1+m)\right) w = 0 \text{ in } D \right\}.$$

The relative scattering operator $\mathcal{S}^+$ has a similar extension:

$$\mathcal{S}^+_D : B^0_D \longrightarrow {B^0_D}^*,$$
$$w^0 \overset{\mathcal{S}^+_D}{\longmapsto} \frac{k^n}{2i} \left\langle m \mathcal{S}_D w^0, \cdot \right\rangle.$$

The scattering and relative scattering operators $\mathcal{S}_D$ and $\mathcal{S}^+_D$ are extensions of $\mathcal{S}$ and $\mathcal{S}^+$ in the sense that, for $u^0, w^0 \in B^0$, then $\mathcal{S}_D u^0$ is the restriction of $\mathcal{S}u^0$ to D and $\langle \mathcal{S}^+_D u^0, w^0 \rangle = \langle \mathcal{S}^+ u^0, w^0 \rangle$.

4. The interior transmission problem. Let D be a bounded domain and $\operatorname{supp} m \subset D$. We will use the notation

$$P^0 = \left(\Delta + k^2\right),$$
$$P^m = \left(\Delta + k^2(1+m)\right),$$
$$H^k(D) = \left\{ u \in L^2(D) \,\middle|\, D^\alpha u \in L^2(D) \quad \forall\ |\alpha| \le k \right\},$$
$$H^k_0(D) = \text{the completion of } C^\infty_0(D) \text{ in } H^k(D).$$

Definition 8. *We say that a wavenumber k is a D-transmission eigenvalue of $m \in L^\infty(D)$ if any of the equivalent conditions in Theorem 9 below are satisfied.*

Theorem 9. *The following are equivalent:*

1. *There exist nontrivial $u^0 \in B^0_D$ and $u^m \in B^m_D$ with $u^0 - u^m \in H^2_0(D)$.*[5]

[5]This is a restatement of (1.2)–(1.4). The condition that $u^0 \in B^0_D$ is (1.3), $u^m \in B^m_D$ is (1.2), and $u^0 - u^m \in H^2_0(D)$ is (1.4).

2. *There exists nontrivial* $u^m \in B_D^m$ *such that the unique outgoing solution* u^+ *to*

$$P^0 u^+ = -k^2 m u^m \tag{4.1}$$

belongs to $H_0^2(D)$.
3. *There exist nontrivial* $u^m \in B_D^m$ *and some* $v \in H_0^2(D)$ *satisfying* (4.1).
4. *There exists nontrivial* $u^0 \in B_D^0$ *such that the unique outgoing solution* u^+ *to*

$$P^m u^+ = -k^2 m u^0 \tag{4.2}$$

belongs to $H_0^2(D)$.
5. *There exist nontrivial* $u^0 \in B_D^0$ *and some* $v \in H_0^2(D)$ *satisfying* (4.2).
6. *There exists nontrivial* $u^0 \in \ker \mathcal{S}_D^+$.
7. *There exists nontrivial* $u^0 \in \operatorname{coker} \mathcal{S}_D^+$.

Proof. We first show that items 1–5 are equivalent.

Condition 2 obviously implies 3, but any $H_0^2(D)$ solution, v, to (4.1) extended to be zero in $\mathbb{R}^n \setminus D$ is outgoing. Since the outgoing solution to (4.1) is unique, $v = u^+$, so 3 implies 2.

Similarly, 4 obviously implies 5, but uniqueness of the outgoing solution to (4.2) implies that any $H_0^2(D)$ solution to (4.2), extended to be zero outside D, must be u^+, so 5 implies 4.

Because Theorem 3 gives a unique decomposition,

$$u^m = u^0 + u^+, \tag{4.3}$$

the unique outgoing solution to (4.1) is also the unique outgoing solution to (4.2). Thus 4 and 2 are equivalent.

The same decomposition shows that $u^+ = u^m - u^0$, so the left-hand side is in $H_0^2(D)$ if and only if the right-hand side is; hence 1 is equivalent to 2.

The equivalence of items 6 and 2 is based on a calculation. Let u^0 and w_0 belong to B_D^0,

$$\begin{aligned} \langle \overline{w^0}, \mathcal{S}_D^+ u^0 \rangle &= -\frac{k^n}{2i} \left\langle \overline{w^0}, m \mathcal{S}_D u^0 \right\rangle \\ &= -\frac{k^n}{2i} \int_D \overline{w^0} m u^m, \end{aligned} \tag{4.4}$$

where u^m in the line above and u^+ in the line below are those uniquely related to u^0 by (4.3) and Theorem 3,

$$= -\frac{k^{n-2}}{2i} \int_D \overline{w^0} P^0 u^+ \tag{4.5}$$

$$= \frac{k^{n-2}}{2i} \int_{\partial D} \frac{\partial \overline{w^0}}{\partial \nu} u^+ - \overline{w^0} \frac{\partial u^+}{\partial \nu}. \tag{4.6}$$

The right-hand side of (4.6) is clearly zero for every w^0 if $u^+ \in H_0^2(D)$, so 2 implies 6. To see the converse, choose $w^0 = \mathcal{H}\omega^0$ (i.e., $w^0 \in B^0$ with asymptotics as in (2.10)). Every $u^+ \in B^+$ has asymptotics as in (2.11), so we may continue the previous calculation,

$$\begin{aligned} \langle \overline{w^0}, \mathcal{S}_D^+ u^0 \rangle &= \frac{k^{n-2}}{2i} \lim_{R \to \infty} \int_{B_R} \frac{\partial \overline{w^0}}{\partial \nu} u^+ - \overline{w^0} \frac{\partial u^+}{\partial \nu} \\ &= \int_{S^{n-1}} \overline{\omega^0} \mu^+. \end{aligned}$$

We conclude that, if the left-hand side vanishes for every w^0, so does the right-hand side for every ω^0, so $\mu^+ \equiv 0$. Now Rellich's lemma and unique continuation tell us that $u^+ \in H_0^2(D)$, so 6 implies 2.

Verifying the equivalence of items 7 and 2 requires a similar computation,

$$\begin{aligned}\frac{2i}{k^{n-2}}\langle u^0, \mathcal{S}_D^+ w^0\rangle &= -\int_D u^0 k^2 m w^m \\ &= \int_D u^0 P^0 w^m \\ &= \int_{\partial D} \frac{\partial u^0}{\partial \nu} w^m - u^0 \frac{\partial w^m}{\partial \nu} \\ &= \int_{\partial D} \frac{\partial u^0}{\partial \nu} w^m - u^0 \frac{\partial w^m}{\partial \nu} - \int_{\partial D} \frac{\partial u^m}{\partial \nu} w^m - u^m \frac{\partial w^m}{\partial \nu},\end{aligned}$$

because the second integral on the right is always zero. Combining the two terms gives

$$\frac{2i}{k^{n-2}}\langle u^0, \mathcal{S}_D^+ w^0\rangle = -\int_{\partial D} \frac{\partial u^+}{\partial \nu} w^m - u^+ \frac{\partial w^m}{\partial \nu}. \tag{4.7}$$

Now 2 implies that the right-hand side of (4.7) is zero, so the left-hand side is zero for every w^0, which implies 7. If we choose $w^0 \in B^0$ and continue the calculation,

$$= \int_{S^{n-1}} \mu^+ \omega^m. \tag{4.8}$$

Item 7 implies that the integral in (4.8) vanishes for every ω^m, so $\mu^+ \equiv 0$. Rellich's lemma and unique continuation then guarantee that $u^+ \in H_0^2(D)$, which implies item 2. □

Note that if $\operatorname{supp} m \subset \tilde{D} \subset D$, then $\mathcal{S}_{\tilde{D}}$ is an extension of $\mathcal{S}_D$. The smaller we make D, the larger we make B_D^0, the domain of the operator $\mathcal{S}_D$. Therefore, if k is a D-transmission eigenvalue of m, then k is also a $\tilde{D}$-transmission eigenvalue.

5. Existence of transmission eigenvalues. In this section we restrict our attention to the case that $D = \operatorname{supp} m$. We assume further that m is bounded away from zero in D. The theorem below was first proved in [12].

THEOREM 10. *If $|m| > \delta > 0$ in D, then k is a D-transmission eigenvalue if and only if there exists $u^+ \in H_0^2(D)$ satisfying*

$$P^m \frac{1}{m} P^0 u^+ = 0. \tag{5.1}$$

Proof. We show that (5.1) is equivalent to item 2 in Theorem 9. If $u^+ \in H_0^2(D)$ satisfies

$$P^0 u^+ = -k^2 m u^m, \tag{5.2}$$

then

$$\frac{1}{m} P^0 u^+ = -k^2 u^m, \tag{5.3}$$

and

$$P^m \frac{1}{m} P^0 u^+ = 0.$$

To see the reverse implication, suppose that $u^+ \in H_0^2(D)$ satisfies (5.1) (recall that any $u^+ \in H_0^2(D)$ is outgoing), and define u^m so that (5.3) holds. It is a consequence of (5.1) that $u^m \in B_D^m$ so that (5.2) implies (4.1). □

Theorem 10 tells us that k is a D-transmission eigenvalue whenever the operator $P^m \frac{1}{m} P^0$ has a kernel in $H_0^2(D)$. We will investigate the existence of this kernel (5.1) by examining the spectrum of the operator as k^2 changes. We will make use of several equivalent formulas for $P^m \frac{1}{m} P^0$ which we list below. We will let $\tau = k^2$.

$$\begin{aligned} P^m \frac{1}{m} P^0 &= P^0 \frac{1}{m} P^m \\ &= \Delta \frac{1}{m} \Delta + \tau \left(\Delta \frac{1}{m} + \left(1 + \frac{1}{m} \right) \Delta \right) + \tau^2 \left(1 + \frac{1}{m} \right) \\ &= (\Delta + \tau) \frac{1}{m} (\Delta + \tau) + \tau (\Delta + \tau) \\ &= (\Delta + \tau(1+m)) \frac{1}{m} (\Delta + \tau(1+m)) - \tau (\Delta + \tau(1+m)) . \end{aligned} \tag{5.4}$$

The following lemma asserts that $P^m \frac{1}{m} P^0$, with the appropriate domain, defines a semibounded self-adjoint operator on $L^2(D)$.

LEMMA 11. *For $\tau \geq 0$, t_τ, defined by*

$$t_\tau(u) = \int_D \frac{1}{m} |(\Delta + \tau) u|^2 - \tau \int_D |\operatorname{grad} u|^2 + \tau^2 \int_D |u|^2 \tag{5.5}$$

with form domain $H_0^2(D)$, is a densely defined, closed, semibounded quadratic form on $L^2(D)$. T_τ, The unique densely defined self-adjoint operator associated to t_τ, T_τ, is equal to $P^m \frac{1}{m} P^0$ on its domain

$$D(T_\tau) = \left\{ u \in H_0^2(D) \quad \middle| \quad \frac{1}{m}(\Delta + \tau) \in H^2(D) \right\}. \tag{5.6}$$

Proof. We state without proof that $H_0^2(D)$ is dense in $L^2(D)$. To see that t_τ is semibounded, we write

$$\begin{aligned} t_\tau(u) &= \int_D \frac{1}{m} |(\Delta + \tau) u|^2 + \tau \int_D \overline{u}((\Delta + \tau) u) \\ &\geq \frac{1}{\sup(m)} ||(\Delta + \tau) u||^2 - \tau ||(\Delta + \tau) u|| ||u|| \\ &\geq \left(\frac{1}{\sup(m)} - \tau\varepsilon \right) ||(\Delta + \tau) u||^2 - \frac{\tau}{\varepsilon} ||u||^2 \\ &\geq \frac{1}{2\sup(m)} ||(\Delta + \tau) u||^2 - 2\sup(m)\tau^2 ||u||^2 \end{aligned} \tag{5.7}$$

after choosing $\varepsilon = \frac{1}{2\tau \sup(m)}$. We record for later use the consequence of (5.7) that

$$||(\Delta + \tau) u||^2 \leq 2\sup(m) t_\tau(u) + (2\sup(m)\tau)^2 ||u||^2. \tag{5.8}$$

Every densely defined semibounded quadratic form defines a unique self-adjoint operator [11, page 278], T_τ, with domain the set of $u \in H_0^2(D)$ such that there is an $f \in L^2(D)$ with

$$t(v, u) = (v, f)$$

for all $v \in H_0^2(D)$, where $t(v,u)$ is the bilinear form

$$\begin{aligned} t(v,u) &= \int_D (\overline{(\Delta+\tau)\, v} \frac{1}{m} (\Delta+\tau)\, u + \tau \overline{v} (\Delta+\tau)\, u \\ &= \int_D \overline{v} \left((\Delta+\tau) \frac{1}{m} (\Delta+\tau) \right) u + \tau \int_D \overline{v}\, (\Delta+\tau)\, u \\ &= (v, T_\tau u)\,, \end{aligned}$$

where the second and third equalities hold for all $u \in D(T_\tau)$ and illustrate that $T_\tau = P^m \frac{1}{m} P^0$ with $D(T_\tau)$, as asserted in (5.6). □

LEMMA 12. *T_τ has discrete spectrum which depends continuously on τ.*

Proof. Because T_τ is semibounded and $H_0^2(D)$ is compactly embedded in $L^2(D)$, T_τ has a compact resolvent and therefore discrete spectrum. For m's that are not smooth, the domains of T_τ may depend on τ. We give a direct proof of the continuity of the eigenvalues. We shall show below that, for all positive real σ and τ,

$$t_\sigma(u) \le (1 + M|\sigma-\tau|)\, t_\tau(u) + M(\tau^2+\sigma+1)|\sigma-\tau|\ ||u||^2, \tag{5.9}$$

where the constant M depends only on m. We recall the min-max characterization of the eigenvalues of a self-adjoint operator defined by a quadratic form [13, p. 71]

$$\lambda^n = \max_{W \in \mathcal{W}_n} \min_{\substack{u \in W \\ ||u||=1}} q(u), \tag{5.10}$$

where $\mathcal{W}_n$ denotes the codimension n subspaces of the form domain of q. An immediate consequence of (5.10) is that inequalities between quadratic forms imply the same inequalities for their ordered eigenvalues so that (5.9) implies

$$\lambda_\sigma^n \le (1 + M|\sigma-\tau|)\, \lambda_\tau^n + M(\tau^2+\sigma+1)|\sigma-\tau|$$

and, consequently,

$$\lambda_\sigma^n - \lambda_\tau^n \le |\sigma-\tau| M \left(\lambda_\tau^n + (\tau^2+\sigma+1) \right). \tag{5.11}$$

Because we may interchange σ and τ,

$$|\lambda_\sigma^n - \lambda_\tau^n| \le |\sigma-\tau| M \left(\max(\lambda_\tau^n, \lambda_\sigma^n) + 2(\tau^2+\sigma^2+1) \right). \tag{5.12}$$

First fix σ in (5.11), and set $\tau = 0$ to conclude that each λ_σ^n varies only over a compact set when σ varies over a compact set. Thus the maximum, $\max(\lambda_\tau^n, \lambda_\sigma^n)$, is bounded for σ and τ on compact sets, and therefore (5.12) proves continuity of the eigenvalues.

It remains only to prove (5.9). We begin by writing

$$\begin{aligned} t_\sigma(u) - t_\tau(u) &= (\sigma-\tau) \int \left(\overline{u} \frac{1}{m} (\Delta+\tau)\, u + \overline{(\Delta+\tau)\, u} \frac{1}{m} u + \tau^2 |u|^2 \right) \\ &\quad + (\sigma-\tau)^2 \int \left(\overline{u}\, (\Delta+\tau)\, u + \frac{1}{m} |u|^2 \right) \\ &\le |\sigma-\tau|(1+|\sigma-\tau|) M \left(||u||\ ||\, (\Delta+\tau)\, u|| + \tau^2 ||u||^2 \right), \end{aligned}$$

where M depends only on $\frac{1}{m}$. For any $\varepsilon > 0$

$$\le |\sigma-\tau|(1+|\sigma-\tau|) M \left(\varepsilon ||\, (\Delta+\tau)\, u||^2 + \left(\tau^2 + \frac{1}{\varepsilon} \right) ||u||^2 \right).$$

We make use of (5.8) to obtain with a different M

$$\leq |\sigma-\tau|(1+|\sigma-\tau|)M\left(\varepsilon t_\tau(u)+\left((\varepsilon+1)\tau^2+\frac{1}{\varepsilon}\right)||u||^2\right)$$
$$\leq |\sigma-\tau|M\left(t_\tau(u)+(\tau^2+\sigma+1)||u||^2\right)$$

after choosing $\frac{1}{\varepsilon}=1+|\sigma-\tau|$. ∎

LEMMA 13. *If*

$$\operatorname{sign}(m)\inf_{u\in H_0^2(D)}\frac{t_\tau(u)}{||u||^2}>0, \tag{5.13}$$

then τ is not a transmission eigenvalue. If there exists $u\in H_0^2(D)$ such that

$$\operatorname{sign}(m)\frac{t_\tau(u)}{||u||^2}\leq 0, \tag{5.14}$$

then there is a transmission eigenvalue $\tau^*\in[0,\tau]$.

Proof. The hypothesis (5.13) implies that the spectrum of T_τ is strictly positive or strictly negative; hence it has no kernel.

The hypothesis (5.14) implies that $\operatorname{sign}(m)T_\tau$ has at least one nonpositive eigenvalue. But $\operatorname{sign}(m)T_0$ is easily seen to be positive definite, so the lowest eigenvalue, which is a continuous function of τ, must have passed through zero for some $\tau^*\in[0,\tau]$. ∎

We will use a simple modification of Lemma 13 to show the existence of more than one transmission eigenvalue. We define the multiplicity of a transmission eigenvalue τ_* to be the multiplicity of 0 as an eigenvalue of T_{τ_*}.

LEMMA 14. *If there exists a $\tau>0$ and a p-dimensional subspace $V^p\in H_0^2(D)$ such that*

$$\operatorname{sign}(m)\frac{t_\tau(u)}{||u||^2}\leq 0$$

for all $u\in V^p$, then there are p-transmission eigenvalues, counting multiplicity, in $[0,\tau]$.

Proof. The hypothesis guarantees that t_τ has p negative eigenvalues, counting multiplicity. The continuity of the spectrum implies that each of those eigenvalues must pass through zero as τ^* decreases from τ to 0. Each time an eigenvalue passes through 0, the dimension of the negative definite subspace, V^p, decreases by the multiplicity of the zero eigenvalue, so the sum of the multiplicities of the transmission eigenvalues between 0 and τ must be at least p. ∎

We will need a few simple inequalities to prove the theorems to follow. We collect them in the lemma below.

LEMMA 15.

$$\lambda_0(D)=\inf_{u\in H_0^1(D)}\frac{\int_D|\operatorname{grad}u|^2}{\int_D|u|^2}=\inf_{u\in H_0^2(D)}\frac{\int_D|\operatorname{grad}u|^2}{\int_D|u|^2}>0, \tag{5.15}$$

$$\mu_0(D)=\inf_{u\in H_0^2(D)}\frac{\int_D|\Delta u|^2}{\int_D|u|^2}\geq\inf_{u\in H_0^1\cap H^2}\frac{\int_D|\Delta u|^2}{\int_D|u|^2}=\lambda_0(D)^2. \tag{5.16}$$

If $u\in H_0^2(D)$,

$$\lambda_0(D)\leq\frac{\int_D|\operatorname{grad}u|^2}{\int_D|u|^2}\leq\frac{\left(\int_D|\Delta u|^2\right)^{\frac{1}{2}}}{\left(\int_D|u|^2\right)^{\frac{1}{2}}}. \tag{5.17}$$

Proof. The first equality in (5.15) is the Rayleigh–Ritz characterization of the first Dirichlet eigenvalue. The second follows because $H_0^2(D)$ is dense in $H_0^1(D)$. The first equality in (5.16) is the Rayleigh–Ritz characterization of the lowest eigenvalue of the biharmonic operator with Dirichlet boundary conditions, the lowest eigenvalue of the *clamped plate*. The inequality holds because $H_0^2(D) \subset H_0^1(D) \bigcap H^2(D)$, so the first infimum must be larger. The second infimum is exactly the Rayleigh–Ritz characterization for the lowest eigenvalue of the Dirichlet Laplacian squared,[6] which is the square of the first Dirichlet eigenvalue, which proves the final equality in (5.16). The first inequality in (5.17) follows from the meaning of infimum and the second from integration by parts and the Cauchy–Schwarz inequality. ∎

THEOREM 16. *Suppose that $m > -1$ is a constant. If*

$$\tau \leq \min\left(1, \frac{1}{m+1}\right) \lambda_0(D), \tag{5.18}$$

then τ is not a transmission eigenvalue. If

$$\frac{(1+\frac{m}{2})^2}{1+m} \geq \frac{\mu_p}{\lambda_0^2} \geq 1, \tag{5.19}$$

where $\mu_p(D)$ is the $(p+1)$st clamped plate eigenvalue, then there are $p+1$ transmission eigenvalues τ with

$$\tau \leq \left(\frac{m+2}{m+1}\right) \frac{\lambda_0(D)}{2}. \tag{5.20}$$

Proof. It follows from (5.4) that

$$\begin{aligned} mt_\tau(u) &= ||\left(\Delta + \tau(1+m)\right) u||^2 - m\tau \int_D \overline{u}\left(\Delta + \tau(1+m)\right) u \\ &> m\tau\left[||\operatorname{grad} u||^2 - (1+m)\tau||u||^2\right] \\ &\geq m\tau\left[\lambda_0(D) - (1+m)\tau\right]||u||^2, \end{aligned}$$

which shows that, for $0 < m$ and $\tau \leq \frac{\lambda_0(D)}{1+m}$, t_τ is positive definite and therefore that τ is not a transmission eigenvalue. If $m < 0$, we express t_τ as in (5.5),

$$\begin{aligned} mt_\tau(u) &= ||\left(\Delta + \tau\right) u||^2 - m\tau||\operatorname{grad} u||^2 + m\tau^2||u||^2 \\ &\geq (-m)\tau||u||^2(\lambda_0(D) - \tau), \end{aligned}$$

which shows that t_τ is positive definite as long as $\tau < \lambda_0(D)$ and finishes the proof of the assertion that τ satisfying (5.18) is not a transmission eigenvalue.

[6] Functions in the domain of the square of the Dirichlet Laplacian must satisfy a second boundary condition, $\Delta u\big|_{\partial D} = 0$. Analogous to the case of the Neumann Laplacian, this is a free boundary condition which does not appear explicitly in the definition of the form domain and therefore does not appear explicitly in (5.16).

To prove the existence of transmission eigenvalues, we will use Lemma 14. Restricting our attention to the sphere, $||u||^2 = 1$, we may write

$$\begin{aligned} mt_\tau(u) &= (m+1)\tau^2 - 2\left(1+\frac{m}{2}\right)||\operatorname{grad} u||^2\tau + ||\Delta u||^2 \\ &\le (m+1)\tau^2 - 2\left(1+\frac{m}{2}\right)\lambda_0\tau + ||\Delta u||^2. \end{aligned}$$

We choose $\tau = \frac{1+\frac{m}{2}}{1+m}\lambda_0$ to obtain

$$\le -\frac{\left(1+\frac{m}{2}\right)^2}{1+m}\lambda_0^2 + ||\Delta u||^2$$

and restrict u to the eigenspace associated with the lowest $p+1$ clamped plate eigenvalues so that

$$mt_\tau(u) \le -\frac{\left(1+\frac{m}{2}\right)^2}{1+m}\lambda_0^2 + \mu_p.$$

Our hypothesis (5.19) is that this quantity is negative, so the conclusion (5.20) follows from Lemma 14. □

THEOREM 17. *Suppose that $m \in L^\infty(D)$. If*

$$\tau \le \min\left(1, \frac{1}{\sup(m)+1}\right)\lambda_0(D),$$

then τ is not a transmission eigenvalue. If $m > 0$ and

$$\inf(m) \ge 4\frac{\mu_p^{\frac{1}{2}}}{\lambda_0} + \frac{\mu_p}{\lambda_0^2}, \tag{5.21}$$

then there are $p+1$ transmission eigenvalues τ with

$$\tau \le \frac{\lambda_0(D)}{2}\left(\frac{\inf(m) - 2\frac{\mu_p^{\frac{1}{2}}}{\lambda_0}}{\inf(m)+1}\right).$$

Proof. For $m > 0$,

$$\begin{aligned} t_\tau(u) &= \int \frac{1}{m}|\left(\Delta + \tau(1+m)\right)u|^2 - \tau\int \overline{u}\left(\Delta + \tau(1+m)\right)u \\ &\ge \tau||\operatorname{grad} u||^2 - \tau^2\int(1+m)|u|^2 \\ &\ge \tau||u||^2\left(\lambda_0 - \tau(1+\sup m)\right), \end{aligned}$$

which shows that t_τ is positive definite if $\tau < \frac{\lambda_0}{1+\inf m}$ and therefore that τ is not a transmission eigenvalue. For $m < 0$

$$\begin{aligned} -t_\tau(u) &= \int \frac{1}{|m|}|\left(\Delta + \tau\right)u|^2 - \tau\int \overline{u}\left(\Delta + \tau\right)u \\ &> \tau||\operatorname{grad} u||^2 - \tau^2||u||^2 \\ &\ge \tau||u||^2\left(\lambda_0 - \tau\right) \end{aligned}$$

so that $-t_\tau$ is positive definite if $\tau < \lambda_0$, completing the proof of the first assertion.

To prove existence, we write

$$t_\tau(u) = \tau^2 \int \left(1 + \frac{1}{m}\right) |u|^2 - \tau \left(|| \operatorname{grad} u||^2 + \int \frac{1}{m} \left(\overline{u}\Delta u + u\Delta\overline{u}\right)\right) + \int \frac{1}{m} |\Delta u|^2.$$

We restrict our attention to functions u with $||u||^2 = 1$ and write $S = \sup(\frac{1}{m})$ to see that

$$t_\tau(u) \leq \tau^2(1+S) - \tau \left(|| \operatorname{grad} u||^2 - 2S||\Delta u|| \right) + S||\Delta u||^2.$$

Restricting to V^p gives

$$t_\tau(u) \leq \tau^2(1+S) - \tau \left(\lambda_0 - 2S\mu_p^{\frac{1}{2}} \right) + S\mu_p.$$

We minimize the sum of the first two terms by choosing $\tau = \frac{\lambda_0 - 2S\mu_p^{\frac{1}{2}}}{2(1+S)}$ to obtain

$$\leq -\frac{\left(\lambda_0 - 2S\mu_p^{\frac{1}{2}}\right)^2}{4(1+S)} + S\mu_p.$$

If we set $A = \frac{\lambda_0}{\mu_p^{\frac{1}{2}}}$, t_τ restricted to V^p is nonpositive if

$$\begin{aligned} (A-2S)^2 - 4S(1+S) &\geq 0, \\ A^2 - 4(A+1)S &\geq 0, \\ \frac{A^2}{4(A+1)} &\geq S, \end{aligned}$$

which is equivalent to (5.21). ∎

6. Conclusions. Under the hypothesis that the perturbation of the index of refraction is large enough, we have shown the existence of D-transmission eigenvalues, given upper and lower bounds for their locations, and identified the corresponding solutions to the transmission eigenvalue problem with the kernel of a scattering operator.

The upper and lower bounds for the transmission eigenvalues depend on the lowest eigenvalues of the Dirichlet Laplacian and the Dirichlet bi-Laplacian (the *clamped plate* operator). These bounds show that the lowest transmission eigenvalue increases as the L^∞-norm of m, or the size of its support, decreases. All of our bounds depend on D only through these eigenvalues and on m only through its infimum or supremum. Thus our estimates for the transmission eigenvalues, k^2, scale with dilations just like the Dirichlet eigenvalues, as the reciprocal of the area of D.

In the Born or weak scattering approximation, there are no transmission eigenvalues [7] when m is strictly positive or strictly negative. Our results are consistent with this, but we do not know if there is a threshold below which there are no transmission eigenvalues, or if the lowest transmission eigenvalue simply goes to infinity as m decreases to zero.[7]

In the radial case, there are infinitely many transmission eigenvalues, so it is reasonable to expect the same result here, but we have no results in this direction.

In summary, there are many questions remaining, some of which may be accessible by a further analysis of the quadratic forms of the operators introduced here. Because

[7] See [3] for an inequality relating the lowest transmission eigenvalue (if it exists) to the supremum of m and the diameter of D.

array imaging techniques are making the scattering operator, and hence its kernel, possible to measure, these questions are becoming increasingly relevant.

PRESSURELESS EULER/EULER–POISSON SYSTEMS VIA ADHESION DYNAMICS AND SCALAR CONSERVATION LAWS*

TRUYEN NGUYEN† AND ADRIAN TUDORASCU‡

Abstract. The "sticky particles" model at the discrete level is employed to obtain global solutions for a class of systems of conservation laws among which lie the pressureless Euler and the pressureless attractive/repulsive Euler–Poisson system with zero background charge. We consider the case of finite, nonnegative initial Borel measures with finite second-order moment, along with continuous initial velocities of at most quadratic growth and finite energy. We prove the time regularity of the solution for the pressureless Euler system and obtain that the velocity satisfies the Oleinik entropy condition, which leads to a partial result on uniqueness. Our approach is motivated by earlier work of Brenier and Grenier, who showed that one-dimensional conservation laws with special initial conditions and fluxes are appropriate for studying the pressureless Euler system.

Key words. pressureless Euler, Euler–Poisson system, sticky particles, scalar conservation laws, Wasserstein distance, adhesion dynamics

1. Introduction.

Let $\alpha,\ \beta \in \mathbb{R}$ and consider the system

$$\begin{cases} \partial_t \rho + \partial_x(\rho v) = 0, \\ \partial_t(\rho v) + \partial_x(\rho v^2) = \rho(\alpha \partial_x \Phi + \beta) \quad \text{in } \mathbb{R} \times (0,T), \\ \partial_{xx}^2 \Phi = \rho. \end{cases} \tag{1}$$

If $\alpha = \beta = 0$, then (1) describes the pressureless Euler system in spatial dimension one. The most commonly known form of the pressureless, attractive/repulsive Euler–Poisson system with zero background charge is also obtained from (1) by taking $\alpha = \pm 1$ and $\beta = 0$. In this paper, we are concerned with global existence of solutions for the initial value problem. Unlike the Euler with pressure case, the natural environment for the evolution is the space of nonnegative Borel measures on the real line. We consider the case of finite total mass, which we normalize to unity. The pressureless Euler ($\alpha = \beta = 0$) problem was studied using different techniques in [5], [6], [7], [9], [23], [15], [16], [17], [18], [20]. We point out that in these papers, generally, the velocity is taken to be at least bounded on the support of the initial measure. It appears that [23] and [20] are the only references (to our knowledge) which allow for unbounded velocities. Also, [23] is remarkable for dealing with the gravitational term as well ($\alpha = -1,\ \beta = 0$). In spite of that, the serious limitation of [23] is the assumptions that the initial velocity be sublinear growth and the initial mass distribution ρ_0 be either discrete or absolutely continuous with respect to the Lebesgue measure. Our main contribution is proving existence of global solutions for (1) if ρ_0 is just in $\mathcal{P}_2(\mathbb{R})$

and v_0 is continuous of at most quadratic growth and finite energy. As a consequence of an important result from [13], we also manage to show that the solution we obtain for Euler pressureless satisfies the Oleinik entropy condition which was conjectured in [7] and [23]. Note that similar constraints to ours on ρ_0 and v_0 were anticipated by Shnirelman [20] for the pressureless Euler system. However, our approach is more general than that of Shnirelman which cannot easily accommodate the α and β terms on the right-hand side of the momentum equation. The solutions constructed by Shnirelman were expressed in the form of a variational problem, which was shown in [3] to be equivalent to the variational principle considered in [23].

During the last decade, significant progress has been achieved in the study of partial differential equations in the context of optimal mass transportation. Much of the work on parabolic, dissipative equations was synthesized and placed in a very general setting in [2]. Much more recent and much less explored is the study of Hamiltonian systems in this context [1], [14]. The connection with the pressureless Euler system in arbitrary dimension was discovered by Benamou and Brenier [4], who showed that this system describes the geodesics in the Wasserstein space $\mathcal{P}_2(\mathbb{R})$. By definition, $\mathcal{P}_p(\mathbb{R})$ is the set of all Borel probabilities on $\mathbb{R}$ with finite p-order moment. The set $\mathcal{P}_2(\mathbb{R})$ is endowed with the quadratic Wasserstein metric defined by

$$W_2^2(\mu,\nu) := \min_{\gamma} \int_{\mathbb{R}^2} |x-y|^2 d\gamma(x,y),$$

where the infimum is taken among all probabilities γ on the product space $\mathbb{R}^2$ with marginals $\mu,\ \nu$. The theory of absolutely continuous curves in $\mathcal{P}_2(\mathbb{R})$ [2] asserts the existence of velocities satisfying the conservation of mass equation in (1), regarded as a continuity equation. The left-hand side of the momentum equation can also be interpreted as the acceleration along the curve. We shall discuss these interesting connections at the end of this paper. A different version of the pressureless Euler–Poisson system was analyzed in [13] in the context of optimal mass transportation. The focus was on the two-point boundary problem, and existence and uniqueness for solutions as action-minimizing paths in $\mathcal{P}_2(\mathbb{R})$ were obtained.

We shall need the following assumptions:

(H1) *The initial distribution of mass* $\rho_0 \in \mathcal{P}_2(\mathbb{R})$.

(H2) *There exists* $0 \le \Lambda < +\infty$ *such that*

$$v_0 \in C(\mathbb{R}) \cap L^2(\rho_0) \text{ and } |v_0(x)| \le \Lambda(1+x^2) \text{ for all } x \in \mathbb{R}.$$

The main objective is the following result.

THEOREM 1.1. *The initial-value problem for* (1) *admits a global weak solution in the sense of distributions if* (H1) *and* (H2) *hold.*

Two independent papers that appeared in 1996 and 1998 used adhesion dynamics to obtain global solutions for (1) in the $\alpha = \beta = 0$ case [7], [23] and in the $\alpha = -1$, $\beta = 0$ case [23]. Not only are we able to deal with the more general (1), but we also establish our results under less restrictive conditions on the initial mass distribution and velocity. In [7] the initial ρ_0 is compactly supported, while the initial velocity v_0 is continuous and bounded. These assumptions are relaxed in [23], e.g., $\sup_{|x|\le R} |v_0(x)|/R \to 0$ as $R \to +\infty$, while $\mathrm{spt}(\rho_0)$ may be unbounded, in which case $\int_0^x y \mathrm{d}\rho_0(y) \to +\infty$ as $|x| \to +\infty$. As opposed to [7], however, [23] makes the extra assumptions that ρ_0 be either discrete or absolutely continuous with respect to the Lebesgue measure, in which case $\rho_0 > 0$ on $\mathrm{spt}(\rho_0)$.

More recent work [16] treats the case $\alpha = \beta = 0$ for nonnegative Radon measures ρ_0 (not necessarily of finite total mass) and velocities $v_0 \in L^\infty(\rho_0)$. This paper is also remarkable in that it gives a necessary and sufficient condition for uniqueness of the Oleinik entropy solution—the initial weak continuity of the energy. As the example showing the necessity of this condition involves infinite mass initial measures, it remains unclear whether that is really needed in the finite mass case. Another paper that deals with possibly discontinuous (but bounded) initial velocities is [9], where the solution is produced constructively.

In [5] we find the concept of duality solutions, which is based on earlier work by the same authors. Existence and uniqueness are obtained under the assumption of atom-free initial density and bounded and continuous initial velocity. Boudin [6] obtains global existence of smooth solutions when the initial data has some higher regularity and is bounded away from zero and infinity (and thus of infinite total mass). Interestingly, the initial velocity does not have to be nondecreasing in order to rule out formation of singularities in finite time. We will consider this issue in section 4.3.

Whereas [7] and [23] use different approaches, they are still closely connected in principle. The fundamental underlying assumption for the discrete dynamics is the "sticky particle" hypothesis. The idea goes back to Zeldovich [24] and can be briefly described as follows. If $m_i,\ i = 1, n$ is a discrete system of masses initially located at $-\infty < x_1 < \cdots < x_n < +\infty$ and moving with initial velocities $v_i,\ i = 1, n$, then one makes the assumption that the velocities remain constant while there is no collision. At the collision of a group of particles, the particles stick together and the initial velocity of the newly formed particle is given by the conservation of momentum. In [23] the authors successfully implemented a version adapted to the case $\alpha = -1,\ \beta = 0$. Instead of the constant speed intercollisional motion, we now assume uniformly accelerated motion between collisions. The acceleration is of gravitational nature and is proportional to the difference between the total mass to the left and the total mass to the right. Thus, in both cases, the trajectory of the ith particle before collision is given by

$$x_i(t) = x_i + tv_i + \frac{t^2}{2} a_n^i,$$

where

$$a_n^i = \begin{cases} 0 & \text{if } \alpha = \beta = 0, \\ \frac{1}{2}\left(\sum_{j<i} m_j - \sum_{j>i} m_j\right) & \text{if } \alpha = -1,\ \beta = 0. \end{cases}$$

(Here we convene that $m_0 = m_{n+1} = 0$.) If the masses $m_j,\ i \le j \le k$, collide at time $t_0 > 0$, then conservation of momentum yields

$$v_i(t_0+) = \frac{\sum_{j=i}^k m_j v_j(t_0-)}{\sum_{j=i}^k m_j}.$$

Of course, only finitely many collisions can occur; therefore, the evolution of the system is completely determined by the above assumptions.

Next we briefly describe the technique employed in [23], whose approach does not distinguish between the discrete and absolutely continuous cases. Here the problem is attacked from a "continuation of characteristics" point of view. When shocks occur, i.e., when the map $\phi_t(y) := y + tv_0(y) + t^2 a_0(y)/2$ is no longer invertible, one needs to

redefine $\phi_t(y)$ in such a way that it remains nondecreasing and $\phi_{t\#}\rho_0 =: \rho_t$ satisfies the equation in a weak sense. This redefinition uses the so-called generalized variational principle which comes from the intuition provided by the discrete case (see [23] for details).

A more elegant approach [7], in our opinion, makes use of standard results on approximations for scalar conservation laws. It is applied to the Euler pressureless system ($\alpha = \beta = 0$) and relies on the fact that the distribution function M of ρ satisfies an autonomous scalar conservation law. Another advantage lies in the fact that the solution for the continuous problem is obtained from the discrete ones via approximation theory for scalar conservation laws. We shall adopt this point of view and prove the more general Theorem 1.1 by an appropriate adaptation of Brenier and Grenier's method.

The plan is as follows: we use (H1) to produce a sequence of discrete probabilities

$$\rho_0^n := \sum_{i=1}^{n} m_i^{(n)} \delta_{x_i^{(n)}} \to \rho_0 \text{ as } n \to \infty$$

in the 2-Wasserstein distance. We shall, in fact, prove that this sequence may be taken such that $\int_{\mathbb{R}} \zeta \mathrm{d}\rho_0^n$ is uniformly bounded for some superquadratic growth function $\zeta : [0,\infty) \to [0,\infty)$. Denote by M_0^n the right continuous distribution function of ρ_0^n and let

$$a_n(m) := \alpha\Big(\sum_{j=1}^{i} m_j - \frac{1}{2} m_i \Big) + \beta \tag{2}$$

whenever $M_0^n\big(x_i^{(n)} - \big) \le m < M_0^n\big(x_i^{(n)}\big)$. We then define flux functions $\tilde{F}_n : [0,T] \times [0,1] \to \mathbb{R}$ as

$$\tilde{F}_n(t,m) := \int_0^m f_n(\omega)\mathrm{d}\omega + t \int_0^m a_n(\omega)\mathrm{d}\omega, \tag{3}$$

where $N_{0\,\#}^n \chi_{(0,1)} = \rho_0^n$ optimally and $f_n := v_0 \circ N_0^n$ (the map N_0^n is taken to be right continuous). By adhesion dynamics we construct the unique entropy solution M_n for the first-order problem

$$\partial_t M + \partial_x\big[\tilde{F}_n(t,M)\big] = 0, \quad M(0,\cdot) = M_0^n. \tag{4}$$

We then use (H2) to show that, for an appropriate choice of approximating initial data, the sequence M_n will converge in some sense to the unique entropy solution for

$$\partial_t M + \partial_x\big[\tilde{F}(t,M)\big] = 0, \quad M(0,\cdot) = M_0, \tag{5}$$

where $\tilde{F} : [0,T] \times [0,1] \to \mathbb{R}$ is given by

$$\tilde{F}(t,m) := \int_0^m f(\omega)\mathrm{d}\omega + t \int_0^m a(\omega)\mathrm{d}\omega = \int_0^m f(\omega)\mathrm{d}\omega + t(\alpha m^2/2 + \beta m) \tag{6}$$

for $f := v_0 \circ N_0$ and $a(m) := \alpha m + \beta$ for $m \in [0,1]$. Here $N_0 := M_0^{-1}$ (generalized inverse) [12] is the right continuous optimal map pushing $\chi_{(0,1)}$ forward to ρ_0. The solution M of (5) will produce the solution $\rho := \partial_x M$ and $v\rho := \partial_x[\tilde{F}(t,M)]$ for (1) via a generalization of a result due to Volpert [22] on BV calculus. The last section is

dedicated to the $\alpha = 0 = \beta$ case. We give an explicit formula for v in terms of M, and, more importantly, we prove that our solution satisfies the Oleinik entropy condition. Some qualitative properties of the solution are discussed, e.g., time regularity and the impact of the initial velocity on the occurrence of spatial singularities. We finish with a partial result on uniqueness; i.e., we show that the energy of our solution for the pressureless Euler system is weakly continuous initially, which, along with the Oleinik entropy condition, leads to uniqueness in the case of bounded initial velocities [16].

2. Elements of one-dimensional BV calculus.

2.1. A BV chain rule in dimension one. To prove a chain rule for BV functions, we need the following lemma.

LEMMA 2.1. *Let μ be a Borel probability measure on $\mathbb{R}$ and M be its right continuous distribution function. Write*

$$\mu = \sum_{j\in J} m_i \delta_{x_j} + \rho,$$

where $\{x_j\}_{j\in J}$ is the set (at most countable) of discontinuities of M and $m_j := \mu(\{x_j\})$. If ρ is nonzero, then we have

$$M_{\#}\rho = \chi_{U^c} \text{ for } U := \bigcup_{j\in J} \big(M(x_j-), M(x_j)\big). \tag{7}$$

Proof. We first observe that the balance of mass is satisfied. Since M is monotone nondecreasing, (7) is equivalent to the fact that M is the optimal map pushing ρ forward to χ_{U^c}. That is what we prove next. It is well known [12] that, since both measures are atom-free, the optimal map is given by $G^{-1} \circ F$, where F, G are the right continuous distribution functions of ρ and χ_{U^c}, respectively, and G^{-1} is the generalized inverse of G, given by $G^{-1}(y) = \inf\{m \in [0,1] : G(m) > y\}$. We shall show that $M(x) = G^{-1} \circ F(x)$ for ρ-a.e. $x \in \mathrm{spt}(\rho)$, i.e., $G^{-1}(F(x)) = \inf\{m \in [0,1] : G(m) > F(x)\} = M(x)$. Note that

$$F(x) = M(x) - \sum_{x_j \le x} m_j \text{ and } G(m) = m - \sum_{M(x_j)\le m} m_j \text{ if } m \in U^c.$$

Thus, if $m \in U^c$,

$$G(m) - F(x) = \begin{cases} m - M(x) - \sum_{M(x)<M(x_j)\le m} m_j & \text{if } m > M(x), \\ 0 & \text{if } m = M(x), \\ m - M(x) + \sum_{m<M(x_j)\le M(x)} m_j & \text{if } m < M(x). \end{cases}$$

Since $G(M(x)) - F(x) = 0$ and G is a right continuous, nondecreasing function, all we need to prove is that there does not exist a nondegenerate interval $[M(x), M(x)+\epsilon]$ such that $G(m) = F(x)$ for all $m \in [M(x), M(x)+\epsilon]$. Suppose such an interval exists. We know M is right continuous at x; therefore, if $x < z < x + \delta(\epsilon)$, we have that $M(x) \le M(z) \le M(x) + \epsilon$. Thus, as $M(z) \in U^c$, we infer that $M(z) - M(x) - \sum_{x<x_j\le z} m_j = 0$, i.e., $\rho([x,z]) = 0$. This means $x \in \partial\mathrm{spt}(\rho)$, and, by taking $[x, z_x]$, the maximal interval for which $\rho([x,z]) = 0$, we see that $(x, z_x) \cap (y, z_y) = \emptyset$ for any $x \neq y$ in $\partial\mathrm{spt}(\rho)$ for which these nondegenerate intervals exist. This means that there are at most countably many such points, and, since ρ is atom-free, it follows that the ρ-measure of this set of points is zero. The lemma is thus proved. ∎

The following theorem is fundamental. The first part of (i) can be trivially obtained from [22]; see, e.g., [5] for the exact formula on the derivative. The novelty of our result appears in (ii) as we go from the Lipschitz to the $W^{1,p}$ case. However, for the reader's convenience we sketch an elementary proof for (i) as well.

THEOREM 2.2. *Let μ be a Borel probability measure on $\mathbb{R}$ and let M be its right continuous distribution function.*

(i) *Assume $f \in W^{1,\infty}(0,1)$. Then, $f \circ M \in BV(\mathbb{R})$ with distributional derivative $g\mu$, where*

$$g(x) = \begin{cases} \overline{f' \circ M}(x) & \text{if } \mu(\{x\}) = 0, \\ \dfrac{f \circ M(x) - f \circ M(x-)}{\mu(\{x\})} & \text{if } \mu(\{x\}) \neq 0, \end{cases} \tag{8}$$

μ-a.e. for some function $\overline{f' \circ M} \in L^\infty(\mathbb{R})$. Furthermore, suppose f' is defined unambiguously on $(0,1)$, and there exists a bounded $C^1[0,1]$ sequence f_n such that $f_n \to f$ uniformly and $f_n' \to f'$ everywhere on $(0,1)$. Then $\overline{f' \circ M} \equiv f' \circ M$ in the μ-a.e. sense, or, equivalently,

$$g(x) = \int_0^1 f'\big((1-s)M(x-) + sM(x)\big)\mathrm{d}s \text{ for } \mu\text{-a.e. } x \in \mathbb{R}. \tag{9}$$

(ii) *Let $1 \le p < +\infty$ and assume $f \in W^{1,p}(0,1) \cap C^1(0,1)$ and g is given by (8), with $\overline{f' \circ M} \equiv f' \circ M$ in the μ-a.e. sense. Then $g \in L^p(\mu)$ with $\|g\|_{L^p(\mu)} \le \|f'\|_{L^p(0,1)}$ and $f \circ M \in BV(\mathbb{R})$ with distributional derivative $g\mu$.*
Now take $f \in W^{1,p}(0,1)$. Suppose f' is defined unambiguously on $(0,1)$, and there exists a $W^{1,p}(0,1) \cap C^1(0,1)$ sequence f_n such that $f_n \to f$ in $W^{1,p}$ and $f_n' \to f'$ everywhere on $(0,1)$. Then we still have the same result with $\overline{f' \circ M} \equiv f' \circ M$ in the μ-a.e. sense.

Proof. W.l.o.g. we may assume that μ is supported in some bounded interval I. Also, we shall first assume $f \in C^1[0,1]$ to show that (8) is valid with $\overline{f' \circ M} \equiv f' \circ M$. Now consider $\varphi \in C_c^\infty(I)$. We need to show that

$$-\int_I \varphi'(x) f \circ M(x)\mathrm{d}x = \int_I \varphi(x) g(x)\mathrm{d}\mu(x). \tag{10}$$

If μ has finitely many atoms, then the validity of (10) can be checked by direct computation. Indeed, since M is piecewise continuous and bounded, we may approximate it uniformly by nondecreasing piecewise $W^{1,1}$ functions M_ϵ (may take M_ϵ piecewise linear and continuous on each continuity interval for M, such that M and M_ϵ agree at the endpoints). Thus, $\mu_\epsilon := M_\epsilon' \rightharpoonup M' = \mu$ weakly as nonnegative, bounded measures. The chain rule for Sobolev functions [8] applies piecewise and yields (10) for μ_ϵ. Then we pass to the limit to obtain the result for μ. Thus, let us assume $D := \{x_1, x_2, \ldots, x_n, \ldots\}$ is the infinite set of all atoms of μ and write

$$\mu = \sum_{i=1}^\infty m_i \delta_{x_i} + \rho, \text{ where } m_i > 0,\ i = 1, 2, \ldots,$$

and ρ is an atom-free nonnegative Borel measure of total mass $1 - \sum_{i=1}^\infty m_i \ge 0$. We shall call the atomic measure the singular part while ρ shall be called the regular part (although it may not be absolutely continuous with respect to the Lebesgue

measure). Consider now the sequence of measures μ_n given by $\mu_n = \sum_{i=1}^{n} m_i \delta_{x_i} + \rho$. Of course, $\mu_n \rightharpoonup \mu$ weakly $\star$ as measures. Since M_n, the right continuous distribution function of μ_n, has only finitely many discontinuities, (8) holds for μ_n, as proved above. It is easy to see that $M_n \to M$ Lebesgue a.e.; thus, the continuity of f along with its boundedness gives the convergence of the left-hand side of (10) by dominated convergence. Therefore, $f \circ M_n \in BV(\mathbb{R})$ with distributional derivative $g_n \mu_n$, where

$$g_n(x) := \begin{cases} f' \circ M_n(x) & \text{if } \mu_n(\{x\}) = 0, \\ \dfrac{f \circ M_n(x) - f \circ M_n(x-)}{\mu_n(\{x\})} & \text{if } \mu_n(\{x\}) \neq 0. \end{cases}$$

Now we write

$$\int_{\mathbb{R}} \varphi(x) g_n(x) \mathrm{d}\mu_n(x) = \sum_{i=1}^{n} \varphi(x_i)[f(M_n(x_i)) - f(M_n(x_i-))] + \int_{\mathbb{R}} \varphi(x) f' \circ M_n(x) \mathrm{d}\rho(x).$$

By the continuity of f' we obtain the convergence of the second term on the right-hand side. Thus, it remains to prove that

$$\sum_{i=1}^{n} \varphi(x_i)[f(M_n(x_i)) - f(M_n(x_i-))] \to \sum_{i=1}^{\infty} \varphi(x_i)[f(M(x_i)) - f(M(x_i-))],$$

which can be obtained after some calculations as a consequence of the convergence of the series $\sum m_i$ if $f \in C^2[0,1]$, and then for $C^1[0,1]$ functions by approximation. If f is $W^{1,\infty}(0,1)$, then we conclude by taking a sequence of functions in $C^1[0,1]$ such that $f_n \to f$ uniformly and f_n' are uniformly bounded. Indeed, one has

$$-\int_{\mathbb{R}} \varphi' f_n \circ M \mathrm{d}x = \int_{\mathbb{R}} \varphi f_n' \circ M \mathrm{d}\rho + \int_{\mathbb{R}} \varphi(x) \frac{f_n(M(x)) - f_n(M(x-))}{M(x) - M(x-)} \mathrm{d}\mu_s(x),$$

where $\mu_s = \sum m_j \delta_{x_j}$ is the singular part of μ. Note that the ratio in the second term of the right-hand side converges uniformly to $[f(M(x)) - f(M(x-))]/[M(x) - M(x-)]$ on the support of μ_s; thus the uniform bound on f_n' ensures the convergence of the integral by dominated convergence. Since the left-hand side is trivially convergent, it follows that

$$\int_{\mathbb{R}} \varphi(x) f_n' \circ M(x) \mathrm{d}\rho(x) \text{ converges as } n \to \infty,$$

which, along with the uniform bound on f_n', yields the convergence of $f_n' \circ M$ in the L^∞ weak $\star$ topology. We also deduce that the limit, denoted by $\overline{f' \circ M}$, is μ-a.e. independent of the chosen sequence f_n. The second statement from (i) easily follows (by dominated convergence) from the fact that $g_n \to g$ everywhere as an L^∞ bounded sequence.

To prove the first part of (ii) we truncate f' by

$$f_n'(x) := \begin{cases} -n & \text{if } f'(x) < -n, \\ f'(x) & \text{if } |f'(x)| \leq n, \\ n & \text{if } f'(x) > n \end{cases} \tag{11}$$

and let f_n be the antiderivative of f_n' vanishing at zero. Note that $|f_n'| \leq |f'|$ on $(0,1)$, which implies that f_n is uniformly bounded with respect to n in $L^p(0,1)$. First,

since $f_n \in C^1[0,1]$, we infer, according to (i), that $f_n \circ M$ is BV with distributional derivative $g_n\mu$, where

$$g_n(x) := \begin{cases} f_n' \circ M(x) & \text{if } \mu(\{x\}) = 0, \\ \dfrac{f_n \circ M(x) - f_n \circ M(x-)}{\mu(\{x\})} & \text{if } \mu(\{x\}) \neq 0. \end{cases} \tag{12}$$

This (see (9) for the equivalent integral expression) together with the fact that $|f_n'| \leq |f'|$ implies

$$|g_n(x)| \leq \int_0^1 \big|f'\big((1-s)M(x-) + sM(x)\big)\big|\mathrm{d}s =: h(x) \text{ for } x \in I.$$

Since $f_n' \to f'$, we infer that $g_n \to g$ pointwise. Assume that $h \in L^p(\mu)$. Then, we may pass to the limit in the right-hand side of

$$-\int_I \varphi'(x) f_n \circ M(x)\mathrm{d}x = \int_I \varphi(x) g_n(x)\mathrm{d}\mu(x).$$

The left-hand side converges to the appropriate quantity because $f_n \to f$ uniformly and f_n are uniformly bounded.

Thus, we are done if we can prove that $h \in L^p(\mu)$. For this let $\{x_j\}_{j\in J}$ be the set of discontinuities of M and $m_j := \mu(\{x_j\})$. Now consider, for $s \in [0,1]$, the sum

$$\sum_{i=1}^n m_i \big|f'\big((1-s)M(x_i-) + sM(x_i)\big)\big|^p = \sum_{i=1}^n m_i \big|f'\big(M(x_i-) + sm_i\big)\big|^p.$$

By monotone convergence

$$\sum_{i=1}^n \int_0^1 m_i \big|f'\big(M(x_i-) + sm_i\big)\big|^p \mathrm{d}s \to \int_0^1 \sum_{i=1}^\infty m_i \big|f'\big(M(x_i-) + sm_i\big)\big|^p \mathrm{d}s,$$

which, after obvious linear changes of variables, is equivalent to

$$\int_{\cup_{i=1}^n [M(x_i-), M(x_i)]} |f'(m)|^p \mathrm{d}m \to \int_0^1 \sum_{i=1}^\infty m_i \big|f'\big(M(x_i-) + sm_i\big)\big|^p \mathrm{d}s.$$

Again, by monotone convergence the left-hand side converges to $\int_U |f'(m)|^p \mathrm{d}m$, where $U := \bigcup_{j\in J} \big(M(x_j-), M(x_j)\big)$. Thus, since $f' \in L^p(0,1)$ and $U \subset [0,1]$, it follows that

$$\int_0^1 \sum_{i=1}^\infty m_i \big|f'\big(M(x_i-) + sm_i\big)\big|^p \mathrm{d}s = \int_U |f'(m)|^p \mathrm{d}m \leq \|f'\|^p_{L^p(0,1)},$$

so we can apply Fubini's theorem to obtain

$$\int_I \int_0^1 \big|f'\big((1-s)M(x-) + sM(x)\big)\big|^p \mathrm{d}s \mathrm{d}\mu_s(x) = \int_U |f'(m)|^p \mathrm{d}m < +\infty, \tag{13}$$

where μ_s denotes, as before, the singular part of μ (unrelated to the integration variable s). If $\mu = \mu_s$, then we are done. Else, by using Lemma 2.1, we obtain

$$\int_I |f' \circ M(x)|^p \mathrm{d}\rho(x) = \int_{U^c} |f'(m)|^p \mathrm{d}m,$$

which, combined with (13), yields

$$\int_I \int_0^1 |f'\big((1-s)M(x-)+sM(x)\big)|^p \mathrm{d}s\mathrm{d}\mu(x) = \|f'\|^p_{L^p(0,1)}. \tag{14}$$

Therefore, $h \in L^p(\mu)$ with $\|h\|_{L^p(\mu)} \leq \|f'\|_{L^p(0,1)}$ (with equality if $p = 1$). Since $|g| \leq h$ pointwise, the proof of the first part of (ii) is concluded.

Consequently,

$$-\int_{\mathbb{R}} \varphi' f_n \circ M \mathrm{d}x = \int_{\mathbb{R}} \varphi g_n \mathrm{d}\mu \text{ for all positive integers } n, \tag{15}$$

where g_n is defined by (12) for the approximating sequence f_n considered in the second part of (ii). We have, just as in deducing (14), that

$$\begin{aligned}\int_I |g_n(x) - g_m(x)|^p \mathrm{d}\mu(x) \leq & \int_I \int_0^1 |(f_n' - f_m')\big((1-s)M(x-)+sM(x)\big)|^p \mathrm{d}s\mathrm{d}\mu(x) \\ = & \|f_n' - f_m'\|^p_{L^p(0,1)}\end{aligned}$$

for all natural $m,\ n \geq 1$. Thus, $\{g_n\}$ is convergent in $L^p(\mu)$, and, due to the hypothesis of *everywhere* convergence of f_n' to f', we obtain $g_n \to g$ in $L^p(\mu)$, where

$$g(x) := \int_0^1 f'\big((1-s)M(x-)+sM(x)\big)\mathrm{d}s.$$

Passing to the limit in (15) concludes our proof. □

The following corollary holds for any $1 \leq p \leq +\infty$.

COROLLARY 2.3. *Let $f \in L^p(0,1)$ be right continuous (thus unambiguously defined everywhere in $(0,1)$), and take F to be its antiderivative vanishing at zero. If M is the cumulative distribution function of some Borel probability measure μ on $\mathbb{R}$, then $F \circ M \in BV(\mathbb{R})$ with distributional derivative $g\mu$, where*

$$g(x) := \begin{cases} f \circ M(x) & \text{if } \mu(\{x\}) = 0, \\ \dfrac{F \circ M(x) - F \circ M(x-)}{\mu(\{x\})} & \text{if } \mu(\{x\}) \neq 0, \end{cases} \tag{16}$$

in the μ-a.e. sense. Furthermore, $g \in L^p(\mu)$ and $\|g\|_{L^p(\mu)} \leq \|f\|_{L^p(0,1)}$.

The proof is an immediate consequence of Theorem 2.2. Indeed, we take (upon extending f by zero outside $(0,1)$) the function $f_n := \eta^n * f$, where η^n is obtained from the standard mollifier supported in $[-1/n, 1/n]$ by shifting it to the left by $1/n$. The classic properties of mollification still hold, e.g., $f_n \to f$ in $L^p(0,1)$ (if $p \neq +\infty$) and $f_n \in C^\infty[0,1]$. However, the interesting feature of these "shifted mollifiers" is that the right continuity of f on $(0,1)$ is enough to easily prove that $f_n \to f$ *everywhere* in $(0,1)$. Thus, if we take $F_n(m) := \int_0^m f_n(\omega)\mathrm{d}\omega$, we are within the hypotheses of Theorem 2.2.

Remark 2.4. To understand the relevance of this result, observe that the functions $f_n,\ f$ defined in the introduction are right continuous on $(0,1)$. Indeed, that comes as a consequence of the continuity of v_0 on $\mathbb{R}$ and the right continuity of $N_0^n,\ N_0$ on $(0,1)$ (as generalized inverses of nondecreasing, right continuous functions [21]).

2.2. A two-dimensional extension. Now let us assume $M : [0,T]\times\mathbb{R} \to [0,1]$ for some $0 < T < +\infty$, such that $M \in BV([0,T]\times\mathbb{R})$ and $M(t,\cdot)$ is a right continuous probability distribution function for Lebesgue a.e. $t \in (0,T)$. The following lemma is easy to check as a consequence of Fubini's theorem.

LEMMA 2.5. *Let ∇M be the vector-valued measure given by the BV gradient $\nabla = (\partial_t, \partial_x)$ of M. Then, its x-component $\mathrm{d}\partial_x M$ admits the decomposition $\mathrm{d}\partial_x M(t,\cdot)\mathrm{d}t$.*

We shall use this to prove the main result of this section, which we state below. We denote by C_r the space of right continuous functions.

THEOREM 2.6. *Consider $M : [0,T]\times\mathbb{R} \to [0,1]$ as above, and let $f \in L^2(0,1)\cap C_r(0,1)$ and F be its antiderivative vanishing at zero. Assume further that*

$$\partial_t M + \partial_x[F\circ M] = 0 \text{ in } \mathcal{D}'([0,T]\times\mathbb{R}). \tag{17}$$

Then $F\circ M \in BV([0,T]\times\mathbb{R})$ and $\nabla[F\circ M] = g\nabla M$ for some $g \in L^1(|\nabla M|)$.

Proof. We may consider w.l.o.g. the case $f \in C(0,1)$. Else, we simply use Corollary 2.3 instead of Theorem 2.2. Let us start by taking the truncations f_n for f as in (11). The corresponding F_n's are in $C^1[0,1]$, $F_n \to F$ uniformly and $f_n \to f$ in $L^2(0,1)$. According to [22], $F_n\circ M \in BV([0,T]\times\mathbb{R})$ and there exist $\bar f_n \in L^\infty$ such that $\nabla[F_n\circ M] = \bar f_n \nabla M$ as vector-valued measures. This means that

$$-\int_0^T\!\!\int_{\mathbb{R}} F_n(M)\nabla\cdot\boldsymbol{\phi}\mathrm{d}x\mathrm{d}t = \int_0^T\!\!\int_{\mathbb{R}} \bar f_n\phi_1\mathrm{d}\partial_t M + \int_0^T\!\!\int_{\mathbb{R}} \bar f_n\phi_2\mathrm{d}\partial_x M \tag{18}$$

for all $\boldsymbol{\phi} := (\phi_1,\phi_2) \in C_c^\infty((0,T)\times\mathbb{R};\mathbb{R}^2)$. We now use Lemma 2.5 and (17) to infer

$$-\int_0^T\!\!\int_{\mathbb{R}} F_n(M)\nabla\cdot\boldsymbol{\phi}\mathrm{d}x\mathrm{d}t = \int_0^T\!\!\int_{\mathbb{R}} \big(-g\phi_1+\phi_2\big)\bar f_n\mathrm{d}\partial_x M(t,\cdot)\mathrm{d}t, \tag{19}$$

where, according to Theorem 2.2 (ii),

$$g(t,\cdot) := \int_0^1 f\big((1-s)M(t,\cdot-) + sM(t,\cdot)\big)\mathrm{d}s \in L^2(\partial_x M(t,\cdot))$$

for Lebesgue a.e. $t \in (0,T)$. Also, Theorem 2.2 (ii) ensures that

$$\|g(t,\cdot)\|_{L^2(\partial_x M(t,\cdot))} \le \|f\|_{L^2(0,1)} \text{ uniformly with respect to } t.$$

Note that (19) implies

$$-\int_0^T\!\!\int_{\mathbb{R}} F_n(M)\partial_x\phi_1\mathrm{d}x\mathrm{d}t = \int_0^T\!\!\int_{\mathbb{R}} \bar f_n\phi_1\mathrm{d}\partial_x M(t,\cdot)\mathrm{d}t \tag{20}$$

for all $\phi_1 \in C_c^\infty((0,T)\times\mathbb{R})$. For Lebesgue a.e. $t \in (0,T)$ one has (Theorem 2.2 (i))

$$\partial_x[F_n\circ M(t,\cdot)] = g_n(t,\cdot)\partial_x M(t,\cdot) \text{ for } g_n(t,x) := \int_0^1 f_n\big((1-s)M(t,x-)+sM(t,x)\big)\mathrm{d}s$$

and

$$\|g_n(t,\cdot)\|_{L^2(\partial_x M(t,\cdot))} \le \|f\|_{L^2(0,1)} \text{ uniformly in } t \text{ and } n.$$

Along with (20), this implies $\bar f_n \equiv g_n$ in the $\mathrm{d}\partial_x M(t,\cdot)\mathrm{d}t$-a.e. sense. Therefore, (19) is equivalent to

$$-\int_0^T\!\!\int_{\mathbb{R}} F_n(M)\nabla\cdot\boldsymbol{\phi}\mathrm{d}x\mathrm{d}t = \int_0^T\!\!\int_{\mathbb{R}} \big(-g\phi_1+\phi_2\big)g_n\mathrm{d}\partial_x M(t,\cdot)\mathrm{d}t. \tag{21}$$

Furthermore, due to the pointwise convergence and the uniform (in n and t) $L^2(\partial_x M)$-bounds we obtain $g_n \to g$ in $L^2(\mathrm{d}\partial_x M(t,\cdot)\mathrm{d}t)$. By the uniform (and bounded) convergence of F_n to F we can also pass to the limit in the left-hand side. Thus,

$$-\int_0^T\int_{\mathbb{R}} F(M)\nabla\cdot\boldsymbol{\phi}\mathrm{d}x\mathrm{d}t = \int_0^T\int_{\mathbb{R}} \big(-g^2\phi_1 + g\phi_2\big)\mathrm{d}\partial_x M(t,\cdot)\mathrm{d}t,$$

which, after using Lemma 2.5 and (17) once more, leads to

$$-\int_0^T\int_{\mathbb{R}} F(M)\nabla\cdot\boldsymbol{\phi}\mathrm{d}x\mathrm{d}t = \int_0^T\int_{\mathbb{R}} g\phi_1\mathrm{d}\partial_t M + \int_0^T\int_{\mathbb{R}} g\phi_2\mathrm{d}\partial_x M.$$

Since $g \in L^2(\partial_x M) \subset L^1(\partial_x M)$ and $g \in L^1(|\partial_t M|)$, we obtain the result. □

We are going to need a slightly different result which we now state as a consequence. It may be proved by retracing the proof of Theorem 2.6.

COROLLARY 2.7. *Assume now that*

$$\partial_t M + \partial_x[\tilde{F}(t,M)] = 0 \text{ in } \mathcal{D}'([0,T]\times\mathbb{R})$$

for some time-linear perturbation $\tilde{F}(t,\cdot) := F + t\Psi$, $\Psi \in C^1[0,1]$. *Then* $F\circ M \in BV([0,T]\times\mathbb{R})$ *and*

$$\nabla[\tilde{F}(t,M)] = (g + t\psi)\nabla M + \mathbf{V}$$

for g *from Theorem* 2.6, *and the vector field* $\mathbf{V} := \big(\Psi\circ M, 0\big)$. *Here,*

$$\psi(t,x) := \int_0^1 \Psi'\big((1-s)M(t,x-) + sM(t,x)\big)\mathrm{d}s.$$

3. Pressureless Euler/Euler–Poisson systems via scalar conservation laws.

3.1. Convergence of measures and their distribution functions. Let $1 \le p < \infty$, $\mu \in \mathcal{P}_p(\mathbb{R})$, and $v \in L^p(\mu)\cap C(\mathbb{R})$. Then by the de la Vallée-Poussin lemma which can be found in [10], there exists a nonnegative, convex, increasing function $\zeta \in C^1([0,+\infty))$ satisfying $\zeta(0) = 0$ and $\frac{\zeta(t)}{t} \uparrow +\infty$ as $t \to +\infty$ such that

$$\int_{\mathbb{R}} \zeta(|x|^p + |v(x)|^p)\mathrm{d}\mu(x) < +\infty.$$

It is also well known that (see [11], for example) there exist a probability space (Ω,Σ,P) and a sequence of independent random variables $\xi_i : \Omega \to \mathbb{R}$ such that

$$\xi_{i\#}P = \mu.$$

Now for each positive integer n and each $\omega \in \Omega$, define

$$\mu^{n,\omega} := \frac{1}{n}\sum_{i=1}^n \delta_{\xi_i(\omega)}.$$

Then by the strong law of large numbers and the separability of $C_c(\mathbb{R})$ we have for P-a.e. $\omega \in \Omega$

$$\int_{\mathbb{R}} f(x)\mathrm{d}\mu^{n,\omega}(x) = \frac{1}{n}\sum_{i=1}^n f(\xi_i(\omega)) \to \mathbb{E}(f\circ\xi_1) = \int_{\mathbb{R}} f(x)\mathrm{d}\mu(x)$$

for all functions $f \in C_c(\mathbb{R})$. Consequently, $\mu^{n,\omega}$ converges narrowly to μ. Thus, by using the strong law of large numbers again, we also have that for P-a.e. $\omega \in \Omega$

$$\int_{\mathbb{R}} \zeta(|x|^p)\mathrm{d}\mu^{n,\omega}(x) \to \int_{\mathbb{R}} \zeta(|x|^p)\mathrm{d}\mu(x), \quad \int_{\mathbb{R}} \zeta(|v|^p)\mathrm{d}\mu^{n,\omega}(x) \to \int_{\mathbb{R}} \zeta(|v|^p)\mathrm{d}\mu(x).$$

The last fact together with the properties of ζ yields for $k > 0$ large enough

$$\frac{\zeta(k^p)}{k^p} \int_{\{x:|x|\geq k\}} |x|^p \mathrm{d}\mu^{n,\omega} \leq \int_{\{x:|x|\geq k\}} \frac{\zeta(|x|^p)}{|x|^p} |x|^p \mathrm{d}\mu^{n,\omega} \leq \int_{\mathbb{R}} \zeta(|x|^p)\mathrm{d}\mu^{n,\omega} \leq C(\omega).$$

Therefore, $\{\mu^{n,\omega}\}$ has uniformly integrable p-moments. Consequently, by Proposition 7.1.5 in [2] we obtain that for P-a.e. $\omega \in \Omega$, $\mu^{n,\omega} \to \mu$ in W_p and

$$\int_{\mathbb{R}} \zeta(|x|^p)\mathrm{d}\mu^{n,\omega}(x) \to \int_{\mathbb{R}} \zeta(|x|^p)\mathrm{d}\mu(x), \quad \int_{\mathbb{R}} \zeta(|v|^p)\mathrm{d}\mu^{n,\omega}(x) \to \int_{\mathbb{R}} \zeta(|v|^p)\mathrm{d}\mu(x).$$

LEMMA 3.1. *Suppose $1 \leq p < \infty$ and $\{\mu_n\}$ is a sequence of measures in $\mathcal{P}_p(\mathbb{R})$ converging to $\mu \in \mathcal{P}_p(\mathbb{R})$ in W_p. When $p > 1$ we assume further that $\int_{\mathbb{R}} \zeta(|x|^p)\mathrm{d}\mu_n(x)$ is uniformly bounded in n for some nonnegative, convex, increasing function $\zeta \in C^1([0,+\infty))$ satisfying $\zeta(0) = 0$ and $\frac{\zeta(t)}{t} \uparrow +\infty$ as $t \to +\infty$. Then we have the following:*

(i) *The L^1 norm of $M_n - M$ on $\mathbb{R}$ goes to zero, where*

$$M(x) := \mu((-\infty, x]).$$

(ii) *For any nondecreasing C^1 function B on $[0,1]$ such that $B(0) = 0, B(1) = 1$,*

$$\partial_x(B(M_n)) \to \partial_x(B(M)) \quad \text{in} \quad W_p.$$

Proof. From Theorem 6.0.2 in [2], we obtain

$$W_1(\mu_n, \mu) = \int_0^1 |M_n^{-1}(s) - M^{-1}(s)|\mathrm{d}s,$$

where the generalized inverse M^{-1} of M is defined by

$$M^{-1}(s) := \inf\{x \in \mathbb{R} : M(x) > s\}, \quad s \in [0,1].$$

Then by using Fubini's theorem we get $W_1(\mu_n, \mu) = \|M_n - M\|_{L^1(\mathbb{R})}$. This together with the fact that $W_1(\mu_n, \mu) \leq W_p(\mu_n, \mu)$ gives (i). By (i) and the Lipschitz condition on B we clearly have $\|B(M_n) - B(M)\|_{L^1(\mathbb{R})} \to 0$. But as

$$W_1(\partial_x(B(M_n)), \partial_x(B(M))) = \|B(M_n) - B(M)\|_{L^1(\mathbb{R})},$$

we infer in particular that $\partial_x(B(M_n)) \to \partial_x(B(M))$ narrowly.

We have from Theorem 2.2

$$\int_{\mathbb{R}} \zeta(|x|^p)\mathrm{d}\partial_x(B(M_n)) = \int_{\mathbb{R}} \zeta(|x|^p) g_n(x)\mathrm{d}\mu_n(x),$$

where $g_n(x) = \int_0^1 B'(sM_n(x) + (1-s)M_n(x-))\mathrm{d}s$. Therefore,

$$\int_{\mathbb{R}} \zeta(|x|^p)\mathrm{d}\partial_x(B(M_n)) \leq \|B'\|_\infty \int_{\mathbb{R}} \zeta(|x|^p)\mathrm{d}\mu_n(x) \leq C\|B'\|_\infty.$$

It follows from this and the properties of the function ζ that for any $k > 0$ large enough,

$$\int_{\{x:|x|\geq k\}} |x|^p \mathrm{d}\partial_x(B(M_n)) \leq \frac{k^p}{\zeta(k^p)} C\|B'\|_\infty.$$

That is, the sequence of probability measures $\partial_x(B(M_n))$ has uniformly integrable p-moments. Consequently, we can conclude from Proposition 7.1.5 in [2] that

$$\partial_x(B(M_n)) \to \partial_x(B(M))$$

in W_p, as desired. ∎

3.2. Convergence of the discrete problem. Following [7], we take a discrete probability measure

$$\rho_0^n := \sum_{j=1}^n m_j \delta_{x_j}, \quad x_1 < x_2 < \cdots < x_n,$$

and define

$$\rho^n(t,x) := \sum_{j=1}^n m_j \delta_{x_j(t)}, \tag{22}$$

where the characteristics are given by

$$x_j(t) = x_j + tv_j + \frac{t^2}{2} a_n\big(M_n(t, x_j(t)-)\big). \tag{23}$$

Here, as in the introduction, we have

$$a_n\big(M_n(t, x_j(t)-)\big) = \left[\alpha\left(\sum_{i=1}^j m_i - \frac{1}{2}m_j\right) + \beta\right].$$

We impose the adhesion dynamics at collision (see the introduction) and consider

$$M_n(t,x) := \sum_{j=1}^n m_j H\big(x - x_j(t)\big), \tag{24}$$

where H is the right continuous Heaviside function. Since M_n is piecewise constant, we need only show that M_n solves (4) by checking the Rankine–Hugoniot jump conditions across the shocks $x = x_j(t)$, i.e.,

$$\dot{x}_j(t) = \frac{\tilde{F}_n(t, M_n(t, x_j(t))) - \tilde{F}_n(t, M_n(t, x_j(t)-))}{M_n(t, x_j(t)) - M_n(t, x_j(t)-)}, \quad j = 1, \ldots, n. \tag{25}$$

Assume the masses m_i for $j_0 \leq i \leq j_1$, including m_j, are all amassed at time t. Then, exactly as in [7], we have

$$v_j(t) = \frac{F_n(M_n(t, x_j(t))) - F_n(M_n(t, x_j(t)-))}{M_n(t, x_j(t)) - M_n(t, x_j(t)-)}, \quad j = 1, \ldots, n,$$

where F_n is defined by

$$F_n(m) := \int_0^m f_n(\omega)\mathrm{d}\omega \quad \text{for } m \in [0,1].$$

Observe that $\tilde{F}_n(t,m) = F_n(m) + t\int_0^m a_n(\omega)\mathrm{d}\omega$ by the definition of $\tilde{F}_n$ in the introduction. The integrand below is constantly a_n^j on each interval of the form $[M_n(t,x_j(t)-), M_n(t,x_j(t)))$; thus,

$$a_n\big(M_n(t,x_j(t)-)\big)\sum_{i=j_0}^{j_1} m_i = \int_{M_n(t,x_j(t)-)}^{M_n(t,x_j(t))} a_n(\omega)\mathrm{d}\omega$$

implies (25). To prove that M_n is an entropy solution for (4), we check the entropy inequality

$$\dot{x}_j(t) \le \frac{\tilde{F}_n(t,X) - \tilde{F}_n(t,M_n(t,x_j(t)-))}{X - M_n(t,x_j(t)-)}, \tag{26}$$

where $X = \sum_{i\le k} m_i$, for some $j_0 \le k \le j_1$. The inequality

$$v_j(t) \le \frac{F_n(X) - F_n(M_n(t,x_j(t)-))}{X - M_n(t,x_j(t)-)}$$

is justified in [7] as a consequence of the *barycentric lemma* (which simply formulates the fact that if two groups of particles collide, then the averaged velocity of the group to the left decreases). Then we see that

$$a_n\big(M_n(t,x_j(t)-)\big)\sum_{i=j_0}^{k} m_i = \int_{M_n(t,x_j(t)-)}^{X} a_n(\omega)\mathrm{d}\omega,$$

which, together with the previous inequality, yields (26). We have just sketched the proof of the following proposition.

PROPOSITION 3.2. *The function M_n given by* (24) *is the entropy solution of the problem* (4).

Next we want to show that M_n converges in some sense to an entropy solution of (5). The following proposition applies if the initial approximating measures are of the form

$$\rho_0^n := \frac{1}{n}\sum_{i=1}^{n} \delta_{x_i^{(n)}}.$$

Note that section 3.1 shows that we may consider such approximations.

PROPOSITION 3.3. *Let $\rho_0 \in \mathcal{P}_2(\mathbb{R})$ and consider a sequence of discrete probabilities ρ_0^n as above such that $W_2\big(\rho_0,\rho_0^n\big) \to 0$ and*

$$\int_{\mathbb{R}} \zeta(v_0^2)\mathrm{d}\rho_0^n \to \int_{\mathbb{R}} \zeta(v_0^2)\mathrm{d}\rho_0 < +\infty, \ \int_{\mathbb{R}} \zeta(x^2)\mathrm{d}\rho_0^n \to \int_{\mathbb{R}} \zeta(x^2)\mathrm{d}\rho_0 < +\infty \tag{27}$$

for some nonnegative, convex, increasing function $\zeta \in C^1([0,+\infty))$ satisfying $\zeta(0) = 0$ and $\frac{\zeta(t)}{t} \uparrow +\infty$ as $t \to +\infty$. Let M_0^n and M_0 be the right continuous cumulative distribution functions of ρ_0^n and ρ_0, respectively. Consider, as above, the entropy

solutions M_n of (4) *for all* n. *Then there exists a Borel function* $M : [0,\infty)\times\mathbb{R} \to [0,1]$ *such that, for any given* $T > 0$,

$$\max_{0\le t\le T} W_2\left(\partial_x M_n(t,\cdot), \partial_x M(t,\cdot)\right) \to 0 \text{ and } \max_{0\le t\le T} \|M_n(t,\cdot) - M(t,\cdot)\|_{L^1(\mathbb{R})} \to 0. \tag{28}$$

Moreover, M *is the entropy solution of the problem* (5).

Proof. First recall that

$$\rho^n(t,x) := \frac{1}{n}\sum_{j=1}^n \delta_{x_j^{(n)}(t)},$$

where

$$x_j^{(n)}(t) = x_j^{(n)} + tv_j^{(n)} + \frac{t^2}{2}\left(\alpha\frac{2j-1}{2n} + \beta\right).$$

Let $\zeta_t(x) := \zeta(\frac{1}{\kappa}x)$, where κ is some positive constant depending only on t which will be determined later. Then, by the properties of ζ, we have

$$\begin{aligned}
&\int_{\mathbb{R}} \zeta_t(|x|^2)\mathrm{d}\rho_n(t,x)\\
&= \frac{1}{n}\sum_{j=1}^n \zeta\left(\frac{1}{\kappa}|x_j^{(n)}(t)|^2\right) \le \frac{1}{n}\sum_{j=1}^n \zeta\left(\frac{3}{\kappa}\left[|x_j^{(n)}|^2 + t^2|v_j^{(n)}|^2 + \frac{(|\alpha|+|\beta|)^2t^4}{4}\right]\right)\\
&\le \frac{1}{3}\zeta\left(\frac{9(|\alpha|+|\beta|)^2t^4}{4\kappa}\right) + \frac{1}{3n}\sum_{j=1}^n \zeta\left(\frac{9}{\kappa}|x_j^{(n)}|^2\right) + \frac{1}{3n}\sum_{j=1}^n \zeta\left(\frac{9t^2}{\kappa}|v_j^{(n)}|^2\right).
\end{aligned}$$

Hence, by choosing $\kappa = \max\{9, 9t^2\}$ and using again the fact that ζ is increasing, we obtain

$$\int_{\mathbb{R}} \zeta_t(|x|^2)\mathrm{d}\rho_n(t,x) \le C_t + \frac{1}{3}\int_{\mathbb{R}} \zeta(|x|^2)\mathrm{d}\rho_0^n(t,x) + \frac{1}{3}\int_{\mathbb{R}} \zeta(|v_0|^2)\mathrm{d}\rho_0^n(t,x) \le C_t$$

uniformly in n (the last inequality is due to (27)). Since ζ_t has superlinear growth (it is just an argument-rescaled version of ζ), there exists $\rho(t,\cdot) \in \mathcal{P}_2(\mathbb{R})$ such that, up to a subsequence that may depend on t, $W_2(\rho^n(t,\cdot), \rho(t,\cdot)) \to 0$ as $n \to \infty$. By a standard diagonal argument we can choose a subsequence independent of t satisfying $W_2(\rho^n(t,\cdot), \rho(t,\cdot)) \to 0$ for all $t \in [0,\infty)\cap\mathbb{Q}$. In order to see that this conclusion also holds for all t in $[0,\infty)$, we are going to show that the paths $\rho^n(t,\cdot)$ are uniformly locally Lipschitz in t. Indeed, let $T > 0$ and $t, s \in [0,T]$ be arbitrary. Then, since

$$|x_j^{(n)}(t) - x_j^{(n)}(s)|^2 \le C|t-s|^2\left(|v_j^{(n)}|^2 + T^2\right),$$

we have

$$\begin{aligned}
W_2^2(\rho^n(t,\cdot), \rho^n(s,\cdot)) &\le \frac{1}{n}\sum_{j=1}^n |x_j^{(n)}(t) - x_j^{(n)}(s)|^2 \le C|t-s|^2\left(\frac{1}{n}\sum_{j=1}^n |v_j^{(n)}|^2 + T^2\right)\\
&= C|t-s|^2\left(\int_{\mathbb{R}} |v_0(x)|^2\mathrm{d}\rho_0^n + T^2\right) \le C|t-s|^2 \quad \text{uniformly in } n.
\end{aligned}$$

Using this uniformly Lipschitz property, we can conclude that, in fact,

$$W_2(\rho^n(t,\cdot),\rho(t,\cdot)) \to 0 \text{ as } n\to\infty, \text{ uniformly in } t\in[0,T], \tag{29}$$

which yields (28) with $M(t,x) := \rho(t,(-\infty,x])$.

Next we show that M is a solution of (5). By the assumptions and Lemma 3.1, we have

$$\int_{\mathbb{R}} |M_0^n - M_0| \mathrm{d}x \to 0$$

and

$$\partial_x(B(M_0^n)) \to \partial_x(B(M_0)) \quad \text{in} \quad W_2$$

for any nondecreasing C^1 function B on $[0,1]$ satisfying $B(0)=0$ and $B(1)=1$. But as v_0 satisfies the assumption (H2), we obtain

$$\int_{\mathbb{R}} v_0(x)\mathrm{d}\partial_x(B(M_0^n)) \to \int_{\mathbb{R}} v_0(x)\mathrm{d}\partial_x(B(M_0)).$$

By the definitions of f_n and f, this means that

$$\int_0^1 f_n(m)B'(m)\mathrm{d}m \to \int_0^1 f(m)B'(m)\mathrm{d}m$$

for all nondecreasing C^1 functions B on $[0,1]$ satisfying $B(0)=0$ and $B(1)=1$. Indeed,

$$\begin{aligned}\int_{\mathbb{R}} v_0(x)\mathrm{d}\partial_x(B(M_0^n))(x) &= \sum_{i=1}^n v_0(x_i^{(n)})\left[B(M_0^n(x_i^{(n)})) - B(M_0^n(x_i^{(n)}-))\right] \\ &= \sum_{i=1}^n \int_{M_0^n(x_i^{(n)}-)}^{M_0^n(x_i^{(n)})} v_0\circ N_0^n(m)B'(m)\mathrm{d}m = \int_0^1 f_n(m)B'(m)\mathrm{d}m.\end{aligned}$$

For the continuous version we use (7) to conclude in a similar way. It then follows that

$$\int_0^1 f_n(m)g(m)\mathrm{d}m \to \int_0^1 f(m)g(m)\mathrm{d}m \quad \text{for all functions} \quad g\in C([0,1]).$$

This together with the fact

$$\int_0^1 |f_n(m)|\mathrm{d}m = \int_{\mathbb{R}} |v_0(x)|\mathrm{d}\rho_0^n \le C \quad \text{uniformly in } n$$

yields $f_n \to f$ weakly in L^1. By using the uniform convergence of $\tilde{F}_n$ to $\tilde{F}$ as continuous and bounded functions, we deduce that M is a solution of the problem (5). Now, for a fixed $t\ge 0$, let U be any C^1 function on $[0,1]$. Define

$$\tilde{F}_{n,U}(t,m) := \int_0^m \left[f_n(\omega) + ta_n(\omega)\right] U'(\omega)\mathrm{d}\omega,$$

$$\tilde{F}_U(t,m) := \int_0^m \left[f(\omega) + ta(\omega)\right] U'(\omega)\mathrm{d}\omega.$$

Then we use the uniform convergence of a_n to $\alpha\mathrm{id}+\beta$ and the facts that $f_n \to f$ weakly in L^1, and

$$\int_0^1 \zeta(|f_n|)\mathrm{d}m = \int_{\mathbb{R}} \zeta(|v_0|)\mathrm{d}\rho_0^n \le C \tag{30}$$

to deduce that $\tilde{F}_{n,U}$ converges to $\tilde{F}_U$ uniformly in $(t,m)\in[0,T]\times[0,1]$. (Notice that we have used the assumption (H2) to derive (30), the equi-integrability of the sequence $\{f_n\}$ in $L^1([0,1])$.) Therefore, as in [7], we conclude that M is, in fact, an entropy solution for (5). ∎

3.3. The existence result. We finally have all the necessary tools to prove Theorem 1.1. Note, however, that we leave out the proof of the fact that the initial conditions are satisfied. We will show that in Proposition 4.9.

Proof of Theorem 1.1. Since M is a solution of the problem (5) by Proposition 3.3, we can use Corollary 2.7 to conclude that $\partial_t M + v\partial_x M = 0$, where $v(t,\cdot) := g(t,\cdot) + t\psi(t,\cdot)$ is well defined $\partial_x M(t,\cdot) =: \rho(t,\cdot)$-a.e. By differentiation in the sense of distributions, we obtain the first equation in (1). Then, Corollary 2.7 also gives

$$\begin{aligned}\partial_t(\rho v) &= \partial_t\big[\partial_x[\tilde{F}(t,M)]\big] = \partial_x\big[\partial_t[\tilde{F}(t,M)]\big]\\ &= \partial_x[v\partial_t M + \Psi(M)] = \partial_x(-v^2\rho) + \psi\rho.\end{aligned}$$

Note that, in our case, $\Psi(m) = \alpha m^2/2 + \beta m$. Thus,

$$\psi(t,x) = \beta + \alpha\int_0^1 [(1-s)M(t,x-) + sM(t,x)]\mathrm{d}s = \beta + \alpha\left[M(t,x) - \frac{1}{2}\rho(t,\{x\})\right].$$

Since $\partial_x M(t,\cdot) = \rho(t,\cdot)$ and $\rho(t,\cdot)$ has at most countably many atoms, we may take $\Phi(t,x) = \int_{-\infty}^x M(t,y)\mathrm{d}y$ to conclude. ∎

Remark 3.4. Note that the term $M(t,x) - \frac{1}{2}\rho(t,\{x\})$ is precisely the *barycentric projection* [2] onto $\rho(t,\cdot)$ of the *optimal coupling* between $\chi_{(0,1)}$ and $\rho(t,\cdot)$. It differs from the projection considered in [13] by an additive factor of 0.5 due to the fact that, instead of $\chi_{(0,1)}$, the reference measure in [13] was $\chi_{(-0.5,0.5)}$.

4. Time regularity, entropy condition, and shocks. In this section we discuss some qualitative properties of the "sticky particle" solution. The family of absolutely continuous curves in $\mathcal{P}_2(\mathbb{R})$ is central to our approach. Thus, recall that $(\mathcal{P}_2(\mathbb{R}), W_2)$ is a Polish space on which we define absolutely continuous curves by saying that $[0,T]\ni t\to\mu_t\in\mathcal{P}_2(\mathbb{R})$ lies in $AC^2(0,T;\mathcal{P}_2(\mathbb{R}))$ provided that there exists $f\in L^2(0,T)$ such that $W_2(\mu_t,\mu_{t+h})\le\int_t^{t+h} f(s)ds$ for all $0<t<t+h<T$.

4.1. The solution path is locally Lipschitz. First we show that our solution path is locally Lipschitz.

PROPOSITION 4.1. *The solution path $t\to\rho(t,\cdot)$ satisfies the following:*

(i) *For any $0<T<+\infty$, we have*

$$W_2(\rho(t,\cdot),\rho(s,\cdot)) \le C_T|t-s| \quad \textit{for all } t,s\in[0,T].$$

(ii) *The energy is nonincreasing, i.e.,*

$$\int_{\mathbb{R}} |v(t,x)|^2\mathrm{d}\rho(t,x) \le \int_{\mathbb{R}} |v_0(x)|^2\mathrm{d}\rho_0(x) \quad \textit{for all } t\ge 0.$$

Proof. Recall that $\rho^n(t,\cdot)$ are uniformly Lipschitz in n and t. Thus, by the triangle inequality,

$$W_2(\rho(t,\cdot),\rho(s,\cdot)) \le W_2(\rho(t,\cdot),\rho^n(t,\cdot)) + C|t-s| + W_2(\rho^n(s,\cdot),\rho(s,\cdot)).$$

Therefore, by letting n go to infinity and using Proposition 3.3, we obtain (i). Also as $v_n(t,\cdot)\rho^n(t,\cdot) \to v(t,\cdot)\rho(t,\cdot)$ weakly for each t, we deduce that

$$\int_{\mathbb{R}} |v(t,x)|^2 \mathrm{d}\rho(t,x) \le \liminf_{n\to\infty} \int_{\mathbb{R}} |v_n(t,x)|^2 \mathrm{d}\rho^n(t,x) \le \liminf_{n\to\infty} \int_{\mathbb{R}} |v_0(x)|^2 \mathrm{d}\rho_0^n(x)$$

$$= \int_{\mathbb{R}} |v_0(x)|^2 \mathrm{d}\rho_0(x). \qquad \square$$

Remark 4.2. As a consequence of Proposition 4.1, we have $\rho \in AC^2(0,T;\mathcal{P}_2(\mathbb{R}))$.

We now recall a result, slightly modified, proved in [13].

PROPOSITION 4.3. *Suppose $\sigma \in AC^2(0,T;\mathcal{P}_2(\mathbb{R}))$. Let v be the velocity of minimal norm associated to σ and $N(t,\cdot):(0,1)\to\mathbb{R}$ be the monotone nondecreasing map such that $N(t,\cdot)_{\#}\chi_{(0,1)} = \sigma(t,\cdot)$. For each t, modifying $N(t,\cdot)$ on a countable subset of $(0,1)$ if necessary, we may assume w.l.o.g. that $N(t,\cdot)$ is right continuous. Then, $N \in H^1(0,T;L^2(0,1))$ and*

$$\dot{N}(t,x) = v(t,N(t,x)) \tag{31}$$

for $\mathcal{L}^2$-a.e. $(t,x)\in(0,T)\times(0,1)$.

Note that the *minimal norm* assumption is, in fact, redundant. Indeed, we prove the following lemma.

LEMMA 4.4. *Consider the path $t\to\mu\in AC^2(0,T;\mathcal{P}_2(\mathbb{R}))$ for some $0<T<+\infty$. Then the velocity defined in* [2] *(called "of minimal norm") is the unique velocity along the curve μ in the following sense: if*

$$\partial_t\mu + \partial_x(\mu v_i) = 0 \text{ in } \mathcal{D}'([0,T]\times\mathbb{R}),\ i=1,2,$$

for some v_i Borel measurable in (t,x) such that $v_i(t,\cdot)\in L^2(\mu(t,\cdot))$ for Lebesgue a.e. $t\in(0,T)$, then for Lebesgue a.e. $t\in(0,T)$ we have $v_1(t,\cdot)\equiv v_2(t,\cdot)$ in the $\mu(t,\cdot)$-a.e. sense.

Proof. By subtraction and by taking test functions $\varphi(t,x)=\xi(t)\zeta(x)$, the equations above readily yield

$$\int_{\mathbb{R}} u(t,x)\zeta'(x)\mathrm{d}\mu(t,x) = 0 \text{ for a.e. } t\in(0,T) \text{ and any } \zeta\in C_c^1(\mathbb{R}),$$

where $u := v_1 - v_2$. Fix $\varepsilon>0$ and $\phi\in C_c(\mathbb{R})$. If $\phi=0$ on $[R,+\infty)$, consider, for each natural number $n>R$, the function

$$\Phi_n(x) := \begin{cases} \int_{-\infty}^x \phi(y)\mathrm{d}y & \text{if } x<n,\\ \omega(x-n) & \text{if } n\le x\le n+1,\\ 0 & \text{if } x>n+1, \end{cases} \tag{32}$$

where $\omega\in C^1[0,1]$ such that $\omega(0)=\int_{-\infty}^R\phi(y)\mathrm{d}y$, $\omega(1)=0$, and $\omega'(0)=0=\omega'(1)$. Clearly, $\Phi_n\in C_c^1(\mathbb{R})$. Thus,

$$\int_{\mathbb{R}} u(t,x)\phi(x)\mathrm{d}\mu(t,x) + \int_n^{n+1} u(x,t)\omega'(x-n)\mathrm{d}\mu(t,x) = 0 \text{ for a.e. } t\in(0,T).$$

We have $|\omega'(x-n)| \le \|\omega'\|_{L^\infty(0,1)} =: C$ for all $n > R$ and all $x \in (n, n+1)$. Since $\mu(t,\cdot)$ is a Borel probability for Lebesgue a.e. $t \in (0,T)$, we conclude that for such t we have

$$\left| \int_{\mathbb{R}} u(t,x)\phi(x) \mathrm{d}\mu(t,x) \right| \le C\|u(t,\cdot)\|_{L^2(\mu(t,\cdot))}\mu(t,[n,n+1])^{1/2} \le \varepsilon$$

if n is sufficiently large. Due to the arbitrariness of ε and ϕ, the proof is concluded. ∎

Remark 4.5. Note that, in fact, we have just proved that $\{\varphi' : \varphi \in C_c^\infty(\mathbb{R})\}$ is dense in $L^2(\mu)$, *even though* μ may not necessarily have finite p-order moment (for any $p > 0$). Also, as a consequence, the tangent space $\mathcal{T}_\mu\mathcal{P}_2(\mathbb{R})$ [2] is the whole $L^2(\mu)$. This property was brought to our attention by W. Gangbo.

4.2. Recovery of the entropy condition. We shall now prove that the solution we obtained for (1) in the $\alpha = 0 = \beta$ case satisfies the *Oleinik entropy condition*.

THEOREM 4.6. *For Lebesgue a.e.* $t \in (0,T)$ *we have*

$$v(t,x_2) - v(t,x_1) \le \frac{1}{t}(x_2 - x_1) \text{ for } \rho(t,\cdot)\text{-a.e. } x_1 \le x_2. \tag{33}$$

Proof. Let us look back at the discrete problem. Note that

$$N_n(t,\omega) := x_j(t) \text{ whenever } M_n(t,x_j(t)-) \le \omega < M_n(t,x_j(t))$$

is the optimal map such that $N_n(t,\cdot)_{\#\chi_{(0,1)}} = \rho^n(t,\cdot)$. It is known [7], [15] that the discrete problem satisfies the Oleinik entropy condition, i.e.,

$$t\big[v_n(t,x_{i_2}(t)) - v_n(t,x_{i_1}(t))\big] \le x_{i_2}(t) - x_{i_1}(t) \text{ whenever } i_1 \le i_2.$$

Since $v_n(t,x_j(t)) = \dot{x}_j(t)$ away from collision times, we infer that the map $t \to \big[x_{i_2}(t) - x_{i_1}(t)\big]/t$ is piecewise nonincreasing. But this map is continuous, so it is globally nonincreasing, and, due to the definition of N_n, it follows that

$$t \to \frac{1}{t}\big[N_n(t,\omega_2) - N_n(t,\omega_1)\big] \tag{34}$$

is nonincreasing in $(0,T)$ for all $\omega_1 \le \omega_2 \in (0,1)$. Now let $\Delta := \{\omega = (\omega_1,\omega_2) \in [0,1]^2 : \omega_1 \le \omega_2\}$ and $S_n(t,\omega) = N_n(t,\omega_2) - N_n(t,\omega_1)$ be defined on $[0,T]\times\Delta$. It is easy to see that $S_n \in H^1(0,T;L^2(\Delta))$ and that (34) implies

$$\int_0^T\int_\Delta \frac{S_n(t,\omega)}{t}\partial_t\varphi(t,\omega)\mathrm{d}\omega\mathrm{d}t \ge 0 \text{ for all nonnegative } \varphi \in C_c^\infty((0,T)\times\Delta). \tag{35}$$

On the other hand, due to (28), we infer that

$$\|N_n - N\|_{L^1((0,T)\times(0,1))} = \int_0^T W_1(\rho^n(t,\cdot),\rho(t,\cdot))\mathrm{d}t \to 0,$$

where $N(t,\cdot)$ is the optimal map such that $N(t,\cdot)_{\#\chi_{(0,1)}} = \rho(t,\cdot)$. In particular, $(S_n/t) \to (S/t)$ in $\mathcal{D}'((0,T)\times\Delta)$, where $S(t,\omega) = N(t,\omega_2) - N(t,\omega_1)$ if $\omega \in \Delta$. Thus, (35) implies

$$\int_0^T\int_\Delta \frac{S(t,\omega)}{t}\partial_t\varphi(t,\omega)\mathrm{d}\omega\mathrm{d}t \ge 0 \text{ for all nonnegative } \varphi \in C_c^\infty((0,T)\times\Delta).$$

Therefore, $\partial_t[S/t] \le 0$ in the distributional sense, which implies $t\dot{S} - S \le 0$ in the $\mathcal{L}^3$-a.e. sense, i.e.,

$$\dot{N}(t,\omega_2) - \dot{N}(t,\omega_1) \le \frac{1}{t}\big[N(t,\omega_2) - N(t,\omega_1)\big] \text{ for Lebesgue a.e. } (t,\omega) \in (0,T)\times\Delta.$$

Consequently, (31) yields

$$v(t,N(t,\omega_2)) - v(t,N(t,\omega_1)) \le \frac{1}{t}\big[N(t,\omega_2) - N(t,\omega_1)\big] \text{ for } \mathcal{L}^3\text{-a.e. } (t,\omega) \in (0,T)\times\Delta,$$

which, due to $N(t,\cdot)_{\#}\chi_{(0,1)} = \rho(t,\cdot)$, implies (33). ∎

4.3. Formation of shocks. Now let us assume that ρ_0 is atom-free and take N_0 to be the optimal map pushing $\chi_{(0,1)}$ forward to ρ_0.

PROPOSITION 4.7. *Let* $T := \sup\{t \in [0,\infty) : \mathrm{id} + tv_0$ *is nondecreasing on* $\mathrm{spt}(\rho_0)\}$. *If* $T = 0$, *then the solution develops atomic singularities instantaneously. If* $0 < T < +\infty$, *then the solution remains nonatomic before* T *and develops atomic singularities instantaneously after* T. *If* $T = +\infty$, *then the solution is atom-free at all times.*

Proof. Let us treat the case $0 < T < +\infty$. Indeed, it will become clear that the other two cases can be handled almost identically. Note that, due to the definition of T and the fact that ρ_0 is nonatomic, $\mathrm{id} + tv_0$ is (strictly) increasing on $\mathrm{spt}(\rho_0)$ for $t \in [0,T)$. Thus, $N_0 + tv_0 \circ N_0$ is increasing on $(0,1)$ for $t \in [0,T)$. It follows that

$$\bar{M}(t,\cdot) := (N_0 + tv_0 \circ N_0)^{-1} = M_0 \circ (\mathrm{id} + tv_0)^{-1}$$

is the entropy solution (given by characteristics) of

$$\partial_t \bar{M} + \partial_x[F(\bar{M})] = 0, \quad \bar{M}(0,\cdot) = M_0,$$

where $F' = v_0 \circ N_0$, $F(0) = 0$. Due to uniqueness of the entropy solution, we get $\bar{M} \equiv M$. Thus, $\rho(t,\cdot) = (\mathrm{id} + tv_0)_{\#}\rho_0$ for $t \in [0,T]$ (this is precisely the geodesic connecting ρ_0 and ρ_T in $\mathcal{P}_2(\mathbb{R})$). Again, since $\mathrm{id}+tv_0$ is (strictly) increasing on $\mathrm{spt}(\rho_0)$ for $t \in [0,T)$, we deduce that $\rho(t,\cdot)$ has no atoms if $t \in [0,T)$. To conclude, we argue by contradiction and suppose that $\rho(t,\cdot)$ is atom-free on $[0,T+\epsilon]$ for some $\epsilon > 0$. Thus, $M(t,\cdot)$ is continuous, and so $v(t,\cdot) = v_0 \circ N_0 \circ M(t,\cdot)$ for all $t \in [0,T+\epsilon]$. Since $M(t,\cdot)$ is now the optimal map pushing $\rho(t,\cdot)$ forward to $\chi_{(0,1)}$, we infer that

$$v(t,N(t,m)) = v_0 \circ N_0 \circ M(t,N(t,m)) = v_0 \circ N_0(m) \text{ a.e. } m \in (0,1),$$

which, in light of (31), yields $\dot{N}(t,m) = v_0 \circ N_0(m)$ for a.e. $(t,m) \in (0,T+\epsilon)\times(0,1)$. Thus, as an $H^1(0,T+\epsilon;L^2(0,1))$ map, $N(t,\cdot) = N_0 + tv_0 \circ N_0$. In particular, we obtain that $\mathrm{id}+tv_0$ is nondecreasing on the support of ρ_0 for all $t \in [0,T+\epsilon]$, which contradicts the definition of T. Therefore, the solution becomes atomic instantaneously after T. ∎

Remark 4.8. What happens at $t = T$ depends on whether or not $\mathrm{id} + Tv_0$ has "flat spots" on $\mathrm{spt}(\rho_0)$. It is easy to construct examples illustrating that each of these situations may occur.

4.4. Continuity of the energy and a remark on uniqueness.

PROPOSITION 4.9. *Suppose* (ρ_0, v_0) *satisfies the conditions* (H1) *and* (H2). *Let* (ρ, v) *be the weak solution to the system* (1) *given in the proof of Theorem* 1.1 *in subsection* 3.3. *Then* (ρ, v) *has the following property:*

$$\lim_{t\to 0^+} \int_{\mathbb{R}} v(t,x)\varphi(x)\mathrm{d}\rho(t,x) = \int_{\mathbb{R}} v_0(x)\varphi(x)\mathrm{d}\rho_0(x) \quad \textit{for all} \quad \varphi \in C_b(\mathbb{R}), \tag{36}$$

which shows that the initial condition for the velocity is satisfied. Moreover, we have

$$\lim_{t\to 0^+}\int_{\mathbb{R}} v^2(t,x)\varphi(x)\mathrm{d}\rho(t,x)=\int_{\mathbb{R}} v_0^2(x)\varphi(x)\mathrm{d}\rho_0(x)\quad \textit{for all}\quad \varphi\in C_b(\mathbb{R}). \tag{37}$$

Proof. Due to $\|M(t,\cdot)-M_0\|_{L^1(\mathbb{R})}=W_1(\rho(t,\cdot),\rho_0)\to 0$ and the BV calculus, we have for any function $\varphi\in C_c^\infty(\mathbb{R})$

$$\begin{aligned}\lim_{t\to 0^+}\int_{\mathbb{R}} v(t,x)\varphi(x)\mathrm{d}\rho(t,x)&=-\lim_{t\to 0^+}\int_{\mathbb{R}}\varphi'(x)F(M(t,x))\mathrm{d}x\\&=-\int_{\mathbb{R}}\varphi'(x)F(M_0(x))\mathrm{d}x=\int_{\mathbb{R}}\varphi(x)g(x)\mathrm{d}\rho_0(x),\end{aligned} \tag{38}$$

where $g(x)$ is given by

$$g(x)=\int_0^1 v_0\circ N_0\left((1-s)M_0(x-)+sM_0(x)\right)\mathrm{d}s,\quad x\in\mathbb{R}.$$

We claim that $N_0\left((1-s)M_0(x-)+sM_0(x)\right)=x$ for ρ_0-a.e. $x\in\mathbb{R}$. Indeed, if a point x satisfies $\rho_0(\{x\})\neq 0$, then M_0 has a jump at x. Therefore, it is clear in this case that

$$N_0\left((1-s)M_0(x-)+sM_0(x)\right)=\inf\left\{z: M_0(z)>(1-s)M_0(x-)+sM_0(x)\right\}=x.$$

As M_0 has at most countably many "flat spots," the claim shall be proved if we can show that $g(x)=v_0(x)$ whenever x satisfies $x\in\mathrm{spt}(\rho_0)$, $\rho_0(\{x\})=0$ and x is not one of the endpoints of some flat spot of M_0. To see this is true, let x be a point with such properties. Then there exists $\epsilon>0$ such that the function M_0 is strictly increasing on $(x-\epsilon,x+\epsilon)$. It follows that

$$N_0\left((1-s)M_0(x-)+sM_0(x)\right)=N_0\left(M_0(x)\right)=x.$$

Thus, we obtain the claim, which in turn yields $g(x)=v_0(x)$ for ρ_0-a.e. $x\in\mathbb{R}$. Hence, by combining this with (38), we get

$$\lim_{t\to 0^+}\int_{\mathbb{R}} v(t,x)\varphi(x)\mathrm{d}\rho(t,x)=\int_{\mathbb{R}} v_0(x)\varphi(x)\mathrm{d}\rho_0(x)\quad\text{for all}\quad\varphi\in C_c^\infty(\mathbb{R}).$$

By a simple approximation and the fact that $\|v_0\|_{L^2(\rho_0)}$ is finite, this gives (36). As a consequence of (36) and the fact that the energy is nonincreasing which was proved in Proposition 4.1, we obtain (see, e.g., Theorem 5.4.4 in [2])

$$\lim_{t\to 0^+}\int_{\mathbb{R}} v^2(t,x)\mathrm{d}\rho(t,x)=\int_{\mathbb{R}} v_0^2(x)\mathrm{d}\rho_0(x).$$

In addition, we have $W_2(\rho(t,\cdot),\rho_0)\le Ct$ from Proposition 4.1. Therefore, by using Proposition 7.1.5 and Theorem 5.4.4 in [2] we can conclude that (37) holds. ∎

We end the paper by the following remark on the uniqueness of the solution.

Remark 4.10. If we assume, in addition, that v_0 is bounded, then the weak solution (ρ,v) constructed above is the unique weak solution satisfying the entropy condition in Theorem 4.6 and the weak convergence of $v^2(t,\cdot)\,\rho(t,\cdot)$ to $v_0^2\rho_0$ (such a weak solution is called an entropy solution for pressureless gases [16]). This fact follows directly from Theorem 4.6, Proposition 4.9, and the uniqueness result in [16]. Thus, if $v_0\in C_b(\mathbb{R})$, we have proved that any entropy solution to the pressureless gases system can be obtained as a weak limit of sticky particles. We note that a similar result was obtained by Bouchut and James in [5] for duality solutions.

Acknowledgments. The authors would like to thank W. Gangbo, R. Pan, and A. Swiech for numerous and fruitful discussions. We are also grateful to both anonymous referees for their helpful comments and suggestions.

SPREADING SPEEDS AND TRAVELING WAVES FOR NONMONOTONE INTEGRODIFFERENCE EQUATIONS*

SZE-BI HSU† AND XIAO-QIANG ZHAO‡

Abstract. The spreading speeds and traveling waves are established for a class of nonmonotone discrete-time integrodifference equation models. It is shown that the spreading speed is linearly determinate and coincides with the minimal wave speed of traveling waves.

Key words. integrodifference equations, nonmonotone integral operators, spreading speeds, linear determinacy, traveling waves

DOI. 10.1137/070703016

1. Introduction.

The invasion speed is a fundamental characteristic of biological invasions, since it describes the speed at which the geographic range of the population expands; see, e.g., [6, 8, 9, 15] and references therein. Aronson and Weinberger [1, 2] first introduced the concept of the asymptotic speed of spread (in short, spreading speed) for reaction-diffusion equations and showed that it coincides with the minimal wave speed for traveling waves under appropriate assumptions. Weinberger [20] and Lui [13] established the theory of spreading speeds and monostable traveling waves for monotone (order-preserving) operators. This theory has been greatly developed recently in [21, 10, 11, 12] to monotone semiflows so that it can be applied to various discrete- and continuous-time evolution equations admitting the comparison principle.

It is known that many discrete- and continuous-time population models with spatial structure are not monotone. For example, scalar discrete-time integrodifference equations with nonmonotone growth functions, and predator-prey type reaction-diffusion systems are among such models. The spreading speeds were obtained for some nonmonotone continuous-time integral equations and time-delayed reaction-diffusion models in [17, 19], and a general result on the nonexistence of traveling waves was also given in [19, Theorem 3.5]. The existence of monostable traveling waves was established for several classes of nonmonotone time-delayed reaction-diffusion equations in [22, 4, 16, 14]. For certain types of nonmonotone discrete-time integrodifference equation models, nonmonotone traveling waves and even traveling cycles were observed in [7] by numerical simulations. In [7, 9, 15, 8], the monotone linear systems, resulting from the linearization of the nonmonotone discrete-time models at zero, were used to estimate spreading speeds. It is worthy to find sufficient conditions under which the spreading speed is linearly determinate for these nonmonotone systems.

The purpose of our current paper is to study the spreading speeds and traveling waves for nonmonotone discrete-time systems. As a starting point, we consider scalar integrodifference equations with nonmonotone growth functions. The key techniques are to sandwich the given growth function in between two appropriate nondecreasing functions (for spreading speeds) and to construct a closed and convex subset in an appropriate Banach space (for traveling waves). Consequently, we obtain a set of sufficient conditions for the existence of the spreading speed, and the existence and nonexistence of traveling waves. It turns out that the spreading speed is linearly determinate and coincides with the minimal wave speed of traveling waves for this class of nonmonotone discrete-time integrodifference equation population models.

The rest of this paper is organized as follows. In section 2, we first present a general result for monotone integrodifference equations, then we establish the spreading speed c^* by the comparison method and a fluctuation type argument. In section 3, we use the Schauder fixed point theorem to obtain the existence of traveling waves with the wave speed $c > c^*$. The property of the spreading speed is employed to prove the asymptotic property of the wave profile at $+\infty$ and the nonexistence of traveling waves with $c < c^*$. A limiting argument gives the existence of the traveling wave with the wave speed c^*. Section 4 is aimed at the applications of the main results to three types of growth functions arising from population biology.

2. Spreading speeds. Let $\mathcal{C}$ be the space of all bounded and continuous functions from $\mathbb{R}$ to $\mathbb{R}$ equipped with the compact open topology. For a given number $r > 0$, let $\mathcal{C}_r := \{\phi \in \mathcal{C} : 0 \le \phi(x) \le r, \forall x \in \mathbb{R}\}$.

Let $k(x)$ be a nonnegative Lebesgue measurable function on $\mathbb{R}$. Throughout this paper, we assume that the kernel $k(x)$ has the following property:

(K) $\int_{\mathbb{R}} k(y)dy = 1$, $k(-y) = k(y)$, $\forall y \in \mathbb{R}$, and $\int_{\mathbb{R}} e^{-\alpha y}k(y)dy < \infty$, $\forall \alpha \in [0, \Delta)$, where $\Delta > 0$ is the abscissa of convergence and it may be infinity.

We consider a discrete-time integrodifference equation

$$u_{n+1}(x) = \int_{\mathbb{R}} h(u_n(y))k(x-y)dy, \ x \in \mathbb{R}, \ n \ge 0 \tag{2.1}$$

with $u_0 \in \mathcal{C}$. Assume that there exists $\beta > 0$ such that

(H1) $h \in C([0,\beta],[0,\beta])$, $h(0) = 0$, $h'(0) > 1$, $h(\beta) = \beta$, and there is $L_0 > 0$ such that $|h(u_1) - h(u_2)| \le L_0|u_1 - u_2|$, $\forall u_1, u_2 \in [0,\beta]$.

(H2) $u < h(u) \le h'(0)u$, $\forall u \in (0,\beta)$, and $h(u)$ is nondecreasing in $u \in [0,\beta]$.

Let $U(x)$ be a continuous function on $\mathbb{R}$. We say $U(x + cn)$ is a traveling wave solution of (2.1) with the wave speed c if $u_n(x) = U(x + cn)$, $\forall n \ge 0$, satisfies (2.1), and $U(x + cn)$ connects 0 to β if $U(-\infty) = 0$ and $U(+\infty) = \beta$. It is easy to see that $U(x + cn)$ is a traveling wave solution of (2.1) if and only if

$$U(\xi) = \int_{\mathbb{R}} h(U(\xi - c - y))k(y)dy, \quad \forall \xi \in \mathbb{R}.$$

Define

$$c_h^* = \inf_{\mu \in (0,\Delta)} \frac{\ln\left(h'(0)\int_{\mathbb{R}} e^{-\mu y}k(y)dy\right)}{\mu}. \tag{2.2}$$

The following result is essentially due to Weinberger [20], and shows that c_h^* is not only the spreading speed but also the minimal wave speed of monotone traveling waves for system (2.1).

THEOREM 2.1. *Let* (H1) *and* (H2) *hold. Then the following statements are valid:*

(i) *For any $u_0 \in \mathcal{C}_\beta$ with compact support, the solution of* (2.1) *satisfies*

$$\lim_{n\to\infty, |x|\geq cn} u_n(x) = 0, \ \forall c > c_h^*.$$

(ii) *For any $u_0 \in \mathcal{C}_\beta \setminus \{0\}$, the solution of* (2.1) *satisfies*

$$\lim_{n\to\infty, |x|\leq cn} u_n(x) = \beta, \ \forall c \in (0, c_h^*).$$

(iii) *For any $c \geq c_h^*$,* (2.1) *has a traveling wave $U(x + cn)$ connecting 0 to β such that $U(x)$ is nondecreasing in x, and for any $c \in (0, c_h^*)$,* (2.1) *has no traveling wave $U(x + cn)$ connecting 0 to β.*

Proof. The existence of the spreading speed, together with the formula (2.2), and traveling waves is a straightforward consequence of [20, Theorems 6.1–6.6] in the case where $\Delta = +\infty$, and [11, Theorem 2.11 and Theorem 2.15] with $\tau = 0$ in the case where $\Delta < +\infty$. Indeed, the proof of [11, Theorem 3.10] implies that [11, Theorem 3.10] with $\inf_{\mu>0} \Phi(\mu)$ replaced by $\inf_{0<\mu<\Delta} \Phi(\mu)$ is still valid, provided that (C5) holds for all $\mu_1, \mu_2 \in (-\Delta, \Delta)$ and $\Phi(\mu)$ assumes its minimum value at $\mu^* \in (0, \Delta)$. Thus, the formula (2.2) also holds in the case where $\Delta < +\infty$. By [11, Theorem 3.5], it follows that the number $r = r_\sigma$ in [11, Theorem 2.15] can be chosen to be independent of $\sigma > 0$. For any $u_0 \in \mathcal{C}_\beta \setminus \{0\}$, it is easy to show that there exists an integer $n_0 \geq 1$ such that $u_{n_0}(x) > 0$ for x in an interval of length greater $2r$. Taking $u_{n_0}(x)$ as a new initial data, we see that conclusion (ii) holds. The nonexistence of traveling waves is implied by conclusion (ii) (see also [11, Theorem 4.1]). □

Next we consider the discrete-time integrodifference equation

$$u_{n+1}(x) = \int_{\mathbb{R}} f(u_n(y))k(x-y)dy, \quad x \in \mathbb{R}, \ n \geq 0 \tag{2.3}$$

with $u_0 \in \mathcal{C}$. Assume that there exists $b > 0$ such that

(F1) $f \in C([0, b], [0, b])$, $f(0) = 0$, $f'(0) > 1$, and there is $L > 0$ such that $|f(u_1) - f(u_2)| \leq L|u_1 - u_2|$, $\forall u_1, u_2 \in [0, b]$.

(F2) $f(u) \leq f'(0)u$, $\forall u \in [0, b]$, and there is $u^* \in (0, b]$ such that $f(u^*) = u^*$, $f(u) > u$, $\forall u \in (0, u^*)$, and $0 < f(u) < u$, $\forall u \in (u^*, b]$.

Define

$$f^+(u) = \max_{0\leq v\leq u} f(v), \quad f^-(u) = \min_{u\leq v\leq b} f(v), \quad \forall u \in [0, b].$$

It then follows that

$$f^-(u) \leq f(u) \leq f^+(u), \ \forall u \in [0, b],$$

that both f^+ and f^- are nondecreasing and Lipschitz continuous, with the Lipschitz constant L, on $[0, b]$, and that there exists $\delta_0 \in (0, b]$ such that $f^\pm(u) = f(u)$, $\forall u \in [0, \delta_0]$. Let $u_\pm^*$ be such that $f^\pm(u_\pm^*) = u_\pm^*$. Then $0 < u_-^* \leq u^* \leq u_+^* \leq b$.

To obtain the upward convergence as stated in Theorem 2.1 (ii), we need to impose one of the following two additional conditions on f.

(C1) $u^* = b$ and $f(u)$ is nondecreasing in $u \in [b - \epsilon_0, b]$ for some $\epsilon_0 \in (0, b)$.

(C2) $\frac{f(u)}{u}$ is strictly decreasing for $u \in (0, b]$, and $f(u)$ has the property (P) that for any $v, w \in (0, b]$ satisfying $v \leq u^* \leq w$, $v \geq f(w)$ and $w \leq f(v)$, we have $v = w$.

Motivated by the proofs of [17, Theorems 2.9 and 2.12], we have the following observation.

LEMMA 2.1. *Either of the following two conditions is sufficient for the property* (P) *in condition* (C2) *to hold:*

(P1) $uf(u)$ *is strictly increasing for* $u \in (0, b]$.

(P2) $f(u)$ *is nonincreasing for* $u \in [u^*, b]$, *and* $\frac{f^2(u)}{u}$ *is strictly decreasing for* $u \in (0, u^*]$.

Proof. Let $v, w \in (0, b]$ be given such that $v \le u^* \le w$, $v \ge f(w)$, and $w \le f(v)$. In the case where (P1) holds, since $vf(v) \ge f(w)f(v) \ge wf(w)$, it follows that $v \ge w$, and hence $v = w$. In the case where (P2) holds, we have $v \ge f(w) \ge f(f(v)) = f^2(v)$, and hence, $\frac{f^2(v)}{v} \le 1 = \frac{f^2(u^*)}{u^*}$. It then follows that $v \ge u^*$, and hence, $v = u^*$. Since $u^* \le w \le f(v) = f(u^*) = u^*$, we further have $w = u^* = v$. ∎

Now we are in a position to prove the main result of this section.

THEOREM 2.2. *Let* (F1) *and* (F2) *hold and* c_f^* *be defined as in* (2.2) *with* $h = f$. *Then the following statements are valid:*

(1) *For any* $u_0 \in \mathcal{C}_{u_+^*}$ *with compact support, the solution of* (2.3) *satisfies*

$$\lim_{n\to\infty, |x|\ge cn} u_n(x) = 0, \ \forall c > c_f^*.$$

(2) *For any* $u_0 \in \mathcal{C}_{u_+^*} \setminus \{0\}$, *the solution of* (2.3) *satisfies*

$$u_-^* \le \liminf_{n\to\infty, |x|\le cn} u_n(x) \le \limsup_{n\to\infty, |x|\le cn} u_n(x) \le u_+^*, \ \forall c \in (0, c_f^*).$$

(3) *If, in addition, either* (C1) *or* (C2) *holds, then for any* $u_0 \in \mathcal{C}_{u_+^*} \setminus \{0\}$, *the solution of* (2.3) *satisfies*

$$\lim_{n\to\infty, |x|\le cn} u_n(x) = u^*, \ \forall c \in (0, c_f^*).$$

Proof. For convenience, let $c^* = c_f^*$. Define

$$Q(\phi)(x) = \int_{\mathbb{R}} f(\phi(x-y))k(y)dy, \quad Q^{\pm}(\phi)(x) = \int_{\mathbb{R}} f^{\pm}(\phi(x-y))k(y)dy.$$

Clearly, $Q^{\pm}$ is monotone (order preserving) on $\mathcal{C}_b$ and

$$Q^-(\phi) \le Q(\phi) \le Q^+(\phi), \quad \forall \phi \in \mathcal{C}_b.$$

By Theorem 2.1, it follows that c^* is the spreading speed for the discrete-time system $u_{n+1} = Q^{\pm}(u_n)$ on $\mathcal{C}_{u_\pm^*}$.

Case 1. For a given $\phi \in \mathcal{C}_{u_+^*}$ with compact support, let $u_n = Q^n(\phi)$, $u_n^+ = (Q^+)^n(\phi)$, $\forall n \ge 0$. By the comparison principle (see, e.g., [20, Proposition 4.1]), we have

$$0 \le u_n(x) \le u_n^+(x), \quad \forall x \in \mathbb{R}, \ n \ge 0.$$

For any $c > c^*$, Theorem 2.1 (i) implies that $\lim_{n\to\infty, |x|\ge cn} u_n^+(x) = 0$, and hence $\lim_{n\to\infty, |x|\ge cn} u_n(x) = 0$.

Case 2. For a given $\phi \in \mathcal{C}_{u_+^*} \setminus \{0\}$, define $\psi(x) = \min(\phi(x), u_-^*)$. Then $\psi \in \mathcal{C}_{u_-^*} \setminus \{0\}$. Let $u_n^- = (Q^-)^n(\psi)$, $\forall n \ge 0$. Since $\psi \le \phi$, it follows from the comparison principle that

$$0 \le u_n^-(x) \le u_n(x) \le u_n^+(x), \quad \forall x \in \mathbb{R}, \ n \ge 0.$$

For any $c \in (0, c^*)$, Theorem 2.1 (ii) implies that $\lim_{n\to\infty, |x|\le cn} u_n^{\pm}(x) = u_{\pm}^*$. Thus, we have

$$u_-^* \le \liminf_{n\to\infty, |x|\le cn} u_n(x) \le \limsup_{n\to\infty, |x|\le cn} u_n(x) \le u_+^*.$$

Case 3. In the case where (C1) holds, we see that $u^* \le u_+^* \le b = u^*$. Further, it follows from the definition of f^- that $f^-(u) = f(u), \forall u \in [b - \epsilon_0, b]$, and hence, $u_-^* = u^*$. Since $u_-^* = u_+^* = u^*$, the upward convergence in case (3) follows from the conclusion in case (2).

In the case where (C2) holds, we use similar arguments as in the proof of [17, Lemma 3.10] (see also the proof of [19, Theorem 2.5]). For any $(v, w) \in [0, b]^2$, let

$$g(v,w) = \begin{cases} \min\{f(u) : v \le u \le w\}, & \text{if } v \le w, \\ \max\{f(u) : w \le u \le v\}, & \text{if } w \le v. \end{cases} \tag{2.4}$$

Then $g(v, w)$ is nondecreasing in $v \in [0, b]$ and nonincreasing in $w \in [0, b]$. Moreover, $f(u) = g(u, u)$, and $g(v, w)$ is continuous in $(v, w) \in [0, b]^2$ (see [18, section 2]). For a given $u_0 \in \mathcal{C}_{u_+^*} \setminus \{0\}$, let $u_n = Q^n(u_0)$, $\forall n \ge 0$. Then we have

$$u_{n+1}(x) = \int_{\mathbb{R}} g(u_n(x-y), u_n(x-y))k(y)dy, \ \ n \ge 0.$$

For any $\beta \in (0, c^*)$, we define

$$U_*(\beta) := \liminf_{n\to\infty, |x|\le \beta n} u_n(x), \quad U^*(\beta) := \limsup_{n\to\infty, |x|\le \beta n} u_n(x).$$

Let $c \in (0, c^*)$ be given. We fix a number $\gamma \in (c, c^*)$ and define

$$V_*(c,\gamma) = \inf_{c<\beta<\gamma} U_*(\beta), \quad V^*(c,\gamma) = \sup_{c<\beta<\gamma} U^*(\beta).$$

It then follows that

$$V_*(c,\gamma) \le U_*(\beta) \le U^*(\beta) \le V^*(c,\gamma), \quad \forall \beta \in [c,\gamma].$$

By the conclusion in case 2, we have

$$0 < u_-^* \le U_*(\beta) \le U^*(\beta) \le u_+^*, \quad \forall \beta \in (0, c^*),$$

and hence,

$$0 < u_-^* \le V_*(c,\gamma) \le V^*(c,\gamma) \le u_+^* \le b.$$

For any $\beta \in (c, \gamma)$, we choose two sequences $n_j \to \infty$ and $x_j \in \mathbb{R}$ with $|x_j| \le \beta n_j$ such that $\lim_{j\to\infty} u_{n_j}(x_j) = U_*(\beta)$. It is easy to see that

$$U_*(\gamma) \le \liminf_{j\to\infty} u_{n_j-1}(x_j - y) \le \limsup_{j\to\infty} u_{n_j-1}(x_j - y) \le U^*(\gamma), \ \forall y \in \mathbb{R}.$$

Since $u_{n_j}(x_j) = \int_{\mathbb{R}} g(u_{n_j-1}(x_j - y), u_{n_j-1}(x_j - y))k(y)dy$, it follows from Fatou's lemma that

$$U_*(\beta) \ge \int_{\mathbb{R}} \liminf_{j\to\infty} g(u_{n_j-1}(x_j - y), u_{n_j-1}(x_j - y))k(y)dy,$$

and hence

$$\begin{aligned} U_*(\beta) &\geq \int_{\mathbb{R}} g(U_*(\gamma), U^*(\gamma))k(y)dy \\ &= g(U_*(\gamma), U^*(\gamma)) \geq g(V_*(c,\gamma), V^*(c,\gamma)). \end{aligned}$$

Similarly, we have

$$U^*(\beta) \leq g(U^*(\gamma), U_*(\gamma)) \leq g(V^*(c,\gamma), V_*(c,\gamma)).$$

Thus,

$$V_*(c,\gamma) \geq g(V_*(c,\gamma), V^*(c,\gamma)), \quad V^*(c,\gamma) \leq g(V^*(c,\gamma), V_*(c,\gamma)). \tag{2.5}$$

By the definition of function g, we can find $v, w \in [V_*(c,\gamma), V^*(c,\gamma)] \subset (0, b]$ such that

$$g(V^*(c,\gamma), V_*(c,\gamma)) = f(v) \qquad \text{and} \qquad g(V_*(c,\gamma), V^*(c,\gamma)) = f(w).$$

It then follows from (2.5) that

$$f(w) \leq V_*(c,\gamma) \leq v,\ w \leq V^*(c,\gamma) \leq f(v), \tag{2.6}$$

and hence,

$$\frac{f(w)}{w} \leq 1 = \frac{f(u^*)}{u^*} \leq \frac{f(v)}{v}.$$

This, together with the strict monotonicity of $\frac{f(u)}{u}$ on $(0, b]$, implies that $v \leq u^* \leq w$. By (2.6) and the property (P), we obtain $v = w$. It then follows from (2.6) that $V_*(c,\gamma) \geq f(w) = f(v) \geq V^*(c,\gamma)$, and hence, $0 < V_*(c,\gamma) = V^*(c,\gamma) \leq b$. From (2.5), we have

$$V_*(c,\gamma) \geq g(V_*(c,\gamma), V_*(c,\gamma)) \geq V^*(c,\gamma),$$

and hence, $0 < V_*(c,\gamma) = f(V_*(c,\gamma))$. By the uniqueness of the positive fixed point of f in $[0, b]$, it follows that $V_*(c,\gamma) = u^*$. Consequently,

$$u^* = V_*(c,\gamma) \leq U_*(c) \leq U^*(c) \leq V^*(c,\gamma) = u^*,$$

which implies that $\lim_{n\to\infty, |x|\leq cn} u_n(x) = u^*$ for any $c \in (0, c^*)$. □

Remark 2.1. Under the assumption that $\int_{\mathbb{R}^m} k(y)dy = 1$, $k(x) = k(y)$, $\forall x, y \in \mathbb{R}^m$ with $|x| = |y|$, Theorem 2.2 is still valid if we replace $\int_{\mathbb{R}}$ with $\int_{\mathbb{R}^m}$.

3. Traveling waves. In this section, we establish the existence and nonexistence of traveling waves for systems (2.3) by appealing to the Schauder fixed point theorem and the property of the spreading speed.

For a given $\lambda > 0$, let

$$X_\lambda := \{\phi \in C(\mathbb{R}, \mathbb{R}) : \quad \sup_{\xi\in\mathbb{R}} |\phi(\xi)|e^{-\lambda\xi} < +\infty\}$$

and $\|\phi\|_\lambda = \sup_{\xi\in\mathbb{R}} |\phi(\xi)|e^{-\lambda\xi}$. It then follows that $(X_\lambda, \|\cdot\|_\lambda)$ is a Banach space.

Define

$$\Phi(\lambda) = \frac{\ln\left(f'(0)\int_{\mathbb{R}} e^{-\lambda y}k(y)dy\right)}{\lambda}, \quad \forall \lambda \in (0, \Delta),$$

and

$$K(c,\lambda) = f'(0)e^{-c\lambda}\int_{\mathbb{R}} e^{-\lambda y}k(y)dy, \quad \forall c \in \mathbb{R}_+,\ \lambda \in (0,\Delta).$$

By [11, Lemma 3.8], it follows that for any $c > c_f^*$, there exist $0 < \lambda_1 = \lambda_1(c) < \lambda_2 = \lambda_2(c) < \Delta$ such that $\Phi(\lambda_1) = c$ and $\Phi(\lambda) < c$, $\forall \lambda \in (\lambda_1, \lambda_2)$. Thus, we have

$$K(c,\lambda_1) = 1, \quad K(c,\lambda) < 1,\ \forall \lambda \in (\lambda_1, \lambda_2).$$

Note that if $f''(0)$ exists, then $f(u) \geq f'(0)u - au^2$, $\forall u \in [0,\delta]$, for appropriate $a > 0$ and $\delta > 0$. To obtain the existence of traveling waves, we impose the following weaker condition on f (cf. [3]).

(F3) There exist real numbers $\delta^* \in (0, \min(\delta_0, u_+^*)]$, $\sigma > 1$ and $a > 0$ such that $f(u) \geq f'(0)u - au^\sigma$, $\forall u \in [0,\delta^*]$.

THEOREM 3.1. *Let* (F1)–(F3) *hold. Then the following statements are valid:*

(1) *For any* $c \in (0, c_f^*)$, (2.3) *has no traveling wave* $U(x+cn)$ *with* $U \in \mathcal{C}_{u_+^*} \setminus \{0\}$ *and* $U(-\infty) = 0$.

(2) *For any* $c > c_f^*$, (2.3) *has a traveling wave* $U(x+cn)$ *such that* $U \in \mathcal{C}_{u_+^*} \setminus \{0\}$, $U(-\infty) = 0$, *and*

$$u_-^* \leq \liminf_{\xi\to+\infty} U(\xi) \leq \limsup_{\xi\to+\infty} U(\xi) \leq u_+^*.$$

If, in addition, either (C1) *or* (C2) *holds, then* $U(+\infty) = u^*$.

Proof. Case 1. Assume, by contradiction, that for some $c_0 \in (0, c_f^*)$, (2.3) has a traveling wave $u_n(x) := U(x + c_0 n)$ with $U \in \mathcal{C}_{u_+^*} \setminus \{0\}$ and $U(-\infty) = 0$. By Theorem 2.2 (2), there holds

$$\liminf_{n\to\infty, |x|\leq cn} u_n(x) \geq u_-^* > 0, \quad \forall c \in (0, c_f^*).$$

Choose $\tilde{c} \in (c_0, c_f^*)$ and let $x = -\tilde{c}n$. Then $\liminf_{n\to\infty} u_n(-\tilde{c}n) = \liminf_{n\to\infty} U((c_0 - \tilde{c})n) > 0$, but $\lim_{n\to\infty} U((c_0 - \tilde{c})n) = U(-\infty) = 0$, a contradiction.

Case 2. Let $c > c_f^*$ be given. Define a mapping $T : \mathcal{C}_b \to \mathcal{C}_b$ by

$$T(\phi)(\xi) = \int_{\mathbb{R}} f(\phi(\xi - c - y))k(y)dy, \quad \forall \xi \in \mathbb{R},\ \phi \in \mathcal{C}_b. \tag{3.1}$$

Let $T^\pm$ be defined as in (3.1) with f replaced by $f^\pm$. It then follows that $T^\pm$ is nondecreasing with respect to the pointwise ordering on $\mathcal{C}_b$, and that

$$T^-(\phi) \leq T(\phi) \leq T^+(\phi),\ \forall \phi \in \mathcal{C}_b.$$

Following [3], we define

$$\phi^+(\xi) := \min\{u_+^* e^{\lambda_1 \xi}, u_+^*\}, \quad \forall \xi \in \mathbb{R}.$$

Since $f^+(u)$ is nondecreasing in u and $\phi^+(\xi) \leq u_+^*$, $\forall \xi \in \mathbb{R}$, we obtain

$$T^+(\phi^+)(\xi) \leq \int_{\mathbb{R}} f^+(u_+^*)k(y)dy = f^+(u_+^*) = u_+^*, \quad \forall \xi \in \mathbb{R}. \tag{3.2}$$

Note that $f^+(u) \le f'(0)u$, $\forall u \in [0,b]$, and $\phi^+(\xi) \le u_+^* e^{\lambda_1 \xi}$, $\forall \xi \in \mathbb{R}$. Thus, we further have

$$\begin{aligned} T^+(\phi^+)(\xi) &\le \int_{\mathbb{R}} f'(0)\phi^+(\xi - c - y)k(y)dy \\ &\le f'(0) \int_{\mathbb{R}} u_+^* e^{\lambda_1(\xi - c - y)} k(y)dy \\ &= u_+^* e^{\lambda_1 \xi} K(c, \lambda_1) = u_+^* e^{\lambda_1 \xi}, \ \forall \xi \in \mathbb{R}. \end{aligned} \tag{3.3}$$

By (3.2), (3.3), and the definition of ϕ^+, it then follows that $T^+(\phi^+) \le \phi^+$. We first fix a sufficiently small $\epsilon^* \in (0, \lambda_1(\sigma - 1)]$ such that $\lambda_1 + \epsilon^* < \lambda_2$, and hence $K(c, \lambda_1 + \epsilon^*) < 1$. We then choose a sufficiently large number $M \ge 1$ such that

$$\left(1 + \frac{a(u_+^*)^\sigma}{f'(0)\delta^* M}\right) K(c, \lambda_1 + \epsilon^*) < 1. \tag{3.4}$$

Following [19], we define

$$\phi^-(\xi) := \max\{0, \delta^*(1 - Me^{\epsilon^* \xi})e^{\lambda_1 \xi}\}, \quad \forall \xi \in \mathbb{R}.$$

Let $\xi_0 := -\frac{\ln M}{\epsilon^*}$. Then we have

$$\phi^-(\xi) = 0, \ \forall \xi \ge \xi_0, \quad \phi^-(\xi) = \delta^* e^{\lambda_1 \xi} - \delta^* M e^{(\lambda_1 + \epsilon^*)\xi}, \ \forall \xi \le \xi_0.$$

Since $\delta^* \le u_+^*$, $\xi_0 \le 0$, and $0 < \epsilon^* \le \lambda_1(\sigma - 1)$, it is easy to see that

$$0 \le \phi^-(\xi) \le \phi^+(\xi), \quad (\phi^-(\xi))^\sigma \le (u_+^*)^\sigma e^{(\lambda_1 + \epsilon^*)\xi}, \quad \forall \xi \in \mathbb{R}.$$

Clearly, we have

$$T^-(\phi^-)(\xi) \ge 0, \quad \forall \xi \in \mathbb{R}. \tag{3.5}$$

Since $\phi^-(\xi) \ge \delta^* e^{\lambda_1 \xi} - \delta^* M e^{(\lambda_1 + \epsilon^*)\xi}$, $\forall \xi \in \mathbb{R}$, it follows from (3.4) that

$$\begin{aligned} f'(0)\phi^-(\xi) - a(\phi^-(\xi))^\sigma &\ge f'(0)\delta^* e^{\lambda_1 \xi} - f'(0)\delta^* M e^{(\lambda_1 + \epsilon^*)\xi} - a(u_+^*)^\sigma e^{(\lambda_1 + \epsilon^*)\xi} \\ &= f'(0)\delta^* e^{\lambda_1 \xi} - f'(0)\delta^* M e^{(\lambda_1 + \epsilon^*)\xi} \left(1 + \frac{a(u_+^*)^\sigma}{f'(0)\delta^* M}\right) \\ &\ge f'(0)\delta^* e^{\lambda_1 \xi} - \frac{f'(0)\delta^* M}{K(c, \lambda_1 + \epsilon^*)} e^{(\lambda_1 + \epsilon^*)\xi}, \quad \forall \xi \in \mathbb{R}. \end{aligned}$$

In view of (F3) and the fact that $f^-(u) = f(u)$, $\forall u \in [0, \delta_0]$, we then have

$$\begin{aligned} T^-(\phi^-)(\xi) &\ge \int_{\mathbb{R}} \left(f'(0)\phi^-(\xi - c - y) - a(\phi^-(\xi - c - y))^\sigma\right) k(y)dy \\ &\ge \int_{\mathbb{R}} \left(f'(0)\delta^* e^{\lambda_1(\xi - c - y)} - \frac{f'(0)\delta^* M}{K(c, \lambda_1 + \epsilon^*)} e^{(\lambda_1 + \epsilon^*)(\xi - c - y)}\right) k(y)dy \\ &= \delta^* e^{\lambda_1 \xi} K(c, \lambda_1) - \frac{\delta^* M}{K(c, \lambda_1 + \epsilon^*)} e^{(\lambda_1 + \epsilon^*)\xi} K(c, \lambda_1 + \epsilon^*) \\ &= \delta^* e^{\lambda_1 \xi} - \delta^* M e^{(\lambda_1 + \epsilon^*)\xi}, \quad \forall \xi \in \mathbb{R}. \end{aligned} \tag{3.6}$$

By (3.5), (3.6), and the definition of ϕ^-, it follows that $T^-(\phi^-) \ge \phi^-$.

Now we fix a number $\lambda \in (0, \lambda_1)$. It is easy to see that both ϕ^- and ϕ^+ are elements in X_λ. Thus, the set

$$Y := \{\phi \in X_\lambda : \phi^-(\xi) \le \phi(\xi) \le \phi^+(\xi), \forall \xi \in \mathbb{R}\}$$

is a nonempty, closed, and convex subset of X_λ. For any $\phi \in Y$, we have

$$\phi^- \le T^-(\phi^-) \le T^-(\phi) \le T(\phi) \le T^+(\phi) \le T^+(\phi^+) \le \phi^+,$$

and hence $T(Y) \subset Y$. For any $\phi, \psi \in Y$, there holds

$$\begin{aligned}
\|T(\phi) - T(\psi)\|_\lambda &= \sup_{\xi\in\mathbb{R}} |T(\phi)(\xi) - T(\psi)(\xi)| e^{-\lambda\xi} \\
&\le L \cdot \sup_{\xi\in\mathbb{R}} \int_{\mathbb{R}} |\phi(\xi - c - y) - \psi(\xi - c - y)| e^{-\lambda\xi} k(y) dy \\
&\le L\|\phi - \psi\|_\lambda \int_{\mathbb{R}} e^{-\lambda(c+y)} k(y) dy \\
&= \left(L e^{-\lambda c} \int_{\mathbb{R}} e^{-\lambda y} k(y) dy \right) \|\phi - \psi\|_\lambda.
\end{aligned}$$

This implies that $T : Y \to Y$ is continuous. We further show that $T(Y)$ is precompact in X_λ. For any $\phi \in Y$, $\xi_1, \xi_2 \in \mathbb{R}$, we have

$$\begin{aligned}
|T(\phi)(\xi_1) - T(\phi)(\xi_2)| &= \left| \int_{\mathbb{R}} f(\phi(z)) \left(k(\xi_1 - c - z) - k(\xi_2 - c - z) \right) dz \right| \\
&\le b \int_{\mathbb{R}} |k(\xi_1 - c - z) - k(\xi_2 - c - z)| dz \\
&= b \int_{\mathbb{R}} |k(\xi_1 - \xi_2 + y) - k(y)| dy \\
&= b \cdot g(\xi_1 - \xi_2),
\end{aligned}$$

where $g(\xi) = \int_{\mathbb{R}} |k(\xi + y) - k(y)| dy$, $\forall \xi \in \mathbb{R}$. Since $\lim_{\xi\to 0} g(\xi) = 0$, it follows that the family of functions $\{T(\phi)(\xi) : \phi \in Y\}$ is uniformly bounded and equicontinuous in $\xi \in \mathbb{R}$. Thus, for any given sequence $\{\psi_n\}_{n\ge 1}$ in $T(Y)$, there exist $n_k \to \infty$ and $\psi \in C(\mathbb{R}, \mathbb{R})$ such that $\lim_{k\to\infty} \psi_{n_k}(\xi) = \psi(\xi)$ uniformly for ξ in any compact subset of $\mathbb{R}$. Since $\phi^-(\xi) \le \psi_{n_k}(\xi) \le \phi^+(\xi)$, $\forall \xi \in \mathbb{R}$, we have $\phi^-(\xi) \le \psi(\xi) \le \phi^+(\xi)$, $\forall \xi \in \mathbb{R}$, and hence, $\psi \in Y$. Note that

$$\lim_{\xi\to+\infty} (\phi^+(\xi) - \phi^-(\xi)) e^{-\lambda\xi} = 0$$

and

$$\lim_{\xi\to-\infty} (\phi^+(\xi) - \phi^-(\xi)) e^{-\lambda\xi} = 0.$$

Therefore, for any $\epsilon > 0$, there exists $B > 0$ such that

$$0 \le (\phi^+(\xi) - \phi^-(\xi)) e^{-\lambda\xi} < \epsilon, \quad \forall |\xi| \ge B.$$

Since $\lim_{k\to\infty} (\psi_{n_k}(\xi) - \psi(\xi)) e^{-\lambda\xi} = 0$ uniformly for $\xi \in [-B, B]$, there exists an integer $N > 0$ such that

$$|\psi_{n_k}(\xi) - \psi(\xi)| e^{-\lambda\xi} < \epsilon, \quad \forall \xi \in [-B, B],\ k \ge N.$$

It then follows that

$$\|\psi_{n_k} - \psi\|_\lambda = \sup_{\xi\in\mathbb{R}} |\psi_{n_k}(\xi) - \psi(\xi)|e^{-\lambda\xi} \le \epsilon, \quad \forall k \ge N.$$

This implies that $\lim_{k\to\infty} \psi_{n_k} = \psi$ in X_λ. By the Schauder fixed point theorem, there exists $U \in Y$ such that $U = T(U)$, and hence, $U(x + cn)$ is a traveling wave of (2.3). Since $\phi^-(\xi) \le U(\xi) \le \phi^+(\xi)$, $\forall \xi \in \mathbb{R}$, we have $U(-\infty) = 0$ and $U \in \mathcal{C}_{u_+^*} \setminus \{0\}$.

Let $u_n(x) := U(x + cn)$, $\forall n \ge 0$, and fix a number $\bar{c} \in (0, c_f^*)$. By Theorem 2.2 (2), it follows that

$$0 < u_-^* \le \liminf_{n\to\infty, |x|\le \bar{c}n} u_n(x) \le \limsup_{n\to\infty, |x|\le\bar{c}n} u_n(x) \le u_+^*,$$

and hence,

$$u_-^* \le \liminf_{n\to\infty} u_n(-\gamma n) \le \limsup_{n\to\infty} u_n(-\gamma n) \le u_+^*$$

uniformly for $\gamma \in [0, \bar{c}]$. This implies that

$$u_-^* \le \liminf_{n\to\infty} U(sn) \le \limsup_{n\to\infty} U(sn) \le u_+^*$$

uniformly for $s \in [c - \bar{c}, c]$. Let

$$a_n = n(c - \bar{c}), \quad b_n = nc, \quad \forall n \ge 1.$$

Thus, there exists $N_0 > 0$ such that $a_{n+1} - b_n < 0$, $\forall n \ge N_0$, and hence,

$$\cup_{n\ge m}[a_n, b_n] = [a_m, +\infty), \ \forall m \ge N_0.$$

It then follows that

$$u_-^* \le \liminf_{\xi\to+\infty} U(\xi) \le \limsup_{\xi\to+\infty} U(\xi) \le u_+^*.$$

If, in addition, either (C1) or (C2) holds, then Theorem 2.2 (3) implies that

$$\lim_{n\to\infty, |x|\le\bar{c}n} u_n(x) = u^*, \ \forall \bar{c} \in (0, c_f^*).$$

By the same arguments as above, we further have $U(+\infty) = u^*$. □

THEOREM 3.2. *Let* (F1)–(F3) *hold. Then* (2.3) *has a traveling wave* $U(x + c_f^* n)$ *such that* $U \in \mathcal{C}_{u_+^*} \setminus \{0, u^*\}$ *and*

$$u_-^* \le \liminf_{\xi\to+\infty} U(\xi) \le \limsup_{\xi\to+\infty} U(\xi) \le u_+^*.$$

If, in addition, either (C1) *or* (C2) *holds, then* $U(+\infty) = u^*$.

Proof. Choose a sequence $\{c_j\}_{j\ge1} \subset (c_f^*, +\infty)$ such that $\lim_{j\to\infty} c_j = c_f^*$. By Theorem 3.1 (2), it follows that (2.3) has a traveling wave $U_j(x + c_j n)$ such that $U_j \in \mathcal{C}_{u_+^*} \setminus \{0\}$, $U_j(-\infty) = 0$, and

$$u_-^* \le \liminf_{\xi\to+\infty} U_j(\xi) \le \limsup_{\xi\to+\infty} U_j(\xi) \le u_+^*.$$

Without loss of generality, we assume that $U_j(0) = \frac{1}{2}u_-^* > 0$, $\forall j \geq 1$. Note that

$$U_j(\xi) = \int_{\mathbb{R}} f(U_j(\xi - c_j - y))k(y)dy, \ \forall \xi \in \mathbb{R}, \ j \geq 1. \tag{3.7}$$

It follows that

$$|U_j(\xi_1) - U_j(\xi_2)| \leq b \cdot g(\xi_1 - \xi_2), \ \forall \xi_1, \xi_2 \in \mathbb{R}, \ j \geq 1,$$

where $g(\xi)$ is defined as in the proof of Theorem 3.1. Then the family of functions $\{U_j(\xi) : j \geq 1\}$ is uniformly bounded and equicontinuous in $\xi \in \mathbb{R}$. Thus, there exist $j_k \to +\infty$ and $U \in C(\mathbb{R}, \mathbb{R})$ such that $\lim_{k\to\infty} U_{j_k}(\xi) = U(\xi)$ uniformly for ξ in any compact subset of $\mathbb{R}$. Clearly, $U \in \mathcal{C}_{u_+^*}$ and $U(0) = \frac{1}{2}u_-^*$. Letting $j = j_k \to +\infty$ in (3.7) and using the dominated convergence theorem, we obtain

$$U(\xi) = \int_{\mathbb{R}} f(U(\xi - c_f^* - y))k(y)dy, \ \forall \xi \in \mathbb{R},$$

and hence, $u_n(x) := U(x + c_f^* n)$ is a traveling wave of (2.3). As in the proof of Theorem 3.1 (2), we see that Theorem 2.2 (2) and (3) imply the asymptotic behavior of $U(\xi)$ as $\xi \to +\infty$. □

Compared with Theorem 3.1 (2), we expect that $U(-\infty) = 0$ in Theorem 3.2. However, we are not able to prove it at this moment since the limiting function $U(\xi)$ may not be nondecreasing on $\mathbb{R}$.

4. Examples. In this section, we present illustrative examples by choosing three types of growth functions from population biology.

First, we consider the logistic type function $f(u) = ru(1 - \frac{u}{K})$, $r > 0$, $K > 0$. Clearly, $f'(0) = r$, $\max_{u\in[0,K]} f(u) = f(K/2) = \frac{rK}{4}$, $\frac{f(u)}{u} = r(1 - \frac{u}{K})$ is strictly decreasing on $(0, K]$, and $u^* := K(1 - \frac{1}{r})$ is the unique positive fixed point of f on $[0, K]$. Assume that $1 < r < 4$ so that we have $f'(0) > 1$ and $f((0, K]) \subset (0, K]$. It is easy to verify that $f(u)$ is strictly increasing on $[0, u^*]$ if $r \in (0, 2]$. In the case where $r \in (1, 2]$, we choose $b =: u^*$, and hence, $u_-^* = u_+^* = u^*$. In the case $r \in (2, 4)$, we choose $b := \frac{rK}{4}$, and hence, $u_+^* = b$, $u_-^* = f(b) = \frac{r^2K(4-r)}{16}$. Note that

$$\frac{f^2(u)}{u} = \frac{r^2}{K^3}\left(K^2(K - u) - ru(K - u)^2\right).$$

It then follows that $f(u)$ satisfies the property (P2) if $r \in (2, 3]$. By Theorems 2.1 and 2.2 and Theorems 3.1 and 3.2, we have the following result.

EXAMPLE 4.1. *Let $f(u) = ru(1 - \frac{u}{K})$ with $K > 0$ and $r \in (1, 4)$, b, u_+^* and u_-^* be defined as above, and c_f^* be defined as in* (2.2) *with $h = f$. Then the following statements are valid:*

(i) *c_f^* is the spreading speed of* (2.3) *in the sense that both conclusions* (1) *and* (2) *in Theorem* 2.2 *hold. Further, the conclusion* (3) *in Theorem* 2.2 *holds in the case where $r \in (1, 3]$.*

(ii) *For any $c \in (0, c_f^*)$,* (2.3) *has no traveling wave $U(x + cn)$ with $U \in \mathcal{C}_b \setminus \{0\}$ and $U(-\infty) = 0$, and for any $c \geq c_f^*$,* (2.3) *has a traveling wave $U(x + cn)$ with $U \in \mathcal{C}_{u_+^*} \setminus \{0, u^*\}$ and*

$$u_-^* \leq \liminf_{\xi\to+\infty} U(\xi) \leq \limsup_{\xi\to+\infty} U(\xi) \leq u_+^*.$$

Further, $U(+\infty) = u^*$ in the case where $r \in (1, 3]$. If $r \in (1, 2]$, then $U(-\infty) = 0$ and $U(\xi)$ is nondecreasing in ξ for all $c \geq c_f^*$. If $r \in (2, 3]$, then $U(-\infty) = 0$ for all $c > c_f^*$.

In Example 4.1, we can also verify that for any $r > 0$, $uf(u)$ is strictly increasing on $[0, 2K/3]$ and strictly decreasing on $[2K/3, +\infty)$. It then follows that $f(u)$ satisfies the property (P1) if $r \in (2, 8/3]$, but does not satisfy the property (P1) if $r \in (8/3, 4)$. So we chose to use the property (P2) to obtain the upward convergence as stated in Theorem 2.2 (3) for r in a larger interval $(1, 3]$. By taking u_0 as a constant function in integrodifference equation (2.3), we see that the upward convergence implies that u^* is a globally attractive fixed point for the map f on $(0, u_+^*]$. Note that $|f'(u^*)| = |2 - r| > 1$, $\forall r \in (3, 4)$. By [5, Theorem 3.8], it then follows that for any $r \in (3, 4)$, u^* is a unstable fixed point of f. This implies that the upward convergence does not hold for any $r \in (3, 4)$. Thus, the interval $(1, 3]$ for parameter r is optimal for the upward convergence.

Among other things, Kot [7] observed numerically four types of discrete-time traveling waves for the integrodifference equation (2.3) with $f(u) = (1 + r_0)u - r_0u^2$ and $k(x) = 3e^{-6|x|}$: a simple monotone traveling for $r_0 = 0.9$ ([7, Figure 7]); a traveling wave with damped spatial oscillations for $r_0 = 1.9$ ([7, Figure 8]); a traveling two-cycle for $r_0 = 2.2$ ([7, Figures 9a,b]; and a traveling four-cycle for $r_0 = 2.5$ ([7, Figures 10a–d]. Clearly, this system is a special case of Example 4.1 with $r = 1 + r_0$ and $K = (1 + r_0)/r_0$. It is easy to see that our analytic results in Example 4.1 are consistent with these numerical simulations. Note that there is an increasing sequence of parameter values $r_1 = 3 < r_2 \approx 3.449 < r_3 \approx 3.544 < r_4 \approx 3.564 < \dots$ at which the logistic map $f(u) = ru(1 - \frac{u}{K})$ repeatedly undergoes a period-doubling bifurcation (see, e.g., [5, section 3.5]). Further, when $r \approx 3.839$, f has a unique asymptotically stable periodic orbit of minimal period 3. It is a challenging problem to prove the existence of a traveling three-cycle for the integrodifference equation (2.3) associated with the logistic map when $r \approx 3.839$.

Next, we consider the Ricker type function $f(u) = que^{-pu}$, $q > 1$, $p > 0$. Clearly, $f'(0) = q$ and $\frac{f(u)}{u} = qe^{-pu}$ is strictly decreasing on $(0, +\infty)$. It is easy to see that $u^* := \frac{\ln q}{p}$ is the unique positive fixed point of f on $[0, +\infty)$, that $\max_{u \in [0, +\infty)} f(u) = f(1/p) = \frac{q}{pe}$, and that $f(u)$ is strictly increasing on $[0, u^*]$ if $q \in (1, e]$. In the case where $q \in (1, e]$, we choose $b := u^*$, and hence, $u_-^* = u_+^* = u^*$. In the case where $q > e$, we choose $b := \frac{q}{pe}$, and hence, $u_+^* = b$, $u_-^* = f(b) = \frac{q^2}{pe}e^{-q/e}$. Note that

$$\frac{f^2(u)}{u} = q^2 e^{-p(u + que^{-pu})}.$$

An elementary analysis shows that $f(u)$ satisfies the property (P2) if $q \in (e, e^2]$. By Theorems 2.1 and 2.2 and Theorems 3.1 and 3.2, we have the following result.

EXAMPLE 4.2. *Let $f(u) = que^{-pu}$ with $q > 1$ and $p > 0$, b, u_+^* and u_-^* be defined as above, and c_f^* be defined as in* (2.2) *with $h = f$. Then the following statements are valid:*

(i) *c_f^* is the spreading speed of* (2.3) *in the sense that both conclusions* (1) *and* (2) *in Theorem* 2.2 *hold. Further, conclusion* (3) *in Theorem* 2.2 *holds in the case where $q \in (1, e^2]$.*

(ii) *For any $c \in (0, c_f^*)$,* (2.3) *has no traveling wave $U(x + cn)$ with $U \in \mathcal{C}_b \setminus \{0\}$ and $U(-\infty) = 0$, and for any $c \geq c_f^*$,* (2.3) *has a traveling wave $U(x + cn)$*

with $U \in \mathcal{C}_{u_+^*} \setminus \{0, u^*\}$ *and*

$$u_-^* \le \liminf_{\xi\to+\infty} U(\xi) \le \limsup_{\xi\to+\infty} U(\xi) \le u_+^*.$$

Further, $U(+\infty) = u^*$ *in the case where* $q \in (1, e^2]$. *If* $q \in (1, e]$, *then* $U(-\infty) = 0$ *and* $U(\xi)$ *is nondecreasing in* ξ *for all* $c \ge c_f^*$. *If* $q \in (e, e^2]$, *then* $U(-\infty) = 0$ *for all* $c > c_f^*$.

In Example 4.2, for any $q > e^2$, we have $|f'(u^*)| = |1 - \ln q| > 1$, and hence, u^* is an unstable fixed point of f. As discussed in Example 4.1, it follows that the interval $(1, e^2]$ for parameter q is optimal for the upward convergence.

Finally, we consider the generalized Beverton–Holt-type function $f(u) = \frac{pu}{q+u^m}$, $m > 0$, and $p > q > 0$. Clearly, $f'(0) = p/q$ and $\frac{f(u)}{u} = \frac{p}{q+u^m}$ is strictly decreasing on $(0, +\infty)$. It is easy to see that $u^* := (p-q)^{\frac{1}{m}}$ is the unique positive fixed point of f on $[0, +\infty)$, and that $f(u)$ is strictly increasing on $[0, +\infty)$ in the case where $m \in (0, 1]$. In the case where $m > 1$, we have

$$\max_{u\in[0,+\infty)} f(u) = f(\bar{u}) = \frac{p(m-1)\bar{u}}{qm}, \quad \bar{u} := \left(\frac{q}{m-1}\right)^{\frac{1}{m}}.$$

By elementary analysis, it follows that $f(u)$ is strictly increasing on $[0, u^*]$ if $m \in (1, p/(p-q)]$, that $uf(u)$ is strictly increasing on $[0, +\infty)$ if $m \in (0, 2]$, and that $uf(u)$ is strictly increasing on $[0, (2q/(m-2))^{\frac{1}{m}}]$ if $m > 2$. Define $b := u^*$ if $m \in (0, p/(p-q)]$ and $b := f(\bar{u})$ if $m > p/(p-q)$. It then follows that $u_-^* = u_+^* = u^*$ in the case where $m \in (1, p/(p-q)]$, and

$$u_+^* = b, \quad u_-^* = f(b) = \frac{p^2(m-1)\bar{u}}{q^2 m + \frac{p^m(m-1)^{m-1}q}{(qm)^{m-1}}},$$

in the case where $m > p/(p-q)$. Note that $f(u)$ satisfies the property (P1) if either $m \in (0, 2]$, or $m > \max(2, p/(p-q))$ and $f(\bar{u}) \le (2q/(m-2))^{\frac{1}{m}}$. By Theorems 2.1 and 2.2 and Theorems 3.1 and 3.2, we have the following result.

EXAMPLE 4.3. *Let* $f(u) = \frac{pu}{q+u^m}$ *with* $m > 0$ *and* $p > q > 0$, b, u_+^* *and* u_-^* *be defined as above, and* c_f^* *be defined as in* (2.2) *with* $h = f$. *Then the following statements are valid:*

(i) c_f^* *is the spreading speed of* (2.3) *in the sense that both conclusions* (1) *and* (2) *in Theorem* 2.2 *hold. Further, conclusion* (3) *in Theorem* 2.2 *holds in the case where either* $m \in (0, \max(2, p/(p-q))]$, *or* $m > \max(2, p/(p-q))$ *and* $f(\bar{u}) \le (2q/(m-2))^{\frac{1}{m}}$.

(ii) *For any* $c \in (0, c_f^*)$, (2.3) *has no traveling wave* $U(x + cn)$ *with* $U \in \mathcal{C}_b \setminus \{0\}$ *and* $U(-\infty) = 0$, *and for any* $c \ge c_f^*$, (2.3) *has a traveling wave* $U(x + cn)$ *with* $U \in \mathcal{C}_{u_+^*} \setminus \{0, u^*\}$ *and*

$$u_-^* \le \liminf_{\xi\to+\infty} U(\xi) \le \limsup_{\xi\to+\infty} U(\xi) \le u_+^*.$$

Further, $U(+\infty) = u^*$ *in the case where either* $m \in (0, \max(2, p/(p-q))]$, *or* $m > \max(2, p/(p-q))$ *and* $f(\bar{u}) \le (2q/(m-2))^{\frac{1}{m}}$. *If* $m \in (0, p/(p-q)]$, *then* $U(-\infty) = 0$ *and* $U(\xi)$ *is nondecreasing in* ξ *for all* $c \ge c_f^*$. *If either* $p/(p-q) < m \le 2$, *or* $m > \max(2, p/(p-q))$ *and* $f(\bar{u}) \le (2q/(m-2))^{\frac{1}{m}}$, *then* $U(-\infty) = 0$ *for all* $c > c_f^*$.

Acknowledgments. We are grateful to two anonymous referees for their careful reading and helpful suggestions which led to an improvement of our original manuscript. Xiao-Qiang Zhao would like to thank the National Center for Theoretical Science, Tsing Hua University, Taiwan for its kind hospitality during his visit there.

ESTIMATES ON THE HAUSDORFF DIMENSION OF THE RUPTURE SET OF A THIN FILM*

KAI-SENG CHOU† AND SHI-ZHONG DU†

Abstract. Upper bounds on the Hausdorff dimensions of the rupture set of a weak solution of the thin film equation in space-time and in space slices are derived. Finite time rupture is shown to occur for a class of thin films obeying the power law with power in $(0, 1/2)$ under periodic boundary conditions.

Key words. Hausdorff measure, Hausdorff dimension, finite time rupture, thin film equation, partial regularity of a suitable weak solution

AMS subject classifications. 35Q35, 76A20, 35B35, 93D20

DOI. 10.1137/070685348

1. Introduction.

In recent years the thin film type equations

$$h_t + (h^n h_{xxx})_x = 0, \quad n > 0, \quad h \geq 0, \tag{1.1}$$

and

$$h_t + (h^n (h_{xx} + f(h))_x)_x = 0, \quad n > 0, \ h \geq 0, \tag{1.2}$$

have attracted much attention. These equations, where h describes the height of an axisymmetric thin film in motion, arise from the lubrication approximation of the Navier–Stokes equations when n is equal to 3 under no-slip boundary conditions at the lower boundary. It also describes the motion of fluid in a Hele–Shaw cell when n is equal to 1. The f-term in the second equation describes the presence of other physical effects such as gravity, the van der Waals forces, and thermocapillary effect. It is called a power law if

$$f(z) = \begin{cases} B\dfrac{z^q}{q}, & q \neq 0, \\ B \log z, & q = 0, \end{cases} \tag{1.3}$$

for some positive B. One may consult the surveys Myers [M] and Oron, Davis, and Bankoff [ODB] for background on these equations and various models. Here we are concerned with the analytic aspects of these equations. To study them one needs to impose initial and boundary conditions so that they become well-posed at least for a short time. In the literature several boundary conditions such as Neumann-type conditions, pressure boundary conditions, and periodic boundary conditions have been used. Throughout this paper we shall employ the periodic boundary conditions. Thus given a nonnegative, periodic function h_0, we would like to consider the solution to (1.1) starting at h_0, which is of the same period as h_0. Observing that the equation is a parabolic equation of fourth order when h is positive, it follows from parabolic theory that, for any positive, sufficiently regular initial datum, the equation admits a classical solution for small time, and it continues to exist as long as the solution

is bounded away from zero. However, unlike second order parabolic equations where positivity is ensured by the maximum principle in an *a prior* way, it is not clear at all whether the film will remain positive for all time, or it will touch down at 0 at some finite time. The film is said to rupture when the latter occurs, and the equation loses its parabolicity. The mathematical foundation of (1.1) was laid down in Bernis-Friedman [BF] where they discovered the following remarkable fact: When $n \geq 4$ equation (1.1) preserves positivity. (Later the requirement $n \geq 4$ was relaxed to $n \geq 3.5$ in Bertozzi et al. [BBDK].) Using this fact, Bernis and Friedman was able to construct a nonnegative, global weak solution of (1.1) for some n less than 4 for nonnegative, H^1-data. After the works of Beretta, Bertsch, and Dal Passo [BBDP], Bertozzi-Pugh [BP1] and [BP2], nowadays it is known that nonnegative, global weak solutions exist for (1.1) and (1.2) for any positive n when f is in $C^1([0,\infty))$ and grows slower less than a cubic power in h at ∞.

A natural question is, For n in $(0, 3.5)$, will rupture occur in finite time for some positive initial data? Observing that, when n is equal to 0, finite time rupture occurs for easily constructed initial data, it would not be surprising that finite time rupture occurs for positive, small n. In fact, under the boundary conditions $h = h_{xx} = 1$ at endpoints, such property is established for (1.1) when n is less than $1/2$ in [BBDP]. However, for the periodic conditions this remains open. Numerical studies show that there is a critical number $n^* \in (1, 2)$ so that finite time rupture occurs for $n < n^*$, and positivity is preserved for $n > n^*$. Likewise, as for (1.2) under the power law $q < 3$ there should be a critical number $n_c(q)$, independent of B and the period, which separates finite time rupture and the preservation of positivity. Numerical results in Goldstein, Pesci, and Shelly [GPS] show that $1 \leq n_c(1) \leq 3$, and those in Laugesen-Pugh [LP2] show that $1.8 < n_c(0.5) < 1.85$ and $1.65 < n_c(2.5) < 1.6625$. Theoretical upper and lower bounds on $n_c(q)$ can be found in Chou-Kwong [CK] for negative q. In this paper we shall show that finite time rupture occurs for (1.2), where f is a power law (1.3) ($q \in (1, 3)$) under the periodic boundary conditions when n is less than $1/2$; see Corollary 3.1 for a precise statement. We shall not consider (1.2) when f grows faster than a cubic power. In addition to the possibility of rupture, it is believed that, in this case the solution may also blow up in finite time. We refer to [BP1] for a conjecture in this direction, and [BP3] and Slepčev-Pugh [SP] for more recent progress.

In this paper we approach the problem of finite time rupture via estimating the possible size of the rupture set. When rupture really occurs, surely our results yield information on the size of the rupture set. On the other hand, even if rupture does not occur, one may still build on these results further criteria for the absence of rupture. A similar situation can be found in the study of the regularity of the weak solution of the three-dimensional Navier–Stokes equations. One may consult Escauriaza, Seregin, and Šverák [ESS] for how the partial regularity estimates in Caffarelli, Kohn, and Nirenberg [CKN] are used in establishing regularity criteria.

Let us review how one excludes finite time rupture for thin films when $n \geq 3.5$. Recall that the weak solution constructed in [BF], [BBDP], [BP1], and [BP2] has many regularity properties including the following two: For any positive initial data, the weak solution of (1.1) or (1.2) ($1 < q < 3$) satisfies, for any $0 < t < T$,

$$\int h_x^2(t) + \int_0^T \int h^n \left[(h_{xx} + f(h))_x\right]^2 \leq C_1, \tag{1.4}$$

and

$$\int h(t)^{3/2-n} \leq C_2 \tag{1.5}$$

for some constants C_1 and C_2 depending on the initial data. It follows from the conservation of area

$$\int h(t) = \int h(0), \quad \text{all } t > 0,$$

and (1.4) that the solution h has a uniformly bounded $C^{1/2}-$norm. At a rupture point (x_0, t) the solution is dominated by a constant multiple of $|x - x_0|^{1/2}$. Putting this estimate into (1.5) yields a contradiction when $n \geq 3.5$, so no finite rupture can occur when $n \geq 3.5$. Even when n is less than 3.5, (1.5) tells us that the rupture set has null measure at every time as long as $n > 1.5$. Our first result gives a more precise estimate.

THEOREM 1.1. *Let h be a suitable weak solution of* (1.1) *or* (1.2)*, where $n \in (1.5, 3.5)$ and f is a power law with $q > 1 - n/2$. Then for any $t > 0$, the $(7 - 2n)/(2n + 1)$-Hausdorff measure of the set $\{x : h(x, t) = 0\}$ is finite, so its Hausdorff dimension cannot exceed $(7 - 2n)/(2n + 1)$.*

Since weak solutions to (1.1) or (1.2) may not be unique, we use the terminology "a suitable weak solution" to refer to a certain weak solution constructed by the methods in [BF], [BBDP], and [BP1] and [BP2]. We shall review its definition in the next section and sketch a construction of these solutions in Appendix A. The proof of our results including Theorem 1.1 and those stated below involves the use of (1.5) in an essential way, so it does not work when n goes below 1.5. We point out that our bound on the Hausdorff dimension $(7 - 2n)/(2n + 1)$ is always less than 1 and is sharp in the sense that it tends to 0 and 1 as n tends to 3.5 and 1.5, respectively.

The proof of Theorem 1.1 follows rather easily from a covering argument coupling with properties (1.4) and (1.5). However, for the proof of the following size estimate in space-time, our main result, we need to make use of the further regularity properties of the suitable weak solution.

THEOREM 1.2. *Let h be a suitable weak solution of* (1.1) *or* (1.2)*, where $n \in (1.5, 3.5)$ and f is a power law with $q > 1 - n/2$. The parabolic Hausdorff dimension of the rupture set $\{(x, t) : h(x, t) = 0\}$ cannot exceed $2n/(2n - 3)$ for $n \in [2, 3.5)$ and $6/n + 1$ for $n \in (1.5, 2)$.*

The parabolic Hausdorff measure, to be discussed in Appendix B, is defined through covering a set by cylinders with different weights in space and time. Here we take the parabolic fourth order weights, so the parabolic Hausdorff dimension is equal to 5 for every open set in space-time. Again we observe that our estimate on the dimension of the rupture set lies between 1.75 and 5 and tends to 1.75 and 5 as n tends to 3.5 and 1.5, respectively.

Finally, we give an estimate on the rupture times.

THEOREM 1.3. *Let h be a suitable weak solution of* (1.1) *or* (1.2)*, where $n \in (2, 3.5)$ and f is a power law with $q > 1 - n/2$. The Hausdorff dimension of the set $\{t > 0 : h(x, t) = 0$ for some $x\}$ cannot exceed $1 - 2(n - 2)^2/(8 - n)$.*

Again this estimate becomes sharp as n tends to 3.5.

Theorems 1.1–1.3 are contained in the results in sections 2 and 3, where we also consider more general f. In section 4 we establish the result on finite time rupture mentioned above.

The problem of rupture for thin films is closely related to the formation of singularities for solutions of (1.1) or (1.2). Indeed, let us assume that the solution remains to be C^2 at the rupture point (x_0, t). Then it is bounded by a constant multiple of $|x - x_0|^2$ near x_0. Putting this into (1.5) yields a contradiction unless $n \leq 2$. It demonstrates that the second derivatives of the solution blow up at any rupture point

when $n > 2$, so the rupture set coincides with the singular set of any weak solution of (1.1) or (1.2) in which (1.4) and (1.5) hold. Our proofs of Theorems 1.1, 1.2, and 1.3 make use of some ideas in known works in the partial regularity of solutions for evolution equations. There are quite a number of works on this topic in recent years. We wish to mention the works of Caffarelli–Kohn–Nirenberg [CKN] (later simplified substantially by Lin [L]) on the three-dimensional Navier–Stokes equations, Struwe [S], and Chen–Struwe [CS] on the harmonic heat flows, Lin–Liu [LL] on the motion of liquid crystals, and Chou–Du–Zheng [CDZ] on the semilinear heat equation with supercritical growth.

In Jiang-Lin [JL] estimates for the Hausdorff dimension of the rupture set of a steady state of a multidimensional thin film type equation are present.

Although we are mainly concerned with thin films whose initial data are not too degenerate in the sense that they have finite entropy (1.5), there are significant results for weak solutions starting from nonnegative initial data that could vanish in an open set. Our results do not apply to these solutions. By restricting to the literature on the one-dimensional case (axisymmetric films) only, we point out Bernis [B1], [B2], and Hulshof-Shishkov [HS], where results on the finite speed of the propagation of zero are established for (1.1). That such property continues to hold for (1.2) is explained in [BP2]. Moreover, a waiting time phenomenon which asserts that the support of a thin film does not increase in a small period of time is established for (1.1) ($n \in (0,3)$) in Dal Passo-Giacomelli-Grun [DPGG]. For $n > 4$, it is known in [BBDP] that the support remains the same all the time.

2. A size estimate on the rupture set in space-time. First we give the definition of a suitable weak solution of the thin film type equation under the periodic boundary conditions. Consider the problem

$$\begin{cases} h_t + \big[h^n\big(h_{xx} + f(h)\big)_x\big]_x = 0, \ (x,t) \in (-L/2, L/2) \times (0,\infty), \\ h \text{ is of period } L \text{ for each } t > 0, \end{cases} \tag{2.1}$$

where n is positive and f is a measurable function in $[0,\infty)$ which belongs to $C^{2,\alpha}\big(0,\infty\big)$, $\alpha \in (0,1)$. Let S_L denote the circle obtained by identifying the endpoints of $(-L/2, L/2)$. A nonnegative function h in

$$C_{x,t}^{\frac{1}{2},\frac{1}{8}}\big(S_L \times (0,\infty)\big) \cap L^\infty\big(0,\infty; H^1(S_L)\big) \cap L^2_{loc}\big(0,\infty; H^2(S_L)\big)$$

is called a suitable weak solution of (2.1) if it fulfills the following requirements. For every $T > 0$,

(H_1) $h^{\frac{n}{2}}\big(h_{xx} + f(h)\big)_x \in L^2(Q_T), Q_T = S_L \times (0,T)$, and

$$\iint_{Q_T} h\Phi_t = -\iint_{Q_T} h^n\big(h_{xx} + f(h)\big)_x \Phi_x$$

for all $\Phi \in H^1(Q_T)$ which are compactly supported in Q_T.

(H_2) The following quantities

$$K_1 = \sup_{[0,T]} \int h_x^2,$$

$$K_2 = \iint_{Q_T} \Big(h^n\big|(h_{xx} + f(h))_x\big|^2 + h^n h_{xxx}^2\Big),$$

$$K_3 = \sup_{[0,T]} \int h^{\frac{3}{2}-n},$$

and

$$K_4 = \iint_{Q_T} \left(h^{-\frac{1}{2}+\delta} h_{xx}^2 + h^{-\frac{5}{2}+\delta} h_x^4 \right) \quad \forall \delta \in \left(0, \min\{1.5, n-1.5\}\right)$$

are finite, where K_1–K_4 depend on T, and K_4 also depends on δ.

(H_3) There exists $\Gamma \subseteq [0,T]$ of full measure such that, for every $t_0 \in \Gamma$, the following local energy inequality and local entropy inequality hold: For $\forall t > t_0, \forall \phi \in C^2(S_L)$,

$$\begin{aligned} \frac{1}{2}\int h_x^2(t)\phi^4 - \int F(h(t))\phi^4 + \int_{t_0}^t \int h^n \left| \left(h_{xx} + f(h)\right)_x \right|^2 \phi^4 \\ \leq -\int_{t_0}^t \int h^n \left(h_{xx} + f(h)\right)_x \left(h_{xx} + f(h)\right)(\phi^4)_x \\ - \int_{t_0}^t \int h^n \left(h_{xx} + f(h)\right)_x \left[h_{xx}(\phi^4)_x + h_x(\phi^4)_{xx} \right] \\ + \frac{1}{2}\int h_x^2(t_0)\phi^4 - \int F(h(t_0))\phi^4, \end{aligned} \tag{2.2}$$

and

$$\begin{aligned} \int h^{\frac{3}{2}-n+\delta}(t)\phi^4 + \sigma \int_{t_0}^t \int \left(h^{-\frac{1}{2}+\delta} h_{xx}^2 \phi^4 + h^{-\frac{5}{2}+\delta} h_x^4 \phi^4 \right) \\ \leq C \int_{t_0}^t \int \left[h^{\frac{3}{2}+\delta}\left(\phi_x^4 + \phi^2 \phi_{xx}^2\right) + f^2(h) h^{-\frac{1}{2}+\delta}\phi^4 \right] \\ + C\int h(t_0)\phi^4 + \int h^{\frac{3}{2}-n+\delta}(t_0)\phi^4, \ \delta \in \left(0, \min\{1.5, n-1.5\}\right), \end{aligned} \tag{2.3}$$

where F is a primitive of f and σ and C are positive constants depending on δ.

From the expression for K_4 we see that it is implicitly assumed $n > 1.5$ in the definition of a suitable weak solution. On the other hand, when $n \geq 3.5$, K_1 and K_3 together imply that a suitable weak solution is always positive; hence by parabolic regularity, it is a classical solution. Consequently we will focus on the range $(1.5, 3.5)$. To state our existence result for these solutions we impose the following assumptions on f: For some constants $C_1 - C_3$,

$$|f(z)| \leq C_1(1 + z^p), \quad z \geq 1 \quad \text{for some } 0 \leq p < 3, \tag{2.4}$$

$$|f'(z)| \leq C_2, \quad z \in (0,1], \tag{2.5}$$

or,

$$|f(z)| + z|f'(z)| \leq C_3 z^q, \quad z \in (0,1] \ \text{ for some } q > 1 - \frac{n}{2}. \tag{2.6}$$

Equation (2.4) restricts the growth of f at infinity. When $f(z)$ grows faster than z^3, it is conjectured that some solutions of (2.1) blow up in finite time. So growth restriction like (2.4) is needed to ensure the existence of a global, weak solution. According to the behavior of f at 0 we impose (2.5) and (2.6), respectively. For power laws the former applies when $q \geq 1$, and the latter applies when $q \in (1 - n/2, 1)$.

THEOREM 2.1. *Consider problem* (2.1), *where* $n \in (1.5, 3.5)$, (2.4) *and* (2.5) *or* (2.6) *hold. Then for any nonnegative* $h_0 \in H^1(S_L)$ *with finite* $||h_0^{3/2-n}||_{L^1}$, (2.1) *admits a suitable weak solution* h *satisfying* $||h(t) - h_0||_{L^2}$ *tends to* 0 *as* $t \downarrow 0$.

An outline of the proof of this theorem can be found in Appendix A. We remark that this theorem is still valid for $p = 3$ in (2.4) provided that $||h_0||_{L^1}$ is sufficiently small.

Weak solutions for (1.1) have been constructed in [BF], [BBDP], and [BP1] and for (1.2) in [BP2]. In particular, in Theorem 3.3 of [BP2] the existence of a weak solution essentially satisfying (H_1) and (H_2) is proved. A slight difference is that our Theorem 2.1 applies to the condition $q > 1 - n/2$, which could be negative when $n > 2$, while q is considered to be positive in the previous works. In (H_3) we also need the local energy and entropy inequalities. The inequalities of this type were derived in [B1], [B2], and [BP2] to study the finite speed of the propagation of the weak solution. Unlike previous works where the initial time is always taken to be zero, here we need these inequalities to be valid starting at initial times which form a subset of the time axis of full measure.

We begin with an estimate on the size of the rupture set in a spatial slice.

THEOREM 2.2. *Let* h *be a nonnegative function in* $L^\infty(0, T; H^1(S_L))$ *satisfying, for some* $n \in (1.5, 3.5)$,

$$\sup_{0<t<T} \int h_x^2 < \infty,$$

and

$$\sup_{0<t<T} \int h^{3/2-n} < \infty.$$

Then for each $T > 0$, *the* $((7-2n)/(2n+1))-$*Hausdorff measure of the set* $\mathcal{R}_T = \{x : h(x, T) = 0\}$ *is finite.*

Proof. Let h be a function satisfying the conditions in the theorem. We claim that

$$\int_{B_R} h_x^2(T) \le R^{\gamma_0}, \quad \gamma_0 = \frac{7-2n}{2n+1}$$

and

$$\int_{B_R} h^{\frac{3}{2}-n}(T) \le \delta_0 R^{\gamma_0}, \quad \delta_0 = \frac{2}{(1+\gamma_0)(\frac{3}{2}-n)+2}$$

hold for all small B_R centered at x_0, then $h(x_0, T) > 0$. Assuming on the contrary that (x_0, T) is a rupture point, we would have

$$\begin{aligned} h(x, T) &= h(x, T) - h(x_0, T) \\ &\le \left| \int_{x_0}^x 1 \right|^{1/2} \left(\int_{x_0}^x h_x^2 \right)^{1/2} \\ &\le |x - x_0|^{\frac{1}{2}(1+\gamma_0)} \end{aligned}$$

for all x sufficiently close to x_0, but then

$$\begin{aligned} \delta_0 R^{\gamma_0} &\ge \int_{B_R} h^{\frac{3}{2}-n}(T) \\ &\ge \frac{2R^{\frac{1}{2}(1+\gamma_0)(\frac{3}{2}-n)+1}}{\frac{1}{2}(1+\gamma_0)(\frac{3}{2}-n)+1}. \end{aligned}$$

As $\gamma_0 = \frac{1}{2}(1+\gamma_0)(\frac{3}{2}-n)+1$, contradiction holds.

Henceforth, at a rupture point (x_0, T) there exists $\{R_j\}$ (depending on x_0) $\downarrow 0$ such that

$$\int_{B_{R_j}} \big(h_x^2 + h^{\frac{3}{2}-n}\big)(T) > \delta_0 R_j^{\gamma_0}.$$

For each $\delta > 0$, the collection $\mathcal{C}_\delta$ of all of these balls B_{R_j}, with radii less than δ forms a covering of the rupture set $\mathcal{R}_T$. By a version of the Vitali covering theorem (see Appendix B) we can select from $\mathcal{C}_\delta$ a mutually disjoint, countable subcollection $\mathcal{C}'_\delta$ such that

$$\mathcal{R}_T \subseteq \bigcup \big\{ B_{5R_j}(x_j) : B_{R_j}(x_j) \in \mathcal{C}'_\delta \big\}.$$

Therefore, according to the definition of the Hausdorff measure Federer [Fe]

$$\begin{aligned}
\mathcal{H}_\delta^{\gamma_0}(\mathcal{R}_T) &\le \alpha(\gamma_0) \sum (5R_j)^{\gamma_0} \\
&\le \frac{5^{\gamma_0}\alpha(\gamma_0)}{\delta_0} \sum \int_{B_{R_j}(x_j)} \big(h_x^2 + h^{\frac{3}{2}-n}\big)(T) \\
&\le \frac{5^{\gamma_0}\alpha(\gamma_0)}{\delta_0} \int \big(h_x^2 + h^{\frac{3}{2}-n}\big)(T), \quad \alpha(s) = \frac{\pi^s/2}{\Gamma(s/2+1)},
\end{aligned}$$

which leads to the desired conclusion after taking $\delta \to 0$. □

Clearly Theorem 1.1 is a special case of Theorem 2.2. Here we have used little beyond the finiteness of K_1 and K_3. Although the proof of Theorem 2.2 is quite simple, as one will see, the same idea works in the size estimate of the rupture set in space-time. In order to obtain such estimates, we need to make use of the finiteness of the integrals in space-time such as the quantities K_2 and K_4. We have the following.

THEOREM 2.3. *Consider any suitable weak solution of* (2.1)*, where* $n \in (2, 3.5)$ *and either* (2.5) *or* (2.6) *hold. The parabolic Hausdorff dimension of the rupture set of this solution cannot exceed* $2n/(2n-3)$.

The proof of this theorem depends on Lemmas 2.1–2.4 below. For the ease of presentation we shall prove the theorem first.

Proof. Let (x_0, T) be a rupture point of the solution h. We claim that, for every $\gamma_0 \in \big(\frac{7+2\delta}{4}, 4+2\delta\big)$, there exists a sequence $\{R_j\}$, $R_j \downarrow 0$, such that

$$\iint_{Q_{R_j}} h^n \Big| \big(h_{xx} + f(h)\big)_x \Big|^2 > R_j^{\gamma_0},$$

or

$$\iint_{Q_{R_j}} h^{-\frac{5}{2}+\delta} h_x^4 > R_j^{\gamma_0}$$

holds. For, were this not true, it means that (2.7) and (2.14) hold for all sufficiently small R. By Lemma 2.4, there exists some $t_1 \in \Gamma \cap [T - R^4, T]$ such that

$$\int_{B_{R/2}} h_x^2(t_1) \le C R^\gamma \quad \forall \gamma \in \Big(0, \frac{4\gamma_0 - 7 - 2\delta}{3+2\delta}\Big).$$

Then by Lemma 2.3,

$$\int_{B_{R/4}} h_x^2 \le C R^\gamma \quad \forall t \in [t_1, T].$$

Lemma 2.2 further gives

$$\sup_{B_{R/4}\times[t_1,T]} h \le CR^{\frac{1+\gamma}{2}},$$

which means that

$$h(x,T) \le C|x-x_0|^{\frac{1+\gamma}{2}}$$

for all x sufficiently close to x_0. However, on the other hand,

$$\begin{aligned}\infty &> \int h^{\frac{3}{2}-n}(T)\\ &\ge C\int |x-x_0|^{\frac{1+\gamma}{2}(\frac{3}{2}-n)} = \infty,\end{aligned}$$

if $(\frac{1+\gamma}{2})(\frac{3}{2}-n) \le -1$, i.e., $\gamma \ge (7-2n)/(2n-3)$. A contradiction will be drawn if we can verify that

$$\frac{7-2n}{2n-3} < \frac{4\gamma_0 - 7 - 2\delta}{3+2\delta}, \quad \text{i.e., } \gamma_0 > \frac{2n+2\delta}{2n-3}.$$

A direct computation shows that this is true if $n > 2$.

Thus, at a rupture point (x_0,T), there exists a sequence of cylinders $\{Q_{R_j}\}$, $R_j \downarrow 0$, satisfying

$$\iint_{Q_{R_j}} \left[h^n \left|\big(h_{xx}+f(h)\big)_x\right|^2 + h^{-\frac{5}{2}+\delta}h_x^4\right] > R_j^{\gamma_0}.$$

The collection of all of these cylinders forms a covering of the rupture set in space-time, and we can replace the arguments in the second half of the proof of Theorem 2.2 involving the Hausdorff measure by the parabolic Hausdorff measure (see Appendix B) to show that the γ_0-parabolic Hausdorff measure of the rupture set is finite for all $\gamma_0 > (2n+2\delta)/(2n-3)$. By letting $\delta \to 0$ we conclude that its parabolic Hausdorff dimension cannot exceed $2n/(2n-3)$. The proof of Theorem 2.3 is completed. □

LEMMA 2.1. *Let χ be a strictly increasing, continuous function in $[0,\infty)$, with $\chi(0) > 0$. Define a sequence $\{\alpha_n\}$ by $\alpha_{n+1} = \chi(\alpha_n)$, $\alpha_1 = 0$. Then $\{\alpha_n\}$ is increasing and*

(a) *it diverges to ∞ if $y = \chi(x)$ has no intersection with $y = x$, or*
(b) *it converges to some α^* which is the $x-$coordinate of the first intersection between $y = \chi(x)$ and $y = x$.*

Consequently, for any α (less than α^* if α^* exists), there exists some N such that $\alpha_N \ge \alpha$.

The proof of this lemma is elementary and is omitted.

LEMMA 2.2. *Let h be a suitable weak solution of (2.1), and (x_0,T) a rupture point of h. Suppose that*

$$\iint_{Q_R} h^n \left|(h_{xx}+f(h))_x\right|^2 \le R^{\gamma_0}, \quad Q_R = (x_0-R,x_0+R)\times(T-R^4,T), \tag{2.7}$$

and

$$\int_{B_R} h_x^2 \le C_4 R^{\gamma} \quad \forall t \in [t_1,T], \quad B_R = (x_0-R,x_0+R), \tag{2.8}$$

hold for some R, γ_0, γ, t_1, *and* C_4, *where* $t_1 \in [T - R^4, T]$, $R^4 < T$, *and* γ *satisfies*

$$\gamma < \frac{2\gamma_0 + n}{2 - n} \quad \text{for } n \in (1.5, 2), \text{ and } < \infty \quad \text{for } n \in [2, 3.5). \tag{2.9}$$

Then for every $\tau_0 \in (0,1)$, *there exists a constant* C *depending on* n, γ_0, γ, C_4, *and* τ_0 *such that*

$$\sup_{B_{\tau_0 R} \times [t_1, T]} h \le C R^{\frac{1+\gamma}{2}}.$$

Proof. By (H_1) in the definition of a suitable weak solution,

$$\iint h \Phi_t = -\iint h^n \big(h_{xx} + f(h)\big)_x \Phi_x \quad \forall \Phi \text{ test function.}$$

We choose $\Phi = \xi(x)\theta_\delta(t)$, where ξ is compactly supported in B_R, and $\theta_\delta(t) = \int_0^t \eta(t)dt$, with η given by

$$\eta = \begin{cases} -\dfrac{1}{2\delta}, & t \in [s - \delta, s + \delta], \\ \dfrac{1}{2\delta}, & t \in [T - \delta, T + \delta], \\ 0, & \text{otherwise}, \end{cases}$$

and s is a fixed number in $[t_1, T]$. Letting $\delta \downarrow 0$, as $\theta_\delta \le 1$, we obtain

$$\left| \int_{B_R} \big(h(x,T) - h(x,t)\big)\xi(x) \right| \le \int_t^T \int_{B_R} h^n \left| \big(h_{xx} + f(h)\big)_x \xi_x \right|, \tag{2.10}$$

where we have changed notation from s to t. Letting $\tau \in (\tau_0, 1)$ to be chosen later, we pick ξ so that $\xi = 1$ in $B_{\tau R}$ and $|\xi_x| \le 1/R(1-\tau)$ in B_R. Using (2.7),

$$\begin{aligned} \int_t^T \int_{B_R} h^n \left| \big(h_{xx} + f(h)\big)_x \xi_x \right| &\le \sqrt{\int_t^T \int_{B_R} h^n \big(h_{xx} + f(h)\big)_x^2} \ \sqrt{\int_t^T \int_{B_R} h^n \xi_x^2} \\ &\le \frac{1}{(1-\tau)} R^{\frac{\gamma_0 + 3}{2}} \sup_{Q_R} h^{\frac{n}{2}}. \end{aligned}$$

It follows from (2.10) that

$$\left| \fint_{B_R} \big(h(x,T) - h(x,t)\big)\xi(x) \right| \le \frac{1}{2\tau(1-\tau)} R^{\frac{\gamma_0 + 1}{2}} \sup_{Q_R} h^{\frac{n}{2}},$$

where we have set $\fint_{B_R} F \equiv \frac{\int_{B_R} F}{\int_{B_R} \xi}$. By (2.8) and (2.10),

$$\begin{aligned} h(x,t) &\le \left| \fint_{B_R} \big(h(x,t) - h(y,t)\big)\xi(y)dy \right| + \left| \fint_{B_R} \big(h(y,t) - h(y,T)\big)\xi(y)dy \right| \\ &\quad + \left| \fint_{B_R} \big(h(y,T) - h(x_0,T)\big)\xi(y)dy \right| \\ &\le 2\sqrt{C_4} R^{\frac{1+\gamma}{2}} + \frac{1}{2\tau(1-\tau)} R^{\frac{1+\gamma_0}{2}} \sup_{Q_R} h^{n/2} \quad \forall x \in B_{\tau R}. \end{aligned} \tag{2.11}$$

Hence in the case

$$\sup_{Q_R} h \le CR^{\alpha} \quad \text{for some } \alpha < \frac{1+\gamma}{2}, \tag{2.12}$$

(2.11) implies that

$$\begin{aligned} \sup_{Q'_R} h &\le C\Big(R^{\frac{1+\gamma}{2}} + R^{\frac{1+\gamma_0+n\alpha}{2}}\Big) \\ &\le CR^{\chi(\alpha)}, \quad Q'_R = B_{\tau R} \times [t_1, T], \end{aligned} \tag{2.13}$$

provided that $\chi(\alpha) \equiv (1+\gamma_0+n\alpha)/2 < (1+\gamma)/2$. Starting at $\alpha = 0$, we bootstrap between (2.12) and (2.13) to obtain

$$\sup_{B_{\tau^k R} \times [t_1, T]} h \le C_k R^{\chi(\alpha_k)}$$

after k times of iterations as long as $\chi(\alpha_k) < (1+\gamma)/2$. When $n \ge 2$, $y = \chi(x)$ does not intersect $y = x$, so there exists an N such that $\chi(\alpha_N) \ge (1+\gamma)/2$. Then the lemma follows by applying the Holder continuity of h in space. When $n \in (1.5, 2)$, the same conclusion holds if $(\gamma+1)/2 < \alpha_*$, the intersection of $y = \chi(x)$, and $y = x$. As α_* is given by $\frac{(1+\gamma_0)/2}{1-n/2} = \frac{1+\gamma_0}{2-n}$, $(\gamma+1)/2 < \alpha_*$ is equivalent to (2.9). ∎

LEMMA 2.3. *Let h be a suitable weak solution of* (2.1)*, where $n \in (1.5, 3.5)$ and* (2.5) *holds, and let (x_0, T) be a rupture point of h. Suppose that* (2.7)*,*

$$\iint_{Q_R} h^{-\frac{5}{2}+\delta} h_x^4 \le R^{\gamma_0} \tag{2.14}$$

and

$$\int_{B_R} h_x^2(t_1) \le C_5 R^{\gamma} \tag{2.15}$$

hold for some $R, \gamma_0, \gamma, t_1 \in \Gamma \cap [T - R^4, T]$, C_5, where γ and γ_0 also satisfy (2.9)*,*

$$\gamma_0 > \frac{7 - 2n + 2\delta}{4}, \quad \delta \in (0, n - 1.5), \tag{2.16}$$

and

$$0 \le \gamma < 3. \tag{2.17}$$

Then for every $\tau_0 \in (0,1)$, there exists a constant C depending on $n, \gamma_0, \gamma, \delta, C_5$, and τ_0 such that

$$\int_{B_{\tau_0 R}} h_x^2 \le CR^{\gamma} \quad \forall t \in [t_1, T].$$

When (2.6) *instead of* (2.5) *holds in the above assumptions, the same conclusion holds when* (2.17) *is replaced by*

$$\gamma < \frac{8-n}{n}. \tag{2.17}'$$

Proof. Let ϕ be a cut-off function supported in B_R, $\phi = 1$ in $B_{\tau R}$, where $\tau \in (\tau_0, 1)$ is to be chosen later. We plug ϕ into the local energy inequality (2.2) and use the Cauchy–Schwarz inequality to get

$$\begin{aligned}&\left|\iint h^n(h_{xx}+f(h))_x(h_{xx}+f(h))(4\phi^3\phi_x)\right|\\&\le \frac{1}{4}\iint h^n\left|(h_{xx}+f(h))_x\right|^2\phi^4 + C\iint h^n(h_{xx}+f(h))^2\phi^2\phi_x^2\end{aligned}$$

and

$$\begin{aligned}&\left|\iint h^n(h_{xx}+f(h))_x\left[4h_{xx}\phi^3\phi_x + h_x(4\phi^3\phi_{xx}+12\phi^2\phi_x^2)\right]\right|\\&\le \frac{1}{4}\iint h^n\left|(h_{xx}+f(h))_x\right|^2\phi^4 + C\iint\left[h^n(h_{xx}^2\phi^2\phi_x^2 + h_x^2(\phi_x^4+\phi^2\phi_{xx}^2)\right].\end{aligned}$$

It follows that

$$\begin{aligned}\frac{1}{2}\int_{B_R} h_x^2\phi^4 &\le \int_{B_R} F(h)\phi^4 + \frac{1}{2}\int_{B_R} h_x^2(t_1)\phi^4 - \int_{B_R} F(h(t_1))\phi^4\\&\quad - \frac{1}{2}\int_{t_1}^t\int_{B_R} h^n\left|\big(h_{xx}+f(h)\big)_x\right|^2\phi^4 + C\left[\int_{t_1}^t\int_{B_R} h^n\big(h_{xx}+f(h)\big)^2\phi^2\phi_x^2\right.\\&\quad\left. + \int_{t_1}^t\int_{B_R} h^n\big(h_{xx}^2\phi^2\phi_x^2 + h_x^2(\phi_x^4+\phi^2\phi_{xx}^2)\big)\right]\\&\le \int_{B_R} F(h)\phi^4 + \frac{1}{2}\int_{B_R} h_x^2(t_1)\phi^4\\&\quad - \int_{B_R} F(h(t_1))\phi^4 - \frac{1}{4}\int_{t_1}^t\int_{B_R} h^n\left|\big(h_{xx}+f(h)\big)_x\right|^2\phi^4\\&\quad + C\left[\int_{t_1}^t\int_{B_R} h^n f'^2(h)h_x^2\phi^4 + \int_{t_1}^t\int_{B_R} h^n f^2(h)\phi^2\phi_x^2\right.\\&\quad\left. + \int_{t_1}^t\int_{B_R} h^n h_x^2(\phi_x^4+\phi^2\phi_{xx}^2) + \int_{t_1}^t\int_{B_R} h^n h_{xx}^2\phi^2\phi_x^2\right]\\&\le \int_{B_R} F(h)\phi^4 + \frac{1}{2}\int_{B_R} h_x^2(t_1)\phi^4\\&\quad - \int_{B_R} F(h(t_1))\phi^4 - \frac{1}{4}\int_{t_1}^t\int_{B_R} h^n\left|\big(h_{xx}+f(h)\big)_x\right|^2\phi^4\\&\quad + C\left[\int_{t_1}^t\int_{B_R} h^n f'^2(h)h_x^2\phi^4 + \int_{t_1}^t\int_{B_R} h^n f^2(h)\phi^2\phi_x^2\right.\\&\quad\left. + \int_{t_1}^t\int_{B_R} h^n h_x^2(\phi_x^4+\phi^2\phi_{xx}^2) + \int_{t_1}^t\int_{B_R} h^{n-2}h_x^4\phi^2\phi_x^2\right].\end{aligned}\tag{2.18}$$

Notice that in the last inequality we have used

$$\begin{aligned}\int_{t_1}^{t}\int_{B_R} h^n h_{xx}^2\phi^2\phi_x^2 &= -\int_{t_1}^{t}\int_{B_R} h^n h_x h_{xxx}\phi^2\phi_x^2 - n\int_{t_1}^{t}\int_{B_R} h^{n-1}h_x^2 h_{xx}\phi^2\phi_x^2\\ &\quad -\int_{t_1}^{t}\int_{B_R} h^n h_x h_{xx}(2\phi\phi_x^3 + 2\phi^2\phi_x\phi_{xx})\\ &\le \varepsilon\int_{t_1}^{t}\int_{B_R} h^n h_{xxx}^2\phi^4 + \varepsilon\int_{t_1}^{t}\int_{B_R} h^n h_{xx}^2\phi^2\phi_x^2\\ &\quad + C_\varepsilon\left[\int_{t_1}^{t}\int_{B_R} h^n h_x^2(\phi_x^4 + \phi^2\phi_{xx}^2) + \int_{t_1}^{t}\int_{B_R} h^{n-2}h_x^4\phi^2\phi_x^2\right].\end{aligned}$$

Therefore, under (2.5), when $f \in C^1[0,\infty)$, we have

$$\begin{aligned}\frac{1}{2}\int_{B_R} h_x^2\phi^4 &\le \int_{B_R} F(h)\phi^4 + \frac{1}{2}\int_{B_R} h_x^2(t_1)\phi^4 - \int_{B_R} F(h(t_1))\phi^4\\ &\quad + C\left[\int_{t_1}^{t}\int_{B_R} h^n h_x^2(\phi^4 + \phi_x^4 + \phi^2\phi_{xx}^2) + \int_{t_1}^{t}\int_{B_R} h^{n-2}h_x^4\phi^2\phi_x^2\right.\\ &\quad \left. + \int_{t_1}^{t}\int_{B_R} h^n\phi^2\phi_x^2\right], \qquad (2.19)\end{aligned}$$

since a suitable weak solution is bounded. Here the constant C depends on f. Suppose that

$$\int_{B_R} h_x^2 \le CR^\alpha \quad \forall t\in[t_1,T] \quad \text{for some } \alpha<\gamma. \qquad (2.20)$$

We claim that

$$\int_{B_{\tau R}} h_x^2 \le C'R^{\chi(\alpha)} \quad \forall t\in[t_1,T], \qquad (2.21)$$

where

$$\chi(\alpha) = \min\left\{\frac{3}{2}+\frac{\alpha}{2}, \frac{n}{2}+\left(1+\frac{n}{2}\right)\alpha, \gamma_0 + \frac{n-\frac{7}{2}-\delta}{2} + \frac{n+\frac{1}{2}-\delta}{2}\alpha\right\}$$

as long as $\alpha<\gamma$. For, by Lemma 2.2 and (2.20), we have

$$\sup_{B_{\tau R}\times[t_1,T]} h \le CR^{\frac{1+\alpha}{2}}.$$

Using this estimate we control the integrals on the right of (2.19) as follows.

$$\begin{aligned}&\int_{B_R} F(h(t))\phi^4 \le CR^{\frac{3}{2}+\frac{\alpha}{2}},\\ &\int_{B_R} h_x^2(t_1)\phi^4 \le C_5R^\gamma, \qquad \text{(from (2.15))}\\ &\int_{t_1}^{t}\int_{B_R} h^n h_x^2\left(\phi^4+\phi_x^4+\phi^2\phi_{xx}^2\right) \le CR^{\alpha+\frac{n}{2}(1+\alpha)},\\ &\int_{t_1}^{t}\int_{B_R} h^{n-2}h_x^4\phi^2\phi_x^2 \le CR^{-2}\sup_{Q_R} h^{n+\frac{1}{2}-\delta}\int_{t_1}^{t}\int_{B_R} h^{-\frac{5}{2}+\delta}h_x^4\\ &\qquad\qquad \le CR^{\gamma_0+\frac{n-\frac{7}{2}-\delta}{2}+\frac{n+\frac{1}{2}-\delta}{2}\alpha},\\ &\int_{t_1}^{t}\int_{B_R} h^n\phi^2\phi_x^2 \le CR^{3+\frac{n}{2}(1+\alpha)} \le CR^{\alpha+\frac{n}{2}(1+\alpha)},\end{aligned}$$

so (2.21) follows after putting these estimates back to (2.19). As (2.20) holds for $\alpha = 0$, we can bootstrap between (2.20) and (2.21) to increases the power in R in (1.20). Observe that the function χ is piecewise linear with slopes equal to $1/2, 1+n/2$, or $(2n+1-2\delta)/4$. As $(2n+1-2\delta)/4 > 1$ for $\delta < n - 3/2$, χ can possibly intersect $y = x$ at $\alpha^* = 3$. The lemma now follows from Lemma 2.1 after taking $\tau^N = \tau_0$.

In case f satisfies (2.6), the local energy inequality reads as

$$\begin{aligned}\frac{1}{2}\int_{B_R} h_x^2\phi^4 \le{}& \frac{B}{q(q+1)}\int_{B_R} h^{q+1}\phi^4 + \frac{1}{2}\int_{B_R} h_x^2(t_1)\phi^4 - \frac{B}{q(q+1)}\int_{B_R} h^{q+1}(t_1)\phi^4\\ &+ C\bigg(\int_{t_1}^t\int_{B_R} h^n h_x^2\big(\phi_x^4 + \phi^2\phi_{xx}^2\big) + \int_{t_1}^t\int_{B_R} h^{n-2}h_x^4\phi^2\phi_x^2\\ &+ \int_{t_1}^t\int_{B_R} h^{n+2q}\phi^2\phi_x^2 + \int_{t_1}^t\int_{B_R} h^{n+2q-2}h_x^2\phi^4\bigg).\end{aligned}$$

Under (2.20), the integral terms involving q can be estimated as follows:

$$\begin{aligned}\int_{B_R} h^{q+1}\phi^4 &\le CR\sup_{B_R} h^{q+1}\\ &\le CR^{\frac{q+3}{2}+\frac{4-n}{4}\alpha}\\ &\le CR^{\frac{8-n}{4}+\frac{4-n}{4}\alpha}, \qquad (\because q > 1 - n/2)\\ \int_{t_1}^t\int_{B_R} h^{n+2q}\phi^2\phi_x^2 &\le CR^3\sup_{Q_R} h^{n+2q}\\ &\le CR^{4+\alpha}\end{aligned}$$

and

$$\begin{aligned}\int_{t_1}^t\int_{B_R} h^{n+2q-2}h_x^2\phi^4 &\le CR^4\bigg(\sup_{[t_1,t]}\int_{B_R} h_x^2\bigg)\sup_{Q_R} h^{n+2q-2}\\ &\le CR^{4+\alpha}, \qquad (\because q > 1 - n/2).\end{aligned}$$

So (2.21) holds after χ is replaced by the function χ':

$$\begin{aligned}\chi'(\alpha) = \min\bigg\{&\frac{8-n}{4} + \frac{4-n}{4}\alpha, 4+\alpha, \frac{n}{2} + \Big(1+\frac{n}{2}\Big)\alpha,\\ &\gamma_0 + \frac{n - \frac{7}{2} - \delta}{2} + \frac{n + \frac{1}{2} - \delta}{2}\alpha\bigg\}.\end{aligned}$$

Arguing as before, we can show that Lemma 2.3 holds when $q > 1 - n/2$ and (2.17) is replaced by (2.17)′. □

LEMMA 2.4. *Let h be a suitable weak solution of* (2.1)*, where $n \in (1.5, 3.5)$ and* (2.5) *holds, and let (x_0, T) be a rupture point of h. Suppose* (2.7)*,* (2.14)*,* (2.16)*, and* (2.17) *hold. Then there exists $t_1 \in \Gamma \cap [T - R^4, T]$ such that*

$$\int_{B_{R/2}} h_x^2(t_1) \le CR^\gamma \quad \forall\gamma \in \bigg(0, \frac{4\gamma_0 - 7 - 2\delta}{3 + 2\delta}\bigg),$$

if

$$\frac{7 + 2\delta}{4} < \gamma_0 \le 4 + 2\delta. \tag{2.22}$$

When (2.5) *is replaced by* (2.6) *and* (2.17) *by* (2.17)′*, respectively, the same conclusion holds when* (2.22) *is replaced by*

$$\frac{7+2\delta}{4} < \gamma_0 < 1 + \frac{6+4\delta}{n}. \tag{2.22}'$$

Proof. We only prove this lemma when f satisfies (2.5), for the other case can be proved in a similar way. From (2.14) there exists $t_1 \in \Gamma$ such that

$$\int_{B_R} h^{-\frac{5}{2}+\delta} h_x^4(t_1) \le R^{\gamma_0 - 4}.$$

Thus

$$\begin{aligned} \int_{B_R} h_x^2(t_1) &\le \sqrt{\int_{B_R} h^{-\frac{5}{2}+\delta}(t_1) h_x^4(t_1)} \ \sqrt{\int_{B_R} h^{\frac{5}{2}-\delta}(t_1)} \\ &\le R^{\frac{\gamma_0-3}{2}} \sup_{B_R} h^{\frac{5-2\delta}{4}}(t_1). \end{aligned} \tag{2.23}$$

Suppose that

$$\int_{B_R} h_x^2(t_1) \le C R^{\alpha} \tag{2.24}$$

for some α satisfying $\alpha < \gamma$. We claim that, for any fixed $\tau_0 \in (0,1)$,

$$\int_{B_{\tau_0 R}} h_x^2(t_1) \le C' R^{\chi(\alpha)}, \tag{2.25}$$

where $\chi(\alpha) = \frac{\gamma_0 - 3}{2} + \frac{5-2\delta}{8}(1+\alpha)$ as long as $\chi(\alpha) < \gamma$. For, using (2.24) and the fact that $\alpha < \gamma$, we can apply Lemma 2.3 to infer that

$$\int_{B_{\frac{1+\tau_0}{2} R}} h_x^2 \le C' R^{\alpha} \quad \forall t \in [t_1, T].$$

By Lemma 2.2,

$$\sup_{B_{\tau_0 R} \times [t_1, T]} h \le C R^{\frac{1+\alpha}{2}}.$$

Plugging this estimate into (2.23) yields (2.25). Now, using the fact that (2.24) holds for $\alpha = 0$, bootstrapping between (2.24) and (2.25) increases the power in R. Noting that the intersection of χ and $y = x$ is at $\alpha^* = (4\gamma_0 - 7 - 2\delta)/(3 + 2\delta)$, we conclude that the lemma holds if $\gamma < (4\gamma_0 - 7 - 2\delta)/(3 + 2\delta)$. Note that in (2.17) it is required that $\gamma < 3$, and this holds if $(4\gamma_0 - 7 - 2\delta)/(3 + 2\delta) < 3$, that is, $\gamma_0 \le 4 + 2\delta$. ∎

An estimate on the Hausdorff dimension of the rupture set is also available in the range $(1.5, 2]$. We need to work a bit harder for it though.

THEOREM 2.4. *Let h be a suitable weak solution of* (2.1)*, where $n \in (1.5, 2]$ and f satisfies either* (2.5) *or* (2.6)*. The Hausdorff dimension of the rupture set of h cannot exceed $1 + 6/n$.*

Proof. Let us consider the case where f satisfies (2.6) only. We claim that at a rupture point (x_0, T) there exists $\{R_j\} \downarrow 0$ such that

$$\iint_{Q_{R_j}} h^n \Big| \big(h_{xx} + f(h)\big)_x \Big|^2 > R_j^{\gamma_0},$$

$$\iint_{Q_{R_j}} h^{-\frac{5}{2}+\delta} h_x^4 > R_j^{\gamma_0},$$

or

$$\iint_{Q_{R_j}} h^{\frac{3}{2}-n+\delta} > R_j^{\gamma_0+\lambda}$$

hold when γ_0 and δ satisfy $(2.22)'$ and λ is a fixed positive number. For, were this not true, that means (2.7), (2.14), and

$$\iint_{Q_R} h^{\frac{3}{2}-n+\delta} \le R^{\gamma_0+\lambda} \tag{2.26}$$

hold for all sufficiently small R. By Lemma 2.4,

$$\int_{B_{R/2}} h_x^2(t_1) \le CR^{\gamma} \quad \text{for } \gamma < \min\left\{\frac{4\gamma_0 - 7 - 2\delta}{3+2\delta}, \frac{8-n}{n}\right\} = \frac{4\gamma_0 - 7 - 2\delta}{3+2\delta}.$$

By Lemma 2.3 we further infer that

$$\int_{B_{R/4}} h_x^2(t) \le C'R^{\gamma} \quad \forall t \in [t_1, T].$$

Consequently,

$$h(x,T) \le C|x - x_0|^{\frac{1+\gamma}{2}} \quad \forall x \text{ sufficiently close to } x_0.$$

On the other hand, (2.26) implies that there exists some $t_2 \in \Gamma$ such that

$$\int_{B_R} h^{\frac{3}{2}-n+\delta}(t_2) \le CR^{\gamma_0-4+\lambda}.$$

By Lemma 2.5,

$$\int_{B_{R/2}} h^{\frac{3}{2}-n+\delta}(t) \le C'R^{\gamma_0-4+\lambda} \quad \forall t \in [t_2, T].$$

So

$$\begin{aligned} 4R^{\gamma_0-4+\lambda} &\ge \int_{B_{R/2}} h^{\frac{3}{2}-n+\delta} \\ &\ge C \int_{B_{R/2}} |x - x_0|^{\frac{1+\gamma}{2}(\frac{3}{2}-n+\delta)} \\ &\ge CR^{\frac{1+\gamma}{2}(\frac{3}{2}-n+\delta)+1} \end{aligned}$$

if

$$\left(\frac{1+\gamma}{2}\right)\left(\frac{3}{2}-n+\delta\right)+1>0.$$

To derive a contradiction we choose

$$\gamma_0 = 1+\frac{6}{n}$$

and

$$\gamma = \frac{4\gamma_0-7}{3}-\sigma,$$

where σ is chosen to be small as δ is small and such that

$$\gamma < \frac{4\gamma_0-7-2\delta}{3+2\delta}$$

and

$$\frac{1+\gamma}{2}\left(\frac{3}{2}-n+\delta\right)+1>0.$$

As $\delta,\ \sigma\to 0$, and γ tends to $(4\gamma_0-7)/3$ and

$$\gamma_0-4+\lambda>\gamma_0-4=\frac{1+\gamma}{2}\left(\frac{3}{2}-n\right)+1,$$

the contradiction holds.

Now a covering argument as in the proof of Theorem 2.3 finishes the job. □

LEMMA 2.5. *Let h be a suitable weak solution* (2.1)*, where $n\in(1.5,2]$ and either* (2.5) *or* (2.6) *hold. There exists a small $R_0>0$ such that if*

$$\int_{B_R} h^{\frac{3}{2}-n+\delta}(t_1)\le C_6R^{\gamma},\quad 0<\delta<n-\frac{3}{2}\ \ \textit{small,}$$

for some $\gamma\in[0,1], R<R_0$ and $t_1\in\Gamma\cap[T-R^4,T]$, then for every $\tau_0\in(0,1)$,

$$\int_{B_{\tau_0 R}} h^{\frac{3}{2}-n+\delta}(t)\le CR^{\gamma}\quad \forall t\in[t_1,T],$$

where C depends on n,q,δ,C_6, and τ_0.

Proof. We focus on the case where (2.6) holds, since the other case can be handled similarly. By the local entropy inequality (2.3) $\forall t\ge t_1$,

$$\begin{aligned}\int_{B_R} h^{\frac{3}{2}-n+\delta}\phi^4 \le &-\sigma\left[\int_{t_1}^{t}\int_{B_R} h^{-\frac{1}{2}+\delta}h_{xx}^2\phi^4+\int_{t_1}^{t}\int_{B_R} h^{-\frac{5}{2}+\delta}h_x^4\phi^4\right]\\ &+C\left[\int_{t_1}^{t}\int_{B_R} h^{\frac{3}{2}+\delta}(\phi_x^4+\phi^2\phi_{xx}^2)+\int_{t_1}^{t}\int_{B_R} h^{2q-\frac{1}{2}+\delta}\phi^4\right]\\ &+\int_{B_R} h^{\frac{3}{2}-n+\delta}(t_1),\end{aligned}$$

where ϕ is supported in B_R. Using $q \geq 1 - n/2$, we have

$$\int_{t_1}^{t} \int_{B_R} h^{\frac{3}{2}+\delta} \left(\phi_x^4 + \phi^2 \phi_{xx}^2\right) \leq CR,$$
$$\int_{t_1}^{t} \int_{B_R} h^{2q-\frac{1}{2}+\delta} \phi^4 \leq C(t-t_1) \sup_{[t_1,t]} \int_{B_R} h^{\frac{3}{2}-n+\delta} \phi^4.$$

Therefore,

$$\sup_{[t_1,t]} \int_{B_R} h^{\frac{3}{2}-n+\delta} \phi^4 \leq C \left[(t-t_1) \sup_{[t_1,t]} \int_{B_R} h^{\frac{3}{2}-n+\delta} + R^{\gamma} \right].$$

By taking t_2 so that $C(t_2 - t_1) = 1/2$, and $\phi \equiv 1$ on $B_{\tau R}$, we get

$$\sup_{[t_1,t_2]} \int_{B_{\tau R}} h^{\frac{3}{2}-n+\delta} \leq CR^{\gamma}.$$

Now we may use t_2 as the initial time to extend the estimate beyond t_2. After finitely many times extensions the lemma follows. □

3. An estimate on rupture times. In this section we establish an estimate on the Hausdorff dimension of the rupture times. An instant t is a rupture time for a suitable weak solution u of (2.1) if $u(x,t) = 0$ for some x. As our derivation does not involve the use of the local energy or entropy inequalities, the condition (H_3) in the definition of a suitable weak solution is not needed. In other words, the main result, Theorem 3.1, holds for any weak solution of (2.1) satisfying (H_1) and (H_2) only.

We start with the following interpolating inequalities controlling $\sup u^{-1}$ in terms of integrals involving the derivatives of the function u and the integrals of its negative powers.

LEMMA 3.1. *Let u be a nonnegative H^1-function of period L. Then for any $p > 2$, there exists a constant C depending on p and L such that*

$$\sup u^{-1} \leq C \left[\left(\int u^{-p} \right)^{\frac{1}{p}} + \left(\int u^{-p} \right)^{\frac{1}{p-2}} \left(\int u_x^2 \right)^{\frac{1}{p-2}} \right].$$

Proof. We have, for $\alpha > 0$,

$$u^{-\alpha}(x) \leq u^{-\alpha}(y) + \alpha \left| \int u^{-\alpha-1} u_x \right|$$
$$\leq u^{-\alpha}(y) + \alpha \left(\int u^{-2\alpha-2} \right)^{\frac{1}{2}} \left(\int u_x^2 \right)^{\frac{1}{2}}.$$

Integrating in y yields

$$u^{-\alpha}(x) \leq \frac{1}{L} \int u^{-\alpha} + \alpha \left(\int u^{-2\alpha-2} \right)^{\frac{1}{2}} \left(\int u_x^2 \right)^{\frac{1}{2}}.$$

Letting $2\alpha = p - 2$, we get

$$u^{-1}(x) \leq C \left[\left(\int u^{\frac{-p+2}{2}} \right)^{\frac{2}{p-2}} + \left(\int u^{-p} \right)^{\frac{1}{p-2}} \left(\int u_x^2 \right)^{\frac{1}{p-2}} \right]$$
$$\leq C \left[\left(\int u^{-p} \right)^{\frac{1}{p}} + \left(\int u^{-p} \right)^{\frac{1}{p-2}} \left(\int u_x^2 \right)^{\frac{1}{p-2}} \right]. \qquad \square$$

LEMMA 3.2. *Let u be a nonnegative H^2-function of period L. Then for $p > 2/3$, there exists a constant C depending on p and L such that*

$$\sup u^{-1} \le C\left[\left(\int u^{-p}\right)^{\frac{3}{3p-2}}\left(\int u_{xx}^2+\beta\right)^{\frac{1}{3p-2}}+\left(\int u_{xx}^2+\beta\right)^{-\frac{1}{2}}\right] \quad \forall \beta \ge 0.$$

Proof. It suffices to establish this inequality by taking u to be positive and C^2. The general case follows from approximation. We assume $u(0) = \inf u$ and set

$$E = \int u^{-p} \text{ and } F = \int u_{xx}^2 + \beta.$$

Then by using Taylor's formula

$$u(x) = u(0) + u_x(0)x + \int_0^x u_{xx}(t)(x-t)dt,$$

we have, for all x,

$$u(x) \le u(0) + \frac{2}{3}F^{\frac{1}{2}}x^{\frac{3}{2}} \quad \forall x \in [0, L].$$

So

$$\int_0^L \frac{dx}{\left(u(0)+\frac{2}{3}F^{\frac{1}{2}}x^{\frac{3}{2}}\right)^p} \le \int u^{-p} \le E,$$

which implies that

$$\int_0^L \frac{dx}{\left(x+2u(0)^{\frac{2}{3}}F^{-\frac{1}{3}}\right)^{\frac{3p}{2}}} \le CEF^{\frac{p}{2}}.$$

After an integration over $(0, L/2)$, we have

$$\left(2u(0)^{\frac{2}{3}}F^{-\frac{1}{3}}\right)^{1-\frac{3p}{2}} \le C\left(EF^{\frac{p}{2}}+1\right),$$

i.e.,

$$\inf u^{-1} \le C\left(E^{\frac{3}{3p-2}}F^{\frac{1}{3p-2}}+F^{-\frac{1}{2}}\right). \qquad \square$$

To apply this lemma to our weak solution, we take advantage of the finite quantities K_4 and K_3. A direct calculation shows that $u = h^{\frac{3+2\delta}{4}}$ satisfies

$$\int u_{xx}^2 \le C_\delta\left(\int h^{-\frac{1}{2}+\delta}h_{xx}^2+\int h^{-\frac{5}{2}+\delta}h_x^4\right).$$

Now, using Lemma 3.2 ($\beta = 1$) we have, for any $p' > 2/3$,

(3.1)

$$\sup h^{-\frac{3+2\delta}{4}} \le C\left[\left(\int h^{-p'\frac{3+2\delta}{4}}\right)^{3/(3p'-2)}\left(\int h^{-\frac{1}{2}+\delta}h_{xx}^2+\int h^{-\frac{5}{2}+\delta}h_x^4\right)^{1/(3p'-2)}+1\right].$$

COROLLARY 3.1. *Let h be a suitable weak solution of* (2.1) *for $n \in (2, 3.5)$. Then*

$$K_5 \equiv \int_0^T \left(\int h^{-p} \right)^{\frac{3(n-2)-\delta}{p+\frac{3}{2}-n}} < \infty \quad \forall p > n - 3/2,\ \delta \in (0, 3(n-2)).$$

Proof. When $\delta \in (0, 3(n-2))$, we can take $p' = (4n-6)/(3+2\delta) > 2/3$ so that $p'(3+2\delta)/4 = n - 3/2$ in (3.1) to get, for $p > n - 3/2$,

$$\begin{aligned} \int h^{-p} &\le \sup(h^{-1})^{p+\frac{3}{2}-n} \int h^{\frac{3}{2}-n} \\ &\le CK_3 \left[K_3^{\frac{1}{n-2-\frac{\delta}{3}}} \left(\int h^{-\frac{1}{2}+\delta} h_{xx}^2 + \int h^{-\frac{5}{2}+\delta} h_x^4 + 1 \right)^{\frac{1}{3(n-2)-\delta}} + 1 \right]^{p+\frac{3}{2}-n}. \end{aligned}$$

Raise both sides to the power $[3(n-2)-\delta]/(p+\frac{3}{2}-n)$ and then integrate over time. The corollary follows from the boundedness of K_3 and K_4. □

Now, we have the following result which contains Theorem 1.3.

THEOREM 3.1. *Let h be a suitable weak solution of* (2.1)*, where $n \in (2, 3.5)$ and either* (2.5) *or* (2.6) *holds. The Hausdorff dimension of the set of rupture times cannot exceed $1 - 2(n-2)^2/(8-n)$.*

Once again we point out that the theorem holds for any weak solution of (2.1) satisfying (H_1) and (H_2) only.

Proof. Let n be given as above and $p,\ \delta$ satisfy

$$p \in (2, n], \quad p + \frac{3}{2} > n, \quad \delta \in (0, 3(n-2)).$$

We claim that there exists a small ε_0 depending on n, p, δ such that whenever

$$\int_{T-R}^T \left(\int h^{-p} \right)^{\beta} \le \varepsilon_0 R^{\gamma} \quad \forall \text{ small } R,$$

where

$$\beta = \frac{3(n-2)-\delta}{p+\frac{3}{2}-n}, \quad \gamma = 1 - \beta\Big(\frac{p-2}{8-n}\Big),$$

then $h(x_0, T) > 0$. To prove this claim we first observe that by the mean-value theorem there is some $t_1 \in [T-R, T]$ such that

$$\int h^{-p}(\cdot, t_1) \le 2\varepsilon_0^{\frac{1}{\beta}} R^{\frac{\gamma-1}{\beta}}.$$

By Lemma 3.1 and $K_1 < \infty$, h is positive at t_1. By continuity h is positive for all t close to t_1, in particular, it is a classical solution near t_1. Let

$$t^* = \sup\big\{ t_2 \in (t_1, T] :\ h \text{ is positive in } [t_1, t_2] \big\}.$$

We shall show that $t^* = T$. As for $t \in (t_1, t^*)$,

$$\begin{aligned} \frac{d}{dt} \int h^{-p} &= -p(p+1) \int h^{n-p-2} h_{xx}^2 - p(p+1)(n-p-2) \int h^{n-p-3} h_x^2 h_{xx} \\ &\quad + p(p+1) \int h^{n-p-2} f'(h) h_x^2. \end{aligned} \tag{3.2}$$

We estimate the integrals on the right as follows: For $p \in (2, n)$,

$$\begin{aligned}
\left| \int h^{n-p-3} h_x^2 h_{xx} \right| &= \left| \frac{n-p-3}{3} \int h^{n-p-4} h_x^4 \right| \\
&\le C \int h^{p-n} \left| \left(h^{\frac{n-p}{2}}\right)_x \right|^4 \\
&\le C \sup(h^{-1})^{n-p} \int \left| \left(h^{\frac{n-p}{2}}\right)_x \right|^4 \\
&\le C \sup(h^{-1})^{n-p} \left(\int \left(h^{\frac{n-p}{2}}\right)_x^2 \right)^{3/2} \left(\int \left(h^{\frac{n-p}{2}}\right)_{xx}^2 \right)^{1/2} \\
&\le \varepsilon \int \left(h^{\frac{n-p}{2}}\right)_{xx}^2 + C \sup(h^{-1})^{2(n-p)} \left(\int \left(h^{\frac{n-p}{2}}\right)_x^2 \right)^3 \\
&\le C\varepsilon \left(\int h^{n-p-2} h_{xx}^2 + \int h^{n-p-4} h_x^4 \right) + C \sup(h^{-1})^{6+p-n} \left(\int h_x^2 \right)^3,
\end{aligned}$$

which means, for small ε,

$$\int h^{n-p-4} h_x^4 \le C \left[\varepsilon \int h^{n-p-2} h_{xx}^2 + \sup(h^{-1})^{6+p-n} \right].$$

By Lemma 3.1 we further have

$$\int h^{n-p-4} h_x^4 \le C \left[\varepsilon \int h^{n-p-2} h_{xx}^2 + C \left(1 + \int h^{-p} \right)^{\frac{6+p-n}{p-2}} \right]. \tag{3.3}$$

By modifying the above arguments slightly we see that (3.3) also holds when $p = n$. For the third term on the right-hand side of (3.2) we have

$$\begin{aligned}
\int h^{n-p-2} f'(h) h_x^2 &\le C \left(\int h^{n-p-2} h_x^2 + \int h^{n-p+q-3} h_x^2 \right) \\
&\le C \left(\int h^{n-p-4} h_x^4 + \int h^{n-p} + \int h^{n-p+2q-2} \right) \\
&\le C \left[\int h^{n-p-4} h_x^4 + \left(\int h^{-p} \right)^{\frac{n-p+2q-2}{-p}} \right]. \qquad (3.4)
\end{aligned}$$

Putting (3.3) and (3.4) back to (3.2) yields, after taking ε small,

$$\frac{d}{dt} \int h^{-p} \le C \left(1 + \int h^{-p} \right)^{\mu},$$

where $\mu = \max\{\frac{6+p-n}{p-2}, \frac{p-n-2q+2}{p}\} = \frac{6+p-n}{p-2}$ (because $n \le 8$). By comparing $\int h^{-p}$ with the solution Y of

$$\frac{dY}{dt} = C(1+Y)^{\mu}, \quad Y(t_1) = 2\varepsilon_0^{\frac{1}{\beta}} R^{\frac{\gamma-1}{\beta}},$$

we see that Y exists in $[t_1, T]$, when $\varepsilon_0^{1/\beta}$ is sufficiently small and $\int h^{-p} \le Y(t)$ as long as both functions exist. So $\int h^{-p}$ is finite in $[t_1, T]$. It follows from Lemma 3.1 that h is positive up to T, that is, $t^* = T$.

We fix an ε_0 satisfying the property in the above claim. It follows that T is a rupture time if and only if there exists $R_j \downarrow 0$ such that

$$\int_{T-R_j}^{T} \left(\int h^{-p} \right)^{\beta} > \varepsilon_0 R_j^{\gamma}$$

for each p, n, δ in the range. Applying a covering argument to the time interval $(0, \infty)$ one can show that, using the finiteness of K_5, the $\gamma-$Hausdorff measure of the set of rupture times is finite for for all $\gamma = 1 - \beta(p-2)/(8-n)$. Letting $\delta \to 0$ and then taking $p = n$, we conclude the proof of this theorem. □

4. A result on finite time rupture. For any positive, smooth, periodic function h_0, it is known that

$$\begin{cases} h_t + \left[h^n \left(h_{xx} + f(h) \right)_x \right]_x = 0, \\ h(0) = h_0 \end{cases} \tag{4.1}$$

admits a unique, classical solution in $[0, \omega)$, which is of the same period in x and is maximal in the sense that whenever ω is finite,

$$\inf_{t \uparrow \omega} h(t) = 0 \quad \text{or} \quad \sup_{t \uparrow \omega} h(t) = \infty.$$

A proof of this fact, which can be found in [BF], is based on parabolic regularity theory (Eidelman [Ei] or Friedman [F1]) when there is no f-term in (4.1). Nevertheless, an examination of their arguments shows that it still works with the presence of the f-term as long as f is in $C^{2,\alpha}((0,\infty))$ for some $\alpha \in (0,1)$. In the following we denote by $X(L, c_0)$ the subset of $H^1(S_L)$ consisting of all of the positive functions with area c_0. As the area is conserved by the equation in (4.1), the classical solution of (4.1) forms a flow in $X(L, c_0)$. For our result the following condition on f will be imposed:

$$f(0) = 0, \quad |f'(z)| \le C_1 z^{q-1}, \quad z \in (0,1] \quad \text{for some } q \ge \frac{1-n}{2}. \tag{4.2}$$

THEOREM 4.1. *Let $n \in (0, 1/2)$ be in (4.1), and $f \in C([0,\infty)) \cap C^{2,\alpha}((0,\infty))$ satisfy (4.2). Suppose that there exists a bounded open set $\mathcal{U}$ in $X(L, c_0)$ satisfying the following properties:*

(P_1) The closure of $\mathcal{U}$ does not contain any positive steady state, fully supported droplet with zero contact angle, or an array of identical droplets with zero contact angle of (4.1); and

(P_2) Any maximal solution h starting at some positive smooth h_0 in $\mathcal{U}$ stays inside $\mathcal{U}$.

Then ω is finite, that is, h ruptures in finite time.

From this theorem we deduce the following result on finite time rupture.

COROLLARY 4.1. *Consider (4.1), where $n \in (0, 1/2)$ and f is a power law, with q satisfying $(1-n)/2 \le q < 3$. Then for any positive c_0, there exists some L_0 depending on q and c_0 such that, for any $L \ge L_0$, there are solutions of (4.1) in $X(L, c_0)$ which rupture in finite time.*

Steady states arise in the study of long-time behavior of the solutions of (4.1), and the definition of a steady state is motivated from the energy dissipation relation. Indeed, a nonnegative function h in the closure of $X(L, c_0)$ is called a steady state of (4.1) if, on each component of the positivity set of h, $h_{xx} + f(h) = c$ holds for some

constant c (which could be different on components). Besides the constant states c_0/L that always exist in any $X(L, c_0)$, there could be other steady states in the same $X(L, c_0)$. Among others, a droplet is a steady state that is positive in some $(-a, a), a \le L/2$ and equal to 0 in $[-L/2, L/2] \setminus (-a, a)$ after a suitable translation. It is of full support if a is equal to $L/2$. The droplet has zero contact angle if its derivatives vanish at $\pm a$. A configuration of droplets is a steady state, where the positivity set $\{x \in (-L/2, L/2) : h(x) > 0\}$ is a union of at least two disjoint, open subintervals of $(-L/2, L/2)$. An array of identical droplets is a configuration of droplets in which, after a suitable translation, there is a partition of $(-L/2, L/2)$ into subintervals with equal length so that the restrictions of the steady state to these subintervals are congruent droplets with full support.

Criteria for the existence and multiplicity of positive steady states and droplets in a given $X(L, c_0)$ for general f and for power laws can be found in [LP1], and the stability of positive steady states, especially those for power laws, is studied systematically in [LP2], [LP3], and [LP4].

Proof of Theorem 4.1. We let $h(t)$ be a solution of (4.1) starting inside $\mathcal{U}$. Under (P_2), h cannot blow up in any time, so either it ruptures in finite time or it is a positive global solution. Assuming that the latter holds we will derive a contradiction.

As h stays inside $\mathcal{U}$, it is uniformly bounded in H^1-norm. From the energy dissipation relation

$$\mathcal{E}(h) + \int_0^T \int h^n \Big| \Big(h_{xx} + f(h) \Big)_x \Big|^2 = \mathcal{E}(h_0),$$

where the energy is given by

$$\mathcal{E}(h) = \frac{1}{2} \int h_x^2 - \int F(h), \quad F'(z) = f(z), \quad F(0) = 0,$$

we know that

$$\int_0^\infty \int \Big| \Big(h_{xx} + f(h) \Big)_x \Big|^2 < \infty. \tag{4.3}$$

On the other hand, the entropy dissipation relation is given by

$$\frac{d}{dt} \int h^{2-n} = -(2-n)(1-n) \int \Big(h_{xx}^2 - f(h) h_{xx} \Big).$$

As h is uniformly bounded for all time and $n < 1$, we can find a constant C_2 so that

$$\int_T^{T+1} \int \Big(h_{xx}^2 - f(h) h_{xx} \Big) \le C_2 \tag{4.4}$$

holds for all $T > 0$. From (4.3) and (4.4) it is easy to find $\{t_j\} \to \infty$ and a constant C_3 such that, for $h_j = h(t_j)$,

$$\int h_j^n \Big(h_{jxx} + f(h_j) \Big)_x^2 \to 0 \tag{4.5}$$

and

$$\int h_{jxx}^2 \le C_3. \tag{4.6}$$

By passing to a subsequence if necessary, we may further assume that

$$\begin{aligned} &h_j \to \hat{h} \text{ in } C^{1,\frac{1}{2}}(S_L),\\ &h_j \rightharpoonup \hat{h} \text{ in } H^2(S_L),\\ &h_j \to \hat{h} \text{ in } C^{2,\frac{1}{2}}_{loc}\big(\{\hat{h}>0\}\big), \end{aligned}$$

where $\hat{h}$ is a steady state of (4.1). By (P_1) $\hat{h}$ cannot be positive, so after a suitable translation, we may assume that there is a component (a,b) of the positivity set of h in $(-L/2, L/2)$ on which

$$\hat{h}'' + f(\hat{h}) = c.$$

(4.6) implies that $\hat{h}'(a) = \hat{h}'(b) = 0$. By integrating this equation we obtain

$$\frac{\hat{h}_x^2}{2} + F(\hat{h}) = c\hat{h}.$$

As $f(0) = 0$, the constant c must be positive unless the derivatives of $\hat{h}$ vanish at the endpoints. But the derivative cannot be equal to 0, for the vanishing of both $\hat{h}$ and $\hat{h}_x$ at the endpoints would force $\hat{h}$ to vanish identically by the uniqueness of the solution to the ordinary differential equation satisfied by $\hat{h}$. Therefore c is positive. By (P_1) there are two possibilities: First, there exists some $\delta_0 > 0$ such that $\hat{h} = 0$ in $[a-\delta_0, a]$ or $[b, b+\delta_0]$. Second, there exist two subintervals (a,b) and (b,b_1) in $(-L/2, L/2)$ such that $\hat{h}_{xx} + f(\hat{h}) = c_1, x \in (a,b)$ and $\hat{h}_{xx} + f(\hat{h}) = c_2, x \in (b,b_1)$, where c_1 and c_2 are different positive constants. Moreover, $\hat{h}_x^-(b) = \hat{h}_x^+(b) = 0$ holds.

Let us treat the first case first. For simplicity we take b to be 0 and so $\hat{h} = 0$ in $[0, \delta_0]$. For each $0 < \delta \le \delta_0$, we rescale h_j and $\hat{h}$ by

$$h_j(x) = \delta^2 H_j\left(\frac{x}{\delta}\right), \quad \hat{h}(x) = \delta^2 \hat{H}\left(\frac{x}{\delta}\right).$$

Then, for each fixed δ,

$$\begin{aligned} H_j \to \hat{H} \qquad & \text{in } C^{1,\frac{1}{2}}([-1,1]) \cap C^{2,\frac{1}{2}}_{loc}((-1,1)),\\ \hat{H}(y),\ \hat{H}_y(y) \to 0 \qquad & \text{as } y \uparrow 0,\\ \hat{H}_{yy}(y) \to c \qquad & \text{as } y \uparrow 0. \end{aligned}$$

We claim that there exists a constant C_* independent of δ such that

$$\int_{-1}^{1} H_j^n H_{jyyy}^2 \ge C_* > 0 \quad \forall j \text{ large}. \tag{4.7}$$

To prove (4.7) we first fix $\sigma_0 \in (-1, 0)$ such that

$$0 > H_{jy}(\sigma_0) \ge -\frac{c}{32}$$

and

$$H_{jyy}(\sigma_0) \ge \frac{c}{2}$$

hold (σ_0 may depend on j). Next we claim that, for each large j, there exists some $\xi \in [\sigma_0, 1]$ such that

$$H_{jyy}(\xi) = \frac{c}{4}.$$

For, if not, then $H_{jyy} > c/4$ in $[\sigma_0, 1]$. By Taylor expansion at σ_0, there exists some $z \in (\sigma_0, 1)$ such that

$$\begin{aligned} H_j(1) &= H_j(\sigma_0) + H_{jy}(\sigma_0)(1-\sigma_0) + \frac{H_{jyy}(z)}{2}(1-\sigma_0)^2 \\ &\geq -\frac{c}{32}(1-\sigma_0) + \frac{c}{8}(1-\sigma_0)^2 \\ &\geq \frac{c}{16}, \end{aligned}$$

contradicting the fact that $H_j(1)$ tends to 0 as $j \to \infty$. Thus $H_{jyy} = c/4$ somewhere in $(\sigma_0, 1)$. Let

$$\sigma_1 = \inf\left\{\sigma > \sigma_0 : \quad H_{jyy}(\sigma) = c/4\right\} < 1.$$

We consider two subcases separately:

(a) H_{jy} does not change sign in (σ_0, σ_1), and

(b) $H_{jy} = 0$ somewhere in (σ_0, σ_1).

In subcase (a), $H_{jy} < 0$ in (σ_0, σ_1) because $H_{jy}(\sigma_0) < 0$. By Taylor expansion at σ_1, for $y \in (\sigma_0, \sigma_1)$,

$$\begin{aligned} H_j(y) &= H_j(\sigma_1) + H_{jy}(\sigma_1)(y-\sigma_1) + \frac{H_{jyy}(z)}{2}(y-\sigma_1)^2 \\ &\geq H_j(\sigma_1) + \frac{c}{8}(y-\sigma_1)^2 \\ &\geq \frac{c}{8}(y-\sigma_1)^2 \quad \forall j \text{ large.} \end{aligned} \tag{4.8}$$

On the other hand,

$$\begin{aligned} \int_{\sigma_0}^{\sigma_1} \left|H_{jyyy}\right| &\geq \left|H_{jyy}(\sigma_1) - H_{jyy}(\sigma_0)\right| \\ &\geq \frac{c}{4}. \end{aligned}$$

So,

$$\begin{aligned} \int_{\sigma_0}^{\sigma_1} H_j^n \left|H_{jyyy}\right|^2 \int_{\sigma_0}^{\sigma_1} H_j^{-n} &\geq \left(\int_{\sigma_0}^{\sigma_1} \left|H_{jyyy}\right|\right)^2 \\ &\geq \frac{c^2}{16}. \end{aligned}$$

By (4.8),

$$\int_{\sigma_0}^{\sigma_1} H_j^{-n} \leq \left(\frac{8}{c}\right)^n \int_{\sigma_0}^{\sigma_1} \frac{1}{(y-\sigma_1)^{2n}} = \left(\frac{8}{c}\right)^n \frac{2}{1-2n}.$$

It follows that

$$\int_{-1}^{1} H_j^n \left|H_{jyyy}\right|^2 \geq C_* \equiv \frac{c^{n+2}(1-2n)}{2^{3n+5}},$$

that is, (4.7) holds.

In subcase (b), let $\sigma_2 \in (\sigma_0, \sigma_1)$ be a point at which $H_{jy}(\sigma_2) = 0$. By Taylor expansion at σ_2, for $y \in (\sigma_0, \sigma_1)$,

$$\begin{aligned} H_j(y) &= H_j(\sigma_2) + \frac{H_{jyy}(z)}{2}(y-\sigma_2)^2 \\ &\geq \frac{c}{8}(y-\sigma_2)^2, \end{aligned}$$

and the above argument still works to show that (4.7) holds for the same C_*.

Now, we scale (4.7) back to get

$$\begin{aligned} \int_{-\delta}^{\delta} h_j^n h_{jxxx}^2 &= \delta^{2n-1} \int_{-1}^{1} H_j^n H_{jyyy}^2 \\ &\geq C_* \delta^{2n-1}. \end{aligned} \tag{4.9}$$

However, on the other hand, for small δ,

$$\begin{aligned} \int_{-\delta}^{\delta} h_j^n h_{jxxx}^2 &\leq \int_{-\delta}^{\delta} h_j^n \Big(h_{jxxx} + f'(h_j) h_{jx} \Big)^2 + 4 \int_{-\delta}^{\delta} f'(h_j)^2 h_{jx}^2 \\ &\leq \int_{-1}^{1} h_j^n \Big(h_{jxxx} + f'(h_j) h_{jx} \Big)^2 + C \int_{-\delta}^{\delta} \big(1 + h_j^{n+2q-2}\big) h_{jx}^2. \end{aligned}$$

As

$$\begin{aligned} \int h_j^{n+2q-2} h_{jx}^2 &= \frac{-1}{n+2q-1} \int h_j^{n+2q-1} h_{jxx} \\ &\leq C \left(\int h_j^{2(n+2q-1)} \right)^{1/2} \left(\int h_{jxx}^2 \right)^{1/2}, \end{aligned}$$

by (4.2), (4.5), and (4.6) we conclude that

$$\int_{-\delta}^{\delta} h_j^n h_{jxxx}^2$$

is bounded uniformly in j, but this is in conflict with (4.9) as $n < 1/2$ and δ could be arbitrarily small, so the classical solution cannot be a global one, contradiction holds.

The proof for the second case is similar. Without loss of generality let us assume that $c_1 > c_2$. Again we take $b = 0$ and fix some small δ_0 so that $\hat{h}$ is decreasing in $(-\delta_0, 0)$ and increasing in $(0, \delta_0)$. For each $\delta < \delta_0$ we use the same rescalings as before to define H_j and $\hat{H}$ and claim that (4.7) holds. For, we pick σ_0 in $(-1, 0)$ such that $H_{jyy}(\sigma_0) = c_1 - \varepsilon_0$, where ε_0 is a fixed number less than $(c_1 - c_2)/2$. As before one can show that there is some $\xi \in (\sigma_0, 1)$ such that $H_{jyy}(\xi) = (c_1 + c_2)/2$. So we can define

$$\sigma_1 = \inf\{\sigma > \sigma_0 : H_{jyy}(\sigma) = (c_1 + c_2)/2\} < 1.$$

We consider the two subcases as before. We have in subcase (a) $H_{jyy} \geq \frac{c_1+c_2}{4}(y-\sigma_1)^2$ and in subcase (b) $H_{jyy} \geq \frac{c_1+c_2}{4}(y-\sigma_2)^2$ for $y \in (\sigma_0, \sigma_1)$. In both cases

$$\int_{\sigma_0}^{\sigma_1} |H_{jyyy}| \geq \left| \frac{c_1 - c_2}{2} - \varepsilon_0 \right| > 0.$$

Now the same arguments as before would show that (4.7) holds, so the same contradiction can be drawn. □

Proof of Corollary 4.1. First of all, from the interpolation inequality [F2] for functions in $H^1(S_L)$:

$$\int u^4 \le C\left(\int |u|\right)^2 \left(\int u_x^2 + \int u^2\right),$$

it is easy to see that, for $q \in (-1, 3)$, the energy $\mathcal{E}(h)$ satisfies

$$\int h_x^2 \le C\mathcal{E}(h)$$

for some positive constant C. By a standard argument based on the direct method, the minimization problem

$$m = \inf\{\mathcal{E}(h) : \quad h \in X(L, c_0)\}$$

admits a minimizer in the closure of $X(L, c_0)$, which is a steady state of (4.1).

Let us examine the candidates for the minimizer. First, according to Theorem 10 in [LP3], the constant state c_0/L becomes energy unstable whenever L satisfies $L > L_1$, where L_1 satisfies $L_1^{3-q} c_0^{q-1} = 4\pi^2$, and hence it cannot be a minimizer. Next, the classification results in [LP1] shows that, for any pair (L, c_0), there are, up to translations, at most finitely many positive steady states with period $L/j, j \ge 2$ in $X(L, c_0)$, but they cannot be minimizers as they are also energy unstable due to Theorem 1 of [LP2]. Furthermore, the classification in section 5 of [LP1] asserts that positive steady states with minimal period and fully supported droplets with zero contact angle do not exist if $L > L_2$ for some L_2, depending on c_0 and q. From the same source we know that there are, up to translations, at most finitely many arrays of identical droplets with zero angle in $X(L, c_0)$. We claim that they too cannot be minimizers. For, consider an array of identical droplets h, which vanishes at $-L/2$ and $L/2$. Define h^* to be the function equal to h on $(-L/2, L/2)$ and zero outside this interval. Then the rearrangement of h^* gives a function which is positive inside and zero outside $(-L/2, L/2)$. Extending the restriction of h^* on $(-L/2, L/2)$ as an L-periodic function h^{**}. From the properties of rearrangement h^{**} belongs to the closure of $X(L, c_0)$, with energy strictly lower than that of h; see, for instance, [LiL]. Therefore h cannot be a minimizer. Since the energy is invariant under translation, we conclude that no array of identical droplets can be a minimizer of the energy.

As a result, for any L greater than L_1 and L_2, if we denote by μ the minimum of the energies of all of the possible positive steady states, fully supported droplets with zero contact angle and arrays of identical droplets with zero contact angle in $X(L, c_0)$, then $m < \mu$. Now the corollary follows from Theorem 4.1 by taking

$$\mathcal{U} = \{h \in X(L, c_0) : \mathcal{E}(h) < (m + \mu)/2\}. \qquad \square$$

Remark 4.1. A sharp version of the interpolation inequality used in the above proof is the Nagy's inequality [SP]:

$$\int u^4 \le \frac{9}{4\pi^2}\left(\int |u|\right)^2 \left(\int u_x^2\right),$$

which is valid for all $u \in H^1(\mathbf{R})$. By modifying this inequality one can show that the following inequality holds for all $u \in H^1(S_L)$:

$$\int u^4 \le C \left(\int |u| \right)^2 \left(\int u_x^2 + \int u^2 \right)$$

for any constant $C > 9/4\pi^2$. Using this result, one can show that Corollary 4.1 continues to hold when $q = 3$ provided c_0 satisfies

$$3Bc_0^2 < 8\pi^2.$$

Appendix A. Suitable weak solutions. Here we give a sketch of the proof of Theorem 2.1. We shall treat problem (2.1), where $n \in (1.5, 3.5)$ in (2.1) and f satisfies (2.4) and (2.6). The proof when f satisfies (2.5) instead of (2.6) can be handled in a similar and simpler way.

Step 1. (2.1) *admits a positive, classical solution for all time if* $n \ge 4$ *and* $f \in C^{2,\alpha}([0,\infty))$.

This is achieved by considering the approximation problem ($\varepsilon > 0$)

$$\begin{cases} h_t + \left[\left(|h|^n + \varepsilon \right) \left(h_{xx} + f(h) \right)_x \right]_x = 0, \\ h(0) = h_0 > 0 \text{ in } C^\infty(S_L). \end{cases}$$

One first shows that this problem admits a global classical solution h_ε. In fact, using the interpolation inequality on $H^1(S_L)$ [F2],

$$\int h^4 \le C \left(\int h \right)^2 \left(\int h_x^2 + \int h^2 \right)$$

for some positive constant C in the energy dissipation relation

$$\frac{1}{2} \int h_{\varepsilon x}^2 - \int F(h_\varepsilon) + \int_0^t \int (|h|^n + \varepsilon) \left| \left(h_{\varepsilon xx} + f(h_\varepsilon) \right)_x \right|^2 = \frac{1}{2} \int h_{0x}^2 - \int F(h_0),$$

where F is a primitive of f, with the help of the conservation of area

$$\int h = c_0 \equiv \int h_0,$$

and the growth condition $p < 3$ in (1.4) or $p = 3$ when c_0 is small one obtains a uniform H^1-bound on h_ε. Using the entropy inequality one further shows that, although h_ε may change sign, its limit of as $\varepsilon \downarrow 0$ through a subsequence is a positive function h which solves (2.1). We refer to [BF] and [BP2] for details.

Step 2. (2.1) *admits a positive, classical solution for all time if* $n \ge 4$ *and* $f \in C^{2,\alpha}((0,\infty))$ *satisfies* (2.4) *(*$p < 3$*) and* (2.6) *(*$q > 1 - n/2$*).*

Consider the approximation problem ($\delta > 0$)

$$\begin{cases} h_t + \left[h^n \left(h_{xx} + f_\delta(h) \right)_x \right]_x = 0, \quad f_\delta(z) = f(z + \delta), \\ h(0) = h_0 > 0 \text{ in } C^\infty(S_L). \end{cases}$$

By Step 1, this problem admits a positive, classical solution h_δ, which is uniformly bounded in H^1-norm again by (2.4) ($p < 3$). Further we compute the change rate of the entropy $\int h_\delta^{2-n}$ as follows:

$$\begin{aligned}\frac{d}{dt}\int h_\delta^{2-n} &= (2-n)(1-n)\int h_{\delta x}\big(h_{\delta xx}+f_\delta(h_\delta)\big)_x\\ &\le -\frac{1}{2}(2-n)(1-n)\int h_{\delta xx}^2 + C\int f_\delta^2(h_\delta)\\ &\le -\frac{1}{2}(2-n)(1-n)\int h_{\delta xx}^2 + C\left(\int h_\delta^{2q}+1\right)\\ &\le C\left(\int h_\delta^{2-n}+1\right)\end{aligned}$$

as $q \ge 1-n/2$. It follows that $||h_\delta^{2-n}||_{L^1}$ is uniformly bounded on every interval $[0,T]$. By passing to limit and using $n \ge 4$, h_δ subconverges to a positive, classical solution of (2.1), with initial datum h_0.

We remark that the assertions in Steps 1 and 2 hold when the coefficient h^n is replaced by some positive, smooth $a(h)$, which behaves like h^n near 0.

Step 3. Equation (2.1) *admits a suitable weak solution if* $n \in (1.5, 4)$, (2.4) *and* (2.6) *hold for* $0 \le p < 3$ *and* $q > 1 - n/2$.

Consider the approximation problem ($\varepsilon > 0$)

$$\begin{cases} h_t + \Big[a_\varepsilon(h)\big(h_{xx}+f(h)\big)_x\Big]_x = 0, \quad a_\varepsilon(z) = \dfrac{z^4}{z^{4-n}+\varepsilon},\\ h(0) = h_0 > 0 \text{ in } C^\infty(S_L).\end{cases}$$

As the coefficients behave like h^4 near 0, Step 2 guarantees that this problem admits a positive, classical solution h_ε for all $\varepsilon \le 1$. Moreover, these solutions satisfy

$$\sup_{[0,T]}\int h_{\varepsilon x}^2 \le C_1 \tag{A.1}$$

and

$$\iint_{Q_T} a_\varepsilon(h_\varepsilon)\Big|\big(h_{\varepsilon xx}+f(h_\varepsilon)\big)_x\Big|^2 \le C_2. \tag{A.2}$$

It follows that

$$||h_\varepsilon||_{C^{\frac{1}{2},\frac{1}{8}}_{x,t}(Q_T)} \le C_3 \tag{A.3}$$

(we refer to [BF] for the deduction of (A.3) from (A.1) and (A.2)), and, by (A.1), (A.2), and (2.6) ($q > 1 - n/2$),

$$\begin{aligned}\iint_{Q_T} a_\varepsilon(h_\varepsilon)h_{\varepsilon xxx}^2 &\le 2\iint_{Q_T} a_\varepsilon(h_\varepsilon)\left|\big(h_{\varepsilon xx}+f(h_\varepsilon)\big)_x\right|^2\\ &\quad + 2\iint_{Q_T} a_\varepsilon(h_\varepsilon)f'^2(h_\varepsilon)h_{\varepsilon x}^2\\ &\le C\left(1+\iint_{Q_T} h_\varepsilon^{n+2q-2}h_{\varepsilon x}^2\right)\\ &\le C\left(1+\iint_{Q_T} h_{\varepsilon x}^2\right) \le C_4.\end{aligned} \tag{A.4}$$

Define

$$G_{s,\varepsilon}(z)=\int_z^M\int_y^M\frac{\tau^s}{a_\varepsilon(\tau)}d\tau dy,$$

where M is a fixed number greater than $\sup_{[0,T]}h_\varepsilon$ for all $\varepsilon\le 1$. Then we have

$$\begin{aligned}\frac{d}{dt}\int G_{s,\varepsilon}(h_\varepsilon)=&-\int\left(h_\varepsilon^s h_{\varepsilon xx}^2+s\int h_\varepsilon^{s-2}h_{\varepsilon x}^2h_{\varepsilon xx}\right)\\&-\int f(h_\varepsilon)\left(h_\varepsilon^s h_{\varepsilon xx}+sh_\varepsilon^{s-1}h_{\varepsilon x}^2\right).\end{aligned}\tag{A.5}$$

We estimate the terms on the left of (A.5) as follows: For $s\in(-1/2,1)$, there exists a positive number σ depending on s such that

$$\int h_\varepsilon^s h_{\varepsilon xx}^2+s\int h_\varepsilon^{s-1}h_{\varepsilon x}^2h_{\varepsilon xx}\ge\sigma_s\left(\int h_\varepsilon^s h_{\varepsilon xx}^2+\int h_\varepsilon^{s-2}h_{\varepsilon x}^4\right),$$

and, for $s=-1/2$,

$$\int h_\varepsilon^s h_{\varepsilon xx}^2+s\int h_\varepsilon^{s-1}h_{\varepsilon x}^2h_{\varepsilon xx}\ge 0.$$

Therefore, as $q\ge 1-n/2$,

$$\begin{aligned}&\left|\int f(h_\varepsilon)\big(h_\varepsilon^s h_{\varepsilon xx}+sh_\varepsilon^{s-1}h_{\varepsilon x}^2\big)\right|\\&\qquad\le\delta\left(\int h_\varepsilon^s h_{\varepsilon xx}^2+\int h_\varepsilon^{s-2}h_{\varepsilon x}^4\right)+C_\delta\int h_\varepsilon^s f^2(h_\varepsilon)\\&\qquad\le\delta\left(\int h_\varepsilon^s h_{\varepsilon xx}^2+\int h_\varepsilon^{s-2}h_{\varepsilon x}^4\right)+C_\delta\Big(\int h_\varepsilon^{s-n+2}+1\Big)\\&\qquad\le\delta\left(\int h_\varepsilon^s h_{\varepsilon xx}^2+\int h_\varepsilon^{s-2}h_{\varepsilon x}^4\right)+C_\delta\left(1+\int h_\varepsilon+\int G_{s,\varepsilon}(h_\varepsilon)\right).\end{aligned}$$

In the last step we have used the relation

$$\begin{aligned}G_{s,\varepsilon}(z)&=\int_z^M\int_y^M\tau^{s-n}d\tau dy+\varepsilon\int_z^M\int_y^M\tau^{s-4}d\tau dy\\&=\frac{1}{(s-n+1)(s-n+2)}z^{s-n+2}-\frac{M^{s-n+1}}{s-n+1}z+\frac{M^{s-n+2}}{s-n+2}\\&\quad+\varepsilon\left[\frac{1}{(s-3)(s-2)}z^{s-2}-\frac{M^{s-3}}{s-3}z+\frac{M^{s-2}}{s-2}\right].\end{aligned}\tag{A.6}$$

Putting this identity back to (A.5) yields, for $s \in (-1/2, \min\{1, n-2\})$,

$$\sup_{[0,T]} \left[\int h_\varepsilon^{s-n+2} + \varepsilon \int h_\varepsilon^{s-2} \right] + \sigma \iint_{Q_T} \left(h_\varepsilon^s h_{\varepsilon xx}^2 + h_\varepsilon^{s-2} h_{\varepsilon x}^4 \right) \le C_5. \tag{A.7}$$

Next, we fix $s' > -1/2$ such that $-\frac{1}{2} - s' + 2q > -n + 2$ still holds. By (A.5) and (A.7),

$$\begin{aligned} \frac{d}{dt} \int G_{-\frac{1}{2},\varepsilon}(h_\varepsilon) &\le C \int \left(h_\varepsilon^q + 1\right) \left(h_\varepsilon^{-1/2} h_{\varepsilon xx} + s h_\varepsilon^{-3/2} h_{\varepsilon x}^2 \right) \\ &\le C \int \left(h_\varepsilon^{s'} h_{\varepsilon xx}^2 + h_\varepsilon^{s'-2} h_{\varepsilon x}^4 \right) + C \left(\int h_\varepsilon^{-1-s'+2q} + 1 \right) \\ &\le C \int \left(h_\varepsilon^{s'} h_{\varepsilon xx}^2 + h_\varepsilon^{s'-2} h_{\varepsilon x}^4 \right) + C \left(\int G_{-\frac{1}{2},\varepsilon}(h_\varepsilon) + \int h_\varepsilon + 1 \right), \end{aligned}$$

so

$$\sup_{[0,T]} \left[\int h_\varepsilon^{\frac{3}{2}-n} + \varepsilon \int h_\varepsilon^{-\frac{5}{2}} \right] \le C_6. \tag{A.8}$$

To let ε go to 0, first observe that, by (A.2) and (A.4),

$$\sqrt{a_\varepsilon(h_\varepsilon)} h_{\varepsilon xxx} \rightharpoonup h^{\frac{n}{2}} h_{xxx} \quad \text{in } L^2(Q_T), \tag{A.9}$$

and

$$\sqrt{a_\varepsilon(h_\varepsilon)} \left(h_{\varepsilon xx} + f(h_\varepsilon) \right)_x \rightharpoonup h^{\frac{n}{2}} \left(h_{xx} + f(h) \right)_x \quad \text{in } L^2(Q_T). \tag{A.10}$$

By parabolic regularity, for all $s > -1/2$ (since h_ε are uniformly bounded in ε, (A.7) holds for all $s > -1/2$),

$$\begin{aligned} &h_\varepsilon^{\frac{s}{2}} h_{\varepsilon xx} \to h^{\frac{s}{2}} h_{xx}, \\ &h_\varepsilon^{\frac{s-2}{4}} h_{\varepsilon x} \to h^{\frac{s-2}{4}} h_x, \text{ uniformly in any compact subset of } \{h > 0\}. \end{aligned}$$

Taking $s' \in (-1/2, s)$ and using (A.7), we have

$$\begin{aligned} \iint_{Q_T} \left| h_\varepsilon^{\frac{s}{2}} h_{\varepsilon xx} - h^{\frac{s}{2}} h_{xx} \right|^2 &= \left(\iint_{\{h \ge \delta\}} + \iint_{\{h < \delta\}} \right) \left| h_\varepsilon^{\frac{s}{2}} h_{\varepsilon xx} - h^{\frac{s}{2}} h_{xx} \right|^2 \\ &\le o(\varepsilon) + C\delta^{s-s'} \to 0, \text{ as } \varepsilon \to 0 \text{ and } \delta \to 0, \end{aligned}$$

so

$$h_\varepsilon^{\frac{s}{2}} h_{\varepsilon xx} \to h^{\frac{s}{2}} h_{xx} \quad \text{in } L^2(Q_T). \tag{A.11}$$

Similarly, we have

$$h_\varepsilon^{\frac{s-2}{4}} h_{\varepsilon x} \to h^{\frac{s-2}{4}} h_x \quad \text{in } L^4(Q_T). \tag{A.12}$$

Now, using (A.9)–(A.12) to pass to limit we obtain a subsequence of h_ε converging uniformly to some h in Q_T. From (A.1)–(A.4), (A.7), and (A.8) we see that (H_1) and (H_2) hold. It remains to establish (H_3).

LEMMA A.1. *There exists a set* Γ *of full measure in* $[0,T]$ *such that, for a sequence* $\varepsilon_j \to 0$,

$$h_{\varepsilon_j}(x,t) \to h(x,t) \quad \text{in } H^1(S_L)\ \forall t \in \Gamma,$$

and

$$\int G_{s,\varepsilon_j}(h_{\varepsilon_j})(t)\phi^4 \to \int G_s(h)(t)\phi^4 \quad \forall t \in [0,T]\ \forall \phi \in C^\infty(S_L),\ s \in (-1/2, n-2).$$

Proof. It follows from (A.12) (taking $s=2$) that

$$\iint_{Q_T} |h_{\varepsilon x} - h_x|^2 \to 0 \quad \text{as } \varepsilon \to 0.$$

Therefore, there exists a subset $\Gamma \subset [0,T]$ with full measure such that, for a subsequence $\varepsilon = \varepsilon_j$,

$$\int |h_{\varepsilon x} - h_x|^2(t) \to 0 \quad \forall t \in \Gamma.$$

To prove the second statement, observe that each $t \in [0,T]$, K_3 implies that $h(x,t) > 0$ a.e. in S_L. So it follows (A.6), (A.7), the pointwise convergence

$$G_{s,\varepsilon}(h_\varepsilon)(t) \to G_s(h)(t) \quad \text{a.e. in } S_L,$$

and the dominated convergence theorem. ∎

Now we can prove (H_3). First, by a direct computation we have

$$\begin{aligned}
&\frac{1}{2}\int h_{\varepsilon x}^2\phi^4 - \int F(h_\varepsilon)\phi^4 + \int_{t_0}^t \int a_\varepsilon(h_\varepsilon)\Big|\big(h_{\varepsilon xx} + f(h_\varepsilon)\big)_x\Big|^2\phi^4 \\
&\qquad = -\int_{t_0}^t \int a_\varepsilon(h_\varepsilon)\big(h_{\varepsilon xx} + f(h_\varepsilon)\big)_x\big(h_{\varepsilon xx} + f(h_\varepsilon)\big)(\phi^4)_x \\
&\qquad\quad -\int_{t_0}^t \int a_\varepsilon(h_\varepsilon)\big(h_{\varepsilon xx} + f(h_\varepsilon)\big)_x\Big[h_{\varepsilon xx}(\phi^4)_x + h_{\varepsilon x}(\phi^4)_{xx}\Big] \\
&\qquad\quad +\frac{1}{2}\int h_{\varepsilon x}^2(t_0)\phi^4 - \int F(h_\varepsilon(t_0))\phi^4, \qquad \text{(A.13)}
\end{aligned}$$

and, for $s = -\frac{1}{2} + \delta \in (-\frac{1}{2}, \min\{1, n-2\})$,

$$\begin{aligned}
\frac{d}{dt}\int G_{s,\varepsilon}(h_\varepsilon)\phi^4 &= \int G'_{s,\varepsilon}(h_\varepsilon)h_{\varepsilon t}\phi^4 \\
&= -\Big[\int h_\varepsilon^s h_{\varepsilon xx}^2\phi^4 + s\int h_\varepsilon^{s-1}h_{\varepsilon x}^2 h_{\varepsilon xx}\phi^4\Big] - \int h_\varepsilon^s h_{\varepsilon x}h_{\varepsilon xx}(\phi^4)_x \\
&\quad -\int f(h_\varepsilon)\big[h_\varepsilon^s h_{\varepsilon xx}\phi^4 + sh_\varepsilon^{s-1}h_{\varepsilon x}^2\phi^4 + h_\varepsilon^s h_{\varepsilon x}(\phi^4)_x\big] \\
&\quad -\int \big[a'_\varepsilon(h_\varepsilon)G'_{s,\varepsilon}(h_\varepsilon) + a_\varepsilon(h_\varepsilon)G''_{s,\varepsilon}(h_\varepsilon)\big]h_{\varepsilon x}\big[h_{\varepsilon xx} + f(h_\varepsilon)\big](\phi^4)_x \\
&\quad -\int a_\varepsilon(h_\varepsilon)G'_{s,\varepsilon}(h_\varepsilon)\big[h_{\varepsilon xx} + f(h_\varepsilon)\big](\phi^4)_{xx} \\
&\le -\sigma\Big[\int h_\varepsilon^s h_{\varepsilon xx}^2\phi^4 + \int h_\varepsilon^{s-2}h_{\varepsilon x}^4\phi^4\Big] \\
&\quad + C\Big[\int h_\varepsilon^{s+2}\big(\phi_x^4 + \phi^2\phi_{xx}^2\big) + \int h_\varepsilon^s f^2(h_\varepsilon)\phi^4\Big], \qquad \text{(A.14)}
\end{aligned}$$

where the constants σ and C are positive constants. Note that, in the last inequality of (A.14), we have used

$$\begin{aligned} a_\varepsilon(z)G_{s,\varepsilon}(z) &= z^s, \\ |a'_\varepsilon(z)G'_{s,\varepsilon}(z)| &\le C_7 z^s, \\ |a_\varepsilon(z)G'_{s,\varepsilon}(z)| &\le C_8 z^{s+1}, \end{aligned}$$

and, for $-1/2 < s < 1$,

$$\begin{aligned} &\int h_\varepsilon^s h_{\varepsilon xx}^2 \phi^4 + s\int h_\varepsilon^{s-1} h_{\varepsilon x}^2 h_{\varepsilon xx}\phi^4 \\ &\qquad \ge \sigma_1 \left[\int h_\varepsilon^s h_{\varepsilon xx}^2\phi^4 + \int h_\varepsilon^{s-2} h_{\varepsilon x}^4 \phi^4\right] - C_1 \left|\int h_\varepsilon^{s-1} h_{\varepsilon x}^3 (\phi^4)_x\right| \\ &\qquad \ge \sigma_2 \left[\int h_\varepsilon^s h_{\varepsilon xx}^2\phi^4 + \int h_\varepsilon^{s-2} h_{\varepsilon x}^4 \phi^4\right] - C_2 \int h_\varepsilon^{s+2}\phi_x^4. \end{aligned}$$

Using (A.9)–(A.12) we can pass limit in (A.13) to obtain the local energy inequality. Similarly, by passing limit in the integral form of (A.14) using also Lemma A.1, we see that the local entropy inequality also holds.

Finally, by an approximation argument the initial data can be taken to be nonnegative H^1-functions, with finite $||h_0^{3/2-n}||_{L^1}$. One may consult [BF] for the proof of $\lim_{t\to 0} h(t) = h_0$ in H^1. We have finished our outline of the proof of Theorem 2.1.

Appendix B. The parabolic Hausdorff dimension. Same as the Hausdorff measures, fourth order parabolic Hausdorff measures can be defined by a general construction due to Carathéordory; see [Fe]. Here we state their definitions and list some of their basic properties.

Let s be nonnegative, and $\delta > 0$. For any set X in $\mathbf{R}^2$, we let $\mathcal{C}$ be a collection of cylinders Q_α of the form $\{(x,t) : |x - x_0| < \rho_\alpha, \text{ and } |t - t_0| < \rho_\alpha^4\}$ $(\rho_\alpha > 0)$ whose union contains X. Then let

$$\mathcal{P}_\delta^s(X) \equiv \inf\left\{\sum \rho_\alpha^s : \text{ All collections } \mathcal{C} \text{ that cover } X \text{ with } \rho_\alpha < \delta\right\},$$

and define the s-parabolic Hausdorff measure to be

$$\mathcal{P}^s(X) = \sup_{\delta\to 0} \mathcal{P}_\delta^s(X).$$

Then $\mathcal{P}_\delta^s$ and $\mathcal{P}^s$ are outer measures for which all Borel subsets are measurable. We define the s-parabolic Hausdorff dimension to be the infimum of $\{s : \mathcal{P}^s(X) = 0.\}$. It is clear that $\mathcal{P}^t(X) = 0$ if $\mathcal{P}^s(X) < \infty$ whenever $t > s$, and $\mathcal{P}^5(X)$ is positive for any bounded, open X.

We state the following version of the Vitali covering theorem; see section 6 in [CKN] for a proof.

THEOREM B.1. *Let $\mathcal{C}$ be a collection of parabolic cylinders described as above. Assuming that there is a uniform bound on the diameters of these cylinders, we can find a countable subcollection consisting of mutually disjoint cylinders $Q_j = \{(x,t) : |x - x_0| < \rho_j, |t - t_0| < \rho_j^4\}$ so that the union of the enlarged cylinders $Q'_j = \{(x,t) : |x - x_0| < 5\rho_j, |t - t_0| < 625\rho_j^4\}$ covers $\mathcal{C}$.*

Acknowledgments. We are grateful to the referees whose suggestions improve the presentation of this work.

THE STABILITY OF THE NORMAL STATE OF SUPERCONDUCTORS IN THE PRESENCE OF ELECTRIC CURRENTS*

Y. ALMOG†

Abstract. The stability of the normal state of superconductors in the presence of electric currents is studied in the large domain limit. The model being used is the time-dependent Ginzburg–Landau model, in the absence of an applied magnetic field, and with the effect of the induced magnetic field being neglected. We find that if the current is nowhere perpendicular to the boundary, or if the minimal current on the boundary, at points where it is perpendicular to it, is greater than the critical current in the one-dimensional case, then the normal state is stable. We also prove some short-time instability when the current is both perpendicular to the boundary and smaller than the one-dimensional critical current.

Key words. superconductivity, Ginzburg–Landau, electric current, non–self-adjoint

1. Introduction.

It is well known that when a superconductor is placed at a temperature lower than the critical one, it loses its electrical resistivity. This means that current can flow through a superconducting sample with a vanishingly small voltage drop. If one raises the current above a certain critical level, superconductivity will be destroyed and the material would revert to the normal state, even if the temperature is kept fixed below the critical one.

The reverse experiment can also be considered. One can flow a strong current through the sample which would set it in the normal state. Then, if we lower the current, there is a critical current where the sample would abruptly become purely superconducting. Though the two experiments substantially differ from each other from a theoretical point of view, hysteresis was not experimentally observed in the current-voltage characteristics of the sample [8, 14, 15].

We consider here the second experiment. To this end we must analyze the stability of the normal state. The model we use in this work is the time-dependent Ginzburg–Landau model [7, 4], presented here in a dimensionless form as follows:

$$\frac{\partial \psi}{\partial t} + i\phi\psi = (\nabla - iA)^2 \psi + \psi\left(1 - |\psi|^2\right) \quad \text{in } \Omega, \tag{1.1a}$$

$$-\kappa^2 \nabla \times (\nabla \times A) - \sigma\left(\frac{\partial A}{\partial t} + \nabla\phi\right) = \frac{i}{2}(\bar{\psi}\nabla\psi - \psi\nabla\bar{\psi}) + |\psi|^2 A \quad \text{in } \Omega, \tag{1.1b}$$

$$\psi = 0 \quad \text{on } \partial\Omega_c, \tag{1.1c}$$

$$(i\nabla + A)\psi \cdot \nu = 0 \quad \text{on } \partial\Omega_i\,. \tag{1.1d}$$

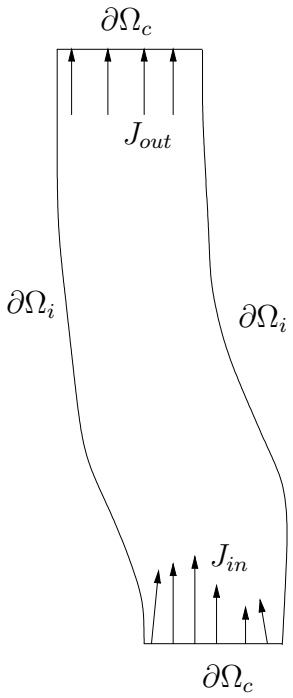

FIG. 1. *Typical superconducting sample. The arrows denote the direction of the current flow (J_{in} for the inlet and J_{out} for the outlet).*

In (1.1) ψ is the superconducting order parameter, so that $|\psi|$ represents the number density of superconducting electrons. Superconductors for which $|\psi| = 1$ are said to be wholly superconducting, and those for which $\psi = 0$ are said to be at the normal state. A is the magnetic vector potential and ϕ is the electric scalar potential. The constant σ is a measure of the normal conductivity of the superconducting material so that $-\sigma\nabla\phi$ is the normal current, and κ is the Ginzburg–Landau parameter. Length has been scaled with the coherence length ξ, which is the natural length-scale for variations in ψ. The domain $\Omega \subset\subset \mathbb{R}^n$ $(n = 1, 2, 3)$, where the superconducting sample resides, is smooth and has an interface, denoted by $\partial\Omega_c$, with a conducting metal which is at the normal state. The rest of the boundary, denoted by $\partial\Omega_i$, is adjacent to an insulator. We allow nonsmoothness of $\partial\Omega$ in the sense that $\partial\Omega_c$ and $\partial\Omega_i$ are required to be perpendicular to each other in order to include cylindrical-like domains. Figure 1 presents a typical two-dimensional sample, where the current flows into the sample from one part of $\partial\Omega_c$ and exits from another part, disconnected from the first one. Most wires would fall into the above class of domains.

