THE ∞-WASSERSTEIN DISTANCE: LOCAL SOLUTIONS AND EXISTENCE OF OPTIMAL TRANSPORT MAPS*

THIERRY CHAMPION†, LUIGI DE PASCALE‡, AND PETRI JUUTINEN§

Abstract. We consider the non-nonlinear optimal transportation problem of minimizing the cost functional $\mathcal{C}_\infty(\lambda) = \lambda\text{-ess sup}_{(x,y)\in\Omega^2} |y-x|$ in the set of probability measures on Ω^2 having prescribed marginals. This corresponds to the question of characterizing the measures that realize the infinite Wasserstein distance. We establish the existence of "local" solutions and characterize this class with the aid of an adequate version of cyclical monotonicity. Moreover, under natural assumptions, we show that local solutions are induced by transport maps.

Key words. infinite Wasserstein distance, restrictable solutions, infinite cyclical monotonicity

1. Introduction.

In this paper, we consider the non-nonlinear optimal transportation problem that can be mathematically stated as the problem of minimizing the cost functional

$$\mathcal{C}_\infty(\lambda) := \lambda\text{-ess sup}_{(x,y)\in\Omega^2} |y-x| \tag{1.1}$$

in the set of probability measures on Ω^2 having prescribed marginals. Here, and throughout the paper, we assume that Ω is a compact subset of $\mathbb{R}^d$, $d \geq 1$, $|\cdot|$ denotes the usual Euclidean norm in $\mathbb{R}^d$, μ, ν are the two (given) Borel probability measures on Ω, and $\Pi(\mu,\nu)$ denotes the set of admissible transport plans, i.e., the set of Borel probability measures λ on $\Omega^2 := \Omega \times \Omega$ with first marginal $\pi_{1\,\#}\lambda = \mu$ and second marginal $\pi_{2\,\#}\lambda = \nu$. Informally, if λ is induced by a transport map $T : \Omega \to \Omega$, i.e., $\lambda = (id \times T)_\# \mu$, then $\mathcal{C}_\infty(\lambda)$ is simply the maximum of the transport distances $|T(x) - x|$.

The problem formulated above corresponds to the question of characterizing the measures that realize the infinite Wasserstein distance

$$(P_\infty) \qquad W_\infty(\mu,\nu) \;=\; \inf\Big\{\mathcal{C}_\infty(\lambda) \;=\; \lambda\text{-ess sup}_{(x,y)\in\Omega^2} |y-x| \;:\; \lambda \in \Pi(\mu,\nu)\Big\}$$

between μ and ν. Clearly, this is the limiting case, as $p \to \infty$, of the more familiar (see, e.g., [1, 2, 32]) p-Wasserstein distance problem

$$(P_p) \quad W_p(\mu,\nu) \;=\; \inf\left\{ \left(\int_{\Omega^2} |y-x|^p d\lambda(x,y) \right)^{\frac{1}{p}} \;:\; \lambda \in \Pi(\mu,\nu) \right\}, \qquad 1 \le p < \infty,$$

which is a model example of a Monge–Kantorovich-type optimal transport problem. Despite the close relationship, there are fundamental differences between these two problems. Most importantly, while (P_p) is linear in λ (removing the $1/p$-power does not change the solution set), the mapping $\lambda \mapsto \mathcal{C}_\infty(\lambda)$ is not even convex. In particular, the problem (P_∞) is not additive, which implies that, unlike in the case of (P_p), a restriction of an optimal transport plan need not be optimal for its own marginals.

In view of simple examples, it turns out that only imposing this "local optimality" property can lead to a satisfactory class of solutions. Hence we introduce in this paper the notion of *restrictable solutions*; this subclass of minimizers of (1.1) is characterized by the property that every portion of μ is transported onto its target in an optimal way; see Definition 4.1 below. The existence of a restrictable solution is obtained with the aid of approximating (P_∞) by the problems (P_p). The same strategy also provides us with the notion of *infinite cyclical monotonicity*, which is derived from the standard c-cyclical monotonicity by applying it to the sequence of costs $c_p(x,y) = |x-y|^p$ and then taking the limit as $p \to \infty$. A reader familiar with the theory of infinity Laplacian and related problems [5] should recognize the analogy between restrictable solutions and absolute minimizers of supremum functionals.

It is one of the main results of this paper that restrictable and infinitely cyclically monotone solutions coincide; see Theorems 3.4 and 4.4 below. We would like to emphasize that although both of these notions are derived via an approximation argument, the proof for their equivalence is completely independent of the derivation. Moreover, this result holds without any further assumptions on the marginals μ and ν. The second principal question we address in this paper is existence and uniqueness of an optimal transport map. Our main result in this direction, Theorem 5.5, states that if $\mu \ll \mathcal{L}^d$, then any infinitely cyclically monotone solution γ to (P_∞) is induced by a map $T : \Omega \to \Omega$, i.e., $\gamma = (id \times T)_\# \mu$. Regarding the question of uniqueness, we are able to show that if, in addition to the previous assumptions, the second marginal ν is discrete, then the infinitely cyclically monotone solution to (P_∞) is unique.

A major technical difficulty that we are facing in the proofs is the absence of a useful duality theory, which is due to the nonconvexity of the objective functional (see section 5.4). As a consequence, we must rely on ad hoc arguments designed for the problem at hand. On the other hand, it is quite clear from the proofs that the machinery we are developing applies to more general problems than just (P_∞). In fact, we could have just as well considered a functional $\lambda \mapsto \lambda\text{-ess}\sup_{(x,y)\in\Omega^2} c(x,y)$, where $c(x,y)$ is, say, nonnegative and lower semicontinuous to begin with. In this work we concentrate on the model case $c(x,y) = |y-x|$ so as to identify the useful tools and notions without coping with the additional technical difficulties required by a more general cost c, which seems to be the natural next step in this study.

Let us finish this introduction by discussing some applications in which the infinite Wasserstein distance W_∞ appears. First on our list is the optimal design problem

$$\sup\left\{ \frac{W_\infty(\mu,\nu)^{p+d}}{W_p(\mu,\nu)^p \| (\frac{d\mu}{dx})^{-1} \|_{L^\infty(U)}} \;:\; (\mu,\nu) \in \mathcal{P}_{a.c.}(U) \times \mathcal{P}(\overline{U}) \right\} \tag{1.2}$$

that appears in [9] in connection with stability estimates for optimal transport maps; here $\mathcal{P}$ and $\mathcal{P}_{a.c.}$ denote the spaces of probability measures and absolutely continuous probability measures, respectively, and $\frac{d\mu}{dx}$ is the Radon–Nikodym derivative of μ with respect to the Lebesgue measure. In [9], the authors prove that if $U \subset \mathbb{R}^d$ is a bounded Lipschitz domain, then the estimate

$$W_\infty(\mu,\nu)^{p+d} \le C_{p,d}(U)\|(\tfrac{d\mu}{dx})^{-1}\|_{L^\infty(U)} W_p(\mu,\nu)^p \tag{1.3}$$

holds for every $p > 1$. The inequality (1.3) is an intrinsic counterpart of a beautiful uniform estimate for the optimal transport maps proved in [9] under stronger regularity assumptions. The optimal constant in (1.3) is given by the supremum in (1.2), and it is conjectured (based on 1-dimensional examples and remarks on increasing transport maps) that it does not blow up when $p \to 1$.

Second, during the last few years, models of branching processes using in one way or another tools from the optimal transportation theory have been proposed by several authors; see, for example, [8, 10, 23, 34]. Roughly speaking, these models favor joint transportation, which in many real world situations, such as in the design of communication or irrigation networks, is more economical than individualized transportation. In particular, in [10] the authors propose minimizing a certain cost functional (which penalizes diffused measures) on the p-Wasserstein space of probability measures. It is remarked in [29] that this model is somewhat less realistic than the others cited above, but it has the advantage of being mathematically simpler. Moreover, as pointed out in Remark 6.2.7, Chapter 4, and section 0.2 of [29], the use of the infinite Wasserstein distance W_∞ in the model of [10] produces results which are closer to the ones derived from the other models.

Then there are applications to PDEs. The metric structure associated with the ∞-Wasserstein distance is a crucial tool in proving the existence of stable solutions for a compressible fluid model of rotating binary stars in [24]. The same metric was used also to bound the growth of the wetted regions in the porous medium flow [13] and to study the long time asymptotics of nonlinear scalar conservation laws [12]. Moreover, the ∞-Wasserstein distance is being used in some N-particle approximations of the Vlaslov equations [21, 22].

Finally, in [11] the authors have considered a mathematical model of the optimal pricing policy for the use of a public transportation network. This model assumes that the price of a ticket (for the use of the network) is a function of the distance traveled. This seems reasonable in the case when each citizen is associated with a single journey, but it is not so realistic if we allow multiple journeys and an inexpensive season ticket is available. In the latter case, the price of a season ticket could be assumed to be a piecewise constant function of the maximal distance traveled, and hence it might be a good idea to insert a component similar to the functional we have considered into the model. It is also quite easy to imagine that in many other transportation problems a significant portion of the total cost is in one way or another connected with the maximal transportation distance. For example, if we assume that the physical transportation device (airplane, car, etc.) is the same for all distances, then it has to be chosen so that the longest transportation can be handled.

2. Existence of global solutions. As pointed out in the introduction, the objective functional

$$\begin{aligned}\lambda \mapsto \mathcal{C}_\infty(\lambda) &:= \operatorname*{\lambda\text{-ess sup}}_{(x,y)\in\Omega^2} |y-x| \\ &= \inf\Big\{t \ge 0 : \lambda(\{(x,y)\in\Omega^2 : |y-x| > t\}) = 0\Big\}\end{aligned}$$

is not linear (and not even convex) in λ, contrary to what is usually the case in classical optimal transport problems. However, it is, quite interestingly, level convex in the sense that if $\lambda_1, \lambda_2 \in \Pi(\mu,\nu)$, then

$$\mathcal{C}_\infty(t\lambda_1 + (1-t)\lambda_2) \le \max\{\mathcal{C}_\infty(\lambda_1), \mathcal{C}_\infty(\lambda_2)\} \qquad \text{for all } t \in (0,1).$$

Note that this implies that the set of solutions to (P_∞) is convex. Moreover, it should be observed that $\mathcal{C}_\infty(\lambda)$ depends on the measure λ only via its support. More precisely, one has

$$\mathcal{C}_\infty(\lambda) \;=\; \sup\{|y-x| \,:\, (x,y) \in \mathrm{supp}(\lambda)\}. \tag{2.1}$$

Thanks to this last property, we are in position to give the following existence result.

PROPOSITION 2.1. *Assume that Ω is a compact subset of $\mathbb{R}^d$ and μ, ν are two probability measures on Ω. Then the problem*

$$W_\infty(\mu,\nu) \;=\; \inf\Big\{\mathcal{C}_\infty(\lambda) := \operatorname*{\lambda\text{-ess\,sup}}_{(x,y)\in\Omega^2} |y-x| \,:\, \lambda \in \Pi(\mu,\nu)\Big\} \tag{P_∞}$$

admits at least one solution $\lambda \in \Pi(\mu,\nu)$.

The optimal set of (P_∞) may be very large thanks to (2.1).

Example 2.2. Let $\mu := \frac{1}{2}\,\mathcal{L}^2\lfloor_{[0,1]^2\cup[2,3]^2}$ and $\nu := \frac{1}{2}(\delta_{(2,1)} + \delta_{(1,2)})$. Then it is clear that the value of (P_∞) is $\sqrt{5}$ and that any admissible transport plan $\lambda \in \Pi(\mu,\nu)$ is a solution of (P_∞).

In the proof of Proposition 2.1, we shall use the following lemma.

LEMMA 2.3. *If the sequence $(\lambda_n)_n$ converges weakly to λ in $\Pi(\mu,\nu)$, then for any $(x,y) \in \mathrm{supp}(\lambda)$ there exists a sequence $((x_n,y_n))_{n\in\mathbb{N}}$ such that*

$$(x_n,y_n) \to (x,y) \text{ as } n\to\infty \quad \text{and} \quad (x_n,y_n) \in \mathrm{supp}(\lambda_n) \quad \text{for all } n \in \mathbb{N}. \tag{2.2}$$

Proof. Suppose $(x,y) \in \Omega$ is such that (2.2) does not hold. Then we may assume without loss of generality that there exists $r > 0$ such that $B((x,y),r) \cap \mathrm{supp}(\lambda_n) = \emptyset$ for any $n \in \mathbb{N}$. It then obviously follows from the weak convergence that $B((x,y),r) \cap \mathrm{supp}(\lambda) = \emptyset$, which concludes the proof. ∎

Proof of Proposition 2.1. Since the set Ω is a compact subset of $\mathbb{R}^d$ and the measures μ and ν are probability measures on Ω, the nonempty set $\Pi(\mu,\nu)$ is compact for the weak convergence of measures (cf. [32, p. 49]). To apply the direct method of the calculus of variations, it remains to notice that $\lambda \mapsto \mathcal{C}_\infty(\lambda)$ is lower semicontinuous for this topology: this is a direct consequence of (2.1) and Lemma 2.3. ∎

3. Infinitely cyclically monotone solutions. The proof of the existence of a solution to (P_∞) given in Proposition 2.1 is intrinsic, but one may obtain this result also via an approximation argument involving the family of problems $(P_p)_{p\ge1}$ given by

$$W_p(\mu,\nu) \;=\; \inf\left\{\mathcal{C}_p(\lambda) := \left(\int_{\Omega^2} |y-x|^p d\lambda(x,y)\right)^{\frac{1}{p}} \,:\, \lambda \in \Pi(\mu,\nu)\right\}; \tag{P_p}$$

that is, the functional $\lambda \mapsto \mathcal{C}_p(\lambda)$ is being minimized over the set $\Pi(\mu,\nu)$.

Alternative Proof of Proposition 2.1. Under the assumptions made on Ω, μ, and ν, for any $p \ge 1$ the problem (P_p) admits at least one solution $\gamma_p \in \Pi(\mu,\nu)$; see, e.g.,

[32, Theorem 1.3]. Since $\Pi(\mu,\nu)$ is compact, we infer that $(\gamma_p)_{p\geq 1}$ converges weakly (up to a subsequence) to some $\gamma_\infty \in \Pi(\mu,\nu)$ as $p\to\infty$. Then, for any $\lambda\in\Pi(\mu,\nu)$, we have by the optimality of γ_p and Hölder's inequality that

$$\mathcal{C}_q(\gamma_p) \;=\; \left(\int_{\Omega^2} |y-x|^q d\gamma_p(x,y)\right)^{\frac{1}{q}} \;\leq\; \mathcal{C}_p(\gamma_p) \;\leq\; \mathcal{C}_p(\lambda)$$

for any $p\geq q\geq 1$. For a fixed $q\geq 1$, since the function $(x,y)\mapsto |y-x|^q$ is continuous and bounded on Ω^2 one has $\mathcal{C}_q(\gamma_p)\to\mathcal{C}_q(\gamma_\infty)$ as $p\to\infty$. Therefore, taking the limit in p and then in q in the above inequality we obtain $\mathcal{C}_\infty(\gamma_\infty)\leq\mathcal{C}_\infty(\lambda)$. Since this holds for any $\lambda\in\Pi(\mu,\nu)$, γ_∞ is a minimizer of (P_∞). ∎

The reason for considering the problems (P_p) in this context is not merely the fact that they provide an alternative route to the existence. Namely, it is known that an element $\gamma_p\in\Pi(\mu,\nu)$ is a solution of (P_p) if and only if its support is p-cyclically monotone; that is,

$$\sum_{i=1}^n |y_i-x_i|^p \;\leq\; \sum_{i=1}^n |y_{\sigma(i)}-x_i|^p \tag{3.1}$$

for every $n\geq 2$, $(x_1,y_1),\dots,(x_n,y_n)\in\operatorname{supp}(\gamma_p)$, and for every permutation $\sigma\in\mathcal{S}_n$. We refer the reader, for example, to Theorem 3.2 in [2] (or to [20, 28, 33]).

By analogy with the p-cyclical monotonicity when $1\leq p<\infty$, we introduce the corresponding notion for the case $p=\infty$ obtained by taking the limit in (3.1).

Definition 3.1. *A transport plan $\gamma\in\Pi(\mu,\nu)$ is* infinitely cyclically monotone *if*

$$\max_{1\leq i\leq n} |y_i-x_i| \;\leq\; \max_{1\leq i\leq n} |y_{\sigma(i)}-x_i|$$

for every $n\geq 2$, $(x_1,y_1),\dots,(x_n,y_n)\in\operatorname{supp}(\gamma)$, and $\sigma\in\mathcal{S}_n$.

Using again the approximation of (P_∞) by the problems (P_p), we obtain the existence of an infinitely cyclically monotone solution to (P_∞).

Theorem 3.2. *For $1\leq p<\infty$, let $\gamma_p\in\Pi(\mu,\nu)$ be a solution to (P_p). Then any cluster point γ_∞ of $(\gamma_p)_{p\geq 1}$ in $\Pi(\mu,\nu)$ as $p\to\infty$ is an infinitely cyclically monotone solution to (P_∞).*

Proof. For simplicity, let us assume that the entire family $(\gamma_p)_{p\geq 1}$ converges weakly to $\gamma_\infty\in\Pi(\mu,\nu)$. It suffices to show that γ_∞ is infinitely cyclically monotone. To this end, let $n\geq 2$, $(x_1,y_1),\dots,(x_n,y_n)\in\operatorname{supp}(\gamma)$, and $\sigma\in\mathcal{S}_n$. We apply Lemma 2.3 to each pair (x_i,y_i) to obtain the existence of sequences $(x_1^p,y_1^p),\dots,(x_n^p,y_n^p)$ such that $(x_i^p,y_i^p)\to(x_i,y_i)$ for any i as $p\to\infty$, and $(x_i^p,y_i^p)\in\operatorname{supp}(\gamma_p)$ for all $1\leq p<\infty$ and $i=1,\dots,n$. Since the support of γ_p is p-cyclically monotone, one has

$$\sum_{i=1}^n |y_i^p-x_i^p|^p \;\leq\; \sum_{i=1}^n |y_{\sigma(i)}^p-x_i^p|^p \qquad \text{for all } 1<p<\infty.$$

Taking the $1/p$-power on both sides and letting p go to ∞, one obtains the desired inequality. ∎

Since for any $1\leq p<\infty$ an admissible transport plan $\lambda\in\Pi(\mu,\nu)$ is a minimizer of (P_p) if and only if it is p-cyclically monotone, it is natural to ask whether this still holds for $p=\infty$. It is, however, quite clear that a generic minimizer of (P_∞) need

not be infinitely cyclically monotone; the following gives a counterexample for this implication.

Example 3.3. As an admissible transport plan for the measures μ and ν in Example 2.2 one may take

$$\lambda := \frac{1}{2}\left(\mathcal{L}^2\lfloor_{[0,1]^2} \times \delta_{(2,1)} + \mathcal{L}^2\lfloor_{[2,3]^2} \times \delta_{(1,2)}\right).$$

Then λ is a minimizer of (P_∞), but it is not infinitely cyclically monotone: for example, $((0,1),(2,1))$ and $((3,2),(1,2))$ belong to $\mathrm{supp}(\lambda)$, and

$$\max\{|(0,1)-(1,2)|,\, |(3,2)-(2,1)|\} \;<\; \max\{|(0,1)-(2,1)|,\, |(3,2)-(1,2)|\}.$$

Notice that in this case, for any $1 < p < \infty$, problem (P_p) admits a unique solution (up to a μ-negligible set) (see [20]), which in fact does not depend on p.

On the other hand, the following result shows that the reverse implication does hold: infinite cyclical monotonicity is indeed a sufficient condition for an admissible plan to be a minimizer of (P_∞).

THEOREM 3.4. *Any infinitely cyclically monotone transport plan $\gamma \in \Pi(\mu,\nu)$ is a solution of the problem (P_∞).*

Proof. We make a proof by contradiction. Let $\gamma \in \Pi(\mu,\nu)$ be infinitely cyclically monotone, and assume that

$$\gamma\text{-}\operatorname*{ess\,sup}_{(x,y)\in\Omega^2} |y-x| \;\geq\; 10\,\varepsilon + \tilde{\gamma}\text{-}\operatorname*{ess\,sup}_{(x,y)\in\Omega^2} |y-x| \tag{3.2}$$

for some $\tilde{\gamma} \in \Pi(\mu,\nu)$ and $\varepsilon > 0$.

Since Ω is compact, there exists a finite family $(c_i)_{1\leq i\leq k}$ such that $\Omega \subset \bigcup_{i=1}^k B(c_i,\varepsilon)$. We shall denote $C := \{c_1,\dots,c_k\}$ and $V_1 := B(c_1,\varepsilon)$, and for any $i \in \{2,\dots,k\}$ we set $V_i := B(c_i,\varepsilon) \setminus \bigcup_{j=1}^{i-1} V_j$; without loss of generality, we assume that $V_i \neq \emptyset$ for all $i \in \{1,\dots,k\}$.

Next we define two discrete measures γ^ε and $\tilde{\gamma}^\varepsilon$ on Ω^2 by

$$\gamma^\varepsilon \;:=\; \sum_{1\leq i,j\leq k} \gamma(V_i\times V_j)\,\delta_{(c_i,c_j)}$$

and

$$\tilde{\gamma}^\varepsilon \;:=\; \sum_{1\leq i,j\leq k} \tilde{\gamma}(V_i\times V_j)\,\delta_{(c_i,c_j)}.$$

Notice that since γ and $\tilde{\gamma}$ have the same marginals, the same holds for γ^ε and $\tilde{\gamma}^\varepsilon$. In particular, one has

$$(x,y) \in \mathrm{supp}(\gamma^\varepsilon) \quad\Rightarrow\quad \text{there exists } \tilde{x} \in C \text{ such that } (\tilde{x},y) \in \mathrm{supp}(\tilde{\gamma}^\varepsilon) \tag{3.3}$$

and

$$(\tilde{x},\tilde{y}) \in \mathrm{supp}(\tilde{\gamma}^\varepsilon) \quad\Rightarrow\quad \text{there exists } y \in C \text{ such that } (\tilde{x},y) \in \mathrm{supp}(\gamma^\varepsilon). \tag{3.4}$$

The following properties will also be useful in our argument.

Claim 1. There exists (x_0,y_0) in the support of γ^ε such that

$$|y_0-x_0| \;\geq\; 5\,\varepsilon + \max\left\{|y-x| \,:\, (x,y) \in \mathrm{supp}(\tilde{\gamma}^\varepsilon)\right\}.$$

Claim 2. For any $n \geq 1$, $(x_1, y_1), \dots, (x_n, y_n) \in \mathrm{supp}(\gamma^\varepsilon)$, and $\sigma \in \mathcal{S}_n$,

$$\max_{1 \leq i \leq n} |y_i - x_i| \ \leq \ 4\,\varepsilon + \max_{1 \leq i \leq n} |y_{\sigma(i)} - x_i|.$$

Above, the first claim is simply a counterpart of the antithesis (3.2) for the discretized measures, while the second says that γ^ε is "almost" infinitely cyclically monotone. We postpone the verification of these two claims until the end of this proof.

Let $(x_0, y_0) \in \mathrm{supp}(\gamma^\varepsilon)$ be given by Claim 1. Owing to (3.3) and (3.4), we can recursively define two sequences $(D_m)_{m \geq 1}$ and $(E_m)_{m \geq 0}$ of subsets of C by setting $E_0 := \{y_0\}$, and for $m \geq 1$,

$$D_m \ := \ \{\tilde{x} \ : \ \text{there exists } y \in E_{m-1} \text{ such that } (\tilde{x}, y) \in \mathrm{supp}(\tilde{\gamma}^\varepsilon)\}$$

and

$$E_m \ := \ \{y \ : \ \text{there exists } \tilde{x} \in D_m \text{ such that } (\tilde{x}, y) \in \mathrm{supp}(\gamma^\varepsilon)\}\,.$$

We then set $D := \bigcup_{m \geq 1} D_m$ and $E := \bigcup_{m \geq 0} E_m$.

There are now two alternatives: either x_0 belongs to D or not.

First case: $x_0 \in D$. In this case, there exists $m \geq 1$ such that $x_0 \in D_m$, and by going backwards from D_m to E_0 it is possible to define two finite families $(x_i)_{0 \leq i \leq m}$ and $(y_i)_{0 \leq i \leq m-1}$ such that

$$\text{for all } i \in \{0, \dots, m-1\}, \quad (x_i, y_i) \in \mathrm{supp}(\gamma^\varepsilon) \quad \text{and} \quad (x_{i+1}, y_i) \in \mathrm{supp}(\tilde{\gamma}^\varepsilon),$$

where we have set $x_m := x_0$. Claim 2 then yields

$$\max_{0 \leq i \leq m-1} |y_i - x_i| - 4\,\varepsilon \ \leq \ \max_{0 \leq i \leq m-1} |y_i - x_{i+1}|.$$

Since $\max_{0 \leq i \leq m-1} |y_i - x_i| \ \geq \ |y_0 - x_0|$, we infer from Claim 1 and the previous inequality that

$$\max\left\{|y - x| \ : \ (x, y) \in \mathrm{supp}(\tilde{\gamma}^\varepsilon)\right\} + \varepsilon \ \leq \ \max_{0 \leq i \leq m-1} |y_i - x_{i+1}|.$$

Since $(x_{i+1}, y_i) \in \mathrm{supp}(\tilde{\gamma}^\varepsilon)$ for any $i \in \{0, \dots, m-1\}$, this yields a contradiction.

Second case: $x_0 \notin D$. From the definitions of D and E, we notice the following two facts:

$$x \in D,\, (x, y) \in \mathrm{supp}(\gamma^\varepsilon) \quad \Rightarrow \quad y \in E \tag{3.5}$$

and

$$\tilde{y} \in E,\, (\tilde{x}, \tilde{y}) \in \mathrm{supp}(\tilde{\gamma}^\varepsilon) \quad \Rightarrow \quad \tilde{x} \in D. \tag{3.6}$$

As a consequence of (3.5) and since γ^ε and $\tilde{\gamma}^\varepsilon$ have the same marginals, one has

$$\gamma^\varepsilon(D \times E) \ = \ \gamma^\varepsilon(D \times C) \ = \ \tilde{\gamma}^\varepsilon(D \times C).$$

Similarly, one has

$$\tilde{\gamma}^\varepsilon(D \times E) \ = \ \tilde{\gamma}^\varepsilon(C \times E) \ = \ \gamma^\varepsilon(C \times E).$$

We then obtain

$$\gamma^\varepsilon(D\times E) \;=\; \tilde\gamma^\varepsilon(D\times C) \;\geq\; \tilde\gamma^\varepsilon(D\times E) \;=\; \gamma^\varepsilon(C\times E).$$

This implies that $\gamma^\varepsilon((C\setminus D)\times E)=0$, whereas by hypothesis one has $(x_0,y_0)\in (C\setminus D)\times E$ and $\gamma^\varepsilon(\{(x_0,y_0)\})>0$ since (x_0,y_0) belongs to the support of the discrete measure γ^ε. This yields a contradiction.

To complete the proof of Theorem 3.4, it remains to prove Claims 1 and 2.

Proof of Claim 1. We infer from (3.2) that

$$\gamma\left(\left\{(x,y)\,:\,|y-x|\geq 9\,\varepsilon+\tilde\gamma\text{-}\operatorname*{ess\,sup}_{(x,y)\in\Omega^2}|y-x|\right\}\right)>0.$$

As a consequence, there exist $i_1,i_2\in\{1,\dots,k\}$ such that

$$\gamma\left((V_{i_1}\times V_{i_2})\cap\left\{(x,y)\,:\,|y-x|\geq 9\,\varepsilon+\tilde\gamma\text{-}\operatorname*{ess\,sup}_{(x,y)\in\Omega^2}|y-x|\right\}\right)>0.$$

Since $V_m\subset B(c_m,\varepsilon)$ for $m=i_1,i_2$, one then has

$$|c_{i_2}-c_{i_1}| \;\geq\; 7\,\varepsilon+\tilde\gamma\text{-}\operatorname*{ess\,sup}_{(x,y)\in\Omega^2}|y-x|, \tag{3.7}$$

and (c_{i_1},c_{i_2}) belongs to the support of γ^ε. On the other hand, if (c_{j_1},c_{j_2}) belongs to the support of $\tilde\gamma^\varepsilon$, then $\tilde\gamma(V_{j_1}\times V_{j_2})>0$, and thus

$$|c_{j_2}-c_{j_1}| \;\leq\; 2\,\varepsilon+\tilde\gamma\text{-}\operatorname*{ess\,sup}_{(x,y)\in\Omega^2}|y-x|.$$

Since this inequality holds whenever $(c_{j_1},c_{j_2})\in\operatorname{supp}(\tilde\gamma^\varepsilon)$, one has

$$\max\{|y-x|\,:\,(x,y)\in\operatorname{supp}(\tilde\gamma^\varepsilon)\} \;\leq\; 2\,\varepsilon+\tilde\gamma\text{-}\operatorname*{ess\,sup}_{(x,y)\in\Omega^2}|y-x|.$$

This together with (3.7) shows that $(x_0,y_0):=(c_{i_1},c_{i_2})$ has the desired property.

Proof of Claim 2. Let $n\geq 1$, $\sigma\in\mathcal{S}_n$, and (x_i,y_i) belong to the support of γ^ε for $i\in\{1,\dots,n\}$. For any $i\in\{1,\dots,n\}$, one has $(x_i,y_i)=(c_{j_1},c_{j_2})$ for some $j_1,j_2\in\{1,\dots,k\}$ with $\gamma(V_{j_1}\times V_{j_2})>0$, and thus there exists $(x_i',y_i')\in(V_{j_1}\times V_{j_2})\cap\operatorname{supp}(\gamma)$. As a consequence,

$$\big|\,|y_r'-x_s'|-|y_r-x_s|\,\big| \;\leq\; 2\,\varepsilon \qquad \text{for all } r,s\in\{1,\dots,n\}.$$

Since γ is infinitely cyclically monotone, we have

$$\max_{1\leq i\leq n}|y_{\sigma(i)}'-x_i'| \;\geq\; \max_{1\leq i\leq n}|y_i'-x_i'|.$$

It follows that

$$4\,\varepsilon+\max_{1\leq i\leq n}|y_{\sigma(i)}-x_i| \;\geq\; \max_{1\leq i\leq n}|y_i-x_i|,$$

which proves the claim. □

Remark 3.5. Observe that in the proof above, we in fact always have $x_0\in D$; that is, the *first case* always occurs. This is a consequence of the conservation of the masses: all the mass transported to E by $\tilde\gamma^\varepsilon$ originates from D, while all the mass in

D is transported to E by γ^ε. Since γ^ε and $\tilde{\gamma}^\varepsilon$ have the same marginals, this implies that both plans transport D exactly to E. The fact that the *second case* never occurs in the above proof also underlies the recursive construction of *Step* II in the proof of Theorem A in [25], even if the arguments are different. That paper deals with the sufficiency of cyclical monotonicity for optimality in the classical case (see also [31]).

Remark 3.6. There is a variation of the self-contained proof given above that relies directly on the fact that the total cost $\mathcal{C}_\infty(\lambda) = \lambda\text{-ess sup}_{(x,y)\in\Omega^2} |y-x|$ depends only on the support of λ and not on its density. In the discrete case this means that, as far as the total cost is concerned, the exact amount of mass transferred from any given point to another is irrelevant: it matters only whether the amount is positive or not. Hence in the proof we are allowed to change the transport plans γ_ε and $\tilde{\gamma}_\varepsilon$, along with their marginals, as long as we do not change their supports and make sure that the marginals of the new transport plans agree with each other. Now assuming that we can change the measures in such a way that all the point masses are of integer size, the problem can be interpreted as a pairing problem in which the infinite cyclical monotonicity is both a necessary and sufficient condition for optimality.

The existence of the required integer transport plans with given supports is non-trivial and follows from Dines' algorithm [17], which provides positive solutions for a system of linear equations.

4. Restrictable solutions. In the previous section, we derived the notion of infinitely cyclically monotone plans from the approximation of the problem (P_∞) by the family of problems (P_p). Another interesting notion may be derived in the same way: let $1 \le p < \infty$ and $\gamma_p \in \Pi(\mu,\nu)$ be a solution to (P_p). Then it follows from the linearity of the functional

$$\gamma \mapsto \mathcal{C}_p(\gamma)^p \;=\; \int_{\Omega^2} |y-x|^p d\lambda(x,y)$$

that any nonzero measure γ' that is majorized by γ_p, i.e., $\gamma'(B) \le \gamma_p(B)$ for all Borel sets $B \subset \Omega\times\Omega$, is an optimal transport plan for the problem

$$\mathcal{C}_p(\gamma') = \inf\left\{\mathcal{C}_p(\gamma) : \gamma \in \Pi(\mu',\nu')\right\},$$

where $\mu' := \pi_1{}_\#\gamma'$ and $\nu' := \pi_2{}_\#\gamma'$. In other words, optimality is automatically inherited by restriction, and hence we may say that a solution $\gamma_p \in \Pi(\mu,\nu)$ of (P_p) is a *restrictable solution* of this problem. By analogy, we may define a similar notion of restrictable solutions for problem (P_∞) as follows.

Definition 4.1. *A transport plan $\gamma \in \Pi(\mu,\nu)$ is a* restrictable solution *of (P_∞) if any nonzero Borel measure γ' in $\Omega\times\Omega$ that is majorized by γ is a solution to the problem*

$$(P'_\infty) \qquad \inf\left\{\lambda\text{-ess sup}_{(x,y)\in\Omega^2} |y-x| \;:\; \lambda \in \Pi(\mu',\nu')\right\},$$

where $\mu' := \pi_1{}_\#\gamma'$ and $\nu' := \pi_2{}_\#\gamma'$.

The reader should notice the obvious abuse of notation above, as the measures μ' and ν' in (P'_∞) are not, in general, probability measures. However, $\mu'(\Omega) = \nu'(\Omega) > 0$, and that is really all that is needed.

Example 4.2. It is quite clear that not every solution of (P_∞) is restrictable. Indeed, the optimal plan λ considered in Example 3.3 admits the following restriction:

$$\lambda' := \frac{1}{2}\left(\mathcal{L}^2\lfloor_{S_1} \times \tfrac{1}{2}\delta_{(2,1)} + \mathcal{L}^2\lfloor_{S_2} \times \tfrac{1}{2}\delta_{(1,2)}\right),$$

where $S_1 := [0, \frac{1}{2}] \times [\frac{1}{2}, 1]$ and $S_2 := [\frac{5}{2}, 3] \times [2, \frac{5}{2}]$. But λ' is not optimal for its own marginals: a better transport plan is the one that takes all the mass that lies in S_1 to $(1, 2)$ and the mass in S_2 to $(2, 1)$.

Remark 4.3. The notion of a restrictable solution bears a strong resemblance to that of an *absolute minimizer* used in connection with the L^∞ variational problems. We recall that a locally Lipschitz continuous function $u : D \to \mathbb{R}^m$, $m \geq 1$, is called an absolute minimizer of the functional $S(\varphi, D) := \operatorname{ess\,sup}_{x \in D} H(x, \varphi(x), D\varphi(x))$ if

$$S(u, V) \leq S(v, V)$$

for every open $V \subset\subset D$ and $v \in W^{1,\infty}(V) \cap C(\overline{V}))$ such that $v|_{\partial V} = u|_{\partial V}$. Absolute minimizers were introduced by Aronsson [3, 4]. It has turned out that this is the proper notion of a solution for this type of minimization problem in the sense that important properties such as uniqueness, regularity, and characterization via an Euler–Lagrange equation can be obtained for this class of functions. Absolute minimizers were introduced by Aronsson [3]; see also, e.g., [6, 5, 30, 14] for further details and background.

It is natural to ask whether any cluster point γ_∞ of $(\gamma_p)_{p \geq 1}$ in $\Pi(\mu, \nu)$ as $p \to \infty$ is a restrictable solution of (P_∞). In view of Theorem 3.2, this can be established by showing that the restrictable solutions coincide with the class of infinitely cyclically monotone solutions.

THEOREM 4.4. *A transport plan $\gamma \in \Pi(\mu, \nu)$ is infinitely cyclically monotone if and only if it is a restrictable solution of the problem (P_∞).*

Notice that Theorem 3.2 provides the existence of restrictable solutions to (P_∞).

Proof. If $\gamma \in \Pi(\mu, \nu)$ is infinitely cyclically monotone, then the same holds for any restriction $\gamma' \leq \gamma$, and Theorem 3.4 then yields that such a restriction γ' is a solution of the corresponding problem (P'_∞).

We now turn to the proof of the sufficiency. Let $\gamma \in \Pi(\mu, \nu)$ be a restrictable solution to (P_∞), and let us fix points $(x_1, y_1), \ldots, (x_m, y_m) \in \operatorname{supp}(\gamma)$, $m \geq 2$, and a permutation σ of $\{1, \ldots, m\}$. Without loss of generality, we may assume that $(x_i, y_i) \neq (x_j, y_j)$ whenever $i \neq j$. Then there is $\varepsilon_0 > 0$ such that for all $0 < \varepsilon \leq \varepsilon_0$, the sets $B_i := B(x_i, \varepsilon) \times B(y_i, \varepsilon)$ are pairwise disjoint and $\gamma(B_i) > 0$ for all $i = 1, \ldots, m$.

We define two measures γ' and γ_σ by setting

$$\gamma' := \sum_{i=1}^m c_i \gamma \lfloor_{B_i} \qquad \text{and} \qquad \gamma_\sigma := \sum_{i=1}^m c_i T^i_\# \gamma \lfloor_{B_i}.$$

Here $T^i_\# \gamma \lfloor_{B_i}$ is the push-forward of $\gamma \lfloor_{B_i}$ by the mapping $T^i(x, y) := (x, y + y_{\sigma(i)} - y_i)$, and the positive numbers

$$c_i := \frac{\min_k \gamma(B_k)}{\gamma(B_i)}$$

are chosen so that $\gamma'(B_i) = \min_k \gamma(B_k) > 0$ is independent of i. Observe that the support of $T^i_\# \gamma \lfloor_{B_i}$ lies in $B^\sigma_i := B(x_i, \varepsilon) \times B(y_{\sigma(i)}, \varepsilon)$ and $\gamma_\sigma(B^\sigma_i) = \gamma'(B_i)$. Moreover, the first marginals $\mu' = \pi_1 \#\gamma'$ and $\mu_\sigma = \pi_1 \#\gamma_\sigma$ are equal.

Since γ' is majorized by the restrictable solution γ, we have

$$\gamma'\text{-}\operatorname*{ess\,sup}_{(x,y) \in \Omega^2} |x - y| = W_\infty(\mu', \nu') = \inf \left\{ \tilde{\gamma}\text{-}\operatorname*{ess\,sup}_{(x,y) \in \Omega^2} |x - y| \, : \, \tilde{\gamma} \in \Pi(\mu', \nu') \right\},$$

where $\nu' = \pi_2{}_\#\gamma'$. On the other hand, since the supports of both ν' and $\nu_\sigma = \pi_2{}_\#\gamma_\sigma$ are contained in the union of the balls $B(y_i, \varepsilon)$ and $\nu'(B(y_i, \varepsilon)) = \nu_\sigma(B(y_i, \varepsilon))$ for every i by the construction of γ' and γ_σ, we can rearrange ν' to ν_σ by transporting mass only within the balls $B(y_i, \varepsilon)$. Thereby we obtain that $W_\infty(\nu', \nu_\sigma) \leq 2\varepsilon$, and hence

$$\begin{aligned}\gamma'\text{-}\operatorname*{ess\,sup}_{(x,y)\in\Omega^2} |x-y| = W_\infty(\mu', \nu') &\leq W_\infty(\mu_\sigma, \nu_\sigma) + W_\infty(\nu_\sigma, \nu') \\ &\leq 2\varepsilon + \gamma_\sigma\text{-}\operatorname*{ess\,sup}_{(x,y)\in\Omega^2} |x-y|.\end{aligned}$$

Now clearly

$$\gamma'\text{-}\operatorname*{ess\,sup}_{(x,y)\in\Omega^2} |x-y| \geq \max_{1\leq i\leq m} |x_i - y_i|$$

and

$$\gamma_\sigma\text{-}\operatorname*{ess\,sup}_{(x,y)\in\Omega^2} |x-y| \leq \max_{1\leq i\leq m} |x_i - y_{\sigma(i)}| + 2\varepsilon,$$

and thus the preceding inequality yields

$$\max_{1\leq i\leq m} |x_i - y_i| \leq \max_{1\leq i\leq m} |x_i - y_{\sigma(i)}| + 4\varepsilon.$$

Since this holds for all $\varepsilon > 0$ small enough we are done. ∎

Observe that for any $\gamma \in \Pi(\mu, \nu)$ and any Borel set $B \subset \Omega\times\Omega$ such that $\gamma(B) > 0$, the measure $\gamma\lfloor_B$ is majorized by γ. Thus, if γ is a restrictable solution of (P_∞), then each such measure $\gamma\lfloor_B$ is an optimal transport plan for its own marginals. It turns out that in general the converse is false; that is, this family of measures alone does not suffice for characterizing the restrictable solutions, as shown in Example 4.5. Notice that this is another difference with the case of integral costs functionals (like the costs $\mathcal{C}_p$), since for those functionals the converse would be true: if $\gamma\lfloor_B$ is an optimal transport plan for its own marginals for any $B \subset \Omega \times \Omega$ with $\gamma(B) > 0$, then γ is a restrictable solution.

Example 4.5. Take $\Omega = [0, 1]$, and let

$$\mu := \frac{1}{3}\delta_0 + \frac{2}{3}\delta_1 \qquad \text{and} \qquad \nu := \frac{2}{3}\delta_0 + \frac{1}{3}\delta_1.$$

Then the plan $\gamma := \frac{1}{3}\delta_{(0,1)} + \frac{2}{3}\delta_{(1,0)}$ is not a restrictable solution since $\gamma' := \frac{1}{3}\delta_{(0,1)} + \frac{1}{3}\delta_{(1,0)}$ is majorized by γ, and it is clearly not an optimal transport plan for its own marginals $\mu' = \frac{1}{3}\delta_0 + \frac{1}{3}\delta_1$ and $\nu' = \frac{1}{3}\delta_0 + \frac{1}{3}\delta_1$. On the other hand, one can check that $\gamma\lfloor_B$ is an optimal transport plan, for its own marginals, for each Borel set $B \subset \Omega^2$. Notice that the only restrictable solution of (P_∞) in this case (which is also the unique solution to (P_p) when $p \geq 1$) is $\gamma_\infty = \frac{1}{3}\delta_{(0,0)} + \frac{1}{3}\delta_{(1,0)} + \frac{1}{3}\delta_{(1,1)}$.

In view of the above example, and under some regularity assumption on the measures μ and ν, it is possible to obtain the following refined version of Theorem 4.4.

PROPOSITION 4.6. *Let $\gamma \in \Pi(\mu, \nu)$ be an optimal transport plan, and assume that neither μ nor ν concentrates on sets of dimension $d-1$. Then the following are equivalent:*

(1) *γ is infinitely cyclically monotone;*
(2) *for each Borel set $B \subset \Omega \times \Omega$, $\gamma\lfloor_B$ is optimal between its projections.*

Proof. We need only prove that under these assumptions (2) implies (1). Assume by contradiction that γ is not infinitely cyclically monotone. Then there exist a family $\{(x_i, y_i)\}_{i=1,\dots,n}$ in $\mathrm{supp}(\gamma)$ and a permutation $\sigma \in \mathcal{S}_n$ such that

$$\max\{|x_1 - y_{\sigma(1)}|, \dots, |x_n - y_{\sigma(n)}|\} < \max\{|x_1 - y_1|, \dots, |x_n - y_n|\}.$$

By continuity, the same inequality holds true for any family $\{(x_i', y_i')\}_{i=1,\dots,n}$ for which $(x_i', y_i') \in B(x_i, \varepsilon) \times B(y_i, \varepsilon)$ for all $i = 1, \dots, n$ and for some small enough $\varepsilon > 0$. Notice that $\gamma(B(x_i, \varepsilon) \times B(y_i, \varepsilon))$ is positive for any i.

For each i we define $g_i : [0, \varepsilon] \to \mathbb{R}^+$ by $g_i(r) := \gamma(B(x_i, r) \times B(y_i, r))$. Since μ and ν do not concentrate on sets of dimension $d-1$, the function g_i is continuous. Let $\alpha = \min_i \gamma(B(x_i, \varepsilon) \times B(y_i, \varepsilon))$, and choose $0 < \tilde{\varepsilon}_i \leq \varepsilon$ so that $g_i(\tilde{\varepsilon}_i) = \alpha$ for all i; this is possible since $\lim_{r \to 0} g_i(r) = 0$.

Following now the proof of sufficiency of the previous theorem we obtain that $\gamma \lfloor_B$ for $B = \bigcup_{i=1}^n B(x_i, \tilde{\varepsilon}_i) \times B(y_i, \tilde{\varepsilon}_i)$ and for $\varepsilon > 0$ small enough is not an optimal transport between its marginals, which contradicts (2). ∎

Remark 4.7. It is natural to ask what happens if $|x - y|$ is replaced by a more general (real-valued) cost function $c(x, y)$; that is, we consider the functional

$$\gamma \mapsto \gamma\text{-ess sup}_{(x,y) \in \Omega^2} c(x, y).$$

As expected, the basic existence results, Proposition 2.1 and Theorem 3.2, remain valid, provided that c is nonnegative and lower semicontinuous with all the relevant concepts appropriately redefined: in particular, in the definition of *infinite cyclical monotonicity* one should replace the support of γ with some appropriate set on which γ is concentrated. Moreover, the proof of the equivalence of restrictable and infinitely cyclically monotone solutions works in this generality if $c(x, y)$ is (uniformly) continuous.

5. Existence and uniqueness of an optimal transport map. In this section, we prove that under reasonably weak assumptions an infinitely cyclically monotone transport plan is induced by a transport map. Moreover, we start the analysis of the uniqueness of such transport maps and then comment on our method of proof in light of the duality issue for problem (P_∞).

5.1. Properties of transport plans. We begin by considering some generic properties of transport plans. This subsection is largely independent of the cost, and the technique detailed below has applications also in the framework of classical transportation problems involving cost functionals in integral form; see [15].

Definition 5.1. *Let $y \in \Omega$ and $r > 0$, and let $\gamma \in \Pi(\mu, \nu)$ be a transport plan. We define*

$$\gamma^{-1}(B(y, r)) := \pi^1((\Omega \times B(y, r)) \cap \mathrm{supp}\, \gamma).$$

In other words, $\gamma^{-1}(B(y, r))$ is the set of points whose mass is partially or completely transported to $B(y, r)$ by γ. We recognize the slight abuse of notation, but if γ is thought of as a device that transports mass, then this seems justifiable. Notice also that $\gamma^{-1}(B(y, r))$ is a Borel set. In fact, it is a countable union of compact sets as shown by the equation

$$\pi^1((\Omega\times B(y,r))\cap\operatorname{supp}\gamma)=\pi^1\left(\bigcup_n(\Omega\times\overline{B(y,r-1/n)})\cap\operatorname{supp}\gamma\right)$$
$$=\bigcup_n\pi^1((\Omega\times\overline{B(y,r-1/n)})\cap\operatorname{supp}\gamma).$$

Since this notion is important in what follows, we recall that when A is $\mathcal{L}^d$-measurable, one has

$$\lim_{r\to 0}\frac{\mathcal{L}^d(A\cap B(x,r))}{\mathcal{L}^d(B(x,r))}\ =\ 1$$

for almost every x in A: we shall call such a point x a Lebesgue point of A, this terminology deriving from the fact that such a point may also be considered as a Lebesgue point of χ_A.

The following lemma, although quite simple, is the cornerstone of the proof of Theorem 5.5 below.

LEMMA 5.2. *Let $\gamma\in\Pi(\mu,\nu)$, and assume that $\mu\ll\mathcal{L}^d$. Then γ is concentrated on a σ-compact set $R(\gamma)$ such that for all $(x,y)\in R(\gamma)$ the point x is a Lebesgue point of $\gamma^{-1}(B(y,r))$ for all $r>0$.*

Proof. In the following, we shall denote by $\mathrm{Leb}(E)$ the set of points $x\in E$ which are Lebesgue points of E. Let

$$A:=\{(x,y)\in\operatorname{supp}(\gamma)\ :\ \ x\notin\mathrm{Leb}(\gamma^{-1}(B(y,r)))\text{ for some }r>0\};$$

we first intend to show that $\gamma(A)=0$. To this end, for each positive integer n we consider a finite covering $\Omega\subset\bigcup_{i\in I(n)}B(y_i^n,\frac{1}{2n})$ by balls of radius $\frac{1}{2n}$. We notice that if $(x,y)\in\operatorname{supp}(\gamma)$ and x is not a Lebesgue point of $\gamma^{-1}(B(y,r))$ for some $r>0$, then for any $n\geq\frac{1}{r}$ and y_i^n such that $|y_i^n-y|<\frac{1}{2n}$ the point x belongs to $\gamma^{-1}(B(y_i^n,\frac{1}{2n}))$ but is not a Lebesgue point of this set. Then

$$\pi^1(A)\ \subset\ \bigcup_{n\geq1}\bigcup_{i\in I(n)}\left(\gamma^{-1}\left(B\left(y_i^n,\frac{1}{2n}\right)\right)\setminus\mathrm{Leb}\left(\gamma^{-1}\left(B_\gamma\left(y_i^n,\frac{1}{2n}\right)\right)\right)\right).$$

Notice that the set on the right-hand side has Lebesgue measure 0 and thus μ-measure 0. It follows that $\gamma(A)\leq\gamma(\pi^1(A)\times\Omega)=\mu(\pi^1(A))=0$.

Finally, since $\mathcal{L}^d(\pi^1(A))=0$, there exists a sequence $(U_k)_{k\geq0}$ of open sets such that

$$\text{for all }k\geq0,\qquad\pi^1(A)\subset U_k\qquad\text{and}\qquad\lim_{k\to\infty}\mathcal{L}^d(U_k)=0.$$

Then the set $R(\gamma):=\operatorname{supp}(\gamma)\cap(\bigcup_{k\geq0}(\Omega\setminus U_k)\times\Omega)$ has the desired properties. ∎

The above lemma yields the introduction of the following notion.

DEFINITION 5.3. *The couple $(x,y)\in\Omega\times\Omega$ is a* γ-regular point *if $x\in\gamma^{-1}(B(y,r))$ is a Lebesgue point of this set for any positive r.*

Notice that any element of the set $R(\gamma)$ of Lemma 5.2 is a γ-regular point.

For future use, we introduce a suitable notation to indicate a cone: let $x_0,\xi\in\mathbb{R}^d$ with $|\xi|=1$, and let $\delta\in[0,2]$. Then we define

$$C(x_0,\xi,\delta):=\left\{x\in\mathbb{R}^d\setminus\{x_0\}\ :\ \frac{x-x_0}{|x-x_0|}\cdot\xi\geq1-\delta\right\}.$$

Notice that if $\delta = 0$, $C(x_0, \xi, 0)$ degenerates to a half-line, while in the case $\delta = 2$, $C(x_0, \xi, 2)$ is $\mathbb{R}^d \setminus \{x_0\}$.

We now remark the following property for the regular points of a transport plan.

PROPOSITION 5.4. *Let (x_0, y_0) be a γ-regular point, $r > 0$, $\alpha \in (0,1)$, and $\delta > 0$. Then for $\varepsilon > 0$ sufficiently small the set of points $x \in \gamma^{-1}(B(y_0, r))$ such that $x \in C(x_0, \xi, \delta) \cap (B(x_0, \varepsilon) \setminus B(x_0, \alpha\varepsilon))$ has positive $\mathcal{L}^d$ measure.*

Proof. It is enough to remark that $x_0 \in \mathrm{Leb}(\gamma^{-1}(B(y_0, r)))$ and then

$$\lim_{\varepsilon \to 0} \frac{\mathcal{L}^d((B(x_0, \varepsilon) \setminus B(x_0, \alpha\varepsilon)) \cap C(x_0, \xi, \delta) \cap \gamma^{-1}(B(y_0, r)))}{\mathcal{L}^d(B(x_0, \varepsilon))} \;=\; c(\alpha, \delta),$$

where $c(\alpha, \delta) := \frac{\mathcal{L}^d((B(x_0,1) \setminus B(x_0,\alpha)) \cap C(x_0,\xi,\delta))}{\mathcal{L}^d(B(x_0,1))} > 0$. ∎

5.2. Existence of an optimal transport map. Our main result in this subsection is the following theorem, which states that under the hypothesis that μ is absolutely continuous with respect to the Lebesgue measure $\mathcal{L}^d$, any optimal infinitely cyclically monotone transport plan for (P_∞) is induced by a transport map. This generalizes the corresponding result for the problem (P_p) when $p \in]1, \infty[$: if one assumes that

$$\mu(B) = 0 \quad \text{whenever} \quad \mathcal{H}^{d-1}(B) < \infty, \tag{5.1}$$

then any p-cyclically monotone transport plan is induced by a transport map (see Remark 4.7 in [20]).

It is in doubt whether (5.1) is sufficient to ensure that the conclusion of Theorem 5.5 holds. In the case $p = 1$, the hypothesis (5.1) is not sufficient to ensure that any 1-cyclically monotone transport plan is induced by a transport map. Even worse, for $\mu = \mathcal{L}^1\lfloor_{[0,1]}$ and $\nu = \frac{1}{2}\mathcal{L}^1\lfloor_{[0,2]}$ there exists an optimal (and hence 1-cyclically monotone) transport plan which is not induced by a transport map; see [2, p. 125].

We now state the main result of this section and refer the reader to section 5.4 for further comments.

THEOREM 5.5. *Assume that $\mu \ll \mathcal{L}^d$, and let $\gamma \in \Pi(\mu, \nu)$ be an infinitely cyclically monotone transport plan. Then there exists a Borel transport map $T : \Omega \to \Omega$ such that $\gamma = (id \times T)_{\#}\mu$.*

Proof. By Proposition 2.1 in [1], it is sufficient to prove that γ is concentrated on a γ-measurable graph. In view of Lemma 5.2, it is then sufficient to prove that $R(\gamma)$ is included in a graph, or more generally that if (x_0, y_0) and (x_0, y_0') are both γ-regular points, then $y_0 = y_0'$.

We divide the proof into two parts and first show that $|x_0 - y_0| = |x_0 - y_0'|$. Arguing by contradiction, we assume that $|x_0 - y_0| < |x_0 - y_0'|$ and suppose for the time being that $x_0 \neq y_0$. Let $\xi' = \frac{y_0' - x_0}{|y_0' - x_0|}$, $0 < \varepsilon < |x_0 - y_0|$, and $0 < r < |y_0' - x_0| - |y_0 - x_0|$. We claim that for $\delta := 1 - \frac{|x_0 - y_0|}{|x_0 - y_0'|}$ one has

$$\max\{|x - y_0'|, |x_0 - y|\} < \max\{|x - y|, |x_0 - y_0'|\} \tag{5.2}$$

for any (x, y) such that $x \in C(x_0, \xi', \delta) \cap B(x_0, \varepsilon) \setminus B(x_0, \frac{1}{2}\varepsilon)$ and $y \in B(y_0, r)$. Indeed, take (x, y) as above; it then follows from the choice of r that $|x_0 - y| < |x_0 - y_0'|$, while on the other hand

$$\begin{aligned} |x - y_0'|^2 &= |x - x_0| \left(|x - x_0| - 2\frac{x - x_0}{|x - x_0|} \cdot (y_0' - x_0) \right) + |x_0 - y_0'|^2 \\ &\leq |x - x_0| \left(|x_0 - y_0| - 2(1 - \delta)|x_0 - y_0'| \right) + |x_0 - y_0'|^2 \;<\; |x_0 - y_0'|^2. \end{aligned}$$

This proves the claim. We now infer from Proposition 5.4 that the set of points $x \in \gamma^{-1}(B(y_0,r))$ such that $x \in C(x_0,\xi',\delta) \cap B(x_0,\varepsilon) \setminus B(x_0,\frac{1}{2}\varepsilon)$ has positive measure when ε is small enough. In particular, this set is nonempty for small ε, and (5.2) then clearly contradicts the infinite cyclical monotonicity of γ. As a consequence, $|x_0 - y_0| = |x_0 - y_0'|$ in the case $x_0 \neq y_0$.

If $x_0 = y_0$, we repeat the argument above with the choices $0 < \varepsilon < \frac{1}{4}|x_0 - y_0'|$, $0 < r < \frac{1}{4}|y_0' - x_0|$, and $\delta = \frac{1}{2}$. Then for any (x,y) such that $x \in C(x_0,\xi',\delta) \cap B(x_0,\varepsilon) \setminus B(x_0,\frac{1}{2}\varepsilon)$ and $y \in B(y_0,r)$, we clearly have $|x_0 - y| < |x_0 - y_0'|$, and the other inequality $|x - y_0'|^2 < |x_0 - y_0'|^2$ follows as above.

We now prove by contradiction that $y_0 = y_0'$. Note that since we already know that $|x_0 - y_0| = |x_0 - y_0'|$, we may assume that $|x_0 - y_0| = |x_0 - y_0'| > 0$. If $y_0 \neq y_0'$, we can find $\xi \in \mathbb{R}^d$ such that

$$\xi \cdot \frac{x_0 - y_0}{|x_0 - y_0|} \, < \, 0 \quad \text{and} \quad \xi \cdot \frac{x_0 - y_0'}{|x_0 - y_0'|} \, > \, 0.$$

Next we choose $r > 0$ such that

$$\sup \left\{ \xi \cdot \frac{x_0 - y}{|x_0 - y|} \, : \, y \in B(y_0,r) \right\} \, < \, 0$$

and $\delta > 0$ such that

$$\alpha \, := \, \inf \left\{ \frac{x_0 - x}{|x_0 - x|} \cdot \frac{x_0 - y_0'}{|x_0 - y_0'|} \, : \, x \in C(x_0,\xi,\delta) \right\} \, > \, 0 \tag{5.3}$$

as well as

$$\sup \left\{ \frac{x_0 - x}{|x_0 - x|} \cdot \frac{x_0 - y}{|x_0 - y|} \, : \, x \in C(x_0,\xi,\delta),\, y \in B(y_0,r) \right\} \, < \, 0. \tag{5.4}$$

We now claim that for $\varepsilon > 0$ small enough, (5.2) holds for any (x,y) such that $x \in C(x_0,\xi,\delta) \cap B(x_0,\varepsilon) \setminus B(x_0,\frac{1}{2}\varepsilon)$ and $y \in B(y_0,r)$. Notice that this claim concludes the proof of $y_0 = y_0'$ modulo applying Proposition 5.4 as before. To verify that (5.2) holds, we first notice that (5.4) implies that

$$\text{for all } x \in C(x_0,\xi,\delta),\, y \in B(y_0,r), \qquad |x_0 - y| \, < \, |x - y| \tag{5.5}$$

since $|x-y|^2 = |x-x_0|^2 - 2(x_0 - x)\cdot(x_0 - y) + |x_0 - y|^2$. We can also infer from (5.3) that

$$|x - y_0'|^2 \, \leq \, |x - x_0| \, (|x_0 - x| - 2\alpha |x_0 - y_0'|) + |x_0 - y_0'|^2$$

for any $x \in C(x_0,\xi,\delta)$. It follows that

$$\text{for all } x \in C(x_0,\xi,\delta) \cap B(x_0,\varepsilon), \qquad |x - y_0'| \, < \, |x_0 - y_0'| \tag{5.6}$$

whenever $0 < \varepsilon < 2\alpha|x_0 - y_0'|$. We then get (5.2) from (5.5) and (5.6), which concludes the proof. □

5.3. Uniqueness of the infinitely cyclically monotone transport map. We now consider the question of the uniqueness of the infinitely cyclically monotone transport map obtained in the preceding section. We recall that when (5.1) holds and $p \in]1,\infty[$, problem (P_p) admits a unique (up to a μ negligible set) p-cyclically

monotone transport map (see, for example, [20] and section 5.4). Notice that in contrast this result does not hold for $p = 1$, not even under the stronger hypothesis that $\mu \ll \mathcal{L}^d$, as shown by Example 1.3 in [1]: when $\mu = \mathcal{L}^1\lfloor_{[0,1]}$ and $\nu = \mathcal{L}^1\lfloor_{[1,2]}$, both transport maps $t \mapsto t+1$ and $t \mapsto 2-t$ are optimal.

In the case of problem (P_∞), the question of uniqueness is largely open. At the moment, we have only the following partial result stating the uniqueness of the infinitely cyclically monotone transport map under the hypothesis that ν is purely atomic with finite support.

THEOREM 5.6. *Suppose that $\mu \ll \mathcal{L}^d$ and $\nu = \sum_{i=0}^k a_i\,\delta_{y_i}$ for some $(y_i)_{0\le i\le k} \subset \Omega$ and positive numbers $a_0, \dots, a_k$. Then there exists a unique (up to a μ-negligible set) infinitely cyclically monotone Borel transport map T from μ to ν.*

Proof. Suppose that there are two distinct infinitely cyclically monotone Borel transport maps T and $\tilde{T}$, and let us introduce the sets

$$U_j^i = T^{-1}(y_j) \cap \tilde{T}^{-1}(y_i).$$

We first claim that it is possible to define a sequence of integers $(i(p))_{p\ge 0}$ such that

$$\text{for all} \quad p \ge 0, \qquad i(p) \neq i(p+1) \quad \text{and} \quad \mu\left(U_{i(p)}^{i(p+1)}\right) > 0.$$

Indeed, the fact that the two transport maps are distinct means that it is possible to choose two indices $i(0) \neq i(1)$ such that $\mu\left(U_{i(0)}^{i(1)}\right) > 0$. Next we notice that since $\tilde{T}$ maps μ to ν,

$$\nu(\{y_{i(1)}\}) \;=\; \sum_{p=0}^{k} \mu\left(U_p^{i(1)}\right) \;\ge\; \mu\left(U_{i(0)}^{i(1)}\right) + \mu\left(U_{i(1)}^{i(1)}\right) \;>\; \mu\left(U_{i(1)}^{i(1)}\right).$$

Since T also maps μ to ν, we infer from the above inequality that there exists $p \neq i(1)$ such that $\mu\left(U_{i(1)}^{p}\right) > 0$: we then set $i(2) = p$ and start again from $U_{i(1)}^{i(2)}$. By repeating the above argument we can build recursively the sequence $(i(p))_{p\ge 0}$ with the desired properties.

Since the sequence $(i(p))_{p\ge 0}$ takes its values in the finite set $\{0, \dots, k\}$, we may assume that there exists some $m \ge 2$ such that $i(m) = i(0)$. For any $p \in \{0, \dots, m-1\}$, the set $U_{i(p)}^{i(p+1)}$ has nonzero Lebesgue measure, so we may choose a Lebesgue point x_p of $U_{i(p)}^{i(p+1)}$ for which $|y_{i(p+1)} - x_p| \neq |y_{i(p)} - x_p|$ and then set $x_m = x_0$. By definition,

$$T(x_p) = y_{i(p)} \quad \text{and} \quad \tilde{T}(x_p) = y_{i(p+1)} \qquad \text{for all } p \in \{0, \dots, m-1\}.$$

Since T and $\tilde{T}$ are infinitely cyclically monotone, we have

$$\max_{0\le p\le m-1} |y_{i(p)} - x_p| \;\le\; \max_{0\le p\le m-1} |y_{i(p+1)} - x_p| \;\le\; \max_{0\le p\le m-1} |y_{i(p)} - x_p|,$$

so that

$$\max_{0\le p\le m-1} |y_{i(p)} - x_p| = \max_{0\le p\le m-1} |y_{i(p+1)} - x_p|. \tag{5.7}$$

Then let $I := \{q : |y_{i(q)} - x_q| = \max_{0\le p\le m-1} |y_{i(p)} - x_p|\}$. We infer from (5.7) and the choice of the points x_p that for any $q \in I$ one has $|y_{i(q)} - x_q| > |y_{i(q+1)} - x_q|$. Since x_q is a Lebesgue point of $U_{i(q)}^{i(q+1)}$, there exists $\tilde{x} \in U_{i(q)}^{i(q+1)}$ arbitrarily close to x_q for which

$$|y_{i(q)} - \tilde{x}| \ > \ |y_{i(q)} - x_q|,$$

and thus we can choose $\tilde{x} \in U_{i(q)}^{i(q+1)}$ such that

$$|y_{i(q)} - \tilde{x}| > \max\{|y_{i(q+1)} - \tilde{x}|, |y_{i(q)} - x_q|\}. \tag{5.8}$$

We now set $\tilde{x}_q := \tilde{x}$ as well as $\tilde{x}_p := x_p$ for $p \neq q$ and notice that (5.7) should in fact also hold for this new choice of elements $\tilde{x}_p$ in $U_{i(p)}^{i(p+1)}$. This leads to a contradiction since we can infer from the definition of I, the choice of q, and (5.8) that

$$\begin{aligned}\max_{0\le p\le m-1} |y_{i(p)} - \tilde{x}_p| &= |y_{i(q)} - \tilde{x}| \\ &> \max\{|y_{i(q+1)} - \tilde{x}|, |y_{i(q)} - x_q|\} \ \ge \ \max_{0\le p\le m-1} |y_{i(p+1)} - \tilde{x}_p|.\end{aligned}$$

This is in contradiction with (5.7) and concludes the proof of the theorem. □

Remark 5.7. The construction of the sequence $(x_p)_{0\le p\le m}$ is close to that proposed in the proof of Theorem 3.4, but it is easier since we do not need that it loops at x_0. Indeed, in the above proof we do not really need that $x_m = x_0$, and we assume this only for convenience of notation, while in the course of the proof of Theorem 3.4 we intended to use Claim 1 and then had to start from the special x_0 found there.

At the moment we are not able to generalize this result to the case where ν is any probability measure on Ω. On the other hand, it is clear that the above uniqueness theorem requires that μ does not concentrate, as the following example shows.

Example 5.8. Assume that $\mu := \mathcal{H}^1\lfloor_{[0,1]\times\{0\}}$, while $\nu := \frac{1}{2}\left(\delta_{(0,-1)} + \delta_{(0,1)}\right)$. Then any transport map T (i.e., any μ-measurable function for which $T_\#\mu = \nu$) is an infinitely cyclically monotone optimal transport map from μ to ν.

5.4. Comments around duality. For $1 \le p < \infty$, the mass transport problem (P_p) may be rewritten as

$$(P_p) \qquad W_p^p(\mu,\nu) \ = \ \inf\left\{\mathcal{C}_p^p(\lambda) \ = \ \int_{\Omega^2} |y-x|^p d\lambda(x,y) \ : \ \lambda \in \Pi(\mu,\nu)\right\}.$$

In this form, the objective functional $\lambda \mapsto \mathcal{C}_p^p(\lambda)$ is linear over the compact convex set $\Pi(\mu,\nu)$, and it is then quite natural to associate with (P_p) its dual problem

$$(D_p) \qquad \sup\left\{\int_\Omega \phi(x)d\mu(x) + \int_\Omega \psi(y)d\nu(y) \ : \ \phi(x)+\psi(y) \le |y-x|^p\right\},$$

where $\phi \in L^1(d\mu)$, $\psi \in L^1(d\nu)$, and the constraint is required to hold for μ a.e. x and ν a.e. y. Due to the regularity of the integrand $c_p(x,y) := |y-x|^p$, the supremum of (D_p) is achieved for a couple (φ, φ^{c_p}) where the Kantorovich potential φ is continuous and c_p-concave. We refer the reader, for example, to section 3 of [2], Part I of [20], section 3.3 of [26], or section 2.4 of [32] for more on the related concepts and results.

The Kantorovich dual problem (D_p) appears to be a fundamental tool in understanding and solving the problems of the characterization, existence, and uniqueness

for an optimal transport map for (P_p). For example, the notion of p-cyclical monotonicity (3.1) naturally appears via the equality $\sup(D_p) = \inf(P_p)$; see, e.g., the proof of Theorem 3.2 in [2] (an alternative and direct proofis, for example, that of Theorem 2.3 in [20]). Moreover, a key point in the construction of an optimal transport map $T_p : \mathrm{supp}(\mu) \to \mathrm{supp}(\nu)$ for (P_p) is to identify the directions of transportation (known as *transport rays* for $p = 1$), that is, to associate with μ a.e. $x \in \mathrm{supp}(\mu)$ the direction $\frac{T_p(x)-x}{|T_p(x)-x|}$ to which the mass present at x is transferred. It is now well understood that this direction may be obtained as the adequate c_p-gradient of an optimal Kantorovich potential φ (see, e.g., [20, 19, 27] or section 2.4 of [32]). In fact, the definition as well as the regularity properties of the transport rays are deeply linked with the fact that the support of an optimal transport plan γ_p for (P_p) is p-cyclically monotone and thus inherits good properties from being included in the subdifferential of a c_p-concave function (which, in turn, turns out to be a Kantorovich potential; see, e.g., section 2.4 of [32]).

In light of the preceding discussion, it is natural to try to develop a duality theory for the problem (P_∞) as well. We hereafter informally discuss this issue.

First, in view of the Example 3.3, it does not seem realistic that one could obtain useful information from an intrinsic approach. Indeed, the optimal transport plan λ proposed in Example 3.3 is not induced by any transport map, so we cannot expect that a dual problem directly associated with (P_∞) via some general construction gives information on the geometry of the optimal transport plans. On the other hand, notice that Theorems 5.5 and 5.6 do indicate that there exists a unique infinitely cyclically monotone optimal transport map for the particular problem of Example 3.3.

In view of the results of the two preceding sections, and since the notion of infinitely cyclically monotone plan was at first obtained via a limiting argument, one is led to study the asymptotic behavior of the family of dual problems (D_p) as $p \to \infty$. But as mentioned above, (D_p) is not directly related to (P_p) but to a reformulation of (P_p) which requires taking the p-power of the objective functional $\mathcal{C}_p$. As a consequence, one should in fact take the $\frac{1}{p}$-power of the objective functional of (D_p) and then study the limiting problem as $p \to \infty$; unfortunately, our research in this direction has been unfruitful up to now. Finally, since the functional $\mathcal{C}_p$ is not convex in λ, the convex duality theory does not apply directly to (P_p). But one may wonder whether it is possible to overcome this difficulty and associate with (P_p) a dual problem with a structure similar to that of (D_p): this is a quite involved question known as Dudley's problem (see, e.g., equation (1.1.10) and Remark 2.6.2 in [26]), and it is out of the scope of the present study.

Despite the above difficulties, we believe that developing a duality theory for the problem (P_∞) is an important issue since it would yield a deeper understanding of the problem of the existence and uniqueness for a particular optimal transport map. Further explorations in this direction could follow the methods of [7, 16, 18].

Acknowledgments. The authors would like to thank Guy Bouchitté for proposing the problem and for several fruitful discussions. The authors also thank Jouni Parkkonen for bringing [17] to their attention.

REGULARITY UP TO THE BOUNDARY FOR NONLINEAR ELLIPTIC SYSTEMS ARISING IN TIME-INCREMENTAL INFINITESIMAL ELASTO-PLASTICITY*

PATRIZIO NEFF† AND DOROTHEE KNEES‡

Abstract. In this paper we investigate the question of higher regularity up to the boundary for quasi-linear elliptic systems which originate from the time discretization of models from infinitesimal elasto-plasticity. Our main focus lies on an elasto-plastic Cosserat model. More specifically we show that the time discretization renders H^2-regularity of the displacement and H^1-regularity for the symmetric plastic strain ε_p up to the boundary, provided that the plastic strain of the previous time step is in H^1 as well. This result contrasts with classical Hencky and Prandtl–Reuss formulations where it is known not to hold due to the occurrence of slip lines and shear bands. Similar regularity statements are obtained for other regularizations of ideal plasticity such as viscosity or isotropic hardening. In the first part we recall the time continuous Cosserat elasto-plasticity problem, provide the update functional for one time step, and show various preliminary results for the update functional (Legendre–Hadamard/monotonicity). Using nonstandard difference quotient techniques we are able to show the higher global regularity. Higher regularity is crucial for qualitative statements of finite element convergence. As a result we may obtain estimates linear in the mesh-width h in error estimates.

Key words. polar materials, perfect plasticity, higher global regularity, quasi-linear elliptic systems, error estimates, time increments

1. Introduction.

1.1. Plasticity and Cosserat models. This article addresses the regularity question for time-incremental formulations of *geometrically linear* elasto-plasticity. As a representative model problem we consider generalized continua of *Cosserat-micropolar* type.

The basic difference of a Cosserat model as compared with classical continuum models is the appearance of a nonsymmetric stress tensor which is augmented by a generalized balance of angular momentum equation allowing one to model interaction of particles not only by surface forces (classical Cauchy continuum) but also through surface couples (Cosserat continuum). General continuum models involving *independent rotations* as additional degrees of freedom were first introduced by the Cosserat brothers in [15]. For an introduction to the theory of Cosserat and micropolar models we refer the reader to the introduction in [49, 43, 45, 44, 48]; see also [22, 9].

There are a great many proposals for extensions of the elastic Cosserat framework to infinitesimal elasto-plasticity. We mention only [17, 19, 31, 55]. Recently the finite-strain formulation has been put into focus; see, e.g., [56, 62, 23] and the references therein.

The first author has also proposed an elasto-plastic Cosserat model [45, 44] in a finite-strain framework. A geometrical linearization of this model has been investigated in [46, 48] and is shown to be well-posed also in the rate-independent limit for both quasi-static and dynamic processes.

When it comes to numerically solving problems in elasto-plasticity, then it is common practice to discretize the time evolution in the flow rule for the plastic variable with a backward Euler method and to consider a sequence of discrete-in-time problems [50]. Provided that the elasto-plastic model has certain variational features (hyperelasticity of the elastic response, associative flow rule) it is possible to recast the problem for one time step (called the update problem in the following) itself into a variational framework: the updated displacement is obtained as a minimizer of some update functional; see, e.g., [61, 60, 2, 66, 67]. This line of thought can be nicely extended to finite-strain multiplicative plasticity; see [52, 37, 36, 38] and the references therein. In the geometrically linear setting the resulting variational update problem usually has the form of a quasi-linear elliptic system whose corresponding energy has only linear growth (in case of perfect plasticity).

For qualitative statements on the rate of convergence of finite element methods it is necessary to know precisely the regularity of the function to be approximated. This then is the question on the regularity of the solution of the quasi-linear elliptic system constituting the update problem.

As far as classical rate-independent (perfect) elasto-plasticity is concerned we remark that global existence for the displacement has been shown only in a very weak, measure-valued sense, while the stresses could be shown to remain in $L^2(\Omega)$, provided that a safe load condition is assumed. For these results we refer the reader, for example, to [3, 13, 64]. If hardening or viscosity is added, then global H^1-displacement solutions are found (see, e.g., [1, 12, 11]), already without safe load assumption. A complete theory for the classical rate-independent case remains, however, elusive; see also the remarks in [13].

Since classical perfect plasticity is, therefore, notoriously ill-posed (the updated displacements have derivatives only in a measure-valued sense) we focus in our investigation of higher regularity on certain modified update functionals which might allow for more regular updates. The Cosserat elasto-plastic model in [46] is our basic candidate. Based on this time-continuous model we investigate the time-incremental formulation and study the global regularity of minimizers of the corresponding update functional. In [49] this time-incremental formulation is the basis of a finite element approximation.

Our focus on Cosserat models is justified by the fact that the Cosserat-type models are today increasingly advocated as a means to regularize the pathological mesh size dependence of localization computations where shear failure mechanisms [14, 40, 4] play a dominant role; for applications in plasticity, see the nonexhaustive list [31, 19, 55, 17].

1.2. Outline of this contribution. Our contribution is organized as follows: first, we recall the time-continuous geometrically linear elasto-plastic Cosserat model as introduced in [45, 44] and investigated mathematically in [46, 48, 47].

Referring to the development in [49] we provide in section 2 the corresponding time-discretized formulation based on a fully implicit backward Euler discretization of the plastic flow rule in time. It is shown in [49] that at each time step t_n the updated displacement field u^n and the updated "Cosserat-microrotation-matrix" A^n can equivalently be obtained from a convex minimization problem which involves only

data from the previous time step. The plastic strain ε_p^n is then derived from A^n and u^n via a simple update formula. Furthermore, in [49] it has been shown that the update problem admits unique minimizers $u^n \in H^1(\Omega, \mathbb{R}^3)$, $A^n \in H^1(\Omega, \mathfrak{so}(3))$, and $\varepsilon_p^n \in L^2(\Omega, \mathrm{Sym}(3))$, provided that the data coming from the previous time step are smooth enough. In order to quantify the rate of convergence of corresponding finite element methods for the update problem we investigate the regularity of the displacements u^n by studying the corresponding weak Euler–Lagrange equations. These equations form a quasi-linear elliptic system of partial differential equations. The main result of this paper is Theorem 5.2 in section 5, where we formulate a global regularity result for weak solutions of a rather general class of quasi-linear elliptic systems of second order. The time-incremental Cosserat plasticity formulation satisfies all the necessary assumptions of the regularity result, which allows us to show higher regularity to the extent that for all $n \in \mathbb{N} : u^n \in H^2(\Omega, \mathbb{R}^3)$, $A^n \in H^2(\Omega, \mathfrak{so}(3))$, and $\varepsilon_p^n \in H^1(\Omega, \mathrm{Sym}(3))$ if pure Dirichlet data are assumed. Let us remark that it remains an open problem whether a similar regularity result is also valid for the time-continuous Cosserat model or other regularized time-continuous plasticity formulations.

The general quasi-linear elliptic systems, which we study in section 5, are of the following type: Find $u \in H_0^1(\Omega)$ such that for every $v \in H_0^1(\Omega)$

$$\int_\Omega \langle \mathcal{M}(x, \nabla u(x), z(x)), \nabla v(x) \rangle \,\mathrm{dx} = \int_\Omega \langle f, v \rangle \,\mathrm{dx}.$$

Here, $z \in L^2(\Omega, \mathbb{R}^N)$ and $f \in L^2(\Omega, \mathbb{R}^3)$ are the given data. For the Cosserat model, z is identified with (ε_p^n, A^n); the explicit structure of $\mathcal{M} = \mathcal{M}_C$ is given in section 2.4. It is shown that $\mathcal{M}_C$ is rank-one monotone in ∇u and Lipschitz continuous but not differentiable. Consequently, we assume in the general case that the function $\mathcal{M} : \Omega \times \mathbb{M}^{m\times d} \times \mathbb{R}^N \to \mathbb{M}^{m\times d}$ is Lipschitz continuous, is rank-one monotone in ∇u, and induces a Gårding inequality. The precise conditions on $\mathcal{M}$ are formulated as R1–R3 in section 5.1. Our main result is Theorem 5.2, where we prove for smooth domains that $u \in H^2(\Omega)$, provided that $z \in H^1(\Omega)$ and $f \in L^2(\Omega)$. We emphasize that we do not need the differentiability of $\mathcal{M}$ and that we require $\mathcal{M}$ to be rank-one monotone, only, instead of uniformly or strongly monotone. A further new aspect compared to systems studied in the literature is the presence of the function z in the definition of the differential operator.

Let us give a short overview on global regularity results for quasi-linear second order systems. Systems with quadratic growth or, more generally, with p growth are studied by several authors. We mention here the books [42, 39, 6] and the paper [53], where global regularity results for systems of the type

$$\mathrm{Div}\, \mathcal{M}(x, \nabla u(x)) + f(x) = 0, \quad u\big|_{\partial\Omega} = g_{\mathrm{D}},$$

are shown for smooth domains assuming that $\mathcal{M}$ is differentiable and strongly monotone. Further results for Lipschitz domains were obtained in [21, 20, 57], again assuming that $\mathcal{M}$ is strongly monotone (or uniformly monotone if $p \neq 2$), that it is differentiable, and that there is a function W such that $\mathcal{M} = DW$. These results are proved with a difference quotient technique which relies on the standard finite differences $\delta_h u(x) := u(x + h) - u(x)$.

In [16] the authors study systems where $\mathcal{M}(x, u, \nabla u) = B(x)\nabla u + h(x, u, \nabla u)$. The main assumption in [16] is that B is uniformly positive definite, h is Hölder-continuous with respect to ∇u, and $h(x, u, \cdot)$ is uniformly monotone in zero. They prove that the gradient of solutions belongs locally to certain Campanato–Spanne

spaces. With our main result we can treat the case where h does not depend on u, where it is Lipschitz continuous and monotone but not necessarily uniformly monotone, and where B induces a rank-one positive quadratic form. We obtain $u \in H^2(\Omega)$ globally.

In [58] a nonlinear elliptic system is studied which is more related to our Cosserat model. There, $\mathcal{M}$ is chosen as $\mathcal{M}(\nabla u) = \frac{h(|\varepsilon(u)|)}{|\varepsilon(u)|}\,\varepsilon(u)$, where $\varepsilon(u)$ is the linearized strain tensor, and it is assumed that h is differentiable except for a finite number of points and that h is strongly monotone. It is shown for smooth domains that $u \in H^2(\Omega)$ by investigating the regularity of functions u_δ with $\mathrm{Div}(\delta\varepsilon(u_\delta) + \mathcal{M}(\varepsilon(u_\delta))) + f = 0$ for $\delta \searrow 0$. The results for u_δ are obtained with standard finite differences. Further results for related models were obtained in [54, 7]. Let us remark that the quasi-linear system we are interested in contains the above described systems as special cases (if $p = 2$) and that our main result is not covered by the above references. The local and global regularity of the stress fields of a class of degenerated quasi-linear elliptic systems is investigated in the papers [10, 33].

Note that higher regularity is not known to hold for the displacements of the classical limit of our formulation, which is the classical time-incremental Prandtl–Reuss model. In the first update step this model in turn is nothing else than the total deformation Hencky plasticity model. The Hencky model does not allow for regular displacements. Here, it is known that the displacement $u \in L^{\frac{3}{2}}(\Omega, \mathbb{R}^3)$ (see, e.g., [6, p. 423]), while the classical symmetric stresses satisfy $\sigma \in H^1_{\mathrm{loc}}(\Omega, \mathrm{Sym}(3)) \cap H^{\frac{1}{2}-\delta}(\Omega)$ for every $\delta > 0$ if the data are sufficiently regular and if Ω is a Lipschitz domain. See [59, 24, 5, 51, 18] for the local and [32] for the global result.

The proof of our own regularity result is split into the three classical steps. In the first step we investigate the tangential regularity of weak solutions in the case where Ω is a cube. Since we assumed rank-one monotonicity, only, we cannot apply the standard difference quotient technique in this step. Instead, we use finite differences which are based on inner variations: $\triangle_h u(x) = u(\tau_h(x)) - u(x)$, where $\tau_h(x) = x + \varphi^2(x)h$ for $h \in \mathbb{R}^d$ and a cut-off function φ. This will be explained in more detail in Remark 5.5. Let us note that these nonstandard differences were recently applied by Nesenenko [51] in order to obtain higher local regularity for models from elasto-plasticity with linear hardening. In the second step we prove higher regularity in directions normal to the boundary. Due to the lack of differentiability of $\mathcal{M}$ we cannot apply the usual arguments (i.e., solving the equation for the normal derivatives) to obtain the differentiability of ∇u in the normal direction. Instead, we exploit the rank-one monotonicity of $\mathcal{M}$ in order to get more information on the missing derivative. In the final step we prove the result for arbitrary bounded $\mathcal{C}^{1,1}$-smooth domains by the usual localization procedure. The notation is found in the appendix.

2. The infinitesimal elasto-plastic Cosserat model. In this section we recall the specific isotropic infinitesimal elasto-plastic Cosserat model which has been proposed in a finite-strain setting in [44] and which was analyzed in [46]. Moreover, we derive a discrete formulation. This section does not contain new results; it serves to provide the clear definition of the problem and to introduce some of the notation.

2.1. Time-continuous infinitesimal elasto-plastic Cosserat model. The geometrically linear time continuous system in variational form with nondissipative Cosserat effects reads as follows: for given body forces $f(t) \in L^2(\Omega, \mathbb{R}^3)$ and given Dirichlet data find the *displacement* $u(t) \in H^1(\Omega, \mathbb{R}^3)$, the *skew-symmetric microrotation* $A(t) \in H^1(\Omega, \mathfrak{so}(3))$, and the *symmetric plastic strain* $\varepsilon_p(t) \in L^2(\Omega, \mathrm{Sym}(3))$

with

$$
\begin{aligned}
&\int_\Omega W(\nabla u, A, \varepsilon_p(t)) - \langle f(t), u\rangle \,\mathrm{d}x \mapsto \min \quad \text{w.r.t. } (u, A) \text{ at fixed } \varepsilon_p(t),\\
&W(\nabla u, A, \varepsilon_p) = \mu \left\|\operatorname{sym}\nabla u - \varepsilon_p\right\|^2\\
&\qquad\qquad + \mu_c \left\|\operatorname{skew}(\nabla u - A)\right\|^2 + \frac{\lambda}{2}\operatorname{tr}\left[\nabla u\right]^2 + 2\mu\, L_c^2 \left\|\nabla \operatorname{axl}(A)\right\|^2,\\
&\dot{\varepsilon_p}(t) \in \partial\chi(T_E(t)), \qquad T_E = 2\mu\,(\varepsilon - \varepsilon_p), \quad \varepsilon_p \in \operatorname{Sym}(3)\cap\mathfrak{sl}(3), \quad \varepsilon_p(0) = \varepsilon_p^0,\\
&u_{|\Gamma_D} = g_{\mathrm{D}}(t,x) - x, \quad A_{|\Gamma_D} = \operatorname{skew}(\nabla g_{\mathrm{D}}(t,x))_{|\Gamma_D}.
\end{aligned}
\tag{2.1}
$$

Here, $\Omega \subset \mathbb{R}^3$ is a bounded smooth domain and $\Gamma_D \subset \partial\Omega$ is that part of the boundary where Dirichlet data are prescribed. The parameters $\mu, \lambda > 0$ are the Lamé constants of isotropic linear elasticity, $\mu_c > 0$ is the Cosserat couple modulus, and $L_c > 0$ is an internal length parameter.[1] The classical symmetric elastic strain $\operatorname{sym}\nabla u$ is denoted by ε. The linear operator $\operatorname{axl} : \mathfrak{so}(3) \to \mathbb{R}^3$ provides the canonical identification between the Lie algebra $\mathfrak{so}(3)$ of skew-symmetric matrices and vectors in $\mathbb{R}^3$. The Lie algebra of trace-free matrices is denoted by $\mathfrak{sl}(3)$, and $\operatorname{dev} : \mathbb{M}^{3\times 3} \to \mathfrak{sl}(3)$, $\operatorname{dev} X = X - \frac{1}{3}\mathbb{1}$ is the orthogonal projection onto $\mathfrak{sl}(3)$. As regards the plastic flow rule, $\partial\chi$ is the subdifferential of a convex flow potential $\chi : \mathbb{M}^{3\times 3} \to \mathbb{R}^+$ acting on the generalized conjugate forces, i.e., the Eshelby stress tensor $T_E = -\partial_{\varepsilon_p} W(\nabla u, A, \varepsilon_p)$, where W is the free energy used in (2.1).[2]

The corresponding system of partial differential equations coupled with the flow rule is given by (note that $\|A\|^2_{\mathbb{M}^{3\times 3}} = 2\left\|\operatorname{axl}(A)\right\|^2_{\mathbb{R}^3}$ for $A \in \mathfrak{so}(3,\mathbb{R})$)

$$
\begin{aligned}
\operatorname{Div}\sigma &= -f, \quad x \in \Omega, \quad \text{balance of forces},\\
\sigma &= 2\mu\,(\varepsilon - \varepsilon_p) + 2\,\mu_c\,(\operatorname{skew}(\nabla u) - A) + \lambda \operatorname{tr}[\varepsilon]\cdot\mathbb{1},\\
-\mu\, L_c^2\,\Delta \operatorname{axl}(A) &= \mu_c \operatorname{axl}(\operatorname{skew}(\nabla u) - A), \quad \text{balance of angular momentum},\\
\dot{\varepsilon_p}(t) &\in \partial\chi(T_E), \quad T_E = 2\mu\,(\varepsilon - \varepsilon_p),\\
u_{|\Gamma_D}(t,x) &= g_{\mathrm{D}}(t,x) - x, \quad A_{|\Gamma_D} = \operatorname{skew}(\nabla g_{\mathrm{D}}(t,x))_{|\Gamma_D},\\
\sigma.\vec{n}|_{\partial\Omega\setminus\Gamma_D}(t,x) &= 0, \quad \mu\, L_c^2 \nabla \operatorname{axl}(A).\vec{n}|_{\partial\Omega\setminus\Gamma_D}(t,x) = 0,\\
\varepsilon_p(0) &\in \operatorname{Sym}(3)\cap\mathfrak{sl}(3).
\end{aligned}
$$

Note that in this model the force stresses σ need not be symmetric and that the Cosserat effects, active through the microrotations A, appear only in the balance equations but not in the plastic flow rule since T_E does not depend on A. It is worth noting that this model is intrinsically thermodynamically correct. If $\Gamma_D = \partial\Omega$, then the model admits global weak solutions with the regularity [46]:

$$
\begin{aligned}
&u \in L^\infty([0,T], H^1(\Omega,\mathbb{R}^3)), \quad A \in L^\infty([0,T], H^1(\Omega, \mathfrak{so}(3))),\\
&\varepsilon_p \in L^\infty([0,T], L^2(\Omega, \operatorname{Sym}(3)\cap\mathfrak{sl}(3))).
\end{aligned}
$$

2.2. Backward Euler time discretization of the flow rule. For a numerical treatment we consider the time discretization of the flow rule with the fully implicit backward Euler scheme. Let $0 = t_0 < t_1 < \cdots < t_N = T$ be a subdivision of the

[1] Observe that for $\mu_c = 0$ or $L_c = 0$ one recovers the classical Prandtl–Reuss formulation for the displacement u.

[2] The specification $\chi = I_K$ as indicator function of some elastic domain is not necessary at this point.

time interval $[0,T]$ with $t_j - t_{j-1} = \Delta t$. Let $f^n(x) = f(x,t_n)$, and assume that at time t_{n-1} a sufficiently regular plastic strain field $\varepsilon_p^{n-1} \in \operatorname{Sym}(3) \cap \mathfrak{sl}(3)$ is given. We want to determine the *updated displacement* $u^n \in H^1(\Omega,\mathbb{R}^3)$, the *updated skew-symmetric microrotation* $A^n \in H^1(\Omega,\mathfrak{so}(3))$ and the *updated symmetric plastic strain* $\varepsilon_p^n \in L^2(\Omega,\operatorname{Sym}(3)\cap\mathfrak{sl}(3))$ satisfying

$$
\begin{aligned}
\operatorname{Div}\sigma^n &= -f^n, \quad x\in\Omega,\\
\sigma^n &= 2\mu\,(\varepsilon^n-\varepsilon_p^n) + 2\,\mu_c\,(\operatorname{skew}(\nabla u^n) - A^n) + \lambda\operatorname{tr}[\varepsilon^n]\cdot\mathbb{1},\\
-\mu\,L_c^2\,\Delta\operatorname{axl}(A^n) &= \mu_c\operatorname{axl}(\operatorname{skew}(\nabla u^n) - A^n),\\
\frac{\varepsilon_p^n-\varepsilon_p^{n-1}}{\Delta t} &\in \partial\chi(T_E^n), \quad T_E^n = 2\mu\,(\varepsilon^n-\varepsilon_p^n),\\
u^n_{|\Gamma_D}(x) &= g_{\mathrm{D}}^n(x) - x, \quad A^n_{|\Gamma_D} = \operatorname{skew}(\nabla g_{\mathrm{D}}^n(x)),\\
\sigma^n.\vec{n}|_{\partial\Omega\setminus\Gamma_D}(x) &= 0, \quad \mu\,L_c^2\nabla\operatorname{axl}(A)^n.\vec{n}|_{\partial\Omega\setminus\Gamma_D}(x) = 0,\\
\varepsilon_p^{n-1} &\in L^2(\Omega,\operatorname{Sym}(3)\cap\mathfrak{sl}(3)).
\end{aligned}
\tag{2.2}
$$

It is possible to explicitly solve the discretized flow rule $(2.2)_4$ for ε_p^n in terms of ε_p^{n-1}, ε^n, and Δt. To see this, consider

$$
\begin{aligned}
\frac{\varepsilon_p^n-\varepsilon_p^{n-1}}{\Delta t} \in \partial\chi(2\mu\,(\varepsilon^n-\varepsilon_p^n)) \;&\Leftrightarrow\; 0 \in \partial\chi(2\mu\,(\varepsilon^n-\varepsilon_p^n)) - \frac{\varepsilon_p^n-\varepsilon_p^{n-1}}{\Delta t}\\
&\Leftrightarrow\; 0 \in \partial_{\varepsilon_p^n}\left(\mu\left\|\varepsilon_p^n-\varepsilon_p^{n-1}\right\|^2 + \Delta t\,\chi(2\mu\,(\varepsilon^n-\varepsilon_p^n))\right).
\end{aligned}
\tag{2.3}
$$

Thus we can define the local potential for the local flow rule

$$
V^{\mathrm{time}}(\varepsilon^n,\varepsilon_p^n,\varepsilon_p^{n-1},\Delta t) := \mu\left\|\varepsilon_p^n-\varepsilon_p^{n-1}\right\|^2 + \Delta t\,\chi(2\mu\,(\varepsilon^n-\varepsilon_p^n)).
\tag{2.4}
$$

It is easy to see that V^{time} is strictly convex in ε_p^n; thus V^{time} admits a unique minimizer satisfying $(2.3)_3$. Moreover, we have

$$
\begin{aligned}
V^{\mathrm{time}}(\varepsilon^n,\varepsilon_p^n,\varepsilon_p^{n-1},\Delta t) &= \mu\left\|\varepsilon_p^n-\varepsilon_p^{n-1}\right\|^2 + \Delta t\,\chi(2\mu\,(\varepsilon^n-\varepsilon_p^n))\\
&= \frac{1}{4\mu}\left\|2\mu(\varepsilon_p^n-\varepsilon^n+\varepsilon^n-\varepsilon_p^{n-1})\right\|^2 + \Delta t\,\chi(2\mu\,(\varepsilon^n-\varepsilon_p^n))\\
&= \frac{1}{4\mu}\left\|\Sigma^n-\Sigma^n_{\mathrm{trial}}\right\|^2 + \Delta t\,\chi(\Sigma^n) = \tilde{V}(\Sigma^n,\Sigma^n_{\mathrm{trial}}),
\end{aligned}
$$

where $\Sigma^n = 2\mu\,(\varepsilon^n-\varepsilon_p^n)$ and the so-called trial stresses $\Sigma^n_{\mathrm{trial}} = 2\mu\,(\varepsilon^n-\varepsilon_p^{n-1})$. Minimizing V^{time} with respect to ε_p^n is equivalent to minimizing $\tilde{V}$ with respect to Σ^n. Proceeding further, we specialize χ. Let us define the elastic domain in stress space

$$
K := \{\Sigma\in\mathbb{M}^{3\times3} \mid \|\operatorname{dev}\Sigma\| \le \sigma_{\mathrm{y}}\},
$$

with initial yield stress σ_{y}, $[\sigma_{\mathrm{y}}] = [\mathrm{MPa}]$, and corresponding indicator function

$$
I_K(\Sigma) = \begin{cases} 0, & \|\operatorname{dev}\Sigma\| \le \sigma_{\mathrm{y}},\\ \infty, & \|\operatorname{dev}\Sigma\| > \sigma_{\mathrm{y}},\end{cases}
$$

and let $\chi = I_K$. We have therefore $\partial\chi = \partial I_K$ in the sense of the subdifferential. With this choice, the unique minimizer of $\tilde{V}$ is simply characterized by

$$
\inf_{\Sigma^n\in K}\left\|\Sigma^n-\Sigma^n_{\mathrm{trial}}\right\|^2,
$$

independent of Δt. The solution is the orthogonal projection of Σ^n_{trial} onto the convex set K, denoted by

$$\Sigma^n = P_K(\Sigma^n_{\text{trial}}) \;\Rightarrow\; 2\mu\,(\varepsilon^n - \varepsilon^n_p) = P_K(2\mu\,(\varepsilon^n - \varepsilon^{n-1}_p)).$$

Reintroducing the last result into the balance of forces equation $(2.2)_1$ delivers

$$\begin{aligned} &\operatorname{Div}\sigma^n = -f^n, \quad x \in \Omega, \\ &\sigma^n = P_K(2\mu\,(\varepsilon^n - \varepsilon^{n-1}_p)) + 2\,\mu_c\,(\operatorname{skew}(\nabla u^n) - A^n) + \lambda \operatorname{tr}[\varepsilon^n]\cdot \mathbb{1}. \end{aligned} \tag{2.5}$$

This step is called *return mapping* [61, 60] in an engineering context of classical plasticity. At the given plastic strain of the previous time step ε^{n-1}_p this equation is the strong form of the update problem for the force-balance equation.

Gathering the previous development the formal problem for the update consists of determining $u^n \in H^1(\Omega, \mathbb{R}^3)$, $A^n \in H^1(\Omega, \mathfrak{so}(3))$, and $\varepsilon^n_p \in L^2(\Omega, \operatorname{Sym}(3) \cap \mathfrak{sl}(3))$ satisfying

$$\begin{aligned} &\operatorname{Div}\sigma^n = -f^n, \quad x \in \Omega, \\ &\sigma^n = P_K(2\mu\,(\varepsilon^n - \varepsilon^{n-1}_p)) + 2\,\mu_c\,(\operatorname{skew}(\nabla u^n) - A^n) + \lambda \operatorname{tr}[\varepsilon^n]\cdot \mathbb{1}, \\ &-\mu\, L_c^2\, \Delta \operatorname{axl}(A^n) = \mu_c \operatorname{axl}(\operatorname{skew}(\nabla u^n) - A^n). \end{aligned} \tag{2.6}$$

The updated plastic strain field is then given by

$$\varepsilon^n_p = \varepsilon^n - \frac{1}{2\mu}\, P_K(2\mu\,(\varepsilon^n - \varepsilon^{n-1}_p)). \tag{2.7}$$

For the precise formulation of this system we need the projection operator onto the yield surface which we recall in the following.

2.3. The projection onto the yield surface. Let K be a convex domain in stress space defined as

$$K := \left\{\Sigma \in \mathbb{M}^{3\times 3} \mid \|\operatorname{dev}\Sigma\| \le \sigma_{\mathrm{y}}\right\}. \tag{2.8}$$

The orthogonal projection $P_K : \mathbb{M}^{3\times 3} \to K$ onto this set is uniquely given by (see, e.g., [29, 30])

$$\begin{aligned} P_K(\Sigma) &= \begin{cases} \Sigma, & \Sigma \in K, \\ \Sigma - (\|\operatorname{dev}\Sigma\| - \sigma_{\mathrm{y}})\, \frac{\operatorname{dev}\Sigma}{\|\operatorname{dev}\Sigma\|}, & \Sigma \notin K \end{cases} \\ &= \begin{cases} \Sigma, & \|\operatorname{dev}\Sigma\| \le \sigma_{\mathrm{y}}, \\ \frac{1}{3}\operatorname{tr}[\Sigma]\,\mathbb{1} + \frac{\sigma_{\mathrm{y}}}{\|\operatorname{dev}\Sigma\|}\operatorname{dev}\Sigma, & \|\operatorname{dev}\Sigma\| > \sigma_{\mathrm{y}}. \end{cases} \end{aligned}$$

It is easy to see that P_K is Lipschitz continuous but not differentiable at Σ with $\|\operatorname{dev}\Sigma\| = \sigma_{\mathrm{y}}$.[3] From convex analysis it is clear that P_K represents a monotone operator which is nonexpansive. Therefore, P_K has Lipschitz constant 1. Observe also that

$$P_K(\Sigma) = \frac{1}{3}\operatorname{tr}[\Sigma]\,\mathbb{1} + P_K(\operatorname{dev}\Sigma). \tag{2.10}$$

[3] Consider the simple example $p : \mathbb{R} \to \mathbb{R}$,

$$p(x) = \begin{cases} x, & |x| \le \sigma_{\mathrm{y}}, \\ \sigma_{\mathrm{y}}\, \frac{x}{|x|}, & |x| > \sigma_{\mathrm{y}}. \end{cases} \tag{2.9}$$

For future reference we calculate also

$$\begin{aligned}\Sigma - P_K(\Sigma) &= \begin{cases} 0, & \|\operatorname{dev}\Sigma\| \le \sigma_{\rm y}, \\ \operatorname{dev}\Sigma\left(1-\frac{\sigma_{\rm y}}{\|\operatorname{dev}\Sigma\|}\right), & \|\operatorname{dev}\Sigma\| > \sigma_{\rm y} \end{cases} \\ &= [\|\operatorname{dev}\Sigma\| - \sigma_{\rm y}]_+ \frac{\operatorname{dev}\Sigma}{\|\operatorname{dev}\Sigma\|}, \qquad (2.11) \\ \|\Sigma - P_K(\Sigma)\|^2 &= [\|\operatorname{dev}\Sigma\| - \sigma_{\rm y}]_+^2 ,\end{aligned}$$

where $[x]_+ := \max\{0, x\}$.

2.4. Weak form of the reduced update problem. From now onwards we take $\Gamma_D = \partial\Omega$ and assume $g_{\rm D} = x$; i.e., the body is fixed everywhere on its boundary and subject only to body forces. This assumption allows us to confine attention to the simpler setting in $H^1_0(\Omega)$. We introduce the nonlinear mapping

$$\begin{aligned}&\mathcal{M}_C : \mathbb{M}^{3\times 3}\times \operatorname{Sym}(3)\times \mathfrak{so}(3) \to \mathbb{M}^{3\times 3}, \\ &\mathcal{M}_C(X,\varepsilon_p,A) := P_K(2\mu(\operatorname{sym}X - \varepsilon_p)) + \lambda \operatorname{tr}[X]\ \mathbb{1} + 2\mu_c(\operatorname{skew}(X) - A). \qquad (2.12)\end{aligned}$$

The weak form of the update problem (2.6) now reads as follows: for given $f^n \in L^2(\Omega,\mathbb{R}^3)$ and $\varepsilon_p^{n-1} \in L^2(\Omega,\operatorname{Sym}(3)\cap\mathfrak{sl}(3))$ find $(u^n, A^n) \in H^1_0(\Omega,\mathbb{R}^3)\times H^1_0(\Omega,\mathfrak{so}(3))$ satisfying for all $v \in H^1_0(\Omega,\mathbb{R}^3)$ and all $B \in H^1_0(\Omega,\mathfrak{so}(3))$

$$\int_\Omega \langle \mathcal{M}_C(\nabla u^n, \varepsilon_p^n, A^n), \nabla v\rangle \,\mathrm{dx} = \int_\Omega \langle f^n, v\rangle \,\mathrm{dx}, \qquad (2.13)$$

$$\mu\, L_c^2 \int_\Omega \langle DA^n, DB\rangle \,\mathrm{dx} = \mu_c \int_\Omega \langle \operatorname{skew}\nabla u^n - A^n, B\rangle \,\mathrm{dx}. \qquad (2.14)$$

The updated plastic strain field ε_p^n is then obtained by (2.7). It is shown in [49] that for every n the system (2.13)–(2.14) admits a unique weak solution $u^n \in H^1_0(\Omega,\mathbb{R}^3)$ and $A^n \in H^1_0(\Omega,\mathfrak{so}(3))$. Equation (2.13) represents the quasi-linear elliptic system for determining u^n, which will be discussed with respect to regularity. Together with $\varepsilon_p^{n-1}, \varepsilon^n \in H^1(\Omega,\operatorname{Sym}(3))$, which we will obtain from the regularity result to be proven below, using (2.7) we see that $\varepsilon_p^n \in H^1(\Omega,\operatorname{Sym}(3))$.

LEMMA 2.1 (strong Legendre–Hadamard ellipticity). *Let $\mu > 0$, $2\mu + 3\lambda > 0$, and $0 < \mu_c$. Then the matrix-valued function $\mathcal{M}_C$ is strongly rank-one monotone; i.e., there exists a constant $c^+_{LH} > 0$ such that for every $X \in \mathbb{M}^{3\times 3}$, $\varepsilon_p \in \operatorname{Sym}(3)$, $A \in \mathfrak{so}(3)$ and for all $\xi,\eta \in \mathbb{R}^3$ we have*

$$\langle \mathcal{M}_C(X + \xi\otimes\eta, \varepsilon_p, A) - \mathcal{M}_C(X,\varepsilon_p,A), \xi\otimes\eta\rangle \ge c^+_{LH}\ \|\xi\|^2\|\eta\|^2 . \qquad (2.15)$$

Proof. The projection P_K itself is monotone, and for $\mu > 0$ there is no sign change. Thus the map $X \to P_K(2\mu(\operatorname{sym}X - \varepsilon_p))$ is also monotone in X. Since (2.10) holds we have

$$\langle P_K(2\mu(\operatorname{sym}X + \xi\otimes\eta - \varepsilon_p)) - P_K(2\mu(\operatorname{sym}X - \varepsilon_p)), \xi\otimes\eta\rangle \ge \frac{2\mu}{3}\operatorname{tr}[\xi\otimes\eta]^2 .$$

For the remaining linear contribution we have

$$\begin{aligned}&\langle \lambda\operatorname{tr}[X+\xi\otimes\eta]\,\mathbb{1} + 2\mu_c\operatorname{skew}(X+\xi\otimes\eta - A) - [\lambda\operatorname{tr}[X]\,\mathbb{1} + 2\mu_c\operatorname{skew}(X-A)], \xi\otimes\eta\rangle \\ &= \lambda\operatorname{tr}[\xi\otimes\eta]^2 + 2\mu_c\|\operatorname{skew}(\xi\otimes\eta)\|^2 .\end{aligned}$$

Thus

(2.16)

$$\begin{aligned}
&\langle \mathcal{M}_C(X+\xi\otimes\eta,\varepsilon_p,A)-\mathcal{M}_C(X,\varepsilon_p,A),\xi\otimes\eta\rangle\\
&\quad\geq \tfrac{2\mu+3\lambda}{3}\operatorname{tr}[\xi\otimes\eta]^2+2\mu_c\left\|\operatorname{skew}(\xi\otimes\eta)\right\|^2=\tfrac{2\mu+3\lambda}{3}\langle\xi,\eta\rangle^2+\mu_c\left(\|\xi\|^2\|\eta\|^2-\langle\xi,\eta\rangle^2\right)\\
&\quad\text{split } \mu_c^1+\mu_c^2=\mu_c\\
&\quad=\left(\tfrac{2\mu+3\lambda}{3}-\mu_c^1\right)\langle\xi,\eta\rangle^2+\mu_c^1\|\xi\|^2\|\eta\|^2+\mu_c^2\underbrace{\left(\|\xi\|^2\|\eta\|^2-\langle\xi,\eta\rangle^2\right)}_{\geq 0}\\
&\quad\geq\left(\tfrac{2\mu+3\lambda}{3}-\mu_c^1\right)\langle\xi,\eta\rangle^2+\mu_c^1\|\xi\|^2\|\eta\|^2\geq\mu_c^1\|\xi\|^2\|\eta\|^2
\end{aligned}$$

if $0<\mu_c^1<\frac{3\lambda+2\mu}{3}$. Thus $\mathcal{M}_C$ generates a strongly Legendre–Hadamard elliptic operator with ellipticity constant $c_{LH}^+=\min(\mu_c,\frac{2\mu+3\lambda}{3})$. ∎

Obviously, $\mathcal{M}$ is Lipschitz continuous: for every $X_i\in\mathbb{M}^{3\times3}$, $P_i\in\operatorname{Sym}(3)$, $A_i\in\mathfrak{so}(3)$ we have

$$\|\mathcal{M}_C(X_1,P_1,A_1)-\mathcal{M}_C(X_2,P_2,A_2)\|\leq L_{\mathcal{M}_C}\left(\|X_1-X_2\|+\|P_1-P_2\|+\|A_1-A_2\|\right).$$

LEMMA 2.2. *Let $\mu>0$, $2\mu+3\lambda>0$, and $\mu_c>0$. The operator $\mathcal{M}_C$ generates a strongly monotone operator on $H_0^1(\Omega,\mathbb{R}^3)$; that is, there exists a constant $c_{\mathcal{M}_C}>0$ such that for every $v_1,v_2\in H_0^1(\Omega,\mathbb{R}^3)$ and for all $\varepsilon_p\in L^2(\Omega,\operatorname{Sym}(3))$ and $A\in L^2(\Omega,\mathfrak{so}(3))$ we have*

(2.17)

$$\int_\Omega\langle\mathcal{M}_C(\nabla v_1,\varepsilon_p,A)-\mathcal{M}_C(\nabla v_2,\varepsilon_p,A),\nabla v_1-\nabla v_2\rangle\,\mathrm{dx}\geq c_{\mathcal{M}_C}\|v_1-v_2\|^2_{H_0^1(\Omega,\mathbb{R}^3)}.$$

Proof. The same calculation as in the proof of Lemma 2.1 yields the estimate

$$\begin{aligned}
&\langle\mathcal{M}_C(\nabla v_1,\varepsilon_p,A)-\mathcal{M}_C(\nabla v_2,\varepsilon_p,A),\nabla v_1-\nabla v_2\rangle\\
&\quad\geq\frac{2\mu+3\lambda}{3}\operatorname{tr}[\nabla v_1-\nabla v_2]^2+2\mu_c\left\|\operatorname{skew}(\nabla v_1-\nabla v_2)\right\|^2.
\end{aligned}$$

Set $u=v_1-v_2$ and consider

$$\frac{2\mu+3\lambda}{3}\operatorname{tr}[\nabla u]^2+2\mu_c\|\operatorname{skew}\nabla u\|^2=\frac{2\mu+3\lambda}{3}|\operatorname{Div}u|^2+\mu_c\|\operatorname{curl}u\|^2. \tag{2.18}$$

The Div/Curl inequality on the space $H_0^1(\Omega)$ guarantees that there exists $C^+>0$ such that

$$\forall\,u\in H_0^1(\Omega,\mathbb{R}^3):\quad\int_\Omega|\operatorname{Div}u|^2+\|\operatorname{curl}u\|^2\,\mathrm{dx}\geq C^+\|u\|^2_{H_0^1(\Omega,\mathbb{R}^3)}; \tag{2.19}$$

see, for example, [28]. Applying this inequality to (2.18) implies finally (2.17). ∎

It is instructive to realize that although the quadratic form (2.18) is formally positive in the sense of Nečas [41] and strongly Legendre–Hadamard elliptic with constant coefficients it is impossible to extend the analysis to Dirichlet boundary conditions given only on a part of the boundary $\partial\Omega$. We observe that

$$\left\|\sqrt{\mu_c}\operatorname{skew}X+\sqrt{\tfrac{\lambda}{2\cdot3}}\operatorname{tr}[X]\,\mathbb{1}\right\|^2=\frac{\lambda}{2}\operatorname{tr}[X]^2+\mu_c\|\operatorname{skew}X\|^2. \tag{2.20}$$

Let $\widehat{\mathcal{A}}$ be the constant-coefficient first order differential operator

$$\widehat{\mathcal{A}}.\nabla u = \sqrt{\mu_c}\,\mathrm{skew}(\nabla u) + \sqrt{\tfrac{\lambda}{2\cdot 3}}\,\mathrm{tr}\,[\nabla u]\,\mathbb{1}.$$

The corresponding Fourier symbol is given as a linear operator $\mathcal{A}(\xi) : \mathbb{C}^3 \to \mathbb{C}^{3\times 3}$ with

$$\mathcal{A}(\xi).\hat{u} := \sqrt{\mu_c}\,\mathrm{skew}(\xi\otimes\hat{u}) + \sqrt{\tfrac{\lambda}{2\cdot 3}}\,\mathrm{tr}\,[\xi\otimes\hat{u}]\,\mathbb{1}. \tag{2.21}$$

From (2.20) it follows that

$$\|\mathcal{A}(\xi).\hat{u}\|^2 = \frac{\lambda}{2}\,\mathrm{tr}\,[\xi\otimes\hat{u}]^2 + \mu_c\,\|\mathrm{skew}\,\xi\otimes\hat{u}\|^2\,.$$

By algebraic completeness of the symbol $\mathcal{A}(\xi) : \mathbb{C}^3 \to \mathbb{C}^{3\times 3}$ it is meant

$$\forall\,\xi\in\mathbb{C}^3,\,\xi\neq 0: \quad \mathcal{A}(\xi).\hat{u} = 0_{\mathbb{C}^{3\times 3}} \;\Rightarrow\; \hat{u} = 0_{\mathbb{C}^3}.$$

Recall that the corresponding statement for real ξ, i.e.,

$$\forall\,\xi\in\mathbb{R}^3,\,\xi\neq 0: \quad \mathcal{A}(\xi).\hat{u} = 0_{\mathbb{R}^{3\times 3}} \;\Rightarrow\; \hat{u} = 0_{\mathbb{R}^3},$$

is a consequence of strict Legendre–Hadamard ellipticity of $\widehat{\mathcal{A}}$. If the symbol is algebraically complete, then, using the result in Nečas [41] the induced quadratic form

$$\int_\Omega \left\|\widehat{\mathcal{A}}.\nabla u\right\|^2 + \|u\|^2\,\mathrm{dx}$$

is an equivalent norm on $H^1(\Omega,\mathbb{R}^3)$. However, we proceed to show that $\mathcal{A}$ as defined in (2.21) corresponding to our quadratic form (2.18) is not algebraically complete.

Proof. To this end we write

$$\mathcal{A}(\xi).\hat{u} = 0 \;\Rightarrow\; \mathrm{tr}\,[\xi\otimes\hat{u}] = 0, \;\text{ and }\; \mathrm{skew}(\xi\otimes\hat{u}) = 0 \;\Rightarrow\; \xi = \hat{u}, \quad \mathrm{tr}\,[\xi\otimes\xi] = 0.$$

Consider for simplicity the two-dimensional case:

$$\xi = \begin{pmatrix}\alpha_1 + i\,\beta_1\\ \alpha_2 + i\,\beta_2\end{pmatrix}, \quad \xi\otimes\xi = \begin{pmatrix}\xi_1\,\xi_1 & \xi_1\,\xi_2\\ \xi_2\,\xi_1 & \xi_2\,\xi_2\end{pmatrix},$$
$$\mathrm{tr}\,[\xi\otimes\xi] = \xi_1\xi_1 + \xi_2\xi_2 = \alpha_1^2 + \alpha_2^2 - (\beta_1^2+\beta_2^2) + 2i(\alpha_1\beta_1 + \alpha_2\beta_2) = 0.$$

Choosing $\xi = (i,1)^T$ shows that $\mathrm{tr}\,[\xi\otimes\xi] = 0$, which proves the claim. ∎

Thence, the quadratic form is not algebraically complete, and this excludes the treatment of mixed boundary conditions on u in the following: we are forced to assume $\Gamma_D = \partial\Omega$. However, inhomogeneous Dirichlet conditions may be prescribed as far as the use of the Div/Curl estimate is concerned.

2.5. Variational form of the update problem. Due to the underlying variational formulation, the weak form (2.13) of the time-incremental Cosserat problem still has a variational structure. In [49] it is shown that solving (2.13)–(2.14) is equivalent to the following minimization problem: find $(u^n, A^n) \in H^1_0(\Omega,\mathbb{R}^3)\times H^1_0(\Omega,\mathfrak{so}(3))$ which minimize the functional

$$I^n_{\mathrm{incr}}(u,A) = \mathcal{E}_{\mathrm{incr}}(u,A,\varepsilon_p^{n-1}) - \int_\Omega \langle f^n, u\rangle\,\mathrm{dx} \tag{2.22}$$

in $H^1_0(\Omega,\mathbb{R}^3)\times H^1_0(\Omega,\mathfrak{so}(3))$. Here, $\mathcal{E}_{\mathrm{incr}}$ denotes the free energy of the incremental problem defined by

$$\begin{aligned}\mathcal{E}_{\mathrm{incr}}(u,A,\varepsilon_p) = \frac{1}{2\mu}\int_\Omega \Psi\big(2\mu(\mathrm{sym}(\nabla u)-\varepsilon_p)\big)\,\mathrm{dx} + \frac{\lambda}{2}\int_\Omega \mathrm{tr}\,[\nabla u]^2\,\mathrm{dx}\\ + \mu_c\int_\Omega \|\mathrm{skew}(\nabla u)-A\|^2\,\mathrm{dx} + \mu L_c^2\int_\Omega \|DA\|^2\,\mathrm{dx},\end{aligned} \tag{2.23}$$

with a potential function $\Psi:\mathbb{M}^{3\times 3}\to\mathbb{R}^+$ of the form

$$\begin{aligned}\Psi(X) &:= \begin{cases}\frac{1}{2}\|X\|^2, & \|\mathrm{dev}\,X\|\le\sigma_{\mathrm{y}},\\ \frac{1}{2}\left(\frac{1}{3}\,\mathrm{tr}\,[X]^2+2\sigma_{\mathrm{y}}\|\mathrm{dev}\,X\|-\sigma_{\mathrm{y}}^2\right), & \|\mathrm{dev}\,X\|>\sigma_{\mathrm{y}}\end{cases}\\ &= \frac{1}{2}\|X\|^2-\frac{1}{2}\left[\|\mathrm{dev}\,X\|-\sigma_{\mathrm{y}}\right]_+^2.\end{aligned} \tag{2.24}$$

Clearly, Ψ is convex but not strongly convex outside the yield surface. Moreover, it has only linear growth outside the yield surface. Note that for the first time step $n=1$ and $\varepsilon_p^0=0$, $\mu_c=0$, $L_c=0$ the functional $I^1_{\mathrm{incr}}(u,0)$ reduces to the primal plastic functional of static perfect plasticity (Hencky plasticity) [35, 63, 24, 25, 6].

Calculating the subdifferential of the convex potential shows that

$$\begin{aligned}\partial\Psi(\Sigma).H &= \begin{cases}\langle\Sigma,H\rangle, & \|\mathrm{dev}\,\Sigma\|\le\sigma_{\mathrm{y}},\\ \frac{1}{3}\,\mathrm{tr}\,[\Sigma]\,\mathrm{tr}\,[H]+\frac{\sigma_{\mathrm{y}}}{\|\mathrm{dev}\,\Sigma\|}\langle\mathrm{dev}\,\Sigma,\mathrm{dev}\,H\rangle, & \|\mathrm{dev}\,\Sigma\|>\sigma_{\mathrm{y}}\end{cases}\\ &= \langle P_K(\Sigma),H\rangle.\end{aligned} \tag{2.25}$$

Hence $\partial\Psi(\Sigma)=P_K(\Sigma)$, motivating the variational structure. The following relationship between the potential Ψ and the projection P_K is also valid:

$$\Psi(X)=\tfrac{1}{2}\|X\|^2-\tfrac{1}{2}\|X-P_K(X)\|^2.$$

For future reference the second differential of the potential Ψ can be calculated in those points where the potential is differentiable. It holds that

$$D^2_X\Psi(X).(H,H) = \begin{cases}\|H\|^2, & \|\mathrm{dev}\,X\|<\sigma_{\mathrm{y}},\\ \text{does not exist}, & \|\mathrm{dev}\,X\|=\sigma_{\mathrm{y}},\\ \frac{1}{3}\,\mathrm{tr}\,[H]^2+\sigma_{\mathrm{y}}\left(\frac{\|\mathrm{dev}\,H\|^2}{\|\mathrm{dev}\,X\|}-\frac{\langle\mathrm{dev}\,X,H\rangle^2}{\|\mathrm{dev}\,X\|^3}\right), & \|\mathrm{dev}\,X\|>\sigma_{\mathrm{y}}.\end{cases} \tag{2.26}$$

The potential Ψ is not strictly rank-one convex in X, since taking $H=\xi\otimes\eta$ with $\langle\xi,\eta\rangle=0$ yields

$$D^2_X\Psi(X).(\xi\otimes\eta,\xi\otimes\eta) = \begin{cases}\|\xi\|^2\|\eta\|^2, & \|\mathrm{dev}\,X\|\le\sigma_{\mathrm{y}},\\ \sigma_{\mathrm{y}}\left(\frac{\|\mathrm{dev}\,\xi\otimes\eta\|^2}{\|\mathrm{dev}\,X\|}-\frac{\langle\mathrm{dev}\,X,\xi\otimes\eta\rangle^2}{\|\mathrm{dev}\,X\|^3}\right), & \|\mathrm{dev}\,X\|>\sigma_{\mathrm{y}}.\end{cases}$$

Taking $X=\xi\otimes\eta$ shows finally

$$D^2_X\Psi(X).(\xi\otimes\eta,\xi\otimes\eta) = \begin{cases}\|\xi\|^2\|\eta\|^2, & \|\mathrm{dev}\,X\|\le\sigma_{\mathrm{y}},\\ 0, & \|\mathrm{dev}\,X\|>\sigma_{\mathrm{y}}.\end{cases}$$

3. Improved error estimates for Cosserat plasticity. Let $h > 0$ be the mesh size of a finite element method, and let $V_h \subset H^1_0(\Omega, \mathbb{R}^3)$ be a corresponding discrete finite element space. Let us concentrate on the displacement approximation only. In [49, Thm. 8] the following error estimate for the discrete solution $u_h^{\mu_c,n} \in V_h$ of the Galerkin approximation of (2.23) in V_h has been shown:

$$\|u^{\mu_c,n} - u_h^{\mu_c,n}\|_{H^1_0(\Omega)} \leq \frac{C_1}{\mu_c} \inf_{v_h \in V_h} \|u^{\mu_c,n} - v_h\|_{H^1_0(\Omega)}\,, \tag{3.1}$$

with a constant $C_1 > 0$. Here, $u^{\mu_c,n} = u^n$ is the exact solution of (2.13).

Using our regularity result from section 5, i.e., $u^{\mu_c,n} \in H^2(\Omega, \mathbb{R}^3)$, the right-hand side can be estimated qualitatively. If V_h is chosen to be the space of piecewise linear finite elements, then it holds [8, p. 107] that

$$\|u^{\mu_c,n} - u_h^{\mu_c,n}\|_{H^1_0(\Omega)} \leq \frac{C_2}{\mu_c}\, h\, \|u^{\mu_c,n}\|_{H^2(\Omega)}\,. \tag{3.2}$$

In [49] it has also been shown that for $\mu_c \to 0$ the classical Prandtl–Reuss symmetric Cauchy stresses σ^0 are approximated by the sequence of nonsymmetric stresses σ^{μ_c} whenever a safe load condition is satisfied. The estimate (3.2) strongly suggests therefore to balance h against μ_c to obtain optimal rates of convergence to the classical solution as in [54], where hardening-type approximations have been considered.

4. Higher regularity for alternative regularized update potentials. Our regularity result can also be applied to many other problems arising in the context of infinitesimal plasticity. There exist several other possibilities to regularize the classical update problem for the Prandtl–Reuss model. We recall the classical update problem: find a minimizer $u^n \in BD(\Omega, \mathbb{R}^3)$ of the functional

$$I^{\text{class}}_{\text{incr}}(u) = \mathcal{E}^{\text{class}}_{\text{incr}}(u, \varepsilon_p^{n-1}) - \int_\Omega \langle f^n, u\rangle \,\mathrm{dx}, \tag{4.1}$$

where $\mathcal{E}^{\text{class}}_{\text{incr}}$ denotes the free energy of the classical incremental problem defined by

$$\mathcal{E}^{\text{class}}_{\text{incr}}(u, \varepsilon_p) = \frac{1}{2\mu} \int_\Omega \Psi\big(2\mu(\operatorname{sym}(\nabla u) - \varepsilon_p)\big)\,\mathrm{dx} + \int_\Omega \frac{\lambda}{2} \operatorname{tr}[\nabla u]^2\,\mathrm{dx}, \tag{4.2}$$

with the potential Ψ as in (2.24). There is a vast literature on this Prandtl–Reuss update problem, mostly for the first time step $n = 1$, in which case it is the classical Hencky problem of total deformation plasticity [63, 54, 24, 25]. In this case, the plastic strain field ε_p is a symmetric bounded measure [63, 6]. The classical symmetric Cauchy stresses $\sigma = 2\mu\,(\operatorname{sym}\nabla u - \varepsilon_p) + \lambda \operatorname{tr}[\nabla u]\,\mathbb{1}$ satisfy $\sigma \in L^2(\Omega, \operatorname{Sym}(3))$; indeed higher regularity for the stresses can be shown in the sense that $\sigma \in H^1_{\text{loc}}(\Omega, \operatorname{Sym}(3)) \cap H^{\frac{1}{2}-\delta}(\Omega)$.

For regularization purposes the following proposals are usually made:

$$\mathcal{E}^{\text{reg}}_{\text{incr}}(u, \varepsilon_p) = \frac{1}{2\mu} \int_\Omega \Psi\big(2\mu(\operatorname{sym}(\nabla u) - \varepsilon_p)\big)\,\mathrm{dx} + \int_\Omega \frac{\lambda}{2} \operatorname{tr}[\nabla u]^2 + \operatorname{Reg}(\nabla u, \varepsilon_p)\,\mathrm{dx}, \tag{4.3}$$

with the function Reg in the form

$$\operatorname{Reg}(\nabla u, \varepsilon_p) = \frac{\mu\,\delta}{2}\,\|\operatorname{dev}\operatorname{sym}\nabla u - \varepsilon_p\|^2\,, \quad \text{Fuchs and Seregin [24, p. 60]}, \tag{4.4}$$

$$\mathrm{Reg}(\nabla u, \varepsilon_p) = \frac{1}{2\,\mu\,(1+\frac{\Delta t}{\eta})}\left[\|\mu(\operatorname{dev}\operatorname{sym}\nabla u - \varepsilon_p)\| - \sigma_{\mathrm{y}}\right]_+^2, \quad \text{linear viscosity } \eta,$$

$$\mathrm{Reg}(\nabla u, \varepsilon_p) = \frac{\mu\,\delta}{2}\left\|\nabla u - \varepsilon_p\right\|^2, \quad \text{locally strictly convex in } \nabla u.$$

In each case, for $\delta > 0$ the density of the update problem is then uniformly convex in the symmetric strain $\varepsilon = \operatorname{sym}\nabla u$. Moreover,

$$\mathrm{Reg}(\nabla u, \varepsilon_p) + \frac{\lambda}{2}\operatorname{tr}\left[\nabla u\right]^2 \geq c^+\left\|\varepsilon - \varepsilon_p\right\|^2, \tag{4.5}$$

Korn's first inequality establishes quadratic growth, and we have uniform convexity for the regularized problem. Our main regularity result applies therefore also to these models.

In the case with linear hardening it is simpler to write the update potential directly. We consider as an example isotropic hardening with the hardening variable $\alpha \geq 0$ (a measure for the accumulated plastic strain in the previous time step). Here, the energy $\mathcal{E}_{\mathrm{incr}}$ can be expressed as (cf. [60, p. 124])

$$\mathcal{E}^{\mathrm{hard}}_{\mathrm{incr}}(u, \varepsilon_p, \alpha) = \frac{1}{2\mu}\int_\Omega \Psi_{\mathrm{hard}}\big(2\mu(\operatorname{sym}(\nabla u) - \varepsilon_p), \alpha\big)\,\mathrm{dx} + \int_\Omega \frac{\lambda}{2}\operatorname{tr}\left[\nabla u\right]^2\mathrm{dx}, \tag{4.6}$$

with (cf. (2.24))

$$\Psi_{\mathrm{hard}}(X,\alpha) = \begin{cases} \frac{1}{2}\left\|X\right\|^2, & \|\operatorname{dev} X\| \leq \sigma_{\mathrm{y}} + H\,\alpha, \\ \frac{1}{2\,(1+\frac{H}{1[\mathrm{MPa}]})}\Big(\frac{H}{1[\mathrm{MPa}]}\left\|X\right\|^2 + \frac{1}{3}\operatorname{tr}\left[X\right]^2 & \\ \quad + 2\,(\sigma_{\mathrm{y}} + H\,\alpha)\,\|\operatorname{dev} X\| - (\sigma_{\mathrm{y}} + H\,\alpha)^2\Big), & \|\operatorname{dev} X\| > \sigma_{\mathrm{y}} + H\,\alpha \end{cases}$$

$$= \frac{1}{2}\left\|X\right\|^2 - \frac{1}{2\,(1+\frac{H}{1[\mathrm{MPa}]})}\left[\|\operatorname{dev} X\| - (\sigma_{\mathrm{y}} + H\,\alpha)\right]_+^2, \tag{4.7}$$

whose second derivative coincides with the consistent tangent method introduced already in [61]. The constant $H > 0$ is the hardening modulus with dimension [MPa]. In this form it is easy to see that for positive hardening modulus $H > 0$ the isotropic hardening update potential is uniformly convex in $\operatorname{sym}\nabla u$ with quadratic growth and has a Lipschitz continuous derivative. Therefore, our main regularity result applies also to this functional.[4] The relative merits of each individual regularization scheme depend on their ability to balance regularization and approximation. Linear viscosity and hardening can be justified on physical grounds, but the (small) viscosity parameter $\eta > 0$ is difficult to estimate, as is the linear hardening modulus $H > 0$. The physically motivated regularization terms have the property to control only the symmetric part of the displacement gradient. The regularization $(4.4)_3$, however, does not satisfy the linearized frame-indifference condition.

All alternative regularization procedures thus establish local coercivity in the strains. In contrast, the Cosserat regularization is weaker in the sense that only strong Legendre–Hadamard ellipticity is reestablished, which, provided that displacement boundary data are prescribed, suffices for existence, uniqueness, and higher regularity. Thus the Cosserat approach appears as the weakest regularization among the ones considered.

[4] Repin [54, eq. (2.3)] calls $(4.4)_2$ linear hardening and shows the regularity $u^\delta \in H^2_{\mathrm{loc}}(\Omega, \mathbb{R}^3)$, while for the planar case $n = 2$ he obtains $u^\delta \in H^2(\Omega, \mathbb{R}^2)$ if $\Gamma = \partial\Omega$ is smooth.

5. The regularity theorem. We know already that problem (2.22) has solutions $u^n \in H^1(\Omega,\mathbb{R}^3)$. Looking at the system for the microrotations A^n at given $\nabla u^n \in L^2(\Omega,\mathbb{M}^{3\times 3})$ we realize at once that the linearity in A^n together with the Laplacian structure allows us to use standard elliptic regularity results for linear systems, which yields higher regularity for the microrotations: $A^n \in H^2(\Omega,\mathfrak{so}(3))$. In this section we study the regularity of the displacement field u^n, which is determined through (2.13).

5.1. Higher regularity for a quasi-linear elliptic system. The quasi-linear elliptic system introduced in section 2.4 is a special case of the systems which we define here below. For $d,m,N\geq 1$ and $\Omega\subset\mathbb{R}^d$ let $\mathcal{M}:\Omega\times\mathbb{M}^{m\times d}\times\mathbb{R}^N\to\mathbb{M}^{m\times d}$ be a matrix-valued function with the following properties.

R1. The mapping $\mathcal{M}:\Omega\times\mathbb{M}^{m\times d}\times\mathbb{R}^N\to\mathbb{M}^{m\times d}$ is a Carathéodory function which is Lipschitz continuous in the following sense: there exist constants $L_1,L_2>0$ such that for every $x,x_i\in\Omega$, $a,a_i\in\mathbb{M}^{m\times d}$, and $z,z_i\in\mathbb{R}^N$ we have

$$\begin{aligned}\|\mathcal{M}(x_1,a,z)-\mathcal{M}(x_2,a,z)\|&\leq L_1(\|a\|+\|z\|)\,\|x_1-x_2\|\,,\\ \|\mathcal{M}(x,a_1,z_1)-\mathcal{M}(x,a_2,z_2)\|&\leq L_2(\|a_1-a_2\|+\|z_1-z_2\|),\\ \mathcal{M}(x,0,0)&=0.\end{aligned}$$

Assumption R1 implies the useful estimate

$$\begin{aligned}&\|\mathcal{M}(x_1,a_1,z_1)-\mathcal{M}(x_2,a_2,z_2)\|\\ &\qquad\leq L_1(\|a_1\|+\|z_1\|)\,\|x_1-x_2\|+L_2(\|a_1-a_2\|+\|z_1-z_2\|).\end{aligned}\tag{5.1}$$

R2. The mapping $\mathcal{M}$ is strongly rank-one monotone. That means that there exists a constant $c_{LH}>0$ such that for every $x\in\overline{\Omega}$, $a\in\mathbb{M}^{m\times d}$, $z\in\mathbb{R}^N$, $\xi\in\mathbb{R}^m$, and $\eta\in\mathbb{R}^d$ we have

$$\langle\mathcal{M}(x,a+\xi\otimes\eta,z)-\mathcal{M}(x,a,z),\xi\otimes\eta\rangle\geq c_{LH}\,\|\xi\|^2\,\|\eta\|^2\,.\tag{5.2}$$

R3. The Gårding inequality shall be satisfied: there exist constants $C_G>0$, $c_G\in\mathbb{R}$ such that for every $u_1,u_2\in H^1(\Omega)$ with $u_1-u_2\in H^1_0(\Omega)$ and for every $z\in L^2(\Omega)$ the following inequality is valid:

$$\begin{aligned}\int_\Omega\langle\mathcal{M}(x,\nabla u_1,z)-\mathcal{M}(x,\nabla u_2,z),\nabla(u_1-u_2)\rangle\,\mathrm{dx}&\\ \geq C_G\,\|\nabla(u_1-u_2)\|^2_{L^2(\Omega)}-c_G\,\|u_1-u_2\|^2_{L^2(\Omega)}\,.&\end{aligned}$$

Remark 5.1. If $\mathcal{M}$ is differentiable, then the Gårding inequality already implies that $\mathcal{M}$ is rank-one monotone; see, for example, [65, Thm. 6.1].

We investigate the regularity properties of weak solutions to the following quasi-linear elliptic boundary value problem. For given $g\in H^{\frac12}(\partial\Omega)$, $z\in L^2(\Omega,\mathbb{R}^N)$, and $f\in L^2(\Omega,\mathbb{R}^m)$ find $u\in H^1(\Omega,\mathbb{R}^m)$ with $u|_{\partial\Omega}=g$ such that for every $v\in H^1_0(\Omega,\mathbb{R}^m)$ we have

$$\int_\Omega\langle\mathcal{M}(x,\nabla u(x),z(x)),\nabla v(x)\rangle\,\mathrm{dx}=\int_\Omega\langle f,v\rangle\,\mathrm{dx}.\tag{5.3}$$

THEOREM 5.2. *Let $\Omega\subset\mathbb{R}^d$ be a bounded $\mathcal{C}^{1,1}$-smooth domain, $m\geq 1$, and $N\geq 1$, and assume that $\mathcal{M}:\Omega\times\mathbb{M}^{m\times d}\times\mathbb{R}^N\to\mathbb{M}^{m\times d}$ satisfies* R1–R3. *Furthermore, let*

$g \in H^{\frac{3}{2}}(\partial\Omega)$, $z \in H^1(\Omega)$, and $f \in L^2(\Omega)$. Every weak solution $u \in H^1(\Omega)$ of (5.3) with $u|_{\partial\Omega} = g$ is an element of $H^2(\Omega)$ and satisfies

$$\|u\|_{H^2(\Omega)} \le c\left(\|g\|_{H^{\frac{3}{2}}(\partial\Omega)} + \|z\|_{H^1(\Omega)} + \|f\|_{L^2(\Omega)} + \|u\|_{H^1(\Omega)}\right).$$

Before we prove Theorem 5.2, we apply it to the situation described in section 2.4. There, $m = d = 3$ and $\mathbb{R}^N$ is identified with $\mathrm{Sym}(3) \times \mathfrak{so}(3)$ so that $z = (\varepsilon_p, A)$. Moreover,

$$\begin{aligned}\mathcal{M}(x, \nabla u, z) &= \mathcal{M}_C(\nabla u, \varepsilon_p, A)\\ &= P_K(2\mu(\mathrm{sym}\,\nabla u - \varepsilon_p)) + \lambda(\mathrm{tr}\,[\nabla u])\mathbb{1} + 2\mu_c(\mathrm{skew}(\nabla u) - A).\end{aligned}$$

Since P_K is a Lipschitz continuous mapping, we see immediately that assumption R1 is satisfied. R2 is proved in Lemma 2.1, and the Gårding inequality is satisfied since $\mathcal{M}_C$ generates a strongly monotone operator on $H^1_0(\Omega)$; see Lemma 2.2. Therefore, we have the following result for the reduced update problem (2.6).

THEOREM 5.3. *Let Ω be $\mathcal{C}^{1,1}$-smooth, $f^n \in L^2(\Omega)$, and $\varepsilon_p^{n-1} \in H^1(\Omega)$. Then $u_n \in H^2(\Omega)$, $A^n \in H^2(\Omega)$, and $\varepsilon_p^n \in H^1(\Omega)$.*

The proof of Theorem 5.2 is carried out with a difference quotient technique. We cover the boundary of Ω with a finite number of domains and map each of these domains with a $C^{1,1}$ diffeomorphism onto the unit cube in such a way that the image of the boundary of Ω lies on the midplane of the unit cube. We first prove higher regularity in directions tangential to the midplane by estimating difference quotients. The regularity in the normal direction is then obtained on the basis of the tangential regularity and by using the differential equation together with the rank-one monotonicity of $\mathcal{M}$.

Since $\mathcal{M}$ is nonlinear and since we assumed rank-one monotonicity instead of strong monotonicity, we cannot use as test functions the usual finite differences of the type $h^{-1}\varphi^2(x)(u(x+h) - u(x))$, where φ is a cut-off function. Instead, we use differences which are based on inner variations. We begin the proof of Theorem 5.2 by studying a model problem on a half cube.

5.2. A model problem on a half cube. Let $C_r = \{x \in \mathbb{R}^d; |x_i| < r, 1 \le i \le d\}$ be a cube with side length $2r$, $C_r^{\pm}$ the upper and lower half cube, respectively, and $M_r = \{x \in C_r;\, x_d = 0\}$ the midplane.

LEMMA 5.4. *Let $\Omega = C_1^-$, $f \in L^2(C_1^-)$, and $z \in H^1(C_1^-)$, and assume that $u \in H^1(C_1^-)$ with $u|_{M_1} = 0$ satisfies (5.3). Then for every $r \in (0,1)$ and for $1 \le i \le d-1$ we have $\partial_i u \in H^1(C_r^-)$. Moreover, there is a constant $c_r > 0$ such that*

$$\|\partial_i u\|_{H^1(C_r^-)} \le c_r\big(\|u\|_{H^1(C_1^-)} + \|z\|_{H^1(C_1^-)} + \|f\|_{L^2(C_1^-)}\big). \tag{5.4}$$

Proof. Let $r \in (0,1)$ and $\varphi \in \mathcal{C}_0^\infty(C_1)$ with $\varphi(x) = 1$ on C_r. For $h \in \mathbb{R}^d$ we introduce the mapping

$$\tau_h : C_1 \to \mathbb{R}^d : x \to \tau_h(x) = x + \varphi(x)h.$$

Let $h_0 = \|\varphi\|^{-1}_{W^{1,\infty}(C_1)} \min\big\{1, \mathrm{dist}(\mathrm{supp}\,\varphi, \partial C_1)\big\}$. For every $h \in \mathbb{R}^d$ with $|h| < h_0$ and h parallel to the plane M_1, the mapping τ_h is a diffeomorphism from C_1 onto itself with $\tau_h(C_1^{\pm}) = C_1^{\pm}$, $\tau_h(M_1) = M_1$, and $\tau_h(x) = x$ for every $x \in \partial C_1$; see, e.g., [26]. Moreover, τ_h has the following properties (if $|h| < h_0$):

$$\nabla\tau_h(x) = \big(\mathbb{1} + h \otimes \nabla\varphi(x)\big), \quad \det[\nabla\tau_h(x)] = 1 + \langle h, \nabla\varphi(x)\rangle,$$
$$\nabla_y\tau_h^{-1}(y) = \big(\mathbb{1} + h \otimes \nabla\varphi\big)^{-1}\big|_{\tau_h^{-1}(y)} = \mathbb{1} - \big((1 + \langle h, \nabla\varphi\rangle)^{-1} h \otimes \nabla\varphi\big)\big|_{\tau_h^{-1}(y)}.$$

For a function $v : C_1^- \to \mathbb{R}^s$ we introduce

$$\triangle_h v = v \circ \tau_h - v, \qquad \triangle^h v = v - v \circ \tau_h^{-1}.$$

For $f, g \in L^2(C_1^-)$, $|h| < h_0$ and $h \parallel M_1$ the following product rule is valid:

$$\int_{C_1^-} f \triangle^h g \,\mathrm{dx} = -\int_{C_1^-} g \triangle_h f \,\mathrm{dx} - \int_{C_1^-} (f \circ \tau_h \, g) \,\langle h, \nabla\varphi\rangle \,\mathrm{dx}. \tag{5.5}$$

This identity can be shown by a transformation of coordinates $y = \tau_h(x)$ in the term $(g \circ \tau_h^{-1})f$. Let $u \in H_0^1(C_1^-)$ be a solution of (5.3). For $h \in \mathbb{R}^d$ with $|h| < h_0$ and $h \parallel M_1$ we define the double difference $v_h(x) = \triangle^h(\triangle_h u(x))$. In view of the assumptions on φ, h_0, and h it follows that $v_h \in H_0^1(C_1^-)$. Inserting v_h into (5.3) yields

$$\int_{C_1^-} \langle \mathcal{M}(x, \nabla u, z), \nabla v_h\rangle \,\mathrm{dx} = \int_{C_1^-} \langle f, v_h\rangle \,\mathrm{dx}. \tag{5.6}$$

Note that $\nabla v_h = \triangle^h \nabla(\triangle_h u) + [(\det[\nabla\tau_h])^{-1}(\nabla\triangle_h u)\, h \otimes \nabla\varphi] \circ \tau_h^{-1}$, and therefore (5.6) is equivalent to

$$\begin{aligned}
&\int_{C_1^-} \langle \mathcal{M}(x, \nabla u, z), \triangle^h \nabla(\triangle_h u)\rangle \,\mathrm{dx} \\
&\quad = -\int_{C_1^-} \big\langle \mathcal{M}(x, \nabla u, z), \big(\det[\nabla\tau_h]^{-1}(\nabla\triangle_h u)\, h \otimes \nabla\varphi\big) \circ \tau_h^{-1}\big\rangle \,\mathrm{dx} + \int_{C_1^-} \langle f, \triangle^h\triangle_h u\rangle \,\mathrm{dx}.
\end{aligned}$$

Furthermore, the product rule (5.5) entails

$$\begin{aligned}
\int_{C_1^-} \langle \triangle_h \mathcal{M}(x, \nabla u, z), \nabla\triangle_h u\rangle \,\mathrm{dx} &= -\int_{C_1^-} \langle \mathcal{M}(x, \nabla u, z) \circ \tau_h, \nabla\triangle_h u\rangle \langle h, \nabla\varphi\rangle \,\mathrm{dx} \\
&\quad + \int_{C_1^-} \big\langle \mathcal{M}(x, \nabla u, z), \big((\det[\nabla\tau_h])^{-1}(\nabla\triangle_h u)\, h \otimes \nabla\varphi\big) \circ \tau_h^{-1}\big\rangle \,\mathrm{dx} \\
&\quad + \int_{C_1^-} \langle f, \triangle^h\triangle_h u\rangle \,\mathrm{dx} \\
&=: S_1 + S_2 + S_3.
\end{aligned} \tag{5.7}$$

Finally we have

$$\begin{aligned}
&\int_{C_1^-} \langle \mathcal{M}(x, \nabla(u \circ \tau_h), z) - \mathcal{M}(x, \nabla u, z), \nabla\triangle_h u\rangle \,\mathrm{dx} \\
&\qquad = \int_{C_1^-} \langle \triangle_h \mathcal{M}(x, \nabla u, z), \nabla\triangle_h u\rangle \,\mathrm{dx} \\
&\qquad\quad + \int_{C_1^-} \langle \mathcal{M}(x, \nabla(u \circ \tau_h), z) - \mathcal{M}(x, \nabla u, z) \circ \tau_h, \nabla\triangle_h u\rangle \,\mathrm{dx} \\
&\qquad \overset{(5.7)}{=} S_1 + S_2 + S_3 + \int_{C_1^-} \langle \mathcal{M}(x, \nabla(u \circ \tau_h), z) - \mathcal{M}(x, \nabla u, z) \circ \tau_h, \nabla\triangle_h u\rangle \,\mathrm{dx} \\
&\qquad = S_1 + \cdots + S_4.
\end{aligned} \tag{5.8}$$

The next task is to show that there is a constant $c > 0$, which does not depend on h, such that

$$|S_1 + \cdots + S_4| \le c\,|h| \left(\|u\|_{H^1(C_1^-)} + \|z\|_{H^1(C_1^-)} + \|f\|_{L^2(C_1^-)}\right) \|\triangle_h u\|_{H^1(C_1^-)}. \tag{5.9}$$

Due to the Lipschitz assumptions on $\mathcal{M}$ we have

$$\begin{aligned}|S_1| + |S_2| &\le c\,|h|\,\|\mathcal{M}(\cdot,\nabla u,z)\|_{L^2(C_1^-)}\,\|\triangle_h u\|_{H^1(C_1^-)}\\ &\le c\,|h|\,\big(\|u\|_{H^1(C_1^-)} + \|z\|_{L^2(C_1^-)}\big)\,\|\triangle_h u\|_{H^1(C_1^-)}\,.\end{aligned}$$

Moreover, since $f \in L^2(C_1^-)$, the term S_3 can be estimated as

$$|S_3| \le c\,|h|\,\|f\|_{L^2(C_1^-)}\,\|\triangle_h u\|_{H^1(C_1^-)}\,.$$

By inequality (5.1) we see that

$$\begin{aligned}|S_4| &\le cL_1\,|h|\,\big(\|u\|_{H^1(C_1^-)} + \|z\|_{H^1(C_1^-)}\big)\,\|\triangle_h u\|_{H^1(C_1^-)}\\ &\quad + cL_2\big(\|\nabla(u\circ\tau_h) - (\nabla u)\circ\tau_h\|_{L^2(C_1^-)} + c\,|h|\,\|z\|_{H^1(C_1^-)}\big)\,\|\triangle_h u\|_{H^1(C_1^-)}\,.\end{aligned}$$

The identity $\nabla(u\circ\tau_h) - (\nabla u)\circ\tau_h = (\nabla u)\circ\tau_h\,(h\otimes\nabla\varphi)$ leads to

$$|S_4| \le c\,|h|\,\big(\|u\|_{H^1(C_1^-)} + \|z\|_{H^1(C_1^-)}\big)\,\|\triangle_h u\|_{H^1(C_1^-)}\,.$$

Collecting all the above estimates we finally arrive at inequality (5.9). Gårding's inequality (see R3) and Poincaré's inequality imply that

$$\begin{aligned}\int_{C_1^-} &\langle \mathcal{M}(x,\nabla(u\circ\tau_h),z) - \mathcal{M}(x,\nabla u,z), \nabla\triangle_h u\rangle\,\mathrm{dx}\\ &\ge C_G\,\|\nabla\triangle_h u\|^2_{L^2(C_1^-)} - c_G\,\|\triangle_h u\|^2_{L^2(C_1^-)}\\ &\ge c\big(\|\triangle_h u\|^2_{H^1(C_1^-)} - |h|^2\,\|u\|^2_{H^1(C_1^-)}\big).\end{aligned}$$

Combining the above estimates with (5.8) and (5.9) results finally in

$$\begin{aligned}\|\triangle_h u\|^2_{H^1(C_1^-)} &\le c\,|h|\,\big(\|u\|_{H^1(C_1^-)} + \|z\|_{H^1(C_1^-)} + \|f\|_{L^2(C_1^-)}\big)\,\|\triangle_h u\|_{H^1(C_1^-)}\\ &\quad + c\,|h|^2\,\|u\|^2_{H^1(C_1^-)}\,,\end{aligned}$$

and the constant c is independent of h. From Young's inequality we obtain

$$|h|^{-1}\,\|\triangle_h u\|_{H^1(C_1^-)} \le c\big(\|u\|_{H^1(C_1^-)} + \|z\|_{H^1(C_1^-)} + \|f\|_{L^2(C_1^-)}\big). \tag{5.10}$$

It follows from this inequality that $\partial_i u \in H^1(C_r^-)$ for $1 \le i \le d-1$ and that $\|\partial_i u\|_{H^1(C_r^-)}$ is bounded by the right-hand side in (5.10); see, e.g., [34]. □

Remark 5.5. If we choose the usual finite differences as test functions, i.e., $\tilde{v}_h(x) = \delta_{-h}(\varphi^2\delta_h u)$, where $\delta_h u = u(x+h) - u(x)$, then similar calculations as those for v_h lead to the estimate

$$\begin{aligned}\int_{C_1^-} &\varphi^2(x)\langle \mathcal{M}(x,\nabla u(x+h),z(x)) - \mathcal{M}(x,\nabla u(x),z(x)), \delta_h\nabla u\rangle\,\mathrm{dx}\\ &\le c\,|h|\,\big\|\varphi^2\delta_h u\big\|_{H^1(C_1^-)}\,;\end{aligned} \tag{5.11}$$

compare also (5.8) and (5.9). But now neither R2 nor R3 helps us to find a lower bound for the left-hand side of (5.11) in terms of $\|\varphi^2\delta_h\nabla u\|^2_{L^2(C_1^-)}$, since in general $\delta_h\nabla u$ is not a rank-one matrix, and since we cannot interchange φ and $\mathcal{M}$ due to the nonlinearity of $\mathcal{M}$.