Equations (1.1) are gauge invariant in the sense that they are invariant under transformations of the form

$$A \to A + \nabla\omega\,, \quad \phi \to \phi - \frac{\partial\omega}{\partial t}\,, \quad \psi \to \psi e^{i\kappa\omega}\,.$$

Note that none of the important physical properties, i.e., $|\psi|$, the magnetic field $H = \nabla \times A$, and the electric field $E = -\partial A/\partial t - \nabla\phi$, are altered by the above transformation.

To obtain a well-posed problem one must add to (1.1) initial conditions, and the equations satisfied by A and ϕ outside Ω, that is, the Maxwell equations. Continuity

of the tangential components of A and $\nabla \times A$ through $\partial\Omega$ and some conditions on $\nabla \times A$ at infinity should be required as well. Since these details are irrelevant in the context of the present contribution, we omit them. Interested readers may be able to find them in [4, 6].

We consider here the stability of the normal state. If $\psi \equiv 0$, we obtain that the steady state solution must satisfy

$$\nabla \times H = -\frac{\sigma}{\kappa^2}\nabla\phi\,,$$

and hence ϕ is harmonic in Ω. To obtain ϕ we thus need to solve the following problem:

$$\begin{cases} \Delta\phi = 0 & \text{in } \Omega, \\ \phi = \phi_0(x) & \text{on } \partial\Omega_c, \\ \frac{\partial\phi}{\partial\nu} = 0 & \text{on } \partial\Omega_i. \end{cases} \tag{1.2}$$

We note that instead of prescribing the potential on $\partial\Omega_c$ we can prescribe the current in the normal direction to the boundary $J_n(x) = -\sigma\partial\phi/\partial\nu$. For simplicity we assume that $\nabla\phi \neq 0$ everywhere in Ω. This can easily be achieved; for instance, for the samples described in Figure 1, if $\inf\phi$ on one connected component of $\partial\Omega_c$ is greater than the $\sup\phi$ on the other connected component, then $\nabla\phi$ never vanishes.

Once (1.2) is solved, one can solve for the magnetic field. Here we need to solve a problem in $\mathbb{R}^n$,

$$\begin{cases} \nabla \times H = -\frac{\sigma}{\kappa^2}\nabla\phi = \frac{1}{\kappa^2}J & \text{in } \Omega, \\ \nabla \times H = 0 & \text{in } \mathbb{R}^n \setminus \Omega, \\ H \to h_{ex} & \text{as } |x| \to \infty, \end{cases} \tag{1.3}$$

with H continuous across $\partial\Omega$. We assume zero applied magnetic field ($h_{ex} = 0$). To simplify our problem further we shall assume $A = H = 0$. This assumption can be justified in the case where $\kappa \gg 1$ in view of (1.3). However, since we intend to consider large domains, one must assume that $\kappa \gg \operatorname{diam}\Omega$. In real-world coordinates this means that our domain size must be much larger than the coherence length ξ but also much smaller than the penetration depth λ, which is the length-scale characterizing variations in H ($\kappa = \lambda/\xi$). While this assumption significantly limits the validity of our results, it has been made very often by physicists [15, 8] and is reasonable to adopt as a starting point.

Once the above assumption is adopted one obtains

$$\begin{cases} \frac{\partial\psi}{\partial t} - \Delta\psi + i\phi\psi - \psi(1 - |\psi|^2) = 0 & \text{in } \Omega, \\ \psi = 0 & \text{on } \partial\Omega_c, \\ \frac{\partial\psi}{\partial\nu} = 0 & \text{on } \partial\Omega_i, \\ \psi(x, 0) = \psi_0(x) & \text{in } \Omega. \end{cases}$$

It should be noted that in [6] Du and Gray prove, within the framework of a more general case, convergence in the limit $\kappa \to \infty$ of (1.1) to a different limit problem where the magnetic field is not negligible. The domain size considered there is, however, much larger than in our case, as it is comparable with the penetration depth.

Linearizing the above near the normal state, we obtain

$$\begin{cases} \frac{\partial \psi}{\partial t} - \Delta \psi + i\phi\psi - \psi = 0 & \text{in } \Omega, \\ \psi = 0 & \text{on } \partial\Omega_c, \\ \frac{\partial \psi}{\partial \nu} = 0 & \text{on } \partial\Omega_i, \\ \psi(x,0) = \psi_0(x) & \text{in } \Omega. \end{cases} \tag{1.4}$$

The above problem has been analyzed by physicists in one-dimensional settings. Ivlev and Kopnin review these results in [8]. In these settings we have $\phi = Jx + \mu$, where J (denoting the current) and μ are constants. Previous results include the closed form solution of (1.4) in $\mathbb{R}$ for any initial condition. In $\mathbb{R}_+$, the first critical current J_c for which a steady state solution ($\partial|\psi|/\partial t = 0$) exists is found. Then weakly nonlinear analysis is performed, where it is shown that [9] the bifurcation taking place near $J = J_c$ is subcritical (i.e., unstable).

We consider (1.4) in three-dimensional settings. While all the results are stated for three-dimensional objects, they are equally valid for two-dimensional objects as well. We deal with (1.4) in the large domain limit; i.e., we consider a domain Ω_R which is obtained from Ω via the transformation

$$x \to Rx\,. \tag{1.5}$$

The portions of the boundaries $\partial\Omega_R^c$ and $\partial\Omega_R^i$ are similarly obtained from $\partial\Omega_c$ and $\partial\Omega_i$, respectively. To keep $\nabla\phi$ unaltered we consider also potentials of the form

$$\phi_R = R\phi(x/R)\,.$$

Thus, we consider the following problem:

$$\begin{cases} \frac{\partial \psi_R}{\partial t} - \Delta \psi_R + i\phi_R\psi_R - \psi_R = 0 & \text{in } \Omega_R, \\ \psi_R = 0 & \text{on } \partial\Omega_R^c, \\ \frac{\partial \psi_R}{\partial \nu} = 0 & \text{on } \partial\Omega_R^i, \\ \psi_R(x,0) = \psi_0(x) & \text{in } \Omega_R. \end{cases} \tag{1.6}$$

Our main result is the following.

THEOREM 1.1. *Let ϕ satisfy* (1.2). *Let $\partial\Omega_c^n$ denote the portion of $\partial\Omega_c$ on which $\nabla\phi$ is perpendicular to the boundary. Let further*

$$J_m = \min_{x\in\partial\Omega_c^n} \left|\frac{\partial\phi}{\partial\nu}\right|,$$

and let J_c denote the critical current for the problem in $\mathbb{R}_+$ (which is precisely defined in (2.19)*). Suppose further that $|J| > 0$ everywhere on $\partial\Omega_c$. Then, if $J_m > J_c$, or if $\partial\Omega_c^n$ is empty, there exists $R_0 > 0$ such that $\psi_R \equiv 0$ is a stable solution of* (1.6) *in the sense of $L^2(\Omega_R)$ for all $R > R_0$.*

Furthermore, if $J_m < J_c$, there exists $\psi_0 \in L^2(\Omega_R)$ and $T_R > 0$ such that

$$\liminf_{R\to\infty} \frac{T_R}{\ln R} > 0\,,$$

and such that the solution ψ_R of (1.6) *has the following property:*

$$t < T_R \Rightarrow \|\psi_R\|_{L^2(\Omega_R)} > \frac{1}{2}\|\psi_0\|_{L^2(\Omega_R)} e^{\beta t}\,, \tag{1.7}$$

where

$$\beta = 1 - (J/J_c)^{2/3}\,.$$

In the next section we review and enhance the results in [8] in the one-dimensional case. In section 3 we extend some of the results in section 2 to unbounded three-dimensional domains. In section 4 we provide the proof of the theorem. Finally, in the last section we highlight some possible directions for future research. The appendix provides a technical result needed in section 2.

2. One-dimensional problems. In this section we consider (1.4) in two different one-dimensional settings: on $\mathbb{R}$ and on $\mathbb{R}_+$. The solution of these simple problems would provide us with some important intuition on the solution of (1.6) in three-dimensional bounded domains in the large domain limit. In both cases we shall assume $\phi = Jx$, i.e., that the current is uniform and equals J throughout the sample.

2.1. Infinite one-dimensional domain. Here we consider the problem

$$\frac{\partial \psi}{\partial t} - \psi'' - \psi + iJx\psi = 0\,. \tag{2.1}$$

We consider here only the case $J > 0$. Otherwise, if $J < 0$, we can consider the complex conjugate of (2.1). Applying the coordinate transformation

$$x \to J^{1/3}x; \qquad t \to J^{2/3}t, \tag{2.2}$$

we obtain the problem

$$\frac{\partial \psi}{\partial t} + \mathcal{L}\psi = \lambda_J \psi\,,$$

where

$$\mathcal{L}\psi = -\psi'' + ix\psi\,, \tag{2.3}$$

and $\lambda_J = J^{-2/3}$.

We first focus our interest on the spectrum of the operator $\mathcal{L} : \mathcal{D}_{\mathbb{R}}(\mathcal{L}) \to L^2(\mathbb{R}, \mathbb{C})$, where $\mathcal{D}_{\mathbb{R}}(\mathcal{L})$ is the dense subset of $L^2(\mathbb{R}, \mathbb{C})$ defined as

$$\mathcal{D}_{\mathbb{R}}(\mathcal{L}) = \{u \in L^2(\mathbb{R}, \mathbb{C}) \,|\, -u'' + ixu \in L^2(\mathbb{R}, \mathbb{C})\}\,.$$

LEMMA 2.1. *The operator $\mathcal{L} - \lambda I$ is invertible for all $\lambda \in \mathbb{C}$. (Thus $\sigma(\mathcal{L}) = \phi$.)*

Proof. It is sufficient to consider here $\lambda \in \mathbb{R}$. Otherwise, if $\lambda = \lambda_r + i\lambda_i$, we apply the transformation $x \to x - \lambda_i$.

Though it is not necessary, we first prove injectivity of $\mathcal{L} - \lambda I$. We shall later make use of a similar argument in three dimensions. To the problem

$$\mathcal{L}u = \lambda u$$

we apply the Fourier transform

$$\hat{u}(\omega) = \mathcal{F}(u) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} e^{-i\omega x} u(x) dx \tag{2.4}$$

to obtain

$$\omega^2 \hat{u} - \frac{\partial \hat{u}}{\partial \omega} = \lambda \hat{u}\,.$$

Since the above equation doesn't possess any nontrivial solutions with bounded $L^2(\mathbb{R})$ norm, $\mathcal{L} - \lambda I$ must be injective.

To find the spectrum of $\mathcal{L}$ we construct the Green's function of $\mathcal{L} - \lambda I$. Let

$$\begin{cases} w_1(x,\lambda) = A_i\big(e^{i\pi/6}x + \lambda e^{i2\pi/3}\big), \\ w_2(x,\lambda) = A_i\big(-e^{-i\pi/6}x + \lambda e^{-i2\pi/3}\big), \end{cases} \tag{2.5}$$

where A_i denotes Airy's function [1] (cf. (A.2) in Appendix A for the asymptotic behavior of A_i). It is easy to show that u_1, u_2 constitute a fundamental set of solutions to $(\mathcal{L} - \lambda I)u = 0$ [13]. We can now write the Green's function in the form

$$G(x,\xi,\lambda) = \begin{cases} \frac{w_2(\xi,\lambda)}{W(w_1,w_2)} w_1(x,\lambda), & x > \xi, \\ \frac{w_1(\xi,\lambda)}{W(w_1,w_2)} w_2(x,\lambda), & x < \xi, \end{cases}$$

where $W(w_1, w_2)$ denote the Wronskian (which is a constant that clearly doesn't vanish since w_1 and w_2 are linearly independent).

Using the asymptotic behavior of Airy's functions [1], we can show, using the same procedure applied in Appendix A to the semi-infinite case, that $G(\cdot,\lambda) \in L^2(\mathbb{R}^2,\mathbb{C})$ for all $\lambda \in \mathbb{R}$. The lemma is proved. □

The spectrum of the operator $\mathcal{L} : \mathcal{D}_{\mathbb{R}}(\mathcal{L}) \to L^2(\mathbb{R},\mathbb{C})$ can therefore teach us very little on the stability of the normal state in this case. The following lemma proves its stability in a direct manner.

LEMMA 2.2. *The trivial solution of* (2.1), $\psi \equiv 0$, *is globally stable in* L^2*; i.e., if* $f(x) \in L^2(\mathbb{R},\mathbb{C})$, *then the solution of* (2.1), $\psi(x,t)$, *satisfying the initial condition* $\psi(x,0) = f(x)$ *satisfies* $\psi(x,t) \xrightarrow[t\to\infty]{} 0$ *in* $L^2(\mathbb{R},\mathbb{C})$.

Proof. As long as $\psi(x,t) \in L^2(\mathbb{R},\mathbb{C})$, we can apply to (2.1) the Fourier transform (2.4). We obtain

$$\frac{\partial \hat{\psi}}{\partial t} + \omega^2 \hat{\psi} - \frac{\partial \hat{\psi}}{\partial \omega} - \lambda_J \hat{\psi} = 0\,.$$

The unique solution to the above problem is given by

$$\hat{\psi}(\omega,t) = \hat{f}(\omega) \exp\left\{ -\omega^2 t - \omega t^2 - \frac{1}{3}t^3 + \lambda_J t \right\}, \tag{2.6}$$

in which $\hat{f}(\omega)$ denotes the Fourier transform of f. Integrating the modulus square of the above over $\mathbb{R}$ with respect to ω, we obtain

$$\|\psi(.,t)\|_2 \le C\|f\|_2 \exp\left\{ -\frac{1}{12}t^3 + \lambda_J t \right\},$$

where $\|\cdot\|_2$ denotes the $L^2(\mathbb{R},\mathbb{C})$ norm. □

The above superlinear convergence is in accordance with the result proved in the previous lemma by which the spectrum of $\mathcal{L}$ is empty. We note that in [8] the inverse transform of (2.6) is obtained, but no decay proof is given.

2.2. Semi-infinite one-dimensional domain. We now consider (2.1) on $\mathbb{R}_+$. We concentrate here on the Dirichlet boundary condition $\psi(0)=0$; however, the same analysis applies to Neumann and mixed boundary conditions as well.

We start by proving the following result on the spectrum of the operator $\mathcal{L}:\mathcal{D}_{\mathbb{R}_+}(\mathcal{L})\to L^2(\mathbb{R},\mathbb{C})$, where

$$\mathcal{D}_{\mathbb{R}_+}(\mathcal{L})=\{u\in L^2(\mathbb{R}_+,\mathbb{C})\,|\,-u''+ixu\in L^2(\mathbb{R}_+,\mathbb{C}),\ u\in H_0^1(\mathbb{R}_+,\mathbb{C})\}\,.$$

LEMMA 2.3.

1. *There exists a sequence of eigenvalues* $\{\lambda_n\}_{n=1}^{\infty}$ *and eigenfunctions of* $\mathcal{L}$*, with unity norm,* $\{u_n\}_{n=1}^{\infty}\subset\mathcal{D}_{\mathbb{R}_+}(\mathcal{L})$*, i.e.,*
$$\mathcal{L}u_n=\lambda_n u_n\,.$$
2. *We have*
$$m=\max_{n\in\mathbb{N}}\Re\lambda_n>0. \tag{2.7}$$
3. $\operatorname{span}\{u_n\}_{n=1}^{\infty}=L^2(\mathbb{R}_+,\mathbb{C})$.
4. *Suppose that* $u,v\in L^2(\mathbb{R}_+,\mathbb{C})$ *can be represented in the form*
$$v=\sum_{n=1}^{\infty}\alpha_n u_n;\qquad w=\sum_{n=1}^{\infty}\beta_n u_n,$$
where the convergence is in the L^2 *sense. Let then*
$$\langle v,w\rangle_U=\sum_{n=1}^{\infty}\alpha_n\bar{\beta}_n\,. \tag{2.8}$$
Then,
$$\inf_{v\in\mathcal{D}_{\mathbb{R}_+}(\mathcal{L})}\Re\langle v,\mathcal{L}v\rangle_U\geq m\|v\|_U^2\,, \tag{2.9}$$
where $\|\cdot\|_U$ *denotes the norm induced by* (2.8).

Proof. Let
$$z=-ix+\lambda.$$
Let $u(x,\lambda)\in\mathcal{D}_{\mathbb{R}_+}(\mathcal{L})$ denote an eigenfunction of $\mathcal{L}$, i.e., $\mathcal{L}u=\lambda u$. Let $v(z,\lambda)=u(x,\lambda)$. We have
$$\begin{cases}\frac{\partial^2 v}{\partial z^2}-zv=0, & z\in\mathbb{C},\\ v(\lambda,\lambda)=0.\end{cases} \tag{2.10}$$
Since $u\in L^2(\mathbb{R}_+,\mathbb{C})$, v must be subdominant (i.e., it decays exponentially fast [13]) in the sector
$$S_1:\ -\pi<\arg z<-\frac{\pi}{3}\,.$$
The decaying solution of (2.10) in S_1 is given by (cf. [13])
$$v=A_i\big(e^{2\pi i/3}z\big)\,.$$

Since the zeros of Airy's functions are eigenvalues of the self-adjoint operator $d^2/dx^2 - x$ in $\mathcal{D}_{\mathbb{R}_+}(\mathcal{L})$, they must all be real. Let $\{\mu_n\}_{n=1}^{\infty} \subset \mathbb{R}$ denote the zeroes of Airy's function on the real axis. By the maximum principle they must all be strictly negative. We arrange them so that $\mu_n \downarrow -\infty$. As every eigenvalue of $\mathcal{L}$ must satisfy $v(\lambda, \lambda) = 0$, the set $\{\lambda_n\}_{n=1}^{\infty}$, where

$$\lambda_n = e^{-i2\pi/3}\mu_n, \tag{2.11}$$

contains all the eigenvalues of $\mathcal{L}$. Since $\mu_1 < 0$ we have that

$$m = \Re\lambda_1 = -\frac{\mu_1}{2} > 0\,.$$

The set $\{\tilde{u}_n\}_{n=1}^{\infty}$ of eigenfunctions of $\mathcal{L}$ in $\mathcal{D}_{\mathbb{R}_+}(\mathcal{L})$ is given by

$$\tilde{u}_n = A_i\big(e^{i2\pi/3}(-ix + \lambda_n)\big) = A_i\big(e^{i\pi/6}x + \mu_n\big) \quad \forall n \in \mathbb{N}\,. \tag{2.12}$$

We then set

$$u_n = \frac{\tilde{u}_n}{\|\tilde{u}_n\|_{L^2(\mathbb{R}_+)}}\,. \tag{2.13}$$

To prove that $\{u_n\}_{n=1}^{\infty}$ is complete in $L^2(\mathbb{R}, \mathbb{C})$ we consider the resolvent $\mathcal{L}_\lambda^{-1} = (\mathcal{L} - \lambda I)^{-1}$ (which is also the modified resolvent of $\mathcal{L}^{-1}$). We have

$$\mathcal{L}_\lambda^{-1} f = \int_0^\infty \tilde{G}(x, \xi, \lambda) f(\xi) d\xi\,, \tag{2.14a}$$

in which

$$\tilde{G}(x, \xi, \lambda) = \begin{cases} \frac{\tilde{w}_2(\xi,\lambda)}{W(w_1, \tilde{w}_2)} w_1(x, \lambda), & x > \xi, \\ \frac{w_1(\xi,\lambda)}{W(w_1, \tilde{w}_2)} \tilde{w}_2(x, \lambda), & x < \xi, \end{cases} \tag{2.14b}$$

where

$$\tilde{w}_2(x, \lambda) = \frac{w_1(0, \lambda)}{w_2(0, \lambda)} w_1(x, \lambda) - w_2(x, \lambda)\,, \tag{2.15}$$

and w_1 and w_2 are given in (2.5). In Appendix A, we prove that $\tilde{G} \in L^2(\mathbb{R}_+ \times \mathbb{R}_+)$, and that

$$\|\tilde{G}(., ., \lambda)\|_{L^2(\mathbb{R}_+ \times \mathbb{R}_+)} \leq e^{M|\lambda|^{3/2}}\,, \tag{2.16}$$

as long as $\lambda \notin \{\lambda_n\}_{n=1}^{\infty}$.

Let $u \in \mathcal{D}_{\mathbb{R}_+}(\mathcal{L})$. We now multiply $\mathcal{L}u$ by $e^{i\theta}\bar{u}$ and integrate over $\mathbb{R}_+$ to obtain

$$\Re < e^{i\theta}\mathcal{L}u, u >= \int_0^\infty (\cos\theta |u'|^2 - \sin\theta x |u|^2) dx\,.$$

By Theorem 12.8 in [2] we have that every direction $e^{i \arg\lambda}$ with

$$\pi/2 < \arg\lambda < 3\pi/2$$

is a direction of minimal growth of the resolvent of $e^{i\theta}\mathcal{L}$ for every $-\pi/2 < \theta < 0$. Consequently, every direction $e^{i \arg \lambda}$ with

$$\pi/2 < \arg \lambda < 2\pi$$

is a direction of minimal growth of $\mathcal{L}_\lambda^{-1}$, i.e. (cf. [2]),

$$\|\mathcal{L}_\lambda^{-1}\| \sim \mathcal{O}(|\lambda|^{-1}) \quad \pi/2 < \arg \lambda < 2\pi\,. \tag{2.17}$$

We now apply the same argument used in the proof of Theorem 16.4 in [2]. Let $f \in L^2(\mathbb{R}_+)$, and let $g \in V^\perp$, where $V = \operatorname{span}\{A_i(e^{i\pi/6}x + \mu_n)\}_{n=1}^\infty = \operatorname{sp}'(\mathcal{L}^{-1})$. Then,

$$F(\lambda) = \langle \mathcal{L}_\lambda^{-1} f, g\rangle$$

is an entire function (cf. [2]) of λ satisfying, by (2.16) and (2.17),

$$\begin{cases} |F(\lambda)| \le \frac{C}{|\lambda|}, & \pi/2 < \arg \lambda < 2\pi, \\ |F(\lambda)| \le Ce^{M|\lambda|^{3/2}}, & \lambda \in \mathbb{C}. \end{cases}$$

By Theorem 16.1 in [2] (or the Phragmen–Leindelöf theorem) and Liouville's theorem, we must have $F(\lambda) \equiv 0$. Hence, $\overline{V} = \overline{\operatorname{range}(\mathcal{L}^{-1})} = \overline{\mathcal{D}_{\mathbb{R}_+}(\mathcal{L})}$.

It remains still necessary to prove (2.9). Let $w \in \mathcal{D}_{\mathbb{R}_+}(\mathcal{L})$. Then,

$$w = \sum_{n=1}^\infty \alpha_n u_n$$

and

$$\mathcal{L}w = \sum_{n=1}^\infty \alpha_n \lambda_n u_n\,.$$

Hence

$$\Re \langle w, \mathcal{L}w\rangle_U = \sum_{n=1}^\infty \Re\lambda_n |\alpha_n|^2 \ge m\|w\|_U^2\,. \qquad \square$$

Similar techniques were used in [12, 10] to prove completeness of the system of eigenfunctions of some nonlinear eigenvalue problems in $\mathbb{R}$. We note that the set $\{u_n\}_{n=1}^\infty$ is not a basis in the usual sense in Banach spaces. In fact, it has been demonstrated in [5] that the system $\{\tilde{u}_n, \overline{\tilde{u}_n}\}_{n=1}^\infty$, which is a biorthogonal system after we appropriately normalize it, is wild. This means that $\|\tilde{u}_n\|_2$ grows faster than any algebraic rate as $n \to \infty$.

We now prove the existence of a critical current J_c obtained in [8, 9].

LEMMA 2.4. *Let $\psi(x,t) \in H_0^2(\mathbb{R}_+ \times \mathbb{R}_+, \mathbb{C})$ denote a solution of the equation*

$$\frac{\partial \psi}{\partial t} - \frac{\partial^2 \psi}{\partial x^2} - \psi + iJx\psi = 0 \quad \text{in } \mathbb{R}_+ \times \mathbb{R}_+\,. \tag{2.18}$$

If

$$J > J_c = \left(-\frac{\mu_1}{2}\right)^{-3/2}, \tag{2.19}$$

in which μ_1 is the rightmost zero of Airy's function, then $\|\psi(\cdot,t)\|_U \xrightarrow[t\to\infty]{} 0$. Otherwise, if $J < J_c$, then $\psi \equiv 0$ is an unstable solution of (2.18).

Proof. We first apply (2.2) to obtain

$$\begin{cases} \frac{\partial \psi}{\partial t} + \mathcal{L}\psi - \lambda_J \psi = 0, \\ \psi(0,t) = 0, \\ \psi(x,0) = \psi_0(x), \end{cases}$$

where $\|\psi_0\|_U < \infty$. Taking the inner product (2.8) of the above equation with ψ, we obtain

$$\frac{1}{2}\frac{d}{dt}\|\psi\|_U^2 \le \left(\lambda_J + \frac{\mu_1}{2}\right)\|u\|_U^2 .$$

Hence, if (2.19) is satisfied, we have $\lambda_J + \mu_1/2 < 0$, and hence ψ tends to 0 exponentially fast as $t \to \infty$, in the $\|\cdot\|_U$ sense.

If $J < J_c$, let $\psi(x,0) = u_1(x)$, where u_1 is given in (2.13). Then

$$\psi(x,t) = u_1(x) e^{(\lambda_J + \mu_1/2)t} .$$

Returning to the original variables by applying the inverse of (2.2), we obtain

$$\psi(x,t) = u_1(J^{1/3}x) e^{[1-(J/J_c)^{2/3}]t} ,$$

and hence $\psi \equiv 0$ is unstable. ∎

3. Unbounded domains in $\mathbb{R}^3$. In this section we consider several different problems: in $\mathbb{R}^3$, in $\mathbb{R}^3_+$, and in a quarter-space. In contrast with the previous section, we consider these problems only to the extent needed in the next section, that is, we analyze the existence of eigenvalues with nonpositive real part of the elliptic operator in the right-hand side of (1.4).

3.1. Eigenfunctions in $\mathbb{R}^3$. We consider here (1.4) with $\phi = Jx_1$. This choice summarizes all possible electric potentials with constant gradients, as the problem is invariant to translations and rotations. Thus, we have for every eigenfunction u,

$$-\Delta u - u + iJx_1 u = -\lambda u . \tag{3.1}$$

We shall assume here that $\lambda \in \mathbb{R}$; otherwise we can apply the transformation $x_1 \to x_1 - \Im\lambda/J$.

It is easy to find all L^2 solutions of (3.1) in $\mathbb{R}^3$ as follows: apply the Fourier transform (2.4) in the x_2 and x_3 directions (using the respective Fourier coordinates ω_2 and ω_3) to obtain

$$\mathcal{L}\hat{u} = \big((1-\lambda)J^{-2/3} - \omega_2^2 - \omega_3^2\big)\hat{u}, \tag{3.2}$$

where assuming $J > 0$ we have applied the transformation

$$x \to J^{1/3}x .$$

(We confine the discussion in what follows to the case $J > 0$. If $J < 0$, we can consider the complex conjugate of (3.2) to obtain a new problem with $J > 0$.)

By Lemma 2.1 we have that $\hat{u} \equiv 0$ is the unique L^2 solution of (3.2). However, for the blow-up arguments employed in the next section we need to obtain the above result for any uniformly bounded solution of (3.1) in $\mathbb{R}^3$. This is exactly what the next lemma states.

LEMMA 3.1. *Let u denote a uniformly bounded solution of* (3.1) *in* $\mathbb{R}^3$. *Then,* $u \equiv 0$.

Proof. We first show that $u(., x_2, x_3) \in L^2(\mathbb{R}, \mathbb{C})$. Let $\chi_r \in C^\infty(\mathbb{R}_+, [0,1])$ satisfy

$$\chi_r(x) = \begin{cases} 1 & x < r/2, \\ 0 & x > r, \end{cases} \qquad |\chi'| \leq \frac{C}{r}\,. \tag{3.3}$$

Multiplying (3.1) by $\chi_r^2(|x - x_0|)\bar{u}$ we obtain, taking the real part of identity, that

$$\int_{B(x_0,r)} |\nabla(\chi_r u)|^2 \leq \int_{B(x_0,r)} \left[\chi^2 + |\nabla\chi|^2\right]|u|^2\,. \tag{3.4}$$

Consequently, since u is bounded in $L^\infty(\mathbb{R}^3)$, we have

$$\int_{B(x_0,r/2)} |\nabla u|^2 \leq C \quad \forall x_0 \in \mathbb{R}^3\,. \tag{3.5}$$

From the imaginary part of the identity, we obtain that

$$\int_{B(x_0,r)} \left(\nabla(\chi_r^2) \cdot \Im\left(\bar{u}\nabla u\right) + J x_1 \chi_r |u|^2\right) = 0\,.$$

Let $x_0 = (x_0^1, x_0^2, x_0^3)$. Then,

$$\int_{B(x_0,r/2)} |x_1||u|^2 dx_1 \leq C \int_{B(x_0,r)} \left[|u|^2 + |\nabla u|^2\right]\,.$$

Consequently, for $|x_0^1| > r$, since u is bounded and in view of (3.5), we have

$$\int_{B(x_0,r/2)} |u|^2 \leq \frac{C}{|x_0^1| - \frac{r}{2}} \leq \frac{C}{|x_0^1|}\,.$$

Repeating the above steps (from (3.4) to the above inequality) k times we obtain that

$$\int_{B(x_0,r/2^k)} |u|^2 \leq \frac{C_k}{|x_0^1|^k}.$$

Hence,

$$\int_{B(x_0,r/2^k)} |x_1|^2|u|^2 \leq \frac{C_k}{|x_0^1|^{k-2}}\,,$$

which allows us to apply standard elliptic estimates [3] to obtain that

$$|u| \leq \frac{C_k}{(|x_1| + 1)^k} \quad \forall k \in \mathbb{N}\,.$$

In view of the above we have that $x_1^k u(x_1, x') \in L^2(\mathbb{R}, \mathbb{C})$ for all fixed $x' \in \mathbb{R}^2$. Thus, one can apply to (3.1) the Fourier transform (2.4) to obtain

$$-\Delta_\perp \hat{u} + (\omega^2 - 1 + \lambda)\hat{u} - J\frac{\partial \hat{u}}{\partial \omega} = 0\,, \tag{3.6}$$

where

$$-\Delta_\perp = \frac{\partial^2}{\partial x_2^2} + \frac{\partial^2}{\partial x_3^2}\,.$$

Let

$$\tilde{x}_r(x) = \begin{cases} 1, & |x| < r, \\ e^{-\frac{1}{r}(|x|-r)}, & |x| > r. \end{cases} \tag{3.7}$$

Multiplying (3.6) by $\tilde{\chi}_r^2(|x' - x^0|)\overline{\hat{u}}$ and integrating over $\mathbb{R}^2$, we obtain

$$-J\frac{dU_r}{d\omega} + (\omega^2 - 1 + \lambda)U_r = \int_{\mathbb{R}^2} \left(-|\nabla(\tilde{\chi}_r\hat{u})|^2 + |\nabla\tilde{\chi}_r|^2|\hat{u}|^2\right) dx',$$

where

$$U_r(\omega) = \int_{\mathbb{R}^2} \tilde{\chi}_r^2|\hat{u}|^2 dx'\,.$$

For the last term, we have

$$\int_{\mathbb{R}^2} |\nabla\tilde{\chi}_r|^2|\hat{u}|^2 \le \frac{1}{r^2}U_r\,.$$

Consequently,

$$-J\frac{dU_r}{d\omega} + (\omega^2 - 1 + \lambda - r^{-2})U_r \le 0\,,$$

and therefore, for every $\omega_0 \in \mathbb{R}$ and $\omega > \omega_0$, we have

$$U_r(\omega) \ge U_r(\omega_0)\exp\left\{\frac{1}{3}(\omega^3 - \omega_0^3) - (1 + \lambda + r^{-2})(\omega - \omega_0)\right\}.$$

Thus, since U_r is positive, it must diverge exponentially fast, unless

$$U_r \equiv 0,$$

from which the lemma easily follows. □

3.1.1. Eigenfunctions in $\mathbb{R}^3_+$: Perpendicular current. Let

$$\mathbb{R}^3_+ = \{(x_1, x_2, x_3)\,|\,x_1 > 0\}\,.$$

We consider here solutions of (3.1) in $\mathbb{R}^3_+$ satisfying a Dirichlet boundary condition on $\partial\mathbb{R}^3_+$. Instead of considering complex eigenvalues, we consider only real ones and treat their imaginary part as part of the electric potential.

LEMMA 3.2. *Let $u \in H^2(\mathbb{R}^3_+)$ denote a uniformly bounded solution of*

$$\begin{cases} -\Delta u - u + iJ(x_1 - \mu)u = -\lambda u & \text{in } \mathbb{R}^3_+, \\ u = 0 & \text{on } \partial\mathbb{R}^3_+\,, \end{cases} \tag{3.8}$$

with $\lambda \in \mathbb{R}_+$. Then, if $J > J_c$, where J_c is defined as in (2.19)*, u must vanish identically.*

Proof. Let $u_n(x_1)$ be defined as in (2.12). Let further

$$a_n(x_2,x_3)=\int_0^\infty u_n(x_1)u(x_1,x_2,x_3)dx_1=\langle u_n,\bar{u}\rangle\,,$$

where the inner product is in the regular L^2 sense. Clearly, a_n is uniformly bounded in $\mathbb{R}^2$ as $u\in L^\infty(\mathbb{R}^3,\mathbb{C})$ and $u_n\in L^1(\mathbb{R},\mathbb{C})$.

Applying the transformation

$$x\to J^{1/3}x\,, \tag{3.9}$$

multiplying (3.8) by u_n, and integrating over $\mathbb{R}_+$ with respect to x_1 we obtain, in view of the boundedness of u and the exponential rate of decay of u_n as $x_1\to\infty$, that

$$-\Delta_\perp a_n+(\lambda_n-\tilde{\lambda}_J-i\mu)a_n=0\,, \tag{3.10}$$

where $\tilde{\lambda}_J=(1-\lambda)J^{-2/3}$ and the definition of λ_n is given as in Lemma 2.3. Multiplying (3.10) by $\tilde{\chi}_r(|x'|)$, we obtain for the real part

$$\left(\frac{|\mu_n|}{2}-\tilde{\lambda}_J\right)\int_{\mathbb{R}^2}|\tilde{\chi}_r|^2|a_n|^2=-\int_{\mathbb{R}^2}|\nabla(\tilde{\chi}_r a_n)|^2+\int_{\mathbb{R}^2}|\nabla\tilde{\chi}_r|^2|a_n|^2\le\frac{C}{r^2}\int_{\mathbb{R}^2}|\tilde{\chi}_r|^2|a_n|^2\,.$$

Since $\tilde{\lambda}_J<|\mu_1|/2\le|\mu_n|/2$ by our assumption we obtain that for sufficiently large r we must have

$$\int_{\mathbb{R}^2}|\tilde{\chi}_r|^2|a_n|^2=0\,.$$

Hence, $a_n\equiv 0$ in $\mathbb{R}^2$. Since by Lemma 2.3 $\{u_n\}_{n=1}^\infty$ is a basis for $L^2(\mathbb{R}_+,\mathbb{C})$, we must have $u\equiv 0$. ∎

3.1.2. Steady solutions in $\mathbb{R}^3_+$: Nonperpendicular current. This problem is very similar to the problem in $\mathbb{R}^3$. Consider the equation

$$\begin{cases}-\Delta u-u+i(J_1x_1+J_2x_2-\mu)u=-\lambda u & \text{in } \mathbb{R}^3_+,\\ u=0 & \text{on } \partial\mathbb{R}^3_+,\end{cases} \tag{3.11}$$

with $J_2\neq 0$ and $\lambda\in\mathbb{R}_+$. Like the problem in $\mathbb{R}^3$, there is no need to consider $\mu\neq 0$ here since the transformation

$$x_2\to x_2+\frac{\mu}{J_2}$$

sets $\mu=0$ in the transformed problem. Furthermore, we also obtain the following result, which is exactly the same as the result obtained in $\mathbb{R}^3$.

LEMMA 3.3. *Let u denote a bounded solution of* (3.11) *with $J_2\neq 0$. Then $u\equiv 0$.*

Proof. Consider first the case where $J_1\neq 0$. We first apply the transformation (3.9) with $J=J_1$ to obtain

$$-\Delta_\perp u+\mathcal{L}u-\tilde{\lambda}_{J_1}u+i\gamma x_2u=0\,, \tag{3.12}$$

where $\tilde{\lambda}_{J_1}=(1-\lambda)J_1^{-2/3}$ and $\gamma=J_2/J_1$. Multiplying (3.12) by u_n and integrating over $\mathbb{R}_+$ with respect to x_1, we obtain

$$-\Delta_\perp a_n+(\lambda_n-\tilde{\lambda}_{J_1})a_n+i\gamma x_2a_n=0\quad\text{in } \mathbb{R}^2\,,$$

where $a_n = \langle u_n, \bar{u} \rangle$. The above equation cannot have any nontrivial bounded solution in $\mathbb{R}^2$; otherwise it would also be a bounded solution in $\mathbb{R}^3$, which by Lemma 3.1 must identically vanish. Consequently, since a_n must be bounded, we must have $a_n \equiv 0$ for all n, from which the lemma easily follows in this case.

Consider now the case where $J_1 = 0$. Here we define

$$\tilde{u}(x_1, x_2, x_3) = \begin{cases} u(x_1, x_2, x_3), & x_1 > 0, \\ -u(-x_1, x_2, , x_3), & x_1 < 0. \end{cases}$$

Clearly, $\tilde{u}$ is a bounded weak solution of (3.1) in $\mathbb{R}^3$ and hence, by Lemma 3.1, $\tilde{u} \equiv 0$. □

For later reference we shall also need the following lemma.

LEMMA 3.4. *Let u denote a bounded solution of*

$$\begin{cases} -\Delta u - u + iJ_2 x_2 u = -\lambda u & \text{in } \mathbb{R}^3_+, \\ \frac{\partial u}{\partial x_1} = 0 & \text{on } \partial\mathbb{R}^3_+, \end{cases}$$

with $\lambda \in \mathbb{R}_+$. Then $u \equiv 0$.

Proof. Once again we define, this time an even function,

$$\tilde{u}(x_1, x_2, x_3) = \begin{cases} u(x_1, x_2, x_3), & x_1 > 0, \\ u(-x_1, x_2, , x_3), & x_1 < 0. \end{cases}$$

Clearly, $\tilde{u}$ is a bounded weak solution of (3.1) in $\mathbb{R}^3$ and hence, by Lemma 3.1, $\tilde{u} \equiv 0$. □

The last result in this section is needed in the next section in order to deal with the interface between $\partial\Omega^i$ and $\partial\Omega_n$ (that are perpendicular by assumption).

LEMMA 3.5. *Let*

$$Q = \{(x_1, x_2, x_3) \in \mathbb{R}^3_+ \,|\, x_2 > 0\}.$$

Let u denote a bounded solution of

$$\begin{cases} -\Delta u - u + i(J_2 x_2 + J_3 x_3)u = -\lambda u & \text{in } Q, \\ \frac{\partial u}{\partial x_1}(0, x_2, x_3) = 0, & x_2 > 0, \quad x_3 \in \mathbb{R}, \\ u(x_1, 0, x_3) = 0, & x_1 > 0, \quad x_3 \in \mathbb{R}, \end{cases}$$

with $\lambda \in \mathbb{R}_+$. Then $u \equiv 0$.

Proof. Once again we define an even extension of u,

$$\tilde{u}(x_1, x_2, x_3) = \begin{cases} u(x_1, x_2, x_3), & x_1 > 0, \\ u(-x_1, x_2, , x_3), & x_1 < 0. \end{cases}$$

By Lemma 3.3, $\tilde{u} = 0$. □

4. Large bounded domains in $\mathbb{R}^3$. We consider here (1.6) in the limit $R \to \infty$ which is the large domain limit. We first show that any eigenfunctions of the elliptic operator in (1.6) must decay exponentially fast, as $R \to \infty$ away from the boundary. As in the previous section we insert the imaginary part of λ into the electric potential

(and consequently consider a family of potentials) and then confine the discussion to real values of λ.

Before getting into the main discussion we repeat here the definition of ϕ_R from section 1 and list some of its properties. Recall that ϕ is the unique solution of (1.2), and that

$$\phi_R(x) = R\phi(x/R)\,.$$

The following proposition lists some of the properties of ϕ and ϕ_R.

PROPOSITION 4.1. *Let ϕ denote a solution of* (1.2) *and $\phi_R(x) = R\phi(x/R)$. Let $\mu \in \mathbb{R}$ and $\mu_R = R\mu$. Let further $x_j \in \Omega_{R_j}$ where $R_j \uparrow \infty$, and $\{\mu_j\}_{j=1}^{\infty} \subset \mathbb{R}$. Then*

(i) *we have either $|\phi_{R_j}(x_j) - \mu_j|$ is unbounded, or else we must have, up to a subsequence,*

$$\exists (b, J) \in \mathbb{R} \times \mathbb{R}^3 : \ \|\phi_{R_j} - \mu_j - J \cdot x - b\|_{L^\infty(D_r(x_j))} \to 0 \quad \forall r > 0\,,$$

where $D_r(x_j) = \Omega_R \cap B(x_j, r)$.

(ii) *we let Γ_μ denote the level set $\phi = \mu$. Let $M = \max_{x \in \partial\Omega_c} \phi(x)$ and $m = \min_{x \in \partial\Omega_c} \phi(x)$. If $\mu \notin [m, M]$, then Γ_μ is empty.*

(iii) *assume that $\partial\Omega_c$ is composed of exactly two connected sets as in Figure* 1*, and that Ω is diffeomorphic to a cylinder. If $\mu \in [m, M]$, but $\mu \notin \phi(\partial\Omega_c)$, then $\Gamma_\mu \cap \partial\Omega_i$ is a simple closed contour, separating $\partial\Omega$ into two subsets, such that none of them is a subset of $\partial\Omega_i$. Furthermore, $\nabla\phi \neq 0$ on Γ_μ.*

Proof. Let $b_j = \phi_{R_j}(x_j) - \mu_j$ and $J_j = \nabla\phi_{R_j}(x_j)$. To prove (i) we first choose a subsequence such that $(b_j, J_j) \to (b, J)$. The claim then follows from the Taylor expansion of ϕ_{R_j} near x_j.

The proof of (ii) follows immediately from the maximum principle.

To prove (iii) we notice first that since ϕ is real analytic, Γ_μ must either be closed or intersect $\partial\Omega$. If it is closed, then $\phi \equiv \mu$ inside Γ_μ, and hence also outside Γ_μ (in view of its analyticity), which is clearly a contradiction. Thus Γ_μ must intersect the boundary on $\partial\Omega_i$.

Since ϕ is continuous and since on one of the connected sets we must have $\phi < \mu$ and on the other one $\phi > \mu$, the intersection of $\partial\Omega_i$ with Γ_μ must contain at least one closed contour. This contour separates $\partial\Omega$ into two disjoints subsets $\partial\Omega_+$ and $\partial\Omega_-$, the first of them contains the connected subset of $\partial\Omega_c$; over which $\phi > \mu$, and contains a portion of $\partial\Omega^i$. Moreover, this contour is the boundary of a continuous subset of Γ_μ which we denote by A.

To see this, define cylindrical coordinates (r, θ, z) in Ω, where $\theta \in [-\pi, \pi)$ and $0 \leq r < R(\theta, z)$. Then, for each (r, θ) there exists a finite (as ϕ is real analytic) set $\{z_j\}$ such that $(r, \theta, z_j) \in \Gamma_\mu$. Denote the minimum in this set by z_m. Clearly, $z = z_m(r, \theta)$ is continuous, and thus we can define

$$A = \{(r, \theta, z) \,|\, z = z_m(r, \theta)\}\,.$$

We now consider the problem for ϕ in a subdomain of Ω whose boundary consists of A and $\partial\Omega_+$. By the maximum principle and Hopf's lemma we have $\phi > \mu$ on $\partial\Omega_+$ and in the interior. In a similar manner we show that $\phi < \mu$ both on $\partial\Omega_-$ and in the interior of the subdomain surrounded by A and $\partial\Omega_-$. This shows that $A = \Gamma_\mu$. From Hopf's lemma it follows that $\nabla\phi \neq 0$ on Γ_μ. ∎

Remark 4.1. While property (i) will be used extensively throughout this section, properties (ii) and (iii) are brought here to provide the reader with some intuition of the behavior of ϕ in the "wire-like" domain presented in Figure 1.

Since (1.6) contains the term $i(\phi_R-\mu_R)\psi_R$ which might be unbounded as $R\to\infty$, we must provide here the following elliptic estimate.

LEMMA 4.1. *Let u_R denote a solution of*

$$\begin{cases} -\Delta u_R - u_R + i(\phi_R-\mu_R)u_R = -\lambda u_R & \text{in } \Omega_R, \\ \frac{\partial \psi_R}{\partial \nu} = 0, & \text{on } \partial\Omega_R^i, \\ \psi_R = 0, & \text{on } \partial\Omega_R^c, \end{cases} \tag{4.1}$$

in which $\lambda\in\mathbb{R}_+$. Let $D_r(x_0)=\Omega_R\cap B_r(x_0)$, where $x_0\in\Omega_R$ is chosen such that either

(i) *$D_r(x_0)=B_r(x_0)$, or*

(ii) *$x_0\in\partial\Omega_R$ and either $(\partial D_r(x_0)\cap\partial\Omega_R)\subset\partial\Omega_R^c$ or $(\partial D_r(x_0)\cap\partial\Omega_R)\subset\partial\Omega_R^i$.*

Then,

$$\exists \tilde r>0:\ \|u_R\|_{L^\infty(D_r(x_0))}\le C_r\|u_R\|_{L^2(D_{2r}(x_0))} \quad \forall x_0\in\Omega_R,\ r<\tilde r\,, \tag{4.2}$$

where C_r is independent of R and x_0.

Proof. Let $\rho_R=|u_R|$. By (4.1) we have that

$$-\Delta\rho_R-\rho_R\le 0$$

in Ω_R. Let $x_0\in\Omega_R$. We set U_r to be the solution (we discuss its existence below) of

$$\begin{cases} -\Delta U_r - U_r = 0 & \text{in } D_r(x_0), \\ U_r = 0 & \text{on } \partial D_r^c(x_0), \\ \frac{\partial U_r}{\partial \nu} = 0 & \text{on } \partial D_r^i(x_0), \\ U_r = \rho_R & \text{on } \partial D_r^s(x_0), \end{cases} \tag{4.3}$$

where $\partial D_r^c(x_0)=\partial D_r(x_0)\cap\partial\Omega_R^c$, $\partial D_r^i(x_0)=\partial D_r(x_0)\cap\partial\Omega_R^i$, and $\partial D_r^s(x_0)=\partial D_r(x_0)\setminus(\partial D_r(x_0)\cap\partial\Omega_R)$. Note that either $\partial D_r^c(x_0)=\phi$ or $\partial D_r^i(x_0)=\phi$. Clearly, there exists $\tilde r$, independent of x_0 and R, such that for every $r<\tilde r$, we have

$$\inf_{u\in\mathcal{D}}\frac{\text{int}_{D_r(x_0)}|\nabla u|^2}{\text{int}_{D_r(x_0)}|u|^2}>1\,, \tag{4.4}$$

where

$$\mathcal{D}=\{u\in H^1(D_r)\,|\,u=0 \text{ on } \partial D_r(x_0)\setminus\partial D_r^i(x_0)\}\,.$$

For $r<\tilde r$ the elliptic operator in (4.3) is invertible, and hence a unique U_r exists.

Let then $V=\rho_R-U_r$. Clearly,

$$\begin{cases} -\Delta V - V\le 0 & \text{in } D_r(x_0), \\ \frac{\partial V}{\partial \nu} = 0 & \text{on } \partial D_r^i(x_0), \\ V = 0 & \text{on } \partial D_r(x_0)\setminus\partial D_r^i(x_0). \end{cases} \tag{4.5}$$

Let further

$$V_+=\begin{cases} V, & V\ge 0, \\ 0, & V<0. \end{cases}$$

Multiplying (4.5) by V_+ and integrating over $D_r(x_0)$, we obtain that

$$\int_{D_r} |\nabla V_+|^2 - |V_+|^2 \leq 0\,,$$

and since $V \in \mathcal{D}$, we obtain by (4.4) that $V_+ = 0$. Consequently we have

$$\rho_R \leq U_r \quad \text{in } D_r(x_0). \tag{4.6}$$

To complete the proof of (4.2) it is thus necessary to obtain an estimate of $\|U_r\|_{L^\infty(D_r)}$ in terms of $\|\rho_R\|_{L^2(D_r)}$. In case (i) above, since U_r is unique, we can use Theorem 10.5 in [3], together with Sobolev embeddings, to obtain

$$\|U_r\|_{L^\infty(D_r(x_0))} \leq C_r \|\rho_R\|_{H^{1/2}(\partial D_r^s)}\,, \tag{4.7}$$

where C_r is independent of x_0 and R.

In case (ii) $D_r(x_0)$ is diffeomorphic to a hemisphere with radius r. Denote the diffeomorphism by T_{R,x_0}. Note that $T_{R,x_0} \to I$ as $R \to \infty$ uniformly in x_0 (as long as the assumption in (ii) holds) in view of the transformation (1.5). Let $B_+ = T_{R,x_0}(D_r)$. On the flat surface of B_+ we have either $\partial U_r/\partial \nu = 0$ or $U_r = 0$. In the first case one can extend U_r evenly to a sphere B, whereas in the second case we use an odd extension for that matter. In both cases U_r satisfies

$$A : \nabla(A^t \nabla U_r) + U_r = 0 \quad \text{in } B\,,$$

where $A = DT_{R,x_0}$ is smooth in B and satisfies $A \to I$ uniformly in B as $R \to \infty$. On ∂B, U_r is equal to either the even extension or the odd extension of ρ_R. Hence, for sufficiently large R, U_r must satisfy (4.7) in case (ii) as well.

Clearly,

$$\|\rho_R\|_{H^{1/2}(\partial D_r^s)} \leq \|\rho_R\|_{H^1(D_r(x_0))}\,. \tag{4.8}$$

Multiplying (4.1) by $\chi_{2r}^2(|x-x_0|)\bar{u}_R$ and integrating over Ω_R, we obtain from the real part of the identity

$$\int_{D_{2r}(x_0)} |\nabla(\chi_{2r} u_R)|^2 - \big(|\nabla \chi_{2r}|^2 + (1-\lambda)\chi_{2r}^2\big)|u_R|^2 = 0\,.$$

Hence,

$$\int_{D_r(x_0)} |\nabla \rho_R|^2 \leq C_r \int_{D_{2r}(x_0)} |\rho_R|^2\,. \tag{4.9}$$

Combining the above with (4.6)–(4.8) yields (4.2). □

As an immediate conclusion of Lemma 4.1 we prove the following lemma

LEMMA 4.2. *Let u_R denote a solution of (4.1) with $\lambda \in \mathbb{R}_+$. Let X_R denote a maximum point of $|u_R|$ in Ω_R. Then, $|\phi_R(x_R) - \mu_R|$ is bounded as $R \to \infty$.*

Proof. We first normalize u_R by $|u_R(x_R)|$ so that $\|u_R\|_\infty = 1$. Let $D_r(x_R) = B(x_R, r) \cap \Omega_R$. Multiplying (4.1) by $\chi_r^2(|x - x_R|)\bar{u}_R$ and integrating over Ω_R, we obtain from the imaginary part of the identity

$$\int_{D_r} \nabla(\chi_r^2) \cdot \frac{1}{2i}(\bar{u_R}_j \nabla u_R - \nabla \bar{u}_R) + \int_{D_r} \chi_r^2(\phi_R - \mu_R)|u_R|^2 = 0\,.$$

Let $b_R = \phi_R(x_R) - \mu_R$. Since $\nabla\phi_R$ is bounded in Ω_R, and since r is fixed, we have

$$\inf_{x\in D_r} |\phi_R - \mu_R| \geq \frac{1}{2} b_R \,.$$

Thus,

$$b_R \int_{D_{r/2}} |u_R|^2 \leq C_r \int_{D_r} |u_R|^2 + |\nabla u_R|^2 \,.$$

Using (4.9) and the fact that $|u_R| \leq 1$, we obtain that

$$\int_{D_{r/2}} |u_R|^2 \leq \frac{C}{b_R} \,.$$

By Lemma 4.1 we then have that

$$1 = |u_R(x_R)| \leq \frac{C_r}{b_R},$$

from which the lemma immediately follows. □

Remark 4.2. Note that if $\phi_R \neq \mu_R$ for all $x \in \Omega_R$, then $u_R \equiv 0$ must be the unique solution of (4.1). To see this multiply (4.1) by $\bar{u}_R$ and integrate over Ω_R to obtain from the imaginary part,

$$\int_{\Omega_R} (\phi_R - \mu_R)|u_R|^2 = 0 \,.$$

Since $\phi_R - \mu_R$ is either positive or negative throughout Ω_R, u_R must vanish everywhere.

Denote the curve in Ω along which we have $\phi = \mu$ by Γ_μ. Denote its image under the mapping (1.5) by Γ_R. By the previous lemma we have that $d(x_R, \Gamma_R)$ is bounded as $R \to \infty$. We now prove that u_R must decay exponentially fast away from Γ_R.

LEMMA 4.3. *Let u_R denote a solution of* (4.1) *with $\lambda \in \mathbb{R}_+$. Then, there exists $\alpha > 0$ such that*

$$\int_{\Omega_R} |u_R|^2 e^{2\alpha s} \leq C \,, \tag{4.10}$$

where $s = d(x, \Gamma_R)$ and C is independent of R.

Recall that by Proposition 4.1, for domains that are diffeomorphic to a cylinder, when $\phi \neq \mu$ for every $x \in \partial\Omega^c$, Γ_μ must be a surface whose boundary is a closed simple contour on $\partial\Omega^i$. We also have $\nabla\phi \neq 0$ on Γ_μ. Note also that by the above remark, if Γ_R is empty, then $u_R \equiv 0$.

Proof. It is convenient to consider here u_R for which $\|u_R\|_{L^2(\Omega_R)} = 1$. Let Ω_β^+ and Ω_β^- be, respectively, defined by

$$\Omega_\beta^+ = \{x \in \Omega_R \,|\, \phi_R - \mu_R > \beta\},$$

$$\Omega_\beta^- = \{x \in \Omega_R \,|\, \phi_R - \mu_R < -\beta\}$$

for some $\beta > 0$ which is independent of R.

Let $\eta_\beta^+ \in C^\infty(\Omega_R,[0,1])$ and η_β^-, respectively, be defined by

$$\eta_\beta^+ = \begin{cases} 1, & x \in \Omega_\beta^+, \\ 0, & x \in \Omega_0^-, \end{cases}$$

and

$$\eta_\beta^- = \begin{cases} 1, & x \in \Omega_\beta^-, \\ 0, & x \in \Omega_0^+. \end{cases}$$

Let $\mathcal{C}_\beta^\pm$ denote the portion of $\partial\Omega_\beta^\pm$ which is not on $\partial\Omega_R$. As $\nabla\phi_R(x) = \nabla\phi(x/R)$ and since $\nabla\phi$ is bounded in Ω, we have that

$$d(\mathcal{C}_\beta^\pm, \Gamma_\mu) \geq \frac{\beta}{\|\nabla\phi\|_{L^\infty(\Omega)}}\,.$$

Hence, we can choose $\eta_\beta^\pm$ such that $|\nabla\eta_\beta^\pm| < C$. Let

$$D_\beta^+ = \{x \in \Omega_R \,|\, 0 < \eta_\beta^+ < 1\}\,.$$

We choose $\eta_\beta^\pm$ such that

$$\sup_{x\in D_\beta^+} s \leq 1\,.$$

Multiplying (4.1) by $(\eta_\beta^+)^2 e^{2\alpha s}\bar{u}_R$ and integrating over Ω_R we obtain, for the imaginary part and the real part, respectively,

(4.11a)
$$\int_{\Omega_R} \nabla((\eta_\beta^+)^2 e^{2\alpha s})\cdot\frac{1}{2i}(\bar{u}_R\nabla u_R - u_R\nabla\bar{u}_R) + \int_{\Omega_R}(\phi_R-\mu_R)(\eta_\beta^+)^2|u_R|^2 e^{2\alpha s} = 0\,,$$

(4.11b)
$$\int_{\Omega_R}(\eta_\beta^+)^2|\nabla u_R|^2 e^{2\alpha s} = (1-\lambda)\int_{\Omega_R}(\eta_\beta^+)^2|u_R|^2 e^{2\alpha s} - \frac{1}{2}\int_{\Omega_R}\nabla((\eta_\beta^+)^2 e^{2\alpha s})\cdot\nabla|u_R|^2\,.$$

From the real part, (4.11b), we obtain that for every $\epsilon > 0$ we have

(4.12)
$$(1-2\alpha\epsilon)\int_{\Omega_R}(\eta_\beta^+)^2 e^{2\alpha s}|\nabla u_R|^2 \leq \Big(1+\frac{\alpha}{2\epsilon}\Big)\int_{\Omega_R}(\eta_\beta^+)^2 e^{2\alpha s}|u_R|^2 + C\int_{D_\beta^+} e^{2\alpha s}|\nabla u_R|^2\,.$$

From (4.11a), or the imaginary part, we obtain

$$\beta\int_{\Omega_\beta^+}|u_R|^2 e^{2\alpha s} \leq \alpha\int_{\Omega_R}(\eta_\beta^+)^2 e^{2\alpha s}[|u_R|^2+|\nabla u_R|^2] + C\int_{D_\beta^+} e^{2\alpha s}[|u_R|^2+|\nabla u_R|^2].$$

Combining the above with (4.12) for $\epsilon = 4\alpha^{-1}$, we obtain

$$(\beta - 2\alpha - 4\alpha^3)\int_{\Omega_\beta^+}|u_R|^2 e^{2\alpha s} \leq C\int_{D_\beta^+} e^{2\alpha s}[|u_R|^2+|\nabla u_R|^2]\,. \tag{4.13}$$

Multiplying (4.1) by $\bar{u}_R$ and integrating over Ω_R, we obtain (for the real part)

$$\int_{\Omega_R} |\nabla u_R|^2 = (1-\lambda) \int_{\Omega_R} |u_R|^2 = 1-\lambda\,.$$

Consequently, we obtain from (4.13) that for any given α we may choose β to be sufficiently large (but still independent of R) so that $\beta > 2\alpha + 4\alpha^3$, and hence

$$\int_{\Omega_\beta^+} |u_R|^2 e^{2\alpha s} \le Ce^{2\alpha} \int_{D_\beta^+} [|u_R|^2 + |\nabla u_R|^2] \le 2Ce^{2\alpha}\,. \qquad \square$$

Remark 4.3. By Lemma 4.1 it follows that $|u_R|$ decays exponentially fast away from Γ_R also in a pointwise sense.

We now prove that any eigenfunction corresponding to a nonpositive eigenvalue must decay exponentially fast away from the boundary.

LEMMA 4.4. *Let u_R denote a solution of* (4.1). *Then*

$$\exists \alpha > 0 : \ |u_R| \le Ce^{-\alpha d(x,\partial\Omega)} \quad \forall \mu_R \in \mathbb{R}\,, \tag{4.14}$$

where α is independent of R, μ_R, and λ. Furthermore, denote by x_R the maximum point of $|u_R|$. Then $d(x_R, \partial\Omega_R)$ is bounded as $R \to \infty$.

Proof. We apply standard blow-up arguments to prove the lemma. Let

$$\Omega(R,k,s) = \{x \in \Omega_R |\ d(x,\partial\Omega_R) \ge ks\}\,.$$

We prove the exponential rate of decay by showing first that

$$\exists R_0, s_0 : \ \|u_R\|_{L^\infty\left(\Omega(R,k+1,s)\right)} \le \frac{1}{2} \|u_R\|_{L^\infty\left(\Omega(R,k,s)\right)} \quad \forall s > s_0,\ R > R_0,\ k \in \mathbb{N}. \tag{4.15}$$

Suppose, for contradiction, that (4.15) does not hold. Then, there exist sequences $\{R_j\}_{j=1}^\infty$, $\{s_j\}_{j=1}^\infty$, and $\{k_j\}_{j=1}^\infty$ satisfying $R_j \uparrow \infty$, $s_j \uparrow \infty$, $k_j \in \mathbb{N}$, and

$$\left\|u_{R_j}\right\|_{L^\infty\left(\Omega(R_j,k_j+1,s_j)\right)} \ge \frac{1}{2} \left\|u_{R_j}\right\|_{L^\infty\left(\Omega(R_j,k_j,s_j)\right)} \stackrel{def}{=} \frac{1}{2} m_j. \tag{4.16}$$

Let

$$\tilde{u}_{R_j} = \frac{u_{R_j}}{m_j}.$$

By (4.15) there exists $x_j \in \Omega(R_j, k_j+1, s_j)$ such that

$$|\tilde{u}_{R_j}(x_j)| \ge \frac{1}{2}\,. \tag{4.17}$$

For notational convenience we also let $f_j(x) = \tilde{u}_{R_j}(x_j + x)$.

We now distinguish between two different cases.

Case 1.

$$b_j = \inf_{x \in B(x_j, s_j)} |\phi_{R_j} - \mu_{R_j}| \to \infty$$

up to a subsequence.

Let $\chi_r \in C^\infty(\mathbb{R}_+, [0,1])$ be defined by (3.3). Since f_j satisfies (4.1) we multiply it by $\chi_r^2(0)\overline{f}_j$ and integrate over $B(0,r)$ to obtain, for the imaginary part,

$$\int_{B(0,r)} \nabla(\chi_r^2) \cdot \frac{1}{2i}(\bar{f}_j \nabla f_j - f_j \nabla \bar{f}_j) + \int_{B(0,r)} \chi_r^2(\phi_{R_j} - \mu_{R_j})|f_j|^2 = 0,$$

yielding

$$b_j \int_{B(0,r/2)} |f_j|^2 \leq C_r \int_{B(0,r)} |f_j|^2 + |\nabla f_j|^2 \tag{4.18}$$

for all $r < s_j$. For the real part we obtain that

$$\int_{B(0,r)} |\nabla(\chi_r f_j)|^2 - \left(|\nabla \chi_r|^2 + (1-\lambda)\chi_r^2\right)|f_j|^2 = 0\,,$$

and hence

$$\int_{B(0,r/2)} |\nabla f_j|^2 \leq C \int_{B(0,r)} |f_j|^2\,. \tag{4.19}$$

Combining (4.18) with (4.19), we obtain

$$\int_{B(0,r/2)} |f_j|^2 \leq \frac{C_r}{b_j} \int_{B(0,2r)} |f_j|^2\,.$$

As $|f_j| \leq 1$ we obtain that

$$\int_{B(0,r/2)} |f_j|^2 \to 0$$

as $j \to \infty$, and by Lemma 4.1 also that $f_j(0) \to 0$, a contradiction.

Case 2. $\limsup_{j\to\infty} b_j < \infty$.

Let $J = |\nabla\phi|$. We choose a coordinate system, where $\nabla\phi(x_j)$ is parallel to the x_1 axis. Then, by Lemma 4.2 we have a subsequence for which

$$\phi_{R_j} - \mu_{R_j} \to Jx_1 + b$$

uniformly in $B(0,r)$ for all $r > 0$, where b is a constant. Thus, by standard elliptic estimates and Sobolev embeddings, there exists a subsequence $\{f_{j_k}\}_{k=1}^\infty$ such that $f_{j_k} \to f_\infty$ uniformly on every compact set in $\mathbb{R}^3$ and such that f_∞ is a bounded solution of

$$-\Delta f_\infty - f_\infty + i(Jx_1 + b)f_\infty = -\lambda f_\infty \quad \text{in } \mathbb{R}^3\,.$$

By Lemma 3.1 we must have $f_\infty \equiv 0$, a contradiction.

Thus, we have proved (4.15), and hence also (4.14). The boundedness of $d(x_R, \partial\Omega_R)$ follows from (4.14) as well. □

The following lemma provides the basis for our main stability result.

LEMMA 4.5. *Let $\partial\Omega_n$ denote the subset of $\partial\Omega_c$, where $\nabla\phi$ is perpendicular to $\partial\Omega$. Suppose that either $|\nabla\phi| > J_c$ for all $x \in \partial\Omega_n$ or that $\partial\Omega_n$ is empty. Then, for sufficiently large R, $u_R \equiv 0$ is the unique solution of* (4.1) *for all $\mu_R \in \mathbb{R}$.*

Proof. Let x_R be the point where u_R obtains its maximum in Ω_R. Let x_0^R denote its projection on $\partial\Omega_R$. Recall that by Lemma 4.4 $|x_R - x_0^R|$ is bounded as $R \to \infty$. Note that by Lemma 4.2 ϕ_R converges uniformly to a linear function in $D_r(x_0^R)$ for all fixed $r > 0$ as $R \to \infty$. Suppose first that $x_0^R \in \partial\Omega_i^R$. Following [11], let (t_1, t_2, t_3) denote a local curvilinear coordinate system, whose origin lies at x_0^R, such that $t_3 = d(x, \partial\Omega_R)$ when $x \in \Omega_R$ and such that the t_1 and t_2 curves on $\partial\Omega$ are the lines of curvature. Let further κ_1^R and κ_2^R denote the respective principal curvatures on $\partial\Omega_R$. Clearly, $\kappa_i^R = \kappa_i/R$ $(i = 1, 2)$, where κ_i is the corresponding principal curvature on $\partial\Omega$, at $x_0 = x_0^R/R$.

Since $\partial\Omega$ is smooth near x_0^R, this curvilinear coordinate system is properly defined in some neighborhood of x_0^R. Let

$$B^+(0, r) = \{(t_1, t_2, t_3) \in B(0, r) \,|\, t_3 > 0\}\,.$$

Then, the above coordinate system is well defined in $B^+(0, \delta R)$ for some $\delta > 0$. We can now present any x in this neighborhood by

$$x = r(t_1, t_2) - t_3\nu\,,$$

where ν is the outward normal at $(t_1, t_2, 0)$. Let

$$g_{ij}(t_1, t_2) = \frac{\partial r}{\partial t_i} \cdot \frac{\partial r}{\partial t_j}, \quad i, j = 1, 2,$$

and

$$G_{ij} = [1 - \kappa_i t_3/R] g_{ij}, \quad i, j = 1, 2\,.$$

Since our coordinate system is orthogonal, we have

$$g_{12} = 0\,.$$

Furthermore, we can scale t_1 and t_2 so that

$$g_{11} = g_{22} = 1 + O(1/R) \quad \text{as } R \to \infty$$

uniformly in $B^+(0, r)$ for every fixed $r > 0$. Finally, we define

$$\begin{cases} G = \sqrt{G_{11} G_{22}}, \\ \alpha_j = \frac{G}{G_{jj}}, \qquad j = 1, 2. \\ \alpha_3 = G, \end{cases}$$

Let $w_R(x) = u_R(x)/|u_R(x_R)|$. In the new coordinates, (4.1) takes the form

$$-\sum_{j=1}^{3} \frac{1}{G} \frac{\partial}{\partial t_j} \left(\alpha_j \frac{\partial w_R}{\partial t_j} \right) - w_R + i(\phi_R - \mu_R) w_R = -\lambda w_R$$

in $B^+(0, \delta R)$. Standard elliptic estimates then prove the existence of a sequence $\{w_{R_j}\}_{j=1}^{\infty}$ such that $w_{R_j} \to w_\infty$ uniformly on every compact set in $\mathbb{R}^3_+$, where here

$$\mathbb{R}^3_+ = \{(t_1, t_2, t_3) \,|\, t_3 > 0\}\,.$$

By standard elliptic estimates again we have that w_∞ satisfies the following problem:

$$\begin{cases} -\Delta w_\infty - w_\infty + i(J_1 t_1 + J_2 t_2 + b) w_\infty = -\lambda w_\infty & \text{in } \mathbb{R}^3_+, \\ \frac{\partial w_\infty}{\partial \nu} = 0 & \text{on } \partial\mathbb{R}^3_+. \end{cases}$$

By Lemma 3.4 we have $w_\infty \equiv 0$ in $\mathbb{R}^3_+$, a contradiction since $|w_R(x_R)| = 1$ and $|x_R - x_0^R|$ is bounded.

Consider now the case where $x_0^R \in \partial\Omega_c^R$. Following the same procedure as before we obtain that $w_R \to w_\infty$ uniformly on every compact set in $\mathbb{R}^3_+$, where w_∞ must satisfy

$$\begin{cases} -\Delta w_\infty - w_\infty + i(J_1 t_1 + J_2 t_2 + J_3 t_3 + b) w_\infty = -\lambda w_\infty & \text{in } \mathbb{R}^3_+, \\ w_\infty = 0 & \text{on } \partial\mathbb{R}^3_+. \end{cases}$$

If $\partial\Omega_n$ is empty, we have $J_1^2 + J_2^2 > 0$. By Lemma 3.3 we then have $w_\infty \equiv 0$. Otherwise, if $x_0 \in \partial\Omega_n$, we must have $w_\infty \equiv 0$ by Lemma 3.2 since $J_3 > J_c$.

Finally, if x_0 lies on the interface between $\partial\Omega_i$ and $\partial\Omega_c$, we obtain that w_∞ must satisfy, since the two surfaces are perpendicular to each other at the interface, a problem in Q, where

$$Q = \{(t_1, t_2, t_3) \,|\, t_3 > 0,\ t_1 > 0\}\,.$$

We have

$$\begin{cases} -\Delta w_\infty - w_\infty + i(J_1 t_1 + J_2 t_2 + b) w_\infty = 0 & \text{in } Q, \\ \frac{\partial w_\infty}{\partial \nu} = 0, & x \in \partial Q\ t_3 = 0, \\ w_\infty = 0, & x \in \partial Q :\ t_1 = 0. \end{cases}$$

By Lemma 3.5 we have $w_\infty \equiv 0$. (Note that some modification of the local coordinate system is necessary in this case.) □

Proof of Theorem 1.1. Since the principal part of the differential operator on the left-hand side of (4.1) is the Laplacian, it can be regarded as a perturbation of a self-adjoint operator. Thus, it follows from the discussion below Theorem 15.2 in [2] regarding such perturbations that it has exactly one direction which is not a direction of minimal growth, that is, $\arg\lambda = 0$. Hence, it follows from Theorem 15.1 in [2] that the spectrum of this differential operator must be discrete and that all its eigenvalues must have finite multiplicity. Furthermore, by Theorem 16.5 in [2], the eigenfunctions span $L^2(\Omega_R, \mathbb{C})$. Hence, for $J > J_c$, since all the eigenvalues of the above operator must have positive real part, the normal state must be stable.

Consider now the case when a point $x \in \partial\Omega_c$ exists, where

$$\left|\frac{\partial\phi}{\partial\nu}\right| = |\nabla\phi| = J < J_c\,.$$

To prove the short-time instability we look at the solution of (1.6), after applying to it the transformation (2.2), with the initial condition

$$\psi(x, 0) = u_1(t_3)\chi_{R^{1/2}}(t_1, t_2)\eta_R(t_3)\,,$$

where (t_1, t_2, t_3) are the above-defined system of local curvilinear coordinates, χ_r is defined in (3.3), and

$$\eta_R(x) = \begin{cases} 1, & x < \frac{1}{2}\delta R, \\ 0, & x > \delta R, \end{cases}$$

is a smooth cutoff function.

Let $\tilde{\beta} = \lambda_J - \lambda_{J_c}$. We write

$$\psi_R = v + \psi_0(x) e^{\tilde{\beta} t} \tag{4.20}$$

to obtain

$$\frac{\partial v}{\partial t} - \Delta v - \lambda_J v = f\,. \tag{4.21}$$

The precise form of f need not concern us except for the fact that

$$\|f\|_2 \le \frac{C_\alpha}{R^\alpha} \|\psi_0\|_2 e^{\tilde{\beta} t} \quad \forall \alpha < 1\,. \tag{4.22}$$

Multiplying (4.21) by $\bar{v}$ and integrating by parts, we obtain for the real part

$$\begin{cases} \frac{\partial \|v\|_2}{\partial t} - \lambda_J \|v\|_2 = \|f\|_2, \\ \|v\|_2(0) = 0. \end{cases}$$

Consequently,

$$\|v\|_2(t) \le \int_0^t e^{\lambda(t-\tau)} \|f\|_2(\tau) d\tau\,,$$

and hence,

$$\|v\|_2 \le \frac{C_\alpha}{R^\alpha} \|\psi_0\|_2 e^{(\lambda_J + \tilde{\beta}) t}\,.$$

Clearly, there exist $T_R \sim \mathcal{O}(\ln R)$, as $R \to \infty$, such that

$$t < T_R \Rightarrow \frac{C_\alpha}{R^\alpha} e^{\lambda_J t} < \frac{1}{2}\,,$$

and thus

$$t < T_R \Rightarrow \|\psi\|_2 \ge \frac{1}{2} \|\psi_0\|_2 e^{\tilde{\beta} t}\,.$$

Applying the inverse of (2.2), we obtain (1.7). □

The above instability result is valid, of course, only for $T < T_R$. Proving long-time instability appears to be a much more difficult problem. The stability proof presented above relies on the convergence of any solution of (4.1) to a solution of (3.8) uniformly on every compact set near the point on the boundary where J is perpendicular to it. This, however, does not prove convergence of the spectrum or even of its bottom. What has been demonstrated is only the upper semicontinuity of the spectrum of the differential operator on the left-hand side of (4.1). Lower semicontinuity of the spectrum appears to be much harder to prove, especially since the operator is not self-adjoint. Nevertheless, it does seem reasonable to conjecture that the solution would continue to grow exponentially fast as $t \to \infty$, in view of the above short-time instability result. Further research is necessary in order to establish that result.

5. Concluding remarks. In the previous section we proved that the normal state remains stable in the large domain limit, as long as the current on the boundary, at points where it is perpendicular to it, is greater than J_c. If the current is nowhere perpendicular to the boundary, then as long as it doesn't vanish there, the normal state must be stable. We also demonstrate short-time instability when $J_m < J_c$.

In the following we provide a short list of interesting problems that are waiting to be resolved:

1. Proving long-time instability when $J > J_c$. We have elaborated on this matter at the end of the preceding section.
2. Adding the effect of magnetic fields. This magnetic field can be either induced by the electric current (via (1.3)) or else be applied externally (or both). It has been verified experimentally that an induced magnetic field can generate vortices [14] if the current is sufficiently large and the material is close to the wholly superconducting state. However, its effect on the critical current J_c has not been investigated. It is reasonable to believe that J_c would become smaller if we add the effect of the magnetic field.
3. Adding the effect of temperature, since electric currents have the tendency to heat the sample, thereby creating vortices [14]. Incorporating this effect requires modification of (1.1), and the use of different nondimensionalization; otherwise the domain would become temperature-dependent.
4. Proving that the bifurcating branch (at $J = J_c$) is unstable.

Appendix A. The Hilbert–Schmidt norm of $\mathcal{L}_\lambda^{-1}$.

LEMMA A.1. *Let $\tilde{G}$ be as given by* (2.14b). *Then, for any $\lambda \in \mathbb{C} \setminus \{\lambda_n\}_{n=1}^{\infty}$, where $\{\lambda_n\}_{n=1}^{\infty}$ are given as in* (2.11),

$$\exists C, M > 0 : \ \|\tilde{G}\| \leq C e^{M\lambda^{3/2}} . \tag{A.1}$$

Proof. We first note that

$$W(w_1, \tilde{w}_2)(x,\lambda) = w_2'(x,\lambda) w_1(x,\lambda) - w_1'(x,\lambda) w_2(x,\lambda)$$

is independent of x by Abel's formula. Furthermore, for $y = x + i\lambda$ we have

$$W(w_1, \tilde{w}_2)(x,\lambda) = W(w_1, \tilde{w}_2)(y,0) = W(w_1, \tilde{w}_2)(0,0) .$$

Therefore, W is independent of both x and λ.

Since W is constant, it follows that $\tilde{G}$ is symmetric, i.e.,

$$\tilde{G}(x,\xi,\lambda) = \tilde{G}(\xi,x,\lambda) .$$

Consequently, it suffices to prove that

$$\int_0^\infty d\xi \int_\xi^\infty dx |\tilde{G}(x,\xi)|^2 = C_1 \int_0^\infty d\xi |\tilde{w}_2(\xi)|^2 \int_\xi^\infty dx |\tilde{w}_1(x)|^2 \leq C e^{M\lambda^{3/2}} ,$$

where C, C_1, and M are all independent of λ.

To obtain the above estimate we use asymptotic properties of Airy's functions [1, 13], from which it follows that

$$|A_i(z)| \leq \frac{C}{|z|^{1/4}} \left| e^{-\frac{2}{3} z^{3/2}} \right| . \tag{A.2}$$

Consider then first the domain $\xi > M_0\lambda$ for sufficiently large $M_0 > 0$. We have

$$\int_\xi^\infty |w_1(x)|^2 dx \le \int_\xi^\infty \frac{dx}{|x+i\lambda|^{1/2}} e^{-\beta(x)|x+i\lambda|^{3/2}},$$

where

$$\beta(x) = \frac{4}{3}\cos\left(\frac{3}{2}\arg(x+i\lambda) + \frac{\pi}{4}\right).$$

It is easy to show that

$$\begin{cases} |\beta'(x)| \le C\frac{|\lambda|}{|x+i\lambda|^2}, \\ |\beta'(x)| \le C\frac{|\lambda|}{|x+i\lambda|^3}. \end{cases} \tag{A.3}$$

Let then

$$\gamma(x) = \beta(x)|x+i\lambda|^{3/2}.$$

By (A.3) we have

$$\begin{cases} |\gamma'(x)| \ge \frac{3}{2}\beta(x)|x+i\lambda|^{1/2}\left[1 - C\frac{|\lambda|}{|x+i\lambda|}\right], \\ |\gamma''(x)| \le \frac{3}{4}\beta(x)|x+i\lambda|^{-1/2}\left[1 + C\frac{|\lambda|}{|x+i\lambda|}\right]. \end{cases} \tag{A.4}$$

Using (A.4) and integration by parts, we obtain

$$\begin{aligned} \int_\xi^\infty e^{-\gamma(x)}dx &\le \frac{1}{|\gamma'(\xi)|}e^{-\gamma(\xi)} + \int_\xi^\infty \frac{|\gamma''(x)|}{|\gamma'(x)|}e^{-\gamma(x)}dx \\ &\le \frac{C}{|\xi+i\lambda|^{1/2}}e^{-\gamma(\xi)} + \frac{C}{|\xi+i\lambda|^{3/2}}\int_\xi^\infty e^{-\gamma(x)}dx. \end{aligned}$$

Hence,

$$\int_\xi^\infty e^{-\gamma(x)}dx \le \frac{C}{|\xi+i\lambda|^{1/2}}e^{-\gamma(\xi)},$$

from which we easily obtain that

$$\int_\xi^\infty |w_1(x)|^2 dx \le \frac{C}{|\xi+i\lambda|}e^{-\gamma(\xi)}. \tag{A.5}$$

From the asymptotic behavior of Airy's function (A.2), we obtain again

$$|\tilde{w}_2(\xi)|^2 \le \frac{C}{|\xi+i\lambda|^{1/2}}e^{\gamma(\xi)}.$$

Thus,

$$\int_{M_0\lambda}^\infty d\xi|\tilde{w}_2(\xi)|^2 \int_\xi^\infty dx|\tilde{w}_1(x)|^2 \le \frac{C}{\lambda^{1/2}}.$$

To complete the proof we need to bound the norm for $0 < \xi < M_0\lambda$. By (A.2) and (2.14b) we have

$$|\tilde{G}(x,\xi,\lambda)| \leq C \exp\left\{\frac{2}{3}(M_0+1)^{3/2}|\lambda|^{3/2}\right\}.$$

Consequently, from the above and (A.5) we obtain

$$\int_0^{M_0\lambda} d\xi |\tilde{w}_2(\xi)|^2 \int_\xi^\infty dx |\tilde{w}_1(x)|^2 = \int_0^{M_0\lambda} d\xi |\tilde{w}_2(\xi)|^2 \int_\xi^{M_0\lambda} dx |\tilde{w}_1(x)|^2$$
$$+ \int_0^{M_0\lambda} d\xi |\tilde{w}_2(\xi)|^2 \int_{M_0\lambda}^\infty dx |\tilde{w}_1(x)|^2 \leq C M_0^2 \lambda^2 \exp\left\{\frac{2}{3}(M_0+1)^{3/2}|\lambda|^{3/2}\right\},$$

from which (A.1) easily follows. □

Acknowledgments. The author wishes to thank Professor Bernard Helffer and Professor Yehuda Pinchover for their comments.

CARLEMAN AND OBSERVABILITY ESTIMATES FOR STOCHASTIC WAVE EQUATIONS*

XU ZHANG†

Abstract. Based on a fundamental identity for stochastic hyperbolic-like operators, we derive in this paper a global Carleman estimate (with singular weight function) for stochastic wave equations. This leads to an observability estimate for stochastic wave equations with nonsmooth lower order terms. Moreover, the observability constant is estimated by means of an explicit function of the norm of the coefficients involved in the equation. An application to the state observation problem for semilinear stochastic wave equations is also given.

Key words. Carleman estimate, singular weight function, observability estimate, stochastic wave equation, state observation problem

1. Introduction.

Let $T > 0$, $G \subset \mathbb{R}^n$ ($n \in \mathbb{N}$) be a given bounded domain with a C^2 boundary Γ, with Γ_0 a given nonempty open subset of Γ. Put $Q \triangleq (0,T) \times G$, $\Sigma \triangleq (0,T) \times \Gamma$, and $\Sigma_0 \triangleq (0,T) \times \Gamma_0$. Throughout this paper, we will use C to denote a generic positive constant depending only on T, G, and Γ_0, which may change from line to line.

Let $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t\geq 0}, P)$ be a complete filtered probability space on which a one dimensional standard Brownian motion $\{B(t)\}_{t\geq 0}$ is defined. Let H be a Banach space. We denote by $L^2_{\mathcal{F}}(0,T;H)$ the Banach space consisting of all H-valued $\{\mathcal{F}_t\}_{t\geq 0}$-adapted processes $X(\cdot)$ such that $\mathbb{E}(|X(\cdot)|^2_{L^2(0,T;H)}) < \infty$, with the canonical norm; by $L^\infty_{\mathcal{F}}(0,T;H)$ the Banach space consisting of all H-valued $\{\mathcal{F}_t\}_{t\geq 0}$-adapted bounded processes; and by $L^2_{\mathcal{F}}(\Omega; C([0,T];H))$ the Banach space consisting of all H-valued $\{\mathcal{F}_t\}_{t\geq 0}$-adapted continuous processes $X(\cdot)$ such that $\mathbb{E}(|X(\cdot)|^2_{C([0,T];H)}) < \infty$, with the canonical norm (similarly, one can define $L^2_{\mathcal{F}}(\Omega; C^k([0,T];H))$ for any positive integer k).

Let us consider the following stochastic wave equation:

$$\begin{cases} dy_t - \Delta y dt = (a_1 y_t + a_2 \cdot \nabla y + a_3 y + f)dt + (a_4 y + g)dB(t) & \text{in } Q, \\ y = 0 & \text{on } \Sigma, \\ y(0) = y_0, \quad y_t(0) = y_1 & \text{in } G, \end{cases} \tag{1.1}$$

with initial data $(y_0, y_1) \in L^2(\Omega, \mathcal{F}_0, P; H^1_0(G) \times L^2(G))$, suitable coefficients a_i ($i = 1,2,3,4$), and source terms f and g. Here, $y_t = \frac{dy}{dt}$.

Put

$$\mathcal{H}_T \stackrel{\triangle}{=} L^2_{\mathcal{F}}(\Omega; C([0,T]; H_0^1(G))) \bigcap L^2_{\mathcal{F}}(\Omega; C^1([0,T]; L^2(G))). \tag{1.2}$$

Clearly, $\mathcal{H}_T$ is a Banach space with the canonical norm. We begin with the following notion.

DEFINITION 1.1. *We call $y \in \mathcal{H}_T$ a solution of* (1.1) *if the following hold:*
(i) $y(0) = y_0$ *in* G, P*-a.s.*
(ii) *For any $t \in [0,T]$ and any $\eta \in H_0^1(G)$, it holds that*

$$\begin{aligned}
&\int_G y_t(t,x)\eta(x)dx - \int_G y_t(0,x)\eta(x)dx \\
&= \int_0^t \int_G \Big\{ -\nabla y(s,x)\cdot\nabla\eta(x) + \Big[a_1(s,x)y_t(s,x) + a_2(s,x)\cdot\nabla y(s,x) \\
&\qquad + a_3(s,x)y(s,x) + f(s,x)\Big]\eta(x)\Big\}dxds \\
&\quad + \int_0^t \int_G \Big[a_4(s,x)y(s,x) + g(s,x)\Big]\eta(x)dxdB(s), \qquad P\text{-a.s.}
\end{aligned} \tag{1.3}$$

Under some assumptions, for any initial data $(y_0, y_1) \in L^2(\Omega, \mathcal{F}_0, P;\ H_0^1(G) \times L^2(G))$, one can show that system (1.1) admits one and only one solution $y \in \mathcal{H}_T$ (see Proposition 3.1 in section 3).

The main purpose of this paper is to derive a (partial) boundary observability estimate for system (1.1), i.e., find (if possible) a constant $\mathcal{C}(a_1, a_2, a_3, a_4) > 0$ such that solutions of system (1.1) satisfy

$$\begin{aligned}
&|(y(T), y_t(T))|_{L^2(\Omega,\mathcal{F}_T,P;H_0^1(G)\times L^2(G))} \\
&\le \mathcal{C}(a_1,a_2,a_3,a_4)\left[\left|\frac{\partial y}{\partial \nu}\right|_{L^2_{\mathcal{F}}(0,T;L^2(\Gamma_0))} + |f|_{L^2_{\mathcal{F}}(0,T;L^2(G))} + |g|_{L^2_{\mathcal{F}}(0,T;L^2(G))}\right] \\
&\qquad \forall\ (y_0,y_1) \in L^2(\Omega,\mathcal{F}_0,P;H_0^1(G)\times L^2(G)).
\end{aligned} \tag{1.4}$$

As we shall see in the last section of this paper, inequality (1.4) is strongly related to the state observation problem of semilinear stochastic wave equations.

It is well known that the observability estimate is an important tool for the study of stabilization and controllability problems for deterministic PDEs. We refer the reader to [16] for a recent survey in this respect. Although there are numerous references addressing the observability problems for deterministic PDEs, very little is known for the stochastic counterpart, and it remains to be further understood. Indeed, to the best of our knowledge, [1] is the only publication in this direction, which is devoted to the controllability/observability for the stochastic heat equation. As far as we know, nothing is known for the observability estimate on the stochastic wave equation.

Similar to the deterministic setting, we shall use a stochastic version of the global Carleman estimate to establish inequality (1.4). The difficulty in doing this is the very fact that, unlike the deterministic situation, system (1.1), a stochastic wave equation, is *time-irreversible*. Therefore, one cannot simply mimic the usual Carleman inequality for the deterministic wave equations (see [3, 4, 5, 8, 9, 13] and the references cited therein). Rather, in order to overcome this difficulty, instead of the usual smooth

weight function, we need to introduce another singular weight function in this paper to derive the desired Carleman estimate for system (1.1) (see (2.13) in the next section).

On the other hand, the Carleman estimate is itself a fundamental tool for the study of control and inverse problems for deterministic PDEs (see [7, 16] and the references cited therein). Similar to the situation for the observability estimate, although there are numerous references addressing the Carleman estimate for deterministic PDEs, to the best of our knowledge, [1, 12] are the only references for the stochastic counterpart, which are devoted to the stochastic heat equation. It would be quite interesting to extend the deterministic Carleman estimate for other PDEs to the stochastic ones, but there are many things to be done, and some of them seem to be challenging. In this paper, in order to present the key idea in the simplest way, we do not pursue the full technical generality.

The rest of this paper is organized as follows. The main results of this paper are stated in section 2. In section 3, we show some preliminary results. In section 4, we present a crucial identity for a stochastic hyperbolic-like operator. Then, in section 5, we derive pointwise Carleman-type estimates for the stochastic wave operator. Section 6 is devoted to the proof of Theorems 2.1–2.2. Finally, section 7 addresses giving an application of our observability result.

2. Statement of the main results. Fix any $x_0 \in \mathbb{R}^d \setminus \overline{G}$. It is clear that

$$0 < R_0 \triangleq \min_{x\in G} |x - x_0| < R_1 \triangleq \max_{x\in G} |x - x_0|. \tag{2.1}$$

Put

$$\Gamma_0 \triangleq \big\{x \in \Gamma \,\big|\, (x - x_0) \cdot \nu(x) > 0\big\}, \tag{2.2}$$

where $\nu(x)$ is the unit outward normal vector of G at $x \in \Gamma$.

Assume that

$$\begin{aligned} &a_1 \in L^\infty_{\mathcal{F}}(0,T;L^\infty(G)), \qquad && a_2 \in L^\infty_{\mathcal{F}}(0,T;L^\infty(G;\mathbb{R}^n)),\\ &a_3 \in L^\infty_{\mathcal{F}}(0,T;L^n(G)), && a_4 \in L^\infty_{\mathcal{F}}(0,T;L^\infty(G)) \end{aligned} \tag{2.3}$$

and that

$$f \in L^2_{\mathcal{F}}(0,T;L^2(G)), \qquad g \in L^2_{\mathcal{F}}(0,T;L^2(G)). \tag{2.4}$$

In what follows, we use the following notation:

$$\begin{aligned} \mathcal{A}(a_1,a_2,a_3,a_4) \triangleq\ & |(a_1,a_4)|^2_{L^\infty_{\mathcal{F}}(0,T;(L^\infty(G))^2)} + |a_2|^2_{L^\infty_{\mathcal{F}}(0,T;L^\infty(G;\mathbb{R}^n))}\\ &+ |a_3|^2_{L^\infty_{\mathcal{F}}(0,T;L^n(G))}. \end{aligned} \tag{2.5}$$

We choose a sufficiently small constant $c \in (0,1)$ so that (recall (2.1) for R_0 and R_1)

$$\frac{(4+5c)R_0^2}{9c} > R_1^2. \tag{2.6}$$

In what follows, we take $T(> 2R_1)$ sufficiently large such that

$$\frac{4(4+5c)R_0^2}{9c} > c^2T^2 > 4R_1^2. \tag{2.7}$$

Our observability estimate for system (1.1) is stated as follows.

THEOREM 2.1. *Let* (2.3)–(2.4) *hold,* Γ_0 *be given by* (2.2), *and* T *satisfy* (2.7). *Then solutions of system* (1.1) *satisfy* (1.4) *with*

$$\mathcal{C}(a_1,a_2,a_3,a_4)=Ce^{C\mathcal{A}(a_1,a_2,a_3,a_4)}. \tag{2.8}$$

Remark 2.1. From the proof of Theorem 2.1, it is easy to see that the conclusion can be slightly strengthened as follows: for any $t\in(0,T]$, solutions of system (1.1) satisfy

(2.9)

$$\begin{aligned}&|(y(t),y_t(t))|_{L^2(\Omega,\mathcal{F}_t,P;H_0^1(G)\times L^2(G))}\\&\le e^{Ct^{-1}}\mathcal{C}(a_1,a_2,a_3,a_4)\left[\left|\frac{\partial y}{\partial\nu}\right|_{L^2_{\mathcal{F}}(0,T;L^2(\Gamma_0))}+|f|_{L^2_{\mathcal{F}}(0,T;L^2(G))}+|g|_{L^2_{\mathcal{F}}(0,T;L^2(G))}\right]\\&\qquad\forall\ (y_0,y_1)\in L^2(\Omega,\mathcal{F}_0,P;H_0^1(G)\times L^2(G)),\end{aligned}$$

where $\mathcal{C}(a_1,a_2,a_3,a_4)$ is given by (2.8).

Remark 2.2. A deterministic version of (1.1) reads

$$\begin{cases} w_{tt}-\Delta w=b_1w_t+b_2\cdot\nabla w+b_3w+h & \text{in } Q,\\ w=0 & \text{on } \Sigma,\\ w(0)=w_0,\quad w_t(0)=w_1 & \text{in } G,\end{cases} \tag{2.10}$$

where $b_1\in L^\infty(Q)$, $b_2\in L^\infty(Q;\mathbb{R}^n)$, $b_3\in L^\infty(0,T;L^p(G))$ with $p\in[n,\infty]$, and $h\in L^2(Q)$. As a special case of [3, Theorems 2.2 and 2.3] and noting the time reversibility of system (2.10), the following counterpart of Theorem 2.1 holds: If $T>2R_1$, then solutions of (2.10) satisfy

$$\begin{aligned}&|(w(T),w_t(T))|_{H_0^1(G)\times L^2(G)}\\&\le Ce^{C\left[|b_1|^2_{L^\infty(Q)}+|b_2|^2_{L^\infty(Q;\mathbb{R}^n)}+|b_3|^{\frac{1}{3/2-n/p}}_{L^\infty(0,T;L^p(G))}\right]}\left[\left|\frac{\partial w}{\partial\nu}\right|_{L^2(\Sigma_0)}+|h|_{L^2(Q)}\right]\\&\qquad\forall\ (w_0,w_1)\in H_0^1(G)\times L^2(G).\end{aligned} \tag{2.11}$$

There are three main differences between Theorem 2.1 and this result. The first is that one can replace the left-hand side of (2.11) by $|(w_0,w_1)|_{H_0^1(G)\times L^2(G)}$. However, due to the time irreversibility of system (1.1), one cannot do the same in the stochastic setting, i.e., replacing the left-hand side of (1.4) by $|(y_0,y_1)|_{L^2(\Omega,\mathcal{F}_0,P;H_0^1(G)\times L^2(G))}$. The second is that we assume that T in Theorem 2.1 satisfies (2.7), which is usually much more restrictive than that $T>2R_1$ for the deterministic setting (see Remark 2.4 below for more explanation about this). The third is that the observability constant $\mathcal{C}(a_1,a_2,a_3,a_4)$ in Theorem 2.1 is not as sharp as that in (2.11). Indeed, it is clear that (recall (2.5) for $\mathcal{A}(\cdot,\cdot,\cdot,\cdot)$)

$$|b_1|^2_{L^\infty(Q)}+|b_2|^2_{L^\infty(Q;\mathbb{R}^n)}+|b_3|^{\frac{1}{3/2-n/p}}_{L^\infty(0,T;L^p(G))}\le\mathcal{A}(b_1,b_2,b_3,0)+C\qquad\forall\ p\in[n,\infty].$$

Remark 2.3. It is well known that a sharp condition guaranteeing observability inequality (2.11) (at least when b_1, b_2, and b_3 are time-invariant) is that the triple

(G, Γ_0, T) satisfies the geometric optic condition introduced in [2]. It would be quite interesting to extend this result to the stochastic setting, but this is an open problem.

As mentioned in section 1, in order to prove Theorem 2.1, we need to derive a Carleman estimate (with singular weight function) for system (1.1). For this purpose, for any (large) $\lambda > 0$ and $c \in (0,1)$ given in (2.6), set

$$\ell = \ell(t,x) \triangleq \lambda \left[|x - x_0|^2 - c\left(t - \frac{T}{2}\right)^2 \right], \qquad \theta \triangleq e^{\ell}. \tag{2.12}$$

Also, for any $\beta > 0$, set

$$\Theta = \Theta(t) \triangleq \exp\left\{ -\frac{\beta}{t(T-t)} \right\}, \qquad 0 < t < T. \tag{2.13}$$

It is easy to see that $\Theta(t)$ decays rapidly to 0 as $t \to 0$ or $t \to T$. Our Carleman estimate for system (1.1) is stated as follows.

THEOREM 2.2. *Let* (2.3)–(2.4) *hold,* Γ_0 *be given by* (2.2), *and* c *and* T *satisfy, respectively,* (2.6) *and* (2.7). *Then there exist a constant* $\beta > 0$ *(which is very small) and a constant*

$$\lambda^* = C\Big[1 + \mathcal{A}(a_1, a_2, a_3, a_4)\Big]$$

such that solutions of system (1.1) *satisfy*

$$\begin{aligned} &\lambda \mathbb{E} \int_Q \Theta\theta^2 (y_t^2 + |\nabla y|^2 + \lambda^2 y^2) dxdt \\ &\le C\mathbb{E}\left\{ \lambda \int_{\Sigma_0} \Theta\theta^2 \left| \frac{\partial y}{\partial \nu} \right|^2 d\Sigma_0 + \int_Q \Theta\theta^2 (f^2 + \lambda g^2) dxdt \right\} \\ &\qquad \forall\, (y_0, y_1) \in L^2(\Omega, \mathcal{F}_0, P; H_0^1(G) \times L^2(G)), \quad \forall\, \lambda \ge \lambda^*. \end{aligned} \tag{2.14}$$

Remark 2.4. The restriction on T in (2.7) is a technical condition, which does not seem to be natural. However, this condition plays a key role in Step 3 in the proof of Theorem 5.1, a crucial preliminary for the proof of Theorem 2.2. As in the deterministic setting (recall Remark 2.2), it is reasonable to expect that it should be improved to be $T > 2R_1$. But this is an open problem.

Remark 2.5. We now recall the Carleman estimate for the deterministic wave equation, i.e., system (2.10). Fix a constant $c \in (0,1)$ so that $\left(\frac{2R_1}{T}\right)^2 < c < \frac{2R_1}{T}$ (which is possible since $T > 2R_1$ for the deterministic situation). By [5, equation (11.12) in the proof of Theorem 5.1] and similar to [3, Theorem 2.3], we conclude that there exists a constant

$$\lambda_* = C\Big[1 + |b_1|^2_{L^\infty(Q)} + |b_2|^2_{L^\infty(Q;\mathbb{R}^n)} + |b_3|^{\frac{1}{3/2 - n/p}}_{L^\infty(0,T;L^p(G))}\Big]$$

such that solutions of system (2.10) satisfy

$$\begin{aligned} &\lambda \int_Q \theta^2 (\lambda^2 w^2 + w_t^2 + |\nabla w|^2) dxdt \le C\left[\lambda \int_{\Sigma_0} \theta^2 \Big| \frac{\partial w}{\partial \nu} \Big|^2 d\Sigma_0 + \int_Q \theta^2 |h|^2 dxdt \right] \\ &\qquad \forall\, (w_0, w_1) \in H_0^1(G) \times L^2(G), \quad \forall\, \lambda \ge \lambda_*. \end{aligned} \tag{2.15}$$

The main difference between Theorem 2.2 and this result is, as mentioned before, one has to introduce a singular weight Θ in (2.14).

Remark 2.6. We consider here the simplest case of one dimensional standard Brownian motion. It would be interesting to extend the results in this paper to the case of colored (infinite dimensional) noise, or even with both state- and control-dependent noise. But these remain to be done.

Remark 2.7. It would be quite interesting to study Carleman and observability estimates for backward stochastic wave equations. To the best of our knowledge, this is a challenging problem, and nothing is known in this respect.

3. Preliminaries. In this section, we show some preliminary results that will subsequently be used.

In what follows, for simplicity, we denote $\sum_{i,j=1}^n$ and $\sum_{i=1}^n$ simply by $\sum_{i,j}$ and $\sum_i$, respectively. Also, we will use the notation $u_i = u_{x_i}$, where x_i is the ith coordinate of a generic point $x = (x_1, \dots, x_n)$ in $\mathbb{R}^n$. In a similar manner, we use the notation ℓ_i, v_i, etc., for the partial derivatives of ℓ and v with respect to x_i.

First of all, we have the following well-posedness result for system (1.1).

PROPOSITION 3.1. *Under assumptions* (2.3)–(2.4), *for any* $(y_0, y_1) \in L^2(\Omega, \mathcal{F}_0, P; H_0^1(G) \times L^2(G))$, *system* (1.1) *admits one and only one solution* $y \in \mathcal{H}_T$. *Moreover (recall* (2.8) *for* $\mathcal{C}(a_1, a_2, a_3, a_4)$*),*

$$
\begin{aligned}
|y|_{\mathcal{H}_T} \le \mathcal{C}(a_1, a_2, a_3, a_4) \Big[& |(y_0, y_1)|_{L^2(\Omega, \mathcal{F}_0, P; H_0^1(G) \times L^2(G))} + |f|_{L^2_{\mathcal{F}}(0,T; L^2(G))} \\
& + |g|_{L^2_{\mathcal{F}}(0,T; L^2(G))} \Big].
\end{aligned} \tag{3.1}
$$

Proof. The detailed proof is lengthy but almost standard. Therefore, we give below only a sketch.

Step 1. First of all, following the *parabolic regularization approach* in the proof of [6, Theorem 4.1, p. 159] (for this, one needs to make numerous but small changes), one can show that, for any $(w_0, w_1) \in L^2(\Omega, \mathcal{F}_0, P; H_0^1(G) \times L^2(G))$, $\hat{f} \in L^2_{\mathcal{F}}(0, T; L^2(G))$, and $\hat{g} \in L^2_{\mathcal{F}}(0, T; L^2(G))$, the system

$$
\begin{cases}
dw_t - \Delta w dt = \hat{f} dt + \hat{g} dB(t) & \text{in } Q, \\
w = 0 & \text{on } \Sigma, \\
w(0) = w_0, \quad w_t(0) = w_1 & \text{in } G
\end{cases} \tag{3.2}
$$

admits a unique solution $w \in \mathcal{H}_T$. Furthermore, there is a constant $C = C(T) > 0$ such that, for any $\tau \in [0, T]$, it holds that

$$
|w|_{\mathcal{H}_\tau} \le C \Big[|(w_0, w_1)|_{L^2(\Omega, \mathcal{F}_0, P; H_0^1(G) \times L^2(G))} + |\hat{f}|_{L^2_{\mathcal{F}}(0,\tau; L^2(G))} + |\hat{g}|_{L^2_{\mathcal{F}}(0,\tau; L^2(G))} \Big], \tag{3.3}
$$

where $\mathcal{H}_\tau$ is defined similarly to (1.2).

Step 2. Next, we show that system (1.1) admits a local (in time) solution $y \in \mathcal{H}_\tau$ for small $\tau \in (0, T]$. For this purpose, fixing any $y \in \mathcal{H}_\tau$, we solve the following system:

$$
\begin{cases}
dz_t - \Delta z dt = (a_1 y_t + a_2 \cdot \nabla y + a_3 y + f) dt + (a_4 y + g) dB(t) & \text{in } Q, \\
z = 0 & \text{on } \Sigma, \\
z(0) = y_0, \quad z_t(0) = y_1 & \text{in } G.
\end{cases} \tag{3.4}
$$

By Step 1, system (3.4) (by viewing, respectively, $a_1y_t+a_2\cdot\nabla y+a_3y+f$ and a_4y+g as nonhomogeneous terms $\hat{f}$ and $\hat{g}$) admits a unique solution $z\in\mathcal{H}_\tau$. We define a map $\mathcal{F}$ from $\mathcal{H}_\tau$ into itself by

$$\mathcal{F}(y)=z.$$

For any $y^1,y^2\in\mathcal{H}_\tau$, by means of (3.3), it is easy to verify that

$$|\mathcal{F}(y^1)-\mathcal{F}(y^2)|_{\mathcal{H}_\tau}\le C\tau|y^1-y^2|_{\mathcal{H}_\tau}.$$

This shows that the map $\mathcal{F}$ is contractive when τ is small enough. Therefore, $\mathcal{F}$ admits a fixed point $y\in\mathcal{H}_\tau$. Hence, system (1.1) admits a local (in time) solution $y\in\mathcal{H}_\tau$.

Step 3. To conclude the proof of Proposition 3.1, it suffices to show that estimate (3.1) holds.

For any $\tau\in[0,T]$, applying estimate (3.3) to system (1.1) (by viewing, respectively, $a_1y_t+a_2\cdot\nabla y+a_3y+f$ and a_4y+g as nonhomogeneous terms $\hat{f}$ and $\hat{g}$), we obtain (recall (2.5) for $\mathcal{A}(a_1,a_2,a_3,a_4)$)

(3.5)

$$\begin{aligned}|y|^2_{\mathcal{H}_\tau}&\le C\Big[|(y_0,y_1)|^2_{L^2(\Omega,\mathcal{F}_0,P;H_0^1(G)\times L^2(G))}\\&\qquad+|a_1y_t+a_2\cdot\nabla y+a_3y+f|^2_{L^2_{\mathcal{F}}(0,\tau;L^2(G))}+|a_4y+g|^2_{L^2_{\mathcal{F}}(0,\tau;L^2(G))}\Big]\\&\le C\bigg[|(y_0,y_1)|^2_{L^2(\Omega,\mathcal{F}_0,P;H_0^1(G)\times L^2(G))}+|f|^2_{L^2_{\mathcal{F}}(0,\tau;L^2(G))}+|g|^2_{L^2_{\mathcal{F}}(0,\tau;L^2(G))}\\&\qquad+\mathcal{A}(a_1,a_2,a_3,a_4)\int_0^\tau|y|^2_{\mathcal{H}_s}ds\bigg].\end{aligned}$$

Now the desired result (3.1) follows from (3.5) and Gronwall's inequality. □

Next, we show the following identity.

PROPOSITION 3.2. *Let $\mu=\mu(x)\overset{\triangle}{=}(\mu^1,\dots,\mu^n):\mathbb{R}^n\to\mathbb{R}^n$ be a vector field of class C^1 and w an $H^2_{loc}(\mathbb{R}^n)$-valued $\{\mathcal{F}_t\}_{t\ge0}$-adapted process such that w_t is an $L^2_{loc}(\mathbb{R}^n)$-valued semimartingale. Then, for a.e. $x\in\mathbb{R}^n$ and P-a.s. $\omega\in\Omega$, it holds that*

$$\begin{aligned}&-\nabla\cdot\left[2(\mu\cdot\nabla w)\nabla w+\mu\left(w_t^2-|\nabla w|^2\right)\right]dt\\&=2\left[\mu\cdot\nabla w(dw_t-\Delta w dt)-d(w_t\mu\cdot\nabla w)-\sum_{i,j}w_iw_j\frac{\partial\mu^j}{\partial x_i}dt\right]\\&\quad+(|\nabla w|^2-w_t^2)\nabla\cdot\mu dt.\end{aligned}\tag{3.6}$$

Proof. Noting that μ is time-independent, it follows that

$$2\left[\mu\cdot\nabla w\Delta w dt+d(w_t\mu\cdot\nabla w)\right]=2\left[\sum_{i,j}\mu^j w_j w_{ii}dt+\mu\cdot\nabla w dw_t+w_t\mu\cdot\nabla w_t dt\right]$$

$$=2\sum_{i,j}\left[\left(w_i\mu^j w_j\right)_i-w_i w_j\frac{\partial\mu^j}{\partial x_i}\right]dt-\mu\cdot\nabla|\nabla w|^2dt+2\mu\cdot\nabla w dw_t+\mu\cdot\nabla w_t^2dt$$

$$=\nabla\cdot\left[2(\mu\cdot\nabla w)\nabla w+\mu\left(w_t^2-|\nabla w|^2\right)\right]dt+2\left[\mu\cdot\nabla w dw_t-\sum_{i,j}w_i w_j\frac{\partial\mu^j}{\partial x_i}dt\right]$$

$$+(|\nabla w|^2-w_t^2)\nabla\cdot\mu dt.$$

This gives (3.6). □

Finally, we show the following hidden regularity for the solution of system (1.1) (here, by hidden regularity we mean that it follows from the equation rather than from the usual trace theorem in the theory of Sobolev spaces).

PROPOSITION 3.3. *Under assumptions* (2.3)–(2.4), *for any* $(y_0,y_1)\in L^2(\Omega,\mathcal{F}_0,P;H_0^1(G)\times L^2(G))$, *the solution of system* (1.1) *satisfies* $\frac{\partial y}{\partial\nu}\in L^2_{\mathcal{F}}(0,T;L^2(\Gamma))$. *Moreover,*

(3.7)

$$\left|\frac{\partial y}{\partial\nu}\right|_{L^2_{\mathcal{F}}(0,T;L^2(\Gamma))}$$

$$\le C\Big[|(y_0,y_1)|_{L^2(\Omega,\mathcal{F}_0,P;H_0^1(G)\times L^2(G))}+|f|_{L^2_{\mathcal{F}}(0,T;L^2(G))}+|g|_{L^2_{\mathcal{F}}(0,T;L^2(G))}\Big]$$

$$\times\exp\Big\{C\Big[|(a_1,a_4)|^2_{L^\infty_{\mathcal{F}}(0,T;(L^\infty(G))^2)}+|a_2|^2_{L^\infty_{\mathcal{F}}(0,T;L^\infty(G;\mathbb{R}^n))}+|a_3|^2_{L^\infty_{\mathcal{F}}(0,T;L^n(G))}\Big]\Big\}.$$

Proof. Since $\Gamma\in C^2$, one can find a vector field $\mu_0=(\mu_0^1,\dots,\mu_0^n)\in C^1(\overline{\Omega};\mathbb{R}^n)$ such that $\mu_0=\nu$ on Γ (see [10]). Applying Proposition 3.2 with $\mu=\mu_0$ and $w=y$, by means of Proposition 3.1, following [10, 13], it is not difficult to show $\frac{\partial y}{\partial\nu}\in L^2_{\mathcal{F}}(0,T;L^2(\Gamma))$ and the desired estimate (3.7) (hence we omit the details). □

4. Identity for a stochastic hyperbolic-like operator. In this section, we show the following fundamental identity for a stochastic hyperbolic-like operator.

THEOREM 4.1. *Let* $b^{ij}\in C^1((0,T)\times\mathbb{R}^n)$ *satisfy*

$$b^{ij}=b^{ji},\qquad i,j=1,2,\dots,n, \tag{4.1}$$

$\ell,\ \Psi\in C^2((0,T)\times\mathbb{R}^n)$. *Assume* u *is an* $H^2_{loc}(\mathbb{R}^n)$*-valued* $\{\mathcal{F}_t\}_{t\ge0}$*-adapted process such that* u_t *is an* $L^2_{loc}(\mathbb{R}^n)$*-valued semimartingale. Set* $\theta=e^\ell$ *and* $v=\theta u$. *Then, for*

a.e. $x \in \mathbb{R}^n$ *and* P*-a.s.* $\omega \in \Omega$,

$$
\begin{aligned}
&\theta\left(-2\ell_t v_t + 2\sum_{i,j} b^{ij}\ell_i v_j + \Psi v\right)\left[du_t - \sum_{i,j}(b^{ij}u_i)_j dt\right] \\
&\quad + \sum_{i,j}\Bigg[\sum_{i',j'}\left(2b^{ij}b^{i'j'}\ell_{i'}v_i v_{j'} - b^{ij}b^{i'j'}\ell_i v_{i'}v_{j'}\right) - 2b^{ij}\ell_t v_i v_t + b^{ij}\ell_i v_t^2 \\
&\qquad\qquad + \Psi b^{ij}v_i v - \left(A\ell_i + \frac{\Psi_i}{2}\right)b^{ij}v^2\Bigg]_j dt \\
&\quad + d\left[\sum_{i,j} b^{ij}\ell_t v_i v_j - 2\sum_{i,j} b^{ij}\ell_i v_j v_t + \ell_t v_t^2 - \Psi v_t v + \left(A\ell_t + \frac{\Psi_t}{2}\right)v^2\right] \\
&= \Bigg\{\left[\ell_{tt} + \sum_{i,j}(b^{ij}\ell_i)_j - \Psi\right]v_t^2 - 2\sum_{i,j}\left[(b^{ij}\ell_j)_t + b^{ij}\ell_{tj}\right]v_i v_t \\
&\quad + \sum_{i,j}\left[(b^{ij}\ell_t)_t + \sum_{i',j'}\left(2b^{ij'}(b^{i'j}\ell_{i'})_{j'} - (b^{ij}b^{i'j'}\ell_{i'})_{j'}\right) + \Psi b^{ij}\right]v_i v_j \\
&\quad + Bv^2 + \left(-2\ell_t v_t + 2\sum_{i,j} b^{ij}\ell_i v_j + \Psi v\right)^2\Bigg\}dt + \theta^2\ell_t(du_t)^2,
\end{aligned}
\tag{4.2}
$$

where $(du_t)^2$ *denotes the quadratic variation process of* u_t,

$$
\begin{cases}
A \triangleq (\ell_t^2 - \ell_{tt}) - \sum_{i,j}(b^{ij}\ell_i\ell_j - b^{ij}_j\ell_i - b^{ij}\ell_{ij}) - \Psi, \\
B \triangleq A\Psi + (A\ell_t)_t - \sum_{i,j}(Ab^{ij}\ell_i)_j + \frac{1}{2}\left[\Psi_{tt} - \sum_{i,j}(b^{ij}\Psi_i)_j\right].
\end{cases}
\tag{4.3}
$$

Proof. By $v(t,x) = \theta(t,x)u(t,x)$, we have $u_t = \theta^{-1}(v_t - \ell_t v)$ and $u_j = \theta^{-1}(v_j - \ell_j v)$ for $j = 1, 2, \ldots, n$. Hence,

$$
du_t = \theta^{-1}[dv_t - 2\ell_t v_t dt + (\ell_t^2 - \ell_{tt})v dt]. \tag{4.4}
$$

Similarly, by symmetry condition (4.1), one may check that

$$
\sum_{i,j}(b^{ij}u_i)_j = \theta^{-1}\sum_{i,j}\left[(b^{ij}v_i)_j - 2b^{ij}\ell_i v_j + (b^{ij}\ell_i\ell_j - b^{ij}_j\ell_i - b^{ij}\ell_{ij})v\right]. \tag{4.5}
$$

Therefore, by (4.4)–(4.5) and recalling the definition of A in (4.3), we get

$$
\begin{aligned}
&\theta\left(-2\ell_t v_t+2\sum_{i,j}b^{ij}\ell_i v_j+\Psi v\right)\left[du_t-\sum_{i,j}(b^{ij}u_i)_j dt\right]\\
&=\left(-2\ell_t v_t+2\sum_{i,j}b^{ij}\ell_i v_j+\Psi v\right)\left\{dv_t-\left[\sum_{i,j}(b^{ij}v_i)_j-Av\right.\right.\\
&\qquad\left.\left.+2\ell_t v_t-2\sum_{i,j}b^{ij}\ell_i v_j-\Psi v\right]dt\right\}\\
&=\left(-2\ell_t v_t+2\sum_{i,j}b^{ij}\ell_i v_j+\Psi v\right)dv_t\\
&\quad+\left(-2\ell_t v_t+2\sum_{i,j}b^{ij}\ell_i v_j+\Psi v\right)\left[-\sum_{i,j}(b^{ij}v_i)_j+Av\right]dt\\
&\quad+\left(-2\ell_t v_t+2\sum_{i,j}b^{ij}\ell_i v_j+\Psi v\right)^2 dt.
\end{aligned}
\tag{4.6}
$$

We now analyze the first two terms in the right-hand side of (4.6). First, using Itô's formula, we have

$$
\begin{aligned}
&\left(-2\ell_t v_t+2\sum_{i,j}b^{ij}\ell_i v_j+\Psi v\right)dv_t\\
&=d\left[\left(-\ell_t v_t+2\sum_{i,j}b^{ij}\ell_i v_j+\Psi v\right)v_t\right]\\
&\quad-\left[-\ell_{tt}v_t^2+2\sum_{i,j}(b^{ij}\ell_i)_t v_j v_t+2\sum_{i,j}b^{ij}\ell_i v_{tj}v_t+\Psi v_t^2+\Psi_t v v_t\right]dt+\ell_t(dv_t)^2\\
&=d\left(-\ell_t v_t^2+2\sum_{i,j}b^{ij}\ell_i v_j v_t+\Psi v v_t-\frac{\Psi_t}{2}v^2\right)\\
&\quad+\left\{-\sum_{i,j}(b^{ij}\ell_i v_t^2)_j+\left[\ell_{tt}+\sum_{i,j}(b^{ij}\ell_i)_j-\Psi\right]v_t^2-2\sum_{i,j}(b^{ij}\ell_j)_t v_i v_t+\frac{\Psi_{tt}}{2}v^2\right\}dt\\
&\quad+\theta^2\ell_t(du_t)^2.
\end{aligned}
\tag{4.7}
$$

Next,

$$
\begin{aligned}
&-2\ell_t v_t\left[-\sum_{i,j}(b^{ij}v_i)_j+Av\right]\\
&=2\left[\sum_{i,j}(b^{ij}\ell_t v_i v_t)_j-\sum_{i,j}b^{ij}\ell_{tj}v_i v_t\right]-\sum_{i,j}b^{ij}\ell_t(v_i v_j)_t-A\ell_t(v^2)_t\\
&=2\left[\sum_{i,j}(b^{ij}\ell_t v_i v_t)_j-\sum_{i,j}b^{ij}\ell_{tj}v_i v_t\right]+\sum_{i,j}(b^{ij}\ell_t)_t v_i v_j\\
&\quad-\left(\sum_{i,j}b^{ij}\ell_t v_i v_j+A\ell_t v^2\right)_t+(A\ell_t)_t v^2.
\end{aligned}
\tag{4.8}
$$

Further, by means of a direct computation, one may check that

$$
\begin{aligned}
&2\sum_{i,j}b^{ij}\ell_i v_j\left[-\sum_{i,j}(b^{ij}v_i)_j+Av\right]\\
&=-\sum_{i,j}\left[\sum_{i',j'}\left(2b^{ij}b^{i'j'}\ell_{i'}v_i v_{j'}-b^{ij}b^{i'j'}\ell_i v_{i'}v_{j'}\right)-Ab^{ij}\ell_i v^2\right]_j\\
&\quad+\sum_{i,j,i',j'}\left[2b^{ij'}(b^{i'j}\ell_{i'})_{j'}-(b^{ij}b^{i'j'}\ell_{i'})_{j'}\right]v_i v_j-\sum_{i,j}(Ab^{ij}\ell_i)_j v^2
\end{aligned}
\tag{4.9}
$$

and

$$
\begin{aligned}
\Psi v\left[-\sum_{i,j}(b^{ij}v_i)_j+Av\right]&=-\sum_{i,j}\left(\Psi b^{ij}v_i v-\frac{\Psi_i}{2}b^{ij}v^2\right)_j+\Psi\sum_{i,j}b^{ij}v_i v_j\\
&\quad+\left[-\frac{1}{2}\sum_{i,j}(b^{ij}\Psi_i)_j+A\Psi\right]v^2.
\end{aligned}
\tag{4.10}
$$

Finally, combining (4.6)–(4.10), we arrive at the desired equality (4.2). ∎

5. Pointwise Carleman-type estimates for the stochastic wave operator. In this section, we show a pointwise Carleman-type estimate (with singular weight) for the stochastic wave operator "$du_t-\Delta u dt$."

To begin with, by taking $(b^{ij})_{n\times n}=I$, the identity matrix, and $\theta=e^{\ell}$ (with ℓ given in (2.12)) in Theorem 4.1, one obtains the following pointwise Carleman-type estimate for the stochastic wave operator.

LEMMA 5.1. *Let $\ell,\ \Psi\in C^2((0,T)\times\mathbb{R}^n)$ and $k\in\mathbb{R}$. Assume u is an $H^2_{loc}(\mathbb{R}^n)$-valued $\{\mathcal{F}_t\}_{t\geq 0}$-adapted process such that u_t is an $L^2_{loc}(\mathbb{R}^n)$-valued semimartingale.*

Set $v=\theta u$. Then, for a.e. $x\in\mathbb{R}^n$ and P-a.s. $\omega\in\Omega$, it holds that

$$
\begin{aligned}
&\theta(-2\ell_t v_t+2\nabla\ell\cdot\nabla v+\psi v)(du_t-\Delta u dt)\\
&\quad+d\Big[\ell_t(v_t^2+|\nabla v|^2)-2(\nabla\ell)\cdot(\nabla v)v_t-\Psi v v_t+A\ell_t v^2\Big]\\
&\quad+\sum_i\Big\{2v_i(\nabla\ell)\cdot(\nabla v)-\ell_i|\nabla v|^2-2\ell_t v_t v_i+\ell_i v_t^2+\Psi v v_i-A\ell_i v^2\Big\}_i dt\\
&\geq\Big[(1-k)\lambda v_t^2+(k+3-4c)\lambda|\nabla v|^2+Bv^2\\
&\quad+\Big(-2\ell_t v_t+2\nabla\ell\cdot\nabla v+\psi v\Big)^2\Big]dt+\theta^2\ell_t(du_t)^2,
\end{aligned}
\tag{5.1}
$$

where

$$
\begin{cases}
\Psi\triangleq(2n-2c-1+k)\lambda,\\
A=4\left[c^2\left(t-\dfrac{T}{2}\right)^2-|x-x_0|^2\right]\lambda^2+\lambda(4c+1-k),\\
B=4\left[(4c+5-k)|x-x_0|^2-(8c+1-k)c^2\left(t-\dfrac{T}{2}\right)^2\right]\lambda^3+O(\lambda^2).
\end{cases}
\tag{5.2}
$$

The desired pointwise Carleman-type estimate (with singular weight function Θ) for the stochastic wave operator reads as follows.

THEOREM 5.1. *Assume u is an $H^2(G)$-valued $\{\mathcal{F}_t\}_{t\geq0}$-adapted process such that u_t is an $L^2(G)$-valued semimartingale. Let $v=\theta u$ and T satisfy* (2.7)*. Then there exist three constants $\lambda_0>0$, $\beta_0>0$, and $c_0>0$, independent of u, such that, for all $\beta\in(0,\beta_0)$ and $\lambda\geq\lambda_0$ and a.e. $x\in G$ and P-a.s. $\omega\in\Omega$, it holds that*

(5.3)

$$
\begin{aligned}
&\Theta\theta(-2\ell_t v_t+2\nabla\ell\cdot\nabla v+\psi v)(du_t-\Delta u dt)\\
&\quad+d\Big\{\Theta\Big[\ell_t(v_t^2+|\nabla v|^2)-2(\nabla\ell)\cdot(\nabla v)v_t-\Psi v v_t+A\ell_t v^2\Big]\Big\}\\
&\quad+\sum_i\Big\{\Theta\Big[2v_i(\nabla\ell)\cdot(\nabla v)-\ell_i|\nabla v|^2-2\ell_t v_t v_i+\ell_i v_t^2+\Psi v v_i-A\ell_i v^2\Big]\Big\}_i dt\\
&\geq\Big[c_0\lambda\Theta\theta^2(u_t^2+|\nabla u|^2+\lambda^2u^2)+\Theta\Big(-2\ell_t v_t+2\nabla\ell\cdot\nabla v+\psi v\Big)^2\Big]dt+\Theta\theta^2\ell_t(du_t)^2,
\end{aligned}
$$

with A and Ψ given by (5.2)*.*

Remark 5.1. The main difference between the pointwise estimates (5.1) and (5.3) is that we introduce a singular "pointwise" weight in (5.3). Another difference between (5.1) and (5.3) is that T is arbitrary in the former estimate, while for the latter one needs to take T to be large enough.

Proof of Theorem 5.1. We borrow some idea from the proof of [15, Theorem 1]. The proof is divided into several steps.

Step 1. We multiply both sides of inequality (5.1) by Θ. Obviously, we have (recall (5.2) for A and Ψ)

$$\begin{aligned}
&\Theta d\Big[\ell_t(v_t^2+|\nabla v|^2)-2(\nabla\ell)\cdot(\nabla v)v_t-\Psi vv_t+A\ell_t v^2\Big]\\
&=d\Big\{\Theta\Big[\ell_t(v_t^2+|\nabla v|^2)-2(\nabla\ell)\cdot(\nabla v)v_t-\Psi vv_t+A\ell_t v^2\Big]\Big\}\\
&\quad-\frac{\beta(T-2t)}{t^2(T-t)^2}\Theta\Big[\ell_t(v_t^2+|\nabla v|^2)-2(\nabla\ell)\cdot(\nabla v)v_t-\Psi vv_t+A\ell_t v^2\Big]dt.
\end{aligned}\tag{5.4}$$

Note that

$$\begin{aligned}
&\left|-\frac{\beta(T-2t)}{t^2(T-t)^2}\Theta\left[-2(\nabla\ell)\cdot(\nabla v)v_t-\Psi vv_t\right]\right|\\
&\le\frac{\beta|T-2t|}{t^2(T-t)^2}\Theta\left[2|(\nabla\ell)\cdot(\nabla v)v_t|+|\Psi v_t v|\right]\\
&\le\frac{\beta|T-2t|}{t^2(T-t)^2}\Theta\left[(|\nabla\ell|+1)v_t^2+|\nabla\ell||\nabla v|^2+\frac{1}{4}\Psi^2v^2\right].
\end{aligned}\tag{5.5}$$

Thus, by (5.1) and using (5.4)–(5.5), we get

$$\begin{aligned}
&\Theta\theta(-2\ell_t v_t+2\nabla\ell\cdot\nabla v+\psi v)(du_t-\Delta u dt)\\
&\quad+d\Big\{\Theta\Big[\ell_t(v_t^2+|\nabla v|^2)-2(\nabla\ell)\cdot(\nabla v)v_t-\Psi vv_t+A\ell_t v^2\Big]\Big\}\\
&\quad+\sum_i\Big\{\Theta\Big[2v_i(\nabla\ell)\cdot(\nabla v)-\ell_i|\nabla v|^2-2\ell_t v_t v_i+\ell_i v_t^2+\Psi vv_i-A\ell_i v^2\Big]\Big\}_i dt\\
&\ge\Big\{\Theta(1-k)\lambda v_t^2+\Theta(k+3-4c)\lambda|\nabla v|^2+\frac{\beta(T-2t)}{t^2(T-t)^2}\ell_t\Theta(v_t^2+|\nabla v|^2)\\
&\quad-\frac{\beta|T-2t|}{t^2(T-t)^2}\Theta\left[(|\nabla\ell|+1)v_t^2+|\nabla\ell||\nabla v|^2\right]\\
&\quad+\left[B+\frac{\beta(T-2t)}{t^2(T-t)^2}\ell_t A-\frac{\beta|T-2t|}{4t^2(T-t)^2}\Psi^2\right]\Theta v^2\\
&\quad+\Theta\Big(-2\ell_t v_t+2\nabla\ell\cdot\nabla v+\psi v\Big)^2\Big\}dt+\Theta\theta^2\ell_t(du_t)^2,
\end{aligned}\tag{5.6}$$

where B is given by (5.2).

Step 2. Recalling that ℓ and Ψ are given, respectively, by (2.12) and (5.2), we get

$$\begin{aligned}
\text{right-hand side of (5.6)}=&\Big[\lambda\Theta(F_1v_t^2+F_2|\nabla v|^2)+\lambda^3\Theta Gv^2\\
&+\Theta\Big(-2\ell_t v_t+2\nabla\ell\cdot\nabla v+\psi v\Big)^2\Big]dt+\Theta\theta^2\ell_t(du_t)^2,
\end{aligned}\tag{5.7}$$

where

$$F_1\triangleq 1-k+\frac{c\beta(T-2t)^2}{t^2(T-t)^2}-\frac{\beta|T-2t|}{t^2(T-t)^2}(2|x-x_0|+\lambda^{-1}),\tag{5.8}$$

$$F_2\triangleq k+3-4c+\frac{c\beta(T-2t)^2}{t^2(T-t)^2}-\frac{2\beta|T-2t||x-x_0|}{t^2(T-t)^2},\tag{5.9}$$

and

$$
\begin{aligned}
G \triangleq\ & 4\left[(4c+5-k)|x-x_0|^2-(8c+1-k)c^2\left(t-\frac{T}{2}\right)^2\right]+O(\lambda^{-1})\\
&+\frac{\beta|T-2t|}{t^2(T-t)^2}\Big\{4c|T-2t|\Big[c^2(t-T/2)^2-|x-x_0|^2\Big]+O(\lambda^{-1})\Big\}.
\end{aligned}
\tag{5.10}
$$

Step 3. Let us show that F_1, F_2, and G are positive when λ is large enough and β is sufficiently small. For this, put

$$
\begin{aligned}
&F_1^0 \triangleq 1-k, \qquad F_2^0 \triangleq k+3-4c,\\
&G^0 \triangleq 4\left[(4c+5-k)|x-x_0|^2-(8c+1-k)c^2\left(t-\frac{T}{2}\right)^2\right]+O(\lambda^{-1}),
\end{aligned}
$$

which are, respectively, the nonsingular part of F_1, F_2, and G. Similarly, put

$$
\begin{aligned}
&F_1^1 \triangleq \frac{c\beta(T-2t)^2}{t^2(T-t)^2}-\frac{\beta|T-2t|}{t^2(T-t)^2}(2|x-x_0|+\lambda^{-1}),\\
&F_2^1 \triangleq \frac{c\beta(T-2t)^2}{t^2(T-t)^2}-\frac{2\beta|T-2t||x-x_0|}{t^2(T-t)^2},\\
&G^1 \triangleq \frac{\beta|T-2t|}{t^2(T-t)^2}\Big\{4c|T-2t|\Big[c^2(t-T/2)^2-|x-x_0|^2\Big]+O(\lambda^{-1})\Big\},
\end{aligned}
$$

which are, respectively, the singular part of F_1, F_2, and G.

Further, we choose $k=1-c$. It is easy to see that both F_1^0 and F_1^0 are positive, and

$$
G^0 \geq 4(4+5c)R_0^2-9c^3T^2+O(\lambda^{-1}),
$$

which, via the first inequality in (2.7), is positive, provided that λ is sufficiently large.

When t is close to 0 or T, i.e., $t\in I_0 \triangleq (0,\delta_0)\cup(T-\delta_0,T)$ for some sufficiently small $\delta_0\in(0,T/2)$, the dominant terms in F_i $(i=1,2)$ and G are the singular ones. For $t\in I_0$,

$$
F_1^1 \geq \frac{\beta|T-2t|}{t^2(T-t)^2}[c(T-2\delta_0)-2R_1-\lambda^{-1})] = \frac{\beta|T-2t|}{t^2(T-t)^2}(cT-2R_1-2c\delta_0-\lambda^{-1}),
$$

which, via the second inequality in (2.7), is positive, provided that both δ_0 and λ^{-1} are sufficiently small. Similarly, for $t\in I_0$, F_2^0 is positive, provided that δ_0 is sufficiently small. Further, for $t\in I_0$,

$$
\begin{aligned}
G^1 &\geq \frac{\beta|T-2t|}{t^2(T-t)^2}\Big\{4c|T-2\delta_0|\Big[c^2(\delta_0-T/2)^2-R_1^2\Big]+O(\lambda^{-1})\Big\}\\
&\geq \frac{\beta|T-2t|}{t^2(T-t)^2}\Big\{4c|T-2\delta_0|\Big[c^2T^2/4-R_1^2+c^2\delta_0(\delta_0-T)\Big]+O(\lambda^{-1})\Big\},
\end{aligned}
$$

which, via the second inequality in (2.7), is positive, provided that both δ_0 and λ^{-1} are sufficiently small.

By (5.8)–(5.10), we see that $F_1 = F_1^0 + F_1^1$, $F_2 = F_2^0 + F_2^1$, and $G = G^0 + G^1$. Noting the positivity of F_1^0, F_2^0, and G^0, by the above argument, we see that F_1, F_2, and G are positive for $t \in I_0$. For $t \in (0,T) \setminus I_0$, noting again the positivity of F_1^0, F_2^0, and G^0, one can choose $\beta > 0$ small enough such that F_1^1, F_2^1, and G^1 are very small so that F_1, F_2, and G are positive. Hence (5.6)–(5.7) yield the desired (5.3). This completes the proof of Theorem 5.1. ∎

6. Proof of Theorems 2.1–2.2. We are now in a position to prove Theorems 2.1–2.2.

Proof of Theorem 2.2. The key idea is to apply Theorem 5.1. Integrating both sides of (5.3) (with u replaced by y, and $v = \theta y$), using integration by parts, and recalling that $\Theta(t)$ decays exponentially to 0 as $t \to 0$ or $t \to T$, noting that $v|_\Sigma = 0$ (and hence $\nabla v = \frac{\partial v}{\partial \nu}\nu$ on Σ), we arrive at

$$\begin{aligned}
&\mathbb{E}\int_Q \left[c_0\lambda\Theta\theta^2(y_t^2 + |\nabla y|^2 + \lambda^2 y^2) + \Theta\Big(-2\ell_t v_t + 2\nabla\ell\cdot\nabla v + \psi v\Big)^2\right] dxdt \\
&\le \mathbb{E}\int_Q \Theta\theta\left[(-2\ell_t v_t + 2\nabla\ell\cdot\nabla v + \psi v)(dy_t - \Delta y dt) - \theta\ell_t(dy_t)^2\right] dx \\
&\quad + \mathbb{E}\int_\Sigma \Theta\frac{\partial\ell}{\partial\nu}\left|\frac{\partial v}{\partial\nu}\right|^2 d\Gamma dt.
\end{aligned} \tag{6.1}$$

By the first equation of system (1.1), we get

(6.2)

$$\begin{aligned}
&\mathbb{E}\int_Q \Theta\theta\left[(-2\ell_t v_t + 2\nabla\ell\cdot\nabla v + \psi v)(dy_t - \Delta y dt) - \theta\ell_t(dy_t)^2\right] dx \\
&= \mathbb{E}\int_Q \Theta\theta\Big[(-2\ell_t v_t + 2\nabla\ell\cdot\nabla v + \psi v)(a_1 y_t + a_2\cdot\nabla y + a_3 y + f) \\
&\qquad\qquad - \theta\ell_t(a_4 y + g)^2\Big] dxdt \\
&\le \mathbb{E}\int_Q \Theta\Big(-2\ell_t v_t + 2\nabla\ell\cdot\nabla v + \psi v\Big)^2 dxdt \\
&\quad + C\left\{\mathbb{E}\int_Q \Theta\theta^2\Big(a_1 y_t + a_2\cdot\nabla y + a_3 y + f\Big)^2 dxdt + \lambda\mathbb{E}\int_Q \Theta\theta^2(a_4 y + g)^2 dxdt\right\} \\
&\le \mathbb{E}\int_Q \Theta\Big(-2\ell_t v_t + 2\nabla\ell\cdot\nabla v + \psi v\Big)^2 dxdt \\
&\quad + C\left\{\mathbb{E}\int_Q \Theta\theta^2(f^2 + \lambda g^2) dxdt + |a_1|^2_{L^\infty_{\mathcal{F}}(0,T;(L^\infty(G))}\mathbb{E}\int_Q \Theta\theta^2 y_t^2 dxdt\right. \\
&\quad + \lambda\Big[\lambda|a_3|^2_{L^\infty_{\mathcal{F}}(0,T;L^n(G))} + |a_4|^2_{L^\infty_{\mathcal{F}}(0,T;(L^\infty(G))}\Big]\mathbb{E}\int_Q \Theta\theta^2 y^2 dxdt \\
&\quad \left. + \Big[|a_2|^2_{L^\infty_{\mathcal{F}}(0,T;L^\infty(G;\mathbb{R}^n))} + |a_3|^2_{L^\infty_{\mathcal{F}}(0,T;L^n(G))}\Big]\mathbb{E}\int_Q \Theta\theta^2|\nabla y|^2 dxdt\right\}.
\end{aligned}$$

On the other hand, recalling (2.2), we have

$$\begin{aligned}(6.3)\qquad &\mathbb{E}\int_\Sigma \Theta\frac{\partial \ell}{\partial \nu}\left|\frac{\partial v}{\partial \nu}\right|^2 d\Gamma dt = 2\lambda\mathbb{E}\int_\Sigma \Theta\theta^2(x-x_0)\cdot\nu(x)\left|\frac{\partial y}{\partial \nu}\right|^2 d\Gamma dt\\ &\le 2\lambda\mathbb{E}\int_{\Sigma_0}\Theta\theta^2(x-x_0)\cdot\nu(x)\left|\frac{\partial y}{\partial \nu}\right|^2 d\Gamma_0 dt \le C\lambda\mathbb{E}\int_{\Sigma_0}\Theta\theta^2\left|\frac{\partial y}{\partial \nu}\right|^2 d\Gamma_0 dt.\end{aligned}$$

Finally, combining (6.1), (6.2), and (6.3), we arrive at the desired estimate (2.14). This completes the proof of Theorem 2.2. □

Proof of Theorem 2.1. The proof follows easily from Theorem 2.2 and the energy estimate in Proposition 3.1. We omit the details. □

7. Application to state observation problem of semilinear stochastic wave equations. This section is devoted to giving an application of the observability inequality in section 2. Fixing two known nonlinear functions $F(\eta, v, \zeta) : \mathbb{R}^1 \times \mathbb{R}^1 \times \mathbb{R}^n \to \mathbb{R}^1$ and $G(\eta) : \mathbb{R}^1 \to \mathbb{R}^1$, and unknown initial data $(w_0, w_1) \in L^2(\Omega, \mathcal{F}_0, P; H_0^1(G) \times L^2(G))$, for the semilinear stochastic wave equation

$$(7.1)\qquad \begin{cases} dw_t - \Delta w dt = F(w, w_t, \nabla w)dt + G(w)dB(t) & \text{in } Q,\\ w = 0 & \text{on } \Sigma,\\ w(0) = w_0, \quad w_t(0) = w_1 & \text{in } G,\end{cases}$$

we consider the following.

State observation problem: Let $T > 0$ be given. Determine the state $(w(t), w_t(t)) \in L^2(\Omega, \mathcal{F}_t, P; H_0^1(G) \times L^2(G))$ of (7.1) (for $t \in (0, T]$) from the observed boundary data

$$\frac{\partial w}{\partial \nu}(t, x), \qquad (t, x) \in \Sigma_0, \quad P\text{-a.s.}$$

We refer the reader to [11, 14] for some studies on the state observation problems for (deterministic) semilinear wave equations. To the best of our knowledge, nothing is published for the stochastic setting. We need the following assumption:

(H) The nonlinear functions $F(\cdot)$ and $G(\cdot)$ satisfy the following:

(1)

$$\begin{aligned}|F(\eta_1, v, \zeta) - F(\eta_2, v, \zeta)| + |G(\eta_1) - G(\eta_2)| &\le L(1 + |\eta_1|^{p-1} + |\eta_2|^{p-1})|\eta_1 - \eta_2|\\ &\forall\ \eta_1, \eta_2, v \in \mathbb{R}^1,\ \zeta \in \mathbb{R}^n\end{aligned}$$

with $1 \le p \le \frac{n}{n-2}$ if $n \ge 3$; $1 \le p < \infty$ if $n = 1, 2$;

(2)

$$\begin{aligned}&|F(\eta, v_1, \zeta_1) - F(\eta, v_2, \zeta_2)| \le L(|v_1 - v_2| + |\zeta_1 - \zeta_2|)\\ &\qquad\forall\ (\eta, v_i, \zeta_i) \in \mathbb{R}^1 \times \mathbb{R}^1 \times \mathbb{R}^n,\ i = 1, 2,\\ &|F(0, v, \zeta)| \le L(|v| + |\zeta|)\ \ \forall\ (v, \zeta) \in \mathbb{R}^1 \times \mathbb{R}^n\end{aligned}$$

for some constant $L > 0$;

(3) for any given initial data $(w_0, w_1) \in L^2(\Omega, \mathcal{F}_0, P; H_0^1(G) \times L^2(G))$, (7.1) admits a unique solution $w = w(\cdot\,; w_0, w_1) \in \mathcal{H}_T$ (the solution of (7.1) is defined similarly to Definition 1.1).

Since we do not introduce any sign condition on the nonlinearities $F(\cdot)$ and $G(\cdot)$, the global existence of a solution of (7.1) is not guaranteed. This is why we need to impose the third assumption in (H). The (global) well-posedness of (7.1) is an interesting but difficult problem, which is beyond the scope of this paper.

It is easy to see that, by the Sobolev embedding theorem, assumption (H) implies that

$$F(z, z_t, \nabla z) \in L^2_{\mathcal{F}}(0,T;L^2(G)), \quad G(z) \in L^2_{\mathcal{F}}(0,T;L^2(G))$$

for any $z \in \mathcal{H}_T$. Thus, thanks to Proposition 3.3, we can define a nonlinear map $\gamma:\ L^2(\Omega,\mathcal{F}_0,P;H_0^1(G)\times L^2(G)) \to L^2_{\mathcal{F}}(0,T;L^2(\Gamma_0))$ by

$$\gamma(w_0,w_1) = \left.\frac{\partial w}{\partial \nu}\right|_{\Sigma_0\times\Omega},$$

where w is the solution of (7.1). Now we have the following result.

THEOREM 7.1. *Let* (H) *hold,* Γ_0 *be given by* (2.2), *and* T *satisfy* (2.7). *Then, for any* $(w_0,w_1),(\hat{w}_0,\hat{w}_1) \in L^2(\Omega,\mathcal{F}_0,P;H_0^1(G)\times L^2(G))$ *and any* $t\in(0,T]$, *there exists a constant* $\widetilde{C} = \widetilde{C}(F,G,w_0,\hat{w}_0,w_1,\hat{w}_1) > 0$ *such that*

$$\begin{aligned}&|(w(t)-\hat{w}(t), w_t(t)-\hat{w}_t(t))|_{L^2(\Omega,\mathcal{F}_t,P;H_0^1(G)\times L^2(G))}\\ &\le e^{Ct^{-1}}\widetilde{C}|\gamma(w_0,w_1)-\gamma(\hat{w}_0,\hat{w}_1)|_{L^2_{\mathcal{F}}(0,T;L^2(\Gamma_0))},\end{aligned}$$

where $\hat{w} = \hat{w}(\cdot\,;\hat{w}_0,\hat{w}_1) \in \mathcal{H}_T$ *is the solution of* (7.1) *with* (w_0,w_1) *replaced by* $(\hat{w}_0,\hat{w}_1)$.

Remark 7.1. Theorem 7.1 indicates that the state $(w(t),w_t(t)) \in L^2(\Omega,\mathcal{F}_t,P;H_0^1(G)\times L^2(G))$ of (7.1) (for $t\in(0,T]$) can be uniquely determined from the observed boundary data $\frac{\partial w}{\partial\nu}(t,x)\big|_{\Sigma_0}$, P-a.s., and continuously depend on it.

Proof of Theorem 7.1. Set

$$y = \hat{w} - w.$$

It is easy to see that y is a solution of (1.1) with

$$\begin{cases} a_1 = \displaystyle\int_0^1 \partial_\eta F(w+s(\hat{w}-w),w_t,\nabla w)ds, \quad a_2 = \int_0^1 \partial_v(\hat{w},w_t+s(\hat{w}_t-w_t),\nabla w)ds,\\ a_3 = \displaystyle\int_0^1 \partial_\zeta F(\hat{w},\hat{w}_t,\nabla w+s(\nabla\hat{w}-\nabla w))ds, \quad a_4 = \int_0^1 \partial_\eta G(w+s(\hat{w}-w))ds.\end{cases}$$

The desired result follows immediately from Remark 2.1. ∎

Acknowledgments. The author acknowledges Professor Shanjian Tang for stimulating discussion and the anonymous referees for helpful comments.

GLOBAL BEHAVIOR OF SPHERICALLY SYMMETRIC NAVIER–STOKES EQUATIONS WITH DEGENERATE VISCOSITY COEFFICIENTS*

MINGJUN WEI†, TING ZHANG†, AND DAOYUAN FANG†

Abstract. In this paper, we study a free boundary problem for compressible spherically symmetric Navier–Stokes equations with a gravitational force and degenerate viscosity coefficients. Under certain assumptions that are imposed on the initial data, we obtain the global existence and uniqueness of the weak solution and give some uniform bounds (with respect to time) of the solution. Moreover, we obtain some stabilization rate estimates in L^∞-norm and weighted H^1-norm of the solution. The results show that such a system is stable under small perturbations and could be applied to the astrophysics.

Key words. compressible Navier–Stokes equations, density-dependent viscosity, free boundary, asymptotic behavior

AMS subject classifications. 35Q35, 35D05, 76N10

DOI. 10.1137/070681703

1. Introduction.

We consider the compressible Navier–Stokes equations with density-dependent viscosity in $\mathbb{R}^n (n \geq 2)$, which can be written in Eulerian coordinates as

$$\begin{cases} \partial_\tau \rho + \nabla \cdot (\rho \vec{u}) = 0, \\ \partial_\tau (\rho \vec{u}) + \nabla \cdot (\rho \vec{u} \otimes \vec{u}) + \nabla P = \mathrm{div}(\mu(\nabla \vec{u} + \nabla \vec{u}^\top)) + \nabla(\lambda \mathrm{div} \vec{u}) - \rho \vec{f}, \end{cases} \tag{1.1}$$

in a domain $\{(\vec{\xi}, \tau) \big| \vec{\xi} \in \Omega_\tau \subset \mathbb{R}^n, \tau > 0\}$, the initial conditions and boundary conditions are

$$(\rho, \vec{u})(\vec{\xi}, 0) = (\rho_0, u_0)(\vec{\xi}), \ \vec{\xi} \in \Omega_0 = \{\vec{\xi} \in \mathbb{R}^n \big| a < |\vec{\xi}| < b\}, \tag{1.2}$$

$$\vec{u}|_{|\vec{\xi}|=a} = 0, \ \rho|_{\vec{\xi} \in \partial\Omega_\tau \setminus \{|\vec{\xi}|=a\}} = 0, \tag{1.3}$$

where $0 < a < b < \infty$, $\Omega_\tau = \psi(\Omega_0, \tau)$ and ψ is the flow of $\vec{u}$:

$$\begin{cases} \partial_\tau \psi(\vec{\xi}, \tau) = \vec{u}(\psi(\vec{\xi}, \tau), \tau), \quad \vec{\xi} \in \mathbb{R}^n, \\ \psi(\vec{\xi}, 0) = \vec{\xi}. \end{cases} \tag{1.4}$$

Here ρ, P, $\vec{u} = (\mathrm{u}_1, \ldots, \mathrm{u}_n)$, and $\vec{f}$ are the density, pressure, velocity, and external force, respectively; $\lambda = \lambda(\rho)$ and $\mu = \mu(\rho)$ are the viscosity coefficients.

For the initial-boundary value problem (1.1)–(1.3) with the spherically symmetric initial data and external force

$$(\rho,\vec{u})(\vec{\xi},0)=\left(\rho_0(r),u_0(r)\frac{\vec{\xi}}{r}\right),\ \vec{\xi}\in\Omega_0,$$
$$\vec{f}=f(m,r,\tau)\frac{\vec{\xi}}{r},\ m(\rho,r)=\int_a^r\rho(s,\tau)s^{n-1}ds,\ \vec{\xi}\in\Omega_\tau,$$

where $r=|\vec{\xi}|=\sqrt{\xi_1^2+\cdots+\xi_n^2}$, we are looking for spherically symmetric solutions $(\rho,\vec{u})$:

$$\rho(\vec{\xi},\tau)=\rho(r,\tau),\quad \vec{u}(\vec{\xi},\tau)=u(r,\tau)\frac{\vec{\xi}}{r},\ \vec{\xi}\in\Omega_\tau,$$

where $\Omega_\tau=\{\vec{\xi}\in\mathbb{R}^n\ \big|\ a<|\vec{\xi}|<b(\tau),b(0)=b,b'(\tau)=u(b(\tau),\tau)\}$. Then $(\rho,u)(r,\tau)$ is determined by

$$\text{(1.5)}\quad\begin{cases}\partial_t\rho+\partial_r(\rho u)+\frac{n-1}{r}\rho u=0,\\ \rho(\partial_t u+u\partial_r u)+\partial_r P=\partial_r[(\lambda+2\mu)(\partial_r u+\frac{n-1}{r}u)]-2(n-1)\frac{u}{r}\partial_r\mu-\rho f,\end{cases}$$

where $(r,\tau)\in(a,b(\tau))\times(0,\infty)$, with the initial data

$$(\rho,u)|_{\tau=0}=(\rho_0,u_0)(r),\ a\le r\le b,\tag{1.6}$$

the boundary conditions

$$u|_{r=a}=0,\ \rho|_{r=b(\tau)}=0,\tag{1.7}$$

where $b(0)=b$, $b'(\tau)=u(b(\tau),\tau)$, $\tau>0$.

To simplify the presentation, we consider only the famous polytropic model, i.e., $P(\rho)=A\rho^\gamma$, with $\gamma>1$ and $A>0$ being constants. And we assume that the viscosity coefficients μ and λ are proportional to ρ^θ, i.e., $\mu(\rho)=c_1\rho^\theta$ and $\lambda(\rho)=c_2\rho^\theta$, where c_1,c_2, and θ are three constants.

Additionally, we assume that the external force $f(m,r,\tau)$ satisfies

$$f(m,r,\tau)=f_\infty(m,r)+\Delta f(m,r,\tau),\tag{1.8}$$

for all $m\ge0$, $r\ge a$, and $\tau\ge0$, with

$$f_\infty(m,r)=G\frac{M_0+m}{r^{n-1}},\ \Delta f(m,r,\tau)\in C^1(\mathbb{R}_+\times\mathbb{R}_+\times\mathbb{R}_+)\tag{1.9}$$

$$\|\Delta f(\cdot,\cdot,\tau)\|_{L^\infty(\mathbb{R}_+\times\mathbb{R}_+)}\le f_1(\tau),\ \|(\partial_r\Delta f,\partial_\tau\Delta f)(\cdot,\cdot,\tau)\|_{L^\infty(\mathbb{R}_+\times\mathbb{R}_+)}\le f_2(\tau),\tag{1.10}$$

$$f_1\in L^\infty\cap L^2(\mathbb{R}_+),\quad f_2\in L^2(\mathbb{R}_+),\tag{1.11}$$

where $\mathbb{R}_+=[0,\infty)$, $G>0$ is a constant, $M_0\ge0$ is the total mass of the solid core surrounded by the gas, and the perturbation Δf tends to 0 as $\tau\to\infty$ in some weak sense. If $M_0=0$, we ignore the gravitational effect of the solid core. Δf expresses the influence of the outside gravitational force, f_∞ is the precise expression for its own gravitational force and the gravitational force of the solid core, in the astrophysical case (with spherical symmetry).

It is very interesting to study the stabilization problem for the model of the atmosphere of a planet, whose evolution is influenced by the gravitational force. In [22], we considered a simple model that is one-dimensional Navier–Stokes equations. In this paper, we study the stabilization problem of the spherically symmetric model (1.5). We should consider the essential multidimensional model in the future.

Now, we consider the stationary problem, namely

$$(P(\rho_\infty))_r = -\rho_\infty f_\infty(m(\rho_\infty, r), r) \tag{1.12}$$

in an interval $r \in (a, l_\infty)$, with the end l_∞ satisfying

$$\rho_\infty(l_\infty) = 0, \ \int_a^{l_\infty} \rho_\infty r^{n-1} dr = M := \int_a^b \rho_0 r^{n-1} dr. \tag{1.13}$$

The unknown quantities are the stationary density $\rho_\infty \geq 0$ and free boundary $l_\infty > 0$. If $\gamma > \frac{2n-2}{n}$, from Proposition 2.5, we know that there exists a unique solution (ρ_∞, l_∞) to the stationary system (1.12)–(1.13), satisfying $\rho_\infty(r) \sim (l_\infty^n - r^n)^{\frac{1}{\gamma-1}}$, $(\rho_\infty)_r(r) < 0$, $a < r < l_\infty$, with $l_\infty < +\infty$.

To handle the free boundary problem (1.5)–(1.7), it is convenient to reduce the problem in Eulerian coordinates (r, τ) to the problem in Lagrangian coordinates (x, t) moving with the fluids, via the transformation:

$$x = \int_a^r y^{n-1} \rho(y, \tau) dy, \ t = \tau. \tag{1.14}$$

Then the fixed boundary $r = a$ and the free boundary $r = b(\tau)$ become

$$x = 0 \ \text{ and } x = \int_a^{b(\tau)} y^{n-1} \rho(y, \tau) dy = \int_a^b y^{n-1} \rho_0(y) dy = M,$$

where M is the total mass initially so that the region $\{(r, \tau) | a \leq r \leq b(\tau), \tau \geq 0\}$ under consideration is transformed into the region $\{(x, t) | 0 \leq x \leq M, t \geq 0\}$, and the function $m(\rho, r)$ becomes x. Under the coordinate transformation (1.14), the equations (1.5)–(1.7) are transformed into

$$\begin{cases} \partial_t \rho(x,t) = -\rho^2 \partial_x (r^{n-1} u), \\ \partial_t u(x,t) = r^{n-1} \left\{ \partial_x [\rho(\lambda + 2\mu) \partial_x (r^{n-1} u) - P] - 2(n-1) \frac{u}{r} \partial_x \mu \right\} - f(x, r, t), \\ r^n(x,t) = a^n + n \int_0^x \rho^{-1}(y, t) dy, \end{cases} \tag{1.15}$$

where $(x, t) \in (0, M) \times (0, \infty)$, with the initial data

$$(\rho, u)|_{t=0} = (\rho_0, u_0)(x), r|_{t=0} = r_0(x) = \left(a^n + n \int_0^x \rho_0^{-1}(y) dy \right)^{\frac{1}{n}}, \tag{1.16}$$

and the boundary conditions

$$u|_{x=0} = 0, \ \rho|_{x=M} = 0, \ t > 0. \tag{1.17}$$

It is standard that if we can solve the problem (1.15)–(1.17), then the free boundary problem (1.1)–(1.3) has a solution.

From (1.12)–(1.13), it is easy to see that $\rho_\infty(x)$ is the solution to the stationary system

$$Ar_\infty^{n-1}(\rho_\infty^\gamma)_x = -f_\infty(x, r_\infty),\ r_\infty^n(x) = a^n + n\int_0^x \rho_\infty^{-1}(y)dy,\ x \in (0, M), \tag{1.18}$$

$$\rho_\infty(M) = 0. \tag{1.19}$$

The results in [8, 20] show that the compressible Navier–Stokes system with the constant viscosity coefficient has the singularity at the vacuum. Considering the modified Navier–Stokes system in which the viscosity coefficient depends on the density, Liu, Xin, and Yang [11] proved that such system is local well posed. It is motivated by the physical consideration that, in the derivation of the Navier–Stokes equations from the Boltzmann equation through the Chapman–Enskog expansion to the second order, cf. [6], viscosity is a function of temperature. If we consider the case of isentropic fluids, this dependence is reduced to the dependence on the density function.

Since $n \geq 2$ and the viscosity coefficient μ depends on ρ, the nonlinear term $2(n-1)\frac{1}{r}u\partial_x\mu$ in $(1.15)_2$ makes the analysis significantly different from the one-dimensional case [11, 15, 19, 21, 22]. When $\mu \geq \underline{\mu} > 0$ and $\rho_0 \geq \underline{\rho} > 0$, authors in [4, 24] obtained the existence, uniqueness, and global behavior of the solution for compressible spherically symmetric Navier–Stokes equations with an external pressure and without the nonlinear term $2(n-1)\frac{1}{r}u\partial_x\mu$. Following the ideas in [24], we can obtain the existence and uniqueness results for the stationary problem in section 2. In this paper, since viscosity coefficients and density will degenerate at the free boundary, we need to use the weighted function $(M-x)$ to control the lower bound of the density in section 3.

Considering the system (1.15)–(1.17) with a general external force, Chen-Zhang obtained the local existence and uniqueness of the solution in [3]. In this paper, when the initial data (ρ_0, u_0, r_0) are close to the stationary state $(\rho_\infty, 0, r_\infty)$, we will obtain some appropriate a priori estimates and prove that the maximum existence time $T^* = \infty$. The difficulty of this problem is to obtain the lower bound of the density ρ. The key ideas are using the classical continuation method and the result of Claim 1. In Claim 1, we want to prove that there is a small positive constant ϵ_1, such that, for any $T > 0$, if

$$I(t) = \|g(\cdot, t) - g_\infty\|_{L^\infty} \leq 2\epsilon_1\ \forall\ t \in [0, T], \tag{1.20}$$

where $g(x,t) = (M-x)^{-\frac{1}{\gamma}}\rho(x,t)$ and $g_\infty(x) = (M-x)^{-\frac{1}{\gamma}}\rho_\infty(x)$, then

$$I(t) \leq \epsilon_1\ \forall\ t \in [0, T]. \tag{1.21}$$

Using the energy method and induction method, we can estimate the weighted L^2- norm of $g - g_\infty$ in Lemma 3.7. In such a process (see Lemmas 3.5–3.6), we use the weight function $(1+t)^\alpha$ (with $\alpha = -\frac{5}{8}$) to remedy the disadvantage of the nonlinear term $2(n-1)\frac{1}{r}u\partial_x\mu$, and we use the induction method to increase α to $-\epsilon_2$. Then, by the reduction to absurdity, we can finish the proof of Claim 1 in Lemma 3.8.

Our results show that such a system is stable under small perturbations, it does not develop vacuum states or concentration states for all time, and the interface $\partial\Omega_\tau$ propagates with finite speed.

The assumptions on c_1, c_2, θ, γ, and initial data can be stated as follows:

(A1) $\gamma > \frac{2n-2}{n}$, $\theta \in (0, \gamma-1) \cap (0, \frac{\gamma}{2}]$, c_1 and c_2 satisfy that $c_1 > 0$ and $2c_1 + nc_2 > 0$;

(A2) $N_1(M-x)^{1/\gamma} \le \rho_0 \le N_2(M-x)^{1/\gamma}$, with some positive constants $0 < N_1 < N_2$, and $(M-x)^{1-\frac{\theta}{\gamma}}(\rho_0^\theta)_x^2 \in L^1([0,M])$, $(\rho_0^\gamma)_x \in L^2([0,M])$;

(A3) $u_0 \in L^2([0,M])$, $\rho_0^{\frac{\theta+1}{2}}(u_0)_x \in L^2([0,M])$, $u_0(0) = 0$,

$$\big((2c_1+c_2)\rho_0^{\theta+1}(r_0^{n-1}u_0)_x\big)_x - 2c_1(n-1)\frac{u_0}{r_0}(\rho_0^\theta)_x \in L^2([0,M]). \tag{1.22}$$

Under the above assumptions (A1)–(A3), we will prove the existence of the global weak solution to the initial-boundary value problem (1.15)–(1.17) in the sense of the following definition.

DEFINITION 1.1. *A pair of functions $(\rho,u,r)(x,t)$ is called a global weak solution to the initial-boundary value problem* (1.15)–(1.17) *if, for any $T > 0$,*

$$\rho, u \in L^\infty([0,M]\times[0,T]) \cap C^1([0,T]; L^2([0,M])),$$

$$r \in C^1([0,T]; L^\infty([0,M])),$$

$$\rho^{-1},\ (r^{n-2}u)_x,\ (r^{n-1})_x \in L^\infty([0,T]; L^1([0,M])),$$

and

$$\rho^{1+\theta}(r^{n-1}u)_x \in L^\infty([0,M]\times[0,T]) \cap C^{\frac{1}{2}}([0,T]; L^2([0,M])).$$

Furthermore, the following equations hold:

$$\rho_t + \rho^2(r^{n-1}u)_x = 0,\ \rho(x,0) = \rho_0(x),\ a.e.$$

$$r_t = u,\ r(x,0) = r_0(x),\ r^n(x,t) = a^n + n\int_0^x \rho^{-1}(y,t)dy,\ a.e.$$

$$\int_0^\infty\int_0^M [u\psi_t + (P - \rho(\lambda+2\mu)(r^{n-1}u)_x)(r^{n-1}\psi)_x$$
$$+ 2(n-1)\mu(r^{n-2}u\psi)_x - f(x,r,t)\psi]dxdt + \int_0^M u_0(x)\psi(x,0)dx = 0$$

for any test function $\psi(x,t) \in C_0^\infty(\Omega)$, with $\Omega = \{(x,t) \mid 0 < x \le M,\ t \ge 0\}$ and

$$\lim_{\epsilon\to 0}\frac{1}{\epsilon}\int_0^\epsilon u dx = \lim_{\epsilon\to 0}\frac{1}{\epsilon}\int_{1-\epsilon}^1 \rho dx = 0.$$

In what follows, we always use $C(C_i)$ to denote a generic positive constant depending only on γ, θ, f_1, f_2, and the initial data, independent of the given time T.

We now state the main theorems in this paper.

THEOREM 1.1. *Under the conditions* (1.8)–(1.11) *and* (A1)–(A3)*, there exists a constant $\epsilon_0 > 0$ such that if*

$$\|f_1\|_{L^\infty}^2 + \int_0^\infty (1+t)f_1^2(t)dt \le \epsilon_0^2 \tag{1.23}$$

and

$$\|u_0\|_{L^2} + \|(M-x)^{-\frac{1}{\gamma}}(\rho_0 - \rho_\infty)\|_{L^\infty} \le \epsilon_0, \tag{1.24}$$

then the system (1.15)–(1.17) *has a unique global weak solution* (ρ, u, r) *satisfying*

$$C^{-1}(M-x)^{\frac{1}{\gamma}} \le \rho(x,t) \le C(M-x)^{\frac{1}{\gamma}}, \tag{1.25}$$

$$r(x,t) \in [a, C], \tag{1.26}$$

$$\int_0^M (M-x)^{1-\frac{\theta}{\gamma}}(\rho^\theta - \rho_\infty^\theta)_x^2 dx \le C \tag{1.27}$$

and

$$\|u(\cdot,t)\|_{L^\infty} + \|[\rho(r^{n-1}u)_x](\cdot,t)\|_{L^\infty} \le C \tag{1.28}$$

for all $t \ge 0$ *and* $x \in [0, M]$. *Furthermore, if* $(1+t)^{\frac{2(\gamma+\theta)}{\gamma+\theta+1}} f_1^2(t) \in L^1(\mathbb{R}_+)$, *for any* $\eta > 0$, *we have*

$$\int_0^M \left\{u^2 + (M-x)^{\frac{\gamma-1}{\gamma}}(g-g_\infty)^2 + (r-r_\infty)^2\right\} dx \le C_\eta (1+t)^{-\frac{2(\gamma+\theta)}{\gamma+\theta+1}+\eta}, \tag{1.29}$$

$$\int_0^M \left(\rho^{\theta-1}u^2 + \rho^{\theta+1}u_x^2\right) dx \le C_\eta (1+t)^{-\frac{2(\gamma+\theta)}{\gamma+\theta+1}+\eta}, \tag{1.30}$$

$$\int_0^M (M-x)^{2-\frac{2\theta}{\gamma}}(\rho^\theta - \rho_\infty^\theta)_x^2 dx \le C_\eta (1+t)^{-\frac{\gamma+\theta-1}{\gamma+\theta+1}+\eta}, \tag{1.31}$$

$$\|\rho^\gamma(\cdot,t) - \rho_\infty^\gamma(\cdot)\|_{L^\infty} \le C_\eta (1+t)^{-\frac{3\gamma+3\theta-1}{4(\gamma+\theta+1)}+\frac{\eta}{2}}, \tag{1.32}$$

and

$$\|\rho^{\frac{\gamma+\theta}{2}}(\cdot,t) - \rho_\infty^{\frac{\gamma+\theta}{2}}(\cdot)\|_{L^\infty}^2 + \|u(\cdot,t)\|_{L^\infty} \le C_\eta (1+t)^{-\frac{\gamma+\theta}{\gamma+\theta+1}+\frac{\eta}{2}}, \tag{1.33}$$

for all $t \ge 0$, *where* C_η *is a positive constant depending on* η.

Remark 1.1. The constant $\epsilon_0 = \epsilon_0(G, A, M_0, M, a, n, \gamma, \theta, c_1, c_2)$ is defined in (3.55). There are no smallness assumptions on $\|(M-x)^{1-\frac{\theta}{\gamma}}(\rho_0^\theta)_x^2\|_{L^1}$ and $\|\rho_0^{\frac{1+\theta}{2}}(u_0)_x\|_{L^2}$.

Remark 1.2. The uniqueness of the solution in Theorems 1.1 or 3.1 means that if (ρ_1, u_1, r_1) and (ρ_2, u_2, r_2) are two solutions to the system (1.15)–(1.17) with the same initial data (ρ_0, u_0, r_0) and satisfy regularity conditions in the theorem, then we have that $(\rho_1, u_1, r_1) = (\rho_2, u_2, r_2)$.

Remark 1.3. In particular, the viscosity of the gas is proportional to the square root of the temperature for the hard sphere model (as pointed out in [15, 21]), and the relation between θ and γ is

$$\theta = \frac{\gamma - 1}{2}.$$

Our condition (A1) covers it. Since the Navier–Stokes system with constant viscosity coefficients has the singularity at the vacuum [8, 20], we assume that $\theta > 0$ in (A1).

Remark 1.4. Considering the no-vacuum system in an exterior domain in $\mathbb{R}^3$, Kobayashi and Shibata [9] obtained $\|(\rho-\rho_\infty, u)(\cdot,t)\|_{L^2} \lesssim (1+t)^{-\frac{3}{4}}$ and $\|(\rho-\rho_\infty, u)(\cdot,t)\|_{L^\infty} \lesssim (1+t)^{-\frac{3}{2}}$ when ρ_∞ is a positive constant. Considering the no-vacuum system in $\mathbb{R}^n$ $(n \ge 3)$, Ukai, Yang, and Zhao [18] obtained $\|(\rho-\rho_\infty, u)(\cdot,t)\|_{L^2\cap L^\infty} \le C(1+t)^{-\frac{n}{4}+\epsilon}$ when ρ_∞ is close to a positive constant. Considering the one-dimensional system with a degenerate viscosity coefficient, we [22] obtained $\|(\rho^\gamma - \rho_\infty^\gamma, u)(\cdot,t)\|_{L^\infty} \le$

$C(1+t)^{-\frac{1}{2}}$ when the external force f_∞ is close to a positive constant N_0 and the stationary density ρ_∞ is close to $(\frac{N_0(M-x)}{A})^{\frac{1}{\gamma}}$. Since $\frac{\gamma+\theta}{\gamma+\theta+1} > \frac{1}{2}$ and $\frac{3\gamma+3\theta-1}{4(\gamma+\theta+1)} > \frac{1}{2}$ (if $\gamma+\theta > 3$), it is easy to see that our results in Theorem 1.1 are better than that in [22]. Using similar arguments as that in Theorem 1.1, we can also obtain similar results in the one-dimensional case, which are better than that in [22]. For example, the stabilization rate estimate $\|(\rho^\gamma - \rho_\infty^\gamma, u)(\cdot,t)\|_{L^\infty} \le C(1+t)^{-\frac{1}{2}}$ in [22] can be replaced by $\|(\rho^\gamma - \rho_\infty^\gamma, u)(\cdot,t)\|_{L^\infty} \le C_\eta(1+t)^{-\frac{\gamma+\theta}{\gamma+\theta+1}+\frac{\eta}{2}}$, $\|\rho^{\frac{\gamma+\theta}{2}}(\cdot,t) - \rho_\infty^{\frac{\gamma+\theta}{2}}(\cdot)\|_{L^\infty} \le C_\eta(1+t)^{-\frac{\gamma+\theta}{2(\gamma+\theta+1)}+\frac{\eta}{4}}$, $t \ge 0$ for any $\eta > 0$.

Remark 1.5. Since the information of the dimension n mainly appear in the index of the radii r, and we consider only the system with a solid core $r \ge a > 0$ in this paper; our results cannot show the effect of the dimension. In [23], we studied the global behavior of the solution to a similar problem with a positive external pressure and without a solid core, and we obtained the stabilization rate estimates for the solution of exponential type. The admissible range of the parameter $\frac{\lambda}{\mu}$ depends on the dimension n in [23]. We will study the system without a solid core $r \ge 0$ and with degenerate viscosity coefficients in the future, and we will guess that stabilization rate estimates of the solution cannot be better than that in Theorem 1.1.

THEOREM 1.2 (continuous dependence). *For each $i = 1, 2$, let (ρ_i, u_i, r_i) be the solution to the system* (1.15)–(1.17) *with the initial data $(\rho_{0i}, u_{0i}, r_{0i})$, which satisfies regularity conditions in Theorem* 1.1. *Then, we have*

$$\int_0^M \left((u_1-u_2)^2 + \rho_1^{1-\theta}\rho_2^{2\theta-4}(\rho_1-\rho_2)^2 + \rho_1^\theta\rho_2^{-1}(r_1-r_2)^2\right)dx$$
$$\le Ce^{Ct}\int_0^M \left((u_{01}-u_{02})^2 + \rho_{01}^{1-\theta}\rho_{02}^{2\theta-4}(\rho_{01}-\rho_{02})^2 + \rho_{01}^\theta\rho_{02}^{-1}(r_{01}-r_{02})^2\right)dx$$

for all $t \ge 0$.

Remark 1.6. Using similar arguments as that in [3], we can easily obtain such continuous dependence of the solution on the initial data and omit the details.

Remark 1.7. If we ignore the influence of self-gravitation, i.e., $f_\infty(m,r) = G\frac{M_0}{r^{n-1}}$, with $M_0 > 0$, then we can also obtain the same results in Theorems 1.1–1.2.

We now briefly review the previous works in this direction. For the related free boundary problem of one-dimensional isentropic fluids with density-dependent viscosity (like $\mu(\rho) = c\rho^\theta$), see [11, 15, 19, 21, 22] and the references therein. For the related stabilization rate estimates of the one-dimensional free boundary problem, see [5, 12, 16, 22], etc. For the spherically symmetric solutions of the Navier–Stokes equations with a free boundary, see [2, 4, 13, 14, 23, 24], etc. Also see Bresch and Desjardins [1], Lions [10], and Vaigant and Kazhikhov [17] for multidimensional isentropic fluids.

The rest of this paper is organized as follows. First, we obtain the existence and the uniqueness of the solution to the stationary problem in section 2. In section 3, we will prove some a priori estimates and extend the local solution in [3] to the global solution in time. In section 4, we obtain the stabilization rate estimates of the solution.

2. The stationary problem. Zlotnik and Ducomet [24] obtained the existence of the positive solution to the stationary problem with a positive external pressure. Using similar arguments as that in [24], we can obtain the following results for the stationary problem without an external pressure. We start with a proof of the existence of a nonnegative solution to the Lagrangian stationary problem.

PROPOSITION 2.1. *If*

$$\gamma > \frac{2n-2}{n} \tag{2.1}$$

or

$$\gamma = \frac{2n-2}{n} \quad \textit{and} \quad \left(\frac{n\gamma}{(\gamma-1)}M^{\frac{\gamma-1}{\gamma}}\right)^{\frac{2n-2}{n}} < \frac{G}{A}\left(\frac{M}{2}+M_0\right), \tag{2.2}$$

or

$$n>2,\ 1<\gamma<\frac{2n-2}{n} \quad \textit{and} \quad \delta_6^{\gamma}\left(a^n+\frac{n\gamma}{\delta_6(\gamma-1)}M^{\frac{\gamma-1}{\gamma}}\right)^{\frac{2n-2}{n}} \le \frac{G}{A}\left(\frac{M}{2}+M_0\right), \tag{2.3}$$

where $\delta_6 = a^{-n}(1-\frac{\gamma n}{2n-2})\frac{2n-2}{\gamma-1}M^{\frac{\gamma-1}{\gamma}}$, *then the Lagrangian stationary problem* (1.18)–(1.19) *has a nonnegative solution* $\rho_\infty \in W^{1,\beta}([0,M])$ *satisfying* $C^{-1}(M-x)^{\frac{1}{\gamma}} \le \rho_\infty(x) \le C(M-x)^{\frac{1}{\gamma}}$, *where* $\beta \in [1, \frac{\gamma}{\gamma-1})$ *is a constant.*

Proof. We introduce the nonlinear operator

$$I : K \to W^{1,\beta}([0,M]),$$

where $K = \{f \in C([0,M]) | f \ge 0, \|\frac{(M-x)^{\frac{1}{\gamma}}}{f(x)}\|_{L^\infty} < \infty, \|\frac{f(x)}{(M-x)^{\frac{1}{\gamma}}}\|_{L^\infty} < \infty,\}$, by setting

$$I(f)(x) = \left(\frac{\int_x^M G\frac{M_0+y}{r_f^{2n-2}(y)}dy}{A}\right)^{\frac{1}{\gamma}}, \text{with } r_f^n(x) = a^n + n\int_0^x f^{-1}(y)dy,\ x\in[0,M].$$

We can restate the problem (1.18)–(1.19) as the fixed-point problem

$$\rho_\infty = I(\rho_\infty). \tag{2.4}$$

For all $f \in K_{\delta_1,\delta_2} = \{f \in K | \delta_1(M-x)^{\frac{1}{\gamma}} \le f(x) \le \delta_2(M-x)^{\frac{1}{\gamma}}\}$, with $0 < \delta_1 \le \delta_2 < \infty$, we have

$$a^n \le r_f^n(x) \le a^n + \frac{n\gamma}{\delta_1(\gamma-1)}M^{\frac{\gamma-1}{\gamma}} := B^n$$

and

$$\left(\frac{G(\frac{M}{2}+M_0)}{AB^{2n-2}}\right)^{\frac{1}{\gamma}}(M-x)^{\frac{1}{\gamma}} \le I(f)(x) \le \left(\frac{G(M+M_0)}{Aa^{2n-2}}\right)^{\frac{1}{\gamma}}(M-x)^{\frac{1}{\gamma}}, x\in[0,M].$$

If $\gamma > \frac{2n-2}{n}$, then $I(K_{\delta_3,\delta_4}) \subset K_{\delta_3,\delta_4}$, where $\delta_4 = (\frac{G(M+M_0)}{Aa^{2n-2}})^{\frac{1}{\gamma}}$ and δ_3 is a positive constant satisfying $\delta_3^{\gamma}(a^n + \frac{n\gamma}{\delta_3(\gamma-1)}M^{\frac{\gamma-1}{\gamma}})^{\frac{2n-2}{n}} \le \frac{G}{A}(\frac{M}{2}+M_0)$. And one can immediately verify that I is a compact operator on K_{δ_3,δ_4}. Since K_{δ_3,δ_4} is a convex closed bounded nonempty subset of $C([0,M])$, the problem (2.4) has a solution $\rho \in K_{\delta_3,\delta_4}$ by Schauder's fixed-point theorem.

Similarly, if $\gamma = \frac{2n-2}{n}$ and $(\frac{n\gamma}{(\gamma-1)}M^{\frac{\gamma-1}{\gamma}})^{\frac{2n-2}{n}} < \frac{G}{A}(\frac{M}{2}+M_0)$, then $I(K_{\delta_5,\delta_4}) \subset K_{\delta_5,\delta_4}$, where $\delta_5 = a^{-n}[(\frac{G}{A}(\frac{M}{2}+M_0))^{\frac{n}{2n-2}} - \frac{n\gamma}{(\gamma-1)}M^{\frac{\gamma-1}{\gamma}}]$, and problem (2.4) has a solution $\rho \in K_{\delta_5,\delta_4}$.

Similarly, if $n>2$, $1<\gamma<\frac{2n-2}{n}$ and $\delta_6^{\gamma}(a^n + \frac{n\gamma}{\delta_6(\gamma-1)}M^{\frac{\gamma-1}{\gamma}})^{\frac{2n-2}{n}} \le \frac{G}{A}(\frac{M}{2}+M_0)$, then $I(K_{\delta_6,\delta_4}) \subset K_{\delta_6,\delta_4}$, and problem (2.4) has a solution $\rho \in K_{\delta_6,\delta_4}$. □

Similar to [24], we say a stationary solution $(\rho_\infty, r_\infty^n)$ is *statically stable* if

$$
\begin{aligned}
J[W] &:= \int_0^M \left(\gamma A\rho_\infty^{1+\gamma}W_x^2 - (2n-2)G(M_0+x)r_\infty^{2-3n}W^2\right)dx \\
&\ge \delta_7\int_0^M \left((M-x)^{\frac{1+\gamma}{\gamma}}W_x^2 + W^2\right)dx
\end{aligned} \tag{2.5}
$$

for some $\delta_7>0$ and all $W\in K_1$,

$$
K_1 = \left\{ f\in C([0,M]) \,\middle|\, f(0)=0, \|(M-x)^{\frac{1}{\gamma}}f'(x)\|_{L^\infty} < \infty, \left\|\frac{1}{(M-x)^{\frac{1}{\gamma}}f'(x)}\right\|_{L^\infty} < \infty \right\}.
$$

Now, the static potential energy takes the following form:

$$
S[V] = \int_0^M \left(\frac{A}{\gamma-1}(V_x)^{1-\gamma} + \int_{\frac{a^n}{n}}^V G(M_0+x)(nh)^{\frac{2-2n}{n}}dh\right)dx. \tag{2.6}
$$

We call

$$
\begin{aligned}
V\in K_2 = \Bigg\{ f\in C([0,M]) \,\Big|\, & f(0) = \frac{a^n}{n}, \|(M-x)^{\frac{1}{\gamma}}f'(x)\|_{L^\infty} < \infty, \\
& \left\|\frac{1}{(M-x)^{\frac{1}{\gamma}}f'(x)}\right\|_{L^\infty} < \infty \Bigg\}
\end{aligned}
$$

is a point of *local quadratic minimum of* S if

$$
S[V+W] - S[V] \ge \delta_8\int_0^M \left((M-x)^{\frac{1+\gamma}{\gamma}}W_x^2 + W^2\right)dx, \tag{2.7}
$$

for all $W\in K_1$ and $\|(M-x)^{\frac{1}{\gamma}}W_x\|_{L^\infty([0,M])} + \|W\|_{L^\infty} \le \delta_9$, for some $\delta_8>0$ and $\delta_9>0$.

PROPOSITION 2.2. *If* $\gamma > \frac{2n-2}{n}$ *and* ρ_∞ *is a solution of the problem* (1.18)–(1.19) *satisfying* $\rho_\infty \in W^{1,\beta}([0,M])$ *and* $C^{-1}(M-x)^{\frac{1}{\gamma}} \le \rho_\infty(x) \le C(M-x)^{\frac{1}{\gamma}}$, *then we have that* (2.5) *and* (2.7) *hold, with* $V = V_\infty = \frac{r_\infty^n}{n}$.

Proof. From $r_\infty \ge a$, $(A\rho_\infty^\gamma)_x = -G\frac{M_0+x}{r_\infty^{2n-2}}$ and $(r_\infty^n)_x = n\rho_\infty^{-1}$, using integration by parts, we have

$$
\begin{aligned}
J[W] &= \int_0^M \left(\gamma A\rho_\infty^{1+\gamma}W_x^2 + (2n-2)A(\rho_\infty^\gamma)_x r_\infty^{-n}W^2\right)dx \\
&= \int_0^M \Big(\gamma A\rho_\infty^{1+\gamma}W_x^2 - 2(2n-2)A\rho_\infty^\gamma r_\infty^{-n}WW_x \\
&\quad + n(2n-2)A\rho_\infty^{\gamma-1}r_\infty^{-2n}W^2\Big)dx \text{ for all } W\in K_1.
\end{aligned}
$$

If $\gamma > \frac{2n-2}{n}$, we have

$$J[W] \geq C^{-1} \int_0^M \left((M-x)^{\frac{1+\gamma}{\gamma}} W_x^2 + (M-x)^{\frac{\gamma-1}{\gamma}} W^2 \right) dx.$$

From $r_\infty \geq a$ and $(A\rho_\infty^\gamma)_x = -G\frac{M_0+x}{r_\infty^{2n-2}}$, using integrating by parts and the Cauchy–Schwarz inequality, we have

$$\begin{aligned} \int_0^M W^2 dx &\leq C \int_0^{\frac{M}{2}} (M-x)^{1-\frac{1}{\gamma}} W^2 dx + C \int_0^M G \frac{M_0+x}{r_\infty^{2n-2}} W^2 dx \\ &= C \int_0^{\frac{M}{2}} (M-x)^{1-\frac{1}{\gamma}} W^2 dx - C \int_0^M A(\rho_\infty^\gamma)_x W^2 dx \\ &\leq C \int_0^M \left((M-x)^{\frac{1+\gamma}{\gamma}} W_x^2 + (M-x)^{\frac{\gamma-1}{\gamma}} W^2 \right) dx, \end{aligned} \tag{2.8}$$

then we can immediately obtain (2.5), with some $\delta_7 = \delta_7(G, A, M_0, M, a, n, \gamma)$.

Similarly, we obtain

$$\begin{aligned} & S[V_\infty + W] - S[V_\infty] \\ &= \frac{1}{2} \int_0^M \Big\{ A[\gamma + O(|(M-x)^{\frac{1}{\gamma}} W_x|)] \rho_\infty^{1+\gamma} W_x^2 \\ &\quad - [2n-2+O(|W|)] G(M_0+x) r_\infty^{2-3n} W^2 \Big\} dx \\ &\geq \frac{\delta_7}{2} \int_0^M \left((M-x)^{\frac{1+\gamma}{\gamma}} W_x^2 + W^2 \right) dx \\ &\quad + \int_0^M \Big\{ O(|(M-x)^{\frac{1}{\gamma}} W_x|) \rho_\infty^{1+\gamma} W_x^2 + O(|W|) G(M_0+x) r_\infty^{2-3n} W^2 \Big\} dx \end{aligned}$$

for all $W \in K_1$. Here, $O(d)$ means $O(d) \to 0$ as $d \to 0$. If $\gamma > \frac{2n-2}{n}$, choosing δ_9 small enough, we can immediately obtain (2.7), with some $(\delta_8, \delta_9)(G, A, M_0, M, a, n, \gamma)$. ∎

Using a similar argument as that in Proposition 2.2, we could obtain the following uniqueness result.

PROPOSITION 2.3. *Let ρ_∞ be a solution obtained in Proposition* 2.1, *and ρ_2 be another solution of the problem* (1.18)–(1.19) *satisfying $\rho_2 \in W^{1,\beta}([0,M])$ and $C^{-1}(M-x)^{\frac{1}{\gamma}} \leq \rho_2(x) \leq C(M-x)^{\frac{1}{\gamma}}$. If $\gamma > \frac{2n-2}{n}$ and $\|(M-x)^{-\frac{1}{\gamma}}(\rho_\infty - \rho_2)(x)\|_{L^\infty} \leq \delta_{10}$ with a small enough positive constant δ_{10}, then we have that $\rho_\infty(x) = \rho_2(x)$, a.e. $x \in [0,M]$.*

Proof. From (1.18)–(1.19), we have

$$\begin{aligned} A\rho_\infty^\gamma(x) &= \int_x^M G \frac{M_0+y}{r_\infty^{2n-2}} dy, \ r_\infty^n(x) = a^n + n \int_0^x \rho_\infty^{-1}(y) dy, \\ A\rho_2^\gamma(x) &= \int_x^M G \frac{M_0+y}{r_2^{2n-2}} dy, \ r_2^n(x) = a^n + n \int_0^x \rho_2^{-1}(y) dy, \end{aligned}$$

and

$$A(\rho_\infty^\gamma - \rho_2^\gamma) = \int_x^M G(M_0+y) \left(r_\infty^{2-2n} - r_2^{2-2n} \right) dy.$$

Multiplying the above equality by $(\rho_\infty^{-1}-\rho_2^{-1})$, integrating over $[0,M]$, and using the fact that $\int_0^M n(\rho_\infty^{-1}-\rho_2^{-1})(x)\int_x^M g(y)dydx = \int_0^M g(r_\infty^n - r_2^n)dx$, we obtain

$$\begin{aligned}
0 &= \int_0^M \left\{ A(\rho_\infty^\gamma - \rho_2^\gamma)(\rho_\infty^{-1}-\rho_2^{-1}) - G\frac{(M_0+x)}{n}(r_\infty^{2-2n}-r_2^{2-2n})(r_\infty^n - r_2^n)\right\} dx \\
&= \int_0^M \Big\{ - A[\gamma + O(|(M-x)^{-\frac{1}{\gamma}}(\rho_\infty-\rho_2)|)]\rho_\infty^{1+\gamma}(\rho_\infty^{-1}-\rho_2^{-1})^2 \\
&\quad - \frac{A}{n^2}[2n-2+O(|r_\infty^n - r_2^n|)](\rho_\infty^\gamma)_x r_\infty^{-n}(r_\infty^n - r_2^n)^2\Big\} dx \\
&\le -C^{-1}\int_0^M \left((M-x)^{\frac{1+\gamma}{\gamma}}(\rho_\infty^{-1}-\rho_2^{-1})^2 + (r_\infty^n - r_2^n)^2\right) dx,
\end{aligned}$$

when $\gamma > \frac{2n-2}{n}$ and δ_{10} is small enough. Thus, we can immediately obtain that $\rho_\infty = \rho_2$. □

Now, we shall use the shooting method to prove the uniqueness of the solution $\rho_\infty \in K$.

PROPOSITION 2.4. *Under the assumption* (2.1)*, the Lagrangian stationary problem* (1.18)–(1.19) *has a unique solution* $\rho_\infty \in K$.

Proof. We consider the Cauchy problem

$$(A\rho^\gamma)_x = -G(M_0+x)(nV)^{\frac{2-2n}{n}},\ (V)_x = \rho^{-1},\ x\in(0,M), \tag{2.9}$$

$$\rho\big|_{x=0} = \sigma,\ V\big|_{x=0} = \frac{a^n}{n} \tag{2.10}$$

for the unknown functions $\rho(\sigma,x)$ and $V(\sigma,x)$, where $\sigma>0$ is the shooting parameter. Thus, for each $\sigma>0$, using the classical ODE theory, there exists a unique solution to the problem (2.9)–(2.10) satisfying $\rho(\sigma,x)>0$ for $x\in[0,M_\sigma)$, where either $\rho\big|_{x=M_\sigma} = 0$ and $M_\sigma\in(0,M)$ or $M_\sigma = M$.

Clearly, if $\rho_\infty\in K$ is a solution to the problem (1.18)–(1.19), then ρ_∞ satisfies (2.9)–(2.10) for some $\sigma_0>0$, and $M_{\sigma_0} = M$. We will show that it is possible only for one value of σ. Using similar arguments as that in [7, section V.3], we obtain that $(\partial_\sigma\rho^\gamma, \partial_\sigma V)$ is well defined and satisfies the linear Cauchy problem

$$A(\partial_\sigma\rho^\gamma)_x = (2n-2)G(M_0+x)(nV)^{\frac{2-3n}{n}}\partial_\sigma V,\ (\partial_\sigma V)_x = -\frac{1}{\gamma}\rho^{-\gamma-1}\partial_\sigma\rho^\gamma,\ x\in[0,M_\sigma), \tag{2.11}$$

$$\partial_\sigma\rho^\gamma\big|_{x=0} = 1,\ \partial_\sigma V\big|_{x=0} = 0. \tag{2.12}$$

It is easy to see that

$$\partial_\sigma\rho^\gamma > 0,\ (\partial_\sigma V)_x < 0,\ \text{and } \partial_\sigma V < 0$$

hold on $(0,M_4)$, where either $\partial_\sigma\rho^\gamma\big|_{x=M_4} = 0$ and $M_4\in(0,M_\sigma)$ or $M_4 = M_\sigma$. We claim that only $M_4 = M_\sigma$ can occur.

Assume that $M_4\in(0,M_\sigma)$. Letting $\phi = A\rho^\gamma(\partial_\sigma V)_x + \frac{n}{2n-2}A\partial_\sigma\rho^\gamma(V)_x$, from (2.9) and (2.11), we have

$$\int_0^{M_4}\phi dx = \left\{A\rho^\gamma\partial_\sigma V + \frac{n}{2n-2}A\partial_\sigma\rho^\gamma V\right\}\Big|_0^{M_4}.$$

By the estimates $\rho(\sigma, M_4) > 0$, $\partial_\sigma \rho^\gamma\big|_{x=M_4} = 0$, $\partial_\sigma V\big|_{x=M_4} < 0$ and the initial conditions (2.10) and (2.12), we get

$$\int_0^{M_4} \phi dx < 0.$$

On the other hand, from (2.9) and (2.11), we have

$$\phi = A\rho^{-1}\partial_\sigma \rho^\gamma \left(\frac{n}{2n-2} - \frac{1}{\gamma}\right) > 0,\ x \in (0, M_4).$$

It is a contradiction.

Thus, we obtain

$$\rho(\sigma, x) > 0,\ \partial_\sigma \rho(\sigma, x) > 0,\ x \in (0, M_\sigma),$$

and M_σ is nondecreasing on $\sigma \in (0, \infty)$. Therefore, for each fixed point $x \in [0, M_b)$, the function $\rho(\sigma, x)$ is strictly increasing on $\sigma \geq b$.

If there exists $\sigma_1 \neq \sigma_0$ such that $M_{\sigma_1} = M_{\sigma_0} = M$ and $\rho(\sigma_1, x) \in K$, then there exists $\min\{\sigma_0, \sigma_1\} < \sigma_2 < \max\{\sigma_0, \sigma_1\}$ such that $0 < \|(M-x)^{-\frac{1}{\gamma}}(\rho(\sigma_2, x) - \rho(\sigma_0, x))\|_{L^\infty} \leq \delta_{10}$. From Proposition 2.3, we have that $\rho(\sigma_2, x) = \rho(\sigma_0, x) = \rho_\infty(x)$, which is a contradiction. Thus, we finish the proof of Proposition 2.4. □

Using the properties of the transformation (1.14) and Propositions 2.1–2.4, we can immediately obtain the following proposition.

PROPOSITION 2.5. *Under the assumption* (2.1)*, the Eulerian stationary problem* (1.12)–(1.13) *has a unique solution* (ρ_∞, l_∞) *satisfying* $\rho_\infty(r) \sim (l_\infty^n - r^n)^{\frac{1}{\gamma-1}}$, $(\rho_\infty)_r < 0$, $a < r < l_\infty$, *with* $l_\infty < +\infty$.

Remark 2.1. The uniqueness of the solution in Proposition 2.5 means that if $(\rho_{\infty 1}, l_{\infty 1})$ and $(\rho_{\infty 2}, l_{\infty 2})$ are two solutions to the Eulerian stationary problem (1.12)–(1.13) with the same total mass M, and satisfy $\rho_{\infty i}(r) \sim (l_{\infty i}^n - r^n)^{\frac{1}{\gamma-1}}$, $i = 1, 2$, then we have that $(\rho_{\infty 1}, l_{\infty 1}) = (\rho_{\infty 2}, l_{\infty 2})$.

3. Global existence. Using similar arguments as that in [3], we obtain the following local existence and uniqueness result and omit the proof.

THEOREM 3.1 (local result). *Under the assumptions in Theorem* 1.1*, there is a positive constant* $T_1 > 0$ *such that the free boundary problem* (1.15)–(1.17) *admits a unique weak solution* $(\rho, u, r)(x, t)$ *on* $[0, M] \times [0, T_1]$ *in the sense that*

$$\rho(x,t), u(x,t), r(x,t) \in L^\infty([0,M] \times [0,T_1]) \cap C^1([0,T_1]; L^2([0,M])),$$

$$\rho^{\theta+1}\partial_x(r^{n-1}u) \in L^\infty([0,M] \times [0,T_1]) \cap C^{\frac{1}{2}}([0,T_1]; L^2([0,M])),$$

$$\partial_x r^{n-1}, \partial_x(r^{n-2}u) \in L^\infty([0,T_1], L^1([0,M])),$$

and the following equations hold:

$$\partial_t \rho = -\rho^2 \partial_x(r^{n-1}u), \qquad \rho(x,0) = \rho_0,$$

$$\partial_t r(x,t) = u(x,t),\ r^n(x,t) = a^n + n\int_0^x \rho^{-1}(y,t)dy, \tag{3.1}$$

$$(r^\beta(\rho^\theta)_x)_t = -\frac{\theta r^{1+\beta-n}}{2c_1+c_2}u_t - \frac{\theta}{2c_1+c_2}\left(Ar^\beta(\rho^\gamma)_x + r^{1+\beta-n}f\right), \tag{3.2}$$

$$
\begin{aligned}
&(2c_1+c_2)\rho^{1+\theta}(r^{n-1}u)_x\\
&= A\rho^\gamma + 2c_1(n-1)\rho^\theta\frac{u}{r} + \int_x^M \left\{-\frac{u_t}{r^{n-1}} + 2c_1(n-1)\rho^\theta\left(\frac{u}{r}\right)_x - \frac{f}{r^{n-1}}\right\}dy,
\end{aligned}
\tag{3.3}
$$

for almost all $x\in[0,M]$, *any* $t\in[0,T_1]$, *where* $\beta=\frac{2(n-1)c_1\theta}{2c_1+c_2}$,

$$
\begin{aligned}
&\int_0^\infty\int_0^M [u\psi_t + (P-\rho(\lambda+2\mu)(r^{n-1}u)_x)(r^{n-1}\psi)_x\\
&+2(n-1)\mu(r^{n-2}u\psi)_x - f(x,r,t)\psi]dxdt + \int_0^M u_0(x)\psi(x,0)dx = 0
\end{aligned}
\tag{3.4}
$$

for any test function $\psi(x,t)\in C_0^\infty((0,M]\times[0,T_1))$. *Furthermore, we have*

$$
\frac{N_1}{3}(1-x)^{\frac{1}{\gamma}} \le \rho(x,t) \le 3N_2(1-x)^{\frac{1}{\gamma}},\ (x,t)\in[0,M]\times[0,T_1],
\tag{3.5}
$$

$$
\begin{aligned}
&(M-x)^{-\frac{1}{\gamma}}\rho(x,t)\in C([0,T_1];L^\infty([0,M])),\\
&(M-x)^{\frac{\gamma-\theta}{2\gamma}}(\rho^\theta)_x,\ \rho_t,\ u_t\in L^\infty([0,T_1];L^2([0,M])),
\end{aligned}
\tag{3.6}
$$

and

$$
\rho^{\frac{\theta+1}{2}}u_{xt}\in L^2([0,M]\times[0,T_1]),\ \rho\partial_x u\in L^\infty([0,M]\times[0,T_1]).
$$

Remark 3.1. From $(1.15)_1$, (3.5), and $\rho\partial_x u\in L^\infty_{t,x}$, we have that $(M-x)^{-\frac{1}{\gamma}}\partial_t\rho\in L^\infty_{tx}$. Thus, (3.6) holds.

Assume the maximum existence time of the weak solution in Theorem 3.1 is T^*. In this section, under the small assumptions on the initial data, we will obtain the following a priori estimates and prove that $T^*=\infty$. In the following, we may assume that $(\rho,u,r)(x,t)$ is suitably smooth since the following estimates are valid for the solutions with the regularities indicated in Theorem 3.1 by using the Friedrichs mollifier.

From (1.9), (1.18), and Proposition 2.1, we could easily obtain the following lemma.

LEMMA 3.1. *Under the assumptions of Theorem* 1.1, *we have*

$$
A\rho_\infty^\gamma(x) = \int_x^M G\frac{M_0+y}{r_\infty^{2n-2}}dy,
\tag{3.7}
$$

$$
C^{-1}(M-x)^{\frac{1}{\gamma}} \le \rho_\infty \le C(M-x)^{\frac{1}{\gamma}},\ r_\infty(x)\in[a,C],
\tag{3.8}
$$

and

$$
\frac{d}{dx}\left(A\rho_\infty^\gamma(x)\right) = -G\frac{M_0+x}{r_\infty^{2n-2}},\ C^{-1}\le(M-x)^{1-\frac{1}{\gamma}}\frac{d}{dx}\rho_\infty(x)\le C
\tag{3.9}
$$

for all $x\in[0,M]$.

LEMMA 3.2. *Under the assumptions of Theorem* 1.1, *we have*

$$
\begin{aligned}
&\frac{d}{dt}\int_0^M\left(\frac{1}{2}u^2 + \frac{A\rho^{\gamma-1}}{\gamma-1} + \int_a^r G\frac{M_0+x}{s^{n-1}}ds\right)dx\\
&+\int_0^M\left\{\left(\frac{2}{n}c_1+c_2\right)\rho^{1+\theta}[\partial_x(r^{n-1}u)]^2 + \frac{2(n-1)}{n}c_1\rho^{1+\theta}\left(r^{n-1}u_x - \frac{u}{r\rho}\right)^2\right\}dx\\
&= -\int_0^M \Delta f u dx,\ t\in[0,T^*).
\end{aligned}
\tag{3.10}
$$

Proof. Multiplying $(1.15)_2$ by u, integrating the resulting equation over $[0, M]$, and using integration by parts and the boundary conditions (1.17), we obtain

(3.11)
$$\frac{d}{dt}\int_0^M \frac{1}{2}u^2 dx + \int_0^M \left\{(2c_1+c_2)\rho^{1+\theta}[\partial_x(r^{n-1}u)]^2 - 2c_1(n-1)\rho^\theta \partial_x(r^{n-2}u^2)\right\} dx$$
$$= \int_0^M A\rho^\gamma \partial_x(r^{n-1}u)dx - \int_0^M f u dx.$$

From (1.15), we have

$$\int_0^M A\rho^\gamma \partial_x(r^{n-1}u)dx = -\frac{d}{dt}\int_0^M \frac{A}{\gamma-1}\rho^{\gamma-1}dx, \tag{3.12}$$

$$-\int_0^M f u dx = -\frac{d}{dt}\int_0^M \int_a^r G\frac{M_0+x}{s^{n-1}}dsdx - \int_0^M \Delta f u dx, \tag{3.13}$$

and

$$\begin{aligned}&(2c_1+c_2)\rho^{1+\theta}[\partial_x(r^{n-1}u)]^2 - 2c_1(n-1)\rho^\theta\partial_x(r^{n-2}u^2)\\ &= \left(\frac{2}{n}c_1+c_2\right)\rho^{1+\theta}[\partial_x(r^{n-1}u)]^2 + \frac{2(n-1)}{n}c_1\rho^{1+\theta}\left(r^{n-1}u_x - \frac{u}{r\rho}\right)^2.\end{aligned} \tag{3.14}$$

From (3.11)–(3.14), we can immediately obtain (3.10). ∎

Now, using the classical continuation method, we will obtain the estimate of $\|(M-x)^{-\frac{1}{\gamma}}(\rho-\rho_\infty)\|_{L^\infty}$.

Claim 1. *Under the assumptions of Theorem* 1.1*, for any* $T \in (0, T^*)$*, if*

$$I(t) = \|g(\cdot,t) - g_\infty\|_{L^\infty} \le 2\epsilon_1 \ \forall\ t \in [0,T], \tag{3.15}$$

where $g(x,t) = (M-x)^{-\frac{1}{\gamma}}\rho(x,t)$ *and* $g_\infty(x) = (M-x)^{-\frac{1}{\gamma}}\rho_\infty(x)$*, then*

$$I(t) \le \epsilon_1 \ \forall\ t \in [0,T], \tag{3.16}$$

where

$$\epsilon_1 = \epsilon_0 + C_{10}\epsilon_0^{\frac{\theta}{\gamma}2^{-N_4-1}},$$

and positive constants N_4 *and* C_{10} *are defined in Lemmas* 3.6 *and* 3.8*, respectively.*

Using the results in Lemmas 3.3–3.8, we can finish the proof of Claim 1.

Lemma 3.3. *Under the assumptions of Theorem* 1.1 *and* (3.15)*, if* ϵ_1 *is small enough, then there exists a positive constant* $C_1 = C_1(G, A, M_0, M, a, n, \gamma)$ *such that*

$$C_1^{-1}(M-x)^{\frac{1}{\gamma}} \le \rho(x,t) \le C_1(M-x)^{\frac{1}{\gamma}}, \tag{3.17}$$

$$r(x,t) \in [a, C_1] \tag{3.18}$$

for all $t \in [0,T]$ *and* $x \in [0,M]$.

Proof. From $(1.15)_3$, (3.15), and Lemma 3.1, we can easily obtain the estimate (3.17) and (3.18), when $4\epsilon_1 < \min_{x\in[0,M]} g_\infty$. ∎

LEMMA 3.4. *Under the assumptions of Lemma* 3.3*, if* ϵ_1 *is small enough, then there exists a positive constant* $C_2 = C_2(G, A, M_0, M, a, n, \gamma, \theta, c_1, c_2)$ *such that*

$$\int_0^M \left\{u^2 + (M-x)^{\frac{\gamma-1}{\gamma}}(g-g_\infty)^2 + (r-r_\infty)^2\right\} dx \le C_2\epsilon_0^2, \tag{3.19}$$

and

$$\int_0^t \|u(\cdot,s)\|_{L^\infty}^2 ds + \int_0^t \int_0^M \left(\rho^{\theta+1}u_x^2 + \rho^{\theta-1}u^2\right)(x,s)dxds \le C_2\epsilon_0^2 \tag{3.20}$$

for all $t \in [0,T]$.

Proof. From (2.6), (3.7), and (3.10), we have

$$\begin{aligned}
&\frac{d}{dt}\left(\int_0^M \frac{1}{2}u^2dx + S[V] - S[V_\infty]\right) \\
&+ \int_0^M \left\{\left(\frac{2}{n}c_1 + c_2\right)\rho^{1+\theta}[\partial_x(r^{n-1}u)]^2 + \frac{2(n-1)}{n}c_1\rho^{1+\theta}\left(r^{n-1}u_x - \frac{u}{r\rho}\right)^2\right\} dx \\
&= -\int_0^M \Delta f u dx,
\end{aligned} \tag{3.21}$$

where $V_\infty = \frac{r_\infty^n}{n}$ and $V = \frac{r^n}{n}$. From (2.7), (3.17)–(3.18), and Proposition 2.2, we have

$$\begin{aligned}
&C^{-1}\int_0^M (M-x)^{\frac{\gamma-1}{\gamma}}(g-g_\infty)^2 + (r-r_\infty)^2 dx \\
&\le S[V] - S[V_\infty] \le C\int_0^M (M-x)^{\frac{\gamma-1}{\gamma}}(g-g_\infty)^2 + (r-r_\infty)^2 dx,
\end{aligned} \tag{3.22}$$

when $\|(M-x)^{\frac{1}{\gamma}}(\rho^{-1} - \rho_\infty^{-1})\|_{L_x^\infty} + \|\frac{1}{n}(r^n - r_\infty^n)\|_{L_x^\infty} \le C_3\epsilon_1 \le \delta_9$. From (1.24), (3.17)–(3.18), and (3.21)–(3.22), we obtain

$$\begin{aligned}
&\int_0^M \left\{u^2 + (M-x)^{\frac{\gamma-1}{\gamma}}(g-g_\infty)^2 + (r-r_\infty)^2\right\} dx \\
&+ \int_0^t \int_0^M \left\{\rho^{\theta+1}u_x^2 + \rho^{\theta-1}u^2\right\} dxds \\
&\le C\epsilon_0^2 + C\int_0^t f_1(s)\|u(\cdot,s)\|_{L^\infty} ds.
\end{aligned} \tag{3.23}$$

Since $\theta \in (0, \gamma-1)$, we obtain

$$\begin{aligned}
|u(x,t)| &= \left|\int_0^x u_x dy\right| \le C\left(\int_0^x \rho^{\theta+1}u_x^2 dy\right)^{\frac{1}{2}}\left(\int_0^x \rho^{-\theta-1}dy\right)^{\frac{1}{2}} \\
&\le C\left(\int_0^x \rho^{\theta+1}u_x^2 dy\right)^{\frac{1}{2}}\left(\int_0^x (M-y)^{-\frac{\theta+1}{\gamma}}dy\right)^{\frac{1}{2}} \le C\left(\int_0^x \rho^{\theta+1}u_x^2 dy\right)^{\frac{1}{2}}
\end{aligned} \tag{3.24}$$

and

$$C\int_0^t f_1(s)\|u(\cdot,s)\|_{L^\infty} ds \le \frac{1}{2}\int_0^t \int_0^M \rho^{\theta+1}u_x^2 dyds + C^2\int_0^t f_1^2 dt. \tag{3.25}$$

From (1.23) and (3.23)–(3.25), we can immediately obtain (3.19)–(3.20). ∎

LEMMA 3.5. *Under the assumptions of Lemma* 3.3*, if* ϵ_1 *is small enough, then there exists a positive constant* $C_4 = C_4(G, A, M_0, M, a, n, \gamma, \theta, c_1, c_2)$ *such that*

$$\begin{aligned}&(1+t)^\alpha \int_0^M \rho_\infty^{\theta-1}(g-g_\infty)^2 dx\\ &+ \int_0^t \int_0^M (1+s)^\alpha \left[\rho_\infty^{\gamma-1}(g-g_\infty)^2 + (r-r_\infty)^2\right] dxds \le C_4\epsilon_0\end{aligned} \tag{3.26}$$

for all $t \in [0,T]$*, where* $\alpha = -\frac{5}{8}$.

Proof. Multiplying $(1.15)_2$ by $(1+t)^\alpha r^{1-n}(\frac{r^n}{n} - \frac{r_\infty^n}{n})$, and integrating over $[0,M]$, using integration by parts and the boundary conditions (1.17), we obtain

$$\begin{aligned}&(1+t)^\alpha \int_0^M \left[A(\rho_\infty^\gamma - \rho^\gamma)(\rho^{-1} - \rho_\infty^{-1}) + G(M_0+x)(r^{2-2n} - r_\infty^{2-2n})\left(\frac{r^n}{n} - \frac{r_\infty^n}{n}\right)\right] dx\\ &= -(1+t)^\alpha \int_0^M \frac{u_t}{r^{n-1}}\left(\frac{r^n}{n} - \frac{r_\infty^n}{n}\right) dx - (1+t)^\alpha \int_0^M \Delta f r^{1-n}\left(\frac{r^n}{n} - \frac{r_\infty^n}{n}\right) dx\\ &+ (1+t)^\alpha \int_0^M (2c_1+c_2)\rho^{1+\theta}\partial_x(r^{n-1}u)(\rho_\infty^{-1} - \rho^{-1}) dx\\ &+ (1+t)^\alpha \int_0^M 2c_1(n-1)\rho^\theta \left(\frac{u}{r}\left(\frac{r^n}{n} - \frac{r_\infty^n}{n}\right)\right)_x dx := \sum_{i=1}^4 B_i.\end{aligned} \tag{3.27}$$

We can rewrite the left-hand side (L.H.S.) of (3.27) as follows:

$$\begin{aligned}\text{L.H.S. of (3.27)} = (1+t)^\alpha \int_0^M \Bigg[&A(\gamma + O(\epsilon_1))\rho_\infty^{\gamma+1}(\rho^{-1} - \rho_\infty^{-1})^2\\ &-(2n-2+O(\epsilon_1))G(M_0+x)r_\infty^{2-3n}\left(\frac{r^n}{n} - \frac{r_\infty^n}{n}\right)^2\Bigg] dx.\end{aligned}$$

Similar to (2.5), we have

$$\text{L.H.S. of (3.27)} \ge C_5(1+t)^\alpha \int_0^M \left[\rho_\infty^{\gamma-1}(g-g_\infty)^2 + (r-r_\infty)^2\right] dx, \tag{3.28}$$

when $\epsilon_1 \le \delta_{10}$ is small enough.

Using (3.17)–(3.19), integration by parts, and Hölder's inequality, we can estimate B_i as follows:

$$\begin{aligned}B_1 &= -\frac{d}{dt}\int_0^M (1+t)^\alpha \frac{u}{r^{n-1}}\left(\frac{r^n}{n} - \frac{r_\infty^n}{n}\right) dx + \alpha(1+t)^{\alpha-1}\int_0^M \frac{u}{r^{n-1}}\left(\frac{r^n}{n} - \frac{r_\infty^n}{n}\right) dx\\ &\quad + (1+t)^\alpha \int_0^M u^2\left(\frac{1}{n} + \frac{(n-1)r_\infty^n}{nr^n}\right) dx\\ &\le -\frac{d}{dt}\int_0^M (1+t)^\alpha \frac{u}{r^{n-1}}\left(\frac{r^n}{n} - \frac{r_\infty^n}{n}\right) dx + C\int_0^M u^2 dx + C\epsilon_0^2(1+t)^{\alpha-1},\end{aligned} \tag{3.29}$$

$$B_2 \le C\epsilon_0(1+t)^{\alpha} f_1, \tag{3.30}$$

$$\begin{aligned} B_3 &= -\frac{2c_1+c_2}{\theta}\int_0^M (\rho^{\theta})_t (1+t)^{\alpha}\left(\frac{1}{\rho_\infty}-\frac{1}{\rho}\right)dy \\ &= -\frac{2c_1+c_2}{\theta}\int_0^M \partial_t h(\rho,\rho_\infty)(1+t)^{\alpha}dx \\ &= -\frac{2c_1+c_2}{\theta}\frac{d}{dt}\int_0^M h(\rho,\rho_\infty)(1+t)^{\alpha}dx + \frac{\alpha(2c_1+c_2)}{\theta}\int_0^M h(\rho,\rho_\infty)(1+t)^{\alpha-1}dx, \end{aligned} \tag{3.31}$$

where $h(\rho,\rho_\infty)=\int_{\rho_\infty}^{\rho}\theta s^{\theta-1}(\frac{1}{\rho_\infty}-\frac{1}{s})ds \sim \rho_\infty^{\theta-1}(g-g_\infty)^2$ and

$$\begin{aligned} B_4 &\le C(1+t)^{\alpha}\int_0^M \left[\rho^{\theta}|u_x| + \rho^{\theta-1}|u|\right]dx \\ &\le C(1+t)^{\alpha}\left[\int_0^M \left(\rho^{\theta+1}u_x^2+\rho^{\theta-1}u^2\right)dx\right]^{\frac{1}{2}}\left[\int_0^M (M-x)^{\frac{\theta-1}{\gamma}}\right]^{\frac{1}{2}} \\ &\le C(1+t)^{\alpha}\left[\int_0^M \left(\rho^{\theta+1}u_x^2+\rho^{\theta-1}u^2\right)dx\right]^{\frac{1}{2}}, \end{aligned} \tag{3.32}$$

since $\gamma+\theta-1>0$. From (3.27)–(3.32), we get

$$\begin{aligned} &\frac{d}{dt}\int_0^M (1+t)^{\alpha}\left\{\frac{u}{r^{n-1}}\left(\frac{r^n}{n}-\frac{r_\infty^n}{n}\right)+\frac{2c_1+c_2}{\theta}h(\rho,\rho_\infty)\right\}dx \\ &+C^{-1}\int_0^M (1+t)^{\alpha-1}\rho_\infty^{\theta-1}(g-g_\infty)^2 + (1+t)^{\alpha}\left\{\rho_\infty^{\gamma-1}\left[(g-g_\infty)^2+(r-r_\infty)^2\right]\right\}dx \\ &\le C(1+t)^{\alpha}\left[\int_0^M \rho_\infty^{\theta+1}u_x^2dx + \|u(\cdot,t)\|_{L^\infty}^2\right]^{\frac{1}{2}} + C\epsilon_0(1+t)^{\alpha}f_1 \\ &+C\int_0^M u^2dx + C\epsilon_0^2(1+t)^{\alpha-1}. \end{aligned}$$

And using (1.23), (3.17)–(3.20), and Hölder's inequality, we can immediately obtain (3.26). □

Let $\epsilon_2 \in (0,\min\{\frac{1}{4},\ \frac{\gamma-\theta-1}{\gamma-\theta},\frac{\gamma-1}{2(3\gamma-1)}\})$ be a constant. Define $\{\beta_j\}$ and $\{\alpha_j\}$ by $\beta_{j+1}=\frac{\beta_j}{2}+\frac{1}{2}-\frac{\epsilon_2}{4}$, $\alpha_j=\frac{\beta_j}{2}-\frac{1}{2}-\frac{\epsilon_2}{4}$ and $\alpha_0=\alpha=-\frac{5}{8}$, $j=0,1,\dots$. Let N_4 be an integer satisfying $\beta_{N_4}\in[1-\epsilon_2,1-\frac{3\epsilon_2}{4})$ and $\alpha_{N_4}\in(-\epsilon_2,-\frac{\epsilon_2}{4})$. It is easy to see that $\beta_0=-\frac{1}{4}+\frac{\epsilon_2}{2}<0$, $\alpha_j\in[-\frac{5}{8},-\frac{\epsilon_2}{4})$ and $\beta_j\in(-\frac{1}{4},1-\frac{3\epsilon_2}{4})$, $j=0,1,\dots,N_4$. Then, the following lemma can be proved by induction.

LEMMA 3.6. *Under the assumptions of Lemma* 3.3, *if* ϵ_1 *is small enough, then there exists a positive constant* $C_7=C_7(G,A,M_0,M,a,n,\gamma,\theta,c_1,c_2)$ *such that*

$$\int_0^M \left\{u^2+(M-x)^{\frac{\gamma-1}{\gamma}}(g-g_\infty)^2+(r-r_\infty)^2\right\}dx \le C_7\epsilon_0^{2^{1-N_4}}(1+t)^{\epsilon_2-1}, \tag{3.33}$$

$$\int_0^t (1+s)^{1-\epsilon_2}\|u(\cdot,s)\|_{L^\infty}^2 ds + \int_0^t\int_0^M (1+s)^{1-\epsilon_2}\left(\rho^{\theta+1}u_x^2+\rho^{\theta-1}u^2\right)dxds \le C_7\epsilon_0^{2^{1-N_4}}, \tag{3.34}$$

and

(3.35)
$$\int_0^M \frac{(M-x)^{\frac{\theta-1}{\gamma}}}{(1+t)^{\epsilon_2}}(g-g_\infty)^2dx+\int_0^t\int_0^M \frac{\rho_\infty^{\gamma-1}(g-g_\infty)^2+(r-r_\infty)^2}{(1+s)^{\epsilon_2}}dxds\le C_7\epsilon_0^{2^{-N_4}}$$

for all $t\in[0,T]$.

Proof. The following estimates can be proved by induction:

$$\int_0^M \left\{u^2+(M-x)^{\frac{\gamma-1}{\gamma}}(g-g_\infty)^2+(r-r_\infty)^2\right\}dx\le C_{j,\epsilon_2}\epsilon_0^{2^{1-j}}(1+t)^{-\beta_j}, \tag{3.36}$$

(3.37)
$$\int_0^t(1+s)^{\beta_j}\|u(\cdot,s)\|_{L^\infty}^2ds+\int_0^t\int_0^M(1+s)^{\beta_j}\left(\rho^{\theta+1}u_x^2+\rho^{\theta-1}u^2\right)(x,s)dxds\le C_{j,\epsilon_2}\epsilon_0^{2^{1-j}},$$

and

$$\begin{aligned}&(1+t)^{\alpha_j}\int_0^M\rho_\infty^{\theta-1}(g-g_\infty)^2dx\\&+\int_0^t\int_0^M(1+s)^{\alpha_j}\left[\rho_\infty^{\gamma-1}(g-g_\infty)^2+(r-r_\infty)^2\right]dxds\le C_{j,\epsilon_2}\epsilon_0^{2^{-j}}\end{aligned} \tag{3.38}$$

for all $t\ge0$, where C_{j,ϵ_2} is a constant depending on j and ϵ_2, $j=0,1,\dots,N_4$.

From (3.19)–(3.20) and (3.26), we obtain that (3.36)–(3.38) hold with $j=0$. Now, suppose that (3.36)–(3.38) hold with $j=k\ge0$. To show (3.36)–(3.37) hold with $j=k+1$, from (3.21), we have

$$\begin{aligned}&\frac{d}{dt}\left\{(1+t)^{\beta_{k+1}}\left(\int_0^M\frac{1}{2}u^2dx+S[V]-S[V_\infty]\right)\right\}\\&+(1+t)^{\beta_{k+1}}\int_0^M\left(\frac{2}{n}c_1+c_2\right)\rho^{1+\theta}[\partial_x(r^{n-1}u)]^2+\frac{2(n-1)}{n}c_1\rho^{1+\theta}\left(r^{n-1}u_x-\frac{u}{r\rho}\right)^2dx\\&=\beta_{k+1}(1+t)^{\alpha_k}\left(\int_0^M\frac{1}{2}u^2(x,t)dx+S[V]-S[V_\infty]\right)-(1+t)^{\beta_{k+1}}\int_0^M\Delta fudx.\end{aligned}$$

Integrating the above equality in $[0,t]$, using (1.24), (3.17)–(3.20), (3.22), and (3.38) with $j=k$ and the fact that $\alpha_k<0$, we obtain

$$\begin{aligned}&(1+t)^{\beta_{k+1}}\int_0^M\left\{u^2(x,t)+(M-x)^{\frac{\gamma-1}{\gamma}}(g-g_\infty)^2+(r-r_\infty)^2\right\}dx\\&+\int_0^t\int_0^M(1+s)^{\beta_{k+1}}\left\{\rho^{\theta+1}u_x^2+\rho^{\theta-1}u^2\right\}dxds\\&\le C\epsilon_0^{2^{-k}}+C\int_0^t(1+s)^{\beta_{k+1}}f_1(s)\|u(\cdot,s)\|_{L^\infty}ds.\end{aligned} \tag{3.39}$$

From (1.23) and (3.25), we can immediately obtain (3.36)–(3.37) with $j=k+1$.

To show (3.38) with $j = k+1$, from (3.27)–(3.28), we have

$$
\begin{aligned}
&(1+t)^{\alpha_{k+1}} \int_0^M \Big[A(\rho_\infty^\gamma - \rho^\gamma)(\rho^{-1} - \rho_\infty^{-1}) \\
&+ G(M_0+x)(r^{2-2n} - r_\infty^{2-2n}) \left(\frac{r^n}{n} - \frac{r_\infty^n}{n} \right) \Big] dx \\
&= -(1+t)^{\alpha_{k+1}} \int_0^M \frac{u_t}{r^{n-1}} \left(\frac{r^n}{n} - \frac{r_\infty^n}{n} \right) dx - (1+t)^{\alpha_{k+1}} \int_0^M \Delta f r^{1-n} \left(\frac{r^n}{n} - \frac{r_\infty^n}{n} \right) dx \\
&+ (1+t)^{\alpha_{k+1}} \int_0^M (2c_1 + c_2) \rho^{1+\theta} \partial_x (r^{n-1} u)(\rho_\infty^{-1} - \rho^{-1}) dx \\
&+ (1+t)^{\alpha_{k+1}} \int_0^M 2c_1 (n-1) \rho^\theta \left(\frac{u}{r} \left(\frac{r^n}{n} - \frac{r_\infty^n}{n} \right) \right)_x dx := \sum_{i=1}^4 E_i, \qquad (3.40)
\end{aligned}
$$

and

$$
\text{L.H.S. of (3.40)} \geq C_8 (1+t)^{\alpha_{k+1}} \int_0^M \left[\rho_\infty^{\gamma-1} (g - g_\infty)^2 + (r - r_\infty)^2 \right] dx. \qquad (3.41)
$$

Similar to (3.29)–(3.32), applying the estimates (3.17)–(3.19), integration by parts, Hölder's inequality, and the fact that $\alpha_{k+1} < 0$, we can estimate E_i as follows:

$$
E_1 \leq -\frac{d}{dt} \int_0^M (1+t)^{\alpha_{k+1}} \frac{u}{r^{n-1}} \left(\frac{r^n}{n} - \frac{r_\infty^n}{n} \right) dx + C \|u\|_{L_x^\infty}^2 + C \epsilon_0^2 (1+t)^{\alpha_{k+1}-1}, \qquad (3.42)
$$

$$
E_2 \leq C \epsilon_0 f_1 (1+t)^{\alpha_{k+1}}, \qquad (3.43)
$$

$$
\begin{aligned}
E_3 = &-\frac{2c_1 + c_2}{\theta} \frac{d}{dt} \int_0^M h(\rho, \rho_\infty)(1+t)^{\alpha_{k+1}} dx \\
&+ \frac{\alpha_{k+1}(2c_1 + c_2)}{\theta} \int_0^M h(\rho, \rho_\infty)(1+t)^{\alpha_{k+1}-1} dx, \qquad (3.44)
\end{aligned}
$$

and

$$
E_4 \leq C (1+t)^{-\frac{1}{2} - \frac{\epsilon_2}{4}} \left[(1+t)^{\beta_{k+1}} \int_0^M \rho^{\theta+1} u_x^2 dx + \|u(\cdot,t)\|_{L^\infty}^2 \right]^{\frac{1}{2}}. \qquad (3.45)
$$

Using (1.23), (3.40)–(3.45), (3.36)–(3.37) with $j = k+1$ and Hölder's inequality, we get

$$
\begin{aligned}
&\int_0^M (1+t)^{\alpha_{k+1}} \rho_\infty^{\theta-1} (g - g_\infty)^2 dx + \int_0^t \int_0^M (1+s)^{\alpha_{k+1}-1} \rho_\infty^{\theta-1} (g - g_\infty)^2 dx ds \\
&+ \int_0^t \int_0^M (1+s)^{\alpha_{k+1}} \left\{ \rho_\infty^{\gamma-1} \left[(g - g_\infty)^2 + (r - r_\infty)^2 \right] \right\} dx ds \\
&\leq C (1+t)^{\alpha_{k+1}} \int_0^M |u||r - r_\infty| dx + C \int_0^M |u_0||r_0 - r_\infty| dx \\
&+ C \int_0^t \left[f_1 (1+s)^{\alpha_{k+1}} + \epsilon_0^2 (1+s)^{\alpha_{k+1}-1} + \|u\|_{L_x^\infty}^2 \right] ds \\
&+ C \int_0^t (1+s)^{-\frac{1}{2} - \frac{\epsilon_2}{4}} \left[(1+t)^{\beta_{k+1}} \left(\int_0^M \rho^{\theta+1} u_x^2 dx + \|u(\cdot,t)\|_{L^\infty}^2 \right) \right]^{\frac{1}{2}} ds \\
&\leq C \epsilon_0^{2^{-(k+1)}} \qquad (3.46)
\end{aligned}
$$

and finish the proof of (3.38) with $j = k+1$. Thus, we show that (3.36)–(3.38) hold for $j = 0, 1, \ldots, N_4$ and obtain (3.33)–(3.35). ∎

From Lemma 3.6, we can obtain the following estimate of the weighted L^2-norm of $g - g_\infty$.

LEMMA 3.7. *Under the assumptions of Lemma* 3.3*, then there exists a positive constant* $C_9 = C_9(G, A, M_0, M, a, n, \gamma, \theta, c_1, c_2)$ *such that*

$$\int_0^M (M-x)^{\frac{\theta-1+(\gamma-\theta)\epsilon_2}{\gamma}}(g-g_\infty)^2 dx \le C_9\epsilon_0^{2^{-N_4}},\ t\in[0,T]. \tag{3.47}$$

Proof. Using (3.33), (3.35), and Hölder's inequality, we have

$$\begin{aligned}
&\int_0^M (M-x)^{\frac{\theta-1+(\gamma-\theta)\epsilon_2}{\gamma}}(g-g_\infty)^2 dx\\
&\le C\left[\int_0^M (1+t)^{1-\epsilon_2}(M-x)^{\frac{\gamma-1}{\gamma}}(g-g_\infty)^2 dx\right]^{\epsilon_2}\left[\int_0^M \frac{(M-x)^{\frac{\theta-1}{\gamma}}}{(1+t)^{\epsilon_2}}(g-g_\infty)^2 dx\right]^{1-\epsilon_2}\\
&\le C\epsilon_0^{2^{-N_4}}. \qquad ∎
\end{aligned}$$

Then, using a similar argument as that in [22], we can finish the proof of Claim 1 in the following lemma.

LEMMA 3.8. *Under the assumptions of Lemma* 3.3*, if* ϵ_0 *is small enough, then there exists a positive constant* $C_{10} = C_{10}(G, A, M_0, M, a, n, \gamma, \theta, c_1, c_2)$ *such that*

$$|g(x,t) - g_\infty(x)| \le C_{10}\epsilon_0^{\frac{\theta}{\gamma}2^{-N_4-1}} \quad \text{for all } (x,t)\in[0,M]\times[0,T]. \tag{3.48}$$

Proof. From (3.2), for any fixed $x \in [0, M]$, we have

$$\begin{aligned}
&I_1(x,t) + \frac{\theta}{2c_1+c_2}\int_0^t Ar^\beta(x,\tau)(\rho^\gamma(x,\tau) - \rho_\infty^\gamma(x))d\tau\\
&= r_0^\beta(x)\rho_0^\theta(x) + I_2(x,t),\ x\in[0,M],\ t\in[0,T],
\end{aligned} \tag{3.49}$$

where

$$\begin{aligned}
I_1(x,t) = {}& r_\infty^\beta(x)\rho^\theta(x,t) - (r_\infty^\beta(x) - r^\beta(x,t))\rho^\theta(x,t)\\
&+ \int_x^M \beta[(r^{\beta-n}\rho^{\theta-1})(y,t) - (r_0^{\beta-n}\rho_0^{\theta-1})(y)]dy\\
&- \frac{\theta}{2c_1+c_2}\int_x^M [(r^{\beta-n+1}u)(y,t) - (r_0^{\beta-n+1}u_0)(y)]dy\\
&+ \frac{\theta(\beta-n+1)}{2c_1+c_2}\int_0^t\int_x^M r^{\beta-n}u^2 dy d\tau
\end{aligned}$$

and

$$\begin{aligned}
&I_2(x,t)\\
&= -\frac{\theta A\beta}{2c_1+c_2}\int_0^t\int_x^M r^{\beta-n}\frac{\rho^\gamma - \rho_\infty^\gamma}{\rho}dy d\tau\\
&\quad + \frac{\theta}{2c_1+c_2}\int_0^t\int_x^M \left\{r^\beta G(M_0+y)(r^{2-2n} - r_\infty^{2-2n}) + r^{\beta-n+1}\Delta f\right\}dy d\tau.
\end{aligned}$$

Using (3.17)–(3.18), (3.47), Hölder's inequality, and the condition $\epsilon_2 < \frac{\gamma-\theta-1}{\gamma-\theta}$, i.e., $\frac{\theta+1+(\gamma-\theta)\epsilon_2}{\gamma} < 1$, we have

$$\begin{aligned}
&|(r-r_\infty)(x)| \le C|r^n - r_\infty^n| \\
&\le C\int_0^x |\rho^{-1}-\rho_\infty^{-1}|dy \le C\int_0^x (M-y)^{-\frac{1}{\gamma}}|g-g_\infty|dy \\
&\le C\left(\int_0^x (M-y)^{\frac{\theta-1+(\gamma-\theta)\epsilon_2}{\gamma}}(g-g_\infty)^2 dy\right)^{\frac{1}{2}}\left(\int_0^x (M-y)^{-\frac{\theta+1+(\gamma-\theta)\epsilon_2}{\gamma}}dy\right)^{\frac{1}{2}} \\
&\le C\epsilon_0^{2^{-N_4-1}} \qquad (3.50)
\end{aligned}$$

and

$$\begin{aligned}
&\int_x^M |\rho^{\theta-1}-\rho_\infty^{\theta-1}|dy \le C\int_x^M (M-y)^{\frac{\theta-1}{\gamma}}|g-g_\infty|dy \\
&\le C\left(\int_x^M (M-y)^{\frac{\theta-1+(\gamma-\theta)\epsilon_2}{\gamma}}(g-g_\infty)^2 dy\right)^{\frac{1}{2}}\left(\int_x^M (M-y)^{\frac{2\theta}{\gamma}-\frac{\theta+1+(\gamma-\theta)\epsilon_2}{\gamma}}dy\right)^{\frac{1}{2}} \\
&\le C\epsilon_0^{2^{-N_4-1}}(M-x)^{\frac{\theta}{\gamma}}. \qquad (3.51)
\end{aligned}$$

From the fact $\theta \in (0, \frac{\gamma}{2}]$ and the estimate (3.18)–(3.19), we have

$$\begin{aligned}
&\left|-\frac{\theta}{2c_1+c_2}\int_x^M [(r^{\beta-n+1}u)(y,t) - (r_0^{\beta-n+1}u_0)(y)]dy\right| \\
&\le C(M-x)^{\frac{1}{2}}(\|u\|_{L_x^2} + \|u_0\|_{L_x^2}) \\
&\le C\epsilon_0^{2^{-N_4-1}}(M-x)^{\frac{\theta}{\gamma}},\ x\in[0,M]. \qquad (3.52)
\end{aligned}$$

Thus, from (1.23), (3.17)–(3.20), and (3.50)–(3.52), we obtain

$$|I_1(x,t) - r_\infty^\beta \rho^\theta| \le C_{1,1}(M-x)^{\frac{\theta}{\gamma}}\epsilon_0^{2^{-N_4-1}}, \qquad (3.53)$$

and

$$|I_2(x,t_1) - I_2(x,t_2)| \le C_{1,2}(M-x)\epsilon_0^{2^{-N_4-1}}|t_2-t_1|,\ x\in[0,M]. \qquad (3.54)$$

Claim 2. *For any fixed $x \in [0,M]$, we have*

$$\begin{aligned}
I_1(x,t) &\ge \min\left\{I_1(x,0), r_\infty^\beta\left(\rho_\infty^\gamma - \frac{C_{1,2}}{C_{1,3}}\epsilon_0^{2^{-N_4-1}}(M-x)\right)^{\frac{\theta}{\gamma}} - C_{1,1}\epsilon_0^{2^{-N_4-1}}(M-x)^{\frac{\theta}{\gamma}}\right\} \\
&:= M_{1,1},
\end{aligned}$$

where $C_{1,3} := \frac{A\theta a^\beta}{2c_1+c_2} \le \frac{A\theta r^\beta}{2c_1+c_2}$.

Proof of Claim 2. If not, there exists $t_{1,1} > 0$ such that $I_1(x,t_{1,1}) < M_{1,1}$, then we can find $t_{1,2} \in (0,t_{1,1})$ such that $I_1(x,t_{1,2}) = M_{1,1}$ and $I_1(x,t) < M_{1,1}$ for all $t \in (t_{1,2}, t_{1,1})$. From (3.54), we have

$$I_1(x,t_{1,1}) - I_1(x,t_{1,2}) + \frac{A\theta}{2c_1+c_2}\int_{t_{1,2}}^{t_{1,1}} r^\beta(\rho^\gamma - \rho_\infty^\gamma) \ge -C_{1,2}\epsilon_0^{2^{-N_4-1}}(M-x)(t_{1,1}-t_{1,2}).$$

From (3.53), we have

$$\rho^\theta(x,t) = r_\infty^{-\beta}(I_1(x,t) - (I_1(x,t) - r_\infty^\beta \rho^\theta))$$
$$\le r_\infty^{-\beta}(M_{1,1} + C_{1,1}\epsilon_0^{2^{-N_4-1}}(M-x)^{\frac{\theta}{\gamma}}) \le \left(\rho_\infty^\gamma - \frac{C_{1,2}}{C_{1,3}}\epsilon_0^{2^{-N_4-1}}(M-x)\right)^{\frac{\theta}{\gamma}}$$

and

$$\rho^\gamma \le \rho_\infty^\gamma - \frac{C_{1,2}}{C_{1,3}}\epsilon_0^{2^{-N_4-1}}(M-x),$$

then $I_1(x,t_{1,1}) \ge I_1(x,t_{1,2})$. It is a contradiction. Thus, Claim 2 holds.

Similarly, we can obtain the following claim.

Claim 3. *For any fixed $x \in [0,M]$, we have*

$$I_1(x,t) \le \max\left\{I_1(x,0), r_\infty^\beta\left(\rho_\infty^\gamma + \frac{C_{1,2}}{C_{1,4}}\epsilon_0^{2^{-N_4-1}}(M-x)\right)^{\frac{\theta}{\gamma}} + C_{1,1}\epsilon_0^{2^{-N_4-1}}(M-x)^{\frac{\theta}{\gamma}}\right\}$$
$$:= M_{1,2},$$

where $C_{1,4}$ is a positive constant satisfying $C_{1,4} \ge \frac{A\theta r^\beta}{2c_1+c_2}$.

From Claims 2 and 3, we have

$$|g(x,t) - g_\infty(x)| \le C_{1,5}\epsilon_0^{\frac{\theta}{\gamma}2^{-N_4-1}}, \ x \in [0,M], \ t \in [0,T],$$

when $\epsilon_0 \le \delta_{11}$, with a small positive constant $\delta_{11}(G, A, M_0, M, a, n, \gamma, \theta, c_1, c_2)$. □

Using the results in Lemmas 3.3–3.8, we have that there exists ϵ_0 satisfying

$$4\epsilon_1 < \min_{x\in[0,M]} g_\infty, \ C_3\epsilon_1 \le \delta_9, \ \epsilon_1 \le \delta_{10} \ \text{ and } \ \epsilon_0 \le \delta_{11} \tag{3.55}$$

such that Claim 1 holds with

$$\epsilon_1 = \epsilon_0 + C_{10}\epsilon_0^{\frac{\theta}{\gamma}2^{-N_4-1}}.$$

From (3.6) and Claim 1, using the classical continuation method, we can easily obtain the following lemma.

Lemma 3.9. *Under the assumptions of Theorem* 1.1*, we obtain that* (3.17)–(3.18)*,* (3.33)–(3.35)*,* (3.48)*, and*

$$|r(x,t) - r_\infty(x)| \le C_{11}\epsilon_0^{\frac{\theta}{\gamma}2^{-N_4-1}} \tag{3.56}$$

hold for all $x \in [0,M]$ and $t \in [0,T^*)$.

Proof. Let $\mathcal{A} = \{T \in [0,T^*) \mid I(t) \le \epsilon_1 \ \text{ for all } \ t \in [0,T]\}$. Since $I(0) \le \epsilon_0 < \epsilon_1$ and $I(t) \in C([0,T^*))$, then there exists a constant $T_0 > 0$ such that $I(t) \le \epsilon_1$ for all $t \in [0,T_0]$. Thus, $\mathcal{A}$ is not empty and relatively closed in $[0,T^*)$. To show that $\mathcal{A}$ is also relatively open in $[0,T^*)$, and hence the entire interval, it therefore suffices to show that the weaker bound

$$I(t) \le 2\epsilon_1, \ \text{ for all } \ t \in [0,T'] \subset [0,T^*),$$

implies $I(t) \le \epsilon_1$ for all $t \in [0,T']$. From Claim 1, we have that $\mathcal{A} = [0,T^*)$.

Then, from Lemmas 3.3–3.8, we obtain that (3.17)–(3.18), (3.33)–(3.35), (3.48), and (3.56) hold for all $x \in [0,M]$ and $t \in [0,T^*)$. □

We will prove an estimate in weighted $L^2([0,M]\times[0,T^*))$-norm of the function $g - g_\infty$.

LEMMA 3.10. *Under the assumptions of Theorem* 1.1*, we obtain*

$$\int_0^t \int_0^M (1+s)^{-\epsilon_2}(g-g_\infty)^2 dxds \le C, \tag{3.57}$$

where $t \in [0, T^*)$.

Proof. From (1.15), we have

$$\begin{aligned} A(\rho^\gamma - \rho_\infty^\gamma) = &\int_x^M \left(\frac{u_t}{r^{n-1}} + \frac{\Delta f}{r^{n-1}}\right) dy + \int_x^M G(M_0+y)(r^{2-2n} - r_\infty^{2-2n}) dy \\ &+ (2c_1+c_2)\rho^{\theta+1}(r^{n-1}u)_x - 2c_1(n-1)\rho^\theta \frac{u}{r} - 2c_1(n-1)\int_x^M \rho^\theta \left(\frac{u}{r}\right)_x dy. \end{aligned}$$

Multiplying the above equality by $(1+t)^{-\epsilon_2}(M-x)^{-2}(\rho^\gamma - \rho_\infty^\gamma)$, and integrating the resulting equation over $[0,M]\times[0,t]$, we obtain

$$\begin{aligned} &\int_0^t \int_0^M A(1+s)^{-\epsilon_2}(M-x)^{-2}(\rho^\gamma - \rho_\infty^\gamma)^2 dxds \\ &= \int_0^t \int_0^M (1+s)^{-\epsilon_2}(M-x)^{-2}(\rho^\gamma - \rho_\infty^\gamma) \int_x^M \frac{u_t}{r^{n-1}} dydxds \\ &\quad + \int_0^t \int_0^M (1+s)^{-\epsilon_2}(M-x)^{-2}(\rho^\gamma - \rho_\infty^\gamma) \int_x^M \frac{\Delta f}{r^{n-1}} dydxds \\ &\quad + \int_0^t \int_0^M (1+s)^{-\epsilon_2}(M-x)^{-2}(\rho^\gamma - \rho_\infty^\gamma) \int_x^M G(M_0+y)(r^{2-2n} - r_\infty^{2-2n}) dydxds \\ &\quad + \int_0^t \int_0^M (2c_1+c_2)(1+s)^{-\epsilon_2}(M-x)^{-2}(\rho^\gamma - \rho_\infty^\gamma)\rho^{\theta+1}(r^{n-1}u)_x dxds \\ &\quad - \int_0^t \int_0^M 2c_1(n-1)(1+s)^{-\epsilon_2}(M-x)^{-2}(\rho^\gamma - \rho_\infty^\gamma)\rho^\theta \frac{u}{r} dxds \\ &\quad - \int_0^t \int_0^M 2c_1(n-1)(1+s)^{-\epsilon_2}(M-x)^{-2}(\rho^\gamma - \rho_\infty^\gamma) \int_x^M \rho^\theta \left(\frac{u}{r}\right)_x dydxds \\ &:= \sum_{i=1}^6 F_i. \end{aligned} \tag{3.58}$$

Using (1.15), (1.23), Lemma 3.9, integration by parts, and the Cauchy–Schwarz inequality, we can estimate F_i as follows.

$$\begin{aligned} F_1 = &\left\{ \int_0^M (1+s)^{-\epsilon_2}(M-x)^{-2}(\rho^\gamma - \rho_\infty^\gamma) \int_x^M \frac{u}{r^{n-1}} dydx \right\}\Bigg|_0^t \\ &+ \int_0^t \int_0^M \epsilon_2(1+s)^{-\epsilon_2-1}(M-x)^{-2}(\rho^\gamma - \rho_\infty^\gamma) \int_x^M \frac{u}{r^{n-1}} dydxds \\ &+ \int_0^t \int_0^M \gamma(1+s)^{-\epsilon_2}(M-x)^{-2}\rho^{\gamma+1}(r^{n-1}u)_x \int_x^M \frac{u}{r^{n-1}} dydxds \\ &+ \int_0^t \int_0^M (n-1)(1+s)^{-\epsilon_2}(M-x)^{-2}(\rho^\gamma - \rho_\infty^\gamma) \int_x^M \frac{u^2}{r^n} dydxds \end{aligned} \tag{3.59}$$

$$
\begin{aligned}
&\le C\|g-g_\infty\|_{L^\infty_{xt}}\left(\int_0^M u^2dx\right)^{\frac12}\left(\int_0^M (M-x)^{-\frac12}dx\right)^{\frac12}+C\\

&\le C.
\end{aligned}\tag{3.65}
$$

From (3.58)–(3.65), we can immediately get (3.57). □

LEMMA 3.11. *Under the assumptions of Theorem* 1.1*, we obtain*

$$
\begin{aligned}
&(1+t)^{-\epsilon_2}\int_0^M (M-x)^{1-\frac{\theta}{\gamma}}(\rho^\theta-\rho_\infty^\theta)_x^2(x,t)dx\\
&+\int_0^t\int_0^M (1+s)^{-\epsilon_2}(M-x)^{2-\frac{2\theta}{\gamma}}(\rho^\theta-\rho_\infty^\theta)_x^2(x,s)dxds\le C
\end{aligned}\tag{3.66}
$$

for all $t\in[0,T^*)$.

Proof. From (3.2), we have

$$
\begin{aligned}
&\partial_t\left[\frac{\theta}{2c_1+c_2}r^{1+\beta-n}u+r^\beta(\rho^\theta)_x-r_\infty^\beta(\rho_\infty^\theta)_x\right]\\
&+\frac{A\gamma\rho^{\gamma-\theta}}{2c_1+c_2}\left[\frac{\theta}{2c_1+c_2}r^{1+\beta-n}u+r^\beta(\rho^\theta)_x-r_\infty^\beta(\rho_\infty^\theta)_x\right]\\
&=\frac{A\gamma\theta}{(2c_1+c_2)^2}\rho^{\gamma-\theta}r^{1+\beta-n}u+\frac{\theta(1+\beta-n)}{2c_1+c_2}r^{\beta-n}u^2-\frac{\theta}{2c_1+c_2}r^{1+\beta-n}\Delta f\\
&-\frac{\theta}{2c_1+c_2}\left(r^\beta\frac{G(M_0+x)}{r^{2n-2}}+r_\infty^\beta\frac{\rho^{\gamma-\theta}}{\rho_\infty^{\gamma-\theta}}(A\rho_\infty^\gamma)_x\right).
\end{aligned}\tag{3.67}
$$

Let $H=\frac{\theta}{2c_1+c_2}r^{1+\beta-n}u+r^\beta(\rho^\theta)_x-r_\infty^\beta(\rho_\infty^\theta)_x$. Multiplying (3.67) by $(1+t)^{-\epsilon_2}(M-x)^{1-\frac{\theta}{\gamma}}H$, integrating the resulting equation over $[0,M]$, and using the Cauchy–Schwarz

inequality, we obtain

$$\begin{aligned}
&\frac{d}{dt}\int_0^M (1+t)^{-\epsilon_2}(M-x)^{1-\frac{\theta}{\gamma}}H^2dx + C_{13}\int_0^M (1+t)^{-\epsilon_2}(M-x)^{2-\frac{2\theta}{\gamma}}H^2dx\\
&\le C\int_0^M (1+t)^{-\epsilon_2}(M-x)^{1-\frac{\theta}{\gamma}}\left((M-x)^{1-\frac{\theta}{\gamma}}|Hu| + |u^2H| + |\Delta fH|\right)dx\\
&\quad + \int_0^M (1+t)^{-\epsilon_2}(M-x)^{1-\frac{\theta}{\gamma}}\left|r^\beta G\frac{M_0+x}{r^{2n-2}} + \frac{\rho^{\gamma-\theta}r_\infty^\beta}{\rho_\infty^{\gamma-\theta}}(A\rho_\infty^\gamma)_x\right||H|dx\\
&\le \frac{C_{13}}{4}\int_0^M (1+t)^{-\epsilon_2}(M-x)^{2-\frac{2\theta}{\gamma}}H^2dx + C\|u(\cdot,t)\|_{L^\infty}^2 + C\|u(\cdot,t)\|_{L^\infty}^2\|u(\cdot,t)\|_{L^2}^2\\
&\quad + Cf_1^2 + C\int_0^M (1+t)^{-\epsilon_2}\left|r^\beta G\frac{M_0+x}{r^{2n-2}} + \frac{\rho^{\gamma-\theta}r_\infty^\beta}{\rho_\infty^{\gamma-\theta}}(A\rho_\infty^\gamma)_x\right|^2dx. \qquad (3.68)
\end{aligned}$$

Here, we use the estimates (3.17)–(3.18) and the condition $\theta \in (0, \gamma-1)$. From (3.9) and (3.17)–(3.18), we have

$$\begin{aligned}
&\int_0^M (1+t)^{-\epsilon_2}\left|r^\beta G\frac{M_0+x}{r^{2n-2}} + \frac{\rho^{\gamma-\theta}r_\infty^\beta}{\rho_\infty^{\gamma-\theta}}(A\rho_\infty^\gamma)_x\right|^2dx\\
&= \int_0^M (1+t)^{-\epsilon_2}\left|r^\beta G\frac{M_0+x}{r^{2n-2}} - G\frac{(\rho^{\gamma-\theta}r_\infty^\beta)(M_0+x)}{(\rho_\infty^{\gamma-\theta})(r_\infty^{2n-2})}\right|^2dx\\
&\le C\int_0^M (1+t)^{-\epsilon_2}\left[(r-r_\infty)^2 + (g-g_\infty)^2\right]dx. \qquad (3.69)
\end{aligned}$$

From (3.33) and (3.68)–(3.69), we obtain

$$\begin{aligned}
&\frac{d}{dt}\int_0^M (1+t)^{-\epsilon_2}(M-x)^{1-\frac{\theta}{\gamma}}H^2dx + \frac{C_{13}}{2}\int_0^M (1+t)^{-\epsilon_2}(M-x)^{2-\frac{2\theta}{\gamma}}H^2dx\\
&\le C\int_0^M (1+t)^{-\epsilon_2}\left((r-r_\infty)^2 + (g-g_\infty)^2\right)dx + C\|u(\cdot,t)\|_{L^\infty}^2 + Cf_1^2. \qquad (3.70)
\end{aligned}$$

From (A2), (1.23), (3.33)–(3.35), (3.56)–(3.57), and (3.70), we can immediately obtain (3.66). □

LEMMA 3.12. *Under the assumptions of Theorem* 1.1*, we obtain*

$$(1+t)^{1-\epsilon_2}\int_0^M \left(\rho^{\theta-1}u^2 + \rho^{\theta+1}u_x^2\right)(x,t)dx + \int_0^t\int_0^M (1+s)^{1-\epsilon_2}u_t^2(x,s)dxds \le C, \qquad (3.71)$$

$$\|u(\cdot,t)\|_{L^\infty} \le C(1+t)^{-\frac{1}{2}+\frac{\epsilon_2}{2}} \qquad (3.72)$$

for all $t \in [0, T^*)$.

Proof. Multiplying $(1.15)_2$ by $(1+t)^{1-\epsilon_2}u_t$, integrating the resulting equation over $[0,M]\times[0,t]$, and using integration by parts and the boundary conditions (1.17), we obtain

(3.73)
$$\begin{aligned}
&\int_0^t\int_0^M (1+s)^{1-\epsilon_2}u_t^2(x,s)dxds\\
&= \int_0^t\int_0^M A(1+s)^{1-\epsilon_2}\rho^\gamma\partial_x(r^{n-1}u_t)dxds\\
&\quad - \int_0^t\int_0^M (2c_1+c_2)(1+s)^{1-\epsilon_2}\rho^{1+\theta}\partial_x(r^{n-1}u)\partial_x(r^{n-1}u_t)dxds\\
&\quad + \int_0^t\int_0^M 2c_1(n-1)(1+s)^{1-\epsilon_2}\rho^\theta\partial_x(r^{n-2}uu_t)dxds - \int_0^t\int_0^M (1+s)^{1-\epsilon_2}fu_tdxds\\
&:= \sum_{i=1}^4 H_i.
\end{aligned}$$

Using (A3), (1.23), (3.17)–(3.18), (3.33)–(3.34), and the Cauchy–Schwarz inequality, we obtain

$$\begin{aligned}
&H_2+H_3\\
&= \left\{(1+s)^{1-\epsilon_2}\int_0^M\left[-\frac{2c_1+c_2}{2}\rho^{1+\theta}[\partial_x(r^{n-1}u)]^2\right.\right.\\

&\quad + \int_0^t\int_0^M (1+s)^{1-\epsilon_2}\left\{(2c_1+c_2)(n-1)\rho^{1+\theta}\partial_x(r^{n-1}u)\partial_x(r^{n-2}u^2)\right.\\
&\quad - \frac{(2c_1+c_2)}{2}(1+\theta)\rho^{2+\theta}[\partial_x(r^{n-1}u)]^3 + 2\theta c_1(n-1)\rho^{\theta+1}\frac{u}{r}[\partial_x(r^{n-1}u)]^2\\
&\quad - \theta c_1n(n-1)\rho^\theta\frac{u^2}{r^2}\partial_x(r^{n-1}u) + 2nc_1(n-1)(n-2)\rho^{\theta-1}\frac{u^3}{r^3}\\
&\quad \left. - 3c_1(n-1)(n-2)\rho^\theta\ \frac{u^2}{r^2}\partial_x(r^{n-1}u)\right\}dxds\\
&\le C + C\int_0^t\left(\|u\|_{L_x^\infty} + \|\rho(r^{n-1}u)_x\|_{L_x^\infty}\right)(1+s)^{1-\epsilon_2}\\
&\qquad\qquad \int_0^M\left[\rho^{1+\theta}(r^{n-1}u)_x^2 + \rho^{\theta-1}u^2\right]dxds\\
&\quad - C_{14}(1+t)^{1-\epsilon_2}\int_0^M[\rho^{1+\theta}(r^{n-1}u)_x^2 + \rho^{\theta-1}u^2]dx, \qquad (3.74)
\end{aligned}$$

$$
\begin{aligned}
H_1 = & \left\{(1+s)^{1-\epsilon_2}\int_0^M A\rho^\gamma \partial_x(r^{n-1}u)dx\right\}\Big|_0^t \\
& + \int_0^t\int_0^M A\gamma(1+s)^{1-\epsilon_2}\rho^{\gamma+1}[\partial_x(r^{n-1}u)]^2 dxds \\
& - \int_0^t\int_0^M 2A(n-1)(1+s)^{1-\epsilon_2}\rho^\gamma \frac{u}{r}\partial_x(r^{n-1}u)dxds \\
& + \int_0^t\int_0^M An(n-1)(1+s)^{1-\epsilon_2}\rho^{\gamma-1}\frac{u^2}{r^2}dxds \\
& - \int_0^t\int_0^M A(1-\epsilon_2)(1+s)^{-\epsilon_2}\rho^\gamma \partial_x(r^{n-1}u)dxds \\
\le & (1+s)^{1-\epsilon_2}\int_0^M A\rho^\gamma\partial_x(r^{n-1}u)dx + C, \qquad (3.75)
\end{aligned}
$$

and

$$
\begin{aligned}
H_4 = & -\left\{(1+s)^{1-\epsilon_2}\int_0^M G\frac{u(M_0+x)}{r^{n-1}}dx\right\}\Big|_0^t - \int_0^t\int_0^M (1+s)^{1-\epsilon_2}\Delta f u_t dxds \\
& + (1-\epsilon_2)\int_0^t\int_0^M (1+s)^{-\epsilon_2}\frac{Gu(M_0+x)}{r^{n-1}}dxds \\
& + \int_0^t\int_0^M (1-n)(1+s)^{1-\epsilon_2}G(M_0+x)r^{-n}u^2 dxds \\
\le & -(1+s)^{1-\epsilon_2}\int_0^M G\frac{u(M_0+x)}{r^{n-1}}dx + C + \frac{1}{2}\int_0^t\int_0^M (1+s)^{1-\epsilon_2}u_t^2 dxds. \qquad (3.76)
\end{aligned}
$$

Using (3.17)–(3.18), (3.24), (3.33), integration by parts, and the Cauchy–Schwarz inequality, we obtain

(3.77)

$$
\begin{aligned}
& (1+s)^{1-\epsilon_2}\int_0^M A\rho^\gamma\partial_x(r^{n-1}u)dx - (1+s)^{1-\epsilon_2}\int_0^M G\frac{u(M_0+x)}{r^{n-1}}dx \\
= & (1+s)^{1-\epsilon_2}\int_0^M \left(A(\rho^\gamma-\rho_\infty^\gamma)\partial_x(r^{n-1}u) - Gr^{n-1}u(M_0+x)(r^{2-2n}-r_\infty^{2-2n})\right)dx \\
\le & \frac{C_{14}}{4}(1+t)^{1-\epsilon_2}\int_0^M \rho^{1+\theta}(r^{n-1}u)_x^2 dx + C.
\end{aligned}
$$

From (3.73)–(3.77), we can obtain

$$
\begin{aligned}
& (1+t)^{1-\epsilon_2}\int_0^M \left[\rho^{1+\theta}(r^{n-1}u)_x^2 + \rho^{\theta-1}u^2\right]dx + \int_0^t\int_0^M (1+s)^{1-\epsilon_2}u_t^2 dxds \\
\le & C + C\int_0^t \left(\|u\|_{L_x^\infty} + \|\rho(r^{n-1}u)_x\|_{L_x^\infty}\right)(1+s)^{1-\epsilon_2} \\
& \times \int_0^M \left[\rho^{1+\theta}(r^{n-1}u)_x^2 + \rho^{\theta-1}u^2\right]dxds. \qquad (3.78)
\end{aligned}
$$

From (3.3), we have

$$\rho(r^{n-1}u)_x = \frac{1}{(2c_1+c_2)\rho^\theta}\left\{A\rho^\gamma + 2c_1(n-1)\rho^\theta\frac{u}{r} + \int_x^M\left[-\frac{u_t}{r^{n-1}} + 2c_1(n-1)\rho^\theta\left(\frac{u}{r}\right)_x - \frac{f}{r^{n-1}}\right]dy\right\}.$$

Using conditions $\theta \in (0, \frac{\gamma}{2}] \cap (0, \gamma-1)$, (1.23), estimates (3.17)–(3.20), and Hölder's inequality, we conclude that

$$\|\rho\partial_x(r^{n-1}u)\|_{L_x^\infty} \le C + C\left(\|u(\cdot,t)\|_{L^\infty}^2 + \int_0^M\left[\rho^{1+\theta}(r^{n-1}u)_x^2 + u_t^2\right]dx\right)^{\frac{1}{2}}. \tag{3.79}$$

Using (3.24), (3.34), (3.78)–(3.79), and the Cauchy–Schwarz inequality, we can obtain

$$\begin{aligned}&(1+t)^{1-\epsilon_2}\int_0^M\left[\rho^{1+\theta}(r^{n-1}u)_x^2 + \rho^{\theta-1}u^2\right]dx + \int_0^t\int_0^M(1+s)^{1-\epsilon_2}u_t^2dxds\\ &\le C + C\int_0^t\left(\int_0^M(1+s)^{1-\epsilon_2}\left[\rho^{1+\theta}(r^{n-1}u)_x^2 + \rho^{\theta-1}u^2\right]dx\right)^2 ds.\end{aligned}$$

Using Gronwall's inequality and the estimate (3.34), we can immediately get (3.71).

From (3.17), (3.71), and the fact $\theta \in (0, \gamma-1)$, we can obtain

$$\begin{aligned}|u(x,t)| &\le \left|\int_0^x u_x dy\right| \le C\left(\int_0^x \rho^{\theta+1}u_x^2 dy\right)^{\frac{1}{2}}\left(\int_0^x (M-y)^{-\frac{\theta+1}{\gamma}}dy\right)^{\frac{1}{2}}\\ &\le C(1+t)^{-\frac{1}{2}+\frac{\epsilon_2}{2}},\ (x,t)\in[0,M]\times[0,T^*).\end{aligned}$$ □

LEMMA 3.13. *Under the assumptions of Theorem* 1.1*, we obtain*

$$\int_0^M u_t^2(x,t)dx + \int_0^t\int_0^M\left[\rho^{\theta+1}u_{xt}^2 + \rho^{\theta-1}u_t^2\right]dxds \le C_{11}, \tag{3.80}$$

$$\|\rho(r^{n-1}u)_x(\cdot,t)\|_{L^\infty} \le C_{11} \tag{3.81}$$

for all $t \in [0, T^*)$.

Proof. We differentiate the equation $(1.15)_2$ with respect to t, multiply it by u_t, and integrate it over $[0,M]\times[0,t]$ using the boundary conditions (1.17), then derive

(3.82)

$$\begin{aligned}&\int_0^M\frac{1}{2}u_t^2dx\\ &= \int_0^M\frac{1}{2}u_t^2(x,0)dx - \int_0^t\int_0^M\left[(2c_1+c_2)\rho^{1+\theta}\partial_x(r^{n-1}u) - A\rho^\gamma - 2c_1(n-1)\rho^\theta\frac{u}{r}\right]\\ &\times\partial_x((n-1)r^{n-2}uu_t)dxds - \int_0^t\int_0^M\partial_t\left[(2c_1+c_2)\rho^{1+\theta}\partial_x(r^{n-1}u) - A\rho^\gamma\right.\\ &\left.- 2c_1(n-1)\rho^\theta\frac{u}{r}\right]\partial_x(r^{n-1}u_t)dxds + \int_0^t\int_0^M 2c_1(n-1)\partial_t\left(r^{n-1}\rho^\theta\partial_x\left(\frac{u}{r}\right)\right)u_t dxds\end{aligned}$$

$$
\begin{aligned}
&- \int_0^t \int_0^M f_t u_t dxds \\
&:= \sum_{i=1}^{5} J_i.
\end{aligned}
$$

From (A2)–(A3), we have

$$
\begin{aligned}
J_1 &\le C \left(\left\| \left((2c_1 + c_2)\rho_0^{\theta+1} (r_0^{n-1} u_0)_x \right)_x - 2c_1(n-1) \frac{u_0}{r_0} (\rho_0^\theta)_x \right\|_{L^2} \right. \\
&\quad \left. + \|(\rho_0^\gamma)_x\|_{L^2} + \|f(x, r_0, 0)\|_{L^2} \right)^2 \\
&\le C. \qquad (3.83)
\end{aligned}
$$

From (3.17)–(3.20) and the Cauchy–Schwarz inequality, we get

$$
\begin{aligned}
&J_3 + J_4 \\
&= - \int_0^t \int_0^M \left[(2c_1 + c_2)\rho^{1+\theta} (r^{n-1} u_t)_x^2 - 2c_1(n-1)\rho^\theta (r^{n-2} u_t^2)_x \right] dxds \\
&\quad + \int_0^t \int_0^M \left\{ (2c_1 + c_2)(1+\theta)\rho^{\theta+2} [\partial_x (r^{n-1} u)]^2 - (n-1)(2c_1 + c_2)\rho^{1+\theta} \partial_x (r^{n-2} u^2) \right. \\
&\quad \left. - \gamma \rho^{\gamma+1} \partial_x (r^{n-1} u) - 2c_1(n-1)\theta \rho^{\theta+1} \partial_x (r^{n-1} u) \frac{u}{r} - 2c_1(n-1)\rho^\theta \frac{u^2}{r^2} \right\} \\
&\quad \times \left[(n-1) \frac{u_t}{r\rho} + r^{n-1} u_{tx} \right] dxds + 2c_1(n-1) \int_0^t \int_0^M \left\{ (n-1) r^{n-2} u \rho^\theta \left(\frac{u}{r} \right)_x u_t \right. \\
&\quad \left. - \theta r^{n-1} \rho^{\theta+1} (r^{n-1} u)_x \left(\frac{u}{r} \right)_x u_t - r^{n-1} \rho^\theta \left(\frac{u^2}{r^2} \right)_x u_t \right\} dxds \\
&\le - C_{15} \int_0^t \int_0^M (\rho^{\theta+1} u_{xt}^2 + \rho^{\theta-1} u_t^2) dxds + C \\
&\quad + C \int_0^t \left(\|u\|_{L_x^\infty}^2 + \|\rho (r^{n-1} u)_x\|_{L_x^\infty}^2 \right) \int_0^M \left[\rho^{\theta+1} u_x^2 + \rho^{\theta-1} u^2 \right] dxds. \qquad (3.84)
\end{aligned}
$$

From (1.11), (3.17)–(3.20), and the Cauchy–Schwarz inequality, we obtain

$$
\begin{aligned}
J_2 &\le \frac{C_{15}}{8} \int_0^t \int_0^M \left(\rho^{\theta-1} u_t^2 + \rho^{\theta+1} u_{xt}^2 \right) dxds + C \\
&\quad + C \int_0^t \left(\|u\|_{L_x^\infty}^2 + \|\rho (r^{n-1} u)_x\|_{L_x^\infty}^2 \right) \int_0^M \left[\rho^{\theta+1} u_x^2 + \rho^{\theta-1} u^2 \right] dxds \qquad (3.85)
\end{aligned}
$$

and

$$
\begin{aligned}
J_5 &\le \frac{C_{15}}{8} \int_0^t \int_0^M \rho^{\theta-1} u_t^2 dxds \\
&\quad + C \int_0^t \int_0^M (G(M_0 + x) r^{-n} |u| + |\partial_r \Delta f u| + |\partial_t \Delta f|)^2 \rho^{1-\theta} dxds \\
&\le \frac{C_{15}}{8} \int_0^M r^{\alpha-2} u_t^2 dxds + C. \qquad (3.86)
\end{aligned}
$$

From (3.82)–(3.86), we have

$$\int_0^M u_t^2(x,t)dx + \int_0^t \int_0^M \left[\rho^{\theta+1}u_{xt}^2 + \rho^{\theta-1}u_t^2\right] dxds$$
$$\leq C + C\int_0^t \left(\|u\|_{L_x^\infty}^2 + \|\rho(r^{n-1}u)_x\|_{L_x^\infty}^2\right) \int_0^M \left[\rho^{\theta+1}u_x^2 + \rho^{\theta-1}u^2\right] dxds. \tag{3.87}$$

From (3.71)–(3.72) and (3.79), we have

$$\|\rho\partial_x(r^{n-1}u)\|_{L_x^\infty} \leq C + C\|u_t\|_{L_x^2}. \tag{3.88}$$

From (3.20), (3.71)–(3.72), and (3.87)–(3.88), we obtain

$$\int_0^M u_t^2(x,t)dx + \int_0^t \int_0^M \left[\rho^{\theta+1}u_{xt}^2 + \rho^{\theta-1}u_t^2\right] dxds$$
$$\leq C + C\int_0^t \int_0^M \left[\rho^{\theta+1}u_x^2 + \rho^{\theta-1}u^2\right] dx\|u_t\|_{L_x^2}^2 ds.$$

Using Gronwall's inequality and the estimate (3.20), we can immediately obtain (3.80)–(3.81). □

Proof of existence and uniqueness. If $T^* < \infty$, from Lemmas 3.9–3.13, we have, for all $t \in [0, T^*)$,

$$C^{-1}(M-x)^{1/\gamma} \leq \rho(x,t) \leq C(M-x)^{1/\gamma},\ x \in [0,M],$$

$$\int_0^M (M-x)^{1-\frac{\theta}{\gamma}}(\rho^\theta)_x^2 dx \leq C,\ \int_0^M (\rho^\gamma)_x^2 dx \leq C,$$

$$\int_0^M u^2 + (M-x)^{\frac{\theta+1}{\gamma}}u_x^2 dx \leq C,\ u(0,t) = 0$$

and

$$\int_0^M \left\{\left((2c_1+c_2)\rho^{\theta+1}(r^{n-1}u)_x\right)_x - 2c_1(n-1)\frac{u}{r}\partial_x\rho^\theta\right\}^2 dx \leq C.$$

Thus, from Theorem 3.1, there exists $T_2 > 0$ such that the free boundary problem (1.15)–(1.17) admits a unique weak solution $(\rho_2, u_2, r_2)(x,t)$ on $[0,M]\times[T^* - \frac{T_2}{2}, T^* + \frac{T_2}{2}]$, with initial data $(\rho,u,r)(x, T^* - \frac{T_2}{2})$. Using the uniqueness result in Theorem 3.1, we obtain that

$$(\tilde\rho, \tilde u, \tilde r)(x,t) = \begin{cases} (\rho,u,r)(x,t), & t \in [0, T^* - \frac{T_2}{2}], \\ (\rho_2,u_2,r_2)(x,t), & t \in [T^* - \frac{T_2}{2}, T^* + \frac{T_2}{2}], \end{cases}$$

is a solution of the system (1.15)–(1.17), which is in contradiction with the definition of T^*. Thus, we have that $T^* = \infty$. From Lemmas 3.9–3.13, we can show that the global weak solution satisfies the regularity conditions (1.25)–(1.26) and (1.28) in Theorem 1.1.

Remark 3.2. The uniqueness of the solution of Theorem 3.1 is obtained by the energy method. Let (u_i, ρ_i, r_i), $i = 1, 2$, be two solutions of the system (1.15)–(1.17)

satisfying the regularity conditions in Theorem 1.1. Using similar arguments as that in the uniqueness part in [3], we can obtain, for all $T > 0$,

$$\begin{aligned}
&\frac{d}{dt}\int_0^M \left(w^2 + \rho_1^{1-\theta}\rho_2^{2\theta-4}\varrho^2 + \rho_1^{\theta}\rho_2^{-1}\mathcal{R}^2\right) dx \\
&+ C^{-1}\int_0^M \rho_1^{1+\theta}\left(\rho_1 r_1^{2n-2}\left(\partial_x w\right)^2 + \frac{w^2}{r_1^2\rho_1}\right) dx \\
&\le C\int_0^M \left(w^2 + \rho_1^{1-\theta}\rho_2^{2\theta-4}\varrho^2 + \rho_1^{\theta}\rho_2^{-1}\mathcal{R}^2\right) dx,\ t \in [0,T],
\end{aligned}$$

where $(w, \varrho, \mathcal{R}) = (u_1 - u_2, \rho_1 - \rho_2, r_1 - r_2)$. Using Gronwall's inequality, we could obtain that $(u_1, \rho_1, r_1) = (u_2, \rho_2, r_2)$, a.e. $(x,t) \in [0,M] \times [0,T]$.

4. Further decay result.

LEMMA 4.1. *Let ν be a positive constant satisfying $\nu < \min\{1, \frac{2\gamma-2}{\gamma+\theta}\}$. Under the assumptions of Theorem* 1.1*, we obtain*

$$\left\|\rho^{\frac{\gamma+\theta}{2}}(\cdot,t) - \rho_\infty^{\frac{\gamma+\theta}{2}}(\cdot)\right\|_{L^\infty} \le C(1+t)^{-\frac{1}{4}+\frac{\epsilon_2}{2}}, \tag{4.1}$$

and

$$\|r(\cdot,t) - r_\infty(\cdot)\|_{L^\infty} \le C_\nu(1+t)^{-\frac{1}{4}\nu+\frac{\epsilon_2\nu}{2}} \tag{4.2}$$

for all $t \ge 0$, where C_ν is a positive constant depending on ν.

Proof. From (3.48), (3.56), and (3.66), we have

$$\int_0^M \left(\rho^{\frac{\gamma+\theta}{2}} - \rho_\infty^{\frac{\gamma+\theta}{2}}\right)_x^2 dx \le C(1+t)^{\epsilon_2},\ t \ge 0. \tag{4.3}$$

Combining (3.33) and the Galiardo–Nirenberg inequality $\|\phi\|_{L^\infty} \le \|\phi\|_{L^2}^{\frac{1}{2}}\|\phi'\|_{L^2}^{\frac{1}{2}}$, we obtain

$$\left\|\rho^{\frac{\gamma+\theta}{2}} - \rho_\infty^{\frac{\gamma+\theta}{2}}\right\|_{L^\infty} \le C(1+t)^{-\frac{1}{4}+\frac{\epsilon_2}{2}},\ t \ge 0.$$

From (3.17)–(3.18), (3.48), and (4.1), we have

$$\left\|\rho^{\frac{\nu(\gamma+\theta)}{2}}(\cdot,t) - \rho_\infty^{\frac{\nu(\gamma+\theta)}{2}}(\cdot)\right\|_{L^\infty} \le C\|\rho^{\frac{\gamma+\theta}{2}}(\cdot,t) - \rho_\infty^{\frac{\gamma+\theta}{2}}(\cdot)\|_{L^\infty}^{\nu} \le C(1+t)^{-\frac{\nu}{4}+\frac{\epsilon_2\nu}{2}}$$

and

$$\begin{aligned}
\|r(\cdot,t) - r_\infty(\cdot)\|_{L^\infty} &\le C\int_0^M |\rho^{-1} - \rho_\infty^{-1}|dx \\
&\le C\|\rho^{\frac{\nu(\gamma+\theta)}{2}}(\cdot,t) - \rho_\infty^{\frac{\nu(\gamma+\theta)}{2}}(\cdot)\|_{L^\infty}\int_0^M (M-x)^{-\frac{1}{\gamma}-\frac{\nu(\gamma+\theta)}{2\gamma}}dx \\
&\le C_\nu(1+t)^{-\frac{\nu}{4}+\frac{\epsilon_2\nu}{2}}
\end{aligned}$$

for all $t \ge 0$. ∎

Using similar arguments as that in Lemmas 3.6, 3.11–3.12, and 4.1 with $\nu = \frac{\gamma-1}{2\gamma}$, we can obtain the following lemma and omit the proof.

LEMMA 4.2. *Under the assumptions of Theorem* 1.1*, we have*

$$\int_0^M (M-x)^{\frac{\theta-1}{\gamma}}(g-g_\infty)^2dx+\int_0^t\int_0^M \left[\rho_\infty^{\gamma-1}(g-g_\infty)^2+(r-r_\infty)^2\right]dxds\le C, \tag{4.4}$$

$$\int_0^M \left\{u^2(x,t)+(M-x)^{\frac{\gamma-1}{\gamma}}(g-g_\infty)^2+(r-r_\infty)^2\right\}dx\le C(1+t)^{-1}, \tag{4.5}$$

$$\int_0^t(1+s)\|u(\cdot,s)\|_{L^\infty}^2ds+\int_0^t\int_0^M(1+s)\left(\rho^{\theta+1}u_x^2+\rho^{\theta-1}u^2\right)(x,s)dxds\le C, \tag{4.6}$$

$$\int_0^M (M-x)^{1-\frac{\theta}{\gamma}}(\rho^\theta-\rho_\infty^\theta)_x^2dx+\int_0^t\int_0^M(M-x)^{2-\frac{2\theta}{\gamma}}(\rho^\theta-\rho_\infty^\theta)_x^2dxds\le C, \tag{4.7}$$

and

$$(1+t)\int_0^M\left(\rho^{\theta-1}u^2+\rho^{\theta+1}u_x^2\right)(x,t)dx+\int_0^t\int_0^M(1+s)u_t^2(x,s)dxds\le C \tag{4.8}$$

for all $t\ge 0$.