LEMMA 5.6 (regularity in the normal direction). *With the same assumptions as in Lemma 5.4 it follows for every $r \in (0,1)$ that $\partial_d u \in H^1(C_r^-)$. Furthermore, there exists a constant $c_r > 0$ such that*

$$\|u\|_{H^2(C_r^-)} \leq c_r\big(\|z\|_{H^1(C_1^-)} + \|f\|_{L^2(C_1^-)} + \|u\|_{H^1(C_1^-)}\big). \tag{5.12}$$

Proof. Let $r \in (0,1)$. Equation (5.3) implies that

$$\operatorname{Div} \mathcal{M}(x, \nabla u(x), z(x)) + f(x) = 0 \tag{5.13}$$

for almost every $x \in C_1^-$. Let $\mathcal{M}_i$ denote the columns of the matrix-valued function $\mathcal{M}$, i.e., $\mathcal{M}_i(x,a,z) = (\mathcal{M}_i^\alpha(x,a,z))_{1\leq\alpha\leq m} \in \mathbb{R}^m$ for $1 \leq i \leq d$. The Lipschitz continuity of $\mathcal{M}$ and the tangential regularity proved in Lemma 5.4 guarantee that $\partial_i \mathcal{M}_i(\cdot, \nabla u, z) \in L^2(C_r^-)$ for $1 \leq i \leq d-1$ and is bounded by the right-hand side in (5.4). Together with (5.13) we obtain therefore

$$\partial_d \mathcal{M}_d(\cdot, \nabla u, z) = -f - \sum_{i=1}^{d-1} \partial_i \mathcal{M}_i(\cdot, \nabla u, z) \in L^2(C_r^-).$$

By Lemma 7.23 in [27] the derivative ∂_d can be replaced with a finite difference in the following way: For every $\Omega' \subset\subset C_r^-$ and every $h \in \mathbb{R}^d$ with $|h| < \operatorname{dist}(\Omega', \partial C_r^-)$ and $h \perp M_1$ we have

$$\begin{aligned} \|\delta_h \mathcal{M}_d(\cdot, \nabla u, z)\|_{L^2(\Omega')} &\leq \left(\|f\|_{L^2(C_r^-)} + \sum_{i=1}^{d-1} \|\partial_i \mathcal{M}_i(\cdot, \nabla u, z)\|_{L^2(C_r^-)} \right) |h| \\ &=: c_0 \, |h| \,. \end{aligned} \tag{5.14}$$

Here, $\delta_h v(x) := v(x+h) - v(x)$ for $h \in \mathbb{R}^d$. Thus, for every $h \perp M_1$ with $|h| < \operatorname{dist}(\Omega', \partial C_r^-)$ we have

$$\int_{\Omega'} \langle \delta_h \mathcal{M}_d(x, \nabla u, z), \delta_h \partial_d u \rangle \, \mathrm{dx} \leq c_0 \, |h| \, \|\delta_h \partial_d u\|_{L^2(\Omega')} \,, \tag{5.15}$$

where c_0 is the constant from (5.14). We now split the left-hand side into a term which can be estimated from below due to the rank-one monotonicity of $\mathcal{M}$ and into terms which may be estimated from above using the Lipschitz continuity of $\mathcal{M}$ and the regularity results from Lemma 5.4. For functions $v : C_1^- \to \mathbb{R}^m$ we define $\tilde{\nabla} v(x) = (\partial_1 v(x), \dots, \partial_{d-1} v(x), 0) \in \mathbb{M}^{m\times d}$. Furthermore, $v_h(x) := v(x+h)$ and $e_d = (0, \dots, 0, 1)^\top \in \mathbb{R}^d$. With these notations we have

$$\begin{aligned} &\int_{\Omega'} \langle \mathcal{M}_d(x, \tilde{\nabla} u + \partial_d u_h \otimes e_d, z) - \mathcal{M}_d(x, \nabla u, z), \delta_h \partial_d u \rangle \, \mathrm{dx} \\ &\quad = \int_{\Omega'} \langle \delta_h \mathcal{M}_d(x, \nabla u, z), \delta_h \partial_d u \rangle \, \mathrm{dx} \\ &\qquad + \int_{\Omega'} \langle \mathcal{M}_d(x, \tilde{\nabla} u + \partial_d u_h \otimes e_d, z) - \mathcal{M}_d(x+h, \nabla u_h, z_h), \delta_h \partial_d u \rangle \, \mathrm{dx} \\ &\quad = S_1 + S_2. \end{aligned} \tag{5.16}$$

The term S_1 is already estimated in (5.15). From the Lipschitz continuity of $\mathcal{M}$ (see (5.1)) and the regularity results of Lemma 5.4 we obtain by straightforward

calculations

(5.17)
$$\begin{aligned}|S_2| &\le c\,\|\delta_h\partial_d u\|_{L^2(\Omega')}\left(\left(\left\|\tilde\nabla u+\partial_d u_h\otimes e_d\right\|_{L^2(\Omega')}+\|z\|_{H^1(C_1^-)}\right)|h|+\left\|\delta_h\tilde\nabla u\right\|_{L^2(\Omega')}\right)\\ &\le c\,|h|\left(\|u\|_{H^1(C_1^-)}+\|z\|_{H^1(C_1^-)}+\left\|\partial_d\tilde\nabla u\right\|_{L^2(C_r^-)}\right)\|\delta_h\partial_d u\|_{L^2(\Omega')},\end{aligned}$$

and the constant c is independent of Ω' and h. Moreover, choosing $\xi=\partial_d u_h$ and $\eta=e_d$ in (5.2), we obtain for the left-hand side in (5.16) from the rank-one monotonicity of $\mathcal{M}$ that

$$\begin{aligned}&\int_{\Omega'}\langle\mathcal{M}_d(x,\tilde\nabla u+\partial_d u_h\otimes e_d,z)-\mathcal{M}_d(x,\nabla u,z),\delta_h\partial_d u\rangle\,\mathrm{dx}\\ &\qquad\qquad\ge c_{LH}\,\|\delta_h\partial_d u\|^2_{L^2(\Omega')}.\end{aligned}\tag{5.18}$$

Estimates (5.15)–(5.18) together with Young's inequality finally imply that

$$|h|^{-1}\,\|\delta_h\partial_d u\|_{L^2(\Omega')}\le c\big(\|u\|_{H^1(C_1^-)}+\|z\|_{H^1(C_1^-)}+\left\|\partial_d\tilde\nabla u\right\|_{L^2(C_r^-)}\big)\tag{5.19}$$

for every $h\perp M_1$. The constant c is independent of h and $\Omega'\Subset C_r^-$. This implies that $\partial_d^2 u\in L^2(C_r^-)$ and that $\|\partial_d^2 u\|_{L^2(c_r^-)}$ is bounded by the right-hand side in (5.19). Estimate (5.12) is a combination of (5.19) and (5.4). ∎

5.3. Proof of Theorem 5.2. Let the assumptions of Theorem 5.2 be valid, and assume that $g=0$. Choose $x_0\in\partial\Omega$, and let U_{x_0} be a neighborhood of x_0 such that there exists a $\mathcal{C}^{1,1}$ diffeomorphism $\Phi_{x_0}:U_{x_0}\to C_1$, where C_1 is the unit cube in $\mathbb{R}^d$, with the following properties (we omit the index x_0): $\Phi(U)=C_1$, $\Phi(U\cap\Omega)=C_1^-$, $\Phi(U\setminus\overline{\Omega})=C_1^+$, $\Phi(U\cap\partial\Omega)=M_1$, and $\Phi(x_0)=0$. Let $u\in H_0^1(\Omega)$ be a solution for (5.3) with the data $f\in L^2(\Omega)$ and $z\in H^1(\Omega)$. It follows that

$$\int_{U\cap\Omega}\langle\mathcal{M}(x,\nabla u,z),\nabla v\rangle\,\mathrm{dx}=\int_{U\cap\Omega}\langle f,v\rangle\,\mathrm{dx}$$

for every $v\in H_0^1(\Omega\cap U)$. After a transformation of coordinates with $y=\Phi(x)$ and $\Psi:=\Phi^{-1}$, the previous equation can be written as follows: Let $\tilde u(y)=u(\Psi(y))$. For every $v\in H_0^1(C_1^-)$ we have

$$\int_{C_1^-}\langle\tilde{\mathcal{M}}(y,\nabla\tilde u,\tilde z),\nabla v\rangle\,\mathrm{dy}=\int_{C_1^-}\langle\tilde f,v\rangle\,\mathrm{dy}.$$

Here, we use the abbreviations

$$\tilde{\mathcal{M}}(y,a,\zeta)=|\det[\nabla\Psi(y)]|\,\mathcal{M}(\Psi(y),a(\nabla\Psi(y))^{-1},\zeta)(\nabla\Psi(y))^{-\top},\tag{5.20}$$

$$\tilde f(y)=|\det[\nabla\Psi(y)]|\,f(\Psi(y)),\tag{5.21}$$

$$\tilde z(y)=z(\Psi(y))\tag{5.22}$$

for $y\in C_1^-$, $a\in\mathbb{M}^{m\times d}$, and $\zeta\in\mathbb{R}^N$. It follows immediately from the properties of the diffeomorphism Φ and from those of $\mathcal{M}$ that $\tilde{\mathcal{M}}$ satisfies R1–R3 with respect to C_1^-. Furthermore, $\tilde f$ and $\tilde z$ have the smoothness required in Lemma 5.4. Thus, Lemmata 5.4 and 5.6 guarantee that $\tilde u\in H^2(C_r^-)$ for every $r<1$ and that estimate (5.12) is valid. After applying the inverse transformation $\Psi:C_1^-\to U\cap\Omega$, we have finally shown the following: For every $x_0\in\overline{\Omega}$ there exists an open neighborhood $\tilde U_{x_0}$ such

that $u|_{\tilde{U}_{x_0}\cap\Omega} \in H^2(\tilde{U}_{x_0}\cap\Omega)$ and estimate (5.12) is valid with respect to $\tilde{U}_{x_0}\cap\Omega$. The constants may depend on x_0. Since Ω is assumed to be bounded, we can cover $\overline{\Omega}$ by a finite number of the domains $\tilde{U}_{x_0}$ and obtain finally that $u \in H^2(\Omega)$ with

$$\|u\|_{H^2(\Omega)} \leq c\big(\|z\|_{H^1(\Omega)} + \|f\|_{L^2(\Omega)} + \|u\|_{H^1(\Omega)}\big). \tag{5.23}$$

This proves Theorem 5.2 for the case of vanishing Dirichlet conditions. The general case can be seen as follows. There exists a linear and continuous extension operator $F : H^{\frac{3}{2}}(\partial\Omega) \to H^2(\Omega)$ with $(F(g))\big|_{\partial\Omega} = g$ for every $g \in H^{\frac{3}{2}}(\Omega)$; see, for example, [68]. Then $u \in H^1(\Omega)$ with $u|_{\partial\Omega} = g$ for some $g \in H^{\frac{3}{2}}(\partial\Omega)$ is a solution to (5.3) if and only if there exists an element $\tilde{u} \in H^1_0(\Omega)$ with $u = \tilde{u} + F(g)$ and for every $v \in H^1_0(\Omega)$, $\tilde{u}$ satisfies

$$\int_\Omega \langle \hat{\mathcal{M}}(x, \nabla\tilde{u}, \tilde{z}), \nabla v\rangle \,\mathrm{dx} = \int_\Omega \langle f, v\rangle \,\mathrm{dx},$$

where $\tilde{z} = (F(g), z)$ and $\hat{\mathcal{M}}(x, a, \tilde{z}) = \mathcal{M}(x, a + F(g)(x), z)$. Clearly, $\hat{\mathcal{M}}$ satisfies R1–R3 as well, and by the first part of this proof it follows that $\tilde{u} \in H^2(\Omega)$. This finishes the proof of Theorem 5.2.

6. Discussion. We have shown that the time-incremental Cosserat elasto-plasticity problem admits $H^1(\Omega)$-regular updates of the symmetric plastic strain ε_p^n, provided that the previous plastic strain ε_p^{n-1} is in $H^1(\Omega)$ and the domain and data are suitably regular. Altogether, the time-incremental problem allows the regularity for all $n \in \mathbb{N} : u^n \in H^2(\Omega, \mathbb{R}^3)$, $\varepsilon_p^n \in H^1(\Omega, \mathrm{Sym}(3))$, and $A^n \in H^2(\Omega, \mathfrak{so}(3))$. Uniform bounds in time are missing, and it is an open question whether a similar result holds for the time-continuous problem.

The presented method of proof for higher regularity uses a difference quotient method which is based on inner variations and can be extended to more general problems. This will be the subject of further investigations.

Appendix. Notation. We denote by $\mathbb{M}^{3\times3}$ the set of real 3×3 second order tensors, written with capital letters. The standard Euclidean scalar product on $\mathbb{M}^{3\times3}$ is given by $\langle X, Y\rangle_{\mathbb{M}^{3\times3}} = \mathrm{tr}\,[XY^T]$, and thus the Frobenius tensor norm is $\|X\|^2 = \langle X, X\rangle_{\mathbb{M}^{3\times3}}$ (we use these symbols indifferently for tensors and vectors). The identity tensor on $\mathbb{M}^{3\times3}$ will be denoted by $\mathbb{1}$, so that $\mathrm{tr}\,[X] = \langle X, \mathbb{1}\rangle$. We let Sym and PSym denote the symmetric and positive definite symmetric tensors, respectively. We adopt the usual abbreviations of Lie algebra theory; i.e., $\mathfrak{so}(3) := \{X \in \mathbb{M}^{3\times3} \mid X^T = -X\}$ are skew symmetric second order tensors, and $\mathfrak{sl}(3) := \{X \in \mathbb{M}^{3\times3} \mid \mathrm{tr}\,[X] = 0\}$ are traceless tensors. We set $\mathrm{sym}(X) = \frac{1}{2}(X^T + X)$ and $\mathrm{skew}(X) = \frac{1}{2}(X - X^T)$ such that $X = \mathrm{sym}(X) + \mathrm{skew}(X)$. For $X \in \mathbb{M}^{3\times3}$ we set for the deviatoric part $\mathrm{dev}\,X = X - \frac{1}{3}\,\mathrm{tr}\,[X]\,\mathbb{1} \in \mathfrak{sl}(3)$.

For a second order tensor X we let $X.e_i$ be the application of the tensor X to the column vector e_i. The first and second differential of a scalar-valued function $W(F)$ are written $D_F W(F).H$ and $D^2_F W(F).(H, H)$, respectively. Sometimes we use also $\partial_X W(X)$ to denote the first derivative of W with respect to X. We employ the standard notation of Sobolev spaces, i.e., $L^2(\Omega)$, $H^{1,2}(\Omega)$, $H^{1,2}_\circ(\Omega)$, which we use indifferently for scalar-valued functions as well as for vector-valued and tensor-valued functions.

Acknowledgments. The idea for this work was conceived during a visit of P.N. at the Weierstrass Institute, Berlin. The kind hospitality of A. Mielke is gratefully

acknowledged. P.N. has also profited from the exchange with M. Costabel regarding Div/Curl systems. P.N. and D.K. both acknowledge the help of inspiring discussions on regularity of nonlinear elliptic problems with J. Frehse.

GLOBAL EXISTENCE RESULTS AND UNIQUENESS FOR DISLOCATION EQUATIONS*

GUY BARLES†, PIERRE CARDALIAGUET‡, OLIVIER LEY†, AND RÉGIS MONNEAU§

Abstract. We are interested in nonlocal eikonal equations arising in the study of the dynamics of dislocation lines in crystals. For these nonlocal but also nonmonotone equations, only the existence and uniqueness of Lipschitz and local-in-time solutions were available in some particular cases. In this paper, we propose a definition of weak solutions for which we are able to prove the existence for all time. Then we discuss the uniqueness of such solutions in several situations, both in the monotone and the nonmonotone case.

Key words. nonlocal Hamilton–Jacobi equations, dislocation dynamics, nonlocal front propagation, level-set approach, geometrical properties, lower-bound gradient estimate, viscosity solutions, eikonal equation, L^1-dependence in time

1. Introduction.

In this article we are interested in the dynamics of defects in crystals, called dislocations. The dynamics of these dislocations is the main microscopic explanation of the macroscopic behavior of metallic crystals (see, for instance, the physical monographs of Nabarro [24], Hirth and Lothe [19], or Lardner [21] for a mathematical presentation). A dislocation is a line moving in a crystallographic plane, called a slip plane. The typical length of such a dislocation line is of the order of 10^{-6} m. Its dynamics is given by a normal velocity proportional to the Peach–Koehler force acting on this line.

This Peach–Koehler force may have two possible contributions: the first one is the self-force created by the elastic field generated by the dislocation line itself (i.e., this self-force is a nonlocal function of the shape of the dislocation line); the second one is the force created by everything exterior to the dislocation line, such as the exterior stress applied on the material, or the force created by other defects. In this paper, we study a particular model introduced in Rodney, Le Bouar, and Finel [27].

More precisely, if, at time t, the dislocation line is the boundary of an open set $\Omega_t \subset \mathbb{R}^N$ with $N = 2$ for the physical application, the normal velocity to the set Ω_t is given by

$$V_n = c_0 \star \mathbb{1}_{\overline{\Omega}_t} + c_1, \tag{1}$$

where $\mathbb{1}_{\overline{\Omega}_t}(x)$ is the indicator function of the set $\overline{\Omega}_t$, which is equal to 1 if $x \in \overline{\Omega}_t$ and equal to 0 otherwise. The function $c_0(x,t)$ is a kernel which depends only on the physical properties of the crystal and on the choice of the dislocation line, whose

evolution we follow. In the special case of application to dislocations, the kernel c_0 does not depend on time, but to keep a general setting we allow here a dependence on the time variable. Here $\star$ denotes the convolution is space, namely

$$(c_0(\cdot,t) \star \mathbb{1}_{\overline{\Omega}_t})(x) = \int_{\mathbb{R}^N} c_0(x-y,t)\mathbb{1}_{\overline{\Omega}_t}(y)dy, \tag{2}$$

and this term appears to be the Peach–Koehler self-force created by the dislocation itself, while $c_1(x,t)$ is an additional contribution to the velocity, created by everything exterior to the dislocation line. We refer the reader to Alvarez et al. [3] for a detailed presentation and a derivation of this model.

We proceed as in the level-set approach to derive an equation for the dislocation line. We replace the evolution of a set Ω_t (the strong solution) by the evolution of a function u such that $\Omega_t = \{u(\cdot,t) > 0\}$. Roughly speaking the dislocation line is represented by the zero level-set of the function u which solves the following equation:

$$\begin{cases} \dfrac{\partial u}{\partial t} = (c_0(\cdot,t) \star \mathbb{1}_{\{u(\cdot,t)\geq 0\}}(x) + c_1(x,t))|Du| & \text{in } \mathbb{R}^N \times (0,T), \\ u(\cdot,0) = u_0 \quad \text{in } \mathbb{R}^N, \end{cases} \tag{3}$$

where (2) now reads

$$c_0(\cdot,t) \star \mathbb{1}_{\{u(\cdot,t)\geq 0\}}(x) = \int_{\mathbb{R}^N} c_0(x-y,t)\mathbb{1}_{\{u(\cdot,t)\geq 0\}}(y)dy. \tag{4}$$

Note that (3) is not really a level-set equation since it is not invariant under non-decreasing changes of functions $u \to \varphi(u)$, where φ is nondecreasing. As noticed by Slepčev [28], the natural level-set equation should be (11); see section 1.2.

Although (3) seems very simple, there are only a few known results. Under suitable assumptions on the initial data and on c_0, c_1, the existence and uniqueness of the solution is known in two particular cases: either for short time (see [3]), or for all time under the additional assumption that $V_n \geq 0$, which is, for instance, always satisfied for c_1 satisfying $c_1(x,t) \geq |c_0(\cdot,t)|_{L^1(\mathbb{R}^N)}$ (see [2, 12, 5] for a level-set formulation).

In the general case, the existence for all time of solutions to (3) is not known and, in particular, in the case when the kernel c_0 has negative values; indeed, in this case, the front propagation problem (3) does not satisfy any monotonicity property (preservation of inclusions), and therefore, even if a level-set-type equation can be derived, viscosity solution theory cannot be readily used. At this point, it is worth pointing out that a key property in the level-set approach is the comparison principle for viscosity solutions which is almost equivalent to this monotonicity property (see, for instance, Giga's monograph [18]). On the other hand, one may try to partly use viscosity solution theory together with some other approximation and/or compactness arguments to prove at least the existence of weak solutions (in a suitable sense). But here also the bad sign of the kernel creates difficulties since one cannot readily use the classical half-relaxed limits techniques to pass to the limit in the approximate problems. Additional arguments are needed to obtain weak solutions.

The aim of this paper is to describe a general approach of these dislocations' dynamics, based on the level-set approach, which allows us to introduce a suitable notion of weak solutions, to prove the existence of these weak solutions for all time, and to analyze the uniqueness (or nonuniqueness) of these solutions.

1.1. Weak solutions of the dislocation equation. We introduce the following definition of weak solutions, which itself uses the definition of L^1-viscosity solutions, recalled in Appendix A.

DEFINITION 1.1 (classical and weak solutions). *For any $T > 0$, we say that a function $u \in W^{1,\infty}(\mathbb{R}^N \times [0,T))$ is a weak solution of* (3) *on the time interval $[0,T)$ if there is some measurable map $\chi : \mathbb{R}^N \times (0,T) \to [0,1]$ such that u is an L^1-viscosity solution of*

$$\begin{cases} \dfrac{\partial u}{\partial t} = \bar{c}(x,t)|Du| \quad \text{in } \mathbb{R}^N \times (0,T), \\ u(\cdot,0) = u_0 \quad \text{in } \mathbb{R}^N, \end{cases} \tag{5}$$

where

$$\bar{c}(x,t) = c_0(\cdot,t) \star \chi(\cdot,t)(x) + c_1(x,t) \tag{6}$$

and

$$\mathbb{1}_{\{u(\cdot,t)>0\}}(x) \;\le\; \chi(x,t) \;\le \mathbb{1}_{\{u(\cdot,t)\ge 0\}}(x) \tag{7}$$

for almost all $(x,t) \in \mathbb{R}^N \times [0,T]$. We say that u is a classical solution of (3) *if u is a weak solution to* (5) *and if*

$$\mathbb{1}_{\{u(\cdot,t)>0\}}(x) = \mathbb{1}_{\{u(\cdot,t)\ge 0\}}(x) \tag{8}$$

for almost all $(x,t) \in \mathbb{R}^N \times [0,T]$.

Note that we have $\chi(x,t) = \mathbb{1}_{\{u(\cdot,t)>0\}}(x) = \mathbb{1}_{\{u(\cdot,t)\ge 0\}}(x)$ for almost all $(x,t) \in \mathbb{R}^N \times [0,T]$ for classical solutions.

To state our first existence result, we use the following assumptions.

(H0) $u_0 \in W^{1,\infty}(\mathbb{R}^N)$, $-1 \le u_0 \le 1$, and there exists $R_0 > 0$ such that $u_0(x) \equiv -1$ for $|x| \ge R_0$,

(H1) $c_0 \in C([0,T); L^1(\mathbb{R}^N))$, $D_x c_0 \in L^\infty([0,T); L^1(\mathbb{R}^N))$, $c_1 \in C(\mathbb{R}^N \times [0,T))$, and there exist constants M_1, L_1 such that, for any $x, y \in \mathbb{R}^N$ and $t \in [0,T]$,

$$|c_1(x,t)| \le M_1 \quad \text{and} \quad |c_1(x,t) - c_1(y,t)| \le L_1|x-y|.$$

In what follows, we denote by M_0, L_0 constants such that, for any (or almost every) $t \in [0,T)$, we have

$$|c_0(\cdot,t)|_{L^1(\mathbb{R}^N)} \le M_0 \quad \text{and} \quad |D_x c_0(\cdot,t)|_{L^1(\mathbb{R}^N)} \le L_0.$$

Our first main result is the following.

THEOREM 1.2 (existence of weak solutions). *Under assumptions* (H0)–(H1)*, for any $T > 0$ and for any initial data u_0, there exists a weak solution of* (3) *on the time interval $[0,T)$ in the sense of Definition* 1.1.

Our second main result states that a weak solution is a classical one if the evolving set is expanding and if the following additional condition is fulfilled

(H2) c_1 and c_0 satisfy (H1), and there exist constants m_0, N_1 and a positive function $N_0 \in L^1(\mathbb{R}^N)$ such that, for any $x, h \in \mathbb{R}^N$, $t \in [0,T)$, we have

$$|c_0(x,t)| \le m_0,$$

$$|c_1(x+h,t) + c_1(x-h,t) - 2c_1(x,t)| \le N_1|h|^2,$$

$$|c_0(x+h,t) + c_0(x-h,t) - 2c_0(x,t)| \le N_0(x)|h|^2.$$

THEOREM 1.3 (some links between weak solutions and classical continuous viscosity solutions and uniqueness results). *Assume* (H0)–(H1)*, and suppose that there is some* $\delta \geq 0$ *such that, for all measurable maps* $\chi : \mathbb{R}^N \times (0,T) \to [0,1]$,

$$\text{for all } (x,t) \in \mathbb{R}^N \times [0,T], \quad c_0(\cdot,t) \star \chi(\cdot,t)(x) + c_1(x,t) \geq \delta, \tag{9}$$

and that the initial data u_0 *satisfies (in the viscosity sense)*

$$-|u_0| - |Du_0| \leq -\eta_0 \quad \text{in } \mathbb{R}^N \tag{10}$$

for some $\eta_0 > 0$*. Then any weak solution* u *of* (3) *in the sense of Definition* 1.1 *is a classical continuous viscosity solution of* (3)*. This solution is unique if* (H2) *holds and*

(i) *either* $\delta > 0$,

(ii) *or* $\delta = 0$ *and* u_0 *is semiconvex, i.e., satisfies for some constant* $C > 0$

$$u_0(x+h) + u_0(x-h) - 2u_0(x) \geq -C|h|^2 \quad \text{for all } x, h \in \mathbb{R}^N.$$

Assumption (9) ensures that the velocity V_n in (1) is positive for positive δ. Of course, we can state similar results in the case of negative velocity. Assumption (10) means that u_0 is a viscosity subsolution of $-|v(x)| - |Dv(x)| + \eta_0 \leq 0$. When u_0 is C^1, it follows that the gradient of u_0 does not vanish on the set $\{u_0 = 0\}$ (see [22] for details). Point (ii) of the theorem is the main result of [2, 5]. We also point out that, with adapted proofs, only a bound from below could be required in (H2) on $c_1(x+h,t) + c_1(x-h,t) - 2c_1(x,t)$ and $c_0(x+h,t) + c_0(x-h,t) - 2c_0(x,t)$.

Remark 1.1. In particular Theorem 1.3 implies uniqueness in the case $c_0 \geq 0$ and $c_1 \equiv 0$. The general study of nonnegative kernels is provided below (see Theorem 1.5 and Remark 1.3).

1.2. Nonnegative kernel $c_0 \geq 0$. In the special case where the kernel c_0 is nonnegative, an inclusion principle for the dislocation lines, or equivalently a comparison principle for the functions of the level-set formulations, is expected (cf. Cardaliaguet [11] and Slepčev [28]).

Moreover, in the classical level-set approach, all the level-sets of u should have the same type of normal velocity, and Slepčev [28] remarked that a formulation with a nonlocal term of the form $\{u(\cdot,t) \geq u(x,t)\}$ is more appropriate. Therefore it is natural to start studying the following equation (which replaces (3)):

$$\begin{cases} \dfrac{\partial u}{\partial t} = (c_0(\cdot,t) \star \mathbb{1}_{\{u(\cdot,t) \geq u(x,t)\}}(x) + c_1(x,t))|Du| & \text{in } \mathbb{R}^N \times (0,T)\,, \\ u(\cdot,0) = u_0 & \text{in } \mathbb{R}^N\,, \end{cases} \tag{11}$$

where $\star$ denotes the convolution in space as in (4).

The precise meaning of a viscosity solution of (11) is given in Definition 5.1.

In this context, assumption (H0) can be weakened into the following condition, which allows us to consider unbounded evolving sets:

(H0′) $u_0 \in BUC(\mathbb{R}^N)$.

Our main result for this equation is the following.

THEOREM 1.4 (existence and uniqueness). *Assume that* $c_0 \geq 0$ *on* $\mathbb{R}^N \times [0,T]$ *and that* (H0′)–(H1) *hold. Then there exists a unique viscosity solution* u *of* (11).

Remark 1.2. The comparison principle for this equation (see Theorem 5.2) is a generalization of [28, Theorem 2.3]: indeed, in [28], everything takes place in a fixed

bounded set, whereas here one has to deal with unbounded sets. See also [15] for related results.

Now we turn to the connections with weak solutions. To do so, if u is the unique continuous solution of (11) given by Theorem 1.4, we introduce the functions $\rho^+, \rho^- : \mathbb{R}^N \times [0,T] \to \mathbb{R}$ defined by

$$\rho^+ := \mathbb{1}_{\{u \geq 0\}} \quad \text{and} \quad \rho^- := \mathbb{1}_{\{u > 0\}} .$$

Our result is the following.

THEOREM 1.5 (maximal and minimal weak solutions). *Under the assumptions of Theorem* 1.4, *the maximal and minimal weak solutions of* (3) *are the continuous functions v^+, v^- which are the unique L^1-viscosity solutions of the equations*

$$\begin{cases} \dfrac{\partial v^\pm}{\partial t} = c[\rho^\pm](x,t)|Dv^\pm| & \text{in } \mathbb{R}^N \times (0,T), \\ v^\pm(x,0) = u_0(x) & \text{in } \mathbb{R}^N, \end{cases} \tag{12}$$

where

$$c[\rho](x,t) := c_0(\cdot,t) \star \rho(\cdot,t)(x) + c_1(x,t) \quad \text{in} \quad \mathbb{R}^N \times (0,T).$$

The functions $v^\pm$ satisfy $\{v^+(\cdot,t) \geq 0\} = \{u(\cdot,t) \geq 0\}$ and $\{v^-(\cdot,t) > 0\} = \{u(\cdot,t) > 0\}$, where u is the solution of (11).

Moreover, if the set $\{u(\cdot,t) = 0\}$ has a zero-Lebesgue measure for almost all $t \in (0,T)$, then problem (3) *has a unique weak solution which is also a classical one.*

Remark 1.3. 1. Theorem 1.5 shows that, in the case when $c_0 \geq 0$, Slepčev's approach allows us to identify the maximal and minimal weak solutions as being associated with $\rho^\pm$.

2. Equalities $\{v^-(\cdot,t) \geq 0\} = \{u(\cdot,t) \geq 0\}$ and $\{v^+(\cdot,t) > 0\} = \{u(\cdot,t) > 0\}$ do not hold in general (see, for instance, Example 3.1 in section 3).

3. If the set $\{v^\pm(\cdot,t) = 0\}$ develops an interior, a dramatic loss of uniqueness for the weak solution of (3) may occur. This is illustrated by Example 3.1 below, where we are able to build infinitely many solutions after the onset of fattening.

4. We have uniqueness for (3) if $\{u(\cdot,t) = 0\}$ has a zero-Lebesgue measure for almost all $t \in (0,T)$. This condition is fulfilled when, for instance, $c[\rho] \geq 0$ holds for any indicator function ρ and (10) holds (see also Remark 1.1).

1.3. Organization of the paper. In section 2, we recall basic results for the classical eikonal equation which are used throughout the paper. In section 3, we prove the existence of weak solutions for (3), namely Theorem 1.2, and give a counterexample to the uniqueness in general. Let us mention that this first part of the paper, even if it requires rather deep results of viscosity solution theory, is of a general interest for a wide audience and can be read without having an expertise in this theory since one just needs to apply the results which, anyway, are rather natural. In section 4, we prove Theorem 1.3 in the case of expanding dislocations. The arguments we use here are far more involved from a technical point of view: in particular we need some fine estimates of the perimeter of the evolving sets. In section 5, we study the Slepčev formulation in the case of nonnegative kernels and prove Theorems 1.4 and 1.5. In spirit, this section is closely related to the classical level-set approach but is more technical. Finally, for sake of completeness, we recall in Appendix A the definition of L^1-viscosity solutions and a new stability result proved by Barles in [4].

2. Some basic results for the classical (local) eikonal equation. We want to recall in this section some basic results on the level-set equation

$$\begin{cases} \dfrac{\partial v}{\partial t} = a(x,t)|Dv| & \text{in } \mathbb{R}^N \times (0,T), \\ v(\cdot,0) = u_0 & \text{in } \mathbb{R}^N, \end{cases} \tag{13}$$

where $T > 0$ and $a : \mathbb{R}^N \times [0,T] \to \mathbb{R}$ is, at least, a continuous function.

We provide some classical estimates on the solutions to (13) when a satisfies suitable assumptions. Our result is the following.

THEOREM 2.1. *If u_0 satisfies* (H0) *and a satisfies the assumptions of c_1 in* (H1)*, then* (13) *has a unique continuous solution v which is Lipschitz continuous in $\mathbb{R}^N \times [0,T]$ and which satisfies*

(i) $-1 \le v \le 1$ *in* $\mathbb{R}^N \times (0,T)$*,* $v(x,t) \equiv -1$ *for* $|x| \ge R_0 + M_1 t$*,*

(ii) $|Dv(\cdot,t)|_\infty \le |Du_0|_\infty \, \mathrm{e}^{L_1 t}$*,*

(iii) $|v_t(\cdot,t)|_\infty \le M_1 |Du_0|_\infty \, \mathrm{e}^{L_1 t}$*.*

We skip the very classical proof of Theorem 2.1; we just point out that the first point comes from the comparison result for (13) and the "finite speed of propagation property" (see Crandall and Lions [14]), while the second one is a basic gradient estimate (see, for example, Ley [22]), and the last one comes directly from the fact that the equation is satisfied almost everywhere.

The main consequence of this result is that the solution remains in a compact subset of the Banach space $(C(\mathbb{R}^N \times [0,T]), |\cdot|_\infty)$ as long as u_0 and a satisfy (H0)–(H1) with fixed constants.

Let us introduce the following.

DEFINITION 2.2 (interior ball property). *We say that a closed set $K \subset \mathbb{R}^N$ has an interior ball property of radius $r > 0$ if, for any $x \in K$, there exists $p \in \mathbb{R}^N \setminus \{0\}$ such that $B(x - r\frac{p}{|p|}, r) \subset K$.*

We will also use the following result, due to Cannarsa and Frankowska [10], the proof of which is given in Appendix B for the sake of completeness.

LEMMA 2.3 (interior ball regularization). *Suppose* (H0) *and that a satisfies the assumptions of c_1 in* (H1)–(H2) *and there exists a constant $\delta > 0$ such that*

$$c_1 \ge \delta > 0 \quad \text{on} \quad \mathbb{R}^N \times [0,T].$$

Then there exists a constant γ (depending in particular on $\delta > 0$ and T and on the other constants of the problem) such that for the solution v of (13)*, the set $\{v(\cdot,t) \ge 0\}$ has an interior ball property of radius $r_t \ge \gamma t$ for $t \in (0,T)$.*

3. Existence of weak solutions for (3). We aim to solve (3), i.e.,

$$\begin{cases} \dfrac{\partial u}{\partial t} = (c_0(\cdot,t) \star \mathbb{1}_{\{u(\cdot,t)\ge 0\}}(x) + c_1(x,t))|Du| & \text{in } \mathbb{R}^N \times (0,T), \\ u(\cdot,0) = u_0 & \text{in } \mathbb{R}^N, \end{cases}$$

proving Theorem 1.2, which states the existence of weak solutions as introduced in Definition 1.1.

A key difficulty in solving (3) comes from the fact that, in this kind of level-set equation, one may face the so-called nonempty interior difficulty, i.e., that the 0–level-set of the solution is "fat," which may mean that it has either a nonempty interior or a nonzero Lebesgue measure. Clearly, in both cases, $\mathbb{1}_{\{u(\cdot,t)\ge 0\}}$ is different from

$\mathbb{1}_{\{u(\cdot,t)>0\}}$, and this leads to rather bad stability properties for (3) and therefore to difficulties in proving the existence of a solution (and even more for the uniqueness). The notion of weak solution (5)–(7) emphasizes this difficulty. On the contrary, if $\bar{c}(x,t) \geq 0$ in $\mathbb{R}^N \times [0,T]$, it is known that the "nonempty interior difficulty" cannot happen (see Barles, Soner, and Souganidis [6] and Ley [22]), and we recover a more classical formulation. We discuss this question in the next section as well as some uniqueness issues for our weak solutions. Let us finally note that weak solutions for (3) satisfy the following inequalities.

PROPOSITION 3.1. *Let u be a weak solution to* (3). *Then u also satisfies in the L^1-sense*

$$\frac{\partial u}{\partial t} \leq \left(c_0^+(\cdot,t) \star \mathbb{1}_{\{u(\cdot,t)\geq 0\}}(x) - c_0^-(\cdot,t) \star \mathbb{1}_{\{u(\cdot,t)>0\}}(x) + c_1(x,t)\right)|Du|, \tag{14}$$

$$\frac{\partial u}{\partial t} \geq \left(c_0^+(\cdot,t) \star \mathbb{1}_{\{u(\cdot,t)>0\}}(x) - c_0^-(\cdot,t) \star \mathbb{1}_{\{u(\cdot,t)\geq 0\}}(x) + c_1(x,t)\right)|Du| \tag{15}$$

in $\mathbb{R}^N \times (0,T)$, where $c_0^+ = \max(0,c_0)$ and $c_0^- = \max(0,-c_0)$.

Proof of Proposition 3.1. Let $\bar{c}$ be associated with u as in (5)–(7). Then we have

$$\bar{c}(x,t) \geq c_0^+(\cdot,t) \star \mathbb{1}_{\{u(\cdot,t)>0\}}(x) - c_0^-(\cdot,t) \star \mathbb{1}_{\{u(\cdot,t)\geq 0\}}(x) + c_1(x,t)$$

for every $x \in \mathbb{R}^N$ and almost every $t \in (0,T)$. We note that the right-hand side of the inequality is lower semicontinuous. Following Lions and Perthame [23], u then solves (15) in the usual viscosity sense. The proof of (14) can be achieved in a similar way. □

Proof of Theorem 1.2. 1. *Introduction of a perturbated equation.* First we are going to solve the equation

$$\frac{\partial u}{\partial t} = \left(c_0(\cdot,t) \star \psi_\varepsilon(u(\cdot,t))(x) + c_1(x,t)\right)|Du| \quad \text{in } \mathbb{R}^N \times (0,T)\,, \tag{16}$$

where $\psi_\varepsilon : \mathbb{R} \to \mathbb{R}$ is a sequence of continuous functions such that $\psi_\varepsilon(t) \equiv 0$ for $t \leq -\varepsilon$, $\psi_\varepsilon(t) \equiv 1$ for $t \geq 0$, and ψ_ε is an affine function on $[-\varepsilon, 0]$.

We aim at applying Schauder's fixed point theorem to a suitable map. We note that an alternative proof could be given by using techniques developed by Alibaud in [1].

2. *Definition of a map $\mathcal{T}$.* We introduce the convex and compact (by Ascoli's theorem) subset

$$X = \{u \in C(\mathbb{R}^N \times [0,T]) : u \equiv -1 \text{ in } \mathbb{R}^N \backslash B(0, R_0 + MT),$$
$$|Du|, |u_t|/M \leq |Du_0|_\infty e^{LT}\}$$

of $(C(\mathbb{R}^N \times [0,T]), |\cdot|_\infty)$, for $M = M_0 + M_1$ and $L = L_0 + L_1$, and the map $\mathcal{T} : X \to X$ defined as follows: if $u \in C(\mathbb{R}^N \times [0,T])$, then $\mathcal{T}(u)$ is the unique solution v of (13) for

$$c_\varepsilon(x,t) = c_0(\cdot,t) \star \psi_\varepsilon(u(\cdot,t))(x) + c_1(x,t)$$
$$= \int_{\mathbb{R}^N} c_0(x-z,t)\psi_\varepsilon(u(z,t))dz + c_1(x,t).$$

This definition is justified by the fact that, under assumption (H1) on c_1 and c_0, c_ε satisfies (H1) with fixed constants $M = M_0 + M_1$ and $L = L_0 + L_1$; indeed M is a bound on $\sup_{[0,T]} |c_0(\cdot,t)|_{L^1} + M_1$, while L is estimated by the following calculation: for all $x, y \in \mathbb{R}^N$, $t \in [0,T]$, and $u \in X$, we have

$$
\begin{aligned}
(17)\qquad & c_\varepsilon(x,t) - c_\varepsilon(y,t) \\
&= \int_{\mathbb{R}^N} (c_0(x-z,t) - c_0(y-z,t))\psi_\varepsilon(u(z,t))dz + c_1(x,t) - c_1(y,t) \\
&\le \int_{\mathbb{R}^N} |c_0(x-z,t) - c_0(y-z,t)|dz + |c_1(x,t) - c_1(y,t)| \\
&\le (L_0 + L_1)|x-y|,
\end{aligned}
$$

since $0 \le \psi_\varepsilon \le 1$.

Finally, under assumptions (H0)–(H1), for any $u \in X$, the results of Theorem 2.1 apply to (16), which imply that $\mathcal{T}(u) \in X$. It follows that $\mathcal{T}$ is well defined.

3. *Application of Schauder's fixed point theorem to* $\mathcal{T}$. The map $\mathcal{T}$ is continuous since ψ_ε is continuous by using the classical stability result for viscosity solutions (see, for instance, (30) in section 4). Therefore $\mathcal{T}$ has a fixed point u_ε which is bounded in $W^{1,\infty}(\mathbb{R}^N \times [0,T])$ uniformly with respect to ε (since M and L are independent of ε).

4. *Convergence of the fixed point when* $\varepsilon \to 0$. From Ascoli's theorem, we extract a subsequence $(u_{\varepsilon'})_{\varepsilon'}$ which converges locally uniformly to a function denoted by u (in fact globally since the $u_{\varepsilon'}$ are equal to -1 outside a fixed compact subset).

The functions $\chi_{\varepsilon'} := \psi_{\varepsilon'}(u_{\varepsilon'})$ satisfy $0 \le \chi_{\varepsilon'} \le 1$. Therefore we can extract a subsequence—still denoted $(\chi_{\varepsilon'})$—which converges weakly$-*$ in $L^\infty_{\mathrm{loc}}(\mathbb{R}^N \times [0,T])$ to some function $\chi : \mathbb{R}^N \times (0,T) \to [0,1]$. Therefore, for all $\varphi \in L^1_{\mathrm{loc}}(\mathbb{R}^N \times [0,T])$,

$$
(18)\qquad \int_0^T \int_{\mathbb{R}^N} \varphi \chi_{\varepsilon'} dxdt \to \int_0^T \int_{\mathbb{R}^N} \varphi \chi dxdt.
$$

From Fatou's lemma, if φ is nonnegative, it follows that

$$
\begin{aligned}
\int_0^T \int_{\mathbb{R}^N} \varphi(x,t)\chi(x,t)dxdt &\le \int_0^T \int_{\mathbb{R}^N} \varphi(x,t) \limsup_{\varepsilon' \to 0} \chi_{\varepsilon'}(x,t)dxdt \\
&\le \int_0^T \int_{\mathbb{R}^N} \varphi(x,t) \limsup_{\varepsilon' \to 0, x' \to x, t' \to t} \chi_{\varepsilon'}(x',t')dxdt \\
&\le \int_0^T \int_{\mathbb{R}^N} \varphi(x,t) \mathbb{1}_{\{u(\cdot,t) \ge 0\}}(x)dxdt.
\end{aligned}
$$

Since the previous inequalities hold for any nonnegative $\varphi \in L^1_{\mathrm{loc}}(\mathbb{R}^N \times [0,T])$, we obtain that, for almost every $(x,t) \in \mathbb{R}^N \times (0,T)$,

$$
\chi(x,t) \le \mathbb{1}_{\{u(\cdot,t) \ge 0\}}(x).
$$

Similarly we get

$$
\mathbb{1}_{\{u(\cdot,t) > 0\}}(x) \le \chi(x,t).
$$

Furthermore, setting $c_{\varepsilon'} = c_0 \star \chi_{\varepsilon'} + c_1$, from (18), we have, for all $(x,t) \in \mathbb{R}^N \times [0,T]$,

$$\begin{aligned}\int_0^t c_{\varepsilon'}(x,s)ds &= \int_0^t \int_{\mathbb{R}^N} c_0(x-y,s)\chi_{\varepsilon'}(y,s)dyds + \int_0^t c_1(x,s)ds \\ &\to \int_0^t \bar{c}(x,s)ds,\end{aligned}$$

where $\bar{c}(x,t) = c_0(\cdot,t) \star \chi(\cdot,t)(x) + c_1(x,t)$. The above convergence is pointwise, but, noticing that $c_{\varepsilon'}$ satisfies (H3) (with $M := M_0 + M_1$ and $L := L_0 + L_1$) and using Remark A.1, we can apply the stability theorem (Theorem A.3) given in Appendix A. We obtain that u is an L^1-viscosity solution to (5) with $\bar{c}$ satisfying (6)–(7). ∎

The following example is inspired from [6].

Example 3.1 (counterexample to the uniqueness of weak solutions). Let us consider, in dimension $N = 1$, the following equation of type (3),

$$\begin{cases} \dfrac{\partial U}{\partial t} = (1 \star \mathbb{1}_{\{U(\cdot,t)\geq 0\}}(x) + c_1(t))|DU| & \text{in } \mathbb{R} \times (0,2], \\ U(\cdot,0) = u_0 & \text{in } \mathbb{R}, \end{cases} \tag{19}$$

where we set $c_0(x,t) := 1$, $c_1(x,t) := c_1(t) = 2(t-1)(2-t)$, and $u_0(x) = 1 - |x|$. Note that $1 \star \mathbb{1}_A = \mathcal{L}^1(A)$ for any measurable set $A \subset \mathbb{R}$, where $\mathcal{L}^1(A)$ is the Lebesgue measure on $\mathbb{R}$.

We start by solving auxiliary problems for time in $[0,1]$ and $[1,2]$ in order to produce a family of solutions for the original problem in $[0,2]$.

1. *Construction of a solution for* $0 \leq t \leq 1$. The function $x_1(t) = (t-1)^2$ is the solution of the ODE

$$\dot{x}_1(t) = c_1(t) + 2x_1(t) \text{ for } 0 \leq t \leq 1, \quad \text{and } x(0) = 1$$

(note that $\dot{x}_1 \leq 0$ in $[0,1]$). Consider

$$\begin{cases} \dfrac{\partial u}{\partial t} = \dot{x}_1(t) \left|\dfrac{\partial u}{\partial x}\right| & \text{in } \mathbb{R} \times (0,1], \\ u(\cdot,0) = u_0 & \text{in } \mathbb{R}. \end{cases} \tag{20}$$

There exists a unique continuous viscosity solution u of (20). Looking for u under the form $u(x,t) = v(x,\Gamma(t))$ with $\Gamma(0) = 0$, we obtain that v satisfies

$$\frac{\partial v}{\partial t}\,\dot{\Gamma}(t) = \dot{x}_1(t) \left|\frac{\partial v}{\partial x}\right|.$$

Choosing $\Gamma(t) = -x_1(t) + 1$, we get that v is the solution of

$$\begin{cases} \dfrac{\partial v}{\partial t} = -\left|\dfrac{\partial v}{\partial x}\right| & \text{in } \mathbb{R} \times (0,1], \\ v(\cdot,0) = u_0 & \text{in } \mathbb{R}. \end{cases}$$

By the Oleinik–Lax formula, $v(x,t) = \inf_{|x-y|\leq t} u_0(y)$. Since u_0 is even, we have, for all $(x,t) \in \mathbb{R} \times [0,1]$,

$$u(x,t) = \inf_{|x-y|\leq \Gamma(t)} u_0(y) = u_0(|x| + \Gamma(t)) = u_0(|x| - x_1(t) + 1).$$

Therefore, for $0 \le t \le 1$,

$$\{u(\cdot,t) > 0\} = (-x_1(t), x_1(t)) \quad \text{and} \quad \{u(\cdot,t) \ge 0\} = [-x_1(t), x_1(t)]. \tag{21}$$

We will see in step 3 that u is a solution of (19) in $[0,1]$.

2. *Construction of solutions for* $1 \le t \le 2$. Consider now, for any measurable function $0 \le \gamma(t) \le 1$, the unique solution y_γ of the ODE

$$\dot{y}_\gamma(t) = c_1(t) + 2\gamma(t) y_\gamma(t) \text{ for } 1 \le t \le 2, \quad \text{and } y_\gamma(1) = 0. \tag{22}$$

By comparison, we have $0 \le y_0(t) \le y_\gamma(t) \le y_1(t)$ for $1 \le t \le 2$, where y_0, y_1 are the solutions of (22) obtained with $\gamma(t) \equiv 0, 1$. In particular, it follows that $\dot{y}_\gamma \ge 0$ in $[1,2]$. Consider

$$\begin{cases} \dfrac{\partial u_\gamma}{\partial t} = \dot{y}_\gamma(t) \left| \dfrac{\partial u_\gamma}{\partial x} \right| & \text{in } \mathbb{R} \times (1,2], \\ u_\gamma(\cdot,1) = u(\cdot,1) & \text{in } \mathbb{R}, \end{cases}$$

where u is the solution of (20). Again, this problem has a unique continuous viscosity solution u_γ, and setting $\Gamma_\gamma(t) = y_\gamma(t) \ge 0$ for $1 \le t \le 2$, we obtain that v_γ defined by $v_\gamma(x, \Gamma_\gamma(t)) = u_\gamma(x,t)$ is the unique continuous viscosity solution of

$$\begin{cases} \dfrac{\partial v_\gamma}{\partial t} = \left| \dfrac{\partial v_\gamma}{\partial x} \right| & \text{in } \mathbb{R} \times (0, \Gamma_\gamma(2)], \\ v_\gamma(\cdot,0) = u(\cdot,1) & \text{in } \mathbb{R}. \end{cases}$$

Therefore, for all $(x,t) \in \mathbb{R} \times [1,2]$, we have

$$u_\gamma(x,t) = \sup_{|x-y| \le y_\gamma(t)} u(y,1) = \begin{cases} 0 & \text{if } |x| \le y_\gamma(t), \\ u(|x| - y_\gamma(t), 1) & \text{otherwise.} \end{cases}$$

(Note that $u(-x,t) = u(x,t)$ since u_0 is even and, since $u(\cdot,1) \le 0$, by the maximum principle, we have $u_\gamma \le 0$ in $\mathbb{R} \times [1,2]$.) It follows that, for all $1 \le t \le 2$,

$$\{u_\gamma(\cdot,t) > 0\} = \emptyset \quad \text{and} \quad \{u_\gamma(\cdot,t) \ge 0\} = \{u_\gamma(\cdot,t) = 0\} = [-y_\gamma(t), y_\gamma(t)]. \tag{23}$$

3. *There are several weak solutions of* (19). Set, for $0 \le \gamma(t) \le 1$,

$$\begin{aligned} &c_\gamma(t) = c_1(t) + 2x_1(t), && U_\gamma(x,t) = u(x,t) && \text{if } (x,t) \in \mathbb{R} \times [0,1], \\ &c_\gamma(t) = c_1(t) + 2\gamma(t) y_\gamma(t), && U_\gamma(x,t) = u_\gamma(x,t) && \text{if } (x,t) \in \mathbb{R} \times [1,2]. \end{aligned}$$

Then, from steps 1 and 2, U_γ is the unique continuous viscosity solution of

$$\begin{cases} \dfrac{\partial U_\gamma}{\partial t} = c_\gamma(t) \left| \dfrac{\partial U_\gamma}{\partial x} \right| & \text{in } \mathbb{R} \times (0,2], \\ U_\gamma(\cdot,0) = u_0 & \text{in } \mathbb{R}. \end{cases} \tag{24}$$

Taking $\chi_\gamma(\cdot,t) = \gamma(t) \mathbb{1}_{[-y_\gamma(t), y_\gamma(t)]}$ for $1 \le t \le 2$, from (21) and (23), we have

$$\mathbb{1}_{\{U_\gamma(\cdot,t) > 0\}} \le \chi_\gamma(\cdot,t) \le \mathbb{1}_{\{U_\gamma(\cdot,t) \ge 0\}}$$

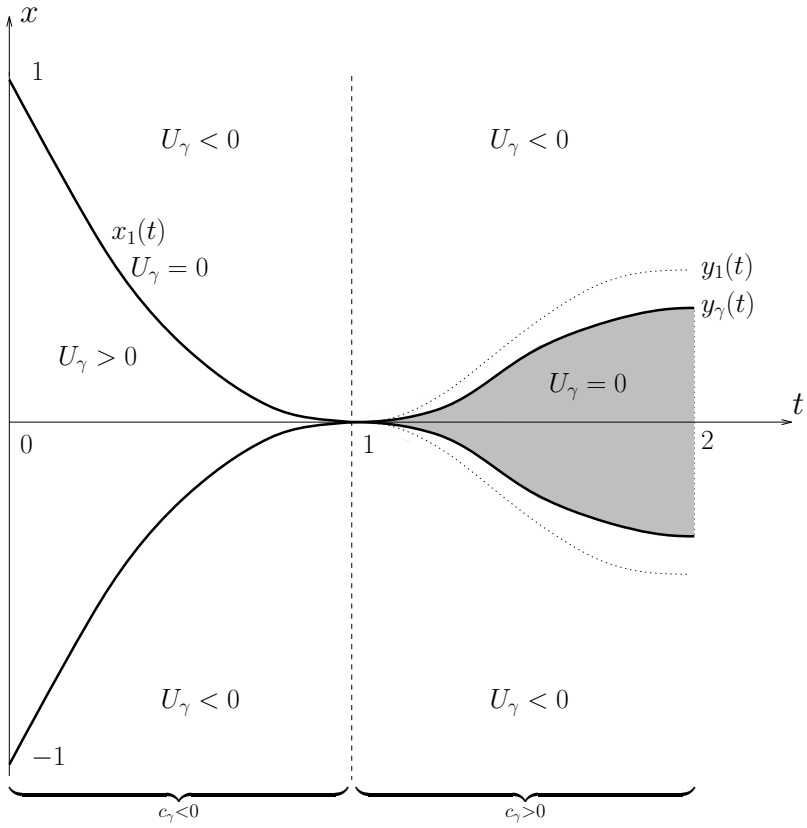

FIG. 1. *Fattening phenomenon for the functions* U_γ.

(see Figure 1). It follows that all the U_γ's, for measurable $0 \le \gamma(t) \le 1$, are all weak solutions of (19), so we do not have uniqueness and the set of solutions is quite large.

Let us complete this counterexample by pointing out the following:

(i) As in [6], nonuniqueness comes from the fattening phenomenon for the front which is due to the fact that c_γ in (24) changes its sign at $t = 1$. It is even possible to build an autonomous counterexample up to start with a front with several connected components.

(ii) $c_0 \ge 0$, and therefore it also complements the results of section 5; indeed the unique solution u of (11) has the same 0–level-set as U_1 (obtained with $\gamma(t) \equiv 1$), and, with the notation of Theorem 1.5, $\rho^+ = \mathbb{1}_{\{U^1(\cdot,t)\ge 0\}}$ and $\rho^- = \mathbb{1}_{\{U^1(\cdot,t)>0\}}$. In particular, for $t \ge 1$,

$$\{v^+(\cdot,t) \ge 0\} = \{U^1(\cdot,t) \ge 0\} = [-y_1(t), y_1(t)]$$

and

$$\{v^-(\cdot,t) > 0\} = \{U^1(\cdot,t) > 0\} = \emptyset.$$

Finally, we note that there are no strong solutions since (8) is obviously never satisfied.

(iii) $c_0 = 1$ does not satisfies (H1), but because of the finite speed of propagation property, it is possible to keep the same solution on a large ball in space and for $t \in (0,T)$ if we replace c_0 by a function with compact support in space such that

$c_0(x,t) = 1$ for $|x| \le R$ with R large enough. In this way, it is possible for c_0 to satisfy (H1).

4. Uniqueness results for weak solutions of (3). Uniqueness of weak solutions of (3) is false in general, as shown in the counterexample of the previous section for sign changing velocities c_1. This is in particular related to the "fattening phenomenon." In [2] and [5] the authors proved that there is a unique "classical" viscosity solution for (3) under the assumptions that the initial set $\{u(\cdot,0) \ge 0\}$ has the "interior sphere property" and that $c_1(\cdot,t) \ge |c_0(\cdot,t)|_{L^1}$ for any $t \ge 0$—a condition which ensures that the velocity $\bar{c}$ is nonnegative. By "classical" continuous viscosity solutions we mean that $t \to \mathbb{1}_{\{u(\cdot,t)\ge 0\}}$ is continuous in L^1, which entails that $(x,t) \mapsto \bar{c}(x,t)$ is continuous, and that (3) holds in the usual viscosity sense.

Here we prove Theorem 1.3. If the condition $c_1(\cdot,t) \ge |c_0(\cdot,t)|_{L^1}$ is satisfied, then weak solutions are viscosity solutions. We also prove that the weak solution is unique if we suppose, moreover, either that the initial condition has the interior sphere property or that the strict inequality $c_1(\cdot,t) > |c_0(\cdot,t)|_{L^1}$ holds for any $t \ge 0$.

Proof of Theorem 1.3. 1. *Weak solutions are classical continuous viscosity solutions.* Let u be a weak solution, and let $\bar{c}$ be associated with u as in Definition 1.1. Then, for any $x \in \mathbb{R}^N$ and for almost all $t \in [0,T]$, we have

$$\begin{aligned}\bar{c}(x,t) &\ge c_1(x,t) + c_0^+(\cdot,t) \star \mathbb{1}_{\{u(\cdot,t)>0\}}(x) - c_0^-(\cdot,t) \star \mathbb{1}_{\{u(\cdot,t)\ge 0\}}(x)\\ &\ge c_1(x,t) - |c_0^-(\cdot,t)|_{L^1}\\ &\ge \delta \ge 0\,.\end{aligned}$$

From [22, Theorem 4.2], there exists a constant η which depends on T such that (10) implies

$$-|u| - |Du| \le -\eta \quad \text{on } \mathbb{R}^N \times (0,T) \tag{25}$$

when we assume, moreover, that $\bar{c}$ is continuous. In our case, where $\bar{c}$ is not assumed continuous in time, (10) follows from the L^1-stability result, Theorem A.3, where we approximate $\bar{c}$ by a continuous function, and from the usual stability for L^1-viscosity subsolutions.

Let us note that from the proof of [5, Corollary 2.5] we have in the viscosity sense

$$-|u(\cdot,t)| - |Du(\cdot,t)| \le -\eta \quad \text{on } \mathbb{R}^N \text{ for every } t \in (0,T)\,. \tag{26}$$

Following [5, Corollary 2.5], we get that, for every $t \in (0,T)$, the 0–level-set of $u(\cdot,t)$ has a zero-Lebesgue measure. Then we deduce that

$$\chi(x,t) = \mathbb{1}_{\{u(\cdot,t)\ge 0\}}(x) \quad \text{for a.e. } x \in \mathbb{R}^N \quad \text{and} \quad \text{for all } t \in (0,T),$$

which (with (7)) entails that

$$\bar{c}(x,t) = c_1 + c_0 \star \mathbb{1}_{\{u(\cdot,t)\ge 0\}}$$

for any (x,t). Moreover, $t \mapsto \mathbb{1}_{\{u(\cdot,t)\ge 0\}}$ is also continuous in L^1, and then $\bar{c}$ is continuous. Therefore u is a classical viscosity solution of (3).

2. *Uniqueness when u_0 is semiconvex (part* (ii)*).* If we assume that (9) and (10) hold and that u_0 is semiconvex, then weak solutions are viscosity solutions, and we can apply the uniqueness result for viscosity solutions given in [5], namely Theorem 4.2

(which remains true under our assumptions), which requires, in particular, semiconvexity of the velocity; see assumption (H2).

3. *A Gronwall-type inequality (part* (i)*).* From now on we assume that $\delta > 0$, and we aim to prove that the solution to (3) is unique. Let u_1, u_2 be two solutions. We set

$$\rho_i = \mathbb{1}_{\{u_i(\cdot,t)\geq 0\}} \qquad \text{and} \qquad \bar{c}_i(x,t) = c_0 \star \rho_i + c_1 \qquad \text{for } i = 1,2.$$

We want to prove in a first step the following Gronwall-type inequality for any t sufficiently small:

$$\begin{aligned} &|\rho_1(\cdot,t) - \rho_2(\cdot,t)|_{L^1} \\ &\leq\ C\left[\mathrm{per}(\{u_1(\cdot,t)\geq 0\}) + \mathrm{per}(\{u_2(\cdot,t)\geq 0\})\right] \int_0^t |\rho_1(\cdot,s) - \rho_2(\cdot,s)|_{L^1} ds, \end{aligned} \tag{27}$$

where C is a constant depending on the constants of the problem, where $\mathrm{per}(\{u_i(\cdot,t)\geq 0\})$ is the $\mathcal{H}^{N-1}$ measure of the set $\partial\{u_i(\cdot,t)\geq 0\}$ (for $i = 1,2$).

We have

$$|\rho_1(\cdot,t) - \rho_2(\cdot,t)|_{L^1} \leq \mathcal{L}^N(\{-\alpha_t \leq u_1(\cdot,t) < 0\}) + \mathcal{L}^N(\{-\alpha_t \leq u_2(\cdot,t) < 0\})\ , \tag{28}$$

where $\mathcal{L}^N$ is the Lebesgue measure in $\mathbb{R}^N$ and

$$\alpha_t = \sup_{s\in[0,t]} |(u_1 - u_2)(\cdot,s)|_\infty \qquad \text{for any } t \in (0,T). \tag{29}$$

In order to estimate the right-hand side of inequality (28), as in the proof of [5, Theorem 4.2], we need a lower-gradient bound as well as a semiconvexity property for u_1 and u_2. We already know from step 1 that $\bar{c}_i$ is continuous for $i = 1,2$.

Let us start to estimate the right-hand side of (28). From the "stability estimates" on the solutions with respect to variations of the velocity (see [5, Lemma 2.2]), we have

$$\alpha_t \leq |Du_0|_\infty e^{Lt} \int_0^t |(\bar{c}_1 - \bar{c}_2)(\cdot,s)|_\infty ds\ , \tag{30}$$

where $L = L_0 + L_1$. Therefore

$$\alpha_t \leq m_0\ |Du_0|_\infty e^{Lt} \int_0^t |(\rho_1 - \rho_2)(\cdot,s)|_{L^1} ds\ . \tag{31}$$

where the constant m_0 is given in (H2). In particular, since the $\rho_i(\cdot,t)$ are continuous in L^1 and equal at time $t = 0$ for $i = 1,2$, we have $\alpha_t/t \to 0$ as $t \to 0^+$.

From now on, we mimic the proof of [5, Proposition 4.5]. Using the lower-gradient bound (25) for $u_i(\cdot,t)$ combined with the increase principle (see [5, Lemma 2.3]), we obtain for $\alpha_t < \eta/2$ that

$$\{-\alpha_t \leq u_i(\cdot,t) < 0\} \subset \{u_i(\cdot,t)\geq 0\} + (2\alpha_t/\eta)\overline{B}(0,1)$$

for $i = 1,2$. From the interior ball regularization lemma (Lemma 2.3), the set $\{u_i(\cdot,t)\geq 0\}$ satisfies for $t \in (0,T)$ the interior ball property of radius $r_t = \eta t/C_0$.

Applying [2, Lemmas 2.5 and 2.6], we obtain for $\sigma_t = 2\alpha_t/\eta$ that

$$\begin{aligned}\mathcal{L}^N(\{-\alpha_t \le u_i(\cdot,t) < 0\}) \le\ & \mathcal{L}^N\left((\{u_i(\cdot,t) \ge 0\} + \sigma_t\,\overline{B}(0,1))\backslash\{u_i(\cdot,t) \ge 0\}\right)\\ &\le \frac{r_t}{N}\left[\left(1+\frac{\sigma_t}{r_t}\right)^N - 1\right]\mathrm{per}(\{u_i(\cdot,t)\ge 0\})\\ &\le \frac{2^N\alpha_t}{\eta}\mathrm{per}(\{u_i(\cdot,t)\ge 0\})\end{aligned}$$

(using $(1+a)^N - 1 \le aN(1+a)^{N-1}$ for $a \ge 0$) for $t \in [0,\tau]$, where $0 < \tau \le T$ is defined by

$$\tau = \sup\left\{t > 0 : \alpha_t < \frac{\eta}{2} \text{ and } 2\frac{C_0}{\eta^2}\frac{\alpha_t}{t} \le 1\right\}. \tag{32}$$

Putting together (31), (28), and the previous inequality proves (27).

4. *Uniqueness when $\delta > 0$ (part* (i)*).* We now complete the uniqueness proof under the assumption $\delta > 0$. For this we first show that $\rho_1 = \rho_2$ in $[0,\tau]$. In order to apply the Gronwall lemma to the L^1-estimate (27) obtained in step 3, it is enough to prove that the functions $t \mapsto \mathrm{per}(\{u_i(\cdot,t)\ge 0\})$ belong to L^1. For this, let us set

$$w_i(x) = \inf\{t \ge 0\ :\ u_i(x,t) \ge 0\}\ .$$

Since u_i solves the eikonal equation $(u_i)_t = \bar{c}_i(x,t)|Du_i|$, from classical representation formulae, we have

$$\begin{aligned}\{u_i(\cdot,t)\ge 0\} = \{x\ :\ &\exists y(\cdot),\ |\dot y(s)| \le c(y(s),s),\ 0\le s\le t,\\ &u_0(y(0)) \ge 0 \text{ and } y(t) = x\}.\end{aligned}$$

Therefore

$$\begin{aligned}w_i(x) = \inf\{t \ge 0\ :\ &\exists y(\cdot),\ |\dot y(s)| \le c(y(s),s),\ 0\le s\le t,\\ &u_0(y(0)) \ge 0 \text{ and } y(t) = x\}.\end{aligned}$$

Applying the dynamic programming principle, since $\bar{c}_i \ge \delta > 0$, we obtain that w_i is Lipschitz continuous and is a viscosity solution of the autonomous equation $\bar{c}_i(x,w_i(x))|Dw_i(x)| = 1$. Note that $\{u_i(\cdot,t)\ge 0\} = \{w_i \le t\}$. In particular, by Theorem 2.1(i), $\{w_i \le t\} \subset B(0, R_0 + (M_0+M_1)T)$ is bounded for any t. From the coarea formula, we have

$$\begin{aligned}\int_0^t \mathrm{per}(\{u_i(\cdot,s)\ge 0\})ds\ &=\ \int_0^t \mathrm{per}(\{w_i \le s\})ds\\ &=\ \int_{\{w_i\le t\}} |Dw_i(x)|dx,\end{aligned}$$

which is finite since w_i is Lipschitz continuous. Therefore we have proved that $t \mapsto \mathrm{per}(\{u_i(\cdot,t)\ge 0\})$ belongs to $L^1([0,\tau])$, which entails from the Gronwall lemma that $\rho_1 = \rho_2$ in $[0,\tau]$ since $\rho_1(\cdot,0) = \rho_2(\cdot,0)$. Hence $\bar{c}_1 = \bar{c}_2$ and $u_1 = u_2$ in $[0,\tau]$. From the definition of α_t and τ (see (29) and (32)), necessarily $\tau = T$. It completes the proof. □

5. Nonnegative kernel c_0 and Slepčev formulation for the nonlocal term. In this section, we deal with nonnegative kernels $c_0 \geq 0$. In this monotone framework, inclusion principles for evolving sets and comparison for solutions to the dislocation equation are expected (see Cardaliaguet [11] for related results). We start by studying the right level-set equation using a Slepčev formulation with the convolution term using all the level-sets $\{u(\cdot,t) \geq u(x,t)\}$ instead of only one level-set $\{u(\cdot,t) \geq 0\}$. This choice is motivated by the good stability properties of the Slepčev formulation.

The equation we are concerned with is

$$\begin{cases} \dfrac{\partial u}{\partial t} = c^+[u](x,t)|Du| & \text{in } \mathbb{R}^N \times (0,T), \\ u(\cdot,0) = u_0 & \text{in } \mathbb{R}^N, \end{cases} \tag{33}$$

where the nonlocal velocity is

$$\begin{aligned} c^+[u](x,t) &= c_1(x,t) + c_0(\cdot,t) \star \mathbb{1}_{\{u(\cdot,t) \geq u(x,t)\}}(x) \\ &= c_1(x,t) + \int_{\mathbb{R}^N} c_0(x-z,t)\mathbb{1}_{\{u(\cdot,t) \geq u(x,t)\}}(z)dz \end{aligned} \tag{34}$$

and the additional velocity c_1 has no particular sign.

We denote

$$c^-[u](x,t) = c_1(x,t) + \int_{\mathbb{R}^N} c_0(x-z,t)\mathbb{1}_{\{u(\cdot,t) > u(x,t)\}}(z)dz.$$

We recall the notion of viscosity solutions for (33) as it appears in [28].

DEFINITION 5.1 (Slepčev viscosity solutions). *An upper semicontinuous function $u : \mathbb{R}^N \times [0,T] \to \mathbb{R}$ is a viscosity subsolution of* (33) *if, for any $\varphi \in C^1(\mathbb{R}^N \times [0,T])$, for any maximum point $(\bar{x},\bar{t})$ of $u - \varphi$, if $\bar{t} > 0$, then*

$$\frac{\partial \varphi}{\partial t}(\bar{x},\bar{t}) \leq c^+[u](\bar{x},\bar{t})|D\varphi(\bar{x},\bar{t})|$$

and $u(\bar{x},0) \leq u_0(\bar{x})$ if $\bar{t} = 0$.

A lower semicontinuous function $u : \mathbb{R}^N \times [0,T] \to \mathbb{R}$ is a viscosity supersolution of (33) *if, for any $\varphi \in C^1(\mathbb{R}^N \times [0,T])$, for any minimum point $(\bar{x},\bar{t})$ of $u - \varphi$, if $\bar{t} > 0$, then*

$$\frac{\partial \varphi}{\partial t}(\bar{x},\bar{t}) \geq c^-[u](\bar{x},\bar{t})|D\varphi(\bar{x},\bar{t})|$$

and $u(\bar{x},0) \geq u_0(\bar{x})$ if $\bar{t} = 0$.

A locally bounded function is a viscosity solution of (33) *if its upper semicontinuous envelope is a subsolution and its lower semicontinuous envelope is a supersolution of* (33).

Note that for the supersolution, we require the viscosity inequality with c^- instead of c^+. It is the definition providing the expected stability results (see [28]).

THEOREM 5.2 (comparison principle). *Assume* (H0′) *and that the kernels $c_0 \geq 0$ and c_1 satisfy* (H1). *Let u (respectively, v) be a bounded upper semicontinuous subsolution (respectively, a bounded lower semicontinuous supersolution) of* (33). *Then $u \leq v$ in $\mathbb{R}^N \times [0,T]$.*

Remark 5.1. We could deal with second-order terms in (33) (for instance we can add the mean curvature to the velocity (1)). See Forcadel [17] and Srour [29] for related results.

Before giving the proof of Theorem 5.2, let us note the following consequence.

Proof of Theorem 1.4. The uniqueness of a continuous viscosity solution to (33) is an immediate consequence of Theorem 5.2. Then existence is proved by Perron's method using classical arguments (see, for instance, [16, Theorem 1.2]), so we skip the details. □

Proof of Theorem 5.2. 1. *The test function.* Since $u - v$ is a bounded upper semicontinuous function, for any $\varepsilon, \eta, \alpha > 0$ and $K = 2(L_0 + L_1) \geq 0$, the supremum

$$M_{\varepsilon,\eta,\alpha} = \sup_{(x,y,t)\in(\mathbb{R}^N)^2\times[0,T]} \left\{ u(x,t) - v(y,t) - \mathrm{e}^{Kt}\left(\frac{|x-y|^2}{\varepsilon^2} + \alpha|x|^2 + \alpha|y|^2\right) - \eta t \right\}$$

is finite and achieved at a point $(\bar{x}, \bar{y}, \bar{t})$. Classical arguments show that

$$\liminf_{\varepsilon,\eta,\alpha\to 0} M_{\varepsilon,\eta,\alpha} = \sup_{\mathbb{R}^N\times[0,T]} \{u - v\}$$

and that

$$\frac{|\bar{x}-\bar{y}|^2}{\varepsilon^2}, \alpha|\bar{x}|^2, \alpha|\bar{y}|^2 \leq M_\infty, \tag{35}$$

where $M_\infty = |u|_\infty + |v|_\infty$.

2. *Viscosity inequalities when* $\bar{t} > 0$. Writing the viscosity inequalities for the subsolution u and the supersolution v, we obtain

$$K\mathrm{e}^{K\bar{t}}\left(\frac{|\bar{x}-\bar{y}|^2}{\varepsilon^2} + \alpha|\bar{x}|^2 + \alpha|\bar{y}|^2\right) + \eta \leq c^+[u](\bar{x},\bar{t})|\bar{p} + \bar{q}_x| - c^-[v](\bar{y},\bar{t})|\bar{p} - \bar{q}_y|, \tag{36}$$

where $\bar{p} = 2e^{K\bar{t}}(\bar{x} - \bar{y})/\varepsilon^2$, $\bar{q}_x = 2e^{K\bar{t}}\alpha\bar{x}$, and $\bar{q}_y = 2e^{K\bar{t}}\alpha\bar{y}$. We point out a difficulty in obtaining this inequality: in general, one gets it by doubling the time variable first and then by passing to the limit in the time penalization. This is not straightforward here because of the dependence with respect to time of the nonlocal terms. But the stability arguments of the Slepčev formulation take care of this difficulty.

3. *Difference between* $\{u(\cdot,\bar{t}) \geq u(\bar{x},\bar{t})\}$ *and* $\{v(\cdot,\bar{t}) > v(\bar{y},\bar{t})\}$. We have

$$\{u(\cdot,\bar{t}) \geq u(\bar{x},\bar{t})\} \subset \{v(\cdot,\bar{t}) > v(\bar{y},\bar{t})\} \cup \mathcal{E}, \tag{37}$$

where $\mathcal{E} = \{u(\cdot,\bar{t}) \geq u(\bar{x},\bar{t})\} \cap \{v(\cdot,\bar{t}) \leq v(\bar{y},\bar{t})\}$. If $x \in \mathcal{E}$, then $u(\bar{x},\bar{t}) - v(\bar{y},\bar{t}) \leq u(x,\bar{t}) - v(x,\bar{t})$. But from the definition of $M_{\varepsilon,\eta,\alpha}$,

$$\begin{aligned} &u(x,\bar{t}) - v(x,\bar{t}) - \mathrm{e}^{K\bar{t}}2\alpha|x|^2 - \eta\bar{t} \\ &\leq u(\bar{x},\bar{t}) - v(\bar{y},\bar{t}) - \mathrm{e}^{K\bar{t}}\left(\frac{|\bar{x}-\bar{y}|^2}{\varepsilon^2} + \alpha|\bar{x}|^2 + \alpha|\bar{y}|^2\right) - \eta\bar{t}. \end{aligned}$$

It follows that

$$\mathcal{E} \subset \left\{ x \in \mathbb{R}^N : |x|^2 \geq \frac{1}{2}(|\bar{x}|^2 + |\bar{y}|^2) + \frac{|\bar{x}-\bar{y}|^2}{2\alpha\varepsilon^2} \right\}.$$

4. *Upper bound for* $c^+[u](\bar{x},\bar{t})$. We have

$$c^+[u](\bar{x},\bar{t}) = \int_{\mathbb{R}^N} c_0(\bar{x}-z,\bar{t})\mathbb{1}_{\{u(\cdot,\bar{t})\geq u(\bar{x},\bar{t})\}}(z)dz + c_1(\bar{x},\bar{t}) \tag{38}$$

$$\leq \int_{\mathbb{R}^N} (c_0(\bar{x}-z,\bar{t}) - c_0(\bar{y}-z,\bar{t}))\mathbb{1}_{\{u(\cdot,\bar{t})\geq u(\bar{x},\bar{t})\}}(z)dz$$

$$+ \int_{\mathbb{R}^N} c_0(\bar{y}-z,\bar{t})\mathbb{1}_{\{u(\cdot,\bar{t})\geq u(\bar{x},\bar{t})\}}(z)dz + c_1(\bar{x},\bar{t}).$$

Using that $c_0 \geq 0$ and (37), we obtain

$$\int_{\mathbb{R}^N} c_0(\bar{y}-z,\bar{t})\mathbb{1}_{\{u(\cdot,\bar{t})\geq u(\bar{x},\bar{t})\}}(z)dz \leq \int_{\{v(\cdot,\bar{t})>v(\bar{y},\bar{t})\}\cup\mathcal{E}} c_0(\bar{y}-z,\bar{t})dz.$$

From (38), we get

$$c^+[u](\bar{x},\bar{t}) \leq c^-[v](\bar{y},\bar{t}) + \mathcal{I}_1 + \mathcal{I}_2 + c_1(\bar{x},\bar{t}) - c_1(\bar{y},\bar{t}), \tag{39}$$

where

$$\mathcal{I}_1 = \int_{\mathbb{R}^N} (c_0(\bar{x}-z,\bar{t}) - c_0(\bar{y}-z,\bar{t}))\mathbb{1}_{\{u(\cdot,\bar{t})\geq u(\bar{x},\bar{t})\}}(z)dz$$

and

$$\mathcal{I}_2 = \int_{\mathcal{E}} c_0(\bar{y}-z,\bar{t})dz.$$

5. *Estimate of* $\mathcal{I}_1$ *using* (H1). We have

$$c_0(\bar{x}-z,t) - c_0(\bar{y}-z,t) = \int_0^1 D_x c_0((1-\lambda)(\bar{y}-z) + \lambda(\bar{x}-z),\bar{t})(\bar{x}-\bar{y})d\lambda.$$

It follows that

$$|\mathcal{I}_1| \leq \int_{\mathbb{R}^N}\int_0^1 |D_x c_0((1-\lambda)(\bar{y}-z) + \lambda(\bar{x}-z),\bar{t})||\bar{x}-\bar{y}|d\lambda dz$$

$$\leq |D_x c_0(\cdot,\bar{t})|_{L^1}|\bar{x}-\bar{y}|$$

$$\leq L_0|\bar{x}-\bar{y}|. \tag{40}$$

6. *Estimate of the right-hand side of inequality* (36). Noticing that $|\bar{p}||\bar{x}-\bar{y}| = 2\mathrm{e}^{K\bar{t}}|\bar{x}-\bar{y}|^2/\varepsilon^2$ and using (40), (39), and (H1), we have

$$c^+[u](\bar{x},\bar{t})|\bar{p}+\bar{q}_x| - c^-[v](\bar{y},\bar{t})|\bar{p}-\bar{q}_y|$$

$$\leq (c^-[v](\bar{y},\bar{t}) + \mathcal{I}_1 + \mathcal{I}_2 + c_1(\bar{x},\bar{t}) - c_1(\bar{y},\bar{t}))|\bar{p}+\bar{q}_x| - c^-[v](\bar{y},\bar{t})|\bar{p}-\bar{q}_y|$$

$$\leq \left|c^-[v](\bar{y},\bar{t})\right||\bar{q}_x+\bar{q}_y| + (L_0+L_1)|\bar{x}-\bar{y}||\bar{p}+\bar{q}_x| + \mathcal{I}_2|\bar{p}+\bar{q}_x|$$

$$\leq (M_0+M_1)(|\bar{q}_x|+|\bar{q}_y|) + 2\mathrm{e}^{K\bar{t}}(L_0+L_1)\frac{|\bar{x}-\bar{y}|^2}{\varepsilon^2}$$

$$+(L_0+L_1)|\bar{x}-\bar{y}||\bar{q}_x| + \mathcal{I}_2\left(|\bar{q}_x| + 2\mathrm{e}^{K\bar{t}}\frac{|\bar{x}-\bar{y}|}{\varepsilon^2}\right).$$

Since $|\bar{q}_x|, |\bar{q}_y| \to 0$ as $\alpha \to 0$ (see (35)) and $\mathcal{I}_2$ is bounded by $|c_0(\cdot,\bar{t})|_{L^1} \leq L_0$, there exists a modulus $m_\varepsilon(\alpha) \to 0$ as $\alpha \to 0$ such that (36) becomes

$$K\mathrm{e}^{K\bar{t}}\left(\frac{|\bar{x}-\bar{y}|^2}{\varepsilon^2}+\alpha|\bar{x}|^2+\alpha|\bar{y}|^2\right)+\eta$$

$$\leq m_\varepsilon(\alpha)+2(L_0+L_1)\mathrm{e}^{K\bar{t}}\frac{|\bar{x}-\bar{y}|^2}{\varepsilon^2}+2\,\mathcal{I}_2\,\mathrm{e}^{K\bar{t}}\frac{|\bar{x}-\bar{y}|}{\varepsilon^2}.$$

Recalling that we chose $K \geq 2(L_0+L_1)$, we finally obtain

$$0<\eta\leq m_\varepsilon(\alpha)+2\,\mathcal{I}_2\,\mathrm{e}^{K\bar{t}}\frac{|\bar{x}-\bar{y}|}{\varepsilon^2}. \tag{41}$$

7. *Limit when* $\alpha \to 0$. First, suppose that

$$\frac{|\bar{x}-\bar{y}|^2}{\varepsilon^2}\to 0 \quad \text{as } \alpha\to 0. \tag{42}$$

It follows that $|\bar{x}-\bar{y}| \to 0$ as $\alpha \to 0$. Passing to the limit in (41), we obtain a contradiction. Therefore, (42) cannot hold, and, up to extracting a subsequence, there exists $\delta > 0$ such that

$$\frac{|\bar{x}-\bar{y}|^2}{\varepsilon^2}\geq\delta>0 \quad \text{for } \alpha>0 \text{ small enough.} \tag{43}$$

From (41) and (35), we get

$$\eta\leq\limsup_{\alpha\to0}2\,\mathcal{I}_2\,\mathrm{e}^{K\bar{t}}\frac{|\bar{x}-\bar{y}|}{\varepsilon^2}\leq\frac{2\mathrm{e}^{K\bar{t}}M_\infty^{1/2}}{\varepsilon}\limsup_{\alpha\to0}\mathcal{I}_2. \tag{44}$$

To obtain a contradiction, it suffices to show that $\limsup_{\alpha\to0}\mathcal{I}_2 = 0$.

8. *Convergence of* $\mathcal{I}_2$ *to* 0 *when* $\alpha \to 0$. By a change of variable, we have

$$\mathcal{I}_2=\int_{\mathcal{E}}c_0(\bar{y}-z,\bar{t})dz\leq\int_{\bar{\mathcal{E}}}c_0(z,\bar{t})dz,$$

where

$$\bar{\mathcal{E}}=\left\{x\in\mathbb{R}^N:|x-\bar{y}|^2\geq\frac{1}{2}(|\bar{x}|^2+|\bar{y}|^2)+\frac{|\bar{x}-\bar{y}|^2}{2\alpha\varepsilon^2}\right\}.$$

Since $|c_0(\cdot,\bar{t})|_{L^1} \leq L_0$, to prove that $\mathcal{I}_2 \to 0$, it suffices to show that $\bar{\mathcal{E}} \subset \mathbb{R}^N \backslash B(0,R_\alpha)$ with $R_\alpha \to +\infty$. From (43), if $x \in \bar{\mathcal{E}}$, then

$$|x|^2\geq-2|x||\bar{y}|+\frac{1}{2}|\bar{x}|^2-\frac{1}{2}|\bar{y}|^2+\frac{\delta}{2\alpha}$$

$$\geq-2|x||\bar{y}|-|\bar{y}||\bar{x}-\bar{y}|+\frac{\delta}{2\alpha}$$

$$\geq\frac{1}{2\alpha}(\delta-2(C^2+2C|x|)\sqrt{\alpha}),$$

since by (35), there exists $C > 0$ such that $|\bar{x}|, |\bar{y}| \leq C/\sqrt{\alpha}$ and $|\bar{x}-\bar{y}| \leq C$. It follows that

$$|x|\geq\frac{1}{\sqrt{\alpha}}\left(-C+\sqrt{C^2+\delta/2-C^2\sqrt{\alpha}}\right):=R_\alpha\underset{\alpha\to0}{\longrightarrow}+\infty.$$

9. *End of the proof.* Finally, for every ε, if $\alpha = \alpha_\varepsilon$ is small enough, the supremum $M_{\varepsilon,\eta,\alpha}$ is necessarily achieved for $\bar{t} = 0$. It follows that

$$M_{\varepsilon,\eta,\alpha} \leq u(\bar{x},0) - v(\bar{y},0) - \frac{|\bar{x}-\bar{y}|^2}{\varepsilon^2} \leq u_0(\bar{x},0) - u_0(\bar{y},0) - \frac{|\bar{x}-\bar{y}|^2}{\varepsilon^2}.$$

Since u_0 is uniformly continuous, for all $\rho > 0$, there exists $C_\rho > 0$ such that

$$M_{\varepsilon,\eta,\alpha} \leq \rho + C_\rho|\bar{x}-\bar{y}| - \frac{|\bar{x}-\bar{y}|^2}{\varepsilon^2} \leq \rho + \frac{C_\rho^2\varepsilon^2}{4}.$$

Passing to the limits $\varepsilon \to 0$ and then $\rho, \alpha, \eta \to 0$, we obtain that $\sup\{u - v\} \leq 0$. □

Now we turn to the connections with *discontinuous solutions* and weak solutions, which are closely connected. To do so, if u is the unique continuous solution of (33) given by Theorem 1.4, we recall that we use the notation

$$\rho^+ := \mathbb{1}_{\{u\geq 0\}}, \quad \rho^- := \mathbb{1}_{\{u>0\}}, \quad \text{and} \quad c[\rho](x,t) = c_0(\cdot,t) \star \rho(\cdot,t)(x) + c_1(x,t).$$

Proof of Theorem 1.5. 1. *Claim: Under the assumptions of Theorem* 1.5*, the functions ρ^+ and ρ^- are L^1-viscosity solutions of the equation*

$$\text{(45)} \qquad \begin{cases} \rho_t = c[\rho]|D\rho| & \text{in } \mathbb{R}^N \times [0,T)\,, \\ \rho(x,0) = \mathbb{1}_{\{u_0\geq 0\}} & \text{in } \mathbb{R}^N\,. \end{cases}$$

We consider two sequences of smooth nondecreasing functions $(\psi_\alpha)_\alpha$, $(\psi^\alpha)_\alpha$, taking values in $[0,1]$, such that, for any $s \in \mathbb{R}$,

$$\psi_\alpha(s) \leq \mathbb{1}_{\{x>0\}}(s) \leq \mathbb{1}_{\{x\geq 0\}}(s) \leq \psi^\alpha(s)\,,$$

and such that, as $\alpha \to 0$, $\psi_\alpha \uparrow \mathbb{1}_{\{x>0\}}$, $\psi^\alpha \downarrow \mathbb{1}_{\{x\geq 0\}}$.

We first remark that u satisfies, in the sense of Definition 5.1,

$$u_t \leq c[\psi^\alpha(u(\cdot,t) - u(x,t))]|Du| \quad \text{in } \mathbb{R}^N \times (0,T)\,,$$

$$u_t \geq c[\psi_\alpha(u(\cdot,t) - u(x,t))]|Du| \quad \text{in } \mathbb{R}^N \times (0,T)$$

since u is a continuous solution of (33), $c^+[u](x,t) \leq c[\psi^\alpha(u(\cdot,t) - u(x,t))]$, and $c^-[u](x,t) \geq c[\psi_\alpha(u(\cdot,t) - u(x,t))]$. The point for doing that is that the functions $c[\psi^\alpha(u(\cdot,t) - u(x,t))]$, $c[\psi_\alpha(u(\cdot,t) - u(x,t))]$ are now continuous in x and t.

Then we show that ρ^+, ρ^- satisfy the same inequalities, the functions $c[\psi^\alpha(u(\cdot,t) - u(x,t))]$, $c[\psi_\alpha(u(\cdot,t) - u(x,t))]$ being considered as fixed functions (in other words, we forget that they depend on u). In fact, we just provide the proof in detail for ρ^+, the one for ρ^- being analogous. Following the proof of [6], we set

$$u_\varepsilon(x,t) := \frac{1}{2}\left(1 + \tanh\left(\varepsilon^{-1}(u(x,t) + \varepsilon^{1/2})\right)\right)\,.$$

Noticing that $u_\varepsilon = \phi_\varepsilon(u)$ for an increasing function ϕ_ε, we have that the function u_ε still satisfies the two above inequalities. It is easy to see that

$$\rho^+ = \limsup{}^*\, u_\varepsilon \quad \text{and} \quad (\rho^+)_* = \liminf_*\, u_\varepsilon\,,$$

and the half-relaxed limits method indeed shows that

$$(\rho^+)^*_t \le c[\psi^\alpha(u(\cdot,t)-u(x,t))]|D(\rho^+)^*| \quad \text{in } \mathbb{R}^N\times(0,T)\ ,$$
$$((\rho^+)_*)_t \ge c[\psi_\alpha(u(\cdot,t)-u(x,t))]|D(\rho^+)_*| \quad \text{in } \mathbb{R}^N\times(0,T)\ .$$

The next step consists of remarking that the viscosity sub- and supersolution inequalities for ρ^+ are obviously satisfied in the complementary of $\partial\{u\ge 0\}$ since ρ^+ is locally constant there, and therefore it is a classical solution of the problem. The only nontrivial viscosity sub- and supersolution inequalities we have to check are at points $(x,t)\in\partial\{u\ge 0\}$, i.e., such that $u(x,t)=0$ since u is continuous. For such points, as $\alpha\to 0$,

$$c[\psi^\alpha(u(\cdot,t)-u(x,t))]\to c[\rho^+](x,t)=c[(\rho^+)^*](x,t)$$

since ρ^+ is upper semicontinuous, and

$$c[\psi_\alpha(u(\cdot,t)-u(x,t))]\to c[\rho^-](x,t).$$

The stability result for equations with an L^1-dependence in time yields the inequalities

$$(\rho^+)^*_t \le c[(\rho^+)^*]|D(\rho^+)^*| \quad \text{in } \mathbb{R}^N\times(0,T),$$
$$((\rho^+)_*)_t \ge c[\rho^-]|D(\rho^+)_*| \quad \text{in } \mathbb{R}^N\times(0,T). \tag{46}$$

The second inequality is weaker than the one we claim: to obtain $c[(\rho^+)_*]$ instead of $c[\rho^-]$, we have to play with the different level-sets of u: for $\beta>0$ small, we set $\rho^+_\beta=\mathbb{1}_{\{u\ge-\beta\}}$. Since u is a solution of (33) and $\psi_{\alpha,\beta}:=\psi_\alpha(\cdot+\beta)$ is nondecreasing, then $\psi_{\alpha,\beta}(u)$ is a (continuous) supersolution of

$$(\psi_{\alpha,\beta}(u))_t \ge c^-[\psi_{\alpha,\beta}(u)]|D\psi_{\alpha,\beta}(u)| \quad \text{in } \mathbb{R}^N\times(0,T).$$

By stability we get, as $\alpha\to 0$,

$$((\rho^+_\beta)_*)_t \ge c^-[(\rho^+_\beta)_*]|D(\rho^+_\beta)_*| \quad \text{in } \mathbb{R}^N\times(0,T).$$

But, for $(x,t)\in\partial\{u\ge-\beta\}$,

$$c^-[(\rho^+_\beta)_*](x,t)=c[\mathbb{1}_{\{(\rho^+_\beta)_*(\cdot,t)>0\}}](x,t)=c[(\rho^+_\beta)_*](x,t)\ge c[\rho^+](x,t). \tag{47}$$

It follows that $(\rho^+_\beta)_*$ is a supersolution of the eikonal equation with $c[\rho^+](x,t)$ (as before, the only nontrivial inequalities we have to check are on $\partial\{u\ge-\beta\}$, and they are true because of (47)). Letting β tend to 0 and using that $(\rho^+)_*=\liminf_*(\rho^+_\beta)_*$, we obtain the expected inequality (even something better since (46) holds actually with $c[\rho^+](x,t)$). In particular, we get that ρ^+ is a solution of

$$\begin{cases} \rho_t = c[\rho^+]|D\rho| & \text{in } \mathbb{R}^N\times[0,T),\\ \rho(x,0)=\mathbb{1}_{\{u_0\ge 0\}} & \text{in } \mathbb{R}^N. \end{cases} \tag{48}$$

The proof of the claim is complete.

2. *The functions $v^\pm$ are weak solutions of* (3). Let us start with the "+" case. We first remark that the existence and uniqueness of v^+ follows from the standard theory for equations with an L^1-dependence in time (see Appendix A).

To prove that v^+ is a weak solution of (3), it remains to prove that (7) holds. It is sufficient to show that

$$\{v^+(\cdot,t)>0\}\subset\{u(\cdot,t)\geq 0\}\subset\{v^+(\cdot,t)\geq 0\}\ . \tag{49}$$

We use again the functions ψ_α,ψ^α introduced above. We remark that

$$\psi_\alpha(u_0)\leq\rho^+(x,0)\leq\psi^\alpha(u_0)\quad\text{in }\mathbb{R}^N\ .$$

Moreover, v^+ and ρ^+ are solutions of the same equation, namely (48) with $c[\rho^+]$, which is considered as a fixed function, and so are $\psi_\alpha(v^+)$ and $\psi^\alpha(v^+)$ because the equation is geometric. Therefore, a standard comparison result implies

$$\psi_\alpha(v^+)\leq(\rho^+)_*\leq\rho^+=(\rho^+)^*\leq\psi^\alpha(v^+)\quad\text{in }\mathbb{R}^N\times[0,T)\ .$$

Letting α tend to 0, these inequalities imply (49).

We can prove the symmetric result for v^-, the only difference being that inclusion (49) has to be replaced by

$$\{v^-(\cdot,t)>0\}\subset\{u(\cdot,t)>0\}\subset\{v^-(\cdot,t)\geq 0\}\ . \tag{50}$$

3. *Claim: If v is a weak solution of* (3)*, then $\mathbb{1}_{\{v(\cdot,t)\geq 0\}}$ is an L^1-subsolution of* (45). From Proposition 3.1 and since $c_0\geq 0$, v satisfies in the L^1-sense

$$v_t\leq c[\mathbb{1}_{\{v(\cdot,t)\geq 0\}}]|Dv|\quad\text{in }\mathbb{R}^N\times[0,T)\ . \tag{51}$$

By similar arguments as we used above, the function $\mathbb{1}_{\{v(\cdot,t)\geq 0\}}$ satisfies the same inequality which gives the result.

4. *The function ρ^+ is the maximal L^1-subsolution of* (45). Let w be an L^1-(upper semicontinuous) subsolution of (45). First we have $w\leq 1$ in $\mathbb{R}^N\times[0,T)$ by comparison with the constant supersolution 1 for the equation with $c[w]$ fixed. By considering $\max(w,0)$ we may assume that $0\leq w\leq 1$ in $\mathbb{R}^N\times[0,T)$. By similar arguments as we already used in step 1, we can show that $\mathbb{1}_{\{w(\cdot,t)>0\}}$ is also an L^1-subsolution of (45); thus we can assume that w is a characteristic function.

Then we remark that w is also a subsolution of (33): indeed, again, the only nontrivial viscosity inequalities are on the boundary of the set $\{w=1\}$, and if (x,t) is such a point, we have $w(x,t)=1$ because w is upper semicontinuous and $w=\mathbb{1}_{\{w(\cdot,t)\geq w(x,t)\}}$. Since u is a solution of the geometric equation (33), $\psi^\alpha(u)$ is still a solution which satisfies $\psi^\alpha(u)(x,0)\geq\mathbb{1}_{\{u_0\geq 0\}}\geq w(x,0)$ in $\mathbb{R}^N$. By Theorem 5.2 we obtain

$$w\leq\psi^\alpha(u)\quad\text{in }\mathbb{R}^N\times[0,T)\ .$$

Letting α tend to 0 provides $w\leq\rho^+$, which proves that ρ^+ is the maximal subsolution of (45).

5. *The function v^+ is the maximal weak solution of* (3). Let v be a weak solution of (3). From steps 3 and 4, we get $\mathbb{1}_{\{v(\cdot,t)\geq 0\}}\leq\rho^+(\cdot,t)$ in $\mathbb{R}^N\times[0,T)$, and (51) implies

$$v_t\leq c[\rho^+]|Dv|\quad\text{in }\mathbb{R}^N\times[0,T)\ .$$

Therefore v is a subsolution of (12), and by a standard comparison result, this leads to $v\leq v^+$ in $\mathbb{R}^N\times[0,T)$, which proves the result.

6. *We have* $\{v^+(\cdot,t)\geq 0\}=\{u(\cdot,t)\geq 0\}$ *and* $\{v^-(\cdot,t)>0\}=\{u(\cdot,t)>0\}$. From step 5, we get $\mathbb{1}_{\{v^+(\cdot,t)\geq 0\}}\leq \rho^+(\cdot,t)=\mathbb{1}_{\{u(\cdot,t)\geq 0\}}$. The conclusion follows for v^+ using (49). The inclusion for v^- uses symmetric arguments.

7. *Uniqueness when* $\{u(\cdot,t)=0\}$ *has Lebesgue measure* 0. If $\mathcal{L}^N(\{u(\cdot,t)=0\})=0$, then $c[\rho^+]=c[\rho^-]$. Hence $v^+=v^-$ is the unique weak solution of (3), and it is obviously a classical one. ∎

Appendix A. A stability result for eikonal equations with L^1-dependence in time. The aim of this appendix is to provide a self-contained presentation of a stability result for viscosity solutions of eikonal equations with L^1-dependences in time which handles the case of weak convergence of the equations instead of the classical strong L^1-convergence. This stability result is a particular case of a general stability result proved by Barles in [4].

For $T>0$, we are interested in solutions of the following equation:

$$\begin{cases} \dfrac{\partial v}{\partial t}=\bar{c}(x,t)|Dv| & \text{in } \mathbb{R}^N\times(0,T),\\ v(\cdot,0)=u_0 & \text{in } \mathbb{R}^N, \end{cases} \tag{52}$$

where the velocity $\bar{c}:\mathbb{R}^N\times(0,T)\to\mathbb{R}$ is defined for almost every $t\in(0,T)$. We also assume that $\bar{c}$ satisfies the following.

(H3) The function $\bar{c}$ is continuous with respect to $x\in\mathbb{R}^N$ and measurable in t. For all $x,y\in\mathbb{R}^N$ and almost all $t\in[0,T]$,

$$|\bar{c}(x,t)|\leq M \quad\text{and}\quad |\bar{c}(x,t)-\bar{c}(y,t)|\leq L|x-y|.$$

Let us underline that we do not assume any continuity in time of $\bar{c}$. We recall the following (under assumption (H0)).

Definition A.1 (L^1-viscosity solutions). *An upper semicontinuous (respectively, lower semicontinuous) function v on $\mathbb{R}^N\times[0,T]$ is an L^1-viscosity subsolution (respectively, supersolution) of* (52) *if*

$$v(0,\cdot)\leq u_0 \quad (\textit{respectively,}\quad v(0,\cdot)\geq u_0)$$

and if for every $(x_0,t_0)\in\mathbb{R}^N\times[0,T]$, $b\in L^1(0,T)$, $\varphi\in C^\infty(\mathbb{R}^N\times(0,T))$, and continuous function $G:\mathbb{R}^N\times(0,T)\times\mathbb{R}^N\to\mathbb{R}$ such that

(i) *the function*

$$(x,t)\longmapsto v(x,t)-\int_0^t b(s)ds-\varphi(x,t)$$

has a local maximum (respectively, minimum) at (x_0,t_0) over $\mathbb{R}^N\times(0,T)$ and such that

(ii) *for almost every $t\in(0,T)$ in some neighborhood of t_0 and for every (x,p) in some neighborhood of (x_0,p_0) with $p_0=\nabla\varphi(x_0,t_0)$, we have*

$$\bar{c}(x,t)|p|-b(t)\leq G(x,t,p) \quad (\textit{respectively,}\quad \bar{c}(x,t)|p|-b(t)\geq G(x,t,p)),$$

then

$$\frac{\partial\varphi}{\partial t}(x_0,t_0)\leq G(x_0,t_0,p_0) \quad \left(\textit{respectively,}\quad \frac{\partial\varphi}{\partial t}(x_0,t_0)\geq G(x_0,t_0,p_0)\right).$$

Finally, we say that a locally bounded function v defined on $\mathbb{R}^N \times [0,T]$ is an L^1-viscosity solution of (52) *if its upper semicontinuous (respectively, lower semicontinuous) envelope is an L^1-viscosity subsolution (respectively, supersolution).*

Let us recall that viscosity solutions in the L^1-sense were introduced in Ishii's paper [20]. We refer the reader to Nunziante [25, 26] and Bourgoing [7, 8] for a complete presentation of the theory.

Then we have the following result.

THEOREM A.2 (existence and uniqueness). *For any $T > 0$, under assumptions* (H0) *and* (H3)*, there exists a unique L^1-viscosity solution to* (52).

Finally, let us consider the solutions v^ε to the following equation:

$$\begin{cases} \dfrac{\partial v^\varepsilon}{\partial t} = \bar{c}^\varepsilon(x,t)|Dv^\varepsilon| & \text{in } \mathbb{R}^N \times (0,T), \\ v^\varepsilon(\cdot,0) = u_0 & \text{in } \mathbb{R}^N. \end{cases} \tag{53}$$

Then we have the following.

THEOREM A.3 (L^1-stability [4]). *Under assumption* (H0)*, let us assume that the velocity $\bar{c}^\varepsilon$ satisfies* (H3) *(with some constants M, L independent of ε). Let us consider the L^1-viscosity solution v^ε to* (53)*. Assume that v^ε converges locally uniformly to a function v and, for all $x \in \mathbb{R}^N$,*

$$\int_0^t \bar{c}^\varepsilon(x,s)ds \to \int_0^t \bar{c}(x,s)ds \quad \textit{locally uniformly in } (0,T). \tag{54}$$

Then v is a L^1-viscosity solution of (52).

Remark A.1. Theorem A.3 is stated as in [4], but note that, under (H3), assumption (54) is automatically satisfied as soon as the convergence is merely pointwise. Indeed, since

$$\left|\int_0^t \bar{c}^\varepsilon(x,s)ds\right| \le MT \quad \text{and} \quad \left|\int_0^t \bar{c}^\varepsilon(x,s)ds - \int_0^{t'} \bar{c}^\varepsilon(x,s)ds\right| \le M|t-t'|,$$

from Ascoli's theorem, the convergence is uniform.

Appendix B. Interior ball regularization (proof of Lemma 2.3). The proof of this result can be adapted from those of Cannarsa and Frankowska [10] or [2] (see also [9] for related perimeter estimates for general equations). For the sake of completeness, we give a proof close to the one of [10] (this latter holds for much more general, but time-independent, dynamics). The unique (and small) contribution of this part amounts to explaining how this proof can be simplified in the particular case of dynamics of the form (55) and to point out that the time dependence is not an issue for the results of [10] to hold.

We first prove that the reachable set for controlled dynamics of the form

$$\dot{x}(t) = c(x(t),t)u(t), \quad u \in L^\infty([0,T], \overline{B}(0,1)), \tag{55}$$

enjoys the interior ball property for positive time. We assume that $c : [0,T] \times \mathbb{R}^N \to \mathbb{R}$ satisfies, for any $x, y \in \mathbb{R}^N$ and $t \in [0,T]$,

$$\begin{cases} \text{(i)} & c \text{ is Borel measurable,} \\ & \text{differentiable with respect to the space variable for a.e. time,} \\ \text{(ii)} & |c(x,t) - c(y,t)| \le L_1|x-y|, \\ \text{(iii)} & |D_x c(x,t) - D_x c(y,t)| \le N_1|x-y|, \\ \text{(iv)} & M_1 \ge c(x,t) \ge \delta > 0, \end{cases}$$

where $L_1, N_1 \geq 0$ and $M_1, \delta > 0$ are given constants. Let $K_0 \subset \mathbb{R}^N$ be the initial set. We define the reachable set $\mathcal{R}(t)$ from K_0 for (55) at time t by

$$\mathcal{R}(t) = \{x(t)\ ,\ x(\cdot) \text{ solution to (55) with } x(0) \in K_0\}.$$

It is known that $\mathcal{R}(t)$ is a closed subset of $\mathbb{R}^N$. Let y_0 be an extremal solution on the time interval $[0,T]$, i.e., a solution of (55) such that

$$y_0(0) \in K_0 \quad \text{and} \quad y_0(T) \in \partial\mathcal{R}(T).$$

From the Pontryagin maximum principle for extremal trajectories (see, for instance, [13]), there is some adjoint function $p_0 : [0,T] \to \mathbb{R}^N\backslash\{0\}$ such that (y_0, p_0) is a solution to

$$\begin{cases} \dot{y}_0(t) = c(y_0(t),t)\dfrac{p_0(t)}{|p_0(t)|}, \\ -\dot{p}_0(t) = D_x c(y_0(t),t)|p_0(t)|. \end{cases}$$

Since the system is positively homogeneous with respect to p, we can assume, without loss of generality, that $|p_0(T)| = 1$, and we set $\theta_0 := p_0(T)$.

Let P be the matrix-valued solution to

$$\begin{cases} \dot{P}(t) = \dfrac{p_0(t)}{|p_0(t)|}[D_x c(y_0(t),t)]^* P(t), \\ P(T) = Id. \end{cases}$$

A straightforward computation shows that $P^*(t)p_0(t) = \theta_0$ for any $t \in [0,T]$.

Let us fix some parameter $\gamma > 0$ to be chosen later, $\theta \in B(0,1)$ and let us set, for all $t \in [0,T]$,

$$y_\theta(t) = y_0(t) - \gamma t P(t)(\theta_0 - \theta).$$

Our aim is to show that y_θ is a solution to (55). Indeed we have

$$\begin{aligned} |\dot{y}_\theta|^2 &= \left| c(y_0,t)\frac{p_0}{|p_0|} - \gamma P(\theta_0-\theta) - \gamma t \frac{p_0}{|p_0|} D_x c^* P(\theta_0-\theta) \right|^2 \\ &= |c(y_\theta,t)|^2 - 2\gamma c(y_0,t)\left\langle \frac{p_0}{|p_0|}, P(\theta_0-\theta)\right\rangle \\ &\quad + |c(y_0,t)|^2 - |c(y_\theta,t)|^2 - 2\gamma t c(y_0,t)\left\langle \frac{p_0}{|p_0|}, \frac{p_0}{|p_0|} D_x c^* P(\theta_0-\theta)\right\rangle \\ &\quad + \gamma^2 \left| P(\theta_0-\theta) + t\frac{p_0}{|p_0|} D_x c^* P(\theta_0-\theta)\right|^2 \\ &\leq |c(y_\theta,t)|^2 - 2\gamma \frac{c(y_0,t)}{|p_0|}\langle \theta_0, \theta_0-\theta\rangle \quad (\text{because } P^* p_0 = \theta_0) \\ &\quad + c^2(y_0,t) - c^2(y_\theta,t) - \langle D_x(c^2)(y_0,t), y_0 - y_\theta\rangle + \gamma^2 M|\theta_0-\theta|^2 \\ &\leq |c(y_\theta,t)|^2 - \gamma\frac{\delta}{|p_0|}|\theta_0-\theta|^2 \ + \ M_1'|y_0-y_\theta|^2 + \gamma^2 M|\theta_0-\theta|^2 \\ &\leq |c(y_\theta,t)|^2 - \gamma\frac{\delta}{|p_0|}|\theta_0-\theta|^2 \ + \ \gamma^2 M'|\theta_0-\theta|^2, \end{aligned}$$

with $M_1' = L_1^2 + M_1 N_1$, and where M and M' depend only on T, L_1, N_1, M_1 because $|p_0(t)|$ is bounded from below by a constant depending only on T, L_1. Hence, for γ sufficiently small, y_θ is a solution of (55) starting from $y_0(0) \in K_0$ and therefore $y_\theta(T) \in \mathcal{R}(T)$.

Finally, $\mathcal{R}(T)$ contains all the $y_\theta(T)$ for $\theta \in B(0,1)$, i.e., the ball centered at $y_0(T) - \gamma T \theta_0$ and of radius γT (since $P(T) = Id$).

We apply the previous result with $c = c_1$ and $K_0 = \{v(\cdot, 0) \geq 0\}$. Then $\{v(\cdot, t) \geq 0\} = \mathcal{R}(t)$ for all $t > 0$.

We end with a remark: in the statement of Lemma 2.3, c_1 is assumed to be continuous in time. As we have seen, it is not necessary; c_1 can be merely measurable in time up to considering the L^1-solution v of (13), as recalled in Appendix A. ∎

REFINABLE FUNCTIONS AND CASCADE ALGORITHMS IN WEIGHTED SPACES WITH HÖLDER CONTINUOUS MASKS*

BIN HAN†

Abstract. Refinable functions and cascade algorithms play a fundamental role in wavelet analysis, which is useful in many applications. In this paper we shall study several properties of refinable functions, cascade algorithms, and wavelets, associated with Hölder continuous masks, in the weighted subspaces $L_{2,p,\gamma}(\mathbb{R})$ of $L_2(\mathbb{R})$, where $1 \leqslant p \leqslant \infty$, $\gamma \geqslant 0$ and $f \in L_{2,p,\gamma}(\mathbb{R})$ means $\|f\|_{L_{2,p,\gamma}(\mathbb{R})} := \|\sum_{k\in\mathbb{Z}} |\widehat{e^{\gamma|\cdot|}f}(\cdot+2\pi k)|^2\|^{1/2}_{L_p(\mathbb{T})} < \infty$. In particular, $\|f\|_{L_{2,1,\gamma}(\mathbb{R})} = \|fe^{\gamma|\cdot|}\|_{L_2(\mathbb{R})}$ and $\|f\|_{L_{2,\infty,0}(\mathbb{R})} = \|\sum_{k\in\mathbb{Z}} |\hat{f}(\cdot+2\pi k)|^2\|^{1/2}_{L_\infty(\mathbb{T})}$. For a mask $\hat{a} \in C^\beta(\mathbb{T})$ with $\beta > 0$ and $\hat{a}(0) = 1$ (that is, $\hat{a}$ is a Hölder continuous mask with Hölder exponent β), we prove that the cascade algorithm associated with the mask $\hat{a}$ converges in the space $L_{2,\infty,0}(\mathbb{R})$ if and only if $\nu_2(\hat{a}) > 0$, where the quantity $\nu_2(\hat{a})$ will be defined in this paper and plays an important role in our study of refinable functions and cascade algorithms with Hölder continuous masks. In particular, if the shifts of a refinable function ϕ, satisfying $\hat{\phi}(2\cdot) = \hat{a}\hat{\phi}$, are stable in $L_2(\mathbb{R})$, then we must have $\nu_2(\hat{a}) > 0$, and therefore the cascade algorithm associated with mask $\hat{a}$ converges in the space $L_{2,\infty,0}(\mathbb{R})$. Based on this result, we are able to settle several problems on refinable functions, cascade algorithms, and wavelets associated with masks having infinitely many nonzero Fourier coefficients. As an application of the characterization of the convergence of a cascade algorithm in the space $L_{2,\infty,0}(\mathbb{R})$, we are able to show that for a mask $\hat{a}$ having exponential decay of order $r > 0$, the cascade algorithm associated with mask $\hat{a}$ converges in the weighted space $L_{2,1,\gamma}(\mathbb{R})$ for $0 < \gamma < 2r$ if and only if $\nu_2(\hat{a}) > 0$. Consequently, if a mask $\hat{a}$ has exponential decay of order $r > 0$ and $\nu_2(\hat{a}) > 0$, then its standard refinable function ϕ, defined by $\hat{\phi}(\xi) := \prod_{j=1}^\infty \hat{a}(2^{-j}\xi)$, must have exponential decay of order $2r$ in $L_2(\mathbb{R})$; that is, $\|\phi\|^2_{L_{2,1,\gamma}(\mathbb{R})} = \int_{\mathbb{R}} |\phi(x)|^2 e^{2\gamma|x|}\,dx < \infty$ for all $0 < \gamma < 2r$. As another application of the characterization of the convergence of a cascade algorithm in the space $L_{2,\infty,0}(\mathbb{R})$, we completely characterize biorthogonal wavelets and Riesz wavelets in $L_2(\mathbb{R})$, which are derived from refinable functions and whose involved wavelet filters in the frequency domain are Hölder continuous. We shall also investigate some basic properties of the quantity $\nu_2(\hat{a})$ and discuss how to calculate and estimate $\nu_2(\hat{a})$. Examples using fractional splines and the Butterworth filters will be given to illustrate the results in this paper.

Key words. refinable functions, cascade algorithms, Hölder continuous masks, masks having infinitely many nonzero Fourier coefficients, transition operator, weighted L_2 spaces, biorthogonal wavelets, Riesz wavelets, exponential decay

1. Introduction and motivation.

A wavelet system is generally derived from a refinable function via a multiresolution analysis (MRA). We say that ϕ is *a refinable function* if it satisfies the refinement equation:

$$\hat{\phi}(2\xi) = \hat{a}(\xi)\hat{\phi}(\xi) \qquad \text{a.e. } \xi \in \mathbb{R}, \tag{1.1}$$

where $\hat{a}$ is a 2π-periodic function, called the *mask* (or filter) for ϕ, and the Fourier transform is defined to be $\hat{f}(\xi) := \int_{\mathbb{R}} f(x)e^{-ix\xi}\,dx$ for $f \in L_1(\mathbb{R})$.

For a 2π-periodic function $\hat{a}$, we say that $\hat{a}$ has *exponential decay of order* r if $\hat{a}$ is the restriction of a 2π-periodic function $\hat{a}(z)$ on the real line $\mathrm{Im}(z) = 0$ such that $\hat{a}(z)$ is holomorphic in the strip $\{z \in \mathbb{C} : |\mathrm{Im}(z)| < r\}$, where $\mathrm{Im}(z)$ denotes the imaginary part of the complex number z. Write $\hat{a}(\xi) = \sum_{k\in\mathbb{Z}} a_k e^{-ik\xi}$ in terms of its Fourier series. It is easy to check that $\hat{a}$ has exponential decay of order r if and only if for every $0 \leqslant \gamma < r$, there is a positive constant C_γ such that $|a_k| \leqslant C_\gamma e^{-\gamma|k|}$ for all $k \in \mathbb{Z}$. A particular family of masks with exponential decay consists of rational masks that can be written in the form of $\hat{b}(\xi)/\hat{c}(\xi)$ for some 2π-periodic trigonometric polynomials $\hat{b}$ and $\hat{c}$ such that $\hat{c}(\xi) \neq 0$ for all $\xi \in \mathbb{R}$. For example, the well-known Butterworth filters are rational masks [5, 11, 18, 25].

Masks with infinitely many nonzero Fourier coefficients, or equivalently, filters with infinite support, are called infinite impulse response (IIR) filters in electrical engineering. Due to some desirable properties, IIR filters, including masks with exponential decay and masks for bandlimited wavelets [7] and fractional splines [27], are of interest in some applications and have been extensively designed for various purposes in the area of digital signal processing in electrical engineering [3, 5, 18, 25, 27]. In contrast to the case of trigonometric polynomial masks whose various mathematical properties have been extensively studied and more or less well understood in the literature (see [1, 4, 6, 7, 8, 10, 15, 19, 26, 28] and the references therein), there are still several unsolved questions related to refinable functions and wavelets with masks having infinitely many nonzero Fourier coefficients. For example, Daubechies and Huang in [9] showed that if the standard refinable function ϕ, defined by

$$\hat{\phi}(\xi) := \prod_{j=1}^{\infty} \hat{a}(2^{-j}\xi), \qquad \xi \in \mathbb{R}, \tag{1.2}$$

lies in $L_1(\mathbb{R})$ with a mask $\hat{a}$ having an absolutely summable sequence of Fourier coefficients, and if ϕ has exponential decay, then the mask $\hat{a}$ must have exponential decay. But to the best of our knowledge, there are very few results on the converse direction, and it is widely believed that for a mask $\hat{a}$ with exponential decay, its standard refinable function ϕ in (1.2) should also have exponential decay in certain spaces in some sense. This is one of our motivations to study refinable functions and cascade algorithms, associated with masks having infinitely many nonzero Fourier coefficients, in some weighted subspaces of $L_2(\mathbb{R})$.

Before proceeding further, let us introduce some definitions and notation. Let $\mathbb{T} := \mathbb{R}/[2\pi\mathbb{Z}]$ and $L_p(\mathbb{T})$ denote the linear space of all 2π-periodic measurable functions $f : \mathbb{R} \mapsto \mathbb{C}$ such that $2\pi\|f\|^p_{L_p(\mathbb{T})} := \int_{-\pi}^{\pi} |f(x)|^p\, dx < \infty$ for $1 \leqslant p < \infty$ and $\|f\|_{L_\infty(\mathbb{T})}$ denotes its essential upper bound. For $\gamma \geqslant 0$ and $1 \leqslant p \leqslant \infty$, throughout the paper, the space $L_{2,p,\gamma}(\mathbb{R})$ denotes the subspace of all $f \in L_2(\mathbb{R})$ such that

$$\|f\|_{L_{2,p,\gamma}(\mathbb{R})} := \left\| \left[\widehat{e^{\gamma|\cdot|}f}, \widehat{e^{\gamma|\cdot|}f}\right] \right\|^{1/2}_{L_p(\mathbb{T})} < \infty, \tag{1.3}$$

where the *bracket product* [20] is defined to be

$$[f, g](\xi) := \sum_{k\in\mathbb{Z}} f(\xi + 2\pi k)\overline{g(\xi + 2\pi k)}, \qquad \xi \in \mathbb{R},\ f, g \in L_2(\mathbb{R}). \tag{1.4}$$

It is easy to verify that $[f, g] \in L_2(\mathbb{T})$ for $f, g \in L_2(\mathbb{R})$ and $L_{2,p,\gamma}(\mathbb{R})$ is a Banach space. In particular, by Plancherel's theorem, we have

$$\|f\|^2_{L_{2,1,\gamma}(\mathbb{R})} = \|e^{\gamma|\cdot|}f\|^2_{L_2(\mathbb{R})} = \int_{\mathbb{R}} |f(x)|^2 e^{2\gamma|x|}\, dx.$$

Therefore, $L_{2,1,\gamma}(\mathbb{R})$ is a weighted subspace of $L_2(\mathbb{R})$, and it is a natural candidate of subspaces to measure the exponential decay of a function in $L_2(\mathbb{R})$. Note that $L_{2,1,0}(\mathbb{R}) = L_2(\mathbb{R})$.

We say that the shifts of a function f are *stable* in $L_2(\mathbb{R})$ if there exists a positive constant C such that $C^{-1} \leqslant [\hat{f}, \hat{f}](\xi) \leqslant C$ for almost every $\xi \in \mathbb{R}$. It is well known that stability plays an important role in wavelet analysis [3, 4, 7]. If the shifts of a function f are stable in $L_2(\mathbb{R})$, then it is obvious that $f \in L_{2,\infty,0}(\mathbb{R})$, since $\|f\|_{L_{2,\infty,0}(\mathbb{R})} := \|[\hat{f}, \hat{f}]\|^{1/2}_{L_\infty(\mathbb{T})} < \infty$. On the other hand, we shall see in Proposition 6.1 that $L_{2,1,\gamma}(\mathbb{R}) \subseteq L_{2,\infty,0}(\mathbb{R})$ for any $\gamma > 0$. In particular, all compactly supported functions in $L_2(\mathbb{R})$ are included in $L_{2,\infty,0}(\mathbb{R})$. Therefore, the space $L_{2,\infty,0}(\mathbb{R})$ is a large enough subspace of $L_2(\mathbb{R})$ and includes most interesting functions in wavelet analysis. In this paper, we are particularly interested in the subspaces $L_{2,\infty,0}(\mathbb{R})$ and $L_{2,1,\gamma}(\mathbb{R})$ for $\gamma > 0$.

In the following, let us introduce a basic quantity $\nu_2(\hat{a})$, which plays a critical role in our study of refinable functions, cascade algorithms, and wavelets with masks having infinitely many nonzero Fourier coefficients. For 2π-periodic functions $\hat{a}$ and f, the *transition operator* $T_{\hat{a}}$ is defined to be

$$[T_{\hat{a}} f](\xi) := |\hat{a}(\xi/2)|^2 f(\xi/2) + |\hat{a}(\xi/2+\pi)|^2 f(\xi/2+\pi), \qquad \xi \in \mathbb{R}. \tag{1.5}$$

For $\tau \in \mathbb{R}$ and $1 \leqslant p \leqslant \infty$, we define a quantity

$$\rho_\tau(\hat{a}, p) := \limsup_{n\to\infty} \|T^n_{\hat{a}} \left(|\sin(\cdot/2)|^\tau\right)\|^{1/n}_{L_p(\mathbb{T})}. \tag{1.6}$$

Now we define the quantity $\nu_2(\hat{a})$ in this paper as follows:

$$\nu_2(\hat{a}) := -[\log_2 \rho(\hat{a})]/2, \tag{1.7}$$

where

$$\rho(\hat{a}) := \inf\{\rho_\tau(\hat{a}, \infty) \ : \ |\hat{a}(\cdot+\pi)|^2/|\sin(\cdot/2)|^\tau \in L_\infty(\mathbb{T}) \ \text{ and } \ \tau \geqslant 0\}. \tag{1.8}$$

When $\hat{a}$ is a 2π-periodic trigonometric polynomial, the quantity $\nu_2(\hat{a})$ in (1.7) agrees with the one in [13] and can be calculated by finding the spectral radius of an associated finite matrix generated by $\hat{a}$. See section 4 for details on calculating and estimating the quantity $\nu_2(\hat{a})$. The quantity $\nu_2(\hat{a})$ in (1.7), whose definition appears to be a little bit technical in its nature, plays a very important role in investigating many problems in wavelet analysis. See [13] for applications and the importance of $\nu_2(\hat{a})$ in wavelet analysis with 2π-periodic trigonometric polynomial masks $\hat{a}$.

We say that f belongs to the *Hölder class* $C^\beta(\mathbb{T})$ with $\beta > 0$ if f is a 2π-periodic continuous function such that $f \in C^n(\mathbb{T})$ and there exists a positive constant C satisfying $|f^{(n)}(x) - f^{(n)}(y)| \leqslant C|x-y|^{\beta-n}$ for all $x, y \in \mathbb{T}$, where n is the largest integer such that $n \leqslant \beta$ and $f^{(n)}$ denotes the nth derivative of f. Throughout the paper, we say that $\hat{a}$ is *a Hölder continuous mask* if $\hat{a} \in C^\beta(\mathbb{T})$ for some $\beta > 0$ and $\hat{a}(0) = 1$. That $\hat{a}$ is a Hölder continuous mask is a very natural and weak condition to guarantee that as the Fourier transform of the standard refinable function ϕ with mask $\hat{a}$, the function $\hat{\phi}$, which is defined through the infinite product in (1.2), is well defined.

In section 2, we shall present a necessary and sufficient condition in Theorem 2.1 for the convergence of a cascade algorithm in the space $L_{2,\infty,0}(\mathbb{R})$. Theorem 2.1 plays a central role in our study of refinable functions with exponential decay in $L_2(\mathbb{R})$ and

of MRA Riesz wavelet bases in $L_2(\mathbb{R})$. More precisely, we prove in Theorem 2.1 that for a mask $\hat{a} \in C^\beta(\mathbb{T})$ with $\hat{a}(0) = 1$ and $\beta > 0$ (that is, $\hat{a}$ is a Hölder continuous mask), the cascade algorithm associated with mask $\hat{a}$ converges in the space $L_{2,\infty,0}(\mathbb{R})$ if and only if $\nu_2(\hat{a}) > 0$. As a direct consequence of Theorem 2.1, we show in Corollary 2.2 that if the refinement equation $\hat{\phi}(2\cdot) = \hat{a}\hat{\phi}$ has a solution ϕ such that the shifts of ϕ are stable in $L_2(\mathbb{R})$, then we must have $\nu_2(\hat{a}) > 0$, and therefore the cascade algorithm associated with mask $\hat{a}$ converges in the space $L_{2,\infty,0}(\mathbb{R})$.

Cascade algorithms in $l_2(\mathbb{R})$ and other spaces with 2π-periodic trigonometric polynomial masks have been extensively studied in the literature. To cite only a few references here, we refer the reader to [1, 4, 6, 7, 8, 10, 15, 19, 22, 26, 28] and the references therein, where the property of the masks being 2π-periodic trigonometric polynomials plays a critical role. The study of cascade algorithms and refinable functions with Hölder continuous masks in this paper is not a trivial generalization of the known results in the literature, as we shall see in sections 4–6.

As an application of Theorem 2.1, we are able to prove in Theorem 2.3 that for a mask $\hat{a}$ having exponential decay of order $r > 0$, the cascade algorithm associated with the mask $\hat{a}$ converges in the space $L_{2,1,\gamma}(\mathbb{R})$ for $0 < \gamma < 2r$ if and only if $\nu_2(\hat{a}) > 0$. Consequently, the standard refinable function ϕ associated with mask $\hat{a}$ in (1.2) must have exponential decay of order $2r$, namely,

$$\|\phi\|^2_{L_{2,1,\gamma}(\mathbb{R})} = \int_{\mathbb{R}} |\phi(x)|^2 e^{2\gamma|x|}\, dx < \infty \qquad \forall\, 0 \leqslant \gamma < 2r. \tag{1.9}$$

An MRA wavelet function ψ is obtained from a refinable function ϕ with mask $\hat{a}$ via

$$\hat{\psi}(2\xi) := \hat{b}(\xi)\hat{\phi}(\xi), \qquad \xi \in \mathbb{R}, \tag{1.10}$$

for some 2π-periodic measurable function $\hat{b}$. We say that ψ generates *a Riesz wavelet basis* in $L_2(\mathbb{R})$ if $\operatorname{span}\{\psi_{j,k} := 2^{j/2}\psi(2^j \cdot -k) \,:\, j,k \in \mathbb{Z}\}$ is dense in $L_2(\mathbb{R})$ and there exists a positive constant C such that

$$C^{-1} \sum_{j\in\mathbb{Z}} \sum_{k\in\mathbb{Z}} |c_{j,k}|^2 \leqslant \left\| \sum_{j\in\mathbb{Z}} \sum_{k\in\mathbb{Z}} c_{j,k}\psi_{j,k} \right\|^2_{L_2(\mathbb{R})} \leqslant C \sum_{j\in\mathbb{Z}} \sum_{k\in\mathbb{Z}} |c_{j,k}|^2 \tag{1.11}$$

for all finitely supported sequences $\{c_{j,k}\}_{j,k\in\mathbb{Z}}$. MRA Riesz wavelet bases in $L_2(\mathbb{R})$ are of interest in some applications [2, 5, 17, 21, 24]. A natural and important question here is when ψ generates a Riesz wavelet basis in $L_2(\mathbb{R})$. MRA Riesz wavelet bases with compact support have been investigated in [5, 14, 16, 17, 21, 24], where some necessary and sufficient conditions have been obtained for trigonometric polynomial masks. Most approaches in these papers rely largely on an interesting result of Cohen and Daubechies in [5] saying that for a mask $\hat{a}$ with exponential decay, the transition operator $T_{\hat{a}}$ acting on some weighted subspaces of $\ell_2(\mathbb{Z})$ is a compact operator. Built on this interesting result of [5], a characterization of Riesz wavelets with trigonometric polynomial masks is obtained in [16] (also cf. [5]) in terms of the spectrum of $T_{\hat{a}}$. However, the approach in [5, 16, 24] seems difficult, if not impossible, to be generalized to masks without exponential decay, since the compactness of the operator $T_{\hat{a}}$ may be lost.

In order to study biorthogonal wavelets and Riesz wavelets with Hölder continuous masks, using a quite different approach in this paper, as another application

of Theorem 2.1, we shall prove in Theorem 3.2 that for $\hat{a}, \hat{b} \in C^\beta(\mathbb{T})$ with $\beta > 0$, assuming that the shifts of the standard refinable function ϕ with mask $\hat{a}$ are stable in $L_2(\mathbb{R})$, then ψ in (1.10) generates a Riesz wavelet basis in $L_2(\mathbb{R})$ if and only if (i) $\hat{b}(0) = 0$ and $d(\xi) := \hat{a}(\xi)\overline{\hat{b}(\xi+\pi)} - \hat{a}(\xi+\pi)\hat{b}(\xi) \neq 0$ for all $\xi \in \mathbb{R}$; (ii) $\nu_2(\hat{a}) > 0$ and $\nu_2(\hat{\tilde{a}}) > 0$, where $\hat{\tilde{a}}(\xi) := \overline{\hat{b}(\xi+\pi)}/\overline{d(\xi)}$. Moreover, in the case that $\hat{a}$ is a 2π-periodic trigonometric polynomial, we prove that the shifts of $\phi \in L_2(\mathbb{R})$ must be stable in $L_2(\mathbb{R})$ if ψ generates a Riesz wavelet basis in $L_2(\mathbb{R})$. Even for the case that both $\hat{a}$ and $\hat{b}$ are 2π-periodic trigonometric polynomials, the mask $\hat{\tilde{a}}$ is generally not a 2π-periodic trigonometric polynomial, and consequently refinable functions with masks being nontrigonometric polynomials will naturally appear in our study of MRA Riesz wavelet bases in $L_2(\mathbb{R})$. This is another motivation for us to study refinable functions, cascade algorithms, and wavelets with masks having infinitely many nonzero Fourier coefficients.

To illustrate the results in this paper, we shall apply the results in sections 2 and 3 to a family of Hölder continuous masks $\widehat{a_{\beta_1,\beta_2,\beta_3}}$ and $|\widehat{a_{\beta_1,\beta_2,\beta_3}}|$, where

$$\widehat{a_{\beta_1,\beta_2,\beta_3}}(\xi) := \frac{2^{-2\beta_1}(1+e^{-i\xi})^{2\beta_1}}{\big(|\cos(\xi/2)|^{2\beta_2} + |\sin(\xi/2)|^{2\beta_2}\big)^{\beta_3}}, \qquad \beta_1, \beta_2, \beta_3 > 0. \tag{1.12}$$

In fact, the masks for the B-splines correspond to the case $\widehat{a_{\beta_1,\beta_2,\beta_3}}$ with $\beta_2 = 1$ and $2\beta_1 \in \mathbb{N}$. The masks for various types of fractional splines in [27] correspond to the case $\widehat{a_{\beta_1,\beta_2,\beta_3}}$ or $|\widehat{a_{\beta_1,\beta_2,\beta_3}}|$ with $\beta_2 = 1$. The classical Butterworth filters in [5, 11, 18, 25] correspond to the case $|\widehat{a_{\beta_1,\beta_2,\beta_3}}|$ with $\beta_3 = 1$ and $\beta_1 = \beta_2 \in \mathbb{N}$. To illustrate the main results in sections 2 and 3, we shall study the convergence of cascade algorithms and MRA Riesz wavelet bases associated with the masks given in (1.12).

Since the quantity $\nu_2(\hat{a})$ plays a very important role in our study of refinable functions, cascade algorithms, and wavelets with Hölder continuous masks, we shall investigate in section 4 some basic properties of the quantity $\nu_2(\hat{a})$ and discuss how to calculate and estimate the quantity $\nu_2(\hat{a})$ for a mask $\hat{a}$ being a general Lebesgue measurable 2π-periodic function. In section 4, we shall generalize a well-known result on $\nu_2(\hat{a})$, whose proof in the general case of Hölder continuous masks is nontrivial and will be presented in the last section of this paper. The general discussion on the quantity $\nu_2(\hat{a})$ in section 4 is of interest in its own right, and the results in section 4 may be useful elsewhere.

For simplicity of presentation and readability of this paper, the proofs of Theorems 2.1 and 2.3 in section 2, which are a little bit technical in their nature, will be postponed to sections 5 and 6, respectively. The results in this paper can be nontrivially generalized to high dimensions and multiwavelets, which we shall discuss elsewhere.

2. Convergence of cascade algorithms in subspaces of $L_2(\mathbb{R})$. In this section, we shall present the main results on the convergence of cascade algorithms in the subspaces $L_{2,\infty,0}(\mathbb{R})$ and $L_{2,1,\gamma}(\mathbb{R})$. For simplicity of presentation, the proofs of the main results in this section will be postponed to sections 5 and 6. To illustrate the results in this section, we shall apply these results to the masks in (1.12), which include the Butterworth filters in [25] and the masks for fractional splines in [27] as special cases.

For a quotient function f/g, throughout the paper, we use the convention that $(f/g)(\xi)$ is equal to $f(\xi)/g(\xi)$ if $g(\xi) \neq 0$, 1 if $f(\xi) = g(\xi) = 0$, or $+\infty$ if $g(\xi) = 0$ but

$f(\xi) \neq 0$. We say that a function $f \in L_2(\mathbb{R})$ is *admissible with respect to* $\hat{a}$ if there exists a positive number $\tau > 0$ such that

$$[\hat{a}(\cdot/2)\hat{f}(\cdot/2) - \hat{f}, \hat{a}(\cdot/2)\hat{f}(\cdot/2) - \hat{f}]/|\sin(\cdot/2)|^\tau \in L_\infty(\mathbb{T}). \tag{2.1}$$

Note that all compactly supported functions in $L_2(\mathbb{R})$ belong to $L_{2,1,\gamma}(\mathbb{R})$ for all $\gamma > 0$. For every $f \in L_{2,1,\gamma}(\mathbb{R})$ with $\gamma > 0$ such that $\hat{f}(2\pi k) = 0$ for all $k \in \mathbb{Z}\backslash\{0\}$, we shall show in Proposition 6.2 that f is admissible with respect to $\hat{a}$ for any $\hat{a} \in C^\beta(\mathbb{T})$ with $\hat{a}(0) = 1$, $\hat{a}(\pi) = 0$, and $\beta > 0$.

For $0 < \beta \leqslant 1$, we say that f belongs to the Lipschitz class $\Lambda^\beta(\mathbb{T})$ if there is a positive constant C such that $|f(x) - f(y)| \leqslant C|x - y|^\beta$ for all $x, y \in \mathbb{T}$.

Now we have the following result on the convergence of cascade algorithms in the space $L_{2,\infty,0}(\mathbb{R})$, which plays a central role in this paper and whose proof will be given in section 5.

THEOREM 2.1. *Let $\hat{a} \in C^\beta(\mathbb{T})$ with $\hat{a}(0) = 1$ and $\beta > 0$ (that is, $\hat{a}$ is a Hölder continuous mask). Then the following are equivalent:*

(i) *$\hat{a}(\pi) = 0$, and for every admissible function $f \in L_{2,\infty,0}(\mathbb{R})$ with respect to $\hat{a}$, $\{f_n\}_{n=1}^\infty$ is a Cauchy sequence in $L_{2,\infty,0}(\mathbb{R})$, where the functions f_n are defined by*

$$\widehat{f_n}(\xi) := \hat{a}(\xi/2)\widehat{f_{n-1}}(\xi/2) = \hat{f}(2^{-n}\xi)\prod_{j=1}^{n}\hat{a}(2^{-j}\xi), \qquad \xi \in \mathbb{R}, n \in \mathbb{N}. \tag{2.2}$$

(ii) *For one admissible function $f \in L_{2,\infty,0}(\mathbb{R})$ with respect to $\hat{a}$ such that the shifts of f are stable, $\{f_n\}_{n=1}^\infty$ is a Cauchy sequence in $L_{2,\infty,0}(\mathbb{R})$.*

(iii) *For every $\tau > 0$, $\rho_\tau(\hat{a}, \infty) < 1$, where $\rho_\tau(\hat{a}, \infty)$ is defined in* (1.6).

(iv) *$\nu_2(\hat{a}) > 0$; that is, $\rho(\hat{a}) < 1$, where $\nu_2(\hat{a})$ and $\rho(\hat{a})$ are defined in* (1.7) *and* (1.8)*, respectively.*

(v) *For at least one $\tau > 0$, $\rho_\tau(\hat{a}, \infty) < 1$ and $|\hat{a}(\cdot + \pi)|^2/|\sin(\cdot/2)|^\tau \in L_\infty(\mathbb{T})$.*

Let ϕ denote the standard refinable function associated with the mask $\hat{a}$ in (1.2)*. If $\nu_2(\hat{a}) > 0$, then $\hat{\phi}$ belongs to the Lipschitz class $\Lambda^{\min(1,\beta)}(\mathbb{R})$, $[\hat{\phi}, \hat{\phi}] \in \Lambda^{\min(1,\beta)}(\mathbb{T})$, and for any $0 \leqslant \nu < \nu_2(\hat{a})$,*

$$[\hat{\phi}, \hat{\phi}]_\nu := \sum_{k\in\mathbb{Z}}(1 + |\cdot + 2\pi k|^2)^\nu |\hat{\phi}(\cdot + 2\pi k)|^2 \in C(\mathbb{T}). \tag{2.3}$$

In fact, by a more complicated argument, we could show in Theorem 2.1 that $\hat{\phi} \in C^\beta(\mathbb{R})$ and $[\hat{\phi}, \hat{\phi}] \in C^\beta(\mathbb{T})$, which we shall address elsewhere. According to the proof of Theorem 2.1 in section 5, (ii) implies $\nu_2(\hat{a}) > 0$ without the admissibility condition on f; that is, if $\{f_n\}_{n=1}^\infty$ is a Cauchy sequence in $L_{2,\infty,0}(\mathbb{R})$ for a function $f \in L_{2,\infty,0}(\mathbb{R})$ with stability, then $\nu_2(\hat{a}) > 0$. We say that the cascade algorithm associated with a mask $\hat{a}$ converges in a given function space if for every admissible function f in that space with respect to $\hat{a}$, the sequence $\{f_n\}_{n=1}^\infty$ defined in (2.2) is a Cauchy sequence in that space.

As a direct consequence of Theorem 2.1, we have the following corollary.

COROLLARY 2.2. *Let $\hat{a} \in C^\beta(\mathbb{T})$ with $\hat{a}(0) = 1$ and $\beta > 0$. Suppose that ϕ is a (not necessarily the standard) refinable function such that $\hat{\phi}(2\xi) = \hat{a}(\xi)\hat{\phi}(\xi)$ a.e. $\xi \in \mathbb{R}$ and the shifts of ϕ are stable in $L_2(\mathbb{R})$. Then $\nu_2(\hat{a}) > 0$ and the cascade algorithm associated with mask $\hat{a}$ must converge in the space $L_{2,\infty,0}(\mathbb{R})$.*

Proof. Since the shifts of ϕ are stable in $L_2(\mathbb{R})$, we have $[\hat{\phi}, \hat{\phi}] \in L_\infty(\mathbb{T})$, and so $\phi \in L_{2,\infty,0}(\mathbb{R})$. Since $\hat{a}(\cdot/2)\hat{\phi}(\cdot/2) - \hat{\phi} = 0$, ϕ is an admissible function in $L_{2,\infty,0}(\mathbb{R})$

with respect to $\hat{a}$. So, for $f = \phi$, (ii) of Theorem 2.1 holds since $f_n = \phi$ for all $n \in \mathbb{N}$. Now by Theorem 2.1, $\nu_2(\hat{a}) > 0$. □

For a mask with exponential decay, using Theorem 2.1, we characterize the convergence of a cascade algorithm with an exponentially decaying mask in the spaces $L_{2,p,\gamma}(\mathbb{R})$ in the following result, whose proof will be given in section 6.

THEOREM 2.3. *Let $\hat{a}$ be a mask such that $\hat{a}(0) = 1$ and $\hat{a}$ has exponential decay of order r for some $r > 0$. Then the following are equivalent:*

(i) *$\hat{a}(\pi) = 0$, and for every $0 < \gamma < 2r$ and every admissible function $f \in L_{2,1,\gamma}(\mathbb{R})$ with respect to $\hat{a}$, $\{f_n\}_{n=1}^{\infty}$ is a Cauchy sequence in $L_{2,1,\gamma}(\mathbb{R})$, where f_n are defined in (2.2).*

(ii) *$\hat{a}(\pi) = 0$, and for every $0 < \gamma < 2r$, every $1 \leqslant p \leqslant \infty$, and every admissible function $f \in L_{2,p,\gamma}(\mathbb{R})$ with respect to $\hat{a}$, $\{f_n\}_{n=1}^{\infty}$ is a Cauchy sequence in $L_{2,p,\gamma}(\mathbb{R})$.*

(iii) *$\hat{a}(\pi) = 0$, and for some $0 < \gamma < 2r$, some $1 \leqslant p \leqslant \infty$, and every admissible function $f \in L_{2,p,\gamma}(\mathbb{R})$ with respect to $\hat{a}$, $\{f_n\}_{n=1}^{\infty}$ is a Cauchy sequence in $L_{2,p,\gamma}(\mathbb{R})$.*

(iv) *For some $0 < \gamma < 2r$, some $1 \leqslant p \leqslant \infty$, and one admissible function $f \in L_{2,p,\gamma}(\mathbb{R})$ with respect to $\hat{a}$ such that the shifts of f are stable in $L_2(\mathbb{R})$, the sequence $\{f_n\}_{n=1}^{\infty}$ is a Cauchy sequence in $L_{2,p,\gamma}(\mathbb{R})$.*

(v) *$\nu_2(\hat{a}) > 0$.*

In particular, if $\nu_2(\hat{a}) > 0$ and $\hat{a}$ has exponential decay of order r, then the standard refinable function ϕ with mask $\hat{a}$ in (1.2) must have exponential decay of order $2r$; that is, (1.9) holds.

In the following, we shall apply the above results to the masks in (1.12), which include both the classical Butterworth filters in [25] and the masks for the fractional splines in [27] as special cases.

Example 2.4. Let $\hat{a} = \widehat{a_{\beta_1,\beta_2,\beta_3}}$ or $\hat{a} = |\widehat{a_{\beta_1,\beta_2,\beta_3}}|$, where the masks $a_{\beta_1,\beta_2,\beta_3}$ are defined in (1.12). By Proposition 4.2, it is easy to check that $\hat{a} \in C^{\beta}(\mathbb{T})$ for some $\beta > 0$. Denote

$$\hat{B}(\xi) = (|\cos(\xi/2)|^{2\beta_2} + |\sin(\xi/2)|^{2\beta_2})^{\beta_3}.$$

Then $|\hat{a}(\xi)| = 2^{-2\beta_1}|1 + e^{-i\xi}|^{2\beta_1}/\hat{B}(\xi)$. By calculation, it is easy to deduce that

$$\min(1, 2^{1-\beta_2}) \leqslant |\cos(\xi/2)|^{2\beta_2} + |\sin(\xi/2)|^{2\beta_2} \leqslant \max(1, 2^{1-\beta_2}) \qquad \forall\, \xi \in \mathbb{R}. \tag{2.4}$$

Consequently, we have $\hat{B}(\xi) \geqslant \min(1, 2^{(1-\beta_2)\beta_3})$ for all $\xi \in \mathbb{R}$ and $\beta_2, \beta_3 > 0$.

For $0 < \beta_2 \leqslant 1$, by Theorem 4.1 and Lemma 4.3, it follows from $\hat{B}(\xi) \geqslant \min(1, 2^{(1-\beta_2)\beta_3}) = 1$ that

$$\rho(\hat{a}) = \rho_{4\beta_1}(\hat{a}, \infty) = \rho_0(2^{-2\beta_1}/\hat{B}, \infty) \leqslant \rho_0(2^{-2\beta_1}, \infty) = 2^{1-4\beta_1},$$

since for a constant c, $T_c^n 1 = 2^n |c|^{2n}$, and therefore

$$\rho_0(c, \infty) = \limsup_{n\to\infty} \|T_c^n 1\|_{L_\infty(\mathbb{T})}^{1/n} = 2|c|^2.$$

For $\beta_2 > 1$, by Theorem 4.1 and Lemma 4.3, it follows from $\hat{B}(\xi) \geqslant 2^{(1-\beta_2)\beta_3}$ that

$$\rho(\hat{a}) = \rho_{4\beta_1}(\hat{a}, \infty) = \rho_0(2^{-2\beta_1}/\hat{B}, \infty) \leqslant \rho_0(2^{-2\beta_1-(1-\beta_2)\beta_3}, \infty) = 2^{1-4\beta_1-2(1-\beta_2)\beta_3}.$$

Therefore, for

$$\beta_1, \beta_2, \beta_3 > 0 \quad \text{satisfying} \quad \beta_1 > 1/4 + \max(0, (\beta_2 - 1)\beta_3/2), \tag{2.5}$$

we have $\rho(\hat{a}) < 1$; that is, $\nu_2(\hat{a}) > 0$. By Theorem 2.1, the cascade algorithm associated with mask $\hat{a}$ converges in the space $L_{2,\infty,0}(\mathbb{R})$.

The classical Butterworth filters in [25] correspond to the case $\beta_3 = 1$ and $\beta_1 = \beta_2 \in \mathbb{N}$. The condition in (2.5) holds for all $\beta_3 = 1$ and $\beta_1 = \beta_2 \in \mathbb{N}$, that is, holds for all Butterworth filters.

For the fractional splines in [27], since $\beta_2 = 1$, the condition in (2.5) becomes $\beta_1 > 1/4$. Note that when $\beta_2 = 1$, the standard refinable function ϕ associated with mask $\hat{a}$ in (1.2) satisfies $|\hat{\phi}(2\xi)| = |(\sin\xi)/\xi|^{2\beta_1}$. Clearly, if $0 < \beta_1 \leqslant 1/4$, then $\hat{\phi} \notin L_2(\mathbb{R})$. So, the condition in (2.5), that is, $\beta_1 > 1/4$, is sharp for the case of fractional splines in [27].

Now we consider the case that $\hat{a}$ has exponential decay; that is, $\hat{a}(\xi) = \widehat{a_{\beta_1,\beta_2,\beta_3}}(\xi)$ with $2\beta_1 \in \mathbb{N}$ and $\beta_2 \in \mathbb{N}$. In this case, by the definition of the masks $\widehat{a_{\beta_1,\beta_2,\beta_3}}$ in (1.12), it is easy to see that $\hat{a}$ can be extended into a holomorphic function on some strip $\{z \in \mathbb{C} \ : \ |\mathrm{Im}(z)| < r\}$ for some $r > 0$ depending only on β_2. So, $\hat{a}$ has exponential decay of order r. Now by Theorem 2.3, if (2.5) holds with $2\beta_1 \in \mathbb{N}$ and $\beta_2 \in \mathbb{N}$, then the cascade algorithm associated with mask $\hat{a}$ converges in the spaces $L_{2,p,\gamma}(\mathbb{R})$ for all $0 \leqslant \gamma < 2r$ and the standard refinable function ϕ associated with mask $\hat{a}$ must have exponential decay of order $2r$ in $L_2(\mathbb{R})$.

3. Characterization of MRA biorthogonal wavelets and Riesz wavelets. In this section, using Theorem 2.1, we shall study MRA biorthogonal wavelets and Riesz wavelets with Hölder continuous masks.

Let us first recall the definition of biorthogonal wavelets in [6]. For two functions $\psi, \tilde{\psi} \in L_2(\mathbb{R})$, we say that $(\psi, \tilde{\psi})$ generates *a pair of biorthogonal wavelet bases* in $L_2(\mathbb{R})$ if each of ψ and $\tilde{\psi}$ generates a Riesz wavelet basis in $L_2(\mathbb{R})$ and the following biorthogonality relation holds:

$$\langle \psi_{j,k}, \tilde{\psi}_{j',k'} \rangle := \int_{\mathbb{R}} \psi_{j,k}(x)\overline{\tilde{\psi}_{j',k'}(x)}\,dx = \delta_{j-j'}\delta_{k-k'} \qquad \forall\, j, j', k, k' \in \mathbb{Z}, \tag{3.1}$$

where $\psi_{j,k} := 2^{j/2}\psi(2^j \cdot -k)$ and δ denotes the *Dirac sequence* such that $\delta_0 = 1$ and $\delta_k = 0$ for all $k \neq 0$. Compactly supported biorthogonal wavelets have been investigated in [4, 6, 7, 12] and other papers.

As an application of Theorem 2.1, we have the following result on biorthogonal wavelets with Hölder continuous masks.

THEOREM 3.1. *Let $\hat{a}, \hat{\tilde{a}} \in C^\beta(\mathbb{T})$ with $\hat{a}(0) = \hat{\tilde{a}}(0) = 1$ and $\beta > 0$. Define two refinable functions $\hat{\phi}$ and $\hat{\tilde{\phi}}$ associated with masks $\hat{a}$ and $\hat{\tilde{a}}$ by*

$$\hat{\phi}(\xi) := \prod_{j=1}^{\infty} \hat{a}(2^{-j}\xi) \quad \text{and} \quad \hat{\tilde{\phi}}(\xi) := \prod_{j=1}^{\infty} \hat{\tilde{a}}(2^{-j}\xi), \qquad \xi \in \mathbb{R}. \tag{3.2}$$

Then the following are equivalent:

(i) *$[\hat{\phi}, \hat{\phi}], [\hat{\tilde{\phi}}, \hat{\tilde{\phi}}] \in L_\infty(\mathbb{T})$ and $[\hat{\phi}, \hat{\tilde{\phi}}] = 1$; or equivalently, the shifts of both ϕ and $\tilde{\phi}$ are stable in $L_2(\mathbb{R})$ and the biorthogonality relation holds:*

$$\langle \phi, \tilde{\phi}(\cdot - k) \rangle = \int_{\mathbb{R}} \phi(x)\overline{\tilde{\phi}(x-k)}\,dx = \delta_k \qquad \forall\, k \in \mathbb{Z}. \tag{3.3}$$

(ii) $\nu_2(\hat{a})>0$, $\nu_2(\hat{\tilde{a}})>0$, *and* $\hat{\tilde{a}}$ *is a dual mask of* $\hat{a}$, *where we say that* $\hat{\tilde{a}}$ *is a dual mask of* $\hat{a}$ *if*

$$\overline{\hat{a}(\xi)}\hat{\tilde{a}}(\xi)+\overline{\hat{a}(\xi+\pi)}\hat{\tilde{a}}(\xi+\pi)=1. \tag{3.4}$$

Let $\hat{b},\hat{\tilde{b}}\in C^\beta(\mathbb{T})$ *such that* $\hat{b}(0)=\hat{\tilde{b}}(0)=0$. *Define two wavelet functions* ψ *and* $\tilde{\psi}$ *by*

$$\hat{\psi}(\xi):=\hat{b}(\xi/2)\hat{\phi}(\xi/2)\quad \textit{and}\quad \hat{\tilde{\psi}}(\xi):=\hat{\tilde{b}}(\xi/2)\hat{\tilde{\phi}}(\xi/2). \tag{3.5}$$

If $\nu_2(\hat{a})>0$, $\nu_2(\hat{\tilde{a}})>0$, *and*

$$\begin{bmatrix}\hat{a}(\xi) & \hat{a}(\xi+\pi)\\ \hat{b}(\xi) & \hat{b}(\xi+\pi)\end{bmatrix}\overline{\begin{bmatrix}\hat{\tilde{a}}(\xi) & \hat{\tilde{a}}(\xi+\pi)\\ \hat{\tilde{b}}(\xi) & \hat{\tilde{b}}(\xi+\pi)\end{bmatrix}}^T=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}, \tag{3.6}$$

then $(\psi,\tilde{\psi})$ *generates a pair of biorthogonal wavelet bases in* $L_2(\mathbb{R})$.

Proof. Suppose that (i) holds. By $1=|[\hat{\phi},\hat{\tilde{\phi}}]|^2\leqslant[\hat{\phi},\hat{\phi}][\hat{\tilde{\phi}},\hat{\tilde{\phi}}]$, we have $[\hat{\phi},\hat{\phi}]\geqslant\|[\hat{\tilde{\phi}},\hat{\tilde{\phi}}]\|^{-1}_{L_\infty(\mathbb{T})}$ and $[\hat{\tilde{\phi}},\hat{\tilde{\phi}}]\geqslant\|[\hat{\phi},\hat{\phi}]\|^{-1}_{L_\infty(\mathbb{T})}$. Therefore, the shifts of ϕ and $\tilde{\phi}$ are stable in $L_2(\mathbb{R})$. By Corollary 2.2, we have $\nu_2(\hat{a})>0$ and $\nu_2(\hat{\tilde{a}})>0$. Now by $[\hat{\phi},\hat{\tilde{\phi}}]=1$, it follows directly from the refinement equations $\hat{\phi}(2\xi)=\hat{a}(\xi)\hat{\phi}(\xi)$ and $\hat{\tilde{\phi}}(2\xi)=\hat{\tilde{a}}(\xi)\hat{\tilde{\phi}}(\xi)$ that

$$\begin{aligned}1=[\hat{\tilde{\phi}},\hat{\phi}](2\xi)&=\overline{\hat{a}(\xi)}\hat{\tilde{a}}(\xi)[\hat{\tilde{\phi}},\hat{\phi}](\xi)+\overline{\hat{a}(\xi+\pi)}\hat{\tilde{a}}(\xi+\pi)[\hat{\tilde{\phi}},\hat{\phi}](\xi+\pi)\\&=\overline{\hat{a}(\xi)}\hat{\tilde{a}}(\xi)+\overline{\hat{a}(\xi+\pi)}\hat{\tilde{a}}(\xi+\pi).\end{aligned}$$

So, $\hat{\tilde{a}}$ is a dual mask of $\hat{a}$. Therefore, (i)⇒(ii).

To prove (ii)⇒(i), since $\nu_2(\hat{a})>0$ and $\nu_2(\hat{\tilde{a}})>0$, by Theorem 2.1, we see that (i) of Theorem 2.1 holds for both $\hat{a}$ and $\hat{\tilde{a}}$. Moreover, by (2.3), we have $[\hat{\phi},\hat{\phi}],[\hat{\tilde{\phi}},\hat{\tilde{\phi}}]\in L_\infty(\mathbb{T})$.

Take $\hat{f}:=\chi_{[-\pi,\pi]}$, the characteristic function of the interval $[-\pi,\pi]$. By (i) of Theorem 2.1, we have $\hat{a}(\pi)=\hat{\tilde{a}}(\pi)=0$. Since $\hat{a},\hat{\tilde{a}}\in C^\beta(\mathbb{T})$ and $\hat{a}(0)=\hat{\tilde{a}}(0)=1$, it is easy to directly verify that f is an admissible function in $L_{2,\infty,0}(\mathbb{R})$ with respect to both $\hat{a}$ and $\hat{\tilde{a}}$. Define

$$\widehat{f_n}(\xi):=\hat{f}(2^{-n}\xi)\prod_{j=1}^n\hat{a}(2^{-j}\xi)\quad\text{and}\quad\widehat{\tilde{f}_n}(\xi):=\hat{f}(2^{-n}\xi)\prod_{j=1}^n\hat{\tilde{a}}(2^{-j}\xi),\qquad n\in\mathbb{N}.$$

Then by (i) of Theorem 2.1, both $\{f_n\}_{n=1}^\infty$ and $\{\tilde{f}_n\}_{n=1}^\infty$ are Cauchy sequences in $L_{2,\infty,0}(\mathbb{R})$. Note that $\lim_{n\to\infty}\widehat{f_n}(\xi)=\hat{\phi}(\xi)$ and $\lim_{n\to\infty}\widehat{\tilde{f}_n}(\xi)=\hat{\tilde{\phi}}(\xi)$. So, we must have

$$\lim_{n\to\infty}\|f_n-\phi\|_{L_{2,\infty,0}(\mathbb{R})}=\lim_{n\to\infty}\|\tilde{f}_n-\tilde{\phi}\|_{L_{2,\infty,0}(\mathbb{R})}=0.$$

Since $[\hat{f},\hat{f}]=1$ and the discrete biorthogonality relation in (3.4) holds, it is easy to show by induction that $[\widehat{f_n},\widehat{\tilde{f}_n}]=1$ for all $n\in\mathbb{N}$. Consequently, we must have $[\hat{\phi},\hat{\tilde{\phi}}]=1$. Therefore, (ii)⇒(i).

If $\nu_2(\hat{a})>0$, $\nu_2(\hat{\tilde{a}})>0$, and (3.6) holds, then all the conditions in (ii) hold. So, $[\hat{\phi},\hat{\tilde{\phi}}]=1$. Now it follows from (3.6) that $[\hat{\phi},\hat{\tilde{\psi}}]=0$, $[\hat{\psi},\hat{\tilde{\phi}}]=0$, and $[\hat{\psi},\hat{\tilde{\psi}}]=1$. By a

standard argument on MRA [4, 6], we deduce that (3.1) holds. Since $\hat{\phi}(0) = \hat{\tilde{\phi}}(0) = 1$ and both $\hat{\phi}$ and $\hat{\tilde{\phi}}$ are continuous, by the standard argument on MRA, we see that both $\{\psi_{j,k} : j,k \in \mathbb{Z}\}$ and $\{\tilde{\psi}_{j,k} : j,k \in \mathbb{Z}\}$ are dense in $L_2(\mathbb{R})$. To show that both ψ and $\tilde{\psi}$ generate Riesz wavelet bases in $L_2(\mathbb{R})$, we need to show that ψ and $\tilde{\psi}$ satisfy (1.11). By the biorthogonality relation in (3.1), it suffices to show that the right-hand inequality in (1.11) holds for both ψ and $\tilde{\psi}$ [4], which is equivalent to showing that there exists a positive constant C such that

$$\sum_{j\in\mathbb{Z}}\sum_{k\in\mathbb{Z}}\big[|\langle f,\psi_{j,k}\rangle|^2 + |\langle f,\tilde{\psi}_{j,k}\rangle|^2\big] \leqslant C\|f\|^2 \qquad \forall\, f \in L_2(\mathbb{R}). \tag{3.7}$$

Since $\nu_2(\hat{a}) > 0$ and $\nu_2(\hat{\tilde{a}}) > 0$, by Theorem 2.1, we have $[\hat{\phi},\hat{\phi}]_\nu, [\hat{\tilde{\phi}},\hat{\tilde{\phi}}]_\nu \in L_\infty(\mathbb{T})$ for $0 < \nu < \min(\nu_2(\hat{a}), \nu_2(\hat{\tilde{a}}))$. Using Fourier transform and the Parseval's identity, by $\hat{\psi}(\xi) = \hat{b}(\xi/2)\hat{\phi}(\xi/2)$, we have

$$\begin{aligned}
2\pi\sum_{k\in\mathbb{Z}}|\langle f,\psi_{j,k}\rangle|^2 &= 2^j\int_{-\pi}^{\pi}|[\hat{f}(2^j\cdot),\hat{\psi}](\xi)|^2\,d\xi\\
&\leqslant 2^{j+1}\int_{-\pi}^{\pi}|\hat{b}(\xi)|^2|[\hat{f}(2^{j+1}\cdot),\hat{\phi}](\xi)|^2\,d\xi\\
&\leqslant 2^{j+1}\int_{-\pi}^{\pi}|\hat{b}(\xi)|^2[\hat{f}(2^{j+1}\cdot),\hat{f}(2^{j+1}\cdot)]_{-\nu}(\xi)[\hat{\phi},\hat{\phi}]_\nu(\xi)\,d\xi\\
&\leqslant \|[\hat{\phi},\hat{\phi}]_\nu\|_{L_\infty(\mathbb{T})}2^{j+1}\int_{-\pi}^{\pi}|\hat{b}(\xi)|^2[\hat{f}(2^{j+1}\cdot),\hat{f}(2^{j+1}\cdot)]_{-\nu}(\xi)\,d\xi\\
&= \|[\hat{\phi},\hat{\phi}]_\nu\|_{L_\infty(\mathbb{T})}\int_{\mathbb{R}}\frac{|\hat{b}(2^{-j-1}\xi)|^2}{(1+|2^{-j-1}\xi|^2)^\nu}|\hat{f}(\xi)|^2\,d\xi.
\end{aligned}$$

Note that $\hat{b}(0) = \hat{\tilde{b}}(0) = 0$ and $\hat{b},\hat{\tilde{b}} \in C^\beta(\mathbb{T})$ with $\beta > 0$. Consequently, we see that (3.7) holds with

$$\begin{aligned}
C = \|[\hat{\phi},\hat{\phi}]_\nu\|_{L_\infty(\mathbb{T})}&\left\|\sum_{j\in\mathbb{Z}}\frac{|\hat{b}(2^j\cdot)|^2}{(1+|2^j\cdot|^2)^\nu}\right\|_{L_\infty(\mathbb{R})}\\
&+\|[\hat{\tilde{\phi}},\hat{\tilde{\phi}}]_\nu\|_{L_\infty(\mathbb{T})}\left\|\sum_{j\in\mathbb{Z}}\frac{|\hat{\tilde{b}}(2^j\cdot)|^2}{(1+|2^j\cdot|^2)^\nu}\right\|_{L_\infty(\mathbb{R})} < \infty.
\end{aligned}$$

Therefore, $(\psi,\tilde{\psi})$ generates a pair of biorthogonal wavelet bases in $L_2(\mathbb{R})$. □

As an application of Theorems 2.1 and 3.1, we characterize MRA Riesz wavelet bases in $L_2(\mathbb{R})$ in the following result, which improves and generalizes [14, Theorem 6] and [16, Theorem 1.1] by taking a different approach.

THEOREM 3.2. *Let $\hat{a},\hat{b} \in C^\beta(\mathbb{T})$ with $\hat{a}(0) = 1$ and $\beta > 0$. Define ϕ and ψ by*

$$\hat{\phi}(\xi) := \prod_{j=1}^{\infty}\hat{a}(2^{-j}\xi) \quad \textit{and} \quad \hat{\psi}(\xi) := \hat{b}(\xi/2)\hat{\phi}(\xi/2), \qquad \xi \in \mathbb{R}. \tag{3.8}$$

Then the shifts of ϕ are stable in $L_2(\mathbb{R})$ and ψ generates a Riesz wavelet basis in $L_2(\mathbb{R})$ if and only if

(i) $\hat{b}(0) = 0$ *and* $d(\xi) := \hat{a}(\xi)\overline{\hat{b}(\xi+\pi)} - \hat{a}(\xi+\pi)\overline{\hat{b}(\xi)} \neq 0$ *for all* $\xi \in \mathbb{R}$,

(ii) $\nu_2(\hat{a}) > 0$ *and* $\nu_2(\hat{\tilde{a}}) > 0$, *where* $\hat{\tilde{a}}(\xi) := \overline{\hat{b}(\xi+\pi)}/\overline{d(\xi)}$.

In the case that $\hat{a}$ is a 2π-periodic trigonometric polynomial, then the shifts of $\phi \in L_2(\mathbb{R})$ must be stable in $L_2(\mathbb{R})$ if ψ generates a Riesz wavelet basis in $L_2(\mathbb{R})$.

Proof. Suppose that (i) and (ii) hold. Define $\hat{\tilde{b}}(\xi) := -\overline{\hat{a}(\xi+\pi)}/\overline{d(\xi)}$. Since $\hat{a}, \hat{b} \in C^\beta(\mathbb{T})$ and $d(\xi) \neq 0$ for all $\xi \in \mathbb{R}$, it is evident that $\hat{\tilde{a}}, \hat{\tilde{b}} \in C^\beta(\mathbb{T})$. By $\nu_2(\hat{a}) > 0$ and Theorem 2.1, $\hat{a}(\pi) = 0$. Since $\hat{a}(0) = 1$ and $\hat{b}(0) = 0$, we must have $\hat{\tilde{a}}(0) = 1$ and $\hat{\tilde{a}}(\pi) = 0$. Moreover, it is easy to check that (3.6) holds. Define $\tilde{\phi}$ and $\tilde{\psi}$ as in (3.2) and (3.5). Now it follows from Theorem 3.1 that $(\psi, \tilde{\psi})$ generates a pair of biorthogonal wavelet bases in $L_2(\mathbb{R})$. In particular, we conclude that ψ generates a Riesz wavelet basis in $L_2(\mathbb{R})$.

Conversely, suppose that the shifts of ϕ are stable in $L_2(\mathbb{R})$ and ψ generates a Riesz wavelet basis in $L_2(\mathbb{R})$. Since the shifts of ϕ are stable in $L_2(\mathbb{R})$, by Corollary 2.2, we have $\nu_2(\hat{a}) > 0$ and $\hat{a}(\pi) = 0$. Since $\hat{\psi}$ is continuous and ψ generates a Riesz wavelet basis in $L_2(\mathbb{R})$, we must have $\hat{\psi}(0) = 0$, and therefore $\hat{b}(0) = 0$ by $\hat{\phi}(0) = 1$. So, $\hat{\tilde{a}}(0) = \overline{\hat{b}(\pi)}/\overline{d(0)} = 1$. By [14, Lemma 1], we see that (i) must hold and there exists a function $\tilde{\phi} \in L_2(\mathbb{R})$ such that the shifts of $\tilde{\phi}$ are stable in $L_2(\mathbb{R})$ and $\hat{\tilde{\phi}}(2\xi) = \hat{\tilde{a}}(\xi)\hat{\tilde{\phi}}(\xi)$. Since $\hat{\tilde{a}} \in C^\beta(\mathbb{T})$ and $\hat{\tilde{a}}(0) = 1$, by Corollary 2.2, we have $\nu_2(\hat{\tilde{a}}) > 0$. Therefore, both (i) and (ii) hold.

Suppose that $\hat{a}$ is a 2π-periodic trigonometric polynomial and the shifts of $\phi \in L_2(\mathbb{R})$ are not stable in $L_2(\mathbb{R})$. Since ϕ is compactly supported, by [19, Theorem 5.3], there exists a compactly supported refinable function $\eta \in L_2(\mathbb{R})$ with stable shifts in $L_2(\mathbb{R})$ such that $\hat{\eta}(2\xi) = \hat{c}(\xi)\hat{\eta}(\xi)$ for some 2π-periodic trigonometric polynomial $\hat{c}$, and $\hat{\phi}(\xi) = \theta(\xi)\hat{\eta}(\xi)$ for some 2π-periodic trigonometric polynomial θ. Note that $[\hat{\phi}, \hat{\phi}](\xi) = |\theta(\xi)|^2[\hat{\eta}, \hat{\eta}](\xi)$ and $\hat{a}(\xi) = \theta(2\xi)\hat{c}(\xi)/\theta(\xi)$. Since the shifts of the compactly supported function ϕ are not stable in $L_2(\mathbb{R})$, there is $\xi_0 \in \mathbb{R}\backslash[2\pi\mathbb{Z}]$ such that $\theta(\xi_0) = 0$.

Since $\hat{\psi}(2\xi) = \hat{b}(\xi)\hat{\phi}(\xi) = \hat{b}(\xi)\theta(\xi)\hat{\eta}(\xi)$ and the shifts of η are stable in $L_2(\mathbb{R})$, if ψ generates a Riesz wavelet basis in $L_2(\mathbb{R})$, by what has been proved, then we must have

$$0 \neq \mathring{d}(\xi) := \hat{c}(\xi)\overline{\hat{b}(\xi+\pi)}\theta(\xi+\pi) - \hat{c}(\xi+\pi)\overline{\hat{b}(\xi)}\theta(\xi) = \frac{\theta(\xi)\theta(\xi+\pi)}{\theta(2\xi)}d(\xi) \quad \forall\, \xi \in \mathbb{R} \tag{3.9}$$

and $\nu_2(\hat{c}) > 0$, $\nu_2(\hat{\mathring{a}}) > 0$, where $\hat{\mathring{a}}(\xi) := \overline{\hat{b}(\xi+\pi)\theta(\xi+\pi)}/\overline{\mathring{d}(\xi)}$.

By (3.9), we conclude that if $\xi \in \mathbb{R}$ is a zero of θ, then 2ξ must also be a zero of θ. Since $\theta(\xi_0) = 0$, we now see that $\theta(2^j\xi_0) = 0$ for all $j \in \mathbb{N} \cup \{0\}$. By the definition of $\mathring{d}(\xi)$ in (3.9), for all $j \in \mathbb{N} \cup \{0\}$, we have

$$\begin{aligned}\mathring{d}(2^j\xi_0) &:= \hat{c}(2^j\xi_0)\overline{\hat{b}(2^j\xi_0+\pi)}\theta(2^j\xi_0+\pi) - \hat{c}(2^j\xi_0+\pi)\overline{\hat{b}(2^j\xi_0)}\theta(2^j\xi_0)\\ &= \hat{c}(2^j\xi_0)\overline{\hat{b}(2^j\xi_0+\pi)}\theta(2^j\xi_0+\pi).\end{aligned}$$

Now by the definition of $\hat{\hat{a}}$, we deduce that

$$\hat{\hat{a}}(2^j\xi_0) = \frac{\overline{\hat{b}(2^j\xi_0+\pi)\theta(2^j\xi_0+\pi)}}{\overline{\hat{c}(2^j\xi_0)\hat{b}(2^j\xi_0+\pi)\theta(2^j\xi_0+\pi)}} = \frac{1}{\overline{\hat{c}(2^j\xi_0)}} \qquad \forall\, j \in \mathbb{N}\cup\{0\},$$

from which we see that

$$\prod_{j=0}^{n} \hat{\hat{a}}(2^j\xi_0) = \frac{1}{\prod_{j=0}^{n}\overline{\hat{c}(2^j\xi_0)}} \qquad \forall\, n \in \mathbb{N}. \tag{3.10}$$

Since the shifts of η are stable, there exists $k_0 \in \mathbb{Z}$ such that $\hat{\eta}(\xi_0+2\pi k_0) \neq 0$. Since $\xi_0 \notin 2\pi\mathbb{Z}$, we have $\xi_0 + 2\pi k_0 \neq 0$, and therefore $\lim_{n\to\infty}\hat{\eta}(2^n(\xi_0+2\pi k_0)) = 0$ by $\eta \in L_1(\mathbb{R})\cap L_2(\mathbb{R})$. Now by (3.10), we have

$$\left|\prod_{j=0}^{n}\hat{\hat{a}}(2^j\xi_0)\right| = \frac{1}{\left|\prod_{j=0}^{n}\hat{c}(2^j\xi_0)\right|} = \frac{1}{\left|\prod_{j=0}^{n}\hat{c}(2^j(\xi_0+2\pi k_0))\right|}$$

$$= \frac{|\hat{\eta}(\xi_0+2\pi k_0)|}{|\hat{\eta}(2^{n+1}(\xi_0+2\pi k_0))|} \to \infty$$

as $n \to \infty$, which is a contradiction to [14, Lemma 1] (also see (5.19)), since $\hat{\hat{a}} \in C^\beta(\mathbb{T})$. Therefore, the shifts of $\phi \in L_2(\mathbb{R})$ must be stable in $L_2(\mathbb{R})$. □

To illustrate the results in this section, we consider MRA Riesz wavelet bases in $L_2(\mathbb{R})$ using the masks in (1.12). The following result generalizes [17, Theorem 2.2] for the case of B-splines.

THEOREM 3.3. *Let $\hat{a} = \widehat{a_{\beta_1,\beta_2,\beta_3}}$ or $\hat{a} = |\widehat{a_{\beta_1,\beta_2,\beta_3}}|$, where the masks $\widehat{a_{\beta_1,\beta_2,\beta_3}}$ are defined in* (1.12). *Let ϕ denote the standard refinable function associated with mask $\hat{a}$ in* (1.2) *and define a wavelet function ψ by*

$$\hat{\psi}(2\xi) := e^{-i\xi}\overline{\hat{a}(\xi+\pi)}\hat{\phi}(\xi), \qquad \xi \in \mathbb{R}. \tag{3.11}$$

Then the shifts of ϕ are stable in $L_2(\mathbb{R})$ and the wavelet function ψ generates a Riesz wavelet basis in $L_2(\mathbb{R})$, provided that $\beta_1, \beta_2, \beta_3 > 0$ satisfy

$$\beta_1 > 1/4 + |\beta_2 - 1|\beta_3/2,\ (\beta_2-1)\beta_3 > -1/2 \quad \textit{or} \quad \beta_1 \geqslant 1,\ (\beta_2-1)\beta_3 \leqslant -1/2. \tag{3.12}$$

Proof. Let $\hat{b}(\xi) := e^{-i\xi}\overline{\hat{a}(\xi+\pi)}$. Then $\hat{\psi}(2\xi) = \hat{b}(\xi)\hat{\phi}(\xi)$. Clearly, $\hat{a}, \hat{b} \in C^\beta(\mathbb{T})$ for some $\beta > 0$ and $\hat{b}(0) = 0$. By calculation, we have

$$d(\xi) = e^{-i(\xi+\pi)}\big(|\hat{a}(\xi)|^2 + |\hat{a}(\xi+\pi)|^2\big) = e^{-i(\xi+\pi)}\frac{|\cos(\xi/2)|^{4\beta_1} + |\sin(\xi/2)|^{4\beta_1}}{\big(|\cos(\xi/2)|^{2\beta_2} + |\sin(\xi/2)|^{2\beta_2}\big)^{2\beta_3}}.$$

So, $d(\xi) \neq 0$ for all $\xi \in \mathbb{R}$, and (i) of Theorem 3.2 holds.

By calculation, we have

$$|\hat{\tilde{a}}(\xi)| = |\overline{\hat{b}(\xi+\pi)}/\overline{d(\xi)}| = 2^{-2\beta_1}|1+e^{-i\xi}|^{2\beta_1}\hat{c}(\xi),$$

where

$$\hat{c}(\xi) := \frac{\big(|\cos(\xi/2)|^{2\beta_2} + |\sin(\xi/2)|^{2\beta_2}\big)^{\beta_3}}{|\cos(\xi/2)|^{4\beta_1} + |\sin(\xi/2)|^{4\beta_1}}.$$

Now it follows from the inequalities in (2.4) that

$$0 < \hat{c}(\xi) \leqslant c_{\beta_1,\beta_2,\beta_3} := \frac{\max(1, 2^{(1-\beta_2)\beta_3})}{\min(1, 2^{1-2\beta_1})} \qquad \forall\, \xi \in \mathbb{R}.$$

If (3.12) holds, then (2.5) must be true, and therefore, by Example 2.4, we have $\nu_2(\hat{a}) > 0$. By Theorem 4.1 and Lemma 4.3, if (3.12) holds, then we have

$$\rho(\hat{\tilde{a}}) = \rho_{4\beta_1}(\hat{\tilde{a}}, \infty) = \rho_0(2^{-2\beta_1}\hat{c}, \infty) \leqslant \rho_0(2^{-2\beta_1}c_{\beta_1,\beta_2,\beta_3}, \infty) = 2^{1-4\beta_1}|c_{\beta_1,\beta_2,\beta_3}|^2 < 1,$$

since the last inequality combined with (2.5) is equivalent to (3.12). Now by Theorem 3.2, the shifts of ϕ are stable in $L_2(\mathbb{R})$, and the function ψ generates a Riesz wavelet basis in $L_2(\mathbb{R})$. □

For the fractional splines in [27], we have $\beta_2 = 1$, and the condition in (3.12) becomes $\beta_1 > 1/4$. As discussed in Example 2.4, the standard refinable function associated with mask $\hat{a}$ and $\beta_2 = 1$ does not belong to $L_2(\mathbb{R})$ for $0 < \beta_1 \leqslant 1/4$. So, Theorem 3.3 is sharp for all the fractional splines in [27].

For the classical Butterworth filters, we have $\beta_3 = 1$ and $\beta_1 = \beta_2 \in \mathbb{N}$. Now the condition in (3.12) becomes $\beta_1 > 1/2$. Therefore, Theorem 3.3 holds for all the classical Butterworth filters in [25].

4. Some properties and estimate of the quantity $\nu_2(\hat{a})$. In this section, we shall investigate some properties of the quantity $\nu_2(\hat{a})$ in (1.7) and discuss how to estimate the quantity $\nu_2(\hat{a})$. Some results in this section will be needed in our study of refinable functions, cascade algorithms, and wavelets with Hölder continuous masks. The results in this section for the general case of Lebesgue measurable masks are also of interest in their own right and may be useful elsewhere.

The following result generalizes a well-known result for a univariate 2π-periodic trigonometric polynomial $\hat{a}$ and a positive integer τ in the wavelet literature. The proof of the following result for the general case of Hölder continuous masks is nontrivial and will be presented in section 7.

THEOREM 4.1. *Let $\hat{a}$ be a 2π-periodic measurable function such that $|\hat{a}|^2 \in C^\beta(\mathbb{T})$ with $|\hat{a}(0)|^2 \neq 0$ and $\beta > 0$. If $|\hat{a}(\xi)|^2 = |1+e^{-i\xi}|^{2\tau}|\hat{A}(\xi)|^2$ a.e. $\xi \in \mathbb{R}$ for some $\tau \geqslant 0$ such that $\hat{A} \in L_\infty(\mathbb{T})$, then*

$$\begin{aligned}\rho_{2\tau}(\hat{a}, \infty) &= \inf_{n\to\infty} \left\| \frac{T_{\hat{a}}^n(|\sin(\cdot/2)|^{2\tau})}{|\sin(\cdot/2)|^{2\tau}} \right\|_{L_\infty(\mathbb{T})}^{1/n} \\ &= \lim_{n\to\infty} \|T_{\hat{A}}^n 1\|_{L_\infty(\mathbb{T})}^{1/n} = \inf_{n\in\mathbb{N}} \|T_{\hat{A}}^n 1\|_{L_\infty(\mathbb{T})}^{1/n}.\end{aligned} \tag{4.1}$$

As in (1.7), we define a similar quantity as follows:

$$\nu_2(\hat{a}, p) := -[\log_2 \rho(\hat{a}, p)]/2, \qquad 1 \leqslant p \leqslant \infty, \tag{4.2}$$

where the quantity $\rho(\hat{a}, p)$, using $\rho_\tau(\hat{a}, p)$ in (1.6), is defined to be

$$\rho(\hat{a}, p) := \inf\{\rho_\tau(\hat{a}, p) \ : \ |\hat{a}(\cdot + \pi)|^2 / |\sin(\cdot/2)|^\tau \in L_\infty(\mathbb{T}) \ \text{ and } \ \tau \geqslant 0\}. \tag{4.3}$$

Clearly, $\nu_2(\hat{a}) = \nu_2(\hat{a}, \infty)$ and $\rho(\hat{a}) = \rho(\hat{a}, \infty)$. For a 2π-periodic trigonometric polynomial $\hat{a}$, we can write $\hat{a}(\xi) = (1 + e^{-i\xi})^\tau \hat{A}(\xi)$ for some nonnegative integer τ and some 2π-periodic trigonometric polynomial $\hat{A}$ with $\hat{A}(\pi) \neq 0$. Write $|\hat{A}(\xi)|^2 = \sum_{k=-K}^{K} c_k e^{-ik\xi}$. It is known [7, 13, 15] that $\nu_2(\hat{a}, p) = \nu_2(\hat{a}) = -1/2 - \log_2 \sqrt{\rho}$, where ρ is the spectral radius of the square matrix $(c_{2j-k})_{-K \leqslant j,k \leqslant K}$.

In the following, we shall investigate the mutual relations among the quantities $\nu_2(\hat{a}, p)$.

PROPOSITION 4.2. *The following statements hold:*

(1) *For $0 < \tau < 1$, $|\sin(\cdot/2)|^\tau \in C^\tau(\mathbb{T})$ and $|\cos(\cdot/2)|^\tau \in C^\tau(\mathbb{T})$.*

(2) *For a 2π-periodic measurable function $\hat{a}$ and $0 \leqslant \tau_1 \leqslant \tau_2$,*

$$\rho_{\tau_2}(\hat{a}, p) \leqslant \rho_{\tau_1}(\hat{a}, p) \leqslant \rho_{\tau_1}(\hat{a}, q) \quad \text{and} \quad \nu_2(\hat{a}, q) \leqslant \nu_2(\hat{a}, p) \quad \forall\, 1 \leqslant p \leqslant q \leqslant \infty. \tag{4.4}$$

(3) *If $\hat{a} \in C^\beta(\mathbb{T})$ with $\hat{a}(0) = 1$ and $\beta > 0$, then the condition*

$$\liminf_{n \to \infty} \|T_{\hat{a}}^n(|\sin(\cdot/2)|^\tau)\|_{L_1(\mathbb{T})} = 0 \quad \text{for some } \tau \geqslant 0 \tag{4.5}$$

implies $\hat{a}(\pi) = 0$. In particular, (4.5) holds if $\nu_2(\hat{a}, p) > 0$ for some $1 \leqslant p \leqslant \infty$.

Proof. It is easy to prove that $1 - x^\tau \leqslant (1 - x)^\tau$ for all $0 < \tau \leqslant 1$ and $0 \leqslant x \leqslant 1$. Consequently, we have

$$||\sin(x/2)|^\tau - |\sin(y/2)|^\tau| \leqslant |\sin(x/2) - \sin(y/2)|^\tau \leqslant |x - y|^\tau.$$

So, $|\sin(\cdot/2)|^\tau \in C^\tau(\mathbb{T})$, and it follows that $|\cos(\cdot/2)|^\tau \in C^\tau(\mathbb{T})$. So, (1) holds.

Since $0 \leqslant \tau_1 \leqslant \tau_2$, it is evident that $|\sin(\xi/2)|^{\tau_2} \leqslant |\sin(\xi/2)|^{\tau_1}$ for all $\xi \in \mathbb{R}$. Therefore,

$$T_{\hat{a}}^n\left(|\sin(\cdot/2)|^{\tau_2}\right) \leqslant T_{\hat{a}}^n\left(|\sin(\cdot/2)|^{\tau_1}\right).$$

Now the claim in (4.4) follows directly from the above inequality and the fact that $\|\cdot\|_{L_p(\mathbb{T})} \leqslant \|\cdot\|_{L_q(\mathbb{T})}$ for all $1 \leqslant p \leqslant q \leqslant \infty$. So, (2) holds.

To prove (3), we denote $\Phi(\xi) := \prod_{j=1}^{\infty} |\hat{a}(2^{-j}\xi)|^2$. Since $\hat{a} \in C^\beta(\mathbb{T})$ with $\hat{a}(0) = 1$ and $\beta > 0$, Φ is well defined and is continuous with $\Phi(0) = 1$. Suppose that $\hat{a}(\pi) \neq 0$. Then there exist $0 < \varepsilon < \pi/2$ and a positive constant C such that $|\hat{a}(\xi + \pi)|^2 |\sin(\xi/2 + \pi/2)|^\tau \geqslant C$ and $C \leqslant \Phi(\xi) \leqslant 1/C$ for all $\xi \in (-2\varepsilon, 2\varepsilon)$. By the

definition of $T_{\hat{a}}$, we deduce that

$$\begin{aligned}\int_0^{2\pi}[T_{\hat{a}}^n(|\sin(\cdot/2)|^\tau)](\xi)\,d\xi &= 2^n\int_0^{2\pi}|\sin(\xi/2)|^\tau|\hat{a}(\xi)|^2|\hat{a}(2\xi)|^2\cdots|\hat{a}(2^{n-1}\xi)|^2\,d\xi\\ &\geqslant 2^n\int_{\pi-\varepsilon}^{\pi+\varepsilon}|\sin(\xi/2)|^\tau|\hat{a}(\xi)|^2|\hat{a}(2\xi)|^2\cdots|\hat{a}(2^{n-1}\xi)|^2\,d\xi\\ &\geqslant 2^nC\int_{\pi-\varepsilon}^{\pi+\varepsilon}|\hat{a}(2\xi)|^2\cdots|\hat{a}(2^{n-1}\xi)|^2\,d\xi\\ &= 2^{n-1}C\int_{-2\varepsilon}^{2\varepsilon}|\hat{a}(\xi)|^2\cdots|\hat{a}(2^{n-2}\xi)|^2\,d\xi\\ &= 2^{n-1}C\int_{-2\varepsilon}^{2\varepsilon}\frac{\Phi(2^{n-1}\xi)}{\Phi(\xi)}\,d\xi\\ &\geqslant 2^{n-1}C^2\int_{-2\varepsilon}^{2\varepsilon}\Phi(2^{n-1}\xi)\,d\xi\\ &= C^2\int_{-2^n\varepsilon}^{2^n\varepsilon}\Phi(\xi)\,d\xi.\end{aligned}$$

Hence,

$$\liminf_{n\to\infty}\|T_{\hat{a}}^n(|\sin(\cdot/2)|^\tau)\|_{L_1(\mathbb{T})}\geqslant(2\pi)^{-1}C^2\int_{\mathbb{R}}\Phi(\xi)\,d\xi>0,$$

since $\Phi\geqslant 0$ is continuous and $\Phi(0)=1$. This is a contradiction to our assumption in (4.5). So, we must have $\hat{a}(\pi)=0$. If $\nu_2(\hat{a},p)>0$, then $\nu_2(\hat{a},1)\geqslant\nu_2(\hat{a},p)>0$, and therefore (4.5) holds. □

The following result will be needed later in this section.

LEMMA 4.3. *Let $\hat{a}$ and $\hat{c}$ be 2π-periodic measurable functions such that $|\hat{a}(\xi)|\leqslant|\hat{c}(\xi)|$ for almost every $\xi\in\mathbb{R}$. Then*

$$\rho_\tau(\hat{a},p)\leqslant\rho_\tau(\hat{c},p)\quad\text{and}\quad\nu_2(\hat{c},p)\leqslant\nu_2(\hat{a},p)\qquad\forall\,1\leqslant p\leqslant\infty,\tau\in\mathbb{R}.\tag{4.6}$$

Proof. To prove (4.6), since $|\hat{a}(\xi)|^2\leqslant|\hat{c}(\xi)|^2$, it is obvious that

$$0\leqslant[T_{\hat{a}}^n(|\sin(\cdot/2)|^\tau)](\xi)\leqslant[T_{\hat{c}}^n(|\sin(\cdot/2)|^\tau)](\xi)\qquad\text{a.e. }\xi\in\mathbb{R}.$$

Therefore, $\|T_{\hat{a}}^n(|\sin(\cdot/2)|^\tau)\|_{L_p(\mathbb{T})}\leqslant\|T_{\hat{c}}^n(|\sin(\cdot/2)|^\tau)\|_{L_p(\mathbb{T})}$, which implies the first part of (4.6).

If $|\hat{c}(\cdot+\pi)|^2/|\sin(\cdot/2)|^\tau\in L_\infty(\mathbb{T})$ for some τ, then we also have

$$|\hat{a}(\cdot+\pi)|^2/|\sin(\cdot/2)|^\tau\in L_\infty(\mathbb{T})$$

since $|\hat{a}(\xi)|\leqslant|\hat{c}(\xi)|$. Now by the definition of $\nu_2(\hat{a},p)$ in (4.2) and the first part of (4.6), it is easy to see that $\nu_2(\hat{c},p)\leqslant\nu_2(\hat{a},p)$. □

For a particular family of masks, the following result reveals the mutual relations among the quantities $\nu_2(\hat{a},p)$ for different $1\leqslant p\leqslant\infty$.

LEMMA 4.4. *Let $\hat{a}$ be a 2π-periodic measurable function such that $|\hat{a}(\xi)| = |1 + e^{-i\xi}|^\tau |\hat{A}(\xi)|$ for some $\tau \geqslant 0$ and some 2π-periodic trigonometric polynomial $\hat{A}$ with $\hat{A}(0) \neq 0$. Then*

$$\rho_{2\tau}(\hat{a}, p) = \lim_{n\to\infty} \left\| T_{\hat{a}}^n (|\sin(\cdot/2)|^{2\tau}) \right\|_{L_p(\mathbb{T})}^{1/n} = \rho_0(\hat{A}, \infty) = \inf_{n\in\mathbb{N}} \|T_{\hat{A}}^n 1\|_{L_\infty(\mathbb{T})}^{1/n} \quad \forall\, 1 \leqslant p \leqslant \infty. \tag{4.7}$$

In particular, $\nu_2(\hat{a}, p) = \nu_2(\hat{a}) = \nu_2(\hat{A})$ for all $1 \leqslant p \leqslant \infty$. That is, $\nu_2(\hat{a}, p)$ is independent of p.

Proof. Let N be an integer such that $N \geqslant \tau$. Define $\hat{c}(\xi) := (1 + e^{-i\xi})^N \hat{A}(\xi)$. By calculation, it follows from $|\hat{a}(\xi)|^2 = 2^{2\tau} |\cos(\xi/2)|^{2\tau} |\hat{A}(\xi)|^2$ that

$$\begin{aligned}
\left[T_{\hat{a}}(f(\cdot)|\sin(\cdot/2)|^{2\tau})\right](\xi) &= |\hat{a}(\xi/2)|^2 |\sin(\xi/4)|^{2\tau} f(\xi/2) \\
&\quad + |\hat{a}(\xi/2+\pi)|^2 |\sin(\xi/4+\pi/2)|^{2\tau} f(\xi/2+\pi) \\
&= |\sin(\xi/2)|^{2\tau} [|\hat{A}(\xi/2)|^2 f(\xi/2) + |\hat{A}(\xi/2+\pi)|^2 f(\xi/2+\pi)] \\
&= |\sin(\xi/2)|^{2\tau} [T_{\hat{A}} f](\xi).
\end{aligned}$$

That is, when $|\hat{a}(\xi)|^2 = 2^{2\tau} |\cos(\xi/2)|^{2\tau} |\hat{A}(\xi)|^2$, for any 2π-periodic function f, by induction, we have

$$\left[T_{\hat{a}}^n (f(\cdot)|\sin(\cdot/2)|^{2\tau})\right](\xi) = |\sin(\xi/2)|^{2\tau} [T_{\hat{A}}^n f](\xi), \qquad n \in \mathbb{N}. \tag{4.8}$$

Setting $f = 1$ in (4.8), we have

$$[T_{\hat{a}}^n (|\sin(\cdot/2)|^{2\tau})](\xi) = |\sin(\xi/2)|^{2\tau} [T_{\hat{A}}^n 1](\xi) \leqslant [T_{\hat{A}}^n 1](\xi). \tag{4.9}$$

Note that $2N - 2\tau \geqslant 0$. Similarly, by $|\hat{c}(\xi)|^2 = 2^{2N-2\tau} |\cos(\xi/2)|^{2N-2\tau} |\hat{a}(\xi)|^2$, setting $f(\xi) = |\sin(\xi/2)|^{2\tau}$ and replacing τ by $N - \tau$ in (4.8), we have

$$\begin{aligned}
[T_{\hat{c}}^n (|\sin(\cdot/2)|^{2N})](\xi) &= |\sin(\xi/2)|^{2N-2\tau} [T_{\hat{a}}^n (|\sin(\cdot/2)|^{2\tau})](\xi) \\
&\leqslant [T_{\hat{a}}^n (|\sin(\cdot/2)|^{2\tau})](\xi).
\end{aligned} \tag{4.10}$$

Thus, it follows from (4.9) and (4.10) that

$$\begin{aligned}
\|T_{\hat{c}}^n (\sin^{2N}(\cdot/2))\|_{L_p(\mathbb{T})} &\leqslant \|T_{\hat{a}}^n (|\sin(\cdot/2)|^{2\tau})\|_{L_p(\mathbb{T})} \leqslant \|T_{\hat{A}}^n 1\|_{L_p(\mathbb{T})} \\
&\leqslant \|T_{\hat{A}}^n 1\|_{L_\infty(\mathbb{T})}.
\end{aligned} \tag{4.11}$$

Since both $|\hat{c}|^2$ and $\sin^{2N}(\cdot/2)$ are 2π-periodic trigonometric polynomials, by induction, it is known [4, 7, 15] that $\{T_{\hat{c}}^n (\sin^{2N}(\cdot/2))\}_{n=1}^\infty$ spans a finite dimensional space and in fact the degrees of all trigonometric polynomials $T_{\hat{c}}^n (\sin^{2N}(\cdot/2))$ are uniformly bounded. Therefore, there exists a positive constant C, independent of all n, such that

$$C\|T_{\hat{c}}^n (\sin^{2N}(\cdot/2))\|_{L_\infty(\mathbb{T})} \leqslant \|T_{\hat{c}}^n (\sin^{2N}(\cdot/2))\|_{L_p(\mathbb{T})} \qquad \forall\, 1 \leqslant p \leqslant \infty, n \in \mathbb{N}.$$

Hence, we conclude from the above inequality and (4.11) that for $1 \leqslant p \leqslant \infty$,

$$C^{1/n}\|T_{\hat{c}}^n(\sin^{2N}(\cdot/2))\|_{L_\infty(\mathbb{T})}^{1/n} \leqslant \|T_{\hat{a}}^n(|\sin(\cdot/2)|^{2\tau})\|_{L_p(\mathbb{T})}^{1/n} \leqslant \|T_{\hat{A}}^n 1\|_{L_\infty(\mathbb{T})}^{1/n} \quad \forall\, n \in \mathbb{N}. \tag{4.12}$$

Since $\hat{c}(\xi) = (1+e^{-i\xi})^N \hat{A}(\xi)$ and $\hat{A}(0) \neq 0$, by Theorem 4.1, we have

$$\rho_{2N}(\hat{c},\infty) = \lim_{n\to\infty} \|T_{\hat{c}}^n(\sin^{2N}(\cdot/2))\|_{L_\infty(\mathbb{T})}^{1/n} = \lim_{n\to\infty} \|T_{\hat{A}}1\|_{L_\infty(\mathbb{T})}^{1/n} = \inf_{n\in\mathbb{N}} \|T_{\hat{A}}1\|_{L_\infty(\mathbb{T})}^{1/n}.$$

Now (4.7) follows directly from (4.12).

Since $\hat{A}$ is a 2π-periodic trigonometric polynomial, we can write $\hat{A}(\xi) = (1+e^{-i\xi})^k \hat{B}(\xi)$ for some nonnegative integer k and some 2π-periodic trigonometric polynomial $\hat{B}$ such that $\hat{B}(\pi) \neq 0$. So, $|\hat{a}(\xi)| = |1+e^{-i\xi}|^{k+\tau}|\hat{B}(\xi)|$. Now by the definition of $\nu_2(\hat{a},p)$ and Theorem 4.1, it follows from (4.7) that

$$\begin{aligned}\nu_2(\hat{a},p) &:= -[\log_2 \rho_{2k+2\tau}(\hat{a},p)]/2 = -[\log_2 \rho_0(\hat{B},\infty)]/2\\ &= -[\log_2 \rho_{2k}(\hat{A},\infty)]/2 = \nu_2(\hat{A}).\end{aligned}$$

Therefore, $\nu_2(\hat{a},p) = \nu_2(\hat{A})$ for all $1 \leqslant p \leqslant \infty$. □

In the following, we shall discuss how to approximate the quantity $\rho_0(\hat{A},\infty)$.

PROPOSITION 4.5. *Let $\hat{A}, \widehat{A_j} \in L_\infty(\mathbb{T})$, $j \in \mathbb{N}$ such that $\lim_{j\to\infty} \|\widehat{A_j} - \hat{A}\|_{L_\infty(\mathbb{T})} = 0$. Then*

$$\limsup_{j\to\infty} \rho_0(\widehat{A_j},\infty) \leqslant \rho_0(\hat{A},\infty). \tag{4.13}$$

If in addition $|\hat{A}(\xi)| \leqslant |\widehat{A_j}(\xi)|$ for almost every $\xi \in \mathbb{R}$ and for all $j \in \mathbb{N}$, then

$$\lim_{j\to\infty} \rho_0(\widehat{A_j},\infty) = \rho_0(\hat{A},\infty). \tag{4.14}$$

Proof. By Proposition 7.1, $\rho_0(\hat{A},\infty) = \inf_{n\in\mathbb{N}} \|T_{\hat{A}}^n 1\|_{L_\infty(\mathbb{T})}$. Therefore, for any $\varepsilon > 0$, there exists a positive integer N such that $\|T_{\hat{A}}^N 1\|_{L_\infty(\mathbb{T})}^{1/N} < \rho_0(\hat{A},\infty) + \varepsilon$. Now by $\lim_{j\to\infty} \|\widehat{A_j} - \hat{A}\|_{L_\infty(\mathbb{T})} = 0$, there exists a positive integer J such that

$$\|T_{\widehat{A_j}}^N 1\|_{L_\infty(\mathbb{T})}^{1/N} < \rho_0(\hat{A},\infty) + \varepsilon \qquad \forall\, j \geqslant J.$$

Consequently, by Proposition 7.1, we deduce that

$$\rho_0(\widehat{A_j},\infty) = \inf_{n\in\mathbb{N}} \|T_{\widehat{A_j}}^n 1\|_{L_\infty(\mathbb{T})}^{1/n} \leqslant \|T_{\widehat{A_j}}^N 1\|_{L_\infty(\mathbb{T})}^{1/N} < \rho_0(\hat{A},\infty) + \varepsilon \qquad \forall\, j \geqslant J.$$

Hence, we have $\limsup_{j\to\infty} \rho_0(\widehat{A_j},\infty) \leqslant \rho_0(\hat{A},\infty) + \varepsilon$. Taking $\varepsilon \to 0$, we conclude that (4.13) holds. If $|\hat{A}| \leqslant |\widehat{A_j}|$, then by Lemma 4.3, $\rho_0(\hat{A},\infty) \leqslant \rho_0(\widehat{A_j},\infty)$ for all $j \in \mathbb{N}$. Therefore, $\rho_0(\hat{A},\infty) \leqslant \liminf_{j\to\infty} \rho_0(\widehat{A_j},\infty)$. Now it follows from (4.13) that (4.14) holds. □

As a consequence of Proposition 4.5, we have the following corollary.

COROLLARY 4.6. *Let $\hat{A} \in C^\beta(\mathbb{T})$ with $\hat{A}(0) \neq 0$, $\hat{A}(\pi) \neq 0$, and $\beta > 0$. Suppose that there is a sequence $\{\widehat{A_j}\}_{j\in\mathbb{N}}$ in $C^\beta(\mathbb{T})$ such that $\lim_{j\to\infty} \|\widehat{A_j} - \hat{A}\|_{L_\infty(\mathbb{T})} = 0$, and*

$|\hat{A}(\xi)| \leqslant |\widehat{A_j}(\xi)|$ *for all* $\xi \in \mathbb{R}$ *and* $j \in \mathbb{N}$. *For* $\tau \geqslant 0$ *and a* 2π*-periodic trigonometric polynomial* $\hat{c}$ *with* $\hat{c}(0) \neq 0$, *let* $\hat{a}(\xi) := (1+e^{-i\xi})^\tau \hat{c}(\xi)\hat{A}(\xi)$ *and* $\widehat{a_j}(\xi) := (1+e^{-i\xi})^\tau \hat{c}(\xi)\widehat{A_j}(\xi)$. *Then* $\lim_{j\to\infty} \nu_2(\widehat{a_j}) = \nu_2(\hat{a})$ *and* $\nu_2(\widehat{a_j}) \leqslant \nu_2(\hat{a})$ *for all* $j \in \mathbb{N}$.

Proof. Write $\hat{c}(\xi) = (1+e^{-i\xi})^k \hat{B}(\xi)$ for some nonnegative integer k and some 2π-periodic trigonometric polynomial $\hat{B}$ with $\hat{B}(\pi) \neq 0$. Since $\hat{A}(\pi) \neq 0$ and $\lim_{j\to\infty} \|\widehat{A_j} - \hat{A}\|_{L_\infty(\mathbb{T})} = 0$, by $\widehat{A_j} \in C^\beta(\mathbb{T})$, we have $\widehat{A_j}(\pi) \neq 0$ for sufficiently large j. Now by Theorem 4.1 and Proposition 4.5, we have

$$\begin{aligned}\rho(\hat{a},\infty) = \rho_{2k+2\tau}(\hat{a},\infty) = \rho_0(\hat{A}\hat{B},\infty) &= \lim_{j\to\infty} \rho_0(\widehat{A_j}\hat{B},\infty)\\ &= \lim_{j\to\infty} \rho_{2k+2\tau}(\widehat{a_j},\infty) = \lim_{j\to\infty} \rho(\widehat{a_j},\infty).\end{aligned}$$

It follows from the definition of $\nu_2(\hat{a})$ that $\nu_2(\hat{a}) = \lim_{j\to\infty} \nu_2(\widehat{a_j})$. Now by $|\hat{a}(\xi)| \leqslant |\widehat{a_j}(\xi)|$, it follows from Lemma 4.3 that $\nu_2(\widehat{a_j}) \leqslant \nu_2(\hat{a})$. □

PROPOSITION 4.7. *Let* $\hat{a}$ *and* $\widehat{a_j}$, $j \in \mathbb{N}$, *be* 2π*-periodic measurable functions such that*

$$\lim_{j\to\infty} \|\widehat{a_j}/\hat{a}\|_{L_\infty(\mathbb{T})} = \lim_{j\to\infty} \|\hat{a}/\widehat{a_j}\|_{L_\infty(\mathbb{T})} = 1, \tag{4.15}$$

where by convention $(\widehat{a_j}/\hat{a})(\xi)$ *is equal to* $\widehat{a_j}(\xi)/\hat{a}(\xi)$ *if* $\hat{a}(\xi) \neq 0$, 1 *if* $\hat{a}(\xi) = \widehat{a_j}(\xi) = 0$, *or* $+\infty$ *if* $\hat{a}(\xi) = 0$ *but* $\widehat{a_j}(\xi) \neq 0$. *Then*

$$\lim_{j\to\infty} \nu_2(\widehat{a_j},p) = \nu_2(\hat{a},p) \qquad \forall\, 1 \leqslant p \leqslant \infty. \tag{4.16}$$

Moreover, if $\nu_2(\widehat{a_j},p) = \nu_2(\widehat{a_j})$ *for all* $j \in \mathbb{N}$, *then* $\nu_2(\hat{a},p) = \nu_2(\hat{a})$. *In particular, if a mask* $\hat{a}$ *has exponential decay, then* $\nu_2(\hat{a},p) = \nu_2(\hat{a})$ *for all* $1 \leqslant p \leqslant \infty$.

Proof. Denote $\widehat{c_j} = \widehat{a_j}/\hat{a}$. By convention and (4.15), $0 < |\widehat{c_j}(\xi)| < \infty$ for almost every $\xi \in \mathbb{R}$, and it is easy to check that $\widehat{a_j}(\xi) = \widehat{c_j}(\xi)\hat{a}(\xi)$ and $\hat{a}(\xi) = \widehat{a_j}(\xi)/\widehat{c_j}(\xi)$ for almost every $\xi \in \mathbb{R}$. For $\tau \geqslant 0$, we now have

$$\begin{aligned}\|1/\widehat{c_j}\|_{L_\infty(\mathbb{T})}^{-2n}[T_{\hat{a}}^n(|\sin(\cdot/2)|^\tau)](\xi) &\leqslant [T_{\widehat{a_j}}^n(|\sin(\cdot/2)|^\tau)](\xi)\\ &\leqslant \|\widehat{c_j}\|_{L_\infty(\mathbb{T})}^{2n}[T_{\hat{a}}^n(|\sin(\cdot/2)|^\tau)](\xi).\end{aligned}$$

Consequently, we have

$$\begin{aligned}\|1/\widehat{c_j}\|_{L_\infty(\mathbb{T})}^{-2}\|T_{\hat{a}}^n(|\sin(\cdot/2)|^\tau)\|_{L_p(\mathbb{T})}^{1/n} &\leqslant \|T_{\widehat{a_j}}^n(|\sin(\cdot/2)|^\tau)\|_{L_p(\mathbb{T})}^{1/n}\\ &\leqslant \|\widehat{c_j}\|_{L_\infty(\mathbb{T})}^2\|T_{\hat{a}}^n(|\sin(\cdot/2)|^\tau)\|_{L_p(\mathbb{T})}^{1/n}.\end{aligned}$$

Hence, we deduce that

$$\|1/\widehat{c_j}\|_{L_\infty(\mathbb{T})}^{-2}\rho_\tau(\hat{a},p) \leqslant \rho_\tau(\widehat{a_j},p) \leqslant \|\widehat{c_j}\|_{L_\infty(\mathbb{T})}^2\rho_\tau(\hat{a},p) \qquad \forall\, j \in \mathbb{N}, 1 \leqslant p \leqslant \infty. \tag{4.17}$$

By our assumption in (4.15), we have $\lim_{j\to\infty} \|1/\widehat{c_j}\|_{L_\infty(\mathbb{T})} = \lim_{j\to\infty} \|\widehat{c_j}\|_{L_\infty(\mathbb{T})} = 1$. Now by the definition of $\nu_2(\hat{a})$ and (4.17), we must have $\lim_{j\to\infty} \nu_2(\widehat{a_j},p) = \nu_2(\hat{a},p)$ for all $1 \leqslant p \leqslant \infty$.

If $\nu_2(\widehat{a_j},p) = \nu_2(\widehat{a_j})$, then $\nu_2(\hat{a},p) = \lim_{j\to\infty} \nu_2(\widehat{a_j},p) = \lim_{j\to\infty} \nu_2(\widehat{a_j}) = \nu_2(\hat{a})$.

If $\hat{a}$ has exponential decay, then we can write $\hat{a}(\xi) = \hat{c}(\xi)\hat{A}(\xi)$, where $\hat{c}$ is a 2π-periodic trigonometric polynomial and $\hat{A}$ has exponential decay satisfying $\hat{A}(\xi) \neq 0$

for all $\xi \in \mathbb{R}$. Now it is easy to see that there is a sequence $\{\widehat{A_j}\}_{j=1}^{\infty}$ of 2π-periodic trigonometric polynomials such that $\lim_{j\to\infty} \|\widehat{A_j}/\hat{A}\|_{L_\infty(\mathbb{T})} = \lim_{j\to\infty} \|\hat{A}/\widehat{A_j}\|_{L_\infty(\mathbb{T})} = 1$. Taking $\widehat{a_j}(\xi) := \hat{c}(\xi)\widehat{A_j}(\xi)$, then (4.15) holds, and by Lemma 4.4, $\nu_2(\widehat{a_j}, p) = \nu_2(\widehat{a_j})$ for all $1 \leqslant p \leqslant \infty$ and $j \in \mathbb{N}$. By what has been proved, we have $\nu_2(\hat{a}, p) = \lim_{j\to\infty} \nu_2(\widehat{a_j}, p) = \lim_{j\to\infty} \nu_2(\widehat{a_j}) = \nu_2(\hat{a})$. □

In passing, we mention that the quantity defined in [14, equation (2.16)] corresponds to $\nu_2(\hat{a}, 1)$ in (4.2) of this paper. For a mask with exponential decay, by Proposition 4.7, the quantity $\nu_2(\hat{a})$ in [14, equation (2.16)] agrees with the one in this paper. However, it is not clear whether $\nu_2(\hat{a}, p) = \nu_2(\hat{a})$ for all $1 \leqslant p \leqslant \infty$ if $\hat{a} \in C^\beta(\mathbb{T})$ for some $\beta > 0$.

5. Proof of Theorem 2.1. Since $\hat{a}(0) = 1$ and $\hat{a} \in C^\beta(\mathbb{T})$ with $\beta > 0$, we see that $\hat{\phi}$ in (1.2) is well defined and $\hat{\phi}$ is continuous. If $\{f_n\}_{n=1}^{\infty}$ is a Cauchy sequence in $L_{2,\infty,0}(\mathbb{R})$ and $\lim_{n\to\infty} \hat{f}(2^{-n}\xi) = 1$ for almost every $\xi \in \mathbb{R}$, by $\hat{\phi}(\xi) = \lim_{n\to\infty} \widehat{f_n}(\xi)$ for almost every $\xi \in \mathbb{R}$, then we must have $\phi \in L_{2,\infty,0}(\mathbb{R})$ and $\lim_{n\to\infty} \|f_n - \phi\|_{L_{2,\infty,0}(\mathbb{R})} = 0$.

We shall prove in the order that (i)⇒(ii)⇒(iii)⇒(iv) ⇒(v)⇒(ii) and (iii)⇒(i). Note that $\hat{a} \in C^\beta(\mathbb{T})$ implies $\hat{a} \in C^{\min(1,\beta)}(\mathbb{T})$. So, without loss of generality, we replace β by $\min(1, \beta)$. That is, we assume $0 < \beta \leqslant 1$, and the following proof depends only on the fact that $\hat{a} \in C^\alpha(\mathbb{T})$ for a small number $\alpha > 0$.

We show (i)⇒(ii) by constructing an admissible function η in $L_{2,\infty,0}(\mathbb{R})$ such that the shifts of η are stable in $L_2(\mathbb{R})$ and $\hat{\eta}$ is compactly supported; such an admissible initial function η will be used in several places in this proof. Since $\hat{\phi}$ is a continuous function with $\hat{\phi}(0) = 1$, there exists $0 < \varepsilon < \pi$ such that $1/2 \leqslant |\hat{\phi}(\xi)| \leqslant 3/2$ for all $|\xi| \leqslant \varepsilon$. Define a function $\hat{\eta}$ by

$$\hat{\eta}(\xi) := \begin{cases} \hat{\phi}(\xi) & \text{if } |\xi| \leqslant \varepsilon, \\ \hat{\phi}(-\varepsilon)(3\pi + 2\xi)/(3\pi - 2\varepsilon) & \text{if } -3\pi/2 \leqslant \xi < -\varepsilon, \\ \hat{\phi}(\varepsilon)(3\pi - 2\xi)/(3\pi - 2\varepsilon) & \text{if } \varepsilon < \xi \leqslant 3\pi/2, \\ 0 & \text{otherwise.} \end{cases} \tag{5.1}$$

Note that $\hat{\eta}(\xi) - \hat{a}(\xi/2)\hat{\eta}(\xi/2) = 0$ for all $|\xi| \leqslant \varepsilon$. By the assumption $\hat{a}(\pi) = 0$ in (i) and $\hat{a} \in C^\beta(\mathbb{T})$, we see that $|\hat{a}(\cdot + \pi)|^2/|\sin(\cdot/2)|^{2\beta} \in L_\infty(\mathbb{T})$. Since $\hat{\eta}$ is supported inside $[-3\pi/2, 3\pi/2]$, now we can easily verify that η is an admissible function in $L_{2,\infty,0}(\mathbb{R})$ with respect to $\hat{a}$, since the condition in (2.1) holds with $\tau = 2\beta > 0$. By the definition of $\hat{\eta}$, we have $1/32 \leqslant [\hat{\eta}, \hat{\eta}] \leqslant 9/2$. Therefore, the shifts of η are stable in $L_2(\mathbb{R})$. Taking $f = \eta$, it follows directly from (i) that (ii) holds.

Now we prove (ii)⇒(iii) without the condition that the initial function f is admissible. By the definition of f_n in (2.2) and induction, we deduce that

$$[\widehat{f_n}, \widehat{f_n}](\xi) = \sum_{k=0}^{2^n-1} \prod_{j=1}^{n} |\hat{a}(2^{-j}(\xi + 2\pi k))|^2 [\hat{f}, \hat{f}](2^{-n}(\xi + 2\pi k)) = (T_{\hat{a}}^n [\hat{f}, \hat{f}])(\xi). \tag{5.2}$$

Since the shifts of f are stable in $L_2(\mathbb{R})$ and $\{f_n\}_{n=1}^{\infty}$ is a Cauchy sequence in $L_{2,\infty,0}(\mathbb{R})$, there exists a positive constant C_1 such that

$$\|f_n\|^2_{L_{2,\infty,0}(\mathbb{R})} = \|[\widehat{f_n}, \widehat{f_n}]\|_{L_\infty(\mathbb{T})} \leqslant C_1$$

for all $n \in \mathbb{N}$ and $1/C_1 \leqslant [\hat{f}, \hat{f}](\xi) \leqslant C_1$ for almost every $\xi \in \mathbb{R}$. Now it follows from (5.2) that

$$0 \leqslant [T_{\hat{a}}^n 1](\xi) \leqslant C_1 (T_{\hat{a}}^n C_1^{-1})(\xi) \leqslant C_1 (T_{\hat{a}}^n [\hat{f}, \hat{f}])(\xi) = C_1 [\widehat{f_n}, \widehat{f_n}](\xi) \leqslant C_1^2.$$

That is, we have

$$\|T_{\hat{a}}^n 1\|_{L_\infty(\mathbb{T})} \leqslant C_1^2 \qquad \forall\, n \in \mathbb{N} \cup \{0\}. \tag{5.3}$$

Since $\hat{a} \in C^\beta(\mathbb{T})$, we have $|\hat{a}|^2 \in C^\beta(\mathbb{T})$, and there exists a positive constant C_2 such that

$$\big\| |\hat{a}|^2 - |\hat{a}(\cdot - h)|^2 \big\|_{L_\infty(\mathbb{T})} \leqslant C_2 h^\beta \qquad \forall\, h > 0. \tag{5.4}$$

Now we are going to extend an interesting idea in [23] to show that $T_{\hat{a}}^n g$, $n \in \mathbb{N}$, are equicontinuous if $g \in C^\tau(\mathbb{T})$ for some $\tau > 0$. For $g \in L_\infty(\mathbb{T})$, we denote

$$\omega_n(\xi, h) := \left| [T_{\hat{a}}^n g](\xi) - [T_{\hat{a}}^n g](\xi - h) \right|, \qquad \xi \in \mathbb{R}, h > 0, n \in \mathbb{N} \cup \{0\}. \tag{5.5}$$

Setting

$$C_3 := \max(C_1^2, 2^{1-\beta} C_1^4 C_2/(1 - 2^{-\beta})) < \infty,$$

we show that (5.3) and (5.4) imply that

$$\|h^{-\beta} \omega_{n+k}(\cdot, h)\|_{L_\infty(\mathbb{T})} \leqslant C_3 \Big(2^{-n\beta} \|(2^{-n}h)^{-\beta} \omega_k(\cdot, 2^{-n}h)\|_{L_\infty(\mathbb{T})} + \|T_{\hat{a}}^k g\|_{L_\infty(\mathbb{T})} \Big)$$

$$\forall\, h > 0,\ k, n \in \mathbb{N} \cup \{0\}, g \in L_\infty(\mathbb{T}). \tag{5.6}$$

By the definition of $T_{\hat{a}}$, we have

$$\begin{aligned}
&[T_{\hat{a}}^n g](\xi) - [T_{\hat{a}}^n g](\xi - h) \\
&\quad = |\hat{a}(\xi/2)|^2 \left([T_{\hat{a}}^{n-1} g](\xi/2) - [T_{\hat{a}}^{n-1} g](\xi/2 - h/2) \right) \\
&\qquad + |\hat{a}(\xi/2 + \pi)|^2 \left([T_{\hat{a}}^{n-1} g](\xi/2 + \pi) - [T_{\hat{a}}^{n-1} g](\xi/2 + \pi - h/2) \right) \\
&\qquad + \left(|\hat{a}(\xi/2)|^2 - |\hat{a}(\xi/2 - h/2)|^2 \right) [T_{\hat{a}}^{n-1} g](\xi/2 - h/2) \\
&\qquad + \left(|\hat{a}(\xi/2 + \pi)|^2 - |\hat{a}(\xi/2 + \pi - h/2)|^2 \right) [T_{\hat{a}}^{n-1} g](\xi/2 + \pi - h/2).
\end{aligned}$$

It follows from (5.4) that

$$\begin{aligned}
\omega_n(\xi, h) &\leqslant |\hat{a}(\xi/2)|^2 \omega_{n-1}(\xi/2, h/2) + |\hat{a}(\xi/2 + \pi)|^2 \omega_{n-1}(\xi/2 + \pi, h/2) \\
&\qquad + 2C_2 (h/2)^\beta \|T_{\hat{a}}^{n-1} g\|_{L_\infty(\mathbb{T})} \\
&= [T_{\hat{a}} \omega_{n-1}(\cdot, h/2)](\xi) + 2^{1-\beta} C_2 h^\beta \|T_{\hat{a}}^{n-1} g\|_{L_\infty(\mathbb{T})}.
\end{aligned}$$

Consequently, by induction on n, we deduce from the above inequality that for all $k, n \in \mathbb{N} \cup \{0\}$,

$$\begin{aligned}
\omega_{n+k}(\xi, h) &\leqslant [T_{\hat{a}}^n \omega_k(\cdot, 2^{-n}h)](\xi) \\
&\qquad + 2C_2 h^\beta \sum_{j=1}^{n} 2^{-j\beta} \|T_{\hat{a}}^{n+k-j} g\|_{L_\infty(\mathbb{T})} \|T_{\hat{a}}^{j-1} 1\|_{L_\infty(\mathbb{T})}.
\end{aligned} \tag{5.7}$$

In fact, (5.7) clearly holds for $n=0$ and all $k\in\mathbb{N}\cup\{0\}$. Suppose that (5.7) holds for n and all $k\in\mathbb{N}\cup\{0\}$. Then by induction hypothesis we have

$$\begin{aligned}\omega_{n+1+k}(\xi,h)&\leqslant[T_{\hat{a}}^n\omega_{k+1}(\cdot,2^{-n}h)](\xi)\\&\quad+2C_2h^\beta\sum_{j=1}^n2^{-j\beta}\|T_{\hat{a}}^{n+k+1-j}g\|_{L_\infty(\mathbb{T})}\|T_{\hat{a}}^{j-1}1\|_{L_\infty(\mathbb{T})}.\end{aligned}$$

Note that we proved in the inequality above (5.7) that

$$\omega_{k+1}(\xi,2^{-n}h)\leqslant[T_{\hat{a}}\omega_k(\cdot,2^{-1-n}h)](\xi)+2^{1-\beta}C_2(2^{-n}h)^\beta\|T_{\hat{a}}^kg\|_{L_\infty(\mathbb{T})}.$$

Applying the operator $T_{\hat{a}}^n$ on both sides of the above inequality, we deduce that

$$T_{\hat{a}}^n\omega_{k+1}(\xi,2^{-n}h)\leqslant[T_{\hat{a}}^{n+1}\omega_k(\cdot,2^{-1-n}h)](\xi)+2^{1-\beta}C_2(2^{-n}h)^\beta\|T_{\hat{a}}^kg\|_{L_\infty(\mathbb{T})}[T_{\hat{a}}^n1](\xi).$$

Combining all the above inequalities together, we see that (5.7) holds for $n+1$ and all $k\in\mathbb{N}\cup\{0\}$. So, by induction, (5.7) holds for all $k,n\in\mathbb{N}\cup\{0\}$.

By (5.3), we have

$$\|T_{\hat{a}}^{n+k-j}g\|_{L_\infty(\mathbb{T})}\leqslant\|T_{\hat{a}}^{n-j}1\|_{L_\infty(\mathbb{T})}\|T_{\hat{a}}^kg\|_{L_\infty(\mathbb{T})}\leqslant C_1^2\|T_{\hat{a}}^kg\|_{L_\infty(\mathbb{T})}$$

and

$$\|T_{\hat{a}}^n\omega_k(\cdot,2^{-n}h)\|_{L_\infty(\mathbb{T})}\leqslant\|T_{\hat{a}}^n1\|_{L_\infty(\mathbb{T})}\|\omega_k(\cdot,2^{-n}h)\|_{L_\infty(\mathbb{T})}\leqslant C_1^2\|\omega_k(\cdot,2^{-n}h)\|_{L_\infty(\mathbb{T})}.$$

Therefore, we deduce from (5.7) that

$$\begin{aligned}\|\omega_{n+k}(\cdot,h)\|_{L_\infty(\mathbb{T})}&\leqslant C_1^2\|\omega_k(\cdot,2^{-n}h)\|_{L_\infty(\mathbb{T})}+2C_1^4C_2h^\beta\|T_{\hat{a}}^kg\|_{L_\infty(\mathbb{T})}\sum_{j=1}^\infty2^{-j\beta}\\&\leqslant C_3\left(\|\omega_k(\cdot,2^{-n}h)\|_{L_\infty(\mathbb{T})}+h^\beta\|T_{\hat{a}}^kg\|_{L_\infty(\mathbb{T})}\right).\end{aligned}$$

That is, (5.6) has been proved. In particular, for any $\tau>0$, we take $g(\xi)=|\sin(\xi/2)|^\tau$ and $\nu:=\min(\beta,\tau)>0$. By Proposition 4.2, $g\in C^\nu(\mathbb{T})$. It is evident that $\|T_{\hat{a}}^0g\|_{L_\infty(\mathbb{T})}=\|g\|_{L_\infty(\mathbb{T})}=1$. By $g\in C^\nu(\mathbb{T})$, there exists a positive constant C_4 such that

$$(2^{-n}h)^{-\nu}\omega_0(\xi,2^{-n}h)=(2^{-n}h)^{-\nu}|g(\xi)-g(\xi-2^{-n}h)|\leqslant C_4. \tag{5.8}$$

Since $0<\nu\leqslant\beta$, we see that (5.4) holds with β being replaced by ν (now the constant C_2 in (5.4) may be different). That is, for all $k,n\in\mathbb{N}\cup\{0\}$ and $h>0$, (5.6) becomes

$$\begin{aligned}&\|h^{-\nu}\omega_{n+k}(\cdot,h)\|_{L_\infty(\mathbb{T})}\\&\quad\leqslant C_3\Big(2^{-n\nu}\|(2^{-n}h)^{-\nu}\omega_k(\cdot,2^{-n}h)\|_{L_\infty(\mathbb{T})}+\|T_{\hat{a}}^kg\|_{L_\infty(\mathbb{T})}\Big).\end{aligned} \tag{5.9}$$

Setting $k=0$ in (5.9), we deduce that

$$\|h^{-\nu}\omega_n(\cdot,h)\|_{L_\infty(\mathbb{T})}\leqslant C_3(2^{-n\nu}C_4+1)\leqslant C_3(C_4+1)<\infty\qquad\forall\,h>0,n\in\mathbb{N}. \tag{5.10}$$

By the definition of $\omega_n(\xi,h)$ in (5.5), this is equivalent to saying that

$$|[T_{\hat{a}}^ng](\xi_1)-[T_{\hat{a}}^ng](\xi_2)|\leqslant C_3(C_4+1)|\xi_1-\xi_2|^\nu\qquad\forall\,n\in\mathbb{N},\xi_1,\xi_2\in\mathbb{R}.$$

Note that $\hat{a}$ is continuous and $\|T_{\hat{a}}^n g\|_{L_\infty(\mathbb{T})} \leqslant \|T_{\hat{a}}^n 1\|_{L_\infty(\mathbb{T})}\|g\|_{L_\infty(\mathbb{T})} \leqslant C_1^2$. So, the sequence $\{T_{\hat{a}}^n g\}_{n=1}^\infty$ is bounded and equicontinuous in $C(\mathbb{T})$. By the Arzela–Ascoli theorem, there is a subsequence $\{T_{\hat{a}}^{n_k} g\}_{k=1}^\infty$ converging to $g_\infty \in C(\mathbb{T})$ as $k \to \infty$; that is,

$$\lim_{k\to\infty} \|T_{\hat{a}}^{n_k} g - g_\infty\|_{C(\mathbb{T})} = 0. \tag{5.11}$$

Since all $T_{\hat{a}}^{n_k} g \geqslant 0$, we must have $g_\infty \geqslant 0$. Now we show that if (ii) holds, then we must have $g_\infty \equiv 0$. Define

$$\begin{aligned} g_n(\xi) &:= g(2^{-n}\xi)|\widehat{f_n}(\xi)|^2 = |\sin(2^{-1-n}\xi)|^\tau |\widehat{f_n}(\xi)|^2 \\ &= |\sin(2^{-1-n}\xi)|^\tau |\hat{f}(2^{-n}\xi)|^2 \prod_{j=1}^n |\hat{a}(2^{-j}\xi)|^2. \end{aligned}$$

By induction, we observe that $[g_n, g_n] = T_{\hat{a}}^n([\hat{f}, \hat{f}]g)$ for all $n \in \mathbb{N}$. Since $[\hat{f}, \hat{f}] \geqslant 1/C_1$, we conclude that

$$[T_{\hat{a}}^n g](\xi) \leqslant C_1[T_{\hat{a}}^n([\hat{f}, \hat{f}]g)](\xi) = C_1[g_n, g_n](\xi).$$

Therefore,

$$\int_0^{2\pi} [T_{\hat{a}}^n g](\xi)\, d\xi \leqslant C_1 \int_0^{2\pi} [g_n, g_n](\xi)\, d\xi = C_1 \int_{\mathbb{R}} g(2^{-n}\xi)|\widehat{f_n}(\xi)|^2\, d\xi. \tag{5.12}$$

By $g(\xi) = |\sin(\xi/2)|^\tau$ and $\tau > 0$, we have $\lim_{n\to\infty} g(2^{-n}\xi) = g(0) = 0$. Since $\hat{a} \in C^\beta(\mathbb{T})$ with $\hat{a}(0) = 1$, we have $\lim_{n\to\infty} \prod_{j=1}^n |\hat{a}(2^{-j}\xi)|^2 = |\hat{\phi}(\xi)|^2$. Observing that

$$\begin{aligned} 0 \leqslant g(2^{-n}\xi)|\widehat{f_n}(\xi)|^2 &= g(2^{-n}\xi)|\hat{f}(2^{-n}\xi)|^2 \prod_{j=1}^n |\hat{a}(2^{-j}\xi)|^2 \\ &\leqslant \|f\|_{L_{2,\infty,0}}^2(\mathbb{R}) g(2^{-n}\xi) \prod_{j=1}^n |\hat{a}(2^{-j}\xi)|^2, \end{aligned}$$

we see that $\lim_{n\to\infty} g(2^{-n}\xi)|\widehat{f_n}(\xi)|^2 = 0$ for almost every $\xi \in \mathbb{R}$.

Since $\{f_n\}_{n=1}^\infty$ is a Cauchy sequence in $L_{2,\infty,0}(\mathbb{R})$, the sequence $\{f_n\}_{n=1}^\infty$ must also be a Cauchy sequence in $L_2(\mathbb{R})$ by $\|f\|_{L_2(\mathbb{R})} \leqslant \|f\|_{L_{2,\infty,0}(\mathbb{R})}$. Consequently,

$$\lim_{n\to\infty} \int_{\mathbb{R}} |\widehat{f_n}(\xi)|^2\, d\xi = \lim_{n\to\infty} \int_0^{2\pi} [\widehat{f_n}, \widehat{f_n}](\xi)\, d\xi$$

exists and is finite. Now by $0 \leqslant g(2^{-n}\xi)|\widehat{f_n}(\xi)|^2 \leqslant |\widehat{f_n}(\xi)|^2$ and the generalized Lebesgue dominated convergence theorem, we conclude that

$$\lim_{n\to\infty} \int_{\mathbb{R}} g(2^{-n}\xi)|\widehat{f_n}(\xi)|^2\, d\xi = \int_{\mathbb{R}} \lim_{n\to\infty} g(2^{-n}\xi)|\widehat{f_n}(\xi)|^2\, d\xi = \int_{\mathbb{R}} 0\, d\xi = 0.$$

Hence, by (5.12), we get

$$\lim_{n\to\infty} \int_0^{2\pi} [T_{\hat{a}}^n g](\xi)\, d\xi = 0. \tag{5.13}$$

Now it follows from (5.11) and (5.13) that

$$\int_0^{2\pi} g_\infty(\xi)\,d\xi = \lim_{k\to\infty}\int_0^{2\pi} [T_{\hat a}^{n_k} g](\xi)\,d\xi = 0.$$

Since $g_\infty \geqslant 0$, we must have $g_\infty = 0$. That is, (5.11) becomes

$$\lim_{k\to\infty} \|T_{\hat a}^{n_k} g\|_{L_\infty(\mathbb{T})} = 0. \tag{5.14}$$

Setting $k = n_k$ in (5.9), by (5.10), we deduce that

$$\|h^{-\nu}\omega_{n+n_k}(\cdot,h)\|_{L_\infty(\mathbb{T})} \leqslant C_3(2^{-n\nu}C_3(C_4+1) + \|T_{\hat a}^{n_k} g\|_{L_\infty(\mathbb{T})}).$$

So, when n and k are large enough, by (5.14) and $\nu > 0$, setting $N = n + n_k$, we must have

$$h^{-\nu}\omega_N(\xi,h) \leqslant \pi^{-\nu} \qquad \forall\, \xi \in \mathbb{R}, h > 0.$$

In particular, setting $\xi = 0$ or $-h$ in the above inequality, we have

$$\big|[T_{\hat a}^N g](h) - [T_{\hat a}^N g](0)\big| \leqslant \pi^{-\nu}|h|^\nu \qquad \forall\, h \in \mathbb{R}.$$

By (5.13) and Proposition 4.2, we see that $\hat a(\pi) = 0$. Since $g(0) = \hat a(\pi) = 0$, by induction, one can verify that $[T_{\hat a}^n g](0) = 0$ for all $n \in \mathbb{N}$. Therefore, it follows from the above inequality that

$$\frac{[T_{\hat a}^N g](h)}{|\sin(h/2)|^\nu} \leqslant (\pi/2)^\nu \frac{[T_{\hat a}^N g](h)}{|h|^\nu} \leqslant 2^{-\nu} < 1 \qquad \forall\, h \in [-\pi,\pi]\backslash\{0\}.$$

In order to show that (ii)⇒(iii), by Proposition 4.2, it suffices to show $\rho_\tau(\hat a,\infty) < 1$ for sufficiently small $\tau > 0$. Since $\hat a \in C^\beta(\mathbb{T})$ with $\beta > 0$, we must have $|\hat a(\cdot+\pi)|^2/|\sin(\cdot/2)|^{2\beta} \in L_\infty(\mathbb{T})$. So, for any $0 < \tau < \beta$, by $\nu = \min(\beta,\tau)$, we have $\nu = \tau$, and by Theorem 4.1, we must have

$$\rho_\tau(\hat a,\infty) = \inf_{n\in\mathbb{N}} \|[T_{\hat a}^n g]/g\|_{L_\infty(\mathbb{T})}^{1/n} \leqslant \big\|[T_{\hat a}^N g]/g\big\|_{L_\infty(\mathbb{T})}^{1/N} \leqslant 2^{-\nu/N} < 1.$$

So, (iii) holds for all $0 < \tau < \beta$, and therefore (iii) holds for all $\tau > 0$. Hence, (ii)⇒(iii).

By (iii) and Proposition 4.2, we have $\hat a(\pi) = 0$. So, it follows from $\hat a \in C^\beta(\mathbb{T})$ that $|\hat a(\cdot+\pi)|^2/|\sin(\cdot/2)|^{2\beta} \in L_\infty(\mathbb{T})$. Now it is straightforward to see that (iii)⇒(iv), since $\rho(\hat a) \leqslant \rho_{2\beta}(\hat a,\infty) < 1$.

By the definition of $\rho(\hat a)$, (iv) implies that $\rho_\tau(\hat a,\infty) < 1$ and $|\hat a(\cdot+\pi)|^2/|\sin(\cdot/2)|^\tau \in L_\infty(\mathbb{T})$ for some $\tau \geqslant 0$. On the other hand, since $\hat a(0) = 1$ and $\hat a$ is continuous, by $[T_{\hat a}^n 1](0) \geqslant |\hat a(0)|^n = 1$, we must have $\rho_0(\hat a,\infty) \geqslant 1$. Therefore, $\tau > 0$, and so (iv)⇒(v).

Now we show that (v)⇒(ii). By (v) and Proposition 4.2, $\hat a(\pi) = 0$ and $|\hat a(\cdot+\pi)|^2/|\sin(\cdot/2)|^\tau \in L_\infty(\mathbb{T})$. Let $\hat\eta$ be defined in (5.1). Then $\eta \in L_{2,\infty,0}(\mathbb{R})$ and the shifts of η are stable in $L_2(\mathbb{R})$. Consequently, it is easy to directly verify that

$$H := [\hat a(\cdot/2)\hat\eta(\cdot/2) - \hat\eta, \hat a(\cdot/2)\hat\eta(\cdot/2) - \hat\eta]/|\sin(\cdot/2)|^\tau \in L_\infty(\mathbb{T}). \tag{5.15}$$

So, η is an admissible function in $L_{2,\infty,0}(\mathbb{R})$ with respect to $\hat a$ such that the shifts of η are stable in $L_2(\mathbb{R})$. Taking $f = \eta$ and defining f_n as in (2.2), we show that $\{f_n\}_{n=1}^\infty$ is a Cauchy sequence in $L_{2,\infty,0}(\mathbb{R})$.

Note that

$$|\widehat{f_{n+1}}(\xi) - \widehat{f_n}(\xi)| = |\hat{a}(2^{-1-n}\xi)\hat{f}(2^{-1-n}\xi) - \hat{f}(2^{-n}\xi)| \prod_{j=1}^{n} |\hat{a}(2^{-j}\xi)|. \tag{5.16}$$

Consequently, we have

$$[\widehat{f_{n+1}} - \widehat{f_n}, \widehat{f_{n+1}} - \widehat{f_n}](\xi) = \left[T_{\hat{a}}^n([\hat{a}(\cdot/2)\hat{f}(\cdot/2) - \hat{f}, \hat{a}(\cdot/2)\hat{f}(\cdot/2) - \hat{f}])\right](\xi) \qquad \forall\, n \in \mathbb{N}.$$

By (5.15), we have

$$[\hat{a}(\cdot/2)\hat{f}(\cdot/2) - \hat{f}, \hat{a}(\cdot/2)\hat{f}(\cdot/2) - \hat{f}](\xi) = H(\xi)g(\xi)$$

and $H \in L_\infty(\mathbb{T})$, where $g(\xi) := |\sin(\xi/2)|^\tau$. Hence, we have

$$\|f_{n+1} - f_n\|^2_{L_{2,\infty,0}(\mathbb{R})} = \|[\widehat{f_{n+1}} - \widehat{f_n}, \widehat{f_{n+1}} - \widehat{f_n}]\|_{L_\infty(\mathbb{T})} \leqslant \|H\|_{L_\infty(\mathbb{T})} \|T_{\hat{a}}^n g\|_{L_\infty(\mathbb{T})}. \tag{5.17}$$

By our assumption in (v), we have $\rho_\tau(\hat{a}, \infty) < 1$, and therefore, for any ρ such that $\rho_\tau(\hat{a}, \infty) < \rho < 1$, there exists a positive constant C such that $\|T_{\hat{a}}^n g\|_{L_\infty(\mathbb{T})} \leqslant C\rho^n$ for all $n \in \mathbb{N}$. Now it follows from (5.17) that

$$\|f_{n+1} - f_n\|_{L_{2,\infty,0}(\mathbb{R})} \leqslant \|H\|^{1/2}_{L_\infty(\mathbb{T})} C^{1/2} \rho^{n/2} \qquad \forall\, n \in \mathbb{N}, \tag{5.18}$$

which yields, by $0 < \rho < 1$, that $\{f_n\}_{n=1}^\infty$ is a Cauchy sequence in $L_{2,\infty,0}(\mathbb{R})$. So, (v)⇒(ii).

Finally, we show that (iii)⇒(i). Let f be an admissible function in $L_{2,\infty,0}(\mathbb{R})$ with respect to $\hat{a}$ such that (2.1) holds for some $\tau > 0$. By Proposition 4.2 and (iii), we have $\hat{a}(\pi) = 0$. Now by $\hat{a} \in C^\beta(\mathbb{T})$, we must have $|\hat{a}(\cdot + \pi)|^2/|\sin(\cdot/2)|^{2\beta} \in L_\infty(\mathbb{T})$. Replacing τ by $\min(\tau, 2\beta)$, we see that (2.1) still holds and $|\hat{a}(\cdot + \pi)|^2/|\sin(\cdot/2)|^\tau \in L_\infty(\mathbb{T})$. By our assumption in (iii) and $\tau > 0$, we have $\rho_\tau(\hat{a}, \infty) < 1$. Now by the same proof for showing (v)⇒(ii), we see that $\{f_n\}_{n=1}^\infty$ is a Cauchy sequence in $L_{2,\infty,0}(\mathbb{R})$. Therefore, (iii)⇒(i).

Now we prove the rest of Theorem 2.1. Since $\nu_2(\hat{a}) > 0$, we must have $\hat{a}(\pi) = 0$, and (5.3) holds. Consequently,

$$\prod_{j=1}^{n} |\hat{a}(2^{-j}\xi)|^2 \leqslant \|T_{\hat{a}}^n 1\|_{L_\infty(\mathbb{T})} \leqslant C_1^2 \qquad \forall\, n \in \mathbb{N}, \xi \in \mathbb{R}. \tag{5.19}$$

Since $\hat{a} \in C^\beta(\mathbb{T})$ and since we assumed $0 < \beta \leqslant 1$, there exists a positive constant C such that $|\hat{a}(\xi_1) - \hat{a}(\xi_2)| \leqslant C|\xi_1 - \xi_2|^\beta$ for all $\xi_1, \xi_2 \in \mathbb{R}$. We deduce that

$$\begin{aligned}
|\hat{\phi}(\xi_1) - \hat{\phi}(\xi_2)| &= \left| \sum_{j=1}^{\infty} \left[\prod_{k=1}^{j-1} \hat{a}(2^{-k}\xi_1) \right] [\hat{a}(2^{-j}\xi_1) - \hat{a}(2^{-j}\xi_2)] \left[\prod_{\ell=j+1}^{\infty} \hat{a}(2^{-\ell}\xi_2) \right] \right| \\
&\leqslant \sum_{j=1}^{\infty} \left| \prod_{k=1}^{j-1} \hat{a}(2^{-k}\xi_1) \right| \times \left| \hat{a}(2^{-j}\xi_1) - \hat{a}(2^{-j}\xi_2) \right| \times \left| \prod_{\ell=j+1}^{\infty} \hat{a}(2^{-\ell}\xi_2) \right| \\
&\leqslant C_1^2 C \sum_{j=1}^{\infty} 2^{-j\beta} |\xi_1 - \xi_2|^\beta \leqslant |\xi_1 - \xi_2|^\beta C_1^2 C/(1 - 2^{-\beta}).
\end{aligned}$$

So, $\hat{\phi} \in \Lambda^\beta(\mathbb{R})$. Let $\hat{\eta}$ be defined in (5.1). Take $f = \eta$ and define f_n as in (2.2). Since $\nu_2(\hat{a}) > 0$, $\{f_n\}_{n=1}^\infty$ is a Cauchy sequence in $L_{2,\infty,0}(\mathbb{R})$. In particular, by $\lim_{n\to\infty} \widehat{f_n}(\xi) = \hat{\phi}(\xi)$, we have $\phi \in L_{2,\infty,0}(\mathbb{R})$ and $\lim_{n\to\infty} \|f_n - \phi\|_{L_{2,\infty,0}(\mathbb{R})} = 0$. By induction, we have $[\widehat{f_n}, \widehat{f_n}] = T_{\hat{a}}^n[\hat{f}, \hat{f}]$. Note that $[\widehat{f_n}, \widehat{f_n}]$ is continuous. Now define $g := [\hat{\eta}, \hat{\eta}]$. By the definition of $\hat{\eta}$ in (5.1) and $\hat{\phi} \in C^\beta(\mathbb{R})$, it is easy to check that $g \in C^\beta(\mathbb{T})$. Consequently, taking $k = 0$ in (5.6), wee see that a similar result as in (5.10) holds; that is, there exists a positive constant C_5 such that

$$h^{-\beta} \Big\| [\widehat{f_n}, \widehat{f_n}] - [\widehat{f_n}, \widehat{f_n}](\cdot - h) \Big\|_{L_\infty(\mathbb{T})} = h^{-\beta} \|\omega_n(\cdot, h)\|_{L_\infty(\mathbb{T})} \leqslant C_5 \qquad \forall\, h > 0, \tag{5.20}$$

where ω_n is defined in (5.5) and we used the fact $[\widehat{f_n}, \widehat{f_n}] = T_{\hat{a}}^n[\hat{f}, \hat{f}] = T_{\hat{a}}^n g$. Since $\lim_{n\to\infty} \|f_n - \phi\|_{L_{2,\infty,0}(\mathbb{R})} = 0$, we deduce that $\lim_{n\to\infty} \|[\widehat{f_n}, \widehat{f_n}] - [\hat{\phi}, \hat{\phi}]\|_{C(\mathbb{T})} = 0$. Now it follows from (5.20) that $\|[\hat{\phi}, \hat{\phi}] - [\hat{\phi}, \hat{\phi}](\cdot - h)\|_{C(\mathbb{T})} \leqslant C_5 h^\beta$ for all $h > 0$. So, $[\hat{\phi}, \hat{\phi}] \in \Lambda^\beta(\mathbb{T})$.

Now we prove (2.3). Since $0 \leqslant \nu < \nu_2(\hat{a})$, by the definition of $\nu_2(\hat{a})$, there exists $\tau > 0$ such that $\rho_\tau(\hat{a}, \infty) < 2^{-2\nu}$ and $|\hat{a}(\cdot + \pi)|^2/|\sin(\cdot/2)|^\tau \in L_\infty(\mathbb{T})$. Let $\hat{\eta}$ be defined in (5.1). Take $f = \eta$ and define f_n as in (2.2). As in the proof of (v)$\Rightarrow$(ii), we see that (5.18) holds for $\rho_\tau(\hat{a}, \infty) < \rho < 2^{-2\nu}$. Denote $g_n := \widehat{f_{n+1}} - \widehat{f_n}$ and

$$[g_n, g_n]_\nu(\xi) := \sum_{k\in\mathbb{Z}} |g_n(\xi + 2\pi k)|^2 (1 + |\xi + 2\pi k|^2)^\nu, \qquad \xi \in [-\pi, \pi].$$

Since $\hat{f} = \hat{\eta}$ is supported inside $[-3\pi/2, -\varepsilon] \cup [\varepsilon, 3\pi/2]$, it follows from (5.16) that g_n is supported inside $[-3\pi 2^n, -\varepsilon 2^n] \cup [\varepsilon 2^n, 3\pi 2^n]$. Therefore, for $\xi \in [-\pi, \pi]$, it follows from (5.18) that

$$\begin{aligned}
[g_n, g_n]_\nu(\xi) &= \sum_{|\xi+2\pi k| \leqslant 3\pi 2^n} |g_n(\xi + 2\pi k)|^2 (1 + |\xi + 2\pi k|^2)^\nu \\
&\leqslant (1 + (3\pi 2^n)^2)^\nu \sum_{k\in\mathbb{Z}} |g_n(\xi + 2\pi k)|^2 \\
&= (1 + (3\pi 2^n)^2)^\nu \|f_{n+1} - f_n\|^2_{L_{2,\infty,0}(\mathbb{R})} \leqslant C_6 (2^{2\nu}\rho)^n,
\end{aligned}$$

where $C_6 := 18^\nu \pi^{2\nu} C \|[h, h]\|_{L_\infty(\mathbb{T})} < \infty$. Since $[g_n, g_n]$ is continuous, we conclude that

$$[g_n, g_n]_\nu(\xi) \leqslant C_6 (2^{2\nu}\rho)^n \qquad \forall\, n \in \mathbb{N},\ \xi \in [-\pi, \pi]. \tag{5.21}$$

Since $\nu_2(\hat{a}) > 0$, we have $\phi = \eta + \sum_{n=0}^\infty (f_{n+1} - f_n)$ in $L_{2,\infty,0}(\mathbb{R})$ with $f_0 := \eta$. Since all $\hat{\phi}, \hat{\eta}$, and $g_n, n \in \mathbb{N}$, are continuous and g_n is supported inside $[-3\pi 2^n, -\varepsilon 2^n] \cup [\varepsilon 2^n, 3\pi 2^n]$, we must have $\hat{\phi}(\xi) = \hat{\eta}(\xi) + \sum_{n=0}^\infty g_n(\xi)$ for all $\xi \in \mathbb{R}$, where the series is in fact a finite sum for any ξ in any bounded set. Therefore, for all $\xi \in [-2\pi, 2\pi]$ and $N \geqslant 3$, we have

$$\begin{aligned}
\left(\sum_{|k|=N+1}^\infty (1 + |\xi + 2\pi k|^2)^\nu |\hat{\phi}(\xi + 2\pi k)|^2 \right)^{1/2} &\leqslant \sum_{n=\log_2(N/3)}^\infty [g_n, g_n]_\nu^{1/2}(\xi) \\
&\leqslant C_6^{1/2} \sum_{n=\log_2(N/3)}^\infty (2^\nu \rho^{1/2})^n \leqslant C_6^{1/2} (N/3)^{\log_2(2^\nu \rho^{1/2})} / (1 - 2^\nu \rho^{1/2}).
\end{aligned}$$

Since $2^\nu \rho^{1/2} < 1$, we have $\log_2(2^\nu \rho^{1/2}) < 0$, and therefore $\lim_{N\to\infty}(N/3)^{\log_2(2^\nu\rho^{1/2})} = 0$. Hence, the series $\sum_{k=-N}^{N}(1+|\xi+2\pi k|^2)^\nu |\hat\phi(\xi+2\pi k)|^2$ is uniformly convergent as $N\to\infty$ for all $\xi\in[-2\pi,2\pi]$. Since $\hat\phi$ is continuous, we conclude that $[\hat\phi,\hat\phi]_\nu \in C(\mathbb{T})$. That is, (2.3) holds. □

For a mask $\hat a \in C^\beta(\mathbb{T})$ with $\beta>0$, a more complicated argument can be used to show a stronger statement that $\hat\phi\in C^\beta(\mathbb{R})$ and $[\hat\phi,\hat\phi]\in C^\beta(\mathbb{T})$, instead of the result $\hat\phi\in\Lambda^{\min(1,\beta)}(\mathbb{R})$ and $[\hat\phi,\hat\phi]\in\Lambda^{\min(1,\beta)}(\mathbb{T})$ stated in Theorem 2.1. We shall address this technical issue elsewhere.

6. Proof of Theorem 2.3. Before we present the proof of Theorem 2.3, we need the two following auxiliary results.

PROPOSITION 6.1. *Let $f\in L_{2,1,\gamma_2}(\mathbb{R})$ with $\gamma_2>0$. Then for $0\leqslant\gamma_1<\gamma_2$,*

$$[\hat f,\hat f](\xi+i\zeta) := \sum_{k\in\mathbb{Z}} |\hat f(\xi+i\zeta)|^2 \leqslant C_{\gamma_2-\gamma_1}\|f\|^2_{L_{2,1,\gamma_2}(\mathbb{R})} \tag{6.1}$$
$$\forall\,\xi\in\mathbb{R},\ \zeta\in[-\gamma_1,\gamma_1],$$

where

$$C_\gamma := \left\| \sum_{k\in\mathbb{Z}} e^{-2\gamma|\cdot-k|} \right\|_{L_\infty(\mathbb{R})} < \infty$$

for $\gamma>0$. If in addition $\hat f(2\pi k)=0$ for all $k\in\mathbb{Z}$, then $f=h-h(\cdot-1)$ and $h\in L_{2,1,\gamma_1}(\mathbb{R})$ for all $0\leqslant\gamma_1<\gamma_2$, where $h:=\sum_{k=0}^\infty f(\cdot-k)$.

Proof. Since $f\in L_{2,1,\gamma_2}(\mathbb{R})$, by the Cauchy–Schwarz inequality, for $0\leqslant\gamma_1<\gamma_2$, we have

$$\int_0^1 \left(\sum_{k\in\mathbb{Z}} |f(x-k)|e^{\gamma_1|x-k|}\right)^2 dx \leqslant C_\gamma \int_0^1 \sum_{k\in\mathbb{Z}} |f(x-k)|^2 e^{2\gamma_2|x-k|}\,dx \tag{6.2}$$
$$= C_\gamma \|f\|^2_{L_{2,1,\gamma_2}(\mathbb{R})},$$

where $\gamma:=\gamma_2-\gamma_1>0$. Using the Fourier series of $[\hat f,\hat f]$ and $\hat f(\xi+i\zeta)=\widehat{e^{\zeta\cdot}f}(\xi)$, for any fixed $\zeta\in[-\gamma_1,\gamma_1]$ and almost every $\xi\in\mathbb{R}$, we deduce from (6.2) that

$$[\hat f,\hat f](\xi+i\zeta) = \left|\sum_{k\in\mathbb{Z}} e^{ik\xi}\int_{\mathbb{R}} e^{\zeta x} f(x)\overline{e^{\zeta(x+k)}f(x+k)}\,dx\right|$$
$$\leqslant \sum_{k\in\mathbb{Z}}\int_{\mathbb{R}} e^{|\zeta x|}|f(x)|e^{|\zeta(x+k)|}|f(x+k)|\,dx$$
$$= \int_0^1 \left(\sum_{k\in\mathbb{Z}} |f(x+k)|e^{|\zeta|\times|x+k|}\right)^2 dx \leqslant C_\gamma\|f\|^2_{L_{2,1,\gamma_2}(\mathbb{R})}.$$

Since $\hat f$ is continuous, it follows from the above inequality that (6.1) holds for all $\xi\in\mathbb{R}$.

If $\hat f(2\pi k)=0$ for all $k\in\mathbb{Z}$, then we have $\sum_{k\in\mathbb{Z}} f(\cdot-k)=0$. From the definition of h, we see that $f=h-h(\cdot-1)$ and $h=-\sum_{k=-\infty}^{-1} f(\cdot-k)$. We now verify

that $h \in L_{2,1,\gamma_3}$ for all $0 < \gamma_3 < \gamma_2$. Take γ_1 such that $\gamma_3 < \gamma_1 < \gamma_2$. Then by $h = \sum_{k=0}^{\infty} f(\cdot - k)$, we have

$$\sum_{j=0}^{\infty} |h(x-j)|e^{\gamma_3|x-j|} \leqslant \sum_{j=0}^{\infty}\sum_{k=0}^{\infty} |f(x-j-k)|e^{\gamma_3|x-j|}$$

$$= \sum_{k=0}^{\infty} |f(x-k)|e^{\gamma_1|x-k|}e^{-\gamma_1|x-k|}\sum_{j=0}^{k} e^{\gamma_3|x-j|}.$$

For $x \in [0,1]$, by $\gamma_3 < \gamma_1 < \gamma_2$ and $k \geqslant 0$, we have

$$e^{-\gamma_1|x-k|}\sum_{j=0}^{k} e^{\gamma_3|x-j|} \leqslant e^{-\gamma_1(k-1)}\sum_{j=0}^{k} e^{\gamma_3(j+1)} \leqslant \frac{e^{\gamma_2+2\gamma_3}}{e^{\gamma_3}-1} := C.$$

Therefore, we deduce that

$$\sum_{j=0}^{\infty} |h(x-j)|e^{\gamma_3|x-j|} \leqslant C\sum_{k=0}^{\infty} |f(x-k)|e^{\gamma_1|x-k|}, \qquad x \in [0,1].$$

Similarly, using $h = -\sum_{k=-\infty}^{-1} f(\cdot - k)$, we have

$$\sum_{j=-\infty}^{-1} |h(x-j)|e^{\gamma_3|x-j|} \leqslant C\sum_{k=-\infty}^{-1} |f(x-k)|e^{\gamma_1|x-k|}, \qquad x \in [0,1].$$

Hence,

$$\sum_{j\in\mathbb{Z}} |h(x-j)|e^{\gamma_3|x-j|} \leqslant C\sum_{k\in\mathbb{Z}} |f(x-k)|e^{\gamma_1|x-k|}.$$

By (6.2), we conclude that

$$\|h\|^2_{L_{2,1,\gamma_3}(\mathbb{R})} = \int_0^1 \sum_{j\in\mathbb{Z}} |h(x-j)e^{\gamma_3|x-k|}|^2\,dx \leqslant \int_0^1 \left(\sum_{j\in\mathbb{Z}} |h(x-j)|e^{\gamma_3|x-j|}\right)^2 dx$$

$$\leqslant C\int_0^1 \left(\sum_{k\in\mathbb{Z}} |f(x-k)|e^{\gamma_1|x-k|}\right)^2 dx \leqslant CC_{\gamma_2-\gamma_1}\|f\|^2_{L_{2,1,\gamma_2}(\mathbb{R})}.$$

So, $h \in L_{2,1,\gamma_3}(\mathbb{R})$ for all $0 < \gamma_3 < \gamma_2$. This completes the proof. □

It follows from (6.1) and $\hat{f}(\xi + i\zeta) = \widehat{e^{\zeta\cdot}f}(\xi)$ that for any $1 \leqslant p, q \leqslant \infty$,

$$\|f\|^2_{L_{2,p,\gamma_1}(\mathbb{R})} \leqslant \|f\|^2_{L_{2,\infty,\gamma_1}(\mathbb{R})} \leqslant C_{\gamma_2-\gamma_1}\|f\|^2_{L_{2,1,\gamma_2}(\mathbb{R})} \leqslant C_{\gamma_2-\gamma_1}\|f\|^2_{L_{2,q,\gamma_2}(\mathbb{R})}$$
$$\forall\ 0 \leqslant \gamma_1 < \gamma_2. \tag{6.3}$$

Consequently, $L_{2,q,\gamma_2}(\mathbb{R}) \subseteq L_{2,p,\gamma_1}(\mathbb{R})$ for all $1 \leqslant p, q \leqslant \infty$ and $0 \leqslant \gamma_1 < \gamma_2$.

Now we have the following result on admissible functions in a cascade algorithm.

PROPOSITION 6.2. *Let $f \in L_{2,1,\gamma}(\mathbb{R})$ for some $\gamma > 0$ such that f satisfies*

$$\hat{f}(2\pi k) = 0 \qquad \forall\ k \in \mathbb{Z}\backslash\{0\}. \tag{6.4}$$

Then f is admissible with respect to $\hat{a}$ for any $\hat{a} \in C^\beta(\mathbb{T})$ with $\hat{a}(0) = 1$, $\hat{a}(\pi) = 0$, and $\beta > 0$.

Proof. Let $\widehat{f_1} := \hat{f}(2\cdot + 2\pi)$ and $\widehat{f_2} := \hat{f} - \hat{f}(2\cdot)$. Then $f_1, f_2 \in L_{2,1,\gamma/2}(\mathbb{R})$ and $\widehat{f_1}(2\pi k) = \widehat{f_2}(2\pi k) = 0$ for all $k \in \mathbb{Z}$. By Proposition 6.1, $f_1 = h_1 - h_1(\cdot - 1)$ and $f_2 = h_2 - h_2(\cdot - 1)$ for some $h_1, h_2 \in L_{2,1,\gamma_1}(\mathbb{R})$ with $0 < \gamma_1 < \gamma/2$. Therefore, we have

$$[\widehat{f_1}, \widehat{f_1}](\xi) = |1 - e^{-i\xi}|^2 [\widehat{h_1}, \widehat{h_1}](\xi) \quad \text{and} \quad [\widehat{f_2}, \widehat{f_2}](\xi) = |1 - e^{-i\xi}|^2 [\widehat{h_2}, \widehat{h_2}](\xi). \tag{6.5}$$

Since $\hat{a} \in C^\beta(\mathbb{T})$ with $\hat{a}(0) = 1$ and $\hat{a}(\pi) = 0$, there exists a positive constant C such that

$$|\hat{a}(\xi) - 1| \leqslant C|1 - e^{-i\xi}|^\beta \quad \text{and} \quad |\hat{a}(\xi + \pi)| \leqslant C|1 - e^{-i\xi}|^\beta \qquad \forall\, \xi \in \mathbb{R}. \tag{6.6}$$

Now it follows from (6.5) and (6.6) that

$$\begin{aligned}
&\sum_{k\in\mathbb{Z}} \big|\hat{a}(\xi/2 + 2\pi k)\hat{f}(\xi/2 + 2\pi k) - \hat{f}(\xi + 4\pi k)\big|^2 \\
&\qquad = \sum_{k\in\mathbb{Z}} \big|[\hat{a}(\xi/2) - 1]\hat{f}(\xi/2 + 2\pi k) + \widehat{f_2}(\xi/2 + 2\pi k)\big|^2 \\
&\qquad \leqslant 2|\hat{a}(\xi/2) - 1|^2 [\hat{f}, \hat{f}](\xi/2) + 2[\widehat{f_2}, \widehat{f_2}](\xi/2) \\
&\qquad \leqslant 2C^2|1 - e^{-i\xi/2}|^{2\beta} \big(\|[\hat{f}, \hat{f}]\|_{L_\infty(\mathbb{T})} + 2^{2-2\beta}\|[\widehat{h_2}, \widehat{h_2}]\|_{L_\infty(\mathbb{T})}\big).
\end{aligned}$$

Similarly, by $\hat{f}(\xi + 2\pi + 4\pi k) = \widehat{f_1}(\xi/2 + 2\pi k)$, we have

$$\begin{aligned}
&\sum_{k\in\mathbb{Z}} \big|\hat{a}(\xi/2 + \pi + 2\pi k)\hat{f}(\xi/2 + \pi + 2\pi k) - \hat{f}(\xi + 2\pi + 4\pi k)\big|^2 \\
&\qquad \leqslant 2|\hat{a}(\xi/2 + \pi)|^2 [\hat{f}, \hat{f}](\xi/2 + \pi) + 2[\widehat{f_1}, \widehat{f_1}](\xi/2) \\
&\qquad \leqslant 2C^2|1 - e^{-i\xi/2}|^{2\beta} \big(\|[\hat{f}, \hat{f}]\|_{L_\infty(\mathbb{T})} + 2^{2-2\beta}\|[\widehat{h_1}, \widehat{h_1}]\|_{L_\infty(\mathbb{T})}\big).
\end{aligned}$$

Letting $C_1 := 8C^2(\|[\hat{f}, \hat{f}]\|_{L_\infty(\mathbb{T})} + \|[\widehat{h_1}, \widehat{h_1}]\|_{L_\infty(\mathbb{T})} + \|[\widehat{h_2}, \widehat{h_2}]\|_{L_\infty(\mathbb{T})}) < \infty$, combining the above two inequalities, for almost every $\xi \in [-\pi, \pi]$, we have

$$[\hat{a}(\cdot/2)\hat{f}(\cdot/2) - \hat{f}, \hat{a}(\cdot/2)\hat{f}(\cdot/2) - \hat{f}](\xi) \leqslant C_1|1 - e^{-i\xi/2}|^{2\beta} \leqslant 2^\beta C_1 |\sin(\xi/2)|^{2\beta}.$$

Therefore, (2.1) holds with $\tau = 2\beta > 0$. ∎

Proof of Theorem 2.3. By (6.3), it is easy to see that (i)⇒(ii). (ii)⇒(iii) is obvious. To show that (iii)⇒(iv), we take $f = \max(0, 1 - |\cdot|)$. It is easy to check that f satisfies the condition in (6.4) and the shifts of f are stable. By $\hat{a}(\pi) = 0$ and Proposition 6.2, $f \in L_{2,p,\gamma}(\mathbb{R})$ is admissible with respect to $\hat{a}$. Therefore, (iii)⇒(iv).

If (iv) holds, by Proposition 6.1 or (6.3), $f \in L_{2,\infty,0}(\mathbb{R})$ and f is admissible with respect to $\hat{a}$. Now it follows from (iv) and (6.3) that $\{f_n\}_{n=1}^\infty$ is a Cauchy sequence in $L_{2,\infty,0}(\mathbb{R})$. Therefore, (ii) of Theorem 2.1 holds, and consequently $\nu_2(\hat{a}) > 0$. So, (iv)⇒(v).

To complete the proof, we have to show that (v)⇒(i), which is the major part of this proof. By Proposition 4.2, $\nu_2(\hat{a}) > 0$ implies $\hat{a}(\pi) = 0$. So, we can write $\hat{a}(\xi) = (1 + e^{-i\xi})\hat{A}(\xi)$, where $\hat{A}$ also has exponential decay of order r. By Theorems 2.1 and 4.1, it follows from $\nu_2(\hat{a}) > 0$ and $\hat{a}(\xi) = (1 + e^{-i\xi})\hat{A}(\xi)$ that $\inf_{n\in\mathbb{N}} \|T_{\hat{A}}^n 1\|_{L_\infty(\mathbb{T})}^{1/n} =$

$\rho_0(\hat{A},\infty)=\rho_2(\hat{a},\infty)<1$. Therefore, there exist $0<\rho<1$ and $N\in\mathbb{N}$ such that $\|T_{\hat{A}}^N 1\|_{L_\infty(\mathbb{T})}^{1/N}<\rho<1$. Since $\hat{A}$ has exponential decay of order r, the operator $[T_{\hat{A}}^n 1](\xi)$ in (1.5) is well defined for $\xi\in\Gamma_{2r}:=\{z\in\mathbb{C}\,:\,|\mathrm{Im}(z)|<2r\}$. Since $\hat{A}$ is a 2π-periodic continuous function on the strip Γ_r, there exists $\gamma_1>0$ such that

$$\|[T_{\hat{A}}^N 1](\cdot+i\zeta)\|_{L_\infty(\mathbb{T})}\leqslant\rho^N<1\qquad\forall\,\zeta\in[-\gamma_1,\gamma_1]. \tag{6.7}$$

Take m to be the smallest nonnegative integer such that $2^{1-m}r<\gamma_1$. For each $n\geqslant N+m$, we can uniquely write $n=Nk+j$, where $j\in\{m,m+1,\ldots,m+N-1\}$ and $k\in\mathbb{N}$. So, for every $\zeta\in[-\gamma,\gamma]$ and $0<\gamma<2r$, by (6.7) and the extended definition of $T_{\hat{A}}$ in (1.5), we have $|2^{-j}\zeta|\leqslant 2^{-m}\gamma<2^{1-m}r<\gamma_1$ and

$$\begin{aligned}\|[T_{\hat{A}}^n 1](\cdot+i\zeta)\|_{L_\infty(\mathbb{T})}&=\|[T_{\hat{A}}^j T_{\hat{A}}^{Nk}1](\cdot+i\zeta)\|_{L_\infty(\mathbb{T})}\\&\leqslant\|[T_{\hat{A}}^j 1](\cdot+i\zeta)\|_{L_\infty(\mathbb{T})}\|[T_{\hat{A}}^{Nk}1](\cdot+i2^{-j}\zeta)\|_{L_\infty(\mathbb{T})}\\&\leqslant\|[T_{\hat{A}}^j 1](\cdot+i\zeta)\|_{L_\infty(\mathbb{T})}\rho^{Nk}\leqslant C_1\rho^n,\end{aligned}$$

where

$$C_1:=\rho^{1-m-N}\sup\big\{\|[T_{\hat{A}}^j 1](\cdot+i\zeta)\|_{L_\infty(\mathbb{T})}\,:\,j=m,\ldots,m+N-1,\zeta\in[-\gamma,\gamma]\big\}<\infty.$$

That is, we have

$$\|[T_{\hat{A}}^n 1](\cdot+i\zeta)\|_{L_\infty(\mathbb{T})}\leqslant C_1\rho^n\qquad\forall\,n\geqslant N+m,\zeta\in[-\gamma,\gamma]. \tag{6.8}$$

Denote $\hat{F}(\xi):=\hat{a}(\xi/2)\hat{f}(\xi/2)-\hat{f}(\xi)$. Since f is admissible with respect to $\hat{a}$ and $F\in L_{2,1,\gamma}(\mathbb{R})$, we must have $\hat{F}(2\pi k)=0$ for all $k\in\mathbb{Z}$. By Proposition 6.1, $\hat{F}(\xi)=(1-e^{-i\xi})\hat{h}(\xi)$ for some $h\in L_{2,1,\gamma/2}(\mathbb{R})$. Denote $g_n:=\widehat{f_{n+1}}-\widehat{f_n}$ with $g:=g_0:=\widehat{f_1}-\hat{f}$. Then $g(\xi)=\hat{F}(\xi)$. Therefore, by Proposition 6.1, we conclude that

$$\begin{aligned}[g,g](\xi)=[\hat{F},\hat{F}](\xi)=|1-e^{-i\xi}|^2[\hat{h},\hat{h}](\xi)\leqslant C_2|1-e^{-i\xi}|^2\\ \forall\,\xi\in\Gamma_{\gamma_2}:=\{z\in\mathbb{C}\,:\,|\mathrm{Im}(z)|<\gamma_2\},\end{aligned} \tag{6.9}$$

where $\gamma_2:=\gamma/4>0$, $C_2:=C_{\gamma/4}\|h\|_{L_{2,1,\gamma/2}(\mathbb{R})}<\infty$, and $C_{\gamma/4}$ is defined in Proposition 6.1.

By the definition of f_n and by induction on n, for $n\geqslant n_0:=1-\log_2(\gamma_2/r)$, we have that $g_n(\xi)=g(2^{-n}\xi)\prod_{j=1}^n\hat{a}(2^{-j}\xi)$ for $\xi\in\Gamma_{2r}$ and g_n is holomorphic on Γ_{2r}, since $2^{-n}\Gamma_{2r}\subseteq\Gamma_{\gamma_2}$ for all $n\geqslant n_0$. Now by induction, it follows from (6.9) that

$$[g_n,g_n](\xi)=(T_{\hat{a}}^n[g,g])(\xi)\leqslant C_2(T_{\hat{a}}^n(|1-e^{-i\cdot}|^2))(\xi),\qquad\xi\in\Gamma_{2r}. \tag{6.10}$$

By $\hat{a}(\xi)=(1+e^{-i\xi})\hat{A}(\xi)$, we have $|\hat{a}(\xi)|^2=2^2|\cos(\xi/2)|^2|\hat{A}(\xi)|^2$. So, (4.8) holds with $\tau=1$. So, we deduce that

$$[T_{\hat{a}}^n(|1-e^{-i\cdot}|^2)](\xi)=|1-e^{-i\xi}|^2[T_{\hat{A}}^n 1](\xi)\leqslant(1+e^{2r})^2[T_{\hat{A}}^n 1](\xi),\qquad\xi\in\Gamma_{2r}.$$

Consequently, since $0<\gamma<2r$, it follows from (6.8) and (6.10) that

$$\begin{aligned}[g_n,g_n](\xi)\leqslant C_2(1+e^{2r})^2|[T_{\hat{A}}^n 1](\xi)|\leqslant C_1C_2(1+e^{2r})^2\rho^n\leqslant C_3\rho^n\\ \forall\,n\geqslant n_1,|\mathrm{Im}(\xi)|\leqslant\gamma,\end{aligned} \tag{6.11}$$

where $C_3 := C_1C_2(1+e^{2r})^2 < \infty$ and $n_1 = \max(n_0, N+m)$. Note that $g_n(\cdot + i\zeta)$ is the Fourier transform of $e^{\zeta\cdot}(f_{n+1} - f_n)$. For $\zeta \in [-\gamma, \gamma]$, we have

$$2\pi\|(f_{n+1}-f_n)e^{\zeta\cdot}\|^2_{L_2(\mathbb{R})} = \|g_n(\cdot+i\zeta)\|^2_{L_2(\mathbb{R})} = 2\pi\|[g_n, g_n](\cdot+i\zeta)\|_{L_1(\mathbb{T})}$$
$$\leqslant 2\pi\|[g_n, g_n](\cdot+i\zeta)\|_{L_\infty(\mathbb{T})}.$$

Now by the definition of the space $L_{2,1,\gamma}(\mathbb{R})$, it follows from the above inequality and (6.11) that

$$\|f_{n+1}-f_n\|^2_{L_{2,1,\gamma}(\mathbb{R})} = \|(f_{n+1}-f_n)e^{\gamma|\cdot|}\|^2_{L_2(\mathbb{R})} \leqslant 2C_3\rho^n \qquad \forall\, n \geqslant n_0.$$

Consequently, $\{f_n\}_{n=1}^\infty$ is a Cauchy sequence in $L_{2,1,\gamma}(\mathbb{R})$. So, (v)⇒(i).

Now we show that ϕ has exponential decay of order $2r$. Since $\hat\phi(\xi) := \prod_{j=1}^\infty \hat a(2^{-j}\xi)$ and $\hat a$ has exponential decay of order r with $\hat a(0) = 1$, we see that $\hat\phi$ can be extended into a holomorphic function in the strip Γ_{2r}. If $\nu_2(\hat a) > 0$, for every $0 < \gamma < 2r$, by (i) and $\lim_{n\to\infty} \widehat{f_n}(\xi) = \hat\phi(\xi)$ for all $\xi \in \mathbb{R}$ (here we additionally assumed that $\lim_{\xi\to 0}\hat f(\xi) = 1$, which is satisfied by many initial admissible functions), we see that $\lim_{n\to\infty}\|f_n - \phi\|_{L_{2,1,\gamma}(\mathbb{R})} = 0$ and hence $\phi \in L_{2,1,\gamma}(\mathbb{R})$. Therefore, $\phi \in L_{2,1,\gamma}(\mathbb{R})$ for all $0 \leqslant \gamma < 2r$. That is, (1.9) holds. □

7. Proof of Theorem 4.1. Before we present a proof of Theorem 4.1, we need the following result.

PROPOSITION 7.1. *Let $\hat a$ and f be 2π-periodic measurable functions. Assume that $f(\xi) > 0$ for almost every $\xi \in \mathbb{R}$ and $[T^n_{\hat a} f]/f \in L_\infty(\mathbb{T})$ for all $n \geqslant n_0$, where $n_0 \in \mathbb{N}$. Then*

$$\limsup_{n\to\infty} \|[T^n_{\hat a} f]/f\|^{1/n}_{L_\infty(\mathbb{T})} = \lim_{n\to\infty} \|[T^n_{\hat a} f]/f\|^{1/n}_{L_\infty(\mathbb{T})} = \inf_{n\geqslant n_0} \|[T^n_{\hat a} f]/f\|^{1/n}_{L_\infty(\mathbb{T})}. \tag{7.1}$$

Proof. Denote $\rho := \inf_{n\geqslant n_0} \|[T^n_{\hat a} f]/f\|^{1/n}_{L_\infty(\mathbb{T})}$. Then $\rho < \infty$ by $[T^{n_0}_{\hat a} f]/f \in L_\infty(\mathbb{T})$. Since for all $n \geqslant n_0$, $\|[T^n_{\hat a} f]/f\|^{1/n}_{L_\infty(\mathbb{T})} \geqslant \rho$, we have

$$\liminf_{n\to\infty} \|[T^n_{\hat a} f]/f\|^{1/n}_{L_\infty(\mathbb{T})} \geqslant \rho. \tag{7.2}$$

For any $\varepsilon > 0$, there exists $m \in \mathbb{N}$ such that $m \geqslant n_0$ and $\|[T^m_{\hat a} f]/f\|^{1/m}_{L_\infty(\mathbb{T})} \leqslant \rho + \varepsilon$. Since $f(\xi) > 0$ for almost every $\xi \in \mathbb{R}$, we deduce that

$$[T^m_{\hat a} f](\xi) \leqslant \|[T^m_{\hat a} f]/f\|_{L_\infty(\mathbb{T})} f(\xi) \leqslant f(\xi)(\rho+\varepsilon)^m \qquad \text{a.e. } \xi \in \mathbb{R}. \tag{7.3}$$

For each $n \geqslant 2m$, we can uniquely write $n = mN + j$, where $N \in \mathbb{N}$ and $j \in \{m, m+1, \dots, 2m-1\}$. Therefore, by (7.3),

$$[T^n_{\hat a} f](\xi) = [T^j_{\hat a}(T^{mN}_{\hat a} f)](\xi) \leqslant (\rho+\varepsilon)^{mN}[T^j_{\hat a} f](\xi).$$

Since $f(\xi) > 0$ for almost every $\xi \in \mathbb{R}$, the above inequality yields that

$$\frac{[T^n_{\hat a} f](\xi)}{f(\xi)} \leqslant (\rho+\varepsilon)^{mN}\frac{[T^j_{\hat a} f](\xi)}{f(\xi)} \leqslant C(\rho+\varepsilon)^n \qquad \text{a.e. } \xi \in \mathbb{R},$$

where

$$C := \max\{(\rho+\varepsilon)^{-j}\|[T^j_{\hat a} f]/f\|_{L_\infty(\mathbb{T})} \,:\, j = m, \dots, 2m-1\} < \infty.$$

Thus, $\|[T_{\hat a}^n f]/f\|_{L_\infty(\mathbb{T})}^{1/n} \leqslant C^{1/n}(\rho+\varepsilon)$ for all $n \geqslant 2m$. Consequently,

$$\limsup_{n\to\infty} \|[T_{\hat a}^n f]/f\|_{L_\infty(\mathbb{T})}^{1/n} \leqslant (\rho+\varepsilon).$$

Taking $\varepsilon \to 0$, we have $\limsup_{n\to\infty} \|[T_{\hat a}^n f]/f\|_{L_\infty(\mathbb{T})}^{1/n} \leqslant \rho$. By (7.2), (7.1) holds. ∎

Proof of Theorem 4.1. Without loss of generality, we can assume that $|\hat a(0)|^2 = 1$; otherwise, we consider $\hat a/|\hat a(0)|$. By $|\hat a(\xi)|^2 = 2^{2\tau}|\cos(\xi/2)|^{2\tau}|\hat A(\xi)|^2$, (4.8) holds. Setting $f = 1$ in (4.8), we have

$$\left[T_{\hat a}^n(|\sin(\cdot/2)|^{2\tau})\right](\xi) = |\sin(\xi/2)|^{2\tau}[T_{\hat A}^n 1](\xi) \qquad \forall\, n \in \mathbb{N} \text{ a.e. } \xi \in \mathbb{R}. \tag{7.4}$$

Since $|\sin(\xi/2)|^{2\tau} \leqslant 1$, it follows from (7.4) that

$$\|T_{\hat a}^n(|\sin(\cdot/2)|^{2\tau})\|_{L_\infty(\mathbb{T})} \leqslant \|T_{\hat A}^n 1\|_{L_\infty(\mathbb{T})}$$

for all $n \in \mathbb{N}$. Consequently, by $\hat A \in L_\infty(\mathbb{T})$ and Proposition 7.1, we conclude that

$$\rho := \rho_{2\tau}(\hat a, \infty) := \limsup_{n\to\infty} \left\|T_{\hat a}^n(|\sin(\cdot/2)|^{2\tau})\right\|_{L_\infty(\mathbb{T})}^{1/n} \leqslant \limsup_{n\to\infty} \|T_{\hat A}^n 1\|_{L_\infty(\mathbb{T})}^{1/n}. \tag{7.5}$$

On the other hand, by (7.4), we have

$$[T_{\hat A}^n 1](\xi) = \frac{[T_{\hat a}^n(|\sin(\cdot/2)|^{2\tau})](\xi)}{|\sin(\xi/2)|^{2\tau}} =: g_n(\xi) \qquad \forall\, n \in \mathbb{N}. \tag{7.6}$$

By the definition of $T_{\hat a}$ and g_n, we have

$$g_n(\xi) = |\hat A(\xi/2)|^2 g_{n-1}(\xi/2) + \frac{|\hat a(\xi/2+\pi)|^2}{|\sin(\xi/2)|^{2\tau}}[T_{\hat a}^{n-1}(|\sin(\cdot/2)|^{2\tau})](\xi/2+\pi).$$

Since $\tau \geqslant 0$, for almost every $\xi \in [-\pi,\pi]$, we have

$$|\hat a(\xi/2+\pi)|^2/|\sin(\xi/2)|^{2\tau} = |\hat A(\xi/2+\pi)|^2/|\cos(\xi/4)|^{2\tau} \leqslant 2^\tau \|\hat A\|_{L_\infty(\mathbb{T})},$$

from which we see that

$$g_n(\xi) \leqslant |\hat A(\xi/2)|^2 g_{n-1}(\xi/2) + 2^\tau \|\hat A\|_{L_\infty(\mathbb{T})} \|T_{\hat a}^{n-1}(|\sin(\cdot/2)|^{2\tau})\|_{L_\infty(\mathbb{T})} \quad \text{a.e. } \xi \in [-\pi,\pi].$$

By induction on n and $g_0 = 1$, we deduce from the above inequality that for almost every $\xi \in [-\pi,\pi]$ and all $n \in \mathbb{N}$,

$$\begin{aligned} g_n(\xi) &\leqslant \prod_{j=1}^n |\hat A(2^{-j}\xi)|^2 \\ &\quad + 2^\tau \|\hat A\|_{L_\infty(\mathbb{T})} \sum_{j=1}^{n-1} \|T_{\hat a}^j(|\sin(\cdot/2)|^{2\tau})\|_{L_\infty(\mathbb{T})} \prod_{k=1}^{n-j-1} |\hat A(2^{-k}\xi)|^2. \end{aligned} \tag{7.7}$$

Since $|\hat a|^2 \in C^\beta(\mathbb{T})$ and $|\hat a(0)|^2 = 1$, we define

$$\Phi(\xi) := \prod_{j=1}^\infty |\hat a(2^{-j}\xi)|^2, \qquad \xi \in \mathbb{R}.$$

Then Φ is continuous and $\Phi(0) = 1$. Thus, there exists $0 < \varepsilon_0 < \pi$ such that $1/2 \leqslant \Phi(\xi) \leqslant 3/2$ for all $\xi \in [-\varepsilon_0, \varepsilon_0]$. By

$$|\hat{a}(\xi)|^2 = 2^{2\tau} |\cos(\xi/2)|^{2\tau} |\hat{A}(\xi)|^2,$$

for $n \geqslant \log_2(\pi/\varepsilon_0)$ and $\xi \in [-\pi, \pi]$, we have

$$\begin{aligned}\prod_{j=1}^{n} |\hat{A}(2^{-j}\xi)|^2 &= \Big|\frac{\sin(2^{-1-n}\xi)}{\sin(\xi/2)}\Big|^{2\tau} \prod_{j=1}^{n} |\hat{a}(2^{-j}\xi)|^2 \\ &= \Big|\frac{\sin(2^{-1-n}\xi)}{\sin(\xi/2)}\Big|^{2\tau} \frac{\Phi(\xi)}{\Phi(2^{-n}\xi)} \leqslant \Big|\frac{2^{-1-n}\xi}{\xi/\pi}\Big|^{2\tau} \frac{\Phi(\xi)}{1/2} \\ &\leqslant 2^{1-2\tau}\pi^{2\tau} \|\Phi\|_{L_\infty([-\pi,\pi])} 2^{-2\tau n}.\end{aligned}$$

Therefore, we have

$$\prod_{j=1}^{n} |\hat{A}(2^{-j}\xi)|^2 \leqslant C_1 2^{-2\tau n} \qquad \forall\, \xi \in [-\pi, \pi] \tag{7.8}$$

with $C_1 := 2^{1-2\tau}\pi^{2\tau}\|\Phi\|_{L_\infty([-\pi,\pi])} < \infty$. Since $\prod_{j=1}^{n} |\hat{a}(2^{-j}\xi)|^2 = \Phi(\xi)/\Phi(2^{-n}\xi)$ and $1/2 \leqslant \Phi(\xi) \leqslant 3/2$ for $\xi \in [-\varepsilon_0, \varepsilon_0]$, we have

$$\begin{aligned}\|T_{\hat{a}}^n(|\sin(\cdot/2)|^{2\tau})\|_{L_\infty(\mathbb{T})} &\geqslant \Big\| |\sin(2^{-1-n}\cdot)|^{2\tau} \prod_{j=1}^{n} |\hat{a}(2^{-j}\cdot)|^2 \Big\|_{L_\infty([-\pi,\pi])} \\ &= \big\| |\sin(2^{-1-n}\cdot)|^{2\tau} \Phi(\cdot)/\Phi(2^{-n}\cdot) \big\|_{L_\infty([-\pi,\pi])} \\ &\geqslant |\sin(2^{-1-n}\varepsilon_0)|^{2\tau} \Phi(\varepsilon_0)/\Phi(2^{-n}\varepsilon_0) \\ &\geqslant 3^{-1}\pi^{-2\tau}\varepsilon_0^{2\tau} 2^{-2\tau n}.\end{aligned}$$

By the definition of ρ, it follows from the above inequality that $\rho \geqslant 2^{-2\tau}$. By (7.8) and the definition of ρ in (7.5), for any $\varepsilon > 0$, there exists a positive constant C with $C \geqslant C_1$ such that

$$\Big\| \prod_{j=1}^{n} |\hat{A}(2^{-j}\cdot)|^2 \Big\|_{L_\infty([-\pi,\pi])} \leqslant C 2^{-2\tau n} \leqslant C(\rho + \varepsilon)^n$$

and

$$\|T_{\hat{a}}^n(|\sin(\cdot/2)|^{2\tau})\|_{L_\infty(\mathbb{T})} \leqslant C(\rho + \varepsilon)^n \quad \forall\, n \in \mathbb{N}.$$

Now it follows from (7.7) and the above inequalities that

$$\|g_n\|_{L_\infty(\mathbb{T})} = \|g_n\|_{L_\infty([-\pi,\pi])} \leqslant C(\rho + \varepsilon)^n + 2^\tau \|\hat{A}\|_{L_\infty(\mathbb{T})} C^2 n (\rho + \varepsilon)^{n-1},$$

from which we deduce that $\limsup_{n\to\infty} \|g_n\|_{L_\infty(\mathbb{T})}^{1/n} \leqslant \rho + \varepsilon$. Taking $\varepsilon \to 0$, by the definition of g_n in (7.6), we conclude that

$$\limsup_{n\to\infty} \|T_{\hat{A}}^n 1\|_{L_\infty(\mathbb{T})}^{1/n} = \limsup_{n\to\infty} \|g_n\|_{L_\infty(\mathbb{T})}^{1/n} \leqslant \rho.$$

So, by Proposition 7.1, the proof is completed by the above inequality and (7.5). □

PROPAGATION THROUGH GENERIC LEVEL CROSSINGS: A SURFACE HOPPING SEMIGROUP*

CLOTILDE FERMANIAN KAMMERER† AND CAROLINE LASSER‡

Abstract. We construct a surface hopping semigroup, which asymptotically describes nuclear propagation through crossings of electron energy levels. The underlying time-dependent Schrödinger equation has a matrix-valued potential, whose eigenvalue surfaces have a generic intersection of codimension two, three, or five in Hagedorn's classification. Using microlocal normal forms reminiscent of the Landau–Zener problem, we prove convergence to the true solution with an error of the order $\varepsilon^{1/8}$, where ε is the semiclassical parameter. We present numerical experiments for an algorithmic realization of the semigroup illustrating the convergence of the algorithm.

Key words. time-dependent Schrödinger system, eigenvalue crossing, microlocal normal form, surface hopping

1. Introduction.

In the framework of time-dependent Born–Oppenheimer approximation, the dynamics of molecules can approximately be reduced to matrix-valued Schrödinger equations on the nucleonic configuration space,

$$\begin{cases} i\varepsilon\partial_t\psi^\varepsilon(q,t) = \left(-\frac{\varepsilon^2}{2}\Delta_q + V(q)\right)\psi^\varepsilon(q,t), \quad (q,t)\in\mathbb{R}^d\times\mathbb{R}, \\ \psi^\varepsilon(q,0) = \psi_0^\varepsilon(q); \end{cases} \tag{1.1}$$

see, for example, [12, 19]. The linear Schrödinger equation (1.1) has a unique global solution $\psi^\varepsilon \in C(\mathbb{R}, L^2(\mathbb{R}^d,\mathbb{C}^N))$ for all square-integrable initial data ψ_0^ε. The parameter $\varepsilon > 0$ is small and causes a highly oscillatory behavior of the solution in space and time. It can be thought of as the square root of the ratio of electronic mass and the average mass of the nuclei. Moreover, the solution itself does not have any direct physical interpretation. It is the position density $|\psi^\varepsilon(q,t)|^2$ which gives the probability of finding the nuclei in the configuration $q\in\mathbb{R}^d$ at time t. We are interested in an asymptotic description for the time evolution of quadratic quantities like the position density with the following properties. First, it shall be effective in the sense that it unfolds characteristic dynamical properties. Second, it shall be explicit enough, such that it allows an algorithmic realization. Third, the resulting algorithm shall be applicable on high-dimensional nucleonic configuration spaces $\mathbb{R}^d$, $d\gg 1$.

Hagedorn rigorously derived and classified Schrödinger systems for molecular propagation through electron energy level crossings of minimal multiplicity [13]. He obtained potentials of the form

$$V(q) = v(q)\,\mathrm{Id} + V_\ell\left(\phi(q)\right), \quad \ell\in\{2,3,3',5\},$$

where $v(q) \in \mathcal{C}^\infty(\mathbb{R}^d, \mathbb{R})$ is a smooth real-valued function, Id is the identity matrix in $\mathbb{C}^{2\times 2}$ or $\mathbb{C}^{4\times 4}$, and $q \mapsto \phi(q)$ is a smooth vector-valued function with $\phi(q) \in \mathbb{R}^2$, $\mathbb{R}^3$, or $\mathbb{R}^5$. The matrices V_ℓ are given by

$$V_2(\phi) = \begin{pmatrix} \phi_1 & \phi_2 \\ \phi_2 & -\phi_1 \end{pmatrix}, \qquad V_3(\phi) = \begin{pmatrix} \phi_1 & \phi_2 + i\phi_3 \\ \phi_2 - i\phi_3 & -\phi_1 \end{pmatrix}, \tag{1.2}$$

$$V_{3'}(\phi) = \begin{pmatrix} \begin{pmatrix} \phi_1 & \phi_2 + i\phi_3 \\ \phi_2 - i\phi_3 & -\phi_1 \end{pmatrix} & \mathbf{0} \\ \mathbf{0} & \begin{pmatrix} \phi_1 & \phi_2 - i\phi_3 \\ \phi_2 + i\phi_3 & -\phi_1 \end{pmatrix} \end{pmatrix}, \tag{1.3}$$

$$V_5(\phi) = \begin{pmatrix} \phi_0 \ \mathrm{Id} & \begin{pmatrix} \phi_1 + i\phi_2 & \phi_3 + i\phi_4 \\ -\phi_3 + i\phi_4 & \phi_1 - i\phi_2 \end{pmatrix} \\ \begin{pmatrix} \phi_1 - i\phi_2 & -\phi_3 - i\phi_4 \\ \phi_3 - i\phi_4 & \phi_1 + i\phi_2 \end{pmatrix} & -\phi_0 \ \mathrm{Id} \end{pmatrix}. \tag{1.4}$$

For these four matrices, the eigenvalues are $\pm|\phi|$. Therefore, the eigenvalues of $V(q)$ are $v(q) \pm |\phi(q)|$, and $q^* \in \mathbb{R}^d$ is a point of crossing eigenvalues if and only if $\phi(q^*) = 0$. We shall say that this crossing is generic if

$$\mathrm{d}\phi \text{ is of maximal rank on } \{\phi = 0\},$$

i.e., of rank 2 for $\ell = 2$, of rank 3 for $\ell = 3, 3'$, and of rank 5 for $\ell = 5$. This explains why these crossings are usually referred to as codimension two, three, and five crossings and enlightens the choice of the index ℓ we have made. Hagedorn's codimension one crossings are not considered here, since they violate the above rank condition and also show a different dynamical behavior than systems with crossings of higher codimension. We set

$$N(2) = N(3) = 2, \quad N(3') = N(5) = 4,$$

so that the potential $V(q)$, the wave function $\psi^\varepsilon(q,t)$, and the differential $\mathrm{d}\phi(q)$ belong to $\mathbb{C}^{N(\ell)\times N(\ell)}$, $\mathbb{C}^{N(\ell)}$, and $\mathbb{R}^{\ell\times d}$, respectively. For $\ell = 3'$ we set $\mathbb{R}^{3'} = \mathbb{R}^3$. The orthogonal eigenprojectors

$$\Pi^\pm(q) = \tfrac{1}{2}\left(\mathrm{Id} \pm |\phi(q)|^{-1} V_\ell(\phi(q))\right)$$

of the matrix $V(q)$ have a conical singularity at points of crossing eigenvalues q^*; that is, $\nabla\Pi^\pm(q) = O(|q - q^*|^{-1})$ as $q \to q^*$. This motivates the notion of conical intersections, by which especially codimension two crossings are frequently referred to.