Remark 4.1. The key point is as follows: Similar to (3.32), using the estimates (3.18), (3.34), (4.2), and the condition $\epsilon_2<\frac{\gamma-1}{2(3\gamma-1)}$, we have

$$\begin{aligned}
&\int_0^t\int_0^M 2c_1(n-1)\rho^\theta\left(\frac{u}{r}\left(\frac{r^n}{n}-\frac{r_\infty^n}{n}\right)\right)_x dxds\\
&\le C\int_0^t\int_0^M\left\{|r-r_\infty|\left(|\rho^\theta u_x|+|\rho^{\theta-1}u|\right)+\rho^\theta|u(\rho^{-1}-\rho_\infty^{-1})|\right\}dxds\\
&\le C\int_0^t\int_0^M(1+s)^{1-\epsilon_2}\left(\rho^{\theta+1}u_x^2+\rho^{\theta-1}u^2\right)(x,s)dxds\\
&\quad+C\int_0^t(1+s)^{\epsilon_2-1}\|r(\cdot,t)-r_\infty(\cdot)\|_{L^\infty}^2\int_0^M(M-x)^{\frac{\theta-1}{\gamma}}dxds\\
&\quad+C\int_0^t(1+s)^{\epsilon_2-1}\|\rho^{\frac{\nu(\gamma+\theta)}{2}}(\cdot,t)-\rho_\infty^{\frac{\nu(\gamma+\theta)}{2}}(\cdot)\|_{L^\infty}^2\int_0^M(M-x)^{\frac{\theta+1}{\gamma}-\frac{2}{\gamma}-\frac{\nu(\gamma+\theta)}{\gamma}}dxds\\
&\le C+C\int_0^t(1+s)^{\epsilon_2-1-\frac{\nu}{2}+\epsilon_2\nu}ds\le C,\quad t\ge 0.
\end{aligned}$$

Without loss of generality, we assume that $\eta\in(0,\frac{2(\gamma+\theta)}{\gamma+\theta+1})$. Let $\epsilon_4\in(0,\frac{\gamma+\theta-1}{3(\gamma+\theta)})$ be a constant satisfying $\frac{1-\epsilon_4}{2-\frac{3\gamma+3\theta-1}{2(\gamma+\theta)}+\frac{\epsilon_4}{2}}>\frac{2(\gamma+\theta)}{\gamma+\theta+1}-\eta$. Define $\{\kappa_j\}$ and $\{\eta_j\}$ by $\eta_{j+1}=1+\kappa_j$, $\kappa_j=\frac{3\gamma+3\theta-1}{4(\gamma+\theta)}\eta_j-\frac{\epsilon_4}{4}\eta_j-\frac{1}{2}-\frac{\epsilon_4}{2}$, and $\eta_0=1$. Let N_5 be a positive integer satisfying $\eta_{N_5}>\frac{2(\gamma+\theta)}{\gamma+\theta+1}-\eta$. It is easy to see that $\eta<2$ and $\kappa_j<1$, $j=0,1\ldots,N_5$. Using similar arguments as that in Lemma 4.2, applying the induction method, we can obtain the following lemma and omit the proof.

LEMMA 4.3. *Under the assumptions of Theorem* 1.1*, we have*

$$\int_0^M\left\{u^2(x,t)+(M-x)^{\frac{\gamma-1}{\gamma}}(g-g_\infty)^2+(r-r_\infty)^2\right\}dx\le C_{\eta,j}(1+t)^{-\eta_j}, \tag{4.9}$$

$$\int_0^t(1+s)^{\eta_j}\|u(\cdot,s)\|_{L^\infty}^2ds+\int_0^t\int_0^M(1+s)^{\eta_j}\left(\rho^{\theta+1}u_x^2+\rho^{\theta-1}u^2\right)(x,s)dxds\le C_{\eta,j}, \tag{4.10}$$

$$\left\|\rho^{\frac{\gamma+\theta}{2}}(\cdot,t)-\rho_\infty^{\frac{\gamma+\theta}{2}}(\cdot)\right\|_{L^\infty}\le C_{\eta,j}(1+t)^{-\frac{\eta_j}{4}}, \tag{4.11}$$

$$\int_0^t\int_0^M(1+s)^{\kappa_j}\left[\rho_\infty^{\gamma-1}(g-g_\infty)^2+(r-r_\infty)^2\right]dxds\le C_{\eta,j}, \tag{4.12}$$

$$(1+t)^{\eta_j}\int_0^M\left(\rho^{\theta-1}u^2+\rho^{\theta+1}u_x^2\right)(x,t)dx+\int_0^t\int_0^M(1+s)^{\eta_j}u_t^2(x,s)dxds\le C_{\eta,j}, \tag{4.13}$$

and

$$\|u(\cdot,t)\|_{L^\infty}\le C_{\eta,j}(1+t)^{-\frac{\eta_j}{2}} \tag{4.14}$$

for all $t\ge 0$, $j=0,\dots,N_5$, where $C_{\eta,j}$ is a positive constant depending on η and j.

Remark 4.2. The main difficulty is to show (4.12) with $j=k$, when (4.9)–(4.11) hold with $j=k$. From (3.27)–(3.28), we have

$$\begin{aligned}
&\int_0^T\int_0^M(1+t)^{\kappa_k}\left[A(\rho_\infty^\gamma-\rho^\gamma)(\rho^{-1}-\rho_\infty^{-1})\right.\\
&\left.+G(M_0+x)(r^{2-2n}-r_\infty^{2-2n})\left(\frac{r^n}{n}-\frac{r_\infty^n}{n}\right)\right]dxdt\\
=&-\int_0^T\int_0^M(1+t)^{\kappa_k}\frac{u_t}{r^{n-1}}\left(\frac{r^n}{n}-\frac{r_\infty^n}{n}\right)dxdt\\
&-\int_0^T\int_0^M(1+t)^{\kappa_k}\Delta f r^{1-n}\left(\frac{r^n}{n}-\frac{r_\infty^n}{n}\right)dxdt\\
&+\int_0^T\int_0^M(1+t)^{\kappa_k}(2c_1+c_2)\rho^{1+\theta}\partial_x(r^{n-1}u)(\rho_\infty^{-1}-\rho^{-1})dxdt\\
&+\int_0^T\int_0^M(1+t)^{\kappa_k}2c_1(n-1)\rho^\theta\left(\frac{u}{r}\left(\frac{r^n}{n}-\frac{r_\infty^n}{n}\right)\right)_x dxdt\\
:=&\sum_{i=1}^4 Q_i,\ T>0
\end{aligned} \tag{4.15}$$

and

$$\text{L.H.S. of (4.15)}\ge C_{12}\int_0^T\int_0^M(1+t)^{\kappa_k}\left[\rho_\infty^{\gamma-1}(g-g_\infty)^2+(r-r_\infty)^2\right]dxdt. \tag{4.16}$$

Similar to (3.29)–(3.32), applying the estimates (3.17)–(3.20), (4.4), integration by parts, the Cauchy–Schwarz inequality, and the fact that $\kappa_j=\frac{3\gamma+3\theta-1}{4(\gamma+\theta)}\eta_j-\frac{\epsilon_4}{4}\eta_j-\frac12-\frac{\epsilon_4}{2}<\eta_j$, we can estimate Q_i as follows:

$$\begin{aligned}
Q_1\le&-\int_0^M(1+t)^{\kappa_k}\frac{u}{r^{n-1}}\left(\frac{r^n}{n}-\frac{r_\infty^n}{n}\right)dx\Big|_0^T+C\int_0^T(1+t)^{\kappa_k}\|u\|_{L_x^\infty}^2dt\\
&+C\int_0^T\int_0^M(1+t)^{\kappa_k-1}|u||r-r_\infty|dxdt\\
\le&\ C,
\end{aligned} \tag{4.17}$$

$$Q_2\le\frac{C_{12}}{6}\int_0^T\int_0^M(1+t)^{\kappa_k}(r-r_\infty)^2dxdt+C\int_0^T f_1^2(1+t)^{\kappa_k}dt$$

$$\leq \frac{C_{12}}{6}\int_0^T\int_0^M (1+t)^{\kappa_k}\,(r-r_\infty)^2\,dxdt + C, \tag{4.18}$$

$$\begin{aligned} Q_3 &\leq C\int_0^T\int_0^M (1+t)^{\eta_k}\rho^{1+\theta}(r^{n-1}u_x)_x^2 dxdt \\ &\quad + C\int_0^T\int_0^M (1+t)^{2\kappa_k-\eta_k-\frac{\eta_k\nu_1}{2}}(M-x)^{\frac{\theta-1}{\gamma}-\frac{\nu_1(\gamma+\theta)}{\gamma}}dxdt \\ &\leq C, \end{aligned} \tag{4.19}$$

where $\nu_1 = \frac{\gamma+\theta-1}{\gamma+\theta} - \epsilon_4$,

$$\|r(\cdot,t) - r_\infty(\cdot)\|_{L^\infty} \leq C(1+t)^{\frac{\nu_1\eta_k}{4}},$$

and

$$\begin{aligned} Q_4 &\leq C\int_0^T\int_0^M (1+t)^{\eta_k}\left(\rho^{1+\theta}(r^{n-1}u_x)_x^2 + \rho^{\theta-1}u^2\right)dxdt \\ &\quad + C\int_0^T\int_0^M (1+t)^{2\kappa_k-\eta_k-\frac{\eta_k\nu_1}{2}}(M-x)^{\frac{\theta-1}{\gamma}}dxdt \\ &\leq C. \end{aligned} \tag{4.20}$$

From (4.15)–(4.20), we finish the proof of (4.12) with $j = k$.

From (4.12) with $j = N_5$, using similar arguments as that in Lemma 3.11, we can obtain the following lemma and omit the proof.

LEMMA 4.4. *Under the assumptions of Theorem* 1.1*, we have*

$$\int_0^M (M-x)^{2-\frac{2\theta}{\gamma}}(\rho^\theta - \rho_\infty^\theta)_x^2 dx \leq C_\eta(1+t)^{\eta-\frac{\gamma+\theta-1}{\gamma+\theta}}, \tag{4.21}$$

and

$$\|\rho^\gamma(\cdot,t) - \rho_\infty^\gamma(\cdot)\|_{L^\infty} \leq C(1+t)^{\frac{\eta}{2}-\frac{3\gamma+3\theta-1}{4(\gamma+\theta+1)}},\ t \geq 0. \tag{4.22}$$

Thus, we finish the proof of Theorem 1.1.

COMPACTLY SUPPORTED SYMMETRIC C^∞ WAVELETS WITH SPECTRAL APPROXIMATION ORDER*

BIN HAN† AND ZUOWEI SHEN‡

Abstract. In this paper, we obtain symmetric C^∞ real-valued tight wavelet frames in $L_2(\mathbb{R})$ with compact support and the spectral frame approximation order. Furthermore, we present a family of symmetric compactly supported C^∞ orthonormal complex wavelets in $L_2(\mathbb{R})$. A complete analysis of nonstationary tight wavelet frames and orthonormal wavelet bases in $L_2(\mathbb{R})$ is given.

Key words. symmetric tight wavelet frames, spectral frame approximation order, symmetric orthonormal complex wavelets, nonstationary cascade algorithm, nonstationary C^∞ wavelets

1. Introduction.

In this paper, we are interested in symmetric compactly supported C^∞ tight wavelet frames with the spectral frame approximation order. Since it is impossible to achieve all these properties under the framework of stationary tight wavelet frames, it is natural for us to consider nonstationary tight wavelet frames, in particular, nonstationary tight wavelet frames derived from nonstationary multiresolution analysis by the new (nonstationary) unitary extension principle.

We start with a family of 2π-periodic trigonometric polynomials $\widehat{a_j}, j \in \mathbb{N}$, and their associated nonstationary refinable functions (or tempered distributions) $\phi_{j-1}, j \in \mathbb{N}$, defined by

$$\widehat{\phi_{j-1}}(\xi) := \widehat{a_j}(\xi/2)\widehat{\phi_j}(\xi/2) = \prod_{n=1}^{\infty} \widehat{a_{n+j-1}}(2^{-n}\xi), \qquad \xi \in \mathbb{R},\ j \in \mathbb{N}, \tag{1.1}$$

where the 2π-periodic trigonometric polynomials $\widehat{a_j}$, $j \in \mathbb{N}$, are called refinement *masks*. Here, the Fourier transform $\hat{f}$ of a function $f \in L_1(\mathbb{R})$ used in this paper is defined to be $\hat{f}(\xi) := \int_{\mathbb{R}} f(t)e^{-it\xi}\,dt$ and can be naturally extended to square integrable functions and tempered distributions.

The stationary multiresolution analysis corresponds to the case that all the masks $\widehat{a_j}$ are the same; therefore, all the functions ϕ_j are the same, and, in particular, $\widehat{\phi_0}(\xi) = \widehat{a_1}(\xi/2)\widehat{\phi_1}(\xi/2)$. We say that a function $\phi : \mathbb{R} \mapsto \mathbb{C}$ is refinable with a 2π-periodic trigonometric polynomial refinement mask $\hat{a}$ if $\hat{\phi}(\xi) = \hat{a}(\xi/2)\hat{\phi}(\xi/2)$. The frame generators ψ^ℓ are generally obtained from the refinable function ϕ via $\widehat{\psi^\ell}(\xi) = \widehat{b^\ell}(\xi/2)\hat{\phi}(\xi/2)$ for some 2π-periodic trigonometric polynomials $\widehat{b^\ell}$ with some desirable properties.

A tight wavelet frame in $L_2(\mathbb{R})$ (in the stationary case) is generated by the integer translates and dyadic dilates of a finite set of elements in $L_2(\mathbb{R})$. More precisely, we say that $\{\psi^1, \ldots, \psi^L\}$ generates a (normalized) *tight wavelet frame* in $L_2(\mathbb{R})$ if

$$\|f\|^2_{L_2(\mathbb{R})} = \sum_{\ell=1}^{L} \sum_{j\in\mathbb{Z}} \sum_{k\in\mathbb{Z}} |\langle f, \psi^\ell_{j,k}\rangle|^2 \qquad \forall\, f \in L_2(\mathbb{R}), \tag{1.2}$$

where $\psi^\ell_{j,k} := 2^{j/2}\psi^\ell(2^j \cdot -k)$ and $\langle f, g\rangle := \int_{\mathbb{R}} f(t)\overline{g(t)}\, dt$. As a redundant wavelet system, tight frame wavelet systems are easier to design and provide more flexibilities in applications than orthonormal wavelet bases, especially in image inpainting (see [1, 2, 3, 4, 5] for details). Because of this, tight wavelet frames have been extensively studied in the literature; to mention only a few, see [6, 7, 8, 14, 16, 18, 19, 21, 25, 26, 27, 33] and the many references therein.

Tight wavelet frames obtained from refinable functions are of particular interest, due to their associated multiresolution structure (which we refer to as MRA-based) and fast frame algorithms. Constructions of tight wavelet frames from a refinable function can be done by the unitary extension principle in [33]. In fact, many tight wavelet frames have been constructed in [6, 16, 33]. Later, by using the more general oblique extension principle, which is independently developed in [7, 14], more tight wavelet frames with various desirable properties have been obtained in [7, 14, 21, 25, 26, 27] and many other references therein.

For the stationary case, it already has been pointed out in [13] that there does not exist a compactly supported refinable function ϕ with a 2π-periodic trigonometric polynomial refinement mask such that ϕ belongs to $C^\infty(\mathbb{R})$. Hence, it is impossible to obtain MRA-based compactly supported (stationary) tight wavelet frames in $L_2(\mathbb{R})$ whose generators are in $C^\infty(\mathbb{R})$. However, it is shown in [10] that, by using the class of masks for orthonormal refinable functions of [12] whose integer shifts form an orthonormal system, one can obtain a family of nonstationary refinable functions such that every nonstationary refinable function belongs to $C^\infty(\mathbb{R})$ and its integer shifts still form an orthonormal system in $L_2(\mathbb{R})$. For this family of nonstationary refinable functions, a C^∞ nonstationary orthonormal wavelet basis in $L_2(\mathbb{R})$ is derived in [10]. In fact, ideas of generating a class of nonstationary refinable functions in $C^\infty(\mathbb{R})$ from a given family of masks for stationary refinable functions have already been discussed in [15, 35]. One such example is the *up-function* [10, 15, 35] generated from the family of masks for the B-splines. Let $\widehat{a_j}(\xi) = 2^{-j}(1 + e^{-i\xi})^j, j \in \mathbb{N}$, be the mask for the B-spline of order j and define $\phi_{j-1}, j \in \mathbb{N}$, as in (1.1). Then all $\phi_{j-1}, j \in \mathbb{N}$, are compactly supported C^∞ functions. In particular, the function ϕ_0 is supported on $[0, 2]$ (see [10, 15, 35]).

Motivated by the interesting work of Cohen and Dyn [10] and equipped with the pseudosplines (a more general class of refinable functions containing B-splines, interpolatory refinable functions, and Daubechies orthonormal refinable functions in [12] as special cases), together with the idea of the unitary extension principle, we establish the analysis needed here for constructing nonstationary $C^\infty(\mathbb{R})$ tight wavelet frames in $L_2(\mathbb{R})$ with desirable properties, especially the symmetry property, which cannot be achieved by real-valued orthonormal dyadic refinable functions. As we will see, the construction more or less follows the idea of the unitary extension principle for the stationary case, while the main analysis of this paper is somehow different from that of [10]. For example, in the orthonormal wavelet case, the approximation order of the truncated wavelet series in [10] is the same as that of the (nonstationary)

multiresolution analysis, while in the tight wavelet frame case, they are different, even for the stationary case, as shown in [14].

Next, we briefly describe ideas of the construction of tight wavelet frames. Although one of our major objectives of this paper is to use the family of refinement masks for pseudosplines to construct tight wavelet frames and to provide the corresponding analysis, the construction in this paper is given for the general setting.

We start with 2π-periodic measurable functions $\widehat{a_j}$, $j \in \mathbb{N}$, as a sequence of refinement masks. To make the idea of the unitary extension principle work, it is necessary to require that for every $j \in \mathbb{N}$, the mask $\widehat{a_j}$ should satisfy

$$|\widehat{a_j}(\xi)|^2 + |\widehat{a_j}(\xi+\pi)|^2 \leqslant 1 \qquad \text{a.e. } \xi \in \mathbb{R}. \tag{1.3}$$

Since we are interested only in compactly supported tight wavelet frames, it is natural to start with compactly supported refinable functions ϕ_j, which, in turn, require that the degrees of the trigonometric polynomials $\widehat{a_j}$ do not increase too fast. For a 2π-periodic trigonometric polynomial $\hat{a}$, we denote $\deg(\hat{a})$ the smallest nonnegative integer such that its Fourier coefficients of $\hat{a}$ vanish outside $[-\deg(\hat{a}), \deg(\hat{a})]$. We note that $\deg(\hat{a})$ defined here is somewhat slightly different from the usual definition of the degree of a trigonometric polynomial; $\deg(\hat{a})$ here is the minimal integer k such that $[-k,k]$ contains the support of the Fourier coefficients of both $\hat{a}$ and $\hat{a}(-\cdot)$. For ϕ_0 in (1.1) to be compactly supported, by a simple calculation, it is very natural to require [10] that

$$\sum_{j=1}^{\infty} 2^{-j} \deg(\widehat{a_j}) < \infty. \tag{1.4}$$

With (1.3) and (1.4), under the condition that $\sum_{j=1}^{\infty} |\widehat{a_j}(0) - 1| < \infty$, it can be proved that all the corresponding refinable functions ϕ_{j-1} in (1.1) are well-defined compactly supported functions in $L_2(\mathbb{R})$.

Wavelet functions ψ_{j-1}^ℓ, $j \in \mathbb{N}$ and $\ell \in \{1, \dots, \mathcal{J}_j\}$, are obtained from ϕ_j by

$$\widehat{\psi_{j-1}^\ell}(\xi) := \widehat{b_j^\ell}(\xi/2)\widehat{\phi_j}(\xi/2), \qquad \ell = 1, \dots, \mathcal{J}_j, \tag{1.5}$$

where $\mathcal{J}_j$ are positive integers and each $\widehat{b_j^\ell}$, $\ell = 1, \dots, \mathcal{J}_j$, is called a (high-pass) wavelet mask. Denote $\mathbb{N}_0 := \mathbb{N} \cup \{0\}$. We say that $\{\phi_0\} \cup \{\psi_j^\ell \,:\, j \in \mathbb{N}_0, \ell = 1, \dots, \mathcal{J}_{j+1}\}$ generates *a nonstationary tight wavelet frame* in $L_2(\mathbb{R})$ if

$$\{\phi_0(\cdot - k) \,:\, k \in \mathbb{Z}\} \cup \{\psi_{j;j,k}^\ell := 2^{j/2}\psi_j^\ell(2^j \cdot - k) \,:\, j \in \mathbb{N}_0, k \in \mathbb{Z}, \ell = 1, \dots, \mathcal{J}_{j+1}\} \tag{1.6}$$

is a tight frame of $L_2(\mathbb{R})$; that is, the following holds:

$$\|f\|_{L_2(\mathbb{R})}^2 = \sum_{k\in\mathbb{Z}} |\langle f, \phi_0(\cdot - k)\rangle|^2 + \sum_{j=0}^{\infty} \sum_{\ell=1}^{\mathcal{J}_{j+1}} \sum_{k\in\mathbb{Z}} |\langle f, \psi_{j;j,k}^\ell\rangle|^2 \quad \forall\, f \in L_2(\mathbb{R}). \tag{1.7}$$

We say that ψ_j^ℓ has ν *vanishing moments* if $\widehat{\psi_j^\ell}^{(n)}(0) = 0$ for all $n = 0, \dots, \nu - 1$, where $\widehat{\psi_j^\ell}^{(n)}$ denotes the nth derivative of $\widehat{\psi_j^\ell}$. It is clear that (1.7) is equivalent to

$$f = \sum_{k\in\mathbb{Z}} \langle f, \phi_0(\cdot - k)\rangle \phi_0(\cdot - k) + \sum_{j=0}^{\infty} \sum_{\ell=1}^{\mathcal{J}_{j+1}} \sum_{k\in\mathbb{Z}} \langle f, \psi_{j;j,k}^\ell\rangle \psi_{j;j,k}^\ell, \qquad f \in L_2(\mathbb{R}). \tag{1.8}$$

The frame approximation operators $Q_n, n \in \mathbb{N}$, associated with the truncation of the tight wavelet frame in (1.6) at level n, are defined to be

$$Q_n(f) := \sum_{k\in\mathbb{Z}} \langle f, \phi_0(\cdot-k)\rangle \phi_0(\cdot-k) + \sum_{j=0}^{n-1} \sum_{\ell=1}^{\mathcal{J}_{j+1}} \sum_{k\in\mathbb{Z}} \langle f, \psi^\ell_{j;j,k}\rangle \psi^\ell_{j;j,k}, \qquad f \in L_2(\mathbb{R}). \tag{1.9}$$

For $\nu \geqslant 0$, we denote $W_2^\nu(\mathbb{R})$ the Sobolev space of all functions $f \in L_2(\mathbb{R})$ such that

$$\|f\|^2_{W_2^\nu(\mathbb{R})} := \int_{\mathbb{R}} (1+|\xi|^{2\nu}) |\hat{f}(\xi)|^2 \, d\xi < \infty. \tag{1.10}$$

The Sobolev seminorm $|f|_{W_2^\nu(\mathbb{R})}$ is defined to be

$$|f|^2_{W_2^\nu(\mathbb{R})} := \int_{\mathbb{R}} |\xi|^{2\nu} |\hat{f}(\xi)|^2 \, d\xi, \qquad f \in W_2^\nu(\mathbb{R}). \tag{1.11}$$

The unitary extension principle provides a sufficient condition on the wavelet masks $\widehat{a_j}$ and $\widehat{b_j^\ell}$, $\ell = 1, \ldots, \mathcal{J}_j$, so that, with ψ^ℓ_{j-1} defined in (1.5), the wavelet system in (1.6) forms a tight frame in $L_2(\mathbb{R})$. Altogether, we have the following result on nonstationary tight wavelet frames in $L_2(\mathbb{R})$.

THEOREM 1.1. *Let $\widehat{a_j}, j \in \mathbb{N}$, be 2π-periodic trigonometric polynomials with $\widehat{a_j}(0) = 1$ for all $j \in \mathbb{N}$. If (1.3) and (1.4) hold, letting ϕ_j and ψ^ℓ_{j-1}, $j \in \mathbb{N}$ and $\ell \in \{1, \ldots, \mathcal{J}_j\}$, be defined in (1.1) and (1.5), respectively, then the following hold:*

(i) *All functions ϕ_{j-1}, $j \in \mathbb{N}$, are well-defined compactly supported functions in $L_2(\mathbb{R})$.*

(ii) *If $\widehat{b_j^\ell}$, $j \in \mathbb{N}$ and $\ell \in \{1, \ldots, \mathcal{J}_j\}$, are 2π-periodic trigonometric polynomials satisfying*

$$\begin{aligned} &|\widehat{a_j}(\xi)|^2 + \sum_{\ell=1}^{\mathcal{J}_j} |\widehat{b_j^\ell}(\xi)|^2 = 1 \quad \text{and} \\ &\widehat{a_j}(\xi)\overline{\widehat{a_j}(\xi+\pi)} + \sum_{\ell=1}^{\mathcal{J}_j} \widehat{b_j^\ell}(\xi)\overline{\widehat{b_j^\ell}(\xi+\pi)} = 0, \end{aligned} \tag{1.12}$$

then the wavelet system in (1.6) is a compactly supported tight wavelet frame in $L_2(\mathbb{R})$.

(iii) *If, in addition to (1.12), we assume that*

$$\deg(\widehat{a_j}) = O(j^\alpha 2^{\beta j}) \qquad \text{as} \quad j \to \infty \quad \text{for some} \quad \alpha \geqslant 0,\ 0 \leqslant \beta < 1 \tag{1.13}$$

and assume that there exist a positive number $\nu \in \frac{1}{2}\mathbb{N}$ and a positive integer N such that $1 - |\widehat{a_j}(\xi)|^2$ has a zero of order 2ν at $\xi = 0$ for all $j \geqslant N$, that is, for $j \geqslant N$,

$$|\widehat{a_j}(\xi)|^2 = 1 + O(|\xi|^{2\nu}), \qquad \xi \to 0, \tag{1.14}$$

then there exists a positive constant C, independent of f and n, such that

$$\begin{aligned} \|f - Q_n(f)\|_{L_2(\mathbb{R})} &\leqslant C n^{\nu\alpha} 2^{-\nu(1-\beta)n} |f|_{W_2^\nu(\mathbb{R})} \\ &\forall\, f \in W_2^\nu(\mathbb{R}) \quad \text{and} \quad n \geqslant N, \end{aligned} \tag{1.15}$$

where the linear operators Q_n are defined in (1.9).

Item (ii) of Theorem 1.1 is called the unitary extension principle for the nonstationary case. Theorem 1.1 will be proved in section 4. As we shall see in section 4, the main effort there is to prove items (i) and (iii) of Theorem 1.1. To show item (ii) of Theorem 1.1, one needs to show the convergence of the frame series in the right side of (1.8) to the function f in $L_2(\mathbb{R})$. When (1.13) holds, the convergence of the frame series follows from (iii) by observing that the masks in item (ii) satisfy (1.14) for $\nu = 1/2$. Furthermore, a refined analysis establishes the convergence of the frame series even without assuming (1.13).

We further remark that (1.12) guarantees the multiresolution frame decomposition algorithm whose proof can be straightforwardly verified and is more or less known. In fact, Theorem 1.1 generalizes the unitary extension principle from the stationary case in [33] to the general nonstationary case. It is clear that, similar to the stationary case, for every fixed $j \in \mathbb{N}$, in order to construct a set of 2π-periodic trigonometric polynomials $\widehat{b_j^\ell}$, $\ell = 1, \ldots, \mathcal{J}_j$, derived from the mask $\widehat{a_j}$ so that (1.12) is satisfied, the mask $\widehat{a_j}$ must satisfy (1.3). Hence, (1.3) is a necessary and sufficient condition to make (1.12) hold, as we shall see later in this section.

Nonstationary spline tight wavelet frames using the oblique extension principle developed in [7, 14] have been systematically studied in Chui, He, and Stöckler [8] recently. There, they considered an even more general nonstationary setting; i.e., it is not even shift-invariant at each level. Since the oblique extension principle is a generalization of the unitary extension principle, the proof of [8] might be modified to prove item (ii) of Theorem 1.1. However, this at most leads to the conclusion $Q_n(f) \to f$ in $L_2(\mathbb{R})$. Our approach of item (ii) is beyond the proof of the tight frame property itself in (1.8). Instead, we analyze the approximation power of the truncated tight wavelet frame series as stated in item (iii) of Theorem 1.1. As a consequence of this analysis, we obtain the tight frame property stated in item (ii) of Theorem 1.1. Finally, we remark that a systematic study of general nonstationary wavelet frames that may not be MRA-based was given in [34]

Following [14], we say that a tight wavelet frame $\{\phi_0(\cdot - k) : k \in \mathbb{Z}\} \cup \{\psi_{j;j,k}^\ell : j \in \mathbb{N}_0, k \in \mathbb{Z}, \ell = 1, \ldots, \mathcal{J}_{j+1}\}$ provides *frame approximation order* ν if there exist a positive constant C, independent of f and n, and a positive integer N such that

$$\|f - Q_n(f)\|_{L_2(\mathbb{R})} \leqslant C2^{-\nu n}|f|_{W_2^\nu(\mathbb{R})} \quad \forall\, f \in W_2^\nu(\mathbb{R}) \quad \text{and} \quad n \geqslant N. \tag{1.16}$$

We say that a tight wavelet frame provides *the spectral frame approximation order* if it provides frame approximation order ν for any positive integer ν. Here, we point out that for the frame approximation order discussed in this paper, the constant C in (1.15) of Theorem 1.1 and the constant C in (1.16) of Theorems 1.2 and 1.4 can be explicitly obtained.

In section 4, we shall study when $Q_n(f)$ approaches f with an approximation order ν as $n \to \infty$. As a consequence, we prove item (ii) of Theorem 1.1 and (1.8) by showing that $Q_n(f) \to f$ in $L_2(\mathbb{R})$ as $n \to \infty$ for every $f \in L_2(\mathbb{R})$, provided that the conditions in Theorem 1.1 are satisfied. The approximation order of $Q_n(f)$ was not studied in [10], since it was not needed there. In fact, since only orthonormal wavelet systems were considered in [10], the associated operators Q_n become orthogonal projections and attain the approximation order provided by the nonstationary multiresolution analysis. Therefore, one only needs to understand the conditions under which $Q_n(f) \to f$ in $L_2(\mathbb{R})$ as $n \to \infty$ in the orthonormal wavelet case. Nevertheless, our approach here applies to this special case as well and simplifies the conditions given in [10]. The approximation order of $Q_n(f)$ was not studied in [8] either, since it is a

more challenging problem in its more general setting of [8]. For the stationary case, it is evident that (1.13) holds with $\alpha = \beta = 0$ and, consequently, the notion of the frame approximation power in (1.15) agrees with that of the frame approximation order in (1.16). However, we shall present an example of nonstationary tight wavelet frames derived from the up-function (see Theorem 1.3) to demonstrate that (1.15) holds with $\nu = 2$, $\alpha = 1$, and $\beta = 0$, while (1.16) fails for any $\nu > 0$; that is, this particular nonstationary tight wavelet frame has a "weak" frame approximation order 2 in the sense of (1.15), but it does not have any "strong" frame approximation order in the sense of (1.16).

Finally, we note that the 2π-periodic trigonometric polynomial wavelet masks $\widehat{b_j^\ell}$, $j \in \mathbb{N}$ and $\ell \in \{1, \ldots, \mathcal{J}_j\}$, can be constructed from the masks $\widehat{a_j}$ by many ways provided that the refinement masks $\widehat{a_j}, j \in \mathbb{N}$, satisfy (1.3). Here is one such construction modified from the stationary case of [6] (also cf. [16, 27, 25]). For every $j \in \mathbb{N}$, from the mask $\widehat{a_j}$ with real coefficients and satisfying (1.3), define

$$\begin{aligned} \widehat{b_j^1}(\xi) &:= e^{-i\xi}\overline{\widehat{a_j}(\xi+\pi)}, \\ \widehat{b_j^2}(\xi) &:= 2^{-1}[A_j(\xi) + e^{-i\xi}\overline{A_j(\xi)}], \\ \widehat{b_j^3}(\xi) &:= 2^{-1}[A_j(\xi) - e^{-i\xi}\overline{A_j(\xi)}], \end{aligned} \tag{1.17}$$

where A_j is a π-periodic trigonometric polynomial with real coefficients such that

$$|A_j(\xi)|^2 = 1 - |\widehat{a_j}(\xi)|^2 - |\widehat{a_j}(\xi+\pi)|^2.$$

Then, $\widehat{a_j}, \widehat{b_j^1}, \widehat{b_j^2}$, and $\widehat{b_j^3}$, $j \in \mathbb{N}$, satisfy (1.12) with $\mathcal{J}_j = 3$. Furthermore, the corresponding wavelets defined by (1.5) using masks in (1.17) are symmetric or antisymmetric whenever ϕ_j is symmetric.

After establishing Theorem 1.1, we focus on constructing nonstationary $C^\infty(\mathbb{R})$ wavelets derived from a family of refinement masks for pseudosplines. Pseudosplines (of type I) were first introduced in [14] and [36] to improve the approximation order of truncated tight wavelet frame series for the tight wavelet frame system obtained by the unitary extension principle. The pseudosplines in [14] are generally not symmetric. The pseudosplines of type II are symmetric and were introduced in [16]. Since we are aiming at constructing symmetric tight wavelet frames, we will use pseudosplines of type II. For positive integers $m, l \in \mathbb{N}$, throughout the paper we denote

$$P_{m,l}(x) := \sum_{j=0}^{l-1} \binom{m+j-1}{j} x^j = \sum_{j=0}^{l-1} \frac{(m+j-1)!}{j!(m-1)!} x^j, \qquad x \in \mathbb{R}. \tag{1.18}$$

The masks for pseudosplines of type II with order (m, l) [16] are given by

$$\widehat{a_{m,l}}(\xi) := \cos^{2m}(\xi/2) P_{m,l}(\sin^2(\xi/2)), \qquad m \in \mathbb{N},\ l = 1, \ldots, m. \tag{1.19}$$

Since it is evident that $\widehat{a_{m,l}}(\xi) \geqslant 0$ for all $\xi \in \mathbb{R}$, the mask $\widehat{a_{m,l}^I}$, for the pseudospline of type I with order (m, l) introduced in [14] and [36], is obtained by taking the square root of the mask $\widehat{a_{m,l}}$ in (1.19) for the pseudospline of type II with order (m, l) using the Fejér–Riesz lemma such that

$$|\widehat{a_{m,l}^I}(\xi)|^2 = \widehat{a_{m,l}}(\xi), \qquad \xi \in \mathbb{R}. \tag{1.20}$$

While the pseudosplines of type II and their masks in (1.19) are symmetric, their type I counterparts usually do not have symmetry. For the case $l = 1$, the corresponding refinable pseudosplines are B-splines for both types. For the case $l = m$, the corresponding refinable pseudospline ϕ of type I with mask $\widehat{a^I_{m,m}}$ in (1.20) has orthonormal integer shifts (i.e., $\{\phi(\cdot - k) : k \in \mathbb{Z}\}$ is an orthonormal system in $L_2(\mathbb{R})$), and the corresponding refinable pseudospline ϕ of type II with mask $\widehat{a_{m,m}}$ in (1.19) is interpolatory (i.e., $\phi(0) = 1$ and $\phi(k) = 0$ for all $k \in \mathbb{Z}\backslash\{0\}$). It is easy to verify that the condition in (1.3) is satisfied for all the masks for pseudosplines of type I and type II (e.g., see [14, 16]).

Our construction here employs masks $\widehat{a_{m,l}}$ in (1.19) for pseudosplines of type II, since we are interested in constructing symmetric tight wavelet frames. We have the following result on symmetric C^∞ tight wavelet frames in $L_2(\mathbb{R})$ with compact support and the spectral frame approximation order.

THEOREM 1.2. *Let $\widehat{a_j} := \widehat{a_{m_j,l_j}}$ be defined in* (1.19)*, where $1 \leqslant l_j \leqslant m_j$ and m_j ($j \in \mathbb{N}$) are positive integers satisfying*

$$\lim_{j\to\infty} m_j = \infty \quad \text{and} \quad \sum_{j=1}^{\infty} 2^{-j} m_j < \infty. \tag{1.21}$$

For $j \in \mathbb{N}$, define ϕ_{j-1} as in (1.1) *and ψ^1_{j-1}, ψ^2_{j-1}, and ψ^3_{j-1} as in* (1.5) *with the wavelet masks $\widehat{b^1_j}$, $\widehat{b^2_j}$, and $\widehat{b^3_j}$ being derived from $\widehat{a_j}$ in* (1.17)*. Then the following hold:*

1. *Each nonstationary refinable function ϕ_j, $j \in \mathbb{N}_0$, is a compactly supported C^∞ real-valued function that is symmetric about the origin: $\phi_j(-\cdot) = \phi_j$.*
2. *Each wavelet function ψ^ℓ_j, $\ell = 1, 2, 3$ and $j \in \mathbb{N}_0$, is a compactly supported C^∞ function with l_{j+1} vanishing moments and satisfies $\psi^\ell_j(1 - \cdot) = \psi^\ell_j$ for $\ell = 1, 2$ and $\psi^3_j(1 - \cdot) = -\psi^3_j$.*
3. *The system $\{\phi_0(\cdot - k) : k \in \mathbb{Z}\} \cup \{\psi^\ell_{j;j,k} := 2^{j/2}\psi^\ell_j(2^j \cdot -k) : j \in \mathbb{N}_0, k \in \mathbb{Z}, \ell = 1, 2, 3\}$ is a compactly supported symmetric C^∞ tight wavelet frame in $L_2(\mathbb{R})$.*
4. *If in addition $\liminf_{j\to\infty} l_j/m_j > 0$, then the tight wavelet frame in item* (3) *has the spectral frame approximation order.*

The simplest choice in Theorem 1.2 is $m_j = l_j = j$ for all $j \in \mathbb{N}$, for which the condition in (1.21) is evidently satisfied and $\liminf_{j\to\infty} l_j/m_j = 1 > 0$. Therefore, by Theorem 1.2, we have a symmetric C^∞ tight wavelet frame in $L_2(\mathbb{R})$ with compact support and the spectral frame approximation order. Of course, the claims in Theorem 1.2 also hold if one chooses $m \approx \rho_1 j$ and $l_j \approx \rho_2 j$ for all $j \in \mathbb{N}$ with some fixed positive numbers ρ_1 and ρ_2. In order to have refinable functions ϕ_j, $j \in \mathbb{N}$, in (1.1) with support as small as possible, one should choose a sequence $\{m_j\}_{j=1}^\infty$ so that m_j goes to ∞ as slowly as possible. This is one of our motivations to choose a general integer m_j instead of the standard choice $m_j = j$ for our setup. We point out that such a strategy has already been considered by Cohen [9]. We also mention that all the claims in Theorem 1.2 hold, except possibly for the symmetry property, if one chooses the masks $\widehat{a_j} := \widehat{a^I_{m_j,l_j}}$ in (1.20) for the pseudosplines of type I instead of type II in Theorem 1.2.

It is clear that the frame approximation order in (1.16) implies (1.15). For the stationary case, it is evident that (1.13) holds with $\alpha = \beta = 0$ and, consequently, the notion of the frame approximation power in (1.15) agrees with that of the frame approximation order in (1.16). However, as illustrated by the following result, they could be quite different in the case of nonstationary tight wavelet frames.

THEOREM 1.3. *Let* $\widehat{a_j}(\xi) := 2^{-j}(1+e^{-i\xi})^j$, $j \in \mathbb{N}$, *be the masks for the up-function; in other words, we take* $m_j := j$ *and* $l_j := 1$ *in Theorem* 1.2. *For* $j \in \mathbb{N}$, *define* ϕ_{j-1} *as in* (1.1) *and* ψ^1_{j-1}, ψ^2_{j-1}, *and* ψ^3_{j-1} *as in* (1.5) *with the wavelet masks* $\widehat{b^1_j}$, $\widehat{b^2_j}$, *and* $\widehat{b^3_j}$ *being derived from* $\widehat{a_j}$ *in* (1.17). *Then the following hold:*

(i) $\{\phi_0(\cdot - k) : k \in \mathbb{Z}\} \cup \{\psi^\ell_{j;j,k} : j \in \mathbb{N}_0, k \in \mathbb{Z}, \ell = 1,2,3\}$ *is a compactly supported symmetric* C^∞ *tight wavelet frame in* $L_2(\mathbb{R})$, *and each* ψ_j *has one vanishing moment.*

(ii) *There exists a positive constant* C, *independent of* f *and* n, *such that*

$$\|f - Q_n(f)\|_{L_2(\mathbb{R})} \leqslant Cn^2 2^{-2n} |f|_{W^2_2(\mathbb{R})} \quad \forall\, f \in W^2_2(\mathbb{R}) \quad \text{and} \quad n \geqslant 2, \tag{1.22}$$

where the linear operators Q_n *are defined in* (1.9).

(iii) *The nonstationary tight wavelet frame in* (i) *does not have any frame approximation order; i.e., for any given* $\nu > 0$, *there does not exist a positive constant* C *such that* (1.16) *is satisfied.*

The Daubechies orthogonal masks $\widehat{a^I_{j,j}}$ in (1.20) with real coefficients for the pseudosplines of type I with order (j,j) have been considered in [10] (also see [9] for the general case $\widehat{a^I_{m_j,m_j}}$) to obtain C^∞ compactly supported (nonstationary) orthonormal refinable functions, from which (nonstationary) orthonormal wavelets with the spectral approximation order are derived in [9, 10]. However, it is well known [13] that such Daubechies orthogonal masks $\widehat{a^I_{j,j}}$, having real coefficients and obtained from $\widehat{a_{j,j}}$ via the Fejér–Riesz lemma in (1.20), are not symmetric (except $j = 1$) and therefore, all the associated nonstationary refinable functions $\phi_j, j \in \mathbb{N}_0$, are not symmetric. One way to achieve symmetry is to split the masks $\widehat{a_{j,j}}$ into masks that are similar to $\widehat{a^I_{j,j}}$ in (1.20) but allow complex-valued coefficients (see [30]). Examples of symmetric orthonormal complex wavelets were first constructed in [30] in this way from Daubechies orthogonal masks of odd orders. Recently, symmetric orthonormal complex-valued wavelets have been systematically studied in Han [23].

Let $P_{j,j}$ be the polynomial defined in (1.18). For an odd integer j, one can always construct [23, Lemma 6 and section 2] two polynomials P^r_j and P^i_j with real coefficients such that

$$P_{j,j}(x) = [P^r_j(x)]^2 + [P^i_j(x)]^2, \qquad x \in \mathbb{R} \quad \text{with} \quad P^r_j(0) = 1, \quad P^i_j(0) = 0. \tag{1.23}$$

Now define

$$\widehat{a^S_j}(\xi) := e^{i(j-1)\xi/2} 2^{-j}(1+e^{-i\xi})^j [P^r_j(\sin^2(\xi/2)) + iP^i_j(\sin^2(\xi/2))]. \tag{1.24}$$

It is easy to check [23, Lemma 3] that $|\widehat{a^S_j}(\xi)|^2 = |\widehat{a^I_{j,j}}(\xi)|^2 = \widehat{a_{j,j}}(\xi)$ and the integer shifts of the stationary refinable function associated with the mask $\widehat{a^S_j}$ are orthonormal. Using this family of masks, one can obtain symmetric C^∞ orthonormal complex wavelets with compact support. We summarize the above discussion into the following result.

THEOREM 1.4. *Let* $m_j, j \in \mathbb{N}$, *be positive odd integers such that* (1.21) *holds. Take* $\widehat{a_j}(\xi) := \widehat{a^S_{m_j}}$, *where* $\widehat{a^S_{m_j}}$ *is defined in* (1.24). *Define*

$$\widehat{\psi_{j-1}}(2\xi) := e^{-i\xi}\overline{\widehat{a_j}(\xi+\pi)}\widehat{\phi_j}(\xi), \qquad j \in \mathbb{N},$$

where $\phi_j, j \in \mathbb{N}_0$, *are defined in* (1.1). *Then the following hold:*

(1) *Each refinable function* $\phi_j, j \in \mathbb{N}_0$, *is a compactly supported* C^∞ *complex-valued function such that* $\phi_j(1-\cdot) = \phi_j$ *and* $\{\phi_j(\cdot - k) : k \in \mathbb{Z}\}$ *is an orthonormal system in* $L_2(\mathbb{R})$.

(2) *Each wavelet function* $\psi_j, j \in \mathbb{N}_0$, *is a compactly supported* C^∞ *complex-valued function such that* $\psi_j(1-\cdot) = -\psi_j$ *and* ψ_j *has* m_{j+1} *vanishing moments.*

(3) $\{\phi_0(\cdot - k) : k \in \mathbb{Z}\} \cup \{\psi_{j;j,k} := 2^{j/2}\psi_j(2^j \cdot -k) : j \in \mathbb{N}_0, k \in \mathbb{Z}\}$ *is a compactly supported symmetric* C^∞ *orthonormal basis of* $L_2(\mathbb{R})$ *and has the spectral approximation order.*

This paper is organized as follows. In section 2, we shall discuss nonstationary cascade algorithms and some properties of nonstationary refinable functions. In particular, we study the initial functions in a nonstationary cascade algorithm and provide a sufficient condition for the convergence of a nonstationary cascade algorithm in a Sobolev space $W_2^\nu(\mathbb{R})$. As a consequence, we obtain a characterization for nonstationary orthonormal wavelet bases in $L_2(\mathbb{R})$. In section 3, we shall study the frame approximation order of a nonstationary tight wavelet frame. The proofs of Theorems 1.1–1.4 will be given in section 4.

2. Nonstationary cascade algorithms and refinable functions. In this section, we first discuss the existence of L_2-solutions of nonstationary refinable functions for a general set of masks satisfying (1.3). In fact, this follows from the following result, proved in this section:

$$[\widehat{\phi_j}, \widehat{\phi_j}](\xi) := \sum_{k\in\mathbb{Z}} |\widehat{\phi_j}(\xi + 2\pi k)|^2 \leqslant 1, \qquad \text{a.e. } \xi \in \mathbb{R} \quad \forall\, j \in \mathbb{N}_0 \tag{2.1}$$

for all masks satisfying (1.3), provided that the infinite products in (1.1) exist almost everywhere. The above inequality plays a critical role in our study of nonstationary tight wavelet frames and their frame approximation orders.

The question of when the refinable functions are in Sobolev spaces is discussed next. In fact, we prove it as a consequence of the convergence of the cascade algorithm in various Sobolev spaces when $\widehat{a_j}$, $j \in \mathbb{N}$, are masks of pseudosplines. The proof is done in the Fourier domain with the initial function whose Fourier transform is the characteristic function of $[-\pi, \pi]$. We then prove that when the cascade algorithm converges for one initial function, it converges for a large class of functions. Although a similar result is well known for the stationary case, it is not straightforward for the case of nonstationary cascade algorithms. However, this result is important in computer aided geometric design, because it results in a compactly supported function in each iteration of the cascade algorithm that generates a curve from a finitely supported sequence of points to approximate the underlying curve. Hence, it is desirable to prove the convergence of a cascade algorithm with a compactly supported initial function instead of an infinitely supported band-limited function in computer aided geometric design [17].

For the nonstationary refinable functions $\phi_j, j \in \mathbb{N}_0$, defined by masks for pseudosplines as in Theorem 1.2, one could use the same techniques developed in [10] to show that the cascade algorithm converges for the special initial function whose Fourier transform is the characteristic function of $[-\pi, \pi]$ that leads to $\phi_j \in C^\infty(\mathbb{R})$ for all $j \in \mathbb{N}_0$. But our discussion on nonstationary cascade algorithms in this section will supplement the results in [10] on nonstationary cascade algorithms. We use the results in [10] whenever they can be directly applied, e.g., Lemma 2.1, and at the same

time develop our own results to achieve our goal with a systematic and comprehensive approach. We also believe that some results (e.g., Theorem 2.4 and Lemmas 2.2 and 2.7) derived in this section have their own value in addition to being used to prove Theorem 2.8 in this section.

2.1. L_2-solutions. We start with a basic property about the pointwise convergence of the infinite product in (1.1). A sufficient condition for the convergence of the infinite product in (1.1) has been established in the following lemma by Cohen and Dyn in [10, Theorem 2.1].

LEMMA 2.1. *Let $\widehat{a_j}, j \in \mathbb{N}$, be 2π-periodic trigonometric polynomials such that $\sup_{j\in\mathbb{N}} \|\widehat{a_j}\|_{L_\infty(\mathbb{R})} < \infty$. If (1.4) holds and $\sum_{j=1}^{\infty} |\widehat{a_j}(0) - 1| < \infty$, then the infinite product in (1.1) converges uniformly on every compact set of $\mathbb{R}$ and all $\phi_j, j \in \mathbb{N}_0$, in (1.1) are well-defined compactly supported tempered distributions.*

Next, we consider when $\phi_j \in L_2(\mathbb{R})$, $j \in \mathbb{N}_0$, provided that the infinite products in (1.1) exist almost everywhere. In order to investigate the frame approximation order of a nonstationary tight wavelet frame, we establish (2.1), which is the following lemma.

LEMMA 2.2. *Let $\widehat{a_j}, j \in \mathbb{N}$, be 2π-periodic measurable functions satisfying (1.3) for each $j \in \mathbb{N}$. Assume that, for every $j \in \mathbb{N}_0$, $\widehat{\phi_j}(\xi) := \lim_{N\to\infty} \prod_{n=1}^{N} \widehat{a_{n+j}}(2^{-n}\xi)$ is well defined for almost every $\xi \in \mathbb{R}$; that is, the infinite product in (1.1) exists for almost every point in $\mathbb{R}$. Then (2.1) holds, and, consequently, $\phi_j \in L_2(\mathbb{R})$ with $\|\phi_j\|_{L_2(\mathbb{R})} \leqslant 1$ for every $j \in \mathbb{N}_0$.*

Proof. It suffices to prove the case $j = 0$, since the proof of the general case $j \in \mathbb{N}_0$ is the same. Note that $\widehat{\phi_0}(\xi) = \lim_{n\to\infty} \prod_{j=1}^{n} \widehat{a_j}(2^{-j}\xi)$ for almost every $\xi \in \mathbb{R}$. For any fixed positive integer K, we have

$$\sum_{k=-K}^{K} |\widehat{\phi_0}(\xi + 2\pi k)|^2 = \lim_{n\to\infty} \sum_{k=-K}^{K} \prod_{j=1}^{n} \big|\widehat{a_j}\big(2^{-j}(\xi + 2\pi k)\big)\big|^2 \qquad \text{a.e. } \xi \in \mathbb{R}. \tag{2.2}$$

Let N be the smallest positive integer such that $N > 1 + \log_2 K$. Then we have $[-K, K] \subseteq [-K, 2^N - 1 - K]$. Consequently, for all $n \geqslant N$, we have $[-K, K] \subseteq [-K, 2^n - 1 - K]$ and

$$\sum_{k=-K}^{K} \prod_{j=1}^{n} \big|\widehat{a_j}\big(2^{-j}(\xi + 2\pi k)\big)\big|^2 \leqslant \sum_{k=-K}^{2^n-1-K} \prod_{j=1}^{n} \big|\widehat{a_j}\big(2^{-j}(\xi + 2\pi k)\big)\big|^2. \tag{2.3}$$

Let $L_\infty(\mathbb{T}) := \{f \in L_\infty(\mathbb{R}) : f \text{ is } 2\pi\text{-periodic}\}$. The transition operator $T_j : L_\infty(\mathbb{T}) \to L_\infty(\mathbb{T})$ is defined for each $f \in L_\infty(\mathbb{T})$ as follows:

$$[T_j f](\xi) := |\widehat{a_j}(\xi/2)|^2 f(\xi/2) + |\widehat{a_j}(\xi/2 + \pi)|^2 f(\xi/2 + \pi), \qquad \xi \in \mathbb{R}.$$

Observing that $|[T_j f](\xi)| \leqslant \big[|\widehat{a_j}(\xi/2)|^2 + |\widehat{a_j}(\xi/2+\pi)|^2\big]\|f\|_{L_\infty(\mathbb{R})}$, by (1.3), we deduce that

$$\|T_j f\|_{L_\infty(\mathbb{R})} \leqslant \|f\|_{L_\infty(\mathbb{R})} \big\||\widehat{a_j}(\cdot/2)|^2 + |\widehat{a_j}(\cdot/2 + \pi)|^2\big\|_{L_\infty(\mathbb{R})} \leqslant \|f\|_{L_\infty(\mathbb{R})}. \tag{2.4}$$

By induction on n, we can verify (e.g., [21, Lemma 2.1]) that

$$\sum_{k=-K}^{2^n-1-K} \prod_{j=1}^{n} \big|\widehat{a_j}\big(2^{-j}(\xi + 2\pi k)\big)\big|^2 = [T_1 T_2 \cdots T_{n-1} T_n 1](\xi), \qquad \xi \in \mathbb{R}. \tag{2.5}$$

Now it follows from (2.3) and (2.4) that, for $n \geqslant N$ and for almost every $\xi \in \mathbb{R}$,

$$\sum_{k=-K}^{K} \prod_{j=1}^{n} \bigl|\widehat{a_j}\bigl(2^{-j}(\xi+2\pi k)\bigr)\bigr|^2 \leqslant [T_1T_2\cdots T_{n-1}T_n1](\xi) \leqslant \|T_1T_2\cdots T_{n-1}T_n1\|_{L_\infty(\mathbb{R})} \leqslant 1.$$

That is, we have

$$\sum_{k=-K}^{K} \prod_{j=1}^{n} \bigl|\widehat{a_j}\bigl(2^{-j}(\xi+2\pi k)\bigr)\bigr|^2 \leqslant 1 \qquad \text{a.e. } \xi \in \mathbb{R},\ n \geqslant N.$$

It follows from the above inequality and (2.2) that, for any fixed positive integer K,

$$\sum_{k=-K}^{K} |\widehat{\phi_0}(\xi+2\pi k)|^2 = \lim_{n\to\infty} \sum_{k=-K}^{K} \prod_{j=1}^{n} \bigl|\widehat{a_j}\bigl(2^{-j}(\xi+2\pi k)\bigr)\bigr|^2 \leqslant 1 \qquad \text{a.e. } \xi \in \mathbb{R}.$$

Taking $K \to \infty$ in the above inequality, we conclude that (2.1) is true for $j = 0$.

Since (2.1) implies that $\|\widehat{\phi_j}\|^2_{L_2(\mathbb{R})} = \int_{-\pi}^{\pi} [\widehat{\phi_j}, \widehat{\phi_j}](\xi)\, d\xi \leqslant \int_{-\pi}^{\pi} 1\, d\xi = 2\pi$, by Plancherel's theorem, it follows that $\|\phi_j\|_{L_2(\mathbb{R})} \leqslant 1$. □

As Lemma 2.1 states, the assumption that, for $j \in \mathbb{N}_0$,

$$\widehat{\phi_j}(\xi) := \lim_{N\to\infty} \prod_{n=1}^{N} \widehat{a_{n+j}}(2^{-n}\xi)$$

is well defined for almost every $\xi \in \mathbb{R}$, required in Lemma 2.2, is satisfied whenever the conditions $\widehat{a_j}(0) = 1$, $j \in \mathbb{N}$, and (1.4) hold. In other words, Lemma 2.2 says that if the masks $\widehat{a_j}$, $j \in \mathbb{N}$, satisfy (1.3), (1.4), and $\widehat{a_j}(0) = 1$, then the corresponding nonstationary refinable functions $\phi_j \in L_2(\mathbb{R})$, $j \in \mathbb{N}_0$.

Since the approximation property of $\phi_j, j \in \mathbb{N}_0$, discussed in this paper depends only on ϕ_j for large enough j, without loss of generality, throughout the paper we shall assume that the normalization condition $\widehat{a_j}(0) = 1$ holds for all $j \in \mathbb{N}$. In fact, if the conclusion in Lemma 2.1 holds, since $\prod_{n=1}^{\infty} \widehat{a_{n+j}}(0)$ converges and is nonzero for sufficiently large j, then we can replace $\widehat{\phi_j}$ and $\widehat{a_j}$ with $\widehat{\phi_j}/\widehat{\phi_j}(0)$ and $\widehat{a_j}(\xi)/\widehat{a_j}(0)$, respectively.

2.2. Cascade algorithms. A cascade algorithm is often used to study various properties of refinable functions and is closely related to a subdivision scheme in computer aided geometric design for generating smooth curves [10, 15, 20, 24]. For a given sequence of masks $\{\widehat{a_j}\}_{j=1}^{\infty}$, starting with an initial function $f \in L_2(\mathbb{R})$, one computes a sequence of cascade functions f_n by

$$\widehat{f_n}(\xi) := \hat{f}(2^{-n}\xi) \prod_{j=1}^{n} \widehat{a_j}(2^{-j}\xi), \qquad \xi \in \mathbb{R},\ n \in \mathbb{N}. \tag{2.6}$$

If $\lim_{n\to\infty} \hat{f}(2^{-n}\xi) = 1$ and $\hat{\phi}(\xi) := \lim_{n\to\infty} \prod_{j=1}^{n} \widehat{a_j}(2^{-j}\xi)$ exists for almost every $\xi \in \mathbb{R}$, then by (2.6) it is evident that $\lim_{n\to\infty} \widehat{f_n}(\xi) = \hat{\phi}(\xi)$ for almost every $\xi \in \mathbb{R}$.

The cascade algorithm is closely related to another algorithm, called a subdivision scheme, which we define next. For a sequence $u : \mathbb{Z} \mapsto \mathbb{C}$, we denote $\hat{u}$ its Fourier series as $\hat{u}(\xi) := \sum_{k\in\mathbb{Z}} u(k)e^{-ik\xi}$. In particular, by δ we denote the *Dirac sequence* on $\mathbb{Z}$ such

that $\delta(0)=1$ and $\delta(k)=0$ for $k\in\mathbb{Z}\backslash\{0\}$. That is, $\hat{\delta}=1$. For a sequence u and a mask a, the subdivision operator S_a maps the sequence u into a new sequence, $S_a u$ on $\mathbb{Z}$, which is determined by $\widehat{S_a u}(\xi)=2\hat{a}(\xi)\hat{u}(2\xi)$. In fact, the product $2^n\prod_{j=1}^n \widehat{a_j}(2^{n-j}\xi)$ is the Fourier series of the subdivision sequence $S_{a_n}S_{a_{n-1}}\cdots S_{a_2}S_{a_1}\delta$. More precisely, it follows from (2.6) that the cascade sequence $\{f_n\}_{n=1}^\infty$ and the subdivision sequence $\{S_{a_n}S_{a_{n-1}}\cdots S_{a_2}S_{a_1}\delta\}_{n=1}^\infty$ are related by

$$f_n=\sum_{k\in\mathbb{Z}}[S_{a_n}S_{a_{n-1}}\cdots S_{a_2}S_{a_1}\delta](k)f(2^n\cdot-k),\qquad n\in\mathbb{N}. \tag{2.7}$$

Recall that $f\in W_2^\nu(\mathbb{R})$ if $\|f\|^2_{W_2^\nu(\mathbb{R})}:=\int_{\mathbb{R}}(1+|\xi|^{2\nu})|\hat{f}(\xi)|^2\,d\xi<\infty$. For a sequence of masks $\{\widehat{a_j}\}_{j=1}^\infty$ and an initial function $f\in W_2^\nu(\mathbb{R})$, we say that the (nonstationary) cascade algorithm associated with masks $\{\widehat{a_j}\}_{j=1}^\infty$ and an initial function f converges in the Sobolev space $W_2^\nu(\mathbb{R})$ if $f_n\in W_2^\nu(\mathbb{R})$ for all $n\in\mathbb{N}$ and the sequence $\{f_n\}_{n=1}^\infty$ is convergent in $W_2^\nu(\mathbb{R})$. Many (but not all) functions in $W_2^\nu(\mathbb{R})$ can serve as an initial function in a cascade algorithm. One popular and natural choice of an initial function f in computer aided geometric design is from the B-spline functions, since they are compactly supported functions of piecewise polynomials. Hence, it is easy to compute the values of the underlying approximating function. However, to analyze the convergence of the cascade algorithm in the frequency domain, the sinc function $f(x)=\frac{\sin(\pi x)}{\pi x}$, that is, $\widehat{f}=\chi_{[-\pi,\pi]}$, the characteristic function of the interval $[-\pi,\pi]$, is a more natural choice (see, e.g., [9, 10, 11, 13, 22]). Our analysis will show that the cascade algorithm generated by pseudospline masks with the sinc function being the initial function converges in $W_2^\nu(\mathbb{R})$. To make sure that this cascade algorithm also converges in $W_2^\nu(\mathbb{R})$ when the initial seed is replaced by splines, we prove a more general result as follows: if a cascade algorithm converges in $W_2^\nu(\mathbb{R})$ for one initial seed with stable integer shifts, then it converges in $W_2^\nu(\mathbb{R})$ for a class of initial functions. As we will see, the proof is more technical than the stationary case, because a stationary refinable function is a fixed point of a stationary cascade algorithm, while this is no longer the case for the nonstationary case.

Before proceeding further, let us introduce the following notation. For $\nu\in\mathbb{R}$ and $f\in L_2(\mathbb{R})$, we define

$$[\hat{f},\hat{f}]_\nu(\xi):=\frac{1}{|\xi|^{2\nu}}\sum_{k\in\mathbb{Z}}|\hat{f}(\xi+2\pi k)|^2|\xi+2\pi k|^{2\nu},\qquad \xi\in\mathbb{R}, \tag{2.8}$$

and

$$\{\hat{f},\hat{f}\}_\nu(\xi):=\frac{1}{|\xi|^{2\nu}}\sum_{k\in\mathbb{Z}\backslash\{0\}}|\hat{f}(\xi+2\pi k)|^2|\xi+2\pi k|^{2\nu},\qquad \xi\in\mathbb{R}. \tag{2.9}$$

Clearly, we have $[\hat{f},\hat{f}]:=[\hat{f},\hat{f}]_0=\sum_{k\in\mathbb{Z}}|\hat{f}(\cdot+2\pi k)|^2$ and

$$[\hat{f},\hat{f}]_\nu(\xi)=\{\hat{f},\hat{f}\}_\nu(\xi)+|\hat{f}(\xi)|^2. \tag{2.10}$$

Following [20, 22], we introduce the set $\mathcal{F}_\nu$ of initial functions in a cascade algorithm as

$$\begin{aligned}\mathcal{F}_\nu:=\Big\{f\in W_2^\nu(\mathbb{R})\ :\ &\lim_{n\to\infty}\hat{f}(2^{-n}\xi)=1,\quad \lim_{n\to\infty}\{\hat{f},\hat{f}\}_\nu(2^{-n}\xi)=0,\\ &\text{a.e. }\xi\in[-\pi,\pi],\quad [\hat{f},\hat{f}]_\nu\in L_\infty([-\pi,\pi])\Big\}.\end{aligned} \tag{2.11}$$

The following result will be needed later; its proof is rather simple and therefore is omitted.

LEMMA 2.3. *Let $f \in \mathcal{F}_\nu$ for some $\nu \geqslant 0$. Then $[\hat{f}, \hat{f}](\xi) \leqslant [\hat{f}, \hat{f}]_\nu(\xi)$ for almost every $\xi \in [-\pi, \pi]$ (consequently, $[\hat{f}, \hat{f}] \in L_\infty(\mathbb{R})$), and*

$$\lim_{n\to\infty} [\hat{f}, \hat{f}](2^{-n}\xi) = \lim_{n\to\infty} [\hat{f}, \hat{f}]_\nu(2^{-n}\xi) = 1 \qquad \text{a.e. } \xi \in \mathbb{R}. \tag{2.12}$$

We say that the integer shifts of a function $f \in L_2(\mathbb{R})$ are *stable* in $L_2(\mathbb{R})$ if there exists a positive constant C such that

$$C^{-1} \leqslant [\hat{f}, \hat{f}](\xi) \leqslant C, \qquad \text{a.e. } \xi \in \mathbb{R}. \tag{2.13}$$

Now we state the following result on an initial function with stable integer shifts in a nonstationary cascade algorithm.

THEOREM 2.4. *Let $\widehat{a_j}, j \in \mathbb{N}$, be 2π-periodic measurable functions such that*

$$\widehat{f_\infty}(\xi) := \lim_{n\to\infty} \prod_{j=1}^{n} \widehat{a_j}(2^{-j}\xi)$$

exists for almost every $\xi \in \mathbb{R}$. For a function $f \in \mathcal{F}_\nu$ with $\nu \geqslant 0$ and stable integer shifts, define $f_n, n \in \mathbb{N}$, by (2.6). Assume that $\{f_n\}_{n=1}^\infty$ converges in $W_2^\nu(\mathbb{R})$. Then it converges to f_∞ in $W_2^\nu(\mathbb{R})$. Furthermore, for every $g \in \mathcal{F}_\nu$, the sequence of functions $g_n, n \in \mathbb{N}$, defined by

$$\widehat{g_n}(\xi) := \hat{g}(2^{-n}\xi) \prod_{j=1}^{n} \widehat{a_j}(2^{-j}\xi), \qquad \xi \in \mathbb{R},\ n \in \mathbb{N}, \tag{2.14}$$

converges to f_∞ in $W_2^\nu(\mathbb{R})$.

Proof. By the definition of f_n in (2.6), we deduce that

$$\begin{aligned}
&\int_{\mathbb{R}} (1 + |\xi|^{2\nu}) |\widehat{f_n}(\xi)|^2 \, d\xi \\
&\qquad = \int_{\mathbb{R}} \chi_{[-\pi,\pi]}(2^{-n}\xi) \Big([\hat{f}, \hat{f}](2^{-n}\xi) + |\xi|^{2\nu} [\hat{f}, \hat{f}]_\nu(2^{-n}\xi) \Big) \prod_{j=1}^{n} |\widehat{a_j}(2^{-j}\xi)|^2 \, d\xi.
\end{aligned}$$

That is, (2.6) implies

$$\|f_n\|^2_{W_2^\nu(\mathbb{R})} := \int_{\mathbb{R}} (1 + |\xi|^{2\nu}) |\widehat{f_n}(\xi)|^2 \, d\xi = \int_{\mathbb{R}} F_n(\xi) \, d\xi \tag{2.15}$$

with

$$F_n(\xi) := \Big([\hat{f}, \hat{f}](2^{-n}\xi) + |\xi|^{2\nu} [\hat{f}, \hat{f}]_\nu(2^{-n}\xi) \Big) \chi_{[-\pi,\pi]}(2^{-n}\xi) \prod_{j=1}^{n} |\widehat{a_j}(2^{-j}\xi)|^2, \quad \xi \in \mathbb{R}.$$

Similarly, by (2.14), we deduce that

$$\|g_n\|^2_{W_2^\nu(\mathbb{R})} := \int_{\mathbb{R}} (1 + |\xi|^{2\nu}) |\widehat{g_n}(\xi)|^2 \, d\xi = \int_{\mathbb{R}} G_n(\xi) \, d\xi \tag{2.16}$$

with

$$G_n(\xi) := \Big([\hat{g},\hat{g}](2^{-n}\xi) + |\xi|^{2\nu}[\hat{g},\hat{g}]_\nu(2^{-n}\xi)\Big)\chi_{[-\pi,\pi]}(2^{-n}\xi)\prod_{j=1}^{n}|\widehat{a_j}(2^{-j}\xi)|^2.$$

On the one hand, since $g \in \mathcal{F}_\nu$, by the definition of $\mathcal{F}_\nu$ in (2.11) and Lemma 2.3, we see that there exists a positive constant C_1 such that $[\hat{g},\hat{g}](\xi) \leqslant [\hat{g},\hat{g}]_\nu(\xi) \leqslant C_1$ for almost every $\xi \in [-\pi,\pi]$. By Lemma 2.3, it follows from (2.13) that $C^{-1} \leqslant [\hat{f},\hat{f}]_\nu(\xi)$ for almost every $\xi \in [-\pi,\pi]$ and

$$[\hat{g},\hat{g}](\xi) \leqslant C_1 \leqslant CC_1[\hat{f},\hat{f}](\xi) \quad \text{and} \quad [\hat{g},\hat{g}]_\nu(\xi) \leqslant C_1 \leqslant CC_1[\hat{f},\hat{f}]_\nu(\xi) \quad \text{a.e. } \xi \in [-\pi,\pi].$$

Now it follows from the above inequalities that

$$|G_n(\xi)| \leqslant CC_1F_n(\xi) \qquad \text{a.e. } \xi \in \mathbb{R} \quad \text{and} \quad n \in \mathbb{N}. \tag{2.17}$$

On the other hand, by $f, g \in \mathcal{F}_\nu$ and Lemma 2.3, since $\lim_{n\to\infty}\prod_{j=1}^{n}\widehat{a_j}(2^{-j}\xi) = \widehat{f_\infty}(\xi)$ for almost every $\xi \in \mathbb{R}$, we see that $\lim_{n\to\infty}F_n(\xi) = \lim_{n\to\infty}G_n(\xi) = (1+|\xi|^{2\nu})|\widehat{f_\infty}(\xi)|^2$ for almost every $\xi \in \mathbb{R}$. Since $\{f_n\}_{n=1}^\infty$ is a convergent sequence in $W_2^\nu(\mathbb{R})$ and $\lim_{n\to\infty}\widehat{f_n}(\xi) = \widehat{f_\infty}(\xi)$ for almost every $\xi \in \mathbb{R}$, we have $f_\infty \in W_2^\nu(\mathbb{R})$ and $\lim_{n\to\infty}\|f_n - f_\infty\|_{W_2^\nu(\mathbb{R})} = 0$. In particular, we have $\lim_{n\to\infty}\|f_n\|^2_{W_2^\nu(\mathbb{R})} = \|f_\infty\|^2_{W_2^\nu(\mathbb{R})}$. By (2.15), we have $\|f_n\|^2_{W_2^\nu(\mathbb{R})} = \int_{\mathbb{R}}F_n(\xi)\,d\xi$. Therefore, we conclude that $\lim_{n\to\infty}\int_{\mathbb{R}}F_n(\xi)\,d\xi = \|f_\infty\|^2_{W_2^\nu(\mathbb{R})}$. Now by (2.17) and the generalized Lebesgue dominated convergence theorem, it follows from (2.16) and $\lim_{n\to\infty}G_n(\xi) = (1+|\xi|^{2\nu})|\widehat{f_\infty}(\xi)|^2$ for almost every $\xi \in \mathbb{R}$ that

$$\lim_{n\to\infty}\int_{\mathbb{R}}(1+|\xi|^{2\nu})|\widehat{g_n}(\xi)|^2\,d\xi = \lim_{n\to\infty}\int_{\mathbb{R}}G_n(\xi)\,d\xi = \int_{\mathbb{R}}(1+|\xi|^{2\nu})|\widehat{f_\infty}(\xi)|^2\,d\xi. \tag{2.18}$$

But we also have

$$(1+|\xi|^{2\nu})|\widehat{g_n}(\xi) - \widehat{f_\infty}(\xi)|^2 \leqslant 2(1+|\xi|^{2\nu})\Big[|\widehat{g_n}(\xi)|^2 + |\widehat{f_\infty}(\xi)|^2\Big].$$

By (2.18), we have

$$\lim_{n\to\infty}\int_{\mathbb{R}}2(1+|\xi|^{2\nu})\Big[|\widehat{g_n}(\xi)|^2 + |\widehat{f_\infty}(\xi)|^2\Big]\,d\xi = 4\int_{\mathbb{R}}(1+|\xi|^{2\nu})|\widehat{f_\infty}(\xi)|^2\,d\xi < \infty.$$

Now by the generalized Lebesgue dominated convergence theorem again, we conclude that

$$\begin{aligned}\lim_{n\to\infty}\|g_n - f_\infty\|^2_{W_2^\nu(\mathbb{R})} &= \lim_{n\to\infty}\int_{\mathbb{R}}(1+|\xi|^{2\nu})|\widehat{g_n}(\xi) - \widehat{f_\infty}(\xi)|^2\,d\xi \\ &= \int_{\mathbb{R}}(1+|\xi|^{2\nu})\lim_{n\to\infty}|\widehat{g_n}(\xi) - \widehat{f_\infty}(\xi)|^2\,d\xi = 0,\end{aligned}$$

since $\lim_{n\to\infty}\widehat{g_n}(\xi) = \widehat{f_\infty}(\xi)$ for almost every $\xi \in \mathbb{R}$. This completes the proof. □

As shown in the next result, the conditions in (2.11) and (2.13) are not very restrictive. In fact, the sinc function and all B-spline functions belong to $\mathcal{F}_\nu$ for some ν.

PROPOSITION 2.5. *If $f(x) := \frac{\sin(\pi x)}{\pi x}$, then $f \in \mathcal{F}_\nu$ for all $\nu \geqslant 0$ and (2.13) holds, where $\mathcal{F}_\nu$ is defined in (2.11). For the* B*-spline B_m of order m, that is, $\widehat{B_m}(\xi) =$*

$\left(\frac{1-e^{-i\xi}}{i\xi}\right)^m$, $B_m \in \mathcal{F}_\nu$ *and* (2.13) *holds for all* $0 \leqslant \nu < m - 1/2$. *Note that* $B_m \notin W_2^{m-1/2}(\mathbb{R})$.

Proof. Letting $\nu \geqslant 0$, we note that $\hat{f} = \chi_{[-\pi,\pi]}$ and therefore, $f \in W_2^\nu(\mathbb{R})$. For $\xi \in (-\pi, \pi)$, we have $\hat{f}(\xi + 2\pi k) = 0$ for all $k \in \mathbb{Z}\backslash\{0\}$ and, hence,

$$\{\hat{f}, \hat{f}\}_\nu(\xi) := \frac{1}{|\xi|^{2\nu}} \sum_{k\in\mathbb{Z}\backslash\{0\}} |\hat{f}(\xi + 2\pi k)|^2 |\xi + 2\pi k|^{2\nu} = 0, \qquad \xi \in (\pi, \pi)\backslash\{0\}.$$

Therefore, it is evident that $\lim_{n\to\infty} \hat{f}(2^{-n}\xi) = 1$ and $\lim_{n\to\infty}\{\hat{f}, \hat{f}\}_\nu(2^{-n}\xi) = 0$ for almost every $\xi \in [-\pi, \pi]$. Moreover, by (2.10), we have

$$[\hat{f}, \hat{f}]_\nu(\xi) = |\hat{f}(\xi)|^2 + \{\hat{f}, \hat{f}\}_\nu(\xi) = |\hat{f}(\xi)|^2 = 1, \qquad \xi \in (-\pi, \pi)\backslash\{0\}.$$

Hence, $[\hat{f}, \hat{f}]_\nu \in L_\infty([-\pi, \pi])$. Thus, $f \in \mathcal{F}_\nu$. Inequality (2.13) is obviously true by $[\hat{f}, \hat{f}](\xi) = 1$ for almost every $\xi \in \mathbb{R}$.

Letting $0 \leqslant \nu < m-1/2$, from $\widehat{B_m}(\xi) = \left(\frac{1-e^{-i\xi}}{i\xi}\right)^m$, we have $\lim_{j\to\infty} \widehat{B_m}(2^{-j}\xi) = \widehat{B_m}(0) = 1$, $B_m \in W_2^\nu(\mathbb{R})$, and $|\widehat{B_m}(\xi)|^2 = \frac{\sin^{2m}(\xi/2)}{(\xi/2)^{2m}}$. Now a simple computation shows that

$$\{\widehat{B_m}, \widehat{B_m}\}_\nu(\xi) \leqslant 2^{2(m-\nu)} \sin^{2(m-\nu)}(\xi/2) \sum_{k\in\mathbb{Z}\backslash\{0\}} |\xi + 2\pi k|^{-2(m-\nu)}.$$

Since $0 \leqslant \nu < m - 1/2$, we have $2(m - \nu) > 1$. Hence, for all $\xi \in [-\pi, \pi]$, the series $\sum_{k\in\mathbb{Z}\backslash\{0\}} |\xi + 2\pi k|^{-2(m-\nu)}$ uniformly converges and therefore is uniformly bounded. Now it follows from the above inequality that $\{\widehat{B_m}, \widehat{B_m}\}_\nu(\xi)$ is uniformly bounded on $[-\pi, \pi]$ and

$$\lim_{n\to\infty} \{\widehat{B_m}, \widehat{B_m}\}_\nu(2^{-n}\xi) \leqslant \lim_{n\to\infty} \sin^{2(m-\nu)}(2^{-n-1}\xi) = 0 \qquad \forall\, \xi \in [-\pi, \pi].$$

Now it follows from (2.10) that $[\widehat{B_m}, \widehat{B_m}]_\nu \in L_\infty([-\pi, \pi])$, since $\widehat{B_m} \in L_\infty(\mathbb{R})$ and $\{\widehat{B_m}, \widehat{B_m}\}_\nu \in L_\infty([-\pi, \pi])$. It is well known that (2.13) holds for B_m. □

The following result provides us a sufficient condition on the convergence of a nonstationary cascade algorithm in a Sobolev space $W_2^\nu(\mathbb{R})$. As we will see, this result is sufficient to study the convergence of nonstationary cascade algorithms with masks for pseudosplines.

PROPOSITION 2.6. *Let* $\widehat{a_j}$ *and* $\widehat{b_j}$ $(j \in \mathbb{N})$ *be* 2π*-periodic measurable functions such that, for all* $j \in \mathbb{N}$,

$$|\widehat{a_j}(\xi)| \leqslant |\widehat{b_j}(\xi)| \qquad \text{a.e. } \xi \in \mathbb{R}. \tag{2.19}$$

Let $\eta \in W_2^\nu(\mathbb{R})$ *such that* $\lim_{j\to\infty} \hat{\eta}(2^{-j}\xi) = 1$ *for almost every* $\xi \in \mathbb{R}$. *Define*

$$\widehat{f_n}(\xi) := \hat{\eta}(2^{-n}\xi) \prod_{j=1}^n \widehat{a_j}(2^{-j}\xi) \quad \text{and} \quad \widehat{g_n}(\xi) := \hat{\eta}(2^{-n}\xi) \prod_{j=1}^n \widehat{b_j}(2^{-j}\xi), \qquad \xi \in \mathbb{R}.$$

Assume that $\widehat{f_\infty}(\xi) := \lim_{n\to\infty} \prod_{j=1}^n \widehat{a_j}(2^{-j}\xi)$ *and* $\widehat{g_\infty}(\xi) := \lim_{n\to\infty} \prod_{j=1}^n \widehat{b_j}(2^{-j}\xi)$ *are well defined for almost every* $\xi \in \mathbb{R}$. *Then,* $\lim_{n\to\infty} \|g_n - g_\infty\|_{W_2^\nu(\mathbb{R})} = 0$ *implies*

$\lim_{n\to\infty}\|f_n - f_\infty\|_{W_2^\nu(\mathbb{R})} = 0$. *In particular, suppose that there are a positive integer* J *and a* 2π*-periodic measurable function* $\hat{b}$ *such that*

$$|\widehat{a_j}(\xi)| \leqslant |\hat{b}(\xi)| \qquad \text{a.e. } \xi \in \mathbb{R},\ \forall\, j > J \quad \text{and} \quad \widehat{a_j} \in L_\infty(\mathbb{R}), \qquad 1 \leqslant j \leqslant J. \tag{2.20}$$

For $n \in \mathbb{N}$, *define* $\widehat{h_n}(\xi) := \hat{\eta}(2^{-n}\xi)\prod_{j=1}^n \hat{b}(2^{-j}\xi)$. *If* $\{h_n\}_{n=1}^\infty$ *converges in* $W_2^\nu(\mathbb{R})$, *then* f_n *converges to* f_∞ *in* $W_2^\nu(\mathbb{R})$; *i.e.,* $\lim_{n\to\infty}\|f_n - f_\infty\|_{W_2^\nu(\mathbb{R})} = 0$.

Proof. The assumption that the functions $\widehat{f_\infty}$ and $\widehat{g_\infty}$ are well defined implies that $\lim_{n\to\infty}\widehat{f_n}(\xi) = \widehat{f_\infty}(\xi)$ and $\lim_{n\to\infty}\widehat{g_n}(\xi) = \widehat{g_\infty}(\xi)$ for almost every $\xi \in \mathbb{R}$.

By assumption, $\{g_n\}_{n=1}^\infty$ converges to g_∞ in $W_2^\nu(\mathbb{R})$; together with the fact that $\lim_{n\to\infty}\widehat{g_n}(\xi) = \widehat{g_\infty}(\xi)$ for almost every $\xi \in \mathbb{R}$, we must have $g_\infty \in W_2^\nu(\mathbb{R})$ and $\lim_{n\to\infty}\|g_n - g_\infty\|_{W_2^\nu(\mathbb{R})} = 0$. In particular, we have

$$\lim_{n\to\infty}\int_{\mathbb{R}}(1+|\xi|^{2\nu})|\widehat{g_n}(\xi)|^2\,d\xi = \int_{\mathbb{R}}(1+|\xi|^{2\nu})|\widehat{g_\infty}(\xi)|^2\,d\xi < \infty.$$

Denote $\eta_n(\xi) := 2(1+|\xi|^{2\nu})\big[|\widehat{g_n}(\xi)|^2 + |\widehat{g_\infty}(\xi)|^2\big]$. It follows from the above identity that

$$\lim_{n\to\infty}\int_{\mathbb{R}}\eta_n(\xi)\,d\xi = 4\int_{\mathbb{R}}(1+|\xi|^{2\nu})|\widehat{g_\infty}(\xi)|^2\,d\xi < \infty. \tag{2.21}$$

By (2.19), it follows from the definition of $\widehat{g_n}$ and $\widehat{f_n}$ that $|\widehat{f_n}(\xi)| \leqslant |\widehat{g_n}(\xi)|$ for almost every $\xi \in \mathbb{R}$. Since we have $\lim_{n\to\infty}\widehat{f_n}(\xi) = \widehat{f_\infty}(\xi)$ for almost every $\xi \in \mathbb{R}$, we also have $|\widehat{f_\infty}(\xi)| \leqslant |\widehat{g_\infty}(\xi)|$ for almost every $\xi \in \mathbb{R}$. Consequently, by $g_\infty, g_n \in W_2^\nu(\mathbb{R})$ for all $n \in \mathbb{N}$, we have $f_\infty, f_n \in W_2^\nu(\mathbb{R})$ for all $n \in \mathbb{N}$. Moreover, we have

$$(1+|\xi|^{2\nu})|\widehat{f_n}(\xi) - \widehat{f_\infty}(\xi)|^2 \leqslant 2(1+|\xi|^{2\nu})\big[|\widehat{f_n}(\xi)|^2 + |\widehat{f_\infty}(\xi)|^2\big] \leqslant \eta_n(\xi) \qquad \text{a.e. } \xi \in \mathbb{R}.$$

By (2.21) and the generalized Lebesgue dominated convergence theorem, we conclude that

$$\begin{aligned}\lim_{n\to\infty}\|f_n - f_\infty\|_{W_2^\nu(\mathbb{R})}^2 &= \lim_{n\to\infty}\int_{\mathbb{R}}(1+|\xi|^{2\nu})|\widehat{f_n}(\xi) - \widehat{f_\infty}(\xi)|^2\,d\xi \\ &= \int_{\mathbb{R}}\lim_{n\to\infty}(1+|\xi|^{2\nu})|\widehat{f_n}(\xi) - \widehat{f_\infty}(\xi)|^2\,d\xi = 0.\end{aligned}$$

Therefore, $\lim_{n\to\infty}\|g_n - g_\infty\|_{W_2^\nu(\mathbb{R})} = 0$ implies $\lim_{n\to\infty}\|f_n - f_\infty\|_{W_2^\nu(\mathbb{R})} = 0$.

If (2.20) holds, for $n > J$ we deduce that, for almost every $\xi \in \mathbb{R}$,

$$\begin{aligned}|\widehat{f_n}(\xi)| &= \left[\prod_{j=1}^J |\widehat{a_j}(2^{-j}\xi)|\right]|\hat{\eta}(2^{-n}\xi)|\prod_{j=J+1}^n |\widehat{a_j}(2^{-j}\xi)| \\ &\leqslant C|\hat{\eta}(2^{-n}\xi)|\prod_{j=J+1}^n |\hat{b}(2^{-j}\xi)| = C|\widehat{h_{n-J}}(2^{-J}\xi)|,\end{aligned}$$

where $C := \prod_{j=1}^J \|\widehat{a_j}\|_{L_\infty(\mathbb{R})} < \infty$. Since $\{h_n\}_{n=1}^\infty$ is convergent in $W_2^\nu(\mathbb{R})$, it is evident that $\{2^J h_{n-J}(2^J\cdot)\}_{n=J+1}^\infty$ is also convergent in $W_2^\nu(\mathbb{R})$. Note that the Fourier transform of $2^J h_{n-J}(2^J\cdot)$ is $\widehat{h_{n-J}}(2^{-J}\cdot)$. Now by the generalized Lebesgue dominated

convergence theorem, we conclude that $\{f_n\}_{n=1}^\infty$ is also convergent in $W_2^\nu(\mathbb{R})$; that is, we have $\lim_{n\to\infty}\|f_n - f_\infty\|_{W_2^\nu(\mathbb{R})} = 0$. □

Let $\{\widehat{a_j}\}_{j=1}^\infty$ be a sequence of 2π-periodic measurable functions. Define $\{f_n\}_{n=1}^\infty$ by

$$\widehat{f_n}(\xi) := \chi_{[-\pi,\pi]}(2^{-n}\xi)\prod_{j=1}^{n}\widehat{a_j}(2^{-j}\xi), \qquad \xi\in\mathbb{R},\ n\in\mathbb{N}, \tag{2.22}$$

where $\chi_{[-\pi,\pi]}$ denotes the characteristic function of the interval $[-\pi,\pi]$. This can be understood as a representation of the nonstationary cascade algorithm associated with the masks $\{\widehat{a_j}\}_{n=1}^\infty$ in the frequency domain. Due to Theorem 2.4, we say that a nonstationary cascade algorithm associated with masks $\{\widehat{a_j}\}_{j=1}^\infty$ converges in $W_2^\nu(\mathbb{R})$ if the sequence $\{f_n\}_{n=1}^\infty$ in (2.22) converges in $W_2^\nu(\mathbb{R})$. Note that the initial function here in (2.22) is the sinc function $f(x) = \frac{\sin(\pi x)}{\pi x}$ since $\hat{f}(\xi) = \chi_{[-\pi,\pi]}$. Similarly, we say that a stationary cascade algorithm associated with a mask $\hat{a}$ converges in $W_2^\nu(\mathbb{R})$ if the cascade algorithm associated with $\{\widehat{a_j}\}_{j=1}^\infty$ converges in $W_2^\nu(\mathbb{R})$ with $\widehat{a_j} = \hat{a}$ for all $j\in\mathbb{N}$.

Basically, Proposition 2.6 says that if (2.19) holds and if the nonstationary cascade algorithm associated with $\{\widehat{b_j}\}_{j=1}^\infty$ converges in $W_2^\nu(\mathbb{R})$, then so does the nonstationary cascade algorithm associated with $\{\widehat{a_j}\}_{j=1}^\infty$. Similarly, if (2.20) holds and the stationary cascade algorithm associated with mask $\hat{b}$ converges in $W_2^\nu(\mathbb{R})$, then Proposition 2.6 says that the nonstationary cascade algorithm associated with masks $\{\widehat{a_j}\}_{j=1}^\infty$ must converge in $W_2^\nu(\mathbb{R})$.

The convergence of a stationary cascade algorithm associated with a finitely supported mask can be verified easily by calculating the spectrum of the transition operator. Let $\hat{a}$ be a 2π-periodic trigonometric polynomial with $\hat{a}(0) = 1$. Write $\hat{a}(\xi) = (1+e^{-i\xi})^m\hat{c}(\xi)$ for some nonnegative integer m and some 2π-periodic trigonometric polynomial $\hat{c}(\xi)$ with $\hat{c}(\pi)\neq 0$. Write $|\hat{c}(\xi)|^2 = \sum_{k=-K}^K c_k e^{-ik\xi}$, where K is some nonnegative integer. Denote $\rho(\hat{a})$ the spectral radius of the square matrix $(c_{2j-k})_{-K\leqslant j,k\leqslant K}$ and define $\nu_2(\hat{a}) := -1/2 - \log_2\sqrt{\rho(\hat{a})}$. It is known ([20, Theorem 4.3 and Proposition 7.2] and [22, Theorem 2.1]) that the stationary cascade algorithm associated with a 2π-periodic trigonometric polynomial mask $\hat{a}$ converges in $W_2^\nu(\mathbb{R})$ if and only if $\nu_2(\hat{a}) > \nu$. Moreover, $\phi\in W_2^\nu(\mathbb{R})$ for all $0\leqslant\nu<\nu_2(\hat{a})$, where ϕ is the nontrivial compactly supported refinable function associated with mask $\hat{a}$ such that $\hat{\phi}(2\xi) = \hat{a}(\xi)\hat{\phi}(\xi)$. Moreover, $\phi\notin W_2^\nu(\mathbb{R})$ for $\nu>\nu_2(\hat{a})$ whenever the integer shifts of ϕ are stable. See [17, 20, 22, 24, 32, 37] and the many references therein on the convergence of stationary cascade algorithms.

2.3. Convergence of cascade algorithms with pseudospline masks. We show that the nonstationary cascade algorithm associated with masks for pseudosplines in Theorem 1.2 converges in $W_2^\nu(\mathbb{R})$ for arbitrary $\nu\geqslant 0$. We first prove the following lemma which is not only used in the proof of the convergence of the nonstationary cascade algorithms associated with pseudospline refinement masks, but also plays an important role in our proof of Theorem 1.2 and the spectral frame approximation order.

LEMMA 2.7. *Let $\widehat{a_{m,l}}$ be the refinement mask for the pseudospline of type* II *with order (m,l) in* (1.19). *For positive integers m_1, m_2, and l_2 such that $1\leqslant m_1\leqslant m_2$*

and $1 \leqslant l_2 \leqslant m_2$*, the following inequality holds:*

$$|\widehat{a_{m_2,l_2}}(\xi)| \leqslant |\widehat{a^I_{m_2,l_2}}(\xi)| \leqslant |\widehat{b_{m_1}}(\xi)| \qquad \forall\, \xi \in \mathbb{R} \quad \textit{with}$$
$$\widehat{b_{m_1}}(\xi) := 2(1+e^{-i\xi})^{-1}\widehat{a^I_{m_1,m_1}}(\xi). \tag{2.23}$$

Note that $\widehat{b_{m_1}}$ *is uniquely determined by* $\widehat{a^I_{m_1,m_1}}(\xi) = 2^{-1}(1+e^{-i\xi})\widehat{b_{m_1}}(\xi)$.

Proof. Since $|\widehat{a_{m,l}}(\xi)| \leqslant 1$ for all $\xi \in \mathbb{R}$ and $1 \leqslant l \leqslant m$, it follows from the relation $|\widehat{a^I_{m,l}}(\xi)|^2 = \widehat{a_{m,l}}(\xi)$ and (1.18) that $|\widehat{a_{m,l}}(\xi)| \leqslant |\widehat{a^I_{m,l}}(\xi)| \leqslant |\widehat{a^I_{m,m}}(\xi)|$ for all $\xi \in \mathbb{R}$ and $1 \leqslant l \leqslant m$. Now in order to prove (2.23), it suffices to prove that $\widehat{a_{m_2,m_2}}(\xi) = |\widehat{a^I_{m_2,m_2}}(\xi)|^2 \leqslant |\widehat{b_{m_1}}(\xi)|^2$ for all $\xi \in \mathbb{R}$ and $1 \leqslant m_1 \leqslant m_2$.

Setting $x = \sin^2(\xi/2)$, by the definition of $\widehat{a_{m_2,m_2}}$ in (1.19), we see that $\widehat{a_{m_2,m_2}}(\xi) \leqslant |\widehat{b_{m_1}}(\xi)|^2$ for all $\xi \in \mathbb{R}$ and $1 \leqslant m_1 \leqslant m_2$ is equivalent to

$$(1-x)^{m_2}P_{m_2,m_2}(x) \leqslant (1-x)^{m_1-1}P_{m_1,m_1}(x) \qquad \forall\, x \in [0,1] \quad \text{and} \quad 1 \leqslant m_1 \leqslant m_2. \tag{2.24}$$

By the definition of $P_{m,l}$ in (1.18), we deduce that

$$\begin{aligned}
(1-x)^{m+1}P_{m+1,m+1}(x) &= (1-x)^{m+1}\sum_{j=0}^{m}\frac{(m+j)!}{j!m!}x^j \\
&= (1-x)^m\sum_{j=0}^{m}\frac{(m+j)!}{j!m!}(x^j - x^{j+1}) \\
&= (1-x)^m\left[\sum_{j=0}^{m}\frac{(m+j)!}{j!m!}x^j - \sum_{j=1}^{m+1}\frac{(m+j-1)!}{(j-1)!m!}x^j\right] \\
&= (1-x)^m\left[1 - \frac{(2m)!}{m!m!}x^{m+1} + \sum_{j=1}^{m}\left(\frac{(m+j)!}{j!m!} - \frac{(m+j-1)!}{(j-1)!m!}\right)x^j\right] \\
&= (1-x)^m\left[1 - \frac{(2m)!}{m!m!}x^{m+1} + \sum_{j=1}^{m}\frac{(m+j-1)!}{j!(m-1)!}x^j\right].
\end{aligned}$$

That is, we have

$$\begin{aligned}
&(1-x)^{m+1}P_{m+1,m+1}(x) \\
&\quad= (1-x)^m\left[\frac{(2m-1)!}{m!(m-1)!}x^m - \frac{(2m)!}{m!m!}x^{m+1} + \sum_{j=0}^{m-1}\frac{(m+j-1)!}{j!(m-1)!}x^j\right] \\
&\quad= (1-x)^m\left[\frac{(2m-1)!}{m!(m-1)!}x^m(1-2x) + P_{m,m}(x)\right] \\
&\quad= (1-x)^mP_{m,m}(x) - \frac{(2m-1)!}{m!(m-1)!}x^m(1-x)^m(2x-1) \qquad \forall\, m \in \mathbb{N}.
\end{aligned}$$

Consequently, for $x \in [1/2, 1]$ and $m_2 \geqslant m_1$, we have $2x - 1 \geqslant 0$ and

$$(1-x)^{m_2} P_{m_2,m_2}(x) \leqslant (1-x)^{m_2-1} P_{m_2-1,m_2-1}(x) \leqslant \cdots \leqslant (1-x)^{m_1} P_{m_1,m_1}(x)$$
$$\leqslant (1-x)^{m_1-1} P_{m_1,m_1}(x).$$

Therefore, (2.24) holds for $x \in [1/2, 1]$.

It remains to prove (2.24) for all $x \in [0, 1/2]$. Since

$$(1-x)^{m_2} P_{m_2,m_2}(x) \leqslant (1-x)^{m_2} P_{m_2,m_2}(x) + x^{m_2} P_{m_2,m_2}(1-x) = 1,$$

in order to prove (2.24) for all $x \in [0, 1/2]$, now it suffices to show that

$$1 \leqslant (1-x)^{m_1-1} P_{m_1,m_1}(x) \qquad \forall\, x \in [0, 1/2]. \tag{2.25}$$

Note that

$$1 = (1-x)(1-x)^{m_1-1} P_{m_1,m_1}(x) + x x^{m_1-1} P_{m_1,m_1}(1-x)$$
$$= (1-x)^{m_1-1} P_{m_1,m_1}(x) - x\big[(1-x)^{m_1-1} P_{m_1,m_1}(x) - x^{m_1-1} P_{m_1,m_1}(1-x)\big],$$

from which we have

$$(1-x)^{m_1-1} P_{m_1,m_1}(x) = 1 + x\big[(1-x)^{m_1-1} P_{m_1,m_1}(x) - x^{m_1-1} P_{m_1,m_1}(1-x)\big].$$

In order to prove (2.25), by the above identity, it suffices to prove that

$$(1-x)^{m_1-1} P_{m_1,m_1}(x) \geqslant x^{m_1-1} P_{m_1,m_1}(1-x) \qquad \forall\, x \in [0, 1/2]. \tag{2.26}$$

Note that for $x \in [0, 1/2]$, we have $0 \leqslant x/(1-x) \leqslant 1$. By the definition of $P_{m_1,m_1}(x) := \sum_{j=0}^{m_1-1} \binom{m_1+j-1}{j} x^j$, we have

$$1 = \frac{1}{1} \geqslant \frac{\binom{m_1}{1} x}{\binom{m_1}{1}(1-x)} \geqslant \frac{\binom{m_1+1}{2} x^2}{\binom{m_1+1}{2}(1-x)^2} \geqslant \cdots \geqslant \frac{\binom{2m_1-2}{m_1-1} x^{m_1-1}}{\binom{2m_1-2}{m_1-1}(1-x)^{m_1-1}}$$
$$= \frac{x^{m_1-1}}{(1-x)^{m_1-1}}, \quad x \in [0, 1/2].$$

But for positive numbers a, b, c, d, it is easy to see that $\frac{a}{b} \geqslant \frac{c}{d}$ implies $\frac{a}{b} \geqslant \frac{a+c}{b+d} \geqslant \frac{c}{d}$. Now it follows from the above inequalities that

$$1 \geqslant \frac{P_{m_1,m_1}(x)}{P_{m_1,m_1}(1-x)} = \frac{\sum_{j=0}^{m_1-1} \binom{m_1+j-1}{j} x^j}{\sum_{j=0}^{m_1-1} \binom{m_1+j-1}{j}(1-x)^j} \geqslant \frac{x^{m_1-1}}{(1-x)^{m_1-1}}, \qquad x \in [0, 1/2],$$

from which we see that (2.26) holds. □

Next we establish the following result on C^∞ nonstationary refinable functions. In fact, we prove that the nonstationary cascade algorithm associated with the masks for pseudosplines of type I or type II in Theorem 1.2 converges in $W_2^\nu(\mathbb{R})$ for any $\nu \geqslant 0$.

THEOREM 2.8. *Let $\widehat{a_j}$ be the mask for the pseudospline of type* I *or type* II *with order (m_j, l_j), where $1 \leqslant l_j \leqslant m_j$ and $j \in \mathbb{N}$ are positive integers such that* (1.21) *holds. Then, for every $n \in \mathbb{N}_0$, the nonstationary cascade algorithm* (2.22)

associated with $\{\widehat{a_{j+n}}\}_{j=1}^{\infty}$ *converges in* $W_2^\nu(\mathbb{R})$ *for any* $\nu \geqslant 0$. *Consequently, the nonstationary refinable functions* $\phi_j, j \in \mathbb{N}_0$, *in* (1.1) *must be well-defined compactly supported* $C^\infty(\mathbb{R})$ *functions.*

Proof. Since $\widehat{a_j}(\xi) = \widehat{a_{m_j,l_j}}(\xi)$ or $\widehat{a_j}(\xi) = \widehat{a^I_{m_j,l_j}}(\xi)$, it is easy to see that $\deg(\widehat{a_j}) \leqslant 2m_j$ and $\widehat{a_j}(0) = 1$. Therefore, by our assumption in (1.21), we see that

$$\sum_{j=1}^{\infty} 2^{-j} \deg(\widehat{a_j}) \leqslant 2 \sum_{j=1}^{\infty} 2^{-j} m_j < \infty.$$

Moreover, we have $|\widehat{a_j}(\xi)| \leqslant 1$ for all $j \in \mathbb{N}$ and $\xi \in \mathbb{R}$. Thus, the condition of Lemma 2.1 is satisfied. By Lemma 2.1, we conclude that $\phi_j, j \in \mathbb{N}_0$, are well-defined compactly supported tempered distributions.

Let $\widehat{a_{j,j}}$ be the refinement mask for the pseudospline of type II with order (j, j). It was proved by Daubechies [12, 13] that $\lim_{j\to\infty} \nu_2(\widehat{a_{j,j}}) = \lim_{j\to\infty} \nu_2(\widehat{a^I_{j,j}}) = \infty$. Hence, there exists a positive integer J such that $\nu_2(\widehat{a^I_{J,J}}) \geqslant \nu + 2$. By $\lim_{j\to\infty} m_j = \infty$, there exists a positive integer N such that

$$m_j \geqslant J \quad \text{and} \quad \nu_2(\widehat{a_j}) \geqslant \nu_2(\widehat{a^I_{J,J}}) \geqslant \nu + 2 \qquad \forall\, j \geqslant N. \tag{2.27}$$

Let $\hat{b}$ be the unique 2π-periodic trigonometric polynomial such that $\widehat{a^I_{J,J}}(\xi) = 2^{-1}(1 + e^{-i\xi})\hat{b}(\xi)$. By the definition of $\nu_2(\hat{b})$ and (2.27), it is straightforward to see that $\nu_2(\hat{b}) = \nu_2(\widehat{a^I_{J,J}}) - 1 \geqslant \nu + 1 > \nu$. Therefore, the stationary cascade algorithm associated with the mask $\hat{b}$ converges in $W_2^\nu(\mathbb{R})$ (see [20, Theorem 4.3]). On the other hand, by (2.23) of Lemma 2.7, since $m_j \geqslant J$ for $j \geqslant N$, we deduce that

$$|\widehat{a_j}(\xi)| \leqslant |\widehat{a^I_{m_j,l_j}}(\xi)| \leqslant |\hat{b}(\xi)| \qquad \forall\, \xi \in \mathbb{R},\ j \geqslant N.$$

Since the stationary cascade algorithm associated with the mask $\hat{b}$ converges in $W_2^\nu(\mathbb{R})$, by Proposition 2.6, the nonstationary cascade algorithm associated with masks $\{\widehat{a_j}\}_{j=1}^{\infty}$ converges in $W_2^\nu(\mathbb{R})$. Therefore, we have $\phi_0 \in W_2^\nu(\mathbb{R})$ for all $\nu \geqslant 0$. That is, ϕ_0 is a compactly supported C^∞ function. The same proof works for every ϕ_n and for the nonstationary cascade algorithm associated with masks $\{\widehat{a_{n+j}}\}_{j=1}^{\infty}$. ∎

In computer aided geometric design, it is of interest to consider the convergence of a subdivision scheme and a cascade algorithm in $C^\kappa(\mathbb{R})$, the space of functions with the κth continuous derivative, instead of the Sobolev space $W_2^\nu(\mathbb{R})$. When a cascade algorithm is implemented in the space domain as given in (2.7), the initial function is often chosen to be a compactly supported function such as spline functions of order ν with $\nu > \kappa + 1/2$. This is indeed true and can be proved easily by the imbedding theorems of Sobolev spaces.

COROLLARY 2.9. *Let* $\widehat{a_j}$ $(j \in \mathbb{N})$ *be the masks satisfying the conditions given in Theorem* 2.8. *Let* κ *be any nonnegative integer, and let* f *be a compactly supported initial function in* $W_2^\nu \cap \mathcal{F}_\nu$ *with* $\nu > \kappa + 1/2$. *Then the nonstationary cascade algorithm defined by* (2.7) *associated with* $\{\widehat{a_{n+j}}\}_{j=1}^{\infty}$ *converges in* $C^\kappa(\mathbb{R})$.

Proof. The convergence of the cascade algorithm in $W_2^\nu(\mathbb{R})$ defined by (2.7) follows from Proposition 2.6 and Theorem 2.8. Since all f_n $(n \in \mathbb{N}_0)$ and ϕ_0 are supported inside some compact set, it follows from the imbedding theorem that the sequence f_n also converges in $C^\kappa(\mathbb{R})$. ∎

2.4. Orthogonality. For the stationary case, it is well known that for a compactly supported refinable function ϕ with a 2π-periodic trigonometric polynomial $\hat{a}$, the integer shifts of ϕ form an orthonormal system if and only if its refinement mask $\hat{a}$ satisfies

$$|\hat{a}(\xi)|^2 + |\hat{a}(\xi+\pi)|^2 = 1 \qquad \text{a.e. } \xi \in \mathbb{R}$$

and the corresponding stationary cascade algorithm converges in $L_2(\mathbb{R})$ (that is, $\nu_2(\hat{a}) > 0$; see [20, 22]). Furthermore, if one chooses the wavelet function ψ by $\hat{\psi}(2\xi) := e^{-i\xi}\overline{\hat{a}(\xi+\pi)}\hat{\phi}(\xi)$, then the wavelet system generated by ψ forms an orthonormal basis in $L_2(\mathbb{R})$. For example, see [11, 12, 13, 20, 22, 24, 31, 32, 37] and the references therein. It turns out that this is also true for the nonstationary case, as a consequence of the proof of Theorem 2.4.

THEOREM 2.10. *Let $\widehat{a_j}, j \in \mathbb{N}$, be 2π-periodic measurable functions such that, for every $j \in \mathbb{N}_0$, $\widehat{\phi_j}(\xi) := \lim_{N\to\infty}\prod_{n=1}^{N}\widehat{a_{n+j}}(2^{-n}\xi)$ is well defined for almost every $\xi \in \mathbb{R}$. Then the integer shifts of ϕ_j form an orthonormal system in $L_2(\mathbb{R})$ for all $j \in \mathbb{N}$; i.e.,*

$$\langle \phi_j(\cdot - k), \phi_j\rangle := \int_{\mathbb{R}} \phi_j(x-k)\overline{\phi_j(x)}\,dx = \delta(k) \qquad \forall\, k \in \mathbb{Z} \quad \text{and} \quad j \in \mathbb{N}_0, \tag{2.28}$$

where $\delta(0) = 1$ and $\delta(k) = 0$ for all $k \neq 0$ if and only if

(1) *all the masks $\widehat{a_j}$ satisfy*

$$|\widehat{a_j}(\xi)|^2 + |\widehat{a_j}(\xi+\pi)|^2 = 1 \qquad \text{a.e. } \xi \in \mathbb{R}, \quad \forall\, j \in \mathbb{N}_0; \tag{2.29}$$

(2) *the nonstationary cascade algorithm associated with masks $\{a_{n+j}\}_{n=1}^{\infty}$ converges in $L_2(\mathbb{R})$ for large enough $j \in \mathbb{N}_0$.*

Moreover, if (1.4) and (2.28) hold, define $\widehat{\psi_{j-1}}(\xi) := e^{-i\xi/2}\overline{\widehat{a_j}(\xi/2+\pi)}\widehat{\phi_j}(\xi/2)$ for $j \in \mathbb{N}$; then $\{\phi_0(\cdot - k) : k \in \mathbb{Z}\} \cup \{\psi_{j;j,k} : j \in \mathbb{N}_0, k \in \mathbb{Z}\}$ is an orthonormal basis of $L_2(\mathbb{R})$.

Proof. It is known that (2.28) holds for each j if and only if $[\widehat{\phi_j}, \widehat{\phi_j}](\xi) = 1$ almost everywhere $\xi \in \mathbb{R}$.

Assume that (1) and (2) hold. Then $[\widehat{\phi_j}, \widehat{\phi_j}](\xi) = 1$ almost everywhere $x \in \mathbb{R}$ for all $j \in \mathbb{N}_0$ can be proved by an argument similar to that in the stationary case (see [11, 13, 22, 24, 32]). We omit the details here.

The necessity part is proved as follows. If (2.28) holds, then $[\widehat{\phi_j}, \widehat{\phi_j}] = 1$ for all $j \in \mathbb{N}_0$. Now (2.29) can be verified by the same argument as in the stationary case. So, item (1) holds. Next, we prove item (2); that is, the sequence $\{f_N\}_{N=1}^{\infty}$, defined by

$$\widehat{f_N}(\xi) := \chi_{[-\pi,\pi]}(2^{-N}\xi)\prod_{n=1}^{N}\widehat{a_{n+j}}(2^{-n}\xi), \qquad N \in \mathbb{N},$$

converges in $L_2(\mathbb{R})$ for every $j \in \mathbb{N}_0$. By the relation $\widehat{\phi_j}(\xi) = \widehat{a_{j+1}}(\xi/2)\widehat{\phi_{j+1}}(\xi/2)$, we deduce that

$$\widehat{\phi_j}(\xi) = \widehat{\phi_{N+j}}(2^{-N}\xi)\prod_{n=1}^{N}\widehat{a_{n+j}}(2^{-n}\xi), \qquad N \in \mathbb{N} \quad \text{and} \quad j \in \mathbb{N}_0. \tag{2.30}$$

Applying (2.30) and $[\widehat{\phi_N}, \widehat{\phi_N}] = 1$, one obtains that

$$\|\widehat{\phi_j}\|^2_{L_2(\mathbb{R})} = \int_{\mathbb{R}} |\widehat{f_N}(\xi)|^2 \, d\xi, \qquad N \in \mathbb{N}.$$

In particular, we have $\lim_{N\to\infty} \int_{\mathbb{R}} |\widehat{f_N}(\xi)|^2 \, d\xi = \|\widehat{\phi_j}\|^2_{L_2(\mathbb{R})} < \infty$. Note that

$$|\widehat{f_N}(\xi) - \widehat{\phi_j}(\xi)|^2 \leqslant 2\Big[|\widehat{f_N}(\xi)|^2 + |\widehat{\phi_j}(\xi)|^2\Big] =: \eta_N(\xi), \qquad \xi \in \mathbb{R},$$

and

$$\lim_{N\to\infty} \int_{\mathbb{R}} \eta_N(\xi) \, d\xi = 4 \int_{\mathbb{R}} |\widehat{\phi_j}(\xi)|^2 \, d\xi < \infty.$$

By $\lim_{N\to\infty} \widehat{f_N}(\xi) = \widehat{\phi_j}(\xi)$ for almost every $\xi \in \mathbb{R}$ and the generalized Lebesgue dominated convergence theorem, we conclude that $\lim_{N\to\infty} \|\widehat{f_N} - \widehat{\phi_j}\|_{L_2(\mathbb{R})} = 0$. Thus, for every $j \in \mathbb{N}_0$, the cascade algorithm associated with masks $\{\widehat{a_{n+j}}\}_{n=1}^{\infty}$ converges in $L_2(\mathbb{R})$.

If (2.28) holds, by the definition of ψ_j and (2.29), then it is easy to check that $\{\phi_0(\cdot - k) \, : \, k \in \mathbb{Z}\} \cup \{\psi_{j;j,k} \, : \, j \in \mathbb{N}_0, k \in \mathbb{Z}\}$ is an orthonormal system of $L_2(\mathbb{R})$. By Theorem 1.1, we see that $\{\phi_0(\cdot - k) \, : \, k \in \mathbb{Z}\} \cup \{\psi_{j;j,k} \, : \, j \in \mathbb{N}_0, k \in \mathbb{Z}\}$ is a tight frame in $L_2(\mathbb{R})$. Therefore, $\{\phi_0(\cdot - k) \, : \, k \in \mathbb{Z}\} \cup \{\psi_{j;j,k} \, : \, j \in \mathbb{N}_0, k \in \mathbb{Z}\}$ is an orthonormal basis of $L_2(\mathbb{R})$. □

3. The approximation order of the truncated frame series. In this section, we shall study the approximation property of a nonstationary tight wavelet frame, i.e., the frame approximation properties of the operators Q_n in (1.9). The approximation operators Q_n and their approximation order for a given stationary tight wavelet frame have been extensively studied in [14]. The approximation operators Q_n provide a simple approximation scheme for a given tight wavelet frame and have close links to the frame decomposition and reconstruction algorithms for a tight wavelet frame (see, e.g., [14]). Moreover, their approximation order determines the accuracy of the truncation operators and is not necessarily equal to the best approximation order provided by the underlying nonstationary multiresolution analysis.

Since the approximation operators Q_n provide a simple approximation scheme for a given tight wavelet frame, they are often used in various applications. For example, in [1, 2, 3, 4, 5], where the (stationary) tight wavelet frame based algorithms for high/super resolution image reconstructions, image inpainting, and deconvolutions are given, the operators Q_n are used there to approximate the underlying function from a given data set. The interested reader should consult [1, 2, 3, 4, 5] for details.

The operators Q_n are closely related to other operators. For a sequence $\{\phi_n\}_{n=0}^{\infty}$ of functions in $L_2(\mathbb{R})$, we define the linear operators $P_n(f), n \in \mathbb{N}_0$, by

$$P_n(f) := \sum_{k\in\mathbb{Z}} \langle f, \phi_{n;n,k}\rangle \phi_{n;n,k}, \qquad f \in L_2(\mathbb{R}) \quad \text{with} \tag{3.1}$$

$$\phi_{n;n,k} := 2^{n/2} \phi_n(2^n \cdot - k).$$

Similar to the stationary case, by calculation, it is easy to verify that (1.12) implies

$$\begin{aligned}(3.2)\qquad &\sum_{\ell=1}^{\mathcal{J}_j}\sum_{k\in\mathbb{Z}}\langle f,\psi^\ell_{j-1;j-1,k}\rangle\psi^\ell_{j-1;j-1,k}\\ &\qquad=\sum_{k\in\mathbb{Z}}\langle f,\phi_{j;j,k}\rangle\phi_{j;j,k}-\sum_{k\in\mathbb{Z}}\langle f,\phi_{j-1;j-1,k}\rangle\phi_{j-1;j-1,k}\end{aligned}$$

for $f\in L_2(\mathbb{R})$. Consequently, by the definition of the linear operators Q_n in (1.9), it follows from the relation in (3.2) that

$$\begin{aligned}Q_n(f)&=\sum_{k\in\mathbb{Z}}\langle f,\phi_0(\cdot-k)\rangle\phi_0(\cdot-k)+\sum_{j=0}^{n-1}\sum_{\ell=1}^{\mathcal{J}_{j+1}}\sum_{k\in\mathbb{Z}}\langle f,\psi^\ell_{j;j,k}\rangle\psi^\ell_{j;j,k}\\ &=\sum_{k\in\mathbb{Z}}\langle f,\phi_{n;n,k}\rangle\phi_{n;n,k}=P_n(f).\end{aligned}$$

That is, if (1.12) holds, then the linear operators Q_n in (1.9) and P_n in (3.1) are the same.

The approximation order of Q_n's for a stationary tight wavelet frame is investigated in [14] through that of P_n's, since $Q_n=P_n$ for a tight frame system constructed from the unitary extension principle. The relationship has been studied in [14] for stationary tight wavelet frames between the approximation order of P_n's and the (best) approximation order provided by the spaces $S_n(\phi_n)$, where $S_n(\phi_n)$ is the smallest closed subspace of $L_2(\mathbb{R})$ generated by the linear span of $\phi_n(2^n\cdot-k)$, $k\in\mathbb{Z}$; that is, $S_n(\phi_n)$ is the same as the smallest closed subspace of $L_2(\mathbb{R})$ containing the truncated tight frame system $\{\phi_0(\cdot-k)\,:\,k\in\mathbb{Z}\}\cup\{\psi^\ell_{j;j,k}\,:\,k\in\mathbb{Z},0\leqslant j<n,\ell=1,\dots,\mathcal{J}_{j+1}\}$. It is well known that the approximation order provided by the spaces $S_n(\phi_n)$ is determined by the order of the Strang–Fix conditions satisfied by ϕ_n. However, the approximation order of P_n's is determined by the order of the zero at the origin of the function $1-|\widehat{\phi}|^2$, in addition to the order of the Strang–Fix conditions satisfied by ϕ_n. Consequently, the frame approximation order can be (much) smaller than the approximation order provided by the spaces $S_n(\phi_n)$ (see [14] for details). This is also true for the nonstationary case. For example, let $\widehat{a_j}(\xi):=2^{-j}(1+e^{-i\xi})^j$, $j\in\mathbb{N}$, be the masks for the up-functions. Then, item (iii) of Theorem 1.3 says that it does not have any "strong" frame approximation order in the sense of (1.16); i.e., for any given $\nu>0$, there does not exist a positive constant C such that (1.16) is satisfied. But one can check that the corresponding spaces $S_n(\phi_n)$ provide a spectral approximation order.

If the integer shifts of ϕ_n are orthonormal, then the linear operator P_n in (3.1) becomes an orthogonal projection from $L_2(\mathbb{R})$ to $S_n(\phi_n)$. That is, for this case, $P_n(f)$ is the best approximation of $f\in L_2(\mathbb{R})$ in the closed subspace $S_n(\phi_n)$ of $L_2(\mathbb{R})$. This is the reason why the approximation order of Q_n's is identified with the best approximation order provided by the spaces $S_n(\phi_n)$ in [10], which is simpler to understand, since only orthonormal wavelets are studied in [10].

To summarize our discussion here, the understanding of the approximation order of the approximation operators Q_n for a given tight wavelet frame is necessary, since it is simple and used in applications such as image inpainting, and since, unlike orthonormal wavelets, the approximation order of a truncated tight frame series is

not necessarily the same as the best approximation order provided by the underlying nonstationary multiresolution analysis.

The main result of this section is Theorem 3.2, which is interesting in its own right and is independent of its role in our proofs of some of major parts of Theorems 1.1–1.4.

The following result can be directly obtained by applying Jetter and Zhou [28] and [29, Theorem 2.1].

PROPOSITION 3.1. *Let $\varphi \in L_2(\mathbb{R})$ and $\nu \geqslant 0$. Define a linear operator P by*

$$P(f) := \sum_{k\in\mathbb{Z}} \langle f, \varphi(\cdot - k)\rangle \varphi(\cdot - k), \qquad f \in L_2(\mathbb{R}).$$

Then $\|f - P(f)\|_{L_2(\mathbb{R})} \leqslant C_\varphi |f|_{W_2^\nu(\mathbb{R})}$ for all $f \in W_2^\nu(\mathbb{R})$ with a positive constant

$$C_\varphi := \pi^{-1/2} \sqrt{\max(c_1, c_3) + \max(2c_2, 2c_4 + 1)}, \tag{3.3}$$

provided that there exist positive constants c_1, c_2, c_3, c_4 such that, for almost every $\xi \in [-\pi, \pi]$, the following inequalities hold:

$$\left|1 - |\hat{\varphi}(\xi)|^2\right|^2 \leqslant c_1 |\xi|^{2\nu}, \tag{3.4}$$

$$\sum_{k\in\mathbb{Z}\setminus\{0\}} |\hat{\varphi}(\xi)|^2 |\hat{\varphi}(\xi + 2\pi k)|^2 \leqslant c_2 |\xi|^{2\nu}, \tag{3.5}$$

$$\sum_{k\in\mathbb{Z}\setminus\{0\}} |\xi + 2\pi k|^{-2\nu} |\hat{\varphi}(\xi)|^2 |\hat{\varphi}(\xi + 2\pi k)|^2 \leqslant c_3, \tag{3.6}$$

$$\sum_{k\in\mathbb{Z}\setminus\{0\}} |\xi + 2\pi k|^{-2\nu} \sum_{\ell\in\mathbb{Z}\setminus\{0\}} |\hat{\varphi}(\xi + 2\pi\ell)|^2 |\hat{\varphi}(\xi + 2\pi k)|^2 \leqslant c_4. \tag{3.7}$$

Next, we present the following result on the approximation properties of the operators P_n defined in (3.1).

THEOREM 3.2. *Let $\widehat{a_j}, j \in \mathbb{N}$, be 2π-periodic measurable functions such that* (1.3) *holds for all $j \in \mathbb{N}$, and, for every $n \in \mathbb{N}_0$, the function $\widehat{\phi_n}(\xi) := \lim_{J\to\infty} \prod_{j=1}^{J} \widehat{a_{j+n}}(2^{-j}\xi)$ is well defined for almost every $\xi \in \mathbb{R}$. Let $\nu \geqslant 0$. If, for $n \in \mathbb{N}$,*

$$\begin{aligned} &\left|1 - |\widehat{\phi_n}(\xi)|^2\right|^2 \leqslant C_{\phi_n} |\xi|^{2\nu} \qquad \text{a.e. } \xi \in [-\pi, \pi], \\ &\sum_{k\in\mathbb{Z}\setminus\{0\}} |\widehat{\phi_n}(\xi)|^2 |\widehat{\phi_n}(\xi + 2\pi k)|^2 \leqslant C_{\phi_n} |\xi|^{2\nu} \qquad \text{a.e. } \xi \in [-\pi, \pi], \end{aligned} \tag{3.8}$$

where C_{ϕ_n} is a constant depending only on ϕ_n, then, for the linear operators P_n in (3.1),

$$\|f - P_n(f)\|_{L_2(\mathbb{R})} \leqslant \max(2, \sqrt{C_{\phi_n}})\, 2^{-\nu n} |f|_{W_2^\nu(\mathbb{R})} \quad \forall\, f \in W_2^\nu(\mathbb{R}) \quad \text{and} \quad n \in \mathbb{N}. \tag{3.9}$$

In particular, (3.8) *is satisfied if*

$$1 - |\widehat{\phi_n}(\xi)|^2 \leqslant C_{\phi_n} |\xi|^{2\nu} \qquad \text{a.e. } \xi \in [-\pi, \pi]. \tag{3.10}$$

Proof. By (1.3) and Lemma 2.2, we have $\phi_n \in L_2(\mathbb{R})$ for all $n \in \mathbb{N}_0$. For each fixed $n \in \mathbb{N}_0$, we denote $P_{n,0}$ the following linear operator on $L_2(\mathbb{R})$:

$$P_{n,0}(f) := \sum_{k\in\mathbb{Z}} \langle f, \phi_n(\cdot - k)\rangle \phi_n(\cdot - k), \qquad f \in L_2(\mathbb{R}).$$

It is apparent [28] that the operators P_n and $P_{n,0}$ are linked through the relation $P_n(f) = [P_{n,0}(f(2^{-n}\cdot))](2^n\cdot)$ and

$$\|f - P_n(f)\|_{L_2(\mathbb{R})} = 2^{-n/2}\|f(2^{-n}\cdot) - P_{n,0}(f(2^{-n}\cdot))\|_{L_2(\mathbb{R})}. \tag{3.11}$$

Since (1.3) holds, by Lemma 2.2, we have

$$[\widehat{\phi_n}, \widehat{\phi_n}](\xi) := \sum_{k\in\mathbb{Z}} |\widehat{\phi_n}(\xi + 2\pi k)|^2 \leqslant 1 \quad \text{a.e. } \xi \in \mathbb{R}.$$

In particular, we have $|\widehat{\phi_n}(\xi)| \leqslant 1$ for almost every $\xi \in \mathbb{R}$.

Since $\nu \geqslant 0$, for $\xi \in [-\pi, \pi]$, it is evident that $|\xi + 2\pi k|^{-2\nu} \leqslant 1$ for all $k \in \mathbb{Z}\backslash\{0\}$ and

$$\sum_{k\in\mathbb{Z}\backslash\{0\}} |\xi + 2\pi k|^{-2\nu} \sum_{\ell\in\mathbb{Z}\backslash\{0\}} |\widehat{\phi_n}(\xi + 2\pi\ell)|^2 |\widehat{\phi_n}(\xi + 2\pi k)|^2$$

$$\leqslant \sum_{k\in\mathbb{Z}} |\widehat{\phi_n}(\xi + 2\pi k)|^2 \sum_{\ell\in\mathbb{Z}} |\widehat{\phi_n}(\xi + 2\pi\ell)|^2 \leqslant 1.$$

Hence, (3.7) holds with $c_4 = 1$ and $\varphi = \phi_n$. Similarly, for $\xi \in [-\pi, \pi]$, we have

$$\sum_{k\in\mathbb{Z}\backslash\{0\}} |\xi + 2\pi k|^{-2\nu} |\widehat{\phi_n}(\xi)|^2 |\widehat{\phi_n}(\xi + 2\pi k)|^2 \leqslant \sum_{k\in\mathbb{Z}} |\widehat{\phi_n}(\xi + 2\pi k)|^2 \leqslant 1.$$

Therefore, (3.6) holds with $c_3 = 1$ and $\varphi = \phi_n$.

By (3.8), we see that (3.4) and (3.5) hold with $c_1 = c_2 = C_{\phi_n}$ and $\varphi = \phi_n$.

Note that $|f(2^{-n}\cdot)|_{W_2^\nu(\mathbb{R})} = 2^{n/2}2^{-\nu n}|f|_{W_2^\nu(\mathbb{R})}$. Therefore, by Proposition 3.1 and (3.11), we conclude that, for all $f \in W_2^\nu(\mathbb{R})$,

$$\begin{aligned}\|f - P_n(f)\|_{L_2(\mathbb{R})} &= 2^{-n/2}\|f(2^{-n}\cdot) - P_{n,0}(f(2^{-n}\cdot))\|_{L_2(\mathbb{R})} \\ &\leqslant \max(2, \sqrt{C_{\phi_n}})2^{-\nu n}|f|_{W_2^\nu(\mathbb{R})},\end{aligned} \tag{3.12}$$

since

$$\max(c_1, c_3) + \max(2c_2, 2c_4 + 1) = \max(C_{\phi_n}, 1) + \max(2C_{\phi_n}, 3) \leqslant \max(3C_{\phi_n}, 6)$$

$$\leqslant \pi \max(C_{\phi_n}, 4).$$

Therefore, (3.9) is verified.

If (3.10) holds, then

$$\big|1 - |\widehat{\phi_n}(\xi)|^2\big|^2 \leqslant C_{\phi_n}^2 |\xi|^{2\nu}|\xi|^{2\nu} \leqslant C_{\phi_n}|\xi|^{2\nu}, \qquad |\xi| \leqslant C_{\phi_n}^{-\frac{1}{2\nu}},$$

and by $|\widehat{\phi_n}(\xi)| \leqslant 1$,

$$\big|1 - |\widehat{\phi_n}(\xi)|^2\big|^2 \leqslant 1 = C_{\phi_n}[C_{\phi_n}^{-\frac{1}{2\nu}}]^{2\nu} \leqslant C_{\phi_n}|\xi|^{2\nu}, \qquad |\xi| \geqslant C_{\phi_n}^{-\frac{1}{2\nu}}.$$

Also, by $|\widehat{\phi_n}(\xi)|^2 \leqslant [\widehat{\phi_n}, \widehat{\phi_n}](\xi) \leqslant 1$ and the above two inequalities, we have

$$\sum_{k\in\mathbb{Z}\backslash\{0\}} |\widehat{\phi_n}(\xi)|^2 |\widehat{\phi_n}(\xi + 2\pi k)|^2 \leqslant \sum_{k\in\mathbb{Z}\backslash\{0\}} |\widehat{\phi_n}(\xi + 2\pi k)|^2 = [\widehat{\phi_n}, \widehat{\phi_n}](\xi) - |\widehat{\phi_n}(\xi)|^2$$

$$\leqslant 1 - |\widehat{\phi_n}(\xi)|^2.$$

Consequently, (3.10) implies (3.8). □

The behavior of $1-|\widehat{\phi_n}(\xi)|^2$ near the origin $\xi=0$ in (3.10) is closely related to that of the masks $1-|\widehat{a_j}(\xi)|^2$ for all $j\in\mathbb{N}$ near the origin $\xi=0$. As we will see in the proof of the next section, when only masks are available and the nonstationary refinable functions are not explicitly given, one can use the estimate of $1-|\widehat{a_j}(\xi)|^2$ near $\xi=0$ for all $j\in\mathbb{N}$ to obtain the estimate of $1-|\widehat{\phi_n}(\xi)|^2$ near $\xi=0$. The following result provides the estimate of $1-|\widehat{a_j}(\xi)|^2$ near the origin for the masks of pseudosplines, which will be needed later in our proof of the spectral frame approximation order in Theorems 1.2 and 1.4.

LEMMA 3.3. *Let $\widehat{a^I_{m,l}}$ and $\widehat{a_{m,l}}$ be pseudospline masks of types* I *and* II *of order (m,l) defined in* (1.19) *and* (1.20)*, respectively. For any $0<\rho\leqslant 1$ and $\nu\geqslant 0$, there exist a positive integer N and a positive constant C (both of them depend only on ρ and ν), such that, for all $N\leqslant \rho m<l\leqslant m$,*

$$0\leqslant 1-|\widehat{a^I_{m,l}}(\xi)|^2\leqslant 1-|\widehat{a_{m,l}}(\xi)|^2\leqslant C|\xi|^{2\nu}\qquad \forall\,\xi\in[-\pi,\pi]. \tag{3.13}$$

Proof. Since $|\widehat{a^I_{m,l}}(\xi)|^2=\widehat{a_{m,l}}(\xi)\leqslant 1$, we have

$$0\leqslant 1-|\widehat{a^I_{m,l}}(\xi)|^2\leqslant 1-|\widehat{a_{m,l}}(\xi)|^2=[1+\widehat{a_{m,l}}(\xi)][1-\widehat{a_{m,l}}(\xi)]\leqslant 2[1-\widehat{a_{m,l}}(\xi)].$$

Setting $x=\sin^2(\xi/2)$, by the definition of $\widehat{a_{m,l}}(\xi)$ in (1.19), we have $\widehat{a_{m,l}}(\xi)=(1-x)^mP_{m,l}(x)$, where the polynomial $P_{m,l}$ is defined in (1.18). In order to prove (3.13), now it is easy to see that it is equivalent to proving that, for any $0<\rho\leqslant 1$ and any positive integer ν, there exist a positive integer N and a positive constant C, all depending only on ρ and ν, such that

$$1-(1-x)^mP_{m,l}(x)\leqslant Cx^\nu\qquad \forall\,x\in[0,1]\quad\text{and}\quad N\leqslant\rho m<l\leqslant m. \tag{3.14}$$

Since $(1-x)^mP_{m,m}(x)+x^mP_{m,m}(1-x)=1$, we deduce that

$$\begin{aligned}1-(1-x)^mP_{m,l}(x)&=(1-x)^mP_{m,m}(x)+x^mP_{m,m}(1-x)-(1-x)^mP_{m,l}(x)\\&=x^mP_{m,m}(1-x)+(1-x)^m\sum_{j=l}^{m-1}\frac{(m+j-1)!}{j!(m-1)!}x^j.\\&=x^\nu\left[x^{m-\nu}P_{m,m}(1-x)+(1-x)^m\sum_{j=l}^{m-1}\frac{(m+j-1)!}{j!(m-1)!}x^{j-\nu}\right].\end{aligned}$$

By Lemma 2.7, (2.24) holds. In particular, replacing x by $1-x$ in (2.24), we conclude that

$$x^{m-\nu}P_{m,m}(1-x)\leqslant x^{N-\nu-1}P_{N,N}(1-x)\qquad\forall\,x\in[0,1]\quad\text{and}\quad m\geqslant N\geqslant\nu+1.$$

Therefore, on the one hand, we have

$$x^{m-\nu}P_{m,m}(1-x)\leqslant C_N:=\max_{x\in[0,1]}x^{N-\nu-1}P_{N,N}(1-x)<\infty\qquad\forall\,x\in[0,1],\ m\geqslant N\geqslant\nu+1. \tag{3.15}$$

On the other hand, for $x \in [0,1]$, we have

$$\begin{aligned}(1-x)^m \sum_{j=l}^{m-1} \frac{(m+j-1)!}{j!(m-1)!} x^{j-\nu} &= (1-x)^m x^{l-\nu} \sum_{j=l}^{m-1} \frac{(m+j-1)!}{j!(m-1)!} x^{j-l} \\ &\leqslant (1-x)^m x^{l-\nu} \sum_{j=l}^{m-1} \frac{(m+j-1)!}{j!(m-1)!} \\ &= (1-x)^m x^{l-\nu} \sum_{j=l}^{m-1} \left[\frac{(m+j)!}{j!m!} - \frac{(m+j-1)!}{(j-1)!m!} \right] \\ &\leqslant (1-x)^m x^{l-\nu} \frac{(2m-1)!}{(m-1)!m!}.\end{aligned}$$

By Stirling's formula, we have $\lim_{n\to\infty} \frac{n!}{\sqrt{2\pi} n^{n+1/2} e^{-n}} = 1$. Thus, when m is large enough and for all $x \in [0,1]$, we have

$$\frac{(2m-1)!}{(m-1)!m!} = \frac{1}{2} \frac{(2m)!}{m!m!} \leqslant \frac{1}{\sqrt{2\pi}} \frac{(2m)^{2m+1/2} e^{-2m}}{m^{2m+1} e^{-2m}} \leqslant 4^m m^{-1/2}.$$

Thus, for large enough m, we have

$$(1-x)^m \sum_{j=l}^{m-1} \frac{(m+j-1)!}{j!(m-1)!} x^{j-\nu} \leqslant (1-x)^m x^{l-\nu} 4^m m^{-1/2} = [4(1-x)x^{(l-\nu)/m}]^m m^{-1/2}.$$

Since $\rho m < l$, we have $l/m > \rho$. Since ν is fixed, when m is large enough, we have $(l-\nu)/m \geqslant \rho$ and, hence, $x^{(l-\nu)/m} \leqslant x^\rho$ for all $x \in [0,1]$. Therefore, we have

$$(1-x)^m \sum_{j=l}^{m-1} \frac{(m+j-1)!}{j!(m-1)!} x^{j-\nu} \leqslant [4(1-x)x^\rho]^m m^{-1/2} \qquad \forall\, x \in [0,1].$$

Note that $\rho > 0$. The continuous function $(1-x)x^\rho$ has only one critical point $x = \frac{\rho}{1+\rho}$ on the interval $(0,1)$, and it takes value zero at $x = 0$. Thus, we can choose $0 < \tau \leqslant 1$ such that $4(1-x)x^\rho \leqslant 1$ for all $x \in [0,\tau]$; one may prefer to choose such τ as large as possible; in particular, τ may be obtained by solving $4(1-\tau)\tau^\rho = 1$. Therefore, there exists a positive integer N such that, for $N \leqslant \rho m < l \leqslant m$,

$$(1-x)^m \sum_{j=l}^{m-1} \frac{(m+j-1)!}{j!(m-1)!} x^{j-\nu} \leqslant [4(1-x)x^\rho]^m m^{-1/2} \leqslant m^{-1/2} \leqslant 1 \qquad \forall\, x \in [0,\tau]. \tag{3.16}$$

Combining (3.15) and (3.16), we conclude that

$$1 - (1-x)^m P_{m,l}(x) \leqslant x^\nu [C_N + 1] \qquad \forall\, x \in [0,\tau],\ N \leqslant \rho m < l \leqslant m.$$

Observing that $0 \leqslant (1-x)^m P_{m,l}(x) \leqslant 1$ for all $x \in [0,1]$, we deduce that

$$1 - (1-x)^m P_{m,l}(x) \leqslant 1 = x^{-\nu} x^\nu \leqslant \tau^{-\nu} x^\nu \qquad \forall\, x \in [\tau,1],\ 1 \leqslant l \leqslant m,\ m \in \mathbb{N}.$$

Thus, (3.14) is verified with $C := \max(C_N + 1, \tau^{-\nu})$. This completes the proof. ∎

4. Proofs of Theorems 1.1–1.4. In this section, we shall prove Theorems 1.1–1.4. We start with a proof of Theorem 1.1.

Proof of Theorem 1.1. By our assumption in Theorem 1.1, item (i) follows from Lemmas 2.1 and 2.2. Since (1.3) holds, by Lemma 2.2, we have $[\widehat{\phi_n}, \widehat{\phi_n}] \leqslant 1$ and $\phi_n \in L_2(\mathbb{R})$. Therefore, the linear operators Q_n in (1.9) and P_n in (3.1) are well defined, bounded, and the same (see section 3).

Let us first prove (1.15) in item (iii). In order to do so, in the following we estimate the constants C_{ϕ_n} in (3.10). Denote $\widehat{d_j}(\xi) := |\widehat{a_j}(\xi)|^2$ for $j \in \mathbb{N}$. Since $\widehat{a_j}(0) = 1$, we have $\widehat{d_j}(0) = 1$ for all $j \in \mathbb{N}$. By our assumption and Lemma 2.1, we have $|\widehat{\phi_n}(\xi)|^2 = \prod_{j=1}^{\infty} \widehat{d_{j+n}}(2^{-j}\xi)$ for all $\xi \in \mathbb{R}$. Therefore, we have

$$\begin{aligned} 1 - |\widehat{\phi_n}(\xi)|^2 &= \prod_{j=1}^{\infty} \widehat{d_{j+n}}(0) - \prod_{j=1}^{\infty} \widehat{d_{j+n}}(2^{-j}\xi) \\ &= \sum_{\ell=1}^{\infty} \Big[\prod_{j=1}^{\ell-1} \widehat{d_{j+n}}(0) \Big] [\widehat{d_{\ell+n}}(0) - \widehat{d_{\ell+n}}(2^{-\ell}\xi)] \Big[\prod_{j=\ell+1}^{\infty} \widehat{d_{j+n}}(2^{-j}\xi) \Big]. \end{aligned}$$

Since $\widehat{d_{j+n}}(0) = 1$ and $0 \leqslant \widehat{d_{j+n}}(\xi) \leqslant 1$ by (1.3), we conclude that

$$0 \leqslant 1 - |\widehat{\phi_n}(\xi)|^2 \leqslant \sum_{\ell=1}^{\infty} |\widehat{d_{\ell+n}}(0) - \widehat{d_{\ell+n}}(2^{-\ell}\xi)|, \qquad \xi \in \mathbb{R}. \tag{4.1}$$

Since $\widehat{a_j}$ is a 2π-periodic trigonometric polynomial, by the definition of $\widehat{d_j}$, we see that $\widehat{d_j}$ is a real-valued C^∞ function. Note that, by our assumption, 2ν is a positive integer. Therefore, for $\xi \in [-\pi, \pi]$, there exists $\zeta_{\xi,j} \in [-\pi, \pi]$ such that

$$\widehat{d_j}(\xi) = \widehat{d_j}(0) + \frac{\widehat{d_j}^{(1)}(0)}{1!}\xi + \cdots + \frac{\widehat{d_j}^{(2\nu-1)}(0)}{(2\nu-1)!}\xi^{2\nu-1} + \frac{\widehat{d_j}^{(2\nu)}(\zeta_{\xi,j})}{(2\nu)!}\xi^{2\nu}. \tag{4.2}$$

By Bernstein's inequality and $0 \leqslant \widehat{d_j}(\xi) \leqslant 1$, we have

$$\|\widehat{d_j}^{(2\nu)}\|_{L_\infty(\mathbb{R})} \leqslant [\deg(\widehat{d_j})]^{2\nu} \|\widehat{d_j}\|_{L_\infty(\mathbb{R})} \leqslant [\deg(\widehat{d_j})]^{2\nu}.$$

By assumption in (1.14), for $j \geqslant N$, we have $\widehat{d_j}^{(\ell)}(0) = 0$ for all $\ell = 1, \ldots, 2\nu - 1$. Therefore, it follows from (4.2) that, for $n \geqslant N$, $\ell \in \mathbb{N}$, and $\xi \in [-\pi, \pi]$,

$$|\widehat{d_{\ell+n}}(0) - \widehat{d_{\ell+n}}(2^{-\ell}\xi)| \leqslant \frac{[\deg(\widehat{d_{\ell+n}})]^{2\nu}}{(2\nu)!} |2^{-\ell}\xi|^{2\nu} \leqslant \frac{1}{(2\nu)!} |\xi|^{2\nu} 2^{-2\nu\ell} [\deg(\widehat{d_{\ell+n}})]^{2\nu}.$$

Therefore, we have

$$\sum_{\ell=1}^{\infty} |\widehat{d_{\ell+n}}(0) - \widehat{d_{\ell+n}}(2^{-\ell}\xi)| \leqslant \frac{1}{(2\nu)!} |\xi|^{2\nu} \sum_{\ell=1}^{\infty} 2^{-2\nu\ell} [\deg(\widehat{d_{\ell+n}})]^{2\nu}.$$

That is, by (4.1) we see that, for every $n \geqslant N$, (3.10) holds with

$$C_{\phi_n} := \frac{1}{(2\nu)!} \sum_{\ell=1}^{\infty} 2^{-2\nu\ell} [\deg(\widehat{d_{\ell+n}})]^{2\nu}. \tag{4.3}$$

Now we estimate C_{ϕ_n} using the condition in (1.13). By (1.13), there exists a positive constant C_1 such that

$$\deg(\widehat{a_j}) \leqslant C_1 j^\alpha 2^{\beta j} \qquad \forall\, j \in \mathbb{N}. \tag{4.4}$$

By the definition of $\widehat{d_j}$, we have $\deg(\widehat{d_j}) \leqslant 2\deg(\widehat{a_j})$ for all $j \in \mathbb{N}$. Therefore, from (4.4), we deduce that

$$\begin{aligned} 2^{-2\nu\ell}[\deg(\widehat{d_{\ell+n}})]^{2\nu} &\leqslant 2^{2\nu} C_1^{2\nu} (\ell+n)^{2\nu\alpha} 2^{2\nu\beta(\ell+n)} 2^{-2\nu\ell} \\ &= 2^{2\nu} C_1^{2\nu} n^{2\nu\alpha} 2^{2\nu\beta n} (1+\ell/n)^{2\nu\alpha} 2^{-2\nu(1-\beta)\ell} \\ &\leqslant 2^{2\nu} C_1^{2\nu} n^{2\nu\alpha} 2^{2\nu\beta n} (1+\ell)^{2\nu\alpha} 2^{-2\nu(1-\beta)\ell}. \end{aligned}$$

Consequently, we have the following estimate for the constant C_{ϕ_n}:

$$\begin{aligned} C_{\phi_n} &= \frac{1}{(2\nu)!} \sum_{\ell=1}^{\infty} 2^{-2\nu\ell} [\deg(\widehat{d_{\ell+n}})]^{2\nu} \leqslant \frac{2^{2\nu} C_1^{2\nu}}{(2\nu)!} n^{2\nu\alpha} 2^{2\nu\beta n} \sum_{\ell=1}^{\infty} (1+\ell)^{2\nu\alpha} 2^{-2\nu(1-\beta)\ell} \\ &= C_2 n^{2\nu\alpha} 2^{2\nu\beta n}, \end{aligned}$$

where $C_2 := 2^{2\nu} C_1^{2\nu} [(2\nu)!]^{-1} \sum_{\ell=1}^{\infty} (1+\ell)^{2\nu\alpha} 2^{-2\nu(1-\beta)\ell} < \infty$, since $1-\beta > 0$ and $\nu > 0$. Since $Q_n = P_n$, by Theorem 3.2, we conclude that

$$\|f - Q_n(f)\|_{L_2(\mathbb{R})} \leqslant \max(2, \sqrt{C_2}) n^{\nu\alpha} 2^{-\nu(1-\beta)n} |f|_{W_2^\nu(\mathbb{R})} \quad \forall\, f \in W_2^\nu(\mathbb{R}) \quad \text{and} \quad n \geqslant N.$$

That is, (1.15) holds with $C := \max(2, \sqrt{C_2}) < \infty$, which is independent of f and n.

Now we prove item (ii). In order to show that $\{\phi_0(\cdot - k) : k \in \mathbb{Z}\} \cup \{\psi_{j;j,k}^\ell : j \in \mathbb{N}_0, k \in \mathbb{Z}, \ell = 1, \ldots, \mathcal{J}_{j+1}\}$ is a tight frame of $L_2(\mathbb{R})$, since $Q_n = P_n$, it now suffices to show that

$$\lim_{n\to\infty} \|f - Q_n(f)\|_{L_2(\mathbb{R})} = \lim_{n\to\infty} \|f - P_n(f)\|_{L_2(\mathbb{R})} = 0 \qquad \forall\, f \in L_2(\mathbb{R}).$$

Since $\widehat{a_j}(0) = 1$ and $\widehat{d_j}(\xi) = |\widehat{a_j}(\xi)|^2$, it is evident that $\widehat{d_j}(0) = 1$. Since $\widehat{d_j}$ is a 2π-periodic trigonometric polynomial, the condition in (1.14) is automatically satisfied with $\nu = 1/2$.

Now from the above proof of item (iii) and by Theorem 3.2, we see that (3.9) holds with the constant C_{ϕ_n} defined in (4.3) and $\nu = 1/2$. More precisely, by Theorem 3.2, for $\nu = 1/2$, we have

$$\|f - P_n(f)\|_{L_2(\mathbb{R})}^2 \leqslant C_n |f|_{W_2^{1/2}(\mathbb{R})}^2 \qquad \forall\, f \in W_2^{1/2}(\mathbb{R}) \tag{4.5}$$

with

$$C_n := \max(4, C_{\phi_n}) 2^{-n} \quad \text{and} \quad C_{\phi_n} := \sum_{\ell=1}^{\infty} 2^{-\ell} \deg(\widehat{d_{\ell+n}}). \tag{4.6}$$

Now we prove that $\lim_{n\to\infty} C_n = 0$ by showing $\lim_{n\to\infty} 2^{-n} C_{\phi_n} = 0$. Note that

$$2^{-n} C_{\phi_n} = \sum_{\ell=1}^{\infty} 2^{-(\ell+n)} \deg(\widehat{d_{\ell+n}}) = \sum_{j=n+1}^{\infty} 2^{-j} \deg(\widehat{d_j}). \tag{4.7}$$

Since $\deg(\widehat{d_j}) \leqslant 2\deg(\widehat{a_j})$, by our assumption in (1.4), we have

$$\sum_{j=1}^{\infty} 2^{-j}\deg(\widehat{d_j}) \leqslant 2\sum_{j=1}^{\infty} 2^{-j}\deg(\widehat{a_j}) < \infty.$$

Consequently, by (4.7), we conclude that

$$0 \leqslant \lim_{n\to\infty} 2^{-n}C_{\phi_n} \leqslant \lim_{n\to\infty} \sum_{j=n+1}^{\infty} 2^{-j}\deg(\widehat{d_j}) = 0.$$

That is, $\lim_{n\to\infty} 2^{-n}C_{\phi_n} = 0$. Thus, we have $\lim_{n\to\infty} C_n = \lim_{n\to\infty} \max(4, C_{\phi_n})2^{-n} = 0$. Now from (4.5), we see that

$$\lim_{n\to\infty} \|f - P_n(f)\|^2_{L_2(\mathbb{R})} = \lim_{n\to\infty} C_n|f|^2_{W_2^{1/2}(\mathbb{R})} = 0 \qquad \forall\, f \in W_2^{1/2}(\mathbb{R}).$$

Since $P_n = Q_n$ in (3.1), we conclude that

$$\|f\|^2_{L_2(\mathbb{R})} = \lim_{n\to\infty} \langle Q_n(f), f\rangle = \sum_{k\in\mathbb{Z}} |\langle f, \phi_0(\cdot - k)\rangle|^2 + \sum_{j=0}^{\infty}\sum_{\ell=1}^{\mathcal{J}_{j+1}}\sum_{k\in\mathbb{Z}} |\langle f, \psi^{\ell}_{j;j,k}\rangle|^2$$

$$\forall\, f \in W_2^{1/2}(\mathbb{R}).$$

Since $W_2^{1/2}(\mathbb{R})$ is dense in $L_2(\mathbb{R})$, (1.2) must hold for all $f \in L_2(\mathbb{R})$. Therefore, $\{\phi_0(\cdot - k) : k \in \mathbb{Z}\} \cup \{\psi^{\ell}_{j;j,k} : j \in \mathbb{N}_0, k \in \mathbb{Z}, \ell = 1, \ldots, \mathcal{J}_{j+1}\}$ is a tight frame of $L_2(\mathbb{R})$. □

Next, we prove Theorem 1.2.

Proof of Theorem 1.2. For item (1), applying Theorem 2.8, we conclude that all $\phi_j, j \in \mathbb{N}_0$, are compactly supported functions in $C^{\infty}(\mathbb{R})$. Since all the masks $\widehat{a_j}$ are 2π-periodic trigonometric polynomials with real coefficients and are symmetric about the origin, we have $\overline{\widehat{a_j}(\xi)} = \widehat{a_j}(\xi)$. Now by the definition of $\widehat{\phi_j}$ in (1.1), it is straightforward to see that all $\phi_j, j \in \mathbb{N}_0$, are real-valued and $\overline{\widehat{\phi_j}(\xi)} = \widehat{\phi_j}(\xi)$; that is, all $\phi_j, j \in \mathbb{N}_0$, are symmetric about the origin.

By the definition of $\widehat{a^I_{m,l}}$ and $\widehat{a_{m,l}}$, we have

$$1 - |\widehat{a^I_{m,l}}(\xi)|^2 = 1 + O(|\xi|^{2l}) \quad \text{and} \quad 1 - |\widehat{a_{m,l}}(\xi)|^2 = 1 + O(|\xi|^{2l}), \qquad \xi \to 0. \tag{4.8}$$

By (1.12) and (4.8), we see that $\widehat{b^{\ell}_j}(\xi) = O(|\xi|^{l_j})$ as $\xi \to 0$. Therefore, ψ^{ℓ}_j has l_{j+1} vanishing moments. Thus, item (2) holds.

For item (3), by the definition of $\widehat{b^{\ell}_j}$ in (1.17), it is straightforward to check that (1.12) holds with $\mathcal{J}_j = 3$ for all $j \in \mathbb{N}$. Now by Theorem 1.1, we see that $\{\phi_0(\cdot - k) : k \in \mathbb{Z}\} \cup \{\psi^{\ell}_{j;j,k} : j \in \mathbb{N}_0, k \in \mathbb{Z}, \ell = 1, \ldots, \mathcal{J}_{j+1}\}$ is a tight wavelet frame in $L_2(\mathbb{R})$.

Now we prove item (4) by using Theorem 3.2 and Lemma 3.3. Let ν be an arbitrary positive integer. Since $\liminf_{j\to\infty} l_j/m_j > 0$, there exist a positive integer N and $0 < \rho < \liminf_{j\to\infty} l_j/m_j$ such that $2\nu < N < \rho m_j < l_j \leqslant m_j$ for all $j \geqslant N$. Denote $\widehat{d_j}(\xi) := |\widehat{a_j}(\xi)|^2$. By Lemma 3.3, we see that (3.13) holds. That is, there exists a positive constant C, independent of j, such that

$$0 \leqslant 1 - \widehat{d_j}(\xi) \leqslant C|\xi|^{2\nu}, \qquad \xi \in [-\pi, \pi] \quad \text{and} \quad j \geqslant N. \tag{4.9}$$

We now use (4.9) to estimate the constants C_{ϕ_n} in (3.10) of Theorem 3.2. For $n \geqslant N$ and $\ell \in \mathbb{N}$, since $\widehat{d_{\ell+n}}(0) = 1$, it follows from (4.9) that

$$|\widehat{d_{\ell+n}}(0) - \widehat{d_{\ell+n}}(2^{-\ell}\xi)| = |1 - \widehat{d_{\ell+n}}(2^{-\ell}\xi)| \leqslant C 2^{-2\nu\ell}|\xi|^{2\nu} \qquad \forall\, \xi \in [-\pi, \pi].$$

Now by (4.1), we conclude that

$$1 - |\widehat{\phi_n}(\xi)|^2 \leqslant C|\xi|^{2\nu} \sum_{\ell=1}^{\infty} 2^{-2\nu\ell}, \qquad \xi \in [-\pi, \pi].$$

Therefore, (3.10) holds with

$$C_{\phi_n} := C \sum_{\ell=1}^{\infty} 2^{-2\nu\ell} = \frac{C}{1 - 2^{-2\nu}} < \infty.$$

Consequently, by $Q_n = P_n$ and Theorem 3.2, we conclude that

$$\|f - Q_n(f)\|_{L_2(\mathbb{R})} \leqslant C_1 2^{-\nu n} |f|_{W_2^\nu(\mathbb{R})} \qquad \forall\, f \in W_2^\nu(\mathbb{R}) \quad \text{and} \quad n \geqslant N,$$

where

$$C_1 := \max(2, \sqrt{C/(1 - 2^{-2\nu})}) < \infty$$

is independent of f and n. Since ν is arbitrary, the tight wavelet frame has the desired spectral frame approximation order. □

Now we prove Theorem 1.3.

Proof of Theorem 1.3. Item (i) has been proved in Theorem 1.2. It is evident that

$$\deg(\widehat{a_j}) = j \quad \text{and} \quad |\widehat{a_j}(\xi)|^2 = \cos^{2j}(\xi/2) = 1 + O(|\xi|^2), \qquad \xi \to 0.$$

Now it follows from the proof of item (iii) of Theorem 1.1 that there exists a positive constant C_1 such that

$$1 - |\widehat{\phi_n}(\xi)|^2 \leqslant C_1 n^2 |\xi|^2 \qquad \forall\, \xi \in [-\pi, \pi] \quad \text{and} \quad n \in \mathbb{N}.$$

That is, we conclude that

$$\left|1 - |\widehat{\phi_n}(\xi)|^2\right|^2 \leqslant C_1^2 n^4 |\xi|^4 \qquad \forall\, \xi \in [-\pi, \pi] \quad \text{and} \quad n \in \mathbb{N}. \tag{4.10}$$

Let B_2 be the B-spline of order 2. Then

$$|\widehat{B_2}(\xi)|^2 = \frac{\sin^4(\xi/2)}{(\xi/2)^4} \quad \text{and} \quad |\widehat{B_2}(2\xi)|^2 = \cos^4(\xi/2)|\widehat{B_2}(\xi)|^2.$$

Since $|\widehat{a_j}(\xi)|^2 = \cos^{2j}(\xi/2) \leqslant \cos^4(\xi/2)$ for all $\xi \in \mathbb{R}$ and $j \geqslant 2$, it is evident that $|\widehat{\phi_n}(\xi)|^2 \leqslant |\widehat{B_2}(\xi)|^2$ for all $\xi \in \mathbb{R}$ and $n \geqslant 2$. In particular, for $\xi \in [-\pi, \pi]$, we deduce that

$$\begin{aligned} \sum_{k \in \mathbb{Z}\setminus\{0\}} |\widehat{\phi_n}(\xi)|^2 |\widehat{\phi_n}(\xi + 2\pi k)|^2 &\leqslant \sum_{k \in \mathbb{Z}\setminus\{0\}} |\widehat{B_2}(\xi + 2\pi k)|^2 \\ &= |\xi|^4 \frac{\sin^4(\xi/2)}{(\xi/2)^4} \sum_{k \in \mathbb{Z}\setminus\{0\}} |\xi + 2\pi k|^{-4}. \end{aligned}$$

Setting $C_2 := \sup_{\xi\in[-\pi,\pi]} \sum_{k\in\mathbb{Z}\setminus\{0\}} |\xi+2\pi k|^{-4} < \infty$, we conclude that

$$\sum_{k\in\mathbb{Z}\setminus\{0\}} |\widehat{\phi_n}(\xi)|^2 |\widehat{\phi_n}(\xi+2\pi k)|^2 \leqslant C_2|\xi|^4, \qquad \xi\in[-\pi,\pi] \quad \text{and} \quad n\geqslant 2.$$

Now taking into account (4.10), we see that the two inequalities in (3.8) hold with $\nu=2$ and $C_{\phi_n} := \max(C_1,C_2)n^4$. Thus, by Theorem 3.2, we see that item (ii) holds.

Now we prove item (iii) using proof by contradiction. Suppose that (1.16) holds for some $\nu>0$. By [29, Theorem 2.2], we have $\big|1-|\widehat{\phi_n}(\xi)|^2\big|^2 \leqslant \pi C^2|\xi|^{2\nu}$ for almost every $\xi\in[-\pi,\pi]$ and $n\geqslant N$, where C is the positive constant in (1.16). That is, we must have

$$1-|\widehat{\phi_j}(\xi)|^2 \leqslant C_3|\xi|^\nu \qquad \forall\, \xi\in[-\pi,\pi] \quad \text{and} \quad j\geqslant N, \tag{4.11}$$

where $C_3 := \sqrt{\pi}C$ is a positive constant independent of j.

By the definition of $\widehat{\phi_j}$ in (1.1) and $\widehat{a_j}(\xi) = 2^{-j}(1+e^{-i\xi})^j$, it is evident that $\widehat{\phi_j}(\xi) = \widehat{B_j}(\xi)\widehat{\phi_0}(\xi)$, where B_j is the B-spline of order j. Since $|\widehat{\phi_0}(\xi)| \leqslant 1$, by $\widehat{\phi_j}(\xi) = \widehat{B_j}(\xi)\widehat{\phi_0}(\xi)$, we have $|\widehat{\phi_j}(\xi)| \leqslant |\widehat{B_j}(\xi)|$, and, therefore, it follows from (4.11) that

$$1-|\widehat{B_j}(\xi)|^2 \leqslant 1-|\widehat{\phi_n}(\xi)|^2 \leqslant C_3|\xi|^\nu \qquad \forall\, \xi\in[-\pi,\pi] \quad \text{and} \quad j\geqslant N. \tag{4.12}$$

Since $|\widehat{B_j}(\xi)|^2 = \cos^{2j}(\xi/4)|\widehat{B_j}(\xi/2)|^2$ and $|\widehat{B_j}(\xi)| \leqslant 1$, we have

$$1-|\widehat{B_j}(4\xi)|^2 = 1-\cos^{2j}(\xi)+\cos^{2j}(\xi)(1-|\widehat{B_j}(2\xi)|^2) \geqslant 1-\cos^{2j}(\xi).$$

Consequently, (4.12) implies

$$\frac{1-\cos^{2j}(\xi)}{|\xi|^\nu} \leqslant \frac{1-|\widehat{B_j}(4\xi)|^2}{|\xi|^\nu} \leqslant C_4 \qquad \forall\, \xi\in[-\pi/4,\pi/4] \quad \text{and} \quad j\geqslant N, \tag{4.13}$$

where $C_4 := 4^\nu C_3 < \infty$. Noting $1=[\cos^2(\xi)+\sin^2(\xi)]^j \geqslant \cos^{2j}(\xi)+j\cos^{2j-2}(\xi)\sin^2(\xi)$, by $4\pi^{-2}\xi^2 \leqslant \sin^2(\xi) \leqslant |\xi|^2$ for all $\xi\in[-\pi/2,\pi/2]$, we deduce that, for $\xi\in[-\pi/4,\pi/4]$,

$$\begin{aligned}\frac{1-\cos^{2j}(\xi)}{|\xi|^\nu} &\geqslant j\frac{\sin^2(\xi)\cos^{2j-2}(\xi)}{|\xi|^\nu} = j\frac{\sin^2(\xi)(1-\sin^2(\xi))^{j-1}}{|\xi|^\nu}\\ &\geqslant 4\pi^{-2}j(\xi^2)^{1-\nu/2}(1-\xi^2)^{j-1}.\end{aligned}$$

Taking $\xi_j := \sqrt{\frac{1-\nu/2}{j-\nu/2}}$, we observe that $\lim_{j\to\infty}\xi_j = 0$, and it follows from the above inequalities and (4.13) that, for $\xi\in[-\pi/4,\pi/4]$ and sufficiently large j,

$$\begin{aligned}C_4 &\geqslant \frac{1-\cos^{2j}(\xi_j)}{|\xi_j|^\nu} \geqslant 4\pi^{-2}j(\xi_j^2)^{1-\nu/2}(1-\xi_j^2)^{j-1}\\ &= 4\pi^{-2}j\frac{(1-\nu/2)^{1-\nu/2}(j-1)^{j-1}}{(j-\nu/2)^{j-\nu/2}} := C_5c_j,\end{aligned}$$

where $0<C_5 := 4\pi^{-2}(1-\nu/2)^{1-\nu/2} < \infty$ and $c_j := j\frac{(j-1)^{j-1}}{(j-\nu/2)^{j-\nu/2}}$. That is, we must have

$$c_j := j\frac{(j-1)^{j-1}}{(j-\nu/2)^{j-\nu/2}} \leqslant C_4/C_5 \tag{4.14}$$

for all sufficiently large integers j.

By calculation, we have

$$c_j = j\frac{(j-1)^{j-1}}{(j-\nu/2)^{j-\nu/2}} = j\frac{j^{j-1}(1-\frac{1}{j})^{j-1}}{j^{j-\nu/2}(1-\frac{\nu}{2j})^{j-\nu/2}} = j^{\nu/2}\Big(1-\frac{1}{j}\Big)^{j-1}\Big(1-\frac{\nu}{2j}\Big)^{-j+\nu/2}.$$

We note that $\lim_{j\to\infty}(1-\frac{1}{j})^{j-1} = e^{-1}$ and $\lim_{j\to\infty}(1-\frac{\nu}{2j})^{-j+\nu/2} = e^{\nu/2}$. Hence, by $\nu > 0$, we conclude that $\lim_{j\to\infty} c_j = \lim_{j\to\infty} j^{\nu/2}e^{\nu/2-1} = \infty$, which is a contradiction to (4.14). So, the tight wavelet frame does not have any frame approximation order. Now item (iii) is verified. □

We finish this paper by proving Theorem 1.4.

Proof of Theorem 1.4. For item (1), by a direct calculation [23, Lemma 3], we observe that

$$\begin{aligned}|\widehat{a_j}(\xi)|^2 &= \cos^{2m_j}(\xi/2)([P^r_{m_j}(\sin^2(\xi/2))]^2 + [P^i_{m_j}(\sin^2(\xi/2))]^2)\\ &= \cos^{2m_j}(\xi/2)P_{m_j,m_j}(\sin^2(\xi/2)) = |\widehat{a^I_{m_j,m_j}}(\xi)|^2.\end{aligned}$$

Hence $|\widehat{a_j}(\xi)|^2 + |\widehat{a_j}(\xi+\pi)|^2 = 1$. By Theorem 2.8 and Proposition 2.6, we see that the nonstationary cascade algorithm associated with $\{\widehat{a_j}\}_{j=1}^\infty$ converges in $W_2^\nu(\mathbb{R})$ for any $\nu \geqslant 0$ and, therefore, all ϕ_j, $j \in \mathbb{N}_0$, are well-defined compactly supported functions in $C^\infty(\mathbb{R})$. By Theorem 2.10, (2.28) holds, and $\{\phi_0(\cdot - k) \ : \ k \in \mathbb{Z}\} \cup \{\psi_{j;j,k} \ : \ j \in \mathbb{N}_0, k \in \mathbb{Z}\}$ is an orthonormal basis of $L_2(\mathbb{R})$. By the same proof as in Theorem 1.2 and Lemma 3.3 with $l_j = m_j$, this orthonormal wavelet basis has the spectral approximation order. So, item (3) is verified.

The symmetry $\phi_j(1-\cdot) = \phi_j$ follows [23, Lemma 2] from the definition of ϕ_j in (1.1) and the symmetry of the masks $\widehat{a_j}$: $\widehat{a_j}(\xi) = e^{-i\xi}\widehat{a_j}(-\xi)$. Item (2) can be easily verified by (4.8). □

STABILITY AND SYNCHRONISM OF CERTAIN COUPLED DYNAMICAL SYSTEMS*

JOSÉ A. BARRIONUEVO† AND JACQUES A. L. SILVA†

Abstract. We obtain sufficient conditions for the stability of the synchronized solution for certain classes of coupled dynamical systems. These discrete time systems can be used to describe population patches coupled by migration, which are density and/or time dependent. Our results follow from an analytic expression for the transverse Lyapunov exponent obtained through spectral analysis. We then indicate some applications to population dynamics.

Key words. coupled dynamical systems, synchronism

1. Introduction.

The study of coupled dynamical systems has received considerable attention recently for its interest from the mathematical, physical, and biological points of view; see, for instance, [22], [1], [7], [29], [26], and [3], among others. One concern about such systems is whether or not they will present synchronization phenomena and whether or not such synchronization is stable.

The system below describes the evolution of a system consisting of d identical subsystems where, on every iteration, each subsystem undergoes its common local evolution determined by f, followed by a density-dependent coupling process encoded by C and φ. The system can model a population consisting of d patches, x_j, $j = 1, \dots, d$, where, in the absence of migration, patch j is controlled by a *local dynamics* $x^j_{t+1} = f(x^j_t)$. When migration is present, $\varphi(f(x^j_t))$ individuals leave patch j and are distributed with density c_{ji} on patch i. The *global dynamics* is then

$$x^j_{t+1} = f(x^j_t) - \varphi(f(x^j_t)) + \sum_{i=1}^{d} c_{ji}\varphi(f(x^i_t)); \;\; i, j = 1, \dots, d. \tag{1}$$

Here f is a bounded C^1 map on $[0, \infty)$, $C = [c_{ij}]$ is doubly stochastic, that is, $c_{ij} \geq 0$, and for all i, j, $\sum_{i=1}^{d} c_{ij} = \sum_{j=1}^{d} c_{ij} = 1$. Furthermore we will assume φ differentiable a.e. with φ' bounded. The models in population dynamics considered in [1], [7], [8], [27], [13], [26] are all particular cases of (1) for special choices of C and φ.

The condition on C being doubly stochastic reflects that there are no losses during the migration process. It is also necessary for the invariance of the diagonal of the phase space, that is, for $x^j_t = x^i_t = x_t$ to be a solution of (1), where each x^j_t satisfies $x^j_{t+1} = f(x^j_t)$.

In this paper we obtain sufficient conditions for the stability of the aforementioned synchronized solutions. The criteria involve the Lyapunov exponents, to be defined below, of the one-dimensional map f and of the codimension one transverse dynamical system.

The paper is organized as follows. In the next section we provide a criterion for stability for general systems. In section 3 we improve our result for the case of normal operators. In section 4 we consider a system where the coupling/migration process is time dependent. We formulate and prove the corresponding results of the previous sections in this setting. In the last section we indicate some applications to population dynamics.

Previous results treated only the cases where φ' is a constant or a 2-valued step function, as well as particular examples of matrices C, and these cases are covered by our results. Our treatment only requires φ' to be bounded and C to be doubly stochastic and irreducible. This last condition is easily seen to be necessary; see below. Moreover, we are unaware of any treatment of the systems as in section 4 in the literature. Thus we extend some of the results of [7], [8], [10], [11], [27], [15], [3], [13], and others to these more general situations.

2. Stability: General case. In order to understand the behavior of orbits starting at nearby points of the diagonal of the phase space, we first linearize (1). If $J_t = [\alpha_{ij}]$ denotes the Jacobian matrix of (1) restricted to the synchronized orbit, we have

$$\alpha_{ij} = \begin{cases} f'(x_t)\,(1-(1-c_{ii})\varphi'(f(x_t))) & \text{for } \ i=j, \\ f'(x_t)\varphi'(f(x_t))c_{ij} & \text{for } \ i\neq j. \end{cases}$$

We have $J_t = f'(x_t)H_t$, where $H_t = I - \varphi'(f(x_t))B$, and $B = I - C$.

We will assume that C is irreducible. This is almost a necessary condition, for otherwise it permits the existence of uncoupled unsynchronized subsystems that are each synchronized. In this case we can apply the Fröbenius theorem [12] to show that $\lambda = 1$ is the simple dominant eigenvalue of C, associated to the eigenvector $v = (1,\dots,1)$. This furnishes the decomposition $\mathbb{R}^d = \mathbb{R}v \oplus W$, where W is a C-invariant $(d-1)$-dimensional subspace. Under these conditions,

$$B = P^{-1}\begin{bmatrix} 0 & \\ & A \end{bmatrix} P, \tag{2}$$

where P is the matrix of the appropriate change of basis. This decomposition implies that the stability of the synchronized solution of (1) is a consequence of the stability of the trivial solution of the transversal component, w_t, which satisfies

$$w_{t+1} = f'(x_t)\,(I - \varphi'(f(x_t))A)\,w_t. \tag{3}$$

We will show that under a certain integrability condition the map above is in fact a contraction, which in turn implies the stability of $w_t \equiv 0$. The analysis of (3) will be based on the Lyapunov exponents (see [17], [18]) of (3). Define

$$K_n(x) = \left|\left|\prod_{k=0}^{n-1} f'(f^k(x))\,\big(I - \varphi'(f^{k+1}(x))A\big)\right|\right|^{1/n},$$

where $f^0(x) = x$ and $f^k(x) = f(f^{k-1}(x))$ for $k > 0$. Clearly if $\mathcal{K} = \limsup K_n$ satisfies $\mathcal{K} < 1$, we have that (3) is a contraction. Now observe

$$K_n(x) = L_n(x)\Lambda_n(x) = \left|\prod_{k=0}^{n-1} f'(f^k(x))\right|^{1/n} \left|\left|\prod_{k=0}^{n-1} I - \varphi'(f^{k+1}(x))A\right|\right|^{1/n}. \tag{4}$$

$L_n(x)$ depends only on the local dynamics f, while $\Lambda_n(x)$ reflects also the effects of φ and C. Let ρ be an invariant measure of the local system. Define for $x > 0$, $\ln^+(x) = \max(\ln(x), 0)$. By Birkhoff's ergodic theorem, if $\ln^+ |f'| \in L^1(\rho)$, there exists $\lim_n \exp(\frac{1}{n}\sum_{k=0}^{n-1} \ln |f'(f^k(x))|)$ for ρ-a.e. x. For ρ ergodic, this limit, call it L, is independent of x and is given by $\exp\left(\int_0^\infty \ln |f'(s)|\, d\rho(s)\right)$. L is the Lyapunov exponent of the local system governed by f.

Similarly the ergodic theorem of Oseledec [18] implies that if

$$\int_0^\infty \ln^+ ||I - \varphi'(s)A||\, d\rho(s) < \infty, \tag{5}$$

there exists $\lim_n \Lambda_n(x) =: \Lambda(x)$ for ρ-a.e. x, and this limit is independent of x provided ρ is ergodic. In the rest of the paper we will assume that the f-invariant measure, ρ, is ergodic. Nonergodic ρ can be treated at the cost of additional technicalities. See remark (iii) in section 2.1. Our first result is the following.

THEOREM 1. *Consider the system* (1), *where f is a C^1 map, φ' is bounded, and C is doubly stochastic and irreducible such that $\ln^+ ||I - \varphi'(s)A||$ and $\ln^+ |f'(s)|$ are in $L^1(\rho)$, where ρ is an ergodic f-invariant measure. Let $L = \lim_n L_n(x)$ and $\Lambda = \lim_n \Lambda_n(x)$ be as above. If $L\,\Lambda < 1$, there exists a set E with $\rho(E) = 1$ such that for all $x \in E$, the synchronized solution of* (1) *is asymptotically stable.*

Proof. By Birkhoff's theorem there exists a set E with $\rho(E) = 1$ such that for all x in E, $\lim_n \Lambda_n(x) = \Lambda$. We claim that

$$\Lambda \le \exp\left(\int_0^\infty \ln^+ ||I - \varphi'(s)A||\, d\rho(s)\right). \tag{6}$$

By the continuity of the norm and the function $\ln^+(\cdot)$, the dominated convergence theorem implies that we need only prove (6) for φ' simple.

Let $\varphi'(x) = \sum_{k=1}^r a_k \chi_{E_k}(x)$, where E_k are measurable and disjoint with $\rho(E_k) > 0$ and such $E \subset \bigcup_k E_k$. For $1 \le k \le r$, and x in E, define $\rho_{k,n} = \rho_{k,n}(x)$ by

$$\rho_{k,n} = \frac{\sharp\{0 \le j < n : f^j(x) \in E_k\}}{n}.$$

To keep the notation simple we omit the dependence of $\rho_{k,n}$ on x since Birkhoff's ergodic theorem applied to χ_{E_k} shows that for $1 \le k \le r$, and all x in E, we have

$$\lim_n \rho_{k,n} = \rho(E_k).$$

This gives

$$\Lambda_n(x) = \left|\left| \prod_k (I - a_k A)^{n\rho_{k,n}} \right|\right|^{1/n},$$

which imply

$$\Lambda_n(x) \le \prod_k ||I - a_k A||^{\rho_{k,n}} \text{ and}$$

$$\ln \Lambda_n(x) \le \sum_k \rho_{k,n} \ln ||I - a_k A||.$$

Therefore, given $\epsilon > 0$, there exists n_0 such that for $n > n_0$, we have $\rho_{k,n} \leq (1+\epsilon)\rho(E_k)$ and $L_n(x) \leq (1+\epsilon)L$. Since $\ln(\cdot) \leq \ln^+(\cdot)$,

$$\ln \Lambda_n(x) \leq (1+\epsilon) \sum_{k=1}^{r} \ln^+ ||I - a_k A||\, \rho(E_k) = (1+\epsilon) \int_0^\infty \ln^+ ||I - \varphi'(s)A||\, d\rho(s).$$

This proves (6). Note that the right-hand side is independent of x. Thus for $n > n_0$,

$$K_n(x) = L_n(x)\, \Lambda_n(x) \leq (1+\epsilon) L\, \Lambda^{1+\epsilon},$$

and since $\epsilon > 0$ is arbitrary we have

$$\lim_n K_n(x) \leq L\, \Lambda < 1,$$

and thus the transversal map (3) is a contraction. □

2.1. Remarks.

(i) If $E = [0, \infty)$, $L\ \Lambda \leq 1$ is necessary for the stability of the synchronized solution.

(ii) In certain cases, which include the case H_t semisimple, we will prove below that the norm $||I - \varphi'(f^k(x))A||$ is simply the spectral radius, $\sigma_{-1}(H_t)$, of the restriction of H_t to the subspace W. Therefore, with the same hypothesis on f and φ, we have

$$\Lambda \leq \Lambda_1 = \exp\left(\int_0^\infty \ln\, \sigma_{-1}(H_{\varphi'(s)})\, d\rho(s) \right), \tag{7}$$

and thus $L\Lambda_1 < 1$ is a sufficient condition for the stability of the synchronized solution of (1).

(iii) If ρ fails to be ergodic, a deep result of Choquet (Theorem 31.3 in [6]) gives the representation

$$\rho = \int_{\mathcal{E}(P_1)} \pi\, d\nu(\pi), \tag{8}$$

where P_1 is the space of f-invariant probability measures and $\mathcal{E}(P_1)$ is the set of extreme points of P_1, that is, the ergodic f-invariant probability measures, and ν is a probability measure on $\mathcal{E}(P_1)$. Also equality in (8) is, in the weak sense,

$$\int \Psi\, d\rho = \int_{\mathcal{E}(P_1)} \left(\int \Psi\, d\pi \right) d\nu(\pi)$$

for all continuous Ψ. Given $\pi \in \mathcal{E}(P_1)$, we apply Theorem 1 to obtain a set E_π of full π measure such that for all $x \in E_\pi$, the limit $\Lambda_\pi = \lim_n \Lambda_n(x)$ exists and

$$\Lambda_\pi \leq \exp\left(\int_0^\infty \ln^+ ||I - \varphi'(s)A||\, d\pi(s) \right).$$

Similarly, if $\ln^+ |f'| \in L^1(\pi)$, by Birkhoff's theorem, there exists $L_\pi = \exp(\lim_n \frac{1}{n} \sum_{k=0}^{n-1} \ln |f'(f^k(x))|)$ for $x \in E_\pi$, and it is given by $L_\pi = \exp(\int_0^\infty \ln |f'(s)|\, d\pi(s))$. From Theorem 1 it follows that if $L_\pi\, \Lambda_\pi < 1$, then the synchronized solution of (1) is stable for all initial x in $D_\pi = \{(x, x, \ldots, x) : x \in E_\pi\}$. Since any two distinct ergodic f-invariant measures are mutually singular, the sets E_π form a partition of the whole space $[0, \infty)$ modulo null sets. Therefore, if $\sup_{\pi \in \mathcal{E}(P_1)} L_\pi\, \Lambda_\pi < 1$, we have that the synchronized solution of (1) is asymptotically stable. Since the set of ergodic invariant measures can be very complicated, it might be difficult to verify the above condition in general.

3. Stability: Normal operators. In the case of normal operators, that is, $AA^* = A^*A$, one can improve the previous result with the help of the functional calculus of [16] and [23]. Let L_n be as in (4) and define the operator valued cocycle

$$\mathcal{O}_n(x) = \prod_{k=0}^{n-1} \big(I - \varphi'(f^{k+1}(x))A\big) \tag{9}$$

so that we have $K_n(x) = L_n(x)\,||\mathcal{O}_n||^{1/n}$. The proof of Oseledec's theorem in [24] shows that

$$\lim_n (\,\mathcal{O}_n^*(x)\mathcal{O}_n(x)\,)^{\frac{1}{2n}} = \mathcal{O}(x) \tag{10}$$

exists a.e. in operator norm. The ergodicity of ρ implies that $\mathcal{O}(x)$ is independent of x; call it $\mathcal{O}$. Spectral analysis of $\mathcal{O}$ determines the Lyapunov exponents and respective subspaces. Oseledec's theorem was extended to operator valued cocycles in Hilbert and Banach spaces in [25] and [21] under an additional compactness hypothesis and with the operator norm convergence replaced by strong convergence in (10). The *very special* nature of our cocycles (9) allows us to determine $\mathcal{O}$ above whenever A is a bounded, normal, and not necessarily compact operator on a Hilbert space $\mathcal{H}$. We present the result in this generality for its own sake and because it involves little extra work. Note, however, that the study of the stability of synchronized solutions of (1) for $d = \infty$ offers additional difficulties; see the remarks in section 3.1.

If A is normal, Theorem 12.23 in [23] gives

$$A = \int_{\sigma(A)} \lambda \, dP(\lambda), \tag{11}$$

where $dP(\lambda)$ are the spectral projections associated with A; that is, for all u, v in $\mathcal{H}$, $d\,\langle P(\lambda)u, v\rangle$ is a complex measure and

$$\langle Au,\, v\rangle = \int_{\sigma(A)} \lambda \, d\,\langle P(\lambda)u, v\rangle. \tag{12}$$

For a bounded measurable function $F : \sigma(A) \to \mathbb{C}$, $F(A)$ is defined by

$$F(A) = \int_{\sigma(A)} F(\lambda)\, dP(\lambda). \tag{13}$$

Observe that

$$||F(A)|| \le ||F(\lambda)||_{L^\infty(\sigma(A))}, \tag{14}$$

implying that if $F_n(\lambda) \to F(\lambda)$ in $L^\infty(\sigma(A))$, $F_n(A) \to F(A)$ in operator norm.

Setting $\ln 0 = -\infty$, $e^{-\infty} = 0$, and recalling that an *upper semicontinuous* real valued function satisfies that for all $\alpha \in \mathbb{R}$, $\{\lambda : F(\lambda) < \alpha\}$ is open, we now prove the following.

PROPOSITION 2. *The function $F : \mathbb{C} \to \mathbb{R}$ defined by*

$$F(\lambda) = \exp\left(\int_0^\infty \ln|1 - \lambda\varphi'(s)|\, d\rho(s)\right) \tag{15}$$

is upper semicontinuous and therefore bounded on compact subsets of $\mathbb{C}$.

Proof. First note that $F(\lambda) \geq 0$ and

$$F(\lambda) = 0, \text{ if and only if } \int_0^\infty \ln|1 - \lambda\varphi'(s)|\, d\rho(s) = -\infty. \tag{16}$$

Moreover, f bounded implies that the support of ρ, supp ρ, is compact and Jenssen's inequality gives

$$F(\lambda) \leq \int_{supp\,\rho} |1 - \lambda\varphi'(s)|\, d\rho(s) \leq 1 + K|\lambda| < \infty, \tag{17}$$

where $K = \sup\{\, |\varphi'(s)| : s \in \operatorname{supp}\rho\}$. Thus $F(\lambda)$ is a well-defined nonnegative real number. Defining

$$F_M(\lambda) = \exp\left(\int_0^\infty g_M(\lambda, s)\, d\rho(s)\right), \text{ where } g_M(\lambda, s) = \max\{\, -M,\, \ln|1 - \lambda\varphi'(s)|\,\},$$

we have $F_{M+1}(\lambda) \leq F_M(\lambda)$, and monotone convergence gives $F(\lambda) = \lim_M F_M(\lambda)$. Since $g_M(\lambda, s)$ is continuous with respect to λ on $\mathbb{C} \times$ supp ρ and supp ρ is compact, F_M is continuous on $\mathbb{C}$. Thus F is the pointwise limit of a nonincreasing sequence of continuous functions and is therefore upper semicontinuous. ∎

The proposition enables us to define $\mathcal{O} = F(A)$,

$$\mathcal{O} = \int_{\sigma(A)} \exp\left(\int_0^\infty \ln|1 - \lambda\varphi'(s)|\, d\rho(s)\right) dP(\lambda). \tag{18}$$

The spectral mapping theorem then implies

$$\sigma(\mathcal{O}) = F(\sigma(A)) = \{F(\lambda) : \lambda \in \sigma(A)\}. \tag{19}$$

The application of (10) to synchronization is contained in the next theorem.

THEOREM 3. *Let f, φ', C, and L be as in Theorem* 1. *Assume A is normal and let Λ be the spectral radius of* (18). *Then, if $L\,\Lambda < 1$, the synchronized solution of* (1) *is asymptotically stable.*

Proof. As in Theorem 1 the inequality $L\ \Lambda < 1$ implies that the transverse component (3) is a contraction, implying the stability of the synchronized solution. Therefore, in order to prove the theorem we need only establish (10) in the strong sense, with $\mathcal{O}$ given by (18). We first consider φ' simple. Let $\varphi' = \sum_{k=1}^N \varphi_k \chi_{E_k}$, where E_k are disjoint measurable. As before, we define

$$\rho_{k,n} = \frac{\sharp\{0 \leq j < n : f^j(x) \in E_k\}}{n}.$$

Then

$$(\mathcal{O}_n^* \mathcal{O}_n)^{\frac{1}{2n}} = \prod_{k=1}^N |I - \varphi_k A|^{\rho_{k,n}} = \int_{\sigma(A)} \left(\prod_{k=1}^N |1 - \lambda\varphi_k|^{\rho_{k,n}}\right) dP(\lambda). \tag{20}$$

For each n, $F_n(\lambda) = \prod_{k=1}^N |1 - \lambda\varphi_k|^{\rho_{k,n}}$ is continuous. Moreover, for $k = 1, \ldots, N$, Birkhoff's theorem gives $\lim_n \rho_{n,k} = \rho(E_k) > 0$. Since $\sigma(A)$ is compact, we have that

$$\lim_n F_n(\lambda) = F(\lambda) = \prod_{k=1}^N |1 - \lambda\varphi_k|^{\rho(E_k)}$$

uniformly for λ in $\sigma(A)$. We can rewrite this as

$$\lim_n F_n(\lambda) = \exp\left(\sum_{k=1}^{N} \rho(E_k) \ln|1-\lambda\varphi_k|\right) = \exp\left(\int_0^\infty \ln|1-\lambda\varphi'(s)|\, d\rho(s)\right),$$

where the last equality is just the definition of the Lebesgue integral. By (14), we have (10) for φ' simple. For an arbitrary φ', the right-hand side of (10) is already well defined by (18). We now have

$$(\mathcal{O}_n^*\mathcal{O}_n)^{\frac{1}{2n}} = \int_{\sigma(A)} F_n(\lambda)\, dP(\lambda),$$

where $F_n(\lambda) = \left(\prod_{k=1}^n |1-\lambda\varphi'(x_k)|\right)^{1/n}$. Since one can approximate φ' uniformly by simple functions, the ergodic theorem and the above result for simple functions imply that for all λ in $\sigma(A)$, $\lim_n F_n(\lambda) = F(\lambda)$-pointwise convergence.

Thus for all u, v in $\mathcal{H}$, the Lebesgue dominated convergence theorem implies

$$\lim_n \int_{\sigma(A)} F_n(\lambda)\langle dP(\lambda)u, v\rangle = \int_{\sigma(A)} F(\lambda)\,\langle dP(\lambda)u, v\rangle.$$

Since $dP(\lambda)$ is a resolution of the identity, this implies that

$$\lim_n \left|\left|\left((\mathcal{O}_n^*\mathcal{O}_n)^{\frac{1}{2n}} - F(A)\right)u\right|\right| = 0$$

for all u in $\mathcal{H}$, which establish strong convergence in (10). This finishes the proof of Theorem 3. □

3.1. Remarks.

(i) In finite dimension we have $\sigma(A) = \{\lambda_1, \ldots, \lambda_M\}$ with corresponding spaces E_j, mutually orthogonal, with $\mathbb{R}^{d-1} = E_1 \oplus \cdots \oplus E_M$, and the conclusion of the theorem is that if $u \neq 0$ is in E_j, then $\lim_n ||(\mathcal{O}_n^*\mathcal{O}_n)^{\frac{1}{2n}}u|| = F(\lambda_j)$.

(ii) Since for all $\lambda \in \sigma(A)$, $|1-\lambda\varphi'(s)| \leq ||I - \varphi'(s)A||$, we have $\Lambda \leq \exp\left(\int_0^\infty \ln^+ ||I-\varphi'(s)A||\, d\rho(s)\right)$, and therefore Theorem 3 is an improvement of Theorem 1.

(iii) By definition $\Lambda = \sup\{|F(\lambda)| : \lambda \in \sigma(A)\}$, and thus (19) gives (7). All the effect of coupling to synchronization is reflected in Λ and can therefore, in certain cases, be independent of d; see section 5.

(iv) The case $d = \infty$ is more subtle. First, the choice of a function space for $\{x_j(t)\}_j$ plays an important role. For instance, the synchronized solution belongs to l^p only for $p = \infty$. Second, the Fröbenius theorem is not valid in the same generality. Third, if the function space considered is not a Hilbert space, the functional calculus above is not available.

4. Extensions. The analysis above can be applied to more general systems. One such instance is the case below, where the coupling/migration process no longer depends on the density but instead obeys a seasonal dynamics; that is, on each cycle a time-dependent fraction μ_t of each patch will mix according to a time-dependent distribution $C_t = [c_{ij}^t]$ as follows:

$$x_{t+1}^j = f(x_t^j) - \mu_t\, f(x_t^j) + \sum_{i=1}^{d} c_{ji}^t\, \mu_t\, f(x_t^i);\ \ i,j = 1,\ldots,d. \tag{21}$$

Again f is a C^1 map on $[0,\infty)$. The evolution of the migration parameters μ_t and C_t is governed by maps g and h on $[0,1]$. The idea is to write $\mu_{t+1} = g(\mu_t)$ and $C_{t+1} = h(C_t)$, but this is not accurate. To make this precise we argue as follows. For g continuous on $[0,1]$ and μ_0 arbitrary, we assume that $\mu_t = \mu_t(\mu_0)$ is given by $\mu_{t+1} = g(\mu_t)$. Similarly if $\{C_s\}_{s\in[0,1]}$ is a family of doubly stochastic irreducible matrices, h is a continuous map on $[0,1]$, and s_0 is arbitrary, we define $s_{t+1} = h(s_t)$ and $C_t = C_t(s_0)$ by $C_{t+1} = C_{h(s_t)}$. Assume that $G(\mu, s) = \mu\, C_s$ is a measurable operator valued map with respect to the product measure $\nu \times \eta$ on $[0,1]\times[0,1]$, where ν and η are, respectively, a g-invariant and h-invariant *ergodic* measure on $[0,1]$. Under these assumptions the diagonal of the phase space, $x_t^i = x_t^j = x_t$, is a synchronized solution and we are interested in its stability. This system falls under the general theory of random dynamical systems as presented in [2] and thus obeys, under the appropriate integrability condition, a mutiplicative ergodic theorem. Our approach is direct and avoids the use of this theory. Moreover, due to the particular nature of (21), we are able, as in the previous sections, to obtain much more precise information about the limit operators than is given by the ergodic theorem alone.

The Jacobian matrix of (21), $J_t = [\alpha_{ij}^t]$, is now given by

$$\alpha_{ij} = \begin{cases} f'(x_t)\,(1-\mu_t(1-c_{ii}^t)) & \text{for } i = j, \\ f'(x_t)\,\mu_t\,c_{ij}^t & \text{for } i \neq j, \end{cases}$$

yielding $J_t = f'(x_t)(I - \mu_t B_t)$, where $B_t = I - C_t$. Our first task is to decompose the linearized system into diagonal and transversal components and then estimate the respective Lyapunov exponents by the appropriate ergodic theorem. This cannot be done in general for arbitrary families $\{C_t\}$; therefore we will consider special cases of increasing generality.

4.1. Simultaneous diagonalizable matrices. This includes the families of commuting symmetric matrices and of circulant matrices. In this case there exists a matrix P such that for all t, $B_t = P^{-1}\, M_t\, P$, where M_t is a diagonal matrix with entries $\{0, \lambda_2(t), \ldots, \lambda_d(t)\}$ in its diagonal. Each $\lambda_j(t)$ is measurable and satisfies $0 < |1 - \lambda_j(t)| < 1$ by the Fröbenius theorem (applied to C_t). In the symmetric (commuting) case the $\lambda_j(t)$ are real and lie in $(0,2)$. We obtain that the transversal component of (21) satisfies

$$w_{t+1} = f'(x_t)\,(I - \mu_t\, D_t)\, w_t, \tag{22}$$

where D_t is the $(d-1)$-dimensional $\{\lambda_2(t), \ldots, \lambda_d(t)\}$ diagonal matrix. As before, the synchronized solution of (21) is stable if and only if $w_t = 0$ is a stable solution of (22). For each x, μ_0, s_0 in $[0,1]$, define $L_n(x)$ as in (4), and for $j = 2, \ldots, d$, define

$$\Lambda_{j\,n}(\mu_0,\, s_0) = \left(\prod_{k=0}^{n-1} |1 - g^k(\mu_0)\, \lambda_j(h^k(s_0))| \right)^{1/n}.$$

The analogue of Theorem 3 is as follows.

THEOREM 4. *Consider the system* (21) *under the above conditions. Assume in addition that*

(i) $\ln^+ |f'(s)|$ *belongs to* $L^1(\rho)$, *where* ρ *is an ergodic* f*-invariant probability measure on* $[0,\infty)$.

(ii) *for all* $2 \le j \le d$, $\ln^+ |1 - \mu\, \lambda_j(s)|$ *belong to* $L^1(\nu \times \eta)$.

Then there exist sets $E \subset [0,\infty)$ *and* $F \subset [0,1]\times[0,1]$ *with* $\rho(E) = (\nu\times\eta)(F) = 1$, *such that for all* $x \in E$ *and* $(\mu_0, s_0) \in F$, *the limits* $L = \lim_n L_n(x)$ *and* $\Lambda_j = \lim_n \Lambda_{j\,n}(\mu_0, s_0)$ *exist and are independent of* x *and* (μ_0, s_0). *Moreover, if* $\Lambda = \max_j \Lambda_j$ *satisfies* $L\Lambda < 1$, *the synchronized solution of* (21) *is asymptotically stable.*

Proof. The existence of $L(x)$ for x in a set of full measure follows, as before, from Birkhoff's ergodic theorem applied to $\ln L_n(\cdot)$ and (i). In addition, the limit is independent of x since ρ is ergodic. The decomposition (22) allows us to derive the transversal component directly without making use of Oseledec's theorem. For $2 \le j \le d$, $(\mu_0, s_0) \in [0,1]\times[0,1]$, we can write

$$\Lambda_{j\,n}(\mu_0, s_0) = \exp\left(\frac{1}{n}\sum_{k=0}^{n-1} \ln|1 - g^k(\mu_0)\,\lambda_j(h^k(s_0))|\right).$$

Condition (ii) and a $(d-1)$-fold application of Birkhoff's ergodic theorem imply the existence of a set F, with $\nu\times\eta\,(F) = 1$ such that for all j and all $(\mu_0, s_0) \in F$, there exists $\Lambda_j(\mu_0, s_0) = \lim_n \Lambda_{j\,n}(\mu_0, s_0)$. Since, in addition, $\nu\times\eta$ is ergodic, the limit is independent of (μ_0, s_0) and is given by

$$\Lambda_j = \exp\left(\int_{[0,1]\times[0,1]} \ln|1 - \mu\,\lambda_j(s)|\; d(\nu\times\eta)(\mu, s)\right). \tag{23}$$

This gives $\operatorname{diag}\{\Lambda_2, \ldots, \Lambda_d\}$ as the analogue of (18). Its spectral radius is then $\Lambda = \max_j \Lambda_j$. Thus, if $L\,\Lambda < 1$, the synchronized solution is asymptotically stable. □

4.2. Symmetric (noncommuting) matrices. In this case we no longer have a decomposition yielding a diagonal transversal component, like (22), and therefore our conclusions are somewhat weaker than the previous theorem. Since each C_t is symmetric, doubly stochastic, and irreducible, $\lambda = 1$ is the dominant eigenvalue with corresponding eigenvector $v = \{1, \ldots, 1\}$. Moreover, the $(d-1)$-dimensional subspace $W = (\mathbb{R}v)^{\perp}$ is invariant for all C_t. This provides a decomposition like (2),

$$B_t = P^{-1}\begin{bmatrix} 0 & \\ & A_t \end{bmatrix} P. \tag{24}$$

Accordingly, the transversal component of (21) now satisfies

$$w_{t+1} = f'(x_t)\,(I - \mu_t\, A_t)\, w_t. \tag{25}$$

The following theorem is the analogue of Theorem 1 in the present situation.

THEOREM 5. *Consider the system* (21), *where* f *and* μ_t *are as in Theorem* 4, *and assume* $\{C_t\}$ *as above. For each* (μ_0, s_0), *define*

$$\Lambda_n(\mu_0, s_0) = \left|\left|\prod_{k=0}^{n-1}\left(I - g^k(\mu_0)A_{h^k(s_0)}\right)\right|\right|^{1/n}.$$

Assume that $\ln^+ ||I - \mu\, A_{h(s)}||$ *belongs to* $L^1(\nu\times\eta)$. *Then there exists a set* $F \subset [0,1]\times[0,1]$ *of full* $\nu\times\eta$*-measure such that for all* $(\mu_0, s_0) \in F$, *the limit* $\Lambda = \lim_n \Lambda_n(\mu_0, s_0)$ *exists and is independent of* (μ_0, s_0). *Moreover, if* Λ *satisfies* $L\,\Lambda < 1$, *the synchronized solution of* (21) *is asymptotically stable.*

Proof. Consider the map $\mathcal{Q}$ on $[0,1]\times[0,1]$, given by $\mathcal{Q}(\mu, s) = (g(\mu), h(s))$. Clearly $\nu\times\eta$ is $\mathcal{Q}$ invariant, and by assumption, $\Lambda_n(\mu, s)$ above defines a $(\nu\times\eta)$-measurable cocycle. The existence of $\Lambda(\mu_0, s_0)$ for (μ_0, s_0) on a set of full measure

then follows from Oseledec's ergodic theorem applied to $\Lambda_n(\mu, s)$. We also have that for a.e. (μ_0, s_0),

$$\Lambda(\mu_0, s_0) \leq \exp\left(\int_{[0,1]\times[0,1]} \ln^+ ||I - \mu A_{h(s)}||\, d(\nu \times \eta)(\mu, s)\right). \tag{26}$$

The proof of (26) follows the same path as the proof of (6), and thus we will omit the details. Note that since each A_t is symmetric, there exists $\lambda(t) \in \sigma(A_t)$ for which $||I - \mu\, A_t|| = |1 - \mu\lambda(t)|$. $\lambda(t)$ is the lowest eigenvalue of C_t. Moreover, since $\nu \times \eta$ is ergodic, $\Lambda(\mu_0, s_0)$, is independent of (μ_0, s_0), and in this case we have

$$\Lambda = \exp\left(\int_{[0,1]\times[0,1]} \ln\, |1 - \mu\, \lambda(h(s))|\, d(\nu \times \eta)(\mu, s)\right)$$

as a consequence of Birkhoff's theorem. As in the previous theorems, the condition $L\,\Lambda < 1$ implies the asymptotic stability of the synchronized solution. □

4.3. Remarks.

(i) The assumptions on the continuity of g and h above can be relaxed. All that is needed is that each map possess an ergodic invariant probability measure, ν and η.

(ii) Similarly to the density-dependent migration, the results above *do not* extend to the $d = \infty$ case even though, once again, the effect of d is encoded in the joint spectrum of $\{C_t\}$.

4.4. Examples. Some special cases of (23) and (26) are worth mentioning.

(i) If s_0 is a periodic point for h, that is, $h^p(s_0) = s_0$, and we take $\eta = \frac{1}{p}\sum_{k=0}^{p-1} \delta_{h^k(s_0)}$, then (23) becomes

$$\Lambda_j = \exp\left(\frac{1}{p}\sum_{k=0}^{p-1} \int_{[0,1]} \ln\, |1 - \mu\, \lambda_j(s_k)|\, d\nu(\mu)\right).$$

A similar expression corresponding to the case of a periodic point for g also holds.

(ii) If $g = h$ and $\eta = \nu$, but $\mu_0 \neq s_0$, we get for (23),

$$\Lambda_j = \exp\left(\int_{[0,1]\times[0,1]} \ln\, |1 - \mu\, \lambda_j(s)|\, d(\nu \times \nu)(\mu, s)\right).$$

(iii) If in (ii) we have, in addition, $\mu_0 = s_0$, that is, the term $\mu_t\, A_t$ in (25) is of the form $g^t(s_0)\, A_{g^t(s_0)}$, then (23) becomes

$$\Lambda_j = \exp\left(\int_{[0,1]} \ln\, |1 - s\, \lambda_j(s)|\, d\nu(s)\right).$$

Similar corresponding expressions can be obtained, without difficulty, to represent (26) in the special cases above. We leave the details, as well as the formulation of other special instances of (26), to the interested reader. These formulas are useful in cases where ν and η are known, say Lebesgue, for they permit the exact calculations of the Lyapunov numbers of the transversal dynamical system.

5. Applications. In this section we will restrict ourselves to the density-dependent system (1) and leave the corresponding formulations of the results related to the time-dependent system (21) to the interested reader.

A direct problem consists of determining stability once f, φ, and C are given. In such situations we compute the eigenvalues $\lambda_1, \dots, \lambda_d$ of C. Discarding the eigenvalue 1, we evaluate the integrals defining the spectrum of Λ above by Birkhoff's ergodic theorem

$$\int_0^\infty \ln|1-\lambda\varphi'(s)|\, d\rho(s) = \lim_n \frac{1}{n}\sum_{k=0}^{n-1} \ln|1-\lambda\varphi'(f^k(x))|, \tag{27}$$

and then the maximum of these values gives the spectral radius Λ and we can then determine stability once the Lyapunov exponent for f is known. We note that in order to use (27) we need the ergodic f-invariant measure, ρ, to be such that for x belonging to a set E of full Lebesgue measure, and all continuous functions Ψ,

$$\lim_n \frac{1}{n}\sum_{j=0}^{n-1} \Psi(f^i(x)) = \int \Psi(s)\, d\rho(s).$$

Such measures, called physical or SRB (Sinai–Ruelle–Bowen) measures, are known to exist in certain important cases, such as expansive maps, piecewise monotonic maps of the interval, as well as *axiom A* diffeomorphisms, even though a recent result of Ávila and Bochi [4] shows that they are not typical in the C^1-topology. Further information can be found in [31], [19], [20]. See also [32] for a survey.

In [5] we consider the following particular instance of (1). The local map f is taken from the Riker family, $f(x) = xe^{r(1-x)}$, $r > 0$, often considered in population dynamics. It is known that there exists an ergodic f-invariant probability SRB measure ρ which describes the asymptotic distribution of almost all orbits of f (see Theorems 25 and 29 in [30]). We let $\varphi(x) = x\mu(x)$, where the dispersal fraction, $\mu(x)$, is a sigmoidal function

$$\mu(x) = \frac{\alpha}{1+e^{\beta(\gamma-x)}}, \tag{28}$$

where the parameter $\alpha \in (0,1)$ determines the maximal dispersal, and β describes the steepness of dispersal. Moreover, the sign of β determines whether dispersal is positively or negatively density dependent. γ is the inflection point, at which dispersal is half of its maximum. The cases $\beta = \pm\infty$ correspond to threshold population size triggering migration and have been considered in [8]. Here we consider the following two extreme types of coupling:

(I) A ring configuration of d patches, each patch connected to the $2k$-nearest neighbors, with uniform dispersion, that is, $c_{ij} = 1/2k$ for $0 < |i-j| \le k$ and $c_{ij} = 0$ otherwise. In this case the eigenvalues of B are given by (see [27], [28], where the stability of equilibria is analyzed)

$$\lambda_j = 1 - \left(\frac{D_k(\frac{2\pi(j-1)}{d}) - 1}{2k}\right), \qquad j = 1, 2, \dots, d,$$

where $D_k(x) = \sin(k+\frac{1}{2})x / \sin\frac{x}{2}$.

(II) Global uniform coupling, that is, each of the d patches is connected to the others yielding $c_{ii} = 0$ and $c_{ij} = 1/(d-1)$ for $i \neq j$. Here the eigenvalues of B are $\lambda_1 = 0$ and $\lambda_2 = \cdots = \lambda_d = d/(d-1)$.

For $i = \text{I, II}$, let $\Lambda_i = \Lambda_i(d, r, \alpha, \beta, \gamma)$ be the value of Λ, obtained using (27), for the respective configuration. In [5] we observe numerically the dependence of Λ_i on the different parameters and its effects on the stability of synchronization. For instance, one can prove (see Corollary 3.1 there) that $\lim_{d\to\infty} \Lambda_I \geq 1$, independent of the other parameters, which are kept fixed. This easily implies the impossibility of chaotic synchronization for sufficiently large ring configurations such as (I). The situation is different for (II), where, given any d, one can find a local chaotic map f ($L > 1$) and migration parameters, α, β, and γ, yielding a stable synchronized dynamics ($L\,\Lambda < 1$).

One feature of Theorems 1 and 3 is their continuous dependence on φ', that is, C^1-uniform topology. This follows directly from the formulas for Λ above. On the other hand, by analyzing (27) one can see that for certain f, C, it is possible to make Λ arbitrarily large by taking $||\varphi'||_{L^\infty(\rho)}$ large. In our case, where φ is given using (28), this implies that there exist situations where threshold triggered migration, $\beta = \pm\infty$, that present chaotic synchronization, while all systems with β greater than a certain β_0 have unstable synchronized orbits. The same reasoning proves that, in general, there is no continuity of Λ in φ in the C^0-topology.

We can also make use of the results from previous sections to study an inverse problem. In this case f and φ are given and one is interested in finding a double stochastic matrix C, if possible, yielding the desired stability behavior for the synchronized solution of (1). In this regard, Theorem 7 below gives a partial result for symmetric matrices. We will make use of the following result from [14].

PROPOSITION 6. *The following are Corollaries* 7 *and* 8 *from* [14].

(i) *If* $\{\lambda_2, \ldots, \lambda_d\} \in [-1/(d-1), 1]$, *then there exists a symmetric doubly stochastic matrix* C *with* $\sigma(C) = \{1, \lambda_2, \ldots, \lambda_d\}$.

(ii) *If* $\lambda \in (-1, 1]$, *there exists a positive symmetric doubly stochastic matrix* C *such that* $\lambda \in \sigma(C)$.

The proof of Proposition 6 in [14] provides algorithms to find the matrices C in (i) and (ii) above.

THEOREM 7. *Let* f *and* φ *be as in Theorems* 1 *and* 3. *Let* L *denote the Lyapunov exponent of the one-dimensional map* f. *For* $\lambda \in [0, 2]$, *let* $F(\lambda)$ *be as in* (15), *and define* $m = \inf F(\lambda)$ *and* $M = \sup F(\lambda)$. *Then*

(i) *if* $L\,m > 1$, *the synchronized solution of* (1) *is unstable for* all *symmetric configurations* C.

(ii) *if* $L\,M < 1$, *the synchronized solution of* (1) *is stable for* all *symmetric configurations* C.

(iii) *if* $L \in (\frac{1}{M}, \frac{1}{m})$, *it is possible to find a symmetric doubly stochastic matrix* C *such that the synchronized solution of* (1) *has a prescribed stability behavior.*

Proof. Let us first note that any nonnegative symmetric doubly stochastic matrix has its spectrum contained in $(-1, 1]$. This follows from Gershgorin's theorem [9] which states that $\sigma(C)$ is contained in the set $\{\lambda \in \mathbb{C} : \text{ for all } i, |\lambda - c_{ii}| \leq \sum_{j\neq i} |c_{ij}|\}$. The hypotheses on C then imply that $\sigma(C) \subset [-1, 1]$. If C is positive, it is not difficult to show that -1 cannot be an eigenvalue of C. Since $B = I - C$, we have $\sigma(B) \subset [0, 2)$. Since $F(\lambda)$ gives the spectrum of $F(A)$, Theorem 7 now follows easily from Theorem 3 and Proposition 6. □

Acknowledgments. The authors would like thank the anonymous referees for carefully reading an earlier version of this work and for providing a long list of improvements. We also thank A. Lopes for some helpful conversations.

STABILITY OF SINGLE-WAVE-FORM SOLUTIONS IN THE UNDERDAMPED FRENKEL–KONTOROVA MODEL*

WEN-XIN QIN†, CHUN-LAN XU†, AND XIN MA‡

Abstract. Via the monotonicity approach, we prove that the single-wave-form solution for the underdamped Frenkel–Kontorova model with dc-driving and periodic boundary conditions is globally stable, provided the driving force is large enough.

Key words. single-wave-form solution, Frenkel–Kontorova model, monotonicity

1. Introduction. The dynamics of many physical systems, including charge density waves and Josephson junctions, can be described by the standard Frenkel–Kontorova (F-K) model [5, 6], which can also be seen as a one-dimensional lattice of identical pendula oscillating in parallel planes, coupled to the nearest neighbors. The equation of the F-K model with dc-driving is

$$\ddot{u}_j + \Gamma \dot{u}_j + \sin u_j = K(u_{j-1} - 2u_j + u_{j+1}) + F, \tag{1.1}$$

where $\Gamma > 0$ denotes the damping effect, $K > 0$ measures the coupling strength, and $F \geq 0$ is the constant driving force.

In this paper we are concerned with the single-wave-form solutions of the F-K model (1.1) with periodic boundary conditions

$$u_{j+N}(t) = u_j(t) + 2\pi M, \tag{1.2}$$

where M and N are positive integers. A solution $\{u_j(t)\}$ of system (1.1)–(1.2) is called a single-wave-form solution if there exist a constant $T > 0$ and a waveform function $f\colon \mathbb{R} \to \mathbb{R}$ satisfying

$$f(t+T) = f(t) + 2\pi, \quad t \in \mathbb{R}, \tag{1.3}$$

such that

$$u_j(t) = f\left(t + jTM/N\right).$$

The positive number T is said to be the period of the waveform function f.

A running periodic solution is one for which there is a minimal $T > 0$ such that $u_j(t+T) = u_j(t) + 2\pi$ for $t \in \mathbb{R}$ and $j = 1, \ldots, N$. Note that a single-wave-form solution is a special form of running periodic solution with the same waveform and

equal phase lags. Single-wave-form solutions are also called ponies on a merry-go-round [1], discrete rotating waves [2], or splay-phase solutions [11] in the literature. Although single-wave-form solutions in the coupled oscillators systems play an important role, it is not easy, as remarked in [16], to give mathematically rigorous analysis of their existence and stability. For the small coupling case, Levi proved by the Brouwer fixed point theorem the existence result in [9]. By reformulating the existence problem as a fixed point problem in a Banach space and applying the Schauder fixed point theorem, Katriel [7] presented a rigorous and detailed analysis on the existence of single-wave-form solutions of system (1.1)–(1.2). The method used in [7] is close in spirit to that in [12], which studied the existence of single-wave-form solutions for the Josephson junction systems. We remark that the stability question was not touched upon in [7] and [12]; see also the open problems in [16]. For the small coupling case, the local stability of the single-wave-form solutions, as remarked by Levi in [9], can be proved by applying the approach used in [8]. Meanwhile, by computing the Floquet multipliers and applying perturbation analysis, Watanabe and Swift investigated the local stability of single-wave-form solutions in series arrays of Josephson junctions [15]. Recently, Baesens and MacKay found the monotonicity for the F-K model under the overdamped condition $\Gamma > 2\sqrt{2K+1}$. It can be inferred from the results of [3, 4] that the single-wave-form solution of the overdamped F-K model (1.1)–(1.2) is globally stable if there is no equilibrium. Note that from [3] we know that there exists $F_d \geq 0$, which depends on Γ and K, such that the F-K model has equilibria for $0 \leq F \leq F_d$ and has no equilibria for $F > F_d$.

The goal of this paper is to study the global stability of the single-wave-form solutions for the underdamped F-K model, the existence of which was demonstrated by Katriel [7]. By global stability we mean that given any initial value $\{u_j(0)\}$ satisfying the periodic boundary condition $u_{j+N}(0) = u_j(0) + 2\pi M$, the solution $\{u_j(t)\}$ approaches the single-wave-form solution $\{\hat{u}_j(t)\}$ as $t \to +\infty$. Moreover, we will show that $\{\hat{u}_j(t)\}$ attracts each orbit with phase; i.e., for a solution $\{u_j(t)\}$, there exists a $\tau \in \mathbb{R}$, such that $\lim_{t\to+\infty} |u_j(t) - \hat{u}_j(t+\tau)| = 0$.

THEOREM 1.1. *Assume that $\Gamma > 2\sqrt{2K}$. Then there exists $F_0 > 1$, such that the F-K model* (1.1)–(1.2) *with $F \geq F_0$ admits a globally stable single-wave-form solution, which attracts each orbit with phase.*

The main idea of the proof is as follows. Inspired by the work of [3, 4, 13], we know that strong monotonicity generally implies stability of running periodic solutions. Therefore, as the first step, we show that the Poincaré map P^{mT} of system (1.1)–(1.2), where T is the period of the waveform function and m is some positive integer, is strongly monotone if $\Gamma > 2\sqrt{2K}$ and the driving force F is large enough. Then we prove via the strong monotonicity that the single-wave-form solution is globally stable.

We should remark that under the overdamped condition, i.e., $\Gamma > 2\sqrt{2K+1}$, the strong monotonicity found by Baesens and MacKay together with the approach presented for finite chains in [3] leads immediately to the stability of single-wave-form solutions. Here we extend the parameter range to the underdamped case, where the damping coefficient Γ could be small if the coupling strength K is small.

2. Trapping region. Let $u = (u_1, \ldots, u_N)^T \in \mathbb{R}^N$. Then system (1.1)–(1.2) can be written as

$$\ddot{u} + \Gamma\dot{u} + S(u) = -KAu + E, \tag{2.1}$$

where

$$A = \begin{pmatrix} 2 & -1 & 0 & \cdots & 0 & -1 \\ -1 & 2 & -1 & \cdots & 0 & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \vdots \\ -1 & 0 & \cdots & 0 & -1 & 2 \end{pmatrix}$$

is an $N \times N$ matrix, $S(u) = (\sin u_1, \ldots, \sin u_N)^T$, $E = (-2\pi KM + F, F, F, \ldots, F, F, 2\pi KM + F)^T$. The eigenvalues of matrix A are

$$\lambda_j = 4 \sin^2 \frac{j\pi}{N}, \quad j = 0, 1, \ldots, N-1.$$

Let

$$\hat{e}_j = \left(1, \cos\frac{2j\pi}{N}, \ldots, \cos\frac{(N-1)2j\pi}{N}\right)^T, \ \tilde{e}_j = \left(0, \sin\frac{2j\pi}{N}, \ldots, \sin\frac{(N-1)2j\pi}{N}\right)^T,$$

$j = 1, \ldots, [\frac{N}{2}]$. Then $\hat{e}_j$ and $\tilde{e}_j$ are eigenvectors corresponding to $\lambda_j = \lambda_{N-j}$. Note that if N is even, then $\lambda_{N/2}$ is a simple eigenvalue with eigenvector $\hat{e}_{N/2}$. Let $e_j = \hat{e}/|\hat{e}_j|$ and $e_{N-j} = \tilde{e}_j/|\tilde{e}_j|$ for $j = 1, \ldots, [\frac{N}{2}]$. Then e_j is the normalized eigenvector corresponding to λ_j, $j = 1, \ldots, N-1$. The normalized eigenvector corresponding to $\lambda_0 = 0$ is $e_0 = (1/\sqrt{N}, \ldots, 1/\sqrt{N})^T$. Denoting $\mathbf{u} = (u, \dot{u})^T$, we have

$$\dot{\mathbf{u}} = C\mathbf{u} + \mathbf{S}(\mathbf{u}) + \mathbf{E}, \tag{2.2}$$

where

$$C = \begin{pmatrix} 0 & I \\ -KA & -\Gamma I \end{pmatrix}, \quad \mathbf{S}(\mathbf{u}) = \begin{pmatrix} 0 \\ -S(u) \end{pmatrix}, \quad \mathbf{E} = \begin{pmatrix} 0 \\ E \end{pmatrix}.$$

The eigenvalues of matrix C are

$$\mu_j^{\pm} = \frac{-\Gamma \pm \sqrt{\Gamma^2 - 4K\lambda_j}}{2},$$

with the corresponding eigenvector being $(e_j, \mu_j^{\pm} e_j)^T$, $j = 0, \ldots, N-1$. In particular, $\mu_0^+ = 0$, $\mu_0^- = -\Gamma$.

The conclusions of the following lemma have been proved by Katriel; see Theorem 2 in [7].

LEMMA 2.1. *System* (1.1)–(1.2) *admits a single-wave-form solution, provided* $F > 1$. *Moreover, the period* T *of the waveform function satisfies*

$$2\pi\Gamma/(F+1) \le T \le 2\pi\Gamma/(F-1).$$

The method of proof involves reformulating the problem as a fixed point problem in a Banach space and applying the Schauder fixed point theorem. The uniqueness of the single-wave-form solution needs some further assumptions; see the last section in [7].

A closed subset Ω of the phase space $\mathbb{R}^{2N}$ is called a trapping region of (2.2) if it is positively invariant for the flow generated by (2.2), and for each point $\mathbf{u}_0 \in \mathbb{R}^{2N}$,

there exists t_0 such that the orbit $\{\mathbf{u}(t)\}$ with $\mathbf{u}(0) = \mathbf{u}_0$ enters Ω and remains there for $t > t_0$.

LEMMA 2.2. *System* (2.2) *has a trapping region* Ω. *Moreover, there exist constants* $b > 0$, *independent of* F, v_-, *and* v^+, *depending upon the driving force* F, *such that*

$$|u_{j-1} - 2u_j + u_{j+1}| \le b, \qquad v_- \le \dot{u}_j \le v^+, \quad j = 1, \dots, N,\ u_0 = u_N,\ u_1 = u_{N+1},$$

for $\mathbf{u} = (u_1, \dots, u_n, \dot{u}_1, \dots, \dot{u}_N) \in \Omega$.

Proof. There exists an orthonormal matrix D, the jth column being e_{j-1}, such that $D^{-1}AD = \operatorname{diag}(\lambda_0, \lambda_1, \dots, \lambda_{N-1}) \triangleq \Lambda$. Note that $D^{-1} = D^T$, the transpose of D since D is an orthonormal matrix. Making a transformation $x = D^{-1}u$, where $x = (x_1, x_2, \dots, x_N)^T$, we convert system (2.1) into

$$\ddot{x} + \Gamma\dot{x} + D^{-1}S(Dx) = -K\Lambda x + D^{-1}E. \tag{2.3}$$

Noting that the jth element of $D^{-1}S(Dx)$ is $\langle e_{j-1}, S(Dx)\rangle$, denoted by $g_j(x,t)$, we have the fact that $|g_j(x,t)| \le \sqrt{N}$. Meanwhile, it follows that

$$D^{-1}E = D^{-1}\begin{pmatrix} F \\ F \\ \vdots \\ F \\ F \end{pmatrix} + D^{-1}\begin{pmatrix} -2\pi KM \\ 0 \\ \vdots \\ 0 \\ 2\pi KM \end{pmatrix} \triangleq \begin{pmatrix} f_1 \\ f_2 \\ \vdots \\ f_{N-1} \\ f_N \end{pmatrix},$$

and hence

$$f_1 = \sqrt{N}F, \qquad |f_j| \le 2\sqrt{2}\pi KM, \quad j = 2, \dots, N.$$

Consequently, we derive that in an x-coordinate system,

$$\ddot{x}_j + \Gamma\dot{x}_j + K\lambda_{j-1}x_j = -g_j(x,t) + f_j. \tag{2.4}$$

There are three cases to discuss.

(1) $\Gamma^2 > 4K\lambda_{j-1}$. In this case the matrix

$$C_j = \begin{pmatrix} 0 & 1 \\ -K\lambda_{j-1} & -\Gamma \end{pmatrix}$$

has two real eigenvalues, $\mu_{j-1}^{\pm} = (-\Gamma \pm \sqrt{\Gamma^2 - 4K\lambda_{j-1}})/2$. It then follows that there exists a real matrix

$$T_j = \begin{pmatrix} 1 & 1 \\ \mu_{j-1}^+ & \mu_{j-1}^- \end{pmatrix}, \quad \text{such that} \quad T_j^{-1}C_jT_j = \begin{pmatrix} \mu_{j-1}^+ & 0 \\ 0 & \mu_{j-1}^- \end{pmatrix}.$$

Let

$$\begin{pmatrix} y_j \\ z_j \end{pmatrix} = T_j^{-1}\begin{pmatrix} x_j \\ \dot{x}_j \end{pmatrix}.$$

Then from (2.4) we have

$$\begin{pmatrix} \dot{y}_j \\ \dot{z}_j \end{pmatrix} = \begin{pmatrix} \mu_{j-1}^+ & 0 \\ 0 & \mu_{j-1}^- \end{pmatrix} \begin{pmatrix} y_j \\ z_j \end{pmatrix} + T_j^{-1} \begin{pmatrix} 0 \\ -g_j(x,t) + f_j \end{pmatrix}.$$

Denoting

$$Y_j = \begin{pmatrix} y_j \\ z_j \end{pmatrix}, \quad \Lambda_j = \begin{pmatrix} \mu_{j-1}^+ & 0 \\ 0 & \mu_{j-1}^- \end{pmatrix}, \quad \text{and} \quad h_j(x,t) = T_j^{-1} \begin{pmatrix} 0 \\ -g_j(x,t) + f_j \end{pmatrix}$$

yields $\dot{Y}_j = \Lambda_j Y_j + h_j(x,t)$, and hence

$$Y_j(t) = e^{\Lambda_j t} Y_j(0) + \int_0^t e^{\Lambda_j (t-\tau)} h_j(x(\tau),\tau) d\tau.$$

The boundedness of $g_j(x,t)$ and f_j implies that there exists $d_j > 0$, such that $\sup_t |h_j(x(t),t)| \le d_j$, and

$$|Y_j(t)| \le e^{(\mu_{j-1}^+)t} |Y_j(0)| + \frac{d_j}{|\mu_{j-1}^+|} \left(1 - e^{(\mu_{j-1}^+)t}\right), \quad t \ge 0.$$

Note that d_j $(j = 2, \ldots, N)$ are independent of F. Let $b_j = (d_j + 1)/|\mu_{j-1}^+|$. Then it follows that $|Y_j(t)| \le b_j$ for all $t \ge 0$ if $|Y_j(0)| \le b_j$. Moreover, for each solution of (2.2), there exists $t_0 > 0$ such that $|Y_j(t)| \le b_j$ for $t > t_0$.

In particular, when $j = 1$, we have the following estimates:

$$T_1 = \begin{pmatrix} 1 & 1 \\ 0 & \mu_0^- \end{pmatrix} \quad \text{and} \quad T_1^{-1} = \begin{pmatrix} 1 & -1/\mu_0^- \\ 0 & 1/\mu_0^- \end{pmatrix}.$$

As a consequence, it follows that

$$\dot{z}_1 = \mu_0^- z_1 - \frac{g_1(x,t)}{\mu_0^-} + \frac{f_1}{\mu_0^-} = -\Gamma z_1 + \frac{1}{\Gamma}(g_1(x,t) - f_1).$$

Let $b_1^- = -\Gamma^{-2}\sqrt{N}(F+1)$ and $b_1^+ = -\Gamma^{-2}\sqrt{N}(F-1)$. Then we have $z_1(t) \in [b_1^-, b_1^+]$ for all $t \ge 0$ if $z_1(0) \in [b_1^-, b_1^+]$. Moreover if $z_1(0) \notin [b_1^-, b_1^+]$, then there exists $t_0 > 0$ such that $z_1(t) \in [b_1^-, b_1^+]$ for all $t > t_0$.

(2) $\Gamma^2 = 4K\lambda_{j-1}$. In this case, taking

$$C_j = \begin{pmatrix} 0 & 1 \\ -K\lambda_{j-1} & -\Gamma \end{pmatrix} \quad \text{and} \quad T_j = \begin{pmatrix} 1 & 1 \\ -\Gamma/4 & -3\Gamma/4 \end{pmatrix},$$

we have

$$\begin{aligned} T_j^{-1} C_j T_j &= T_j^{-1} \begin{pmatrix} 0 & 1 \\ -\frac{3}{4}K\lambda_{j-1} & -\Gamma \end{pmatrix} T_j + T_j^{-1} \begin{pmatrix} 0 & 0 \\ -\frac{1}{4}K\lambda_{j-1} & 0 \end{pmatrix} T_j \\ &= \begin{pmatrix} -\frac{\Gamma}{4} & 0 \\ 0 & -\frac{3}{4}\Gamma \end{pmatrix} - \frac{\Gamma}{8} \begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix}. \end{aligned}$$

For each $z=(z_1,z_2)\in\mathbb{R}^2$, it follows that

$$\langle T_j^{-1}C_jT_jz,z\rangle=-\frac{\Gamma}{4}z_1^2-\frac{3}{4}\Gamma z_2^2-\frac{\Gamma}{8}(z_1^2-z_2^2)\le-\frac{\Gamma}{4}(z_1^2+z_2^2)=-\frac{\Gamma}{4}|z|^2.$$

Let

$$\begin{pmatrix} y_j \\ z_j \end{pmatrix}=T_j^{-1}\begin{pmatrix} x_j \\ \dot{x}_j \end{pmatrix}.$$

Then we have $\dot{Y}_j=\Lambda_jY_j+h_j(x,t)$, where $\Lambda_j=T_j^{-1}C_jT_j$. Since $\langle\Lambda_jz,z\rangle\le-\frac{\Gamma}{4}|z|^2$, then $\|e^{\Lambda_jt}\|\le e^{-\frac{\Gamma}{4}t}$ for $t\ge0$, and hence

$$\begin{aligned}|Y_j(t)|&\le e^{-\frac{\Gamma}{4}t}|Y_j(0)|+\int_0^t e^{-\frac{\Gamma}{4}(t-\tau)}|h_j(x(\tau),\tau)|d\tau\\&\le e^{-\frac{\Gamma}{4}t}|Y_j(0)|+\frac{4d_j}{\Gamma}\left(1-e^{-\frac{\Gamma}{4}t}\right),\quad t\ge0.\end{aligned}$$

Let $b_j=(4d_j+1)/\Gamma$. Then we obtain the same conclusion as in case (1).

(3) $\Gamma^2<4K\lambda_{j-1}$. In this case, the eigenvalues of the matrix C_j are a pair of conjugate complex numbers $\mu_{j-1}^{\pm}=\alpha_j\pm i\beta_j=(-\Gamma\pm\sqrt{\Gamma^2-4K\lambda_{j-1}})/2$, where $\alpha_j=-\Gamma/2<0$. Taking

$$T_j=\begin{pmatrix}1&0\\ \alpha_j&\beta_j\end{pmatrix}\ \text{ yields }\ T_j^{-1}C_jT_j=\begin{pmatrix}\alpha_j&\beta_j\\ -\beta_j&\alpha_j\end{pmatrix}\triangleq\Lambda_j.$$

Making a transformation

$$\begin{pmatrix} y_j \\ z_j \end{pmatrix}=T_j^{-1}\begin{pmatrix} x_j \\ \dot{x}_j \end{pmatrix},$$

we obtain from (2.4) that $\dot{Y}_j=\Lambda_jY_j+h_j(x,t)$. From the fact $\|e^{\Lambda_jt}\|\le e^{\alpha_jt}$ for $t\ge0$, it follows that

$$|Y_j(t)|\le e^{\alpha_jt}|Y_j(0)|+\frac{d_j}{|\alpha_j|}(1-e^{\alpha_jt}).$$

Taking $b_j=(d_j+1)/|\alpha_j|$ leads to the same conclusion as in case (1).

Consequently, the set

$$\Omega'=\{(y_1,z_1,\dots,y_N,z_N)\,|\,b_1^-\le z_1\le b_1^+,|(y_j,z_j)|\le b_j,j=2,\dots,N\}$$

is a trapping region. Let Ω denote this trapping region in a $\mathbf{u}$-coordinate system. For each $\mathbf{u}=(u,\dot{u})^T=(u_1,\dots,u_N,\dot{u}_1,\dots,\dot{u}_N)^T\in\Omega$, let $x=(x_1,\dots,x_N)^T=D^{-1}u$ and $\hat{x}=(0,x_2,\dots,x_N)^T$. Since $\mathbf{u}\in\Omega$, then the corresponding $(y_1,z_1,\dots,y_N,z_N)$ satisfies $|(y_j,z_j)|\le b_j$ for $j=2,\dots,N$, and

$$|(x_j,\dot{x}_j)|\le\|T_j\||(y_j,z_j)|\le b_j\|T_j\|\triangleq\hat{b}_j,\quad j=2,\dots,N,\tag{2.5}$$

implying that $|x_j|\le\hat{b}_j$, and $|\hat{x}|\le\sum_{j=2}^N\hat{b}_j$. From $ADx=AD\hat{x}$ we deduce that

$$|u_{j-1}-2u_j+u_{j+1}|=|Au|=|ADx|=|AD\hat{x}|\le\|A\|\|D\||\hat{x}|\le4|\hat{x}|\le4\sum_{j=2}^N\hat{b}_j\triangleq b.$$

Note that b_j $(j = 2, \ldots, N)$ are independent of F. So is b. From the facts $\dot{x}_1 = \mu_0^- z_1 = -\Gamma z_1$ and $z_1 \in [b_1^-, b_1^+]$ we derive that

$$\dot{x}_1 \in \left[\Gamma^{-1}\sqrt{N}(F-1), \Gamma^{-1}\sqrt{N}(F+1)\right].$$

Denoting $D = (D_{jk})$, we have from $\dot{u} = D\dot{x}$ that

$$\dot{u}_j = \frac{1}{\sqrt{N}}\dot{x}_1 + D_{j2}\dot{x}_2 + \cdots + D_{jN}\dot{x}_N,$$

implying by (2.5) that

$$\frac{F-1}{\Gamma} - \sum_{k=2}^{N} |D_{jk}|\hat{b}_k \le \dot{u}_j \le \frac{F+1}{\Gamma} + \sum_{k=2}^{N} |D_{jk}|\hat{b}_k.$$

Let $b^* = \sqrt{\sum_{k=2}^{N} \hat{b}_k^2}$. Then b^* is independent of F, and $\sum_{k=2}^{N} |D_{jk}|\hat{b}_k < b^*$ by the Cauchy inequality. Taking

$$v_- = \frac{F-1}{\Gamma} - b^* \quad \text{and} \quad v^+ = \frac{F+1}{\Gamma} + b^* \tag{2.6}$$

yields $v_- \le \dot{u}_j \le v^+,\ j = 1, \ldots, N.$ □

Let $\hat{\mathbf{u}}(t) = (\hat{u}(t), \dot{\hat{u}}(t))^T = (\hat{u}_1(t), \ldots, \hat{u}_N(t), \dot{\hat{u}}_1(t), \ldots, \dot{\hat{u}}_N(t))^T$ denote the single-wave-form solution obtained in Lemma 2.1.

LEMMA 2.3. *The single-wave-form solution* $\hat{\mathbf{u}}(t) \in \Omega$ *for* $t \in \mathbb{R}$.

Proof. Let $\hat{\mathbf{x}}(t) = (\hat{x}_1(t), \ldots, \hat{x}_N(t), \dot{\hat{x}}_1(t), \ldots, \dot{\hat{x}}_N(t))^T = (D^{-1}\hat{u}(t), D^{-1}\dot{\hat{u}}(t))^T$. Then it is easy to check that $\hat{x}_1(t+T) = \hat{x}_1(t) + 2\pi\sqrt{N}$ for $t \in \mathbb{R}$, and the other components are periodic with period $T > 0$, where T is the period of the waveform function corresponding to $\hat{\mathbf{u}}(t)$. From the proof of Lemma 2.2 we can denote this single-wave-form solution by $(\hat{y}_1(t), \hat{z}_1(t), \ldots, \hat{y}_N(t), \hat{z}_N(t))$. It follows that all the components, except $\hat{y}_1(t)$, are periodic, implying that the single-wave-form solution belongs to the trapping region Ω' for all $t \in \mathbb{R}$. □

In the remainder of this paper, we assume that $F \ge F_1 = \Gamma b^* + 1$ such that $v_- > 0$. Let $T_0 = 2\pi/b^*$. Then from Lemma 2.1 it follows that $0 < T \le T_0$ if $F \ge F_1$. Let

$$c = \frac{2}{v_-} + \frac{v^+ T_0(Kb + F + 1 + \Gamma v^+ + 2\pi KM)}{v_-^3}. \tag{2.7}$$

Note that c is a continuous function of F and $c \to 0$ as $F \to +\infty$.

LEMMA 2.4. *Assume that* $\mathbf{u}(t) = (u_1(t), \ldots, u_N(t), \dot{u}_1(t), \ldots, \dot{u}_N(t))$ *is a solution of* (2.2) *with* $\mathbf{u}(t) \in \Omega$ *for* $t \ge 0$. *Then*

$$\left| \int_{t_0}^{t_1} \cos u_j(t) dt \right| \le c,$$

where $0 \le t_0 < t_1$ *and* $t_1 - t_0 \le T_0$, $j = 1, \ldots, N$.

Proof. From Lemma 2.2 it follows that for $t \ge 0$,

$$\left|\frac{\ddot{u}_j}{\dot{u}_j}\right| = \left|\frac{K(u_{j-1} + u_{j+1} - 2u_j) - \sin u_j + F - \Gamma\dot{u}_j}{\dot{u}_j}\right|$$

$$\le \frac{Kb + F + 1 + \Gamma v^+ + 2\pi KM}{v_-},$$

and hence

$$\left|\int_{t_0}^{t_1}\cos u_j(t)dt\right| = \left|\int_{t_0}^{t_1}\frac{\cos u_j}{\dot u_j}du_j\right| = \left|\int_{t_0}^{t_1}\frac{1}{\dot u_j}d(\sin u_j)\right|$$

$$\le \left|\frac{\sin u_j}{\dot u_j}|_{t_0}^{t_1} + \int_{t_0}^{t_1}\frac{\sin u_j}{(\dot u_j)^2}d\dot u_j\right| \le \frac{2}{v_-} + \left|\int_{t_0}^{t_1}\frac{\sin u_j}{(\dot u_j)^2}\frac{\ddot u_j}{\dot u_j}du_j\right|$$

$$\le \frac{2}{v_-} + \frac{1}{v_-^2}\left(\frac{Kb+F+1+\Gamma v^+ + 2\pi KM}{v_-}\right)\left|\int_{t_0}^{t_1}du_j\right|$$

$$\le \frac{2}{v_-} + \frac{v^+T_0(Kb+F+1+\Gamma v^+ + 2\pi KM)}{v_-^3} = c. \qquad \square$$

3. Strong monotonicity. We know from [3] that there exists $F_d \ge 0$, which depends on Γ and K, such that the F-K model has equilibria for $0 \le F \le F_d$ and has no equilibria for $F > F_d$. Meanwhile, strong monotonicity generally implies stability of running periodic solutions if there is no equilibrium; see [3] and [13]. Therefore, we investigate in this section the strong monotonicity of system (1.1)–(1.2). To proceed, we make a transformation of variables:

$$\xi_j = u_j + \Gamma^{-1}\dot u_j, \quad \eta_j = \Gamma^{-1}\dot u_j, \quad j = 1, 2, \dots, N, \tag{3.1}$$

i.e., $\Xi = I_\Gamma\,\mathbf{u}$, in which $\Xi = (\xi, \eta)^T$, $\xi = (\xi_1, \dots, \xi_N)^T$, $\eta = (\eta_1, \dots, \eta_N)^T$,

$$I_\Gamma = \begin{pmatrix} I & \Gamma^{-1}I \\ 0 & \Gamma^{-1}I \end{pmatrix},$$

and I is the identity matrix of order N. Now the system (1.1)–(1.2) becomes

(3.2)

$$\begin{cases}
\dot\xi_1 = -\Gamma^{-1}\sin(\xi_1-\eta_1) + \Gamma^{-1}K[\xi_2-\eta_2+\xi_N-\eta_N-2(\xi_1-\eta_1)] \\
\qquad -2\pi K\Gamma^{-1}M + \Gamma^{-1}F, \\
\dot\xi_2 = -\Gamma^{-1}\sin(\xi_2-\eta_2) + \Gamma^{-1}K[\xi_1-\eta_1+\xi_3-\eta_3-2(\xi_2-\eta_2)] \\
\qquad +\Gamma^{-1}F, \\
\quad\vdots \\
\dot\xi_{N-1} = -\Gamma^{-1}\sin(\xi_{N-1}-\eta_{N-1}) \\
\qquad +\Gamma^{-1}K[\xi_{N-2}-\eta_{N-2}+\xi_N-\eta_N-2(\xi_{N-1}-\eta_{N-1})] + \Gamma^{-1}F, \\
\dot\xi_N = -\Gamma^{-1}\sin(\xi_N-\eta_N) + \Gamma^{-1}K[\xi_1-\eta_1+\xi_{N-1}-\eta_{N-1}-2(\xi_N-\eta_N)] \\
\qquad +2\pi K\Gamma^{-1}M + \Gamma^{-1}F, \\
\dot\eta_1 = -\Gamma\eta_1 + \dot\xi_1, \\
\quad\vdots \\
\dot\eta_N = -\Gamma\eta_N + \dot\xi_N.
\end{cases}$$

Set $\Phi = (\phi_1, \ldots, \phi_N)^T$ and $\Psi = (\psi_1, \ldots, \psi_N)^T$. The linearized equations along a solution $\Xi(t) \in I_\Gamma\Omega$ $(t \geq 0)$ are

$$\begin{cases} \dot{\phi}_j = -\Gamma^{-1}(\cos(\xi_j - \eta_j))(\phi_j - \psi_j) + \Gamma^{-1}K[\phi_{j+1} - \psi_{j+1} \\ \qquad + \phi_{j-1} - \psi_{j-1} - 2(\phi_j - \psi_j)] \triangleq L_j(\Phi, \Psi, t), \\ \dot{\psi}_j = -\Gamma\psi_j + \dot{\phi}_j \triangleq H_j(\Phi, \Psi, t), \end{cases} \tag{3.3}$$

in which $j = 1, 2, \ldots, N$, $\phi_0 = \phi_N, \phi_{N+1} = \phi_1, \psi_0 = \psi_N,\ \psi_{N+1} = \psi_1$.

First we study the properties of the auxiliary equations

$$\dot{\phi}_j = L_j(\Phi, \Psi, t) + \varepsilon, \quad \dot{\psi}_j = H_j(\Phi, \Psi, t), \tag{3.4}$$

in which $\varepsilon > 0$. Let

$$\Sigma = \left\{(\Phi, \Psi) \in \mathbb{R}^{2N} \mid -\phi_j \leq \psi_j \leq \phi_j,\ \ \phi_j \geq 0,\ j = 1, \ldots, N\right\}. \tag{3.5}$$

Let $\operatorname{int}\Sigma$ and $\partial\Sigma$ denote the interior and boundary of Σ, respectively.

Consider a first order equation

$$\dot{w} = \frac{1}{\Gamma}\left[-\Gamma^2 w - 2K(1-w)^2 - \cos u_j(t)(1-w)^2\right], \tag{3.6}$$

where $u_j(t)$ is a component of $\mathbf{u}(t)$ and $\mathbf{u}(t) \in \Omega$ $(t \geq 0)$ is a solution of (2.2) with external force F. The proof of the following lemma is postponed to the appendix.

LEMMA 3.1. *Assume $\Gamma > 2\sqrt{2K}$. Then there exists $F_0 \geq F_1$, such that each solution $w(t)$ of (3.6), in which $u_j(t)$ is a component of a solution $\mathbf{u}(t) \in \Omega$ $(t \geq 0)$ to (2.2) with $F \geq F_0$, satisfies that if $w(0) \in [-1, 1]$, then $1 - \Gamma^2/(4K) < w(t) < 1$ for all $t > 0$ and $-1 < w(t) < 1$ for $t \in [T_0/2, T_0]$.*

We remark that F_0 increases as N and M increase, as can be seen from the value F_1, which depends on the eigenvalues of matrix A and the proof in the appendix.

LEMMA 3.2. *Assume $\Gamma > 2\sqrt{2K}$ and $F \geq F_0$. Then the solution $(\Phi(\varepsilon, t), \Psi(\varepsilon, t))$ of (3.4), in which $\Xi(t) \in I_\Gamma\Omega$ $(t \geq 0)$ is a solution to (3.2), satisfies that $\phi_j(\varepsilon, t) > 0$ and $1 - \Gamma^2/(4K) < \psi_j(\varepsilon, t)/\phi_j(\varepsilon, t) < 1$ for all $t > 0$, and $-1 < \psi_j(\varepsilon, t)/\phi_j(\varepsilon, t) < 1$ for $t \in [T_0/2, T_0]$, $j = 1, \ldots, N$, if $(\Phi(\varepsilon, 0), \Psi(\varepsilon, 0)) \in \partial\Sigma\backslash\{0\}$.*

Proof. There are three cases to discuss for $(\Phi(\varepsilon, 0), \Psi(\varepsilon, 0)) \in \partial\Sigma\backslash\{0\}$.

(i) $\phi_j(\varepsilon, 0) > 0$ and $\phi_j(\varepsilon, 0) = \psi_j(\varepsilon, 0)$. Then there is a maximum $t_j^0 > 0$, or $t_j^0 = +\infty$, such that $\phi_j(\varepsilon, t) > 0$ for $t \in [0, t_j^0)$. Let $w_j(\varepsilon, t) = \psi_j(\varepsilon, t)/\phi_j(\varepsilon, t)$ for $t \in [0, t_j^0)$. Then it follows that

$$\begin{aligned} \dot{w}_j &= (\dot{\psi}_j\phi_j - \psi_j\dot{\phi}_j)/\phi_j^2 \\ &= \Gamma^{-1}\left[-\Gamma^2 w_j - 2K(1-w_j)^2 - \cos(\xi_j - \eta_j)(1-w_j)^2\right] - \varepsilon w_j/\phi_j \\ &\quad + \frac{K}{\Gamma\phi_j}(\phi_{j-1} - \psi_{j-1} + \phi_{j+1} - \psi_{j+1})(1 - w_j), \end{aligned}$$

and hence

$$\dot{w}_j|_{w_j=1, t=0} = -\Gamma - \varepsilon/\phi_j(\varepsilon, 0) < 0,$$

implying that $w_j(\varepsilon, t) < 1$ as long as $\phi_j(\varepsilon, t) > 0$, i.e., $\psi_j(\varepsilon, t) < \phi_j(\varepsilon, t)$ for $t \in (0, t_j^0)$.

(ii) $\phi_j(\varepsilon,0)=\psi_j(\varepsilon,0)=0$. In this case we have that $L_j(\Phi,\Psi,t)|_{(\Phi(\varepsilon,0),\Psi(\varepsilon,0))}\geq 0$, i.e., $\dot{\phi}_j|_{t=0}\geq\varepsilon>0$, and

$$0\leq\frac{H_j(\Phi,\Psi,t)}{L_j(\Phi,\Psi,t)+\varepsilon}\bigg|_{(\Phi(\varepsilon,0),\Psi(\varepsilon,0))}=\frac{\Gamma^{-1}K(\phi_{j-1}-\psi_{j-1}+\phi_{j+1}-\psi_{j+1})}{\Gamma^{-1}K(\phi_{j-1}-\psi_{j-1}+\phi_{j+1}-\psi_{j+1})+\varepsilon}<1.$$

Consequently, there is a maximum $t_j^0>0$, or $t_j^0=+\infty$, such that $\phi_j(\varepsilon,t)>0$ and $\psi_j(\varepsilon,t)/\phi_j(\varepsilon,t)<1$ for $t\in(0,t_j^0)$.

(iii) $\phi_j(\varepsilon,0)>0$ and $\psi_j(\varepsilon,0)=-\phi_j(\varepsilon,0)$. Then there exists a maximum $t_j^0>0$, or $t_j^0=+\infty$, such that $\phi_j(\varepsilon,t)>0$ and $\psi_j(\varepsilon,t)<\phi_j(\varepsilon,t)$ for $t\in(0,t_j^0)$. From the discussions of cases (i) and (ii) we know that

$$\frac{K}{\Gamma\phi_j}(\phi_{j-1}-\psi_{j-1}+\phi_{j+1}-\psi_{j+1})(1-w_j)\geq 0$$

for $t\in(0,t_0)$, where $t_0=\min_j\{t_j^0\}$. Furthermore, from the fact $\frac{-\varepsilon w_j}{\phi_j}|_{w_j=-1,t=0}>0$, Lemma 3.1, and the comparison principle we deduce that $\phi_j(\varepsilon,t)>0$ and $1-\Gamma^2/(4K)<w_j(\varepsilon,t)=\psi_j(\varepsilon,t)/\phi_j(\varepsilon,t)<1$ for $t\in(0,t_0)$. We claim that $t_0=+\infty$. If this is not true, then we have $\phi_j(\varepsilon,t)\to 0$ or $w_j(\varepsilon,t)\to 1$ as $t\to t_0^-$. In the former case, we have $\psi_j(\varepsilon,t)\to 0$ as $t\to t_0^-$, leading to a contradiction of the fact $\lim_{t\to t_0^-}\dot{\phi}_j(\varepsilon,t)\geq\varepsilon>0$. The latter case is also impossible. Indeed, if $\phi_j(\epsilon,t)\geq a>0$, where a is a positive number, then from part (i) we have that $w_j(\epsilon,t)<1-\delta$ for some small positive number δ since $\dot{w}|_{w_j=1,t=0}<0$. Consequently, we have $t_0=+\infty$. Another direct consequence from Lemma 3.1 and the comparison principle is that $-1<\psi_j(\varepsilon,t)/\phi_j(\varepsilon,t)<1$ for $t\in[T_0/2,T_0]$. Note that $\frac{-\varepsilon w_j}{\phi_j}|_{w_j=-1}>0$ and $\frac{-\varepsilon w_j}{\phi_j}|_{w_j=1}<0$. Then for $t\in[T_0/2,T_0]$, we have from the comparison principle that $-1<\psi_j(\varepsilon,t)/\phi_j(\varepsilon,t)<1$ holds true uniformly with respect to $\varepsilon>0$. ∎

LEMMA 3.3. *Assume that* $\Gamma>2\sqrt{2K}$ *and* $F\geq F_0$. *Then the solution* $(\Phi(t),\Psi(t))$ *of* (3.3), *the linearized equations of* (3.2) *along* $\Xi(t)\in I_\Gamma\Omega$ $(t\geq 0)$, *satisfies that* $\phi_j(t)\geq 0$ *and* $[1-\Gamma^2/(4K)]\phi_j(t)\leq\psi_j(t)\leq\phi_j(t)$ *for all* $t>0$, $j=1,\ldots,N$, *if* $(\Phi(0),\Psi(0))\in\partial\Sigma\backslash\{0\}$.

Proof. Assume that $(\Phi(\varepsilon,t),\Psi(\varepsilon,t))$ is a solution of the auxiliary equations (3.4) with the initial values $\Phi(\varepsilon,0)=\Phi(0)$ and $\Psi(\varepsilon,0)=\Psi(0)$. Then from Lemma 3.2 it follows that $[1-\Gamma^2/(4K)]\phi_j(\varepsilon,t)<\psi_j(\varepsilon,t)<\phi_j(\varepsilon,t)$ and $\phi_j(\varepsilon,t)>0$ for all $t>0$. Keeping t fixed and taking $\varepsilon\to 0$, we complete the proof. ∎

In fact, we have further conclusions on $\phi_j(t)$ and $\psi_j(t)$ under the same conditions of Lemma 3.3.

LEMMA 3.4. *Assume that* $\Gamma>2\sqrt{2K}$ *and* $F\geq F_0$. *Then the solution* $(\Phi(t),\Psi(t))$ *of* (3.3), *the linearized equations of* (3.2) *along* $\Xi(t)\in I_\Gamma\Omega$ $(t\geq 0)$, *satisfies that* $\phi_j(t)>0$ *for all* $t>0$, *and* $-\phi_j(t)<\psi_j(t)<\phi_j(t)$ *for* $t\in[T_0/2,T_0]$, $j=1,\ldots,N$, *if* $(\Phi(0),\Psi(0))\in\partial\Sigma\backslash\{0\}$.

Proof. Since $(\Phi(0),\Psi(0))\in\partial\Sigma\backslash\{0\}$, then we may assume that there is some k such that $\phi_k(0)>0$. From Lemma 3.3 we know that $[1-\Gamma^2/(4K)]\phi_k(t)\leq\psi_k(t)\leq\phi_k(t)$, $\psi_{k+1}(t)\leq\phi_{k+1}(t)$, and $\psi_{k-1}(t)\leq\phi_{k-1}(t)$ for $t\geq 0$, and thus we obtain from (3.3)

$$\dot{\phi}_k(t)\geq-\Gamma^{-1}\Gamma^2/(4K)\phi_k(t)-2\Gamma^{-1}K\Gamma^2/(4K)\phi_k(t)=-\frac{\Gamma(2K+1)}{4K}\phi_k(t),$$

implying from the Gronwall inequality that

$$\phi_k(t)\geq\phi_k(0)\,e^{\frac{-\Gamma(2K+1)\,t}{4K}}>0\quad\text{for}\quad t>0.$$

Let $w_k(t) = \psi_k(t)/\phi_k(t)$. Then

$$\dot{w}_k = \Gamma^{-1}\left[-\Gamma^2 w_k - 2K(1-w_k)^2 - \cos(\xi_k - \eta_k)(1-w_k)^2\right]$$
$$+ \frac{K}{\Gamma\phi_k}(\phi_{k-1} - \psi_{k-1} + \phi_{k+1} - \psi_{k+1})(1-w_k).$$

From the fact $\dot{w}_k|_{w_k=1} = -\Gamma < 0$, we obtain $w_k(t) < 1$, i.e., $\phi_k(t) - \psi_k(t) > 0$ for $t > 0$. Therefore from (3.3) we have that

$$\dot{\phi}_{k+1} \geq -\frac{\Gamma(2K+1)}{4K}\phi_{k+1} + \Gamma^{-1}K(\phi_k(t) - \psi_k(t))$$

and, again by the Gronwall inequality, that

$$\phi_{k+1}(t) \geq e^{\frac{-\Gamma(2K+1)\,t}{4K}}\phi_{k+1}(0) + \int_0^t e^{\frac{-\Gamma(2K+1)(t-\tau)}{4K}}\,\Gamma^{-1}K\left(\phi_k(\tau) - \psi_k(\tau)\right)d\tau > 0,\ \ t > 0.$$

With the same reasoning we have that $\phi_{k+2}(t) > 0$, $t > 0$, ..., and $\phi_{k-1}(t) > 0$, $t > 0, \ldots$. Consequently, we derive that $\phi_j(t) > 0$ for $t > 0$, $j = 1, \ldots, N$.

Keeping $t \in [T_0/2, T_0]$ fixed, we know from Lemma 3.2 that there exists $\delta > 0$ such that the solution $(\Phi(\varepsilon, t), \Psi(\varepsilon, t))$ of the auxiliary equations (3.4) with the initial values $\Phi(\varepsilon, 0) = \Phi(0)$ and $\Psi(\varepsilon, 0) = \Psi(0)$ has the property that

$$-1 + \delta \leq \frac{\psi_j(\varepsilon, t)}{\phi_j(\varepsilon, t)} \leq 1 - \delta.$$

We remark by virtue of the proof of Lemma 3.2 that δ is independent of ε. Taking $\varepsilon \to 0$, we derive that $-1 + \delta \leq \psi_j(t)/\phi_j(t) \leq 1 - \delta$. □

Now we define a partial order in the phase space $\mathbb{R}^{2N}$. Let $\Xi = (\xi_1, \ldots, \xi_N, \eta_1, \ldots, \eta_N)^T$ and $\Xi' = (\xi'_1, \ldots, \xi'_N, \eta'_1, \ldots, \eta'_N)^T$.

DEFINITION 3.5. *We define* $\Xi \leq \Xi'$ *if* $\xi_j \leq \xi'_j$ *and* $|\eta_j - \eta'_j| \leq |\xi_j - \xi'_j|$ *for* $j = 1, \ldots, N$. *We also define* $\Xi < \Xi'$ *if* $\Xi \leq \Xi'$ *and* $\Xi \neq \Xi'$, *and*

$$\Xi \ll \Xi' \ \text{ if } \ \xi_j < \xi'_j \ \text{ and } |\eta_j - \eta'_j| < |\xi_j - \xi'_j| \ \text{ for } j = 1, \ldots, N.$$

We remark that $\Xi \leq \Xi'$ if and only if $\Xi' - \Xi \in \Sigma$, and $\Xi \ll \Xi'$ if and only if $\Xi' - \Xi \in \text{int}\,\Sigma$. Let P^t denote the Poincaré map of system (3.2), i.e., $P^t\Xi = \Xi(t)$, in which $\Xi(t)$ is a solution of (3.2) with initial condition $\Xi(0) = \Xi$.

DEFINITION 3.6. *The Poincaré map* P^t $(t > 0)$ *of system* (3.2) *is said to be strongly monotone in the set* $\mathcal{B}$ *with* $P^t(\mathcal{B}) \subset \mathcal{B}$ *if*

$$\Xi_0 < \Xi'_0 \Rightarrow P^t\Xi_0 \ll P^t\Xi'_0 \ \text{ for } \ t > 0 \ \text{ and } \ \Xi_0, \Xi'_0 \in \mathcal{B}.$$

Now we can prove strong monotonicity by the above discussion and defining a homotopy as in [4, 14].

LEMMA 3.7. *Assume that* $\Gamma > 2\sqrt{2K}$ *and* $F \geq F_0$. *Then the Poincaré map* P^t *of system* (3.2) *is strongly monotone in* $I_\Gamma\Omega$ *for* $t \in [T_0/2, T_0]$.

Proof. Assume that $\Xi_0, \Xi'_0 \in I_\Gamma\Omega$, that $\Xi_0 < \Xi'_0$, and that $\Xi(t)$ and $\Xi'(t)$ are two solutions of (3.2) with initial values $\Xi(0) = \Xi_0$ and $\Xi'(0) = \Xi'_0$, respectively. Let

$$\Xi(\lambda, 0) = (1-\lambda)\Xi(0) + \lambda\Xi'(0),$$

where $\lambda \in [0,1]$. Assume that $\Xi(\lambda,t)$ is a solution of (3.2) with initial value $\Xi(\lambda,0)$. Then $\Xi(\lambda,t) \in I_\Gamma\Omega$ for $t \geq 0$ since $I_\Gamma\Omega$ is convex and positively invariant for system (3.2). Set

$$\Upsilon(\lambda,t) = \frac{\partial\, \Xi(\lambda,t)}{\partial\lambda} = (\phi_1(\lambda,t),\dots,\phi_N(\lambda,t),\psi_1(\lambda,t),\dots,\psi_N(\lambda,t))^T.$$

Then

$$\Upsilon(\lambda,0) = \frac{\partial\, \Xi(\lambda,0)}{\partial\lambda} = \Xi'(0) - \Xi(0) \quad \text{and} \quad \Xi'(t) - \Xi(t) = \int_0^1 \Upsilon(\lambda,t)d\lambda.$$

One can easily verify that $\Upsilon(\lambda,t)$ is a solution of the linearized equations (3.3) with initial value $\Upsilon(\lambda,0)$. Since $\Xi(0) < \Xi'(0)$, then

$$\phi_j(\lambda,0) \geq 0 \ \text{ and } \ |\psi_j(\lambda,0)| \leq \phi_j(\lambda,0), \quad j = 1,\dots,N,$$

i.e., $\Upsilon(\lambda,0) \in \Sigma\backslash\{0\}$. From Lemma 3.4 it follows that $\Upsilon(\lambda,t) \in \operatorname{int}\Sigma$ for $t \in [T_0/2, T_0]$, i.e.,

$$\phi_j(\lambda,t) > 0 \ \text{ and } \ |\psi_j(\lambda,t)| < \phi_j(\lambda,t), \quad j = 1,\dots,N, \quad t \in [T_0/2, T_0],$$

which implies that

$$\xi_j'(t) - \xi_j(t) = \int_0^1 \phi_j(\lambda,t)d\lambda > \int_0^1 |\psi_j(\lambda,t)|d\lambda \geq \left|\int_0^1 \psi_j(\lambda,t)d\lambda\right| = |\eta_j'(t) - \eta_j(t)|,$$

i.e., $\Xi(t) \ll \Xi'(t)$, $t \in [T_0/2, T_0]$. This completes the proof. □

4. Stability analysis. In this section we assume that $\Gamma > 2\sqrt{2K}$ and $F \geq F_0$ so that the conclusion of Lemma 3.7 holds true. We know from Lemma 2.1 that system (1.1)–(1.2) admits a single-wave-form solution $(\hat{u}_1(t),\dots,\hat{u}_N(t))$ since $F \geq F_0 > 1$. Let us denote it in the Ξ-coordinate system by $\hat{\Xi}(t) = (\hat{\xi}_1(t),\dots,\hat{\xi}_N(t),\hat{\eta}_1(t),\dots,\hat{\eta}_N(t))$, i.e.,

$$\hat{\xi}_j(t) = \hat{u}_j(t) + \Gamma^{-1}\dot{\hat{u}}_j(t), \quad \hat{\eta}_j(t) = \Gamma^{-1}\dot{\hat{u}}_j(t), \quad j = 1,\dots,N.$$

Consequently, $\hat{\Xi}(t)$ has the following property:

$$\hat{\Xi}(t+T) = \hat{\Xi}(t) + 2\pi\mathbf{e}, \tag{4.1}$$

where $\mathbf{e} = (\mathbf{1},0)^T$, and $\mathbf{1}$ denotes a vector in $\mathbb{R}^N$ with all components equal to 1. From Lemma 2.1 it follows that there exists an integer m such that $mT \in [T_0/2, T_0]$. Let

$$\ell = \{\hat{\Xi}(t) | t \in \mathbb{R}\} \quad \text{and} \quad Q(\Xi) = P^{mT}\Xi - 2m\pi\mathbf{e}.$$

The following properties will be used in the subsequent discussion.

(I) Q is strongly monotone in $I_\Gamma\Omega$, and each point in ℓ is a fixed point of the map Q.

(II) For any $\Xi \in \mathbb{R}^{2N}$, there exist $\Xi_1, \Xi_2 \in \ell$ such that $\Xi_1 \ll \Xi \ll \Xi_2$. Indeed, we can take $\Xi_1 = \hat{\Xi}(-nT)$ and $\Xi_2 = \hat{\Xi}(nT)$ with n large enough.

LEMMA 4.1. *$\hat{\Xi}(t_1) \ll \hat{\Xi}(t_2)$ if $t_1 < t_2$.*

Proof. First we show that every two points in ℓ are ordered by the partial order "$\leq$." Assume that there are two points $\hat{\Xi}(t_1)$ and $\hat{\Xi}(t_2)$ $(t_1 < t_2)$ which are unordered, i.e., $\hat{\Xi}(t_2) - \hat{\Xi}(t_1) \notin \Sigma$. From the above property (II) we know that there exists a t' such that $\hat{\Xi}(t') \ll \hat{\Xi}(t_2)$, i.e., $\hat{\Xi}(t_2) - \hat{\Xi}(t') \in \operatorname{int}\Sigma$. Increasing t', we deduce from the continuity that there exists t_0 such that $\hat{\Xi}(t_2) - \hat{\Xi}(t_0) \in \partial\Sigma$, implying by the strong monotonicity of Q that $Q\hat{\Xi}(t_2) - Q\hat{\Xi}(t_0) \in \operatorname{int}\Sigma$. This is a contradiction since $\hat{\Xi}(t_2)$ and $\hat{\Xi}(t_0)$ are fixed points of Q.

Now we show that $\hat{\Xi}(t_1) \ll \hat{\Xi}(t)$ for all $t > t_1$. The above property (II) implies that there exists t_2 such that $\hat{\Xi}(t_1) \ll \hat{\Xi}(t)$ for $t \geq t_2$. Let

$$t_0 = \sup\{t \geq t_1 \,|\, \hat{\Xi}(t) - \hat{\Xi}(t_1) \in \partial\Sigma\}.$$

It is evident that $t_0 = t_1$. Indeed, if $t_0 > t_1$, then $\hat{\Xi}(t_0) - \hat{\Xi}(t_1) \in \partial\Sigma$, which is impossible by the strong monotonicity of Q. Therefore, $\hat{\Xi}(t) - \hat{\Xi}(t_1) \in \operatorname{int}\Sigma$, i.e., $\hat{\Xi}(t_1) \ll \hat{\Xi}(t)$ for $t > t_1$. □

Proof of Theorem 1.1. Let

$$[\Xi_1, \Xi_2] = \{\Xi \,|\, \Xi_1 \leq \Xi \leq \Xi_2\} \quad \text{for } \Xi_1 \leq \Xi_2.$$

For each $\Xi_0 \in I_\Gamma\Omega$, by the above property (II), there always exist Ξ_1 and $\Xi_2 \in \ell$ such that $\Xi_1 \ll \Xi_2$ and $\Xi_0 \in [\Xi_1, \Xi_2]$. The strong monotonicity of Q leads to the conclusion that $\{Q^n\Xi_0\}_{n=1}^{+\infty} \subset [\Xi_1, \Xi_2]$ since $Q(\Xi_1) = \Xi_1$ and $Q(\Xi_2) = \Xi_2$. From the boundedness of the set $[\Xi_1, \Xi_2]$, it follows that the ω-limit set $\omega(\Xi_0)$ of $\{Q^n\Xi_0\}_{n=1}^{+\infty}$ is nonempty. Define for $n \geq 0$

$$\tau_-(n; \Xi_0) = \sup\{\tau \in \mathbb{R} \,|\, \hat{\Xi}(\tau) \leq Q^n(\Xi_0)\},$$

$$\tau_+(n; \Xi_0) = \inf\{\tau \in \mathbb{R} \,|\, Q^n(\Xi_0) \leq \hat{\Xi}(\tau)\}.$$

From Lemma 4.1 and the strong monotonicity of Q we know that $\tau_-(n; \Xi_0)$ is strictly increasing, $\tau_+(n; \Xi_0)$ is strictly decreasing with respect to n, and $\tau_-(n; \Xi_0) \leq \tau_+(n; \Xi_0)$. Moreover, $\tau_\pm(n; \Xi_0)$ are continuous with respect to Ξ_0. If $\tau_-(0; \Xi_0) = \tau_+(0; \Xi_0) = \tau$, then $\Xi_0 = \hat{\Xi}(\tau)$ and $\Xi_0(t) = \hat{\Xi}(t + \tau)$, $t \in \mathbb{R}$, where $\Xi_0(t)$ is a solution of (3.2) with initial value Ξ_0 at $t = 0$. If $\tau_-(0; \Xi_0) < \tau_+(0; \Xi_0)$, let

$$\tau_-^\infty = \sup_{n\geq 0}\{\tau_-(n; \Xi_0)\}, \quad \tau_+^\infty = \inf_{n\geq 0}\{\tau_+(n; \Xi_0)\}.$$

Then $\tau_-^\infty \leq \tau_+^\infty$. If $\tau_-^\infty < \tau_+^\infty$, denote a limit point of $\{Q^n\Xi_0\}$ by $\tilde{\Xi}_0$. Then $\tau_\pm(0; \tilde{\Xi}_0) = \tau_\pm^\infty$, and

$$\tau_-^\infty = \tau_-(0; \tilde{\Xi}_0) < \tau_-(1; \tilde{\Xi}_0) \leq \tau_+(1; \tilde{\Xi}_0) < \tau_+(0; \tilde{\Xi}_0) = \tau_+^\infty.$$

Take k large enough such that $Q^k(\Xi_0)$ is sufficiently close to $\tilde{\Xi}_0$. Then we have

$$\tau_-^\infty < \tau_-(1; Q^k\Xi_0) \leq \tau_+(1; Q^k\Xi_0) < \tau_+^\infty,$$

i.e.,

$$\tau_-^\infty < \tau_-(k+1; \Xi_0) \leq \tau_+(k+1; \Xi_0) < \tau_+^\infty,$$

implying a contradiction. Consequently, $\tau_-^\infty = \tau_+^\infty \triangleq \tau$. We deduce that $|\Xi_0(nmT) - \hat{\Xi}(nmT + \tau)| \to 0$ as $n \to +\infty$, leading to the conclusion $|\Xi_0(t) - \hat{\Xi}(t + \tau)| \to 0$ as $t \to +\infty$. □

Appendix. Proof of Lemma 3.1. Since $u_j(t)$ in the right-hand side of (3.6) depends upon the external driving force F, so does the solution $w(t)$ of (3.6). If $w(0) = 1$, then since $\dot{w}|_{w=1} = -\Gamma < 0$, it is easy to check that $w(t) < 1$ for $t > 0$. Now we assume that $w(0) = -1$. First we show by contradiction that $1 - \frac{\Gamma^2}{4K} < w(t) < 1$ for $t \in [0, T_0]$ if F is large enough.

Assume that there exists $\hat{t} \in [0, T_0]$ such that $w(\hat{t}) \le 1 - \frac{\Gamma^2}{4K} < -1$. Taking

$$t_1 = \inf\left\{ t \,\middle|\, t \in (0, \hat{t}], w(t) = 1 - \Gamma^2/(4K) \right\} \quad \text{and} \quad t_0 = \sup\{ t \,|\, t \in [0, t_1), w(t) = -1 \}$$

yields that $w(t) \in [1 - \frac{\Gamma^2}{4K}, -1]$ for $t \in [t_0, t_1]$. Note that the function $f(x) = -\Gamma^2 x - 2K(1-x)^2$ is positive on the interval $[1 - \frac{\Gamma^2}{4K}, -1]$. It follows that

$$w(t_1) = w(t_0) + \int_{t_0}^{t_1} \frac{1}{\Gamma} \left[-\Gamma^2 w(t) - 2K(1 - w(t))^2 - \cos u_j(t)(1 - w(t))^2 \right] dt$$

$$> -1 - \frac{1}{\Gamma} \left| \int_{t_0}^{t_1} \cos u_j(t)(1 - w(t))^2 dt \right|.$$

Note also that

$$\int_{t_0}^{t_1} \cos u_j(t)(1 - w(t))^2 dt = \int_{t_0}^{t_1} (1 - w(t))^2 d \left(\int_{t_0}^{t} \cos u_j(\tau) d\tau \right)$$

$$= (1 - w(t))^2 \int_{t_0}^{t} \cos u_j(\tau) d\tau \Big|_{t_0}^{t_1} + 2 \int_{t_0}^{t_1} \left[\int_{t_0}^{t} \cos u_j(\tau) d\tau \right] (1 - w(t)) \dot{w}(t) dt.$$

Since $[t_0, t_1] \in [0, T_0]$, we deduce from Lemma 2.4 that

$$\left| (1 - w(t))^2 \int_{t_0}^{t} \cos u_j(\tau) d\tau \Big|_{t_0}^{t_1} \right| \le c(\Gamma^2/4K)^2. \tag{A.1}$$

From the fact

$$\max_{x \in [1 - \frac{\Gamma^2}{4K}, -1]} f(x) = \Gamma^2 \left(\frac{\Gamma^2}{8K} - 1 \right),$$

it follows that for $t \in [t_0, t_1]$,

$$|\dot{w}| = \frac{1}{\Gamma} \left| -\Gamma^2 w - 2K(1 - w)^2 - \cos u_j (1 - w)^2 \right|$$

$$\le \frac{1}{\Gamma} \left| -\Gamma^2 w - 2K(1 - w)^2 \right| + \frac{1}{\Gamma} \left| \cos u_j (1 - w)^2 \right|$$

$$\le \Gamma \left(\frac{\Gamma^2}{8K} - 1 \right) + \frac{1}{\Gamma} \left(\frac{\Gamma^2}{4K} \right)^2,$$

and hence

$$\begin{aligned}
&\left|\int_{t_0}^{t_1}\left[\int_{t_0}^{t}\cos u_j(\tau)d\tau\right](1-w(t))\dot{w}(t)dt\right| \\
&\leq \sup_{t\in[t_0,t_1]}\left\{|1-w(t)|\cdot|\dot{w}(t)|\cdot\left|\int_{t_0}^{t}\cos u_j(\tau)d\tau\right|\right\}\cdot(t_1-t_0) \\
&\leq \frac{c\,T_0\Gamma^2}{4K}\left[\Gamma\left(\frac{\Gamma^2}{8K}-1\right)+\frac{1}{\Gamma}\left(\frac{\Gamma^2}{4K}\right)^2\right]. \qquad \text{(A.2)}
\end{aligned}$$

Combining $(A.1)$ and $(A.2)$ yields

$$\begin{aligned}
&\frac{1}{\Gamma}\left|\int_{t_0}^{t_1}\cos u_j(t)(1-w(t))^2dt\right| \\
&< \frac{c}{\Gamma}\left(\frac{\Gamma^2}{4K}\right)^2+\frac{c\,T_0\Gamma}{2K}\left[\Gamma\left(\frac{\Gamma^2}{8K}-1\right)+\frac{1}{\Gamma}\left(\frac{\Gamma^2}{4K}\right)^2\right]=c\,\Delta, \qquad \text{(A.3)}
\end{aligned}$$

where

$$\Delta=\frac{1}{\Gamma}\left(\frac{\Gamma^2}{4K}\right)^2+\frac{T_0}{2K}\left[\Gamma^2\left(\frac{\Gamma^2}{8K}-1\right)+\left(\frac{\Gamma^2}{4K}\right)^2\right].$$

From (2.6) and (2.7) it follows that $c\to 0$ as $F\to+\infty$. Choosing F large enough, we have $c\,\Delta<\frac{\Gamma^2}{4K}-2$ and hence a contradiction with $w(t_1)=1-\frac{\Gamma^2}{4K}$. Consequently, there exists $F_2\geq F_1$ such that $1-\frac{\Gamma^2}{4K}<w(t)<1$ for $t\in[0,T_0]$ if $F\geq F_2$.

Now we construct a first order equation

$$\dot{s}=\Gamma^{-1}\left[-\Gamma^2 s-2K(1-s)^2\right].$$

It is easy to check by the assumption $\Gamma>2\sqrt{2K}$ that $s(t)\in(-1,1)$ for $t>0$ if $s(0)\in[-1,1]$. Assume that $s(0)=w(0)=-1$. Then for $t\in[0,T_0]$ it follows that

$$\begin{aligned}
|w(t)-s(t)|\leq{}&\frac{1}{\Gamma}\left|\int_0^t\left(2K(w(\tau)+s(\tau)-2)+\Gamma^2\right)(w(\tau)-s(\tau))d\tau\right| \\
&+\frac{1}{\Gamma}\left|\int_0^t\cos u_j(\tau)(1-w(\tau))^2d\tau\right|.
\end{aligned}$$

Since $s(t)\in(-1,1)$ and $1-\frac{\Gamma^2}{4K}<w(t)<1$ for $t\in(0,T_0]$, then we have

$$\left|\int_0^t\left(2K(w(\tau)+s(\tau)-2)+\Gamma^2\right)(w(\tau)-s(\tau))d\tau\right|\leq\int_0^t\Gamma^2\,|w(\tau)-s(\tau)|\,d\tau, \qquad \text{(A.4)}$$

and hence by (A.3) and (A.4),

$$|w(t)-s(t)|\leq\int_0^t\Gamma\,|w(\tau)-s(\tau)|\,d\tau+c\,\Delta.$$

The Gronwall inequality implies that

$$|w(t) - s(t)| \le c\,\Delta e^{\Gamma t} \le c\,\Delta e^{\Gamma T_0}, \quad t \in [0, T_0].$$

As a consequence, there exists $F_3 \ge F_1$, such that if $F \ge F_3$, then

$$c\,\Delta e^{\Gamma T_0} < s(T_0/2) + 1,$$

and hence $w(t) > -1$ for $t \in [T_0/2, T_0]$. Meanwhile, since $w(T_0) > -1$, then it follows that $1 - \Gamma^2/(4K) < w(t) < 1$ for $t \in [T_0, 2T_0]$ if $F \ge F_2$, and thus $1 - \Gamma^2/(4K) < w(t) < 1$ for all $t > 0$. The proof is completed by taking $F_0 = \max\{F_2, F_3\}$. □

We should mention here that the above proof was highly inspired by Levi's idea on dealing with a single oscillator [10].

ERGODICITY AND RATE OF CONVERGENCE FOR A NONSECTORIAL FIBER LAY-DOWN PROCESS*

MARTIN GROTHAUS† AND AXEL KLAR†

Abstract. A stochastic model for the lay-down of fibers on a conveyor belt in the production process of nonwovens is investigated. In particular, convergence of the stochastic process to the stationary solution is proven and estimates on the speed of convergence are given. Numerical results and examples are presented and compared with the analytical estimates on the speed of convergence.

Key words. fiber dynamics, Fokker–Planck equations, Dirichlet forms, ergodicity, rate of convergence

DOI. 10.1137/070697173

1. Introduction.

The understanding of the forms generated by the lay-down of flexible fibers onto a moving conveyor belt is of great interest in the production process of nonwovens that find their applications, e.g., in composite materials (filters), textiles, and the hygiene industry. In the melt-spinning process of nonwoven materials, hundreds of individual endless fibers obtained by the continuous extrusion of a melted polymer are stretched and entangled by highly turbulent air flows to finally form a web on the conveyor belt. The quality of this web and the resulting nonwoven material—in terms of homogeneity and load capacity—depends essentially on the dynamics and the deposition of the fibers.

For the description of the interaction between fibers and turbulent flow a stochastic force model is derived and analyzed in [MW06]. Applying this concept, the fiber fabric can in principle be numerically generated and its quality investigated. However, these or similar simulations usually lead to excessively large computation times, when all physical details of the production process are considered. Thus, simplified models for the lay-down process are needed. In particular, this is true for optimization and control procedures where many different simulations are needed. In [GKM+07] a new simplified stochastic model for the fiber lay-down process, i.e., for the generation of a fiber web on a conveyor belt, has been presented. The process, which takes into account the fiber motion under the influence of turbulence, is described by a stochastic differential system; see section 2.

The solution of the associated Fokker–Planck equation gives the density of the stochastic process. An important criterion for the quality of the web and the resulting nonwoven material is how it converges to equilibrium. In particular, the speed of convergence to the stationary solution is important. The faster this convergence is, the more uniform the produced textile will be. This means that process parameters should be adjusted such that the speed of convergence to equilibrium is optimal.

The trend to equilibrium for Fokker–Planck-type equations has been investigated in many papers. In [AMTU01] a unified presentation of entropy methods for

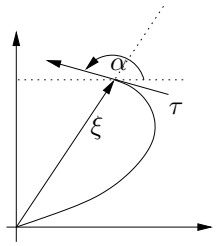

FIG. 1. *Fiber scenario on the conveyor belt.*

nondegenerate linear and nonlinear Fokker–Planck-type equations is given. In [DV01] the linear kinetic Fokker–Planck equation is discussed. In this case the degeneracy of the diffusion operator is similar to the present case. A more general theory for degenerate linear and nonlinear problems has been developed in [Vil06]. A more detailed discussion of these methods with respect to the present problem is given in the next section.

As in the above-mentioned papers, the purpose of the present paper is to investigate analytically the convergence to equilibrium. In particular, we aim at obtaining explicit estimates on the rate of convergence. However, instead of using entropy methods we use here Dirichlet form and operator semigroup techniques.

The paper is organized as follows. In section 2 we present the stochastic model for the fiber dynamics. Furthermore, we relate our convergence result for the solution of the stochastic differential equation with the convergence of the solution of the associated Fokker–Planck equation and outline our strategy for proving ergodicity. In section 3 we prove existence results for the stochastic process as well as several other properties of the process which are important for our analysis. Section 4 investigates several properties of an associated nondegenerate Ornstein–Uhlenbeck-type process. Section 5 proves the ergodicity of the original process and gives explicit bounds on the rates to convergence. Section 6 is devoted to some numerical results comparing the analytical rates of convergence with the numerical ones.

2. The stochastic model for the fiber lay-down process and its associated Fokker–Planck equation. Focusing on a single slender elastic inextensible fiber in a lay-down process, the fiber on the nonmoving conveyor belt can be described by an arc-length parameterized curve $\xi : \mathbb{R}_0^+ \to \mathbb{R}^2$, as visualized in Figure 1.