Eigenvalue crossings are ubiquitous in the quantum mechanical description of polyatomic molecules, that is, molecules with more than two nuclei. The collection [4] provides an exposition of this active area of research in theoretical chemistry. As for a prominent example of an ultrafast isomerization on the femtosecond time scale, a codimension two crossing of energy levels explains the effectiveness of the first step of vision, the cis-trans isomerization of retinal in rhodopsin; see also [14] and section 3 below for related numerical experiments.

The analysis of scalar Schrödinger equations teaches us that the direct study of the time evolution of quadratic quantities like the position density $|\psi^\varepsilon(q,t)|^2$ is

impossible. The oscillations of $\psi^\varepsilon(q,t)$ have to be taken into account, and one has to work in the space of positions and momenta (q,p), the phase space $\mathbb{R}^d_q \times \mathbb{R}^d_p$. Therefore, one studies the Wigner function of $\psi^\varepsilon(q,t)$ in a suitable ε-dependent scaling, which resolves the highly oscillatory features of the solution,

$$W^\varepsilon(\psi^\varepsilon(t))(q,p) = (2\pi)^{-d} \int_{\mathbb{R}^d} \psi^\varepsilon\big(q - \tfrac{\varepsilon}{2}v, t\big) \otimes \overline{\psi}^\varepsilon\big(q + \tfrac{\varepsilon}{2}v, t\big)\ \mathrm{e}^{i\,v\cdot p}\,\mathrm{d}v.$$

It plays the role of a generalized probability density on phase space. For square-integrable wave functions ψ, the Wigner function $W^\varepsilon(\psi)$ is a square-integrable function on phase space with values in the space of hermitian matrices. One recovers the position density by

$$|\psi(q)|^2 = \operatorname{tr} \int_{\mathbb{R}^d} W^\varepsilon(\psi)(q,p)\,\mathrm{d}p.$$

Besides, the action of the Wigner function against compactly supported smooth test functions $a \in \mathcal{C}^\infty_c(\mathbb{R}^{2d}, \mathbb{C}^{N(\ell)\times N(\ell)})$ is simply expressed in terms of the semiclassical pseudodifferential operator with symbol a, which is defined by

$$\mathrm{op}_\varepsilon(a)\psi(q) = (2\pi\varepsilon)^{-d} \int_{\mathbb{R}^{2d}} a\left(\tfrac{1}{2}(q+v), p\right) \mathrm{e}^{\frac{i}{\varepsilon}p\cdot(q-v)}\psi(v)\,\mathrm{d}v\,\mathrm{d}p$$

for $\psi \in L^2(\mathbb{R}^d, \mathbb{C}^{N(\ell)})$. Indeed, we have

$$\operatorname{tr} \int_{\mathbb{R}^{2d}} W^\varepsilon(\psi)(q,p)a(q,p)\,\mathrm{d}q\,\mathrm{d}p = \left(\mathrm{op}_\varepsilon(a)\psi\,,\,\psi\right)_{L^2(\mathbb{R}^d,\mathbb{C}^{N(\ell)})}.$$

It is our aim to construct an asymptotic semigroup, which approximately propagates the initial data's Wigner function for all generic level crossings of Hagedorn's classification. Our approximation relies on a microlocal normal form for operators with eigenvalue crossings, which has been derived in [1, 2, 6]. Roughly speaking, near a crossing point the Schrödinger operator

$$-i\varepsilon\partial_t - \tfrac{\varepsilon^2}{2}\Delta_q + V(q)$$

is equivalent to the normal form

$$-i\varepsilon\partial_t + V_\ell\Big(t, \mathrm{op}_\varepsilon(|\mathrm{d}\phi(q)p|^{-\frac{1}{2}}\pi_\ell(q,p)\phi(q))\Big),$$

where $\pi_\ell(q,p)$ denotes the orthogonal projection onto the hyperplane normal to the vector $\mathrm{d}\phi(q)p \in \mathbb{R}^\ell$. In the case $\ell = 2$, this resembles the Landau–Zener system

$$i\varepsilon\tfrac{\mathrm{d}}{\mathrm{d}t}\psi(t) = \begin{pmatrix} t & \gamma \\ \gamma & -t \end{pmatrix}\psi(t), \qquad \gamma > 0,$$

for which the probability that a solution starting at time $t = -\infty$ in the one eigenspace will have passed over to the other eigenspace at time $t = +\infty$, which has explicitly been computed by Landau [16] and Zener [21] in the 1930s. This famous Landau–Zener transition rate reads as

$$\exp\Big(-\frac{\pi}{\varepsilon}\gamma^2\Big),$$

and in [8] it is proven that the rate still gives the correct asymptotics if γ is replaced by a bounded operator. Our semigroup combines effective transitions between eigenspaces close to points of crossing eigenvalues on the one hand with classical transport in the adiabatic regime on the other hand. More precisely, the V-diagonal components $\Pi^{\pm}W^{\varepsilon}(\psi_0^{\varepsilon})\Pi^{\pm}$ of the initial Wigner function are transported along the Hamiltonian curves of the eigenvalues of the Schrödinger operator's symbol

$$\tfrac{1}{2}|p|^2 + v(q) \pm |\phi(q)|.$$

Whenever one of the trajectories $(q^{\pm}(t), p^{\pm}(t))$ attains a local minimal gap between the eigenvalues, there is an effective nonadiabatic transfer of weight according to the ε-dependent transition rate

$$\exp\left(-\frac{\pi}{\varepsilon}\frac{|\pi_\ell(q,p)\phi(q)|^2}{|\mathrm{d}\phi(q)p|}\right).$$

Since the rate is negligibly small, when the eigenvalue gap is larger than $\sqrt{\varepsilon}$, the nonadiabatic transfer of weight is effectively performed at times t^* with

$$t \mapsto |\phi(q^{\pm}(t))| \text{ has a local minimum in } t = t^* \text{ and } |\phi(q^{\pm}(t^*))| \leq R\sqrt{\varepsilon}$$

for some fixed $R > 0$. Our main result is that this dynamical description yields approximate solutions with an error of order $\varepsilon^{1/8}$ when choosing $R = \varepsilon^{-1/8}$. Moreover, it is explicit enough for an algorithmic realization, whose performance on a model for retinal in rhodopsin is studied here as well. The algorithm is a mathematical counterpart to the popular surface hopping algorithms of chemical physics introduced by Tully and Preston in [20].

Quantum dynamical descriptions in terms of classical transport as described above, that is, in the spirit of an Egorov theorem, are well established and have been given for Wigner functions, for example, in [10, 11]: for Schrödinger systems they hold to leading order in ε, until classical trajectories come close to a point of crossing eigenvalues. Then, as already mentioned, the adiabatic approximation is no longer valid, and there are leading order nonadiabatic transitions between the levels (the energy propagated on one level to the crossing may pass partially or completely on the other level). This phenomenon has been precisely analyzed in the case of Gaussian wave packet propagation by Hagedorn [13] for all generic electron level crossings. For initial data, which are less specific than Gaussian wave packets, the evolution of appropriate two-scale Wigner measures has been studied. These measures are weak limits of the Wigner function and incorporate information on concentration effects close to trajectories, which touch points of crossing eigenvalues, with respect to the second scale $\sqrt{\varepsilon}$. These Wigner measures have been analyzed for a linear codimension two crossing in [7], for general two-level systems in [8], and for all of Hagedorn's models in [5]. In [18], the results of [7] have been lifted to a leading order approximation of the Wigner function. Here, we aim at approximating the Wigner function for all generic crossings, while additionally proving a convergence rate.

We will proceed as follows. Section 2 constructs the surface hopping semigroup, states the main result, that is, the validity of our approximation with an error of order $\varepsilon^{1/8}$, and discusses the strategy of the proof. In section 3, numerical results are presented for an algorithmic realization of the semigroup applied to a retinal model. In section 4, the proof for propagation away from the crossing is carried out, while the microlocal normal form yields the correct nonadiabatic transition rates, as proven

in section 5. In section 6, the main result is extended to observables, which are more pertinent for the crossings with degenerate eigenvalues ($\ell = 3', 5$). Finally, the appendix summarizes basic facts of Weyl calculus.

2. Main result. Propagation through level crossings can be approximated by a proper combination of classical transport and nonadiabatic transitions. For this, we study the underlying classical flows and combine them with effective nonadiabatic transitions to an asymptotic semigroup.

2.1. Transport and transitions. We consider the classical flows

$$\Phi_\pm^{-t} : \mathbb{R}^{2d} \to \mathbb{R}^{2d}, \quad \Phi_\pm^{-t}(q_0, p_0) = \big(q^\pm(t), p^\pm(t)\big)$$

associated with the Hamiltonian curves of $\frac{1}{2}|p|^2 + v(q) \pm |\phi(q)|$. These curves are solutions to the Hamiltonian systems

$$\begin{cases} \dot q^\pm(t) = p^\pm(t), \;\; \dot p^\pm(t) = -\nabla v\,(q^\pm(t)) \mp {}^t\mathrm{d}\phi\,(q^\pm(t))\,\frac{\phi\left(q^\pm(t)\right)}{|\phi(q^\pm(t))|}, \\ q^\pm(0) = q_0, \;\; p^\pm(0) = p_0. \end{cases}$$

We consider only initial phase space points $(q_0, p_0) \in \mathbb{R}^{2d}$ such that for $t > 0$

$$\phi(q^\pm(t)) = 0 \;\Rightarrow\; \mathrm{d}\phi(q^\pm(t))p^\pm(t) \neq 0. \tag{2.1}$$

This condition guarantees that classical trajectories arrive transversally at the crossing set and have a unique smooth continuation through this singularity; see Proposition 1 in [5].

For a large class of test functions and under suitable restrictions on the time interval, the classical flows are enough for approximating the dynamics up to an error of order ε. Indeed, one considers observables $a \in \mathcal{C}_c^\infty(\mathbb{R}^{2d}, \mathbb{C}^{N(\ell)\times N(\ell)})$ such that

$$a = a^+\Pi^+ + a^-\Pi^-, \qquad a^\pm \in \mathcal{C}_c^\infty(\mathbb{R}^{2d} \setminus \{\phi = 0\}, \mathbb{C}). \tag{2.2}$$

For $\ell = 2, 3$, the eigenspaces are one-dimensional, and these observables focus on the V-diagonal elements of the Wigner matrix, where V-diagonal means diagonal with respect to the decomposition of $\mathbb{C}^{N(\ell)}$ by the eigenprojectors $\Pi^+(q)$ and $\Pi^-(q)$. For $\ell = 3', 5$, however, the eigenspaces are two-dimensional, and observables of the form (2.2) are not enough to completely resolve all dynamical features within the eigenspaces. We will address this issue in section 6.

For all times $t \in [0, T]$, such that the classical trajectories $\Phi_\pm^t$ arriving on the support of a have not passed the crossing set $\{\phi = 0\}$, the action of the Wigner function on $a = a^\pm\Pi^\pm$ obeys

$$\begin{aligned} \operatorname{tr} \int_{\mathbb{R}^{2d}} W^\varepsilon(\psi^\varepsilon(t))\,(q,p)\,\Pi^\pm(q) a^\pm(q,p)\,\mathrm{d}q\,\mathrm{d}p \\ - \operatorname{tr} \int_{\mathbb{R}^{2d}} \big(\Pi^\pm W^\varepsilon(\psi_0^\varepsilon)\Pi^\pm \circ \Phi_\pm^{-t}\big)(q,p)\,a^\pm(q,p)\,\mathrm{d}q\,\mathrm{d}p = O(\varepsilon) \end{aligned}$$

as $\varepsilon \to 0$. Such Egorov-type descriptions hold, until classical trajectories come close to a crossing point $(q, p) \in \{\phi = 0\}$ and leading order nonadiabatic transitions occur. These transitions depend on how the solution $\psi^\varepsilon(t)$ concentrates on the ingoing trajectories with respect to the scale $\sqrt{\varepsilon}$. For the linear codimension two crossing with $\phi(q) = q$, $q \in \mathbb{R}^2$, the two-scale Wigner measure's description of [7] is lifted

to an approximation of the Wigner function in [18]. This linear model has specific features; see also [9]. In particular, all classical trajectories which meet the crossing are included in the set $\{q \wedge p = 0\}$, where $q \wedge p := q_2 p_1 - q_1 p_2$ for $q, p \in \mathbb{R}^2$. The idea of [18] is to propagate the V-diagonal parts of the initial Wigner function along the classical trajectories and to apply the ε-dependent transition coefficient

$$T^{\varepsilon}_{lin}(q^*, p^*) = \exp\left(-\frac{\pi}{\varepsilon}\frac{|q^* \wedge p^*|^2}{|p^*|^3}\right),$$

as soon as the trajectories reach their minimal distance from the crossing set, which is easy to check since $q \cdot p = 0$ at such a point. Theorem 3.2 in [18] proves that under suitable conditions on the initial data this ε-dependent propagation is correct in the limit $\varepsilon \to 0$. We construct here an extension, which covers the general situation described above, and give a convergence proof including a convergence rate. Our approach draws from the understanding of the nonadiabatic mechanism as developed in [5].

2.2. A surface hopping semigroup. Let $R > 0$. In the general case, the crucial points in phase space are those where the classical trajectories attain a *local minimal gap between the two eigenvalues.* These points fulfill the condition

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\left|\phi\left(q^{\pm}(t)\right)\right|^2\right) = 2\,\mathrm{d}\phi\left(q^{\pm}(t)\right)p^{\pm}(t)\,\cdot\,\phi\left(q^{\pm}(t)\right) = 0,$$

and one performs an effective nonadiabatic transfer of weight, whenever a trajectory passes the set

$$S_{\varepsilon,R} = \left\{(q,p) \in \mathbb{R}^{2d} \mid |\phi(q)| \leq R\sqrt{\varepsilon},\, \mathrm{d}\phi(q)p \cdot \phi(q) = 0\right\}.$$

The microlocal normal form, which will be given later in Theorem 5.2, suggests the transition rate

$$T^{\varepsilon}(q^*, p^*) = \exp\left(-\frac{\pi}{\varepsilon}\frac{|\pi_\ell(q^*, p^*)\phi(q^*)|^2}{|\mathrm{d}\phi(q^*)p^*|}\right),$$

where $\pi_\ell(q^*, p^*)$ is the orthogonal projection from the Euclidean space $\mathbb{R}^\ell$ into the hyperplane normal to the vector $\mathrm{d}\phi(q^*)p^* \in \mathbb{R}^\ell$. Since $\mathrm{d}\phi(q^{\pm}(t))p^{\pm}(t)$ does not vanish when the considered trajectories arrive at the crossing set $\{\phi = 0\}$, it is also nonzero when arriving at the jump manifold $S_{\varepsilon,R}$ if $R\sqrt{\varepsilon}$ is small enough. Besides, for $\ell = 2$, one has

$$|\,\pi_\ell(q,p)\phi(q)\,| = |\,\phi(q) \wedge \tfrac{\mathrm{d}\phi(q)p}{|\mathrm{d}\phi(q)p|}\,|,$$

and we recover the transition coefficient $T^{\varepsilon}_{lin}(q^*, p^*)$ for $\phi(q) = q$, $q \in \mathbb{R}^2$.

We attach the labels -1 and $+1$ to phase space. For points $(q, p, j) \in \mathbb{R}^{2d}_{\pm} := \mathbb{R}^{2d} \times \{-1, +1\}$, we consider trajectories

$$\mathcal{T}^{(q,p,j)}_{\varepsilon,R} : [0, +\infty) \to \mathbb{R}^{2d}_{\pm},$$

which combine deterministic classical transport and random jumps between the levels at the manifold $S_{\varepsilon,R}$. More precisely, we set $\mathcal{T}^{(q,p,j)}_{\varepsilon,R}(t) = \left(\Phi^t_j(q,p), j\right)$ as long as $\Phi^t_j(q,p) \notin S_{\varepsilon,R}$. Whenever the deterministic flow $\Phi^t_j(q,p)$ hits the manifold $S_{\varepsilon,R}$ at

a point (q^*, p^*), a random jump from j to $-j$ occurs with probability $T^\varepsilon(q^*, p^*)$. For points (q, p, j) generating classical trajectories, which either violate the non-degeneracy condition (2.1) or do not leave the set $S_{\varepsilon,R}$, there is either no transport or no jump at all. Since the trajectories which touch the crossing set arrive there transversally, each path

$$(q, p, j) \to \mathcal{T}_{\varepsilon,R}^{(q,p,j)}(t)$$

has a finite number of jumps and remains in a bounded region of $\mathbb{R}^{2d}_{\pm}$ within a bounded time interval $[0, T]$. Away from the jump manifold $S_{\varepsilon,R} \times \{-1, +1\}$ each path is smooth. Hence, the random trajectories define a time-dependent Markov process with state space $\mathbb{R}^{2d}_{\pm}$. The associated transition function $P_{\varepsilon,R}(p, q, j; t, \Gamma)$ describes the probability of being at time t in the measurable set $\Gamma \subset \mathbb{R}^{2d}_{\pm}$ having started in (q, p, j). Its action on bounded measurable scalar functions $f : \mathbb{R}^{2d}_{\pm} \to \mathbb{C}$ defines a semigroup $(\mathcal{L}^t_{\varepsilon,R})_{t\geq 0}$ by

$$(\mathcal{L}^t_{\varepsilon,R} f)(q, p, j) := \int_{\mathbb{R}^{2d}\times\{-1,+1\}} f(x, \xi, k)\, P_{\varepsilon,R}(q, p, j; t, \mathrm{d}(x, \xi, k)).$$

For introducing the semigroup's action on Wigner functions, we use the following space of continuous V-diagonal test functions satisfying T^ε-dependent boundary conditions at the jump manifold.

DEFINITION 2.1. *A continuous function $a \in \mathcal{C}_c(\mathbb{R}^{2d} \setminus S_{\varepsilon,R}, \mathbb{C}^{N(\ell)\times N(\ell)})$ belongs to the space $\mathcal{C}_{\varepsilon,R}$ if it has the following properties:*

i. *$a = a^+\Pi^+ + a^-\Pi^-$ with $a^\pm \in \mathcal{C}_c(\mathbb{R}^{2d} \setminus S_{\varepsilon,R}, \mathbb{C})$.*

ii. *The function $f_a : (\mathbb{R}^{2d} \setminus S_{\varepsilon,R}) \times \{-1, +1\} \to \mathbb{C}$,*

$$f_a(q, p, +) = a^+(q, p), \quad f_a(q, p, -) = a^-(q, p),$$

satisfies for all $(q, p, j) \in S_{\varepsilon,R} \times \{-1, +1\}$

$$\begin{aligned}
&\lim_{\delta\to-0} f_a(q + \delta p, p + \delta(-\nabla v(q) - j\ {}^t\mathrm{d}\phi(q)\phi(q)/|\phi(q)|), j)\\
&= \lim_{\delta\to+0} (T^\varepsilon f_a)(q + \delta p, p + \delta(-\nabla v(q) + j\ {}^t\mathrm{d}\phi(q)\phi(q)/|\phi(q)|), -j)\\
&= \lim_{\delta\to+0} ((1 - T^\varepsilon) f_a)(q + \delta p, p + \delta(-\nabla v(q) - j\ {}^t\mathrm{d}\phi(q)\phi(q)/|\phi(q)|), j).
\end{aligned}$$

For test functions $a \in \mathcal{C}_{\varepsilon,R}$, the action of $(\mathcal{L}^t_{\varepsilon,R})_{t\geq 0}$ is naturally given by

$$(\mathcal{L}^t_{\varepsilon,R}\, a)(q, p) := \left(\mathcal{L}^t_{\varepsilon,R} f_a\right)(q, p, +1)\, \Pi^+(q) + \left(\mathcal{L}^t_{\varepsilon,R} f_a\right)(q, p, -1)\, \Pi^-(q).$$

By construction, the semigroup leaves $\mathcal{C}_{\varepsilon,R}$ invariant, and duality allows us to define its action on Wigner functions. More precisely, let $W^\varepsilon(\psi)$ be the Wigner function of some wave function $\psi \in L^2(\mathbb{R}^d, \mathbb{C}^{N(\ell)})$. Then, $\mathcal{L}^t_{\varepsilon,R} W^\varepsilon(\psi)$ acts on $a \in \mathcal{C}_{\varepsilon,R}$ by

$$\left(\mathcal{L}^t_{\varepsilon,R} W^\varepsilon(\psi), a\right) = \mathrm{tr} \int_{\mathbb{R}^{2d}} W^\varepsilon(\psi)(q, p)(\mathcal{L}^t_{\varepsilon,R}\, a)(q, p)\, \mathrm{d}q\, \mathrm{d}p,$$

defining a locally integrable function on phase space. We finally choose an ε-dependent hopping range $R(\varepsilon) = \varepsilon^{-1/8}$ and set

$$(\mathcal{L}^t_\varepsilon)_{t\geq 0} := (\mathcal{L}^t_{\varepsilon,R(\varepsilon)})_{t\geq 0}.$$

2.3. Assumptions and main result. Let $\psi^\varepsilon(t)$ be the solution of the Schrödinger equation (1.1) with initial datum ψ_0^ε. We now state the precise assumptions, under which the action of the semigroup $(\mathcal{L}_\varepsilon^t)_{t\geq 0}$ on the initial Wigner function $W^\varepsilon(\psi_0^\varepsilon)$ approximates the V-diagonal components of $W^\varepsilon(\psi^\varepsilon(t))$.

(A0) $V \in \mathcal{C}^\infty(\mathbb{R}^d, \mathbb{C}^{N(\ell)\times N(\ell)})$ is of subquadratic growth and of the form

$$V(q) = v(q)\,\mathrm{Id} + V_\ell\left(\phi(q)\right), \quad \ell \in \{2, 3, 3', 5\},$$

where the matrices $V_\ell(\phi(q))$ have been defined in (1.2), (1.3), and (1.4). We assume the eigenvalue crossings to be generic in the sense that $\mathrm{d}\phi$ is of maximal rank on the crossing set $\{\phi = 0\}$.

(A1) $(\psi_0^\varepsilon)_{\varepsilon>0}$ is a bounded family in $L^2\big(\mathbb{R}^d, \mathbb{C}^{N(\ell)}\big)$ associated with $\mathrm{Ran}\Pi^+$,

$$\|\Pi^-\psi_0^\varepsilon\|_{L^2(\mathbb{R}^d,\mathbb{C}^{N(\ell)})} = O(\varepsilon^{\beta_1}), \quad \beta_1 \geq 1/8.$$

We suppose that the initial data are localized away from the crossing $\{\phi = 0\}$; i.e., for all $b \in \mathcal{C}_c^\infty(\mathbb{R}^{2d}, \mathbb{C}^{N(\ell)\times N(\ell)})$ with $\mathrm{supp}(b) \subset \{|\phi| \leq R\sqrt{\varepsilon}\}$, $R = \varepsilon^{-1/8}$,

$$\int_{\mathbb{R}^{2d}} W^\varepsilon(\psi_0^\varepsilon)(q,p)\, b(q,p)\,\mathrm{d}q\,\mathrm{d}p = O(\varepsilon^{\beta_2}), \quad \beta_2 \geq 1/8.$$

We also assume localization away from the set

$$\left\{(q_0,p_0) \in \mathbb{R}^{2d} \mid \exists t > 0 : \phi(q^\pm(t)) = 0,\ \mathrm{d}\phi(q^\pm(t))p^\pm(t) = 0\right\},$$

which contains the points issuing classical trajectories, which arrive at the crossing without a unique continuation through it.

(A2) The test function $a \in \mathcal{C}_c^\infty\left(\mathbb{R}^{2d}, \mathbb{C}^{N(\ell)\times N(\ell)}\right)$ has its support at a distance larger than $R\sqrt{\varepsilon}$ with $R = \varepsilon^{-1/8}$ from the crossing; that is,

$$\mathrm{supp}(a) \cap \left\{(q,p) \in \mathbb{R}^{2d} \mid |\phi(q)| \leq R\sqrt{\varepsilon}\right\} = \emptyset, \qquad R = \varepsilon^{-1/8},$$

and

$$a(q,p) = a^+(q,p)\Pi^+(q) + a^-(q,p)\Pi^-(q), \qquad (q,p) \in \mathbb{R}^{2d},$$

with scalar-valued $a^\pm \in \mathcal{C}_c^\infty(\mathbb{R}^{2d}, \mathbb{C})$.

(A3) Within the time interval $[0,T]$, each of the plus-trajectories arriving at the support of a^+ at time T has performed at most one jump, generating minus-trajectories arriving at the support of a^-, which have not jumped at all.

Alternatively, assumptions (A1) and (A3) could also require that the initial data are associated with $\mathrm{Ran}\Pi^-$ and that each of the minus-trajectories arriving at the support of a^- at time T has performed at most one jump, generating plus-trajectories arriving at the support of a^+, which have not jumped at all.

THEOREM 2.2. *Let the potential V, the initial data $(\psi_0^\varepsilon)_{\varepsilon>0}$, the observable a, and the time interval $[0,T]$ fulfill assumptions* (A0), (A1), (A2), *and* (A3). *Let $\chi \in \mathcal{C}_c^\infty([0,T],\mathbb{R})$. Then, there exist positive constants $C, \varepsilon_0 > 0$ such that for all $0 < \varepsilon < \varepsilon_0$ the solution $\psi^\varepsilon(t)$ of the Schrödinger equation* (1.1) *satisfies*

$$\left|\mathrm{tr}\int_{\mathbb{R}^{2d+1}} \chi(t)\left(W^\varepsilon(\psi^\varepsilon(t)) - \mathcal{L}_\varepsilon^t W^\varepsilon(\psi_0)\right)(q,p)\, a(q,p)\,\mathrm{d}q\,\mathrm{d}p\,\mathrm{d}t\right| \leq C\,\varepsilon^{1/8}. \tag{2.3}$$

Before entering the proof, we add some remarks. First, if one allows initial data in assumption (A1) with $\beta_1, \beta_2 > 0$, then the result holds with convergence

rate $\varepsilon^{\min(\beta_1,\beta_2,1/8)}$. Second, pointwise convergence holds on time intervals without nonadiabatic jumps, that is, when the solution has passed by the jump manifold; see also [18]. However, for pointwise convergence only the limit behavior without convergence rate can be deduced, since the constants C and ε_0 depend on the cut-off function χ and its derivatives in a way that possible oscillations in time are not controlled. Finally, in section 6 an extension of the approximation for the cases $\ell = 3', 5$ with degenerate eigenvalues is given. There, assumption (A2) is generalized to observables a which commute with V, that is, $a = \Pi^+ a \Pi^+ + \Pi^- a \Pi^-$.

2.4. Strategy of the proof. For notational convenience, we suppose $\beta_1 = \beta_2 = 1/2$. Otherwise, one has to add $O(\varepsilon^{1/8})$ in all the estimates. We work with the semigroup $(\mathcal{L}^t_{\varepsilon,R})_{t\geq 0}$ and prove convergence with an error of order

$$O(1/(R^5\sqrt{\varepsilon})) + O(R^3\sqrt{\varepsilon}) + O(1/R^2) + O(\sqrt{\varepsilon}\,|\ln\varepsilon|)$$

as $\varepsilon \to 0$ and $R \to +\infty$, which gives the claimed rate when choosing $R = \varepsilon^{-1/8}$. We distinguish between regions of large and small eigenvalue gap, that is, between sets $\{|\phi| > C\,R\sqrt{\varepsilon}\}$ with $C = \frac{1}{2}, 1$ on the one hand and $\{|\phi| \leq R\sqrt{\varepsilon}\}$ on the other hand. For a large gap we prove classical transport with an error of size $O(1/(R^5\sqrt{\varepsilon})) + O(1/R^2) + O(\sqrt{\varepsilon})$. Close to the crossing set, proving the relevance of nonadiabatic transitions, we use a microlocal normal form, which reduces the Schrödinger equation to a Landau–Zener-type problem with explicitly computable transition rates. There, we introduce an error of order $O(R^3\sqrt{\varepsilon}) + O(1/R^2) + O(\sqrt{\varepsilon}|\ln\varepsilon|) + O(1/(R^5\sqrt{\varepsilon}))$. The combination of both errors will then yield the final estimate of Theorem 2.2.

PROPOSITION 2.3. *Let $c \in \mathcal{C}^\infty_c(\mathbb{R}^{2d}, \mathbb{C})$, and let $b \in \mathcal{C}^\infty(\mathbb{R}^\ell, \mathbb{C})$ with ∇b compactly supported. If there exist $C > 0$ and $s_0 > 0$ such that*

$$\forall r \in [-s_0, s_0]: \quad \Phi^r_\pm(\mathrm{supp}(c)) \subset \{|\phi| > C\,R\sqrt{\varepsilon}\},$$

then for all $\chi \in \mathcal{C}^\infty_c(\mathbb{R}, \mathbb{R})$ and for all $s \in [t - s_0, t + s_0]$

$$\begin{aligned}
&\mathrm{tr} \int_{\mathbb{R}^{2d+1}} \chi(t)\, c(q,p)\, b\Big(\tfrac{\phi(q)}{R\sqrt{\varepsilon}}\Big)\, \Pi^\pm(q) W^\varepsilon(\psi^\varepsilon(t))(q,p)\, \mathrm{d}q\, \mathrm{d}p\, \mathrm{d}t \\
&= \mathrm{tr} \int_{\mathbb{R}^{2d+1}} \chi(t)\, c(q,p)\, b\Big(\tfrac{\phi(q)}{R\sqrt{\varepsilon}}\Big)\, \big(\Pi^\pm W^\varepsilon(\psi^\varepsilon(s))\, \Pi^\pm \circ \Phi^{-t+s}_\pm\big)(q,p)\, \mathrm{d}q\, \mathrm{d}p\, \mathrm{d}t \\
&\qquad + O\Big(\tfrac{1}{R^5\sqrt{\varepsilon}}\Big) + O\big(\tfrac{1}{R^2}\big) + O(\sqrt{\varepsilon}).
\end{aligned}$$

Proposition 2.3 will be proved in section 4. To use it for the main proof, we need to specify which points of $\mathrm{supp}(a^\pm)$ arrive close to the crossing. We denote the sets of trajectories arriving at (respectively, arising from) the crossing set $\{\phi = 0\}$ by

$$M^{\pm,in} = \big\{\Phi^t_\pm(q,p) \in \mathbb{R}^{2d} \mid \Phi^t_\pm(q,p) \notin \{\phi = 0\}, \exists t_0 < t : \Phi^{t_0}_\pm(q,p) \in \{\phi = 0\}\big\},$$

$$M^{\pm,out} = \big\{\Phi^t_\pm(q,p) \in \mathbb{R}^{2d} \mid \Phi^t_\pm(q,p) \notin \{\phi = 0\}, \exists t_0 > t : \Phi^{t_0}_\pm(q,p) \in \{\phi = 0\}\big\}.$$

The sets $M^{\pm,in/out}$ are smooth submanifolds of $\mathbb{R}^{2d}$. By construction of the semigroup, all phase space points generating backward trajectories passing through the zone of small gap $\{|\phi| \leq R\sqrt{\varepsilon}\}$ and performing a jump are contained in a neighborhood $\Omega^\pm$ of the intersection of the support of $a^\pm$ with $M^{\pm,out}$.

Some of the random trajectories reaching $\Omega^\pm$ touch the crossing set. We consider one of them, which arrives at time t_0 at (q_0, p_0) with $\phi(q_0) = 0$, $\mathrm{d}\phi(q_0)p_0 \neq 0$,

and choose the associated point (q_0, t_0, p_0, τ_0) in the phase space of space-time, where $\tau_0 = -\frac{1}{2}|p_0|^2 - v(q_0)$ is the energy coordinate. The normal form theorems [1, 2, 6] give neighborhoods of these points, on which the Schrödinger equation (1.1) microlocally reduces to a Landau–Zener-type problem

$$-i\varepsilon\partial_s v^\varepsilon = V_\ell(s, \tilde{z} + \gamma_\varepsilon(z,\zeta))v^\varepsilon + O(\varepsilon^\infty).$$

These model problems have explicitly computable transition rates in the scattering regime; see [7, 8]. The compact subset of $\{|\phi| < R\sqrt{\varepsilon}\}$, which is touched by the backward trajectories coming from $\Omega^\pm$, can be covered by finitely many of these neighborhoods projected to $\mathbb{R}^{2d}$, and without loss of generality we assume that one of them suffices.

Moreover, for each point in $\Omega^\pm$ being reached by a random trajectory at time t there are positive numbers $0 < t_{\mathrm{f}}^\pm < t_{\mathrm{i}}^\pm$, such that at time $t - t_{\mathrm{i}}^\pm$ and $t - t_{\mathrm{f}}^\pm$ the trajectories are contained in an annulus $\{C_1\sqrt{\varepsilon} < |\phi| < C_2\sqrt{\varepsilon}\}$ with $C_1, C_2 > 0$ and have performed their only jump within the interval $]t - t_{\mathrm{i}}^\pm, t - t_{\mathrm{f}}^\pm[$, whose length is denoted by $\delta_t^\pm = t_{\mathrm{i}}^\pm - t_{\mathrm{f}}^\pm$. These quantities are well defined, since the trajectories are transverse to the crossing set. Choosing $C_1 = \frac{R}{2}$ and $C_2 = R$, $\Omega^\pm$ can be covered by finitely many open sets, such that each of these sets can be associated with such points of time $t_{\mathrm{i}}^\pm$ and $t_{\mathrm{f}}^\pm$. Without loss of generality, we assume that one of them is enough. Then, we have by Proposition 2.3 with $C = \frac{1}{2}$

$$\begin{aligned}
&\operatorname{tr}\int_{\mathbb{R}^{2d+1}} \chi(t)\, a^\pm(q,p)\, \Pi^\pm(q) W^\varepsilon(\psi^\varepsilon(t))(q,p)\,\mathrm{d}q\,\mathrm{d}p\,\mathrm{d}t \\
&= \operatorname{tr}\int_{\mathbb{R}^{2d+1}} \chi(t)\, a^\pm(q,p)\, \left(\Pi^\pm W^\varepsilon\big(\psi^\varepsilon(t - t_{\mathrm{f}}^\pm)\big)\, \Pi^\pm \circ \Phi_\pm^{-t_{\mathrm{f}}^\pm}\right)(q,p)\,\mathrm{d}q\,\mathrm{d}p\,\mathrm{d}t \\
&\qquad\qquad + O(1/(R^5\sqrt{\varepsilon})) + O(1/R^2) + O(\sqrt{\varepsilon}).
\end{aligned}$$

Then, we perform a cut-off of the symbol $a^\pm \circ \Phi_\pm^{t_{\mathrm{f}}^\pm}$. We consider a smooth compactly supported function $\chi_0 \in \mathcal{C}_c^\infty(\mathbb{R}^\ell, \mathbb{R})$ such that $\chi_0(u) = 1$ on $\{|u| < 1\}$ and $\chi_0(u) = 0$ for $\{|u| > 2\}$. We write

$$\begin{aligned}
\left(a^\pm \circ \Phi_\pm^{t_{\mathrm{f}}^\pm}\right)(q,p) &= a_{BO}^\pm(q,p) + a_{LZ}^\pm(q,p), \\
a_{BO}^\pm(q,p) &= \left(a^\pm \circ \Phi_\pm^{t_{\mathrm{f}}^\pm}\right)(q,p)\left(1 - \chi_0\Big(\tfrac{\phi(q)}{R\sqrt{\varepsilon}}\Big)\right), \\
a_{LZ}^\pm(q,p) &= \left(a^\pm \circ \Phi_\pm^{t_{\mathrm{f}}^\pm}\right)(q,p)\,\chi_0\Big(\tfrac{\phi(q)}{R\sqrt{\varepsilon}}\Big).
\end{aligned}$$

Since the trajectories, which pass within the time interval $]t - t_{\mathrm{i}}^\pm, t - t_{\mathrm{f}}^\pm[$ through the support of $a_{BO}^\pm$, do not jump, Proposition 2.3 with $C = 1$ is enough to deal with the Born–Oppenheimer part. The analysis of the Landau–Zener part, however, involves nonadiabatic transitions. For points $(q,p) \in \operatorname{supp}(a_{LZ}^\pm)$ we have $|\phi(q)| \leq 2R\sqrt{\varepsilon}$. Hence, not all of the trajectories passing through the support of $a_{LZ}^\pm$ jump. Nevertheless, we argue as if all of them did. Indeed, the transition coefficients generated by these added jumps are exponentially small with respect to ε, since they occur for points (q,p) with $|\phi(q)| > R\sqrt{\varepsilon}$.

PROPOSITION 2.4. *Let $0 < t_{\mathrm{f}}^\pm < t_{\mathrm{i}}^\pm$ be such that at $t - t_{\mathrm{i}}^\pm$ and $t - t_{\mathrm{f}}^\pm$ all random trajectories arriving at time t in $\Omega^\pm$ are contained in $\left\{\frac{R}{2}\sqrt{\varepsilon} \leq |\phi| \leq R\sqrt{\varepsilon}\right\}$ and have*

performed their only jump within the interval $]t - t_{\rm i}^{\pm}, t - t_{\rm f}^{\pm}[$ *of length* $\delta_t^{\pm} = t_{\rm i}^{\pm} - t_{\rm f}^{\pm}$. *Then, for all* $\chi \in \mathcal{C}_c^{\infty}([0,T],\mathbb{R})$

$$\begin{aligned}
&\operatorname{tr} \int_{\mathbb{R}^{2d+1}} \chi(t)\, W^{\varepsilon}(\psi^{\varepsilon}(t))(q,p)\, a_{LZ}^{\pm}(q,p)\Pi^{\pm}(q)\,\mathrm{d}q\,\mathrm{d}p\,\mathrm{d}t \\
&= \operatorname{tr} \int_{\mathbb{R}^{2d+1}} \chi(t)\, W^{\varepsilon}(\psi^{\varepsilon}(t-\delta_t^{\pm}))(q,p)(\mathcal{L}_{\varepsilon,R}^{\delta_t^{\pm}} a_{LZ}^{\pm})(q,p)\,\Pi^{+}(q)\,\mathrm{d}q\,\mathrm{d}p\,\mathrm{d}t \\
&\qquad + O(1/R^2) + O(R^3\sqrt{\varepsilon}) + O(\sqrt{\varepsilon}|\ln\varepsilon|) + O(1/(R^5\sqrt{\varepsilon})). \qquad (2.4)
\end{aligned}$$

One observes that in the right-hand side of (2.4) only the plus-projector Π^+ appears. This comes from the fact that at time $t - t_{\rm i}^{\pm}$ the contribution on the minus-mode is of order $O(1/(R^5\sqrt{\varepsilon})) + O(1/R^2) + O(\sqrt{\varepsilon})$, which is due to Proposition 2.3 and the initial data being associated only with $\operatorname{Ran}\Pi^+$. Finally, again the classical transport result of Proposition 2.3 relates the right-hand side of (2.4) with the initial data, and the proof of our main result, Theorem 2.2, is complete.

3. Numerical experiments. Before giving the detailed proof, we present numerical experiments illustrating the theoretical convergence result and the effectiveness of the algorithm. We consider a two-level Schrödinger equation with codimension two crossing in two space dimensions, which models the photoisomerization of retinal in rhodopsin. This conformational change is considered as the first step of vision. In [14], computations with the model Hamiltonian

$$-\tfrac{\omega}{2}\partial_x^2 - \tfrac{1}{2m}\partial_\varphi^2 + \tfrac{1}{2}\omega x^2 + \begin{pmatrix} \frac{1}{2}W_0(1-\cos\varphi) & \lambda x \\ \lambda x & E_1 - \frac{1}{2}W_1(1-\cos\varphi) + \kappa x \end{pmatrix}$$

have qualitatively reproduced spectroscopic information of the molecule. The two effective coordinates $(\varphi, x) \in]-\frac{\pi}{2}, \frac{3\pi}{2}] \times \mathbb{R}$ consist of the reaction coordinate ϕ and a collective coordinate x. The parameters are $m^{-1} = 4.84 \cdot 10^{-4}$, $E_1 = 2.48$, $W_0 = 3.6$, $W_1 = 1.09$, $\omega = \lambda = 0.19$, and $\kappa = 0.1$ (all in eV, $\hbar = 1$); see note 18 in [14]. Setting

$$\varepsilon = m^{-1/2} = 0.022, \qquad q_1 = \varphi, \qquad q_2 = \frac{\varepsilon}{\sqrt{\omega}}\, x,$$

one obtains a rescaled Hamiltonian $-\frac{\varepsilon^2}{2}\Delta_q + V(q)$ with potential

$$V(q) = \tfrac{1}{2}(\beta q_2)^2 + \begin{pmatrix} \frac{1}{2}W_0(1-\cos q_1) & \alpha_1 q_2 \\ \alpha_1 q_2 & E_1 - \frac{1}{2}W_1(1-\cos q_2) + \alpha_2 q_2 \end{pmatrix},$$

whose parameters $(\alpha_1, \alpha_2) = \frac{\sqrt{\omega}}{\varepsilon}(\kappa, \lambda) \approx (2,\, 3.8)$ and $\beta = \omega/\varepsilon \approx 8.6$ are of order one with respect to ε. Fixing these values of (α_1, α_2) and β, we run a series of experiments for varying values of the semiclassical parameter ε and hopping ranges R,

$$\varepsilon \in \{0.0005, 0.001, 0.005, 0.01, 0.015, 0.02, 0.022, 0.03\}, \qquad R \in \{1, 2, 3\},$$

in the following set-up. We consider normalized Gaussian initial data associated with the plus-level, that is,

$$\psi_0^{\varepsilon}(q) = (\varepsilon\pi)^{-1/2} \exp\bigl(-\tfrac{1}{2\varepsilon}|q - q_0^{\varepsilon}|^2 + \tfrac{i}{\varepsilon}\, p_0 \cdot (q - q_0^{\varepsilon})\bigr)\, v^{+}(q),$$

TABLE 1

The table shows final level populations and particle numbers as well as the accuracy of the reference solver. The population of the upper level $\|\Pi^+\psi^\varepsilon(t)\|^2$ at the final time $T = 7\sqrt{\varepsilon}$ is computed by the reference solver, a pseudospectral Strang splitting scheme, and illustrates leading order nonadiabatic transitions for all test cases. Depending on the hopping range R, the final particle numbers of the surface hopping algorithm vary between 3000 and 30000. The reference accuracy is the difference in L^2-norm of the final wave function computed with full and half resolution. For all computations it is less than 10^{-4}.

ε	0.0005	0.001	0.005	0.01	0.015	0.02	0.022	0.03
$\|\Pi^+\psi^\varepsilon(t)\|^2$	0.499	0.576	0.792	0.378	0.263	0.276	0.276	0.239
♯ particles, $R=1$	5396	5229	3730	3548	3316	3274	3482	3292
♯ particles, $R=2$	6650	6353	4732	4766	4801	5569	6106	8281
♯ particles, $R=3$	7392	6881	5809	6155	7119	10 536	12 581	34 485
Ref. accuracy $\cdot 10^5$	3.44	2.89	7.57	2.56	2.47	2.45	2.47	2.63

where $v^+(q)$ is a normalized eigenvector of $V(q)$ for the eigenvalue $v(q)+|\phi(q)|$, which depends smoothly on q. The initial center in position space

$$q_0^\varepsilon = \big(1.63 - 4\sqrt{\varepsilon},\, 0.5\sqrt{\varepsilon}\big)$$

is chosen left of the two crossing points $(\gamma_\mathrm{l}, 0)$, $(\gamma_\mathrm{r}, 0)$, where $\gamma_{\mathrm{l,r}}$ are the two solutions of $\cos\varphi = 1 - 2E_1/(W_0 + W_1)$ for $\varphi \in]-\frac{\pi}{2}, \frac{3\pi}{2}]$, that is, $\gamma_\mathrm{l} \approx 1.63$ and $\gamma_\mathrm{r} \approx 4.65$. The initial momentum center and the time interval,

$$p_0 = (1, 0), \qquad [0, T] = [0, 7\sqrt{\varepsilon}],$$

are chosen such that the wave function passes only the left crossing point $(\gamma_\mathrm{l}, 0)$ once without returning to it again. The upper level populations $\|\Pi^+\psi^\varepsilon(t)\|^2$ at the final time $T = 7\sqrt{\varepsilon}$, which are given in Table 1, confirm that the experimental set-up produces leading order nonadiabatic transitions.

The numerical realization of the surface hopping semigroup $(\mathcal{L}^t_{\varepsilon,R})_{t\geq 0}$ is the same as for the simulations of models with a linear isotropic potential matrix presented in [17], up to adding the $R\sqrt{\varepsilon}$-dependent jump criterion

$$t \mapsto |\phi(q^\pm(t))| \text{ has a local minimum in } t = t^* \text{ and } |\phi(q^\pm(t^*))| \leq R\sqrt{\varepsilon}.$$

The initial sampling is performed on 16×16 grids in position and momentum space, and the classical transport is discretized by the explicit Runge–Kutta method of Dormand and Prince `DOPRI45`. For comparison, we have also solved the Schrödinger equation (1.1) by a numerically converged pseudospectral Strang splitting scheme. The solutions obtained with a 1024×512 space grid on the computational domain $[1.63 - 8\sqrt{\varepsilon}, 1.63 + 16\sqrt{\varepsilon}] \times [-6\sqrt{\varepsilon}, 6\sqrt{\varepsilon}]$ and with 10^4 time steps are regarded as a reference, since they differ in L^2-norm from the corresponding solution with a fourth of the grid points and half the time steps by less than 10^{-4}; see Table 1. We have computed the following quadratic quantities of the wave function at final time $T = 7\sqrt{\varepsilon}$: the level populations $\|\Pi^\pm\psi^\varepsilon(t)\|^2$ and the expectation values of position and momentum on each level,

$$\langle \Pi^\pm(q)\psi^\varepsilon(q,t), q\Pi^\pm(q)\psi^\varepsilon(q,t)\rangle, \qquad \langle \Pi^\pm(q)\psi^\varepsilon(q,t), -i\varepsilon\nabla_q\Pi^\pm(q)\psi^\varepsilon(q,t)\rangle.$$

We note that the reference solver restricts the length of the time interval to $7\sqrt{\varepsilon}$, since the dynamics can be resolved only as long as the solution stays well localized in the computational domain, while for the fixed number of 1024×512 grid points the size of the computational domain affects the numerical accuracy.

Comparing the outcome of the two algorithms, we find all errors within and below the corridor $[\frac{1}{5}\sqrt{\varepsilon}, 5\sqrt{\varepsilon}]$ (see Figure 1), which is better than the proven convergence rate $\varepsilon^{1/8}$. Moreover, the errors increase monotonically when increasing the semiclassical parameter; however, when entering the range $\varepsilon \geq 0.01$ we observe different dependencies. The level populations' error starts decreasing, while the error of the momentum expectation oscillates. We have no mathematical explanation for these observations and can make only an educated guess. The good convergence rate might be caused by the localization properties of the initial Gaussian wave packet combined with the short length of the time interval. Indeed, the error terms $O(1/R^2)$ and $O(1/(R^5\sqrt{\varepsilon}))$ in the approximation by classical transport in Proposition 2.3 might be negligible in this case as well as the contribution $O(1/R^2)$ in Proposition 2.4, which is due to localization in energy. The tendencies for a large semiclassical parameter, however, are clearly beyond the reach of our asymptotic analysis.

Table 1 shows that an increase of the hopping range R increases the number of final particles, that is, the number of jumps within the overall time interval. We obtain particle numbers around 3000 and 30000 for $R = 1$ and $R = 3$, respectively, resulting in half a minute and 5 minutes computing time for our implementation of the algorithm in MATLAB 7.0 on a 3GHz Pentium 4 computer. However, an enlarged hopping range need not improve the accuracy of the approximation. The plots in Figure 1 mostly display smaller errors for larger R, but the level populations in the physical relevant range of $\varepsilon = 0.022$ have the most accurate computation for $R = 2$.

Summarizing, the numerical experiments are consistent with the theoretical result, but also present a better convergence rate and tendencies in the range of a larger semiclassical parameter, which seem to be unexplainable by our asymptotic analysis. A systematic comparison with the well-established surface hopping algorithms of chemical physics is in progress.

4. Propagation outside the crossing zone. We now begin proving our main result. The first step is to establish the validity of the classical transport approximation in the zone of large eigenvalue gap $\{|\phi| \geq C\, R\sqrt{\varepsilon}\}$.

Proof of Proposition 2.3. Our aim is to prove

$$\operatorname{tr} \int \left\{\chi(t)c(q,p)b\Big(\tfrac{\phi(q)}{R\sqrt{\varepsilon}}\Big), \tau + \tfrac{1}{2}|p|^2 + v(q) \pm |\phi(q)|\right\} \Pi^{\pm}(q) W^{\varepsilon}(\psi^{\varepsilon}(t))(q,p)\, \mathrm{d}q\, \mathrm{d}p\, \mathrm{d}t$$
$$= O\big(\tfrac{1}{R^2}\big) + O\Big(\tfrac{1}{R^5\sqrt{\varepsilon}}\Big) + O(\sqrt{\varepsilon}),$$

since then classical transport follows immediately. The key argument is the estimation of the action of the commutator

$$K = \tfrac{1}{\varepsilon}\left[\chi(t)\mathrm{op}_{\varepsilon}\Big(c(q,p)b\Big(\tfrac{\phi(q)}{R\sqrt{\varepsilon}}\Big)\,\Pi^{\pm}(q)\Big)\ ,\ -i\varepsilon\partial_t - \tfrac{\varepsilon^2}{2}\Delta_q + V(q)\right]$$

on the solution of the Schrödinger equation (1.1). Indeed, observing that

$$(K\psi^{\varepsilon}, \psi^{\varepsilon})_{L^2(\mathbb{R}^{d+1})} = 0,$$

we are going to prove

$$(K\psi^{\varepsilon}, \psi^{\varepsilon})_{L^2(\mathbb{R}^{d+1})} = O\big(\tfrac{1}{R^2}\big) + O\Big(\tfrac{1}{R^5\sqrt{\varepsilon}}\Big) + O(\sqrt{\varepsilon})$$
$$+ \left(\mathrm{op}_{\varepsilon}\left(\left\{\chi(t)c(q,p)b\Big(\tfrac{\phi(q)}{R\sqrt{\varepsilon}}\Big), \tau + \tfrac{1}{2}|p|^2 + v(q) \pm |\phi(q)|\right\}\Pi^{\pm}(q)\right)\psi^{\varepsilon}, \psi^{\varepsilon}\right)_{L^2(\mathbb{R}^{d+1})},$$

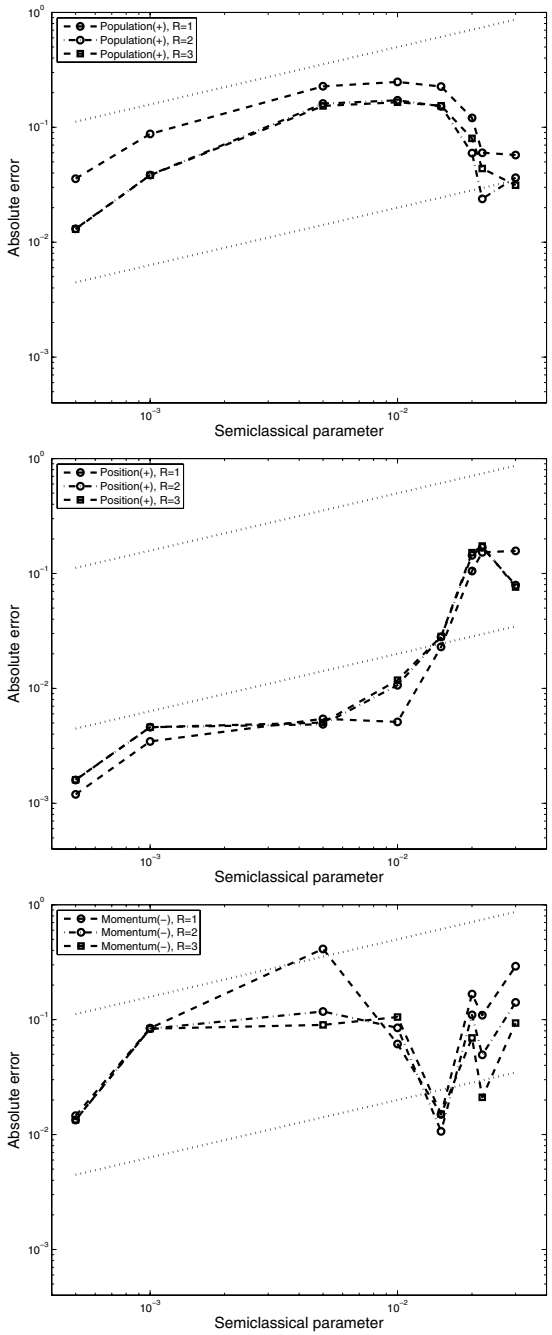

FIG. 1. *Double logarithmic plots of the absolute error, when comparing the outcome of the surface hopping algorithm with a numerically converged pseudospectral splitting scheme. The semiclassical parameter ε varies in the set $\{0.0005, 0.001, 0.005, 0.01, 0.015, 0.02, 0.022, 0.03\}$. The dashed, dashed-dotted, and solid lines refer to a hopping range $R = 1, 2, 3$, respectively. The three plots show the error of the level population $\|\Pi^+(q)\psi^\varepsilon(q,t)\|^2$, of the position expectation value $\langle \Pi^+(q)\psi^\varepsilon(q,t), q\Pi^+(q)\psi^\varepsilon(q,t)\rangle$, and of the momentum expectation $\langle \Pi^-(q)\psi^\varepsilon(q,t), -i\varepsilon\nabla_q\Pi^-(q)\psi^\varepsilon(q,t)\rangle$ at the final time $T = 7\sqrt{\varepsilon}$. All errors lie in and below the corridor defined by the two functions $\varepsilon \mapsto 5\sqrt{\varepsilon}$ and $\varepsilon \mapsto \frac{1}{5}\sqrt{\varepsilon}$, which are represented by dotted lines.*

where op_ε also denotes Weyl quantized operators acting on space-time variables. We use the scaling operator

$$T : L^2_{\mathrm{loc}}(\mathbb{R}^{d+1}) \to L^2_{\mathrm{loc}}(\mathbb{R}^{d+1}), \quad (T\psi)(t,q) = \varepsilon^{d/4}\psi(t,\sqrt{\varepsilon}q) \tag{4.1}$$

and write

$$T^*KT = \tfrac{1}{\varepsilon}\Big[\mathrm{op}_1\Big(\chi(t)c(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)b\Big(\tfrac{\phi(\sqrt{\varepsilon}q)}{R\sqrt{\varepsilon}}\Big)\,\Pi^\pm(\sqrt{\varepsilon}q)\Big)\ ,\ -i\varepsilon\partial_t - \tfrac{\varepsilon}{2}\Delta_q + V(\sqrt{\varepsilon}q)\Big].$$

We have to deal carefully with the ε, R dependence of the symbol in the left-hand side of the commutator. For all multi-indices $\alpha \in \mathbb{N}^d$,

$$D^\alpha\big(\Pi^\pm(q)\big) = O(|\phi(q)|^{-|\alpha|}).$$

Since $|\phi(q)| > C\,R\sqrt{\varepsilon}$ on the support of $b_{\varepsilon,R}(q,p) := c(q,p)b(\frac{\phi(q)}{R\sqrt{\varepsilon}})$, we have

$$D^\alpha_q\big((b_{\varepsilon,R}\Pi^\pm)(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\big) = O(1), \quad D^\alpha_p\big((b_{\varepsilon,R}\Pi^\pm)(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\big) = O(\varepsilon^{|\alpha|/2}) \tag{4.2}$$

for $\alpha \in \mathbb{N}^d$. By the symbolic calculus of Lemma A.2,

$$\begin{aligned}\tfrac{1}{\varepsilon}\big[\mathrm{op}_1\big((b_{\varepsilon,R}\Pi^\pm)\big(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p\big)\big),\mathrm{op}_1\big(\tfrac{\varepsilon}{2}|p|^2\big)\big] &= \tfrac{1}{i}\,\mathrm{op}_1(\{(b_{\varepsilon,R}\Pi^\pm)\big(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p\big),\tfrac{1}{2}|p|^2\}) \\ &= \tfrac{1}{i}\,\mathrm{op}_1\big(\{b_{\varepsilon,R}(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p),\tfrac{1}{2}|p|^2\}\Pi^\pm(\sqrt{\varepsilon}q)\big) - \tfrac{1}{i}\,\mathrm{op}_1\big(r_0(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\big),\end{aligned}$$

where

$$r_0(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p) = b_{\varepsilon,R}(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\sum_{j=1}^d \sqrt{\varepsilon}p_j(\partial_{q_j}\Pi^\pm)(\sqrt{\varepsilon}q). \tag{4.3}$$

Moreover, in view of $[\Pi^\pm, V] = 0$ and (4.2),

$$\begin{aligned}\tfrac{1}{\varepsilon}\big[\mathrm{op}_1\big((b_{\varepsilon,R}\Pi^\pm)\big(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p\big)\big)\,,\,V(\sqrt{\varepsilon}q)\big] &= \tfrac{1}{2i\varepsilon}\,\mathrm{op}_1(\{(b_{\varepsilon,R}\Pi^\pm)(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p),V(\sqrt{\varepsilon}q)\}) \\ &\quad - \tfrac{1}{2i\varepsilon}\,\mathrm{op}_1(\{V(\sqrt{\varepsilon}q),(b_{\varepsilon,R}\Pi^\pm)(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\}) + O(\varepsilon).\end{aligned}$$

Working on the Poisson brackets involving $V = v + V_\ell(\phi)$, we first observe that

$$\big\{b_{\varepsilon,R}\Pi^\pm, V_\ell(\phi)\big\} - \big\{V_\ell(\phi), b_{\varepsilon,R}\Pi^\pm\big\} = \Pi^\pm\,\{b_{\varepsilon,R}, V_\ell(\phi)\} - \{V_\ell(\phi), b_{\varepsilon,R}\}\,\Pi^\pm.$$

Using that $V_\ell(\phi) = |\phi|(\Pi^+ - \Pi^-)$ and $\partial_{q_j}\Pi^\pm = \Pi^\pm(\partial_{q_j}\Pi^\pm) + (\partial_{q_j}\Pi^\pm)\Pi^\pm$, we get

$$\big\{b_{\varepsilon,R}\Pi^\pm, V_\ell(\phi)\big\} - \big\{V_\ell(\phi), b_{\varepsilon,R}\Pi^\pm\big\} = \pm 2\{b_{\varepsilon,R},|\phi|\}\Pi^\pm \pm 2\,|\phi|\sum_{j=1}^d \big(\partial_{p_j}b_{\varepsilon,R}\big)\,\partial_{q_j}\Pi^\pm$$

and set

$$\begin{aligned} r_1(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p) &= \tfrac{1}{\varepsilon}|\phi(\sqrt{\varepsilon}q)|\sum_{j=1}^d \partial_{p_j}\big(b_{\varepsilon,R}(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\big)\,\partial_{q_j}\big(\Pi^\pm(\sqrt{\varepsilon}q)\big) \\ &= |\phi(\sqrt{\varepsilon}q)|\sum_{j=1}^d (\partial_{p_j}c)(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\,b\Big(\tfrac{\phi(\sqrt{\varepsilon}q)}{R\sqrt{\varepsilon}}\Big)\,(\partial_{q_j}\Pi^\pm)(\sqrt{\varepsilon}q).\end{aligned} \tag{4.4}$$

Now, collecting all the different pieces, we have

$$K = \mathrm{op}_\varepsilon\big(\{\chi(t)b_{\varepsilon,R}(q,p)\,,\,\tau+\tfrac12|p|^2+v(q)\pm|\phi(q)|\}\,\Pi^\pm(q)\big)$$
$$+\mathrm{op}_\varepsilon(\chi(t)r_0(q,p))+\mathrm{op}_\varepsilon(\chi(t)r_1(q,p))+O(\varepsilon).$$

Hence, our claim follows from the analysis of r_0 and r_1, which is carried out in Lemma 4.1. ∎

LEMMA 4.1. *Let ψ^ε solve the Schrödinger equation* (1.1). *For the matrix-valued functions r_0 and r_1 defined in* (4.3) *and* (4.4), *respectively, one has*

$$\left(\mathrm{op}_\varepsilon\left(\chi(t)r_0(q,p)\right)\psi^\varepsilon,\psi^\varepsilon\right)_{L^2(\mathbb{R}^{d+1})}=O(\sqrt{\varepsilon})+O(1/R^2)+O(1/(R^5\sqrt{\varepsilon})),$$

$$\left(\mathrm{op}_\varepsilon\left(\chi(t)r_1(q,p)\right)\psi^\varepsilon,\psi^\varepsilon\right)_{L^2(\mathbb{R}^{d+1})}=O(\sqrt{\varepsilon})+O(1/R^2).$$

Proof. Both functions have off-diagonal matrix structure; that is, $r_0(q,p)$ and $r_1(q,p)$ do not commute with $V(q)$. However, since r_1 contains an additional factor $|\phi|$, it is less singular than r_0, in the sense that for $\alpha\in\mathbb{N}^d$ and (q,p) with $|\phi(\sqrt{\varepsilon}q)|>CR\sqrt{\varepsilon}$

$$D_q^\alpha\big(r_0(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\big)=O(R^{-|\alpha|-1}\varepsilon^{-1/2}),\qquad D_q^\alpha\big(r_1(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\big)=O(R^{-|\alpha|}).$$

We begin with r_1. We write $r_1=\Pi^-r_1\Pi^++\Pi^+r_1\Pi^-$ and work successively with each part. Thus, without loss of generality, we suppose that $\Pi^-r_1\Pi^+=r_1$. The strategy is to reuse the Schrödinger equation, since

$$r_1=\Pi^-r_1\Pi^+=\tfrac{1}{2|\phi|}[r_1,V_\ell(\phi)]=\tfrac{1}{2|\phi|}[r_1,\tau+\tfrac12|p|^2+V].$$

With the scaling operator T defined in (4.1), we obtain

$$\mathrm{op}_\varepsilon(\chi(t)r_1(q,p))=T^*\mathrm{op}_1\Big(\Big[\tfrac{\chi(t)}{2|\phi(\sqrt{\varepsilon}q)|}\,r_1(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p),\varepsilon\tau+\tfrac{\varepsilon}{2}|p|^2+V(\sqrt{\varepsilon}q)\Big]\Big)\,T.$$

Then, by the symbolic calculus of Lemma A.2,

$$\mathrm{op}_1\Big(\Big[\tfrac{\chi(t)}{2|\phi(\sqrt{\varepsilon}q)|}\,r_1(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p),\varepsilon\tau+\tfrac{\varepsilon}{2}|p|^2+V(\sqrt{\varepsilon}q)\Big]\Big)$$
$$=\Big[\mathrm{op}_1\Big(\tfrac{\chi(t)}{2|\phi(\sqrt{\varepsilon}q)|}\,r_1(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\Big),\mathrm{op}_1\big(\varepsilon\tau+\tfrac{\varepsilon}{2}|p|^2+V(\sqrt{\varepsilon}q)\big)\Big]+\mathrm{op}_1(r_2(t,\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)),$$

where

$$r_2(t,\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)=\chi(t)\tilde r_1(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)+\varepsilon\tfrac{\chi'(t)}{2|\phi(\sqrt{\varepsilon}q)|}\,r_1(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)+\varepsilon\chi(t)\tilde r_2(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)$$

with

$$\tilde r_1(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)=\tfrac{1}{2i}\Big\{\tfrac{1}{2|\phi(\sqrt{\varepsilon}q)|}\,r_1(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\,,\,\tfrac{\varepsilon}{2}|p|^2+V(\sqrt{\varepsilon}q)\Big\}$$
$$-\tfrac{1}{2i}\Big\{\tfrac{\varepsilon}{2}|p|^2+V(\sqrt{\varepsilon}q)\,,\,\tfrac{1}{2|\phi(\sqrt{\varepsilon}q)|}\,r_1(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\Big\}.$$

The term $\tilde r_2(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)$ contains the commutator of second derivatives in p of the symbol $|\phi(\sqrt{\varepsilon}q)|^{-1}\,r_1(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)$ with second derivatives of $V(\sqrt{\varepsilon}q)$ and a linear combination of derivatives in (q,p) of order greater than or equal to three. Hence, by Lemma A.2

$$\mathrm{op}_\varepsilon\left(\chi(t)\tilde r_2(q,p)\right)=O(\varepsilon\sqrt{\varepsilon})+O(\varepsilon/R^4)\ \text{ in }\ \mathcal{L}(L^2(\mathbb{R}^{d+1})).$$

It remains to study $\tilde{r}_1$. Since derivatives in p of $r_1(\sqrt{\varepsilon}q, \sqrt{\varepsilon}p)$ generate powers of $\sqrt{\varepsilon}$, the bracket with $V(\sqrt{\varepsilon}q)$ gives

$$\mathrm{op}_1\Big(\chi(t)\Big\{\tfrac{1}{2|\phi(q\sqrt{\varepsilon})|}r_1(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p), V(\sqrt{\varepsilon}q)\Big\}\Big) = O\Big(\tfrac{\sqrt{\varepsilon}}{R}\Big) \text{ in } \mathcal{L}(L^2(\mathbb{R}^{d+1})).$$

For the bracket with $\frac{\varepsilon}{2}|p|^2$ one has

$$\Big\{\tfrac{1}{2|\phi(\sqrt{\varepsilon}q)|}r_1(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\,,\,\tfrac{\varepsilon}{2}|p|^2\Big\}$$
$$= \tfrac{\sqrt{\varepsilon}}{2|\phi(\sqrt{\varepsilon}q)|}\sqrt{\varepsilon}p\cdot\nabla_q\big(r_1(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\big) + \tfrac{\varepsilon}{2}\tfrac{\mathrm{d}\phi(\sqrt{\varepsilon}q)\sqrt{\varepsilon}p\cdot\phi(\sqrt{\varepsilon}q)}{|\phi(\sqrt{\varepsilon}q)|^3}\,r_1(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p).$$

Both terms give a contribution of order $O(1/R^2)$, but since they are not purely off-diagonal, the preceding commutator argument cannot be reiterated. Hence,

$$\mathrm{op}_\varepsilon(\chi(t)\tilde{r}_1(q,p)) = O\big(\tfrac{1}{R^2}\big) + O\Big(\tfrac{\sqrt{\varepsilon}}{R}\Big), \qquad \mathrm{op}_\varepsilon\Big(\varepsilon\tfrac{\chi'(t)}{|\phi(q)|}\,r_1(q,p)\Big) = O\Big(\tfrac{\sqrt{\varepsilon}}{R}\Big)$$

in $\mathcal{L}(L^2(\mathbb{R}^{d+1}))$, and we have proven one part of the lemma.

In the case of the more singular symbol r_0, the previous strategy results in an error of size

$$1/R\sqrt{\varepsilon}\,\big(O(\varepsilon\sqrt{\varepsilon}) + O(\varepsilon/R^4) + O(\sqrt{\varepsilon}/R) + O(1/R^2)\big)$$
$$= O(\sqrt{\varepsilon}) + O(1/R^2) + O(1/(R^3\sqrt{\varepsilon})).$$

However, the special form of r_0 allows us to ameliorate the term of order $O(1/(R^3\sqrt{\varepsilon}))$, which stems from the Poisson bracket with $\frac{\varepsilon}{2}|p|^2$. Indeed, we observe that

$$p\cdot\nabla\Pi^+(q) = \tfrac{1}{4|\phi(q)|^3}\left[V_\ell(\phi(q))\,,\,[V_\ell(\phi(q)), V_\ell(\mathrm{d}\phi(q)p)]\right].$$

Therefore, the bracket with $\frac{\varepsilon}{2}|p|^2$ in the $\tilde{r}_1$ term writes as

$$\Big\{\tfrac{1}{4|\phi(\sqrt{\varepsilon}q)|^3}\,b_{\varepsilon,R}(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\left[V_\ell(\phi(\sqrt{\varepsilon}q)), V_\ell(\mathrm{d}\phi(\sqrt{\varepsilon}q)\sqrt{\varepsilon}p)\right],\tfrac{\varepsilon}{2}|p|^2\Big\}$$
$$= \tfrac{\varepsilon}{|\phi(\sqrt{\varepsilon}q)|^4}\left[V_\ell(\phi(\sqrt{\varepsilon}q)), G_\varepsilon(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\right]$$

for some matrix-valued function G_ε with

$$D_q^\alpha\big(G_\varepsilon(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\big) = O(1), \qquad D_p^\alpha\big(G_\varepsilon(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\big) = O(\varepsilon^{|\alpha|/2})$$

for all $\alpha\in\mathbb{N}^d$. We then set

$$\tilde{r}_3(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p) := \tfrac{\varepsilon}{|\phi(\sqrt{\varepsilon}q)|^4}\left[V_\ell(\phi(\sqrt{\varepsilon}q)), G_\varepsilon(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\right]$$
$$= -\Big[\tfrac{\varepsilon}{|\phi(\sqrt{\varepsilon}q)|^4}\,G_\varepsilon(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\,,\,\tau+\tfrac{\varepsilon}{2}|p|^2+V(\sqrt{\varepsilon}q)\Big]$$

and obtain

$$\big(\mathrm{op}_\varepsilon(\chi(t)\tilde{r}_3(q,p))\,\psi^\varepsilon\,,\,\psi^\varepsilon\big)_{L^2(\mathbb{R}^{d+1})}$$
$$= \Big(T^*\mathrm{op}_1\Big(\Big[\tfrac{\varepsilon\chi(t)}{|\phi(\sqrt{\varepsilon}q)|^4}\,G_\varepsilon(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\,,\,\varepsilon\tau+\tfrac{\varepsilon}{2}|p|^2+V(\sqrt{\varepsilon}q)\Big]\Big)\,T\psi^\varepsilon\,,\,\psi^\varepsilon\Big)_{L^2(\mathbb{R}^{d+1})}$$

$$= \tfrac{1}{2i}\Big(T^*\mathrm{op}_1\Big(\Big\{\tfrac{\varepsilon\chi(t)}{|\phi(\sqrt{\varepsilon}q)|^4}\,G_\varepsilon(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\,,\,\varepsilon\tau+\tfrac{\varepsilon}{2}|p|^2+V(\sqrt{\varepsilon}q)\Big\}\Big)\,T\psi^\varepsilon\,,\,\psi^\varepsilon\Big)_{L^2(\mathbb{R}^{d+1})}$$

$$- \tfrac{1}{2i}\Big(T^*\mathrm{op}_1\Big(\Big\{\varepsilon\tau+\tfrac{\varepsilon}{2}|p|^2+V(\sqrt{\varepsilon}q)\,,\,\tfrac{\varepsilon\chi(t)}{|\phi(\sqrt{\varepsilon}q)|^4}\,G_\varepsilon(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)\Big\}\Big)\,T\psi^\varepsilon\,,\,\psi^\varepsilon\Big)_{L^2(\mathbb{R}^{d+1})}$$

$$+ \big(T^*\mathrm{op}_1(\tilde r_4(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p))T\psi^\varepsilon\,,\,\psi^\varepsilon\big)_{L^2(\mathbb{R}^{d+1})}\,,$$

where $\tilde r_4(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)$ contains the commutator of second order derivatives in p of $\varepsilon\,\chi(t)|\phi(\sqrt{\varepsilon}q)|^{-4}\,G_\varepsilon(\sqrt{\varepsilon}q,\sqrt{\varepsilon}p)$ with second derivatives of $V(\sqrt{\varepsilon}q)$ and a linear combination of higher order derivatives in (q,p). Hence, $\mathrm{op}_\varepsilon(\tilde r_4(q\sqrt{\varepsilon},p\sqrt{\varepsilon}))=O(\varepsilon/R^4)$ in $\mathcal{L}(L^2(\mathbb{R}^{d+1}))$. Since the Poisson brackets give a contribution of order $O(1/(R^5\sqrt{\varepsilon}))+O(1/R^4)$, the other part of the lemma is proven, too. ∎

5. Transitions near the crossing. The microlocal normal form used for proving Proposition 2.4 holds locally near some point $(q_0,t_0,p_0,\tau_0)\in\mathbb{R}^{2d+2}$ of the phase space of space-time, which is a crossing point in the sense that $\phi(q_0)=0$ and $\tau_0+v(q_0)+\frac12|p_0|^2=0$.

5.1. Localization in energy. For localization in energy, we consider a cut-off function $\theta\in\mathcal{C}_c^\infty(\mathbb{R})$, $0\le\theta\le1$, with $\theta(x)=1$ for $|x|\le\frac12$ and $\theta(x)=0$ for $|x|>1$. We set

$$\lambda^\pm(q,p,\tau)=\tau+v(q)+\tfrac12|p|^2\pm|\phi(q)|$$

and crucially use the following lemma for suitably reformulating Proposition 2.4.

LEMMA 5.1. *Let $c\in\mathcal{C}_c^\infty(\mathbb{R}^{2d+1+\ell},\mathbb{C})$. If $c_{\varepsilon,R}(t,q,p)=c(t,q,p,\phi(q)/(R\sqrt{\varepsilon}))$ is supported in $\{|\phi|\ge\frac{R}{2}\sqrt{\varepsilon}\}$, then*

$$\mathrm{tr}\int_{\mathbb{R}^{2d+1}} W^\varepsilon(\psi^\varepsilon(t))(q,p)c_{\varepsilon,R}(t,q,p)\Pi^\pm(q)\mathrm{d}q\,\mathrm{d}p\,\mathrm{d}t=O\big(\tfrac{1}{R^2}\big)+O(\sqrt{\varepsilon})$$

$$+\Big(\mathrm{op}_\varepsilon\Big(c_{\varepsilon,R}(t,q,p)\theta\Big(\tfrac{\lambda^\pm(q,p,\tau)}{R\sqrt{\varepsilon}}\Big)\,\Pi^\pm(q)\Big)\,\psi^\varepsilon,\psi^\varepsilon\Big)_{L^2(\mathbb{R}^{d+1})}.$$

Proof. Writing $1-\theta(u)=u\,G(u)$ with $G\in\mathcal{C}^\infty(\mathbb{R})$, we have

$$1-\theta\Big(\tfrac{\lambda^\pm(q,p,\tau)}{R\sqrt{\varepsilon}}\Big)=\tfrac{1}{R\sqrt{\varepsilon}}\lambda^\pm(q,p,\tau)G\Big(\tfrac{\lambda^\pm(q,p,\tau)}{R\sqrt{\varepsilon}}\Big).$$

We now argue as in section 4, using the estimates on $\Pi^\pm$ and $\lambda^\pm(q,p,\tau)\Pi^\pm(q)=\Pi^\pm(q)\big(\tau+\frac12|p|^2+V(q)\big)$. The symbolic calculus of Lemma A.2 yields in $\mathcal{L}(L^2(\mathbb{R}^{d+1}))$

$$\mathrm{op}_\varepsilon\Big(c_{\varepsilon,R}(t,q,p)\,\Big(1-\theta\Big(\tfrac{\lambda^\pm(q,p,\tau)}{R\sqrt{\varepsilon}}\Big)\Big)\,\Pi^\pm(q)\Big)=O(\sqrt{\varepsilon})+O\big(\tfrac{1}{R^2}\big)$$

$$+\tfrac{1}{R\sqrt{\varepsilon}}\,\mathrm{op}_\varepsilon\Big(c_{\varepsilon,R}(t,q,p)G\Big(\tfrac{\lambda^\pm(q,p,\tau)}{R\sqrt{\varepsilon}}\Big)\,\Pi^\pm(q)\Big)\,\mathrm{op}_\varepsilon\big(\tau+\tfrac12|p|^2+V(q)\big).$$

Indeed, the derivatives of the projectors are less harmful than in section 4, since they are divided only by $\sqrt{\varepsilon}$ and not by ε. Since ψ^ε solves the equation, we obtain

$$\Big(\mathrm{op}_\varepsilon\Big(c_{\varepsilon,R}(t,q,p)\,\Big(1-\theta\Big(\tfrac{\lambda^\pm(q,p,\tau)}{R\sqrt{\varepsilon}}\Big)\Big)\,\Pi^\pm(q)\Big)\,\psi^\varepsilon,\psi^\varepsilon\Big)_{L^2(\mathbb{R}^{d+1})}=O\big(\tfrac{1}{R^2}\big)+O(\sqrt{\varepsilon}).$$ ∎

By Lemma 5.1, we introduce the energy cut-off on both sides of equality (2.4), adding an error of order $O(1/R^2) + O(\sqrt{\varepsilon})$. Then, the left-hand side reads

$$\operatorname{tr} \int_{\mathbb{R}^{2d+1}} \chi(t)\, W^\varepsilon(\psi^\varepsilon(t))(q,p) a^\pm_{LZ}(q,p)\, \Pi^\pm(q) \mathrm{d}q\, \mathrm{d}p\, \mathrm{d}t = O\big(\tfrac{1}{R^2}\big) + O(\sqrt{\varepsilon}) + \Big(\mathrm{op}_\varepsilon\Big(a^\pm_{LZ}(q,p)\chi(t)\,\theta\Big(\tfrac{\lambda^\pm(q,p,\tau)}{R\sqrt{\varepsilon}}\Big)\,\Pi^\pm(q)\Big)\,\psi^\varepsilon\,,\,\psi^\varepsilon\Big)_{L^2(\mathbb{R}^{d+1})}.$$

Using the notation

$$f^\pm_a(q,p,j) = \mathbf{1}_{\{j=\pm 1\}}(j)\, a^j(q,p), \qquad (q,p,j) \in \mathbb{R}^{2d}_\pm,$$

for a V-diagonal matrix-valued symbol a, the action of the semigroup on $a^\pm_{LZ}$ can be written as

$$(\mathcal{L}^{\delta^\pm_t}_{\varepsilon,R} a^\pm_{LZ})(q,p)\,\Pi^\pm(q) = (\mathcal{L}^{\delta^\pm_t}_{\varepsilon,R} f^\pm_{a_{LZ}})(q,p,+)\,\Pi^+(q).$$

Then, the right-hand side of (2.4) is

$$\operatorname{tr} \int_{\mathbb{R}^{2d+1}} \chi(t+\delta^\pm_t)\, W^\varepsilon(\psi^\varepsilon(t))(q,p)\,(\mathcal{L}^{\delta^\pm_t}_{\varepsilon,R} a^\pm_{LZ})(q,p)\,\Pi^+(q)\,\mathrm{d}q\,\mathrm{d}p\,\mathrm{d}t = \Big(\mathrm{op}_\varepsilon\Big(\chi(t+\delta_t)\,\theta\Big(\tfrac{\lambda^+(q,p,\tau)}{R\sqrt{\varepsilon}}\Big)\,(\mathcal{L}^{\delta^\pm_t}_{\varepsilon,R} f^\pm_{a_{LZ}})(q,p,+)\,\Pi^+(q)\Big)\,\psi^\varepsilon\,,\,\psi^\varepsilon\Big)_{L^2(\mathbb{R}^{d+1})} + O\big(\tfrac{1}{R^2}\big) + O(\sqrt{\varepsilon}),$$

and the proof of Proposition 2.4 reduces to showing that

$$\Big(\mathrm{op}_\varepsilon\Big(a^\pm_{LZ}(q,p)\chi(t)\theta\Big(\tfrac{\lambda^\pm(q,p,\tau)}{R\sqrt{\varepsilon}}\Big)\,\Pi^\pm(q)\Big)\,\psi^\varepsilon\,,\,\psi^\varepsilon\Big)_{L^2(\mathbb{R}^{d+1})} = \Big(\mathrm{op}_\varepsilon\Big(\chi(t+\delta^\pm_t)\theta\Big(\tfrac{\lambda^+(q,p,\tau)}{R\sqrt{\varepsilon}}\Big)\,(\mathcal{L}^{\delta^\pm_t}_{\varepsilon,R} f^\pm_{a_{LZ}})(q,p,+)\,\Pi^+(q)\Big)\,\psi^\varepsilon\,,\,\psi^\varepsilon\Big)_{L^2(\mathbb{R}^{d+1})} + O\big(\tfrac{1}{R^2}\big) + O(R^3\sqrt{\varepsilon}) + O(\sqrt{\varepsilon}|\ln\varepsilon|) + O\Big(\tfrac{1}{R^5\sqrt{\varepsilon}}\Big). \tag{5.1}$$

For points $(q,t,p,\tau,j) \in \mathbb{R}^{2d+2} \times \{\pm 1\}$, we consider random trajectories

$$\mathcal{T}^{(q,t,p,\tau,j)}_{\varepsilon,R} : [0,+\infty) \to \big(\mathbb{R}^{2d+2} \times \{\pm 1\}\big)$$

with $\mathcal{T}^{(q,t,p,\tau,j)}_{\varepsilon,R}(r) = \big(q^j(r), r+t, p^j(r), \tau, j\big)$ as long as $(q^j(r),p^j(r)) \notin S_{\varepsilon,R}$ and a jump from j to $-j$ with probability $T^\varepsilon(q^*,p^*)$, whenever $(q^j(r),p^j(r))$ hits $S_{\varepsilon,R}$ at a point (q^*,p^*). We keep the notation $(\mathcal{L}^r_{\varepsilon,R})_{r\geq 0}$ for the associated semigroup and set

$$c^\pm_{\varepsilon,R}(q,t,p,\tau) = a^\pm_{LZ}(q,p)\,\chi(t)\,\theta\Big(\tfrac{\lambda^\pm(q,p,\tau)}{R\sqrt{\varepsilon}}\Big). \tag{5.2}$$

Since $r \mapsto \lambda^\pm(q^\pm(r),p^\pm(r),\tau)$ is a constant function, and since within $[t-t_{\mathrm{i}}, t-t_{\mathrm{f}}]$ all involved random trajectories perform a jump, we have

$$(\mathcal{L}^{\delta^\pm_t}_{\varepsilon,R} f^+_{c_{\varepsilon,R}})(q,t,p,\tau,+) = \chi(t+\delta_t)\,\theta\Big(\tfrac{\lambda^+(q,p,\tau)}{R\sqrt{\varepsilon}}\Big)\,(\mathcal{L}^{\delta_t}_{\varepsilon,R} f^+_{a_{LZ}})(q,p,+),$$

$$(\mathcal{L}^{\delta_t}_{\varepsilon,R} f^-_{c_{\varepsilon,R}})(q,t,p,\tau,+) = \chi(t+\delta_t)\,\theta\Big(\tfrac{\lambda^+(q,p,\tau)}{R\sqrt{\varepsilon}}\Big)\,(\mathcal{L}^{\delta_t}_{\varepsilon,R} f^-_{a_{LZ}})(q,p,+).$$

With this notation, (5.1) and, consequently, Proposition 2.4 are equivalent to

$$\begin{aligned}\Big(\mathrm{op}_\varepsilon\Big(c^\pm_{\varepsilon,R}(q,t,p,\tau)\Pi^\pm(q)\Big)\,\psi^\varepsilon\,,\,\psi^\varepsilon\Big)_{L^2(\mathbb{R}^{d+1})}\\ =\Big(\mathrm{op}_\varepsilon\Big((\mathcal{L}^{\delta^\pm_t}_{\varepsilon,R}f^\pm_{c_{\varepsilon,R}})(q,t,p,\tau,+)\,\Pi^+(q)\Big)\,\psi^\varepsilon\,,\,\psi^\varepsilon\Big)_{L^2(\mathbb{R}^{d+1})}\\ +O(1/R^2)+O(R^3\sqrt{\varepsilon})+O(\sqrt{\varepsilon}|\ln\varepsilon|)+O(1/(R^5\sqrt{\varepsilon})).\end{aligned}\tag{5.3}$$

We emphasize that the symbols $c^\pm_{\varepsilon,R}$ and $\mathcal{L}^{\delta^\pm_t}_{\varepsilon,R}f^\pm_{c_{\varepsilon,R}}$ are compactly supported inside the annulus $\{\frac{R}{2}\sqrt{\varepsilon}<|\phi|<R\sqrt{\varepsilon}\}$ at a distance of order $R\sqrt{\varepsilon}$ of $J^{\pm,out}$, where

$$J^{\pm,in/out}=\Big\{(q,t,p,\tau)\in\mathbb{R}^{2d+2}\mid(q,p)\in M^{\pm,in/out},\,\tau+v(q)+\tfrac12|p|^2\pm|\phi(q)|=0\Big\}$$

denote the submanifolds, which consist of all Hamiltonian trajectories entering (respectively, leaving) the crossing set.

5.2. The normal form. Let us first recall some basic facts about canonical transforms and Fourier integral operators. The phase space $T^*\mathbb{R}^{d+1}=\mathbb{R}^{d+1}\times\mathbb{R}^{d+1}$ is a symplectic space, once endowed with the symplectic form $\omega=\mathrm{d}\tau\wedge\mathrm{d}t+\mathrm{d}p\wedge\mathrm{d}q$. A canonical transform $\kappa:T^*\mathbb{R}^{d+1}\to T^*\mathbb{R}^{d+1}$ is a change of coordinates, which preserves the symplectic form. With a canonical transform κ, one associates a unitary operator $U:L^2(\mathbb{R}^{d+1})\to L^2(\mathbb{R}^{d+1})$ such that for all $a\in\mathcal{C}^\infty_c(\mathbb{R}^{2d+2},\mathbb{C}^{N(\ell)\times N(\ell)})$

$$U^*\mathrm{op}_\varepsilon(a)\,U=\mathrm{op}_\varepsilon(a\circ\kappa)+O(\varepsilon^2)$$

as bounded operators on $L^2(\mathbb{R}^{d+1})$; see, for example, section 2.2 in [7]. The operator U is a Fourier integral operator. The last equality extends to symbols of the form

$$b_{\varepsilon,R}(q,t,p,\tau)=b\Big(q,t,p,\tau,\tfrac{f(q,p)}{R\sqrt{\varepsilon}}\Big)$$

with $b\in\mathcal{C}^\infty_c(\mathbb{R}^{2d+3},\mathbb{C}^{N(\ell)\times N(\ell)})$ and $f\in\mathcal{C}^\infty(\mathbb{R}^{2d},\mathbb{R})$ according to

$$U^*\mathrm{op}_\varepsilon(b_{\varepsilon,R})\,U=\mathrm{op}_\varepsilon(b_{\varepsilon,R}\circ\kappa)+O(\sqrt{\varepsilon}).\tag{5.4}$$

The proof of this statement follows the proof of Lemma 2 in [7]: one uses symbolic calculus for the commutator of a usual semiclassical pseudodifferential operator and a two-scale one of the form $\mathrm{op}_\varepsilon(b_{\varepsilon,R})$, hence the gain of $\sqrt{\varepsilon}$.

We shall crucially use the following microlocal normal form result, which for codimension two and three crossings is proven in [1, 2], however, without the explicit equations (5.6)–(5.9). These equations, including the normal form for codimension five crossings, are provided in Theorem 1 and Proposition 4 of [6].

THEOREM 5.2 (see [6]). *We consider $\rho_0=(q_0,t_0,p_0,\tau_0=-v(q_0)-\frac12|p_0|^2)$ such that $\phi(q_0)=0$, $\mathrm{d}\phi(q_0)p_0\neq0$, and $\mathrm{d}\phi$ is of maximal rank near q_0. Then, there exists a local canonical transform κ from a neighborhood of ρ_0 into some neighborhood Ω of 0,*

$$\kappa:(q,t,p,\tau)\mapsto(z,s,\zeta,\sigma),\quad\kappa(\rho_0)=0.$$

There exist a Fourier integral operator U associated with κ^{-1} and an invertible matrix-valued symbol $A_\varepsilon=A_0+\varepsilon A_1+\varepsilon^2A_2+\cdots$ such that $v^\varepsilon=U^*\mathrm{op}_\varepsilon(A_\varepsilon)^{-1}\psi^\varepsilon$ satisfies for all $\varphi\in\mathcal{C}^\infty_c(\Omega,\mathbb{R})$

$$\mathrm{op}_\varepsilon(\varphi)\,\mathrm{op}_\varepsilon\left(-\sigma+V_\ell\left(s,\tilde z+\gamma_\varepsilon(z,\zeta)\right)\right)v^\varepsilon=O(\varepsilon^\infty)\tag{5.5}$$

in $L^2(\mathbb{R}^{d+1})$, *where* $z=(\tilde z,z')\in\mathbb{R}^d$ *with* $\tilde z\in\mathbb{R}^{\ell-1}$ *and* $\gamma_\varepsilon=\gamma_\varepsilon(z,\zeta)$ *is a vector-valued symbol* $\gamma_\varepsilon=\gamma_0+\varepsilon\gamma_1+\varepsilon^2\gamma_2+\cdots\in\mathbb{R}^{\ell-1}$ *with*

$$\gamma_\varepsilon=0 \ \text{ for } \ \ell=2, \qquad \gamma_\varepsilon=O(|\tilde z|^2) \ \text{ for } \ \ell>2.$$

$\tilde z\in\mathbb{R}^{\ell-1}$ *contains the coordinates of the vector* $|\mathrm{d}\phi(q)p|^{-1/2}\pi_\ell(q,p)\phi(q)$ *in an orthonormal basis of the hyperplane normal to* $\mathrm{d}\phi(q)p$ *up to* $O(|\phi(q)|^2)$, *while*

$$\begin{aligned} s&=-|\mathrm{d}\phi(q)p|^{-1/2}\tfrac{\mathrm{d}\phi(q)p}{|\mathrm{d}\phi(q)p|}\cdot\phi(q)+O(s^2+\sigma^2+|\tilde z|^2),\\ \sigma&=|\mathrm{d}\phi(q)p|^{-1/2}\left(\tau+\tfrac12|p|^2+v(q)\right)+O(s^2+\sigma^2+|\tilde z|^2). \end{aligned}\tag{5.6}$$

Moreover,

$$J^{\pm,in}=\{\sigma\mp s=0,\ \tilde z=0,\ s\le0\},\quad J^{\pm,out}=\{\sigma\pm s=0,\ \tilde z=0,\ s\ge0\},\tag{5.7}$$

and there exists $\gamma\in\{-1,+1\}$ *such that for all* $\rho=(q,t,p,\tau)$ *with* $\kappa(\rho)=(z,s,\zeta,\sigma)$

$$A_0^*(\rho)\left(\tau+\tfrac12|p|^2+V(q)\right)A_0(\rho)=\gamma\left(-\sigma+V_\ell(s,\tilde z+\gamma_0(z,\zeta))\right),\tag{5.8}$$

$$A_0^*(\rho)V_\ell\Big(\tfrac{\pi_\ell(q,p)\phi(q)}{|\pi_\ell(q,p)\phi(q)|}\Big)A_0(\rho)=\gamma\,V_\ell\Big(0,\tfrac{\tilde z}{|\tilde z|}\Big)+O(\sqrt{\sigma^2+s^2+|\tilde z|^2}).\tag{5.9}$$

We denote by

$$\widetilde\Pi^\pm(z,s,\zeta)=\tfrac12\left(\mathrm{Id}\mp\tfrac{1}{\sqrt{s^2+|\tilde z+\gamma_0(z,\zeta)|^2}}V_\ell(s,\tilde z+\gamma_0(z,\zeta))\right),$$

$$\tilde\lambda^\pm(z,s,\zeta,\sigma)=-\sigma\mp\sqrt{s^2+|\tilde z+\gamma_0(z,\zeta)|^2}$$

the spectral projectors and the eigenvalues of $-\sigma+V_\ell(s,\tilde z+\gamma_0(z,\zeta))$. Due to the relation $J^{\pm,in/out}\subseteq\{-\sigma\mp\sqrt{s^2+|\tilde z|^2}=0,\tilde z=0\}$, the labeling of $\widetilde\Pi^\pm$ coincides on $J^{\pm,in/out}$ with the one for $\Pi^\pm$.

Proposition 5.3. *There exist functions* $k^\pm$ *such that if* $\kappa(q,t,p,\tau)=(z,s,\zeta,\sigma)$, *the projectors* $\Pi^\pm$ *and* $\widetilde\Pi^\pm$ *are related by*

$$\widetilde\Pi^\pm(z,s,\zeta,\sigma)=\left(k^\pm A_0^*\Pi^\pm A_0\right)(q,t,p,\tau) \ \text{ on } \ \Sigma^\mp=\{\lambda^\mp=0\}.\tag{5.10}$$

If $S=\{\phi(q)=0,\ \tau+\frac12|p|^2+v(q)=0\}$, *then* $k^+_{|S}=k^-_{|S}=e\neq0$ *and* $(e\,A_0^*A_0)_{|S}=\mathrm{Id}_{|S}$. *Moreover, on* $\Sigma^\pm\cap\{0<|\phi|\le R\sqrt\varepsilon\}$,

$$\widetilde\Pi^\pm(z,s,\zeta,\sigma)=e(A_0^*\Pi^\pm A_0)(q,t,p,\tau)+O(R\sqrt\varepsilon).\tag{5.11}$$

Proof. For convenience, we set

$$P=\tau+\tfrac12|p|^2+V(q),\quad \widetilde P=-\sigma+V_\ell(s,\tilde z+\gamma_0(z,\zeta)).$$

By (5.8), the use of determinants gives $\Sigma^+\cup\Sigma^-=\kappa^{-1}(\{\tilde\lambda^+=0\}\cup\{\tilde\lambda^-=0\})$. Considering the equations of $J^{\pm,in/out}$, the only possibility is

$$\Sigma^\pm=\kappa^{-1}\left(\{\tilde\lambda^\pm=0\}\right).$$

Therefore, for $\rho \in \Sigma^+$ we have

$$\gamma \widetilde{P}(\kappa(\rho)) = \gamma(\tilde{\lambda}^- \widetilde{\Pi}^-)(\kappa(\rho)) = (A_0^* P A_0)(\rho) = (\lambda^- A_0^* \Pi^- A_0)(\rho).$$

The same argument for Σ^- gives (5.10).

The fact $k^+_{|S} = k^-_{|S}$ comes from the precise analysis of the Hamiltonian vector fields associated with the eigenvalues $\lambda^\pm$. Let $\rho \in S$. We find in [6, section 5] that if

$$H(\rho) = \lim_{\alpha \to 0^\mp} H_{\lambda^\pm}(\Phi^\alpha_\pm(q,p)), \quad H'(\rho) = \lim_{\alpha \to 0^\pm} H_{\lambda^\pm}(\Phi^\alpha_\pm(q,p)),$$

then there exists a nonzero function e such that

$$H = e(\partial_s + \partial_\sigma), \quad H' = e(\partial_s - \partial_\sigma) \text{ on } S.$$

Since $\lambda^\pm = 0$ and $\tilde{\lambda}^\pm = 0$ on S, we have $k^+_{|S} = k^-_{|S} = e$. Next, we consider the limit of the projectors $\Pi^\pm$ along outgoing trajectories,

$$\Pi^\mp_S(\rho) = \lim_{\alpha \to 0^-} \Pi^\mp(\Phi^\alpha_\pm(q,p)) = \tfrac{1}{2}\left(\mathrm{Id} \mp V_\ell\Big(\tfrac{\mathrm{d}\phi(q)p}{|\mathrm{d}\phi(q)p|}\Big)\right).$$

Then, (5.10) gives on S

$$eA_0^* A_0 = eA_0^*\left(\Pi^+_S + \Pi^-_S\right) A_0 = \left(\widetilde{\Pi}^+ + \widetilde{\Pi}^-\right) \circ \kappa = \mathrm{Id}.$$

Finally, let $\rho \in \Sigma^+$. By relation (5.8), we have for any vector $w \in \mathbb{C}^{N(\ell)}$ that $w \in \operatorname{Ker} \widetilde{P}(\kappa(\rho))$ if and only if $A_0(\rho) w \in \operatorname{Ker} P(\rho)$. Moreover, $\operatorname{Ker} P(\rho) = \operatorname{Ran} \Pi^+(\rho)$ and $\operatorname{Ker} \widetilde{P}(\kappa(\rho)) = \operatorname{Ran} \widetilde{\Pi}^+(\kappa(\rho))$. We therefore obtain

$$\operatorname{Ran} \widetilde{\Pi}^+(\kappa(\rho)) = \operatorname{Ran} (A_0^{-1} \Pi^+ A_0)(\rho).$$

Since $\sqrt{e} A_0$ is unitary on S, we have

$$(A_0^{-1}\Pi^+ A_0)^*(\rho) = (A_0^{-1}\Pi^+ A_0)(\rho) + O(R\sqrt{\varepsilon})$$

for $\rho \in \Sigma^+ \cap \{|\phi| \leq R\sqrt{\varepsilon}\}$. Since the two projectors $\widetilde{\Pi}^+(\kappa(\rho))$ and $(A_0^{-1}\Pi^+ A_0)(\rho)$ have the same range, while one of them is orthogonal and the other orthogonal up to $O(R\sqrt{\varepsilon})$, they coincide up to $O(R\sqrt{\varepsilon})$. The same argument holds for $\rho \in \Sigma^-$, and we have proven relation (5.11). ∎

As the next step towards proving the claimed identity (5.3), we perform the canonical change of coordinates for arriving at the microlocal normal form.

PROPOSITION 5.4. *Let $c^\pm_{\varepsilon,R} \in \mathcal{C}^\infty_c(\mathbb{R}^{2d+2}, \mathbb{C})$ be the functions defined in* (5.2) *and $v^\varepsilon = U^* \mathrm{op}_\varepsilon(A_\varepsilon)^{-1} \psi^\varepsilon$. Denote*

$$\widetilde{T}^\varepsilon(\tilde{z}) = \exp(-\tfrac{\pi}{\varepsilon}|\tilde{z}|^2). \tag{5.12}$$

Then, there exist functions $b^\pm \in \mathcal{C}^\infty_c(\mathbb{R}^{2d+2}, \mathbb{C})$ and $s^\pm_1 \in \mathbb{R}$, such that $b^\pm(z,s,\zeta,\eta)$ and $b^\pm(z, s^\pm_1 + s, \zeta, \eta)$ are compactly supported in $\{s > 0\}$ and $\{s < 0\}$, respectively, and satisfy

$$\left(\mathrm{op}_\varepsilon\Big(c^+_{\varepsilon,R}(q,t,p,\tau)\Pi^+(q)\Big)\psi^\varepsilon(q,t), \psi^\varepsilon(q,t)\right)_{L^2}$$

$$= \Big(\mathrm{op}_\varepsilon\Big(b^+\Big(z,s,\zeta,\tfrac{\tilde z}{R\sqrt\varepsilon}\Big)\Big)\, v_2^\varepsilon(z,s), v_2^\varepsilon(z,s)\Big)_{L^2} + O(R\sqrt\varepsilon),$$

$$\Big(\mathrm{op}_\varepsilon\Big((\mathcal{L}^{\delta_t}_{\varepsilon,R} f^+_{c_{\varepsilon,R}})(q,t,p,\tau,+)\Pi^+(q)\Big)\,\psi^\varepsilon(q,t), \psi^\varepsilon(q,t)\Big)_{L^2}$$

$$= \Big(\mathrm{op}_\varepsilon\Big((1-\widetilde T^\varepsilon(\tilde z))b^+\Big(z,s+s_1^+,\zeta,\tfrac{\tilde z}{R\sqrt\varepsilon}\Big)\Big)\, v_1^\varepsilon(z,s), v_1^\varepsilon(z,s)\Big)_{L^2} + O(R^3\sqrt\varepsilon),$$

$$\Big(\mathrm{op}_\varepsilon\Big(c^-_{\varepsilon,R}(q,t,p,\tau)\Pi^-(q)\Big)\,\psi^\varepsilon(q,t), \psi^\varepsilon(q,t)\Big)_{L^2}$$

$$= \Big(\mathrm{op}_\varepsilon\Big(b^-\Big(z,s,\zeta,\tfrac{\tilde z}{R\sqrt\varepsilon}\Big)\Big)\, v_1^\varepsilon(z,s), v_1^\varepsilon(z,s)\Big)_{L^2} + O(R\sqrt\varepsilon),$$

$$\Big(\mathrm{op}_\varepsilon\Big((\mathcal{L}^{\delta_t}_{\varepsilon,R} f^-_{c_{\varepsilon,R}})(q,t,p,\tau,+)\Pi^+(q)\Big)\,\psi^\varepsilon(q,t), \psi^\varepsilon(q,t)\Big)_{L^2}$$

$$= \Big(\mathrm{op}_\varepsilon\Big(\widetilde T^\varepsilon(\tilde z)\, b^-\Big(z,s+s_1^-,\zeta,\tfrac{\tilde z}{R\sqrt\varepsilon}\Big)\Big)\, v_1^\varepsilon(z,s), v_1^\varepsilon(z,s)\Big)_{L^2} + O(R^3\sqrt\varepsilon).$$

Proof. We prove only the first two equalities, since one deals similarly with the other two. By symbolic calculus and the transformation property (5.4), the canonical transform κ^{-1} of Theorem 5.2 acts as

$$\Big(\mathrm{op}_\varepsilon\Big(c^+_{\varepsilon,R}(q,t,p,\tau)\Pi^+(q)\Big)\,\psi^\varepsilon(q,t), \psi^\varepsilon(q,t)\Big)_{L^2}$$

$$= \Big(\mathrm{op}_\varepsilon\Big(\big((c^+_{\varepsilon,R}A_0^*\Pi^+A_0)\circ\kappa^{-1}\big)(z,s,\zeta,\sigma)\Big)\, v^\varepsilon(z,s)\ ,\ v^\varepsilon(z,s)\Big)_{L^2} + O(\sqrt\varepsilon).$$

The compactly supported function $c^+_{\varepsilon,R}\circ\kappa^{-1}$ is localized near $J^{+,out}$, that is, near $\{\sigma+s=0,\ \tilde z=0,\ s>0\}$. The relation (5.11) between the projectors gives a function $b\in\mathcal{C}^\infty_c(\mathbb{R}^{2d+2+\ell},\mathbb{C})$ compactly supported in $\{s>0\}$ such that

$$\big((c^+_{\varepsilon,R}A_0^*\Pi^+A_0)\circ\kappa^{-1}\big)(z,s,\zeta,\sigma)$$

$$= b\Big(z,s,\zeta,\sigma,\tfrac{\tilde z}{R\sqrt\varepsilon},\tfrac{\tilde\lambda^+(z,s,\zeta,\sigma)}{R\sqrt\varepsilon}\Big)\,\widetilde\Pi^+(z,s,\zeta)+O(R\sqrt\varepsilon)$$

$$=: b_{\varepsilon,R}(z,s,\zeta,\sigma)\widetilde\Pi^+(z,s,\zeta)+O(R\sqrt\varepsilon)$$

as functions in $\mathcal{C}^\infty_c(\mathbb{R}^{2d+2},\mathbb{C})$. Hence, we obtain

$$\Big(\mathrm{op}_\varepsilon\Big(c^+_{\varepsilon,R}(q,t,p,\tau)\Pi^+(q)\Big)\,\psi^\varepsilon(q,t)\ ,\ \psi^\varepsilon(q,t)\Big)_{L^2}$$

$$= \Big(\mathrm{op}_\varepsilon\Big(b_{\varepsilon,R}(z,s,\zeta,\sigma)\widetilde\Pi^+(z,s,\zeta)\Big)\, v^\varepsilon(z,s)\ ,\ v^\varepsilon(z,s)\Big)_{L^2} + O(R\sqrt\varepsilon).$$

For $|\tilde z|=O(R\sqrt\varepsilon)$ we have

$$\widetilde\Pi^+(z,s,\zeta)=\begin{pmatrix}0&0\\0&\mathrm{Id}\end{pmatrix}+O(R\sqrt\varepsilon)\ \text{ in }\ \{s>0\},$$

$$\widetilde\Pi^+(z,s,\zeta)=\begin{pmatrix}\mathrm{Id}&0\\0&0\end{pmatrix}+O(R\sqrt\varepsilon)\ \text{ in }\ \{s<0\}, \tag{5.13}$$

and therefore

$$\Big(\mathrm{op}_\varepsilon\Big(b_{\varepsilon,R}(z,s,\zeta,\sigma)\widetilde{\Pi}^+(z,s,\zeta)\Big)\,v^\varepsilon(z,s)\,,\,v^\varepsilon(z,s)\Big)_{L^2}$$
$$=\left(\mathrm{op}_\varepsilon\left(b_{\varepsilon,R}(z,s,\zeta,\sigma)\right)v_2^\varepsilon(z,s)\,,\,v_2^\varepsilon(z,s)\right)_{L^2}+O(R\sqrt{\varepsilon}).$$

We now remove the σ-dependence of the symbol. Taylor expanding around $\sigma=-\sqrt{s^2+|\tilde z+\gamma_0(z,\zeta)|^2}$, we write

$$b_{\varepsilon,R}(z,s,\zeta,\sigma)=b\Big(z,s,\zeta,-\sqrt{s^2+|\tilde z+\gamma_0(z,\zeta)|^2},\tfrac{\tilde z}{R\sqrt{\varepsilon}},0\Big)$$
$$+\tfrac{1}{R\sqrt{\varepsilon}}\tilde\lambda^+(s,z,\sigma,\zeta)\,G\Big(z,s,\zeta,\sigma,\tfrac{\tilde z}{R\sqrt{\varepsilon}},\tfrac{\tilde\lambda^+(z,s,\sigma,\zeta)}{R\sqrt{\varepsilon}}\Big)$$

with $G\in\mathcal{C}_c^\infty(\mathbb{R}^{2d+2+\ell},\mathbb{C})$. Since

$$\tilde\lambda^+(z,s,\zeta,\sigma)\tilde\Pi^+(z,s,\zeta)=\widetilde{\Pi}^+(z,s,\zeta)\,(\sigma-V_\ell(s,\tilde z+\gamma_0(z,\zeta))\,,$$

and since v^ε solves the Landau–Zener-type problem (5.5), an argument analogous to the proof of Lemma 5.1 yields

$$\left(\mathrm{op}_\varepsilon\left(b_{\varepsilon,R}(z,s,\zeta,\sigma)\right)v_2^\varepsilon(z,s)\,,\,v_2^\varepsilon(z,s)\right)_{L^2}=O\big(\tfrac{1}{R^2}\big)+O(\sqrt{\varepsilon})$$
$$+\Big(\mathrm{op}_\varepsilon\Big(b\big(z,s,\zeta,-\sqrt{s^2+|\tilde z+\gamma_0(z,\zeta)|^2},\tfrac{\tilde z}{R\sqrt{\varepsilon}},0\big)\Big)\,v_2^\varepsilon(z,s)\,,\,v_2^\varepsilon(z,s)\Big)_{L^2}.$$

Setting $b^+(z,s,\zeta,\eta)=b(z,s,\zeta,-s,\eta,0)$, we obtain

$$\Big(\mathrm{op}_\varepsilon\Big(c^+_{\varepsilon,R}(q,t,p,\tau)\Pi^+(q)\Big)\,\psi^\varepsilon(q,t)\,,\,\psi^\varepsilon(q,t)\Big)_{L^2}$$
$$=\Big(\mathrm{op}_\varepsilon\Big(b^+\Big(z,s,\zeta,\tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\,v_2^\varepsilon(z,s)\,,\,v_2^\varepsilon(z,s)\Big)_{L^2}+O(R\sqrt{\varepsilon})+O\big(\tfrac{1}{R^2}\big).$$

Next, we focus on the second claimed identity, which contains nonadiabatic transitions. We have

$$\Big(\mathrm{op}_\varepsilon\Big((\mathcal{L}^{\delta_t}_{\varepsilon,R}f^+_{c_{\varepsilon,R}})(q,t,p,\tau,+)\Pi^+(q)\Big)\,\psi^\varepsilon(q,t)\,,\,\psi^\varepsilon(q,t)\Big)_{L^2}$$
$$=\Big(\mathrm{op}_\varepsilon\Big(\big((\mathcal{L}^{\delta_t}_{\varepsilon,R}f^+_{c_{\varepsilon,R}})A_0^*\Pi^+A_0\big)(\kappa^{-1}(z,s,\zeta,\sigma),+)\Big)\,v^\varepsilon(z,s)\,,\,v^\varepsilon(z,s)\Big)_{L^2}+O(\sqrt{\varepsilon}).$$

Let $r\mapsto(z^+(r),s^+(r),\zeta^+(r),\sigma^+(r))$ be the Hamiltonian trajectory of

$$\dot z=\partial_\zeta\tilde\lambda^+={}^t\mathrm{d}_\zeta\gamma_0(z,\zeta)(\tilde z+\gamma_0(z,\zeta))\,(s^2+|\tilde z+\gamma_0(z,\zeta)|^2)^{-1/2},$$
$$\dot s=\partial_\sigma\tilde\lambda^+=1,$$
$$\dot\zeta=-\partial_z\tilde\lambda^+=-{}^t\mathrm{d}_z(\tilde z+\gamma_0(z,\zeta))(\tilde z+\gamma_0(z,\zeta))(s^2+|\tilde z+\gamma_0(z,\zeta)|^2)^{-1/2},$$
$$\dot\sigma=-\partial_s\tilde\lambda^+=-s\,(s^2+|\tilde z+\gamma_0(z,\zeta)|^2)^{-1/2}$$

with $(z(0),s(0),\zeta(0),\sigma(0))=(z,s,\zeta,\sigma)=\kappa(q,t,p,\tau)$. A trajectory jumps for $r=r_*$ if $s^+(r_*)=O(|\phi(q)|^2)=O(R^2\varepsilon)$. Then, $\sigma^+(r_*)=O(R^2\varepsilon)$ as well. Since

$$\tfrac{\mathrm{d}}{\mathrm{d}r}\big(s^+(r)+\sigma^+(r)\big)=O(|\tilde z|^2)\quad\text{on}\quad J^{+,out}=\{\sigma+s=0,\,\tilde z=0,\,s>0\},$$

and since $|\tilde z| = O(R\sqrt{\varepsilon})$ on the support of our symbol, we have

$$z^+(r) = z + O(R^3\varepsilon^{3/2}), \quad s^+(r) = s + r,$$
$$\zeta^+(r) = \zeta + O(R\sqrt{\varepsilon}), \quad \sigma^+(r) = -s^+(r) + O(R^2\varepsilon).$$

These asymptotics together with conservation of energy along Hamiltonian flows yield

$$b\Big(z^+(r), s^+(r), \zeta^+(r), \sigma^+(r), \tfrac{\tilde z^+(r)}{R\sqrt{\varepsilon}}, \tfrac{\tilde\lambda^+(z^+(r),s^+(r),\zeta^+(r),\sigma^+(r))}{R\sqrt{\varepsilon}}\Big)$$
$$= b\Big(z, s+r, \zeta, -(s+r), \tfrac{\tilde z}{R\sqrt{\varepsilon}}, \tfrac{\tilde\lambda^+(z,s,\zeta,\sigma)}{R\sqrt{\varepsilon}}\Big) + O(R\sqrt{\varepsilon}).$$

Jumps occur for $|\phi(q)| \le R\sqrt{\varepsilon}$, that is, for

$$|\tilde z|^2 = |\mathrm{d}\phi(q)p|^{-1}|\pi_\ell(q,p)\phi(q)|^2 + O(|\phi(q)|^3)$$
$$= |\mathrm{d}\phi(q)p|^{-1}|\pi_\ell(q,p)\phi(q)|^2 + O(R^3\varepsilon^{3/2}).$$

Therefore, the transition rate $T^\varepsilon(q,p)$ reads in the new coordinates as

$$T^\varepsilon(q,p) = \exp\big(-\tfrac{\pi}{\varepsilon}|\mathrm{d}\phi(q)p|^{-1}|\pi_\ell(q,p)\phi(q)|^2\big)$$
$$= \exp\big(-\tfrac{\pi}{\varepsilon}|\tilde z|^2\big) + O(R^3\sqrt{\varepsilon}) = \widetilde T^\varepsilon(\tilde z) + O(R^3\sqrt{\varepsilon}),$$

and there exists $s_1^+ \in \mathbb{R}$ such that

$$\big((\mathcal{L}^{\delta_t}_{\varepsilon,R} f^+_{c_{\varepsilon,R}})A_0^*\Pi^+A_0\big)(\kappa^{-1}(z,s,\zeta,\sigma),+)$$
$$= \Big(1 - \widetilde T^\varepsilon(\tilde z)\Big)\, b\Big(z, s+s_1^+, \zeta, -(s+s_1^\pm), \tfrac{\tilde z}{R\sqrt{\varepsilon}}, \tfrac{\tilde\lambda^+(z,s,\zeta,\sigma)}{R\sqrt{\varepsilon}}\Big)\, \widetilde\Pi^+(z,s,\zeta) + O(R^3\sqrt{\varepsilon}).$$

By the asymptotics (5.13) of $\widetilde\Pi^+$ above $\{s<0\}$, we then get

$$\Big(\mathrm{op}_\varepsilon\Big(\big((\mathcal{L}^{\delta_t}_{\varepsilon,R} f^+_{c_{\varepsilon,R}})A_0^*\Pi^+A_0\big)(\kappa^{-1}(z,s,\zeta,\sigma),+)\Big)\, v^\varepsilon(z,s)\ ,\ v^\varepsilon(z,s)\Big)_{L^2} = O(R^3\sqrt{\varepsilon})$$
$$+ \Big(\mathrm{op}_\varepsilon\Big(\big(1-\widetilde T^\varepsilon(\tilde z)\big) b\Big(z, s+s_1^+, \zeta, -(s+s_1^\pm), \tfrac{\tilde z}{R\sqrt{\varepsilon}}, \tfrac{\tilde\lambda^+(z,s,\zeta,\sigma)}{R\sqrt{\varepsilon}}\Big)\Big)\, v_1^\varepsilon(z,s), v_1^\varepsilon(z,s)\Big)_{L^2}.$$

As before, we remove the σ-dependence of the symbol and obtain

$$\Big(\mathrm{op}_\varepsilon\Big((\mathcal{L}^{\delta_t}_{\varepsilon,R} f^+_{c_{\varepsilon,R}})(q,t,p,\tau,+)\Pi^+(q)\Big)\, \psi^\varepsilon(q,t)\ ,\ \psi^\varepsilon(q,t)\Big)_{L^2}$$
$$= \Big(\mathrm{op}_\varepsilon\Big(\big(1-\widetilde T^\varepsilon(\tilde z)\big) b^+\Big(z, s+s_1^+, \zeta, \tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\, v_1^\varepsilon(z,s)\ ,\ v_1^\varepsilon(z,s)\Big)_{L^2} + O(R^3\sqrt{\varepsilon}). \qquad \square$$

5.3. The transitions. It remains to analyze $v^\varepsilon = U^*\mathrm{op}_\varepsilon(A_\varepsilon^{-1})\psi^\varepsilon$ for proving the equality of each pair in Proposition 5.4 up to an error of $O(1/R^2) + O(R^3\sqrt{\varepsilon}) + O(\sqrt{\varepsilon}|\ln\varepsilon|) + O(1/(R^5\sqrt{\varepsilon}))$, concluding the proof of our main result. We consider the solution u^ε of

$$-i\varepsilon\partial_s u^\varepsilon = \begin{pmatrix} s\,\mathrm{Id} & \sqrt{\varepsilon}\,G \\ \sqrt{\varepsilon}G^* & -s\,\mathrm{Id}\end{pmatrix} u^\varepsilon, \qquad u^\varepsilon_{|s=0} = v^\varepsilon_{|s=0}, \tag{5.14}$$

where G is one of the operators

$$G_2 = \tfrac{1}{\sqrt{\varepsilon}}\varphi\left(\tfrac{\tilde z}{R\sqrt{\varepsilon}}\right)\tilde z, \qquad G_3 = \tfrac{1}{\sqrt{\varepsilon}}\varphi\left(\tfrac{\tilde z}{R\sqrt{\varepsilon}}\right)(Z_1 + iZ_2),$$

$$G_5 = \tfrac{1}{\sqrt{\varepsilon}}\varphi\left(\tfrac{\tilde z}{R\sqrt{\varepsilon}}\right)\begin{pmatrix} Z_1+iZ_2 & Z_3+iZ_4 \\ -Z_3+iZ_4 & Z_1-iZ_2\end{pmatrix}$$

with $Z = \mathrm{op}_\varepsilon(\tilde z + \gamma_\varepsilon(z,\zeta))$ and $\varphi \in \mathcal{C}_c^\infty(\mathbb{R}^{\ell-1},\mathbb{R})$. In all three cases, G is a bounded operator on $L^2(\mathbb{R}^d)$ with $\|G\| = O(R)$, and we have

$$\|u^\varepsilon - v^\varepsilon\|_{L^2_{loc}(\mathbb{R}^{d+1})} = O(\varepsilon^\infty).$$

The following Landau–Zener-type formula is given in Proposition 7 of [8], up to the explicit error terms.

PROPOSITION 5.5. *Let u^ε be the solution of* (5.14). *There exist vector-valued functions $\alpha^\varepsilon = (\alpha_1^\varepsilon, \alpha_2^\varepsilon)$, $\omega^\varepsilon = (\omega_1^\varepsilon, \omega_2^\varepsilon) \in L^2(\mathbb{R}^d, \mathbb{C}^{N(\ell)})$ such that for any function $\chi \in \mathcal{C}_c^\infty(\{x \in \mathbb{R} \mid |x| \le R^2\},\mathbb{R})$ the families $(\chi(GG^*)\alpha_1^\varepsilon)_{\varepsilon>0}$, $(\chi(G^*G)\alpha_2^\varepsilon)_{\varepsilon>0}$, $(\chi(GG^*)\omega_1^\varepsilon)_{\varepsilon>0}$, $(\chi(G^*G)\omega_2^\varepsilon)_{\varepsilon>0}$ are bounded in $L^2(\mathbb{R}^d,\mathbb{C})$ and satisfy*

$$\chi(GG^*)u_1^\varepsilon(z,s) = \chi(GG^*)\mathrm{e}^{is^2/(2\varepsilon)}\left|\tfrac{s}{\sqrt{\varepsilon}}\right|^{i\frac{GG^*}{2}} k_1^\varepsilon(z) + O(R^2\sqrt{\varepsilon}),$$

$$\chi(G^*G)u_2^\varepsilon(z,s) = \chi(G^*G)\mathrm{e}^{-is^2/(2\varepsilon)}\left|\tfrac{s}{\sqrt{\varepsilon}}\right|^{-i\frac{G^*G}{2}} k_2^\varepsilon(z) + O(R^2\sqrt{\varepsilon})$$

in $L^2(\mathbb{R}^d,\mathbb{C})$, where $k_j^\varepsilon = \alpha_j^\varepsilon$ and $k_j^\varepsilon = \omega_j^\varepsilon$ for $s<0$ and $s>0$, respectively, $j \in \{1,2\}$. Moreover,

$$\begin{pmatrix}\omega_1^\varepsilon \\ \omega_2^\varepsilon\end{pmatrix} = \begin{pmatrix} a(GG^*) & -\overline{b}(GG^*)G \\ b(G^*G)G^* & a(G^*G)\end{pmatrix}\begin{pmatrix}\alpha_1^\varepsilon \\ \alpha_2^\varepsilon\end{pmatrix} \tag{5.15}$$

with

$$a(\lambda) = \mathrm{e}^{-\pi\lambda/2}, \qquad b(\lambda) = \tfrac{2i\mathrm{e}^{i\pi/4}}{\lambda\sqrt{\pi}}2^{-i\lambda/2}\mathrm{e}^{-\pi\lambda/4}\Gamma(1+i\tfrac{\lambda}{2})\sinh(\tfrac{\pi\lambda}{2}).$$

Proof. Lemma 7 in [8] is the crucial step in the proof of Proposition 7 for which we have to check that the leading order error estimate is indeed $O(R^2\sqrt{\varepsilon})$. For this, we turn to the explicit calculations in the proof of Lemma 11 in [7] and study the two integrals

$$A_0 = s^{-1+i\eta^2/2}\mathrm{e}^{-is^2/2}\int_{\mathbb{R}}\tilde\chi\left(\sqrt{2}-\sqrt{2-\tfrac{2z}{s^2}}\right)\left|\sqrt{2}-\sqrt{2-\tfrac{2z}{s^2}}\right|^{i\eta^2/2}\frac{\mathrm{e}^{iz}}{\sqrt{2-\frac{2z}{s^2}}}\,\mathrm{d}z,$$

$$B_0 = s^{1+i\eta^2/2}\int_{\mathbb{R}}(1-\tilde\chi(y))\,\mathrm{e}^{-\frac{i}{2}s^2(1+y^2-2\sqrt{2}y)}|y|^{i\eta^2/2}\mathrm{d}y,$$

where $\tilde\chi \in \mathcal{C}_c^\infty(\mathbb{R},\mathbb{R})$ is a function with $0 \le \tilde\chi \le 1$, $\tilde\chi(y) = 0$ for $|y| \ge \sqrt{2}/2$, and $\tilde\chi(y) = 1$ for $|y| \le \sqrt{2}/4$. The phase function $y \mapsto -\frac{1}{2}(1+y^2-2\sqrt{2}y)$ of B_0 has the stationary point $y = \sqrt{2}$, and Taylor expansion of $y \mapsto \ln|y|$ around $y = \sqrt{2}$ yields

$$B_0 = \sqrt{2\pi}\mathrm{e}^{-i\pi/4}2^{i\eta^2/4}s^{i\eta^2/2}\mathrm{e}^{is^2/2} + O(\eta^2 s^{-2}),$$

while integration by parts gives

$$A_0 = O(\eta^2 s^{-1})$$

as $\eta, s \to \infty$. Since the asymptotics of the other relevant integrals can be obtained analogously, the claimed error estimates follow by setting $s = O(\varepsilon^{-1/2})$ and $\eta = O(R)$. □

For implementing these Landau–Zener asymptotics, we need the following additional relations, which are literally contained in the proofs of Lemmas 8 and 9 in [8].

LEMMA 5.6. *For any $\chi \in \mathcal{C}_c^\infty(\mathbb{R}, \mathbb{R})$ and $b \in \mathcal{C}_c^\infty(\mathbb{R}^{2d+N(\ell)-1}, \mathbb{C})$, we have*

$$\chi\Big(\tfrac{|\tilde z|^2}{\varepsilon}\Big) = \chi(GG^*) + O(\sqrt{\varepsilon}) = \chi(G^*G) + O(\sqrt{\varepsilon}),$$

$$\Big|\tfrac{s}{\sqrt{\varepsilon}}\Big|^{\pm i\frac{G^*G}{2}} \operatorname{op}_\varepsilon\Big(b\Big(z, \zeta, \tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big) \Big|\tfrac{s}{\sqrt{\varepsilon}}\Big|^{\mp i\frac{G^*G}{2}} = \operatorname{op}_\varepsilon\Big(b\Big(z, \zeta, \tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big) + O(\sqrt{\varepsilon}|\ln\varepsilon|).$$

Now, we are ready to conclude the proof of Theorem 2.2. We discuss only the first pair of terms in Proposition 5.4, since the other pair can be dealt with analogously. We set

$$I^1_{\varepsilon,R} = \Big(\operatorname{op}_\varepsilon\Big(b^+\Big(z, s, \zeta, \tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\, u_2^\varepsilon(z,s), u_2^\varepsilon(z,s)\Big)_{L^2},$$

$$I^2_{\varepsilon,R} = \Big(\operatorname{op}_\varepsilon\Big((1-\widetilde T^\varepsilon(\tilde z))b^+\Big(z, s+s_1^+, \zeta, \tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\, u_1^\varepsilon(z,s), u_1^\varepsilon(z,s)\Big)_{L^2}.$$

By Lemma 5.6 and Proposition 5.5, we have

$$\begin{aligned} I^1_{\varepsilon,R} &= \Big(\operatorname{op}_\varepsilon\Big(b^+\Big(z, s, \zeta, \tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\, \chi(G^*G)u_2^\varepsilon(z,s), \chi(G^*G)u_2^\varepsilon(z,s)\Big)_{L^2} + O(\sqrt{\varepsilon}) \\ &= \left(\operatorname{op}_\varepsilon\Big(b^+\Big(z, s, \zeta, \tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\, \mathrm{e}^{-i\frac{s^2}{2\varepsilon}} \Big|\tfrac{s}{\sqrt{\varepsilon}}\Big|^{-i\frac{G^*G}{2}} \omega_2^\varepsilon(z), \mathrm{e}^{-i\frac{s^2}{2\varepsilon}} \Big|\tfrac{s}{\sqrt{\varepsilon}}\Big|^{-i\frac{G^*G}{2}} \omega_2^\varepsilon(z)\right)_{L^2} \\ &\qquad + O(R^2\sqrt{\varepsilon}) \\ &= \Big(\operatorname{op}_\varepsilon\Big(b^+\Big(z, s, \zeta, \tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\, \omega_2^\varepsilon(z), \omega_2^\varepsilon(z)\Big)_{L^2} + O(R^2\sqrt{\varepsilon}) + O(\sqrt{\varepsilon}|\ln\varepsilon|) \\ &= \Big(\operatorname{op}_\varepsilon\Big(b^+\Big(z, s+s_1^+, \zeta, \tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\, \omega_2^\varepsilon(z), \omega_2^\varepsilon(z)\Big)_{L^2} + O(R^2\sqrt{\varepsilon}) + O(\sqrt{\varepsilon}|\ln\varepsilon|) \end{aligned}$$

because $s_1^\pm = O(R\sqrt{\varepsilon})$ and analogously

$$\begin{aligned} I^2_{\varepsilon,R} = \Big(\operatorname{op}_\varepsilon\Big((1-\widetilde T^\varepsilon(\tilde z))\, b^+\Big(z, s+s_1^+, \zeta, \tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\, \alpha_1^\varepsilon(z), \alpha_1^\varepsilon(z)\Big)_{L^2} \\ + O(R^2\sqrt{\varepsilon}) + O(\sqrt{\varepsilon}|\ln\varepsilon|). \end{aligned}$$

By the scattering identity (5.15), we have $\omega_2^\varepsilon = b(G^*G)G^*\alpha_1^\varepsilon + a(G^*G)\alpha_2^\varepsilon$ and

$$\begin{aligned} I^1_{\varepsilon,R} = \Big(\operatorname{op}_\varepsilon\Big(b^+\Big(z, s+s_1^+, \zeta, \tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\, (b(G^*G)G^*\alpha_1^\varepsilon(z) + a(G^*G)\alpha_2^\varepsilon(z)), \\ b(G^*G)G^*\alpha_1^\varepsilon(z) + a(G^*G)\alpha_2^\varepsilon(z)\Big)_{L^2} + O(R^2\sqrt{\varepsilon}) + O(\sqrt{\varepsilon}|\ln\varepsilon|). \end{aligned}$$

Since the wave function $\psi^\varepsilon(q,t)$ is of order $O(1/R^2)+O(\sqrt{\varepsilon})+O(1/(R^5\sqrt{\varepsilon}))$ near the set $J^{-,in}=\{\sigma+s=0,\,\tilde z=0,\,s<0\}$, we have

$$\begin{pmatrix} 0 \\ v_2^\varepsilon(z,s)\end{pmatrix} = \mathrm{op}_\varepsilon\Big(\widetilde\Pi^-(z,s,\zeta)\Big)\, v^\varepsilon(z,s)+O(R\sqrt{\varepsilon})$$
$$= O(1/R^2)+O(R\sqrt{\varepsilon})+O(1/(R^5\sqrt{\varepsilon}))$$

as functions in $L^2_{loc}(\mathbb{R}^{d+1})$ localized near $J^{-,in}$. The preceding arguments expressing $I^1_{\varepsilon,R}$ and $I^2_{\varepsilon,R}$ in terms of α^ε and ω^ε then yield

$$a(G^*G)\alpha_2^\varepsilon(z)=O(1/R^2)+O(R^2\sqrt{\varepsilon})+O(\sqrt{\varepsilon}|\ln\varepsilon|)+O(1/(R^5\sqrt{\varepsilon}))$$

near $J^{-,in}$, and hence

$$I^1_{\varepsilon,R}=\Big(\mathrm{op}_\varepsilon\Big(b^+\Big(z,s+s_1^+,\zeta,\tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\, b(G^*G)G^*\alpha_1^\varepsilon(z), b(G^*G)G^*\alpha_1^\varepsilon(z)\Big)_{L^2}$$
$$+O\big(\tfrac{1}{R^2}\big)+O(R^2\sqrt{\varepsilon})+O(\sqrt{\varepsilon}|\ln\varepsilon|)+O\Big(\tfrac{1}{R^5\sqrt{\varepsilon}}\Big).$$

Lemma 5.6 together with the relations $G^*b(GG^*)=b(G^*G)G^*$ and

$$\lambda|b(\lambda)|^2=1-\mathrm{e}^{-\pi\lambda}$$

implies

$$G\,\overline{b}(G^*G)\,\mathrm{op}_\varepsilon\Big(b^+\Big(z,s+s_1^+,\zeta,\tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\, b(G^*G)G^*\alpha_1^\varepsilon(z)$$
$$= G\,\overline{b}(G^*G)b(G^*G)G^*\,\mathrm{op}_\varepsilon\Big(b^+\Big(z,s+s_1^+,\zeta,\tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\,\alpha_1^\varepsilon(z)+O(\sqrt{\varepsilon})$$
$$= GG^*\overline{b}(GG^*)b(GG^*)\,\mathrm{op}_\varepsilon\Big(b^+\Big(z,s+s_1^+,\zeta,\tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\,\alpha_1^\varepsilon(z)+O(\sqrt{\varepsilon})$$
$$= (1-\widetilde T^\varepsilon(\tilde z))\,\mathrm{op}_\varepsilon\Big(b^+\Big(z,s+s_1^+,\zeta,\tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\,\alpha_1^\varepsilon(z)+O(\sqrt{\varepsilon}) \tag{5.16}$$

and finally

$$I^1_{\varepsilon,R}=I^2_{\varepsilon,R}+O(1/R^2)+O(R^2\sqrt{\varepsilon})+O(\sqrt{\varepsilon}|\ln\varepsilon|)+O(1/(R^5\sqrt{\varepsilon})).$$

6. Eigenvalues of multiplicity two. We have assumed that the matrix-valued observable a is V-diagonal in the sense that $a=a^+\Pi^++a^-\Pi^-$ with scalar-valued functions $a^\pm$. The more natural assumption, that a commutes with V,

$$a=\Pi^+a\Pi^++\Pi^-a\Pi^-,$$

does not change the situation in the case $\ell=2,3$ but enlarges the class of observables for $\ell=3',5$. For observables of this form, one has to modify the Markov process to account for a polarization effect. The state space requires an additional component $w\in\mathbb{C}^4$, and when the deterministic flow $\Phi_j^t(q,p)$ hits the jump manifold $S_{\varepsilon,R}$ in a point (q^*,p^*) a more general branching occurs. The state (q^*,p^*,j,w) changes with probability $T^\varepsilon(q^*,p^*)$ to $(q^*,p^*,-j,w)$ and with probability $1-T^\varepsilon(q^*,p^*)$ to $(q^*,p^*,j,\mathcal{R}(q^*,p^*)w)$, where

$$\mathcal{R}(q,p)=V_\ell\Big(\tfrac{\pi_\ell(q,p)\phi(q)}{|\pi_\ell(q,p)\phi(q)|}\Big).$$

This phenomenon is also described in Theorem 1 of [5] for two-scale Wigner measures. Our main result, Theorem 2.2, for the propagation of Wigner functions still applies for the semigroup, which incorporates polarization.

Proof of Theorem 2.2 *for* $a = \Pi^+ a \Pi^+ + \Pi^- a \Pi^-$ *if* $\ell = 3', 5$. Let us first prove classical transport. We set $A^+ = \Pi^+ a \Pi^+$ and focus on the + mode. We extensively use $\Pi^+ A^+ = A^+ \Pi^+ = A^+$. The strategy is similar to the one of section 4, and we have to focus on the Poisson brackets

$$\tfrac{1}{2}\{A^+(q,p), \tau + \tfrac{1}{2}|p|^2 + v(q) + V_\ell(\phi(q))\} - \tfrac{1}{2}\{\tau + \tfrac{1}{2}|p|^2 + v(q) + V_\ell(\phi(q)), A^+(q,p)\}.$$

We set $\mu(q,p,\tau) = \tau + \frac{1}{2}|p|^2 + v(q)$ and write

$$\{A^+, \mu\} = \Pi^+\{A^+, \mu\}\Pi^+ + A^+\{\Pi^+, \mu\} + \{\Pi^+, \mu\}A^+.$$

We observe that

$$r_0 = A^+\{\Pi^+, \mu\} + \{\Pi^+, \mu\}A^+ = -A^+(\nabla_q \Pi^+ \cdot p) - (\nabla_q \Pi^+ \cdot p)A^+$$

can be treated as in section 4. Indeed, since A^+ commutes with $V_\ell(\phi)$, one has for any matrix G that $A^+[V_\ell(\phi), G] = [V_\ell(\phi), A^+ G]$, $[V_\ell(\phi), G]A^+ = [V_\ell(\phi), GA^+]$, and consequently

$$\begin{aligned} r_0 &= -\tfrac{1}{4|\phi|^3}\left[V_\ell(\phi), \left[V_\ell(\phi), A^+ V_\ell(\mathrm{d}\phi p)\right]\right] - \tfrac{1}{4|\phi|^3}\left[V_\ell(\phi), \left[V_\ell(\phi), V_\ell(\mathrm{d}\phi p)A^+\right]\right] \\ &= -\left[\mu + V_\ell(\phi), \tfrac{1}{4|\phi|^3}\left[V_\ell(\phi), A^+ V_\ell(\mathrm{d}\phi p)\right]\right] - \left[\mu + V_\ell(\phi), \tfrac{1}{4|\phi|^3}\left[V_\ell(\phi), V_\ell(\mathrm{d}\phi p)A^+\right]\right]. \end{aligned}$$

The most harmful of the arising terms contains the brackets with $\frac{1}{2}|p|^2$, that is,

$$\tilde{r}_0 = -\left\{\tfrac{1}{2}|p|^2, \tfrac{1}{4|\phi|^3}\left[V_\ell(\phi), A^+ V_\ell(\mathrm{d}\phi p)\right]\right\} - \left\{\tfrac{1}{2}|p|^2, \tfrac{1}{4|\phi|^3}\left[V_\ell(\phi), V_\ell(\mathrm{d}\phi p)A^+\right]\right\}.$$

Since the term containing the derivatives of $V_\ell(\phi)$ vanishes,

$$-\tfrac{1}{4|\phi|^3}\left[V_\ell(\mathrm{d}\phi p), A^+ V_\ell(\mathrm{d}\phi p)\right] - \tfrac{1}{4|\phi|^3}\left[V_\ell(\mathrm{d}\phi p), V_\ell(\mathrm{d}\phi p)A^+\right] = 0,$$

there is a matrix-valued function G_ε with suitable bounds on its derivatives, such that $\tilde{r}_0 = |\phi|^{-4}[V_\ell(\phi), G_\varepsilon]$, and hence the other arguments of Lemma 4.1 apply for the analysis of r_0.

For the brackets with the matrix part, we write

$$\tfrac{1}{2}\{A^+, V_\ell(\phi)\} - \tfrac{1}{2}\{V_\ell(\phi), A^+\} = \Pi^+\{A^+, |\phi|\}\Pi^+ + |\phi|\left(\{A^+, \Pi^+\} - \{\Pi^+, A^+\}\right).$$

The second part,

$$r_1 = |\phi|\left(\{A^+, \Pi^+\} - \{\Pi^+, A^+\}\right) = |\phi|\left(\nabla_p A^+ \cdot \nabla_q \Pi^+ + \nabla_q \Pi^+ \nabla_p A^+\right),$$

is off-diagonal with respect to V, since $\nabla_p A^+ = \Pi^+ \nabla_p A^+ = \nabla_p A^+ \Pi^+$, $\Pi^\pm \Pi^\mp = 0$, and $\Pi^\pm \nabla_q \Pi^+ \Pi^\pm = 0$ imply

$$\Pi^\pm\left(\nabla_p A^+ \cdot \nabla_q \Pi^+ + \nabla_q \Pi^+ \nabla_p A^+\right)\Pi^\pm = 0.$$

Hence, Lemma 4.1 applies.

The importance of $\mathcal{R}(q,p)$ for the nonadiabatic transitions becomes clear, when recasting (5.16) in the previous section as

$$\begin{pmatrix} 0 & G^* \\ G & 0 \end{pmatrix} \overline{b}(G^*G)\,\mathrm{op}_\varepsilon\Big(b^+\Big(z, s+s_1^+, \zeta, \tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\, b(G^*G) \begin{pmatrix} 0 & G \\ G^* & 0 \end{pmatrix} \begin{pmatrix} \alpha_1^\varepsilon(z) \\ 0 \end{pmatrix}$$

$$= V_\ell^*(0, \tfrac{\tilde z}{|\tilde z|})(G^*G)^{\frac12}\, \overline{b}(G^*G)\,\mathrm{op}_\varepsilon\Big(b^+\Big(z, s+s_1^+, \zeta, \tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)$$

$$\times\, b(G^*G)(G^*G)^{\frac12}\, V_\ell^*\left(0, \tfrac{\tilde z}{|\tilde z|}\right) \begin{pmatrix} \alpha_1^\varepsilon(z) \\ 0 \end{pmatrix} + O(\sqrt{\varepsilon})$$

$$= (1-\widetilde{T}^\varepsilon(\tilde z))\, V_\ell^*\left(0, \tfrac{\tilde z}{|\tilde z|}\right)\, \mathrm{op}_\varepsilon\Big(b^+\Big(z, s+s_1^+, \zeta, \tfrac{\tilde z}{R\sqrt{\varepsilon}}\Big)\Big)\, V_\ell\left(0, \tfrac{\tilde z}{|\tilde z|}\right) \begin{pmatrix} \alpha_1^\varepsilon(z) \\ 0 \end{pmatrix} + O(\sqrt{\varepsilon})$$

and observing that the normal form transformation relates $V_\ell(0, \tilde z/|\tilde z|)$ and $\mathcal{R}(q,p)$ by identity (5.9) of Theorem 5.2. ∎

Appendix A. Weyl calculus. For the convenience of the reader, we formulate the key technical lemma of the calculus of Weyl quantized pseudodifferential operators.

DEFINITION A.1. *A smooth matrix-valued function $a \in \mathcal{C}^\infty(\mathbb{R}^{2d}, \mathbb{C}^{N\times N})$ is of subquadratic growth if for all $|\alpha|+|\beta| \geq 2$ there exists $C_{\alpha,\beta} > 0$ such that*

$$\|\partial_q^\alpha \partial_p^\beta a\|_\infty \leq C_\alpha.$$

LEMMA A.2. *Let $a \in \mathcal{C}_c^\infty(\mathbb{R}^{2d}, \mathbb{C}^{N\times N})$, and let $b \in \mathcal{C}^\infty(\mathbb{R}^{2d}, \mathbb{C}^{N\times N})$ be of subquadratic growth. Then, for all $\psi \in \mathcal{C}_c^\infty(\mathbb{R}^d, \mathbb{C}^N)$*

$$\mathrm{op}_1(a)\mathrm{op}_1(b)\psi = \big(\mathrm{op}_1(ab) + \tfrac{1}{2i}\mathrm{op}_1\left(\{a,b\}\right) + \mathrm{op}_1(c) + \mathrm{op}_1(r)\big)\,\psi,$$

with $\{a,b\} = \partial_p a \partial_q b - \partial_q a \partial_p b$ the Poisson bracket, c a linear combination of

$$\partial_{q_j,p_j} a\, \partial_{q_j,p_j} b,\ \partial_{q_j}^2 a\, \partial_{p_j}^2 b,\ \partial_{p_j}^2 a\, \partial_{q_j}^2 b,$$

and $r \in \mathcal{C}^\infty(\mathbb{R}^{2d}, \mathbb{C}^{N\times N})$ such that

$$N_k(r) := \sup_{|\alpha|+|\beta|\leq k} \|\partial_q^\alpha \partial_p^\beta r\|_\infty \leq C_k \sum_{m+m'=k} \big(N_m(D^3 a)\, N_{m'}(D^3 b)\big)$$

for all $k \in \mathbb{N}$.

For a proof of this classical lemma, the reader can refer to [15] or to [3]. The theorem of Calderon and Vaillancourt implies that $\mathrm{op}_1(r)$ is a bounded operator on $L^2(\mathbb{R}^d, \mathbb{C}^N)$.

ON A MODEL OF MULTIPHASE FLOW*

DEBORA AMADORI† AND ANDREA CORLI‡

Abstract. We consider a hyperbolic system of three conservation laws in one space variable. The system is a model for fluid flow allowing phase transitions; in this case the state variables are the specific volume, the velocity, and the mass density fraction of the vapor in the fluid. For a class of initial data having large total variation we prove the global existence of solutions to the Cauchy problem.

Key words. hyperbolic systems of conservation laws, phase transitions

1. Introduction.

We consider a model for the one-dimensional flow of an inviscid fluid capable of undergoing phase transitions. Both liquid and vapor phases are possible, as well as mixtures of them. In Lagrangian coordinates the model is

$$\begin{cases} v_t - u_x & = 0, \\ u_t + p(v,\lambda)_x & = 0, \\ \lambda_t & = 0\,. \end{cases} \tag{1.1}$$

Here $t > 0$ and $x \in \mathbb{R}$; moreover, $v > 0$ is the specific volume, u the velocity, and λ the mass density fraction of vapor in the fluid. Then $\lambda \in [0,1]$, with $\lambda = 0$ characterizing the liquid and $\lambda = 1$ the vapor phase; the intermediate values of λ model the mixtures of the two pure phases. The pressure is denoted by $p = p(v,\lambda)$; under natural assumptions the system is strictly hyperbolic.

This model is a simplified version of a model proposed by Fan [13], where also viscous and relaxation terms were taken into account. The model is isothermal (see (2.1) below); in the presence of phase transitions this physical assumption is meaningful for retrograde fluids. A study of the Riemann problem for a 2×2 relaxation approximation of (1.1) has been done in [10]. We focus here on the global existence of solutions to the Cauchy problem for (1.1), namely, for initial data

$$(v,u,\lambda)(0,x) = \big(v_o(x), u_o(x), \lambda_o(x)\big)$$

having finite total variation. This problem is motivated by the study of more complete models, where (1.1) is supplemented by source terms.

The problem of the global existence of solutions to strictly hyperbolic system of conservation laws has been studied for a long time; see [9, 11, 24, 25, 26] for general information. If the initial data have *small* total variation, then the Glimm theorem [14] applies; we refer the reader again to [9] for the analogous results obtained by a

wave-front tracking algorithm as well as for uniqueness and continuous dependence of the solutions on the initial data.

Some special systems allow, however, initial data with *large* total variation. For the system of isothermal gasdynamics Nishida [19] proved that it is sufficient that the variation $\mathrm{TV}(v_o, u_o)$ of the initial data is finite in order to have globally defined solutions. This result was extended by Nishida and Smoller [20] to any pressure law $p = k/v^\gamma$, $\gamma > 1$, provided that $(\gamma - 1)\mathrm{TV}(v_o, u_o)$ is small; related results are in [12]. For the full nonisentropic system of 3×3 gasdynamics, where $p = k \exp(\frac{\gamma-1}{R} s)/v^\gamma$ and s denotes the entropy, Liu [17, 16] proved the global existence of solutions if $(\gamma - 1)\mathrm{TV}(v_o, p_o)$ is small and $\mathrm{TV}(s_o)$ bounded. Temple [27] and Peng [21] obtained similar results. All these papers use the Glimm scheme. Analogous results making use of a wave-front tracking scheme have been given recently by Asakura [4, 5]; we point out that the use of wave-front tracking schemes in case of data with large variation is far from being trivial, and a deep analysis of the wave interactions is required. Very general results can be proved for systems with coinciding shock and rarefaction curves [8]; however, system (1.1) is not of this type.

In comparison with the above systems of gasdynamics, in (1.1) we keep a γ-law for the pressure with $\gamma = 1$ but add a dependence of p on λ: we then take $p = a(\lambda)/v$ for a suitable function a. System (1.1) has close connections to a system introduced by Benzoni-Gavage [6] and studied by Peng [22]; it seems, however, that the proof in [22] is not complete. A comparison of these models is done in subsection 3.1. We mention that the method of compensated compactness has also been applied to (1.1) (see [15, 7] and [18, sections 12.3 and 16]) but for different pressure laws.

In this paper we prove by a wave-front tracking scheme the global existence of solutions to (1.1) for a wide class of initial data with large total variation. We first introduce a *weighted total variation* (WTV) of $a(\lambda_o)$; this quantity arises in a natural way in the problem and also has an analytical meaning, being the logarithmic variation in the case of continuous functions. We prescribe a bound, on $\mathrm{WTV}\,(a(\lambda_o))$; for the variation $\mathrm{TV}(v_o, u_o)$ there is not such a bound, but, roughly speaking, the larger $\mathrm{TV}(v_o, u_o)$ is, the smaller $\mathrm{WTV}\,(a(\lambda_o))$ must be. An important point is that we give explicit expressions for these bounds; then our results are qualitatively different from some of those quoted above, where a generic smallness is required.

The plan of the paper is the following. The main result is stated in section 2, Theorem 2.2. The Riemann problem is reviewed in section 3 together with related results; proofs have been given in [2]. The definition of the algorithm is in section 4. The core of the proof is section 5—where interactions are studied in detail—and section 6—where we prove the convergence and consistence of the scheme. A careful analysis is needed due to the presence of large waves.

The paper is completed by two appendices. In the first one we prove the main result on the WTV. In the second we study the interaction of two shock waves to the light of section 5; namely, we look for precise bounds of the damping coefficient that controls the reflected wave produced in the interaction; we think that this analysis is interesting on its own. Good reading!