Due to its inextensibility, $\|\partial_t \xi\| = 1$ holds. The web-forming is modeled as

$$\partial_t \xi = \tau(\alpha),$$
$$\partial_t \alpha = -\nabla\phi(\xi) \cdot \tau^\perp(\alpha),$$

where $\tau(\alpha) = (\cos\alpha, \sin\alpha)^T$ denotes the normalized tangent on the fiber. Since a curved fiber tends back to its starting point, the change of the angle α is assumed to be proportional to $\nabla\phi(\xi)\cdot\tau^\perp(\alpha)$ with $\tau^\perp(\alpha) = (-\sin\alpha, \cos\alpha)^T$. The potential of this drive is prescribed by a function $\phi : \mathbb{R}^2 \to \mathbb{R}$ with the generic example $\phi(\xi) = \|\xi\|^2/2$. In general, the potential depends on the physical process and needs to be adapted to the experimental parameters.

Considering a turbulent flow in the deposition region of the fiber close to the conveyor belt, the fiber lay-down is additionally affected by a stochastic force that can be modeled by a Wiener process B_t in $\mathbb{R}$ with amplitude σ.

The resulting stochastic differential system reads

$$\mathrm{d}\xi_t = \tau(\alpha_t)\,\mathrm{d}t, \tag{2.1}$$

$$\mathrm{d}\alpha_t = -\nabla\phi(\xi_t)\cdot\tau^{\perp}(\alpha_t)\,\mathrm{d}t + \sigma\,\mathrm{d}B_t, \tag{2.2}$$

where the conservation of length $\|\partial_t\xi\| = 1$ is still valid. For details on the mathematical modeling of the process we refer to [GKM+07]. An illustration of the pathwise behavior of the process for different σ and $\phi(\xi) = \|\xi\|^2/2$ is displayed in Figure 2, where the paths of Monte Carlo simulations for different σ are shown. The slow convergence to equilibrium is clearly seen for small and large values of σ.

The density of the above stochastic process can be found by solving the associated Fokker–Planck equation:

$$\partial_t u + \cos(\alpha)\partial_{\xi^1} u + \sin(\alpha)\partial_{\xi^2} u - \partial_\alpha\left(\nabla\phi(\xi)\begin{pmatrix} -\sin(\alpha) \\ \cos(\alpha)\end{pmatrix} u\right) = \frac{\sigma^2}{2}\partial_\alpha^2 u. \tag{2.3}$$

A stationary solution of (2.3) is the function

$$(\xi,\alpha)\mapsto m(\xi) := \frac{1}{N}\exp(-\phi(\xi)), \quad N > 0.$$

For $\phi(\xi) = \|\xi\|^2/2$ we obtain the standard Gaussian as stationary distribution. By μ we denote the measure on $E = \mathbb{R}^2 \times [0, 2\pi]$ having density m with respect to (w.r.t.) the Lebesgue measure. Except for sections 3 and 4 we consider only potentials ϕ such that m is integrable and choose N as a normalizing constant to obtain a probability measure μ. In the following sections we are concerned with the approach to equilibrium of the stochastic process (2.1) or the convergence to the stationary solution of (2.3), respectively.

Remark 2.1. A formal argument for convergence to equilibrium of the solution of (2.3) is given by the following computations; cf. [DV01]. Define the relative entropy

$$H(u/m) = \int_{\mathbb{R}^2}\int_0^{2\pi} u\log\left(\frac{u}{m}\right) d\alpha d\xi.$$

An easy computation gives

$$\partial_t H(u/m) = -\int_{\mathbb{R}^2}\int_0^{2\pi} u\left(\partial_\alpha\log\left(\frac{u}{m}\right)\right)^2 d\alpha d\xi.$$

This vanishes if and only if

$$u = \rho(t,\xi)m(\xi).$$

That means u converges formally to a local equilibrium. Plugging $u = \rho(t,\xi)m(\xi)$ into the evolution equation, one obtains

$$m\partial_t\rho + \cos(\alpha)\left(\partial_{\xi^1}(\rho m) + \rho m\partial_{\xi^1}\phi\right) + \sin(\alpha)\left(\partial_{\xi^2}(\rho m) + \rho m\partial_{\xi^2}\phi\right) = 0$$

or

$$\partial_t\rho = 0, \quad \partial_{\xi^1}\rho = 0, \quad \partial_{\xi^2}\rho = 0.$$

This means $u = m(\xi)$, i.e., convergence to global equilibrium.

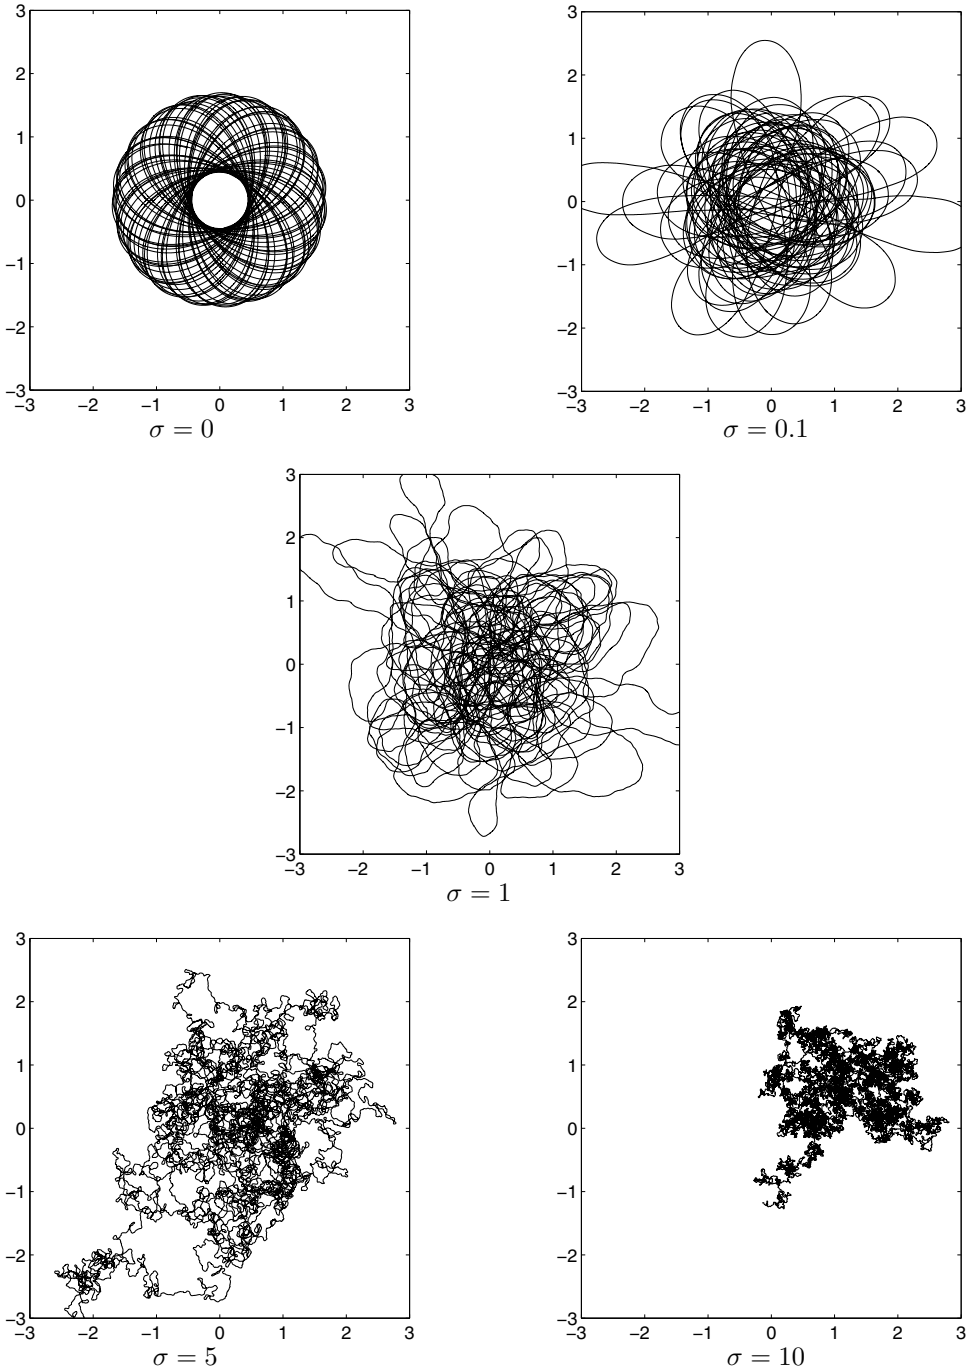

FIG. 2. *Representative path behavior for balanced ($\sigma = 1$) as well as deterministic ($\sigma < 1$) and stochastic ($\sigma > 1$) dominated (ξ, α)-systems.*

In [Vil06] the arguments described in the above remark were rigorously justified for similar equations. To apply these methods in the context of the present paper among other conditions, the existence of proper Liapunov functions would be necessary. Their existence is another open problem. In the following we choose a different route and consider the stochastic differential equation (2.1) directly.

In section 3 we construct a diffusion process solving (2.1) and having μ as an invariant measure. The law of this process we denote by $\mathbf{P}_\mu$. Then in section 5 we prove that this diffusion is ergodic with rate of convergence

$$\begin{aligned}(2.4)\quad &\Big\|\frac{1}{t}\int_0^t f(\mathbf{X}_s)\,ds - \mathbf{E}_\mu[f]\Big\|_{L^2(\mathbf{P}_\mu)}\\ &\le \frac{1}{c^{1/2}}\Big(\frac{2}{t}+\frac{1}{t^{1/2}}\Big(\frac{A(C)c^{1/2}+B(C)c^{-1/2}}{\sigma}+(1+2^{-1/2})\sigma\Big)\Big)\|f-\mathbf{E}_\mu[f]\|_{L^2(\mu)},\quad t>0;\end{aligned}$$

see Theorem 5.3 for details. The convergence in (2.4) implies mean ergodicity of the corresponding semigroup $(T_t)_{t\ge 0}$, i.e.,

$$\begin{aligned}(2.5)\quad &\Big\|\frac{1}{t}\int_0^t T_s f\,ds - \mathbf{E}_\mu[f]\Big\|_{L^2(\mu)}\\ &\le \frac{1}{c^{1/2}}\Big(\frac{2}{t}+\frac{1}{t^{1/2}}\Big(\frac{A(C)c^{1/2}+B(C)c^{-1/2}}{\sigma}+(1+2^{-1/2})\sigma\Big)\Big)\|f-\mathbf{E}_\mu[f]\|_{L^2(\mu)},\quad t>0.\end{aligned}$$

In the case of an analytic semigroup from (2.5) we even could conclude strongly mixing, i.e.,

$$\lim_{t\to\infty}\|T_t f-\mathbf{E}_\mu[f]\|_{L^2(\mu)}=0;$$

see, e.g., [Gol85, Exer. 8.24.17]. In our case, however, the corresponding generator

$$(2.6)\qquad L=S+A,\quad S=\frac{\sigma^2}{2}\partial_\alpha^2,\quad A=\cos(\alpha)\partial_{\xi^1}+\sin(\alpha)\partial_{\xi^2}-\nabla\phi(\xi)\cdot\tau^\perp(\alpha)\partial_\alpha$$

is nonsectorial. Hence, $(T_t)_{t\ge 0}$ cannot be the restriction of an analytic semigroup; see, e.g., [Gol85, Thm. 5.9].

However, since the adjoint to L w.r.t. the scalar product in $L^2(\mu)$ is given by $L^*=S-A$, then also for the adjoint process and semigroup we have ergodicity with the same rate of convergence.

Now, strong mixing of $(T_t^*)_{t\ge 0}$ would imply L^1-convergence of the solution u of the associated Fokker–Planck equation (2.3) with normalized nonnegative initial distribution $u(0)=f$, because

$$\|u(t)-m\|_{L^1(dx)}=\Big\|\frac{u(t)}{m}-1\Big\|_{L^1(\mu)}=\|T_t^*f-1\|_{L^1(\mu)}\le\|T_t^*f-1\|_{L^2(\mu)}.$$

Although $(L,D(L))$ is nonsectorial, we are convinced that for C^∞-potentials ϕ we have strong mixing by another reasoning not worked out rigorously in the present paper. Since the generator $(L,D(L))$ is hypoelliptic in the sense of Hörmander, it is not too hard to show that $(T_t)_{t\ge 0}$ is strong Feller. Showing that $(T_t)_{t\ge 0}$ additionally is irreducible, strong mixing then follows from Doob's theorem; see, e.g., [DPZ96, Prop. 4.1.1, Thm. 4.2.1]. But here we would like to stress that this does not give an explicit rate of convergence. Moreover, our approach also applies to C^3-potentials ϕ.

That $((T_t)_{t\geq 0})$ is weak mixing, i.e.,

$$\lim_{t\to\infty, t\in I} \|T_t f - \mathbf{E}_\mu[f]\|_{L^2(\mu)} = 0,$$

where $I \subset \mathbb{R}_0^+$ has relative measure 1, follows from weaker spectral properties of $(L, D(L))$ than those giving rise to a corresponding analytic semigroup. Sufficient for $(T_t)_{t\geq 0}$ being weak mixing is the following condition:

Let $f \in L^2(\mu; \mathbb{C})$ and $\lambda \in \mathbb{R}$. If

$$T_t f = \exp(i\lambda t) f \quad \text{for all} \quad t \geq 0, \tag{2.7}$$

then $\lambda = 0$ and f is constant; see, e.g., [DPZ96, Thm. 3.4.1]. Here of course we have to consider the corresponding complexified spaces.

The condition in (2.7) implies that $f \in D(L)$ is an eigenvector to the eigenvalue $i\lambda$, $\lambda \in \mathbb{R}$. If f is now sufficiently smooth, such that we can apply the operators S and A from (2.6) separately, then this condition easily can be verified (S is a symmetric and A an antisymmetric operator in $L^2(\mu)$). Hence it is left to show that eigenvectors to $(L, D(L))$ are sufficiently smooth. This is not clear a priori, since S is degenerated. But $L = S + A$ is of Hörmander form such that we expect to obtain hypoelliptic estimates.

The interplay of S and A is very crucial for our proof of ergodicity. Only the operator S without A would not give ergodic behavior. The idea is to project onto the orthogonal complement of the kernel of $(S, D(S))$. On this subspace $(S, D(S))$ has a bounded inverse. On the kernel of $(S, D(S))$ in turn, L can be associated with a nondegenerated, self-adjoint operator $(G, D(G))$ in $L^2(\gamma)$, where γ is the marginal measure of μ on $\mathbb{R}^2$. Assuming that the Dirichlet form corresponding to $(G, D(G))$ fulfills a Poincaré inequality, finally ergodicity can be shown. Such ideas have been used before in, e.g., [OT03] in the context of scaling limit for interacting particles systems.

Crucial for the rate of convergence is Lemma 4.1. There Kato perturbation techniques and a ground state transform are used to show that the functions $h = \nabla_\xi g \cdot \tau$, $g \in D(G)$, are in $D(L)$. These functions are our "key functions" for relating $(L, D(L))$ with $(G, D(G))$; see the proof of Theorem 5.3. The explicit estimates obtained in the proof of Lemma 4.1 finally provide us with the constants for our rate of convergence (2.4).

3. Stochastic differential equation and its solution. We are considering the following stochastic differential equation in $E := \mathbb{R}^2 \times [0, 2\pi]$:

$$\begin{aligned} d\xi_t &= \tau(\alpha_t)\, dt, \\ d\alpha_t &= -\nabla\phi(\xi_t) \cdot \tau^\perp(\alpha_t)\, dt + \sigma\, dB_t, \quad \sigma > 0, \quad t \geq 0. \end{aligned} \tag{3.1}$$

Using Itô's formula we find the generator of the corresponding Markov process:

$$L = S + A, \quad S = \frac{\sigma^2}{2}\partial_\alpha^2, \quad A = \cos(\alpha)\partial_{\xi^1} + \sin(\alpha)\partial_{\xi^2} - \nabla\phi(\xi) \cdot \tau^\perp(\alpha)\partial_\alpha.$$

Set

$$D := C^\infty_{0,\mathrm{pb}}(E) := \{f|_E \,|\, f \in C_0^\infty(\mathbb{R}^3),\ f(\xi, 0) = f(\xi, 2\pi) \text{ for all } \xi \in \mathbb{R}^2 \text{ and the same holds for all derivatives of } f\},$$

where $C_0^\infty(\mathbb{R}^3)$ denotes the set of compactly supported, infinitely differentiable functions on $\mathbb{R}^3$. (S, D) is symmetric and (A, D) is antisymmetric w.r.t. the scalar product in $L^2(\mu)$, where μ is the measure on E having density m w.r.t. the Lebesgue measure.

In the following theorem $H^{1,\infty}(\mathbb{R}^2)$ denotes the Sobolev space of weakly differentiable functions on $\mathbb{R}^2$, which are essentially bounded together with their derivative. The adjoint operator $(L^*, D(L^*))$ to (L, D) obviously is a closed extension of $(S - A, D)$.

LEMMA 3.1. *Let $\phi \in H^{1,\infty}(\mathbb{R}^2)$. Then (L, D) and $(L^*|_D, D)$ are essentially m-dissipative Dirichlet operators in $L^2(\mu)$. In particular, $(L^*, D(L^*))$ is the m-dissipative extension of $(L^*|_D, D)$. The m-dissipative extension (closure) of (L, D) we denote by $(L, D(L))$.*

Proof. Since (S, D) is dissipative and (A, D) is antisymmetric, obviously

$$(Lf, f)_{L^2(\mu)} \leq 0 \quad \text{for all} \quad f \in D,$$

i.e., (L, D) is dissipative. Moreover, as in, e.g., [CG08a] one can show that

$$(Lf, (f-1)^+)_{L^2(\mu)} \leq 0 \quad \text{for all} \quad f \in D,$$

i.e., (L, D) is a Dirichlet operator (here $g^+ := (|g| + g)/2$ for a mapping $g : E \to \mathbb{R}$). Analogously one obtains that $(L^*|_D, D)$ is also a dissipative Dirichlet operator in $L^2(\mu)$. Hence it is left to show that D is a core for the m-dissipative extensions of (L, D) and $(L^*|_D, D)$.

First we consider the case $\phi = 0$. Then we have

$$Lf = Sf + \cos(\alpha)\partial_{\xi^1} f + \sin(\alpha)\partial_{\xi^2} f, \quad f \in D.$$

In the following we show that in this case L is essentially m-dissipative on

$$F := S(\mathbb{R}^2) \times C^\infty_{\mathrm{pb}}([0, 2\pi]),$$

where $S(\mathbb{R}^2)$ denotes the space of infinitely differentiable, more than polynomial decreasing functions on $\mathbb{R}^2$. Since $D \subset F$ is dense in graph norm, this implies that (L, D) is essentially m-dissipative.

Consider the complexified setting, i.e., the corresponding spaces

$$F_{\mathbb{C}} := S(\mathbb{R}^2; \mathbb{C}) \times C^\infty_{\mathrm{pb}}([0, 2\pi]; \mathbb{C}) \subset L^2(\mu; \mathbb{C}),$$

of complex valued functions, and let L act componentwise. Then we apply the Fourier transform $\mathcal{F}$ in the first variable and obtain the corresponding operator

$$\hat{L} := \mathcal{F} L \mathcal{F}^{-1} = Sf + i\cos(\alpha)\xi_1 + i\sin(\alpha)\xi_2.$$

Recall that $\mathcal{F} : F_{\mathbb{C}} \to F_{\mathbb{C}}$ is a continuous isomorphism and $\mathcal{F} : L^2(\mu; \mathbb{C}) \to L^2(\mu; \mathbb{C})$ is a unitary isomorphism. Furthermore, by an elementary consideration one shows that $F_{\mathbb{C}}$ is a core for the m-dissipative extension of $(\hat{L}, F_{\mathbb{C}})$. Hence, L is essentially m-dissipative on F.

Finally the case $\phi \in H^{1,\infty}(\mathbb{R}^2)$ follows by a standard Kato perturbation technique. The adjoint operator can be treated analogously. ∎

Since $(L, D(L))$ is m-dissipative, it generates a semigroup of contractions $(T_t)_{t\geq 0}$. Let $(T_t^*)_{t\geq 0}$ denote the dual semigroup. It is well known that its generator is $(L^*, D(L^*))$. The corresponding stochastic process we can construct as a diffusion process

(i.e., Markov process with continuous sample path) only on the manifold $\mathbb{R}^2 \times S^1$ which is naturally associated with E. Here S^1 denotes the unit circle. Since the measure μ and above function spaces naturally can be lifted on $\mathbb{R}^2 \times S^1$, in what follows we simply identify

$$E = \mathbb{R}^2 \times S^1.$$

By γ we denote the marginal measure of μ on $\mathbb{R}^2$.

THEOREM 3.2. *Let m be bounded and continuous, $m > 0$ almost everywhere w.r.t. the Lebesgue measure on $\mathbb{R}^2$, and ϕ weakly differentiable on $\{m > 0\}$ with $\nabla\phi \in L^2(\gamma)$. Furthermore, let $\nabla\phi$ be bounded on the sets $\{\phi \le K\}$ for all $K \in \mathbb{R}$. Then for any probability measure ν which is absolutely continuous and has a bounded density w.r.t. μ there exists a Markov process $(C([0,\infty); E), \mathcal{B}, (\mathbf{F}_t)_{t\ge 0}, (\mathbf{X}_t)_{t\ge 0}, \mathbf{P}_\nu)$ having the following properties:*

(i) *The initial distribution of the process is given by ν. If μ is a probability measure, then it is an invariant measure for the process.*

(ii) *Finite-dimensional distributions of $\mathbf{P}_\nu$ are given in terms of a contraction semigroup $(T_t)_{t\ge 0}$ having as generator $(L, D(L))$ an m-dissipative extension of (L, D). This determines the law $\mathbf{P}_\nu$ uniquely.*

(iii) *The process solves* (3.1) *in the sense of the corresponding martingale problem, i.e., for all $f \in D$,*

$$\mathbf{M}(f)_t = f(\mathbf{X}_t) - f(\mathbf{X}_0) - \int_0^t Lf(\mathbf{X}_s)\, ds, \quad t \ge 0,$$

is an $\mathbf{F}_t$-martingale under $\mathbf{P}_\nu$.

Analogous statements hold for the adjoint operators. The associated stochastic process $(C([0,\infty); E), \mathcal{B}, (\mathbf{F}_t)_{t\ge 0}, (\mathbf{X}_t)_{t\ge 0}, \mathbf{P}^*_\nu)$ is called the adjoint process.

Proof. First we consider $\phi \in H^{1,\infty}(\mathbb{R}^2)$. Then from Lemma 3.1 we can conclude that $(L, D(L))$ is an m-dissipative Dirichlet operator with core D. Hence $(L, D(L))$ generates a quasi-regular, generalized Dirichlet form and therefore has an associated Markov process; see [Sta99].

For a general ϕ a corresponding stochastic process can be constructed as in [CG08b, sec. 2.3] by an approximation via Markov process associated to potentials from $H^{1,\infty}(\mathbb{R}^2)$.

Then as in [CG08b] and [CG08a], respectively, one can show that it is a diffusion with the properties (i)–(iii). ∎

Remark 3.3. (i) For $\phi \in H^{1,\infty}(\mathbb{R}^2)$ one can obtain much stronger existence results, as shown in [CG08a], where the concepts of generalized Dirichlet forms were applied to a similar problem.

(ii) The process $(\mathbf{X}_t)_{t\ge 0}$ in Theorem 3.2 is the coordinate process, i.e., $X_t(\omega) = \omega(t)$, $t \ge 0$, $\omega \in C([0,\infty); E)$, $\mathcal{B}$ is the Borel σ-algebra, and $(\mathbf{F}_t)_{t\ge 0}$ is the corresponding natural filtration.

COROLLARY 3.4. *Let the assumptions of Theorem* 3.2 *hold and let μ be a probability measure. Then*

$$\mathbf{M}(f)_t = f(\mathbf{X}_t) - f(\mathbf{X}_0) - \int_0^t Lf(\mathbf{X}_s)\, ds, \quad t \ge 0, \tag{3.2}$$

is a $\mathbf{F}_t$*-martingale under* $\mathbf{P}_\mu$ *for all* f *from* $\overline{D}^L$*, the closure of* D *w.r.t. the graph norm to* $(L, D(L))$*. For* $f \in \overline{D}^L$ *the quadratic variation process of* $\mathbf{M}(f)_t$ *is given by*

$$\langle \mathbf{M}(f) \rangle_t = \sigma^2 \int_0^t |\partial_\alpha f|^2(\mathbf{X}_s)\, ds, \quad t \geq 0. \tag{3.3}$$

The corresponding statement holds for the adjoint process. The corresponding martingale we denote by

$$\mathbf{M}^*(f)_t := f(\mathbf{X}_t) - f(\mathbf{X}_0) - \int_0^t L^* f(\mathbf{X}_s)\, ds, \quad t \geq 0, \tag{3.4}$$

where $f \in \overline{D}^{L^*}$*. For* $f \in \overline{D}^{L^*}$ *again we have*

$$\langle \mathbf{M}^*(f) \rangle_t = \sigma^2 \int_0^t |\partial_\alpha f|^2(\mathbf{X}_s)\, ds, \quad t \geq 0. \tag{3.5}$$

Proof. The enlargement of the class of admissible functions for the martingale problem is obvious. Formulas (3.3) and (3.5) for the corresponding quadratic variation processes can be derived as in [CG08b, sec. 3]. □

4. Associated nondegenerated generator. In $L^2(\gamma)$ we consider the pre-Dirichlet form

$$\mathcal{E}(f, g) = \frac{1}{2} \int_{\mathbb{R}^2} \nabla_\xi f \cdot (\nabla_\xi g)^T \, d\gamma, \quad f, g \in C_0^\infty(\mathbb{R}^2).$$

Its closure $(\mathcal{E}, D(\mathcal{E}))$ has a corresponding self-adjoint generator $(G, D(G))$ which on smooth, compactly supported functions is given by

$$Gf = \frac{1}{2}\Delta_\xi f - \frac{1}{2}\nabla_\xi \phi \cdot (\nabla_\xi f)^T, \quad f \in C_0^\infty(\mathbb{R}^2).$$

LEMMA 4.1. *Let* $\phi \in C^3(\mathbb{R}^2)$*,* $\nabla\phi \in L^2(\gamma)$*, and assume there exist* $0 < C < \infty$ *and* $K \subset \mathbb{R}^2$ *compact such that*

$$\begin{aligned}(\partial_{\xi^i}\partial_{\xi^j}\partial_{\xi^k}\phi(\xi))^2 + (\partial_{\xi^i}\partial_{\xi^j}\phi(\xi))^2 \\ \leq C\big(\partial_{\xi^1}\phi(\xi)\big)^2 + \big(\partial_{\xi^2}\phi(\xi)\big)^2 \quad \text{for all} \quad i, j, k \in \{1, 2\},\ \xi \in \mathbb{R}^2 \setminus K.\end{aligned}$$

Then

$$\nabla_\xi f \cdot \tau \in \overline{D}^L \subset D(L)$$

for all $f \in D(G)$*.*

Proof. First recall that $D(\mathcal{E}) \subset D(G)$; hence $\nabla_\xi f \cdot \tau \in L^2(\gamma)$ is well-defined. Our assumptions imply that $(G, C_0^\infty(\mathbb{R}^2))$ is essentially self-adjoint; see, e.g., [BKR97, Thm. 7]. Hence there exists a sequence $(f_n)_{n\in\mathbb{N}}$ in $C_0^\infty(\mathbb{R}^2)$ which converges to f in the graph norm. Moreover

$$\nabla_\xi f_n \cdot \tau \in D \subset D(L) \quad \text{for all} \quad n \in \mathbb{N}.$$

Obviously, $(\nabla_\xi f_n \cdot \tau)_{n\in\mathbb{N}}$ converges to $\nabla_\xi f \cdot \tau$ in $L^2(\mu)$. Hence it is sufficient to show that $(L(\nabla_\xi f_n \cdot \tau))_{n\in\mathbb{N}}$ is a Cauchy sequence in $L^2(\mu)$.

We fix $g \in C_0^\infty(\mathbb{R}^2)$. Then

$$\begin{aligned}(4.1)\quad \|L(\nabla_\xi g\cdot\tau)\|^2_{L^2(\mu)} &= \int_{\mathbb{R}^2}\int_{[0,2\pi]} (L(\cos(\alpha)\partial_{\xi^1}g(\xi)+\sin(\alpha)\partial_{\xi^2}g(\xi)))^2\,d\alpha\,d\gamma(\xi)\\ &= \frac{1}{8}\Big(\sigma^4\mathcal{E}(g,g)+\int_{\mathbb{R}^2}\big((2\partial_{\xi^1}\partial_{\xi^2}+\partial_{\xi^1}\phi(\xi)\partial_{\xi^2}+\partial_{\xi^2}\phi(\xi)\partial_{\xi^1})g(\xi)\big)^2\\ &\quad+3\big((\partial^2_{\xi^1}-\partial_{\xi^2}\phi(\xi)\partial_{\xi^2})g(\xi)\big)^2+3\big((\partial^2_{\xi^2}-\partial_{\xi^1}\phi(\xi)\partial_{\xi^1})g(\xi)\big)^2\\ &\quad+2(\partial^2_{\xi^1}-\partial_{\xi^2}\phi(\xi)\partial_{\xi^2})g(\xi)(\partial^2_{\xi^2}-\partial_{\xi^1}\phi(\xi)\partial_{\xi^1})g(\xi)d\gamma(\xi)\Big).\end{aligned}$$

Therefore $(L(\nabla_\xi f_n\cdot\tau))_{n\in\mathbb{N}}$ is a Cauchy sequence if the operators

$$\partial_{\xi^i}\partial_{\xi^j},\quad \partial_{\xi^i}\phi(\xi)\partial_{\xi^j},\quad i,j\in\{1,2\},$$

are Kato bounded by G on $C_0^\infty(\mathbb{R}^2)$.

To show this, it is useful to introduce the operators

$$G_i := \partial^2_{\xi^i}-\partial_{\xi^i}\phi(\xi)\partial_{\xi^i},\quad i\in\{1,2\}.$$

A straightforward integration by parts yields the following for $g\in C_0^\infty(\mathbb{R}^2)$:

$$\begin{aligned}\big(G_1g,G_1g\big)_{L^2(\gamma)}+\big(G_2g,G_2g\big)_{L^2(\gamma)} &\le C_1\big(Gg,Gg\big)_{L^2(\gamma)}+C_2\big(g,g\big)_{L^2(\gamma)}\\ &\quad+C_3\sum_{i=1}^2\big((\partial_{\xi^i}\phi)g,(\partial_{\xi^i}\phi)g\big)_{L^2(\gamma)}+C_4\sum_{i,j=1}^2\big((\partial_{\xi^i}\partial_{\xi^j}\phi)g,(\partial_{\xi^i}\partial_{\xi^j}\phi)g\big)_{L^2(\gamma)}\\ &\quad+C_5\sum_{i,j,k=1}^2\big((\partial_{\xi^i}\partial_{\xi^j}\partial_{\xi^k}\phi)g,(\partial_{\xi^i}\partial_{\xi^j}\partial_{\xi^k}\phi)g\big)_{L^2(\gamma)}\end{aligned}$$

and

$$\begin{aligned}\big(\partial^2_{\xi^i}g,\partial^2_{\xi^i}g\big)_{L^2(\gamma)} &\le C_6\big(G_ig,G_ig\big)_{L^2(\gamma)}+C_7\big(g,g\big)_{L^2(\gamma)}+C_8\big((\partial^2_{\xi^i}\phi)g,(\partial^2_{\xi^i}\phi)g\big)_{L^2(\gamma)}\\ &\quad+C_9\big((\partial^3_{\xi^i}\phi)g,(\partial^3_{\xi^i}\phi)g\big)_{L^2(\gamma)},\quad i\in\{1,2\},\end{aligned}$$

and

$$\begin{aligned}\big(\partial_{\xi^2}\partial_{\xi^1}g,\partial_{\xi^2}\partial_{\xi^1}g\big)_{L^2(\gamma)} &\le C_{10}\big(G_1g,G_1g\big)_{L^2(\gamma)}+C_{11}\big(G_2g,G_2g\big)_{L^2(\gamma)}+C_{12}\big(g,g\big)_{L^2(\gamma)}\\ &\quad+C_{13}\sum_{i,j,k=1}^2\big((\partial_{\xi^i}\partial_{\xi^j}\partial_{\xi^k}\phi)g,(\partial_{\xi^i}\partial_{\xi^j}\partial_{\xi^k}\phi)g\big)_{L^2(\gamma)}\end{aligned}$$

and

$$\begin{aligned}\big(\partial_{\xi^i}\phi\partial_{\xi^j}g,\partial_{\xi^i}\phi\partial_{\xi^j}g\big)_{L^2(\gamma)} &\le C_{14}\big(G_jg,G_jg\big)_{L^2(\gamma)}+C_{15}\big(g,g\big)_{L^2(\gamma)}+C_{16}\big((\partial_{\xi^i}\phi)g,(\partial_{\xi^i}\phi)g\big)_{L^2(\gamma)}\\ &\quad+C_{17}\sum_{k,l=1}^2\big((\partial_{\xi^k}\partial_{\xi^l}\phi)g,(\partial_{\xi^k}\partial_{\xi^l}\phi)g\big)_{L^2(\gamma)},\ i\ne j,i,j\in\{1,2\},\end{aligned}$$

where $0 < C_1, \dots, C_{17} < \infty$ are constants. Hence it is left to show that the operators given through multiplication by the functions $\partial_{\xi^i}\phi$, $\partial_{\xi^i}\partial_{\xi^j}\phi$ and $\partial_{\xi^i}\partial_{\xi^j}\partial_{\xi^k}\phi$, $i,j,k \in \{1,2\}$, are Kato bounded by G on $C_0^\infty(\mathbb{R}^2)$.

To get this, we transform the problem to $L^2(dx)$. That is, we use the isometric isomorphism

$$L^2(\gamma) \ni f \mapsto \exp(-\phi/2)f \in L^2(dx)$$

to define

$$\hat{G} := \exp(-\phi/2)G\exp(\phi/2) = -\frac{1}{2}\Delta_\xi + \frac{1}{8}\Big(\big(\partial_{\xi^1}\phi\big)^2 + \big(\partial_{\xi^2}\phi\big)^2\Big) - \frac{1}{4}\Big(\big(\partial^2_{\xi^1}\phi\big) + \big(\partial^2_{\xi^2}\phi\big)\Big)$$

on $\hat{D} := \{\exp(-\phi/2)f \mid f \in C_0^\infty(\mathbb{R}^2)\}$. Using our assumptions on ϕ one easily shows that the multiplication operators $\partial_{\xi^i}\phi$, $\partial_{\xi^i}\partial_{\xi^j}\phi$ and $\partial_{\xi^i}\partial_{\xi^j}\partial_{\xi^k}\phi$, $i,j,k \in \{1,2\}$, are Kato bounded by $\hat{G}$ on $\hat{D}$. Hence they are also Kato bounded by G on $C_0^\infty(\mathbb{R}^2)$. ∎

Remark 4.2. The assumptions in Lemma 4.1 allow a large class of potentials ϕ. For example, the potentials $\phi = \|\cdot\|^p$, $p = 2, 4$ or $p \geq 6$, are admissible. Of course, ϕ may also be nonisotropic.

Remark 4.3. It is interesting to note that the stochastic process associated to the generator G is obtained from the original process (2.1) in the large σ-limit; see [BGK+07].

5. Ergodicity and rate of convergence. From now on we assume that μ is a probability measure on E. We are interested in the convergence to zero of

$$\Big\|\frac{1}{t}\int_0^t f(\mathbf{X}_s)\,ds - \mathbf{E}_\mu[f]\Big\|_{L^2(\mathbf{P}_\mu)} = \mathbf{E}_{\mathbf{P}_\mu}\Big[\Big(\frac{1}{t}\int_0^t f(\mathbf{X}_s)\,ds - \mathbf{E}_\mu[f]\Big)^2\Big]^{1/2} \quad \text{as} \quad t \to \infty$$

for $f \in L^2(\mu)$. Denote by $\mathbf{E}_\mu[f|p^1]$ the conditional expectation of $f \in L^2(\mu)$ w.r.t. the σ-algebra in $E = \mathbb{R}^2 \times [0, 2\pi]$ generated by the projection on the first variable. Note that

$$\mathbf{E}_\mu[f|p^1](\xi,\alpha) = \frac{1}{2\pi}\int_{[0,2\pi]} f(\xi,\alpha)\,d\alpha \quad \text{for } \mu \text{ a.a. } (\xi,\alpha) \in E,$$

i.e., $\mathbf{E}_\mu[f|p^1]$ has a version which is independent of $\alpha \in [0, 2\pi]$. Each $f \in L^2(\mu)$ we can write as

$$f = (f - \mathbf{E}_\mu[f|p^1]) + \mathbf{E}_\mu[f|p^1], \tag{5.1}$$

where

$$\mathbf{E}_\mu[(f - \mathbf{E}_\mu[f|p^1])|p^1]) = 0. \tag{5.2}$$

Hence, by the triangle inequality, it is sufficient to consider the following two types of functions: (i) $f \in L^2(\mu)$ with $\mathbf{E}_\mu[f|p^1] = 0$. (ii) $\mathbf{E}_\mu[f|p^1]$ with $f \in L^2(\mu)$.

Denote by $(S, D(S))$ the closure of (S, D). Of course, $(S, D(S))$ is self-adjoint.

PROPOSITION 5.1. *Let the assumptions of Theorem* 3.2 *hold and let* $f \in D(S)$. *Then*

$$\mathbf{E}_{\mathbf{P}_\mu}\Big[\Big(\frac{1}{t}\int_0^t Sf(\mathbf{X}_s)\,ds\Big)^2\Big] \leq \frac{\sigma^2}{t}\|\partial_\alpha f\|^2_{L^2(\mu)}, \quad t > 0.$$

Proof. It is sufficient to consider $f \in D$. We fix $t > 0$ and below we canonically project the laws of the equilibrium processes $\mathbf{P}_\mu$ onto $C([0,t],E)$ without expressing this explicitly. We define the time reversal $r_t(\omega) := \omega(t-\cdot)$, $\omega \in C([0,t],E)$.

Using that

$$S = \frac{1}{2}(L + L^*) \quad \text{on} \quad D,$$

we obtain

$$-\int_0^t Sf(\mathbf{X}_s)\,ds = \frac{1}{2}\Big(\mathbf{M}(f)_t - \mathbf{R}^*(f)_0\Big),$$

where $\mathbf{M}(f)_t$ is the martingale as in (3.2) and

$$\mathbf{R}^*(f)_u := f(\mathbf{X}_t) - f(\mathbf{X}_u) + \int_u^t L^* f(\mathbf{X}_s)\,ds, \quad 0 \le u \le t.$$

Observe that

$$-\mathbf{R}^*(f)_{t-u} = \mathbf{M}^*(f)_u \circ r_t, \quad 0 \le u \le t,$$

where $\mathbf{M}^*(f)_t$ is the martingale as in (3.4). Hence

$$\mathbf{E}_{\mathbf{P}_\mu}\big[\big(\mathbf{R}^*(f)_0\big)^2\big] = \mathbf{E}_{\mathbf{P}^*_\mu}\big[\big(\mathbf{M}^*(f)_t\big)^2\big],$$

because time reversal gives the adjoint process. Now by the Burkholder–Gundy–Davis inequality and (3.3), (3.5) we obtain

$$\begin{aligned}\mathbf{E}_{\mathbf{P}_\mu}\Big[\Big(\frac{1}{t}\int_0^t Sf(\mathbf{X}_s)\,ds\Big)^2\Big]^{1/2} &\le \frac{1}{2t}\mathbf{E}_{\mathbf{P}_\mu}\big[\big(\mathbf{M}(f)_t\big)^2\big]^{1/2} + \frac{1}{2t}\mathbf{E}_{\mathbf{P}^*_\mu}\big[\big(\mathbf{M}^*(f)_t\big)^2\big]^{1/2}\\ &\le \frac{1}{2t}\mathbf{E}_{\mathbf{P}_\mu}\big[\,\langle \mathbf{M}(f)\rangle_t\,\big]^{1/2} + \frac{1}{2t}\mathbf{E}_{\mathbf{P}^*_\mu}\big[\,\langle \mathbf{M}^*(f)\rangle_t\,\big]^{1/2} \le \frac{\sigma}{t^{1/2}}\|\partial_\alpha f\|_{L^2(\mu)}. \qquad \square\end{aligned}$$

COROLLARY 5.2. *Let the assumptions of Theorem* 3.2 *hold and let* $f \in L^2(\mu)$ *with* $\mathbf{E}_\mu[f|p^1] = 0$. *Then*

$$\mathbf{E}_{\mathbf{P}_\mu}\Big[\Big(\frac{1}{t}\int_0^t f(\mathbf{X}_s)\,ds\Big)^2\Big] \le \frac{4}{\sigma^2 t}\|f\|^2_{L^2(\mu)}, \quad t > 0.$$

Proof. Since $\mathbf{E}_\mu[f|p^1] = 0$, f is in the orthogonal complement of the kernel of $(S, D(S))$. But the orthogonal complement of the kernel of $(S, D(S))$ is the range of $(S, D(S))$, because $(S, D(S))$ is self-adjoint. Hence there exists $S^{-1}f \in D(S)$. Then Proposition 5.1 yields

$$\mathbf{E}_{\mathbf{P}_\mu}\Big[\Big(\frac{1}{t}\int_0^t f(\mathbf{X}_s)\,ds\Big)^2\Big] \le \frac{\sigma^2}{t}\|\partial_\alpha S^{-1} f\|^2_{L^2(\mu)} \le \frac{4}{\sigma^2 t}\|f\|^2_{L^2(\mu)},$$

because S^{-1} is bounded by $2\sigma^{-2}$ on the range of $(S, D(S))$. $\square$

THEOREM 5.3. *Let* $\phi \in C^3(\mathbb{R}^2)$, $\nabla\phi \in L^2(\gamma)$, *and assume there exist* $0 < C < \infty$ *and* $K \subset \mathbb{R}^2$ *compact such that*

$$\begin{aligned}&(\partial_{\xi^i}\partial_{\xi^j}\partial_{\xi^k}\phi(\xi))^2 + (\partial_{\xi^i}\partial_{\xi^j}\phi(\xi))^2\\ &\qquad \le C\big(\partial_{\xi^1}\phi(\xi)\big)^2 + \big(\partial_{\xi^2}\phi(\xi)\big)^2 \quad \textit{for all} \quad i,j,k \in \{1,2\},\ \xi \in \mathbb{R}^2 \setminus K.\end{aligned}$$

Furthermore assume that the Dirichlet form $(\mathcal{E}, D(\mathcal{E}))$ corresponding to the nondegenerated generator from section 4 fulfills a Poincaré inequality, i.e., there exists $0 < c < \infty$ such that

$$\mathcal{E}(f - \mathbf{E}_\gamma[f], f - \mathbf{E}_\gamma[f]) \geq c\,\big(f - \mathbf{E}_\gamma[f], f - \mathbf{E}_\gamma[f]\big)_{L^2(\gamma)} \quad \textit{for all} \quad f \in D(\mathcal{E}).$$

Then

$$\begin{aligned}(5.3)\quad &\Big\|\frac{1}{t}\int_0^t f(\mathbf{X}_s)\,ds - \mathbf{E}_\mu[f]\Big\|_{L^2(\mathbf{P}_\mu)} \\ &\leq \frac{1}{c^{1/2}}\Big(\frac{2}{t} + \frac{1}{t^{1/2}}\Big(\frac{A(C)c^{1/2} + B(C)c^{-1/2}}{\sigma} + (1 + 2^{-1/2})\sigma\Big)\Big)\|f - \mathbf{E}_\mu[f]\|_{L^2(\mu)}\end{aligned}$$

for some constants $0 < A(C), B(C) < \infty$ independent of $c, \sigma > 0$, $f \in L^2(\mu)$, and $t > 0$.

Proof. Let $f \in L^2(\mu)$, and without lost of generality we assume $\mathbf{E}_\mu[f] = 0$. Since $(\mathcal{E}, D(\mathcal{E}))$ fulfills a Poincaré inequality, there exists $g \in D(G)$ such that

$$Gg = \mathbf{E}_\mu[f|p^1].$$

Now consider

$$h := \nabla_\xi g \cdot \tau.$$

Then $h \in \overline{D}^L$ by Lemma 4.1 and

$$\begin{aligned}Lh - \mathbf{E}_\mu[f|p^1] = Lh - Gg = &-\frac{\sigma^2}{2}\Big(\cos(\alpha)\partial_{\xi^1} g + \sin(\alpha)\partial_{\xi^2} g\Big) \\ &+ 2\sin(\alpha)\cos(\alpha)\partial_{\xi^2}\partial_{\xi^1} g + \Big(\cos(\alpha)^2 - \frac{1}{2}\Big)\partial^2_{\xi^1} g + \Big(\sin(\alpha)^2 - \frac{1}{2}\Big)\partial^2_{\xi^2} g \\ &- \partial_{\xi^1}\phi(\xi)\Big(\Big(\sin(\alpha)^2 - \frac{1}{2}\Big)\partial_{\xi^1} g - \cos(\alpha)\sin(\alpha)\partial_{\xi^2} g\Big) \\ &- \partial_{\xi^2}\phi(\xi)\Big(\Big(\cos(\alpha)^2 - \frac{1}{2}\Big)\partial_{\xi^2} g - \cos(\alpha)\sin(\alpha)\partial_{\xi^1} g\Big).\end{aligned}$$

It is easy to check that

$$\mathbf{E}_\mu[Lh - \mathbf{E}_\mu[f|p^1]|p^1] = 0.$$

Hence $Lh - \mathbf{E}_\mu[f|p^1]$ can be treated by Corollary 5.2. Thus by (5.1), (5.2) it is only left to consider Lh. Using (3.2), the Burkholder–Gundy–Davis inequality, and (3.3) we obtain

$$\begin{aligned}(5.4)\quad &\Big\|\frac{1}{t}\int_0^t Lh(\mathbf{X}_s)\,ds\Big\|_{L^2(\mathbf{P}_\mu)} \leq \frac{1}{t}\|h(\mathbf{X}_t) - h(\mathbf{X}_0)\|_{L^2(\mathbf{P}_\mu)} + \frac{1}{t}\|\mathbf{M}^h_t\|_{L^2(\mathbf{P}_\mu)} \leq \frac{2}{t}\|h\|_{L^2(\mu)} \\ &+ \frac{1}{t}\mathbf{E}_{\mathbf{P}_\mu}\big[\langle \mathbf{M}^h\rangle_t\big]^{1/2} \leq \frac{2}{t}\|\nabla_\xi g\|_{L^2(\gamma)} + \frac{\sigma}{t^{1/2}}\|\partial_\alpha h\|_{L^2(\mu)} \leq \frac{2 + \sigma t^{1/2}}{t}\|\nabla_\xi g\|_{L^2(\gamma)} \\ &= \frac{2 + \sigma t^{1/2}}{t}\big(G^{-1}\mathbf{E}_\mu[f|p^1], \mathbf{E}_\mu[f|p^1]\big)^{1/2}_{L^2(\gamma)} \leq \frac{(2 + \sigma t^{1/2})}{c^{1/2} t}\|f\|_{L^2(\mu)}, \quad t > 0,\end{aligned}$$

where $0 < c < \infty$ is the spectral gap of G.

Now we obtain by Corollary 5.2 and (5.4) for $t > 0$

$$\begin{aligned}
&\Big\|\frac{1}{t}\int_0^t f(\mathbf{X}_s)\,ds\Big\|_{L^2(\mathbf{P}_\mu)} \\
&\quad\le \Big\|\frac{1}{t}\int_0^t (f-\mathbf{E}_\mu[f|p^1])(\mathbf{X}_s)\,ds\Big\|_{L^2(\mathbf{P}_\mu)} + \Big\|\frac{1}{t}\int_0^t \mathbf{E}_\mu[f|p^1](\mathbf{X}_s)\,ds\Big\|_{L^2(\mathbf{P}_\mu)} \\
&\le \frac{2}{\sigma t^{1/2}}\|f\|_{L^2(\mu)} + \Big\|\frac{1}{t}\int_0^t (\mathbf{E}_\mu[f|p^1]-Lh)(\mathbf{X}_s)\,ds\Big\|_{L^2(\mathbf{P}_\mu)} + \Big\|\frac{1}{t}\int_0^t Lh(\mathbf{X}_s)\,ds\Big\|_{L^2(\mathbf{P}_\mu)} \\
&\qquad\le \frac{2}{\sigma t^{1/2}}\big(\|f\|_{L^2(\mu)} + \|Lh\|_{L^2(\mu)}\big) + \frac{(2+\sigma t^{1/2})}{c^{1/2}t}\|f\|_{L^2(\mu)}.
\end{aligned}$$

To obtain the last inequality we used the fact that

$$\|Lh - \mathbf{E}_\mu[f|p^1]\|^2_{L^2(\mu)} = (Lh-Gg, Lh-Gg)_{L^2(\mu)} = (Lh,Lh)_{L^2(\mu)} - (Gg,Gg)_{L^2(\mu)},$$

because

$$(Lh, Gg)_{L^2(\mu)} = (Gg,Gg)_{L^2(\mu)}.$$

Finally, using (4.1) and the Kato bound provided in Lemma 4.1, we get the estimate (5.3). □

Remark 5.4. The assumptions in Theorem 5.3 also allow potentials of the form $\phi = \|\cdot\|^p$, $p = 2, 4$, or $p \ge 6$, as in Remark 4.2, since in these cases also a Poincaré inequality holds. More generally, under our assumptions on the potential a Poincaré inequality holds if ϕ grows as fast as or faster than $\|x\|$ for large $x \in \mathbb{R}^2$; see [RW01].

6. Numerical Results. For a numerical investigation of the rate of convergence to equilibrium for (2.3) we use a semi-Lagrangian method. The method consists of two fractional steps. The first step is the Lagrangian interpretation for the advection part of (2.3) by the modified method of characteristics, while the second step uses Eulerian coordinates for the discretization of the reaction-diffusion part in (2.3). To preserve mass we use the modified method of characteristics with adjusted advection; see [DHP99]. For details on the numerical method we refer to [KRS07]. We consider the cases $\phi(\xi) = \|\xi\|$ and $\phi(\xi) = \|\xi\|^2/2$. We concentrate on the behavior of the relative entropy. One could also consider other observables. However, since convergence of the relative entropy is stronger than convergence of the distribution functions or convergence of time averages, we restrict ourselves to the investigation of the time development of the relative entropy. Figures 3 and 4 show log-plots of the time development of the relative entropy $H(u/m)(t)$ for different values of σ, and Figure 5 shows plots of the inverse decay rate

$$\lim_{T\to\infty} \int_0^T H(u/m)(t)dt$$

for various values of σ. The quantitative behavior depends on the initial values chosen; however, for other initial values qualitatively similar results are obtained. From Figures 3 and 4 an exponential decay seems possible. Moreover, one observes from Figure 5 that the optimal rate of convergence is found for a finite value of σ. On the other hand, considering the analytical estimate (5.3) one notes that the speed of convergence is dominated by the factor

$$\frac{1}{c^{1/2}t^{1/2}}\Big(\frac{A(C)c^{1/2} + B(C)c^{-1/2}}{\sigma} + (1+2^{-1/2})\sigma\Big).$$

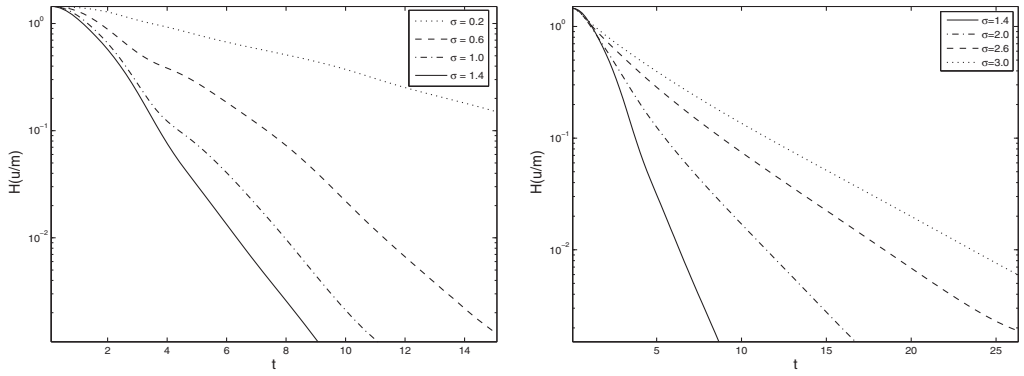

FIG. 3. $H(u/m)(t)$ *for* $\phi(\xi) = \|\xi\|$.

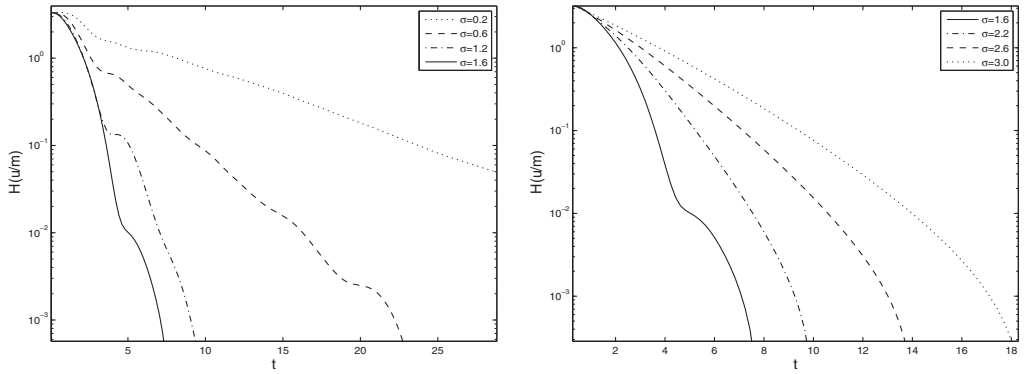

FIG. 4. $H(u/m)(t)$ *for* $\phi(\xi) = \|\xi\|^2/2$.

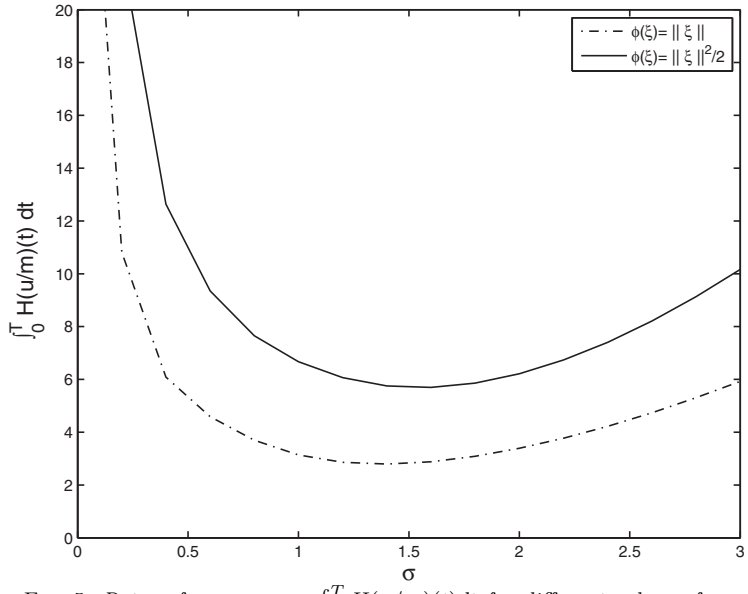

FIG. 5. *Rates of convergence* $\int_0^T H(u/m)(t)dt$ *for different values of* σ.

Obviously, a minimal rate of convergence can be determined—as from the numerical results—for a finite value of σ. Moreover, these observations fit the Monte Carlo results shown in Figure 2. From a practical point of view, this means that the process parameters have to be adapted such that σ is in an intermediate range of values to obtain the fastest possible decay to equilibrium and a fiber web which is as uniform as possible.

7. Concluding remarks. A stochastic model for fiber lay-down processes has been investigated analytically. Existence and ergodicity of the process have been shown and estimates on the rates of convergence presented. The results are supported by numerical simulations. According to these results the fastest decay to equilibrium is obtained for process parameters giving a diffusion coefficient σ in an intermediate range of values. We plan to extend this work to problems with moving conveyor belts; see [BGK+07]. In this case an additional difficulty is given by the fact that the stationary solution is not known explicitly.

Acknowledgment. We are grateful to L. Bonilla, F. Conrad, N. Marheineke, M. Seaid, and C. Villani as well as to the unknown referees for helpful discussions.

DETERMINATION OF A LINEAR CRACK IN AN ELASTIC BODY FROM BOUNDARY MEASUREMENTS—LIPSCHITZ STABILITY*

ELENA BERETTA†, ELISA FRANCINI‡, AND SERGIO VESSELLA§

Abstract. We discuss the stability issue for the problem of determining a thin inclusion in a homogeneous isotropic elastic body from boundary measurements. This problem is severely ill-posed, but in this paper we prove that by restricting ourselves to the class of thin neighborhoods of line segments, a Lipschitz stability estimate holds.

Key words. inverse problems, linear elasticity, cracks

AMS subject classification. 35R30

1. Introduction.

Let $\Omega \subset \mathbb{R}^2$ be a bounded connected domain, with a sufficiently smooth boundary, representing the region occupied by an elastic, homogeneous, isotropic material.

Let $\sigma \subset \Omega$ be a simple smooth curve and define, for a positive small ϵ, the set

$$\omega_\epsilon = \{x \in \Omega \,:\, d(x,\sigma) < \epsilon\},$$

which represents an inclusion of small size made of a different elastic material.

Let $\mathbb{C}_0$ and $\mathbb{C}_1$ be the elastic tensor fields in $\Omega \setminus \overline{\omega}_\epsilon$ and ω_ϵ, respectively.

Given a traction field g on $\partial\Omega$, the displacement field u_ϵ, generated by this traction in the body containing the inclusion ω_ϵ, solves the following system of linearized elasticity:

$$\begin{cases} \operatorname{div}\left(\mathbb{C}_\epsilon \widehat{\nabla} u_\epsilon\right) = 0 & \text{in} \quad \Omega, \\ (\mathbb{C}_\epsilon \widehat{\nabla} u_\epsilon)\nu = g & \text{on} \quad \partial\Omega, \end{cases} \tag{1}$$

where $\mathbb{C}_\epsilon = \mathbb{C}_0 \chi_{\Omega\setminus\omega_\epsilon} + \mathbb{C}_1 \chi_{\omega_\epsilon}$, $\widehat{\nabla} u_\epsilon = \frac{1}{2}\left(\nabla u_\epsilon + (\nabla u_\epsilon)^T\right)$ is the symmetric deformation tensor and ν denotes the outward unit normal to $\partial\Omega$.

Let us also introduce the background displacement field u_0 generated by the same traction g in the absence of the inclusion, namely, the solution of

$$\begin{cases} \operatorname{div}\left(\mathbb{C}_0 \widehat{\nabla} u_0\right) = 0 & \text{in} \quad \Omega, \\ (\mathbb{C}_0 \widehat{\nabla} u_0)\nu = g & \text{on} \quad \partial\Omega. \end{cases} \tag{2}$$

In [BF06] the following asymptotic expansion for $(u_\epsilon - u_0)|_{\partial\Omega}$ as $\epsilon \to 0$ has been derived:

$$(u_\epsilon - u_0)(y) = 2\epsilon \int_\sigma \mathcal{M}(x)\widehat{\nabla}u_0(x) \cdot \widehat{\nabla}N(x,y)\, d\sigma(x) + O(\epsilon^{1+\theta}) \quad \text{for } y \in \partial\Omega, \tag{3}$$

where $N(x,y)$ denotes the Neumann function for the operator $\operatorname{div}\big(\mathbb{C}_0\widehat{\nabla}\cdot\big)$ in Ω, $\mathcal{M}$ is a fourth order symmetric tensor which depends on σ and on the elastic properties of the material occupied by the region Ω, and $\theta \in (0,1)$ is independent of ϵ.

In the following, the symbol "$\cdot$" (as in formula (3)) will denote the usual scalar product between matrices ($A \cdot B = \sum_{ij} a_{ij}b_{ij}$) or vectors ($u \cdot v = \sum_i u_i v_i$).

Clearly, in order to get information on ω_ϵ, we need to consider the first order term of the expansion (3). Let us consider

$$u_\sigma(y) = 2\int_\sigma \mathcal{M}(x)\widehat{\nabla}u_0(x) \cdot \widehat{\nabla}N(x,y)\, d\sigma(x) \quad \text{for } y \in \overline{\Omega}\backslash\sigma. \tag{4}$$

The inverse problem we are interested in is the following:

Given the trace of the correction term u_σ on some open subset Γ of $\partial\Omega$, determine the curve σ.

Due to the nonlinearity, the problem is severely ill-posed and the reconstruction of an arbitrary smooth curve is expected to fail. On the other hand, restricting the class of admissible curves σ, we expect to regularize the problem. In fact, in the scalar conductivity case, if σ is restricted to be linear, it is possible to show a Lipschitz continuous dependence of the segment σ from the boundary data $u_\sigma|_{\partial\Omega}$ (cf. [ABF04, ABF06]).

In this paper we show that the same type of continuous dependence holds true in the elastic case. More precisely, in Theorem 2.2 we prove a Lipschitz continuous dependence of the segment σ from boundary data of the correction term u_σ. In order to do this we use the qualitative properties of the correction term and quantitative estimates of the unique continuation property for elliptic systems with constant coefficients. In Corollary 2.3 we show that the segment σ depends Lipschitz continuously on the rescaled boundary deviation of the solution u_ϵ.

Our method allows us to detect thin elastic inclusions from knowledge of one boundary measurement. In the book [AK04], the authors deal with a similar problem for diametrically small inclusions. We would like to point out that this analysis is on one side motivated by applications (breast imaging, mine detection), and, on the other side, it is not known if an arbitrary inclusion can be detected with a finite number of boundary measurements, not even in the scalar case.

The plan of the paper is the following: In section 2 we introduce some notation and the main assumptions, and we state the main result. In section 3 we describe some properties and the asymptotic behavior near the endpoints of the crack σ of the function u_σ. Section 4 contains the proof of the main result. The final section is devoted to the proof of some auxiliary lemmas and propositions stated in section 4.

2. The main result. We introduce some notation and assumptions that will be useful in what follows. For any $r > 0$ we denote

$$\Omega_r = \{x \in \Omega \mid d(x, \partial\Omega) > r\},$$

and by $diam\,\Omega$ the diameter of Ω. We also denote by $B_r(P)$ the open disc centered in P with radius r.

For any $P, Q \in \mathbb{R}^2$ we denote by $[P, Q]$ the segment with endpoints P and Q; more precisely,

$$[P, Q] = \{P + t(Q - P) \mid t \in [0, 1]\}.$$

Given positive constants $\gamma, \rho_0, E_0, E_1, L, \gamma_0$ with $L \geq 1$ and $\gamma \in (0, 1]$, which we shall name a priori data,

(H1) we assume that Ω is a bounded simply connected domain of $\mathbb{R}^2$ such that

$$diam\, \Omega \leq E_1.$$

Concerning the regularity of $\partial\Omega$, we assume that

$$\partial\Omega \text{ is of class } C^{2,\gamma} \text{ with constants } \rho_0, E_0.$$

More precisely, for any point $\tilde{P} \in \partial\Omega$, there exists a rigid transformation of coordinates under which we have $\tilde{P} = 0$ and

$$\Omega \cap B_{\rho_0}(0) = \{x \in B_{\rho_0}(0) \quad | \quad x_2 > \psi(x_1)\},$$

where ψ is a $C^{2,\gamma}$ function on $(-\rho_0, \rho_0) \subset \mathbb{R}$ satisfying

$$\psi(0) = 0, \qquad \psi'(0) = 0, \qquad \text{and} \qquad \|\psi\|_{C^{2,\gamma}(-\rho_0,\rho_0)} \leq E_0.$$

Moreover we assume that there exists an open subset Γ of $\partial\Omega$ such that for some point $\tilde{Q} \in \Gamma$,

$$\partial\Omega \cap B_{\rho_0}(\tilde{Q}) \subset \Gamma.$$

(H2) We assume that σ is a segment of endpoints P, Q satisfying

$$L^{-1} \leq |P - Q| \leq L \qquad \text{and} \qquad d(\sigma, \mathbb{R}^2 \backslash \Omega) \geq L^{-1}.$$

(H3) We will assume Ω and ω_ϵ are both homogeneous and isotropic, i.e., the elastic tensor fields $\mathbb{C}_0$ and $\mathbb{C}_1$ are of the form

$$(\mathbb{C}_m)_{ijlk} = \lambda_m \delta_{ij}\delta_{kl} + \mu_m(\delta_{ki}\delta_{lj} + \delta_{kj}\delta_{li}) \quad \text{for } i, j, k, l = 1, 2, \;\; m = 0, 1,$$

where (λ_0, μ_0) and (λ_1, μ_1) are the Lamé coefficients corresponding to $\Omega \setminus \overline{\omega}_\epsilon$ and ω_ϵ, respectively, and satisfy the monotonicity condition

$$(\lambda_0 - \lambda_1)(\mu_0 - \mu_1) \geq \gamma_0$$

for some positive constant γ_0.

(H4) There are two positive constants α_0, β_0 such that

$$\min(\mu_0, \mu_1) \geq \alpha_0, \quad \min(\lambda_0 + \mu_0, \lambda_1 + \mu_1) \geq \beta_0/2.$$

We note that hypothesis (H4) ensures that $\mathbb{C}_\epsilon$ is strongly convex in Ω; i.e., if we set $\xi_0 = \min(2\alpha_0, \beta_0)$, then

$$\mathbb{C}_\epsilon A \cdot A \geq \xi_0 |A|^2$$

for any symmetric 2×2 matrix A.

(H5) We shall prescribe the traction field g on $\partial\Omega$ of the form

$$g = (\mathbb{C}_0 W)\nu,$$

where W is a nonzero symmetric 2×2 constant matrix.

Remark 2.1. Under assumptions (H3), (H4) there exist weak solutions u_ϵ and u_0 in $H^1(\Omega, \mathbb{R}^2)$ of (1) and of (2), respectively (see, for example, [F72]). In particular u_0 can be explicitly calculated and corresponds to a pure strain displacement

$$u_0(x) = Wx + c,$$

where c is an arbitrary constant vector. We observe that choosing g as in (H5) is not too restrictive since a pure strain can always be accomplished either by simple extensions in perpendicular directions or by a uniform dilation followed by an isochoric pure strain [G72].

In order to uniquely determine u_ϵ and u_0, we assume that they satisfy the following normalization conditions:

$$\int_{\partial\Omega} u = 0, \quad \int_\Omega \nabla u - (\nabla u)^T = 0. \tag{5}$$

For $y \in \Omega$, we will denote by $N(\cdot, y)$ the Neumann function related to Ω, i.e., the weak solution to the problem

$$\begin{cases} \operatorname{div}\left(\mathbb{C}_0 \widehat{\nabla} \mathrm{N}(\cdot, \mathrm{y})\right) = -\delta_y \,\mathrm{Id} \quad \text{in} \quad \Omega, \\ \left(\mathbb{C}_0 \widehat{\nabla} N(\cdot, y)\right) \cdot \nu = -\frac{1}{|\partial\Omega|} \,\mathrm{Id} \quad \text{on} \quad \partial\Omega, \end{cases}$$

with the normalization conditions (5). Here Id is the identity matrix in $\mathbb{R}^2$. Note that by well-known regularity results for elliptic systems (cf. [C80]) we have

$$N(x, y) = \Gamma(x - y) + w(x, y), \tag{6}$$

where w is a smooth function of x and y and $\Gamma(x, y)$ is the fundamental free space solution of $\operatorname{div}\big(\mathbb{C}_0 \widehat{\nabla} \cdot\big)$, given by

$$\Gamma_{ij}(x) = \frac{A}{2\pi}\, \delta_{ij} \log|x| - \frac{B}{2\pi} \frac{x_i x_j}{|x|^2}, \quad i, j = 1, 2, \tag{7}$$

where $A = \frac{1}{2}\big(\frac{1}{\mu_0} + \frac{1}{\lambda_0 + 2\mu_0}\big)$ and $B = \frac{1}{2}\big(\frac{1}{\mu_0} - \frac{1}{\lambda_0 + 2\mu_0}\big)$.

Let us fix an orthonormal system (n, τ) on σ such that n is a unit normal vector field to the segment and τ is a unit tangent vector field.

By Theorem 2.1 of [BF06] we have that, for any $y \in \partial\Omega$, the first order term u_σ of the expansion of $u_\epsilon - u_0$ can be computed explicitly up to a reminder term and has the form

$$u_\sigma(y) = 2 \int_\sigma \mathcal{M} W \cdot \widehat{\nabla} N(x, y)\, d\sigma(x), \tag{8}$$

where

$$\mathcal{M} W = a(\mathrm{tr} W)\mathrm{Id} + bW + c(\tau^T W \tau)\tau \otimes \tau + d(n^T W n) n \otimes n.$$

Here tr$W$ denotes the trace of the matrix W and the coefficients are given by

$$a = (\lambda_1 - \lambda_0)\frac{\lambda_0 + 2\mu_0}{\lambda_1 + 2\mu_1}, \quad b = 2(\mu_1 - \mu_0)\frac{\mu_0}{\mu_1}, \tag{9}$$

$$c = 2(\mu_1 - \mu_0)\left[\left(\frac{2\lambda_1 + 2\mu_1 - \lambda_0}{\lambda_1 + 2\mu_1} - \frac{\mu_0}{\mu_1}\right)\right], \tag{10}$$

and

$$d = 2(\mu_1 - \mu_0)\frac{\mu_1\lambda_0 - \mu_0\lambda_1}{\mu_1(\lambda_1 + 2\mu_1)}. \tag{11}$$

We are now ready to state our main result.

THEOREM 2.2. *Let σ_0 and σ_1 be two segments satisfying assumption* (H2). *Assume* (H1), (H3), (H4), *and* (H5). *Let u_{σ_0} and u_{σ_1} be the functions defined by* (8) *where σ is replaced by σ_0 and σ_1, respectively. Then there exists a constant C, depending only on the a priori data, such that*

$$d_{\mathcal{H}}(\sigma_0, \sigma_1) \leq C\|u_{\sigma_0} - u_{\sigma_1}\|_{L^2(\Gamma)}.$$

Here $d_{\mathcal{H}}$ denotes the Hausdorff distance

$$d_{\mathcal{H}}(\sigma_0, \sigma_1) = \min\{\max\{|P_0 - P_1|, |Q_0 - Q_1|\}, \max\{|P_0 - Q_1|, |Q_0 - P_1|\}\},$$

where P_0, Q_0 and P_1, Q_1 are the endpoints of σ_0 and σ_1, respectively.

The proof of Theorem 2.2 is postponed to section 4.

A straightforward consequence of Theorem 2.2 and of the asymptotic formula (3) is the following.

COROLLARY 2.3. *Let σ_0 and σ_1 be as in Theorem* 2.2. *For $i = 0, 1$, let u_ϵ^i be the solution of* (1) *corresponding to $\omega_\epsilon^i = \{x \in \Omega : d(x, \sigma_i) < \epsilon\}$. Then there exist a positive constant C and $\theta \in (0, 1)$, depending only on the a priori data, such that*

$$d_{\mathcal{H}}(\sigma_0, \sigma_1) \leq C\left(\epsilon^{-1}\|u_\epsilon^0 - u_\epsilon^1\|_{L^2(\Gamma)} + \epsilon^\theta\right).$$

Remark 2.4. A similar rescaled stability estimate has been obtained, for example, in [FV89] and in [CMV98] for the case of diametrically small inclusions.

3. Properties of the function u_σ. In this section we first establish a representation formula for the function u_σ (defined in (4)), and then we deduce some results concerning the regularity of this function and its behavior near the endpoints of σ.

LEMMA 3.1. *Let $\sigma = [P, Q]$, and fix $\tau = \frac{Q-P}{|Q-P|}$ and let $n = \tau^\perp$. For $y \in \overline{\Omega} \setminus \sigma$,*

$$u_\sigma(y) = \int_\sigma \mathbb{C}_0\widehat{\nabla}N(x, y)n \cdot \varphi_\sigma \, d\sigma(x) + (N(Q, y) \cdot \tau - N(P, y) \cdot \tau)\, f_\sigma, \tag{12}$$

where φ_σ is the vector whose components in the (n, τ) directions are given by

$$\begin{aligned} \varphi_\sigma \cdot n &= \frac{2}{\lambda_1 + 2\mu_1}((\lambda_1 - \lambda_0)\,\mathrm{tr}W + 2(\mu_1 - \mu_0)\, n^T W n), \\ \varphi_\sigma \cdot \tau &= \frac{4(\mu_1 - \mu_0)}{\mu_1}\, n^T W \tau \end{aligned} \tag{13}$$

and f_σ is the constant function

$$f_\sigma = \alpha \operatorname{tr} W - \beta\, n^T W n, \tag{14}$$

where

$$\alpha = \frac{4}{\lambda_1 + 2\mu_1}((\mu_1 - \mu_0)(\lambda_1 + 2\mu_1) + \mu_1(\lambda_1 - \lambda_0)), \quad \beta = \frac{8(\mu_1 - \mu_0)}{\lambda_1 + 2\mu_1}(\lambda_1 + \mu_1).$$

Proof. By straightforward calculations and by the symmetry of N and W, one can easily check that

$$u_\sigma(y) = \int_\sigma \mathbb{C}_0 \widehat{\nabla} N(x,y) n \cdot \varphi_\sigma \, d\sigma(x) + 2 \int_\sigma \tau^T \widehat{\nabla} N(x,y) \tau f_\sigma d\sigma(x). \tag{15}$$

Finally an integration by parts in (15) gives the thesis. ∎

Let us consider the double layer potential

$$\mathcal{D}_\sigma \varphi(y) = \int_\sigma \mathbb{C}_0 \widehat{\nabla} \Gamma(x,y) n \cdot \varphi \, d\sigma(x), \quad y \in R^2 \backslash \sigma,$$

with φ constant vector field. Let us point out the following properties.

LEMMA 3.2. *We have*

$$[\mathcal{D}_\sigma \varphi]_\sigma = \varphi, \tag{16}$$

and there exists a positive constant C such that, for any $y \in \mathbb{R}^2 \backslash \sigma$,

$$|\mathcal{D}_\sigma \varphi(y)| \le C \left(\left| \log \frac{|Q-y|}{|P-y|} \right| + 1 \right) |\varphi|,$$

$$|\nabla \mathcal{D}_\sigma \varphi(y)| \le C \left(\frac{1}{|P-y|} + \frac{1}{|Q-y|} + 1 \right) |\varphi|,$$

where $[\mathcal{D}_\sigma \varphi]_\sigma$ denotes the jump of $\mathcal{D}_\sigma \varphi$ across σ.

Proof. Formula (16) follows from standard properties of double layer potentials (see, for example, [AK04]). The behavior of $\mathcal{D}_\sigma \varphi$ at the endpoints of segment σ follows from straightforward computations. ∎

We are now ready to state and prove the following.

PROPOSITION 3.3. *Under assumptions* (H1)–(H5), *u_σ satisfies*

$$\begin{cases} \operatorname{div}\left(\mathbb{C}_0 \widehat{\nabla} u_\sigma \right) = 0 & \text{in} \quad \Omega \backslash \sigma, \\ (\mathbb{C}_0 \widehat{\nabla} u_\sigma) \nu = 0 & \text{on} \quad \partial\Omega, \end{cases} \tag{17}$$

and the normalization condition (5).

The function u_σ has a jump on σ given by

$$[u_\sigma]_\sigma = \varphi_\sigma. \tag{18}$$

Moreover there exists a positive constant C, depending only on the a priori data, such that

$$|u_\sigma(y)| \le C \left(\left| \log \frac{|Q-y|}{|P-y|} \right| + 1 \right). \tag{19}$$

Proof. From the representation formula (12) and by the properties of the function N it is easy to see that u_σ satisfies (17). Recalling that u_σ is the correction term in the expansion of $u_\epsilon - u_0$ and that u_ϵ and u_0 have the same Neumann condition on $\partial\Omega$, and observing that the expansion (3) holds true in a neighborhood of $\partial\Omega$, it follows that u_σ satisfies the homogeneous Neumann datum.

Observe now that u_σ is expressed in terms of a double layer potential and the Neumann function at the endpoints of σ. From (6) and Lemma 3.2, equations (18) and (19) follow. ∎

4. Proof of Theorem 2.2. We start by establishing a first rough estimate of $d_{\mathcal{H}}(\sigma_0, \sigma_1)$ in terms of the boundary data error.

LEMMA 4.1. *Let $\sigma_0 = [P_0, Q_0]$ and $\sigma_1 = [P_1, Q_1]$ be two segments satisfying assumption* (H2). *Assume* (H1), (H3), (H4), *and* (H5). *Let $u_{\sigma_0}, u_{\sigma_1}$ be the functions defined by* (12) *and corresponding to σ_0 and σ_1, respectively. Let $\varepsilon := \|u_{\sigma_0} - u_{\sigma_1}\|_{L^2(\Gamma)}$; then*

$$d_{\mathcal{H}}(\sigma_0, \sigma_1) \leq \omega_1(\varepsilon),$$

where $\omega_1(s) = C\left(\log|\log(\varepsilon)|\right)^{-1/4}$ for some positive constant C depending only on the a priori data.

Proof. We first describe the proof in the case $\varepsilon = 0$ (corresponding to the uniqueness).

Let $u := u_{\sigma_0} - u_{\sigma_1}$. Recalling that $(\mathbb{C}_0\widehat{\nabla}u_{\sigma_0}) \cdot \nu = (\mathbb{C}_0\widehat{\nabla}u_{\sigma_1}) \cdot \nu = 0$ on $\partial\Omega$, we have that

$$u = (\mathbb{C}_0\widehat{\nabla}u) \cdot \nu = 0 \quad \text{on} \quad \partial\Omega.$$

Since u is solution of

$$\operatorname{div}\left(\mathbb{C}_0\widehat{\nabla}u\right) = 0 \quad \text{in} \quad \Omega\backslash(\sigma_0 \cup \sigma_1),$$

by the unique continuation property of solutions to elliptic systems with constant coefficients (see [AM01] and [MR04]) we have that

$$u = 0 \quad \text{in} \quad \Omega\backslash(\sigma_0 \cup \sigma_1). \tag{20}$$

Assume that $\sigma_0 \neq \sigma_1$. Then there exists a portion Σ, for instance, of σ_0, containing an endpoint P_0 of σ_0 such that Σ is not contained in σ_1. For the sake of simplicity, let us denote $\varphi_0 := \varphi_{\sigma_0}$ and $f_0 := f_{\sigma_0}$ the functions appearing in (12) corresponding to σ_0. By (20), $[u]_\Sigma = 0$, and since $[u]_\Sigma = [u_{\sigma_0}]_\Sigma = \varphi_0$ we get

$$\varphi_0 = 0. \tag{21}$$

Furthermore, from the representation formula (12), u_{σ_0} has logarithmic singularities at the endpoints P_0, Q_0. Hence again by (20) and by (12) we have

$$f_0 = 0. \tag{22}$$

Recalling (13) and (14), conditions (21) and (22) can be written as

$$\begin{cases} n_0^T W \tau_0 = 0, \\ \alpha(\operatorname{tr}W) - \beta n_0^T W n_0 = 0, \\ a(\operatorname{tr}W) + (b+d) n_0^T W n_0 = 0, \end{cases} \tag{23}$$

where n_0 and τ_0 denote the normal and tangent unit vector to σ_0, the numbers a, b, and d are defined in (9), (10), (11), and α and β are defined in (14). By assumption (H3) it is easy to see that the conditions (23) imply $\mathrm{tr}W = 0$, $n_0^T W n_0 = 0$, from which it follows that $\tau_0^T W \tau_0 = 0$. Finally, by the symmetry of W, since $n_0^T W \tau_0 = \tau_0^T W n_0$ we get that also $\tau_0^T W n_0 = 0$. Hence $W = 0$, which contradicts assumption (H5).

The proof of the case $\varepsilon > 0$ is a quantitative version of the uniqueness part. For the sake of simplicity we postpone this part of the proof to section 5. □

Denote by σ_t the segment $[P_t, Q_t]$, where

$$P_t = (1-t)P_0 + tP_1, \quad Q_t = (1-t)Q_0 + tQ_1,$$

and for $y \in \Omega \backslash \sigma_t$ let

$$u_t(y) := u_{\sigma_t}(y) = \int_0^1 \mathbb{C}_0 \widehat{\nabla} N((1-s)P_t + sQ_t, y) n_t \cdot \varphi_t |Q_t - P_t| \, ds + (N(Q_t, y)\cdot \tau_t - N(P_t, y)\cdot \tau_t) f_t,$$

where $\tau_t = \frac{Q_t - P_t}{|Q_t - P_t|}$, $n_t = \tau_t^\perp$, $f_t := f_{\sigma_t}$, and $\varphi_t := \varphi_{\sigma_t}$. Clearly, from the above formula, u_t is differentiable for any $t \in [0,1]$ and its derivative u_t' satisfies the problem

$$\begin{cases} \mathrm{div}\left(\mathbb{C}_0 \widehat{\nabla} u_t'\right) = 0 \quad \text{in} \quad \Omega \backslash \sigma_t, \\ (\mathbb{C}_0 \widehat{\nabla} u_t')\nu = 0 \quad \text{on} \quad \partial\Omega \end{cases} \tag{24}$$

and the normalization condition (5).

The following statements, whose proof we defer until section 5, allow us to conclude the proof of Theorem 2.2.

LEMMA 4.2. *For any $y \in \partial\Omega$*

$$\begin{aligned} u_t'(y) &:= \frac{d}{dt} u_t(y) \\ &= -\int_0^1 \mathbb{C}_0 \widehat{\nabla} N((1-s)P_t + sQ_t, y) n_t \cdot \varphi_t((Q_1 - Q_0 - (P_1 - P_0))\cdot \tau_t) ds \\ &\quad + \int_0^1 \mathbb{C}_0 \widehat{\nabla} N((1-s)P_t + sQ_t, y) n_t \cdot \frac{d}{dt}(\varphi_t |Q_t - P_t|)\, ds \\ &\quad + \mathbb{C}_0 \widehat{\nabla} N(Q_t, y)\left((Q_1 - Q_0)\cdot \tau_t) n_t - (Q_1 - Q_0)\cdot n_t)\tau_t\right)\cdot \varphi_t \\ &\quad - \mathbb{C}_0 \widehat{\nabla} N(P_t, y)\left((P_1 - P_0)\cdot \tau_t) n_t - (P_1 - P_0)\cdot n_t)\tau_t\right)\cdot \varphi_t \\ &\quad + \left(\nabla N(Q_t, y)\frac{dQ_t}{dt}\cdot \tau_t - \nabla N(P_t, y)\frac{dP_t}{dt}\cdot \tau_t\right) f_t \\ &\quad + (N(Q_t, y) - N(P_t, y))\frac{d(\tau_t f_t)}{dt}. \end{aligned} \tag{25}$$

PROPOSITION 4.3. *There exist constants C_0, $m_0 > 0$, depending only on the a priori data, such that*

$$\|u_0'\|_{L^2(\Gamma)} \geq m_0 d_{\mathcal{H}}(\sigma_0, \sigma_1)$$

and

$$\|u_t' - u_0'\|_{L^2(\Gamma)} \leq C_0 (d_{\mathcal{H}}(\sigma_0, \sigma_1))^2. \tag{26}$$

Let us conclude now the proof of Theorem 2.2.

Let $\varepsilon_0 > 0$ such that

$$\omega_1(\varepsilon_0) \leq \frac{m_0}{2C_0}, \tag{27}$$

where ω_1 is defined as in Lemma 4.1.

Let us distinguish two cases:

(1) $\varepsilon \in (0, \varepsilon_0]$. By the differentiability of u_t we have that for any $x \in \Gamma$

$$u_{\sigma_1}(x) - u_{\sigma_0}(x) = \int_0^1 u_t'(x)\, dt = u_0'(x) + \int_0^1 (u_t'(x) - u_0'(x))\, dt.$$

By the triangular inequality we get

$$\varepsilon = \|u_{\sigma_1} - u_{\sigma_0}\|_{L^2(\Gamma)} \geq \|u_0'\|_{L^2(\Gamma)} - \|u_t' - u_0'\|_{L^2(\Gamma)}.$$

By Proposition 4.3 we get

$$\varepsilon \geq (m_0 - C_0 d_{\mathcal{H}}(\sigma_0, \sigma_1))\, d_{\mathcal{H}}(\sigma_0, \sigma_1). \tag{28}$$

On the other hand, from Lemma 4.1 we have that

$$d_{\mathcal{H}}(\sigma_0, \sigma_1) \leq \omega_1(\varepsilon_0).$$

Hence, by (27), we get

$$m_0 - C_0 d_{\mathcal{H}}(\sigma_0, \sigma_1) \geq m_0 - C_0 \omega_1(\varepsilon_0) \geq \frac{m_0}{2}.$$

By the last inequality and (28) we derive

$$d_{\mathcal{H}}(\sigma_0, \sigma_1) \leq \frac{2}{m_0}\, \varepsilon. \tag{29}$$

(2) Let us consider the case $\varepsilon \geq \varepsilon_0$. One easily gets

$$d_{\mathcal{H}}(\sigma_0, \sigma_1) \leq diam\, \Omega \leq E_1 \frac{\varepsilon}{\varepsilon_0}. \tag{30}$$

Hence, by (29) and (30) we have

$$d_{\mathcal{H}}(\sigma_0, \sigma_1) \leq \max\left\{ \frac{E_1}{\varepsilon_0}, \frac{2}{m_0} \right\} \varepsilon,$$

which concludes the proof of the theorem. □

5. Proofs of the preliminary results.

5.1. Proof of Lemma 4.1. Let us now consider the case $\varepsilon > 0$. Let $d := d_{\mathcal{H}}(\sigma_0, \sigma_1)$ and let us assume that $d = |P_0 - P_1|$. By classical regularity results in

potential theory and by Lemma 3.2 we have that $u_{\sigma_j} \in C^1(\overline{\Omega}\backslash\sigma_j)$ for $j = 0, 1$ and, for any $r \in (0, \rho_1)$, where $\rho_1 = \min(L^{-1}, \rho_0)$,

$$\begin{aligned} \|u_{\sigma_j}\|_{L^\infty(\Omega\backslash(B_r(P_j)\cup B_r(Q_j)))} &\le C\left(\log\tfrac{1}{r} + 1\right), \\ \|\nabla u_{\sigma_j}\|_{L^\infty(\Omega\backslash(\sigma_j\cup B_r(P_j)\cup B_r(Q_j)))} &\le C\tfrac{1}{r}, \end{aligned} \tag{31}$$

where C depends only on the a priori data. From stability estimates for the Cauchy problem for solutions of elliptic systems (cf. [MR04]) and by (31) we have

$$\|u_{\sigma_j}\|_{L^\infty\left(\Omega\cap B_{\frac{\rho_1}{2}}(\overline{P})\right)} \le C\varepsilon^\delta, \tag{32}$$

where $\overline{P}$ is a point on Γ and $C > 0$, $\delta \in (0, 1)$ depend on the a priori data only. Starting from (32) we now establish a propagation error estimate in a neighborhood of $\Omega\backslash(\sigma_0 \cup \sigma_1)$. Let $r \in (0, \frac{\rho_1}{156})$, and define

$$(\sigma_i)_{8r} = \{x \in \Omega : dist(x, \sigma_i) > 8r\} \quad \text{for} \quad i = 0, 1 \tag{33}$$

and $\Omega'_{(r)} = \Omega_{8r}\backslash((\sigma_0)_{8r}) \cup (\sigma_1)_{8r})$ and let $z_0 = \overline{P} - \frac{\nu}{16}\rho_1$, where ν is the outward unit normal vector to $\partial\Omega$ at the point $\overline{P}$. Let $x \in \Omega'_{(r)}$ and let $\gamma \subset \Omega'_{(r)}$ be an open arc joining x to z_0. With the usual procedure we construct a chain of balls with centers along γ where we apply the three-spheres inequality (cf. [AM01] and [MR04]),

$$\int_{B_{3r}} |u|^2 \le C\left(\int_{B_r} |u|^2\right)^\tau \left(\int_{B_{4r}} |u|^2\right)^{1-\tau}$$

($\tau \in (0, 1), C > 0$ absolute constants), in order to give an estimate of the propagation of the error from $B_r(z_0)$ to x. In fact, by (31) and (32) and the above inequality we get

$$\int_{B_{3r}(x)} |u|^2 \le Cr^2(\varepsilon^\delta)^{\tau^{N_r}} \left(\log\frac{1}{r}\right)^{1-\tau^{N_r}},$$

where $N_r \le \frac{|\Omega|}{\pi r^2}$. Finally by interpolation we get

$$|u(x)| \le \omega(\varepsilon, r) := C(\varepsilon^\delta)^{\tau^{N_r}} \left(\log\frac{1}{r}\right)^{1-\tau^{N_r}} \tag{34}$$

for every $x \in \Omega'_{(r)}$.

It is easy to check that there exist a constant C_0, $0 < C_0 < 1/2$, depending only on the a priori constants such that if $d > 0$ and $\rho \le C_0 d^2$, then at least one of the following conditions is satisfied:

$$B_\rho(P_0) \cap \sigma_1 = \emptyset \quad \text{or} \quad B_\rho(P_1) \cap \sigma_0 = \emptyset. \tag{35}$$

Without loss of generality we might assume that

$$B_\rho(P_0) \cap \sigma_1 = \emptyset.$$

Up to a rigid transformation we might assume that $P_0 = 0$ and that σ_0 lies along the positive x_1 axis. For $t \in (0, 1], \rho \in (0, C_0 d^2)$, let

$$x^+_{t\rho} = \overline{x}_\rho + e_2\frac{\rho t}{2}, \quad x^-_{t\rho} = \overline{x}_\rho - e_2\frac{\rho t}{2},$$

where $\overline{x}_\rho = (\rho/2, 0)$ and $e_2 = (0, 1)$. Let

$$u^{\pm}_{\sigma_0}(\overline{x}_\rho) = \lim_{s\to 0^+} u_{\sigma_0}(\overline{x}_\rho \pm s e_2)$$

and

$$u^{\pm}(\overline{x}_\rho) = \lim_{s\to 0^+} u(\overline{x}_\rho \pm s e_2).$$

We have

$$|[u_{\sigma_0}(\overline{x}_\rho)]_{\sigma_0}| = |[u(\overline{x}_\rho)]_{\sigma_0}| \le |u^+(\overline{x}_\rho) - u(x^+_{t\rho})| + |u^-(\overline{x}_\rho) - u(x^-_{t\rho})| + |u(x^+_{t\rho})| + |u(x^-_{t\rho})|.$$

By applying the second of (31) we get

$$|u^+(\overline{x}_\rho) - u(x^+_{t\rho})| \le Ct$$

and

$$|u^-(\overline{x}_\rho) - u(x^-_{t\rho})| \le Ct,$$

where $C > 0$ depends only on the a priori data. Hence using (34) and the last inequalities we derive

$$|[u_{\sigma_0}(\overline{x}_\rho)]| \le Ct + 2\omega(\varepsilon; t\rho/2).$$

Therefore, from the properties of double layer potentials, we get

$$|\varphi_0| = |[u_{\sigma_0}(\overline{x}_\rho)]| \le Ct + 2\omega(\varepsilon; t\rho/2), \tag{36}$$

where C depends only on the a priori constants.

Now we argue by contradiction. Assume

$$d \ge \eta_\varepsilon,$$

where

$$\eta_\varepsilon := \frac{\sqrt{2}}{\sqrt{C_0}} \left(\frac{8E_1^2 |\log \tau|}{\log |\log \varepsilon^\delta|} \right)^{1/8}.$$

Let

$$\rho = \left(\frac{8E_1^2 |\log \tau|}{\log |\log \varepsilon^\delta|} \right)^{1/4} \qquad \text{and} \qquad t = \left(\frac{8E_1^2 |\log \tau|}{\log |\log \varepsilon^\delta|} \right)^{1/4}.$$

By (36) there exists $\varepsilon_0 > 0$, depending only on the a priori data, such that if $\varepsilon \le \varepsilon_0$ and

$$d \ge \eta_\varepsilon,$$

then

$$|\varphi_0| \le \omega_1(\varepsilon) := C \left(\log |\log(\varepsilon)| \right)^{-1/4}, \tag{37}$$

where C depends only on the a priori constants.

By using (12) for σ_0 and σ_1 and estimating the difference, we can easily see that

$$|\Gamma(P_0,y)\tau_0 f_0| \le |\Gamma(Q_0,y)\tau_0 f_0| + \left|\int_{\sigma_0} \mathbb{C}_0\widehat{\nabla}N(x,y)n_0\cdot\varphi_0\,ds(x)\right| + \left|\int_{\sigma_1} \mathbb{C}_0\widehat{\nabla}N(x,y)n_1\cdot\varphi_1\,ds(x)\right| + |(N(P_0,y)-\Gamma(P_0,y))\tau_0 f_0| + |u(y)| + |N(Q_1,y)\tau_1 f_1| + |N(P_1,y)\tau_1 f_1|.$$

From Lemma 3.2 and (37) we get, for any $y\in\Omega\backslash\sigma_0$

$$\left|\int_{\sigma_0} \mathbb{C}_0\widehat{\nabla}N(x,y)n_0\cdot\varphi_0\,ds(x)\right| \le C\omega_1(\varepsilon)\left|\log\frac{|y-P_0|}{|y-Q_0|}\right|$$

and, for any $y\in\Omega\backslash\sigma_1$,

$$\left|\int_{\sigma_1} \mathbb{C}_0\widehat{\nabla}N(x,y)n_1\cdot\varphi_1\,ds(x)\right| \le C|\varphi_1|\left|\log\frac{|y-P_1|}{|y-Q_1|}\right|,$$

where C depends only on the a priori data. Furthermore, by regularity estimates, we have

$$|N(P_0,y)-\Gamma(P_0,y)| \le C \quad \text{for every} \quad y\in\Omega,$$

where C depends only on the a priori constants. It is now straightforward to see that there exists $\varepsilon_1>0$, depending only on the a priori data, such that if $\varepsilon\le\varepsilon_1$ and

$$d \ge \left(\log(\log|\log\varepsilon^\delta|)\right)^{-1},$$

then

$$|f_0| \le C\omega_1(\varepsilon). \tag{38}$$

Hence, for $\varepsilon\le\varepsilon_2 := \min(\varepsilon_0,\varepsilon_1)$ and $d\ge\left(\log(\log|\log\varepsilon^\delta|)\right)^{-1}$, inequalities (37) and (38) hold true and we get

$$\begin{cases} |n_0^T W\tau_0| \le C\omega_1(\varepsilon), \\ |\alpha(\mathrm{tr}W)-\beta n_0^T W n_0| \le C\omega_1(\varepsilon), \\ |a(\mathrm{tr}W)+(b+d)n_0^T W n_0| \le C\omega_1(\varepsilon), \end{cases}$$

which lead to

$$k_0 = \max_{|x|=1}|x^T W x| \le C\omega_1(\varepsilon),$$

a contradiction for ε small enough. Hence

$$d \le \left(\log(\log|\log\varepsilon^\delta|)\right)^{-1}$$

for every $\varepsilon\le\varepsilon_2$. If $\varepsilon\ge\varepsilon_2$, then

$$d \le E_1 \le E_1\frac{\varepsilon}{\varepsilon_1}$$

and the proof is complete. □

5.2. Proof of Lemma 4.2. Taking the derivative of u_t,

$$
\begin{aligned}
u_t'(y) &= \int_0^1 \left(\frac{d}{dt} \mathbb{C}_0 \widehat{\nabla} N((1-s)P_t + sQ_t, y) \right) n_t \cdot \varphi_t |Q_t - P_t| \, ds \\
&\quad + \int_0^1 \mathbb{C}_0 \widehat{\nabla} N((1-s)P_t + sQ_t, y) n_t \cdot \frac{d}{dt} (\varphi_t |Q_t - P_t|) \, ds \\
&\quad + \int_0^1 \mathbb{C}_0 \widehat{\nabla} N((1-s)P_t + sQ_t, y) \left(\frac{d}{dt} n_t \right) \cdot \varphi_t |Q_t - P_t| \, ds \\
&\quad + \left(\nabla N(Q_t, y) \frac{dQ_t}{dt} \cdot \tau_t - \nabla N(P_t, y) \frac{dP_t}{dt} \cdot \tau_t \right) f_t \qquad (39) \\
&\quad + (N(Q_t, y) - N(P_t, y)) \frac{d(\tau_t f_t)}{dt} \\
&:= I_1 + I_2 + I_3 + \left(\nabla N(Q_t, y) \frac{dQ_t}{dt} \cdot \tau_t - \nabla N(P_t, y) \frac{dP_t}{dt} \cdot \tau_t \right) f_t \\
&\quad + (N(Q_t, y) - N(P_t, y)) \frac{d(\tau_t f_t)}{dt}.
\end{aligned}
$$

Observe that

$$
\begin{aligned}
&\frac{d}{dt} \mathbb{C}_0 \widehat{\nabla} N((1-s)P_t + sQ_t, y) \\
&= \nabla_x (\mathbb{C}_0 \widehat{\nabla} N((1-s)P_t + sQ_t, y)) \bullet ((1-s)(P_1 - P_0) + s(Q_1 - Q_0)),
\end{aligned}
$$

where the symbol $\bullet$ should be intended in the following way:

$$
\nabla_x M \bullet v := \sum_i \frac{\partial M}{\partial x_i} v_i.
$$

On the other hand

$$
\begin{aligned}
\frac{d}{ds} \Big(\mathbb{C}_0 \widehat{\nabla} N((1-s)P_t + sQ_t, y) \Big) &= \nabla_x (\mathbb{C}_0 \widehat{\nabla} N((1-s)P_t + sQ_t, y)) \bullet (Q_t - P_t) \\
&= \nabla_x (\mathbb{C}_0 \widehat{\nabla} N((1-s)P_t + sQ_t, y)) \bullet \tau_t |Q_t - P_t|.
\end{aligned}
$$

Set

$$
(1-s)(P_1 - P_0) + s(Q_1 - Q_0) = A_t(s)\tau_t + B_t(s) n_t,
$$

where

$$
A_t(s) = (1-s)(P_1 - P_0) \cdot \tau_t + s(Q_1 - Q_0) \cdot \tau_t
$$

and

$$
B_t(s) = (1-s)(P_1 - P_0) \cdot n_t + s(Q_1 - Q_0) \cdot n_t.
$$

Hence

$$I_1 = \int_0^1 \left(\nabla_x(\mathbb{C}_0\widehat{\nabla}N((1-s)P_t+sQ_t,y)) \bullet (A_t(s)\tau_t + B_t(s)n_t)\right) n_t\cdot\varphi_t\, ds$$

$$= \int_0^1 A_t(s)\frac{d}{ds}\left(\mathbb{C}_0\widehat{\nabla}N((1-s)P_t+sQ_t,y)\right) n_t\cdot\varphi_t\, ds \tag{40}$$

$$+ \int_0^1 B_t(s)\left(\nabla_x(\mathbb{C}_0\widehat{\nabla}N((1-s)P_t+sQ_t,y)) \bullet n_t\right) n_t\cdot\varphi_t|Q_t-P_t|\, ds.$$

Integrating by parts the first integral appearing on the right-hand side of (40), we obtain

$$I_1 = A_t(1)\mathbb{C}_0\widehat{\nabla}N(Q_t,y)n_t\cdot\varphi_t - A_t(0)\mathbb{C}_0\widehat{\nabla}N(P_t,y)n_t\cdot\varphi_t$$

$$- \int_0^1 \mathbb{C}_0\widehat{\nabla}N((1-s)P_t+sQ_t,y)\frac{d}{ds}\left(A_t(s)n_t\cdot\varphi_t\right)\, ds \tag{41}$$

$$+ \int_0^1 B_t(s)\left(\nabla_x(\mathbb{C}_0\widehat{\nabla}N((1-s)P_t+sQ_t,y)) \bullet n_t\right) n_t\cdot\varphi_t|Q_t-P_t|\, ds.$$

Observing now that, for any $y\in\partial\Omega$,

$$\nabla_x\left(\mathbb{C}_0\widehat{\nabla}N(\cdot,y)n_t\right)\bullet n_t + \nabla_x\left(\mathbb{C}_0\widehat{\nabla}N(\cdot,y)\cdot\tau_t\right)\bullet\tau_t = 0 \quad \text{in} \quad \Omega,$$

we can rewrite

$$\int_0^1 B_t(s)\left(\nabla_x(\mathbb{C}_0\widehat{\nabla}N((1-s)P_t+sQ_t,y)) \bullet n_t\right) n_t\cdot\varphi_t|Q_t-P_t|ds$$

$$= -\int_0^1 B_t(s)\left(\nabla_x(\mathbb{C}_0\widehat{\nabla}N((1-s)P_t+sQ_t,y)) \bullet \tau_t\right) \tau_t\cdot\varphi_t|Q_t-P_t|ds$$

$$= -\int_0^1 B_t(s)\left(\frac{d}{ds}\mathbb{C}_0\widehat{\nabla}N((1-s)P_t+sQ_t,y)\right)\tau_t\cdot\varphi_t ds$$

$$= -B_t(1)\mathbb{C}_0\widehat{\nabla}N(Q_t,y)\tau_t\cdot\varphi_t + B_t(0)\mathbb{C}_0\widehat{\nabla}N(P_t,y)\tau_t\cdot\varphi_t \tag{42}$$

$$+ \int_0^1 \mathbb{C}_0\widehat{\nabla}N((1-s)P_t+sQ_t,y)\frac{d}{ds}\left(B_t(s)\tau_t\cdot\varphi_t\right) ds.$$

Inserting (42) into (41) we derive finally

$$I_1 = \mathbb{C}_0\widehat{\nabla}N(Q_t,y)(A_t(1)n_t - B_t(1)\tau_t)\cdot\varphi_t$$

$$- \mathbb{C}_0\widehat{\nabla}N(P_t,y)(A_t(0)n_t - B_t(0)\tau_t)\cdot\varphi_t \tag{43}$$

$$- \int_0^1 \mathbb{C}_0\widehat{\nabla}N((1-s)P_t+sQ_t,y)\frac{d}{ds}\left(A_t(s)n_t\cdot\varphi_t - B_t(s)\tau_t\cdot\varphi_t\right) ds,$$

where

$$\frac{d}{ds}\left(A_t(s)n_t - B_t(s)\tau_t\right)\cdot\varphi_t$$
$$= \{((Q_1-Q_0)-(P_1-P_0))\cdot\tau_t)n_t - ((Q_1-Q_0)-(P_1-P_0))\cdot n_t)\tau_t\}\cdot\varphi_t,$$
$$A_t(1) = (Q_1-Q_0)\cdot\tau_t, \qquad A_t(0) = (P_1-P_0)\cdot\tau_t$$

and

$$B_t(1) = (Q_1-Q_0)\cdot n_t, \qquad B_t(0) = (P_1-P_0)\cdot n_t.$$

It is easy to calculate

$$\frac{d}{dt}n_t = -\left(\frac{(Q_1-Q_0)-(P_1-P_0)}{|Q_t-P_t|}\cdot n_t\right)\tau_t,$$

and, with this, we get

$$I_3 = -\int_0^1 \mathbb{C}_0\widehat{\nabla}N((1-s)P_t+sQ_t,y)\tau_t\cdot\varphi_t((Q_1-Q_0)-(P_1-P_0))\cdot n_t\,ds. \tag{44}$$

Inserting (43) and (44) into (39) gives (25), which concludes the proof. ∎

5.3. Proof of Proposition 4.3. In Lemma 4.2 we established that

$$\begin{aligned}
u_0'(y) = &-\int_0^1 \mathbb{C}_0\widehat{\nabla}N((1-s)P_0+sQ_0,y)n_0\cdot\varphi_0((Q_1-Q_0)-(P_1-P_0))\cdot\tau_0\\
&+\int_0^1 \mathbb{C}_0\widehat{\nabla}N((1-s)P_0+sQ_0,y)n_0\cdot\frac{d}{dt}(\varphi_t|Q_t-P_t|)|_{t=0}\\
&+\mathbb{C}_0\widehat{\nabla}N(Q_0,y)\left(((Q_1-Q_0)\cdot\tau_0)n_0-((Q_1-Q_0)\cdot n_0)\tau_0\right)\cdot\varphi_0\\
&-\mathbb{C}_0\widehat{\nabla}N(P_0,y)\left(((P_1-P_0)\cdot\tau_0)n_0-((P_1-P_0)\cdot n_0)\tau_0\right)\cdot\varphi_0\\
&+\left(\nabla N(Q_0,y)(Q_1-Q_0)-\nabla N(P_0,y)(P_1-P_0)\right)\cdot\tau_0 f_0\\
&+(N(Q_0,y)-N(P_0,y))\,\frac{d(\tau_t f_t)}{dt}|_{t=0}.
\end{aligned} \tag{45}$$

We divide the proof of the first inequality of Proposition 4.3 into two steps.

(1) We first prove that if

$$\|u_0'\|_{L^2(\partial\Omega)} = 0, \quad \text{then} \quad d_{\mathcal{H}}(\sigma_0,\sigma_1) = 0. \tag{46}$$

Since $d_{\mathcal{H}}(\sigma_0,\sigma_1) = |P_1-P_0|$ it will be sufficient to show that $P_1 = P_0$.

By (24), (46), and the unique continuation property, we have that

$$u_0'(y) = 0 \quad \text{for} \quad y\in\overline{\Omega}\backslash\sigma_0.$$

In particular u_0' is zero in a neighborhood of P_0 contained in $\Omega\backslash\sigma_0$. From (45) it is immediate to see that u_0' has a singularity at P_0 whose leading term is

$$-\mathbb{C}_0\widehat{\nabla}\Gamma(P_0,y)\left((P_1-P_0)^{\perp}\right)\cdot\varphi_0-\nabla\Gamma(P_0,y)(P_1-P_0)\cdot\tau_0 f_0. \tag{47}$$

Without loss of generality let us now fix the coordinate system in such a way that $P_0=0$, $\tau_0=(1,0)$, and $n_0=(0,1)$, let $\varphi_0=(\varphi_0^1,\varphi_0^2)$, and let us set $h_1=(h_1^1,h_1^2):=(P_1-P_0)$. Since the leading singularity given by (47) cannot appear and by the definition of $\mathbb{C}_0$, we must have, for $i=1,2$ and for any $y\in B_r(0)\setminus\sigma_0$ for some small and positive radius r,

$$\alpha_1\,\partial_1\Gamma_{i1}(y)+\alpha_2\,\partial_1\Gamma_{i2}(y)+\alpha_3\,\partial_2\Gamma_{i1}(y)+\alpha_4\,\partial_2\Gamma_{i2}(y)=0, \tag{48}$$

where the coefficients are given by

$$\begin{aligned}&\alpha_1=\lambda_0(h_1^1\varphi_0^2-h_1^2\varphi_0^1)-2\mu_0h_1^2\varphi_0^1+h_1^1f_0, \qquad \alpha_2=-\mu_0h_1^2\varphi_0^2+\mu_0h_1^1\varphi_0^1,\\ &\alpha_3=-\mu_0h_1^2\varphi_0^2+\mu_0h_1^1\varphi_0^1+h_1^2f_0, \qquad \alpha_4=\lambda_0(-h_1^2\varphi_0^1+h_1^1\varphi_0^2)+2\mu_0h_1^1\varphi_0^2.\end{aligned} \tag{49}$$

By calculating explicitly the derivatives of Γ, equations (48) become

$$\begin{aligned}&\frac{1}{2\pi|y|^4}\left[y_1^3(A\alpha_1-B\alpha_4)+y_1^2y_2(B\alpha_2+(A+2B)\alpha_3)+y_1y_2^2((A-2B)\alpha_1+B\alpha_4)\right.\\ &\left.+y_2^3(-B\alpha_2+A\alpha_3)\right]=0 \quad \text{for every} \quad y\in B_r(0)\setminus\sigma_0\end{aligned} \tag{50}$$

for $i=1$, and

$$\begin{aligned}&\frac{1}{2\pi|y|^4}\left[y_1^3(A\alpha_2-B\alpha_3)+y_1^2y_2(B\alpha_1+(A-2B)\alpha_4)+y_1y_2^2((A+2B)\alpha_2+B\alpha_3)\right.\\ &\left.+y_2^3(-B\alpha_1+A\alpha_4)\right]=0 \quad \text{for every} \quad y\in B_r(0)\sigma_0\end{aligned} \tag{51}$$

for $i=2$.

Equations (50) and (51) can be satisfied if and only if each coefficient of the polynomials appearing in the numerators is zero. Since $A+B$ and $A-B$ are different from zero this implies that

$$\alpha_1=\alpha_2=\alpha_3=\alpha_4=0.$$

Easy computations show that these four equations can be satisfied for some vector $h_1\neq(0,0)$ only if

$$f_0=\varphi_0^1=\varphi_0^2=0,$$

which implies that W is identically zero, leading to a contradiction. Hence $h_1=P_1-P_0=0$ and the first step is proved.

(2) Since u_0' depends linearly on $h:=(h_1,h_2):=(P_1-P_0,Q_1-Q_0)$, in order to prove the estimate from below it is sufficient to show that if $|h|_{\mathbb{R}^4}=(|h_1|^2+|h_2|^2)^{1/2}=1$, then

$$\|u_0'\|_{L^2(\partial\Omega)}\geq m_0,$$

where $m_0>0$ depends only on the a priori data.

Let $h \in \mathbb{R}^4$ be such that $|h|_{\mathbb{R}^4} = 1$, where $d_{\mathcal{H}}(\sigma_0, \sigma_1) = |h_1|_{\mathbb{R}^2} \geq |h_2|_{\mathbb{R}^2}$. Denote

$$v = u_0', \qquad \text{and} \qquad \theta = \|v\|_{L^2(\partial\Omega)}.$$

Recall that v is a solution of (24) and proceed similarly as in Lemma 4.1. If we define $\rho_1 := \min\left(L^{-1}, \rho_0\right)$, we have, for any $r \in (0, \rho_1/156)$,

$$|v(x)| \leq \omega(\theta, r) := C(\theta^\delta)^{\tau^{N_r}} \left(\log \frac{1}{r}\right)^{1-\tau^{N_r}}$$

for every $x \in \Omega_r' := \Omega_{8r} \backslash (\sigma_0)_{8r}$, where $(\sigma_0)_{8r}$ is defined as in (33), $\tau, \delta \in (0,1)$ and $C > 1$ depend on the a priori data only, and $N_r \leq \frac{|\Omega|}{\pi r^2}$. Without loss of generality we might assume that $P_0 = 0$. By (44) we have that

$$v(y) = \frac{H(y)}{|y|^4} + J(y) \quad \text{for} \quad y \in \Omega \backslash \sigma_0, \tag{52}$$

where H is an homogeneous polynomial of degree three whose coefficients are equal to the expressions in (50) and (51), and J satisfies the inequality

$$|J(y)| \leq C\,|\log|y|| \quad \text{for} \quad y \in \Omega\backslash\sigma_0,\ |y| \leq \frac{1}{2L},$$

where C depends on the a priori data only. Let $\overline{y} \in \mathbb{R}^2$, $|y| = 1$ such that

$$|H(\overline{y})| = \max_{|y|=1} |H(y)|.$$

Denote

$$M = |H(\overline{y})|, \quad y_r = 8r\overline{y}.$$

Since $|H(y_r)| = |H(-y_r)|$ and y_r or $-y_r \in \Omega_r'$, it is not restrictive to assume that $y_r \in \Omega_r'$.

By (52) we have

$$|H(\overline{y})| = \frac{|H(y_r)|}{|y_r|^3} \leq |y_r||v(y_r)| + |y_r||J(y_r)|,$$

and hence

$$M \leq 8r\omega(\theta; r) + Cr \log \frac{1}{r} \tag{53}$$

for every $0 \leq r \leq \rho_2$, where $\rho_2 = \frac{1}{256} \min\left(L^{-1}, \rho_0\right)$. Denote

$$r_\theta = \left(\frac{E_1^2 |\log\tau|}{\log|\log\theta^\delta|}\right)^{1/2}.$$

There exists $\theta_0 < e^{-1/\delta}$, θ_0 depending only on the a priori data, such that if $\theta \in (0, \theta_0)$, then $r_\theta \in (0, \rho_2)$. We now choose, for $\theta \in (0, \theta_0)$, $r = r_\theta$ and by (53) we have

$$M \leq C\omega_2(\theta), \tag{54}$$

where

$$\omega_2(\theta) = \left(\log|\log\theta^\delta|\right)^{-1/4}$$

and C depends only on the a priori data. This implies that each coefficient of the polynomials appearing in the numerators of (50) and (51) are bounded by $C\omega_2(\theta)$ for some positive constant C depending only on a priori data.

Now, proceeding as in step (1) we derive easily that

$$\text{if} \quad \theta \in (0,\theta_0), \quad \text{then} \quad |h_2| \le |h_1| \le C\omega_2(\theta), \tag{55}$$

where C depends only on the a priori data. On the other hand, since $|h_1|^2+|h_2|^2 = 1$, by (55) we obtain that

$$\text{if } \theta \in (0,\theta_0), \quad \text{then} \quad 1 \le 2C_0^2(\omega_2(\theta))^2. \tag{56}$$

Denote by $\theta_1 = \min\{\theta_0, \exp(-\frac{1}{\delta}\exp(16C_0^4))\}$. By (55) we get that if $\theta \in (0,\theta_1)$, then $1 \le 2C_0^2(\omega_2(\theta))^2 \le 1/2$, a contradiction. Therefore $\theta \ge \theta_1$ and recalling that $v = u_0'$, and $\theta = \|v\|_{L^2(\partial\Omega)}$, we get the thesis for $m_0 = \theta_1$.

Let us finally prove (26). Observe that u_t' is differentiable in t and taking, for instance, the following term appearing in $u_t' - u_0'$ we get

$$\begin{aligned}
&|\nabla N(Q_t,y)(Q_1-Q_0)\cdot\tau_t f_t - \nabla N(Q_0,y)(Q_1-Q_0)\cdot\tau_0 f_0| \\
&\quad\le |(\nabla N(Q_t,y)-\nabla N(Q_0,y))||(Q_1-Q_0)\cdot\tau_t f_t| \\
&\qquad + |\nabla N(Q_0,y)(Q_1-Q_0)\cdot(\tau_t-\tau_0) f_t| \\
&\qquad + |\nabla N(Q_0,y)(Q_1-Q_0)\cdot\tau_0(f_t-f_0)|.
\end{aligned}$$

Since

$$|\nabla N(Q_t,y)-\nabla N(Q_0,y)| \le C|Q_1-Q_0| \le Cd_{\mathcal{H}}(\sigma_0,\sigma_1),$$
$$|\tau_t-\tau_0| \le C|P_1-P_0| = Cd_{\mathcal{H}}(\sigma_0,\sigma_1),$$

and, also,

$$|f_t-f_0| \le C|Q_1-Q_0| \le Cd_{\mathcal{H}}(\sigma_0,\sigma_1),$$

where C is a constant depending only on the a priori data, hence

$$|\nabla N(Q_t,y)(Q_1-Q_0)\cdot\tau_t f_t - \nabla N(Q_0,y)(Q_1-Q_0)\cdot\tau_0 f_0| \le C\left(d_{\mathcal{H}}(\sigma_0,\sigma_1)\right)^2.$$

Evaluating the other terms appearing in $u_t' - u_0'$ in a similar way, we get the desired inequality and the proof is concluded. □

NEUTRAL FUNCTIONAL DIFFERENTIAL EQUATIONS WITH APPLICATIONS TO COMPARTMENTAL SYSTEMS*

VÍCTOR MUÑOZ-VILLARRAGUT†, SYLVIA NOVO†, AND RAFAEL OBAYA†

Abstract. We study the monotone skew-product semiflow generated by a family of neutral functional differential equations with infinite delay and stable D-operator. The stability properties of D allow us to introduce a new order and to take the neutral family to a family of functional differential equations with infinite delay. Next, we establish the 1-covering property of omega-limit sets under the componentwise separating property and uniform stability. Finally, the obtained results are applied to the study of the long-term behavior of the amount of material within the compartments of a neutral compartmental system with infinite delay.

Key words. nonautonomous dynamical systems, monotone skew-product semiflows, neutral functional differential equations, infinite delay, compartmental systems

DOI. 10.1137/070711177

1. Introduction.

After the pioneering work of Hale and Meyer [11], the theory of neutral functional differential equations (NFDE) aroused considerable interest and a fast development ensued. At present a wide collection of theoretical and practical results make up the main body of the theory of NFDEs (see Hale [10], Hale and Verduyn Lunel [12], Kolmanovskii and Myshkis [18], and Salamon [22], among many others). In particular, a substantial number of results for delayed functional differential equations (FDEs) have been generalized for NFDEs solving new and challenging problems in these extensions.

In this paper we provide a dynamical theory for nonautonomous monotone NFDEs with infinite delay and autonomous stable D-operator along the lines of the results by Jiang and Zhao [17] and Novo, Obaya, and Sanz [20]. We assume some recurrence properties on the temporal variation of the NFDE. Thus, its solutions induce a skew-product semiflow with minimal flow on the base. In particular, the uniform almost periodic and almost automorphic cases are included in this formulation. The skew-product formalism permits the analysis of the dynamical properties of the trajectories using methods of ergodic theory and topological dynamics.

Novo et al. [20] study the existence of recurrent solutions of nonautonomous FDEs with infinite delay using the phase space $BU \subset C((-\infty, 0], \mathbb{R}^m)$ of bounded and uniformly continuous functions with the supremum norm. Assuming some technical conditions on the vector field, it is shown that every bounded solution is relatively compact for the compact-open topology, and its omega-limit set admits a flow extension. An alternative method for the study of recurrent solutions of almost periodic FDEs with infinite delay makes use of a *fading memory* Banach phase space (see Hino, Murakami, and Naiko [13] for an axiomatic definition and main properties). Since this kind of space contains BU and, under natural assumptions, the restriction of the norm

topology to the closure of a bounded solution agrees with the compact-open topology, it seems that the approach considered in Novo et al. [20] becomes natural in many cases of interest.

In this paper we consider NFDEs with linear autonomous operator D defined on BU which is continuous for the norm, continuous for the compact-open topology on bounded sets, and atomic at zero. We obtain an integral representation of D by means of Riesz theorem $Dx = \int_{-\infty}^{0} [\, d\mu]\, x$, where μ is a real Borel measure with finite total variation. The convolution operator $\widehat{D}$ defined by $\widehat{D}x(s) = \int_{-\infty}^{0} [d\mu(\theta)]\, x(\theta + s)$ maps BU into BU. We prove that if D is stable in the sense of Hale [10], then $\widehat{D}$ is an isomorphism of BU which is continuous for the norm and continuous for the compact-open topology on bounded sets. Moreover, $\widehat{D}^{-1}$ inherits these same properties and is associated to a linear stable operator D^*. In fact, the mentioned behavior of $\widehat{D}^{-1}$ characterizes the stability of the operator D. The proofs are self-contained and require only quantitative estimates associated to the stability of the operator D.

Staffans [24] shows that every NFDE with finite delay and autonomous stable D-operator can be written as an FDE with infinite delay in an appropriate fading memory space. A more systematic study on the inversion of the convolution operator $\widehat{D}$ can be found in the work of Gripenberg, Londen, and Staffans [4]. The papers by Haddock et al. [8, 9], Arino and Bourad [1], among others, make a systematic use of these ideas which have a theoretical and practical interest. We give a version of the above results for infinite delay NFDEs. It is obvious that the inversion of the convolution operator $\widehat{D}$ on BU allows us to transform the original equation into a retarded nonautonomous FDE with infinite delay. In addition, we transfer the dynamical theory of Jiang and Zhao [17] and Novo et al. [20] to nonautonomous monotone NFDEs with infinite delay and autonomous stable D-operator. In an appropriate dynamical framework we assume that the trajectories are bounded, uniformly stable, and satisfy a componentwise separating property, and we show that the omega-limit sets are all copies of the base. It is important to mention that no conditions of strong monotonicity are required, which permits the application of the results under natural physical conditions.

In this paper we provide a detailed description of the long-term behavior of the dynamics in some classes of compartmental systems extensively studied in the literature. Compartmental systems have been used as mathematical models for the study of the dynamical behavior of many processes in biological and physical sciences, which depend on local mass balance conditions (see Jacquez [14], Jacquez and Simon [15, 16], and the references therein). Some initial results for models described by FDEs with finite and infinite delay can be found in Györi [5] and Györi and Eller [6]. The paper by Arino and Haourigui [2] proves the existence of almost periodic solutions for compartmental systems described by almost periodic finite delay FDEs. NFDEs represent systems where the compartments produce or swallow material. Györi and Wu [7] and Wu and Freedman [28] study autonomous NFDEs with finite and infinite delay similar to those considered in this paper. We provide a nonautonomous version, under more general assumptions, of the monotone theory for NFDEs included in Wu and Freedman [28] and Wu [27]. More precise results for the case of scalar NFDEs can be found in Arino and Bourad [1] and Krisztin and Wu [19].

We study the dynamics of monotone compartmental systems in terms of the geometrical structure of the pipes connecting the compartments. Irreducible subsets of the set of indices detect the occurrence of subsystems on the complete system which reduce the dimension of the problem being studied. When the system is closed,

the total mass is an invariant continuous function which implies the stability and boundedness of the solutions. In particular, the omega-limit set of every solution is a minimal set and a copy of the base. In a general compartmental system the existence of a bounded solution assures that every solution is bounded and uniformly stable. We first check that when there is no inflow of material then all the compartments of each irreducible subset with some outflow of material are empty on minimal subsets. On the contrary, when the solutions remain bounded and there is an inflow of material in some compartment of an irreducible subset, then for the indices of this irreducible subset all the minimal sets agree, and all the compartments contain some material. Finally, we describe natural physical conditions which ensure the existence of a unique minimal set asymptotically stable.

This paper is organized as follows. Basic notions in topological dynamics, used throughout the rest of the sections, are stated in section 2. Section 3 is devoted to the study of general and stability properties of linear autonomous operators from BU to $\mathbb{R}^m$, as well as the behavior of solutions of the corresponding homogeneous and nonhomogeneous equations given by them. In section 4, we study the monotone skew-product semiflow generated by a family of NFDEs with infinite delay and stable D-operator. In particular, we establish the 1-covering property of omega-limit sets under the componentwise separating property and uniform stability. These results are applied in section 5 to show that the solutions of a compartmental system given by a monotone NFDE with infinite delay are asymptotically of the same type as the transport functions. Finally, section 6 deals with the long-term behavior of its solutions in terms of the geometrical structure of the pipes, as explained above.

2. Some preliminaries. Let (Ω, d) be a compact metric space. A real *continuous flow* $(\Omega, \sigma, \mathbb{R})$ is defined by a continuous mapping $\sigma : \mathbb{R} \times \Omega \to \Omega,\ (t, \omega) \mapsto \sigma(t, \omega)$ satisfying

(i) $\sigma_0 = \mathrm{Id}$,

(ii) $\sigma_{t+s} = \sigma_t \circ \sigma_s$ for each $s,\ t \in \mathbb{R}$,

where $\sigma_t(\omega) = \sigma(t, \omega)$ for all $\omega \in \Omega$ and $t \in \mathbb{R}$. The set $\{\sigma_t(\omega) \mid t \in \mathbb{R}\}$ is called the *orbit* or the *trajectory* of the point ω. We say that a subset $\Omega_1 \subset \Omega$ is *σ-invariant* if $\sigma_t(\Omega_1) = \Omega_1$ for every $t \in \mathbb{R}$. A subset $\Omega_1 \subset \Omega$ is called *minimal* if it is compact, σ-invariant, and its only nonempty compact σ-invariant subset is itself. Every compact and σ-invariant set contains a minimal subset; in particular it is easy to prove that a compact σ-invariant subset is minimal if and only if every trajectory is dense. We say that the continuous flow $(\Omega, \sigma, \mathbb{R})$ is *recurrent* or *minimal* if Ω is minimal.

The flow $(\Omega, \sigma, \mathbb{R})$ is *distal* if for any two distinct points $\omega_1,\ \omega_2 \in \Omega$ the orbits keep at a positive distance, that is, $\inf_{t\in\mathbb{R}} d(\sigma(t, \omega_1), \sigma(t, \omega_2)) > 0$. The flow $(\Omega, \sigma, \mathbb{R})$ is *almost periodic* when for every $\varepsilon > 0$ there is a $\delta > 0$ such that if $\omega_1,\ \omega_2 \in \Omega$ with $d(\omega_1, \omega_2) < \delta$, then $d(\sigma(t, \omega_1), \sigma(t, \omega_2)) < \varepsilon$ for every $t \in \mathbb{R}$. If $(\Omega, \sigma, \mathbb{R})$ is almost periodic, it is distal. The converse is not true; even if $(\Omega, \sigma, \mathbb{R})$ is minimal and distal, it does not need to be almost periodic. For the basic properties of almost periodic and distal flows we refer the reader to Ellis [3] and Sacker and Sell [21].

A *flow homomorphism* from another continuous flow $(Y, \Psi, \mathbb{R})$ to $(\Omega, \sigma, \mathbb{R})$ is a continuous map $\pi\colon Y \to \Omega$ such that $\pi(\Psi(t, y)) = \sigma(t, \pi(y))$ for every $y \in Y$ and $t \in \mathbb{R}$. If π is also bijective, it is called a *flow isomorphism*. Let $\pi : Y \to \Omega$ be a surjective flow homomorphism and suppose $(Y, \Psi, \mathbb{R})$ is minimal (then so is $(\Omega, \sigma, \mathbb{R})$). $(Y, \Psi, \mathbb{R})$ is said to be an *almost automorphic extension* of $(\Omega, \sigma, \mathbb{R})$ if there is $\omega \in \Omega$ such that $\mathrm{card}(\pi^{-1}(\omega)) = 1$. Then actually $\mathrm{card}(\pi^{-1}(\omega)) = 1$ for ω in a residual subset $\Omega_0 \subseteq \Omega$; in the nontrivial case $\Omega_0 \subsetneq \Omega$ the dynamics can be very complicated. A minimal flow

$(Y, \Psi, \mathbb{R})$ is *almost automorphic* if it is an almost automorphic extension of an almost periodic minimal flow $(\Omega, \sigma, \mathbb{R})$. We refer the reader to the work of Shen and Yi [23] for a survey of almost periodic and almost automorphic dynamics.

Let E be a complete metric space and $\mathbb{R}^+ = \{t \in \mathbb{R} \,|\, t \geq 0\}$. A *semiflow* $(E, \Phi, \mathbb{R}^+)$ is determined by a continuous map $\Phi : \mathbb{R}^+ \times E \to E,\ (t, x) \mapsto \Phi(t, x)$ which satisfies

(i) $\Phi_0 = \mathrm{Id}$,

(ii) $\Phi_{t+s} = \Phi_t \circ \Phi_s$ for all $t,\, s \in \mathbb{R}^+$,

where $\Phi_t(x) = \Phi(t, x)$ for each $x \in E$ and $t \in \mathbb{R}^+$. The set $\{\Phi_t(x) \mid t \geq 0\}$ is the *semiorbit* of the point x. A subset E_1 of E is *positively invariant* (or just Φ-*invariant*) if $\Phi_t(E_1) \subset E_1$ for all $t \geq 0$. A semiflow $(E, \Phi, \mathbb{R}^+)$ admits a *flow extension* if there exists a continuous flow $(E, \widetilde{\Phi}, \mathbb{R})$ such that $\widetilde{\Phi}(t, x) = \Phi(t, x)$ for all $x \in E$ and $t \in \mathbb{R}^+$. A compact and positively invariant subset admits a flow extension if the semiflow restricted to it admits one.

Write $\mathbb{R}^- = \{t \in \mathbb{R} \,|\, t \leq 0\}$. A *backward orbit* of a point $x \in E$ in the semiflow $(E, \Phi, \mathbb{R}^+)$ is a continuous map $\psi : \mathbb{R}^- \to E$ such that $\psi(0) = x$ and for each $s \leq 0$ it holds that $\Phi(t, \psi(s)) = \psi(s + t)$ whenever $0 \leq t \leq -s$. If for $x \in E$ the semiorbit $\{\Phi(t, x) \mid t \geq 0\}$ is relatively compact, we can consider the *omega-limit set* of x,

$$\mathcal{O}(x) = \bigcap_{s \geq 0} \mathrm{closure}\{\Phi(t + s, x) \mid t \geq 0\}\,,$$

which is a nonempty compact connected and Φ-invariant set. Namely, it consists of the points $y \in E$ such that $y = \lim_{n\to\infty} \Phi(t_n, x)$ for some sequence $t_n \uparrow \infty$. It is well known that every $y \in \mathcal{O}(x)$ admits a backward orbit inside this set. Actually, a compact positively invariant set M admits a flow extension if every point in M admits a unique backward orbit which remains inside the set M (see Shen and Yi [23, part II]).

A compact positively invariant set M for the semiflow $(E, \Phi, \mathbb{R}^+)$ is *minimal* if it does not contain any nonempty compact positively invariant set other than itself. If E is minimal, we say that the semiflow is minimal.

A semiflow is of *skew-product type* when it is defined on a vector bundle and has a triangular structure; more precisely, a semiflow $(\Omega \times X, \tau, \mathbb{R}^+)$ is a *skew-product* semiflow over the product space $\Omega \times X$, for a compact metric space (Ω, d) and a complete metric space (X, d), if the continuous map τ is as follows:

$$\begin{array}{rccc} \tau\colon & \mathbb{R}^+ \times \Omega \times X & \longrightarrow & \Omega \times X \\ & (t, \omega, x) & \mapsto & (\omega{\cdot}t, u(t, \omega, x))\,, \end{array} \tag{2.1}$$

where $(\Omega, \sigma, \mathbb{R})$ is a real continuous flow $\sigma : \mathbb{R} \times \Omega \to \Omega,\ (t, \omega) \mapsto \omega{\cdot}t$, called the *base flow*. The skew-product semiflow (2.1) is *linear* if $u(t, \omega, x)$ is linear in x for each $(t, \omega) \in \mathbb{R}^+ \times \Omega$.

Now, we introduce some definitions concerning the stability of the trajectories. A forward orbit $\{\tau(t, \omega_0, x_0) \mid t \geq 0\}$ of the skew-product semiflow (2.1) is said to be *uniformly stable* if for every $\varepsilon > 0$ there is a $\delta(\varepsilon) > 0$, called the *modulus of uniform stability*, such that if $s \geq 0$ and $\mathsf{d}(u(s, \omega_0, x_0), x) \leq \delta(\varepsilon)$ for certain $x \in X$, then for each $t \geq 0$,

$$\mathsf{d}(u(t + s, \omega_0, x_0), u(t, \omega_0{\cdot}s, x)) = \mathsf{d}(u(t, \omega_0{\cdot}s, u(s, \omega_0, x_0)), u(t, \omega_0{\cdot}s, x)) \leq \varepsilon\,.$$

A forward orbit $\{\tau(t, \omega_0, x_0) \mid t \geq 0\}$ of the skew-product semiflow (2.1) is said to be *uniformly asymptotically stable* if it is uniformly stable and there is a $\delta_0 > 0$ with

the following property: for each $\varepsilon > 0$ there is a $t_0(\varepsilon) > 0$ such that if $s \geq 0$ and $\mathsf{d}(u(s, \omega_0, x_0), x) \leq \delta_0$, then

$$\mathsf{d}(u(t+s, \omega_0, x_0), u(t, \omega_0 \cdot s, x)) \leq \varepsilon \quad \text{for each } t \geq t_0(\varepsilon)\,.$$

3. Stable *D*-operators. We consider the Fréchet space $X = C((-\infty, 0], \mathbb{R}^m)$ endowed with the compact-open topology, i.e., the topology of uniform convergence over compact subsets, which is a metric space for the distance

$$\mathsf{d}(x, y) = \sum_{n=1}^{\infty} \frac{1}{2^n} \frac{\|x - y\|_n}{1 + \|x - y\|_n}\,, \quad x, y \in X\,,$$

where $\|x\|_n = \sup_{s \in [-n, 0]} \|x(s)\|$ and $\|\cdot\|$ denotes the maximum norm on $\mathbb{R}^m$.

Let $BU \subset X$ be the Banach space

$$BU = \{x \in X \mid x \text{ is bounded and uniformly continuous}\}$$

with the supremum norm $\|x\|_\infty = \sup_{s \in (-\infty, 0]} \|x(s)\|$. Given $r > 0$, we will denote

$$B_r = \{x \in BU \mid \|x\|_\infty \leq r\}\,.$$

As usual, given $I = (-\infty, a] \subset \mathbb{R}$, $t \in I$, and a continuous function $x : I \to \mathbb{R}^m$, x_t will denote the element of X defined by $x_t(s) = x(t + s)$ for $s \in (-\infty, 0]$.

This section is devoted to the study of general and stability properties of linear autonomous operators $D\colon BU \to \mathbb{R}^m$, as well as the behavior of solutions of the corresponding homogeneous equation $Dx_t = 0$, $t \geq 0$, and nonhomogeneous equations $Dx_t = h(t)$, $t \geq 0$, for $h \in C([0, \infty), \mathbb{R}^m)$. We will assume the following:

(D1) D is linear and continuous for the norm.

(D2) For each $r > 0$, $D\colon B_r \to \mathbb{R}^m$ is continuous when we take the restriction of the compact-open topology to B_r; i.e., if $x_n \overset{\mathsf{d}}{\to} x$ as $n \to \infty$ with x_n, $x \in B_r$, then $\lim_{n \to \infty} Dx_n = Dx$.

(D3) D is atomic at 0 (see the definition in Hale [10] or Hale and Verduyn Lunel [12]).

From (D1) and (D2) we obtain the following representation.

PROPOSITION 3.1. *If $D\colon BU \to \mathbb{R}^m$ satisfies* (D1) *and* (D2)*, then for each $x \in BU$*

$$Dx = \int_{-\infty}^{0} [d\mu(s)]\, x(s),$$

where $\mu = [\mu_{ij}]$ and μ_{ij} is a real regular Borel measure with finite total variation $|\mu_{ij}|(-\infty, 0] < \infty$ for all i, $j \in \{1, \ldots, m\}$.

Proof. From Riesz representation theorem we obtain the above relation for each x whose components are of compact support. Moreover, if $x \in BU$, there are an $r > 0$ and a sequence of functions of compact support $\{x_n\}_{n \in \mathbb{N}} \subset B_r$ with $\|x_n\|_\infty \leq \|x\|_\infty$ such that $x_n \overset{\mathsf{d}}{\to} x$ as $n \to \infty$ and, from hypothesis (D2), $\lim_{n \to \infty} Dx_n = Dx$. However,

$$Dx_n = \int_{-\infty}^{0} [d\mu(s)]\, x_n(s),$$

and the Lebesgue-dominated convergence theorem yields

$$\lim_{n \to \infty} Dx_n = \int_{-\infty}^{0} [d\mu(s)]\, x(s)\,,$$

which finishes the proof. □

Since in addition D is atomic at 0, $\det[\mu_{ij}(\{0\})] \neq 0$, and without loss of generality, we may assume that

$$Dx = x(0) - \int_{-\infty}^{0} [d\nu(s)]\, x(s), \tag{3.1}$$

where $\nu = [\nu_{ij}]_{i,j\in\{1,\dots,m\}}$, ν_{ij} is a real regular Borel measure with finite total variation, and $|\nu_{ij}|(\{0\}) = 0$ for all $i,\ j \in \{1,\dots,m\}$. We will denote by $|\nu|[-r,0]$ the $m \times m$ matrix $[\,|\nu_{ij}|[-r,0]\,]$ and by $\|\nu\|_\infty[-r,0]$ the corresponding matricial norm.

From now on, we will assume that the operator D satisfying (D1)–(D3) has the form (3.1). First, it is easy to check the following result, whose proof is omitted.

PROPOSITION 3.2. *For all $h \in C([0,\infty),\mathbb{R}^m)$ and $\varphi \in BU$ with $D\varphi = h(0)$, the nonhomogeneous equation*

$$\begin{cases} Dx_t = h(t)\,, \quad t \geq 0\,, \\ x_0 = \varphi \end{cases} \tag{3.2}$$

has a solution defined for all $t \geq 0$.

Next we obtain a bound for the solution in a finite interval $[0,T]$, in terms of the initial data and the independent term h, which in particular implies the uniqueness of the solution of (3.2).

LEMMA 3.3. *Given $T > 0$, there are positive constants k_T^1, k_T^2 such that if x is a solution of (3.2), then for each $t \in [0,T]$*

$$\|x_t\|_\infty \leq k_T^1 \sup_{0\leq u\leq t} \|h(u)\| + k_T^2\, \|\varphi\|_\infty\,. \tag{3.3}$$

Proof. Since $|\nu_{ij}|[-r,0] \to 0$ as $r \to 0$, for each $i,\ j \in \{1,\dots,m\}$, there is an $r > 0$ such that $\|\nu\|_\infty[-r,0] < 1/2$. Let x be a solution of (3.2). From (3.1),

$$x(t) = h(t) + \int_{-t}^{0} [d\nu(s)]\, x(t+s) + \int_{-\infty}^{-t} [d\nu(s)]\, \varphi(t+s)$$

for each $t \geq 0$. Consequently, if $t \in [0,r]$,

$$\|x(t)\| \leq \|h(t)\| + \frac{1}{2} \sup_{0\leq u\leq t} \|x(u)\| + \|\varphi\|_\infty \|\nu\|_\infty(-\infty,0]\,,$$

from which we deduce that if $t \in [0,r]$,

$$\sup_{0\leq u\leq t} \|x(u)\| \leq 2 \sup_{0\leq u\leq t} \|h(u)\| + 2\,a\,\|\varphi\|_\infty\,, \tag{3.4}$$

where $a = \|\nu\|_\infty(-\infty,0]$. Next, let $y(t) = x(t+r)$, which is a solution of

$$\begin{cases} Dy_t = h(t+r)\,, \quad t \geq 0\,, \\ y_0 = x_r\,. \end{cases}$$

As above, we conclude that if $t \in [0,r]$,

$$\sup_{0\leq u\leq t} \|y(u)\| \leq 2 \sup_{0\leq u\leq t} \|h(u+r)\| + 2\,a\,\|x_r\|_\infty\,,$$

which together with $\|x_r\|_\infty \le \|\varphi\|_\infty + \sup_{0\le u\le r}\|x(u)\|$ and (3.4) yields

$$\sup_{0\le u\le t}\|x(u)\| \le b \sup_{0\le u\le t}\|h(u)\| + c\,\|\varphi\|_\infty$$

for $t \in [r, 2\,r]$ and some positive constants b and c independent of h and φ. This way, the result is obtained in a finite number of steps. □

Following Hale [10], we introduce the concept of stability for the operator D. Although the initial definition is given for the homogeneous equation, it is easy to deduce quantitative estimates in terms of the initial data for the solution of a nonhomogeneous equation.

DEFINITION 3.4. *The linear operator D is said to be* stable *if there is a continuous function $c \in C([0,\infty), \mathbb{R}^+)$ with $\lim_{t\to\infty} c(t) = 0$ such that, for each $\varphi \in BU$ with $D\varphi = 0$, the solution of the homogeneous problem*

$$\begin{cases} Dx_t = 0\,, \quad t \ge 0, \\ x_0 = \varphi \end{cases}$$

satisfies $\|x(t)\| \le c(t)\,\|\varphi\|_\infty$ for each $t \ge 0$.

PROPOSITION 3.5. *Let us assume that D is stable. Then there is a positive constant $d > 0$ such that, for each $h \in C([0,\infty), \mathbb{R}^m)$ with $h(0) = 0$, the solution of*

$$\begin{cases} Dx_t = h(t)\,, \quad t \ge 0\,, \\ x_0 = 0 \end{cases}$$

satisfies $\|x(t)\| \le d \sup_{0\le u\le t}\|h(u)\|$ for each $t \ge 0$.

Proof. Let $\{e_1, \dots, e_m\}$ be the canonical basis of $\mathbb{R}^m$. A proof similar to that of Lemma 3.2 of Hale [10, sec. 12] shows that there are m functions $\phi_1, \dots, \phi_m \in BU$ such that $D\phi_j = e_j$ for each $j \in \{1, \dots, m\}$. We will denote by Φ the $m \times m$ matrix function $\Phi = [\phi_1, \dots, \phi_m]$ and by $\|\Phi\|_\infty$ the matricial norm corresponding to the norm $\|\cdot\|_\infty$ on BU.

Let $c \in C([0,\infty), \mathbb{R}^m)$ be the function given in Definition 3.4. Assume that c is decreasing and take $T > 0$ such that $c(T) < 1$. From Lemma 3.3, $\|x(t)\| \le k_T^1 \sup_{0\le u\le t}\|h(u)\|$, provided that $t \in [0, T]$.

If $t \ge T$, there is a $j \in \mathbb{N}$ such that $t \in [j\,T, (j+1)\,T]$ and it is easy to check that $x(t) = x^1(t - (j-1)\,T) + x^2(t - (j-1)\,T)$, where x^1 and x^2 are the solutions of

$$\begin{cases} Dx_t^1 = 0\,, \quad t \ge 0\,, \\ x_0^1 = x_{(j-1)\,T} - \Phi\,h((j-1)\,T)\,, \end{cases} \qquad \begin{cases} Dx_t^2 = h(t + (j-1)\,T)\,, \quad t \ge 0\,, \\ x_0^2 = \Phi\,h((j-1)\,T)\,, \end{cases}$$

respectively. From the stability of D and Lemma 3.3, we deduce that

$$\|x(t)\| \le c(t - (j-1)\,T)\,\|x_{(j-1)\,T} - \Phi\,h((j-1)\,T)\|_\infty + k_{2T} \sup_{(j-1)\,T\le u\le t}\|h(u)\|\,.$$

In addition, since $t - (j-1)\,T \ge T$ and c is decreasing we conclude that

$$\|x(t)\| \le c(T)\,c_j + (c(T)\,\|\Phi\|_\infty + k_{2T}) \sup_{0\le u\le t}\|h(u)\|\,, \quad t \in [j\,T, (j+1)\,T], \tag{3.5}$$

where $c_j = \|x_{jT}\|_\infty = \sup_{0\le u\le jT}\|x(u)\|$.

Let $a_T = \max\{k_T^1,\, c(T)\,\|\Phi\|_\infty + k_{2T}\}$. We have $c_1 \le a_T \sup_{0\le u\le T}\|h(u)\|$ and from (3.5), if $j \ge 2$,

$$c_j \le \max\left\{c_{j-1},\, c(T)\,c_{j-1} + a_T \sup_{0\le u\le j\,T}\|h(u)\|\right\}.$$

Hence, we check that for each $j \ge 2$

$$c_j \le a_T\left(1 + c(T) + \cdots + c(T)^{j-1}\right)\sup_{0\le u\le j\,T}\|h(u)\|,$$

and again from (3.5) we finally deduce that for $t \ge 0$ (and hence $t \in [j\,T, (j+1)\,T]$ for some $j \ge 0$)

$$\|x(t)\| \le a_T \sum_{k=0}^{j} c(T)^k \sup_{0\le u\le t}\|h(u)\| \le \frac{a_T}{1-c(T)}\sup_{0\le u\le t}\|h(u)\|,$$

which finishes the proof. □

THEOREM 3.6. *Let us assume that D is stable. Then there is a continuous function $c \in C([0,\infty), \mathbb{R}^+)$ with $\lim_{t\to\infty} c(t) = 0$ and a positive constant $k > 0$ such that the solution of* (3.2) *satisfies*

$$\|x(t)\| \le c(t)\,\|\varphi\|_\infty + k \sup_{0\le u\le t}\|h(u)\|$$

for each $t \ge 0$.

Proof. It is not hard to check that $x(t) = x^1(t) + x^2(t)$, where x^1 and x^2 are the solutions of

$$\begin{cases} Dx_t^1 = \psi(t)\,h(t), & t \ge 0, \\ x_0^1 = \varphi, \end{cases} \qquad \begin{cases} Dx_t^2 = (1-\psi(t))\,h(t), & t \ge 0, \\ x_0^2 = 0, \end{cases}$$

respectively, and

$$\begin{array}{rccl} \psi\colon & [0,\infty) & \longrightarrow & \mathbb{R} \\ & t & \mapsto & \psi(t) = \begin{cases} 1-t, & 0 \le t \le 1, \\ 0, & 1 \le t. \end{cases} \end{array}$$

Moreover, since $y(t) = x^1(t+1)$ satisfies $Dy_t = 0$, $t \ge 0$, with $y_0 = x_1^1$, the result follows from the application of Definition 3.4, Lemma 3.3, and Proposition 3.5 to y, x^1 on $[0,1]$, and x^2, respectively. □

The conclusions of Theorem 3.6 are essential in what follows. In particular, it allows us to estimate the norm of a function x in terms of the norm of the function $(-\infty, 0] \to \mathbb{R}^m$, $s \mapsto Dx_s$.

PROPOSITION 3.7. *Let us assume that D is stable. Then there is a positive constant $k > 0$ such that $\|x^h\|_\infty \le k\,\|h\|_\infty$ for all $h \in BU$ and $x^h \in BU$ satisfying $Dx_s^h = h(s)$ for $s \le 0$.*

Proof. Let $x(t)$ be the solution of

$$\begin{cases} Dx_t = h(0), & t \ge 0, \\ x_0 = x^h, \end{cases}$$

$$\widetilde{h}(t) = \begin{cases} h(t)\,, & t \le 0\,, \\ h(0)\,, & t \ge 0\,, \end{cases}$$

and for $s \le 0$ we define

$$y^s(t) = \begin{cases} x(t+s)\,, & t+s \ge 0\,, \\ x^h(t+s)\,, & t+s \le 0\,. \end{cases}$$

Then

$$\begin{cases} Dy_t^s = \widetilde{h}(t+s)\,, & t \ge 0\,, \\ y_0^s = x_s^h\,, \end{cases}$$

and Theorem 3.6 yields

$$\|y^s(t)\| \le c(t)\,\|x_s^h\|_\infty + k \sup_{0\le u\le t} \|\widetilde{h}(u+s)\|_\infty \le c(t)\,\|x^h\|_\infty + k\,\|h\|_\infty$$

for all $t \ge 0$ and $s \le 0$. Hence, $\|x^h(s)\| = \|y^{s-t}(t)\| \le c(t)\,\|x^h\|_\infty + k\,\|h\|_\infty$, and as $t \to \infty$ we prove the result. □

Let D be stable and given by (3.1). We define the linear operator

$$\begin{array}{rccccc} \widehat{D}\colon & BU & \longrightarrow & BU & & \\ & x & \mapsto & \widehat{D}x\colon (-\infty,0] & \to & \mathbb{R}^m \\ & & & s & \mapsto & Dx_s\,, \end{array} \tag{3.6}$$

that is, $\widehat{D}x(s) = x(s) - \int_{-\infty}^0 [d\nu(\theta)]\,x(\theta+s)$ for each $s \in (-\infty,0]$, which is well defined, i.e., $h = \widehat{D}x \in BU$, provided that $x \in BU$ because D is bounded and $h(s+\tau) - h(s) = D\,(x_{s+\tau} - x_s)$ for all τ, $s \le 0$. Moreover, it is easy to check that $\widehat{D}$ is bounded for the norm and uniformly continuous when we take the restriction of the compact-open topology to B_r; i.e., given $\varepsilon > 0$ there is a $\delta(r) > 0$ such that $\mathsf{d}(\widehat{D}x_1, \widehat{D}x_2) < \varepsilon$ for all x_1, $x_2 \in B_r$ with $\mathsf{d}(x_1,x_2) < \delta(r)$. The next result shows, after proving that $\widehat{D}$ is invertible, that the same happens for $\widehat{D}^{-1}$.

THEOREM 3.8. *Let us assume that D is stable. Then $\widehat{D}$ is invertible, and $\widehat{D}^{-1}$ is bounded for the norm and uniformly continuous when we take the restriction of the compact-open topology to B_r; i.e., given $\varepsilon > 0$ there is a $\delta(r) > 0$ such that $\mathsf{d}(\widehat{D}^{-1}h_1, \widehat{D}^{-1}h_2) < \varepsilon$ for all h_1, $h_2 \in B_r$ with $\mathsf{d}(h_1,h_2) < \delta(r)$.*

Proof. $\widehat{D}$ is injective because from Proposition 3.7 the only solution of $Dx_s = 0$ for $s \le 0$ is $x = 0$. To show that $\widehat{D}$ is onto, let $h \in BU$ and $\{h_n\}_{n\in\mathbb{N}} \subset B_r$, for some $r > 0$, be a sequence of continuous functions whose components are of compact support such that $h_n \xrightarrow{\mathsf{d}} h$ as $n \uparrow \infty$. Moreover, it is easy to choose them with the same modulus of uniform continuity as h. It is not hard to check that for each $n \in \mathbb{N}$ there is an $x^n \in BU$ such that $\widehat{D}x^n = h_n$, that is, $Dx_s^n = h_n(s)$ for $s \le 0$ and $n \in \mathbb{N}$. From Proposition 3.7, $x^n \in B_{kr}$ because $\|x^n\|_\infty \le k\,\|h_n\|_\infty \le k\,r$ and $\|x^n - x_\tau^n\|_\infty \le k\,\|h_n - (h_n)_\tau\|_\infty$ for each $\tau \le 0$ and $n \in \mathbb{N}$, which implies that $\{x_n\}_{n\in\mathbb{N}}$ is equicontinuous, and hence relatively compact for the compact-open topology. Hence, there is a convergent subsequence, let us assume the whole sequence; i.e., there is a continuous function x such that $x^n \xrightarrow{\mathsf{d}} x$ as $n \uparrow \infty$. From this, $x_s^n \xrightarrow{\mathsf{d}} x_s$ for each $s \le 0$ and (3.1) yields $Dx_s^n = h_n(s) \to Dx_s$, i.e., $Dx_s = h(s)$ for $s \le 0$ and $\widehat{D}x = h$. It is immediate to check that $x \in BU$ and then $\widehat{D}$ is onto, as claimed.

Since $\widehat{D}$ is linear, bounded for the norm, and bijective, the continuity of $\widehat{D}^{-1}$ for the norm is immediate. However, it also follows from Proposition 3.7 which reads as $\|\widehat{D}^{-1}h\|_\infty \leq k\,\|h\|_\infty$. Finally, since $\widehat{D}^{-1}$ is linear, to check the uniform continuity for the metric on each B_r, it is enough to prove the continuity at 0, i.e., $\widehat{D}^{-1}x_n \xrightarrow{\mathsf{d}} 0$ as $n \uparrow \infty$, whenever $x_n \xrightarrow{\mathsf{d}} 0$ as $n \uparrow \infty$ and $\{x_n\}_{n\in\mathbb{N}} \subset B_r$. Let $y^n = \widehat{D}^{-1}x_n \in B_{kr}$. We extend the definition of y^n to $t \geq 0$ as the solution of

$$\begin{cases} Dy^n_t = x_n(0)\,, \quad t \geq 0\,, \\ y^n_0 = y^n\,. \end{cases}$$

The stability of D provides

$$\|y^n(t+s)\| \leq c(t)\,\|y^n\|_\infty + k \sup_{s\leq u\leq 0} \|x_n(u)\| \tag{3.7}$$

for all $t \geq 0$ and $s \leq 0$. Now we check that $\{y^n\}_{n\in\mathbb{N}}$ converges uniformly to 0 on each compact set $K = [-a, 0]$. Given $\varepsilon > 0$, there is a $t_0 > 0$ such that $c(t_0)\,\|y^n\|_\infty < \varepsilon/2$ for each $n \in \mathbb{N}$. Moreover, $x_n \to 0$ in $\widetilde{K} = [-a - t_0, 0]$, and hence there is an n_0 such that for each $n \geq n_0$ we have $k\,\|x_n\|_{\widetilde{K}} < \varepsilon/2$. Therefore, from (3.7) we deduce that for all $u \in K = [-a, 0]$ and $n \geq n_0$,

$$\|y^n(u)\| = \|y^n(t_0 + u - t_0)\| < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon\,,$$

that is, $\|y^n\|_K < \varepsilon$, and $\widehat{D}^{-1}x_n = y^n \xrightarrow{\mathsf{d}} 0$ as $n \uparrow \infty$, which finishes the proof. □

A more systematic study of the properties of the linear operator $\widehat{D}$ defined in (3.6) can be found in Staffans [25]. The next result provides a necessary and sufficient condition for a continuous operator D to be stable. In particular, if $\widehat{D}$ is invertible and $\widehat{D}^{-1}$ is continuous for the restriction of the compact-open topology to B_r, then D is stable.

THEOREM 3.9. *Let $D\colon BU \to \mathbb{R}^m$ be given by* (3.1) *and let $\widehat{D}$ be the linear operator in BU defined in* (3.6)*. The following statements are equivalent:*

(i) *D is stable.*

(ii) *For each $r > 0$ and each sequence $\{x_n\}_{n\in\mathbb{N}}$ in BU such that $\|\widehat{D}x_n\|_\infty \leq r$ and $\widehat{D}x_n \xrightarrow{\mathsf{d}} 0$ as $n \uparrow \infty$, $x_n(0) \to 0$ as $n \uparrow \infty$.*

Proof. (i) ⇒ (ii) is a consequence of Theorem 3.8.

(ii) ⇒ (i) For each $T > 0$ we define $\mathcal{L}_T\colon \{\varphi \in BU \mid D\varphi = 0\} \to \mathbb{R}^m$, $\varphi \mapsto x(T)$, where x is the solution of

$$\begin{cases} Dx_t = 0\,, \quad t \geq 0\,, \\ x_0 = \varphi\,. \end{cases}$$

It is easy to check that $\mathcal{L}_T$ is well defined and linear. In addition, from (3.3) we deduce that $\|\mathcal{L}_T(\varphi)\| \leq \|x_T\|_\infty \leq k_T^2\,\|\varphi\|_\infty$, and hence it is bounded.

Next we check that $\|\mathcal{L}_T\|_\infty \to 0$ as $T \to \infty$, which shows the stability of D because $\|x(T)\| \leq c(T)\,\|\varphi\|_\infty$ for $c(T) = \|\mathcal{L}_T\|_\infty$. Let us assume, on the contrary, that there exist $\delta > 0$, a sequence $T_n \uparrow \infty$, and a sequence $\{\varphi_n\}_{n\in\mathbb{N}}$ with $\|\varphi_n\|_\infty \leq 1$ and $D\varphi_n = 0$ such that $\|\mathcal{L}_{T_n}(\varphi_n)\| \geq \delta$ for each $n \in \mathbb{N}$. That is, $\|x^n(T_n)\| \geq \delta$, where x^n is the solution of

$$\begin{cases} Dx^n_t = 0\,, \quad t \geq 0\,, \\ x^n_0 = \varphi_n\,. \end{cases}$$

Therefore,

$$\begin{cases} D((x^n_{T_n})_s) = D(x^n_{T_n+s}) = 0 & \text{if } s \in [-T_n, 0]\,, \\ D((x^n_{T_n})_s) = D((\varphi_n)_{T_n+s}) & \text{if } s \le -T_n\,, \end{cases}$$

and taking $r = \|D\|_\infty$, the sequence $\{x^n_{T_n}\}_{n\in\mathbb{N}} \subset BU$ satisfies $\|\widehat{D}x_n\|_\infty \le r$ and $\widehat{D}x^n_{T_n} \xrightarrow{\mathsf{d}} 0$ as $n \uparrow \infty$. Consequently, $x^n_{T_n}(0) = x^n(T_n) \to 0$ as $n \uparrow \infty$, which contradicts the fact that $\|x^n(T_n)\| \ge \delta$ and finishes the proof. □

PROPOSITION 3.10. *Let $D\colon BU \to \mathbb{R}^m$ be a stable operator given by* (3.1) *and let $\widehat{D}$ be the linear operator in BU defined in* (3.6). *Then*

$$\begin{array}{rccc} D^*\colon & BU & \longrightarrow & \mathbb{R}^m \\ & x & \mapsto & \widehat{D}^{-1}x(0) \end{array}$$

is also stable and satisfies (D1)–(D3).

Proof. From Theorem 3.8, we deduce that D^* satisfies (D1)–(D2). Hence as in Proposition 3.1, there is a real regular Borel measure μ^* with finite total variation such that $D^*x = \int_{-\infty}^0 [d\mu^*(s)]\, x(s)$ for each $x \in BU$. We can write $\mu^* = A\,\delta - \nu^*$ with $A = [\mu^*_{ij}(\{0\})]$. We claim that D^* is atomic at 0, i.e., $\det A \ne 0$. Assume, on the contrary, that $\det A = 0$ and let $v \in \mathbb{R}^m$ be a unitary vector with $A\,v = 0$. For each $\varepsilon > 0$ we take $\varphi_\varepsilon\colon (-\infty, 0] \to \mathbb{R}$ with $\|\varphi_\varepsilon\|_\infty = \varphi_\varepsilon(0) = 1$ and $\varphi_\varepsilon(s) = 0$ for each $s \in (-\infty, -\varepsilon]$. Let $x^{\,\varepsilon} \in BU$ be defined by $x^{\,\varepsilon}(s) = \varphi_\varepsilon(s)\, v$. The continuity of $\widehat{D}$ yields

$$1 = \|x^{\,\varepsilon}\|_\infty \le c\, \|\widehat{D}^{-1}x^{\,\varepsilon}\|_\infty\,. \tag{3.8}$$

However, for each $s \in (-\infty, 0]$

$$\widehat{D}^{-1}x^{\,\varepsilon}(s) = D^*x^{\,\varepsilon}_s = \varphi_\varepsilon(s)A\,v - \int_{-\infty}^0 [d\nu^*(\theta)]\, \varphi_\varepsilon(\theta + s)\, v$$

and, consequently, $\|\widehat{D}^{-1}x^{\,\varepsilon}\|_\infty \le \|\nu^*\|_\infty(-\varepsilon, 0]$, which tends to 0 as $\varepsilon \to 0$, contradicts (3.8) and shows that D^* is atomic at 0. Finally, D^* is stable as a consequence of Theorem 3.9. Notice that μ^* is the inverse of the measure μ for the convolution defining the operator $\widehat{D}$. □

4. Monotone NFDEs. Throughout this section, we will study the monotone skew-product semiflow generated by a family of NFDEs with infinite delay and stable D-operator. In particular, we establish the 1-covering property of omega-limit sets under the componentwise separating property and uniform stability, as in Jiang and Zhao [17] for FDEs with finite delay, and Novo, Obaya, and Sanz [20] for infinite delay. The main tool in the proof of the result is the transformation of the initial family of NFDEs into a family of FDEs with infinite delay in whose study the results of Novo et al. [20] turn out to be useful.

Let $(\Omega, \sigma, \mathbb{R})$ be a minimal flow over a compact metric space (Ω, d) and denote $\sigma(t, \omega) = \omega{\cdot}t$ for all $\omega \in \Omega$ and $t \in \mathbb{R}$. In $\mathbb{R}^m$, we take the maximum norm $\|v\| = \max_{j=1,\dots,m} |v_j|$ and the usual partial order relation

$$\begin{aligned} v \le w \quad &\Longleftrightarrow \quad v_j \le w_j \quad \text{for } j = 1, \dots, m\,, \\ v < w \quad &\Longleftrightarrow \quad v \le w \quad \text{and} \quad v_j < w_j \quad \text{for some } j \in \{1, \dots, m\}\,. \end{aligned}$$

As in section 3, we consider the Fréchet space $X = C((-\infty, 0], \mathbb{R}^m)$ endowed with the compact-open topology, i.e., the topology of uniform convergence over compact subsets, and $BU \subset X$ the Banach space of bounded and uniformly continuous functions with the supremum norm $\|x\|_\infty = \sup_{s\in(-\infty,0]} \|x(s)\|$.

Let $D\colon BU \to \mathbb{R}^m$ be an autonomous and stable linear operator satisfying hypotheses (D1)–(D3) and given by relation (3.1). The subset

$$BU_D^+ = \{x \in BU \mid Dx_s \geq 0 \ \text{ for each } \ s \in (-\infty, 0]\}$$

is a positive cone in BU, because it is a nonempty closed subset $BU_D^+ \subset BU$ satisfying $BU_D^+ + BU_D^+ \subset BU_D^+$, $\mathbb{R}^+ BU_D^+ \subset BU_D^+$, and $BU_D^+ \cap (-BU_D^+) = \{0\}$. As usual, a partial order relation on BU is induced, given by

$$x \leq_D y \quad \Longleftrightarrow \quad Dx_s \leq Dy_s \quad \text{for each } s \in (-\infty, 0]\,,$$

$$x <_D y \quad \Longleftrightarrow \quad x \leq_D y \quad \text{and} \quad x \neq y\,.$$

Remark 4.1. Notice that if we denote the usual partial order of BU

$$x \leq y \quad \Longleftrightarrow \quad x(s) \leq y(s) \quad \text{for each } s \in (-\infty, 0]\,,$$

we have that $x \leq_D y$ if and only if $\widehat{D}\, x \leq \widehat{D}\, y$, where $\widehat{D}$ is defined by relation (3.6). Although in some cases they may coincide, this new order is different from the one given by Wu and Freedman in [28].

We consider the family of nonautonomous NFDEs with infinite delay and stable D-operator

$$\frac{d}{dt} Dz_t = F(\omega{\cdot}t, z_t)\,, \quad t \geq 0\,,\ \omega \in \Omega\,, \tag{4.1}_\omega$$

defined by a function $F\colon \Omega \times BU \to \mathbb{R}^m$, $(\omega, x) \mapsto F(\omega, x)$ satisfying the following conditions:

- (F1) F is continuous on $\Omega \times BU$ and locally Lipschitz in x for the norm $\|\cdot\|_\infty$.
- (F2) For each $r > 0$, $F(\Omega \times B_r)$ is a bounded subset of $\mathbb{R}^m$.
- (F3) For each $r > 0$, $F\colon \Omega \times B_r \to \mathbb{R}^m$ is continuous when we take the restriction of the compact-open topology to B_r; i.e., if $\omega_n \to \omega$ and $x_n \xrightarrow{\mathsf{d}} x$ as $n \to \infty$ with $x \in B_r$, then $\lim_{n\to\infty} F(\omega_n, x_n) = F(\omega, x)$.
- (F4) If $x, y \in BU$ with $x \leq_D y$ and $D_j\, x = D_j\, y$ holds for some $j \in \{1, \ldots, m\}$, then $F_j(\omega, x) \leq F_j(\omega, y)$ for each $\omega \in \Omega$.

From hypothesis (F1), the standard theory of NFDEs with infinite delay (see Wang and Wu [26] and Wu [27]) assures that for each $x \in BU$ and each $\omega \in \Omega$ the system $(4.1)_\omega$ locally admits a unique solution $z(t, \omega, x)$ with initial value x, i.e., $z(s, \omega, x) = x(s)$ for each $s \in (-\infty, 0]$. Therefore, the family $(4.1)_\omega$ induces a local skew-product semiflow

$$\begin{aligned} \tau \quad &: \mathbb{R}^+ \times \Omega \times BU \quad \longrightarrow \quad \Omega \times BU \\ &\qquad (t, \omega, x) \qquad\quad \mapsto \quad (\omega{\cdot}t, u(t, \omega, x))\,, \end{aligned} \tag{4.2}$$

where $u(t, \omega, x) \in BU$ and $u(t, \omega, x)(s) = z(t + s, \omega, x)$ for $s \in (-\infty, 0]$.

As proved in Theorem 3.8, the operator $\widehat{D}$ defined by relation (3.6) is an isomorphism of BU. Hence, the change of variable $y = \widehat{D}z$ takes $(4.1)_\omega$ to

$$y'(t) = G(\omega{\cdot}t, y_t)\,, \quad t \geq 0\,,\ \omega \in \Omega\,, \tag{4.3}_\omega$$

with $G\colon \Omega \times BU \to \mathbb{R}^m$, $(\omega, x) \mapsto G(\omega, x) = F(\omega, \widehat{D}^{-1}x)$ satisfying the following conditions:

(H1) G is continuous on $\Omega \times BU$ and locally Lipschitz in x for the norm $\|\cdot\|_\infty$.

(H2) For each $r > 0$, $G(\Omega \times B_r)$ is a bounded subset of $\mathbb{R}^m$.

(H3) For each $r > 0$, $G\colon \Omega \times B_r \to \mathbb{R}^m$ is continuous when we take the restriction of the compact-open topology to B_r, i.e., if $\omega_n \to \omega$ and $x_n \xrightarrow{\mathsf{d}} x$ as $n \to \infty$ with $x \in B_r$, then $\lim_{n\to\infty} G(\omega_n, x_n) = G(\omega, x)$.

(H4) If $x, y \in BU$ with $x \le y$ and $x_j(0) = y_j(0)$ holds for some $j \in \{1, \dots, m\}$, then $G_j(\omega, x) \le G_j(\omega, y)$ for each $\omega \in \Omega$.

From hypothesis (H1), the standard theory of infinite delay FDEs (see Hino, Murakami, and Naiko [13]) assures that for each $x \in BU$ and each $\omega \in \Omega$ the system $(4.3)_\omega$ locally admits a unique solution $y(t, \omega, x)$ with initial value x, i.e., $y(s, \omega, x) = x(s)$ for each $s \in (-\infty, 0]$. Therefore, the new family $(4.3)_\omega$ induces a local skew-product semiflow

$$\begin{array}{rccl} \widehat{\tau} & : \mathbb{R}^+ \times \Omega \times BU & \longrightarrow & \Omega \times BU \\ & (t, \omega, x) & \mapsto & (\omega{\cdot}t, \widehat{u}(t, \omega, x))\,, \end{array} \tag{4.4}$$

where $\widehat{u}(t, \omega, x) \in BU$ and $\widehat{u}(t, \omega, x)(s) = y(t + s, \omega, x)$ for $s \in (-\infty, 0]$, and it is related to the previous one, (4.2), by

$$\widehat{u}(t, \omega, x) = \widehat{D}\, u(t, \omega, \widehat{D}^{-1}\, x)\,. \tag{4.5}$$

As a consequence, most of the results obtained in Novo et al. [20] for the skew-product semiflow (4.4) can now be translated to (4.2).

From hypotheses (F1) and (F2), each bounded solution $z(t, \omega_0, x_0)$ provides a relatively compact trajectory, as deduced from Proposition 4.1 of Novo et al. [20].

PROPOSITION 4.2. *Let $z(t, \omega_0, x_0)$ be a bounded solution of $(4.1)_{\omega_0}$, that is, $r = \sup_{t\in\mathbb{R}} \|z(t, \omega_0, x_0)\| < \infty$. Then* $\operatorname{closure}_X\{u(t, \omega_0, x_0) \mid t \ge 0\}$ *is a compact subset of BU for the compact-open topology.*

From hypotheses (F1), (F2), and (F3) and Proposition 4.2 and Corollary 4.3 of Novo et al. [20] for the skew-product semiflow (4.4), we can deduce the continuity of the semiflow (4.2) restricted to some compact subsets $K \subset \Omega \times BU$ when the compact-open topology is considered on BU.

PROPOSITION 4.3. *Let $K \subset \Omega \times BU$ be a compact set for the product metric topology and assume that there is an $r > 0$ such that $\tau_t(K) \subset \Omega \times B_r$ for all $t \ge 0$. Then the map*

$$\begin{array}{rccl} \tau & : \mathbb{R}^+ \times K & \longrightarrow & \Omega \times BU \\ & (t, \omega, x) & \mapsto & (\omega{\cdot}t, u(t, \omega, x)) \end{array}$$

is continuous when the product metric topology is considered.

From Proposition 4.2, when $z(t, \omega_0, x_0)$ is bounded we can define the omega-limit set of the trajectory of the point (ω_0, x_0) as

$$\mathcal{O}(\omega_0, x_0) = \{(\omega, x) \in \Omega \times BU \mid \exists\, t_n \uparrow \infty \ \text{ with } \omega_0{\cdot}t_n \to \omega\,,\ u(t_n, \omega_0, x_0) \xrightarrow{\mathsf{d}} x\}\,.$$

Notice that the omega-limit set of a pair $(\omega_0, x_0) \in \Omega \times BU$ makes sense whenever $\operatorname{closure}_X\{u(t, \omega_0, x_0) \mid t \ge 0\}$ is a compact set, because then $\{u(t, \omega_0, x_0)(0) = z(t, \omega_0, x_0) \mid t \ge 0\}$ is a bounded set. Proposition 4.3 implies that the restriction

of the semiflow (4.2) to $\mathcal{O}(\omega_0, x_0)$ is continuous for the compact-open topology. The following result is a consequence of Proposition 4.4 of Novo et al. [20].

PROPOSITION 4.4. *Let* $(\omega_0, x_0) \in \Omega \times BU$ *be such that* $\sup_{t\geq 0} \|z(t, \omega_0, x_0)\| < \infty$. *Then* $K = \mathcal{O}(\omega_0, x_0)$ *is a positively invariant compact subset admitting a flow extension.*

From hypothesis (F4), the monotone character of the semiflow (4.2) is deduced.

PROPOSITION 4.5. *For all* $\omega \in \Omega$ *and* $x, y \in BU$ *such that* $x \leq_D y$ *it holds that*

$$u(t, \omega, x) \leq_D u(t, \omega, y)$$

whenever they are defined.

Proof. From $x \leq_D y$ we know that $\widehat{D}\, x \leq \widehat{D}\, y$, and since (F4) $\Rightarrow$ (H4), from Proposition 4.5 of Novo et al. [20] we deduce that $\widehat{u}(t, \omega, \widehat{D}\, x) \leq \widehat{u}(t, \omega, \widehat{D}\, y)$ whenever they are defined, that is,

$$u(t, \omega, x) = \widehat{D}^{-1}\, \widehat{u}(t, \omega, \widehat{D}\, x) \leq_D \widehat{D}^{-1} \widehat{u}(t, \omega, \widehat{D}\, y) = u(t, \omega, y)\,,$$

as stated. ∎

We establish the 1-covering property of omega-limit sets when in addition to hypotheses (F1)–(F4) the componentwise separating property and uniform stability are assumed:

(F5) If $x, y \in BU$ with $x \leq_D y$ and $D_i\, x < D_i\, y$ holds for some $i \in \{1, \ldots, m\}$, then $D_i\, z_t(\omega, x) < D_i\, z_t(\omega, y)$ for all $t \geq 0$ and $\omega \in \Omega$.

(F6) There is an $r > 0$ such that all the trajectories with initial data in $\widehat{D}^{-1} B_r$ are uniformly stable in $\widehat{D}^{-1} B_{r'}$ for each $r' > r$, and relatively compact for the product metric topology.

From relation (4.5) we deduce that the transformed skew-product semiflow (4.4) satisfies the following:

(H5) If $x, z \in BU$ with $x \leq z$ and $x_i(0) < z_i(0)$ holds for some $i \in \{1, \ldots, m\}$, then $y_i(t, \omega, x) < y_i(t, \omega, z)$ for all $t \geq 0$ and $\omega \in \Omega$.

(H6) There is an $r > 0$ such that all the trajectories with initial data in B_r are uniformly stable in $B_{r'}$ for each $r' > r$, and relatively compact for the product metric topology.

Finally, from Theorem 5.3 of Novo et al. [20] applied to the skew-product semiflow (4.4) satisfying hypotheses (H1)–(H6), we obtain the next result for NFDEs with infinite delay.

THEOREM 4.6. *Assume that hypotheses* (F1)–(F6) *hold and let* $(\omega_0, x_0) \in \Omega \times \widehat{D}^{-1} B_r$ *be such that* $K = \mathcal{O}(\omega_0, x_0) \subset \Omega \times \widehat{D}^{-1} B_r$. *Then* $K = \{(\omega, c(\omega)) \mid \omega \in \Omega\}$ *is a copy of the base and*

$$\lim_{t\to\infty} d(u(t, \omega_0, x_0), c(\omega_0 \cdot t)) = 0\,,$$

where $c : \Omega \to BU$ *is a continuous equilibrium, i.e.,* $c(\omega \cdot t) = u(t, \omega, c(\omega))$ *for any* $\omega \in \Omega$, $t \geq 0$, *and it is continuous for the compact-open topology on* BU.

Remark 4.7. It is easy to check that it is enough to ask for property (F5) (and for (H5) in the case of FDEs with infinite delay) for initial data in BU whose trajectories are globally defined on $\mathbb{R}$.

5. Compartmental systems. We consider compartmental models for the mathematical description of processes in which the transport of material between compartments takes a nonnegligible length of time, and each compartment produces or swallows material. We provide a nonautonomous version, without strong monotonicity assumptions, of previous autonomous results by Wu and Freedman [28] and Wu [26].

First, we introduce the model with which we are going to deal as well as some notation. Let us suppose that we have a system formed by m compartments $C_1, \dots, C_m$. Denote by C_0 the environment surrounding the system, and by $z_i(t)$ the amount of material within compartment C_i at time t for each $i \in \{1, \dots, m\}$. Material flows from compartment C_j into compartment C_i through a pipe P_{ij} having a transit time distribution given by a positive regular Borel measure μ_{ij} with finite total variation $\mu_{ij}(-\infty, 0] = 1$ for each $i,\ j \in \{1, \dots, m\}$. Let $\widetilde{g}_{ij} : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ be the so-called *transport function* determining the volume of material flowing from C_j to C_i given in terms of the time t and the value of $z_j(t)$ for $i \in \{0, \dots, m\}, j \in \{1, \dots, m\}$. For each $i \in \{1, \dots, m\}$, we will assume that there exists an incoming flow of material $\tilde{I}_i$ from the environment into compartment C_i which depends only on time. For each $i \in \{1, \dots, m\}$, at time time $t \geq 0$, the compartment C_i produces material itself at a rate $\sum_{j=1}^{m} \int_{-\infty}^{0} z_j'(t+s)\, d\nu_{ij}(s)$, where ν_{ij} is a positive regular Borel measure with finite total variation $\nu_{ij}(-\infty, 0] < \infty$ and $\nu_{ij}(\{0\}) = 0$ for all $i,\ j \in \{1, \dots, m\}$.

Once the destruction and creation of material is taken into account, the change of the amount of material of any compartment C_i, $1 \leq i \leq m$, equals the difference between the amount of total influx into and total outflux out of C_i, and we obtain a model governed by the following system of infinite delay NFDEs:

$$\frac{d}{dt}\left[z_i(t) - \sum_{j=1}^{m} \int_{-\infty}^{0} z_j(t+s)\, d\nu_{ij}(s) \right] = -\widetilde{g}_{0i}(t, z_i(t)) - \sum_{j=1}^{m} \widetilde{g}_{ji}(t, z_i(t)) + \sum_{j=1}^{m} \int_{-\infty}^{0} \widetilde{g}_{ij}(t+s, z_j(t+s))\, d\mu_{ij}(s) + \tilde{I}_i(t), \tag{5.1}$$

$i = 1, \dots, m$. For simplicity, we denote $\widetilde{g}_{i0} : \mathbb{R} \times \mathbb{R} \to \mathbb{R}^+,\ (t, v) \mapsto \widetilde{I}_i(t)$ for $i \in \{1, \dots, m\}$ and let $\widetilde{g} = (\widetilde{g}_{ij})_{i,j} : \mathbb{R} \times \mathbb{R} \to \mathbb{R}^{m(m+2)}$. We will assume that

- (C1) $\widetilde{g}$ is C^1-*admissible*, i.e., $\widetilde{g}$ is C^1 in its second variable and $\widetilde{g}$, $\frac{\partial}{\partial v}\widetilde{g}$ are uniformly continuous and bounded on $\mathbb{R} \times \{v_0\}$ for all $v_0 \in \mathbb{R}$; all its components are monotone in the second variable, and $\widetilde{g}_{ij}(t, 0) = 0$ for each $t \in \mathbb{R}$;
- (C2) $\widetilde{g}$ is a recurrent function, i.e., its *hull* is minimal;
- (C3) $\mu_{ij}(-\infty, 0] = 1$ and $\int_{-\infty}^{0} |s|\, d\mu_{ij}(s) < \infty$;
- (C4) $\nu_{ij}(\{0\}) = 0$ and $\sum_{j=1}^{m} \nu_{ij}(-\infty, 0] < 1$, which implies that the operator $D\colon BU \to \mathbb{R}^m$, with $D_i\, x = x_i(0) - \sum_{j=1}^{m} \int_{-\infty}^{0} x_j(s)\, d\nu_{ij}(s)$, $i = 1, \dots, m$, is stable and satisfies (D1)–(D3);
- (C5) the measures $d\eta_{ij} = c_{ij}\, d\mu_{ij} - \sum_{k=0}^{m} d_{ki}\, d\nu_{ij}$ are positive, where

$$c_{ij} = \inf_{(t,\, v) \in \mathbb{R}^2} \frac{\partial \widetilde{g}_{ij}}{\partial v}(t, v) \quad \text{and} \quad d_{ij} = \sup_{(t,\, v) \in \mathbb{R}^2} \frac{\partial \widetilde{g}_{ij}}{\partial v}(t, v)\,.$$

In practical cases, in which the solutions with physical interest belong to the positive cone and the functions g_{ij} are only defined on $\mathbb{R} \times \mathbb{R}^+$, we can extend them to $\mathbb{R} \times \mathbb{R}$ by $g_{ij}(t, -v) = -g_{ij}(t, v)$ for all $v \in \mathbb{R}^+$. Note that (C5) is a condition for controlling the material produced in the compartments in terms of the material transported through the pipes.

The above formulation includes some particularly interesting cases. When the measures ν_{ij} and μ_{ij} are concentrated on a compact set, then (5.1) is an NFDE with finite delay. When the measures $\nu_{ij} \equiv 0$, then (5.1) is a family of FDEs with finite or infinite delay.

As usual, we include the nonautonomous system (5.1) in a family of nonautonomous NFDEs with infinite delay and stable D-operator of the form $(4.1)_\omega$ as follows.

Let Ω be the *hull* of $\widetilde{g}$, namely, the closure of the set of mappings $\{\widetilde{g}_t \mid t \in \mathbb{R}\}$, with $\widetilde{g}_t(s,v) = \widetilde{g}(t+s,v)$, $(s,v) \in \mathbb{R}^2$, with the topology of uniform convergence on compact sets, which from (C1) is a compact metric space (more precisely from the admissibility of $\widetilde{g}$; see Hino et al. [13]). Let $(\Omega, \sigma, \mathbb{R})$ be the continuous flow defined on Ω by translation, $\sigma : \mathbb{R} \times \Omega \to \Omega$, $(t,\omega) \mapsto \omega{\cdot}t$, with $\omega{\cdot}t(s,v) = \omega(t+s,v)$. By hypothesis (C2), the flow $(\Omega, \sigma, \mathbb{R})$ is minimal. In addition, if $\widetilde{g}$ is almost periodic (resp., almost automorphic) the flow will be almost periodic (resp., almost automorphic). Notice that these two cases are included in our formulation.

Let $g : \Omega \times \mathbb{R} \to \mathbb{R}^{m(m+2)}$, $(\omega, v) \mapsto \omega(0,v)$, continuous on $\Omega \times \mathbb{R}$ and denote $g = (g_{ij})_{i,j}$. It is easy to check that, for all $\omega = (\omega_{ij})_{i,j} \in \Omega$ and all $i \in \{1,\dots,m\}$, ω_{i0} is a function dependent only on t; thus, we can define $I_i = \omega_{i0}$, $i \in \{1,\dots,m\}$. Let $F : \Omega \times BU \to \mathbb{R}^m$ be the map defined by

$$F_i(\omega, x) = -g_{0i}(\omega, x_i(0)) - \sum_{j=1}^{m} g_{ji}(\omega, x_i(0)) + \sum_{j=1}^{m} \int_{-\infty}^{0} g_{ij}(\omega{\cdot}s, x_j(s))\, d\mu_{ij}(s) + I_i(\omega)$$

for $(\omega, x) \in \Omega \times BU$ and $i \in \{1,\dots,m\}$. Hence, the family

$$\frac{d}{dt} D z_t = F(\omega{\cdot}t, z_t)\,, \quad t \geq 0\,,\ \omega \in \Omega\,, \tag{5.2}_\omega$$

where the stable operator D is defined in (C4) and satisfies (D1)–(D3), includes system (5.1) when $\omega = \widetilde{g}$.

It is easy to check that this family satisfies hypotheses (F1)–(F3). The following lemma will be useful when proving (F4) and (F5). We omit its proof, which is analogous to the one given in Wu and Freedman [28] for the autonomous case with finite delay.

LEMMA 5.1. *For all $\omega \in \Omega$, x, $y \in BU$ with $x \leq_D y$, and $i = 1,\dots,m$*

$$F_i(\omega, y) - F_i(\omega, x) \geq -\sum_{j=0}^{m} d_{ji}\,[D_i y - D_i x] + \sum_{j=1}^{m} \int_{-\infty}^{0} (y_j(s) - x_j(s))\, d\eta_{ij}(s), \tag{5.3}$$

where the measures η_{ij} are defined in (C5).

Condition (C5) is essential to proving the monotone character of the semiflow. It can be improved in some cases (see Arino and Bourad [1] for the scalar case).

PROPOSITION 5.2. *Under assumptions* (C1)–(C5)*, the family* $(5.2)_\omega$ *satisfies hypotheses* (F4), (F5) *and $\Omega \times BU_D^+$ is positively invariant.*

Proof. Let x, $y \in BU$ with $x \leq_D y$ and $D_i\, x = D_i\, y$ for some $i \in \{1,\dots,m\}$. From (C4), apart from the stability of the operator D, it is easy to prove that the inverse operator of $\widehat{D}$ defined by (3.6) is positive. Hence, from $x \leq_D y$, that is, $\widehat{D}\, x \leq \widehat{D}\, y$, we also deduce that $x \leq y$, which, together with $D_i\, x = D_i\, y$, relation (5.3), and hypothesis (C5), yields $F_i(\omega, y) \geq F_i(\omega, x)$, that is, hypothesis (F4) holds.

Next, we check hypothesis (F5). Let x, $y \in BU$ with $x \leq_D y$ and $D_i\, x < D_i\, y$ for some $i \in \{1,\dots,m\}$. Since (F4) holds, from Proposition 4.5 $u(t,\omega,x) \leq_D u(t,\omega,y)$ and, as before, we deduce in this case that $u(t,\omega,x) \leq u(t,\omega,y)$, i.e., $z_t(\omega,x) \leq z_t(\omega,y)$ for all $t \geq 0$ and $\omega \in \Omega$. Let $h(t) = D_i z_t(\omega,y) - D_i z_t(\omega,x)$. From $(5.2)_\omega$ and

Lemma 5.1

$$h'(t) = F_i(\omega{\cdot}t, z_t(\omega, y)) - F_i(\omega{\cdot}t, z_t(\omega, x))$$
$$\geq -\sum_{j=0}^{m} d_{ji} h(t) + \sum_{j=1}^{m} \int_{-\infty}^{0} (z_j(t+s, \omega, y) - z_j(t+s, \omega, x))\, d\eta_{ij}(s)\,,$$

and again from hypothesis (C5) we deduce that $h'(t) \geq -dh(t)$ for some $d \geq 0$, which together with $h(0) > 0$ yields $h(t) = D_i z_t(\omega, y) - D_i z_t(\omega, x) > 0$ for each $t \geq 0$ and (F5) holds. Finally, since $I_i(\omega) \geq 0$ for each $\omega \in \Omega$ and $i \in \{1, \ldots, m\}$, and the semiflow is monotone, a comparison argument shows that $\Omega \times BU_D^+$ is positively invariant, as stated. □

Next we will study some cases in which hypothesis (F6) is satisfied. In order to do this, we define $M\colon \Omega \times BU \to \mathbb{R}$, the *total mass* of the system $(5.2)_\omega$, as

$$M(\omega, x) = \sum_{i=1}^{m} D_i x + \sum_{i=1}^{m} \sum_{j=1}^{m} \int_{-\infty}^{0} \left(\int_{s}^{0} g_{ji}(\omega{\cdot}\tau, x_i(\tau))\, d\tau \right) d\mu_{ji}(s) \tag{5.4}$$

for all $\omega \in \Omega$ and $x \in BU$, which is well defined from condition (C3). The next result shows the continuity properties of M and its variation along the flow.

Proposition 5.3. *The total mass M is a continuous function on all the sets of the form $\Omega \times B_r$ with $r > 0$ for the product metric topology. Moreover, for each $t \geq 0$*

$$\frac{d}{dt} M(\tau_t(\omega, x)) = \sum_{i=1}^{m} \left[I_i(\omega{\cdot}t) - g_{0i}(\omega{\cdot}t, z_i(t, \omega, x)) \right]. \tag{5.5}$$

Proof. The continuity follows from (D2), (C1), and (C3). A straightforward computation similar to that given in Wu and Freedman [28] shows that

$$M(\omega{\cdot}t, z_t(\omega, x)) = M(\omega, x) + \sum_{i=1}^{m} \int_{0}^{t} \left[I_i(\omega{\cdot}s) - g_{0i}(\omega{\cdot}s, z_i(s, \omega, x)) \right] ds\,, \tag{5.6}$$

from which (5.5) is deduced. □

The following lemma is essential in the proof of the stability of solutions.

Lemma 5.4. *Let x, $y \in BU$ with $x \leq_D y$. Then*

$$0 \leq D_i z_t(\omega, y) - D_i z_t(\omega, x) \leq M(\omega, y) - M(\omega, x)$$

for each $i = 1, \ldots, m$ and whenever $z(t, \omega, x)$ and $z(t, \omega, y)$ are defined.

Proof. From Propositions 5.2 and 4.5 the skew-product semiflow induced by $(5.2)_\omega$ is monotone. Hence, if $x \leq_D y$, then $u(t, \omega, x) \leq_D u(t, \omega, y)$ whenever they are defined. From this, as before, since $\widehat{D}^{-1}$ is positive we also deduce that $x \leq y$ and $u(t, \omega, x) \leq u(t, \omega, y)$. Therefore, $D_i z_t(\omega, x) \leq D_i z_t(\omega, y)$ and $z_i(t, \omega, x) \leq z_j(t, \omega, y)$ for each $i = 1, \ldots, m$. In addition, the monotonicity of transport functions yields $g_{ij}(\omega, z_j(t, \omega, x)) \leq g_{ij}(\omega, z_j(t, \omega, y))$ for each $\omega \in \Omega$. From all these inequalities and (5.4) and (5.6) we deduce that

$$0 \leq D_i z_t(\omega, y) - D_i z_t(\omega, x) \leq \sum_{i=1}^{m} \left[D_i z_t(\omega, y) - D_i z_t(\omega, x) \right]$$
$$\leq M(\omega{\cdot}t, z_t(\omega, y)) - M(\omega{\cdot}t, z_t(\omega, x)) \leq M(\omega, y) - M(\omega, x)\,,$$

as stated. □

PROPOSITION 5.5. *Fix $r > 0$. Then given $\varepsilon > 0$ there exists $\delta > 0$ such that if x, $y \in B_r$ with $\mathsf{d}(x, y) < \delta$, then $\|z(t, \omega, x) - z(t, \omega, y)\| \leq \varepsilon$ whenever they are defined.*

Proof. Let $c = \max_i \sum_{j=1}^{m} \nu_{ij}(-\infty, 0] < 1$. From the continuity of M, given $\varepsilon_0 = \varepsilon\,(1 - c) > 0$ there exists $0 < \delta < \varepsilon_0$, such that if x, $y \in B_r$ with $\mathsf{d}(x, y) < \delta$, then $|M(\omega, y) - M(\omega, x)| < \varepsilon_0$. Therefore, if x, $y \in B_r$ and $x \leq_D y$, from Lemma 5.4 we deduce that $0 \leq D_i z_t(\omega, y) - D_i z_t(\omega, x) < \varepsilon_0$ whenever $\mathsf{d}(x, y) < \delta$. The definition of D_i yields

$$0 \leq z_i(t, \omega, y) - z_i(t, \omega, x) < \varepsilon_0 + \sum_{j=1}^{m} \int_{-\infty}^{0} [z_j(t + s, \omega, y) - z_j(t + s, \omega, x)]\, d\nu_{ij}(s)$$

$$\leq \varepsilon_0 + \|z_t(\omega, y) - z_t(\omega, x)\|_\infty \sum_{j=1}^{m} \nu_{ij}(-\infty, 0]\,,$$

from which we deduce that $\|z_t(\omega, y) - z_t(\omega, x)\|_\infty (1 - c) < \varepsilon_0 = \varepsilon(1 - c)$, that is, $\|z(t, \omega, x) - z(t, \omega, y)\| \leq \varepsilon$ whenever they are defined. The case in which x and y are not ordered follows easily from this one. ∎

As a consequence, from the existence of a bounded solution for one of the systems of the family, the boundedness of all solutions is inferred, and this is the case in which hypothesis (F6) holds.

THEOREM 5.6. *Under assumptions* (C1)–(C5)*, if there exists $\omega_0 \in \Omega$ such that $(5.2)_{\omega_0}$ has a bounded solution, then all solutions of $(5.2)_\omega$ are bounded as well, hypothesis* (F6) *holds, and all omega-limit sets are copies of the base.*

Proof. The boundedness of all solutions is an easy consequence of the previous proposition and the continuity of the semiflow. Let $(\omega, x) \in \Omega \times BU$ and $r' > 0$ such that $z_t(\omega, x) \in B_{r'}$ for all $t \geq 0$. Then also from Proposition 5.5, we deduce that given $\varepsilon > 0$ there exists a $\delta > 0$ such that

$$\|z(t + s, \omega, x) - z(t, \omega{\cdot}s, y)\| = \|z(t, \omega{\cdot}s, z_s(\omega, x)) - z(t, \omega{\cdot}s, y)\| < \varepsilon$$

for all $t \geq 0$ whenever $y \in B_{r'}$ and $\mathsf{d}(z_s(\omega, x), y) < \delta$, which shows the uniform stability of the trajectories in $B_{r'}$ for each $r' > 0$. Moreover, for each $r > 0$ there is an $r' > 0$ such that $\widehat{D}^{-1} B_r \subset B_{r'}$. Hence, hypothesis (F6) holds for all $r > 0$ and Theorem 4.6 applies for all initial data, which finishes the proof. ∎

Concerning the solutions of the original compartmental system, we obtain the following result providing a nontrivial generalization of the autonomous case, in which the asymptotical constancy of the solutions was shown (see Wu and Freedman [28]). Although the theorem is stated in the almost periodic case, similar conclusions are obtained changing almost periodic to periodic, almost automorphic, or recurrent, that is, all solutions are asymptotically of the same type as the transport functions.

THEOREM 5.7. *Under assumptions* (C1)–(C5) *and in the almost periodic case, if there is a bounded solution of* (5.1)*, then there is at least an almost periodic solution and all the solutions are asymptotically almost periodic. For closed systems, i.e., $\widetilde{I}_i \equiv 0$ and $\widetilde{g}_{0i} \equiv 0$ for each $i = 1, \ldots, m$, there are infinitely many almost periodic solutions and the rest of them are asymptotically almost periodic.*

Proof. The first statement is an easy consequence of the previous theorem. Let $\omega_0 = \widetilde{g}$. The omega-limit of each solution $z(t, \omega_0, x_0)$ is a copy of the base $\mathcal{O}(\omega_0, x_0) = \{(\omega, x(\omega)) \mid \omega \in \Omega\}$, and hence $z(t, \omega_0, x(\omega_0)) = x(\omega_0{\cdot}t)(0)$ is an almost periodic solution of (5.1) and

$$\lim_{t \to \infty} \|z(t, \omega_0, x_0) - z(t, \omega_0, x(\omega_0))\| = 0\,.$$

The statement for closed systems follows in addition from (5.6), which implies that the mass is constant along the trajectories. Hence, there are infinitely many minimal subsets because from the definition of the mass and (C4), given $c > 0$ there is an $(\omega_0, x_0) \in \Omega \times BU_D^+$ such that $M(\omega_0, x_0) = c$ and hence $M(\omega, x) = c$ for each $(\omega, x) \in \mathcal{O}(\omega_0, x_0)$. □

6. Long-term behavior of compartmental systems. This section deals with the long-term behavior of the amount of material within the compartments of the compartmental system (5.1) satisfying hypotheses (C1)–(C5). As in the previous section, the study of the minimal sets for the corresponding skew-product semiflow (4.2) induced by the family $(5.2)_\omega$ will be essential. In addition to hypotheses (C1)–(C5) we will assume the following hypothesis:

(C6) Given $i \in \{0, \dots, m\}$ and $j \in \{1, \dots, m\}$ either $\widetilde{g}_{ij} \equiv 0$ on $\mathbb{R} \times \mathbb{R}^+$ (and hence $g_{ij} \equiv 0$ on $\Omega \times \mathbb{R}^+$), i.e., *there is not a pipe from compartment C_j to compartment C_i*, or for each $v > 0$ there is a $\delta_v > 0$ such that $\widetilde{g}_{ij}(t, v) \geq \delta_v$ for all $t \in \mathbb{R}$ (and hence $g_{ij}(\omega, v) > 0$ for all $\omega \in \Omega$ and $v > 0$). In this case we will say that the pipe P_{ij} *carries material (or that there is a pipe from compartment C_j to compartment C_i).*

Let $I = \{1, \dots, m\}$. $\mathcal{P}(I)$ denotes, as usual, the set of all subsets of I.

DEFINITION 6.1. *Let $\zeta : \mathcal{P}(I) \to \mathcal{P}(I)$, $J \mapsto \cup_{j \in J}\{i \in I \mid P_{ij}$ carries material$\}$. A subset J of I is said to be* irreducible *if $\zeta(J) \subset J$ and no proper subset of J has that property. System* (5.1) *is* irreducible *if the whole set I is irreducible.*

Note that $\zeta(I) \subset I$, so there is always some irreducible subset of I. Irreducible sets detect the occurrence of dynamically independent subsystems. Our next result gives a useful property of irreducible sets with more than one element.

PROPOSITION 6.2. *If a subset J of I is irreducible, then, for all $i, j \in J$ with $i \neq j$, there exist $p \in \mathbb{N}$ and $i_1, \dots, i_p \in J$ such that $P_{i_1 i}$, $P_{i_2 i_1}, \dots, P_{i_p i_{p-1}}$, and $P_{j i_p}$ carry material.*

Proof. Let us assume, on the contrary, that $j \notin \cup_{n=1}^{\infty} \zeta^n(\{i\}) = \widetilde{J}_i$. Then $\widetilde{J}_i \subsetneq J$ and, obviously, $\zeta(\widetilde{J}_i) \subset \widetilde{J}_i$, which contradicts the fact that J is irreducible. □

Let $J_1, \dots, J_k$ be all the irreducible subsets of I and let $J_0 = I \setminus \cup_{l=1}^{k} J_l$. These sets reflect the geometry of the compartmental system in a good enough way as to describe the long-term behavior of the solutions, as we will see below.

Let K be any minimal subset of $\Omega \times BU$ for the skew-product semiflow induced by $(5.2)_\omega$. From Theorem 5.6, K is of the form $K = \{(\omega, x(\omega)) \mid \omega \in \Omega\}$, where x is a continuous map from Ω into BU. All of the subsequent results give qualitative information about the long-term behavior of the solutions. Let us see that, provided that we are working on a minimal set K, if there is no inflow from the environment, then the total mass is constant on K, all compartments out of an irreducible subset are empty, and, in an irreducible subset, either all compartments are empty or all are never empty. In particular, in any irreducible subset *with some outflow of material*, all compartments are empty.

THEOREM 6.3. *Assume that $\tilde{I}_i \equiv 0$ for each $i \in I$ and let $K = \{(\omega, x(\omega)) \mid \omega \in \Omega\}$ be a minimal subset of $\Omega \times BU$ with $K \subset \Omega \times BU_D^+$. Then the following hold:*

(i) *There exists $c \geq 0$ such that $M|_K \equiv c$.*

(ii) *$x_i \equiv 0$ for each $i \in J_0$.*

(iii) *If, for some $l \in \{1, \dots, k\}$, there exists $j_l \in J_l$ such that $x_{j_l} \equiv 0$, then $x_i \equiv 0$ for each $i \in J_l$. In particular, this happens if there is a $j_l \in J_l$ such that there is an outflow of material from C_{j_l}.*

Proof. We first suppose that the system is closed, i.e., $\widetilde{g}_{0i} \equiv 0$, $\widetilde{I}_i \equiv 0$ for all $i \in I$, from which we deduce $g_{0i} \equiv 0$ and $I_i \equiv 0$ for all $i \in I$.

(i) From (5.6) the total mass M is constant along the trajectories, and hence $M(\omega{\cdot}t, x(\omega{\cdot}t)) = M(\omega, x(\omega))$ for all $t \geq 0$ and $\omega \in \Omega$, which together with the fact that Ω is minimal and M continuous shows the statement.

(ii) Let $i \in J_0$. The set $\widetilde{J}_i = \cup_{n=1}^{\infty} \zeta^n(\{i\})$ satisfies $\zeta(\widetilde{J}_i) \subset \widetilde{J}_i$ and hence contains an irreducible set J_l for some $l \in \{1, \dots, k\}$. Consequently, there are $i_1, \dots, i_p \in J_0$ and $j_l \in J_l$ such that $P_{j_l i_p}$ carry material.

It is easy to prove that there is an $r > 0$ such that $\|x(\omega)\|_\infty \leq r$ for each $\omega \in \Omega$. We define $M_l \colon \Omega \times BU \to \mathbb{R}$, the *mass restricted to* J_l, as

$$M_l(\omega, y) = \sum_{i \in J_l} D_i y + \sum_{i,j \in J_l} \int_{-\infty}^{0} \left(\int_s^0 g_{ji}(\omega{\cdot}\tau, y_i(\tau))\, d\tau \right) d\mu_{ji}(s)\,, \tag{6.1}$$

which is continuous on $\Omega \times B_r$. From $x(\omega) \geq_D 0$, which also implies $x(\omega) \geq 0$, and (C1), we have $0 \leq M_l(\omega, x(\omega)) \leq M(\omega, x(\omega)) = c$ for each $\omega \in \Omega$.

Since J_l is irreducible, for all $i \in J_l$ and $\omega \in \Omega$

$$\frac{d}{dt} D_i x(\omega{\cdot}t) = -\sum_{j \in J_l} g_{ji}(\omega{\cdot}t, x_i(\omega{\cdot}t)(0)) + \sum_{j \in J_l \cup J_0} \int_{-\infty}^{0} g_{ij}(\omega{\cdot}(s+t), x_j(\omega{\cdot}t)(s))\, d\mu_{ij}(s)$$

because the rest of the terms vanish. Consequently,

$$\frac{d}{dt} M_l(\omega{\cdot}t, x(\omega{\cdot}t)) = \sum_{i \in J_l} \sum_{j \in J_0} \int_{-\infty}^{0} g_{ij}(\omega{\cdot}(s+t), x_j(\omega{\cdot}t)(s))\, d\mu_{ij}(s) \geq 0 \tag{6.2}$$

for each $\omega \in \Omega$. We claim that $M_l(\omega, x(\omega))$ is constant for each $\omega \in \Omega$. Assume, on the contrary, that there are $\omega_1, \omega_2 \in \Omega$ such that $M_l(\omega_1, x(\omega_1)) < M_l(\omega_2, x(\omega_2))$, and let $t_n \uparrow \infty$ such that $\lim_{n\to\infty} \omega_2{\cdot}t_n = \omega_1$. From (6.2) we deduce that $M_l(\omega_2, x(\omega_2)) \leq M_l(\omega_2{\cdot}t_n, x(\omega_2{\cdot}t_n))$ for each $n \in \mathbb{N}$, and taking limits as $t \to \infty$ we conclude that $M_l(\omega_2, x(\omega_2)) \leq M_l(\omega_1, x(\omega_1))$, a contradiction. Hence $M_l(\omega, x(\omega))$ is constant and from (6.2)

$$\sum_{i \in J_l} \sum_{j \in J_0} \int_{-\infty}^{0} g_{ij}(\omega{\cdot}(s+t), x_j(\omega{\cdot}t)(s))\, d\mu_{ij}(s) = 0\,. \tag{6.3}$$

Next we check that $x_{i_p} \equiv 0$. From (6.3) we deduce that for each $\omega \in \Omega$

$$\int_{-\infty}^{0} g_{j_l i_p}(\omega{\cdot}s, x_{i_p}(\omega)(s))\, d\mu_{j_l i_p}(s) = 0\,. \tag{6.4}$$

Assume that there is an $\omega_0 \in \Omega$ such that $x_{i_p}(\omega_0)(0) > 0$. Hence there is an $\varepsilon > 0$ with $x_{i_p}(\omega_0)(s) > 0$ for each $s \in (-\varepsilon, 0]$, and since $P_{j_l i_p}$ carries material $g_{j_l i_p}(\omega_0{\cdot}s, x_{i_p}(\omega_0)(s)) > 0$ for $s \in (-\varepsilon, 0]$. In addition, from $\mu_{j_l i_p}(-\infty, 0] = 1$ there is a $b \leq 0$ such that $\mu_{j_l i_p}(b - \varepsilon, b] > 0$. Hence, denoting $\omega_0{\cdot}(-b) = \omega_1$ we deduce that

$$\int_{b-\varepsilon}^{b} g_{j_l i_p}(\omega_1{\cdot}s, x_{i_p}(\omega_1)(s))\, d\mu_{j_l i_p}(s) > 0\,,$$

which contradicts (6.4) and shows that $x_{i_p} \equiv 0$, as claimed. Since $x(\omega) \geq_D 0$, we have $D_{i_p} x(\omega) \geq 0$ and from the definition of D_{i_p} we deduce that $D_{i_p} x(\omega) = 0$ for each

$\omega \in \Omega$. Therefore,

$$0 = \frac{d}{dt} D_{i_p} x(\omega \cdot t) = \sum_{j=1}^{m} \int_{-\infty}^{0} g_{i_p j}(\omega \cdot (t+s), x_j(\omega \cdot t)(s))\, d\mu_{i_p j}(s)\,,$$

from which $\int_{-\infty}^{0} g_{i_p i_{p-1}}(\omega \cdot s, x_{i_{p-1}}(\omega)(s))\, d\mu_{i_p i_{p-1}}(s) = 0$, and as before $x_{i_{p-1}} \equiv 0$. In a finite number of steps we check that $x_i \equiv 0$, as stated.

(iii) From Proposition 6.2, given i, $j_l \in J_l$ there exist $p \in \mathbb{N}$ and $i_1, \ldots, i_p \in J_l$ such that $P_{i_1 i}$, $P_{i_2 i_1}, \ldots, P_{i_p i_{p-1}}$, and $P_{j_l i_p}$ carry material. If $x_{j_l} \equiv 0$, the same argument given in the last part of (ii) shows that $x_i \equiv 0$, which finishes the proof for closed systems.

Next we deal with the case when $\tilde{I}_i \equiv 0$ for each $i \in I$ but the system is not necessarily closed. We also have $I_i \equiv 0$ and from (5.5) we deduce that the total mass M is decreasing along the trajectories. In particular,

$$\frac{d}{dt} M(\omega \cdot t, x(\omega \cdot t)) = -\sum_{i=1}^{n} g_{0i}(\omega \cdot t, x_i(\omega \cdot t)(0)) \leq 0\,. \tag{6.5}$$

Assume that there are ω_1, $\omega_2 \in \Omega$ such that $M(\omega_1, x(\omega_1)) < M(\omega_2, x(\omega_2))$, and let $t_n \uparrow \infty$ such that $\lim_{n\to\infty} \omega_1 \cdot t_n = \omega_2$. From relation (6.5) we deduce that $M(\omega_1 \cdot t_n, x(\omega_1 \cdot t_n)) \leq M(\omega_1, x(\omega_1))$ for each $n \in \mathbb{N}$, and taking limits as $n \uparrow \infty$ we conclude that $M(\omega_2, x(\omega_2)) \leq M(\omega_1, x(\omega_1))$, a contradiction, which shows that M is constant on K, as stated in (i). Consequently, the derivative in (6.5) vanishes and $g_{0i}(\omega \cdot t, x_i(\omega \cdot t)(0)) = 0$ for all $i \in I$, $\omega \in \Omega$, and $t \geq 0$. This means that $z(t, \omega, x(\omega)) = x(\omega \cdot t)(0)$ is a solution of a closed system, and (ii) and the first part of (iii) follow from the previous case.

Finally, let $j_l \in J_l$ be such that there is an outflow of material from C_{j_l}, that is, $g_{0 j_l}(\omega, v) > 0$ for all $\omega \in \Omega$ and $v > 0$. Moreover, as before, $g_{0 j_l}(\omega, x_{j_l}(\omega)(0)) = 0$ for each $\omega \in \Omega$, which implies that $x_{j_l} \equiv 0$ and completes the proof. □

Remark 6.4. Notice that, concerning the solutions of the family of systems $(5.2)_\omega$ and hence the solutions of the original system (5.1) when $\omega = \widetilde{g}$, we deduce that in the case of no inflow from the environment, $\lim_{t\to\infty} z_i(t, \omega, x_0) = 0$ for all $i \in J_0$, $i \in J_l$ for compartments J_l with some outflow, and each $x_0 \geq_D 0$.

Remark 6.5. If there is no inflow from the environment and for all $l \in \{1, \ldots, k\}$ there is a $j_l \in J_l$ such that there is outflow of material from C_{j_l}, then the only minimal set in $\Omega \times BU_D^+$ is $K = \{(\omega, 0) \mid \omega \in \Omega\}$ and all the solutions $z(t, \omega, x_0)$ with initial data $x_0 \geq_D 0$ tend to 0 as $t \to \infty$.

In a nonclosed system, that is, a system which may have any inflow and any outflow of material, if there exists a bounded solution, i.e., all solutions are bounded as shown above, and an irreducible set which has *some inflow*, then, working on a minimal set, all compartments of that irreducible set are nonempty and there must be some outflow from the irreducible set.

THEOREM 6.6. *Assume that there exists a bounded solution of* (5.1) *and let* $K = \{(\omega, x(\omega)) \mid \omega \in \Omega\}$ *be a minimal subset of* $\Omega \times BU_D^+$. *If, for some* $l \in \{1, \ldots, k\}$, *there is a* $j_l \in J_l$ *such that* $\widetilde{I}_{j_l} \neq 0$, *i.e., there is some inflow into* C_{j_l}, *then*

(i) $x_i \not\equiv 0$ *for each* $i \in J_l$, *and*

(ii) *there is a* $j \in J_l$ *such that there is outflow of material from* C_j.

Proof. (i) Let us assume, on the contrary, that there is an $i \in J_l$ such that $x_i \equiv 0$. Then since $x(\omega) \geq_D 0$ we have that $0 \leq D_i x(\omega)$, and from the definition of D_i given

in (C4) we deduce that $D_i x(\omega) = 0$ for each $\omega \in \Omega$. Therefore,

$$0 = \frac{d}{dt} D_i x(\omega \cdot t) = \sum_{j=1}^{m} \int_{-\infty}^{0} g_{ij}(\omega \cdot (t+s), x_j(\omega \cdot t)(s))\, d\mu_{ij}(s) + I_i(\omega \cdot t) \tag{6.6}$$

for all $\omega \in \Omega$, $t \geq 0$, and, as in (ii) of Theorem 6.3, we check that $x_{j_l} \equiv 0$. However, since $\widetilde{I}_{j_l} \not\equiv 0$, there is an $\omega_0 \in \Omega$ such that $I_{j_l}(\omega_0) > 0$, which contradicts (6.6) for $\omega = \omega_0$, $i = j_l$ at $t = 0$.

(ii) Assume, on the contrary, that $g_{0j} \equiv 0$ for each $j \in J_l$. Then if we consider (6.1) the restriction of the mass to J_l, we check that

$$\frac{d}{dt} M_l(\omega \cdot t, x(\omega \cdot t)) = \sum_{i \in J_l} \left[I_i(\omega \cdot t) + \sum_{j \in J_0} \int_{-\infty}^{0} g_{ij}(\omega \cdot (s+t), x_j(\omega \cdot t)(s))\, d\mu_{ij}(s) \right] \geq 0$$

for all $\omega \in \Omega$ and $t \geq 0$. A similar argument to the one given in (ii) of Theorem 6.3 shows that $M_l(\omega, x(\omega))$ is constant for each $\omega \in \Omega$, which contradicts the fact that the above derivative is strictly positive for $\omega = \omega_0$ at $t = 0$ and proves the statement. ∎

Finally, we will change hypothesis (C6) to the following, slightly stronger one.

(C6)* Given $i \in \{0, \dots, m\}$ and $j \in \{1, \dots, m\}$ either $\widetilde{g}_{ij} \equiv 0$ on $\mathbb{R} \times \mathbb{R}^+$ (and hence $g_{ij} \equiv 0$ on $\Omega \times \mathbb{R}^+$), i.e., *there is not a pipe from compartment C_j to compartment C_i*, or for each $v \geq 0$ there is a $\delta_v > 0$ such that $\frac{\partial}{\partial v} \widetilde{g}_{ij}(t, v) \geq \delta_v$ for each $t \in \mathbb{R}$ (and hence $\frac{\partial}{\partial v} g_{ij}(\omega, v) > 0$ for all $\omega \in \Omega$ and $v \geq 0$). In this case we will say that the pipe P_{ij} *carries material (or that there is a pipe from compartment C_j to compartment C_i).*

In this case, we are able to prove that if there exists a bounded solution, then all the minimal sets coincide both on irreducible sets having *some outflow* and out of irreducible sets. Concerning the solutions of the initial compartmental system (5.1),

$$\lim_{t \to \infty} |z_i(t, x_0) - z_i(t, y_0)| = 0$$

for all $i \in J_0$, $i \in J_l$ for compartments J_l with some outflow, and all x_0, $y_0 \geq_D 0$.

THEOREM 6.7. *Let us assume that hypotheses* (C1)–(C5) *and* (C6)* *hold and that there exists a bounded solution of system* (5.1). *Let* $K_1 = \{(\omega, x(\omega)) \mid \omega \in \Omega\}$ *and* $K_2 = \{(\omega, y(\omega)) \mid \omega \in \Omega\}$ *be two minimal subsets of* $\Omega \times BU_D^+$. *Then*

(i) $x_i \equiv y_i$ *for each* $i \in J_0$;

(ii) *if, for some* $l \in \{1, \dots, k\}$, *there is a* $j_l \in J_l$ *such that there is outflow of material from* C_{j_l}, *then* $x_i \equiv y_i$ *for each* $i \in J_l$.

Proof. For each $i \in \{0, \dots, m\}$ and each $j \in \{1, \dots, m\}$ we define $h_{ij} \colon \Omega \to \mathbb{R}^+$ as

$$h_{ij}(\omega) = \int_0^1 \frac{\partial g_{ij}}{\partial v}(\omega, s\, x_j(\omega)(0) + (1-s)\, y_j(\omega)(0))\, ds \geq 0\,,$$

and we consider the family of monotone linear compartmental systems

$$\begin{aligned} (6.7)_\omega \quad \frac{d}{dt} D_i \hat{z}_t = {} & -h_{0i}(\omega \cdot t)\, \hat{z}_i(t) - \sum_{j=1}^{m} h_{ji}(\omega \cdot t)\, \hat{z}_i(t) \\ & + \sum_{j=1}^{m} \int_{-\infty}^{0} h_{ij}(\omega \cdot (s+t))\, \hat{z}_j(t+s)\, d\mu_{ij}(s)\,, \quad \omega \in \Omega, \end{aligned}$$

satisfying the corresponding hypotheses (C1)–(C4) and (C6). Moreover, (C5) for each of the systems $(6.7)_\omega$, follows from

$$\inf_{\omega\in\Omega} h_{ij}(\omega) \geq \inf_{v\geq 0\,,\,\omega\in\Omega} \frac{\partial g_{ij}}{\partial v}(\omega, v)\,, \quad \sup_{\omega\in\Omega} h_{ij}(\omega) \leq \sup_{v\geq 0\,,\,\omega\in\Omega} \frac{\partial g_{ij}}{\partial v}(\omega, v)\,,$$

and (C5) for (5.1). From the definition of h_{ij} and (C6)* we deduce that the irreducible sets for the families $(6.7)_\omega$ and $(5.2)_\omega$ coincide. Consequently, Theorem 6.3 (see Remark 6.4) applies to this case, and we deduce that if $z_0 \geq_D 0$ and J_l is a compartment with some outflow of material, then

$$\lim_{t\to\infty} \hat{z}_i(t, \omega, z_0) = 0 \qquad \text{for each } i \in J_0 \cup J_l\,.$$

The same happens for $z_0 \leq_D 0$ because the systems are linear.

Let $z(\omega) = x(\omega) - y(\omega)$ for each $\omega \in \Omega$. It is easy to check $\hat{z}(t, \omega, z(\omega)) = z(\omega{\cdot}t)(0)$ for all $\omega \in \Omega$ and $t \geq 0$. Moreover, we can find $z_1 \leq_D 0$ and $z_0 \geq_D 0$ such that $z_1 \leq_D z(\omega) \leq_D z_0$ for each $\omega \in \Omega$. Hence, the monotonicity of the induced skew-product semiflow and the positivity of $\widehat{D}^{-1}$ yields

$$\hat{z}(t, \omega, z_1) \leq z(\omega{\cdot}t)(0) \leq \hat{z}(t, \omega, z_0) \quad \text{for all } \omega \in \Omega\ t \geq 0\,,$$

from which we deduce that $z_i \equiv 0$ for all $i \in J_0$, $i \in J_l$ and (i) and (ii) follow. □

As a consequence, under the same assumptions of the previous theorem, when for all $l \in \{1, \ldots, k\}$ there is an outflow of material from one of the compartments in J_l, there is a unique minimal set $K = \{(\omega, x(\omega)) \mid \omega \in \Omega\}$ in $\Omega \times BU_D^+$ attracting all the solutions with initial data in BU_D^+; i.e.,

$$\lim_{t\to\infty} \|z(t, \omega, x_0) - x(\omega{\cdot}t)(0)\| = 0\,, \qquad \text{whenever } \ x_0 \geq_D 0\,.$$

Moreover, $x \not\equiv 0$ if and only if there is some $j \in \{1, \ldots, m\}$ such that $\widetilde{I}_j \neq 0$; i.e., there is some inflow into one of the compartments C_j.

For the next result, in addition to hypotheses (C1)–(C5) and (C6)* we will assume the following hypothesis:

(C7) If $K_1 = \{(\omega, x(\omega)) \mid \omega \in \Omega\}$ and $K_2 = \{(\omega, y(\omega)) \mid \omega \in \Omega\}$ are two minimal subsets of $\Omega \times BU_D^+$ such that $x(\omega) \leq_D y(\omega)$ and $D_i x(\omega_0) = D_i y(\omega_0)$ for some $\omega_0 \in \Omega$ and $i \in \{1, \ldots, m\}$, then $x(\omega) = y(\omega)$ for each $\omega \in \Omega$, i.e., $K_1 = K_2$.

Note that if $D_i x(\omega_0) = D_i y(\omega_0)$ holds for some $\omega_0 \in \Omega$ and $i \in \{1, \ldots, m\}$, then from hypothesis (F5) we deduce that it holds for each $\omega \in \Omega$.

Hypothesis (C7) is relevant when it applies to closed systems, and it holds in many cases studied in the literature. A closed system satisfying (C7) is irreducible. Systems with a unique compartment, studied by Arino and Bourad [1] and Krisztin and Wu [19], satisfy (C7). It follows from Theorem 6.3 that irreducible closed systems described by FDEs (see Arino and Haourigui [2]) satisfy (C7). Closed systems given by Wu [27], and Wu and Freedman [28] in the strongly ordered case, also satisfy (C7).

DEFINITION 6.8. *Let $K_1 = \{(\omega, x(\omega)) \mid \omega \in \Omega\}$ and $K_2 = \{(\omega, y(\omega)) \mid \omega \in \Omega\}$ be two minimal subsets. It is said that $K_1 <_D K_2$ if $x(\omega) <_D y(\omega)$ for each $\omega \in \Omega$.*

Hypothesis (C7) allows us to classify the minimal subsets in terms of the value of their total mass, as shown in the next result.

THEOREM 6.9. *Assume that system* (5.1) *is closed (i.e., $\widetilde{I}_i \equiv 0$ and $\widetilde{g}_{0i} \equiv 0$ for each $i \in \{1, \ldots, m\}$), and hypotheses* (C1)–(C5), (C6)*, *and* (C7) *hold. Then for*

each $c > 0$ there is a unique minimal subset K_c such that $M|_{K_c} = c$. Moreover, $K_c \subset \Omega \times BU_D^+$ and $K_{c_1} <_D K_{c_2}$ whenever $c_1 < c_2$.

Proof. Since the minimal subsets are copies of the base, and the total mass (5.4) is constant along the trajectories and increasing for the D-order because $\widehat{D}^{-1}$ is positive, it is easy to check that given $c > 0$ there is a minimal subset $K_c \subset \Omega \times BU_D^+$ such that $M|_{K_c} = c$.

Let $\widehat{D}$ be the isomorphism of BU defined by the relation (3.6). For each $x \in BU$ we define $x^+ = \widehat{D}^{-1} \sup(0, \widehat{D}x)$. Hence $0 \leq_D x^+$, $x \leq_D x^+$, and if $y \in BU$ with $x \leq_D y$ and $0 \leq_D y$, then $x^+ \leq_D y$.

Since the semiflow is monotone, from $x \leq_D x^+$ we deduce that $u(t,\omega,x) \leq_D u(t,\omega,x^+)$. Since the system is closed, $u(t,\omega,0) = 0$, and from $0 \leq_D x^+$ we check that $0 \leq_D u(t,\omega,x^+)$. Consequently $u(t,\omega,x)^+ \leq_D u(t,\omega,x^+)$ for each $t \geq 0$.

Next we check that if $K = \{(\omega, x(\omega)) \mid \omega \in \Omega\}$ is minimal, the same happens for $K^+ = \{(\omega, x(\omega)^+) \mid \omega \in \Omega\}$. Since $x(\omega{\cdot}t) = u(t,\omega,x)$ for each $t \geq 0$, we deduce that $x(\omega{\cdot}t)^+ = u(t,\omega,x(\omega))^+ \leq_D u(t,\omega,x(\omega)^+)$, and the fact that $\widehat{D}^{-1}$ is positive yields $x(\omega{\cdot}t)^+ \leq u(t,\omega,x(\omega)^+)$ for each $t \geq 0$. In addition, since the total mass (5.4) is constant along the trajectories and increasing for the D-order, we deduce that $M(\omega, x(\omega)^+) = M(\omega{\cdot}t, u(t,\omega,x(\omega)^+)) \geq M(\omega{\cdot}t, u(t,\omega,x(\omega))^+) = M(\omega{\cdot}t, x(\omega{\cdot}t)^+)$ for each $t \geq 0$. Moreover, since $x(\omega)^+$ is a continuous function in ω and Ω is minimal, a similar argument to the one given in (ii) of Theorem 6.3 shows that $M(\omega, x(\omega)^+)$ is constant on Ω and, consequently, $M(\omega{\cdot}t, u(t,\omega,x(\omega)^+) = M(\omega{\cdot}t, x(\omega{\cdot}t)^+)$ for each $\omega \in \Omega$ and $t \geq 0$. Hence, from (5.4) we conclude that

$$0 = \sum_{i=1}^{m} D_i(u(t,\omega,x(\omega)^+) - x(\omega{\cdot}t)^+)\,,$$

that is, $D(u(t,\omega,x(\omega)^+)) = D(x(\omega{\cdot}t)^+)$ for each $\omega \in \Omega$ and $t \geq 0$. In addition, it is easy to check that $(\varphi_s)^+ = (\varphi^+)_s$ whenever $\varphi \in BU$ and $s \leq 0$, from which we deduce that $D((u(t,\omega,x(\omega)^+))_s) = D((x(\omega{\cdot}t)^+)_s)$ for each $s \leq 0$, $t \geq 0$, and $\omega \in \Omega$. That is, $\widehat{D}(u(t,\omega,x(\omega)^+)) = \widehat{D}(x(\omega{\cdot}t)^+)$ for each $t \geq 0$ and $\omega \in \Omega$, and since $\widehat{D}$ is an isomorphism $u(t,\omega,x(\omega)^+) = x(\omega{\cdot}t)^+$ for each $t \geq 0$ and $\omega \in \Omega$, which shows that K^+ is a minimal subset, as stated. Let $K_1 = \{(\omega, x(\omega)) \mid \omega \in \Omega\}$ and $K_2 = \{(\omega, y(\omega)) \mid \omega \in \Omega\}$ be two minimal subsets such that $M|_{K_i} = c$ for $i = 1, 2$. We fix $\omega \in \Omega$. The change of variable $\widehat{z}(t) = z(t) - y(\omega{\cdot}t)$ takes $(5.2)_\omega$ to

$$\frac{d}{dt} D\widehat{z}_t = G(\omega{\cdot}t, \widehat{z}_t)\,, \quad t \geq 0\,,\ \omega \in \Omega\,,$$

where $G(\omega{\cdot}t, \widehat{z}_t) = F(\omega{\cdot}t, \widehat{z}_t + y(\omega{\cdot}t)) - F(\omega{\cdot}t, y(\omega{\cdot}t))$. It is not hard to check that this is a new family of compartmental systems satisfying the corresponding hypotheses (C1)–(C5) and (C6)*, and

$$\widehat{K} = \{(\omega, x(\omega) - y(\omega)) \mid \omega \in \Omega\}$$

is one of its minimal subsets. As before

$$\widehat{K}^+ = \{(\omega, (x(\omega) - y(\omega))^+) \mid \omega \in \Omega\}$$

is also a minimal subset, and hence

$$K^+ = \{(\omega, y(\omega) + (x(\omega) - y(\omega))^+) \mid \omega \in \Omega\} = \{(\omega, z(\omega)) \mid \omega \in \Omega\}$$

is a minimal set for the initial family. For each $\omega \in \Omega$ we have $z(\omega) \geq_D y(\omega)$.

Let us assume that $Dz(\omega) \gg Dy(\omega)$ for each $\omega \in \Omega$, which implies that $D((x(\omega) - y(\omega))^+) \gg 0$ for each $\omega \in \Omega$. Consequently, $D((x(\omega) - y(\omega))_s^+) = D(((x(\omega) - y(\omega))_s)^+) = D((x(\omega \cdot s) - y(\omega \cdot s))^+) \gg 0$ for each $s \leq 0$, and we deduce that $\widehat{D}x(\omega) > \widehat{D}y(\omega)$, i.e., $x(\omega) >_D y(\omega)$ for each $\omega \in \Omega$, and $M|_{K_1} > M|_{K_2}$, a contradiction. Hence, there are an $\omega_0 \in \Omega$ and an $i \in \{1, \ldots, m\}$ such that $D_i z(\omega_0) = D_i y(\omega_0)$, and hypothesis (C7) provides that $z(\omega) = y(\omega)$ for each $\omega \in \Omega$. That is, $(x(\omega) - y(\omega))^+ \equiv 0$ for each $\omega \in \Omega$, or equivalently $x(\omega) - y(\omega) \leq_D 0$ for each $\omega \in \Omega$. Finally, as before, from $M|_{K_1} = M|_{K_2}$ we conclude by contradiction that $x(\omega) = y(\omega)$ for each $\omega \in \Omega$, and the minimal set K_c is unique, as stated. The same argument shows that $K_{c_1} <_D K_{c_2}$ whenever $c_1 < c_2$ and finishes the proof. ∎

COARSENING IN NONLOCAL INTERFACIAL SYSTEMS*

DEJAN SLEPČEV†

Abstract. We consider coarsening in interfacial systems driven by nonlocal energies. Of particular interest are the nonlocal Cahn–Hilliard equation and models of biological aggregation. The energies considered cause the system to separate into phases. The pattern of interfaces evolves under nonlocal surface-tension-type effects. The typical length scales grow and the pattern coarsens. We prove a rigorous upper bound on the coarsening rate. The proof uses the energy-based approach to estimates on rate of coarsening introduced by Kohn and Otto [*Comm. Math. Phys.*, 229 (2002), pp. 375–395]. To show the required estimates on the flatness of the energy landscape we develop a geometric approach which is applicable to a wider class of problems, which includes ones based on local, gradient-type energies.

Key words. coarsening, interpolation inequality, nonlocal equation, phase segregation, biological aggregation, Wasserstein distance

1. Introduction.

Our main focus is systems driven by nonlocal energies. Of particular interest are nonlocal Cahn–Hilliard-type equations and equations modeling biological aggregation. The nonlocal Cahn–Hilliard equations that we consider were derived by Giacomin and Lebowitz [8] as limits of the lattice-gas dynamics modeling phase segregation in binary alloys. In this setting, they represent a refinement in modeling over the standard, fourth order Cahn–Hilliard equations. The equations modeling biological aggregation were derived by Topaz, Bertozzi, and Lewis [18].

The mathematical descriptions of these systems are rather similar. Both equations are gradient flows of the same general energy:

$$E(u) := \iint (u(x) - u(y))^2 K(x-y)dxdy + \int W(u(x))dx. \tag{1}$$

Here $K \geq 0$ is the interaction kernel, and W is a double-well potential whose minima are at 0 and 1. We leave the domain of integration vague at the moment. Heuristically it is convenient to consider the domains to be $\mathbb{R}^N \times \mathbb{R}^N$ and $\mathbb{R}^N$, respectively. However, for technical reasons, when stating and proving rigorous results we consider the problem on a finite domain.

The equations we study are gradient flows of the energy, in the appropriate metrics:

$$u_t - \nabla \cdot \left(\mu(u) \nabla \left(\frac{\delta E}{\delta u} \right) \right) = 0. \tag{2}$$

That is,

$$u_t - \nabla \cdot \left(\mu(u) \nabla \left(4 \int K(y)dy\, u - 4K * u + W'(u) \right) \right) = 0. \tag{3}$$

For both equations the mobility μ is a nonnegative function. More precisely, for the aggregation equation $\mu(u) = u$, while for the nonlocal Cahn–Hilliard equation $\mu > 0$ on $[0, 1]$.

The second term of the energy causes the system to separate into phases, while the first term penalizes the existence of interfaces. The energy E is a nonlocal counterpart of the energy

$$E_{loc}(u) := \int \frac{1}{2}|\nabla u(x)|^2 + W(u(x))dx. \tag{4}$$

Roughly speaking, both of the energies measure interfacial area. The longer the length scale in the system, the better the approximation to the interfacial area. More precisely, for both energies, the Γ-limit of the appropriately rescaled energy is the functional measuring perimeter of the set occupied by one of the phases

$$E \xrightarrow{\Gamma} \text{const.}\, E_{per}.$$

E_{per} is defined for BV functions with the range $\{0, 1\}$. For E_{loc} this is the result of Modica and Mortola [15] (see also [14]), while for E it was proven by Alberti et al. [2] (see also [1]). Moreover matched asymptotics arguments (by Giacomin and Lebowitz [9] and by Bertozzi and Slepčev [4]) show that the sharp-interface limits of the dynamics described by (2) are the Mullins–Sekerka (MS) equation for the nonlocal Cahn–Hilliard equation and the Hele–Shaw (HS) equation for the aggregation model.

After the interfaces have formed, the system slowly evolves, reducing the interfacial area. During this process the length scales that characterize the coarseness of a configuration grow. We are interested in the rate at which these length scales grow—the rate of coarsening. The fact that the sharp interface limits, (MS) and (HS), are both invariant under the scaling $x \to \lambda x$, $t \to \lambda^3 t$ suggests that the typical length scale grows as $t^{1/3}$. We prove a weak formulation of this statement, following the technique of Kohn and Otto [10], who proved the result for gradient flows of local energies (4). We use the energy as the measure of the coarseness of the system. In particular let $\overline{E}$ be the energy density, that is, the energy per unit volume. Note that $\overline{E}$ has units of $1/\textit{length}$. We show a weak version of the statement

$$\overline{E} \gtrsim t^{-1/3}.$$

This provides an upper bound on rate of coarsening as it shows that the interfacial area cannot decay faster than the given rate.

Outline. In the remainder of the introduction we discuss the gradient-flow structure of the equations, and the framework for obtaining rigorous result on coarsening rates introduced by Kohn and Otto. We also introduce the two applications we have in mind in more detail. In section 2 we list the assumptions needed and give the precise formulation of the main results on the rate of coarsening. In particular we present a relaxed formulation of the abstract Kohn–Otto framework that is applicable to weak solutions of gradient-flow equations. We also show that the "geodesic distance" associated to the metric of the configuration space can be utilized even when the mobility is nonlinear. In section 3 we present the proof of the bound on the rate of coarsening. The main technical ingredient, the interpolation inequality, is proved in section 4. The approach we take in proving the interpolation inequality is general; essentially the same proof covers both types of mobilities and both nonlocal and local energies. We illustrate the application to local energies in subsection 4.1.

1.1. Gradient flow structure. We now introduce the geometric structure of (2). It is based on the formal Riemannian viewpoint developed by Otto [16]. Equation (2) can be understood as a gradient flow of the energy (1) on the manifold of configurations. Since the equation is in divergence form it preserves the integral of u over the space. Thus the solution of the equation is a path on the manifold of functions with the same integral.

At each point the tangent space is the set of possible perturbations, all of which have mean zero. The local metric is defined as follows: Let s_1, s_2 be two tangent vectors at u. Then

$$g_u(s_1, s_2) = \int \mu(u) \nabla p_1 \cdot \nabla p_2, \tag{5}$$

where

$$-\nabla \cdot (\mu(u) \nabla p_i) = s_i \quad \text{for } i = 1, 2.$$

Equation (2) is the gradient flow of energy (1) with respect to the metric (5), that is, for every tangent vector s

$$g(u_t, s) = -\frac{\delta E}{\delta u}[s].$$

Considering the configuration space as a manifold enables us to measure the steepness of the energy landscape in a certain sense. This information provides bounds on the speed of the dynamics.

In particular the local metric gives rise to a global metric on the manifold. Given a regular enough path, $v(s)$ for, say, $s \in [0, 1]$, on the manifold, we can measure its length

$$\text{length}(v) = \int_0^1 \sqrt{g_{v(s)}(v', v')}\, ds.$$

We can then define the global metric on the manifold: Let the distance of u_1 and u_2 be

$$d(u_1, u_2) = \inf\{\text{length}(v) \,:\, v \text{ is a path connecting } u_1 \text{ and } u_2\}.$$

It turns out that when $\mu = \text{const.}$, then $d(u_1, u_2)$ is a multiple of the H^{-1} norm, while for $\mu(u) = u$ the distance becomes the Wasserstein metric.

1.2. Kohn–Otto framework. Kohn and Otto [10] introduced an approach for obtaining information on the flatness of the energy landscape, and consequently on the rate of coarsening. The approach is robust and has been applied to studies of coarsening in epitaxial growth, mean-field models, thin-liquid films, and other systems [6, 7, 5, 11, 12, 17]. See also [13] for a related result.

We first present it in the abstract setting used in [17], which applies to gradient flows. Consider an energy E on a Riemannian manifold $(\mathcal{M}, g)$. The metric g introduces a global distance on $\mathcal{M}$, which we denote by d.

PROPOSITION 1. *Let $h^* \in \mathcal{M}$. Let $h : \mathbb{R}_+ \to \mathcal{M}$ be a solution of*

$$h_t \;=\; -\text{grad}E(h), \tag{6}$$

and let $h(0) = h_0$.

Assume that for some $\alpha \geq 0$ the interpolation inequality

$$E(h)\,\mathrm{dist}(h,h^*)^\alpha \geq 1 \quad \text{for all } h \in \mathcal{M} \text{ with } E(h) \leq \varepsilon \tag{7}$$

holds. Then for $\sigma \in (1, 1+\frac{2}{\alpha})$

$$\int_0^T E(h(t))^\sigma \, dt \gtrsim \int_0^T (t^{-\frac{\alpha}{\alpha+2}})^\sigma \, dt, \tag{8}$$

provided $T \gg \mathrm{dist}(h_0,h^*)^{\alpha+2}$ and $E(h(0)) \leq \varepsilon$.

Remark 1. The precise meaning of $\gtrsim$ and $\gg$ is the following: For all $\sigma \in (1, 1+\frac{2}{\alpha})$ there exists a constant $C = C(\alpha,\sigma)$ such that for all $\delta > 0$ there exists $C_\delta = C(\alpha,\sigma,\delta)$:

$$\int_0^T E(h(t))^\sigma \, dt \geq (1-\delta)C \int_0^T (t^{-\frac{\alpha}{\alpha+2}})^\sigma \, dt, \tag{9}$$

provided $T \geq C_\delta \,\mathrm{dist}(h_0,h^*)^{\alpha+2}$.

Proof of the proposition is based on the ODE arguments of [10] and can be found in [17].

We adapt Proposition 1 to our setting in section 2 (Theorem 2). In particular since the Riemannian structure is only formal, the theorem states precisely which elements of the geometric structure are needed. Furthermore it applies to weak solutions of the gradient flow equations.

The main technical difficulty in applying the proposition is showing the interpolation inequality. Section 4 is devoted to proving interpolation inequalities relevant to nonlocal energies.

1.3. Nonlocal Cahn–Hilliard equation. Equation (2) is a rescaled version of the model by Giacomin and Lebowitz [8, 9]. We introduce it in original variables below and, for completeness, present the rescaling needed.

The free energy is given by

$$\mathcal{E} = \frac{1}{4}\int_\Omega \int_{\mathbb{R}^N} K(x-y)(\rho(x)-\rho(y))^2 dxdy + \int_\Omega f_c(\rho(x))dx.$$

The associated gradient flow is

$$\rho_t - \nabla \cdot \left(\sigma(\rho)\,\nabla\left(\frac{\delta \mathcal{E}}{\delta \rho}\right)\right) = 0.$$

Here $K \geq 0$ is a smooth kernel with symmetry $K(x) = K(-x)$. Giacomin and Lebowitz assume that K is compactly supported, with support contained in Ω. This assumption is physically quite reasonable, but it is not necessary from the mathematical point of view. The function f_c is a double-well potential, symmetric about $\frac{1}{2}$ with minima at $\frac{1}{2} \pm m$. The mobility function σ is assumed to be smooth, symmetric about $\frac{1}{2}$, and positive on $(0,1)$, with

$$\sigma(0) = 0 \quad \text{and} \quad \sigma(1) = 0. \tag{GL1}$$

Let

$$f(\rho) = f_c(\rho) + \frac{\int_{\mathbb{R}^N} K(x)dx}{2}\left(\rho - \frac{1}{2}\right)^2.$$

Giacomin and Lebowitz assume that for some $c > 0$ and for all $\rho \in (0,1)$

$$\frac{1}{c} \le \sigma(\rho) f''(\rho) \le c. \tag{GL2}$$

This assumption is needed for the existence/uniqueness theory they use (it makes the equation uniformly parabolic), but is not directly required for the coarsening estimates.

Under the assumptions above, Giacomin and Lebowitz show that for initial datum $0 < \rho_0 < 1$, there exists a unique weak solution $\rho \in L^2([0,T], H^1(\Omega))$ with $\rho_t \in L^2([0,T], H^{-1}(\Omega))$ for any $T > 0$. Furthermore $0 < \rho < 1$.

Rescaling. We rescale the dependent variable, the potential, and the mobility so that the wells of the new potential are 0 and 1. Let

$$\begin{aligned} u &= \frac{1}{2m}\left(\rho - \frac{1}{2}\right) + \frac{1}{2}, \\ W_m(u) &= \frac{1}{4m^2} f_c(\rho) = \frac{1}{4m^2} f_c\left(2m\left(u - \frac{1}{2}\right) + \frac{1}{2}\right), \\ \mu_m(u) &= \sigma(\rho) = \sigma\left(2m\left(u - \frac{1}{2}\right) + \frac{1}{2}\right). \end{aligned}$$

Under this rescaling u solves (2) and is hence a gradient flow of (1).

1.4. Biological aggregation. Topaz, Bertozzi, and Lewis [18] introduced a model of biological aggregation that emerges due to "social forces" between individuals. That is, the individuals are attracted to other individuals of their species, but avoid overcrowding. The population is modeled by its density u. The velocity of individuals is modeled as

$$v = v_a + v_r = \nabla(K * u) - \nabla g(u),$$

where $v_a = \nabla(K * u)$ is the term modeling attraction to other individuals which are being sensed through the kernel K. The term modeling repulsion, v_r, is given by a local operator $v_r = -\nabla g(u)$, where g is an increasing function. The continuity equation then reads

$$u_t + \nabla \cdot (u\, v) = u_t + \nabla \cdot (u \nabla (K * u - g(u))) = 0.$$

From a biological perspective it is reasonable to assume that $g'(0) = 0$ and g is strictly convex. However, it is sufficient to assume that

$$\begin{aligned} &\text{the function } g'(z) - \int_{R^N} K(x)dx \text{ has exactly one zero on } \mathbb{R}^+, \\ &g'(0) < \int_{R^N} K(x)dx \quad \text{and} \quad \liminf_{z\to\infty} g'(z) - \int_{\mathbb{R}^N} K(x)dx > 0. \end{aligned} \tag{BA}$$

Under this assumption u solves (3) for some double-well potential W. More precisely, let $G(z) := \int_0^z g(s)ds$ and $\tilde{W}(z) := G(z) - \frac{1}{2}\int_{\mathbb{R}^N} K(x)dx\, z^2$. The condition (BA) implies that $\tilde{W}$ is concave at 0, and has exactly one inflection point. Thus we can define

$$W(z) := 4\left(\tilde{W}(z) - \left(\min_{s>0} \frac{\tilde{W}(s)}{s}\right) z\right).$$

Then W is a double-well potential on $[0,\infty)$ with one well at 0. It follows that

$$u_t - \nabla \cdot \left(u \nabla \left(\int_{\mathbb{R}^N} K(y)dy\, u - K * u + \frac{1}{4} W'(u) \right) \right) = 0,$$

which after scaling the time by factor 4 is (3).

On the level of the model, the equation provides information on why herds (or other animal groups) form, why they have an almost constant density, why they have sharp boundaries, and how they evolve. Numerical simulations conducted in one dimension in [18] also observe the coarsening phenomenon. The primary driving force for coarsening in one dimension is the nonlocal interaction via kernel K, as there are no surface-tension-like effect. The rate of coarsening depends on the decay of K at ∞. Nevertheless the rigorous bounds we prove still apply and are in fact optimal for certain kernels.

2. Statement of the result. When thinking about coarsening we have in mind an infinite domain on which coarsening persists for all time. However, building the theory for such solutions poses major challenges. We instead consider domains of finite size and prove results that are independent of the domain size. In particular we consider the domain $\Omega = [0,\Lambda]^N$. We investigate the dynamics of periodic configurations on $\mathbb{R}^N$ with period cell Ω. Thus we consider Ω with the topology of the torus $\mathbb{R}^N/(\Lambda\mathbb{Z})^N$. In particular the distances on Ω are measured on the torus, and thus may be different from the ones measured in $\mathbb{R}^N$.

Throughout the paper we use the following, somewhat nonstandard notation. For $U \subseteq \Omega$ and a function u,

$$⨍_U f(x)dx := \frac{1}{|\Omega|} \int_U f(x)dx \quad \text{and} \quad \|U\| := \frac{|U|}{|\Omega|}.$$

Let P be the maximal interval containing 1 on which $\mu > 0$:

$$P = \{z \,:\, z \le 1,\ \ \mu|_{[z,1]} > 0\} \cup \{z \,:\, z \ge 1,\ \ \mu|_{[1,z]} > 0\}.$$

The configuration space is

$$\mathcal{M} := L^1(\Omega, \overline{P}).$$

While the configurations are functions defined on Ω, when convenient we also consider them as periodic functions of $\mathbb{R}^N$.

To a configuration, u, we associate the energy density

$$\overline{E}(u) := ⨍_\Omega \int_{\mathbb{R}^N} (u(x) - u(y))^2 K(x-y)dxdy + ⨍_\Omega W(u(x))dx. \tag{10}$$

If the expression is not defined, we say that the energy density is infinite. Conditions on the interaction kernel, K, and the double-well potential, W, are described below.

We make the following assumptions on the interaction kernel K:

(K1) K is nonnegative and $K \in L^1(\mathbb{R}^N) \cap C^2(\mathbb{R}^N)$.

(K2) $K(x) = K(-x)$ for all $x \in \mathbb{R}^N$. (This condition ensures the symmetry of the interaction term in (10) with respect to x and y.)

(K3) $K(0) > 0$.

(K4) $K \in W^{2,1}(\mathbb{R}^N)$ and $\|K\|_{C^2(\mathbb{R}^N)} < \infty$.

The last condition is needed only for the existence theory [4]. Condition (K3) is not essential either, but significantly simplifies parts of the presentation. In particular it enables us to associate a length scale to a kernel in the following way: For $r > 0$ let

$$\kappa(x) := \frac{1}{|B(0,1)|}\chi_{B(0,1)}(x) \quad \text{and} \quad \kappa_r(x) := \frac{1}{r^N}\,\kappa\left(\frac{x}{r}\right), \tag{11}$$

where χ_U is the characteristic function of the set U. Given $r > 0$ let $h_K(r) := \sup\{c : K \geq c\kappa_r\}$. Note that by assumption (K3), $h_K(r) > 0$ for r small. It is not hard to prove that $h_K(r) \to 0$ as $r \to 0$ and also as $r \to \infty$. Consider the location of the maximum of $h_K(r)$. If there is more than one maximum, we pick the first one. More precisely let

$$r_K := \min\{r_{max} \mid h_K(r_{max}) = \max_{r>0} h_K(r)\}. \tag{12}$$

We let

$$H_K = h_K(r_K).$$

To state the conditions on the potential W we define

$$a := \fint_\Omega u(x,0)dx.$$

To simplify the presentation, from here on we restrict our attention only to

$$0 < a \leq \frac{1}{2}. \tag{13}$$

We assume the following:

(W1) W is a nonnegative continuous function.

(W2) $W(0) = W(1) = 0$ and $W > 0$ on $\overline{P}\backslash\{0,1\}$.

(W3) At least linear growth at $\pm\infty$: There exists a constant h_W such that $W(z) \geq 8h_W(z-1)$ for all $z \in P\cap(\frac{9}{8},\infty)$ and $W(z) \geq h_W|z|$ for all $z \in P\cap(-\infty,-\frac{a}{4})$. We can furthermore require

$$h_W \leq W(z) \text{ for all } z \in \left[\frac{a}{4},\frac{7}{8}\right].$$

The condition on growth of W is needed only if P is infinite.

We now state the main results. Theorem 2 is an adaptation of Proposition 1 that applies to the configuration spaces we are investigating. In particular the paths are given as weak solutions of the continuity equation. Having the gradient-flow structure is reduced to requiring a dissipation inequality. The theorem relies on interpolation inequalities we establish in section 4. In Corollary 3 we apply the theorem to the main equations of our interest. The classes of solutions of (3) studied in [9] and [4] satisfy the conditions of the theorem, and thus the bounds on coarsening hold.

Below, by C^{weak} we mean continuous with respect to weak topology of the target space.

THEOREM 2. *Let $\Omega = [0,\Lambda]^N$. Assume that conditions* (13), (K1)–(K3), *and* (W1)–(W3) *hold and that mobility $\mu(z) \equiv z$ or that $\mu \in C(P,(0,c_\mu])$. Suppose that $u \in C^{weak}([0,\infty),L^1(\Omega,\overline{P}))$ is a weak solution of*

$$u_t + \nabla \cdot J = 0$$

for some flux $J \in L^1(\Omega, \mathbb{R}^N)$. *Assume that the energy dissipation inequality holds: For almost all* $0 \le t_1 < t_2$

$$\int_{t_1}^{t_2} \int_\Omega \frac{1}{\mu(u)} |J|^2 dx dt \le -(E(u(t_2)) - E(u(t_1))). \tag{14}$$

In the case $\mu(z) \not\equiv z$ *we also need the regularity assumption that* $u(t) \in L^2(\Omega)$ *for all* $t \ge 0$ *and that the range of* $u(\cdot, 0)$ *is contained in* P. *Assume further that* $\limsup_{t\to 0+} \overline{E}(u(\cdot, t)) \ll 1$.

Then for all $\sigma \in (1, 2)$ *there exists a constant* $C = C(\sigma, a, H_K, r_K, c_\mu)$ *such that for all* $T \gg 1$

$$\int_0^T \overline{E}(u(t))^\sigma dt \ge C \int_0^T \left(t^{-\frac{1}{3}}\right)^\sigma dt. \tag{15}$$

The precise meaning of condition $\overline{E} \ll 1$ is that $\overline{E}$ has to be small enough for the interpolation inequality to hold. Precise values can be found in the statement of Theorem 6.

By weak solution we mean that for all $\phi \in C_c^\infty(\Omega \times [0, \infty))$

$$\iint_{[0,\infty)\times\Omega} u\phi_t + J \cdot \nabla\phi \, dx dt + \int_\Omega u(x, 0)\phi(x, 0) dx = 0.$$

Recall that we consider Ω with the topology of a torus, which means that the test functions used in the definition of a weak solution are also defined on the torus; in other words they are periodic.

The form of the equation ensures (via testing against test functions with only time dependence) that

$$\int_\Omega u(x, t) dx = \text{const}.$$

Note that the dissipation inequality (14) is an equality if u is a classical solution of the gradient flow (2), when $J = -\mu(u)\nabla\frac{\delta E}{\delta u}$.

COROLLARY 3. *Let* $\Omega = [0, \Lambda]^N$. *Assume that conditions* (K1)–(K4) *and* (W1)–(W3) *hold. Assume only one of the following holds:*

(i) $\mu(z) \equiv z$, $W \in C^2([0, \infty))$ *with* $W'' > -4\int_{\mathbb{R}^N} K(y)dy$ *on* $\mathbb{R}^+$, *and* u *is the solution of* (3) *in the sense of* [4] *with* $u(\cdot, 0) \in L^\infty(\Omega)$.

(ii) $\mu(z) \le c_\mu$ *for all* z, *conditions* (GL1) *and* (GL2) *hold, and* u *is a solution of* (3) *in the sense of* [9]. *Furthermore assume that the range of* $u(\cdot, 0)$ *is contained in the interior of* P.

(iii) $0 < \mu(z) \le c_\mu$ *for all* z, (GL2) *holds on* $\mathbb{R}$, *and* u *is a solution of* (3) *in the sense of* [9]. *Furthermore assume that* $u(\cdot, 0) \in L^\infty(\Omega)$.

Assume that $\limsup_{t\to 0+} \overline{E}(u(\cdot, t)) \ll 1$ *and* (13) *holds. Then for all* $\sigma \in (1, 2)$ *there exists a constant* $C = C(\sigma, a, H_K, r_K, c_\mu)$ *such that for all* $T \gg 1$

$$\int_0^T \overline{E}(u(t))^\sigma dt \ge C \int_0^T \left(t^{-\frac{1}{3}}\right)^\sigma dt. \tag{16}$$

Proof. In the first case the conditions of W imply that associated $g(z) := \int_{\mathbb{R}^N} K(x)dx + \frac{1}{4}W'(z)$ is an increasing function. This in turn implies that the conditions under which Bertozzi and Slepčev [4] proved existence of solutions of (3) hold.

Properties of solutions ensuring that the assumptions of Theorem 2 hold were also established. This implies the claim of the corollary.

Case (ii) the existence theory needed for Theorem 2 to apply was established by Giacomin and Lebowitz [9].

The case (iii) is in principle simpler than case (ii) and includes the constant mobility case. The only technical issue is that the L^∞ bounds used in [9] follow from condition (GL1). In our case appropriate bounds can be established, for example, as in [4]. □

3. Proof of Theorem 2. We seek to apply the framework of Proposition 1. However, the configuration space, $\mathcal{M}$, is not a true Riemannian manifold and the only remnant of the gradient flow structure is the energy dissipation inequality (14). Nevertheless arguments of the proof of the proposition can be adapted to include this setting. We define the "geodesic distance" on $\mathcal{M}$ as follows: Given $u_0, u_1 \in \mathcal{M}$ let us first define a representation of admissible paths between u_0 and u_1:

$$\mathcal{A}(u_0,u_1) := \Big\{ (u,J) \ : u:[0,1]\to\mathcal{M}, J\in L^1(\Omega\times[0,1],\mathbb{R}^N) \text{ such that}$$
$$u_t + \nabla\cdot J = 0 \quad \text{on } \Omega\times[0,1] \text{ weakly},$$
$$u\in C^{weak}([0,1],L^1(\Omega)) \text{ and } u(0)=u_0, u(1)=u_1, \text{ and}$$
$$\int_0^1\int_\Omega \frac{1}{\mu(u(x,t))}\,|J(x,t)|^2 dxdt < \infty\Big\}.$$

We define

$$d^2(u_0,u_1) := \inf_{(u,J)\in\mathcal{A}} \int_0^1\int_\Omega \frac{1}{\mu(u(x,t))}\,|J(x,t)|^2 dxdt. \tag{17}$$

Here $\frac{0}{0}=0$. We note that d may, in general, be infinite. It follows from the definition that d satisfies the triangle inequality. This can be shown by concatenating the appropriate test flows (with optimally rescaled times).

Let u be as in the statement of the theorem. We define

$$L(t) := d(u(t),a), \qquad \overline{L}(t) := \frac{1}{\sqrt{|\Omega|}}\, d(u(t),a). \tag{18}$$

In the case $\mu(u)=u$ it follows from the characterization of d given below in (19) that $L(t)$ is finite for all t. In the other case, from the assumption on the range of u_0 it follows that $L(0)$ is finite. To see this it is enough to consider the test pair $(\tilde{u},\tilde{J})$ with $\tilde{u}(s)=u_0+s(a-u_0)$ for $s\in[0,1]$ and $\tilde{J}=\nabla p$, where p solves $-\Delta p = a-u_0$. The fact that $L(t)$ is finite for all t then follows from the argument for continuity of L given in Lemma 4.

Let

$$\overline{E}(t) := \overline{E}(u(t)).$$

From (14) we have that $\overline{E}$ is nonincreasing almost everywhere. We now modify $\overline{E}$ on a set of measure 0 to ensure that it is nonincreasing:

$$\overline{E}_{new}(t) = \min\{\liminf_{s\to t-} \overline{E}(s), \overline{E}(t)\}.$$

Inspecting the proof of Proposition 1 from [17] shows that in addition to the interpolation inequality, one only needs the inequality

$$\left(\frac{d\overline{L}}{d\overline{E}}\right)^2 \leq -\frac{dt}{d\overline{E}}$$

(since $\overline{E}$ is nonincreasing, $\overline{L}$ can be considered as a function of $\overline{E}$), which follows from the more familiar form of the dissipation inequality,

$$\left(\frac{d\overline{L}}{dt}\right)^2 \leq -\frac{d\overline{E}}{dt},$$

where both inequalities are to be understood as a comparison of measures (with given densities). The latter inequality in turn follows from the assumption (14). We prove these claims in Lemmas 4 and 5.

To be able to prove the interpolation inequalities we need a more workable form of d. In the case $\mu(u) = u$ the distance d is nothing else than the Wasserstein distance. This was shown by Benamou and Brenier [3] (see also section 8.1 in Villani's book [19]):

(19)
$$d_W(u_0,u_1)^2 \;=\; \inf\left\{\iint_{\Omega\times\Omega}|x-y|^2 d\pi(x,y) \;\Big|\; \int_\Omega d\pi(\cdot,y)=u_0,\ \int_\Omega d\pi(x,\cdot)=u_1\right\}.$$

The distance above, $|x-y|$, is taken on torus Ω.

In the case $\mu(u) \leq c_\mu$ first note that from the definition of the distance (17), it follows that the distance corresponding to $\mu(u)$ is greater than the distance corresponding to constant mobility c_μ. Thus

$$\overline{L}_\mu \geq \overline{L}_{c_\mu} = \frac{1}{c_\mu}\overline{L}_1.$$

Thus it is enough to establish the interpolation inequality for $\overline{L} = \overline{L}_1$. But for mobility equal to one, the distance is the H^{-1} norm. More precisely, for $u_0, u_1 \in \mathcal{M} \cap L^2(\Omega)$, $\int_\Omega u_1 - u_0 dx = 0$, and hence we can consider the following representation of the H^{-1} norm:

$$d(u_0,u_1)^2 = \|u_0-u_1\|_{H^{-1}}^2 = \int_\Omega |\nabla p|^2 dx,$$

where $p \in H^2(\Omega)$ (p is periodic by topology of Ω) is a solution of

$$-\Delta p = u_1 - u_0.$$

Proof of this claim is straightforward; it relies on convexity in J of the functional on the right-hand side of (17) and the observation that $J = \nabla p$, along with $u(t) = u_0 + t(u_1 - u_0)$, minimizes the action functional. One can also show that for $u \in \mathcal{M} \cap L^2(\Omega)$

(20)
$$\overline{L}(u) = \max_{\xi\in H^1(\Omega),\ \xi\not\equiv\text{const.}} \frac{⨍_\Omega (u-a)\xi dx}{\sqrt{⨍_\Omega |\nabla\xi|^2 dx}}$$

by using Cauchy–Schwarz inequality to show that $\xi = p$ (with $u_1 = u$ and $u_2 = a$) is the maximizing function. Given that $u(t) \in \mathcal{M} \cap L^2(\Omega)$ for all t we can use this characterization.

Thus to complete the proof of the theorem one only needs the interpolation inequalities established in section 4.

We now prove the two lemmas that were used in the arguments above.

LEMMA 4. *Assume that u satisfies the conditions of Theorem 2 and $\overline{L}$ is defined in* (18). *Then $\overline{L}$ is a continuous function and for almost all $t \geq 0$ and $h > 0$*

$$\left(\frac{\overline{L}(u(t+h)) - \overline{L}(u(t))}{h}\right)^2 \leq -\frac{\overline{E}(u(t+h)) - \overline{E}(u(t))}{h}.$$

Proof. By the assumptions of the theorem u is a distributional solution of

$$u_t + \nabla \cdot J = 0 \qquad \text{on } \Omega \times [t, t+h].$$

Moreover it follows from assumption (14) for all $t \geq 0$ and all $h > 0$ that

$$\int_t^{t+h} \int_\Omega \frac{1}{\mu(u)} |J|^2 dx dt \leq \limsup_{s \to 0+} E(u(s)) < \infty.$$

Note that it was also assumed that $u \in C^{weak}([t, t+h], L^1(\Omega))$. Thus (u, J), after appropriate rescaling in time, belongs to $\mathcal{A}(u(t), u(t+h))$. By the triangle inequality,

$$\begin{aligned}\left(\overline{L}(u(t+h)) - \overline{L}(u(t))\right)^2 &\leq \inf_{(\tilde{u},\tilde{J}) \in \mathcal{A}(u(t),u(t+h))} \int_0^1 \int_\Omega \frac{1}{\mu(\tilde{u}(x,s))} |\tilde{J}(x,s)|^2 \, dx \, ds \\ &\leq h \int_0^h \int_\Omega \frac{1}{\mu(u(x,t+s))} |J|^2 dx ds.\end{aligned}$$

Thus $\overline{L}$ is a continuous function. Dividing the above by h^2 and using (14) gives that for almost all $t \geq 0$ and $h > 0$

$$\begin{aligned}\left(\frac{\overline{L}(u(t+h)) - \overline{L}(u(t))}{h}\right)^2 &\leq \frac{1}{h} \int_0^h \int_\Omega \frac{1}{\mu(u(x,t+s))} |J|^2 dx ds \\ &\leq -\frac{\overline{E}(u(t+h)) - \overline{E}(u(t))}{h}. \qquad \square\end{aligned}$$

For a function e on $\mathbb{R}$ let us define $e(t+) := \lim_{s \to t+} e(s)$ and $e(t-) := \lim_{s \to t-} e(s)$.

LEMMA 5. *Let e be a nonnegative, nonincreasing function on $[0, \infty)$. Let l be a continuous function on $[0, \infty)$, such that*

$$\left(\frac{l(t_2) - l(t_1)}{t_2 - t_1}\right)^2 \leq -\frac{e(t_2) - e(t_1)}{t_2 - t_1} \qquad \text{for almost all } t_2 > t_1 \geq 0. \tag{21}$$

Then $l(t)$ is an absolutely continuous function on $[0, \infty)$ and for all $\tau_2 > \tau_1 \geq 0$

$$\int_{\tau_1}^{\tau_2} \left(\frac{dl}{dt}\right)^2 dt \leq e(\tau_1+) - e(\tau_2-).$$

Furthermore, consider $t(e) := \sup\{t \,:\, e(t) \geq e\}$, the "inverse" of the function e and $l(e) := l(t(e))$. Then

$$\left(\frac{l(e_2) - l(e_1)}{e_2 - e_1}\right)^2 \leq -\frac{t(e_2) - t(e_1)}{e_2 - e_1} \qquad \text{for all } e(0) \geq e_1 > e_2 \geq 0.$$

Consequently l is an absolutely continuous function of e, and for all $e(0) \geq e_1 > e_2 \geq 0$

$$\int_{e_2}^{e_1} \left(\frac{dl}{de}\right)^2 de \leq t(e_2+) - t(e_1-).$$

Proof. If $e(0) = 0$, the proof is trivial. So assume $e(0) > 0$. Continuity of l implies that

$$\left(\frac{l(t_2) - l(t_1)}{t_2 - t_1}\right)^2 \leq -\frac{e(t_2-) - e(t_1+)}{t_2 - t_1} \qquad \text{for all } t_2 > t_1 \geq 0.$$

Let $\varepsilon > 0$ and $\delta := \varepsilon^2/e(0)$. Let $[x_i, y_i]$ for $i = 1, \ldots, m$ be a family of disjoint intervals on $[0, \infty)$ of total length less than δ:

$$\sum_{i=1}^{m} y_i - x_i < \delta.$$

Then

$$\begin{aligned}\sum_{i=1}^{m} |l(y_i) - l(x_i)| &\leq \sum_{i=1}^{m} \sqrt{e(x_i) - e(y_i)}\,\sqrt{y_i - x_i} \\ &\leq \sqrt{\sum_{i=1}^{m} e(x_i) - e(y_i)}\,\sqrt{\sum_{i=1}^{m} y_i - x_i} \\ &\leq \sqrt{e(0)}\,\sqrt{\delta} = \varepsilon.\end{aligned}$$

So l is absolutely continuous.

To prove the second claim note that for any $h > 0$

$$\begin{aligned}\int_{\tau_1}^{\tau_2} \left(\frac{l(t+h) - l(t)}{h}\right)^2 dt &\leq \int_{\tau_1}^{\tau_2} \frac{e(t+) - e(t+h-)}{h} dt \\ &\leq \frac{1}{h}\left(\int_{\tau_1}^{\tau_1+h} e(t+)dt - \int_{\tau_2}^{\tau_2+h} e(t-)dt\right).\end{aligned}$$

By taking the $\liminf_{h\to 0}$ and using Fatou's lemma we obtain

$$\int_{\tau_1}^{\tau_2} \left(\frac{dl}{dt}\right)^2 dt \leq e(\tau_1+) - e(\tau_2+).$$

Now use this claim on interval $(\tau_1, \tau_2 - \varepsilon)$ and take the limit as $\varepsilon \to 0$.

To prove the remaining claims, note that

$$(l(t(e_2)) - l(t(e_1)))^2 \leq (e(t(e_2)-) - e(t(e_1)+))(t(e_2) - t(e_1)).$$

Observing that $e(t(e_2)-) \geq e_2$ and $e(t(e_1)+) \leq e_1$ yields the desired inequality. The claims then follow from the arguments presented above. ∎

4. Interpolation inequalities. In this section we prove the interpolation inequalities needed. As shown in section 3 we only need to consider the $\overline{L}$ corresponding Wasserstein distance (19) and to H^{-1} norm (20).

The proof we present is general and extends to local energies, which we discuss in subsection 4.1. It also captures the improved constants established in [5]; see Remark 2. It is based on simple geometric heuristic. Consider function $\tilde{u}$ with range $\{0,1\}$ and $\kappa_r * \tilde{u}$, its average over ball of radius r. Then for r small

$$\int |\tilde{u} - \kappa_r * \tilde{u}| dx$$

contains information about the interfacial area, while for r large it carries information on the distance $d(\tilde{u}, a)$. This allows us to interpolate between the energy and the distance. We divided the proof into steps and present the motivation at their beginning.

THEOREM 6 (interpolation inequality). *Let $0 < a \leq \frac{1}{2}$. Assume K satisfies conditions* (K1)–(K3) *and W satisfies* (W1)–(W3). *There exists a constant $C = C(a, h_W, r_K, H_K) > 0$ such that for all $\Lambda > 0$ and all configurations $u \in \mathcal{M}$ for which $\overline{E}(u) < \frac{a}{64}\left(\frac{h_W}{1+h_W}\right)H_K$, and in the H^{-1} case also $\overline{E}(u) < \frac{1}{2^{N+2}}\frac{ah_W}{20}H_K$, the following holds:*

$$\overline{E}(u)\overline{L}(u) \geq C. \tag{22}$$

The constant $C = c(N)r_K\left(\frac{h_W}{1+h_W}\right)a^{3/2}H_K$.

Proof. Step 1: Reduction. Let κ_{r_K} be as defined by (11) and (12). We use the notation $\kappa_r := \kappa_{r_K}$. To make the distinction between energies, let $\overline{E}_K$ and $\overline{E}_{\kappa_r}$ be the energy densities corresponding to kernels K and κ_r, respectively. Note that $\overline{E}_K \geq H_K\overline{E}_{\kappa_r}$. So it is enough to show the above claim for κ_r, with $r_K = r$ and $H_K = 1$. Therefore from here on we consider only $K = \kappa_r$.

Step 2: u is separated into phases. We show that any low-energy-density configuration, u, has a significant portion of the mass on the set where values of u are close to 1. More precisely:

Claim. Let $A := \{x : u(x) \geq \frac{7}{8}\}$ and $\tilde{u} := \chi_A$. For future reference let $\underline{A} := \{x : u(x) < \frac{a}{4}\}$ and let I be the interfacial region, $I := \Omega\backslash(A \cup \underline{A})$. Assume $\overline{E}(u) < \frac{3}{32}ah_W$. Then

$$\|A\| = \frac{|A|}{|\Omega|} = \fint_\Omega \tilde{u}(x)dx > \frac{1}{2}\fint_\Omega u(x)dx = \frac{a}{2} \quad \text{and} \quad \|A\| \leq 2a. \tag{23}$$

Proof. Due to assumption (W3)

$$\overline{E}(u) \geq h_W\left(\left\|\left\{\frac{a}{4} < u \leq \frac{7}{8}\right\}\right\| + \left\|\left\{\frac{9}{8} < u\right\}\right\|\right).$$

Consequently

$$\begin{aligned}
a = \fint_\Omega u dx &= \fint_{\{u \leq \frac{a}{4}\}} u dx + \fint_{\{\frac{a}{4} < u \leq \frac{7}{8}\}} u dx + \fint_{\{\frac{7}{8} < u \leq \frac{9}{8}\}} u dx + \fint_{\{\frac{9}{8} < u\}} u dx \\
&\leq \frac{a}{4} + \frac{7}{8}\left\|\left\{\frac{a}{4} < u \leq \frac{7}{8}\right\}\right\| + \frac{9}{8}\fint_\Omega \tilde{u}dx + \left\|\left\{\frac{9}{8} < u\right\}\right\| + \frac{1}{h_W}\fint_{\{\frac{9}{8} < u\}} W(u)dx \\
&\leq \frac{a}{4} + \frac{\overline{E}}{h_W} + \frac{9}{8}\fint_\Omega \tilde{u}dx + \frac{\overline{E}}{h_W} \\
&< \frac{a}{4} + \frac{3a}{16} + \frac{9}{8}\fint_\Omega \tilde{u}dx.
\end{aligned}$$

Therefore $\fint_\Omega \tilde{u}dx > \frac{a}{2}$.

To prove the second claim, note that

$$\begin{aligned} a = \fint_\Omega u(x)dx &\geq \frac{7}{8}\|A\| + \fint_{\{-\frac{a}{4}\leq a<0\}} u(x)dx + \fint_{\{u<-\frac{a}{4}\}} u(x)dx \\ &\geq \frac{7}{8}\|A\| - \frac{a}{4} - \frac{1}{h_W}\fint_\Omega W(u(x))dx \\ &\geq \frac{7}{8}\|A\| - \frac{a}{4} - \frac{\overline{E}}{h_W} \\ &\geq \frac{7}{8}\|A\| - \frac{a}{2}. \qquad \square \end{aligned}$$

Step 3*: Energy bounds a measure of interfacial area.*
Claim.

$$\fint_\Omega |\tilde{u} - \kappa_r * \tilde{u}|dx \leq \left(\frac{16}{9} + \frac{2}{h_W}\right)\overline{E}.$$

Heuristically, when r is small the expression on the left-hand side measures r times the area of the boundary of $\{\tilde{u} = 1\}$. More precisely the area is measured in such a way that features of size less than r are smoothed out, and thus neglected, to some extent.

Proof. We use the following notation for the sum of sets $X + Y := \{x + y \mid x \in X,\ y \in Y\}$. Using the fact that $\tilde{u}$ takes only values 0 and 1, we obtain

$$\begin{aligned} &\fint_\Omega \left|\tilde{u}(x) - \int_{\mathbb{R}^N} \kappa_r(x-y)\tilde{u}(y)dy\right|dx \\ &\qquad = \fint_\Omega \int_{\mathbb{R}^N} |\tilde{u}(x) - \tilde{u}(y)|\kappa_r(x-y)dydx \\ &\qquad \leq \frac{1}{|\Omega|}\left[\int_A \int_{\underline{A}+\Lambda\mathbb{Z}^N} + \int_{\underline{A}} \int_{A+\Lambda\mathbb{Z}^N} |\tilde{u}(x) - \tilde{u}(y)|^2\kappa_r(x-y)dydx \right. \\ &\qquad\qquad \left. + \int_I \int_{\mathbb{R}^N} + \int_\Omega \int_{I+\Lambda\mathbb{Z}^N} \kappa_r(x-y)dydx\right] \\ &\qquad \leq \left(\frac{3}{4}\right)^{-2} \fint_\Omega \int_{\mathbb{R}^N} |u(x) - u(y)|^2\kappa_r(x-y)dydx + 2\left\|\left\{\frac{a}{4} \leq u \leq \frac{7}{8}\right\}\right\| \\ &\qquad \leq \left(\frac{16}{9} + \frac{2}{h_W}\right)\overline{E}. \qquad \square \end{aligned}$$

Step 4. *Claim.* $\phi : (0,\infty) \to [0,\infty)$ defined by

$$\phi(s) := \fint_\Omega |\tilde{u} - \tilde{u} * \kappa_s|dx$$

is subadditive.

One should note that some other possible measures of surface area (for example, the volume of appropriate tubular neighborhood) do not have this property in general and may have a superlinear growth (for appropriate range of r).

Proof. Let $s = p + q$ for some $p, q > 0$. As in Step 3 we have

$$\phi(s) = \fint_\Omega \int_{\mathbb{R}^N} |\tilde{u}(x) - \tilde{u}(y)| \kappa_s(y) dy dx.$$

Now let $z = x - \frac{p}{s} y$. Using periodicity and the scaling properties of kernel κ_s one finds

$$\begin{aligned}\phi(s) &\le \fint_\Omega \int_{\mathbb{R}^N} (|\tilde{u}(x) - \tilde{u}(z)| + |\tilde{u}(z) - \tilde{u}(y)|) \kappa_s(y) dy dx \\ &= \fint_\Omega \int_{\mathbb{R}^N} \left|\tilde{u}(x) - \tilde{u}\left(x - \frac{p}{s} y\right)\right| \kappa_s(y) dy dx + \fint_\Omega \int_{\mathbb{R}^N} \left|\tilde{u}(z) - \tilde{u}\left(z - \frac{q}{s} y\right)\right| \kappa_s(y) dy dz;\end{aligned}$$

substitute $\tilde{y} = \frac{p}{s}\, y$ in the first integral and $\tilde{y} = \frac{q}{s}\, y$ and $x = z$ in the second to obtain

$$\begin{aligned}&= \fint_\Omega \int_{\mathbb{R}^N} |\tilde{u}(x) - \tilde{u}(\tilde{y})| \kappa_p(\tilde{y}) d\tilde{y} dx + \fint_\Omega \int_{\mathbb{R}^N} |\tilde{u}(x) - \tilde{u}(\tilde{y})| \kappa_q(\tilde{y}) d\tilde{y} dx \\ &= \phi(p) + \phi(q). \qquad \square\end{aligned}$$

Step 5. $\kappa_l * \tilde{u} \sim \tilde{u}$ for some l of size $\frac{1}{\overline{E}}$. More precisely:

Claim. Let $\mu > 2$ be a constant, which we specify later. If $\overline{E} < \frac{a}{\mu}\left(\frac{h_W}{1+h_W}\right)$, then for

$$l = \left\lfloor \frac{a}{\mu} \left(\frac{h_W}{1 + h_W}\right) \frac{1}{\overline{E}} \right\rfloor r \;=: i\, r \tag{24}$$

the following holds:

$$\phi(l) = \fint_\Omega |\tilde{u} - \kappa_l * \tilde{u}|\, dx < \frac{2}{\mu}\, a. \tag{25}$$

Proof. The assumption on $\overline{E}$ implies that $l > \frac{1}{2} \frac{a}{\mu} \left(\frac{h_W}{1+h_W}\right) \frac{1}{\overline{E}}\, r > 0$. Subadditivity of ϕ established in Step 4 and the bound of Step 3 imply

$$\fint_\Omega |\tilde{u} - \kappa_l * \tilde{u}|\, dx \le i \fint_\Omega |\tilde{u} - \kappa_r * \tilde{u}|\, dx \le \left\lfloor \frac{a}{\mu} \left(\frac{h_W}{1 + h_W}\right) \frac{1}{\overline{E}} \right\rfloor 2 \left(1 + \frac{1}{h_w}\right) \overline{E} \le \frac{2}{\mu}\, a. \qquad \square$$

Step 6. If for some $l > 1$,

$$\kappa_l * \tilde{u} \sim \tilde{u}, \quad \text{then} \quad \overline{L} \gtrsim l.$$

More precisely:

Claim. Set $\mu = 64$. There exists a constant c, depending only on dimension N and on a, such that for any $l > 1$,

$$\text{if} \quad \fint_\Omega |\tilde{u} - \kappa_l * \tilde{u}|\, dx < \frac{2}{\mu}\, a, \quad \text{then} \quad \overline{L} > cl. \tag{26}$$

We split the proof of this claim into four parts. First we establish two auxiliary claims. Then we prove claim (26) for the Wasserstein metric case and for the H^{-1} metric case separately.

Step 6a. Let $A_l := \{x \in \Omega \,:\, \tilde{u} * \kappa_l > \frac{7}{8}\}$. If

$$\fint_\Omega |\tilde{u} - \kappa_l * \tilde{u}|\, dx < \frac{2}{\mu}\, a,$$

then

$$\|A_l\| > \frac{\mu - 32}{2\mu}\, a. \tag{27}$$

By the assumption

$$\frac{2}{\mu}\, a > \fint_\Omega |\tilde{u} - \kappa_l * \tilde{u}|\, dx \geq \fint_{A\setminus A_l} \frac{1}{8}\, dx = \frac{1}{8}\|A\setminus A_l\|.$$

From (23) we have $\|A\| > \frac{a}{2}$. Combining the two inequalities gives

$$\|A_l\| \geq \|A\| - \|A\setminus A_l\| > \left(\frac{1}{2} - \frac{16}{\mu}\right)\, a.$$

Remark. From this point on the proof does not require the closeness of $\tilde{u}$ and $\kappa_l * \tilde{u}$ explicitly, but rather it uses only the fact that A_l is large, as described by (27). That is, we require only that after $\tilde{u}$ is averaged over radius l it still have well-developed interfaces.

Step 6b. A significant subset of A_l can be well approximated by balls of radius l. More precisely:

Claim. Set $\mu = 64$. There exists a finite subset, J, of A_l such that for $A_{ball} = \cup_{x\in J} B(x, l)$,

$$\frac{8}{7}\|A_{ball} \cap A\| \geq \|A_{ball}\| > \frac{1}{2^{N+2}}\, a. \tag{28}$$

This claim has its roots in [5]; see also [17]. Let J be a maximal family of points in A_l such that balls in $\{B(x, l)\}_{x\in J}$ are disjoint. Then $A_l \subset \cup_{x\in J} B(x, 2l)$, by definition. Therefore, using (27)

$$\|A_{ball}\| \geq \frac{1}{2^N}\|A_l\| > \frac{1}{2^{N+2}} a.$$

Since $J \subset A_l$, for all $x \in J$ we have that

$$\frac{7}{8} \leq k_l * \tilde{u}(x) \leq \frac{|B(x, l) \cap A|}{|B(x, l)|}.$$

Summing over $x \in J$ gives the first inequality.

Step 6c (Wasserstein). Let $\gamma = \left(\frac{9}{8}\right)^{1/N} - 1$. For set U and $\lambda \geq 0$, let

$$U^\lambda := \{x \in \Omega \,:\, \operatorname{dist}(x, U) \leq \lambda\}.$$

Let $\lambda = \gamma l$. Using Lemma 8 and the fact that $u \geq 0$,

$$\begin{aligned}\overline{L}^2 = \frac{d_{Wass}(u,a)^2}{|\Omega|} &\geq \lambda^2 \left(\fint_{A_{ball}} u(x)dx - a\|A^\lambda_{ball}\| \right) \\ &\geq \lambda^2 \left(\frac{7}{8}\|A \cap A_{ball}\| - a\left(1+\frac{\lambda}{l}\right)^N \|A_{ball}\| \right) \\ &\geq \gamma^2 l^2 \left(\frac{49}{64} - \frac{1}{2}(1+\gamma)^N \right) \|A_{ball}\| \\ &\geq \gamma^2 \frac{1}{5}\frac{1}{2^{N+2}} a\, l^2.\end{aligned}$$

Combining the conclusions of Steps 5 and 6 now proves the interpolation inequality (22). In particular

$$\overline{L} \geq c(N) r \left(\frac{h_W}{1+h_W} \right) a^{3/2} \frac{1}{\overline{E}}.$$

Step 6d (H^{-1}). Assume $\overline{E} < \frac{1}{20}\frac{1}{2^{N+2}} a h_w$. To obtain a lower bound on $\overline{L}$, given by (20), we first build a local test function. For $\gamma > 1$ to be determined, let $\eta : [0,\infty) \to [0,1]$ be defined by

$$\eta(z) := \begin{cases} 1 & \text{if } z \in [0,l], \\ l - \frac{z-l}{\gamma l - l} & \text{if } l < z < \gamma l, \\ 0 & \text{if } \gamma l \leq z. \end{cases}$$

Let $\bar{\xi}(x) := \eta(|x|)$. This is the local test function. Assume, for the moment, that $0 \in A_l$. Let $\hat{u}(x) := \max\left\{u(x), -\frac{a}{4}\right\}$. Then

$$\int_{B(0,\gamma l)} |\nabla \bar{\xi}|^2 dx = (\gamma^N - 1)|B(0,l)| \frac{1}{(\gamma-1)^2 l^2}. \tag{29}$$

Also

$$\begin{aligned}&\int_{B(0,\gamma l)} (\hat{u} - a)\bar{\xi} dx \\ &\qquad \geq \frac{7}{8}|A \cap B(0,l)| - \frac{a}{4}\left(|B(0,l)\backslash A| + (\gamma^N - 1)|B(0,l)| \right) - a\gamma^N |B(0,l)| \\ &\qquad \geq \left(\left(\frac{7}{8}\right)^2 - \frac{a}{32} - \frac{a(\gamma^N - 1)}{4} - a\gamma^N \right) |B(0,l)|.\end{aligned}$$

Let us now set $\gamma = \left(\frac{8}{7}\right)^{1/N}$. Then

$$\int_{B(0,\gamma l)} (\hat{u} - a)\bar{\xi} dx \geq \frac{3}{20}|B(0,l)|. \tag{30}$$

Now let us construct the (global) test function on Ω. Let

$$\xi(x) = \sup_{y \in J} \bar{\xi}(x - y).$$

Using (29), (23), and (28) we obtain

$$\fint_\Omega |\nabla \xi|^2 dx \le \frac{\gamma^N - 1}{(\gamma-1)^2 l^2} \|A_{ball}\| \le \frac{a}{(\gamma-1)^2 l^2}. \tag{31}$$

Using the fact that balls of radius l centered at points in J are disjoint we obtain

$$\begin{aligned}
\fint_\Omega (u-a)\xi dx &\ge \fint_\Omega (\hat{u}-a)\xi dx + \fint_{\{u<-\frac{a}{4}\}} u dx \\
&\ge \frac{3}{20}\|A_{ball}\| - \frac{1}{h_W}\fint_\Omega W(u) dx \\
&\ge \frac{3}{20}\,\frac{1}{2^{N+2}} a - \frac{\overline{E}}{h_w} \\
&\ge \frac{1}{10}\,\frac{1}{2^{N+2}} a.
\end{aligned}$$

Here we used the assumption $\overline{E} < \frac{1}{20}\,\frac{1}{2^{N+2}} a h_w$. Therefore

$$\overline{L} \ge \frac{\fint_\Omega (u-a)\xi dx}{\sqrt{\fint_\Omega |\nabla \xi|^2 dx}} \ge \tilde{c}(N)\sqrt{a} l.$$

The definition of l now implies

$$\overline{L} \ge c(N) r \left(\frac{h_W}{1+h_W}\right) a^{3/2} \frac{1}{\overline{\overline{E}}},$$

which proves the interpolation inequality. ∎

Remark 2. In the case $N = 2$, one can obtain a sharper result with respect to scaling in a (as $a \to 0^+$) by considering more carefully constructed test functions. This was done for the Mullins–Sekerka evolution by Conti, Niethammer, and Otto in [5]. In particular if γ is taken of size $a^{-1/2}$, and on $[l, cl]$, we replace the linear η by the optimal one, $\eta(z) = (\ln \gamma l - \ln z)/\ln \gamma$. By using such a test function one obtains that

$$\overline{L} \ge c(N) r \left(\frac{h_W}{1+h_W}\right) a^{3/2} |\ln a|^{1/2} \frac{1}{\overline{\overline{E}}}.$$

4.1. Interpolation inequalities for the local energy. Let us now consider the case of the local energy density:

$$\overline{E}(u) := \fint_\Omega \frac{1}{2}|\nabla u(x)|^2 + W(u(x)) dx. \tag{32}$$

The method developed in the proof of Theorem 6 applies to the local energy with minor modifications.

COROLLARY 7 (interpolation inequality). *Let $0 < a \le \frac{1}{2}$. Assume W satisfies* (W1)–(W3). *There exists a constant $C = C(a, h_W) > 0$ such that for all $\Lambda > 0$ and all configurations $u \in \mathcal{M}$ for which $\overline{E}(u) < \frac{a}{64}\left(\frac{h_W}{1+h_W}\right)$, and in the H^{-1} case also $\overline{E}(u) < \frac{1}{2^{N+2}}\frac{a h_W}{20}$, the following holds:*

$$\overline{E}(u)\overline{L}(u) \ge C. \tag{33}$$

The constant $C = c(N)\left(\frac{h_W}{1+h_W}\right) a^{3/2}$.

Proof. Note that Step 1 is not needed, while the estimate of Step 2 used only the W term, which is the same for both the local and the nonlocal energy. The main fact we need to check is the statement of Step 3, which we prove below for $r^2 = \frac{1}{2}$. Steps 4, 5, and 6 do not require any modifications.

To prove that

$$⨍_\Omega |\tilde{u} - \kappa_r * \tilde{u}| dx \le \left(\frac{16}{9} + \frac{2}{h_W}\right) \overline{E}$$

with $r^2 = \frac{1}{2}$ we begin as in Step 3 of the proof of Theorem 6:

$$\begin{aligned} ⨍_\Omega \left|\tilde{u}(x) - \int_{\mathbb{R}^N} \kappa_r(x-y)\tilde{u}(y)dy\right| dx \\ &\le \left(\frac{3}{4}\right)^{-2} ⨍_\Omega \int_{\mathbb{R}^N} |u(x)-u(y)|^2 \kappa_r(x-y)dydx + 2\left\|\left\{\frac{a}{4} \le u \le \frac{7}{8}\right\}\right\| \\ &\le \frac{16}{9} ⨍_\Omega \frac{1}{|B(x,r)|} \int_{B(x,r)} |u(x)-u(y)|^2 dydx + \frac{2}{h_W}\overline{E}. \end{aligned}$$

It remains to further estimate the first term:

$$\begin{aligned} ⨍_\Omega \frac{1}{|B(x,r)|} \int_{B(x,r)} |u(x)-u(y)|^2 dydx \\ &\le ⨍_\Omega \frac{1}{|B(0,r)|} \int_{B(x,r)} |x-y|^2 \left|\int_0^1 \nabla u(x - s(x-y))ds\right|^2 dydx \\ &\le \frac{1}{2} ⨍_\Omega \frac{1}{|B(0,r)|} \int_{B(0,r)} \int_0^1 |\nabla u(x-sz)|^2 dsdzdx \\ &\le \frac{1}{2} \frac{1}{|B(0,r)|} \int_{B(0,r)} \int_0^1 2\overline{E} dsdz = \overline{E}. \qquad \square \end{aligned}$$

5. Appendix.

5.1. A property of Wasserstein distance. The following lemma is analogous to Lemma 5 in [17]. We state it in large generality, the reason being that we want to consider Ω with metric from the torus $R^N/(\Lambda\mathbb{Z})^N$. In applications σ is the Lebesgue measure.

LEMMA 8. *Let (Ω, d, σ) be a metric space endowed with finite measure σ. Let $u \in L^1(\Omega)$ be a nonnegative function with average $a := ⨍_\Omega u(x)d\sigma(x)$. Let $A \subset \Omega$ measurable, and let $A^l := \{x \in \Omega : d(x,A) \le l\}$. Then*

$$d^2_{Wass}(u,a) \ge l^2 \left(\int_A u(x)d\sigma(x) - a\sigma(A^l)\right).$$

Proof. We use the definition of Wasserstein distance. Let π be an admissible transportation plan, that is, a measure on $\Omega \times \Omega$ with marginals $u(x)d\sigma(x)$ and $a\sigma(y)$.

Then

$$\begin{aligned}\int_{\Omega\times\Omega} |x-y|^2 d\pi(x,y) &= \int_{A\times(\Omega\setminus A^l)} |x-y|^2 d\pi(x,y)\\ &\geq l^2\,\pi(A\times(\Omega\setminus A^l))\\ &\geq l^2(\pi(A\times\Omega)-\pi(\Omega\times A^l))\\ &= l^2\left(\int_A u(x)d\sigma(x) - \int_{A^l} a d\sigma(y)\right)\\ &= l^2\left(\int_A u(x)d\sigma(x) - a\sigma(A^l)\right). \qquad \square\end{aligned}$$

UNIQUENESS OF POSITIVE BOUND STATES TO SCHRÖDINGER SYSTEMS WITH CRITICAL EXPONENTS*

CONGMING LI† AND LI MA‡

Abstract. We prove the uniqueness of the positive solutions of the following elliptic system: (1) $-\Delta(u(x)) = u(x)^{\alpha}v(x)^{\beta}$, (2) $-\Delta(v(x)) = u(x)^{\beta}v(x)^{\alpha}$. Here $x \in R^n$, $n \geq 3$, and $1 \leq \alpha < \beta \leq \frac{n+2}{n-2}$ with $\alpha + \beta = \frac{n+2}{n-2}$. In the special case when $n = 3$ and $\alpha = 2$, $\beta = 3$, the system is closely related to the ones from the stationary Schrödinger system with critical exponents for the Bose–Einstein condensate. As the first step, we prove the radial symmetry of the positive solutions to the elliptic system above with critical exponents. We then prove that $u = v$, which is a key point for our uniqueness result.

1. Introduction.

In this paper, we consider the uniqueness of positive solutions to the following stationary Schrödinger system:

$$\begin{cases} -\Delta(u(x)) = u(x)^{\alpha}v(x)^{\beta}, \\ -\Delta(v(x)) = u(x)^{\beta}v(x)^{\alpha}. \end{cases} \tag{1}$$

Here, in the special case when $n = 3$ and $\alpha = 2, \beta = 3$, and $u = v$, system (1) is reduced to the quintic Schrödinger equation considered by Bourgain [1]. We prove in this paper that there is a uniqueness result for the system above. In general, our system is related to the ones from the stationary Schrödinger system with critical exponents for the Bose–Einstein condensate (see [15], [19], [20], and [23]). In the earlier works [19], [20], and [23], more attention was paid to the elliptic system (1) with subcritical exponents. Very interestingly, Chen and Li proved that the best constant in the weighted Hardy–Littlewood–Sobolev inequality can be achieved by explicit radial symmetric functions (see [5] and [18]). As a consequence of their work, the uniqueness of positive solutions to the corresponding elliptic system (it is (1) in the case when $\alpha = 0$ and $\beta = \frac{n+2}{n-2}$) has been settled. However, when $0 < \alpha, \beta \leq \frac{n+2}{n-2}$, the uniqueness of smooth positive solutions to the stationary Schrödinger system (1) is an open question. Generally speaking, there are very few results even for the uniqueness of positive solutions to ordinary differential systems. The aim of this paper is to prove the radial symmetry and uniqueness of positive solutions to (1) with critical exponents and $1 \leq \alpha < \beta \leq \frac{n+2}{n-2}$.

As one can expect, just like in the work of Weinstein [28] in the scalar case with subcritical exponent, there is a close relationship between the stationary Schrödinger system with critical exponent and the Hardy–Littlewood–Sobolev inequality. As we show below, this is true.

Since we shall use Hardy–Littlewood–Sobolev inequality to prove radial symmetry of our solutions, let's first explore the recent progress of Lieb's conjecture. We begin by recalling the well-known Hardy–Littlewood–Sobolev inequality. Let $0 < \lambda < n$, $1 < s, r < \infty$, and $\|f\|_p$ be the $L^p(R^n)$ norm of the function f. We shall write by $\|f\|_{p,\Omega}$ the L^p norm of the function f on the domain Ω. Then the classical Hardy–Littlewood–Sobolev inequality states that

$$\int_{R^n}\int_{R^n} \frac{f(x)g(y)}{|x-y|^\lambda}dxdy \le C_{s,\lambda,n}\|f\|_r\|g\|_s \tag{2}$$

for any $f \in L^r(R^n)$, $g \in L^s(R^n)$, and for $\frac{1}{r}+\frac{1}{s}+\frac{\lambda}{n}=2$. Hardy and Littlewood also introduced the double weighted inequality, which was later generalized by Stein and Weiss in [26] in the following form:

$$\left|\int_{R^n}\int_{R^n} \frac{f(x)g(y)}{|x|^{\alpha_0}|x-y|^\lambda|y|^{\beta_0}}dxdy\right| \le C_{\alpha_0,\beta_0,s,\lambda,n}\|f\|_r\|g\|_s, \tag{3}$$

where $\alpha_0+\beta_0 \ge 0$,

$$1-\frac{1}{r}-\frac{\lambda}{n} < \frac{\alpha_0}{n} < 1-\frac{1}{r} \quad \text{and} \quad \frac{1}{r}+\frac{1}{s}+\frac{\lambda+\alpha_0+\beta_0}{n}=2. \tag{4}$$

The best constant in the weighted inequality (3) can be obtained by maximizing the functional

$$J(f,g)=\int_{R^n}\int_{R^n} \frac{f(x)g(y)}{|x|^{\alpha_0}|x-y|^\lambda|y|^{\beta_0}}dxdy \tag{5}$$

under the constraints $\|f\|_r = \|g\|_s = 1$. Then the corresponding Euler–Lagrange equations are the system of integral equations

$$\begin{cases} \lambda_1 r f(x)^{r-1} = \frac{1}{|x|^{\alpha_0}}\int_{R^n}\frac{g(y)}{|y|^{\beta_0}|x-y|^\lambda}dy, \\ \lambda_2 s g(x)^{s-1} = \frac{1}{|x|^{\beta_0}}\int_{R^n}\frac{f(y)}{|y|^{\alpha_0}|x-y|^\lambda}dy, \end{cases} \tag{6}$$

where $f, g \ge 0$, $x \in R^n$, and $\lambda_1 r = \lambda_2 s = J(f,g)$.

Let $u = c_1 f^{r-1}$, $v = c_2 g^{s-1}$, $p = \frac{1}{r-1}$, $q = \frac{1}{s-1}$, $pq \ne 1$, and for a proper choice of constants c_1 and c_2, system (6) becomes

$$\begin{cases} u(x) = \frac{1}{|x|^{\alpha_0}}\int_{R^n}\frac{v(y)^q}{|y|^{\beta_0}|x-y|^\lambda}dy, \\ v(x) = \frac{1}{|x|^{\beta_0}}\int_{R^n}\frac{u(y)^p}{|y|^{\alpha_0}|x-y|^\lambda}dy, \end{cases} \tag{7}$$

where $u, v \ge 0$, $0 < p, q < \infty$, $0 < \lambda < n$, $\frac{\alpha_0}{n} < \frac{1}{p+1} < \frac{\lambda+\alpha_0}{n}$, and $\frac{1}{p+1}+\frac{1}{q+1} = \frac{\lambda+\alpha_0+\beta_0}{n}$.

Note that in the special case where $\alpha_0 = 0$ and $\beta_0 = 0$, system (7) reduces to the following system:

$$\begin{cases} u(x) = \int_{R^n} \frac{v^q(y)}{|x-y|^\lambda} dy, \\ v(x) = \int_{R^n} \frac{u^p(y)}{|x-y|^\lambda} dy \end{cases} \tag{8}$$

with

$$\frac{1}{q+1} + \frac{1}{p+1} = \frac{\lambda}{n}. \tag{9}$$

It is well known that this integral system is closely related to the system of partial differential equations

$$\begin{cases} (-\Delta)^{\gamma/2} u = v^q, \quad u > 0, \text{ in } R^n, \\ (-\Delta)^{\gamma/2} v = u^p, \quad v > 0, \text{ in } R^n, \end{cases} \tag{10}$$

where $\gamma = n - \lambda$.

When $p = q = \frac{n+\gamma}{n-\gamma}$ and $u(x) = v(x)$, system (8) becomes the single equation

$$u(x) = \int_{R^n} \frac{u(y)^{\frac{n+\gamma}{n-\gamma}}}{|x-y|^{n-\gamma}} dy, \quad u > 0, \text{ in } R^n. \tag{11}$$

The corresponding PDE is the well-known family of semilinear equations

$$(-\Delta)^{\gamma/2} u = u^{(n+\gamma)/(n-\gamma)}, \quad u > 0, \quad \text{in } R^n. \tag{12}$$

In particular, when $n \geq 3$, and $\gamma = 2$, (12) becomes

$$-\Delta u = u^{(n+2)/(n-2)}, \quad u > 0, \text{ in } R^n. \tag{13}$$

The classification of the solutions of (13) has provided an important ingredient in the study of the well-known Yamabe problem and the prescribing scalar curvature problem. Equation (13) was studied by Gidas, Ni, and Nirenberg [11], Caffarelli, Gidas, and Spruck [2], Chen and Li [3], and Li [16]. They classified all the positive solutions. Recently, Wei and Xu [27] generalized this result to the solutions of the more general equation (12) with γ being any even number between 0 and n. Some results of Chen, Li, and Ou have been improved by Hang in [12]. One may see related results in [14] and [17].

Although the systems for other real values of α, β between 0 and n are of interest to some, we shall concentrate in this paper only on the system (1) with critical exponents when $1 \leq \alpha, \beta \leq \frac{n+2}{n-2}$ and $\alpha + \beta = \frac{n+2}{n-2}$.

Our main results are the following two theorems.

THEOREM 1. *Assume that $n \geq 3$, $1 \leq \alpha, \beta \leq \frac{n+2}{n-2}$, and $\alpha + \beta = \frac{n+2}{n-2}$. Then any $L^{\frac{2n}{n-2}}(\mathbf{R}^n) \times L^{\frac{2n}{n-2}}(\mathbf{R}^n)$ positive solution pair (u, v) to system (1) is radial symmetric.*

THEOREM 2. *Assume that $n \geq 3$, $1 \leq \alpha \leq \beta \leq \frac{n+2}{n-2}$, and $\alpha + \beta = \frac{n+2}{n-2}$. Then any $L^{\frac{2n}{n-2}}(\mathbf{R}^n) \times L^{\frac{2n}{n-2}}(\mathbf{R}^n)$ radial symmetric solution pair (u, v) to system (1) is unique and $u = v$.*

In the proof of Theorem 1, we shall use the equivalent integral form for the nonnegative solutions

$$(u, v) \in L^{\frac{2n}{n-2}}(\mathbf{R}^n) \times L^{\frac{2n}{n-2}}(\mathbf{R}^n)$$

to system (1):

$$u(x) = \int_{R^n} \frac{u^\alpha v^\beta(y)}{|x-y|^{n-2}} dy$$

and

$$v(x) = \int_{R^n} \frac{v^\alpha u^\beta(y)}{|x-y|^{n-2}} dy.$$

This equivalent form can be proved in the same way as in section 4 in the work of Chen, Li, and Ou [8].

We point out that when $u = v$, the elliptic system (1) reduces to the elliptic equation (13) with critical exponent. Then $u = v$ is in a special family of functions:

$$\phi_{x_o,t}(x) = c\left(\frac{t}{t^2 + |x - x_o|^2}\right)^{(n-2)/2}, \tag{14}$$

where $t > 0$, $x_o \in \mathbf{R}^n$, with some positive constant c such that each $\phi_{x_o,t}(x)$ solves (13). This special family of functions is important in the study of (1).

Our results are motivated by the previous work [6], where Chen, Li, and Ou considered the more general system (8) and established the symmetry and monotonicity of the solutions. In [4], Chen and Li also obtained a regularity result of the solutions to (8). To establish the symmetry of the solutions to (8), Chen, Li, and Ou [8], [6], [7] introduced a new idea: an integral form of the method of moving planes. It is entirely different from the traditional method used for PDEs. Instead of relying on maximum principles, certain integral norms were estimated. The new method is a very powerful tool in studying qualitative properties of other integral equations and systems. In fact, following Chen, Li, and Ou's work, Jin and Li [13] studied the symmetry of the solutions to the more general system (7).

Using the maximum principle trick, de Figueiredo and Felmer [10] found an interesting Liouville-type result for certain type of elliptic systems. Recently Ma and Chen [21] discussed the Liouville-type theorem for the positive solutions to the elliptic system (10). They also discussed the radial symmetry property of nonnegative solutions to a higher-order differential equation [22]. Naito and Usami [24] studied the existence of nonoscillatory solutions to second-order elliptic systems of Emden–Fowler type. Some nonexistence results for the Emden–Fowler system can be found in [25]. We refer to [13], [9], and [24] for more references about elliptic systems.

We first prove the radial symmetry of the solutions to (1) with critical exponents. It is obvious that the radial symmetry of the solutions reduces (1) to a system of ODEs, which has the special solution pair $(\phi_{o,t}(x), \phi_{o,t}(x))$. To prove the uniqueness, we prove that $u(0) = v(0)$. Then by the uniqueness of the initial value problem for ODEs, we conclude that $u = v = \phi_{o,t}$. This is the key observation in establishing the uniqueness of positive solutions for (1) with critical exponents.

Theorems 1 and 2 will be proved in the next two sections.

2. Proof of the radial symmetry. We use the moving plane method introduced by Chen, Li, and Ou in [8] to study system (1). We recall the Hardy–Littlewood–Sobolev inequality:

$$|Tf|_p \le C(n,p)|f|_{\frac{np}{n+2p}}, \tag{15}$$

where $C(n,p)$ is a uniform positive constant and

$$Tf(x) = \int_{\mathbf{R}^n} |x-y|^{2-n} f(y)dy.$$

Proof of Theorem 1. For each $\lambda \in \mathbf{R}$, we denote

$$H_\lambda = \{x \in \mathbf{R}^n; x_1 < \lambda\}.$$

For each $x = (x_1, x') \in \mathbf{R}^n$, we let

$$x_\lambda = (2\lambda - x_1, x')$$

be the reflection point of x with respect to the hyperplane ∂H_λ. We let $e_1 = (1, 0, \dots, 0)$.

We define

$$u_\lambda(x) = u(x_\lambda), \quad B_\lambda^u = \{x \in H_\lambda; u_\lambda(x) > u(x)\}$$

and

$$v_\lambda(x) = v(x_\lambda), \quad B_\lambda^v = \{x \in H_\lambda; v_\lambda(x) > v(x)\}.$$

To do the moving plane method, we need the following formula, which is obtained by a change of variables.

$$u(x) = \int_{H_\lambda} \frac{u^\alpha v^\beta(y)}{|x-y|^{n-2}}dy + \int_{H_\lambda} \frac{u_\lambda^\alpha v_\lambda^\beta(y)}{|x_\lambda - y|^{n-2}}dy$$

and

$$u_\lambda(x) = \int_{H_\lambda} \frac{u^\alpha v^\beta(y)}{|x_\lambda-y|^{n-2}}dy + \int_{H_\lambda} \frac{u_\lambda^\alpha v_\lambda^\beta(y)}{|x-y|^{n-2}}dy.$$

Then we have

$$u_\lambda(x) - u(x) = \int_{H_\lambda} (u_\lambda^\alpha v_\lambda^\beta - u^\alpha v^\beta)(y) \left(\frac{1}{|x-y|^{n-2}} - \frac{1}{|x_\lambda - y|^{n-2}} \right) dy. \tag{16}$$

Note that for $x \in H_\lambda$, we have

$$\frac{1}{|x-y|^{n-2}} > \frac{1}{|x_\lambda - y|^{n-2}}.$$

Then for $x \in B_\lambda^u$, using the mean value theorem to

$$u_\lambda^\alpha v_\lambda^\beta - u^\alpha v^\beta = (u_\lambda^\alpha - u^\alpha)v_\lambda^\beta + u^\alpha(v_\lambda^\beta - v^\beta)$$

and after dropping the term of the integration on the region $v_\lambda - v \le 0$, we have

$$\begin{cases} 0 \le u_\lambda(x) - u(x) \\ \quad \le \alpha \int_{B_\lambda^u} \frac{u_\lambda^{\alpha-1} v_\lambda^\beta (u_\lambda - u)}{|x-y|^{n-2}} dy + \beta \int_{B_\lambda^v} \frac{u_\lambda^\alpha v_\lambda^{\beta-1}(v_\lambda - v)}{|x-y|^{n-2}} dy \\ \quad := I + II. \end{cases} \tag{17}$$

Let $p = \frac{2n}{n-2}$. Using the Hardy–Littlewood–Sobolev inequality (15) we can bound the first term I in (17) by

$$\begin{cases} |I|_p \le C(n,p) |u_\lambda^{\alpha-1} v_\lambda^\beta (u_\lambda - u)|_{\frac{2n}{n+2}} \\ \le C(n,p) |u_\lambda|_p^{\alpha-1} |v_\lambda|_p^\beta |u_\lambda - u|_p. \end{cases} \tag{18}$$

Here the integrations are over the set B_λ^u.

Using again the Hardy–Littlewood–Sobolev inequality (15) we can bound the first term II in (17) by

$$\begin{cases} |II|_p \le C(n,p) |u_\lambda^\alpha v_\lambda^{\beta-1} (v_\lambda - v)|_{\frac{2n}{n+2}} \\ \le C(n,p) |u_\lambda|_p^\alpha |v_\lambda|_p^{\beta-1} |v_\lambda - v|_p. \end{cases} \tag{19}$$

Here the integrations are over the domain B_λ^v. Hence, we have

$$\begin{aligned} &|u_\lambda - u|_{p, B_\lambda^u} \\ &\le C(n,p) (|u_\lambda|_{p,B_\lambda^u}^{\alpha-1} |v_\lambda|_{p,B_\lambda^u}^\beta |u_\lambda - u|_{p,B_\lambda^u} + |u_\lambda|_{p,B_\lambda^v}^\alpha |v_\lambda|_{p,B_\lambda^v}^{\beta-1} |v_\lambda - v|_{p,B_\lambda^v}). \end{aligned} \tag{20}$$

Similarly, we have the following formulae for v and v_λ:

$$v(x) = \int_{H_\lambda} \frac{v^\alpha u^\beta(y)}{|x-y|^{n-2}} dy + \int_{H_\lambda} \frac{v_\lambda^\alpha u_\lambda^\beta(y)}{|x_\lambda - y|^{n-2}} dy$$

and

$$v_\lambda(x) = \int_{H_\lambda} \frac{v^\alpha u^\beta(y)}{|x_\lambda - y|^{n-2}} dy + \int_{H_\lambda} \frac{v_\lambda^\alpha u_\lambda^\beta(y)}{|x-y|^{n-2}} dy.$$

Then we have the following estimate:

$$\begin{aligned} &|v_\lambda - v|_{p, B_\lambda^v} \\ &\le C(n,p) (|v_\lambda|_{p,B_\lambda^v}^{\alpha-1} |u_\lambda|_{p,B_\lambda^v}^\beta |v_\lambda - v|_{p,B_\lambda^v} + |v_\lambda|_{p,B_\lambda^u}^\alpha |u_\lambda|_{p,B_\lambda^u}^{\beta-1} |u_\lambda - u|_{p,B_\lambda^u}). \end{aligned} \tag{21}$$

After these preparations, we can use the moving plane method as developed in [8] to prove the radial symmetry of the solutions.

At first, let's start the plane from infinity. Indeed, for $\lambda \gg 1$ large enough, we know that the quantities

$$|v_\lambda|_{p,B_\lambda^u}, |u_\lambda|_{p,B_\lambda^u}, |v_\lambda|_{p,B_\lambda^v}$$

and

$$|u_\lambda|_{p,B_\lambda^v}$$

all are small, which give us that

$$|u_\lambda - u|_{p,B_\lambda^u} \le \frac{1}{4}(|v_\lambda - v|_{p,B_\lambda^v} + |u_\lambda - u|_{p,B_\lambda^u})$$

and

$$|v_\lambda - v|_{p,B_\lambda^v} \le \frac{1}{4}(|v_\lambda - v|_{p,B_\lambda^v} + |u_\lambda - u|_{p,B_\lambda^u}).$$

These imply that $|u_\lambda - u|_{p,B_\lambda^u} = 0$ and $|v_\lambda - v|_{p,B_\lambda^v} = 0$. In other words, $B_\lambda^u = \phi$ and $B_\lambda^v = \phi$.

Next we define

$$\lambda_0 = \inf\{\lambda \in \mathbf{R}; B_{\lambda'}^u = B_{\lambda'}^v = \phi \ \forall\ \lambda' \ge \lambda\}.$$

Then it comes from the fact that $u(x) \to 0$ as $|x| \to \infty$ and $u(x) > 0$ in $\mathbf{R}^n$ that $\lambda_0 < +\infty$. By the definition of λ_0, we have $u_{\lambda_0}(x) \le u(x)$ for $x \in H_{\lambda_0}$. If u or v is not symmetric in the x_1 direction at λ_0, then using the expression (16), we see that $u_{\lambda_0}(x) < u(x)$ and $v_{\lambda_0}(x) < v(x)$ for $x \in H_{\lambda_0}$. This implies that both of $B_{\lambda_0}^u$ and $B_{\lambda_0}^v$ are empty. Then by the absolute continuity of the integral with respect to the domain we see that $|v_\lambda|_{p,B_\lambda^u}, |u_\lambda|_{p,B_\lambda^u}, |v_\lambda|_{p,B_\lambda^v}$, and $|u_\lambda|_{p,B_\lambda^v}$ are small for λ close to λ_0 and enable us to repeat the above argument showing that both of B_λ^u and B_λ^v are empty for λ close to λ_0. This contradicts the definition of λ_0.

3. Proof of the uniqueness. In some sense, the proof of Theorem 2 is just at hand by using the integral expression of the solution pair (u, v).

Proof of Theorem 2. Let $(u, v) \in L^{\frac{2n}{n-2}}(\mathbf{R}^n) \times L^{\frac{2n}{n-2}}(\mathbf{R}^n)$ be a pair of solutions to system (1). By Theorem 1, we know that u and v are radial symmetric about some point x_0, say, $x_0 = 0$. We will consider only the case when $1 \le \alpha < \beta < \frac{n+2}{n-2}$, and the case when $\alpha = \beta$ can be done similarly.

Since $u \in L^{\frac{2n}{n-2}}(\mathbf{R}^n)$ and $v \in L^{\frac{2n}{n-2}}(\mathbf{R}^n)$, using the same method in [8], we have that $u \in C^2(\mathbf{R}^n)$ and $v \in C^2(\mathbf{R}^n)$ with

$$u(x) \to 0, \qquad v(x) \to 0,$$

as $|x| \to \infty$.

Since our solution u is radial symmetric, we can write, in polar coordinates, the first equation in (1) as

$$(r^{n-1}u'(r))' = -r^{n-1}u(r)^\alpha v(r)^\beta,$$

where $r = |x|$.

Integrating both sides of the above equation from 0 to r yields

$$r^{n-1}u'(r) = -\int_0^r s^{n-1}u^\alpha v^\beta(s)ds.$$

It follows by another integration that

$$u(r) = u(0) - \int_0^r \frac{1}{\tau^{n-1}} \int_0^\tau s^{n-1}u^\alpha v^\beta ds d\tau. \tag{22}$$

Similarly, for $v(r)$, we have

$$v(r) = v(0) - \int_0^r \frac{1}{\tau^{n-1}} \int_0^\tau s^{n-1}v^\alpha u^\beta ds d\tau. \tag{23}$$

As we mentioned in the introduction, we need to show only that $u(0) = v(0)$. Otherwise, suppose that

$$u(0) < v(0). \tag{24}$$

Then by continuity, for all small $r > 0$,

$$u(r) < v(r). \tag{25}$$

In other words, there exists an $R > 0$, such that

$$u(r) < v(r) \ \ \forall r \in (0, R). \tag{26}$$

Let R_o be the supreme value of R such that (26) holds. Then $R_o \leq \infty$ and $u(R_o) = v(R_o)$, where we have used the fact that $u(+\infty) = v(+\infty) = 0$. By the definition of R_o and $\alpha < \beta$, we have that

$$u(r)^\alpha v(r)^\beta > v(r)^\alpha u(r)^\beta \ \ \forall r \in (0, R_o). \tag{27}$$

Then we have from (22) and (23) that

$$0 > u(0) - v(0) = \int_0^{R_o} \frac{1}{\tau^{n-1}} \int_0^\tau s^{n-1}(u^\alpha v^\beta - u^\beta v^\alpha)(s) ds d\tau > 0.$$

This is impossible.

Similarly, one can show that $u(0) > v(0)$ is impossible too. Therefore, we must have

$$u(0) = v(0).$$

Finally, by the standard ODE theory, we arrive at

$$u(r) \equiv v(r).$$

Hence, our elliptic system (1) has been reduced to the elliptic equation (13) with the critical exponent. By now, it is standard that our solution pair u and v is of the form (14). This completes the proof of Theorem 2.

Acknowledgments. The second author expresses his deep appreciation to Prof. W. X. Chen for helpful discussions on the method of moving planes. This work was done while the first author was visiting the Department of Mathematical Sciences in Tsinghua University, Beijing, which he would like to thank for their hospitality. Both authors thank the referees for detailed comments and suggestions on the original manuscript.

STABILITY OF TRAVELING WAVES IN QUASI-LINEAR HYPERBOLIC SYSTEMS WITH RELAXATION AND DIFFUSION*

TONG LI†

Abstract. We establish the existence and the stability of traveling wave solutions of a quasi-linear hyperbolic system with both relaxation and diffusion. The traveling wave solutions are shown to be asymptotically stable under small disturbances and under the subcharacteristic condition using a weighted energy method. The delicate balance between the relaxation and the diffusion that leads to the stability of the traveling waves is identified; namely, the diffusion coefficient is bounded by a constant multiple of the relaxation time. Such a result provides an important first step toward the understanding of the transition from stability to instability as parameters vary in physical problems involving both relaxation and diffusion.

Key words. stability, traveling wave, relaxation, diffusion, weighted energy method, traffic flow

1. Introduction.

The phenomenon of relaxation arises in many physical problems such as kinetic relaxation to fluid dynamics, gases not in local thermodynamic equilibrium, elasticity with memory, phase transitions, shallow water waves, and traffic flows. A remarkable development of the stability theory for various relaxation systems has appeared in past decades; see, e.g., [1, 2, 8, 10, 11, 13, 15, 16, 18, 23]. The real physical problems usually involve both relaxation and diffusion. It was found by asymptotic analysis and numerical simulations that the fine interplay between the relaxation and the diffusion may enhance physically interesting behavior such as soliton waves and oscillatory solutions [4, 3, 5, 6, 7, 9, 14, 17, 20, 22, 24]. However, the rigorous stability theory for such systems has not been well studied. In the current paper, we establish rigorously the existence and the stability of traveling wave solutions of a quasi-linear hyperbolic system with both relaxation and diffusion. The delicate balance between the relaxation and the diffusion that leads to the nonlinear stability of the traveling wave fronts is identified to occur when the diffusion coefficient is bounded by a constant multiple of the relaxation time. Such a result provides an important first step toward understanding the transition from stability to instability as the diffusion coefficient and the relaxation time vary in the physical problems.

Consider the following quasi-linear hyperbolic system with relaxation and diffusion:

$$\begin{cases} v_t - u_x = 0, \\ u_t + p(v)_x = \dfrac{1}{\tau}(u_e(v) - u) + \mu u_{xx} \end{cases} \tag{1}$$

subject to the initial data

$$(v,u)(x,0) = (v_0,u_0)(x) \to (v_\pm,u_\pm) \text{ as } x \to \pm\infty, \quad u_\pm = u_e(v_\pm), \tag{2}$$

where, in the context of traffic flows, v is specific volume and u velocity. The first equation in (1) is a conservation law, while the second describes drivers' acceleration

behavior. The first term on the right-hand side of the second equation in (1) expresses the tendency of traffic at a given specific volume v to relax to some equilibrium speed u_e satisfying

$$u_e'(v) > 0.$$

The parameter $\tau > 0$ corresponds to drivers' response time to the traffic. The second term on the left-hand side of the second equation in (1) is an anticipation factor: drivers slow down at the sight of an increase in traffic density ahead. The function p is the so-called traffic pressure satisfying

$$p'(v) < 0. \tag{3}$$

The last term on the right-hand side of the second equation in (1) models viscosity with coefficient $\mu > 0$, a presumed tendency to adjust one's speed to that of the surrounding traffic.

A strict subcharacteristic condition,

$$-\sqrt{-p'(v)} < u_e'(v) < \sqrt{-p'(v)}, \tag{4}$$

is imposed for all v under consideration. Subcharacteristic condition (4) is a necessary condition for linear stability (Whitham [23]) and for nonlinear stability (Li and Liu [10] and Liu [15]) when $\mu = 0$.

The purpose of this paper is to show the existence and stability of the traveling wave solutions $(V, U)(x - st)$ of (1) under appropriate conditions on the relaxation time τ and the diffusion coefficient μ.

A traveling wave solution is a solution of the form

$$(v, u)(x, t) = (V, U)(x - st) \equiv (V, U)(z),$$

where $z = x - st$, satisfying

$$(V, U)(z) \to (v_\pm, u_\pm) \text{ as } z \to \pm\infty, \quad u_\pm = u_e(v_\pm), \tag{5}$$

where v_+, v_-, and s satisfy the Rankine–Hugoniot condition

$$-s(v_+ - v_-) - u_e(v_+) + u_e(v_-) = 0 \tag{6}$$

and the entropy condition

$$(v_+ - v_-)(u_e(v) - u_e(v_\pm) + s(v - v_\pm)) < 0 \tag{7}$$

for all v in between v_+ and v_-. Indeed, the corresponding jump (v_-, v_+) is an admissible shock of the equilibrium equation

$$v_t - u_e(v)_x = 0. \tag{8}$$

Furthermore, the speed s of the traveling wave must be subcharacteristic; i.e., for all $z \in R$ it holds

$$-\sqrt{-p'(V(z))} < s < \sqrt{-p'(V(z))}. \tag{9}$$

For a weight function $w \geq 0$, L^2_w denotes the space of measurable functions f satisfying $\sqrt{w} f \in L^2$ with norm

$$||f||_{L^2_w} = \left(\int w(x) |f(x)|^2 dx \right)^{1/2}.$$

H_w^j, $j \geq 0$, denotes the weighted Sobolev space with norm

$$||f||_{H_w^j} = \left(\sum_{k=0}^{j} ||\partial_x^k f||_w^2 \right)^{1/2}.$$

We now state our main results.

THEOREM 1.1. *Suppose that subcharacteristic conditions* (4) *and* (9)*, the Rankine–Hugoniot condition* (6)*, and the entropy condition* (7) *hold, and suppose that the diffusion coefficient is appropriately small,*

$$0 < \mu \leq m\tau, \tag{10}$$

for some $m > 0$ critically depending on subcharacteristic conditions (4) *and* (9)*. Then there exists a traveling wave solution $(V, U)(x - st)$ of* (1) *and* (5)*, which is unique up to a shift.*

Moreover, there exists a constant $\varepsilon_0 > 0$ such that if

$$|v_- - v_+| + ||v_0(\cdot) - V(\cdot + x_0)||_2 + ||u_0(\cdot) - U(\cdot + x_0)||_2 + ||(\phi_0, \phi_{0,x}, \psi_0)||_{L_w^2} \leq \varepsilon_0,$$

where x_0 is determined by

$$\int_{-\infty}^{+\infty} (v_0 - V)(x)dx = x_0(v_+ - v_-) \tag{11}$$

and

$$(\phi_0, \psi_0)(x) = \left(\int_{-\infty}^{x} (v_0(y) - V(y + x_0))dy, u_0(x) - U(x + x_0) \right)$$

and where the weight function w is defined as

$$w(V(x + x_0)) = \frac{(V(x + x_0) - v_+)(V(x + x_0) - v_-)}{Q(V(x + x_0))}, \tag{12}$$

then the Cauchy problem (1), (2) *has a unique global solution $(v, u)(x, t)$ satisfying*

$$v(x,t) - V(x + x_0 - st), u(x,t) - U(x + x_0 - st) \in C^0(0, \infty; H^2 \cap L_w^2) \cap L^2(0, \infty; H^2 \cap L_w^2)$$

and

$$\sup_{x \in R} |(v, u)(x, t) - (V, U)(x + x_0 - st)| \to 0 \quad as \quad t \to +\infty. \tag{13}$$

Previously, Jin and Liu [4] derived that the weakly nonlinear limit of the relaxation system of Jin and Xin [2] with a viscous term is governed by the Kortweg–de Vries (KdV) equation and dispersive waves are enhanced when the diffusion coefficient dominates in the sense that

$$\tau \ll O(\tau^{\frac{1}{4}}) \ll \mu.$$

When the diffusion coefficient is not too small, Kerner and Konhäuser [6], Kurtze and Hong [7], Lee, Lee, and Kim [9], and Ou et al. [22] were able to derive a modified KdV equation and obtain soliton-like solutions and oscillatory solutions for traffic flow models similar to (1) by asymptotic analysis and numerical simulations. The

phenomena occur in other applications. Keener [5] studied the diffusion induced insulin oscillatory secretion. He found that oscillatory secretion of insulin results from an important interplay between flow rate of the reactor and insulin diffusion.

In the absence of the diffusion term,

$$\mu = 0,$$

Li and Liu [10] established the nonlinear stability of traveling waves of (1) under the subcharacteristic conditions (4) and (9). The stability result is a consequence of the nonlinearity, the relaxation, and the subcharacteristic conditions (4) and (9).

In the current paper, we prove that, in addition to assuming the subcharacteristic conditions (4) and (9), if the diffusion coefficient is appropriately small (10), then traveling wave solutions of (1) are stable. In the context of traffic flows, our results indicate that the stability of the traveling fronts is guaranteed if the diffusion mechanism, the tendency to adjust one's speed to that of the surrounding traffic, is dominated by the relaxation mechanism, the tendency of traffic to relax to some equilibrium speed.

The plan of this paper is the following. In section 2, we prove the existence of traveling wave solutions of the relaxation system with viscosity (1) by the phase plane analysis provided that the diffusion coefficient is appropriately small (10). In section 3, the stability problem is reformulated in terms of perturbations to the underlying traveling wave. Section 4 is devoted to establishing the desired a priori estimates for the nonlinear stability of the traveling wave solutions. When the equilibrium function $u_e(v)$ is nonconvex, there are traveling wave solutions that decay at an algebraic decay rate at infinity. A weighted energy method was developed to establish the stability of such degenerate traveling wave profiles [12, 10, 16, 19]. We adapt the weighted energy method developed in [12, 10, 16, 19] to a system of conservation laws with both relaxation and diffusion (1). It is under condition (10) that we prove the desired weighted energy estimates that lead to the stability of the traveling wave solutions.

2. Existence of traveling wave profiles. In this section, we prove the existence of traveling wave solutions of the relaxation system with viscosity (1). We show that, under the subcharacteristic conditions (4) and (9), and when the diffusion coefficient is appropriately small (10), there is a traveling wave profile of (1) connecting two states satisfying the Rankine–Hugoniot condition (6) and the entropy condition (7).

LEMMA 2.1. *Assume that v_+, v_-, and s satisfy the Rankine–Hugoniot condition* (6)*, the entropy condition* (7)*, and the subcharacteristic conditions* (4), (9)*, and that the diffusion coefficient is appropriately small* (10)*. There exists a traveling wave solution $(V,U)(x-st)$ of* (1) *with boundary condition* (5)*, which is unique up to a shift.*

Moreover, the profile $V = V(z)$ is monotone and

$$(v_+ - v_-)(u_e(V(z)) - u_e(v_\pm) + s(V(z) - v_\pm)) < 0 \tag{14}$$

for all $z \in R$.

Proof. Substituting

$$(v,u)(x,t) = (V,U)(z), \quad z = x - st,$$

into (1), we have

$$\begin{cases} -sV_z - U_z = 0, \\ -sU_z + p(V)_z = \frac{u_e(V)-U}{\tau} + \mu U_{zz}. \end{cases} \tag{15}$$

Integrating the first equation of (15) over $(\pm\infty, z)$ and using boundary condition (5) yield

$$-sV - U = -sv_\pm - u_\pm = -sv_\pm - u_e(v_\pm). \tag{16}$$

Therefore the Rankine–Hugoniot condition (6) for the equilibrium equation (8) is satisfied by the end states of the traveling wave of the relaxation system (1).

We derive from (15), (16), and (5) that V satisfies a second order nonlinear differential equation

$$V_{zz} + \frac{p'(V) + s^2}{s\mu} V_z - \frac{u_e(V) - u_e(v_\pm) + s(V - v_\pm)}{\tau s\mu} = 0 \tag{17}$$

and

$$V(z) \to v_\pm \ \text{ as } \ z \to \pm\infty. \tag{18}$$

We will establish the existence of solutions for (17) and (18) by phase plane analysis.

Let $W = V'$. Equation (17) is rewritten as a system of first order differential equations

$$\begin{cases} V' = W, \\ W' = -\frac{p'(V)+s^2}{s\mu} W + \frac{u_e(V)-u_e(v_\pm)+s(V-v_\pm)}{\tau s\mu}. \end{cases} \tag{19}$$

$(v_\pm, 0)$ are two equilibrium points of (19). Without loss of generality, we assume that $v_- > v_+$. Other cases can be treated similarly.

The entropy condition (7) implies that

$$Q(V) \equiv -\frac{1}{\tau}(u_e(V) - u_e(v_\pm) + s(V - v_\pm)) < 0, \ \ v_+ < V < v_-, \tag{20}$$

and consequently

$$-u_e'(v_+) \le s < -u_e'(v_-) \le 0.$$

Consider

$$-u_e'(v_+) < s < -u_e'(v_-) < 0. \tag{21}$$

The degenerate cases $-u_e'(v_+) = s$ and $s = -u_e'(v_-)$ can be treated similarly.

Linearize the system of nonlinear equations (19) at equilibrium points $(v_\pm, 0)$ to obtain

$$\begin{cases} (V - v_\pm)' = W, \\ W' = -\frac{p'(v_\pm)+s^2}{s\mu} W + \frac{u_e'(v_\pm)+s}{\tau s\mu}(V - v_\pm). \end{cases} \tag{22}$$

The eigenvalues of the Jacobian of (22) satisfy

$$\lambda^2 + \lambda \frac{p'(v_\pm) + s^2}{s\mu} - \frac{u_e'(v_\pm) + s}{\tau s\mu} = 0.$$

The entropy condition (21), the subcharacteristic condition (9), and $s < 0$ imply that

$$-\frac{u_e'(v_-) + s}{\tau s\mu} < 0, \ \ \frac{p'(v_-) + s^2}{s\mu} > 0. \tag{23}$$

Thus $(v_-, 0)$ is a saddle with eigenvalues

$$\lambda_{1-} > 0 > \lambda_{2-}$$

and the corresponding right eigenvectors

$$r_{1-} = (1, \lambda_{1-})^T, \;\; r_{2-} = (1, \lambda_{2-})^T.$$

Therefore the unstable manifold of (19) at $(v_-, 0)$ is tangent to r_{1-}.

Similarly, the entropy condition (21), the subcharacteristic condition (9), and $s < 0$ imply that

$$-\frac{u_e'(v_+) + s}{\tau s \mu} > 0, \;\; \frac{p'(v_+) + s^2}{s\mu} > 0. \tag{24}$$

Thus $(v_+, 0)$ is a stable node provided that

$$\left(\frac{p'(v_+) + s^2}{s\mu}\right)^2 + 4\frac{u_e'(v_+) + s}{\tau s \mu} > 0$$

or

$$0 < \frac{\mu}{\tau} < -\frac{(p'(v_+) + s^2)^2}{4s(u_e'(v_+) + s)}.$$

The above inequality holds provided that the diffusion coefficient is appropriately small (10).

The eigenvalues of the Jacobian of (22) satisfy

$$0 > \lambda_{1+} > \lambda_{2+},$$

and the corresponding right eigenvectors are

$$r_{1+} = (1, \lambda_{1+})^T, \;\; r_{2+} = (1, \lambda_{2+})^T.$$

The nullclines of (19) consist of

$$W = 0 \tag{25}$$

and

$$W = \frac{u_e(V) - u_e(v_\pm) + s(V - v_\pm)}{\tau(p'(V) + s^2)} \equiv g(V). \tag{26}$$

The nullclines intersect at the equilibrium points $(v_\pm, 0)$, where

$$g(v_\pm) = 0.$$

Moreover, by using the entropy condition (21) and the subcharacteristic condition (9), we have

$$g'(v_-) = \frac{u_e'(v_-) + s}{(p'(v_-) + s^2)\tau} > 0, \;\; g'(v_+) = \frac{u_e'(v_+) + s}{(p'(v_+) + s^2)\tau} < 0, \tag{27}$$

and

$$g(V) < 0, \;\; v_+ < V < v_-.$$

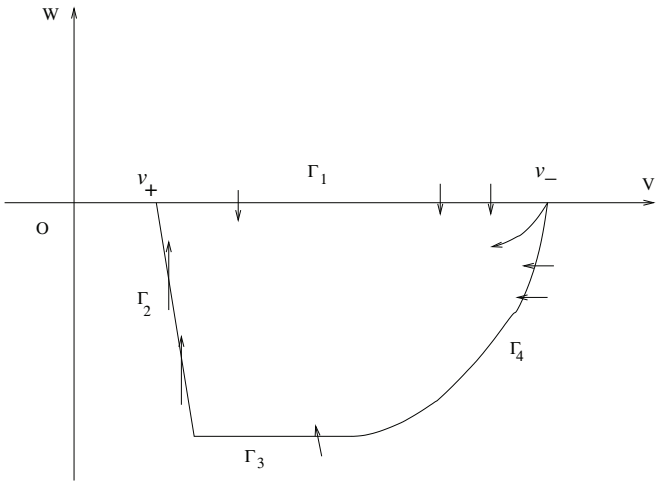

FIG. 1. *The invariant domain D.*

Let $v_0 \in (v_+, v_-)$ be the minimum point of g on $[v_+, v_-]$ and

$$W_0 = g(v_0) = \min_{v_+ < V < v_-} g(V).$$

Then

$$W_0 < 0, \;\; g'(v_0) = 0.$$

Let D be a region bounded by the following curves on the phase plane (see Figure 1):

$$\Gamma_1 : \;\; W = 0, \;\; v_+ \le V \le v_-,$$

$$\Gamma_2 : \;\; W = -a(V - v_+), \;\; v_+ \le V \le v_1,$$

$$\Gamma_3 : \;\; W = W_0 = g(v_0), \;\; v_1 \le V \le v_0,$$

$$\Gamma_4 : \;\; W = g(V), \;\; v_0 \le V \le v_-,$$

where $a > 0$ is to be determined and (v_1, W_0) is the intersection point of Γ_2 and Γ_3 satisfying

$$W_0 = -a(v_1 - v_+), \;\; v_+ \le v_1 \le v_0.$$

We will show that, under the condition that the diffusion coefficient is appropriately small (10), a can be chosen such that D is an invariant region of (19).

(i) From (19) and (21) we derive that on the top boundary of D, Γ_1, $W' < 0$, the flow points downward toward the interior of D.

(ii) On the bottom boundary of D, Γ_3, the flow points in the upper left direction, which points toward the interior of D. This is because Γ_3 lies below the nullcline $W = g(V)$ and thus $W' > 0$.

(iii) On the right boundary of D, Γ_4, which is part of the nullcline $W = g(V)$, the flow points leftward toward the interior of D. This is because $V' = W \le 0$ and $W' = 0$.

(iv) It remains to show that the flow points toward the interior of D on the left boundary of D, Γ_2.

Statement (iv) is true if we can choose $a > 0$ such that

$$\left.\frac{dW}{dV}\right|_{\Gamma_2} < -a < 0, \quad v_+ \le V \le v_1. \tag{28}$$

We show that such $a > 0$ exists if the diffusion coefficient μ is appropriately small (10). Noting (24) and (27), we have

$$\lambda_{1+} = \frac{2\frac{u_e'(v_+)+s}{\tau s\mu}}{\sqrt{\left(\frac{p'(v_+)+s^2}{s\mu}\right)^2 + 4\frac{u_e'(v_+)+s}{\tau s\mu}} + \frac{p'(v_+)+s^2}{s\mu}} < g'(v_+) < 0.$$

Thus Γ_2 is below $W = g(V)$ for V near v_+, $V \in (v_+,\ v_+ + \epsilon)$ for some $\epsilon > 0$.

Indeed, if $\lambda_{1+} < \min_{[v_+,v_0]} g'(V)$, we will choose a satisfying

$$\lambda_{1+} < -a < \min_{[v_+,v_0]} g'(V) < 0.$$

Thus Γ_2 is below $W = g(V)$ for $v_+ \le V \le v_1$.

We now show that (28) is satisfied. Since

$$\lambda_{2+} < \lambda_{1+} < -a < g'(v_+) < 0,$$

there is an $\epsilon > 0$, such that

$$\left.\frac{dW}{dV}\right|_{\Gamma_2} < -a < 0, \quad v_+ \le V \le v_+ + \epsilon. \tag{29}$$

If V is away from v_+, then there is a $\delta > 0$ such that

$$0 < \frac{g(V)}{W} \le 1 - \delta, \quad v_+ + \epsilon \le V \le v_1.$$

From (19) we have

$$\left.\frac{dW}{dV}\right|_{\Gamma_2} = \frac{W'}{V'} = -\frac{p'(V)+s^2}{s\mu}\left(1 - \frac{g(V)}{W}\right) \le -\delta\frac{p'(V)+s^2}{s\mu} < 0$$

for $v_+ + \epsilon \le V \le v_1$. Noting the definition of g and (26) and assuming that the diffusion coefficient μ is appropriately small (10), we have

$$\left.\frac{dW}{dV}\right|_{\Gamma_2} \le -\delta\frac{p'(V)+s^2}{s\mu} < g'(V) < 0, \quad v_+ + \epsilon \le V \le v_1.$$

Thus

$$\left.\frac{dW}{dV}\right|_{\Gamma_2} < -a < 0, \quad v_+ + \epsilon \le V \le v_1. \tag{30}$$

Combining (29) and (30), we prove that there is an a satisfying (28). If $\min_{[v_+,v_0]} g'(V) < \lambda_{1+}$, we consider a piecewise linear curve Γ_2 instead. The above argument can be modified to prove (28).

Therefore D is an invariant region of (19).

Now we look for a trajectory connecting the two equilibrium points $(v_\pm, 0)$. Noting (23) and (27), we have

$$0 < \lambda_{1-} = \frac{2\frac{u_e'(v_-)+s}{\tau s\mu}}{\sqrt{\left(\frac{p'(v_-)+s^2}{s\mu}\right)^2 + 4\frac{u_e'(v_-)+s}{\tau s\mu}} + \frac{p'(v_-)+s^2}{s\mu}} < g'(v_-).$$

Since the unstable manifold of (19) at $(v_-, 0)$ is tangent to $r_{1-} = (1, \lambda_{1-})^T$ with $0 < \lambda_{1-} < g'(v_-)$, there is a trajectory of (19) originating from $(v_-, 0)$ that enters the domain D. Since D is an invariant region, such a trajectory is trapped inside D. Therefore the trajectory flows into the stable node $(v_+, 0)$ as $t \to +\infty$.

We thus find a solution V of (17) and (18) which is monotone decreasing. The entropy condition (7) follows from (20) and the above monotonicity. The existence of the traveling wave profile (V, U) of (15) and (5) is proved by using (16).

Lemma 2.1 is proved. □

3. Reformulation of the stability problem. In this section, we reformulate the problem that the solution $(v, u)(x, t)$ of (1), (2) exists globally and approaches a shifted traveling wave solution $(V, U)(x+x_0-st)$ under the subcharacteristic condition (4) and under condition (10) as $t \to \infty$.

We will look for a solution of the following form:

$$(v, u)(x, t) = (V, U)(z + x_0) + (\phi_z, \psi)(z, t), \tag{31}$$

where $z = x - st$.

For initial data satisfying (11), the conservation law in (1) implies that

$$\phi(\pm\infty, t) = \int_{-\infty}^{+\infty} (v(x,t) - V(x + x_0 - st))dx = \int_{-\infty}^{+\infty} (v_0(x) - V(x + x_0))dx$$

$$= x_0(v_+ - v_-) - \int_{-\infty}^{+\infty} (V(x + x_0) - V(x))dx = 0.$$

For simplicity of notation, we assume the shift $x_0 = 0$ in the rest of the paper.

We substitute (31) into (1), by virtue of (15), and integrate the first equation once with respect to z, to obtain that the perturbation (ϕ, ψ) satisfies

$$\begin{cases} \phi_t - s\phi_z - \psi = 0, \\ \psi_t - s\psi_z + (p(V + \phi_z) - p(V))_z \\ = \dfrac{1}{\tau}(u_e(V + \phi_z) - u_e(V) - \psi) + \mu\psi_{zz}. \end{cases} \tag{32}$$

The first equation of (32) gives

$$\psi = \phi_t - s\phi_z. \tag{33}$$

Substituting (33) into the second equation of (32), we get a closed equation for ϕ,

$$L(\phi) \equiv (\phi_t - s\phi_z)_t - s(\phi_t - s\phi_z)_z + (p'(V)\phi_z)_z + \frac{1}{\tau}\phi_t + \lambda\phi_z - \mu(\phi_t - s\phi_z)_{zz}$$

$$= -F(V, \phi_z), \tag{34}$$

where $Q < 0$ is defined in (20) and

$$\lambda = Q'(V) = -\frac{1}{\tau}(u_e'(V) + s),$$

and

$$F(V, \phi_z) = F_1 + F_2$$

with

$$F_1 := -\frac{1}{\tau}(u_e(V + \phi_z) - u_e(V) - u_e'(V)\phi_z), \tag{35}$$

$$F_2 := (p(V + \phi_z) - p(V) - p'(V)\phi_z)_z = (G(V, \phi_z)\phi_z^2)_z, \tag{36}$$

and

$$G(V, \phi_z) := \int_0^1 \int_0^1 p''(V + \theta\eta\phi_z)\theta d\theta d\eta$$

which is the error term due to nonlinearity of the function p.

The corresponding initial data for (34) become

$$\phi(z, 0) = \phi_0(z), \quad \phi_t(z, 0) = s\phi_0'(z) - \psi_0 = \phi_1(z). \tag{37}$$

The asymptotic stability of the profile (V, U) means that the perturbation (ϕ_z, ψ) decays to zero as $t \to +\infty$.

First, by noting (14), we have that the weight function defined in (12) satisfies $w(V) > 0$.

Now we introduce the solution space of the problem (34), (37) as follows:

$$X(0, T) =$$
$$\{\phi(z, t) : \ \phi \in C^0([0, T); H^3 \cap L^2_w) \cap C^1(0, T; H^2 \cap L^2_w), \ \ \phi_z, \phi_t \in L^2(0, T; H^2 \cap L^2_w)\}$$

with $0 < T \le +\infty$.

By virtue of (33), we have

$$\psi \in C^0([0, T); H^2 \cap L^2_w) \cap L^2(0, T; H^2 \cap L^2_w).$$

By the Sobolev embedding theorem, if we let

$$N(t) = \sup_{0 \le s \le t} \{||\phi(s)||_3 + ||\phi_t(s)||_2 + \|\phi(s)\|_{H^1_w} + ||\phi_t(s)||_{L^2_w}\}, \tag{38}$$

then

$$\sup_{z \in R} \{|\phi|, |\phi_z|, |\phi_{zz}|, |\phi_t|, |\phi_{tz}|\} \le CN(t). \tag{39}$$

Thus Theorem 1.1 is a consequence of the following theorem.

THEOREM 3.1. *Under the conditions of Theorem* 1.1, *there exist positive constants* δ_1, C, *and* C_1 *such that if* $N(0) \le \delta_1$, *then the problem* (34), (37) *has a unique global solution* $\phi \in X(0, +\infty)$ *satisfying*

$$||\phi(t)||_3^2 + ||\phi_t||_2^2 + ||\phi||_{H^1_w}^2 + ||\phi_t||_{L^2_w}^2 + \int_0^t ||(\phi_t, \phi_z)(s)||_2^2 ds$$
$$+ \ C_1\mu \left(\int_0^t ||(\phi_t - s\phi_z)_z||_{L^2_w}^2 ds + \int_0^t ||(\phi_t - s\phi_z)_{zz}||_1^2 ds \right) \le CN^2(0) \tag{40}$$

for $t \in [0, +\infty)$. Furthermore,

$$\sup_{z \in R} |(\phi_z, \phi_t)(z,t)| \to 0 \quad \textit{as} \ \ t \to \infty. \tag{41}$$

If ϕ is the global solution in the above theorem, then (ϕ, ψ), defined in (33), becomes a global solution of the problem (32) with $(\phi, \psi)(z,0) = (\phi_0, \psi_0)(z)$, and consequently we have the desired solution of the problem (1), (2) through the relation (31). On the other hand, the solution of (1) is unique in the space $C^0(0,T; H^2 \cap L^2_w)$; therefore Theorem 1.1 follows from Theorem 3.1. The estimate (40) gives

$$\begin{aligned} \phi_t^2 + \phi_z^2 &= \int_{-\infty}^{z} (2\phi_t \phi_{tz} + 2\phi_z \phi_{zz})(y,t)dy \\ &\le \left(\int_{-\infty}^{+\infty} (\phi_t^2 + \phi_z^2) dy \right)^{1/2} \left(\int_{-\infty}^{+\infty} (\phi_{tz}^2 + \phi_{zz}^2) dy \right)^{1/2} \to 0 \ \text{ as } \ t \to \infty \end{aligned}$$

as claimed in Theorem 1.1.

Global existence for ϕ will be derived from the following local existence theorem for ϕ combined with a priori estimates.

PROPOSITION 3.2 (local existence). *For any $\delta_0 > 0$, there exists a positive constant T_0 depending on δ_0, such that if $\phi_0 \in H^3 \cap H^1_w$ and $\phi_1 \in H^2 \cap L^2_w$, with $N(0) < \delta_0/2$, then the problem* (34), (37) *has a unique solution $\phi \in X(0, T_0)$ satisfying*

$$N(t) < 2N(0) \tag{42}$$

for any $0 \le t \le T_0$.

PROPOSITION 3.3 (a priori estimates). *Let $\phi \in X(0,T)$ be a solution for a positive constant T; then there exists a positive constant δ_2 independent of T such that if*

$$N(t) < \delta_2, \ \ t \in [0,T],$$

then ϕ satisfies (40) *for any $0 \le t \le T$.*

The local existence is classical, so we omit the proof; cf. [21]. Proving Proposition 3.3 is our main task in the following section.

4. Energy estimates. In this section, we will complete the proof of our stability theorem by establishing the desired a priori estimates. The stability result is a consequence of the compressibility of the traveling wave profile (14), the subcharacteristic conditions (4) and (9), the fact that the diffusion coefficient is bounded by a constant multiple of the relaxation time (10), and the weighted energy estimates.

LEMMA 4.1. *Under the conditions of Theorem* 1.1*, there are positive constants C and C_1 such that if subcharacteristic condition* (4) *is satisfied for $v \in [v_+, v_-]$, then any solution $\phi \in X(0,T)$ of problem* (34), (37) *satisfies*

$$||\phi(t)||^2_{H^1_w} + ||\phi_t(t)||^2_{L^2_w} + \int_0^t ||(\phi_t, \phi_z)(s)||^2_{L^2_w} ds$$

$$+ \int_0^t \int_R |U_z| \phi^2 dz ds + C_1 \mu \int_0^t \int_R w(\phi_t - s\phi_z)_z^2 dz ds$$

$$\leq C\left\{||\phi_0||^2_{H^1_w}+||\phi_1||^2_{L^2_w}+\int_0^t\int_R w|F|(|\phi|+|(\phi_t,\phi_z)|)dzds\right\} \tag{43}$$

for $t\in[0,T]$.

Proof. Let $w=w(V)>0$ be the weight function defined in (12).

Multiplying (34) by $2w(V)\phi$, we obtain

$$2w(V)\phi L(\phi)=-2Fw(V)\phi. \tag{44}$$

The left-hand side of (44) is reduced to

$$\begin{aligned}
&2[(\phi_t-s\phi_z)_t-s(\phi_t-s\phi_z)_z+(p'(V)\phi_z)_z]w\phi+2\left(\frac{1}{\tau}\phi_t+\lambda\phi_z\right)w\phi\\
&-2\mu w\phi(\phi_t-s\phi_z)_{zz}\\
=&\left[\frac{1}{\tau}w\phi^2+2w\phi(\phi_t-s\phi_z)\right]_t-2w(\phi_t-s\phi_z)^2-2wp'(V)\phi_z^2+(p'(V)w_z)_z\phi^2\\
&-(\lambda w)_z\phi^2+sw_z(\phi^2)_t-s^2\{w_z(\phi^2)\}_z+s^2w_{zz}\phi^2\\
&+\{-2sw\phi(\phi_t-s\phi_z)+2p'(V)w\phi\phi_z-p'(V)w_z\phi^2+\lambda w\phi^2-2\mu w\phi(\phi_t-s\phi_z)_z\}_z\\
&+2\mu w_z\phi(\phi_t-s\phi_z)_z+2\mu w\phi_z(\phi_t-s\phi_z)_z\\
=&\left[\frac{1}{\tau}w\phi^2+2w\phi(\phi_t-s\phi_z)+sw_z\phi^2\right]_t-2w(\phi_t-s\phi_z)^2-2p'(V)w\phi_z^2+A(V)\phi^2\\
&+2\mu w_z\phi(\phi_t-s\phi_z)_z+2\mu w\phi_z(\phi_t-s\phi_z)_z+2\mu sw'(V)V_{zz}\phi\phi_z+\{\cdots\}_z,
\end{aligned} \tag{45}$$

where $\{\cdots\}_z$ denotes the terms which will disappear after integration with respect to $z\in R$ and

$$\begin{aligned}
A(V)&=-\{(-p'(V)-s^2)w'(V)V_z+\lambda w-\mu sw'(V)V_{zz}\}_z\\
&=-\{w'(V)Q(V)+Q'(V)w\}_z\\
&=-\{wQ\}''(V)V_z,
\end{aligned} \tag{46}$$

where the second equality is due to (17).

Since V is monotone decreasing and

$$(wQ)''(V)=2,$$

therefore

$$A(V)=-2V_z>0. \tag{47}$$

Then we calculate

$$2(\phi_t-s\phi_z)wL(\phi)=-2F(\phi_t-s\phi_z)w. \tag{48}$$

The left-hand side of (48) is

$$
\begin{aligned}
&2[(\phi_t - s\phi_z)_t - s(\phi_t - s\phi_z)_z + (p'(V)\phi_z)_z]w(\phi_t - s\phi_z)\\
&+ \frac{2}{\tau}w(\phi_t - s\phi_z)(\phi_t - s\phi_z - uV_e'(V)\phi_z) - 2\mu w(\phi_t - s\phi_z)(\phi_t - s\phi_z)_{zz}\\
&= [w(\phi_t - s\phi_z)^2]_t + \left(\frac{2}{\tau}w + sw_z\right)(\phi_t - s\phi_z)^2 - 2p'(V)w_z\phi_z(\phi_t - s\phi_z)\\
&- \frac{2}{\tau}wu_e'(V)\phi_z(\phi_t - s\phi_z) - [p'(V)w\phi_z^2]_t + [swp'(V)\phi_z^2]_z - s(wp'(V))_z\phi_z^2\\
&- [sw(\phi_t - s\phi_z)^2 - 2p'(V)w\phi_z(\phi_t - s\phi_z)]_z\\
&- (2\mu w(\phi_t - s\phi_z)(\phi_t - s\phi_z)_z)_z + 2\mu w_z(\phi_t - s\phi_z)(\phi_t - s\phi_z)_z + 2\mu w(\phi_t - s\phi_z)_z^2\\
&= [-wp'(V)\phi_z^2 + w(\phi_t - s\phi_z)^2]_t + \left(\frac{2}{\tau}w + sw_z\right)(\phi_t - s\phi_z)^2\\
&- s(wp'(V))_z\phi_z^2 - \frac{2}{\tau}u_e'(V)w\phi_z(\phi_t - s\phi_z) - 2p'(V)w_z\phi_z(\phi_t - s\phi_z)\\
&+ 2\mu w_z(\phi_t - s\phi_z)(\phi_t - s\phi_z)_z + 2\mu w(\phi_t - s\phi_z)_z^2 + \{\cdots\}_z.
\end{aligned}
$$

Hence, the combination (44) + (48) $\times 2\tau$ yields

$$
\begin{aligned}
&\{E_1(\phi, (\phi_t - s\phi_z)) + E_3(\phi_z)\}_t + E_2(\phi_z, (\phi_t - s\phi_z)) + E_4(\phi) + 4\mu\tau w(\phi_t - s\phi_z)_z^2\\
&\qquad + 2\mu w_z\phi(\phi_t - s\phi_z)_z + 2\mu w\phi_z(\phi_t - s\phi_z)_z + 2\mu sw'(V)V_{zz}\phi\phi_z\\
&\qquad + 4\mu\tau w_z(\phi_t - s\phi_z)(\phi_t - s\phi_z)_z + \{\cdots\}_z = -2Fw\{\phi + 2\tau(\phi_t - s\phi_z)\},
\end{aligned}
\tag{49}
$$

where

$$
\begin{aligned}
E_1(\phi, (\phi_t - s\phi_z)) &= 2\tau w(\phi_t - s\phi_z)^2 + 2w\phi(\phi_t - s\phi_z) + \left(\frac{1}{\tau}w + sw_z\right)\phi^2,\\
E_3(\phi_z) &= -2\tau wp'(V)\phi_z^2,\\
E_2(\phi_z, (\phi_t - s\phi_z)) &= 2(w + \tau sw_z)(\phi_t - s\phi_z)^2\\
&\quad + 4(-u_e'(V)w - \tau p'(V)w_z)\phi_z(\phi_t - s\phi_z)\\
&\quad + 2(-wp'(V) - \tau s(wp'(V))_z)\phi_z^2,\\
E_4(\phi) &= A(V)\phi^2,
\end{aligned}
\tag{50}
$$

where $A(V)$ is defined in (46).

The discriminants of the quadratics $E_j (j = 1, 2)$ are, respectively,

$$D_1 = -4w[w + 2\tau sw_z],$$

$$D_2 = 16\{(-u_e'(V)w - \tau p'(V)w_z)^2 + (w + \tau sw_z)(wp'(V) + \tau s(wp'(V))_z)\}.$$

We claim that

$$D_1 < 0, \quad D_2 < 0, \tag{51}$$

provided that $|v_+ - v_-|$ is suitably small and subcharacteristic condition (4) is satisfied.

Indeed, the two inequalities in (51) are equivalent to

$$1 + 2s\tau\frac{w_z}{w} > 0, \tag{52}$$

$$\left(-u_e'(V)-\tau p'(V)\frac{w_z}{w}\right)^2 < \left(1+s\tau\frac{w_z}{w}\right)\left(-p'(V)-s\tau\frac{(wp'(V))_z}{w}\right). \tag{53}$$

Noticing that $|\tau(w(V))_z|$ and $|\tau(w(V)p'(V))_z|$ are small provided that $|v_+ - v_-|$ is suitably small and subcharacteristic condition (4) is satisfied, we derive inequalities (52) and (53). Thus condition (51) is satisfied.

Therefore there exist positive constants M_0 and M such that

$$\begin{cases} M_0 w\{\phi^2+(\phi_t-s\phi_z)^2\} \;\le\; E_1 \;\le\; Mw\{\phi^2+(\phi_t-s\phi_z)^2\}, \\ \\ M_0 w\{\phi_z^2+(\phi_t-s\phi_z)^2\} \;\le\; E_2. \end{cases} \tag{54}$$

Furthermore, (3) and (47) yield

$$\begin{cases} E_3 = -2\tau w p'(V)\phi_z^2 \ge 0, \\ \\ E_4 \ge 2|V_z|\phi^2 \ge 0. \end{cases} \tag{55}$$

Now we estimate terms containing μ in (49).

First, note that $4\mu\tau w(\phi_t - s\phi_z)_z^2$ is a good term, namely, nonnegative. Other terms containing μ are estimated by using the Cauchy–Schwarz inequality, estimate (54), the fact that $|w(V)_z|$ and $|V_{zz}|$ are small, and (10). Indeed, let us estimate the second term

$$\begin{aligned} &|2\mu w\phi_z(\phi_t-s\phi_z)_z| \\ &\le \mu\tau w(\phi_t-s\phi_z)_z^2 + \frac{\mu}{4\tau}w\phi_z^2 \le \mu\tau w(\phi_t-s\phi_z)_z^2 + \frac{1}{4}M_0 w\phi_z^2 \end{aligned} \tag{56}$$

provided that $\frac{\mu}{\tau} \le m \le M_0$ (10).

Substituting estimates (54), (55), and (56) into (49) and integrating the result with respect to t and z, we arrive at the desired estimate (43).

This completes the proof of Lemma 4.1. □

Next we estimate the higher order derivatives of ϕ.

Let $\phi_z = \Phi$; then

$$\begin{aligned} \partial_z L(\phi) &= (\phi_{zt}-s\phi_{zz})_t - s(\phi_{zt}-s\phi_{zz})_z + (p'(V)\phi_z)_{zz} \\ &\quad + \phi_{zt} + \lambda\phi_{zz} + \lambda_z\phi_z - \mu(\phi_{zt}-s\phi_{zz})_{zz} \\ &= L(\phi_z) + \lambda_z\phi_z + (p'(V)_z\phi_z)_z = L(\Phi) + \lambda_z\Phi + (p'(V)_z\Phi)_z. \end{aligned} \tag{57}$$

Multiplying the derivative of (34) with respect to z by $2\phi_z$ and $2(\phi_t - s\phi_z)_z$, respectively, we have

$$\begin{aligned} 2\partial_z L(\phi)\phi_z &= -2F_z\phi_z, \\ 2\partial_z L(\phi)(\phi_t-s\phi_z)_z &= -2F_z(\phi_t-s\phi_z)_z. \end{aligned}$$

By a similar argument used in obtaining estimates for the first order derivatives with $w = 1$, we have

$$\begin{aligned} &\left[\frac{1}{\tau}\Phi^2 + 2\Phi(\Phi_t - s\Phi_z)\right]_t - 2p'(V)\Phi_z^2 - 2(\Phi_t-s\Phi_z)^2 + \lambda_z\Phi^2 \\ &\quad + 2\mu\Phi_z(\Phi_t-s\Phi_z)_z - 2p'(V)_z\Phi\Phi_z + \{\cdots\}_z = -2F_z\Phi \end{aligned} \tag{58}$$

and

$$[(\Phi_t - s\Phi_z)^2 - p'(V)\Phi_z^2]_t + \frac{2}{\tau}(\Phi_t - s\Phi_z)^2 - \frac{2}{\tau}u_e'(V)\Phi_z(\Phi_t - s\Phi_z)$$
$$- sp'(V)_z\Phi_z^2 + 2\lambda_z\Phi(\Phi_t - s\Phi_z) + 2(p'(V)\Phi)_z(\Phi_t - s\Phi_z) + \{\cdots\}_z$$
$$+ 2\mu(\Phi_t - s\Phi_z)_z^2 = -2F_z(\Phi_t - s\Phi_z). \tag{59}$$

The combination (58) + (59) $\times\, 2\tau$ yields

$$\{E_1(\Phi, (\Phi_t - s\Phi_z)) + E_3(\Phi_z)\}_t + E_2(\Phi_z, (\Phi_t - s\Phi_z)) + H(\Phi) + \{\cdots\}_z$$
$$+ 4\mu\tau(\Phi_t - s\Phi_z)_z^2 + 2\mu\Phi_z(\Phi_t - s\Phi_z)_z = -F_z\{2\Phi + 4\tau(\Phi_t - s\Phi_z)\}, \tag{60}$$

where

(61)

$$H(\Phi) = \lambda_z\Phi^2 + 4\tau\lambda_z\Phi(\Phi_t - s\Phi_z) - 2p'(V)_z\Phi\Phi_z + 4\tau(p'(V)\Phi)_z(\Phi_t - s\Phi_z),$$
$$E_1(\Phi, (\Phi_t - s\Phi_z)) = 2\tau(\Phi_t - s\Phi_z)^2 + 2\Phi(\Phi_t - s\Phi_z) + \frac{1}{\tau}\Phi^2,$$
$$E_3(\Phi_z) = -2p'(V)\Phi_z^2,$$
$$E_2(\Phi_z, (\Phi_t - s\Phi_z)) = 2(\Phi_t - s\Phi_z)^2 - 4u_e'(V)\Phi_z(\Phi_t - s\Phi_z)$$
$$-2(p'(V) + s\tau p'(V)_z)\Phi_z^2.$$

Integrating (60) with respect to t and z and taking $\frac{\mu}{\tau}$ and $|v_+ - v_-|$ suitably small, we have the following estimate:

$$||\Phi(t)||_1^2 + ||\Phi_t(t)||^2 + \int_0^t ||(\Phi_t, \Phi_z)(s)||^2 ds + C_1\mu\int_0^t ||(\Phi_t - s\Phi_z)_z(s)||^2 ds$$
$$\le C\left\{||\Phi_0||_1^2 + ||\Phi_1||^2 + \int_0^t\int |H(\Phi)|dzds + \int_0^t\int_R |F_z|(|\Phi| + |(\Phi_t, \Phi_z)|)dzds\right\}, \tag{62}$$

where $\Phi_0 = \phi_0'$ and $\Phi_1 = \phi_1'$, and C and C_1 are positive constants.

Using the estimate (43), we obtain

$$\int_0^t\int_R |H(\Phi)|dzds \le \frac{1}{2}\int_0^t ||(\Phi_t, \Phi_z)(s)||^2 ds + C\int_0^t\int_R \Phi^2 dzds$$
$$\le \frac{1}{2}\int_0^t ||(\Phi_t, \Phi_z)(s)||^2 ds$$
$$+ C\left\{||\phi_0||_{H_w^1}^2 + ||\phi_1||_{L_w^2}^2 + \int_0^t\int w|F|(|\phi| + |(\phi_t, \phi_z)|)dzds\right\}. \tag{63}$$

Substituting (63) into (62) and replacing Φ by $\partial_z\phi$, we have the following lemma.

LEMMA 4.2. *Under the conditions of Theorem* 1.1*, there are positive constants* C *and* C_1 *such that if subcharacteristic condition* (4) *is satisfied for all* $v \in [v_+, v_-]$*, then any solution* $\phi \in X(0,T)$ *of problem* (34), (37) *satisfying*

$$||\partial_z\phi||_1^2 + ||\partial_z\phi_t||^2 + \frac{1}{2}\int_0^t ||(\partial_z\phi_t, \partial_z\phi_z)(s)||^2 ds + C_1\mu\int_0^t ||(\phi_t - s\phi_z)_{zz}(s)||^2 ds$$
$$\le C\left\{||\phi_0||_2^2 + ||\phi_1||_1^2 + \int_0^t\int |F_z|(|\partial_z\phi| + |(\partial_z\phi_t, \partial_z\phi_z)|)dzds\right.$$
$$\left. + ||\phi_0||_{H_w^1}^2 + ||\phi_1||_{L_w^2}^2 + \int_0^t\int w|F|(|\phi| + |(\phi_t, \phi_z)|)dzds\right\} \tag{64}$$

holds for $t \in [0,T]$.

Next we calculate the equality

$$\partial_z^2\phi\partial_z^2 L(\phi) + 2\partial_z^2(\phi_t - s\phi_z)\partial_z^2 L(\phi) = -F_{zz}(\partial_z^2\phi + 2\partial_z^2(\phi_t - s\phi_z))$$

in the same way as in the proof of Lemma 4.2. Setting $\Psi := \partial_z^2\phi$, we have

$$\partial_z^2 L(\phi) = L(\Psi) + (p'(V)\Phi)_{zzz} - (p'(V)\Psi_z)_z + (\lambda\Phi)_{zz} - \lambda\Psi_z.$$

A straightforward calculation gives

$$\begin{aligned}
&\left[2\tau(\Psi_t - s\Psi_z)^2 - 2\tau p'(V)\Psi_z^2 + 2\tau\Psi(\Psi_t - s\Psi_z) + \frac{1}{\tau}\Psi^2\right]_t + 2(\Psi_t - s\Psi_z)^2 \\
&\quad - 4u_e'(V)\Psi_z(\Psi_t - s\Psi_z) + 2(-p'(V) - s\tau p'(V)_z)\Psi_z^2 + 8\tau\lambda_z\Psi(\Psi_t - s\Psi_z) \\
&\qquad + 3\tau\lambda_z\Psi^2 + 2\tau\lambda_{zz}\Psi\phi_z + 4\tau\lambda_{zz}\phi_z(\Psi_t - s\Psi_z) + 4\mu\tau(\Psi_t - s\Psi_z)_z^2 \\
&\qquad + 2\mu\Psi_z(\Psi_t - s\Psi_z)_z + \{\cdots\}_z = -2F_{zz}[\Psi + 2\tau(\Psi_t - s\Psi_z)] + J, \qquad (65)
\end{aligned}$$

where J satisfies

$$\begin{aligned}
|J| &= |[-(p'(V)\Phi)_{zzz} + (p'(V)\Psi_z)_z][\Psi + 2\tau(\Psi_t - s\Psi_z)]| \\
&\le \frac{1}{3}|(\Psi_t, \Psi_z)|^2 + C|(\Phi, \Psi)|^2.
\end{aligned}$$

Thus, noting $\Psi = \phi_{zz}$ and (10), we derive from (65) and $|v_+ - v_-| \ll 1$ that

$$\begin{aligned}
&||\partial_z^2\phi(t)||_1^2 + ||\partial_z^2\phi_t||^2 + \frac{2}{3}\int_0^t ||(\partial_z^2\phi_t, \partial_z^2\phi_z)(s)||^2 ds - C\int_0^t (||\partial_z^2\phi||^2 + ||\phi_z||^2) ds \\
&\qquad + C_1\mu\int_0^t ||(\partial_z^2\phi_t - s\partial_z^2\phi_z)_{zz}(s)||^2 ds \\
&\qquad \le C\left\{||\phi_0||_3^2 + ||\phi_1||_2^2 + \left|\int_0^t\int F_{zz}(\partial_z^2\phi + 2\partial_z^2(\phi_t - s\phi_z)) dz ds\right|\right\}, \qquad (66)
\end{aligned}$$

where C and C_1 are positive constants.

Combining successively estimates (43), (64), and (66), we have

$$\begin{aligned}
&||\phi(t)||_3^2 + ||\phi_t(t)||_2^2 + ||\phi(t)||_{H_w^1}^2 + ||\phi_t(t)||_{L_w^2}^2 + \int_0^t\int |\lambda_z|\phi^2 dz ds + \int_0^t ||(\phi_t, \phi_z)||_2^2 ds \\
&+ \int_0^t ||(\phi_t, \phi_z)(s)||_{L_w^2} w^2 ds + C_1\mu\left(\int_0^t ||(\phi_t - s\phi_z)_z||_{L_w^2}^2 ds + \int_0^t ||(\phi_t - s\phi_z)_{zz}||_1^2 ds\right) \\
&\qquad \le C\Big\{||\phi_0||_3^2 + ||\phi_1||_2^2 + ||\phi_0||_{H_w^1}^2 + ||\phi_1||_{L_w^2}^2 \\
&\qquad + \int_0^t\int (w|F|(|\phi| + |(\phi_t, \phi_z)|) + |F_z|(|\partial_z\phi| + |(\partial_z\phi_t, \partial_z\phi_z)|)) dz ds \\
&\qquad + \left|\int_0^t\int F_{zz}(\partial_z^2\phi + 2\partial_z^2(\phi_t - s\phi_z)) dz ds\right|\Big\}, \qquad (67)
\end{aligned}$$

where

$$F = F_1 + F_2 = O(1)(\phi_z^2 + \phi_{zz}^2)$$

as defined in (35), (36). There are terms containing fourth order derivatives of ϕ in $F_{2,zz}$. The energy estimates for the derivatives of ϕ up to fourth order can be established; see [10].

Thus by virtue of (39), the integrals on the right-hand side of (67) are majored by

$$CN(t)\left(\int_0^t ||(\phi_t,\phi_z)||_2^2 ds + \int_0^t ||(\phi_t,\phi_z)(s)||_{L_w^2}^2 ds\right);$$

then we have

$$\begin{aligned} &N^2(t) + \int_0^t ||(\phi_t,\phi_z)||_2^2 ds + \int_0^t ||(\phi_t,\phi_z)(s)||_{L_w^2}^2 ds \\ &\le CN^2(0) + CN(t)\left(\int_0^t ||(\phi_t,\phi_z)||_2^2 ds + \int_0^t ||(\phi_t,\phi_z)(s)||_{L_w^2}^2 ds\right). \end{aligned}$$

Therefore, by assuming $N(T) \le \frac{1}{2C} = \delta_2$, we obtain the desired estimate

$$N^2(t) + \int_0^t ||(\phi_t,\phi_z)||_2^2 ds + \int_0^t ||(\phi_t,\phi_z)(s)||_{L_w^2}^2 ds \le CN^2(0) \quad \text{for} \quad t \in [0,T].$$

By choosing $N(0) \le \delta_1$ small, we arrive at $N(T) \le \delta_2$ for any $T > 0$.

Thus the proof of Proposition 3.3 is completed. □

In summary, we established the weighted energy estimates by assuming the smallness of $|v_+ - v_-|$, the compressibility of the traveling wave profile (14), the subcharacteristic conditions (4) and (9), and the fact that the diffusion coefficient is bounded by a constant multiple of the relaxation time (10).

NONEXISTENCE OF SUPERSONIC TRAVELING WAVES FOR NONLINEAR SCHRÖDINGER EQUATIONS WITH NONZERO CONDITIONS AT INFINITY*

MIHAI MARIŞ†

Abstract. We prove that the nonexistence of supersonic finite-energy traveling waves for nonlinear Schrödinger equations with nonzero conditions at infinity is a general phenomenon which holds for a large class of equations. The same is true for sonic traveling waves in two dimensions. In higher dimensions we prove that sonic traveling waves, if they exist, must approach their limit at infinity in a very rigid way. In particular, we infer that there are no sonic traveling waves with finite energy and finite momentum.

Key words. nonlinear Schrödinger equation, nonzero conditions at infinity, traveling wave, integral identities, Gross–Pitaevskii equations and systems, cubic-quintic nonlinear Schrödinger equation

1. Introduction.

The aim of this paper is to study traveling wave solutions for nonlinear Schrödinger equations

$$i\frac{\partial \Phi}{\partial t} + \Delta \Phi + F(x, |\Phi|^2)\Phi = 0 \qquad \text{in } \mathbf{R}^N, \tag{1.1}$$

where F is a real-valued function defined on $\mathbf{R}^N \times \mathbf{R}_+$, Φ is a complex-valued function on $\mathbf{R}^N$ satisfying the "boundary condition" $|\Phi| \longrightarrow r_0$ as $|x| \longrightarrow \infty$, and r_0 is a positive constant verifying $\lim_{|x|\to\infty,\ s\to r_0^2} F(x,s) = 0$.

The above equation with the considered nonzero conditions at infinity arises in a large variety of physical problems, such as superconductivity, superfluidity in helium II, phase transitions, and Bose–Einstein condensates. Two important particular cases of (1.1) have been extensively studied both by physicists and by mathematicians: the Gross–Pitaevskii equation (where $F(x,s) = 1 - s$) and the so-called cubic-quintic Schrödinger equation (where $F(x,s) = -\alpha_1 + \alpha_3 s - \alpha_5 s^2$, α_1, α_3, α_5 are positive, and $\frac{3}{16} < \frac{\alpha_1\alpha_5}{\alpha_3^2} < \frac{1}{4}$).

Equation (1.1) has a Hamiltonian structure: denoting $V(x,s) = \int_s^{r_0^2} F(x,\tau)\,d\tau$, it is easy to see that, at least formally, the "energy"

$$E(\Phi) = \int_{\mathbf{R}^N} |\nabla \Phi|^2\,dx + \int_{\mathbf{R}^N} V(x, |\Phi|^2)\,dx \tag{1.2}$$

is a conserved quantity. There is another important (vector) quantity associated to (1.1), namely, the momentum. It is given by

$$P(\Phi) = (P_1(\Phi), \dots, P_N(\Phi)), \text{where } P_k(\Phi) = \int_{\mathbf{R}^N} \left(i\frac{\partial \Phi}{\partial x_k}, \Phi \right) dx = \int_{\mathbf{R}^N} \mathrm{Re}\left(i\frac{\partial \Phi}{\partial x_k}\overline{\Phi} \right) dx. \tag{1.3}$$

*Received by the editors December 17, 2007; accepted for publication (in revised form) June 17, 2008; published electronically October 17, 2008.

Note that, in general, the momentum is not well-defined for any function Φ of finite energy. In the case where F does not depend on the variable x_k, the momentum with respect to the x_k-direction, P_k, is conserved by those solutions of (1.1) for which it can be well-defined.

It is worth noting that (1.1) can be put into a hydrodynamical form by using Madelung's transformation $\Phi(x,t) = \sqrt{\rho(x,t)}e^{i\theta(x,t)}$ (which is singular when $\Phi = 0$). A straightforward computation shows that in the region where $\Phi \neq 0$, the functions $\rho = |\Phi|^2$ and θ satisfy the system

$$\rho_t + 2\mathrm{div}(\rho\nabla\theta) = 0, \tag{1.4}$$

$$\theta_t + |\nabla\theta|^2 - \frac{\Delta\rho}{2\rho} + \frac{|\nabla\rho|^2}{4\rho} - F(x,\rho) = 0. \tag{1.5}$$

Equation (1.4) and the derivatives with respect to $x_1, \ldots, x_N$ of (1.5) are, respectively, the equation of conservation of mass and Euler's equations for a compressible inviscid fluid of density ρ and velocity $2\nabla\theta$.

Let us assume that F admits a partial derivative with respect to the last variable (in what follows, this derivative will be denoted by $\partial_{N+1}F$ or by $\frac{\partial F}{\partial s}$) and that $\lim_{|x|\to\infty,\ \rho\to r_0^2} \partial_{N+1}F(x,\rho) = -L$, where L is a positive constant. Taking the derivative with respect to t of (1.5) and substituting ρ_t from (1.4) we obtain

$$\theta_{tt} + 2\partial_{N+1}F(x,\rho)(\rho\Delta\theta + \nabla\rho.\nabla\theta) + \frac{\partial}{\partial t}\left(|\nabla\theta|^2 - \frac{\Delta\rho}{2\rho} + \frac{|\nabla\rho|^2}{4\rho}\right) = 0. \tag{1.6}$$

For a small oscillatory motion (i.e., a sound wave), all nonlinear terms in (1.6), except $2\rho\Delta\theta$, may be neglected. In view of the behavior of ρ and $\partial_{N+1}F(x,\rho)$ for large $|x|$, we find that in a neighborhood of infinity, the velocity potential θ essentially obeys the wave equation $\theta_{tt} - 2r_0^2L\Delta\theta = 0$. It is well known that the solutions of the wave equation propagate with a finite speed; in the present situation, we infer that the velocity of sound waves at infinity is $r_0\sqrt{2L}$. In what follows we will always assume that $\partial_{N+1}F(x,\rho) \longrightarrow -L$ as $|x| \longrightarrow \infty$ and $\rho \longrightarrow r_0^2$ (the convergence being in a sense to be defined) and we will denote by $v_s = r_0\sqrt{2L}$ the sound velocity at infinity.

For a fixed $y \in S^{N-1}$, a traveling wave for (1.1) moving with velocity c in direction y is a solution of the form $\Phi(x,t) = \psi(x - cty)$. Without loss of generality we will assume that $y = (1,0,\ldots,0)$, i.e., traveling waves move in the x_1-direction. The traveling wave profile satisfies the equation

$$-ic\frac{\partial\psi}{\partial x_1} + \Delta\psi + F(x,|\psi|^2)\psi = 0 \qquad \text{in } \mathbf{R}^N. \tag{1.7}$$

In a series of papers, Grant, Jones, Putterman, and Roberts, among others, formally and numerically studied traveling waves for the Gross–Pitaevskii equation and related systems (see, e.g., [16], [19], [21], [22], [5], and the references therein). In particular, they conjectured that such solutions exist if and only if their speed c belongs to the interval $(-v_s, v_s)$. For the cubic-quintic nonlinear Schrödinger equation, the existence of subsonic traveling waves in one dimension has been proved in [1] and their stability has been studied in [2]. The nonexistence of such solutions for sonic and supersonic speeds has also been conjectured in any space dimension. In the case of the Gross–Pitaevskii equation, it has been shown in [17] that any traveling wave of finite energy and speed $c > v_s$ must be constant. It has also been proved in [18] that the same result is true if $N = 2$ and $c^2 = v_s^2$. The proofs in

[17], [18] strongly depend on the special algebraic structure of the nonlinearity in the Gross–Pitaevskii equation. In the present paper we show that the nonexistence of finite-energy traveling waves moving faster than the sound velocity is a general phenomenon which holds for a large class of equations and systems of the form (1.1). We also prove that there are no finite-energy sonic traveling waves in space dimension two. In higher dimensions we show that any finite-energy sonic traveling wave ψ must satisfy $|\psi|^2 - r_0^2 \in L^p(\mathbf{R}^N)$ for any $p > \frac{2N-1}{2N-3}$. On the other hand, if a sonic traveling wave satisfies $|\psi|^2 - r_0^2 \in L^{\frac{2N-1}{2N-3}}(\mathbf{R}^N)$, then it must be constant.

This article is organized as follows: In the next section we prove that traveling waves, whenever they exist, are smooth functions. If their speed is supersonic (or sonic, provided they converge sufficiently fast at infinity), then they must satisfy a special integral identity. This will be proved in section 3. In section 4 we show how this identity implies, under general assumptions, the nonexistence of traveling waves with finite energy. We apply our results to the Gross–Pitaevskii equation, to the cubic-quintic Schrödinger equation, and to a Gross–Pitaevskii–Schrödinger system, which describes the motion of an uncharged impurity in a Bose condensate. In the last section we describe all supersonic and sonic traveling waves (with finite or infinite energy) for one-dimensional equations with nonlinearities independent on the space variable.

2. Basic properties of traveling waves. We keep the previous notation and consider the following set of assumptions:

- **(H1)** $F : \mathbf{R}^N \times [0,\infty) \longrightarrow \mathbf{R}$ is a measurable function which has the following properties:
  (a) for any $s \in [0,\infty)$, $F(\cdot, s)$ is measurable;
  (b) for any $x \in \mathbf{R}^N$, $F(x,\cdot)$ is continuous;
  (c) F is bounded on bounded subsets of $\mathbf{R}^N \times [0,\infty)$.
- **(H2)** There exist $\alpha > 0$, $C > 0$, and $r_* > 0$ such that for any $x \in \mathbf{R}^N$ and for any $s \geq r_*$ we have $F(x,s) \leq -Cs^\alpha$.
- **(H3)** $\lim_{|x|\to\infty} F(x, r_0^2) = 0$ and $F(\cdot, r_0^2) \in L^1(\mathbf{R}^N)$.
- **(H4)** F admits a partial derivative with respect to the last variable and $\partial_{N+1}F$ is bounded on bounded subsets of $\mathbf{R}^N \times [0,\infty)$. Moreover, $\lim_{|x|\to\infty} \partial_{N+1}F(x, r_0^2) = -L$, where $L > 0$ and $\partial_{N+1}F(\cdot, r_0^2) + L \in L^{p_0}(\mathbf{R}^N)$ for some $p_0 \in [1,2]$.
- **(H5)** There are some positive constants R_0, η, M such that $\partial_{N+1}^2 F$ exists on $(\mathbf{R}^N \setminus \overline{B}(0,R_0)) \times (r_0^2 - \eta, r_0^2 + \eta)$ and

$$|\partial_{N+1}^2 F(x,s)| \leq M \qquad \text{for all } (x,s) \in (\mathbf{R}^N \setminus \overline{B}(0,R_0)) \times (r_0^2 - \eta, r_0^2 + \eta).$$

Definition 2.1. *A traveling wave (of speed c) for* (1.1) *is a function $\psi \in L^1_{loc}(\mathbf{R}^N)$ that satisfies* (1.7) *in $\mathcal{D}'(\mathbf{R}^N)$ together with the "boundary condition" $|\psi| \longrightarrow r_0$ as $|x| \longrightarrow \infty$.*

In view of (1.2)*, we say that a traveling wave ψ has finite energy if $\nabla\psi \in L^2(\mathbf{R}^N)$ and $V(\cdot, |\psi|^2) \in L^1(\mathbf{R}^N)$.*

We have the following result concerning the regularity of traveling waves.

Proposition 2.2. *Let ψ be a finite-energy traveling wave for* (1.1).

(i) *Assume that $F : \mathbf{R}^N \times \mathbf{R}_+ \longrightarrow \mathbf{R}$ is measurable and satisfies* (H1a), (H1b), (H2)*, the function $x \longmapsto \int_{r_0^2}^{r_*} F(x,\tau)\, d\tau$ belongs to $L^1_{loc}(\mathbf{R}^N)$ (where r_* is given by* (H2)*), and $F(\cdot, |\psi|^2)\psi \in L^1_{loc}(\mathbf{R}^N)$. Then $\psi \in L^\infty(\mathbf{R}^N)$.*

If, in addition, F satisfies (H1c), *then $\psi \in W^{2,p}_{loc}(\mathbf{R}^N)$ for any $p \in [1,\infty)$. In particular, $\psi \in C^{1,\alpha}(\mathbf{R}^N)$ for any $\alpha \in [0,1)$.*

(ii) *Suppose that $F \in C^k(\mathbf{R}^N \times [0,\infty))$ for some $k \in \mathbf{N}^*$,* (H2) *holds, and $F(\cdot,|\psi|^2)\psi \in L^1_{loc}(\mathbf{R}^N)$. Then $\psi \in W^{k+2,p}_{loc}(\mathbf{R}^N)$ for any $p \in [1,\infty)$. In particular, if F is C^∞, then $\psi \in C^\infty(\mathbf{R}^N)$.*

Proof. (i) The proof relies upon the ideas and methods developed by Farina in [13], [14]. By (H2) we have

$$V(x,s) = -\int_{r_0^2}^{s} F(x,\tau)\,d\tau \geq -\int_{r_0^2}^{r_*} F(x,\tau)\,d\tau + \int_{r_*}^{s} C\tau^\alpha\,d\tau$$
$$= -\int_{r_0^2}^{r_*} F(x,\tau)\,d\tau + \frac{C}{\alpha+1}(s^{\alpha+1} - r_*^{\alpha+1}).$$

Consequently, for any $s \geq r_*$ we get $s^{\alpha+1} \leq r_*^{\alpha+1} + \frac{\alpha+1}{C}(V(x,s) + \int_{r_0^2}^{r_*} F(x,\tau)\,d\tau)$, so that

$$|\psi|^{2\alpha+2}(x) \leq \max\Big(r_*^{\alpha+1}, r_*^{\alpha+1} + \frac{\alpha+1}{C}\Big(V(x,|\psi|^2(x)) + \int_{r_0^2}^{r_*} F(x,\tau)\,d\tau\Big)\Big).$$

Since $V(\cdot,|\psi|^2)$ and $\int_{r_0^2}^{r_*} F(\cdot,\tau)\,d\tau$ belong to $L^1_{loc}(\mathbf{R}^N)$, we infer that $\psi \in L^{2\alpha+2}_{loc}(\mathbf{R}^N)$.

We will use a well-known inequality of Kato (see Lemma A, p. 138, in [23]):

If $u \in L^1_{loc}(\mathbf{R}^N)$ is a real-valued function and $\Delta u \in L^1_{loc}(\mathbf{R}^N)$, then

$$\Delta(u^+) \geq \operatorname{sgn}^+(u)\Delta u \qquad \text{in } \mathcal{D}'(\mathbf{R}^N). \tag{2.1}$$

Let $\varphi(x) = e^{-\frac{icx_1}{2}}\psi(x)$. Then $\varphi \in L^{2\alpha+2}_{loc}(\mathbf{R}^N) \subset L^1_{loc}(\mathbf{R}^N)$ and an easy computation shows that φ satisfies

$$\Delta\varphi + \Big(F(x,|\varphi|^2) + \frac{c^2}{4}\Big)\varphi = 0 \qquad \text{in } \mathcal{D}'(\mathbf{R}^N). \tag{2.2}$$

It is clear that $F(\cdot,|\varphi|^2)\varphi \in L^1_{loc}(\mathbf{R}^N)$ (because $F(x,|\psi|^2)\psi \in L^1_{loc}(\mathbf{R}^N)$ by hypothesis) and it follows from (2.2) that $\Delta\varphi \in L^1_{loc}(\mathbf{R}^N)$. Choose $\tilde r \geq r_*$ and $C_1 > 0$ such that $Cs^{2\alpha} - \frac{c^2}{4} \geq C_1(s-\tilde r)^{2\alpha}$ for any $s \geq \tilde r$. Denoting $\varphi_1 = \operatorname{Re}(\varphi)$, $\varphi_2 = \operatorname{Im}(\varphi)$ and using Kato's inequality for $\varphi_i - \tilde r$, $i = 1,2$, then using (2.2) and (H2) we get

$$\begin{aligned}\Delta(\varphi_i - \tilde r)^+ &\geq \operatorname{sgn}^+(\varphi_i - \tilde r)\Delta(\varphi_i - \tilde r) = \operatorname{sgn}^+(\varphi_i - \tilde r)\left[-\left(F(x,|\varphi|^2) + \frac{c^2}{4}\right)\varphi_i\right]\\ &\geq \operatorname{sgn}^+(\varphi_i - \tilde r)\left[C|\varphi|^{2\alpha} - \frac{c^2}{4}\right]\varphi_i \geq \operatorname{sgn}^+(\varphi_i - \tilde r)\left[C|\varphi_i|^{2\alpha} - \frac{c^2}{4}\right]\varphi_i\\ &\geq C_1 \operatorname{sgn}^+(\varphi_i - \tilde r)(\varphi_i - \tilde r)^{2\alpha+1} = C_1[(\varphi_i - \tilde r)^+]^{2\alpha+1}.\end{aligned} \tag{2.3}$$

Next we use the following result of Brézis (Lemma 2, p. 273, in [9]).

LEMMA 2.3 (see [9]). *Let $p \in (1,\infty)$. Assume that $u \in L^p_{loc}(\mathbf{R}^N)$ satisfies*

$$-\Delta u + |u|^{p-1}u \leq 0 \qquad \text{in } \mathcal{D}'(\mathbf{R}^N).$$

Then $u \leq 0$ a.e. on $\mathbf{R}^N$.

It follows from (2.3) that the function $u_i = (C_1)^{\frac{1}{2\alpha}}(\varphi_i - \tilde r)^+$ satisfies $-\Delta u_i + |u_i|^{2\alpha}u_i \leq 0$ in $\mathcal{D}'(\mathbf{R}^N)$. Since $u_i \in L^{2\alpha+1}_{loc}(\mathbf{R}^N)$, we may use Lemma 2.3 and thus get $u_i \leq 0$ a.e. in $\mathbf{R}^N$, that is, $\varphi_i \leq \tilde r$ a.e. in $\mathbf{R}^N$.

It is obvious that both φ and $-\varphi$ satisfy (2.2). Repeating the above argument for $-\varphi$, we infer that $-\varphi_i \le \tilde{r}$ a.e. on $\mathbf{R}^N$. Therefore we have $|\varphi_i| \le \tilde{r}$ a.e. on $\mathbf{R}^N$, $i = 1, 2$, which implies that $\varphi \in L^\infty(\mathbf{R}^N)$. Since $|\varphi| = |\psi|$, we have proved that $\psi \in L^\infty(\mathbf{R}^N)$.

Using (H1c) and (2.2) we infer that $\Delta\varphi \in L^\infty(B(x,2R)) \subset L^p(B(x,2R))$ for any $x \in \mathbf{R}^N$, $R > 0$, and $p \ge 1$. By standard elliptic estimates we obtain $\varphi \in W^{2,p}(B(x,R))$ for any $x \in \mathbf{R}^N$, $R > 0$, and $p \in (1,\infty)$. Thus $\psi = e^{\frac{icx_1}{2}}\varphi \in W^{2,p}_{loc}(\mathbf{R}^N)$ for any $p \in (1,\infty)$, and consequently ψ belongs to $C^{1,\alpha}_{loc}(\mathbf{R}^N)$ for any $\alpha \in [0,1)$ by the Sobolev embedding theorem.

(ii) Assume $F \in C^1(\mathbf{R}^N \times [0,\infty))$. Differentiating (1.7) with respect to x_k we get

$$-ic\psi_{x_1x_k} + \Delta\psi_{x_k} + \frac{\partial F}{\partial x_k}(x,|\psi|^2)\psi + 2\partial_{N+1}F(x,|\psi|^2)\left(\psi.\frac{\partial\psi}{\partial x_k}\right)\psi + F(x,|\psi|^2)\frac{\partial\psi}{\partial x_k} = 0 \tag{2.4}$$

in $\mathcal{D}'(\mathbf{R}^N)$. Hence $\Delta\psi_{x_k} \in L^p_{loc}(\mathbf{R}^N)$ for $1 \le p < \infty$. By standard elliptic regularity theory we get $\psi_{x_k} \in W^{2,p}_{loc}(\mathbf{R}^N)$ for $1 < p < \infty$, $1 \le k \le N$; therefore $\psi \in W^{3,p}_{loc}(\mathbf{R}^N)$ for $1 \le p < \infty$. If $F \in C^k(\mathbf{R}^N \times [0,\infty))$, we may differentiate (2.4) further and repeat the above arguments. After an easy induction, we get $\psi \in W^{k+2,p}_{loc}(\mathbf{R}^N)$ for any $p \in (1,\infty)$. □

LEMMA 2.4. *Assume that* (H1), (H3), (H4), (H5) *hold and* $u \in L^4_{loc}(\mathbf{R}^N,\mathbf{C})$ *satisfies* $|u(x)| \longrightarrow r_0$ *as* $|x| \longrightarrow \infty$ *and* $V(\cdot,|u|^2) \in L^1(\mathbf{R}^N)$.

Then $|u|^2 - r_0^2 \in L^2(\mathbf{R}^N)$.

Proof. Let R_0, η, M be as in (H5). From (H4) and the fact that $|u(x)| \longrightarrow r_0$ as $|x| \longrightarrow \infty$ it follows that there exists $R_1 > R_0$ such that

$$\partial_{N+1}F(x,r_0^2) < -\frac{L}{2} \quad \text{and} \quad |u(x)|^2 \in (r_0^2-\eta, r_0^2+\eta) \quad \text{for any } x \text{ satisfying } |x| \ge R_1.$$

For $(x,s) \in (\mathbf{R}^N \setminus B(0,R_1)) \times (r_0^2-\eta, r_0^2+\eta)$ we get, by Taylor's formula with respect to the $(N+1)$th variable,

$$V(x,s) = -(s-r_0^2)F(x,r_0^2) - \frac{1}{2}(s-r_0^2)^2\partial_{N+1}F(x,r_0^2) - \frac{1}{2}\int_{r_0^2}^{s}(s-\tau)^2\partial^2_{N+1}F(x,\tau)\,d\tau.$$

In particular, for $s = |u(x)|^2$ we obtain

$$-\frac{1}{2}(|u(x)|^2 - r_0^2)^2\partial_{N+1}F(x,r_0^2) = V(x,|u(x)|^2) + (|u(x)|^2 - r_0^2)F(x,r_0^2) + \frac{1}{2}\int_{r_0^2}^{|u(x)|^2}(|u(x)|^2-\tau)^2\partial^2_{N+1}F(x,\tau)\,d\tau. \tag{2.5}$$

For $x \in \mathbf{R}^N \setminus B(0,R_1)$ we get by (H5)

$$\left|\int_{r_0^2}^{|u(x)|^2}(|u(x)|^2-\tau)^2\partial^2_{N+1}F(x,\tau)\,d\tau\right| \le M\left|\int_{r_0^2}^{|u(x)|^2}(|u(x)|^2-\tau)^2\,d\tau\right| = \frac{M}{3}\big|(|u(x)|^2 - r_0^2)\big|^3.$$

It is clear that there exists $R_2 \geq R_1$ such that $\frac{M}{3}\big||u(x)|^2 - r_0^2\big| \leq \frac{L}{4}$ on $\mathbf{R}^N \setminus B(0,R_2)$. Using (H4) and (2.5) we infer that

$$\begin{aligned}
&\frac{L}{4}(|u(x)|^2 - r_0^2)^2 \leq -\frac{1}{2}(|u(x)|^2 - r_0^2)^2 \partial_{N+1}F(x,r_0^2)\\
&\leq V(x,|u(x)|^2) + (|u(x)|^2 - r_0^2)F(x,r_0^2) + \frac{1}{2}\cdot\frac{M}{3}\Big||u(x)|^2 - r_0^2\Big|^3\\
&\leq V(x,|u(x)|^2) + (|u(x)|^2 - r_0^2)F(x,r_0^2) + \frac{L}{8}\Big||u(x)|^2 - r_0^2\Big|^2 \qquad \text{on } \mathbf{R}^N \setminus B(0,R_2).
\end{aligned}$$

Consequently

$$\frac{L}{8}(|u(x)|^2 - r_0^2)^2 \leq V(x,|u(x)|^2) + (|u(x)|^2 - r_0^2)F(x,r_0^2) \text{ on } \mathbf{R}^N \setminus B(0,R_2). \tag{2.6}$$

Since $F(\cdot,r_0^2) \in L^1(\mathbf{R}^N)$ by (H3), $V(\cdot,|u|^2) \in L^1(\mathbf{R}^N)$, and $\big||u(x)|^2 - r_0^2\big| \leq \frac{3L}{4M}$ on $\mathbf{R}^N \setminus B(0,R_2)$, using (2.6) we get $(|u|^2 - r_0^2)^2 \in L^1(\mathbf{R}^N \setminus B(0,R_2))$. It is obvious that $(|u|^2 - r_0^2)^2 \in L^1(B(0,R_2))$ because $u \in L^4_{loc}(\mathbf{R}^N)$. Hence $(|u|^2 - r_0^2)^2 \in L^1(\mathbf{R}^N)$ and Lemma 2.4 is proved. ∎

PROPOSITION 2.5. *Assume that* (H1)–(H5) *hold and let ψ be a finite-energy traveling wave for* (1.1) *(in the sense of Definition* 2.1*) such that $F(\cdot,|\psi|^2)\psi \in L^1_{loc}(\mathbf{R}^N)$. Then the following hold:*

(i) *$\nabla\psi \in W^{1,p}(\mathbf{R}^N)$ for any $p \in [2,\infty)$.*

(ii) *Let $R_* \geq 0$ be such that $|\psi(x)| \geq \frac{r_0}{2}$ for $|x| \geq R_*$. There exists a real-valued function θ such that $\theta \in W^{2,p}_{loc}(\mathbf{R}^N \setminus \overline{B}(0,R_*))$ for any $p < \infty$, $\nabla\theta \in W^{1,p}(\mathbf{R}^N \setminus \overline{B}(0,R_*))$ for any $p \in [2,\infty)$, and*

$$\psi(x) = |\psi(x)|e^{i\theta(x)} \qquad \text{on } \mathbf{R}^N \setminus B(0,R_*).$$

Proof. (i) We already know by Proposition 2.2(i) and Lemma 2.4 that ψ is bounded, $\psi \in W^{2,p}_{loc}(\mathbf{R}^N)$ for any $p \in [1,\infty)$, and $|\psi|^2 - r_0^2 \in L^2(\mathbf{R}^N)$.

Let R_0, η, M be as in (H5). Choose $R_1 > R_0$ such that $|\psi|^2(x) \in (r_0^2 - \eta, r_0^2 + \eta)$ for $x \in \mathbf{R}^N \setminus B(0,R_1)$.

By using Taylor's formula with respect to the last variable for the function F we get

$$F(x,s) = F(x,r_0^2) + (s - r_0^2)\partial_{N+1}F(x,r_0^2) + \int_{r_0^2}^{s}(s-\tau)\partial^2_{N+1}F(x,\tau)\,d\tau \tag{2.7}$$

if $(x,s) \in (\mathbf{R}^N \setminus \overline{B}(0,R_0)) \times (r_0^2 - \eta, r_0^2 + \eta)$; hence

$$\begin{aligned}
F(x,|\psi|^2(x))\psi(x) &= F(x,r_0^2)\psi(x) + (|\psi|^2(x) - r_0^2)\partial_{N+1}F(x,r_0^2)\psi(x)\\
&\quad + \psi(x)\int_{r_0^2}^{|\psi|^2(x)}(|\psi|^2(x) - \tau)\partial^2_{N+1}F(x,\tau)\,d\tau \quad \text{for any } |x| \geq R_1.
\end{aligned} \tag{2.8}$$

We analyze the three terms on the right-hand side of (2.8). Assumptions (H1) and (H3) imply $F(\cdot,r_0^2) \in L^1 \cap L^\infty(\mathbf{R}^N)$. Since $\psi \in L^\infty(\mathbf{R}^N)$, it follows that $F(\cdot,r_0^2)\psi \in L^1 \cap L^\infty(\mathbf{R}^N)$.

We may write $(|\psi|^2 - r_0^2)\partial_{N+1}F(\cdot,r_0^2)\psi = -L(|\psi|^2 - r_0^2)\psi + (|\psi|^2 - r_0^2)(L + \partial_{N+1}F(\cdot,r_0^2))\psi$. We know that $\psi \in L^\infty(\mathbf{R}^N)$, $|\psi|^2 - r_0^2 \in L^2 \cap L^\infty(\mathbf{R}^N)$ and by (H4)

we have $L + \partial_{N+1}F(\cdot, r_0^2) \in L^{p_0} \cap L^\infty(\mathbf{R}^N)$ for some $p_0 \in [1,2]$, so we infer that $(|\psi|^2 - r_0^2)\partial_{N+1}F(\cdot, r_0^2)\psi \in L^2 \cap L^\infty(\mathbf{R}^N)$.

As in the proof of Lemma 2.4, for $x \in \mathbf{R}^N \setminus B(0,R_1)$ we have

$$\left| \int_{r_0^2}^{|\psi|^2(x)} (|\psi|^2(x) - \tau)\partial_{N+1}^2 F(x,\tau)\, d\tau \right| \leq M \left| \int_{r_0^2}^{|\psi|^2(x)} \Big| |\psi|^2(x) - \tau \Big| d\tau \right| = \frac{M}{2}(|\psi|^2(x) - r_0^2)^2. \tag{2.9}$$

Consequently the function $x \longmapsto \int_{r_0^2}^{|\psi|^2(x)} (|\psi|^2(x) - \tau)\partial_{N+1}^2 F(x,\tau)\, d\tau$ belongs to $L^1 \cap L^\infty(\mathbf{R}^N \setminus B(0,R_1))$.

Summing up, we have proved that $F(\cdot, |\psi|^2)\psi \in L^2 \cap L^\infty(\mathbf{R}^N \setminus B(0,R_1))$. From (H1) and the fact that ψ is bounded on $\mathbf{R}^N$ it follows that $F(\cdot, |\psi|^2)\psi$ is bounded on $B(0,R_1)$, and hence $F(\cdot, |\psi|^2)\psi \in L^2 \cap L^\infty(\mathbf{R}^N)$.

We have $\frac{\partial \psi}{\partial x_k} \in L^2(\mathbf{R}^N)$ because ψ has finite energy. Coming back to (1.7), we get

$$\Delta\psi = ic\frac{\partial \psi}{\partial x_1} - F(\cdot, |\psi|^2)\psi \in L^2(\mathbf{R}^N).$$

It is well known that $\Delta\psi \in L^p(\mathbf{R}^N)$ with $1 < p < \infty$ implies $\frac{\partial^2 \psi}{\partial x_j \partial x_k} \in L^p(\mathbf{R}^N)$ for any $j,k \in \{1,\dots,N\}$ (this follows, e.g., from the fact that $\frac{\xi_j \xi_k}{|\xi|^2}$ is a Fourier multiplier on $L^p(\mathbf{R}^N)$ if $1 < p < \infty$; see Theorem 3, p. 96, in [27]). Therefore all second derivatives of ψ are in $L^2(\mathbf{R}^N)$, so that $\frac{\partial \psi}{\partial x_k} \in H^1(\mathbf{R}^N) = W^{1,2}(\mathbf{R}^N)$ for $k = 1,\dots,N$.

The rest of the proof is an easy bootstrap argument. Assume that $\nabla\psi \in W^{1,p}(\mathbf{R}^N)$ for some $p \geq 2$. In case $p < N$, it follows from the Sobolev embedding theorem that $\nabla\psi \in L^{p^*}(\mathbf{R}^N)$, where $\frac{1}{p^*} = \frac{1}{p} - \frac{1}{N}$. From (1.7) we have $\Delta\psi = ic\frac{\partial \psi}{\partial x_1} - F(\cdot, |\psi|^2)\psi \in L^{p^*}(\mathbf{R}^N)$ and infer as previously that $\nabla\psi \in W^{1,p^*}(\mathbf{R}^N)$. Repeating this argument if necessary, after a finite number of steps we get $\nabla\psi \in W^{1,q}(\mathbf{R}^N)$ for some $q \geq N$. Then by Sobolev embedding we get $\nabla\psi \in L^r(\mathbf{R}^N)$ for any $r \in [q,\infty)$. From (1.7) we obtain $\Delta\psi \in L^p(\mathbf{R}^N)$ for $p \in [2,\infty)$ and infer that $\nabla\psi \in W^{1,p}(\mathbf{R}^N)$ for any $p \in [2,\infty)$.

(ii) Take $R_* > 0$ such that $|\psi(x)| \geq \frac{r_0}{2}$ on $\mathbf{R}^N \setminus B(0,R_*)$ and denote $\tilde{\psi}(x) = \frac{\psi(x)}{|\psi(x)|}$. It is then standard to prove that $\tilde{\psi} \in W^{2,p}_{loc}(\mathbf{R}^N \setminus \overline{B}(0,R_*))$ for $p \in [1,\infty)$ and $\nabla\tilde{\psi} \in W^{1,p}(\mathbf{R}^N \setminus \overline{B}(0,R_*))$ for any $p \in [2,\infty)$ (see, e.g., Lemma C1, p. 66, in [11]).

Let us consider first the case $N \geq 3$. For $R_* \leq R_1 < R_2$, the domain $\Omega_{R_1,R_2} = B(0,R_2) \setminus \overline{B}(0,R_1)$ is simply connected in $\mathbf{R}^N$. It follows from Theorem 3, p. 38, in [11] that there exists a real-valued function $\theta_{R_1,R_2} \in W^{2,p}(\Omega_{R_1,R_2})$ $(1 < p < \infty)$ such that $\tilde{\psi} = e^{i\theta_{R_1,R_2}}$ on Ω_{R_1,R_2}. If $R_* \leq R_1 < R_2$, $R_* \leq R_3 < R_4$, and $(R_1,R_2) \cap (R_3,R_4) \neq \emptyset$, then $\tilde{\psi} = e^{i\theta_{R_1,R_2}} = e^{i\theta_{R_3,R_4}}$ on $\Omega_{R_1,R_2} \cap \Omega_{R_3,R_4}$, and thus $\theta_{R_3,R_4} - \theta_{R_1,R_2} \in 2\pi\mathbf{Z}$ on $\Omega_{R_1,R_2} \cap \Omega_{R_3,R_4}$. Since functions in $W^{s,p}(\Omega_{R_1,R_2} \cap \Omega_{R_3,R_4})$ with values in $\mathbf{Z}$ are constant when $sp \geq 1$ (see Theorem B1, p. 65, in [11]), there exists $k \in \mathbf{Z}$ such that $\theta_{R_3,R_4} - \theta_{R_1,R_2} = 2\pi k$ on $\Omega_{R_1,R_2} \cap \Omega_{R_3,R_4}$. Let $(R_n)_{n \geq 1}$ be an increasing sequence such that $R_* < R_1$ and $R_n \longrightarrow \infty$. Let $k_n \in \mathbf{Z}$ be such that $\theta_{R_*,R_n} = \theta_{R_*,R_1} + 2\pi k_n$ on Ω_{R_*,R_1}. Define $\theta(x) = \theta_{R_*,R_n}(x) - 2\pi k_n$ for $x \in \Omega_{R_*,R_n}$. It is clear that θ is well-defined on $\mathbf{R}^N \setminus \overline{B}(0,R_*)$, $\tilde{\psi} = e^{i\theta}$, and $\theta \in W^{2,p}_{loc}(\mathbf{R}^N \setminus \overline{B}(0,R_*))$ for any $p \in [1,\infty)$.

Next we consider the case $N = 2$. Since ψ is C^1 and $|\psi| \geq \frac{r_0}{2}$ on $\mathbf{R}^2 \setminus \overline{B}(0,R_*)$, the topological degree $deg(\psi, \partial B(0,R))$ is well-defined for any $R \geq R_*$ and does not depend on R. It is well known that ψ admits a C^1 lifting θ (i.e., $\psi = |\psi|e^{i\theta}$)

on $\mathbf{R}^2 \setminus \overline{B}(0,R_*)$ if and only if $deg(\psi, \partial B(0,R)) = 0$ for $R \geq R_*$. Denoting by $\tau = (-\sin\zeta, \cos\zeta)$ the unit tangent vector at $\partial B(0,R)$ at a point $Re^{i\zeta}$, we get

$$\begin{aligned} |deg(\psi, \partial B(0,R))| &= \left| \frac{1}{2i\pi} \int_0^{2\pi} \frac{\frac{\partial}{\partial\zeta}(\psi(Re^{i\zeta}))}{\psi(Re^{i\zeta})}\, d\zeta \right| = \left| \frac{R}{2i\pi} \int_0^{2\pi} \frac{\frac{\partial\psi}{\partial\tau}(Re^{i\zeta})}{\psi(Re^{i\zeta})}\, d\zeta \right| \\ &\leq \frac{R}{2\pi} \int_0^{2\pi} \frac{2}{r_0} |\nabla\psi(Re^{i\zeta})|\, d\zeta \leq \frac{R}{\pi r_0}\sqrt{2\pi} \left(\int_0^{2\pi} |\nabla\psi(Re^{i\zeta})|^2\, d\zeta \right)^{\frac{1}{2}}. \end{aligned} \tag{2.10}$$

On the other hand,

$$\int_{\mathbf{R}^2\setminus\overline{B}(0,R_*)} |\nabla\psi(x)|^2\, dx = \int_{R_*}^{\infty} R \int_0^{2\pi} |\nabla\psi(Re^{i\zeta})|^2\, d\zeta\, dR.$$

We have $\int_{\mathbf{R}^2\setminus\overline{B}(0,R_*)} |\nabla\psi(x)|^2\, dx < \infty$ (because ψ has finite energy) and infer that there exists $R_1 > R_*$ such that $R_1 \int_0^{2\pi} |\nabla\psi(R_1 e^{i\zeta})|^2\, d\zeta < \frac{\pi r_0^2}{8} \frac{1}{R_1}$. From (2.10) we get

$$|deg(\psi, \partial B(0,R_1))| < \frac{R_1}{\pi r_0}\sqrt{2\pi} \left(\frac{\pi r_0^2}{8} \frac{1}{R_1^2} \right)^{\frac{1}{2}} = \frac{1}{2}.$$

Since the topological degree is an integer, we have necessarily $deg(\psi, \partial B(0,R_1)) = 0$. Consequently $deg(\psi, \partial B(0,R)) = 0$ for any $R \geq R_*$ and ψ admits a C^1 lifting θ. In fact, $\theta \in W^{2,p}_{loc}(\mathbf{R}^2 \setminus \overline{B}(0,R_*))$ because $\psi \in W^{2,p}_{loc}(\mathbf{R}^2 \setminus \overline{B}(0,R_*))$ (see Theorem 3, p. 38, in [11]).

If $N = 1$, the existence of a lifting $\psi = |\psi| e^{i\theta}$ follows immediately from Theorem 1, p. 27, in [11].

Finally, it is easy to see that $|\frac{\partial\tilde{\psi}}{\partial x_j}| = |\frac{\partial\theta}{\partial x_j}|$ and $|\frac{\partial^2\tilde{\psi}}{\partial x_j \partial x_k}|^2 = |\frac{\partial^2\theta}{\partial x_j \partial x_k}|^2 + |\frac{\partial\theta}{\partial x_j}|^2 |\frac{\partial\theta}{\partial x_k}|^2 \geq |\frac{\partial^2\theta}{\partial x_j \partial x_k}|^2$, and (i) implies $\nabla\theta \in W^{1,p}(\mathbf{R}^N \setminus \overline{B}(0,R_*))$ for any $p \in [2,\infty)$. ∎

3. An integral identity. The main result of this section is given by the next theorem.

THEOREM 3.1. *Assume that* (H1)–(H5) *hold. Let* $\psi = \psi_1 + i\psi_2$ *be a finite-energy traveling wave for* (1.1) *such that* $F(\cdot, |\psi|^2) \in L^1_{loc}(\mathbf{R}^N)$. *Let* R_* *be sufficiently big, so that* $|\psi| \geq \frac{r_0}{2}$ *on* $\mathbf{R}^N \setminus B(0,R_*)$, *and let* θ *be the lifting given by Proposition* 2.5 (ii). *Let* $\chi \in C^\infty(\mathbf{R}^N)$ *be a cut-off function such that* $\chi = 0$ *on* $B(0,2R_*)$ *and* $\chi = 1$ *on* $\mathbf{R}^N \setminus B(0,3R_*)$. *Then the following hold:*

(i) *The functions* $F(\cdot,|\psi|^2)|\psi|^2 + \frac{v_s^2}{2}(|\psi|^2 - r_0^2)$ *and* $G_j = \psi_1 \frac{\partial\psi_2}{\partial x_j} - \psi_2 \frac{\partial\psi_1}{\partial x_j} - r_0^2 \frac{\partial}{\partial x_j}(\chi\theta)$, $j = 1,\dots,N$, *belong to* $L^1 \cap L^\infty(\mathbf{R}^N)$. *(We always extend* $\chi\theta$ *by zero on* $\overline{B}(0,R_*)$.*)*

(ii) *If* $N \geq 2$ *and* $c^2 > v_s^2$, *we have the identity*

$$\begin{aligned} &\int_{\mathbf{R}^N} |\nabla\psi|^2 - F(x,|\psi|^2)|\psi|^2 - \frac{v_s^2}{2}(|\psi|^2 - r_0^2)\, dx \\ &= c\left(1 - \frac{v_s^2}{c^2}\right) \int_{\mathbf{R}^N} \psi_1 \frac{\partial\psi_2}{\partial x_1} - \psi_2 \frac{\partial\psi_1}{\partial x_1} - r_0^2 \frac{\partial}{\partial x_1}(\chi\theta)\, dx. \end{aligned} \tag{3.1}$$

(iii) *Identity* (3.1) *holds if* $c^2 = v_s^2$ *and either*

- $N = 2$ *or*
- $N \geq 3$, *and we assume in addition that* $\psi_1 \frac{\partial\psi_2}{\partial x_1} - \psi_2 \frac{\partial\psi_1}{\partial x_1} \in L^{\frac{2N-1}{2N-3}}(\mathbf{R}^N)$.

Proof. (i) Let R_0, η, M be as in (H5) and take $R_1 > R_0$ such that $|\psi|^2(x) \in (r_0^2 - \eta, r_0^2 + \eta)$ for $x \in \mathbf{R}^N \setminus B(0, R_1)$. Using (2.7) and the fact that $v_s^2 = 2Lr_0^2$ we get

$$\begin{aligned} &F(x, |\psi|^2(x))|\psi|^2(x) + \frac{v_s^2}{2}(|\psi|^2(x) - r_0^2) = F(x, r_0^2)|\psi|^2(x) \\ &+ (|\psi|^2(x) - r_0^2)[\partial_{N+1}F(x, r_0^2) + L]|\psi|^2(x) - L\left(|\psi|^2(x) - r_0^2\right)^2 \\ &+ |\psi|^2(x)\int_{r_0^2}^{|\psi|^2(x)} (|\psi|^2(x) - \tau)\partial_{N+1}^2 F(x, \tau)\, d\tau \qquad \text{for any } |x| \geq R_1. \end{aligned} \tag{3.2}$$

Since $\psi \in L^\infty(\mathbf{R}^N)$ by Proposition 2.2 (i) and $F(\cdot, r_0^2) \in L^1 \cap L^\infty(\mathbf{R}^N)$ by (H1) and (H3), we infer that $F(\cdot, r_0^2)|\psi|^2 \in L^1 \cap L^\infty(\mathbf{R}^N)$.

We have $\psi \in L^\infty(\mathbf{R}^N)$, $\partial_{N+1}F(\cdot, r_0^2) + L \in L^{p_0} \cap L^\infty(\mathbf{R}^N)$ by (H4) and $|\psi|^2 - r_0^2 \in L^2 \cap L^\infty(\mathbf{R}^N)$ by Lemma 2.4; hence $(|\psi|^2 - r_0^2)[\partial_{N+1}F(\cdot, r_0^2) + L]|\psi|^2 \in L^1 \cap L^\infty(\mathbf{R}^N)$.

From Proposition 2.2 (i), Lemma 2.4, and (2.9) it follows that the last two terms on the right-hand side of (3.2) are in $L^1 \cap L^\infty(\mathbf{R}^N \setminus \overline{B}(0, R_1))$. Hence $F(\cdot, |\psi|^2)|\psi|^2 + \frac{v_s^2}{2}(|\psi|^2 - r_0^2) \in L^1 \cap L^\infty(\mathbf{R}^N \setminus \overline{B}(0, R_1))$. Clearly, the function $F(\cdot, |\psi|^2)|\psi|^2 + \frac{v_s^2}{2}(|\psi|^2 - r_0^2)$ is bounded on $\overline{B}(0, R_1)$; therefore this function belongs to $L^1 \cap L^\infty(\mathbf{R}^N)$.

Since $\psi_1 = |\psi| \cos\theta$ and $\psi_2 = |\psi| \sin\theta$, a straightforward computation gives

$$\psi_1 \frac{\partial \psi_2}{\partial x_j} - \psi_2 \frac{\partial \psi_1}{\partial x_j} = (\psi_1^2 + \psi_2^2)\frac{\partial \theta}{\partial x_j} \qquad \text{on } \mathbf{R}^N \setminus \overline{B}(0, R_*). \tag{3.3}$$

Therefore

$$\psi_1 \frac{\partial \psi_2}{\partial x_j} - \psi_2 \frac{\partial \psi_1}{\partial x_j} - r_0^2 \frac{\partial}{\partial x_j}(\chi\theta) = (|\psi|^2 - r_0^2)\frac{\partial \theta}{\partial x_j} \qquad \text{on } \mathbf{R}^N \setminus \overline{B}(0, 3R_*). \tag{3.4}$$

From Lemma 2.4, Proposition 2.5 (ii), and the Sobolev embedding theorem we have $|\psi|^2 - r_0^2 \in L^2 \cap L^\infty(\mathbf{R}^N)$ and $\frac{\partial \theta}{\partial x_j} \in L^2 \cap L^\infty(\mathbf{R}^N \setminus \overline{B}(0, R_*))$, respectively. Identity (3.4) implies $G_j \in L^1 \cap L^\infty(\mathbf{R}^N \setminus \overline{B}(0, 3R_*))$. Since G_j is continuous on $\mathbf{R}^N$, we conclude that $G_j \in L^1 \cap L^\infty(\mathbf{R}^N)$.

(ii) Equation (1.7) is equivalent to the system

$$c\frac{\partial \psi_2}{\partial x_1} + \Delta\psi_1 + F(x, |\psi|^2)\psi_1 = 0 \qquad \text{in } \mathcal{D}'(\mathbf{R}^N), \tag{3.5}$$

$$-c\frac{\partial \psi_1}{\partial x_1} + \Delta\psi_2 + F(x, |\psi|^2)\psi_2 = 0 \qquad \text{in } \mathcal{D}'(\mathbf{R}^N). \tag{3.6}$$

In view of Proposition 2.2 (i), equalities (3.5) and (3.6) hold in $L^p_{loc}(\mathbf{R}^N)$ for $1 \leq p < \infty$. Multiplying (3.5) by ψ_2 and (3.6) by ψ_1 and then subtracting the resulting equalities gives us

$$\frac{c}{2}\frac{\partial}{\partial x_1}(|\psi|^2 - r_0^2) = \operatorname{div}(\psi_1 \nabla\psi_2 - \psi_2 \nabla\psi_1). \tag{3.7}$$

We multiply (3.5) by ψ_1 and (3.6) by ψ_2, then add the corresponding equalities to obtain

$$|\nabla\psi_1|^2 + |\nabla\psi_2|^2 - F(x, |\psi|^2)|\psi|^2 - c\left(\psi_1 \frac{\partial \psi_2}{\partial x_1} - \psi_2 \frac{\partial \psi_1}{\partial x_1}\right) = \frac{1}{2}\Delta(|\psi|^2 - r_0^2). \tag{3.8}$$

From (3.7) and (3.8) we get

$$\frac{c}{2}\frac{\partial}{\partial x_1}(|\psi|^2-r_0^2)=\operatorname{div}(\psi_1\nabla\psi_2-\psi_2\nabla\psi_1-r_0^2\nabla(\chi\theta))+r_0^2\Delta(\chi\theta), \tag{3.9}$$

respectively,

(3.10)

$$\begin{aligned}\frac{1}{2}\Delta(|\psi|^2-r_0^2)-\frac{v_s^2}{2}(|\psi|^2-r_0^2)&=|\nabla\psi_1|^2+|\nabla\psi_2|^2-F(x,|\psi|^2)|\psi|^2-\frac{v_s^2}{2}(|\psi|^2-r_0^2)\\&\quad-c\left(\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}-r_0^2\frac{\partial}{\partial x_1}(\chi\theta)\right)-cr_0^2\frac{\partial}{\partial x_1}(\chi\theta).\end{aligned}$$

Since $\psi\in W^{2,p}_{loc}(\mathbf{R}^N)$, equalities (3.7)–(3.10) hold in $L^p_{loc}(\mathbf{R}^N)$ for $1\le p<\infty$. We denote

$$H=|\nabla\psi_1|^2+|\nabla\psi_2|^2-F(x,|\psi|^2)|\psi|^2-\frac{v_s^2}{2}(|\psi|^2-r_0^2)-c\left(\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}-r_0^2\frac{\partial}{\partial x_1}(\chi\theta)\right).$$

We take the derivative of (3.9) with respect to x_1 (in $\mathcal{D}'(\mathbf{R}^N)$), multiply it by c, and then take the Laplacian of (3.10) (in $\mathcal{D}'(\mathbf{R}^N)$). Summing up the resulting equalities, we obtain

$$\frac{1}{2}\Big(\Delta^2-v_s^2\Delta+c^2\frac{\partial^2}{\partial x_1^2}\Big)(|\psi|^2-r_0^2)=\Delta H+c\frac{\partial}{\partial x_1}(\operatorname{div}(G))\qquad\text{in }\mathcal{D}'(\mathbf{R}^N). \tag{3.11}$$

From (i) we have $H,G_1,\dots,G_N\in L^1\cap L^\infty(\mathbf{R}^N)$, and we know from Lemma 2.4 that $|\psi|^2-r_0^2\in L^2\cap L^\infty(\mathbf{R}^N)$. Therefore $H,G_1,\dots,G_N,|\psi|^2-r_0^2\in\mathcal{S}'(\mathbf{R}^N)$, and we infer that, in fact, equality (3.11) holds in $\mathcal{S}'(\mathbf{R}^N)$. Taking the Fourier transform of (3.11) we get

$$\frac{1}{2}(|\xi|^4+v_s^2|\xi|^2-c^2\xi_1^2)\mathcal{F}(|\psi|^2-r_0^2)=-|\xi|^2\widehat{H}-c\sum_{k=1}^N\xi_1\xi_k\widehat{G_k}\quad\text{in }\mathcal{S}'(\mathbf{R}^N). \tag{3.12}$$

We have $\widehat{H}$, $\widehat{G_k}\in L^\infty\cap C^0(\mathbf{R}^N)$ because H, $G_k\in L^1(\mathbf{R}^N)$. Thus the right-hand side of (3.12) is a continuous function on $\mathbf{R}^N$. Since $|\psi|^2-r_0^2\in L^2(\mathbf{R}^N)$, we have $\mathcal{F}(|\psi|^2-r_0^2)\in L^2(\mathbf{R}^N)$ and infer that the left-hand side of (3.12) belongs to $L^2_{loc}(\mathbf{R}^N)$ and (3.12) holds a.e. on $\mathbf{R}^N$.

We denote

$$\Gamma=\{\xi\in\mathbf{R}^N\mid|\xi|^4+v_s^2|\xi|^2-c^2\xi_1^2=0\}.$$

If $c^2\le v_s^2$, we have $\Gamma=\{0\}$. If $c^2>v_s^2$, it is easy to see that Γ is a nontrivial submanifold of $\mathbf{R}^N$. In the latter case, we claim that

$$|\xi|^2\widehat{H}(\xi)+c\sum_{k=1}^N\xi_1\xi_k\widehat{G_k}(\xi)=0\qquad\text{for any }\xi\in\Gamma. \tag{3.13}$$

To prove this claim, we argue by contradiction and suppose that there exists $\xi^0\in\Gamma$ such that $|\xi^0|^2\widehat{H}(\xi^0)+c\sum_{k=1}^N\xi_1^0\xi_k^0\widehat{G_k}(\xi^0)\neq0$. By continuity, there exist

$m > 0$ and a neighborhood U of ξ_0 such that $\big|\,|\xi|^2\widehat{H} + c\sum_{k=1}^N \xi_1\xi_k\widehat{G_k}\big| \geq m$ on U. From (3.12) we infer that

$$|\mathcal{F}(|\psi|^2 - r_0^2)(\xi)| \geq \frac{2m}{|\,|\xi|^4 + v_s^2|\xi|^2 - c^2\xi_1^2|} \qquad \text{a.e. on } U \setminus \Gamma.$$

Since 0 and $(\sqrt{c^2 - v_s^2}, 0, \dots, 0)$ are not isolated points of Γ, we may assume that $\xi^0 \neq 0$ and $\xi^0 \neq (\sqrt{c^2 - v_s^2}, 0, \dots, 0)$. A straightforward computation (details can be found in [17, p. 98] in the case $v_s^2 = 2$; the general case is similar) shows that

$$\int_{U\setminus\Gamma} \frac{1}{|\,|\xi|^4 + v_s^2|\xi|^2 - c^2\xi_1^2|^2}\, d\xi = \infty;$$

consequently $\int_{U\setminus\Gamma} |\mathcal{F}(|\psi|^2 - r_0^2)(\xi)|^2\, d\xi = \infty$. But this is in contradiction with $\mathcal{F}(|\psi|^2 - r_0^2) \in L^2(\mathbf{R}^N)$ and the claim is proved.

It is not difficult to see that $\Gamma = \{(\xi_1, \xi') \in \mathbf{R}\times\mathbf{R}^{N-1} \mid |\xi'|^2 = \frac{1}{2}(-v_s^2 - 2\xi_1^2 + \sqrt{v_s^4 + 4c^2\xi_1^2})\}$. Let $f(t) = \sqrt{\frac{1}{2}\big(-v_s^2 - 2t^2 + \sqrt{v_s^4 + 4c^2t^2}\big)}$. The function f is well-defined for $t \in [-\sqrt{c^2 - v_s^2}, \sqrt{c^2 - v_s^2}]$, $f(0) = 0$, and $\lim_{t\to 0}\frac{f^2(t)}{t^2} = -1 + \frac{c^2}{v_s^2}$. Fix $j \in \{2, \dots, N\}$. For $t \in (0, \sqrt{c^2 - v_s^2}]$, let $\xi(t) = (t, 0, \dots, 0, f(t), 0, \dots, 0)$ and $\tilde{\xi}(t) = (t, 0, \dots, 0, -f(t), 0, \dots, 0)$, where $f(t)$, respectively, $-f(t)$, stand at the jth place. It is obvious that $\xi(t), \tilde{\xi}(t) \in \Gamma$. From (3.13) we obtain, respectively,

$$(t^2 + f^2(t))\widehat{H}(\xi(t)) + ct^2\widehat{G_1}(\xi(t)) + ctf(t)\widehat{G_j}(\xi(t)) = 0, \tag{3.14}$$

$$(t^2 + f^2(t))\widehat{H}(\tilde{\xi}(t)) + ct^2\widehat{G_1}(\tilde{\xi}(t)) - ctf(t)\widehat{G_j}(\tilde{\xi}(t)) = 0. \tag{3.15}$$

We multiply (3.14) and (3.15) by $\frac{1}{t^2}$, then pass to the limit as $t \downarrow 0$ to obtain, respectively,

$$\frac{c^2}{v_s^2}\widehat{H}(0) + c\widehat{G_1}(0) + c\sqrt{-1 + \frac{c^2}{v_s^2}}\widehat{G_j}(0) = 0, \tag{3.16}$$

$$\frac{c^2}{v_s^2}\widehat{H}(0) + c\widehat{G_1}(0) - c\sqrt{-1 + \frac{c^2}{v_s^2}}\widehat{G_j}(0) = 0. \tag{3.17}$$

From (3.16) and (3.17) we infer that $\frac{c^2}{v_s^2}\widehat{H}(0) + c\widehat{G_1}(0) = 0$ and $\widehat{G_j}(0) = 0$, that is, $\int_{\mathbf{R}^N} H(x) + \frac{v_s^2}{c}G_1(x)\, dx = 0$ and $\int_{\mathbf{R}^N} G_j(x)\, dx = 0$. The first of these integral identities is exactly (3.1) and the latter can be written as

$$\int_{\mathbf{R}^N} \psi_1\frac{\partial\psi_2}{\partial x_j} - \psi_2\frac{\partial\psi_1}{\partial x_j} - r_0^2\frac{\partial}{\partial x_j}(\chi\theta)\, dx = 0 \qquad \text{for } j = 2, \dots, N. \tag{3.18}$$

(iii) Assume that $c^2 = v_s^2$. Then (3.1) is equivalent to $\widehat{H}(0) + c\widehat{G_1}(0) = 0$. Denoting $\xi = (\xi_1, \xi')$, where $\xi' = (\xi_2, \dots, \xi_N)$, identity (3.12) implies

$$\begin{aligned}\mathcal{F}(|\psi|^2 - r_0^2)(\xi) &= -2\frac{\xi_1^2}{|\xi|^4 + c^2|\xi'|^2}(\widehat{H}(\xi) + c\widehat{G_1}(\xi)) \\ &- 2c\sum_{k=2}^N \frac{\xi_1\xi_k}{|\xi|^4 + c^2|\xi'|^2}\widehat{G_k}(\xi) - 2\frac{|\xi'|^2}{|\xi|^4 + c^2|\xi'|^2}\widehat{H}(\xi) \qquad \text{a.e. } \xi \in \mathbf{R}^N.\end{aligned} \tag{3.19}$$

For $\varepsilon \in (0,1]$, we denote $\Omega_\varepsilon = \{(\xi_1,\xi') \in \mathbf{R}\times\mathbf{R}^{N-1} \mid \xi_1 \in [0,\varepsilon],\ 0 \le |\xi'| \le \xi_1\}$. We will use the following lemma.

LEMMA 3.2. *Let $N \ge 2$ and $k \in \{2,\dots,N\}$.*

(i) *The function $\xi \longmapsto \frac{\xi_1^2}{\xi_1^4+c^2|\xi'|^2}$ belongs to $L^p(\Omega_\varepsilon)$ if and only if $p < N-\frac{1}{2}$.*

(ii) *The function $\xi \longmapsto \frac{\xi_1\xi_k}{\xi_1^4+c^2|\xi'|^2}$ belongs to $L^p(\Omega_\varepsilon)$ for any $p \in [1,2N-1)$.*

Proof of Lemma 3.2. (i) Using Fubini's theorem for positive functions, then passing to spherical coordinates in $\mathbf{R}^{N-1}$ and making the change of variables $r = \xi_1^2 t$ we get

(3.20)
$$\begin{aligned}
&\int_{\Omega_\varepsilon}\left(\frac{\xi_1^2}{\xi_1^4+c^2|\xi'|^2}\right)^p d\xi = \int_0^\varepsilon \xi_1^{2p}\int_{\{|\xi'|\le\xi_1\}}\frac{1}{(\xi_1^4+c^2|\xi'|^2)^p}\,d\xi'\,d\xi_1\\
&= \int_0^\varepsilon \xi_1^{2p}|S^{N-2}|\int_0^{\xi_1}\frac{r^{N-2}}{(\xi_1^4+c^2r^2)^p}\,dr\,d\xi_1\\
&= |S^{N-2}|\int_0^\varepsilon \xi_1^{2p}\int_0^{\frac{1}{\xi_1}}\frac{(\xi_1^2t)^{N-2}}{(\xi_1^4+c^2\xi_1^4t^2)^p}\xi_1^2\,dt\,d\xi_1 \quad \text{(change of variables } r=\xi_1^2t)\\
&= |S^{N-2}|\int_0^\varepsilon \xi_1^{2(N-1-p)}\int_0^{\frac{1}{\xi_1}}\frac{t^{N-2}}{(1+c^2t^2)^p}\,dt\,d\xi_1.
\end{aligned}$$

Assume that $p < N-\frac{1}{2}$. Obviously $\frac{t^{N-2}}{(1+c^2t^2)^p} \le 1$ for $t\in[0,1]$ and $\frac{t^2}{1+c^2t^2} \le \frac{1}{c^2}$, and thus we have

$$\int_0^{\frac{1}{\xi_1}}\frac{t^{N-2}}{(1+c^2t^2)^p}\,dt \le 1+\frac{1}{c^{2p}}\int_1^{\frac{1}{\xi_1}} t^{N-2p-2}\,dt = \begin{cases} C_1+\frac{C_2}{\xi_1^{N-2p-1}} & \text{if } p\ne\frac{N-1}{2},\\ C_3+C_4\ln\xi_1 & \text{if } p=\frac{N-1}{2},\end{cases}$$

where C_j are some positive constants. This estimate implies that the right-hand side of (3.20) is finite if $p < N-\frac{1}{2}$.

If $p \ge N-\frac{1}{2}$, denote $c_p = \int_0^1 \frac{t^{N-2}}{(1+c^2t^2)^p}\,dt > 0$. Since $\frac{1}{\xi_1} > 1$ for $\xi_1 \in (0,\varepsilon)$, the right-hand side of (3.20) is greater than $|S^{N-2}|c_p\int_0^\varepsilon \xi_1^{2(N-1-p)}\,d\xi_1 = \infty$.

(ii) Proceeding as above, we have

(3.21)
$$\begin{aligned}
&\int_{\Omega_\varepsilon}\left|\frac{\xi_1\xi_k}{\xi_1^4+c^2|\xi'|^2}\right|^p d\xi \le \int_{\Omega_\varepsilon}\frac{\xi_1^p|\xi'|^p}{(\xi_1^4+c^2|\xi'|^2)^p}\,d\xi = \int_0^\varepsilon \xi_1^p|S^{N-2}|\int_0^{\xi_1}\frac{r^{p+N-2}}{(\xi_1^4+c^2r^2)^p}\,dr\,d\xi_1\\
&= |S^{N-2}|\int_0^\varepsilon \xi_1^p\int_0^{\frac{1}{\xi_1}}\frac{(\xi_1^2t)^{p+N-2}}{(\xi_1^4+c^2\xi_1^4t^2)^p}\xi_1^2\,dt\,d\xi_1 \qquad \text{(change of variables } r=\xi_1^2t)\\
&= |S^{N-2}|\int_0^\varepsilon \xi_1^{2N-p-2}\int_0^{\frac{1}{\xi_1}}\frac{t^{p+N-2}}{(1+c^2t^2)^p}\,dt\,d\xi_1.
\end{aligned}$$

As previously,

$$\int_0^{\frac{1}{\xi_1}}\frac{t^{p+N-2}}{(1+c^2t^2)^p}\,dt < \frac{1}{c^{2p}}\int_0^{\frac{1}{\xi_1}} t^{N-p-2}\,dt = \frac{1}{c^{2p}(N-p-1)}\frac{1}{\xi_1^{N-p-1}} \quad \text{if } N-p-1>0.$$

Therefore in the case $p < N-1$, the right-hand side of (3.21) is less than $C\int_0^\varepsilon \xi_1^{N-1}d\xi_1 < \infty$. If $p > N-1$, the integral $\int_0^\infty \frac{t^{p+N-2}}{(1+c^2t^2)^p}\,dt$ converges. Let a_p be its value. If

$N-1<p<2N-1$, we get $\int_{\Omega_\varepsilon}\left|\frac{\xi_1\xi_k}{\xi_1^4+c^2|\xi'|^2}\right|^p d\xi \le |S^{N-2}|a_p\int_0^\varepsilon \xi_1^{2N-2-p}d\xi_1<\infty$ by (3.21). □

Remark. It can be proved that the function $\xi\longmapsto\frac{\xi_1\xi_k}{\xi_1^4+c^2|\xi'|^2}$ does not belong to $L^p(\Omega_\varepsilon)$ if $p\ge 2N-1$, but we will not make use of this fact here.

Now we come back to the proof of Theorem 3.1. All we have to do is to show that $\widehat{H}(0)+c\widehat{G_1}(0)=0$. We argue by contradiction and assume that $\widehat{H}(0)+c\widehat{G_1}(0)\neq 0$. Since the functions $\widehat{H}$ and $\widehat{G_j}$ are continuous, there exists $\varepsilon\in(0,1)$ such that $|\widehat{H}(\xi)+c\widehat{G_1}(\xi)|\ge\frac{1}{2}|\widehat{H}(0)+c\widehat{G_1}(0)|$ for any $\xi\in\Omega_\varepsilon$. Taking a smaller ε if necessary, we may also assume that $|\xi|^4+c^2|\xi'|^2\le 2(\xi_1^4+c^2|\xi'|^2)$ for any $\xi\in\Omega_\varepsilon$. By (3.19) we have

(3.22)
$$\begin{aligned}&\frac{1}{2}\frac{\xi_1^2}{\xi_1^4+c^2|\xi'|^2}|\widehat{H}(0)+c\widehat{G_1}(0)|\le 2\frac{\xi_1^2}{|\xi|^4+c^2|\xi'|^2}|\widehat{H}(\xi)+c\widehat{G_1}(\xi)|\\&\le|\mathcal{F}(|\psi|^2-r_0^2)(\xi)|+2|c|\sum_{k=2}^N\frac{|\xi_1\xi_k|}{\xi_1^4+c^2|\xi'|^2}|\widehat{G_k}(\xi)|+2\frac{|\xi'|^2}{|\xi|^4+c^2|\xi'|^2}|\widehat{H}(\xi)|\quad\text{a.e. on }\Omega_\varepsilon.\end{aligned}$$

Consider first the case $N=2$. We know that $\mathcal{F}(|\psi|^2-r_0^2)\in L^2(\mathbf{R}^2)$, and consequently $\mathcal{F}(|\psi|^2-r_0^2)\in L^p(\Omega_\varepsilon)$ for any $p\in[1,2]$. Since $\widehat{G_k}$ are continuous and bounded, by Lemma 3.2 (ii) we infer that the functions $\xi\longmapsto\frac{\xi_1\xi_k}{\xi_1^4+c^2|\xi'|^2}\widehat{G_k}(\xi)$ belong to $L^p(\Omega_\varepsilon)$ for any $p\in[1,3)$. It is obvious that $\frac{|\xi'|^2}{|\xi|^4+c^2|\xi'|^2}|\widehat{H}(\xi)|\le\frac{1}{c^2}|\widehat{H}(\xi)|$ and $\widehat{H}$ is continuous and bounded on $\mathbf{R}^N$. We conclude that the right-hand side of (3.22) belongs to $L^p(\Omega_\varepsilon)$ for any $p\in[1,2]$. Then (3.22) implies that $\xi\longmapsto\frac{\xi_1^2}{\xi_1^4+c^2|\xi'|^2}$ belongs to $L^2(\Omega_\varepsilon)$, which contradicts Lemma 3.2 (i). This contradiction proves that $\widehat{H}(0)+c\widehat{G_1}(0)=0$.

Next we assume that $N\ge 3$ and $\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}\in L^{\frac{2N-1}{2N-3}}(\mathbf{R}^N)$. Equation (3.8) can be written as

$$\begin{aligned}&-\frac{1}{2}\Delta(|\psi|^2-r_0^2)+\frac{v_s^2}{2}(|\psi|^2-r_0^2)\\&=-|\nabla\psi_1|^2-|\nabla\psi_2|^2+F(x,|\psi|^2)|\psi|^2+\frac{v_s^2}{2}(|\psi|^2-r_0^2)+c\left(\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}\right).\end{aligned}$$

(3.23)

We have already proved that $F(\cdot,|\psi|^2)|\psi|^2+\frac{v_s^2}{2}(|\psi|^2-r_0^2)\in L^1\cap L^\infty(\mathbf{R}^N)$. From Proposition 2.5 (i) we have $|\nabla\psi|^2\in L^p(\mathbf{R}^N)$ for any $p\in[1,\infty]$. Using the assumption $\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}\in L^{\frac{2N-1}{2N-3}}(\mathbf{R}^N)$, we infer that the right-hand side of (3.23) belongs to $L^{\frac{2N-1}{2N-3}}(\mathbf{R}^N)$. By the Hausdorff–Young inequality, for any function $f\in L^p(\mathbf{R}^N)$ with $1\le p\le 2$ we have $\mathcal{F}(f)\in L^{p'}(\mathbf{R}^N)$, where $\frac{1}{p}+\frac{1}{p'}=1$ (see, e.g., Theorem 1.2.1, p. 6, in [4]). Passing to Fourier transforms in (3.23) we get

$$\begin{aligned}\mathcal{F}(|\psi|^2-r_0^2)(\xi)=\frac{2}{|\xi|^2+v_s^2}\mathcal{F}\Bigg[&-|\nabla\psi|^2+\left(F(\cdot,|\psi|^2)|\psi|^2+\frac{v_s^2}{2}(|\psi|^2-r_0^2)\right)\\&+c\left(\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}\right)\Bigg](\xi)\qquad\text{a.e. }\xi\in\mathbf{R}^N.\end{aligned}$$

(3.24)

We obtain from (3.24) that $\mathcal{F}(|\psi|^2-r_0^2)\in L^{N-\frac{1}{2}}(\mathbf{R}^N)$. Combined with Lemma 3.2 (ii) and the fact that $\widehat{H}$, $\widehat{G_j}$, and $\xi\longmapsto\frac{|\xi'|^2}{|\xi|^4+c^2|\xi'|^2}$ are bounded, this implies that the last

expression in (3.22) is in $L^{N-\frac{1}{2}}(\Omega_\varepsilon)$. We infer that the function $\xi \longmapsto \frac{\xi_1^2}{\xi_1^4+c^2|\xi'|^2}|\widehat{H}(0)+c\widehat{G_1}(0)|$ must be in $L^{N-\frac{1}{2}}(\Omega_\varepsilon)$ for any sufficiently small ε. If $\widehat{H}(0)+c\widehat{G_1}(0)\neq 0$, this contradicts Lemma 3.2 (i). Thus necessarily $\widehat{H}(0)+c\widehat{G_1}(0)=0$ and the proof of Theorem 3.1 is complete. ∎

It is an open problem whether any finite-energy traveling wave ψ of (1.1) moving with speed $c=\pm v_s$ satisfies $\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}\in L^{\frac{2N-1}{2N-3}}(\mathbf{R}^N)$. Even for very particular cases of (1.1), such as the Gross–Pitaevskii equation, the answer to this question is not known. However, we have the following.

PROPOSITION 3.3. *Assume that* (H1)–(H5) *hold and let* $\psi=\psi_1+i\psi_2$ *be a finite-energy traveling wave for* (1.1) *such that* $F(\cdot,|\psi|^2)\in L^1_{loc}(\mathbf{R}^N)$. *Let* R_* *be sufficiently big so that* $|\psi|\geq\frac{r_0}{2}$ *on* $\mathbf{R}^N\setminus B(0,R_*)$, *let* θ *be the lifting given by Proposition* 2.5 (ii), *and let* $\chi\in C^\infty(\mathbf{R}^N)$ *be a cut-off function as in Theorem* 3.1. *Then the following hold:*

(i) *Let* $p\in(1,\infty)$. *The following assertions are equivalent:*
  (a) $\nabla(\chi\theta)\in L^p(\mathbf{R}^N)$;
  (b) $\psi_1\frac{\partial\psi_2}{\partial x_j}-\psi_2\frac{\partial\psi_1}{\partial x_j}\in L^p(\mathbf{R}^N)$ *for any* $j\in\{1,\dots,N\}$;
  (c) $\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}\in L^p(\mathbf{R}^N)$;
  (d) $|\psi|^2-r_0^2\in W^{2,p}(\mathbf{R}^N)$;
  (e) $|\psi|^2-r_0^2\in L^p(\mathbf{R}^N)$.

(ii) *If* $N\geq 3$, *there exists* $\theta_0\in\mathbf{R}$ *such that* $\chi\theta-\theta_0\in W^{2,q}(\mathbf{R}^N)$ *for any* $q\in[\frac{2N}{N-2},\infty)$.

Moreover, if $c^2=v_s^2$, *we have the following:*

(iii) $|\psi|^2-r_0^2\in L^p(\mathbf{R}^N)$ *and* $\psi_1\frac{\partial\psi_2}{\partial x_j}-\psi_2\frac{\partial\psi_1}{\partial x_j}\in L^p(\mathbf{R}^N)$ *for any* $p>\frac{2N-1}{2N-3}$ *and* $j\in\{1,\dots,N\}$.

(iv) $\nabla(|\psi|^2-r_0^2)\in L^p(\mathbf{R}^N)$ *for any* $p>\frac{2N-1}{2N-2}$.

(v) $\partial_{j,k}^2(|\psi|^2-r_0^2)\in L^p(\mathbf{R}^N)$ *for any* $p\in(1,\infty)$.

Proof. (i) Since $\psi\in L^\infty(\mathbf{R}^N)$ and (3.3) holds, the equivalence (a) ⇔ (b) is clear. It is also obvious that (b) ⇒ (c).

From the classical Marcinkiewicz theorem (see Theorem 3, p. 96, in [27]) it follows that the functions $\frac{1}{|\xi|^2+v_s^2}$, $\frac{\xi_j}{|\xi|^2+v_s^2}$, and $\frac{\xi_j\xi_k}{|\xi|^2+v_s^2}$ are L^p-multipliers for $1<p<\infty$. Assume that $\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}\in L^p(\mathbf{R}^N)$. Since $|\nabla\psi|^2\in L^1\cap L^\infty(\mathbf{R}^N)$ and $F(\cdot,|\psi|^2)|\psi|^2+\frac{v_s^2}{2}(|\psi|^2-r_0^2)\in L^1\cap L^\infty(\mathbf{R}^N)$ by Theorem 3.1 (i), we have $-|\nabla\psi|^2+(F(\cdot,|\psi|^2)|\psi|^2+\frac{v_s^2}{2}(|\psi|^2-r_0^2))+c(\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1})\in L^p(\mathbf{R}^N)$ and infer from (3.24) that $|\psi|^2-r_0^2\in W^{2,p}(\mathbf{R}^N)$. Hence (c) ⇒ (d). It is obvious that (d) ⇒ (e).

It follows from Proposition 2.5 (ii) that $\partial_k(\chi\theta)\in\mathcal{S}'(\mathbf{R}^N)$. It is then clear that all terms appearing in (3.9) belong to $\mathcal{S}'(\mathbf{R}^N)$. We take the derivative of (3.9) with respect to x_k (in $\mathcal{S}'(\mathbf{R}^N)$), then take the Fourier transform of the resulting equality to obtain

$$r_0^2\mathcal{F}\left(\frac{\partial}{\partial x_k}(\chi\theta)\right)=-\sum_{j=1}^N\frac{\xi_j\xi_k}{|\xi|^2}\widehat{G_j}+\frac{c}{2}\frac{\xi_1\xi_k}{|\xi|^2}\mathcal{F}(|\psi|^2-r_0^2)$$

or, equivalently,

$$r_0^2\frac{\partial}{\partial x_k}(\chi\theta)=\sum_{j=1}^N R_jR_k(G_j)-\frac{c}{2}R_1R_k(|\psi|^2-r_0^2), \tag{3.25}$$

where R_j is the Riesz transform, $R_j\phi = \mathcal{F}^{-1}(i\frac{\xi_j}{|\xi|}\widehat{\phi})$. It is well known that the Riesz transform maps continuously $L^p(\mathbf{R}^N)$ into $L^p(\mathbf{R}^N)$ for $1 < p < \infty$ (see, e.g., Theorem 3, p. 96, and Example (iii), p. 95, in [27]). From Theorem 3.1 (i) we have $G_j \in L^1 \cap L^\infty(\mathbf{R}^N)$; therefore $R_jR_k(G_j) \in L^q(\mathbf{R}^N)$ for any $q \in (1,\infty)$. Assume that $|\psi|^2 - r_0^2 \in L^p(\mathbf{R}^N)$ for some $p \in (1,\infty)$. Then $R_1R_k(|\psi|^2 - r_0^2) \in L^p(\mathbf{R}^N)$ and from (3.25) we infer that $\frac{\partial}{\partial x_k}(\chi\theta) \in L^p(\mathbf{R}^N)$ for any $k \in \{1,\dots,N\}$. Thus (e) $\Rightarrow$ (a) and (i) is proved.

(ii) It is well known that for any function ϕ satisfying $\nabla\phi \in L^p(\mathbf{R}^N)$ with $p < N$, there exists a constant λ such that $\phi - \lambda \in L^{p^*}(\mathbf{R}^N)$, where $\frac{1}{p^*} = \frac{1}{p} - \frac{1}{N}$ (see Theorem 4.5.9 in [20] or Lemma 7 and Remark 4.2 in [15, pp. 774–775] for a different proof). From Proposition 2.5 (ii) we have $\nabla(\chi\theta) \in W^{1,p}(\mathbf{R}^N)$ for any $p \in [2,\infty)$. If $N \geq 3$, we infer that there exists $\theta_0 \in \mathbf{R}$ such that $\chi\theta - \theta_0 \in L^q(\mathbf{R}^N)$ for $q \in [\frac{2N}{N-2},\infty)$. Therefore $\chi\theta - \theta_0 \in W^{2,q}(\mathbf{R}^N)$ for any $q \in [\frac{2N}{N-2},\infty)$ and, in particular, $\chi\theta - \theta_0 \longrightarrow 0$ as $|x| \longrightarrow \infty$.

(iii) We will use the following result due to Lizorkin (see Theorem 8, p. 288, in [24]).

THEOREM 3.4 (see [24]). *Let $\beta \in [0,1)$ and let $K \in L^\infty(\mathbf{R}^N) \cap C^N(\mathbf{R}^N \setminus \{0\})$. Assume that*

$$\Big(\prod_{j=1}^N |\xi_j|^{k_j+\beta}\Big)\partial_1^{k_1}\dots\partial_N^{k_N}K \in L^\infty(\mathbf{R}^N) \qquad \text{for any } k_1,\dots,k_N \in \{0,1\}.$$

Then K is a Fourier multiplier from $L^p(\mathbf{R}^N)$ to $L^{\frac{p}{1-\beta p}}(\mathbf{R}^N)$ for any $p \in (1,\frac{1}{\beta})$.

Let $K(\xi) = \frac{|\xi|^2}{|\xi|^4 + c^2|\xi'|^2}$, where $\xi' = (\xi_2,\dots,\xi_N)$. A straightforward but tedious computation shows that K satisfies the assumptions of Lizorkin's theorem for $\beta = \frac{1}{2N-1}$. From (3.19) we obtain

$$\begin{aligned}(3.26)\qquad |\psi|^2 - r_0^2 &= 2R_1^2\left(\mathcal{F}^{-1}\left(K(\widehat{H} + c\widehat{G_1})\right)\right)\\ &\quad + 2c\sum_{j=2}^N R_1R_j\left(\mathcal{F}^{-1}(K\widehat{G_j})\right) + 2\sum_{j=2}^N R_j^2\left(\mathcal{F}^{-1}(K\widehat{H})\right),\end{aligned}$$

where R_j's denote Riesz transforms. Since $H, G_1,\dots,G_N \in L^1 \cap L^\infty(\mathbf{R}^N)$, by (3.26) and Lizorkin's theorem we infer that $|\psi|^2 - r_0^2 \in L^p(\mathbf{R}^N)$ for any $p \in (\frac{2N-1}{2N-3},\infty)$. The rest of (iii) follows from part (i), (b) $\Leftrightarrow$ (e).

(iv) and (v) From (iii) and (i), (d) $\Leftrightarrow$ (e) it follows immediately that $|\psi|^2 - r_0^2 \in W^{2,p}(\mathbf{R}^N)$ for any $p \in (\frac{2N-1}{2N-3},\infty)$. Using (3.19) we obtain

$$\begin{aligned}(3.27)\qquad &\partial_{k\ell}^2\left(|\psi|^2 - r_0^2\right) = 2R_kR_\ell R_1^2\left(\mathcal{F}^{-1}\left(|\xi|^2K(\widehat{H} + c\widehat{G_1})\right)\right)\\ &+2c\sum_{j=2}^N R_kR_\ell R_1R_j\left(\mathcal{F}^{-1}(|\xi|^2K\widehat{G_j})\right)\\ &+2\sum_{j=2}^N R_kR_\ell R_j^2\left(\mathcal{F}^{-1}(|\xi|^2K\widehat{H})\right) \qquad \text{in } \mathcal{S}'(\mathbf{R}^N).\end{aligned}$$

It can be proved by direct computation that the function $|\xi|^2K$ satisfies the assumptions of Lizorkin's theorem for $\beta = 0$. Consequently $|\xi|^2K$ is an L^p-multiplier for

$1 < p < \infty$. Since $H, G_j \in L^1 \cap L^\infty(\mathbf{R}^N)$, it follows from (3.27) that $\partial^2_{k\ell}\left(|\psi|^2 - r_0^2\right) \in L^p(\mathbf{R}^N)$ for $1 < p < \infty$.

By using the Gagliardo–Nirenberg inequality

$$||\nabla\phi||^2_{L^p} \le C||\phi||_{L^q}||\nabla^2\phi||_{L^r} \qquad \text{if} \quad \frac{1}{p} = \frac{1}{2}\left(\frac{1}{q} + \frac{1}{r}\right),$$

we infer that $\nabla(|\psi|^2 - r_0^2) \in L^p(\mathbf{R}^N)$ for any $p > \frac{2N-1}{2N-2}$. □

COROLLARY 3.5. *Under the assumptions of Theorem* 3.1, *assume that* $N \ge 3$, $c^2 = v_s^2$, *and the momentum of* ψ *with respect to the* x_1*-direction is well-defined, that is,* $\psi_1 \frac{\partial\psi_2}{\partial x_1} - \psi_2 \frac{\partial\psi_1}{\partial x_1} \in L^1(\mathbf{R}^N)$. *Then* ψ *satisfies* (3.1).

Proof. From Proposition 3.3 (iii) and (i) we have $\psi_1 \frac{\partial\psi_2}{\partial x_1} - \psi_2 \frac{\partial\psi_1}{\partial x_1} \in L^p(\mathbf{R}^N)$ for $p \in (\frac{2N-1}{2N-3}, \infty)$. Then the assumption $\psi_1 \frac{\partial\psi_2}{\partial x_1} - \psi_2 \frac{\partial\psi_1}{\partial x_1} \in L^1(\mathbf{R}^N)$ implies $\psi_1 \frac{\partial\psi_2}{\partial x_1} - \psi_2 \frac{\partial\psi_1}{\partial x_1} \in L^p(\mathbf{R}^N)$ for any $p \in [1, \infty)$. Now the conclusion follows from Theorem 3.1 (iii). □

4. Nonexistence results. In this section we show how Theorem 3.1 may be used to prove nonexistence of supersonic and sonic traveling waves with finite energy for some equations of type (1.1).

4.1. Equations invariant by translations. We consider the equation

$$i\frac{\partial\Phi}{\partial t} + \Delta\Phi + G(|\Phi|^2)\Phi = 0 \qquad \text{in } \mathbf{R}^N. \tag{4.1}$$

We assume that the function $G : [0, \infty) \longrightarrow \mathbf{R}$ satisfies the following assumptions:

- **(A1)** $G \in C^2([0, \infty), \mathbf{R})$ and there exists $r_0 > 0$ such that $G(r_0^2) = 0$ and $G'(r_0^2) < 0$.
- **(A2)** There exists $\alpha > 0$ such that $\limsup_{s\to\infty} \frac{G(s)}{s^\alpha} < 0$.

Obviously, (4.1) is of the form (1.1). As previously, we associate to (4.1) the "boundary condition" $|\Phi| \longrightarrow r_0^2$ as $|x| \longrightarrow \infty$. In this context, the sound velocity at infinity is $v_s = r_0\sqrt{-2G'(r_0^2)}$. The energy corresponding to (4.1) is $E(\Phi) = \int_{\mathbf{R}^N} |\nabla\Phi|^2\, dx + \int_{\mathbf{R}^N} V(|\Phi|^2)\, dx$, where $V(s) = \int_s^{r_0^2} G(\tau)\, d\tau$. Let ψ be a finite-energy traveling wave for (4.1) (in the sense of Definition 2.1) moving with speed c. Then ψ satisfies the equation

$$-ic\frac{\partial\psi}{\partial x_1} + \Delta\psi + G(|\psi|^2)\psi = 0 \qquad \text{in } \mathcal{D}'(\mathbf{R}^N), \qquad |\psi| \longrightarrow r_0 \quad \text{as } |x| \longrightarrow \infty. \tag{4.2}$$

If G satisfies (A1)–(A2), it is easy to see that $F(x, s) := G(s)$ satisfies the assumptions (H1)–(H5) in section 2 (with $L = -G'(r_0^2)$). It is then clear that the conclusions of Propositions 2.2 and 2.5 and Theorem 3.1 (i) are valid for ψ. Moreover, we have the following.

PROPOSITION 4.1 (Pohozaev identities). *Let* ψ *be as above. Choose* $R_* > 0$ *such that* $|\psi| \ge \frac{r_0}{2}$ *on* $\mathbf{R}^N \setminus B(0, R_*)$. *Let* θ *be the lifting of* $\frac{\psi}{|\psi|}$ *on* $\mathbf{R}^N \setminus B(0, R_*)$ *(as given by Proposition* 2.5 (ii)*) and let* χ *be a cut-off function as in Theorem* 3.1. *The following identities hold:*

$$-\int_{\mathbf{R}^N} \left|\frac{\partial\psi}{\partial x_1}\right|^2 dx + \int_{\mathbf{R}^N} \sum_{j=2}^N \left|\frac{\partial\psi}{\partial x_j}\right|^2 dx + \int_{\mathbf{R}^N} V(|\psi|^2)\, dx = 0, \tag{4.3}$$

$$
\begin{aligned}
&-\int_{\mathbf{R}^N}\left|\frac{\partial\psi}{\partial x_k}\right|^2 dx+\int_{\mathbf{R}^N}\sum_{j=1,\ j\neq k}^{N}\left|\frac{\partial\psi}{\partial x_j}\right|^2 dx+\int_{\mathbf{R}^N}V(|\psi|^2)\,dx\\
&\quad -c\int_{\mathbf{R}^N}\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}-r_0^2\frac{\partial}{\partial x_1}(\chi\theta)\,dx=0\qquad \textit{for } k=2,\dots,N.
\end{aligned}
\tag{4.4}
$$

It is worth noting that Proposition 4.1 is valid for any speed $c\in\mathbf{R}$.

Proof. Since the arguments are rather classical, we only sketch the proof.

Formally, traveling waves are critical points of the functional $E_c=E+cP_1$, where E is the energy and P_1 is the momentum with respect to the x_1-direction (see (1.3)). Identities (4.3) and (4.4) are simple consequences of the behavior of E_c with respect to dilations in $\mathbf{R}^N$. To be more precise, define $\psi_{k,t}(x)=\psi(x_1,\dots,x_{k-1},tx_k,x_{k+1},\dots,x_N)$ and $g_k(t)=E_c(\psi_{k,t})$. If ψ is a critical point of E_c, one would expect that $g_k'(1)=\frac{d}{dt}(E_c(\psi_{k,t}))\big|_{t=1}=0$, and this is precisely (4.3) if $k=1$, respectively, (4.4) if $k\geq 2$. However, this argument is not rigorous for at least two reasons. First, it is not clear what function space one should consider to define E_c (and this could not be a vector space because of the boundary conditions at infinity). Second, even if an appropriate function space is found, we do not know whether $\frac{d}{dt}(\psi_{k,t})\big|_{t=1}=x_k\frac{\partial\psi}{\partial x_k}$ belong to the tangent space at ψ of the considered function space.

The most convenient way to prove Pohozaev identities is to use a truncation argument. Fix a function $\eta\in C_c^\infty(\mathbf{R}^N)$ such that $\eta=1$ on $B(0,1)$ and $\eta=0$ on $\mathbf{R}^N\setminus B(0,2)$. For $n\geq 1$, define $\eta_n(x)=\eta(\frac{x}{n})$. We take the scalar product of (4.2) by $x_k\eta_n(x)\frac{\partial\psi}{\partial x_k}$ and integrate by parts the resulting equality. It is standard (see, e.g., Proposition 1, p. 320, in [3] or Lemma 2.4, p. 104, in [10]) to prove that

$$
\begin{aligned}
&\lim_{n\to\infty}\int_{\mathbf{R}^N}\left(\Delta\psi,x_k\eta_n(x)\frac{\partial\psi}{\partial x_k}\right)dx\\
&=-\int_{\mathbf{R}^N}\left|\frac{\partial\psi}{\partial x_k}\right|^2 dx+\frac{1}{2}\int_{\mathbf{R}^N}|\nabla\psi|^2\,dx
\end{aligned}
\tag{4.5}
$$

and

$$
\lim_{n\to\infty}\int_{\mathbf{R}^N}\left(G(|\psi|^2)\psi,x_k\eta_n(x)\frac{\partial\psi}{\partial x_k}\right)dx=\frac{1}{2}\int_{\mathbf{R}^N}V(|\psi|^2)\,dx.
\tag{4.6}
$$

It is obvious that $(ic\frac{\partial\psi}{\partial x_1},\eta_n(x)x_1\frac{\partial\psi}{\partial x_1})=c\eta_n(x)x_1(i\frac{\partial\psi}{\partial x_1},\frac{\partial\psi}{\partial x_1})=0$. Thus taking the scalar product of (4.2) by $x_1\eta_n(x)\frac{\partial\psi}{\partial x_1}$, integrating, and using (4.5) and (4.6) we get (4.3).

By (3.3) we have $(-i\frac{\partial\psi}{\partial x_j},\psi)=\psi_1\frac{\partial\psi_2}{\partial x_j}-\psi_2\frac{\partial\psi_1}{\partial x_j}=|\psi|^2\frac{\partial\theta}{\partial x_j}$ on $\mathbf{R}^N\setminus\overline{B}(0,R_*)$. Using the convention $\partial^\alpha(\chi\theta)=0$, $(\partial^\alpha\chi)\theta=0$ on $B(0,2R_*)$, we have

$$
\begin{aligned}
&\left(-i\frac{\partial\psi}{\partial x_j},\psi\right)=(1-\chi)\left(-i\frac{\partial\psi}{\partial x_j},\psi\right)+\chi|\psi|^2\frac{\partial\theta}{\partial x_j}\\
&=(1-\chi)\left(-i\frac{\partial\psi}{\partial x_j},\psi\right)+|\psi|^2\frac{\partial(\chi\theta)}{\partial x_j}-|\psi|^2\theta\frac{\partial\chi}{\partial x_j}\qquad\text{on }\mathbf{R}^N.
\end{aligned}
\tag{4.7}
$$

Therefore we get for $k = 2, \dots, N$

$$\begin{aligned}
&\int_{\mathbf{R}^N} \left(-ic\frac{\partial \psi}{\partial x_1}, x_k \eta_n(x) \frac{\partial \psi}{\partial x_k} \right) dx \\
&= \frac{c}{2} \int_{\mathbf{R}^N} x_k \eta_n(x) \left[\frac{\partial}{\partial x_1} \left(-i\psi, \frac{\partial \psi}{\partial x_k} \right) + \frac{\partial}{\partial x_k} \left(-i\frac{\partial \psi}{\partial x_1}, \psi \right) \right] dx \\
&= -\frac{c}{2} \int_{\mathbf{R}^N} x_k \frac{\partial \eta_n}{\partial x_1}(x) \left(-i\psi, \frac{\partial \psi}{\partial x_k} \right) + \left(\eta_n(x) + x_k \frac{\partial \eta_n}{\partial x_k}(x) \right) \left(-i\frac{\partial \psi}{\partial x_1}, \psi \right) dx \\
&= \frac{c}{2} \int_{\mathbf{R}^N} x_k \frac{\partial \eta_n}{\partial x_1}(x) \left[(1-\chi) \left(-i\frac{\partial \psi}{\partial x_k}, \psi \right) + |\psi|^2 \frac{\partial(\chi\theta)}{\partial x_k} - |\psi|^2 \theta \frac{\partial \chi}{\partial x_k} \right] dx \\
&\quad -\frac{c}{2} \int_{\mathbf{R}^N} \eta_n(x) \left(-i\frac{\partial \psi}{\partial x_1}, \psi \right) dx \\
&\quad -\frac{c}{2} \int_{\mathbf{R}^N} x_k \frac{\partial \eta_n}{\partial x_k}(x) \left[(1-\chi) \left(-i\frac{\partial \psi}{\partial x_1}, \psi \right) + |\psi|^2 \frac{\partial(\chi\theta)}{\partial x_1} - |\psi|^2 \theta \frac{\partial \chi}{\partial x_1} \right] dx \\
&= \frac{c}{2} \int_{\mathbf{R}^N} x_k |\psi|^2 \left(\frac{\partial \eta_n}{\partial x_1} \frac{\partial(\chi\theta)}{\partial x_k} - \frac{\partial \eta_n}{\partial x_k} \frac{\partial(\chi\theta)}{\partial x_1} \right) - \eta_n(x) \left(-i\frac{\partial \psi}{\partial x_1}, \psi \right) dx \quad \text{if } n > 3R_*
\end{aligned} \tag{4.8}$$

because $\operatorname{supp}(1-\chi) \subset \overline{B}(0, 3R_*)$ and $\operatorname{supp}\nabla\eta_n \subset \overline{B}(0, 2n) \setminus B(0, n)$, and consequently $(1-\chi)\frac{\partial \eta_n}{\partial x_j} = 0$ and $\frac{\partial \chi}{\partial x_\ell}\frac{\partial \eta_n}{\partial x_j} = 0$ on $\mathbf{R}^N$ for $n > 3R_*$.

It is obvious that

$$\begin{aligned}
&\int_{\mathbf{R}^N} x_k \Big(\frac{\partial \eta_n}{\partial x_1} \frac{\partial(\chi\theta)}{\partial x_k} - \frac{\partial \eta_n}{\partial x_k} \frac{\partial(\chi\theta)}{\partial x_1} \Big) dx \\
&= \int_{\mathbf{R}^N} x_k \Big[\frac{\partial}{\partial x_1} \Big(\eta_n \frac{\partial(\chi\theta)}{\partial x_k} \Big) - \frac{\partial}{\partial x_k} \Big(\eta_n \frac{\partial(\chi\theta)}{\partial x_1} \Big) \Big] dx = \int_{\mathbf{R}^N} \eta_n \frac{\partial(\chi\theta)}{\partial x_1} dx.
\end{aligned} \tag{4.9}$$

Since $|\psi|^2 - r_0^2$ and $\nabla(\chi\theta)$ belong to $L^2(\mathbf{R}^N)$, using the dominated convergence theorem we obtain

$$\begin{aligned}
&\left| \int_{\mathbf{R}^N} x_k (|\psi|^2 - r_0^2) \left(\frac{\partial \eta_n}{\partial x_1} \frac{\partial(\chi\theta)}{\partial x_k} - \frac{\partial \eta_n}{\partial x_k} \frac{\partial(\chi\theta)}{\partial x_1} \right) dx \right| \\
&\quad \le 4 ||\nabla \eta||_{L^\infty(\mathbf{R}^N)} \int_{B(0,2n)\setminus B(0,n)} |\,|\psi|^2 - r_0^2| \cdot |\nabla(\chi\theta)|\, dx \longrightarrow 0 \qquad \text{as } n \longrightarrow \infty.
\end{aligned} \tag{4.10}$$

Recall that $\psi_1 \frac{\partial \psi_2}{\partial x_1} - \psi_2 \frac{\partial \psi_1}{\partial x_1} - r_0^2 \frac{\partial(\chi\theta)}{\partial x_1} \in L^1(\mathbf{R}^N)$ by Theorem 3.1 (i), and by dominated convergence we get

$$\begin{aligned}
&\int_{\mathbf{R}^N} \eta_n \Big[\Big(-i\frac{\partial \psi}{\partial x_1}, \psi \Big) - r_0^2 \frac{\partial(\chi\theta)}{\partial x_1} \Big] dx = \int_{\mathbf{R}^N} \eta_n \Big[\psi_1 \frac{\partial \psi_2}{\partial x_1} - \psi_2 \frac{\partial \psi_1}{\partial x_1} - r_0^2 \frac{\partial(\chi\theta)}{\partial x_1} \Big] dx \\
&\longrightarrow \int_{\mathbf{R}^N} \psi_1 \frac{\partial \psi_2}{\partial x_1} - \psi_2 \frac{\partial \psi_1}{\partial x_1} - r_0^2 \frac{\partial(\chi\theta)}{\partial x_1} dx \qquad \text{as } n \longrightarrow \infty.
\end{aligned} \tag{4.11}$$

Combining (4.8)–(4.11) we find

$$\lim_{n\to\infty}\int_{\mathbf{R}^N}\left(-ic\frac{\partial\psi}{\partial x_1},x_k\eta_n(x)\frac{\partial\psi}{\partial x_k}\right)dx = -\frac{c}{2}\int_{\mathbf{R}^N}\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}-r_0^2\frac{\partial(\chi\theta)}{\partial x_1}\,dx. \tag{4.12}$$

Taking the scalar product of (4.2) by $\eta_n(x)x_k\frac{\partial\psi}{\partial x_k}$, integrating over $\mathbf{R}^N$, and using (4.5), (4.6), and (4.12) we obtain (4.4). ∎

THEOREM 4.2. *Assume that $N\geq 2$,* (A1), (A2) *hold and let ψ be a finite-energy traveling wave for* (3.1) *such that $G(|\psi|^2)\psi\in L^1_{loc}(\mathbf{R}^N)$. Suppose that either*

- *$c^2>v_s^2$, where $v_s=r_0\sqrt{-2G'(r_0^2)}$ is the sound velocity at infinity, or*
- *$N=2$ and $c^2=v_s^2$, or*
- *$N\geq 3$, $c^2=v_s^2$, and $\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}\in L^{\frac{2N-1}{2N-3}}(\mathbf{R}^N)$.*

Moreover, assume that G satisfies

- **(A3)** *there exists $\alpha\in[-1+\frac{N-3}{N-1}(1-\frac{v_s^2}{c^2}),\frac{v_s^2}{c^2}]$ such that*

$$sG(s)+\frac{v_s^2}{2}(s-r_0^2)+\left(1-\alpha-\frac{v_s^2}{c^2}\right)V(s)\leq 0 \qquad \text{for any } s\geq 0.$$

Then ψ is constant.

Proof. It follows from Propositions 2.2 and 2.5 that ψ is smooth, and Proposition 4.1 implies that ψ satisfies (4.3) and (4.4). Summing up the identities (4.4) for $k=2,\dots,N$ we get

$$\begin{aligned}&\int_{\mathbf{R}^N}\left|\frac{\partial\psi}{\partial x_1}\right|^2+\frac{N-3}{N-1}\sum_{k=2}^N\left|\frac{\partial\psi}{\partial x_k}\right|^2dx+\int_{\mathbf{R}^N}V(|\psi|^2)\,dx\\ &-c\int_{\mathbf{R}^N}\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}-r_0^2\frac{\partial(\chi\theta)}{\partial x_1}\,dx=0.\end{aligned} \tag{4.13}$$

On the other hand, from Theorem 3.1 we have

$$\begin{aligned}&\int_{\mathbf{R}^N}|\nabla\psi|^2-G(|\psi|^2)|\psi|^2-\frac{v_s^2}{2}(|\psi|^2-r_0^2)\,dx\\ &-c\left(1-\frac{v_s^2}{c^2}\right)\int_{\mathbf{R}^N}\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}-r_0^2\frac{\partial}{\partial x_1}(\chi\theta)\,dx=0.\end{aligned} \tag{4.14}$$

We multiply (4.13) by $-1+\frac{v_s^2}{c^2}$ and add the resulting equality to (4.14) to get

$$\begin{aligned}&\int_{\mathbf{R}^N}\frac{v_s^2}{c^2}\left|\frac{\partial\psi}{\partial x_1}\right|^2+\left(1-\left(1-\frac{v_s^2}{c^2}\right)\frac{N-3}{N-1}\right)\sum_{k=2}^N\left|\frac{\partial\psi}{\partial x_k}\right|^2dx\\ &-\int_{\mathbf{R}^N}G(|\psi|^2)|\psi|^2+\frac{v_s^2}{2}(|\psi|^2-r_0^2)+\left(1-\frac{v_s^2}{c^2}\right)V(|\psi|^2)\,dx=0.\end{aligned} \tag{4.15}$$

Let α satisfy (A3). Multiplying (4.3) by α and adding it to (4.15) we obtain

$$\begin{aligned}&\int_{\mathbf{R}^N}\left(\frac{v_s^2}{c^2}-\alpha\right)\left|\frac{\partial\psi}{\partial x_1}\right|^2+\left(\alpha+1-\left(1-\frac{v_s^2}{c^2}\right)\frac{N-3}{N-1}\right)\sum_{k=2}^N\left|\frac{\partial\psi}{\partial x_k}\right|^2dx\\ &=\int_{\mathbf{R}^N}G(|\psi|^2)|\psi|^2+\frac{v_s^2}{2}(|\psi|^2-r_0^2)+\left(1-\alpha-\frac{v_s^2}{c^2}\right)V(|\psi|^2)\,dx.\end{aligned} \tag{4.16}$$

By (A3), the right-hand side of (4.16) is less than or equal to zero. If $\alpha \in (-1+(1-\frac{v_s^2}{c^2})\frac{N-3}{N-1}, \frac{v_s^2}{c^2})$, it follows from (4.16) that $\int_{\mathbf{R}^N} \left|\frac{\partial\psi}{\partial x_k}\right|^2 dx = 0$ for $k = 1, \dots, N$, which implies $\nabla\psi = 0$ on $\mathbf{R}^N$, i.e., ψ is constant. If $\alpha = -1 + (1 - \frac{v_s^2}{c^2})\frac{N-3}{N-1}$, we infer from (4.16) that $\int_{\mathbf{R}^N} \left|\frac{\partial\psi}{\partial x_1}\right|^2 dx = 0$; consequently $\frac{\partial\psi}{\partial x_1} = 0$ on $\mathbf{R}^N$, which implies that ψ does not depend on x_1. Since $\int_{\mathbf{R}^N} |\nabla\psi|^2\, dx$ is finite, we have necessarily $\nabla\psi = 0$ on $\mathbf{R}^N$, which means that is ψ is constant. A similar argument shows that ψ is constant in the case $\alpha = \frac{v_s^2}{c^2}$. ∎

Remark. Let α, C_1, and $\tilde{r}$ be positive constants satisfying $G(s^2) + \frac{c^2}{4} \le -C_1(s - \tilde{r})^{2\alpha}$ for any $s \ge \tilde{r}$ (such constants exist by assumption (A2)). Let ψ be as in Theorem 4.2. It follows from the proof of Proposition 2.2 (i) that $|\psi(x)| \le \tilde{r}\sqrt{2}$ for any x. Therefore the proof of Theorem 4.2 is still valid if the inequality in (A3) holds only for all $s \in [0, 2\tilde{r}^2]$.

If $c^2 = v_s^2$, $N \ge 3$, and ψ is as above, we already know from Proposition 3.3 (iii) that $\psi_1\frac{\partial\psi_2}{\partial x_1} - \psi_2\frac{\partial\psi_1}{\partial x_1} \in L^p(\mathbf{R}^N)$ for any $p \in (\frac{2N-1}{2N-3}, \infty)$. Therefore we have the following.

COROLLARY 4.3. *Assume that* (A1), (A2), (A3) *hold,* $N \ge 3$, *and* $c^2 = v_s^2$. *Let* ψ *be a traveling wave for* (4.1) *having finite energy, finite momentum with respect to the* x_1*-direction (i.e.,* $\psi_1\frac{\partial\psi_2}{\partial x_1} - \psi_2\frac{\partial\psi_1}{\partial x_1} \in L^1(\mathbf{R}^N)$*), and such that* $G(|\psi|^2)\psi \in L^1_{loc}(\mathbf{R}^N)$. *Then* ψ *is constant.*

Example 4.4. The Gross–Pitaevskii equation is of type (4.1) with $G(s) = 1 - s$. In this case we have $r_0 = 1$, $V(s) = \frac{1}{2}(s-1)^2$, and $v_s = \sqrt{2}$. For any finite-energy function ψ we have $\int_{\mathbf{R}^N}(|\psi|^2 - 1)^2\, dx < \infty$; hence $\psi \in L^4_{loc}(\mathbf{R}^N)$ and consequently $G(|\psi|^2)\psi \in L^1_{loc}(\mathbf{R}^N)$. Assumptions (A1) and (A2) are clearly satisfied. We find $sG(s) + \frac{v_s^2}{2}(s - r_0^2) + (1 - \alpha - \frac{v_s^2}{c^2})V(s) = -(\frac{1}{2} + \alpha + \frac{v_s^2}{c^2})(1-s)^2$. The last expression is nonpositive for any s if $\alpha \ge -\frac{1}{2} - \frac{v_s^2}{c^2}$, and thus assumption (A3) is also satisfied. Hence the conclusion of Theorem 4.2 holds for the Gross–Pitaevskii equation. In particular, we recover the nonexistence results in [17], [18].

Example 4.5. The cubic-quintic Schrödinger equation is of the form (4.1) with $G(s) = -\alpha_1 + \alpha_3 s - \alpha_5 s^2$, where α_1, α_3, α_5 are positive and $\frac{3}{16} < \frac{\alpha_1\alpha_5}{\alpha_3^2} < \frac{1}{4}$. The nonlinearity G can be written as $G(s) = -\alpha_5(s - r_1^2)(s - r_0^2)$, where $0 < r_1 < r_0$. In this case we have $v_s^2 = -2r_0^2G'(r_0) = 2\alpha_5 r_0^2(r_0^2 - r_1^2)$ and $V(s) = \frac{\alpha_5}{3}(s - r_0^2)^2(s + \frac{1}{2}r_0^2 - \frac{3}{2}r_1^2)$. For any function ψ with finite energy we have $V(|\psi|^2) \in L^1(\mathbf{R}^N)$, which implies $\psi \in L^6_{loc}(\mathbf{R}^N)$ and consequently $G(|\psi|^2)\psi \in L^1_{loc}(\mathbf{R}^N)$. It is obvious that G satisfies (A1) and (A2). If $c^2 \ge v_s^2$, we have $-\frac{v_s^2}{c^2} \in [-1 + \frac{N-3}{N-1}(1 - \frac{v_s^2}{c^2}), \frac{v_s^2}{c^2}]$ and an easy computation shows that $sG(s) + \frac{v_s^2}{2}(s - r_0^2) + V(s) = -\frac{\alpha_5}{6}(4s + 5r_0^2 - 3r_1^2) \le 0$ for any $s \ge 0$. Hence assumption (A3) holds for $\alpha = -\frac{v_s^2}{c^2}$; therefore the conclusion of Theorem 4.2 is valid for the cubic-quintic Schrödinger equation.

Remark. The proof of nonexistence of supersonic and sonic traveling waves for equations of type (1.1) relies on identity (3.1), combined with Pohozaev identities. We have proved (3.1) in an "indirect" way, starting from (3.11), using the Fourier transform and analyzing the behavior near the origin of the symbols of the differential operators involved. A natural question is whether (3.1) could be proved "directly" by multiplying the equations by appropriate functions and integrating by parts (and it is very tempting to try to do so because of the form of (3.7) and (3.8)!). We suspect that it is not possible to find such a proof, a heuristical reason being the following: If a "direct" proof of (3.1) could be found, it should be valid for any value of c.

Since Pohozaev identities are also valid for any c, one could infer that, for any c, equation (4.1) and system (4.17)–(4.18) below do not admit nontrivial finite-energy traveling waves. However, in the case of the Gross–Pitaevskii equation the existence of nontrivial, finite-energy traveling waves moving with sufficiently small speed c has been proved in [5] in dimension $N = 2$, respectively, in [7] and [12] in dimension $N = 3$. In a recent work [6], existence of traveling waves has been proved in space dimensions $N = 2$ and $N = 3$ for a wider range of speeds, including speeds c close to (and less than) v_s if $N = 2$. For Schrödinger equations of cubic-quintic type, the existence of small velocity traveling waves has been proved in [25] in any space dimension $N \geq 4$. Even for these particular cases, the question of whether such solutions exist for any speed $c \in (-v_s, v_s)$ is, to our knowledge, still open.

4.2. A Gross–Pitaevskii–Schrödinger system. Our second application concerns the system

$$i\frac{\partial \Psi}{\partial t} + \Delta \Psi - \frac{1}{\varepsilon^2}\left(|\Psi|^2 + \frac{1}{\varepsilon^2}|\Phi|^2 - 1\right)\Psi = 0 \qquad \text{in } \mathbf{R}^N, \tag{4.17}$$

$$i\delta\frac{\partial \Phi}{\partial t} + \Delta \Phi - \frac{1}{\varepsilon^2}(q^2|\Psi|^2 - \varepsilon^2 k^2)\Phi = 0 \qquad \text{in } \mathbf{R}^N, \tag{4.18}$$

which describes the motion of an uncharged impurity in a Bose condensate (see [16]). Here Ψ and Φ are the wavefunctions for bosons, respectively, for the impurity, and ε, δ, q, k are dimensionless physical constants. Assuming that the condensate is at rest at infinity, the functions Ψ and Φ must satisfy the "boundary conditions" $|\Psi| \longrightarrow 1$ and $|\Phi| \longrightarrow 0$ as $|x| \longrightarrow \infty$.

System (4.17)–(4.18) has a Hamiltonian structure, the associated energy being

$$E(\Psi, \Phi) = \int_{\mathbf{R}^N} |\nabla \Psi|^2 + \frac{1}{\varepsilon^2 q^2}|\nabla \Phi|^2 + \frac{1}{2\varepsilon^2}(|\Psi|^2 - 1)^2 + \frac{1}{\varepsilon^4}|\Psi|^2|\Phi|^2 - \frac{k^2}{\varepsilon^2 q^2}|\Phi|^2\, dx. \tag{4.19}$$

We are interested in traveling wave solutions for (4.17)–(4.18), i.e., solutions of the form $\Psi(x,t) = \psi(x_1 - ct, x_2, \ldots, x_N)$, $\Phi(x,t) = \varphi(x_1 - ct, x_2, \ldots, x_N)$. Such solutions must satisfy the equations

$$-ic\frac{\partial \psi}{\partial x_1} + \Delta \psi - \frac{1}{\varepsilon^2}\left(|\psi|^2 + \frac{1}{\varepsilon^2}|\varphi|^2 - 1\right)\psi = 0, \tag{4.20}$$

$$-ic\delta\frac{\partial \varphi}{\partial x_1} + \Delta \varphi - \frac{1}{\varepsilon^2}(q^2|\psi|^2 - \varepsilon^2 k^2)\varphi = 0, \tag{4.21}$$

together with the boundary conditions $|\psi| \longrightarrow 1$ and $|\varphi| \longrightarrow 0$ as $|x| \longrightarrow \infty$.

Equation (4.17) is of type (1.1). In view of the analysis in the introduction, the associated sound velocity at infinity is $\frac{\sqrt{2}}{\varepsilon}$.

In one space dimension, system (4.20)–(4.21) with the considered boundary conditions has been studied in [26]. It was proved that it admits nontrivial solutions if c is less than the sound velocity at infinity; in this case the structure of the set of traveling waves has been investigated, and it was proved that it contains global subcontinua in appropriate (weighted) Sobolev spaces.

Here we study the finite-energy traveling waves for (4.17)–(4.18) in dimension $N \geq 2$. In view of (4.19), by *finite-energy traveling wave* we mean a couple of functions

$(\psi,\varphi)\in L^1_{loc}(\mathbf{R}^N)\times L^1_{loc}(\mathbf{R}^N)$ which satisfy (4.20)–(4.21) in $\mathcal{D}'(\mathbf{R}^N)$, the boundary conditions $|\psi|\longrightarrow 1$, $\varphi\longrightarrow 0$ as $|x|\longrightarrow\infty$, and such that $\nabla\psi$, $\nabla\varphi$, $\varphi\in L^2(\mathbf{R}^N)$, $(|\psi|^2-1)^2+\frac{2}{\varepsilon^2}|\psi|^2|\varphi|^2\in L^1(\mathbf{R}^N)$. As before, we denote $\psi_1=\mathrm{Re}(\psi)$, $\psi_2=\mathrm{Im}(\psi)$, $\varphi_1=\mathrm{Re}(\varphi)$, $\varphi_2=\mathrm{Im}(\varphi)$. We have the following.

PROPOSITION 4.6. *Let $c\in\mathbf{R}$ and let (ψ,φ) be a finite-energy traveling wave for* (4.17)–(4.18). *Then the following hold.*

(i) *The function ψ is bounded and C^∞ and $\varphi,\nabla\psi\in W^{k,p}(\mathbf{R}^N)$ for any $k\in\mathbf{N}$ and $p\geq 2$.*

(ii) *There exist $R_*\geq 0$ and a real-valued function θ such that $\psi=|\psi|e^{i\theta}$ on $\mathbf{R}^N\setminus B(0,R_*)$ and $\nabla\theta\in W^{k,p}(\mathbf{R}^N\setminus B(0,R_*))$ for any $k\in\mathbf{N}$ and $p\geq 2$.*

(iii) *Let $\chi\in C^\infty(\mathbf{R}^N)$ be a cut-off function such that $\chi=0$ on $B(0,2R_*)$ and $\chi=1$ on $\mathbf{R}^N\setminus B(0,3R_*)$. We have $\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}-\frac{\partial}{\partial x_1}(\chi\theta)\in L^1(\mathbf{R}^N)$ and the following Pohozaev-type identities hold:*

$$\begin{aligned}&\int_{\mathbf{R}^N}-\left|\frac{\partial\psi}{\partial x_1}\right|^2-\frac{1}{\varepsilon^2q^2}\left|\frac{\partial\varphi}{\partial x_1}\right|^2+\sum_{j=2}^N\left(\left|\frac{\partial\psi}{\partial x_j}\right|^2+\frac{1}{\varepsilon^2q^2}\left|\frac{\partial\varphi}{\partial x_j}\right|^2\right)dx\\&+\int_{\mathbf{R}^N}\frac{1}{2\varepsilon^2}(|\psi|^2-1)^2+\frac{1}{\varepsilon^4}|\psi|^2|\varphi|^2-\frac{k^2}{\varepsilon^2q^2}|\varphi|^2\,dx=0,\end{aligned}\tag{4.22}$$

and for any $k\in\{2,\dots,N\}$,

$$\begin{aligned}&\int_{\mathbf{R}^N}-\left|\frac{\partial\psi}{\partial x_k}\right|^2-\frac{1}{\varepsilon^2q^2}\left|\frac{\partial\varphi}{\partial x_k}\right|^2+\sum_{j=1,\,j\neq k}^N\left(\left|\frac{\partial\psi}{\partial x_j}\right|^2+\frac{1}{\varepsilon^2q^2}\left|\frac{\partial\varphi}{\partial x_j}\right|^2\right)dx\\&+\int_{\mathbf{R}^N}\frac{1}{2\varepsilon^2}(|\psi|^2-1)^2+\frac{1}{\varepsilon^4}|\psi|^2|\varphi|^2-\frac{k^2}{\varepsilon^2q^2}|\varphi|^2\,dx\\&-c\int_{\mathbf{R}^N}\psi_1\frac{\partial\psi_2}{\partial x_1}-\psi_2\frac{\partial\psi_1}{\partial x_1}-\frac{\partial}{\partial x_1}(\chi\theta)\,dx-\frac{2c\delta}{\varepsilon^2q^2}\int_{\mathbf{R}^N}\varphi_1\frac{\partial\varphi_2}{\partial x_1}\,dx=0.\end{aligned}\tag{4.23}$$

Proof. Putting $F(x,s)=-\frac{1}{\varepsilon^2}(s+\frac{1}{\varepsilon^2}|\varphi(x)|^2-1)$, equation (4.20) is a particular case of (1.7). Clearly, in this case we have $r_0=1$.

It is obvious that F satisfies the assumptions (H1a) and (H1b) in section 2. Clearly, $F(x,s)\leq-\frac{1}{\varepsilon^2}(s-1)\leq-\frac{1}{2\varepsilon^2}s$ for any $s\geq 2$ and $x\in\mathbf{R}^N$, and hence F satisfies (H2) for $r_*=2$. Moreover, $\int_{r_0^2}^{r_*}F(x,\tau)\,d\tau=-\frac{1}{\varepsilon^2}(\frac{1}{2}+\frac{1}{\varepsilon^2}|\varphi(x)|^2)$ is a locally integrable function of x. We have $|\psi|^4\leq 2(|\psi|^2-1)^2+2$ and $(|\psi|^2-1)^2\in L^1(\mathbf{R})$ because (ψ,φ) has finite energy, and hence $\psi\in L^4_{loc}(\mathbf{R}^N)$. We also have $||\varphi|^2\psi|\leq\frac{1}{2}(|\varphi|^2+|\varphi|^2|\psi|^2)$ and $|\varphi|^2$, $|\varphi|^2|\psi|^2\in L^1(\mathbf{R})$. It is then clear that $F(\cdot,|\psi|^2)\psi=-\frac{1}{\varepsilon^2}|\psi|^2\psi-\frac{1}{\varepsilon^4}|\varphi|^2\psi+\frac{1}{\varepsilon^2}\psi$ belongs to $L^1_{loc}(\mathbf{R}^N)$. Hence we may use Proposition 2.2 (i) and infer that $\psi\in L^\infty(\mathbf{R}^N)$.

By hypothesis we have $\varphi\in L^2(\mathbf{R}^N)$ and $\nabla\varphi\in L^2(\mathbf{R}^N)$, that is, $\varphi\in W^{1,2}(\mathbf{R}^N)$. Assume that $\varphi\in W^{1,p}(\mathbf{R}^N)$ for some $p\in(1,\infty)$. Since ψ is bounded, by (4.21) we find $\Delta\varphi\in L^p(\mathbf{R}^N)$, and we infer that $\varphi\in W^{2,p}(\mathbf{R}^N)$. If $p<N$, by the Sobolev embedding we have $\varphi\in L^{p^*}(\mathbf{R}^N)$ and $\nabla\varphi\in L^{p^*}(\mathbf{R}^N)$ (where $\frac{1}{p^*}=\frac{1}{p}-\frac{1}{N}$), and hence $\varphi\in W^{1,p^*}(\mathbf{R}^N)$. Repeating the above argument if necessary, after a finite number of steps we find $\varphi\in W^{2,q}(\mathbf{R}^N)$ for some $q\geq N$ and the Sobolev embedding implies $\varphi\in L^r(\mathbf{R}^N)$ and $\nabla\varphi\in L^r(\mathbf{R}^N)$ for any $r\in[q,\infty)$. Using (4.21) again, we conclude that $\Delta\varphi\in L^r(\mathbf{R}^N)$, and hence $\varphi\in W^{2,r}(\mathbf{R}^N)$ for any $r\in[2,\infty)$.

It follows that $\varphi \in C^1(\mathbf{R}^N)$, which implies $F \in C^1(\mathbf{R}^N)$ (and consequently F satisfies (H1c)). By Proposition 2.2 (ii) we get $\psi \in W^{3,p}_{loc}(\mathbf{R}^N)$ for any $p \in [1,\infty)$. In particular, $\psi \in C^2(\mathbf{R}^N)$.

We have $F(x,1) = -\frac{1}{\varepsilon^4}|\varphi(x)|^2$, and F clearly satisfies assumption (H3). It is obvious that $\partial_{N+1}F(x,s) = -\frac{1}{\varepsilon^2}$ and $\partial^2_{N+1}F(x,s) = 0$ on $\mathbf{R}^N \times \mathbf{R}_+$, and therefore F satisfies (H4) and (H5). Thus we may use Proposition 2.5 (i) and infer that $\nabla\psi \in W^{1,p}(\mathbf{R}^N)$ for any $p \in [2,\infty)$.

The rest of the proof is a very easy induction. For $k \in \mathbf{N}^*$, assume that $\nabla\psi \in W^{k,p}(\mathbf{R}^N)$ and $\varphi \in W^{k+1,p}(\mathbf{R}^N)$ for any $p \in [2,\infty)$. Consider $\alpha \in \mathbf{N}^N$ such that $|\alpha| = k$. Differentiating (4.20) and (4.21) we obtain, respectively,

$$\Delta(\partial^\alpha\psi) = ic\partial^\alpha\frac{\partial\psi}{\partial x_1} + \frac{1}{\varepsilon^2}\partial^\alpha\Big(\Big(|\psi|^2 + \frac{1}{\varepsilon^2}|\varphi|^2 - 1\Big)\psi\Big),$$
$$\Delta(\partial^\alpha\varphi) = ic\delta\partial^\alpha\frac{\partial\varphi}{\partial x_1} + \frac{1}{\varepsilon^2}\partial^\alpha\Big((q^2|\psi|^2 - \varepsilon^2k^2)\varphi\Big).$$

We infer that $\Delta(\partial^\alpha\psi),\ \Delta(\partial^\alpha\varphi) \in L^p(\mathbf{R}^N)$ for any $p \in [2,\infty)$. By hypothesis we have $\partial^\alpha\psi,\ \partial^\alpha\varphi \in L^p(\mathbf{R}^N)$, and therefore $\partial^\alpha\psi,\ \partial^\alpha\varphi \in W^{2,p}(\mathbf{R}^N)$ for any $p \in [2,\infty)$. Since this is true for any α with $|\alpha| = k$, we have $\nabla\psi \in W^{k+1,p}(\mathbf{R}^N)$ and $\varphi \in W^{k+2,p}(\mathbf{R}^N)$. We conclude that $\nabla\psi$ and φ belong to $W^{k,p}(\mathbf{R}^N)$ for any $k \in \mathbf{N}$ and $p \in [2,\infty)$.

(ii) is an immediate corollary of Proposition 2.5 (ii).

(iii) It follows directly from Theorem 3.1 (i) that $\psi_1\frac{\partial\psi_2}{\partial x_1} - \psi_2\frac{\partial\psi_1}{\partial x_1} - \frac{\partial}{\partial x_1}(\chi\theta) \in L^1(\mathbf{R}^N)$. The proof of (4.22) and (4.23) is similar to that of (4.3) and (4.4) (multiply (4.20) by $x_j\eta_n\frac{\partial\psi}{\partial x_j}$ and (4.21) by $\frac{1}{\varepsilon^2q^2}x_j\eta_n\frac{\partial\varphi}{\partial x_j}$, where $\eta_n(x) = \eta(\frac{x}{n})$ is a cut-off function, add the resulting equalities, integrate by parts, and pass to the limit as $n \longrightarrow \infty$). We omit the details. □

We have the following result concerning the nonexistence of supersonic traveling waves for (4.17)–(4.18).

THEOREM 4.7. *Let $N \geq 2$ and let (ψ,φ) be a finite-energy traveling wave for the system* (4.17)–(4.18)*, moving with velocity c. Assume that either*

- $c^2 > \frac{2}{\varepsilon^2}$, *or*
- $N = 2$ *and* $c^2 = \frac{2}{\varepsilon^2}$, *or*
- $N \geq 3$, $c^2 = \frac{2}{\varepsilon^2}$, *and* $\psi_1\frac{\partial\psi_2}{\partial x_1} - \psi_2\frac{\partial\psi_1}{\partial x_1} \in L^{\frac{2N-1}{2N-3}}(\mathbf{R}^N)$.

Then $\varphi = 0$ and ψ is constant on $\mathbf{R}^N$.

Proof. Let θ, χ be as in Proposition 4.6 and let $F(x,s) = -\frac{1}{\varepsilon^2}(s + \frac{1}{\varepsilon^2}|\varphi(x)|^2 - 1)$. We have already seen that F satisfies assumptions (H1)–(H5), and it follows that identity (3.1) holds. Taking into account the particular form of F, this identity can be written as

$$\begin{aligned}&\int_{\mathbf{R}^N}|\nabla\psi|^2 + \frac{1}{\varepsilon^2}(|\psi|^2-1)^2 + \frac{1}{\varepsilon^4}|\varphi|^2|\psi|^2\,dx\\ &= c\left(1 - \frac{2}{\varepsilon^2c^2}\right)\int_{\mathbf{R}^N}\psi_1\frac{\partial\psi_2}{\partial x_1} - \psi_2\frac{\partial\psi_1}{\partial x_1} - \frac{\partial}{\partial x_1}(\chi\theta)\,dx.\end{aligned} \tag{4.24}$$

We take the scalar product of (4.21) by φ, then integrate the resulting equality to get

$$\int_{\mathbf{R}^N}|\nabla\varphi|^2\,dx + \frac{q^2}{\varepsilon^2}\int_{\mathbf{R}^N}|\varphi|^2|\psi|^2\,dx - k^2\int_{\mathbf{R}^N}|\varphi|^2\,dx - 2c\delta\int_{\mathbf{R}^N}\varphi_1\frac{\partial\varphi_2}{\partial x_1}\,dx = 0. \tag{4.25}$$

Summing up the identities (4.23) for $k = 2, 3, \dots, N$, we find

$$\begin{aligned}
&\int_{\mathbf{R}^N} \left|\frac{\partial\psi}{\partial x_1}\right|^2 + \frac{1}{\varepsilon^2 q^2}\left|\frac{\partial\varphi}{\partial x_1}\right|^2 + \frac{N-3}{N-1}\sum_{j=2}^{N}\left(\left|\frac{\partial\psi}{\partial x_j}\right|^2 + \frac{1}{\varepsilon^2 q^2}\left|\frac{\partial\varphi}{\partial x_j}\right|^2\right) dx \\
&+ \int_{\mathbf{R}^N} \frac{1}{2\varepsilon^2}(|\psi|^2-1)^2 + \frac{1}{\varepsilon^4}|\psi|^2|\varphi|^2 - \frac{k^2}{\varepsilon^2 q^2}|\varphi|^2\, dx \\
&- c\int_{\mathbf{R}^N} \psi_1\frac{\partial\psi_2}{\partial x_1} - \psi_2\frac{\partial\psi_1}{\partial x_1} - \frac{\partial}{\partial x_1}(\chi\theta)\, dx - \frac{2c\delta}{\varepsilon^2 q^2}\int_{\mathbf{R}^N}\varphi_1\frac{\partial\varphi_2}{\partial x_1}\, dx = 0.
\end{aligned} \tag{4.26}$$

Next we combine equalities (4.24)–(4.26) in order to eliminate the terms $\int_{\mathbf{R}^N}\varphi_1\frac{\partial\varphi_2}{\partial x_1}dx$ and $\int_{\mathbf{R}^N}\psi_1\frac{\partial\psi_2}{\partial x_1} - \psi_2\frac{\partial\psi_1}{\partial x_1} - \frac{\partial}{\partial x_1}(\chi\theta)\, dx$. We find

$$\begin{aligned}
&\frac{2}{\varepsilon^2 c^2}\int_{\mathbf{R}^N}\left|\frac{\partial\psi}{\partial x_1}\right|^2 dx + \Big(1 - \Big(1 - \frac{2}{\varepsilon^2 c^2}\Big)\frac{N-3}{N-1}\Big)\int_{\mathbf{R}^N}\sum_{j=2}^{N}\left|\frac{\partial\psi}{\partial x_j}\right|^2 dx \\
&+ \frac{2}{(N-1)\varepsilon^2 q^2}\Big(1 - \frac{2}{\varepsilon^2 c^2}\Big)\int_{\mathbf{R}^N}\sum_{j=2}^{N}\left|\frac{\partial\varphi}{\partial x_j}\right|^2 dx \\
&+ \frac{1}{2\varepsilon^2}\Big(1 + \frac{2}{\varepsilon^2 c^2}\Big)\int_{\mathbf{R}^N}(|\psi|^2-1)^2\, dx + \frac{1}{\varepsilon^4}\int_{\mathbf{R}^N}|\varphi|^2|\psi|^2\, dx = 0.
\end{aligned} \tag{4.27}$$

Obviously, all integrals in (4.27) are nonnegative. If $c^2 \geq \frac{2}{\varepsilon^2}$, all coefficients are also nonnegative, and therefore each term in (4.27) must be zero. In particular, $\int_{\mathbf{R}^N}\left|\frac{\partial\psi}{\partial x_k}\right|^2 dx = 0$ for any $k \in \{1, \dots, N\}$, which implies $\nabla\psi = 0$ on $\mathbf{R}^N$, i.e., ψ is constant. Since $\int_{\mathbf{R}^N}(|\psi|^2-1)^2\, dx = 0$, necessarily $|\psi| = 1$. We also have $0 = \int_{\mathbf{R}^N}|\varphi|^2|\psi|^2\, dx = \int_{\mathbf{R}^N}|\varphi|^2\, dx$, and hence $\varphi = 0$ on $\mathbf{R}^N$. ∎

5. The one-dimensional case. Since most of the proofs in the preceding section are not valid in space dimension $N = 1$ (in particular, we do not have identities analogous to (4.4) and (4.23)), we treat separately the one-dimensional case. It turns out that some integrations can be performed explicitly and some of the results are stronger than in higher dimensions.

Let $G : [0, \infty) \longrightarrow \mathbf{R}$ be a function satisfying the following assumption:

- **(A)** $G \in C([0,\infty))$ and there exists $r_0 > 0$ such that $G(r_0^2) = 0$. Moreover, $G \in C^1([r_0^2 - \eta, r_0^2 + \eta])$ for some $\eta > 0$ and $G'(r_0^2) = -L < 0$.

We consider the Schrödinger equation

$$i\frac{\partial\Psi}{\partial t} + \Psi_{xx} + G(|\Psi|^2)\Psi = 0 \qquad \text{in } \mathbf{R}, \tag{5.1}$$

together with the "boundary condition" $|\Psi| \longrightarrow r_0$ as $x \longrightarrow \pm\infty$. We have seen in the introduction that the sound velocity at infinity associated to (5.1) and to the considered boundary condition is $v_s = r_0\sqrt{2L}$. As usually, a traveling wave moving with velocity c is a solution of the form $\Psi(x,t) = \psi(x - ct)$. It must satisfy

$$-ic\psi' + \psi'' + G(|\psi|^2)\psi = 0 \qquad \text{in } \mathbf{R}, \qquad |\psi(x)| \longrightarrow r_0 \qquad \text{as } x \longrightarrow \pm\infty. \tag{5.2}$$

We have the following result concerning supersonic and sonic traveling waves.

THEOREM 5.1. *Let $\psi \in L^1_{loc}(\mathbf{R})$ be a solution of (5.2) in $\mathcal{D}'(\mathbf{R})$ such that $G(|\psi|^2)\psi \in L^1_{loc}(\mathbf{R})$. Assume that G satisfies* (A) *and either*

(i) $c^2 > v_s^2$, *or*

(ii) $c^2 = v_s^2$ *and, denoting* $V(s) = \int_s^{r_0^2} G(\tau)\,d\tau$ *and* $W(s) = v_s^2 s^2 - 4(s + r_0^2)V(s + r_0^2)$, *there exists* $\varepsilon > 0$ *such that one of the following conditions is verified:*

(a) $W(s) > 0$ *on* $(-\varepsilon, 0) \cup (0, \varepsilon)$;

(b) $W(s) > 0$ *on* $(-\varepsilon, 0)$ *and* $W(s) < 0$ *on* $(0, \infty)$;

(c) $W(s) > 0$ *on* $(0, \varepsilon)$ *and* $W(s) < 0$ *on* $[-r_0^2, 0)$.

Then either ψ *is constant or* $\psi(x) = r_0 e^{i(cx+\theta_0)}$, *where* θ_0 *is a real constant.*

Remark. Theorem 5.1 gives *all* supersonic and sonic traveling waves for (5.1), no matter whether their energy is finite or not (and we see that finite-energy traveling waves must be constant).

It is easy to see that W is C^2 near 0 and $W(0) = W'(0) = W''(0) = 0$. Condition (ii)(a) is satisfied, for instance, if G is C^3 near r_0^2 (this clearly implies that W is C^4 near 0) and $W'''(0) = 0$, $W^{(iv)}(0) > 0$, or equivalently $r_0^2 G''(r_0^2) = 3L$ and $4G''(r_0^2) + r_0^2 G'''(r_0^2) > 0$. The condition $W(s) > 0$ on $(-\varepsilon, 0)$ in (ii)(b), respectively, $W(s) > 0$ on $(0, \varepsilon)$ in (ii)(c), is satisfied if G is C^3 near r_0^2 and $W'''(0) < 0$ (respectively, $W'''(0) > 0$); however, in these cases only the information on the behavior of G in a neighborhood of r_0^2 is not sufficient to get the conclusion of Theorem 5.1.

Proof of Theorem 5.1. Let $\varphi(x) = e^{-\frac{icx}{2}}\psi(x)$. Then $\varphi \in L^1_{loc}(\mathbf{R})$ and it is easy to see that

$$\varphi'' + \Big(G(|\varphi|^2) + \frac{c^2}{4}\Big)\varphi = 0 \qquad \text{in } \mathcal{D}'(\mathbf{R}). \tag{5.3}$$

From (5.3) we get $\varphi'' \in L^1_{loc}(\mathbf{R})$. This implies that φ' is a continuous function on $\mathbf{R}$ (see, e.g., Lemma VIII.2, p. 123, in [8]). Thus $\varphi \in C^1(\mathbf{R})$. Since $|\varphi| \longrightarrow r_0$ as $x \longrightarrow \pm\infty$, we infer that φ is bounded on $\mathbf{R}$. Coming back to (5.3) we see that φ'' is continuous and bounded on $\mathbf{R}$. In particular $\varphi \in C^2(\mathbf{R})$, and this implies $\psi \in C^2(\mathbf{R})$.

Denoting $\psi_1 = \mathrm{Re}(\psi)$, $\psi_2 = \mathrm{Im}(\psi)$, equation (5.2) is equivalent to the system

$$c\psi_2' + \psi_1'' + G(|\psi|^2)\psi_1 = 0, \tag{5.4}$$

$$-c\psi_1' + \psi_2'' + G(|\psi|^2)\psi_2 = 0 \qquad \text{in } \mathbf{R}. \tag{5.5}$$

We multiply (5.4) by $2\psi_1'$ and (5.5) by $2\psi_2'$, then add the resulting equalities to get $[(\psi_1')^2 + (\psi_2')^2]' - (V(|\psi|^2))' = 0$. Hence there exists $k_1 \in \mathbf{R}$ such that

$$|\psi'|^2(x) - V(|\psi|^2)(x) = k_1 \qquad \text{for any } x \in \mathbf{R}. \tag{5.6}$$

Multiplying (5.4) by ψ_2 and (5.5) by $-\psi_1$, then summing up the corresponding equations we obtain $\frac{c}{2}(|\psi|^2 - r_0^2)' - (\psi_1\psi_2' - \psi_2\psi_1')' = 0$. Consequently there is some $k_2 \in \mathbf{R}$ such that

$$\frac{c}{2}(|\psi|^2 - r_0^2) - (\psi_1\psi_2' - \psi_2\psi_1') = k_2 \qquad \text{in } \mathbf{R}. \tag{5.7}$$

Next we multiply (5.4) by $2\psi_1$ and (5.5) by $2\psi_2$, then add the resulting equalities to find

$$2c(\psi_1\psi_2' - \psi_2\psi_1') + (|\psi|^2 - r_0^2)'' - 2|\psi'|^2 + 2G(|\psi|^2)|\psi|^2 = 0. \tag{5.8}$$

Taking into account (5.6) and (5.7), equation (5.8) can be written as

$$(|\psi|^2 - r_0^2)'' + c^2(|\psi|^2 - r_0^2) - 2V(|\psi|^2) + 2G(|\psi|^2)|\psi|^2 = 2k_1 + 2ck_2. \tag{5.9}$$

Denote $v(x) = |\psi|^2(x) - r_0^2$. Then v is real-valued, C^2, and tends to zero as $x \longrightarrow \pm\infty$, and hence there exists a sequence $x_n \longrightarrow \infty$ such that $v''(x_n) \longrightarrow 0$. Writing (5.9) for x_n, then passing to the limit as $n \longrightarrow \infty$ we see that necessarily $k_1 + ck_2 = 0$ and v satisfies the equation

$$v'' + c^2 v - 2V(v + r_0^2) + 2(v + r_0^2)G(v + r_0^2) = 0 \qquad \text{in } \mathbf{R}. \tag{5.10}$$

Next we multiply (5.10) by $2v'$, then integrate the resulting equation and obtain $(v')^2 + c^2v^2 - 4(v + r_0^2)V(v + r_0^2) = k_3$ in $\mathbf{R}$, where k_3 is a constant. It is clear that there exists a sequence $y_n \longrightarrow \infty$ such that $v'(y_n) \longrightarrow 0$; consequently $k_3 = 0$ and we have

$$(v')^2(x) + c^2v^2(x) - 4(v + r_0^2)V(v + r_0^2)(x) = 0 \qquad \text{for any } x \in \mathbf{R}. \tag{5.11}$$

Our aim is to prove that, under the assumptions of Theorem 5.1, we have $v = 0$ on $\mathbf{R}$.

Suppose first that $c^2 > v_s^2 = 2Lr_0^2$. Since G satisfies (A), it follows that $V \in C^2([r_0^2 - \eta, r_0^2 + \eta])$ and we have by Taylor's formula

$$V(r_0^2+s) = V(r_0^2)+sV'(r_0^2)+\frac{1}{2}s^2V''(r_0^2)+s^2h(s) = \frac{1}{2}Ls^2+s^2h(s) \qquad \text{for } s \in [-\eta, \eta],$$

where $h(s) \longrightarrow 0$ as $s \longrightarrow 0$. Take $\varepsilon_1 \in (0, \eta]$ such that $c^2 - v_s^2 - 2Ls - 4(s+r_0^2)h(s) > 0$ for any $s \in [-\varepsilon_1, \varepsilon_1]$. Suppose that $v(x_0) \in [-\varepsilon_1, 0) \cup (0, \varepsilon_1]$ for some $x_0 \in \mathbf{R}$. By (5.11) we obtain

$$0 = (v')^2(x_0) + v^2(x_0)[c^2 - v_s^2 - 2Lv(x_0) - 4(v(x_0) + r_0^2)h(v(x_0))] > 0,$$

a contradiction. Consequently we cannot have $v(x) \in [-\varepsilon_1, 0) \cup (0, \varepsilon_1]$. Since v is continuous and $v(x) \longrightarrow 0$ as $x \longrightarrow \pm\infty$, we infer that necessarily $v(x) = 0$ for any $x \in \mathbf{R}$.

Next assume that $c^2 = v_s^2$. Equation (5.11) can be written as

$$(v')^2(x) + W(v(x)) = 0 \qquad \text{on } \mathbf{R}. \tag{5.12}$$

If assumption (iia) is verified, we cannot have $v(x) \in (-\varepsilon, 0) \cup (0, \varepsilon)$ and we infer, as above, that $v = 0$ on $\mathbf{R}$. In case (iib), we cannot have $v(x) \in (-\varepsilon, 0)$ and we infer that $v(x) \geq 0$ for any $x \in \mathbf{R}$. Since $v(x) \longrightarrow 0$ as $x \longrightarrow \infty$, there is some x_0 such that v achieves a nonnegative maximum at x_0. Then $v'(x_0) = 0$ and from (5.12) we get $W(v(x_0)) = 0$. But $W(s) < 0$ for $s > 0$ by (iib); hence $v(x_0) = 0$ and consequently $v = 0$ on $\mathbf{R}$. Similarly we have $v = 0$ in the case (iic) (note that $v = |\psi|^2 - r_0^2 \geq -r_0^2$ and it suffices to know that $W < 0$ on $[-r_0^2, 0)$).

Thus we always have $v = 0$, that is, $|\psi|^2 = r_0^2$ on $\mathbf{R}$. Consequently there exists a lifting $\theta \in C^2(\mathbf{R}, \mathbf{R})$ such that $\psi(x) = r_0 e^{i\theta(x)}$ for any $x \in \mathbf{R}$. It is clear that $\psi_1\psi_2' - \psi_2\psi_1' = |\psi|^2\theta' = r_0^2\theta'$ (see (3.3)). On the other hand we have $\psi_1\psi_2' - \psi_2\psi_1' = -k_2$ by (5.7), and hence $\theta' = -\frac{k_2}{r_0^2}$ is constant; therefore $\theta(x) = -\frac{k_2}{r_0^2}x + \theta_0$, where θ_0 is a real constant. Since $\psi = r_0 e^{i(-(k_2/r_0^2)x + \theta_0)}$ satisfies (5.2), we find $-c\frac{k_2}{r_0^2} - \left(\frac{k_2}{r_0^2}\right)^2 = 0$, and thus either $\frac{k_2}{r_0^2} = 0$ or $\frac{k_2}{r_0^2} = -c$. Finally we have either $\psi(x) = e^{i\theta_0}$ or $\psi(x) = e^{i(cx+\theta_0)}$ and the proof is complete. □

Example 5.2. In the case of the Gross–Pitaevskii equation we have $G(s) = 1 - s$ and obtain $W(s) = -2s^3$ (see Example 4.4). In the case of the cubic-quintic nonlinearity we have $G(s) = -\alpha_5(s - r_1^2)(s - r_0^2)$, where $\alpha_5 > 0$, $0 < r_1 < r_0$ (see Example 4.5)

and a simple computation gives $W(s) = -2\alpha_5 s^3(\frac{4}{3}r_0^2 - r_1^2 + \frac{1}{3}s)$. Therefore both the Gross–Pitaevskii and the cubic-quintic nonlinearities satisfy assumption (iib) and Theorem 5.1 gives all sonic and supersonic traveling waves for these equations.

Remark. The proof of Theorem 5.1 provides a method to find subsonic traveling waves for (5.1). With the above notation, it follows from (5.11) that on any interval where $v' \neq 0$ we have $v'(x) = \pm\sqrt{4(v + r_0^2)V(v + r_0^2)(x) - c^2v^2(x)}$. In many interesting applications this equation can be integrated, and we obtain explicitly $v = |\psi|^2 - r_0^2$. Then it is not hard to find (up to a constant) the corresponding phase θ.

Remark. Assume that $N = 1$ and let (ψ, φ) be a finite-energy traveling wave for system (4.17)–(4.18). It follows from the proof of Proposition 4.6 that ψ and φ are C^∞ functions and $\psi', \varphi \in W^{k,p}(\mathbf{R})$ for any $k \in \mathbf{N}$ and $p \geq 2$. If $c^2 \geq \frac{2}{\varepsilon^2}$ (recall that $\frac{\sqrt{2}}{\varepsilon}$ is the sound velocity at infinity associated to (3.21)–(3.22)) and if there is a lifting $\psi(x) = v(x)e^{i\alpha(x)}$, $\varphi(x) = u(x)e^{i\beta(x)}$, where v, u, α, β are real-valued functions of class C^2, [26, Proposition 3.1, p. 1545] implies that $v = 1$, α is constant, and $\varphi = 0$ on $\mathbf{R}$.

EULERIAN CALCULUS FOR THE DISPLACEMENT CONVEXITY IN THE WASSERSTEIN DISTANCE*

SARA DANERI† AND GIUSEPPE SAVARÉ‡

Abstract. In this paper we give a new proof of the (strong) displacement convexity of a class of integral functionals defined on a compact Riemannian manifold satisfying a lower Ricci curvature bound. Our approach does not rely on existence and regularity results for optimal transport maps on Riemannian manifolds, but it is based on the Eulerian point of view recently introduced by Otto and Westdickenberg [*SIAM J. Math. Anal.*, 37 (2005), pp. 1227–1255] and on the metric characterization of the gradient flows generated by the functionals in the Wasserstein space.

Key words. gradient flows, displacement convexity, heat and porous medium equation, nonlinear diffusion, optimal transport, Kantorovich-Rubinstein-Wasserstein distance, Riemannian manifolds with a lower Ricci curvature bound

DOI. 10.1137/08071346X

1. Introduction.

In this paper we give a new proof, based on a gradient flow approach and on the Eulerian point of view introduced by [19], of the so-called "displacement convexity" for integral functionals as

$$\mathcal{E}(\mu) := \int_{\mathbb{M}} e(\rho)\,\mathrm{dV} + e'(\infty)\,\mu^{\perp}(\mathbb{M}), \quad \rho = \frac{\mathrm{d}\mu}{\mathrm{dV}}, \tag{1.1}$$

where μ is a Borel probability measure on a compact, connected Riemannian manifold without boundary $(\mathbb{M}, \mathsf{g})$, V is the volume measure on $\mathbb{M}$ induced by the metric tensor g, $\mu^{\perp}$ is the singular part of μ with respect to V, $e : [0, +\infty) \to \mathbb{R}$ is a smooth convex function satisfying the so-called McCann conditions (see (1.7) below), and $e'(\infty) = \lim_{r\to+\infty} \frac{e(r)}{r}$. When e has a superlinear growth, $e'(\infty) = +\infty$ so that μ should be absolutely continuous with respect to V when $\mathcal{E}(\mu)$ is finite.

Displacement convexity for integral functionals. The notion of *displacement convexity* has been introduced by [15] to study the behavior of integral functionals like (1.1) along optimal transportation paths, i.e., geodesics in the space of Borel probability measures $\mathcal{P}(\mathbb{M})$ endowed with the L^2-Kantorovich-Rubinstein-Wasserstein distance.

Recall that (the square of) this distance can be defined by the following optimal transport problem

$$\begin{aligned} W_2^2(\mu^0, \mu^1) := \min \Bigg\{ & \int_{\mathbb{M}\times\mathbb{M}} \mathsf{d}^2(x, y)\,\mathrm{d}\boldsymbol{\sigma}(x, y) : \boldsymbol{\sigma} \in \mathcal{P}(\mathbb{M}\times\mathbb{M}), \\ & \boldsymbol{\sigma}(B\times\mathbb{M}) = \mu^0(B),\ \boldsymbol{\sigma}(\mathbb{M}\times B) = \mu^1(B) \quad \forall\, B \text{ Borel set in } \mathbb{M} \Bigg\} \end{aligned} \tag{1.2}$$

for the cost function induced by the Riemannian distance d on the manifold $\mathbb{M}$. We keep the usual notation to denote by $\mathcal{P}_2(\mathbb{M})$ the metric space $(\mathcal{P}(\mathbb{M}), W_2)$, which is called Wasserstein space; being $\mathbb{M}$ compact, W_2 induces the topology of the weak convergence of probability measures (i.e., the weak* topology associated with the duality of $\mathcal{P}(\mathbb{M})$ with $C^0(\mathbb{M})$).

As in any metric space (minimal, constant speed) *geodesics* can be defined as curves $\mu : s \in [0,1] \mapsto \mu^s \in \mathcal{P}_2(\mathbb{M})$ between μ^0 and μ^1, satisfying

$$W_2(\mu^r, \mu^s) = |s-r|\, W_2\left(\mu^0, \mu^1\right) \quad \forall\ 0 \le r \le s \le 1. \tag{1.3}$$

A functional $\mathcal{E} : \mathcal{P}(\mathbb{M}) \to (-\infty, +\infty]$ is then *(strongly) displacement convex* (or, more generally, *(strongly) displacement λ-convex* for some $\lambda \in \mathbb{R}$) if, *for all* Wasserstein geodesics $\{\mu^s\}_{0\le s\le 1} \subset \mathcal{P}_2(\mathbb{M})$, we have

$$\mathcal{E}(\mu^s) \le (1-s)\mathcal{E}\left(\mu^0\right) + s\mathcal{E}\left(\mu^1\right) - \frac{\lambda}{2} s(1-s) W_2^2\left(\mu^0, \mu^1\right), \quad \forall\, s \in [0,1]. \tag{1.4}$$

A weaker notion is also often considered: one can ask that there exists *at least one* geodesic connecting μ^0 to μ^1 along which (1.4) holds. Figalli and Villani [12] has recently proved that for the class of integral functionals (1.1) considered in the present paper these two notions are equivalent.

The term "displacement convexity" arises from the strictly related concept of "displacement interpolation" introduced by [15] in the Euclidean case $\mathbb{M} = \mathbb{R}^d$; in a general metric setting, property (1.4) is simply called, as in the Riemannian case, "$\lambda-$geodesic convexity" (or "geodesic convexity" if $\lambda = 0$).

It is possible to show [4] that, in the Euclidean case, the measures μ^s can also be defined through the formula

$$\mu^s(B) := \boldsymbol{\sigma}\left(\left\{(x,y) \in \mathbb{R}^d \times \mathbb{R}^d : (1-s)x + sy \in B\right\}\right), \quad \text{where } \boldsymbol{\sigma} \text{ is a minimizer of (1.2).} \tag{1.5}$$

A similar construction can also be performed in a Riemannian manifold [14, 20, 13]: the segments $s \mapsto (1-s)x + sy$ should be substituted by a Borel map $\boldsymbol{\gamma} : \mathbb{M} \times \mathbb{M} \to C^0([0,1]; \mathbb{M})$ that at each couple $(x,y) \in \mathbb{M} \times \mathbb{M}$ associate a (minimal, constant speed) geodesic $s \mapsto \boldsymbol{\gamma}^s(x,y)$ in $\mathbb{M}$ connecting x to y. We have the representation formula

$$\mu^s(B) := \boldsymbol{\sigma}\left(\{(x,y) \in \mathbb{M} \times \mathbb{M} : \boldsymbol{\gamma}^s(x,y) \in B\}\right), \quad \text{where } \boldsymbol{\sigma} \text{ is a minimizer of (1.2).} \tag{1.6}$$

After the pioneering paper [15], the notion of displacement convexity for integral functionals found applications in many different fields, as functional inequalities [18, 2, 9], generation, contraction, and asymptotic properties of diffusion equations and gradient flows [17, 1, 19, 4, 8, 5], Riemannian geometry, and synthetic study of metric-measure spaces [20, 21, 14].

In the context of Riemannian manifolds it turns out that displacement λ-convexity of certain classes of entropy functionals is equivalent to a lower bound for the Ricci curvature of the manifold. The connection between displacement convexity and Ricci curvature, introduced by [18], was then further deeply studied by [9, 10, 20]; the equivalence has been proved by Sturm and Von Renesse in [24], who considered the case in which the domain of the functional consists only of measures that are absolutely continuous with respect to the volume measure, and then completed by Lott and Villani [14] (with the remarks made in [12], where convexity in the strong form has

been proved), who extended the previous results to the functionals defined by (1.1) on all $\mathcal{P}(\mathbb{M})$. We refer to the forthcoming monograph [23] for further references, details, and discussions.

The strategy followed by the authors of [9] (and by all the following contributions) in order to characterize the displacement convexity of entropy functionals relies on a characterization of optimal transportation and Wasserstein geodesics [16] and on a careful study of the Jacobian properties of the exponential function which are crucial to estimate the integral functionals along this class of curves. The lack of regularity of Wasserstein geodesics and the lack of global smoothness of the squared distance function d^2 on the manifold $\mathbb{M}$ (due to the existence of the cut-locus) require a careful use of nonsmooth analysis arguments and nontrivial approximation processes to extend the results to geodesics between arbitrary measures (see [14, 12]).

The main result is the following.

THEOREM 1.1. (I) *If $e \in C^\infty(0,+\infty)$ satisfies the McCann conditions*

(1.7)
$$U(\rho) := \rho e'(\rho) - \big(e(\rho) - e(0_+)\big) \geq 0, \qquad \rho U'(\rho) - \left(1 - \frac{1}{n}\right) U(\rho) \geq 0, \quad n := \dim(\mathbb{M}) > 1$$

and $\mathbb{M}$ has nonnegative *Ricci curvature, then the functional $\mathcal{E}$ defined by* (1.1) *is* (strongly) displacement convex.

(II) *If $\mathcal{E}$ is the relative entropy functional, corresponding to $e(\rho) = \rho \log \rho$ (which satisfies* (1.7) *in any dimension) in* (1.1)*, and there exists $\lambda \in \mathbb{R}$ such that*

$$\mathrm{Ric}_{\mathsf{g}_x}(\xi,\xi) \geq \lambda \langle \xi, \xi \rangle_{\mathsf{g}_x} \quad \forall\, x \in \mathbb{M}, \quad \forall\, \xi \in T_x\mathbb{M}, \tag{1.8}$$

then the functional $\mathcal{E}$ defined by (1.1) *is* (strongly) displacement λ-convex.

Remark 1.2. Besides the logarithmic entropy corresponding to $e(\rho) = \rho \log \rho$ (and $U(\rho) = \rho$), typical examples of functionals that satisfy properties (1.7) are

$$e(\rho) = \frac{1}{m-1}\rho^m, \quad U(\rho) = \rho^m, \quad m \geq 1 - \frac{1}{n}. \tag{1.9}$$

We recall that assumptions (1.7) imply the convexity of the function $\rho \mapsto e(\rho)$ (since the dimension n is greater than 1, they are in fact more restrictive).

Aim of the paper: an Eulerian approach to displacement convexity. In this paper we present an alternative proof of Theorem 1.1, which does not rely on the existence and smoothness of optimal transport maps and geodesics for the Wasserstein distance.

Our strategy can be described in three steps:

1. Following the approach suggested by Otto and Westdickenberg in [19], we work in the subspace $\mathcal{P}_2^{ar}(\mathbb{M})$ of measures with smooth and positive densities, and we use the "Riemannian" formula for the Wasserstein distance, originally introduced in the Euclidean framework by Benamou and Brenier [6]: if $\mu^i = \rho^i \,\mathrm{V} \in \mathcal{P}_2^{ar}(\mathbb{M})$, $i = 0, 1$, then [19, Proposition 4.3]

$$W_2^2\left(\mu^0, \mu^1\right) = \inf_{\mathcal{C}(\mu^0,\mu^1)} \left\{ \int_0^1 \int_M |\nabla \phi^s|^2 \rho^s \,\mathrm{dV}\,\mathrm{d}s \right\} \qquad \forall\, \mu^0, \mu^1 \in \mathcal{P}_2^{ar}(\mathbb{M}) \tag{1.10}$$

where

$$\begin{aligned} \mathcal{C}\left(\mu^0, \mu^1\right) = \Big\{ &(\rho, \phi) : \rho \in C^\infty([0,1] \times \mathbb{M}; \mathbb{R}_+), \quad \phi \in C^\infty([0,1] \times \mathbb{M}) \\ &\partial_s \rho^s + \nabla \cdot (\rho^s \nabla \phi^s) = 0 \ \text{ in } (0,1) \times \mathbb{M}, \quad \mu^i = \rho^i \,\mathrm{V} \Big\}. \end{aligned} \tag{1.11}$$

Even though the Wasserstein space can't be endowed with a smooth Riemannian structure, (1.11) still shows a "Riemannian" characterization of the Wasserstein distance on $\mathcal{P}_2^{ar}(\mathbb{M})$.

2. The second important fact, originally showed by the so-called "Otto calculus" in [17], is that the nonlinear diffusion equation

$$\partial_t \rho_t - \Delta_{\mathbf{g}}\, U(\rho_t) = 0 \quad \text{in } [0,+\infty)\times\mathbb{M}, \qquad \rho_{|_{t=0}} = \rho_0, \tag{1.12}$$

where $U : \mathbb{R}^+ \to \mathbb{R}$ is the function defined in (1.7) and $\Delta_{\mathbf{g}}$ is the Laplace–Beltrami operator on $\mathbb{M}$, is the gradient flow of the functional (1.1) in $\mathcal{P}_2(\mathbb{M})$. Indeed, (1.12) corresponds to the heat equation if U is the logarithmic entropy and to the porous medium equation if U is defined by (1.9).

Starting directly from (1.10) and owing to the fact that the flow generated by (1.12) preserves smooth and positive densities, when $\mathrm{Ric}_{\mathbf{g}}(\mathbb{M}) \geq 0$ we shall show that the measures $\mu_t = \rho_t \mathrm{V} \in \mathcal{P}_2^{ar}(\mathbb{M})$ associated to the solutions of (1.12) also solve the Evolution Variational Inequality (E.V.I.)

$$\frac{1}{2}\frac{\mathrm{d}^+}{\mathrm{d}t} W_2^2(\nu,\mu_t) \leq \mathcal{E}(\nu) - \mathcal{E}(\mu_t) \quad \forall\, t \geq 0,\ \nu \in \mathcal{P}_2^{ar}(\mathbb{M}), \tag{1.13}$$

which has been introduced in [4] as a purely metric characterization of the gradient flows of geodesically convex functionals in metric spaces (and, in particular, in $\mathcal{P}_2(\mathbb{R}^d)$); here

$$\frac{\mathrm{d}^+}{\mathrm{d}t}\zeta(t) = \limsup_{h\downarrow 0} \frac{\zeta(t+h)-\zeta(t)}{h} \tag{1.14}$$

for every real function $\zeta : [0,+\infty) \to \mathbb{R}$.

When $\mathrm{Ric}\,(\mathbb{M}) \geq \lambda$ (a shorthand for (1.8)), we also show that the solutions of the heat equation satisfy the modified inequality

$$\frac{1}{2}\frac{\mathrm{d}^+}{\mathrm{d}t} W_2^2(\nu,\mu_t) + \frac{\lambda}{2} W_2^2(\nu,\mu_t) \leq \mathcal{E}(\nu) - \mathcal{E}(\mu_t) \quad \forall\, t \geq 0,\ \nu \in \mathcal{P}_2^{ar}(\mathbb{M}), \tag{1.15}$$

where $\mathcal{E}$ is the relative entropy functional whose integrand function is $e(\rho) = \rho\log\rho$. Note that (1.15) reduces to (1.13) when $\lambda = 0$. In order to prove (1.13) and (1.15), we propose an "Eulerian" strategy which could be adapted to more general situations.

3. The third crucial fact is the following: whenever a functional $\mathcal{E}$ satisfies (1.13) (or, more generally, (1.15)) for a given semigroup $\mathcal{S}_t : \mu_0 = \rho_0\mathrm{V} \mapsto \mu_t = \rho_t\mathrm{V}$ in $\mathcal{P}_2^{ar}(\mathbb{M})$, $\mathcal{E}$ is displacement convex (resp., displacement λ-convex). Thus, the question of the behavior of $\mathcal{E}$ along geodesics can be reduced to a differential estimate of $\mathcal{E}$ along the smooth and positive solutions of its gradient flow.

Plan of the paper. In section 2 we present the main ideas of our approach in the simplified (finite-dimensional and smooth) setting of geodesically convex functions on Riemannian manifolds. We think that these ideas are sufficiently general to be useful in other circumstances, at least for distances which admits a Riemannian characterization as (1.10), see, e.g., [11, 7].

After a brief review of the definition of (gradient) λ-flows in arbitrary metric spaces (basically following the ideas of [4]), we present in section 3 our first result, showing that the existence of a flow satisfying the E.V.I. (1.15) (even on a dense subset of initial data, such as $\mathcal{P}_2^{ar}(\mathbb{M})$) entails the (strong) displacement λ-convexity of the functional $\mathcal{E}$.

Following the strategy explained in the second section, in the last two sections we prove the differential estimates showing that (1.12) satisfies (1.13) (in section 4) or, in the case of the Heat equation, (1.15) (in section 5).

2. Gradient flows and geodesic convexity in a smooth setting.

Contraction semigroups and action integrals. In order to explain the main point of our strategy, let us first consider the simple setting of a smooth function $F : \mathrm{X} \to \mathbb{R}$ on a complete Riemannian manifold X with metric $\langle \cdot, \cdot \rangle_g$, (squared) norm $|\xi|_g^2 = \langle \xi, \xi \rangle_g$, and the endowed Riemannian distance

$$d^2(u,v) := \min \left\{ \int_0^1 \left|\dot\gamma^s\right|_g^2 \,\mathrm{d}s, \quad \gamma : [0,1] \to \mathrm{X},\ \gamma^0 = v,\ \gamma^1 = u \right\}. \tag{2.1}$$

In a smooth setting, the geodesic λ-convexity of F can be expressed through the differential condition

$$\frac{\mathrm{d}^2}{\mathrm{d}s^2} F(\gamma^s) \geq \lambda \left|\dot\gamma^s\right|_g^2 \tag{2.2}$$

along any geodesic curve γ minimizing (2.1). As we discussed in the introduction, the direct computation of (2.2) could be difficult in a nonsmooth, infinite dimensional setting; it is therefore important to find equivalent conditions which avoid twofold differentiation along geodesics. One possibility, suggested in [19], is to find equivalent conditions to geodesic λ-convexity in terms of the gradient flow generated by F.

Let us recall that the gradient flow of F is a continuous semigroup of (time-dependent) maps $\mathsf{S}_t : \mathrm{X} \to \mathrm{X}$, $t \in [0, +\infty)$, which at every initial datum u associate the curve $u_t := \mathsf{S}_t(u)$ solution of the differential equation

$$\dot u_t = -\nabla F(u_t) \quad \forall\, t \geq 0, \quad u_0 = u. \tag{2.3}$$

It is well known that, when F is geodesically λ-convex, S_t is λ-contracting; i.e.,

$$d^2(\mathsf{S}_t(u), \mathsf{S}_t(v)) \leq e^{-2\lambda t} d^2(u,v), \quad \forall\, t \geq 0, \qquad \forall\, u, v \in \mathrm{X}. \tag{2.4}$$

By the semigroup property, (2.4) is also equivalent to the differential inequality (see (1.14))

$$\frac{\mathrm{d}^+}{\mathrm{d}t} d^2(\mathsf{S}_t(u), \mathsf{S}_t(v))\Big|_{t=0} \leq -2\lambda\, d^2(u,v) \quad \forall\, u, v \in \mathrm{X}. \tag{2.5}$$

Otto and Westdickenberg [19] revert this argument and observe that it could be easier to directly prove (2.5) by a differential estimate involving only the action of the semigroup along smooth curves; as a byproduct, one should obtain the convexity of F. To this aim, they consider a smooth curve γ^s, $s \in [0,1]$, connecting v to u, and the action integral $\mathcal{A}_t$ associated with its smooth perturbation

$$\gamma_t^s := \mathsf{S}_t(\gamma^s), \quad A_t^s := \left|\partial_s \gamma_t^s\right|_g^2, \quad \mathcal{A}_t := \int_0^1 A_t^s \,\mathrm{d}s, \tag{2.6}$$

where $\partial_s \gamma$ denotes the tangent vector in $T_\gamma \mathrm{X}$ obtained by differentiating w.r.t. s. Since, by the very definition of d,

$$d^2(\mathsf{S}_t(v), \mathsf{S}_t(u)) \leq \mathcal{A}_t \tag{2.7}$$

and for every $\varepsilon > 0$ one can always find a curve γ^s so that $\mathcal{A}_0 \le d^2(u,v) + \varepsilon$ (in a smooth setting one can take $\varepsilon = 0$), (2.5) surely holds if one can prove that

$$\frac{\mathrm{d}^+}{\mathrm{d}t}\mathcal{A}_t\Big|_{t=0} \le -2\lambda\,\mathcal{A}_0, \quad \text{or its pointwise version} \quad \frac{\partial^+}{\partial t}\Big|_{t=0} A_t^s \le -2\lambda\, A_0^s. \tag{2.8}$$

Having obtained the contraction property from (2.8), it still remains open how to deduce that F is geodesically convex. Notice that along an arbitrary curve η^s

$$\frac{\partial}{\partial s}F(\eta^s) = \langle \nabla F(\eta^s), \partial_s \eta^s\rangle_g = -\langle \partial_r \mathsf{S}_r(\eta^s)_{|r=0}, \partial_s\eta^s\rangle_g; \tag{2.9}$$

applied to $\eta^s := \gamma_t^s$, (2.9) and the semigroup property $\mathsf{S}_r(\gamma_t^s) = \gamma_{t+r}^s$ yield

$$\frac{\partial}{\partial s}F(\gamma_t^s) = -\langle \partial_t\gamma_t^s, \partial_s\gamma_t^s\rangle_g. \tag{2.10}$$

In a smooth setting we can assume that γ^s is a minimal geodesic; operating a further differentiation with respect to s, we obtain

$$\begin{aligned}
\frac{\partial^2}{\partial s^2}F(\gamma^s) &\overset{(2.10)}{=} -\frac{\partial}{\partial s}\langle \partial_t\gamma_t^s, \partial_s\gamma_t^s\rangle_g\Big|_{t=0} = -\langle D_{\partial_s}\partial_t\gamma_t^s, \partial_s\gamma_t^s\rangle_g\Big|_{t=0} \\
&\quad - \langle \partial_t\gamma_t^s, D_{\partial_s}\partial_s\gamma_t^s\rangle_g\Big|_{t=0} \\
&= -\langle D_{\partial_s}\partial_t\gamma_t^s, \partial_s\gamma_t^s\rangle_g\Big|_{t=0} = -\langle D_{\partial_t}\partial_s\gamma_t^s, \partial_s\gamma_t^s\rangle_g\Big|_{t=0} \\
&= -\frac{1}{2}\frac{\partial}{\partial t}\langle \partial_s\gamma_t^s, \partial_s\gamma_t^s\rangle_g\Big|_{t=0} \\
&\overset{(2.6)}{=} -\frac{1}{2}\frac{\partial}{\partial t}\Big|_{t=0} A_t^s \overset{(2.8)}{\ge} \lambda\,\big|\partial_s\gamma^s\big|_g^2,
\end{aligned} \tag{2.11, 2.12}$$

where we used the standard properties of the covariant differentiations $D_{\partial_s}, D_{\partial_t}$ and, in (2.11), the fact that at $t = 0$ $D_{\partial_s}\partial_s\gamma_t^s = 0$, being $\gamma_t^s = \gamma^s$ a geodesic.

A metric derivation of convexity. Even if the previous differential argument shows that (2.8) implies geodesic λ-convexity, it still requires nice smooth properties on geodesics and covariant differentiation, which could be hard to extend to a nonsmooth setting.

This is not at all surprising, since the contraction property (2.5) and its action-differential characterization (2.8) do not carry all the information linking the semigroup S to F: in order to conclude the argument in (2.11), we had therefore to insert the information coming from (2.9).

To overcome these difficulties, we shall deal with a more precise metric characterization of S than (2.4). As it has been proposed and studied in [4], gradient flows of geodesically λ-convex functionals in "almost" Euclidean settings should satisfy a purely metric formulation in terms of the E.V.I.

$$\frac{1}{2}\frac{\mathrm{d}^+}{\mathrm{d}t}d^2(\mathsf{S}_t(u), v) + \frac{\lambda}{2}d^2(\mathsf{S}_t(u), v) + F(\mathsf{S}_t(u)) \le F(v), \quad \forall\, v \in \mathrm{X},\ t > 0. \tag{2.13}$$

It can be proved (see [5]) that (2.13) characterizes S and implies the contractivity property (2.4).

As we discussed before, here we invert the usual procedure (starting from a convex functional, construct its gradient flow) and we suppose that there exists a smooth flow

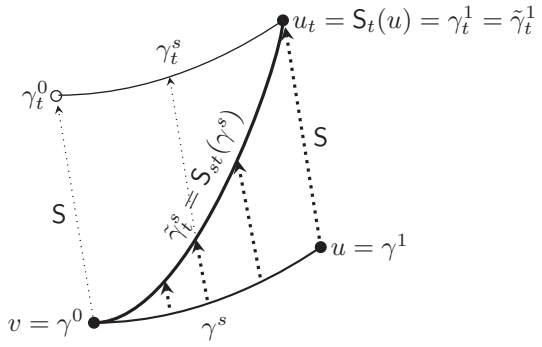

FIG. 1. *Variation of the curve γ^s under the action of the semigroup S.*

S_t satisfying (2.13). The following result, whose proof will be postponed (in a more general form) to Theorem 3.2 in the next section, shows that F is geodesically λ-convex.

THEOREM 2.1. *Suppose that there exists a continuous semigroup of maps $\mathsf{S}_t \in C^0(\mathrm{X};\mathrm{X})$, $t \ge 0$, satisfying* (2.13). *Then for every (minimal, constant speed) geodesic $\gamma : [0,1] \to \mathrm{X}$*

$$F(\gamma^s) \le (1-s)F\left(\gamma^0\right) + sF\left(\gamma^1\right) - \frac{\lambda}{2}s(1-s)d^2\left(\gamma^0,\gamma^1\right), \quad \forall\, s \in [0,1]; \tag{2.14}$$

i.e., F is (strongly) geodesically λ-convex.

E.V.I. through action-differential estimates. Thanks to Theorem 2.1, it is possible to prove the geodesic λ-convexity of F by exhibiting a flow S satisfying the E.V.I. (2.13). According to the general strategy suggested by [19], we want to reduce (2.13) to a suitable family of differential inequalities satisfied by the action A_t^s of (2.6).

The idea here is to consider a different family of perturbations of a given smooth curve $\gamma : [0,1] \to \mathrm{X}$, still induced by the semigroup S. In fact, differently from the contraction estimate (2.5) where we are flowing both the points u, v through S_t, in (2.13) we want to keep the point $v := \gamma^0$ fixed and to vary only $u := \gamma^1$. If γ^s is a smooth curve connecting them, it is then natural to consider the new families (see Figure 1)

$$\tilde\gamma_t^s := \mathsf{S}_{st}(\gamma^s) = \gamma_{st}^s, \quad \tilde F_t^s := F(\tilde\gamma_t^s) \qquad s \in [0,1],\ t \ge 0. \tag{2.15}$$

Notice that $\tilde\gamma_0^s = \gamma^s$, $\tilde\gamma_t^0 = \gamma^0 = v$, and $\tilde\gamma_t^1 = \mathsf{S}_t(\gamma^1) = \mathsf{S}_t(u)$. As before, we introduce the quantities

$$\tilde A_t^s := \left|\partial_s \tilde\gamma_t^s\right|_g^2, \quad \tilde{\mathcal{A}}_t := \int_0^1 \tilde A_t^s \,\mathrm{d}s. \tag{2.16}$$

THEOREM 2.2 (A differential inequality linking action and flow). *Suppose that for every smooth curve $\gamma : [0,1] \to \mathrm{X}$, the quantities $\tilde A_t^s, \tilde F_t^s$ induced by the flow S through* (2.15),(2.16) *satisfy*

$$\frac{1}{2}\frac{\partial}{\partial t}\tilde A_t^s + \frac{\partial}{\partial s}\tilde F_t^s \le -\lambda\, s\, \tilde A_t^s, \quad \forall\, t \ge 0. \tag{2.17}$$

Then S satisfies (2.13), *it is the gradient flow of F, and F is geodesically λ-convex. Moreover, it is sufficient to check* (2.17) *at $t = 0$.*

Proof. Let us first observe that (2.17) yields, after an integration with respect to s in $[0,1]$,

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\tilde{\mathcal{A}}_t + \tilde{F}_t^1 - \tilde{F}_t^0 \le -\lambda \int_0^1 s\tilde{A}_t^s \,\mathrm{d}s. \tag{2.18}$$

By the semigroup property, it is sufficient to prove (2.13) at $t = 0$. We choose a geodesic γ^s connecting v to u, and we consider the curves given by (2.15). Since

$$d^2(\mathsf{S}_t(u), v) \le \int_0^1 \tilde{A}_t^s \,\mathrm{d}s = \tilde{\mathcal{A}}_t, \tag{2.19}$$

$$d^2(v,u) = \int_0^1 \tilde{A}_0^s \,\mathrm{d}s = \tilde{\mathcal{A}}_0, \quad \tilde{F}_t^1 = F(\mathsf{S}_t(u)), \quad \tilde{F}_t^0 = F(v),$$

by (2.18) at $t = 0$ we obtain

$$\frac{1}{2}\frac{\mathrm{d}^+}{\mathrm{d}t} d^2(\mathsf{S}_t(u), v)\Big|_{t=0} + F(u) - F(v) \le -\lambda \int_0^1 s\, \tilde{A}_0^s \,\mathrm{d}s = -\frac{\lambda}{2} d^2(u,v), \tag{2.20}$$

where in the last identity we used the fact that γ^s is a geodesic, and therefore $\tilde{A}_0^s = |\partial_s \gamma^s|_g^2$ is constant in $[0,1]$ and takes the value $d^2(\gamma^0, \gamma^1) = d^2(v,u)$.

Since $\tilde{\gamma}^s_{t_0+t} = \mathsf{S}_{st}\tilde{\gamma}^s_{t_0}$ by the semigroup property, if S satisfies (2.17) at the initial time $t = 0$ for an arbitrary smooth curve γ, then it also satisfies (2.17) for $t > 0$. ∎

Our last result provides a simple criterion to check (2.17):

THEOREM 2.3. *Suppose that $\mathsf{S} : [0,+\infty) \times \mathrm{X} \to \mathrm{X}$ is the "differential" gradient flow of F satisfying* (2.9) *for any smooth curve γ^s, let $\gamma_t^s, \tilde{\gamma}_t^s, A_t^s, \tilde{A}_t^s, \tilde{F}_t^s$ be defined as in* (2.6), (2.15), *and* (2.16), *and let us set*

$$\tilde{D}_r^s := \frac{1}{2}\lim_{h\downarrow 0} h^{-1}\Big(\big|\partial_s \gamma^s_{sr+h}\big|_g^2 - \big|\partial_s \gamma^s_{sr}\big|_g^2\Big). \tag{2.21}$$

Then

$$\frac{1}{2}\frac{\partial}{\partial t}\tilde{A}_t^s + \frac{\partial}{\partial s}\tilde{F}_t^s = s\tilde{D}_t^s. \tag{2.22}$$

Furthermore, if (2.8) *holds, then*

$$\tilde{D}_t^s \le -\lambda\, \tilde{A}_t^s, \tag{2.23}$$

and (2.17) *holds, too, so that F is geodesically λ-convex, and S is also its "metric" gradient flow, characterized by the E.V.I.* (2.13).

Proof. Let us set

$$\tilde{\gamma}^s_{t,\tau} := \mathsf{S}_\tau \tilde{\gamma}_t^s = \gamma^s_{st+\tau}, \quad \tilde{A}^s_{t,\tau} := \big|\partial_s \tilde{\gamma}^s_{t,\tau}\big|_g^2, \tag{2.24}$$

so that

$$\tilde{\gamma}^s_{t+h} = \tilde{\gamma}^s_{t,sh}, \quad \partial_s \tilde{\gamma}^s_{t+h} = \partial_s \tilde{\gamma}^s_{t,\tau} + h\partial_\tau \tilde{\gamma}^s_{t,\tau}\Big|_{\tau=sh}, \quad \tilde{D}_t^s = \frac{1}{2}\frac{\partial}{\partial\tau}\tilde{A}^s_{t,\tau}\Big|_{\tau=0}. \tag{2.25}$$

Observe that the identity

$$|x+y|_g^2 = 2\langle x+y, y\rangle_g + |x|_g^2 - |y|_g^2, \qquad \forall\, x, y \in T_\gamma X \tag{2.26}$$

yields

$$\begin{aligned}\tilde A^s_{t+h} &= \big|\partial_s\tilde\gamma^s_{t+h}\big|^2_g \overset{(2.25)}{=} \big|\partial_s\tilde\gamma^s_{t,\tau}+h\partial_\tau\tilde\gamma^s_{t,\tau}\big|^2_g\Big|_{\tau=sh}\\ &\overset{(2.26)}{=} \Big[2h\langle\partial_s\tilde\gamma^s_{t,\tau}+h\partial_\tau\tilde\gamma^s_{t,\tau},\partial_\tau\tilde\gamma^s_{t,\tau}\rangle+\big|\partial_s\tilde\gamma^s_{t,\tau}\big|^2_g-h^2\big|\partial_\tau\tilde\gamma^s_{t,\tau}\big|^2_g\Big]\Big|_{\tau=sh}\\ &= 2h\,\langle\partial_s\tilde\gamma^s_{t+h},\partial_\theta \mathsf{S}_\theta(\tilde\gamma^s_{t+h})\rangle\Big|_{\theta=0}+\tilde A^s_{t,sh}-o(h)\overset{(2.9)}{=}-2h\,\frac{\partial}{\partial s}F(\tilde\gamma^s_{t+h})+\tilde A^s_{t,sh}-o(h).\end{aligned}$$

We thus get

$$\frac{1}{2h}\big(\tilde A^s_{t+h}-\tilde A^s_t\big)+\frac{\partial}{\partial s}F(\tilde\gamma^s_{t+h})=\frac{1}{2h}\big(\tilde A^s_{t,sh}-\tilde A^s_t\big)-o(1), \tag{2.27}$$

so that, passing to the limit as $h\downarrow 0$ we get (2.22). □

Remark 2.4. Notice that the remainder term $o(1)$ in (2.27) is nonnegative, so it can be simply neglected, if one is just interested in the inequality (2.17).

3. Gradient flows and geodesic convexity in a metric setting. In this section we will briefly recall some basic definitions and properties of gradient flows in a metric setting, and we will prove Theorem 2.1 in a slightly more general framework.

Let (X,d) be a metric space (not necessarily complete) and let $F:\mathrm{X}\to(-\infty,+\infty]$ be a lower semicontinuous functional, whose proper domain $D(F):=\big\{w\in\mathrm{X}: F(w)<+\infty\big\}$ is dense in X (otherwise we can always restrict all the next statements to the closure of $D(F)$ in X). We also assume that F is bounded from below, i.e., $F_{\inf}:=\inf_{u\in\mathrm{X}}F(u)>-\infty$.

A C^0-semigroup S in $C^0(\mathrm{X};\mathrm{X})$ is a family S_t, $t\ge0$, of continuous maps in X such that

$$\mathsf{S}_{t+h}(u)=\mathsf{S}_h\big(\mathsf{S}_t(u)\big),\quad \lim_{t\downarrow0}\mathsf{S}_t(u)=\mathsf{S}_0(u)=u\quad\forall\,u\in\mathrm{X},\ t,h\ge0. \tag{3.1}$$

Given a real number $\lambda\in\mathbb{R}$, we say that S is the λ-(gradient) flow of F if it satisfies

$$\mathsf{S}_t(\mathrm{X})\subset D(F)\text{ for every }t>0; \tag{3.2a}$$

$$\text{the map } t\mapsto F(\mathsf{S}_t(u))\text{ is not increasing in }(0,+\infty); \tag{3.2b}$$

$$\frac12\frac{\mathrm{d}^+}{\mathrm{d}t}d^2(\mathsf{S}_t(u),v)+\frac{\lambda}{2}d^2(\mathsf{S}_t(u),v)+F(\mathsf{S}_t(u))\le F(v),\quad\forall\,u\in\mathrm{X},\,v\in D(F),\,t\ge0. \tag{3.2c}$$

Clearly, if S is a λ-flow for F, then it is also a λ'-flow for every $\lambda'\le\lambda$. The next proposition collects some useful properties of λ-flows.

Proposition 3.1 (Integral characterization of flows and contraction). *A C^0-semigroup S satisfies* (3.2a,b,c) *if and only if it satisfies the following integrated form*

$$\frac{e^{\lambda(t_1-t_0)}}{2}d^2(\mathsf{S}_{t_1}(u),v)-\frac12 d^2(\mathsf{S}_{t_0}(u),v)\le \mathsf{E}_\lambda(t_1-t_0)\,(F(v)-F(\mathsf{S}_{t_1}(u)))\quad\forall\,0\le t_0<t_1, \tag{3.3}$$

for every $u\in\mathrm{X}$, $v\in D(F)$, where

$$\mathsf{E}_\lambda(t):=\int_0^t e^{\lambda r}\,\mathrm{d}r=\begin{cases}\frac{e^{\lambda t}-1}{\lambda} & \text{if }\lambda\neq0,\\ t & \text{if }\lambda=0.\end{cases}$$

In particular, S *satisfies the uniform regularization bound*

$$F(\mathsf{S}_t(u)) \le F(v) + \frac{1}{2\,\mathsf{E}_\lambda(t)} d^2(u,v) \quad \forall\, u \in \mathrm{X},\ v \in D(F),\ t > 0, \tag{3.4}$$

the uniform continuity estimate

$$d^2(\mathsf{S}_{t_1}(u), \mathsf{S}_{t_0}(u)) \le 2\mathsf{E}_{-\lambda}(t_1 - t_0)\,(F(\mathsf{S}_{t_0}u) - F_{\inf}) \quad \forall\, u \in D(F),\ 0 \le t_0 \le t_1, \tag{3.5}$$

and the λ*-contraction property, i.e.,*

$$d(\mathsf{S}_t(u), \mathsf{S}_t(v)) \le e^{-\lambda t} d(u,v) \quad \forall\, u, v \in \mathrm{X},\ t \ge 0. \tag{3.6}$$

Proof. Clearly (3.3) yields (3.2a), being $D(F) \neq \emptyset$; (3.2b) and (3.5) follow by taking $v := \mathsf{S}_{t_0}(u)$, and (3.2c) can be proved by dividing both sides of (3.3) by $t_1 - t_0$ and passing to the limit as $t_1 \downarrow t_0$. In order to prove the converse implication, let us first observe that for a continuous real function $\zeta : [0, +\infty) \to \mathbb{R}$

$$\liminf_{h \downarrow 0} \frac{\zeta(t+h) - \zeta(t)}{h} \le 0 \quad \forall\, t > 0 \qquad \Longrightarrow \qquad \zeta \text{ is not increasing.} \tag{3.7}$$

In fact, if $0 \le t_0 < t_0 + \tau$ existed with $\delta := \tau^{-1}\big(\zeta(t_0+\tau) - \zeta(t_0)\big) > 0$, then a minimum point $\bar t \in [t_0, t_0 + \tau)$ of $t \mapsto \zeta(t) - \zeta(t_0) - \delta(t - t_0)$ would satisfy

$$\liminf_{h \downarrow 0} \frac{\zeta(\bar t + h) - \zeta(\bar t)}{h} - \delta \ge 0, \quad \text{which contradicts (3.7).}$$

(3.3) then follows by (3.2c), after a multiplication by $e^{\lambda t}$ and choosing

$$\zeta(t) := \frac{e^{\lambda t}}{2} d^2(\mathsf{S}_t(u), v) + \int_{\bar t}^{t} e^{\lambda r} \big(F(\mathsf{S}_r(u)) - F(v)\big)\,\mathrm{d}r, \quad \bar t > 0,$$

and recalling the monotonicity property (3.2b). A similar argument shows that

$$\frac{1}{2} d^2(\mathsf{S}_{t_1}(u), v) - \frac{1}{2} d^2(\mathsf{S}_{t_0}(u), v) + \frac{\lambda}{2} \int_{t_0}^{t_1} d^2(\mathsf{S}_r(u), v)\,\mathrm{d}r \le (t_1 - t_0)\,(F(v) - F(\mathsf{S}_{t_1}(u)))\,, \tag{3.8}$$

for every $0 \le t_0 < t_1$, $u \in \mathrm{X}$, and $v \in D(F)$. In order to prove the λ-contracting property, we apply (3.8) obtaining

$$\begin{aligned} &d^2(\mathsf{S}_h(u), \mathsf{S}_h(v)) - d^2(u,v) = d^2(\mathsf{S}_h(u), \mathsf{S}_h(v)) - d^2(\mathsf{S}_h(u), v) + d^2(\mathsf{S}_h(u), v) - d^2(u,v) \\ &\le -\lambda \int_0^h \big(d^2(\mathsf{S}_h(u), \mathsf{S}_r(v)) + d^2(\mathsf{S}_r(u), v)\big)\,\mathrm{d}r + 2h\,(F(v) - F(\mathsf{S}_h(v)))\,. \end{aligned}$$

We divide this inequality by h, and we pass to the limit as $h \downarrow 0$; the continuity of S_t, the lower semicontinuity of F, and the semigroup property of S yield

$$\frac{\mathrm{d}^+}{\mathrm{d}t} d^2(\mathsf{S}_t(u), \mathsf{S}_t(v)) \le -2\lambda\, d^2(u,v) \qquad \forall\, u, v \in \mathrm{X},\ t > 0, \tag{3.9}$$

which yields (3.6) thanks to (3.7). ∎

We can now prove the main result of this section: if a functional F admits a λ-flow, then F is geodesically λ-convex.