2. Main results. We consider the system of conservation laws (1.1). The pressure is given by

$$p(v, \lambda) = \frac{a^2(\lambda)}{v}, \tag{2.1}$$

where a is a smooth ($\mathbf{C^1}$) function defined on $[0, 1]$ satisfying for every $\lambda \in [0, 1]$

$$a(\lambda) > 0, \qquad a'(\lambda) > 0\,; \tag{2.2}$$

see Figure 2.1. For instance $a^2(\lambda) = k_0 + \lambda(k_1 - k_0)$ for $0 < k_0 < k_1$. As a consequence of (2.1) and (2.2) we have, for every $(v, \lambda) \in (0, +\infty) \times [0, 1]$,

$$p > 0, \qquad p_v < 0, \qquad p_{vv} > 0, \tag{2.3}$$

$$p_\lambda > 0, \qquad p_{v\lambda} < 0\,. \tag{2.4}$$

Remark that assumptions (2.3) and (2.4) are analogous to those usually made on the pressure in the full nonisentropic case [17], the entropy replacing λ.

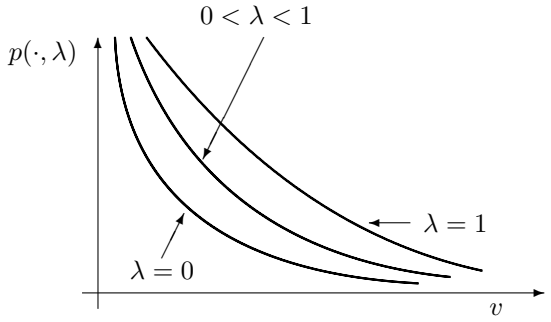

FIG. 2.1. *Pressure curves as functions of v.*

We denote $U = (v, u, \lambda) \in \Omega = (0, +\infty) \times \mathbb{R} \times [0, 1]$. Under assumptions (2.1) and (2.2) the system (1.1) is strictly hyperbolic in the whole Ω with eigenvalues $e_1 = -\sqrt{-p_v(v, \lambda)}$, $e_2 = 0$, $e_3 = \sqrt{-p_v(v, \lambda)}$. We write $c = \sqrt{-p_v} = a(\lambda)/v$. The eigenvectors associated with the eigenvalues e_i, $i = 1, 2, 3$, are $r_1 = (1, c, 0)$, $r_2 = (-p_\lambda, 0, p_v)$, $r_3 = (-1, c, 0)$. Because of the third inequality in (2.3) the eigenvalues e_1, e_3 are genuinely nonlinear with $\nabla e_i \cdot r_i = p_{vv}/(2c) > 0$, $i = 1, 3$, while e_2 is linearly degenerate. Pairs of Riemann invariants are $R_1 = \{u - a(\lambda) \log v, \lambda\}$, $R_2 = \{u, p\}$, $R_3 = \{u + a(\lambda) \log v, \lambda\}$.

We denote by $\mathrm{TV}(f)$ the total variation of a function f. In the case $f : \mathbb{R} \to (0, +\infty)$ we define the *weighted total variation* of f by

$$\mathrm{WTV}(f) = 2 \sup \sum_{j=1}^{n} \frac{|f(x_j) - f(x_{j-1})|}{f(x_j) + f(x_{j-1})},$$

where the supremum is taken over all $n \geq 1$ and $(n + 1)$-tuples of points x_j with $x_o < x_1 < \cdots < x_n$. This variation is motivated by the definition (3.6) of strength for the waves of the second family. If f is bounded and bounded away from zero, then

$$\frac{1}{\sup f} \mathrm{TV}(f) \leq \mathrm{WTV}(f) \leq \frac{1}{\inf f} \mathrm{TV}(f)\,.$$

PROPOSITION 2.1. *Consider $f : \mathbb{R} \to (0, +\infty)$; then*

$$\frac{\inf f}{\sup f} \mathrm{TV}\left(\log(f)\right) \leq \mathrm{WTV}(f) \leq \mathrm{TV}\left(\log(f)\right)\,. \tag{2.5}$$

Moreover, if $f \in C(\mathbb{R})$, then $\mathrm{WTV}(f) = \mathrm{TV}\left(\log(f)\right)$.

The proof is deferred to Appendix A. In (2.5), in the inequality on the right, the strict sign may occur if f is discontinuous; see Remark A.1.

We provide system (1.1) with initial data

$$U(x,0) = U_o(x) = (v_o(x), u_o(x), \lambda_o(x)) \tag{2.6}$$

for $x \in \mathbb{R}$. Denote $a_o(x) \doteq a(\lambda_o(x))$, $p_o(x) \doteq p(v_o(x), \lambda_o(x))$; remark that $\inf a_o(x) \geq a(0) > 0$. The main result of this paper now follows.

THEOREM 2.2. *Assume* (2.1), (2.2). *Consider initial data* (2.6) *with* $v_o(x) \geq \underline{v} > 0$ *for some constant* $\underline{v}$ *and* $0 \leq \lambda_o(x) \leq 1$. *For every* $m > 0$ *and a suitable function* $k(m) \in (0, 1/2)$ *the following holds. If*

$$\mathrm{TV}\left(\log(p_o)\right) + \frac{1}{\inf a_o}\mathrm{TV}(u_o) < 2\Big(1 - 2\mathrm{WTV}(a_o)\Big)m, \tag{2.7}$$

$$\mathrm{WTV}(a_o) < k(m), \tag{2.8}$$

then the Cauchy problem (1.1), (2.6) *has a weak entropic solution* (v, u, λ) *defined for* $t \in [0, +\infty)$. *Moreover, the solution is valued in a compact set of* Ω, *and there is a constant* $C(m)$ *such that for every* $t \in [0, +\infty)$

$$\mathrm{TV}\left(v(t,\cdot), u(t,\cdot)\right) \leq C(m)\,. \tag{2.9}$$

The function $k(m)$, whose expression is given in (6.22), deserves some comments. The interaction of two waves α, α' of the same family $i = 1, 3$ produces a wave β of the same family i and a "reflected" wave δ of the other family j ($j = 1, 3$, $j \neq i$). For a suitable definition of the strengths of the waves we prove that $|\delta| \leq d \cdot \min\{|\alpha|, |\alpha'|\}$ for a damping coefficient $d < 1$ depending on α and α'; see Lemma 5.6. The function k above depends essentially on the supremum of such coefficients d; we prove that $k(0) = 1/2$ and that $k(m)$ decreases to 0 as $m \to +\infty$. In particular then $\mathrm{WTV}(a_o) < 1/2$. The assumptions (2.7), (2.8) read as analogous to those in [20]: the larger m is, the smaller $k(m)$ is, and vice versa. The occurrence of a possible blow-up when the bound on $\mathrm{WTV}(a_o)$ does not hold is an interesting open problem.

The variation of λ_o appears both in condition (2.7), because of p_o, and in (2.8). Using the definition of the pressure, we can replace (2.7) by the slightly stronger condition $\mathrm{TV}\log(v_o) + 2\mathrm{TV}\log(a_o) + \frac{1}{\inf a_o}\mathrm{TV}(u_o) \leq 2\big(1 - 2\mathrm{WTV}(a_o)\big)m$ or even

$$\mathrm{TV}\log(v_o) + \frac{1}{a(0)}\mathrm{TV}(u_o) \leq 2m\left(1 - \frac{2m+1}{m}\mathrm{TV}(\log(a_o))\right)$$

by making use of (2.5). In particular if λ_o is constant, we recover the famous result by Nishida [19].

Clearly $\lambda(t,x) = \lambda_o(x)$ for any t because of the third equation in (1.1); this is why only v and u appear in the estimate (2.9). In other words system (1.1) can be rewritten as a p-system of two conservation laws with flux depending on x, namely, for the pressure law $p = p(v, \lambda_o(x)) = a^2(\lambda_o(x))/v$.

The proof of Theorem 2.2 makes use of a wave-front tracking scheme where we exploit the special structure of system (1.1) by differentiating the treatment of 1- and 3-waves from that of 2-waves. Our algorithm is a natural extension of that in [3], where the system for λ_o constant is studied, in the presence of a relaxation term.

Here we consider a linear functional as in [3] that accounts for the strengths of all 1- and 3-waves, with a weight $\xi > 1$ assigned to shock waves; a crucial point in

the proof is the choice of ξ as a function of m. This functional differs from that in [19, 4], where ξ is missing and only the variation of shocks is taken into account. Moreover, motivated again by [3], we do not introduce a simplified Riemann solver for interactions between 1- and 3-waves but only for interactions involving the 2-contact discontinuities. The interaction potential then uniquely considers interactions of 2-waves with 1- or 3-waves approaching it.

System (1.1) can be written in Eulerian coordinates. Denoting $\rho = 1/v$ the density, the pressure law becomes $p = a^2(\lambda)\rho$, and (1.1) turns into

$$\begin{cases} \rho_t + (\rho u)_x & = 0, \\ (\rho u)_t + \big(\rho u^2 + p(\rho, \lambda)\big)_x & = 0, \\ (\rho\lambda)_t + (\rho\lambda u)_x & = 0\,. \end{cases} \tag{2.10}$$

A global existence result of weak solutions for (2.10) holds by Theorem 2.2 because of [28].

3. Preliminaries.

3.1. Comparison with other models. In [6] many models for diphasic flows are proposed and studied. In a simple case (no source terms, the fluid in either a dispersed or separated configuration) and keeping notation as in [6, page 35], they can be written as

$$\begin{cases} (\rho_l R_l)_t + (\rho_l R_l u_l)_x & = 0, \\ (\rho_g R_g)_t + (\rho_g R_g u_g)_x & = 0, \\ (\rho_l R_l u_l + \rho_g R_g u_g)_t + (\rho_l R_l u_l^2 + \rho_g R_g u_g^2 + p)_x & = 0\,. \end{cases} \tag{3.1}$$

Here the indexes l and g stand for *liquid* and *gas*. Therefore ρ_l, R_l, u_l are the liquid density, phase fraction, and velocity, and analogously for the gas; clearly $R_l + R_g = 1$. The pressure law is $p = a^2\rho_g$ for $a > 0$ a constant. Equations (3.1) state the conservation of mass of either phase and the total momentum.

A case studied in [6, page 44] is when $u_l = u_g$ and ρ_l is constant, say, equal to 1. The unknown variables are then R_l, u, ρ_g, and it is assumed $0 < R_l < 1$ and $\rho_g > 0$; as a consequence $0 < R_g < 1$. Under these conditions, and still writing ρ_l instead of 1 for clarity, we define the concentration $c = \frac{\rho_g R_g}{\rho_l R_l} > 0$ and deduce the pressure law $p = a^2 c \frac{R_l}{1-R_l}$. We obtain exactly the model of [22]:

$$\begin{cases} (R_l)_t + (R_l u)_x & = 0, \\ (R_l c)_t + (R_l c u)_x & = 0, \\ (R_l(1+c)u)_t + \big(R_l(1+c)u^2 + p\big)_x & = 0\,. \end{cases} \tag{3.2}$$

This system is strictly hyperbolic for $c > 0$. Remark that the three eigenvalues of (3.2) coincide with u at $c = 0$, and if c vanishes identically, then (3.2) reduces to the pressureless gasdynamics system. System (3.2) is analogous to (2.10), but the pressure laws are different. In fact the variables ρ and λ of (2.10) write $\rho = \rho_l R_l + \rho_g R_g$ and $\lambda = \frac{\rho_g R_g}{\rho_l R_l + \rho_g R_g} = \frac{c}{1+c}$, and then $R_l = (1-\lambda)\rho$, $\rho_g = \frac{\lambda}{\rho^{-1} - (1-\lambda)}$. If we sum up the first two equations in (3.2), we find the first equation in (2.10); the third (resp., second) equation in (3.2) becomes the second (resp., third) equation in (2.10). The choice $p = a^2\rho_g$ for the pressure in (3.1) gives $p = a^2 \frac{\lambda}{\frac{1}{\rho} - (1-\lambda)}$.

Notice that the pressure vanishes in the presence of a pure liquid phase, and this is the main difference with (2.1), (2.2).

We now compare (2.10) and (3.2) in Lagrangian coordinates. Consider for (3.2) the change of coordinates $y = R_l dx - R_l u dt$ based on the streamlines of the liquid particles (because $R_l = \rho_l R_l$) [22]. Denote $w = \frac{1}{R_l} - 1 = \frac{R_g}{R_l} = \frac{c}{\rho_g}$. Then for $p = \frac{a^2 c}{w}$ system (3.2) turns into

$$\begin{cases} w_t - u_x & = 0, \\ ((1+c)u)_t + p_x & = 0, \\ c_t & = 0\,. \end{cases} \tag{3.3}$$

It is more interesting, however, to consider for system (3.2) the change $y = (1+c)R_l dx - (1+c)R_l u dt = \rho dx - \rho u dt$ into Lagrangian coordinates based on the streamlines of the *full* density ρ. Let w be as above and $v = \frac{w}{1+c} = \frac{R_g}{\rho}$. Then system (3.2) becomes system (1.1) with $a^2(\lambda) = a^2 \frac{c}{1+c} = a^2\lambda$. As a consequence the pressure law $p(v,\lambda) = a^2(\lambda)/v$ does not satisfy (2.2). This difficulty can be overcome as follows. Fix any $0 < a_1 < a_2 < a$ and consider for $c_i = \frac{a_i^2}{a^2 - a_i^2}$ the invariant domain $\{(R_l, u, c)\colon 0 < c_1 \le c \le c_2\}$ [22]. In this domain $0 < b_1 \le \lambda \le b_2 < 1$ for $b_i = a_i^2/a^2$. If we denote $\mu = \frac{\lambda - b_1}{b_2 - b_1}$, then the function $b(\mu) = a(\lambda) = a(b_1 + (b_2 - b_1)\mu)$ makes the pressure law $p(v,\lambda) = b^2(\mu)/v$, with $\mu \in [0,1]$, satisfy both conditions in (2.2).

3.2. Wave curves and the Riemann problem. In this section we recall some results about the wave curves for system (1.1) and the solution to the Riemann problem; see [2] for more details.

The shock-rarefaction curves through the point $U_o = (v_o, u_o, \lambda_o)$ for (1.1) are

$$\Phi_i(v, U_o) = (v, \phi_i(v, U_o), \lambda_o)\,, \qquad i = 1, 3, \tag{3.4}$$

$$\phi_1(v, U_o) = \begin{cases} u_o + a(\lambda_o)\cdot(v - v_o)/\sqrt{v v_o}, & v < v_o, \quad \text{shock}, \\ u_o + a(\lambda_o)\log(v/v_o), & v > v_o\,, \quad \text{rarefaction}, \end{cases}$$

$$\phi_3(v, U_o) = \begin{cases} u_o - a(\lambda_o)\log(v/v_o), & v < v_o, \quad \text{rarefaction}, \\ u_o - a(\lambda_o)\cdot(v - v_o)/\sqrt{v v_o}, & v > v_o\,, \quad \text{shock}, \end{cases}$$

$$\Phi_2(\lambda, U_o) = \left(v_o \frac{a^2(\lambda)}{a^2(\lambda_o)}, u_o, \lambda\right)\,, \qquad \lambda \in [0,1], \quad \text{contact discontinuity}. \tag{3.5}$$

The curves Φ_1, Φ_2, and Φ_3 are *plane* curves: Φ_1 and Φ_3 lie on the plane $\lambda = \lambda_o$, while Φ_2 on $u = u_o$.

DEFINITION 3.1 (wave strengths). *Under the notation* (3.4), (3.5) *we define the strength* ε_i *of an* i*-wave as*

$$\varepsilon_1 = \frac{1}{2}\log\left(\frac{v}{v_o}\right), \quad \varepsilon_2 = 2\,\frac{a(\lambda) - a(\lambda_o)}{a(\lambda) + a(\lambda_o)}, \quad \varepsilon_3 = \frac{1}{2}\log\left(\frac{v_o}{v}\right)\,. \tag{3.6}$$

According to this definition, rarefaction waves have positive strengths and shock waves have negative strengths. Given the initial datum $\lambda_o = \lambda_o(x)$, denote

$$a^* \doteq \sup_{x\in\mathbb{R}} a\big(\lambda_o(x)\big)\,, \quad a_* \doteq \inf_{x\in\mathbb{R}} a\big(\lambda_o(x)\big)\,, \quad [a]_* \doteq \frac{a^* - a_*}{a^* + a_*}\,. \tag{3.7}$$

Then $[a]_* \le \frac{a(1)-a(0)}{a(1)+a(0)} < 1$ and $|\varepsilon_2| \le 2[a]_* < 2$. It is useful to also define the function (see [22])

$$h(\varepsilon) = \begin{cases} \varepsilon & \text{if } \varepsilon \ge 0\,, \\ \sinh \varepsilon & \text{if } \varepsilon < 0\,. \end{cases} \tag{3.8}$$

Then we have for $i = 1, 3$

$$\phi_i(v, U_o) = u_o + a(\lambda_o) \cdot 2h(\varepsilon_i)\,. \tag{3.9}$$

At last we consider the Riemann problem. This is the initial value problem for (1.1) under the piecewise constant initial condition

$$(v, u, \lambda)(0, x) = \begin{cases} (v_\ell, u_\ell, \lambda_\ell) = U_\ell & \text{if } x < 0, \\ (v_r, u_r, \lambda_r) = U_r & \text{if } x > 0 \end{cases} \tag{3.10}$$

for U_ℓ and U_r in Ω. We denote $a_r = a(\lambda_r)$, $p_r = a_r^2/v_r$, and similarly for a_ℓ, p_ℓ.

PROPOSITION 3.2. *Fix any pair of states U_ℓ, U_r in Ω; then the Riemann problem* (1.1), (3.10) *has a unique Ω-valued solution in the class of solutions consisting of simple Lax waves. If ε_i is the strength of the i-wave, $i = 1, 2, 3$, then*

$$\varepsilon_3 - \varepsilon_1 = \frac{1}{2} \log\left(\frac{p_r}{p_\ell}\right), \qquad 2\big(a_\ell h(\varepsilon_1) + a_r h(\varepsilon_3)\big) = u_r - u_\ell\,.$$

Moreover, let $\underline{v} > 0$ be a fixed number. There exists a constant $C_1 > 0$ depending on $\underline{v}$ and $a(\lambda)$ such that if v_l, $v_r \ge \underline{v}$, then

$$|\varepsilon_1| + |\varepsilon_2| + |\varepsilon_3| \le C_1 |U_\ell - U_r|\,. \tag{3.11}$$

For the proof, see [2]. One can easily find that

$$\begin{aligned} |\varepsilon_1| + |\varepsilon_3| &\le \frac{1}{2} |\log(p_r) - \log(p_\ell)| + \frac{1}{2\min\{a_\ell, a_r\}} |u_r - u_\ell| \\ &\le \frac{1}{2} |\log(v_r) - \log(v_\ell)| + |\log(a_r) - \log(a_\ell)| + \frac{1}{2\min\{a_\ell, a_r\}} |u_r - u_\ell|\,. \end{aligned} \tag{3.12}$$

We remark that for any Riemann data $(v_\ell, u_\ell, \lambda_\ell)$, (v_r, u_r, λ_r), the λ component of the solution takes value λ_ℓ for $x < 0$ and λ_r for $x > 0$. The fact that the interfaces between different phases are connected by a stationary wave can then be interpreted as a "kinetic condition" [1], analogous to Maxwell's rule.

4. The approximate solution. In this section we define a wave-front tracking scheme [9] to build up piecewise constant approximate solutions to (1.1). More precisely, we follow the algorithm introduced in [3].

First, we approximate the initial data. For any $\nu \in \mathbb{N}$ we take a sequence $(v_o^\nu, u_o^\nu, \lambda_o^\nu)$ of piecewise constant functions with a finite number of jumps such that

(i) $\mathrm{TV} p_o^\nu \le \mathrm{TV} p_o$, $\mathrm{TV} u_o^\nu \le \mathrm{TV} u_o$, $\mathrm{WTV} a(\lambda_o^\nu) \le \mathrm{WTV} a(\lambda_o)$, $\inf a_o^\nu \ge \inf a_o$;
(ii) $\lim_{x \to -\infty} (v_o^\nu, u_o^\nu, \lambda_o^\nu)(x) = \lim_{x \to -\infty} (v_o, u_o, \lambda_o)(x)$;
(iii) $\|(v_o^\nu, u_o^\nu, \lambda_o^\nu) - (v_o, u_o, \lambda_o)\|_{\mathbf{L^1}} \le \frac{1}{\nu}$,

where $p_o^\nu = a^2(\lambda_o^\nu)/v_o^\nu$. Second, we define the approximate Riemann solver. We introduce positive parameters $\eta = \eta_\nu$, $\rho = \rho_\nu$; they control, respectively, the size of rarefactions and the threshold when a simplified Riemann solver is used. Define also a parameter $\hat{s} > 0$ strictly larger than all possible speeds of wave fronts of both families 1 and 3. These parameters will be determined at the end of section 6.

- At time $t = 0$ we solve the Riemann problems at each point of jump of $(v_o^\nu, u_o^\nu, \lambda_o^\nu)(0+, \cdot)$ as follows: shocks are not modified while rarefactions are approximated by fans of waves, each of them having size less than η. More precisely, a rarefaction of size ε is approximated by $N = [\varepsilon/\eta]+1$ waves whose size is $\varepsilon/N < \eta$; we set their speeds to be equal to the characteristic speed of the state at the right.
  Then $(v, u, \lambda)(t, \cdot)$ is defined until some wave fronts interact; by slightly changing the speed of some waves [9] we can assume that only *two* fronts interact at a time.
- When two wave fronts of families either 1 or 3 interact we solve the Riemann problem at the interaction point. If one of the incoming waves is a rarefaction, after the interaction it is prolonged (if it still exists) as a single discontinuity with speed equal to the characteristic speed of the state at the right. If a new rarefaction is generated, we employ the Riemann solver described before and divide it into a fan of waves having size less than η.
- When a wave front of family either 1 or 3 interacts with a 2-wave we proceed as follows. Let δ_2 be the size of the 2-wave and δ the size of the other wave.
  - If $|\delta_2\delta| \geq \rho$, we solve the Riemann problem as above, that is, with the *accurate Riemann solver*.
  - If $|\delta_2\delta| < \rho$, we prolong the 1- or 3- wave with a wave of the same family and size. Since the two waves do not commute, a *nonphysical* front is introduced [9], with fixed speed $\hat{s} > 0$. The size of a nonphysical wave is set to be $|u_r - u_\ell|$, where u_ℓ, u_r are the u components of the left and right states of the wave. We call this solver the *simplified Riemann solver*.
- When a nonphysical front interacts with a front of family 1, 2, or 3 ("physical"), we prolong the solution with a physical wave of the same size and a nonphysical one, consequently computing the intermediate value.

We refer for the last two items to Proposition 5.12 below. Remark that two nonphysical fronts cannot interact since they have the same constant speed $\hat{s}$. We denote by $\mathcal{NP}$ the set of nonphysical waves.

5. Interactions. Fix the index ν introduced in the previous section. We shall prove in subsection 6.1 that the algorithm described above is defined for any $t > 0$ and provides for any initial data $(v_o^\nu, u_o^\nu, \lambda_o^\nu)$ a piecewise constant approximate solution $(v^\nu, u^\nu, \lambda^\nu) = (v, u, \lambda)$, where we dropped for simplicity the index ν. Here we study the interaction of waves.

For $K_{np} > 0$ and $t > 0$ we define the functional L and the interaction potential Q, both referred to $(v, u, \lambda)(t, \cdot)$, by

$$L(t) = \sum_{i=1,3} |\gamma_i| + K_{np} L_{np}\,, \qquad L_{np} = \sum_{\gamma \in \mathcal{NP}} |\gamma|,$$

$$Q(t) = \sum_{\gamma_3 \text{ at the left of } \delta_2} |\gamma_3||\delta_2| + \sum_{\gamma_1 \text{ at the right of } \delta_2} |\delta_2||\gamma_1|\,. \tag{5.1}$$

Remark that L takes into account only the strengths of both 1- and 3-waves and that of nonphysical waves. For contact discontinuities we define

$$L_{cd} = \sum |\gamma_2| = \mathrm{WTV}a(\lambda_o^\nu)\,.$$

Finally, for $\xi \geq 1$ and $K \geq 0$ we introduce

$$L_\xi = \sum_{\substack{i=1,3\\ \gamma_i>0}} |\gamma_i| + \xi \sum_{\substack{i=1,3\\ \gamma_i<0}} |\gamma_i| + K_{np} L_{np}\,, \tag{5.2}$$

$$F = L_\xi + KQ\,. \tag{5.3}$$

For simplicity we omitted noting the dependence on K_{np} in the functional L_ξ and on K_{np}, ξ, K in F; the choice of K_{np} shall depend on that of K; see Proposition 5.12.

Observe that if λ_o is constant, then $Q = 0$ and $F = L_\xi$, whose variation was analyzed in Lemma 3.2 of [3]. Hence we will assume from now on that

$$A_o \doteq \mathrm{WTV}(a_o) > 0\,. \tag{5.4}$$

By assumption (i) in section 4, one has $L_{cd} \leq A_o$.

In the following sections we analyze in detail the different types of interactions. Recalling the definition of h, (3.8), and with the notation of Figure 5.1, we introduce the following identities (see (3.1), (3.2) in [22]):

$$\varepsilon_3 - \varepsilon_1 = \alpha_3 + \beta_3 - \alpha_1 - \beta_1, \tag{5.5}$$

$$a_\ell h(\varepsilon_1) + a_r h(\varepsilon_3) = a_\ell h(\alpha_1) + a_m h(\alpha_3) + a_m h(\beta_1) + a_r h(\beta_3)\,. \tag{5.6}$$

Formula (5.5) does not depend on λ and follows easily by equating the specific volumes v before and after the interaction time. By equating the velocities u we obtain (5.6). These properties are a consequence of the definition (3.6) of the strengths for 1- and 3-waves and of (3.9).

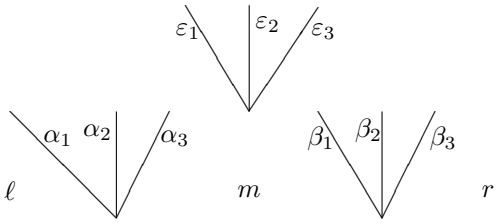

FIG. 5.1. *A general interaction pattern.*

5.1. Interactions with a 2-wave. We first consider the interactions of 1- or 3-waves with a 2-wave; see Figure 5.2.

PROPOSITION 5.1 (see [2]). *Denote by λ_ℓ, λ_r the side states of a 2-wave. The interactions of 1- or 3-waves with the 2-wave give rise to the following pattern of solutions:*

Interaction	*Outcome*	
	$\lambda_\ell < \lambda_r$	$\lambda_\ell > \lambda_r$
$2 \times 1R$	$1R + 2 + 3R$	$1R + 2 + 3S$
$2 \times 1S$	$1S + 2 + 3S$	$1S + 2 + 3R$
$3R \times 2$	$1S + 2 + 3R$	$1R + 2 + 3R$
$3S \times 2$	$1R + 2 + 3S$	$1S + 2 + 3S$

The next lemma is concerned instead with the *strengths* of waves involved in the interaction above. The inequalities (5.8) improve the inequality (3.3) in [22] in the special case of two interacting wave fronts, one of them being of the second family. More precisely, under the notation of [22] we find a term $1/(a_r + a_\ell)$ instead of $1/\min\{a_r, a_\ell\}$. The proof differs from Peng's. Our estimates are sharp: in some cases (5.8) reduces to an identity.

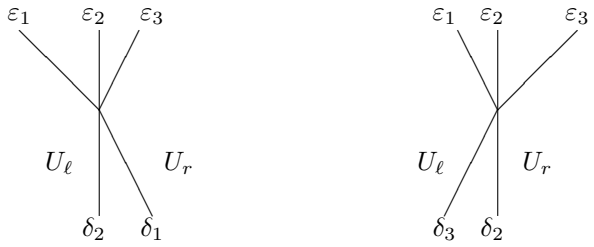

FIG. 5.2. *Interactions.* (a) *from the right;* (b) *from the left.*

LEMMA 5.2 (see [2]). *Assume that a* 1*-wave of strength* δ_1 *or a* 3*-wave of strength* δ_3 *interacts with a* 2*-wave of strength* $\delta_2 = 2(a_r - a_\ell)/(a_r + a_\ell)$. *Then the strengths* ε_i *of the outgoing waves satisfy* $\varepsilon_2 = \delta_2$ *and*

$$|\varepsilon_i - \delta_i| = |\varepsilon_j| \le \frac{1}{2}\,|\delta_2| \cdot |\delta_i| \le [a]_* |\delta_i| \tag{5.7}$$

for $i, j = 1, 3$, $i \neq j$. *Moreover,*

$$|\varepsilon_1| + |\varepsilon_3| \le \begin{cases} |\delta_1| + |\delta_1|[\delta_2]_+ & \text{if } 1 \text{ interacts}, \\ |\delta_3| + |\delta_3|[\delta_2]_- & \text{if } 3 \text{ interacts}. \end{cases} \tag{5.8}$$

Here $[x]_+ = \max\{x, 0\}$, $[x]_- = \max\{-x, 0\}$, $x \in \mathbb{R}$. Remark that the colliding 1- or 3-wave does not change sign across the interaction. Moreover, the functional L increases iff the incoming and the reflected waves are of the same type; this happens when the colliding wave is moving toward a more liquid phase.

Now we prove that F is decreasing for suitable K when an interaction with a 2-wave occurs. The potential Q is needed to balance the possible increase of L_ξ.

PROPOSITION 5.3. *Assume* $A_o < 2$ *and consider an interaction of a* 1*- or* 3*-wave with a* 2*-wave, with the notation of Lemma* 5.2. *Then* $\Delta Q < 0$. *If, moreover,*

$$\xi \ge 1 \qquad \text{and} \qquad K > \frac{2\xi}{2 - A_o}, \tag{5.9}$$

then

$$\xi|\varepsilon_j| = \xi\big||\varepsilon_i| - |\delta_i|\big| < \frac{K}{2}|\Delta Q|, \tag{5.10}$$

and hence $\Delta F < 0$.

Proof. We consider the interaction of a 1-wave with a 2-wave; the symmetric case follows in an analogous way. We use the notation as in Figure 5.2(a). We define $L^*_{cd} = L^-_{cd} + L^+_{cd}$, $L^\pm_{cd}$, meaning *right or left* of the 2-wave under consideration.

By assumption, one has

$$L_{cd} = L_{cd}^- + L_{cd}^+ + |\delta_2| = L_{cd}^* + |\delta_2| \le A_o < 2\,. \tag{5.11}$$

Recall that $\varepsilon_1 - \delta_1 = \varepsilon_3$ and by Proposition 5.1

$$|\varepsilon_1| - |\delta_1| = |\varepsilon_3| \qquad \text{if } \delta_2 > 0\,, \tag{5.12}$$

$$|\varepsilon_1| - |\delta_1| = -|\varepsilon_3| \qquad \text{if } \delta_2 < 0\,, \tag{5.13}$$

so that in particular $|\varepsilon_3| = \big||\varepsilon_1| - |\delta_1|\big|$. An estimate for ΔQ follows at once because of (5.11):

$$\Delta Q = -|\delta_2\delta_1| + (|\varepsilon_1| - |\delta_1|)\, L_{cd}^- + |\varepsilon_3| L_{cd}^+ \le \frac{1}{2}|\delta_2\delta_1|(L_{cd}^* - 2)$$

$$\le \frac{1}{2}|\delta_2\delta_1|(A_o - 2) < 0\,. \tag{5.14}$$

Hence, using (5.7), we get

$$\xi|\varepsilon_3| + \frac{K}{2}\Delta Q \le \frac{1}{2}|\delta_2\delta_1|\left\{\xi + \frac{K}{2}(A_o - 2)\right\} < 0 \tag{5.15}$$

because of (5.9); this proves (5.10). Finally, by using (5.15) we get

$$\Delta F = \Delta L_\xi + K\Delta Q \le \xi|\varepsilon_3| + \xi|\varepsilon_1 - \delta_1| + K\Delta Q < 0\,. \tag{5.16}$$

□

5.2. Interactions between 1- and 3-waves. Here we analyze the possible interactions between 1- and 3-waves. Two situations may occur; see Figure 5.3: either the waves belong to different families or they both belong to the same family. In this last case, at least one of the waves must be a shock.

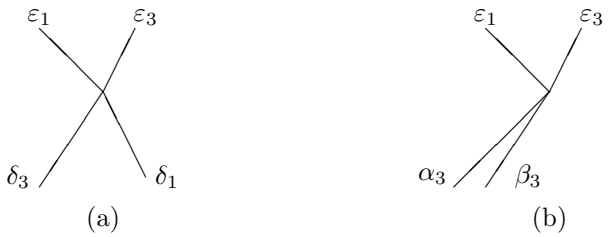

FIG. 5.3. *Interactions of* 1- *and* 3-*waves.*

LEMMA 5.4 (different families interacting). *If a wave of the third family interacts with a wave of the first family, they cross each other without changing their strength.*

Proof. See also Lemma 3.1 in [3]. Using notation as in Figure 5.3(a) we have $\varepsilon_3 - \varepsilon_1 = \delta_3 - \delta_1$ and $h(\varepsilon_1) + h(\varepsilon_3) = h(\delta_1) + h(\delta_3)$. The uniqueness of solutions to the Riemann problem implies $\varepsilon_1 = \delta_1$, $\varepsilon_3 = \delta_3$.

Remark that here $\Delta L_\xi = 0 = \Delta Q$ and then $\Delta F = 0$ for all $\xi \ge 1$ and K. □

LEMMA 5.5 (same family interacting: outcome). *Assume that a wave α_3 of the third family interacts with a wave β_3 of the third family, giving rise to waves ε_1, ε_3. Then*

(i) $\alpha_3 < 0$, $\beta_3 < 0 \Rightarrow \varepsilon_1 > 0$, $\varepsilon_3 < 0$,

(ii) $\alpha_3\beta_3 < 0 \Rightarrow \varepsilon_1 < 0$.

An analogous result holds for interacting waves of the first family.

Proof. The proof can be done in a geometric way by observing the mutual positions of the curves [19, 26]. A simple alternative proof by analytical arguments now follows. We have

$$\varepsilon_3 - \varepsilon_1 = \alpha_3 + \beta_3, \tag{5.17}$$

$$h(\varepsilon_1) + h(\varepsilon_3) = h(\alpha_3) + h(\beta_3)\,. \tag{5.18}$$

In case (i) these formulas read $\varepsilon_1 - \varepsilon_3 = |\alpha_3| + |\beta_3| > 0$ and $-h(\varepsilon_1) - h(\varepsilon_3) = \sinh(|\alpha_3|) + \sinh(|\beta_3|) > 0$. If it were $\varepsilon_3 > 0$, then $\varepsilon_1 > 0$ from the first equality and $\varepsilon_1 < 0$ from the second, a contradiction. Therefore $\varepsilon_3 < 0$ so that $\varepsilon_1 + |\varepsilon_3| = |\alpha_3| + |\beta_3|$ and $-h(\varepsilon_1) + \sinh(|\varepsilon_3|) = \sinh(|\alpha_3|) + \sinh(|\beta_3|)$. Analogously, if it were $\varepsilon_1 < 0$, using elementary inequalities we get $0 = \sinh(|\varepsilon_1|) + \sinh(|\alpha_3| + |\beta_3| + |\varepsilon_1|) - \sinh(|\alpha_3|) - \sinh(|\beta_3|) \geq 2\sinh(|\varepsilon_1|)$, a contradiction again. Hence $\varepsilon_1 > 0$.

In case (ii) assume $\alpha_3 < 0$, $\beta_3 > 0$; the other case is dealt with analogously since (5.17), (5.18) are symmetric in α_3, β_3. We have $\varepsilon_3 - \varepsilon_1 = -|\alpha_3| + |\beta_3|$ and $h(\varepsilon_1) + h(\varepsilon_3) = -\sinh(|\alpha_3|) + |\beta_3|$; then $[h(\varepsilon_1) + \varepsilon_1] + [h(\varepsilon_3) - \varepsilon_3] = |\alpha_3| - \sinh(|\alpha_3|) < 0$. If $\varepsilon_3 > 0$, this last equality becomes $h(\varepsilon_1) + \varepsilon_1 = |\alpha_3| - \sinh(|\alpha_3|) < 0$, which implies $\varepsilon_1 < 0$. If $\varepsilon_3 < 0$, then $h(\varepsilon_1) + \varepsilon_1 = [|\alpha_3| - \sinh(|\alpha_3|)] - [|\varepsilon_3| - \sinh(|\varepsilon_3|)]$. If it were $\varepsilon_1 > 0$, it would be $|\alpha_3| < |\varepsilon_3|$, since the map $x \mapsto x - \sinh x$ is decreasing; but from $|\varepsilon_3| + |\varepsilon_1| = |\alpha_3| - |\beta_3|$ we would get that $|\varepsilon_3| < |\alpha_3|$, a contradiction. Hence in all cases one has $\varepsilon_1 < 0$. ∎

Now we give sharper estimates for the interaction of waves of the same family: we prove that the strength of the reflected wave is bounded by the size of each incoming wave, multiplied by a damping factor smaller than 1. This property will be crucial in the next section, and it holds also for interactions with a 2-wave, with damping factor $[a]_*$; see (5.7). In the case below, however, the coefficient depends on the strengths of the incoming waves; this happens also when nonphysical waves are generated; see Proposition 5.12. We assume that

$$\begin{aligned} &\textit{the strength of any interacting } i\textit{-wave is less than } m \\ &\textit{for some } m > 0 \textit{ and } i = 1, 3. \end{aligned} \tag{5.19}$$

In the special case of interaction of waves of the same family producing two outgoing shocks we give a more precise result in Appendix B.

LEMMA 5.6 (same family interacting). *Consider the interaction of two waves of the same family, of sizes α_i and β_i, $i = 1, 3$, producing two outgoing waves ε_1, ε_3; assume* (5.19). *Then the following hold.*

(i) *There exists a damping coefficient $d = d(m)$, with $0 < d < 1$, such that*

$$|\varepsilon_j| \leq d(m) \cdot \min\{|\alpha_i|, |\beta_i|\}\,, \qquad j \neq i\,. \tag{5.20}$$

(ii) *If the incoming waves are both shocks, the resulting shock satisfies $|\varepsilon_i| > \max\{|\alpha_i|, |\beta_i|\}$. If the incoming waves have different signs, both the amount of shocks and the amount of rarefactions of the ith family decrease across the interaction.*

In any case

$$|\varepsilon_i| \leq |\alpha_i| + |\beta_i|\,. \tag{5.21}$$

Proof. (i) To fix the ideas, assume $i = 3$. We have

$$\varepsilon_3 - \varepsilon_1 = \alpha_3 + \beta_3, \tag{5.22}$$

$$h(\varepsilon_1) + h(\varepsilon_3) = h(\alpha_3) + h(\beta_3), \tag{5.23}$$

and then

$$h(\varepsilon_1) + h(\varepsilon_1 + \alpha_3 + \beta_3) = h(\alpha_3) + h(\beta_3)\,. \tag{5.24}$$

Remark that (5.24) is symmetric in α_3, β_3; from the implicit function theorem we find that $\varepsilon_1 = \varepsilon_1(\alpha_3, \beta_3)$ is $\mathbf{C^1}$. Using the notation $\varepsilon_1 = \tau$, $\alpha_3 = a$, $\beta_3 = b$, the identity (5.24) rewrites as

$$h(\tau) + h(\tau + a + b) - h(a) - h(b) = 0\,, \tag{5.25}$$

with $\tau = \tau(a, b)$. One verifies that $\tau(a, 0) = \tau(0, b) = 0$ and that

$$\tau_a = \frac{h'(a) - h'(\tau + a + b)}{h'(\tau) + h'(\tau + a + b)}, \qquad \tau_b = \frac{h'(b) - h'(\tau + a + b)}{h'(\tau) + h'(\tau + a + b)}\,.$$

As $a \to 0$, one has $\tau_a \to (1 - h'(b))/(1 + h'(b))$; then $|\tau_a(0, b)| < 1$, and it can be bounded by a positive constant less than 1 that depends on m. The same argument works for τ_b.

To complete the proof, we show that $|\tau| < \min\{|a|, |b|\}$ in the nontrivial case $a \neq 0 \neq b$. We argue by contradiction, using an argument of [23]. Suppose that $|\tau| \geq |a|$; we can assume $\tau > 0$, since the case $\tau < 0$ can be proved by using the equality (5.25) written in terms of $G(t) = -h(-t)$. Since the function h is increasing we have, for $\tau \geq |a|$,

$$h(\tau) \geq h(a), \qquad h(\tau + a + b) \geq h(b).$$

Moreover, one of the two inequalities is strict: if $a < 0$, the first; if $a > 0$, the second. Hence we contradict (5.25).

(ii) From [3] we already know that $\Delta L = |\varepsilon_1| + |\varepsilon_3| - |\alpha_3| - |\beta_3| \leq 0$, and hence (5.21).

If the incoming waves are both shocks, then (5.22) becomes

$$|\varepsilon_3| + |\varepsilon_1| = |\alpha_3| + |\beta_3|\,. \tag{5.26}$$

From (i) we have $|\varepsilon_1| < |\alpha_3|$, $|\beta_3|$ and hence the first part of (ii). On the other hand, if $\alpha_3\beta_3 < 0$, we have $\varepsilon_1 < 0$. We can assume $\alpha_3 < 0 < \beta_3$; hence (5.22) becomes $\varepsilon_3 = |\beta_3| - |\alpha_3| - |\varepsilon_1|$. If $\varepsilon_3 > 0$, then $|\varepsilon_3| < |\beta_3|$; if $\varepsilon_3 < 0$, using (i) again one finds that $|\varepsilon_3| < |\alpha_3|$. ∎

Remark 5.7. The damping coefficient $d(m)$ (see Figure 5.4) is given by

$$d(m) = \max_{\substack{|a| \leq m \\ |b| \leq m}} \frac{|\varepsilon(a, b)|}{\min\{|a|, |b|\}}\,,$$

where the function $\varepsilon(a, b)$ satisfies $h(\varepsilon) + h(\varepsilon + a + b) - h(a) - h(b) = 0$; see (5.24). Hence $d(m)$ increases with m and vanishes as $m \to 0$ because quadratic interaction estimates hold for m small.

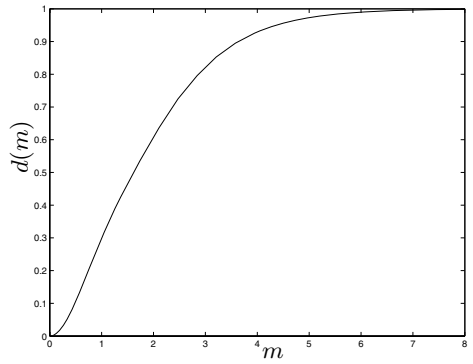

FIG. 5.4. *The coefficient* $d(m)$.

Moreover, it is asymptotic to 1 for m large. Indeed, from the proof of Lemma 5.6 we have $\tau_a(0,b) = \frac{1-h'(b)}{1+h'(b)}$; then $\tau_a(0,b) = 0$ if $b > 0$ and $|\tau_a(0,b)| = \frac{\cosh(b)-1}{\cosh(b)+1} \leq \frac{\cosh m-1}{\cosh m+1}$ if $b < 0$. Therefore $|\tau_a(0,b)| \leq \frac{\cosh m-1}{\cosh m+1}$ for every b, and an analogous estimate holds for $|\tau_b(0,a)|$. Hence $d(m) \geq \frac{\cosh m-1}{\cosh m+1} \doteq c(m)$; we refer to Lemma B.1 for the role of this quantity.

Remark 5.8. When a rarefaction interacts with a 1- or 3-wave, its size does not increase. Indeed, the size does not change upon interactions with waves of the other family by Lemma 5.4; if the rarefaction interacts with a shock of the same family, we apply Lemma 5.6(ii). Remark, moreover, that by Lemma 5.5, when a rarefaction and a shock of the same family interact, the reflected wave is never a rarefaction.

Remark 5.9. If two waves of the same family interact, the wave belonging to that family can be missing, while the "reflected" wave is always present. This follows easily from (5.22), (5.23).

PROPOSITION 5.10 (variation of F). *Consider the interactions of any two wave fronts of the same family,* 1 *or* 3*, and assume* (5.4), (5.19). *If*

$$1 < \xi < \frac{1}{d} \qquad \text{and} \qquad K < \frac{\xi - 1}{A_o}, \tag{5.27}$$

then $\Delta L_\xi < 0$ *and* $\Delta F < 0$.

Proof. Let two waves α_i, β_i interact, $i = 1, 3$, giving rise to waves ε_1, ε_3. We consider $i = 3$, the other case being analogous. Using (5.21), we get

$$\Delta Q = (|\varepsilon_3| - |\alpha_3| - |\beta_3|)\, L^+_{cd} + |\varepsilon_1| L^-_{cd} \leq |\varepsilon_1| L^-_{cd} \leq |\varepsilon_1| A_o\,. \tag{5.28}$$

Now we claim that

$$\Delta L_\xi + |\varepsilon_1|(\xi - 1) \leq 0\,. \tag{5.29}$$

From this estimate it follows that $\Delta F = \Delta L_\xi + K\Delta Q \leq |\varepsilon_1|\,(1 - \xi + KA_o) < 0$ because of (5.27). To prove our claim we consider the possible cases; we make use of (5.22).

$\boxed{SS \to RS}$. Since $\Delta L = 0$, then

$$\Delta L_\xi + (\xi - 1)|\varepsilon_1| = \xi(|\varepsilon_1| + |\varepsilon_3| - |\alpha_3| - |\beta_3|) \leq 0\,. \tag{5.30}$$

$\boxed{SR,\, RS \to SR}$. Assume $\alpha_3 < 0 < \beta_3$; then (5.29) reads $(2\xi - 1)|\varepsilon_1| + |\varepsilon_3| - |\beta_3| - \xi|\alpha_3| \le 0$. For later use we prove the stronger inequality

$$\xi^2|\varepsilon_1| + |\varepsilon_3| - |\beta_3| - \xi|\alpha_3| \le 0\,. \tag{5.31}$$

Indeed, from Lemma 5.6(ii) we have $|\varepsilon_3| < |\beta_3|$, while $\xi|\varepsilon_1| \le |\alpha_3|$ from (5.20), $(5.27)_1$.

$\boxed{SR,\, RS \to SS}$. Assume $\alpha_3 < 0 < \beta_3$; then (5.29) is $(2\xi - 1)|\varepsilon_1| + \xi(|\varepsilon_3| - |\alpha_3|) - |\beta_3| \le 0$. We prove also in this case the stronger inequality

$$\xi^2|\varepsilon_1| + \xi(|\varepsilon_3| - |\alpha_3|) - |\beta_3| \le 0. \tag{5.32}$$

Indeed, by (5.17) and again because of (5.20), $(5.27)_1$, one has

$$\begin{aligned}\xi^2|\varepsilon_1| + \xi(|\varepsilon_3| - |\alpha_3|) - |\beta_3| &= \xi^2|\varepsilon_1| + \xi(|\varepsilon_1| - |\beta_3|) - |\beta_3| \\ &= (\xi + 1)(\xi|\varepsilon_1| - |\beta_3|) \le 0\,.\end{aligned}$$

This proves the claim and concludes the proof. □

Remark 5.11. From the above proof we see that $\Delta L_\xi \le 0$ for $\xi = 1$. This was a key point in [19], where, however, a different choice of strengths was made. In [3] the inequality $\Delta L_\xi \le 0$ was proved to hold also for $1 < \xi \le \xi_o$ for some $\xi_o > 1$; the condition $(5.27)_1$ gives an estimate of such a threshold.

More precisely, in the first two cases of Proposition 5.10 we have $\Delta L_\xi \le 0$ for every $\xi \ge 1$. The third case is analyzed in detail in Lemma B.1; we prove there that $\Delta L_\xi \le 0$ for any $\xi > 1$ if $c(m) \le 1/2$, while we need $1 < \xi \le \frac{1}{2c(m)-1}$ if $c(m) > 1/2$.

5.3. Nonphysical waves. In this subsection we compute the strength of a nonphysical wave generated by an interaction and prove that it does not change in subsequent interactions. We introduce the following notation: given $U_\ell = (v_\ell, u_\ell, \lambda_\ell)$ and λ_r we define by

$$U^*_{\ell r} = \Phi_2(\lambda_r, U_\ell) = (A_{r\ell} v_\ell, u_\ell, \lambda_r)$$

the state on the right of a 2-wave with left state $U_\ell = (v_\ell, u_\ell, \lambda_\ell)$ and $\lambda = \lambda_r$ on the right, where $A_{r\ell} = a^2(\lambda_r)/a^2(\lambda_\ell)$. See (3.5) and [2].

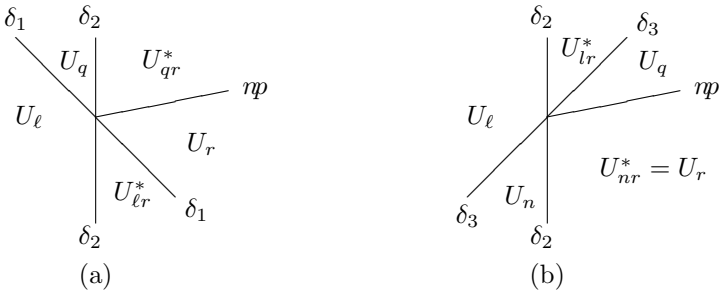

FIG. 5.5. *Simplified Riemann solver.*

PROPOSITION 5.12 (nonphysical waves). *Consider $U_\ell = (v_\ell, u_\ell, \lambda_\ell)$. Let $U_r = (v_r, u_r, \lambda_r)$ be connected to $U^*_{\ell r}$ by a 1-wave of size δ_1 and $U_q = (v_q, u_q, \lambda_\ell)$ be connected to U_ℓ by a 1-wave of size δ_1; see Figure* 5.5(a). *Assume* (5.19).

Then U^*_{qr} and U_r differ only in the u component; if δ_2 denotes the size of the 2-wave, there exists a constant $C_o = C_o(m)$ such that

$$\|U^*_{qr} - U_r\| = |u_q - u_r| \le C_o|\delta_2\delta_1|\,. \tag{5.33}$$

A similar result holds for the interaction of a 3-wave (see Figure 5.5(b)), again under (5.19).

Moreover, the size of a nonphysical wave does not change in subsequent interactions. For any $K > 0$ and $K_{np} < K/C_o$ at any interaction involving a nonphysical wave we have

$$\Delta F \le 0\,, \tag{5.34}$$

with $\Delta F < 0$ when a nonphysical wave is generated.

Proof. Recalling [2, Lemma 2], only the u component will be different after commutation of the 1- and the 2-wave. We find that

$$u_q - u_\ell = 2a_\ell h(\delta_1), \qquad u_r - u_\ell = 2a_r h(\delta_1),$$

and hence

$$|u_q - u_r| = 2|a_\ell - a_r| \cdot |h(\delta_1)| \le |\delta_2\delta_1| \cdot 2a(1) \max_{0<\eta\le m} \frac{\sinh\eta}{\eta}\,.$$

Then (5.33) follows with $C_o(m) \doteq 2a(1) \cdot \frac{\sinh m}{m}$.

Next, assume that a nonphysical wave interacts with a 2-wave. Since the values of u do not change across a 2-wave, the left and right values of u of the nonphysical wave do not change across the interaction; hence the size does not change.

Assume then that a nonphysical wave interacts with a 1- or 3-wave of size δ. Since λ is constant, we refer only to the components v, u. Let (v_ℓ, u_ℓ) and (v_ℓ, u_q) be the side states of the nonphysical wave before the interaction and (v_ℓ, u_q), (v_r, u_r) be the side states of the physical wave. After the interaction, let $(\tilde v_\ell, \tilde u_\ell)$ be the intermediate state. One has

$$u_r - u_q = 2a(\lambda)h(\delta) = \tilde u_\ell - u_\ell\,,$$

and hence $|u_q - u_\ell| = |u_r - \tilde u_\ell|$.

At last, we consider the functional F. The potential Q is unaltered when nonphysical waves interact with other waves. The only cases in which L_{np} changes are when a nonphysical wave arises. Assume that a 1- or a 3-wave of size δ interacts with a 2-wave of size δ_2, producing a wave of the same size and a nonphysical wave. Then $\Delta Q = -|\delta\delta_2|$ and $\Delta L_\xi = K_{np}\Delta L_{np} \le K_{np}C_o|\delta\delta_2|$; hence $\Delta F = \Delta L_\xi + K\Delta Q \le |\delta\delta_2|(K_{np}C_o - K)$, and then (5.34). ∎

5.4. Decreasing of the functional F and control of the variations. We first collect the previous results into a single proposition.

PROPOSITION 5.13 (local decreasing). *Consider the interaction of any two waves either of families 1, 2, 3 or nonphysical. Assume (5.19) for some $m > 0$; let $C_o = C_o(m)$ as in Proposition 5.12. Finally, let A_o satisfy*

$$0 < A_o < 2\frac{1-d}{3-d}\,. \tag{5.35}$$

If ξ, K, K_{np} satisfy

$$\frac{2-A_o}{2-3A_o} < \xi < \frac{1}{d}\,, \qquad \frac{2\xi}{2-A_o} < K < \frac{\xi-1}{A_o}\,, \qquad K_{np} < \frac{K}{C_o}, \tag{5.36}$$

then

$$\Delta F \le 0\,. \tag{5.37}$$

Proof. The condition on K comes from (5.9) and $(5.27)_2$. The interval where K lies is not empty if $A_o < \frac{2}{3}$ and $\xi > \frac{2-A_o}{2-3A_o}$; together with $(5.27)_1$ this gives the assumption required on ξ. In turn, it is possible to choose ξ in such an interval if (5.35) holds. Remark that $2\frac{1-d}{3-d} \le \frac{2}{3}$, so the previous condition on A_o holds. Therefore the assumptions of Propositions 5.3, 5.10, and 5.12 hold, and then (5.37) follows. ∎

PROPOSITION 5.14 (global decreasing). *Let $m > 0$; assume* (5.35), (5.36),

$$L(0+) < \frac{m}{2\xi - 1} \tag{5.38}$$

and that the approximate solution U is defined in $[0,T]$. Then $L(t) < m$ for any $t \in (0,T]$; as a consequence, condition (5.19) *holds for any* 1- *or* 3-*wave in U. Finally, $\Delta F(t) \le 0$ for all times $t \in [0,T]$.*

Proof. Since L may change value only at the times of interaction, we use an induction argument based on Proposition 5.13.

First, we have $L(0+) < m$ because $\xi \ge 1$ and (5.38). Now assume that $L(\tau) < m$ for all $0 < \tau < t$. By Proposition 5.13 one has both $\Delta F(\tau) \le 0$ and $\Delta F(t) \le 0$, so that

$$F(t) \le F(0+) \le \xi L(0+) + KQ(0+)\,.$$

Since $Q(0+) \le L(0+)L_{cd} \le L(0+)A_o$, and recalling $(5.36)_2$, we get

$$F(t) \;\le\; L(0+)\cdot(\xi + KA_o) \;\le\; L(0+)\cdot(2\xi - 1) \;<\; m\,, \tag{5.39}$$

again because of (5.38). Finally, since $L(t) \le L_\xi(t) \le F(t)$ we arrive at the conclusion. ∎

Remark 5.15. From (5.38) we see that, in order to have $L(t) < m$, the smaller ξ is, the larger the $L(0+)$ can be chosen.

Remark 5.16. From Proposition 5.14 we deduce that v remains bounded away from zero. Indeed, recalling (3.6), (3.5) and that v is constant across nonphysical waves, we have

$$\frac{1}{2}\mathrm{TV}(\log v(t,\cdot)) \le L(t) + \mathrm{TV}(\log a_o) \le m + \mathrm{TV}(\log a_o)\,.$$

6. The convergence and the consistence of the algorithm. In this section we prove Theorem 2.2. We first show that for fixed ν the algorithm introduced in section 4 gives an approximate solution defined for every $t > 0$; more precisely, we prove that at every time the number of interactions is bounded. Then we prove that the total amount of nonphysical waves in each approximate solution is very small. The convergence of a suitable subsequence is assured by Helly's theorem; then consistence follows.

6.1. Control of the number of interactions. We prove first that the size of the rarefactions in the scheme is small.

LEMMA 6.1. *Consider a rarefaction of size ε; then*

$$|\varepsilon| < \eta \mathrm{e}^{\frac{A_o}{2}} . \tag{6.1}$$

Proof. We analyze all possible situations. When the rarefaction is generated, one has $0 < \varepsilon < \eta$. When it interacts with a 1- or 3-wave, the size does not increase; see Remark 5.8. By Proposition 5.12 the size does not change when interactions with nonphysical waves occur.

The last case to be considered is when a rarefaction interacts with a 2-wave. In this case the size may increase; however, a rarefaction can meet a fixed 2-wave only once. Consider the case of a 1-rarefaction of size δ_1, as in Proposition 5.3, the other being analogous. If $\delta_2 < 0$, then the size decreases; see (5.13). If $\delta_2 > 0$, by (5.12) we have

$$|\varepsilon_1| = |\delta_1| + |\varepsilon_3| \leq |\delta_1| \left(1 + \frac{1}{2}|\delta_2|\right) < |\delta_1| \mathrm{e}^{\frac{|\delta_2|}{2}} .$$

Summarizing the three cases above, we get $|\varepsilon| < \eta \mathrm{e}^{L_{cd}^{+}/2}$ (or $|\varepsilon| < \eta \mathrm{e}^{L_{cd}^{-}/2}$) for a 1-rarefaction (resp., 3-rarefaction), where $L_{cd}^{\pm}$ is the sum of the 2-waves at the right or left of the rarefaction. Then (6.1) follows. ∎

Next, we prove that the number of interactions remains bounded in finite time, so that the approximate solution is well defined for all $t > 0$. We first give a lemma.

LEMMA 6.2. *Consider the wave-front tracking algorithm described in section* 4, *under the assumptions of Proposition* 5.14. *Then*

(i) *the number of interactions involving a* 2*-wave and solved by the accurate Riemann solver is finite;*

(ii) *the number of interactions where a new rarefaction of size $\varepsilon \geq \eta$ arises is finite.*

Proof. First consider (i) and refer to Proposition 5.3. Then, using (5.16), we have $\Delta F \leq \rho\,(\xi + K(A_o - 2)/2) < 0$, and hence F decreases by a uniform positive quantity; since it is nonincreasing, this can happen only a finite number of times.

Then consider (ii). After (i), it remains only to consider the case of two shocks of the same family interacting.

Under the notation of the corresponding case in the proof of Proposition 5.10 we have $\varepsilon = \varepsilon_1 \geq \eta$ and

$$\Delta F \leq |\varepsilon_1|\,(1 - \xi + KA_o) \leq \eta\,(1 - \xi + KA_o) < 0$$

because of (5.36). Arguing similarly as in (i), this can happen only a finite number of times. ∎

Regarding (ii) in Lemma 6.2, recall that if $\varepsilon \geq \eta$, then the new rarefaction must be split into more than one wave. Therefore Lemma 6.2 can be rephrased by saying that, except for finite interactions, the number of waves emitted in an interaction is at most three, and this case occurs precisely when a nonphysical wave is generated; moreover, in every interaction at most one wave per family is emitted.

In a schematic way, apart from a finite number of interactions, in our algorithm the following hold (we will consider the set of nonphysical waves as a fourth family of waves):

(a) the interaction of an i-wave, $i = 1, 3$, with a 2-wave is solved by a single i-wave, a 2-wave, and a 4-wave;
(b) in the interaction of just 1- and/or 3-waves, there is at most one outgoing wave of each family 1 and 3;
(c) the interaction of a i-wave, $i = 1, 2, 3$, with a 4-wave is solved by an i-wave and a 4-wave.

The next proposition extends the result of Lemma 2.5 in [3].

PROPOSITION 6.3. *Consider the wave-front algorithm described in section* 4 *and assume in the strip* $[0, T) \times \mathbb{R}$ *the following:*

for some $a_1 < a_2 < 0 < b_1 < b_2$ *the waves of the first (resp., third) family have speeds in the interval* $[a_1, a_2]$ *(resp.,* $[b_1, b_2]$*).*

Then the number of interactions in the region $[0, T) \times \mathbb{R}$ *is finite.*

Proof. Assume by contradiction that in the region $[0, T) \times \mathbb{R}$ there exists an infinite number of interactions. Unless we take a smaller T we can assume that the number of interactions is finite in every strip $[0, t] \times \mathbb{R}$, $0 < t < T$, and that T is an accumulation point for the times of interaction. Because of the finite propagation speed, the interaction points are also bounded in space.

Then there exists a bounded sequence (t_j, x_j), $j = 1, 2, \dots$, of interaction points such that

$$0 < t_j < t_{j+1} < T \quad \text{for all } j \quad \text{and } (t_j, x_j) \to (T, \bar{x})$$

for some $\bar{x}$. Denote $\mathcal{J} = \{(t_j, x_j) : j = 1, 2, \dots\}$ the set of all interaction points.

The situation described in items (a)–(c) above holds except in a finite number of interactions; let $\tau < T$ be the maximum time of these "exceptional" interactions. It is not restrictive to assume that $\tau < t_j < T$ for all $j = 1, 2, \dots$.

Starting from a point of $\mathcal{J}$, we "trace back" all the segments up to $t = 0$; we repeat the procedure for all the points of $\mathcal{J}$ and call $\mathcal{F}$ the set of the "traced segments" obtained in this way. In other words, a segment belongs to the set $\mathcal{F}$ iff it can be joined forward in time to some point of $\mathcal{J}$ by a continuous path along the wave fronts. The set $\mathcal{F}$ is not empty: for instance, two segments interacting at the point (t_j, x_j) belong to $\mathcal{F}$ for any $j = 1, 2, \dots,$. Observe the following dichotomy property of $\mathcal{F}$ which is used just below:

two interacting waves either both belong to $\mathcal{F}$ or none of them does; moreover, if at least one of the outgoing waves belong to $\mathcal{F}$, then both the incoming waves must belong to $\mathcal{F}$.

We now partition all the interaction points of the algorithm that occur for times $t > \tau$ into the following sets:

- $\mathcal{I}_0$: the interaction points where no ingoing wave belongs to $\mathcal{F}$;
- $\mathcal{I}_1$: the interaction points where both incoming waves belong to $\mathcal{F}$ and at most one outgoing segment belongs to $\mathcal{F}$;
- $\mathcal{I}_2$: the interaction points where exactly two outgoing segments belong to $\mathcal{F}$;
- $\mathcal{I}_3$: the interaction points where three outgoing waves all belong to $\mathcal{F}$.

Because of the dichotomy property quoted above no outgoing wave in case $\mathcal{I}_0$ can belong to $\mathcal{F}$. On the contrary, both incoming waves in $\mathcal{I}_1$, $\mathcal{I}_2$, $\mathcal{I}_3$ must belong to $\mathcal{F}$.

Recall that we are considering times $t > \tau$. Therefore the maximum number of emitted waves in an interaction is three, and this happens only in the situation considered in $\mathcal{I}_3$, that is, for interactions as in (a) above. The case of more than one emitted wave per family cannot occur, and so the outgoing waves in $\mathcal{I}_2$ belong to different families. By definition we have $\mathcal{J} \cap \mathcal{I}_0 = \emptyset$, and so $\mathcal{J} \subset \mathcal{I}_1 \cup \mathcal{I}_2 \cup \mathcal{I}_3$.

Let $\mathcal{V}(t)$ be the total number of wave fronts of the families 1, 2, and 3 that belong to $\mathcal{F}$ at time t. The functional $\mathcal{V}(t)$ is nonincreasing, and it decreases at least by 1 across $\mathcal{I}_1$. Then $\mathcal{I}_1$ is finite. As a consequence, all the interaction points of $\mathcal{J}$ belong to $\mathcal{I}_2 \cup \mathcal{I}_3$, except at most a finite number. Let $\tau_1 \in [\tau, T)$ be a time such that all points in $\mathcal{I}_1$ lie in $t < \tau_1$.

Let $P = \{x_1, \dots, x_{N_1}\}$ be the set of points of the x-axis where a 2-wave is located. We consider two cases and make use of [3, Lemma 2.5].

$\boxed{\bar{x} \notin P}$. In this case we can choose a time $\tau_1 < T$ such that after that time no segment belonging to $\mathcal{F}$ crosses a 2-wave. Then all the points in $\mathcal{J}$ with $t_j > \tau_1$ belong to $\mathcal{I}_2$.

Take a point $(t^*, x^*) \in \mathcal{J}$ with $t^* > \tau_1$, so that $(t^*, x^*) \in \mathcal{I}_2$. At (t^*, x^*) there are two outgoing segments, both of them belonging to $\mathcal{F}$; for $t > t^*$ and t close to t^* we define $\gamma_\ell(t)$ to be the segment on the left and $\gamma_r(t)$ that on the right. When $\gamma_\ell(t)$ (resp., $\gamma_r(t)$) reaches an interaction point, we prolong it by the segment of $\mathcal{F}$ outgoing from that point and located on the left (resp., on the right).

In this way we define recursively for any $t < T$ two paths: $\gamma_\ell(t)$ is made by segments of the families 1 or 3, while $\gamma_r(t)$ is made by segments of the families 3 or 4.

We claim that the speeds of the two paths are strictly separated. Indeed, if γ_r starts following a 3-segment, then γ_ℓ starts with a 1-segment and so will always follow 1-segments; therefore $\dot\gamma_\ell(t) \le a_2 < 0 < b_1 \le \dot\gamma_r(t)$. If γ_r starts following a 4-segment, then it will always follow 4-segments; in this case $\dot\gamma_\ell(t) \le b_2 < \hat{s} = \dot\gamma_r(t)$.

Thus for $c = \min\{\hat{s} - b_2, b_1 - a_2\} > 0$ we have $\gamma_r(t) - \gamma_\ell(t) \ge c(t - t^*)$. Now set $\rho = c(T - t^*)$ and choose $t_n \in (t^*, T)$, with $(t_n, x_n) \in \mathcal{J}$, such that

$$c(t_n - t^*) > \frac{\rho}{2}, \qquad (T - t_n)(|a_1| + \hat{s}) < \frac{\rho}{4}. \tag{6.2}$$

By definition of $\mathcal{F}$, the points $(t_n, \gamma_\ell(t_n))$ and $(t_n, \gamma_r(t_n))$ can be joined forward in time to points (t_h, x_h), resp., (t_k, x_k), of $\mathcal{J}$, with $h, k > n$. Then

$$x_h \le \gamma_\ell(t_n) + \hat{s}(t_h - t_n), \qquad x_k \ge \gamma_r(t_n) - |a_1|(t_k - t_n).$$

Thanks to (6.2), we get

$$x_k - x_h \ge c(t_n - t^*) - (|a_1| + \hat{s})(T - t_n) \; > \; \frac{\rho}{4}.$$

Since n can be taken arbitrarily large, the last inequality contradicts the convergence of the sequence x_j.

$\boxed{\bar{x} \in P}$. Consider case (a) above. The possibility that the outgoing waves belonging to $\mathcal{F}$ are precisely one physical and one nonphysical wave may happen only a finite number of times, since the functional $\mathcal{V}(t)$ is nonincreasing. Therefore we can assume that, for $t > \tau_1$, in case (a) the two outgoing physical waves belong to $\mathcal{F}$.

Let $(t^*, x^*) \in \mathcal{J}$ with $t^* > \tau_1$. As before we define for $t \in [t^*, T)$ two continuous paths $\gamma_\ell(t)$, $\gamma_r(t)$ starting at (t^*, x^*) in the following way.

At (t^*, x^*) there are either two or three outgoing segments belonging to $\mathcal{F}$; for times $t > t^*$ and sufficiently close to t^* we define $\gamma_\ell(t)$ to be the segment on the left and $\gamma_r(t)$ the one on the right. When $\gamma_\ell(t)$ ($\gamma_r(t)$) reaches an interaction point, it is prolonged by the segment of $\mathcal{F}$ on the left (resp., on the right). Then the path $\gamma_\ell(t)$ is made by segment of the families 1, 2, or 3, while $\gamma_r(t)$ is made by segments of families 3 or 4; in fact the interaction of a 1-wave with a 2-wave always produces a 4-wave (except in a finite number of cases).

Now we prove that the speeds of the paths $\gamma_\ell(t)$, $\gamma_r(t)$ are strictly separated. Indeed, if $\gamma_r(t)$ starts following a 3-segment, then γ_ℓ starts with either a 2- or a 1-segment and, by the remark at the beginning of this subcase, $\dot\gamma_\ell(t) \le 0 < b_1 \le \dot\gamma_r(t)$. If $\gamma_r(t)$ starts following a 4-segment, then $\dot\gamma_\ell(t) \le b_2 < \hat s = \dot\gamma_r(t)$.

Finally, for $c = \min\{\hat s - b_2, b_1\}$ the same argument exploited in the other case leads to a contradiction. □

6.2. Control of the total size of nonphysical fronts. Assume as above that the assumptions of Proposition 5.14 hold. We assign inductively to each wave α a *generation order* k_α as in [9, page 140]. This is done according to the following procedure. First, at time $t = 0$ each wave has order 1. Second, assume that two waves α and β interact at time t; if α and β belong to different families, the outgoing waves of those families keep the order of the incoming waves, and the other waves assume order $\max\{k_\alpha, k_\beta\} + 1$; if α and β belong to the same family, and the outgoing wave of that family takes the order $\min\{k_\alpha, k_\beta\}$, and the other waves are assigned order $\max\{k_\alpha, k_\beta\} + 1$.

When specialized to the current setting this has the following consequences:

- every 2-wave has order 1; when an i-wave, $i = 1, 3$, of order k interacts with a 2-wave, the outgoing i-wave has order k, and the other outgoing wave (of the family j, $j = 1, 3$, $j \neq i$, or a nonphysical wave) has order $k + 1$;
- in the interaction of a 1- with a 3-wave the waves cross without changing order; in the interaction of two waves α, β of the same family $i = 1, 3$, the outgoing wave of the family i takes order $\min\{k_\alpha, k_\beta\}$, and the wave of the family $j = 1, 3$, $j \neq i$, has order $\max\{k_\alpha, k_\beta\} + 1$;
- when a nonphysical wave interacts with any other wave, both waves cross without changing order; in particular a nonphysical wave keeps the order it has been assigned when generated.

For $t \ge 0$ not an interaction time and any $k = 1, 2, \dots$ define (see (5.2), (5.1))

$$V_k(t) = \sum_{\substack{\gamma>0\\ k_\gamma=k}} |\gamma| + \xi \sum_{\substack{\gamma<0\\ k_\gamma=k}} |\gamma| + K_{np} \sum_{\substack{\gamma\in\mathcal{NP}\\ k_\gamma=k}} |\gamma|,$$

$$Q_k(t) = \sum_{\substack{\gamma_3 \text{ at the left of } \delta_2\\ k_{\gamma_3}=k}} |\gamma_3||\delta_2| + \sum_{\substack{\gamma_1 \text{ at the right of } \delta_2\\ k_{\gamma_1}=k}} |\delta_2||\gamma_1|,$$

$$F_k(t) = V_k(t) + KQ_k(t),$$

and

$$\tilde V_k(t) = \sum_{\ell\ge k} V_\ell(t)\,, \qquad \tilde Q_k(t) = \sum_{\ell\ge k} Q_\ell(t)\,, \qquad \tilde F_k(t) = \tilde V_k(t) + K\tilde Q_k(t)\,.$$

We remark that

$$\tilde F_1(0+) = L_\xi(0+) + KQ(0+), \qquad \tilde F_k(0+) = 0 \qquad \text{for } k \ge 2.$$

Observe that if a nonphysical front interacts with another wave, the functionals above do not change; the same holds for interactions between 3- and 1-waves. Then we focus on interactions of waves of the same i family, $i = 1, 3$ (as usual denote $j = 1, 3$, $j \neq i$), and on interactions between 1- or 3-waves with a 2-wave.

For $h \in \mathbb{N}$, denote by I_h the set of times t when an interaction occurs between two waves α and β of families 1 or 3 with $\max\{k_\alpha, k_\beta\} = h$; denote by J_h the set of interaction times t of a 1- or 3-wave of order h with a 2-wave. Finally, denote $\mathcal{T}_h = I_h \cup J_h$ and $I = \bigcup_{h\geq 1} I_h$, $J = \bigcup_{h\geq 1} J_h$, $\mathcal{T} = I \cup J$.

In order to control the total size of nonphysical fronts we must strengthen the assumptions (5.35), (5.36) required in Proposition 5.14. First, for any fixed $m > 0$, instead of (5.35) we require the stronger condition

$$0 < A_o < \frac{1-\sqrt{d}}{2-\sqrt{d}}\,. \tag{6.3}$$

Then denote

$$\lambda \doteq \frac{1+KA_o}{\xi}\,, \qquad \lambda_2 \doteq \frac{\xi + KA_o}{K(2-A_o)-\xi}\,, \qquad \mu \doteq \max\left\{\lambda\,, \lambda_2, \frac{K_{np}C_o}{K}\right\}\,. \tag{6.4}$$

We need $0 < \mu < 1$. From $(5.36)_3$ we have $K_{np}C_o < K$; moreover, we have $0 < \lambda < 1$ and $\lambda_2 > 0$ because of $(5.36)_2$. At last $\lambda_2 < 1$ holds iff $\frac{\xi}{1-A_o} < K$; this condition is stronger than the left inequality in $(5.36)_2$. Hence, instead of (5.36) we assume

$$\frac{1-A_o}{1-2A_o} < \xi < \frac{1}{\sqrt{d}}\,, \qquad \frac{\xi}{1-A_o} < K < \frac{\xi-1}{A_o}\,, \qquad K_{np} < \frac{K}{C_o}\,. \tag{6.5}$$

Remark the new upper bound required on ξ. As in the proof of Proposition 5.13, the interval where K varies is not empty if $A_o < \frac{1}{2}$ and $\xi > \frac{1-A_o}{1-2A_o}$. In turn, we can find ξ satisfying $(6.5)_1$ if (6.3) holds; remark that $\frac{1-\sqrt{d}}{2-\sqrt{d}} \leq \frac{1}{2}$. The last condition in (6.5) coincides with that in (5.36).

Remark 6.4. Proposition 5.14 still holds under the stronger assumptions (6.3), (6.5) under the same condition (5.38), because the inequality on the right-hand side in $(6.5)_2$ has not changed; see (5.39).

PROPOSITION 6.5. *Fix $m > 0$ and assume* (6.3), (6.5). *We have the following:*

1. *$\tau \in \mathcal{T}_h$, $h \leq k-2$: then $\Delta\tilde{F}_k = \Delta F_k = 0$.*
2. *$\tau \in \mathcal{T}_{k-1}$: then $\Delta F_{k-1} < 0$, $\Delta\tilde{F}_k = \Delta F_k > 0$, and*

$$[\Delta\tilde{F}_k]_+ \leq \mu\left([\Delta F_{k-1}]_- - \sum_{\ell=1}^{k-2}[\Delta F_\ell]_+\right)\,. \tag{6.6}$$

3. *$\tau \in \mathcal{T}_h$, $h \geq k$: if $h = k$, then $\Delta F_k < 0$; in any case $\Delta\tilde{F}_k < 0$ and*

$$\sum_{\ell=1}^{k-1}[\Delta F_\ell]_+ < [\Delta\tilde{F}_k]_-\,. \tag{6.7}$$

Proof. As we pointed out above, for $\tau \in I$ only interactions of waves of the same family are taken into account; see Figure 6.1. Remark that by Proposition 5.14 we have

$$\sum_{\ell=1}^{k-1}\Delta F_\ell \;+\; \Delta\tilde{F}_k < 0\,. \tag{6.8}$$

1. If $h \leq k-2$, no waves with order $\geq k$ are involved, and then $\Delta\tilde{F}_k = \Delta F_k = 0$.
2. Let $h = k-1$. First, consider $\tau \in I_{k-1}$; then $\Delta\tilde{V}_k = \Delta V_k > 0$. We prove that

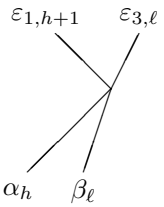

FIG. 6.1. *Interactions of 3-waves; $h \geq \ell$ denote generation orders.*

$$[\Delta \tilde{V}_k]_+ \leq \frac{1}{\xi} \left([\Delta V_{k-1}]_- - \sum_{\ell=1}^{k-2} [\Delta V_\ell]_+ \right) . \tag{6.9}$$

Indeed, from (5.30)–(5.32), we deduce that

$$\xi[\Delta \tilde{V}_k]_+ + \Delta V_{k-1} + \sum_{\ell=1}^{k-2} \Delta V_\ell \leq 0 . \tag{6.10}$$

If $\min\{k_\alpha, k_\beta\} = k-1$, then $\Delta V_\ell = 0$ for $\ell = 1, \dots, k-2$ and (6.10) becomes $\xi[\Delta \tilde{V}_k]_+ + \Delta V_{k-1} < 0$; this implies $\Delta V_{k-1} < 0$ and hence $[\Delta \tilde{V}_k]_+ < (1/\xi)[\Delta V_{k-1}]_-$, that is, (6.9). Moreover, in this case, one easily finds that $\Delta Q_{k-1} \leq 0$, because of (5.21).

If $\min\{k_\alpha, k_\beta\} = \ell \leq k-2$, then $\Delta V_{k-1} < 0$ and $\Delta Q_{k-1} < 0$, since no waves of order $k-1$ are present after the interaction. Therefore the estimate (6.10) becomes

$$\xi[\Delta \tilde{V}_k]_+ - [\Delta V_{k-1}]_- + \Delta V_\ell \leq 0 .$$

If $\Delta V_\ell \geq 0$, we get (6.9). If $\Delta V_\ell < 0$, we check directly that $\xi[\Delta \tilde{V}_k]_+ - [\Delta V_{k-1}]_- \leq \xi^2 |\varepsilon_1| - |\alpha_3| < 0$ because of (5.20) and $(6.5)_1$. This completes the proof of (6.9).

From this proof we see also that $\Delta F_{k-1} = \Delta V_{k-1} + K \Delta Q_{k-1} < 0$, since both terms in the sum are negative. Then we use (6.9) and $0 \leq \Delta \tilde{Q}_k \leq A_o \Delta \tilde{V}_k$ to get

$$0 < \Delta \tilde{F}_k \leq (1 + KA_o)[\Delta \tilde{V}_k]_+ \leq \lambda \left([\Delta V_{k-1}]_- - \sum_{\ell=1}^{k-2} [\Delta V_\ell]_+ \right) . \tag{6.11}$$

We now prove that

$$[\Delta Q_{k-1}]_- - \sum_{\ell=1}^{k-2} [\Delta Q_\ell]_+ \geq 0 . \tag{6.12}$$

We have only to consider the case in which $[\Delta Q_\ell]_+ > 0$ for some $\ell \leq k-2$; but in this case $[\Delta Q_{k-1}]_- - \sum_{\ell=1}^{k-2} [\Delta Q_\ell]_+ = L_{cd}^+ (|\alpha_3| + |\beta_3| - |\varepsilon_3|) \geq 0$ because of (5.21).

Therefore (6.6) for $\tau \in I_{k-1}$ follows from (6.11) and (6.12).

Second, assume $\tau \in J_{k-1}$; we prove that

$$[\Delta \tilde{F}_k]_+ \leq \mu [\Delta F_{k-1}]_- . \tag{6.13}$$

Indeed, if the reflected wave is a physical wave, then, under the notation of Proposition 5.3,

$$\Delta V_{k-1} \leq \xi \frac{|\delta_1 \delta_2|}{2} , \qquad \Delta Q_{k-1} \leq -|\delta_1 \delta_2| + \frac{|\delta_1 \delta_2|}{2} A_o = -\frac{|\delta_1 \delta_2|}{2} (2 - A_o)$$

so that $\Delta F_{k-1} \le [\xi - K(2-A_o)]\,|\delta_1\delta_2|/2 < 0$ because of (6.5). Then (6.13) follows since $\Delta\tilde F_k = \Delta F_k > 0$ and

$$[\Delta\tilde F_k]_+ \le \frac{|\delta_1\delta_2|}{2}(\xi + KA_o) = \frac{|\delta_1\delta_2|}{2}\,[K(2-A_o)-\xi]\cdot\lambda_2 \le \lambda_2[\Delta F_{k-1}]_- \le \mu[\Delta F_{k-1}]_-\,.$$

If the reflected wave is a nonphysical wave, we have, under the notation of Proposition 5.12,

$$0 < \Delta F_k = \Delta V_k \le K_{np}C_o|\delta\delta_2|\,, \qquad \Delta V_{k-1} = 0\,, \qquad \Delta Q_{k-1} = -|\delta\delta_2|,$$

and then

$$[\Delta F_{k-1}]_- = K|\delta\delta_2|\,, \qquad [\Delta F_k]_+ \le \frac{K_{np}C_o}{K}[\Delta F_{k-1}]_- \le \mu[\Delta F_{k-1}]_-\,.$$

The estimate (6.13) is then completely proved. From (6.13) we get (6.6) since no 1-, 3-, or nonphysical waves of order $\le k-2$ are involved in the interaction.

3. Finally, let $h \ge k$. We first consider $\tau \in I_h$. If $\min\{k_\alpha, k_\beta\} \ge k$, then $\Delta\tilde V_k = \Delta L_\xi < 0$ and $\Delta\tilde F_k = \Delta F < 0$. If $\min\{k_\alpha, k_\beta\} \le k-1$, assume $k_\alpha \ge k$ and $k_\beta \le k-1$; then $\Delta\tilde V_k \le \xi|\varepsilon_1| - |\alpha_3| \le (\xi d - 1)|\alpha_3| < 0$ by (5.20) and $(5.36)_1$. Moreover, $\Delta\tilde Q_k = |\varepsilon_1|L^-_{cd} - |\alpha_3|L^+_{cd} \le |\varepsilon_1|A_o \le dA_o|\alpha_3|$ again by (5.20). Then

$$\Delta\tilde F_k \;\le\; [(\xi + KA_o)d - 1]\cdot|\alpha_3|,$$

and since, because of (6.5),

$$(\xi + KA_o)d - 1 < (2\xi - 1)d - 1 < \left(\frac{2}{\sqrt{d}} - 1\right)d - 1 = -(1-\sqrt{d})^2 < 0\,,$$

we proved that $\Delta\tilde F_k < 0$. Now from (6.8) we deduce that $\sum_{\ell=1}^{k-1}\Delta F_\ell < [\Delta\tilde F_k]_-$. Since at most one nonzero term is present in the first sum, (6.7) follows. If $h = k$, we are in the same situation as in case 2, so we have $\Delta F_k < 0$.

Now assume $\tau \in J_h$. Then $\Delta\tilde F_k = \Delta F < 0$ and no 1-, 3-, or nonphysical waves of order $< k$ are present, so (6.7) holds. If $h = k$ and the reflected wave is physical, from the proof of Proposition 5.3 and (6.5) we find that

$$\Delta F_k = \Delta V_k + K\Delta Q_k \le \frac{|\delta_1\delta_2|}{2}\,(\xi - 2K + KA_o) < 0\,.$$

If $h = k$ and the reflected wave is nonphysical, then $\Delta V_k = 0$, $\Delta Q_k < 0$, and $\Delta F_k < 0$. □

Summarizing, for $\tau \in \mathcal{T}$ we have the following table:

$\mathcal{T}_h$; h	$\le k-2$	$k-1$	k	$\ge k+1$
ΔF_k	0	+	−	±
$\Delta\tilde F_k$	0	+	−	−

We write $\tilde F_k^{\pm}(t) = \sum_{\tau\le t}[\Delta\tilde F_k(\tau)]_\pm$ for $k \ge 2$. For simplicity the time τ in such sums is omitted.

LEMMA 6.6. *Under the assumptions of Proposition* 6.5 *we have*

$$\tilde F_2^+(t) \le \mu\left(L_\xi(0) + KQ(0)\right) + \sum_{\mathcal{T}_h,\, h\ge 2} \left[\Delta F_1\right]_+, \tag{6.14}$$

$$\tilde F_k^+(t) \le \mu\left(\tilde F_{k-1}^+(t) + \sum_{\mathcal{T}_h,\, h\ge k} \left[\Delta F_{k-1}\right]_+ - \sum_{\mathcal{T}_{k-1}} \sum_{\ell=1}^{k-2} \left[\Delta F_\ell\right]_+\right), \qquad k \ge 3\,. \tag{6.15}$$

Proof. By Proposition 6.5 (see also the table above), the functional F_k increases at times $\tau \in \mathcal{T}_{k-1}$ and decreases at times $\tau \in \mathcal{T}_k$, while it does not have a given sign at times $\tau \in \mathcal{T}_h$, with $h \ge k+1$.

First, by summing up (6.6) we obtain

$$\tilde F_k^+(t) \le \mu \sum_{\mathcal{T}_{k-1}} \left(\left[\Delta F_{k-1}\right]_- - \sum_{\ell=1}^{k-2} \left[\Delta F_\ell\right]_+\right) \tag{6.16}$$

for $k \ge 2$, where the last term in (6.16) is missing if $k = 2$.

Now recall that $F_1(0) = L_\xi(0) + KQ(0)$; therefore

$$F_1(t) \le L_\xi(0) + KQ(0) - \sum_{\mathcal{T}_1} \left[\Delta F_1\right]_- + \sum_{\mathcal{T}_h,\, h\ge 2} \left[\Delta F_1\right]_+$$

and then

$$\sum_{\mathcal{T}_1} \left[\Delta F_1\right]_- \le L_\xi(0) + KQ(0) + \sum_{\mathcal{T}_h,\, h\ge 2} \left[\Delta F_1\right]_+ . \tag{6.17}$$

On the other hand, $F_k(0) = 0$ for $k \ge 2$; from Proposition 6.5 we have

$$F_k(t) \le \sum_{\mathcal{T}_{k-1}} \left[\Delta F_k\right]_+ - \sum_{\mathcal{T}_k} \left[\Delta F_k\right]_- + \sum_{\mathcal{T}_h,\, h\ge k+1} \left[\Delta F_k\right]_+ .$$

Moreover,

$$\sum_{\mathcal{T}_{k-1}} \left[\Delta F_k\right]_+ = \sum_{\mathcal{T}_{k-1}} \left[\Delta \tilde F_k\right]_+ = \tilde F_k^+(t)$$

and then

$$\sum_{\mathcal{T}_k} \left[\Delta F_k\right]_- \le \tilde F_k^+(t) + \sum_{\mathcal{T}_h,\, h\ge k+1} \left[\Delta F_k\right]_+ . \tag{6.18}$$

From (6.16), (6.17), (6.18) we get (6.14), (6.15). □

Proposition 6.7 (a contraction property). *Under the assumptions of Proposition* 6.5, *for any* $t \ge 0$ *and* $k \ge 1$ *we have*

$$\tilde V_k(t) \le \tilde F_k(t) \le \mu^{k-1} \cdot \left(L_\xi(0) + KQ(0)\right) . \tag{6.19}$$

Proof. The estimate (6.19) holds for $k = 1$ because $\tilde F_1(t) = F(t) \le L_\xi(0) + KQ(0)$. Next, we prove by induction on $k \ge 2$ that for any t

$$\tilde F_k^+(t) \le \mu^{k-1}\left(L_\xi(0) + KQ(0)\right) + \sum_{\mathcal{T}_h,\, h\ge k} \sum_{\ell=1}^{k-1} \left[\Delta F_\ell\right]_+ . \tag{6.20}$$

Since by summing up (6.7) we obtain

$$\tilde{F}_k^-(t) \geq \sum_{\mathcal{T}_h,\, h\geq k} \sum_{\ell=1}^{k-1} [\Delta F_\ell]_+, \tag{6.21}$$

then (6.19) will follow from (6.20) for any $k \geq 2$ because of (6.21).

Formula (6.20) for $k = 2$ reduces to (6.14). Next, assume that (6.20) holds for some $k \geq 2$. By (6.15) and the induction assumption

$$\begin{aligned}
\tilde{F}_{k+1}^+(t) \;&\leq\; \mu \left(\tilde{F}_k^+(t) + \sum_{\mathcal{T}_h,\, h\geq k+1} [\Delta F_k]_+ - \sum_{\mathcal{T}_k} \sum_{\ell=1}^{k-1} [\Delta F_\ell]_+ \right) \\
&\leq \mu^k \left(L_\xi(0) + KQ(0) \right) + \mu \left(\sum_{\mathcal{T}_h,\, h\geq k} \sum_{\ell=1}^{k-1} [\Delta F_\ell]_+ + \sum_{\mathcal{T}_h,\, h\geq k+1} [\Delta F_k]_+ - \sum_{\mathcal{T}_k} \sum_{\ell=1}^{k-1} [\Delta F_\ell]_+ \right) \\
&\leq \mu^k \left(L_\xi(0) + KQ(0) \right) + \mu \sum_{\mathcal{T}_h,\, h\geq k+1} \sum_{\ell=1}^{k} [\Delta F_\ell]_+ .
\end{aligned}$$

Since $\mu < 1$, we get (6.20) for $k+1$. □

Remark 6.8. We now comment on the case $A_o = 0$. In this case system (1.1) reduces to the p-system with pressure law given by (2.1) for fixed λ. According to our front-tracking algorithm, stationary and nonphysical waves do not appear, and so $L_{cd} = Q = 0$; the algorithm reduces to the one introduced in [3]. Then Proposition 6.5 holds with $\tilde{V}_k$ and $1/\xi$ replacing $\tilde{F}_k$ and μ, respectively, and at last (6.19) reads

$$\tilde{V}_k(t) \leq \frac{1}{\xi^{k-1}} \cdot L_\xi(0)\,.$$

Next, we conclude that the total strength of all nonphysical waves is small by proceeding as in [9, page 142]. Recall the notation in section 4. First, by Remark 5.16, the sequence $\{v^\nu\}$ is uniformly bounded from above and away from 0; then the eigenvalues e_1 and e_3 are bounded, and this makes possible the choice of a suitable $\hat{s}$. We have two more parameters η, ρ to be chosen. Fix $\eta > 0$ with the condition $\eta = \eta_\nu \to 0$ as $\nu \to \infty$ and estimate the total number of waves of order $< k$. We have

$$\begin{aligned}
\sum_{\gamma\in\mathcal{NP}} |\gamma|(t) &\leq \tilde{V}_k(t) \;+ \sum_{\gamma\in\mathcal{NP},\, k_\gamma<k} |\gamma|(t) \\
&\leq \mu^{k-1} \cdot \left(L_\xi(0) + KQ(0) \right) \;+\; C_o\rho \cdot [\text{number of fronts of order} < k] \leq \frac{1}{\nu}
\end{aligned}$$

by choosing k sufficiently large to have the first term $\leq 1/(2\nu)$ and then choose ρ small enough to have the second term $\leq 1/(2\nu)$.

We now accomplish the proof of Theorem 2.2. First define

$$k(m) = \frac{1 - \sqrt{d(m)}}{2 - \sqrt{d(m)}}\,. \tag{6.22}$$

From the properties of the function $d(m)$ stated in Remark 5.7 we see that $k(0) = 1/2$ and that $k(m)$ is decreasing, tending to 0 for $m \to +\infty$. The assumption (2.8) implies that (6.3) holds.

Now, by hypotheses (2.7) it follows that we can choose ξ such that

$$\frac{1}{2}\mathrm{TV}\log(p_o) + \frac{1}{2\inf a_o}\mathrm{TV}(u_o) < \frac{m}{2\xi - 1} < \big(1 - 2A_o\big)m$$

and that $(6.5)_1$ holds. Hence, using (3.12) and (i) in section 4, we have

$$L(0+) \le \frac{1}{2}\mathrm{TV}\log(p_o) + \frac{1}{2\inf a_o}\mathrm{TV}(u_o) < \frac{m}{2\xi - 1}$$

so that the hypotheses (5.38) of Proposition 5.14 hold. Theorem 2.2 now follows along the lines of [9, section 7.4].

Appendix A. The weighted total variation. In this appendix we prove Proposition 2.1. Remark that the map $d(a,b) \doteq \frac{|a-b|}{a+b}$ is a distance on $\mathbb{R}_+$, as one can easily prove.

We start with the proof of the inequality on the right in (2.5). It is enough to prove that

$$2\sum_{j=1}^{n} \frac{|f(x_j) - f(x_{j-1})|}{f(x_j) + f(x_{j-1})} \le \sum_{j=1}^{n} |\log f(x_j) - \log f(x_{j-1})| \,. \tag{A.1}$$

We claim that

$$\log t \ge \frac{2(t-1)}{t+1} \quad \text{for } t \ge 1, \tag{A.2}$$

where the inequality is strict if $t > 1$. To prove the claim it is sufficient to notice that the function $\phi(t) = \log t - 2\frac{t-1}{t+1}$ vanishes in 1 and $\phi'(t) = \frac{(t-1)^2}{t(t+1)^2} > 0$ if $t > 1$.

We apply (A.2) to $t = x/y$ for $0 < y \le x$ and arguing by symmetry deduce that

$$|\log x - \log y| \ge \frac{2|x-y|}{x+y} \quad \text{for every } x, y > 0\,.$$

Then (A.1) follows. The proof of the inequality on the left in (2.5) is analogous, starting from the inequality

$$\frac{1}{t}\log t \le \frac{2(t-1)}{t+1} \quad \text{for } t \ge 1 \tag{A.3}$$

with strict inequality if $t > 1$.

Now assume that $f \in C(\mathbb{R})$. To show that $\mathrm{WTV}(f) = \mathrm{TV}\,(\log(f))$, we have to prove that the inequality

$$\mathrm{TV}\,(\log(f)) \le 2\sup \sum_{j=1}^{n} \frac{|f(x_j) - f(x_{j-1})|}{f(x_j) + f(x_{j-1})} \tag{A.4}$$

holds for any $[a,b] \subset \mathbb{R}$, the supremum being taken on the set of all partitions $a = x_o < x_1 < \cdots < x_n = b$, $n \in \mathbb{N}$. Consider any such partition; by the mean value theorem and by the intermediate value theorem applied to f, we get

$$\begin{aligned} |\log(f(x_j)) - \log(f(x_{j-1}))| &= \frac{|f(x_j) - f(x_{j-1})|}{\zeta_j} \\ &= \frac{f(x_j) + f(x_{j-1})}{2f(\eta_j)} \cdot 2\frac{|f(x_j) - f(x_{j-1})|}{f(x_j) + f(x_{j-1})} \end{aligned}$$

for some ζ_j between $f(x_j)$ and $f(x_{j-1})$ and $\eta_j \in [x_{j-1}, x_j]$. We exploit again the continuity of f in $[a,b]$. On one hand, its image is compact; then $\min_{[a,b]} f = m > 0$. On the other hand, f is uniformly continuous in $[a,b]$, so that for any $\varepsilon > 0$ there exists $\delta_\varepsilon > 0$ such that $|f(x) - f(y)| < \varepsilon$ if $|x - y| < \delta_\varepsilon$ for $x, y \in [a,b]$.

Now fix any $\varepsilon > 0$; without loss of generality we can consider partitions of the interval $[a,b]$ of mesh less than δ_ε. Assume for instance $f(x_{j-1}) \le f(x_j)$; then from the inequalities

$$f(x_j) - f(x_{j-1}) \ < \ \varepsilon\,, \qquad f(x_{j-1}) \le f(\eta_j) \le f(x_j)$$

it follows that

$$\frac{f(x_j) + f(x_{j-1})}{2f(\eta_j)} \le \frac{2f(x_{j-1}) + \varepsilon}{2f(x_{j-1})} \le 1 + \frac{\varepsilon}{m}\,.$$

The inequality (A.4) follows by remarking that then for any partition of mesh less than δ_ε

$$\sum_{j=1}^{n} |\log(f(x_j)) - \log(f(x_{j-1}))| \le \Big(1 + \frac{\varepsilon}{m}\Big)\, 2 \sum_{j=1}^{n} \frac{|f(x_j) - f(x_{j-1})|}{f(x_j) + f(x_{j-1})}\,.$$

The proof of Proposition 2.1 is complete.

Remark A.1. Observe that if $\mathrm{TV}(\log(f)) < \infty$ and f is discontinuous, then the inequality on the right in (2.5) is strict, because of the strict inequality in (A.2). For example, if f has a single jump and assumes the values $c > 0$ and $d > 0$, then $\mathrm{WTV}(f) = 2\frac{|c-d|}{c+d} < |\log c - \log d| = \mathrm{TV}(\log(f))$.

Remark, moreover, that WTV and TV are not equivalent, in the sense that there does not exist a positive constant C such that $C \cdot \mathrm{TV}(\log(f)) \le \mathrm{WTV}(f)$. This follows from the fact that clearly the inequality $C \log t \le \frac{2(t-1)}{t+1}$ does not hold for every $t \ge 1$.

Appendix B. Shock-rarefaction interactions. In this appendix we consider a particular case of Lemma 5.6. Actually, this is the only case needed in order to define a decreasing functional (see section 5); however, we needed further analysis for the control and treatment of the nonphysical waves.

LEMMA B.1 (the case SR, $RS \to SS$). *Consider the interaction of a shock α_i and a rarefaction β_i of the same family, $i = 1, 3$, producing two outgoing shocks ε_1, ε_3. Then there exists a smooth function B satisfying $|\alpha_i| \le B(\alpha_i) \le \min\{\sinh(|\alpha_i|), 2|\alpha_i|\}$ such that*

$$0 < \beta_i \le B(\alpha_i)\,. \tag{B.1}$$

Moreover, assume

$$|\alpha_i| \le m \tag{B.2}$$

for some $m > 0$ and denote $c = c(m) = \frac{\cosh(m)-1}{\cosh(m)+1}$. Then both the variation of shock waves and the reflected wave ε_j, $j \ne i$, $j = 1, 3$, are estimated by the interacting rarefaction as

$$|\varepsilon_1| + |\varepsilon_3| - |\alpha_i| \le (2c - 1) \cdot |\beta_i|\,, \tag{B.3}$$

$$|\varepsilon_j| \le c \cdot |\beta_i|\,. \tag{B.4}$$

Proof. We focus on the case $i = 3$, $j = 1$; see Figure 5.3(b). Therefore we consider $\alpha_3 < 0$, $\beta_3 > 0$ and $\varepsilon_1 < 0$, $\varepsilon_3 < 0$. Then (5.5), (5.6) become

$$|\varepsilon_1| - |\varepsilon_3| = |\beta_3| - |\alpha_3|, \tag{B.5}$$

$$\sinh(|\varepsilon_1|) + \sinh(|\varepsilon_3|) = \sinh(|\alpha_3|) - |\beta_3|\,. \tag{B.6}$$

From the second equation $|\varepsilon_1| < |\alpha_3|$, $|\varepsilon_3| < |\alpha_3|$, and $|\beta_3| < \sinh(|\alpha_3|)$; using the first equation and $|\varepsilon_3| < |\alpha_3|$, we get $|\varepsilon_1| < |\beta_3|$. Therefore in conclusion

$$|\varepsilon_1| < \min\{|\alpha_3|, |\beta_3|\}, \qquad |\varepsilon_3| < |\alpha_3|, \qquad |\beta_3| < \sinh(|\alpha_3|)\,. \tag{B.7}$$

Step 1: *notation.* We set $x = |\beta_3|$, $y = |\varepsilon_1|$, $z = |\alpha_3|$, so that

$$|\varepsilon_3| = y - x + z\,; \tag{B.8}$$

see Figure B.1. Under this notation, (B.6) writes as

$$F(x, y; z) = \sinh y + \sinh(y - x + z) - \sinh z + x = 0 \tag{B.9}$$

for $x \geq 0$, $y \geq 0$, $z \geq 0$, $y - x + z \geq 0$. By (B.7), any solution of (B.9) satisfies

$$y < z\,, \qquad y < x\,, \qquad x < \sinh(z)\,. \tag{B.10}$$

Step 2: *the threshold.* Observe that, despite the last inequality in (B.7), we may well have $|\beta_3| > |\alpha_3|$, that is, $x > z$. Consider in fact the limit case of $\varepsilon_3 = 0$: we have $y = x - z > 0$ and $\sinh(y) = \sinh(z) - x$ that give

$$\sinh(x - z) = \sinh(z) - x, \qquad x > z\,.$$

The last equality is the relation needed for β_3, α_3 in order to have that the shock and rarefaction cancel out exactly, giving rise only to a wave of the opposite family. Observe that the size of the rarefaction must be larger than the one of the shock. Under the notation above, the threshold curve separating the case of the outgoing waves S_1S_3 from the case S_1R_3 is given by

$$f(x, z) = \sinh(x - z) - \sinh(z) + x = 0\,. \tag{B.11}$$

Since $f_x = \cosh(x - z) + 1 > 0$ and $f(z, z) < 0$, the implicit equation $f(x, z) = 0$ is solved by $x = x_o(z) \geq z$ with $x_o'(z) = \frac{\cosh(x-z)+\cosh(z)}{\cosh(x-z)+1} > 0$ for every $z \geq 0$; the curve has for tangent at $(0, 0)$ the line $z = x$. Observe that $x_o(z) \leq 2z$ because $f(2z, z) = z \geq 0$. In conclusion

$$z \leq x_o(z) \leq 2z\,; \tag{B.12}$$

see Figure B.2(a). This estimate and the third inequality in (B.7) prove (B.1) for $B(\alpha_i) = x_o(|\alpha_i|)$. We can prove more than (B.12), that is,

$$\lim_{z \to +\infty} (x_o(z) - 2z) = 0\,. \tag{B.13}$$

Indeed, we show that the inequality $x_o(z) > 2z - q$ holds for large z and $q > 0$. This follows from $f(2z - q, z) = \sinh(z - q) - \sinh z + 2z - q \sim e^z\,(e^{-q} - 1)\,/2 \to -\infty$ for $z \to \infty$.

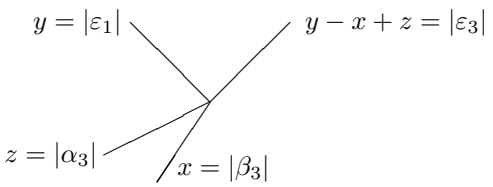

FIG. B.1. *Interactions.*

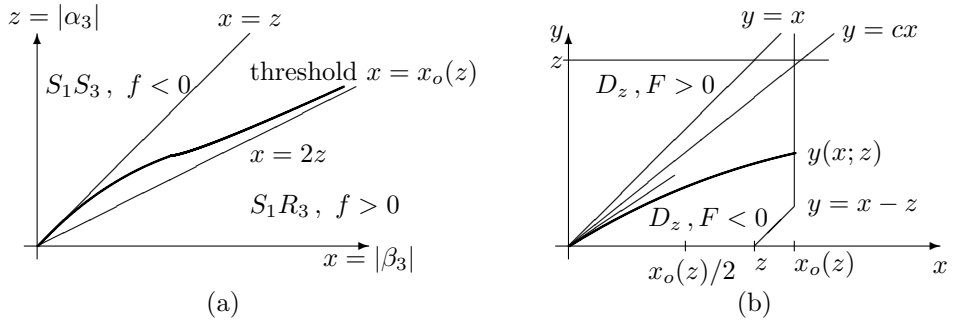

FIG. B.2. (a) *the threshold curve* $f(x, z) = \sinh(x - z) - \sinh(z) + x = 0$*;* (b) *the domain* D_z *and the function* $y = y(x; z)$*.*

Remark that the fact that ε_3 is a shock implies that

$$f(x, z) = \sinh(x - z) - \sinh(z) + x < 0\,. \tag{B.14}$$

Step 3: *the amount of shocks can increase.* From (B.5) we have

$$|\varepsilon_1| + |\varepsilon_3| - |\alpha_3| = 2|\varepsilon_1| - |\beta_3|\,. \tag{B.15}$$

We now prove that the inequality $|\varepsilon_1| + |\varepsilon_3| - |\alpha_3| < 0$, or equivalently $|\varepsilon_1| < \frac{1}{2}|\beta_3|$, does not hold if m is large.

The equation giving $|\varepsilon_1| = y$ in terms of $|\beta_3| = x$, for a given parameter $|\alpha_3| = z$, is (B.9), to be considered in the domain

$$D_z = \{(x, y):\ 0 \le x \le x_o(z)\,,\ y \ge \max\{0, x - z\}\} \qquad \text{for } z \ge 0,$$

where $x_o(z)$ satisfies (B.11); see Figure B.2(b). Since $F_y = \cosh y + \cosh(y - x + z) > 0$, the implicit equation (B.9) defines a function $y = y(x; z)$ with $0 \le y(x; z) \le x$ and $y(x; z) \le z$; see (B.10). Remark that $F(x, x; z) = \sinh x + x > 0$. Moreover, $F(x, 0; z) = \sinh(z - x) - \sinh z + x$ so that $F(0, 0; z) = 0$; by $F_x = 1 - \cosh(z - x) < 0$, we deduce that $F(x, 0; z) < 0$ if $x > 0$. By the implicit function theorem we have $y'(x; z) \ge 0$,

$$y'(0; z) = \frac{\cosh(z) - 1}{\cosh(z) + 1} \in [0, 1), \tag{B.16}$$

and $y''(0; z) = -\frac{4\sinh(z)}{(1+\cosh(z))^2} \le 0$. The function $\frac{\cosh(z)-1}{\cosh(z)+1}$ is increasing, and then for $z \in [0, m]$ its maximum is $\frac{\cosh(m)-1}{\cosh(m)+1}$; this quantity is strictly larger than $1/2$ if $m > \log(3 + 2\sqrt{2})$. Thus in general the estimate $y(x; z) < x/2$ cannot hold.

Step 4: *proof of the estimate.* From (B.15) we see that $|\varepsilon_1| + |\varepsilon_3| - |\alpha_3| \le (2c - 1) \cdot |\beta_3| \iff |\varepsilon_1| \le c \cdot |\beta_3|$, that is, that (B.3) and (B.4) are equivalent; we shall prove (B.4). To bypass the study of the function $y(x; z)$ we define

$$\Phi(x;z,c) = F\left(x, cx; z\right) = \sinh(cx) + \sinh\left(z - (1-c)x\right) - \sinh z + x\,.$$

If $1/2 \le c < 1$, then $z > (1-c)x$ and $\Phi(0;z,c) = 0$,

$$\Phi_x(x;z,c) = 1 + c\cosh(cx) - (1-c)\cosh\left(z-(1-c)x\right)\,,$$

$$\Phi_{xx}(x;z,c) = c^2\sinh(cx) + (1-c)^2\sinh\left(z-(1-c)x\right) > 0\,.$$

Therefore the function $x \to \Phi_x(x;z,c)$ is increasing, and then $\Phi(x;z,c) \ge 0$ if

$$\Phi_x(0;z,c) = (1+c) - (1-c)\cosh(z) > 0\,,$$

that is, if $\cosh(z) \le \frac{1+c}{1-c}$; this is just (B.2). Then $y(x;z) \le cx$ for all $x \in (0, x_o(z))$, and so (B.4) is proved. □

Remark B.2. From (B.16) we see that condition (B.2) is equivalent to the geometric condition $y'(0;z) = (\cosh z - 1)/(\cosh z + 1) < c$. Moreover, as we noticed in the above proof, condition (B.2) is equivalent to

$$\cosh(|\alpha_i|) \le \frac{1+c}{1-c}\,, \tag{B.17}$$

which, in turn, is equivalent to

$$|\alpha_i| \le \log\frac{(1+\sqrt{c})^2}{1-c}\,. \tag{B.18}$$

From the definition of the strength, one has that $|\alpha_i| = (1/2)\log(v_{max}/v_{min})$, where $v_{max} = \max\{v_\ell, v_r\}$, $v_{min} = \min\{v_\ell, v_r\}$, v_ℓ, v_r being, respectively, the left and right values of v for the wave of size α_i. Hence (B.18) is equivalent to

$$\sqrt{\frac{v_{max}}{v_{min}}} \le \frac{\left(1+\sqrt{c}\right)^2}{1-c}\,.$$

Remark B.3. In the proof above we showed that $\Delta L_{\text{shocks}} = |\varepsilon_1| + |\varepsilon_3| - |\alpha_3| = 2|\varepsilon_1| - |\beta_3|$ may be positive, differently from Nishida's paper, where it is always decreasing. This depends on the definition of the wave strengths, which was imposed to us in order to have good estimates when dealing with interactions with the 2-waves. In any case $\Delta L = \Delta L_{\text{shocks}} + \Delta L_{\text{rarefactions}} \le 0$.

Remark B.4. Under the notation and assumptions of Lemma B.1 we verify that

$$|\varepsilon_j| \le c \cdot |\alpha_i|\,. \tag{B.19}$$

This estimate, together with (B.4), allows us to obtain (in a special case) the analogue of (5.20) with c in place of d.

The proof makes use of a numerical computation. As in that lemma we consider the case $j = 1$, $i = 3$. Let $z > 0$ be fixed and $0 \le x \le x_o(z)$. From the proof of Lemma B.1 we deduce that $y = y(x,z)$; for z fixed the function $x \to y(x,z)$ is increasing. Then define

$$Y(z) = y(x_o(z), z) = x_o(z) - z\,.$$

In order to prove (B.19) it is sufficient to prove that

$$Y(z) \le cz \quad \text{if} \quad \cosh(z) \le \frac{1+c}{1-c}\,.$$

Remark that from (B.13) we know that $Y(z)/z \to 1$ for $z \to +\infty$; however, the constraint (B.17) implies that z is bounded. The inequality $Y(z) \le cz$ is equivalent to $x_o(z) - z \le cz$, i.e., $x_o(z) \le (1+c)z$. Therefore we need to prove that

$$\text{(B.20)} \quad \phi(z,c) \doteq \sinh(cz) - \sinh(z) + (1+c)z \ge 0 \quad \text{if} \quad \cosh(z) \le \frac{1+c}{1-c}\,.$$

Notice that $\cosh(z) \le \frac{1+c}{1-c}$ means $0 \le z \le z_c$ for $z_c = \log(\frac{1+c}{1-c} + \sqrt{(\frac{1+c}{1-c})^2 - 1}\,)$. Formula (B.20) is shown to hold true by numerical computations. Remark, however, that

$$\phi'(z,c) = c\cosh(cz) - \cosh(z) + 1 + c,$$

$$\phi''(z,c) = c^2\sinh(cz) - \sinh(z) \le 0,$$

so $\phi'(0,c) = 2c$, $\phi(\cdot,c)$ is concave, $\lim_{z\to+\infty}\phi(z,c) = -\infty$, and $\phi(\cdot,c)$ has a single point of maximum; at last $\phi'(z_c) = c\,(\cosh(cz_c) - \cosh(z_c)) < 0$. This concludes the proof of (B.19).

Remark that if $c = 1/2$, then $\phi(z,c) = \sinh(z/2) - \sinh z + \frac{3}{2}z$. If z is such that $\cosh z = 3$, then $\sinh z = 2\sqrt{2}$, $\sinh(z/2) = 1$, $z = \log(3+\sqrt{8})$, and (B.20) holds with strict inequality.

Acknowledgment. The authors thank Graziano Guerra for stimulating remarks and Umberto Massari for hints on BV functions.

ON THE GLOBAL WELL-POSEDNESS OF THE CRITICAL QUASI-GEOSTROPHIC EQUATION*

HAMMADI ABIDI† AND TAOUFIK HMIDI†

Abstract. We prove the global well-posedness of the critical dissipative quasi-geostrophic equation for large initial data belonging to the critical Besov space $\dot{B}^0_{\infty,1}(\mathbb{R}^2)$.

Key words. quasi-geostrophic equation, global existence, Besov spaces

1. Introduction.

In this paper we are concerned with the initial value problem of the 2D (two-dimensional) dissipative quasi-geostrophic equation

$$(\mathrm{QG})_\alpha \begin{cases} \partial_t\theta + v\cdot\nabla\theta + |\mathrm{D}|^{2\alpha}\theta = 0, \\ \theta_{|t=0} = \theta^0, \end{cases}$$

where the scalar function θ represents the potential temperature and the parameter $\alpha \in]0,1]$. The velocity $v = (v^1, v^2)$ is determined by Riesz transforms of θ,

$$v = (-\partial_2|\mathrm{D}|^{-1}\theta, \partial_1|\mathrm{D}|^{-1}\theta) := (-R_2\theta, R_1\theta), \quad |\mathrm{D}| = \sqrt{-\Delta}.$$

In addition to its intrinsic mathematical importance, this equation serves as a 2D model in geophysical fluid dynamics; for more details about the subject, see [6, 19].

This equation has been intensively investigated, and much attention is devoted to the problem of global well-posedness. For the subcritical case ($\alpha > \frac{1}{2}$) the theory seems to be in a satisfactory state. Indeed, global existence and uniqueness for arbitrary initial data are established in various function spaces (see, for example, [8, 20]). However, the critical and supercritical cases, corresponding respectively to $\alpha = \frac{1}{2}$ and $\alpha < \frac{1}{2}$, are harder to deal with. In the supercritical case, we have until now only global results for small initial data; see, for instance, [3, 5, 12, 13, 23, 24]. For the critical case, Constantin, Córdoba, and Wu showed in [7] the global existence in Sobolev space H^1 under a smallness assumption of the L^∞ norm of θ^0. Many other relevant results can be found in [9, 14, 15, 17]. Very recently, Kiselev, Nazarov, and Volberg proved in [16] global well-posedness for arbitrary periodic smooth initial data by using an elegant argument of the modulus of continuity. In [2], Caffarelli and Vasseur established the global regularity of weak solutions associated with L^2 initial data.

The main goal of this work is to establish global well-posedness in the critical case when initial data belong to the homogeneous critical Besov space $\dot{B}^0_{\infty,1}(\mathbb{R}^2)$: we remove the periodic condition, and we weaken the initial regularity. Before giving our main result let us first specify our notion of critical spaces. Let θ be a solution of

*Received by the editors February 9, 2007; accepted for publication (in revised form) December 3, 2007; published electronically April 4, 2008.

$(\mathrm{QG})_\alpha$ and $\lambda > 0$; then $\theta_\lambda(t,x) = \theta(\lambda t, \lambda x)$ is also a solution. One class of scaling invariant spaces is the homogeneous Besov spaces $(\dot{B}^{2/p}_{p,r})$, with p, $r \in [1,\infty]$.

Our first main result reads as follows.

THEOREM 1.1. *Let $\theta^0 \in \dot{B}^0_{\infty,1}$; then there exists a unique global solution θ to $(\mathrm{QG})_\alpha$ such that*

$$\theta \in \mathcal{C}(\mathbb{R}_+;\, \dot{B}^0_{\infty,1}) \cap L^1_{loc}(\mathbb{R}_+;\, \dot{B}^1_{\infty,1}).$$

The proof relies essentially on two facts: the first is the establishment of local existence, which is the major part of this paper, and the derivation of some smoothing effects of the solution, described in the next theorem. The second is the use of the modulus of continuity, as used in [16]. We mention that the property allowing us to remove the periodicity is the spatial decay of the solution. The key to our local existence result is some new estimates for the following transport-diffusion equation:

$$(\mathrm{TD}) \begin{cases} \partial_t \theta + v \cdot \nabla \theta + |\mathrm{D}|\theta = f, \\ \theta_{|t=0} = \theta^0, \end{cases}$$

where v and f are given and θ is the unknown scalar function. We now state our second main result.

THEOREM 1.2. *Let $s \in \,]-1,1[$, $r, \bar{r} \in [1,+\infty]$ with $r \geq \bar{r}$, $f \in \widetilde{L}^{\bar{r}}_{\mathrm{loc}}(\mathbb{R}_+; \dot{B}^{s+\frac{1}{\bar{r}}-1}_{\infty,1})$, and v be a divergence-free vector field belonging to $L^1_{\mathrm{loc}}(\mathbb{R}_+; \mathrm{Lip}(\mathbb{R}^2))$. We consider a smooth solution θ of the transport-diffusion equation* (TD)*; then there exists a constant C depending only on s such that for every $t \in \mathbb{R}_+$*

$$\|\theta\|_{\widetilde{L}^r_t \dot{B}^{s+\frac{1}{r}}_{\infty,1}} \leq C e^{C\int_0^t \|\nabla v(\tau)\|_{L^\infty} d\tau} \big(\|\theta^0\|_{\dot{B}^s_{\infty,1}} + \|f\|_{\widetilde{L}^{\bar{r}}_t \dot{B}^{s+\frac{1}{\bar{r}}-1}_{\infty,1}} \big).$$

Additionally, if $v = \nabla^\perp |\mathrm{D}|^{-1}\theta$, then we have for all $s \geq 1$

$$\|\theta\|_{\widetilde{L}^r_t \dot{B}^{s+\frac{1}{r}}_{\infty,1}} \leq C e^{C\int_0^t (\|\nabla\theta(\tau)\|_{L^\infty} + \|\nabla v(\tau)\|_{L^\infty}) d\tau} \big(\|\theta^0\|_{\dot{B}^s_{\infty,1}} + \|f\|_{\widetilde{L}^{\bar{r}}_t \dot{B}^{s+\frac{1}{\bar{r}}-1}_{\infty,1}} \big).$$

We use for the proof a new approach based on Lagrangian coordinates combined with paradifferential calculus and a new commutator estimate. This idea has been recently used by the second author in [11, 12].

The rest of the paper is structured as follows. In section 2 we review some basic results of Littlewood–Paley theory, and we give some useful lemmas. Section 3 deals with a new commutator estimate which is needed for the proof of Theorem 1.2, done in section 4. Theorem 1.1 is proved in section 5.

2. Preliminaries. Throughout the paper, C stands for a constant which may be different in each occurrence. We shall sometimes use the notation $A \lesssim B$ instead of $A \leq CB$, and $A \approx B$ means that $A \lesssim B$ and $B \lesssim A$. We denote by $\mathcal{F}f$ the Fourier transform of f and by $[\eta]$ the whole part of η.

One starts with recalling a traditional result that will be frequently used.

LEMMA 2.1 (Bernstein). *Let $f \in L^p(\mathbb{R}^2)$, with $1 \leq p \leq \infty$ and $0 < r < R$. Then there exists a constant $C > 0$ such that $\forall\, k \in \mathbb{N}$ and $\lambda > 0$ we have*

$$\mathrm{supp}\, \mathcal{F}f \subset B(0, \lambda r) \Longrightarrow \sup_{|\beta|=k} \|\partial^\beta f\|_{L^q} \leq C^k \lambda^{k+2(\frac{1}{p}-\frac{1}{q})} \|f\|_{L^p},$$

$$\mathrm{supp}\, \mathcal{F}f \subset \mathcal{C}(0, \lambda r, \lambda R) \Longrightarrow C^{-k}\lambda^k \|f\|_{L^p} \leq \sup_{|\beta|=k} \|\partial^\beta f\|_{L^p} \leq C^k \lambda^k \|f\|_{L^p}.$$

These estimates hold true if we replace the derivation ∂^β by $|\mathrm{D}|^{|\beta|}$.

To define Besov spaces we need to recall the homogeneous Littlewood–Paley decomposition based on a dyadic unity partition. Let φ be a smooth function supported in the ring $\mathcal{C} := \{\xi \in \mathbb{R}^2, \frac{3}{4} \leq |\xi| \leq \frac{8}{3}\}$ and such that

$$\sum_{q\in\mathbb{Z}} \varphi(2^{-q}\xi) = 1 \quad \text{for} \quad \xi \neq 0.$$

Now, for $u \in \mathcal{S}'$ we set

$$\forall q \in \mathbb{Z}, \quad \Delta_q u = \varphi(2^{-q}\mathrm{D})u \qquad \text{and} \qquad S_q u = \sum_{j\leq q-1} \Delta_j u.$$

We have the formal decomposition

$$u = \sum_{q\in\mathbb{Z}} \Delta_q\, u \quad \forall\, u \in \mathcal{S}'(\mathbb{R}^2)/\mathcal{P}[\mathbb{R}^2],$$

where $\mathcal{P}[\mathbb{R}^2]$ is the set of polynomials (see [18]). Moreover, the Littlewood–Paley decomposition satisfies the property of almost orthogonality:

$$\Delta_k\Delta_q u \equiv 0 \quad \text{if} \quad |k-q| \geq 2, \quad \text{and} \quad \Delta_k(S_{q-1}u\Delta_q u) \equiv 0 \quad \text{if} \quad |k-q| \geq 5. \tag{1}$$

We recall now the definition of Besov spaces. Letting $(p,m) \in [1,+\infty]^2$, $s \in \mathbb{R}$, and $u \in \mathcal{S}'$, we set

$$\|u\|_{\dot{B}^s_{p,m}} := \Big(2^{qs}\|\Delta_q u\|_{L^p}\Big)_{\ell^m}, \quad \dot{\mathcal{B}}^s_{p,m} := \Big\{u \in \mathcal{S} \;\Big|\; \|u\|_{\dot{B}^s_{p,m}} < \infty\Big\}.$$

- For $s < \frac{2}{p}$ (or $s \leq \frac{2}{p}$ if $m = 1$), we then define $\dot{B}^s_{p,m}$ as the completion of $\dot{\mathcal{B}}^s_{p,m}$ for $\|\cdot\|_{\dot{B}^s_{p,m}}$.
- If $k \in \mathbb{N}$ and $\frac{2}{p} + k - 1 \leq s < \frac{2}{p} + k$ (or $s = \frac{2}{p} + k$ if $m = 1$), then $\dot{B}^s_{p,m}$ is defined as the subset of distributions $u \in \mathcal{S}'$ such that $\partial^\beta u \in \dot{B}^{s-k}_{p,m}$ whenever $|\beta| = k$.

Another characterization of the homogeneous Besov spaces that will be needed later is the following; see, for instance, [21]. For $s \in]0,1[$, $p,m \in [1,\infty]$

$$\left(\int_{\mathbb{R}^2} \frac{\|u(\cdot - x) - u(\cdot)\|^m_{L^p}}{|x|^{sm}} \frac{dx}{|x|^2}\right)^{\frac{1}{m}} \approx \|u\|_{\dot{B}^s_{p,m}}, \tag{2}$$

with the usual modification if $m = \infty$.

In our next study we require two kinds of coupled space-time Besov spaces. The first one is defined in the following manner: for $T > 0$ and $m \geq 1$, we denote by $L^r_T\dot{B}^s_{p,m}$ the set of all tempered distributions u satisfying

$$\|u\|_{L^r_T\dot{B}^s_{p,m}} := \Big\|\Big(2^{qs}\|\Delta_q u\|_{L^p}\Big)_{\ell^m}\Big\|_{L^r_T} < \infty.$$

The second mixed space is $\widetilde{L}^r_T\dot{B}^s_{p,m}$, which is the set of tempered distributions u satisfying

$$\|u\|_{\widetilde{L}^r_T\dot{B}^s_{p,m}} := \Big(2^{qs}\|\Delta_q u\|_{L^r_T L^p}\Big)_{\ell^m} < \infty.$$

We can define in the same way the spaces $L^r_T B^s_{p,m}$ and $\widetilde{L}^r_T B^s_{p,m}$. The following embeddings are a direct consequence of Minkowski's inequality.

Let $s \in \mathbb{R}$, $r \geq 1$, and $\big(p, m\big) \in [1, \infty]^2$; then we have

$$L^r_T \dot{B}^s_{p,m} \hookrightarrow \widetilde{L}^r_T \dot{B}^s_{p,m} \quad \text{if} \quad m \geq r \quad \text{and} \tag{3}$$

$$\widetilde{L}^r_T \dot{B}^s_{p,m} \hookrightarrow L^r_T \dot{B}^s_{p,m} \quad \text{if} \quad r \geq m.$$

The next lemma will be useful.

PROPOSITION 2.2. *The following results hold true:*

- $$\dot{B}^s_{p,m} \hookrightarrow \dot{B}^{s-2(\frac{1}{p}-\frac{1}{p_1})}_{p_1,m_1} \quad \textit{for} \quad p \leq p_1 \quad \textit{and} \quad m \leq m_1.$$
- *Let* $|\mathrm{D}| := \sqrt{-\Delta}$ *and* $\sigma \in \mathbb{R}$*; then the operator* $|\mathrm{D}|^\sigma$ *is an isomorphism from* $\dot{B}^s_{p,m}$ *to* $\dot{B}^{s-\sigma}_{p,m}$.
- *Let* $\gamma \in]0,1[$, s_1, $s_2 \in \mathbb{R}$ *such that* $s_1 < s_2$ *and* $u \in \dot{B}^{s_1}_{p,\infty} \cap \dot{B}^{s_2}_{p,\infty}$*; then*

$$\|u\|_{\dot{B}^{\gamma s_1 + (1-\gamma)s_2}_{p,1}} \lesssim \|u\|^{\gamma}_{\dot{B}^{s_1}_{p,\infty}} \|u\|^{1-\gamma}_{\dot{B}^{s_2}_{p,\infty}}.$$

- *For* $s > 0$, $\dot{B}^s_{p,m} \cap L^\infty$ *is an algebra.*

We now recall some commutator estimates (see [4, 10] and the references therein).

LEMMA 2.3. *Let* $p, r \in [1, \infty]$, $1 = \frac{1}{r} + \frac{1}{r'}$, $\rho_1 < 1$, $\rho_2 < 1$*, and* v *be a divergence-free vector field of* $\mathbb{R}^2$*. Assume in addition that*

$$\rho_1 + \rho_2 + 2\min\{1, 2/p\} > 0 \quad \textit{and} \quad \rho_1 + 2/p > 0.$$

Then we have

$$\sum_{q \in \mathbb{Z}} 2^{q(\frac{2}{p}+\rho_1+\rho_2-1)} \big\| [\Delta_q, v \cdot \nabla] u \big\|_{L^1_t L^p} \lesssim \|v\|_{\widetilde{L}^r_t \dot{B}^{\frac{2}{p}+\rho_1}_{p,1}} \|u\|_{\widetilde{L}^{r'}_t \dot{B}^{\frac{2}{p}+\rho_2}_{p,1}}.$$

Moreover, we have for $s \in]-1, 1[$

$$\sum_{q \in \mathbb{Z}} 2^{qs} \big\| [\Delta_q, v \cdot \nabla] u \big\|_{L^p} \lesssim \|\nabla v\|_{L^\infty} \|u\|_{\dot{B}^s_{p,1}}.$$

If $v = \nabla^\perp |\mathrm{D}|^{-1} \theta$*, then the above estimate holds true for* $s \geq 1$ *if we replace* $\|\nabla v\|_{L^\infty}$ *by* $\|\nabla v\|_{L^\infty} + \|\nabla u\|_{L^\infty}$.

The following result is due to Vishik [22].

LEMMA 2.4. *Let* f *be a function in the Schwartz class and* ψ *a diffeomorphism preserving Lebesgue measure; then* $\forall\ p \in [1, +\infty]$ *and* $\forall\ j, q \in \mathbb{Z}$,

$$\|\Delta_j (\Delta_q f \circ \psi)\|_{L^p} \leq C 2^{-|j-q|} \|\nabla \psi^{\epsilon(j,q)}\|_{L^\infty} \|\Delta_q f\|_{L^p},$$

with

$$\epsilon(j, q) = \mathit{sign}(j - q).$$

The following result is proved in [9].

PROPOSITION 2.5. *Let v be a smooth divergence-free vector field and f be a smooth function. We assume that θ is a smooth solution of the equation*

$$\partial_t\theta + v\cdot\nabla\theta + \kappa|\mathrm{D}|^{2\alpha}\theta = f, \quad \text{with} \quad \kappa \geq 0 \quad \text{and} \quad \alpha \in [0,1].$$

Then for $p \in [1,+\infty]$ we have

$$\|\theta(t)\|_{L^p} \leq \|\theta(0)\|_{L^p} + \int_0^t \|f(\tau)\|_{L^p} d\tau.$$

We can find a proof of the next proposition in [12].

PROPOSITION 2.6. *Let $\mathcal{C}$ be a ring and $\alpha \in \mathbb{R}_+$. There exists a positive constant C such that, for any $p \in [1;+\infty]$, for any pair (t,λ) of positive real numbers, we have*

$$\operatorname{supp}\mathcal{F}u \subset \lambda\mathcal{C} \Rightarrow \|e^{-t|\mathrm{D}|^\alpha}u\|_{L^p} \leq Ce^{-C^{-1}t\lambda^\alpha}\|u\|_{L^p}.$$

3. Commutator estimate. The main result of this section is the following estimate that will play a crucial role for the proof of Theorem 1.2.

PROPOSITION 3.1. *Let v be a divergence-free vector field belonging to $L^1_{\mathrm{loc}}(\mathbb{R}_+;\mathrm{Lip}(\mathbb{R}^2))$. For $q \in \mathbb{Z}$ we denote by ψ_q the flow of the regularized vector field $S_{q-1}v$. Then for $f \in \dot{B}^1_{\infty,\infty}$ and for $q \in \mathbb{Z}$ we have*

$$\big\||\mathrm{D}|(\Delta_q f\circ\psi_q) - (|\mathrm{D}|\Delta_q f)\circ\psi_q\big\|_{L^\infty} \leq Ce^{CV(t)}V^{\frac12}(t)2^q\|\Delta_q f\|_{L^\infty},$$

where $V(t) = \|\nabla v\|_{L^1_t L^\infty(\mathbb{R}^2)}$ and C is an absolute constant.

Proof. We set $f_q := \Delta_q f$, and then it is obvious that

$$\begin{aligned}
|\mathrm{D}|(f_q\circ\psi_q) - (|\mathrm{D}|f_q)\circ\psi_q &= |\mathrm{D}|^{\frac12}\{(|\mathrm{D}|^{\frac12}f_q)\circ\psi_q\} - \{|\mathrm{D}|^{\frac12}(|\mathrm{D}|^{\frac12}f_q)\}\circ\psi_q \\
&\quad + |\mathrm{D}|^{\frac12}\big\{|\mathrm{D}|^{\frac12}(f_q\circ\psi_q) - (|\mathrm{D}|^{\frac12}f_q)\circ\psi_q\big\} \\
&:= \mathrm{I} + \mathrm{II}.
\end{aligned}$$

For the first term we apply Proposition 3.1 from [12], with $\alpha = \frac12$ and $F_q = |\mathrm{D}|^{\frac12}f_q$, yielding

$$\begin{aligned}
\|\mathrm{I}\|_{L^\infty} &\leq Ce^{CV(t)}(e^{CV(t)}-1)\|F_q\|_{\dot{B}^{\frac12}_{\infty,1}} \\
&\leq Ce^{CV(t)}(e^{CV(t)}-1)2^q\|f_q\|_{L^\infty} \\
&\lesssim e^{CV(t)}V^{\frac12}(t)2^q\|f_q\|_{L^\infty}.
\end{aligned}$$

For the second term we use the following formula for the fractional Laplacian:

$$|\mathrm{D}|^{\frac12}f(x) = C\int_{\mathbb{R}^2}\frac{f(x)-f(y)}{|x-y|^{\frac52}}dy.$$

Since the flow ψ_q preserves Lebesgue measure, we easily get

$$\begin{aligned}
|\mathrm{D}|^{\frac12}(f_q\circ\psi_q)(x) - (|\mathrm{D}|^{\frac12}f_q)\circ\psi_q(x) &= C\int_{\mathbb{R}^2}\frac{f_q(\psi_q(x)) - f_q(\psi_q(y))}{|x-y|^{\frac52}} \\
&\quad\times\left(1 - \frac{|x-y|^{\frac52}}{|\psi_q(x)-\psi_q(y)|^{\frac52}}\right)dy.
\end{aligned}$$

We denote $g_q(x)=f_q(\psi_q(x))$ and we set $h=x-y$:

$$|\mathrm{D}|^{\frac12}(f_q\circ\psi_q)(x)-(|\mathrm{D}|^{\frac12}f_q)\circ\psi_q(x)=C\int_{\mathbb{R}^2}\frac{g_q(x)-g_q(x-h)}{|h|^{\frac52}}\bar{\psi}_q(x,h)dh,$$

with

$$\bar{\psi}_q(x,h)=1-\frac{|h|^{\frac52}}{|\psi_q(x)-\psi_q(x-h)|^{\frac52}}.$$

It follows from law products and the embedding $\dot{B}^0_{\infty,1}\hookrightarrow L^\infty$ that

$$\begin{aligned}\|\mathrm{II}\|_{L^\infty}&\leq\big\||\mathrm{D}|^{\frac12}(f_q\circ\psi_q)-(|\mathrm{D}|^{\frac12}f_q)\circ\psi_q\big\|_{\dot{B}^{\frac12}_{\infty,1}}\\&\leq C\|\bar{\psi}_q\|_{L^\infty(\mathbb{R}^4)}\int_{\mathbb{R}^2}|h|^{-\frac52}\|g_q(\cdot)-g_q(\cdot-h)\|_{\dot{B}^{\frac12}_{\infty,1}}dh\\&+C\sup_{h\in\mathbb{R}^2}\|\bar{\psi}_q(\cdot,h)\|_{\dot{B}^{\frac12}_{\infty,1}}\int_{\mathbb{R}^2}|h|^{-\frac52}\|g_q(\cdot)-g_q(\cdot-h)\|_{L^\infty}dh\\&=J^1_q+J^2_q.\end{aligned}$$

We intend to estimate J^1_q. It is plain from the mean value theorem that

$$\frac{1}{\|\nabla\psi\|^{\frac52}_{L^\infty}}\leq\frac{|h|^{\frac52}}{|\psi(x)-\psi(x-h)|^{\frac52}}\leq\|\nabla\psi^{-1}\|^{\frac52}_{L^\infty},$$

which easily gives the inequality

$$\|\bar{\psi}_q\|_{L^\infty(\mathbb{R}^4)}\leq\max\Big(|1-\|\nabla\psi_q^{-1}\|^{\frac52}_{L^\infty}|;|1-\|\nabla\psi_q\|^{-\frac52}_{L^\infty}|\Big).$$

On the other hand, we have the classical estimates

$$\begin{aligned}e^{-C\|S_{q-1}\nabla v\|_{L^1_tL^\infty}}\leq\|\nabla\psi_q^{\mp1}\|_{L^\infty}\leq e^{C\|S_{q-1}\nabla v\|_{L^1_tL^\infty}}\\\text{and}\quad\|S_{q-1}\nabla v\|_{L^1_tL^\infty}\leq CV(t).\end{aligned}\tag{4}$$

We thus get

$$\|\bar{\psi}_q\|_{L^\infty(\mathbb{R}^4)}\leq Ce^{CV(t)}(e^{CV(t)}-1).\tag{5}$$

Using the definition of Besov spaces and the commutation of Δ_j with translation operators, one finds

$$\begin{aligned}&\int_{\mathbb{R}^2}|h|^{-\frac52}\|g_q(\cdot)-g_q(\cdot-h)\|_{\dot{B}^{\frac12}_{\infty,1}}dh\\&\qquad\leq\sum_j2^{\frac12j}\int_{\mathbb{R}^2}|h|^{-\frac12}\|\Delta_jg_q(\cdot)-(\Delta_jg_q)(\cdot-h)\|_{L^\infty}\frac{dh}{|h|^2}.\end{aligned}$$

Applying the characterization of Besov spaces (2) yields

$$\begin{aligned}\int_{\mathbb{R}^2} |h|^{-\frac{5}{2}} \|g_q(\cdot) - g_q(\cdot - h)\|_{\dot{B}^{\frac{1}{2}}_{\infty,1}} dh &\leq C \sum_j 2^{\frac{1}{2}j} \|\Delta_j g_q\|_{\dot{B}^{\frac{1}{2}}_{\infty,1}} \\ &\leq C \sum_{|j-k|\leq 1} 2^{j\frac{1}{2}} 2^{\frac{1}{2}k} \|\Delta_j \Delta_k g_q\|_{L^\infty} \\ &\leq C \|g_q\|_{\dot{B}^1_{\infty,1}}.\end{aligned}$$

Now we use the following interpolation estimate:

$$\begin{aligned}\|g_q\|_{\dot{B}^1_{\infty,1}} &\lesssim \|g_q\|^{\frac{1}{2}}_{L^\infty} \|\Delta g_q\|^{\frac{1}{2}}_{L^\infty} \\ &\lesssim \|f_q\|^{\frac{1}{2}}_{L^\infty} \|\Delta g_q\|^{\frac{1}{2}}_{L^\infty}.\end{aligned}$$

It is easy to check from Leibniz rule that

$$\Delta g_q = \Delta(f_q \circ \psi_q) = \sum_{i=1}^{d} \langle (\nabla^2 f_q) \circ \psi_q \cdot \partial_i \psi_q, \partial_i \psi_q \rangle + (\nabla f_q) \circ \psi_q \cdot \Delta \psi_q.$$

Applying the Bernstein inequality, we get

$$\|\Delta g_q\|_{L^\infty} \lesssim e^{CV(t)} 2^{2q} \|f_q\|_{L^\infty} + 2^q \|f_q\|_{L^\infty} \|\Delta \psi_q\|_{L^\infty}.$$

The derivative of the flow equation with respect to x and the use of the Gronwall and Bernstein inequalities gives

$$\begin{aligned}\|\nabla^2 \psi_q(t)\|_{L^\infty} &\lesssim e^{CV(t)} \int_0^t \|\nabla^2 S_{q-1} v(\tau)\|_{L^\infty} d\tau \\ &\lesssim e^{CV(t)} 2^q. \qquad (6)\end{aligned}$$

Combining both last estimates, we obtain

$$\|\Delta g_q\|_{L^\infty} \lesssim e^{CV(t)} 2^{2q} \|f_q\|_{L^\infty}. \qquad (7)$$

Putting together (5) and (7), we conclude that

$$\|J^1_q(t)\|_{L^\infty} \lesssim e^{CV(t)} (e^{CV(t)} - 1) 2^q \|f_q\|_{L^\infty}.$$

Let us now turn to the second term J^2_q. The integral term can be estimated from (2) as follows:

$$\int_{\mathbb{R}^2} |h|^{-\frac{5}{2}} \|g_q(\cdot) - g_q(\cdot - h)\|_{L^\infty} dh \lesssim \|g_q\|_{\dot{B}^{\frac{1}{2}}_{\infty,1}}.$$

According to the classical composition result we write

$$\begin{aligned}\|g_q(t)\|_{\dot{B}^{\frac{1}{2}}_{\infty,1}} &\lesssim \|\nabla \psi_q\|^{\frac{1}{2}}_{L^\infty} \|f_q\|_{\dot{B}^{\frac{1}{2}}_{\infty,1}} \\ &\lesssim e^{CV(t)} 2^{q\frac{1}{2}} \|f_q\|_{L^\infty}. \qquad (8)\end{aligned}$$

In order to estimate $\bar{\psi}_q$ we use the interpolation inequality

$$\|\bar{\psi}_q(\cdot,h)\|_{\dot{B}^{\frac{1}{2}}_{\infty,1}} \lesssim \|\bar{\psi}_q(\cdot,h)\|^{\frac{1}{2}}_{L^\infty}\|\nabla_x\bar{\psi}_q(\cdot,h)\|^{\frac{1}{2}}_{L^\infty}.$$

This leads in view of (5) to

$$\|\bar{\psi}_q(\cdot,h)\|_{\dot{B}^{\frac{1}{2}}_{\infty,1}} \leq Ce^{CV(t)}(e^{CV(t)}-1)^{\frac{1}{2}}\|\nabla_x\bar{\psi}_q(\cdot,h)\|^{\frac{1}{2}}_{L^\infty}. \tag{9}$$

The derivative of $\bar{\psi}_q$ with respect to x yields

$$\begin{aligned}|\nabla_x\bar{\psi}_q(x,h)| &\lesssim \frac{|h|^{\frac{7}{2}}}{|\psi_q(x)-\psi_q(x-h)|^{\frac{7}{2}}}\frac{|\nabla_x\psi_q(x)-\nabla_x\psi_q(x-h)|}{|h|}\\ &\lesssim \|\nabla\psi_q^{-1}\|^{\frac{7}{2}}_{L^\infty}\|\nabla^2\psi_q\|_{L^\infty}.\end{aligned}$$

Combining (4) and (6), we obtain

$$\|\nabla_x\bar{\psi}_q(t)\|_{L^\infty(\mathbb{R}^4)} \lesssim e^{CV(t)}2^q. \tag{10}$$

Plugging (10) into (9), we find

$$\|\bar{\psi}_q(\cdot,h)\|_{\dot{B}^{\frac{1}{2}}_{\infty,1}} \lesssim e^{CV(t)}V^{\frac{1}{2}}(t)2^{\frac{q}{2}}. \tag{11}$$

Thus we deduce from (11) and (8) that

$$\|J^2_q(t)\|_{L^\infty} \leq Ce^{CV(t)}V^{\frac{1}{2}}(t)2^q\|f_q(t)\|_{L^\infty}.$$

This achieves the proof. □

4. Proof of Theorem 1.2. The Fourier localized function $\theta_q := \Delta_q\theta$ satisfies

$$\partial_t\theta_q + S_{q-1}v\cdot\nabla\theta_q + |\mathrm{D}|\theta_q = -[\Delta_q, v\cdot\nabla]\theta + (S_{q-1}v-v)\cdot\nabla\theta_q + f_q := \mathcal{R}_q. \tag{12}$$

Let ψ_q denote the flow of the velocity $S_{q-1}v$, and set

$$\bar{\theta}_q(t,x) = \theta_q(t,\psi_q(t,x)) \quad \text{and} \quad \bar{\mathcal{R}}_q(t,x) = \mathcal{R}_q(t,\psi_q(t,x)).$$

Since ψ_q is an homeomorphism, then

$$\|\bar{\mathcal{R}}_q\|_{L^\infty} \leq \|[\Delta_q, v\cdot\nabla]\theta\|_{L^\infty} + \|(S_{q-1}v-v)\cdot\nabla\theta_q\|_{L^\infty} + \|f_q\|_{L^\infty}. \tag{13}$$

It is not hard to check that the function $\bar{\theta}_q$ satisfies

$$\partial_t\bar{\theta}_q + |\mathrm{D}|\bar{\theta}_q = |\mathrm{D}|(\theta_q\circ\psi_q) - (|\mathrm{D}|\theta_q)\circ\psi_q + \bar{\mathcal{R}}_q := \bar{\mathcal{R}}^1_q. \tag{14}$$

From Proposition 3.1 we find that for $q\in\mathbb{Z}$

$$\||\mathrm{D}|(\theta_q\circ\psi_q) - (|\mathrm{D}|\theta_q)\circ\psi_q\|_{L^\infty} \lesssim e^{CV(t)}V^{\frac{1}{2}}(t)2^q\|\theta_q(t)\|_{L^\infty}, \tag{15}$$

where $V(t) := \|\nabla v\|_{L^1_tL^\infty}$. Putting together (13) and (15) yields

$$\begin{aligned}\|\bar{\mathcal{R}}^1_q(t)\|_{L^\infty} \lesssim \|f_q(t)\|_{L^\infty} &+ \|(S_{q-1}v-v)\cdot\nabla\theta_q\|_{L^\infty} + \|[\Delta_q, v\cdot\nabla]\theta\|_{L^\infty}\\ &+ e^{CV(t)}V^{\frac{1}{2}}(t)2^q\|\theta_q(t)\|_{L^\infty}.\end{aligned}$$

Applying the operator Δ_j to (14) and using Proposition 2.6, we obtain

$$\|\Delta_j\bar{\theta}_q(t)\|_{L^\infty} \lesssim e^{-ct2^j}\|\Delta_j\theta_q^0\|_{L^\infty} + \int_0^t e^{-c(t-\tau)2^j}\|f_q(\tau)\|_{L^\infty}d\tau \tag{16}$$

$$+ e^{CV(t)}V^{\frac{1}{2}}(t)2^q\int_0^t e^{-c(t-\tau)2^j}\|\theta_q(\tau)\|_{L^\infty}d\tau$$

$$+ \int_0^t e^{-c(t-\tau)2^j}\|[\Delta_q, v\cdot\nabla]\theta(\tau)\|_{L^\infty}d\tau$$

$$+ \int_0^t e^{-c(t-\tau)2^j}\|(S_{q-1}v - v)\cdot\nabla\theta_q(\tau)\|_{L^\infty}d\tau. \tag{17}$$

Integrating this estimate with respect to the time and using the Young inequality, we get

$$\|\Delta_j\bar{\theta}_q\|_{L^r_tL^\infty} \lesssim 2^{-\frac{j}{r}}(1-e^{-crt2^j})^{\frac{1}{r}}\|\Delta_j\theta_q^0\|_{L^\infty} + 2^{-j(1+\frac{1}{r}-\frac{1}{\overline{r}})}\|f_q\|_{L^{\overline{r}}_tL^\infty}$$

$$+ e^{CV(t)}V^{\frac{1}{2}}(t)2^{(q-j)}\|\theta_q\|_{L^r_tL^\infty}$$

$$+ 2^{-\frac{j}{r}}\int_0^t \|[\Delta_q, v\cdot\nabla]\theta(\tau)\|_{L^\infty}d\tau$$

$$+ 2^{-\frac{j}{r}}\int_0^t \|(S_{q-1}v - v)\cdot\nabla\theta_q(\tau)\|_{L^\infty}d\tau. \tag{18}$$

Since the flow ψ is a homeomorphism, one writes

$$\begin{aligned}2^{q(s+\frac{1}{r})}\|\theta_q\|_{L^r_tL^\infty} &= 2^{q(s+\frac{1}{r})}\|\bar{\theta}_q\|_{L^r_tL^\infty}\\ &\le 2^{q(s+\frac{1}{r})}\left(\sum_{|j-q|>N}\|\Delta_j\bar{\theta}_q\|_{L^r_tL^\infty} + \sum_{|j-q|\le N}\|\Delta_j\bar{\theta}_q\|_{L^r_tL^\infty}\right)\\ &:= \mathrm{I} + \mathrm{II}.\end{aligned}$$

To estimate the term I we appeal to Lemma 2.4,

$$\begin{aligned}\|\Delta_j\bar{\theta}_q\|_{L^r_tL^\infty} &\lesssim 2^{-|q-j|}e^{C\int_0^t\|\nabla v(\tau)\|_{L^\infty}d\tau}\|\theta_q\|_{L^r_tL^\infty}\\ &\le C2^{-|q-j|}e^{CV(t)}\|\theta_q\|_{L^r_tL^\infty}.\end{aligned}$$

Therefore we get

$$\mathrm{I} \le C2^{-N}e^{CV(t)}2^{q(s+\frac{1}{r})}\|\theta_q\|_{L^r_tL^\infty}. \tag{19}$$

In order to bound the second term II we use (18):

$$\mathrm{II} \lesssim (1-e^{-crt2^q})^{\frac{1}{r}}2^{qs}\|\theta_q^0\|_{L^\infty} + 2^{N(\frac{1}{r}+1-\frac{1}{\overline{r}})}2^{q(s+\frac{1}{\overline{r}}-1)}\|f_q\|_{L^{\overline{r}}_tL^\infty}$$

$$+ 2^Ne^{CV(t)}V^{\frac{1}{2}}(t)2^{q(s+\frac{1}{r})}\|\theta_q\|_{L^r_tL^\infty}$$

$$+ 2^{\frac{N}{r}}2^{qs}\int_0^t\|[\Delta_q, v\cdot\nabla]\theta(\tau)\|_{L^\infty}d\tau$$

$$+ 2^{\frac{N}{r}}2^{qs}\int_0^t\|(S_{q-1}v - v)\cdot\nabla\theta_q(\tau)\|_{L^\infty}d\tau. \tag{20}$$

Denoting $Z_q^r(t) := 2^{q(s+\frac{1}{r})}\|\theta_q\|_{L^r_t L^\infty}$, we then obtain, in view of (19) and (20),

$$\begin{aligned}
Z_q^r(t) &\leq C(1-e^{-crt2^q})^{\frac{1}{r}}2^{qs}\|\theta_q^0\|_{L^\infty} + C2^{N(\frac{1}{r}+1-\frac{1}{\overline{r}})}2^{q(s+\frac{1}{\overline{r}}-1)}\|f_q\|_{L^{\overline{r}}_t L^\infty}\\
&\quad + C\big\{2^N e^{CV(t)}V^{\frac{1}{2}}(t) + 2^{-N}e^{CV(t)}\big\}Z_q^r(t)\\
&\quad + C2^{\frac{N}{r}}2^{qs}\int_0^t \|[\Delta_q, v\cdot\nabla]\theta(\tau)\|_{L^\infty}d\tau\\
&\quad + C2^{\frac{N}{r}}2^{qs}\int_0^t \|(S_{q-1}v - v)\cdot\nabla\theta_q(\tau)\|_{L^\infty}d\tau.
\end{aligned}$$

It is easy to check the existence of two absolute constants N and C_0 such that

$$V(t)\leq C_0 \Rightarrow C2^{-N}e^{CV(t)} + C2^N e^{CV(t)}V^{\frac{1}{2}}(t)\leq \frac{1}{2}\cdot$$

Thus we obtain under this condition

$$\begin{aligned}
Z_q^r(t) &\lesssim (1-e^{-crt2^q})^{\frac{1}{r}}2^{qs}\|\theta_q^0\|_{L^\infty} + 2^{q(s+\frac{1}{\overline{r}}-1)}\|f_q\|_{L^{\overline{r}}_t L^\infty}\\
&\quad + 2^{qs}\int_0^t \Big(\|[\Delta_q, v\cdot\nabla]\theta(\tau)\|_{L^\infty} + \|(S_{q-1}v - v)\cdot\nabla\theta_q\|_{L^\infty}\Big)d\tau. \qquad (21)
\end{aligned}$$

Summing over q and using Lemma 2.3 leads, for $V(t)\leq C_0$, to

$$\begin{aligned}
\|\theta\|_{\widetilde{L}^r_t \dot{B}^{s+\frac{1}{r}}_{\infty,1}} &\lesssim \|\theta^0\|_{\dot{B}^s_{\infty,1}} + \|f\|_{\widetilde{L}^{\overline{r}}_t \dot{B}^{s+\frac{1}{\overline{r}}-1}_{\infty,1}} + \int_0^t \|\nabla v(\tau)\|_{L^\infty}\|\theta(\tau)\|_{\dot{B}^s_{\infty,1}}d\tau\\
&\lesssim \|\theta^0\|_{\dot{B}^s_{\infty,1}} + \|f\|_{\widetilde{L}^{\overline{r}}_t \dot{B}^{s+\frac{1}{\overline{r}}-1}_{\infty,1}} + C_0\|\theta\|_{L^\infty_t \dot{B}^s_{\infty,1}}. \qquad (22)
\end{aligned}$$

Let us show how to conclude the proof in the case of $r=\infty$. If C_0 is sufficiently small, then we obtain from (22) the desired estimate:

$$\|\theta\|_{\widetilde{L}^\infty_t \dot{B}^s_{\infty,1}} \lesssim \|\theta^0\|_{\dot{B}^s_{\infty,1}} + \|f\|_{\widetilde{L}^{\overline{r}}_t \dot{B}^{s+\frac{1}{\overline{r}}-1}_{\infty,1}}. \qquad (23)$$

Now for an arbitrary positive time T we take a partition $(T_i)_{i=0}^M$ of $[0,T]$ such that $\int_{T_i}^{T_{i+1}}\|\nabla v(\tau)\|_{L^\infty}d\tau \approx C_0$. We can proceed analogously to the above calculus and obtain

$$\|\theta\|_{\widetilde{L}^\infty_{[T_i,T_{i+1}]}\dot{B}^s_{\infty,1}} \lesssim \|\theta(T_i)\|_{\dot{B}^s_{\infty,1}} + \|f\|_{\widetilde{L}^{\overline{r}}_{[T_i,T_{i+1}]}\dot{B}^{s+\frac{1}{\overline{r}}-1}_{\infty,1}}.$$

An iteration argument leads to

$$\|\theta\|_{\widetilde{L}^\infty_{[T_i,T_{i+1}]}\dot{B}^s_{\infty,1}} \leq C^{i+1}\Big(\|\theta^0\|_{\dot{B}^s_{\infty,1}} + \|f\|_{\widetilde{L}^{\overline{r}}_{[0,T_{i+1}]}\dot{B}^{s+\frac{1}{\overline{r}}-1}_{\infty,1}}\Big).$$

The triangle inequality and the fact that $C_0 M \simeq 1 + V(t)$ give

$$\|\theta\|_{\widetilde{L}^\infty_T \dot{B}^s_{\infty,1}} \leq Ce^{C\int_0^T\|\nabla v(\tau)\|_{L^\infty}}\Big(\|\theta^0\|_{\dot{B}^s_{\infty,1}} + \|f\|_{\widetilde{L}^{\overline{r}}_T \dot{B}^{s+\frac{1}{\overline{r}}-1}_{\infty,1}}\Big). \qquad (24)$$

Let us now turn to the case of finite r. Combining (22) and (23), we obtain under the assumption $V(t) \leq C_0$

$$\|\theta\|_{\widetilde{L}^r_t \dot{B}^{s+\frac{1}{r}}_{\infty,1}} \lesssim \|\theta^0\|_{\dot{B}^s_{\infty,1}} + \|f\|_{\widetilde{L}^{\overline{r}}_t \dot{B}^{s+\frac{1}{\overline{r}}-1}_{\infty,1}}. \tag{25}$$

This gives the result for a short time, and as for the case $r = \infty$, we obtain the required global estimate.