THEOREM 3.2 (Geodesic convexity via E.V.I.). *Let us suppose that* S *is a* λ*-flow for the functional* F*, according to* (3.2a,b,c)*, and let* $\gamma : [0,1] \to \mathrm{X}$ *be a Lipschitz curve satisfying*

$$d(\gamma^r,\gamma^s) \le L\,|r-s|, \quad L^2 \le d^2\left(\gamma^0,\gamma^1\right) + \varepsilon^2 \quad \forall\, r,s \in [0,1], \tag{3.10}$$

for some constant $\varepsilon \ge 0$*. Then for every* $t > 0$ *and* $s \in [0,1]$

$$F(\mathsf{S}_t(\gamma^s)) \le (1-s)F\left(\gamma^0\right) + sF\left(\gamma^1\right) - \frac{\lambda}{2}s(1-s)d^2\left(\gamma^0,\gamma^1\right) + \frac{\varepsilon^2}{2\mathsf{E}_\lambda(t)}s(1-s). \tag{3.11}$$

In particular, when γ *is a geodesic (i.e.,* γ *satisfies* (3.10) *with* $L = d(\gamma^0,\gamma^1)$*,* $\varepsilon = 0$*), we have*

$$F(\gamma^s) \le (1-s)F\left(\gamma^0\right) + sF\left(\gamma^1\right) - \frac{\lambda}{2}s(1-s)d^2\left(\gamma^0,\gamma^1\right); \tag{3.12}$$

i.e., F is (strongly) geodesically λ*-convex.*

Proof. Let γ be satisfying (3.10) and let us set $\gamma_t^s := \mathsf{S}_t(\gamma^s)$. Choosing $t_0 = 0$, $t_1 = t$, $u := \gamma^s$, and taking a convex combination of (3.3) written for $v := \gamma^0$, and $v := \gamma^1$, we get

$$\begin{aligned}\frac{e^{\lambda t}}{2}\left((1-s)\,d^2(\gamma_t^s,\gamma^0) + s\,d^2(\gamma_t^s,\gamma^1)\right) - \frac{1}{2}\left((1-s)\,d^2(\gamma^s,\gamma^0) + s\,d^2(\gamma^s,\gamma^1)\right)\\ \le \mathsf{E}_\lambda(t)\left((1-s)F(\gamma^0) + sF(\gamma^1) - F(\gamma_t^s)\right).\end{aligned} \tag{3.13}$$

We now observe that the elementary inequality

$$(1-s)a^2 + sb^2 \ge s(1-s)(a+b)^2 \quad \forall\, a,b \in \mathbb{R}, \quad s \in [0,1], \tag{3.14}$$

and the triangular inequality yield

$$\begin{aligned}(1-s)d^2\left(\gamma_t^s,\gamma^0\right) + sd^2\left(\gamma_t^s,\gamma^1\right) &\overset{(3.14)}{\ge} s(1-s)\left(d\left(\gamma_t^s,\gamma^0\right) + d\left(\gamma_t^s,\gamma^1\right)\right)^2\\ &\ge s(1-s)d^2\left(\gamma^0,\gamma^1\right).\end{aligned} \tag{3.15}$$

On the other hand, (3.10) yields

$$(1-s)\,d^2\left(\gamma^s,\gamma^0\right) + s\,d^2\left(\gamma^s,\gamma^1\right) \le L^2 s(1-s). \tag{3.16}$$

Inserting (3.16) and (3.15) in (3.13) we obtain

$$\frac{e^{\lambda t}-1}{2}s(1-s)d^2\left(\gamma^0,\gamma^1\right) - \frac{\varepsilon^2}{2}s(1-s) \le \mathsf{E}_\lambda(t)\left((1-s)F\left(\gamma^0\right) + sF\left(\gamma^1\right) - F(\gamma_t^s)\right). \tag{3.17}$$

Dividing then both sides of (3.17) by $\mathsf{E}_\lambda(t)$ we get (3.11); when $\varepsilon = 0$ we can pass to the limit as $t \downarrow 0$ obtaining (3.12). □

We conclude this section by considering the case when the flow S is defined only on a *dense* subset X_0 of $D(F)$ (which is dense in X). In order to prove the geodesic convexity of F in X by Theorem 3.2 we first have to extend S to the whole space X. This can be achieved by a density argument, if X is complete and the lower semicontinuous functional F satisfies the following approximation property:

$$\forall\, u \in D(F) \quad \exists\, u_n \in \mathrm{X}_0: \qquad \lim_{n\to\infty} d(u_n, u) = 0, \quad \lim_{n\to\infty} F(u_n) = F(u). \tag{3.18}$$

We state the precise extension result in the next theorem.

THEOREM 3.3. *Suppose that the functional F and the subset $\mathrm{X}_0 \subset D(F)$ satisfy* (3.18) *and let S be a λ-flow for F in X_0. If* X *is complete, S can be extended to a unique λ-flow $\bar{\mathsf{S}}$ in* X*, and therefore F is (strongly) geodesically λ-convex in* X.

Proof. Given $u \in \mathrm{X}$ and a sequence $u_n \in \mathrm{X}_0$ converging to u (X_0 is also dense in X), we can define

$$\bar{\mathsf{S}}_t(u) := \lim_{n\to\infty} \mathsf{S}_t(u_n) \quad \forall\, t > 0, \tag{3.19}$$

where it is clear that the limit in (3.19) exists (being X complete and S_t Lipschitz by (3.6)) and does not depend on the particular sequence u_n we used to approximate u. Moreover, $\bar{\mathsf{S}}_t$ is a semigroup and satisfies the estimate (3.5) and the λ-contracting property (3.6); being X_0 dense in X, it is not difficult to combine (3.5), (3.6), and (3.18) to show that $\lim_{t\downarrow 0} \mathsf{S}_t(u) = u$ for every $u \in \mathrm{X}$.

In order to prove that $\bar{\mathsf{S}}$ is still a λ-flow for F in X we have to check (3.3) in X: we fix $v \in D(F)$ and a sequence $v_n \in \mathrm{X}_0$ converging to v with $F(v_n) \to F(v)$, and we pass to the limit as $n \to \infty$ in the inequalities

$$\frac{e^{\lambda(t_1-t_0)}}{2} d^2(\mathsf{S}_{t_1}(u_n), v_n) - \frac{1}{2} d^2(\mathsf{S}_{t_0}(u_n), v_n) \le \mathsf{E}_\lambda(t_1 - t_0)\big(F(v_n) - F(\mathsf{S}_{t_1}(u_n)\big), \tag{3.20}$$

using the lower semicontinuity of F. ∎

4. Nonlinear diffusion equations as gradient flows of entropy functionals in $\mathcal{P}_2(\mathbb{M})$. We apply the strategy described in the section 2 to prove the geodesic convexity of the integral functional (1.1) in the case of a Riemannian manifold of nonnegative Ricci curvature. We therefore exhibit a smooth flow (induced by the nonlinear diffusion equation (1.12) on the dense subset $\mathcal{P}_2^{ar}(\mathbb{M})$) which satisfies the E.V.I. (1.13).

Before stating the main theorem of this section, let us recall a fundamental result on this kind of evolution equations, which can be found in [22, 19]:

THEOREM 4.1 (Classical solutions of nonlinear diffusion equations). *Let $e \in C^\infty(\mathbb{R}^+)$ and U be functions that satisfy the assumptions* (1.7) *of Theorem* 1.1. *For every $\rho_0 \in C^\infty(\mathbb{M})$ with $\rho_0 > 0$, there exists a unique smooth positive solution $\rho \in C^\infty([0,+\infty) \times \mathrm{X})$ to the Cauchy problem*

$$\partial_t \rho_t = \Delta_{\mathsf{g}} U(\rho_t), \qquad \rho_{|_{t=0}} = \lim_{t\downarrow 0} \rho_t = \rho_0. \tag{4.1}$$

Moreover, given a one-parameter family of positive initial data $s \mapsto \rho_0^s \in C^\infty([0,1] \times \mathbb{M})$, the corresponding solutions ρ_t^s of the equation (4.1) *depend smoothly on s, t.*

For every $\mu_0 = \rho_0 \mathrm{V} \in \mathcal{P}_2^{ar}(\mathbb{M})$ we denote by $\mathcal{S}_t(\mu_0) \in \mathcal{P}_2^{ar}(\mathbb{M})$ the measure $\mu_t = \rho_t \mathrm{V}$. The main result that we show in this section is the following.

THEOREM 4.2. *Let $e \in C^\infty(\mathbb{R}^+)$ and U be functions that satisfy the assumptions* (1.7) *of Theorem* 1.1 *and let us suppose that*

$$\mathrm{Ric}_{\mathsf{g}}(x) \ge 0 \quad \forall\, x \in \mathbb{M}. \tag{4.2}$$

The semigroup $\mathcal{S}$ induced by (4.1) *in $\mathcal{P}_2^{ar}(\mathbb{M})$ is a 0-flow in $\mathcal{P}_2^{ar}(\mathbb{M})$ for the functional*

$$\mathcal{E}(\mu) = \int_{\mathbb{M}} e(\rho)\, \mathrm{dV}, \quad \forall\, \mu = \rho \mathrm{V} \in \mathcal{P}_2^{ar}(\mathbb{M}). \tag{4.3}$$

In particular, for every $\mu_0 = \rho_0 \mathrm{V}, \nu \in \mathcal{P}_2^{ar}(\mathbb{M})$*, the measures* $\mu_t = \mathcal{S}_t(\mu_0) = \rho_t \mathrm{V} \in \mathcal{P}_2^{ar}(\mathbb{M})$ *solving* (4.1) *satisfy the E.V.I.*

$$\frac{1}{2}\frac{\mathrm{d}^+}{\mathrm{d}t} W_2^2(\nu, \mu_t) \le \mathcal{E}(\nu) - \mathcal{E}(\mu_t) \quad \forall\, t \in [0, +\infty). \tag{4.4}$$

In order to prove Theorem 4.2, thanks to the "Riemannian-like" characterization of the Wasserstein distance provided by (1.10), we can follow the strategy presented in section 2; in particular we want to prove the differential inequality of Theorem 2.2. Following Otto's formalism [17], we collect in the next table the formal correspondences between the various objects:

X, Riemannian manifold, with distance d	$\mathcal{P}_2^{ar}(\mathbb{M})$ with distance W_2
a smooth curve γ^s in X	a smooth family $\mu^s = \rho^s \mathrm{V} \in \mathcal{P}_2^{ar}(\mathbb{M})$
the tangent vector $\partial_s \gamma^s$ in $T_{\gamma^s}\mathrm{X}$	the vector field $\nabla\phi^s$ where $-\nabla\cdot(\rho^s \nabla\phi^s) = \frac{\partial}{\partial s}\rho^s$
$\lvert\partial_s \gamma^s\rvert_g^2$	$\int_{\mathbb{M}} \lvert\nabla\phi^s(x)\rvert_{\mathsf{g}}^2 \rho^s(x)\,\mathrm{dV}(x)$
$\gamma_t^s := \mathsf{S}_t(\gamma^s)$, $\tilde\gamma_t^s := \gamma_{st}^s = \mathsf{S}_{st}(\gamma^s)$	$\mu_t^s = \rho_t^s \mathrm{V} := \mathcal{S}_t(\mu^s)$, $\tilde\mu_t^s = \tilde\rho_t^s \mathrm{V} := \mu_{st}^s = \mathcal{S}_{st}(\mu^s)$
$\tilde A_t^s = \lvert\partial_s \tilde\gamma_t^s\rvert_g^2$	$\int_{\mathbb{M}} \lvert\nabla\tilde\phi_t^s(x)\rvert_{\mathsf{g}}^2 \tilde\rho_t^s(x)\,\mathrm{dV}(x)$
$F(\gamma^s)$	$\mathcal{E}(\mu^s) = \int_{\mathbb{M}} e(\rho^s)\,\mathrm{dV}$
$(\partial_\theta \mathsf{S}_\theta \gamma^s)_{\lvert\theta=0} = -\nabla F(\gamma^s)$	$-\nabla U(\rho^s)/\rho^s = -\nabla e'(\rho^s)$.

The core of the proof of Theorem 4.2 lies in the following lemma:

LEMMA 4.3. *Let* $\mu^s = \rho^s \mathrm{V}$, $s \in [0,1]$*, be a smooth family of measures in* $\mathcal{P}_2^{ar}(\mathbb{M})$ *and let* $\tilde\mu_t^s = \tilde\rho_t^s \mathrm{V} = \mathcal{S}_{st}(\mu^s)$ *be obtained by flowing* ρ^s *along the flow* (4.1)*; i.e.,* $\tilde\rho_t^s = \rho_{st}^s$ *where* ρ_t^s *satisfies*

$$\frac{\partial}{\partial t}\rho_t^s - \Delta_{\mathsf{g}}\, U(\rho_t^s) = 0 \ \text{in } \mathbb{M}, \quad \forall\, s \in [0,1],\ t > 0; \qquad \rho_{t=0}^s = \rho^s. \tag{4.5}$$

Let $\tilde\phi_t^s \in C^\infty([0,1] \times [0,+\infty) \times \mathbb{M})$ *be the functions defined by the equation*

$$-\nabla\cdot\big(\tilde\rho_t^s \nabla\tilde\phi_t^s\big) = \partial_s \tilde\rho_t^s \quad \text{in } \mathbb{M}, \quad \int_{\mathbb{M}} \tilde\phi_t^s(x)\,\mathrm{dV}(x) = 0 \quad \forall\, s \in [0,1],\ t \in [0,+\infty), \tag{4.6}$$

and let us set

$$\tilde A_t^s := \int_{\mathbb{M}} |\nabla\tilde\phi_t^s(x)|_{\mathsf{g}}^2\, \tilde\rho_t^s(x)\,\mathrm{dV}(x), \tag{4.7}$$

$$\tilde D_t^s := -\int_{\mathbb{M}} \left[\Big(|\mathrm{Hess}\,\tilde\phi_t^s|_{\mathsf{g}}^2 + \mathrm{Ric}_{\mathsf{g}}\Big(\nabla\tilde\phi_t^s, \nabla\tilde\phi_t^s\Big)\Big)\, U\left(\tilde\rho_t^s\right) + \left(\Delta_{\mathsf{g}}\,\tilde\phi_t^s\right)^2 \left(\tilde\rho_t^s U'(\tilde\rho_t^s) - U\left(\tilde\rho_t^s\right)\right) \right] \mathrm{dV}.$$

Then, we have the formula

$$\frac{\partial}{\partial t}\frac{1}{2}\tilde A_t^s + \frac{\partial}{\partial s}\mathcal{E}(\tilde\rho_t^s \mathrm{V}) = s\tilde D_t^s, \quad \forall\, t \in [0,+\infty),\ \forall\, s \in [0,1]. \tag{4.8}$$

In particular, if $\mathbb{M}$ *has nonnegative Ricci curvature, then* $\tilde D_t^s \le 0$ *and therefore*

$$\frac{\partial}{\partial t}\frac{1}{2}\tilde A_t^s + \frac{\partial}{\partial s}\mathcal{E}(\tilde\rho_t^s \mathrm{V}) \le 0. \tag{4.9}$$

Proof. Being $\tilde\rho_t^s := \rho_\tau^\sigma|_{\sigma=s,\tau=st}$ we get

$$\frac{\partial}{\partial s}\tilde\rho_t^s = \left(\frac{\partial}{\partial\sigma}\rho_\tau^\sigma + t\frac{\partial}{\partial\tau}\rho_\tau^\sigma\right)_{\sigma=s,\tau=st}, \qquad \frac{\partial}{\partial t}\tilde\rho_t^s = s\partial_\tau\rho_\tau^s|_{\tau=st} = s\Delta_{\mathsf g}\,U\,(\tilde\rho_t^s), \tag{4.10}$$

$$\frac{\partial^2}{\partial t\,\partial s}\tilde\rho_t^s \overset{(4.6)}{=} -\nabla\cdot\left(\frac{\partial}{\partial t}\tilde\rho_t^s\,\nabla\tilde\phi_t^s\right) - \nabla\cdot\left(\tilde\rho_t^s\,\frac{\partial}{\partial t}\nabla\tilde\phi_t^s\right), \tag{4.11}$$

$$\frac{\partial^2}{\partial s\,\partial t}\tilde\rho_t^s \overset{(4.10)}{=} s\Delta_{\mathsf g}\left(U'\,(\tilde\rho_t^s)\;\frac{\partial}{\partial s}\tilde\rho_t^s\right) + \Delta_{\mathsf g}\,U\,(\tilde\rho_t^s)$$

$$\overset{(4.6)}{=} -s\Delta_{\mathsf g}\left(U'\,(\tilde\rho_t^s)\;\nabla\cdot\left(\tilde\rho_t^s\nabla\tilde\phi_t^s\right)\right) + \Delta_{\mathsf g}\,U\,(\tilde\rho_t^s). \tag{4.12}$$

Differentiation and integration by parts yield

$$\begin{aligned}
&\frac{\partial}{\partial t}\int_{\mathbb M}\frac12|\nabla\tilde\phi_t^s|_{\mathsf g}^2\,\tilde\rho_t^s\,\mathrm{dV} = \int_{\mathbb M}\left\langle\frac{\partial}{\partial t}\nabla\tilde\phi_t^s,\nabla\tilde\phi_t^s\right\rangle_{\mathsf g}\tilde\rho_t^s\,\mathrm{dV} + \frac12\int_{\mathbb M}|\nabla\tilde\phi_t^s|_{\mathsf g}^2\,\frac{\partial}{\partial t}\tilde\rho_t^s\,\mathrm{dV}\\
&= -\int_{\mathbb M}\nabla\cdot\left(\tilde\rho_t^s\frac{\partial}{\partial t}\nabla\tilde\phi_t^s\right)\tilde\phi_t^s\,\mathrm{dV} \overset{(4.10)}{+} \frac12 s\int_{\mathbb M}\Delta_{\mathsf g}\left(|\nabla\tilde\phi_t^s|_{\mathsf g}^2\right)U(\tilde\rho_t^s)\,\mathrm{dV}\\
&\overset{(4.11)}{=}\int_{\mathbb M}\frac{\partial^2}{\partial t\partial s}\tilde\rho_t^s\,\tilde\phi_t^s\,\mathrm{dV} + \int_{\mathbb M}\left(\nabla\cdot\left(\frac{\partial}{\partial t}\tilde\rho_t^s\nabla\tilde\phi_t^s\right)\right)\tilde\phi_t^s\,\mathrm{dV} + \frac12 s\int_{\mathbb M}\Delta_{\mathsf g}\left(|\nabla\tilde\phi_t^s|_{\mathsf g}^2\right)U(\tilde\rho_t^s)\,\mathrm{dV}
\end{aligned} \tag{4.13}$$

$$\begin{aligned}
&\overset{(4.12)}{=}\int_{\mathbb M}\left(\Delta_{\mathsf g}\,U\,(\tilde\rho_t^s) - s\Delta_{\mathsf g}\left(U'(\tilde\rho_t^s)\,\nabla\cdot\left(\tilde\rho_t^s\nabla\tilde\phi_t^s\right)\right)\right)\tilde\phi_t^s\,\mathrm{dV}\\
&\quad - s\int_{\mathbb M}\Delta_{\mathsf g}U(\tilde\rho_t^s)\,|\nabla\tilde\phi_t^s|_{\mathsf g}^2\,\mathrm{dV} + \frac{s}{2}\int_{\mathbb M}\Delta_{\mathsf g}\left(|\nabla\tilde\phi_t^s|_{\mathsf g}^2\right)U(\tilde\rho_t^s)\,\mathrm{dV}\\
&= \int_{\mathbb M}U(\tilde\rho_t^s)\,\Delta_{\mathsf g}\,\tilde\phi_t^s\,\mathrm{dV} - s\int_{\mathbb M}\Big(\left\langle\nabla U(\tilde\rho_t^s),\nabla\tilde\phi_t^s\right\rangle_{\mathsf g}\Delta_{\mathsf g}\,\tilde\phi_t^s + \tilde\rho_t^s\,U'\,(\tilde\rho_t^s)\left(\Delta_{\mathsf g}\,\tilde\phi_t^s\right)^2\Big)\,\mathrm{dV}\\
&\quad - \frac{s}{2}\int_{\mathbb M}\Delta_{\mathsf g}\left(|\nabla\tilde\phi_t^s|_{\mathsf g}^2\right)U(\tilde\rho_t^s)\,\mathrm{dV}\\
&= -\int_{\mathbb M}\left\langle\nabla U\,(\tilde\rho_t^s),\nabla\tilde\phi_t^s\right\rangle_{\mathsf g}\mathrm{dV} + s\int_{\mathbb M}\left[-\frac12\Delta_{\mathsf g}\left(|\nabla\tilde\phi_t^s|_{\mathsf g}^2\right) + \left\langle\nabla\tilde\phi_t^s,\nabla\Delta_{\mathsf g}\,\tilde\phi_t^s\right\rangle_{\mathsf g}\right]U\,(\tilde\rho_t^s)\,\mathrm{dV}
\end{aligned} \tag{4.14}$$

$$+\;s\int_{\mathbb M}\left(\Delta_{\mathsf g}\,\tilde\phi_t^s\right)^2\left(U\,(\tilde\rho_t^s) - \tilde\rho_t^s U'(\tilde\rho_t^s)\right)\mathrm{dV}$$

Applying Bochner formula:

$$\langle\nabla\phi,\nabla\Delta_{\mathsf g}\,\phi\rangle_{\mathsf g} - \frac12\Delta_{\mathsf g}\left(|\nabla\phi|_{\mathsf g}^2\right) = -|\mathrm{Hess}\,\phi|_{\mathsf g}^2 - \mathrm{Ric}_{\mathsf g}(\nabla\phi,\nabla\phi), \tag{4.15}$$

we get

$$\frac{\partial}{\partial t}\frac12\int_{\mathbb M}|\nabla\tilde\phi_t^s|_{\mathsf g}^2\,\tilde\rho_t^s\,\mathrm{dV} + \int_{\mathbb M}\left\langle\nabla U(\tilde\rho_t^s),\nabla\tilde\phi_t^s\right\rangle_{\mathsf g}\mathrm{dV} = s\tilde D_t^s. \tag{4.16}$$

Now we observe that the second term in the right-hand side of (4.16) is the derivative of the functional (4.3) along the curve $s\mapsto\tilde\rho_t^sV\in\mathcal P_2^{ar}(\mathbb M)$:

$$\frac{\partial}{\partial s}\mathcal E(\tilde\mu_t^s) = \int_{\mathbb M}e'(\tilde\rho_t^s)\,\frac{\partial}{\partial s}\tilde\rho_t^s\,\mathrm{dV} = -\int_{\mathbb M}e'(\tilde\rho_t^s)\nabla\cdot\left(\tilde\rho_t^s\nabla\tilde\phi_t^s\right)\mathrm{dV} = \int_{\mathbb M}\nabla U\,(\tilde\rho_t^s)\cdot\nabla\tilde\phi_t^s\,\mathrm{dV}, \tag{4.17}$$

and we eventually obtain (4.8).

Finally, when $\mathrm{Ric}_{\mathsf{g}}(\mathbb{M}) \geq 0$, using the inequality $(\Delta_{\mathsf{g}}\,\phi)^2 \leq n|\mathrm{Hess}\,\phi|^2_{\mathsf{g}}$ and (1.7) we easily get $\tilde{D}^s_t \leq 0$ and (4.9). ∎

Proof of Theorem 4.2. We argue as in the proof of Theorem 2.2: we fix $\varepsilon > 0$ and we choose a smooth curve $(\rho, \phi) \in \mathcal{C}(\nu, \mu)$ such that

$$\int_0^1 \tilde{A}^s_0 \,\mathrm{d}s = \int_0^1 \int_{\mathbb{M}} |\nabla \phi^s|^2_{\mathsf{g}}\, \rho^s \,\mathrm{dV}\mathrm{d}s \leq W_2^2(\nu,\mu) + \varepsilon. \tag{4.18}$$

Let $(\tilde{\rho}, \tilde{\phi})$ be a smooth variation defined as in Lemma 4.3; since $\tilde{\rho}^0_t \mathrm{V} = \rho^0 \mathrm{V} = \nu$ and $\tilde{\rho}^1_t \mathrm{V} = \mu_t$, for every $t > 0$ we have $(\tilde{\rho}^s_t, \tilde{\phi}^s_t) \in \mathcal{C}(\nu, \mu_t)$, and therefore

$$W_2^2(\nu,\mu_t) \leq \int_0^1 \int_{\mathbb{M}} |\nabla \tilde{\phi}^s_t|^2_{\mathsf{g}}\, \tilde{\rho}^s_t \,\mathrm{dV}\,\mathrm{d}s = \int_0^1 \tilde{A}^s_t \,\mathrm{d}s. \tag{4.19}$$

Integrating (4.9) for $s \in [0,1]$ and $t \in [0,\tau]$ and recalling that $t \mapsto \mathcal{E}(\mu_t)$ is not increasing, we get

$$\frac{1}{2}\int_0^1 \tilde{A}^s_\tau \,\mathrm{d}s - \frac{1}{2}\int_0^1 \tilde{A}^s_0 \,\mathrm{d}s \leq \tau\left(\mathcal{E}(\nu) - \mathcal{E}(\mu_\tau)\right). \tag{4.20}$$

Combining (4.20) with (4.19) and (4.18) we get

$$\frac{1}{2}W_2^2(\nu,\mu_\tau) - \frac{1}{2}W_2^2(\nu,\mu) \leq \tau\left(\mathcal{E}(\nu) - \mathcal{E}(\mu_\tau)\right) + \varepsilon, \tag{4.21}$$

and, as ε is arbitrary,

$$\frac{1}{2}W_2^2(\nu,\mu_\tau) - \frac{1}{2}W_2^2(\nu,\mu) \leq \tau\left(\mathcal{E}(\nu) - \mathcal{E}(\mu_\tau)\right). \tag{4.22}$$

Since the semigroup associated with (4.1) is translation invariant, (4.22) is the integral formulation (3.3) of (4.4). ∎

Remark 4.4. Taking into account Theorem 2.3, (4.8) perfectly fits with the calculation performed by [19, Lemma 4.4], which provides the same expression for $\tilde{D}^s_t$. Applying now Theorem 3.3, with the choices $\mathrm{X} := \mathcal{P}_2(\mathbb{M})$, $\mathrm{X}_0 := \mathcal{P}_2^{ar}(\mathbb{M})$, and $F := \mathcal{E}$ (which satisfies the approximation condition (3.18); see [3]), we can prove the first part of Theorem 1.1.

Corollary 4.5. *Let $\mathcal{E} : \mathcal{P}_2(\mathbb{M}) \to (-\infty, +\infty]$ be the functional defined in* (1.1). *If $\mathcal{E}$ satisfies McCann conditions* (1.7) *and $Ric_{\mathsf{g}}(\mathbb{M}) \geq 0$, then $\mathcal{E}$ is (strongly) displacement convex along* every *geodesic $\mu : s \in [0,1] \mapsto \mu^s \in \mathcal{P}_2(\mathbb{M})$, i.e.,*

$$\mathcal{E}(\mu^s) \leq (1-s)\mathcal{E}(\mu^0) + s\mathcal{E}(\mu^1) \quad \forall\, s \in [0,1]. \tag{4.23}$$

5. The heat equation and the displacement λ-convexity of the logarithmic entropy. In this last section we prove the second part of Theorem 1.1: we thus assume that the Riemannian manifold $\mathbb{M}$ satisfies the lower Ricci curvature bound

$$\mathrm{Ric}_{\mathsf{g}}(\mathbb{M}) \geq \lambda \quad \text{i.e.,} \quad \mathrm{Ric}_{\mathsf{g}_x}(\xi,\xi) \geq \lambda\,|\xi|^2_{\mathsf{g}} \quad \forall\, \xi \in T_x\,\mathbb{M}, \tag{5.1}$$

and we consider the logarithmic entropy functional

$$\mathcal{E}(\mu) = \int_{\mathbb{M}} \rho \log \rho \,\mathrm{dV}, \quad \rho = \frac{d\mu}{\mathrm{dV}}, \tag{5.2}$$

corresponding to $e(\rho) := \rho\log\rho$. Since $U(\rho) = \rho$, the Wasserstein gradient flow associated to $\mathcal{E}$ is the Heat equation

$$\frac{\partial}{\partial t}\rho_t - \Delta_{\mathbf{g}}\,\rho_t = 0 \quad \text{in } \mathbb{M}, \qquad \rho_{|_{t=0}} = \rho_0. \tag{5.3}$$

The main result of this section is the following.

THEOREM 5.1. *The semigroup $\mathcal{S}_t : \mu_0 = \rho_0\mathrm{V} \mapsto \mu_t = \rho_t\mathrm{V}$, generated by the solution of the Heat equation* (5.3)*, is a λ-flow in $\mathcal{P}_2^{ar}(\mathbb{M})$ for the logarithmic entropy functional; i.e., μ_t satisfies the inequality*

$$\frac{1}{2}\frac{\mathrm{d}^+}{\mathrm{d}t}W_2^2(\nu,\mu_t) + \frac{\lambda}{2}W_2^2(\nu,\mu_t) \le \mathcal{E}(\nu) - \mathcal{E}(\mu_t) \quad \forall\, t\in[0,+\infty),\ \nu\in\mathcal{P}_2^{ar}(\mathbb{M}). \tag{5.4}$$

In particular, the logarithmic entropy functional (5.2) *is (strongly) displacement λ-convex; i.e., for every geodesic $\mu^s : [0,1] \to \mathcal{P}_2(\mathbb{M})$ between μ^0 and μ^1, we have*

$$\mathcal{E}(\mu^s) \le (1-s)\mathcal{E}(\mu^0) + s\mathcal{E}(\mu^1) - \frac{\lambda}{2}s(1-s)W_2^2(\mu^0,\mu^1), \quad \forall\, s\in[0,1]. \tag{5.5}$$

Proof. By Theorem 3.3, if $\mathcal{S}$ is a λ-flow for the functional (5.2) in $\mathcal{P}_2^{ar}(\mathbb{M})$, then $\mathcal{E}$ is (strongly) displacement λ-convex. In order to prove that $\mathcal{S}$ is a λ-flow, since (3.2a,b) are immediate, we check that $\mathcal{S}$ satisfies the E.V.I. (3.2c), and we argue as in the proof of Theorem 4.2 and Theorem 2.2. We thus fix $\varepsilon > 0$, and we choose a smooth curve $(\rho,\phi) \in \mathcal{C}(\nu,\mu)$

$$\int_0^1 \tilde{A}_0^s\,\mathrm{d}s = \int_0^1\int_{\mathbb{M}} |\nabla\phi^s|_{\mathbf{g}}^2\,\rho^s\,\mathrm{dV}\mathrm{d}s \le W_2^2(\nu,\mu) + \varepsilon^2. \tag{5.6}$$

By a standard reparametrization technique (see next Lemma 5.1), we can also assume that

$$W_2(\mu^{s_0},\mu^{s_1}) \le L|s_0 - s_1|, \quad L^2 := W_2^2(\nu,\mu) + \varepsilon^2 \qquad \forall\, s_0,s_1\in[0,1]; \qquad \mu^s := \rho^s\,\mathrm{V}. \tag{5.7}$$

We keep the same notation of Theorem 4.2 and Lemma 4.3; i.e.,

$$\tilde{\mu}_t^s = \tilde{\rho}_t^s\,\mathrm{V} := \mathcal{S}_{st}(\mu^s), \quad \tilde{A}_t^s := \int_{\mathbb{M}} |\nabla\tilde{\phi}_t^s|_{\mathbf{g}}^2\,\tilde{\rho}_t^s\,\mathrm{dV}, \quad \tilde{F}_t^s = \mathcal{E}(\tilde{\mu}_t^s), \tag{5.8}$$

where $\tilde{\phi}_t^s$ is a family of potentials associated with $\tilde{\rho}_t^s$ as in (4.6). Since $U(\rho) = \rho$, the term $\rho U'(\rho) - U(\rho)$ in the definition of $\tilde{D}_t^s$ vanishes, so that in the present case

$$\tilde{D}_t^s = -\int_{\mathbb{M}} \left(|\mathrm{Hess}\,\tilde{\phi}_t^s|_{\mathbf{g}}^2 + \mathrm{Ric}_{\mathbf{g}}\left(\nabla\tilde{\phi}_t^s,\nabla\tilde{\phi}_t^s\right)\right)\tilde{\rho}_t^s\,\mathrm{dV} \overset{(5.1)}{\le} -\lambda\int_{\mathbb{M}} |\nabla\tilde{\phi}_t^s|_{\mathbf{g}}^2\tilde{\rho}_t^s\,\mathrm{dV} = -\lambda\tilde{A}_t^s, \tag{5.9}$$

and (4.8) yields the differential inequality

$$\frac{1}{2}\frac{\partial}{\partial t}\tilde{A}_t^s + \lambda s\tilde{A}_t^s + \frac{\partial}{\partial s}\tilde{F}_t^s \le 0 \qquad \forall\, s\in[0,1], \quad \forall\, t>0. \tag{5.10}$$

Multiplying inequality (5.10) by $e^{2\lambda st} > 0$ we obtain

$$\frac{1}{2}\frac{\partial}{\partial t}\left(e^{2\lambda st}\tilde{A}_t^s\right) + \frac{\partial}{\partial s}\left(e^{2\lambda st}\tilde{F}_t^s\right) \le 2\lambda t\,e^{2\lambda st}\,\tilde{F}_t^s. \tag{5.11}$$

Integrating with respect to s from 0 to 1 we get

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac12\int_0^1 e^{2\lambda st}\tilde A_t^s\,\mathrm{d}s\right)+e^{2\lambda t}\tilde F_t^1-\tilde F_t^0\le\int_0^1 2\lambda\,t\,e^{2\lambda st}\tilde F_t^s\,\mathrm{d}s, \tag{5.12}$$

and a further integration with respect to t yields

$$\frac12\int_0^1 e^{2\lambda st}\tilde A_t^s\,\mathrm{d}s-\frac12\int_0^1 A_0^s\,\mathrm{d}s+\mathsf{E}_{2\lambda}(t)\mathcal{E}(\mu_t)-t\mathcal{E}(\nu)\le\int_0^t\int_0^1 2\lambda\,r\,e^{2\lambda sr}\,\tilde F_r^s\,\mathrm{d}s\,\mathrm{d}r. \tag{5.13}$$

Applying the next Lemma 5.1, since for $\lambda\neq0$ $\int_0^1\frac{1}{e^{2\lambda st}}\,\mathrm{d}s=\frac{1-e^{-2\lambda t}}{2\lambda t}=\frac{1}{e^{\lambda t}\mathsf{s}(\lambda t)}$, $\mathsf{s}(t):=\frac{t}{\sinh(t)}$, we get

$$\begin{aligned}&\frac{e^{\lambda t}\mathsf{s}(\lambda t)}{2}W_2^2(\mu_t,\nu)-\frac12W_2^2(\mu,\nu)+\mathsf{E}_{2\lambda}(t)\mathcal{E}(\mu_t)-t\mathcal{E}(\nu)\\&\qquad\le\int_0^t\int_0^1 2\lambda r e^{2\lambda sr}\tilde F_r^s\,\mathrm{d}s\mathrm{d}r+\varepsilon^2/2.\end{aligned} \tag{5.14}$$

Let us first consider the case $\lambda\le0$: being $\mathcal{E}$ nonnegative, the right-hand side in (5.14) is less or equal than ε; since $\varepsilon>0$ is arbitrary, we obtain the same inequality with 0 in the right-hand side. Since $t^{-1}\mathsf{E}_{2\lambda}(t)\to1$ as $t\downarrow0$ and $\mathsf{s}(0)=1$, we thus obtain

$$\frac12\frac{\mathrm{d}^+}{\mathrm{d}t}\Big(e^{\lambda t}\mathsf{s}(\lambda t)W_2^2(\mu_t,\nu)\Big)\Big|_{t=0}+\mathcal{E}(\mu)\le\mathcal{E}(\nu). \tag{5.15}$$

Being $\mathsf{s}'(0)=0$ it is then easy to check that

$$\frac{\mathrm{d}^+}{\mathrm{d}t}\Big(e^{\lambda t}\mathsf{s}(\lambda t)W_2^2(\mu_t,\nu)\Big)\Big|_{t=0}=\frac{\mathrm{d}^+}{\mathrm{d}t}\Big(W_2^2(\mu_t,\nu)\Big)\Big|_{t=0}+\lambda\,W_2^2(\mu,\nu),$$

which yields (5.4).

Let us now consider the case $\lambda>0$. Notice that we already know that $\mathcal{S}$ is a 0-flow; by (5.7) we can apply the estimate (3.11) with $\lambda=0$ obtaining

$$\begin{aligned}r\tilde F_r^s=r\mathcal{E}(\mathcal{S}_{rs}(\mu^s))&\overset{(3.11)}{\le}r\left((1-s)\mathcal{E}\left(\mu^0\right)+s\mathcal{E}\left(\mu^1\right)+\frac{\varepsilon^2}{2\,rs}s(1-s)\right)\\&\le r\left(\mathcal{E}\left(\mu^0\right)+\mathcal{E}\left(\mu^1\right)\right)+\varepsilon^2/2,\end{aligned}$$

since $s\in[0,1]$. We thus get

$$\int_0^t\int_0^1 2\lambda\,r\,e^{2\lambda sr}\tilde F_r^s\,\mathrm{d}s\,\mathrm{d}r\le\lambda te^{2\lambda t}\Big(t\big(\mathcal{E}(\mu_0)+\mathcal{E}(\mu_1)\big)+\varepsilon^2\Big); \tag{5.16}$$

inserting this bound in (5.14) and passing to the limit as $\varepsilon\downarrow0$ we find

$$\frac{e^{\lambda t}\mathsf{s}(\lambda t)}{2}W_2^2(\mu_t,\nu)-\frac12W_2^2(\mu,\nu)+\mathsf{E}_{2\lambda}(t)\mathcal{E}(\mu_t)-t\mathcal{E}(\nu)\le\lambda t^2e^{2\lambda t}\left(\mathcal{E}(\mu_0)+\mathcal{E}(\mu_1)\right). \tag{5.17}$$

Dividing by t and letting t tend to 0, the second term vanishes, so we obtain the E.V.I. also in the case in which $\lambda>0$. ∎

LEMMA 5.1. *Let $\nu,\mu\in\mathcal{P}_2^{ar}(\mathbb{M})$ and let $(\rho,\phi)\in\mathcal{C}(\nu,\mu)$ be a smooth solution of the continuity equation*

$$\frac{\partial}{\partial s}\rho^s+\nabla\cdot(\rho^s\,\nabla\phi^s)=0\quad \textit{in } [0,1]\times\mathbb{M}\quad \textit{with}$$
$$\rho^0\mathrm{V}=\nu,\ \rho^1\mathrm{V}=\mu,\quad \textit{and}\quad A^s:=\int_{\mathbb{M}}|\nabla\phi^s|^2_{\mathsf{g}}\,\rho^s\,\mathrm{dV}.$$

For every positive function $f\in C^\infty[0,1]$

$$W_2^2(\nu,\mu)\le L_f\int_0^1 f(s)A^s\,ds,\quad \textit{where}\quad L_f:=\int_0^1\frac{1}{f(s)}\,ds. \tag{5.18}$$

Moreover, for every $\varepsilon>0$ there exists a smooth rescaling $\mathsf{s}_\varepsilon:[0,1]\to[0,1]$ so that the reparametrized families

$$\bar\rho^r:=\rho^{\mathsf{s}_\varepsilon(r)},\quad \bar\phi^r:=\mathsf{s}_\varepsilon'(r)\phi^{\mathsf{s}_\varepsilon(r)},\quad \bar\mu^r:=\bar\rho^r\,\mathrm{V} \tag{5.19}$$

satisfy

$$\big(\bar\rho,\bar\phi\big)\in\mathcal{C}(\nu,\mu),\quad W_2(\bar\mu^{r_0},\bar\mu^{r_1})\le L|r_0-r_1|,\quad L^2\le\int_0^1 A^s\,\mathrm{d}s+\varepsilon^2. \tag{5.20}$$

Proof. Let us consider the smooth increasing map $\mathsf{r}:[0,1]\to[0,1]$

$$\mathsf{r}(s):=L_f^{-1}\int_0^s\frac{1}{f(s)}\,ds\quad\text{and its inverse } \mathsf{s}:=\mathsf{r}^{-1}\quad\text{with}\quad \mathsf{s}'(\mathsf{r}(s))=L_f f(s).$$

It is immediate to check that the smooth (reparametrized) curve

$$\bar\rho^r(x):=\rho^{\mathsf{s}(r)}(x),\quad \bar\phi^r(x):=\mathsf{s}'(r)\phi^{\mathsf{s}(r)}(x) \tag{5.21}$$

belongs to $\mathcal{C}(\nu,\mu)$. It follows that

$$W_2^2(\nu,\mu)\le\int_0^1\bar A^r\,\mathrm{d}r,\quad\text{where}\quad \bar A^r:=\int_{\mathbb{M}}|\nabla\bar\phi^r|^2_{\mathsf{g}}\,\bar\rho^r\,\mathrm{dV}\overset{(5.21)}{=}\big(\mathsf{s}'(r)\big)^2A^{\mathsf{s}(r)},$$

so that

$$\int_0^1\bar A^r\mathrm{d}r=\int_0^1 A^{\mathsf{s}(r)}\big(\mathsf{s}'(r)\big)^2\,\mathrm{d}r=\int_0^1 A^s\mathsf{s}'(\mathsf{r}(s))\,\mathrm{d}s=L_f\int_0^1 f(s)A^s\,\mathrm{d}s.$$

Choosing now the reparametrization s_ε corresponding to the choice

$$f_\varepsilon(s):=\frac{1}{\sqrt{\varepsilon^2+A^s}},\quad L_{f_\varepsilon}:=\int_0^1\sqrt{\varepsilon^2+A^s}\,\mathrm{d}s,\quad L_{f_\varepsilon}^2\le\varepsilon^2+\int_0^1 A^s\,\mathrm{d}s, \tag{5.22}$$

we get

$$W^2(\bar\mu^{r_0},\bar\mu^{r_1})\le|r_1-r_0|\textstyle\int_{r_0}^{r_1}\bar A^r\,\mathrm{d}r=|r_1-r_0|L_{f_\varepsilon}^2\int_{r_0}^{r_1}A^{\mathsf{s}(r)}f_\varepsilon^2(\mathsf{s}(r))\,\mathrm{d}r$$
$$\le(r_1-r_0)^2L_{f_\varepsilon}^2,$$

which yields (5.20). ∎

POSITIVITY PROPERTIES OF THE FOURIER TRANSFORM AND THE STABILITY OF PERIODIC TRAVELLING-WAVE SOLUTIONS*

JAIME ANGULO PAVA† AND FÁBIO M. A. NATALI‡

Abstract. In this paper we establish a method to obtain the stability of periodic travelling-wave solutions for equations of Korteweg–de Vries-type $u_t + u^p u_x - Mu_x = 0$, with M being a general pseudodifferential operator and where $p \geq 1$ is an integer. Our approach uses the theory of totally positive operators, the Poisson summation theorem, and the theory of Jacobi elliptic functions. In particular we obtain the stability of a family of periodic travelling waves solutions for the Benjamin–Ono equation. The present technique gives a new way to obtain the existence and stability of cnoidal and dnoidal waves solutions associated with the Korteweg–de Vries and modified Korteweg–de Vries equations, respectively. The theory has prospects for the study of periodic travelling-wave solutions of other partial differential equations.

Key words. dispersive equations, Korteweg–de Vries-type equations, periodic travelling waves, Jacobi elliptic functions, nonlinear stability

1. Introduction.

One of the main properties of dispersive nonlinear evolution equations is that usually they sustain steadily translating waves called travelling waves. These solutions imply a balance between the effects of nonlinearity and of frequency dispersion. By depending on specific boundary conditions on the wave's shape, for instance, in the case of water waves, these special states of motion can arise either solitary or periodic waves. The study of these special steady waveforms is essential to the explanation of many wave phenomena observed in the practice, for instance, in surface water waves propagating in a canal, in propagation of internal waves, or in shallow-water ocean surface waves (see Benjamin [12], [13], [14] and Osborne et al. [44]).

In the water wave context, Constantin in [21] and Constantin and Escher in [22] analyzed a free boundary problem for harmonic functions and showed that periodic or solitary travelling waves possess stability properties within the shallow-water regime (see also Toland [47] and Constantin and Strauss [23] and the citations therein). Moreover, various nonlinear dispersive model equations are an accurate approximation to the governing equations for water waves (see [5]). From these considerations, questions about the stability of travelling waves and their existence as exact solutions of the dynamical equations are very important.

The solitary waves are in general single crested, symmetric, localized travelling waves, whose hyperbolic sech profiles are well known (see Ono [43] and Benjamin [16] for the existence of solitary waves of algebraic type or with a finite number of oscillations). The study of the nonlinear stability or instability in the form of solitary waves has had a terrific development and refinement in recent years. The proofs have

been simplified and sufficient conditions were obtained to ensure the stability to small localized perturbations in the waveform. Those conditions have shown to be effective in a variety of circumstances; see, for example, [2], [3], [4], [14], [17], [27], [28], [49], and [48].

The situation regarding periodic travelling waves is very different. The stability and the existence of explicit formulas of these progressive wavetrains have received comparatively little attention. A first study of these waveforms was detemined by Benjamin in [16] with regard to the periodic steady solutions called *cnoidal waves*, which were found initially by Korteweg and de Vries in [34] for the equation currently called the Korteweg–de Vries equation (KdV henceforth):

$$u_t + uu_x + u_{xxx} = 0, \tag{1.1}$$

where $u = u(x,t)$ is a real-valued function of the two variables $x, t \in \mathbb{R}$. Benjamin put forward an approach to the stability of cnoidal waves in the form

$$\varphi(\xi) = \beta_2 + (\beta_3 - \beta_2)\mathrm{cn}^2\left(\sqrt{\frac{\beta_3 - \beta_1}{12}}\xi; k\right),$$

but did not provide a detailed justification of his assertions, and several aspects seem problematic. The first result of stability for periodic solutions of the KdV was obtained by McKean in [37], who considered the orbital stability of all periodic finite-genus solutions with respect to perturbations of the same period. McKean's approach was based on the integrable structure of the KdV. More recently Angulo, Bona, and Scialom in [10] returned to Benjamin's original question and gave a complete theory of stability of cnoidal waves for (1.1) with respect to perturbations of the same period (see also [7]). The approach for obtaining this result was based on the ideas of Bona, Weinstein, and Grillakis, Shatah, and Strauss (see [17], [27], [48]) but adapted to the periodic context. So new theories of stability for other dispersive equations such as the focusing nonlinear Schrödinger equation and the modified KdV has been obtained (see Angulo [9], [8]). It is remarkable to see that in all these works the use of an elaborated spectral theory for the periodic eigenvalue problem was necessary (see [29], [36]),

$$\begin{cases} \dfrac{d^2}{dx^2}\Psi + [\rho - n(n+1)k^2 sn^2(x;k)]\Psi = 0, \\ \Psi(0) = \Psi(2K(k)), \quad \Psi'(0) = \Psi'(2K(k)), \end{cases} \tag{1.2}$$

with specific values of $n \in \mathbb{N}$. In (1.2), $sn(\cdot;k)$ represents the Jacobi elliptic function of type snoidal with *modulus* k, $k \in (0,1)$, and K represents the complete elliptic integral of the first kind defined by

$$K(k) = \int_0^1 \frac{dt}{\sqrt{(1-t^2)(1-k^2t^2)}}.$$

We recall that the second order differential equation in (1.2) is known as the *Jacobi form of the Lamé equation*.

We note also that Gardner in [26] provided a theory for determining that the large wavelength periodic waves are linearly unstable whenever the limiting homoclinic wave (solitary wave) is unstable. He applied it for diverse types of nonlinear evolution equations in one space variable, in the case of the generalized KdV equations

$$u_t + u^p u_x + u_{xxx} = 0,$$

$p \in \mathbb{N}$, and assuming that this equation admits a family of large wavelength periodic waves U^α such that the period T_α tends to infinity as α tends to zero, then they are unstable whenever $p > 4$ and $\alpha > 0$ is sufficiently small.

Then, the main focus in this paper will be the study of the existence and stability of periodic travelling-wave solutions for equations of the form

$$u_t + u^p u_x - M u_x = 0, \tag{1.3}$$

where $p \geq 1$ is an integer and M is a differential or pseudodifferential operator in the framework of periodic functions. M is defined as a Fourier multiplier operator by

$$\widehat{Mg}(k) = \alpha(k)\widehat{g}(k), \quad k \in \mathbb{Z}, \tag{1.4}$$

where the symbol α of M is assumed to be a mensurable, locally bounded, even function on $\mathbb{R}$, satisfying the conditions

$$A_1|k|^{m_1} \leqq \alpha(k) \leqq A_2(1+|k|)^{m_2} \tag{1.5}$$

for $m_1 \leqq m_2$, $|k| \geq k_0$, $\alpha(k) > b$ for all $k \in \mathbb{Z}$ and $A_i > 0$. The travelling-wave solutions for (1.3) will have the form

$$u(x,t) = \varphi_c(x - ct),$$

where the profile φ_c is a smooth periodic function with an a priori fundamental period $2L$, $L > 0$. Hence substituting this form of u into (1.3) and integrating once (with the integration constant being considered zero throughout our theory), one obtains that $\varphi = \varphi_c$ is the solution of the equation

$$(M + c)\varphi - \frac{1}{p+1}\varphi^{p+1} = 0. \tag{1.6}$$

Associated with (1.6) we consider the linear, closed, unbounded, self-adjoint operator $\mathcal{L} : D(\mathcal{L}) \to L^2_{per}([-L, L])$ defined on a dense subspace of $L^2_{per}([-L, L])$ by

$$\mathcal{L}u = (M + c)u - \varphi^p u. \tag{1.7}$$

From the theory of compact symmetric operators applied to the periodic eigenvalue problem

$$\begin{cases} \mathcal{L}\psi \quad\quad = \lambda\psi, \\ \psi(-L) = \psi(L), \quad \psi'(-L) = \psi'(L), \end{cases} \tag{1.8}$$

it is possible to see that the spectrum of $\mathcal{L}$ is a countable infinite set of eigenvalues, $\{\lambda_n\}$, with

$$\lambda_0 \leq \lambda_1 \leq \lambda_2 \leq \lambda_3 \leq \cdots, \tag{1.9}$$

where $\lambda_n \to \infty$ as $n \to \infty$ (see Proposition 3.1 below for a proof of this assertion). In particular, from (1.6) we obtain that $\mathcal{L}$ has zero as an eigenvalue with eigenfunction

$d\varphi/dx$. As is well known this property of $\mathcal{L}$ is deduced from the invariance of the solutions of (1.3) by translations.

A set of sharp conditions is available in the literature to imply the stability of the orbit generated by φ_c, namely, $\Omega_{\varphi_c} = \{\varphi_c(\cdot + y) : y \in \mathbb{R}\}$. So, we say that Ω_{φ_c} (or φ_c) is stable in $H^{m_2}_{per}([-L, L])$ by the periodic flow generated by (1.3) if, for any $\epsilon > 0$, there exists a $\delta > 0$ such that, for $u_0 \in H^{m_2}_{per}([-L, L])$ with $d(u_0, \Omega_{\varphi_c}) \equiv inf_{y\in\mathbb{R}}$ $\|u_0 - \varphi_c(\cdot + y)\|_{H^{m_2}_{per}} < \delta$, the solution u of (1.3) with $u(x, 0) = u_0$ is global in time and satisfies $d(u(t), \Omega_{\varphi_c}) < \epsilon$ for all $t \in \mathbb{R}$. Thus, from [14], [17], [49], [27] the conditions that imply stability are the following:

(1.10)

(P_0) there is a nontrivial smooth curve of periodic solutions for (1.6) of the form

$c \in I \subseteq \mathbb{R} \to \varphi_c \in H^{m_2}_{per}([-L, L])$;

(P_1) $\mathcal{L}$ has an unique negative eigenvalue λ, and it is simple;

(P_2) the eigenvalue 0 is simple;

(P_3) $\dfrac{d}{dc}\displaystyle\int_{-L}^{L} \varphi_c^2(x)dx > 0.$

The problem about the existence of a nontrivial smooth curve of periodic solutions in the form required by (P_0) above presents new and delicate aspects that need to be handled. The possibility of finding explicit solutions for (1.6) will depend naturally on the form of M. If it is a differential operator of the form $M = -\partial_x^2$, then we use the quadrature method (it means writing (1.6) in the form $[\varphi_c']^2 = F(\varphi_c)$), and the theory of elliptic functions has shown to be a main tool. So, the solutions will depend on the Jacobi elliptic functions of *snoidal, cnoidal*, and *dnoidal* types (see [9], [8], [10], [15]). Now, since the period of these functions depends on the complete elliptic integral $K(k)$, we have that the elliptic modulus k will depend on the velocity c, and therefore we have that a priori the period of φ_c will depend on c. Hence, by using the implicit function theorem, the wanted smooth branch of periodic solutions with a fixed minimal period has been obtained in many cases. We note that the procedure of the quadrature method in general does not work if M is a pseudodifferential operator such as the nonlocal operator $\mathcal{H}\partial_x$, with $\mathcal{H}$ being the Hilbert transform. In this paper we will make a different approach to obtain explicit solutions of (1.6) for a specific form of M and values of p. This approach will be based on the classical *Poisson summation theorem* (see [38], [45], [46]). At least two important advantages of this approach can be obtained: The first one is that it can be used for obtaining solutions when M is a pseudodifferential operator, for example, in the case of $\mathcal{H}\partial_x$. The other one is that related with computing the integral in (1.10). In general obtaining property (P_3) can be very difficult in the periodic case, as the results that have appeared in the literature have shown, since the use of nontrivial identities for the complete elliptic integrals of the first and the second kinds sometimes come on the scene as a fundamental piece in the analysis. As we will see our method to obtain property (P_3) can be very easy as a combination of the *Poisson summation theorem* and the *Parseval theorem*.

With regard to conditions (P_1) and (P_2), the problem is very delicate. One of the most remarkable results in the theory of stability of solitary wave solutions was given by Albert [2] and Albert and Bona [3], where sufficient conditions to obtain properties (P_1) and (P_2) were given. The advantage of that approach is that it does not require an explicit computation of the spectrum of the linear operator (1.7), since (P_1) and

(P_2) are obtained exclusively from positivity properties of the Fourier transform of the solitary wave in question. The present paper establishes an extension of the theory in [2] and [3] in the case of periodic travelling-wave solutions. The periodic problem has new points not encountered when considering issues related to the solitary waves. Our analysis also relies upon the theory of totally positive operators, and so the class $PF(2)$ defined by Karlin in [32] (see also [2]) is basic in our study.

Our theory leads to a significant simplification of some recent proofs of stability of periodic travelling-wave solutions of KdV-type equations (see [9], [7], [10]) such as in the case of the KdV and the modified KdV equations, since in those cases the verification of properties (P_1) and (P_2) required the determination of the instability intervals associated with the Lamé equation in (1.2) and of an explicit formula of at least the first three eigenvalues ρ (see [36]). *Our analysis does not need this information.*

Such as will be shown in section 4, this method establishes the first result about the stability of periodic travelling-wave solutions found by Benjamin in [15] for the Benjamin–Ono equation

$$u_t + uu_x - \mathcal{H}u_{xx} = 0, \tag{1.11}$$

where $\mathcal{H}$ denotes the periodic Hilbert transform defined by

$$\mathcal{H}f(x) = \frac{1}{2L}\, p.v. \int_{-L}^{L} cotg\Big[\frac{\pi(x-y)}{2L}\Big] f(y)\, dy. \tag{1.12}$$

The associated periodic waves for (1.11) with a minimal period $2L$ are given for $c > \frac{\pi}{L}$ as

$$\varphi_c(x) = \frac{2\pi}{L}\left(\frac{\operatorname{senh}(\gamma)}{\cosh(\gamma) - \cos\left(\frac{\pi x}{L}\right)}\right), \tag{1.13}$$

such that $\gamma > 0$ satisfies $\tanh(\gamma) = \frac{\pi}{cL}$.

It is important to note that the stability results now presented are obtained by periodic initial disturbances having *the same minimal period* of our periodic solutions. This method cannot be extended for obtaining stability results with more general periodic perturbations, for instance, by periodic disturbances of two times the minimal period of our periodic solutions. In section 6 we give an explanation of this fact.

The plan of this paper is as follows. The next section is devoted to describing briefly the notation that will be used and making a few preliminary remarks regarding periodic Sobolev spaces, the Poisson summation theorem, and some results of global well-posedness in the periodic case of the KdV, modified KdV, and the Benjamin–Ono equations. Sections 3 and 4 contain our full theory which relates positivity properties of periodic travelling-wave solutions to the stability theory of [27]. Applications of section 4 to specific periodic travelling waves are presented in section 5. In section 6 some comments about the $PF(2)$ property in the periodic case are established. Finally, the appendix contains some basic properties of the elliptic integrals which are relevant to the theory of section 5, and the proof of an inequality of Poincaré–Wintinger type for nonlocal operators is established.

2. Notation and preliminaries.

2.1. Function classes. Let Ω be an open set of the real line $\mathbb{R}$ and $1 \leq p \leq \infty$; then $L^p(\Omega)$ is the usual Banach space of (equivalence classes of) real- or

complex-valued Lebesgue measurable functions defined on Ω provided with the norm

$$||f||_p = \left(\int_\Omega |f(x)|^p dx \right)^{\frac{1}{p}}$$

if $1 \leq p < \infty$. When $p = \infty$ we have $||f||_\infty = supess_{x\in\Omega}|f(x)|$. When $p = 2$ the Banach space $L^p(\Omega)$ is a Hilbert space with inner product defined by $(f,g)_2 = \int_\Omega f(x)\overline{g(x)}dx$, where $f, g \in L^2(\Omega)$. The L^2-based Sobolev spaces of periodic functions are defined as follows [30]. If $\mathcal{P} = C^\infty_{per}$ denotes the collection of all of the functions $f : \mathbb{R} \to \mathbb{C}$ which are C^∞ and periodic with period $2l > 0$, the collection $\mathcal{P}'$ of all continuous linear functionals from $\mathcal{P}$ into $\mathbb{C}$ is the set of periodic distributions. If $\Psi \in \mathcal{P}'$, we denote the evaluation of Ψ at φ by $\Psi(\varphi) = \langle \Psi, \varphi\rangle$ for $\varphi \in \mathcal{P}$. For $k \in \mathbb{Z}$, let $\Theta_k(x) = e^{\frac{ik\pi x}{l}}$, $x \in \mathbb{R}$. The Fourier transform of $\Psi \in \mathcal{P}'$ is a function $\widehat{\Psi} : \mathbb{Z} \to \mathbb{C}$ defined by $\widehat{\Psi}(k) = \frac{1}{2l}\langle \Psi, \Theta_k\rangle$, $k \in \mathbb{Z}$. $\widehat{\Psi}(k)$ are called the Fourier coefficients of Ψ. As usual, a function $\psi \in L^p([-l,l])$, $p \geq 1$, is an element of $\mathcal{P}'$ by defining

$$\langle \psi, \varphi\rangle = \frac{1}{2l}\int_{-l}^{l} \psi(x)\varphi(x)dx, \qquad \varphi \in \mathcal{P}.$$

If $\psi \in L^p([-l,l])$ for some $p \geq 1$, then, for $k \in \mathbb{Z}$,

$$\widehat{\psi}(k) = \frac{1}{2l}\int_{-l}^{l} \psi(x)e^{-\frac{ik\pi x}{l}}dx.$$

The Fourier inverse transform of a sequence $\alpha = (\alpha_k)_{k\in\mathbb{Z}} \in \mathcal{S}(\mathbb{Z})$, where $\mathcal{S}(\mathbb{Z})$ denotes the space of the rapidly decreasing sequences, is the function $\check{\alpha} \in \mathcal{P}$ defined by $\check{\alpha}(x) = \sum_{k\in\mathbb{Z}} \alpha_k\Theta_k(x)$. We consider the space $\mathcal{P}'$ provided with the usual weak-star topology, but it will not be needed here. We denote by C_{2l} the space of the continuous and $2l$-periodic functions. Let $\alpha = (\alpha_k)_{k\in\mathbb{Z}}$ be a sequence of complex value. The Hilbert space $\ell^2 := \ell^2(\mathbb{Z})$ is defined by

$$\ell^2 = \left\{ \alpha;\ ||\alpha||_{\ell^2} := \left(\sum_{k=-\infty}^{+\infty} |\alpha_k|^2 \right)^{\frac{1}{2}} < \infty \right\}.$$

For $s \in \mathbb{R}$, the Sobolev space $H^s_{per}([-l,l]) := H^s_{2l}$ is the set of all $f \in \mathcal{P}'$ such that

$$||f||^2_{H^s_{2l}} \equiv 2l \sum_{k=-\infty}^{+\infty} (1+|k|^2)^s |\widehat{f}(k)|^2 < \infty.$$

The collection H^s_{2l} is a Hilbert space with inner product

$$(f,g)_{H^s_{2l}} = 2l \sum_{k=-\infty}^{+\infty} (1+|k|^2)^s \widehat{f}(k)\overline{\widehat{g}(k)}.$$

When $s = 0$, H^s_{2l} is a Hilbert space that is isometrically isomorphic to a subspace of $L^2([-l,l])$ and $(f,g)_{H^0_{2l}} = (f,g) = \int_{-l}^{l} f(x)\overline{g(x)}dx$. The space H^0_{2l} will be denoted by L^2_{2l}, and its norm will be $||.||_{L^2_{2l}}$. Of course, $H^s_{2l} \subseteq L^2_{2l}$ for all $s \geq 0$, and we have

for $s > 1/2$ the Sobolev embedding $H^s_{2l} \hookrightarrow C_{2l}$ (see [30]). The space $\ell^2_{s,2l} := \ell^2_{s,2l}(\mathbb{Z})$, $s \in \mathbb{R}$, is defined by

$$\ell^2_{s,2l}(\mathbb{Z}) := \left\{ \alpha = (\alpha_k)_{k\in\mathbb{Z}};\ ||\alpha||_{\ell^2_s} := \left(2l \sum_{k=-\infty}^{+\infty} (1+|k|^2)^s |\alpha_k|^2 \right)^{\frac{1}{2}} < +\infty \right\}.$$

$\ell^2_{s,2l}$ is a Hilbert space with inner product

$$(\alpha,\beta)_{\ell^2_{s,2l}} = 2l \sum_{k=-\infty}^{+\infty} (1+|k|^2)^s \alpha_k \overline{\beta_k},$$

where $\alpha = (\alpha_k)_{k\in\mathbb{Z}}$ and $\beta = (\beta_k)_{k\in\mathbb{Z}}$. Then we have that $f \in H^s_{2l}$ if and only if $(\widehat{f}(k))_{k\in\mathbb{Z}} \in \ell^2_{s,2l}$, and so from the Parseval theorem (see [30]), $||\widehat{f}\ ||^2_{\ell^2} = \frac{1}{2l}||f||^2_{L^2_\ell}$, it follows that $||f||_{H^s_{2l}} = ||\widehat{f}||_{\ell^2_{s,2l}}$. The convolution of two sequences α and β is the sequence $\alpha * \beta$ defined, for all $k \in \mathbb{Z}$, by $(\alpha*\beta)_k = \sum_{j=-\infty}^{+\infty} \alpha_{k-j}\beta_j$, whenever the right-hand side of the identity above makes sense. Next, we present some results that we will need throughout this work. We start with the Young inequality (see [38]).

PROPOSITION 2.1. *Let $\alpha \in \ell^1(\mathbb{Z})$ and $\beta \in \ell^2(\mathbb{Z})$. Then $\alpha * \beta \in \ell^2(\mathbb{Z})$. Moreover,*

$$||\alpha*\beta||_{\ell^2} \le ||\alpha||_{\ell^1}||\beta||_{\ell^2}.$$

In particular, for every $\alpha \in \ell^1$ fixed, the linear operator $\beta \in \ell^2 \mapsto \alpha*\beta \in \ell^2$ is continuous.

Now, we present the Poisson summation theorem. It will be used to find the explicit form of the periodic travelling-wave solutions for some equations.

THEOREM 2.1. *Let $\widehat{f}(x) = \int_{-\infty}^{+\infty} f(y)e^{-ixy}dy$ and $f(y) = \int_{-\infty}^{\infty} \widehat{f}(x)e^{ixy}dx$ satisfying*

$$|f(y)| \le \frac{A}{(1+|y|)^{1+\delta}} \qquad \text{and} \qquad |\widehat{f}(x)| \le \frac{A}{(1+|x|)^{1+\delta}},$$

where $\delta > 0$ and $A > 0$ (then $\widehat{f}$ and f can be assumed to be continuous functions). Thus, for $L > 0$,

$$\sum_{n=-\infty}^{+\infty} f(x+2Ln) = \frac{1}{2L} \sum_{n=-\infty}^{+\infty} \widehat{f}\left(\frac{n}{2L}\right) e^{\frac{\pi i n x}{L}}.$$

The two series above converge absolutely.

Proof. See [38], [45], and [46]. □

2.2. Results of global well-posedness. Some results about local and global well-posedness associated with (1.3) in the periodic case were initially established in [1]. Here we establish two results that we will use in our theory.

THEOREM 2.2. *Let $s \ge 1$ be given. For each $u_0 \in H^s_{2l}$ there is a unique solution of (1.3), for the cases $p = 1, 2$ and $M = -\partial_x^2$, that for each $T > 0$ lies in $C(0,T;H^s_{2l})$. Moreover, the correspondence $u_0 \mapsto u$ is an analytic function of the relevance function spaces.*

Proof. See [20]. □

THEOREM 2.3. *Let $s \ge \frac{1}{2}$ be given. For each $u_0 \in H^s_{2l}$ there is a unique solution of (1.3), for the cases $p = 1$ and $M = \mathcal{H}\partial_x$, that for each $T > 0$ lies in $C(0,T;H^s_{2l})$.*

Moreover, the correspondence $u_0 \mapsto u$ is a continuous function of the relevance function spaces.

Proof. See [39], [41], and [40]. □

3. Basic functional spaces. In this section we establish the main spaces in our study of the stability of periodic wave solutions associated with (1.6) for the case of the Benjamin–Ono (BO), Korteweg–de Vries (KdV), and modified Korteweg–de Vries (mKdV) equations. For the KdV and mKdV cases we have in (1.6), $M = -\partial_x^2$ with symbol $\left(\frac{\pi}{L}\right)^2 n^2$, $p = 1$, and $p = 2$, respectively. Next, the BO equation is obtained with $M = \mathcal{H}\partial_x$, with the symbol being $\frac{\pi}{L}|n|$ and $p = 1$. Here, $\mathcal{H}$ denotes the periodic Hilbert transform defined in (1.12) and such that via the Fourier transform satisfies $\widehat{\mathcal{H}f}(n) = -isgn(n)\widehat{f}(n)$ for all $n \in \mathbb{Z}$. Then, our three periodic travelling-wave equations are

$$\begin{aligned} &\mathcal{H}\varphi_c' + c\varphi_c - \tfrac{1}{2}\varphi_c^2 = 0 \qquad \text{(BO)},\\ &\varphi_c'' + \tfrac{1}{2}\varphi_c^2 - c\varphi_c = 0 \qquad \text{(KdV)},\\ &\varphi_c'' + \tfrac{1}{3}\varphi_c^3 - c\varphi_c = 0 \qquad \text{(mKdV)}. \end{aligned} \tag{3.1}$$

Remark 3.1. (a) Here, we shall consider a more convenient form for the mKdV travelling-wave equation, namely,

$$\varphi_c'' + \varphi_c^3 - c\varphi_c = 0. \tag{3.2}$$

(b) The periodic travelling-wave solutions for the KdV and mKdV will be considered of period L, but the periodic travelling-wave solution for the BO equation will be considered of period $2L$ only by convenience.

(c) After a "bootstrap" argument, we can conclude that every φ_c belongs to H^s_{2L} for all $s \in \mathbb{R}$. Thus, φ is infinitely differentiable, with all derivatives in L^2_{2L}.

We will suppose that $c > -b$, where b satisfies $\alpha(k) > b$ for all $k \in \mathbb{Z}$. With this condition $M + c$ represents a positive operator. Then, by using the spectral theorem for compact and self-adjoint operators we have the following characterization of the spectrum of $\mathcal{L}$ defined in (1.7).

PROPOSITION 3.1. *The operator $\mathcal{L}$ in* (1.7) *is a closed, unbounded, self-adjoint operator on L^2_{2L} whose spectrum consists of an enumerable (infinite) set of eigenvalues $\{\lambda_k\}_{k=0}^{\infty}$ satisfying $\lambda_0 \le \lambda_1 \le \lambda_2 \le \cdots$, and $\lambda_k \to \infty$ as $k \to \infty$. In particular, $\mathcal{L}$ has 0 as an eigenvalue with eigenfunction $\frac{d}{dx}\varphi_c$.*

Proof. We suppose that our periodic functions have period L. Clearly $\mathcal{L}$ defined on $H^{m_2}_L$ is a closed, unbounded, self-adjoint operator on $L^2_{per}([0, L])$. Let us proof that the spectrum of $\mathcal{T} := M + c$ is a countable infinite set of eigenvalues, $\{\gamma_n\}$, with

$$\gamma_0 \le \gamma_1 \le \gamma_2 \le \gamma_3 \le \cdots, \tag{3.3}$$

where $\gamma_n \to \infty$ as $n \to \infty$. In fact, let $R_c = (M + c)^{-1}$, whose symbol is $\frac{1}{c+\alpha(k)}$ for $k \in \mathbb{Z}$. Since $\frac{1}{c+\alpha(k)} \in \ell^2(\mathbb{Z})$ we have that there is a unique $G_c \in L^2_{per}([0, L])$ such that $\widehat{G_c}(k) = \frac{1}{c+\alpha(k)}$, and, because of this, we have the action

$$R_c f(x) = \frac{1}{L}\int_0^L G_c(x - y)f(y)dy,$$

defined for $f \in L^2_{per}([0, L])$. Since $[0, L]$ is a bounded set we have that the kernel $\widetilde{G_c}(x, y) := G_c(x - y) \in L^2([0, L] \times [0, L])$. So, R_c is a Hilbert–Schmidt operator on

$L^2_{per}([0,L])$ (see [33]), and therefore R_c is a compact operator on $L^2_{per}([0,L])$ for all $c>0$ (here we supposed without loss of generality that $b=0$), and so we obtain (3.3).

Next, we will show that there is a μ_1 (large enough) such that $\mathcal{M}=(\mathcal{L}+\mu_1)^{-1}$ exists and is a bounded, positive, compact, and self-adjoint operator. In fact, first of all, it is easy to see that $\mathcal{L}$ is limited below; that is, if $f\in D(\mathcal{L})$, we have $\langle \mathcal{L}f,f\rangle \geq -\beta\langle f,f\rangle$, where $\beta=||\varphi_c||_{L^\infty_{per}}+c$. Then, we can choose a μ_1 such that $\mathcal{L}+\mu_1>0$; that is, $\mathcal{M}$ is positive. We denote $\mu_1:=\mu$ only by convenience. Let ν be a positive number such that $\nu+\varphi_c-c>0$ and $\nu+\mu>0$. Thus, for $\mu>0$ we have $f=(\mathcal{L}+\mu)g \Leftrightarrow (I-M)g=\Upsilon f$, where $Mg=R_{\mu+\nu}[(\nu+\varphi_c-c)g]$, $\Upsilon=R_{\nu+\mu}$, and we denote $h=\nu+\varphi_c-c$. Next, from the Parseval theorem, it follows that

$$||Mg||_{L^2_{per}} \leq \sup_{k\in\mathbb{Z}}\left\{\frac{1}{\alpha(k)+\nu+\mu}\right\}||h||_{L^\infty_{per}}||g||_{L^2_{per}}.$$

Thus, we can choose μ such that $||M||_{B(L^2_{per})}<1$ and $\mathcal{L}+\mu>0$. Then, $I-M$ is invertible, and we have $g=(I-M)^{-1}\Upsilon f$ and write $\mathcal{M}=(\mathcal{L}+\mu)^{-1}=(I-M)^{-1}\Upsilon$. Υ being a compact operator and $(I-M)^{-1}\in B(L^2_{per})$ we have that $\mathcal{M}$ is a compact operator. Then, there is an orthonormal basis $\{\varphi_k\}_{k=0}^\infty$ of L^2_{per} consisting of eigenfunctions of $\mathcal{M}$ with nonzero eigenvalues $\{\mu_k\}_{k=0}^\infty$ satisfying $\mu_1\geq\mu_2\geq\mu_3\geq\cdots>0$, and $\mu_k\to 0$ as $k\to\infty$. Since $\mathcal{M}\varphi_k=\mu_k\varphi_k\in D(\mathcal{L}+\mu)$ we have that

$$\mathcal{L}\varphi_k=\left(\frac{1}{\mu_k}-\mu\right)\varphi_k:=\lambda_k\varphi_k.$$

Thus, there is a sequence of eigenvalues of $\mathcal{L}$, $\{\lambda_k\}_{k=0}^\infty$, satisfying $\lambda_0\leq\lambda_1\leq\lambda_2\leq\cdots$, and $\lambda_k\to\infty$ as $k\to\infty$. This argument shows what is desired. □

The next step will be centralized in the study of some specific spectral properties of the operator $\mathcal{L}$. For this, let us define two families of linear operators. They will be related with $\mathcal{L}$ but with the advantage that both of them are compacts. The results that will be present below are extensions of the results about stability of solitary waves solutions in Albert [2] and Albert and Bona [3] to the periodic case.

For every $\theta\geq 0$ define the operator $S_\theta:\ell^2(\mathbb{Z})\to\ell^2(\mathbb{Z})$ by considering

$$S_\theta\alpha(n)=\frac{1}{\omega_\theta(n)}\sum_{j=-\infty}^{\infty}K(n-j)\alpha_j=\frac{1}{\omega_\theta(n)}(K*\alpha)_n,$$

where $\omega_\theta(n)=\alpha(n)+\theta+c$, $K(n)=\widehat{\varphi_c^p}(n)$, $n\in\mathbb{Z}$. Since $\omega_\theta(n)>0$ for all $n\in\mathbb{Z}$, it follows that the space X defined by

$$X=\left\{\alpha\in\ell^2(\mathbb{Z});||\alpha||_{X,\theta}:=\left(\sum_{n=-\infty}^{\infty}|\alpha_n|^2\omega_\theta(n)\right)^{\frac{1}{2}}<\infty\right\}$$

is a Hilbert space with norm $||\alpha||_{X,\theta}$ and corresponding inner product $\langle\alpha,\beta\rangle_{X,\theta}=\sum_{n=-\infty}^{\infty}\alpha_n\overline{\beta_n}\omega_\theta(n)$.

PROPOSITION 3.2. (a) *If $\alpha\in\ell^2$ is an eigensequence of S_θ for a nonzero eigenvalue, then $\alpha\in X$.*

(b) *The restriction of S_θ to X is a compact, self-adjoint operator on X with respect to the norm $||\cdot||_{X,\theta}$.*

Proof. In fact, we denote the norm in X simply by $||\cdot||_X$, and the operator S_θ by S, and $\mu:=\mu_\theta=\frac{1}{\omega_\theta}$. It will be shown that $S^2g=S(Sg)\in X$, since $g=\frac{1}{\gamma}Sg=\frac{1}{\gamma^2}S^2g$;

this will prove the proposition. By the Minkowski, Hölder, and Young inequalities we obtain

(3.4)

$$
\begin{aligned}
||S^2\alpha||_X &= \left\| \sum_j K(\cdot - j)\mu(\cdot) S\alpha(j) \right\|_X = \left\| \sum_j \sum_m K(\cdot - j)\mu(\cdot) K(j-m)\mu(j)\alpha(m) \right\|_X \\
&\leq \sum_j \sum_m \left[\sum_n K(n-j)^2 \mu(n) \right]^{\frac{1}{2}} K(j-m)\mu(j)|\alpha(m)| \\
&\leq ||K^2||_{\ell^1} ||\mu||_{\ell^2}^{\frac{1}{2}} ||\mu^{\frac{3}{2}}||_{\ell^1}^{\frac{1}{4}} ||\mu^{\frac{5}{4}}||_{\ell^1}^{\frac{1}{2}} ||\alpha||_{\ell^2}.
\end{aligned}
$$

Since $|\mu(x)| \leq B(1+|x|)^{-1}$ for every $x \in \mathbb{R}$ and some $B > 0$, all of the quantities in the last expression on the right-hand side in (3.4) are finite. The proof of (a) is complete.

Next, we prove that $S\big|_X$ determines a compact and self-adjoint operator. Let

$$
\widetilde{K}(n,j) = \frac{K(n-j)}{\omega_\theta(n)\omega_\theta(j)};
$$

then, by the Cauchy–Schwarz inequality we have

$$
\begin{aligned}
&\sum_n \sum_j \widetilde{K}^2(n,j)\omega_\theta(n)\omega_\theta(j) = \sum_n \sum_j \frac{K^2(n-j)}{\omega_\theta(n)\omega_\theta(j)} \\
= \quad &\sum_n (K^2 * \mu)(n)\mu(n) \leq ||K^2 * \mu||_{\ell^2} ||\mu||_{\ell^2} \leq ||K^2||_{\ell^1} ||\mu||_{\ell^2}^2 < \infty.
\end{aligned}
$$

That is, $S_\theta\alpha(n) = \sum_{j=-\infty}^{\infty} \widetilde{K}(n,j)\alpha_n\omega_\theta(j)$ is a Hilbert–Schmidt operator, and thus $S\big|_X$ is compact. To prove that S_θ is self-adjoint it is necessary to observe that ω_θ and $\widehat{\varphi_c}$ being even, the real kernel K is symmetric. □

The next two results are immediate consequences of Proposition 3.2 and the spectral theorem for compact, self-adjoint operators on a Hilbert space.

COROLLARY 3.1. *Suppose $\theta \geq 0$. Then, 1 is an eigenvalue of S_θ (as an operator of X) if and only if $-\theta$ is an eigenvalue of $\mathcal{L}$ (as an operator of L^2_{2L}). Furthermore, both eigenvalues have the same multiplicity.* □

COROLLARY 3.2. *For every $\theta \geq 0$, S_θ has a family of eigensequences $\{\psi_{i,\theta}\}_{i=0}^{\infty}$ forming an orthonormal basis of X with respect to the norm $||\cdot||_{X,\theta}$. The eigensequences correspond to real eigenvalues $\{\lambda_i(\theta)\}_{i=0}^{\infty}$ whose only possible accumulation point is zero.* □

In this way, the eigenvalues can be enumerated in order of decreasing absolute value, that is, $|\lambda_0(\theta)| \geq |\lambda_1(\theta)| \geq |\lambda_2(\theta)| \geq \cdots$.

4. Positivity properties for periodic travelling-wave solutions. In this section we give sufficient conditions to obtain properties (P_1) and (P_2) in (1.10).

DEFINITION 4.1. *We say that a sequence $\alpha = (\alpha_n)_{n\in\mathbb{Z}} \subseteq \mathbb{R}$ is in the class $PF(2)$ discrete if*

(i) $\alpha_n > 0$ *for all* $n \in \mathbb{Z}$,

(ii) $\alpha_{n_1-m_1}\alpha_{n_2-m_2} - \alpha_{n_1-m_2}\alpha_{n_2-m_1} > 0$ *for* $n_1 < n_2$ *and* $m_1 < m_2$.

The definition above is a particular case of the continuous ones which appear in [2] and [32]; namely, we say that a function $g : \mathbb{R} \to \mathbb{R}$ is in the class $PF(2)$ if

(i) $g(x) > 0$ for all $x \in \mathbb{R}$,

(ii) $g(x_1 - y_1)g(x_2 - y_2) - g(x_1 - y_2)g(x_2 - y_1) > 0$ for $x_1 < x_2$ and $y_1 < y_2$.

As an example, consider $g(x) = \operatorname{sech}^2(x)$.

The next result gives us a sufficient condition for a function g belonging to the $PF(2)$ continuous class. This result is very useful for our purpose (see [3]).

LEMMA 4.1. *Suppose g is a positive, twice-differentiable function on $\mathbb{R}$ satisfying*

$$\frac{d^2}{dx^2}(\log g(x)) < 0 \quad \textit{for} \quad x \neq 0.$$

Then $g \in PF(2)$. □

The main result of this paper is now presented.

THEOREM 4.1. *Suppose that φ_c is a positive even solution of* (1.6) *such that $\widehat{\varphi_c} > 0$ and $K = \widehat{\varphi_c^p} \in PF(2)$ discrete. Then (P_1) and (P_2) in* (1.10) *hold for the operator $\mathcal{L}$ in* (1.7).

Proof. First, we noticed that, S_θ being a compact operator on X, we get a set of eigenvalues $\{\lambda_i(\theta)\}_{i=0}^{\infty}$ and the corresponding set of eigenfunctions $\{\psi_{i,\theta}\}_{i=0}^{\infty}$, which form an orthonormal basis for X. Moreover, we have $|\lambda_0(\theta)| \geq |\lambda_1(\theta)| \geq |\lambda_2(\theta)| \geq \cdots$. It will show that the eigenvalues $\lambda_0(\theta)$ and $\lambda_1(\theta)$ *are positive, distinct, and simple.* In fact, since $S_\theta\big|_X$ is a compact, self-adjoint operator it follows that

$$\lambda_0(\theta) = \pm \sup_{||\alpha||_X = 1} |\langle S_\theta \alpha, \alpha \rangle_X|. \tag{4.1}$$

Let $\psi(\theta) := \psi$ be an eigensequence of S_θ corresponding to $\lambda_0(\theta) := \lambda_0$. We will show that ψ is one-signed; that is, either $\psi(n) \leq 0$ or $\psi(n) \geq 0$. By contradiction, suppose ψ takes both negative and positive values. Since by hypotheses the kernel K *is positive* we have

$$\begin{aligned} S_\theta|\psi|(n) &= \frac{1}{\omega_\theta(n)} \sum_{j=-\infty}^{\infty} K(n-j)\psi^+(j) + \frac{1}{\omega_\theta(n)} \sum_{j=-\infty}^{\infty} K(n-j)\psi^-(j) \\ &> \left| \frac{1}{\omega_\theta(n)} \sum_{j=-\infty}^{\infty} K(n-j)\psi^+(j) - \frac{1}{\omega_\theta(n)} \sum_{j=-\infty}^{\infty} K(n-j)\psi^-(j) \right|, \end{aligned}$$

where ψ^+ e ψ^- are the positive and negative parts of ψ, respectively. Then,

$$S_\theta|\psi|(n) > \left| \frac{1}{\omega_\theta(n)} \sum_{j=-\infty}^{\infty} K(n-j)\psi(j) \right| = |S_\theta\psi(n)| = |\lambda_0||\psi(n)|,$$

where "$>$" holds because ψ, by supposition, takes both positive and negative values. From the last inequality we conclude that

$$\begin{aligned} \langle S_\theta(|\psi|), |\psi| \rangle_{X,\theta} &= \sum_{n=-\infty}^{\infty} S_\theta|\psi|(n)|\psi(n)|\omega_\theta(n) \\ &> \sum_{n=-\infty}^{\infty} |\lambda_0||\psi(n)|^2\omega_\theta(n) = |\lambda_0|\|\psi\|_{X,\theta}^2. \end{aligned}$$

Hence, if we assume that $||\psi||_X = 1$, we obtain $\langle S_\theta(|\psi|), |\psi|\rangle_X\rangle|\lambda_0|$, which contradicts (4.1). Then, there is an eigensequence ψ_0 which is nonnegative. Since K *is a positive sequence* and $S_\theta(\psi_0) = \lambda_0\psi_0$, we have $\psi_0(n) > 0$ for all $n \in \mathbb{Z}$. Now, such a ψ_0 cannot be orthogonal to any nontrivial one-signed eigensequence in X, and so λ_0 is a simple eigenvalue. Notice that the preceding argument also shows that $-\lambda_0$ cannot be an eigenvalue of S_θ; therefore it follows that $|\lambda_1| < \lambda_0$.

Next, we will study the eigenvalue $\lambda_1(\theta) = \lambda_1$. But, first, we need some definitions and results. We consider the following set of indices:

$$\triangle = \{(n_1, n_2) \in \mathbb{Z} \times \mathbb{Z};\ n_1 < n_2\}.$$

Denoting $\overline{n} = (n_1, n_2)$ and $\overline{m} = (m_1, m_2)$, we define for $\overline{n}$, $\overline{m} \in \triangle$ the following sequence:

$$K_2(\overline{n}, \overline{m}) := K(n_1 - m_1)K(n_2 - m_2) - K(n_1 - m_2)K(n_2 - m_1).$$

By hypothesis $K \in PF(2)$ discrete it follows that $K_2 > 0$. Next, let $\ell^2(\triangle)$ be defined as

$$\ell^2(\triangle) = \left\{ \alpha = (\alpha_{\overline{n}})_{\overline{n}\in\triangle}; \sum\sum_{\triangle} |\alpha_{\overline{n}}|^2 := \sum_{n_1\in\mathbb{N}} \sum_{\substack{n_1<n_2 \\ n_2\in\mathbb{Z}}} |\alpha(n_1, n_2)|^2 < +\infty \right\},$$

and define the operator $S_{2,\theta} : \ell^2(\triangle) \to \ell^2(\triangle)$ by

$$S_{2,\theta}g(\overline{n}) = \sum\sum_{\triangle} G_{2,\theta}(\overline{n}, \overline{m})g(\overline{m}),$$

where $G_{2,\theta}(\overline{n}, \overline{m}) = \frac{K_2(\overline{n},\overline{m})}{\omega_\theta(n_1)\omega_\theta(n_2)}$. We also consider the space

$$W = \left\{ \alpha \in \ell^2(\triangle); ||\alpha||_{W,\theta} := \left(\sum\sum_{\triangle} |\alpha(\overline{n})|^2 \omega_\theta(n_1)\omega_\theta(n_2) \right)^{\frac{1}{2}} < \infty \right\}.$$

Then W is a Hilbert space with norm $||\cdot||_{W,\theta}$ given above and with inner product

$$\langle \alpha, \beta\rangle_{W,\theta} = \sum\sum_{\triangle} \alpha(\overline{n})\overline{\beta(\overline{n})}\omega_\theta(n_1)\omega_\theta(n_2).$$

Remark 4.1. (1) We can show, in an analogous way to Proposition 3.2, that $S_{2,\theta}\big|_W$ is a self-adjoint, compact operator. Therefore, the associated eigenvalues can be enumerated in order of decreasing absolute value, that is, $|\mu_0(\theta)| \geq |\mu_1(\theta)| \geq |\mu_2(\theta)| \geq \cdots$.

(2) A similar argument can be used to show that $\mu_0(\theta) := \mu_0$ is positive and simple and $|\mu_1| < \mu_0$.

Definition 4.2. *Let α^1, $\alpha^2 \in \ell^2(\mathbb{Z})$; we define the wedge product $\alpha^1 \wedge \alpha^2$ in $\triangle$ by*

$$(\alpha^1 \wedge \alpha^2)(n_1, n_2) = \alpha^1(n_1)\alpha^2(n_2) - \alpha^1(n_2)\alpha^2(n_1).$$

We have the following results from Definition 4.2.

Lemma 4.2. *Let $A = \{\alpha^1 \wedge \alpha^2;$ for $\alpha^1,\ \alpha^2 \in X,\ \alpha^1 \wedge \alpha^2 \in \ell^2(\triangle)\}$. Then A is dense in W.*

Proof. See [31] and [32]. □

LEMMA 4.3. *Let* $\alpha^1,\ \alpha^2 \in \ell^2(\mathbb{Z})$. *Then* $S_{2,\theta}(\alpha^1 \wedge \alpha^2) = S_\theta\alpha^1 \wedge S_\theta\alpha^2$.

Proof. See [31] and [32]. □

In what follows, we will represent by S_θ^X the restriction of S_θ on the Hilbert space X. We shall use some spectral results in Kato [33]. In fact, we decompose S_θ^X into the form $S_\theta^X = \lambda_0 P_\theta + Q_\theta$, where P_θ is the orthogonal projection on $M_0 = [\psi_0]$, $P_\theta Q_\theta = Q_\theta P_\theta = 0$, and $spectrum(Q_\theta) = spectrum(P_\theta) \setminus \{\lambda_0\}$. Moreover, in this case we have that the spectral radius of Q_θ when restricted to the subspace $N = \mathrm{Ker}P_\theta$ is exactly $|\lambda_1|$. Furthermore, we know that the eigenvalue $\lambda_0 = \lambda_0(\theta)$ is differentiable with respect to $\theta \geq 0$. The same argument can be applied to μ_0. Then, as a consequence ψ_0 and $\tau_0 =$ eigensequence associated with μ are differentiable eigensequences with respect to θ.

LEMMA 4.4. (a) *In the notation given above we have*

$$\frac{(S_\theta^X)^m}{\lambda_0^m} \longrightarrow P_\theta,$$

where $m \to +\infty$ *on the strong topology of* $B(X, X)$.

(b) *The statement in part* (a) *is valid if* S_θ^X *is replaced by* $S_{2,\theta}$, *the eigenvalues* λ_0 *and* λ_1 *are replaced by* μ_0 *and* μ_1, *and* P_θ, M_0, *and* Q_θ *are replaced by appropriate operators and subspaces of* X.

Proof. The proof is analogous as viewed in [2], [3] in the case of sequences. □

LEMMA 4.5. (a) $\mu_0(\theta) = \lambda_0(\theta)\lambda_1(\theta)$. *Then, we can conclude that* $\lambda_1 > 0$.

(b) λ_1 *is simple.*

Proof. (a) In fact, from Lemma 4.3 we have that $\lambda_0\lambda_1$ is an eigenvalue of $S_{2,\theta}$ whose eigensequence is $\psi_0 \wedge \psi_1$, where $\psi_1(\theta) := \psi_1$ is the eigensequence associated with λ_1. Hence $\mu_0 \geq \lambda_0|\lambda_1|$. Then, since $-\mu_0$ cannot be an eigenvalue of $S_{2,\theta}$, we will show that $\mu_0 \leq \lambda_0|\lambda_1|$. If $|\lambda_1| < \frac{\mu_0}{\lambda_0}$, let P_θ be as in Lemma 4.4 and write $W = M_0 \oplus N$. Let $\alpha^1 = r_1\psi_0 + \omega\gamma^1$ and $\alpha^2 = r_2\psi_0 + \omega\gamma^2$, where $r_1,\ r_2 \in \mathbb{R}$ and $\gamma^1,\ \gamma^2 \in N$. For instance, from the induction principle we have

(4.2)

$$\begin{aligned}\left(\frac{S_{2,\theta}}{\mu_0}\right)^m \left(\alpha^1 \wedge \alpha^2\right)(n_1, n_2) &= r_1\left[\psi_0(n_1)\left(\frac{S_\theta}{\beta}\right)^m \gamma^2(n_2) - \psi_0(n_2)\left(\frac{S_\theta}{\beta}\right)^m \gamma^2(n_1)\right] \\ &+ r_2\left[\psi_0(n_2)\left(\frac{S_\theta}{\beta}\right)^m \gamma^1(n_1) - \psi_0(n_1)\left(\frac{S_\theta}{\beta}\right)^m \gamma^1(n_2)\right] \\ &+ \left(\frac{S_\theta}{\lambda_0}\right)^m \gamma^1(n_1)\left(\frac{S_\theta}{\beta}\right)^m \gamma^2(n_2) \\ &- \left(\frac{S_\theta}{\lambda_0}\right)^m \gamma^1(n_2)\left(\frac{S_\theta}{\beta}\right)^m \gamma^2(n_1),\end{aligned}$$

where $\beta = \frac{\mu_0}{\lambda_0} > |\lambda_1|$. Since $(\frac{S_\theta^X}{\lambda_0})^m \to P_\theta$ with $P_\theta \equiv 0$ on N and β is strictly greater than the spectral radius of the restriction of S_θ^X to N, each term on the right-hand side of the preceding equality tends to zero as $m \to \infty$. But the set A defined in Lemma 4.2 is dense in W. Then, we can conclude from (4.2), after a computation, that $(\frac{S_{2,\theta}}{\mu_0})^m g \to 0$ strongly. But this contradicts Lemma 4.4. The proof of item (a) is completed.

(b) The next step is to show that λ_1 is simple. We write $\psi_1 = \psi_1^P + \psi_1^I$, where ψ_1^P and ψ_1^I denote, respectively, the even and odd parts of ψ_1. We begin by showing that $\psi_1^P \equiv 0$. Since the kernel K of S_θ is symmetric and ω_θ is even, we have S_θ map even sequences into even sequences and odd sequences into odd sequences. Then, we get that $\psi_0 \wedge \psi_1^P$ satisfies $S_{2,\theta}(\psi_0 \wedge \psi_1^P) = \lambda_0\lambda_1(\psi_0 \wedge \psi_1^P)$. Since $\mu_0 > 0$ and simple we obtain $\psi_0 \wedge \psi_1^P \in [\tau_0]$. Therefore, either $\psi_0 \wedge \psi_1^P \equiv 0$ or $\psi_0 \wedge \psi_1^P \neq 0$; that is, $\psi_0 \wedge \psi_1^P$ is one-signed. With this fact, if ψ_1^P does not vanish, then it will have at most one zero. Then, ψ_1^P being an even sequence, either $\psi_1^P \equiv 0$ or else ψ_1^P is one-signed, except possibly in $n = 0$. If the second case holds, we have to consider three cases: $\psi_1^P(0) = 0$, $\psi_1^P(0) > 0$, and $\psi_1^P(0) < 0$. If $\psi_1^P(0) = 0$, then we should have, from the definition of wedge product above, that $0 < (\psi_0 \wedge \psi_1^P)(0, n) = \psi_0(0)\psi_1^P(n)$ for $n > 0$ (where we are assuming that $\psi_0 > 0$ and $\psi_0 \wedge \psi_1^P > 0$). Then, $\psi_1^P(n) > 0$ for all $n \in \mathbb{Z}$ because $\psi_1^P(n)$ is an even sequence. Next, if $\psi_1^P(0) > 0$, then for $n > 0$ we get $0 < (\psi_0 \wedge \psi_1^P)(0, n) = \psi_0(0)\psi_1^P(n) - \psi_0(n)\psi_1^P(0) < \psi_0(0)\psi_1^P(n)$ and therefore $\psi_1^P > 0$. The last case is similar to the second one. These considerations make ψ_1^P a one-signed eigensequence of S_θ (except possibly in $n \neq 0$), and so the inner product $\langle \psi_1^P, \psi_0 \rangle_{X,\theta}$ is also one-signed. But this a contradiction because we have two eigensequences of a self-adjoint operator associated with distinct eigenvalues whose inner product is nonzero. Therefore, $\psi_1^P \equiv 0$, and so ψ_1 is odd. A similar argument shows that ψ_1 can have at most one zero. Of course, this one must be in $n = 0$.

The sequence ψ_1 shown previously was an arbitrary sequence, and this is associated with eigenvalue λ_1. Then, we show that any eigensequence ψ associated with λ_1 must be odd and $\psi(n) = 0 \Leftrightarrow n = 0$. But, two eigensequences of this kind cannot be orthogonal since the product of them is even, and thus λ_1 is simple. This fact completes the proof of the lemma. □

We turn back to the proof of Theorem 4.1. Let us consider $||\psi_i(\theta)||_{X,\theta} = 1$ for $i = 0, 1$. From Lemma 4.5, $\mu_0(\theta) = \lambda_0(\theta)\lambda_1(\theta)$ with μ_0 and λ_0 differentiable with respect to θ, and we have that λ_1 is also differentiable with respect to this parameter. Hence, the associated eigensequence ψ_1 is also differentiable since $S_\theta\psi_1(\theta) = \lambda_1(\theta)\psi_1(\theta)$. Next, we will show that

$$\frac{d}{d\theta}\lambda_i(\theta) < 0, \quad i = 0, 1, \quad \theta \geq 0. \tag{4.3}$$

In fact, writing $\psi_i(\theta)$, $i = 0, 1$, instead of $\psi_{i,\theta}(n)$, we have

$$\frac{d}{d\theta}\lambda_i(\theta) = \frac{d}{d\theta}\sum_{n=-\infty}^{\infty} S_\theta\psi_i(\theta)\psi_i(\theta)\omega_\theta(n).$$

Thus,

$$\begin{aligned}
\frac{d}{d\theta}\lambda_i(\theta) &= 2\sum_{n=-\infty}^{\infty}\frac{d}{d\theta}\psi_i(\theta)S_\theta\psi_i(\theta)\omega_\theta(n) = 2\lambda_i(\theta)\sum_{n=-\infty}^{\infty}\left(\frac{d}{d\theta}\psi_i(\theta)\right)\psi_i(\theta)\omega_\theta(n) \\
&= 2\lambda_i(\theta)\left\{\frac{d}{d\theta}\frac{1}{2}\left(\sum_{n=-\infty}^{\infty}\psi_i(\theta)^2\omega_\theta(n)\right) - \frac{1}{2}\sum_{n=-\infty}^{\infty}\psi_i(\theta)^2\right\} \\
&= -\lambda_i(\theta)\sum_{n=-\infty}^{\infty}\psi_i(\theta)^2 < 0,
\end{aligned}$$

which shows the affirmation. Next, for $\theta \geq 0$,

$$\begin{aligned}\lambda_0(\theta) &= r(S_\theta^X) = ||S_\theta^X||_{B(X,X)} \leq \left(\sum_{n=-\infty}^{\infty} \sum_{m=-\infty}^{\infty} \left\{ \frac{K(n-m)}{\omega_\theta(n)} \right\}^2 \right)^{\frac{1}{2}} \\ &= \left\| K^2 * \frac{1}{\omega_\theta^2} \right\|_{\ell^1(\mathbb{Z})}^{\frac{1}{2}} \leq \|K\|_{\ell^2(\mathbb{Z})} \left\| \frac{1}{\omega_\theta} \right\|_{\ell^2(\mathbb{Z})}.\end{aligned}$$

Since $\frac{1}{\omega_\theta} \to 0$ as $\theta \to +\infty$ and $(\frac{1}{\omega_\theta})^2 \in \ell^1$ with $|\frac{1}{\omega_\theta}|^2 \leq (\frac{B}{1+|n|})^2$, for some $B > 0$, $\|\frac{1}{\omega_\theta}\|_{\ell^2} \to 0$ as $\theta \to +\infty$. Therefore,

$$\lim_{\theta \to +\infty} \lambda_0(\theta) = 0. \tag{4.4}$$

The next step is to show that

$$\lambda_1(0) = 1. \tag{4.5}$$

In fact, since $\frac{d}{dx}\varphi_c$ is an eigenfunction of $\mathcal{L}$ with eigenvalue $\theta = 0$, we can conclude from Corollary 3.1 that $\widehat{\frac{d}{dx}\varphi_c}$ is an eigensequence of S_θ with eigenvalue 1. On the other hand, $\widehat{\frac{d}{dx}\varphi_c}(n) = -in\frac{\pi}{L}\widehat{\varphi}_c(n)$ is odd and vanishes only at $n = 0$. Since ψ_1 is also odd and vanishes at $n = 0$ we must have $\langle \psi_1, \widehat{\frac{d}{dx}\varphi_c} \rangle_{X,\theta} \neq 0$. It follows that ψ_1 and $\widehat{\frac{d}{dx}\varphi_c}$ cannot be eigensequences of S_θ for distinct eigenvalues. Then, ψ_1 and $\widehat{\frac{d}{dx}\varphi_c}$ are associated with the same eigenvalue, and therefore $\lambda_1(0) = 1$. With this fact, since $\lambda_0(0) > \lambda_1(0) = 1$, from (4.3) and (4.4) it follows that there is a unique $\theta_0 \in (0, +\infty)$ such that $\lambda_0(\theta_0) = 1$. Then, from Corollary 3.1, if we consider $\kappa = -\theta_0 < 0$, then $\mathcal{L}$ has a negative eigenvalue which is simple. Now, for $i \geq 2$ and $\theta > 0$ we have from (4.5) that

$$\lambda_i(\theta) \leq \lambda_1(\theta) < \lambda_1(0) = 1.$$

It is straightforward to see that 1 cannot be an eigenvalue of S_θ for all $\theta \in (0, +\infty) \setminus \{\theta_0\}$, since 1 is an eigenvalue only for $\theta = 0$ and $\theta = \theta_0$. Then we obtain (P_1).

Because $\lambda_1(0) = 1$ and λ_1 is a simple eigenvalue it follows that $\theta = 0$ is a simple eigenvalue of $\mathcal{L}$ by the Corollary 3.1. This fact shows (P_2) and as a consequence the theorem. □

Remark 4.2. The Fourier transform in Theorem 4.1 needs to be evaluated in the minimal period of φ_c (see section 6).

5. Stability of periodic travelling-wave solutions. In this section we are interested in applying the theory in section 4 to obtain the stability of specific periodic travelling waves associated with the KdV, mKdV, and BO equations. Our approach to obtain condition (P_0) in (1.10) will be based on the Poisson summation theorem and the implicit function theorem. This new approach, in the periodic context, will give a simple way to calculate condition (P_3) in (1.10). We start with the definition of stability.

DEFINITION 5.1. *Let φ be a periodic travelling-wave solution with period $2L$ of (1.6), and consider $\tau_r\varphi(x) = \varphi(x + r)$, $x \in \mathbb{R}$, and $r \in \mathbb{R}$. We define the set $\Omega_\varphi \subset H_{2L}^{\frac{m_2}{2}}$, the orbit generated by φ, as*

$$\Omega_\varphi = \{g;\ g = \tau_r\varphi \text{ for some } r \in \mathbb{R}\}.$$

And, for any $\eta > 0$, define the set $U_\eta \subset H_{2L}^{\frac{m_2}{2}}$ by

$$U_\eta = \left\{ f;\ \inf_{g\in\Omega_\varphi} ||f-g||_{H_{2L}^{\frac{m_2}{2}}} < \eta \right\}.$$

With this terminology, we say that φ is (orbitally) stable in $H_{2L}^{\frac{m_2}{2}}$ by the flow generated by (1.3) *if the following hold:*

(i) *There is s_0 such that $H_{2L}^{s_0} \subseteq H_{2L}^{\frac{m_2}{2}}$ and the initial value problem associated with* (1.3) *is globally well-posed in $H_{2L}^{s_0}$ (see Theorems* 2.2 *and* 2.3*).*

(ii) *For every $\varepsilon > 0$, there is $\delta > 0$ such that, for all $u_0 \in U_\delta \cap H_{2L}^{s_0}$, the solution u of* (1.3) *with $u(0,x) = u_0(x)$ satisfies $u(t) \in U_\varepsilon$ for all $t > 0$.*

The proof of the following general stability theorem can be shown by using the techniques in Grillakis, Shatah, and Strauss [27] (see also Angulo [6]).

THEOREM 5.1. *Let φ_c be a periodic travelling-wave solution of* (1.6)*, and suppose that part* (i) *of the definition of stability holds. Suppose also that the operator $\mathcal{L}$ defined previously in* (1.7) *has properties* (P_1) *and* (P_2) *in* (1.10)*. Choose $\chi \in L_{2L}^2$ such that $\mathcal{L}\chi = \varphi_c$, and define $I = (\chi, \varphi_c)_{L_{2L}^2}$. If $I < 0$, then φ_c is stable.*

Remark 5.1. In our cases the function χ in Theorem 5.1 satisfies that $\chi = -\frac{d}{dc}\varphi_c$. Then, we need to verify properties (P_0) and (P_3) in (1.10).

5.1. Stability of periodic travelling-wave solutions for the BO equation. This section is concerned with the stability theory of periodic travelling-wave solutions to the BO equation found initially by Benjamin in [13]. Next, we will present an interesting method for obtaining an explicit solution to the BO equation in (3.1), by using the Poisson summation theorem. In fact, consider the following equation:

$$\mathcal{H}\phi_\omega' + \omega\phi_\omega - \frac{1}{2}\phi_\omega^2 = 0.$$

This equation determines solitary travelling-wave solutions to the BO equation on $\mathbb{R}$ in the form

$$\phi_\omega(x) = \frac{4\omega}{1+\omega^2x^2}, \quad \omega > 0.$$

Its Fourier transform is given by

$$\widehat{\phi_\omega}^{\mathbb{R}}(x) = 4\pi e^{\frac{-2\pi}{\omega}|x|}.$$

Then, by the Poisson summation theorem, we obtain that

$$\begin{aligned}
\psi_\omega(x) &\equiv \sum_{n=-\infty}^{+\infty} \phi_\omega(x+2Ln) = \frac{2\pi}{L}\sum_{n=-\infty}^{+\infty} e^{\frac{-\pi|n|}{\omega L}} e^{\frac{\pi i n x}{L}} \\
&= \frac{2\pi}{L}\sum_{n=0}^{+\infty} \varepsilon_n e^{\frac{-\pi n}{\omega L}} \cos\left(\frac{n\pi x}{L}\right) = \frac{2\pi}{L}\mathrm{Re}\left[\coth\left(\frac{\pi}{2\omega L} + \frac{i\pi x}{2L}\right)\right] \qquad (5.1)\\
&= \frac{2\pi}{L}\left(\frac{\operatorname{senh}\left(\frac{\pi}{\omega L}\right)}{\cosh\left(\frac{\pi}{\omega L}\right) - \cos\left(\frac{\pi x}{L}\right)}\right),
\end{aligned}$$

where

$$\varepsilon_n = \begin{cases} 1 & \text{if} \quad n = 0, \\ 2 & \text{if} \quad n = 1,2,3,\ldots. \end{cases}$$

Let φ_c, $c>0$, be a smooth periodic solution of the first equation in (3.1). Thus, φ_c can be expressed as a Fourier series

$$\varphi_c(x)=\sum_{n=-\infty}^{+\infty} a_n e^{\frac{in\pi x}{L}}. \tag{5.2}$$

Substituting the expression above into the BO equation in (3.1), we get

$$\left[\frac{\pi|n|}{L}+c\right]a_n=\frac{1}{2}\sum_{m=-\infty}^{+\infty}a_{n-m}a_m.$$

Next, from (5.1) we consider $a_n\equiv\frac{2\pi}{L}e^{-\gamma|n|}$, $n\in\mathbb{Z}$, $\gamma\in\mathbb{R}$. Substituting a_n into the last identity we have

$$\sum_{m=-\infty}^{+\infty}a_{n-m}a_m=\frac{4\pi^2}{L^2}e^{-\gamma|n|}\left[|n|+1+2\sum_{k=1}^{+\infty}e^{-2\gamma k}\right]=\frac{4\pi^2}{L^2}e^{-\gamma|n|}(|n|+\coth\gamma).$$

Then, we conclude that

$$c+\frac{\pi|n|}{L}=\frac{2\pi}{L}\cdot\frac{1}{2}(|n|+\coth\gamma). \tag{5.3}$$

We denote $\gamma=\frac{\pi}{\omega L}$ and consider $c>\frac{\pi}{L}$. Then, if we choose $\omega=\omega(c)>0$ such that $\tanh(\gamma)=\frac{\pi}{cL}$, we obtain from (5.3) that $\psi_{\omega(c)}=\varphi_c$ (hence, φ_c is given by (5.1)). Therefore, we obtain that φ_c has the form in (1.13) with $\gamma>0$ satisfying $\tanh(\gamma)=\frac{\pi}{cL}$.

Thus, from (5.1) we have that $\varphi_c>0$, and $\gamma:=\gamma(c)=\tanh^{-1}\left(\frac{\pi}{cL}\right)$ being a differentiable function for $c>\frac{\pi}{L}$, it follows that

$$c\in\left(\frac{\pi}{L},+\infty\right)\mapsto\varphi_c\in H^n_{2L}$$

is a smooth curve of periodic travelling-wave solutions for the BO equation for all $n\in\mathbb{N}$. Then, by defining χ in Theorem 5.1 as $\chi=-\frac{d}{dc}\varphi_c$, we obtain from the first equation in (3.1) that $\mathcal{L}\chi=\varphi_c$. Then $I=(\chi,\varphi_c)_{L^2_{2L}}$ becomes

$$I=-\frac{1}{2}\frac{d}{dc}||\varphi_c||^2_{L^2_{2L}}. \tag{5.4}$$

We will show that $I<0$. Indeed, from (5.2) and (5.1) we get

$$\varphi_c(x)=\frac{2\pi}{L}\sum_{n=-\infty}^{+\infty}e^{-\gamma|n|}e^{\frac{\pi inx}{L}}; \tag{5.5}$$

then, from the Parseval theorem we conclude that

(5.6)

$$\begin{aligned} I &= -\frac{1}{2}\frac{d}{dc}||\varphi_c||^2_{L^2_{2L}}=-\frac{1}{2}\frac{d}{dc}||\widehat{\varphi_c}||^2_{\ell^2}\cdot 2L=-\frac{1}{2}\frac{d}{dc}\left(\frac{4\pi^2}{L^2}\sum_{n=-\infty}^{\infty}e^{-2\gamma|n|}\right)\cdot 2L\\ &= -\frac{4\pi^3}{c^2L^3}\left(\frac{1}{1-\left(\frac{\pi}{cL}\right)^2}\right)\left(\sum_{n=-\infty}^{\infty}|n|e^{-2\gamma|n|}\right)\cdot 2L<0. \end{aligned}$$

Finally, we will verify that conditions (P_1) and (P_2) are true for the operator

$$\mathcal{L}_{BO} = \mathcal{H}\partial_x + c - \varphi_c.$$

Let $\widehat{\varphi_c}(n) = \frac{2\pi}{L} e^{-\gamma|n|}$ be the Fourier coefficients of φ_c. In Albert [2] it has already been seen that the function $f(x) = e^{-\gamma|x|}$ belongs to the $PF(2)$ class in the continuous case, and so $\widehat{\varphi_c}$ is in the $PF(2)$ class in the sense of Definition 4.1. Hence, we obtain from Theorem 2.3 the stability of the periodic solutions (1.13) in $H^{\frac{1}{2}}_{2L}$ by the periodic flow of the BO equation.

5.1.1. Stability of the constant solutions. To complete the investigation about periodic travelling-wave solutions for the BO equation, we will study the stability of the constant solutions. Hence, if $\varphi_c(x) \equiv \tau$ is a constant solution to the BO equation, we have $\varphi_c \equiv 2c$ and $\varphi_c \equiv 0$ as solutions. We consider only the first case. The next result will resume our purpose.

PROPOSITION 5.1. *Let $L > 0$ and $c > 0$ be given. Consider $\psi_0 \equiv 2c$ to be a nontrivial constant solution of* (3.1). *Then, ψ_0 is stable in $H^{\frac{1}{2}}_{2L}([-L, L])$, provided $c < \frac{\pi}{L}$.*

Proof. The proof of this proposition follows from standard ideas (see [10], [15]) and from the following nonlocal Poincaré–Wirtinger-type inequality: for $f \in H^{\frac{1}{2}}_{2L}$ such that $\int_{-L}^{L} f(x)dx = 0$, we have $\int_{-L}^{L} [D^{\frac{1}{2}} f(x)]^2 dx \geq \frac{\pi}{L} \int_{-L}^{L} f^2(x)dx$, where $D = \mathcal{H}\partial_x$ (see the appendix for a proof of this inequality). □

5.2. Stability of periodic travelling-wave solutions for the mKdV equation. Next, we will establish the existence of a smooth curve of periodic travelling-wave solutions for the mKdV equation

$$u_t + 3u^2 u_x + u_{xxx} = 0, \tag{5.7}$$

of the form $u(x,t) = \varphi(x - ct) := \varphi_c(\xi)$, where $\xi = x - ct$, $c \in \mathbb{R}$, and is of period L. The equation which determines the periodic travelling-wave solutions is

$$\varphi_c{}'' + \varphi_c^3 - c\varphi_c = 0. \tag{5.8}$$

Next, we obtain an explicit solution for (5.8) using the Poisson summation theorem. It considers for $\omega > 0$ the solitary wave solutions for the mKdV equation on $\mathbb{R}$:

$$\phi_\omega(x) = \sqrt{2\omega}\, \mathrm{sech}(\sqrt{\omega}x), \quad x \in \mathbb{R}.$$

Its Fourier transform is $\widehat{\phi}_\omega(x) = \sqrt{2}\pi \mathrm{sech}(\frac{\pi x}{2\sqrt{\omega}})$, where $\omega > 0$, and it will be chosen later. From the Poisson summation theorem we obtain the following periodic function of period L:

$$\psi_\omega(\xi) = \frac{\sqrt{2}\pi}{L} \sum_{n=0}^{\infty} \varepsilon_n \mathrm{sech}\left(\frac{\pi n}{2\sqrt{\omega}L}\right) \cos\left(\frac{2\pi n \xi}{L}\right), \tag{5.9}$$

where

$$\varepsilon_n = \begin{cases} 1, & n = 0, \\ 2, & n = 1, 2, 3 \ldots. \end{cases}$$

On the other hand, it considers the Fourier expansion of the Jacobi elliptic function *dnoidal*, dn, of period L (see [19], [35], [42]),

$$\frac{2K}{L}\mathrm{dn}\left(\frac{2K\xi}{L};k\right)=\frac{\pi}{L}+\frac{4\pi}{L}\sum_{n=1}^{+\infty}\frac{q^n}{1+q^{2n}}\cos\left(\frac{2n\pi\xi}{L}\right),$$

where $K=K(k)$ is the complete elliptic integral of the first kind and $q=e^{(-\frac{\pi K'}{K})}$, which is called the "nome." Here, $K'(k)=K(\sqrt{1-k^2})$. We can conclude that

$$\frac{q^n}{1+q^{2n}}=\frac{1}{2}\mathrm{sech}\left(\frac{n\pi K'}{K}\right).$$

Therefore,

$$\frac{2K}{L}\mathrm{dn}\left(\frac{2K\xi}{L};k\right)=\frac{\pi}{L}+\frac{2\pi}{L}\sum_{n=1}^{+\infty}\mathrm{sech}\left(\frac{n\pi K'}{K}\right)\cos\left(\frac{2n\pi\xi}{L}\right).$$

Because of the shape of the series that determines ψ_ω given above (see [35]), let $\varphi_c(\xi)=\eta\mathrm{dn}(\frac{\eta\xi}{\sqrt{2}};k)$ be a periodic solution of period L for (5.8), with $\eta>0$ and $k\in(0,1)$ fixed. Then, the following identities should be satisfied:

$$c=\frac{\eta^2}{2}(1+k'^2)\ \text{ and }\ \eta=\frac{2\sqrt{2}K(k)}{L} \tag{5.10}$$

with $k'^2=1-k^2$. Thus, for $k\in(0,1)$ we should have that $\eta\in(\sqrt{c},\sqrt{2c})$ and from the asymptotic properties of K that $c>\frac{2\pi^2}{L^2}$. Next, for $k\in(0,1)$ fixed, η is immediately defined from (5.10), and so

$$c=\frac{4K^2(k)}{L^2}(2-k^2)>\frac{2\pi^2}{L^2} \tag{5.11}$$

since $k\to K^2(k)(2-k^2)$ is a strictly increasing function. Therefore, with $k\in(0,1)$ and c defined in (5.11) we define $\omega=\omega(c)$ as

$$\omega=\frac{c}{16(2-k^2)K'^2(k)}.$$

Therefore, from (5.9) it follows that $\psi_{\omega(c)}=\varphi_c$ is a solution of (5.8).

Next, it is necessary to build a smooth curve, $c\to\varphi_c$, of dnoidal wave solutions. Initially, we obtain the following a priori estimate for the fundamental period of φ_c. Namely,

$$T_{\varphi_c}(\eta)=\frac{2K(k(\eta))}{\sqrt{c}}\sqrt{2-k^2}>\frac{\sqrt{2}\pi}{\sqrt{c}}, \tag{5.12}$$

where $k^2(\eta)=2-\frac{2c}{\eta^2}$. In fact, for $\eta\to\sqrt{c}$ it follows that $k\to0^+$ and thus $T_{\varphi_c}(\eta)\to\frac{\pi\sqrt{2}}{\sqrt{c}}$. For $\eta\to\sqrt{2c}$ we have $k\to1^-$ and therefore $T_{\varphi_c}(\eta)\to+\infty$. But, $\eta\mapsto T_{\varphi_c}(\eta)$ being a strictly increasing function (see Theorem 2.1 in Angulo [9]) we get (5.12).

Remark 5.2. The function φ_c obtained previously, that is,

$$\varphi_c(\xi)=\eta\mathrm{dn}\left(\frac{\eta}{\sqrt{2}}\xi;k\right), \tag{5.13}$$

is a positive function and has been built by the periodization of the solitary wave solution associated with (5.7). Thus, it is natural to ask if we can again obtain this solitary wave. Indeed, this fact can be determined by (5.13), since for $\eta \to \sqrt{2c}$ we have $k \to 1^-$ and then $\mathrm{dn}(u;1^-) = \mathrm{sech}(u)$. Hence we have formally that $\varphi_c(\xi) = \sqrt{2c}\ \mathrm{sech}(\sqrt{c}\xi)$. The other limit case, that is, $\eta \to \sqrt{c}$, we have $k \to 0^+$ and so $\mathrm{dn}(u;0^+) = 1$; then we get $\varphi_c(\xi) = \sqrt{c}$, the nontrivial constant solutions for the mKdV.

Now, we construct a family of dnoidal waves solutions with period L. Let $c > 0$ such that $\sqrt{c} > \frac{\pi\sqrt{2}}{L}$. Since $\eta \in (\sqrt{c}, \sqrt{2c}) \mapsto T_{\varphi_c}(\eta)$ is a strictly increasing mapping, it follows from (5.12) and from Theorem 2.1 in Angulo [9] that there is a unique $\eta \equiv \eta(c) \in (\sqrt{c}, \sqrt{2c})$ such that the fundamental period of the dnoidal wave φ_c will be $T_{\varphi_c}(\eta(c)) = L$. Moreover, we have $c \in \left(2\pi^2/L^2, +\infty\right) \to \varphi_c \in H^n_{per}([0,L])$ is a smooth curve, $c \in \left(2\pi^2/L^2, +\infty\right) \to \eta = \eta(c)$ is a strictly increasing function, and its derivative with respect to the velocity c is given by

$$\frac{d\eta}{dc} = \frac{\eta}{2c} + \frac{k^2k'^2\eta^3(2-k^2)K}{\sqrt{c^3}((2-k^2)E - 2(1-k^2)K)}.$$

The next result gives us a relation between the velocity of the solitary and periodic waves associated with the mKdV, and it will be useful later.

THEOREM 5.2. *We consider the mapping* $\omega : \left(2\pi^2/L^2, +\infty\right) \mapsto \mathbb{R}$, *given by*

$$\omega(c) = c/(16(2-k^2)K'^2(k)); \tag{5.14}$$

then $\frac{d\omega}{dc} > 0$.

Proof. Indeed, $\frac{d\omega}{dc} = [4(2-k^2)K'^2 + 8K'c\frac{dk}{dc}(kK' - (2-k^2)\frac{dK'}{dk})]/[16(2-k^2)^2K'^4]$. Since $\frac{dK'}{dk} = -(\frac{E'-k^2K'}{kk'^2}) < 0$, it suffices to show that $\frac{dk}{dc} > 0$. So, since

$$\frac{dk}{dc} = \frac{2}{\eta^3}\left(2c\frac{d\eta}{dc} - \eta\right),$$

we need to verify the sign of the expression $2c\frac{d\eta}{dc} - \eta$. Next, we calculate the exact value of $\frac{d\eta}{dc}$. In fact,

$$\frac{d\eta}{dc} = \frac{\eta}{2c} + \underbrace{\frac{k^2k'^2\eta^3(2-k^2)K}{\sqrt{c^3}((2-k^2)E - 2(1-k^2)K)}}_{A}.$$

Thus, $2c\frac{d\eta}{dc} - \eta = 2cA$ and therefore $\frac{dk}{dc} > 0$. This fact completes the proof of the theorem. □

Next, we will show that $\widehat{\varphi_c} > 0$ and $K = \widehat{\varphi_c^2}$ belongs to $PF(2)$ discrete. It is easy to see that $\widehat{\varphi_c} > 0$ because of the form of the Fourier coefficients of φ_c given by (5.9). Moreover, $\widehat{\varphi_c} \in PF(2)$ discrete because the function $f(x) = \mu\mathrm{sech}(\nu x)$ belongs to $PF(2)$ continuous (see [2]). So, since the convolution of even sequences in $PF(2)$ discrete is a sequence in $PF(2)$ discrete (see [32]) we can conclude that $K = \widehat{\varphi_c^2} \in PF(2)$ discrete. Now, by choosing $\chi = -\frac{d}{dc}\varphi_c$ we have that $\mathcal{L}\chi = \varphi_c$. Then, by the Parseval theorem, $I = -\frac{1}{2}\frac{d}{dc}\|\varphi_c\|^2_{L^2_{per}} = -\frac{L}{2}\frac{d}{dc}\|\widehat{\varphi_c}\|^2_{\ell^2}$. Since $\|\widehat{\varphi_c}\|^2_{\ell^2} =$

$2\frac{\pi^2}{L^2}\sum_{n=-\infty}^{+\infty}\operatorname{sech}^2(\frac{\pi n}{\sqrt{\omega(c)}L})$, we have that

$$\frac{d}{dc}\|\widehat{\varphi_c}\|_{\ell^2}^2 = \frac{C_1(L)}{\sqrt{\omega(c)^3}}\frac{d\omega}{dc}\sum_{n=-\infty}^{+\infty}\operatorname{sech}^2\left(\frac{\pi n}{\sqrt{\omega(c)}L}\right)n\operatorname{tgh}\left(\frac{\pi n}{\sqrt{\omega(c)}L}\right).$$

Since $(n\ \operatorname{tgh}(\frac{\pi n}{\sqrt{\omega(c)}L}))_{n\in\mathbb{Z}}$ is a positive sequence we have from Theorem 5.2 that $\frac{d}{dc}\|\widehat{\varphi_c}\|_{\ell^2}^2 > 0$. Thus, we obtain that the dnoidal wave φ_c in (5.14) is stable in $H^1_{per}([0,L])$ by the flow of the mKdV.

5.3. Stability of periodic travelling-wave solutions for the KdV equation. Now, we apply the results obtained previously to the proof of the stability of periodic travelling-wave solutions of cnoidal type associated with the KdV equation and satisfying

$$\varphi_c'' + \frac{1}{2}\varphi_c^2 - c\varphi_c = 0. \tag{5.15}$$

We consider the solitary wave solutions $\phi_\omega(x) = 3\omega\operatorname{sech}^2(\frac{\sqrt{\omega}x}{2})$, whose Fourier transform is given by $\widehat{\phi}_\omega(x) = \frac{12\pi x}{\operatorname{senh}\left(\frac{\pi x}{\sqrt{\omega}}\right)}$; then from the Poisson summation theorem we consider

$$\psi_\omega(\xi) = \frac{12\sqrt{\omega}}{L} + \frac{12\pi}{L^2}\sum_{n\neq 0} n\operatorname{csch}\left(\frac{\pi n}{\sqrt{\omega}L}\right)e^{\frac{2\pi i n\xi}{L}}. \tag{5.16}$$

Since ω is arbitrary, consider $\omega := \omega(k)$ such that $\sqrt{\omega(k)} = \frac{K(k)}{K(k')L}$, $k\in(0,1)$, $k'^2 = 1-k^2$. Then, we obtain

$$\psi_{\omega(k)}(\xi) = \frac{12\sqrt{\omega}}{L} + \frac{24\pi}{L^2}\sum_{n=1}^{+\infty} n\operatorname{csch}\left(\frac{\pi nK'}{K}\right)\cos\left(\frac{2\pi n\xi}{L}\right). \tag{5.17}$$

Now, we invoke the Fourier expansion of dn^2 (see [19], [42]), that is,

$$K^2\left(\operatorname{dn}^2\left(\frac{2K\xi}{L};k\right) - \frac{E}{K}\right) = 2\pi\sum_{n=1}^{+\infty}\frac{nq^n}{1-q^{2n}}\cos\left(\frac{2\pi n\xi}{L}\right),$$

where $q = e^{-(\frac{\pi K'}{K})}$. We can conclude that

$$\frac{q^n}{1-q^{2n}} = \frac{1}{2}\operatorname{csch}\left(\frac{n\pi K'}{K}\right).$$

Then, we get from (5.17)

$$\psi_{\omega(k)}(\xi) = \frac{12\sqrt{\omega(k)}}{L} + \frac{24K^2}{L^2}\left(\operatorname{dn}^2\left(\frac{2K\xi}{L};k\right) - \frac{E}{K}\right) \tag{5.18}$$

for $k\in(0,1)$.

Next, because of the equality (5.18), we consider $\varphi_c(\xi) = a + b\left(\mathrm{dn}^2(dx;k) - \frac{E}{K}\right)$ a periodic travelling-wave solution for (5.15) of period L. Then, the following nonlinear system is obtained:

$$\left\{\begin{array}{l} \dfrac{b^2}{2} - 6d^2 b = 0, \quad 4bd^2(1+k'^2) + ab - b^2\dfrac{E}{K} - cb = 0, \\ \dfrac{a^2}{2} - \dfrac{abE}{K} + \dfrac{b^2}{2}\left(\dfrac{E}{K}\right)^2 - ac - cb\dfrac{E}{K} - 2bd^2k'^2 = 0. \end{array}\right. \tag{5.19}$$

Since φ_c is periodic of period L it follows that $d = \frac{2K(k)}{L}$. Then, from the first equation of the system above we have that $b = \frac{48K^2}{L^2}$. Substituting those values at the second equation we get

$$c = \frac{16K}{L^2}\left[(1+k'^2)K - 3E\right] + a. \tag{5.20}$$

From the third equation in (5.19) and the value of c in (5.20) we have the quadratic equation in terms of a,

(5.21)

$$a^2 + \frac{32K}{L^2}\left[(1+k'^2)K - 3E\right]a - \frac{(1+k'^2)1536K^3E}{L^4} + \frac{768K^4k'^2}{L^4} + \frac{2304K^2E^2}{L^4} = 0,$$

whose positive solution is

$$a = -\frac{16K}{L^2}\left[(1+k'^2)K - 3E\right] + \frac{16K^2}{L^2}\sqrt{1-k^2+k^4}.$$

Thus, the value of c is $c = \frac{16K^2}{L^2}\sqrt{1-k^2+k^4}$. Hence, for $k \in (0,1)$ we have that $c \in (\frac{4\pi^2}{L^2}, +\infty)$. Therefore, writing φ_c in a convenient form, in terms of cn^2, we obtain

$$\varphi_c(\xi) = \frac{16K^2}{L^2}\left[\sqrt{1-k^2+k^4} + 1 - 2k^2\right] + \frac{48K^2k^2}{L^2}\mathrm{cn}^2\left(\frac{2K}{L}\xi;k\right).$$

We can see that this formula is the same that was obtained by Angulo in [7] and it can be rewritten as

$$\varphi_c(\xi) = \beta_2 + (\beta_3 - \beta_2)\mathrm{cn}^2\left(\sqrt{\frac{\beta_3-\beta_1}{12}}\xi;k\right), \tag{5.22}$$

where

$$\beta_2 = \frac{16K^2}{L^2}\left[\sqrt{1-k^2+k^4} + 1 - 2k^2\right], \quad \beta_3 = \frac{16K^2}{L^2}\left[\sqrt{1-k^2+k^4} + 1 + k^2\right],$$

and β_1 is such that

$$\beta_3 - \beta_1 = \frac{48K^2}{L^2}.$$

By making a similar analysis such as in the case of the mKdV equation, we can obtain a smooth curve of positive cnoidal waves with the form in (5.22), $c \in$

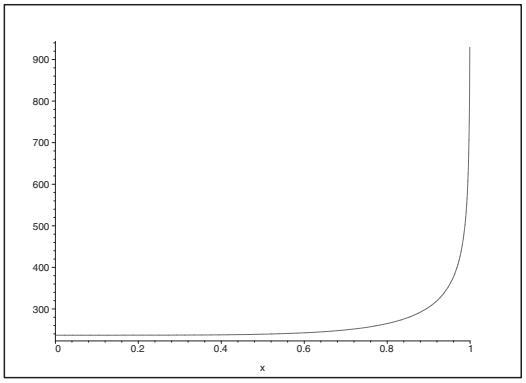

FIG. 1. *Graphic of the function $a(k)$ with period $L = 1$.*

$(\frac{4\pi^2}{L^2}, +\infty) \mapsto \varphi_c \in H^n_{per}([0, L])$, such that $k := k(c)$ is a strictly increasing smooth function (see [7]) for all $n \in \mathbb{N}$. Moreover, we can determine that for $k \in (0, 1)$ there is a unique $c \in (\frac{4\pi^2}{L^2}, +\infty)$ such that $k(c) = k$. Therefore, the function $\omega(k)$ defined above can be expressed as a function of c, $\omega = \omega(k(c))$, and it is a strictly increasing function (it will be seen later). Then, since $\frac{K(k)}{K(k')} \in (0, +\infty)$ it follows that for $c \in (\frac{4\pi^2}{L^2}, +\infty)$ we obtain $\omega(k(c)) \in (0, +\infty)$. Therefore, the mapping $c \in (\frac{4\pi^2}{L^2}, +\infty) \mapsto \psi_{\omega(k(c))} \in H^n_{per}([0, L])$ is a smooth curve for all $n \in \mathbb{N}$. Next, we note that $2\psi_{\omega(k(c))}(\xi) - \varphi_c(\xi) = \frac{24\sqrt{\omega(k(c))}}{L} - a(k(c))$, where for $k = k(c)$

$$a(k) = \frac{16K^2}{L^2}\left[\sqrt{1 - k^2 + k^4} + 2 - k^2 + 3\frac{E}{K}\right].$$

Thus, for $s(k(c)) \equiv a(k(c)) - \frac{24\sqrt{\omega(k(c))}}{L}$, we can write $\varphi_c(\xi) \equiv s(k(c)) + \psi_{\omega(k(c))}(\xi)$. Therefore, we obtain immediately that the Fourier coefficients of φ_c are

$$\widehat{\varphi_c}(n) = \begin{cases} a(k), & n = 0, \\ \dfrac{12\pi}{L^2} n \operatorname{csch}\left(\dfrac{\pi n}{\sqrt{\omega(k)}L}\right), & n \neq 0. \end{cases}$$

Remark 5.3. After some calculations, we can obtain that $s(k)$ is a positive function defined in $(0, 1)$. Making use of Maple, we can also determine that $s(k)$ does not have any root on the extremes of the interval $(0, 1)$. We can also determine that the function $a(k)$ is a positive strictly increasing function (see Figure 1).

Since $s(k) > 0$ and the function $f : \mathbb{R} \to \mathbb{R}$ defined by $f(x) = \frac{12\pi}{L^2} x \operatorname{csch}(\frac{\pi x}{\sqrt{\omega}L})$, belongs to $PF(2)$ in the continuous case, we can use Lemma 4.1 for obtaining that $\widehat{\varphi_c}$ belongs to the $PF(2)$ discrete case. Indeed, since

$$a(k) > \frac{24\sqrt{\omega(k)}}{L} > \frac{12\sqrt{\omega(k)}}{L} = f(0) > f(x), \quad x \neq 0,$$

we can redefine f by a smooth function $h : \mathbb{R} \to \mathbb{R}$ such that $h(0) = a(k)$, $h(x) \equiv f(x)$ on $(-\infty, -1] \cup [1, +\infty)$ and on the interval $(-1, 1)$ we "complete" f in a differentiable

way, such that h belongs to $PF(2)$ continuous. Therefore, the sequence to be obtained (if we look only at the set of integers numbers) will be $h(n) = \widehat{\varphi_c}(n)$.

Next, let $\chi = -\frac{d}{dc}\varphi_c$ such that $\mathcal{L}\chi = \varphi_c$. Then by the Parseval theorem, it follows that $I = -\frac{L}{2}\frac{d}{dc}\left(\|\widehat{\varphi_c}\|^2_{\ell^2}\right)$. Hence,

$$\begin{aligned}\frac{d}{dc}\|\widehat{\varphi_c}\|^2_{L^2_{per}} &= C_1 a(k)\frac{da}{dk}\frac{dk}{dc} \\ &+ \frac{C_2}{\sqrt{\omega(k)^3}}\frac{d\omega}{dk}\frac{dk}{dc}\sum_{\substack{n=-\infty\\ n\neq 0}}^{+\infty}\underbrace{n^3\operatorname{csch}^2\left(\frac{\pi n}{L\sqrt{\omega(k)}}\right)\coth\left(\frac{\pi n}{L\sqrt{\omega(k)}}\right)}_{b_n},\end{aligned}$$

where $C_1 := C_1(L)$, $C_2 := C_2(L) > 0$. Next, we need to show only that the quantities $\frac{da}{dk}$ and $\frac{d\omega}{dk}$ are positive because $k := k(c)$ is a strictly increasing function and $(b_n)_{n\in\mathbb{Z}}$ is obviously a positive sequence. Hence, we have

$$\frac{d\omega}{dk} = 2\frac{K\left(\frac{dK}{dk}K' - K\frac{dK'}{dk}\right)}{K'^3}.$$

Since $\frac{dK}{dk} > 0$ and $\frac{dK'}{dk} < 0$ we get that $\frac{d\omega}{dk} > 0$. By making use of a similar argument, we can also show that $\frac{da}{dk} > 0$ because we have that

$$a(k) = \frac{16K(k)^2}{L^2}\left[\sqrt{1-k^2+k^4}+2-k^2\right] + 48\frac{E(k)K(k)}{L^2}.$$

Therefore, $I < 0$ and the positive cnoidal waves φ_c are stable in $H^1_{per}([0,L])$ by the periodic flow of the KdV equation.

6. Comments. In this section we make some basic remarks about the results contained in the body of this paper.

6.1. General perturbations. In contrast to the case of solitary waves for which the natural class of disturbance in the stability problem is that of localized disturbances, for periodic waves there are several classes of disturbance for which stability needs to be addressed. Here we consider periodic perturbations with the same fundamental period of the periodic travelling waves. For disturbance, for example, with a double period, stability results remain open in the context of KdV-type equations. If we consider the KdV equation, our stability result in $H^1_{per}([0,L])$ was based on the spectral structure of the operator $\mathcal{L}_{\rm cn} = -\frac{d^2}{dx^2} + c - \varphi_c$, with φ_c defined in (5.22). Now, if we consider this operator with domain $H^2_{per}([0,2L])$, then the number of negative eigenvalues will be exactly 3 (see [10]). Moreover, since the function $\frac{d}{dc}\int_{-L}^{L}\varphi_c^2(x)dx$ is even positive, the abstract setting of Grillakis, Shatah, and Strauss in [27] and [28] cannot be applied. We note that in the case of the focusing Schrödinger equation

$$iu_t + u_{xx} + |u|^2 u = 0,$$

Angulo in [9] showed an instability result for dnoidal waves solutions when the class of periodic disturbance is two times the minimal period of the periodic travelling wave in question (see also Gallay and Hărăguş [24], [25] for recent new results of stability for periodic travelling waves of Schrödinger equations).

6.2. Property $PF(2)$ discrete. We consider the BO equation (but we can do an analogous analysis with the other two equations); then we have seen throughout this paper that the spectral properties of the operator $\mathcal{L} = \mathcal{H}\partial_x + c - \varphi_c$ were obtained from the fact that the Fourier coefficients of the periodic travelling-wave solution given by (1.13) are in $PF(2)$. The Poisson summation theorem was used to find such a wave with a minimal period $2L$. Moreover, the Fourier coefficients were calculated with this period. If we double the period, that is, if we consider $\mathcal{L}$ with domain $D(\mathcal{L}) = H^1_{4L}$, *the property* $PF(2)$ *is not satisfied* to $\widetilde{K} = \widehat{\varphi_c}^{(4L)}$, where $\widehat{\varphi_c}^{(4L)}$ denotes the periodic Fourier transform of φ_c but with period $4L$. Indeed, we consider the Fourier expansion in the form $\varphi_c(x) = \sum_{n=0}^{+\infty} \widehat{\varphi_c}^{(4L)}(n)\cos\left(\frac{n\pi x}{2L}\right)$. Since $\varphi_c(0) = \varphi_c(2L)$, $\sum_{n=0}^{+\infty} \widehat{\varphi_c}^{(4L)}(n)(\cos(n\pi) - 1) = 0$. Thus, $-2\sum_{\substack{n=2k+1\\ k\in\mathbb{N}}} \widehat{\varphi_c}^{(4L)}(n) = 0$. Therefore, $\widetilde{K} = \widehat{\varphi_c}^{(4L)}$ cannot belong to $PF(2)$. Then, we cannot affirm anything about the stability of the wave φ_c when this case is considered. So, Theorem 4.1 cannot be applied here.

In Theorem 4.1, the Fourier transform needs to be evaluated in the minimal period for the solution φ_c. In fact, let L be this minimal period, and we evaluate the Fourier transform of φ_c as being of period $2L$; then

$$\begin{aligned}\widehat{\varphi_c}(k) &= \frac{1}{2L}\int_{-L}^{L} \varphi_c(x)e^{-\frac{ik\pi x}{L}}dx = \frac{1}{2L}\int_{-L}^{L} \varphi_c(x+L)e^{-\frac{ik\pi x}{L}}dx \\ &= \frac{1}{2L}\int_{0}^{2L} \varphi_c(y)e^{-\frac{ik\pi y}{L}}e^{i\pi k}dx = (-1)^k\widehat{\varphi_c}(k).\end{aligned}$$

Then, for k being odd we have $\widehat{\varphi_c}(k) = 0$. Thus, we cannot apply our theory if the minimal period is not fixed.

6.3. Positivity of the periodic travelling waves. Another fact that deserves a special mention is about the condition that the solution φ_c in Theorem 4.1 needs to be a positive solution. Indeed, the classical Fourier theorem (see [30]) told us that this is necessary. Suppose without loss of generality that $\varphi_c(0) = 0$. Then, φ_c being smooth it follows that $\varphi_c^p(0) = \sum_{n=-\infty}^{+\infty} \widehat{\varphi_c^p}(n) = 0$. In other words some Fourier coefficient of φ_c^p must be negative.

6.4. Stability and instability of periodic travelling waves for the critical KdV and NLS. In a forthcoming paper [11] we apply the theory in section 4 to obtain the stability/instability of a special family of periodic travelling-wave solutions for the critical KdV equation

$$u_t + 5u^4u_x + u_{xxx} = 0$$

and for the critical nonlinear Schrödinger (NLS) equation

$$iu_t + u_{xx} + |u|^4u = 0.$$

7. Appendix.

7.1. Jacobi elliptic functions. We establish some basic properties of Jacobian elliptic integrals (see [18] and [19]). The normal elliptic integral of the first kind is

$$\int_0^y \frac{dt}{\sqrt{(1-t^2)(1-k^2t^2)}} = \int_0^\varphi \frac{d\theta}{\sqrt{1-k^2\sin^2\theta}} \equiv F(\varphi, k),$$

where $y=\sin\varphi$, whereas the normal elliptic integral of the second kind is

$$\int_0^y \sqrt{\frac{1-k^2t^2}{1-t^2}}dt=\int_0^{\varphi}\sqrt{1-k^2\sin^2\theta}d\theta\equiv E(\varphi,k).$$

The number k is called the modulus and belongs to the interval $(0,1)$. The number $k'=\sqrt{1-k^2}$ is called the complementary modulus. The parameter φ is called the argument of the normal elliptic integrals. It is usually understood that $0\leq y\leq 1$ or $0\leq\varphi\leq\frac{\pi}{2}$. For $y=1$, the integrals above are said to be complete. In this case, one writes

$$\int_0^1\frac{dt}{\sqrt{(1-t^2)(1-k^2t^2)}}=\int_0^{\frac{\pi}{2}}\frac{d\theta}{\sqrt{1-k^2\sin^2\theta}}\equiv F\left(\frac{\pi}{2},k\right)\equiv K(k)\equiv K$$

and

$$\int_0^1\sqrt{\frac{1-k^2t^2}{1-t^2}}dt=\int_0^{\frac{\pi}{2}}\sqrt{1-k^2\sin^2\theta}d\theta\equiv E\left(\frac{\pi}{2},k\right)\equiv E(k)\equiv E.$$

Clearly, we have $K(0)=E(0)=\frac{\pi}{2}$, while $E(1)=1$ and $K(1)=+\infty$. For $k\in(0,1)$, $\frac{dK}{dk}>0$, $\frac{d^2K}{dk^2}>0$, $\frac{dE}{dk}<0$, $\frac{d^2E}{dk^2}<0$, and $E(k)<K(k)$. Moreover, $E(k)+K(k)$ and $E(k)K(k)$ are strictly increasing functions for every $k\in(0,1)$. Next, we have some derivatives of the complete elliptical integrals K and E used in this work,

$$\frac{dK}{dk}=\frac{E-k'^2K}{kk'^2},\quad \frac{dE}{dk}=\frac{E-K}{k}.$$

The Jacobian elliptic functions are usually defined as follows. It considers the elliptic integral

$$u(y_1;k)\equiv u=\int_0^{y_1}\frac{dt}{\sqrt{(1-t^2)(1-k^2t^2)}}=\int_0^{\varphi}\frac{d\theta}{\sqrt{1-k^2\sin^2\theta}}\equiv F(\varphi,k),$$

which is a strictly increasing function of the variable y_1. Its inverse function is written $y_1=\sin\varphi\equiv\mathrm{sn}(u;k)$, or briefly $y_1=\mathrm{sn}u$ when it is not necessary to emphasize the modulus k. The other two basic elliptic functions, the cnoidal and dnoidal functions, are defined in terms of sn by

$$\mathrm{cn}(u;k)=\sqrt{1-y_1^2}=\sqrt{1-\mathrm{sn}^2(u;k)},\quad \mathrm{dn}(u;k)=\sqrt{1-k^2y_1^2}=\sqrt{1-k^2\mathrm{sn}^2(u;k)}.$$

Note that these functions are normalized by the requirements $\mathrm{sn}(0;k)=0$, $\mathrm{cn}(0;k)=1$, and $\mathrm{dn}(0;k)=1$. The functions $\mathrm{cn}(\cdot;k)$ and $\mathrm{dn}(\cdot;k)$ are even functions. These functions are periodic with $\mathrm{sn}(u+4K(k);k)=\mathrm{sn}(u;k)$, $\mathrm{cn}(u+4K(k));k)=\mathrm{cn}(u;k)$, $\mathrm{dn}(u+2K(k);k)=\mathrm{dn}(u;k)$. Moreover, we have the relations $\mathrm{sn}^2u+\mathrm{cn}^2u=1$, $k^2\mathrm{sn}^2u+\mathrm{dn}^2u=1$, $k'^2\mathrm{sn}^2u+\mathrm{cn}^2u=\mathrm{dn}^2u$, $\mathrm{sn}(u+2K;k)=-\mathrm{sn}(u;k)$, $\mathrm{cn}(u+4K;k)=-\mathrm{cn}(u;k)$. We also have the following explicit values: $\mathrm{sn}(0)=0$, $\mathrm{cn}(0)=1$, $\mathrm{sn}(K)=0$, $\mathrm{cn}(K)=0$ and the asymptotic behaviors $\mathrm{sn}(u;0)=\sin u$, $\mathrm{cn}(u;0)=\cos u$, $\mathrm{sn}(u;1)=\tanh u$, $\mathrm{cn}(u;1)=\mathrm{sech}u$. Finally, the formulas

$$\frac{\partial}{\partial u}\mathrm{sn}u=\mathrm{cn}u\mathrm{dn}u,\ \frac{\partial}{\partial u}\mathrm{cn}u=-\mathrm{sn}u\mathrm{dn}u,\ \frac{\partial}{\partial u}\mathrm{dn}u=-k^2\mathrm{cn}u\mathrm{sn}u$$

are straightforwardly deduced from the foregoing material.

7.2. A nonlocal Poincaré–Wirtinger inequality. The following inequality was used in Proposition 5.1. Suppose $f \in H^{\frac{1}{2}}_{2L}$ such that $\int_{-L}^{L} f(x)dx = 0$; then for $D = \mathcal{H}\partial_x$

$$\int_{-L}^{L} [D^{\frac{1}{2}} f]^2 dx \geq \frac{\pi}{L} \int_{-L}^{L} f^2 dx.$$

Proof. Let f be in $\mathcal{P}$, and consider the Fourier expansion of f given by

$$f(x) = \sum_{n=-\infty}^{+\infty} a_n e^{\frac{in\pi x}{L}} = \sum_{n=-\infty}^{+\infty} \widehat{f}(n) e^{\frac{in\pi x}{L}},$$

where $\widehat{f}(n) = \frac{1}{2L}\int_{-L}^{L} f(x)e^{-\frac{in\pi x}{L}}dx$, with $\widehat{f}(0) = 0$. Then, $\mathcal{H}\partial_x f(x) = \frac{\pi}{L}\sum_{n=-\infty}^{+\infty} a_n|n|e^{\frac{in\pi x}{L}}$. From the Parseval theorem we obtain

$$\int_{-L}^{L} f\mathcal{H}\partial_x f dx = 2L \sum_{n=-\infty}^{+\infty} \frac{\pi}{L}|a_n|^2|n| = 2L \sum_{n\neq 0} \frac{\pi}{L}|a_n|^2|n|$$

and

$$\int_{-L}^{L} f^2 dx = 2L \sum_{n\neq 0} |a_n|^2.$$

Therefore,

$$\int_{-L}^{L} f\mathcal{H}\partial_x f dx = 2L \sum_{n\neq 0} \frac{\pi}{L}|a_n|^2|n| \geq \frac{\pi}{L} \int_{-L}^{L} f^2 dx.$$

So, using density arguments, we can show that the inequality above occurs for $f \in H^{\frac{1}{2}}_{2L}$. This completes the proof of the inequality. ∎

Acknowledgments. The second author would like to express his thanks to the Institute of Mathematics and Statistic (IME) of the University of São Paulo/SP-Brazil for its hospitality. The authors also thank the referees for some helpful comments.

INHOMOGENEOUS BOUNDARY VALUE PROBLEMS FOR COMPRESSIBLE NAVIER–STOKES EQUATIONS: WELL-POSEDNESS AND SENSITIVITY ANALYSIS*

P. I. PLOTNIKOV†, E. V. RUBAN†, AND J. SOKOLOWSKI‡

Abstract. In this paper compressible, stationary Navier–Stokes equations are considered. A framework for analysis of such equations is established. In particular, the well-posedness for inhomogeneous boundary value problems of elliptic-hyperbolic type is shown. Analysis is performed for small perturbations of the so-called *approximate solutions* that take form (1.12). The approximate solutions are determined from Stokes problem (1.11). The small perturbations are given by solutions to (1.13). The uniqueness of solutions for problem (1.13) is proved, and, in addition, the differentiability of solutions with respect to the coefficients of differential operators is shown. The results on the well-posedness of nonlinear problems are interesting on their own and are used to obtain the shape differentiability of the drag functional for incompressible Navier–Stokes equations. The shape gradient of the drag functional is derived in the classical and useful for computations form; an appropriate adjoint state is introduced to this end. The *material* derivatives of solutions to the Navier–Stokes equations are given by smooth functions; however, the shape differentiability is shown in a weak norm. The method of analysis proposed in this paper is general and can be used to establish the well-posedness for distributed and boundary control problems as well as for inverse problems in the case of the state equations in the form of compressible Navier–Stokes equations. The differentiability of solutions to the Navier–Stokes equations with respect to the data leads to the first order necessary conditions for a broad class of optimization problems.

1. Introduction.

Shape optimization for compressible Navier–Stokes equations is important for applications [27] and is investigated from a numerical point of view; however, the mathematical analysis of such problems is not available in the existing literature. One of the reasons is the lack of existence results for inhomogeneous boundary value problems for such equations.

The results established in this paper lead in particular to the first order optimality conditions for a class of shape optimization problems for compressible Navier–Stokes equations.

1.1. Problem formulation.

In this paper we prove the well-posedness and perform the sensitivity analysis for inhomogeneous boundary value problems for the compressible Navier–Stokes equations. We restrict ourselves to the case of a specific shape optimization problem for stationary motion of viscous compressible non–heat-conducting isentropic gas. However, the technique of modelling and analysis presented here is general and can be used for a broad class of optimization problems for nonlinear elliptic-hyperbolic equations. The sensitivity analysis is the necessary

step for numerical methods of solution for optimization problems. In general the mathematical analysis of optimization problems includes the following steps, with the mathematical proofs of the required facts:

- existence of solutions,
- uniqueness and optimality conditions,
- numerical method of solution.

The existence of an optimal shape for the drag minimization is shown in [40] under assumptions that are compared to the assumptions in the present paper. Here we present the necessary mathematical tools required for the second step of analysis, i.e., the derivation of an optimality system. In particular, we prove the shape differentiability of solutions to (1.9) and provide the classical representation of the shape derivatives of integral shape functionals in terms of an appropriate adjoint state.

We consider in detail all questions on the existence, uniqueness, and shape differentiability of solutions to stationary boundary value problems for compressible Navier–Stokes equations. Such boundary value problems can be regarded as the mathematical models of viscous gas flow around a body tested in the wind tunnel. We assume that the viscous gas occupies the double-connected domain $\Omega = B\backslash S$, where $B \subset \mathbb{R}^3$ is a hold-all domain with the smooth boundary $\Sigma = \partial B$, and $S \subset B$ is a compact obstacle. Furthermore, we assume that the velocity of the gas coincides with a given vector field $\mathbf{U} \in C^\infty(\mathbb{R}^3)^3$ on the surface Σ. In this framework, the boundary of the flow domain Ω is divided into three subsets, inlet $\Sigma_{\rm in}$, outgoing set $\Sigma_{\rm out}$, and characteristic set Σ_0, which are defined by the equalities

$$\Sigma_{\rm in} = \{x \in \Sigma : \mathbf{U} \cdot \mathbf{n} < 0\}, \quad \Sigma_{\rm out} = \{x \in \Sigma : \mathbf{U} \cdot \mathbf{n} > 0\}, \tag{1.1}$$

$\Sigma_0 = \{x \in \partial\Omega : \mathbf{U} \cdot \mathbf{n} = 0\}$, where $\mathbf{n}$ stands for the unit outward normal to $\partial\Omega = \Sigma \cup \partial S$. In turn the compact $\Gamma = \Sigma_0 \cap \Sigma$ splits the surface Σ into three disjoint parts $\Sigma = \Sigma_{\rm in} \cup \Sigma_{\rm out} \cup \Gamma$. The problem is to find the velocity field $\mathbf{u}$ and the gas density ϱ satisfying the following equations along with the boundary conditions:

$$\Delta\mathbf{u} + \lambda\nabla \operatorname{div}\mathbf{u} = R\varrho\mathbf{u} \cdot \nabla\mathbf{u} + \frac{R}{\epsilon^2}\nabla p(\varrho) \ \text{ in } \ \Omega, \tag{1.2a}$$

$$\operatorname{div}(\varrho\mathbf{u}) = 0 \ \text{ in } \ \Omega, \tag{1.2b}$$

$$\mathbf{u} = \mathbf{U} \ \text{ on } \ \Sigma, \quad \mathbf{u} = 0 \ \text{ on } \ \partial S, \tag{1.2c}$$

$$\varrho = \varrho_0 \ \text{ on } \ \Sigma_{\rm in}, \tag{1.2d}$$

where the pressure $p = p(\varrho)$ is a smooth, strictly monotone function of the density, ϵ is the Mach number, R is the Reynolds number, λ is the viscosity ratio, and ϱ_0 is a positive constant.

For the derivation of equations (1.2) we refer to [22]. The general theory of compressible Navier–Stokes equations is covered by the monographs [11], [25], and [33]. In particular, the main results on the existence of global weak solutions for stationary problems with the zero velocity boundary conditions were established in [25] and sharpened in [33]. See also [14], [38], [39] for generalizations.

There are numerous papers dealing with the zero velocity boundary value problem for steady compressible Navier–Stokes equations in the context of small data. We recall only that there are three different approaches to this problem proposed in [2], [35], and [30], [32], respectively. The basic results on the local existence and uniqueness of strong solutions are assembled in [33]. For an interesting overview see [36].

The inhomogeneous boundary problems were studied in papers [20] and [21], where the local existence and uniqueness results were obtained in the two-dimensional

case under the assumption that the velocity $\mathbf{u}$ is close to a given constant vector. The question of the existence of strong solutions to boundary value problems in three spatial dimensions with nonzero velocity boundary data in smooth domains is still an open problem. There are difficulties including the problems of the total mass control and the singularities developed by solutions at the manifold $\overline{\Sigma}_{in} \cap \overline{\Sigma_0 \cup \Sigma}_{out}$. In this paper we prove the local existence and uniqueness of strong solutions to problem (1.2) in fractional Sobolev spaces, under the assumption that the given vector field $\mathbf{U}$ satisfies the emergent vector field conditions (**H1**)–(**H3**) on Γ. It seems that a condition of this type is necessary for the continuity of mass density ϱ.

Shape optimization problems. Among many shape optimization problems for Navier–Stokes equations, we could list the drag minimization problem, which is investigated in this paper and in [37], [38], [39], [40]. It is important to note that the drag from one side depends on the shape of the obstacle, and from the other side on the design of its surface structure as well as on the quality of its surface. The problem of the drag reduction includes the optimal design of the shape of the obstacle and control of the flow near its surface. The last question was investigated in paper [17], which also contains an overview of the problem.

Another problem of practical interest concerns the optimal shape of tunnels [27]. In the specific problem the required mass distribution on the outlet of the tunnel is given. The associated shape optimization problem can be formulated as follows. Determine an admissible domain such that the mass distribution at the inlet is given, the velocity field is prescribed on the boundary of the domain, and the mass distribution at the outlet is as close as possible to a given function. Inlet and outlet subsets are defined by the vector field $\mathbf{U}$ which serves as the inhomogeneous boundary condition for the law of momentum conservation in the form of a Navier–Stokes stationary system. The shape optimization problem as it is formulated in [27] enters into our framework, and the results on shape sensitivity analysis can be applied to solve the problem. Another class of problems which can be investigated using the tools proposed in the paper are optimal control problems, e.g., with the boundary controls. These topics are, however, beyond the scope of the paper, and we present the drag minimization problem as an example to the general theory.

Drag minimization. One of the main applications of the theory of compressible viscous flows is the optimal shape design in aerodynamics. The classical sample is the problem of the minimization of the drag of airfoil travelling in atmosphere with uniform speed $\mathbf{U}_\infty$. Recall that in our framework the hydrodynamical force acting on the body S is defined by the formula [41]

$$\mathbf{J}(S) = -\int_{\partial S} \left(\nabla \mathbf{u} + (\nabla \mathbf{u})^* + (\lambda - 1) \operatorname{div} \mathbf{u} \mathbf{I} - \frac{R}{\epsilon^2} p \mathbf{I} \right) \cdot \mathbf{n} dS.$$

In a frame attached to the moving body the drag is the component of $\mathbf{J}$ parallel to $\mathbf{U}_\infty$,

$$J_D(S) = \mathbf{U}_\infty \cdot \mathbf{J}(S), \tag{1.3}$$

and the lift is the component of $\mathbf{J}$ in the direction orthogonal to $\mathbf{U}_\infty$. For the fixed data, the drag can be regarded as a functional depending on the shape of the obstacle S. The drag minimization and the lift maximization are between shape optimization problems of some practical importance. The questions of the domain dependence of solutions to nonstationary compressible Navier–Stokes equations and of the solvability of the drag optimization problem were considered in papers [12], [13]. The solvability

of the drag minimization problem for stationary equations (1.2) is shown in [37], [40]. For incompressible Navier–Stokes equations, the existence of material derivatives of solutions and the formula for the shape derivative of the drag functional and adjoint state were obtained in [4], [5], and [42]; see also [43] and [44] for some generalizations. The growing literature on numerical and applied aspects of the problem is nicely surveyed in [18] and [27]. To the best of our knowledge, the mathematical sensitivity analysis for the compressible Navier–Stokes equations has not been studied yet. We derive the formula for the shape derivatives of the drag functional which can be used, in particular, for the explicit formulation of optimality conditions. In order to define the shape derivatives of the shape functional we combine the material derivatives of the solutions to the governing PDEs with an appropriate adjoint state according to the same scheme as is proposed, e.g., in [42] for steady incompressible equations.

We start with a description of our framework for shape sensitivity analysis, or more generally, for well-posedness of compressible Navier–Stokes equations. To this end we choose the vector field $\mathbf{T} \in C^2(\mathbb{R}^3)^3$ vanishing in the vicinity of Σ and define the mapping

$$y = x + \varepsilon \mathbf{T}(x), \tag{1.4}$$

which describes the perturbation of the shape of the obstacle. We refer the reader to [45] for more general framework and results in shape optimization and to [28] for shape calculus in the framework of fluid-structure interaction. For small ε, the mapping $x \to y$ diffeomorphically takes the flow region Ω onto $\Omega_\varepsilon = B \setminus S_\varepsilon$, where the perturbed obstacle $S_\varepsilon = y(S)$. Let $(\bar{\mathbf{u}}_\varepsilon, \bar{\varrho}_\varepsilon)$ be solutions to problem (1.2) in Ω_ε. After substituting $(\bar{\mathbf{u}}_\varepsilon, \bar{\varrho}_\varepsilon)$ into the formula for $\mathbf{J}$, the drag becomes the function of the parameter ε. Our aim is, in fact, to prove that this function is well defined and differentiable at $\varepsilon = 0$. This leads to the first order shape sensitivity analysis for solutions to compressible Navier–Stokes equations. It is convenient to reduce such an analysis to the analysis of dependence of solutions with respect to the coefficients of the governing equations. To this end, we introduce the functions $\mathbf{u}_\varepsilon(x)$ and $\varrho_\varepsilon(x)$ defined in the unperturbed domain Ω by the formulae

$$\mathbf{u}_\varepsilon(x) = \mathbf{N}\bar{\mathbf{u}}_\varepsilon(x + \varepsilon\mathbf{T}(x)), \quad \varrho_\varepsilon(x) = \bar{\varrho}_\varepsilon(x + \varepsilon\mathbf{T}(x)),$$

where

$$\mathbf{N}(x) = \det\,(\mathbf{I} + \varepsilon\mathbf{T}'(x))(\mathbf{I} + \varepsilon\mathbf{T}'(x))^{-1} \tag{1.5}$$

is the adjugate matrix of the Jacobi matrix $\mathbf{I} + \varepsilon\mathbf{T}'$. Furthermore, we also use the notation $\mathfrak{g}(x) = \sqrt{\det\,\mathbf{N}}$. It is easy to see that the matrices $\mathbf{N}(x)$ depend analytically upon the small parameter ε and

$$\mathbf{N} = \mathbf{I} + \varepsilon\mathbf{D}(x) + \varepsilon^2\mathbf{D}_1(\varepsilon, x), \tag{1.6}$$

where $\mathbf{D} = \operatorname{div}\mathbf{T}\mathbf{I} - \mathbf{T}'$. Calculations show that, for $\mathbf{u}_\varepsilon, \varrho_\varepsilon$, the following boundary value problem is obtained:

$$\Delta\mathbf{u}_\varepsilon + \nabla\left(\lambda\mathfrak{g}^{-1}\operatorname{div}\mathbf{u}_\varepsilon - \frac{R}{\epsilon^2}p(\varrho_\varepsilon)\right) = \mathscr{A}(\mathbf{u}_\varepsilon) + R\mathscr{B}(\varrho_\varepsilon, \mathbf{u}_\varepsilon, \mathbf{u}_\varepsilon) \ \text{ in } \ \Omega, \tag{1.7a}$$

$$\operatorname{div}\left(\varrho_\varepsilon\mathbf{u}_\varepsilon\right) = 0 \ \text{ in } \ \Omega, \tag{1.7b}$$

$$\mathbf{u}_\varepsilon = \mathbf{U} \ \text{ on } \ \Sigma, \quad \mathbf{u}_\varepsilon = 0 \ \text{ on } \ \partial S, \tag{1.7c}$$

$$\varrho_\varepsilon = \varrho_0 \ \text{ on } \ \Sigma_{\text{in}}. \tag{1.7d}$$

Here the linear operator $\mathscr{A}$ and the nonlinear mapping $\mathscr{B}$ are defined in terms of $\mathbf{N}$:

$$\begin{aligned}\mathscr{A}(\mathbf{u}) &= \Delta\mathbf{u} - (\mathbf{N}^*)^{-1}\operatorname{div}\big(\mathfrak{g}^{-1}\mathbf{N}\mathbf{N}^*\nabla(\mathbf{N}^{-1}\mathbf{u})\big),\\ \mathscr{B}(\varrho,\mathbf{u},\mathbf{w}) &= \varrho(\mathbf{N}^*)^{-1}\Big(\mathbf{u}\,\nabla\big(\mathbf{N}^{-1}\mathbf{w}\big)\Big).\end{aligned} \tag{1.8}$$

For the derivation of these equations, see Appendix C.

The specific structure of the matrix $\mathbf{N}$ does not play any particular role in the further analysis. Therefore, we consider a general problem of the existence, uniqueness, and dependence on coefficients of the solutions to equations (1.7) under the assumption that $\mathbf{N}$ is a given matrix-valued function which is close, in an appropriate norm, to the identity mapping $\mathbf{I}$ and coincides with $\mathbf{I}$ in the vicinity of Σ. By abuse of notation, we write simply $\mathbf{u}$ and ϱ, instead of $\mathbf{u}_\varepsilon$ and ϱ_ε, when studying the well-posedness and dependence on $\mathbf{N}$. Before formulation of main results we write the governing equation in more transparent form using the change of unknown functions proposed in [35], [15]. To do so we introduce *the effective viscous pressure*

$$q = \frac{R}{\epsilon^2}\,p(\varrho) - \lambda\mathfrak{g}^{-1}\operatorname{div}\mathbf{u}$$

and rewrite equations (1.7) in the equivalent form

$$\Delta\mathbf{u} - \nabla q = \mathscr{A}(\mathbf{u}) + R\mathscr{B}(\varrho,\mathbf{u},\mathbf{u}) \ \text{ in } \ \Omega, \tag{1.9a}$$

$$\operatorname{div}\mathbf{u} = \mathfrak{g}\sigma_0 p(\varrho) - \frac{\mathfrak{g}q}{\lambda} \ \text{ in } \ \Omega, \tag{1.9b}$$

$$\mathbf{u}\cdot\nabla\varrho + \mathfrak{g}\sigma_0 p(\varrho)\,\varrho = \frac{\mathfrak{g}q}{\lambda}\varrho \ \text{ in } \ \Omega, \tag{1.9c}$$

$$\mathbf{u} = \mathbf{U} \ \text{ on } \ \Sigma, \quad \mathbf{u} = 0 \ \text{ on } \ \partial S, \tag{1.9d}$$

$$\varrho = \varrho_0 \ \text{ on } \ \Sigma_{\text{in}}, \tag{1.9e}$$

where $\sigma_0 = R/(\lambda\epsilon^2)$. In the new variables $(\mathbf{u}, q, \varrho)$ the expression for the force $\mathbf{J}$ reads

$$\mathbf{J} = -\int_\Omega \big[\mathfrak{g}^{-1}\big(\mathbf{N}^*\nabla(\mathbf{N}^{-1}\mathbf{u}) + \nabla(\mathbf{N}^{-1}\mathbf{u})^*\mathbf{N} - \operatorname{div}\mathbf{u}\big) - q - R\varrho\mathbf{u}\otimes\mathbf{u}\big]\mathbf{N}^*\nabla\eta\,dx, \tag{1.10}$$

where $\eta \in C^\infty(\Omega)$ is an arbitrary function, which is equal to 1 in an open neighborhood of the obstacle S and 0 in a vicinity of Σ. The value of $\mathbf{J}$ is independent of the choice of the function η.

We assume that $\lambda \gg 1$ and $R \ll 1$, which corresponds to almost incompressible flow with low Reynolds number. In such a case, the *approximate solutions* to problem (1.9) can be chosen in the form $(\varrho_0, \mathbf{u}_0, q_0)$, where ϱ_0 is a constant in boundary condition (1.9e), and $(\mathbf{u}_0, q_0)$ is a solution to the boundary value problem for the Stokes equations,

$$\begin{gathered}\Delta\mathbf{u}_0 - \nabla q_0 = 0, \quad \operatorname{div}\mathbf{u}_0 = 0 \ \text{ in } \ \Omega,\\ \mathbf{u}_0 = \mathbf{U} \ \text{ on } \ \Sigma, \quad \mathbf{u}_0 = 0 \ \text{ on } \ \partial S, \quad \Pi q_0 = q_0.\end{gathered} \tag{1.11}$$

In our notation Π is the projector:

$$\Pi u = u - \frac{1}{\operatorname{meas}\Omega}\int_\Omega u\,dx.$$

Equations (1.11) can be obtained as the limit of equations (1.9) for the passage $\lambda \to \infty$, $R \to 0$. It follows from the standard elliptic theory that, for the boundary $\partial\Omega \in C^\infty$, we have $(\mathbf{u}_0, q_0) \in C^\infty(\Omega)$. We look for solutions to problem (1.9) in the form

$$\mathbf{u} = \mathbf{u}_0 + \mathbf{u}, \quad \varrho = \varrho_0 + \varphi, \quad q = q_0 + \lambda\sigma_0 p(\varrho_0) + \pi + \lambda m, \tag{1.12}$$

with the unknowns functions $\vartheta = (\mathbf{u}, \pi, \varphi)$ and the unknown constant m. Substituting (1.12) into (1.9) we obtain the following boundary problem for ϑ:

$$\begin{aligned} \Delta\mathbf{u} - \nabla\pi &= \mathscr{A}(\mathbf{u}) + R\mathscr{B}(\varrho, \mathbf{u}, \mathbf{u}) \ \text{ in } \ \Omega, \\ \operatorname{div}\mathbf{u} &= \mathfrak{g}\left(\frac{\sigma}{\varrho_0}\varphi - \Psi[\vartheta] - m\right) \ \text{ in } \ \Omega, \\ \mathbf{u}\cdot\nabla\varphi + \sigma\varphi &= \Psi_1[\vartheta] + m\mathfrak{g}\varrho \ \text{ in } \ \Omega, \\ \mathbf{u} = 0 \ \text{ on } \ \partial\Omega, \quad \varphi = 0 \ \text{ on } \ \Sigma_{\text{in}}, &\quad \Pi\pi = \pi, \end{aligned} \tag{1.13a}$$

where

$$\Psi_1[\vartheta] = \mathfrak{g}\left(\varrho\Psi[\vartheta] - \frac{\sigma}{\varrho_0}\varphi^2\right) + \sigma\varphi(1-\mathfrak{g}), \quad \Psi[\vartheta] = \frac{q_0+\pi}{\lambda} - \frac{\sigma}{p'(\varrho_0)\varrho_0}H(\varphi),$$
$$\sigma = \sigma_0 p'(\varrho_0)\varrho_0, \quad H(\varphi) = p(\varrho_0+\varphi) - p(\varrho_0) - p\prime(\varrho_0)\varphi,$$

and the vector field $\mathbf{u}$ and the function ϱ are given by (1.12). Finally, we specify the constant m. In our framework, in contrast to the case of the homogeneous boundary problem, the solution to such a problem is not trivial. Note that, since $\operatorname{div}\mathbf{u}$ is of the null mean value, the right-hand side of $(1.13\text{a})_3$ must satisfy the compatibility condition

$$m\int_\Omega \mathfrak{g}\,dx = \int_\Omega \mathfrak{g}\left(\frac{\sigma}{\varrho_0}\varphi - \Psi[\vartheta]\right)\,dx,$$

which formally determines m. This choice of m leads to essential mathematical difficulties. To make this issue clear note that in the simplest case $\mathfrak{g} = 1$ we have $m = \varrho_0^{-1}\sigma(\mathbf{I}-\Pi)\varphi + O(|\vartheta|^2, \lambda^{-1})$, and the principal linear part of the governing equations (1.13a) becomes

$$\begin{pmatrix} \Delta & -\nabla & 0 \\ \operatorname{div} & 0 & -\frac{\sigma}{\varrho_0} \\ 0 & 0 & \mathbf{u}\nabla + \sigma \end{pmatrix} \begin{pmatrix} \mathbf{u} \\ \pi \\ \varphi \end{pmatrix} + \begin{pmatrix} 0 \\ m \\ -m\varrho_0 \end{pmatrix} \sim \begin{pmatrix} \Delta\mathbf{u} - \nabla\pi \\ \operatorname{div}\mathbf{u} - \frac{\sigma}{\varrho_0}\Pi\varphi \\ \mathbf{u}\nabla\varphi + \sigma\Pi\varphi \end{pmatrix}.$$

Hence, the question of solvability of the linearized equations derived for (1.13) can be reduced to the question of solvability of the boundary value problem for the nonlocal transport equation

$$\mathbf{u}\nabla\varphi + \sigma\Pi\varphi = f,$$

which is very difficult because of the loss of maximum principle. In fact, this question is concerned with the problem of the control of the total gas mass in compressible flows. Recall that the absence of the mass control is the main obstacle for proving the global solvability of inhomogeneous boundary problems for compressible Navier–Stokes equations; we refer to [25] for discussion. In order to cope with this difficulty we write the compatibility condition in a sophisticated form, which allows us to control

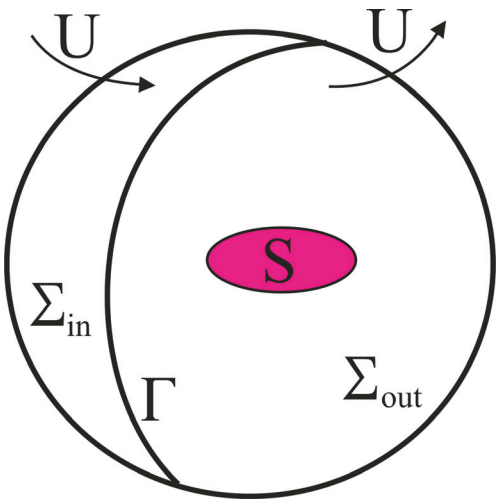

FIG. 1. *Flow domain Ω with an obstacle S.*

the total mass of the gas. To this end we introduce the auxiliary function ζ satisfying the equations

$$-\operatorname{div}(\mathbf{u}\zeta) + \sigma\zeta = \sigma\mathfrak{g} \ \text{ in } \ \Omega, \quad \zeta = 0 \ \text{ on } \ \Sigma_{\text{out}}, \tag{1.13b}$$

and fix the constant m as follows:

$$m = \varkappa \int_\Omega (\varrho_0^{-1}\Psi_1[\vartheta]\zeta - \mathfrak{g}\Psi[\vartheta])\,dx, \quad \varkappa = \left(\int_\Omega \mathfrak{g}(1 - \zeta - \varrho_0^{-1}\zeta\varphi)\,dx\right)^{-1}. \tag{1.13c}$$

In this way the auxiliary function ζ becomes an integral part of the solution to problem (1.13). Now our aim is to prove the existence and uniqueness of solutions to problem (1.13) and investigate the dependence of the solutions on matrices $\mathbf{N}$. Before the presentation of the main results we introduce some notation and formulate preliminary results.

Geometrical conditions on the flow region. We assume that a surface $\Sigma = \Sigma_{\text{in}} \cup \Sigma_{\text{out}} \cup \Gamma$ and a given vector field $\mathbf{U}$ satisfy the following conditions, referred to as the *emergent vector field conditions*.

CONDITION 1.1. *The set Γ is a closed $C^{2+\alpha}$ one-dimensional manifold. Moreover, there is a positive constant c such that*

$$\mathbf{U} \cdot \nabla(\mathbf{U} \cdot \mathbf{n}) > c > 0 \quad \textit{on} \quad \Gamma. \tag{1.14}$$

These conditions have a simple geometric interpretation, that $\mathbf{U} \cdot \mathbf{n}$ vanishes only up to the first order at Γ, and $\mathbf{U}$ is transversal to Γ; furthermore, for each point $P \in \Gamma$, the vector $\mathbf{U}(P)$ points to the part of Σ where $\mathbf{U}$ is an exterior vector field (see Figure 1). Note that the emergent vector field condition plays an important role in the theory of the classical oblique derivative problem; see [16]. In the context of our problem it is equivalent to the following conditions:

(**H1**) The boundary of Ω belongs to class $C^{2+\alpha}$, $\alpha \in (0,1)$. For each point $P \in \Gamma$ there exist the local Cartesian coordinates (x_1, x_2, x_3) with the origin at P such that in the new coordinates $\mathbf{U}(P) = (U, 0, 0)$ with $U = |\mathbf{U}(P)|$, and

$\mathbf{n}(P) = (0, 0, -1)$. Moreover, there is a neighborhood $\mathcal{O} = [-k, k]^2 \times [-t, t]$ of P such that the intersections $\Sigma \cap \mathcal{O}$ and $\Gamma \cap \mathcal{O}$ are defined by the equations

$$F_0(x) \equiv x_3 - F(x_1, x_2) = 0, \quad \nabla F_0(x) \cdot \mathbf{U}(x) = 0,$$

and $\Omega \cap \mathcal{O}$ is the epigraph $\{F_0 > 0\} \cap \mathcal{O}$. The function F satisfies the conditions

$$\|F\|_{C^2([-k,k]^2)} \le K, \quad F(0,0) = 0, \quad \nabla F(0,0) = 0, \tag{1.15}$$

where the constants $k, t < 1$ and $K > 1$ depend only on the curvature of Σ and are independent of the point P.

(**H2**) For a suitable choice of the constant k, with k independent of $P \in \Gamma$, the manifold $\Gamma \cap \mathcal{O}$ admits the parameterization

$$x = \mathbf{x}^0(x_2) := \big(\Upsilon(x_2),\, x_2,\, F(\Upsilon(x_2), x_2)\big) \tag{1.16}$$

such that $\Upsilon(0) = 0$ and $\|\Upsilon\|_{C^2([-k,k])} \le C_\Gamma$, where the constant $C_\Gamma > 1$ depends only on Σ and $\mathbf{U}$.

(**H3**) There are positive constants $N^\pm$ independent of P such that for $x \in \Sigma$ given by the condition $F_0(x_1, x_2, x_3) = x_3 - F(x_1, x_2) = 0$ we have

(1.17)
$$N^-\big(x_1 - \Upsilon(x_2)\big) \le -\nabla F_0(x) \cdot \mathbf{U}(x) \le N^+\big(x_1 - \Upsilon(x_2)\big) \quad \text{for} \quad x_1 > \Upsilon(x_2),$$
$$-N^-\big(x_1 - \Upsilon(x_2)\big) \le \nabla F_0(x) \cdot \mathbf{U}(x) \le -N^+\big(x_1 - \Upsilon(x_2)\big) \quad \text{for} \quad x_1 < \Upsilon(x_2).$$

Function spaces. In this paragraph we assemble some technical results which are used throughout the paper. Function spaces play a central role, and we recall some notation, fundamental definitions, and properties, which can be found in [1] and [6]. For the convenience of the reader we collect in Appendix B the basic facts from the theory of interpolation spaces. For our applications we need the results in three spatial dimensions; however, the results are presented for the dimension $d \ge 2$.

Let Ω be the whole space $\mathbb{R}^d$ or a bounded domain in $\mathbb{R}^d$ with the boundary $\partial\Omega$ of class C^1. For an integer $l \ge 0$ and for an exponent $r \in [1, \infty)$, we denote by $W^{l,r}(\Omega)$ the Sobolev space endowed with the norm $\|u\|_{W^{l,r}(\Omega)} = \sup_{|\alpha| \le l} \|\partial^\alpha u\|_{L^r(\Omega)}$. For real $0 < s < 1$, the fractional Sobolev space $W^{s,r}(\Omega)$ is obtained by the real interpolation method (see [46] for the proofs) between $L^r(\Omega)$ and $W^{1,r}(\Omega)$ and consists of all measurable functions with the finite norm

$$\|u\|_{W^{s,r}(\Omega)} = \|u\|_{L^r(\Omega)} + |u|_{s,r,\Omega},$$

where

$$|u|^r_{s,r,\Omega} = \int_{\Omega \times \Omega} |x - y|^{-d-rs} |u(x) - u(y)|^r \, dxdy. \tag{1.18}$$

In the general case, the Sobolev space $W^{l+s,r}(\Omega)$ is defined as the space of measurable functions with the finite norm $\|u\|_{W^{l+s,r}(\Omega)} = \sup_{|\alpha| \le l} \|\partial^\alpha u\|_{W^{s,r}(\Omega)}$. For $0 < s < 1$, the Sobolev space $W^{s,r}(\Omega)$ is, in fact [6], the interpolation space $[L^r(\Omega), W^{1,r}(\Omega)]_{s,r}$.

Furthermore, the notation $W^{l,r}_0(\Omega)$, with an integer l, stands for the closed subspace of the space $W^{l,r}(\Omega)$ of all functions $u \in L^r(\Omega)$ which being extended by zero outside of Ω belong to $W^{l,r}(\mathbb{R}^d)$.

Denote by $\mathcal{W}_0^{0,r}(\Omega)$ and $\mathcal{W}_0^{1,r}(\Omega)$ the subspaces of $L^r(\mathbb{R}^d)$ and $W^{1,r}(\mathbb{R}^d)$, respectively, of all functions vanishing outside of Ω. Obviously $\mathcal{W}_0^{1,r}(\Omega)$ and $W_0^{1,r}(\Omega)$ are isomorphic topologically and algebraically and we can identify them. However, we need the interpolation spaces $\mathcal{W}_0^{s,r}(\Omega)$ for nonintegers, in particular, for $s = 1/r$.

DEFINITION 1.2. *For all $0 < s \le 1$ and $1 < r < \infty$, we denote by $\mathcal{W}_0^{s,r}(\Omega)$ the interpolation space $[\mathcal{W}_0^{0,r}(\Omega), \mathcal{W}_0^{1,r}(\Omega)]_{s,r}$ endowed with one of the equivalent norms* (6.1) *and* (6.3) *defined by the interpolation method.*

It follows from the definition of interpolation spaces (see Appendix B) that $\mathcal{W}_0^{s,r}(\Omega) \subset W^{s,r}(\mathbb{R}^d)$ and, for all $u \in \mathcal{W}_0^{s,r}(\Omega)$,

$$\|u\|_{W^{s,r}(\mathbb{R}^d)} \le c(r,s)\|u\|_{\mathcal{W}_0^{s,r}(\Omega)}, \quad u = 0 \quad \text{outside} \ \ \Omega. \tag{1.19}$$

In other words, $\mathcal{W}_0^{s,r}(\Omega)$ consists of all elements $u \in W^{s,r}(\Omega)$ such that the extension $\overline{u}$ of u by 0 outside of Ω has the finite $[\mathcal{W}_0^{0,r}(\Omega), \mathcal{W}_0^{1,r}(\Omega)]_{s,r}$-norm. We identify u and $\overline{u}$ for the elements $u \in \mathcal{W}_0^{s,r}(\Omega)$. With this identification it follows that $W_0^{1,r}(\Omega) \subset \mathcal{W}_0^{s,r}(\Omega)$ and the space $C_0^\infty(\Omega)$ is dense in $\mathcal{W}_0^{s,r}(\Omega)$. It is worthy to note that for $0 < s < 1$ and for $1 < r < \infty$, the function $\overline{u}$ belongs to the space $W^{s,r}(\mathbb{R}^d)$ if and only if $u \in W^{s,r}(\Omega)$ and $\operatorname{dist}(x, \partial\Omega)^{-s} u \in L^r(\Omega)$. We also point out that the interpolation space $\mathcal{W}_0^{s,r}(\Omega)$ coincides with the Sobolev space $W_0^{s,r}(\Omega)$ for $s \ne 1/r$. Recall that the standard space $W_0^{s,r}(\Omega)$ is the completion of $C_0^\infty(\Omega)$ in the $W^{s,r}(\Omega)$-norm.

Embedding theorems. For $sr > d$ and $0 \le \alpha < s - r/d$, the embedding $W^{s,r}(\Omega) \hookrightarrow C^\alpha(\Omega)$ is continuous and compact. In particular, for $sr > d$, the Sobolev space $W^{s,r}(\Omega)$ is a commutative Banach algebra; i.e., for all $u, v \in W^{s,r}(\Omega)$,

$$\|uv\|_{W^{s,r}(\Omega)} \le c(r,s)\|u\|_{W^{s,r}(\Omega)}\|v\|_{W^{s,r}(\Omega)}. \tag{1.20}$$

If $sr < d$ and $t^{-1} = r^{-1} - d^{-1}s$, then the embedding $W^{s,r}(\Omega) \hookrightarrow L^t(\Omega)$ is continuous, [1, Thm. 7.57]. We also have [1, Thm. 7.58], for $\alpha < s$, $(s - \alpha)r < d$ and $\beta^{-1} = r^{-1} - d^{-1}(s - \alpha)$,

$$\|u\|_{W^{\alpha,\beta}(\Omega)} \le c(r,s,\alpha,\beta,\Omega)\|u\|_{W^{s,r}(\Omega)}. \tag{1.21}$$

It follows from (1.19) that all the embedding inequalities remain true for the elements of the interpolation space $\mathcal{W}_0^{s,r}(\Omega)$.

Duality. We define

$$\langle u, v\rangle = \int_\Omega u\, v\, dx \tag{1.22}$$

for any functions such that the right-hand side makes sense. For $r \in (1, \infty)$, each element $v \in L^{r'}(\Omega)$, $r' = r/(r-1)$, determines the functional L_v of $(\mathcal{W}_0^{s,r}(\Omega))'$ by the identity $L_v(u) = \langle u, v\rangle$. We introduce the $(-s, r')$-norm of an element $v \in L^{r'}(\Omega)$ to be by definition the norm of the functional L_v, that is

$$\|v\|_{\mathcal{W}^{-s,r'}(\Omega)} = \sup_{\substack{u \in \mathcal{W}_0^{s,r}(\Omega) \\ \|u\|_{\mathcal{W}_0^{s,r}(\Omega)} = 1}} |\langle u, v\rangle|. \tag{1.23}$$

We let $\mathcal{W}^{-s,r'}(\Omega)$ denote the completion of the space $L^{r'}(\Omega)$ with respect to the $(-s, r')$-norm. For an integer s, $\mathcal{W}^{-s,r'}(\Omega)$ is topologically and algebraically isomorphic to $(W_0^{s,r}(\Omega))'$. Moreover, we can identify $\mathcal{W}^{-s,r'}(\Omega)$ with the interpolation space

$[L^{r'}(\Omega), W_0^{-1,r'}(\Omega)]_{s,r}$; see [6] and Appendix B. With this denotation we have the duality principle

$$\|u\|_{\mathcal{W}_0^{s,r}(\Omega)} = \sup_{\substack{v\in C_0^\infty(\Omega)\\ \|v\|_{\mathcal{W}^{-s,r'}(\Omega)}=1}} |\langle u, v\rangle|. \tag{1.24}$$

With applications to the theory of Navier–Stokes equations in mind, we introduce the smaller dual space defined as follows. We identify the function $v \in L^{r'}(\Omega)$ with the functional $L_v \in (W^{s,r}(\Omega))'$ and denote by $\mathbb{W}^{-s,r'}(\Omega)$ the completion of $L^{r'}(\Omega)$ in the norm

$$\|v\|_{\mathbb{W}^{-s,r'}(\Omega)} := \sup_{\substack{u\in W^{s,r}(\Omega)\\ \|u\|_{W^{s,r}(\Omega)}=1}} |\langle u, v\rangle|. \tag{1.25}$$

In the sense of this identification the space $C_0^\infty(\Omega)$ is dense in the interpolation space $\mathbb{W}^{-s,r}(\Omega)$. It follows immediately from the definition that

$$\mathbb{W}^{-s,r'}(\Omega) \subset (W^{s,r}(\Omega))' \subset \mathcal{W}^{-s,r'}(\Omega).$$

For an arbitrary bounded domain $\Omega \subset \mathbb{R}^3$ with a Lipschitz boundary, we introduce the Banach spaces

$$X^{s,r} = W^{s,r}(\Omega) \cap W^{1,2}(\Omega), \quad Y^{s,r} = W^{s+1,r}(\Omega) \cap W^{2,2}(\Omega),$$
$$Z^{s,r} = \mathcal{W}^{s-1,r}(\Omega) \cap L^2(\Omega)$$

equipped with the norms

$$\|u\|_{X^{s,r}} = \|u\|_{W^{s,r}(\Omega)} + \|u\|_{W^{1,2}(\Omega)}, \quad \|u\|_{Y^{s,r}} = \|u\|_{W^{1+s,r}(\Omega)} + \|u\|_{W^{2,2}(\Omega)},$$
$$\|u\|_{Z^{s,r}} = \|u\|_{\mathcal{W}^{s-1,r}(\Omega)} + \|u\|_{L^2(\Omega)}.$$

It can be easily seen that the embeddings $Y^{s,r} \hookrightarrow X^{s,r} \hookrightarrow Z^{s,r}$ are compact and, for $sr > 3$, each of the spaces $X^{s,r}$ and $Y^{s,r}$ is a commutative Banach algebra.

Stokes equations. The following lemma is a straightforward consequence of classical results on solvability of the first boundary value problem for Stokes equations (see [9]) and the interpolation theory.

LEMMA 1.3. *Let $\Omega \subset \mathbb{R}^3$ be a bounded domain with $\partial\Omega \in C^2$ and $(F, G) \in \mathcal{W}^{s-1,r}(\Omega) \times W^{s,r}(\Omega)$ $(0 \le s \le 1, 1 < r < \infty)$. Then the boundary value problem*

$$\begin{gathered}\Delta\mathbf{u} - \nabla\pi = F, \quad \operatorname{div}\mathbf{u} = \Pi G \quad \text{in } \Omega,\\ \mathbf{u} = 0 \quad \text{on } \partial\Omega, \quad \Pi\pi = \pi,\end{gathered} \tag{1.26}$$

has a unique solution $(\mathbf{u}, \pi) \in W^{s+1,r}(\Omega) \times W^{s,r}(\Omega)$ such that

$$\|\mathbf{u}\|_{W^{s+1,r}(\Omega)} + \|\pi\|_{W^{s,r}(\Omega)} \le c(\Omega, r, s)(\|F\|_{\mathcal{W}^{s-1,r}(\Omega)} + \|G\|_{W^{s,r}(\Omega)}). \tag{1.27}$$

In particular, we have

$$\|\mathbf{u}\|_{Y^{s,r}} + \|\pi\|_{X^{s,r}} \le c(\Omega, r, s)(\|F\|_{Z^{s,r}} + \|G\|_{X^{s,r}}).$$

Proof. The proof is in Appendix B. □

Note that the lemma works for singular values $s = 1/r +$ integer. But in this case the traces of solutions at the boundary are not defined.

1.2. Results. *Transport equations.* Today there exists a complete theory of generalized solutions to the class of hyperbolic-elliptic equations developed in [10] and [34] under the assumptions that the equations have C^1 coefficients and satisfy the maximum principle. The questions on smoothness properties of solutions are more difficult. We recall the classical results of [19], [34], related to the case of $\overline{\Sigma}_{\rm in}\cap\overline{\Sigma}_{\rm out}=\emptyset$. The particular case, with $\Sigma_{\rm in}=\Sigma_{\rm out}=\emptyset$, in the Sobolev spaces is covered in the papers [3] and [30], [31]. The case of the nonempty interface $\Gamma=\overline{\Sigma}_{\rm in}\cap\overline{\Sigma}_{\rm out}$ is still weakly investigated. The theory of boundary value problems for transport equations is an integral part of the theory of multicomponents and inhomogeneous flows. In this context this problem has been considered by many authors; see [24] and [29] for discussion.

In general the existence of strong solutions to inhomogeneous boundary value problems for transport equations is still an open problem. The following theorem, which is used throughout this paper, partially fills this gap. Let us consider the following boundary value problems for linear transport equations:

$$\mathscr{L}\varphi:=\mathbf{u}\nabla\varphi+\sigma\varphi=f \quad \text{in } \Omega, \quad \varphi=0 \quad \text{on } \Sigma_{\rm in}, \tag{1.28}$$

$$\mathscr{L}^*\varphi^*:=-\operatorname{div}(\varphi^*\mathbf{u})+\sigma\varphi^*=f \quad \text{in } \Omega, \quad \varphi^*=0 \quad \text{on } \Sigma_{\rm out}. \tag{1.29}$$

The bounded functions φ, φ^* are called the generalized solutions to problems (1.28), (1.29), respectively, if the integral identities

$$\int_\Omega(\varphi\mathscr{L}^*\zeta^*-f\zeta^*)\,dx=0, \quad \int_\Omega(\varphi^*\mathscr{L}\zeta-f\zeta)\,dx=0 \tag{1.30}$$

hold true for all test functions $\zeta^*,\zeta\in C(\Omega)\cap W^{1,1}(\Omega)$, respectively, such that $\zeta^*=0$ on $\Sigma_{\rm out}$ and $\zeta=0$ on $\Sigma_{\rm in}$.

THEOREM 1.4. *Assume that* Σ *and* $\mathbf{U}$ *satisfy conditions* (**H1**)–(**H3**)*, the exponents* s,r *satisfy the inequalities*

$$1/2<s\le 1, \quad 1<r<3/(2s-1), \tag{1.31}$$

and the vector field $\mathbf{u}$ *belongs to the class* $C^1(\Omega)$ *and satisfies the boundary condition*

$$\mathbf{u}=\mathbf{U} \ \text{ on } \ \Sigma, \quad \mathbf{u}=0 \ \text{ on } \ \partial S. \tag{1.32}$$

Then there are positive constants σ^* *and* δ^* *depending only on* Σ, $\mathbf{U}$, s, r, *and* $\|\mathbf{u}\|_{C^1(\Omega)}$ *such that the following hold:*

(i) *For any* $\sigma>\sigma^*$ *and* $f\in W^{s,r}(\Omega)\cap L^\infty(\Omega)$, *problem* (1.28) *has a unique solution* $\varphi\in W^{s,r}(\Omega)\cap L^\infty(\Omega)$ *satisfying the inequalities*

$$\|\varphi\|_{W^{s,r}(\Omega)}\le C\|f\|_{W^{s,r}(\Omega)}, \quad \|\varphi\|_{L^\infty(\Omega)}\le\sigma^{-1}\|f\|_{L^\infty(\Omega)}. \tag{1.33}$$

(ii) *If, in addition,* $\|\operatorname{div}\mathbf{u}\|_{W^{s,r}(\Omega)}+\|\operatorname{div}\mathbf{u}\|_{L^\infty(\Omega)}\le\delta^*$, *problem* (1.29) *has a unique solution* $\varphi^*\in W^{s,r}(\Omega)\cap L^\infty(\Omega)$, *which admits the estimates*

$$\|\varphi^*\|_{W^{s,r}(\Omega)}\le C\|f\|_{W^{s,r}(\Omega)}, \quad \|\varphi^*\|_{L^\infty(\Omega)}\le(\sigma-\delta^*)^{-1}\|f\|_{L^\infty(\Omega)}. \tag{1.34}$$

The constant C *depends only on* $\|\mathbf{u}\|_{C^1(\Omega)}$, r,s σ, $\mathbf{U}$, *and* Ω.

Restriction $s\ge 1/2$ in condition (1.31) is not essential and can be removed. But it plays an important role in the proof of Lemma 1.7 and the main theorem, Theorem 1.9. On the other hand, the inequality $r<3/(2s-1)$ is crucial for the

control of singularities of solutions at the characteristic manifold Γ. It is connected with the behavior of $\mathbf{U}$ in the vicinity of Γ and does not depend on the dimension of the ambient space. Note also that solution is strong for $s = 1$, but not continuous since $W^{1,3}(\Omega)$ is not embedded in $C(\Omega)$. On the other hand, $sr \to \infty$ as $s \to 1/2$ and solution is continuous for s close to $1/2$. In order to obtain continuous strong solutions we have to consider the problem in the scale of spaces $X^{s,r}$

Since for $sr > 3$, the embeddings $X^{s,r} \hookrightarrow C(\Omega)$, $Y^{s,r} \hookrightarrow C^1(\Omega)$ are bounded, we have the following result on solvability of problems (1.28), (1.29) in space $X^{s,r}$.

COROLLARY 1.5. *Assume that $sr > 3$ and the vector field $\mathbf{u}$ has the representation $\mathbf{u} = \mathbf{u}_0 + \mathbf{u}$, where $\mathbf{u}_0 \in C^\infty(\Omega)^3$ is a solution to problem* (1.11). *Then there exist $\tau^* \in (0, 1]$ and σ^*, depending only on $\Sigma, \mathbf{u}_0$, and s, r, such that, for all $\mathbf{u}$ with $\|\mathbf{u}\|_{Y^{s,r}} \le \tau^*$, $\sigma > \sigma^*$, and $f \in X^{s,r}$, each of problems* (1.28) *and* (1.29) *has a unique solution satisfying the inequalities*

$$\|\varphi\|_{X^{s,r}} \le C\|f\|_{X^{s,r}}, \quad \|\varphi^*\|_{X^{s,r}} \le C\|f\|_{X^{s,r}}. \tag{1.35}$$

Existence and uniqueness theory. The second main result of this paper concerns the existence and local uniqueness of solutions to problem (1.13). Denote by E the closed subspace of the Banach space $Y^{s,r}(\Omega)^3 \times X^{s,r}(\Omega)^2$ in the form

$$E = \{\vartheta = (\mathbf{u}, \pi, \varphi) \ : \ \mathbf{u} = 0 \ \text{ on } \ \partial\Omega, \quad \varphi = 0 \ \text{ on } \ \Sigma_{\text{in}}, \quad \Pi\pi = \pi\}, \tag{1.36}$$

and denote by $\mathcal{B}_\tau \subset E$ the closed ball of radius τ centered at 0. Next, note that, for $sr > 3$, elements of the ball $\mathcal{B}_\tau$ satisfy the inequality

$$\|\mathbf{u}\|_{C^1(\Omega)} + \|\pi\|_{C(\Omega)} + \|\varphi\|_{C(\Omega)} \le c_e(r, s, \Omega)\|\vartheta\|_E \le c_e\tau, \tag{1.37}$$

where the norm in E is defined by

$$\|\vartheta\|_E = \|\mathbf{u}\|_{Y^{s,r}(\Omega)} + \|\pi\|_{X^{s,r}(\Omega)} + \|\varphi\|_{X^{s,r}(\Omega)}.$$

THEOREM 1.6. *Assume that the surface Σ and given vector field $\mathbf{U}$ satisfy conditions* (**H**1)–(**H**3). *Furthermore, let σ^*, τ^* be constants given by Corollary* 1.5, *and let positive numbers r, s, σ satisfy the inequalities*

$$1/2 < s \le 1, \quad 1 < r < 3/(2s - 1), \quad sr > 3, \quad \sigma > \sigma^*. \tag{1.38}$$

Then there exists $\tau_0 \in (0, \tau^*]$, depending only on $\mathbf{U}, \Omega, r, s, \sigma$, such that, for all

$$\tau \in (0, \tau_0], \quad \lambda^{-1}, R \in (0, \tau^2], \quad \|\mathbf{N} - \mathbf{I}\|_{C^2(\Omega)} \le \tau^2, \tag{1.39}$$

problem (1.13), *with $\mathbf{u}_0$ given by* (1.11), *has a unique solution $\vartheta \in B_\tau$. Moreover, the auxiliary function ζ and the constants $\varkappa, m$ admit the estimates*

$$\|\zeta\|_{X^{s,r}} + |\varkappa| \le c, \quad |m| \le c\tau < 1, \tag{1.40}$$

where the constant c depends only on $\mathbf{U}, \Omega, r, s$, and σ.

Material derivatives of solutions. Theorem 1.6 guarantees the existence and uniqueness of solutions to problem (1.13) for all $\mathbf{N}$ close to the identity matrix $\mathbf{I}$. The totality of such solutions can be regarded as the mapping from $\mathbf{N}$ to the solution to Navier–Stokes equations. The natural question is the smoothness properties of this mapping, in particular, its differentiability. With application to shape optimization problems in mind, we consider the particular case where the matrices $\mathbf{N}$ depend on

the small parameter ε and have representation (1.6). We assume that C^1-norms of the matrix-valued functions $\mathbf{D}$ and $\mathbf{D}_1(\varepsilon)$ in (1.6) have a majorant independent of ε. By virtue of Theorem 1.6, there are the positive constants ε_0 and τ such that, for all sufficiently small R, λ^{-1} and $\varepsilon \in [0, \varepsilon_0]$, problem (1.13) with $\mathbf{N} = \mathbf{N}(\varepsilon)$ has a unique solution $\vartheta(\varepsilon) = (\mathbf{u}(\varepsilon), \pi(\varepsilon), \varphi(\varepsilon))$, $\zeta(\varepsilon), m(\varepsilon)$, which admits the estimate

$$\|\vartheta(\varepsilon)\|_E + |m(\varepsilon)| \le c\tau, \quad \|\zeta(\varepsilon)\|_{X^{s,r}} \le c, \tag{1.41}$$

where the constant c is independent of ε, and the Banach space E is defined by (1.36). Denote the solution $(\vartheta(0), m(0), \zeta(0))$ for $\varepsilon = 0$ by (ϑ, m, ζ), and define the finite differences with respect to ε,

$$(\mathbf{w}_\varepsilon, \omega_\varepsilon, \psi_\varepsilon) = \varepsilon^{-1}(\vartheta - \vartheta(\varepsilon)), \quad \xi_\varepsilon = \varepsilon^{-1}(\zeta - \zeta(\varepsilon)), \quad n_\varepsilon = \varepsilon^{-1}(m - m(\varepsilon)).$$

Formal calculations show that the limit $(\mathbf{w}, \omega, \psi, \xi, n) = \lim_{\varepsilon \to 0}(\mathbf{w}_\varepsilon, \omega_\varepsilon, \psi_\varepsilon, \xi_\varepsilon, n_\varepsilon)$ is a solution to linearized equations

$$\begin{aligned}
\Delta \mathbf{w} - \nabla \omega &= R\mathscr{C}_0(\mathbf{w}, \psi) + \mathscr{D}_0(\mathbf{D}) \ \text{ in } \ \Omega,\\
\operatorname{div} \mathbf{w} &= b^0_{21}\,\psi - b^0_{22}\,\omega + b^0_{23}\,n + b^0_{20}\,\mathfrak{d} \ \text{ in } \ \Omega,\\
\mathbf{u}\nabla\psi + \sigma\psi &= -\mathbf{w}\cdot\nabla\varphi + b^0_{11}\,\psi + b^0_{12}\,\omega + b^0_{13}\,n + b^0_{10}\,\mathfrak{d} \ \text{ in } \ \Omega,\\
-\operatorname{div}(\mathbf{u}\xi) + \sigma\xi &= \operatorname{div}(\zeta\mathbf{w}) + \sigma\mathfrak{d} \ \text{ in } \ \Omega,\\
\mathbf{w} = 0 \ \text{ on } \ \partial\Omega, &\quad \psi = 0 \ \text{ on } \ \Sigma_{\text{in}}, \quad \xi = 0 \ \text{ on } \ \Sigma_{\text{out}},\\
\omega - \Pi\omega = 0, &\quad n = \varkappa \int_\Omega \left(b^0_{31}\,\psi + b^0_{32}\,\omega + b^0_{34}\,\xi + b^0_{30}\,\mathfrak{d}\right) dx,
\end{aligned} \tag{1.42}$$

where $\mathfrak{d} = 1/2\,\operatorname{Tr}\,\mathbf{D}$ and the variable coefficients b^0_{ij} and the operators $\mathscr{C}_0$, $\mathscr{D}_0$, are defined by the formulae

$$\begin{aligned}
b^0_{11} &= \Psi[\vartheta] - \varrho H'(\varphi) + m - \frac{2\sigma}{\varrho_0}\varphi, \ \ b^0_{12} = \lambda^{-1}\varrho, \ \ b^0_{13} = \varrho,\\
b^0_{10} &= \varrho\Psi[\vartheta] - \frac{\sigma}{\varrho_0}\varphi^2 - \sigma\varphi + m\varrho, \ \ b^0_{21} = \frac{\sigma}{\varrho_0}\psi_0 + H'(\varphi),\\
b^0_{22} &= -\lambda^{-1}, \ \ b^0_{23} = -1, \ \ b^0_{20} = \sigma\varphi\varrho_0^{-1} - \Psi[\vartheta] - m,\\
b^0_{31} &= \varrho_0^{-1}\zeta\left(\Psi[\vartheta] - \varrho H'(\varphi) - \frac{2\sigma}{\varrho_0}\varphi\right) - H'(\varphi) + m\varrho_0^{-1}\zeta,\\
b^0_{32} &= (\lambda\varrho_0)^{-1}\varrho\zeta b^0_{12} + \lambda^{-1}, \ \ b^0_{34} = \varrho_0^{-1}\Psi_1[\vartheta] + m(1 + \varrho_0^{-1}\varphi),\\
b^0_{30} &= \varrho_0^{-1}\zeta(\Psi_1[\vartheta] - m\varrho) + \Psi[\vartheta] - m(1 - \zeta - \varrho_0^{-1}\zeta\varphi),
\end{aligned} \tag{1.43}$$

$$\mathscr{C}_0(\psi, \mathbf{w}) = R\psi\mathbf{u}\nabla\mathbf{u} + R\varrho\mathbf{w}\nabla\mathbf{u} + R\varrho\mathbf{u}\nabla\mathbf{w}, \tag{1.44}$$

$$\begin{aligned}
\mathscr{D}_0(\mathbf{D}) &= R\mathbf{u}\nabla(\mathbf{D}\mathbf{u}) + R\mathbf{D}^*(\mathbf{u}\nabla\mathbf{u})\\
&+ \operatorname{div}\left((\mathbf{D} + \mathbf{D}^*)\nabla\mathbf{u} - \frac{1}{2}\operatorname{Tr}\,\mathbf{D}\nabla\mathbf{u}\right) - \mathbf{D}^*\Delta\mathbf{u} - \Delta(\mathbf{D}\mathbf{u}).
\end{aligned} \tag{1.45}$$

The justification of the formal procedure meets the serious problems, since the smoothness of solutions to problem (1.13) is not sufficient for the well-posedness of problem (1.42) in the standard weak formulation. In order to cope with this difficulty we define *very weak solutions* to problem (1.42). The construction of such solutions is based on

the following lemma, and the proof is given in Appendix A. The lemma is given in $\mathbb{R}^d$, for our application $d = 3$.

LEMMA 1.7. *Let $\Omega \subset \mathbb{R}^d$ be a bounded domain with the Lipschitz boundary, let exponents s and r satisfy the inequalities $sr > d$, $1/2 \le s \le 1$, and $\varphi, \varsigma \in W^{s,r}(\Omega) \cap W^{1,2}(\Omega)$, $\mathbf{w} \in \mathcal{W}_0^{1-s,r'}(\Omega) \cap W_0^{1,2}(\Omega)$. Then there is a constant c depending only on s, r, and Ω, such that the trilinear form*

$$\mathfrak{B}(\mathbf{w}, \varphi, \varsigma) = -\int_\Omega \varsigma \mathbf{w} \cdot \nabla \varphi \, dx$$

satisfies the inequality

$$|\mathfrak{B}(\mathbf{w}, \varphi, \varsigma)| \le c \|\mathbf{w}\|_{\mathcal{W}_0^{1-s,r'}(\Omega)} \|\varphi\|_{W^{s,r}(\Omega)} \|\varsigma\|_{W^{s,r}(\Omega)} \tag{1.46}$$

and can be continuously extended to $\mathfrak{B} : \mathcal{W}_0^{1-s,r'}(\Omega)^d \times W^{s,r}(\Omega)^2 \mapsto \mathbb{R}$. In particular, we have $\varsigma \nabla \varphi \in \mathcal{W}^{s-1,r}(\Omega)$ and $\|\varsigma \nabla \varphi\|_{W^{1-s,r}(\Omega)} \le c \|\varphi\|_{W^{s,r}(\Omega)} \|\varsigma\|_{W^{s,r}(\Omega)}$.

DEFINITION 1.8. *The vector field $\mathbf{w} \in \mathcal{W}_0^{1-s,r'}(\Omega)^3$, functionals $(\omega, \psi, \xi) \in \mathbb{W}^{-s,r'}(\Omega)^3$, and constant n are said to be a weak solution to problem (1.42) if $\langle \omega, 1 \rangle = 0$ and the identity*

$$\begin{aligned} &\int_\Omega \mathbf{w}\Big(\mathbf{H} - R\varrho \nabla \mathbf{u} \cdot \mathbf{h} + R\varrho \nabla \mathbf{h}^* \mathbf{u}\Big) \, dx - \mathfrak{B}(\mathbf{w}, \varphi, \varsigma) - \mathfrak{B}(\mathbf{w}, \upsilon, \zeta) \\ &+ \big\langle \omega, G - b_{12}^0 \varsigma - b_{22}^0 g - \varkappa b_{32}^0 \big\rangle + \big\langle \psi, F - b_{11}^0 \varsigma - b_{21}^0 g - \varkappa b_{31}^0 - R\mathbf{u} \cdot \nabla \mathbf{u} \cdot \mathbf{h} \big\rangle \\ &+ \big\langle \xi, M - \varkappa b_{34}^0 \big\rangle + n\big(1 - \big\langle 1, b_{13}^0 \varsigma \big\rangle\big) \\ &= \big\langle \mathfrak{d}, b_{10}^0 \varsigma + b_{20}^0 g + \varkappa b_{30}^0 + \sigma \upsilon \big\rangle + \big\langle \mathscr{D}_0, \mathbf{h} \big\rangle \end{aligned} \tag{1.47}$$

holds true for all $(\mathbf{H}, G, F, M) \in (C^\infty(\Omega))^6$ such that $G = \Pi G$. Here $\mathfrak{d} = 1/2 \ Tr \, \mathbf{D}$, and the test functions $\mathbf{h}$, g, ς, υ are defined by the solutions to adjoint problems

$$\Delta \mathbf{h} - \nabla g = \mathbf{H}, \quad \operatorname{div} \mathbf{h} = G, \quad \mathscr{L}^* \varsigma = F, \quad \mathscr{L} \upsilon = M \ \text{ in } \ \Omega, \tag{1.48}$$

$$\mathbf{h} = 0 \ \text{ on } \ \partial\Omega, \quad \Pi g = g, \quad \varsigma = 0 \ \text{ on } \ \Sigma_{\text{out}}, \quad \upsilon = 0 \ \text{ on } \ \Sigma_{\text{in}}. \tag{1.49}$$

We are now in a position to formulate the third main result of this paper.

THEOREM 1.9. *Under the above assumptions,*

$$\begin{aligned} &\mathbf{w}_\varepsilon \to \mathbf{w} \ \text{ weakly in } \ \mathcal{W}_0^{1-s,r'}(\Omega), \quad n_\varepsilon \to n \ \text{ in } \ \mathbb{R}, \\ &\psi_\varepsilon \to \psi, \quad \omega_\varepsilon \to \omega, \quad \xi_\varepsilon \to \xi \ (*)\text{-weakly in } \ \mathbb{W}^{-s,r'}(\Omega) \ \text{ as } \ \varepsilon \to 0, \end{aligned} \tag{1.50}$$

where the limits, vector field $\mathbf{w}$, functionals ψ, ω, ξ, and the constant n are given by the weak solution to problem (1.42).

Note that the matrix $\mathbf{N}(\varepsilon)$ defined by equalities (1.5) meets all requirements of Theorem 1.9, and in the special case we have in representation (1.6)

$$\mathbf{D}(x) = \operatorname{div} \mathbf{T}(x) \, \mathbf{I} - \mathbf{T}'(x). \tag{1.51}$$

Therefore, Theorem 1.9, combined with formulae (1.3) and (1.10), implies the existence of the shape derivative for the drag functional at $\varepsilon = 0$. Straightforward calculations lead to the following result.

THEOREM 1.10. *Under the assumptions of Theorem* 1.9*, there exists the shape derivative*

$$\frac{d}{d\varepsilon} J_D(S_\varepsilon)\Big|_{\varepsilon=0} = L_e(\mathbf{T}) + L_u(\mathbf{w}, \omega, \psi),$$

where the linear forms L_e *and* L_u *are defined by the equalities*

$$L_e(\mathbf{T}) = \int_\Omega \operatorname{div}\mathbf{T}(\nabla\mathbf{u} + \nabla\mathbf{u}^* - \operatorname{div}\mathbf{u}\mathbf{I})\nabla\eta\mathbf{U}_\infty\,dx$$
$$- \int_\Omega \big[\nabla\mathbf{u} + \nabla\mathbf{u}^* - \operatorname{div}\mathbf{u} - q\mathbf{I} - R\varrho\mathbf{u}\otimes\mathbf{u}\big]\mathbf{D}\nabla\eta\cdot\mathbf{U}_\infty\,dx$$
$$- \int_\Omega \big[\mathbf{D}^*\nabla\mathbf{u} + \nabla\mathbf{u}^*\mathbf{D} - \nabla(\mathbf{D}\mathbf{u}) - \nabla(\mathbf{D}\mathbf{u})^*\big]\nabla\eta\cdot\mathbf{U}_\infty\,dx$$

and

$$L_u(\mathbf{w}, \omega, \psi) = \int_\Omega \mathbf{w}\big[\Delta\eta\mathbf{U}_\infty + R\varrho(\mathbf{u}\cdot\nabla\eta)\mathbf{U}_\infty + R\varrho(\mathbf{u}\cdot\mathbf{U}_\infty)\nabla\eta\big]\,dx$$
$$+ \big\langle\omega, \nabla\eta\cdot\mathbf{U}_\infty\big\rangle + R\big\langle\psi, (\mathbf{u}\cdot\nabla\eta)(\mathbf{u}\cdot\mathbf{U}_\infty)\big\rangle.$$

While L_e depends directly on the vector field $\mathbf{T}$, the linear form L_u depends on the weak solution $(\mathbf{w},\ \psi, \omega)$ to problem (1.42), and thus depends on the *direction* $\mathbf{T}$ in a very implicit manner, which is inconvenient for applications. In order to cope with this difficulty, we define the *adjoint state* $\mathbf{Y} = (\mathbf{h}, g, \varsigma, \upsilon, l)^\top$ given as a solution to the linear equation

$$\mathfrak{L}\mathbf{Y} - \mathfrak{U}\mathbf{Y} - \mathfrak{V}\mathbf{Y} = \Theta, \tag{1.52}$$

supplemented with boundary conditions (1.49). Here the operators $\mathfrak{L}$, $\mathfrak{U}$, $\mathfrak{V}$ and the vector field Θ are defined by

$$\mathfrak{L} = \begin{pmatrix} \Delta & -\nabla & 0 & 0 & 0 \\ \operatorname{div} & 0 & 0 & 0 & 0 \\ 0 & 0 & \mathscr{L}^* & 0 & 0 \\ 0 & 0 & 0 & \mathscr{L} & 0 \\ 0 & 0 & -\mathbb{B}_{13} & 0 & 1 \end{pmatrix}, \quad \mathfrak{U} = \begin{pmatrix} 0 & 0 & -\nabla\varphi & -\zeta\nabla & 0 \\ 0 & 0 & \Pi_{12} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\mathfrak{V} = \begin{pmatrix} R\varrho(\nabla\mathbf{u} - \mathbf{u}\nabla) & 0 & 0 & 0 & 0 \\ 0 & -\lambda^{-1}\Pi & 0 & 0 & \varkappa\Pi b^0_{32} \\ R\mathbf{u}\cdot\nabla\mathbf{u} & b^0_{21} & b^0_{11} & 0 & \varkappa b^0_{31} \\ 0 & 0 & 0 & 0 & \varkappa b^0_{34} \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\Theta = (\Delta\eta\mathbf{U}_\infty + R\varrho(\nabla\eta\otimes\mathbf{U}_\infty + \mathbf{U}_\infty\otimes\nabla\eta)\mathbf{u},\quad \Pi(\nabla\eta\cdot\mathbf{U}_\infty),\quad R(\mathbf{u}\nabla\eta)(\mathbf{u}\mathbf{U}_\infty), 0, 0)\,,$$
$$\Pi_{2i}(\cdot) = \Pi(b^0_{2i}(\cdot)),\quad \mathbb{B}_{13}(\cdot) = \big\langle 1, b^0_{13}(\cdot)\big\rangle.$$

The following theorem guarantees the existence of the adjoint state and gives the expression of the shape derivative for the drag functional in terms of the vector field $\mathbf{T}$.

THEOREM 1.11. *Let a given solution* $\vartheta \in \mathcal{B}_\tau$, $(\zeta, m) \in X^{s,r}\times\mathbb{R}$, *to problem* (1.13) *meet all requirements of Theorem* 1.6*. Then there exists positive constant* τ_1 *(depending only on* $\mathbf{U}$, Ω, *and* r, s*) such that if* $\tau \in (0, \tau_1]$ *and* R, $\lambda^{-1} \le \tau_1^2$, *then*

there exists a unique solution $\mathbf{Y} \in (Y^{s,r})^3 \times (X^{s,r})^3 \times \mathbb{R}$ *to problem* (1.52), (1.49). *The form* L_u *has the representation*

$$L_u(\mathbf{w},\psi,\omega) = \int_\Omega \big[\operatorname{div} \mathbf{T}\big(b^0_{10}\varsigma + b^0_{20} g + \sigma \upsilon + \varkappa b^0_{30}\big) + \mathscr{D}_0(\operatorname{div}\mathbf{T} - \mathbf{T}')\mathbf{h}\big]\, dx, \tag{1.53}$$

where the coefficients b^0_{ij} *and the operator* $\mathscr{D}_0$ *are defined by formulae* (1.43) *and* (1.45).

Method and structure of the paper. The following aspects of our method deserve a brief description:

- extended form (1.13) of the governing equations which allows us to cope with the mass control problem;
- the splitting of the boundary value problem for the transport equation into two parts: the local problem in the vicinity of inlet, and the global problem with the modified vector field $\tilde{\mathbf{u}}$ and the empty inlet $\tilde{\Sigma}_{\mathrm{in}}$;
- the estimates of solutions to the model problem (4.19) in the fractional Sobolev spaces, which cannot be obtained by the interpolation method;
- the very weak formulation of linearized equations introduced to assure the existence of material derivatives.

Now we can explain the organization of this paper. Section 2 is devoted to the proof of Theorem 1.6. First of all, we establish the existence of solutions to problem (1.13) using the Schauder fixed point theorem. Next we consider the linear equations for the difference of two solutions $(\mathbf{u}_i, \varphi_i)$, $i = 1, 2$, corresponding to arbitrary matrix-valued functions $\mathbf{N}_i$. Using Theorem 1.4 we deduce the weak formulation of the boundary value problem for linearized equations. The main result of this section is Theorem 2.3, which shows that solutions of the linearized problem are stable with respect to perturbations of data in the dual Sobolev space. This result implies the local uniqueness of solutions to problem (1.13). In section 3 we exploit Theorem 2.3 to prove the existence of the material derivative of solutions. The last section is devoted to the proof of Theorem 1.4.

2. Existence and uniqueness of local solutions. Proof of Theorem 1.6.

2.1. Existence theory. In this paragraph we establish the local solvability of problem (1.13) and prove the first part of Theorem 1.6. In our notation, c denotes generic constants, which are different in different places and depend only on Ω, $\mathbf{U}$, σ, and r, s. The proof is based on the following lemma which furnishes the regularity properties of composed functions. Let us consider functions $u, v : \Omega \mapsto B_K$, where $B_K = \{\mathbf{x} : |\mathbf{x}| \le K\} \subset \mathbb{R}^3$ is the ball of radius K centered at 0.

LEMMA 2.1. *Assume that* $u, v \in X^{s,r}$, $s \in (0, 1]$, $sr > 3$, *and* $\mathfrak{f} \in C^3(\Omega \times B_K)$. *Then we have*

$$\|\mathfrak{f}(\cdot, u)\|_{X^{s,r}} \le c(r,s)\|\mathfrak{f}\|_{C^1(\Omega\times B_K(0))}(1 + \|u\|_{X^{s,r}}), \tag{2.1}$$

$$\|\mathfrak{f}(\cdot, v) - \mathfrak{f}(\cdot, u)\|_{X^{s,r}} \le c(r,s)\|\mathfrak{f}\|_{C^2(\Omega\times B_K)}(1 + \|u\|_{X^{s,r}} + \|v\|_{X^{s,r}})\|u - v\|_{X^{s,r}}. \tag{2.2}$$

Proof. In order to prove (2.1) it suffices to note that

$$|\mathfrak{f}(x, u(x)) - \mathfrak{f}(y, u(y))|^r \le c(r)\|\mathfrak{f}\|^r_{C^1(\Omega\times B_K)}(|x - y|^r + |u(x) - u(y)|^r),$$

which, in view of the inequality

$$\int_{\Omega\times\Omega} |x - y|^{r-3-rs}\, dxdy \le c(r,s),$$

yields

$$|\mathfrak{f}(\cdot,u)|_{s,r,\Omega}\le c(r,s)\|\mathfrak{f}\|_{C^1(\Omega\times B_K(0))}(1+|u|_{s,r,\Omega}).$$

On the other hand, we have

$$\|\nabla\mathfrak{f}(\cdot,u)\|_{L^2(\Omega)}\le\|\mathfrak{f}\|_{C^1(\Omega\times B_K(0))}\|\nabla u\|_{L^2(\Omega)}.$$

Combining obtained inequalities we get (2.1). It remains to note that (2.2) follows from (2.1) and the Hadamard formula for the first order expansion of $\mathfrak{f}$. □

Fix sufficiently small positive τ such that

$$c_e\tau<\delta^*, \tag{2.3}$$

where δ^* is the constant determined in Corollary 1.5 and c_e is the constant from inequality (1.37). By virtue of Corollary 1.5, there is σ^*, depending only on Ω, $\mathbf{U}$, and r,s, such that, for all $\vartheta\in\mathcal{B}_\tau$ and $\sigma>\sigma^*$, problems (1.28) and (1.29) have solutions satisfying inequalities (1.35). Finally, fix an arbitrary $\sigma>\sigma^*$.

We solve problem (1.13) by an application of the Schauder fixed point theorem in the following framework. Choose an arbitrary element $\vartheta\in\mathcal{B}_\tau$. As mentioned above, the problem

$$\mathbf{u}\cdot\nabla\varphi_1+\sigma\varphi_1=\Psi_1[\vartheta]+m\mathfrak{g}\varrho\ \text{ in }\ \Omega,\ \ \varphi_1=0\ \text{ on }\ \Sigma_{\text{in}}, \tag{2.4}$$

has a unique solution satisfying the inequality

$$\|\varphi_1\|_{X^{s,r}}\le c(\Omega,U,\sigma,r,s)(\|\Psi_1[\vartheta]\|_{X^{s,r}}+|m|). \tag{2.5}$$

Next, define $\mathbf{u}_1$ and π_1 to be the solutions of the boundary value problem for the Stokes equations

$$\begin{aligned}\Delta\mathbf{u}_1-\nabla\pi_1&=\mathscr{A}(\mathbf{u})+R\mathscr{B}(\varrho,\mathbf{u},\mathbf{u})\equiv F[\vartheta]\ \text{ in }\ \Omega,\\ \varrho_0\operatorname{div}\mathbf{u}_1&=\Pi(\mathfrak{g}\sigma\varphi_1-\mathfrak{g}\varrho_0\Psi[\vartheta]-\mathfrak{g}m\varrho_0)\ \text{ in }\ \Omega,\\ \mathbf{u}_1&=0\ \text{ on }\ \partial\Omega,\quad \pi_1-\Pi\pi_1=0,\end{aligned} \tag{2.6}$$

where m is given by (1.13c). By Lemma 1.3, this problem admits a unique solution such that

$$\|\mathbf{u}_1\|_{Y^{s,r}}+\|\pi_1\|_{X^{s,r}}\le c(\|F[\vartheta]\|_{Z^{s,r}}+|\Psi[\vartheta]|_{X^{s,r}}+\|\varphi_1\|_{X^{s,r}}+|m|). \tag{2.7}$$

Equations (2.4), (2.6), (1.13c) define the mapping $\Xi:\vartheta\to\vartheta_1=(\mathbf{u}_1,\pi_1,\varphi_1)$. We claim that for a suitable choice of the constant τ, Ξ is a weakly continuous automorphism of the ball $\mathcal{B}_\tau$. We begin with the estimates for nonlinear operators present in (2.4). Fix an arbitrary $\vartheta\in\mathcal{B}_\tau$. Applying inequality (2.2) from Lemma 2.1 to the function H which is a part of $\Psi[\vartheta]$, we obtain $\|H(\varphi)\|_{X^{s,r}}\le c\tau^2$, which leads to the estimate

$$\|\Psi[\vartheta]\|_{X^{s,r}}\le\frac{c}{\lambda}(\|q_0\|_{C^1(\Omega)}+\|\pi\|_{X^{s,r}})+c\tau^2\le\frac{c}{\lambda}+c\tau^2\le c\tau^2. \tag{2.8}$$

Since, under assumptions of Theorem 1.6, $X^{s,r}(\Omega)$ is a Banach algebra and $\|\varrho\|_{X^{s,r}}\le c+\|\varphi\|_{X^{s,r}}\le const$, we conclude from this and (2.5) that

$$\|\varphi_1\|_{X^{s,r}}\le c/\lambda+c\tau^2+c|m|\le c\tau^2+c|m|. \tag{2.9}$$

In order to estimate the right-hand side of the first equation in (2.6) we introduce the vector function $\mathbf{z} = (\mathbf{u}, \nabla\mathbf{u}, \pi, \varphi)$ and proceed as follows. It can be easily seen that $\|\mathbf{z}\|_{X^{s,r}} \le \|\vartheta\|_E \le \tau$ and $|\mathbf{z}| \le c\tau$. Recall that the operator $\mathscr{B}$ constitutes a cubic polynomial of $\mathbf{u}$ and ϱ. By Lemma 2.1, we have

$$R\|\mathscr{B}(\varrho, \mathbf{u}, \mathbf{u})\|_{X^{s,r}} \le cR(1 + \|\varrho\|_{X^{s,r}} + \|\mathbf{z}\|_{X^{s,r}}) \le c\tau^2(1+\tau) \ \text{ in } \ \mathcal{B}_\tau. \tag{2.10}$$

Next note that

$$\|\mathscr{A}(\mathbf{u})\|_{Z^{s,r}} \le c(\|\mathfrak{g} - 1\|_{C^2(\Omega)} + \|\mathbf{N} - \mathbf{I}\|_{C^2(\Omega)})(1 + \|\mathbf{u}\|_{Y^{s,r}}) \le c\tau^2\|\mathbf{u}\|_{Y^{s,r}},$$

which along with (1.39) and (2.10) implies

$$\|F[\vartheta]\|_{Z^{s,r}} \le c\tau^2(1+\tau) \ \text{ in } \ \mathcal{B}_\tau. \tag{2.11}$$

Combining inequalities (2.8) and (2.9) we get the estimate

$$\|\sigma\varphi_1 + \Psi[\vartheta]\|_{X^{s,r}} \le c\tau^2.$$

From this, (2.11), (2.7), and Lemma 1.3 we finally obtain

$$\|\mathbf{u}_1\|_{Y^{s,r}} + |\pi_1|_{X^{s,r}} \le c\tau^2 + c|m|. \tag{2.12}$$

It remains to estimate m. Recall that the vector field $\mathbf{u}$ and parameter σ meet all requirements of Corollary 1.5. Therefore, problem (1.13b) has a unique solution $\zeta \in W^{s,r}(\Omega)$ for all s, r satisfying (1.38). In particular, inequalities (1.35) yield the estimate $\|\zeta\|_{X^{s,r}} \le c$. Since, by virtue of (1.38), the pair $s = 2/3$, $r = 6$ is admissible and the embedding $W^{2/3,6}(\Omega) \hookrightarrow C^{1/6}(\Omega)$ is bounded, estimates (1.33) and (1.34) for $rs > 3$ yield

$$\|\zeta\|_{C^{1/6}(\Omega)} + \|\zeta\|_{W^{1,2}(\Omega)} \le C(\mathbf{U}, \Omega, \sigma). \tag{2.13}$$

Recalling that $\operatorname{div}\mathbf{u} = \operatorname{div}\mathbf{u}$, we obtain $|\operatorname{div}\mathbf{u}| \le c_e\tau$. From this, the inequality $|\mathfrak{g}| \le 1 + c\tau^2$, and the maximum principle (1.34), we conclude that

$$\|\zeta\|_{C(\Omega)} \le (1 + c\tau^2)(1 - \sigma^{-1}c\tau)^{-1} \le (1 - c\tau)^{-1}, \tag{2.14}$$

which leads to the following estimate:

$$|1 - \zeta| \le c\tau(1 - c\tau)^{-1}.$$

Now we can estimate the right-hand side of (1.13c). Rewrite the first integral in the form

$$\int_\Omega \mathfrak{g}(1 - \zeta - \varrho_0^{-1}\zeta\varphi)\,dx = \int_\Omega (1-\zeta)^+\,dx + \int_\Omega (\mathfrak{g} - 1)(1 - \zeta - \varrho_0^{-1}\zeta\varphi)\,dx - \int_\Omega ((1-\zeta)^- + \varrho_0^{-1}\zeta\varphi)\,dx.$$

We have

$$|(\mathfrak{g} - 1)(1 - \zeta - \varrho_0^{-1}\zeta\varphi)| \le c\tau^2, \quad |(1-\zeta)^- + \varrho_0^{-1}\zeta\varphi)| \le c_e\tau + c\tau(1 - c\tau)^{-1}.$$

On the other hand, we have $\|(1-\zeta)^+\|_{C^{1/6}(\Omega)} \le c(\mathbf{U},\Omega,\sigma)$ and $(1-\zeta)^+ = 1$ on Σ_{out}. Hence

$$\int_\Omega (1-\zeta)^+\,dx > \kappa(\mathbf{U},\Omega,\sigma) > 0.$$

Thus, we get

$$\varkappa^{-1} \ge \kappa\bigl(1 - c\kappa^{-1}\tau(1-c\tau)^{-1}\bigr).$$

In particular, there is a positive τ_0 depending only on $\mathbf{U}$, Ω, and σ, such that

$$|\varkappa| \le c \quad \text{for all} \quad \tau \le \tau_0.$$

Repeating these arguments and using inequalities (2.8), (1.13c), we arrive at $|m| \le c\tau^2$. Combining this estimate with (2.9) and (2.12), we finally obtain $\|\vartheta_1\|_{X^{s,r}} \le c\tau^2$. Choose sufficiently small $\tau_0 = \tau_0(\mathbf{U},\Omega,\sigma)$ such that $c\tau_0^2 < \tau_0$. Thus, for all $\tau \le \tau_0$, Ξ maps the ball $\mathcal{B}_\tau$ into itself. Let us show that Ξ is weakly continuous. Choose an arbitrary sequence $\vartheta_n \in \mathcal{B}_\tau$ such that $\vartheta_n = (\mathbf{u}_n, \pi_n, \varphi_n)$ converges weakly in E to some ϑ. Since the ball $\mathcal{B}_\tau$ is closed and convex, ϑ belongs to $\mathcal{B}_\tau$. Let us consider the corresponding sequences of the elements $\vartheta_{1,n} = \Xi(\vartheta_n) \in \mathcal{B}_\tau$ and functions ζ_n. There are subsequences $\{\vartheta_{1,j}\} \subset \{\vartheta_{1,n}\}$ and $\{\zeta_j\} \subset \{\zeta_n\}$ such that $\vartheta_{1,j}$ converges weakly in E to some element $\vartheta_1 \in \mathcal{B}_\tau$ and ζ_j converges weakly in $X^{s,r}$ to some function $\zeta \in X^{s,r}$. Since the embedding $E \hookrightarrow C(\Omega)^5$ is compact, we have $\vartheta_n \to \vartheta$, $\vartheta_{1j} \to \vartheta_1$ in $C(\Omega)^5$, and

$$\nabla\zeta_j \rightharpoonup \nabla\zeta \ \text{ weakly in } \ L^2(\Omega), \ \ \zeta_j \to \zeta \ \text{ in } \ C(\Omega).$$

Substituting ϑ_j and $\vartheta_{1,j}$ into equations (2.4), (2.6), (1.13c) and letting $j \to \infty$, we obtain that the limits ϑ and ϑ_1 also satisfy (2.4), (2.6), (1.13c). Thus, we get $\vartheta_1 = \Xi(\vartheta)$. Since for given ϑ, a solution to equations (2.4), (2.6) is unique, we conclude from this that all weakly convergent subsequences of $\vartheta_{1,n}$ have the unique limit ϑ_1. Therefore, the whole sequence $\vartheta_{1,n} = \Xi(\vartheta_n)$ converges weakly to $\Xi(\vartheta)$. Hence the mapping $\Xi : \mathcal{B}_\tau \mapsto \mathcal{B}_\tau$ is weakly continuous, and, by virtue of the Schauder fixed point theory, there is $\vartheta \in \mathcal{B}(\tau)$ such that $\vartheta = \Xi(\vartheta)$.

It remains to prove that ϑ is given by a solution to problem (1.13a). For $\vartheta_1 = \vartheta$, the only difference between problems (1.13a) and (2.6), (1.13c) is the presence of the projector Π in the right-hand side of (2.6). Hence, it suffices to show that

$$\Pi(\varrho_0^{-1}\mathfrak{g}\sigma\varphi - \mathfrak{g}\Psi[\vartheta] - \mathfrak{g}m) = \varrho_0^{-1}\mathfrak{g}\sigma\varphi - \mathfrak{g}\Psi[\vartheta] - \mathfrak{g}m. \tag{2.15}$$

To this end we note that φ is a generalized solution to the transport equation

$$\mathbf{u}\cdot\nabla\varphi + \sigma\varphi = \Psi_1[\vartheta] + m\mathfrak{g}\varrho.$$

Using ζ as a test function and recalling the integral identity (1.30) we obtain

$$\sigma\int_\Omega \varphi\mathfrak{g}\,dx = \int_\Omega \zeta(\Psi_1[\vartheta] + m\mathfrak{g}\varrho)\,dx.$$

On the other hand, equality (1.13c) reads

$$\int_\Omega \zeta(\varrho_0^{-1}\Psi_1[\vartheta] + m\mathfrak{g}(1+\varphi\varrho_0^{-1}))\,dx = \int_\Omega (\mathfrak{g}\Psi[\vartheta] + \mathfrak{g}m)\,dx.$$

Combining these equalities and noting that $1+\varrho_0^{-1}\varphi=\varrho/\varrho_0$, we obtain

$$\int_\Omega \Big(\frac{\mathfrak{g}\sigma}{\varrho_0}\varphi-\mathfrak{g}\Psi[\vartheta]-m\mathfrak{g}\Big)\,dx=0$$

which yields (2.15), and the proof of Theorem 1.6 is completed. □

2.2. Uniqueness and stability. In this paragraph we prove that, under the assumptions of Theorem 1.6, a solution to problem (1.13) is unique, and we investigate in detail the dependence of the solution on the matrix function $\mathbf{N}$.

Weak formulation of linearized equations. Assume that matrices $\mathbf{N}_i$, $i=1,2$, satisfy conditions of Theorem 1.6, and denote by $(\vartheta_i,\zeta_i,m_i)\in E\times X^{s,r}\times\mathbb{R}$, $i=1,2$, the corresponding solutions to problem (1.13). Recall that the solutions $(\vartheta_i,\zeta_i,m_i)$, together with the constants $\varkappa_i$, satisfy the inequalities

$$|m_i|+\|\vartheta_i\|_E\le c\tau,\quad |\varkappa_i|+\|\zeta_i\|_{X^{s,r}}\le c, \tag{2.16}$$

where the constant c depends only on $\mathbf{U},\Omega$, r,s, and σ. We denote $\mathbf{u}_i=\mathbf{u}_0+\mathbf{u}_i$, $i=1,2$, the solutions to (1.9) for $\mathbf{N}_i$, $i=1,2$. Now set

$$\mathfrak{d}=\mathfrak{g}_1-\mathfrak{g}_2\equiv\sqrt{\det\,\mathbf{N}_1}-\sqrt{\det\,\mathbf{N}_2},$$
$$\mathbf{w}=\mathbf{u}_1-\mathbf{u}_2,\quad \omega=\pi_1-\pi_2,\quad \psi=\varphi_1-\varphi_2,,\ \ \xi=\zeta_1-\zeta_2,\ \ n=m_1-m_2.$$

It follows from (1.13) that

$$\begin{aligned}
\mathbf{u}_1\nabla\psi+\sigma\psi&=-\mathbf{w}\cdot\nabla\varphi_2+b_{11}\psi+b_{12}\omega+b_{13}n+b_{10}\mathfrak{d}\ \ \text{in}\ \ \Omega,\\
\Delta\mathbf{w}-\nabla\omega&=\mathscr{A}_1(\mathbf{w})+R\mathscr{C}_1(\psi,\mathbf{w})+\mathscr{D}\ \ \text{in}\ \ \Omega,\\
\operatorname{div}\mathbf{w}&=b_{21}\psi+b_{22}\omega+b_{23}n+b_{20}\mathfrak{d}\ \ \text{in}\ \ \Omega,\\
-\operatorname{div}(\mathbf{u}_1\xi)+\sigma\xi&=\operatorname{div}(\zeta_2\mathbf{w})+\sigma\mathfrak{d}\ \ \text{in}\ \ \Omega,\\
\mathbf{w}&=0\ \ \text{on}\ \ \partial\Omega,\ \ \psi=0\ \ \text{on}\ \ \Sigma_{\text{in}},\ \ \xi=0\ \ \text{on}\ \ \Sigma_{\text{out}},\\
\omega-\Pi\omega&=0,\quad n=\varkappa\int_\Omega\Big(b_{31}\psi+b_{32}\omega+b_{34}\xi+b_{30}\mathfrak{d}\Big)\,dx.
\end{aligned}\tag{2.17}$$

Here the coefficients are given by the formula

$$\begin{aligned}
b_{11}&=\sigma(1-\mathfrak{g}_2)+\mathfrak{g}_2\Psi[\vartheta_1]-\mathfrak{g}_2\varrho_2\Phi_1(\varphi_1,\varphi_2)+\mathfrak{g}_2m_2-\frac{\sigma\mathfrak{g}_2}{\varrho_0}(\varphi_1+\varphi_2),\\
b_{12}&=\lambda^{-1}\varrho_2\mathfrak{g}_2,\quad b_{13}=\mathfrak{g}_2\varrho_1,\quad b_{10}=\varrho_1\Psi[\vartheta_1]-\frac{\sigma}{\varrho_0}\varphi_1^2-\sigma\varphi_1+m_1\varrho_1,\\
b_{21}&=\mathfrak{g}_2\left(\frac{\sigma}{\varrho_0}+\Phi_1(\varphi_1,\varphi_2)\right),\quad b_{22}=-\mathfrak{g}_2/\lambda,\\
b_{23}&=-\mathfrak{g}_2,\quad b_{20}=\sigma\varphi_1\varrho_0^{-1}-\Psi[\vartheta_1]-m_2,\\
b_{31}&=\varrho_0^{-1}\zeta_1\Big(\sigma(1-\mathfrak{g}_2)+\mathfrak{g}_2\Psi[\vartheta_1]-\mathfrak{g}_2\varrho_2\Phi_1(\varphi_1,\varphi_2)\\
&\quad-\frac{\mathfrak{g}_2\sigma}{\varrho_0}(\varphi_1+\varphi_2)\Big)-\mathfrak{g}_2\Phi_1(\varphi_1,\varphi_2)+m_2\mathfrak{g}_1\varrho_0^{-1}\zeta_2,\\
b_{32}&=\varrho_0^{-1}\zeta_1b_{12}-b_{22},\quad b_{34}=\varrho_0^{-1}\Psi_1[\vartheta_2]+m_2\mathfrak{g}_1(1+\varrho_0^{-1}\varphi_1),\\
b_{30}&=\varrho_0^{-1}\zeta_1(b_{10}-m_1\varrho_1)+\Psi[\vartheta_1]-m_2(1-\zeta_2-\varrho_0^{-1}\zeta_2\varphi_2),\\
\Phi_1(\varphi_1,\varphi_2)&=(p'(\varrho_0)\varrho_0)^{-1}\sigma\int_0^1H'(\varphi_1s+\varphi_2(1-s))\,ds,
\end{aligned}\tag{2.18}$$

and the operators $\mathscr{C}_1$ and $\mathscr{D}$ are defined by the equalities

$$\mathscr{C}(\mathbf{w}) = \mathscr{B}_1(\psi, \mathbf{u}_1, \mathbf{u}_1) + \mathscr{B}_1(\varrho_2, \mathbf{w}, \mathbf{u}_1) + \mathscr{B}_1(\varrho_2, \mathbf{u}_2, \mathbf{w}),$$
$$\mathscr{D} = \mathscr{A}_1(\mathbf{u}_2) - \mathscr{A}_2(\mathbf{u}_2) + R(\mathscr{B}_1(\varrho_2, \mathbf{u}_2, \mathbf{u}_2) - \mathscr{B}_2(\varrho_2, \mathbf{u}_2, \mathbf{u}_2)),$$

where $\mathscr{A}_i$ and $\mathscr{B}_i$ are given by (1.8) with $\mathbf{N}_i$ instead of $\mathbf{N}$.

We consider $\mathscr{D}$ and $\mathfrak{d}$ as *given functions* and equality (2.17) as the system of equations and boundary conditions for unknowns $\mathbf{w}$, ψ, ξ, and n. The next step is crucial for further analysis. We replace equations (2.17) by an integral identity, which leads to the notion of a very weak solution to problem (2.17). To this end choose an arbitrary function $(\mathbf{H}, G, F, M) \in C^\infty(\Omega)^6$ such that $G - \Pi G = 0$, and consider the auxiliary boundary value problems

$$\mathscr{L}^*\varsigma = F, \quad \mathscr{L}\upsilon = M \ \text{ in } \ \Omega, \quad \varsigma = 0 \ \text{ on } \ \Sigma_{\text{out}}, \quad \upsilon = 0 \ \text{ on } \ \Sigma_{\text{in}}. \tag{2.19}$$

$$\Delta\mathbf{h} - \nabla g = \mathbf{H}, \quad \operatorname{div}\mathbf{h} = \Pi G \ \text{ in } \ \Omega, \quad \mathbf{h} = 0 \ \text{ on } \ \partial\Omega, \quad \Pi g = g. \tag{2.20}$$

Since, under the assumptions of Theorem 1.6, $\mathbf{u}$ and σ meet all requirements of Corollary 1.5, each of problems (2.19) has a unique solution such that

$$\|\varsigma\|_{W^{s,r}(\Omega)} \le c\|F\|_{W^{s,r}(\Omega)}, \quad \|\upsilon\|_{W^{s,r}(\Omega)} \le c\|M\|_{W^{s,r}(\Omega)}, \tag{2.21}$$

where c depends only on $\mathbf{U}$, Ω, r, s, and σ. On the other hand, by virtue of Lemma 1.3, problem (2.20) has a unique solution satisfying the inequality

$$\|\mathbf{h}\|_{W^{1+s,r}(\Omega)} + \|g\|_{W^{s,r}(\Omega)} \le c\|\mathbf{H}\|_{W^{1+s,r}(\Omega)} + c\|G\|_{W^{s,r}(\Omega)}. \tag{2.22}$$

Recall that $\mathbf{w} \in W^{2,2}(\Omega)^3 \cap C^1(\Omega)^3$ vanishes on $\partial\Omega$, and $(\omega, \psi, \xi) \in W^{1,2}(\Omega)^3 \cap C(\Omega)^3$. Multiplying both sides of the first equation in system (2.17) by ς, both sides of the fourth equation in (2.17) by υ, integrating the results over Ω, and using the Green formula for the Stokes equations, we obtain the system of integral equalities

$$\begin{aligned}
&\int_\Omega \psi F\,dx = \int_\Omega (-\mathbf{w}\cdot\nabla\varphi_2 + b_{11}\psi + b_{12}\omega + b_{13}n + b_{10}\mathfrak{d})\varsigma\,dx,\\
&\int_\Omega \mathbf{w}\mathbf{H}\,dx + \int_\Omega \omega G\,dx = \int_\Omega \big(b_{21}\psi + b_{22}\omega + b_{23}n + b_{20}\mathfrak{d}\big)g\,dx\\
&+ \int_\Omega (\mathscr{A}_1(\mathbf{w}) + R\mathscr{C}(\mathbf{w},\psi) + \mathscr{D})\mathbf{h}\,dx, \quad \int_\Omega \xi M\,dx = \int_\Omega (\operatorname{div}(\zeta_2\mathbf{w}) + \sigma\mathfrak{d})\upsilon\,dx.
\end{aligned} \tag{2.23}$$

Next, since $\operatorname{div}(\varrho_2\mathbf{u}_2) = 0$, we have

$$\begin{aligned}
&\int_\Omega (\mathscr{B}_1(\varrho_2, \mathbf{w}, \mathbf{u}_1) + \mathscr{B}_1(\varrho_2, \mathbf{u}_2, \mathbf{w}))\cdot\mathbf{h}\,dx\\
&\qquad = \int_\Omega \varrho_2\mathbf{w}\cdot\Big(\nabla(\mathbf{N}_1^{-1}\mathbf{u}_1)\cdot(\mathbf{N}_1^{-1}\mathbf{h}) - (\mathbf{N}_1^{-1})^*\nabla(\mathbf{N}_1^{-1}\mathbf{h})^*\mathbf{u}_2\Big)\,dx.
\end{aligned}$$

On the other hand, integration by parts gives

$$\int_\Omega \operatorname{div}(\zeta_2\mathbf{w})\upsilon\,dx = -\int_\Omega \zeta_2\mathbf{w}\nabla\upsilon\,dx.$$

Using these identities and recalling the duality pairing, we can collect relations (2.23), together with the expression for n, in one integral identity

$$\begin{aligned}&\int_\Omega \mathbf{w}\Big(\mathbf{H} - R\varrho_2\nabla(\mathbf{N}_1^{-1}\mathbf{u}_1)\cdot(\mathbf{N}_1^{-1}\mathbf{h}) + R\varrho_2(\mathbf{N}_1^{-1})^*\nabla(\mathbf{N}_1^{-1}\mathbf{h})^*\mathbf{u}_2\Big)\,dx\\ &\quad - \mathfrak{B}(\mathbf{w},\varphi_2,\varsigma) - \mathfrak{B}(\mathbf{w},\upsilon,\zeta_2) - \mathfrak{A}_1(\mathbf{w},\mathbf{h}) + \big\langle\omega, G - b_{12}\varsigma - b_{22}g - \varkappa b_{32}\big\rangle\\ &\quad + \big\langle\psi, F - b_{11}\varsigma - b_{21}g - \varkappa b_{31} - R\mathbf{u}_1\cdot\nabla(\mathbf{N}_1^{-1}\mathbf{u}_1)\cdot\mathbf{N}_1^{-1}\mathbf{h}\big\rangle\\ &+ \big\langle\xi, M - \varkappa b_{34}\big\rangle + n - n\big\langle 1, b_{13}\varsigma + b_{23}g\big\rangle = \big\langle\mathfrak{d}, b_{10}\varsigma + b_{20}g + \varkappa b_{30} + \sigma\upsilon\big\rangle + \big\langle\mathscr{D},\mathbf{W}\big\rangle.\end{aligned}\tag{2.24}$$

Here, the trilinear form $\mathfrak{B}$ and the bilinear form $\mathfrak{A}_1$ are defined by the equalities

$$\mathfrak{B}(\mathbf{w},\varphi_2,\varsigma) = -\int_\Omega \varsigma\mathbf{w}\cdot\nabla\varphi_2\,dx,\quad \mathfrak{A}_1(\mathbf{w},\mathbf{h}) = \int_\Omega \mathscr{A}_1(\mathbf{w})\cdot\mathbf{h}\,dx.$$

Note that relations (2.24) are well defined for all $\mathbf{w}\in\mathcal{W}_0^{1-s,r'}(\Omega)$ and $\psi,\xi\in\mathbb{W}^{-s,r'}(\Omega)$. It is obviously true for all terms, with the possible exception of $\mathfrak{A}_1$ and $\mathfrak{B}$. Well-posedness of the form $\mathfrak{B}$ follows from Lemma 1.7. The well-posedness of the form $\mathfrak{A}_1$ results from the following lemma; the proof is given in Appendix A.

LEMMA 2.2. *Let $sr>3$, $1/2\le s\le 1$, and $\mathbf{w}\in\mathcal{W}_0^{1-s,r'}(\Omega)\cap W_0^{1,2}(\Omega)$, $\mathbf{h}\in W^{1+s,r}(\Omega)$, and $\mathbf{N}_1$ satisfy* (1.39). *Then there is a constant c depending only on s,r, and Ω such that*

$$|\mathfrak{A}_1(\mathbf{w},\mathbf{h})|\le c\tau^2\|\mathbf{w}\|_{\mathcal{W}_0^{1-s,r'}(\Omega)}\|\mathbf{h}\|_{W^{1+s,r}(\Omega)}.\tag{2.25}$$

Consequently, the form $\mathfrak{A}_1$ can be continuously extended to $\mathfrak{A}_1 : \mathcal{W}_0^{1-s,r'}(\Omega)^3\times W^{1+s,r}(\Omega)^3\mapsto\mathbb{R}$.

Thus, relations (2.24) are well defined for all $(\mathbf{w},\psi,\omega,\xi)\in\mathcal{W}_0^{1-s,r'}(\Omega)^3\times\mathbb{W}^{-s,r'}(\Omega)^3$. Equalities (2.24) along with (2.19), (2.20) are called *the very weak formulation* of problem (2.17). The natural question is the uniqueness of solutions to such weak formulation. The following theorem, which is the main result of this section, guarantees the uniqueness of very weak solutions for sufficiently small τ.

THEOREM 2.3. *Let s,r, and σ satisfy condition* (1.38), *parameters λ,R and matrices $\mathbf{N}_i$, $i=1,2$, satisfy conditions* (1.39), *and constants τ meet all requirements of Theorem* 1.6. *Also let the solutions $(\vartheta_i,\zeta_i,m_i)$, $i=1,2$, to problem* (1.13) *with the matrices $\mathbf{N}_i$, $i=1,2$, belong to $\mathcal{B}_\tau\times X^{s,r}\times\mathbb{R}$. Furthermore, assume that, for any $(\mathbf{H},G,F,M)\in C^\infty(\Omega)^6$ and for $(\varsigma,\upsilon,\mathbf{h},g)$ satisfying* (2.19)–(2.20), *the elements $(\mathbf{w},\omega,\psi,\xi)\in\mathcal{W}_0^{1-s,r'}(\Omega)^3\times\mathbb{W}^{-s,r'}(\Omega)^3$ and the constant n satisfy identity* (2.24).

Then there are constants c, τ_1 depending only on s,r,σ, and Ω, $\mathbf{U}$ such that, for $\tau\in(0,\tau_1]$, we have

$$\begin{aligned}&\|\mathbf{w}\|_{\mathcal{W}_0^{1-s,r'}(\Omega)} + \|\omega\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|\psi\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|\xi\|_{\mathbb{W}^{-s,r'}(\Omega)} + |n|\\ &\qquad\le c(\|\mathscr{D}\|_{L^1(\Omega)} + \|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)}).\end{aligned}\tag{2.26}$$

Proof. The proof is based upon two auxiliary lemmas; the first lemma establishes the bounds for coefficients of problem (2.17).

LEMMA 2.4. *Under the assumptions of Theorem* 2.3, *all the coefficients of identity* (2.24) *satisfy the inequalities $\|b_{ij}\|_{X^{s,r}}\le c$; furthermore*

$$\begin{aligned}\|b_{12}\|_{X^{s,r}} + \|b_{22}\|_{X^{s,r}} + \|b_{11}\|_{X^{s,r}} + \|b_{10}\|_{X^{s,r}} + \|b_{20}\|_{X^{s,r}}\le c\tau,\\ \|b_{31}\|_{X^{s,r}} + \|b_{32}\|_{X^{s,r}} + \|b_{34}\|_{X^{s,r}}\le c\tau.\end{aligned}\tag{2.27}$$

Proof. The proof follows from Lemma 2.1 combined with formula (2.18). ∎

In order to formulate the second auxiliary result we introduce the following denotations:

$$\mathfrak{I}_1 = \langle \psi, b_{11}\varsigma\rangle + \langle \omega, b_{12}\varsigma\rangle + \langle \mathfrak{d}, b_{10}\varsigma\rangle, \quad \mathfrak{I}_2 = \langle \psi, b_{21}g\rangle + \langle \omega, b_{22}g\rangle + \langle \mathfrak{d}, b_{20}g\rangle,$$
$$\mathfrak{I}_3 = \varkappa\big(\langle \psi, b_{31}\rangle + \langle \omega, b_{32}\rangle + \langle \xi, b_{34}\rangle + \langle \mathfrak{d}, b_{30}\rangle\big), \quad \mathfrak{I}_4 = \Big\langle \psi, \mathbf{u}_2\nabla(\mathbf{N}_1\mathbf{u}_1)\cdot\mathbf{N}_1^{-1}\mathbf{h}\Big\rangle,$$
$$\mathfrak{I}_5 = \int_\Omega \varrho_2\mathbf{w}\cdot\Big(\nabla(\mathbf{N}_1^{-1}\mathbf{u}_1)\cdot(\mathbf{N}_1^{-1}\mathbf{h}) - (\mathbf{N}_1^{-1})^*\nabla(\mathbf{N}_1^{-1}\mathbf{h})^*\mathbf{u}_2\Big)\,dx,$$
$$\mathfrak{G} = \|\mathbf{w}\|_{\mathcal{W}_0^{1-s,r'}(\Omega)} + \|\psi\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|\omega\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|\xi\|_{\mathbb{W}^{-s,r'}(\Omega)},$$
$$\mathfrak{Q} = \|\mathbf{H}\|_{\mathcal{W}^{s-1,r}(\Omega)} + \|G\|_{W^{s,r}(\Omega)} + \|F\|_{W^{s,r}(\Omega)} + \|M\|_{W^{s,r}(\Omega)}.$$

LEMMA 2.5. *Under the assumptions of Theorem* 2.3*, there is a constant c, depending only on $\mathbf{U}$, Ω, s, r, and σ, such that*

$$\mathfrak{I}_1 \le c\tau\mathfrak{Q}\big[\mathfrak{G} + \|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)}\big], \tag{2.28}$$
$$\mathfrak{I}_2 \le c\mathfrak{Q}\big[\tau\mathfrak{G} + \|\psi\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)}\big], \tag{2.29}$$
$$\mathfrak{I}_3 \le c\tau\big[\mathfrak{G} + \|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)}\big], \quad \mathfrak{I}_4 + \mathfrak{I}_5 \le c\mathfrak{Q}\mathfrak{G}. \tag{2.30}$$

Proof. We have

$$\langle \psi, b_{11}\varsigma\rangle + \langle \omega, b_{12}\varsigma\rangle + \langle \mathfrak{d}, b_{10}\varsigma\rangle \le \|b_{11}\varsigma\|_{W^{s,r}(\Omega)}\|\psi\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|b_{12}\varsigma\|_{W^{s,r}(\Omega)}\|\omega\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|b_{10}\varsigma\|_{W^{s,r}(\Omega)}\|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)}.$$

Recall that, for $rs > 3$, $W^{s,r}(\Omega)$ is a Banach algebra. From this, estimate (2.21), and inequalities (2.27), we obtain

$$\begin{aligned}
&\|b_{11}\varsigma\|_{W^{s,r}(\Omega)}\|\psi\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|b_{12}\varsigma\|_{W^{s,r}(\Omega)}\|\omega\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|b_{10}\varsigma\|_{W^{s,r}(\Omega)}\|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)}\\
&\quad\le c\|\varsigma\|_{W^{s,r}(\Omega)}(\|b_{11}\|_{W^{s,r}(\Omega)}\|\psi\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|b_{12}\|_{W^{s,r}(\Omega)}\|\omega\|_{\mathbb{W}^{-s,r'}(\Omega)}\\
&\qquad\qquad + \|b_{10}\|_{W^{s,r}(\Omega)}\|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)})\\
&\quad\le c\tau\|F\|_{W^{s,r}(\Omega)}(\|\psi\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|\omega\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)}),
\end{aligned}$$

which gives (2.28). Repeating these arguments and using inequality (2.21), we obtain the estimates for $\mathfrak{I}_2$ and $\mathfrak{I}_3$. Next we have

$$\begin{aligned}
\|\mathbf{u}_2\cdot\nabla(\mathbf{N}_1^{-1}\mathbf{u}_1)\cdot\mathbf{N}_1^{-1}\mathbf{h}\|_{W^{s,r}(\Omega)} &\le c\|\mathbf{u}_2\|_{W^{s,r}(\Omega)}\|\mathbf{u}_1\|_{W^{1+s,r}(\Omega)}\|\mathbf{h}\|_{W^{1+s,r}(\Omega)}\\
&\le c\|\mathbf{H}\|_{W^{1+s,r}(\Omega)},
\end{aligned}$$

which gives the estimate for $\mathfrak{I}_4$. Since the embeddings $W^{s,r}(\Omega)\hookrightarrow C(\Omega)$, $W^{1+s,r}(\Omega)\hookrightarrow C^1(\Omega)$ are bounded and $\|\mathbf{N}^{\pm1}\|_{C^1(\Omega)} \le c$, we have

$$\varrho_2|\nabla(\mathbf{N}_1^{-1}\mathbf{u}_1)||\mathbf{N}_1^{-1}\mathbf{h}| + \varrho_2|(\mathbf{N}_1^{-1}\mathbf{u}_2)||\nabla(\mathbf{N}_1^{-1}\mathbf{h})| \le c\|\mathbf{h}\|_{W^{1+s,r}(\Omega)},$$

which leads to the inequality

$$\mathfrak{I}_5 \le c\|\mathbf{h}\|_{W^{1+s,r}(\Omega)}\|\mathbf{w}\|_{L^1(\Omega)} \le c(\|\mathbf{H}\|_{\mathcal{W}^{s-1,r}(\Omega)} + \|G\|_{W^{s,r}(\Omega)})\|\mathbf{w}\|_{\mathcal{W}^{1-s,r'}(\Omega)},$$

and the proof of Lemma 2.5 is completed. ∎

Let us return to the proof of Theorem 2.3. It follows from the duality principle that the theorem is proved provided we show that, under the assumptions of Theorem 1.6, the following inequality holds:

$$\begin{aligned}&\sup_{\mathfrak{Q}(\mathbf{H},G,F,M)=1}\big(\big\langle\mathbf{w},\mathbf{H}\big\rangle+\big\langle\omega,G\big\rangle+\big\langle\psi,F\big\rangle+\big\langle\xi,M\big\rangle\big)+|n|\\&\le c\tau\left(\mathfrak{G}\big(\mathbf{w},\omega,\psi,\xi\big)+|n|\right)+c\big(\|\mathscr{D}\|_{L^1(\Omega)}+\|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)}\big),\end{aligned}\tag{2.31}$$

where the constant c depends only on $\Omega,\mathbf{U}$ and r,s,σ. Therefore, our task is to estimate step by step all terms in the left-hand side of (2.31). We begin with an estimate for the term $\langle\psi,F\rangle$. To this end, take $\mathbf{H}=\mathbf{h}=0$, $G=g=0$, $M=\upsilon=0$, and rewrite identity (2.24) in the form

$$\big\langle\psi,F\big\rangle=\mathfrak{B}(\mathbf{w},\varphi_2,\varsigma)+\mathfrak{I}_1+\mathfrak{I}_3+n\big\langle1,b_{13}\varsigma\big\rangle-n.$$

By virtue of Lemma 1.7 and estimate (2.22), we have

$$\mathfrak{B}(\mathbf{w},\varphi_2,\varsigma)\le c\tau\|\mathbf{w}\|_{\mathcal{W}_0^{1-s,r'}(\Omega)}\|\varsigma\|_{W^{s,r}(\Omega)}\le c\tau\|\mathbf{w}\|_{W^{1-s,r'}(\Omega)}\|F\|_{W^{s,r}(\Omega)}.\tag{2.32}$$

On the other hand, Lemma 2.4 and inequality (2.21) yield $|\big\langle1,b_{13}\varsigma\big\rangle|\le c\|F\|_{W^{s,r}(\Omega)}$. From this and (2.28), (2.30) we finally obtain

$$\big\langle\psi,F\big\rangle\le|n|+c\|F\|_{W^{s,r}(\Omega)}\left[\,\tau\mathfrak{G}+\|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)}+|n|\,\right].\tag{2.33}$$

Moreover, by virtue of the duality principle

$$\|\psi\|_{\mathbb{W}^{-s,r'}(\Omega)}=\sup_{\|F\|_{W^{s,r}(\Omega)}=1}\big|\big\langle\psi,F\big\rangle\big|,$$

we have the following estimate for ψ:

$$\|\psi\|_{\mathbb{W}^{-s,r'}(\Omega)}\le c\tau\mathfrak{G}+c\|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)}+c|n|.\tag{2.34}$$

Let us estimate $\mathbf{w}$ and ω. Substituting $F=\varsigma=0$ and $M=\upsilon=0$ into (2.24) we obtain

$$\big\langle\mathbf{w},\mathbf{H}\big\rangle+\big\langle\omega,G\big\rangle=\mathfrak{A}_1(\mathbf{w},\mathbf{h})+\mathfrak{I}_2+\mathfrak{I}_3+R\mathfrak{I}_4+R\mathfrak{I}_5+n\big\langle1,b_{23}g\big\rangle-n+\big\langle\mathscr{D},\mathbf{h}\big\rangle.$$

By virtue of Lemma 2.2 and (2.22), the first term in the right-hand side is bounded:

$$|\mathfrak{A}_1(\mathbf{w},\mathbf{h})|\le c\tau^2(\|\mathbf{H}\|_{\mathcal{W}^{s-1,r}(\Omega)}+\|G\|_{W^{s,r}(\Omega)})\|\mathbf{w}\|_{\mathcal{W}_0^{1-s,r'}(\Omega)}.$$

Next we have

$$|n\big\langle1,b_{23}g\big\rangle|\le c(\|\mathbf{H}\|_{\mathcal{W}^{s-1,r}(\Omega)}+\|G\|_{W^{s,r}(\Omega)})|n|.$$

Obviously

$$|\big\langle\mathscr{D},\mathbf{W}\big\rangle|\le c\|\mathscr{D}\|_{L^1(\Omega)}\|\mathbf{h}\|_{C(\Omega)}\le c(\|\mathbf{H}\|_{\mathcal{W}^{s-1,r}(\Omega)}+\|G\|_{W^{s,r}(\Omega)})\|\mathscr{D}\|_{L^1(\Omega)}.$$

These inequalities together with estimates (2.29)–(2.30) and inequality $R\le\tau^2$ imply

$$\begin{aligned}&\big\langle\mathbf{w},\mathbf{H}\big\rangle+\big\langle\omega,G\big\rangle\le|n|+c\tau\mathfrak{Q}\mathfrak{G}\\&+c\mathfrak{Q}\Big(\|\psi\|_{\mathbb{W}^{-s,r'}(\Omega)}+|n|+\|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)}+\|\mathscr{D}\|_{L^1(\Omega)}\Big).\end{aligned}$$

Combining this result with (2.34), we obtain

$$\big\langle \mathbf{w}, \mathbf{H}\big\rangle + \big\langle \omega, G\big\rangle \le |n| + c\tau\mathfrak{Q}\mathfrak{G} + c\mathfrak{Q}\big(|n| + \|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|\mathscr{D}\|_{L^1(\Omega)}\big), \tag{2.35}$$

where $\mathfrak{Q} = \mathfrak{Q}(\mathbf{H}, G, 0, 0)$. For $G = 0$ and by the duality principle

$$\|\mathbf{w}\|_{\mathcal{W}_0^{1-s,r'}(\Omega)} = \sup_{\|\mathbf{H}\|_{\mathcal{W}^{s-1,r}(\Omega)}=1} \big\langle \mathbf{H}, \mathbf{w}\big\rangle,$$

we conclude that

$$\|\mathbf{w}\|_{\mathcal{W}_0^{1-s,r'}(\Omega)} \le |n| + c\tau\mathfrak{G} + c\Big(|n| + \|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|\mathscr{D}\|_{L^1(\Omega)}\Big). \tag{2.36}$$

Next, substituting $\mathbf{H} = \mathbf{h} = 0$, $G = g = F = \varsigma = 0$ into identity (2.24), we arrive at

$$\big\langle \xi, M\big\rangle = \mathfrak{B}(\mathbf{w}, \zeta_2, \upsilon) + \mathfrak{I}_3 + \sigma\big\langle \mathfrak{d}, \upsilon\big\rangle - n.$$

Lemma 1.7 and (2.21) give the estimate for the first term:

$$|\mathfrak{B}(\mathbf{w}, \zeta_2, \upsilon)| \le c\|\mathbf{w}\|_{\mathcal{W}_0^{1-s,r'}(\Omega)}\|\upsilon\|_{W^{s,r}(\Omega)} \le c\|\mathbf{w}\|_{\mathcal{W}_0^{1-s,r'}(\Omega)}\|M\|_{W^{s,r}(\Omega)}.$$

From this and estimates (2.30), (2.21), we obtain

$$\big\langle \xi, M\big\rangle \le c\tau\mathfrak{Q}\mathfrak{G} + c\mathfrak{Q}(\|\mathbf{w}\|_{\mathcal{W}_0^{1-s,r'}(\Omega)} + \|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)}) + |n|.$$

Combining this result with inequality (2.36), we arrive at

$$\big\langle \xi, M\big\rangle \le c\mathfrak{Q}(\tau\mathfrak{G} + |n| + \|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|\mathscr{D}\|_{L^1(\Omega)}) + c|n|. \tag{2.37}$$

Finally, choosing all test functions in (2.24) equal to 0, we obtain $n = \mathfrak{I}_3$, which together with (2.30) yields

$$|n| \le c\tau\mathfrak{Q}(\mathfrak{G} + \|\mathfrak{d}\|_{\mathbb{W}^{-s,r'}(\Omega)}). \tag{2.38}$$

From (2.33), (2.35), (2.37), combined with (2.38), it follows (2.31), and the proof of Theorem 2.3 is completed. □

Uniqueness of solutions. The important consequence of Theorem 2.3 is the following result on uniqueness of solutions to problem (1.13).

PROPOSITION 2.6. *Under the assumptions of Theorem* 1.6*, there exists a positive* τ_0 *such that, for all* $\tau \in (0, \tau_0]$*, problem* (1.13) *admits a unique solution in the ball* $\mathcal{B}_\tau$*.*

Proof. If for some $\mathbf{N}$ the problem has two distinct solutions $(\vartheta_i, \zeta_i, m_i)$, $i = 1, 2$, with $\vartheta_i \in \mathcal{B}_\tau$, then the corresponding *finite differences* of the solutions $\mathbf{w}$, ψ, ω, and ξ meet all requirements of Theorem 2.3 with $\mathfrak{d} = 0$ and $\mathscr{D} = 0$. Therefore, in view of (2.26) all the elements $\mathbf{w}$, ψ, ω, and ξ are equal to 0, which completes the proof. □

3. Proofs of Theorems 1.9 and 1.11.

Proof of Theorem 1.9. Let us consider a family of matrices $\mathbf{N}(\varepsilon)$ having representation (1.6) and the sequence of corresponding solutions $(\vartheta(\varepsilon), \zeta(\varepsilon), m(\varepsilon))$ to problem (1.13), where $\vartheta(\varepsilon) = (\mathbf{u}(\varepsilon), \pi(\varepsilon), \varphi(\varepsilon))$. By virtue of (1.41), we can assume that, possibly after passing to a subsequence, the sequence $(\vartheta(\varepsilon), \zeta(\varepsilon), m(\varepsilon))$ converges weakly in $(Y^{s,r})^3 \times (X^{s,r})^3 \times \mathbb{R}$ to some element (ϑ, ζ, m), which satisfies equations (1.13) with $\mathbf{N} = \mathbf{I}$ and meets all requirements of Theorem 1.6. Since the solution (ϑ, ζ, m) to problem (1.13) is unique, the limit is independent of the choice of a subsequence,

and the whole sequence converges to the limit (ϑ, ζ, m). It follows from (2.17) that the differences $\vartheta - \vartheta(\varepsilon)$, $\zeta - \zeta(\varepsilon)$, $m - m(\varepsilon)$ satisfy (2.17), with the coefficients $b_{ij}^{(\varepsilon)}$ and the operator $\mathscr{D}_\varepsilon$ given by formula (2.18) with

$$\mathbf{N}_1 = \mathbf{I}, \mathbf{N}_2 = \mathbf{N}(\varepsilon), (\vartheta_1, \zeta_1, m_1) = (\vartheta, \zeta, m), (\vartheta_2, \zeta_2, m_2) = (\vartheta(\varepsilon), \zeta(\varepsilon), m(\varepsilon)).$$

In particular, the operator $\mathscr{D}_\varepsilon$ is defined by the equality

$$\begin{aligned}\mathscr{D}_\varepsilon &= R\varrho(\varepsilon)\Big(\mathbf{u}(\varepsilon)\nabla\mathbf{u}(\varepsilon) - (\mathbf{N}(\varepsilon)^*)^{-1}\big(\mathbf{u}(\varepsilon)\nabla\big(\mathbf{N}(\varepsilon)^{-1}\mathbf{u}(\varepsilon)\big)\big)\Big)\\ &+ (\mathbf{N}(\varepsilon)^*)^{-1}\operatorname{div}\big(\mathfrak{g}^{-1}(\varepsilon)\mathbf{N}(\varepsilon)\mathbf{N}(\varepsilon)^*\nabla(\mathbf{N}(\varepsilon)^{-1}\mathbf{u}(\varepsilon))\big) - \Delta\mathbf{u}(\varepsilon)\end{aligned}$$

and admits the representation $\mathscr{D}_\varepsilon = \varepsilon\mathscr{D}_0(\mathfrak{d}, \mathbf{D}) + \varepsilon^2\mathscr{D}_1(\varepsilon)$, where $\mathscr{D}_0$ is given by (1.45). Moreover, since the norms $\|\varrho(\varepsilon)\|_{C(\Omega)}$ and $\|\mathbf{u}(\varepsilon)\|_{W^{2,2}(\Omega)}$ are uniformly bounded, we have

$$\|\mathscr{D}_1(\varepsilon)\|_{L^2(\Omega)} \le c(\mathbf{U}, \Omega, \sigma). \tag{3.1}$$

Next note that $\mathfrak{g}(\varepsilon)$ admits the decomposition $\mathfrak{g}(\varepsilon) = 1 + \varepsilon\mathfrak{d} + \varepsilon^2\mathfrak{d}_1(\varepsilon)$, where $\mathfrak{d} = \operatorname{Tr}\mathbf{D}$ and the reminder $\mathfrak{d}_1(\varepsilon)$ is uniformly bounded in $C^1(\Omega)$. Proceeding as in the previous section and recalling the equalities $\mathscr{A}_1 = \mathfrak{A}_1 = 0$, we conclude that the finite differences

$$(\mathbf{w}_\varepsilon, \omega_\varepsilon, \psi_\varepsilon) = \varepsilon^{-1}(\vartheta - \vartheta(\varepsilon)), \quad \xi_\varepsilon = \varepsilon^{-1}(\zeta - \zeta(\varepsilon)), \quad n_\varepsilon = \varepsilon^{-1}(m - m(\varepsilon))$$

satisfy the integral identity

$$\begin{aligned}&\int_\Omega \mathbf{w}_\varepsilon\Big(\mathbf{H} - \varrho(\varepsilon)\nabla\mathbf{u}\cdot\mathbf{h} + R\varrho(\varepsilon)\nabla\mathbf{h}^*\mathbf{u}(\varepsilon)\Big)\,dx\\ &- \mathfrak{B}(\mathbf{w}_\varepsilon, \varphi(\varepsilon), \varsigma) - \mathfrak{B}(\mathbf{w}_\varepsilon, \upsilon, \zeta(\varepsilon)) + \big\langle\omega_\varepsilon, G - b_{12}^{(\varepsilon)}\varsigma - b_{22}^{(\varepsilon)}g - \varkappa b_{32}^{(\varepsilon)}\big\rangle\\ &+ \big\langle\psi_\varepsilon, F - b_{11}^{(\varepsilon)}\varsigma - b_{21}^{(\varepsilon)}g - \varkappa b_{31}^{(\varepsilon)} - R\mathbf{u}\cdot\nabla\mathbf{u}\cdot\mathbf{h}\big\rangle + \big\langle\xi_\varepsilon, M - \varkappa b_{34}^{(\varepsilon)}\big\rangle + n_\varepsilon\\ &- n_\varepsilon\big\langle 1, b_{13}^{(\varepsilon)}\varsigma + b_{23}^{(\varepsilon)}g\big\rangle = \big\langle\mathfrak{d} + \varepsilon\mathfrak{d}_1(\varepsilon), b_{10}^{(\varepsilon)}\varsigma + b_{20}^{(\varepsilon)}g + \varkappa b_{30}^{(\varepsilon)} + \sigma\upsilon\big\rangle + \big\langle\mathscr{D}_0 + \varepsilon\mathscr{D}_1(\varepsilon), \mathbf{h}\big\rangle,\end{aligned} \tag{3.2}$$

along with the orthogonality conditions $\big\langle\omega_\varepsilon, 1\big\rangle = 0$. Here $(\mathbf{H}, G, F, M)$ are arbitrary smooth functions such that $G = \Pi G$, and the test functions ς, υ, g, and $\mathbf{h}$ are defined by equations (2.19), (2.20); therefore, the test functions are independent of ε. Recall that the elements $\vartheta_1 = \vartheta$ and $\vartheta_2 = \vartheta(\varepsilon)$ belong to the ball $\mathcal{B}_\tau$ and meet all requirements of Theorem 2.3. Hence, there exists $\tau_1 > 0$, depending only on $\Omega, \mathbf{U}$ and s, r, σ, such that the conditions

$$\lambda^{-1}, \quad R \le \tau^2, \quad \|\mathbf{N}(\varepsilon) - \mathbf{I}\|_{C^1(\Omega)} \le \tau^2, \quad 0 < \tau \le \tau_1,$$

imply

$$\begin{aligned}\|\mathbf{w}_\varepsilon\|_{\mathcal{W}_0^{1-s,r'}(\Omega)} + \|\omega_\varepsilon\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|\psi_\varepsilon\|_{\mathbb{W}^{-s,r'}(\Omega)} + \|\xi_\varepsilon\|_{\mathbb{W}^{-s,r'}(\Omega)} + |n_\varepsilon|\\ \le c(\|\mathscr{D}_0 + \varepsilon\mathscr{D}_1\|_{L^1(\Omega)} + \|\mathfrak{d} + \varepsilon\mathfrak{d}_1\|_{C^2(\Omega)}) \le c.\end{aligned}$$

Therefore, after possibly passing to a subsequence, we can assume that the sequence $\mathbf{w}_\varepsilon$ converges to $\mathbf{w}$ weakly in $\mathcal{W}_0^{1-s,r'}(\Omega)$, and $(\omega_\varepsilon, \psi_\varepsilon, \xi_\varepsilon)$ converge to (ω, ψ, ξ) $(*)$-weakly in $\mathbb{W}^{-s,r'}(\Omega)$ as $\varepsilon \to 0$.