Concerning the last estimate of Theorem 1.2, we use in the commutator term of (21) the last part of Lemma 2.3. □

5. Proof of Theorem 1.1. The proof is divided into two parts: in the first one we construct a local unique solution and give a criterion of global existence. However, in the second part we discuss the global existence by reproducing an idea of [16].

5.1. Local existence. We aim to prove the following result.

PROPOSITION 5.1. *Given any $\theta^0 \in \dot{B}^0_{\infty,1}$, there is $T > 0$ such that the $(\mathrm{QG})_\alpha$ equation has a unique solution θ with*

$$\theta \in \widetilde{L}^\infty_T \dot{B}^0_{\infty,1} \cap L^1_T \dot{B}^1_{\infty,1}.$$

Moreover, for all $\beta \in \mathbb{R}_+$ we have $t^\beta \theta \in \widetilde{L}^\infty_T \dot{B}^\beta_{\infty,1}$.

Proof. The existence is based on Theorem 1.2 and an iterative method. We denote $\theta_0(t,x) := e^{-t|\mathrm{D}|}\theta^0(x)$, $v_0 := (-R_2\theta_0, R_1\theta_0)$, and θ_{n+1} the solution of the linear system

$$\begin{cases} \partial_t \theta_{n+1} + v_n \cdot \nabla \theta_{n+1} + |\mathrm{D}|\theta_{n+1} = 0, \\ v_n = (-R_2\theta_n, R_1\theta_n), \\ \theta_{n+1|t=0} = \theta^0. \end{cases}$$

Since $\theta_0 \in L^1(\mathbb{R}_+; \dot{B}^1_{\infty,1})$ and from the continuity of Riesz transforms in the homogeneous Besov spaces we find $v_0 \in L^1(\mathbb{R}_+; \dot{B}^1_{\infty,1})$. Thus by iteration and thanks to Theorem 1.2, one deduces that $\forall n \in \mathbb{N}$,

$$\theta_n \in \widetilde{L}^\infty(\mathbb{R}_+; \dot{B}^0_{\infty,1}) \cap L^1(\mathbb{R}_+; \dot{B}^1_{\infty,1}).$$

Step 1: *Uniform bounds.* Now we intend to obtain uniform bounds, with respect to the parameter n, for some $T > 0$ independent of n.

By (21), we have for all $T \geq 0$ such that

$$\int_0^T \|\theta_n(\tau)\|_{\dot{B}^1_{\infty,1}} d\tau \leq C_1 (:= CC_0) \tag{26}$$

the following estimate:

$$\begin{aligned} \|\theta_{n+1}\|_{\widetilde{L}^2_T \dot{B}^{\frac{1}{2}}_{\infty,1}} + \|\theta_{n+1}\|_{L^1_T \dot{B}^1_{\infty,1}} &\lesssim \sum_{q\in\mathbb{Z}} (1 - e^{-cT2^q})^{\frac{1}{2}} \|\Delta_q \theta^0\|_{L^\infty} \\ &+ \sum_{q\in\mathbb{Z}} \int_0^T \|[\Delta_q, v_n \cdot \nabla]\theta_{n+1}(\tau)\|_{L^\infty} d\tau \\ &+ \sum_{q\in\mathbb{Z}} \int_0^T \|(S_{q-1}v_n - v_n) \cdot \nabla \Delta_q \theta_{n+1}(\tau)\|_{L^\infty} d\tau. \end{aligned}$$

Since $\operatorname{div} v_n = 0$, then Lemma 2.3 combined with the continuity of Riesz transforms gives

$$\sum_{q\in\mathbb{Z}}\int_0^T \|[\Delta_q, v_n\cdot\nabla]\theta_{n+1}(\tau)\|_{L^\infty}d\tau \lesssim \|v_n\|_{\widetilde{L}^2_T\dot{B}^{\frac{1}{2}}_{\infty,\infty}}\|\theta_{n+1}\|_{\widetilde{L}^2_T\dot{B}^{\frac{1}{2}}_{\infty,1}}$$
$$\lesssim \|\theta_n\|_{\widetilde{L}^2_T\dot{B}^{\frac{1}{2}}_{\infty,\infty}}\|\theta_{n+1}\|_{\widetilde{L}^2_T\dot{B}^{\frac{1}{2}}_{\infty,1}}.$$

We deduce from the Hölder and Young inequalities that

$$\sum_{q\in\mathbb{Z}}\int_0^t \|(S_qv_n - v_n)\cdot\nabla\Delta_q\theta_{n+1}\|_{L^\infty}d\tau \lesssim \sum_{q\in\mathbb{Z}} 2^q\|\Delta_q\theta_{n+1}\|_{L^2_tL^\infty}\|S_qv_n - v_n\|_{L^2_tL^\infty}$$
$$\lesssim \sum_{q\in\mathbb{Z}} 2^{\frac{1}{2}q}\|\Delta_q\theta_{n+1}\|_{L^2_tL^\infty}\sum_{k\geq q}2^{\frac{1}{2}(q-k)}2^{\frac{1}{2}k}\|\Delta_kv_n\|_{L^2_tL^\infty}$$
$$\lesssim \|\theta_{n+1}\|_{\widetilde{L}^2_t\dot{B}^{\frac{1}{2}}_{\infty,1}}\|\theta_n\|_{\widetilde{L}^2_t\dot{B}^{\frac{1}{2}}_{\infty,\infty}}.$$

Therefore we obtain from the above inequalities

$$\|\theta_{n+1}\|_{\widetilde{L}^2_t\dot{B}^{\frac{1}{2}}_{\infty,1}} + \|\theta_{n+1}\|_{L^1_t\dot{B}^1_{\infty,1}} \lesssim \sum_{q\in\mathbb{Z}}(1-e^{-ct2^q})^{\frac{1}{2}}\|\Delta_q\theta^0\|_{L^\infty}$$
$$+ \|\theta_{n+1}\|_{\widetilde{L}^2_t\dot{B}^{\frac{1}{2}}_{\infty,1}}\|\theta_n\|_{\widetilde{L}^2_t\dot{B}^{\frac{1}{2}}_{\infty,1}}.$$

Thus there exists an absolute constant $\varepsilon_0 > 0$ such that, if

$$\sum_{q\in\mathbb{Z}}(1-e^{-cT2^q})^{\frac{1}{2}}\|\Delta_q\theta^0\|_{L^\infty} \leq \varepsilon_0, \tag{27}$$

then

$$\|\theta_{n+1}\|_{\widetilde{L}^2_T\dot{B}^{\frac{1}{2}}_{\infty,1}} + \|\theta_{n+1}\|_{L^1_T\dot{B}^1_{\infty,1}} \leq 2\varepsilon_0. \tag{28}$$

The existence of $T > 0$ is due to the Lebesgue theorem.

Hence, by using the estimate

$$\int_0^T \|\nabla v(\tau)\|_{L^\infty}d\tau \lesssim \int_0^T \|\theta(\tau)\|_{\dot{B}^1_{\infty,1}}d\tau$$

and Theorem 1.2, we obtain

$$\|\theta_{n+1}\|_{\widetilde{L}^\infty_T\dot{B}^0_{\infty,1}} \lesssim \|\theta^0\|_{\dot{B}^0_{\infty,1}}.$$

Thus we prove that the sequence $(v_n,\theta_n)_{n\in\mathbb{N}}$ is uniformly bounded in the space $\widetilde{L}^\infty_T\dot{B}^0_{\infty,1}\cap L^1_T\dot{B}^1_{\infty,1}$.

Step 2: *Strong convergence.* We will prove that (v_n,θ_n) is a Cauchy sequence in $\widetilde{L}^\infty_T\dot{B}^0_{\infty,1}$. Let $(n,m)\in\mathbb{N}^2$, $\theta_{n,m} =: \theta_{n+1}-\theta_{m+1}$, and $v_{n,m} := v_n - v_m$; then

$$\begin{cases} \partial_t\theta_{n,m} + v_n\cdot\nabla\theta_{n,m} + |\mathrm{D}|\theta_{n,m} = -v_{n,m}\cdot\nabla\theta_{m+1}, \\ \theta_{n,m_{|t=0}} = 0. \end{cases}$$

Applying Theorem 1.2 to this equation gives

$$\|\theta_{n,m}\|_{\widetilde{L}^\infty_t \dot{B}^0_{\infty,1}} \leq Ce^{C\|\theta_n\|_{L^1_t \dot{B}^1_{\infty,1}}} \int_0^t \|v_{n,m}\cdot\nabla\theta_{m+1}(\tau)\|_{\dot{B}^0_{\infty,1}} d\tau. \tag{29}$$

Thanks to Bony's decomposition [1], the embedding $\dot{B}^0_{\infty,1} \hookrightarrow L^\infty$, and the fact that $\operatorname{div} v_{n,m} = 0$,

$$\|v_{n,m}\cdot\nabla\theta_{m+1}\|_{\dot{B}^0_{\infty,1}} \lesssim \|v_{n,m}\|_{\dot{B}^0_{\infty,1}} \|\theta_{m+1}\|_{\dot{B}^1_{\infty,1}}. \tag{30}$$

Since Riesz transforms continuously map $\dot{B}^0_{\infty,1}$ into itself, we get

$$\|v_{n,m}\cdot\nabla\theta_{m+1}\|_{\dot{B}^0_{\infty,1}} \lesssim \|\theta_{n-1,m-1}\|_{\dot{B}^0_{\infty,1}} \|\theta_{m+1}\|_{\dot{B}^1_{\infty,1}}. \tag{31}$$

Thus we infer

$$\|\theta_{n,m}\|_{\widetilde{L}^\infty_t \dot{B}^0_{\infty,1}} \leq C\|\theta_{n-1,m-1}\|_{\widetilde{L}^\infty_t \dot{B}^0_{\infty,1}} e^{C\|\theta_n\|_{L^1_t \dot{B}^1_{\infty,1}}} \int_0^t \|\theta_{m+1}(\tau)\|_{\dot{B}^1_{\infty,1}} d\tau.$$

According to the inequality (28) one can choose ε_0 small such that

$$\|\theta_{n,m}\|_{\widetilde{L}^\infty_T \dot{B}^0_{\infty,1}} \leq \eta\|\theta_{n-1,m-1}\|_{\widetilde{L}^\infty_T \dot{B}^0_{\infty,1}}$$

with $\eta < 1$. Let us suppose that $n \geq m$; then by induction one finds

$$\|\theta_{n,m}\|_{\widetilde{L}^\infty_T \dot{B}^0_{\infty,1}} \lesssim \eta^m \|\theta^0\|_{\dot{B}^0_{\infty,1}}.$$

Thus $(\theta_n)_{n\in\mathbb{N}}$ is a Cauchy sequence in $\widetilde{L}^\infty_T \dot{B}^0_{\infty,1}$. Then there exists $\theta \in \widetilde{L}^\infty_t \dot{B}^0_{\infty,1}$ such that θ_n converges strongly to θ in $\widetilde{L}^\infty_t \dot{B}^0_{\infty,1}$. Moreover, the Fatou lemma and inequality (28) imply that $\theta \in L^1_t \dot{B}^1_{\infty,1}$. These pieces of information allow us to pass to the limit into the equation.

Step 3: *Uniqueness.* Let $X_T := L^\infty_T \dot{B}^0_{\infty,1} \cap L^1_T \dot{B}^1_{\infty,1}$, and θ_i, $i = 1, 2$ (v_i the corresponding velocity), be two solutions of the $(\mathrm{QG})_\alpha$ equation with the same initial data and belonging to the space X_T. We set $\theta_{1,2} = \theta_1 - \theta_2$ and $v_{1,2} = v_1 - v_2$; then it is plain that

$$\partial_t\theta_{1,2} + v^1\cdot\nabla\theta_{1,2} + |\mathrm{D}|\theta_{1,2} = -v_{1,2}\cdot\nabla\theta^2, \quad \theta_{1,2}{}_{|t=0} = 0.$$

Thanks to the inequalities (29) and (31), we have

$$\|\theta_{1,2}\|_{\widetilde{L}^\infty_t \dot{B}^0_{\infty,1}} \leq Ce^{C\|\theta_1\|_{L^1_t \dot{B}^1_{\infty,1}}} \int_0^t \|\theta_{1,2}\|_{\widetilde{L}^\infty_\tau \dot{B}^0_{\infty,1}} \|\theta_2(\tau)\|_{\dot{B}^1_{\infty,1}} d\tau.$$

Thus Gronwall's inequality gives the desired result.

Step 4: *Smoothing effect.* We will show the precise estimate: $\forall\, \beta \in \mathbb{R}_+$ we have

$$\|t^\beta\theta(t)\|_{\widetilde{L}^\infty_T \dot{B}^\beta_{\infty,1}} \leq C_\beta e^{C(\beta+1)\|\theta\|_{L^1_T \dot{B}^1_{\infty,1}}} \|\theta\|_{\widetilde{L}^\infty_T \dot{B}^0_{\infty,1}}. \tag{32}$$

It is clear that

$$\begin{cases} \partial_t(t^\beta\theta) + v\cdot\nabla(t^\beta\theta) + |\mathrm{D}|(t^\beta\theta) = \beta t^{\beta-1}\theta, \\ (t^\beta\theta)_{|t=0} = 0. \end{cases}$$

We will proceed by induction and start the proof with the case $\beta \in \mathbb{N}$.

For $\beta = 1$, we apply Theorem 1.2 with $\bar{r} = +\infty$,

$$\|t\theta(t)\|_{\widetilde{L}^\infty_T \dot{B}^1_{\infty,1}} \lesssim e^{C\|\theta\|_{L^1_T \dot{B}^1_{\infty,1}}} \|\theta\|_{\widetilde{L}^\infty_T \dot{B}^0_{\infty,1}}.$$

Assume that (32) holds for degree n; we will prove it for $n+1$.

Applying Theorem 1.2 to the equation of $t^{n+1}\theta$, we get

$$\begin{aligned}\|t^{n+1}\theta(t)\|_{\widetilde{L}^\infty_T \dot{B}^{n+1}_{\infty,1}} &\le C(n+1) e^{C\|\theta\|_{L^1_T \dot{B}^1_{\infty,1}}} \|t^n\theta\|_{\widetilde{L}^\infty_T \dot{B}^n_{\infty,1}} \\ &\le C_n e^{C(n+2)\|\theta\|_{L^1_T \dot{B}^1_{\infty,1}}} \|\theta\|_{\widetilde{L}^\infty_T \dot{B}^0_{\infty,1}}.\end{aligned}$$

For $\beta \in \mathbb{R}_+$, we have $[\beta] \le \beta < [\beta]+1$, and by interpolation, one has

$$\|t^\beta\theta\|_{\widetilde{L}^\infty_T(\dot{B}^\beta_{\infty,1})} \lesssim \Big\|t^{[\beta]}\theta\Big\|^{1+[\beta]-\beta}_{\widetilde{L}^\infty_T(\dot{B}^{[\beta]}_{\infty,1})} \Big\|t^{[\beta]+1}\theta\Big\|^{\beta-[\beta]}_{\widetilde{L}^\infty_T(\dot{B}^{[\beta]+1}_{\infty,1})}.$$

This completes the proof. □

5.2. Blowup criteria. The main result of this section is the following.

PROPOSITION 5.2. *Let T^* be the maximum local existence time of θ in $\widetilde{L}^\infty_T \dot{B}^0_{\infty,1} \cap L^1_T \dot{B}^1_{\infty,1}$. There exists an absolute constant $\varepsilon_0 > 0$ such that if $T^* < \infty$, then*

$$\liminf_{t \to T^*} (T^* - t)\|\nabla\theta(t)\|_{L^\infty} \ge \varepsilon_0.$$

Proof. From local existence theory and especially (27) we see that if $T^* < \infty$, then necessarily

$$\liminf_{t \to T^*} \sum_{q \in \mathbb{Z}} (1 - e^{-c(T^*-t)2^q})^{\frac{1}{2}} \|\theta_q(t)\|_{L^\infty} \ge \varepsilon_0;$$

otherwise we can continue the solution over T^*. It follows that

$$\liminf_{t \to T^*} \sum_{q \in \mathbb{Z}} (1 - e^{-c(T^*-t)2^q})^{\frac{1}{2}} \sup_{t \le T^*} \|\theta_q(t)\|_{L^\infty} \ge \varepsilon_0.$$

Consequently from the Lebesgue theorem we obtain

$$\|\theta\|_{\widetilde{L}^\infty_{T^*}(\dot{B}^0_{\infty,1})} = \infty.$$

Using the Bernstein inequality and the fact that $\|\theta_q\|_{L^\infty} \lesssim \|\theta^0\|_{L^\infty}$, we have

$$\begin{aligned}\varepsilon_0 &\le \liminf_{t \to T^*} \Bigg\{ \sum_{q \le N} (1 - e^{-c(T^*-t)2^q})^{\frac{1}{2}} \|\theta_q(t)\|_{L^\infty} \\ &\qquad + \sum_{q \ge N} (1 - e^{-c(T^*-t)2^q})^{\frac{1}{2}} \|\theta_q(t)\|_{L^\infty} \Bigg\} \\ &\lesssim \liminf_{t \to T^*} \Bigg\{ (T^*-t)^{\frac{1}{2}} \|\theta^0\|_{L^\infty} \sum_{q \le N} 2^{q/2} + \|\nabla\theta(t)\|_{L^\infty} \sum_{q \ge N} 2^{-q} \Bigg\} \\ &\lesssim \liminf_{t \to T^*} \Big\{ (T^*-t)\|\theta^0\|_{L^\infty} 2^N + \|\nabla\theta(t)\|_{L^\infty} 2^{-N} \Big\}.\end{aligned}$$

Choosing judiciously N, we obtain the desired result. □

5.3. Global existence. We will use the idea of [16]. Let T^* be the maximal time existence of the solution in the space $\widetilde{L}^{\infty}_{\rm loc}([0,T^*[,\dot{B}^0_{\infty,1})\cap L^1_{\rm loc}([0,T^*[,\dot{B}^1_{\infty,1})$. From the local existence, there exists $T_0>0$ such that

$$\forall t\in[0,T_0],\quad t\|\nabla\theta(t)\|_{L^\infty}\leq C\|\theta^0\|_{\dot{B}^0_{\infty,1}}.$$

Let λ be a real positive number that will be fixed later and $T_1\in\,]0,T_0[$. We define the set

$$I:=\Big\{T\in[T_1,T^*[;\forall t\in[T_1,T],\forall x\neq y\in\mathbb{R}^2,|\theta(t,x)-\theta(t,y)|<\omega_\lambda(|x-y|)\Big\},$$

where

$$\omega:\ \ \mathbb{R}_+\longrightarrow\mathbb{R}_+$$

is strictly nondecreasing, concave, $\omega(0)=0$, $\omega'(0)<+\infty$, $\lim_{\xi\longrightarrow 0^+}\omega''(\xi)=-\infty$, and

$$\omega_\lambda(|x-y|)=\omega(\lambda|x-y|).$$

The function ω is a modulus of continuity chosen as in [16]. We shall first check that I is nonempty. It suffices for this purpose to prove that T_1 belongs to I under suitable conditions over λ. Let C_0 be a large positive number such that

$$\omega(C_0)>2\|\theta^0\|_{L^\infty}. \tag{33}$$

Since ω is a strictly nondecreasing function, then we get from the maximum principle that

$$\forall x,y,\quad \lambda|x-y|\geq C_0\Rightarrow|\theta(T_1,x)-\theta(T_1,y)|\leq 2\|\theta^0\|_{L^\infty}<\omega_\lambda(|x-y|).$$

On the other hand, we have from the mean value theorem

$$|\theta(T_1,x)-\theta(T_1,y)|\leq|x-y|\|\nabla\theta(T_1)\|_{L^\infty}.$$

Let $0<\delta_0<C_0$. Then using the concavity of ω, one obtains

$$\lambda|x-y|\leq\delta_0\Rightarrow\omega_\lambda(|x-y|)\geq\frac{\omega(\delta_0)}{\delta_0}\lambda|x-y|.$$

If we choose λ so that

$$\lambda>\frac{\delta_0}{\omega(\delta_0)}\|\nabla\theta(T_1)\|_{L^\infty},$$

then we get

$$0<\lambda|x-y|\leq\delta_0\Rightarrow|\theta(T_1,x)-\theta(T_1,y)|<\omega_\lambda(|x-y|).$$

Let us now move to the case $\delta_0\leq\lambda|x-y|\leq C_0$. By an obvious computation we find

$$|\theta(T_1,x)-\theta(T_1,y)|\leq\frac{C_0}{\lambda}\|\nabla\theta(T_1)\|_{L^\infty}\quad\text{and}$$

$$\omega(\delta_0)\leq\omega(\lambda|x-y|).$$

Choosing λ such that

$$\lambda > \frac{C_0}{\omega(\delta_0)}\|\nabla\theta(T_1)\|_{L^\infty},$$

then we obtain

$$\delta_0 \leq \lambda|x-y| \leq C_0 \Rightarrow |\theta(T_1,x)-\theta(T_1,y)| < \omega_\lambda(|x-y|).$$

All the preceding conditions over λ can be obtained if we take

$$\lambda = \frac{\omega^{-1}(3\|\theta^0\|_{L^\infty})}{2\|\theta^0\|_{L^\infty}}\|\nabla\theta(T_1)\|_{L^\infty}. \tag{34}$$

From the construction, the set I is an interval of the form $[T_1, T_*)$. We have three possibilities. The first one is $T_* = T^*$, and in this case we must have $T^* = +\infty$ because the Lipschitz norm of θ does not blow up. The second one is $T_* \in I$, and we will show that is not possible. Indeed, let C_0 be as in (33); then $\forall\ t \in [T_1, T^*)$

$$\lambda|x-y| \geq C_0 \Rightarrow |\theta(t,x)-\theta(t,y)| < \omega_\lambda(|x-y|).$$

Since $\nabla\theta(t)$ belongs to $C(]0,T^*); \dot{B}^0_{\infty,1})$, then for $\epsilon > 0$ there exist $\eta_0, R > 0$ such that

$$\forall t \in [T_*, T_*+\eta_0] \Rightarrow \|\nabla\theta(t)\|_{L^\infty} \leq \|\nabla\theta(T_*)\|_{L^\infty} + \epsilon/2 \quad \text{and}$$

$$\|\nabla\theta(T_*)\|_{L^\infty(B^c_{(0,R)})} \leq \epsilon/2,$$

where $B_{(0,R)}$ is the ball of radius R and with center the origin.

Hence for $\lambda|x-y| \leq C_0$ and x or $y \in B^c_{(0,R+\frac{C_0}{\lambda})}$ we have for $t \in [T_*, T_*+\eta_0]$

$$\begin{aligned}|\theta(t,x)-\theta(t,y)| &\leq |x-y|\|\nabla\theta(t)\|_{L^\infty(B^c_{(0,R)})}\\ &\leq \epsilon|x-y|.\end{aligned}$$

On the other hand, from the concavity of ω we have

$$\lambda|x-y| \leq C_0 \Rightarrow \frac{\omega(C_0)}{C_0}\lambda|x-y| \leq \omega_\lambda(|x-y|).$$

Thus if we take ϵ sufficiently small such that

$$\epsilon < \frac{\omega(C_0)}{C_0}\lambda,$$

then we find that

$$\lambda|x-y| \leq C_0,\ x \text{ or } y \in B^c_{(0,R+\frac{C_0}{\lambda})} \Rightarrow |\theta(t,x)-\theta(t,y)| < \omega_\lambda(|x-y|).$$

It remains to study the case where $x, y \in B_{(0,R+\frac{C_0}{\lambda})}$. Since $\|\nabla^2\theta(T_*)\|_{L^\infty}$ is finite (see Proposition 5.1), we get for each $x \in \mathbb{R}^2$

$$|\nabla\theta(T_*,x)| < \lambda\omega'(0).$$

For the proof, see [16, p. 3]. From the continuity of $x \longmapsto |\nabla\theta(T_*, x)|$ we obtain

$$\|\nabla\theta(T_*)\|_{L^\infty(B_{(0,R+\frac{C_0}{\lambda})})} < \lambda\omega'(0).$$

Let $\delta_0 \ll 1$; then using the continuity in time of the quantity $\|\nabla\theta(t)\|_{L^\infty}$, one can find $\eta_1 > 0$ such that $\forall t \in [T_*, T_* + \eta_1]$

$$\|\nabla\theta(t)\|_{L^\infty(B_{(0,R+\frac{C_0}{\lambda})})} < \lambda\frac{\omega(\delta_0)}{\delta_0}.$$

For $\lambda|x-y| \le \delta_0$ and $x \neq y$ belonging together to $B_{(0,R+\frac{C_0}{\lambda})}$ we have

$$\begin{aligned}|\theta(t,x) - \theta(t,y)| &\le |x-y|\|\nabla\theta(t)\|_{L^\infty(B_{(0,R+\frac{C_0}{\lambda})})} \\ &< \lambda|x-y|\frac{\omega(\delta_0)}{\delta_0} \le \omega_\lambda(|x-y|).\end{aligned}$$

Now for the other case we have

$$\forall x, y \in B_{(0,R+\frac{C_0}{\lambda})}, \quad \delta_0 \le \lambda|x-y|; \quad |\theta(T_*,x) - \theta(T_*,y)| < \omega_\lambda(|x-y|);$$

then we get from a standard compact argument the existence of $\eta_2 > 0$ such that $\forall\ t \in [T_*, T_* + \eta_2]$

$$\forall x, y \in B_{(0,R+\frac{C_0}{\lambda})}, \quad \delta_0 \le \lambda|x-y|; \quad |\theta(t,x) - \theta(t,y)| < \omega_\lambda(|x-y|).$$

Taking $\eta = \min\{\eta_0, \eta_1, \eta_2\}$, we obtain that $T_* + \eta \in I$, which contradicts the fact that T_* is maximal.

The last case that we have to treat is that T_* does not belong to I. Thus we have by the time continuity of θ the existence of $x \neq y$ such that

$$\theta(T_*, x) - \theta(T_*, y) = \omega_\lambda(\xi), \quad \text{with} \quad \xi = |x-y|.$$

We will show that this scenario cannot occur, and more precisely

$$f'(T_*) < 0, \quad \text{where} \quad f(t) = \theta(t,x) - \theta(t,y).$$

This is impossible since $f(t) \le f(T_*)\ \forall t \in [0, T_*]$. The proof is the same as in [16], but for the convenience of the reader we will outline the proof. From the regularity of the solution we see that $(\mathrm{QG})_\alpha$ can be defined in the classical manner and

$$f'(T_*) = (u\cdot\nabla\theta)(T_*,x) - (u\cdot\nabla\theta)(T_*,y) + |\mathrm{D}|\theta(T_*,x) - |\mathrm{D}|\theta(T_*,y).$$

From [16] we have

$$(u\cdot\nabla\theta)(T_*,x) - (u\cdot\nabla\theta)(T_*,y) \le \Omega_\lambda(\xi)\omega'_\lambda(\xi),$$

where

$$\Omega_\lambda(\xi) = C\left(\int_0^\xi \frac{\omega_\lambda(\eta)}{\eta}d\eta + \xi\int_\xi^\infty \frac{\omega_\lambda(\eta)}{\eta^2}d\eta\right) = \Omega(\lambda\xi).$$

Again from [16],

$$|\mathrm{D}|\theta(T_*,x)-|\mathrm{D}|\theta(T_*,y)\le \frac{1}{\pi}\int_0^{\frac{\xi}{2}}\frac{\omega_\lambda(\xi+2\eta)+\omega_\lambda(\xi-2\eta)-2\omega_\lambda(\xi)}{\eta^2}d\eta$$
$$+\frac{1}{\pi}\int_{\frac{\xi}{2}}^{\infty}\frac{\omega_\lambda(2\eta+\xi)-\omega_\lambda(2\eta-\xi)-2\omega_\lambda(\xi)}{\eta^2}d\eta$$
$$\le \lambda\,\mathcal{I}(\lambda\xi),$$

where

$$\mathcal{I}(\xi)=\frac{1}{\pi}\int_0^{\frac{\xi}{2}}\frac{\omega(\xi+2\eta)+\omega(\xi-2\eta)-2\omega(\xi)}{\eta^2}d\eta$$
$$+\frac{1}{\pi}\int_{\frac{\xi}{2}}^{\infty}\frac{\omega(2\eta+\xi)-\omega(2\eta-\xi)-2\omega(\xi)}{\eta^2}d\eta.$$

Thus we get

$$f'(T_*)=\lambda(\Omega\omega'+\mathcal{I})(\lambda\xi).$$

Now, we choose the same function as [16] (see p. 5):

$$\omega(\xi)=\xi-\xi^{\frac{3}{2}}\quad \text{if } \xi\in[0,\delta],$$

and

$$\omega'(\xi)=\frac{\gamma}{\xi(4+\log(\xi/\delta))}\quad \text{if } \xi>\delta,$$

where δ and γ are small numbers and satisfy $0<\gamma<\delta$. It is shown in [16] that

$$\Omega(\xi)\omega'(\xi)+\mathcal{I}(\xi)<0\qquad \forall\xi\neq 0.$$

This yields $f'(T_*)<0$.

Finally we have $T^*=+\infty$ and

$$\forall t\in[T_1,+\infty),\quad \|\nabla\theta(t)\|_{L^\infty}\le\lambda.$$

The value of λ is given by (34).

A Γ-CONVERGENCE RESULT FOR THIN MARTENSITIC FILMS IN LINEARIZED ELASTICITY*

PETER HORNUNG†

Abstract. The elastic energy of a thin film Ω_h of thickness h with displacement $u : \Omega_h \to \mathbb{R}^3$ is given by the functional $E^h(u) = \int_{\Omega_h} W(\nabla u)$. We consider materials whose energy density W is linearly frame indifferent and vanishes on two linearized wells which are compatible in the plane but incompatible in the thickness direction. We prove compactness of displacement sequences $u^{(h)} : \Omega_h \to \mathbb{R}^3$ satisfying $E^h(u^{(h)}) \leq Ch^2$, and we derive the Γ-limit of the functionals $\frac{1}{h^2}E^h$ as $h \to 0$.

Key words. singular variational problems, thin films, martensitic phase transitions, Γ-convergence

1. Introduction.

The study of solid-solid phase transitions in thin elastic films leads to functionals of the form

$$E^h(v) = \int_{\Omega_h} W(\nabla v(x))\, dx, \tag{1}$$

where $\Omega_h = S \times (-\frac{h}{2}, \frac{h}{2})$ is a cylindrical domain of thickness h, $S \subset \mathbb{R}^2$ is a bounded Lipschitz domain, $v : \Omega_h \to \mathbb{R}^3$ is the elastic deformation (in the nonlinear setting) or the displacement (in the linearized setting), and W is a free energy density with n energy minima F_i, i.e., $W(F_i) = 0$ for $i = 1, \ldots, n$. In the context of nonlinear elasticity W is invariant under proper rotations, and in the context of linearized elasticity it is invariant under addition of skew symmetric matrices. In [10] it was observed (in the context of nonlinear elasticity) that for many materials which undergo austenite-martensite phase transitions, the low-energy states of very thin samples of material display a much richer variety of structures than bulk samples made of the same material. The reason is that three dimensional compatibility requires a plane on which two juxtaposed affine deformations coincide, i.e., that their gradients be rank-one connected. In contrast, two dimensional compatibility is already satisfied if there exists one in-plane vector on which the two deformations agree, so a rank-two connection between the gradients suffices. This fact leads to the existence of many nontrivial low-energy states, including laminates, tunnels, and tents; see, e.g., [11] for experimental results. This rich structure makes thin martensitic films particularly interesting for applications.

In this article we study the asymptotic behavior of thin martensitic films in the context of linearized elasticity. In our model the zero set of the energy density W consists of two linearized wells which are incompatible in bulk but compatible in the plane (see section 2 for details). We study the asymptotic behavior of the functionals (1) in the thin film-limit $h \to 0$. We prove compactness of displacement sequences

†Fachbereich Mathematik, Universität Duisburg-Essen, Lotharstrasse 65, 47057 Duisburg, Germany (peter.hornung@uni-due.de).

whose energy scales like h^2, and we derive the Γ-limit of the functionals $\frac{1}{h^2}E^h$ as the film thickness h converges to zero. To our knowledge this is the first Γ-convergence result for thin martensitic films in which both the domain and the image space are three dimensional and no interfacial energy term is added to the elastic energy. In our model, the formation of interfaces is penalized in a natural way by the interplay of nonzero film thickness with incompatibility of the energy wells in the thickness direction.

Thin films of single-well materials have been studied, e.g., in [1, 3, 12, 17] (in a linearized setting) and in [34, 13, 28, 29] (in a nonlinear setting). Thin films of multiwell materials have been studied, e.g., in [19] (in a linearized setting) and in [37, 10, 15, 6] (in a nonlinear setting).

To state our main result let us introduce the functionals

$$I^h(u;S) = \begin{cases} \frac{1}{h^2}\int_{S\times(-\frac{h}{2},\frac{h}{2})} W(\nabla u(x))\,dx & \text{if } u \in W^{1,2}(S\times(-\frac{h}{2},\frac{h}{2});\mathbb{R}^3), \\ +\infty & \text{otherwise} \end{cases}$$

and

$$I^0(w;S) = \begin{cases} \int_J k(\nu(x))d\mathcal{H}^1(x) & \text{if } w \in \mathcal{A}(S), \\ +\infty & \text{otherwise,} \end{cases}$$

where the class $\mathcal{A}(S)$ of admissible limiting displacements is given in (30) below, J denotes the jump set of $\operatorname{sym}\nabla' w \in BV$, and ν denotes the normal to it, which can assume only two values (up to a sign). The function k is a "surface tension" which depends on the normal and which we define in (29) below. Let us write v' to denote the first two entries of $v \in \mathbb{R}^3$, and let us call a domain $S \subset \mathbb{R}^2$ strictly star-shaped if there is $z \in S$ such that for all $z' \in \bar{S}$ the open segment (z, z') is contained in S. Our main result is the following theorem.

THEOREM 1. *Let $A, B \in \mathbb{R}^{3\times 3}$ satisfy* (i)–(iv) *from section* 2, *let W satisfy the conditions* (4)–(6) *below, and let $S \subset \mathbb{R}^2$ be a bounded strictly star-shaped Lipschitz domain. Then a Γ-type convergence $I^h(\cdot;S) \xrightarrow{\Gamma} I^0(\cdot;S)$ holds in the following sense:*

(i) Ansatz-free lower bound. *Let $w \in L^2(S;\mathbb{R}^2)$, $h_n \to 0$, let $v_n \in W^{1,2}(S\times(-\frac{h_n}{2},\frac{h_n}{2});\mathbb{R}^3)$, and set $w_n(x') = \frac{1}{h_n}\int_{-\frac{h_n}{2}}^{\frac{h_n}{2}} v_n'(x',x_3)\,dx_3$. If $w_n \to w$ in $L^2(S;\mathbb{R}^2)$, then $\liminf_{n\to\infty} I^{h_n}(v_n;S) \geq I^0(w;S)$.*

(ii) Existence of recovery sequences. *Let $w \in L^2(S;\mathbb{R}^2)$ and $h_n \to 0$. Then there is a sequence $v_n \in W^{1,2}(S\times(-\frac{h_n}{2},\frac{h_n}{2});\mathbb{R}^3)$ such that, setting $w_n(x') = \frac{1}{h_n}\int_{-\frac{h_n}{2}}^{\frac{h_n}{2}} v_n'(x',x_3)\,dx_3$, we have $w_n \to w$ strongly in $W^{1,2}(S;\mathbb{R}^2)$ and $\lim_{n\to\infty} I^{h_n}(v_n;S) = I^0(w;S)$.*

Remarks. (i) Theorem 1 is complemented by a compactness result for sequences v_n whose energy $E^{h_n}(v_n)$ scales like h_n^2 (Theorem 6 below).

(ii) Notice that in Theorem 1(ii) we state the existence of recovery sequences for any given sequence $h_n \to 0$.

(iii) The vertical average w_n can be interpreted as the in-plane displacement of the midplane S of the thin film; compare, e.g., [3].

(iv) The lower bound (i) is true for general (also non–star-shaped) Lipschitz domains S; see Theorem 12. Star-shapedness is used in the proof of the upper bound (ii) to show that limiting displacements with finitely many well-separated interfaces are energy dense and to avoid the necessity of a lateral matching of two local recovery sequences. The same technical difficulty concerning non–star-shaped domains occurs

in [19, 20] and in [18]. A figure depicting the problematic situation can be found in [18, Figure 4].

(v) The Γ-limit obtained in Theorem 1 has the same structure as that derived in [19]. The reason is that the functionals I^h are related to singularly perturbed functionals of the form

$$J^{(\varepsilon)}(u;S) = \int_S \frac{1}{\varepsilon} W_{2D}(\nabla u(x')) + \varepsilon |\nabla^2 u(x')|^2 \, dx'. \tag{2}$$

The asymptotic behavior of singularly perturbed functionals has been extensively studied in the literature (see [35, 27, 26, 5, 38] and, for gradient phase transitions, see [25, 18, 19, 20]). Recently, Conti and Schweizer derived the Γ-limit of the functionals (2) both under the assumption of linearized frame indifference [19] and under nonlinear frame indifference [20] of W_{2D}. Their results are restricted to two dimensions.

There are two crucial differences between functionals of the form (2) and the model studied in this article: In the former the domain and the image space are two dimensional and an extra term $\int |\nabla^2 u|^2$, weighted with some small parameter ε^2, is added to the elastic energy. The role of this term is to penalize the formation of phase interfaces. In our model (1), the domain and the image space are genuinely three dimensional and the energy functional does not involve higher derivatives: It is a key property of our model that no interfacial energy contribution is added to the elastic energy (this also contrasts with other thin film models [10, 37, 6]). The formation of phase interfaces is naturally penalized by the interplay of nonzero film thickness with the fact that the zero energy displacements $A + \text{Skew}$ and $B + \text{Skew}$ are incompatible in the thickness direction.

Lemma 14 makes the relation between (1) and (2) more precise. This requires a subtle mollification argument since (2) requires control on the second derivatives. Lemma 14 suggests that the small parameter ε should be interpreted as the film thickness h.

(vi) No nonlinear version of Theorem 1 has yet been proven. The only result in this direction is [15], where it is shown that the energy of thin-film deformations consisting of two phases scales like h^2. Notice that, in contrast to the linearized setting, the model considered in [20] would not be appropriate to describe thin martensitic films since it is too rigid. Nonlinearly elastic rods of multiphase materials were studied in [36].

This article is organized as follows. In section 2 we introduce some definitions and reduce the problem to a canonical form. Then we prove a two-well analogue of Korn's inequality, Theorem 3, which applies to incompatible linear wells. Then we apply this result to deduce the compactness result Theorem 6. In section 3 we obtain the lower bound, Theorem 12, by an abstract scaling argument. Finally, in section 4 we derive the upper bound by constructing three dimensional recovery sequences. The proof of Theorem 1 closes section 4.

Notation. We use the letter C to denote constants depending only on the domain and on W. Within an expression the explicit value of C may change from line to line. A bar above a given 3×3 matrix denotes its upper left 2×2 submatrix, and in general we use barred letters to denote 2×2 matrices. Primes on 3-vectors will denote the 2-vector consisting of the first two entries, so in particular $x = (x', x_3)$. For a matrix A we write $\operatorname{sym} A = \frac{1}{2}(A + A^T)$, $\operatorname{skew} A = \frac{1}{2}(A - A^T)$, and $|A|^2 = \operatorname{Tr}(A^T A)$, where Tr denotes the trace. By a subscript $_i$ we will denote the partial derivative with respect to the x_i-variable. By ∇' we denote the in-plane gradient, that is, $\nabla' w = (w_{,1}|w_{,2})$. For $h > 0$ we set $I_h = (-\frac{h}{2}, \frac{h}{2})$. All intervals in this article are implicitly assumed to

be nonempty and bounded. We use a dashed integral sign $\fint$ to denote the average. Often we will simply write $\{f = a\}$ instead of $\{x \in S : f(x) = a\}$. For $\rho > 0$ we set $[\rho] = \max\{n \in \mathbb{N} : n \le \rho\}$. If $E \subset \mathbb{R}^n$, then $|E|$ denotes its n dimensional Lebesgue measure and $\mathcal{H}^k(E)$ its k dimensional Hausdorff measure [24]. For $j \in \{1, 2\}$ we denote by e_j the jth unit vector, by $\pi_j : \mathbb{R}^2 \to \operatorname{span}\{e_j\}$ the orthogonal projection onto $\operatorname{span}\{e_j\}$, and by $\pi_j^\perp : \mathbb{R}^2 \to \{e_j\}^\perp$ the orthogonal projection onto $\{e_j\}^\perp$. If $E \subset \mathbb{R}^n$, then $B_\varepsilon(E) = \{x \in \mathbb{R}^n : \operatorname{dist}_E(x) < \varepsilon\}$.

2. Preliminaries and compactness. We consider the functional, defined for any Lipschitz domain $U \subset \mathbb{R}^2$,

$$I^h(u; U) = \begin{cases} \frac{1}{h^2} \int_{U \times I_h} W(\nabla u(x))\, dx & \text{if } u \in W^{1,2}(U \times I_h; \mathbb{R}^3), \\ +\infty & \text{otherwise.} \end{cases} \tag{3}$$

Throughout this article, W is assumed to satisfy the following conditions:

$$W : \mathbb{R}^{3\times 3} \to \mathbb{R} \text{ is continuous,} \tag{4}$$

$$\text{linearized frame indifference: } W(F) = W(\operatorname{sym} F) \text{ for all } F \in \mathbb{R}^{3\times 3}, \tag{5}$$

$$\text{quadratic growth and coercivity: } c_0 W_0(F) \le W(F) \le C_0 W_0(F), \tag{6}$$

where c_0, C_0 are positive constants. Here we have introduced the standard energy density $W_0(F) = \operatorname{dist}^2(\operatorname{sym} F, \{A, B\})$, where A and B are symmetric 3×3 matrices to be specified below. We define the reduced functional

$$I^h_{2D}(w; U) = \begin{cases} \int_U \frac{1}{h} W_{2D}(\nabla' w) + h|\nabla'^2 w|^2 & \text{if } w \in W^{2,2}(U; \mathbb{R}^2), \\ +\infty & \text{otherwise,} \end{cases}$$

where $W_{2D}(\bar F) = \operatorname{dist}^2(\operatorname{sym} \bar F, \{\bar A, \bar B\})$. We make the following assumptions on the wells A and B:

(i) $A \in \mathbb{R}^{3\times 3}$ and $B \in \mathbb{R}^{3\times 3}$ are symmetric; i.e., $A = \operatorname{sym} A$ and $B = \operatorname{sym} B$.

(ii) *Incompatibility in bulk.* $\operatorname{rank}(A - B + T) \ge 2$ for all $T \in \mathbb{R}^{3\times 3}$ with $\operatorname{sym} T = 0$.

(iii) *Compatibility in the plane.* There exists $\bar T \in \mathbb{R}^{2\times 2}$ with $\operatorname{sym} \bar T = 0$ such that $\operatorname{rank}(\bar A - \bar B + \bar T) \le 1$.

(iv) *Nondegeneracy.* $\det(\bar A - \bar B) \ne 0$.

Item (iii) is satisfied if and only if there exists $t \in \mathbb{R}$ such that

$$0 = \det\left(\bar A - \bar B + \begin{pmatrix} 0 & t \\ -t & 0 \end{pmatrix}\right) = \det(\bar A - \bar B) + t^2,$$

whence (iii) is equivalent to $\det(\bar A - \bar B) \le 0$ with equality if and only if $\bar A$ and $\bar B$ are rank-one connected. Thus (iii) and (iv) together are equivalent to $\det(\bar A - \bar B) < 0$. Table 11.1 in [7] shows that conditions (i)–(iv) are generically satisfied by real materials (in a linearized framework).

Let us now reduce the set of all matrices satisfying (i)–(iv) to a canonical form. Let $\tilde A$, $\tilde B$ satisfy conditions (i)–(iv) but be arbitrary otherwise. Then there is an orthogonal matrix $R \in O(3)$ with $Re_3 = e_3$ such that

$$R^T(\tilde B - \tilde A)R = \lambda_1 e_1 \otimes e_1 + \lambda_2 e_2 \otimes e_2 + \sum_{i=1}^{3} \tilde\mu_i \frac{e_i \otimes e_3 + e_3 \otimes e_i}{2},$$

where λ_i are the eigenvalues of the matrix $\bar{B} - \bar{A}$ and $\tilde{\mu}_i$ are some real numbers. By possibly choosing R differently (by interchanging the first two columns), we may assume that $\lambda_1 \geq \lambda_2$, so since $\det(\bar{A} - \bar{B}) < 0$, we must in fact have $\lambda_1 > 0 > \lambda_2$. Let $Q = \operatorname{diag}(|\lambda_1|^{-\frac{1}{2}}, |\lambda_2|^{-\frac{1}{2}}, 1)$ and set $\hat{B} = QR^T(\tilde{B} - \tilde{A})RQ$. This gives $\hat{B} = e_1 \otimes e_1 - e_2 \otimes e_2 + \sum_{i=1}^{3} \hat{\mu}_i \frac{e_i \otimes e_3 + e_3 \otimes e_i}{2}$, where $\hat{\mu}_i$ are related to $\tilde{\mu}_i$ and λ_i. Now we can find a proper rotation $\hat{Q} \in SO(3)$ with eigenvector e_3 such that

$$B = \hat{Q}^T \hat{B} \hat{Q} = e_1 \otimes e_2 + e_2 \otimes e_1 + \sum_{i=1}^{3} \mu_i \frac{e_i \otimes e_3 + e_3 \otimes e_i}{2} \tag{7}$$

for some $\mu_i \in \mathbb{R}$. Since the structural assumptions on the energy density W and on the shape of the domain (i.e., strict star-shapedness with respect to the origin and a cylindrical form $S \times I_h$) are invariant under the transformations introduced above, we obtain the following lemma.

LEMMA 2. *If Theorem* 1 *is shown for the special pairs A, B given by $A = 0$ and B as in* (7)*, then it holds for all possible choices of A and B which satisfy conditions* (i)–(iv).

2.1. Korn's inequality for two incompatible strains. The following theorem provides a generalization of Korn's inequality to the case of two incompatible linearized wells. A nonquantitative version of this result can be found in [22]; compare also [39, 9, 8, 21]. In [19] an example is provided which shows that no Korn-type rigidity like the one derived here can be expected in the case of two compatible wells.

THEOREM 3. *Let $\Omega \subset \mathbb{R}^n$ be a bounded connected Lipschitz domain, $n \geq 2$, and $K = (A + \mathrm{Skew}) \cup (B + \mathrm{Skew})$, where A and B are incompatible strains, i.e., $(B - A) + \mathrm{Skew}$ does not contain rank-one matrices. Then there exists a positive constant $C(\Omega, A, B)$ with the following property: For every $u \in W^{1,2}(\Omega; \mathbb{R}^n)$, there exists an associated $R \in K$ such that $\|\nabla u - R\|_{L^2(\Omega;\mathbb{R}^{n\times n})} \leq C(\Omega, A, B) \|\operatorname{dist}(\nabla u, K)\|_{L^2(\Omega;\mathbb{R}^{n\times n})}$.*

This theorem will follow from the interior estimate provided by the following lemma.

LEMMA 4. *With assumptions as in Theorem* 3 *and $\bar{U} \subset \Omega$, where U is Lipschitz and connected, there is a constant $C(U, \Omega, A, B)$ such that the following holds: For every $u \in W^{1,2}(\Omega; \mathbb{R}^n)$, there exists an associated $R \in K$ such that*

$$\|\nabla u - R\|_{L^2(U;\mathbb{R}^{n\times n})} \leq C(U, \Omega, A, B) \|\operatorname{dist}(\nabla u, K)\|_{L^2(\Omega;\mathbb{R}^{n\times n})}. \tag{8}$$

Proof. From (15) on this proof follows [14] rather closely with some minor changes. Define $d(F) = \operatorname{dist}(F, \{A, B\})$ and set $\varepsilon^2 = \int_\Omega \operatorname{dist}^2(\nabla u, K)$. Notice that $\operatorname{dist}^2(F, K) = d^2(\operatorname{sym} F)$ for all $F \in \mathbb{R}^{n\times n}$. Since $|F - A| \leq d(F) + |A - B|$, by Korn's inequality there exists $C > 0$ with the property that (8) is satisfied whenever u is such that $\varepsilon \geq 1$. Hence we may assume without loss of generality that $\varepsilon < 1$. By setting $\tilde{B} = B - A$ and applying the lemma to $\tilde{u}(x) = u(x) - Ax$ we may also assume without loss of generality that $A = 0$.

Denote by $P : \mathbb{R}^{n\times n} \to \big((\operatorname{span}\{B\}) \oplus \mathrm{Skew}\big)^\perp$ the orthogonal projection onto the orthogonal complement of the subspace $(\operatorname{span}\{B\}) \oplus \mathrm{Skew}$. Since $B + \mathrm{Skew}$ does not contain rank-one matrices, the only rank-one matrix contained in $(\operatorname{span}\{B\}) \oplus \mathrm{Skew}$ is the zero matrix. Thus $|P(a \otimes b)|^2 > 0$ for all $a, b \neq 0$. Hence, by continuity and by compactness of the sphere, P satisfies the Legendre–Hadamard ellipticity condition $\Lambda |a|^2 |b|^2 \geq |P(a \otimes b)|^2 \geq \lambda |a|^2 |b|^2$ for some $\Lambda > \lambda > 0$. Now let $w \in W^{1,2}(\Omega; \mathbb{R}^n)$ be

a weak solution of the linear elliptic system with constant coefficients

$$\text{div } P(\nabla w) = 0 \text{ in } \Omega, \tag{9}$$
$$w = u \text{ on } \partial\Omega.$$

Set $z = u - w$. Then $z \in W_0^{1,2}(\Omega; \mathbb{R}^n)$ is a weak solution of div $P(\nabla z) =$ div $P(\nabla u)$. Testing this with z gives

$$\int_\Omega P(\nabla z) : \nabla z = \int_\Omega P(\nabla u) : \nabla z \le \left(\int_\Omega |P(\nabla u)|^2 \right)^{\frac{1}{2}} \left(\int_\Omega |\nabla z|^2 \right)^{\frac{1}{2}}. \tag{10}$$

Since by ellipticity the left-hand side of (10) is greater than $\int_\Omega \lambda |\nabla z|^2$, we conclude

$$\int_\Omega |\nabla z|^2 \le C \int_\Omega |P(\nabla u)|^2 = C \int_\Omega \text{dist}^2(\text{sym } \nabla u,\ \text{span}\{B\}) \le C\varepsilon^2. \tag{11}$$

Thus it remains to prove that there exists $R \in K$ such that $\int_\Omega |\nabla w(x) - R|^2 \, dx \le C\varepsilon^2$, where C is independent of w.

Set $e_w =$ sym ∇w and let $y \in \Omega$ be such that $B(y, 2r) \subset \Omega$. By Korn's inequality there is a $C = C(n)$ (which by scaling invariance is independent of r), and $T \in \mathbb{R}^{n \times n}$ with sym $T = 0$ such that

$$\int_{B(y,2r)} |\nabla w - T|^2 \le C \int_{B(y,2r)} |e_w|^2. \tag{12}$$

Since by $P(M) = P(\text{sym } M)$ we have $P(T) = 0$, the mapping $v(x) = w(x) - Tx$ is a weak solution of

$$\text{div } P(\nabla v) = 0 \text{ in } \Omega,$$
$$v = u - Tx \text{ on } \partial\Omega. \tag{13}$$

By standard elliptic regularity for linear systems with constant coefficients (see, e.g., [30]), we obtain the inequality

$$\int_{B(y,r)} |\nabla^2 v|^2 \le \frac{C}{r^2} \int_{B(y,2r)} |\nabla v|^2 = \frac{C}{r^2} \int_{B(y,2r)} |\nabla w - T|^2. \tag{14}$$

We have $|\nabla e_w|^2 = \frac{1}{4} \sum_{i,j,k} (w_{i,jk} + w_{j,ik})^2 \le |\nabla^2 w|^2$. Hence by the choice of T and since $|\nabla^2 w|^2 = |\nabla^2 v|^2$ on $B(y, 2r)$, we conclude from (12) and (14) that

$$\int_{B(y,r)} |\nabla e_w|^2 \le \frac{C}{r^2} \int_{B(y,2r)} |e_w|^2. \tag{15}$$

This inequality holds for all $y \in \Omega$ with $B(y, 2r) \subset \Omega$.

Fix $r_0 \in (0, \frac{\text{dist}(U, \partial\Omega)}{4})$ such that there exists $c_0 > 0$ with the property that $|B_r(x) \cap U| \ge c_0 |B_r|$ for all $x \in U$ and for all $r \le r_0$. (Here and in what follows we will sometimes omit the center of the ball when denoting its volume.) Existence of such an r_0 follows from the Lipschitz property of U, and c_0 will depend on U. Covering $\bar{U}$ with finitely many balls of radius $\frac{1}{3}$ dist$(U, \partial\Omega)$ and applying (15) shows that $\int_U |\nabla e_w|^2$ is bounded by a constant independent of u (since $|e_w| \le d(e_w) + C$

and $\int_\Omega d^2(e_w) \le C\varepsilon^2$ by (11)). Hence, by applying Lemma 5 below with $K_1 = \{0\}$, $K_2 = \{B\}$, and $F = e_w$, we obtain

$$\min\left\{\int_U |e_w - B|^2, \int_U |e_w|^2\right\} \le C\left(\int_U d^2(e_w)\int_U |\nabla e_w|^2\right)^{\frac{n}{2(n-1)}} + \int_U d^2(e_w) \le C(\varepsilon^{\frac{n}{n-1}} + \varepsilon^2). \tag{16}$$

Set $\rho = \frac{|B|}{2}$, and let us assume that B is the minority phase in U; i.e., the set $E = \{x \in U : |e_w(x) - B|^2 \le \rho^2\}$ satisfies $|E| \le |\{x \in U : |e_w(x)|^2 \le \rho^2\}|$. (The case when A is the minority phase is treated similarly.) In particular, this implies $|E| \le |U \setminus E|$ by the choice of ρ. We have $\rho^2|E| \le \int_U |e_w|^2$ because $|e_w| \ge \rho$ on E, and similarly $\rho^2|E| \le \rho^2|U \setminus E| \le \int_U |e_w - B|^2$. Thus by (16), whenever $\varepsilon < 1$,

$$|E| \le C_1\left(\varepsilon^{\frac{n}{n-1}} + \varepsilon^2\right) \tag{17}$$

for some constant C_1 independent of u. Now we fix $\varepsilon_0 \in (0,1)$ such that $C_1(\varepsilon_0^{\frac{n}{n-1}} + \varepsilon_0^2) < \frac{c_0}{2}|B_{r_0}|$. From now on we assume that $\varepsilon \le \varepsilon_0$; the other case is treated at the end of this proof. From (17) we deduce that $|E| < \frac{c_0}{2}|B_{r_0}|$. Our aim is to show that

$$|E| \le C\varepsilon^2 \tag{18}$$

for a constant C independent of u. Using Lemma 5 (notice that the constant in its conclusion is invariant under a rescaling of the domain) as in (16) with B_r replacing U, and then dividing through $|B_r|$ and applying (15), one obtains

$$\min\left\{\fint_{B_r(x)} |e_w|^2, \fint_{B_r(x)} |e_w - B|^2\right\} \le C\left[\left(\mathcal{M}(|e_w|^2)(x)\fint_{B_r(x)} d^2(e_w)\right)^{\frac{n}{2(n-1)}} + \fint_{B_r(x)} d^2(e_w)\right] \tag{19}$$

for all $x \in \Omega$ and for all $r > 0$ such that $B_{2r}(x) \subset \Omega$. Here $\mathcal{M}$ denotes the Hardy–Littlewood maximal function, $\mathcal{M}(f)(x) = \sup_{r>0} \fint_{B_r(x)} |f|$. Above and in what follows we extend e_w by zero outside Ω.

Claim 1. The set $A_\infty = \{x \in \Omega : \mathcal{M}(|e_w|^2)(x) \ge 10|B|^2\}$ satisfies $|A_\infty| \le C\varepsilon^2$.

In fact, $\mathcal{M}(|e_w|^2) \le \mathcal{M}(|e_w|^2 - 5|B|^2)_+ + 5|B|^2$, whence $x \in A_\infty$ implies $\mathcal{M}(|e_w|^2 - 5|B|^2)_+(x) \ge 5|B|^2$. Since $|e_w|^2 \le 2(d^2(e_w) + |B|^2)$, we have $d^2(e_w) \ge \frac{1}{2}(|e_w|^2 - 5|B|^2)_+$. We conclude that $A_\infty \subset \{\mathcal{M}(d^2(e_w)) \ge \frac{5}{2}|B|^2\}$. Thus, by the Hardy–Littlewood maximal theorem [31, Chapter 4], $|A_\infty| \le |\{\mathcal{M}(d^2(e_w)) \ge \frac{5}{2}|B|^2\}| \le C\int_\Omega d^2(e_w)$, which proves Claim 1.

For almost every $x \in E \setminus A_\infty$ there is an $r_x \le r_0$ such that

$$\frac{|E \cap B_{r_x}(x)|}{|B_{r_x}(x)|} = \frac{c_0}{2}. \tag{20}$$

In fact, by the Lebesgue point theorem, for almost all $x \in E \setminus A_\infty$, we have $\frac{|E\cap B_r(x)|}{|B_r|} \to 1$ as $r \to 0$. On the other hand, $\frac{|E\cap B_r(x)|}{|B_r(x)|} \le \frac{|E|}{|B_r|}$, which is strictly less than $c_0/2$ for $r > r_0$ by the choice of ε_0. In particular, $B_{2r_x}(x) \subset \Omega$ for every x as above, by the choice of r_0.

By Vitali's covering theorem [24, Theorem 1, section 1.5] we can choose countably many $x_i \in E \setminus A_\infty$ satisfying (20) and such that

$$|E \setminus A_\infty| \le C \sum |B_{r_{x_i}}(x_i)| \tag{21}$$

with pairwise disjoint balls on the right-hand side. By (20) and since $|e_w|^2 \ge \rho^2$ on E and $|e_w - B|^2 \ge \rho^2$ on $U \setminus E$, for every i we have

$$\begin{aligned} \frac{c_0\rho^2}{2} &\le \frac{1}{|B_{r_{x_i}}|} \min\left\{ \int_{B_{r_{x_i}}(x_i)\cap E} |e_w|^2, \int_{B_{r_{x_i}}(x_i)\cap U\setminus E} |e_w - B|^2 \right\} \\ &\le C\left[\left(\fint_{B_{r_{x_i}}(x_i)} d^2(e_w) \right)^{\frac{n}{2n-2}} + \fint_{B_{r_{x_i}}(x_i)} d^2(e_w) \right]. \end{aligned} \tag{22}$$

For the first inequality we have used that $x_i \in U$, whence $|B_{r_{x_i}}(x_i) \cap U| \ge c_0 |B_{r_{x_i}}|$ by definition of c_0, and so $|B_{r_{x_i}}(x_i) \cap U \setminus E| \ge \frac{c_0}{2}|B_{r_{x_i}}|$ by (20). For the second inequality we have used (19) and the definition of A_∞. From (22) we have $\frac{c_0\rho^2}{2} \le 2C \max\left\{ (\fint_{B_{r_{x_i}}(x_i)} d^2(e_w))^{\frac{n}{2n-2}}, \fint_{B_{r_{x_i}}(x_i)} d^2(e_w) \right\}$. We conclude that $|B_{r_{x_i}}(x_i)| \le \max\left\{ \frac{4C}{c_0\rho^2}, \left(\frac{4C}{c_0\rho^2}\right)^{\frac{2n-2}{n}} \right\} \int_{B_{r_{x_i}}(x_i)} d^2(e_w)$. Summing over i, from the disjointedness of the $B_{r_{x_i}}(x_i)$ and from (21) we conclude that $|E \setminus A_\infty| \le C\varepsilon^2$, since $\int_\Omega d^2(e_w) \le C\varepsilon^2$ by (11). By Claim 1 this implies (18) in the case $\varepsilon \le \varepsilon_0$. But (18) also holds when $\varepsilon > \varepsilon_0$ by (17) (e.g., by choosing $C = \frac{2C_1}{\varepsilon_0^2}$ in (18); recall that $\varepsilon < 1$). Using (18) we can finally estimate

$$\int_U |e_w|^2 = \int_{U\setminus E} |e_w|^2 + \int_E |e_w|^2 \le C\left[\int_{U\setminus E} d^2(e_w) + |E| + \int_E d^2(e_w) \right] \le C\varepsilon^2.$$

The desired estimate now follows from Korn's inequality. □

The proof of Theorem 3 is completed using a cube decomposition of Ω and applying a weighted Poincaré inequality exactly as in the proof of Theorem 2 in [14]. We have used the following lemma, the proof of which is the same as that of Lemma 2.4 in [14], where one can replace ∇w throughout by an arbitrary matrix-valued $W^{1,2}$-function F.

LEMMA 5. *Let $n \ge 2$, let $\Omega \subset \mathbb{R}^n$ be a bounded and connected Lipschitz domain, and let K_1, K_2 be compact disjoint subsets of $\mathbb{R}^{n\times n}$, $K = K_1 \cup K_2$. Then there is a constant $C = C(K, \Omega)$, such that for any $F \in W^{1,2}(\Omega; \mathbb{R}^{n\times n})$*

$$\begin{aligned} \min_{i=1,2} \int_\Omega \operatorname{dist}^2(F, K_i) &\le C(K,\Omega) \left(\int_\Omega \operatorname{dist}^2(F,K) \int_\Omega |\nabla F|^2 \right)^{\frac{n}{2(n-1)}} \\ &\quad + C(K,\Omega) \int_\Omega \operatorname{dist}^2(F,K). \end{aligned}$$

2.2. Compactness. The following theorem provides the compactness result which complements the Γ-convergence result of Theorem 1. Its proof uses some facts which were derived in [15] (in order to prove a lower scaling bound in a nonlinearly elastic setting) and which in spirit are close to [28]. It is different from the Young

measure arguments used in the literature of singularly perturbed functionals (e.g., [27, 18, 19, 20]).

THEOREM 6. *Let $S \subset \mathbb{R}^2$ be a bounded Lipschitz domain, let $A, B \in \mathbb{R}^{2\times 2}$ be symmetric and such that $(B-A)+Skew$ does not contain rank-one matrices, and set $K = (A+Skew)\cup(B+Skew)$. Let $h_n \to 0$, set $\Omega_{h_n} = S \times I_{h_n}$, and suppose that a sequence $u_n \in W^{1,2}(\Omega_{h_n};\mathbb{R}^3)$ satisfies*

$$\limsup_{n\to\infty} \frac{1}{h_n^2} \int_{\Omega_{h_n}} \operatorname{dist}^2(\nabla u_n, K) < \infty. \tag{23}$$

Set $w_n(x') = \fint_{I_{h_n}} (u_n(x',x_3))'\,dx_3$. Then there exist a subsequence (not relabeled) and affine mappings $f_n : \mathbb{R}^2 \to \mathbb{R}^2$ with sym $\nabla' f_n = 0$, and there is $w_0 \in W^{1,2}(S;\mathbb{R}^2)$ satisfying sym $\nabla' w_0 \in BV(S;\{\bar A, \bar B\})$ such that $w_n + f_n \to w_0$ strongly in $W^{1,2}(S;\mathbb{R}^2)$.

Proof. For $h>0$ we consider a lattice of squares $S_{a,h} = a + (-\frac{h}{2},\frac{h}{2})^2, a \in h\mathbb{Z}^2$, and we let $S_h' = \bigcup_{\{a\in h\mathbb{Z}^2 : S_{a,h}\subset S\}} S_{a,h}$. Now apply Theorem 3 to $u^{(h)}$ (here and in what follows we write $u^{(h)}$ instead of u_n and h instead of h_n to avoid cumbersome notation) restricted to each cube $a + (-\frac{h}{2},\frac{h}{2})^3$ with $a \in h\mathbb{Z}^2$. This yields a piecewise constant map $R^{(h)} : S_h' \to K$ such that

$$\int_{S_{a,h}\times I_h} |\nabla u^{(h)}(x) - R^{(h)}(x')|^2\,dx \le C \int_{S_{a,h}\times I_h} \operatorname{dist}^2(\nabla u^{(h)}(x), K)\,dx. \tag{24}$$

Define the piecewise constant map $L^{(h)} : S_h' \to \{A,B\}$ by setting $L^{(h)}(x) = \text{sym}\ R^{(h)}(x)$. Let $\varepsilon > 0$ be sufficiently small (to be fixed below). We divide the family of squares $\{S_{a,h} : a \in h\mathbb{Z}^2 \text{ and } S_{a,h}\subset S\}$ into three different groups:

$$a \in \mathcal{A}_0^h \text{ if and only if } \int_{S_{a,h}\times I_h} \operatorname{dist}^2(\nabla u^{(h)}(x), K)\,dx \ge \varepsilon h^3. \tag{25}$$

If $a \notin \mathcal{A}_0^h$, then the matrix $L^{(h)}(a) \in \{A,B\}$ is such that $\frac{1}{h^3}\int_{S_{a,h}\times I_h} |\text{sym}\ \nabla u^{(h)} - L^{(h)}(a)|^2 \le C\varepsilon$. This follows from (24) and (25) by the definition of $L^{(h)}(a)$. Now define

$$a \in \mathcal{A}_1^h \text{ if and only if } a \notin \mathcal{A}_0^h \text{ and } L^{(h)}(a) = A,$$

$$a \in \mathcal{A}_2^h \text{ if and only if } a \notin \mathcal{A}_0^h \text{ and } L^{(h)}(a) = B. \tag{26}$$

For ε small enough, each square $S_{a,h}$ belongs to exactly one of these three groups. Thus the sets

$$\Omega_i^h = \operatorname{int}\left(\bigcup_{a\in\mathcal{A}_i^h} \bar S_{a,h}\right), \tag{27}$$

$i = 0, 1, 2$, are disjoint and cover S'_h up to an $\mathcal{H}^2$ null set. As in [15] one can prove that, for ε small enough, the following implication holds:

$$a \in \mathcal{A}_i^h, a' \in \mathcal{A}_j^h, \text{ and } \mathcal{H}^1(\bar{S}_{a',h} \cap \bar{S}_{a,h}) > 0 \implies j \in \{0, i\}, \tag{28}$$

that is, a square of type $\mathcal{A}_1^h$ can only have neighboring squares of type $\mathcal{A}_1^h$ or $\mathcal{A}_0^h$ (never of type $\mathcal{A}_2^h$), and the analogous statement holds with $\mathcal{A}_1^h$ and $\mathcal{A}_2^h$ swapped. But from (23) and from (25) we deduce $\#\mathcal{A}_0^h \le \frac{C}{h}$. Since the side-length of each square $S_{a,h}$ is h, this leads to the estimate $\mathcal{H}^1(\partial\Omega_1^h \setminus \partial S) \le C$; compare [15]. This implies that the characteristic functions $\chi_{\Omega_1^h}$ are bounded in $BV(S)$, whence they have a subsequence converging strongly in $L^1(S)$ and hence (by interpolation) in all $L^p(S)$ with $p < \infty$. Since $\#\mathcal{A}_0^h \le \frac{C}{h}$, we have $|\Omega_0^h| \le Ch$, whence $\chi_{\Omega_0^h} \to 0$ in $L^1(\mathbb{R}^2)$. Hence we also have strong $L^1(S)$-convergence of $\chi_{\Omega_2^h}$. Note that the respective limit functions, which we denote χ_{Ω_1} and χ_{Ω_2}, both belong to $BV(S)$.

On the other hand, $L^{(h)} = A\chi_{\Omega_1^h} + B\chi_{\Omega_2^h} + L^{(h)}\chi_{\Omega_0^h}$. Let us extend $L^{(h)}$ by zero to all of S. By the convergence $\chi_{S'_h} \to 1$ in $L^1(S)$ we obtain that $L^{(h)} \to L$ strongly in $L^2(S; \mathbb{R}^{2\times 2})$, where $L = \chi_{\Omega_1} A + \chi_{\Omega_2} B \in BV(S; \{A, B\})$. By (24), (23), and Jensen's inequality we have $\int_{S'_h} |\operatorname{sym} \nabla' w^{(h)} - \bar{L}^{(h)}|^2 \le Ch$. Using $L^{(h)} = 0$ on $S \setminus S'_h$ and applying Jensen's inequality, we find $\int_{S\setminus S'_h} |\operatorname{sym} \nabla' w^{(h)} - \bar{L}^{(h)}|^2 \le C|S \setminus S'_h| + Ch$. We conclude that $\operatorname{sym} \nabla' w^{(h)} \to \bar{L}$ strongly in $L^2(S; \mathbb{R}^{2\times 2})$. Since the subspace of symmetrized gradients is strongly closed in $L^2(S; \mathbb{R}^{2\times 2})$, there is a $w_0 \in W^{1,2}(S; \mathbb{R}^2)$ such that $\operatorname{sym} \nabla' w_0 = \bar{L} \in BV(S; \{\bar{A}, \bar{B}\})$. An application of Korn's and of Poincaré's inequalities on S for each h yields affine mappings $f^{(h)} : \mathbb{R}^2 \to \mathbb{R}^2$ with $\operatorname{sym} \nabla' f^{(h)} = 0$ (explicitly, e.g., $\nabla' f^{(h)} = \operatorname{skew} \fint_S \nabla'(w^{(h)} - w_0)$) such that $\|w^{(h)} + f^{(h)} - w_0\|^2_{W^{1,2}(S;\mathbb{R}^2)} \le C \int_S |\operatorname{sym} \nabla' w^{(h)} - \operatorname{sym} \nabla' w_0|^2$. This converges to zero because $\operatorname{sym} \nabla' w^{(h)} \to \bar{L}$ in $L^2(S; \mathbb{R}^{2\times 2})$. □

Remark. Let $y^{(h)}(x', x_3) = u^{(h)}(x', hx_3)$ be the rescaled displacements defined on $\Omega = S \times (-\frac{1}{2}, \frac{1}{2})$ and set $\nabla_h y = (\nabla' y | \frac{1}{h} y_{,3})$. Then the proof of Theorem 6 shows that $\operatorname{sym} \nabla_h y^{(h)} \to L$ strongly in $L^2(\Omega; \mathbb{R}^{3\times 3})$. Thus $\nabla'(y^{(h)})' \to \bar{L}$ and $y_{,3} \to 0$ strongly in L^2. If, using a scaling analogous to that in [17, section 1.3], we set $(\bar{y}^{(h)})' = (y^{(h)})'$ and $(\bar{y}^{(h)})_3 = h(y^{(h)})_3$, then Korn's inequality on Ω implies that there are affine mappings $F^{(h)} : \mathbb{R}^3 \to \mathbb{R}^3$ with $\operatorname{sym} \nabla F^{(h)} = 0$ and such that $\bar{y}^{(h)} + F^{(h)} \to F_L$ strongly in $W^{1,2}(\Omega; \mathbb{R}^3)$, where $F_L(x) = \left(\begin{smallmatrix} \bar{L}x' \\ 0 \end{smallmatrix}\right)$.

In [19, Proposition 2.2], the following characterization is provided for functions whose symmetrized gradient has bounded variation and is supported on two incompatible matrices $\bar{A}, \bar{B}$. (For earlier results in this direction, compare [23].)

PROPOSITION 7. *Let $S \subset \mathbb{R}^2$ be a bounded Lipschitz domain. Let $\bar{A}, \bar{B}$ satisfy* (iii)–(iv) *from the beginning of section* 2, *let ν_1, ν_2 be linearly independent solutions to $\bar{A} - \bar{B} + t(e_1 \otimes e_2 - e_2 \otimes e_1) = a \otimes \nu_i$, where $a \in \mathbb{R}^3$ and $t \in \mathbb{R}$, and let $w \in W^{1,2}(S; \mathbb{R}^2)$ satisfy sym $\nabla' w \in BV(S; \{\bar{A}, \bar{B}\})$. Then the jump set J of sym $\nabla' w$ consists of countably many disjoint segments whose endpoints belong to ∂S and which have normal directions ν_1 or ν_2. In addition, $\nabla' w$ is constant on each connected component of $S \setminus J$.*

3. Lower bound. In this section we prove part (i) of Theorem 1. From now on we assume that $A = 0$ and B is as in (7). This choice allows exactly two different directions for the interface normal; the directions are orthogonal to each other: Setting $T_1 = e_2 \otimes e_1 - e_1 \otimes e_2$ and $T_2 = e_1 \otimes e_2 - e_2 \otimes e_1$, we have $\bar{B} + T_1 = 2e_2 \otimes e_1$, giving the normal $\nu_1 = e_1$, and $\bar{B} + T_2 = 2e_1 \otimes e_2$, giving the normal $\nu_2 = e_2$. Notice that,

if $\bar{T} \in \mathbb{R}^{2\times 2} \setminus \{T_1, T_2\}$ with $\operatorname{sym} \bar{T} = 0$, then $\det(\bar{B} + \bar{T}) \neq 0$. Define the piecewise constant mappings $F_i^{\pm} : \mathbb{R}^2 \to \mathbb{R}^{2\times 2}$ by

$$F_i^{\pm}(x') = \begin{cases} 0 & \text{for } \pm x' \cdot \nu_i < 0, \\ \bar{B} + T_i & \text{otherwise,} \end{cases}$$

and set $w_i^{\pm}(x') = F_i^{\pm}(x')x'$; note that the jump set of $\nabla' w_i^{\pm}$ agrees with $\{\nu_i\}^{\perp}$.

DEFINITION 8. *Let $\sigma \in \{-,+\}$, $i \in \{1,2\}$, let J_1, J_2 be open intervals, and set $S = J_1 \times J_2$.*

(i) *We set $w_{i,S}^{\sigma}(x') = w_i^{\sigma}(x' - \xi e_i)$, where $\xi = \frac{1}{2}(\sup J_i - \inf J_i)$. The set $\mathcal{J}_{i,S} = S \cap (\xi\nu_i + \{\nu_i\}^{\perp})$ is called the interface of $w_{i,S}^{\sigma}$.*

(ii) *A pair of sequences (u_n, h_n) is called (σ, i)-admissible on S, provided that $h_n \in \mathbb{R}_+$, $h_n \to 0$, $u_n \in W^{1,2}(S \times I_{h_n}; \mathbb{R}^3)$, and $\fint_{I_{h_n}} u_n' \, dx_3 \to w_{i,S}^{\sigma}$ in $L^2(S; \mathbb{R}^2)$.*

(iii) *If $J_1 = \emptyset$ or $J_2 = \emptyset$, then we set $\mathcal{F}_i^{\sigma}(S) = 0$. Otherwise, we define*

$$\mathcal{F}_i^{\sigma}(S) = \inf \Big\{ \liminf_{n\to\infty} I^{h_n}(u_n; S) : \text{There exist } (h_n) \text{ and } (u_n) \text{ such that } (u_n, h_n) \text{ is } (\sigma, i)\text{-admissible on } S \Big\}.$$

We define

$$k(\nu_i) = \mathcal{F}_i^{+}\bigg(\Big(-\frac{1}{2}, \frac{1}{2}\Big) \times \Big(-\frac{1}{2}, \frac{1}{2}\Big)\bigg). \tag{29}$$

(iii) *A pair of sequences (u_n, h_n) is called a (σ, i)-recovery sequence on S, provided that (u_n, h_n) is (σ, i)-admissible on S and $\lim_{n\to\infty} I^{h_n}(u_n; S) = \mathcal{F}_i^{\sigma}(S)$.*

Remarks. (i) Our definition of $\mathcal{F}_i^{\sigma}$ differs slightly from the usual one. If one sets $\tilde{\mathcal{F}}_1^{\sigma}(J; \varepsilon) = \mathcal{F}_1^{\sigma}((-\varepsilon, \varepsilon) \times J)$ and $\tilde{\mathcal{F}}_2^{\sigma}(J; \varepsilon) = \mathcal{F}_2^{\sigma}(J \times (-\varepsilon, \varepsilon))$, then the $\tilde{\mathcal{F}}_i^{\sigma}$ correspond to the $\mathcal{F}_i^{\sigma}$ as defined, e.g., in [18, formula (4.2)].

(ii) In Lemma 13 we will show that for any *fixed* sequence $h_n \to 0$ there exist u_n such that (u_n, h_n) is a (σ, i)-recovery sequence.

(iii) When it is clear from the context which sequence $h_n \to 0$ is meant, then we will often just say that u_n is a (σ, i)-recovery sequence. Also, we will drop the prefix (σ, i) when it is clear from the context.

LEMMA 9. *Let J_1, J_2 be open intervals, set $S = J_1 \times J_2$, and let $i \in \{1,2\}$. Then $\mathcal{F}_i^{+}(S) = \mathcal{F}_i^{-}(S) = k(\nu_i)\ |\pi_i^{\perp}(S)|$. (Recall that $\pi_i^{\perp}$ denotes the orthogonal projection onto $\{e_i\}^{\perp} = \{\nu_i\}^{\perp}$.)*

Proof. Similar to [18, Lemma 4.3] or [19, Lemma 3.2], one can prove the lemma by showing the following facts. Let $J_1' \subset J_1$, $J_2' \subset J_2$ be open intervals and set $S' = J_1' \times J_2'$. Then

(i) $\mathcal{F}_i^{+}(S) = \mathcal{F}_i^{-}(S) =: \mathcal{F}_i(S)$.

(ii) Behavior under homotheties. $\mathcal{F}_i(x' + \lambda S) = \lambda \mathcal{F}_i(S)$ for all $x' \in \mathbb{R}^2$ and all $\lambda > 0$.

(iii) Monotonicity. $\mathcal{F}_i(S') \leq \mathcal{F}_i(S)$.

(iv) Concentration. $\mathcal{F}_i(S') = \mathcal{F}_i(S)$ if $|\pi_i^{\perp}(S')| = |\pi_i^{\perp}(S)|$. ∎

LEMMA 10. *Let $i \in \{1,2\}$, $\sigma \in \{+,-\}$, let J_1, J_2 be open intervals, let $\lambda > 0$, $y \in \mathbb{R}^2 \times \{0\}$, and let (v_n, h_n) be a (σ, i)-recovery sequence on $S = J_1 \times J_2$. Set $\hat{v}_n(x) = \lambda v_n(\frac{x-y}{\lambda})$ for all $n \in \mathbb{N}$. Then $(\hat{v}_n, \lambda h_n)$ is a (σ, i)-recovery sequence on $y' + \lambda S$.*

Proof. Since from Lemma 9 we have $\mathcal{F}_i^{\sigma}(y' + S) = \mathcal{F}_i^{\sigma}(S)$, we may assume without loss of generality that $y = 0$ and that S is centered about the origin. Since (v_n, h_n)

is (σ,i)-admissible on S, $(\hat{v}_n,\lambda h_n)$ is also (σ,i)-admissible on λS. By Lemma 9 and a change of variables we have $\limsup_{n\to\infty} I^{\lambda h_n}(\hat{v}_n;\lambda S)=\limsup_{n\to\infty}\lambda I^{h_n}(v_n;S)=\lambda\mathcal{F}_i^\sigma(S)=\mathcal{F}_i^\sigma(\lambda S)$. □

LEMMA 11. *Let $i\in\{1,2\}$, $\sigma\in\{+,-\}$, let J_j, J_j' be open intervals with $J_j'\subset J_j$, $j=1,2$, and set $S=J_1\times J_2$, $S'=J_1'\times J_2'$. Let (v_n,h_n) be a (σ,i)-recovery sequence on S. Then the following hold:*

(i) *If $\overline{S'}\cap\mathcal{J}_{i,S}=\emptyset$, then $\lim_{n\to\infty} I^{h_n}(v_n;S')=0$.*

(ii) *If $S'\cap\mathcal{J}_{i,S}\neq\emptyset$, then $\lim_{n\to\infty} I^{h_n}(v_n;S')=\mathcal{F}_i^\sigma(S')$.*

Proof. By translation invariance we may assume without loss of generality that S is centered about the origin, so $\mathcal{J}_{i,S}=S\cap\{\nu_i\}^\perp$. Statement (i) is an immediate consequence of Lemma 9. In fact, let $\varepsilon>0$ be so small that $S_\varepsilon=\{x'\in S:|x'\cdot\nu_i|<\varepsilon\}$ satisfies $S_\varepsilon\cap S'=\emptyset$. Then $\mathcal{F}_i^\sigma(S_\varepsilon)=\mathcal{F}_i^\sigma(S)$ by Lemma 9 because $|\pi_i^\perp(S_\varepsilon)|=|\pi_i^\perp(S)|$. Hence $\lim_{n\to\infty} I^{h_n}(v_n;S\setminus S_\varepsilon)=0$.

To prove statement (ii) notice that by Lemma 11(i) we may assume without loss of generality that $\pi_i(S')=\pi_i(S)$ (recall that π_i denotes the orthogonal projection onto the subspace spanned by $e_i=\nu_i$). In other words, $J_i'=J_i$, so S' is a stripe of width $|\pi_i^\perp(S')|$ perpendicular to the interface $\mathcal{J}_{i,S}$. Assume that (ii) is false, and so, since v_n is admissible on S', we have $\limsup_{n\to\infty} I^{h_n}(v_n;S')>\mathcal{F}_i^\sigma(S')$. If $S'=S$, then this would contradict the fact that v_n is a recovery sequence on S. Otherwise, denote by S_1, S_2 the two connected components of $S\setminus S'$. (If $S\setminus S'$ consists of only one connected component, then we call it S_1 and set $S_2=\emptyset$.) After passing to subsequences (not relabeled) we may assume that $I^{h_n}(v_n;S')$ and $I^{h_n}(v_n;S_j)$, $j=1,2$, converge. Hence we obtain the contradiction

$$\begin{aligned}\mathcal{F}_i^\sigma(S)&=\mathcal{F}_i^\sigma(S')+\mathcal{F}_i^\sigma(S_1)+\mathcal{F}_i^\sigma(S_2)\\&<\lim_{n\to\infty} I^{h_n}(v_n;S')+\lim_{n\to\infty} I^{h_n}(v_n;S_1)+\lim_{n\to\infty} I^{h_n}(v_n;S_2)\\&=\lim_{n\to\infty} I^{h_n}(v_n;S)=\mathcal{F}_i^\sigma(S).\end{aligned}$$

The first equality follows from Lemma 9; the strict inequality holds because $(v_n|_{S_j},h_n)$ are admissible on S_j and because by assumption we have $\lim I^{h_n}(v_n;S')>\mathcal{F}_i(S')$. The last equality holds because (v_n,h_n) is a recovery sequence on S. □

Now we define the set of admissible limiting functions as

$$\mathcal{A}(S)=\Big\{w\in W^{1,2}(S;\mathbb{R}^2):\operatorname{sym}\nabla' w\in BV(S;\{0,\bar{B}\})\Big\}\tag{30}$$

and the limiting functional

$$I^0(w;S)=\begin{cases}\int_J k(\nu(x))d\mathcal{H}^1(x) & \text{if } w\in\mathcal{A}(S),\\ +\infty & \text{otherwise.}\end{cases}\tag{31}$$

Here J denotes the jump set of $\operatorname{sym}\nabla' w$, also called the phase interface, and ν denotes the normal (the sign does not matter), which up to a sign can assume only the values $\nu_1=e_1$ and $\nu_2=e_2$.

THEOREM 12. *Let $S\subset\mathbb{R}^2$ be a bounded Lipschitz domain and $w\in L^2(S;\mathbb{R}^2)$. Then, for all $h_n\to 0$ and all $u_n\in L^2(S\times I_{h_n};\mathbb{R}^3)$ satisfying $\fint_{I_{h_n}} u_n' dx_3\to w$ in $L^2(S;\mathbb{R}^2)$, one has $\liminf_{n\to\infty} I^{h_n}(u_n;S)\geq I^0(w;S)$.*

Proof. If $\liminf_{n\to\infty} I^{h_n}(u_n;S)=\infty$, then there is nothing to prove. Otherwise, by passing to a subsequence (not relabeled) we may assume that the sequence

$I^{h_n}(u_n;S)$ converges, so, in particular, $\limsup_{n\to\infty} I^{h_n}(u_n;S)<\infty$. After passing to a further subsequence, Theorem 6 implies that there is a sequence of affine mappings $f_n:\mathbb{R}^2\to\mathbb{R}^2$ with $\operatorname{sym}\nabla f_n=0$ such that $w_n+f_n\to w_0$ in $W^{1,2}(S;\mathbb{R}^2)$ for some $w_0\in\mathcal{A}(S)$, where we have set $w_n=\fint_{I_{h_n}} u_n'\,dx_3$. Since $w_n\to w$ in $L^2(S;\mathbb{R}^2)$, we deduce that f_n converges in $L^2(S;\mathbb{R}^2)$, whence there is $\bar T\in\mathbb{R}^{2\times 2}$ with $\operatorname{sym}\bar T=0$ and a vector $c\in\mathbb{R}^2$ such that $f_n(x')\to c+\bar T x'$ for all $x'\in S$. Hence $w=w_0-\bar T x'-c$, and, in particular, we have $w\in\mathcal{A}(S)$. By the strong $W^{1,2}$-convergence of both w_n+f_n and f_n we have $w_n\to w$ in $W^{1,2}(S;\mathbb{R}^2)$. By Proposition 7 the jump set of $\operatorname{sym}\nabla' w$ consists of a countable union of disjoint segments $\mathcal{J}_k$ with normal ν_1 or ν_2. The rest of the proof is standard: One covers each $\mathcal{J}_k$ with a box, applies Lemma 9 to each box separately, and uses the minimality of $\mathcal{F}_i^{\pm}$ (see, e.g., the proof of Proposition 3.1 in [19] for the details). □

4. Upper bound. In this section we will show that for any admissible limit function w and for any given sequence $h_n\to 0$ one can find a sequence (v_n,h_n) such that $\fint_{I_{h_n}} v_n'\,dx_3\to w$ strongly in $W^{1,2}(S;\mathbb{R}^2)$ and $I^{h_n}(v_n;S)\to I^0(w;S)$. We will first show that given (σ,i) and *any* sequence $h_n\to 0$ one can find a sequence (v_n) such that (v_n,h_n) is a (σ,i)-recovery sequence on S. A key difference from the proof of the analogous Proposition 5.5 in [19] is that we do not rely on the existence of special recovery sequences which are affine away from the interface but work directly with an arbitrary recovery sequence.

LEMMA 13. *Let J_1,J_2 be open intervals and set $S=J_1\times J_2$. Let $\sigma\in\{+,-\}$, $i\in\{1,2\}$, and $H_n\to 0$ be given. Then we have*

$$\mathcal{F}_i^{\sigma}(S)=\inf\Big\{\liminf_{n\to\infty} I^{H_n}(u_n;S) : \text{there is } (u_n) \text{ such that } (u_n,H_n) \text{ is } (\sigma,i)\text{-admissible on } S\Big\}.$$

Proof. Clearly we must prove only the "$\geq$"-inequality, and by Lemmas 10 and 11 we may assume without loss of generality that $S=(-\frac12,\frac12)^2$. In fact, suppose Lemma 13 is shown for this particular case. Now let $H_n\to 0$ and an arbitrary S be given and assume without loss of generality (by translation invariance) that S is centered about the origin. Then there is $\lambda>0$ such that $\lambda S\subset(-\frac12,\frac12)^2$. By the special case of Lemma 13 there is a recovery sequence $(v_n,\lambda H_n)$ on $(-\frac12,\frac12)^2$. By Lemma 11(ii) we have that $(v_n|_{\lambda S},\lambda H_n)$ is a recovery sequence on λS. By Lemma 10, setting $\hat v_n(x)=\frac{1}{\lambda}v_n(\lambda x)$, we conclude that $(\hat v_n,H_n)$ is a recovery sequence on S.

So suppose that $S=(-\frac12,\frac12)^2$ and let $H_n\to 0$ be given. Let us restrict our attention to the case $\sigma=+$ and $i=1$, so the interface normal is $\nu_1=e_1$, the phase "0" is used on the left, $\{\nabla' w_1^+=0\}=S\cap\{x_1<0\}$, and $\{\nabla' w_1^+=\bar B+T_1\}=S\cap\{x_1>0\}$ up to a null set; the other cases are similar. Note that the infimum in the definition of $\mathcal{F}_i^{\sigma}(S)=k(\nu_i)$ is attained; i.e., there is a sequence $h_n\to 0$ and $v_n\in W^{1,2}(S\times I_{h_n};\mathbb{R}^3)$ such that $\fint_{I_{h_n}} v_n'dx_3\to w_1^+$ in $L^2(S;\mathbb{R}^2)$ and $\lim_{n\to\infty} I^{h_n}(v_n;S)=k(\nu_1)$. Since after passing to subsequences this equality remains valid, we may assume without loss of generality that $h_n\ll H_n$, i.e., $\alpha_n=\frac{H_n}{h_n}\to\infty$.

Set $y_1^{(n)}=\frac{1}{2\alpha_n}-\frac12$ and $y_{m+1}^{(n)}=y_m^{(n)}+\frac{1}{\alpha_n}$, $m=1,\dots,[\alpha_n]-1$, and let $S_m^{(n)}=(-\frac12,\frac12)\times(y_m^{(n)}-\frac{1}{2\alpha_n},y_m^{(n)}+\frac{1}{2\alpha_n})$. We recall (25)–(28) from the proof of Theorem 6 and apply them to v_n instead of $u^{(h)}$. Define $S_{m,1}^{(n)}=S_m^{(n)}\cap\Omega_1^{h_n}\cap\{\nabla' w_1^+=0\}$ and $S_{m,2}^{(n)}=S_m^{(n)}\cap\Omega_2^{h_n}\cap\{\nabla' w_1^+=\bar B+T_1\}$. It follows from the proof of Theorem 6 applied to v_n that $\chi_{\Omega_1^{h_n}}\to\chi_{\{\nabla' w_1^+=0\}\cap S}$ and $\chi_{\Omega_2^{h_n}}\to\chi_{\{\nabla' w_1^+=\bar B+T_1\}\cap S}$ strongly in $L^1(\mathbb{R}^2)$

(notice that, by uniqueness of the limits, the full sequence indeed converges). Now denote by $G_n = \{m = 1, \dots, [\alpha_n] : |S^{(n)}_{m,1}| > \frac{1}{3\alpha_n}$ and $|S^{(n)}_{m,2}| > \frac{1}{3\alpha_n}\}$ the index set of "good" stripes, and for $i = 1, 2$ set $M_{n,i} = \{m = 1, \dots, [\alpha_n] : |S^{(n)}_{m,i}| \le \frac{1}{3\alpha_n}\}$. We claim that

$$\frac{\#G_n}{\alpha_n} \to 1 \text{ as } n \to \infty. \tag{32}$$

Indeed, if (32) were false, then by definition of G_n there would exist $i \in \{1, 2\}$, $\gamma > 0$, and a subsequence (not relabeled) such that $\frac{\#M_{n,i}}{\alpha_n} \in (\frac{5}{6}\gamma, \gamma)$ for all n. For definiteness suppose that $i = 1$; the case $i = 2$ is similar. But for all n we have $\Omega_1^{h_n} \cap \{\nabla' w_1^+ = 0\} \subset (S \setminus \bigcup_{m=1}^{[\alpha_n]} S^{(n)}_m) \cup \bigcup_{m \notin M_{n,1}} S^{(n)}_{m,1} \cup \bigcup_{m \in M_{n,1}} S^{(n)}_{m,1}$. Taking measures on both sides, we find (notice that by definition $|S^{(n)}_{m,i}| \le \frac{1}{2\alpha_n}$)

$$\begin{aligned} |\Omega_1^{h_n} \cap \{\nabla' w_1^+ = 0\}| &\le 1 - \frac{[\alpha_n]}{\alpha_n} + \frac{1}{2\alpha_n}([\alpha_n] - \#M_{n,1}) + \frac{1}{3\alpha_n}\#M_{n,1} \\ &\le 1 - \frac{[\alpha_n]}{\alpha_n} + \frac{1}{2}\left(1 - \frac{5}{6}\gamma\right) + \frac{\gamma}{3}. \end{aligned}$$

As $n \to \infty$, the left-hand side converges to $\frac{1}{2}$ and the right-hand side converges to $\frac{1}{2} - \frac{1}{12}\gamma$. This contradiction proves (32).

From (32) one deduces that

$$\limsup_{n\to\infty} \big(\alpha_n \min_{m \in G_n} I^{h_n}(v_n; S^{(n)}_m)\big) \le \limsup_{n\to\infty} I^{h_n}(v_n; S). \tag{33}$$

In fact, if (33) were false, then (after passing to an unrelabeled subsequence) there would exist $\gamma > 0$ such that $I^{h_n}(v_n; S^{(n)}_m) - \frac{1}{\alpha_n} I^{h_n}(v_n; S) \ge \frac{\gamma}{\alpha_n}$ for all n and for all $m \in G_n$. Summing over $m \in G_n$ we would find $(1 - \frac{\#G_n}{\alpha_n}) I^{h_n}(v_n; S) \ge I^{h_n}(v_n; \bigcup_{m \in G_n} S^{(n)}_m) - \frac{\#G_n}{\alpha_n} I^{h_n}(v_n; S) \ge \frac{\#G_n}{\alpha_n}\gamma$. By (32) the left-hand side converges to zero as $n \to \infty$, while the right-hand side converges to γ, which is a contradiction proving (33).

Now choose $m_n \in G_n$ such that $I^{h_n}(v_n; S^{(n)}_{m_n}) = \min_{m \in G_n} I^{h_n}(v_n; S^{(n)}_m)$, and set $\hat{y}_n = y^{(n)}_{m_n}$. Let $r^{(n)} = (-\frac{l}{2\alpha_n}, \frac{l}{2\alpha_n}) \times (\hat{y}_n - \frac{1}{2\alpha_n}, \hat{y}_n + \frac{1}{2\alpha_n})$, where $l = 1 + \frac{k(\nu_1)}{k(\nu_2)}$. Consider the functions $g_n(x_1) = |\Omega_1^{h_n} \cap \big((x_1, 0) + r^{(n)}\big)|$. Since $m_n \in G_n$, there is $x_1 \le 0$ such that $g_n(x_1) > \frac{|r^{(n)}|}{2}$. The existence of such x_1 can be seen, e.g., by the following argument (another argument uses Fubini's theorem): Set $x_1^k = \frac{l}{2\alpha_n} - \frac{1}{2} + \frac{kl}{\alpha_n}$, $k = 0, \dots, N_n$, where $N_n = [\frac{\alpha_n}{2l} - \frac{1}{2}]$. Then $x_1^k \le 0$ for all $k = 0, \dots, N_n$ and

$$S^{(n)}_{m_n} \cap \{\nabla' w_1^+ = 0\} \subset \hat{r}^{(n)} \cup \bigcup_{k=0}^{N_n} \big((x_1^k, 0) + r^{(n)}\big), \tag{34}$$

where $\hat{r}^{(n)}$ is a rectangle with $|\hat{r}^{(n)}| \le |r^{(n)}|$. If $g_n(x_1^k) \le \frac{|r^{(n)}|}{2}$ for all $k = 0, \dots, N_n$, then $|\Omega_1^{h_n} \cap \big((x_1^k, 0) + r^{(n)}\big)| \le \frac{|r^{(n)}|}{2}$ for all k. Intersecting (34) with $\Omega_1^{h_n}$, taking measures, and multiplying by α_n, we find $\alpha_n |S^{(n)}_{m_n,1}| \le \alpha_n |\hat{r}^{(n)}| + \alpha_n (N_n + 1)\frac{|r^{(n)}|}{2} \le \frac{C}{\alpha_n} + \frac{1}{4}$ since $|r^{(n)}| = \frac{l}{\alpha_n^2}$. As $n \to \infty$, the right-hand side converges to $\frac{1}{4}$, while the left-hand side is greater than $\frac{1}{3}$ because $m_n \in G_n$, which is a contradiction. Similarly, one proves existence of $x_1 \ge 0$ such that $g_n(x_1) < \frac{|r^{(n)}|}{2}$.

Since g_n is continuous, we conclude that there is some $\hat{x}_n$ with $g_n(\hat{x}_n) = \frac{|r^{(n)}|}{2}$. By (33) and the choice of m_n the rectangle $\hat{S}_n = (\hat{x}_n - \frac{l}{2\alpha_n}, \hat{x}_n + \frac{l}{2\alpha_n}) \times (\hat{y}_n - \frac{1}{2\alpha_n}, \hat{y}_n + \frac{1}{2\alpha_n})$ satisfies $\limsup \alpha_n I^{h_n}(v_n; \hat{S}_n) \leq k(\nu_1)$. Recalling (25) we set $\hat{\mathcal{A}}_0^{(n)} = \{a \in \mathcal{A}_0^{h_n} : a + (-\frac{h_n}{2}, \frac{h_n}{2})^2 \subset \hat{S}_n\}$. Then by (25) we have $\#\hat{\mathcal{A}}_0^{(n)} \leq \frac{C}{h_n^3} \int_{\hat{S}_n} W(\nabla v_n) \leq \frac{C}{h_n \alpha_n}$. Hence $|\Omega_0^{h_n} \cap \hat{S}_n| \leq |\bigcup_{a \in \hat{\mathcal{A}}_0^{(n)}} (a + (-\frac{h_n}{2}, \frac{h_n}{2})^2)| + h_n \cdot \mathcal{H}^1(\partial \hat{S}_n) \leq \frac{C h_n}{\alpha_n}$. But $\frac{C h_n}{\alpha_n} \ll \frac{l}{\alpha_n^2} = |\hat{S}_n|$ because $H_n \to 0$. Hence $\frac{|\Omega_0^{h_n} \cap \hat{S}_n|}{|\hat{S}_n|} \to 0$, so we conclude that

$$\frac{|\Omega_i^{h_n} \cap \hat{S}_n|}{|\hat{S}_n|} \to \frac{1}{2} \text{ for } i = 1, 2 \text{ as } n \to \infty. \tag{35}$$

In fact, we have $|\hat{S}_n \cap \Omega_1^{h_n}| = \frac{|\hat{S}_n|}{2}$ by the choice of $\hat{x}_n$. Now set $V_n(x) = \alpha_n v_n\big(\frac{x}{\alpha_n} + (\hat{x}_n, \hat{y}_n)\big)$ and $S' = (-l/2, l/2) \times (-\frac{1}{2}, \frac{1}{2})$. Then $V_n \in W^{1,2}\big(S' \times (-\frac{H_n}{2}, \frac{H_n}{2}); \mathbb{R}^3\big)$ and $\limsup I^{H_n}(V_n; S') \leq k(\nu_1)$. Set $W_n = \fint_{I_{H_n}} V_n' dx_3$. After possibly reflecting V_n about $\{\nu_1\}^\perp$ we may assume that

$$\begin{aligned} &\left|\left\{x \in S' : x_1 < 0, \operatorname{sym} \nabla' W_n(x) \leq \frac{|B|}{4}\right\}\right| \\ &\qquad \leq \left|\left\{x \in S' : x_1 > 0, \operatorname{sym} \nabla' W_n(x) \leq \frac{|B|}{4}\right\}\right| \end{aligned} \tag{36}$$

for all n. By Theorem 6, for every subsequence there is a further subsequence, labeled with an index m, and there are affine mappings $F_m : \mathbb{R}^2 \to \mathbb{R}^2$ with $\operatorname{sym} \nabla F_m = 0$ such that $W_m + F_m \to W_0$ strongly in $W^{1,2}(S'; \mathbb{R}^2)$, where $W_0 \in \mathcal{A}(S')$. Moreover, we may assume that $\lim_{m \to \infty} I^{H_m}(V_m; S') = k(\nu_1)$. Theorem 12 implies that $I^0(W_0; S') \leq k(\nu_1)$. Since S' is a rectangle with sides parallel to e_1 and e_2, Proposition 7 implies that W_0 has either only interfaces with normal $\nu_1 = e_1$ or only interfaces with normal $\nu_2 = e_2$. If it had an interface of the latter type, we would obtain the contradiction $I^0(W_0; S') \geq lk(\nu_2) > k(\nu_1)$, by the choice of l. Thus W_0 has only interfaces with normal ν_1, and since $\limsup I^{H_n}(V_n; S') \leq k(\nu_1)$, there can be at most one such interface. On the other hand, by (35) we have $|\{\operatorname{sym} \nabla' W_0 = 0\}| = |\{\operatorname{sym} \nabla' W_0 = \bar{B}\}| = \frac{|S'|}{2}$, so there must be at least one interface. Hence W_0 has exactly one interface, it has normal ν_1, and by (35) it lies in $\{\nu_1\}^\perp$. By (36) we have $(-\frac{l}{2}, 0) \times (-\frac{1}{2}, \frac{1}{2}) = \{\operatorname{sym} \nabla' W_0 = 0\}$ up to a null set, so the mapping $w_1^+ - W_0$ is affine with $\operatorname{sym} \nabla'(w_1^+ - W_0) = 0$. We conclude that $\operatorname{sym} \nabla' W_m \to \operatorname{sym} \nabla' w_1^+$ strongly in $L^2(S'; \mathbb{R}^{2\times 2})$. Since the same limit is obtained for all subsequences, we conclude that the full sequence satisfies $\operatorname{sym} \nabla' W_n \to \operatorname{sym} \nabla' w_1^+$. By Korn's inequality on S', there exist affine mappings $\tilde{F}_n : \mathbb{R}^2 \to \mathbb{R}^2$ with $\operatorname{sym} \nabla' \tilde{F}_n = 0$ such that $W_n + \tilde{F}_n \to w_1^+$ strongly in $W^{1,2}(S'; \mathbb{R}^2)$. Denote by u_n the restriction of $x \mapsto V_n(x) + \binom{\tilde{F}_n(x')}{0}$ to S. This sequence satisfies $\fint_{I_{H_n}} u_n' \, dx_3 \to w_1^+$ in $W^{1,2}(S; \mathbb{R}^2)$ and $\limsup I^{H_n}(u_n; S) = k(\nu_1)$. □

Notation. From now on we will drop the index n when dealing with sequences $h_n \to 0$ because, in view of Lemma 13, there exists a recovery sequence (v_n, h_n) for a particular sequence $h_n \to 0$ if and only if there exists one for *every* sequence $h_n \to 0$. We say that there exists a (σ, i)-recovery sequence $u^{(h)}$ on S if for all (h_n) there exist (u_n) such that (u_n, h_n) is a (σ, i)-recovery sequence on S.

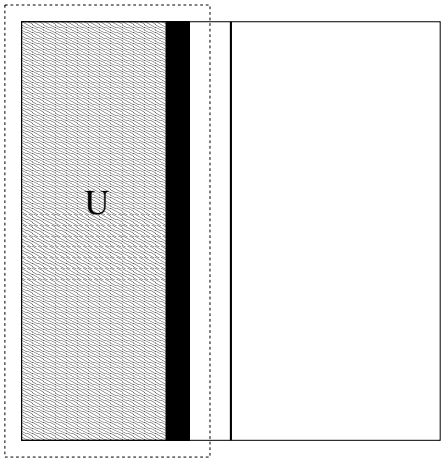

FIG. 1. *Proof of Lemma* 14*: The black region represents the interpolation layer. The dashed rectangle denotes the boundary of* V.

In a first modification step we will now change the recovery sequence furnished by Definition 8 and Lemma 13 in such a way that its vertical averages become smooth away from the interface. Lemma 14 provides a link between (1) and (2).

LEMMA 14. *Let* J_1, J_2 *be open intervals, set* $S = J_1 \times J_2$, *and let* $\sigma \in \{+,-\}$, $i \in \{1,2\}$. *Let* $\varepsilon > 0$ *and set* $Q = S \cap B_\varepsilon(\mathcal{J}_{i,S})$. *Then there exists a* (σ,i)*-recovery sequence* $u^{(h)} \in W^{1,2}(S \times I_h;\mathbb{R}^3)$ *on* S *such that* $w^{(h)}(x') = \fint_{I_h} (u^{(h)})'(x)\ dx_3$ *and* $\tau^{(h)}(x') = \fint_{I_h} u_3^{(h)}(x)\ dx_3$ *satisfy* $w^{(h)} \in C^\infty(S \setminus \bar{Q};\mathbb{R}^2)$ *and* $\tau^{(h)} \in C^\infty(S \setminus \bar{Q})$. *Moreover,*

$$\lim_{h\to 0} \left(I^h_{2D}(w^{(h)}; S \setminus Q) + h \int_{S\setminus Q} |\nabla' {}^2 \tau^{(h)}(x')|^2\ dx' \right) = 0. \tag{37}$$

Proof. Arguing as at the beginning of the proof of Lemma 13, we may assume without loss of generality that $S = (-\frac{1}{2},\frac{1}{2})^2$. Moreover, we will prove the statement for $i = 1$, $\sigma = +$ only, the other cases being analogous. Recall that $\{\nabla' w_1^+ = 0\} = \{x \in \mathbb{R}^2 : x_1 < 0\}$ up to a null set. Let $v^{(h)} \in W^{1,2}((2S) \times I_h;\mathbb{R}^3)$ be a $(+,1)$-recovery sequence on $2S$, so by Lemma 11(ii) we have $\lim_{h\to 0} I^h(v^{(h)}; S) = k(\nu_1)$. Fix $a > 0$ satisfying $(-9a, 9a) \times (-\frac{1}{2},\frac{1}{2}) \subset Q$, set $V = (-\frac{1+a}{2}, -\frac{a}{2}) \times (-\frac{1+a}{2}, \frac{1+a}{2})$, and let $U = (-\frac{1}{2}, -a) \times (-\frac{1}{2},\frac{1}{2})$, so $\bar{U} \subset V \subset \{\nabla' w_1^+ = 0\} \cap (2S)$. The situation is depicted in Figure 1. To obtain mappings defined on the full plate thickness, we mollify slicewise in horizontal planes: Let ψ be a standard mollifier supported on $(-\frac{1}{2},\frac{1}{2})^2$, and set $\psi_h(x') = \frac{1}{h^2}\psi(\frac{x'}{h})$. Set

$$\tilde{v}^{(h)}(x) = \big(\psi_h * v^{(h)}(\cdot, x_3)\big)(x') = \fint_{I_h^2} \psi\left(\frac{y'}{h}\right) v^{(h)}(x' - y', x_3)\ dy',$$

which for h small enough is well defined on $S \times I_h$ (recall that $v^{(h)}$ is defined on $(2S) \times I_h$). Recall the definition of S'_h and of $R^{(h)} : S'_h \to \mathrm{Skew} \cup (B + \mathrm{Skew})$ introduced before (24) in the proof of Theorem 6. Adopting the notation introduced there, we have $S \subset (2S)'_h$ for h small enough, so $R^{(h)}$ is defined everywhere on S.

Since $\nabla\tilde{v}^{(h)}(x) = \big(\psi_h * \nabla v^{(h)}(\cdot, x_3)\big)(x')$, we can estimate

$$\begin{aligned}
&\int_{U\times I_h} |\nabla\tilde{v}^{(h)}(x) - R^{(h)}(x')|^2 dx \\
&\quad\le \frac{C}{h^2}\int_{\text{spt }\psi_h} dy' \int_{U\times I_h} \Big(|\nabla v^{(h)}(x'-y', x_3) - R^{(h)}(x'-y')|^2 \\
&\qquad + |R^{(h)}(x'-y') - R^{(h)}(x')|^2\Big) dx \\
&\quad\le C\int_{V\times I_h} W(\nabla v^{(h)}(x))\, dx. \qquad (38)
\end{aligned}$$

In the first step we have applied Jensen's inequality and have added and subtracted $R^{(h)}(x'-y')$. In the last step we used that spt $\psi_h \subset (-\frac{h}{2}, \frac{h}{2})^2$ and applied the estimate

$$\int_U |R^{(h)}(x'+\zeta) - R^{(h)}(x')|^2\, dx' \le C\int_{V\times I_h} W(\nabla v^{(h)}(x))\, dx, \qquad (39)$$

which holds for all $\zeta \in \mathbb{R}^2$ with $|\zeta_1|, |\zeta_2| \le h$. (The estimate (39) can be derived by arguments similar to the first part of the proof of Theorem 4.1 in [28], with our Theorem 3 replacing their Theorem 3.1.) From (38) we deduce $I^h(\tilde{v}^{(h)}; U) \le CI^h(v^{(h)}; V)$ by (6) since sym $R^{(h)} \in \{A, B\}$. Let $w^{(h)} = \fint_{I_h}(v^{(h)})'\, dx_3$, $\tau^{(h)} = \fint_{I_h}(v^{(h)})_3\, dx_3$ and $\tilde{w}^{(h)} = \fint_{I_h}(\tilde{v}^{(h)})'\, dx_3$, $\tilde{\tau}^{(h)} = \fint_{I_h}(\tilde{v}^{(h)})_3\, dx_3$. Since sym $\bar{R}^{(h)} \in \{\bar{A}, \bar{B}\}$, by Jensen's inequality and by (38) we can estimate

$$\begin{aligned}
\int_{U\times I_h} W_{2D}(\nabla'\tilde{w}^{(h)}(x'))\, dx &\le \int_{U\times I_h} |\text{sym }\nabla'\tilde{w}^{(h)}(x') - \text{sym }\bar{R}^{(h)}(x')|^2\, dx \\
&\le \int_{U\times I_h} |\nabla\tilde{v}^{(h)}(x) - R^{(h)}(x')|^2\, dx \le C\int_{V\times I_h} W(\nabla v^{(h)}(x))\, dx.
\end{aligned}$$

Since $\nabla\tilde{v}^{(h)}(x) = \big(\psi_h * \nabla v^{(h)}(\cdot, x_3)\big)(x')$, for $\alpha \in \{1, 2\}$ we have $(\nabla\tilde{v}^{(h)})_{,\alpha}(x) = \int \psi_{,\alpha}(y')(\nabla v(x'-y', x_3) - \nabla v(x', x_3))dy'$ (where we have added a term which is zero by $\int \nabla'\psi_h = 0$). Using this together with Jensen's inequality and the fact that $|\nabla'\psi_h|^2 \le \frac{C}{h^2}$ while $|\text{spt }\psi_h| \le h^2$, an argument similar to (38) leads to $h\int_U |\nabla'^2\tilde{w}^{(h)}(x')|^2\, dx' + h\int_U |\nabla'^2\tilde{\tau}^{(h)}(x')|^2\, dx' \le CI^h(v^{(h)}; V)$. Summarizing, we have shown that

$$I^h_{2D}(\tilde{w}^{(h)}; U) + h\int_U |\nabla'^2\tilde{\tau}^{(h)}(x')|^2\, dx' \le CI^h(v^{(h)}; V). \qquad (40)$$

For $\kappa \in (0, a)$ let ϕ be a smooth cutoff function that decreases from one to zero within the transition layer $(-a-\kappa, -a)$ with $\|\phi'\|_\infty \le \frac{2}{\kappa}$. Consider the linear interpolation $u^{(h)}_\kappa(x) = v^{(h)}(x) + \phi(x_1)(\tilde{v}^{(h)}(x) - v^{(h)}(x))$. Since $\fint_{I_h}(\tilde{v}^{(h)})'\, dx_3 \to w_1^+$ and $\fint_{I_h}(v^{(h)})'\, dx_3 \to w_1^+$ in $L^2(U; \mathbb{R}^2)$, we also have $\fint_{I_h}(u^{(h)}_\kappa)'\, dx_3 \to w_1^+$ in $L^2(U; \mathbb{R}^2)$. Moreover, by (6) the energy $\int_{T_h} W(\nabla u^{(h)}_\kappa)$ on the transition layer

$T_h = (-a-\kappa, -a) \times (-\frac{1}{2}, \frac{1}{2}) \times I_h$ is bounded by

$$\begin{aligned} C \int_{T_h} W_0(\nabla u_\kappa^{(h)}(x))\, dx &\le C \int_{T_h} W_0(\nabla v^{(h)}(x)) + \frac{1}{\kappa^2} |\tilde{v}^{(h)}(x) - v^{(h)}(x)|^2 \\ &\quad + |\nabla \tilde{v}^{(h)}(x) - \nabla v^{(h)}(x)|^2\, dx \\ &\le \frac{C}{\kappa^2} \int_{T_h} W_0(\nabla v^{(h)}(x)) + |\nabla \tilde{v}^{(h)}(x) - \nabla v^{(h)}(x)|^2\, dx \\ &\le \frac{C}{\kappa^2} \int_{V \times I_h} W(\nabla v^{(h)}(x))\, dx. \end{aligned} \tag{41}$$

In passing to the second line we have assumed, by possibly adding a constant $c^{(h)}$ to $\tilde{v}^{(h)}$, that $\int_{T_h} \left(\tilde{v}^{(h)}(x) - v^{(h)}(x)\right) dx = 0$, so we could apply Poincaré's inequality to estimate the term involving $|\tilde{v}^{(h)} - v^{(h)}|^2$ (the varying domain causes no problem in the application of Poincaré's inequality; one could, e.g., apply it separately in the in-plane and in the x_3-directions). Note that $c^{(h)} \to 0$, since $w^{(h)}$ and $\tilde{w}^{(h)}$ converge to the same limit w_1^+ in $W^{1,2}(S;\mathbb{R}^2)$. In the last step in (41) we have used the fact that by (38) and since $\int_{U \times I_h} |\nabla v^{(h)} - R^{(h)}|^2 \le C \int_{V \times I_h} W(\nabla v^{(h)})$ (by the definition of $R^{(h)}$), we have $\int_{V \times I_h} |\nabla \tilde{v}^{(h)} - \nabla v^{(h)}|^2 \le C \int_{V \times I_h} W(\nabla v^{(h)})$. After applying the analogous construction to the right of the interface (adding a different constant $c_2^{(h)}$ to the corresponding $\tilde{v}^{(h)}$), the lemma follows because by Lemma 11(i) we have $\frac{1}{h^2} \int_{V \times I_h} W(\nabla v^{(h)}) \to 0$ as $h \to 0$. □

In the next lemma we further modify the recovery sequence such that the resulting functions are affine away from the interface. This is achieved via a two-step interpolation depicted in Figure 2. In the first step the recovery sequence is modified in such a way that it uses only one well away from the interface—namely, the one

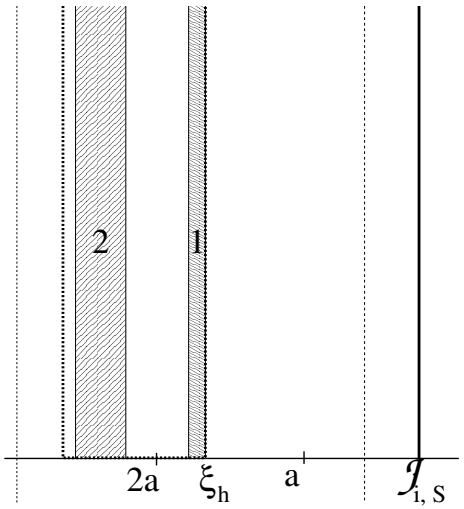

FIG. 2. *The shaded regions represent the interpolation layers whose numbers correspond to the steps in Lemma* 15. *The bold dashed lines belong to* ∂U_h, *the thin dashed lines to* ∂U, *and the solid horizontal line to* ∂S.

which is being used by the limiting mapping on that region. In a second step, it is further modified to become affine with gradient in the corresponding well.

LEMMA 15. *Let J_1, J_2 be open intervals, set $S = J_1 \times J_2$, and let $\sigma \in \{+,-\}$, $i \in \{1,2\}$. Then there is a (σ,i)-recovery sequence $v^{(h)}$ on S with the following property: For any $\varepsilon > 0$ there is $h_0 > 0$ such that, writing $Q = S \cap B_\varepsilon(\mathcal{J}_{i,S})$, the following holds: For $h \in (0,h_0)$ the mapping $v^{(h)}$ is affine on each connected component of $(S \setminus Q) \times I_h$, and $\nabla v^{(h)} \in Skew \cup (B + Skew)$ on $(S \setminus Q) \times I_h$.*

Proof. Arguing as at the beginning of the proof of Lemma 13, we may assume without loss of generality that $S = (-\frac{1}{2}, \frac{1}{2})^2$. We perform the construction only for $\sigma = +$ and $i = 1$ and only on the left side of the interface; the other cases are similar.

Set $\hat{S} = (-1,1)^2$ and fix $a \in (0, \frac{1}{100})$. Let $v^{(h)}$ be a $(+,1)$-recovery sequence on $\hat{S}$ as provided by Lemma 14, whose vertical averages $w^{(h)}(x') = \fint_{I_h} (v^{(h)}(x))' dx_3$ and $\tau^{(h)}(x') = \fint_{I_h} v_3^{(h)}(x) dx_3$ satisfy $w^{(h)} \in C^\infty(\hat{S} \setminus \{|x_1| < \frac{a}{10}\}; \mathbb{R}^2)$ and $\tau^{(h)} \in C^\infty(\hat{S} \setminus \{|x_1| < \frac{a}{10}\})$. Set $U = (-5a, -\frac{a}{2}) \times (-1,1)$. We may assume without loss of generality that $h < \frac{a}{100}$, and by Lemma 11(i) we have $I^h(v^{(h)}; U) \to 0$ as $h \to 0$. By the strong convergence $w^{(h)} \to w_1^+$ in $W^{1,2}(\hat{S}; \mathbb{R}^2)$ and since $U \subset \{\nabla' w_1^+ = 0\}$ we have $\int_U |\nabla' w^{(h)}|^2 \to 0$. Hence, using (37) in the conclusion of Lemma 14, we can write

$$I^h(v^{(h)}; U) + I^h_{2D}(w^{(h)}; U) + h \int_U |\nabla'^2 \tau^{(h)}(x')|^2 dx' + \int_U |\nabla' w^{(h)}(x')|^2 dx' = \eta_h, \tag{42}$$

where $\eta_h \to 0$ as $h \to 0$.

Step 1. *Interpolation to a displacement with low one-well energy.* As in the proof of Theorem 6 set $S_{z,h} = z + (-\frac{h}{2}, \frac{h}{2})^2$ and $\hat{S}'_h = \bigcup_{\{z \in h\mathbb{Z}^2 : S_{z,h} \subset \hat{S}\}} S_{z,h}$, and define the mapping $R^{(h)} : S'_h \to K$ to be constant on each $S_{z,h}$ with $z \in h\mathbb{Z}^2$ and such that $\int_{S_{z,h} \times I_h} |\nabla v^{(h)} - R^{(h)}|^2 \le C \int_{S_{z,h} \times I_h} \operatorname{dist}^2(\nabla v^{(h)}, K)$. (Here C is a universal constant given by applying Theorem 3 to a cube.) Let $G^{(h)} = h\mathbb{Z} \cap (-2a, -a)$ and set $N_h = \#G^{(h)}$. To every $\xi \in G^{(h)}$ define the column $Z_h(\xi) = \big((\xi - \frac{h}{2}, \xi + \frac{h}{2}) \times (-1,1)\big) \cap \hat{S}'_h$. By definition of U and since $h < \frac{a}{2}$, we have $Z_h(\xi) \subset U$ for all $\xi \in G^{(h)}$. Hence

$$\sum_{\xi \in G^{(h)}} \int_{Z_h(\xi)} |\nabla' w^{(h)}(x')|^2 dx' \le \int_U |\nabla' w^{(h)}(x')|^2 dx' \le \eta_h. \tag{43}$$

Now fix $\rho \in (0,1)$ such that $(1-4\rho)^2 > \frac{2}{3}$ and denote by $G_1^{(h)}$ the set of all $\xi \in G^{(h)}$ with the property that

$$\int_{Z_h(\xi)} |\nabla' w^{(h)}(x')|^2 dx' \le \frac{\eta_h}{[\rho N_h]}. \tag{44}$$

The estimate (43) implies that $\#G_1^{(h)} \ge (1-\rho)N_h$. Notice that by (44) and since $N_h \ge \frac{a}{2h}$, for $\xi \in G_1^{(h)}$ we have

$$\int_{Z_h(\xi)} |\nabla' w^{(h)}(x')|^2 dx' \le C\eta_h h. \tag{45}$$

Now set $L^{(h)} = \operatorname{sym} R^{(h)}$ and define $\mathcal{A}_i^h$ as in (25)–(26) and Ω_i^h as in (27), $i = 0,1,2$. By (42) and (25) we have $h \cdot \#(\mathcal{A}_0^h \cap U) \to 0$ as $h \to 0$. Hence the set $G_2^{(h)}$ of all $\xi \in G^{(h)}$ with the property that $Z_h(\xi) \cap \mathcal{A}_0^h = \emptyset$ satisfies $\frac{\#G_2^{(h)}}{N_h} \ge \frac{N_h - \#(\mathcal{A}_0^h \cap U)}{N_h} \to 1$

as $h \to 0$ because $hN_h \geq \frac{a}{2} > 0$. On the other hand, by the L^1-convergence $\chi_{\Omega_1^h} \to \chi_{\hat{S}\cap\{\nabla' w_1^+ = 0\}}$, the set $G_3^{(h)}$ of all $\xi \in G^{(h)}$ with the property that $Z_h(\xi) \cap \mathcal{A}_1^h \neq \emptyset$ satisfies $\frac{\#G_3^{(h)}}{N_h} \to 1$ as well. By these two cardinality estimates, for h small enough we have $\#(G_2^{(h)} \cap G_3^{(h)}) \geq (1-\rho)N_h$, and since also $\#G_1^{(h)} \geq (1-\rho)N_h$, we conclude that $\#(G_1^{(h)} \cap G_2^{(h)} \cap G_3^{(h)}) \geq (1-4\rho)N_h$. On the other hand, $N_h \geq \frac{a}{h} - 2 \geq (1-4\rho)\frac{a}{h}$ for small h. Hence by the choice of ρ we conclude

$$\#(G_1^{(h)} \cap G_2^{(h)} \cap G_3^{(h)}) > \frac{2a}{3h} \tag{46}$$

for small h. From (28) we deduce that if $\xi \in G_2^{(h)} \cap G_3^{(h)}$, then $Z_h(\xi) \subset \Omega_1^h$. Hence using that by definition sym $R^{(h)} = 0$ on Ω_1^h, from (24), (42), and the definition of $R^{(h)}$ we conclude that $\xi \in G_2^{(h)} \cap G_3^{(h)}$ implies

$$\begin{aligned}\int_{Z_h(\xi)\times I_h} |\text{sym } \nabla v^{(h)}(x)|^2 dx &= \int_{Z_h(\xi)\times I_h} |\text{sym } \nabla v^{(h)}(x) - \text{sym } R^{(h)}(\xi, x_2)|^2 dx \\ &\leq Ch^2 I^h(v^{(h)}; U) \leq C\eta_h h^2. \end{aligned} \tag{47}$$

Let $\tilde{J}_2^{(h)}$ be the set of all $\xi \in (-2a, -a)$ satisfying the property (P_h) (defined in the statement of Lemma 18 in the appendix) for $w^{(h)}$. Applying Lemma 18 on the domain $(-2a, -a) \times (-1, 1)$, for h small enough, we have $\mathcal{H}^1(\tilde{J}_2^{(h)}) \geq \frac{a}{2}$. For every $\xi \in \tilde{J}_2^{(h)}$ there is $\tilde{w}^{(h)} \in W^{1,2}((\xi - a, \xi) \times (-\frac{1}{2}, \frac{1}{2}); \mathbb{R}^2)$ satisfying $w^{(h)}(\xi, \cdot) = \tilde{w}^{(h)}(\xi, \cdot)$ in the trace sense and

$$\begin{aligned}\frac{1}{h}\int_{(\xi-a,\xi)\times(-\frac{1}{2},\frac{1}{2})} |\text{sym } \nabla' \tilde{w}^{(h)}(x')|^2 dx' &\leq C\left(I_{2D}^h(w^{(h)}; U) + \int_U |\nabla' w^{(h)}(x')|^2 dx'\right) \\ &\leq C\eta_h \end{aligned} \tag{48}$$

with C independent of ξ and h. We restrict the further construction to the domain of interest $S = (-\frac{1}{2}, \frac{1}{2})^2$. For $\xi \in (-2a, -a)$ define the columns

$$Z_h'(\xi) = \left(\xi - \frac{h}{8}, \xi\right) \times \left(-\frac{1}{2}, \frac{1}{2}\right) \tag{49}$$

and consider $\tilde{J}_1^{(h)} = \bigcup_{\xi \in \bigcap_{i=1}^3 G_i^{(h)}} (\xi - \frac{3h}{8}, \xi + \frac{3h}{8})$. By (46) we have $\mathcal{H}^1(\tilde{J}_1^{(h)} \cap (-2a, -a)) = \frac{3}{4}h \cdot (\#\bigcap_{i=1}^3 G_i^{(h)}) > \frac{a}{2}$. Since $\tilde{J}_2^{(h)} \subset (-2a, -a)$ and $\mathcal{H}^1(\tilde{J}_2^{(h)}) \geq \frac{a}{2}$ we conclude that there is $\xi_h \in \tilde{J}_1^{(h)} \cap \tilde{J}_2^{(h)}$ with $\xi_h \in (-2a, -a)$. Note that, in general, $\xi_h \notin G^{(h)}$ but that $Z_h'(\xi_h) \subset Z_h(\xi)$ for some $\xi \in \cap_{i=1}^3 G_i^{(h)}$ by the definitions of $\tilde{J}_1^{(h)}$ and $Z_h'(\xi)$. Let us introduce the set $U_h = (\xi_h - a, \xi_h) \times (-\frac{1}{2}, \frac{1}{2})$, which satisfies $U_h \subset (-3a, -a) \times (-\frac{1}{2}, \frac{1}{2}) \subset U$ for all h, since $\xi_h \in (-2a, -a)$. Setting

$$W_h = \text{skew} \fint_{U_h} \nabla' \tilde{w}^{(h)}(x')\, dx', \tag{50}$$

we apply Korn's inequality in the plane to deduce that there is an affine mapping $f^{(h)}$ with $\nabla f^{(h)} = W_h$ such that

$$\int_{U_h} |\tilde{w}^{(h)} - f^{(h)}|^2 + |\nabla' \tilde{w}^{(h)} - W_h|^2 dx' \leq C \int_{U_h} |\text{sym } \nabla' \tilde{w}^{(h)}|^2 dx' \leq Ch\eta_h, \tag{51}$$

where the last estimate holds by (48). Notice that C in (51) is independent of h because the constant appearing in Korn's inequality is invariant under translation of the domain. We claim that

$$W_h \to 0 \text{ in } \mathbb{R}^{2\times 2}. \tag{52}$$

Indeed, consider any subsequence. By the trace inequality and the fact that $\tilde{w}$ and w agree on $\{x \in S : x_1 = \xi_h\}$ we have

$$\begin{aligned}\int_{-\frac{1}{2}}^{\frac{1}{2}} |f^{(h)}(\xi_h, x_2)|^2 dx_2 &\le C \int_{-\frac{1}{2}}^{\frac{1}{2}} |f^{(h)}(\xi_h, x_2) - \tilde{w}^{(h)}(\xi_h, x_2)|^2 dx_2 \\ &\quad + C \int_{-\frac{1}{2}}^{\frac{1}{2}} |w^{(h)}(\xi_h, x_2)|^2 dx_2 \\ &\le C \int_{U_h} |f^{(h)}(x') - \tilde{w}^{(h)}(x')|^2 + |W_h - \nabla' \tilde{w}^{(h)}(x')|^2 \\ &\quad + |w^{(h)}(x')|^2 + |\nabla' w^{(h)}(x')|^2 dx',\end{aligned}$$

which tends to zero by (51) and since $w^{(h)} \to w_1^+$ in $W^{1,2}(S;\mathbb{R}^2)$. Hence (after passing to a subsequence) $f^{(h)}(\xi_h, x_2) \to 0$ for all $x_2 \in (-\frac{1}{2}, \frac{1}{2})$. From this and using that sym $W_h = 0$ we deduce (52).

Now we extend $\tilde{w}^{(h)}$ to a three dimensional displacement $\tilde{v}^{(h)}$ by defining

$$\tilde{v}^{(h)}(x) = \begin{pmatrix} \tilde{w}^{(h)}(x') \\ \tau^{(h)}(x') \end{pmatrix} + x_3 \begin{pmatrix} -\tau^{(h)}_{,1}(x') \\ -\tau^{(h)}_{,2}(x') \\ 0 \end{pmatrix}. \tag{53}$$

By (42) and (48) we have

$$\begin{aligned}\int_{U_h \times I_h} |\text{sym } \nabla \tilde{v}^{(h)}(x)|^2 \, dx &\le h^3 \int_{U_h} |\nabla'^2 \tau^{(h)}(x')|^2 \, dx' + h \int_{U_h} |\text{sym } \nabla' \tilde{w}^{(h)}(x')|^2 dx' \\ &\le C\eta_h h^2. \end{aligned} \tag{54}$$

(Later we will repeat this construction on the other side of the interface. Then one must replace the second summand in (53) by $x_3\big(\mu_2 - \tau^{(h)}_{,1}(x'),\ \mu_1 - \tau^{(h)}_{,2}(x'),\ \mu_3\big)^T$.) Now consider the interpolation

$$u^{(h)}(x) = v^{(h)}(x) + \phi^{(h)}(x_1)(\tilde{v}^{(h)}(x) - v^{(h)}(x)), \tag{55}$$

where $\phi^{(h)} : \mathbb{R} \to [0,1]$ denotes a smooth cutoff function that decreases from one to zero within the interval $(\xi_h - \frac{h}{8}, \xi_h)$, so spt $(\phi^{(h)})' \subset (\xi_h - \frac{h}{8}, \xi_h)$. We claim that

$$\int_{U_h \times I_h} |\text{sym } \nabla u^{(h)}(x)|^2 dx \le C\tilde{\eta}_h h^2, \tag{56}$$

where $\tilde{\eta}_h = \eta_h + |W_h|^2$ converges to zero as $h \to 0$.

To prove (56), recall that by the definition of U_h and (49) we have $Z_h'(\xi_h) \subset U_h$. Now notice that $u^{(h)} = \tilde{v}^{(h)}$ on $\big(U_h \times I_h\big) \setminus \big(Z_h'(\xi_h) \times I_h\big)$, whence by (54) we have

$\int_{(U_h\setminus Z_h'(\xi_h))\times I_h}|\text{sym }\nabla u^{(h)}|^2\le C\eta_h h^2$. It remains to prove (56) with the integration domain $Z_h'(\xi_h)\times I_h$ replacing $U_h\times I_h$. We make a standard calculation to obtain

$$\int_{Z_h'(\xi_h)\times I_h}|\text{sym }\nabla u^{(h)}(x)|^2dx$$

$$\le C\int_{Z_h'(\xi_h)\times I_h}|\text{sym }\nabla v^{(h)}(x)|^2+|\text{sym }\nabla\tilde v^{(h)}(x)|^2+\frac{1}{h^2}|\tilde v^{(h)}(x)-v^{(h)}(x)|^2dx. \tag{57}$$

Since $\xi_h\in G_2^{(h)}\cap G_3^{(h)}$, the first term on the right-hand side is estimated by (47). By (54) the second term in (57) satisfies $\int_{Z_h'(\xi_h)\times I_h}|\text{sym }\nabla\tilde v(x)|^2dx\le C\eta_h h^2$. Let us estimate the third term in (57). Since

$$\begin{pmatrix}w^{(h)}(x')\\ \tau^{(h)}(x')\end{pmatrix}=\fint_{I_h}v^{(h)}(x)dx_3=\fint_{I_h}v^{(h)}(x)+x_3(\nabla'\tau^{(h)}(x'))^Tdx_3$$

and since $w^{(h)}=\tilde w^{(h)}$ on the line $\{x\in S:x_1=\xi_h\}$, we can apply a Poincaré inequality (see, e.g., [16, Theorem 6.1-8]) to estimate the second term in the last step in (58) below. The first term in that step is estimated by the usual Poincaré inequality in the x_3-direction:

$$\int_{Z_h'(\xi_h)\times I_h}\frac{1}{h^2}|v^{(h)}(x)-\tilde v^{(h)}(x)|^2dx$$

$$\le\frac{C}{h^2}\int_{Z_h'(\xi_h)\times I_h}\left|v^{(h)}(x)+x_3\begin{pmatrix}\tau_{,1}^{(h)}(x')\\ \tau_{,2}^{(h)}(x')\\ 0\end{pmatrix}-\begin{pmatrix}w^{(h)}(x')\\ \tau^{(h)}(x')\end{pmatrix}\right|^2+|w^{(h)}(x')-\tilde w^{(h)}(x')|^2dx$$

$$\le C\int_{Z_h'(\xi_h)\times I_h}\left|v_{,3}^{(h)}(x)+\begin{pmatrix}\tau_{,1}^{(h)}(x')\\ \tau_{,2}^{(h)}(x')\\ 0\end{pmatrix}\right|^2+|\nabla'w^{(h)}(x')-\nabla'\tilde w^{(h)}(x')|^2dx. \tag{58}$$

To estimate the first term in (58), we observe that $(\tau_{,1}^{(h)}(x'),\tau_{,2}^{(h)}(x'),0)=\nabla\fint_{I_h}v_3^{(h)}(x)\,dx_3$, so we have

$$\int_{Z_h'(\xi_h)\times I_h}\left|v_{,3}^{(h)}(x)+\begin{pmatrix}\tau_{,1}^{(h)}(x')\\ \tau_{,2}^{(h)}(x')\\ 0\end{pmatrix}\right|^2dx\le\ C\int_{Z_h'(\xi_h)\times I_h}\left|v_{,3}^{(h)}(x)-\fint_{I_h}v_{,3}^{(h)}(x',z)dz\right|^2$$

$$+\left|\fint_{I_h}v_{,3}^{(h)}(x',z)dz+\left(\nabla\fint_{I_h}v_3^{(h)}(x',z)dz\right)^T\right|^2dx.$$

The second term is bounded by $\int_{Z_h'(\xi_h)\times I_h}|\text{sym }\nabla v^{(h)}|^2$ and can therefore be estimated by (47). By the x_3-independence of $R^{(h)}$, by Jensen's inequality, by definition of $R^{(h)}$,

and by (42), the first term can be estimated as follows:

$$\begin{aligned}\int_{Z_h'(\xi_h)\times I_h} \left| v_{,3}^{(h)}(x) - \fint_{I_h} v_{,3}^{(h)}(x',z)\,dz\right|^2\,dx \\ \leq C\int_{Z_h'(\xi_h)\times I_h} |v_{,3}^{(h)}(x) - R_3^{(h)}(x')|^2 + \left|\fint_{I_h} R_3^{(h)}(x') - v_{,3}^{(h)}(x',z)\,dz\right|^2\,dx \\ \leq C\eta_h h^2.\end{aligned}$$

Finally, the second term in (58) is bounded by

$$\begin{aligned}C\int_{Z_h'(\xi_h)\times I_h} |\nabla' w^{(h)}(x')|^2 + |\nabla'\tilde{w}^{(h)}(x') - W_h|^2 + |W_h|^2\,dx \\ \leq C\big(\eta_h h^2 + |Z_h'(\xi_h)\times I_h||W_h|^2\big).\end{aligned}$$

We have applied (52) and (45) multiplied by h (recall that $\xi_h \in G_1^{(h)}$), since here we are integrating over the thickness on the left-hand side. This proves (56) and finishes the first interpolation step.

Step 2. *Interpolation to an affine displacement.* We apply Lemma 16 to the mapping $u^{(h)}$ defined in (55) with $J_h = (\xi_h - a, \xi_h)$ instead of J_1, (so $J_h \times (-\frac{1}{2}, \frac{1}{2}) = U_h$) and with $t = \xi_h - \frac{a}{2}$ and $b = \frac{a}{4}$. Lemma 16 furnishes a mapping $\tilde{u}^{(h)}$ which agrees with $u^{(h)}$ on $\{x \in S\times I_h : x_1 > \xi_h - \frac{a}{2}\}$ and on $\{x \in S\times I_h : x_1 < \xi_h - \frac{3a}{4}\}$ agrees with an affine function $f^{(h)}$ with sym $\nabla f^{(h)} = 0$ (the mapping $\tilde{u}^{(h)}$ is at first not defined on $\{x_1 < \xi_h - a\}$, but since it is affine on $\{x \in S\times I_h : x_1 \in (\xi_h - a, \xi_h - \frac{3a}{4})\}$ we can extend it affinely). Moreover, $\tilde{u}^{(h)}$ satisfies $\int_{U_h\times I_h} |\text{sym }\nabla\tilde{u}^{(h)}|^2 \leq \frac{C}{a^4}\int_{U_h\times I_h} |\text{sym }\nabla u^{(h)}|^2$. Combining this with (56) and with the fact that $\tilde{u}^{(h)} = v^{(h)}$ on $\{x \in S\times I_h : x_1 > \xi_h\}$ and sym $\nabla\tilde{u}^{(h)} = 0$ on $\{x \in S\times I_h : x_1 < \xi_h - \frac{3a}{4}\}$, we conclude that

$$I^h(\tilde{u}^{(h)}; S) \to k(\nu_1). \tag{59}$$

Step 3. *Convergence.* Now we apply Steps 1 and 2 with obvious modifications also on the other side of the interface. Let us denote the resulting mappings by $\tilde{u}_a^{(h)}$. Hence $\tilde{u}_a^{(h)}$ is a $(+,1)$-recovery sequence on S which is affine on $\{x \in S\times I_h : |x_1| > 5a\}$ with sym $\nabla\tilde{u}_a^{(h)} = 0$ on $\{x \in S\times I_h : x_1 < -5a\}$ and sym $\nabla\tilde{u}_a^{(h)} = B$ on $\{x \in S\times I_h : x_1 > 5a\}$. By Proposition 19 there exists a sequence $a^{(h)} \to 0$ such that

$$\limsup_{h\to 0} I^h(\tilde{u}_{a^{(h)}}^{(h)}; S) = \limsup_{a\to 0}\limsup_{h\to 0} I^h(\tilde{u}_a^{(h)}; S) = k(\nu_1). \tag{60}$$

Theorem 6 implies that there exist affine mappings $f^{(h)}$ with sym $\nabla f^{(h)} = 0$ and $w \in \mathcal{A}(S)$ such that, after passing to an unrelabeled subsequence,

$$\bar{w}^{(h)} + f^{(h)} \to w \text{ strongly in } W^{1,2}(S;\mathbb{R}^2), \tag{61}$$

where we have set $\bar{w}^{(h)}(x') = \fint_{I_h} (\tilde{u}_{a^{(h)}}^{(h)}(x', x_3))'\,dx_3$. By Theorem 12 and (60) the limiting function w satisfies $I^0(w; S) \leq k(\nu_1)$. But by (61) and the properties of $\tilde{u}_{a^{(h)}}^{(h)}$ necessarily sym $\nabla' w = 0$ on $\{x \in S : x_1 < 0\}$ and sym $\nabla' w = \bar{B}$ on $\{x \in S : x_1 > 0\}$. Hence after possibly adding $w_1^+ - w$ to all $f^{(h)}$ (notice that $w_1^+ - w$ is affine with sym $\nabla'(w_1^+ - w) = 0$) we may assume that (61) holds with $w = w_1^+$ on the right-hand side. Since the same limit is obtained for every subsequence, (61) holds for the full

sequence with $w = w_1^+$, whence $x \mapsto \tilde{u}^{(h)}_{a^{(h)}}(x) + \binom{f^{(h)}(x')}{0}$ is the sought recovery sequence. ∎

LEMMA 16. *Let J_1, J_2 be open intervals, set $U = J_1 \times J_2$, let $i \in \{1,2\}$, and let $D \in \mathbb{R}^{3\times 3}$ be a symmetric matrix. Then there is a constant $C > 0$ such that the following holds: For every $h \in (0,1)$, for every $u^{(h)} \in W^{1,2}(U \times I_h; \mathbb{R}^3)$, for every $t \in J_i$, and for every $b \in (0,1)$ satisfying $t + b \in J_i$ (resp., $t - b \in J_i$), there exist $c^{(h)} \in \mathbb{R}^3$, $T^{(h)} \in \mathbb{R}^{3\times 3}$ with sym $T^{(h)} = 0$, and $\tilde{u}^{(h)} \in W^{1,2}(U \times I_h; \mathbb{R}^3)$ such that $\tilde{u}^{(h)} = u^{(h)}$ on $\{x \in U \times I_h : x_i < t\}$ (resp., $\{x \in U \times I_h : x_i > t\}$) and $\tilde{u}^{(h)} = Dx + T^{(h)}x + c^{(h)}$ on $\{x \in U \times I_h : x_i > t + b\}$ (resp., $\{x \in U \times I_h : x_i < t - b\}$) and such that $\int_{U\times I_h} |sym\ \nabla \tilde{u}^{(h)} - D|^2 \le \frac{C}{b^4} \int_{U\times I_h} |sym\ \nabla u^{(h)} - D|^2$. One can take*

$$T^{(h)} = skew \fint_{U\times I_h} \nabla u^{(h)}(x)\, dx \text{ and } c^{(h)} = \fint_{U\times I_h} u^{(h)}(x)\, dx. \tag{62}$$

Proof. We may assume without loss of generality that $D = 0$. (In fact, if $D \neq 0$, then apply the lemma with $D = 0$ to $\hat{u}^{(h)}(x) = u^{(h)}(x) - Dx$ instead of $u^{(h)}$ to obtain $\hat{u}^{(h)}$. Then define $\tilde{u}^{(h)}(x) = \hat{u}^{(h)}(x) + Dx$.) Moreover, we prove only the case when $i = 1$ and $t + b \in J_1$. By Proposition 17(ii) and Poincaré's inequality the mappings $f^{(h)}(x) = T^{(h)}x + c^{(h)}$ with $T^{(h)}$ and $c^{(h)}$ as in (62) satisfy

$$\int_{U\times I_h} |u^{(h)}(x) - f^{(h)}|^2 + |\nabla u^{(h)}(x) - T^{(h)}|^2 dx \le \frac{C}{h^2} \int_{U\times I_h} |\text{sym } \nabla u^{(h)}(x)|^2 dx. \tag{63}$$

Also, by Proposition 17(iii)

$$\int_{U\times I_h} |(u^{(h)})'(x) - (f^{(h)})'(x)|^2 dx \le C \int_{U\times I_h} |\text{sym } \nabla u^{(h)}(x)|^2 dx. \tag{64}$$

Fix a smooth cutoff function $\phi(x_1)$ which decreases from one to zero within the interval $(t + \frac{b}{4}, t + \frac{3b}{4})$. Set

$$\tilde{u}^{(h)}(x) = f^{(h)}(x) + \phi(x_1)(u^{(h)}(x) - f^{(h)}(x)) - x_3\phi'(x_1)(u_3^{(h)}(x) - f_3^{(h)}(x))e_1.$$

Then

$$\begin{aligned}\nabla \tilde{u}^{(h)}(x) &= T^{(h)} + \phi(x_1)(\nabla u^{(h)}(x) - T^{(h)}) + \begin{pmatrix} (u^{(h)} - f^{(h)})'(x) \\ 0 \end{pmatrix} \otimes e_1\phi'(x_1) \\ &\quad + (u^{(h)} - f^{(h)})_3(x)e_3 \otimes e_1\phi'(x_1) - (u^{(h)} - f^{(h)})_3(x)e_1 \otimes e_3\phi'(x_1) \\ &\quad - x_3 \left(\phi''(x_1)(u^{(h)} - f^{(h)})_3(x)e_1 \otimes e_1 + \phi'(x_1)e_1 \otimes (\nabla u_3^{(h)}(x) - (T^{(h)})^T e_3)\right).\end{aligned}$$

Upon taking the symmetric part of the above expression, the second line cancels, so we obtain

$$\begin{aligned}\int_{U\times I_h} |\text{sym } \nabla \tilde{u}^{(h)}|^2\, dx &\le C \int_{U\times I_h} |\text{sym } \nabla u^{(h)}|^2 + \frac{1}{b^2}|(u^{(h)} - f^{(h)})'|^2\, dx \\ &\quad + h^2 \int_{U\times I_h} \left(\frac{1}{b^4}|u^{(h)} - f^{(h)}|^2 + \frac{1}{b^2}|\nabla u^{(h)} - T^{(h)}|^2\right) dx,\end{aligned}$$

since $|\phi'| \le \frac{C}{b}$ and $|\phi''| \le \frac{C}{b^2}$. The last term is controlled by (63) and the $(u^{(h)} - f^{(h)})'$-term is controlled by (64). ∎

Proof of Theorem 1. By Lemma 2 we must prove the theorem only for the special case $A = 0$ and B as in (7). Statement (i) just rephrases the content of Theorem 12. The proof of (ii) is similar to that of Proposition 5.1 in [19]; compare also Step 2 in the proof of Theorem 5.6 in [18]. If $I^0(w) = \infty$, then the proof is trivial. Otherwise, $w \in \mathcal{A}(S)$, so by Proposition 7, w is affine on each connected component of $S \setminus \bigcup_{i=1}^{M} \mathcal{J}_i$, where the interfaces $\mathcal{J}_i \subset S$, $i = 1, \dots, M$ ($M \in \mathbb{N} \cup \{\infty\}$), are straight line segments parallel to e_1 or e_2 which intersect ∂S at their ends. By bounded variation we have $\sum_{i=1}^{M} \mathcal{H}^1(\mathcal{J}_i) < \infty$, so if $M = \infty$, then $\mathcal{H}^1(\mathcal{J}_i) \to 0$ as $i \to \infty$, so the $\mathcal{J}_i$ can accumulate only at ∂S. By translation invariance we may assume without loss of generality that S is strictly star-shaped with respect to the origin, so $\bar{S} \subset \eta S$ for any $\eta > 1$. Hence the restriction of $w_\eta(x) = \eta w(\frac{x}{\eta})$ to S is well defined and satisfies $w_\eta|_S \in \mathcal{A}(S)$. The mapping $w_\eta|_S$ has only finitely many interfaces $\mathcal{J}_i^\eta$, $i = 1, \dots, M_\eta$ (recall that the $\mathcal{J}_i$ accumulate only near ∂S), and they satisfy $\operatorname{dist}(\mathcal{J}_i^\eta, \mathcal{J}_k^\eta) > 0$ whenever $k \neq i$. By construction we have $\mathcal{J}_i^\eta = \tilde{\mathcal{J}}_i^\eta \cap S$, where $\tilde{\mathcal{J}}_i^\eta \subset \eta S$ are the interfaces of $w_\eta \in \mathcal{A}(\eta S)$. For $i = 1, \dots, M_\eta$, let $k_i \in \{1, 2\}$ be such that ν_{k_i} is normal to $\mathcal{J}_i^\eta$. Let $\varepsilon > 0$ be small (fixed below) and define the rectangles $S_i = \{x \in \mathbb{R}^2 : \pi_{k_i}(x) \in \pi_{k_i}(\tilde{\mathcal{J}}_i^\eta) + (-\varepsilon, \varepsilon) \text{ and } \pi_{k_i}^\perp(x) \in \pi_{k_i}^\perp(\tilde{\mathcal{J}}_i^\eta)\}$. Since the endpoints of $\tilde{\mathcal{J}}_i^\eta$ lie in $\partial(\eta S)$ and since the $\tilde{\mathcal{J}}_i^\eta$ do not intersect in ηS, for ε small enough the sides of ∂S_i which are parallel to ν_{k_i} do not intersect $\bar{S}$ and the S_i are pairwise disjoint. Define $\sigma_i \in \{-, +\}$ by the requirement that $w_\eta = w_{k_i, S_i}^{\sigma_i}$ on $S_i \cap \eta S$.

Now let $h_n \to 0$ be given and for all $i = 1, \dots, M_\eta$ let $(u_n^{(i)}, h_n)$ be a (σ_i, k_i)-recovery sequence on S_i. By Lemma 15 we may assume that $u_n^{(i)}$ is affine with $\operatorname{sym} \nabla u_n^{(i)} \in \{A, B\}$ in a neighborhood (relatively open in $S \times I_{h_n}$) of $(S \cap \partial S_i) \times I_{h_n}$. Hence we can extend each $u_n^{(i)}$ to all of $S \times I_{h_n}$ in such a way that $u_n^{(i)}$ is affine on each connected component of $(S \setminus S_i) \times I_{h_n}$. For $i, j = 1, \dots, M_\eta$ let us write $i \sim j$ whenever there exists a connected component S'_{ij} of $S \setminus \bigcup_{i=1}^{M_\eta} \mathcal{J}_i^\eta$ satisfying $S \cap \partial S'_{ij} = \mathcal{J}_i^\eta \cup \mathcal{J}_j^\eta$ (i.e., $\mathcal{J}_i^\eta$ and $\mathcal{J}_j^\eta$ are neighbors). By star-shapedness and the fact that $M_\eta < \infty$, and recalling that $u_n^{(i)}$ is affine on $(S \setminus S_i) \times I_{h_n}$, one inductively finds affine mappings $f_n^{(i)} : \mathbb{R}^3 \to \mathbb{R}^3$ with $\operatorname{sym} \nabla f_n^{(i)} = 0$, $i = 1, \dots, M_\eta$, such that $f_n^{(i)} + u_n^{(i)} = f_n^{(j)} + u_n^{(j)}$ on $S'_{ij} \setminus (S_i \cup S_j)$ whenever $i \sim j$. Now, for every $i = 1, \dots, M_\eta$, we set $v_n^\eta = u_n^{(i)} + f_n^{(i)}$ on S_i and extend it affinely to $S \times I_{h_n}$. Then $v_n^\eta \in W^{1,2}(S \times I_{h_n}; \mathbb{R}^3)$ is well defined by the choice of the $f_n^{(i)}$. Moreover, $\limsup_{n\to\infty} I^{h_n}(v_n^\eta; S) \leq I^0(w_\eta; S) + \rho_\eta$, where $\rho_\eta \downarrow 0$ as $\eta \downarrow 1$. By a diagonal sequence argument, this implies part (ii) of Theorem 1, since $w_\eta|_S \to w$ in $W^{1,2}(S; \mathbb{R}^2)$ and $I^0(w_\eta; S) \to I^0(w; S)$ as $\eta \downarrow 1$ (i.e., limiting displacements which arise as rescalings w_η of some $w \in \mathcal{A}(S)$ are energy dense; compare [2, p. 3]). □

Appendix. The following proposition was used in the proof of Lemma 16. Statement (ii) is Korn's inequality for thin films as presented in [3]; see also Problem 1.12 in [17].

PROPOSITION 17. *Let $S \subset \mathbb{R}^2$ be a bounded Lipschitz domain and let $A, B \in \mathbb{R}^{3\times 3}$ be such that rank$(A - B + F) \geq 2$ for all $F \in \mathbb{R}^{3\times 3}$ with sym $F = 0$. Then there is a constant $C(S)$ such that for all $h \in (0, 1)$ and for all $v^{(h)} \in W^{1,2}(S \times I_h; \mathbb{R}^3)$ the following hold:*

(i) *There exists a matrix sym $T^{(h)} \in \{A, B\}$ such that*

$$\int_{S\times I_h} |\nabla v^{(h)}(x) - T^{(h)}|^2 \, dx \leq \frac{C(S)}{h^2} \int_{S\times I_h} \operatorname{dist}^2(\operatorname{sym} \nabla v^{(h)}(x), \{A, B\}) \, dx.$$

(ii) *The estimate*

$$\int_{S\times I_h} |\nabla v^{(h)}(x) - T^{(h)}|^2 \, dx \le \frac{C(S)}{h^2} \int_{S\times I_h} |sym\ \nabla v^{(h)}(x)|^2 dx$$

holds for $T^{(h)} = skew \fint_{S\times I_h} \nabla v^{(h)}$.

(iii) *There exists* $c^{(h)} \in \mathbb{R}^2$ *such that*

$$\int_{S\times I_h} |(v^{(h)})'(x) - (T^{(h)}x)' - c^{(h)}|^2 dx \le C(S) \int_{S\times I_h} |sym\ \nabla v^{(h)}(x)|^2 \, dx$$

for the same $T^{(h)}$ *as in* (ii).

Proof. The proof of (i) is analogous to that of Theorem 10 in [29], with Theorem 3 replacing their geometric rigidity theorem. Statement (ii) can be proven in the same way, with Korn's inequality for one well replacing their geometric rigidity theorem. Another proof is given in [3] and [33]. Notice that if (ii) holds for some skew matrix, then it will also hold for the special choice $T^{(h)} = \text{skew} \fint_{S\times I_h} \nabla v^{(h)} dx$.

To prove statement (iii), set $w^{(h)}(x') = \fint_{I_h} (v^{(h)})'(x', x_3) dx_3$. From Korn's inequality in the plane and from Jensen's inequality we obtain

$$\begin{aligned} \int_S \left|\nabla' w^{(h)}(x') - \bar{T}^{(h)}\right|^2 \, dx' &\le C \int_S \left|\text{sym } \nabla' w^{(h)}(x')\right|^2 \, dx' \\ &\le \frac{C}{h} \int_{S\times I_h} |\text{sym } \nabla v^{(h)}(x)|^2 \, dx. \end{aligned} \tag{65}$$

With $c^{(h)} = \fint_S (w^{(h)}(x') - \bar{T}^{(h)}x') dx'$ we obtain

$$\begin{aligned} &\int_{S\times I_h} \left|(v^{(h)})'(x) - (T^{(h)}x)' - c^{(h)}\right|^2 \, dx \\ &\le C \int_{S\times I_h} \left|(v^{(h)})'(x) - (T_3^{(h)})' x_3 - w^{(h)}(x')\right|^2 + \left|w^{(h)}(x') - \bar{T}^{(h)}x' - c^{(h)}\right|^2 \, dx, \end{aligned}$$

where $T_3^{(h)}$ denotes the third column of $T^{(h)}$. The second term is estimated by applying Poincaré's inequality on S and then (65). To estimate the first term, notice that since the integration domain is symmetric, we have $w^{(h)}(x') = \fint_{I_h} (v'(x) - (T_3^{(h)})' x_3) \, dx_3$. Applying Poincaré's inequality in the x_3-direction for almost every x' and subsequently using (ii) shows that the first term is controlled by $\int_{S\times I_h} |\text{sym } \nabla v^{(h)}|^2$. □

The following lemma is a corollary of Proposition 4.1 in [19]. Notice that their ε corresponds to our h.

LEMMA 18. *Let* $a, l, d > 0$, *let* $U = (-l, l) \times (-d, d)$, *let* $\bar{A} = 0$ *and* $\bar{B} = e_1 \otimes e_2 + e_2 \otimes e_1$, *and let* $\bar{F} \in \{\bar{A}, \bar{B}\}$. *Then there are constants* $\eta_0, C_0 > 0$ *such that for every* $h \in (0, 1)$ *and* $w \in W^{2,2}(U; \mathbb{R}^2)$ *with*

$$I_{2D}^h(w; U) \le \eta_0 \text{ and } \int_U |sym\ \nabla' w(x') - \bar{F}|^2 \, dx' \le \eta_0$$

the set of $\xi \in (-l, l)$ *satisfying property* (P_h) *for* w *has measure not smaller than* l.

We say $\xi \in (-l,l)$ satisfies property (P_h) for $w \in W^{2,2}(U;\mathbb{R}^2)$ if, setting $U_1 = (\xi - a, \xi) \times (-\frac{d}{2}, \frac{d}{2})$ and $U_2 = (\xi, \xi + a) \times (-\frac{d}{2}, \frac{d}{2})$, for each $i = 1, 2$ there exist $\tilde{w}_i \in W^{1,2}\big(U_i;\mathbb{R}^2\big)$ with $\tilde{w}(\xi,\cdot) = w(\xi,\cdot)$ on $(-d/2, d/2)$ and

$$\frac{1}{h}\int_{U_i} |sym\ \nabla' \tilde{w}_i(x') - \bar{F}|^2 dx' \leq C_0 \left(I^h_{2D}\big(w;U\big) + \int_U |sym\ \nabla' w(x') - \bar{F}|^2 dx' \right).$$

An analogous result holds for lines of the form $\{x_2 = \xi\}$.

Proof. Set $\eta = I^h_{2D}(w;U) + \int_U |\mathrm{sym}\ \nabla' w - \bar{F}|^2$. By Proposition 4.1 in [19] there exists a Borel set $\Sigma \subset (-l,l)$ with $|\Sigma| \geq l$ and such that for all $\xi \in \Sigma$ there exists an affine mapping $w_\xi : \mathbb{R}^2 \to \mathbb{R}^2$ with $\mathrm{sym}\ \nabla' w_\xi = \bar{F}$ and

$$\|w(\xi,\cdot) - w_\xi(\xi,\cdot)\|^2_{H^{1/2}((-\frac{d}{2},\frac{d}{2});\mathbb{R}^2)} \leq Ch\eta. \tag{66}$$

By the properties of the $H^{1/2}$-norm (see, e.g., the appendix of [32] for a review), for $i = 1, 2$ there exist $v_i \in W^{1,2}(U_i;\mathbb{R}^2)$ such that

$$\int_{U_i} |\nabla' v_i(x')|^2\ dx' \leq \|w(\xi,\cdot) - w_\xi(\xi,\cdot)\|^2_{H^{1/2}((-\frac{d}{2},\frac{d}{2});\mathbb{R}^2)} \tag{67}$$

and $v_i(\xi,\cdot) = w(\xi,\cdot) - w_\xi(\xi,\cdot)$ on $(-\frac{d}{2}, \frac{d}{2})$ in the trace sense. Setting $\tilde{w}_i = v_i + w_\xi$, we find

$$\frac{1}{h}\int_{U_i} |\mathrm{sym}\ \nabla' \tilde{w}_i(x') - \bar{F}|^2\ dx' \leq \frac{C}{h}\int_{U_i} |\nabla' v_i(x')|^2 + |\mathrm{sym}\ \nabla' w_\xi(x') - \bar{F}|^2\ dx' \leq C\eta$$

and $\tilde{w}_i(\xi,\cdot) = w(\xi,\cdot)$ on $(-\frac{d}{2}, \frac{d}{2})$ in the trace sense. We have used (66)–(67) and the fact that $\mathrm{sym}\ \nabla' w_\xi = \bar{F}$. ∎

The following proposition is a standard diagonalization lemma (compare [4, Corollary 1.16] or [13, Lemma 7.2]).

PROPOSITION 19. *Let $a_{k,j}$ be a doubly indexed sequence of real numbers, $k, j \to \infty$. Then there exists a subsequence $k_j \to \infty$ such that*

$$\limsup_{j\to\infty} a_{k_j,j} = \limsup_{k\to\infty} \limsup_{j\to\infty} a_{k,j}.$$

Acknowledgments. This work is part of my Ph.D. thesis supervised by Prof. S. Müller (Max-Planck-Institute for Mathematics in the Sciences, Leipzig), whom I thank for his steady advice. I also wish to thank Prof. S. Conti for interesting discussions on the topic and for a lot of helpful comments on a preliminary version of this work.

DERIVATION OF A MACROSCOPIC RECEPTOR-BASED MODEL USING HOMOGENIZATION TECHNIQUES*

ANNA MARCINIAK-CZOCHRA† AND MARIYA PTASHNYK‡

Abstract. We study the problem of diffusive transport of biomolecules in the intercellular space, modeled as porous medium, and of their binding to the receptors located on the surface membranes of the cells. Cells are distributed periodically in a bounded domain. To describe this process we introduce a reaction-diffusion equation coupled with nonlinear ordinary differential equations on the boundary. We prove existence and uniqueness of the solution of this problem. We consider the limit, when the number of cells tends to infinity and at the same time their size tends to zero, while the volume fraction of the cells remains fixed. Using the homogenization technique of two-scale convergence, we show that the sequence of solutions of the original problem converges to the solution of the so-called macroscopic problem. To show the convergence of the nonlinear terms on the surfaces we use the unfolding method (periodic modulation). We discuss applicability of the result to mathematical description of membrane receptors of biological cells and compare the derived model with those previously considered.

Key words. homogenization, two-scale convergence, intercellular communication, receptor-ligand binding, reaction-diffusion equations, unfolding method (periodic modulation)

1. Introduction.

Regulatory and signaling molecules (ligands) act by binding and activating receptor molecules. Receptors are usually located in the cell membrane, with some exceptions such as lipophilic ligands, which are located in the cytoplasm [24, 33, 34]. Some receptors interact with surface-bound ligands, such as adhesion proteins and extracellular matrix components. Other receptors bind soluble ligands, such as growth factors and cytokines. There are also many ligands which are present in both forms. As an example, antibodies, which are secreted by B cells as soluble molecules, become surface-bound ligands for the Fc receptors upon binding to antigens deposited on the surface [25].

Soluble molecules which are secreted to the intercellular space and transported via diffusion provide cell-to-cell communication, which results in the activation of processes in cells at a distance from the original signal. This happens, for example, in the case of the bystander effect. There is strong evidence that unirradiated bystander cells respond to signals emitted by irradiated cells [28]. In another case, the interplay between the spatial transport of virons and interferons results in the formation of patterns of infected and resistant cells [10]. Intercellular signaling can also lead to the formation of spatially nonhomogeneous structures, which is especially evident in developmental processes [33, 34]. The effects of the spatial transport of the soluble molecules are even visible in experiments in which only spatial averages are measured in order to understand the time dynamics of a signaling pathway. There is evidence

that different mixing conditions strongly influence quantitative and also qualitative results of such experiments [17]. Therefore, there arises a need to explain how the intercellular transport of the molecules should be described on the macroscopic level.

Models proposed so far are mainly phenomenological and describe all the processes on the macroscale level represented by a two- or three-dimensional sheet of cells [29, 30, 31, 32, 42, 46]. However, the real geometry is much more complicated, and binding a soluble ligand to a cell surface receptor requires interaction of molecules diffusing in three-dimensional space with some molecules attached to a two-dimensional surface. Since the size of a cell is very small compared to the dimension of the whole tissue, systems that include cells have to be treated as multiscale systems.

The aim of the present work is to derive a macroscopic model of receptor-ligand binding, based on a microscopic description, using methods of asymptotic analysis. Such an approach is called homogenization and it hinges on demonstrating the convergence of solutions of a sequence of microscopic problems to the solution of the macroscopic problem in properly chosen function spaces. We use here the two-scale convergence, which was introduced in [2] and [36] for sequences of functions $\{u^\varepsilon\}$ bounded in L^2 or in H^1 on an ε-periodic domain. Then, in [37] and [3], the definition of two-scale convergence was extended to sequences of functions defined on ε-periodic hypersurfaces, with dependence on parameters. This extension was used to homogenize a diffusion-reaction process in a catalyst consisting of distributed bars [37]. A similar problem with convection was studied in [19] using the standard homogenization technique, the energy method. A model describing processes of diffusion, convection, and nonlinear reactions in a periodic array of cells was studied in [20]. In that paper, the convergence of the nonlinear terms was shown using their monotonicity. Homogenization of models of chemical reactive flows in domains with periodically distributed reactive solid grains was also recently studied by Conca et al. [9]. They considered a stationary reaction-diffusion model with nonlinear, fast growing but monotone kinetics on the the surface of reactive solid grains and a model of reaction-diffusion processes both inside and outside of grains. Homogenization of the reaction-diffusion-convection processes with linear reactions on the surface of microstructures was also considered by Hornung in [18].

The model presented in this paper includes the dynamics of molecule concentrations on the surface of microstructures described by nonlinear ordinary differential equations. Therefore, we apply the concept of two-scale convergence of functions from L^∞ on ε-periodic hypersurfaces. To show convergence of the nonlinear terms on the surface of microstructures we use the unfolding method (periodic modulation); see [5, 6, 7].

Our paper is organized as follows. First, we present a precise description of the considered ε-periodic geometry (section 2) and of the equations describing the microscopic nature of the receptor-ligand binding process (section 3). These equations are spatially scaled by ε. Then we show existence and uniqueness of solutions of the microscopic model (section 3.2) and a priori estimates (section 3.3). In section 4, after extension of the solutions from the porous domain to the whole domain, using a priori estimates, we show the convergence of solutions of the microscopic problem to the solutions of a macroscopic homogenized model. Effective macroscopic equations are derived in section 4.2 and formulated in Theorem 4.4. In section 5 we compare a derived macroscopic model of the receptor-ligand binding on cells surfaces with the phenomenological models previously discussed in the literature.

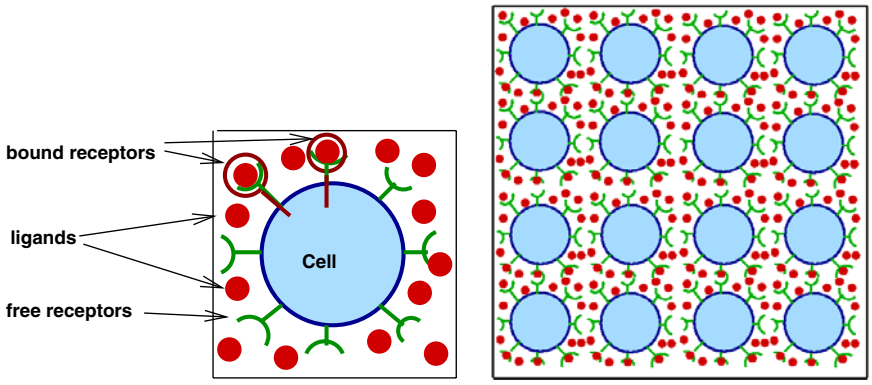

FIG. 1. *Geometry of the model. The array of the cells (on the right-hand side) consists of periodic repetition of the so-called standard cell, $Z = [0,1]^3$ (on the left-hand side), which corresponds to a single biological cell with the surrounding intercellular space.*

2. Problem formulation. We consider a model involving a system of cells, periodically distributed in a three-dimensional cube $\Omega = [a,b]^3$, $a, b \in \mathbb{R}$, $a < b$, with boundary Γ^N. For the mathematical formulation of the problem we consider the so-called standard cell, $Z = [0,1]^3$, periodically repeated over $\mathbb{R}^3$ with $Y_0 \subset Z$, an open subset with a smooth boundary Γ; $Y = Z \backslash \overline{Y}_0$; and ν, the outer normal of Y (see Figure 1).

Let $\varepsilon > 0$ be a given scale factor such that $\varepsilon = \frac{b-a}{n}$, $n \in \mathbb{N}$, denoting the ratio between the size of the cells and the size of the whole domain Ω. Then the geometric structure within the fixed domain Ω is obtained by intersecting the ε-multiple εZ with Ω. We define, for $k \in \mathbb{Z}^3$, a triple of integers; and e_i, unit vectors, $\Gamma^k = \Gamma + \sum_{i=1}^3 k_i e_i$, $Y_0^k = Y_0 + \sum_{i=1}^3 k_i e_i$, $Z^k = Z + \sum_{i=1}^3 k_i e_i$, $\Gamma^* = \cup\{\Gamma^k, \ k \in \mathbb{Z}^3\}$, $Z^* = \cup\{Z^k, \ k \in \mathbb{Z}^3\}$. We further define $\Omega_0^\varepsilon = \cup\{\varepsilon Y_0^k | \varepsilon Z^k \subset \Omega, \ k \in \mathbb{Z}^3\}$, $\Omega^\varepsilon = \Omega \backslash \Omega_0^\varepsilon$, $\Gamma^\varepsilon = \cup\{\varepsilon\Gamma^k | \varepsilon Z^k \subset \Omega, \ k \in \mathbb{Z}^3\}$.

Remark 2.1. The geometry defined above fulfills the assumptions that

1. cells (holes in the domain) do not touch the boundary $\partial\Omega$;
2. cells do not touch each other;
3. cells have smooth boundary.

These assumptions allow for the definition of the functions on the cell boundaries using periodic repetition, and the definition of extension as proposed in [8]. Therefore, these assumptions are important for the methods applied in this paper. Homogenization of the Neumann problem in domains with more complicated geometry was considered in [1] and [4].

We assume that new ligands and new free receptors are produced on the cell surface through a combination of recycling (dissociation of bound receptors) and *de novo* production within the cell. Free receptors exist only on the surfaces, while ligands are transported by diffusion within the intercellular space, which is a porous medium. A ligand reversibly binds to a free receptor, which results in a bound receptor that can be internalized into the cell. Bound receptors also dissociate. Both ligands and free receptors undergo natural decay. We denote the concentration of ligands by $l^\varepsilon : (0,T) \times \Omega^\varepsilon \to \mathbb{R}$. Bound and free receptor densities are denoted by $r_b^\varepsilon : (0,T) \times \Gamma^\varepsilon \to \mathbb{R}$ and $r_f^\varepsilon : (0,T) \times \Gamma^\varepsilon \to \mathbb{R}$, respectively. For simplicity we assume that all binding processes are governed by the law of mass action without saturation effects.

3. Microscopic model.

3.1. Model assumptions. The microscopic model consists of the following equations:

Diffusion equation for ligands in the intercellular space,

$$\frac{\partial}{\partial t}l^\varepsilon(t,x) = \nabla\cdot(D^\varepsilon(t,x)\nabla l^\varepsilon(t,x)) - \mu_l^\varepsilon(t,x)l^\varepsilon(t,x) + p_l^\varepsilon(t,x,l^\varepsilon(x,t)) \quad \text{in } (0,T)\times\Omega^\varepsilon,$$

$$\nu^\varepsilon\cdot\nabla_x l^\varepsilon(t,x) = 0 \quad \text{on } (0,T)\times\Gamma^N,$$

$$l^\varepsilon(x,t) = l_0(x), \quad t=0,\ x\in\Omega^\varepsilon. \tag{1}$$

Binding equation on the surfaces,

$$-D^\varepsilon(t,x)\nabla l^\varepsilon(t,x)\cdot\nu^\varepsilon = \varepsilon(b^\varepsilon(t,x)l^\varepsilon(t,x){r_f}^\varepsilon(t,x) - d^\varepsilon(t,x)r_b^\varepsilon(t,x)) \text{ on } (0,T)\times\Gamma^\varepsilon. \tag{2}$$

Reaction equations for receptors on the surfaces,

$$\frac{\partial}{\partial t}{r_f}^\varepsilon(x,t) = -\mu_f^\varepsilon(t,x){r_f}^\varepsilon(x,t) + p_r^\varepsilon(t,x,r_b^\varepsilon(x,t)) - b^\varepsilon(t,x){r_f}^\varepsilon(x,t)l^\varepsilon(x,t)$$

$$+ d^\varepsilon(t,x){r_b}^\varepsilon(x,t), \tag{3}$$

$$\frac{\partial}{\partial t}{r_b}^\varepsilon(x,t) = -\mu_b^\varepsilon(t,x){r_b}^\varepsilon(x,t) + b^\varepsilon(t,x){r_f}^\varepsilon(x,t)l^\varepsilon(x,t) - d^\varepsilon(t,x){r_b}^\varepsilon(x,t), \tag{4}$$

with initial conditions

$${r_f}^\varepsilon(x,t) = {r_f}_0(x), \quad t=0,\ x\in\Gamma^\varepsilon, \tag{5}$$

$${r_b}^\varepsilon(x,t) = r_{b0}(x), \quad t=0,\ x\in\Gamma^\varepsilon. \tag{6}$$

The following is a list of functional coefficients in these equations:

$\mu_l^\varepsilon : (0,T)\times\Omega\to\mathbb{R}$	rate of decay of ligands,
$p_l^\varepsilon : (0,T)\times\Omega\times\mathbb{R}\to\mathbb{R}$	production of ligands,
$D^\varepsilon : (0,T)\times\Omega\to\mathbb{R}^{3\times 3}$	diffusion coefficient for ligands,
$p_r^\varepsilon : (0,T)\times\Gamma^\varepsilon\times\mathbb{R}\to\mathbb{R}$	production of new free receptors,
$\mu_f^\varepsilon : (0,T)\times\Gamma^\varepsilon\to\mathbb{R}$	rate of decay of free receptors,
$\mu_b^\varepsilon : (0,T)\times\Gamma^\varepsilon\to\mathbb{R}$	rate of decay of bound receptors,
$d^\varepsilon : (0,T)\times\Gamma^\varepsilon\to\mathbb{R}$	rate of dissociation of bound receptors,
$b^\varepsilon : (0,T)\times\Gamma^\varepsilon\to\mathbb{R}$	rate of binding of ligands and free receptors,

where functions on Ω or Γ^ε are defined by Z-periodic function: $D_{i,j}^\varepsilon(t,x) = D_{i,j}(t,\frac{x}{\varepsilon})$, $p_l^\varepsilon(t,x,\xi) = p_l(t,\frac{x}{\varepsilon},\xi)$, $\mu_l^\varepsilon(t,x) = \mu_l(t,\frac{x}{\varepsilon})$, $\mu_f^\varepsilon(t,x) = \mu_f(t,\frac{x}{\varepsilon})$, $\mu_b^\varepsilon(t,x) = \mu_b(t,\frac{x}{\varepsilon})$, $b^\varepsilon(t,x) = b(t,\frac{x}{\varepsilon})$, $d^\varepsilon(t,x) = d(t,\frac{x}{\varepsilon})$, $p_r^\varepsilon(t,x,\xi) = p_r(t,\frac{x}{\varepsilon},\xi)$, defined on Z^* and Γ^*, respectively.

We assume that decay processes are linear and that binding is a product of the density of ligands and free receptors. The proposed functions are the simplest functions usually used to describe decay or binding processes (see the models described in [35]), modeled by the law of mass action. We assume that *de novo* production of free receptors, denoted by p_r, is regulated by bound receptors. We assume that p_r

is a bounded Lipschitz continuous function in r_b and is nonnegative for nonnegative values of r_b, for example a Michaelis–Menten function $p_r = \frac{m_1 r_b}{1+r_b}$. In addition, we assume that the production of ligands depends on their density. It could be regulated via some other receptors not considered in our model. Thus, we assume that p_l is a Lipschitz continuous function in l, nonnegative for nonnegative values of l.

Assumption 3.1.

1. $D \in L^\infty((0,T)\times Z)^{3\times 3}$, $\partial_t D \in L^\infty((0,T)\times Z)^{3\times 3}$, $(D(t,x)\xi,\xi) \ge d_0|\xi|^2$ for some $d_0 > 0$, for every $\xi \in \mathbb{R}^3$, a.a. $(t,x) \in (0,T)\times Z$.
2. $\mu_l \in L^\infty((0,T)\times Z)$ and $\mu_l \ge 0$ a.e. in $(0,T)\times Z$.
3. p_l is measurable in t and x, sublinear, i.e., $|p_l(t,x,\xi)| \le c_1 + c_2|\xi|$ for a.a. $(t,x) \in (0,T)\times Z$, Lipschitz continuous in ξ, and $p_l(t,x,\xi) \ge 0$ for $\xi \ge 0$.
4. $b \in C([0,T]; C^{0,\alpha}(\Gamma))$, $b \ge 0$, in $[0,T]\times\Gamma$, $\partial_t b \in L^\infty((0,T)\times\Gamma)$.
5. $d \in C([0,T]; C^{0,\alpha}(\Gamma))$, $d \ge 0$, in $[0,T]\times\Gamma$, $\partial_t d \in L^\infty((0,T)\times\Gamma)$.
6. $\mu_f, \mu_b \in C([0,T]; C^{0,\alpha}(\Gamma))$, $\mu_f \ge 0$, $\mu_b \ge 0$, in $[0,T]\times\Gamma$.
7. $p_r(\xi) \in C([0,T]; C^{0,\alpha}(\Gamma))$ for all $\xi \in \mathbb{R}$, $p_r(t,x,\xi) \ge 0$ for $\xi \ge 0$, p_r is bounded, i.e., $|p_r(t,x,\xi)| \le m_1$ for all $(t,x,\xi) \in (0,T)\times\Gamma\times\mathbb{R}$ and is Lipschitz continuous in ξ.

3.2. Existence of the solutions of the microscopic model. We start with a weak formulation of the microscopic model.

Definition 3.2. *The triple $(l^\varepsilon, r_f^\varepsilon, r_b^\varepsilon)$ is a solution of problem* (1)–(6) *if $l^\varepsilon \in L^2((0,T); H^1(\Omega^\varepsilon))$, $\partial_t l^\varepsilon \in L^2((0,T)\times\Omega^\varepsilon)$, $l^\varepsilon \in L^\infty((0,T)\times\Omega^\varepsilon)$, r_f^ε, $r_b^\varepsilon \in L^\infty((0,T)\times\Gamma^\varepsilon)$, $\partial_t r_f^\varepsilon$, $\partial_t r_b^\varepsilon \in L^\infty((0,T)\times\Gamma^\varepsilon)$ such that*

1.
$$\begin{aligned}(\partial_t l^\varepsilon, \phi)_{(0,T)\times\Omega^\varepsilon} &= -(D^\varepsilon \nabla l^\varepsilon, \nabla\phi)_{(0,T)\times\Omega^\varepsilon} - (\mu_l^\varepsilon l^\varepsilon, \phi)_{(0,T)\times\Omega^\varepsilon} \\ &\quad + (d^\varepsilon r_b^\varepsilon - b^\varepsilon r_f^\varepsilon l^\varepsilon, \phi)_{(0,T)\times\Gamma^\varepsilon} + (p_l^\varepsilon(l^\varepsilon), \phi)_{(0,T)\times\Omega^\varepsilon}\end{aligned} \tag{7}$$
for all $\phi \in L^2((0,T); H^1(\Omega^\varepsilon))$;
2. *l^ε satisfies the initial condition, i.e., $l^\varepsilon \to l_0$ in $L^2(\Omega^\varepsilon)$ as $t \to 0$;*
3.
$$\begin{cases} \dfrac{\partial}{\partial t} {r_f}^\varepsilon(x,t) = -\mu_f^\varepsilon {r_f}^\varepsilon(x,t) + p_r^\varepsilon(t,x,r_b^\varepsilon(x,t)) \\ \qquad\qquad - b^\varepsilon {r_f}^\varepsilon(x,t) l^\varepsilon(x,t) + d^\varepsilon {r_b}^\varepsilon(x,t), \\ \dfrac{\partial}{\partial t} {r_b}^\varepsilon(x,t) = -\mu_b^\varepsilon {r_b}^\varepsilon(x,t) + b^\varepsilon {r_f}^\varepsilon(x,t) l^\varepsilon(x,t) \\ \qquad\qquad - d^\varepsilon {r_b}^\varepsilon(x,t) \end{cases} \tag{8}$$
a.e. $(0,T)\times\Gamma^\varepsilon$;
4. *${r_f}^\varepsilon, {r_b}^\varepsilon$ satisfy the initial conditions* (5)–(6).

Here $(u,v)_{(0,T)\times\Omega^\varepsilon} = \int_0^T \int_{\Omega^\varepsilon} u\,v\,dx\,dt$ and $(u,v)_{(0,T)\times\Gamma^\varepsilon} = \varepsilon \int_0^T \int_{\Gamma^\varepsilon} u\,v\,d\gamma_x\,dt$.

Theorem 3.3. *Let Assumption* 3.1 *be satisfied and*

$$l_0 \in C^{0,\alpha}(\overline{\Omega}),\ \ l_0 \in H^1(\Omega),\ \ l_0 \ge 0,$$

$$r_{f0}, r_{b0} \in C^{0,\alpha}(\overline{\Omega}),\ \ r_{f0} \ge 0,\ \ r_{b0} \ge 0.$$

Then there exists a unique solution $(l^\varepsilon, r_f^\varepsilon, r_b^\varepsilon)$ of problem (1)–(6), *such that*

$$l^\varepsilon \in H^1(0,T; L^2(\Omega^\varepsilon)),\ l^\varepsilon \in L^2(0,T; H^1(\Omega^\varepsilon)),$$

$$l^\varepsilon \in C^{0,\beta/2}([0,T]; C^{0,\beta}(\overline{\Omega}^\varepsilon)),$$

$$r_f^\varepsilon, r_b^\varepsilon \in C^1([0,T]; C^{0,\beta}(\Gamma^\varepsilon)), \quad \textit{where} \quad \beta \in (0,\alpha],$$

$$\textit{and} \quad l^\varepsilon \ge 0, r_f^\varepsilon \ge 0, r_b^\varepsilon \ge 0.$$

Proof. Existence. The existence of a solution of the system (1), (3), (4) will be proved by showing the existence of a fix point of the operator K defined on $C([0,T]\times\overline{\Omega}^{\varepsilon})$ by $l^{n,\varepsilon}=K(l^{n-1,\varepsilon})$ with $l^{n,\varepsilon}$ given by

$$
(9)\quad \begin{cases} \partial_t\, l^{n,\varepsilon} = \nabla\cdot(D^{\varepsilon}\nabla l^{n,\varepsilon}) - \mu_l^{\varepsilon} l^{n,\varepsilon} + p_l^{\varepsilon}(l^{n-1,\varepsilon}), & t>0,\ x\in\Omega^{\varepsilon},\\ \nabla l^{n,\varepsilon}\cdot\nu^{\varepsilon} = 0, & t>0,\ x\in\Gamma^{N},\\ l^{n,\varepsilon} = l_0, & t=0,\ x\in\Omega^{\varepsilon},\\ -D^{\varepsilon}\nabla l^{n,\varepsilon}\cdot\nu^{\varepsilon} = \varepsilon(b^{\varepsilon} l^{n,\varepsilon} {r_f}^{n,\varepsilon} - d^{\varepsilon}{r_b}^{n,\varepsilon}), & t>0,\ x\in\Gamma^{\varepsilon}, \end{cases}
$$

$$
(10)\quad \begin{cases} \partial_t {r_f}^{n,\varepsilon} = -\mu_f^{\varepsilon}{r_f}^{n,\varepsilon} + p_r^{\varepsilon}({r_b}^{n,\varepsilon}) - b^{\varepsilon}{r_f}^{n,\varepsilon} l^{n-1,\varepsilon} + d^{\varepsilon}{r_b}^{n,\varepsilon}, & t>0,\ x\in\Gamma^{\varepsilon},\\ \partial_t {r_b}^{n,\varepsilon} = -\mu_b^{\varepsilon}{r_b}^{n,\varepsilon} + b^{\varepsilon}{r_f}^{n,\varepsilon} l^{n-1,\varepsilon} - d^{\varepsilon}{r_b}^{n,\varepsilon}, & t>0,\ x\in\Gamma^{\varepsilon},\\ {r_f}^{n,\varepsilon} = r_{f0}, & t=0,\ x\in\Gamma^{\varepsilon},\\ {r_b}^{n,\varepsilon} = r_{b0}, & t=0,\ x\in\Gamma^{\varepsilon}. \end{cases}
$$

For a given $l^{n-1,\varepsilon}\in C([0,T]\times\overline{\Omega}^{\varepsilon})$, $l^{n-1,\varepsilon}\geq 0$ on $[0,T]\times\overline{\Omega}^{\varepsilon}$, there exists a unique solution of system (10), $r_f^{n,\varepsilon}$, $r_b^{n,\varepsilon}\in C^1([0,T];C(\Gamma^{\varepsilon}))$, because the right-hand side of the system of ordinary differential equations (10) is Lipschitz continuous [45]. Since p_r is a nonnegative function for nonnegative values of r_b and $l^{n-1,\varepsilon}\geq 0$ on $[0,T]\times\Gamma^{\varepsilon}$ and $r_{f0}\geq 0$, $r_{b0}\geq 0$, we deduce that $r_f^{n,\varepsilon}\geq 0$, $r_b^{n,\varepsilon}\geq 0$ on $[0,T]\times\Gamma^{\varepsilon}$.

Using the Galerkin method and a priori estimates similar to the estimates in Lemma 3.4, we obtain the existence of a weak solution of (9), $l^{n,\varepsilon}\in L^2(0,T;H^1(\Omega^{\varepsilon}))$, $\partial_t l^{n,\varepsilon}\in L^2(0,T;L^2(\Omega^{\varepsilon}))$; see [23]. Since $l_0\in C^{0,\alpha}(\overline{\Omega})$, there exists $\max_{\overline{\Omega}^{\varepsilon}}|l_0|=M$. In addition, $r_f^{n,\varepsilon}\geq 0$ and $|r_b^{n,\varepsilon}|\leq C$. Thus, we may apply the result from [26] (Theorem 6.40) stating that for parabolic equations with uniformly elliptic operator, sublinear terms of lower order, bounded free terms, and bounded coefficients of Robin boundary conditions, the boundedness of the initial conditions implies the boundedness of the supremum of a solution. From this, we conclude that $\sup_{(0,T)\times\Omega^{\varepsilon}}|l^{n,\varepsilon}|\leq M_1$. Then, since $l_0\in C^{0,\alpha}(\overline{\Omega})$, $r_f^{n,\varepsilon}\geq 0$, and $r_b^{n,\varepsilon}\in C^1([0,T];C(\Gamma^{\varepsilon}))$, we conclude also that $l^{n,\varepsilon}\in C^{0,\beta/2}([0,T];C^{0,\beta}(\overline{\Omega}^{\varepsilon}))$ (see Theorem III.10.1 in [23], generalized for Robin boundary conditions, or [11] and [26]). Using the maximum principle and the continuity of $l^{n,\varepsilon}$, we obtain that $l^{n,\varepsilon}\geq 0$ in $[0,T]\times\overline{\Omega}^{\varepsilon}$ [12].

The space $C^{0,\beta/2}([0,T];C^{0,\beta}(\overline{\Omega}^{\varepsilon}))$ is compact embedded in $C([0,T]\times\overline{\Omega}^{\varepsilon})$. Then, by virtue of the Schauder theorem, there exists a fixed point of K, a solution of the microscopic problem l^{ε}, r_f^{ε}, and r_b^{ε}. In addition, we obtain that $l^{\varepsilon}\geq 0$, $r_f^{\varepsilon}\geq 0$, and $r_b^{\varepsilon}\geq 0$. Since $r_{f0}, r_{b0}\in C^{0,\alpha}(\Omega)$ and $l^{\varepsilon}\in C^{0,\beta/2}([0,T];C^{0,\beta}(\overline{\Omega}^{\varepsilon}))$, we conclude also that $r_f^{\varepsilon}, r_b^{\varepsilon}\in C^1([0,T];C^{0,\beta}(\Gamma^{\varepsilon}))$.

Uniqueness. Suppose there are two solutions of the problem $(l^{1,\varepsilon}, r_f^{1,\varepsilon}, r_b^{1,\varepsilon})$ and $(l^{2,\varepsilon}, r_f^{2,\varepsilon}, r_b^{2,\varepsilon})$. We denote $l^{\varepsilon}=l^{1,\varepsilon}-l^{2,\varepsilon}$ and choose $\phi=l^{\varepsilon}$. We calculate

$$
\frac{1}{2}\int_0^{\tau}\int_{\Omega^{\varepsilon}}\Big(\partial_t|l^{\varepsilon}|^2 + (D^{\varepsilon}\nabla l^{\varepsilon},\nabla l^{\varepsilon}) + \mu_l^{\varepsilon}|l^{\varepsilon}|^2\Big)\,dx\,dt = \int_0^{\tau}\int_{\Omega^{\varepsilon}}(p_l^{\varepsilon}(l^{1,\varepsilon}) - p_l^{\varepsilon}(l^{2,\varepsilon}))l^{\varepsilon}\,dx\,dt
$$

$$
+\varepsilon\int_0^{\tau}\int_{\Gamma^{\varepsilon}}((d^{\varepsilon}r_b^{1,\varepsilon} - b^{\varepsilon}r_f^{1,\varepsilon}l^{1,\varepsilon}) - (d^{\varepsilon}r_b^{2,\varepsilon} - b^{\varepsilon}r_f^{2,\varepsilon}l^{2,\varepsilon}))\,l^{\varepsilon}\,d\gamma\,dt
$$

for any $\tau \in [0,T]$. For r_f^ε and r_b^ε we obtain

$$\frac{\partial}{\partial t}(r_f^{1,\varepsilon} - r_f^{2,\varepsilon}) = -\mu_f^\varepsilon(r_f^{1,\varepsilon} - r_f^{2,\varepsilon}) + (p_r^\varepsilon(r_b{}^{1,\varepsilon}) - p_r^\varepsilon(r_b{}^{2,\varepsilon})) - b^\varepsilon(r_f^{1,\varepsilon} l^{1,\varepsilon} - r_f^{2,\varepsilon} l^{2,\varepsilon}) + d^\varepsilon(r_b^{1,\varepsilon} - r_b^{2,\varepsilon}),$$

$$\frac{\partial}{\partial t}(r_b^{1,\varepsilon} - r_b^{2,\varepsilon}) = -\mu_b^\varepsilon(r_b^{1,\varepsilon} - r_b^{2,\varepsilon}) + b^\varepsilon(r_f^{1,\varepsilon} l^{1,\varepsilon} - r_f^{2,\varepsilon} l^{2,\varepsilon}) - d^\varepsilon(r_b^{1,\varepsilon} - r_b^{2,\varepsilon}).$$

Integrating by parts with respect to time and summing up side by side the last two equations, we obtain

$$|r_f^{1,\varepsilon} - r_f^{2,\varepsilon}| + |r_b^{1,\varepsilon} - r_b^{2,\varepsilon}| \le \int_0^\tau \Big(\mu_f^1 |r_f^{1,\varepsilon} - r_f^{2,\varepsilon}| + \mu_b^1 |r_b^{1,\varepsilon} - r_b^{2,\varepsilon}| + c_r |r_b^{1,\varepsilon} - r_b^{2,\varepsilon}|\Big) dt$$

$$+ \int_0^\tau \Big(2b_1 \max_{[0,T]\times\Gamma^\varepsilon} |l^{1,\varepsilon}||r_f^{1,\varepsilon} - r_f^{2,\varepsilon}| + 2b_1 \max_{[0,T]\times\Gamma^\varepsilon} |r_f^{2,\varepsilon}||l^{1,\varepsilon} - l^{2,\varepsilon}| + 2d_1 |r_b^{1,\varepsilon} - r_b^{2,\varepsilon}|\Big)\, dt,$$

where c_r is the Lipschitz constant of p_r, $\mu_f^1 = \sup_{[0,T]\times\Gamma^\varepsilon} |\mu_f^\varepsilon|$, $\mu_b^1 = \sup_{[0,T]\times\Gamma^\varepsilon} |\mu_b^\varepsilon|$, $b_1 = \sup_{[0,T]\times\Gamma^\varepsilon} |b^\varepsilon|$, $d_1 = \sup_{[0,T]\times\Gamma^\varepsilon} |d^\varepsilon|$. The Gronwall lemma implies

$$|r_f^{1,\varepsilon} - r_f^{2,\varepsilon}| + |r_b^{1,\varepsilon} - r_b^{2,\varepsilon}| \le C \int_0^\tau |l^{1,\varepsilon} - l^{2,\varepsilon}|\, dt. \tag{11}$$

Using the above estimate and nonnegativity of b^ε and $r_f^{2,\varepsilon}$, we obtain

$$\frac{1}{2}\int_0^\tau \int_{\Omega^\varepsilon} \partial_t |l^\varepsilon|^2\, dx\, dt + d_0 \int_0^\tau \int_{\Omega^\varepsilon} |\nabla l^\varepsilon|^2\, dx\, dt + \int_0^\tau \int_{\Omega^\varepsilon} \mu_l^\varepsilon |l^\varepsilon|^2\, dx\, dt$$

$$\le C d_1^2 \varepsilon \frac{1}{2\delta} \int_0^\tau \int_{\Gamma^\varepsilon} \int_0^t |l^\varepsilon|^2\, ds\, d\gamma\, dt + \varepsilon \frac{\delta}{2} \int_0^\tau \int_{\Gamma^\varepsilon} |l^\varepsilon|^2\, d\gamma\, dt + c_l \int_0^\tau \int_{\Omega^\varepsilon} |l^\varepsilon|^2\, dx\, dt$$

$$+ C b_1 \varepsilon \max_{[0,T]\times\Gamma^\varepsilon} |l^{1,\varepsilon}| \int_0^\tau \int_{\Gamma^\varepsilon} \int_0^t |l^\varepsilon|^2\, ds\, d\gamma\, dt + C b_1 \varepsilon \max_{[0,T]\times\Gamma^\varepsilon} |l^{1,\varepsilon}| \int_0^\tau \int_{\Gamma^\varepsilon} |l^\varepsilon|^2\, d\gamma\, dt,$$

where c_l is the Lipschitz constant of p_l. Furthermore, using the estimate

$$\varepsilon \int_0^\tau \int_{\Gamma^\varepsilon} |l^\varepsilon|^2\, d\gamma\, dt \le c \int_0^\tau \int_{\Omega^\varepsilon} |l^\varepsilon|^2\, dx\, dt + c\varepsilon^2 \int_0^\tau \int_{\Omega^\varepsilon} |\nabla l^\varepsilon|^2\, dx\, dt, \tag{12}$$

we obtain

$$\frac{1}{2}\int_{\Omega^\varepsilon} |l^\varepsilon|^2\, dx + (d_0 - \varepsilon^2\delta) \int_0^\tau \int_{\Omega^\varepsilon} |\nabla l^\varepsilon|^2\, dx\, dt + \int_0^\tau \int_{\Omega^\varepsilon} \mu_l^\varepsilon |l^\varepsilon|^2\, dx\, dt$$

$$\le C \frac{1}{\delta} \int_0^\tau \int_0^t \int_{\Omega^\varepsilon} (|l^\varepsilon|^2 + |\nabla l^\varepsilon|^2)\, dx\, ds\, dt + c_l \int_0^\tau \int_{\Omega^\varepsilon} |l^\varepsilon|^2\, dx\, dt.$$

From the Gronwall lemma and $\mu_l^\varepsilon \ge 0$, taking the supremum over $\tau \in [0,T]$, we conclude that

$$\int_{\Omega^\varepsilon} |l^\varepsilon|^2\, dx + C \int_0^T \int_{\Omega^\varepsilon} |\nabla l^\varepsilon|^2\, dx\, dt \le 0$$

and, therefore, $l^{1,\varepsilon} = l^{2,\varepsilon}$ in $(0,T)\times\Omega^\varepsilon$. Due to (11), also $r_f^{1,\varepsilon} = r_f^{2,\varepsilon}$ and $r_b^{1,\varepsilon} = r_b^{2,\varepsilon}$ on $[0,T]\times\Gamma^\varepsilon$. □

3.3. A priori estimates for the microscopic solutions.

LEMMA 3.4. *For any solution of problem* (1)–(6) *from Theorem* 3.3 *the following estimates hold:*

$$\|l^\varepsilon\|_{L^2(0,T;H^1(\Omega^\varepsilon))} \le C, \quad \|\partial_t l^\varepsilon\|_{L^2(0,T;L^2(\Omega^\varepsilon))} \le C,$$

$$\|r_f^\varepsilon\|_{L^\infty((0,T)\times\Gamma^\varepsilon)} \le C, \quad \|r_b^\varepsilon\|_{L^\infty((0,T)\times\Gamma^\varepsilon)} \le C,$$

$$\|\partial_t r_f^\varepsilon\|_{L^2((0,T)\times\Gamma^\varepsilon)} \le C, \quad \|\partial_t r_b^\varepsilon\|_{L^2((0,T)\times\Gamma^\varepsilon)} \le C,$$

where C is a constant independent on ε.

Proof. To show the estimates for r_f^ε and r_b^ε we add (3) and (4) side by side and obtain

$$\partial_t(r_f^\varepsilon + r_b^\varepsilon) \le m_1.$$

Since r_f^ε and r_b^ε are nonnegative (see Theorem 3.3), we conclude that

$$||r_f^\varepsilon||_{L^\infty((0,T)\times\Gamma^\varepsilon)} \le C \quad \text{and} \quad ||r_b^\varepsilon||_{L^\infty((0,T)\times\Gamma^\varepsilon)} \le C.$$

Now we show the estimates for l^ε. We choose $\phi = l^\varepsilon$ as a test function in (7) and calculate

$$\frac{1}{2}\int_0^\tau \int_{\Omega^\varepsilon} \partial_t |l^\varepsilon|^2 \, dx\, dt + \int_0^\tau \int_{\Omega^\varepsilon} (D^\varepsilon \nabla l^\varepsilon, \nabla l^\varepsilon)\, dx\, dt + \int_0^\tau \int_{\Omega^\varepsilon} \mu_l^\varepsilon |l^\varepsilon|^2 \, dx\, dt$$
$$= \varepsilon \int_0^\tau \int_{\Gamma^\varepsilon} (d^\varepsilon r_b^\varepsilon - b^\varepsilon r_f^\varepsilon l^\varepsilon)\, l^\varepsilon \, d\gamma\, dt + \int_0^\tau \int_{\Omega^\varepsilon} p_l^\varepsilon(l^\varepsilon) l^\varepsilon \, dx\, dt$$

for any $\tau \in [0,T]$. Applying the Young inequality we obtain

$$\frac{1}{2}\int_{\Omega^\varepsilon} |l^\varepsilon|^2 \, dx + \int_0^\tau \int_{\Omega^\varepsilon} d_0 |\nabla l^\varepsilon|^2 \, dx\, dt + \int_0^\tau \int_{\Omega^\varepsilon} \mu_l^\varepsilon |l^\varepsilon|^2 \, dx\, dt$$
$$\le \frac{\varepsilon d_1}{2\delta} \int_0^\tau \int_{\Gamma^\varepsilon} |r_b^\varepsilon|^2 \, d\gamma\, dt + \varepsilon \frac{\delta}{2} \int_0^\tau \int_{\Gamma^\varepsilon} |l^\varepsilon|^2 \, d\gamma\, dt$$
$$- \varepsilon \int_0^\tau \int_{\Gamma^\varepsilon} b^\varepsilon r_f^\varepsilon |l^\varepsilon|^2 \, d\gamma\, dt + c_1 \int_0^\tau \int_{\Omega^\varepsilon} |l^\varepsilon|^2 \, dx\, dt + \frac{1}{2}\int_{\Omega^\varepsilon} |l_0^\varepsilon|^2 \, dx.$$

Now we use (12), $\mu_l^\varepsilon \ge 0$, $b^\varepsilon \ge 0$, and $r_f^\varepsilon \ge 0$ and obtain

$$\frac{1}{2}\int_{\Omega^\varepsilon} |l^\varepsilon|^2 \, dx + \int_0^\tau \int_{\Omega^\varepsilon} \left(d_0 - \frac{\delta\varepsilon^2}{2}\right) |\nabla l^\varepsilon|^2 \, dx\, dt$$
$$\le \frac{\varepsilon}{2\delta} \int_0^\tau \int_{\Gamma^\varepsilon} |r_b^\varepsilon|^2 \, d\gamma\, dt + c_1 \int_0^\tau \int_{\Omega^\varepsilon} |l^\varepsilon|^2 \, dx\, dt + \frac{1}{2}\int_{\Omega^\varepsilon} |l_0^\varepsilon|^2 \, dx.$$

Then, from the Gronwall lemma and the estimate for r_b^ε, it follows that

$$\int_\Omega |l^\varepsilon|^2 \, dx + \int_0^T \int_{\Omega^\varepsilon} |\nabla l^\varepsilon|^2 \, dx\, dt \le C.$$

Using the estimates for l^ε, r_f^ε, and r_b^ε, we conclude from (8) that

$$||\partial_t r_f^\varepsilon||_{L^2((0,T)\times\Gamma^\varepsilon)} \le C,$$

$$||\partial_t r_b^\varepsilon||_{L^2((0,T)\times\Gamma^\varepsilon)} \le C.$$

To obtain the estimates for $\partial_t l^\varepsilon$ we choose $\phi = \partial_t l^\varepsilon$ as a test function and calculate

$$\int_0^\tau \int_{\Omega^\varepsilon} |\partial_t l^\varepsilon|^2 \, dx \, dt + \frac{1}{2} \int_0^\tau \int_{\Omega^\varepsilon} \Big(\partial_t (D^\varepsilon \nabla l^\varepsilon, \nabla l^\varepsilon) - (\partial_t D^\varepsilon \nabla l^\varepsilon, \nabla l^\varepsilon) \Big) \, dx \, dt$$

$$= \int_0^\tau \int_{\Omega^\varepsilon} (p_l^\varepsilon(l^\varepsilon) - \mu_l^\varepsilon l^\varepsilon) \partial_t l^\varepsilon \, dx \, dt + \varepsilon \int_0^\tau \int_{\Gamma^\varepsilon} \Big(\partial_t (d^\varepsilon r_b^\varepsilon l^\varepsilon) - d^\varepsilon \partial_t r_b^\varepsilon l^\varepsilon - \partial_t d^\varepsilon r_b^\varepsilon l^\varepsilon \Big) d\gamma \, dt$$

$$+ \varepsilon \int_0^\tau \int_{\Gamma^\varepsilon} \Big(-\partial_t (b^\varepsilon r_f^\varepsilon |l^\varepsilon|^2) + b^\varepsilon \partial_t r_f^\varepsilon |l^\varepsilon|^2 + \partial_t b^\varepsilon r_f^\varepsilon |l^\varepsilon|^2 \Big) d\gamma \, dt.$$

Using the Young inequality we obtain

$$\begin{aligned}
(1-\delta) &\int_0^\tau \int_{\Omega^\varepsilon} |\partial_t l^\varepsilon|^2 \, dx \, dt + \frac{d_0}{2} \int_{\Omega^\varepsilon} |\nabla l^\varepsilon|^2 \, dx \\
&\le \frac{\varepsilon}{2\delta} \int_{\Gamma^\varepsilon} d_1^2 |r_b^\varepsilon|^2 d\gamma + D_2 \int_0^\tau \int_{\Omega^\varepsilon} |\nabla l^\varepsilon|^2 \, dx \, dt \\
&\quad + \varepsilon \frac{\delta}{2} \int_{\Gamma^\varepsilon} |l^\varepsilon|^2 \, d\gamma + \frac{\varepsilon}{2} \int_0^\tau \int_{\Gamma^\varepsilon} (d_1^2 |\partial_t r_b^\varepsilon|^2 + |\partial_t d|^2 |r_b^\varepsilon|^2) \, d\gamma \, dt \\
&\quad + \frac{\varepsilon}{2} \int_0^\tau \int_{\Gamma^\varepsilon} |l^\varepsilon|^2 \, d\gamma \, dt - \varepsilon \int_{\Gamma^\varepsilon} b^\varepsilon r_f^\varepsilon |l^\varepsilon|^2 \, d\gamma \\
&\quad + \frac{1}{2\delta} \int_0^\tau \int_{\Omega^\varepsilon} (|p_l^\varepsilon(l^\varepsilon)|^2 + \mu_l^\varepsilon |l^\varepsilon|^2) \, dx \, dt + \varepsilon \int_{\Gamma^\varepsilon} (d_1 r_{b0} l_0 + b_1 r_{f0} |l_0|^2) \, d\gamma \\
&\quad + D_1 \int_{\Omega^\varepsilon} |\nabla l_0|^2 \, dx + \varepsilon \int_0^\tau \int_{\Gamma^\varepsilon} (\partial_t b^\varepsilon r_f^\varepsilon + b^\varepsilon |\partial_t r_f^\varepsilon|) \, |l^\varepsilon|^2 \, d\gamma \, dt,
\end{aligned}$$

where $D_1 = \sup_{(0,T)\times\Omega} |D^\varepsilon|$, $D_2 = \sup_{(0,T)\times\Omega} |\partial_t D^\varepsilon|$. For the estimate of the last integral we use the embedding for a space of dimension $n = 3$, i.e., $L^\infty(0,T; H^1(\Omega^\varepsilon)) \subset L^4((0,T)\times\Gamma^\varepsilon)$,

$$\begin{aligned}
\varepsilon \int_0^\tau \int_{\Gamma^\varepsilon} b^\varepsilon |\partial_t r_f^\varepsilon| |l^\varepsilon|^2 \, d\gamma \, dt &\le \frac{b_1^2 \varepsilon}{2\delta} \int_0^\tau \int_{\Gamma^\varepsilon} |\partial_t r_f^\varepsilon|^2 \, d\gamma \, dt + \frac{\delta\varepsilon}{2} \int_0^\tau \int_{\Gamma^\varepsilon} |l^\varepsilon|^4 \, d\gamma \, dt \\
&\le \frac{b_1^2 \varepsilon}{2\delta} \int_0^\tau \int_{\Gamma^\varepsilon} |\partial_t r_f^\varepsilon|^2 \, d\gamma \, dt + \frac{\delta}{2} \sup_{[0,T]} \int_{\Omega^\varepsilon} |l^\varepsilon|^2 \, dx + \frac{\delta\varepsilon^2}{2} \sup_{[0,T]} \int_{\Omega^\varepsilon} |\nabla l^\varepsilon|^2 \, dx.
\end{aligned}$$

Using estimate (12) and the positivity of b^ε and r_f^ε we obtain

$$\int_0^T \int_{\Omega^\varepsilon} |\partial_t l^\varepsilon|^2 \, dx \, dt + \sup_{[0,T]} \int_{\Omega^\varepsilon} |\nabla l^\varepsilon|^2 \, dx \le C. \qquad \square$$

To obtain a priori estimates for functions defined in the domain independent of ε, we extend functions l^ε defined on Ω^ε to functions $\bar{l}^\varepsilon$ defined on the whole Ω.

3.4. Extension of l^ε. Since l^ε is defined only on Ω^ε, we extend it onto Ω; see [8] or [19] for the proof.

LEMMA 3.5. 1. *For $l \in H^1(Y)$ there exists an extension $\tilde{l}$ to Z, such that*

$$\|\tilde{l}\|_{L^2(Z)} \leq c\|l\|_{L^2(Y)} \quad \text{and} \quad \|\nabla \tilde{l}\|_{L^2(Z)} \leq c\|\nabla l\|_{L^2(Y)}.$$

2. *For $l^\varepsilon \in H^1(\Omega^\varepsilon)$ there exists an extension $\tilde{l}^\varepsilon$ to Ω, such that*

$$\|\tilde{l}^\varepsilon\|_{H^1(\Omega)} \leq c\|l^\varepsilon\|_{H^1(\Omega^\varepsilon)}.$$

Remark 3.1. For $l^\varepsilon \in L^2(0,T;H^1(\Omega^\varepsilon))$ we define $\bar{l}^\varepsilon(\cdot,t) := \tilde{l}^\varepsilon(\cdot,t)$ for a.a. t. Since the extension operator is linear, then $\bar{l}^\varepsilon \in L^2(0,T;H^1(\Omega))$.

We identify l^ε with the extension $\bar{l}^\varepsilon$. For the extended functions, we obtain a priori estimate of the supremum norm of l^ε.

LEMMA 3.6. *For any solution of problem* (1)–(6), *the following estimate holds:*

$$||l^\varepsilon||_{L^\infty((0,T)\times\Omega)} \leq C, \tag{13}$$

where C is a constant independent on ε.

Estimate (13) follows from the nonnegativity of l^ε, r_f^ε, r_b^ε, the boundedness of r_b^ε and l_0, and the estimate in Lemma 3.5; see Theorem 6.40 in [26] (for the sketch of proof see Appendix 6.1).

4. Convergence of solutions of microscopic problem.

4.1. Convergence of l^ε, r_f^ε, and r_b^ε. To show the convergence results we apply the method of two-scale convergence, introduced in [2] and [36], and extended further in [3, 37]. The definition and theorems concerning the two-scale convergence, used in this section are outlined in Appendix 6.2.

To show the compactness of l^ε we use the following Hilbert space.

DEFINITION 4.1 (see [47]). *Let $W^{\beta,2}(\Omega)$ with $\beta \in \mathbb{R}$, $\beta > 0$ be a Hilbert space defined as the completion of $C^\infty(\Omega)$ with respect to the norm*

$$\|u\|_{W^{\beta,2}(\Omega)} = \|u\|_{W^{k,2}(\Omega)} + \Big\{\int_\Omega \int_\Omega \frac{|u(x)-u(y)|^2}{|x-y|^{n+2(\beta-k)}} dxdy\Big\}^{\frac{1}{2}},$$

where $k = [\beta]$.

LEMMA 4.2. 1. *For a function $v^\varepsilon \in H^1(\Omega^\varepsilon)$ the following estimate holds:*

$$\varepsilon \int_{\Gamma^\varepsilon} |v^\varepsilon|^2 \, d\gamma_x \leq C \int_{\Omega^\varepsilon} |v^\varepsilon|^2 dx + C\varepsilon^2 \int_{\Omega^\varepsilon} |\nabla v^\varepsilon|^2 dx,$$

where C is a constant independent on ε.

2. *For a function $v^\varepsilon \in W^{\beta,2}(\Omega^\varepsilon)$, where $\frac{1}{2} < \beta < 1$, the following estimate holds:*

$$\varepsilon \int_{\Gamma^\varepsilon} |v^\varepsilon|^2 \, d\gamma_x \leq C \int_{\Omega^\varepsilon} |v^\varepsilon|^2 dx + C\varepsilon^{2\beta} \int_{\Omega^\varepsilon} \int_{\Omega^\varepsilon} \frac{|v^\varepsilon(x_1) - v^\varepsilon(x_2)|^2}{|x_1 - x_2|^{n+2\beta}} dx_1 dx_2,$$

where C is a constant independent on ε.

Proof. 1. For the proof see [19, Lemma 3].

2. For a function $v \in W^{\beta,2}(Y)$ the trace theorem implies

$$\int_\Gamma |v|^2 \, d\gamma_y \leq C \int_Y |v|^2 dy + C \int_Y \int_Y \frac{|v(y_1) - v(y_2)|^2}{|y_1 - y_2|^{n+2\beta}} dy_1 dy_2.$$

Changing variables, $y = x/\varepsilon$, we obtain

$$\int_{\varepsilon\Gamma_i} |v^\varepsilon|^2 \frac{d\gamma_x}{\varepsilon^{n-1}} \le C \int_{\varepsilon Y_i} |v^\varepsilon|^2 \frac{dx}{\varepsilon^n} + C \int_{\varepsilon Y_i}\int_{\varepsilon Y_i} \frac{|v^\varepsilon(x_1) - v^\varepsilon(x_2)|^2}{|x_1 - x_2|^{n+2\beta}} \varepsilon^{n+2\beta} \frac{dx_1}{\varepsilon^n}\frac{dx_2}{\varepsilon^n}.$$

Multiplying the inequality side by side with ε^{-n} and summing up over i from 1 to N implies the estimate of the lemma. ∎

Using a priori estimates derived in section 3.3 and the concept of the two-scale convergence, we obtain the following compactness result.

LEMMA 4.3. *There exist functions l, r_f, and r_b such that*

1. $l^\varepsilon \rightharpoonup l$ *in* $L^2(0,T;H^1(\Omega))$, $\partial_t l^\varepsilon \rightharpoonup \partial_t l$ *in* $L^2((0,T)\times\Omega)$, $l^\varepsilon \overset{*}{\rightharpoonup} l$ *in* $L^\infty((0,T)\times\Omega)$,
2. $l^\varepsilon \to l$ *in* $L^2(0,T;W^{\beta,2}(\Omega))$ *for* $\frac{1}{2} < \beta < 1$ *and* $\lim_{\varepsilon\to 0} ||l^\varepsilon - l||_{L^2((0,T)\times\Gamma^\varepsilon)} = 0$,
3. $l^\varepsilon \to l$ *two-scale,* $\nabla l^\varepsilon \to \nabla_x l + \nabla_y l_1$ *two-scale,* $l_1 \in L^2((0,T)\times\Omega; H^1_{per}(Z)/\mathbb{R})$,
4. $r_f^\varepsilon \to r_f$, $r_b^\varepsilon \to r_b$ *two-scale and* $r_f, r_b \in L^\infty((0,T)\times\Omega\times\Gamma)$,
5. $\partial_t r_f^\varepsilon \to \partial_t r_f$, $\partial_t r_b^\varepsilon \to \partial_t r_b$ *two-scale, and* $\partial_t r_f, \partial_t r_b \in L^2((0,T)\times\Omega\times\Gamma)$.

Proof. From the a priori estimates in Lemma 3.4, we obtain weak convergence $l^\varepsilon \rightharpoonup l$ in $L^2(0,T;H^1(\Omega))$, $\partial_t l^\varepsilon \rightharpoonup \partial_t l$ in $L^2((0,T)\times\Omega)$, and $l^\varepsilon \overset{*}{\rightharpoonup} l$ in $L^\infty((0,T)\times\Omega)$.

To obtain strong convergence of l^ε in $L^2((0,T),W^{\beta,2}(\Omega))$, $\frac{1}{2} < \beta < 1$, we use the compact embedding of $W^{\beta,2}(\Omega)$ in $H^1(\Omega)$ and apply the Lions–Aubin lemma [27] with $B = W^{\beta,2}(\Omega)$. Applying Lemma 4.2 we obtain the inequality

$$\|l^\varepsilon\|^2_{\Gamma^\varepsilon} \le c\|l^\varepsilon\|^2_{W^{\beta,2}(\Omega^\varepsilon)}.$$

It follows that

$$\|l^\varepsilon - l\|_{L^2((0,T)\times\Gamma^\varepsilon)} \le c\|l^\varepsilon - l\|^2_{L^2(0,T;W^{\beta,2}(\Omega^\varepsilon))} \le c\|l^\varepsilon - l\|^2_{L^2(0,T;W^{\beta,2}(\Omega))} \to 0 \text{ for } \varepsilon \to 0.$$

Since l^ε is bounded in $L^2(0,T;H^1(\Omega))$, the compactness theorem (see Theorem 6.3 in Appendix 6.2) implies the two-scale convergence of l^ε to the same function l and the existence of a function $l_1 \in L^2((0,T)\times\Omega; H^1_{per}(Z)/\mathbb{R})$ such that, up to a subsequence, ∇l^ε two-scale converges to $\nabla_x l(x) + \nabla_y l_1(x,y)$.

Invoking Theorem 6.5 (see Appendix 6.2) we obtain the two-scale convergence of r_f^ε and r_b^ε to functions in $L^\infty((0,T)\times\Omega\times\Gamma)$. Due to $||\partial_t r_f^\varepsilon||_{L^2((0,T)\times\Gamma^\varepsilon)} \le C$ and [37, Theorem 2.2], we conclude that $\partial_t r_f^\varepsilon \to v$ two-scale and $v \in L^2((0,T)\times\Omega\times\Gamma)$. Then

$$\int_0^T \int_{\Gamma\times\Omega} v\,\phi\,dx\,d\gamma_y\,dt = \lim_{\varepsilon\to 0} \int_0^T \int_{\Gamma^\varepsilon} \partial_t r_f^\varepsilon\,\phi\,d\gamma_x\,dt$$

$$= -\lim_{\varepsilon\to 0} \int_0^T \int_{\Gamma^\varepsilon} r_f^\varepsilon\,\partial_t\phi\,d\gamma_x\,dt = -\int_0^T \int_{\Gamma\times\Omega} r_f\,\partial_t\phi\,dx\,d\gamma_y\,dt.$$

Consequently, we conclude that $v = \partial_t r_f$. Analogously we obtain the two-scale convergence of $\partial_t r_b^\varepsilon$ to $\partial_t r_b$. ∎

4.2. Macroscopic equations.

THEOREM 4.4. *As $\varepsilon \to 0$, the sequence of solutions of the microscopic problem* (1)–(6) *converges to the weak solution* (l, r_f, r_b), $l \in H^1(0,T;L^2(\Omega))$, $l \in L^2(0,T;H^1(\Omega))$, $l \in L^\infty((0,T)\times\Omega)$, r_f, $r_b \in H^1(0,T;L^2(\Omega\times\Gamma))$, r_f, $r_b \in L^\infty((0,T)\times\Omega\times\Gamma)$,

of the following macroscopic problem:

(14)
$$\begin{cases} \partial_t l(t,x) = -\frac{1}{|Y|}\int_\Gamma (b(t,y) r_f(t,x,y) l(t,x) - d(t,y) r_b(t,x,y)) d\gamma_y \\ \qquad\qquad + (\nabla(S(t)\nabla l(t,x))) + \tilde{p}_l(t, l(t,x)) - \tilde{\mu}_l(t) l(t,x), & t>0, x\in\Omega, \\ \nabla l(t,x)\cdot\nu = 0, & t>0, x\in\Gamma^N, \\ l(t,x) = l_0(x), & t=0, x\in\Omega, \end{cases}$$

(15)
$$\begin{cases} \partial_t r_f(t,x,y) = p_r(t,y,r_b(t,x,y)) - b(t,y) r_f(t,x,y) l(t,x) \\ \qquad\qquad + d(t,y) r_b(t,x,y) - \mu_f(t,y) r_f(t,x,y), & y\in\Gamma, x\in\Omega, \\ \partial_t r_b(t,x,y) = b(t,y) r_f(t,x,y) l(t,x) - d(t,y) r_b(t,x,y) \\ \qquad\qquad - \mu_b(t,y) r_b(t,x,y), & y\in\Gamma, x\in\Omega, \\ r_f(t,x,y) = r_{f\,0}(x,y), & t=0, y\in\Gamma, x\in\Omega, \\ r_b(t,x,y) = r_{b0}(x,y), & t=0, y\in\Gamma, x\in\Omega, \end{cases}$$

where $\tilde{\mu}_l(t) = \frac{1}{|Y|}\int_Y \mu_l(t,y)\,dy$, $\tilde{p}(t,l) = \frac{1}{|Y|}\int_Y p(t,y,l)\,dy$, *and the matrix* S *is defined as* $s_{ij} = \frac{1}{|Y|}\sum_{k=1}^3 \int_Y (D_{ij}(t,y) + D_{ik}(t,y)\partial_{y_k} w_j)\,dy$ *with* w_i *being the solutions of the cell problem*

$$-\nabla_y(D(t,y)\nabla_y w_i) = \sum_{k=1}^3 \partial_{y_k} D_{ki}(t,y) \quad in\ Y, \qquad -D(t,y)\frac{\partial w_i}{\partial \nu} = \sum_{k=1}^3 D_{ki}(t,y)\nu_k \quad on\ \Gamma.$$

Proof. To derive a limit equation for l^ε we apply a standard two-scale convergence method and strong convergence of l^ε. Using in (7) a test function of the form $\phi(t,x) = \psi_0(t,x) + \varepsilon\psi_1(t,x,\frac{x}{\varepsilon})$, $\psi_0 \in C^\infty((0,T)\times\Omega)$, $\psi_1 \in C^\infty((0,T)\times\Omega; C^\infty_{per}(Z))$ and passing to the two-scale limit applying Lemma 4.3 yields

$$\begin{aligned} &|Y|\int_0^T\int_\Omega \partial_t l \psi_0(t,x)\,dx\,dt + |Y|\int_0^T\int_\Omega \tilde{\mu}_l(t)\, l(t,x)\,\psi_0(t,x)\,dx\,dt \\ &+ \int_0^T\int_\Omega\int_Y D(t,y)(\nabla_x l(t,x) + \nabla_y l_1(t,x,y))(\nabla_x\psi_0 + \nabla_y\psi_1)\,dy\,dx\,dt \\ &= -\int_0^T\int_\Omega\int_\Gamma [b(t,y) r_f(t,x,y) l(t,x) - d(t,y) r_b(t,x,y)]\psi_0(t,x)\,d\gamma_y\,dx\,dt \\ &+ |Y|\int_0^T\int_\Omega \tilde{p}_l(t,l)\,\psi_0\,dx\,dt. \end{aligned}$$

To show the convergence of the nonlinear term $b^\varepsilon r_f^\varepsilon l^\varepsilon$ of the boundary integral, we rewrite this integral as a sum of two integrals,

$$\begin{aligned} &\varepsilon\int_0^T\int_{\Gamma^\varepsilon} b^\varepsilon r_f^\varepsilon l^\varepsilon \left(\psi_0(t,x) + \varepsilon\psi_1\left(t,x,\frac{x}{\varepsilon}\right)\right) d\gamma_x\,dt \\ &\quad = \varepsilon\int_0^T\int_{\Gamma^\varepsilon} b^\varepsilon r_f^\varepsilon l \left(\psi_0(t,x) + \varepsilon\psi_1\left(t,x,\frac{x}{\varepsilon}\right)\right) d\gamma_x\,dt \\ &\qquad + \varepsilon\int_0^T\int_{\Gamma^\varepsilon} b^\varepsilon r_f^\varepsilon (l^\varepsilon - l) \left(\psi_0(t,x) + \varepsilon\psi_1\left(t,x,\frac{x}{\varepsilon}\right)\right) d\gamma_x\,dt. \end{aligned}$$

The first integral converges to $\int_0^T \int_\Omega \int_\Gamma b(t,y) r_f(t,x,y) l(t,x) \psi_0(t,x)\, d\gamma_y\, dx\, dt$ due to the two-scale convergence of r_f^ε. Since $||l^\varepsilon - l||_{L^2((0,T)\times\Gamma^\varepsilon)} \to 0$ as $\varepsilon \to 0$, we obtain for the second integral

$$\varepsilon \int_0^T \int_{\Gamma^\varepsilon} b^\varepsilon r_f^\varepsilon (l^\varepsilon - l) \left(\psi_0(t,x) + \varepsilon \psi_1\left(t,x,\frac{x}{\varepsilon}\right)\right) d\gamma_x\, dt$$

$$\leq \varepsilon \left(\int_0^T \int_{\Gamma^\varepsilon} |b^\varepsilon r_f^\varepsilon \psi_0|^2 d\gamma_x\, dt\right)^{1/2} \left(\int_0^T \int_{\Gamma^\varepsilon} |l^\varepsilon - l|^2 d\gamma_x\, dt\right)^{1/2}$$

$$+ \varepsilon^2 \left(\int_0^T \int_{\Gamma^\varepsilon} |b^\varepsilon r_f^\varepsilon \psi_1|^2 d\gamma_x\, dt\right)^{1/2} \left(\int_0^T \int_{\Gamma^\varepsilon} |l^\varepsilon - l|^2 d\gamma_x\, dt\right)^{1/2} \to 0 \quad \text{as} \quad \varepsilon \to 0.$$

To determinate the unknown function $l_1 \in L^2((0,T)\times\Omega; H^1_{\text{per}}(Y)/\mathbb{R})$, we set $\psi_0 = 0$ and obtain the equation

$$\int_0^T \int_{\Omega\times Y} D(t,y)(\nabla_x l(t,x) + \nabla_y l_1(t,x,y)) \nabla_y \psi_1(t,x,y)\, dt\, dx\, dy = 0$$

for all ψ_1. From this it follows that l_1 depends linearly on $\nabla_x l$, and it can be written in the form

$$l_1 = \sum_{i=1}^n \frac{\partial l}{\partial x_i} \cdot w_i,$$

where the functions w_i are defined as solutions of the cell problem

$$-\nabla(D(t,y)\nabla w_i) = \sum_{k=1}^3 \partial_{y_k} D_{ki}(t,y) \text{ in } Y, \quad -D(t,y)\frac{\partial w_i}{\partial \nu} = \sum_{k=1}^3 D_{ki}(t,y)\, \nu_k \text{ on } \Gamma.$$

Next, setting $\psi_1 = 0$, we obtain

$$\int_0^T \int_\Omega \int_Y \sum_{i,j=1}^n D_{ij}(t,y)(\partial_{x_i} l(t,x) + \sum_{k=1}^n \partial_{y_i} w_k \partial_{x_k} l(t,x)) \partial_{x_j} \psi_0(t,x)\, dy\, dx\, dt$$

$$= |Y| \int_0^T \int_\Omega \sum_{i,j=1}^n s_{ij} \partial_{x_i} \psi_0(t,x) \partial_{x_j} l(t,x)\, dy\, dx\, dt$$

with $s_{ij} = \frac{1}{|Y|} \sum_{k=1}^3 \int_Y (D_{ij}(t,y) + D_{ik}(t,y)\partial_{y_k} w_j)\, dy$.

The difficulty arises in passing to the limit in nonlinear terms in the ordinary differential equations on the surface of microstructures. We have to show that $p_r^\varepsilon(t,x,r_b^\varepsilon(t,x)) \to p_r(t,y,r_b(t,x,y))$ in the two-scale sense. To cope with this difficulty we apply the unfolding method (periodic modulation), developed in [7, 5, 6]. Following [5] and [6], we define a dilation operator.

DEFINITION 4.5. *For a given $\varepsilon > 0$, we define a dilation operator D^ε mapping measurable functions on $(0,T)\times\Gamma^\varepsilon$ to measurable functions on $(0,T)\times\Omega\times\Gamma$ by*

$$D^\varepsilon u(t,x,y) = u(t, c^\varepsilon(x) + \varepsilon y), \quad y \in \Gamma, \quad (t,x) \in (0,T)\times\Omega,$$

where $c^\varepsilon(x)$ denotes the lattice translation point of the ε-cell domain containing x, $c^\varepsilon(x) = \varepsilon[\frac{x}{\varepsilon}]$. We extend $D^\varepsilon u$ from Γ to $\bigcup_k(\Gamma + k)$ periodically.

Remark 4.1. The dilation operator D^ε is well defined for all $(t, x, y) \in (0, T) \times \Omega \times \Gamma$ under the assumption on the geometry of domain Ω^ε (cf. Remark 2.1).

To proceed, we have to establish the link between the two-scale convergence and the weak convergence of the dilated sequences. Following [6], we formulate the lemma on the convergence of $D^\varepsilon u^\varepsilon : (0, T) \times \Omega \times \Gamma \to \mathbb{R}$. We define $L^2_{\text{per}}(\Gamma)$ as the space of functions $f \in L^2(\Gamma)$ defined on Γ and periodically extended to $\Gamma^* = \bigcup_k(\Gamma + k)$.

LEMMA 4.6. *If $D^\varepsilon u^\varepsilon \rightharpoonup u^*$ weakly in $L^2((0, T) \times \Omega; L^2_{per}(\Gamma))$ and $u^\varepsilon \to u$ two-scale, then $u^* = u$ a.e. in $(0, T) \times \Omega \times \Gamma$.*

Proof. Let u^* be a weak limit of $D^\varepsilon u^\varepsilon$. Then, for a test function $\psi(t, x)h(y)$, where $\psi \in C_0^\infty((0, T) \times \Omega)$ and $h \in C^\infty_{\text{per}}(\Gamma)$, we obtain

$$\int_0^T \int_{\Omega\times\Gamma} D^\varepsilon u^\varepsilon(t, x, y)\psi(t, x)h(y)d\gamma_y dxdt$$

$$\to \int_0^T \int_{\Omega\times\Gamma} u^*(t, x, y)\psi(t, x)h(y)d\gamma_y dxdt \quad \text{as } \varepsilon \to 0.$$

On the other hand, we have

$$\int_0^T \int_{\Omega\times\Gamma} D^\varepsilon u^\varepsilon(t, x, y)\psi(t, x)h(y)d\gamma_y dxdt$$

$$= \int_0^T \int_{\Omega\times\Gamma} u^\varepsilon(t, \varepsilon y + c^\varepsilon(x))\psi(t, x)h(y)d\gamma_y dxdt$$

$$= \sum_{k=1}^N \int_0^T \int_{\varepsilon(Z+k)} \int_\Gamma u^\varepsilon(t, \varepsilon y + c^\varepsilon(x))\psi(t, x)h(y)d\gamma_y dxdt.$$

Changing variables $z = \varepsilon(y + k)$, where $c^\varepsilon(x) = \varepsilon[\frac{x}{\varepsilon}] = \varepsilon k$, and using the periodicity of h, we obtain

$$\int_0^T \sum_{k=1}^N \varepsilon^{-2} \int_{\varepsilon(\Gamma+k)} u^\varepsilon(t, z)h\left(\frac{z}{\varepsilon}\right) \int_{\varepsilon(Z+k)} \psi(t, x)\, dx\, d\gamma_z\, dt$$

$$= \varepsilon \int_0^T \sum_{k=1}^N \int_{\varepsilon(\Gamma+k)} u^\varepsilon(t, z)h\left(\frac{z}{\varepsilon}\right) \psi(t, z)d\gamma_z dt + c\varepsilon^2$$

$$\to \int_0^T \int_\Omega \int_\Gamma u(t, x, y)h(y)\psi(t, x)d\gamma_y dxdt,$$

since from the continuity of ψ we have the estimate

$$|\varepsilon^{-3} \int_{\varepsilon(Z+k)} \big(\psi(t, x) - \psi(t, z)\big)\, dx| \le c\varepsilon \text{ for } z \in \varepsilon(\Gamma + k).$$

Therefore, we conclude that $u^* = u$ a.e. in $(0, T) \times \Omega \times \Gamma$. ∎

In analogy to the above lemma and Lemma 2 in [5], we can prove the following properties of the dilation operator for oscillating surfaces.

LEMMA 4.7. *For* $u \in L^2((0,T)\times\Gamma^\varepsilon)$

$$||D^\varepsilon u||_{L^2(\Omega\times\Gamma)} = ||u||_{L^2(\Gamma^\varepsilon)}.$$

If $u \in L^2(\Omega\times\Gamma)$ *is constant in* y, *then* $D^\varepsilon u \to u$ *as* $\varepsilon \to 0$ *strongly in* $L^2(\Omega\times\Gamma)$.

Changing variables, $\Gamma^\varepsilon \ni x \to \varepsilon y + c^\varepsilon(x)$, $c^\varepsilon(x) = \varepsilon k$ for $x \in \Gamma^\varepsilon$, we obtain equations on the fixed domain $(0,T)\times\Omega\times\Gamma$,

$$\frac{\partial}{\partial t} D^\varepsilon {r_f}^\varepsilon(t,x,y) = -\mu_f(t,y) D^\varepsilon {r_f}^\varepsilon(t,x,y) + p_r(t,y,D^\varepsilon r_b^\varepsilon(t,x,y))$$

$$- b(t,y) D^\varepsilon {r_f}^\varepsilon(t,x,y) D^\varepsilon l^\varepsilon(t,x,y) + d(t,y) D^\varepsilon {r_b}^\varepsilon(t,x,y),$$

$$\frac{\partial}{\partial t} D^\varepsilon {r_b}^\varepsilon(t,x,y) = -\mu_b(t,y) D^\varepsilon {r_b}^\varepsilon(t,x,y)$$

$$+ b(t,y) D^\varepsilon {r_f}^\varepsilon(t,x,y) D^\varepsilon l^\varepsilon(t,x,y) - d(t,y) D^\varepsilon {r_b}^\varepsilon(t,x,y).$$

Applying the estimates for r_f^ε and r_b^ε, we obtain the estimates for $D^\varepsilon {r_f}^\varepsilon$ and $D^\varepsilon {r_b}^\varepsilon$ and the weak convergence of $D^\varepsilon {r_f}^\varepsilon$ to r_f and $D^\varepsilon {r_b}^\varepsilon$ to r_b in $L^2((0,T)\times\Omega; L^2_{\mathrm{per}}(\Gamma))$ (see Lemma 4.6). Since $\sup_{[0,T]\times\overline{\Omega}} |l^\varepsilon| \le C$, we conclude that $\sup_{[0,T]\times\Omega\times\Gamma} |D^\varepsilon l^\varepsilon| \le C$.

Now we prove the strong convergence of $D^\varepsilon {r_f}^\varepsilon$ and $D^\varepsilon {r_b}^\varepsilon$ in $L^2((0,T)\times\Omega; L^2_{\mathrm{per}}(\Gamma))$. For this we show that $D^\varepsilon {r_f}^\varepsilon$ and $D^\varepsilon {r_b}^\varepsilon$ are Cauchy sequences. We consider the equations for $D^{\varepsilon_n} {r_f}^{\varepsilon_n} - D^{\varepsilon_m} {r_f}^{\varepsilon_m}$ and $D^{\varepsilon_n} {r_b}^{\varepsilon_n} - D^{\varepsilon_m} {r_b}^{\varepsilon_m}$, with $n > m$, multiply them side by side with $D^{\varepsilon_n} {r_f}^{\varepsilon_n} - D^{\varepsilon_m} {r_f}^{\varepsilon_m}$ and $D^{\varepsilon_n} {r_b}^{\varepsilon_n} - D^{\varepsilon_m} {r_b}^{\varepsilon_m}$, respectively, and integrate over $\Omega\times\Gamma$.

$$\frac{\partial}{\partial t}\int_{\Omega\times\Gamma} |D^{\varepsilon_n} {r_f}^{\varepsilon_n} - D^{\varepsilon_m} {r_f}^{\varepsilon_m}|^2 dx d\gamma = -\int_{\Omega\times\Gamma} \mu_f(t,y) |D^{\varepsilon_n} {r_f}^{\varepsilon_n} - D^{\varepsilon_m} {r_f}^{\varepsilon_m}|^2 dx d\gamma$$

$$+ \int_{\Omega\times\Gamma} (p_r(t,y,D^{\varepsilon_n} {r_b}^{\varepsilon_n}) - p_r(t,y,D^{\varepsilon_m} r_b^{\varepsilon_m}))(D^{\varepsilon_n} {r_f}^{\varepsilon_n} - D^{\varepsilon_m} {r_f}^{\varepsilon_m}) dx d\gamma$$

$$- \int_{\Omega\times\Gamma} b(t,y)(D^{\varepsilon_n} {r_f}^{\varepsilon_n} D^{\varepsilon_n} l^{\varepsilon_n} - D^{\varepsilon_m} {r_f}^{\varepsilon_m} D^{\varepsilon_m} l^{\varepsilon_m})(D^{\varepsilon_n} {r_f}^{\varepsilon_n} - D^{\varepsilon_m} {r_f}^{\varepsilon_m}) dx d\gamma$$

$$- \int_{\Omega\times\Gamma} d(t,y)(D^{\varepsilon_n} {r_b}^{\varepsilon_n} - D^{\varepsilon_m} {r_b}^{\varepsilon_m})(D^{\varepsilon_n} {r_f}^{\varepsilon_n} - D^{\varepsilon_m} {r_f}^{\varepsilon_m}) dx d\gamma,$$

$$\frac{\partial}{\partial t}\int_{\Omega\times\Gamma} |D^{\varepsilon_n} {r_b}^{\varepsilon_n} - D^{\varepsilon_m} {r_b}^{\varepsilon_m}|^2 dx d\gamma = -\int_{\Omega\times\Gamma} \mu_b(t,y) |D^{\varepsilon_n} {r_b}^{\varepsilon_n} - D^{\varepsilon_m} {r_b}^{\varepsilon_m}|^2 dx d\gamma$$

$$+ \int_{\Omega\times\Gamma} b(t,y)(D^{\varepsilon_n} {r_f}^{\varepsilon_n} D^{\varepsilon_n} l^{\varepsilon_n} - D^{\varepsilon_m} {r_f}^{\varepsilon_m} D^{\varepsilon_m} l^{\varepsilon_m})(D^{\varepsilon_n} {r_b}^{\varepsilon_n} - D^{\varepsilon_m} {r_b}^{\varepsilon_m}) dx d\gamma$$

$$- \int_{\Omega\times\Gamma} d(t,y) |D^{\varepsilon_n} {r_b}^{\varepsilon_n} - D^{\varepsilon_m} {r_b}^{\varepsilon_m}|^2 \, dx d\gamma.$$

Using the Young inequality, we obtain

$$
\begin{aligned}
(16)\qquad & \frac{\partial}{\partial t}\int_{\Omega\times\Gamma}|D^{\varepsilon_n}{r_f}^{\varepsilon_n}-D^{\varepsilon_m}{r_f}^{\varepsilon_m}|^2dxd\gamma \\
&\le C_1\int_{\Omega\times\Gamma}|D^{\varepsilon_n}{r_f}^{\varepsilon_n}-D^{\varepsilon_m}{r_f}^{\varepsilon_m}|^2dxd\gamma \\
&\quad + C_2\int_{\Omega\times\Gamma}|D^{\varepsilon_n}{r_b}^{\varepsilon_n}-D^{\varepsilon_m}{r_b}^{\varepsilon_m}|^2dxd\gamma \\
&\quad + b_1\sup_{(0,T)\times\Omega\times\Gamma}|D^{\varepsilon_n}l^{\varepsilon_n}|\int_{\Omega\times\Gamma}|D^{\varepsilon_n}{r_f}^{\varepsilon_n}-D^{\varepsilon_m}{r_f}^{\varepsilon_m}|^2dxd\gamma \\
&\quad + C_3\int_{\Omega\times\Gamma}|D^{\varepsilon_n}l^{\varepsilon_n}-D^{\varepsilon_m}l^{\varepsilon_m}|^2dxd\gamma,
\end{aligned}
$$

$$
\begin{aligned}
(17)\qquad & \frac{\partial}{\partial t}\int_{\Omega\times\Gamma}|D^{\varepsilon_n}{r_b}^{\varepsilon_n}-D^{\varepsilon_m}{r_b}^{\varepsilon_m}|^2dxd\gamma \\
&\le C_4\int_{\Omega\times\Gamma}|D^{\varepsilon_n}{r_b}^{\varepsilon_n}-D^{\varepsilon_m}{r_b}^{\varepsilon_m}|^2dxd\gamma \\
&\quad + b_1\sup_{(0,T)\times\Omega\times\Gamma}|D^{\varepsilon_n}l^{\varepsilon_n}|\int_{\Omega\times\Gamma}|D^{\varepsilon_n}{r_f}^{\varepsilon_n}-D^{\varepsilon_m}{r_f}^{\varepsilon_m}|^2dxd\gamma \\
&\quad + C_5\int_{\Omega\times\Gamma}|D^{\varepsilon_n}l^{\varepsilon_n}-D^{\varepsilon_m}l^{\varepsilon_m}|^2dxd\gamma.
\end{aligned}
$$

Due to Lemma 4.7 and strong convergence of l^ε on Γ^ε, we obtain

$$
\int_0^T\int_{\Omega\times\Gamma}|D^\varepsilon l^\varepsilon-D^\varepsilon l|^2d\gamma dxdt=\varepsilon\int_0^T\int_{\Gamma^\varepsilon}|l^\varepsilon-l|^2d\gamma_x dt\le C\varepsilon.
$$

Therefore, since $D^{\varepsilon_n}l\to l$ strongly in $L^2((0,T)\times\Omega\times\Gamma)$ (see Lemma 4.7),

$$
\begin{aligned}
&\int_0^T\int_{\Omega\times\Gamma}|D^{\varepsilon_n}l^{\varepsilon_n}-D^{\varepsilon_m}l^{\varepsilon_m}|^2d\gamma dxdt \\
&\quad\le\int_0^T\int_{\Omega\times\Gamma}\Big(|D^{\varepsilon_n}l^{\varepsilon_n}-D^{\varepsilon_n}l|^2+|D^{\varepsilon_n}l-l|^2\Big)d\gamma dxdt \\
&\qquad+\int_0^T\int_{\Omega\times\Gamma}\Big(|D^{\varepsilon_m}l-l|^2+|D^{\varepsilon_m}l^{\varepsilon_m}-D^{\varepsilon_m}l|^2\Big)d\gamma dxdt \\
&\quad\le\varepsilon_n\int_0^T\int_{\Gamma^{\varepsilon_n}}|l^{\varepsilon_n}-l|^2d\gamma_x dt \\
&\qquad\varepsilon_m\int_0^T\int_{\Gamma^{\varepsilon_m}}|l^{\varepsilon_m}-l|^2d\gamma_x dt+\int_0^T\int_{\Omega\times\Gamma}\Big(|D^{\varepsilon_n}l-l|^2+|D^{\varepsilon_m}l-l|^2\Big)d\gamma dxdt \\
&\quad\le C(\varepsilon_n+\varepsilon_m).
\end{aligned}
$$

We add (16) and (17) side by side and integrate with respect to time. Using additionally the boundedness of $D^\varepsilon l^\varepsilon$ on $(0,T)\times\Omega\times\Gamma$, we obtain

$$||D^{\varepsilon_n} r_f{}^{\varepsilon_n} - D^{\varepsilon_m} r_f{}^{\varepsilon_m}||^2 + ||D^{\varepsilon_n} r_b{}^{\varepsilon_n} - D^{\varepsilon_m} r_b{}^{\varepsilon_m}||^2$$
$$\le C_1 \int_0^\tau \big(||D^{\varepsilon_n} r_f{}^{\varepsilon_n} - D^{\varepsilon_m} r_f{}^{\varepsilon_m}||^2 + ||D^{\varepsilon_n} r_b{}^{\varepsilon_n} - D^{\varepsilon_m} r_b{}^{\varepsilon_m}||^2\big) dt + C_2 \frac{1}{n},$$

where $C_1 = C_1(\sup_{(0,T)\times\Omega}|l^\varepsilon|, \sup_{(0,T)\times\Gamma}|\mu_f|, \sup_{(0,T)\times\Gamma}|\mu_b|, \sup_{(0,T)\times\Gamma}|b|, \sup_{(0,T)\times\Gamma}|d|, \sup_{(0,T)\times\Gamma^\varepsilon}|r_f^\varepsilon|)$. Then the Gronwall lemma yields

$$||D^{\varepsilon_n} r_f{}^{\varepsilon_n} - D^{\varepsilon_m} r_f{}^{\varepsilon_m}||_{L^2(\Omega\times\Gamma)} \le C\frac{1}{n},$$

$$||D^{\varepsilon_n} r_b{}^{\varepsilon_n} - D^{\varepsilon_m} r_b{}^{\varepsilon_m}||_{L^2(\Omega\times\Gamma)} \le C\frac{1}{n}.$$

Using strong convergence of $D^\varepsilon r_b{}^\varepsilon$, continuity of p_r, and weak convergence of $p_r(t,y,D^\varepsilon r_b^\varepsilon)$, which results from the boundedness of p_r, we obtain that $p_r(t,y,D^\varepsilon r_b^\varepsilon)$ weakly converges to $p_r(t,y,r_b(t,x,y))$ in $L^2((0,T)\times\Omega; L^2_{\mathrm{per}}(\Gamma))$.

Now we can take the two-scale limit in the equations on the boundary,

$$\varepsilon\int_0^T\int_{\Gamma^\varepsilon} \partial_t r_f^\varepsilon \psi_1\left(t,x,\frac{x}{\varepsilon}\right) d\gamma_x\, dt = \varepsilon\int_0^T\int_{\Gamma^\varepsilon} p_r^\varepsilon(t,x,r_b^\varepsilon(t,x))\psi_1\left(t,x,\frac{x}{\varepsilon}\right) d\gamma_x\, dt$$
$$+\varepsilon\int_0^T\int_{\Gamma^\varepsilon}\Big(-b^\varepsilon r_f^\varepsilon(t,x)l^\varepsilon(t,x) + d^\varepsilon(t,x)r_b^\varepsilon(t,x) - \mu_f^\varepsilon r_f^\varepsilon(t,x)\Big)\psi_1\left(t,x,\frac{x}{\varepsilon}\right) d\gamma_x\, dt,$$

$$\varepsilon\int_0^T\int_{\Gamma^\varepsilon} \partial_t r_b^\varepsilon(t,x)\psi_1\left(t,x,\frac{x}{\varepsilon}\right) d\gamma_x\, dt = \varepsilon\int_0^T\int_{\Gamma^\varepsilon} b^\varepsilon r_f^\varepsilon(t,x)l^\varepsilon(t,x)\psi_1\, d\gamma_x\, dt$$
$$+\varepsilon\int_0^T\int_{\Gamma^\varepsilon}\Big(-d^\varepsilon r_b^\varepsilon(t,x) - \mu_b^\varepsilon r_b^\varepsilon(t,x)\Big)\psi_1\left(t,x,\frac{x}{\varepsilon}\right) d\gamma_x\, dt.$$

The linear terms converge two-scale to their limit functions. The proof of convergence for the nonlinear term $b^\varepsilon r_f^\varepsilon(t,x)l^\varepsilon(t,x)$ is the same as in the equation for l^ε. Due to boundedness of p_r^ε and Lemma 4.6, $p_r^\varepsilon(t,x,r_b^\varepsilon)$ converges two-scale to $p_r(t,y,r_b(t,x,y))$. Therefore, we obtain the macroscopic equations for r_f and r_b. ∎

The uniqueness of the solution of the macroscopic problem can be proved in the same way as for the microscopic problem.

Remark 4.2. Properties of the macroscopic model: Using the framework of bounded invariant rectangles (see [44]) we can show that solutions of system (14)–(15) remain positive for positive initial conditions and that they are also uniformly bounded. This results from the assumption of the nonnegativity of the model parameters and their boundedness independent of time. Methods outlined in [44, Chapter 14] can be used without major modifications.

5. Discussion. In this work, using homogenization techniques, we studied the macroscopic limit of the microscopic model describing receptor-ligand dynamics on cell membranes and in the intercellular space. We tried to answer the question of how processes which take place in different "spaces," such as cells membranes, intercellular space, and also intracellular space, can be described by macroscopic models operating

in homogenized space. On one hand, this work provides a justification of previously proposed models, and on the other hand it is a starting point for further models.

Comparison of the macroscopic model (14)–(15) to the previously considered receptor-based model of the form

$$\begin{aligned}
\frac{\partial}{\partial t} r_f &= -\mu_f r_f + p_r(r_b) - b r_f l + d r_b, \\
\frac{\partial}{\partial t} r_b &= -\mu_b r_b + b r_f l - d r_b, \\
\frac{\partial}{\partial t} l &= \frac{1}{\gamma} \frac{\partial^2}{\partial x^2} l - \mu_l l - b r_f l + p_l(l) + d r_b,
\end{aligned} \tag{18}$$

defined on the macroscopic domain Ω, shows in which cases the "older" models can be derived from the microscopic description. Model (14)–(15) is equivalent to model (18) in the case when neither the model parameters nor the initial conditions for r_f and r_b depend on the surface variable y. It means that the processes described are homogeneous within each cell and that there is no heterogeneity in the dissociation or binding processes on the cell surfaces. For nonadherent cells one can consider receptor production, binding, dissociation, or decay to be uniformly distributed on the cell surface, which results in model coefficients being constant with respect to the surface variable y. Under such assumptions we obtain a macroscopic model, in which the integral in the equation for the ligands disappears and the only difference with respect to model (18) is that the kinetics are multiplied by a coefficient $\int_\Gamma d\gamma_y/|Y|$. However, there is now considerable evidence of the existence of lipid raft microdomains, called membrane rafts, which organize the membrane into specialized functional units [14, 15, 38, 39, 41]. Rafts were described mainly for T-cells and T-cell receptor [15, 39, 40], but now it is clear that they play an important role for many different receptor classes [13, 41]. There are observations that the structure of lipid rafts could control cellular processes such as signaling cascades [40, 43] and receptor synthesis and trafficking [21] as well as cell adhesion and migration [16]. Some membrane proteins are located preferentially on the raft domains, whereas others are excluded from them [14]. Such a situation corresponds to the nonhomogeneous initial distribution of receptors on the cell surface and also *de novo* production terms depending on the surface variable. Our studies show that in such a case the "older" type of receptor-based model is not relevant.

Another example of cells with nonhomogeneous membrane properties are adherent cells. In the case of adherent cells there are two types of polarity, top-bottom and front-back, and it is not easy for the ligand to get in contact with the bottom of the cell. One can imagine that receptors may be concentrated on the frontal end of the cell (this determines cell motility in the case of chemotaxis), and, therefore, all the receptor-ligand processes are nonhomogeneous within the membrane [22].

6. Appendix.

6.1. Supremum estimate for l^ε. We present here a sketch of the proof of Lemma 3.6 used in section 4.

LEMMA. *For any solution of problem* (1)–(6), *the following estimate holds:*

$$||l^\varepsilon||_{L^\infty((0,T)\times\Omega)} \leq C + 2k,$$

where C is a constant independent on ε and $k = \max\{1, \sup_\Omega |l_0|\}$.

Proof. To show the boundedness of l^ε we use the Moser iteration technique, described in the proof of [26, Theorem 6.15]. We choose as a test function $v = \psi(l^\varepsilon)(l^\varepsilon - k)_+$, where $\psi \geq 0$ is a bounded $C^1(\mathbb{R})$ function and which satisfies for $s > k$

$$0 \leq \frac{\psi'(s)(s-k)}{\psi(s)} \leq k_1.$$

Due to the fact that $l_0 \leq k$, we obtain

$$\begin{aligned}
(19) \qquad & \int_\Omega \int_0^{l^\varepsilon} \psi(s)(s-k)_+ \, ds\chi^\varepsilon \, dx + \int_0^\tau \int_\Omega (D^\varepsilon \nabla l^\varepsilon, \psi(l^\varepsilon)\nabla l^\varepsilon)\chi^\varepsilon \, dxdt \\
& \quad + \int_0^\tau \int_\Omega (D^\varepsilon \nabla l^\varepsilon, \psi'(l^\varepsilon)(l^\varepsilon - k)_+ \nabla l^\varepsilon)\chi^\varepsilon \, dxdt \\
& \quad + \int_0^\tau \int_\Omega \mu_l^\varepsilon l^\varepsilon \psi(l^\varepsilon)(l^\varepsilon - k)_+ \chi^\varepsilon dxdt \\
& = \int_0^\tau \int_\Omega p_l^\varepsilon(l^\varepsilon)\psi(l^\varepsilon)(l^\varepsilon - k)_+ \chi^\varepsilon \, dxdt \\
& \quad + \varepsilon \int_0^\tau \int_{\Gamma^\varepsilon} (d^\varepsilon r_b^\varepsilon - b^\varepsilon r_f^\varepsilon l^\varepsilon)\psi(l^\varepsilon)(l^\varepsilon - k)_+ d\gamma_x dt,
\end{aligned}$$

where χ is a characteristic function of Y periodically extended to Z^*, and $\chi^\varepsilon(x) = \chi(\frac{x}{\varepsilon})$. From the properties of ψ, we obtain

$$\int_k^s \psi(t)(t-k)dt \geq \frac{1}{2+k_1}\psi(s)(s-k) \quad \text{for} \quad s \geq k.$$

The third and fourth terms on the left-hand side of (19) are nonnegative; the third term on the right-hand side is nonpositive. Using $l^\varepsilon \geq k \geq 1$ and Lemma 4.2, we obtain the estimate

$$\begin{aligned}
& \varepsilon \int_0^\tau \int_{\Gamma^\varepsilon} \psi(l^\varepsilon)(l^\varepsilon - k)_+ d\gamma_x dt \\
& \quad \leq C \int_0^\tau \int_{\Omega^\varepsilon} \Big(\psi(l^\varepsilon)(l^\varepsilon - k)_+ + \varepsilon^2 \nabla(\psi(l^\varepsilon)(l^\varepsilon - k)_+) \Big) dxdt \\
& \quad \leq C(1 + \frac{1}{\delta})(1+k_1) \int_0^\tau \int_\Omega \psi(l^\varepsilon)|l^\varepsilon|^2 \chi^\varepsilon dxdt + C\varepsilon^2 \delta \int_0^\tau \int_\Omega \psi(l^\varepsilon)|\nabla l^\varepsilon|^2 \chi^\varepsilon dxdt.
\end{aligned}$$

Then boundedness of coefficients and sublinearity of p_l yields

$$\begin{aligned}
& \int_\Omega \psi(l^\varepsilon)(l^\varepsilon - k)^2 \chi^\varepsilon dx + d_0 \int_0^\tau \int_\Omega \psi(l^\varepsilon)|\nabla l^\varepsilon|^2 \chi^\varepsilon dxdt \\
& \qquad \leq C(1+k_1)^2 \int_0^\tau \int_\Omega \psi(l^\varepsilon)|l^\varepsilon|^2 \chi^\varepsilon dxdt.
\end{aligned}$$

Choosing $\psi(s) = (\min\{s, Z\}(1 - k/s)_+)^q$, where q, Z are positive constants, applying the Gronwall and Young inequalities, and taking $Z \to \infty$ leads to

$$\int_0^T \int_\Omega |l^\varepsilon|^{q+2} \chi^\varepsilon \, dxdt \leq C(q)|\Omega|Tk^{q+2}$$

for any positive q. Thus, for a fixed $q > 1$ we can choose $\psi(s) = s^{2q-2}(1-\frac{k}{s})_+^{(n+2)(q-1)}$ and conclude that

$$\int_\Omega (l^\varepsilon)^{2q}\left(1-\frac{k}{l^\varepsilon}\right)_+^{(n+2)q-n}\chi^\varepsilon dx + c(d_0)\int_0^\tau\int_\Omega (l^\varepsilon)^{2q-2}\left(1-\frac{k}{l^\varepsilon}\right)_+^{(n+2)(q-1)}|\nabla l^\varepsilon|^2\chi^\varepsilon dxdt$$

$$\leq Cq^2\int_0^\tau\int_\Omega (l^\varepsilon)^{2q}\left(1-\frac{k}{l^\varepsilon}\right)_+^{(n+2)(q-1)}\chi^\varepsilon dxdt.$$

Setting $h = (l^\varepsilon)^q((1-\frac{k}{l^\varepsilon})_+^{(n+2)q-n})^{1/2}$ gives $|\nabla h|^2 \leq c(n)q^2(l^\varepsilon)^{2q-2}(1-\frac{k}{l^\varepsilon})_+^{(n+2)(q-1)}$ $|\nabla l^\varepsilon|^2$. Using the property of extended function of l^ε, i.e., $||l^\varepsilon||_{H^1(\Omega)} \leq C||l^\varepsilon||_{H^1(\Omega^\varepsilon)}$, with a constant C independent of ε, yields

$$\sup_{(0,T)}\int_\Omega h^2 dx + \int_0^T\int_\Omega |\nabla h|^2 dxdt \leq Cq^4\int_0^T\int_\Omega (l^\varepsilon)^{2q}\left(1-\frac{k}{l^\varepsilon}\right)^{(n+2)(q-1)} dxdt.$$

Invoking the Sobolev embedding theorem on $(0,T)\times\Omega$, we obtain

$$\left(\int_0^T\int_\Omega h^{2\kappa}dxdt\right)^{1/\kappa} \leq Cq^4\int_0^T\int_\Omega (l^\varepsilon)^{2q}\left(1-\frac{k}{l^\varepsilon}\right)_+^{(n+2)q-n-2} dxdt,$$

where $\kappa = (n+2)/n$. Iterating the last inequality for $q = 1, \kappa, \kappa^2, \ldots$, as in [26], implies that

$$\sup_{(0,T)\times\Omega}|l^\varepsilon|^2\left(1-\frac{k}{l^\varepsilon}\right)_+^{n+2} \leq C\int_0^T\int_\Omega |l^\varepsilon|^2 dxdt.$$

Considering separately the cases $\sup_{(0,T)\times\Omega} l^\varepsilon \leq 2k$ and $\sup_{(0,T)\times\Omega} l^\varepsilon \geq 2k$ results in the estimate of the lemma. □

6.2. Two-scale convergence with parameters. We recall here the definition of two-scale convergence for functions dependent on parameters and several important results concerning this notion presented in [37]. The proofs are straightforward modifications of the proofs for the standard two-scale convergence method presented in [2].

DEFINITION 6.1. *Let (u_ε) be a sequence in $L^2(\Lambda\times\Omega)$, where ε is a sequence of strictly positive numbers, which tends to zero. (u_ε) is said to two-scale converge to a (unique) limit $u_0 \in L^2(\Lambda\times\Omega\times Z)$ iff for any $\phi \in \mathcal{D}(\Lambda\times\Omega, C^\infty_{per}(Z))$ we have*

$$\lim_{\varepsilon\to 0}\int_\Lambda\int_\Omega u_\varepsilon(\lambda,x)\phi\left(\lambda,x,\frac{x}{\varepsilon}\right)dxd\lambda = \int_\Lambda\int_\Omega\int_Z u_0(\lambda,x,y)\phi(\lambda,x,y)dxdyd\lambda.$$

THEOREM 6.2. *From each bounded sequence (u_ε) in $L^2(\Lambda\times\Omega)$ we can extract a subsequence which two-scale converges to $u_0 \in L^2(\Lambda\times\Omega\times Z)$.*

THEOREM 6.3. 1. *Let (u_ε) be a bounded sequence in $L^2(\Lambda, H^1(\Omega))$, which converges weakly to a limit function $u \in L^2(\Lambda, H^1(\Omega))$. Then there exists $u_1 \in L^2(\Lambda\times\Omega, H^1_{per}(Z))$ such that, up to a subsequence, u_ε two-scale converges to u and ∇u_ε two-scale converges to $\nabla u(\lambda,x) + \nabla_y u_1(\lambda,x,y)$.*

2. *Let (u_ε) and $(\varepsilon\nabla u_\varepsilon)$ be bounded sequences in $L^2(\Lambda\times\Omega))$. Then there exists $u_0 \in L^2(\Lambda\times\Omega, H^1_{per}(Z))$ such that, up to a subsequence, u_ε and $\varepsilon\nabla u_\varepsilon$ two-scale converge to $u_0(\lambda,x,y)$ and $\nabla_y u_0(\lambda,x,y)$, respectively.*

Now, we transfer the compactness results to the case of a sequence u_ε defined on an $(n-1)$-dimensional ε-periodic manifold $\Gamma^\varepsilon \in \Omega$. Let $\Gamma \in Z$ be a smooth $(n-1)$-dimensional manifold (in our application a sphere, $n=3$). Then Γ^ε is the union of all $\varepsilon\Gamma$. For each Γ^ε we consider the space $L^2(\Gamma^\varepsilon)$ equipped with the scalar product $(u,v)_{\Gamma^\varepsilon} := \varepsilon \int_{\Gamma^\varepsilon} u(x)v(x)dx$.

DEFINITION 6.4 (see [37]). *A sequence of functions $(w_\varepsilon) \in L^2(\Lambda \times \Gamma^\varepsilon)$ is said to two-scale converge to a limit $w \in L^2(\Lambda \times \Omega \times \Gamma)$ iff for any $\psi \in \mathcal{D}(\Lambda \times \Omega, C^\infty_{per}(\Gamma))$ we have*

$$\lim_{\varepsilon\to 0} \varepsilon \int_\Lambda \int_{\Gamma^\varepsilon} w^\varepsilon(\lambda,x)\psi\left(\lambda,x,\frac{x}{\varepsilon}\right) d\gamma_x d\lambda = \int_\Lambda \int_\Omega \int_\Gamma w(\lambda,x,y)\psi(\lambda,x,y)dx d\gamma_y d\lambda.$$

THEOREM 6.5. 1. *From each bounded sequence (w_ε) in $L^2(\Lambda\times\Gamma^\varepsilon)$ we can extract a subsequence which two-scale converges to $w \in L^2(\Lambda\times\Omega\times\Gamma)$.*

2. *If the sequence (w_ε) is bounded in $L^\infty(\Lambda\times\Gamma^\varepsilon)$, then the limit w belongs to $L^\infty(\Lambda\times\Omega\times\Gamma)$.*

Proof. For the proof of 1, see [37].

2. We know that if w^ε is bounded in $L^2((0,T)\times\Gamma^\varepsilon)$, then there exists $w \in L^2((0,T)\times\Omega\times\Gamma)$ such that $w^\varepsilon \to w$ two-scale [37]. Now we use the proof of that theorem and show that if w^ε is bounded in $L^\infty((0,T)\times\Gamma^\varepsilon)$, then $w^\varepsilon \to w$ two-scale and $w \in L^\infty((0,T)\times\Omega\times\Gamma)$. We define $\mu_\varepsilon(\phi) = \varepsilon\int_0^T \int_{\Gamma^\varepsilon} w^\varepsilon(t,x)\phi(t,x,\frac{x}{\varepsilon})\, d\gamma_x^\varepsilon\, dt$ and obtain

$$|\mu_\varepsilon(\phi)| \le ||w^\varepsilon||_{L^2((0,T)\times\Gamma^\varepsilon)} \Big(\int_0^T \int_{\Gamma^\varepsilon} \varepsilon \left|\phi\left(x,\frac{x}{\varepsilon}\right)\right|^2 d\gamma_x^\varepsilon\, dt\Big)^{\frac{1}{2}} \le c||\phi||^2_{C^0([0,T]\times\bar\Omega;C^0_{per}(\Gamma))}.$$

Therefore, $\{\mu_\varepsilon\}$ is a bounded sequence of functionals on $C^0([0,T]\times\bar\Omega; C^0_{per}(\Gamma))$. Since this space is a separable Banach space, there exists a subsequence of μ_ε that converges weakly* to μ. Using the boundedness of w^ε and a variant of the oscillation lemma [2], we obtain

$$|\mu(\phi)| = \lim_{\varepsilon\to 0} |\mu_\varepsilon(\phi)| \le C \lim_{\varepsilon\to 0} \Big(\int_0^T \int_{\Gamma^\varepsilon} \varepsilon \left|\phi\left(x,\frac{x}{\varepsilon}\right)\right|^2 d\gamma_x^\varepsilon\, dt\Big)^{\frac{1}{2}} = c||\phi||_{L^2((0,T)\times\Omega\times\Gamma)}.$$

Therefore, μ is a bounded functional on $L^2((0,T)\times\Omega\times\Gamma)$. The Riesz representation theorem implies the existence of a function $w \in L^2((0,T)\times\Omega\times\Gamma)$. Furthermore, $||w^\varepsilon||_{L^\infty((0,T)\times\Gamma^\varepsilon)} \le C$ yields

$$|\mu(\phi)| = \lim |\mu_\varepsilon(\phi)| \le C \lim_{\varepsilon\to 0} \int_0^T \int_{\Gamma^\varepsilon} \varepsilon \left|\phi\left(x,\frac{x}{\varepsilon}\right)\right| d\gamma_x^\varepsilon\, dt = c||\phi||_{L^1((0,T)\times\Omega\times\Gamma)}.$$

Finally, we conclude

$$||w||_{L^\infty((0,T)\times\Omega\times\Gamma)} = \frac{\langle w,\phi\rangle}{||\phi||_{L^1((0,T)\times\Omega\times\Gamma)}}$$

$$= \frac{|\mu(\phi)|}{||\phi||_{L^1((0,T)\times\Omega\times\Gamma)}} \le \frac{C||\phi||_{L^1((0,T)\times\Omega\times\Gamma)}}{||\phi||_{L^1((0,T)\times\Omega\times\Gamma)}} = C. \qquad \square$$

THEOREM 6.6 (see [37]). *Let (u_ε) and $(\varepsilon\nabla u_\varepsilon)$ be bounded sequences in $L^2(\Lambda\times\Gamma^\varepsilon))$. Then there exists $u_0 \in L^2(\Lambda\times\Omega, H^1_{per}(\Gamma))$ such that, up to a subsequence, u_ε and $\varepsilon\nabla u_\varepsilon$, two-scale converge to $u_0(\lambda,x,y)$ and $\nabla_y u_0(\lambda,x,y)$, respectively.*

INVERSE PROBLEM OF DETERMINING THE DENSITY AND TWO LAMÉ COEFFICIENTS BY BOUNDARY DATA*

M. BELLASSOUED†, O. IMANUVILOV‡, AND M. YAMAMOTO§

Abstract. In this paper we study an inverse problem of determining spatially varying density and two Lamé coefficients by a single measurement of solution in a subboundary over a time interval. By assuming that, in a neighborhood of the boundary of the spatial domain, the density and the Lamé coefficients are known, we prove a logarithmic stability estimate for the inverse problem with a single measurement of data on an arbitrarily given subboundary.

Key words. Carleman estimate, Lamé system, inverse problem, Fourier–Bros–Iagolnitzer transform

1. Introduction.

This paper is concerned with the global stability in determining density and two Lamé coefficients in the classical isotropic elasticity system from data of the solution on a subboundary over a time interval. We will formulate our problem as follows: In a bounded domain $\Omega \subset \mathbb{R}^3$ with sufficiently smooth boundary $\Gamma = \partial\Omega$, we consider the isotropic elasticity system

$$\rho(x)\partial_t^2 \mathbf{u}(x,t) - \mathcal{L}_{\lambda,\mu}(x,\partial_x)\mathbf{u}(x,t) = 0, \quad (x,t) \in Q = \Omega \times (-T,T), \tag{1.1}$$

where

$$\mathcal{L}_{\lambda,\mu}(x,\partial_x)\mathbf{v}(x) \equiv \mu(x)\Delta\mathbf{v}(x) + (\mu(x)+\lambda(x))\,(\nabla \mathrm{div}\,\mathbf{v}(x)) + (\mathrm{div}\,\mathbf{v}(x))\,\nabla\lambda(x) + \left(\nabla\mathbf{v} + (\nabla\mathbf{v})^T\right)\nabla\mu(x), \qquad x \in \Omega.$$

Throughout this paper, t and $x = (x_1, x_2, x_3)$ denote the time variable and the spatial variable, respectively, and $\mathbf{u} = (u_1, u_2, u_3)^T$ denotes the displacement at the location x and the time t, where $\cdot^T$ denotes the transpose of matrices. We will assume that the density ρ and the Lamé parameters μ and λ satisfy

$$\rho, \lambda, \mu \in C^3(\overline{\Omega}), \quad \rho(x) > 0,\ \mu(x) > 0, \quad \lambda(x) + \mu(x) > 0 \quad \text{for } x \in \overline{\Omega}.$$

To system (1.1), we attach initial and boundary conditions:

$$\mathbf{u} = \Phi, \quad \partial_t \mathbf{u} = \Psi \quad \text{on} \quad \Omega \times \{0\} \tag{1.2}$$

and

$$\mathbf{u} = \mathbf{g} \quad \text{on} \quad \Sigma \equiv \Gamma \times (-T, T). \tag{1.3}$$

There exists a unique weak solution $\mathbf{u} \in C([-T,T]; \mathbf{H}_0^1(\Omega))$ for suitable $\Phi, \Psi, \mathbf{g}$ under sufficient compatibility conditions, and by $\mathbf{u}(\lambda, \mu, \rho, \Phi, \Psi, \mathbf{g})$ we denote the solution to (1.1)–(1.3).

The main subject of this paper is the inverse problem of determining $\rho = \rho(x)$, $\lambda = \lambda(x)$, and $\mu = \mu(x)$ from observed data of the solution on a part of the boundary. It is an important problem, for example, in the geophysics to determine ρ, λ, and μ inside an elastic body from measurements on a subboundary. Thus our inverse problem is physically motivated.

1.1. Inverse problem. Let $\Gamma_1 \subset \Gamma$ be given arbitrarily, and let Φ_j, Ψ_j, $\mathbf{g}_j$, $1 \le j \le \mathcal{N}$, be appropriately given. Then we want to determine $\lambda(x)$, $\mu(x)$, $\rho(x)$, $x \in \Omega$, by measurements

$$\partial_\nu \mathbf{u}(\lambda, \mu, \rho, \Phi_j, \Psi_j, \mathbf{g}_j)(x,t), \quad (x,t) \in \Sigma_1 \equiv \Gamma_1 \times (-T,T),\ 1 \le j \le \mathcal{N}.$$

Here $\nu = \nu(x)$ denotes the unit outward normal vector and $\partial_\nu = \nabla \cdot \nu$.

Our formulation of the inverse problem requires only a finite number of observations (i.e., $\mathcal{N} < \infty$). As for inverse problems for a nonstationary Lamé system by infinitely many boundary observations (i.e., Dirichlet-to-Neumann map), we refer to Rachele [42], for example. Moreover see a monograph by Yakhno [48] for inverse problems for the Lamé system.

For the formulation with a finite number of observations, Bukhgeim and Klibanov [10] proposed a remarkable method based on a Carleman estimate and established the uniqueness for similar inverse problems for scalar partial differential equations. See also Baudouin and Puel [2], Bellassoued [4], [5], Bellassoued and Yamamoto [6], [7], Bukhgeim [8], Bukhgeim, Cheng, Isakov, and Yamamoto [9], Imanuvilov and Yamamoto [20], [21], [22], [23], [24], Isakov [25], [26], Isakov and Yamamoto [27], Khaidarov [29], Klibanov [30], [31], Klibanov and Timonov [33], Klibanov and Yamamoto [34], Kubo [35], Li [39], Puel and Yamamoto [40], [41], and Yamamoto [49].

A Carleman estimate is an inequality for a solution to a partial differential equation with weighted L^2-norm and is a strong tool also for proving the uniqueness in the Cauchy problem or the unique continuation for a partial differential equation with nonanalytic coefficients. Moreover Carleman estimates have been applied essentially for estimating the energy (e.g., Kazemi and Klibanov [28], Klibanov and Malinsky [32]), while we refer to [1] as another method for the energy estimate, which is, however, not applicable to our inverse problem.

As a pioneering work concerning a Carleman estimate, we refer to Carleman's paper [11], which proved what is now called a Carleman estimate and applied it for proving the uniqueness in the Cauchy problem for a two-dimensional elliptic equation. Since [11], the theory of Carleman estimates has been studied extensively. We refer to a general theory by Hörmander [14] in the case where the symbol of a partial differential equation is isotropic and functions under consideration have compact supports (that is, they and their derivatives of suitable orders vanish on the boundary of a domain). Later Carleman estimates for functions with compact supports have been obtained for partial differential operators with anisotropic symbols by Isakov [26]. For Carleman estimates for functions without compact supports, see Imanuvilov [17] and Tataru [46]. We further refer to Fursikov and Imanuvilov [13] and Imanuvilov [16]. As

for a direct derivation of pointwise Carleman estimates for hyperbolic equations which are applicable to functions without compact supports, see Klibanov and Timonov [33] and Lavrent'ev, Romanov, and Shishat·skiĭ [36].

The Carleman estimate for the nonstationary Lamé system was obtained for functions with compact supports, by Eller, Isakov, Nakamura, and Tataru [12], Ikehata, Nakamura, and Yamamoto [15], Imanuvilov, Isakov, and Yamamoto [18], and Isakov [25]. Lemma 2.3 is our Carleman estimate for the Lamé system whose solutions have not necessarily compact supports, and the Carleman estimate bounds also the second-order x-derivatives, which is possible because the right-hand side is estimated in the weighted H^1-norm in x, and we can use the identity $\Delta v = -\mathrm{rot}\,\mathrm{rot}\,v + \nabla(\mathrm{div}\,v)$ and the a priori estimate for the Dirichlet problem for the Laplace equation. By the methodology by [10] or [22] with such Carleman estimates, several uniqueness and stability results are available for the inverse problem for the Lamé system (1.1). That is, in [25] Isakov established the uniqueness in determining a single coefficient $\rho(x)$, using four measurements (i.e., $\mathcal{N} = 4$). Later [15] reduced the number of measurements to three. Recently [18] proved conditional stability and the uniqueness in the determination of all three functions λ, μ, and ρ, with two measurements, and Imanuvilov and Yamamoto [23], [24] proved conditional stability results with a single measurement, provided that initial data satisfy some nondegeneracy condition.

In all of the works [15], [18], [23], [24], [25], the authors assume some geometric condition of the observation subboundary. For such a kind of inverse problems, the uniqueness as well as the stability with boundary measurement on an arbitrary part of Γ are open problems. As for the corresponding unique continuation, we can refer to Bellassoued [3], Robbiano [43], and Tataru [46]. However, their methods are not applicable to the inverse problem. In our paper, by assuming that coefficients under consideration are given in a neighborhood of Γ, we will prove a stability result in the inverse problem. The coincidence of coefficients near the boundary is technically restrictive but acceptable from practical viewpoints, because one can directly know physical properties near the boundary.

Our main achievement of this paper is that we can take an arbitrary observation subboundary Γ_1 for the stability estimate. The key idea is a combination of the method (e.g., [10], [23]) by the Carleman estimates and the Fourier–Bros–Iagolnitzer (FBI) transformation which was used for sharp unique continuation by Robbiano [44]. More precisely, we apply the FBI transformation to change the problem near the boundary into a problem to which elliptic estimates can be applied.

1.2. Notation and statement of main results. In order to formulate our results, we need to introduce some notation. Let $x_0 \in \mathbb{R}^3 \setminus \overline{\Omega}$, $M_0 \geq 0$, $0 < \theta_0 \leq 1$, and $\theta_1 > 0$ be arbitrarily fixed, and let us introduce the conditions on a scalar function p:

$$\begin{cases} p(x) \geq \theta_1 > 0, \quad x \in \overline{\Omega}, \\ \\ \|p\|_{C^3(\overline{\Omega})} \leq M_0, \quad \dfrac{(\nabla p(x) \cdot (x - x_0))}{2p(x)} \leq 1 - \theta_0, \quad x \in \overline{\Omega \setminus \omega}. \end{cases} \tag{1.4}$$

Next we define an admissible set of unknown coefficients λ, μ, ρ. Let $\omega \subset \Omega$ be a given arbitrary neighborhood of the boundary Γ. For fixed functions ρ_0, λ_0, μ_0 on ω

and Φ, Ψ in Ω, and a given constant $M_1 > 0$, we set $\Lambda = \Lambda_{M_0,M_1,\theta_0,\theta_1}$

$$\Lambda = \Bigg\{ (\lambda,\mu,\rho) \in \left(C^3(\overline{\Omega})\right)^3 ; (\rho,\lambda,\mu) = (\rho_0,\lambda_0,\mu_0) \quad \text{in } \omega,$$

$$\left(\frac{\lambda+2\mu}{\rho}\right), \left(\frac{\mu}{\rho}\right) \text{ satisfy(1.4)}, \ \|\mathbf{u}(\lambda,\mu,\rho,\Phi,\Psi,\mathbf{g})\|_{W^{s,\infty}(Q)} \le M_1 \Bigg\}. \tag{1.5}$$

Throughout this paper, let $\mathbf{I}_3$ be the 3×3 identity matrix. We note that $\mathcal{L}_{\lambda,\mu}(x,\partial_x)\Phi(x)$ is the 3-column vector for a 3-column vector Φ. Moreover by $\{\mathbf{a}\}_j$ we denote the matrix (or vector) obtained from $\mathbf{a}$ after deleting the jth row, $\det_j A$ means $\det\{A\}_j$ for a square matrix A, and $\langle A\rangle_j$ is the matrix which is obtained from A by deleting the jth column of A. Furthermore we assume that the observation data are measured by the norm:

$$\epsilon(\Sigma_1) = \sum_{|\alpha|=1}^{2} \|\partial_x^\alpha \mathbf{u}(\lambda,\mu,\rho,\Phi,\Psi,\mathbf{g}) - \partial_x^\alpha \mathbf{u}(\widetilde{\lambda},\widetilde{\mu},\widetilde{\rho},\Phi,\Psi,\mathbf{g})\|^2_{L^2(\Sigma_1)} \tag{1.6}$$

for (λ,μ,ρ), $(\widetilde{\lambda},\widetilde{\mu},\widetilde{\rho}) \in \Lambda$.

1.3. Hypotheses $(\mathcal{H}_1)$–$(\mathcal{H}_2)$. Let (λ,μ,ρ) be an arbitrarily fixed element of Λ. For $\Phi = (\phi_1,\phi_2,\phi_3)^T$ and $\Psi = (\psi_1,\psi_2,\psi_3)^T$, we assume that there exist $j_1, j_2, \in \{1,\dots,6\}$ such that for all $x \in \overline{\Omega}$

$(\mathcal{H}_1)$

$$\det_{j_1} \begin{pmatrix} \mathcal{L}_{\lambda,\mu}(x,\partial_x)\Phi(x) & (\operatorname{div}\Phi(x))\mathbf{I}_3 & \left(\nabla\Phi(x) + (\nabla\Phi(x))^T\right)(x-x_0) \\ \mathcal{L}_{\lambda,\mu}(x,\partial_x)\Psi(x) & (\operatorname{div}\Psi(x))\mathbf{I}_3 & \left(\nabla\Psi(x) + (\nabla\Psi(x))^T\right)(x-x_0) \end{pmatrix} \neq 0,$$

$$(\mathcal{H}_2) \qquad \det_{j_2} \begin{pmatrix} \mathcal{L}_{\lambda,\mu}(x,\partial_x)\Phi(x) & \nabla\Phi(x) + (\nabla\Phi(x))^T & (\operatorname{div}\Phi)(x-x_0) \\ \mathcal{L}_{\lambda,\mu}(x,\partial_x)\Psi(x) & \nabla\Psi(x) + (\nabla\Psi(x))^T & (\operatorname{div}\Psi)(x-x_0) \end{pmatrix} \neq 0.$$

Now we are ready to state the main result, which proves that only one observation with a suitable initial value yields the logarithmic conditional stability for our inverse problem.

THEOREM 1.0. *Let $T > 0$ be sufficiently large for Ω, ω, and let $\Lambda = \Lambda_{M_0,M_1,\theta_0,\theta_1}$ be defined by* (1.5). *Moreover let (Φ,Ψ) satisfy the conditions* $(\mathcal{H}_1)$–$(\mathcal{H}_2)$. *Then there exist constants $C > 0$ and $\kappa \in (0,1)$ such that the following estimate holds:*

$$\|\widetilde{\lambda} - \lambda\|_{H^2(\Omega)} + \|\widetilde{\mu} - \mu\|_{H^2(\Omega)} + \|\widetilde{\rho} - \rho\|_{H^1(\Omega)} \le C \left[\log\left(2 + \frac{C}{\epsilon(\Sigma_1)}\right)\right]^{-\kappa}$$

for any $(\tilde{\lambda},\tilde{\mu},\tilde{\rho}) \in \Lambda$.

Here we note that $\epsilon(\Sigma_1)$ is given by (1.6) *and the constants C and $\kappa \in (0,1)$ are dependent on, Ω, ω, T, M_0, M_1 and independent of $(\lambda,\mu,\rho) \in \Lambda$.*

Our stability result requires only one measurement, $\mathcal{N} = 1$, and the stability result is of logarithmic rate and weaker than any Hölder stability. We notice that, with a suitable geometric condition of the observation subboundary, we can prove Hölder (or the Lipschitz) stability by means of the method in Imanuvilov and Yamamoto [23], [24]. By Theorem 1.0, we can readily derive the uniqueness in the inverse problem.

COROLLARY 1.1 (uniqueness). *Under the assumptions in Theorem* 1*, for all* $(\lambda, \mu, \rho), (\tilde{\lambda}, \tilde{\mu}, \tilde{\rho}) \in \Lambda$*, we have the uniqueness*

$$\partial_\nu \mathbf{u}(x,t) = \partial_\nu \widetilde{\mathbf{u}}(x,t), \quad (x,t) \in \Sigma_1 \quad \textit{implies} \quad (\lambda, \mu, \rho) = (\tilde{\lambda}, \tilde{\mu}, \tilde{\rho}) \quad \textit{in } \Omega.$$

For the determination of the three coefficients by a single measurement, we have to choose initial data satisfying conditions $(\mathcal{H}_1)$–$(\mathcal{H}_2)$. Thus conditions $(\mathcal{H}_1)$–$(\mathcal{H}_2)$ are not generic properties, and we should satisfy them artificially and a posteriori. Moreover, as the following example shows, we can take such Φ and Ψ.

Example of Ω*,* Φ*,* Ψ *meeting* $(\mathcal{H}_1)$–$(\mathcal{H}_2)$. For simplicity, we assume that $x_0 = (0,0,0)$, $\overline{\Omega}$ does not intersect any of $\{x_1 = 0\}$, $\{x_2 = 0\}$, $\{x_3 = 0\}$, and $\{x_1 + x_3 = 0\}$, and λ, μ are positive constants. For example, we take

$$\Phi(x) = \begin{pmatrix} 0 \\ x_1 x_2 \\ 0 \end{pmatrix}, \quad \Psi(x) = \begin{pmatrix} x_2^2 \\ 0 \\ x_2^2 \end{pmatrix}.$$

Then, by choosing $j_1 = j_2 = 6$, we can verify that $(\mathcal{H}_1)$–$(\mathcal{H}_2)$ are satisfied.

Thanks to the extra information $(\lambda, \mu, \rho) = (\tilde{\lambda}, \tilde{\mu}, \tilde{\rho})$ in a neighborhood ω of $\partial\Omega$, the sharp unique continuation by Bellassoued [3], implies $\mathbf{u}(\lambda, \mu, \rho, \Phi, \Psi, \mathbf{g})(x,t) = \mathbf{u}(\widetilde{\lambda}, \widetilde{\mu}, \widetilde{\rho}, \Phi, \Psi, \mathbf{g})(x,t)$ on $\partial(\Omega \setminus \overline{\omega}) \times (-T, T)$, provided that $T > 0$ is sufficiently large. Therefore the method in Imanuvilov, Isakov, and Yamamoto[18], and Imanuvilov and Yamamoto [24] directly yields the uniqueness in our inverse problem. However, our main result is concerned with the stability in the inverse problem, and the direct combination of the existing results in [18], [21], [22] does not work. For our purpose, we will use the FBI transformation according to Robbiano [44], [43].

The remainder of the paper is organized as follows. In section 2, we give key estimates. In section 3, we prove Theorem 1.0 on the basis of the weak observation estimate, that is, an estimate of $\mathbf{u}(\lambda, \mu, \rho, \Phi, \Psi, \mathbf{g}) - \mathbf{u}(\widetilde{\lambda}, \widetilde{\mu}, \widetilde{\rho}, \Phi, \Psi, \mathbf{g})$ by data on any small part of the boundary. Section 4 is devoted to the proof of the weak observation estimate.

2. Preliminaries and Carleman estimates. We set

$$\omega(\epsilon) = \{x \in \Omega;\ \operatorname{dist}(x, \partial\Omega) \leq \epsilon\}$$

and

$$\omega(\epsilon_1, \epsilon_2) = \{x \in \Omega;\ \epsilon_1 \leq \operatorname{dist}(x, \partial\Omega) \leq \epsilon_2\},$$

with $0 < \epsilon_1 < \epsilon_2$ and $\epsilon > 0$.

In this section we first derive several estimates. We choose $\epsilon_0, \epsilon_1, \epsilon_2 > 0$ such that

$$\omega(3\epsilon_0) \subset \omega \tag{2.1}$$

and

$$\omega(\epsilon_1, \epsilon_2) \subset \omega, \quad \epsilon_1 < \epsilon_2 < 8\epsilon_0. \tag{2.2}$$

We set

$$\omega_T(\epsilon) = \omega(\epsilon) \times [-T, T], \quad \omega_T(\epsilon_1, \epsilon_2) = \omega(\epsilon_1, \epsilon_2) \times [-T, T].$$

For δ_0 such that $0 < \delta_0 < T$, we set

$$Q_{\delta_0} = \Omega \times [-T + \delta_0, T - \delta_0], \quad Q_{\delta_0}(\epsilon) = (\Omega \setminus \omega(\epsilon)) \times [-T + \delta_0, T - \delta_0].$$

For formulating our Carleman estimate, we need some notation. Set

$$d = (\sup_{x \in \Omega} |x - x_0|^2 - \inf_{x \in \Omega} |x - x_0|^2)^{\frac{1}{2}}, \tag{2.3}$$

where $x_0 \notin \overline{\Omega}$ is arbitrarily fixed. We choose $\theta > 0$ such that

$$\theta + \frac{M_0 d}{\sqrt{\theta_1}} \sqrt{\theta} < \theta_0 \theta_1, \qquad \theta_1 \inf_{x \in \Omega} |x - x_0|^2 - \theta \sup_{x \in \Omega} |x - x_0|^2 > 0. \tag{2.4}$$

Here we note that, since $x_0 \notin \overline{\Omega}$, such $\theta > 0$ exists.

We introduce two functions $\psi, \varphi : \Omega \times \mathbb{R} \longrightarrow \mathbb{R}$ of class C^1 by setting

$$\psi(x,t) = |x - x_0|^2 - \theta |t|^2 \quad \text{for all } x \in \Omega, \quad -T \le t \le T,$$

$$\varphi(x,t) = e^{\beta \psi(x,t)}, \quad \beta > 0, \tag{2.5}$$

where $T > \frac{d}{\sqrt{\theta}}$. Therefore, by (2.4) and (2.5), we have

$$\varphi(x,0) \ge d_0, \quad \varphi(x, \pm T) < d_0, \tag{2.6}$$

with $d_0 = \exp(\beta \inf_{x \in \Omega} |x - x_0|)$. Thus, for a given sufficiently small $\eta > 0$, we can choose a sufficiently small $\delta_0 = \delta_0(\eta)$ such that

$$\varphi(x,t) \le d_0 - \eta \quad \text{for all } \ (x,t) \in Q \backslash \overline{Q_{2\delta_0}}. \tag{2.7}$$

We set $\nabla_{x,t} v(t,x) = (\frac{\partial v}{\partial x_1}, \frac{\partial v}{\partial x_2}, \frac{\partial v}{\partial x_3}, \frac{\partial v}{\partial t}) = (\nabla v, \partial_t v)$, and we shall use the weighted norm:

$$\|u\|^2_{H^{1,\tau}(Q)} = \tau^2 \|u\|^2_{L^2(Q)} + \|\nabla_{x,t} u\|^2_{L^2(Q)}.$$

Moreover $H_x^{k,\tau}(Q)$ is the Sobolev space equipped with the norm

$$\|u\|^2_{H_x^{k,\tau}(Q)} = \sum_{|\alpha| \le k} \tau^{2(k-|\alpha|)} \|\partial_x^\alpha u\|^2_{L^2(Q)}.$$

In what follows, $C > 0$ denote generic constants depending on $\widehat{\beta}$, τ_0, M_0, M_1, θ_0, θ_1, Ω, T, x_0, ω, χ and Φ, Ψ, ϵ, δ but independent of $\tau > \widehat{\tau}$.