Next, choose $s' > s$ satisfying conditions (1.38). By virtue of Theorem 1.6, there exists $\tau_0' > 0$ (depending only on Ω, $\mathbf{U}$, r, s, σ) such that, for all $\tau \in (0, \tau_0']$, the functions $(\vartheta(\varepsilon), \zeta(\varepsilon))$ are bounded in $(Y^{s',r})^3 \times (X^{s',r})^3$. It follows from this that the family $\mathbf{u}(\varepsilon) = \mathbf{u}_0 + \mathbf{u}(\varepsilon)$ converges to $\mathbf{u}$ strongly in $Y^{s,r}$, and $(\varphi(\varepsilon), \pi(\varepsilon), \zeta(\varepsilon))$ converges to (φ, π, ζ) strongly in $X^{s,r}$. Therefore, by virtue of Lemma 2.1, the sequence $b_{ij}^{(\varepsilon)}$ converges strongly in $X^{s,r}$ to b_{ij}^0. Hence, we can pass to the limit in (3.2). It is easy to see that the limits, the vector field $\mathbf{w}$, and the functionals ψ, ω, ξ are given by a unique weak solution to problem (1.42) and, in addition, meet all requirements of Definition 1.8. It remains to note that, by virtue of Theorem 2.3, the limit is independent of the choice of a subsequence, which completes the proof of Theorem 1.9. ∎

Proof of Theorem 1.11. Assume that r, s, σ, and τ satisfy inequalities (1.31), (1.38), and that $\vartheta = (\mathbf{u}, \pi, \varphi) \in \mathcal{B}_\tau$ is a solution to problem (1.13) given by Theorem 1.6. Denote by $Y_0^{s,r}$ the subspace of the space $Y^{s,r}$ of all functions vanishing on $\partial\Omega$, by $X_{\text{in}}^{s,r}$ and $X_{\text{out}}^{s,r}$ the subspaces of $X^{s,r}$ which consist of all functions vanishing on Σ_{in} and Σ_{out}, respectively, and by $X_\Pi^{s,r}$ the subspace of all function in $X^{s,r}$ having the zero mean value. Introduce the Banach spaces $\mathcal{E} = (Y_0^{s,r})^3 \times X_\Pi^{s,r} \times X_{\text{out}}^{s,r} \times X_{\text{in}}^{s,r} \times \mathbb{R}$ and $\mathcal{F} = (Z^{s,r})^3 \times X_\Pi^{s,r} \times (X^{s,r})^2 \times \mathbb{R}$. Our first task is to show that, for all $\Theta \in \mathcal{F}$, problem (1.52), (1.49) has a unique solution $Y \in \mathcal{E}$. We begin with the observation that, by virtue of Lemma 1.3, the Stokes operator has the bounded inverse

$$\begin{pmatrix} \Delta & -\nabla \\ \operatorname{div} & 0 \end{pmatrix}^{-1} : (Z^{s,r})^3 \times X_\Pi^{s,r} \to (Y_0^{s,r})^3 \times X_\Pi^{s,r}.$$

On the other hand, by virtue of Corollary 1.5, the operators $\mathscr{L}$ and $\mathscr{L}^*$ from (1.48) have the bounded inverses $\mathscr{L}^{-1} : X^{s,r} \to X_{\text{in}}^{s,r}$, $(\mathscr{L}^*)^{-1} : X^{s,r} \to X_{\text{out}}^{s,r}$. Therefore, there exists the bounded operator

$$\begin{pmatrix} \mathscr{L}^* & 0 & 0 \\ 0 & \mathscr{L} & 0 \\ -\mathbb{B}_{1,3} & 0 & 1 \end{pmatrix}^{-1} : (X^{s,r})^2 \times \mathbb{R} \to X_{\text{out}}^{s,r} \times X_{\text{in}}^{s,r} \times \mathbb{R}.$$

It follows from this that, for all $\Theta \in \mathcal{F}$, the equation $\mathfrak{L}\mathbf{Y} = \Theta$ has a unique solution satisfying boundary conditions (1.49) and the inequality $\|\mathbf{Y}\|_{\mathcal{E}} \le c\|\Theta\|_{\mathcal{F}}$, where the constant c is independent of τ. Let us consider the operators $\mathfrak{U}$. By virtue of Lemma 1.7, we have

$$\|\varsigma\nabla\varphi\|_{\mathcal{W}^{s-1,r}(\Omega)} \le c\tau\|\varsigma\|_{X^{s,r}}.$$

It is easy to see that

$$\|\varsigma\nabla\varphi\|_{L^2(\Omega)} \le c\|\varsigma\|_{X^{s,r}}\|\nabla\varphi\|_{L^2(\Omega)} \le c\|\varsigma\|_{X^{s,r}}\|\varphi\|_{X^{s,r}} \le c\tau\|\varsigma\|_{X^{s,r}}.$$

Combining the obtained estimates we get the inequality $\|\varsigma\nabla\varphi\|_{Z^{s,r}} \le c\tau\|\varsigma\|_{X^{s,r}}$. Repetition of these arguments gives the inequality $\|\zeta\nabla v\|_{Z^{s,r}} \le c\|v\|_{X^{s,r}}$. Since the norms $\|b_{ij}^0\|_{X^{s,r}}$ are uniformly bounded, we conclude from this that $\|\mathfrak{U}\mathbf{Y}\|_{\mathcal{F}} \le c\|Y\|_{\mathcal{E}}$. Finally, let us consider the operator $\mathfrak{V}$. Since the space $X^{s,r}$ is the commutative Banach algebra and $\nabla\mathbf{u} \in X^{s,r}$, we have

$$\|R\mathbf{u}\nabla\mathbf{u}\mathbf{h}\|_{X^{s,r}} \le c\tau^2\|\mathbf{h}\|_{X^{s,r}}, \quad \|R\varrho(\nabla\mathbf{u} + \mathbf{u}\nabla)\mathbf{h}\|_{X^{s,r}} \le c\tau^2\|\mathbf{h}\|_{Y^{s,r}}.$$

On the other hand, by virtue of Lemma 2.1 and (1.43), the coefficients b_{ij}^0 in the expression for $\mathfrak{V}$ satisfy the inequalities

$$\|b_{12}^0\|_{X^{s,r}} + \|b_{11}^0\|_{X^{s,r}} + \|b_{31}^0\|_{X^{s,r}} + \|b_{32}^0\|_{X^{s,r}} + \|b_{34}^0\|_{X^{s,r}} \le c\tau,$$

which yield the estimate $\|\mathfrak{V}\mathbf{Y}\|_{\mathcal{F}} \le c\tau\|Y\|_{\mathcal{E}}$. Thus we get that the diagonal matrix operator $\mathfrak{L}$ has the bounded inverse, $\mathfrak{U}$ is the bounded upper triangular (with respect to $\mathfrak{L}$) matrix operator, and $\mathfrak{V}$ is the small bounded operator. Hence, for all sufficiently small τ the operator $\mathfrak{L} - \mathfrak{U} - \mathfrak{V} : \mathcal{E} \to \mathcal{F}$ has the bounded inverse, which implies the existence of an adjoint state satisfying (1.52) and boundary conditions (1.49).

It remains to prove identity (1.53). Fix the adjoint state $\mathbf{Y} = (\mathbf{h}, g, \varsigma, \upsilon, l)$, and set

$$\mathbf{H} = \Delta\mathbf{h} - \nabla g, \quad G = \operatorname{div}\mathbf{h}, \quad F = \mathscr{L}^*\varsigma, \quad M = \mathscr{L}\upsilon.$$

It follows from (1.52) that

$$\begin{gathered}
\mathbf{H} - R\varrho(\nabla\mathbf{u} - \mathbf{u}\nabla)\mathbf{h} + \varsigma\nabla\varphi + \zeta\nabla\upsilon = \Delta\eta\mathbf{U}_\infty + R\varrho\big((\mathbf{u}\nabla\eta)\mathbf{U}_\infty + (\mathbf{u}\mathbf{U}_\infty)\nabla\eta\big), \\
G - \Pi(b^0_{21}\varsigma + b^0_{22}g - \varkappa b^0_{32}l) = \Pi(\nabla\eta\mathbf{U}_\infty), \\
F - R\mathbf{u}\nabla\mathbf{u}\mathbf{h} - b^0_{12}g - b^0_{11}\varsigma - \varkappa b^0_{31}l = (\mathbf{u}\nabla\eta)(\mathbf{u}\mathbf{U}_\infty), \quad M = \varkappa b^0_{34}l.
\end{gathered} \tag{3.3}$$

By virtue of Theorem 1.9, the *material* derivative $(\mathbf{w}, \omega, \psi, \xi, n)$ satisfies the integral identities (1.47). On the other hand, $(F, \mathbf{H}, G, M)$ together with the components of the adjoint state $\mathbf{Y}$ can be regarded as a collection of test functions for this identity. Substituting these test functions into (1.47), using equalities (3.3), and recalling the identity $\langle\omega, 1\rangle = 0$, we obtain

$$\begin{gathered}
L_u(\mathbf{w}, \omega, \psi) + \varkappa(l-1)\Big(\big\langle\psi, b^0_{31}\big\rangle + \big\langle\omega, b^0_{32}\big\rangle + \big\langle\xi, b^0_{34}\big\rangle\Big) \\
+ n - n\big\langle 1, b^0_{13}\varsigma\big\rangle = \big\langle\mathfrak{d}, b^0_{10}\varsigma + b^0_{20}g + \varkappa b^0_{30} + \sigma\upsilon\big\rangle + \big\langle\mathscr{D}_0, \mathbf{W}\big\rangle.
\end{gathered}$$

It follows from (1.52) that $l = \big\langle 1, b^0_{13}\varsigma\big\rangle$, which leads to

$$\begin{aligned}
L_u(\mathbf{w}, \omega, \psi) + \varkappa(l-1)\Big(\varkappa\big(\big\langle\psi, b^0_{31}\big\rangle + \big\langle\omega, b^0_{32}\big\rangle + \big\langle\xi, b^0_{34}\big\rangle\big) - n\Big) \\
= \big\langle\mathfrak{d}, b^0_{10}\varsigma + b^0_{20}g + \varkappa b^0_{30} + \sigma\upsilon\big\rangle + \big\langle\mathscr{D}_0, \mathbf{W}\big\rangle.
\end{aligned} \tag{3.4}$$

Next note that the identities (1.42) imply the following expression for the constant n:

$$n = \varkappa\big(\big\langle\psi, b^0_{31}\big\rangle + \big\langle\omega, b^0_{32}\big\rangle + \big\langle\xi, b^0_{34}\big\rangle + \big\langle\mathfrak{d}, b^0_{30}\big\rangle\big).$$

Substituting this equality into (3.4) and noting that $\mathfrak{d} = \operatorname{Tr}\mathbf{D}$, we obtain (1.53), which completes the proof. □

4. Proof of Theorem 1.4. Our strategy is the following. First we use the classical method of characteristics (see [8] for instance) to show that in the vicinity of each point $P \in \Sigma_{\text{in}} \cup \Gamma$ there exist normal coordinates (y_1, y_2, y_3) such that $\mathbf{u}\nabla_x = \mathbf{e}_1\nabla_y$. Hence the problem of existence of solutions to the transport equation in the neighborhood of $\Sigma_{\text{in}} \cap \Gamma$ is reduced to a boundary value problem for the model equation $\partial_{y_1}\varphi + \sigma\varphi = f$ in a parabolic domain. Next we prove that the boundary value problem for the model equation admits a unique solution in fractional Sobolev space, which leads to the existence and uniqueness of solutions in the neighborhood of the inlet set. Using the existence of a local solution we can reduce problem (1.28) to a boundary value problem for the modified equation, which does not require any boundary data. Application of well-known results on solvability of elliptic-hyperbolic equations in the case $\Gamma = \emptyset$ finally gives the existence and uniqueness of solutions to problems (1.28) and (1.29).

First we introduce some notation which will be used throughout this section. For any $a > 0$ we denote by Q_a the cube $[-a, a]^3$ and by Q_a^+ the slab $[-a, a]^2 \times [0, a]$ in the space of points $y = (y_1, y_2, y_3) \in \mathbb{R}^3$. We will write Y instead of (y_2, y_3) so that $y = (y_1, Y)$.

DEFINITION 4.1. *A standard parabolic neighborhood associated with the constant c_0 is a compact subset of the slab Q_a^+, defined by the inequalities*

$$\mathcal{P}_a = \{y = (y_1, Y) \in Q_a^+ : a^-(Y) \le y_1 \le a^+(Y)\}, \tag{4.1}$$

where $a^\pm : [-a, a] \times [0, a] \mapsto \mathbb{R}$ are continuous, piecewise C^1-functions satisfying the inequalities

$$\begin{gathered} -a \le a^-(Y) \le 0 \le a^+(Y) \le a, \\ -c_0\sqrt{y_3} \le a^-(Y) \le a^+(Y) \le c_0\sqrt{y_3}, \\ |\partial_{y_2} a^\pm(Y)| \le c_0, \quad |\partial_{y_3} a^\pm(Y)| \le c_0/\sqrt{y_3}. \end{gathered} \tag{4.2}$$

Set $Q_{\text{in}} = \{Y : a^-(Y) > -a\}$ and $Q_{\text{out}} = \{Y : a^+(Y) < a\}$. Denote by Σ^y_{in} and Σ^y_{out} the surfaces determined by the relations

$$\begin{aligned} \Sigma^y_{\text{in}} &= \{y : Y \in Q_{\text{in}}, \quad y_1 = a^-(Y)\}, \\ \Sigma^y_{\text{out}} &= \{y : Y \in Q_{\text{out}}, \quad y_1 = a^+(Y)\}. \end{aligned}$$

It is clear that $\partial\mathcal{P}_a = (\partial Q_a \cap \partial\mathcal{P}_a) \cup \Sigma^y_{\text{in}} \cup \Sigma^y_{\text{out}}$.

LEMMA 4.2. *Assume that the C^2-manifold $\Sigma = \partial B$ and the vector field $\mathbf{U} \in C^2(\Sigma)^3$ satisfy conditions (**H**1)–(**H**3). Let $\mathbf{u} \in C^1(\mathbb{R}^3)^3$ be a compactly supported vector field such that*

$$\mathbf{u} = \mathbf{U} \ \text{ on } \ \Sigma, \quad \mathbf{u} = 0 \ \text{ on } \ S.$$

Denote $M = \|\mathbf{u}\|_{C^1(\mathbb{R}^3)}$. Then there are positive constants a, c, C, ρ_c, and R_c, depending only on M, $\partial\Omega$, and $\mathbf{U}$, with the following properties:

(**P1**) *For any point $P \in \Gamma$ there exists a mapping $y \to \mathbf{x}(y)$ which takes diffeomorphically the cube Q_a onto a neighborhood $\mathcal{O}_P$ of P and satisfies the equation*

$$\partial_{y_1}\mathbf{x}(y) = \mathbf{u}(\mathbf{x}(y)) \ \text{ in } \ Q_a \tag{4.3}$$

and the inequalities

$$\|\mathbf{x}\|_{C^1(Q_a)} + \|\mathbf{x}^{-1}\|_{C^1(\mathcal{O}_P)} \le C, \quad |\mathbf{x}(y)| \le C|y|. \tag{4.4}$$

(**P2**) *There is a standard parabolic neighborhood $\mathcal{P}_a$ associated with the constant c such that*

$$\mathbf{x}(\mathcal{P}_a) = \mathcal{O}_P \cup \Omega, \quad \mathbf{x}(\Sigma^y_{\text{in}}) = \Sigma_{\text{in}} \cap \mathcal{O}_P, \quad \mathbf{x}(\Sigma^y_{\text{out}}) = \Sigma_{\text{out}} \cap \mathcal{O}_P. \tag{4.5}$$

(**P3**) *Denote by $G_a \subset \mathcal{P}_a$ the domain*

$$G_a = \{y = (y_1, Y) \in \mathcal{P}_a : Y \in Q_{in}\}, \tag{4.6}$$

and by $B_P(\rho)$ the ball $|x - P| \le \rho$. Then we have the inclusions

$$B_P(\rho_c) \cap \Omega \subset \mathbf{x}(G_a) \subset \mathcal{O}_P \cap \Omega \subset B_P(R_c) \cap \Omega. \tag{4.7}$$

Proof. We start with the proof of (**P1**). Recall condition (**H1**) and fix the standard Cartesian coordinate system (x_1, x_2, x_3) associated with the point $P \in \Gamma$. Let us consider the Cauchy problem.

$$\begin{aligned} \partial_{y_1}\mathbf{x} &= \mathbf{u}(\mathbf{x}(y)) \ \text{ in } \ Q_a, \\ x_1(y) = \Upsilon(y_2), \quad x_2(y) &= y_2 \quad \text{for } \ y_1 = 0, \\ x_3 &= F(\Upsilon(y_2), y_2) + y_3 \quad \text{for } \ y_1 = 0. \end{aligned} \tag{4.8}$$

Without any loss of generality we can assume that $0 < a < k < 1$. For any such a, problem (4.8) has a unique solution of class $C^1(Q_a)$. Denote by $\mathfrak{F}(y) = D_y\mathbf{x}(y)$ the Jacobian matrix function. The calculations show that

$$\mathfrak{F}_0 := \mathfrak{F}(y)\Big|_{y_1=0} = \begin{pmatrix} u_1 & \Upsilon'(y_2) & 0 \\ u_2 & 1 & 0 \\ u_3 & \partial_{y_2}F(\Upsilon(y_2), y_2) & 1 \end{pmatrix}, \quad \mathfrak{F}(0) = \begin{pmatrix} U & \Upsilon'(0) & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

which implies

$$\|\mathfrak{F}(0)^{\pm 1}\| \le C/3, \quad \|\mathfrak{F}_0(y) - \mathfrak{F}(0)\| \le ca, \tag{4.9}$$

where the constants C, c are independent of a.

Differentiation of (4.8) leads to the ordinary differential equation for $\mathfrak{F}$

$$\partial_{y_1}\mathfrak{F} = D_y\mathbf{u}(\mathbf{x})\mathfrak{F}, \quad \mathfrak{F}\Big|_{y_1=0} = \mathfrak{F}_0.$$

From this we get

$$\partial_{y_1}\|\mathfrak{F} - \mathfrak{F}_0\| \le M(\|\mathfrak{F} - \mathfrak{F}_0\| + \|\mathfrak{F}_0\|),$$

and hence $\|\mathfrak{F} - \mathfrak{F}_0\| \le c(M)\|\mathfrak{F}_0\|a$. Combining this result with (4.9) we finally arrive at

$$\|\mathfrak{F}(y) - \mathfrak{F}(0)\| \le ca. \tag{4.10}$$

This inequality along with the implicit function theorem implies the existence of $a > 0$, depending only on M and Ω, such that the mapping $x = \mathbf{x}(y)$ takes diffeomorphically the cube Q_a onto some neighborhood of the point P and satisfies inequalities (4.4).

Let us turn to the proof of (**P2**). We begin with the observation that the manifold $\mathbf{x}^{-1}(\partial\Omega \cap \mathcal{O})$ is defined by the equation

$$\Phi_0(y) := x_3(y) - F(x_1(y), x_2(y)) = 0, \quad y \in Q_a.$$

Let us show that Φ_0 is strictly monotone in y_3 and has the opposite signs on the faces $y_3 = \pm a$. To this end note that the formula for $\mathfrak{F}(0)$ along with (4.10) implies the estimates

$$|\partial_{y_3}x_3(y) - 1| + |\partial_{y_3}x_1(y)| + |\partial_{y_3}x_2(y)| \le ca \ \text{ in } \ Q_a.$$

Thus, we get

$$1 - ca \le \partial_{y_3}\Phi_0(y) = \partial_{y_3}x_3(y) - \partial_{x_i}F(x_1, x_2)\partial_{y_3}x_i(y) \le 1 + ca.$$

It follows from (4.10) that, for $y_3 = 0$, we have $|x_3(y)| \le ca|y|$, which along with (4.4) yields the estimate

$$|\Phi_0(y)| \le |x_3(y)| + |F(x(y))| \le ca|y| + KC|y|^2 \le ca^2 \ \text{ for } \ y_3 = 0.$$

Hence there is a positive a, depending only on M and Ω, such that the inequalities

$$1/2 \le \partial_{y_3}\Phi_0(y) \le 2, \quad \pm\Phi_0(y_1, y_2, \pm a) > 0$$

hold true for all $y \in Q_a$. Therefore, the equation $\Phi_0(y) = 0$ has a unique solution $y_3 = \Phi(y_1, y_2)$ in the cube Q_a. Moreover, the function $\Phi \in C^1([-a, a]^2)$ vanishes for $y_1 = y_3 = 0$. Thus, we get

$$\mathcal{P}_a := \mathbf{x}^{-1}(\mathcal{O} \cap \Omega) = \{\Phi(y_1, y_2) < y_3 < a, \quad |y_1|, |y_2| \le a\}.$$

Note that $|\mathbf{u}(\mathbf{x}(y)) - U\mathbf{e}_1| \le M|\mathbf{x}(y)| \le Ca$. Therefore, we can choose $a = a(M, \Omega)$ such that $2U/3 \le u_1 \le 4U/3$ and $C|u_2| \le U/3$ in Q_a. Recall that $x_1(y) - \Upsilon(x_2(y))$ vanishes at the plane $y_1 = 0$ and

$$\partial_{y_1}\big[x_1(y) - \mathfrak{g}(x_2(y))\big] = u_1(y) - \Upsilon'(x_2(y))u_2(y).$$

We obtain from this that, for a suitable choice of a,

$$|y_1|U/3 \le \big|x_1(y) - \Upsilon(x_2(y))\big| \le |y_1|5U/3 \ \text{ for } \ y \in Q_a. \tag{4.11}$$

Equations (4.8) imply the identity

$$\partial_{y_1}\Phi_0(y) \equiv \nabla F_0(\mathbf{x}(y)) \cdot \mathbf{u}(x(y)) = \nabla F_0(\mathbf{x}(y)) \cdot \mathbf{U}(x(y)) \quad \text{for} \ \ \Phi_0(y) = 0.$$

Combining this result with (1.17) and (4.11), we obtain the estimates

$$|y_1|N^-U/3 \le |\partial_{y_1}\Phi_0(y)| \le |y_1|N^+U5/3,$$

which along with the identity

$$\partial_{y_1}\Phi = -\partial_{y_1}\Phi_0(\partial_{y_3}\Phi_0)^{-1}$$

yield the inequalities

$$\begin{aligned} -c < \partial_{y_1}\Phi(y_1, y_2) \le cy_1 \ \ &\text{for} \ \ -a < y_1 < 0, \\ cy_1 < \partial_{y_1}\Phi(y_1, y_2) \le c \ \ &\text{for} \ \ 0 < y_1 < a, \\ |\partial_{y_2}\Phi(y_1, y_2) \le c, 0 \le \Phi(y_1, y_2) \le cy_1^2&. \end{aligned} \tag{4.12}$$

It is clear that for sufficiently small a, depending only on $\mathbf{U}$ and Ω, the functions $\Phi^{\pm}(y_2) = \Phi(\pm a, y_2)$ admit the estimates $ca^2 \le \Phi^{\pm}(y_2) < a$. Set

$$\begin{aligned} Q_{\text{in}} &= \{Y \in [-a, a] \times [0, a] : \ 0 < y_3 < \Phi^-(y_2)\}, \\ Q_{\text{out}} &= \{Y :\in [-a, a] \times [0, a] : \ 0 < y_3 < \Phi^+(y_2)\}. \end{aligned}$$

It follows from (4.12) that for every $Y \in Q_{in}$ ($Y \in Q_{\text{out}}$) the equation $y_3 = \Phi(y_1, y_2)$ has a unique solution $a^-(Y) < 0$ ($a^+(Y) > 0$). We adopt the convention that $a^{\pm}(Y) = \pm a$ for $y_3 > \Phi^{\pm}(y_2)$. It remains to note that, by virtue of (4.12), the functions $a^{\pm}$ meet all requirements of Lemma 4.2. □

The next lemma shows the existence of the normal coordinates in the vicinity of points of the inlet Σ_{in}.

LEMMA 4.3. *Let vector fields* $\mathbf{u}$ *and* $\mathbf{U}$ *meet all requirements of Lemma* 4.2 *and* $U_n = -\mathbf{U}(P) \cdot \mathbf{n} > N > 0$. *Then there is* $b > 0$, *depending only on* N, Σ, *and* $M = \|\mathbf{u}\|_{C^1(\Omega)}$, *with the following properties. There exists a mapping* $y \to \mathbf{x}(y)$,

which takes diffeomorphically the cube $Q_b = [-b,b]^3$ *onto a neighborhood* $\mathcal{O}_P$ *of* P *and satisfies the equations*

$$\partial_{y_3}\mathbf{x}(y) = \mathbf{u}(\mathbf{x}(y)) \ \text{ in } \ Q_b, \quad \mathbf{x}(y_1,y_2,0) \in \Sigma \cap \mathcal{O}_P \ \ \textit{for} \quad |y_2| \le a, \tag{4.13}$$

and the inequalities

$$\|\mathbf{x}\|_{C^1(Q_b)} + \|\mathbf{x}^{-1}\|_{C^1(\mathcal{O}_P)} \le C_{M,N}, \quad |\mathbf{x}(y)| \le C_M|y|, \tag{4.14}$$

where $C_{M,N} = 3(1+N^{-1})(M^2+2)^{1/2}$. *The inclusions*

$$B_P(\rho_i) \cap \Omega \subset \mathbf{x}(Q_b \cap \{y_3 > 0\}) \subset B_P(R_i) \cap \Omega \tag{4.15}$$

hold true for $\rho_i = C_{M,N}^{-1} b$ *and* $R_i = C_{M,N} b$.

Proof. The proof simulates the proof of Lemma 4.2. Choose the local Cartesian coordinates (x_1,x_2,x_3) centered at P such that in new coordinates $\mathbf{n}(P) = \mathbf{e}_3$. By the smoothness of Σ, there is a neighborhood $\mathcal{O} = [-k,k]^2 \times [-t,t]$ such that the manifold $\Sigma \cap \mathcal{O}$ is defined by the equation

$$x_3 = F(x_1,x_2), \quad F(0,0) = 0, \quad |\nabla F(x_1,x_2)| \le K(|x_1| + |x_2|).$$

The constants k, t, and K depend only on Σ. Let us consider the initial value problem

$$\partial_{y_3}\mathbf{x} = \mathbf{u}(\mathbf{x}(y)) \ \text{ in } \ Q_a, \quad \mathbf{x}\Big|_{y_3=0} = (y_1,y_2,F(y_1,y_2)). \tag{4.16}$$

Without any loss of generality we can assume that $0 < b < k < 1$. It follows from (**H1**) that for any such b problem (4.16) has a unique solution of class $C^1(Q_b)$. Next note that for $y_3 = 0$ we have

$$|\mathbf{x}(y)| \le (K+1)|y|, \quad |\mathbf{u}(\mathbf{x}(y)) - \mathbf{u}(0)| \le M(K+1)|y|. \tag{4.17}$$

Denote by $\mathfrak{F}(y) = D_y\mathbf{x}(y)$. The calculations show that

$$\mathfrak{F}_0 := \mathfrak{F}(y)\Big|_{y_3=0} = \begin{pmatrix} 1 & 0 & u_1 \\ 0 & 1 & u_2 \\ 0 & 0 & u_3 \end{pmatrix}, \quad \mathfrak{F}(0) = \begin{pmatrix} 1 & 0 & u_1(P) \\ 0 & 1 & u_2(P) \\ 0 & 0 & U_n \end{pmatrix},$$

which along with (4.17) implies

$$\|\mathfrak{F}(0)^{\pm 1}\| \le C_{M,N}/3, \quad \|\mathfrak{F}_0(y) - \mathfrak{F}(0)\| \le cb. \tag{4.18}$$

Next, differentiation of (4.16) with respect to y leads to the equation

$$\partial_{y_1}\mathfrak{F} = D_y\mathbf{u}(\mathbf{x})\mathfrak{F}, \quad \mathfrak{F}\Big|_{y_3=0} = \mathfrak{F}_0.$$

Arguing as in the proof of Lemma 4.2 we obtain $\|\mathfrak{F} - \mathfrak{F}_0\| \le c(M)\|\mathfrak{F}_0\|b$. Combining this result with (4.18), we finally arrive at $\|\mathfrak{F}(y) - \mathfrak{F}(0)\| \le cb$. From this and the implicit function theorem we conclude that there is positive b, depending only on M and Σ, such that the mapping $x = \mathbf{x}(y)$ takes diffeomorphically the cube Q_b onto some neighborhood of the point P and satisfies inequalities (4.14). Inclusions (4.15) easily follow from (4.14). ∎

Model equation. Let us consider the following boundary value problem in standard parabolic neighborhood $\mathcal{P}_a$:

$$\partial_{y_1}\varphi(y)+\sigma\varphi(y)=f(y) \ \text{ in } \ \mathcal{P}_a, \quad \varphi(y)=0 \ \text{ for } \ y_1=a^-(y_2,y_3). \tag{4.19}$$

LEMMA 4.4. *Assume that*

$$1/2<s\le 1 \quad \textit{and} \quad 1<r<3/(2s-1). \tag{4.20}$$

Then for any $f\in W^{s,r}(Q_a)\cap L^\infty(Q_a^\phi)$, problem (4.19) *has a unique solution satisfying the inequalities*

$$\begin{aligned}\|\varphi\|_{W^{s,r}(\mathcal{P}_a)}\le c(r,s)\Big(a^{4/r-s}\|f\|_{L^\infty(\mathcal{P}_a)}+a^{1/r}\|f\|_{W^{s,r}(\mathcal{P}_a)}\Big),\\ \|\varphi\|_{L^\infty(Q_a^\phi)}\le\sigma^{-1}\|f\|_{L^\infty(Q_a^\phi)}.\end{aligned} \tag{4.21}$$

Proof. It suffices to prove the lemma for $s<1$. For every $y,z\in\mathbb{R}^3$, we denote by $Y=(y_2,y_3)$, $Z=(z_2,z_3)$, respectively. Obviously, we have

$$\varphi(y)=\int_{a^-(Y)}^{y_1}e^{\sigma(x_1-y_1)}f(x_1,Y)\,dx_1 \ \text{ and } \ \sigma\|\varphi\|_{C(\mathcal{P}_a)}\le\|f\|_{C(\mathcal{P}_a)}. \tag{4.22}$$

Therefore, it suffices to estimate the seminorm $|\varphi|_{s,r,\mathcal{P}_a}$. Choose an arbitrary $y,z\in\mathcal{P}_a$. Without any loss of generality we can assume that $a^-(Z)\le a^-(Y)$. The identity

$$\begin{aligned}\varphi(z)-\varphi(y)=\varphi(z_1,Z)-\varphi(y_1,Z)+\int_{a^-(Z)}^{a^-(Y)}e^{\sigma(x_1-y_1)}f(x_1,Z)\,dx_1\\ +\int_{a^-(Y)}^{y_1}e^{\sigma(x_1-y_1)}(f(x_1,Z)-f(x_1,Y))\,dx_1\end{aligned}$$

implies the estimate

$$|\varphi(z)-\varphi(y)|\le\|f\|_{L^\infty(\mathcal{P}_a)}(2|y_1-z_1|+|a^-(Y)-a^-(Z)|)+\int_{-a}^{a}|(f(x_1,Z)-f(x_1,Y))|\,dx_1,$$

which along with the inequality

$$\left(\int_{-a}^{a}|(f(x_1,Z)-f(x_1,Y))|\,dx_1\right)^r\le a^{r-1}\int_{-a}^{a}|(f(x_1,Z)-f(x_1,Y))|^r\,dx_1$$

leads to the estimate

$$|\varphi|^r_{s,r,\mathcal{P}_a}\le 2\|f\|^r_{C(\mathcal{P}_a)}(I_1+I_2)+a^{(r-1)}I_3. \tag{4.23}$$

Here we denote

$$\begin{aligned}I_1=\int_{Q_a\times Q_a}\frac{|y_1-z_1|^r}{|x-y|^{3+rs}}\,dxdy, \quad I_2=\int_{\mathcal{P}_a\times\mathcal{P}_a}\frac{|a^-(Y)-a^-(Z)|^r}{|x-y|^{3+rs}}\,dxdy,\\ I_3=\int_{[-a,a]^4}\int_{-a}^{a}\frac{|f(x_1,Y)-f(x_1,Z)|^r}{|x-y|^{3+rs}}\,dxdy\,dx_1.\end{aligned}$$

Let us estimate the terms I_j, $i = 1, 2, 3$. We begin with the observation that

$$\int_{[-a,a]^2} \frac{dZ}{|x-y|^{3+rs}} = \frac{1}{|y_1 - z_1|^{3+rs}} \int_{[-a,a]^2} \frac{dZ}{(|Y-Z|^2/|y_1-z_1|^2+1)^{(3+rs)/2}}$$
$$\leq \frac{1}{|y_1-z_1|^{1+rs}} \int_{\mathbb{R}^2} \frac{dZ}{(|Z|^2+1)^{(3+rs)/2}} \leq \frac{c}{|y_1-z_1|^{1+rs}},$$

and hence

$$\int_{[-a,a]^4} \frac{dY\,dZ}{|x-y|^{3+rs}} \leq \frac{ca^2}{|y_1-z_1|^{1+rs}}.$$

From this we obtain

$$I_1 \leq ca^2 \int_{-a}^{a} \left(\int_{-a}^{a} |y_1 - z_1|^{r(1-s)-1}\, dz_1 \right) dy_1 \leq c(r,s) a^{3+r(1-s)}. \tag{4.24}$$

In order to estimate I_2, note that, by Lemma 4.2,

$$|a^-(Y) - a^-(Z)| \leq c|Y-Z|^{1/2}, \quad |a^-(Y) - a^-(Z)| \leq c|Y-Z| \left(\frac{1}{\sqrt{y_3}} + \frac{1}{\sqrt{z_3}} \right).$$

Next, it follows from the assumptions of the lemma that there is $\lambda \in (0,1)$ such that

$$\lambda < 3/r, \quad 0 < (1+\lambda)/2 - s < 1/r. \tag{4.25}$$

Noting that

$$|a^-(Y) - a^-(Z)| \leq c|Y-Z|^{(1+\lambda)/2} ((y_3)^{-\lambda/2} + (z_3)^{-\lambda/2}),$$

we obtain

$$I_2 \leq c \int_{\mathcal{P}_a} (y_3)^{-r\lambda/2} \left(\int_{Q_a} \frac{|Y-Z|^{r(1+\lambda)/2}}{|x-y|^{3+rs}}\, dz \right) dy$$
$$+ c \int_{\mathcal{P}_a} (z_3)^{-r\lambda/2} \left(\int_{Q_a} \frac{|Y-Z|^{r(1+\lambda)/2}}{|x-y|^{3+rs}}\, dy \right) dz$$
$$\leq 2c \int_{\mathcal{P}_a} (y_3)^{-r\lambda/2} \left(\int_{Q_a} \frac{|Y-Z|^{r(1+\lambda)/2}}{|x-y|^{3+rs}}\, dz \right) dy.$$

Next, inequalities (4.25) imply

$$\int_{Q_a} \frac{|Y-Z|^{r(1+\lambda)/2}}{|x-y|^{3+rs}}\, dz$$
$$\leq \int_{-a}^{a} |y_1 - z_1|^{-3-rs} \left(\int_{\mathbb{R}^2} \frac{|Y-Z|^{r(1+\lambda)/2}}{(|Y-Z|^2 |y_1-z_1|^{-2}+1)^{(3+rs)/2}}\, dZ \right)$$
$$\leq \int_{-a}^{a} |y_1 - z_1|^{-rs-1+r(1+\lambda)/2} dz_1 \int_{\mathbb{R}^2} \frac{|Z|^{r(1+\lambda)/2}}{(1+|Z|^2)^{(3+rs)/2}}\, dZ$$
$$\leq c(r,s) \int_{-a}^{a} |y_1 - z_1|^{r(1+\lambda)/2 - rs - 1} dz_1 \leq c(r,s).$$

From this and Lemma 4.2 we conclude that

$$\begin{aligned} I_2 &\le c(r,s)\int_{\mathcal{P}_a}(y_3)^{-r\lambda/2}\,dy \\ &\le c(r,s)\int_{[-a,a]^2}\left(\int_{cy_1^2\le y_3\le a}(y_3)^{-r\lambda/2}\,dy_3\right)dy_1dy_2 \\ &\le ac(r,s)\int_{-a}^{a}|y_1|^{2-r\lambda}\,dy_1 \le ac(r,s). \end{aligned} \tag{4.26}$$

The remaining part of the proof is based on the following proposition.

PROPOSITION 4.5. *Let $f\in W^{s,r}(Q_a)$ and $sr>1$. Then f has an extension $\bar f$ onto $\mathbb{R}^3$, which vanishes outside the set Q_{3a} and satisfies*

$$\|\bar f\|_{W^{s,r}}\le ca^{(3-rs)/r}\|f\|_{L^\infty(Q_a)}+|f|_{s,r,Q_a}. \tag{4.27}$$

Proof. Define an extension of f onto the slab $[-3a,3a]\times[-a,a]^2$ by the formula

$$f(x^\pm)=f(x)\ \text{ for }\ x\in Q_a,\ \text{ where }\ x^\pm=(\pm(2a-x_1),x_2,x_3).$$

It easily follows from the definition of the seminorm $|\cdot|_{r,s,\Omega}$ that

$$\|f\|_{W^{s,r}([-3a,3a]\times[-a,a]^2)}\le 3\|f\|_{L^r(Q_a)}+6|f|_{s,r,Q_a}\le 6\|f\|_{W^{s,r}(Q_a)}.$$

Proceeding in the same way as before, first we can extend f onto the plate $[-3a,3a]^2\times[-a,a]$ and then over the cube Q_{3a}. Obviously, the extended function, still denoted by f, satisfies the inequalities

$$\|f\|_{W^{s,r}(Q_{3a})}\le 216\|f\|_{W^{s,r}(Q_a)},\quad \|f\|_{C(Q_{3a})}\le\|f\|_{C(Q_a)}. \tag{4.28}$$

Next choose $\mu\in C^\infty(\mathbb{R}^3)$ such that $0\le\mu\le 1$, $\mu=1$ in Q_1, and $\mu=0$ outside of Q_{22}. Set $\bar f=f\mu_a$, where $\mu_a(x)=\mu(x/a)$. Next, the interpolation inequality along with the estimate $|\nabla\mu_a|\le ca^{-1}$ implies

$$\|\mu_a\|_{W^{s,r}(\mathbb{R}^3)}\le\|\mu_a\|^{1-s}_{L^r(\mathbb{R}^3)}\|\mu_a\|^{s}_{W^{1,r}(\mathbb{R}^3)}\le ca^{3(1-s)/r}a^{(3-r)s/r}=ca^{(3-rs)/r}.$$

From this and the obvious inequality $\|\mu_af\|_{W^{s,r}(\mathbb{R}^3)}\le\|f\|_{L^\infty(Q_{3a})}\|\mu_a\|_{W^{s,r}(\mathbb{R}^3)}+\|f\|_{W^{s,r}(Q_{3a})}$ we conclude that

$$\|\mu_af\|_{W^{s,r}(\mathbb{R}^3)}\le ca^{(3-rs)/r}\|f\|_{L^\infty(Q_a)}+\|f\|_{W^{s,r}(Q_a)}.$$

Hence $\bar f=\mu_af$ satisfies (4.27), and the proposition follows. ∎

Let us return to the proof of Lemma 4.4. We have

$$\begin{aligned} I_3=&\int_{[-a,a]^4}\int_{-a}^{a}|Z-Y|^{-3-rs}(|z_1-y_1|^2|Z-Y|^{-2}+1)^{-(3+rs)/2} \\ &\times|f(x_1,Z)-f(x_1,Y)|^r\,dxdydx_1\le ca\int_{\mathbb{R}}(|t|^2+1)^{-(3+rs)/2}dt \\ &\times\int_{[-a,a]^5}|Z-Y|^{-2-rs}|f(x_1,Z)-f(x_1,Y)|^r\,dXdYdx_1 \\ =&\,ca\int_{-a}^{a}|f(x_1,\cdot)|^r_{r,s,[-a,a]^2}\,dx_1, \end{aligned}$$

which yields

$$I_3 \le ca\|f\|^r_{L^r(-a,a;W^{s,r}([-a,a]^2))} \le ca\|\bar f\|^r_{L^r(\mathbb{R};W^{s,r}(\mathbb{R}^2))}. \tag{4.29}$$

Recall that, for $s = 0, 1$, the embedding operator $W^{s,r}(\mathbb{R}^3) \hookrightarrow L^r(\mathbb{R}; W^{s,r}(\mathbb{R}^2))$ is bounded. By virtue of Lemma B.1, this results holds true for all $s \in [0, 1]$, which along with Proposition 4.5 and inequality (4.29) implies

$$I_3 \le ca^{4-rs}\|f\|^r_{L^\infty(Q_a)} + a(|f|_{s,r,Q_a})^r.$$

Combining this result with (4.24), (4.26), since $3 + r(1 - s) \ge 4 - rs$, we finally obtain

$$\|f\|^r_{L^\infty(Q_a)}(I_1 + I_2) + I_3 \le ca^{4-sr}\|f\|^r_{L^\infty(Q_a)} + ca|f|^r_{s,r,Q_a}.$$

Substituting this inequality into (4.23) gives (4.21), and the lemma follows. □

Let us consider the following boundary value problem in the slab $Q^+_a = [-a, a]^2 \times [0, a]$:

$$\partial_{y_3}\varphi(y) + \sigma\varphi(y) = f(y) \ \text{ in } \ Q^+_a, \quad \varphi(y) = 0 \ \text{ for } \ y_3 = 0. \tag{4.30}$$

Lemma 4.6. *Problem* (4.30) *has a unique solution satisfying the inequality*

$$\|\varphi\|_{W^{s,r}(Q^+_a)} \le c(r, s)\big(a^{4/r-s}\|f\|_{L^\infty(Q^+_a)} + a^{1/r}\|f\|_{W^{s,r}(Q^+_a)}\big). \tag{4.31}$$

Proof. The proof of Lemma 4.4 can also be used in this case. □

Local existence results. It follows from the assumptions of Theorem 1.4 that the vector field $\mathbf{u}$ and the manifold Σ satisfy all assumptions of Lemma 4.2. Therefore, there exist positive numbers a, ρ_c, and R_c, depending only on Σ and $\|\mathbf{u}\|_{C^1(\Omega)}$, such that for all $P \in \Gamma$, the canonical diffeomorphism $\mathbf{x} : Q_a \mapsto \mathcal{O}_P$ is well defined and meets all requirements of Lemma 4.2. Fix an arbitrary point $P \in \Gamma$ and consider the boundary value problem

$$\mathbf{u} \cdot \nabla\varphi + \sigma\varphi = f \ \text{ in } \ \mathcal{O}_P, \quad \varphi = 0 \ \text{ on } \ \Sigma_{\rm in} \cap \mathcal{O}_P. \tag{4.32}$$

Lemma 4.7. *Suppose that the exponents s, r satisfy condition* (1.31). *Then, for any $f \in C^1(\Omega)$, problem* (4.32) *has a unique solution satisfying the inequalities*

$$|\varphi|_{s,r,B_P(\rho_c)} \le c(\|f\|_{C(B_P(R_c))} + |f|_{s,r,B_P(R_c)}), \quad \|\varphi\|_{C(B_P(\rho_c))} \le \sigma^{-1}\|f\|_{C(B_P(R_c))}, \tag{4.33}$$

where the constant c depends only on Σ, M, σ, s, r and the constant ρ_c is determined by Lemma 4.2.

Proof. We transform (4.33) using the normal coordinates (y_1, y_2, y_3) given by Lemma 4.2. Set $\overline{\varphi}(y) = \varphi(\mathbf{x}(y))$ and $\overline{f}(y) = f(\mathbf{x}(y))$. Next note that (4.3) implies the identity $\mathbf{u}\nabla_x\varphi = \partial_{y_1}\overline{\varphi}(y)$. Therefore the function $\overline{\varphi}(y)$ satisfies the following equation along with the boundary conditions:

$$\partial_{y_1}\overline{\varphi} + \sigma\overline{\varphi} = \overline{f} \text{ in } Q_a \cap \{y_3 > \Phi\}, \quad \overline{\varphi} = 0 \ \text{ for } \ y_3 = \Phi(y_1, y_2),\ y_1 < 0. \tag{4.34}$$

It follows from Lemma 4.4 that problem (4.34) has a unique solution $\overline{\varphi} \in W^{s,r}(G_a)$ satisfying the inequality

$$|\overline{\varphi}|_{s,r,G_a} \le c(\|\overline{f}\|_{C(Q_a)} + |\overline{f}|_{s,r,Q_a}), \quad \|\overline{\varphi}\|_{C(G_a)} \le \sigma^{-1}\|f\|_{C(Q_a)}, \tag{4.35}$$

where the domain G_a is defined by (4.6). It remains to note that, by estimate (4.4), the mappings $\mathbf{x}^{\pm 1}$ are uniformly Lipschitz, which along with inclusions (4.7) implies the estimates

$$|\varphi|_{s,r,B_P(\rho_c)} \le c|\overline{\varphi}|_{s,r,G_a}, \quad |\overline{f}|_{s,r,Q_a} \le c|f|_{s,r,B_P(R_c)}.$$

Combining these results with (4.35) we finally obtain (4.33) and the lemma follows. □

In order to formulate the similar result for interior points of the inlet Σ_{in} we introduce the set

$$\Sigma'_{\text{in}} = \big\{x \in \Sigma_{\text{in}} : \ \operatorname{dist}(x, \Gamma) \ge \rho_c/3\big\}, \tag{4.36}$$

where the constant ρ_c is given by Lemma 4.2. It is clear that

$$\inf_{P \in \Sigma'_{\text{in}}} \mathbf{U}(P) \cdot \mathbf{n}(P) \ge N > 0,$$

where the constant N depends only on M and Σ. It follows from Lemma 4.3 that there are positive numbers b, ρ_i, and R_i such that for each $P \in \Sigma'_{\text{in}}$, the canonical diffeomorphism $\mathbf{x} : Q_b \mapsto \mathcal{O}_P$ is well defined and satisfies the hypotheses of Lemma 4.3. The following lemma gives the local existence and uniqueness of solutions to the boundary value problem

$$\mathbf{u} \cdot \nabla\varphi + \sigma\varphi = f \ \text{ in } \ \mathcal{O}_P, \quad \varphi = 0 \ \text{ on } \ \Sigma_{\text{in}} \cap \mathcal{O}_P. \tag{4.37}$$

LEMMA 4.8. *Suppose that the exponents s, r satisfy condition* (1.38). *Then, for any $f \in C^1(\Omega)$ and $P \in \Sigma'_{\text{in}}$, problem* (4.32) *has a unique solution satisfying the inequalities*

$$\begin{aligned} |\varphi|_{s,r,B_P(\rho_i)} &\le c(\|f\|_{C(B_P(R_i))} + |f|_{s,r,B_P(R_i)}), \\ \|\varphi\|_{C(B_P(R))} &\le \sigma^{-1}\|f\|_{C(B_P(R_i))}, \end{aligned} \tag{4.38}$$

where c depends on Σ, M, σ, and exponents s, r.

Proof. Using the normal coordinates given by Lemma 4.3 we rewrite (4.37) in the form

$$\partial_{y_3}\overline{\varphi} + \sigma\overline{\varphi} = \overline{f} \ \text{ in } \ Q_b, \quad \overline{\varphi} = 0 \ \text{ for } \ y_3 = 0.$$

Applying Lemma 4.4 and arguing as in the proof of Lemma 4.7 we obtain (4.38). □

Existence of solutions near inlet. The next step is based on the well-known geometric lemma (see [21, Chap. 3]).

LEMMA 4.9. *Suppose that a given set $A \subset \mathbb{R}^d$ is covered by balls such that each point $x \in A$ is the center of a certain ball $B_x(r(x))$ of radius $r(x)$. If $\sup r(x) < \infty$, then from the system of the balls $\{B_x(r(x))\}$ it is possible to select a countable system $B_{x_k}(r(x_k))$ covering the entire set A and having multiplicity not greater than a certain number $\mathfrak{n}(d)$ depending only on the dimension d.*

The following lemma gives the dependence of the multiplicity of radii of the covering balls.

LEMMA 4.10. *Assume that a collection of balls $B_{x_k}(r) \subset \mathbb{R}^3$ of constant radius r has the multiplicity $\mathfrak{n}_r$. Then the multiplicity of the collections of the balls $B_{x_k}(R)$, $r < R$, is bounded by the constant $27(R/r)^3\mathfrak{n}_r$.*

Proof. Let $\mathfrak{n}_R$ be a multiplicity of the system $\{B_{x_k}(R)\}$. This means that at least $\mathfrak{n}_R$ balls, say $B_{x_1}(R), \dots, B_{x_{\mathfrak{n}_R}}(R)$, have the common point P. In particular, we

have $B_{x_i}(r) \subset B_P(3R)$ for all $i \le \mathfrak{n}_R$. Introduce the counting function $\iota(x)$ for the collection of balls $B_{x_i}(r)$, defined by

$$\iota(x) = \text{ card}\{i : x \in B_{x_i}(r), 1 \le i \le \mathfrak{n}_r\}.$$

Note that $\iota(x) \le \mathfrak{n}_r$. We have

$$\frac{4\pi}{3}\mathfrak{n}_R r^3 = \sum_{i=1}^{\mathfrak{n}_R} \text{meas } B_{x_i}(r) = \int_{\cup_i B_{x_i}(r)} \iota(x)\, dx \le \mathfrak{n}_r \int_{\cup_i B_{x_i}(r)} dx \le \frac{4\pi}{3}(3R)^3 \mathfrak{n}_r,$$

and the lemma follows. □

We are now in a position to prove the local existence and uniqueness of a solution to the first boundary value problem for the transport equation in the neighborhood of the inlet Σ_{in}. Let Ω_t be the t-neighborhood of the set Σ_{in},

$$\Omega_t = \{x \in \Omega : \text{ dist } (x, \Sigma_{\text{in}}) < t\}.$$

LEMMA 4.11. *Let $t = \min\{\rho_c/2, \rho_i/2\}$ and $T = \max\{R_c, R_i\}$, where the constants ρ_α, R_α are defined by Lemmas* 4.2 *and* 4.3. *Then there exists a constant C, depending only on M, Σ, and σ, such that, for any $f \in C^1(\Omega)$, the boundary value problem*

$$\mathbf{u} \cdot \nabla\varphi + \sigma\varphi = f \ \text{ in } \ \Omega_t, \quad \varphi = 0 \ \text{ on } \ \Sigma_{\text{in}} \tag{4.39}$$

has a unique solution satisfying the inequalities

$$|\varphi|_{s,r,\Omega_t} \le C(\|f\|_{C(\Omega_T)} + |f|_{s,r,\Omega_T}), \quad \|\varphi\|_{C(\Omega_t)} \le \sigma^{-1}\|f\|_{C(\Omega_T)}. \tag{4.40}$$

Proof. It follows from Lemma 4.9 that there is a covering of the characteristic manifold Γ by the finite collection of balls $B_{P_i}(\rho_c/4)$, $1 \le i \le \mathfrak{m}$, $P_i \in \Gamma$, of the multiplicity $\mathfrak{n}$. The cardinality $\mathfrak{m}$ of this collection does not exceed $4\mathfrak{n}(\rho_c)^{-1}L$, where L is the length of Γ. Obviously, the balls $B_{P_i}(\rho_c)$ cover the set

$$\mathcal{V}_\Gamma = \{x \in \Omega : \text{ dist } (x, \Gamma) < \rho_c/2\}.$$

By virtue of Lemma 4.7, in each such ball the solution to problem (4.39) satisfies inequalities (4.33), which leads to the estimate

$$|\varphi|^r_{s,r,\mathcal{V}_\Gamma} \le \sum_i |\varphi|^r_{s,r,B_{P_i}(\rho_c)} \le c\sum_i \|f\|^r_{C(B_{P_i}(R_c))} + c\sum_i |f|^r_{s,r,B_{P_i}(R_c)}, \tag{4.41}$$

where c depends only on M, Σ, and σ. By Lemma 4.10, the multiplicity of the system of balls $B_{P_i}(R_c)$ is bounded from above by $12^3(R_c/\rho_c)^3$, which along with the inclusion $\cup_i B_{P_i}(R_c) \subset \Omega_T$ yields

$$\sum_{i=1}^{\mathfrak{m}} |f|^r_{s,r,B_{P_i}(R_c)} \le 12^3(R_c/\rho_c)^3 |f|^r_{s,r,\Omega_T}.$$

Obviously we have

$$\sum_i \|f\|^r_{C(B_{P_i}(R_c))} \le \mathfrak{m}\|f\|^r_{C(\Omega_T)} \le 4\mathfrak{n}(\rho_c)^{-1}L\|f\|^r_{C(\Omega_T)}.$$

Combining these results with (4.41) we obtain the estimates for the solution to problem (4.39) in the neighborhood of the characteristic manifold Γ,

$$|\varphi|_{s,r,\mathcal{V}_\Gamma} \le c\|f\|_{C(\Omega_T)} + c|f|_{s,r,\Omega_T}. \tag{4.42}$$

Our next task is to obtain the similar estimate in the neighborhood of the compact $\Sigma'_{\rm in} \subset \Sigma_{\rm in}$. To this end, we introduce the set

$$\mathcal{V}_{\rm in} = \{x \in \Omega :\ \text{dist}\ (x, \Sigma'_{\rm in}) < \rho_i/2\},$$

where $\Sigma'_{\rm in}$ is given by (4.36). By virtue of Lemma 4.9, there exists the finite collection of balls $B_{P_k}(\rho_i/4)$, $1 \le k \le \mathfrak{m}$, $P_k \in \Sigma'_{\rm in}$, of the multiplicity $\mathfrak{n}$ which covers $\Sigma'_{\rm in}$. Obviously $\mathfrak{m} \le 16n(\rho_i)^{-2}\text{meas}\ \Sigma_{\rm in}$, and the balls $B_{P_k}(\rho_i)$ cover the set $\mathcal{V}_{\rm in}$. From this and Lemma 4.8 we conclude that

$$|\varphi|^r_{s,r,\mathcal{V}_{\rm in}} \le \sum_k |\varphi|^r_{s,r,B_{P_k}(\rho_i)} \le c\sum_k \|f\|^r_{C(B_{P_k}(R_i))} + c\sum_k |f|^r_{s,r,B_{P_k}(R_i)}.$$

By virtue of Lemma 4.10, the multiplicity of the system of balls $B_{P_i}(R_i)$ is not greater than $12^3(R_i/\rho_i)^3$, which yields

$$\sum_i |f|^r_{s,r,B_{P_i}(R_i)} \le 12^3(R_i/\rho_i)^3|f|^r_{s,r,\Omega_T}.$$

Obviously we have

$$\sum_k \|f\|^r_{C(B_{P_k}(R_i))} \le \mathfrak{m}\|f\|^r_{C(\Omega_T)} \le 16\mathfrak{n}(\rho_k)^{-2}\text{meas}\ \Sigma_{\rm in}\|f\|^r_{C(\Omega_T)}.$$

Thus we get

$$|\varphi|_{s,r,\mathcal{V}_{in}} \le c\|f\|_{C(\Omega_T)} + c|f|_{s,r,\Omega_T}. \tag{4.43}$$

Since $\mathcal{V}_\Gamma$ and $\mathcal{V}_{\rm in}$ cover Ω_t, this inequality along with inequality (4.42) yields (4.40), and the lemma follows. □

Partition of unity. Let us turn to the analysis of the general problem

$$\mathscr{L}\varphi := \mathbf{u}\cdot\nabla\varphi + \sigma\varphi = f \ \text{ in } \ \Omega, \quad \varphi = 0 \ \text{ on } \ \Sigma_{\rm in}. \tag{4.44}$$

The next step is based on the theory of partial differential equations with nonnegative characteristic form. The following lemma is a particular case of general results of Oleinik and Radkevich; we refer to Theorems 1.5.1 and 1.6.2 in [34].

LEMMA 4.12. *Assume that Ω is a bounded domain of the class C^2, the vector field $\mathbf{u}$ belongs to the class $C^1(\Omega)^3$, and $\sigma - \operatorname{div}\mathbf{u}(x) > \delta > 0$. Then, for any $f \in L^\infty(\Omega)$, problem (1.28) has a unique solution such that $\|\varphi\|_{L^\infty(\Omega)} \le \delta^{-1}\|f\|_{L^\infty}$. Moreover, this solution is continuous at the interior points of $\Sigma_{\rm in}$ and vanishes on $\Sigma_{\rm in}$. If, in addition, $\Gamma = \ cl\ (\Sigma_{\rm out} \cap \Sigma_0) \cap cl\ \Sigma_{\rm in}$ is a smooth one-dimensional manifold, then a bounded generalized solution to problem (4.44) is unique.*

The question of smoothness of solutions to boundary value problems for transport equations is more complicated. All known results [19], [34] are related to the case of $\Gamma = \emptyset$. The following lemma is a consequence of Theorem 1.8.1 in the monograph [34].

LEMMA 4.13. *Assume that Ω is a bounded domain of the class C^2 and $\Sigma_{\rm out} = \emptyset$. Furthermore, let the following conditions hold.*

(1) *The vector field* $\mathbf{u}$ *and the function* f *belong to the class* $C^1(\mathbb{R}^3)$.
(2) *There is* $\Omega' \ni \Omega$ *such that the inequality*

$$\sigma - \sup_{\Omega'} \left\{ |\operatorname{div} \mathbf{u}| - \frac{1}{2} \sup_i \sum_{j \neq i} \left| \frac{\partial u_i}{\partial x_j} \right| - \frac{1}{2} \sup_j \sum_{j \neq i} \left| \frac{\partial u_j}{\partial x_i} \right| \right\} > 0$$

is fulfilled. Then a weak solution to problem (1.28) *satisfies the Lipschitz condition in* $\overline{\Omega}$.

Using these results we can construct a strong solution to problem (1.28). Recall that by Lemma 4.11, for any $f \in C^1(\Omega)$, problem (4.44) has a unique strong solution defined in neighborhood Ω_t of the inlet Σ_{in}. On the other hand, Lemma 4.12 guarantees the existence and uniqueness of a bounded weak solution to problem (4.44). The following lemma shows that both solutions coincide in Ω_t.

LEMMA 4.14. *Under the assumptions of Theorem* 1.4 *and Lemma* 4.11*, each bounded generalized solution to problem* (4.44) *coincides in* Ω_t *with the local solution* φ_t.

Proof. Let $\varphi \in L^\infty(\Omega)$ be a weak solution to problem (4.44). Recall that each point $P \in \Gamma$ has a canonical neighborhood $\mathcal{O}_P := \mathbf{x}(Q_a)$, where canonical diffeomorphism $\mathbf{x} : Q_a \mapsto \mathcal{O}_P$ is defined by Lemma 4.2. Choose an arbitrary function $\zeta \in C^1(\Omega)$ vanishing on Σ_{in} and outside of $\mathcal{O}_P$ and set

$$\overline{\varphi}(y) = \varphi(\mathbf{x}(y)), \quad \overline{f}(y) = f(\mathbf{x}(y)), \quad \overline{\zeta}(y) = \zeta(\mathbf{x}(y)), \quad y \in Q_a \cap \{y_3 > \Phi\}.$$

By the definition of a weak solution to the transport equation we have

$$\int_{\mathcal{O}_P \cap \Omega} \big(\sigma \varphi \zeta - \varphi \operatorname{div}(\zeta \mathbf{u}) - f\zeta\big)\, dx = 0.$$

Direct calculations lead to the identity $\operatorname{div}_x(\zeta \mathbf{u}) = \det \mathfrak{F}^{-1} \operatorname{div}_y(\overline{\zeta} \det \mathfrak{F}\, \mathfrak{F}^{-1} \overline{\mathbf{u}})$, in which the notation $\mathfrak{F}$ stands for the Jacobi matrix $\mathfrak{F} = D_y \mathbf{x}(y)$. On the other hand, (4.3) implies the equality $\mathfrak{F}^{-1} \overline{\mathbf{u}} = \mathbf{e_1}$. From this we conclude that

$$\int_{Q_a \cap \{y_3 > \Phi\}} \left(\big(\det \mathfrak{F}\, \overline{\zeta}\big)\big(\sigma \overline{\varphi} - \overline{f}\big) - \overline{\varphi} \frac{\partial}{\partial y_1} (\det \mathfrak{F}\, \overline{\zeta}) \right) dy = 0.$$

Recall that, by Lemma 4.2, $\partial_{y_1} \mathfrak{F}$ is continuous and $\det \mathfrak{F}$ is strictly positive in the cube Q_a. Setting $\xi = \det \mathfrak{F} \zeta$ we conclude that the integral identity

$$\int_{Q_a \cap \{y_3 > \Phi\}} \left(\xi\big(\sigma \overline{\varphi} - \overline{f}\big) - \overline{\varphi} \frac{\partial \xi}{\partial y_1} \right) dy = 0$$

holds true for all functions $\xi \in C_0(Q_a)$ having continuous derivative $\partial_{y_1} \zeta \in C(Q_a)$ and vanishing for $y_3 = \Phi(y_1, y_2)$, $y_1 < 0$. Since $\overline{f}$ is continuously differentiable, $\overline{\varphi}$ belongs to the class $C^1_{loc}(Q_a \cap \{y_3 > \Phi\})$ and satisfies (4.34). On the other hand, $\overline{\varphi_t}$ also satisfies (4.34). Obviously, all solutions to problem (4.34) coincide in the domain G_a, and hence $\overline{\varphi}_t = \overline{\varphi}$ in this domain. Recalling that $B_P(\rho_c) \subset \mathbf{x}(G_a)$ we obtain that $\varphi_t = \varphi$ in the ball $B_P(\rho_c)$. The same arguments show that, for any $P \in \Sigma'_{\text{in}}$, the function φ_t is equal to φ in the ball $B_P(\rho_i)$. It remains to note that the balls $B_P(\rho_c)$ and $B_P(\rho_i)$ cover Ω_t, and the lemma follows. ∎

Furthermore, we split the weak solution $\varphi \in L^\infty(\Omega)$ to problem (4.44) into two parts, namely, the local solution φ_t and the remainder vanishing near the inlet. To this end fix a function $\Lambda \in C^\infty(\mathbb{R})$ such that

$$0 \le \Lambda' \le 3, \quad \Lambda(u) = 0 \quad \text{for} \quad u \le 1 \quad \text{and} \quad \Lambda(u) = 1 \quad \text{for} \quad u \ge 3/2, \tag{4.45}$$

and introduce the one-parametric family of smooth functions

$$\chi_t(x) = \frac{1}{t^3} \int_{\mathbb{R}^3} \Theta\left(\frac{2(x-y)}{t}\right) \Lambda\left(\frac{\text{dist} \ \ (y, \Sigma_{\text{in}})}{t}\right) dy, \tag{4.46}$$

where $\Theta \in C^\infty(\mathbb{R}^3)$ is a standard mollifying kernel supported in the unit ball. It follows that

$$\begin{gathered} \chi_t(x) = 0 \ \ \text{for} \ \ \text{dist} \ (x, \Sigma_{\text{in}}) \le t/2, \quad \chi_t(x) = 1 \ \ \text{for} \ \ \text{dist} \ (x, \Sigma_{\text{in}}) \ge 2t, \\ |\partial^l \chi_t(x)| \le \varpi(l) t^{-l} \ \ \text{for all} \ \ l \ge 0, \end{gathered} \tag{4.47}$$

where $\varpi(l)$ is a constant. Now fix a number $t = t(\Sigma, M)$ satisfying all assumptions of Lemma 4.11 and set

$$\varphi(x) = (1 - \chi_{t/2}(x))\varphi_t(x) + \phi(x). \tag{4.48}$$

By virtue of (4.47) and Lemma 4.14, the function $\phi \in L^\infty(\Omega)$ vanishes in $\Omega_{t/2}$ and in a weak sense satisfies the equations

$$\mathbf{u}\nabla\phi + \sigma\phi = \chi_{t/2} f + \varphi_t \mathbf{u} \nabla \chi_{t/2} =: F \ \ \text{in} \ \ \Omega, \ \ \phi = 0 \ \ \text{on} \ \ \Sigma_{\text{in}}.$$

Next introduce a new vector field $\tilde{\mathbf{u}}(x) = \chi_{t/8}(x)\mathbf{u}(x)$. It easy to see that $\chi_{t/8} = 1$ on the support of ϕ, and hence the function ϕ is also a weak solution to the modified transport equation

$$\tilde{\mathscr{L}}\phi := \tilde{\mathbf{u}}\nabla\phi + \sigma\phi = F \ \ \text{in} \ \ \Omega. \tag{4.49}$$

The advantage of such an approach is that the topology of integral lines of the modified vector field $\tilde{\mathbf{u}}$ drastically differs from the topology of integral lines of $\mathbf{u}$. The corresponding inlet, outgoing set, and characteristic set have the other structure and $\tilde{\Sigma}_{\text{in}} = \emptyset$. In particular, (4.49) does not require boundary conditions. Finally note that the C^1-norm of the modified vector fields has the majorant

$$\|\tilde{\mathbf{u}}\|_{C^1(\Omega)} \le M(1 + 16\varpi(1)t^{-1}), \tag{4.50}$$

where $\varpi(1)$ is a constant from (4.47). The following lemma constitutes the existence and uniqueness of solutions to the modified equation.

LEMMA 4.15. *Suppose that*

$$\sigma > \sigma^*(M, \Sigma) = 4M(1 + 16\varpi(1)t^{-1}) + 1, \quad M = \|\mathbf{u}\|_{C^1(\Omega)}, \tag{4.51}$$

and $0 \le s \le 1$, $r > 1$. *Then, for any* $F \in W^{s,r}(\Omega) \cap L^\infty(\Omega)$, (4.49) *has a unique weak solution* $\phi \in W^{s,r}(\Omega) \cap L^\infty(\Omega)$ *such that*

$$\|\phi\|_{W^{s,r}(\Omega)} \le c\|F\|_{W^{s,r}(\Omega)}, \quad \|\phi\|_{L^\infty(\Omega)} \le \sigma^{-1}\|F\|_{L^\infty(\Omega)}, \tag{4.52}$$

where c *depends only on* r.

Proof. Without any loss of generality we can assume that $F \in C^1(\Omega)$. By virtue of (4.50) and (4.51), the vector field $\tilde{\mathbf{u}}$ and σ meet all requirements of Lemma 4.13. Hence (4.49) has a unique solution $\phi \in W^{1,\infty}(\Omega)$. For $i = 1, 2, 3$ and $\tau > 0$, define the finite difference operator

$$\delta_{i\tau}\phi = \frac{1}{\tau}\big(\phi(x + \tau\mathbf{e}_i) - \phi(x)\big).$$

It is easy to see that

$$\tilde{\mathbf{u}}\nabla\delta_{i\tau}\phi + \sigma\delta_{i\tau}\phi = \delta_{i\tau}F - \delta_{i\tau}\tilde{\mathbf{u}}\nabla\phi(x + \tau\mathbf{e}_i) \ \text{ in } \ \Omega \cap (\Omega - \tau\mathbf{e}_i). \tag{4.53}$$

Next introduce the function $\eta \in C^\infty(\mathbb{R})$ such that $\eta' \geq 0$, $\eta(u) = 0$ for $u \leq 1$, and $\eta(u) = 1$ for $u \geq 1$, and set $\eta_h(x) = \eta\big(\operatorname{dist}(x, \partial\Omega)/h\big)$. Since $\tilde{\Sigma}_{\text{in}} = \emptyset$, the inequality

$$\limsup_{h\to 0} \int_\Omega g\tilde{\mathbf{u}} \cdot \nabla\eta_h(x)\, dx \leq 0 \tag{4.54}$$

holds true for all nonnegative functions $g \in L^\infty(\Omega)$. Choosing $h > \tau$, multiplying both sides of (4.53) by $\eta_h|\delta_{i\tau}\phi|^{r-2}\delta_{i\tau}\phi$, and integrating the result over $\Omega \cap (\Omega - \tau\mathbf{e}_i)$, we obtain

$$\begin{aligned}\int_{\Omega\cap(\Omega-\tau\mathbf{e}_i)} \eta_h|\delta_{i\tau}\phi|^r \left(\sigma - \frac{1}{r}\operatorname{div}\tilde{\mathbf{u}}\right) dx - \int_{\Omega\cap(\Omega-\tau\mathbf{e}_i)} |\delta_{i\tau}\phi|^r \tilde{\mathbf{u}}\nabla\eta_h\, dx \\ = \int_{\Omega\cap(\Omega-\tau\mathbf{e}_i)} \big(\delta_{i\tau}F - \delta_{i\tau}\tilde{\mathbf{u}}\nabla\phi(x + \tau\mathbf{e}_i)\big)\eta_h|\delta_{i\tau}\phi|^{r-2}\delta_{i\tau}\phi\, dx.\end{aligned}$$

Letting $\tau \to 0$ and then $h \to 0$ and using inequality (4.54), we obtain

$$\int_\Omega |\partial_{x_i}\phi|^r \left(\sigma - \frac{1}{r}\operatorname{div}\tilde{\mathbf{u}}\right) dx \leq \int_\Omega \big(\partial_{x_i}F - \partial_{x_i}\tilde{\mathbf{u}}\nabla\phi\big)|\partial_{x_i}\phi|^{r-2}\partial_{x_i}\phi\, dx. \tag{4.55}$$

Next note that

$$\sum_i \partial_{x_i}\tilde{\mathbf{u}}\nabla\phi\big|\partial_{x_i}\phi|^{r-2}\partial_{x_i}\phi \leq 3\|\tilde{\mathbf{u}}\|_{C^1(\Omega)} \sum_i |\partial_{x_i}\phi|^r.$$

On the other hand, since $1/r + 3 \leq 4$, inequalities (4.50) and (4.51) imply

$$\sigma - \left(\frac{1}{r} + 3\right)\|\tilde{\mathbf{u}}\|_{C^1(\Omega)} \geq \sigma - 4M(1 + 16\varpi(1)t^{-1}) \geq 1.$$

From this we conclude that

$$\begin{aligned}\sum_i \int_\Omega |\partial_{x_i}\phi|^r\, dx &\leq \sum_i \int_\Omega |\partial_{x_i}\phi|^{r-1}|\partial_{x_i}F|\, dx \\ &\leq \left(\sum_i \int_\Omega |\partial_{x_i}\phi|^{r/(r-1)}\, dx\right)^{(r-1)/r} \left(\sum_i \int_\Omega |\partial_{x_i}F|^r\, dx\right)^{1/r},\end{aligned}$$

which leads to the estimate

$$\|\nabla\phi\|_{L^r(\Omega)} \leq c(r)\|\nabla F\|_{L^r(\Omega)}. \tag{4.56}$$

Next, multiplying both sides of (4.49) by $|\phi|^{r-2}\eta_h$ and integrating the result over Ω, we get the identity

$$\int_\Omega \left(\sigma - \frac{1}{r}\operatorname{div}\tilde{\mathbf{u}}\right)\eta_h|\phi|^r\,dx - \int_\Omega |\phi|^r\tilde{\mathbf{u}}\nabla\eta_h\,dx = \int_\Omega F\eta_h|\phi|^{r-2}\phi\,dx.$$

The passage $h \to 0$ gives the inequality

$$\int_\Omega \left(\sigma - \frac{1}{r}\operatorname{div}\tilde{\mathbf{u}}\right)|\phi|^r\,dx \le \int_\Omega |F||\phi|^{r-1}\,dx.$$

Recalling that $\sigma - 1/r\operatorname{div}\tilde{\mathbf{u}} \ge 1$, we finally obtain

$$\|\phi\|_{L^r(\Omega)} \le c(r)\|F\|_{L^r(\Omega)}. \tag{4.57}$$

Inequalities (4.56) and (4.57) imply estimate (4.52) for $s = 0, 1$. Hence the linear operator $\tilde{\mathscr{L}}^{-1} : F \mapsto \phi$ is continuous in the Banach spaces $W^{0,r}(\Omega)$ and $W^{1,r}(\Omega)$, and its norm does not exceed $c(r)$. Recall that $W^{s,r}(\Omega)$ is the interpolation space $[L^r(\Omega), W^{1,r}(\Omega)]_{s,r}$. From this and Lemma B.1 we conclude that inequality (4.52) is fulfilled for all $s \in [0, 1]$, which completes the proof. □

Proof of Theorem 1.4. We begin with the proof of statement (i). Fix $\sigma > \sigma^*$, where the constant σ^* depends only on Σ, $\mathbf{U}$, and $\|\mathbf{u}\|_{C^1(\Omega)}$ and is defined by (4.51). Without any loss of generality we can assume that $f \in C^1(\Omega)$. The existence and uniqueness of a weak bounded solution for $\sigma > \sigma^*$ follows from Lemma 4.12. Moreover, by virtue of Lemma 4.12, such a solution satisfies the second inequality in (1.33). Therefore, it suffices to prove estimate (1.33) for $\|\varphi\|_{W^{s,r}(\Omega)}$. Since $W^{s,r}(\Omega) \cap L^\infty(\Omega)$ is the Banach algebra, representation (4.48) together with inequality (4.47) implies

$$\|\varphi\|_{W^{s,r}(\Omega)} \le c(1 + t^{-1})(\|\varphi_t\|_{W^{s,r}(\Omega_t)} + \|\varphi_t\|_{L^\infty(\Omega_t)}) + c\|\phi\|_{W^{s,r}(\Omega)}. \tag{4.58}$$

On the other hand, Lemma 4.15 along with (4.49) yields

$$\|\phi\|_{W^{s,r}(\Omega)} \le c\|F\|_{W^{s,r}(\Omega)} \le c\|\chi_{t/2}f\|_{W^{s,r}(\Omega)} + \|\varphi_t\mathbf{u}\nabla\chi_{t/2}\|_{W^{s,r}(\Omega)}.$$

The first term in the right-hand side is bounded:

$$\|\chi_{t/2}f\|_{W^{s,r}(\Omega)} \le c(1 + t^{-1})(\|f\|_{W^{s,r}(\Omega)} + \|\varphi_t\|_{L^\infty(\Omega)}).$$

In order to estimate the second term we note that, by virtue of (4.47), $\|\mathbf{u}\nabla\chi_{t/2}\|_{C^1(\Omega)} \le cM(1 + t^{-2})$, which gives

$$\|\varphi_t\mathbf{u}\nabla\chi_{t/2}\|_{W^{s,r}(\Omega)} \le cM(1 + t^{-2})(\|\varphi_t\|_{W^{s,r}(\Omega_t)} + \|\varphi_t\|_{L^\infty(\Omega_t)}).$$

Substituting the obtained estimates into (4.58) we arrive at the inequality

$$\|\varphi\|_{W^{s,r}(\Omega)} \le c(M+1)(1+t^{-2})\big(\|\varphi_t\|_{W^{s,r}(\Omega)} + \|\varphi_t\|_{L^\infty(\Omega_t)} + \|f\|_{W^{s,r}(\Omega_t)} + \|f\|_{L^\infty(\Omega)}\big),$$

which along with (4.40) leads to the estimate (1.33). In order to prove statement (ii) of Theorem 1.4, we note that the adjoint equation can be written in the form

$$-\mathbf{u}\nabla\varphi^* + \sigma\varphi^* = f + \varphi^*\operatorname{div}\mathbf{u}.$$

Since

$$\|\operatorname{div}\mathbf{u}\varphi^*\|_{W^{s,r}(\Omega)} \le c\big(\|\operatorname{div}\mathbf{u}\|_{W^{s,r}(\Omega)} + \|\operatorname{div}\mathbf{u}\|_{C(\Omega)}\big)\|\varphi^*\|_{W^{s,r}(\Omega)},$$

we have

$$\|\operatorname{div}\mathbf{u}\varphi^*\|_{W^{s,r}(\Omega)} + \|\operatorname{div}\mathbf{u}\varphi^*\|_{C(\Omega)} \le \delta(\|\varphi^*\|_{W^{s,r}(\Omega)} + \|\varphi^*\|_{C(\Omega)}),$$

and the needed result follows from (i) and the contraction mapping principle. □

Appendix A. Proof of Lemmas 1.7 and 2.2.

Proof of Lemma 1.7. Since $\partial\Omega$ belongs to the class C^1, functions φ, ς have the extensions $\overline{\varphi},\overline{\varsigma} \in W^{s,r}(\Omega)\cap W^{1,2}(\Omega)$ such that $\overline{\varphi},\overline{\varsigma}$ are compactly supported in $\mathbb{R}^d$ and

$$\|\overline{\varphi}\|_{W^{s,r}(\mathbb{R}^d)} \le c\|\varphi\|_{W^{s,r}(\Omega)},\ \ \|\overline{\varsigma}\|_{W^{s,r}(\mathbb{R}^d)} \le c\|\varsigma\|_{W^{s,r}(\Omega)}.$$

By virtue of Definition 1.2 and inequality (1.19), function $\mathbf{w}$ has the extension by 0 outside Ω, denoted by $\overline{\mathbf{w}}$, such that

$$\|\overline{\mathbf{w}}\|_{W^{1-s,r'}(\mathbb{R}^d)} \le c\|\mathbf{w}\|_{\mathcal{W}_0^{1-s,r'}(\Omega)}.$$

Obviously we have

$$\mathfrak{B}(\mathbf{w},\varphi,\varsigma) = -\int_{\mathbb{R}^d} \overline{\mathbf{w}}\cdot\nabla\overline{\varphi}\,\overline{\varsigma}\,dx.$$

The following multiplicative inequality is due to Maz'ya [26]. For all $s_1 > 0$, $r_1 > 1$, and $r_1 s_1 < d$,

$$\|uv\|_{W^{s_1,r_1}(\mathbb{R}^d)} \le c(r_1,s_1,d)(\|v\|_{W^{s_1,d/s_1}(\mathbb{R}^d)} + \|v\|_{L^\infty(\mathbb{R}^d)})\|u\|_{W^{s_1,r_1}(\mathbb{R}^d)}. \tag{5.1}$$

By virtue of (5.1), we have

$$\|\overline{\mathbf{w}}\,\overline{\varsigma}\|_{W^{1-s,r'}(\mathbb{R}^d)} \le c\|\overline{\mathbf{w}}\|_{W^{1-s,r'}(\mathbb{R}^d)}\big(\|\overline{\varsigma}\|_{W^{1-s,d/(1-s)}(\mathbb{R}^d)} + \|\overline{\varsigma}\|_{L^\infty(\mathbb{R}^d)}\big).$$

On the other hand, since $r^{-1} - (s-(1-s))/d \le (1-s)/d$ for $sr > d$, embedding inequality (1.21) yields

$$\|\overline{\varsigma}\|_{W^{1-s,d/(1-s)}(\mathbb{R}^d)} \le c\|\overline{\varsigma}\|_{W^{s,r}(\mathbb{R}^d)},\quad \|\overline{\varsigma}\|_{L^\infty(\mathbb{R}^d)} \le c\|\overline{\varsigma}\|_{W^{s,r}(\mathbb{R}^d)}.$$

Thus we get

$$\|\overline{\mathbf{w}}\,\overline{\varsigma}\|_{W^{1-s,r'}(\mathbb{R}^d)} \le c\|\overline{\mathbf{w}}\|_{W^{1-s,r'}(\mathbb{R}^d)}\|\overline{\varsigma}\|_{W^{s,r}(\mathbb{R}^d)}.$$

Next note that the operator $\nabla : W^{1,r}(\mathbb{R}^d) \mapsto W^{0,r}(\mathbb{R}^d)$, $\nabla : W^{0,r}(\mathbb{R}^d) \mapsto W^{-1,r}(\mathbb{R}^d)$ is continuous. By virtue of the basic property of interpolation spaces, the operator $\nabla : W^{s,r}(\mathbb{R}^d) \mapsto W^{s-1,r}(\mathbb{R}^d)$ is continuous for all $s \in [0,1]$. In particular we have $\|\nabla\overline{\varphi}\|_{W^{s-1,r}(\mathbb{R}^d)} \le c\|\overline{\varphi}\|_{W^{s,r}(\mathbb{R}^d)}$. Since $\overline{\varphi}$ and $\overline{\mathbf{w}}\,\overline{\varsigma}$ are compactly supported in $\mathbb{R}^d$, the duality principle implies

$$\begin{aligned}\int_{\mathbb{R}^d} \overline{\mathbf{w}}\,\overline{\varsigma}\nabla\overline{\varphi}\,dx &\le c\|\overline{\mathbf{w}}\,\overline{\varsigma}\|_{W^{1-s,r'}(\mathbb{R}^d)}\|\nabla\overline{\varphi}\|_{W^{s-1,r}(\mathbb{R}^d)}\\ &\le c\|\overline{\mathbf{w}}\|_{W^{1-s,r'}(\mathbb{R}^d)}\|\overline{\varsigma}\|_{W^{s,r}(\mathbb{R}^d)}\|\overline{\varphi}\|_{W^{s,r}(\mathbb{R}^d)},\end{aligned}$$

which completes the proof. □

Proof of Lemma 2.2. By virtue of (1.19), the extension $\overline{\mathbf{w}}$ satisfies the inequalities

$$\|\overline{\mathbf{w}}\|_{W^{1-s,r'}(\mathbb{R}^3)} \le c\|\mathbf{w}\|_{\mathcal{W}_0^{1-s,r'}(\Omega)}, \quad \|\overline{\mathbf{w}}\|_{W^{1,2}(\mathbb{R}^3)} \le c\|\mathbf{w}\|_{W^{1,2}(\Omega)}.$$

On the other hand, the vector field $\mathbf{h}$ has a compactly supported extension $\overline{\mathbf{h}} : \mathbb{R}^3 \to \mathbb{R}^3$ such that $\|\overline{\mathbf{h}}\|_{W^{1+s,r}(\mathbb{R}^3)} \le c\|\mathbf{h}\|_{W^{1+s,r}(\Omega)}$; however, this extension does not vanish outside Ω. Substituting the expression for $\mathscr{A}$ into the formula for $\mathfrak{A}$ and integrating by parts, we conclude that $\mathfrak{A}(\mathbf{w},\mathbf{h})$ equals

$$\int_{\mathbb{R}^3} \mathfrak{g}^{-1}\Big(\nabla\big(((\mathbf{N}_1^*)^{-1}-\mathbf{I})\overline{\mathbf{w}}\big) : \big(\mathbf{N}_1\mathbf{N}_1^*\nabla(\mathbf{N}_1^{-1^*}\overline{\mathbf{h}})\big) + \nabla\overline{\mathbf{w}} : \big(\mathbf{N}_1\mathbf{N}_1^*\nabla(\mathbf{N}_1^{-1^*}\overline{\mathbf{h}}) - \mathfrak{g}\nabla\overline{\mathbf{h}}\big)\Big)\,dx.$$

Since $\|\mathbf{N}_1^{\pm 1} - \mathbf{I}\|_{C^2(\Omega)} \le c\tau^2$, we have

$$\|((\mathbf{N}_1^*)^{-1}-\mathbf{I})\overline{\mathbf{w}}\|_{W^{1-s,r'}(\mathbb{R}^3)} \le c\tau^2\|\overline{\mathbf{w}}\|_{W^{1-s,r'}(\mathbb{R}^3)},$$
$$\|\mathfrak{g}^{-1}(\mathbf{N}_1\mathbf{N}_1^*\nabla(\mathbf{N}_1^{-1^*}\overline{\mathbf{h}})) - \nabla\overline{\mathbf{h}}\|_{W^{s,r}(\mathbb{R}^3)} \le c\tau^2\|\overline{\mathbf{h}}\|_{W^{1+s,r}(\mathbb{R}^3)}.$$

Application of the duality arguments, similar to that in the proof of Lemma 1.7, completes the proof. □

Appendix B. Interpolation. In this section we recall some results from the interpolation theory; see [6] for the proofs. Let A_0 and A_1 be Banach spaces. For $t > 0$ introduce two nonnegative functions $K : A_0 + A_1 \mapsto \mathbb{R}$ and $J : A_0 \cap A_1 \mapsto \mathbb{R}$ defined by

$$K(t,u,A_0,A_1) = \inf_{\substack{u=u_0+u_1\\ u_i\in A_i}} \|u_0\|_{A_0} + t\|u_1\|_{A_1},$$
$$J(t,u,A_0,A_1) = \max\{\|u\|_{A_0}, t\|u\|_{A_1}\}.$$

For each $s \in (0,1)$, $1 < r < \infty$, the K-interpolation space $[A_0,A_1]_{s,r,K}$ consists of all elements $u \in A_0 + A_1$ having the finite norm

$$\|u\|_{[A_0,A_1]_{s,r,K}} = \left(\int_0^\infty t^{-1-sr}K(t,u,A_0,A_1)^r\,dt\right)^{1/r}. \tag{6.1}$$

On the other hand, J-interpolation space $[A_0,A_1]_{s,r,J}$ consists of all elements $u \in A_0 + A_1$ which admit the representation

$$u = \int_0^\infty \frac{v(t)}{t}\,dt, \quad v(t) \in A_1 \cap A_0 \ \text{ for } \ t \in (0,\infty), \tag{6.2}$$

and have the finite norm

$$\|u\|_{[A_0,A_1]_{s,r,J}} = \inf_{v(t)} \left(\int_0^\infty t^{-1-sr}J(t,v(t),A_0,A_1)^r\,dt\right)^{1/r} < \infty, \tag{6.3}$$

where the infimum is taken over the set of all $v(t)$ satisfying (6.2). The first main result of interpolation theory reads as follows: For all $s \in (0,1)$ and $r \in (1,\infty)$ the spaces $[A_0,A_1]_{s,r,K}$ and $[A_0,A_1]_{s,r,J}$ are isomorphic topologically and algebraically. Hence the introduced norms are equivalent, and we can omit indices J and K. The following simple properties of interpolation spaces directly follow from definitions.

(1) If $A_1 \subset A_0$ is dense in A_0, then $[A_0, A_1]_{s,r} \subset A_0$ is dense in A_0.

(2) If $\tilde{A}_i$, $i = 0, 1$, are closed subspaces of A_i, then $[\tilde{A}_0, \tilde{A}_1]_{s,r} \subset [A_0, A_1]_{s,r}$ and $\|u\|_{[A_0,A_1]_{s,r}} \le \|u\|_{[\tilde{A}_0,\tilde{A}_1]_{s,r}}$. One of the important results of the interpolation theory is the following representation for the interpolation of dual spaces. Let A_i be Banach spaces such that $A_1 \cap A_0$ is dense in $A_0 + A_1$. Then the Banach spaces $[(A_0)', (A_1)']_{s,r'}$ and $([A_0, A_1]_{s,r})'$ are isomorphic topologically and algebraically. Hence the spaces can be identified with equivalent norms.

In particular, if $A_1 \subset A_0$, $A_0' \subset A_1'$ are dense in A_0 and A_1', respectively, then $([A_0, A_1]_{s,r})'$ is the completion of A_0' in the $([A_0, A_1]_{s,r})'$-norm.

The following lemma is the central result of the interpolation theory.

LEMMA B.1. *Let A_i, B_i, $i = 0, 1$, be Banach spaces, and let $T : A_i \mapsto B_i$ be a bounded linear operator. Then, for all $s \in (0, 1)$ and $r \in (1, \infty)$, the operator $T : [A_0, A_1]_{s,r} \mapsto [B_0, B_1]_{s,r}$ is bounded and*

$$\|T\|_{\mathcal{L}([A_0,A_1]_{s,r},[X_0,Y_1]_{s,r})} \le \|T\|^s_{\mathcal{L}(A_0,B_0)} \|T\|^{1-s}_{\mathcal{L}(A_1,B_1)}.$$

Now we show that all basic properties of spaces $\mathcal{W}_0^{s,r}$ determined by Definition 1.2 easily follow from previously mentioned results of the interpolation theory. Let Ω be a bounded domain with a boundary of the class C^1 or $\Omega = \mathbb{R}^d$. It is well known (see [46]) that, for all $s \in (0, 1)$ and $r \in (1, \infty)$, the Sobolev space $W^{s,r}(\Omega) = [L^r(\Omega), W^{1,r}(\Omega)]_{s,r}$. Since $\mathcal{W}^{0,r}(\Omega)$ and $\mathcal{W}_0^{1,r}(\Omega)$ are closed subspaces of $W^{0,r}(\mathbb{R}^d)$ and $W^{1,r}(\mathbb{R}^d)$, respectively, the interpolating space $\mathcal{W}_0^{s,r}$ determined by Definition 1.2 satisfies inequality (1.19).

Next note that, by virtue of pairing (1.22), the space $L^{r'}(\Omega)$ can be identified with $(\mathcal{W}_0^{0,r})'$, which is dense in $\mathcal{W}^{-1,r}(\Omega) = (\mathcal{W}_0^{1,r}(\Omega))'$. Therefore, the space $(\mathcal{W}_0^{s,r})'$ is the completion of $L^{r'}(\Omega)$ in the norm of $(\mathcal{W}_0^{s,r}(\Omega))'$, which is exactly equal to the norm of $\mathcal{W}^{-s,r'}(\Omega)$. Hence $(\mathcal{H}_0^{s,r}(\Omega))' = \mathcal{W}^{-s,r'}(\Omega)$, which leads to the duality principle (1.24).

Proof of Lemma 1.3. Finally we show that Lemma 1.3 is a straightforward consequence of classical results on solvability of the first boundary value problem for the Stokes equations. Note that, by virtue of Theorem 6.1 in [9], for any $\mathbf{F} \in \mathcal{H}^{s-1,r}(\Omega)$ and $G \in H^{s,r}(\Omega)$ with $s = 0, 1$, problem (1.26) has a unique solution $\mathbf{u}, \pi$ satisfying inequality

$$\|\mathbf{u}\|_{H^{s+1,r}(\Omega)} + \|\pi\|_{H^{s,r}(\Omega)} \le c(\Omega, r, s)(\|\mathbf{F}\|_{\mathcal{H}^{s-1,r}(\Omega)} + \|G\|_{H^{s,r}(\Omega)}).$$

Thus the relation $(F, G) \mapsto (\mathbf{u}, \pi)$ determines the linear operator $T : \mathcal{H}^{s-1,r}(\Omega) \times H^{s,r}(\Omega) \mapsto H^{s+1,r}(\Omega) \times H^{s,r}(\Omega)$. Therefore, Lemma 1.3 is a consequence of Lemma B.1. □

Appendix C. Change of variables. In this section we derive the equations (1.7). We will write $\mathbf{u}(y)$ and $\varrho(y)$, $y \in \Omega$, and set

$$y = x + \varepsilon \mathbf{T}(x), \quad \mathbf{M}(x) = \mathbf{I} + \varepsilon \mathbf{T}'(x), \quad \tilde{\mathbf{u}}(x) = \mathbf{u}(y(x)), \quad \varrho_\varepsilon(x) = \varrho(y(x)).$$

Thus we get $\mathbf{u}_\varepsilon = N\tilde{\mathbf{u}}$. The Jacobi matrix $\mathbf{M}$ is connected with the matrix $\mathbf{N}$ by the relations

$$\det \mathbf{M} = (\det N)^{1/2} \equiv \mathfrak{g}, \quad \mathbf{M} = \mathfrak{g}\mathbf{N}^{-1}. \tag{7.1}$$

For any function $\phi \in C^1(\Omega)$ we have $\nabla_y \phi = (\mathbf{M}^*)^{-1} \nabla_x \tilde{\phi}$, where $\tilde{\phi}(x) = \phi(y(x))$. It follows from this that the identities

$$\int_{\tilde{\Omega}} (\mathrm{div}_y \mathbf{u})(y(x))\, \tilde{\phi}(x) \det \mathbf{M}\, dx = \int_{\Omega} (\mathrm{div}_y \mathbf{u})(y) \phi(y) \det\ dy = -\int_{\Omega} \mathbf{u} \cdot \nabla_y \phi\, dy$$
$$= -\int_{\tilde{\Omega}} \tilde{\mathbf{u}} \cdot (\mathbf{M}^*)^{-1} \nabla_x \tilde{\phi}(x) \det \mathbf{M}\, dx = \int_{\tilde{\Omega}} \mathrm{div}_x \big((\det \mathbf{M})\, \mathbf{M}^{-1} \tilde{\mathbf{u}} \big)\, \tilde{\phi}(x)\, dx$$

hold true for all $\phi \in C_0^\infty(\Omega)$. On the other hand, by virtue of (7.1) we have $(\det \mathbf{M})\, \mathbf{M}^{-1} \tilde{\mathbf{u}} = \mathbf{u}_\varepsilon(x)$. This leads to the equalities

$$\begin{aligned} (\mathrm{div}_y \mathbf{u})(y(x)) = \mathfrak{g}^{-1} \mathrm{div}_x \big(\mathbf{N}\, \tilde{\mathbf{u}}(x) \big) \equiv \mathfrak{g}^{-1} \mathrm{div}_x \mathbf{u}_\varepsilon(x), \\ \mathrm{div}_y (\varrho \mathbf{u})(y(x)) = \mathfrak{g}^{-1} \mathrm{div}_x (\varrho_\varepsilon \mathbf{u}_\varepsilon), \end{aligned} \tag{7.2}$$

which imply the modified mass balance equation (1.7b). From (7.2) and the identity $(\mathbf{M}^*)^{-1} = \mathfrak{g}^{-1} \mathbf{N}^*$ we obtain

$$\nabla \left(\lambda \mathrm{div} \mathbf{u} - \frac{R}{\epsilon^2} p(\varrho) \right) = \mathfrak{g}^{-1} \mathbf{N}^* \nabla \left(\lambda \mathfrak{g}^{-1} \,\mathrm{div}\, \mathbf{u}_\varepsilon - \frac{R}{\epsilon^2} p(\varrho_\varepsilon) \right). \tag{7.3}$$

Combining (7.2) with the identity $\Delta = \mathrm{div}\, \nabla$ we obtain

$$\begin{aligned} \Delta \mathbf{u}(y) = \mathfrak{g}^{-1}\, \mathrm{div} \left(\mathbf{N} (\mathbf{M}^*)^{-1} \nabla \tilde{\mathbf{u}} \right) \\ = \mathfrak{g}^{-1}\, \mathrm{div} \left(\mathfrak{g}^{-1} \mathbf{N} \mathbf{N}^* \nabla (\mathbf{N}^{-1} \mathbf{u}_\varepsilon) \right) = \mathfrak{g}^{-1} \mathbf{N}^* \left(\Delta \mathbf{u}_\varepsilon - \mathscr{A}(\mathbf{u}_\varepsilon) \right). \end{aligned} \tag{7.4}$$

Next note that the components $(\mathbf{u} \nabla \mathbf{u})_i$ of the vector $\mathbf{u} \nabla \mathbf{u}$ satisfy the equalities

$$(\mathbf{u} \nabla \mathbf{u})_i = \mathbf{u} \cdot \nabla_y u_i = \tilde{\mathbf{u}} \cdot \left((\mathbf{M}^*)^{-1} \nabla \tilde{u}_i \right) = \mathfrak{g}^{-1} \mathbf{N} \tilde{\mathbf{u}} \cdot \nabla \tilde{u}_i = \mathfrak{g}^{-1} \mathbf{u}_\varepsilon \cdot \nabla \big(\mathbf{N}^{-1} \mathbf{u}_\varepsilon \big)_i.$$

This gives

$$\varrho \mathbf{u} \nabla \mathbf{u} = \mathbf{g}^{-1} \mathbf{N}^* \mathscr{B}(\varrho_\varepsilon, \mathbf{u}_\varepsilon, \mathbf{u}_\varepsilon). \tag{7.5}$$

Substituting (7.3)–(7.5) into mass balance equation (1.2a) and multiplying both sides of the resulting equality by $\mathfrak{g}(\mathbf{N}^*)^{-1}$, we obtain modified equation (1.7a).

QUASI-STATIC EVOLUTION FOR A MODEL IN STRAIN GRADIENT PLASTICITY*

ALESSANDRO GIACOMINI† AND LUCA LUSSARDI†

Abstract. We prove the existence of a quasi-static evolution for a model in strain gradient plasticity proposed by Gurtin and Anand concerning isotropic, plastically irrotational materials under small deformations. This is done by means of the energetic approach to rate-independent evolution problems. Finally we study the asymptotic behavior of the evolution as the strain gradient length scales tend to zero recovering in the limit a quasi-static evolution in perfect plasticity.

Key words. variational models, energy minimization, quasi-static evolution, higher-order stress, flow rule

1. Introduction.

Since the early attempts of Aifantis [3], strain gradient plasticity models have been proposed in order to capture [illegible] size effects in metals such as [illegible] and [illegible]. These effects, which take place approximately at the scale of 500 nm–50 μm, cannot be modeled by conventional theories of plasticity. This fact led to the development of continuum theories of plasticity that incorporate size dependence by accounting for strain gradients, namely, the gradient of plastic strains. Following the classical papers by Nye [30] and by Ashby [4, 5], strain gradients induce [illegible], and these dislocations together with [illegible] are mainly responsible for size effects.

Several strain gradient theories, different from one another, have been recently proposed by different authors [1, 7, 10, 11, 14, 15, 16, 17, 18, 20, 12, 21]. In this paper we focus on the theory proposed by Gurtin and Anand [19]. In the context of small deformations, and in the absence of plastic rotation, the strain gradient dependence enters the model via a microstress associated to the gradient of the plastic strain and by a free energy dependent of the macroscopic Burgers tensor.

Let $\Omega \subseteq \mathbb{R}^3$ be the reference configuration of the body. The strain $(\mathbf{E}u)_{ij} := (\partial_i u_j + \partial_j u_i)/2$ of the displacement $u : \Omega \to \mathbb{R}^3$ is decomposed as usual in the form

$$\mathbf{E}u = \mathbf{E}^{\mathrm{e}} + \mathbf{E}^{\mathrm{p}}, \tag{1.1}$$

where $\mathbf{E}^{\mathrm{e}} \in M^{3\times 3}_{\mathrm{sym}}$ is the [illegible] while $\mathbf{E}^{\mathrm{p}}$ is referred to as the [illegible]. It is assumed that $\mathbf{E}^{\mathrm{p}}$ has zero trace; i.e., $\mathbf{E}^{\mathrm{p}}$ belongs to the space of deviatoric matrices $M^{3\times 3}_D$. Besides the usual Cauchy stress $\mathbf{T}$, which satisfies the classical macroscopic force balance, the stress configuration of the system is described by [illegible] tensor $\mathbf{T}^{\mathrm{p}}$ and a [illegible] tensor $\mathbb{K}^{\mathrm{p}}$ which satisfy the equilibrium condition

$$\mathbf{T}_D = \mathbf{T}^{\mathrm{p}} - \mathrm{div}\mathbb{K}^{\mathrm{p}}. \tag{1.2}$$

†Dipartimento di Matematica, Facoltà di Ingegneria, Università degli Studi di Brescia, Via Valotti 9, 25133 Brescia, Italy (alessandro.giacomini@ing.unibs.it, luca.lussardi@ing.unibs.it).

Here $\mathbf{T}_D$ denotes the deviatoric part of $\mathbf{T}$, i.e., $\mathbf{T}_D := \mathbf{T} - \frac{1}{3}\mathrm{tr}(\mathbf{T})Id$. The triple $(\mathbf{T}, \mathbf{T}^{\mathrm{p}}, \mathbb{K}^{\mathrm{p}})$ furnishes the internal power expenditure within a subbody $\mathcal{B} \subseteq \Omega$ by means of the relation

$$\mathcal{W}_{\mathrm{int}}(\mathcal{B}) = \int_{\mathcal{B}} (\mathbf{T} : \dot{\mathbf{E}}^{\mathrm{e}} + \mathbf{T}^{\mathrm{p}} : \dot{\mathbf{E}}^{\mathrm{p}} + \mathbb{K}^{\mathrm{p}} : \nabla\dot{\mathbf{E}}^{\mathrm{p}})\, dx,$$

where $\dot{\mathbf{E}}^{\mathrm{e}}$ and $\dot{\mathbf{E}}^{\mathrm{p}}$ derive from a virtual velocity $(\dot{u}, \dot{\mathbf{E}}^{\mathrm{e}}, \dot{\mathbf{E}}^{\mathrm{p}})$ of the system. So $\mathbf{T}^{\mathrm{p}}$ and $\mathbb{K}^{\mathrm{p}}$ are stresses conjugated to the plastic strain and its gradient, $\mathbb{K}^{\mathrm{p}}$ being a [illegible] since it is conjugated to the gradient of the plastic strain. The balance equations for $\mathbf{T}$, $\mathbf{T}^{\mathrm{p}}$, and $\mathbb{K}^{\mathrm{p}}$ follow by equating the internal power expenditure to the power expenditure associated to the external loads. This entails also boundary conditions for the normal components of $\mathbf{T}$ and $\mathbb{K}^{\mathrm{p}}$ which are connected to the imposed traction and [illegible] on parts of the boundary (see section 3 for details).

The [illegible] of the system is a function of the elastic strain $\mathbf{E}^{\mathrm{e}}$ and of the macroscopic Burgers tensor $\mathbf{G} = \mathrm{curl}\mathbf{E}^{\mathrm{p}}$. In the separable quadratic isotropic case, it assumes the form

$$\psi = \mu|\mathbf{E}^{\mathrm{e}}_D|^2 + \frac{1}{2}k|\mathrm{tr}\mathbf{E}^{\mathrm{e}}|^2 + \frac{\mu L^2}{2}|\mathrm{curl}\mathbf{E}^{\mathrm{p}}|^2, \tag{1.3}$$

where μ and k are the elastic shear and bulk moduli and L is an energetic length scale. The presence of $\mathrm{curl}\mathbf{E}^{\mathrm{p}}$ inside the free energy accounts for the incompatibility of the tensor field $\mathbf{E}^{\mathrm{p}}$, and so it is connected to the presence of geometrically necessary dislocations in Ω. By means of ψ, the energetic third order tensor $\mathbb{K}^{\mathrm{p}}_{\mathrm{en}}$ is defined as the symmetric-deviatoric part (in the first two subscripts) of $\frac{\partial\psi}{\partial\mathbf{G}}$. This entails a decomposition of $\mathbb{K}^{\mathrm{p}}$ into dissipative and energetic parts $\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}$ and $\mathbb{K}^{\mathrm{p}}_{\mathrm{en}}$, respectively, with

$$\mathbb{K}^{\mathrm{p}} = \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}} + \mathbb{K}^{\mathrm{p}}_{\mathrm{en}}.$$

Let Ω be subject to body forces $f(t)$ and to traction forces $g(t)$ on a part $\partial_N\Omega$ of its boundary, with $t \in [0, T]$. Let $\partial\Omega$ be [illegible]; i.e., [illegible] occurs (see section 3 for details). Let us assume that a displacement $w(t)$ is imposed on $\partial_D\Omega := \partial\Omega\setminus\overline{\partial_N\Omega}$. The laws governing the evolution $(u(t), \mathbf{E}^{\mathrm{e}}(t), \mathbf{E}^{\mathrm{p}}(t))$ of the system are obtained by the thermodynamical requirement

$$\dot{\psi}(\mathcal{B}) \le \mathcal{W}_{\mathrm{int}}(\mathcal{B}),$$

where $\psi(\mathcal{B})$ is the free energy of the subbody $\mathcal{B}$ obtained by integrating (1.3) over $\mathcal{B}$ and $\dot{\psi}(\mathcal{B})$ denotes its time derivative. In order to match such an inequality, Gurtin and Anand propose a flow rule involving $\dot{\mathbf{E}}^{\mathrm{p}}(t)$, $\nabla\dot{\mathbf{E}}^{\mathrm{p}}(t)$, $\mathbf{T}^{\mathrm{p}}(t)$, $\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t)$, a [illegible] $l > 0$, and a hardening internal variable. This law reduces to the usual flow rules of classical plasticity when the length scales l and L are set to zero. In the [illegible], and neglecting the hardening internal variable, it takes the form

$$\mathbf{T}^{\mathrm{p}}(t,x) = S_Y\frac{\dot{\mathbf{E}}^{\mathrm{p}}(t,x)}{d^p(t,x)}, \qquad \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x) = S_Y\frac{l^2\nabla\dot{\mathbf{E}}^{\mathrm{p}}(t,x)}{d^p(t,x)}. \tag{1.4}$$

Here $\dot{\mathbf{E}}^{\mathrm{p}}(t,x)$ and $\nabla\dot{\mathbf{E}}^{\mathrm{p}}(t,x)$ denote the time derivative of $\mathbf{E}^{\mathrm{p}}(t,x)$ and $\nabla\mathbf{E}^{\mathrm{p}}(t,x)$, respectively, S_Y is the yield strength, and

$$d^p(t,x) := \sqrt{|\dot{\mathbf{E}}^{\mathrm{p}}(t,x)|^2 + l^2|\nabla\dot{\mathbf{E}}^{\mathrm{p}}(t,x)|^2}$$

is an [illegible]. The stresses $\mathbf{T}^{\mathrm{p}}(t)$ and $\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t)$ satisfy the [illegible]

$$\sqrt{|\mathbf{T}^{\mathrm{p}}(x)|^2 + l^{-2}|\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(x)|^2} \le S_Y, \tag{1.5}$$

and (1.4) is valid when relation (1.5) holds with equality; $(\dot{\mathbf{E}}^{\mathrm{p}}(t), \nabla\dot{\mathbf{E}}^{\mathrm{p}}(t)) = (0,0)$ otherwise. Notice that, by setting $l = L = 0$, we have $\mathbb{K}^{\mathrm{p}} = 0$ and $\mathbf{T}^{\mathrm{p}} = \mathbf{T}_D$ and (1.4) reduces to the usual flow rule of the von Mises type.

The aim of the paper is to provide an existence result of an evolution for the Gurtin–Anand model in the rate-independent case without hardening. The case with positive hardening has been considered recently by Reddy, Ebobisse, and McBride [31]. Adopting a primal formulation, they study the problem by means of variational inequalities in abstract Hilbert spaces. In the case without hardening, coercivity estimates fail, and the use of the abstract setting is no longer possible. This fact reflects what happens also at the level of classical plasticity, where perfect plasticity deserves an "ad hoc" treatment (see [32, 8]).

Inspired by the recent paper of Dal Maso, DeSimone, and Mora [8] concerning perfect plasticity, we recast the problem of the evolution for the Gurtin–Anand model in the framework of the energetic approach to rate-independent processes developed in [24, 25, 27, 28, 29].

Let us consider $\Omega \subseteq \mathbb{R}^N$ open, bounded, and with a Lipschitz boundary ($N \ge 2$). By means of variational arguments, we first construct a discretized-in-time evolution $(u_{k,i}, \mathbf{E}^{\mathrm{e}}_{k,i}, \mathbf{E}^{\mathrm{p}}_{k,i})$ relative to the nodes t^i_k of a subdivision $0 = t^0_k < t^1_k < \cdots < t^k_k = T$ of the time interval $[0,T]$ with step T/k.

In order to enforce variationally the stress constraint (1.5), we consider the function

$$\mathbf{E}^{\mathrm{p}} \mapsto S_Y \int_\Omega \sqrt{|\mathbf{E}^{\mathrm{p}}|^2 + l^2|\nabla\mathbf{E}^{\mathrm{p}}|^2}\, dx.$$

Since this map has linear growth in $\nabla\mathbf{E}^{\mathrm{p}}$, in order to perform direct minimization, we are naturally led to consider $\mathbf{E}^{\mathrm{p}}$ as a [illegible] $BV(\Omega; \mathrm{M}^{N\times N}_D)$ and to relax the functional to the form

$$\mathcal{H}(\mathbf{E}^{\mathrm{p}}) := S_Y \int_\Omega \sqrt{|\mathbf{E}^{\mathrm{p}}|^2 + l^2|\nabla\mathbf{E}^{\mathrm{p}}|^2}\, dx + lS_Y|D^s\mathbf{E}^{\mathrm{p}}|(\Omega),$$

where $D^s\mathbf{E}^{\mathrm{p}}$ denotes the singular part of the derivative of $\mathbf{E}^{\mathrm{p}}$.

The minimization problem that we consider in order to construct $(u_{k,i+1}, \mathbf{E}^{\mathrm{e}}_{k,i+1}, \mathbf{E}^{\mathrm{p}}_{k,i+1})$ relative to the boundary displacement $w(t^{i+1}_k)$ once constructed $(u_{k,i}, \mathbf{E}^{\mathrm{e}}_{k,i}, \mathbf{E}^{\mathrm{p}}_{k,i})$ is the following:

$$\min_{(u,\mathbf{E}^{\mathrm{e}},\mathbf{E}^{\mathrm{p}})\in\mathcal{A}\left(w\left(t^{i+1}_k\right)\right)} \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}) - \left\langle \mathcal{L}\left(t^{i+1}_k\right), u\right\rangle + \mathcal{H}\left(\mathbf{E}^{\mathrm{p}} - \mathbf{E}^{\mathrm{p}}_{k,i}\right). \tag{1.6}$$

Here $\mathcal{A}(w(t^{i+1}_k))$ is the class of admissible configurations for $w(t^{i+1}_k)$,

$$\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}) := \int_\Omega \left(\mu|\mathbf{E}^{\mathrm{e}}_D|^2 + \frac{1}{2}k|\mathrm{tr}\mathbf{E}^{\mathrm{e}}|^2\right) dx, \qquad \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}) := \frac{\mu L^2}{2}\int_\Omega |\mathrm{curl}\mathbf{E}^{\mathrm{p}}|^2\, dx,$$
$$\langle \mathcal{L}(t), u\rangle := \int_\Omega f(t)\cdot u\, dx + \int_{\partial_N\Omega} g(t)\cdot u\, d\mathcal{H}^{N-1},$$

where $\mathcal{H}^{N-1}$ denotes the $(N-1)$-dimensional Hausdorff measure.

In order to have a well-defined energy in (1.6), it suffices that the elastic strain $\mathbf{E}^{\mathrm{e}}$ and the Burgers tensor $\mathrm{curl}\mathbf{E}^{\mathrm{p}}$ belong to the space of square integrable functions. As a consequence, the class $\mathcal{A}(t_k^i)$ turns out to be defined as the triples $(u, \mathbf{E}^{\mathrm{e}}, \mathbf{E}^{\mathrm{p}})$, with

$$u \in W^{1,\frac{N}{N-1}}\left(\Omega;\mathbb{R}^N\right), \qquad \mathbf{E}^{\mathrm{e}} \in L^2\left(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}}\right),$$

$$\mathbf{E}^{\mathrm{p}} \in BV\left(\Omega;\mathrm{M}^{N\times N}_{D}\right), \qquad \mathrm{curl}\mathbf{E}^{\mathrm{p}} \in L^2\left(\Omega;\mathrm{M}^{N\times N}\right),$$

which satisfy the boundary condition $u = w(t_k^i)$ on $\partial_D\Omega$, and such that the compatibility condition (1.1) holds. Notice that the requirement $u \in W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)$ follows by (1.1) and by the assumptions on $\mathbf{E}^{\mathrm{e}}$ and $\mathbf{E}^{\mathrm{p}}$ in view of Korn's inequality. We assume that $f(t) \in L^N(\Omega;\mathbb{R}^N)$ and $g(t) \in L^N(\partial_N\Omega;\mathbb{R}^N)$ so that the work $\mathcal{L}(t)$ of external forces turns out to be well-defined. The displacement on $\partial_D\Omega$ is assumed to be given by the trace of a map in $W^{1,2}(\Omega;\mathbb{R}^N)$.

The minimum problem (1.6) admits solutions in $\mathcal{A}(w(t_k^i))$ provided that the external loads satisfy a suitable safe load condition (see (4.13)–(4.14)) which appears also in the study of evolutions in perfect plasticity. This condition entails some coercivity in BV for $\mathbf{E}^{\mathrm{p}}$ from the interaction between $\mathcal{H}(\mathbf{E}^{\mathrm{p}} - \mathbf{E}^{\mathrm{p}}_{k,i-1})$ and the linear term $\langle \mathcal{L}(t_k^i), u\rangle$. The existence of a solution for (1.6) follows by applying the direct method of the calculus of variations (Lemma 6.1).

The continuous-in-time evolution is obtained by interpolating the discrete evolution $(u_{k,i}, \mathbf{E}^{\mathrm{e}}_{k,i}, \mathbf{E}^{\mathrm{p}}_{k,i})$ and sending $k \to +\infty$ (section 7). If $w \in AC(0,T;W^{1,2}(\Omega;\mathbb{R}^N))$, $f \in AC(0,T;L^N(\Omega;\mathbb{R}^N))$, $g \in AC(0,T;L^\infty(\partial_N\Omega;\mathbb{R}^N))$, and the safe load condition on f, g holds uniformly in time, we prove the convergence towards a quasi-static evolution $t \mapsto (u(t), \mathbf{E}^{\mathrm{e}}(t), \mathbf{E}^{\mathrm{p}}(t)) \in \mathcal{A}(w(t))$ which is absolutely continuous in time and which satisfies the following two conditions:

(a) Global minimality: For every $(v, \mathbf{e}, \mathbf{p}) \in \mathcal{A}(w(t))$

$$\begin{aligned}(1.7)\quad \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)) - \langle \mathcal{L}(t), u(t)\rangle \\ \le \mathcal{Q}_1(\mathbf{e}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{p}) - \langle \mathcal{L}(t), v\rangle + \mathcal{H}(\mathbf{p} - \mathbf{E}^{\mathrm{p}}(t));\end{aligned}$$

(b) Energy balance:

$$\begin{aligned}(1.8)\quad \mathcal{E}(t) + \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}};0,t) = \mathcal{E}(0) + \int_0^t\int_\Omega \mathbf{T}(\tau) : \mathbf{E}\dot{w}(\tau)\,dx\,d\tau \\ - \int_0^t \langle \dot{\mathcal{L}}(\tau), u(\tau)\rangle\,d\tau - \int_0^t \langle \mathcal{L}(\tau), \dot{w}(\tau)\rangle\,d\tau,\end{aligned}$$

where $\mathbf{T}(t)$ is the Cauchy stress tensor, $\mathcal{E}(t) := \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)) - \langle \mathcal{L}(t), u(t)\rangle$, $\dot{\mathcal{L}}(t)$ is associated to $\dot{f}(t)$, $\dot{g}(t)$, and $\mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}};0,t)$ defined as

$$\mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}};a,b) := \sup\left\{\sum_{j=1}^k \mathcal{H}\left(\mathbf{E}^{\mathrm{p}}(t_j) - \mathbf{E}^{\mathrm{p}}(t_{j-1})\right) : a = t_0 < t_1 < \cdots < t_k = b\right\}$$

has the role of a [illegible].

We refer to an evolution satisfying (a) and (b) as a [illegible] for the Gurtin–Anand model (Definition 5.1).

The analysis of the global minimality condition (1.7) leads to the existence of stresses $\mathbf{T}^{\mathrm{p}}(t)$, $\mathbb{K}^{\mathrm{p}}(t)$, and $\mathbb{S}^{\mathrm{p}}(t)$ which together with the Cauchy stress $\mathbf{T}(t)$ satisfy the balance of internal and external powers in Ω

$$\int_\Omega \mathbf{T}(t) : \mathbf{e}\, dx + \int_\Omega \mathbf{T}^{\mathrm{p}}(t) : \mathbf{p}\, dx + \int_\Omega \mathbb{K}^{\mathrm{p}}(t) : \nabla \mathbf{p}\, dx + \langle \mathbb{S}^{\mathrm{p}}(t), D^s \mathbf{p} \rangle = \langle \mathcal{L}(t), v \rangle \tag{1.9}$$

for every virtual velocity $(v, \mathbf{e}, \mathbf{p}) \in \mathcal{A}(0)$ (Lemma 8.1). Notice that a new higher-order stress $\mathbb{S}^{\mathrm{p}}(t)$ conjugated to $D^s\mathbf{E}^{\mathrm{p}}$ appears from our approach: This is somehow natural since $D^s\mathbf{E}^{\mathrm{p}}$ is treated at the same level of $\nabla\mathbf{E}^{\mathrm{p}}$. The balance (1.9) entails the usual balance equation for the Cauchy stress (Proposition 8.2), the balance equation (1.2), the stress constraint (1.5), and the confinement $\|\mathbb{S}^{\mathrm{p}}(t)\| \le l S_Y$ for the singular stress $\mathbb{S}^{\mathrm{p}}(t)$ (Proposition 8.3).

The flow rule (1.4) follows from the analysis of the energy balance equality (1.8) (Proposition 8.10). It is also supplemented by a weak flow rule for the singular stress $\mathbb{S}^{\mathrm{p}}(t)$ (Proposition 8.9).

Concerning the uniqueness of the evolution, it turns out that the maps $t \mapsto \mathbf{E}^{\mathrm{e}}(t)$ and $t \mapsto \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)$ are uniquely determined by the initial conditions (Proposition 8.8). As for the maps $t \mapsto u(t)$ and $t \mapsto \mathbf{E}^{\mathrm{p}}(t)$, we suspect that nonuniqueness can occur as in the case of standard perfect plasticity (see [32, section 2.1]), even if we do not have at the moment an explicit counterexample.

In section 9, we study the asymptotic behavior of a quasi-static evolution for the Gurtin–Anand model when the length scales l and L vanish. As noted previously, by setting l and L equal to zero, the model reduces to the classical model of perfect plasticity of von Mises. Under a suitable assumption on the initial configuration, we prove (Theorem 9.2) that the quasi-static evolution for the Gurtin–Anand model converges in a suitable sense to the evolution for elastic-perfectly plastic bodies in the framework proposed by Dal Maso, DeSimone, and Mora [8]. The main difficulty we have to handle is the change in the mathematical setting of the problem, especially concerning the plastic strain. While in the strain gradient context $\mathbf{E}^{\mathrm{p}}$ is a BV function, in [8] it is modeled simply as a Radon measure.

The paper is organized as follows. In section 2 we fix the notation and recall some basic tools we need from the theory of BV functions. In section 3 we give a brief sketch of the Gurtin–Anand model, while in section 4 we settle the mathematical framework that we adopt in the analysis. The main results are stated in section 5. The existence of a quasi-static evolution is obtained in section 7 after exploiting the convergence of the discrete evolution constructed in section 6. Section 8 is devoted to the proof of the balance equations and the flow rule. Finally section 9 contains the asymptotic analysis as the strain gradient effects vanish.

2. Notation and preliminaries. In this section we recall some basic definitions and results employed in the rest of the paper.

Matrices. We will denote by $\mathrm{M}^{N\times N}$ the space of $N \times N$ matrices $\mathbf{A} = (a_{ij})$, with $a_{ij} \in \mathbb{R}$ endowed with the scalar product

$$\mathbf{A} : \mathbf{B} := \sum_{i,j} a_{ij} b_{ij}. \tag{2.1}$$

The norm of $\mathbf{A}$ induced by the scalar product (2.1) is denoted by $|\mathbf{A}|$.

We will denote by $\mathrm{M}^{N\times N}_{\mathrm{sym}}$ the subspace of symmetric matrices and by $\mathrm{M}^{N\times N}_{D}$ the subspace of $\mathrm{M}^{N\times N}_{\mathrm{sym}}$ of matrices $\mathbf{A}$ with zero trace, that is, such that $\mathrm{tr}\mathbf{A} := \sum_i a_{ii} = 0$.

Given $\mathbf{A} \in \mathrm{M}^{N\times N}_{\mathrm{sym}}$, we denote by $\mathbf{A}_D$ its projection on $\mathrm{M}^{N\times N}_D$, i.e.,

$$\mathbf{A}_D := \mathbf{A} - \frac{1}{N}(\mathrm{tr}A)\mathbf{Id}, \tag{2.2}$$

where $\mathbf{Id}$ is the identity matrix.

The symmetrized gradient of an $\mathbb{R}^N$-valued function $u(x)$ is defined as

$$\mathbf{E}u := \frac{\nabla u + \nabla u^T}{2},$$

where $(\nabla u)_{ij} = \frac{\partial u_i}{\partial x_j}$ is the gradient of u and ∇u^T denotes its transpose.

The gradient, the divergence, and the curl of a $\mathrm{M}^{N\times N}$-valued function $\mathbf{A}(x) = (a_{ij}(x))$ are defined as

$$(\nabla \mathbf{A})_{ijk} := \frac{\partial a_{ij}}{\partial x_k}, \qquad (\mathrm{div}\mathbf{A})_i := \sum_j \frac{\partial a_{ij}}{\partial x_j}, \qquad (\mathrm{curl}\mathbf{A})_{ij} := \sum_{p,q} \epsilon_{ipq}\frac{\partial a_{jq}}{\partial x_p},$$

respectively, where ϵ_{ipq} are the standard permutation symbols.

We will indicate by $\mathrm{M}^{N\times N\times N}$ the space of third order tensors $\mathbb{A} = (a_{ijk})$ with scalar product

$$\mathbb{A} : \mathbb{B} := \sum_{i,j,k} a_{ijk}b_{ijk},$$

and $|\mathbb{A}|$ will denote the induced norm of $\mathbb{A}$.

We say that $\mathbb{A} = (a_{ijk}) \in \mathrm{M}^{N\times N\times N}$ is [illegible] if

$$a_{ijk} = a_{jik} \qquad \text{and} \qquad \sum_p a_{ppk} = 0.$$

We write $\mathbb{A} \in \mathrm{M}^{N\times N\times N}_D$.

The divergence of a $\mathrm{M}^{N\times N\times N}$-valued function $\mathbb{A}(x) = (a_{ijk}(x))$ is given by

$$(\mathrm{div}\mathbb{A})_{ij} := \sum_k \frac{\partial a_{ijk}}{\partial x_k}.$$

Functional spaces and measures. Given $A \subseteq \mathbb{R}^N$ open and $1 \le p < +\infty$, we will denote by $L^p(A;\mathbb{R}^M)$ the space of p-summable functions on A with values in $\mathbb{R}^M$ and by $W^{1,p}(A;\mathbb{R}^M)$ the usual Sobolev space of functions in $L^p(A;\mathbb{R}^M)$ whose derivatives in the sense of distributions belong to L^p. Finally, $\mathcal{M}_b(A;\mathbb{R}^M)$ will denote the space of $\mathbb{R}^M$-valued Radon measures on A, and for every $\mu \in \mathcal{M}_b(A;\mathbb{R}^M)$ we will indicate by $|\mu|(A)$ its total mass. We set $\|\mu\|_{\mathcal{M}_b(A;\mathbb{R}^M)} := |\mu|(A)$. We refer the reader to [9] for the main properties concerning Sobolev spaces and Radon measures.

Let us recall some results from the theory of BV functions. We refer the reader to [2] for an exhaustive treatment of the subject.

We say that $u \in BV(A;\mathbb{R}^M)$ if $u \in L^1(A;\mathbb{R}^M)$, and its distributional derivative Du is a vector-valued Radon measure on A. $BV(A;\mathbb{R}^M)$ is a Banach space with respect to the norm

$$\|u\|_{BV(A;\mathbb{R}^M)} := \|u\|_{L^1(A;\mathbb{R}^M)} + |Du|(A).$$

We will denote by $D^s u$ the singular part of Du with respect to the Lebesgue measure $\mathcal{L}^N$ and by ∇u the density of its absolutely continuous part.

We will say that a sequence $(u_n)_{n\in\mathbb{N}}$ in $BV(A;\mathbb{R}^M)$ converges weakly* in $BV(A;\mathbb{R}^M)$ to $u \in BV(A;\mathbb{R}^M)$ if

$$\begin{aligned} &u_n \to u \qquad \text{strongly in } L^1(A;\mathbb{R}^M),\\ &Du_n \overset{*}{\rightharpoonup} Du \qquad \text{weakly* in } \mathcal{M}_b(A;\mathbb{R}^M). \end{aligned} \tag{2.3}$$

The following compactness result holds: If A is open bounded and with a Lipschitz boundary, every bounded sequence in $BV(A;\mathbb{R}^M)$ admits a subsequence converging weakly* in $BV(A;\mathbb{R}^M)$.

Finally we will use throughout the paper the following embedding property of BV: If A is bounded and with a Lipschitz boundary, then $BV(A;\mathbb{R}^M)$ is continuously embedded into $L^q(A;\mathbb{R}^M)$ for every $1 \le q \le \frac{N}{N-1}$, the embedding being compact for every $1 \le q < \frac{N}{N-1}$.

One-dimensional *AC* and *BV* functions with values in Banach spaces. Let X be a reflexive Banach space or the dual of a separable Banach space. We denote by $BV(a,b;X)$ and $AC(a,b;X)$ the space of functions of bounded variation and the space of absolutely continuous functions from $[a,b]$ to X, respectively. We refer the reader to [6] for the main properties of these spaces. We recall that the variation of $f \in BV(a,b;X)$ is defined as

$$\mathcal{V}(f;a,b) := \sup\left\{ \sum_{j=1}^{k} \|f(t_j) - f(t_{j-1})\|_X \,:\, a = t_0 < t_1 < \cdots < t_k = b \right\}. \tag{2.4}$$

If X is reflexive and $f \in AC(a,b;X)$, then the time derivative $\dot f(t)$ exists for a.e. $t \in [a,b]$. If X is the dual of a separable Banach space (and this is interesting when we consider the plastic strains), the time derivative $\dot f(t)$ exists as a weak* limit of difference quotients for a.e. $t \in [a,b]$ (see [8, Theorem 7.1]).

We will often use the following generalization of Helly's theorem [8, Lemma 7.2] (see also [23, Theorem 3.2]): If X is the dual of a separable Banach space and $(f_k)_{k\in\mathbb{N}}$ a sequence in $BV(a,b;X)$ with $\mathcal{V}(f_k;a,b)$ and $\|f_k(a)\|_X$ uniformly bounded, then there exist $f \in BV(a,b;X)$ and a subsequence $(f_{k_j})_{j\in\mathbb{N}}$ such that $f_{k_j}(t) \overset{*}{\rightharpoonup} f(t)$ weakly* in X for every $t \in [a,b]$.

3. The Gurtin–Anand model. In this section we quickly describe the Gurtin–Anand model [19] in strain gradient plasticity which describes the behavior of isotropic, plastically irrotational materials under small deformations. We present the [illegible] case in which the internal hardening variable is neglected.

Let $\Omega \subseteq \mathbb{R}^N$ be the reference configuration of the body. The starting point of the theory is, as usual, the additive decomposition of the displacement strain $\mathbf{E}u = (\nabla u + \nabla u^T)/2$ into elastic and plastic parts

$$\mathbf{E}u = \mathbf{E}^{\mathrm{e}} + \mathbf{E}^{\mathrm{p}}. \tag{3.1}$$

The symmetric matrices $\mathbf{E}^{\mathrm{e}}$ and $\mathbf{E}^{\mathrm{p}}$ are referred to as the [illegible] and the [illegible], respectively. The plastic part $\mathbf{E}^{\mathrm{p}}$ is supposed to be unable to sustain volumetric changes, so that

$$\mathrm{tr}\mathbf{E}^{\mathrm{p}} = 0;$$

that is, $\mathbf{E}^{\mathrm{p}} \in \mathrm{M}^{N\times N}_D$.

Stresses and balance equations. Given a subbody $\mathcal{B} \subseteq \Omega$, besides the usual Cauchy stress $\mathbf{T} \in \mathrm{M}^{N\times N}_{\mathrm{sym}}$ conjugate to $\mathbf{E}^{\mathrm{e}}$, the analysis of its equilibrium involves also stresses $\mathbf{T}^{\mathrm{p}} \in \mathrm{M}^{N\times N}_{D}$ and $\mathbb{K}^{\mathrm{p}} \in \mathrm{M}^{N\times N\times N}_{D}$ conjugate to $\mathbf{E}^{\mathrm{p}}$ and $\nabla\mathbf{E}^{\mathrm{p}}$, respectively. Given the rate-like kinematical descriptors $(\dot{u}, \dot{\mathbf{E}}^{\mathrm{e}}, \dot{\mathbf{E}}^{\mathrm{p}})$, the power expenditure within $\mathcal{B}$ is given by

$$\mathcal{W}_{\mathrm{int}}(\mathcal{B}) = \int_{\mathcal{B}} (\mathbf{T} : \dot{\mathbf{E}}^{\mathrm{e}} + \mathbf{T}^{\mathrm{p}} : \dot{\mathbf{E}}^{\mathrm{p}} + \mathbb{K}^{\mathrm{p}} : \nabla\dot{\mathbf{E}}^{\mathrm{p}})\, dx.$$

$\mathcal{W}_{\mathrm{int}}(\mathcal{B})$ is balanced by the power expenditure of external forces

$$\mathcal{W}_{\mathrm{ext}}(\mathcal{B}) = \int_{\partial\mathcal{B}} (t(\nu)\cdot\dot{u} + \mathbf{K}(\nu) : \dot{\mathbf{E}}^{\mathrm{p}})\, dA + \int_{\mathcal{B}} f\cdot\dot{u}\, dV,$$

where f is the external body force and $t(\nu)$ is the boundary traction (ν is the outward normal to $\mathcal{B}$) which are associated as usual to $\dot{u}$, while $\mathbf{K}(\nu) \in \mathrm{M}^{N\times N}_{D}$ is a [illegible] associated to the plastic strain rate $\dot{\mathbf{E}}^{\mathrm{p}}$. The balance of power expenditures (that is, $\mathcal{W}_{\mathrm{int}}(\mathcal{B}) = \mathcal{W}_{\mathrm{ext}}(\mathcal{B})$ for every subbody $\mathcal{B}$) leads to the equalities $t(\nu) = \mathbf{T}\nu$ and $\mathbf{K}(\nu) = \mathbb{K}^{\mathrm{p}}\nu$ for the traction and microtraction and to the equilibrium equations

$$-\mathrm{div}\mathbf{T} = f \qquad \text{and} \qquad \mathbf{T}^{\mathrm{p}} = \mathbf{T}_D + \mathrm{div}\mathbb{K}^{\mathrm{p}} \quad \text{in } \Omega,$$

where $\mathbf{T}_D$ is the deviatoric part of $\mathbf{T}$ as defined in (2.2). These equations are supplemented by boundary conditions for $\mathbf{T}$ and $\mathbb{K}^{\mathrm{p}}$. If traction forces g are present on a part $\partial_N\Omega$ of the boundary of Ω, we have as usual

$$\mathbf{T}\nu = g \qquad \text{on } \partial_N\Omega.$$

Concerning $\mathbb{K}^{\mathrm{p}}$, assuming [illegible] at the boundary (see [19, section 8]), we are led to the condition

$$\mathbb{K}^{\mathrm{p}}\nu = 0 \qquad \text{on } \partial\Omega.$$

The free energy. The free energy ψ is assumed to depend on $\mathbf{E}^{\mathrm{e}}$ and $\mathrm{curl}\mathbf{E}^{\mathrm{p}}$: In the quadratic separable case ψ has the form

$$\psi = \frac{1}{2}\mathbb{C}\mathbf{E}^{\mathrm{e}} : \mathbf{E}^{\mathrm{e}} + \frac{\mu L^2}{2}|\mathrm{curl}\mathbf{E}^{\mathrm{p}}|^2, \tag{3.2}$$

where $\mathbb{C}$ is the elastic tensor

$$\mathbb{C}\mathbf{E}^{\mathrm{e}} := 2\mu\mathbf{E}^{\mathrm{e}}_D + k(\mathrm{tr}\mathbf{E}^{\mathrm{e}})\mathbf{I}, \tag{3.3}$$

with μ and k the elastic shear and bulk moduli, respectively. The constant $L > 0$ is an [illegible]. The [illegible] $\mathbb{K}^{\mathrm{p}}_{\mathrm{en}}$ is then defined so that the identity

$$\mu L^2 \mathrm{curl}\mathbf{E}^{\mathrm{p}} : \mathrm{curl}\mathbf{A} = \mathbb{K}^{\mathrm{p}}_{\mathrm{en}} : \nabla\mathbf{A} \tag{3.4}$$

holds for every $\mathrm{M}^{N\times N}$-valued function $\mathbf{A}$. In components we have

$$(\mathbb{K}^{\mathrm{p}}_{\mathrm{en}})_{jqp} := \mu L^2 \left[\frac{\partial \mathbf{E}^{\mathrm{p}}_{jq}}{\partial x_p} - \frac{1}{2}\left(\frac{\partial \mathbf{E}^{\mathrm{p}}_{jp}}{\partial x_q} + \frac{\partial \mathbf{E}^{\mathrm{p}}_{qp}}{\partial x_j}\right) + \frac{1}{N}\delta_{jq}\sum_r \frac{\partial \mathbf{E}^{\mathrm{p}}_{rp}}{\partial x_r}\right], \tag{3.5}$$

where δ_{jq} is the usual Krönecker symbol. The stress $\mathbb{K}^{\mathrm{p}}$ is then additively decomposed in the following way:

$$\mathbb{K}^{\mathrm{p}} = \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}} + \mathbb{K}^{\mathrm{p}}_{\mathrm{en}}.$$

Admissibility of the stresses and the flow rule. Neglecting the hardening internal variable, i.e., if we are in the case without hardening nor softening, the admissibility for the stresses involved in the description of the behavior of Ω reads

$$\sqrt{|\mathbf{T}^{\mathrm{p}}(x)|^2 + l^{-2}|\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(x)|^2} \leq S_Y, \tag{3.6}$$

where $l > 0$ is a [illegible] and S_Y is a [illegible].

Assume now that body and traction forces vary with time, i.e., $f = f(t)$ and $g = g(t)$. The flow rule which drives the system requires that if $(\mathbf{T}^{\mathrm{p}}(t,x), \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x))$ is at the yield surface (that is, (3.6) holds with equality), then

$$\begin{cases} \mathbf{T}^{\mathrm{p}}(t,x) = S_Y \dfrac{\dot{\mathbf{E}}^{\mathrm{p}}(t,x)}{\sqrt{|\dot{\mathbf{E}}^{\mathrm{p}}(t,x)|^2 + l^2|\nabla\dot{\mathbf{E}}^{\mathrm{p}}(t,x)|^2}}, \\ \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x) = S_Y \dfrac{l^2\nabla\dot{\mathbf{E}}^{\mathrm{p}}(t,x)}{\sqrt{|\dot{\mathbf{E}}^{\mathrm{p}}(t,x)|^2 + l^2|\nabla\dot{\mathbf{E}}^{\mathrm{p}}(t,x)|^2}}. \end{cases} \tag{3.7}$$

Here $\dot{\mathbf{E}}^{\mathrm{p}}(t,x)$ and $\nabla\dot{\mathbf{E}}^{\mathrm{p}}(t,x)$ denote the time derivative of $\mathbf{E}^{\mathrm{p}}(t,x)$ and $\nabla\mathbf{E}^{\mathrm{p}}(t,x)$, respectively. If $(\mathbf{T}^{\mathrm{p}}(t,x), \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x))$ is well inside the yield surface, then no plastic phenomenon occurs, i.e., $(\dot{\mathbf{E}}^{\mathrm{p}}, \nabla\dot{\mathbf{E}}^{\mathrm{p}}) = (0,0)$. The flow rule (3.7) is a generalization of the von Mises flow rule in perfect plasticity (set $l = L = 0$, and note that $\mathbf{T}^p = \mathbf{T}_D$). It moreover implies that

$$\int_{\mathcal{B}} \dot{\psi}\, dV \leq \mathcal{W}_{\mathrm{ext}}(\mathcal{B}).$$

The previous inequality reflects the thermodynamical requirement that the increase in free energy of $\mathcal{B}$ is less than or equal to the power expended on $\mathcal{B}$.

4. Functional setting. In this section we state the precise mathematical framework that we adopt to study quasi-static evolutions for the Gurtin–Anand model.

The reference configuration. Let the reference configuration be given by $\Omega \subseteq \mathbb{R}^N$, $N \geq 2$, a bounded open set with a Lipschitz boundary. Let $\partial\Omega$ be partitioned into two open (in the relative topology) disjoint sets $\partial_D\Omega$ and $\partial_N\Omega$ with the same boundary Γ such that $\mathcal{H}^{N-2}(\Gamma) < +\infty$.

Admissible configurations. Let the prescribed boundary displacement on $\partial_D\Omega$ be given by (the trace of) a Sobolev function $w \in W^{1,2}(\Omega;\mathbb{R}^N)$. By an admissible configuration relative to the boundary datum w, we will understand a triple $(u, \mathbf{E}^{\mathrm{e}}, \mathbf{E}^{\mathrm{p}})$ such that

$$u \in W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N), \qquad \mathbf{E}^{\mathrm{e}} \in L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}}), \qquad \mathbf{E}^{\mathrm{p}} \in BV(\Omega;\mathrm{M}^{N\times N}_D), \tag{4.1}$$

with

$$u = w \qquad \text{on } \partial_D\Omega, \tag{4.2}$$

$$\mathbf{E}u = \mathbf{E}^{\mathrm{e}} + \mathbf{E}^{\mathrm{p}}, \tag{4.3}$$

and

$$\mathrm{curl}\mathbf{E}^{\mathrm{p}} \in L^2(\Omega;\mathrm{M}^{N\times N}). \tag{4.4}$$

Equality (4.2) is intended in the sense of traces. Notice that, by the embedding properties of BV, (4.3) entails $\mathbf{E}u \in L^{\frac{N}{N-1}}(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})$; the requirement $u \in W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)$ is then consistent with the regularity implied by Korn's inequality in view of the boundary condition (4.2). Let us denote by $\mathcal{A}(w)$ the family of admissible configurations for the boundary datum w, i.e.,

$$\mathcal{A}(w) := \{(u, \mathbf{E}^{\mathrm{e}}, \mathbf{E}^{\mathrm{p}}) \text{ such that (4.1)–(4.4) are satisfied}\}. \tag{4.5}$$

Notice that $\mathcal{A}(w) \neq \emptyset$ since $(w, \mathbf{E}w, 0) \in \mathcal{A}(w)$: Moreover $\mathcal{A}(w)$ contains the triples $(v, \mathbf{E}v, 0)$, with $v \in W^{1,2}(\Omega;\mathbb{R}^N)$ and $v = w$ on $\partial_D\Omega$, so that [illegible] deformations are admissible (and this motivates the choice $w \in W^{1,2}(\Omega;\mathbb{R}^N)$).

The free energy. The free energy of the configuration $(u, \mathbf{E}^{\mathrm{e}}, \mathbf{E}^{\mathrm{p}}) \in \mathcal{A}(w)$ is given according to (3.2) by

$$\Psi(\mathbf{E}^{\mathrm{e}}, \mathrm{curl}\mathbf{E}^{\mathrm{p}}) := \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}),$$

where

$$\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}) := \frac{1}{2}\int_\Omega \mathbb{C}\mathbf{E}^{\mathrm{e}} : \mathbf{E}^{\mathrm{e}}\, dx \tag{4.6}$$

and

$$\mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}) := \frac{1}{2}\mu L^2 \int_\Omega |\mathrm{curl}\mathbf{E}^{\mathrm{p}}|^2\, dx. \tag{4.7}$$

Here $\mathbb{C}$ denotes the elasticity tensor (3.3), and $\mu > 0$ is the elastic shear modulus: We assume also that $k > 0$, so that there exist $0 < \alpha_{\mathbb{C}} \leq \beta_{\mathbb{C}} < +\infty$ such that for every $\mathbf{A} \in \mathrm{M}^{N\times N}_{\mathrm{sym}}$ we have

$$\alpha_{\mathbb{C}}|\mathbf{A}|^2 \leq \mathbb{C}\mathbf{A} : \mathbf{A} \leq \beta_{\mathbb{C}}|\mathbf{A}|^2. \tag{4.8}$$

The yield function $\mathcal{H}$. In order to get variationally the constraint for the stresses conjugated to the plastic variables according to (3.6), we are led to consider the [illegible]

$$\mathcal{H}(\mathbf{E}^{\mathrm{p}}) := S_Y \int_\Omega \sqrt{|\mathbf{E}^{\mathrm{p}}|^2 + l^2|\nabla\mathbf{E}^{\mathrm{p}}|^2}\, dx + lS_Y|D^s\mathbf{E}^{\mathrm{p}}|(\Omega) \tag{4.9}$$

defined for every $\mathbf{E}^{\mathrm{p}} \in BV(\Omega;\mathrm{M}^{N\times N}_D)$. Simple arguments on subadditive and positively one-homogeneous functions on measures (see [13]) show that $\mathcal{H}$ is the relaxation under the L^1-norm of the map

$$\mathbf{E}^{\mathrm{p}} \mapsto S_Y \int_\Omega \sqrt{|\mathbf{E}^{\mathrm{p}}|^2 + l^2|\nabla\mathbf{E}^{\mathrm{p}}|^2}\, dx$$

defined for a regular plastic strain $\mathbf{E}^{\mathrm{p}}$, which is connected to the effective flow rate proposed by Gurtin and Anand (see [19, section 6.3]). As a consequence, $\mathcal{H}$ turns out to be naturally involved in an analysis which employs direct methods of the calculus of variations.

We will often use the lower semicontinuity of $\mathcal{H}$ along weakly* converging sequences, which is a direct consequence of the relaxation process through which $\mathcal{H}$ is obtained.

LEMMA 4.1. $(\mathbf{E}^{\mathrm{p}}_n)_{n\in\mathbb{N}}$ $BV(\Omega;\mathrm{M}^{N\times N}_D)$

$$\mathbf{E}^{\mathrm{p}}_n \overset{*}{\rightharpoonup} \mathbf{E}^{\mathrm{p}} \quad * \quad BV\left(\Omega;\mathrm{M}^{N\times N}_D\right)$$

$\mathbf{E}^{\mathrm{p}} \in BV(\Omega;\mathrm{M}^{N\times N}_D)$

$$\mathcal{H}(\mathbf{E}^{\mathrm{p}}) \le \liminf_{n\to+\infty} \mathcal{H}(\mathbf{E}^{\mathrm{p}}_n).$$

Prescribed boundary displacements and body/traction forces. We assume that the prescribed boundary displacement on $\partial_D\Omega$ is given by (the trace of) a function $w(t,x)$ which is absolutely continuous in time with values in the Sobolev space $W^{1,2}(\Omega;\mathbb{R}^N)$, i.e.,

$$w \in AC\left(0,T;W^{1,2}(\Omega;\mathbb{R}^N)\right). \tag{4.10}$$

Moreover we assume that the prescribed body forces in Ω and traction forces on $\partial_N\Omega$ are given by

$$f \in AC(0,T;L^N(\Omega;\mathbb{R}^N)) \qquad \text{and} \qquad g \in AC(0,T;L^N(\partial_N\Omega;\mathbb{R}^N)). \tag{4.11}$$

For every $t\in[0,T]$ let us consider $\mathcal{L}(t) : W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N) \to \mathbb{R}$ given by

$$\langle \mathcal{L}(t), u\rangle := \int_\Omega f(t)\cdot u\,dx + \int_{\partial_N\Omega} g(t)\cdot u\,d\mathcal{H}^{N-1}. \tag{4.12}$$

Here $\mathcal{H}^{N-1}$ denotes the $(N-1)$-dimensional Hausdorff measure, which is a generalization to arbitrary sets of the usual surface measure (see [9]). By means of the Sobolev embedding theorem it is easily seen that $\mathcal{L}(t)$ is a continuous linear functional on $W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)$.

Throughout the paper we will assume that the prescribed body and traction forces satisfy the following uniform : We assume that for every $t\in[0,T]$ there exists $\rho(t)\in L^N(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})$ such that

$$\begin{cases} -\mathrm{div}\rho(t) = f(t) & \text{in } \Omega,\\ \rho(t)\nu = g(t) & \text{on } \partial_N\Omega \end{cases} \tag{4.13}$$

and there exists $\alpha>0$ such that for every $\mathbf{A}\in\mathrm{M}^{N\times N}_D$, with $|\mathbf{A}|\le\alpha$, we have

$$|\mathbf{A}+\rho_D(t)| \le S_Y \qquad \text{a.e. in } \Omega. \tag{4.14}$$

Moreover we assume that $t\mapsto\rho(t)$ and $t\mapsto\rho_D(t)$ are absolutely continuous from $[0,T]$ to $L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})$ and $L^\infty(\Omega;\mathrm{M}^{N\times N}_D)$, respectively. Notice that the trace condition in (4.13) is well-defined in the dual of the traces on $\partial_N\Omega$ of $W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)$ since ρ is an L^N-field with divergence in L^N. Moreover, for every $(u,\mathbf{E}^{\mathrm{e}},\mathbf{E}^{\mathrm{p}})\in\mathcal{A}(w)$ we have the following representation formula for $\mathcal{L}(t)$ (here we use $\mathcal{H}^{N-2}(\Gamma)<+\infty$):

$$\langle \mathcal{L}(t), u\rangle = -\langle \rho(t)\nu, w\rangle_{\partial_D\Omega} + \int_\Omega \rho(t) : \mathbf{E}^{\mathrm{e}}\,dx + \int_\Omega \rho_D(t) : \mathbf{E}^{\mathrm{p}}\,dx, \tag{4.15}$$

where the first term on the right-hand side should be interpreted as the pairing between $H^{-1/2}(\partial_D\Omega;\mathbb{R}^N)$ and $H^{1/2}(\partial_D\Omega;\mathbb{R}^N)$.

4.2. Notice that for $\mathcal{L}(t)$ to be well-defined in the dual of $W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)$ it suffices to require $f(t)\in L^{N/2}(\Omega;\mathbb{R}^N)$ (assume that $N\geq 3$, the case $N=2$ being different in view of Sobolev embedding). But in view of the safe load condition (4.13)–(4.14), $\rho(t)$ would be only an element of $L^{N/2}$ with divergence in $L^{N/2}$, so that its normal trace would be defined in the dual of the traces on $\partial\Omega$ of $W^{1,\frac{N}{N-2}}(\Omega;\mathbb{R}^N)$. Then the representation formula (4.15) would no longer be well-defined (since $w\in W^{1,2}(\Omega;\mathbb{R}^N)$).

As a consequence of the safe load condition, we have the following coercivity estimate for $\mathcal{H}$.

LEMMA 4.3. [illegible] $\mathbf{E}^{\mathrm{p}}\in BV(\Omega;\mathrm{M}^{N\times N}_D)$ [illegible]

$$\mathcal{H}(\mathbf{E}^{\mathrm{p}})-\int_\Omega \rho_D(t):\mathbf{E}^{\mathrm{p}}\,dx\geq \frac{\alpha}{2}\|\mathbf{E}^{\mathrm{p}}\|_{L^1(\Omega;\mathrm{M}^{N\times N}_D)} + \min\left\{l\frac{\alpha}{2}, lS_Y\right\}\|D\mathbf{E}^{\mathrm{p}}\|_{\mathcal{M}_b(\Omega;\mathrm{M}^{N\times N\times N}_D)}. \tag{4.16}$$

[illegible] $\alpha_l>0$ [illegible]

$$\mathcal{H}(\mathbf{E}^{\mathrm{p}})-\int_\Omega \rho_D(t):\mathbf{E}^{\mathrm{p}}\,dx\geq \alpha_l\|\mathbf{E}^{\mathrm{p}}\|_{BV(\Omega;\mathrm{M}^{N\times N}_D)}. \tag{4.17}$$

[illegible]. Notice that by Hölder inequality we have

$$S_Y\int_\Omega\sqrt{|\mathbf{E}^{\mathrm{p}}|^2+l^2|\nabla\mathbf{E}^{\mathrm{p}}|^2}\,dx\geq\sup_{(\tau_1,\tau_2)\in\mathcal{K}}\int_\Omega\left[\tau_1:\mathbf{E}^{\mathrm{p}}+\tau_2:\nabla\mathbf{E}^{\mathrm{p}}\right]\,dx,$$

where

$$\mathcal{K}:=\Big\{(\tau_1,\tau_2)\in L^\infty\left(\Omega;\mathrm{M}^{N\times N}_D\right)\times L^\infty\left(\Omega;\mathrm{M}^{N\times N\times N}_D\right)\,:\, \sqrt{|\tau_1|^2+l^{-2}|\tau_2|^2}\leq S_Y \text{ a.e. in } \Omega\Big\}.$$

We deduce that for every $(\tau_1,\tau_2)\in\mathcal{K}$

$$\mathcal{H}(\mathbf{E}^{\mathrm{p}})-\int_\Omega\rho_D(t):\mathbf{E}^{\mathrm{p}}\,dx\geq\int_\Omega\left[(\tau_1-\rho_D(t)):\mathbf{E}^{\mathrm{p}}+\tau_2:\nabla\mathbf{E}^{\mathrm{p}}\right]\,dx+lS_Y|D^s\mathbf{E}^{\mathrm{p}}|(\Omega),$$

so that in view of (4.14) we get

$$\mathcal{H}(\mathbf{E}^{\mathrm{p}})-\int_\Omega\rho_D(t):\mathbf{E}^{\mathrm{p}}\,dx\geq\int_\Omega\left[\tilde\tau_1:\mathbf{E}^{\mathrm{p}}+\tilde\tau_2:\nabla\mathbf{E}^{\mathrm{p}}\right]\,dx+lS_Y|D^s\mathbf{E}^{\mathrm{p}}|(\Omega)$$

for every $\|\tilde\tau_1\|_{L^\infty(\Omega;\mathrm{M}^{N\times N}_D)}\leq\frac{\alpha}{2}$ and $\|\tilde\tau_2\|_{L^\infty(\Omega;\mathrm{M}^{N\times N\times N}_D)}\leq l\frac{\alpha}{2}$. We conclude that

$$\mathcal{H}(\mathbf{E}^{\mathrm{p}})-\int_\Omega\rho_D(t):\mathbf{E}^{\mathrm{p}}\,dx \geq\frac{\alpha}{2}\|\mathbf{E}^{\mathrm{p}}\|_{L^1(\Omega;\mathrm{M}^{N\times N}_D)}+l\frac{\alpha}{2}\|\nabla\mathbf{E}^{\mathrm{p}}\|_{L^1(\Omega;\mathrm{M}^{N\times N\times N}_D)}+lS_Y|D^s\mathbf{E}^{\mathrm{p}}|(\Omega),$$

so that (4.16) holds. Inequality (4.17) follows by choosing $\alpha_l:=\min\{\frac{\alpha}{2},l\frac{\alpha}{2},lS_Y\}$. □

4.4. As mentioned in the introduction, the safe load condition entails in view of Lemma 4.3 some coercivity in BV for $\mathbf{E}^{\mathrm{p}}$ in the step-by-step minimization problems which we use in section 6 in order to construct a quasi-static evolution (see Lemma 6.1). Those problems contain two terms (dissipation and work of external loads) which have linear growth and which can compete, leading, in general, to a loss of compactness: This cannot happen if a safe load condition is assumed.

5. The main results. Let $T > 0$, and let w, f, and g be the prescribed boundary displacements, body forces, and traction forces according to (4.10) and (4.11), respectively. We assume that f and g satisfy the uniform safe load condition (4.13)–(4.14).

We will denote by $\dot{w}(t)$, $\dot{f}(t)$, and $\dot{g}(t)$ the derivative at time $t \in [0,T]$ of w, f, and g, respectively. Notice that these derivatives exist for a.e. $t \in [0,T]$ since the maps are absolutely continuous with values in a reflexive Banach space. We will denote by $\dot{\mathcal{L}}(t)$ the external work associated to $\dot{f}(t)$ and $\dot{g}(t)$.

Given $\mathcal{H}$ as in (4.9), the $\mathcal{H}$-variation on $[a,b] \subseteq [0,T]$ of $t \mapsto \mathbf{E}^{\mathrm{p}}(t)$ is defined as

$$\mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}; a, b) := \sup\left\{ \sum_{j=1}^{k} \mathcal{H}\left(\mathbf{E}^{\mathrm{p}}(t_j) - \mathbf{E}^{\mathrm{p}}(t_{j-1})\right) \,:\, a = t_0 < t_1 < \cdots < t_k = b \right\}. \tag{5.1}$$

The notion of quasi-static evolution for the Gurtin–Anand model is the following.

DEFINITION 5.1 (quasi-static evolution). [illegible]

$$t \mapsto (u(t), \mathbf{E}^{\mathrm{e}}(t), \mathbf{E}^{\mathrm{p}}(t))$$

[illegible] $[0,T]$ [illegible] $W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N) \times L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}}) \times BV(\Omega;\mathrm{M}^{N\times N}_{D})$ [illegible] $t \in [0,T]$ [illegible] $(u(t), \mathbf{E}^{\mathrm{e}}(t), \mathbf{E}^{\mathrm{p}}(t)) \in \mathcal{A}(w(t))$ [illegible]

(a) Global stability [illegible] $(v, \mathbf{e}, \mathbf{p}) \in \mathcal{A}(w(t))$

$$\begin{aligned} \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)) - \langle \mathcal{L}(t), u(t)\rangle \\ \leq \mathcal{Q}_1(\mathbf{e}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{p}) - \langle \mathcal{L}(t), v\rangle + \mathcal{H}(\mathbf{p} - \mathbf{E}^{\mathrm{p}}(t)); \end{aligned} \tag{5.2}$$

(b) Energy balance [illegible] $t \mapsto \mathbf{E}^{\mathrm{p}}(t)$ [illegible] $[0,T]$ [illegible] $BV(\Omega;\mathrm{M}^{N\times N}_{D})$ [illegible]

$$\begin{aligned} \mathcal{E}(t) + \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}; 0, t) = \mathcal{E}(0) + \int_0^t \int_\Omega \mathbf{T}(\tau) : \mathbf{E}\dot{w}(\tau)\, dx\, d\tau \\ - \int_0^t \langle \dot{\mathcal{L}}(\tau), u(\tau)\rangle\, d\tau - \int_0^t \langle \mathcal{L}(\tau), \dot{w}(\tau)\rangle\, d\tau, \end{aligned} \tag{5.3}$$

[illegible] $\mathbf{T}(t) := \mathbb{C}\mathbf{E}^{\mathrm{e}}(t)$

$$\mathcal{E}(t) := \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)) - \langle \mathcal{L}(t), u(t)\rangle, \tag{5.4}$$

[illegible] $\mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}; 0, t)$ [illegible] (5.1)

Our first main result is the following existence theorem.

THEOREM 5.2. [illegible] $(u_0, \mathbf{E}^{\mathrm{e}}_0, \mathbf{E}^{\mathrm{p}}_0) \in \mathcal{A}(w(0))$ [illegible]

$$\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_0) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_0) - \langle \mathcal{L}(0), u_0\rangle \leq \mathcal{Q}_1(\mathbf{e}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{p}) - \langle \mathcal{L}(0), v\rangle + \mathcal{H}(\mathbf{p} - \mathbf{E}^{\mathrm{p}}_0)$$

[illegible] $(v, \mathbf{e}, \mathbf{p}) \in \mathcal{A}(w(0))$ [illegible] $t \mapsto (u(t), \mathbf{E}^{\mathrm{e}}(t), \mathbf{E}^{\mathrm{p}}(t))$ [illegible] $(u(0), \mathbf{E}^{\mathrm{e}}(0), \mathbf{E}^{\mathrm{p}}(0)) = (u_0, \mathbf{E}^{\mathrm{e}}_0, \mathbf{E}^{\mathrm{p}}_0)$

Theorem 5.2 will be proved in section 7 by exploiting the convergence of a discrete-in-time evolution constructed through variational arguments in section 6.

Our second main result shows that a quasi-static evolution satisfies the required constitutive equations, balance equations, and the flow rule of the Gurtin–Anand model.

THEOREM 5.3. [illegible] $t \mapsto (u(t), \mathbf{E}^{\mathrm{e}}(t), \mathbf{E}^{\mathrm{p}}(t))$ [illegible] $t \mapsto u(t), t \mapsto \mathbf{E}^{\mathrm{e}}(t), t \mapsto \mathbf{E}^{\mathrm{p}}(t), t \mapsto \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)$ [illegible] $[0,T]$, $W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)$, $L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})$, $BV(\Omega;\mathrm{M}^{N\times N}_D)$ [illegible] $L^2(\Omega;\mathrm{M}^{N\times N})$ [illegible] $t \to \mathbf{E}^{\mathrm{e}}(t)$ [illegible] $t \mapsto \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)$ [illegible] $t \in [0,T]$

(a) Cauchy stress $\mathbf{T}(t) = \mathbb{C}\mathbf{E}^{\mathrm{e}}(t)$ [illegible] fi [illegible]

$$\begin{cases} -\mathrm{div}\mathbf{T}(t) = f(t) & \text{in } \Omega, \\ \mathbf{T}(t)\nu = g(t) & \text{on } \partial_N\Omega. \end{cases} \tag{5.5}$$

(b) Stresses conjugated to the plastic variables [illegible] $\mathbf{T}^{\mathrm{p}}(t) \in L^\infty(\Omega;\mathrm{M}^{N\times N}_D)$, $\mathbb{K}^{\mathrm{p}}(t) \in L^2(\Omega;\mathrm{M}^{N\times N\times N}_D)$, $\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t) \in L^\infty(\Omega;\mathrm{M}^{N\times N\times N}_D)$, [illegible] $\mathbb{S}^{\mathrm{p}}(t) \in (\mathcal{M}_b(\Omega;\mathrm{M}^{N\times N\times N}_D))^*$ [illegible] fi [illegible] $\mathbb{K}^{\mathrm{p}}_{\mathrm{en}}(t)$ [illegible] (3.5) [illegible] [illegible] $\mathbf{E}^{\mathrm{p}}(t)$ [illegible] [illegible] $\mathbf{T}_D(t) := (\mathbf{T}(t))_D$ [illegible]

$$\mathbb{K}^{\mathrm{p}}(t) = \mathbb{K}^{\mathrm{p}}_{\mathrm{en}}(t) + \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t) \quad \text{in } \Omega,$$

$$\begin{cases} \mathbf{T}^{\mathrm{p}}(t) = \mathbf{T}_D(t) + \mathrm{div}\mathbb{K}^{\mathrm{p}}(t) & \text{in } \Omega, \\ \mathbb{K}^{\mathrm{p}}(t)\nu = 0 & \text{on } \partial\Omega, \end{cases} \tag{5.6}$$

$$\sqrt{|\mathbf{T}^{\mathrm{p}}(t)|^2 + l^{-2}|\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t)|^2} \le S_Y \quad \text{in } \Omega, \tag{5.7}$$

$$\|\mathbb{S}^{\mathrm{p}}(t)\|_{(\mathcal{M}_b(\mathrm{M}^{N\times N\times N}_D))^*} \le lS_Y,$$

[illegible] $(v, \mathbf{e}, \mathbf{p}) \in \mathcal{A}(0)$

$$\int_\Omega \mathbf{T}(t) : \mathbf{e}\, dx + \int_\Omega \mathbf{T}^{\mathrm{p}}(t) : \mathbf{p}\, dx + \int_\Omega \mathbb{K}^{\mathrm{p}}(t) : \nabla\mathbf{p}\, dx + \langle \mathbb{S}^{\mathrm{p}}(t), D^s\mathbf{p}\rangle = \langle \mathcal{L}(t), v\rangle.$$

(c) The flow rule [illegible] $\dot{\mathbf{E}}^{\mathrm{p}}(t)$ [illegible] $x \in \Omega$ [illegible] $\dot{\mathbf{E}}^{\mathrm{p}}(t)$, $\nabla\dot{\mathbf{E}}^{\mathrm{p}}(t)$, $\mathbf{T}^{\mathrm{p}}(t)$, [illegible] $\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t)$ [illegible] fi [illegible] (3.7) [illegible] fi

Notice that the normal trace which appears in (5.5) is well-defined in $H^{-1/2}(\partial\Omega;\mathbb{R}^N)$ since $\mathbf{T}(t)$ is an L^2-field with divergence in L^2. Similarly, the normal trace in (5.6) is well-defined in $H^{-1/2}(\partial\Omega;\mathbb{R}^{N\times N})$ because $\mathbb{K}^{\mathrm{p}}(t)$ is an L^2-field (by the definition of $\mathbb{K}^{\mathrm{p}}_{\mathrm{en}}(t)$ and by the constraint (5.7) for $\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t)$) with divergence in L^2 (by the balance equation (5.6) and by the constraint (5.7) for $\mathbf{T}^{\mathrm{p}}(t)$).

In section 9 we will analyze the behavior of a quasi-static evolution as the length scales l and L go to zero, i.e., when the strain gradient effects vanish. We will prove (Theorem 9.2) that the quasi-static evolution converges to an evolution for perfect plasticity according to the framework recently proposed by Dal Maso, DeSimone, and Mora in [8].

6. The discrete-in-time evolution. In this section we construct a discretized-in-time evolution for the Gurtin–Anand model employing a step-by-step minimization procedure. The convergence of this approximated evolution to a quasi-static evolution for the Gurtin–Anand model as the time step discretization goes to zero will be proved in the next section.

Let $k \in \mathbb{N}$, $k \ge 1$, and let us set $t^i_k := \frac{i}{k}T$ for every $i = 0, 1, \dots, k$. Let us set

$$u_{k,0} := u_0, \qquad \mathbf{E}^{\mathrm{e}}_{k,0} := \mathbf{E}^{\mathrm{e}}_0, \qquad \mathbf{E}^{\mathrm{p}}_{k,0} := \mathbf{E}^{\mathrm{p}}_0,$$

where $(u_0, \mathbf{E}^{\mathrm{e}}_0, \mathbf{E}^{\mathrm{p}}_0) \in \mathcal{A}(w(0))$ is the initial configuration of the system given by Theorem 5.2.

Supposing to have constructed $(u_{k,i}, \mathbf{E}^{\mathrm{e}}_{k,i}, \mathbf{E}^{\mathrm{p}}_{k,i}) \in \mathcal{A}(w(t^i_k))$, let $(u_{k,i+1}, \mathbf{E}^{\mathrm{e}}_{k,i+1}, \mathbf{E}^{\mathrm{p}}_{k,i+1}) \in \mathcal{A}(w(t^{i+1}_k))$ $(i = 0, \dots, k-1)$ be a solution of the following minimization problem:

$$\min_{(u,\mathbf{E}^{\mathrm{e}},\mathbf{E}^{\mathrm{p}})\in\mathcal{A}\left(w\left(t^{i+1}_k\right)\right)} \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}) - \langle \mathcal{L}(t^{i+1}_k), u\rangle + \mathcal{H}(\mathbf{E}^{\mathrm{p}} - \mathbf{E}^{\mathrm{p}}_{k,i}). \tag{6.1}$$

The existence of a solution for problem (6.1) is established in the following lemma.

LEMMA 6.1. [illegible] (6.1) [illegible]

[illegible]. The result follows by applying the direct method of the calculus of variations. In fact, let

$$(u_n, \mathbf{E}^{\mathrm{e}}_n, \mathbf{E}^{\mathrm{p}}_n) \in \mathcal{A}(w(t^{i+1}_k))$$

be a minimizing sequence for (6.1). By comparison with $(w(t^{i+1}_k), \mathbf{E}w(t^{i+1}_k), 0)$ we get

$$\begin{aligned}\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_n) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_n) - \langle \mathcal{L}\left(t^{i+1}_k\right), u_n\rangle + \mathcal{H}(\mathbf{E}^{\mathrm{p}}_n - \mathbf{E}^{\mathrm{p}}_{k,i})\\ \le \mathcal{Q}_1(\mathbf{E}w(t^{i+1}_k)) - \langle \mathcal{L}(t^{i+1}_k), w(t^{i+1}_k)\rangle + \mathcal{H}(\mathbf{E}^{\mathrm{p}}_{k,i}) := C.\end{aligned}$$

By the representation formula (4.15) for $\mathcal{L}(t^{i+1}_k)$ we deduce that

$$\begin{aligned}\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_n) - \int_\Omega \rho(t^{i+1}_k) : \mathbf{E}^{\mathrm{e}}_n\, dx + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_n)\\ + \mathcal{H}(\mathbf{E}^{\mathrm{p}}_n - \mathbf{E}^{\mathrm{p}}_{k,i}) - \int_\Omega \rho_D(t^{i+1}_k) : (\mathbf{E}^{\mathrm{p}}_n - \mathbf{E}^{\mathrm{p}}_{k,i})\, dx\\ \le C + \int_\Omega \rho_D(t^{i+1}_k) : \mathbf{E}^{\mathrm{p}}_{k,i}\, dx - \langle \rho(t^{i+1}_k)\nu, w(t^{i+1}_k)\rangle_{\partial_D\Omega}.\end{aligned}$$

By the coercivity of $\mathcal{Q}_1$ and $\mathcal{Q}_2$ in L^2 and by (4.17) we get

$$\|\mathbf{E}^{\mathrm{e}}_n\|^2_{L^2\left(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}}\right)} + \|\mathrm{curl}\mathbf{E}^{\mathrm{p}}_n\|^2_{L^2(\Omega;\mathrm{M}^{N\times N})} + \|\mathbf{E}^{\mathrm{p}}_n - \mathbf{E}^{\mathrm{p}}_{k,i}\|_{BV\left(\Omega;\mathrm{M}^{N\times N}_D\right)} \le C_1$$

for some $C_1 > 0$. Up to a subsequence we may assume that

$$\mathbf{E}^{\mathrm{e}}_n \rightharpoonup \mathbf{E}^{\mathrm{e}} \qquad \text{weakly in } L^2\left(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}}\right)$$

and

$$\mathbf{E}^{\mathrm{p}}_n \overset{*}{\rightharpoonup} \mathbf{E}^{\mathrm{p}} \qquad \text{weakly* in } BV\left(\Omega;\mathrm{M}^{N\times N}_D\right).$$

As a consequence we get $\mathrm{curl}\mathbf{E}^{\mathrm{p}} \in L^2(\Omega;\mathrm{M}^{N\times N})$ and that

$$\mathrm{curl}\mathbf{E}^{\mathrm{p}}_n \rightharpoonup \mathrm{curl}\mathbf{E}^{\mathrm{p}} \qquad \text{weakly in } L^2\left(\Omega;\mathrm{M}^{N\times N}\right).$$

By the compatibility $\mathbf{E}u_n = \mathbf{E}^{\mathrm{e}}_n + \mathbf{E}^{\mathrm{p}}_n$ and by the embedding $BV(\Omega;\mathrm{M}^{N\times N}_D) \hookrightarrow L^{\frac{N}{N-1}}(\Omega;\mathrm{M}^{N\times N}_D)$, we get that $(\mathbf{E}u_n)_{n\in\mathbb{N}}$ is bounded in $L^{\frac{N}{N-1}}(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})$. In view of the boundary condition $u_n = w_{k,i+1}$ on $\partial_D\Omega$, Korn's inequality implies that $(u_n)_{n\in\mathbb{N}}$ is bounded in $W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)$. Up to a further subsequence we can thus suppose that

$$u_n \rightharpoonup u \qquad \text{weakly in } W^{1,\frac{N}{N-1}}\left(\Omega;\mathbb{R}^N\right)$$

for some $u \in W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)$, with $u = w(t_k^{i+1})$ on $\partial_D\Omega$. We clearly have $(u, \mathbf{E}^{\rm e}, \mathbf{E}^{\rm p}) \in \mathcal{A}(w(t_k^{i+1}))$, and by lower semicontinuity ($\mathcal{Q}_1$ and $\mathcal{Q}_2$ are quadratic, $\mathcal{L}(t_k^{i+1})$ is linear, and $\mathcal{H}$ is lower semicontinuous by Lemma 4.1), we deduce that

$$\begin{aligned}\mathcal{Q}_1(\mathbf{E}^{\rm e}) + \mathcal{Q}_2({\rm curl}\mathbf{E}^{\rm p}) - \langle \mathcal{L}(t_k^{i+1}), u\rangle + \mathcal{H}(\mathbf{E}^{\rm p} - \mathbf{E}^{\rm p}_{k,i}) \\ \leq \liminf_{n\to+\infty} \left[\mathcal{Q}_1(\mathbf{E}^{\rm e}_n) + \mathcal{Q}_2({\rm curl}\mathbf{E}^{\rm p}_n) - \langle \mathcal{L}\left(t_k^{i+1}\right), u_n\rangle + \mathcal{H}(\mathbf{E}^{\rm p}_n - \mathbf{E}^{\rm p}_{k,i})\right].\end{aligned}$$

We conclude that $(u, \mathbf{E}^{\rm e}, \mathbf{E}^{\rm p})$ is a minimizer for problem (6.1), so that the proof is concluded. □

The discretized-in-time evolution is obtained by interpolating the data obtained by the minimization procedure described above. Let us set for $t_k^i \leq t < t_k^{i+1}$

$$w_k(t) := w(t_k^i) \qquad \text{and} \qquad \mathcal{L}_k(t) := \mathcal{L}(t_k^i).$$

We collect the main properties of the discretized-in-time evolution (essential for the passage to the limit as the time step discretization goes to zero) in the following proposition.

PROPOSITION 6.2. [illegible] $t \mapsto (u_k(t), \mathbf{E}^{\rm e}_k(t), \mathbf{E}^{\rm p}_k(t))$ [illegible] $t \in [0,T]$ [illegible] $(u_k(0), \mathbf{E}^{\rm e}_k(0), \mathbf{E}^{\rm p}_k(0)) = (u_0, \mathbf{E}^{\rm e}_0, \mathbf{E}^{\rm p}_0)$ [illegible]

(a) $(u_k(t), \mathbf{E}^{\rm e}_k(t), \mathbf{E}^{\rm p}_k(t)) \in \mathcal{A}(w_k(t))$ [illegible] $t \in [0,T]$ [illegible] $(v, \mathbf{e}, \mathbf{p}) \in \mathcal{A}(w_k(t))$ [illegible]

$$\begin{aligned}\mathcal{Q}_1(\mathbf{E}^{\rm e}_k(t)) + \mathcal{Q}_2({\rm curl}\mathbf{E}^{\rm p}_k(t)) - \langle \mathcal{L}_k(t), u_k(t)\rangle \\ \leq \mathcal{Q}_1(\mathbf{e}) + \mathcal{Q}_2({\rm curl}\mathbf{p}) - \langle \mathcal{L}_k(t), v\rangle + \mathcal{H}(\mathbf{E}^{\rm p}_k(t) - \mathbf{p}).\end{aligned} \tag{6.2}$$

(b) [illegible]

$$\mathcal{E}_k(t) := \mathcal{Q}_1(\mathbf{E}^{\rm e}_k(t)) + \mathcal{Q}_2({\rm curl}\mathbf{E}^{\rm p}_k(t)) - \langle \mathcal{L}_k(t), u_k(t)\rangle,$$

[illegible] $t_k^i \leq t < t_k^{i+1}$

$$\begin{aligned}\mathcal{E}_k(t) + \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\rm p}_k; 0, t) \leq \mathcal{Q}_1(\mathbf{E}^{\rm e}_0) + \mathcal{Q}_2({\rm curl}\mathbf{E}^{\rm p}_0) - \langle \mathcal{L}(0), u_0\rangle \\ + \int_0^{t_k^i}\int_\Omega \mathbb{C}\mathbf{E}^{\rm e}_k(\tau) : \mathbf{E}\dot{w}(\tau)\,dx\,d\tau - \int_0^{t_k^i} \langle \dot{\mathcal{L}}(\tau), u_k(\tau)\rangle\,d\tau \\ - \int_0^{t_k^i} \langle \mathcal{L}_k(\tau), \dot{w}(\tau)\rangle\,d\tau + e_k,\end{aligned} \tag{6.3}$$

[illegible] $e_k \to 0$ [illegible] $k \to +\infty$ [illegible] $\mathcal{D}_{\mathcal{H}}$ [illegible] fi [illegible] (5.1)

(c) [illegible] C [illegible] $k \in \mathbb{N}$ [illegible] $t \in [0,T]$ [illegible]

$$\begin{aligned}\|u_k(t)\|_{W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)} + \|\mathbf{E}^{\rm e}_k(t)\|_{L^2(\Omega;{\rm M}^{N\times N}_{\rm sym})} \\ + \|{\rm curl}\mathbf{E}^{\rm p}_k(t)\|_{L^2(\Omega;{\rm M}^{N\times N})} + \mathcal{V}(\mathbf{E}^{\rm p}_k; 0, t) \leq C,\end{aligned} \tag{6.4}$$

[illegible] $\mathcal{V}(\mathbf{E}^{\rm p}_k; 0, t)$ [illegible] $\mathbf{E}^{\rm p}_k$ [illegible] $[0,t]$ [illegible] fi [illegible] (2.4) [illegible] $X = BV(\Omega; {\rm M}^{N\times N}_D)$)

[illegible]. For every $t_k^i \leq t < t_k^{i+1}$ let us set

$$u_k(t) := u_{k,i}, \qquad \mathbf{E}^{\rm e}_k(t) := \mathbf{E}^{\rm e}_{k,i}, \qquad \text{and} \qquad \mathbf{E}^{\rm p}_k(t) := \mathbf{E}^{\rm p}_{k,i},$$

where $(u_{k,j}, \mathbf{E}^{\mathrm{e}}_{k,j}, \mathbf{E}^{\mathrm{p}}_{k,j}) \in \mathcal{A}(w(t^j_k))$ is a solution of the minimization problem (6.1). The minimality property (6.2) follows immediately by the subadditivity of $\mathcal{H}$.

Let us prove (6.3). By construction, by comparing $(u_{k,j}, \mathbf{E}^{\mathrm{e}}_{k,j}, \mathbf{E}^{\mathrm{p}}_{k,j})$ with

$$(u_{k,j-1} + w(t^j_k) - w(t^{j-1}_k), \mathbf{E}^{\mathrm{e}}_{k,j-1} + \mathbf{E}w(t^j_k) - \mathbf{E}w(t^{j-1}_k), \mathbf{E}^{\mathrm{p}}_{k,j-1}) \in \mathcal{A}(w(t^j_k)),$$

we get

$$\begin{aligned}(6.5)\quad &\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_{k,j}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_{k,j}) + \mathcal{H}(\mathbf{E}^{\mathrm{e}}_{k,j} - \mathbf{E}^{\mathrm{e}}_{k,j-1}) - \langle \mathcal{L}(t^j_k), u_{k,j}\rangle \\ &\qquad \le \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_{k,j-1} + \mathbf{E}w(t^j_k) - \mathbf{E}w(t^{j-1}_k)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_{k,j-1}) \\ &\qquad\qquad - \langle \mathcal{L}(t^j_k), u_{k,j-1} + w(t^j_k) - w(t^{j-1}_k)\rangle \\ &= \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_{k,j-1}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_{k,j-1}) - \langle \mathcal{L}(t^{j-1}_k), u_{k,j-1}\rangle + \int_{t^{j-1}_k}^{t^j_k}\int_\Omega \mathbb{C}\mathbf{E}^{\mathrm{e}}_k(\tau) : \mathbf{E}\dot w(\tau)\,dx\,d\tau \\ &\qquad\qquad - \int_{t^{j-1}_k}^{t^j_k} \langle \dot{\mathcal{L}}(\tau), u_k(\tau)\rangle\,d\tau - \int_{t^{j-1}_k}^{t^j_k} \langle \mathcal{L}_k(\tau), \dot w(\tau)\rangle\,d\tau + \delta_{k,j},\end{aligned}$$

where

$$\delta_{k,j} := \mathcal{Q}_1(\mathbf{E}w(t^j_k) - \mathbf{E}w(t^{j-1}_k)) - \langle \mathcal{L}(t^j_k) - \mathcal{L}(t^{j-1}_k), w(t^j_k) - w(t^{j-1}_k)\rangle.$$

By summing up from $j = 1$ to $j = i$ we get

$$\begin{aligned}\mathcal{E}_k(t) + \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}_k; 0, t) &\le \mathcal{E}_k(0) + \int_0^{t^i_k}\int_\Omega \mathbb{C}\mathbf{E}^{\mathrm{e}}_k(\tau) : \mathbf{E}\dot w(\tau)\,dx\,d\tau \\ &\quad - \int_0^{t^i_k} \langle \dot{\mathcal{L}}(\tau), u_k(\tau)\rangle\,d\tau - \int_0^{t^i_k} \langle \mathcal{L}_k(\tau), \dot w(\tau)\rangle\,d\tau + \sum_{j=1}^{i} \delta_{k,j}.\end{aligned}$$

Since

$$\begin{aligned}\delta_{k,j} &\le \frac{\beta_{\mathbb{C}}}{k}\int_{t^{j-1}_k}^{t^j_k} \|\mathbf{E}\dot w(\tau)\|^2_{L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})}\,d\tau \\ &\quad + \sup_j \Big\|\mathcal{L}(t^j_k) - \mathcal{L}(t^{j-1}_k)\Big\|_{\left(W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)\right)^*} \int_{t^{j-1}_k}^{t^j_k} \|\dot w(\tau)\|_{W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)}\,d\tau,\end{aligned}$$

by setting $e_k := \sum_{j=1}^k \delta_{k,j}$, we get $e_k \to 0$ as $k \to +\infty$. Since

$$\mathcal{E}_k(0) = \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_0) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_0) - \langle \mathcal{L}(0), u_0\rangle,$$

inequality (6.3) follows.

Let us prove (6.4). By using the safe load condition on $f$and g, by (4.15) we can rewrite the first inequality of (6.5) in the following form:

$$\begin{aligned}&\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_{k,j}) - \int_\Omega \rho(t^j_k) : \mathbf{E}^{\mathrm{e}}_{k,j}\,dx + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_{k,j}) + \mathcal{H}(\mathbf{E}^{\mathrm{e}}_{k,j} - \mathbf{E}^{\mathrm{e}}_{k,j-1}) - \int_\Omega \rho_D(t^j_k) : \mathbf{E}^{\mathrm{p}}_{k,j}\,dx \\ &\qquad \le \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_{k,j-1} + \mathbf{E}w(t^j_k) - \mathbf{E}w(t^{j-1}_k)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_{k,j-1}) \\ &\qquad\qquad - \int_\Omega \rho(t^j_k) : \mathbf{E}^{\mathrm{e}}_{k,j-1}\,dx - \int_\Omega \rho_D(t^j_k) : \mathbf{E}^{\mathrm{p}}_{k,j-1}\,dx,\end{aligned}$$

so that

$$\mathcal{Q}_1(\mathbf{E}^{\rm e}_{k,j}) - \int_\Omega \rho(t^j_k) : \mathbf{E}^{\rm e}_{k,j}\,dx + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\rm p}_{k,j}) + \mathcal{H}(\mathbf{E}^{\rm e}_{k,j} - \mathbf{E}^{\rm e}_{k,j-1})$$
$$- \int_\Omega \rho_D(t^j_k) : (\mathbf{E}^{\rm p}_{k,j} - \mathbf{E}^{\rm p}_{k,j-1})\,dx \le \mathcal{Q}_1(\mathbf{E}^{\rm e}_{k,j-1}) - \int_\Omega \rho(t^{j-1}_k) : \mathbf{E}^{\rm e}_{k,j-1}\,dx$$
$$+ \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\rm p}_{k,j-1}) + \int_{t^{j-1}_k}^{t^j_k}\int_\Omega \mathbb{C}\mathbf{E}^{\rm e}_k(\tau) : \mathbf{E}\dot w(\tau)\,dx\,d\tau$$
$$- \int_{t^{j-1}_k}^{t^j_k}\int_\Omega \dot\rho(\tau) : \mathbf{E}^{\rm e}_k(\tau)\,dx\,d\tau + \tilde\delta_{k,j},$$

where

$$\tilde\delta_{k,j} := \mathcal{Q}_1(\mathbf{E}w(t^j_k) - \mathbf{E}w(t^{j-1}_k)) \le \frac{\beta_{\mathbb{C}}}{k}\int_{t^{j-1}_k}^{t^j_k} \|\mathbf{E}\dot w(\tau)\|^2_{L^2(\Omega;\mathrm{M}^{N\times N}_{\rm sym})}\,d\tau.$$

By summing up from 0 to i we have

$$\mathcal{Q}_1(\mathbf{E}^{\rm e}_{k,i}) - \int_\Omega \rho(t^i_k) : (\mathbf{E}^{\rm e}_{k,i} - \mathbf{E}w(t^i_k))\,dx + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\rm p}_{k,i})$$
$$+ \sum_{j=0}^{i}\left[\mathcal{H}(\mathbf{E}^{\rm e}_{k,j} - \mathbf{E}^{\rm e}_{k,j-1}) - \int_\Omega \rho_D(t^j_k) : (\mathbf{E}^{\rm p}_{k,j} - \mathbf{E}^{\rm p}_{k,j-1})\,dx\right]$$
$$\le \mathcal{Q}_1(\mathbf{E}^{\rm e}_{k,0}) - \int_\Omega \rho(0) : (\mathbf{E}^{\rm e}_{k,0} - \mathbf{E}w_{k,0})\,dx + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\rm p}_{k,0})$$
$$+ \int_0^{t^i_k}\int_\Omega \mathbb{C}\mathbf{E}^{\rm e}_k(\tau) : \mathbf{E}\dot w(\tau)\,dx\,d\tau - \int_0^{t^i_k}\int_\Omega \dot\rho(\tau) : (\mathbf{E}^{\rm e}_k(\tau) - \mathbf{E}w_k(\tau))\,dx\,d\tau + \tilde e_k,$$

where $\tilde e_k := \sum_{j=0}^k \tilde\delta_{k,j} \to 0$ as $k \to +\infty$. Since by (4.17) we have

$$\sum_{j=0}^{i}\left[\mathcal{H}(\mathbf{E}^{\rm e}_{k,j} - \mathbf{E}^{\rm e}_{k,j-1}) - \int_\Omega \rho_D(t^j_k) : (\mathbf{E}^{\rm p}_{k,j} - \mathbf{E}^{\rm p}_{k,j-1})\,dx\right]$$
$$\ge \alpha_l \sum_{j=0}^{i} \|\mathbf{E}^{\rm e}_{k,j} - \mathbf{E}^{\rm e}_{k,j-1}\|_{BV(\Omega;\mathrm{M}^{N\times N}_D)},$$

we deduce that

$$\mathcal{Q}_1(\mathbf{E}^{\rm e}_k(t)) - \int_\Omega \rho(t^i_k) : (\mathbf{E}^{\rm e}_k(t) - \mathbf{E}w_k(t))\,dx + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\rm p}_k(t)) + \alpha_l\mathcal{V}(\mathbf{E}^{\rm e}_k;0,t)$$
$$\le C_1 + \int_0^{t^i_k}\int_\Omega \mathbb{C}\mathbf{E}^{\rm e}_k(\tau) : \mathbf{E}\dot w(\tau)\,dx\,d\tau - \int_0^{t^i_k}\int_\Omega \dot\rho(\tau) : (\mathbf{E}^{\rm e}_k(\tau) - \mathbf{E}w_k(\tau))\;dx\,d\tau \tag{6.6}$$

for some $C_1 > 0$ independent of k and t. Since $\mathcal{Q}_1(\mathbf{E}^{\rm e}_k(t))$ is quadratic, we get that $\|\mathbf{E}^{\rm e}_k(t)\|_{L^2}$ is uniformly bounded in k and t. Hence from (6.6) we deduce also that $\|\mathrm{curl}\mathbf{E}^{\rm p}_k(t)\|_{L^2}$ and $\mathcal{V}(\mathbf{E}^{\rm p}_k;0,t)$ are uniformly bounded with respect to k and t. Since $u_k(t) = w_k(t)$ on $\partial_D\Omega$, by Korn's inequality we have also that $u_k(t)$ is uniformly bounded in $W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)$ with respect to k and t. The proof of (6.4) is thus concluded. □

7. Existence of a quasi-static evolution and approximation results. In this section we prove that the discrete evolution $t \mapsto (u_k(t), \mathbf{E}^{\mathrm{e}}_k(t), \mathbf{E}^{\mathrm{p}}_k(t))$ given by Proposition 6.2 admits a subsequence converging (in a suitable sense) to a quasi-static evolution for the Gurtin–Anand model. This will be done in Lemmas 7.1, 7.2, and 7.3. Theorem 5.2 will thus follow by combining these lemmas.

LEMMA 7.1. [illegible] $t \mapsto (u_{k_j}(t), \mathbf{E}^{\mathrm{e}}_{k_j}(t), \mathbf{E}^{\mathrm{p}}_{k_j}(t))$ [illegible] $t \mapsto (u_k(t), \mathbf{E}^{\mathrm{e}}_k(t), \mathbf{E}^{\mathrm{p}}_k(t))$ [illegible] $t \mapsto (u(t), \mathbf{E}^{\mathrm{e}}(t), \mathbf{E}^{\mathrm{p}}(t))$ [illegible] $(u(0), \mathbf{E}^{\mathrm{e}}(0), \mathbf{E}^{\mathrm{p}}(0)) = (u_0, \mathbf{E}^{\mathrm{e}}_0, \mathbf{E}^{\mathrm{p}}_0)$ [illegible] $t \in [0,T]$

$$(u(t), \mathbf{E}^{\mathrm{e}}(t), \mathbf{E}^{\mathrm{p}}(t)) \in \mathcal{A}(w(t)),$$

$$u_{k_j}(t) \rightharpoonup u(t) \quad \text{[illegible] } W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N), \tag{7.1}$$

$$\mathbf{E}^{\mathrm{e}}_{k_j}(t) \rightharpoonup \mathbf{E}^{\mathrm{e}}(t) \quad \text{[illegible] } L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}}), \tag{7.2}$$

$$\mathbf{E}^{\mathrm{p}}_{k_j}(t) \overset{*}{\rightharpoonup} \mathbf{E}^{\mathrm{p}}(t) \quad \text{[illegible] } BV(\Omega;\mathrm{M}^{N\times N}_D), \tag{7.3}$$

[illegible]

$$\mathrm{curl}\mathbf{E}^{\mathrm{p}}_{k_j}(t) \rightharpoonup \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t) \quad \text{[illegible] } L^2(\Omega;\mathrm{M}^{N\times N}). \tag{7.4}$$

[illegible] $t \mapsto \mathbf{E}^{\mathrm{p}}(t)$ [illegible] $C > 0$ [illegible] $t \in [0,T]$

$$\|u(t)\|_{W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)} + \|\mathbf{E}^{\mathrm{e}}(t)\|_{L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})} + \|\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)\|_{L^2(\Omega;\mathrm{M}^{N\times N})} + \mathcal{V}(\mathbf{E}^{\mathrm{p}};0,t) \le C. \tag{7.5}$$

[illegible] $t \in [0,T]$ [illegible] $(v,\mathbf{e},\mathbf{p}) \in \mathcal{A}(w(t))$ [illegible]

$$\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)) - \langle \mathcal{L}(t), u(t)\rangle \le \mathcal{Q}_1(\mathbf{e}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{p}) - \langle \mathcal{L}(t), v\rangle + \mathcal{H}(\mathbf{p} - \mathbf{E}^{\mathrm{p}}(t)). \tag{7.6}$$

[illegible] By Proposition 6.2 we have

$$\|u_k(t)\|_{W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)} + \|\mathbf{E}^{\mathrm{e}}_k(t)\|_{L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})} + \|\mathrm{curl}\mathbf{E}^{\mathrm{p}}_k(t)\|_{L^2(\Omega;\mathrm{M}^{N\times N})} + \mathcal{V}(\mathbf{E}^{\mathrm{p}}_k;0,t) \le C \tag{7.7}$$

for some C independent of k and t. Since $\mathbf{E}^{\mathrm{p}}_k(0) = \mathbf{E}^{\mathrm{p}}_0$ and $\mathcal{V}(\mathbf{E}^{\mathrm{p}}_k;0,T) \le C$, the existence of $\mathbf{E}^{\mathrm{p}} \in BV(0,T;BV(\Omega;\mathrm{M}^{N\times N}_D))$ and of a subsequence $t \mapsto (u_{k_j}(t), \mathbf{E}^{\mathrm{e}}_{k_j}(t), \mathbf{E}^{\mathrm{p}}_{k_j}(t))$ such that (7.3) holds follows by applying the generalized version of Helly's theorem proved in [8, Lemma 7.2] (notice that BV can be seen as the dual of a separable Banach space in such a way that the associated convergence with respect to the weak* topology is precisely the weak* convergence defined in (2.3)).

Since weak* convergence in BV implies strong convergence in L^1, by (7.7) we deduce that $\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t) \in L^2(\Omega;\mathrm{M}^{N\times N})$ and that (7.4) holds.

Let us fix $t \in [0,T]$. In view of the coercivity estimate (7.7), we may assume that there exist $\tilde{u} \in W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)$, $\widetilde{\mathbf{E}^{\mathrm{e}}} \in L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})$, and a further subsequence k_{j_h} (depending a priori on t) such that

$$u_{k_{j_h}}(t) \rightharpoonup \tilde{u} \qquad \text{weakly in } W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)$$

and

$$\mathbf{E}^{\mathrm{e}}_{k_{j_h}}(t) \rightharpoonup \widetilde{\mathbf{E}^{\mathrm{e}}} \qquad \text{weakly in } L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}}). \tag{7.8}$$

It follows easily that $(\tilde u, \widetilde{\mathbf{E}^{\mathrm{e}}}, \mathbf{E}^{\mathrm{p}}(t)) \in \mathcal{A}(w(t))$. We claim that for every $(v,\mathbf{e},\mathbf{p}) \in \mathcal{A}(w(t))$ we have

$$\begin{aligned}\mathcal{Q}_1(\widetilde{\mathbf{E}^{\mathrm{e}}}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)) - \langle \mathcal{L}(t), \tilde u\rangle \\ \le \mathcal{Q}_1(\mathbf{e}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{p}) - \langle \mathcal{L}(t), v\rangle + \mathcal{H}(\mathbf{p}-\mathbf{E}^{\mathrm{p}}(t)).\end{aligned} \tag{7.9}$$

Notice that, in view of (7.9), it turns out that $\tilde u$ and $\widetilde{\mathbf{E}^{\mathrm{e}}}$ are uniquely determined by $\mathbf{E}^{\mathrm{p}}(t)$. In fact, the pair $(\tilde u, \widetilde{\mathbf{E}^{\mathrm{e}}})$ minimizes the convex functional $(v,\mathbf{e}) \mapsto \mathcal{Q}_1(\mathbf{e}) - \langle \mathcal{L}(t), v\rangle$ on the convex set $K := \{(v,\mathbf{e}) : (v,\mathbf{e},\mathbf{E}^{\mathrm{p}}(t)) \in \mathcal{A}(w(t))\}$. Since the functional is strictly convex in $\mathbf{e}$, $\widetilde{\mathbf{E}^{\mathrm{e}}}$ is uniquely determined, and so is $\tilde u$ in view of Korn's inequality. By setting $u(t) := \tilde u$ and $\mathbf{E}^{\mathrm{e}}(t) := \widetilde{\mathbf{E}^{\mathrm{e}}}$, we get that (7.1) and (7.2) hold (without passing to a further subsequence).

In view of (7.7) we deduce that (7.5) holds. Finally, the global stability is given precisely by (7.9).

In order to conclude the proof, we need to prove claim (7.9). Let us set

$$v_h := v - \tilde u + u_{k_{j_h}}(t), \qquad \mathbf{e}_h := \mathbf{e} - \widetilde{\mathbf{E}^{\mathrm{e}}} + \mathbf{E}^{\mathrm{e}}_{k_{j_h}}(t), \qquad \text{and} \qquad \mathbf{p}_h := \mathbf{p} - \mathbf{E}^{\mathrm{p}}(t) + \mathbf{E}^{\mathrm{p}}_{k_{j_h}}(t).$$

We have $(v_h, \mathbf{e}_h, \mathbf{p}_h) \in \mathcal{A}(w_{k_{j_h}}(t))$. By (6.2) we have

$$\begin{aligned}&\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_{k_{j_h}}(t)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_{k_{j_h}}(t)) - \langle \mathcal{L}_{k_{j_h}}(t), u_{k_{j_h}}(t)\rangle \\ &\qquad \le \mathcal{Q}_1(\mathbf{e}_h) + \mathcal{Q}_2(\mathrm{curl}\mathbf{p}_h) - \langle \mathcal{L}_{k_{j_h}}(t), v_h\rangle + \mathcal{H}(\mathbf{p}_h - \mathbf{E}^{\mathrm{p}}_{k_{j_h}}(t)) \\ &\qquad = \mathcal{Q}_1(\mathbf{e} - \widetilde{\mathbf{E}^{\mathrm{e}}} + \mathbf{E}^{\mathrm{e}}_{k_{j_h}}(t)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{p} - \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t) + \mathrm{curl}\mathbf{E}^{\mathrm{p}}_{k_{j_h}}(t)) \\ &\qquad\qquad - \langle \mathcal{L}_{k_{j_h}}(t), v - \tilde u + u_{k_{j_h}}(t)\rangle + \mathcal{H}(\mathbf{p} - \mathbf{E}^{\mathrm{p}}(t)),\end{aligned}$$

so that we get

$$\begin{aligned}0 \le{}& \mathcal{Q}_1(\mathbf{e} - \widetilde{\mathbf{E}^{\mathrm{e}}}) + \int_\Omega \mathbb{C}(\mathbf{e} - \widetilde{\mathbf{E}^{\mathrm{e}}}) : \mathbf{E}^{\mathrm{e}}_{k_{j_h}}(t)\,dx \\ &+ \mathcal{Q}_2(\mathrm{curl}\mathbf{p} - \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)) + \mu L^2 \int_\Omega (\mathrm{curl}\mathbf{p} - \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)) : \mathrm{curl}\mathbf{E}^{\mathrm{p}}_{k_{j_h}}(t)\,dx \\ &\qquad - \langle \mathcal{L}_{k_{j_h}}(t), v - \tilde u\rangle + \mathcal{H}(\mathbf{p} - \mathbf{E}^{\mathrm{p}}(t)).\end{aligned}$$

By letting $h \to +\infty$, in view of (7.8), (7.3), and (7.4) and since $t \mapsto \mathcal{L}(t)$ is absolutely continuous with values in $(W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N))^*$, we obtain

$$\begin{aligned}0 \le{}& \mathcal{Q}_1(\mathbf{e} - \widetilde{\mathbf{E}^{\mathrm{e}}}) + \int_\Omega \mathbb{C}(\mathbf{e} - \widetilde{\mathbf{E}^{\mathrm{e}}}) : \widetilde{\mathbf{E}^{\mathrm{e}}}\,dx \\ &+ \mathcal{Q}_2(\mathrm{curl}\mathbf{p} - \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)) + \mu L^2 \int_\Omega (\mathrm{curl}\mathbf{p} - \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)) : \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)\,dx \\ &\qquad - \langle \mathcal{L}(t), v - \tilde u\rangle + \mathcal{H}(\mathbf{p} - \mathbf{E}^{\mathrm{p}}(t)).\end{aligned}$$

By adding to both sides the term $\mathcal{Q}_1(\widetilde{\mathbf{E}^{\mathrm{e}}}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)) - \langle \mathcal{L}(t), \tilde u\rangle$, we obtain precisely (7.9), so that the proof is concluded. ∎

We have the following estimate from above for the total energy.

LEMMA 7.2. [illegible] $t \mapsto (u(t), \mathbf{E}^{\mathrm{e}}(t), \mathbf{E}^{\mathrm{p}}(t))$ [illegible] 7.1 [illegible] $t \in [0,T]$ [illegible]

$$\mathcal{E}(t) + \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}; 0, t) \le \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_0) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_0) - \langle \mathcal{L}(0), u_0\rangle + \int_0^t \int_\Omega \mathbb{C}\mathbf{E}^{\mathrm{e}}(\tau) : \mathbf{E}\dot{w}(\tau)\, dx\, d\tau - \int_0^t \langle \dot{\mathcal{L}}(\tau), u(\tau)\rangle\, d\tau - \int_0^t \langle \mathcal{L}(\tau), \dot{w}(\tau)\rangle\, d\tau, \tag{7.10}$$

[illegible] $\mathcal{E}(t)$ [illegible] $\mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}; 0, t)$ [illegible] fi[illegible] (5.4) [illegible] (5.1) [illegible]. Let us fix $t \in [0,T]$. By (6.3) we have

$$\mathcal{E}_k(t) + \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}_k; 0, t) \le \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_0) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_0) - \langle \mathcal{L}(0), u_0\rangle + \int_0^{t^i_k} \int_\Omega \mathbb{C}\mathbf{E}^{\mathrm{e}}_k(\tau) : \mathbf{E}\dot{w}(\tau)\, dx\, d\tau - \int_0^{t^i_k} \langle \dot{\mathcal{L}}(\tau), u_k(\tau)\rangle\, d\tau - \int_0^{t^i_k} \langle \mathcal{L}_k(\tau), \dot{w}(\tau)\rangle\, d\tau + e_k, \tag{7.11}$$

where $e_k \to 0$ as $k \to +\infty$. In view of (7.2), (7.4), and (7.1) and since $\mathcal{L}_k(t) \to \mathcal{L}(t)$ strongly in $(W^{1,\frac{N}{N-1}}(\Omega; \mathbb{R}^N))^*$, we get by lower semicontinuity

$$\mathcal{E}(t) \le \liminf_{j \to +\infty} \mathcal{E}_{k_j}(t).$$

Moreover, by (7.3) and the lower semicontinuity of $\mathcal{H}$ with respect to the weak* convergence in BV, the very definition of $\mathcal{D}_{\mathcal{H}}$ implies that

$$\mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}; 0, t) \le \liminf_{j \to +\infty} \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}_{k_j}; 0, t).$$

By Lebesgue dominated convergence we get as $k \to +\infty$

$$\int_0^{t^i_{k_j}} \int_\Omega \mathbb{C}\mathbf{E}^{\mathrm{e}}_{k_j}(\tau) : \mathbf{E}\dot{w}(\tau)\, dx\, d\tau - \int_0^{t^i_{k_j}} \langle \dot{\mathcal{L}}(\tau), u_{k_j}(\tau)\rangle\, d\tau - \int_0^{t^i_{k_j}} \langle \mathcal{L}_{k_j}(\tau), \dot{w}(\tau)\rangle\, d\tau \to \int_0^t \int_\Omega \mathbb{C}\mathbf{E}^{\mathrm{e}}(\tau) : \mathbf{E}\dot{w}(\tau)\, dx\, d\tau - \int_0^t \langle \dot{\mathcal{L}}(\tau), u(\tau)\rangle\, d\tau - \int_0^t \langle \mathcal{L}(\tau), \dot{w}(\tau)\rangle\, d\tau.$$

Then (7.10) follows passing to the limit in (7.11). □

The following estimate from below for the total energy holds.

LEMMA 7.3. [illegible] $t \mapsto (u(t), \mathbf{E}^{\mathrm{e}}(t), \mathbf{E}^{\mathrm{p}}(t))$ [illegible] 7.1 [illegible] $t \in [0,T]$ [illegible]

$$\mathcal{E}(t) + \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}; 0, t) \ge \mathcal{Q}_1\left(\mathbf{E}^{\mathrm{e}}_0\right) + \mathcal{Q}_2\left(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_0\right) - \langle \mathcal{L}(0), u_0\rangle + \int_0^t \int_\Omega \mathbb{C}\mathbf{E}^{\mathrm{e}}(\tau) : \mathbf{E}\dot{w}(\tau)\, dx\, d\tau - \int_0^t \langle \dot{\mathcal{L}}(\tau), u(\tau)\rangle\, d\tau - \int_0^t \langle \mathcal{L}(\tau), \dot{w}(\tau)\rangle\, d\tau, \tag{7.12}$$

[illegible] $\mathcal{E}(t)$ [illegible] $\mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}; 0, t)$ [illegible] fi[illegible] (5.4) [illegible] (5.1) [illegible]

. Let $t \in [0,T]$, $h \geq 1$, and let us set $s_h^j := \frac{j}{h}t$ for $j = 0, 1, \dots h$. By the global stability condition (7.6), by comparing $(u(s_h^j), \mathbf{E}^{\mathrm{e}}(s_h^j), \mathbf{E}^{\mathrm{p}}(s_h^j))$ with

$$\Big(u(s_h^{j+1}) - w(s_h^{j+1}) + w(s_h^j), \\ \mathbf{E}^{\mathrm{e}}(s_h^{j+1}) - \mathbf{E}w(s_h^{j+1}) + \mathbf{E}w(s_h^j), \mathbf{E}^{\mathrm{p}}(s_h^{j+1})\Big) \in \mathcal{A}(w(s_h^j)),$$

we get

$$\begin{aligned}\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(s_h^{j+1}) - \mathbf{E}w(s_h^{j+1}) + \mathbf{E}w(s_h^j)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(s_h^{j+1})) \\ - \langle \mathcal{L}(s_h^j), u(s_h^{j+1}) - w(s_h^{j+1}) + w(s_h^j)\rangle + \mathcal{H}(\mathbf{E}^{\mathrm{p}}(s_h^{j+1}) - \mathbf{E}^{\mathrm{p}}(s_h^j)) \\ \geq \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(s_h^j)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(s_h^j)) - \langle \mathcal{L}(s_h^j), u(s_h^j)\rangle,\end{aligned}$$

which can be rewritten in the following form:

$$\begin{aligned}&\mathcal{Q}_1\left(\mathbf{E}^{\mathrm{e}}\left(s_h^{j+1}\right)\right) + \mathcal{Q}_2\left(\mathrm{curl}\mathbf{E}^{\mathrm{p}}\left(s_h^{j+1}\right)\right) - \langle \mathcal{L}\left(s_h^{j+1}\right), u\left(s_h^{j+1}\right)\rangle \\ &+\mathcal{H}\left(\mathbf{E}^{\mathrm{p}}\left(s_h^{j+1}\right) - \mathbf{E}^{\mathrm{p}}\left(s_h^j\right)\right) \geq \mathcal{Q}_1\left(\mathbf{E}^{\mathrm{e}}\left(s_h^j\right)\right) + \mathcal{Q}_2\left(\mathrm{curl}\mathbf{E}^{\mathrm{p}}\left(s_h^j\right)\right) - \langle \mathcal{L}\left(s_h^j\right), u\left(s_h^j\right)\rangle \\ &+\int_{s_h^j}^{s_h^{j+1}}\int_\Omega \mathbb{C}\overline{\mathbf{E}_h^{\mathrm{e}}}(s) : \mathbf{E}\dot{w}(s)\,dx\,ds - \int_{s_h^j}^{s_h^{j+1}} \langle \dot{\mathcal{L}}(s), \bar{u}_h(s)\rangle\,ds - \int_{s_h^j}^{s_h^{j+1}} \langle \overline{\mathcal{L}_h}(s), \dot{w}(s)\rangle\,ds + \bar{\delta}_{h,j},\end{aligned} \tag{7.13}$$

where for $s_h^j < s \leq s_h^{j+1}$ we set

$$\overline{u_h}(s) := u(s_h^{j+1}), \quad \overline{\mathbf{E}_h^{\mathrm{e}}}(s) := \mathbf{E}^{\mathrm{e}}(s_h^{j+1}), \quad \overline{\mathbf{E}_h^{\mathrm{p}}}(s) := \mathbf{E}^{\mathrm{p}}(s_h^{j+1}), \quad \overline{\mathcal{L}_h}(s) := \mathcal{L}(s_h^{j+1}),$$

and

$$\bar{\delta}_{h,j} := -\mathcal{Q}_1(\mathbf{E}w(s_h^{j+1}) - \mathbf{E}w(s_h^j)) - \langle \mathcal{L}(s_h^{j+1}) - \mathcal{L}(s_h^j), w(s_h^{j+1}) - w(s_h^j)\rangle.$$

By summing up in (7.13) from 0 to $h-1$ we get

$$\begin{aligned}&\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)) - \langle \mathcal{L}(t), u(t)\rangle + \sum_{j=0}^{h-1} \mathcal{H}(\mathbf{E}^{\mathrm{p}}(s_h^{j+1}) - \mathbf{E}^{\mathrm{p}}(s_h^j)) \\ &\qquad \geq \mathcal{Q}_1(\mathbf{E}_0^{\mathrm{e}}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}_0^{\mathrm{p}}) - \langle \mathcal{L}(0), u_0\rangle \\ &\quad + \int_0^t \int_\Omega \mathbb{C}\overline{\mathbf{E}_h^{\mathrm{e}}}(s) : \mathbf{E}\dot{w}(s)\,dx\,ds - \int_0^t \langle \dot{\mathcal{L}}(s), \overline{u_h}(s)\rangle\,ds - \int_0^t \langle \overline{\mathcal{L}_h}(s), \dot{w}(s)\rangle\,ds + \bar{e}_h,\end{aligned}$$

where $\bar{e}_h \to 0$ as $h \to +\infty$. By the very definition of $\mathcal{D}_{\mathcal{H}}$ we get

$$\begin{aligned}\mathcal{E}(t) + \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}; 0, t) \geq \mathcal{Q}_1(\mathbf{E}_0^{\mathrm{e}}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}_0^{\mathrm{p}}) - \langle \mathcal{L}(0), u_0\rangle \\ + \int_0^t \int_\Omega \mathbb{C}\overline{\mathbf{E}_h^{\mathrm{e}}}(s) : \mathbf{E}\dot{w}(s)\,dx\,ds - \int_0^t \langle \dot{\mathcal{L}}(s), \overline{u_h}(s)\rangle\,ds \\ - \int_0^t \langle \overline{\mathcal{L}_h}(s), \dot{w}(s)\rangle\,ds + \bar{e}_h.\end{aligned} \tag{7.14}$$

Since $\mathbf{E}^{\mathrm{p}} \in BV(0,T; BV(\Omega; \mathrm{M}_D^{N\times N}))$, we have that $\mathbf{E}^{\mathrm{p}}(t)$ is continuous in time with respect to the strong topology in $BV(\Omega; \mathrm{M}_D^{N\times N})$ up to a countable set in $[0,T]$. Let $s \in [0,T]$ be a continuity point of $\mathbf{E}^{\mathrm{p}}$, and let $s_n \to s$. Then

$$\mathbf{E}^{\mathrm{e}}(s_n) \rightharpoonup \mathbf{E}^{\mathrm{e}}(s) \qquad \text{weakly in } L^2(\Omega; \mathrm{M}_{\mathrm{sym}}^{N\times N}) \tag{7.15}$$

and

$$u(s_n) \rightharpoonup u(s) \qquad \text{weakly in } W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N). \tag{7.16}$$

In fact up to a subsequence we have that

$$\mathbf{E}^{\mathrm{e}}(s_n) \rightharpoonup \widetilde{\mathbf{E}^{\mathrm{e}}} \qquad \text{weakly in } L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})$$

and

$$u(s_n) \rightharpoonup \tilde{u} \qquad \text{weakly in } W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N),$$

with $(\tilde{u},\widetilde{\mathbf{E}^{\mathrm{e}}},\mathbf{E}^{\mathrm{p}}(s)) \in \mathcal{A}(w(s))$. Given $(v,\mathbf{e},\mathbf{E}^{\mathrm{p}}(s)) \in \mathcal{A}(w(s))$, by the global stability condition (7.6), comparing $(u(s_n),\mathbf{E}^{\mathrm{e}}(s_n),\mathbf{E}^{\mathrm{p}}(s_n))$ with $(v-w(s)+w(s_n),\mathbf{e}-\mathbf{E}w(s)+\mathbf{E}w(s_n),\mathbf{E}^{\mathrm{p}}(s))$, and taking into account the continuity of $\mathcal{H}$ with respect to the BV-norm, we obtain that $(\tilde{u},\widetilde{\mathbf{E}^{\mathrm{e}}})$ is a minimizer of the convex functional $(v,\mathbf{e}) \mapsto \mathcal{Q}_1(\mathbf{e}) - \langle \mathcal{L}(s), v\rangle$ on the convex set $\mathcal{K} := \{(v,\mathbf{e}) : (v,\mathbf{e},\mathbf{E}^{\mathrm{p}}(s)) \in \mathcal{A}(w(s))\}$. By the uniqueness of the minimizer, we have that $\tilde{u} = u(s)$ and $\widetilde{\mathbf{E}^{\mathrm{e}}} = \mathbf{E}^{\mathrm{e}}(s)$, so that (7.15) and (7.16) follow.

By (7.15) and (7.16) we have that for a.e. every $s \in [0,t]$

$$\overline{\mathbf{E}^{\mathrm{e}}_h}(s) \rightharpoonup \mathbf{E}^{\mathrm{e}}(s) \qquad \text{weakly in } L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}}) \tag{7.17}$$

and

$$\overline{u_h}(s) \rightharpoonup u(s) \qquad \text{weakly in } W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N). \tag{7.18}$$

By taking into account that for every $s \in [0,T]$

$$\overline{\mathcal{L}_h}(s) \to \mathcal{L}(s) \qquad \text{strongly in } \left(W^{1,\frac{N}{N-1}}\left(\Omega;\mathbb{R}^N\right)\right)^*,$$

in view of (7.17) and (7.18), passing to the limit in (7.14) we get by dominated convergence (take into account (7.5)) that (7.12) follows. □

We are in a position to prove Theorem 5.2. Indeed, the evolution $t \mapsto (u(t),\mathbf{E}^{\mathrm{e}}(t),\mathbf{E}^{\mathrm{p}}(t))$ given by Lemma 7.1 is a quasi-static evolution for the Gurtin–Anand model because it satisfies the global stability condition in view of (7.6), and it satisfies the energy balance because of (7.10) and (7.12).

The convergence of the discrete-in-time evolution to the continuous one can be improved in the following way.

PROPOSITION 7.4. [illegible] $t \mapsto (u(t),\mathbf{E}^{\mathrm{e}}(t),\mathbf{E}^{\mathrm{p}}(t))$ [illegible] 7.1 [illegible] $t \in [0,T]$ [illegible] $j \to +\infty$

$$\mathcal{E}_{k_j}(t) \to \mathcal{E}(t) \tag{7.19}$$

[illegible]

$$\mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}_{k_j};0,t) \to \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}};0,t). \tag{7.20}$$

[illegible]

$$\mathbf{E}^{\mathrm{e}}_{k_j}(t) \to \mathbf{E}^{\mathrm{e}}(t) \quad \text{[illegible] } L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}}), \tag{7.21}$$

$$\mathrm{curl}\mathbf{E}^{\mathrm{p}}_{k_j}(t) \to \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t) \quad \text{[illegible] } L^2(\Omega;\mathrm{M}^{N\times N}), \tag{7.22}$$

$t \in [0,T]$

$$\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_{k_j}(t)) \to \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t)), \qquad \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_{k_j}(t)) \to \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)) \tag{7.23}$$

$$\langle \mathcal{L}_{k_j}(t), u_{k_j}(t)\rangle \to \langle \mathcal{L}(t), u(t)\rangle. \tag{7.24}$$

. Notice that by lower semicontinuity we have for every $t \in [0,T]$

$$\mathcal{E}(t) \le \liminf_{j\to+\infty} \mathcal{E}_{k_j}(t). \tag{7.25}$$

Moreover, by the lower semicontinuity of $\mathcal{H}$ with respect to the weak* convergence, and by the very definition of $\mathcal{D}_{\mathcal{H}}$, we deduce that for every $t \in [0,T]$

$$\mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}};0,t) \le \liminf_{j\to+\infty} \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}_{k_j};0,t). \tag{7.26}$$

By (6.3) and (7.12) we get that

$$\begin{aligned}
\mathcal{E}(t) + \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}};0,t) &\le \liminf_{j\to+\infty} (\mathcal{E}_{k_j}(t) + \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}_{k_j};0,t)) \\
&\le \limsup_{j\to+\infty} \left(\mathcal{E}_{k_j}(t) + \mathcal{D}_{\mathcal{H}}\left(\mathbf{E}^{\mathrm{p}}_{k_j};0,t\right)\right) \\
&\le \limsup_{j\to+\infty} \left[\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_0) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_0) - \langle \mathcal{L}(0), u_0\rangle + \int_0^{t^i_{k_j}} \int_\Omega \mathbb{C}\mathbf{E}^{\mathrm{e}}_{k_j}(\tau) : \mathbf{E}\dot{w}(\tau)\, dx\, d\tau \right. \\
&\qquad \left. - \int_0^{t^i_{k_j}} \langle \dot{\mathcal{L}}(\tau), u_{k_j}(\tau)\rangle\, d\tau - \int_0^{t^i_{k_j}} \langle \mathcal{L}_{k_j}(\tau), \dot{w}(\tau)\rangle\, d\tau + e_{k_j}\right] \\
&= \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_0) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_0) - \langle \mathcal{L}(0), u_0\rangle + \int_0^t \int_\Omega \mathbb{C}\mathbf{E}^{\mathrm{e}}(\tau) : \mathbf{E}\dot{w}(\tau)\, dx\, d\tau \\
&\qquad - \int_0^t \langle \dot{\mathcal{L}}(\tau), u(\tau)\rangle\, d\tau - \int_0^t \langle \mathcal{L}(\tau), \dot{w}(\tau)\rangle\, d\tau \le \mathcal{E}(t) + \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}};0,t).
\end{aligned}$$

We conclude that for every $t \in [0,T]$

$$\lim_{j\to+\infty} (\mathcal{E}_{k_j}(t) + \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}_{k_j};0,t)) = \mathcal{E}(t) + \mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}};0,t).$$

From (7.25) and (7.26) we deduce that (7.19) and (7.20) hold. Since by lower semicontinuity

$$\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t)) \le \liminf_{j\to+\infty} \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_{k_j}(t)) \qquad \text{and} \qquad \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)) \le \liminf_{j\to+\infty} \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_{k_j}(t)),$$

while

$$\langle \mathcal{L}_{k_j}(t), u_{k_j}(t)\rangle \to \langle \mathcal{L}(t), u(t)\rangle,$$

from (7.19) we deduce that (7.23) and (7.24) hold. In particular (7.21) and (7.22) follow, and the proof is concluded. □

7.5 (convergence for the elastic and the "energetic" plastic strains). Since the maps $t \mapsto \mathbf{E}^{\mathrm{e}}(t)$ and $t \mapsto \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)$ turn out to be uniquely determined by the initial conditions (see Proposition 8.8), we infer that

$$\begin{aligned}
\mathbf{E}^{\mathrm{e}}_k(t) &\to \mathbf{E}^{\mathrm{e}}(t) \qquad \text{strongly in } L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}}), \\
\mathrm{curl}\mathbf{E}^{\mathrm{p}}_k(t) &\to \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t) \qquad \text{strongly in } L^2(\Omega;\mathrm{M}^{N\times N})
\end{aligned}$$

without passing to a subsequence $(k_j)_{j\in\mathbb{N}}$.

8. Balance equations and the flow rule. This section is devoted to the proof of Theorem 5.3; that is, we prove that a quasi-static evolution $t \mapsto (u(t), \mathbf{E}^{\mathrm{e}}(t), \mathbf{E}^{\mathrm{p}}(t))$ for the Gurtin–Anand model satisfies the prescribed regularity and uniqueness properties, the balance equations, and the flow rule.

We need the following lemma.

LEMMA 8.1. [illegible] $t \in [0,T]$ [illegible] $\mathbf{T}^{\mathrm{p}}(t) \in L^\infty(\Omega; \mathrm{M}^{N\times N}_D)$, $\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t) \in L^\infty(\Omega; \mathrm{M}^{N\times N\times N}_D)$, [illegible] $\mathbb{S}^{\mathrm{p}}(t) \in (\mathcal{M}_b(\Omega; \mathrm{M}^{N\times N\times N}_D))^*$ [illegible] $(\mathbf{A}, \mathbb{B}, \mathbb{L}) \in L^1(\Omega; \mathrm{M}^{N\times N}_D) \times L^1(\Omega; \mathrm{M}^{N\times N\times N}_D) \times \mathcal{M}_b(\Omega; \mathrm{M}^{N\times N\times N}_D)$

$$\left| \int_\Omega \mathbf{T}^{\mathrm{p}}(t) : \mathbf{A}\, dx + \int_\Omega \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t) : \mathbb{B}\, dx + \langle \mathbb{S}^{\mathrm{p}}(t), \mathbb{L} \rangle \right| \le S_Y \int_\Omega \sqrt{|\mathbf{A}|^2 + l^2 |\mathbb{B}|^2}\, dx + l S_Y |\mathbb{L}|(\Omega) \tag{8.1}$$

[illegible] $(v, \mathbf{e}, \mathbf{p}) \in \mathcal{A}(0)$

$$\int_\Omega \mathbf{T}(t) : \mathbf{e}\, dx + \mu L^2 \int_\Omega \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t) : \mathrm{curl}\mathbf{p}\, dx - \langle \mathcal{L}(t), v \rangle = -\int_\Omega \mathbf{T}^{\mathrm{p}}(t) : \mathbf{p}\, dx - \int_\Omega \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t) : \nabla \mathbf{p}\, dx - \langle \mathbb{S}^{\mathrm{p}}(t), D^s \mathbf{p} \rangle. \tag{8.2}$$

[illegible] $\mathbb{K}^{\mathrm{p}}(t) := \mathbb{K}^{\mathrm{p}}_{\mathrm{en}}(t) + \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t)$, [illegible] $\mathbb{K}^{\mathrm{p}}_{\mathrm{en}}(t)$ [illegible] (3.4), (3.5) [illegible] $\mathbf{E}^{\mathrm{p}}(t)$, [illegible] $(v, \mathbf{e}, \mathbf{p}) \in \mathcal{A}(0)$ [illegible]

$$\int_\Omega \mathbf{T}(t) : \mathbf{e}\, dx + \int_\Omega \mathbf{T}^{\mathrm{p}}(t) : \mathbf{p}\, dx + \int_\Omega \mathbb{K}^{\mathrm{p}}(t) : \nabla \mathbf{p}\, dx + \langle \mathbb{S}^{\mathrm{p}}(t), D^s \mathbf{p} \rangle = \langle \mathcal{L}(t), v \rangle. \tag{8.3}$$

[illegible]. Let us fix $t \in [0,T]$. From the global stability condition (5.2), for every $(v, \mathbf{e}, \mathbf{p}) \in \mathcal{A}(0)$ and $\varepsilon \in \mathbb{R}$ we get

$$\begin{aligned} &\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)) - \langle \mathcal{L}(t), u(t) \rangle \\ &\qquad \le \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t) + \varepsilon \mathbf{e}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t) + \varepsilon \mathrm{curl}\mathbf{p}) - \langle \mathcal{L}(t), u(t) + \varepsilon v \rangle + \mathcal{H}(\varepsilon \mathbf{p}) \end{aligned}$$

so that

$$\begin{aligned} &\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t) + \varepsilon \mathbf{e}) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t) + \varepsilon \mathrm{curl}\mathbf{p}) - \varepsilon \langle \mathcal{L}(t), v \rangle + \mathcal{H}(\varepsilon \mathbf{p}) \\ &\qquad \ge \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)). \end{aligned}$$

By taking the left and right derivative for $\varepsilon = 0$ we get

$$\int_\Omega \mathbb{C}\mathbf{E}^{\mathrm{e}}(t) : \mathbf{e}\, dx + \mu L^2 \int_\Omega \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t) : \mathrm{curl}\mathbf{p}\, dx - \langle \mathcal{L}(t), v \rangle + \mathcal{H}(\mathbf{p}) \ge 0$$

and

$$\int_\Omega \mathbb{C}\mathbf{E}^{\mathrm{e}}(t) : \mathbf{e}\, dx + \mu L^2 \int_\Omega \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t) : \mathrm{curl}\mathbf{p}\, dx - \langle \mathcal{L}(t), v \rangle - \mathcal{H}(-\mathbf{p}) \le 0$$

so that, since $\mathbf{T}(t) := \mathbb{C}\mathbf{E}^{\mathrm{e}}(t)$,

$$\left| \int_\Omega \mathbf{T}(t) : \mathbf{e}\, dx + \mu L^2 \int_\Omega \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t) : \mathrm{curl}\mathbf{p}\, dx - \langle \mathcal{L}(t), v \rangle \right| \le \mathcal{H}(\mathbf{p}).$$

The previous inequality shows that the linear functional on $\mathcal{A}(0)$

$$(v,\mathbf{e},\mathbf{p})\mapsto\int_\Omega \mathbb{C}\mathbf{E}^{\mathrm{e}}(t):\mathbf{e}\,dx+\mu L^2\int_\Omega \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t):\mathrm{curl}\mathbf{p}\,dx-\langle\mathcal{L}(t),v\rangle$$

depends indeed only on $\mathbf{p}$.

Let $X\subseteq L^1(\Omega;\mathrm{M}_D^{N\times N})\times L^1(\Omega;\mathrm{M}_D^{N\times N\times N})\times\mathcal{M}_b(\Omega;\mathrm{M}_D^{N\times N\times N})$ be the linear subspace generated by $\{(\mathbf{p},\nabla\mathbf{p},D^s\mathbf{p})\,:\,(v,\mathbf{e},\mathbf{p})\in\mathcal{A}(0)$ for some $v\in W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N),\mathbf{e}\in L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})\}$. By applying the Hahn–Banach theorem we deduce that the linear functional

$$\varphi(\mathbf{p},\nabla\mathbf{p},D^s\mathbf{p}):=\int_\Omega \mathbf{T}(t):\mathbf{e}\,dx+\mu L^2\int_\Omega \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t):\mathrm{curl}\mathbf{p}\,dx-\langle\mathcal{L}(t),v\rangle \tag{8.4}$$

on the linear space X can be extended in a continuous way to the entire space $L^1(\Omega;\mathrm{M}_D^{N\times N})\times L^1(\Omega;\mathrm{M}_D^{N\times N\times N})\times\mathcal{M}_b(\Omega;\mathrm{M}_D^{N\times N\times N})$ in such a way that

$$|\varphi(\mathbf{A},\mathbb{B},\mathbb{L})|\le S_Y\int_\Omega\sqrt{|\mathbf{A}|^2+l^2|\mathbb{B}|^2}\,dx+lS_Y|\mathbb{L}|(\Omega) \tag{8.5}$$

for every $(\mathbf{A},\mathbb{B},\mathbb{L})\in L^1(\Omega;\mathrm{M}_D^{N\times N})\times L^1(\Omega;\mathrm{M}_D^{N\times N\times N})\times\mathcal{M}_b(\Omega;\mathrm{M}_D^{N\times N\times N})$. By representing φ, in view of (8.5) and (8.4), we obtain that there exist $\mathbf{T}^{\mathrm{p}}(t)\in L^\infty(\Omega;\mathrm{M}_D^{N\times N})$, $\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t)\in L^\infty(\Omega;\mathrm{M}_D^{N\times N\times N})$, and $\mathbb{S}^{\mathrm{p}}(t)\in(\mathcal{M}_b(\Omega;\mathrm{M}_D^{N\times N\times N}))^*$ such that (8.1) and (8.2) hold. Finally, (8.3) follows by (8.2) in view of the very definition of $\mathbb{K}^{\mathrm{p}}_{\mathrm{en}}(t)$. ∎

The following proposition concerns the balance equation for the Cauchy stress.

Proposition 8.2 (balance equations for the Cauchy stress). $t\in[0,T]$

$$\begin{cases}-\mathrm{div}\mathbf{T}(t)=f(t) & \Omega,\\ \mathbf{T}(t)\nu=g(t) & \partial_N\Omega.\end{cases} \tag{8.6}$$

. Let $v\in C^\infty(\overline{\Omega},\mathbb{R}^N)$ such that $v=0$ on $\partial_D\Omega$. By choosing $(v,\mathbf{E}v,0)\in\mathcal{A}(0)$ in (8.3) we deduce that

$$\int_\Omega \mathbf{T}(t):\mathbf{E}v\,dx=\langle\mathcal{L}(t),v\rangle. \tag{8.7}$$

Then clearly $-\mathrm{div}\mathbf{T}(t)=f(t)$ in the sense of distributions in Ω. Since $\mathbf{T}(t)\in L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})$ and its divergence belongs in particular to $L^2(\Omega;\mathbb{R}^N)$, we have that the normal trace of $\mathbf{T}(t)$ on $\partial\Omega$ is well defined as an element of $H^{-1/2}(\partial\Omega;\mathbb{R}^N)$. By integrating by parts in (8.7) we get immediately the second relation of (8.6). ∎

Concerning the stresses conjugated to the plastic variables, the following result holds.

Proposition 8.3 (stresses conjugated to the plastic variables). $t\in[0,T]$ $\mathbf{T}^{\mathrm{p}}(t)$ $\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t)$ $\mathbb{K}^{\mathrm{p}}(t)$ $\mathbb{S}^{\mathrm{p}}(t)$ 8.1

$$\begin{cases}\mathbf{T}^{\mathrm{p}}(t)=\mathbf{T}_D(t)+\mathrm{div}\mathbb{K}^{\mathrm{p}}(t) & \Omega,\\ \mathbb{K}^{\mathrm{p}}(t)\nu=0 & \partial\Omega,\end{cases} \tag{8.8}$$

$\mathbf{T}_D(t):=(\mathbf{T}(t))_D$ $\mathbf{T}^{\mathrm{p}}(t)$ $\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t)$

$$\sqrt{|\mathbf{T}^{\mathrm{p}}(t,x)|^2+l^{-2}|\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x)|^2}\le S_Y \qquad x\in\Omega, \tag{8.9}$$

$\mathbb{S}^{\mathrm{p}}(t)$ fi

$$\|\mathbb{S}^{\mathrm{p}}(t)\|_{(\mathcal{M}_b(\mathrm{M}_D^{N\times N\times N}))^*} \le lS_Y. \tag{8.10}$$

. The stress constraints (8.9) and (8.10) follow by choosing $(\mathbf{A}, \mathbb{B}, 0)$ and $(0, 0, \mathbb{L})$, respectively, in (8.1).

Let us come to (8.8). Let $\mathbf{p} \in C^\infty(\overline{\Omega}, \mathrm{M}_D^{N\times N})$, so that in particular $(0, -\mathbf{p}, \mathbf{p}) \in \mathcal{A}(0)$. Then (8.3) yields

$$-\int_\Omega \mathbf{T}(t) : \mathbf{p}\, dx + \int_\Omega \mathbf{T}^{\mathrm{p}}(t) : \mathbf{p}\, dx + \int_\Omega \mathbb{K}^{\mathrm{p}}(t) : \nabla \mathbf{p}\, dx = 0.$$

Since $\mathbf{p}$ takes values in the space of deviatoric matrices, we can replace $\mathbf{T}(t)$ by $\mathbf{T}_D(t)$ so that we obtain

$$\int_\Omega (\mathbf{T}^{\mathrm{p}}(t) - \mathbf{T}_D(t)) : \mathbf{p}\, dx + \int_\Omega \mathbb{K}^{\mathrm{p}}(t) : \nabla \mathbf{p}\, dx = 0. \tag{8.11}$$

We conclude that the first relation of (8.8) holds. As a consequence, in view of (8.9) and the definition of $\mathbb{K}^{\mathrm{p}}_{\mathrm{en}}(t)$, we have $\mathbb{K}^{\mathrm{p}}(t) \in L^2(\Omega; \mathrm{M}_D^{N\times N\times N})$ with divergence in $L^2(\Omega; \mathrm{M}_D^{N\times N})$, so that its normal trace on $\partial\Omega$ is well defined as an element of $H^{-1/2}(\partial\Omega; \mathbb{R}^{N\times N})$. By integrating by parts in (8.11) we obtain also the second relation of (8.8), and the proof is concluded. □

8.4. Note that relation (8.3) represents the balance of internal and external power expenditures on the whole body Ω (see section 3). Due to our variational approach which requires $\mathbf{E}^{\mathrm{p}}(t) \in BV(\Omega; \mathrm{M}_D^{N\times N})$ so that $D\mathbf{E}^{\mathrm{p}}(t)$ has also a singular part, a stress $\mathbb{S}^{\mathrm{p}}(t)$ associated to $D^s\mathbf{E}^{\mathrm{p}}(t)$ appears in the balance. In order to get a balance equation for a subbody $\mathcal{B} \subset\subset \Omega$ with a sufficiently smooth boundary, we can reason as follows. Let us assume to be in the physical case $N = 3$. As a consequence, admissible displacements v turn out to belong to $L^3(\Omega; \mathbb{R}^3)$. Let us assume for simplicity that $(v, \mathbf{e}, \mathbf{p}) \in \mathcal{A}(0)$ is such that $\mathbf{p}$ belongs also to $L^2(\Omega; M_D^{3\times 3})$, and let $\varphi \in C_c^\infty(\Omega)$. By (8.3) we can write

(8.12)

$$\begin{aligned}
&\int_\Omega \mathbf{T}(t) : (\varphi\mathbf{e})\, dx + \int_\Omega \mathbf{T}^{\mathrm{p}}(t) : (\varphi\mathbf{p})\, dx + \int_\Omega \mathbb{K}^{\mathrm{p}}(t) : (\varphi\nabla\mathbf{p})\, dx + \langle \mathbb{S}^{\mathrm{p}}(t), \varphi D^s\mathbf{p}\rangle \\
&\quad = \int_\Omega \mathbf{T}(t) : (\varphi\mathbf{e} + v \odot \nabla\varphi)\, dx + \int_\Omega \mathbf{T}^{\mathrm{p}}(t) : (\varphi\mathbf{p})\, dx + \int_\Omega \mathbb{K}^{\mathrm{p}}(t) : \nabla(\varphi\mathbf{p})\, dx \\
&\qquad + \langle \mathbb{S}^{\mathrm{p}}(t), D^s(\varphi\mathbf{p})\rangle - \int_\Omega \mathbf{T}(t) : (v \odot \nabla\varphi)\, dx - \int_\Omega \mathbb{K}^{\mathrm{p}}(t) : (\mathbf{p} \otimes \nabla\varphi)\, dx \\
&\qquad\quad = \langle \mathcal{L}(t), \varphi v\rangle - \int_\Omega \mathbf{T}(t) : (v \odot \nabla\varphi)\, dx - \int_\Omega \mathbb{K}^{\mathrm{p}}(t) : (\mathbf{p} \otimes \nabla\varphi)\, dx,
\end{aligned}$$

where the last equality follows since $(\varphi v, \varphi\mathbf{e} + v \odot \nabla\varphi, \varphi\mathbf{p}) \in \mathcal{A}(0)$ (we use $\mathbf{p} \in L^2(\Omega; M_D^{3\times 3})$ to ensure that $\mathrm{curl}(\varphi\mathbf{p}) \in L^2(\Omega; M^{3\times 3})$). Here $(v \odot \nabla\varphi)_{i,j} = (v_i\partial_j\varphi + v_j\partial_i\varphi)/2$. As a consequence we have that the distribution

$$\varphi \mapsto -\int_\Omega \mathbf{T}(t) : (v \odot \nabla\varphi)\, dx - \int_\Omega \mathbb{K}^{\mathrm{p}}(t) : (\mathbf{p} \otimes \nabla\varphi)\, dx$$

turns out to be a measure $\mu \in \mathcal{M}_b(\Omega)$. Moreover, by considering the measure $\eta \in \mathcal{M}_b(\Omega; \mathbb{R}^3)$ given by

$$\int_\Omega \psi\, d\eta := \int_\Omega \mathbf{T}(t) : (v \odot \psi)\, dx + \int_\Omega \mathbb{K}^{\mathrm{p}}(t) : (\mathbf{p} \otimes \psi)\, dx, \qquad \psi \in C_c^\infty\left(\Omega; \mathbb{R}^3\right),$$

we get immediately that $\mathrm{div}\eta = \mu$. According to [22], for every subset $\mathcal{B} \subset\subset \Omega$ with a sufficiently smooth boundary we have that η admits normal trace $\eta \cdot \nu$ on $\partial\mathcal{B}$ defined as an element of the dual of $C^1(\partial\mathcal{B})$, in such a way that the following Gauss–Green formula holds:

$$\int_{\mathcal{B}} d(\mathrm{div}\eta) = \langle \eta \cdot \nu, 1_{\partial\mathcal{B}} \rangle.$$

Let us denote formally $\eta\cdot\nu$ by $[\mathbf{T}(t)\nu\cdot v + \mathbb{K}^{\mathrm{p}}(t)\nu : \mathbf{p}]$, and let $[\mathbb{K}^{\mathrm{p}}(t) : \nabla\mathbf{p} + \mathbb{S}^{\mathrm{p}}(t) : D^s\mathbf{p}]$ be the measure such that

$$\int_\Omega \varphi\, d[\mathbb{K}^{\mathrm{p}}(t) : \nabla\mathbf{p} + \mathbb{S}^{\mathrm{p}}(t) : D^s\mathbf{p}] = \int_\Omega \mathbb{K}^{\mathrm{p}}(t) : (\varphi\nabla\mathbf{p})\, dx + \langle \mathbb{S}^{\mathrm{p}}(t), \varphi D^s\mathbf{p}\rangle.$$

By (8.12) we can write by choosing $\varphi = 1_{\mathcal{B}}$

$$\begin{aligned}(8.13)\qquad \int_{\mathcal{B}} \mathbf{T}(t) : \mathbf{e}\, dx + \int_{\mathcal{B}} \mathbf{T}^{\mathrm{p}}(t) : \mathbf{p}\, dx + [\mathbb{K}^{\mathrm{p}}(t) : \nabla\mathbf{p} + \mathbb{S}^{\mathrm{p}}(t) : D^s\mathbf{p}](\mathcal{B}) \\ = \int_{\mathcal{B}} f(t)\cdot v\, dx + \langle [\mathbf{T}(t)\nu\cdot v + \mathbb{K}^{\mathrm{p}}(t)\nu : \mathbf{p}], 1_{\partial\mathcal{B}}\rangle,\end{aligned}$$

which is a weak form for the balance of power expenditures for the subbody $\mathcal{B}$ relative to the virtual velocity $(v, \mathbf{e}, \mathbf{p}) \in \mathcal{A}(0)$.

The AC regularity in time for the quasi-static evolution is proved in the following proposition. The proof relies heavily on [8, Theorem 5.2]. We exploit the calculations in our context since we aim to understand the precise dependence on the material length scales l and L of the norms involved in the statement (in view of the convergence result of section 9, where we let $L, l \to 0$).

PROPOSITION 8.5. [illegible] $t \mapsto u(t), t \mapsto \mathbf{E}^{\mathrm{e}}(t), t \mapsto \mathbf{E}^{\mathrm{p}}(t)$ [illegible] $t \mapsto \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)$ [illegible] $[0,T]$ [illegible] $W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)$, $L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})$, $BV(\Omega;\mathrm{M}^{N\times N}_D)$, $L^2(\Omega;\mathrm{M}^{N\times N})$ [illegible] $t \in [0,T]$ [illegible]

$$(8.14)\qquad \|\dot u(t)\|_{W^{1,\frac{N}{N-1}}} \le C_1(w,\rho,\alpha,\mathbb{C},l)[\|\dot\rho(t)\|_{L^2} + \|\dot\rho_D(t)\|_{L^\infty} + \|\mathbf{E}\dot w(t)\|_{L^2}],$$

$$(8.15)\qquad \|\dot{\mathbf{E}}^{\mathrm{e}}(t)\|_{L^2} \le C_2(w,\rho,\alpha,\mathbb{C})[\|\dot\rho(t)\|_{L^2} + \|\dot\rho_D(t)\|_{L^\infty} + \|\mathbf{E}\dot w(t)\|_{L^2}],$$

$$(8.16)\qquad \|\dot{\mathbf{E}}^{\mathrm{p}}(t)\|_{BV} \le C_3(w,\rho,\alpha,\mathbb{C},l)[\|\dot\rho(t)\|_{L^2} + \|\dot\rho_D(t)\|_{L^\infty} + \|\mathbf{E}\dot w(t)\|_{L^2}],$$

$$(8.17)\qquad \|\mathrm{curl}\dot{\mathbf{E}}^{\mathrm{p}}(t)\|_{L^2} \le C_4(w,\rho,\alpha,\mathbb{C},L)[\|\dot\rho(t)\|_{L^2} + \|\dot\rho_D(t)\|_{L^\infty} + \|\mathbf{E}\dot w(t)\|_{L^2}],$$

[illegible] ρ [illegible] α [illegible] (4.13) (4.14) [illegible] $t \mapsto u(t)$ [illegible] $t \mapsto \mathbf{E}^{\mathrm{p}}(t)$ [illegible] $[0,T]$ [illegible] $BD(\Omega)$ [illegible] $L^1(\Omega;\mathrm{M}^{N\times N}_D)$ [illegible] 9 [illegible] [illegible] $t \in [0,T]$

$$(8.18)\qquad \|\dot u(t)\|_{BD} \le C_5(w,\rho,\alpha,\mathbb{C})[\|\dot\rho(t)\|_{L^2} + \|\dot\rho_D(t)\|_{L^\infty} + \|\mathbf{E}\dot w(t)\|_{L^2}],$$

$$(8.19)\qquad \|\dot{\mathbf{E}}^{\mathrm{p}}(t)\|_{L^1} \le C_6(w,\rho,\alpha,\mathbb{C})[\|\dot\rho(t)\|_{L^2} + \|\dot\rho_D(t)\|_{L^\infty} + \|\mathbf{E}\dot w(t)\|_{L^2}].$$

. Let $t_1, t_2 \in [0,T]$, with $t_1 < t_2$. Since by the very definition of $\mathcal{D}_{\mathcal{H}}$ we have $\mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}; t_1, t_2) \geq \mathcal{H}(\mathbf{E}^{\mathrm{p}}(t_2) - \mathbf{E}^{\mathrm{p}}(t_1))$, by the energy balance (5.3) we may write

$$\begin{aligned}(8.20)\quad &\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t_2)) - \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t_1)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_2)) - \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_1))\\ &\qquad + \mathcal{H}(\mathbf{E}^{\mathrm{p}}(t_2) - \mathbf{E}^{\mathrm{p}}(t_1)) - \langle \mathcal{L}(t_2), u(t_2)\rangle + \langle \mathcal{L}(t_1), u(t_1)\rangle\\ &\qquad \leq \int_{t_1}^{t_2}\int_\Omega \mathbf{T}(\tau) : \mathbf{E}\dot{w}(\tau)\, dx\, d\tau - \int_{t_1}^{t_2} \langle \dot{\mathcal{L}}(\tau), u(\tau)\rangle\, d\tau - \int_{t_1}^{t_2} \langle \mathcal{L}(\tau), \dot{w}(\tau)\rangle\, d\tau.\end{aligned}$$

Let us consider $(v, \mathbf{e}, \mathbf{p}) \in \mathcal{A}(0)$ such that

$$v := u(t_2) - u(t_1) - (w(t_2) - w(t_1)), \quad \mathbf{e} := \mathbf{E}^{\mathrm{e}}(t_2) - \mathbf{E}^{\mathrm{e}}(t_1) - (\mathbf{E}w(t_2) - \mathbf{E}w(t_1)),$$

and $\mathbf{p} := \mathbf{E}^{\mathrm{p}}(t_2) - \mathbf{E}^{\mathrm{p}}(t_1)$. By combining (8.1) and (8.2), we deduce that

$$\begin{aligned}(8.21)\quad &-\int_\Omega \mathbf{T}(t_1) : (\mathbf{E}^{\mathrm{e}}(t_2) - \mathbf{E}^{\mathrm{e}}(t_1) - (\mathbf{E}w(t_2) - \mathbf{E}w(t_1)))\, dx\\ &\qquad - \mu L^2 \int_\Omega \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_1) : (\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_2) - \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_1))\, dx\\ &\qquad + \langle \mathcal{L}(t_1), u(t_2) - u(t_1) - (w(t_2) - w(t_1))\rangle \leq \mathcal{H}(\mathbf{E}^{\mathrm{p}}(t_2) - \mathbf{E}^{\mathrm{p}}(t_1)).\end{aligned}$$

By inserting (8.21) into (8.20) and taking into account (4.15), we obtain

$$\begin{aligned}&\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t_2) - \mathbf{E}^{\mathrm{e}}(t_1)) + \mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_2) - \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_1))\\ &\quad \leq \int_{t_1}^{t_2}\int_\Omega \mathbf{T}(\tau) : \mathbf{E}\dot{w}(\tau)\, dx\, d\tau - \int_{t_1}^{t_2} \langle \dot{\mathcal{L}}(\tau), u(\tau)\rangle\, d\tau - \int_{t_1}^{t_2} \langle \mathcal{L}(\tau), \dot{w}(\tau)\rangle\, d\tau\\ &\qquad + \langle \mathcal{L}(t_2) - \mathcal{L}(t_1), u(t_2)\rangle - \int_\Omega \mathbf{T}(t_1) : (\mathbf{E}w(t_2) - \mathbf{E}w(t_1))\, dx\\ &\qquad\qquad + \langle \mathcal{L}(t_1), w(t_2) - w(t_1)\rangle\\ &\quad = \int_{t_1}^{t_2}\int_\Omega (\mathbf{T}(\tau) - \mathbf{T}(t_1)) : \mathbf{E}\dot{w}(\tau)\, dx\, d\tau - \int_{t_1}^{t_2} \langle \dot{\mathcal{L}}(\tau), u(\tau) - u(t_2)\rangle\, d\tau\\ &\qquad\qquad - \int_{t_1}^{t_2} \langle \mathcal{L}(\tau) - \mathcal{L}(t_1), \dot{w}(\tau)\rangle\, d\tau\\ &= \int_{t_1}^{t_2}\int_\Omega (\mathbf{T}(\tau) - \mathbf{T}(t_1)) : \mathbf{E}\dot{w}(\tau)\, dx\, d\tau - \int_{t_1}^{t_2}\int_\Omega \dot{\rho}(\tau) : (\mathbf{E}^{\mathrm{e}}(\tau) - \mathbf{E}^{\mathrm{e}}(t_2))\, dx\, d\tau\\ &- \int_{t_1}^{t_2}\int_\Omega \dot{\rho}_D(\tau) : (\mathbf{E}^{\mathrm{p}}(\tau) - \mathbf{E}^{\mathrm{p}}(t_2))\, dx\, d\tau - \int_{t_1}^{t_2}\int_\Omega (\rho(\tau) - \rho(t_1)) : \mathbf{E}\dot{w}(\tau)\, dx\, d\tau.\end{aligned}$$

By the coercivity estimate (4.8) for the elasticity tensor $\mathbb{C}$ we deduce that

$$\begin{aligned}(8.22)\quad &\alpha_{\mathbb{C}}\|\mathbf{E}^{\mathrm{e}}(t_2) - \mathbf{E}^{\mathrm{e}}(t_1)\|_{L^2}^2 + \frac{\mu L^2}{2}\|\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_2) - \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_1)\|_{L^2}^2\\ &\leq \beta_{\mathbb{C}}\int_{t_1}^{t_2} \|\mathbf{E}^{\mathrm{e}}(\tau) - \mathbf{E}^{\mathrm{e}}(t_1)\|_{L^2}\|\mathbf{E}\dot{w}(\tau)\|_{L^2}\, d\tau + \int_{t_1}^{t_2} \|\dot{\rho}\|_{L^2}\|\mathbf{E}^{\mathrm{e}}(\tau) - \mathbf{E}^{\mathrm{e}}(t_2)\|_{L^2}\, d\tau\\ &+ \int_{t_1}^{t_2} \|\dot{\rho}_D(\tau)\|_{L^\infty}\|\mathbf{E}^{\mathrm{p}}(\tau) - \mathbf{E}^{\mathrm{p}}(t_2)\|_{L^1}\, d\tau + \int_{t_1}^{t_2} \|\rho(\tau) - \rho(t_1)\|_{L^2}\|\mathbf{E}\dot{w}(\tau)\|_{L^2}\, d\tau.\end{aligned}$$

By (4.16) we have for $t_1 \le s \le t_2$

$$\begin{aligned}(8.23)\quad &\frac{\alpha}{2}\|\mathbf{E}^{\mathrm{p}}(t_2)-\mathbf{E}^{\mathrm{p}}(s)\|_{L^1}+\alpha_l\|D\mathbf{E}^{\mathrm{p}}(t_2)-D\mathbf{E}^{\mathrm{p}}(s)\|_{\mathcal{M}_b}\\ &\qquad\le \mathcal{H}\left(\mathbf{E}^{\mathrm{p}}(t_2)-\mathbf{E}^{\mathrm{p}}(s)\right)-\int_\Omega \rho_D(t_2):\left(\mathbf{E}^{\mathrm{p}}(t_2)-\mathbf{E}^{\mathrm{p}}(s)\right)dx,\end{aligned}$$

where $\alpha_l := \min\{l\frac{\alpha}{2}, lS_Y\}$. By combining (8.23) and (8.20) with $t_1 = s$ and using (4.15), we obtain

$$\begin{aligned}(8.24)\quad &\frac{\alpha}{2}\|\mathbf{E}^{\mathrm{p}}(t_2)-\mathbf{E}^{\mathrm{p}}(s)\|_{L^1}+\alpha_l\|D\mathbf{E}^{\mathrm{p}}(t_2)-D\mathbf{E}^{\mathrm{p}}(s)\|_{\mathcal{M}_b}\\ &\quad\le \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(s))-\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t_2))+\mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(s))-\mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_2))\\ &\qquad+\langle\mathcal{L}(t_2),u(t_2)\rangle-\langle\mathcal{L}(s),u(s)\rangle+\int_s^{t_2}\!\!\int_\Omega \mathbf{T}(\tau):\mathbf{E}\dot w(\tau)\,dx\,d\tau\\ &\qquad\qquad-\int_s^{t_2}\langle\dot{\mathcal{L}}(\tau),u(\tau)\rangle\,d\tau-\int_s^{t_2}\langle\mathcal{L}(\tau),\dot w(\tau)\rangle\,d\tau\\ &\qquad\qquad\qquad-\int_\Omega \rho_D(t_2)(\mathbf{E}^{\mathrm{p}}(t_2)-\mathbf{E}^{\mathrm{p}}(s))\,dx\\ &\quad\le \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(s))-\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t_2))+\mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(s))-\mathcal{Q}_2(\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_2))\\ &\qquad+\int_\Omega \rho(t_2):(\mathbf{E}^{\mathrm{e}}(t_2)-\mathbf{E}^{\mathrm{e}}(s))\,dx+\int_\Omega(\rho(t_2)-\rho(s)):\mathbf{E}^{\mathrm{e}}(s)\,dx\\ &\qquad\qquad+\int_\Omega(\rho_D(t_2)-\rho_D(s)):\mathbf{E}^{\mathrm{p}}(s)\,dx\\ &\qquad-\int_s^{t_2}\!\!\int_\Omega\left\{\dot\rho(\tau):\mathbf{E}^{\mathrm{e}}(\tau)+\dot\rho_D(\tau):\mathbf{E}^{\mathrm{p}}(\tau)-(\mathbf{T}(\tau)-\rho(\tau)):\mathbf{E}\dot w(\tau)\right\}dx\,d\tau.\end{aligned}$$

Notice that

$$\sup_\tau\|\rho(\tau)\|_{L^2},\quad \sup_\tau\|\rho_D(\tau)\|_{L^\infty},$$

and

$$\sup_\tau\|\mathbf{E}^{\mathrm{e}}(\tau)\|_{L^2},\quad \sup_\tau\|\mathbf{E}^{\mathrm{p}}(\tau)\|_{L^1},\quad \sup_\tau\|\mathrm{curl}\mathbf{E}^{\mathrm{p}}(\tau)\|_{L^2}$$

are finite (in fact $t\mapsto\mathbf{E}^{\mathrm{p}}(t)$ has bounded variation, while for $\mathbf{E}^{\mathrm{e}}(t)$ and $\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)$ we can use the energy balance (5.3)). From (8.24) we obtain for every $t_1 \le s \le t_2$

$$\begin{aligned}(8.25)\quad &\frac{\alpha}{2}\|\mathbf{E}^{\mathrm{p}}(t_2)-\mathbf{E}^{\mathrm{p}}(s)\|_{L^1}+\alpha_l\|D\mathbf{E}^{\mathrm{p}}(t_2)-D\mathbf{E}^{\mathrm{p}}(s)\|_{\mathcal{M}_b}\\ &\quad\le C_1\left(\|\mathbf{E}^{\mathrm{e}}(t_2)-\mathbf{E}^{\mathrm{e}}(s)\|_{L^2}+\sqrt{\frac{\mu}{2}}L\|\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_2)-\mathrm{curl}\mathbf{E}^{\mathrm{p}}(s)\|_{L^2}\right.\\ &\qquad\qquad\left.+\int_s^{t_2}\psi(\tau)\,d\tau\right),\end{aligned}$$

where

$$(8.26)\qquad \psi(\tau) := \|\dot\rho(\tau)\|_{L^2}+\|\dot\rho_D(\tau)\|_{L^\infty}+\|\mathbf{E}\dot w(\tau)\|_{L^2}$$

and C_1 depends on ρ, $\sup_\tau \|\mathbf{E}^{\mathrm{e}}(\tau)\|_{L^2}$, $\sup_\tau \|\mathbf{E}^{\mathrm{p}}(\tau)\|_{L^1}$, $\sup_\tau L\|\mathrm{curl}\mathbf{E}^{\mathrm{p}}(\tau)\|_{L^2}$, and the elasticity tensor $\mathbb{C}$. By (8.22) we conclude that

$$\begin{aligned}
&\alpha_{\mathbb{C}}\|\mathbf{E}^{\mathrm{e}}(t_2)-\mathbf{E}^{\mathrm{e}}(t_1)\|_{L^2}^2+\frac{\mu L^2}{2}\|\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_2)-\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_1)\|_{L^2}^2\\
&\quad\le C_2\left(\|\mathbf{E}^{\mathrm{e}}(t_2)-\mathbf{E}^{\mathrm{e}}(t_1)\|_{L^2}+\sqrt{\frac{\mu}{2}}L\|\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_2)-\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_1)\|_{L^2}\right)\int_{t_1}^{t_2}\psi(\tau)\,d\tau\\
&\quad+C_2\int_{t_1}^{t_2}\psi(\tau)\left(\|\mathbf{E}^{\mathrm{e}}(\tau)-\mathbf{E}^{\mathrm{e}}(t_1)\|_{L^2}+\sqrt{\frac{\mu}{2}}L\|\mathrm{curl}\mathbf{E}^{\mathrm{p}}(\tau)-\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_1)\|_{L^2}\right)d\tau\\
&\qquad\qquad+C_2\left(\int_{t_1}^{t_2}\psi(\tau)\,d\tau\right)^2,
\end{aligned}$$

where C_2 depends also on α. By Cauchy's inequality we obtain

$$\begin{aligned}
&\|\mathbf{E}^{\mathrm{e}}(t_2)-\mathbf{E}^{\mathrm{e}}(t_1)\|_{L^2}^2+\frac{\mu L^2}{2}\|\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_2)-\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_1)\|_{L^2}^2\\
&\quad\le C_3\int_{t_1}^{t_2}\psi(\tau)\left(\|\mathbf{E}^{\mathrm{e}}(\tau)-\mathbf{E}^{\mathrm{e}}(t_1)\|_{L^2}+\sqrt{\frac{\mu}{2}}L\|\mathrm{curl}\mathbf{E}^{\mathrm{p}}(\tau)-\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_1)\|_{L^2}\right)d\tau\\
&\qquad\qquad+C_3\left(\int_{t_1}^{t_2}\psi(\tau)\,d\tau\right)^2.
\end{aligned}$$

By means of a Gronwall-type lemma [8, Lemma 5.3] we get in particular that

$$\|\mathbf{E}^{\mathrm{e}}(t_2)-\mathbf{E}^{\mathrm{e}}(t_1)\|_{L^2}+\sqrt{\frac{\mu}{2}}L\|\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_2)-\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t_1)\|_{L^2}\le C_4\int_{t_1}^{t_2}\psi(\tau)\,d\tau, \tag{8.27}$$

where C_4 depends on ρ, α, $\sup_\tau \|\mathbf{E}^{\mathrm{e}}(\tau)\|_{L^2}$, $\sup_\tau \|\mathbf{E}^{\mathrm{p}}(\tau)\|_{L^1}$, $\sup_\tau L\|\mathrm{curl}\mathbf{E}^{\mathrm{p}}(\tau)\|_{L^2}$, and the elasticity tensor $\mathbb{C}$. As a consequence we get that $t\mapsto \mathbf{E}^{\mathrm{e}}(t)$ and $t\mapsto \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)$ are absolutely continuous from $[0,T]$ to $L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})$ and $L^2(\Omega;\mathrm{M}^{N\times N})$, respectively. By (8.25), we get that $t\mapsto \mathbf{E}^{\mathrm{p}}(t)$ is absolutely continuous from $[0,T]$ to $BV(\Omega;\mathrm{M}^{N\times N}_D)$.

Let us now come to the proof of (8.14)–(8.17). By the energy balance (5.3), and by the very definition of $\mathcal{H}$, we deduce that

$$\|\mathbf{E}^{\mathrm{p}}(t)\|_{L^1}\le C_5\left(1+\int_0^t(1+\psi(\tau))\|\mathbf{E}^{\mathrm{e}}(\tau)\|_{L^2}\,d\tau+\int_0^t(1+\psi(\tau))\|\mathbf{E}^{\mathrm{p}}(\tau)\|_{L^1}\,d\tau\right),$$

where ψ is as in (8.26) and C_5 depends only on the initial conditions and on w,ρ,α, and $\mathbb{C}$. By means of the classical Gronwall lemma and taking the sup in t, we obtain

$$\sup_{t\in[0,T]}\|\mathbf{E}^{\mathrm{p}}(t)\|_{L^1}\le C_6\left(1+\sup_{t\in[0,T]}\|\mathbf{E}^{\mathrm{e}}(t)\|_{L^2}\right).$$

By the energy balance (5.3) we conclude that $\sup_{t\in[0,T]}\|\mathbf{E}^{\mathrm{e}}(t)\|_{L^2}$ is bounded uniformly independently of l and L, so that the same holds for $\sup_{t\in[0,T]}\|\mathbf{E}^{\mathrm{p}}(t)\|_{L^1}$ and $\sup_{t\in[0,T]}L\|\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)\|_{L^2}$. By (8.27) we conclude that (8.15) and (8.17) hold. Inequalities (8.16) and (8.19) follow by (8.25). Finally the absolute continuity of $t\mapsto u(t)$ from $[0,T]$ to $W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)$ and inequality (8.14) follow from the compatibility condition $\mathbf{E}u(t):=\mathbf{E}^{\mathrm{e}}(t)+\mathbf{E}^{\mathrm{p}}(t)$ and Korn's inequality. Inequality (8.18) follows in a similar way. □

8.6. Notice that the constants $C_1, \dots, C_6$ of Proposition 8.5 depend also on the initial condition $(u_0, \mathbf{E}^{\mathrm{e}}_0, \mathbf{E}^{\mathrm{p}}_0)$. More precisely, from the previous proof it can be evicted that they depend on $|\mathcal{E}(0)|$ and $\|\mathbf{E}^{\mathrm{p}}_0\|_{L^1(\Omega;\mathrm{M}^{N\times N}_D)}$.

In order to prove the uniqueness result and the flow rule, we need the following lemma.

LEMMA 8.7. $t \in [0,T]$ $\dot u(t), \dot{\mathbf{E}}^{\mathrm{e}}(t), \dot{\mathbf{E}}^{\mathrm{p}}(t)$ $\dot w(t)$

$$\mathcal{H}(\dot{\mathbf{E}}^{\mathrm{p}}(t)) = -\int_\Omega \mathbf{T}(t) : (\dot{\mathbf{E}}^{\mathrm{e}}(t) - \mathbf{E}\dot w(t))\,dx - \mu L^2 \int_\Omega \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t) : \mathrm{curl}\dot{\mathbf{E}}^{\mathrm{p}}(t)\,dx + \langle \mathcal{L}(t), \dot u(t) - \dot w(t)\rangle \tag{8.28}$$

$$\mathcal{H}(\dot{\mathbf{E}}^{\mathrm{p}}(t)) = \int_\Omega \mathbf{T}^{\mathrm{p}}(t) : \dot{\mathbf{E}}^{\mathrm{p}}(t)\,dx + \int_\Omega \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t) : \nabla\dot{\mathbf{E}}^{\mathrm{p}}(t)\,dx + \langle \mathbb{S}^{\mathrm{p}}(t), D^s\dot{\mathbf{E}}^{\mathrm{p}}(t)\rangle. \tag{8.29}$$

. Since by Proposition 8.5 the map $t \mapsto \mathbf{E}^{\mathrm{p}}(t)$ is absolutely continuous from $[0,T]$ to $BV(\Omega;\mathrm{M}^{N\times N}_D)$, by [8, Theorem 7.1] we obtain

$$\mathcal{D}_{\mathcal{H}}(\mathbf{E}^{\mathrm{p}}; 0, t) = \int_0^t \mathcal{H}(\dot{\mathbf{E}}^{\mathrm{p}}(\tau))\,d\tau.$$

Then by differentiating the energy balance equation (5.3) we obtain for a.e. $t \in [0,T]$

$$\begin{aligned}\int_\Omega \mathbf{T}(t) : \dot{\mathbf{E}}^{\mathrm{e}}(t)\,dx + \mu L^2 \int_\Omega \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t) : \mathrm{curl}\dot{\mathbf{E}}^{\mathrm{p}}(t)\,dx \\ - \langle \dot{\mathcal{L}}(t), u(t)\rangle - \langle \mathcal{L}(t), \dot u(t)\rangle + \mathcal{H}(\dot{\mathbf{E}}^{\mathrm{p}}(t)) \\ = \int_\Omega \mathbf{T}(t) : \mathbf{E}\dot w(t)\,dx - \langle \dot{\mathcal{L}}(t), u(t)\rangle - \langle \mathcal{L}(t), \dot w(t)\rangle\end{aligned}$$

so that (8.28) follows. Since $(\dot u(t) - \dot w(t), \dot{\mathbf{E}}^{\mathrm{e}}(t) - \mathbf{E}\dot w(t), \dot{\mathbf{E}}^{\mathrm{p}}(t)) \in \mathcal{A}(0)$, by (8.2) we get that (8.29) holds. □

Let us now prove the uniqueness result concerning the elastic strain $\mathbf{E}^{\mathrm{e}}(t)$ and the "energetic plastic strain" $\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)$.

PROPOSITION 8.8. $t \mapsto \mathbf{E}^{\mathrm{e}}(t)$ $t \mapsto \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)$ $(u_0, \mathbf{E}^{\mathrm{e}}_0, \mathbf{E}^{\mathrm{p}}_0)$

. Let $t \mapsto (\tilde u(t), \widetilde{\mathbf{E}^{\mathrm{e}}}(t), \widetilde{\mathbf{E}^{\mathrm{p}}}(t))$ be another quasi-static evolution associated to the same initial condition $(u_0, \mathbf{E}^{\mathrm{e}}_0, \mathbf{E}^{\mathrm{p}}_0)$. Let $\widetilde{\mathbf{T}^{\mathrm{p}}}(t)$, $\widetilde{\mathbb{K}^{\mathrm{p}}}(t)$, and $\widetilde{\mathbb{S}^{\mathrm{p}}}(t)$ be the associated stresses according to Lemma 8.1 and Proposition 8.3. By (8.28), (8.1), and (8.2) we have for a.e. $t \in [0,T]$

$$\begin{aligned}-\int_\Omega \mathbf{T}(t) : (\dot{\mathbf{E}}^{\mathrm{e}}(t) - \mathbf{E}\dot w(t))\,dx - \mu L^2 \int_\Omega \mathrm{curl}\mathbf{E}^{\mathrm{p}}(t) : \mathrm{curl}\dot{\mathbf{E}}^{\mathrm{p}}(t)\,dx \\ + \langle \mathcal{L}(t), \dot u(t) - \dot w(t)\rangle = \mathcal{H}(\dot{\mathbf{E}}^{\mathrm{p}}(t)) \\ \geq \int_\Omega \widetilde{\mathbf{T}^{\mathrm{p}}}(t) : \dot{\mathbf{E}}^{\mathrm{p}}(t)\,dx + \int_\Omega \widetilde{\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}}(t) : \nabla\dot{\mathbf{E}}^{\mathrm{p}}(t)\,dx + \langle \widetilde{\mathbb{S}^{\mathrm{p}}}(t), D^s\dot{\mathbf{E}}^{\mathrm{p}}(t)\rangle \\ = -\int_\Omega \widetilde{\mathbf{T}}(t) : (\dot{\mathbf{E}}^{\mathrm{e}}(t) - \mathbf{E}\dot w(t))\,dx - \mu L^2 \int_\Omega \mathrm{curl}\widetilde{\mathbf{E}^{\mathrm{p}}}(t) : \mathrm{curl}\dot{\mathbf{E}}^{\mathrm{p}}(t)\,dx \\ + \langle \mathcal{L}(t), \dot u(t) - \dot w(t)\rangle.\end{aligned}$$

We obtain

$$\int_\Omega \Big[\mathbf{T}(t)-\widetilde{\mathbf{T}}(t)\Big] : \Big[\dot{\mathbf{E}}^{\mathrm{e}}(t)-\mathbf{E}\dot{w}(t)\Big]\,dx+\mu L^2\int_\Omega \Big[\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)-\mathrm{curl}\widetilde{\mathbf{E}^{\mathrm{p}}}(t)\Big] : \mathrm{curl}\dot{\mathbf{E}}^{\mathrm{p}}(t)\,dx \le 0.$$

Similarly we obtain

$$\int_\Omega \Big[\widetilde{\mathbf{T}}(t)-\mathbf{T}(t)\Big] : \Big[\dot{\widetilde{\mathbf{E}^{\mathrm{e}}}}(t)-\mathbf{E}\dot{w}(t)\Big]\,dx+\mu L^2\int_\Omega \Big[\mathrm{curl}\widetilde{\mathbf{E}^{\mathrm{p}}}(t)-\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)\Big] : \mathrm{curl}\dot{\widetilde{\mathbf{E}^{\mathrm{p}}}}(t)\,dx \le 0.$$

By summing the two inequalities we get

$$\begin{aligned}\int_\Omega \Big[\mathbf{T}(t)-\widetilde{\mathbf{T}}(t)\Big] : \Big[\dot{\mathbf{E}}^{\mathrm{e}}(t)-\dot{\widetilde{\mathbf{E}^{\mathrm{e}}}}(t)\Big]\,dx\\ +\mu L^2\int_\Omega \Big[\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)-\mathrm{curl}\widetilde{\mathbf{E}^{\mathrm{p}}}(t)\Big] : \Big[\mathrm{curl}\dot{\mathbf{E}}^{\mathrm{p}}(t)-\mathrm{curl}\dot{\widetilde{\mathbf{E}^{\mathrm{p}}}}(t)\Big]\,dx \le 0,\end{aligned}$$

so that for a.e. $t\in[0,T]$ we have

$$\begin{aligned}\frac{d}{dt}\Bigg(\int_\Omega \mathbb{C}\Big[\mathbf{E}^{\mathrm{e}}(t)-\widetilde{\mathbf{E}^{\mathrm{e}}}(t)\Big] : \Big[\mathbf{E}^{\mathrm{e}}(t)-\widetilde{\mathbf{E}^{\mathrm{e}}}(t)\Big]\,dx\\ +\mu L^2\int_\Omega |\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)-\mathrm{curl}\widetilde{\mathbf{E}^{\mathrm{p}}}(t)|^2\,dx\Bigg) \le 0.\end{aligned}$$

Since we have $\widetilde{\mathbf{E}^{\mathrm{e}}}(0)=\mathbf{E}^{\mathrm{e}}_0=\mathbf{E}^{\mathrm{e}}(0)$ and $\mathrm{curl}\widetilde{\mathbf{E}^{\mathrm{p}}}(0)=\mathrm{curl}\mathbf{E}^{\mathrm{p}}_0=\mathrm{curl}\mathbf{E}^{\mathrm{p}}(0)$, the previous inequality and the absolute continuity of the maps involved yield that $\mathbf{E}^{\mathrm{e}}(t)=\widetilde{\mathbf{E}^{\mathrm{e}}}(t)$ and $\mathrm{curl}\widetilde{\mathbf{E}^{\mathrm{p}}}(t)=\mathrm{curl}\mathbf{E}^{\mathrm{p}}(t)$ for every $t\in[0,T]$, so that the proof is concluded. □

We are now in a position to prove the flow rule for the Gurtin–Anand model. Let us start with the following weak form.

PROPOSITION 8.9 (weak form of the flow rule). [illegible] $t\in[0,T]$ [illegible]

(a) [illegible] $(\mathbf{A},\mathbb{B})\in L^\infty(\Omega;\mathrm{M}^{N\times N}_D)\times L^\infty(\Omega;\mathrm{M}^{N\times N\times N}_D)$ [illegible] $\sqrt{|\mathbf{A}(x)|^2+l^{-2}|\mathbb{B}(x)|^2}\le S_Y$ [illegible] $x\in\Omega$ [illegible]

$$\int_\Omega (\mathbf{T}^{\mathrm{p}}(t)-\mathbf{A}) : \dot{\mathbf{E}}^{\mathrm{p}}(t)\,dx+\int_\Omega (\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t)-\mathbb{B}) : \nabla\dot{\mathbf{E}}^{\mathrm{p}}(t)\,dx \ge 0. \tag{8.30}$$

(b) [illegible] $\mathbb{L}\in(\mathcal{M}_b(\Omega;\mathrm{M}^{N\times N\times N}_D)^*$ [illegible] $\|\mathbb{L}\|_{(\mathcal{M}_b(\Omega;\mathrm{M}^{N\times N\times N}_D))^*}\le lS_Y$ [illegible]

$$\langle \mathbb{S}^{\mathrm{p}}(t)-\mathbb{L}, D^s\dot{\mathbf{E}}^{\mathrm{p}}(t)\rangle \ge 0. \tag{8.31}$$

[illegible]. Recall that for a.e. $t\in[0,T]$

$$\begin{aligned}\mathcal{H}(\dot{\mathbf{E}}^{\mathrm{p}}(t)) &= \mathcal{F}(\dot{\mathbf{E}}^{\mathrm{p}}(t),\nabla\dot{\mathbf{E}}^{\mathrm{p}}(t),D^s\dot{\mathbf{E}}^{\mathrm{p}}(t))\\ &:= S_Y\int_\Omega \sqrt{|\dot{\mathbf{E}}^{\mathrm{p}}|^2+l^2|\nabla\dot{\mathbf{E}}^{\mathrm{p}}|^2}\,dx+lS_Y|D^s\dot{\mathbf{E}}^{\mathrm{p}}|(\Omega).\end{aligned}$$

Since $\mathcal{F}: L^1(\Omega;\mathrm{M}^{N\times N}_D)\times L^1(\Omega;\mathrm{M}^{N\times N\times N}_D)\times\mathcal{M}_b(\Omega;\mathrm{M}^{N\times N\times N}_D)\to[0,+\infty[$ is continuous (with respect to the strong norm), we have $\mathcal{F}(\dot{\mathbf{E}}^{\mathrm{p}}(t),\nabla\dot{\mathbf{E}}^{\mathrm{p}}(t),D^s\dot{\mathbf{E}}^{\mathrm{p}}(t))=$

$\mathcal{F}^{**}(\dot{\mathbf{E}}^{\mathrm{p}}(t), \nabla\dot{\mathbf{E}}^{\mathrm{p}}(t), D^s\dot{\mathbf{E}}^{\mathrm{p}}(t))$, where $*$ denotes the Fenchel transformation. Moreover, we have that $\mathcal{F}^*$ is the indicator function of the set

$$\mathcal{K} := \Big\{(\mathbf{A},\mathbb{B},\mathbb{L}) \in L^\infty\left(\Omega;\mathrm{M}^{N\times N}_D\right) \times L^\infty\left(\Omega;\mathrm{M}^{N\times N\times N}_D\right) \times \left(\mathcal{M}_b\left(\Omega;\mathrm{M}^{N\times N\times N}_D\right)\right)^* : \sqrt{|\mathbf{A}|^2 + l^{-2}|\mathbb{B}|^2} \le S_Y \text{ a.e. in } \Omega \text{ and } \|\mathbb{L}\|_{\mathcal{M}_b^*} \le lS_Y\Big\}.$$

As a consequence, by (8.29) we deduce that for every $(\mathbf{A},\mathbb{B},\mathbb{L}) \in \mathcal{K}$ we have

$$\int_\Omega (\mathbf{T}^{\mathrm{p}}(t) - \mathbf{A}) : \dot{\mathbf{E}}^{\mathrm{p}}(t)\,dx + \int_\Omega (\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t) - \mathbb{B}) : \nabla\dot{\mathbf{E}}^{\mathrm{p}}(t)\,dx + \langle \mathbb{S}^{\mathrm{p}}(t) - \mathbb{L}, D^s\dot{\mathbf{E}}^{\mathrm{p}}(t)\rangle \ge 0.$$

By choosing $\mathbb{L} = \mathbb{S}^{\mathrm{p}}(t)$, which is possible in view of the constraint (8.10), we obtain (8.30). Inequality (8.31) follows by choosing $\mathbf{A} = \mathbf{T}^{\mathrm{p}}(t)$ and $\mathbb{B} = \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t)$. □

Let us now prove that the weak flow rule (8.30) for the stresses $\mathbf{T}^{\mathrm{p}}(t)$ and $\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t)$ reduces under suitable regularity assumptions to the usual flow rule given by Gurtin and Anand.

PROPOSITION 8.10 (flow rule). [illegible] $t \in [0,T]$ [illegible] $\dot{\mathbf{E}}^{\mathrm{p}}(t)$ [illegible] $x \in \Omega$ [illegible] $\mathbf{T}^{\mathrm{p}}(t)$, $\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t)$, $\dot{\mathbf{E}}^{\mathrm{p}}(t)$, $\nabla\dot{\mathbf{E}}^{\mathrm{p}}(t)$ [illegible]

$$\sqrt{|\mathbf{T}^{\mathrm{p}}(t,x)|^2 + l^{-2}|\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x)|^2} < S_Y,$$

[illegible]

$$(\dot{\mathbf{E}}^{\mathrm{p}}(t,x), \nabla\dot{\mathbf{E}}^{\mathrm{p}}(t,x)) = (0,0), \tag{8.32}$$

[illegible]

$$\sqrt{|\mathbf{T}^{\mathrm{p}}(t,x)|^2 + l^{-2}|\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x)|^2} = S_Y,$$

[illegible]

$$\begin{cases} \mathbf{T}^{\mathrm{p}}(t,x) = S_Y \dfrac{\dot{\mathbf{E}}^{\mathrm{p}}(t,x)}{\sqrt{|\dot{\mathbf{E}}^{\mathrm{p}}(t,x)|^2 + l^2|\nabla\dot{\mathbf{E}}^{\mathrm{p}}(t,x)|^2}}, \\ \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x) = S_Y \dfrac{l^2\nabla\dot{\mathbf{E}}^{\mathrm{p}}(t,x)}{\sqrt{|\dot{\mathbf{E}}^{\mathrm{p}}(t,x)|^2 + l^2|\nabla\dot{\mathbf{E}}^{\mathrm{p}}(t,x)|^2}}. \end{cases} \tag{8.33}$$

[illegible]. Let K be the convex set defined as

$$K := \left\{(\mathbf{A},\mathbb{B}) \in \mathrm{M}^{N\times N}_D \times \mathrm{M}^{N\times N\times N}_D : \sqrt{|\mathbf{A}|^2 + l^{-2}|\mathbb{B}|^2} \le S_Y\right\}.$$

Let π_K denote the projection onto K, and let π^1_K and π^2_K be its components. Let $(\mathbf{A},\mathbb{B}) \in K$, $\varepsilon > 0$, and let us set

$$\mathcal{C}^\varepsilon_{\mathbf{A},\mathbb{B}} := (\mathbf{T}^{\mathrm{p}}(t) + \varepsilon(\mathbf{A} - \mathbf{T}^{\mathrm{p}}(t,x)), \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t) + \varepsilon(\mathbb{B} - \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x))) \in L^\infty\left(\Omega;\mathrm{M}^{N\times N}_D\right) \times L^\infty\left(\Omega;\mathrm{M}^{N\times N\times N}_D\right).$$

For every $r > 0$ let us set

$$\mathbf{F} := \begin{cases} \pi^1_K\left(\mathcal{C}^\varepsilon_{\mathbf{A},\mathbb{B}}\right) & \text{in } B(x,r), \\ \mathbf{T}^{\mathrm{p}}(t) & \text{outside } B(x,r) \end{cases}$$

and

$$\mathbb{G} := \begin{cases} \pi_K^2\left(\mathcal{C}^{\varepsilon}_{\mathbf{A},\mathbb{B}}\right) & \text{in } B(x,r), \\ \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t) & \text{outside } B(x,r). \end{cases}$$

Since $(\mathbf{F}, \mathbb{G})$ are admissible for the weak flow rule (8.30), we obtain

$$\frac{1}{r^N}\left[\int_{B(x,r)} (\mathbf{T}^{\mathrm{p}}(t) - \mathbf{F}) : \dot{\mathbf{E}}^{\mathrm{p}}(t)\, dx + \int_{B(x,r)} (\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t) - \mathbb{G}) : \nabla\dot{\mathbf{E}}^{\mathrm{p}}(t)\, dx\right] \geq 0.$$

Since π_K is a Lipschitz mapping, we have that x is also a Lebesgue point for $\pi_K(\mathcal{C}^{\varepsilon}_{\mathbf{A},\mathbb{B}})$ with Lebesgue value

$$\pi_K(\mathbf{T}^{\mathrm{p}}(t,x) + \varepsilon(\mathbf{A} - \mathbf{T}^{\mathrm{p}}(t,x)), \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x) + \varepsilon(\mathbb{B} - \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x))).$$

By sending $r \to 0$ and considering $0 < \varepsilon < 1$, in view of the convexity of K, we obtain

$$(\mathbf{A} - \mathbf{T}^{\mathrm{p}}(t,x)) : \dot{\mathbf{E}}^{\mathrm{p}}(t,x) + (\mathbb{B} - \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x)) : \nabla\dot{\mathbf{E}}^{\mathrm{p}}(t,x) \leq 0.$$

Since the previous inequality holds for every $(\mathbf{A}, \mathbb{B}) \in K$, we deduce that $(\dot{\mathbf{E}}^{\mathrm{p}}(t,x), \nabla\dot{\mathbf{E}}^{\mathrm{p}}(t,x))$ belongs to the normal cone to K at $(\mathbf{T}^{\mathrm{p}}(t,x), \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x))$. In particular, if $(\mathbf{T}^{\mathrm{p}}(t,x), \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x)) \in \mathrm{int}K$, we get that (8.32) holds, while if $(\mathbf{T}^{\mathrm{p}}(t,x), \mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x)) \in \partial K$, (8.33) follows. ∎

8.11. Notice that, in view of the presence of a singular part for $D\mathbf{E}^{\mathrm{p}}(t)$ and of its associated stress, plasticity can develop at a point $x \in \Omega$ also when $\|\mathbb{S}^{\mathrm{p}}\|_{\mathcal{M}_b(\Omega;\mathrm{M}^{N\times N\times N}_D)} = lS_Y$ and $\sqrt{|\mathbf{T}^{\mathrm{p}}(t,x)|^2 + l^{-2}|\mathbb{K}^{\mathrm{p}}_{\mathrm{diss}}(t,x)|^2} < S_Y$.

9. Asymptotic analysis as $l \to 0$ and $L \to 0$. In this section we want to understand the behavior of a quasi-static evolution for the Gurtin–Anand model as the length scales l and L vanish. Our goal is to prove that the quasi-static evolution converges in a suitable sense to an evolution for perfect plasticity. The result is somehow natural, since the strain gradient effects vanish.

More precisely, we prove under suitable assumptions the convergence to a quasi-static evolution for linearly elastic-perfectly plastic bodies recently proposed by Dal Maso, DeSimone, and Mora [8]. The main mathematical problem that we have to face in order to prove such a convergence is that the functional setting of the problem changes, in particular for what concerns the plastic strains. In fact in the strain gradient context, the plastic strain is a BV function (since its gradient enters in the equations), while in [8] it is modeled only as a Radon measure in $\Omega \cup \partial_D\Omega$. Similar problems occur for the displacements, in view of the compatibility condition.

In section 9.1 we briefly recall the model for quasi-static evolution in perfect plasticity recently proposed in [8]. Section 9.2 is devoted to the proof of the convergence result (Theorem 9.2).

9.1. The Dal Maso–DeSimone–Mora model for perfect plasticity. Let us briefly recall the model for quasi-static evolution in perfect plasticity recently proposed in [8]. We formulate the results in the particular form that we need for our asymptotic problem, using the notation of the previous sections.

Let $\Omega \subseteq \mathbb{R}^N$ $(N \geq 2)$ be open bounded, let $\partial_D\Omega$ and $\partial_N\Omega$ have the same boundary Γ (relative to $\partial\Omega$), and let us assume that

$$\partial\Omega \text{ and } \Gamma \text{ are of class } C^2. \tag{9.1}$$

Given $w \in W^{1,2}(\Omega;\mathbb{R}^N)$, the class of admissible configurations for the boundary datum w is given by

$$\mathcal{A}_{\rm pp}(w) := \big\{(u,\mathbf{E}^{\rm e},\mathbf{E}^{\rm p}) \in BD(\Omega)\times L^2(\Omega;\mathrm{M}^{N\times N}_{\rm sym})\times \mathcal{M}_b(\Omega\cup\partial_D\Omega;\mathrm{M}^{N\times N}_D) : \\ \mathbf{E}u = \mathbf{E}^{\rm e}+\mathbf{E}^{\rm p} \text{ in } \Omega, \mathbf{E}^{\rm p} = (w-u)\odot \nu\, d\mathcal{H}^{N-1} \text{ on } \partial_D\Omega\big\}.$$

Here $BD(\Omega)$ denotes the space of functions with bounded deformation on Ω:

$$BD(\Omega) := \big\{u\in L^1(\Omega;\mathbb{R}^N) : \mathbf{E}u \in \mathcal{M}_b(\Omega;\mathrm{M}^{N\times N}_{\rm sym})\big\},$$

which is a Banach space with respect to the norm

$$\|u\|_{BD(\Omega)} := \|u\|_{L^1(\Omega;\mathbb{R}^N)} + \|\mathbf{E}u\|_{\mathcal{M}_b\left(\Omega;\mathrm{M}^{N\times N}_{\rm sym}\right)}.$$

We refer the reader to [33] for the main properties of $BD(\Omega)$. The term $(w-u)$ on $\partial_D\Omega$ is intended in the sense of traces. Finally the subscripts " pp" stand for "perfect plasticity."

Given $\mathbf{E}^{\rm p}\in\mathcal{M}_b(\Omega\cup\partial_D\Omega;\mathrm{M}^{N\times N}_D)$, we set

$$\mathcal{H}_{\rm pp}(\mathbf{E}^{\rm p}) := S_Y|\mathbf{E}^{\rm p}|(\Omega\cup\partial_D\Omega),$$

while for $\mathbf{E}^{\rm e}\in L^2(\Omega;\mathrm{M}^{N\times N}_{\rm sym})$, we consider $\mathcal{Q}_1(\mathbf{E}^{\rm e})$ as defined in (4.6).

Let $t\in[0,T]$, and let the boundary displacement be given by

$$w \in AC(0,T;W^{1,2}(\Omega;\mathbb{R}^N)). \tag{9.2}$$

Let the body and traction forces be given by

$$f\in AC(0,T;L^N(\Omega;\mathbb{R}^N)) \qquad \text{and} \qquad g\in AC(0,T;L^\infty(\partial_N\Omega;\mathbb{R}^N)), \tag{9.3}$$

respectively, and let us denote by $\mathcal{L}(t)$ the associated work as in (4.12). Let us assume that f and g satisfy the uniform safe load condition (4.13)–(4.14). We can simply suppose as in [8] that $t\mapsto\rho(t)$ is absolutely continuous from $[0,T]$ to $L^2(\Omega;\mathrm{M}^{N\times N}_{\rm sym})$, since in view of the regularity of Ω we get $\rho(t)\in L^N(\Omega;\mathrm{M}^{N\times N}_{\rm sym})$ by the embedding result [22, Proposition 2.5].

Given an initial configuration

$$(u_0,\mathbf{E}^{\rm e}_0,\mathbf{E}^{\rm p}_0)\in\mathcal{A}_{\rm pp}(w(0)),$$

a quasi-static evolution $t\mapsto(u(t),\mathbf{E}^{\rm e}(t),\mathbf{E}^{\rm p}(t))$ in the sense of Dal Maso–DeSimone–Mora [8] is a map from $[0,T]$ to $BD(\Omega)\times L^2(\Omega;\mathrm{M}^{N\times N}_{\rm sym})\times\mathcal{M}_b(\Omega\cup\partial_D\Omega;\mathrm{M}^{N\times N}_D)$ with $(u(0),\mathbf{E}^{\rm e}(0),\mathbf{E}^{\rm p}(0)) = (u_0,\mathbf{E}^{\rm e}_0,\mathbf{E}^{\rm p}_0)$ and such that for every $t\in[0,T]$ the following facts hold:

(a) $(u(t),\mathbf{E}^{\rm e}(t),\mathbf{E}^{\rm p}(t))\in\mathcal{A}_{\rm pp}(w(t))$;

(b) Global stability: For every $(v,\mathbf{e},\mathbf{p})\in\mathcal{A}(w(t))$

$$\mathcal{Q}_1(\mathbf{E}^{\rm e}(t)) - \langle\mathcal{L}(t),u(t)\rangle \le \mathcal{Q}_1(\mathbf{e}) - \langle\mathcal{L}(t),v\rangle + \mathcal{H}_{\rm pp}(\mathbf{p}-\mathbf{E}^{\rm p}(t));$$

(b) Energy balance: The function $t\mapsto\mathbf{E}^{\rm p}(t)$ has a bounded variation from $[0,T]$ to $\mathcal{M}_b(\Omega\cup\partial_D\Omega;\mathrm{M}^{N\times N}_D)$ and

$$\mathcal{E}_{\rm pp}(t)+\mathcal{D}_{\rm pp}(\mathbf{E}^{\rm p};0,t) = \mathcal{E}_{\rm pp}(0) + \int_0^t\int_\Omega \mathbf{T}(\tau):\mathbf{E}\dot w(\tau)\,dx\,d\tau \\ - \int_0^t\langle\dot{\mathcal{L}}(\tau),u(\tau)\rangle\,d\tau - \int_0^t\langle\mathcal{L}(\tau),\dot w(\tau)\rangle\,d\tau,$$

where $\mathbf{T}(t) := \mathbb{C}\mathbf{E}^{\mathrm{e}}(t)$,

$$\mathcal{E}_{\mathrm{pp}}(t) := \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t)) - \langle \mathcal{L}(t), u(t)\rangle$$

and $\mathcal{D}_{\mathrm{pp}}(\mathbf{E}^{\mathrm{p}}; 0, t) := S_Y \mathcal{V}(\mathbf{E}^{\mathrm{p}}; 0, t)$.

In order to prove the convergence result of the next section, we need to recall the pairing between stress and strain which gives a useful representation of the work $\mathcal{L}(t)$ similar to (4.15). Following [8, section 2], for every $t \in [0,T]$ and for every $(v, \mathbf{e}, \mathbf{p}) \in \mathcal{A}(w(t))$ it is possible to define the measure $[\rho_D(t) : \mathbf{p}] \in \mathcal{M}_b(\Omega \cup \partial_D\Omega)$ such that

$$\langle \mathcal{L}(t), v\rangle = -\langle \rho(t)\nu, w(t)\rangle_{\partial_D\Omega} + \int_\Omega \rho(t) : \mathbf{e}\, dx + [\rho_D(t) : \mathbf{p}](\Omega \cup \partial_D\Omega) \tag{9.4}$$

and such that for every $\varphi \in C^1(\overline{\Omega})$

$$\begin{aligned}\int_{\Omega\cup\partial_D\Omega} \varphi\, d[\rho_D(t) : \mathbf{p}] = \langle \mathcal{L}(t), \varphi v\rangle + \langle \rho(t)\nu, \varphi w(t)\rangle_{\partial_D\Omega} \\ - \int_\Omega \rho(t) : \varphi\mathbf{e}\, dx - \int_\Omega \rho(t) : [\nabla\varphi \odot v]\, dx.\end{aligned} \tag{9.5}$$

A similar pairing $[\dot\rho_D(t) : \mathbf{p}] \in \mathcal{M}_b(\Omega \cup \partial_D\Omega)$ can also be defined (for a.e. $t \in [0,T]$), so that (9.4) and (9.5) hold with $\dot\rho_D(t)$, $\dot\rho(t)$, and $\dot{\mathcal{L}}(t)$ in place of $\rho_D(t)$, $\rho(t)$, and $\mathcal{L}(t)$.

9.2. The convergence result as $l, L \to 0$. Let $\Omega \subseteq \mathbb{R}^N$ satisfy (9.1), and let w, f, and g be as in (9.2) and (9.3): Notice that these data are admissible for an evolution for the Gurtin and Anand model. Let us assume that f and g satisfy the uniform safe load condition (4.13)–(4.14).

Let us consider $l_n \to 0$ and $L_n \to 0$, and let us denote by

$$t \mapsto (u_n(t), \mathbf{E}^{\mathrm{e}}_n(t), \mathbf{E}^{\mathrm{p}}_n(t))$$

a quasi-static evolution for the Gurtin–Anand model relative to the data w, f, and g and the material length scales $l = l_n$ and $L = L_n$. Let us denote by $\mathcal{Q}_2^n$, $\mathcal{H}_n$, and $\mathcal{E}_n$ the energies corresponding to $\mathcal{Q}_2$, $\mathcal{H}$, and $\mathcal{E}$, respectively.

Let us assume that the initial configuration $(u_n(0), \mathbf{E}^{\mathrm{e}}_n(0), \mathbf{E}^{\mathrm{p}}_n(0))$ is such that there exist $u_0 \in BD(\Omega)$, $\mathbf{E}^{\mathrm{e}}_0 \in L^2(\Omega; \mathrm{M}^{N\times N}_{\mathrm{sym}})$, and $\mathbf{E}^{\mathrm{p}}_0 \in \mathcal{M}_b(\Omega; \mathrm{M}^{N\times N}_D)$ with

$$u_n(0) \overset{*}{\rightharpoonup} u_0 \qquad \text{weakly* in } BD(\Omega), \tag{9.6}$$

$$\mathbf{E}^{\mathrm{e}}_n(0) \rightharpoonup \mathbf{E}^{\mathrm{e}}_0 \qquad \text{weakly in } L^2(\Omega; \mathrm{M}^{N\times N}_{\mathrm{sym}}), \tag{9.7}$$

and

$$\mathbf{E}^{\mathrm{p}}_n(0) \overset{*}{\rightharpoonup} \mathbf{E}^{\mathrm{p}}_0 \qquad \text{weakly* in } \mathcal{M}_b(\Omega; \mathrm{M}^{N\times N}_D). \tag{9.8}$$

Recall that weak* convergence in $BD(\Omega)$ is given by weak convergence in L^1 for the functions and weak* convergence in the sense of measures for the symmetrized gradients.

Let us assume moreover that convergence for the initial free energies holds, that is,

$$\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_n(0)) + \mathcal{Q}_2^n(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_n(0)) \to \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_0). \tag{9.9}$$

We have the following compactness result.

LEMMA 9.1. [illegible] $(u_n(0), \mathbf{E}^{\mathrm{e}}_n(0), \mathbf{E}^{\mathrm{p}}_n(0))$ [illegible] (9.6) (9.9) [illegible]

$$u \in AC(0,T;BD(\Omega)), \qquad \mathbf{E}^{\mathrm{e}} \in AC(0,T;L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})),$$

[illegible]

$$\mathbf{E}^{\mathrm{p}} \in AC(0,T;\mathcal{M}_b(\Omega\cup\partial_D\Omega;\mathrm{M}^{N\times N}_D))$$

[illegible] $t \in [0,T]$

$$u_n(t) \overset{*}{\rightharpoonup} u(t) \quad \text{[illegible]} \quad BD(\Omega), \tag{9.10}$$

$$\mathbf{E}^{\mathrm{e}}_n(t) \rightharpoonup \mathbf{E}^{\mathrm{e}}(t) \quad \text{[illegible]} \quad L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}}), \tag{9.11}$$

[illegible] $\mathbf{E}^{\mathrm{p}}_n(t) = 0$ [illegible] $\partial_D\Omega$

$$\mathbf{E}^{\mathrm{p}}_n(t) \overset{*}{\rightharpoonup} \mathbf{E}^{\mathrm{p}}(t) \quad \text{[illegible]} \quad \mathcal{M}_b(\Omega\cup\partial_D\Omega;\mathrm{M}^{N\times N}_D). \tag{9.12}$$

[illegible] $t \in [0,T]$

$$(u(t), \mathbf{E}^{\mathrm{e}}(t), \mathbf{E}^{\mathrm{p}}(t)) \in \mathcal{A}_{\mathrm{pp}}(w(t)). \tag{9.13}$$

[illegible]. Let B be an open ball in $\mathbb{R}^N$ such that $\overline{\Omega} \subseteq B$, and let us set $\widetilde{\Omega} := B \setminus \overline{\partial_N\Omega}$. For every $t \in [0,T]$ let us consider $\tilde{u}_n(t) \in W^{1,\frac{N}{N-1}}(\widetilde{\Omega};\mathbb{R}^N)$, $\tilde{\mathbf{E}}^{\mathrm{e}}_n(t) \in L^2(\widetilde{\Omega};\mathrm{M}^{N\times N}_{\mathrm{sym}})$, and $\tilde{\mathbf{E}}^{\mathrm{p}}_n(t) \in BV(\widetilde{\Omega};\mathrm{M}^{N\times N}_D)$ defined as

$$\tilde{u}_n(t) := \begin{cases} u_n(t) & \text{in } \Omega, \\ w(t) & \text{in } \widetilde{\Omega}\setminus\Omega, \end{cases}$$

$$\tilde{\mathbf{E}}^{\mathrm{e}}_n(t) := \begin{cases} \mathbf{E}^{\mathrm{e}}_n(t) & \text{in } \Omega, \\ \mathbf{E}w(t) & \text{in } \widetilde{\Omega}\setminus\Omega, \end{cases}$$

and

$$\tilde{\mathbf{E}}^{\mathrm{p}}_n(t) := \begin{cases} \mathbf{E}^{\mathrm{p}}_n(t) & \text{in } \Omega, \\ 0 & \text{in } \widetilde{\Omega}\setminus\Omega. \end{cases}$$

By (9.6), (9.8), and (9.9) and in view of Remark 8.6 and Proposition 8.5, we deduce that $t \mapsto \tilde{u}_n(t)$, as a map from $[0,T]$ to $BD(\widetilde{\Omega})$, has a variation which is uniformly bounded independently on n. More precisely, the sequence $(u_n)_{n\in\mathbb{N}}$ is equiabsolutely continuous. The same holds for $t \mapsto \tilde{\mathbf{E}}^{\mathrm{e}}_n(t)$ and $t \mapsto \tilde{\mathbf{E}}^{\mathrm{p}}_n(t)$ considered as maps from $[0,T]$ to $L^2(\widetilde{\Omega};\mathrm{M}^{N\times N}_{\mathrm{sym}})$ and $L^1(\widetilde{\Omega};\mathrm{M}^{N\times N}_D)$, respectively.

Recall that $BD(\widetilde{\Omega})$ can be seen as a dual space, with associated weak* convergence given precisely by the weak* convergence in BD previously defined.

Then by considering $BD(\widetilde{\Omega})$ as a dual space and $L^1(\widetilde{\Omega};\mathrm{M}^{N\times N}_D)$ as a subspace of $\mathcal{M}_b(\widetilde{\Omega};\mathrm{M}^{N\times N}_D)$, we may apply the generalized version of Helly's theorem [8, Lemma 7.2] to obtain

$$\tilde{u} \in AC(0,T;BD(\widetilde{\Omega})), \qquad \tilde{\mathbf{E}}^{\mathrm{e}} \in AC(0,T;L^2(\widetilde{\Omega};\mathrm{M}^{N\times N}_{\mathrm{sym}})),$$

and

$$\tilde{\mathbf{E}}^{\mathrm{p}} \in AC(0,T;\mathcal{M}_b(\widetilde{\Omega};\mathrm{M}_D^{N\times N}))$$

such that, up to a subsequence, for every $t\in[0,T]$

$$\tilde{u}_n(t) \overset{*}{\rightharpoonup} \tilde{u}(t) \qquad \text{weakly* in } BD(\widetilde{\Omega}), \tag{9.14}$$

$$\tilde{\mathbf{E}}^{\mathrm{e}}_n(t) \rightharpoonup \tilde{\mathbf{E}}^{\mathrm{e}}(t) \qquad \text{weakly in } L^2(\widetilde{\Omega};\mathrm{M}^{N\times N}_{\mathrm{sym}}), \tag{9.15}$$

and

$$\tilde{\mathbf{E}}^{\mathrm{p}}_n(t) \overset{*}{\rightharpoonup} \tilde{\mathbf{E}}^{\mathrm{p}}(t) \qquad \text{weakly* in } \mathcal{M}_b(\widetilde{\Omega};\mathrm{M}_D^{N\times N}). \tag{9.16}$$

We have clearly that for every $t\in[0,T]$

$$\tilde{u}(t)=w(t), \quad \tilde{\mathbf{E}}^{\mathrm{e}}(t)=\mathbf{E}w(t), \quad \tilde{\mathbf{E}}^{\mathrm{p}}(t)=0 \qquad \text{on } \widetilde{\Omega}\setminus\overline{\Omega}.$$

Let us denote by $u(t)$ and $\mathbf{E}^{\mathrm{e}}(t)$ the restrictions of $\tilde{u}(t)$ and $\tilde{\mathbf{E}}^{\mathrm{e}}(t)$ to Ω, respectively, and let $\mathbf{E}^{\mathrm{p}}(t)$ denote the restriction of $\tilde{\mathbf{E}}^{\mathrm{p}}(t)$ to $\Omega\cup\partial_D\Omega$.

Relations (9.10) and (9.11) follow directly from (9.14) and (9.15). By (9.16), and by taking into account that $\tilde{\mathbf{E}}^{\mathrm{p}}_n(t)=0$ outside $\overline{\Omega}$, we obtain (9.12).

From the compatibility condition

$$\tilde{\mathbf{E}}u_n(t)=\tilde{\mathbf{E}}^{\mathrm{e}}_n(t)+\tilde{\mathbf{E}}^{\mathrm{p}}_n(t),$$

we deduce that in the limit we have

$$\tilde{\mathbf{E}}u(t)=\tilde{\mathbf{E}}^{\mathrm{e}}(t)+\tilde{\mathbf{E}}^{\mathrm{p}}(t)$$

so that

$$\mathbf{E}^{\mathrm{p}}(t)\llcorner\partial_D\Omega=\tilde{\mathbf{E}}^{\mathrm{p}}(t)\llcorner\partial_D\Omega=(w(t)-u(t))\odot\nu\,d\mathcal{H}^{N-1}\llcorner\partial_D\Omega,$$

where $u(t)$ is intended in the sense of traces on $\partial_D\Omega$. We deduce that (9.13) holds, and the proof is concluded. □

The main theorem of the section is the following asymptotic result.

THEOREM 9.2. [illegible] $t\mapsto(u_{l,L}(t),\mathbf{E}^{\mathrm{e}}_{l,L}(t),\mathbf{E}^{\mathrm{p}}_{l,L}(t))$ [illegible] (9.6) (9.9) [illegible] $l,L\to 0$ [illegible] $l_n\to 0$ [illegible] $L_n\to 0$ [illegible] $(l_{n_j},L_{n_j})_{j\in\mathbb{N}}$ [illegible] $t\mapsto(u(t),\mathbf{E}^{\mathrm{e}}(t),\mathbf{E}^{\mathrm{p}}(t))$ [illegible] [8] [illegible]

$$u_j:=u_{l_{n_j},L_{n_j}}, \qquad \mathbf{E}^{\mathrm{e}}_j:=\mathbf{E}^{\mathrm{e}}_{l_{n_j},L_{n_j}}, \qquad \mathbf{E}^{\mathrm{p}}_j:=\mathbf{E}^{\mathrm{p}}_{l_{n_j},L_{n_j}}$$

[illegible] $t\in[0,T]$ [illegible]

$$u_j(t)\overset{*}{\rightharpoonup}u(t) \qquad \text{[illegible] weakly* in } BD(\Omega), \tag{9.17}$$

$$\mathbf{E}^{\mathrm{e}}_j(t)\to\mathbf{E}^{\mathrm{e}}(t) \qquad \text{[illegible] } L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}}), \tag{9.18}$$

[illegible]

$$\mathbf{E}^{\mathrm{p}}_j(t)\overset{*}{\rightharpoonup}\mathbf{E}^{\mathrm{p}}(t) \qquad \text{[illegible] weakly* in } \mathcal{M}_b(\Omega\cup\partial_D\Omega;\mathrm{M}_D^{N\times N}). \tag{9.19}$$

$t \in [0,T]$

$$\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_j(t)) \to \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t)) \qquad \mathcal{Q}_2^{n_j}(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_j(t)) \to 0, \tag{9.20}$$

. We divide the proof into three steps.

1: By Lemma 9.1 there exist a subsequence n_j,

$$u \in AC(0,T;BD(\Omega)), \qquad \mathbf{E}^{\mathrm{e}} \in AC(0,T;L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}})),$$

and

$$\mathbf{E}^{\mathrm{p}} \in AC(0,T;\mathcal{M}_b(\Omega\cup\partial_D\Omega;\mathrm{M}^{N\times N}_D))$$

such that by setting $u_j := u_{n_j}$, $\mathbf{E}^{\mathrm{e}}_j := \mathbf{E}^{\mathrm{e}}_{n_j}$, and $\mathbf{E}^{\mathrm{p}}_j := \mathbf{E}^{\mathrm{p}}_{n_j}$, for every $t \in [0,T]$ relations (9.17) and (9.19) hold,

$$\mathbf{E}^{\mathrm{e}}_j(t) \rightharpoonup \mathbf{E}^{\mathrm{e}}(t) \qquad \text{weakly in } L^2(\Omega;\mathrm{M}^{N\times N}_{\mathrm{sym}}), \tag{9.21}$$

and $(u(t),\mathbf{E}^{\mathrm{e}}(t),\mathbf{E}^{\mathrm{p}}(t)) \in \mathcal{A}_{\mathrm{pp}}(w(t))$, so that the triple $(u(t),\mathbf{E}^{\mathrm{e}}(t),\mathbf{E}^{\mathrm{p}}(t))$ is admissible. Finally, from the energy balance (5.3), and by the assumptions for $t=0$, we deduce that for every $t \in [0,T]$

$$\mathcal{Q}_2^{n_j}(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_j(t)) \le C \tag{9.22}$$

for some constant C independent of j and t.

2: Let us fix $t \in [0,T]$. In order to prove that $(u(t),\mathbf{E}^{\mathrm{e}}(t),\mathbf{E}^{\mathrm{p}}(t)) \in \mathcal{A}_{\mathrm{pp}}(w(t))$ satisfies the global stability condition

$$\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t)) - \langle \mathcal{L}(t), u(t)\rangle \le \mathcal{Q}_1(\mathbf{e}) - \langle \mathcal{L}(t), v\rangle + \mathcal{H}_{\mathrm{pp}}(\mathbf{p}-\mathbf{E}^{\mathrm{p}}(t)) \tag{9.23}$$

for every $(v,\mathbf{e},\mathbf{p}) \in \mathcal{A}_{\mathrm{pp}}(w(t))$, in view of [8, Theorem 3.6] it suffices to prove that the Cauchy stress $\mathbf{T}(t) = \mathbb{C}\mathbf{E}^{\mathrm{e}}(t)$ satisfies the equilibrium conditions

$$\begin{cases} -\mathrm{div}\mathbf{T}(t) = f(t) & \text{in } \Omega,\\ \mathbf{T}(t)\nu = g(t) & \text{on } \partial_N\Omega \end{cases} \tag{9.24}$$

and the constraint

$$|\mathbf{T}_D(t,x)| \le S_Y \qquad \text{for a.e. } x \in \Omega, \tag{9.25}$$

where $\mathbf{T}_D(t) := (\mathbf{T}(t))_D$.

Equation (9.24) follows from the equilibrium equation for the Cauchy stress $\mathbf{T}_j(t) = \mathbb{C}\mathbf{E}^{\mathrm{e}}_j(t)$ given by (8.6) in view of the weak convergence of $\mathbf{T}_j(t)$ to $\mathbf{T}(t)$ which comes from (9.21).

In order to prove (9.25), let us consider the corresponding constraint in the strain gradient context given by (8.9). Let $\mathbb{K}^{\mathrm{p}}_{\mathrm{diss,j}}(t)$, $\mathbb{K}^{\mathrm{p}}_{\mathrm{en},j}(t)$, $\mathbb{K}^{\mathrm{p}}_j(t) = \mathbb{K}^{\mathrm{p}}_{\mathrm{diss},j}(t) + \mathbb{K}^{\mathrm{p}}_{\mathrm{en},j}(t)$ and $\mathbf{T}^{\mathrm{p}}_j(t)$ be the stresses associated to $(u_j(t),\mathbf{E}^{\mathrm{e}}_j(t),\mathbf{E}^{\mathrm{p}}_j(t))$. Notice that, in view of (3.5) and of (9.22), we get

$$\mathbb{K}^{\mathrm{p}}_{\mathrm{en},j}(t) \to 0 \qquad \text{strongly in } L^2(\Omega;\mathrm{M}^{N\times N\times N}_D). \tag{9.26}$$

Moreover by (8.8) and (8.9) we have

$$\mathbf{T}_j^{\mathrm{p}}(t) = (\mathbf{T}_j(t))_D + \mathrm{div}\mathbb{K}_j^{\mathrm{p}}(t), \tag{9.27}$$

and

$$\sqrt{|\mathbf{T}_j^{\mathrm{p}}(t,x)|^2 + l_{n_j}^{-2}|\mathbb{K}_{\mathrm{diss},j}^{\mathrm{p}}(t,x)|^2} \le S_Y \qquad \text{for a.e. } x \in \Omega.$$

In particular we have that $(\mathbf{T}_j^{\mathrm{p}}(t))_{j\in\mathbb{N}}$ is uniformly bounded in $L^\infty(\Omega;\mathrm{M}_D^{N\times N})$ and

$$\mathbb{K}_{\mathrm{diss},j}^{\mathrm{p}}(t) \to 0 \qquad \text{strongly in } L^\infty(\Omega;\mathrm{M}_D^{N\times N\times N}).$$

By (9.26) we conclude that $\mathbb{K}_j^{\mathrm{p}}(t) \to 0$ strongly in $L^2(\Omega;\mathrm{M}_D^{N\times N\times N})$. Notice that from (9.27) we deduce that $\mathrm{div}\mathbb{K}_j^{\mathrm{p}}(t)$ is bounded in $L^2(\Omega;\mathrm{M}_D^{N\times N})$. We obtain

$$\mathrm{div}\mathbb{K}_j^{\mathrm{p}}(t) \rightharpoonup 0 \qquad \text{weakly in } L^2(\Omega;\mathrm{M}_D^{N\times N})$$

so that in view of (9.27) and (9.21)

$$\mathbf{T}_j^{\mathrm{p}}(t) \rightharpoonup \mathbf{T}_D(t) \qquad \text{weakly in } L^2(\Omega;\mathrm{M}_D^{N\times N}). \tag{9.28}$$

Since $\mathbf{T}_j^{\mathrm{p}}(t) \in \mathcal{K} := \{\mathbf{A} \in L^2(\Omega;\mathrm{M}_D^{N\times N}) : |\mathbf{A}| \le S_Y \text{ a.e. in } \Omega\}$, and $\mathcal{K}$ is closed in the weak topology of $L^2(\Omega;\mathrm{M}_D^{N\times N})$, by (9.28) we deduce that (9.25) holds. Hence (9.23) follows, and Step 2 is concluded.

Step 3: [illegible] Since $t \mapsto u_j(t)$ is absolutely continuous from $[0,T]$ to $W^{1,\frac{N}{N-1}}(\Omega;\mathbb{R}^N)$, by integrating by parts we can write the energy balance (5.3) in the following form:

$$\begin{aligned}\mathcal{Q}_1(\mathbf{E}_j^{\mathrm{e}}(t)) + \mathcal{Q}_2^{n_j}(\mathrm{curl}\mathbf{E}_j^{\mathrm{p}}(t)) + \mathcal{D}_{\mathcal{H}_{n_j}}(\mathbf{E}_j^{\mathrm{p}};0,t) - \int_0^t \langle \mathcal{L}(\tau), \dot{u}_j(\tau)\rangle\, d\tau \\ = \mathcal{Q}_1(\mathbf{E}_j^{\mathrm{e}}(0)) + \mathcal{Q}_2^{n_j}(\mathrm{curl}\mathbf{E}_j^{\mathrm{p}}(0)) + \int_0^t \int_\Omega \mathbf{T}_j(\tau) : \mathbf{E}\dot{w}(\tau)\, dx\, d\tau \\ - \int_0^t \langle \mathcal{L}(\tau), \dot{w}(\tau)\rangle\, d\tau.\end{aligned} \tag{9.29}$$

We claim that for every $t \in [0,T]$

$$\begin{aligned}\liminf_{j\to+\infty}\left[\mathcal{D}_{\mathcal{H}_{n_j}}(\mathbf{E}_j^{\mathrm{p}};0,t) - \int_0^t \langle \mathcal{L}(\tau), \dot{u}_j(\tau)\rangle\, d\tau\right] \ge \mathcal{D}_{\mathcal{H}_{\mathrm{pp}}}(\mathbf{E}^{\mathrm{p}};0,t) - \int_0^t \langle \mathcal{L}(\tau), \dot{u}(\tau)\rangle\, d\tau \\ = \mathcal{D}_{\mathcal{H}_{\mathrm{pp}}}(\mathbf{E}^{\mathrm{p}};0,t) - \langle \mathcal{L}(t), u(t)\rangle + \langle \mathcal{L}(0), u(0)\rangle + \int_0^t \langle \dot{\mathcal{L}}(\tau), u(\tau)\rangle\, d\tau.\end{aligned} \tag{9.30}$$

By passing to the limit in (9.29), by (9.21), (9.9), and (9.30) we get for every $t \in [0,T]$

$$\begin{aligned}\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t)) - \langle \mathcal{L}(t), u(t)\rangle + \mathcal{D}_{\mathcal{H}_{\mathrm{pp}}}(\mathbf{E}^{\mathrm{p}};0,t) \le \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(0)) - \langle \mathcal{L}(0), u(0)\rangle \\ + \int_0^t \int_\Omega \mathbf{T}(\tau) : \mathbf{E}\dot{w}(\tau)\, dx\, d\tau - \int_0^t \langle \dot{\mathcal{L}}(\tau), u(\tau)\rangle\, d\tau - \int_0^t \langle \mathcal{L}(\tau), \dot{w}(\tau)\rangle\, d\tau.\end{aligned}$$

In view of the global stability condition (9.23), by [8, Theorem 4.7] we have that also the opposite inequality holds, so that the energy balance follows. From the previous steps, we conclude that $t \mapsto (u(t), \mathbf{E}^{\mathrm{e}}(t), \mathbf{E}^{\mathrm{p}}(t))$ is a quasi-static evolution according to Dal Maso, DeSimone, and Mora [8].

By (9.29), (9.30), and the energy balance, we deduce that for every $t \in [0,T]$ we have

$$\mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}_j(t)) \to \mathcal{Q}_1(\mathbf{E}^{\mathrm{e}}(t)) \qquad \text{and} \qquad \mathcal{Q}_2^{n_j}(\mathrm{curl}\mathbf{E}^{\mathrm{p}}_j(t)) \to 0$$

so that (9.20) holds. In view of (9.21), we conclude that (9.18) follows.

Let us prove claim (9.30). Recall that by [8, Theorem 7.1] we have the following representation of the dissipation:

$$\mathcal{D}_{\mathcal{H}_{n_j}}(\mathbf{E}^{\mathrm{p}}_j; 0, t) = \int_0^t \mathcal{H}_{n_j}(\dot{\mathbf{E}}^{\mathrm{p}}_j(\tau))\, d\tau.$$

From the representation (4.15) we get

(9.31)
$$\mathcal{D}_{\mathcal{H}_{n_j}}(\mathbf{E}^{\mathrm{p}}_j; 0, t) - \int_0^t \langle \mathcal{L}(\tau), \dot{u}_j(\tau)\rangle\, d\tau = \int_0^t \left[\mathcal{H}_{n_j}(\dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)) - \int_\Omega \rho_D(\tau) : \dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)\, dx\right] d\tau$$
$$- \int_0^t \int_\Omega \rho(\tau) : \dot{\mathbf{E}}^{\mathrm{e}}_j(\tau)\, dx\, d\tau + \int_0^t \langle \rho(\tau)\nu, \dot{w}(\tau)\rangle_{\partial_D\Omega}\, d\tau.$$

Moreover for every $0 \le \tau \le t$

$$\mathcal{H}_{n_j}(\dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)) - \int_\Omega \rho_D(\tau) : \dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)\, dx \ge \int_\Omega \left[S_Y|\dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)| - \rho_D(\tau) : \dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)\right] dx,$$

and the integrand of the right-hand side is positive in view of the safe load condition (4.14). Let $\varphi \in C^1(\overline{\Omega})$, with $0 \le \varphi \le 1$ and $\varphi = 0$ near $\overline{\partial_N\Omega}$. By applying again the representation result [8, Theorem 7.1] for the dissipation $\mathcal{D}_{\mathcal{H}_{\mathrm{pp}}}$ we conclude that

(9.32)
$$\begin{aligned}
&\liminf_{j\to+\infty} \int_0^t \left[\mathcal{H}_{n_j}(\dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)) - \int_\Omega \rho_D(\tau) : \dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)\, dx\right] \\
&\qquad \ge \liminf_{j\to+\infty} \int_0^t \int_\Omega \left[S_Y|\dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)| - \rho_D(\tau) : \dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)\right] dx\, d\tau \\
&\qquad \ge \liminf_{j\to+\infty} \int_0^t \int_\Omega \left[S_Y|\varphi\dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)| - \rho_D(\tau) : \varphi\dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)\right] dx\, d\tau \\
&\qquad\qquad = \liminf_{j\to+\infty} \left[\mathcal{D}_{\mathcal{H}_{\mathrm{pp}}}(\varphi\mathbf{E}^{\mathrm{p}}_j; 0, t) - \int_0^t \int_\Omega \rho_D(\tau) : \varphi\dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)\, dx\, d\tau\right].
\end{aligned}$$

By the very definition of $\mathcal{D}_{\mathcal{H}_{\mathrm{pp}}}$ and by (9.19), it is easy to see that

$$\liminf_{j\to+\infty} \mathcal{D}_{\mathcal{H}_{\mathrm{pp}}}(\varphi\mathbf{E}^{\mathrm{p}}_j; 0, t) \ge \mathcal{D}_{\mathcal{H}_{\mathrm{pp}}}(\varphi\mathbf{E}^{\mathrm{p}}; 0, t). \tag{9.33}$$

On the other hand, the absolute continuity of $t \mapsto \mathbf{E}^{\mathrm{p}}_j(t)$ implies that

(9.34)
$$\int_0^t \int_\Omega \rho_D(\tau) : \varphi\dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)\, dx\, d\tau = \int_\Omega \rho_D(t) : \varphi\mathbf{E}^{\mathrm{p}}_j(t)\, dx - \int_\Omega \rho_D(0) : \varphi\mathbf{E}^{\mathrm{p}}_j(0)\, dx$$
$$- \int_0^t \int_\Omega \dot{\rho}_D(\tau) : \varphi\mathbf{E}^{\mathrm{p}}_j(\tau)\, dx\, d\tau.$$

By integrating by parts, for a.e. $\tau \in [0,t]$ we have

$$\int_\Omega \dot\rho_D(\tau) : \varphi \mathbf{E}^{\mathrm{p}}_j(\tau)\,dx = \langle \dot{\mathcal{L}}(\tau), \varphi u_j(\tau)\rangle + \langle \dot\rho(\tau)\nu, w(\tau)\rangle_{\partial_D\Omega} - \int_\Omega \dot\rho(\tau) : \varphi \mathbf{E}^{\mathrm{e}}_j(\tau)\,dx - \int_\Omega \dot\rho(\tau) : [\nabla\varphi \odot u_j(\tau)]\,dx.$$

In view of the embedding result [22, Proposition 2.5], we get $\dot\rho(\tau) \in L^N(\Omega; \mathrm{M}^{N\times N}_{\mathrm{sym}})$ for a.e. $\tau \in [0,t]$. By (9.21) and (9.17), and since $\varphi = 0$ near $\partial_N\Omega$, we deduce for a.e. $\tau \in [0,t]$ that

$$\lim_{j\to+\infty} \int_\Omega \dot\rho_D(\tau) : \varphi \mathbf{E}^{\mathrm{p}}_j(\tau)\,dx = \langle \dot{\mathcal{L}}(\tau), \varphi u(\tau)\rangle + \langle \dot\rho(\tau)\nu, w(\tau)\rangle_{\partial_D\Omega} - \int_\Omega \dot\rho(\tau) : \varphi \mathbf{E}^{\mathrm{e}}(\tau)\,dx - \int_\Omega \dot\rho(\tau) : [\nabla\varphi \odot u(\tau)]\,dx = \int_{\Omega\cup\partial_D\Omega} \varphi\, d[\dot\rho_D(\tau) : \mathbf{E}^{\mathrm{p}}(\tau)], \tag{9.35}$$

where $[\dot\rho_D(\tau) : \mathbf{E}^{\mathrm{p}}(\tau)]$ is the measure defined in the previous subsection, and the last equality follows by (9.5) (with $\dot\rho_D$ in place of ρ_D). Similarly we obtain

$$\lim_{j\to+\infty} \int_\Omega \rho_D(t) : \varphi \mathbf{E}^{\mathrm{p}}_j(t)\,dx = \int_{\Omega\cup\partial_D\Omega} \varphi\, d[\rho_D(t) : \mathbf{E}^{\mathrm{p}}(t)] \tag{9.36}$$

and

$$\lim_{j\to+\infty} \int_\Omega \rho_D(0) : \varphi \mathbf{E}^{\mathrm{p}}_j(0)\,dx = \int_{\Omega\cup\partial_D\Omega} \varphi\, d[\rho_D(0) : \mathbf{E}^{\mathrm{p}}(0)]. \tag{9.37}$$

By letting $\varphi \to 1_{\Omega\cup\partial_D\Omega}$ we obtain from (9.32), (9.33), (9.34), and (9.35)–(9.37)

$$\liminf_{j\to+\infty} \int_0^t \left[\mathcal{H}_{n_j}(\dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)) - \int_\Omega \rho_D(\tau) : \dot{\mathbf{E}}^{\mathrm{p}}_j(\tau)\,dx\right] \ge \mathcal{D}_{\mathcal{H}_{\mathrm{pp}}}(\mathbf{E}^{\mathrm{p}}; 0, t) - [\rho_D(t) : \mathbf{E}^{\mathrm{p}}(t)](\Omega) + [\rho_D(0) : \mathbf{E}^{\mathrm{p}}(0)](\Omega\cup\partial_D\Omega) + \int_0^t [\dot\rho_D(\tau) : \mathbf{E}^{\mathrm{p}}(\tau)](\Omega\cup\partial_D\Omega)\,d\tau = \mathcal{D}_{\mathcal{H}_{\mathrm{pp}}}(\mathbf{E}^{\mathrm{p}}; 0, t) - \int_0^t [\rho_D(\tau) : \dot{\mathbf{E}}^{\mathrm{p}}(\tau)](\Omega\cup\partial_D\Omega)\,d\tau. \tag{9.38}$$

In conclusion, by passing to the limit in (9.31), by (9.38) and (9.21) we get

$$\liminf_{j\to+\infty} \left[\mathcal{D}_{\mathcal{H}_{n_j}}(\mathbf{E}^{\mathrm{p}}_j; 0, t) - \int_0^t \langle \mathcal{L}(\tau), \dot u_j(\tau)\rangle\,d\tau\right] \ge \mathcal{D}_{\mathcal{H}_{\mathrm{pp}}}(\mathbf{E}^{\mathrm{p}}; 0, t) - \int_0^t [\rho_D(\tau) : \dot{\mathbf{E}}^{\mathrm{p}}(\tau)](\Omega\cup\partial_D\Omega)\,d\tau - \int_0^t \int_\Omega \rho(\tau) : \dot{\mathbf{E}}^{\mathrm{e}}(\tau)\,dx\,d\tau + \int_0^t \langle \rho(\tau)\nu, \dot w(\tau)\rangle_{\partial_D\Omega}\,d\tau = \mathcal{D}_{\mathcal{H}_{\mathrm{pp}}}(\mathbf{E}^{\mathrm{p}}; 0, t) - \int_0^t \langle \mathcal{L}(\tau), \dot u(\tau)\rangle\,d\tau,$$

where the last equality comes from the integration by parts (9.4). We deduce that claim (9.30) holds, and the proof is concluded. ∎

9.3. It is interesting to compare our result with the abstract convergence result recently proposed by Mielke, Roubíček, and Stefanelli [26] concerning the asymptotic behavior of quasi-static evolutions with Γ-converging energies and dissipations. Their framework cannot be easily adapted to our context since the total energy and the dissipation functional do not satisfy trivially a sort of Γ-liminf inequality. This is due to the fact that we skip from a BV to a Radon-measure setting for the plastic strain, so that concentration at the boundary $\partial_D\Omega$ can occur, and this has to be taken into account for the dissipation $\mathcal{H}_{\rm pp}$ and the work of the external loads. The safe load condition is the key point to rearrange the terms in order to work out suitable lower semicontinuity inequalities (see the arguments of Step 3) which are essential for the study of the asymptotics of the problem.

ON THE NEW MULTISCALE RODLIKE MODEL OF POLYMERIC FLUIDS*

HUI ZHANG† AND PINGWEN ZHANG‡

Abstract. This paper is concerned with the well-posedness for the new rigid rodlike model in a polymeric fluid recently proposed by W.N. E and P.W. Zhang [*Meth. Appl. Anal.*, 13 (2006), pp. 181–198]. The constitutive relations considered in this work are motivated by the kinetic theory. The micro equations involve five independent spatial variables (degrees of freedom): two in the configuration domain and three in the macro flow domain. We obtain the local existence of solutions with large initial data and also global existence of solutions with small Deborah and Reynolds constants in periodic domains.

Key words. polymeric fluid, rodlike model, kinetic theory, global existence

1. Introduction.

The Doi kinetic theory for spatially homogeneous flow of rodlike molecules has successfully described the properties of liquid crystal polymers in a solvent [6]. One of the simplest models of polymeric fluids described by the Doi theory is the rigid rodlike model, which takes into account the macro and micro behavior of the dilute or solute polymers—the effects of flow, Brownian motion, and intermolecular forces on the molecular orientation distribution (see [6, 10, 11, 16, 17, 23]). However, it does not include the so-called distortional elasticity. The Doi theory is valid only in the limit of spatial homogeneity. For small molecule liquid crystals, distortional elasticity has been formulated in the limit of weak distribution as Frank elasticity. This is one ingredient of the Leslie–Ericken theory. Several attempts have been made to find a theory which encompasses both the molecular visco-elasticity and the distortional elasticity. Marrucci and Greco [18] made a molecular theory of distortional elasticity. They proposed a nonlocal mean field nematic potential for LCPs (liquid crystal polymers), which accounts for spatial variations of the molecular orientation distribution. Tsuji and Rey [21, 22] add distortional elasticity to the rodlike model of the Doi theory but did not give a stress tensor. Edwards and Beris [2] give an ad hoc generalization of the Frank elasticity in tensorial form. Ericksen [9] allowed the order parameter to be a variable but still required the orientation distribution to be uniaxial. An extension of Kuzuu and Doi [13] theory to flowing systems of nonhomogeneous liquid crystalline polymers is made by Wang [25], in which the author models the LCP molecules as spheroids of equal shape and size. He derives an intermolecular potential which could be considered as an extension of Marrucci–Greco potential.

All these approaches are phonomenological in nature. They invariably contain a large number of unknown parameters which in general cannot be determined rationally. Another drawback of the phonomenological theories is the lack of consistency with existing theories and among themselves. Then E and Zhang [8] developed a new model for nonhomogeneous flows of liquid crystalline polymers with a few adjustable parameters that could model a variety of configurations of polymeric liquid crystal molecules. This new model is a combination of macroscopic partial differential equations and microscopic Fokker–Planck equations. In this model, the function $\psi(\mathbf{x}, \mathbf{m}, t)$ describes the distribution of an identical rigid rodlike molecule at $(\mathbf{x}, t)$ with the orientation $\mathbf{m}$. Denoting the velocity and pressure of the fluid by $\mathbf{u}$ and p, the new multiscale rodlike model can be expressed as

$$\begin{aligned}\frac{\partial \psi}{\partial t} + \nabla \cdot (\mathbf{u}\psi) &= \frac{1}{k_B T}\nabla \cdot \big\{[D_{\|}\mathbf{mm} + D_{\perp}(\mathbf{I} - \mathbf{mm})] \cdot (\psi \nabla \mu)\big\} \\ &\quad + \frac{D_r}{k_B T}\mathcal{R} \cdot (\psi \mathcal{R}\mu) - \mathcal{R} \cdot (\mathbf{m} \times \kappa \cdot \mathbf{m}\psi), \quad \mathbf{m} \in \mathbb{S}^2,\end{aligned} \tag{1.1}$$

where k_B is Boltzmann constant and T is the absolute temperature, $D_{\|} \geq 0$ and $D_{\perp} \geq 0$ are translational diffusion coefficients parallel and normal to the orientation of the LCP molecule, $D_r = \frac{\xi_r}{k_B T}$ is the rotary diffusivity and ξ_r is the friction coefficient, ∇ is the gradient operator with respect to the spatial variables $\mathbf{x}$, $\mathcal{R} = \mathbf{m} \times \frac{\partial}{\partial \mathbf{m}}$ is the rotational gradient operator, and $\mathbb{S}^2$ is the unit sphere in $\mathbb{R}^3$. The symbol μ denotes the chemical potential

$$\mu = \ln \psi + \bar{U}, \tag{1.2}$$

and $\bar{U}$ represents the excluded-volume potential [6, 11]

$$\bar{U}(\mathbf{x}, \mathbf{m}, t) = k_B T \alpha \int_{\Omega} \int_{|\mathbf{m}'|=1} B(\mathbf{x}, \mathbf{x}', \mathbf{m}, \mathbf{m}')\psi(\mathbf{x}', \mathbf{m}', t) d\mathbf{m}' d\mathbf{x}'. \tag{1.3}$$

The function B in (1.3) is the interactional factor among rods. Here α denotes the intensity between particles. Now we choose $B(\mathbf{x}, \mathbf{x}', \mathbf{m}, \mathbf{m}') = \frac{1}{\varepsilon^3}\chi(\frac{\mathbf{x}-\mathbf{x}'}{\varepsilon})|\mathbf{m} \times \mathbf{m}'|^2$, where $\chi(\mathbf{x})$ is the smooth kernel; e.g., $\chi(\mathbf{x}) = C \exp(1/(|\mathbf{x}|^2 - 1))$ as $|\mathbf{x}| < 1$, and $\chi(\mathbf{x}) = 0$ as $|\mathbf{x}| \geq 1$, where C is a constant such that $\int_{|\mathbf{x}|\leq 1} \chi(\mathbf{x}) d\mathbf{x} = 1$. $\kappa = (\nabla \mathbf{u})^T$ is the velocity gradient tensor.

Let L_0 be the typical size of the flow region, V_0 be the typical velocity scale, and $T_0 = \frac{L_0}{V_0}$ be a typical convective time scale. Further De is an important parameter called the Deborah number:

$$De = \frac{\frac{\xi_r}{k_B T}}{\frac{L_0}{V_0}} = \frac{\xi_r V_0}{k_B T L_0}. \tag{1.4}$$

It is the ratio of the orientational diffusion time scale of the rods (which is the relevant relaxation time scale) and the convective time scale of the fluid. Set

$$\varepsilon = \frac{L}{L_0}, \tag{1.5}$$

where L is the length of the rods. Thus the nondimensional kinetic equation is

$$\frac{\partial \psi}{\partial t} + \nabla \cdot (\mathbf{u}\psi) = \frac{\varepsilon^2}{De}\nabla \cdot \Big\{ [D_{\|}^{*}\mathbf{mm} + D_{\perp}^{*}(\mathbf{I} - \mathbf{mm})] \cdot (\psi \nabla \mu) \Big\}$$

$$+ \frac{1}{De}\mathcal{R} \cdot (\psi \mathcal{R}\mu) - \mathcal{R} \cdot (\mathbf{m} \times \kappa \cdot \mathbf{m}\psi), \quad \mathbf{m} \in \mathbb{S}^2, \tag{1.6}$$

$$\mu = \ln \psi + U, \tag{1.7}$$

$$U(\mathbf{x}, \mathbf{m}, t) = \alpha \int_{\Omega} \int_{|\mathbf{m}'|=1} B(\mathbf{x}, \mathbf{x}', \mathbf{m}, \mathbf{m}')\psi(\mathbf{x}', \mathbf{m}', t) d\mathbf{m}' d\mathbf{x}'. \tag{1.8}$$

The velocity field satisfies the Navier–Stokes-like equation

$$\rho(\mathbf{u}_t + (\mathbf{u} \cdot \nabla)\mathbf{u}) + \nabla p = \nabla \cdot \tau + F, \tag{1.9}$$

$$\nabla \cdot \mathbf{u} = 0. \tag{1.10}$$

In the LCP system, the extra stress τ is given by two parts, the viscous stress τ_s and the elastic stress τ_e, namely

$$\tau = \tau_s + \tau_e. \tag{1.11}$$

The viscous stress comes from two sources, one from the solvent and the other from the constrain of rods derived in [6],

$$\tau_s = 2\eta_s \mathbf{D} + \frac{1}{2}\xi_r \mathbf{D} : \langle \mathbf{mmmm} \rangle,$$

where $\mathbf{D} = \frac{1}{2}(\kappa + \kappa^T) = \frac{1}{2}(\nabla \mathbf{u} + (\nabla \mathbf{u})^T)$ is the strain rate tensor, η_s is the solvent viscosity, and $\langle (\cdot) \rangle$ denotes averaging with respect to the distribution ψ; i.e., $\langle (g) \rangle = \int_{|\mathbf{m}|=1} g\psi d\mathbf{m}$. The elastic stress is derived through a generalized virtual work principle [6]. The detail can be found in [8]. Now we cite the result from [8],

$$\tau_e = -\langle (\mathbf{m} \times \mathcal{R}\mu)\mathbf{m} \rangle. \tag{1.12}$$

Meanwhile the body force can also be identified as

$$\mathbf{F} = -\langle \nabla \mu \rangle. \tag{1.13}$$

Now let $\eta_p = \xi_r, \eta = \eta_s + \eta_p, \gamma = \frac{\eta_s}{\eta}$, and Re denotes the Reynolds number. Then the nondimensional Navier–Stokes-like equation

$$\mathbf{u}_t + (\mathbf{u} \cdot \nabla)\mathbf{u} + \nabla p = \frac{\gamma}{Re}\triangle \mathbf{u} + \frac{1-\gamma}{2Re}\nabla \cdot (\mathbf{D} : \langle \mathbf{mmmm} \rangle)$$

$$+ \frac{1-\gamma}{ReDe}(\nabla \cdot \tau_e + \mathbf{F}) \text{ for } \mathbf{x} \in \Omega \tag{1.14}$$

$$\nabla \cdot \mathbf{u} = 0, \quad \text{for } \mathbf{x} \in \Omega. \tag{1.15}$$

In this work we mainly investigate the well-posedness of this new multiscale rodlike polymeric model. Moreover, in most cases [6] $D_{\|}^{*}/D_{\perp}^{*} \approx 2$, so we can set $D_{\perp}^{*} = 1$ and $D_{\|}^{*} = 2$ for simple and without the lost of generality. Then (1.6) can be written as

$$\frac{\partial \psi}{\partial t} + \nabla \cdot (\mathbf{u}\psi) = \frac{\varepsilon^2}{De}\nabla \cdot [(\mathbf{I} + \mathbf{mm})(\psi \nabla \mu)]$$

$$+ \frac{1}{De}\mathcal{R} \cdot (\psi \mathcal{R}\mu) - \mathcal{R} \cdot (\mathbf{m} \times \kappa \cdot \mathbf{m}\psi), \quad \mathbf{m} \in \mathbb{S}^2. \tag{1.16}$$

We can verify this system (1.14)–(1.16) satisfies the energy identity in the following way.

Multiplying $\mathbf{u}$ to (1.14) and integrating it over Ω yields

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_\Omega |\mathbf{u}|^2 d\mathbf{x} + \int_\Omega \left[\frac{\gamma}{De}|\nabla \mathbf{u}|^2 + \frac{1-\gamma}{2Re}\langle (\mathbf{mm}:\mathbf{D})^2\rangle\right] d\mathbf{x} \\
&\qquad = \frac{1-\gamma}{ReDe}\int_\Omega [-\tau_e : \nabla \mathbf{u} + \mathbf{F}\cdot\mathbf{u}]\, d\mathbf{x} \\
&\qquad = \frac{1-\gamma}{ReDe}\int_\Omega [\langle (\mathbf{m}\times \mathcal{R}\mu)\mathbf{m}\rangle : \nabla \mathbf{u} - \langle \nabla \mu\rangle \cdot \mathbf{u}]\, d\mathbf{x} \\
&\qquad = \frac{1-\gamma}{ReDe}\int_\Omega \int_{|\mathbf{m}|=1} [(\mathbf{m}\times \mathcal{R}\mu)\mathbf{m}\psi : \nabla \mathbf{u} - \psi \nabla \mu \cdot \mathbf{u}]\, d\mathbf{m}d\mathbf{x}. \qquad (1.17)
\end{aligned}$$

Multiplying μ to (1.16) as well as integrating over in Ω and the unit sphere yields

$$\begin{aligned}
&\int_\Omega \int_{|\mathbf{m}|=1} \frac{\partial \psi}{\partial t}\mu\, d\mathbf{m}d\mathbf{x} + \int_\Omega \left[\frac{\varepsilon^2}{De}\langle \nabla\mu\cdot(\mathbf{I}+\mathbf{mm})\nabla\mu\rangle + \frac{1}{De}\langle \mathcal{R}\mu\cdot\mathcal{R}\mu\rangle\right] d\mathbf{x} \\
&\qquad = \int_\Omega \int_{|\mathbf{m}|=1} \mathbf{m}\times\kappa\cdot\mathbf{m}\psi\cdot\mathcal{R}\mu\, d\mathbf{m}d\mathbf{x} + \int_\Omega \int_{|\mathbf{m}|=1} \mathbf{u}\psi\cdot\nabla\mu\, d\mathbf{m}d\mathbf{x}. \qquad (1.18)
\end{aligned}$$

Additionally, we can calculate

$$\begin{aligned}
&\frac{d}{dt}\int_\Omega \int_{|\mathbf{m}|=1} \left[\psi\ln\psi + \frac{1}{2}\psi U\right] d\mathbf{m}d\mathbf{x} \\
&\qquad = \int_\Omega \int_{|\mathbf{m}|=1} \left[\frac{\partial\psi}{\partial t}\ln\psi + \frac{\partial\psi}{\partial t} + \frac{1}{2}\frac{\partial\psi}{\partial t}U + \frac{1}{2}\psi\frac{\partial U}{\partial t}\right] d\mathbf{m}d\mathbf{x} \\
&\qquad = \int_\Omega \int_{|\mathbf{m}|=1} \left[\frac{\partial\psi}{\partial t}(\ln\psi + U) + \frac{1}{2}\left(\psi\frac{\partial U}{\partial t} - \frac{\partial\psi}{\partial t}U\right)\right] d\mathbf{m}d\mathbf{x} \\
&\qquad = \int_\Omega \int_{|\mathbf{m}|=1} \frac{\partial\psi}{\partial t}\mu\, d\mathbf{m}d\mathbf{x}. \qquad (1.19)
\end{aligned}$$

Combining (1.17)–(1.19), we obtain that the system (1.14)–(1.18) satisfies the energy law:

$$\begin{aligned}
&\frac{d}{dt}\left[\frac{1}{2}\int_\Omega |\mathbf{u}|^2 d\mathbf{x} + \frac{1-\gamma}{ReDe}E(\psi)\right] = -\int_\Omega \left[\frac{\gamma}{De}|\nabla\mathbf{u}|^2 + \frac{1-\gamma}{2Re}\langle(\mathbf{mm}:\mathbf{D})^2\rangle\right] d\mathbf{x} \\
&\qquad - \frac{1-\gamma}{ReDe}\int_\Omega \left[\frac{\varepsilon^2}{De}\langle\nabla\mu\cdot(\mathbf{I}+\mathbf{mm})\nabla\mu\rangle + \frac{1}{De}\langle\mathcal{R}\mu\cdot\mathcal{R}\mu\rangle\right] d\mathbf{x}, \qquad (1.20)
\end{aligned}$$

where $E(\psi)$ is a nonlocal intermolecular potential given by

$$E(\psi) = \int_\Omega \int_{|\mathbf{m}|=1} \psi(\mathbf{x},\mathbf{m},t)\ln\psi(\mathbf{x},\mathbf{m},t) + \frac{1}{2}U(\mathbf{x},\mathbf{m},t)\psi(\mathbf{x},\mathbf{m},t) d\mathbf{m}d\mathbf{x}. \qquad (1.21)$$

By the same way one can see that the original system (1.6)–(1.15) also satisfies the energy law like the form (1.20). Comparing to the Doi model of rodlike polymeric fluid [6], this new model is based on the more rational assumption that the particle distribution function (pdf) ψ is possibly different in the macro variable $\mathbf{x}$. When the pdf is the same at every point $\mathbf{x}$ in the domain Ω, this model is similar to the Doi model. Here the other important difference is the excluded-volume potential (1.3) if we choose $B = |\mathbf{m}\times\mathbf{m}'|^2$ or $B = |\mathbf{m}\times\mathbf{m}'|$ in (1.3), which is the well-known Maier–Saupe or Onsager potential [6]. Now in [8] E and Zhang have proved that the inhomogeneous

property reduces to the Ericksen–Leslie theory in the limit of small Debroah number. Recently numerical simulation results [26, 27] have shown that this model can really describe the anisotropic long-range elasticity of polymeric molecules, and the microstructure and defect dynamics of LCP solution. Moreover they have reported in [26] that there are seven in-plane flow modes in plane Couette flow described by this new model. Four of them have also been reported by Rey and Tsuji [22], and the other three modes are new complicated in-plane modes with inner defects. Furthermore, some significant scaling properties were verified in [26], such as the tumbling period is proportional to the inverse of the shear rate. In plane Poiseuille flow, different local states, such as flow-aligning, tumbling, or wagging, arise in different flow region. There are also some related numerical analysis results for special cases of this model of (1.14)–(1.16), e.g., [3] and references therein. These numerical results require a detailed well-posedness analysis for the system (1.14)–(1.16). This is the main objective of the present work. These related problems for the macroscopic nonlinear elasticity and viscoelasticity cases were recently studied by Sideris and Thomases [23] and Lin, Liu, and Zhang [16]. For the micro-macro model with dumbbell type of potential there are lots of works, e.g., [7, 15, 17] and references therein. In [28], we gave the globally classical existence theory and a numerical analysis for the Dirichlet initial boundary problem of the system (1.14)–(1.16) in a simple case, the 1+1-dimensional case, and the pressure-driven channel flow. More precisely, it is assumed that the rodlike particles rotate in shear plane. That work is a first step towards the better understanding for currently more sophisticated models (1.14)–(1.16).

In this paper we consider the system (1.14)–(1.16) with the initial data

$$\mathbf{u}(\mathbf{x},0)=\mathbf{u}_0,\quad \psi(\mathbf{x},\mathbf{m},0)=\psi_0(\mathbf{x},\mathbf{m}). \tag{1.22}$$

We denote the space of functions by $H^i(\Omega), i\in\mathbb{N}$, which are in $H^i_{loc}(\mathbb{R}^3)$ (i.e., $u|_\Omega$ for every open bounded set Ω) and which are periodic with period Ω: $\mathbf{u}(x_j+Le_j)=\mathbf{u}(x_j)$, $\psi(x_j+Le_j)=\psi(x_j)$, $j=1,2,3$. It is easy to see that ψ is also periodic with respect to the variable $\mathbf{m}$ since $\mathbf{m}\in\mathbb{S}^2$. Denote

$$H^i_d(\Omega)=\text{closure of } \mathcal{V} \text{ in } H^i(\Omega),\ \text{where } \mathcal{V}=C_0^\infty(\Omega)\cap\{\mathbf{u}:\ \text{div } \mathbf{u}=0\}.$$

We can see that $H^i_d(\Omega)$ is a Sobolev space. Moreover, we define the space

$$H^l(\Omega,\mathcal{X}_k)=\left\{\psi:\left|\sum_{j=0}^{l}\sum_{i=0}^{k}\int_\Omega\int_{|\mathbf{m}|=1}|\nabla^j\mathcal{R}^i\psi(\mathbf{x},\mathbf{m},t)|^2d\mathbf{m}d\mathbf{x}<\infty\right.\right\}, \tag{1.23}$$

with the natural topology of a Banach space. Now we state our main results:

THEOREM 1.1 (local existence). [illegible]

*(**A1**)* $\mathbf{u}_0\in H^3_d(\Omega)$ [illegible] $\mathbf{u}_0=0$ $\mathbf{u}_0$ [illegible]

*(**A2**)* $\psi_0\in\cap_{i+j=3}H^i(\Omega,\mathcal{X}_j)$ [illegible] $\mathbf{x}$ [illegible] $\psi_0\ge 0$ [illegible]

$$\int_\Omega\int_{|\mathbf{m}|=1}\psi_0(\mathbf{x},\mathbf{m})d\mathbf{m}d\mathbf{x}=1.$$

[illegible] $\|\mathbf{u}_0\|^2_{H^3_d(\Omega)}+\|\psi_0\|^2_{\cap_{i+j=3}H^i(\Omega,\mathcal{X}_j)}$ [illegible] $T'>0$ [illegible] (1.14)–(1.16) [illegible] (1.22) [illegible] $(\mathbf{u},\psi)$ [illegible]

$$\mathbf{u}\in L^\infty([0,T');H^3_d(\Omega))\cap L^2([0,T);H^4_d(\Omega)); \tag{1.24}$$

$$\psi\in L^\infty([0,T');\cap_{i+j=3}H^i(\Omega,\mathcal{X}_j))\cap L^2([0,T');\cap_{i+j=4}H^i(\Omega,\mathcal{X}_j)), \tag{1.25}$$

THEOREM 1.2 (global existence). *(**A1**) (**A2**)*

$$\|\mathbf{u}_0\|^2_{H^3_d(\Omega))} + \|\psi_0\|^2_{H^3(\Omega,\mathcal{X}_0)\cap H^2(\Omega,\mathcal{X}_1)} \le B,$$

B (1.14) (1.16) (1.22) $(\mathbf{u},\psi)$

$$\mathbf{u} \in L^\infty([0,\infty); H^3_d(\Omega)), \tag{1.26}$$

$$\psi \in L^\infty([0,\infty); H^3(\Omega,\mathcal{X}_0)\cap H^2(\Omega,\mathcal{X}_1)), \tag{1.27}$$

$$\|\mathbf{u}\|^2_{L^\infty([0,\infty);H^3_d(\Omega))} + \|\psi\|^2_{L^\infty([0,\infty);H^3(\Omega,\mathcal{X}_0)\cap H^2(\Omega,\mathcal{X}_1))} \le B$$

$$Re < \gamma/C_2, \qquad De < \varepsilon^2/C_2;$$

C_2 n Ω

1.1. From the proof of Theorem 1.2 in section 4 we see that C_2 is a large positive constant. Thus Theorem 1.2 requires the Deborah and Reynolds numbers to be small enough.

1.2. From the proof of Theorem 1.1 we can also obtain the "global" result for the two-dimensional system. That is, for given $T > 0$, there exists a solution under the conditions of Theorem 1.1,

$$\mathbf{u} \in L^\infty([0,T]; H^3_d(\Omega)) \cap L^2([0,T); H^4_d(\Omega)); \tag{1.28}$$

$$\psi \in L^\infty([0,T]; \cap_{i+j=3} H^i(\Omega,\mathcal{X}_j)) \cap L^2([0,T'); \cap_{i+j=4} H^i(\Omega,\mathcal{X}_j)). \tag{1.29}$$

But the bound of this solution depends on T.

These results are similar to that of the Navier–Stokes of traditional models of complex fluids in the case of the spatially periodic solutions [5, 24] for $n = 3$. However, in contrast to traditional models of complex fluids [5, 24] which express polymer stress τ using empirical constitutive relations; τ in (1.11) expresses the polymer stress in terms of the microscopic conformations of the polymers. So the model considered in this work is closer to the original system for polymeric fluids in kinetic theory of polymers. But, on the other hand, it causes the difficulty of well-posedness analysis and numerical simulation since we have to study the configuration equation (1.16) which involves five spatial freedom variables, two of them are in the configuration domain and the others are in the macro flow domain. We utilized the properties of the Laplace–Bertrami operator on compact Riemannian manifold to obtain the existence and the preservation of the positivity of the solution to the linearized equation of (1.16). Then the regularity of the solution was strengthened by the energy estimates method. Thus, in virtue of the properties of the distribution function ψ, we can obtain the regularity of the stress τ. Then it is finished by the local well-posedness analysis of the rigid rodlike model by utilizing the Galerkin approximation and energy methods. However, we specially point out that the nonlinear stress (1.11) and the nonlinear body force (1.13) concerned with the solution of the micro-scale model (1.16) let us only obtain the global solution for small Deborah and Reynolds numbers in virtue of the method which we choose in this paper.

The paper is organized as follows. In section 2, we give the iterative scheme of the system to obtain the existence of the local solution and the scheme alternates between

solving an equation of the same type as encountered in incompressible elasticity and solving a linear diffusion equation. Section 3 is devoted to giving the detailed proof of the main lemmas. We will investigate the global existence of the solution in section 4. In this paper C denotes different constant depending only on γ, De, Re, Ω, and ε if there are no special notations. Some times we denote $H_d^p(\Omega), L^p(\Omega)$ by H^p, L^p for brevity.

2. Local solution. In this section we will construct an iterative scheme of the system (1.14)–(1.16) with (1.22) and with which we can obtain the existence of the local solution.

Motivated by the approach [12, 20], we construct an iterative scheme of the system (1.14)–(1.16) with (1.22). Given an iteration ψ^l we determine $\mathbf{u}^{l+1}$ by solving the equations

$$\begin{aligned}&\mathbf{u}_t^{l+1} + (\mathbf{u}^{l+1}\cdot\nabla)\mathbf{u}^{l+1} + \nabla p^{l+1}\\ &\quad = \frac{\gamma}{Re}\Delta\mathbf{u}^{l+1} + \frac{1-\gamma}{2Re}\nabla\cdot(\mathbf{D}:\langle\mathbf{mmmm}\rangle)^{l+1} + \frac{1-\gamma}{ReDe}(\nabla\cdot\tau_e^l + F^l),\end{aligned} \tag{2.1}$$

$$\nabla\cdot\mathbf{u}^{l+1} = 0 \tag{2.2}$$

with the initial condition $\mathbf{u}^{l+1}(\mathbf{x},0) = \mathbf{u}_0(\mathbf{x})$, where

$$(\mathbf{D}:\langle\mathbf{mmmm}\rangle)^{l+1} = \mathbf{D}_{ks}^{l+1}\langle m_i m_j m_k m_s\rangle^l, \tag{2.3}$$

$$\langle m_i m_j m_k m_s\rangle^l = \int_{|\mathbf{m}|=1} m_i m_j m_k m_s \psi^l(\mathbf{x},\mathbf{m},t)d\mathbf{m}, \tag{2.4}$$

$$(\tau_e^l) = -\langle(\mathbf{m}\times\mathcal{R}\mu^l)\mathbf{m}\rangle^l, \tag{2.5}$$

$$\mu^l = \ln\psi^l + U^l, \tag{2.6}$$

$$U^l = \alpha\int_\Omega\int_{|\mathbf{m}'|=1} B(\mathbf{x},\mathbf{x}';\mathbf{m},\mathbf{m}')\psi^l(\mathbf{x}',\mathbf{m}',t)d\mathbf{m}'d\mathbf{x}', \tag{2.7}$$

$$\kappa^{l+1} = (\nabla\mathbf{u}^{l+1})^T,\ F^l = -\langle\nabla\mu^l\rangle. \tag{2.8}$$

Meanwhile, for given $\mathbf{u}^l$, we determine ψ^l from the following initial value problem:

$$\begin{aligned}&\frac{\partial\psi^l}{\partial t} + \nabla\cdot(\mathbf{u}^{\mathbf{l}}\psi^l) = \frac{\varepsilon^2}{De}[\nabla\cdot(\mathbf{I}+\mathbf{mm})\nabla\psi^l + \nabla\cdot(\mathbf{I}+\mathbf{mm})(\psi^l\nabla U^l)]\\ &\qquad + \frac{1}{De}[\mathcal{R}\cdot\mathcal{R}\psi^l + \mathcal{R}\cdot(\psi^l\mathcal{R}U^l)] - \mathcal{R}\cdot(\mathbf{m}\times\kappa^l\cdot\mathbf{m}\psi^l),\end{aligned} \tag{2.9}$$

$$\psi^l(\mathbf{x},\mathbf{m},0) = \psi_0(\mathbf{x},\mathbf{m}). \tag{2.10}$$

Our eventual task is to show that the mapping $\mathcal{M}: \mathbf{u}^l \mapsto \mathbf{u}^{l+1}$ has a fixed point in an appropriate complete space of functions. The fixed point of the mapping is the solution we seek.

We will consider the mapping $\mathcal{M}$ in the function space $S(M,T)$, which is defined as a set of all functions $\mathbf{u}: \Omega\times[0,T]\to\mathbb{R}^n (n=2,3)$ with the following properties:

$$\mathbf{u}\in L^\infty([0,T];H_d^3(\Omega))\cap L^2([0,T];H_d^4(\Omega)), \tag{2.11}$$

$$\|\mathbf{u}\|^2_{L^\infty([0,T];H_d^3(\Omega))} + \|\mathbf{u}\|^2_{L^2([0,T];H_d^4(\Omega))} \le M. \tag{2.12}$$

On $S(M,T)$, we define the metric

$$d(\mathbf{u}_1,\mathbf{u}_2) = \|\mathbf{u}_1-\mathbf{u}_2\|_{L^\infty([0,T];H_d^3(\Omega))} + \|\mathbf{u}_1-\mathbf{u}_2\|_{L^2([0,T];H_d^4(\Omega))}. \tag{2.13}$$

It is easy to verify that $S(M,T)$ is complete with the associated metric, and also it is nonempty for large M, as evidenced in [19]. The properties of the mapping $\mathcal{M}$ is established by proving the next three lemmas.

LEMMA 2.1.

$$\|\psi^l\|_{L^\infty([0,T];H^3(\Omega,\mathcal{X}_0))\cap L^2([0,T];H^4(\Omega,\mathcal{X}_0))} \le K. \tag{2.14}$$

$T' > 0$ (2.1)–(2.8)

$$\mathbf{u}^{l+1} \in L^\infty([0,T'];H^3_d(\Omega)) \cap L^2([0,T'];H^4_d(\Omega)) \tag{2.15}$$

$$\|\mathbf{u}^{l+1}\|^2_{L^\infty([0,T'];H^3_d(\Omega))} + \|\mathbf{u}^{l+1}\|^2_{L^2([0,T'];H^4_d(\Omega))} \le \phi_1(T',K), \tag{2.16}$$

$f = \frac{1-\gamma}{ReDe}(\nabla\cdot\tau^l_e + F^l)$

$$\begin{aligned}\phi_1(T,K) &= [\|\mathbf{u}_0\|^2_{H^3_d(\Omega)} + C\|f\|^2_{L^2([0,T],H^2(\Omega))} + C(K)]e^{CK^2T+CK^4T}\\ &\quad + \|\mathbf{u}_0\|^2_{H^3_d(\Omega)} + C\|f\|^2_{L^2([0,T],H^2(\Omega))} + C(K)T.\end{aligned} \tag{2.17}$$

LEMMA 2.2.

$$\tau^l_e \in L^2([0,T];H^3(\Omega)), \qquad F^l \in L^2([0,T];H^2(\Omega)) \tag{2.18}$$

$$\|\tau^l_e\|_{L^2([0,T];H^3(\Omega))} \le C\|\psi^l\|_{L^2([0,T];H^3(\Omega,\mathcal{X}_0))}, \tag{2.19}$$

$$\|F^l\|_{L^2([0,T];H^2(\Omega))} \le C\|\psi^l\|_{L^2([0,T];H^3(\Omega,\mathcal{X}_0))} \tag{2.20}$$

$\psi^l \in L^2([0,T];H^3(\Omega,\mathcal{X}_0))$

LEMMA 2.3. $\mathbf{u}^l \in S(M,T)$ (2.9)–(2.10)

$$\psi^l \in L^\infty([0,T];\cap_{i+j=3}H^i(\Omega,\mathcal{X}_j)) \cap L^2([0,T];\cap_{i+j=4}H^i(\Omega,\mathcal{X}_j)), \tag{2.21}$$

$$\|\psi^l\|^2_{L^2([0,T],\cap_{i+j=3}H^i(\Omega,\mathcal{X}_j))} \le \|\psi_0\|^2_{\cap_{i+j=3}H^i(\Omega,\mathcal{X}_j)}(CT+CTM)\cdot e^{CT+CMT}. \tag{2.22}$$

By combining Lemmas 2.1–2.3, it follows easily that the map $\mathcal{M}: S(M,T') \longrightarrow S(M,T')$ is a compact operator if M is chosen sufficiently large and T' is chosen sufficiently small. In fact, by using (2.22), we know

$$\|\psi\|^2_{L^2([0,T],H^3(\Omega,\mathcal{X}_0))} \le \|\psi_0\|^2_{H^3(\Omega,\mathcal{X}_0))}(CT+CMT)e^{CT+CMT}.$$

Thus

$$\|f\|_{L^2([0,T],H^2(\Omega))} \le C\|\nabla\cdot\tau^l_e + F^l\|_{L^2([0,T],H^2(\Omega))} \le C\|\psi\|_{L^2([0,T],H^3(\Omega,\mathcal{X}_0))}.$$

Then, from (2.17), we have

$$\begin{aligned}&\|\mathbf{u}^{l+1}\|^2_{L^\infty([0,T'];H^3_d(\Omega))} + \|\mathbf{u}^{l+1}\|^2_{L^2([0,T'];H^4_d(\Omega))}\\ &\le [\|\mathbf{u}_0\|^2_{H^3_d(\Omega)} + \|\psi_0\|^2_{H^3(\Omega,\mathcal{X}_0)}(CT+CMT)e^{CT+CMT} + C(K)]e^{CK^2T+CK^4T}\\ &+ \|\mathbf{u}_0\|^2_{H^3_d(\Omega)} + \|\psi_0\|^2_{H^3(\Omega,\mathcal{X}_0)}(CT+CMT)e^{CT+CMT} + C(K)T.\end{aligned}$$

Now we choose

$$M \geq 6\|\mathbf{u}_0\|^2_{H^3(\Omega)} + 2C(K)(2+T_0) + 12CT_0\|\psi_0\|^2_{H^3(\Omega,\mathcal{X}_0))}, \tag{2.23}$$

$$T' \leq T_0 \triangleq \min\left\{\frac{\ln 2}{C(1+M)}, \frac{\ln 2}{C(K^2+K^4)}, \frac{1}{12C\|\psi_0\|^2_{H^3(\Omega,\mathcal{X}_0))}}\right\}. \tag{2.24}$$

Then $e^{CT'+CMT'} \leq 2, e^{CK^2T'+CK^4T'} \leq 2$, and

$$\begin{aligned}
&C\|\psi_0\|^2_{H^3(\Omega,\mathcal{X}_0)}e^{CT'+CMT'}MT'[1+e^{CK^2T'+CK^4T'}] \leq \frac{M}{2},\\
&\|\mathbf{u}_0\|^2_{H^3(\Omega)}(1+e^{CK^2T'+CK^4T'}) + C(K)[T' + e^{CK^2T'+CK^4T'}]\\
&+ C\|\psi_0\|^2_{H^3(\Omega,\mathcal{X}_0)}e^{CT'+CMT'}MT'[1+e^{CK^2T'+CK^4T'}]T' \leq \frac{M}{2}.
\end{aligned}$$

Thus we have (2.12).

Since $S(M,T')$ is clearly a closed, convex subset of $L^2([0,T],H^4_d(\Omega))$ and is also compact, by the fixed point theorem of Leray and Schauder [14], the conclusion of Theorem 1.1 can be obtained.

3. Proof of lemmas.

3.1. Estimates of u. In this section we will give the proof of Lemma 2.1. Let $\mathbf{u}^{l+1} = w$, $q = p^{l+1}$), and the fourth order tensor

$$A(\mathbf{x},t) = (a_{ijks}), \quad \text{where } a_{ijks}(\mathbf{x},t) = \int_{|\mathbf{m}|=1} m_i m_j m_k m_s \psi^l(\mathbf{x},\mathbf{m},t)d\mathbf{m}. \tag{3.1}$$

(2.1) can be rewritten as

$$\begin{aligned}
w_t + (w\cdot\nabla)w + \nabla q &= \frac{\gamma}{Re}\triangle w + f\\
&\quad + \frac{1-\gamma}{2Re}\nabla\cdot[\mathbf{D} : A(\mathbf{x},t)], \qquad (3.2)\\
\nabla\cdot w &= 0, \qquad (3.3)
\end{aligned}$$

where $f = \frac{1-\gamma}{ReDe}(\nabla\cdot\tau_e^l + F^l)$. In the following we solve this problem to obtain the existence and uniqueness of the solution by using the Galerkin approximation similar to solving the standard Navier–Stokes equation [5, 24]. The difference here is the appearance of the term $\frac{1-\gamma}{2Re}\nabla\cdot[\mathbf{D} : A(\mathbf{x},t)]$. We can see that it is a good term when we give a priori estimates because we will obtain $-\frac{1-\gamma}{2Re}\int_\Omega\langle(\mathbf{D}:\mathbf{mm})^2\rangle d\mathbf{x}$ while multiplying w to (3.2) and integrating it in Ω. The high derivatives estimates are obtained similarly. Thus we will obtain the result in Lemma 2.1 provided that

$$f \in L^2([0,T];H^2(\Omega)), \tag{3.4}$$

$$A \in L^\infty([0,T],H^3(\Omega)) \cap L^2([0,T],H^4(\Omega)). \tag{3.5}$$

The regularity of f and A can be easily obtained from the estimates of τ_e and F in section 3.2 and ones of ψ in section 3.3, respectively. Why we need conditions (3.4) and (3.5), for the aim of self-contained, will be answered in the outline of the proof to Lemma 2.1 when $n = 2$ and $n = 3$ in the appendix. We also refer the readers to [5, 24] for further details.

3.2. Estimates of τ_e and F.

Proof of Lemma 2.2. From the definition of τ_e, it is straightforward to obtain its estimates from the assumption of ψ. In fact,

$$\begin{aligned}\tau_e &= -\int_{|\mathbf{m}|=1}(\mathbf{m}\times\mathcal{R}\mu)\mathbf{m}\psi d\mathbf{m}\\ &= -\int_{|\mathbf{m}|=1}\left[\mathbf{m}\times\left(\frac{1}{\psi}\mathcal{R}\psi+\mathcal{R}U\right)\right]\mathbf{m}\psi d\mathbf{m}\\ &= -\int_{|\mathbf{m}|=1}(\mathbf{m}\times\mathcal{R}\psi)\mathbf{m}d\mathbf{m}-\int_{|\mathbf{m}|=1}(\mathbf{m}\times\mathcal{R}U)\mathbf{m}\psi d\mathbf{m}\\ &= -\mathbf{I}+3\int_{|\mathbf{m}|=1}\mathbf{m}\mathbf{m}\psi d\mathbf{m}-\int_{|\mathbf{m}|=1}(\mathbf{m}\times\mathcal{R}U)\mathbf{m}\psi d\mathbf{m},\end{aligned}$$

where we used the property of operators $\mathcal{R}$ and $\int_{|\mathbf{m}|=1}\cdot\, d\mathbf{m}$ (p. 293 in [6]),

$$\int_{|\mathbf{m}|=1}G(\mathbf{m})\mathcal{R}[F(\mathbf{m})]d\mathbf{m}=-\int_{|\mathbf{m}|=1}F(\mathbf{m})\mathcal{R}[G(\mathbf{m})]d\mathbf{m}. \tag{3.6}$$

From the definition (2.7) of U,

$$\begin{aligned}U &= \alpha\int_\Omega\int_{|\mathbf{m}'|=1}\frac{1}{\varepsilon^3}\chi\left(\frac{\mathbf{x}-\mathbf{x}'}{\varepsilon}\right)|\mathbf{m}\times\mathbf{m}'|^2\psi^l(\mathbf{x}',\mathbf{m}',t)d\mathbf{m}'d\mathbf{x}'\\ &= \alpha\int_\Omega\int_{|\mathbf{m}'|=1}\frac{1}{\varepsilon^3}\chi\left(\frac{\mathbf{x}-\mathbf{x}'}{\varepsilon}\right)\psi^l(\mathbf{x}',\mathbf{m}',t)d\mathbf{m}'d\mathbf{x}'\\ &\quad -\alpha\mathbf{m}\mathbf{m}:\int_\Omega\int_{|\mathbf{m}'|=1}\frac{1}{\varepsilon^3}\chi\left(\frac{\mathbf{x}-\mathbf{x}'}{\varepsilon}\right)\mathbf{m}'\mathbf{m}'\psi^l(\mathbf{x}',\mathbf{m}',t)d\mathbf{m}'d\mathbf{x}';\end{aligned} \tag{3.7}$$

here $\varepsilon>0$ is in (1.5) and $\chi(\mathbf{x})$ is a smooth kernel, and we can see that $U\in C^\infty(\Omega\times\mathbb{S}^2)$. But the bounds of the derivatives of U with respect to $\mathbf{x}$ and $\mathbf{m}$ depend on ε, denoted by $C(\varepsilon)$.

Therefore

$$\|\tau_e\|^2_{L^2(\Omega)}\le C(1+\|\psi\|^2_{L^2(\Omega,\mathcal{X}_0)}) \tag{3.8}$$

since $\psi\in L^2([0,T],H^3(\Omega,\mathcal{X}_0))$. Higher derivatives can be obtained similarly. Thus (2.19) is obtained. By the same way we can obtain

$$F=\langle\nabla\mu\rangle=\int_{|\mathbf{m}|=1}(\nabla\psi+\psi\nabla U)d\mathbf{m}\in L^2([0,T];H^2(\Omega)) \tag{3.9}$$

since $\psi\in L^2([0,T],H^3(\Omega,\mathcal{X}_0))$. Hence (2.20) is obtained by using (3.9).

3.3. Estimates of ψ. In this section we first review some results about the Laplace–Beltrami operator on a compact Riemannian manifold which will be utilized to show the existence of the solution of (2.9)–(2.10). Then we will give the regularity estimates of the solution to (2.9)–(2.10).

3.3.1. Review about the Laplace–Beltrami operator. We recall some known results about the Laplace–Beltrami operator on a compact Riemannian manifold (M_n, g); see (section 4 of Chap. 4) of [1] and [14].

LEMMA 3.1. [illegible] $v(Q,t)$ [illegible] $M_n \times [0,t_0]$ [illegible] $v \geq 0$ [illegible] $M_n \times \{0\}$ [illegible] $\partial M_n \times [0,t_0]$ [illegible] *fi*

$$\partial v/\partial t \geq \triangle_{M_n} v + b^i(Q,t)\partial_i v + c(Q,t)v \tag{3.10}$$

[illegible] b^i, c [illegible] $v \geq 0$ [illegible]. This lemma can be proved similar to the proof of the maximum principle in p. 130 of [1]. Let $C_m = \max_{M_n \times \mathbb{R}^+} |c(Q,t)|$ and $w = e^{-(C_m+1)t}v$. Then w and v have the same sign. Since

$$\partial w/\partial t = e^{-(C_m+1)t}[\partial v/\partial t - (C_m+1)v],$$

we have

$$\partial w/\partial t \geq \triangle_{M_n} w + b^i(Q,t)\partial_i w + [c(Q,t) - C_m - 1]w. \tag{3.11}$$

Assume w is negative somewhere and let (Q,t) be a point where w achieves its minimum. Then $\triangle_{M_n} w \geq 0, \partial_i w = 0$, and $\partial w/\partial t \leq 0$. Thus (3.11) implies $w(Q,t) \geq 0$, which yields a contradiction. □

LEMMA 3.2. [illegible] $g \in L^\infty([0,t_0], L^p(M_n))$ [illegible]

$$v \in W^{1,\infty}([0,t_0], W^{2,p}(M_n))$$

[illegible]

$$\partial v^i/\partial t = \triangle_{M_n} v^i + a^i_j \partial_i v^j + b^i_j v^j + g^i, \tag{3.12}$$

[illegible] $1 \leq \alpha \leq k$ [illegible] $v(P,0) \equiv 0$, $P \in M_n$ [illegible] $v^i (i = 1,2,\cdots,k)$ [illegible] k [illegible] $M_n \times [0,\infty)$ [illegible] $g^i (i = 1,2,\cdots,k)$ [illegible] k [illegible] $M_n \times [0,\infty)$. [illegible] *ffi* [illegible] a^i_j [illegible] b^i_j [illegible]

3.1. In fact, the condition on the coefficients a^i_j and b^i_j in the above lemma can be weakened to be bounded in $L^\infty([0,t_0] \times M_n)$. The proof is analogous.

3.3.2. Estimate of ψ.

Proof of Lemma 2.3. In this section we simply denote

$$\phi(\mathbf{x},\mathbf{m},t) = \psi^l(\mathbf{x},\mathbf{m},t) \qquad W = U^l. \tag{3.13}$$

Then (2.9)–(2.10) can be rewritten as

$$\frac{\partial \phi}{\partial t} + \mathbf{u}^l \cdot \nabla \phi = \frac{\varepsilon^2}{De}[\nabla \cdot (\mathbf{I} + \mathbf{mm})\nabla\phi + \nabla \cdot (\mathbf{I} + \mathbf{mm})(\phi \nabla W)]$$

$$+ \frac{1}{De}[\mathcal{R} \cdot \mathcal{R}\phi + \mathcal{R} \cdot (\phi \mathcal{R} W)] - \mathcal{R} \cdot (\mathbf{m} \times \kappa \cdot \mathbf{m}\phi), \tag{3.14}$$

$$\phi(\mathbf{x},\mathbf{m},0) = \psi_0(\mathbf{x},\mathbf{m}). \tag{3.15}$$

Here we still denote $(\nabla \mathbf{u}^l(\mathbf{x},t))^T$ by κ. Equation (3.14) is a nonlinear differential-integral equation. We first linearize (3.14) replacing W by U^{l-1} and obtaining the solution of this linear equation with the initial data (3.15). If now we transform the Cartesian coordinates $\mathbf{m}$ to the local coordinates (θ,φ) of the unit sphere $\mathbb{S}^2$ in

$\mathbb{R}^3$ by $m_1(\theta,\varphi) = \sin\theta\cos\varphi$, $m_2(\theta,\varphi) = \sin\theta\sin\varphi$, and $m_3 = \cos\varphi$, the operator $\mathcal{R}\cdot\mathcal{R}$ is the Laplace–Beltrami operator on the unit sphere [4]. Thus the operator $\frac{\varepsilon^2}{De}\triangle + \frac{1}{De}\mathcal{R}\cdot\mathcal{R}$ is also the Laplace–Beltrami operator. Moreover, the coefficients of (3.14) are all bounded and smooth when κ is bounded, which is obtained from $\mathbf{u}\in L^\infty([0,T];H^3_d(\Omega))$. Therefore we can utilize the above lemmas to show the existence and nonnegativeness of the solution to the linearized equation when the initial data is nonnegative. In fact, using Lemma 3.2 and Remark 3.1 for $v = \phi - \psi_0$, we obtain that (3.14)–(3.15) possesses a unique global solution $v \in W^{1,\infty}([0,T], H^2(\Omega,\mathcal{X}_0)\cap H^1(\Omega,\mathcal{X}_1)\cap L^2(\Omega,\mathcal{X}_2))$. Therefore, $\psi^l \in W^{1,\infty}([0,T];H^2(\Omega,\mathcal{X}_0)\cap H^1(\Omega,\mathcal{X}_1)\cap L^2(\Omega,\mathcal{X}_2))$ for given $T>0$. Now the coefficient of ϕ is $\frac{\varepsilon^2}{De}\nabla\cdot(\mathbf{I}+\mathbf{mm})\nabla W + \frac{1}{De}\mathcal{R}\cdot\mathcal{R}W - \mathcal{R}\cdot(\mathbf{m}\times\kappa\cdot\mathbf{m})$ and it is bounded since $\psi^{l-1}\in L^\infty([0,T];\cap_{i+j=3}H^i(\Omega,\mathcal{X}_j))$ and $\mathbf{u}^l\in L^\infty([0,T];H^3_d(\Omega))$. Then it follows that the positivity is preserved by Lemma 3.1, and by integrating both sides of (3.14) we find that

$$\int_\Omega\int_{|\mathbf{m}|=1}\phi(\mathbf{x},\mathbf{m},t)d\mathbf{m}d\mathbf{x} = \int_\Omega\int_{|\mathbf{m}|=1}\phi(\mathbf{x},\mathbf{m},0)d\mathbf{m}d\mathbf{x} = 1 \text{ for all } t.$$

We can obtain the solution of (3.14) with (3.15) from the solution of the linearized equation to construct a suitable Sobolev space and use the Schauder fixed point theorem in the standard argument. So here we omit the detail.

Next we will further prove the regularity of the solution $\psi^l(\mathbf{x},\mathbf{m},t)$ if the initial data is more regular.

I. The estimate of ϕ. Multiplying ϕ to (3.14) and integrating on $\mathbb{S}^2$ with respect to $\mathbf{m}$ and in Ω with respect to $\mathbf{x}$ yields

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_\Omega\int_{|\mathbf{m}|=1}|\phi|^2d\mathbf{m}d\mathbf{x} + \frac{\varepsilon^2}{De}\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla\phi|^2+|\mathbf{m}\cdot\nabla\phi|^2)d\mathbf{m}d\mathbf{x}\\
&\quad+\frac{1}{De}\int_\Omega\int_{|\mathbf{m}|=1}|\mathcal{R}\phi|^2d\mathbf{m}d\mathbf{x}\\
&=-\frac{\varepsilon^2}{De}\int_\Omega\int_{|\mathbf{m}|=1}(\mathbf{I}+\mathbf{mm})\phi\nabla W\cdot\nabla\phi d\mathbf{m}d\mathbf{x} - \frac{1}{De}\int_\Omega\int_{|\mathbf{m}|=1}\phi\mathcal{R}W\cdot\mathcal{R}\phi d\mathbf{m}d\mathbf{x}\\
&\quad+\int_\Omega\int_{|\mathbf{m}|=1}\mathbf{m}\times\kappa\cdot\mathbf{m}\phi\cdot\mathcal{R}\phi d\mathbf{m}d\mathbf{x},
\end{aligned}$$

where we used the periodic condition. Thus we can obtain the estimate,

$$\begin{aligned}
&\frac{d}{dt}\int_\Omega\int_{|\mathbf{m}|=1}|\phi|^2d\mathbf{m}d\mathbf{x} + \frac{\varepsilon^2}{De}\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla\phi|^2+|\mathbf{m}\cdot\nabla\phi|^2)d\mathbf{m}d\mathbf{x}\\
&\quad+\frac{1}{De}\int_\Omega\int_{|\mathbf{m}|=1}|\mathcal{R}\phi|^2d\mathbf{m}d\mathbf{x}\\
&\le C\int_\Omega\int_{|\mathbf{m}|=1}|\phi|^2d\mathbf{m}d\mathbf{x} + C|\kappa|\int_\Omega\int_{|\mathbf{m}|=1}|\phi|^2d\mathbf{m}d\mathbf{x},
\end{aligned}\tag{3.16}$$

where we used the fact that $|\kappa|$ is also bounded in $\Omega\times[0,T]$ redefined by a set of measure zero from (3.7) since $\mathbf{u}^l\in L^\infty([0,T];H^3(\Omega))$ and $|\nabla W|, |\mathcal{R}W|$ are bounded by $C(\varepsilon)$. Therefore from (3.16) we obtain

$$\sup_{t\in[0,T]}\int_\Omega\int_{|\mathbf{m}|=1}|\phi|^2d\mathbf{m}d\mathbf{x} \le \|\psi_0\|^2_{L^2(\Omega,\mathcal{X}_0)}e^{CT+CMT} \triangleq N_1,\tag{3.17}$$

and

$$\frac{\varepsilon^2}{De}\int_0^T\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla\phi|^2+|\mathbf{m}\cdot\nabla\phi|^2)d\mathbf{m}d\mathbf{x}dt+\frac{1}{De}\int_0^T\int_\Omega\int_{|\mathbf{m}|=1}|\mathcal{R}\phi|^2d\mathbf{m}d\mathbf{x}dt$$
$$\leq CN_1T+CMN_1T\triangleq N_2. \tag{3.18}$$

This shows that

$$\phi\in L^\infty([0,T];L^2(\Omega,\mathcal{X}_0))\cap L^2([0,T];L^2(\Omega,\mathcal{X}_1))\cap L^2([0,T];H^1(\Omega,\mathcal{X}_0))$$

provided that $\psi_0\in L^2(\Omega,\mathcal{X}_0)$ and $\mathbf{u}^l\in S(M,T)$.

II. The estimate of $\mathcal{R}\phi$, ϕ. Applying the operator $\mathcal{R}$ to (3.14) and multiplying $\mathcal{R}\phi$ to (3.14) and integrating on $\mathbb{S}^2$ with respect to $\mathbf{m}$ and in Ω with respect to $\mathbf{x}$, respectively, yields

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_\Omega\int_{|\mathbf{m}|=1}|\mathcal{R}\phi|^2d\mathbf{m}d\mathbf{x}+\frac{\varepsilon^2}{De}\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla\mathcal{R}\phi|^2+|\mathbf{m}\cdot\nabla\mathcal{R}\phi|^2)d\mathbf{m}d\mathbf{x}\\&\quad+\frac{1}{De}\int_\Omega\int_{|\mathbf{m}|=1}|\mathcal{R}\cdot\mathcal{R}\phi|^2d\mathbf{m}d\mathbf{x}\\&=-\frac{\varepsilon^2}{De}\int_\Omega\int_{|\mathbf{m}|=1}\{\mathcal{R}\cdot(\mathbf{I}+\mathbf{mm})\cdot\nabla\phi\cdot\nabla\mathcal{R}\phi-\nabla\cdot[(\mathbf{I}+\mathbf{mm})(\phi\nabla W)]\mathcal{R}\cdot\mathcal{R}\phi\}d\mathbf{m}d\mathbf{x}\\&\quad+\frac{1}{De}\int_\Omega\int_{|\mathbf{m}|=1}\mathcal{R}\cdot(\phi\mathcal{R}W)\mathcal{R}\cdot\mathcal{R}\phi d\mathbf{m}d\mathbf{x}+\int_\Omega\int_{|\mathbf{m}|=1}\mathcal{R}\cdot(\mathbf{m}\times\kappa\cdot\mathbf{m}\phi)\mathcal{R}\cdot\mathcal{R}\phi d\mathbf{m}d\mathbf{x}.\end{aligned}$$

Thus, by using $|\nabla W|,|\nabla^2W|$, $|\nabla\mathcal{R}W|$, $|\mathcal{R}W|,|\mathcal{R}^2W|$ are bounded for all $\mathbf{x}\in\Omega$ and $\mathbf{m}\in\mathbb{S}^2$, and $|\kappa|$ is bounded by redefined in a set of measure zero, we have

$$\begin{aligned}&\frac{d}{dt}\int_\Omega\int_{|\mathbf{m}|=1}|\mathcal{R}\phi|^2d\mathbf{m}d\mathbf{x}+\frac{\varepsilon^2}{De}\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla\mathcal{R}\phi|^2+|\mathbf{m}\cdot\nabla\mathcal{R}\phi|^2)d\mathbf{m}d\mathbf{x}\\&\quad+\frac{1}{De}\int_\Omega\int_{|\mathbf{m}|=1}|\mathcal{R}\cdot\mathcal{R}\phi|^2d\mathbf{m}d\mathbf{x}\\&\leq C\int_\Omega\int_{|\mathbf{m}|=1}(|\mathcal{R}\phi|^2+|\nabla_{\mathbf{x}}\phi|^2+|\phi|^2)d\mathbf{m}d\mathbf{x}\\&\quad+C|\kappa|\int_\Omega\int_{|\mathbf{m}|=1}(|\mathcal{R}\phi|^2+|\phi|^2)d\mathbf{m}d\mathbf{x}.\end{aligned}\tag{3.19}$$

Similarly, differentiating (3.14) with respect to $\mathbf{x}$, then multiplying $\nabla\phi$ and integrating it, we obtain

$$\begin{aligned}&\frac{d}{dt}\int_\Omega\int_{|\mathbf{m}|=1}|\nabla\phi|^2d\mathbf{m}d\mathbf{x}+\frac{\varepsilon^2}{De}\int_\Omega\int_{|\mathbf{m}|=1}(|\triangle\phi|^2+|\mathbf{m}\cdot\nabla^2\phi|^2)d\mathbf{m}d\mathbf{x}\\&\quad+\frac{1}{De}\int_\Omega\int_{|\mathbf{m}|=1}|\nabla\mathcal{R}\phi|^2d\mathbf{m}d\mathbf{x}\\&\leq C\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla\phi|^2+|\mathcal{R}\phi|^2+|\phi|^2)d\mathbf{m}d\mathbf{x}\\&\quad+C|\kappa|\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla\phi|^2+|\phi|^2)d\mathbf{m}d\mathbf{x}.\end{aligned}\tag{3.20}$$

Here we used that $|\nabla W|, |\nabla^2 W|$, $|\mathcal{R}W|, |\mathcal{R}^2 W|$ and κ are bounded. Combination of (3.16), (3.19), and (3.20) and application of the Grownwall inequality yields

$$\begin{aligned}
&\sup_{t\in[0,T]} \int_\Omega \int_{|\mathbf{m}|=1} (|\nabla\phi|^2 + |\mathcal{R}\phi|^2 + |\phi|^2) d\mathbf{m}d\mathbf{x} \\
&\quad \le \int_\Omega \int_{|\mathbf{m}|=1} (|\nabla\psi_0|^2 + |\mathcal{R}\psi_0|^2 + |\psi_0|^2) d\mathbf{m}d\mathbf{x}\ e^{CT+CM} \triangleq N_3, \\
&\frac{\varepsilon^2}{De} \int_0^T \int_\Omega \int_{|\mathbf{m}|=1} (|\nabla\phi|^2 + |\triangle\phi|^2 + |\nabla\mathcal{R}\phi|^2) d\mathbf{m}d\mathbf{x}dt \\
&\quad + \frac{1}{De} \int_0^T \int_\Omega \int_{|\mathbf{m}|=1} |\nabla\mathcal{R}\phi|^2 + |\mathcal{R}\cdot\mathcal{R}\phi|^2 d\mathbf{m}d\mathbf{x}dt \le CN_3T + CMN_3T.
\end{aligned}$$

This shows that

$$\begin{aligned}
&\phi \in L^\infty([0,t]; \cap_{i+j=1,i,j\ge 0} H^i(\Omega, \mathcal{X}_j)) \quad \text{and} \\
&\phi \in L^2([0,t]; \cap_{i+j=2,i,j\ge 0} H^i(\Omega, \mathcal{X}_j))
\end{aligned} \tag{3.21}$$

provided that $\psi_0 \in \cap_{i+j=1,i,j\ge 0} H^i(\Omega, \mathcal{X}_j)$.

III. The estimate of $\mathcal{R}^2\phi$, $^2\phi$, and $\mathcal{R}\phi$. Similar to that in section II, we can obtain the following estimates:

$$\begin{aligned}
&\frac{d}{dt} \int_\Omega \int_{|\mathbf{m}|=1} |\nabla\mathcal{R}\phi|^2 d\mathbf{m}d\mathbf{x} + \frac{\varepsilon^2}{De} \int_\Omega \int_{|\mathbf{m}|=1} (|\triangle\mathcal{R}\phi|^2 + |\mathbf{m}\cdot\nabla^2\mathcal{R}\phi|^2) d\mathbf{m}d\mathbf{x} \\
&\quad + \frac{1}{De} \int_\Omega \int_{|\mathbf{m}|=1} |\nabla\mathcal{R}\cdot\mathcal{R}\phi|^2 d\mathbf{m}d\mathbf{x} \\
&\le C \int_\Omega \int_{|\mathbf{m}|=1} (|\nabla\mathcal{R}\phi|^2 + |\nabla^2_{\mathbf{x}}\phi|^2 + |\nabla\phi|^2 + |\mathcal{R}\phi|^2 + |\phi|^2) d\mathbf{m}d\mathbf{x} \\
&\quad + C|\kappa| \int_\Omega \int_{|\mathbf{m}|=1} (|\mathcal{R}^2\phi|^2 + |\mathcal{R}\phi|^2 + |\phi|^2) d\mathbf{m}d\mathbf{x},
\end{aligned} \tag{3.22}$$

$$\begin{aligned}
&\frac{d}{dt} \int_\Omega \int_{|\mathbf{m}|=1} |\mathcal{R}^2\phi|^2 d\mathbf{m}d\mathbf{x} + \frac{\varepsilon^2}{De} \int_\Omega \int_{|\mathbf{m}|=1} (|\nabla\mathcal{R}\cdot\mathcal{R}\phi|^2 + |\mathbf{m}\cdot\nabla\mathcal{R}^2\phi|^2) d\mathbf{m}d\mathbf{x} \\
&\quad + \frac{1}{De} \int_\Omega \int_{|\mathbf{m}|=1} |\mathcal{R}(\mathcal{R}\cdot\mathcal{R}\phi)|^2 d\mathbf{m}d\mathbf{x} \\
&\le C \int_\Omega \int_{|\mathbf{m}|=1} (|\mathcal{R}^2\phi|^2 + |\mathcal{R}\phi|^2 + |\nabla\phi|^2 + |\nabla\mathcal{R}\phi|^2 + |\phi|^2) d\mathbf{m}d\mathbf{x} \\
&\quad + C|\kappa| \int_\Omega \int_{|\mathbf{m}|=1} (|\mathcal{R}^2\phi|^2 + |\mathcal{R}\phi|^2 + |\phi|^2) d\mathbf{m}d\mathbf{x},
\end{aligned} \tag{3.23}$$

$$\begin{aligned}
&\frac{d}{dt}\int_\Omega\int_{|\mathbf{m}|=1}|\nabla^2\phi|^2d\mathbf{m}d\mathbf{x}+\frac{\varepsilon^2}{De}\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla\triangle\phi|^2+|\mathbf{m}\cdot\nabla^3\phi|^2)d\mathbf{m}d\mathbf{x}\\
&\quad+\frac{1}{De}\int_\Omega\int_{|\mathbf{m}|=1}|\mathcal{R}\triangle_{\mathbf{x}}\phi|^2d\mathbf{m}d\mathbf{x}\\
&\le C\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla^2\phi|^2+|\nabla\phi|^2+|\mathcal{R}\phi|^2+|\nabla\mathcal{R}\phi|^2+|\phi|^2)d\mathbf{m}d\mathbf{x}\\
&\quad+C|\nabla\kappa|\int_\Omega\int_{|\mathbf{m}|=1}(|\mathcal{R}\phi|^2+|\nabla\phi|^2+|\phi|^2)d\mathbf{m}d\mathbf{x}\\
&\quad+C|\kappa|\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla\mathcal{R}\phi|^2+|\nabla\phi|^2)d\mathbf{m}d\mathbf{x}. \qquad (3.24)
\end{aligned}$$

Combining the above estimates and applying the Gronwall inequality with $|\nabla\kappa|\in L^2([0,T],H^4(\Omega))$, we can obtain

$$\begin{aligned}
\|\phi\|^2_{L^\infty([0,t];\cap_{i+j=2,i,j\ge0}H^i(\Omega,\mathcal{X}_j))}&\le\|\psi_0\|^2_{\cap_{i+j=2,i,j\ge0}H^i(\Omega,\mathcal{X}_j)}e^{CT+CMT}\triangleq N_4,\\
\|\phi\|^2_{L^2([0,t];\cap_{i+j=3,i,j\ge0}H^i(\Omega,\mathcal{X}_j))}&\le CN_4T+CMN_4T.
\end{aligned}$$

This implies that

$$\begin{aligned}
&\phi\in L^\infty([0,t];\cap_{i+j=2,i,j\ge0}H^i(\Omega,\mathcal{X}_j))\quad\text{and}\\
&\phi\in L^2([0,t];\cap_{i+j=3,i,j\ge0}H^i(\Omega,\mathcal{X}_j)) \qquad (3.25)
\end{aligned}$$

provided that $\psi_0\in\cap_{i+j=2,i,j\ge0}H^i(\Omega,\mathcal{X}_j)$.

IV. The estimate of $\mathcal{R}^i\ \ ^j\phi(i+j=3)$. Analogously to that in section III, we can obtain the following estimates:

$$\begin{aligned}
&\frac{d}{dt}\int_\Omega\int_{|\mathbf{m}|=1}|\mathcal{R}^3\phi|^2d\mathbf{m}d\mathbf{x}+\frac{\varepsilon^2}{De}\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla\mathcal{R}^3\phi|^2+|\mathbf{m}\cdot\nabla\mathcal{R}^3\phi|^2)d\mathbf{m}d\mathbf{x}\\
&\quad+\frac{1}{De}\int_\Omega\int_{|\mathbf{m}|=1}|\mathcal{R}^4\phi|^2d\mathbf{m}d\mathbf{x}\\
&\le C\int_\Omega\int_{|\mathbf{m}|=1}(|\mathcal{R}^3\phi|^2+|\mathcal{R}^2\phi|^2+|\mathcal{R}\phi|^2+|\phi|^2\\
&\quad+|\nabla\mathcal{R}^2\phi|^2+|\nabla\mathcal{R}\phi|^2+|\nabla\phi|^2)d\mathbf{m}d\mathbf{x}\\
&\quad+C|\kappa|\int_\Omega\int_{|\mathbf{m}|=1}(|\mathcal{R}^3\phi|^2+|\mathcal{R}^2\phi|^2+|\mathcal{R}\phi|^2+|\phi|^2)d\mathbf{m}d\mathbf{x}, \qquad (3.26)\\
&\frac{d}{dt}\int_\Omega\int_{|\mathbf{m}|=1}|\nabla\mathcal{R}^2\phi|^2d\mathbf{m}d\mathbf{x}+\frac{\varepsilon^2}{De}\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla^2\mathcal{R}^2\phi|^2+|\mathbf{m}\cdot\nabla^2\mathcal{R}^2\phi|^2)d\mathbf{m}d\mathbf{x}\\
&\quad+\frac{1}{De}\int_\Omega\int_{|\mathbf{m}|=1}|\mathcal{R}^3\nabla\phi|^2d\mathbf{m}d\mathbf{x}\\
&\le C\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla^2\mathcal{R}\phi|^2+|\nabla^2\phi|^2+|\nabla\mathcal{R}^2\phi|^2+|\nabla\mathcal{R}\phi|^2\\
&\quad+|\nabla\phi|^2+|\mathcal{R}^2\phi|^2+|\phi|^2)d\mathbf{m}d\mathbf{x}\\
&\quad+C|\kappa|\int_\Omega\int_{|\mathbf{m}|=1}|\nabla\phi|^2d\mathbf{m}d\mathbf{x}+C|\nabla\kappa|\int_\Omega\int_{|\mathbf{m}|=1}|\phi|^2d\mathbf{m}d\mathbf{x}, \qquad (3.27)
\end{aligned}$$

$$
\begin{aligned}
&\frac{d}{dt}\int_\Omega\int_{|\mathbf{m}|=1}|\nabla^2\mathcal{R}\phi|^2d\mathbf{m}d\mathbf{x}+\frac{\varepsilon^2}{De}\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla^3\mathcal{R}\phi|^2+|\mathbf{m}\cdot\nabla^3\mathcal{R}\phi|^2)d\mathbf{m}d\mathbf{x}\\
&\quad+\frac{1}{De}\int_\Omega\int_{|\mathbf{m}|=1}|\nabla^2\mathcal{R}^2\phi|^2d\mathbf{m}d\mathbf{x}\\
&\le C\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla^3\phi|^2+|\nabla^2\mathcal{R}\phi|^2+|\nabla\mathcal{R}\phi|^2+|\mathcal{R}\phi|^2\\
&\quad+|\nabla^2\phi|^2+|\nabla\phi|^2+|\phi|^2)d\mathbf{m}d\mathbf{x}\\
&\quad+C|\kappa|\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla\phi|^2+|\nabla\mathcal{R}\phi|^2+|\nabla^2\mathcal{R}\phi|^2+|\nabla\mathcal{R}^2\phi|^2)d\mathbf{m}d\mathbf{x}\\
&\quad+C|\nabla\kappa|\int_\Omega\int_{|\mathbf{m}|=1}(|\mathcal{R}^2\phi|^2+|\nabla\mathcal{R}\phi|^2+|\mathcal{R}\phi|^2+|\phi|^2)d\mathbf{m}d\mathbf{x},
\end{aligned}
\tag{3.28}
$$

$$
\begin{aligned}
&\frac{d}{dt}\int_\Omega\int_{|\mathbf{m}|=1}|\nabla^3\phi|^2d\mathbf{m}d\mathbf{x}+\frac{\varepsilon^2}{De}\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla^4\phi|^2+|\mathbf{m}\cdot\nabla^4\phi|^2)d\mathbf{m}d\mathbf{x}\\
&\quad+\frac{1}{De}\int_\Omega\int_{|\mathbf{m}|=1}|\nabla^3\mathcal{R}\phi|^2d\mathbf{m}d\mathbf{x}\\
&\le C\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla^3\phi|^2+|\nabla^2\phi|^2+|\nabla\phi|^2+|\phi|^2)d\mathbf{m}d\mathbf{x}\\
&\quad+C|\kappa|\int_\Omega\int_{|\mathbf{m}|=1}|\nabla^3\phi|^2d\mathbf{m}d\mathbf{x}+C|\nabla\kappa|\int_\Omega\int_{|\mathbf{m}|=1}|\nabla^2\phi|^2d\mathbf{m}d\mathbf{x}\\
&\quad+C\|\phi\|^2_{\mathcal{X}_0}\int_\Omega|\nabla^3\kappa|^2d\mathbf{x}+C\|\nabla^3\kappa\|^2_{L^2}\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla^2\phi|^2+|\nabla\phi|^2)d\mathbf{m}d\mathbf{x}\\
&\quad+C\|\nabla^2\kappa\|^2_{L^2}\int_\Omega\int_{|\mathbf{m}|=1}(|\nabla\phi|^2+|\phi|^2)d\mathbf{m}d\mathbf{x}.
\end{aligned}
\tag{3.29}
$$

In the last estimate we used the following estimates:

$$
\begin{aligned}
&\int_\Omega\left[|\nabla^2\kappa|\int_{|\mathbf{m}|=1}|\nabla\phi||\nabla^3\mathcal{R}\phi|d\mathbf{m}\right]d\mathbf{x}\\
&\le\int_\Omega|\nabla^2\kappa|\|\nabla\phi\|_{L^2(\mathbb{S}^2)}\|\nabla^3\mathcal{R}\phi\|_{L^2(\mathbb{S}^2)}d\mathbf{x}\\
&\le\|\nabla^2\kappa\|_{L^3(\Omega)}\|\|\nabla\phi\|_{L^2(\mathbb{S}^2)}\|_{L^6(\Omega)}\|\|\nabla^3\mathcal{R}\phi\|_{L^2(\mathbb{S}^2)}\|_{L^2(\Omega)}\\
&\le\|\nabla^2\kappa\|_{H^{\frac12}(\Omega)}\|\|\nabla\phi\|_{L^2(\mathbb{S}^2)}\|_{H^1(\Omega)}\|\|\nabla^3\mathcal{R}\phi\|_{L^2(\mathbb{S}^2)}\|_{L^2(\Omega)}\\
&\le\|\nabla^2\kappa\|_{H^4(\Omega)}\|\phi\|_{H^2(\Omega,\mathcal{X}_0)}\|\|\nabla^3\mathcal{R}\phi\|_{L^2(\mathbb{S}^2)}\|_{L^2(\Omega)}\\
&\le\frac{1}{De}\|\nabla^3\mathcal{R}\phi\|^2_{L^2(\Omega,\mathcal{X}_0)}+C(De)\|\mathbf{u}\|^2_{H^4(\Omega)}\|\phi\|^2_{H^2(\Omega,\mathcal{X}_0)}.
\end{aligned}
\tag{3.30}
$$

Combining the above estimates and applying the Gronwall inequality by using $\mathbf{u}\in L^2([0,T],H^4(\Omega))$, we can obtain

$$
\begin{aligned}
\|\phi\|_{L^\infty([0,t];\cap_{i+j=3,i,j\ge0}H^i(\Omega,\mathcal{X}_j))}&\le\|\psi_0\|_{\cap_{i+j=3,i,j\ge0}H^i(\Omega,\mathcal{X}_j)}e^{CT+CMT}\triangleq N_6,\\
\|\phi\|_{L^2([0,t];\cap_{i+j=4,i,j\ge0}H^i(\Omega,\mathcal{X}_j))}&\le CN_6T+CMN_6T.
\end{aligned}
$$

This implies that

$$
\begin{aligned}
&\phi\in L^\infty([0,t];\cap_{i+j=3,i,j\ge0}H^i(\Omega,\mathcal{X}_j))\quad\text{and}\\
&\phi\in L^2([0,t];\cap_{i+j=4,i,j\ge0}H^i(\Omega,\mathcal{X}_j))
\end{aligned}
\tag{3.31}
$$

provided that $\psi_0\in\cap_{i+j=3,i,j\ge0}H^i(\Omega,\mathcal{X}_j)$.

Up to now, we have completed the proof of Lemma 2.3.

4. Global solution. In this section, we will show that the local solution obtained in Theorem 1.1 is actually defined for $t \in \mathbb{R}^+$ if the Deborah and Reynolds numbers are small enough. To this end we derive some a priori bounds, satisfied by that solution. Notably, C_1 in this section denotes different constants depending only on n and Ω.

4.1. Some a priori estimates. Recall that the local solution $(\mathbf{u}, \psi)$ obtained in Theorem 1.1 satisfies (1.24) and (1.25) together with (1.14) and (1.16). Now we give the detail of a priori estimates for the case $n = 3$. For $n = 2$, it can be similarly obtained.

For (1.14), the inequality (A.36) in the appendix implies that there exists constant C such that

(4.1)
$$\frac{1}{2}\frac{d}{dt}\|\mathbf{u}\|^2_{H^3_d} + \left(\frac{\gamma}{Re} - 5\epsilon - \frac{6\epsilon}{11}\right)\|\mathbf{u}\|^2_{H^4} \le \frac{5\epsilon}{11}\|\psi\|^2_{H^4(\Omega,\mathcal{X}_0)} + \frac{C_1}{\epsilon}[\|\mathbf{u}\|^{14}_{H^1} + \|\mathbf{u}\|^4_{H^1} + \|\mathbf{u}\|^{24}_{H^2} + \|\psi\|^{20}_{H^1(\Omega,\mathcal{X}_0)} + \|\psi\|^{24}_{H^2(\Omega,\mathcal{X}_0)} + \|\psi\|^8_{H^3(\Omega,\mathcal{X}_0)} + \|\psi\|^2_{H^3(\Omega,\mathcal{X}_0)}], \quad (n = 3).$$

Here in the left side of the above inequality we omit the term $\frac{1-\gamma}{2Re}\int_\Omega \langle |\mathbf{mm} : \nabla^3 D|^2\rangle d\mathbf{x}$ since it is positive. The main difficulty to obtain (4.1) is to estimate

$$\int_\Omega \left|\nabla^3\left(\mathbf{D} : \int_{|\mathbf{m}|=1} \mathbf{mmmm}\nabla\psi d\mathbf{m}\right)\nabla^4\mathbf{u}\right| d\mathbf{x}.$$

Now we will use the following inequalities:

$$\begin{aligned}
&\int_\Omega |\nabla^2\mathbf{D}\int_{|\mathbf{m}|=1}\mathbf{mmmm}\nabla\psi d\mathbf{m}\nabla^4\mathbf{u}|d\mathbf{x}\\
&\quad\le C_1\|\nabla^4\mathbf{u}\|_{L^2}\|\nabla^2\mathbf{D}\|_{L^3}\|\nabla\psi\|_{L^6(\Omega,\mathcal{X}_0)}\\
&\quad\le C_1\|\mathbf{u}\|_{H^4}\|\nabla^2\mathbf{D}\|_{H^{\frac{1}{2}}}\|\nabla\psi\|_{H^1(\Omega,\mathcal{X}_0)}\\
&\quad\le C_1\|\mathbf{u}\|_{H^4}\|\mathbf{u}\|_{H^{3+\frac{1}{2}}}\|\psi\|_{H^2(\Omega,\mathcal{X}_0)}\\
&\quad\le C_1\|\mathbf{u}\|_{H^4}\|\mathbf{u}\|^{\frac{5}{6}}_{H^4}\|\mathbf{u}\|^{\frac{1}{6}}_{H^1}\|\psi\|_{H^2(\Omega,\mathcal{X}_0)}\\
&\quad\le \epsilon\|\mathbf{u}\|^2_{H^4} + \frac{C_1}{\epsilon}\|\mathbf{u}\|^2_{H^1}\|\psi\|^{12}_{H^2(\Omega,\mathcal{X}_0)},
\end{aligned} \tag{4.2}$$

where ϵ is a positive constant and will be chosen later. Here we used the Hölder inequality ($\int_\Omega |abc|d\mathbf{x} \le \|a\|_{L^2}\|a\|_{L^3}\|c\|_{L^6}$), Sobolev embedding theorems ($H^1(\Omega) \subset L^6(\Omega), H^{1/2}(\Omega) \subset L^3(\Omega)$ for $n = 3$), the interpolation inequality ($\|\mathbf{u}\|_{H^{3+\frac{1}{2}}} \le C_1\|\mathbf{u}\|^{\frac{5}{6}}_{H^4}\|\mathbf{u}\|^{\frac{1}{6}}_{H^1}$), and Young's inequality ($ab \le \epsilon a^{12/11} + \frac{1}{\epsilon}b^{12}$), respectively. Similarly, we have

$$\begin{aligned}
&\int_\Omega |\nabla\mathbf{D}\int_{|\mathbf{m}|=1}\mathbf{mmmm}\nabla^2\psi d\mathbf{m}\nabla^4\mathbf{u}|d\mathbf{x}\\
&\quad\le \epsilon\|\mathbf{u}\|^2_{H^4} + \frac{C_1}{\epsilon}\|\mathbf{u}\|^2_{H^1}\|\psi\|^4_{H^3(\Omega,\mathcal{X}_0)}.
\end{aligned}$$

Further, a different estimate from the above two is

$$\begin{aligned}
&\int_\Omega |\mathbf{D}\int_{|\mathbf{m}|=1}\mathbf{mmmm}\nabla^3\psi d\mathbf{m}\nabla^4\mathbf{u}|d\mathbf{x}\\
&\quad\le C_1\|\nabla^4\mathbf{u}\|_{L^2}\|\mathbf{D}\|_{L^6}\|\nabla^3\psi\|_{L^3(\Omega,\mathcal{X}_0)}\\
&\quad\le C_1\|\mathbf{u}\|_{H^4}\|\mathbf{D}\|_{H^1}\|\nabla^3\psi\|_{H^{\frac{1}{2}}(\Omega,\mathcal{X}_0)}\\
&\quad\le C_1\|\mathbf{u}\|_{H^4}\|\mathbf{u}\|_{H^2}\|\psi\|^{\frac{1}{6}}_{H^1(\Omega,\mathcal{X}_0)}\|\psi\|^{\frac{5}{6}}_{H^4(\Omega,\mathcal{X}_0)}\\
&\quad\le \epsilon\left[\|\mathbf{u}\|_{H^4}\|\psi\|^{\frac{5}{6}}_{H^4(\Omega,\mathcal{X}_0)}\right]^{\frac{12}{11}}+\frac{C_1}{\epsilon}\|\mathbf{u}\|^{12}_{H^2}\|\psi\|^{10}_{H^1(\Omega,\mathcal{X}_0)}\\
&\quad\le \epsilon\left[\|\mathbf{u}\|^{\frac{12}{11}}_{H^4}\|\psi\|^{\frac{10}{11}}_{H^4(\Omega,\mathcal{X}_0)}\right]+\frac{C_1}{\epsilon}\|\mathbf{u}\|^{12}_{H^2}\|\psi\|^{10}_{H^1(\Omega,\mathcal{X}_0)}\\
&\quad\le \frac{6\epsilon}{11}\|\mathbf{u}\|^2_{H^4}+\frac{5\epsilon}{11}\|\psi\|^2_{H^4(\Omega,\mathcal{X}_0)}+\frac{C_1}{\epsilon}\|\mathbf{u}\|^{12}_{H^2}\|\psi\|^{10}_{H^1(\Omega,\mathcal{X}_0)}.
\end{aligned}\tag{4.3}$$

For the convect term we used the same estimate in [24]

$$\int|(\mathbf{u}\cdot\nabla)\mathbf{u}\triangle^3\mathbf{u}|dx\le\epsilon\|\mathbf{u}\|^2_{H^4}+\frac{C_1}{\epsilon}\|\mathbf{u}\|^{14}_{H^1},$$

and by using the results of Lemma 2.2 we have

$$\begin{aligned}
&\int_\Omega|\nabla^3\tau_e\nabla^4\mathbf{u}|d\mathbf{x}\le\epsilon\|\mathbf{u}\|^2_{H^4}+\frac{C_1}{\epsilon}\|\tau_e\|^2_{H^3}\le\epsilon\|\mathbf{u}\|^2_{H^4}+\frac{C_1}{\epsilon}\|\psi\|^2_{H^3(\Omega,\mathcal{X}_0)},\\
&\int_\Omega|\nabla^2F\nabla^4\mathbf{u}|d\mathbf{x}\le\epsilon\|\mathbf{u}\|^2_{H^4}+\frac{C_1}{\epsilon}\|F\|^2_{H^2}\le\epsilon\|\mathbf{u}\|^2_{H^4}+\frac{C_1}{\epsilon}\|\psi\|^2_{H^3(\Omega,\mathcal{X}_0)}.
\end{aligned}$$

Combination of all yields (4.1). For the equation of ψ, we can obtain the following estimates:

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\psi\|^2_{H^3(\Omega,\mathcal{X}_0)}+\left(\frac{\varepsilon^2}{De}-5\epsilon-\frac{\epsilon}{11}\right)\|\psi\|^2_{H^4(\Omega,\mathcal{X}_0)}+\left(\frac{1}{De}-\frac{5\epsilon}{11}\right)\|\psi\|^2_{H^3(\Omega,\mathcal{X}_1)}\\
&\le\frac{5\epsilon}{11}\|\mathbf{u}\|^2_{H^4}+\frac{C_1}{\epsilon}[\|\mathbf{u}\|^4_{H^3}+\|\mathbf{u}\|^{24}_{H^2}+\|\mathbf{u}\|^4_{H^2}+\|\psi\|^4_{H^3(\Omega,\mathcal{X}_0)}+\|\psi\|^4_{H^1(\Omega,\mathcal{X}_0)}\\
&+\|\psi\|^{24}_{H^1(\Omega,\mathcal{X}_1)}+\|\psi\|^4_{H^2(\Omega,\mathcal{X}_1)}+\|\psi\|^2_{H^3(\Omega,\mathcal{X}_0)}].
\end{aligned}\tag{4.4}$$

Here the difficulties are the estimates to the nonlinear terms $\mathbf{u}\cdot\nabla\psi$ and $\mathcal{R}\cdot(\mathbf{m}\times\kappa\cdot\mathbf{m}\psi)$ in the equation. To overcome them we use the following inequalities similar to (4.2):

$$\begin{aligned}
&\int_\Omega\int_{|\mathbf{m}|=1}|\nabla^2\mathbf{u}\nabla\psi\nabla^4\psi|d\mathbf{m}d\mathbf{x}\le\epsilon\|\psi\|^2_{H^4(\Omega,\mathcal{X}_0)}+\frac{C_1}{\epsilon}\|\mathbf{u}\|^2_{H^3}\|\psi\|^2_{H^2(\Omega,\mathcal{X}_0)},\\
&\int_\Omega\int_{|\mathbf{m}|=1}|\nabla\mathbf{u}\nabla^2\psi\nabla^4\psi d\mathbf{m}d\mathbf{x}\le\epsilon\|\psi\|^2_{H^4(\Omega,\mathcal{X}_0)}+\frac{C_1}{\epsilon}\|\mathbf{u}\|^2_{H^2}\|\psi\|^2_{H^3(\Omega,\mathcal{X}_0)},\\
&\int_\Omega\int_{|\mathbf{m}|=1}|\mathbf{u}\nabla^3\psi\nabla^4\psi d\mathbf{m}d\mathbf{x}\le\epsilon\|\psi\|^2_{H^4(\Omega,\mathcal{X}_0)}+\frac{C_1}{\epsilon}\|\mathbf{u}\|^{12}_{H^1}\|\psi\|^2_{H^1(\Omega,\mathcal{X}_0)}.
\end{aligned}$$

For the other term $\int_\Omega\int_{|\mathbf{m}|=1}|\nabla^2\mathcal{R}\cdot(\mathbf{m}\times\kappa\cdot\mathbf{m}\psi)\nabla^4\psi|d\mathbf{m}d\mathbf{x}$, we used the estimates

obtained similar to (4.3):

$$\begin{aligned}
&\int_\Omega \int_{|\mathbf{m}|=1} |\nabla^2 \kappa \mathcal{R}\psi \nabla^4 \psi| d\mathbf{m} d\mathbf{x} \\
&\qquad \le \frac{6\epsilon}{11}\|\psi\|^2_{H^4(\Omega,\mathcal{X}_0)} + \frac{5\epsilon}{11}\|\mathbf{u}\|^2_{H^4} + \frac{C_1}{\epsilon}\|\mathbf{u}\|^2_{H^1}\|\psi\|^{12}_{H^1(\Omega,\mathcal{X}_1)}, \\
&\int_\Omega \int_{|\mathbf{m}|=1} |\kappa \nabla^2 \mathcal{R}\psi \nabla^4 \psi| d\mathbf{m} d\mathbf{x} \\
&\qquad \le \frac{6\epsilon}{11}\|\psi\|^2_{H^4(\Omega,\mathcal{X}_0)} + \frac{5\epsilon}{11}\|\psi\|^2_{H^3(\Omega,\mathcal{X}_1)} + \frac{C_1}{\epsilon}\|\mathbf{u}\|^{12}_{H^2}\|\psi\|^2_{H^1(\Omega,\mathcal{X}_1)}, \\
&\int_\Omega \int_{|\mathbf{m}|=1} |\nabla \kappa \nabla \mathcal{R}\psi \nabla^4 \psi| d\mathbf{m} d\mathbf{x} \le \epsilon\|\psi\|^2_{H^4(\Omega,\mathcal{X}_0)} + \frac{C_1}{\epsilon}\|\mathbf{u}\|^2_{H^3}\|\psi\|^2_{H^2(\Omega,\mathcal{X}_1)}.
\end{aligned}$$

Now from (4.4), we see that it is necessary to estimate $\|\psi\|^2_{H^2(\Omega,\mathcal{X}_1)}$. But it is not difficult to obtain the following inequality in the similar way with the estimate (4.4).

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\psi\|^2_{H^2(\Omega,\mathcal{X}_1)} + \left(\frac{\varepsilon^2}{De} - 4\epsilon\right)\|\psi\|^2_{H^3(\Omega,\mathcal{X}_1)} + \frac{1}{De}\|\psi\|^2_{H^2(\Omega,\mathcal{X}_2)} \\
&\le \frac{C_1}{\epsilon}\left[\|\mathbf{u}\|^4_{H^3} + \|\mathbf{u}\|^{\frac{16}{3}}_{H^2} + \|\mathbf{u}\|^{16}_{H^1} + \|\psi\|^4_{H^1(\Omega,\mathcal{X}_1)} + \|\psi\|^8_{H^1(\Omega,\mathcal{X}_1)} + \|\psi\|^2_{H^2(\Omega,\mathcal{X}_1)}\right].
\end{aligned} \tag{4.5}$$

For the case $n = 2$, we can obtain a priori estimates by using similar approaches, and we omit the details and give the results directly as follows:

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\mathbf{u}\|^2_{H^3_d} + \left(\frac{\gamma}{Re} - 5\epsilon - \frac{9\epsilon}{16}\right)\|\mathbf{u}\|^2_{H^4} \le \frac{7\epsilon}{16}\|\psi\|^2_{H^4(\Omega,\mathcal{X}_0)} + \frac{C_1}{\epsilon}[\|\mathbf{u}\|^4_{H^1} + \|\mathbf{u}\|^{18}_{H^2} \\
&+ \|\psi\|^{18}_{H^2(\Omega,\mathcal{X}_0)} + \|\psi\|^{\frac{9}{2}}_{H^3(\Omega,\mathcal{X}_0)}], \quad (n = 2).
\end{aligned} \tag{4.6}$$

The a priori estimates for ψ are

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\psi\|^2_{H^3(\Omega,\mathcal{X}_0)} + \left(\frac{\varepsilon^2}{De} - 5\epsilon - \frac{9\epsilon}{16}\right)\|\psi\|^2_{H^4(\Omega,\mathcal{X}_0)} + \left(\frac{1}{De} - \frac{4\epsilon}{13}\right)\|\psi\|^2_{H^3(\Omega,\mathcal{X}_1)} \\
&\le \frac{7\epsilon}{16}\|\mathbf{u}\|^2_{H^4} + \frac{C_1}{\epsilon}[\|\mathbf{u}\|^4_{H^3} + \|\mathbf{u}\|^4_{H^1} + \|\mathbf{u}\|^8_{H^1} + \|\mathbf{u}\|^{18}_{H^1} \\
&+ \|\psi\|^4_{H^1(\Omega,\mathcal{X}_1)} + \|\psi\|^{18}_{H^1(\Omega,\mathcal{X}_1)} + \|\psi\|^4_{H^3(\Omega,\mathcal{X}_0)}].
\end{aligned} \tag{4.7}$$

4.2. Global existence. In this subsection we will give the proof of Theorem 1.2. Let

$$Y(t) = \|\mathbf{u}\|^2_{H^3(\Omega)} + \|\psi\|^2_{H^3(\Omega,\mathcal{X}_0)} + \|\psi\|^2_{H^2(\Omega,\mathcal{X}_1)}. \tag{4.8}$$

Combining the above estimates (4.1), (4.4), and (4.5) we have

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}Y(t) + \left(\frac{\gamma}{Re} - 6\epsilon\right)\|\mathbf{u}\|^2_{H^4} \\
&+ \left(\frac{\varepsilon^2}{De} - 5\epsilon - \frac{6\epsilon}{11}\right)\|\psi\|^2_{H^4(\Omega,\mathcal{X}_0)} + \left(\frac{1}{De} - \frac{5\epsilon}{11}\right)\|\psi\|^2_{H^3(\Omega,\mathcal{X}_1)} \\
&+ \left(\frac{\varepsilon^2}{De} - 4\epsilon\right)\|\psi\|^2_{H^3(\Omega,\mathcal{X}_1)} + \frac{1}{De}\|\psi\|^2_{H^2(\Omega,\mathcal{X}_2)} \\
&\le \frac{C_1}{\epsilon}(Y^{12} + Y^{10} + Y^7 + Y^4 + Y^2 + Y).
\end{aligned} \tag{4.9}$$

Now we choose

$$\epsilon = \min\left\{\frac{\gamma}{7Re}, \frac{\varepsilon^2}{7De}\right\}, \quad \text{and} \quad \beta = \frac{C_1}{\epsilon}. \tag{4.10}$$

Since $Y(t) \le \|\mathbf{u}\|^2_{H^4} + \|\psi\|^2_{H^4(\Omega,\mathcal{X}_0)} + \|\psi\|^2_{H^3(\Omega,\mathcal{X}_1)}$, (4.9) implies

$$Y'(t) + 2\epsilon Y(t) \le 2\beta(Y^{12} + Y^{10} + Y^7 + Y^4 + Y^2 + Y). \tag{4.11}$$

LEMMA 4.1. [illegible] (4.11) [illegible] $0 < B < B_0$ [illegible] B_0 [illegible]

$$B^{11} + B^9 + B^6 + B^3 + B + 1 - \frac{\epsilon}{2\beta} = 0. \tag{4.12}$$

[illegible] $Y(0) \le B$ [illegible] $Y(t)$ [illegible] B [illegible] $t \ge 0$

[illegible]. We will prove it by contradiction. Suppose that there exists a t such that $Y(t) > B$, and define $t^* = \inf\{t \in \mathbb{R}^+, Y(t) > B\}$, then $Y(t^*) = B$ and $Y'(t^*) \ge 0$. However from (4.11) and the hypothesis made on B we deduce

$$\begin{aligned} Y'(t^*) &\le -2\epsilon Y(t^*) + 2\beta[Y^{11}(t^*) + Y^9(t^*) + Y^7(t^*) + Y^4(t^*) + Y^2(t^*) + Y(t^*)] \\ &\le -2\epsilon B + 2B\beta\frac{\epsilon}{2\beta} = -\epsilon B < 0, \end{aligned}$$

which contradicts the above statement. Therefore $Y(t) \le B$ for all $t \in \mathbb{R}^+$. □

[illegible] 1.2. We have seen in subsection 4.1 that a specific norm of the local solution obtained in Theorem 1.1 satisfies an inequality with the form (4.11), where C_1 depends on the domain Ω and n while ϵ depends on $\gamma, Re, \varepsilon^2, De$ from (4.10). Lemma 4.1 shows that there exists a constant B_0, depending on initial data such that

$$Y(t) \le B, \text{ for } t \in \mathbb{R}^+, \quad \text{if} \quad Y(0) \le B < B_0.$$

But B_0 is the unique positive solution of (4.12). From (4.12), we can easily see that (4.12) possesses a unique positive solution if and only if

$$1 - \frac{\epsilon}{2\beta} < 0, \tag{4.13}$$

which implies from (4.10) that

$$Re < \frac{\gamma}{7\sqrt{2C_1}} \quad \text{and} \quad De < \frac{\varepsilon^2}{7\sqrt{2C_1}}. \tag{4.14}$$

This completes the proof of Theorem 1.2 for $n = 3$. □

Denoting

$$Z(t) = \|\mathbf{u}\|^2_{H^3(\Omega)} + \|\psi\|^2_{H^3(\Omega,\mathcal{X}_0)},$$

the addition of (4.6) and (4.7) yields

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}Z(t) + \left(\frac{\gamma}{Re} - 6\epsilon\right)\|\mathbf{u}\|^2_{H^4} \\ &+ \left(\frac{\varepsilon^2}{De} - 6\epsilon\right)\|\psi\|^2_{H^4(\Omega,\mathcal{X}_0)} + \left(\frac{1}{De} - \frac{4\epsilon}{13}\right)\|\psi\|^2_{H^3(\Omega,\mathcal{X}_1)} \\ &\le \frac{C_1}{\epsilon}(Z^9 + Y^4 + Y^{9/4} + Y^2) \quad \text{for } n = 2. \end{aligned} \tag{4.15}$$

By the same way the result of Theorem 1.2 for $n = 2$ can be obtained.

Appendix A. Proof of Lemma 2.1. Now we solve (3.2)–(3.3) with the initial value $\mathbf{u}(\mathbf{x},0)=\mathbf{u}_0$ by using the Galerkin approximation. Let V be the space of all divergence-free vector in $H^1(\Omega)$, and let $\{\omega^i | i\in\mathbb{N}\}$ be a basis for V. We seek an approximation to w of the form

$$w^N(\mathbf{x},t)=\Sigma_{n=1}^N\rho^n(t)\omega^n(\mathbf{x}). \tag{A.1}$$

The function w^N satisfies, instead of (3.2) and (3.3),

$$\begin{aligned} w_t^N+(w^N\cdot\nabla)w^N&=\frac{\gamma}{Re}\triangle w^N+f\\ &\quad+\frac{1-\gamma}{2Re}\nabla\cdot\left[\mathbf{D}^N:A(\mathbf{x},t)\right], \end{aligned} \tag{A.2}$$

$$w^N(\mathbf{x},0)=P_N\mathbf{u}_0(\mathbf{x}), \tag{A.3}$$

where P_N is the orthogonal projector in H_d^1 onto $W_N=Span\{\omega^i, i=1,\cdots,N\}$. The existence and uniqueness of a solution w_N to (A.2)–(A.3) with periodic boundary conditions defined on some interval $(0,T_N), T_N>0$, is clear; in fact, the following estimate shows that $T_N=T$ for $n=2$ and T_N suitably small for $n=3$.

Multiplying w^N to (A.2) and integrating it, we get

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\|w^N\|_{L^2}^2+\frac{\gamma}{Re}\|\nabla w^N\|_{L^2}^2+\frac{1-\gamma}{2Re}\int_\Omega\langle|\mathbf{D}^N:\mathbf{mm}|^2\rangle d\mathbf{x}\\ &\le\frac{\gamma}{2Re}\|w^N\|_{L^2}^2+\frac{Re}{2\gamma}\|f\|_{H^{-1}}^2. \end{aligned} \tag{A.4}$$

This implies that

$$\frac{d}{dt}\|w^N\|_{L^2}^2+\frac{\gamma}{Re}\|\nabla w^N\|_{L^2}^2\le\frac{Re}{\gamma}\|f\|_{H^{-1}}^2. \tag{A.5}$$

It shows that

$$\int_0^T\|\nabla w^N(t)\|_{L^2}^2dt\le K_1, \tag{A.6}$$

where

$$K_1=K_1\left(\mathbf{u}_0,f,\frac{\gamma}{Re},T\right)=\frac{Re}{\gamma}\left(\|\mathbf{u}_0\|_{L^2}^2+\frac{Re}{\gamma}\int_0^T\|f(t)\|_{H^{-1}}^2dt\right). \tag{A.7}$$

For $0<s<T$, by (A.5),

$$\|w^N(s)\|_{L^2}^2\le K_2, \tag{A.8}$$

where

$$K_2=K_2\left(\mathbf{u}_0,f,\frac{\gamma}{Re},T\right)=\frac{\gamma}{Re}K_1. \tag{A.9}$$

Multiplying $\triangle w^N$ by (A.2) and integrating it, we get

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\|\nabla w^N\|_{L^2}^2+\frac{\gamma}{Re}\|\nabla^2 w^N\|_{L^2}^2+\frac{1-\gamma}{2Re}\int_\Omega\langle|\nabla\mathbf{D}^N:\mathbf{mm}|^2\rangle d\mathbf{x}\\ &\le\frac{1}{4}\frac{\gamma}{Re}\|\nabla w^N\|_{L^2}^2+\frac{Re}{\gamma}\|f\|_{L^2}^2\\ &\quad+\int|(w^N\cdot\nabla)w^N\triangle w^N|d\mathbf{x}+\frac{1-\gamma}{2Re}\int|\mathbf{D}^N\nabla A\triangle w^N|d\mathbf{x}. \end{aligned} \tag{A.10}$$

Now the following a priori of $\int |(w^N \cdot \nabla) w^N \triangle w^N| dx$ are different, depending on the dimension. We use the relation [24]

$$\int |(w \cdot \nabla) w \triangle w| dx \le C \|w\|_{L^2}^{1/2} \|\triangle w\|_{L^2}^{3/2} \|\nabla w\|_{L^2}, \qquad (n = 2), \tag{A.11}$$

$$\int |(w \cdot \nabla) w \triangle w| dx \le C \|w\|_{L^2}^{1/4} \|\triangle w\|_{L^2}^{7/4} \|\nabla w\|_{L^2}, \qquad (n = 3), \tag{A.12}$$

and the estimates

$$\int |\mathbf{D}^N \nabla A \triangle w^N| d\mathbf{x} \le C \|\triangle w^N\|_{L^2}^{4/3} \|\nabla^2 A\|_{L^2} \|\nabla w^N\|_{L^2}^{2/3}, \quad (n = 2), \tag{A.13}$$

$$\int |\mathbf{D}^N \nabla A \triangle w^N| d\mathbf{x} \le C \|\triangle w^N\|_{L^2}^{3/2} \|\nabla^2 A\|_{L^2} \|\nabla w^N\|_{L^2}^{1/2}, \quad (n = 3). \tag{A.14}$$

By Young's inequality (A.10) implies

$$\begin{aligned} \frac{d}{dt} \|\nabla w^N\|_{L^2}^2 + \frac{1}{2} \frac{\gamma}{Re} \|\Delta w^N\|_{L^2}^2 &\le \frac{2Re}{\gamma} \|f\|_{L^2}^2 \\ &+ C \|w^N\|_{L^2}^2 \|\nabla w^N\|_{L^2}^4 + C \|\nabla^2 A\|_{L^2}^4 \|\nabla w^N\|_{L^2}^2, \quad (n = 2), \end{aligned} \tag{A.15}$$

$$\begin{aligned} \frac{d}{dt} \|\nabla w^N\|_{L^2}^2 + \frac{3}{2} \frac{\gamma}{Re} \|\Delta w^N\|_{L^2}^2 &\le \frac{2Re}{\gamma} \|f\|_{L^2}^2 \\ &+ C \|w^N\|_{L^2}^2 \|\nabla w^N\|_{L^2}^8 + C \|\nabla^2 A\|_{L^2}^4 \|\nabla w^N\|_{L^2}^2, \quad (n = 3). \end{aligned} \tag{A.16}$$

Since $\psi^l \in L^\infty([0,T], H^3(\Omega, \mathcal{X}_0))$, we can obtain

$$|\nabla A(x,t)| \in L^\infty([0,T]; H^2(\Omega)). \tag{A.17}$$

Then by the same way as the a priori estimate of Theorem 3.2 in [24] we can get for $n = 2$ in virtue of (2.14) and (3.1)

$$\sup_{t \in [0,T]} \|\nabla w^N\|_{L^2}^2 \le K_3, \tag{A.18}$$

where

$$K_3 = K_3 \left(\mathbf{u}_0, f, \frac{\gamma}{Re}, T \right) = \left(\|\mathbf{u}_0\|_{H^1}^2 + C \int_0^T \|f(t)\|_{L^2}^2 dt \right) \exp(CK_1 K_2 + CK^3 T).$$

And

$$\int_0^T \|\triangle w^N\|_{L^2}^2 dt \le K_4, \tag{A.19}$$

where

$$K_4 = K_4(\mathbf{u}_0, f, \frac{\gamma}{Re}, T) = C\gamma \left(\|\mathbf{u}_0\|_{H^1}^2 + C \int_0^T \|f(t)\|_{L^2}^2 dt + CK_2 K_3^2 T + CK^3 K_3 T \right).$$

For $n = 3$, we will estimate in the following from (A.16). Let $y(t) = \|\nabla w^N\|_{L^2}^2 + 1, a(t) = C\|w^N\|_{L^2}^2, b(t) = C\|\nabla^2 A\|_{L^2}^4$, and $c(t) = \frac{2Re}{\gamma} \|f\|_{L^2}^2$. Then from (A.16), we have the inequality

$$\frac{dy}{dt} \le [a(t) + b(t) + c(t)] y^4, \tag{A.20}$$

and

$$\int_0^T [a(t)+b(t)+c(t)]dt \le T(CK_2+CK^6+CK^2), \tag{A.21}$$

where we used the condition of (2.14) and the estimate (3.8) and above estimates. Then they imply that for $t\in[0,T]$ and $T<1/[(CK_2+CK^4+\frac{Re}{\gamma}K^2)y^3(0)]\triangleq T_0$

$$y(t)\le \frac{y(0)}{\sqrt[3]{1-(CK_2+CK^4+\frac{Re}{\gamma}K^2)y^3(0)T}}\triangleq K_5. \tag{A.22}$$

Therefore, when $T<T_0$, we have

$$\sup_{s\in[0,T]}\|\nabla w^N\|_{L^2}^2\le K_5 \tag{A.23}$$

and

$$\int_0^T \|\triangle w^N\|_{L^2}^2 dt\le K_6, \tag{A.24}$$

where

$$K_6=K_6(\mathbf{u}_0,f,\frac{\gamma}{Re},T)=C\left(\|\mathbf{u}_0\|_{H^1}^2+C\int_0^T\|f(t)\|_{L^2}^2dt+CK_1K_5^4T+CK^4K_5T\right).$$

Multiplying $\triangle^2 w^N$ by (A.2) and integrating it, we get

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\nabla^2 w^N\|_{L^2}^2+\frac{\gamma}{Re}\|\nabla^3 w^N\|_{L^2}^2+\frac{1-\gamma}{4Re}\int_\Omega\langle|\nabla^2\mathbf{D}^N:\mathbf{mm}|^2\rangle d\mathbf{x}\\
&\quad\le\frac{1}{4}\frac{\gamma}{Re}\|\nabla\triangle w^N\|_{L^2}^2+C\|\nabla f\|_{L^2}^2\\
&\qquad+\frac{1-\gamma}{2Re}\int[|\mathbf{D}^N\nabla^2A\nabla\triangle w^N|+|\nabla\mathbf{D}^N\nabla A\nabla\triangle w^N|]dx\\
&\qquad+\int|(w^N\cdot\nabla)w^N\triangle^2w^N|dx.
\end{aligned}\tag{A.25}$$

In the following we will estimate (A.25). In virtue of the inequality (p. 31 [24])

$$\int|(w^N\cdot\nabla)w^N\triangle^r w^N|dx\le\frac{1}{4}\frac{\gamma}{Re}\|w^N\|_{H^{r+1}}^2+C\|w^N\|_{H^1}^{2r}\quad(n=2), \tag{A.26}$$

$$\int|(w^N\cdot\nabla)w^N\triangle^r w^N|dx\le\frac{1}{4}\frac{\gamma}{Re}\|w^N\|_{H^{r+1}}^2+C\|w^N\|_{H^1}^{4r+2}\quad(n=3). \tag{A.27}$$

And the estimates

$$\int|\mathbf{D}^N\nabla^2A\nabla^3w^N|d\mathbf{x}\le C\|\nabla^3w^N\|_{L^2}\|\nabla A\|_{L^2}^{1/3}\|\nabla^3A\|_{L^2}^{2/3}\|\nabla^2w^N\|_{L^2},\quad(n=2),$$

$$\int|\mathbf{D}^N\nabla^2A\nabla^3w^N|d\mathbf{x}\le C\|\nabla^3w^N\|_{L^2}\|\nabla A\|_{L^2}^{1/4}\|\nabla^3A\|_{L^2}^{3/4}\|\nabla^2w^N\|_{L^2},\quad(n=3),$$

$$\int|\nabla\mathbf{D}^N\nabla A\nabla^3w^N|d\mathbf{x}\le C\|\nabla^3w^N\|_{L^2}^{5/3}\|\nabla^2A\|_{L^2}\|\nabla w^N\|_{L^2}^{1/3},\quad(n=2),$$

$$\int|\nabla\mathbf{D}^N\nabla A\nabla^3w^N|d\mathbf{x}\le C\|\nabla^3w^N\|_{L^2}^{7/4}\|\nabla^2A\|_{L^2}\|\nabla w^N\|_{L^2}^{1/4}.\quad(n=3).$$

Thus, we have

$$\frac{d}{dt}\|w^N\|_{H^2}^2+\frac{1}{2}\frac{\gamma}{Re}\|w^N\|_{H^3}^2\le C\|w^N\|_{H^1}^4+\frac{Re}{\gamma}\|f\|_{H^1}^2$$
$$+C\|A\|_{H^1}^{2/3}\|A\|_{H^3}^{4/3}\|w^N\|_{H^2}^2+C\|A\|_{H^2}^6\|w^N\|_{H^2}^2,\quad (n=2), \tag{A.28}$$
$$\frac{d}{dt}\|w^N\|_{H^2}^2+\frac{1}{2}\frac{\gamma}{Re}\|w^N\|_{H^3}^2\le C\|w^N\|_{H^1}^{10}+\frac{Re}{\gamma}\|f\|_{H^1}^2$$
$$+C\|A\|_{H^1}^{1/2}\|A\|_{H^3}^{3/2}\|w^N\|_{H^2}^{3/2}+C\|A\|_{H^2}^8\|w^N\|_{H^1}^2,\quad (n=3). \tag{A.29}$$

Similarly we can obtain the following estimates: for $n=2$,

$$\sup_{t\in[0,T]}\|w^N(t)\|_{H^2}^2\le [CK_2^2T+CKK_2T+C\|f\|_{L^2(0,T;H^1)}^2+\|\mathbf{u}_0\|_{H^2}^2]e^{CK^2T+CK^6T}\triangleq K_7, \tag{A.30}$$

and

$$\int_0^T\|w^N(t)\|_{H^3}^2dt\le K_8, \tag{A.31}$$

where

$$K_8=C\left(CK_3^2T+C\|f\|_{L^2(0,T;H^1)}^2+\|\mathbf{u}_0\|_{H^2}^2+CK^2K_7K_1T+CK^6K_7T\right).$$

While for $n=3$,

$$\sup_{t\in[0,T]}\|w^N(t)\|_{H^2}^2\le K_9, \tag{A.32}$$

where

$$K_9=\left[CK_5^5T+CK^8K_1+\frac{Re}{\gamma}\|f\|_{L^2(0,T;H^1)}^2+\|\mathbf{u}_0\|_{H^2}^2\right]e^{CK^2T}.$$

Further, we have

$$\int_0^T\|w^N(t)\|_{H^3}^2dt\le K_{10}, \tag{A.33}$$

where

$$K_{10}=C\left(CK_5^5T+C\|f\|_{L^2(0,T;H^1)}^2+\|\mathbf{u}_0\|_{H^2}^2+CK^8K_1T+CK^2K_9T\right).$$

This shows for T given,

$$w^N\in L^\infty([0,T];H^2(\Omega))\cap L^2([0,T];H^3(\Omega)) \tag{A.34}$$

provided that $f\in L^2([0,T];H^1(\Omega))$ and $A\in L^\infty([0,T];H^3(\Omega))\cap L^2([0,T];H^4(\Omega))$.

Similarly we can obtain the estimates

$$\frac{d}{dt}\|w^N\|_{H^3}^2+\frac{1}{2}\frac{\gamma}{Re}\|w^N\|_{H^4}^2\le C\|w^N\|_{H^1}^6+\frac{Re}{\gamma}\|f\|_{H^2}^2$$
$$+C\|A\|_{H^2}^9\|w^N\|_{H^1}^2+C\|A\|_{H^3}^4\|w^N\|_{H^1}^2$$
$$+C\|A\|_{H^1}^{4/9}\|A\|_{H^4}^{14/9}\|w^N\|_{H^2}^2,\quad (n=2), \tag{A.35}$$
$$\frac{d}{dt}\|w^N\|_{H^3}^2+\frac{1}{2}\frac{\gamma}{Re}\|w^N\|_{H^4}^2\le C\|w^N\|_{H^1}^{14}+\frac{Re}{\gamma}\|f\|_{H^2}^2$$
$$+C\|A\|_{H^2}^{12}\|w^N\|_{H^1}^2+C\|A\|_{H^3}^4\|w^N\|_{H^1}^2$$
$$+C\|A\|_{H^1}^{1/3}\|A\|_{H^4}^{5/3}\|w^N\|_{H^2}^2,\quad (n=3). \tag{A.36}$$

From (A.35), for $n = 2$ we have

$$\sup_{t\in[0,T]} \|w^N(t)\|^2_{H^3} \le K_{11}, \tag{A.37}$$

where

$$K_{11} = \left[\|u_0\|^2_{H^3} + \frac{Re}{\gamma}\|f\|^2_{L^2(0,T;H^2)} + CK_3^3T + CK^4K_1 + CK^9K_1\right] e^{CK^4T}.$$

Furthermore, we have

$$\int_0^T \|w^N(t)\|^2_{H^4} dt \le K_{12}, \tag{A.38}$$

where

$$K_{12} = C\left(\|u_0\|^2_{H^3} + C\|f\|^2_{L^2(0,T;H^2)} + CK_3^3T + CK^4K_1T + CK^2K_{11}T + CK^2K_7T\right).$$

Thus we know that $\phi_1(K,T) = K_{12} + K_{11}$ for $n = 2$.

From (A.36), for $n = 3$ we have

$$\sup_{t\in[0,T]} \|w^N(t)\|^2_{H^3} \le K_{13}, \tag{A.39}$$

where

$$K_{13} = [\|u_0\|^2_{H^3} + C\|f\|^2_{L^2(0,T;H^2)} + CK_3^7T + CK^{12}K_3T + CK^4K_3T]e^{CK^2T}.$$

Moreover,

$$\int_0^T \|w^N(t)\|^2_{H^4} dt \le K_{14}, \tag{A.40}$$

where

$$K_{14} = C\Big(\|u_0\|^2_{H^3} + C\|f\|^2_{L^2(0,T;H^2)} + CK_3^7T + CK^{12}K_3T + CK^4K_3T + CK^2K_{13}T\Big).$$

Thus we know that $\phi_1(K,T) = K_{14} + K_{13}$ for $n = 3$.

Therefore, this implies that for T given,

$$w^N \in L^\infty([0,T];H^3(\Omega)) \cap L^2([0,T];H^4(\Omega)) \tag{A.41}$$

provided that $f \in L^2([0,T];H^2(\Omega))$ and $A \in L^\infty([0,T],H^3(\Omega)) \cap L^2([0,T],H^4(\Omega))$.

Passing $N \to \infty$, we can obtain the estimate (2.16).

Acknowledgments. The authors are very grateful to the referee for his many valuable suggestions. We are very grateful to Professors Weinan E and Chun Liu for their helpful discussions.

A DESCRIPTION OF SEISMIC ACOUSTIC WAVE PROPAGATION IN POROUS MEDIA VIA HOMOGENIZATION*

ANVARBEK MEIRMANOV†

Abstract. We consider a linear system of differential equations describing the joint motion of an elastic porous body and a fluid occupying the porous space. A rigorous justification is performed for the homogenization procedures under various conditions imposed on the physical parameters as the dimensionless size of the pores tends to zero, while the porous body is geometrically periodic and the process's characteristic time is sufficiently small. Such models describe the propagation of seismic acoustic waves. In the present paper, we derive the homogenized equations, which are different types of nonstandard wave equations depending on the relations between the physical parameters. The proofs are based on Nguetseng's two-scale convergence method of homogenization in periodic structures.

Key words. Stokes equations, Lamé's equations, wave equation, two-scale convergence, homogenization of periodic structures

DOI. 10.1137/070697483

1. Introduction. In the present paper, we deal with a problem of joint motion of a deformable solid (the) perforated by a system of channels or pores (the) and a fluid occupying the pore space. In a domain $\Omega \subset \mathbf{R}^3$, the dimensionless displacement vector $\boldsymbol{w}$ of the continuum medium in the dimensionless variables

$$\boldsymbol{x}' = L\boldsymbol{x}, \quad t' = \tau t, \quad \boldsymbol{w}' = \frac{L^2}{g\tau^2}\boldsymbol{w}, \quad \rho_s' = \rho_0\rho_s, \quad \rho_f' = \rho_0\rho_f, \quad \boldsymbol{F}' = g\boldsymbol{F}$$

satisfies the differential equation

$$\bar{\rho}\frac{\partial^2 \boldsymbol{w}}{\partial t^2} = \mathrm{div}P + \bar{\rho}\boldsymbol{F}, \tag{1.1}$$

where

$$P = \bar{\chi}P^f + (1-\bar{\chi})P^s, \tag{1.2}$$

$$P^f = \alpha_\mu D\left(x, \frac{\partial \boldsymbol{w}}{\partial t}\right) - \left(p_f - \alpha_\nu \mathrm{div}\frac{\partial \boldsymbol{w}}{\partial t}\right) I, \tag{1.3}$$

$$P^s = \alpha_\lambda D(x, \boldsymbol{w}) + \alpha_\eta(\mathrm{div}\boldsymbol{w})I, \tag{1.4}$$

$$p_f + \bar{\chi}\alpha_p \mathrm{div}\boldsymbol{w} = 0. \tag{1.5}$$

Hereafter, we use the notation

$$D(x, \boldsymbol{u}) = (1/2)\left(\nabla_x \boldsymbol{u} + (\nabla_x \boldsymbol{u})^T\right), \quad \bar{\rho} = \bar{\chi}\rho_f + (1-\bar{\chi})\rho_s,$$

†Mathematics Department, Belgorod State University, ul.Pobedi 85, 308015 Belgorod, Russia (meirmanov@bsu.edu.ru).

where I is the unit tensor, the given function $\bar{\chi}(\boldsymbol{x})$ is the characteristic function of the pore space, the given function $\boldsymbol{F}(\boldsymbol{x},t)$ is the dimensionless vector of distributed mass forces, P^f is the liquid stress tensor, P^s is the stress tensor in the solid skeleton, and p_f is the liquid pressure.

Equations (1.1)–(1.5) mean that the displacement vector $\boldsymbol{w}$ satisfies the Stokes equations in the pore space Ω_f and the Lamé equations in the solid skeleton Ω_s.

On the "solid skeleton–pore space" common boundary Γ, the displacement vector $\boldsymbol{w}$ and the liquid pressure p_f satisfy the usual continuity condition

$$[\boldsymbol{w}](\boldsymbol{x}_0,t)=0,\quad \boldsymbol{x}_0\in\Gamma,\ t\geq 0, \tag{1.6}$$

and the momentum conservation law in the form

$$[P\cdot\mathbf{n}](\boldsymbol{x}_0,t)=0,\quad \boldsymbol{x}_0\in\Gamma,\ t\geq 0, \tag{1.7}$$

where $\mathbf{n}(\boldsymbol{x}_0)$ is the unit normal to the boundary at the point $\boldsymbol{x}_0\in\Gamma$ and

$$[\varphi](\boldsymbol{x}_0,t)=\varphi_{(s)}(\boldsymbol{x}_0,t)-\varphi_{(f)}(\boldsymbol{x}_0,t),$$
$$\varphi_{(s)}(\boldsymbol{x}_0,t)=\lim_{\substack{\boldsymbol{x}\to\boldsymbol{x}_0\\ \boldsymbol{x}\in\Omega_s}}\varphi(\boldsymbol{x},t),\quad \varphi_{(f)}(\boldsymbol{x}_0,t)=\lim_{\substack{\boldsymbol{x}\to\boldsymbol{x}_0\\ \boldsymbol{x}\in\Omega_f}}\varphi(\boldsymbol{x},t).$$

The problem is endowed with the homogeneous initial and boundary conditions

$$\boldsymbol{w}(\boldsymbol{x},0)=0,\quad \frac{\partial\boldsymbol{w}}{\partial t}(\boldsymbol{x},0)=0,\quad \boldsymbol{x}\in\Omega, \tag{1.8}$$

$$\boldsymbol{w}(\boldsymbol{x},t)=0,\quad \boldsymbol{x}\in S=\partial\Omega,\quad t\geq 0. \tag{1.9}$$

The dimensionless constants α_i $(i=\tau,\nu,\ldots)$ are defined by the formulas

$$\alpha_\mu=\frac{2\mu\tau}{L^2\rho_0},\quad \alpha_\lambda=\frac{2\lambda\tau^2}{L^2\rho_0},\quad \alpha_\nu=\frac{\nu\tau}{L^2\rho_0},$$

$$\alpha_p=\rho_f c_f^2\frac{\tau^2}{L^2},\quad \alpha_\eta=\frac{\eta\tau^2}{L^2\rho_0}=\rho_s c_s^2\frac{\tau^2}{L^2},$$

where μ is the fluid viscosity, ν is the bulk fluid viscosity, λ and η are elastic Lamé's constants, c_f is the speed of sound in fluids, c_s is the speed of sound in solids, L is the characteristic size of the domain under study, τ is the characteristic time of the process, ρ_f and ρ_s are the respective mean dimensionless densities of the liquid and solid phases correlated with the mean density of water ρ_0, and g is the value of acceleration due to gravity.

The corresponding mathematical model described by system (1.1)–(1.9) is commonly used (see [2], [9]) and contains a natural small parameter ε, which is the pore characteristic size l divided by the characteristic size L of the entire porous body:

$$\varepsilon=\frac{l}{L}.$$

Our aim is to derive all possible limiting regimes (the homogenized equations) as $\varepsilon\searrow 0$. Such an approximation significantly simplifies the original problem and at the same time preserves all of its main features. But even this approach is too difficult

to be realized, and some additional simplifying assumptions are necessary. In terms of geometrical properties of the medium, it is most expedient to simplify the problem by postulating that the porous structure is periodic.

We impose the following constraints.

1.

(1) The domain $\Omega = (0,1)^3$ is a periodic repetition of an elementary cell $Y^\varepsilon = \varepsilon Y$, where $Y = (0,1)^3$ and the quantity $1/\varepsilon$ is an integer so that Ω always contains an integer number of elementary cells Y^ε.

(2) Let Y_s be the "solid part" of Y, and let the "liquid part" Y_f of Y be its open complement. We write $\gamma = \partial Y_f \cap \partial Y_s$ and assume that γ is a Lipschitz continuous surface.

(3) The pore space Ω_f^ε is a periodic repetition of the elementary cell εY_f, and the solid skeleton Ω_s^ε is a periodic repetition of the elementary cell εY_s. The Lipschitz continuous boundary $\Gamma^\varepsilon = \partial\Omega_s^\varepsilon \cap \partial\Omega_f^\varepsilon$ is a periodic repetition in Ω of the boundary $\varepsilon\gamma$.

(4) Ω_s^ε Ω_f^ε

Here the essential assumptions are those last three on the geometry of the elementary cells Y_s and Y_f and the domains Ω_s^ε and Ω_f^ε. As for the first assumption, we take the simplest structure of Ω (namely, the cube) just to simplify the procedure. In principle, for the domain Ω we can choose any bounded domain with a Lipschitz continuous boundary $S = \partial\Omega$.

Under these assumptions, we have

$$\bar{\chi}(\boldsymbol{x}) = \chi^\varepsilon(\boldsymbol{x}) = \chi\left(\frac{\boldsymbol{x}}{\varepsilon}\right),$$

$$\bar{\rho} = \rho^\varepsilon(\boldsymbol{x}) = \chi^\varepsilon(\boldsymbol{x})\rho_f + (1 - \chi^\varepsilon(\boldsymbol{x}))\rho_s,$$

where $\chi(\boldsymbol{y})$ is the characteristic function of Y_f in Y.

We assume that all dimensionless parameters depend on the small parameter ε and the (finite or infinite) limits exist:

$$\lim_{\varepsilon\searrow 0} \alpha_\mu(\varepsilon) = \mu_0, \quad \lim_{\varepsilon\searrow 0} \alpha_\lambda(\varepsilon) = \lambda_0, \quad \lim_{\varepsilon\searrow 0} \alpha_\nu(\varepsilon) = \nu_0,$$

$$\lim_{\varepsilon\searrow 0} \alpha_\eta(\varepsilon) = \eta_0, \quad \lim_{\varepsilon\searrow 0} \alpha_p(\varepsilon) = p_*,$$

$$\lim_{\varepsilon\searrow 0} \frac{\alpha_\mu}{\varepsilon^2} = \mu_1, \quad \lim_{\varepsilon\searrow 0} \frac{\alpha_\lambda}{\varepsilon^2} = \lambda_1.$$

The first research aiming to find the limiting regimes in the case where the skeleton was an absolutely rigid body was carried out by Sanchez-Palencia and Tartar. Sanchez-Palencia [9, sect. 7.2] formally obtained Darcy's law of filtration using the method of two-scale asymptotic expansions, and Tartar [9, Appendix] rigorously justified the homogenization procedure. Using the same method of two-scale expansions, Burridge and Keller [2] formally derived a system of Biot's equations from problem (1.1)–(1.9) in the case where the parameter α_μ was of order ε^2 and the rest of the coefficients were fixed independent of ε. Under the same assumptions as in [2], a rigorous justification of Biot's model was given by Nguetseng [8] and later by Clopeaut et al. [3]. The most general case of problem (1.1)–(1.9) where

$$\mu_0,\ \lambda_0^{-1},\ \nu_0,\ p_*^{-1},\ \eta_0^{-1} < \infty$$

was studied in [6].

All these authors used Nguetseng's two-scale convergence method [7, 5].

In the present paper, we use the same method to investigate all possible limiting regimes in problem (1.1)–(1.9) in the cases where

$$\nu_0,\, p_*,\, \eta_0 < \infty; \quad \mu_0 = \lambda_0 = 0, \quad 0 < p_*,\, \eta_0.$$

These cases correspond to the seismic acoustic wave propagation, where all the processes on distances of tens of thousands of meters ($L \nearrow \infty$) come to an end in several seconds ($\tau \searrow 0$).

We show that the homogenized equations are different types of nonstandard wave equations for a two- or one-velocity continuum (Theorem 2.2).

This is a very interesting fact: initially a one-velocity continuum becomes a two-velocity continuum after the homogenization procedure, which appears to be the result of different smoothness of the solution in the solid and liquid components:

$$\int_\Omega \alpha_\mu(\varepsilon)\chi^\varepsilon |\nabla \boldsymbol{w}^\varepsilon|^2 dx \le C_0, \quad \int_\Omega \alpha_\lambda(\varepsilon)(1-\chi^\varepsilon)|\nabla \boldsymbol{w}^\varepsilon|^2 dx \le C_0,$$

where C_0 is a constant independent of the small parameter ε. To preserve the best properties of the solution, we must use the well-known extension lemma [1, 4] and extend the solution from the solid part to the liquid part and conversely. At this stage, the criteria μ_1 and λ_1 become crucial. Namely, let $\boldsymbol{w}_f^\varepsilon$ ($\boldsymbol{w}_s^\varepsilon$) be an extension of the liquid (solid) displacements to the solid (liquid) part, and let $\mu_1 = \lambda_1 = \infty$. Then the limiting (homogenized) system describes the one-velocity continuum. This is because of the fact that each of the sequences $\{\boldsymbol{w}^\varepsilon\}$, $\{\boldsymbol{w}_f^\varepsilon\}$, and $\{\boldsymbol{w}_s^\varepsilon\}$ two-scale converges to a function independent of the fast variable. This statement easily follows from Nguetseng's theorem.

If $\mu_1 < \infty$ and $\lambda_1 = \infty$ or $\mu_1 = \infty$ and $\lambda_1 < \infty$, then the homogenized systems describe the two-velocity continuum.

Finally, we note that, in practice, to solve a real physical problem in, for example, acoustics, one does not want to carry out the limiting procedure but, instead, wants to find a simple and reliable mathematical model describing the process. But there is only one exact (sufficiently reliable) mathematical model (1.1)–(1.9) with given physical constants (densities, viscosities, etc.), the characteristic size L of the physical domain under study, and the characteristic time τ of the physical process. The small parameter ε and the dimensionless quantities α_μ, α_λ, α_p, ... are functions of them. Changing the values of L and τ within some reasonable limits, one may find some rules for the behavior of the dimensionless quantities as the small parameter tends to zero. All possible limits of these quantities are described by conditions on μ_0, λ_0, μ_1, ... and, as was mentioned above, each homogenized system corresponds to a given combination of them. Thus, for a given physical situation, there exists a combination of dimensionless criteria, which would suggest the choice of the form of the homogenized system for obtaining the exact mathematical model. Therefore, to find all possible homogenized systems is very important from both mathematical and practical standpoints.

2. Main results. There are various equivalent (in the sense of distributions) forms of representation of (1.1) and boundary conditions (1.6)–(1.7). In what follows, it is convenient to write them in the form of the integral identities.

We say that four functions $\left(\boldsymbol{w}^\varepsilon, p_f^\varepsilon, p_s^\varepsilon, q^\varepsilon\right)$ are a generalized solution of problem (1.1)–(1.9) if they satisfy the regularity conditions

$$\boldsymbol{w}^\varepsilon,\ \nabla\boldsymbol{w}^\varepsilon,\ p_f^\varepsilon,\ p_s^\varepsilon,\ q^\varepsilon \in L^2(\Omega_T) \tag{2.1}$$

in the domain $\Omega_T = \Omega \times (0,T)$, boundary condition (1.9) in the trace sense, (1.5) and the equations

$$p_s^\varepsilon + (1-\chi^\varepsilon)\alpha_\eta \mathrm{div}\boldsymbol{w}^\varepsilon = 0, \tag{2.2}$$

$$q^\varepsilon = p_f^\varepsilon + \frac{\alpha_\nu}{\alpha_p}\frac{\partial p_f^\varepsilon}{\partial t} \tag{2.3}$$

a.e. in Ω_T, and, finally, the integral identity

$$\left.\begin{aligned}\int_{\Omega_T}\Bigg(\rho^\varepsilon \boldsymbol{w}^\varepsilon\cdot\frac{\partial^2\boldsymbol{\varphi}}{\partial t^2} - \chi^\varepsilon\alpha_\mu D(\boldsymbol{x},\boldsymbol{w}^\varepsilon) : D\left(x,\frac{\partial\boldsymbol{\varphi}}{\partial t}\right) - \rho^\varepsilon \boldsymbol{F}\cdot\boldsymbol{\varphi}\\ + \{(1-\chi^\varepsilon)\alpha_\lambda D(x,\boldsymbol{w}^\varepsilon) - (q^\varepsilon + p_s^\varepsilon)I\} : D(x,\boldsymbol{\varphi})\Bigg)\,dxdt = 0\end{aligned}\right\} \tag{2.4}$$

for all smooth vector-functions $\boldsymbol{\varphi} = \boldsymbol{\varphi}(\boldsymbol{x},t)$ such that $\boldsymbol{\varphi}|_{\partial\Omega} = \boldsymbol{\varphi}|_{t=T} = \partial\boldsymbol{\varphi}/\partial t|_{t=T} = 0$.

In this definition, we changed the form of representation of the stress tensor P in the integral identity (2.4) by introducing two new unknown functions, q^ε and p_s^ε, which in a certain sense have the meaning of pressure. In what follows, we call functions q^ε and p_s^ε the liquid and the solid pressure, respectively, and regard (2.3) as the state equation and equations (1.5) and (2.2) as the continuity equations. This special choice of the continuity and state equations simplifies the use of the homogenization procedure.

In (2.4), by $A : B$ we denote the convolution (or, equivalently, the inner tensor product) of two second-rank tensors along the both indices, i.e., $A : B = \mathrm{tr}\,(B^* \circ A) = \sum_{i,j=1}^3 A_{ij}B_{ji}$.

Theorems 2.1–2.2 are the main results of the paper.

THEOREM 2.1. [illegible] $\boldsymbol{F}$ [illegible] $L^2(\Omega)$ [illegible] $\varepsilon > 0$ [illegible] $[0,T]$ [illegible] (1.1)–(1.9)

$$\max_{0\le t\le T}\left\|\left|\frac{\partial\boldsymbol{w}^\varepsilon}{\partial t}\right| + \sqrt{\alpha_\mu}\chi^\varepsilon|\nabla\boldsymbol{w}^\varepsilon| + (1-\chi^\varepsilon)\sqrt{\alpha_\lambda}|\nabla\boldsymbol{w}^\varepsilon|\right\|_{2,\Omega}(t) \le C_0, \tag{2.5}$$

$$\|q^\varepsilon\|_{2,\Omega_T} + \|p_f^\varepsilon\|_{2,\Omega_T} + \|p_s^\varepsilon\|_{2,\Omega_T} \le C_0, \tag{2.6}$$

[illegible] C_0 [illegible] ε

THEOREM 2.2. [illegible] 2.1 [illegible] $\{\varepsilon > 0\}$ [illegible] $\boldsymbol{w}_f^\varepsilon, \boldsymbol{w}_s^\varepsilon \in L^\infty(0,T; W_2^1(\Omega))$ [illegible]

$$\boldsymbol{w}_f^\varepsilon = \boldsymbol{w}^\varepsilon \text{ [illegible] } \Omega_f^\varepsilon \times (0,T), \qquad \boldsymbol{w}_s^\varepsilon = \boldsymbol{w}^\varepsilon \text{ [illegible] } \Omega_s^\varepsilon \times (0,T),$$

[illegible] $\{p_f^\varepsilon\}$, $\{q^\varepsilon\}$, $\{p_s^\varepsilon\}$, $\{\boldsymbol{w}^\varepsilon\}$, $\{\chi^\varepsilon\boldsymbol{w}^\varepsilon\}$, $\{(1-\chi^\varepsilon)\boldsymbol{w}^\varepsilon\}$, $\{\boldsymbol{w}_f^\varepsilon\}$ [illegible] $\{\boldsymbol{w}_s^\varepsilon\}$ [illegible] $\varepsilon \searrow 0$ [illegible] $L^2(\Omega_T)$ [illegible] p_f, q, p_s, $\boldsymbol{w}$, $\boldsymbol{w}^f$, $\boldsymbol{w}^s$, $\boldsymbol{w}_f$, [illegible] $\boldsymbol{w}_s$ [illegible]

$$\rho_f \frac{\partial^2 \boldsymbol{w}^f}{\partial t^2} + \rho_s(1-m)\frac{\partial^2 \boldsymbol{w}_s}{\partial t^2} = -\frac{1}{m}\nabla q + \hat{\rho}\boldsymbol{F} \tag{2.16}$$

$$\frac{1}{p_*}p_f + \frac{1}{\eta_0}p_s + \mathrm{div}\boldsymbol{w}^f + (1-m)\mathrm{div}\boldsymbol{w}_s = 0, \tag{2.17}$$

$$\frac{\partial \boldsymbol{w}^f}{\partial t} = m\frac{\partial \boldsymbol{w}_s}{\partial t} + \int_0^t B_1^f(t-\tau)\cdot \boldsymbol{z}^f(\boldsymbol{x},\tau)d\tau, \tag{2.18}$$

$$\boldsymbol{z}^f(\boldsymbol{x},t) = -\frac{1}{m}\nabla q(\boldsymbol{x},t) + \rho_f \boldsymbol{F}(\boldsymbol{x},t) - \rho_f \frac{\partial^2 \boldsymbol{w}_s}{\partial t^2}(\boldsymbol{x},t),$$

$\mu_1 > 0$

$$\rho_f \frac{\partial^2 \boldsymbol{w}^f}{\partial t^2} = \rho_f B_2^f \cdot \frac{\partial^2 \boldsymbol{w}_s}{\partial t^2} + (mI - B_2^f)\cdot\left(-\frac{1}{m}\nabla q + \rho_f \boldsymbol{F}\right) \tag{2.19}$$

$\mu_1 = 0$ (2.9), (2.16)–(2.19) (2.10) (2.11) $\boldsymbol{w} = \boldsymbol{w}^f + (1-m)\boldsymbol{w}_s$

(2.18)–(2.19) $B_1^f(t)$ B_2^f (5.44)–(5.45) $(mI - B_2^f)$

(IV) $\mu_1 < \infty$ $\lambda_1 < \infty$ Ω_T $\boldsymbol{w}$, p_f, q p_s (2.8) (2.9)

$$\frac{\partial \boldsymbol{w}}{\partial t} = \int_0^t B(t-\tau)\cdot\nabla q(\boldsymbol{x},\tau)d\tau + \boldsymbol{f}(\boldsymbol{x},t), \tag{2.20}$$

$B(t)$ $\boldsymbol{f}(\boldsymbol{x},t)$ (5.58) (5.59) (2.8), (2.9), (2.20) (2.10) (2.11)

As was mentioned above, even in the most simple case (I) with $\nu_0 = 0$, Theorem 2.2 gives the standard wave equation for the solid pressure p_s but with a completely new speed of sound in the mixture, which includes the porosity, densities, and speeds of sound in the solid and liquid components.

In the next simple case (IV) with $\nu_0 = 0$, Theorem 2.2 gives a new wave equation for the solid pressure in the form

$$\frac{\partial p_s}{\partial t} = \int_0^t \mathrm{div}\big(\widetilde{B}(t-\tau)\cdot\nabla p_s(\boldsymbol{x},\tau)\big)d\tau. \tag{2.21}$$

Here $\widetilde{B}(0) = c^2 I$, where the time derivative of the matrix $\widetilde{B}(t)$ is generally unbounded at $t = 0$. This equation has no simple solutions like traveling waves and requires a special analysis even for the smooth matrix $\widetilde{B}(t)$.

The rest of the homogenized models described by Theorem 2.2 are much more complicated than the model (2.21). This is natural, because one cannot expect that a simple model gives an "accurate" approximation of the very complicated original model (1.1)–(1.9).

3. Preliminaries.

3.1. Two-scale convergence. The justification of Theorem 2.2 is based on a systematic use of the two-scale convergence method, which was proposed by Nguetseng [7] and has been recently used in a wide range of homogenization problems (see, for example, the survey [5]).

DEFINITION 3.1. $\{w^\varepsilon\} \subset L^2(\Omega_T)$ $W \in L^2(\Omega_T \times Y)$

$$\lim_{\varepsilon \searrow 0} \int_{\Omega_T} w^\varepsilon(\boldsymbol{x},t)\, \sigma\left(\boldsymbol{x},t,\frac{\boldsymbol{x}}{\varepsilon}\right) d\boldsymbol{x}dt = \int_{\Omega_T}\int_Y W(\boldsymbol{x},t,\boldsymbol{y})\, \sigma(\boldsymbol{x},t,\boldsymbol{y}) d\boldsymbol{y}d\boldsymbol{x}dt \tag{3.1}$$

$\sigma = \sigma(\boldsymbol{x},t,\boldsymbol{y}) \in C^\infty(\Omega_T \times Y)$ $\boldsymbol{y}$ Ω_T

The existence and the main properties of weakly convergent sequences are established by the following fundamental theorem [7, 5].

THEOREM 3.2 (Nguetseng's theorem). 1. $L^2(\Omega_T)$ $W \in L^2(\Omega_T \times Y)$

2. $\{w^\varepsilon\}$ $\{\varepsilon \nabla_x w^\varepsilon\}$ $L^2(\Omega_T)$ $W = W(\boldsymbol{x},t,\boldsymbol{y})$ $\boldsymbol{y}$ $\{w^\varepsilon\}$ W, $\nabla_y W \in L^2(\Omega_T \times Y)$ $\{w^\varepsilon\}$ $\{\varepsilon \nabla_x w^\varepsilon\}$ W $\nabla_y W$

COROLLARY 3.3. $\sigma \in L^2(Y)$ $\sigma^\varepsilon(\boldsymbol{x}) = \sigma(\boldsymbol{x}/\varepsilon)$ $\{w^\varepsilon\} \subset L^2(\Omega_T)$ $W \in L^2(\Omega_T \times Y)$ $\{\sigma^\varepsilon w^\varepsilon\}$ σW

3.2. An extension lemma. A typical difficulty in homogenization problems like problem (1.1)–(1.7) arises in passing to the limit as $\varepsilon \searrow 0$ because of the fact that the bounds on the displacement gradient $\nabla \boldsymbol{w}^\varepsilon$ may be different in the liquid and solid components. The classical approach to overcoming this difficulty consists in constructing an extension of the displacement field defined merely on Ω_s or Ω_f to the whole Ω. The following lemma is valid due to the well-known results from [1, 4, 8]. We formulate it in the form convenient for us.

LEMMA 3.4. 1 $\boldsymbol{w}^\varepsilon \in \overset{\circ}{W}{}_2^1(\Omega)$ $\boldsymbol{w}_f^\varepsilon, \boldsymbol{w}_s^\varepsilon \in W_2^1(\Omega)$ Ω_f^ε Ω_s^ε w^ε

$$\chi^\varepsilon(\boldsymbol{x})(\boldsymbol{w}_f^\varepsilon(\boldsymbol{x}) - \boldsymbol{w}^\varepsilon(\boldsymbol{x})) = 0, \quad (1-\chi^\varepsilon(\boldsymbol{x}))(\boldsymbol{w}_s^\varepsilon(\boldsymbol{x}) - \boldsymbol{w}^\varepsilon(\boldsymbol{x})) = 0, \quad \boldsymbol{x} \in \Omega, \tag{3.2}$$

$$\|\boldsymbol{w}_i^\varepsilon\|_{2,\Omega} \le C\|\boldsymbol{w}^\varepsilon\|_{2,\Omega_i^\varepsilon}, \quad \|D(x,\boldsymbol{w}_i^\varepsilon)\|_{2,\Omega} \le C\|D(x,\boldsymbol{w}^\varepsilon)\|_{2,\Omega_i^\varepsilon},\ i = f,s, \tag{3.3}$$

C Y ε

3.3. Some notation. Further we denote the following:
(1)

$$\langle\Phi\rangle_Y = \int_Y \Phi dy, \quad \langle\Phi\rangle_{Y_f} = \int_Y \chi\Phi dy, \quad \langle\Phi\rangle_{Y_s} = \int_Y (1-\chi)\Phi dy.$$

(2) If $\mathbf{a}$ and $\mathbf{b}$ are two vectors, then the matrix $\mathbf{a}\otimes\mathbf{b}$ is defined by the formula

$$(\mathbf{a}\otimes\mathbf{b})\cdot\mathbf{c} = \mathbf{a}(\mathbf{b}\cdot\mathbf{c})$$

for any vector $\mathbf{c}$.

4. Proof of Theorem 2.1. Estimates (2.5)–(2.6) follow from the energy equality in the form

$$\frac{d}{dt}\left\{\int_\Omega \rho^\varepsilon\left(\frac{\partial \boldsymbol{w}^\varepsilon}{\partial t}\right)^2 + \alpha_\lambda\int_\Omega (1-\chi^\varepsilon)D(x,\boldsymbol{w}^\varepsilon) : D(x,\boldsymbol{w}^\varepsilon)dx\right.$$
$$\left. + \alpha_p\int_\Omega \chi^\varepsilon(\mathrm{div}\boldsymbol{w}^\varepsilon)^2 dx + \alpha_\eta\int_\Omega (1-\chi^\varepsilon)(\mathrm{div}\boldsymbol{w}^\varepsilon)^2 dx\right\} + \alpha_\nu\int_\Omega \chi^\varepsilon\left(\mathrm{div}\frac{\partial \boldsymbol{w}^\varepsilon}{\partial t}\right)^2 dx$$
$$+ \alpha_\mu\int_\Omega \chi^\varepsilon D\left(x,\frac{\partial \boldsymbol{w}^\varepsilon}{\partial t}\right) : D\left(x,\frac{\partial \boldsymbol{w}^\varepsilon}{\partial t}\right)dx = \int_\Omega \rho^\varepsilon\frac{\partial \boldsymbol{F}}{\partial t}\cdot\frac{\partial \boldsymbol{w}^\varepsilon}{\partial t}dx \tag{4.1}$$

if we use Hölder, Gronwall, and Korn inequalities and extension Lemma 3.4. In turn, the energy equality (4.1) follows from (1.1) if we express the stress tensor P and the liquid pressure p_f using state equations (1.2)–(1.4) and continuity equation (1.5), multiply the result by $\partial\boldsymbol{w}^\varepsilon/\partial t$, and integrate by parts. Note that all terms on the "solid skeleton–pore space" interface Γ^ε disappear due to boundary conditions (1.6)–(1.7).

The same estimates (2.5)–(2.6) guarantee the existence and uniqueness of the generalized solution for problem (1.1)–(1.9).

5. Proof of Theorem 2.2.

5.1. Weak and two-scale limits of sequences of displacements and pressures. First, we use Lemma 3.4 and conclude that there are functions $\boldsymbol{w}_f^\varepsilon$, $\boldsymbol{w}_s^\varepsilon \in L^\infty(0,T;W_2^1(\Omega))$ such that

$$\boldsymbol{w}_f^\varepsilon = \boldsymbol{w}^\varepsilon \text{ in } \Omega_f^\varepsilon\times(0,T), \quad \boldsymbol{w}_s^\varepsilon = \boldsymbol{w}^\varepsilon \text{ in } \Omega_s^\varepsilon\times(0,T).$$

By Theorem 2.1, the sequences $\{p_f^\varepsilon\}$, $\{q^\varepsilon\}$, $\{p_s^\varepsilon\}$, $\{\boldsymbol{w}^\varepsilon\}$, $\{\boldsymbol{w}_f^\varepsilon\}$, $\{\sqrt{\alpha_\mu}\nabla\boldsymbol{w}_f^\varepsilon\}$, $\{\boldsymbol{w}_s^\varepsilon\}$, and $\{\sqrt{\alpha_\lambda}\nabla\boldsymbol{w}_s^\varepsilon\}$ are bounded in $L^2(\Omega_T)$. Hence there exists a subsequence of small parameters $\{\varepsilon>0\}$ and functions p_f, q, p_s, $\boldsymbol{w}$, $\boldsymbol{w}_f$, and $\boldsymbol{w}_s$ such that

$$p_f^\varepsilon \rightharpoonup p_f, \quad q^\varepsilon \rightharpoonup q, \quad p_s^\varepsilon \rightharpoonup p_s, \quad \boldsymbol{w}^\varepsilon \rightharpoonup \boldsymbol{w}, \quad \boldsymbol{w}_f^\varepsilon \rightharpoonup \boldsymbol{w}_f, \quad \boldsymbol{w}_s^\varepsilon \rightharpoonup \boldsymbol{w}_s \tag{5.1}$$

weakly in $L^2(\Omega_T)$ as $\varepsilon\searrow 0$.

Note also that

$$(1-\chi^\varepsilon)\alpha_\lambda D(x,\boldsymbol{w}_s^\varepsilon)\to 0, \quad \chi^\varepsilon\alpha_\mu D(x,\boldsymbol{w}_f^\varepsilon)\to 0 \tag{5.2}$$

strongly in $L^2(\Omega_T)$ as $\varepsilon\searrow 0$.

Relabeling if necessary, we assume that the sequences themselves converge.

By Nguetseng's theorem, there exist functions $P_f(\boldsymbol{x},t,\boldsymbol{y})$, $P_s(\boldsymbol{x},t,\boldsymbol{y})$, $Q(\boldsymbol{x},t,\boldsymbol{y})$, $\boldsymbol{W}(\boldsymbol{x},t,\boldsymbol{y})$, $\boldsymbol{W}_f(\boldsymbol{x},t,\boldsymbol{y})$, and $\boldsymbol{W}_s(\boldsymbol{x},t,\boldsymbol{y})$ that are one-periodic in $\boldsymbol{y}$ and satisfy the condition that the sequences $\{p_f^\varepsilon\}$, $\{p_s^\varepsilon\}$, $\{q^\varepsilon\}$, $\{\boldsymbol{w}^\varepsilon\}$, $\{\boldsymbol{w}_f^\varepsilon\}$, and $\{\boldsymbol{w}_s^\varepsilon\}$ two-scale converge to $P_f(\boldsymbol{x},t,\boldsymbol{y})$, $P_s(\boldsymbol{x},t,\boldsymbol{y})$, $Q(\boldsymbol{x},t,\boldsymbol{y})$, $\boldsymbol{W}(\boldsymbol{x},t,\boldsymbol{y})$, $\boldsymbol{W}_f(\boldsymbol{x},t,\boldsymbol{y})$, and $\boldsymbol{W}_s(\boldsymbol{x},t,\boldsymbol{y})$, respectively.

LEMMA 5.1. If $\mu_1 = \infty$ ($\lambda_1 = \infty$), then $\boldsymbol{W}_f(\boldsymbol{x},t,\boldsymbol{y}) = \boldsymbol{w}_f(\boldsymbol{x},t)$, $\chi(\boldsymbol{y})\boldsymbol{W}(\boldsymbol{x},t,\boldsymbol{y}) = \chi(\boldsymbol{y})\boldsymbol{w}_f(\boldsymbol{x},t)$, and $\boldsymbol{w}^f = \langle \boldsymbol{W}\rangle_{Y_f} = m\boldsymbol{w}_f$ $\big(\boldsymbol{W}_s(\boldsymbol{x},t,\boldsymbol{y}) = \boldsymbol{w}_s(\boldsymbol{x},t)$, $(1-\chi(\boldsymbol{y}))\boldsymbol{W}(\boldsymbol{x},t,\boldsymbol{y}) = (1-\chi(\boldsymbol{y}))\boldsymbol{w}_s(\boldsymbol{x},t)$ and $\boldsymbol{w}^s = \langle \boldsymbol{W}\rangle_{Y_s} = (1-m)\boldsymbol{w}_s\big)$

Proof. Suppose that $\mu_1 = \infty$, and let $\Psi(\boldsymbol{x},t,\boldsymbol{y})$ be an arbitrary smooth scalar function periodic in $\boldsymbol{y}$. The sequence $\{\sigma_{ij}^\varepsilon\}$, where

$$\sigma_{ij}^\varepsilon = \int_\Omega \sqrt{\alpha_\lambda}\frac{\partial w_{f,i}^\varepsilon}{\partial x_j}(\boldsymbol{x},t)\Psi(\boldsymbol{x},t,\boldsymbol{x}/\varepsilon)dx, \quad \boldsymbol{w}_f^\varepsilon = (w_{f,1}^\varepsilon, w_{f,2}^\varepsilon, w_{f,3}^\varepsilon),$$

is uniformly bounded in ε. Therefore,

$$\int_\Omega \varepsilon\frac{\partial w_{f,i}^\varepsilon}{\partial x_j}(\boldsymbol{x},t)\Psi(\boldsymbol{x},t,\boldsymbol{x}/\varepsilon)dx = \frac{\varepsilon}{\sqrt{\alpha_\lambda}}\sigma_{ij}^\varepsilon \to 0$$

as $\varepsilon \searrow 0$, which is equivalent to

$$\int_\Omega\int_Y W_{f,i}(\boldsymbol{x},t,\boldsymbol{y})\frac{\partial\Psi}{\partial y_j}(\boldsymbol{x},t,\boldsymbol{y})dxdy = 0, \quad \boldsymbol{W}_f = (W_{f,1}, W_{f,2}, W_{f,3}),$$

or $\boldsymbol{W}_f(\boldsymbol{x},t,\boldsymbol{y}) = \boldsymbol{w}_f(\boldsymbol{x},t)$. Therefore taking the two-scale limit as $\varepsilon \searrow 0$ in the relation $\chi^\varepsilon(\boldsymbol{w}^\varepsilon - \boldsymbol{w}_f^\varepsilon) = 0$, we arrive at

$$\chi(\boldsymbol{y})\boldsymbol{W}(\boldsymbol{x},t,\boldsymbol{y}) = \chi(\boldsymbol{y})\boldsymbol{w}_f. \qquad \square$$

5.2. Micro- and macroscopic equations. We start the proof of the theorem from the macro- and microscopic equations related to the continuity equations.

LEMMA 5.2. For almost all $\boldsymbol{x} \in \Omega$ and $\boldsymbol{y} \in Y$, the sequences $\{p_f^\varepsilon\}$, $\{p_s^\varepsilon\}$, $\{q^\varepsilon\}$, $\{\boldsymbol{w}^\varepsilon\}$, $\{\boldsymbol{w}_f^\varepsilon\}$, and $\{\boldsymbol{w}_s^\varepsilon\}$ two-scale converge to functions satisfying the relations

$$Q = q\chi/m,\ P_f = p_f\chi/m,\ P_s = p_s(1-\chi)/(1-m),\ Q = P + \nu_0 p_*^{-1}\partial P/\partial t; \tag{5.3}$$

$$q/m = p_s/(1-m), \quad q = p_f + \nu_0 p_*^{-1}\partial p_f/\partial t; \tag{5.4}$$

$$p_f/p_* + p_s/\eta_0 + \mathrm{div}\boldsymbol{w} = 0; \tag{5.5}$$

$$\boldsymbol{w}(\boldsymbol{x},t)\cdot\boldsymbol{n}(\boldsymbol{x}) = 0, \quad \boldsymbol{x}\in S,\ t>0; \tag{5.6}$$

$$\mathrm{div}_y\boldsymbol{W} = 0; \tag{5.7}$$

$$\boldsymbol{W} = \chi\boldsymbol{W}_f + (1-\chi)\boldsymbol{W}_s. \tag{5.8}$$

Proof. In order to prove (5.3), into (2.4) we substitute the test function $\boldsymbol{\psi}^\varepsilon = \varepsilon\boldsymbol{\psi}(\boldsymbol{x},t,\boldsymbol{x}/\varepsilon)$, where $\boldsymbol{\psi}(\boldsymbol{x},t,\boldsymbol{y})$ is an arbitrary one-periodic function of $\boldsymbol{y}$ that is finite on Y_f (or finite on Y_s or finite on Y). Passing to the limit as $\varepsilon \searrow 0$, we obtain

$$\nabla_y Q = 0,\ \boldsymbol{y}\in Y_f;\ \nabla_y P_s = 0,\ \boldsymbol{y}\in Y_s;\ \nabla_y(Q+P_s) = 0,\ \boldsymbol{y}\in Y. \tag{5.9}$$

Next, fulfilling the two-scale passage to the limit in the state equation (2.3) and in the relations

$$(1-\chi^\varepsilon)q^\varepsilon = 0, \quad \chi^\varepsilon p_s^\varepsilon = 0$$

we arrive at the last equation in (5.3) and the relations

$$(1-\chi)Q=0,\quad \chi P_s=0,$$

which together with the first two equations in (5.9) prove the first three equations in (5.3).

The second equation in (5.4) is the result of integration of the last equation in (5.3) over the domain Y_f.

The first relation in (5.4) follows from (5.3) and the last equation in (5.9): the sequence $\{(q^\varepsilon+p_s^\varepsilon)\}$ two-scale converges to $(Q+P_s)=(q+p_s)$.

Equations (5.5)–(5.7) appear as a result of the two-scale passage to the limit in (1.5) and (2.2) with the proper test functions being involved. Thus, for example, (5.5) and (5.6) arise if we consider the linear combination of (1.5) and (2.2)

$$\frac{1}{\alpha_p}p_f^\varepsilon+\frac{1}{\alpha_\eta}p_s^\varepsilon+\mathrm{div}\boldsymbol{w}^\varepsilon=0, \tag{5.10}$$

multiply it by an arbitrary function independent of the "fast" variable $\boldsymbol{x}/\varepsilon$, and then pass to the limit as $\varepsilon\searrow 0$. To prove (5.7), it suffices to consider the two-scale limiting relations in (5.10) as $\varepsilon\searrow 0$ with the test functions $\varepsilon\psi(\boldsymbol{x}/\varepsilon)\,h(\boldsymbol{x},t)$, where ψ and h are arbitrary smooth functions.

To prove (5.8), it suffices to consider the two-scale limiting relations in

$$\boldsymbol{w}^\varepsilon=\chi^\varepsilon\boldsymbol{w}_f^\varepsilon+(1-\chi^\varepsilon)\boldsymbol{w}_s^\varepsilon. \qquad \square$$

LEMMA 5.3. [illegible] $(\boldsymbol{x},t)\in\Omega_T$ [illegible]

$$\rho_f\frac{\partial^2\boldsymbol{w}^f}{\partial t^2}+\rho_s\frac{\partial^2\boldsymbol{w}^s}{\partial t^2}=-\frac{1}{m}\nabla q+\hat\rho\boldsymbol{F} \tag{5.11}$$

[illegible]. Substituting a test function of the form $\boldsymbol{\psi}=\boldsymbol{\psi}(\boldsymbol{x},t)$ into integral identity (2.4) and passing to the limit as $\varepsilon\searrow 0$, we arrive at (5.11). $\square$

LEMMA 5.4. [illegible] $\mu_1=\infty$ [illegible] $\lambda_1<\infty$ [illegible] Y_s [illegible] $\boldsymbol{W}^s=(1-\chi)\boldsymbol{W}$, $\boldsymbol{w}_f$ [illegible] q [illegible]

$$\rho_s\frac{\partial^2\boldsymbol{W}^s}{\partial t^2}=\lambda_1\triangle_y\boldsymbol{W}^s-\nabla_y R^s-\frac{1}{m}\nabla q+\rho_s\boldsymbol{F},\quad \boldsymbol{y}\in Y_s, \tag{5.12}$$

$$\boldsymbol{W}^s=\boldsymbol{w}_f,\quad \boldsymbol{y}\in\gamma, \tag{5.13}$$

[illegible] $\lambda_1>0$ [illegible]

$$\rho_s\frac{\partial^2\boldsymbol{W}^s}{\partial t^2}=-\nabla_y R^s-\frac{1}{m}\nabla q+\rho_s\boldsymbol{F},\quad \boldsymbol{y}\in Y_s, \tag{5.14}$$

$$(\boldsymbol{W}^s-\boldsymbol{w}_f)\cdot\boldsymbol{n}=0,\quad \boldsymbol{y}\in\gamma, \tag{5.15}$$

[illegible] $\lambda_1=0$

$$\boldsymbol{W}^s(\boldsymbol{y},0)=\frac{\partial\boldsymbol{W}^s}{\partial t}(\boldsymbol{y},0)=0,\quad \boldsymbol{y}\in Y_s. \tag{5.16}$$

(5.15) $\boldsymbol{n}$ [illegible] γ [illegible]. The differential equations (5.12) and (5.14) follow as $\varepsilon \searrow 0$ from integral equality (2.4) with the test function $\boldsymbol{\psi} = \boldsymbol{\varphi}(x\varepsilon^{-1}) \cdot h(\boldsymbol{x}, t)$, where $\boldsymbol{\varphi}$ is solenoidal and finite in Y_s.

The boundary condition (5.13) is a consequence of the two-scale convergence of the sequence $\{\sqrt{\alpha_\lambda}\nabla_x \boldsymbol{w}^\varepsilon\}$ to the function $\sqrt{\lambda_1}\nabla_y \boldsymbol{W}(\boldsymbol{x}, t, \boldsymbol{y})$. By this convergence, the function $\nabla_y \boldsymbol{W}(\boldsymbol{x}, t, \boldsymbol{y})$ is L^2-integrable in Y. The boundary condition (5.15) follows from (5.7)–(5.8) and the relation $\boldsymbol{W}_f = \boldsymbol{w}_f$. □

In the same way, one can prove the following lemma.

LEMMA 5.5. [illegible] $\mu_1 < \infty$ [illegible] $\lambda_1 = \infty$ [illegible] Y_f [illegible] $\boldsymbol{W}^f = \chi \boldsymbol{W}$, $\boldsymbol{w}_s$ [illegible] q [illegible]

$$\rho_f \frac{\partial^2 \boldsymbol{W}^f}{\partial t^2} = \mu_1 \triangle_y \frac{\partial \boldsymbol{W}^f}{\partial t} - \nabla_y R^f - \frac{1}{m}\nabla q + \rho_f \boldsymbol{F}, \quad \boldsymbol{y} \in Y_f, \tag{5.17}$$

$$\boldsymbol{W}^f = \boldsymbol{w}_s, \quad \boldsymbol{y} \in \gamma, \tag{5.18}$$

[illegible] $\mu_1 > 0$ [illegible]

$$\rho_f \frac{\partial^2 \boldsymbol{W}^f}{\partial t^2} = -\nabla_y R^f - \frac{1}{m}\nabla q + \rho_f \boldsymbol{F}, \quad \boldsymbol{y} \in Y_f, \tag{5.19}$$

$$(\boldsymbol{W}^f - \boldsymbol{w}_s) \cdot \boldsymbol{n} = 0, \quad \boldsymbol{y} \in \gamma, \tag{5.20}$$

[illegible] $\mu_1 = 0$ [illegible]

$$\boldsymbol{W}^f(\boldsymbol{y}, 0) = \frac{\partial \boldsymbol{W}^f}{\partial t}(\boldsymbol{y}, 0) = 0, \quad \boldsymbol{y} \in Y_f. \tag{5.21}$$

LEMMA 5.6. [illegible] $\mu_1 < \infty$, $\lambda_1 < \infty$, [illegible] $\tilde{\rho} = \rho_f \chi + \rho_s(1 - \chi)$ [illegible] Y, [illegible] $\boldsymbol{W}$ [illegible] q [illegible]

$$\left.\begin{aligned} &\tilde{\rho}\partial^2 \boldsymbol{W}/\partial t^2 + 1/m \nabla q - \tilde{\rho}\boldsymbol{F} \\ &= \operatorname{div}_y\{\mu_1 \chi D(y, \partial \boldsymbol{W}/\partial t) + \lambda_1(1 - \chi)D(y, \boldsymbol{W}) - RI\} \end{aligned}\right\} \tag{5.22}$$

[illegible]

$$\boldsymbol{W}(\boldsymbol{y}, 0) = \frac{\partial \boldsymbol{W}}{\partial t}(\boldsymbol{y}, 0) = 0, \quad \boldsymbol{y} \in Y. \tag{5.23}$$

In the proof of the last lemma, we additionally use Nguetseng's theorem, which states that the sequence $\{\varepsilon D(x, \boldsymbol{w}^\varepsilon)\}$ two-scale converges to the function $D(y, \boldsymbol{W})$.

5.3. Homogenized equations. Lemmas 5.2 and 5.3 imply the following lemma.

LEMMA 5.7. [illegible] $\mu_1 = \lambda_1 = \infty$ [illegible] $\boldsymbol{w}_f = \boldsymbol{w}_s = \boldsymbol{w}$ [illegible] Ω_T [illegible] $\boldsymbol{w}$, p_f, q [illegible] p_s [illegible]

$$\hat{\rho}\frac{\partial^2 \boldsymbol{w}}{\partial t^2} = -\frac{1}{m}\nabla q + \hat{\rho}\boldsymbol{F}, \tag{5.24}$$

$$\frac{1}{p_*}p_f + \frac{1}{\eta_0}p_s + \operatorname{div}\boldsymbol{w} = 0, \tag{5.25}$$

$$q = p_f + \frac{\nu_0}{p_*}\frac{\partial p_f}{\partial t}, \quad \frac{1}{m}q = \frac{1}{1-m}p_s, \tag{5.26}$$

$$\boldsymbol{w}(\boldsymbol{x},0) = \frac{\partial \boldsymbol{w}}{\partial t}(\boldsymbol{x},0) = 0, \quad \boldsymbol{x} \in \Omega, \tag{5.27}$$

$$\boldsymbol{w}(\boldsymbol{x},t)\cdot\boldsymbol{n}(\boldsymbol{x}) = 0, \quad \boldsymbol{x} \in S,\ t > 0. \tag{5.28}$$

LEMMA 5.8. $\mu_1 = \infty$ $\lambda_1 < \infty$ Ω_T $\boldsymbol{w}_f$, $\boldsymbol{w}^s$, p_f, q p_s (5.26)

$$\rho_f m\frac{\partial^2 \boldsymbol{w}_f}{\partial t^2} + \rho_s\frac{\partial^2 \boldsymbol{w}^s}{\partial t^2} = -\frac{1}{m}\nabla q + \hat{\rho}\boldsymbol{F}, \tag{5.29}$$

$$\frac{1}{p_*}p_f + \frac{1}{\eta_0}p_s + m\mathrm{div}\boldsymbol{w}_f + \mathrm{div}\boldsymbol{w}^s = 0, \tag{5.30}$$

$$\frac{\partial \boldsymbol{w}^s}{\partial t} = (1-m)\frac{\partial \boldsymbol{w}_f}{\partial t} + \int_0^t B_1^s(t-\tau)\cdot\boldsymbol{z}^s(\boldsymbol{x},\tau)d\tau, \tag{5.31}$$

$$\boldsymbol{z}^s(\boldsymbol{x},t) = -\frac{1}{m}\nabla q(\boldsymbol{x},t) + \rho_s\boldsymbol{F}(\boldsymbol{x},t) - \rho_s\frac{\partial^2 \boldsymbol{w}_f}{\partial t^2}(\boldsymbol{x},t),$$

$\lambda_1 > 0$

$$\rho_s\frac{\partial^2 \boldsymbol{w}^s}{\partial t^2} = \rho_s B_2^s\cdot\frac{\partial^2 \boldsymbol{w}_f}{\partial t^2} + ((1-m)I - B_2^s)\cdot\left(-\frac{1}{m}\nabla q + \rho_s\boldsymbol{F}\right) \tag{5.32}$$

$\lambda_1 = 0$ (5.26), (5.29)–(5.32) (5.27) (5.28) $\boldsymbol{w} = m\boldsymbol{w}_f + \boldsymbol{w}^s$ (5.31)–(5.32) $B_1^s(t)$ B_2^s (5.37) (5.39) $((1-m)I - B_2^s)$. Equation (5.29) follows directly from (5.11). The continuity equation (5.30) follows from (5.5) if we take into account that

$$\boldsymbol{w} = m\boldsymbol{w}_f + \boldsymbol{w}^s.$$

To find the last two equations (5.31) and (5.32), we just have to solve the system of microscopic equations (5.7), (5.12)–(5.16) and use the formula

$$\boldsymbol{w}^s = \langle \boldsymbol{W}\rangle_{Y_s}.$$

There are two different cases.

(a) If $\lambda_1 > 0$, then the solution of the system of microscopic equations (5.7), (5.12), and (5.13) supplemented with the homogeneous initial data (5.16) is given by the formulas

$$\boldsymbol{W}^s = \int_0^t \left(\boldsymbol{v}(\boldsymbol{x},\tau) + \sum_{i=1}^{3} \boldsymbol{W}^{s,i}(\boldsymbol{y}, t-\tau) z_i^s(\boldsymbol{x},\tau) \right) d\tau,$$

$$R^s = \int_0^t \sum_{i=1}^{3} R^{s,i}(\boldsymbol{y}, t-\tau) z_i^s(\boldsymbol{x},\tau) d\tau, \quad \boldsymbol{z}^s = \left(z_1^s, z_2^s, z_3^s\right),$$

and the functions $\boldsymbol{W}^{s,i}(\boldsymbol{y},t)$ and $R^{s,i}(\boldsymbol{y},t)$ are defined by virtue of the periodic initial boundary value problem

$$\rho_s \frac{\partial^2 \boldsymbol{W}^{s,i}}{\partial t^2} - \lambda_1 \triangle \boldsymbol{W}^{s,i} + \nabla R^{s,i} = 0, \quad \boldsymbol{y} \in Y_s,\ t > 0, \tag{5.33}$$

$$\operatorname{div}_y \boldsymbol{W}^{s,i} = 0, \quad \boldsymbol{y} \in Y_s,\ t > 0, \tag{5.34}$$

$$\boldsymbol{W}^{s,i} = 0, \quad \boldsymbol{y} \in \gamma,\ t > 0, \tag{5.35}$$

$$\boldsymbol{W}^{s,i}(y,0) = 0, \quad \rho_s \frac{\partial \boldsymbol{W}^{s,i}}{\partial t}(\boldsymbol{y},0) = \boldsymbol{e}_i, \quad \boldsymbol{y} \in Y_s. \tag{5.36}$$

In (5.36), $\boldsymbol{e}_i$ is the standard Cartesian basis vector.

Therefore,

$$B_1^s(t) = \left\langle \sum_{i=1}^{3} \frac{\partial \boldsymbol{W}^{s,i}}{\partial t} \right\rangle_{Y_s} (t) \otimes \boldsymbol{e}_i. \tag{5.37}$$

Note that (5.33) is understood in the sense of distributions and the function $B_1^s(t)$ has no time derivative at $t = 0$.

(b) If $\lambda_1 = 0$, then in solving the system (5.7), (5.14), (5.15), and (5.16), we first find the pressure $R^s(\boldsymbol{x}, t, \boldsymbol{y})$ by solving the Neumann problem for the Laplace equation in Y_s in the form

$$R^s(\boldsymbol{x}, t, \boldsymbol{y}) = \sum_{i=1}^{3} R_{s,i}(\boldsymbol{y}) z_i^s(\boldsymbol{x}, t),$$

where $R_{s,i}(\boldsymbol{y})$ is the solution of the problem

$$\triangle_y R_{s,i} = 0, \quad \boldsymbol{y} \in Y_s; \quad \nabla_y R_{s,i} \cdot \boldsymbol{n} = \boldsymbol{n} \cdot \boldsymbol{e}_i, \quad \boldsymbol{y} \in \gamma; \quad \langle R_{s,i} \rangle_{Y_s} = 0. \tag{5.38}$$

Formula (5.32) is the result of integration of (5.14) over the domain Y_s and

$$B_2^s = \sum_{i=1}^{3} \langle \nabla R_{s,i} \rangle_{Y_s} \otimes \boldsymbol{e}_i, \tag{5.39}$$

where the matrix $B = ((1-m)I - B_2^s)$ is symmetric and strictly positive definite. In fact, let $\tilde{R} = \sum_{i=1}^3 R_{s,i}\xi_i$ for any unit vector $\boldsymbol{\xi} = (\xi_1, \xi_2, \xi_3)$. Then

$$(B \cdot \boldsymbol{\xi}) \cdot \boldsymbol{\xi} = \langle (\boldsymbol{\xi} - \nabla \tilde{R})^2 \rangle_{Y_f}$$

and $(B \cdot \boldsymbol{\xi}) \cdot \boldsymbol{\xi} = 0$ if and only if $\tilde{R}$ is a linear function in $\boldsymbol{y}$. On the other hand, it follows from the assumption about the geometry of the domain Y_s that all linear periodic functions on Y_s are constant. Finally, the normalization condition $\langle R_{s,i} \rangle_{Y_s} = 0$ yields that $\tilde{R} = 0$. However, this is impossible, because the functions $R_{s,i}$ are linearly independent. □

LEMMA 5.9. [illegible] $\mu_1 < \infty$ [illegible] $\lambda_1 = \infty$ [illegible] Ω_T [illegible] $\boldsymbol{w}^f$, $\boldsymbol{w}_s$, p_f, q [illegible] p_s [illegible] (5.26) [illegible]

$$\rho_f \frac{\partial^2 \boldsymbol{w}^f}{\partial t^2} + \rho_s (1-m) \frac{\partial^2 \boldsymbol{w}_s}{\partial t^2} = -\frac{1}{m} \nabla q + \hat{\rho} \boldsymbol{F}, \tag{5.40}$$

[illegible]

$$\frac{1}{p_*} p_f + \frac{1}{\eta_0} p_s + \mathrm{div} \boldsymbol{w}^f + (1-m) \mathrm{div} \boldsymbol{w}_s = 0, \tag{5.41}$$

[illegible]

$$\frac{\partial \boldsymbol{w}^f}{\partial t} = m \frac{\partial \boldsymbol{w}_s}{\partial t} + \int_0^t B_1^f (t-\tau) \cdot \boldsymbol{z}^f(\boldsymbol{x}, \tau) d\tau, \tag{5.42}$$

[illegible]

$$\boldsymbol{z}^f(\boldsymbol{x}, t) = -\frac{1}{m} \nabla q(\boldsymbol{x}, t) + \rho_f \boldsymbol{F}(\boldsymbol{x}, t) - \rho_f \frac{\partial^2 \boldsymbol{w}_s}{\partial t^2}(\boldsymbol{x}, t),$$

[illegible] $\mu_1 > 0$ [illegible]

$$\rho_f \frac{\partial^2 \boldsymbol{w}^f}{\partial t^2} = \rho_f B_2^f \cdot \frac{\partial^2 \boldsymbol{w}_s}{\partial t^2} + (mI - B_2^f) \cdot \left(-\frac{1}{m} \nabla q + \rho_f \boldsymbol{F} \right) \tag{5.43}$$

[illegible] $\mu_1 = 0$ [illegible] (5.26), (5.40)–(5.43) [illegible] (5.27) [illegible] (5.28) [illegible] $\boldsymbol{w} = \boldsymbol{w}^f + (1-m)\boldsymbol{w}_s$ [illegible] (5.42)–(5.43) [illegible] $B_1^f(t)$ [illegible] B_2^f [illegible] (5.44)–(5.45) [illegible] $(mI - B_2^f)$ [illegible] f_i [illegible]. The proof of this lemma repeats that of the previous lemma. Here we have to solve the system of microscopic equations (5.7), (5.17)–(5.21) and use the formula

$$\boldsymbol{w}^f = \langle \boldsymbol{W} \rangle_{Y_f}.$$

Thus,

$$B_1^f(t) = \left\langle \sum_{i=1}^3 \frac{\partial \boldsymbol{W}^{f,i}}{\partial t} \right\rangle_{Y_f} (t) \otimes \boldsymbol{e}_i, \tag{5.44}$$

$$B_2^f = \sum_{i=1}^{3} \langle \nabla R_{f,i} \rangle_{Y_f} \otimes \boldsymbol{e}_i, \tag{5.45}$$

where the functions $\boldsymbol{W}^{f,i}(\boldsymbol{y},t)$ solve the periodic initial boundary value problem

$$\rho_f \frac{\partial^2 \boldsymbol{W}^{f,i}}{\partial t^2} - \mu_1 \triangle \frac{\partial \boldsymbol{W}^{f,i}}{\partial t} + \nabla R^{f,i} = 0, \quad \boldsymbol{y} \in Y_f,\ t > 0, \tag{5.46}$$

$$\operatorname{div}_y \boldsymbol{W}^{f,i} = 0, \quad \boldsymbol{y} \in Y_f,\ t > 0, \tag{5.47}$$

$$\boldsymbol{W}^{f,i} = 0, \quad \boldsymbol{y} \in \gamma,\ t > 0, \tag{5.48}$$

$$\boldsymbol{W}^{f,i}(y,0) = 0, \quad \rho_f \frac{\partial \boldsymbol{W}^{f,i}}{\partial t}(y,0) = \boldsymbol{e}_i, \quad \boldsymbol{y} \in Y_f, \tag{5.49}$$

and the functions $R_{f,i}(\boldsymbol{y})$ solve the periodic boundary value problem

$$\triangle_y R_{f,i} = 0, \quad \boldsymbol{y} \in Y_f; \quad \nabla_y R_{f,i} \cdot \boldsymbol{n} = \boldsymbol{n} \cdot \boldsymbol{e}_i, \quad \boldsymbol{y} \in \gamma; \quad \langle R_{f,i} \rangle_{Y_f} = 0. \tag{5.50}$$

Note that, as before, the matrix $(mI - B_2^f)$ is symmetric and strictly positive definite. □

The proof of Theorem 2.2 is completed by the following lemma.

LEMMA 5.10. [illegible] $\mu_1 < \infty$ [illegible] $\lambda_1 < \infty$ [illegible] Ω_T [illegible] $\boldsymbol{w}$, p_f, q, p_s [illegible] (5.25) [illegible] (5.26) [illegible]

$$\frac{\partial \boldsymbol{w}}{\partial t} = \int_0^t B(t-\tau) \cdot \nabla q(\boldsymbol{x},\tau) d\tau + \boldsymbol{f}(\boldsymbol{x},t), \tag{5.51}$$

[illegible] $B(t)$ [illegible] $\boldsymbol{f}(\boldsymbol{x},t)$ [illegible] (5.58) [illegible] (5.59) [illegible] (5.25), (5.26), (5.51) [illegible] (5.27) [illegible] (5.28) [illegible]. To derive the momentum conservation law (5.51), we must solve the system of microscopic equations (5.7), (5.22) with the initial conditions (5.23) and use the formula

$$\boldsymbol{w} = \langle \boldsymbol{W} \rangle_Y.$$

Let

$$\boldsymbol{W} = \int_0^t \sum_{i=1}^{3} \left\{ \boldsymbol{W}^{q,i}(\boldsymbol{y}, t-\tau) \frac{\partial q}{\partial x_i}(\boldsymbol{x},\tau) + \boldsymbol{W}^{F,i}(\boldsymbol{y}, t-\tau) F_i(\boldsymbol{x},\tau) \right\} d\tau,$$

$$R = \int_0^t \sum_{i=1}^{3} \left\{ R^{q,i}(\boldsymbol{y}, t-\tau) \frac{\partial q}{\partial x_i}(\boldsymbol{x},\tau) + R^{F,i}(\boldsymbol{y}, t-\tau) F_i(\boldsymbol{x},\tau) \right\} d\tau,$$

where $\boldsymbol{F} = \sum_{i=1}^{3} F_i \boldsymbol{e}_i$.

Then the pair $\{\boldsymbol{W}, R\}$ is a solution of system (5.7), (5.22) and (5.23) if and only if the functions $\{\boldsymbol{W}^{q,i}(\boldsymbol{y},t), R^{q,i}(\boldsymbol{y},t)\}$ and $\{\boldsymbol{W}^{F,i}(\boldsymbol{y},t), R^{F,i}(\boldsymbol{y},t)\}$ are periodic in $\boldsymbol{y}$ solutions of the equations

$$\mathrm{div}_y\left\{\mu_1\chi D\left(y,\frac{\partial \boldsymbol{W}^{q,i}}{\partial t}\right)+\lambda_1(1-\chi)D(y,\boldsymbol{W}^{q,i})-R^{q,i}I\right\}=\tilde{\rho}\frac{\partial^2\boldsymbol{W}^{q,i}}{\partial t^2}, \tag{5.52}$$

$$\mathrm{div}_y\boldsymbol{W}^{q,i}=0, \tag{5.53}$$

$$\mathrm{div}_y\left\{\mu_1\chi D\left(y,\frac{\partial \boldsymbol{W}^{F,i}}{\partial t}\right)+\lambda_1(1-\chi)D(y,\boldsymbol{W}^{F,i})-R^{F,i}I\right\}=\tilde{\rho}\frac{\partial^2\boldsymbol{W}^{F,i}}{\partial t^2}, \tag{5.54}$$

$$\mathrm{div}_y\boldsymbol{W}^{F,i}=0 \tag{5.55}$$

in the domain Y for $t>0$ and satisfy the initial conditions

$$\boldsymbol{W}^{q,i}(\boldsymbol{y},0)=0,\quad \tilde{\rho}\frac{\partial \boldsymbol{W}^{q,i}}{\partial t}(\boldsymbol{y},0)=-\frac{1}{m}\boldsymbol{e}_i,\quad \boldsymbol{x}\in Y, \tag{5.56}$$

$$\boldsymbol{W}^{F,i}(\boldsymbol{y},0)=0,\quad \frac{\partial \boldsymbol{W}^{F,i}}{\partial t}(\boldsymbol{y},0)=\boldsymbol{e}_i,\quad \boldsymbol{x}\in Y. \tag{5.57}$$

Here $\boldsymbol{e}_i$ is the standard Cartesian basis vector.

Therefore,

$$B(t)=\sum_{i=1}^{3}\left\langle\frac{\partial \boldsymbol{W}^{q,i}}{\partial t}(\boldsymbol{y},t)\right\rangle_Y\otimes\boldsymbol{e}_i, \tag{5.58}$$

$$\mathbf{f}(\boldsymbol{x},t)=\int_0^t\sum_{i=1}^{3}\left\langle\frac{\partial \boldsymbol{W}^{F,i}}{\partial t}(\boldsymbol{y},t-\tau)\right\rangle_Y F_i(\boldsymbol{x},\tau)d\tau. \tag{5.59}$$

The solvability and uniqueness of problems (5.52), (5.53), (5.56) and (5.54), (5.55), (5.57) follow directly from the energy identity

$$\frac{1}{2}\int_Y\left(\tilde{\rho}\left(\frac{\partial \boldsymbol{W}^{j,i}}{\partial t}(\boldsymbol{y},t)\right)^2+\lambda_1 D\big(y,\boldsymbol{W}^{j,i}(\boldsymbol{y},t)\big):D\big(y,\boldsymbol{W}^{j,i}(\boldsymbol{y},t)\big)\right)dy$$

$$+\int_0^t\int_Y\mu_1 D\left(y,\frac{\partial \boldsymbol{W}^{j,i}}{\partial\tau}(\boldsymbol{y},\tau)\right):D\left(y,\frac{\partial \boldsymbol{W}^{j,i}}{\partial\tau}(\boldsymbol{y},\tau)\right)dyd\tau=\frac{1}{2}\beta^j$$

for $i=1,2,3$ and $j=q,F$.

Here

$$\beta^q=\left\langle\frac{1}{\tilde{\rho}}\right\rangle_Y,\quad \beta^F=\langle\tilde{\rho}\rangle_Y.$$

As before, equations (5.51) are understood in the sense of distributions and the function $B(t)$ has no time derivative at $t=0$. □

BOUNDARY BEHAVIOR OF SOLUTIONS OF A CLASS OF GENUINELY NONLINEAR HYPERBOLIC SYSTEMS*

JULIAN GEVIRTZ†

Abstract. We study the set of boundary singularities of arbitrary classical solutions of genuinely nonlinear 2×2 planar hyperbolic systems of the form $D_k R_k = 0$, where D_k denotes differentiation in the direction $e^{i\theta_k(R_1,R_2)}$, $k = 1, 2$, and where the defining functions θ_k satisfy (i) $\theta_2 = \theta_1 + \frac{\pi}{2}$, and (ii) $A \leq |\frac{\partial\theta_k(R)}{\partial R_k}| \leq B$, for all $R \in \mathbb{R}^2$, $k = 1, 2$, for some positive constants A, B. We show that for any system of this kind there is a $\tau < 1$ such that for any locally Lipschitz solution R in a smoothly bounded domain G, the set of points of ∂G at which R fails to have a nontangential limit has Hausdorff dimension at most τ, and, on the other hand, for any such system for which the $\theta_k \in C^\infty(\mathbb{R}^2)$, we construct a C^∞ solution R on a half-plane $\mathbb{H}$ for which the set of points of $\partial\mathbb{H}$ at which R fails to have a nontangential limit has positive Hausdorff dimension. These results are immediately applicable to constant principal strain mappings, which are defined in terms of a system of this kind for which θ_1 is a linear function of R_1 and R_2.

Key words. boundary behavior, constant principal strain mapping, genuinely nonlinear hyperbolic system, Hausdorff dimension, nontangential limit

AMS subject classifications. 35L40, 28A78

DOI. 10.1137/070705507

1. Introduction.

For hyperbolic systems in two independent variables x and t, most often associated with space and time, one usually studies the Cauchy problem, in which one seeks a solution $u(x,t)$, $t \geq 0$, for which $u(x,0)$ coincides with a given $u_0(x)$, the questions considered including well-posedness, global existence, blow-up, and behavior of solutions as $t \to \infty$. In the nonlinear case, discussion is often limited to initial data with a small range, and, even for such data, generalized solutions must be considered.

In this paper we concern ourselves with the following inverse question for a certain family of genuinely nonlinear 2×2 hyperbolic systems: What can be said about the boundary values of an [illegible] classical solution in a plane domain G? Here "classical" can be taken to mean C^∞, although the treatment we give will be valid for locally Lipschitz solutions. In the first place, we are interested in systems whose formulation imposes no a priori limit on the range of characteristic directions, that is, systems such that for a characteristic given parametrically by $z(s)$, $\arg\{z'(s)\}$ can potentially cover all of $\mathbb{R}$, in contrast to what is implicitly the case in the standard space-time context. Second, we are interested in statements valid for [illegible] classical solutions rather than ones known to arise from some form of initial value problem. Because of this generality, even in geometrically simple domains such as disks or half-planes characteristics can be quite contorted curves. Although the specific focus of this paper is the size of the set of boundary points at which classical solutions can fail to have nontangential limits, it would be reasonable to investigate other aspects of their behavior and that of the associated characteristics. In any event, given the nonstandard nature of the boundary value question and of several of the issues that arise in dealing with it, we shall begin with a somewhat detailed discussion of a system

for which it is physically meaningful, namely the system which describes smooth planar mappings with constant principal stretches (cps-mappings), about which we have previously written [ChG], [G1], [G2], [G3], [G4], [G5]. It is in fact the study of the boundary behavior of such mappings that is the main goal of this paper, and we have chosen to work in a wider context only because it is possible to do so with little additional effort, and because this broader approach suggests some interesting questions.

A [illegible] with principal stretch factors $m_1 \neq m_2$ is a mapping $f : G \to \mathbb{C}$ with locally Lipschitz continuous Jacobian

$$J_f = T(-\phi)\sigma(m_1, m_2)T(\theta),$$

where

$$T(\theta) = \begin{bmatrix} \cos\ \theta & \sin\ \theta \\ -\sin\ \theta & \cos\ \theta \end{bmatrix} \quad \text{and} \quad \sigma(m_1, m_2) = \begin{bmatrix} m_1 & 0 \\ 0 & m_2 \end{bmatrix}.$$

As is explained in the cited references, apart from regularity considerations, functions θ and ϕ will correspond to such a mapping on a simply connected domain G if and only if they satisfy the autonomous quasi-linear hyperbolic system

$$D_1(m_1\theta - m_2\phi) = 0, \quad D_2(m_2\theta - m_1\phi) = 0, \tag{1.1}$$

where

$$D_1 u = (\cos\theta)u_x + (\sin\theta)u_y \quad \text{and} \quad D_2 u = (-\sin\theta)u_x + (\cos\theta)u_y.$$

The characteristics of a solution are the integral curves of the fields $e^{i\theta}$ and $ie^{i\theta}$. It turns out that a net $\mathcal{N}$ made up of two mutually orthogonal families of curves covering a simply connected G is the net of characteristics of a cps-mapping if and only if for any two curves C_1, C_2 belonging to one of the families of $\mathcal{N}$ the change in the inclination of the tangent is the same along all subarcs of curves of the [illegible] family which join C_1 to C_2. Nets with this property are known as [illegible]. (See [CS], [G3], [Hem], [Hen], [Hi], [Pr].) The theory of cps-mappings we have developed is based on direct application of (1.1) together with this Hencky–Prandtl (HP) property and the equations

$$D_2D_1\theta = [D_1\theta]^2 \quad \text{and} \quad D_1D_2\theta = -[D_2\theta]^2, \tag{1.2}$$

which are also effectively equivalent to (1.1) and which are very special cases of equations derived by Lax [L] in the context of considerably more general genuinely nonlinear 2×2 hyperbolic systems in the plane and used by him in connection with the inevitability of singularity formation. The [illegible] (1.2) imply that if a characteristic C has curvature κ_0 at p, then the orthogonal characteristic arc emanating from p towards the concave side of C can have length at most $\frac{1}{\kappa_0}$, that is, that the boundary of G must be encountered after moving at most a distance of $\frac{1}{\kappa_0}$ along this orthogonal characteristic. A [illegible] of this kind is a [illegible] for the theory we are developing and plays a fundamental role in all that is to follow.

When regarded as deformations with constant principal strains, cps-mappings are of concrete interest as models in a number of physically interesting contexts (see [Y]).

Consider, for example, a thin liquid film on a plane surface which upon solidification takes on a rectangular cryptocrystalline structure; that is, at each point a suitably oriented minute square of the original liquid becomes a rectangular crystal whose side lengths are constant multiples of the side length of the square. In this light global geometric results for cps-mappings tell one about the extent to which the shape of the original film can change as a result of such solidification and about how matter is moved around in the process, and statements about the existence of boundary limits of θ (and, in light of (1.1), of ϕ, and consequently of the Jacobian of the mapping) tell one to what extent the cryptocrystalline structure is present at the very edge of the solidified lamina. Applied to the system (1.1) the main result of this paper says that [illegible] $\tau < 1$ [illegible] G [illegible] θ [illegible] ϕ [illegible] $S \subset \partial G$ [illegible] τ. On the other hand, the construction of section 5 shows that [illegible] θ [illegible].

Beyond their immediate physical significance, cps-mappings constitute a particularly important and tractable class of planar quasi-isometric mappings, for which we believe they will ultimately be shown to display extremal behavior for many of the as yet unsolved distortion questions (see [J1], [J2]). In this direction a very significant inroad was made a few years ago by Gutlyanskii and Martio [GM], who showed that the [illegible] given by

$$g(re^{i\psi}) = re^{i(\psi+\psi_0 \frac{\log r}{\log \rho})}$$

are extremal for the problem of determining for given $\rho > 1$ and $\psi_0 > 0$ the smallest ratio $\frac{m_1}{m_2} > 1$, such that there is a quasi-isometric mapping f of the annulus $1 < |z| < \rho$ onto itself with stretching bounds m_1, m_2 which satisfies the boundary conditions

$$f(z) = z \quad \text{and} \quad f(\rho z) = \rho e^{i\psi_0} z \quad \text{for} \quad |z| = 1.$$

It is in fact not hard to see that g is indeed a cps-mapping of the entire punctured plane $\mathbb{C}\backslash\{0\}$ with

$$m_1 = \frac{\sqrt{a^2+4}+a}{2} \quad \text{and} \quad m_2 = \frac{\sqrt{a^2+4}-a}{2},$$

where $a = \frac{\psi_0}{\log \rho}$. We call these spiral mappings because the corresponding inclination functions are of the form

$$\theta(re^{i\psi}) = \psi + \alpha, \tag{1.3}$$

where $\tan \alpha = m_2$, which is to say that the characteristics form two mutually orthogonal families of logarithmic spirals, all members of each of which are rotations of each other.

We now describe the class of 2×2 systems for which we treat the boundary limit question. Let $\theta_k = \theta_k(R_1, R_2)$, $k = 1, 2$. For given $R_1(x, y)$, $R_2(x, y)$ and any $u = u(x, y)$ we write

$$D_k u = \cos \theta_k(R_1(x,y), R_2(x,y)) \frac{\partial u}{\partial x} + \sin \theta_k(R_1(x,y), R_2(x,y)) \frac{\partial u}{\partial y}. \tag{1.4}$$

It is well known that in general an autonomous 2×2 quasi-linear homogeneous hyperbolic system for unknown functions f and g is formally equivalent to a system of

the form

$$D_k R_k = 0, \quad k = 1, 2,$$

with appropriate inclination functions $\theta_k(R_1, R_2)$. The relationship between the [illegible] R_1, R_2 and f, g is of the form $R_k(x, y) = F_k(f(x, y), g(x, y))$. Henceforth we write $\Theta = (\theta_1, \theta_2)$ and use the term [illegible] to mean a C^∞ mapping $\Theta : \mathbb{R}^2 \to \mathbb{R}^2$, although the smoothness requirement could be weakened substantially. Obviously, a solution of the system Θ in a domain G of the plane is then a pair of functions $R_1(x, y)$, $R_2(x, y)$ for which R_k is constant on each integral curve (henceforth referred to as a k [illegible]) of the field $e^{i\theta_k(R_1(x,y),R_2(x,y))}$, $k = 1, 2$. A system is said to be [illegible] if the derivatives $\frac{\partial \theta_k}{\partial R_k}$, $k = 1, 2$, never vanish. It is clear that the system (1.1) for the θ and ϕ associated with cps-mappings is already in Riemann invariant form with $R_i = m_i\theta - m_j\phi$, so that in this case the two inclination functions are given by

$$\theta_1 = \theta = \frac{m_1 R_1 - m_2 R_2}{m_1^2 - m_2^2} \quad \text{and} \quad \theta_2 = \theta + \frac{\pi}{2}. \tag{1.5}$$

(Here we have used the convention, in force throughout this paper, to the effect that $\{i, j\} = \{1, 2\}$.) This system is obviously genuinely nonlinear and in fact is the simplest possible such system in that the two families of characteristics are mutually orthogonal and Θ is a linear function of $R = (R_1, R_2)$. We now define the family of systems with which we work.

DEFINITION 1.1. [illegible] normal system [illegible] Θ [illegible]

(i) $\theta_2 = \theta_1 + \frac{\pi}{2}$ [illegible]

(ii) [illegible] A, $B > 0$ [illegible] $A \le |\frac{\partial \theta_k}{\partial R_k}| \le B$ [illegible] $R \in \mathbb{R}^2$

The only hyperbolic systems with which we deal will be normal systems, for which we use the symbol θ to denote θ_1. We shall show that [illegible] Θ [illegible] $\tau = \tau(\Theta) < 1$ [illegible] $G \subset \mathbb{C}$ [illegible] R [illegible] Θ [illegible] G [illegible] ∂G [illegible] R [illegible] ff [illegible] τ. This will follow as an immediate consequence (Corollary 4.3) of our principal result, Main Theorem 2.2, which deals with boundary singularities of a class of functions effectively more general than the class of solutions of normal systems. An outline of the proof, which is actually made simpler by this somewhat greater generality, is given early in section 2, just after the statement of the main theorem. Furthermore, in section 5 we shall show that [illegible] Θ [illegible] C^∞ [illegible] R [illegible] $\mathbb{H}$ [illegible] $\partial\mathbb{H}$ [illegible] R [illegible] ff [illegible]

2. Quasi-HP functions, the characteristic length bound, and related matters. Let $G \subset \mathbb{C}$ be a domain. If θ is a locally Lipschitz function on G, the integral curves of the fields $e^{i\theta(z)}$ and $ie^{i\theta(z)}$ will be called the 1- and 2-characteristics of θ, respectively. The term [illegible] will refer to the complete integral curve, and we will use the term [illegible] to refer to either of the two arcs into which a full characteristic is divided by one of its points. (Characteristics which are closed curves will not arise in this paper since we are dealing with single-valued functions θ.) As indicated in the introduction we will use the convention $\{i, j\} = \{1, 2\}$ throughout. Arcs of k-characteristics will be called k-arcs, or, less specifically, characteristic arcs. With reference to a given θ, a characteristic arc joining points $a, b \in D$ will be denoted by ab and we shall use the abbreviation

$$\Delta\theta(ab) = \theta(b) - \theta(a).$$

A domain $Q \subset G$ will be said to be a [illegible] of θ, and we write $Q = abcd$, if ∂Q is a Jordan curve lying in G containing four points a, b, d, c which occur in that order when ∂Q is traversed in the positive (negative) sense and such that ab and cd are i-arcs and ac and bd are j-arcs. We say that ab and cd are [illegible] of each other with respect to or along any j-characteristic passing through ab. For a curve parameterized by $z = z(s)$, $\alpha < s < \beta$, we use the terms "to the right of C" and "to the left of C" in the obvious sense, so that, for example, if C is a characteristic arc and $p \in C$, we describe an orthogonal characteristic arc or a half-characteristic as emanating from p to the right or left of C.

We shall denote the 2-dimensional measure of $X \subset \mathbb{C}$ by $\mu(X)$ and the 1-dimensional measure of a set A by $\lambda(A)$. The parameter s will always refer to arc length. We use the notation $N(a, r) = \{z : |z - a| < r\}$ and denote the line segment joining a to b by $\overline{ab}$. The overline will also be used to denote closure, but this should cause no confusion. For $X, Y \subset \mathbb{C}$, $\operatorname{dist}(X, Y) = \inf\{|y - x| : x \in X, y \in Y\}$, and for $a \in \mathbb{C}$, $\operatorname{dist}(a, X) = \operatorname{dist}(\{a\}, X)$.

DEFINITION 2.1. [illegible] $K \geq 1$ [illegible] θ [illegible] G [illegible] K-quasi-HP function [illegible] K-quasi-HP property [illegible] $abcd \subset G$ [illegible]

$$\frac{1}{K}|\Delta\theta(ac)| \leq |\Delta\theta(bd)| \leq K|\Delta\theta(ac)|. \tag{2.1}$$

[illegible] 1 [illegible] 2 [illegible] K [illegible] K-quasi-HP net

A simple continuity argument shows that this definition implies that the $\Delta\theta(ac)$ and $\Delta\theta(bd)$ in (2.1) must in fact have the same sign (unless both vanish). It is also obvious that a 1-quasi-HP net is an HP net. Note that while the HP property is a local condition that implies its global counterpart, this is not the case for the K-quasi-HP property when $K > 1$. [illegible] Θ [illegible] K [illegible], where $K = K(\Theta)$. Indeed, if A and B are as in Definition 1.1, then it is clear that we can take $K(\Theta) = B/A$.

We can now state our main theorem.

MAIN THEOREM 2.2. [illegible] $\tau = \tau(K) < 1$ [illegible] θ [illegible] K [illegible] G [illegible] C^2 [illegible] ∂G [illegible] θ [illegible] [illegible] τ

Because the proof of this theorem, to be given in section 4, is quite involved and depends on the prior development of a considerable amount of machinery in this and the following section, we shall briefly explain here how it proceeds. As we shall show (see Proposition 3.29) for any point $p \in \partial G$ at which θ does not have a nontangential limit either there is a nontrivial fan of characteristics emanating from p or, for $k = 1$ or 2, every neighborhood of p completely contains a full k-characteristic of θ; in the latter case we say that p is a k-singularity. Since, as will be apparent, any quasi-HP function can have at most a countable number of fans (see Proposition 3.24), we need only show that the Hausdorff dimension, $\dim(S)$, of the set S of k-singularities satisfies $\dim(S) \leq \tau < 1$. For this to be the case it is enough that there be some $\delta = \delta(K) > 0$ such that any almost straight arc $A \subset \partial G$ has a subarc of length at least $\delta\lambda(A)$ which has at most a countable set of k-singularities of θ. If for some θ there were no such δ, then for any N there would have to be an almost straight arc $A \subset \partial G$ such that there is an N-element set S_N of k-singularities of θ which are essentially uniformly distributed along A. For sufficiently large N, starting with a

set of N small k-characteristics, one very close to each of the points of S_N, we show that there must be a k-characteristic C (where the term "k-characteristic" is used here in an appropriate sense—see the discussion of extended characteristics between Propositions 3.13 and 3.14) whose endpoints lie on A and are at least $\delta'\lambda(A)$ apart (where $\delta' > 0$ depends solely on K) and which is tangent to A at a point $m \in A$, where m is appropriately bounded away from the endpoints of C. We then use this to obtain a subarc A' of A which contains m, whose length is bounded below by $\delta''\lambda(A)$, where δ'', like δ', depends only on K, and on which θ can have at most a countable number of k-singularities (see Proposition 3.33), thereby arriving at the desired contradiction. A good measure of the complexity of the proof lies in establishing the existence of the extended characteristic C, which is carried out in section 4, but which depends on properties of the net of extended characteristics of quasi-HP functions developed in section 3. We begin with the following proposition, which is immediate.

PROPOSITION 2.3 (invariance of K). [illegible] $a, b \in \mathbb{C}$ [illegible] $a \neq 0$ [illegible] $\theta(az+b) - \arg a$ [illegible] $\frac{1}{a}(G-b)$

The next proposition is a special case of [G1, Lemma 2]; a somewhat simpler proof than the one given there is included for the sake of completeness. A function θ is said to be a locally L-Lipschitz function on G if each point of G has a neighborhood in which θ satisfies a Lipschitz condition with constant L.

PROPOSITION 2.4. [illegible] L [illegible] $Q = abcd \subset G$ [illegible] $|b-a| = l$, $|c-a| = \epsilon \leq l$ [illegible] $\operatorname{dist}(Q, \partial G) = \eta > 0$ [illegible] $\overline{l} = \overline{l}(L, \eta) > 0$ [illegible]

$$|d-c| = l - \epsilon\Delta\theta(ab) + O(\epsilon^2 + l^3) \qquad l \leq \overline{l}, \tag{2.2}$$

[illegible] O [illegible] L [illegible] η [illegible]. In what follows, when we say that some quantity is big-O of some expression, we mean that this is so for all l less than some positive number which depends only on L and η, and that the constant corresponding to the big-O depends only on L and η. Let ab and cd be i-arcs. Without loss of generality we can assume that $a = 0$ and $b = l$. Let $\frac{\pi}{2} + \alpha$ and $\frac{\pi}{2} + \beta$ be the inclinations of the tangents to the j-characteristics at a and b, respectively, and let $\frac{\pi}{2} + \alpha' = \arg\{c-a\}$, $\frac{\pi}{2} + \beta' = \arg\{d-b\}$. Clearly, α, β, α', and β' are all $O(l)$ and $\beta - \alpha = \Delta\theta(ab)$. It easily follows from the Lipschitz condition that $\alpha' = \alpha + O(\epsilon)$. We have $d = \epsilon i e^{i\alpha'} + te^{i\gamma}$, where $t = |d-c| = O(l)$ and $\gamma = O(l)$. We also have $d = l + sie^{i\beta'}$, where $s = O(l)$. Just as $\alpha' = \alpha + O(\epsilon)$, one sees that $\beta' = \beta + O(s)$. From the two expressions for d we have that

$$\epsilon i e^{i\alpha'} + te^{i\gamma} = l + sie^{i\beta'},$$

so that considering real and imaginary parts we have

$$-\epsilon \sin\alpha' + t\cos\gamma = l - s\sin\beta' \tag{2.3}$$

and

$$\epsilon\cos\alpha' + t\sin\gamma = s\cos\beta'.$$

The latter equation implies that

$$s(1 + O(l^2)) = \epsilon(1 + O(l^2)) + O(l^2),$$

so that $s = \epsilon + O(l^2)$. Thus, since $\beta' = \beta + O(s)$, we have

$$\beta' = \beta + O(\epsilon + l^2). \tag{2.4}$$

From (2.3) it now follows that

$$\begin{aligned} t(1 + O(l^2)) &= l + \epsilon \sin \alpha' - s \sin \beta' \\ &= l + \epsilon(\alpha' + O(l^3)) - (\epsilon + O(l^2))(\beta' + O(l^3)), \end{aligned}$$

so that from the fact that $\alpha' = \alpha + O(\epsilon)$ and (2.4) it follows that

$$\begin{aligned} |d - c| = t &= l + \epsilon(\alpha' - \beta') + O(l^3) \\ &= l + \epsilon(\alpha + O(\epsilon)) - \epsilon(\beta + O(\epsilon + l^2)) + O(l^3) \\ &= l - \epsilon(\beta - \alpha) + O(\epsilon^2 + l^3). \end{aligned}$$

Since $\beta - \alpha = \Delta\theta(ab)$, we are done. □

Henceforth we use the notation $Df(s)$ to denote $f'(s)$.

PROPOSITION 2.5 (length change estimate). [illegible] θ [illegible] K [illegible] G [illegible] $Q = abcd$ [illegible] $z(s)$ $0 \le s \le \alpha$ [illegible] $z(0) = a$ [illegible] ab [illegible] $s \in [0, \alpha]$ [illegible] $E(s) = z(s)w(s)$ [illegible] ca [illegible] $z(s)$ [illegible] $D\theta(z(s_0)) = \kappa_0$ [illegible] $s_0 \in (0, \alpha)$ [illegible] $\lambda(E(s_0)) = \lambda_0$ [illegible] $\delta > 0$ [illegible] $\tau > 0$ [illegible] $s \in [0, \alpha]$ [illegible] $|z(s) - z(s_0)| < \tau$,

$$|w(s) - w(s_0)| = |z(s) - z(s_0)|(1 - P\lambda_0\kappa_0 + R),$$

[illegible] $\frac{1}{K+\delta} \le P \le K + \delta$, [illegible] $|R| \le \delta$

[illegible]. By replacing G with an appropriate subdomain which contains Q, we can assume that θ is L-Lipschitz on G for some L. Let

$$\psi_0 = \psi_0(s) = \theta(z(s)) - \theta(z(s_0)).$$

For notational convenience we assume that $s > s_0$, the opposite case being effectively the same. Let $u_0(\sigma)$, $0 \le \sigma \le \lambda_0$, be the arc length parameterization of $E(s_0)$ with $u_0(0) = z(s_0)$. For each $\sigma \in [0, \lambda_0]$, let $u(\sigma)$ be the point of $E(s)$ joined to $u_0(\sigma)$ by an i-arc. Let $M(s)$ and $m(s)$ denote the maximum and minimum of $|u(\sigma) - u_0(\sigma)|$ for $0 \le \sigma \le \lambda_0$. Obviously, $M(s) \to 0$ as $s \to 0$. Let $\overline{\tau}$ be so small that

$$M(\overline{\tau}) < \overline{l}(L, \operatorname{dist}(Q, \partial G)), \tag{2.5}$$

where $\overline{l}$ is as in Proposition 2.4. For $\mu \in (0, 1]$ let $\tau_0 \le \overline{\tau}$ be such that

$$|\psi_0(s) - \kappa_0|z(s) - z(s_0)|| < \mu(|\kappa_0| + 1)|z(s) - z(s_0)| \quad \text{for} \quad |s - s_0| < \tau_0. \tag{2.6}$$

We can define an increasing sequence of numbers in $[0, \lambda_0]$ as follows. Let $\sigma_0 = 0$, and let σ_{k+1} be the first number in $[\sigma_k, \lambda_0]$ (as long as there is one) for which $\epsilon_k = |u_0(\sigma_{k+1}) - u(\sigma_k)| = \mu l_k$, where $l_k = |u_0(\sigma_k) - u(\sigma_k)|$. By (2.6) we have

$$|\psi_0 - \kappa_0 l_0| < \mu(|\kappa_0| + 1)l_0. \tag{2.7}$$

Bearing in mind that by the K-quasi-HP property $\Delta\theta(u_0(\sigma_k)u(\sigma_k)) = P_k\psi_0$, where P_k is between $\frac{1}{K}$ and K, we may apply Proposition 2.4 (in light of (2.5)) to conclude that

$$l_{k+1} = l_k - \mu l_k P_k \psi_0 + O((\mu^2 + l_k)l_k^2). \tag{2.8}$$

We continue defining σ_{k+1} until we come to $k = N$, for which $|u_0(\sigma_N) - w(s_0)| < \mu l_N$. Such an N exists, and indeed $(N+1)\mu m(s) \le \lambda_0$. We denote by $T \ge 1$ the constant of the big-O in (2.8). Note that, by the preceding proposition, T depends only on L and $\operatorname{dist}(Q, \partial G))$, and so is independent of the value of μ we ultimately decide to work with.

We now restrict μ to satisfy

$$0 < \mu \le \mu_1 = \frac{1}{T(1+\Lambda_0)\Lambda_0} \le 1, \tag{2.9}$$

where

$$\Lambda_0 = 1 + K(|\kappa_0| + 2)\lambda_0.$$

Note that μ_1 depends only on K, κ_0, λ_0, and T. We show that for $l_0 \le \tau_1 = \min\{\tau_0, \mu^2\}$ we have $l_k \le \Lambda_0 l_0$ for all k. Assume inductively that $l_j \le \Lambda_0 l_0$, $0 \le j \le k$. We now use the facts that $P_k \le K$, and $\Sigma\mu l_j = \Sigma\epsilon_j \le \lambda_0$, and that $|\psi_0| \le (|\kappa_0|+1)l_0$ in light of (2.9) and (2.7). It follows from (2.8) that

$$l_{k+1} = l_0 + \sum_{j=0}^{k} l_{j+1} - l_j = l_0 + \sum_{j=0}^{k}(-\mu l_j P_j \psi_0 + O((\mu^2 + l_j)l_j^2))$$

$$\le l_0 + K|\psi_0|\lambda_0 + T\sum_{j=0}^{k}(\mu^2 + l_j)l_j^2 \le l_0(1 + K(|\kappa_0| + 1)\lambda_0) + \sum_{j=0}^{k} T(\mu^2 + l_j)l_j^2.$$

However,

$$\sum_{j=0}^{k} T(\mu^2 + l_j)l^2 \le T\sum_{j=0}^{k}(\mu^2 + \Lambda_0 l_0)\frac{\epsilon_j}{\mu} l_j \le T\frac{(\mu^2 + \Lambda_0 l_0)\Lambda_0 l_0 \lambda_0}{\mu}$$

$$\le T\frac{(\mu^2 + \Lambda_0\mu^2)\Lambda_0 l_0 \lambda_0}{\mu} \le T\mu(1+\Lambda_0)\Lambda_0 l_0 \lambda_0. \tag{2.10}$$

But by (2.9) this last expression is at most $l_0\lambda_0 \le K l_0 \lambda_0$, so that

$$l_{k+1} \le l_0(1 + K(|\kappa_0| + 1)\lambda_0) + K l_0 \lambda_0 = \Lambda_0 l_0,$$

so that indeed $l_k \le \Lambda_0 l_0$, for all k and all $l_0 \le \tau$, provided only that μ satisfies (2.9) and $l_0 \le \tau_1$. Since $M(s) \to 0$ as $s \to 0$, there is a $\tau_2 = \tau_2(\mu) \le \tau_1$ such that

$$(1-\mu)\lambda_0 \le \sum_{k=0}^{N-1} \epsilon_k \le \lambda_0 \quad \text{for} \quad l_0 \le \tau_2. \tag{2.11}$$

Assume the sequence of σ_k stops at $k = N$. Then $|w(s_0) - u(\sigma_N)| < \mu l_N \le \mu\Lambda_0 l_0$, and, since we are assuming $l_0 = |z(s) - z(s_0)| < \tau_2 \le \mu^2$, Proposition 2.4 implies that

$$||w(s) - w(s_0)| - l_N| \le \mu\Lambda_0 l_0 K\psi_0 + T(\mu^2\Lambda_0^2 l_0^2 + \Lambda_0^3 l_0^3).$$

From this it is easy to see that there is some $\mu \le \mu_1$, which depends only on K, κ_0, λ_0, and T, such that

$$||w(s) - w(s_0)| - l_N| \le \mu l_0. \tag{2.12}$$

As previously,

$$l_N - l_0 = \sum_{k=0}^{N-1} l_{k+1} - l_k = -\sum_{k=0}^{N-1} (\mu l_k P_k \psi_0 + O((\mu^2 + l_k) l_k^2)).$$

By (2.10), the sum of the big-O terms of the immediately preceding displayed line is bounded above by $\Lambda_1 \mu l_0$, where $\Lambda_1 = T(1 + \Lambda_0)\Lambda_0$. For $\psi_0 \ge 0$ it follows from this together with (2.11) and (2.12) that

$$\begin{aligned} |w(s) - w(s_0)| - l_0 &= l_N - l_0 + (|w(s) - w(s_0)| - l_N) \\ &\ge -\sum_{k=0}^{N-1} K\mu l_k \psi_0 - (\Lambda_1 + 1)\mu l_0 \ge -K\psi_0\lambda_0 - (\Lambda_1 + 1)\mu l_0. \end{aligned}$$

But since by (2.7), $\psi_0 \le (\kappa_0 + (|\kappa_0| + 1)\mu) l_0$, it follows that $|w(s) - w(s_0)| - l_0 \ge A l_0$, where

$$A = -K\lambda_0\kappa_0 - \mu(K\lambda_0(|\kappa_0| + 1) + \Lambda_1 + 1).$$

Since (2.7) also implies that $\psi_0 \ge (\kappa_0 - (|\kappa_0| + 1)\mu) l_0$, in an analogous manner one sees that for $\psi_0 \ge 0$

$$\begin{aligned} |w(s) - w(s_0)| - l_0 &\le -\sum_{k=0}^{N-1} \frac{\mu l_k \psi_0}{K} + (\Lambda_1 + 1)\mu l_0 \\ &\le \left(-\frac{1}{K}(1 - \mu)\lambda_0(\kappa_0 - \mu(|\kappa_0| + 1) + (\Lambda_1 + 1)\mu \right) l_0, \end{aligned}$$

so that $|w(s) - w(s_0)| - l_0 \le B l_0$, where

$$B = -\frac{1}{K}\lambda_0\kappa_0 + \mu\left(\frac{1}{K}\lambda_0\kappa_0 + \frac{(1 - \mu)}{K}(|\kappa_0| + 1) + \Lambda_1 + 1 \right).$$

By considering separately the cases $\kappa_0 = 0$ and $\kappa_0 \ne 0$ we obtain the desired conclusion when $\psi_0 \ge 0$ with an appropriate $\mu = \mu(K, \kappa_0, \lambda_0, T, \delta)$. The case $\psi_0 \le 0$ is the same apart from straightforward reversal of inequalities. □

Let ϕ be a real-valued function defined on (α, β), and let $s_0 \in (\alpha, \beta)$. We denote by $D^-\phi(s_0)$ and $D^+\phi(s_0)$ the lower and upper limits of $\frac{\phi(s) - \phi(s_0)}{s - s_0}$ as $s \to s_0$. The remaining three propositions of this section all follow easily from Proposition 2.5 together with elementary measure theory.

PROPOSITION 2.6 (curvature-characteristic length bound). [illegible] $z = z(s)$, $\alpha < s < \beta$, [illegible] K [illegible] θ [illegible] G [illegible] J [illegible] j [illegible] $z(s_0)$ [illegible] C [illegible] ∂G [illegible] $D^+\theta(z(s_0)) \le \frac{K}{\lambda(J)}$.

In particular this says that if C is an i-arc whose curvature $\kappa(p)$ at p exists, then the j-half-characteristic emanating from p towards the [illegible] side of C (that is, to the left or right of C according as $\kappa(p) > 0$ or $\kappa(p) < 0$) has length at most $\frac{K}{\kappa(p)}$.

PROPOSITION 2.7 (length monotonicity). *abcd* θ G $z = z(s)$, $\alpha \le s \le \beta$, $z(\alpha) =$ a ab E λ ab $D\theta(z(s)) \le 0$ E (ab *abcd* E) E' cd E ac $\lambda(E') \ge \lambda(E)$

In section 4 we shall make use of the following two lower bounds for the area of certain regions made up of families of characteristic arcs of a K-quasi-HP function θ; the constants η and η' which appear in them depend solely on K.

PROPOSITION 2.8 (area bounds). C i K θ $w \in C$, $C'(w)$ j C w λ_j $U = \cup\{C'(w) : w \in C\}$

(i) $\mu(U) \ge \eta\lambda(C)\lambda_j$

(ii) $\mu(U) \ge \eta'\lambda_j^2|\Delta\theta(C)|$

3. Extended characteristics and regular and singular boundary behavior. Our approach to boundary behavior requires the examination of curves which are in effect characteristics whose interiors (i.e., sets of nonendpoints) contain boundary points; the subtleties that arise in this connection require careful discussion. Hereafter the symbol $\mathcal{G}$ will denote the family of all Jordan domains $G \subset \mathbb{C}$ for which ∂G is a C^2 curve, and $\mathcal{G}(\rho) \subset \mathcal{G}$ will denote the family of all $G \in \mathcal{G}$ such that for each $p \in \partial G$ the interior of one of the circles of radius ρ tangent to ∂G at p is contained in G and that of the other such circle is contained in $\mathbb{C}\backslash\overline{G}$. Obviously, for $G \in \mathcal{G}(\rho)$ the unsigned curvature of ∂G is everywhere bounded by $\frac{1}{\rho}$, and $\mathcal{G} = \cup\{\mathcal{G}(\rho) : \rho > 0\}$. Furthermore, $\mathrm{HP}(G, K)$ will denote the family of K-quasi-HP functions on G. Although sometimes the hypotheses of the propositions of this section do not state so explicitly, they always deal with $G \in \mathcal{G}$ and $\theta \in \mathrm{HP}(G, K)$. (Although the results of this paper apply to unbounded and multiply connected domains as well, the proof of the main theorem itself will entail only consideration of Jordan domains, and in fact we will be able to work largely with Jordan domains of the kind we call "characteristic subdomains," as defined below.) By an C we shall henceforth mean a continuous one-to-one mapping $z = z(t)$ of a closed interval $[\alpha, \beta]$ into the closure $\overline{G}$ of G, and $z((\alpha, \beta))$ will be referred to as the of C. As in section 2, when an arc is considered to be oriented, we use the term "to (towards) the right (left) of C" to refer to the part of C (immediately) to the right (left) of C, and the term will refer to a complete integral curve of θ or $\theta + \frac{\pi}{2}$ in G. The following proposition was proved in [G5, Proposition 2.8] for HP nets. Although the proof is virtually the same in the present more general context we include it here for the sake of completeness.

PROPOSITION 3.1. *C* G $z = z(s)$, $s \in (\alpha, \beta)$ $\lim_{s\to\beta} z(s)$ ∂G

. Clearly, the conclusion holds if $\beta \ne \infty$, so that we assume $\beta = \infty$. First of all, we show that $\mathrm{dist}(z(s), \partial G) \to 0$ as $s \to \infty$. If this were not true, then there would be a $z_0 \in G$ and an $\epsilon > 0$ such that for some sequence $\{s_i\}$ tending to ∞, $z(s_i) \to z_0$, but $z([s_i, s_{i+1}]) \cap \partial N(z_0, \epsilon) \ne \emptyset$. But from this it would follow that some orthogonal characteristic crosses C twice, an impossible occurrence in light of the simple connectivity of G. We can now show that, in fact, $z(s) \to b \in \partial G$ as $s \to \infty$. If this is not so, the foregoing then implies that there is an arc E of ∂G, $\lambda(E) > 0$, each point of which is an accumulation point of $C_\gamma = \{z(s) : s > \gamma\}$ for each $\gamma \in (\alpha, \infty)$. Since G is bounded and $\beta = \infty$, C cannot be a straight line, so that from the characteristic length bound it follows that there is an orthogonal

half-characteristic C' of finite length which joins some $z(\sigma)$ to a point $e \in \partial G$. Since C cannot cross C' twice in G, $C_\sigma \subset G \backslash C'$. Let z_1, z_2 be distinct points of $E \backslash \{e\}$. For each $\delta > 0$, C_σ has a subarc $pp' \subset N(\partial G, \delta) \backslash C'$, with $p, p' \in N(z_1, \delta)$ and a point $p'' \in pp' \cap N(z_2, \delta)$. For obvious topological reasons, for each sufficiently small δ, there must be a point q on pp' which is joined to a point in $N(z_1, \delta)$ by an orthogonal characteristic arc B of length at least $|z_1 - z_2| - 2\delta$ such that the curvature of C at q exists and tends to infinity as $\delta \to 0$ and C is concave towards the side from which B emanates. But this clearly violates the characteristic length bound (Proposition 2.6), as indicated in the sentence immediately following it. □

DEFINITION 3.2. [illegible] C [illegible] $z(\alpha)$, $z(\beta) \in \partial G$ [illegible] $z((\alpha, \beta)) \subset G$ [illegible] elementary i-characteristic

In other words, an elementary characteristic is a full characteristic together with its endpoints, which are well defined by the preceding proposition. Note that for each $p \in \partial G$, $\{p\}$ is a [illegible] elementary i-characteristic. Subarcs of elementary i-characteristics will be called i [illegible] (or simply i-arcs, for short).

LEMMA 3.3. [illegible] $G \in \mathcal{G}$ [illegible] $B' = B'(G) \in (0, 1]$ [illegible] [illegible] $a, b \in \partial G$ [illegible] C_1 [illegible] C_2 [illegible] [illegible] ∂G [illegible] a [illegible] b ($a = b$, $C_1 = \{a\}$ [illegible] $C_2 = \partial G$) [illegible]

$$\operatorname{dist}(z, C_1) + \operatorname{dist}(z, C_2) \geq B' \operatorname{dist}(z, \{a, b\}) \quad \text{[illegible]} \quad z \in G.$$

[illegible]. This is self-evident. □

PROPOSITION 3.4 (bounded length of characteristics). [illegible] $G \in \mathcal{G}$ [illegible] $M = M(G, K)$ [illegible] $\lambda(C) \leq M$ [illegible] C [illegible] $\theta \in \mathrm{HP}(G, K)$

[illegible]. Let θ be a K-quasi-HP function on G, and let C be an elementary i-characteristic of θ. We regard C as being oriented and let $A = C \cap \partial G$ (A, being the set of endpoints of C, has at most two points). Let $d_0 = \operatorname{diam}(G)$, and let $d = \sup\{\operatorname{dist}(z, A) : z \in C\} \leq d_0$. Clearly,

$$\mu(\{z \in G : \operatorname{dist}(z, A) \leq 8r\}) \leq Br^2, \tag{3.1}$$

where $B = 128\pi$. For $k \geq 0$, let

$$G_k = \left\{ z \in G : \frac{d}{2^k} \leq \operatorname{dist}(z, A) \leq \frac{d}{2^{k-1}} \right\}$$

and

$$C_k = C \cap G_k,$$

so that $C \cap G = \cup\{C_k : k \geq 1\}$. For each nonendpoint p of C, let $J(p)$ denote the elementary j-characteristic containing p. Obviously, $J(p) \cap J(p') \cap G = \emptyset$ for $p \neq p'$. For $k \geq 1$ and $p \in C_k$ let $l(p)$ and $r(p)$ be the first points encountered when moving along $J(p)$ from p to the left and right of C, respectively, which are not in the interior of $G_{k-1} \cup G_k \cup G_{k+1}$. Each $q \in \{l(p), r(p)\}$ is either on ∂G or is in G and satisfies one of $\operatorname{dist}(q, A) = \frac{d}{2^{k+1}}$ or $\operatorname{dist}(q, A) = \frac{d}{2^{k-2}}$. Say $q \notin \partial G$ and $\operatorname{dist}(q, A) = \frac{d}{2^{k+1}}$. Then $|p - q| \geq \frac{d}{2^{k+1}}$, since otherwise $\operatorname{dist}(p, A) \leq |p - q| + \operatorname{dist}(q, A) < \frac{d}{2^k}$, which contradicts the fact that $p \in C_k$. If $q \notin \partial G$ and $\operatorname{dist}(q, A) = \frac{d}{2^{k-2}}$, then $|p - q| \geq \frac{d}{2^{k+1}}$ since otherwise

$$\operatorname{dist}(p, A) \geq \operatorname{dist}(q, A) - |p - q| > \frac{d}{2^{k-2}} - \frac{d}{2^{k+1}} > \frac{d}{2^{k-1}},$$

which is inconsistent with $p \in C_k$. Thus $|p-q| \geq \frac{d}{2^{k+1}}$ if $q \notin \partial G$. Hence, if at least one of $l(p)$, $r(p)$ is not in ∂G, we have for the open subarc $J_1(p)$ of $J(p)$ with endpoints $l(p)$, $r(p)$ that $\lambda(J_1(p)) \geq \frac{d}{2^{k+1}}$. If, on the contrary, $\{l(p), r(p)\} \subset \partial G$, then it follows from the preceding lemma that

$$\lambda(J_1(p)) \geq |l(p) - p| + |p - r(p)| \geq \frac{B'd}{2^k} > \frac{B'd}{2^{k+1}},$$

so that this bound holds in all cases for $p \in C_k$ since $B' \leq 1$. Since $J_1(p) \backslash \{l(p), r(p)\} \subset G_{k-1} \cup G_k \cup G_{k+1}$ for $p \in C_k$, it follows from (3.1) that

$$\begin{aligned} B\left(\frac{d}{2^{k+1}}\right)^2 &\geq \mu\left(\left\{z \in G : \frac{d}{2^{k+1}} \leq \operatorname{dist}(z, \partial G) \leq \frac{d}{2^{k-2}}\right\}\right) \\ &= \mu(G_{k-1} \cup G_k \cup G_{k+1}) \\ &\geq \mu(\cup\{J_1(p) : p \in C_k\}) \geq \eta\lambda(C_k)\frac{B'd}{2^{k+1}}, \end{aligned}$$

by Proposition 2.8(i). From this we have that $\lambda(C_k) \leq \frac{Bd}{\eta B' 2^{k+1}}$. But since $C = \cup\{C_k : k \geq 1\}$, we conclude that $\lambda(C) \leq \frac{Bd}{2B'\eta} \leq \frac{Bd_0}{2B'\eta}$. Since $B = 128\pi$ and B' and d_0 depend only on G, and η depends only on K, we are done. □

DEFINITION 3.5. [illegible] C [illegible] $p \in \partial G$ [illegible] exit G [illegible] p [illegible] C [illegible] $z = z(s)$, $0 \leq s \leq L$ [illegible] $\lim_{s\to 0} \theta(z(s))$ [illegible] C [illegible] regularly [illegible] $z(0)$ [illegible] singularly

PROPOSITION 3.6. [illegible] $G \in \mathcal{G}$ [illegible] $\theta \in \mathrm{HP}(G, K)$ [illegible] $C = ab \subset G$ [illegible] i [illegible] θ [illegible] E [illegible] a [illegible] b [illegible] G [illegible] $E \cap C = \{a, b\}$ [illegible] $\operatorname{diam}(C) \leq 5\lambda(E)$

[illegible]. Let D be the interior of the simple closed curve $C \cup E$. Obviously, $D \subset G$. Let $p \in C$ and $q \in E$ satisfy

$$|p - q| = \sup\{|z - w| : z \in C \text{ and } w \in E\}.$$

Let C' be the elementary j-characteristic containing p. Since a j-characteristic can have at most one point in common with an i-characteristic, there is a point $q' \in E$ such that C' contains a subarc $J = pq'$ whose interior lies in D. Let $\operatorname{diam}(C) = |z_1 - z_2|$, where z_1, $z_2 \in C$. Then

$$\operatorname{diam}(C) = |z_1 - z_2| \leq |z_1 - a| + |a - b| + |b - z_2| \leq 2|p - q| + \lambda(E),$$

since $|z_1 - a|$, $|b - z_2| \leq |p - q|$. But

$$|p - q| \leq |p - q'| + |q' - q| \leq \lambda(J) + \lambda(E),$$

so that

$$\operatorname{diam}(C) \leq 2\lambda(J) + 3\lambda(E).$$

Let J be parameterized by $w(s)$, $0 \leq s \leq l$, with $w(0) = p$. Let I^+ and I^- be the set $s \in (0, l)$ at which $D\theta(w(s)) \geq 0$ and $D\theta(w(s)) \leq 0$, respectively. For $s \in I^+$ ($s \in I^-$) let E^+ (E^-) be the set of points of E joined to $w(s)$ by an i-arc emanating to the

right (left) of J. It follows by a simple argument based on Proposition 2.7 (length monotonicity) that $\lambda(I^+) \le \lambda(E^+)$ and $\lambda(I^-) \le \lambda(E^-)$. But then

$$\lambda(J) \le \lambda(I^+) + \lambda(I^-) \le \lambda(E^+) + \lambda(E^-) \le \lambda(E),$$

from which the desired bound follows immediately. □

PROPOSITION 3.7. [illegible] $p \in \partial G$ [illegible] $q_1, q_2 \in G$ [illegible] $C_1 = pq_1$ [illegible] $C_2 = pq_2$ [illegible] i [illegible] K [illegible] θ [illegible] G [illegible] p [illegible] $J \subset G$ [illegible] j [illegible] c_1 [illegible] $C_1 \cap G$ [illegible] c_2 [illegible] $C_2 \cap G$ [illegible] C_1 C_2 [illegible] J [illegible] T [illegible] $P \subset J$ [illegible] J [illegible] T [illegible] $\lambda(P) = 0$