2.1. Preliminary estimates. The first lemma is a classical Carleman estimate for a scalar hyperbolic equation (e.g., [14], [17], [25], [26]). See also Triggiani and Yao [47].

LEMMA 2.1. *Let φ be defined by* (2.5). *If $\frac{a}{\rho}$ satisfies* (1.4), *then there exists $\widehat{\beta} > 0$ such that for any $\beta > \widehat{\beta}$ we can choose $\widehat{\tau}(\beta) > 0$ such that the following estimate holds true:*

$$\tau \|e^{\tau\varphi} u\|^2_{H^{1,\tau}(Q)} \le C \left\| e^{\tau\varphi} \left(\rho \partial_t^2 - a\Delta \right) u \right\|^2_{L^2(Q)},$$

whenever a function $u \in H^2(Q)$ is supported in Q and $\tau > \widehat{\tau}$.

The next lemma is a weighted estimate for the elliptic equation which follows from the formula

$$|\Delta(\mathbf{v}e^{\tau\varphi})| = O(\tau^2)e^{\tau\varphi}|\mathbf{v}| + O(\tau)e^{\tau\varphi}|\nabla\mathbf{v}|$$

$$+e^{\tau\varphi}|\mathrm{rot}\,(\mathrm{rot}\,\mathbf{v}) - \nabla(\mathrm{div}\,\mathbf{v})|$$

in Q and the standard a priori estimate for the Dirichlet problem for the Poisson equation.

LEMMA 2.2. *There exists a constant $C > 0$ such that*

$$\frac{1}{\tau}\|e^{\tau\varphi}\mathbf{v}\|^2_{H^{2,\tau}_x(Q)} \le C(\tau\|e^{\tau\varphi}\mathbf{v}\|^2_{H^{1,\tau}_x(Q)} + \|e^{\tau\varphi}(\nabla\mathrm{div}\mathbf{v})\|^2_{L^2(Q)} + \|e^{\tau\varphi}(\nabla\mathrm{rot}\mathbf{v})\|^2_{L^2(Q)}),$$

whenever $\mathbf{v} \in H^2(Q)$ and $\mathbf{v}_{|\Sigma} = 0$.

2.2. Carleman estimate for the Lamé system. In order to prove a Carleman estimate, we have to assume a condition called the pseudoconvexity (e.g., [14]) where the coefficient of the principal term is involved. Since such a coefficient is unknown in our inverse problem, we need to establish a Carleman estimate with one possible explicit characterization (1.4) of the coefficients for the pseudoconvexity, and we will argue similarly to Bellassoued [4]. Moreover for our stability estimates, unlike [12], [26], we require a Carleman estimate for functions which do not have compact supports.

Now we will consider the three-dimensional isotropic nonstationary Lamé system

$$P(x,\partial_x,\partial_t)\mathbf{y}(x,t) = \rho(x)\partial_t^2\mathbf{y}(x,t) - \mathcal{L}_{\lambda,\mu}(x,\partial_x)\mathbf{y}(x,t) = \mathbf{f}(x,t), \quad (x,t) \in Q. \tag{2.8}$$

We have a Carleman estimate.

LEMMA 2.3. *There exists $\widehat{\beta} > 0$ such that for any $\beta > \widehat{\beta}$ we can choose $\tau_0 = \tau_0(\beta) > 0$ such that for any solution $\mathbf{y} \in H^2(Q)$ to problem (2.8) the following estimate holds true:*

$$\begin{aligned}\frac{1}{\tau}\|e^{\tau\varphi}\mathbf{y}\|^2_{H^{2,\tau}_x(Q_{\delta_0}(3\epsilon_0))} \le C(&\|e^{\tau\varphi}\mathbf{f}\|^2_{L^2(Q)} + \|e^{\tau\varphi}\nabla\mathbf{f}\|^2_{L^2(Q)} + e^{C\tau}\|\mathbf{y}\|^2_{H^2(\omega_T(\epsilon_0,3\epsilon_0))}\\ &+ e^{2\tau(d_0-\eta)}\|\mathbf{y}\|^2_{H^2(Q)})\end{aligned}$$

for any $\tau \ge \tau_0$, where the constant $C = C(\beta) > 0$ is independent of τ.

Proof. We introduce a cutoff function χ satisfying $0 \le \chi \le 1$, $\chi \in C_0^\infty(\mathbb{R}^3 \times \mathbb{R})$, $\chi_1 \in C_0^\infty(\mathbb{R}^3)$, $\chi_2 \in C_0^\infty(\mathbb{R})$, and

$$\chi(x,t) = \chi_1(x)\chi_2(t), \quad \chi_1(x) = \begin{cases} 0, & x \in \omega(\epsilon_0),\\ 1, & x \in \Omega \setminus \overline{\omega(3\epsilon_0)},\end{cases} \qquad \chi_2(t) = \begin{cases} 0, & |t| > T - \delta_0,\\ 1, & |t| < T - 2\delta_0.\end{cases}$$

Set $\mathbf{v}(x,t) = \chi(x,t)\mathbf{y}(x,t)$. Then we have

$$\partial_t^2\mathbf{v} - \frac{1}{\rho}\mathcal{L}_{\lambda,\mu}(x,\partial_x)\mathbf{v} = \frac{1}{\rho}\widetilde{\mathbf{f}} \quad \text{in } Q, \quad \mathbf{v} = 0 \quad \text{in } \omega(\epsilon_0), \tag{2.9}$$

where

$$\widetilde{\mathbf{f}}(x,t) = \chi(x,t)\mathbf{f} + [P,\chi_1]\chi_2\mathbf{y} + \chi_1[P,\chi_2]\mathbf{y}. \tag{2.10}$$

Let $v = \operatorname{div}\mathbf{v}$ and $\mathbf{w} = \operatorname{rot}\mathbf{v}$. Therefore, by [12], for example, we apply rot and div to (2.9) and obtain

$$\rho(x)\partial_t^2\mathbf{v} - \mu(x)\Delta\mathbf{v} + A_1(\mathbf{v}, v) = \widetilde{\mathbf{f}},$$

$$\rho(x)\partial_t^2 v - (2\mu(x) + \lambda(x))\,\Delta v + A_2(\mathbf{v}, v, \mathbf{w}) = R_1\widetilde{\mathbf{f}},$$
$$\rho(x)\partial_t^2\mathbf{w} - \mu(x)\Delta\mathbf{w} + A_3(\mathbf{v}, v, \mathbf{w}) = R_2\widetilde{\mathbf{f}},$$

where A_j and R_j are linear differential operators of the first order with bounded coefficients in Ω.

Since $\frac{\mu}{\rho}$ and $\frac{2\mu+\lambda}{\rho}$ satisfy (1.4), we have by Lemma 2.1

$$\begin{aligned}
&\tau(\|e^{\tau\varphi}\mathbf{v}\|^2_{H^{1,\tau}(Q)} + \|e^{\tau\varphi}v\|^2_{H^{1,\tau}(Q)} + \|e^{\tau\varphi}\mathbf{w}\|^2_{H^{1,\tau}(Q)})\\
\le& C(\|\tilde{\mathbf{f}}e^{\tau\varphi}\|^2_{L^2(Q)} + \|(\nabla\tilde{\mathbf{f}})e^{\tau\varphi}\|^2_{L^2(Q)} + \|\mathbf{v}e^{\tau\varphi}\|^2_{L^2(Q)} + \|(\nabla\mathbf{v})e^{\tau\varphi}\|^2_{L^2(Q)}\\
&+\|ve^{\tau\varphi}\|^2_{L^2(Q)} + \|(\nabla v)e^{\tau\varphi}\|^2_{L^2(Q)} + \|\mathbf{w}e^{\tau\varphi}\|^2_{L^2(Q)} + \|(\nabla\mathbf{w})e^{\tau\varphi}\|^2_{L^2(Q)}).
\end{aligned}$$

By taking $\tau > 0$ sufficiently large, we have

$$\tau(\|e^{\tau\varphi}\mathbf{v}\|^2_{H^{1,\tau}(Q)} + \|e^{\tau\varphi}v\|^2_{H^{1,\tau}(Q)} + \|e^{\tau\varphi}\mathbf{w}\|^2_{H^{1,\tau}(Q)})$$

$$\le C(\|\tilde{\mathbf{f}}e^{\tau\varphi}\|^2_{L^2(Q)} + \|(\nabla\tilde{\mathbf{f}})e^{\tau\varphi}\|^2_{L^2(Q)}). \tag{2.11}$$

On the other hand, since $[P, \chi_1]$ is a first-order differential operator which is supported in $\omega_T(\epsilon_0, 3\epsilon_0)$ and $[P, \chi_2]$ is a first-order differential operator which is supported in $Q\backslash Q_{2\delta_0}$, we obtain by (2.7) and (2.10)

$$\begin{aligned}
\|e^{\tau\varphi}\widetilde{\mathbf{f}}\|^2_{L^2(Q)} + \|e^{\tau\varphi}\nabla\widetilde{\mathbf{f}}\|^2_{L^2(Q)} \le C(&\|e^{\tau\varphi}\mathbf{f}\|^2_{L^2(Q)} + \|e^{\tau\varphi}\nabla\mathbf{f}\|^2_{L^2(Q)} + e^{C\tau}\|\mathbf{y}\|^2_{H^2(\omega_T(\epsilon_0,3\epsilon_0))}\\
&+e^{2\tau(d_0-\eta)}\|\mathbf{y}\|^2_{H^2(Q)}).
\end{aligned}$$

Thus, in terms of (2.11), we have

$$\begin{aligned}
&\tau(\|e^{\tau\varphi}\mathbf{v}\|^2_{H^{1,\tau}(Q)} + \|e^{\tau\varphi}\operatorname{div}\mathbf{v}\|^2_{H^{1,\tau}(Q)} + \|e^{\tau\varphi}\operatorname{rot}\mathbf{v}\|^2_{H^{1,\tau}(Q)})\\
\le& C(\|e^{\tau\varphi}\mathbf{f}\|^2_{L^2(Q)} + \|e^{\tau\varphi}\nabla\mathbf{f}\|^2_{L^2(Q)} + e^{C\tau}\|\mathbf{y}\|^2_{H^2(\omega_T(\epsilon_0,3\epsilon_0))} + e^{2\tau(d_0-\eta)}\|\mathbf{y}\|^2_{H^2(Q)}).
\end{aligned}$$

By applying Lemma 2.2, we obtain

$$\begin{aligned}
&\frac{1}{\tau}\|e^{\tau\varphi}\mathbf{v}\|^2_{H^{2,\tau}_x(Q)}\\
&\le C(\tau\|e^{\tau\varphi}\mathbf{v}\|^2_{H^{1,\tau}(Q)} + \|e^{\tau\varphi}\operatorname{div}\mathbf{v}\|^2_{H^{1,\tau}(Q)} + \|e^{\tau\varphi}\operatorname{rot}\mathbf{v}\|^2_{H^{1,\tau}(Q)})\\
&\le C(\|e^{\tau\varphi}\mathbf{f}\|^2_{L^2(Q)} + \|e^{\tau\varphi}\nabla\mathbf{f}\|^2_{L^2(Q)} + e^{C\tau}\|\mathbf{y}\|^2_{H^3(\omega_T(\epsilon_0,3\epsilon_0))} + e^{2\tau(d_0-\eta)}\|\mathbf{y}\|^2_{H^2(Q)}).
\end{aligned}$$

Since $\mathbf{v} = \chi\mathbf{y}$ and $\chi = 1$ in $Q_{\delta_0}(3\epsilon_0)$, we can replace $\mathbf{v}$ by $\mathbf{y}$ on the left-hand side, so that the proof of Lemma 2.3 is complete. □

2.3. Carleman estimate for a first-order partial differential operator. We consider a first-order partial differential equation

$$Av = \sum_{j=1}^{n} a_j(x)\partial_j v + a_0(x)v \equiv f(x), \quad x \in \Omega, \tag{2.12}$$

where

$$a_0 \in C(\overline{\Omega}), \quad a = (a_1, \dots, a_n) \in \left[C^1(\overline{\Omega})\right]^n, \tag{2.13}$$

and

$$|a(x) \cdot (x - x_0)| \geq c_0 > 0 \quad \text{on } \overline{\Omega}, \tag{2.14}$$

with a constant $c_0 > 0$. We set

$$\varphi_0(x) = \varphi(x, 0), \qquad x \in \Omega.$$

We have the following.

LEMMA 2.4. *In addition to* (2.14), *we assume that* $\|a_0\|_{C^2(\overline{\Omega})} \leq M$ *and* $\|a_i\|_{C^2(\overline{\Omega})} \leq M$, $1 \leq i \leq 3$. *Then there exists a constant* $\widehat{\beta} > 0$ *such that for all* $\beta > \widehat{\beta}$ *there exist* $\widehat{\tau} = \widehat{\tau}(\beta) > 0$ *and* $C = C(\widehat{\tau}, \widehat{\beta}, \Omega, \omega) > 0$ *such that*

$$\tau^2 \sum_{|\alpha| \leq 2} \int_{\Omega} |\partial_x^\alpha v|^2 e^{2\tau\varphi_0(x)} dx \leq C \sum_{|\alpha| \leq 2} \int_{\Omega} |\partial_x^\alpha f(x)|^2 e^{2\tau\varphi_0(x)} dx$$

for all $\tau > \widehat{\tau}$ *and* $v \in C_0^2(\Omega)$.

Proof. We will repeat the argument of Lemma 3.2 in [23], and, for completeness, we give the proof. We multiply both sides of (2.12) by $v(x)e^{2\tau\varphi_0(x)}$, and, by using the divergence theorem and $v \in C_0^2(\Omega)$, we obtain

$$\begin{aligned}
&\int_{\Omega} Av(x) \cdot v(x) e^{2\tau\varphi_0(x)} dx = \int_{\Omega} \nabla v(x) \cdot \left(e^{2\tau\varphi_0(x)} v(x) a(x)\right) dx + \int_{\Omega} a_0(x) |v(x)|^2 dx \\
&= -\int_{\Omega} v(x) \mathrm{div}\left(e^{2\tau\varphi_0(x)} v(x) a(x)\right) dx + \int_{\Omega} a_0(x) |v(x)|^2 e^{2\tau\varphi_0(x)} dx \\
&= -\int_{\Omega} |v|^2 e^{2\tau\varphi_0(x)} \mathrm{div}(a(x)) dx - 2\tau \int_{\Omega} |v(x)|^2 \nabla\varphi_0 \cdot a(x) e^{2\tau\varphi_0(x)} dx \\
&\quad - \int_{\Omega} e^{2\tau\varphi_0(x)} v(x) \nabla v(x) \cdot a(x) dx + \int_{\Omega} a_0(x) |v(x)|^2 e^{2\tau\varphi_0(x)} dx.
\end{aligned}$$

By (2.14), we obtain

$$|\nabla\varphi_0(x) \cdot a(x)| \geq 2\beta c_0, \quad \nabla v(x) \cdot a(x) = Av - a_0(x)v(x), \quad x \in \Omega,$$

so that the Cauchy–Schwarz inequality yields

$$\begin{aligned}
\tau \int_{\Omega} |v(x)|^2 e^{2\tau\varphi_0(x)} dx &\leq C \int_{\Omega} |(Av(x) \cdot v(x))| e^{2\tau\varphi_0(x)} dx + C \int_{\Omega} |v(x)|^2 e^{2\tau\varphi_0(x)} dx \\
&\leq \frac{C_\varepsilon}{\tau} \int_{\Omega} |Av(x)|^2 e^{2\tau\varphi_0(x)} dx + \varepsilon\tau \int_{\Omega} |v(x)|^2 e^{2\tau\varphi_0(x)} dx \\
&\quad + C \int_{\Omega} |v(x)|^2 e^{2\tau\varphi_0(x)} dx.
\end{aligned}$$

By choosing τ large and ε small, we obtain

$$\tau^2 \int_\Omega |v(x)|^2 e^{2\tau\varphi_0(x)} dx \le C \int_\Omega |Av(x)|^2 e^{2\tau\varphi_0(x)} dx. \tag{2.15}$$

Since $A(\partial_j v) = \partial_j f(x) - \sum_{k=1}^n (\partial_j a_k)\partial_k v - (\partial_j a_0)v$ and $\partial_j v|_{\partial\Omega} = 0$, we apply (2.15) to $\partial_j v$, so that

$$\begin{aligned}\tau^2 \int_\Omega |\partial_j v(x)|^2 e^{2\tau\varphi_0} dx &\le C \int_\Omega (|v(x)|^2 + |\nabla v(x)|^2) e^{2\tau\varphi_0} dx + C \int_\Omega |\partial_j f(x)|^2 e^{2\tau\varphi_0} dx \\ &\le C \int_\Omega (|f(x)|^2 + |\partial_j f(x)|^2) e^{2\tau\varphi_0} dx + C \int_\Omega |\nabla v(x)|^2 e^{2\tau\varphi_0} dx.\end{aligned}$$

Therefore

$$\tau^2 \int_\Omega |\nabla v(x)|^2 e^{2\tau\varphi_0} dx \le C \int_\Omega (|f(x)|^2 + |\nabla f(x)|^2) e^{2\tau\varphi_0} dx + C \int_\Omega |\nabla v(x)|^2 e^{2\tau\varphi_0} dx.$$

By taking $\tau_0 > 0$ sufficiently large, we have

$$\tau^2 \int_\Omega |\nabla v(x)|^2 e^{2\tau\varphi_0} dx \le C \int_\Omega \left(|f(x)|^2 + |\nabla f(x)|^2\right) e^{2\tau\varphi_0} dx.$$

Next we have

$$A(\partial_k \partial_\ell v) = \partial_k \partial_\ell f - \sum_{j=1}^3 (\partial_k a_j)(\partial_\ell \partial_j v) + (\partial_\ell a_j)(\partial_k \partial_j v) + K(v, \nabla v),$$

where K is a linear operator of v and ∇v with bounded coefficients in Ω. Noting that $\partial_k \partial_\ell v = 0$ on $\partial\Omega$, we apply (2.15) to $\partial_k \partial_\ell v$, and we can complete the proof of Lemma 2.4. □

2.4. Weak observation estimate. Let $\mathbf{v}$ satisfy

$$\rho(x)\partial_t^2 \mathbf{v} - \mathcal{L}_{\lambda,\mu}(x, \partial_x)\mathbf{v} = R(x,t) \quad \text{in } Q \equiv \Omega \times (-T, T)$$

and

$$\mathbf{v}(x,t) = 0 \quad \text{on } \Sigma \equiv \Gamma \times (-T, T),$$

where we assume that

$$R(x,t) = 0, \quad (x,t) \in \omega \times (-T, T).$$

The following proposition shows the stability in the unique continuation of solutions of the Lamé system from lateral boundary data on an arbitrarily small part Γ_1 of $\partial\Omega$.

LEMMA 2.5. *For sufficiently large $T > 0$, there exists a constant $C > 0$ such that*

$$\|\mathbf{v}\|^2_{H^2(\omega_T(\epsilon_0, 3\epsilon_0))} \le C \left[\log\left(2 + \frac{C}{\sum_{|\alpha|=1}^2 \|\partial_x^\alpha \mathbf{v}\|^2_{L^2(\Sigma_1)}}\right)\right]^{-1}.$$

In our case, the corresponding uniqueness is already proved in Bellassoued [3] and Eller, Isakov, Nakamura, and Tataru [12]. For similar stability results for a scalar hyperbolic equation, see Bellassoued and Yamamoto [6] and Robbiano [44]. The proof of the lemma is given in section 4.

3. Proof of the main result. This section is devoted to the proof of Theorem 1.0. The key is the combination of Lemma 2.5 and the existing method (e.g., [4]).

3.1. Notation and preliminary estimates. For simplicity, we set

$$\mathbf{u} = \mathbf{u}(\lambda, \mu, \rho, \Phi, \Psi, \mathbf{g}), \quad \widetilde{\mathbf{u}} = \mathbf{u}(\widetilde{\lambda}, \widetilde{\mu}, \widetilde{\rho}, \Phi, \Psi, \mathbf{g}),$$

and

$$\mathbf{u}_* = \mathbf{u} - \widetilde{\mathbf{u}}, \quad \rho_* = \rho - \widetilde{\rho}, \quad \lambda_* = \lambda - \widetilde{\lambda}, \quad \mu_* = \mu - \widetilde{\mu}.$$

Then we obtain

$$\widetilde{\rho}\partial_t^2 \mathbf{u}_*(x,t) = \mathcal{L}_{\widetilde{\lambda},\widetilde{\mu}}(x,\partial_x)\mathbf{u}_*(x,t) + \mathbf{f}(x,t) \quad \text{in} \quad Q, \tag{3.1}$$

$$\mathbf{u}_*(x,0) = \partial_t \mathbf{u}_*(x,0) = 0, \quad x \in \Omega, \tag{3.2}$$

and

$$\mathbf{u}_* = 0 \qquad \text{on} \quad \Sigma = \Gamma \times (-T,T). \tag{3.3}$$

Here we set

$$\begin{aligned}\mathbf{f}(x,t) &= -\rho_*(x)\partial_t^2 \mathbf{u}(x,t) + (\lambda_*(x) + \mu_*(x))\nabla(\operatorname{div}\mathbf{u})(x,t) + \mu_*(x)\Delta\mathbf{u}(x,t)\\ &\quad + (\operatorname{div}\mathbf{u})(x,t)\nabla\lambda_*(x) + \left(\nabla\mathbf{u}(x,t) + (\nabla\mathbf{u}(x,t))^T\right)\nabla\mu_*(x)\\ &= -\left(\rho_*(x)\partial_t^2\mathbf{u} - \mathcal{L}_{\lambda_*,\mu_*}(x,\partial_x)\mathbf{u}\right).\end{aligned}$$

Moreover we set

$$\mathbf{y}_1(x,t) = \partial_t^2 \mathbf{u}_*(x,t), \quad \mathbf{y}_2(x,t) = \partial_t^3 \mathbf{u}_*(x,t), \quad \mathbf{y}_3(x,t) = \partial_t^4 \mathbf{u}_*(x,t).$$

Then we have

$$\widetilde{\rho}\partial_t^2 \mathbf{y}_j - \mathcal{L}_{\widetilde{\lambda},\widetilde{\mu}}(x,\partial_x)\mathbf{y}_j = \partial_t^{j+2}\mathbf{f}. \tag{3.4}$$

For simplicity, it is convenient to use the following notation:

$$\mathcal{D} = \sum_{j=2}^{4} \|\partial_t^j \mathbf{u}_*\|^2_{H^2(\omega_T(\epsilon_0,3\epsilon_0))} = \sum_{j=1}^{3} \|\mathbf{y}_j\|^2_{H^2(\omega_T(\epsilon_0,3\epsilon_0))}$$

and

$$\mathcal{E} = \sum_{|\alpha|\le 1} \|e^{\tau\varphi}\partial_x^\alpha \rho_*\|^2_{L^2(Q)} + \sum_{|\alpha|\le 2} (\|e^{\tau\varphi}\partial_x^\alpha \lambda_*\|^2_{L^2(Q)} + \|e^{\tau\varphi}\partial_x^\alpha \mu_*\|^2_{L^2(Q)}),$$

$$\mathbf{z}_1(x) = \mathbf{y}_1(x,0), \quad \mathbf{z}_2(x) = \mathbf{y}_2(x,0).$$

We have the following.

LEMMA 3.1. *There exists a constant $\widehat{\beta} > 0$ such that for all $\beta \ge \widehat{\beta}$ there exist $\widehat{\tau}$ and $C > 0$ such that*

$$\sum_{|\alpha|\le 2} \int_{\Omega\setminus\omega(3\epsilon_0)} \tau^{4-2|\alpha|} \left(|\partial_x^\alpha \mathbf{z}_1(x)|^2 + |\partial_x^\alpha \mathbf{z}_2(x)|^2\right) e^{2\tau\varphi_0(x)} dx \le C(\tau^4 e^{2\tau(d_0-\eta)} + \tau^2\mathcal{E} + e^{C\tau}\mathcal{D})$$

for all large $\tau > \widehat{\tau}$.

Here we recall that $\varphi_0(x) = \varphi(x,0)$, $x \in \Omega$.

Proof. Noting that $\mathbf{u}_* \in W^{8,\infty}(Q)$, we can apply Lemma 2.3 to (3.4), so that we have

$$\frac{1}{\tau}\left\|e^{\tau\varphi}\mathbf{y}_j\right\|^2_{H^{2,\tau}_x(Q_{\delta_0}(3\epsilon_0))} \le C(\|e^{\tau\varphi}\partial_t^{j+2}\mathbf{f}\|^2_{L^2(Q)} + \|e^{\tau\varphi}\nabla(\partial_t^{j+2}\mathbf{f})\|^2_{L^2(Q)}$$
$$+e^{C\tau}\left\|\mathbf{y}_j\right\|^2_{H^2(\omega_T(\epsilon_0,3\epsilon_0))} + e^{2\tau(d_0-\eta)}\left\|\mathbf{y}_j\right\|^2_{H^2(Q)}), \quad j = 1,2,3. \tag{3.5}$$

By the definition of $\mathbf{f}$, we have

$$\left|\nabla(\partial_t^{j+2}\mathbf{f}(x,t))\right|^2 \le C\left(\sum_{|\alpha|\le 1}|\partial_x^\alpha \rho_*(x)|^2 + \sum_{|\alpha|\le 2}\left(|\partial_x^\alpha\lambda_*(x)|^2 + |\partial_x^\alpha\mu_*(x)|^2\right)\right)$$

and

$$\left|\partial_t^{j+2}\mathbf{f}(x,t)\right|^2 \le C\left(|\rho_*(x)|^2 + \sum_{|\alpha|\le 1}\left(|\partial_x^\alpha\lambda_*(x)|^2 + |\partial_x^\alpha\mu_*(x)|^2\right)\right) \quad \text{in } Q.$$

Therefore

$$\sum_{j=1}^{5}\left(\|e^{\tau\varphi}\nabla(\partial_t^j\mathbf{f})\|^2_{L^2(Q)} + \|e^{\tau\varphi}\partial_t^j\mathbf{f}\|^2_{L^2(Q)}\right) \le C\mathcal{E}.$$

Thus (3.5) implies that

$$\frac{1}{\tau}\sum_{j=1}^{3}\left\|e^{\tau\varphi}\mathbf{y}_j\right\|^2_{H^{2,\tau}_x(Q_{\delta_0}(3\epsilon_0))} \le C(e^{2\tau(d_0-\eta)} + \mathcal{E} + e^{C\tau}\mathcal{D}). \tag{3.6}$$

On the other hand, we introduce a cutoff function $\chi_2 \in C_0^\infty(\mathbb{R})$ satisfying $0 \le \chi_2 \le 1$ and

$$\chi_2(t) = \begin{cases} 0, & |t| > T - \delta_0, \\ 1, & |t| < T - 2\delta_0. \end{cases}$$

Then we have

$$\int_{\Omega\setminus\omega(3\epsilon_0)}|\partial_x^\alpha\mathbf{z}_j(x)|^2 e^{2\tau\varphi_0(x)}dx = \int_{-T}^{0}\frac{\partial}{\partial t}\left(\int_{\Omega\setminus\omega(3\epsilon_0)}|(\partial_x^\alpha\mathbf{y}_j)(x,t)|^2\chi_2(t)^2e^{2\tau\varphi}dx\right)dt$$
$$= 2\int_{-T}^{0}\int_{\Omega\setminus\omega(3\epsilon_0)}(\partial_x^\alpha\mathbf{y}_{j+1}\cdot\partial_x^\alpha\mathbf{y}_j)\chi_2^2(t)e^{2\tau\varphi}dxdt$$
$$+2\tau\int_{-T}^{0}\int_{\Omega\setminus\omega(3\epsilon_0)}|\partial_x^\alpha\mathbf{y}_j|^2\chi_2^2(\partial_t\varphi)e^{2\tau\varphi}dxdt$$
$$+2\int_{-T}^{0}\int_{\Omega\setminus\omega(3\epsilon_0)}|\partial_x^\alpha\mathbf{y}_j|^2\chi_2'(t)\chi_2(t)e^{2\tau\varphi}dxdt, \quad j = 1,2.$$

Since $\chi_2'(t)$ is supported in $[-T,-T+2\delta_0]\cup[T-2\delta_0,T]$, by the Cauchy–Schwarz

inequality we obtain

$$\sum_{j=1}^{2}\sum_{|\alpha|\le 2}\int_{\Omega\setminus\omega(3\epsilon_0)}\tau^{4-2|\alpha|}\left|\partial_x^\alpha \mathbf{z}_j(x)\right|^2 e^{2\tau\varphi_0(x)}dx$$

$$\le C\left(\tau\sum_{j=1}^{3}\|e^{\tau\varphi}\mathbf{y}_j\|^2_{H_x^{2,\tau}(Q_{\delta_0}(3\epsilon_0))}+\tau^4 e^{2\tau(d_0-\eta)}\right). \tag{3.7}$$

Therefore (3.6) completes the proof of the lemma. □

3.2. Estimation for the two Lamé coefficients. We will consider a first-order partial differential equations in λ_*, μ_*, and ρ_*. That is, by (3.1), (3.2), and $\mathbf{u},\mathbf{v}\in W^{8,\infty}(Q)$, we have

$$\widetilde{\rho}\partial_t^2\mathbf{u}_*(x,0)=\mathbf{f}(x,0),\quad \widetilde{\rho}\partial_t^3\mathbf{u}_*(x,0)=\partial_t\mathbf{f}(x,0). \tag{3.8}$$

For simplicity, for $x\in\overline{\Omega}$, we set

$$\mathbf{a}=\begin{pmatrix}-\frac{1}{\rho}\mathcal{L}_{\lambda,\mu}(x,\partial_x)\Phi\\ \\ -\frac{1}{\rho}\mathcal{L}_{\lambda,\mu}(x,\partial_x)\Psi\end{pmatrix},\quad \mathbf{b}_1=\begin{pmatrix}\operatorname{div}\Phi\\0\\0\\\operatorname{div}\Psi\\0\\0\end{pmatrix},$$

$$\mathbf{b}_2=\begin{pmatrix}0\\\operatorname{div}\Phi\\0\\0\\\operatorname{div}\Psi\\0\end{pmatrix},\quad \mathbf{b}_3=\begin{pmatrix}0\\0\\\operatorname{div}\Phi\\0\\0\\\operatorname{div}\Psi\end{pmatrix},$$

$$(\mathbf{d}_1,\mathbf{d}_2,\mathbf{d}_3)=\begin{pmatrix}\nabla\Phi+(\nabla\Phi)^T\\ \\ \nabla\Psi+(\nabla\Psi)^T\end{pmatrix},\quad \mathbf{G}=\begin{pmatrix}\widetilde{\rho}\mathbf{z}_1(x)-(\lambda_*+\mu_*)\nabla(\operatorname{div}\Phi)-\mu_*\Delta\Phi\\ \\ \widetilde{\rho}\mathbf{z}_2(x)-(\lambda_*+\mu_*)\nabla(\operatorname{div}\Psi)-\mu_*\Delta\Psi\end{pmatrix}.$$

Then we can rewrite (3.8) as

$$\mathbf{a}\rho_*+\sum_{k=1}^{3}\mathbf{b}_k\partial_k\lambda_*(x)=\mathbf{G}-\sum_{k=1}^{3}\mathbf{d}_k\partial_k\mu_*(x). \tag{3.9}$$

In view of (3.9), we show the following.

LEMMA 3.2. *Let assumptions* $(\mathcal{H}_1)$*–*$(\mathcal{H}_2)$ *hold true. Then there exists a constant* $C>0$ *such that the following estimate holds:*

$$\sum_{|\alpha|\le 2}\int_\Omega\left(\left|\partial_x^\alpha\mu_*(x)\right|^2+\left|\partial_x^\alpha\lambda_*(x)\right|^2\right)e^{2\tau\varphi_0(x)}dx\le C(\tau^2e^{2\tau(d_0-\eta)}+\mathcal{E}+e^{C\tau}\mathcal{D})$$

provided that τ *is large.*

Proof. By (3.9), for $j_1\in\{1,2,3,4,5,6\}$, we have

$$\{\mathbf{a}\}_{j_1}\rho_*+\sum_{k=1}^{3}\{\mathbf{b}_k\}_{j_1}\partial_k\lambda_*(x)=\{\mathbf{G}\}_{j_1}-\sum_{k=1}^{3}\{\mathbf{d}_k\}_{j_1}\partial_k\mu_*(x)\quad\text{on }\overline{\Omega}.$$

For any fixed $x \in \overline{\Omega}$, we regard this as a system of five linear equations with respect to four unknowns ρ_*, $\partial_1\lambda_*$, $\partial_2\lambda_*$, $\partial_3\lambda_*$, and so, for the existence of solutions, we need the consistency of the coefficients, that is,

$$\det_{j_1}\left(\mathbf{a}, \mathbf{b}_1, \mathbf{b}_2, \mathbf{b}_3, \mathbf{G} - \sum_{k=1}^{3} \mathbf{d}_k \partial_k \mu_*\right) = 0 \quad \text{on } \overline{\Omega}.$$

Hence

$$\sum_{k=1}^{3} \det_{j_1}(\mathbf{a}, \mathbf{b}_1, \mathbf{b}_2, \mathbf{b}_3, \mathbf{d}_k)\partial_k\mu_* = \det_{j_1}(\mathbf{a}, \mathbf{b}_1, \mathbf{b}_2, \mathbf{b}_3, \mathbf{G}) := f \quad \text{on } \overline{\Omega} \tag{3.10}$$

by the linearity of the determinant with respect to the column vectors. Here we note that

$$\sum_{|\alpha|\le 2} |\partial_x^\alpha f(x)| \le C\left(\sum_{|\alpha|\le 2}(|\partial_x^\alpha \mathbf{z}_1(x)| + |\partial_x^\alpha \mathbf{z}_2(x)|) + \sum_{|\alpha|\le 2}(|\partial_x^\alpha \lambda_*(x)| + |\partial_x^\alpha \mu_*(x)|)\right). \tag{3.11}$$

By (3.10) the function $\mu_* \in C_0^2(\Omega)$ solves the following first-order partial differential equation:

$$\sum_{k=1}^{3} a_k(x)\partial_k\mu_*(x) = f(x), \quad x \in \Omega,$$

where

$$a_k(x) = \det_{j_1}(\mathbf{a}, \mathbf{b}_1, \mathbf{b}_2, \mathbf{b}_3, \mathbf{d}_k).$$

In view of $(\mathcal{H}_1)$, we can apply Lemma 2.4 to $v = \mu_*$, and we obtain

$$\tau^2 \sum_{|\alpha|\le 2} \int_\Omega |\partial_x^\alpha \mu_*|^2 e^{2\tau\varphi_0(x)} dx \le C \sum_{|\alpha|\le 2} \int_{\Omega\setminus\omega(3\epsilon_0)} |\partial_x^\alpha f(x)|^2 e^{2\tau\varphi_0(x)} dx,$$

where we have used $\mu_* \equiv 0$ in $\omega \supset \omega(3\epsilon_0)$. Hence (3.11) and Lemma 3.1 yield

$$\begin{aligned}
&\tau^2 \sum_{|\alpha|\le 2} \int_\Omega |\partial_x^\alpha \mu_*(x)|^2 e^{2\tau\varphi_0(x)} dx \le C \sum_{j=1}^{2} \sum_{|\alpha|\le 2} \int_{\Omega\setminus\omega(3\epsilon_0)} |\partial_x^\alpha \mathbf{z}_j(x)|^2 e^{2\tau\varphi_0(x)} dx \\
&+C \sum_{|\alpha|\le 2} \int_\Omega \left(|\partial_x^\alpha \lambda_*(x)|^2 + |\partial_x^\alpha \mu_*(x)|^2\right) e^{2\tau\varphi_0(x)} dx \\
&\le C \sum_{|\alpha|\le 2} \int_\Omega \left(|\partial_x^\alpha \lambda_*(x)|^2 + |\partial_x^\alpha \mu_*(x)|^2\right) e^{2\tau\varphi_0(x)} dx + C(e^{C\tau}\mathcal{D} + \tau^4 e^{2\tau(d_0-\eta)} + \tau^2\mathcal{E})
\end{aligned}$$

for all large $\tau > 0$. Similarly, by assumption $(\mathcal{H}_2)$ we can argue for λ_* and obtain

$$\begin{aligned}
&\tau^2 \sum_{|\alpha|\le 2} \int_\Omega |\partial_x^\alpha \lambda_*(x)|^2 e^{2\tau\varphi_0(x)} dx \\
&\le C \sum_{|\alpha|\le 2} \int_\Omega \left(|\partial_x^\alpha \lambda_*(x)|^2 + |\partial_x^\alpha \mu_*(x)|^2\right) e^{2\tau\varphi_0(x)} dx + C(e^{C\tau}\mathcal{D} + \tau^4 e^{2\tau(d_0-\eta)} + \tau^2\mathcal{E}).
\end{aligned}$$

Hence by adding the two inequalities, we have

$$\begin{aligned}
&\tau^2 \sum_{|\alpha|\le 2} \int_\Omega \left(|\partial_x^\alpha \mu_*(x)|^2 + |\partial_x^\alpha \lambda_*(x)|^2 \right) e^{2\tau\varphi_0(x)} dx \\
&\le C \sum_{|\alpha|\le 2} \int_\Omega \left(|\partial_x^\alpha \mu_*(x)|^2 + |\partial_x^\alpha \lambda_*(x)|^2 \right) e^{2\tau\varphi_0(x)} dx \\
&\quad + C(\tau^4 e^{2\tau(d_0-\eta)} + \tau^2 \mathcal{E} + e^{C\tau}\mathcal{D})
\end{aligned}$$

for all large $\tau > 0$. By taking $\tau > 0$ large, we can absorb the first term on the right-hand side into the left-hand side, and the proof is complete. ∎

3.3. Estimation for the density.

LEMMA 3.3. *Let assumptions* $(\mathcal{H}_1)$–$(\mathcal{H}_2)$ *hold true. Then there exists a constant* $C > 0$ *such that*

$$\sum_{|\alpha|\le 1} \int_\Omega |\partial_x^\alpha \rho_*(x)|^2 e^{2\tau\varphi_0(x)} dx \le C(\tau^2 e^{2\tau(d_0-\eta)} + \mathcal{E} + e^{C\tau}\mathcal{D}),$$

provided that τ *is large.*

Proof. By (3.9), we have

$$\mathbf{a}\rho_*(x) = -\sum_{k=1}^3 \mathbf{b}_k \partial_k \lambda_*(x) + \mathbf{G} - \sum_{k=1}^3 \mathbf{d}_k \partial_k \mu_*(x), \quad x \in \Omega.$$

Moreover, by $(\mathcal{H}_1)$–$(\mathcal{H}_2)$, we see that $|\mathbf{a}(x)| > 0$ for $x \in \overline{\Omega}$, so that

$$|\rho_*(x)| \le C\,|\mathbf{G}(x)| + C \sum_{|\alpha|\le 1} \left(|\partial_x^\alpha \lambda_*(x)| + |\partial_x^\alpha \mu_*(x)| \right).$$

Similarly we have

$$|\partial_j \rho_*(x)| \le C \left(|\mathbf{G}(x)| + |\nabla \mathbf{G}(x)| + \sum_{|\alpha|\le 2} \left(|\partial_x^\alpha \lambda_*(x)| + |\partial_x^\alpha \mu_*(x)| \right) \right).$$

Hence

$$\begin{aligned}
\sum_{|\alpha|\le 1} \int_\Omega |\partial_x^\alpha \rho_*(x)|^2 e^{2\tau\varphi_0(x)} dx &\le C \sum_{|\alpha|\le 1} \int_{\Omega\setminus\omega(3\epsilon_0)} |\partial_x^\alpha \mathbf{G}(x)|^2 e^{2\tau\varphi_0(x)} dx \\
&\quad + C \sum_{|\alpha|\le 2} \int_\Omega \left(|\partial_x^\alpha \lambda_*(x)|^2 + |\partial_x^\alpha \mu_*(x)|^2 \right) e^{2\tau\varphi_0(x)} dx.
\end{aligned}$$

Furthermore we see that

$$\sum_{|\alpha|\le 1} |\partial_x^\alpha \mathbf{G}(x)|^2 \le C \sum_{|\alpha|\le 1} \left(|\partial_x^\alpha \mathbf{z}_1(x)|^2 + |\partial_x^\alpha \mathbf{z}_2(x)|^2 \right) + C \sum_{|\alpha|\le 1} \left(|\partial_x^\alpha \lambda_*(x)|^2 + |\partial_x^\alpha \mu_*(x)|^2 \right).$$

Therefore

$$\begin{aligned}
\sum_{|\alpha|\le 1} \int_\Omega |\partial_x^\alpha \rho_*(x)|^2 e^{2\tau\varphi_0(x)} dx &\le C \sum_{|\alpha|\le 1} \int_{\Omega\setminus\omega(3\epsilon_0)} \left(|\partial_x^\alpha \mathbf{z}_1(x)|^2 + |\partial_x^\alpha \mathbf{z}_1(x)|^2 \right) e^{2\tau\varphi_0(x)} dx \\
&\quad + C \sum_{|\alpha|\le 2} \int_\Omega \left(|\partial_x^\alpha \lambda_*(x)|^2 + |\partial_x^\alpha \mu_*(x)|^2 \right) e^{2\tau\varphi_0(x)} dx.
\end{aligned}$$

By Lemmas 3.1 and 3.2, we obtain the conclusion of the lemma. ∎

3.4. Completion of the proof of the main result. In terms of Lemmas 3.2 and 3.3, we will now complete the proof of Theorem 1.0.

Since $\varphi(x,0) > \varphi(x,t)$ for $t \neq 0$, by the Lebesgue theorem, we have

$$\sum_{|\alpha|\leq 1}\int_Q |\partial_x^\alpha \rho_*(x)|^2 e^{2\tau\varphi} dxdt = \sum_{|\alpha|\leq 1}\int_\Omega |\partial_x^\alpha \rho_*(x)|^2 e^{2\tau\varphi(x,0)} \left(\int_{-T}^T e^{2\tau(\varphi(x,t)-\varphi(x,0))}dt\right) dx$$
$$= o(1)\sum_{|\alpha|\leq 1}\int_\Omega |\partial_x^\alpha \rho_*(x)| e^{2\tau\varphi(x,0)} dx$$

as $\tau \to \infty$. Similarly we obtain

$$\sum_{|\alpha|\leq 2}\int_Q \left(|\partial_x^\alpha \lambda_*(x)|^2 + |\partial_x^\alpha \mu_*(x)|^2\right) e^{2\tau\varphi} dxdt$$
$$= o(1)\sum_{|\alpha|\leq 2}\int_\Omega \left(|\partial_x^\alpha \lambda_*(x)|^2 + |\partial_x^\alpha \mu_*(x)|^2\right) e^{2\tau\varphi(x,0)} dx,$$

as $\tau \to \infty$. We set

$$\mathcal{E}_0 = \sum_{|\alpha|\leq 1} \|e^{\tau\varphi_0}\partial_x^\alpha \rho_*\|^2_{L^2(\Omega)} + \sum_{|\alpha|\leq 2} (\|e^{\tau\varphi_0}\partial_x^\alpha \lambda_*\|^2_{L^2(\Omega)} + \|e^{\tau\varphi_0}\partial_x^\alpha \mu_*\|^2_{L^2(\Omega)}).$$

Therefore, by Lemmas 3.2 and 3.3, we obtain

$$\mathcal{E}_0 \leq C(\tau^2 e^{2\tau(d_0-\eta)} + e^{C\tau}\mathcal{D}) + o(1)\mathcal{E}_0$$

for all large $\tau > 0$.

By (2.6) and $\sup_{\tau>0}(\tau^2 e^{-\tau\eta}) < \infty$, we have

$$\sum_{|\alpha|\leq 1}\int_\Omega |\partial_x^\alpha \rho_*(x)|^2 dx + \sum_{|\alpha|\leq 2}\int_\Omega \left(|\partial_x^\alpha \lambda_*(x)|^2 + |\partial_x^\alpha \mu_*(x)|^2\right) dx \leq Ce^{-\tau\eta} + Ce^{C\tau}\mathcal{D} \tag{3.12}$$

for all large $\tau > \tau_0$. We replace C by $Ce^{C\tau_0}$, and (3.12) holds for any $\tau > 0$. We may assume that $\mathcal{D} < 1$.

Now we choose $\tau > 0$ such that

$$e^{C\tau}\mathcal{D} = e^{-\tau\eta},$$

that is,

$$\tau = -\frac{1}{\eta + C}\log \mathcal{D}.$$

Therefore (3.12) implies

$$\|\rho_*\|^2_{H^1(\Omega)} + \|\lambda_*\|^2_{H^2(\Omega)} + \|\mu_*\|^2_{H^2(\Omega)} \leq 2C\mathcal{D}^{\frac{\eta}{\eta+C}}$$

and

$$\|\rho_*\|^2_{H^1(\Omega)} + \|\lambda_*\|^2_{H^2(\Omega)} + \|\mu_*\|^2_{H^2(\Omega)} \leq C\|\mathbf{u}_*\|^{2\sigma}_{H^6(\omega_T(\epsilon_0,3\epsilon_0))},$$

with $\sigma = \frac{\eta}{\eta+C} \in (0,1)$. Then, noting that $\|\mathbf{u}_*\|_{W^{8,\infty}(Q)} \le M_1$ and the interpolation inequality

$$\|\mathbf{u}_*\|_{H^6(\omega_T(\epsilon_0,3\epsilon_0))} \le C\|\mathbf{u}_*\|^{\frac{1}{3}}_{H^2(\omega_T(\epsilon_0,3\epsilon_0))}\|\mathbf{u}_*\|^{\frac{2}{3}}_{H^8(\omega_T(\epsilon_0,3\epsilon_0))},$$

we apply Lemma 2.5 to $\mathbf{v} = \mathbf{u}_*$, so that

$$\|\rho_*\|^2_{H^1(\Omega)} + \|\lambda_*\|^2_{H^2(\Omega)} + \|\mu_*\|^2_{H^2(\Omega)} \le C\left[\log\left(2 + \frac{C}{\epsilon(\Sigma_1)}\right)\right]^{-2\kappa},$$

where $\kappa \in (0,1)$. Thus the proof of Theorem 1.0 is complete.

4. Proof of Lemma 2.5. We will now prove Lemma 2.5. This will be done in terms of the FBI transformation. For $(\lambda,\mu,\rho) \in \Lambda$, let us recall that $\mathbf{v}$ is a given solution to

$$\rho(x)\partial_t^2\mathbf{v} - \mathcal{L}_{\lambda,\mu}(x,\partial_x)\mathbf{v} = R(x,t) \quad \text{in } Q \equiv \Omega\times(-T,T), \tag{4.1}$$

with the Dirichlet boundary condition

$$\mathbf{v}(x,t) = 0 \quad \text{on } \Sigma \equiv \Gamma\times(-T,T). \tag{4.2}$$

Here and henceforth we assume that

$$R(x,t) = 0, \quad (x,t) \in \omega\times(-T,T). \tag{4.3}$$

4.1. Preliminary and elliptic estimation. Since we can choose $T > 0$ sufficiently large, we may assume that $T > 2$. Denote for $r > 0$

$$\Omega_r = \Omega\times(-r,r); \quad \omega_r(\epsilon_0,3\epsilon_0) = \omega(\epsilon_0,3\epsilon_0)\times(-r,r);$$
$$\Sigma_r = \Gamma\times(-r,r), \quad \Sigma_{1,r} = \Gamma_1\times(-r,r).$$

We introduce $\theta \in C_0^\infty(\mathbb{R})$ to be a cutoff function defined by

$$\theta(t) = \begin{cases} 1, & |t| \le (T-2), \\ 0, & |t| \ge (T-1). \end{cases}$$

Let $\gamma > 0$. We introduce the partial FBI transformation $\mathcal{F}_\gamma$. It is defined for $\mathbf{u} \in \{\mathcal{S}(\mathbb{R}^4)\}^3$, the space of rapidly decreasing functions, by

$$\mathbf{u}_{\gamma,t}(x,s) = \mathcal{F}_\gamma\mathbf{u}(x,z) = \sqrt{\frac{\gamma}{2\pi}}\int_{\mathbb{R}} e^{-\frac{\gamma}{2}(z-y)^2}\theta(y)\mathbf{u}(x,y)dy, \quad z = t+is.$$

Then

$$|D_x^\alpha\mathcal{F}_\gamma\mathbf{u}(x,z)| \le C\sqrt{\frac{\gamma}{2\pi}}e^{\gamma s^2}e^{-\frac{\gamma}{2}(\mathrm{dist}(t,supp(\theta\mathbf{u})))^2}\sup_{x\in\mathbb{R}^3}\|D_x^\alpha\mathbf{u}(x,.)\|^2_{L^2(\mathbb{R})}$$

for any $\mathbf{u} \in C_0^\infty(\mathbb{R}^3\times\mathbb{R})$ (see [45]).

Henceforth C_j, C denote generic constants which are independent of λ,γ,r,τ. Next we assume that T is sufficiently large, $s \in [-3r,3r]$, and $t \in \left[-\frac{T}{2},\frac{T}{2}\right]$. In particular we assume that $\frac{T}{2} > r$. We introduce a cutoff function χ_3 satisfying $0 \le \chi_3 \le 1$, $\chi_3 \in C_0^\infty(\mathbb{R}^3)$, and

$$\chi_3(x) = \begin{cases} 1, & \text{if } x \in \omega(6\epsilon_0), \\ 0, & \text{if } x \in \Omega\setminus\omega(7\epsilon_0). \end{cases}$$

Let $\mathbf{v}(x,t)$ satisfy (4.1). By setting $\mathbf{u}(x,t) = \chi_3(x)\mathbf{v}(x,t)$ and noting that $R(x,t)$ is zero in $\omega(7\epsilon_0)$, we obtain

$$\rho(x)\partial_t^2\mathbf{u} - \mathcal{L}_{\lambda,\mu}(x,\partial_x)\mathbf{u} = -\left[\mathcal{L}_{\lambda,\mu}(x,\partial_x),\chi_3\right]\mathbf{v} \quad \text{in } Q \tag{4.4}$$

and

$$\mathbf{u}(x,t) = 0 \quad \text{on } \Sigma. \tag{4.5}$$

In connection with the operator $\rho(x)\partial_t^2 - \mathcal{L}_{\lambda,\mu}(x,\partial_x)$, we define an elliptic operator by

$$Q_{\rho,\lambda,\mu} = \rho(x)\partial_s^2 + \mathcal{L}_{\lambda,\mu}(x,\partial_x).$$

Noting that

$$\partial_s \int_{\mathbb{R}} e^{-\frac{\gamma}{2}(is+t-y)^2}\theta(y)\mathbf{u}(x,y)dy = i\int_{\mathbb{R}} e^{-\frac{\gamma}{2}(z-y)^2}\partial_y\left[\theta(y)\mathbf{u}(x,y)\right]dy,$$

by integration by parts, we have

$$\begin{aligned} &Q_{\rho,\lambda,\mu}\mathbf{u}_{\gamma,t}(x,s) = F_{\gamma,t}(x,s) + G_{\gamma,t}(x,s) := \mathbf{f}(x,s), (x,s) \in \ \Omega_{3r}, \\ &\mathbf{u}_{\gamma,t}(x,s) = 0, \qquad\qquad (x,s) \in \ \Sigma_{3r}, \end{aligned} \tag{4.6}$$

where

$$F_{\gamma,t}(x,s) = -\sqrt{\frac{\gamma}{2\pi}}\int_{\mathbb{R}} e^{-\frac{\gamma}{2}(z-y)^2}\left(2\theta'(y)\partial_y\mathbf{u}(x,y) + \theta''(y)\mathbf{u}(x,y)\right)dy$$

and

$$G_{\gamma,t}(x,s) = \sqrt{\frac{\gamma}{2\pi}}\int_{\mathbb{R}} e^{-\frac{\gamma}{2}(z-t)^2}\theta(y)\left[\mathcal{L}_{\lambda,\mu}(x,\partial_x),\chi\right]\mathbf{v}(x,y)dy.$$

Since $\theta' = \frac{d\theta}{dy}$ and $\theta'' = \frac{d^2\theta}{dy^2}$ are supported in $T-2 \le |y| \le T-1$, there exists $\eta > 0$, independent of T, such that

$$\|F_{\gamma,t}\|_{H^1(\Omega_{3r})} \le Ce^{-\eta\gamma T}\|\mathbf{u}\|_{H^2(Q)} \quad \forall t \in \left[-\frac{T}{2},\frac{T}{2}\right]. \tag{4.7}$$

Moreover there exists $C_1 > 0$, independent of T, such that

$$\|\mathbf{u}_{\gamma,t}\|_{H^2(\Omega_{3r})} \le Ce^{C_1\gamma}\|\mathbf{u}\|_{H^2(Q)} \quad \forall t \in \left[-\frac{T}{2},\frac{T}{2}\right]. \tag{4.8}$$

By the definition, we easily obtain

$$G_{\gamma,t}(x,s) = 0 \quad \forall x \in \omega(6\epsilon_0). \tag{4.9}$$

Let K be a compact set in $\overline{\Omega}\times(-3r,3r)$ and let $\psi(x,s)$ be a C^∞ function satisfying $\nabla_{x,s}\psi(x,s) \neq 0$ on K. Let

$$\varphi(x,s) = e^{-\beta\psi(x,s)},$$

where $\beta > 0$ is sufficiently large.

Henceforth we set

$$\|u\|^2_{H^j_\tau(\Omega_{3r})} = \sum_{|\alpha|\le j} \tau^{2j-2|\alpha|} \|\partial^\alpha u\|^2_{L^2(\Omega_{3r})}$$

and

$$\|u\|^2_{H^j_\tau(\Sigma_{3r})} = \sum_{|\alpha|\le j} \tau^{2j-2|\alpha|} \|\partial^\alpha u\|^2_{L^2(\Sigma_{3r})}.$$

We note that the right-hand sides include not only tangential derivatives but also normal derivatives on Σ_{3r}.

Consider a scalar second-order elliptic operator

$$P(x,D) = \rho(x)\partial_s^2 + \sum_{j,k=1}^n a_{jk}(x)\partial_j\partial_k + \sum_{j=1}^n b_j(x)\partial_j + c.$$

If we assume that P has C^2 coefficients, then the following Carleman estimate holds true:

$$\begin{aligned} \frac{C}{\tau}\|e^{\tau\varphi}u\|^2_{H^2_\tau(\Omega_{3r})} &\le \|e^{\tau\varphi}Pu\|^2_{L^2(\Omega_{3r})} + \|e^{\tau\varphi}u\|^2_{H^2_\tau(\Sigma_{3r})}, \\ C\tau\|e^{\tau\varphi}u\|^2_{H^1_\tau(\Omega_{3r})} &\le \|e^{\tau\varphi}Pu\|^2_{L^2(\Omega_{3r})} + \tau\|e^{\tau\varphi}u\|^2_{H^1_\tau(\Sigma_{3r})}, \end{aligned} \tag{4.10}$$

whenever $u \in C_0^\infty(K)$ and $\tau > \tau_0$ (see, for example, [37] and [19], respectively, for the first and second Carleman estimates).

By (4.10) we can derive the following Carleman estimate for the elliptic system (4.6).

LEMMA 4.1. *There exist $\tau_0 > 0$ and $C > 0$ such that*

$$\frac{C}{\tau}\|e^{\tau\varphi}\mathbf{u}\|^2_{H^2_\tau(\Omega_{3r})} \le \|e^{\tau\varphi}Q_{\rho,\lambda,\mu}\mathbf{u}\|^2_{H^1(\Omega_{3r})} + \|e^{\tau\varphi}\mathbf{u}\|^2_{H^2_\tau(\Sigma_{3r})},$$

whenever $\mathbf{u} \in C_0^\infty(K)$ and all $\tau > \tau_0$.

Proof. In order to prove Lemma 4.1 we will extend system (4.6) for three unknown functions u_1, u_2, u_3 to a new one for four unknown functions by introducing $v = \mathrm{div}\mathbf{u}$. We refer to Eller, Isakov, Nakamura, and Tataru [12] and Ikehata, Nakamura, and Yamamoto [15]. If $\mathbf{u}$ solves

$$Q_{\rho,\lambda,\mu}\mathbf{u} = \rho(x)\partial_s^2\mathbf{u} + \mathcal{L}_{\lambda,\mu}(x,\partial_x)\mathbf{u} = \mathbf{f},$$

then

$$\rho(x)\partial_s^2 v + (\lambda(x) + 2\mu(x))\Delta v + A_{1,1}(v,\mathbf{u}) = \mathrm{div}\mathbf{f}$$

and

$$\rho(x)\partial_s^2\mathbf{u} + \mu(x)\Delta\mathbf{u} + A_{1,2}(v,\mathbf{u}) = \mathbf{f},$$

where $A_{1,1}$, $A_{1,2}$ are (matrix) linear partial differential operators with measurable and bounded coefficients. By using the scalar Carleman estimate (4.10), we obtain

$$\frac{C}{\tau}\|e^{\tau\varphi}\mathbf{u}\|^2_{H^2_\tau(\Omega_{3r})} \le \|e^{\tau\varphi}\mathbf{f}\|^2_{L^2(\Omega_{3r})} + \|e^{\tau\varphi}\mathbf{u}\|^2_{H^2_\tau(\Sigma_{3r})} + \|e^{\tau\varphi}v\|^2_{H^1_\tau(\Omega_{3r})}$$

and

$$C\tau \left\|e^{\tau\varphi}v\right\|^2_{H^1_\tau(\Omega_{3r})} \le \left\|e^{\tau\varphi}\mathrm{div}\mathbf{f}\right\|^2_{L^2(\Omega_{3r})} + \tau \left\|e^{\tau\varphi}v\right\|^2_{H^1_\tau(\Sigma_{3r})} + \left\|e^{\tau\varphi}\mathbf{u}\right\|^2_{H^1_\tau(\Omega_{3r})}.$$

Therefore, by choosing τ large, we obtain

$$\begin{aligned}\frac{C}{\tau}\left\|e^{\tau\varphi}\mathbf{u}\right\|^2_{H^2_\tau(\Omega_{3r})} \le \left\|e^{\tau\varphi}\mathbf{f}\right\|^2_{L^2(\Omega_{3r})} + \frac{1}{\tau}\left\|e^{\tau\varphi}\nabla\mathbf{f}\right\|^2_{L^2(\Omega_{3r})} \\ + \left\|e^{\tau\varphi}\mathbf{u}\right\|^2_{H^2_\tau(\Sigma_{3r})} + \left\|e^{\tau\varphi}v\right\|^2_{H^1_\tau(\Sigma_{3r})}.\end{aligned}$$

This completes the proof of Lemma 4.1. □

Now we can argue similarly to [6], with suitable modifications. We introduce a cutoff function χ_4 satisfying $0 \le \chi_4 \le 1$, $\chi_4 \in C_0^\infty(\mathbb{R})$, and

$$\chi_4(\eta) = \begin{cases} 0, & \text{if } \eta \le \frac{1}{2},\ \eta \ge 8, \\ 1, & \text{if } \eta \in \left[\frac{3}{4}, 7\right]. \end{cases}$$

Now we proceed to the estimation near Γ_1.

4.2. Estimation near the boundary part Γ_1. We shall estimate $\mathbf{u}_{\gamma,t}$ in a ball $B_1 = B(x^{(1)}, r) = \left\{x \in \mathbb{R}^3;\ |x - x^{(0)}| \le r\right\}$ over a small interval $(-r, r)$ by the velocity trace (in the normal direction) in the given part $\Sigma_{1,3r} = \Gamma_1 \times (-3r, 3r) \subset \Sigma_{3r}$.

LEMMA 4.2. *Let $\mathbf{u}_{\gamma,t}$ be a solution to* (4.6). *Then there exist $\widetilde{B}_1 \equiv B_1 \times (-r, r) \subset \Omega_r$ and $\nu_0 \in]0, 1[$ such that*

$$\left\|\mathbf{u}_{\gamma,t}\right\|_{H^2(\widetilde{B}_1)} \le C\left(\left\|F_{\gamma,t}\right\|_{H^1(\Omega_{3r})} + \left\|\mathbf{u}_{\gamma,t}\right\|_{H^2(\Sigma_{1,3r})}\right)^{\nu_0}\left(\left\|\mathbf{u}_{\gamma,t}\right\|_{H^2(\Omega_{3r})}\right)^{1-\nu_0} \tag{4.11}$$

for some positive constant C.

Proof. Let us choose $\delta > 0$ and $x^{(0)} \in \mathbb{R}^3 \backslash \overline{\Omega}$ such that

$$\delta < \frac{\epsilon_0}{4}, \quad \overline{B(x^{(0)}, \delta)} \cap \overline{\Omega} = \emptyset, \quad B(x^{(0)}, 2\delta) \cap \Omega \ne \emptyset, \quad B(x^{(0)}, 4\delta) \cap \Gamma \subset \Gamma_1. \tag{4.12}$$

That is, $x^{(0)}$ is an outer point of $\overline{\Omega}$ and is near Γ_1. We define the functions $\psi_0(x, s)$ and $\varphi_0(x, s)$ by

$$\psi_0(x, s) = \left|x - x^{(0)}\right|^2 + s^2, \quad \varphi_0(x, s) = e^{-\frac{\widetilde{\beta}}{\delta^2}\psi_0(x,s)}.$$

Here we choose $\widetilde{\beta} > 0$ sufficiently large. Denote

$$\mathbf{w}_{\gamma,t}(x, s) = \chi_4\left(\frac{\psi_0}{\delta^2}\right)\mathbf{u}_{\gamma,t}(x, s).$$

By applying Lemma 4.1, we obtain

$$\frac{C}{\tau}\left\|e^{\tau\varphi_0}\mathbf{w}_{\gamma,t}\right\|^2_{H^2_\tau(\Omega_r)} \le \left\|e^{\tau\varphi_0}Q_{\rho,\lambda,\mu}\mathbf{w}_{\gamma,t}\right\|^2_{H^1(\Omega_{3r})} + \left\|e^{\tau\varphi_0}\chi_4\left(\frac{\psi_0}{\delta^2}\right)\mathbf{u}_{\gamma,t}\right\|^2_{H^2_\tau(\Sigma_{3r})}$$

for $\tau > \tau_0$. Therefore by (4.9), we have

$$\begin{aligned} Q_{\rho,\lambda,\mu}\mathbf{w}_{\gamma,t}(x,s) &= \chi_4\left(\frac{\psi_0}{\delta^2}\right) Q_{\rho,\lambda,\mu}\mathbf{u}_{\gamma,t}(x,s) + \left[Q_{\rho,\lambda,\mu}, \chi_4\left(\frac{\psi_0}{\delta^2}\right)\right]\mathbf{u}_{\gamma,t}(x,s) \\ &= \chi_4\left(\frac{\psi_0}{\delta^2}\right)(F_{\gamma,t}(x,s) + G_{\gamma,t}(x,s)) + \left[Q_{\rho,\lambda,\mu}, \chi_4\left(\frac{\psi_0}{\delta^2}\right)\right]\mathbf{u}_{\gamma,t}(x,s) \\ &= \chi_4\left(\frac{\psi_0}{\delta^2}\right) F_{\gamma,t}(x,s) + \left[Q_{\rho,\lambda,\mu}, \chi_4\left(\frac{\psi_0}{\delta^2}\right)\right]\mathbf{u}_{\gamma,t}(x,s). \end{aligned}$$

Since $[Q_{\rho,\lambda,\mu}, \chi_4(\frac{\psi_0}{\delta^2})]$ is supported in

$$\left|x - x^{(0)}\right|^2 + s^2 \le \frac{3}{4}\delta^2, \quad 7\delta^2 \le \left|x - x^{(0)}\right|^2 + s^2 \le 8\delta^2,$$

by taking (4.12) into account, we see that $\left|x - x^{(0)}\right| \ge \delta$ for all $x \in \overline{\Omega}$ and $\Omega \cap \left\{x;\, \left|x - x^{(0)}\right| \le \frac{3}{4}\delta^2\right\} \ne \emptyset$, so that we obtain

$$\begin{aligned} \frac{C}{\tau}e^{2\tau e^{-4\tilde{\beta}}}\left\|\mathbf{u}_{\tau,t}\right\|^2_{H^2_\tau((\delta^2\le\psi_0\le 4\delta^2)\cap\Omega)} \le{}& \tau^2 e^{2\tau e^{-7\tilde{\beta}}}\left\|\mathbf{u}_{\gamma,t}\right\|^2_{H^2(\psi_0\le 8\delta^2)} \\ &+\tau^2 e^{2\tau e^{-\tilde{\beta}/2}}\left\|F_{\gamma,t}\right\|^2_{H^1(\Omega_{3r})} \\ &+e^{2\tau e^{-\tilde{\beta}/2}}\|\mathbf{u}_{\gamma,t}\|^2_{H^2(\Sigma_{1,3r})}. \end{aligned}$$

We can select $r > 0$ and $x^{(1)} \in \Omega$ such that

$$\operatorname{dist}(x^{(1)}, \Gamma) \ge 4r, \quad \widetilde{B}_1 = B(x^{(1)}, r) \times [-r, r] \subset \left\{\delta^2 \le \psi_0(x,s) \le 4\delta^2\right\}.$$

Then for $\tau > \tau_0$ we have

$$\|\mathbf{u}_{\gamma,t}\|^2_{H^2(\widetilde{B}_1)} \le Ce^{C_1\tau}\left[\|F_{\gamma,t}\|^2_{H^1(\Omega_{3r})} + \|\mathbf{u}_{\gamma,t}\|^2_{H^2(\Sigma_{1,3r})}\right] + e^{-C_2\tau}\left\|\mathbf{u}_{\gamma,t}\right\|^2_{H^2(\Omega_{3r})}.$$

The inequality holds for any $\tau > 0$ by replacing $C > 0$ by $Ce^{C_1\tau_0}$. Now minimize the right-hand side with respect to τ, and with $\nu_0 = \frac{C_2}{C_1+C_2}$ we have

$$\|\mathbf{u}_{\gamma,t}\|^2_{H^2(\widetilde{B}_1)} \le C\left(\|F_{\gamma,t}\|^2_{H^1(\Omega_{3r})} + \|\mathbf{u}_{\gamma,t}\|^2_{H^2(\Sigma_{1,3r})}\right)^{\nu_0}\left(\left\|\mathbf{u}_{\gamma,t}\right\|^2_{H^2(\Omega_{3r})}\right)^{1-\nu_0}.$$

This completes the proof of the lemma. ∎

4.3. Estimation near the boundary. In this subsection we extend the estimation from $\widetilde{B}_1$ to $\omega_r(\epsilon_0, 4\epsilon_0)$. In order to accomplish this, we use the techniques developed in [44]. This will be done by continuing estimates (4.11). Let $B(x^{(j)}, r)$, $2 \le j \le N$, be a covering of $\omega(\epsilon_0, 4\epsilon_0)$. We can assume that $x^{(j)}$ satisfies $\operatorname{dist}(x^{(j)}, \Gamma) \ge 4r$. In what follows, we assume without any restriction in generality that

$$B(x^{(j+1)}, r) \subset B(x^{(j)}, 2r),$$

and we set

$$\widetilde{B}_j = B(x^{(j)}, r) \times (-r, r); \quad 2 \le j \le N.$$

LEMMA 4.3. *Let $\mathbf{u}_{\gamma,t}$ be a solution to* (4.6). *Then there exist a constant $\nu \in (0,1)$ and $C > 0$ such that*

$$\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_{k+1})} \leq C \left(\|F_{\gamma,t}\|_{H^1(\Omega_{3r})} + \|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_k)} \right)^{\nu} \left(\|\mathbf{u}_{\gamma,t}\|_{H^2(\Omega_{3r})} \right)^{1-\nu}, \quad k \geq 1. \tag{4.13}$$

Proof. We define the functions $\psi_k(x,s)$ and $\varphi_k(x,s)$ by

$$\psi_k(x,s) = \left| x - x^{(k)} \right|^2 + s^2, \quad \varphi_k(x,s) = e^{-\frac{\widetilde{\beta}}{r^2}\psi_k(x,s)}.$$

Moreover we set

$$\mathbf{w}_{\gamma,t}(x,s) = \chi_4\left(\frac{\psi_k}{r^2}\right)\mathbf{u}_{\gamma,t}(x,s).$$

By applying Lemma 4.1 in an interior domain, we obtain

$$\frac{C}{\tau}\left\|e^{\tau\varphi_k}\mathbf{w}_{\gamma,t}\right\|^2_{H^2_\tau(\Omega_r)} \leq \left\|e^{\tau\varphi_k}Q_{\rho,\lambda,\mu}\mathbf{w}_{\gamma,t}\right\|^2_{H^1(\Omega_{3r})}. \tag{4.14}$$

In the same way as the proof of Lemma 4.2, we have

$$Q_{\rho,\lambda,\mu}\mathbf{w}_{\lambda,t}(x,s) = \chi_4\left(\frac{\psi_k}{r^2}\right)F_{\lambda,t}(x,s) + \left[Q_{\rho,\lambda,\mu}, \chi_4\left(\frac{\psi_k}{r^2}\right)\right]\mathbf{u}_{\gamma,t}(x,s).$$

Since $[Q_{\rho,\lambda,\mu}, \chi_4(\frac{\psi_k}{r^2})]$ is supported in

$$\frac{r^2}{2} \leq \left|x - x^{(0)}\right|^2 + s^2 \leq r^2, \quad 7r^2 \leq \left|x - x^{(0)}\right|^2 + s^2 \leq 8r^2,$$

it follows from (4.14) that

$$\begin{aligned}\frac{C}{\tau}e^{2\tau e^{-5\widetilde{\beta}}}\left\|\mathbf{u}_{\gamma,t}\right\|^2_{H^2_\tau(r^2\leq\psi_k\leq 5r^2)} &\leq \tau^2 e^{2\tau e^{-\widetilde{\beta}/2}}\left\|\mathbf{u}_{\gamma,t}\right\|^2_{H^2(\psi_k\leq r^2)} + \tau^2 e^{2\tau e^{-7\widetilde{\beta}}}\left\|\mathbf{u}_{\gamma,t}\right\|^2_{H^2(\Omega_{3r})} \\ &\quad + \tau^2 e^{2\tau e^{-\widetilde{\beta}/2}}\left\|F_{\gamma,t}\right\|^2_{H^1(\Omega_{3r})},\end{aligned}$$

and hence for τ large we obtain

$$\begin{aligned}Ce^{2\tau e^{-5\widetilde{\beta}}}\left\|\mathbf{u}_{\gamma,t}\right\|^2_{H^2_\tau(\psi_k\leq 5r^2)} &\leq e^{2\tau e^{-\widetilde{\beta}/3}}\left\|\mathbf{u}_{\gamma,t}\right\|^2_{H^2(\psi_k\leq r^2)} + e^{2\tau e^{-6\widetilde{\beta}}}\left\|\mathbf{u}_{\gamma,t}\right\|^2_{H^2(\Omega_{3r})} \\ &\quad + e^{2\tau e^{-\widetilde{\beta}/3}}\left\|F_{\gamma,t}\right\|^2_{H^1(\Omega_{3r})}.\end{aligned}$$

Thus we obtain

$$\left\|\mathbf{u}_{\gamma,t}\right\|^2_{H^2(\psi_k\leq 5r^2)} \leq e^{C_1\tau}\left[\left\|\mathbf{u}_{\gamma,t}\right\|^2_{H^2(\psi_k\leq r^2)} + \left\|F_{\gamma,t}\right\|^2_{H^1(\Omega_{3r})}\right] + e^{-C_2\tau}\left\|\mathbf{u}_{\gamma,t}\right\|^2_{H^2(\Omega_{3r})}.$$

Now minimize the right-hand side with respect to τ, and with $\nu = \frac{C_2}{C_1+C_2}$ we obtain

$$\left\|\mathbf{u}_{\gamma,t}\right\|^2_{H^2(\psi_k\leq 5r^2)} \leq C\left(\left\|F_{\gamma,t}\right\|^2_{H^1(\Omega_{3r})} + \left\|\mathbf{u}_{\gamma,t}\right\|^2_{H^2(\psi_k\leq r^2)}\right)^{\nu}\left(\left\|\mathbf{u}_{\gamma,t}\right\|^2_{H^2(\Omega_{3r})}\right)^{1-\nu}.$$

Since

$$\widetilde{B}_{k+1} \subset \left\{\psi_k(s,x) \leq 5r^2\right\}, \quad \left\{\psi_k(x,s) \leq r^2\right\} \subset \widetilde{B}_k,$$

we obtain (4.13). This completes the proof of the lemma. □

LEMMA 4.4. *Let $\mathbf{u}_{\gamma,t}$ be a solution to* (4.6). *Then there exist a constant $C>0$ and $\mu=\nu^n$ such that*

$$\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_n)} \le C\left(\|F_{\gamma,t}\|_{H^1(\Omega_{3r})}+\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_1)}\right)^{\mu}\left(\|\mathbf{u}_{\gamma,t}\|_{H^2(\Omega_{3r})}\right)^{1-\mu}, \quad n\ge 1.$$

Here $\nu\in(0,1)$ is the constant given in Lemma 4.3.

Proof. Put

$$a_k=\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_k)}, \quad A=\|F_{\gamma,t}\|_{H^1(\Omega_{3r})}, \quad B=\|\mathbf{u}_{\gamma,t}\|_{H^2(\Omega_{3r})}.$$

By (4.13) we have

$$a_{k+1}\le (C^{\frac{1}{1-\nu}}B)^{1-\nu}(a_k+A)^{\nu}.$$

By applying Lemma 4 in [38] (see also [37]), we obtain for all $\mu\in\,]0,\nu^n]$

$$a_n\le 2^{\frac{1}{1-\nu}}CB^{1-\mu}(a_1+A)^{\mu}.$$

This completes the proof of the lemma. □

LEMMA 4.5. *Let $\mathbf{u}_{\lambda,t}$ be a solution to* (4.6). *Then there exist $C>0$ and $C_1>0$ such that for all n there exist $C_n>0$ and $T_n>0$ such that*

$$C\|\mathbf{u}_{\gamma,t}\|^2_{H^2(\widetilde{B}_n)} \le e^{-C_1\gamma}\|\mathbf{u}\|^2_{H^2(Q)}+e^{C_n\gamma}\|\mathbf{u}\|^2_{H^2(\Sigma_1)} \tag{4.15}$$

for all $t\in\left[-\frac{T}{2},\frac{T}{2}\right]$, where $T>T_n$.

Proof. By Lemma 4.4 and the Young inequality, we easily obtain

$$\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_n)} \le \epsilon^p\|\mathbf{u}_{\gamma,t}\|_{H^2(\Omega_{3r})}+\epsilon^{-p'}\left[\|F_{\gamma,t}\|_{H^1(\Omega_{3r})}+\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_1)}\right]$$

for all $\epsilon>0$. Here

$$p=\frac{1}{1-\mu}, \quad p'=\frac{1}{\mu}, \quad \text{and} \quad \mu=\nu^n.$$

By using estimates (4.7) and (4.8), we have for all $t\in\left[-\frac{T}{2},\frac{T}{2}\right]$

$$\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_n)} \le \epsilon^p e^{C_1\gamma}\|\mathbf{u}\|_{H^2(Q)}+\epsilon^{-p'}\left[e^{-\eta T\gamma}\|\mathbf{u}\|_{H^2(Q)}+\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_1)}\right].$$

By selecting

$$\epsilon=e^{-\frac{2C_1}{p}\gamma},$$

we obtain

$$\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_n)} \le e^{-C_1\gamma}\|\mathbf{u}\|_{H^2(Q)}+e^{-(\eta T-\frac{2C_1p'}{p})\gamma}\|\mathbf{u}\|_{H^2(Q)}+e^{\frac{2C_1p'}{p}\gamma}\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_1)}$$

for all $t\in\left[-\frac{T}{2},\frac{T}{2}\right]$ and $\gamma>0$. Take T sufficiently large such that

$$\eta T-\frac{2C_1p'}{p}>C_1,$$

and we obtain

$$\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_n)} \leq e^{-C_1\gamma}\|\mathbf{u}\|_{H^2(Q)} + e^{\kappa_1\gamma}\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_1)}, \tag{4.16}$$

where we set

$$\kappa_1 = \frac{2C_1p'}{p}.$$

Similarly we obtain from Lemma 4.2 and the Young inequality

$$\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_1)} \leq \epsilon^{p_0}e^{C_1\gamma}\|\mathbf{u}\|_{H^2(Q)} + \epsilon^{-p_0'}\left[e^{-\eta T\gamma}\|\mathbf{u}\|_{H^2(Q)} + \|\mathbf{u}_{\gamma,t}\|_{H^2(\Sigma_{1,3r})}\right],$$

where

$$p_0 = \frac{1}{1-\nu_0}, \quad p_0' = \frac{1}{\nu_0}.$$

Selecting $\epsilon = e^{-(\frac{2C_1+\kappa_1}{p_0})\gamma}$, we obtain for some positive constant κ_2

$$\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_1)} \leq e^{-(C_1+\kappa_1)\gamma}\|\mathbf{u}\|_{H^2(Q)} + e^{-(\eta T - \frac{(2C_1+\kappa_1)p_0'}{p_0})\gamma}\|\mathbf{u}\|_{H^2(Q)} + e^{\kappa_2\gamma}\|\mathbf{u}_{\gamma,t}\|_{H^2(\Sigma_{1,3r})}.$$

Take T large such that

$$\left(\eta T - \frac{(2C_1+\kappa_1)p_0'}{p_0}\right) > C_1 + \kappa_1.$$

Then we obtain

$$\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_1)} \leq e^{-(C_1+\kappa_1)\gamma}\|\mathbf{u}\|_{H^2(Q)} + e^{\kappa_2\gamma}\|\mathbf{u}_{\gamma,t}\|_{H^2(\Sigma_{1,3r})}.$$

By inserting this into (4.16), we have

$$\|\mathbf{u}_{\gamma,t}\|_{H^2(\widetilde{B}_n)} \leq e^{-C_1\gamma}\|\mathbf{u}\|_{H^2(Q)} + e^{C_n\gamma}\|\mathbf{u}_{\gamma,t}\|_{H^2(\Sigma_{1,3r})}$$

for some positive constant C_n. This completes the proof of (4.15). □

4.4. End of the proof of Lemma 2.5. We shall complete the proof of Lemma 2.5 in this subsection.

We fix $T > \max_{1\leq n\leq N} T_n$. Addition of inequalities (4.15) for $n \in \{1,\ldots,N\}$ yields

$$\|\mathbf{u}_{\gamma,t}\|_{H^2(\omega_r(\epsilon_0,3\epsilon_0))} \leq e^{-C_3\gamma}\|\mathbf{u}\|_{H^2(Q)} + e^{C_4\gamma}\|\mathbf{u}\|_{H^2(\Sigma_1)}, \quad t \in \left[-\frac{T}{2},\frac{T}{2}\right], \tag{4.17}$$

for some positive constants C_3 and C_4. We set $\mathbf{u}_\gamma(x,t) = \mathbf{u}_{\gamma,t}(x,0)$. Then we have

$$\mathbf{u}_\gamma(x,t) = \sqrt{\frac{\gamma}{2\pi}}\int_{\mathbb{R}} e^{-\frac{\gamma}{2}(t-y)^2}\theta(y)\mathbf{u}(x,y)dy = (K_\gamma * \theta\mathbf{u})(x,t),$$

where

$$K_\gamma(t) = \sqrt{\frac{\gamma}{2\pi}}e^{-\frac{\gamma}{2}t^2}.$$

LEMMA 4.6. *Let $T^1 = \frac{T}{2} - r$. Then we have*

$$\|\mathbf{u}_\gamma\|^2_{H^2(\omega_{T^1}(\epsilon_0,3\epsilon_0))} \le e^{-\mu\gamma}\|\mathbf{u}\|^2_{H^1(Q)} + e^{\mu'\gamma}\|\mathbf{u}\|^2_{H^2(\Sigma_1)}$$

for some positive constants μ and μ'.

Proof. By the Cauchy formula, for ϱ such that $0 < \varrho < r$, we obtain

$$\mathbf{u}_\gamma(x,a) = \frac{1}{2i\pi}\int_{|w-a|=\varrho} \frac{\mathbf{u}_\gamma(x,w)}{w-a}dw.$$

Thus, by using the polar coordinate, we obtain

$$|\mathbf{u}_\gamma(x,a)|^2 \le C_5 \int_0^{2\pi} \left|\mathbf{u}_\gamma(x,a+\varrho e^{i\theta})\right|^2 d\theta.$$

We integrate $\varrho \in (0,r)$ and obtain

$$|\mathbf{u}_\gamma(x,a)|^2 \le \frac{C_5}{r}\int_0^r\int_0^{2\pi} \left|\mathbf{u}_\gamma(x,a+\varrho e^{i\theta})\right|^2 d\theta d\varrho.$$

Therefore, for $x \in \omega(\epsilon_0,3\epsilon_0)$ and $a \in [-\frac{T}{2}+r, \frac{T}{2}-r]$, we have

$$|\mathbf{u}_\gamma(x,a)|^2 \le C_6\int_{|s|\le r,|t-a|\le r} |\mathbf{u}_\gamma(x,t+is)|^2\, dsdt = C_6\int_{|s|\le r,|t-a|\le r} |\mathbf{u}_{\gamma,t}(x,s)|^2\, dsdt$$

and

$$\begin{aligned}\|\mathbf{u}_\gamma(\cdot,a)\|^2_{L^2(\omega(\epsilon_0,3\epsilon_0))} &\le C_6\int_{-r}^r\int_{|t-a|\le r} \|\mathbf{u}_{\gamma,t}\|^2_{L^2(\omega_r(\epsilon_0,3\epsilon_0))}\, dtds \\ &\le C_7\int_{-r}^r\int_{-T/2}^{T/2} \|\mathbf{u}_{\gamma,t}\|^2_{L^2(\omega_r(\epsilon_0,3\epsilon_0))}\, dtds. \end{aligned} \tag{4.18}$$

We integrate $a \in [-T^1, T^1]$, and by using (4.17) we obtain

$$\|\mathbf{u}_\gamma\|^2_{L^2(\omega_{T^1}(\epsilon_0,3\epsilon_0))} \le C_T(e^{-C_3\gamma}\|\mathbf{u}\|^2_{H^2(Q)} + e^{C_4\gamma}\|\mathbf{u}\|^2_{H^2(\Sigma_1)}).$$

By using the same argument to $\partial^\alpha \mathbf{u}_\gamma$, $|\alpha| \le 2$, we complete the proof of Lemma 4.6. ∎

LEMMA 4.7. *Let $\mathbf{u}$ be a solution of (4.4). Then there exist $C_7 > 0$ and $C_8 > 0$ such that*

$$\|\mathbf{u}\|_{H^2(\omega_{T^1}(\epsilon_0,3\epsilon_0))} \le \frac{C_7}{\sqrt{\gamma}}\|\mathbf{u}\|_{H^3(Q)} + e^{C_7\gamma}\|\mathbf{u}\|_{H^2(\Sigma_1)}.$$

Proof. By $\widehat{\mathbf{u}}(x,\tau)$ we denote the Fourier transform of $\mathbf{u}(x,t)$ in t. We have

$$\widehat{\theta\mathbf{u}}(x,\tau) - \widehat{\mathbf{u}_\gamma}(x,\tau) = (1-\widehat{K_\gamma})\widehat{\theta\mathbf{u}}(x,\tau).$$

Furthermore we can directly verify that

$$\left|(1-\widehat{K_\gamma})(\tau)\right| \le \frac{\tau^2}{\gamma},$$

so that we obtain for $T^1 = T/2 - r$

$$\|\mathbf{u} - \mathbf{u}_\gamma\|_{L^2(\omega_{T^1}(\epsilon_0,3\epsilon_0))} \leq \frac{C_8}{\sqrt{\gamma}} \|\mathbf{u}\|_{H^1(Q)}.$$

Similarly we have

$$\|\mathbf{u} - \mathbf{u}_\gamma\|_{H^2(\omega_{T^1}(\epsilon_0,3\epsilon_0))} \leq \frac{C_9}{\sqrt{\gamma}} \|\mathbf{u}\|_{H^3(Q)}.$$

Hence

$$\begin{aligned}\|\mathbf{u}\|_{H^2(\omega_{T^1}(\epsilon_0,3\epsilon_0))} &\leq C_{10}\left[\|\mathbf{u} - \mathbf{u}_\gamma\|_{H^2(\omega_{T^1}(\epsilon_0,3\epsilon_0))} + \|\mathbf{u}_\gamma\|_{H^2(\omega_{T^1}(\epsilon_0,3\epsilon_0))}\right] \\ &\leq C_{11}\left[\frac{1}{\sqrt{\gamma}}\|\mathbf{u}\|_{H^3(Q)} + \|\mathbf{u}_\gamma\|_{H^2(\omega_{T^1}(\epsilon_0,3\epsilon_0))}\right].\end{aligned}$$

On the other hand, by Lemma 4.6, we obtain

$$\|\mathbf{u}_\gamma\|^2_{H^2(\omega_{T^1}(\epsilon_0,3\epsilon_0))} \leq e^{-\mu\gamma}\|\mathbf{u}\|^2_{H^2(Q)} + e^{\mu'\gamma}\|\mathbf{u}\|^2_{H^2(\Sigma_1)}$$

for some positive constants μ and μ'. This complete the proof of the lemma. □

We now turn to the proof of Lemma 2.6. By Lemma 4.7 and $\mathbf{u} = \chi_3\mathbf{v}$, we obtain

$$\|\mathbf{v}\|_{H^2(\omega_{T^1}(\epsilon_0,3\epsilon_0))} \leq \frac{C_7}{\sqrt{\gamma}}\|\mathbf{v}\|_{H^3(Q)} + e^{C_7\gamma}\|\mathbf{v}\|_{H^2(\Sigma_1)}.$$

By (1.6), we obtain

$$\|\mathbf{u}\|_{H^2(\omega_{T^1}(\epsilon_0,3\epsilon_0))} \leq \frac{M}{\sqrt{\gamma}} + e^{C_7\gamma}\epsilon(\Sigma_1).$$

By selecting

$$\gamma = \frac{1}{2C_7}\log\left(2 + \frac{M}{\epsilon(\Sigma_1)}\right),$$

the proof of Lemma 2.5 is complete. □

THE HUNTER–SAXTON EQUATION: A GEOMETRIC APPROACH*

JONATAN LENELLS†

Abstract. We provide a rigorous foundation for the geometric interpretation of the Hunter–Saxton equation as the equation describing the geodesic flow of the $\dot{H}^1$ right-invariant metric on the quotient space $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ of the infinite-dimensional Banach manifold $\mathcal{D}^k(\mathbb{S})$ of orientation-preserving H^k-diffeomorphisms of the unit circle $\mathbb{S}$ modulo the subgroup of rotations $Rot(\mathbb{S})$. Once the underlying Riemannian structure has been established, the method of characteristics is used to derive explicit formulas for the geodesics corresponding to the $\dot{H}^1$ right-invariant metric, yielding, in particular, new explicit expressions for the spatially periodic solutions of the initial-value problem for the Hunter–Saxton equation.

Key words. diffeomorphism group, Hunter–Saxton equation, geodesic flow

1. Introduction.

The Hunter–Saxton equation

$$u_{txx} = -2u_x u_{xx} - u u_{xxx}, \quad t > 0,\ x \in \mathbb{R}, \tag{1.1}$$

models the propagation of weakly nonlinear orientation waves in a massive nematic liquid crystal director field, x being the space variable in a reference frame moving with the unperturbed wave speed and t being a slow time variable [6]. Equation (1.1) is a bivariational, completely integrable system with a bi-Hamiltonian structure [7], leading to the existence of an infinite family of commuting Hamiltonian flows together with associated conservation laws. Smooth solutions of (1.1) break down in finite time as the slope $u_x \to -\infty$. The existence of global weak solutions was considered in [8]. Weak dissipative solutions of (1.1) have been studied in [1], where also a discussion of different notions of weak solutions can be found.

It was first noticed in [9] that, for spatially periodic functions, (1.1) describes the geodesic flow on the homogeneous space $Rot(\mathbb{S})\backslash\mathcal{D}(\mathbb{S})$ of the infinite-dimensional Lie group $\mathcal{D}(\mathbb{S})$ of orientation-preserving diffeomorphisms of the unit circle $\mathbb{S}$ modulo the subgroup of rotations $Rot(\mathbb{S})$, endowed with the $\dot{H}^1$ right-invariant metric given at the identity by

$$\langle [u], [v] \rangle = \int_{\mathbb{S}} u_x v_x dx, \qquad [u], [v] \in T_{[id]}\big(Rot(\mathbb{S})\backslash\mathcal{D}(\mathbb{S})\big),$$

where $[id]$ denotes the equivalence class in $Rot(\mathbb{S})\backslash\mathcal{D}(\mathbb{S})$ of the identity map $id \in \mathcal{D}(\mathbb{S})$. This makes (1.1) one of the equations (others include the well-known Euler, Burgers, Korteweg–de Vries, and Camassa–Holm equations [4, 3, 15, 13]) that arises as the Euler equation for the geodesic flow corresponding to a right-invariant metric.

In this paper we provide a rigorous foundation for this geometric interpretation of (1.1) within the periodic setting (for the case on the line further technical complications arise due to the need of considering weighted Sobolev spaces—see the discussion

in [2]). Two similar but distinct approaches are possible. We may choose to consider the geodesic flow of the $\dot{H}^1$ right-invariant metric either (1) on the homogeneous space $Rot(\mathbb{S})\backslash\mathcal{D}(\mathbb{S})$, where $\mathcal{D}(\mathbb{S})$ denotes the Fréchet Lie group of smooth diffeomorphisms of $\mathbb{S}$, or (2) on the Banach manifold $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ for $k > 3/2$, where $\mathcal{D}^k(\mathbb{S})$ incorporates all diffeomorphisms of $\mathbb{S}$ of Sobolev class H^k. We will pursue the latter approach. Note that $\mathcal{D}^k(\mathbb{S})$ is a topological group but not a Lie group as the group operation $(\psi, \varphi) \mapsto \psi \circ \varphi$ for $\psi, \varphi \in \mathcal{D}^k(\mathbb{S})$ is continuous but not smooth due to derivative loss (cf. [5]). The advantage of working on $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ is that the theory of Riemannian geometry on Banach manifolds is available—whereas nearly all results familiar from finite-dimensional Riemannian geometry immediately generalize to Banach manifolds (see [10]); a transition to Fréchet manifolds introduces several technical complications (see [5]). In particular, there are no general existence and uniqueness results for differential equations in Fréchet spaces, making it difficult to study geodesic flow and parallel translation. Also, on a Fréchet manifold, since the inverse mapping theorem does not hold, neither the Lie group exponential map nor the Riemannian exponential map is necessarily a local diffeomorphism at the identity. Another advantage of working with the wider class $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ is that when studying partial differential equations it is often preferable to work in Sobolev spaces rather than in the category of C^∞-maps.

We will construct a smooth affine connection on $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ compatible with the $\dot{H}^1$ right-invariant metric. Once this has been established, the general theory of Riemannian geometry on Banach manifolds immediately yields existence of a smooth curvature tensor, existence of normal neighborhoods, existence and uniqueness results for the geodesic flow and parallel translation, locally length-minimizing properties of the geodesics, etc. In this paper we focus on the geodesic flow and its relation to the Hunter–Saxton equation. In particular, we find that if $\varphi \in C^2([0,T);\mathcal{D}^k(\mathbb{S}))$ is a C^2-curve in $\mathcal{D}^k(\mathbb{S})$, then the quotient curve $t \mapsto [\varphi(t)]$ is a geodesic in $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ with respect to the $\dot{H}^1$ right-invariant metric if and only if $u = \varphi_t \circ \varphi^{-1} \in C([0,T);H^k(\mathbb{S})) \cap C^1([0,T);H^{k-1}(\mathbb{S}))$ satisfies (1.1). In a subsequent section the method of characteristics is used to derive explicit formulas for the geodesics corresponding to the $\dot{H}^1$ right-invariant metric. As a byproduct we also obtain explicit formulas for the spatially periodic solutions of the initial-value problem for (1.1). Note that this presents new solutions to (1.1) with respect to earlier presentations (cf. [6, 1])—the requirement that the solutions be spatially periodic introduces nontrivial constants of integration which alter the derivation and its outcome.

The quotient space $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$, the $\dot{H}^1$ right-invariant metric $\langle\cdot,\cdot\rangle$, and a Christoffel map Γ are introduced in section 2. In section 3 it is proved that the covariant derivative induced by Γ is the unique covariant derivative compatible with the $\dot{H}^1$ right-invariant metric. In section 4 the connection between the geodesic flow and the Hunter–Saxton equation is explained, while in section 5 explicit formulas for the geodesics are obtained by means of the method of characteristics.

2. The quotient space $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$. Let $\mathbb{S}$ be the circle of length one and let D_x denote differentiation with respect to x. For $X = [0,1]$ or $X = \mathbb{S}$ we let, for $n \geq 0$, $H^n(X)$ be the space of all functions on X of Sobolev class H^n. By restriction of a periodic function to the unit interval, $H^n(\mathbb{S})$ may be viewed as a closed linear subspace of $H^n[0,1]$.

For an integer $k \geq 3$,[1] let $\mathcal{D}^k(\mathbb{S})$ denote the Banach manifold of orientation-

[1]Even though $k > 3/2$ is sufficient for $\mathcal{D}^k(\mathbb{S})$ to be a topological group [4], we will assume $k \geq 3$ for simplicity; see [11] for an extension of the geometric approach which incorporates weak solutions.

preserving diffeomorphisms of $\mathbb{S}$ of class H^k (cf. [14]). By $Rot(\mathbb{S}) \subset \mathcal{D}^k(\mathbb{S})$ we denote the subgroup of rotations $x \mapsto x + d$, $d \in \mathbb{R}$. Let $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ be the space of right cosets $Rot(\mathbb{S}) \circ \varphi = \{\varphi(\cdot) + d \big| \, d \in \mathbb{R}\}$ for $\varphi \in \mathcal{D}^k(\mathbb{S})$. We will construct a global canonical chart on $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$.

Put $M^k = \{\varphi \in \mathcal{D}^k(\mathbb{S}) \big| \, \varphi(0) = 0\}$. Then the map

$$\varphi \mapsto \big(\varphi(0), \varphi(\cdot) - \varphi(0)\big) : \mathcal{D}^k(\mathbb{S}) \to \mathbb{S} \times M^k \tag{2.1}$$

is a diffeomorphism. Note that M^k can be characterized as

$$M^k = \{\varphi \in H^k[0,1] \big| \, \varphi_x \in H^{k-1}(\mathbb{S}), \varphi_x > 0, \varphi(0) = 0, \varphi(1) = 1\},$$

or, equivalently,

$$M^k = \{u + id \big| \, u \in H^k(\mathbb{S}), u_x > -1, u(0) = 0\}, \tag{2.2}$$

where $id \in \mathcal{D}^k(\mathbb{S})$ is the identity map $id(x) = x$ for $x \in \mathbb{S}$.

From (2.1) we obtain a natural identification $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S}) \simeq M^k$ given by

$$[\varphi] \mapsto \varphi - \varphi(0), \tag{2.3}$$

where $[\varphi]$ denotes the equivalence class of $\varphi \in \mathcal{D}^k(\mathbb{S})$. Let $\mathbf{E}^k \subset H^k(\mathbb{S})$ be the closed linear subspace

$$\mathbf{E}^k = \{u \in H^k(\mathbb{S}) \big| \, u(0) = 0\}$$

with topology induced from $H^k(\mathbb{S})$. The representation (2.2) shows that M^k is an open subset of the closed hyperplane $id + \mathbf{E}^k \subset H^k[0,1]$. Hence M^k provides a global chart for $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$. Moreover, $T(Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})) \simeq TM^k \simeq M^k \times \mathbf{E}^k$, so that a vector field X on $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ can be viewed as a map $M^k \to \mathbf{E}^k$.

The $\dot{H}^1$ right-invariant metric $\langle \cdot, \cdot \rangle$ on $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ is most easily defined in the global chart M^k as follows (see also [9]). Let $A = -D_x^2$ and introduce a positive definite symmetric bilinear form $\langle \cdot, \cdot \rangle_{id}$ on $T_{id}M^k \simeq \mathbf{E}^k$ by

$$\langle u, v \rangle_{id} = \int_{\mathbb{S}} uAv dx = \int_{\mathbb{S}} u_x v_x dx, \qquad u, v \in \mathbf{E}^k.$$

and extend it to $T_\varphi M^k$ for any $\varphi \in M^k$ by right-invariance, so that, for $U, V \in T_\varphi M^k \simeq \mathbf{E}^k$,

$$\langle U, V \rangle_\varphi = \int_{\mathbb{S}} U \circ \varphi^{-1} A (V \circ \varphi^{-1}) dx.$$

We also introduce the closed linear subspace

$$\mathbf{F}^k = \left\{ f \in H^k(\mathbb{S}) \, \middle| \, \int_{\mathbb{S}} f dx = 0 \right\}.$$

It is straightforward to check that $A = -D_x^2$ is an isomorphism $\mathbf{E}^k \to \mathbf{F}^{k-2}$. Denoting its inverse by $A^{-1} : \mathbf{F}^{k-2} \to \mathbf{E}^k$, we infer that, for $u \in H^{k-1}(\mathbb{S})$,

$$-\big(A^{-1} D_x(u)\big)(x) = \int_0^x u(y) dy - x \int_{\mathbb{S}} u dx. \tag{2.4}$$

Now define $\Gamma : M^k \times \mathbf{E}^k \times \mathbf{E}^k \to \mathbf{E}^k$ by

$$\Gamma(\varphi, U, V) = -\frac{1}{2}\Big(A^{-1}D_x\big((U\circ\varphi^{-1})_x(V\circ\varphi^{-1})_x\big)\Big)\circ\varphi, \tag{2.5}$$

and notice that Γ is right-invariant in the sense that

$$\Gamma(\psi, U, V)\circ\varphi = \Gamma(\psi\circ\varphi, U\circ\varphi, V\circ\varphi), \qquad \varphi,\psi\in M^k, \quad U,V\in\mathbf{E}^k. \tag{2.6}$$

The motivation for the definition of Γ comes in section 3, where we will see that Γ is the Christoffel map (the infinite-dimensional analogue of the Christoffel symbols Γ^i_{jk} well known from finite-dimensional Riemannian geometry) for the affine connection on $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ compatible with the $\dot{H}^1$ right-invariant metric.

Although $\mathcal{D}^k(\mathbb{S})$ is a smooth Banach manifold it is not a Lie group. Indeed, the group operation $(\psi,\varphi)\mapsto\psi\circ\varphi : \mathcal{D}^k(\mathbb{S})\times\mathcal{D}^k(\mathbb{S})\to\mathcal{D}^k(\mathbb{S})$ is continuous but not C^1; right multiplication $R_\varphi : \psi\mapsto\psi\circ\varphi$ is smooth, whereas left multiplication $L_\psi : \varphi\mapsto\psi\circ\varphi$ is continuous but not C^1 due to derivative loss (see [5]). Similarly, M^k is a Banach manifold and a topological group but not a Lie group. Therefore, it is not a priori clear that the $\dot{H}^1$ metric and the Christoffel map Γ are smooth objects (that right multiplication is smooth is not enough). The following two propositions deal with this technicality (see [12] for detailed proofs of similar results in the case of the Camassa–Holm equation).

Proposition 2.1. *The map*

$$[\varphi]\mapsto\langle\cdot,\cdot\rangle_{[\varphi]} : Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})\to L^2_{sym}(T_{[\varphi]}\big(Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})\big);\mathbb{R})$$

is a smooth section of the bundle $L^2_{sym}(T\big(Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})\big);\mathbb{R})$.

Proposition 2.2. *Let* Γ *be defined by* (2.5). *The map*

$$\varphi\mapsto\Gamma(\varphi,\cdot,\cdot) : M^k\to L^2_{sym}(\mathbf{E}^k;\mathbf{E}^k)$$

is smooth.

3. Covariant derivative. In this section the covariant derivative induced by the Christoffel map Γ is shown to be compatible with the $\dot{H}^1$ right-invariant metric.

We first recall the general definition of a covariant derivative. Let $\mathcal{M}$ be a Banach manifold endowed with a Riemannian metric $\langle\cdot,\cdot\rangle$ and let $\mathfrak{X}(\mathcal{M})$ denote the space of smooth vector fields on $\mathcal{M}$. For $X,Y\in\mathfrak{X}(\mathcal{M})$ the Lie bracket $[X,Y]$ is defined locally by

$$[X,Y](m) = DY(m)\cdot X(m) - DX(m)\cdot Y(m).$$

Definition 3.1. *An* $\mathbb{R}$*-bilinear operator* $(X,Y)\mapsto\nabla_XY : \mathfrak{X}(\mathcal{M})\times\mathfrak{X}(\mathcal{M})\to\mathfrak{X}(\mathcal{M})$ *is a* Riemannian covariant derivative *if it satisfies*

(a) $X(m)=0$ *implies* $(\nabla_XY)(m)=0$ *for* $m\in\mathcal{M}$ *and* $X,Y\in\mathfrak{X}(\mathcal{M})$ *(punctual dependence on* X*),*
(b) $\nabla_XY-\nabla_YX=[X,Y]$ *for* $X,Y\in\mathfrak{X}(\mathcal{M})$ *(torsion-free),*
(c) $\nabla_X(fY)=(\mathcal{L}_Xf)Y+f\nabla_XY$ *for* $f\in C^\infty(\mathcal{M})$, $X,Y\in\mathfrak{X}(\mathcal{M})$ *(derivation in* Y*),*
(d) $\mathcal{L}_X\langle Y,Z\rangle=\langle\nabla_XY,Z\rangle+\langle Y,\nabla_XZ\rangle$ *for* $X,Y,Z\in\mathfrak{X}(\mathcal{M})$ *(compatible with the metric).*

Define the operator $\nabla : \mathfrak{X}(Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S}))\times\mathfrak{X}(Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})) \to \mathfrak{X}(Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S}))$ in the global chart M^k by

$$(\nabla_X Y)(\varphi) = DY(\varphi)\cdot X(\varphi) - \Gamma(\varphi, Y(\varphi), X(\varphi)), \tag{3.1}$$

where $X, Y : M^k \to \mathbf{E}^k$ are representatives in the chart M^k of two vector fields on $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$.

In the finite-dimensional case, given a Riemannian metric $\langle\cdot,\cdot\rangle$ on a manifold $\mathcal{M}$ there automatically exists a Riemannian covariant derivative ∇ compatible with $\langle\cdot,\cdot\rangle$. For vector fields X, Y, Z on $\mathcal{M}$, $\nabla_X Y$ is defined as the unique vector field such that

$$2\langle\nabla_X Y, Z\rangle = -\langle[Y,X],Z\rangle - \langle X,[Y,Z]\rangle - \langle Y,[X,Z]\rangle + \mathcal{L}_X\langle Y,Z\rangle + \mathcal{L}_Y\langle Z,X\rangle - \mathcal{L}_Z\langle X,Y\rangle. \tag{3.2}$$

Indeed, the bracket $\langle\cdot,\cdot\rangle$ establishes an isomorphism $T_m\mathcal{M} \to T_m^*\mathcal{M}$ for each $m \in \mathcal{M}$, so since the right-hand side is a continuous linear functional of $Z(m)$, existence of $(\nabla_X Y)(m)$ follows immediately.

This approach does not apply to $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ endowed with the $\dot{H}^1$ right-invariant metric. The right-hand side of (3.2) is a continuous linear functional of $Z(\varphi)$ for each $\varphi \in M^k$. But the topology of $T_\varphi M^k \simeq \mathbf{E}^k$ induced by the H^k inner product is much stronger than the topology defined by the $\dot{H}^1$ right-invariant metric $\langle\cdot,\cdot\rangle_\varphi$—the $\dot{H}^1$ right-invariant metric is a *weak Riemannian metric* on $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$. Therefore there are elements in $T_\varphi^* M^k$ that cannot be expressed as $\langle V,\cdot\rangle_\varphi$ for some $V \in T_\varphi M^k$; the spaces $T_\varphi M^k \simeq \mathbf{E}^k$ and $T_\varphi^* M^k \simeq \mathbf{E}^{k*}$ are in duality with respect to the H^k inner product, not with respect to $\langle\cdot,\cdot\rangle_\varphi$. The explicit formula for Γ will help us circumvent this difficulty.

However, even for weak Riemannian metrics *uniqueness* of the Riemannian covariant derivative can be deduced from (3.2). For if ∇ satisfies (a)–(d) of Definition 3.1, then, writing down property (d) for the cyclic permutations of $X, Y, Z \in \mathfrak{X}(M)$, we get

$$\mathcal{L}_X\langle Y,Z\rangle = \langle\nabla_X Y, Z\rangle + \langle Y, \nabla_X Z\rangle,$$

$$\mathcal{L}_Y\langle Z,X\rangle = \langle\nabla_Y Z, X\rangle + \langle Z, \nabla_Y X\rangle,$$

$$\mathcal{L}_Z\langle X,Y\rangle = \langle\nabla_Z X, Y\rangle + \langle X, \nabla_Z Y\rangle.$$

Adding the first two and subtracting the third of these relations, (3.2) drops out. Since $\langle\cdot,\cdot\rangle$ is nondegenerate, (3.2) shows the uniqueness of ∇.

In the proof of Theorem 3.2 the identity

$$\frac{d}{d\epsilon}\bigg|_{\epsilon=0} U\circ(\varphi+\epsilon V)^{-1} = -(U\circ\varphi^{-1})_x V\circ\varphi^{-1}, \qquad \varphi\in\mathcal{D}^k(\mathbb{S}), \quad U,V\in H^k(\mathbb{S}), \tag{3.3}$$

will be used. It is a consequence of

$$\frac{d}{d\epsilon}\bigg|_{\epsilon=0}(\varphi+\epsilon V)^{-1} = -\frac{V\circ\varphi^{-1}}{\varphi_x\circ\varphi^{-1}} \qquad \text{and} \qquad \frac{U_x\circ\varphi^{-1}}{\varphi_x\circ\varphi^{-1}} = (U\circ\varphi^{-1})_x.$$

THEOREM 3.2. *The bilinear map ∇ given by* (3.1) *defines a unique Riemannian covariant derivative on $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ compatible with the $\dot{H}^1$ right-invariant metric.*

Proof. Properties (a)–(c) are immediate from the local formula defining ∇. To establish (d) we compute, for vector fields $X, Y, Z : M^k \to \mathbf{E}^k$,

$$
\begin{aligned}
&(\mathcal{L}_X\langle Y,Z\rangle)(\varphi)\\
&\quad= \frac{d}{d\epsilon}\Big|_{\epsilon=0}\int_{\mathbb{S}} A\big(Y(\varphi+\epsilon X(\varphi))\circ(\varphi+\epsilon X(\varphi))^{-1}\big)\\
&\qquad\cdot Z(\varphi+\epsilon X(\varphi))\circ(\varphi+\epsilon X(\varphi))^{-1}dx\\
&\quad= \int_{\mathbb{S}} A\Big((DY(\varphi)\cdot X(\varphi))\circ\varphi^{-1} - (Y(\varphi)\circ\varphi^{-1})_x X(\varphi)\circ\varphi^{-1}\Big)Z(\varphi)\circ\varphi^{-1}dx\\
&\qquad+\int_{\mathbb{S}} A\Big((DZ(\varphi)\cdot X(\varphi))\circ\varphi^{-1} - (Z(\varphi)\circ\varphi^{-1})_x X(\varphi)\circ\varphi^{-1}\Big)Y(\varphi)\circ\varphi^{-1}dx,
\end{aligned}
$$

where formula (3.3) was used to carry out the differentiation. Define $u, v, w \in \mathbf{E}^k$ by $u = X(\varphi)\circ\varphi^{-1}$, $v = Y(\varphi)\circ\varphi^{-1}$, and $w = Z(\varphi)\circ\varphi^{-1}$. We get

$$
\begin{aligned}
(\mathcal{L}_X\langle Y,Z\rangle)(\varphi) &= \int_{\mathbb{S}} A\Big(\big(DY(\varphi)\cdot X(\varphi)\big)\circ\varphi^{-1}\Big)wdx\\
&+\int_{\mathbb{S}} A\Big(\big(DZ(\varphi)\cdot X(\varphi)\big)\circ\varphi^{-1}\Big)vdx - \int_{\mathbb{S}} A(v_x u)wdx - \int_{\mathbb{S}} A(w_x u)vdx.
\end{aligned}
\tag{3.4}
$$

On the other hand

$$
\langle\nabla_X Y, Z\rangle_\varphi = \int_{\mathbb{S}}\Big(DY(\varphi)\cdot X(\varphi) - \Gamma\big(\varphi, Y(\varphi), X(\varphi)\big)\Big)\circ\varphi^{-1}A(Z(\varphi)\circ\varphi^{-1})dx.
$$

Since $\Gamma(\varphi, Y(\varphi), X(\varphi)) = -\frac{1}{2}\big(A^{-1}D_x(v_x u_x)\big)\circ\varphi$, we get

$$
\langle\nabla_X Y, Z\rangle_\varphi = \int_{\mathbb{S}}\big(DY(\varphi)\cdot X(\varphi)\big)\circ\varphi^{-1}A(w)dx + \frac{1}{2}\int(v_x u_x)_x w dx.
\tag{3.5}
$$

Now, recalling that $A = -D_x^2$, it is easy to check that

$$
-\int_{\mathbb{S}} A(v_x u)wdx - \int_{\mathbb{S}} A(w_x u)vdx = \frac{1}{2}\int(v_x u_x)_x w dx + \frac{1}{2}\int(w_x u_x)_x v dx
$$

so by (3.4) and (3.5) we obtain

$$
(\mathcal{L}_X\langle Y,Z\rangle)(\varphi) = \langle\nabla_X Y, Z\rangle_\varphi + \langle Y, \nabla_X Z\rangle_\varphi.
$$

This proves that ∇ also satisfies (d). □

4. Geodesics and the Hunter–Saxton equation. Since the map Γ defined in (2.5) is a smooth Christoffel map (see Proposition 2.2), all the usual constructions for affine connections on Banach manifolds (cf. [10]) can easily be carried out on $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$. Here we will be concerned with the geodesics on $Rot(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ and their relation to the Hunter–Saxton equation.

4.1. Parallel translation. Let $J \subset \mathbb{R}$ be an open interval and let $\varphi : J \to M^k$ be a C^2-curve. A lift $V : J \to TM^k$ of φ is *φ-parallel* if

$$V_t = \Gamma(\varphi, V, \varphi_t), \qquad t \in J,$$

which is equivalent to $\nabla_{\varphi_t} V \equiv 0$. Applying the general theory for Banach manifolds, we get the following result.

PROPOSITION 4.1. *Let $t_0 \in J$. Given $V_0 \in T_{\varphi(0)}M^k$, there exists a unique φ-parallel lift $t \mapsto V(t; V_0) : J \to TM^k$ such that $V(t_0; V_0) = V_0$.*

Define two continuous maps $u, v : J \to T_{id}M^k \simeq \mathbf{E}^k$ by

$$u(t) = T_{\varphi(t)}R_{\varphi(t)^{-1}}(\varphi_t(t)) = \varphi_t(t) \circ \varphi(t)^{-1}$$

and

$$v(t) = T_{\varphi(t)}R_{\varphi(t)^{-1}}(V(t)) = V(t) \circ \varphi(t)^{-1}.$$

Note that u, v are not C^1-maps as

$$u_t = \varphi_{tt} \circ \varphi^{-1} + \frac{\varphi_{tx} \circ \varphi^{-1}}{\varphi_x \circ \varphi^{-1}}$$

is in general an element in $\mathbf{E}^{k-1}$ but not in $\mathbf{E}^k$. Nevertheless, it is clear that

$$u, v \in C(J; \mathbf{E}^k) \cap C^1(J; \mathbf{E}^{k-1}).$$

THEOREM 4.2. *Let $\varphi : J \to M^k$ be a C^2-curve and $V : J \to TM^k$ a lift of φ. Define $u, v : J \to \mathbf{E}^k$ by*

$$v(t) = V(t) \circ \varphi(t)^{-1}, \qquad u(t) = \varphi_t(t) \circ \varphi(t)^{-1},$$

so that $u, v \in C(J; \mathbf{E}^k) \cap C^1(J; \mathbf{E}^{k-1})$. The following statements are equivalent:

(a) *V is φ-parallel.*

(b) *u and v satisfy, for $t \in J$,*

$$v_t = \Gamma(id, v, u) - v_x u \quad \text{in} \quad \mathbf{E}^{k-1}. \tag{4.1}$$

(c) *u and v solve the equation*

$$v_{txx} = -\frac{3}{2}v_{xx}u_x - \frac{1}{2}v_x u_{xx} - v_{xxx}u, \qquad t \in J,\ x \in \mathbb{S}. \tag{4.2}$$

Proof. First note that

$$v_x u = (V \circ \varphi^{-1})_x \varphi_t \circ \varphi^{-1} = \frac{V_x \circ \varphi^{-1}}{\varphi_x \circ \varphi^{-1}} \varphi_t \circ \varphi^{-1} = -V_x \circ \varphi^{-1} \cdot (\varphi^{-1})_t. \tag{4.3}$$

Suppose V is φ-parallel. Using (4.3), we compute in $\mathbf{E}^{k-1}$

$$v_t = V_t \circ \varphi^{-1} + V_x \circ \varphi^{-1} \cdot (\varphi^{-1})_t = \Gamma(\varphi, V, \varphi_t) \circ \varphi^{-1} - v_x u = \Gamma(id, v, u) - v_x u,$$

where we used the right invariance (2.6) of Γ. Conversely, if (4.1) holds, then (4.3) yields

$$V_t \circ \varphi^{-1} = v_t - V_x \circ \varphi^{-1} \cdot (\varphi^{-1})_t = \Gamma(id, v, u) - v_x u - V_x \circ \varphi^{-1} \cdot (\varphi^{-1})_t = \Gamma(\varphi, V, \varphi_t) \circ \varphi^{-1},$$

showing that V is φ-parallel. This establishes the equivalence of (a) and (b).

Suppose (b) holds. By the definition (2.5) of Γ we rewrite (4.1) as

$$v_t = -\frac{1}{2}A^{-1}D_x(v_x u_x) - v_x u. \tag{4.4}$$

Applying $A = -D_x^2$ to both sides of (4.4) gives (4.2). Conversely, suppose (c) holds. Since at each fixed time both sides of (4.2) belong to $\mathbf{F}^{k-3}$, we may apply the isomorphism $A^{-1} : \mathbf{F}^{k-3} \to \mathbf{E}^{k-1}$ to obtain (4.4). Hence (b) and (c) are equivalent. □

4.2. Geodesics. A C^2-map $\varphi : J \to M^k$ is a geodesic if

$$\varphi_{tt} = \Gamma(\varphi, \varphi_t, \varphi_t).$$

Just like for parallel translation we can express the geodesic equation as an equation for $u = \varphi_t \circ \varphi^{-1}$.

THEOREM 4.3. *Let $\varphi : J \to M^k$ be a C^2-curve and define $u : J \to \mathbf{E}^k$ by $u(t) = \varphi_t(t) \circ \varphi(t)^{-1}$ so that $u \in C(J; \mathbf{E}^k) \cap C^1(J; \mathbf{E}^{k-1})$. Then φ is a geodesic if and only if u solves the Hunter–Saxton equation*

$$u_{txx} = -2u_x u_{xx} - u u_{xxx}, \qquad t \in J,\ x \in \mathbb{S}. \tag{4.5}$$

Proof. φ is a geodesic if and only if φ_t is φ-parallel. The equivalence of (a) and (c) of Theorem 4.2 shows that φ_t is φ-parallel if and only if u satisfies (4.5). □

The condition that $\varphi : J \to M^k \subset \mathcal{D}^k(\mathbb{S})$ imposes the condition $\varphi(t)\big|_{x=0} = 0$ for all t. We now remove this restriction.

Let $\rho : \mathcal{D}^k(\mathbb{S}) \to \mathit{Rot}(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ be the quotient map. Assume $\varphi : J \to \mathcal{D}^k(\mathbb{S})$ is a C^1-curve and denote by $[\varphi] = \rho \circ \varphi : J \to \mathit{Rot}(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ the induced curve in $\mathit{Rot}(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$. A lift $V : J \to T\mathcal{D}^k(\mathbb{S})$ of φ gives rise to a lift $[V] : J \to T\big(\mathit{Rot}(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})\big)$ of $[\varphi]$ given by $[V] = T\rho \circ V$. The next result, which is a fairly straightforward consequence of Theorem 4.2, characterizes the $[\varphi]$-parallel lifts $[V]$ of $[\varphi]$.

PROPOSITION 4.4. *Let $\varphi : J \to \mathcal{D}^k(\mathbb{S})$ be a C^2-curve and let V be a C^1-lift of φ. Define $u, v \in C(J; H^k(\mathbb{S})) \cap C^1(J; H^{k-1}(\mathbb{S}))$ by*

$$u(t) = \varphi_t(t) \circ \varphi(t)^{-1}, \quad v(t) = V(t) \circ \varphi(t)^{-1}.$$

Then $[V] = T\rho \circ V$ is $[\varphi]$-parallel if and only if u, v satisfy

$$v_{txx} = -\frac{3}{2}v_{xx}u_x - \frac{1}{2}v_x u_{xx} - v_{xxx}u, \qquad t \in J, \quad x \in \mathbb{S}. \tag{4.6}$$

The final theorem in this section says that $t \mapsto [\varphi(t)] : J \to \mathit{Rot}(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ is a geodesic if and only if $u = \varphi_t \circ \varphi^{-1}$ solves the Hunter–Saxton equation.

THEOREM 4.5. *Let $\varphi : J \to \mathcal{D}^k(\mathbb{S})$ be a C^2-curve and define $u : J \to H^k(\mathbb{S})$ by $u(t) = \varphi_t(t) \circ \varphi(t)^{-1}$ so that $u \in C(J; H^k(\mathbb{S})) \cap C^1(J; H^{k-1}(\mathbb{S}))$. Then $[\varphi]$ is a geodesic in $\mathit{Rot}(\mathbb{S})\backslash\mathcal{D}^k(\mathbb{S})$ if and only if u is a solution of the Hunter–Saxton equation*

$$u_{txx} = -2u_x u_{xx} - u u_{xxx}, \qquad t \in J,\ x \in \mathbb{S}. \tag{4.7}$$

Proof. $[\varphi]$ is a geodesic if and only if $[\varphi]_t = [\varphi_t]$ is $[\varphi]$-parallel. By Proposition 4.4 this occurs if and only if (4.6) holds with $u = v = \varphi_t \circ \varphi^{-1}$. □

5. Explicit formulas. In this section the method of characteristics is adopted to obtain explicit formulas for the geodesics; as a byproduct new explicit solutions of the periodic Hunter–Saxton equation drop out.

DEFINITION 5.1. *By a solution of the Hunter–Saxton equation with initial data $u_0 \in H^k(\mathbb{S})$, $k \geq 3$, we mean a function $u(t,x)$ with $u \in C([0,T); H^3(\mathbb{S})) \cap C^1([0,T); H^2(\mathbb{S}))$ for some maximal time of existence $T > 0$ such that $u(0) = u_0$ and*

$$u_{txx} = -2u_x u_{xx} - uu_{xxx}, \qquad t \in [0,T),\ x \in \mathbb{S}. \tag{5.1}$$

The next lemma is straightforward to prove.

LEMMA 5.2. *Let $J \subset \mathbb{R}$ be an open interval and let $u \in C(J; H^3(\mathbb{S})) \cap C^1(J; H^2(\mathbb{S}))$. The map*

$$F : (t,\psi) \mapsto u(t) \circ \psi : J \times \mathcal{D}^2(\mathbb{S}) \to H^2(\mathbb{S})$$

is C^1.

Now let $u_0 \in H^k(\mathbb{S})$ and suppose $u(t,x)$ is a solution of the Hunter–Saxton equation with initial data u_0. Integration of (5.1) from 0 to x for each fixed time t gives

$$u_{tx} = -\frac{1}{2}u_x^2 - uu_{xx} + c(t), \qquad t \in [0,T),\ x \in \mathbb{S}, \tag{5.2}$$

for some function $c : [0,T) \to \mathbb{R}$. Since $\int_{\mathbb{S}} u_{tx}(t,x)dx = 0$ for each $t \in [0,T)$, we get

$$\int_{\mathbb{S}} \left(-\frac{1}{2}u_x^2 - uu_{xx} + c(t) \right) dx = 0.$$

An integration by parts yields

$$c(t) = -\frac{1}{2}\int_{\mathbb{S}} u_x^2(t,x)dx.$$

Moreover, by (5.2),

$$\frac{1}{2}\frac{d}{dt}\int_{\mathbb{S}} u_x^2 dx = \int_{\mathbb{S}} u_x u_{tx} dx = -\int_{\mathbb{S}} \left(\frac{1}{2}u_x^3 + uu_x u_{xx} \right) dx = 0,$$

showing that $c(t) = -\frac{1}{2}\int_{\mathbb{S}} u_x^2(t,x)dx$ is a constant function. Assuming that u_0 is nontrivial, we may rescale u_0 so that $\int_{\mathbb{S}} u_{0x}^2 dx = 4$. Then (5.2) becomes

$$u_{tx} = -\frac{1}{2}u_x^2 - uu_{xx} - 2, \qquad t \in [0,T),\ x \in \mathbb{S}.$$

By Lemma 5.2 and the local existence and uniqueness theorem for differential equations in Banach spaces, there exists a unique map $\varphi \in C^1([0,T_1); \mathcal{D}^2(\mathbb{S}))$ such that $\varphi(0) = id$ and

$$\varphi_t(t) = u(t) \circ \varphi(t), \qquad t \in [0,T_1), \tag{5.3}$$

for some maximal existence time $T_1 > 0$. Since

$$(u_x \circ \varphi)_t = u_{tx} \circ \varphi + u_{xx} \circ \varphi \cdot \varphi_t = \big(u_{tx} + uu_{xx}\big) \circ \varphi,$$

this gives

$$(u_x \circ \varphi)_t = \left(-\frac{1}{2}u_x^2 - 2\right) \circ \varphi = -\frac{1}{2}(u_x \circ \varphi)^2 - 2, \qquad t \in [0, T_1),\ x \in \mathbb{S}.$$

Therefore, for a fixed $x \in \mathbb{S}$, the function $t \mapsto (u_x \circ \varphi)(t, x)$ solves the differential equation

$$\dot{z}(t) = -\frac{1}{2}(z(t)^2 + 4). \tag{5.4}$$

The general solution of (5.4) is

$$z(t) = 2\tan\left(\arctan\left(\frac{z(0)}{2}\right) - t\right).$$

As $(u_x \circ \varphi)(0, x) = u_{0x}(x)$ for $x \in \mathbb{S}$, we infer that

$$(u_x \circ \varphi)(t, x) = 2\tan\left(\arctan\left(\frac{u_{0x}(x)}{2}\right) - t\right), \qquad t \in [0, T_1),\ x \in \mathbb{S}. \tag{5.5}$$

Differentiation of (5.3) yields $\varphi_{tx} = u_x \circ \varphi \cdot \varphi_x$, so that, by (5.5),

$$\varphi_{tx}(t, x) = 2\tan\left(\arctan\left(\frac{u_{0x}(x)}{2}\right) - t\right)\varphi_x(t, x).$$

Using the fact that $\varphi_x(0, x) = 1$ for $x \in \mathbb{S}$, we get

$$\varphi_x(t, x) = \exp\left(2\int_0^t \tan\left(\arctan\left(\frac{u_{0x}(x)}{2}\right) - s\right)ds\right), \qquad t \in [0, T_1),\ x \in \mathbb{S}. \tag{5.6}$$

Since

$$2\int_0^t \tan\left(\arctan\left(\frac{u_{0x}(x)}{2}\right) - s\right)ds = \ln\left(\cos^2\left(\arctan\left(\frac{u_{0x}(x)}{2}\right) - t\right)\right) - C(x),$$

where

$$C(x) = \ln\left(\cos^2\left(\arctan\left(\frac{u_{0x}(x)}{2}\right)\right)\right),$$

equation (5.6) yields

$$\varphi_x(t, x) = \frac{\cos^2\left(\arctan\left(\frac{u_{0x}(x)}{2}\right) - t\right)}{\cos^2\left(\arctan\left(\frac{u_{0x}(x)}{2}\right)\right)}. \tag{5.7}$$

We rewrite this as

$$\varphi_x(t, x) = \left(\cos t + \frac{u_{0x}(x)}{2}\sin t\right)^2, \quad t \in [0, T_1),\ x \in \mathbb{S}. \tag{5.8}$$

Hence

$$\varphi(t, x) - \varphi(t, 0) = x\frac{1 + \cos 2t}{2} + \frac{1}{4}\int_0^x u_{0x}^2(y)dy\frac{1 - \cos 2t}{2} + \frac{u_0(x) - u_0(0)}{2}\sin 2t.$$

Since, by (2.4),

$$-\big(A^{-1}D_x(u_{0x}^2)\big)(x) = \int_0^x u_{0x}^2(y)dy - x\int_{\mathbb{S}} u_{0x}^2 dx = \int_0^x u_{0x}^2(y)dy - 4x,$$

we infer that, for $t \in [0, T_1)$ and $x \in \mathbb{S}$,

$$\varphi(t,x) - \varphi(t,0) = x - \frac{1}{8}\big(A^{-1}D_x(u_{0x}^2)\big)(x)\big(1-\cos 2t\big) + \frac{u_0(x)-u_0(0)}{2}\sin 2t. \tag{5.9}$$

The right-hand side of this equation is well-defined for all times $t < T^*$, where

$$T^* = \frac{\pi}{2} + \arctan\bigg(\frac{1}{2}\min_{x\in\mathbb{S}} u_{0x}(x)\bigg).$$

Indeed, it follows from (5.8) that T^* is the first time for which the right-hand side of (5.9) ceases to be a bijective map $\mathbb{S} \to \mathbb{S}$.

The invariance of (5.9) under the transformation $\varphi(t,x) \mapsto \varphi(t,x) + c(t)$ for an arbitrary function $c(t)$ corresponds to the invariance of the Hunter–Saxton equation under the transformation $u(t) \mapsto u(t, \cdot - c(t)) + c'(t)$. It follows that the geodesic $\varphi(t,x)$ can be extended to all times $t < T^*$ unless $\lim_{t\uparrow T} |\varphi(t,0)| = \infty$ for some $T < T^*$. This artificial blow-up at some $T < T^*$ can be avoided by requiring that $u_0(0) = 0$ and that φ be a curve in M^k; this fixes $\varphi(t,0) = 0$ at all times. We summarize what we have obtained in a theorem.

THEOREM 5.3. *Suppose $u_0 \in H^k(\mathbb{S})$ satisfies $\langle u_0, u_0\rangle_{id} = \int_{\mathbb{S}} u_{0x}^2 dx = 4$ and $u_0(0) = 0$. Let $\varphi : [0, T^*) \to M^k$ be the unique geodesic with $\varphi(0) = id$ and $\varphi_t(0) = u_0$ existing for some maximal time $T^* > 0$.*

Then

$$\varphi(t) = id - \frac{1}{8}\big(A^{-1}D_x(u_{0x}^2)\big)\big(1-\cos 2t\big) + \frac{u_0}{2}\sin 2t, \tag{5.10}$$

and T^* is the first time for which $\varphi(t) : \mathbb{S} \to \mathbb{S}$ ceases to be bijective given by

$$T^* = \frac{\pi}{2} + \arctan\bigg(\frac{1}{2}\min_{x\in\mathbb{S}} u_{0x}(x)\bigg) < \frac{\pi}{2}.$$

Moreover, defining $u \in C([0,T^*); \mathbf{E}^k) \cap C^1([0,T^*); \mathbf{E}^{k-1})$ by

$$u(t) = \bigg(-\frac{1}{4}\big(A^{-1}D_x(u_{0x}^2)\big)\sin 2t + u_0\cos 2t\bigg)\circ\varphi(t)^{-1},$$

the set of solutions of the Hunter–Saxton equation with initial data u_0 (see Definition 5.1) is exactly the set of maps

$$\big\{t \mapsto u(t, \cdot - c(t)) + c'(t)\big\} \subset C([0,T); H^k(\mathbb{S})) \cap C^1([0,T); H^{k-1}(\mathbb{S})),$$

where $T \le T^*$ is the maximal time of existence, $c : [0,T) \to \mathbb{R}$ is an arbitrary C^1-function with $c(0) = c'(0) = 0$, and, if $T < T^*$, then $|c(t)| \to \infty$ as $t \uparrow T < T^*$.

Remark. For nonconstant initial data u_0 the assumption $\int_{\mathbb{S}} u_{0x}^2 dx = 4$ is just a matter of scaling; it sets the speed of the geodesic to be 4. The case of a constant u_0 is degenerate as it means that the initial velocity of the geodesic vanishes. For the sake of completeness we note that if u_0 is constant the general solution of (1.1) is $u(t,x) \equiv \bar{u}(t)$, where $\bar{u} : [0,T) \to \mathbb{R}$ is a C^1-function of time with $\bar{u}(0) = u_0$.

Acknowledgments. The research presented in this paper was carried out while the author was a visitor at the Mittag-Leffler Institute in Stockholm, Sweden. The author also thanks the two referees for helpful comments on a first version of the manuscript.

ON THE SCHRÖDINGER EQUATION WITH DISSIPATIVE NONLINEARITIES OF DERIVATIVE TYPE*

NAKAO HAYASHI†, PAVEL I. NAUMKIN‡, AND HIDEAKI SUNAGAWA†

Abstract. We consider the cubic nonlinear Schrödinger equations of derivative type with small initial data. We present a structural condition on the nonlinear terms under which the corresponding Cauchy problem has a dissipative nature.

Key words. Schrödinger equation, dissipative nonlinearity, derivative coupling

AMS subject classifications. 35Q55, 35B40

DOI. 10.1137/070689103

1. Introduction.

We consider the initial value problem for the nonlinear Schrödinger equation of derivative type:

$$\begin{cases} i\partial_t u + \frac{1}{2}\partial_x^2 u = N(u, \partial_x u), & t > 0,\ x \in \mathbf{R}, \\ u(0,x) = u_0(x), & x \in \mathbf{R}, \end{cases} \tag{1.1}$$

where $i = \sqrt{-1}$, $\partial_t = \partial/\partial t$, $\partial_x = \partial/\partial x$, and u is a complex-valued unknown function. We will occasionally write u_x for $\partial_x u$, and $\overline{u}$ denotes the complex conjugate of u. The nonlinear term $N(u, u_x)$ is a cubic homogeneous polynomial in $(u, \overline{u}, u_x, \overline{u}_x)$ with complex coefficients, and it satisfies so-called gauge invariance, that is,

$$N(e^{i\theta}v, e^{i\theta}q) = e^{i\theta}N(v,q) \quad \text{for} \quad v, q \in \mathbf{C} \ \text{ and } \ \theta \in \mathbf{R}. \tag{1.2}$$

The aim of this paper is to present a structural condition on the nonlinear term N under which the corresponding forward Cauchy problem (1.1) has a dissipative nature. To explain the motivation, let us begin with the simplest case where N is independent of u_x, i.e., $N = \lambda|u|^2 u$ with $\lambda \in \mathbf{C}$. Then it is easy to see that

$$\|u(t)\|_{L^2}^2 - 2\,\mathrm{Im}\,\lambda \int_0^t \|u(\tau)\|_{L^4}^4\, d\tau = \|u_0\|_{L^2}^2, \tag{1.3}$$

which suggests a dissipative structure if $\mathrm{Im}\,\lambda < 0$. In fact, it is proved in [18] that the solution decays like $O((t\log t)^{-1/2})$ in L_x^∞ as $t \to +\infty$ if $\mathrm{Im}\,\lambda < 0$ and u_0 is small enough. Since the nontrivial free solution (i.e., the solution to (1.1) for $N \equiv 0$, $u_0 \neq 0$) only decays like $O(t^{-1/2})$, this gain of additional logarithmic time decay reflects a dissipative character. Now we turn our attention to the general gauge-invariant cubic nonlinear terms involving both u and u_x. Note that we cannot expect the conservation law like (1.3) anymore. However, as we shall show below, similar

time decay is still valid if $\sup_{\xi\in\mathbf{R}} \operatorname{Im} N(1,i\xi) < 0$. It gives an answer to one of the questions left unsolved in the previous work [20].

Before stating our result, we introduce function spaces. For $s,\nu \ge 0$, let $H^{s,\nu}$ be the weighted Sobolev space given by $\{\phi \in L^2 : \|\phi\|_{H^{s,\nu}} = \|\langle x\rangle^\nu \langle i\partial_x\rangle^s \phi\|_{L^2} < \infty\}$, where $\langle x\rangle = (1+x^2)^{1/2}$. In particular we set $H^s = H^{s,0}$, which is typically an L^2-based Sobolev space of order s. The main result is as follows.

THEOREM 1.1. *Suppose that N satisfies*

$$\operatorname{Im} N(1,i\xi) \le 0 \quad \textit{for} \quad \xi \in \mathbf{R}. \tag{1.4}$$

Let $u_0 \in H^{2,1}\cap H^3$, and $\varepsilon = \|u_0\|_{H^{2,1}} + \|u_0\|_{H^3}$ is sufficiently small. Then (1.1) admits a unique global solution $u \in C([0,\infty); H^{2,1}\cap H^3)$. Moreover, the following asymptotic expression is valid as $t \to +\infty$ uniformly in $x \in \mathbf{R}$:

$$\begin{aligned} u(t,x) &= \frac{a(\frac{x}{t})\exp\Big\{ i\frac{x^2}{2t} - i|a(\frac{x}{t})|^2 \operatorname{Re} N(1,i\frac{x}{t}) \int_0^{\log t} \frac{d\sigma}{1-2\operatorname{Im} N(1,i\frac{x}{t})(|a(\frac{x}{t})|^2\sigma + b(\frac{x}{t}))} \Big\}}{\sqrt{t}\sqrt{1-2\operatorname{Im} N(1,i\frac{x}{t})\big(|a(\frac{x}{t})|^2\log t + b(\frac{x}{t})\big)}} \\ &\quad + O\big(t^{-3/4+\mu}\big), \end{aligned} \tag{1.5}$$

where $\mu > 0$ is an arbitrarily small constant, and $a(\xi)$, $b(\xi)$ are complex-valued continuous functions of $\xi \in \mathbf{R}$ which satisfy $|a(\xi)| \le C\varepsilon\langle\xi\rangle^{-2}$, $|b(\xi)| \le C\varepsilon^4\langle\xi\rangle^{-4}$ with some positive constant C.

Remark 1.1. As an immediate consequence of (1.5), we can see that

$$\|u(t)\|_{L^\infty} = O((t\log t)^{-1/2}) \quad \text{as} \quad t \to +\infty$$

if $\sup_{\xi\in\mathbf{R}} \operatorname{Im} N(1,i\xi) < 0$. Moreover, as we shall see in Remark 4.1 below, the L^2 norm of $u(t)$ also decays like $O((\log t)^{-1/2})$. Therefore, by interpolation, we obtain

$$\|u(t)\|_{L^p} = O\big(t^{-(1/2-1/p)}(\log t)^{-1/2}\big) \quad \text{as} \quad t \to +\infty$$

for all $p \in [2,\infty]$.

Remark 1.2. Our result can be also viewed as an extension of [9] (see also [3], [2], [4], [10], [13], [15], [16], [17], [18], and [21]) because (1.5) is reduced to

$$u(t,x) = \frac{1}{\sqrt{t}} a(x/t) e^{i\left(x^2/(2t) - |a(x/t)|^2 \operatorname{Re} N(1,ix/t)\log t\right)} + O\big(t^{-3/4+\mu}\big) \quad \text{as} \quad t \to +\infty$$

when $\operatorname{Im} N(1,i\xi) \equiv 0$. An example of the nonlinearity which was not considered previously but satisfies (1.4) is $N = \alpha\bar{u}u_x^2$ with $\operatorname{Im}\alpha > 0$.

Remark 1.3. When $\operatorname{Im} N(1,i\xi_0) > 0$ for some $\xi_0 \in \mathbf{R}$, the authors do not know any global existence or nonexistence results for (1.1). However, in view of the denominator of the leading term of (1.5), it is quite reasonable to expect that small amplitude solutions can blow up in finite time if condition (1.4) is violated. Concerning the lifespan T_ε of the solution for (1.1) with $u_0(x) = \varepsilon\varphi(x)$, the following explicit lower bound is obtained in [20]:

$$\liminf_{\varepsilon\downarrow 0} \varepsilon^2 \log T_\varepsilon \ge \frac{1}{\sup_{\xi\in\mathbf{R}} \big(2|\hat{\varphi}(\xi)|^2 \operatorname{Im} N(1,i\xi)\big)},$$

where $\hat{\varphi}$ denotes the Fourier transform of φ. It may be an interesting open problem to consider whether the corresponding upper estimate holds or not.

Remark 1.4. When we put

$$A(s,\xi)=\frac{a(\xi)\exp\Big\{-i|a(\xi)|^2\,\mathrm{Re}\,N(1,i\xi)\int_0^s\frac{d\sigma}{1-2\,\mathrm{Im}\,N(1,i\xi)(|a(\xi)|^2\sigma+b(\xi))}\Big\}}{\sqrt{1-2\,\mathrm{Im}\,N(1,i\xi)(|a(\xi)|^2s+b(\xi))}},$$

the asymptotic expression (1.5) can be interpreted as

$$u(t,x)\overset{t\to\infty}{\sim}\frac{e^{ix^2/(2t)}}{\sqrt{t}}A\Big(\log t,\frac{x}{t}\Big);\quad i\partial_sA=N(1,i\xi)|A|^2A.$$

This tells us that asymptotic behavior of the solution for (1.1) is characterized by that of the solution for the simpler ordinary differential equation. At the level of the reduced equation, the dissipative nature is transparent via the identity

$$\partial_s\big(|A(s,\xi)|^2\big)=2\,\mathrm{Im}\,N(1,i\xi)|A(s,\xi)|^4.$$

Note that analogous results have been obtained in [19] for nonlinear Klein–Gordon equations and in [14] for nonlinear wave equations.

The rest of this paper is organized as follows: In the next section, we recall several useful identities and inequalities. Section 3 is devoted to getting an a priori estimate, from which global existence follows immediately. After that, we will derive the large time asymptotics of $u(t)$ in section 4 by applying a lemma on ordinary differential equations.

2. Preliminaries. We collect here several identities and inequalities which are useful in the proof of our main theorem. In what follows, we will denote several positive constants by the same letter, C, which is possibly different line by line.

First we put $\mathcal{J}=\mathcal{J}(t)=x+it\partial_x$. It is well known that

$$[\partial_x,\mathcal{J}]=1\quad\text{and}\quad\Big[i\partial_t+\frac{1}{2}\partial_x^2,\mathcal{J}\Big]=0,\tag{2.1}$$

where $[\cdot,\cdot]$ denotes the commutator, i.e., $[\mathcal{A},\mathcal{B}]=\mathcal{A}\mathcal{B}-\mathcal{B}\mathcal{A}$ for linear operators $\mathcal{A}$ and $\mathcal{B}$. Also we have

$$\partial_x(\phi\overline{\psi})=\frac{1}{it}\Big\{(\mathcal{J}\phi)\overline{\psi}-\phi(\overline{\mathcal{J}\psi})\Big\},\tag{2.2}$$

$$\mathcal{J}\big(\theta\phi\overline{\psi}\big)=(\mathcal{J}\theta)\phi\overline{\psi}+\theta(\mathcal{J}\phi)\overline{\psi}-\theta\phi(\overline{\mathcal{J}\psi})\tag{2.3}$$

for smooth functions θ, ϕ, and ψ. Next we denote by $\mathcal{U}=\mathcal{U}(t)$ the free Schrödinger evolution group defined by

$$\big(\mathcal{U}\phi\big)(x)=\frac{e^{-i\pi/4}}{\sqrt{2\pi t}}\int_{\mathbf{R}}e^{i(x-y)^2/(2t)}\phi(y)\,dy.$$

From the relation $\mathcal{J}=\mathcal{U}x\mathcal{U}^{-1}$, we see that

$$\|\mathcal{F}\mathcal{U}^{-1}\phi\|_{H^1_\xi}\le C\|(1+|x|)\mathcal{U}^{-1}\phi\|_{L^2_x}\le C\big(\|\phi\|_{L^2_x}+\|\mathcal{J}\phi\|_{L^2_x}\big),\tag{2.4}$$

where

$$\big(\mathcal{F}\phi\big)(\xi)=\hat{\phi}(\xi)=\frac{1}{\sqrt{2\pi}}\int_{\mathbf{R}}e^{-iy\xi}\phi(y)\,dy.$$

It is also well known that $\mathcal{U}$ is decomposed into $\mathcal{MDFM}$, where

$$\big(\mathcal{M}\phi\big)(x) = e^{ix^2/(2t)}\phi(x),$$
$$\big(\mathcal{D}\phi\big)(x) = \frac{e^{-i\pi/4}}{\sqrt{t}}\phi\Big(\frac{x}{t}\Big).$$

With this notation, we set $\mathcal{W} = \mathcal{FMF}^{-1}$ so that $\mathcal{U} = \mathcal{MDWF}$. It follows from the inequalities $\|\phi\|_{L^\infty} \le C\|\phi\|_{L^2}^{1/2}\|\partial_x\phi\|_{L^2}^{1/2}$ and $|e^{ix^2/(2t)} - 1| \le Ct^{-1/2}|x|$ that

$$\|(\mathcal{W}-1)\phi\|_{L^\infty} \le Ct^{-1/4}\|\phi\|_{H^1}, \quad \|(\mathcal{W}^{-1}-1)\phi\|_{L^\infty} \le Ct^{-1/4}\|\phi\|_{H^1}. \tag{2.5}$$

Consequently we have

$$\begin{aligned}\|\phi - \mathcal{MDFU}^{-1}\phi\|_{L^\infty} &= \|\mathcal{MD}(\mathcal{W}-1)\mathcal{FU}^{-1}\phi\|_{L^\infty}\\ &= t^{-1/2}\|(\mathcal{W}-1)\mathcal{FU}^{-1}\phi\|_{L^\infty}\\ &\le Ct^{-3/4}\|\mathcal{FU}^{-1}\phi\|_{H^1}\\ &\le Ct^{-3/4}\big(\|\phi\|_{L^2} + \|\mathcal{J}\phi\|_{L^2}\big)\end{aligned} \tag{2.6}$$

and

$$\begin{aligned}\|\phi\|_{L^\infty} &\le \|\mathcal{MDFU}^{-1}\phi\|_{L^\infty} + \|\phi - \mathcal{MDFU}^{-1}\phi\|_{L^\infty}\\ &\le t^{-1/2}\|\mathcal{FU}^{-1}\phi\|_{L^\infty} + Ct^{-3/4}\big(\|\phi\|_{L^2} + \|\mathcal{J}\phi\|_{L^2}\big).\end{aligned} \tag{2.7}$$

Also it follows from the inequality $\|\mathcal{W}^{-1}\phi\|_{L^\infty} \le Ct^{1/2}\|\phi\|_{L^1}$ that

$$\begin{aligned}\|\mathcal{FU}^{-1}(\theta\phi\overline{\psi})\|_{L^\infty} &= \frac{1}{t}\Big\|\mathcal{W}^{-1}\Big\{(\mathcal{WFU}^{-1}\theta)(\mathcal{WFU}^{-1}\phi)\overline{(\mathcal{WFU}^{-1}\psi)}\Big\}\Big\|_{L^\infty}\\ &\le \frac{C}{t^{1/2}}\big\|(\mathcal{WFU}^{-1}\theta)(\mathcal{WFU}^{-1}\phi)(\mathcal{WFU}^{-1}\psi)\big\|_{L^1}\\ &\le \frac{C}{t^{1/2}}\|\theta\|_{L^2}\|\phi\|_{L^2}\big\|\mathcal{WFU}^{-1}\psi\big\|_{L^\infty}\\ &\le C\|\theta\|_{L^2}\|\phi\|_{L^2}\Big\{\|\psi\|_{L^\infty} + t^{-3/4}\big(\|\psi\|_{L^2} + \|\mathcal{J}\psi\|_{L^2}\big)\Big\}.\end{aligned} \tag{2.8}$$

3. A priori estimates. This section is devoted to getting suitable a priori estimate for the solution of (1.1). Since the local existence is well known (see, e.g., [1], [11], [13]), we can deduce global existence from this estimate. From now on, let $u(t)$ be the solution of (1.1) for $t \in [0,T]$ with some $T > 0$ and define

$$E_\delta(T) = \sup_{0\le t\le T}\left\{(1+t)^{-\delta}\sum_{j=0}^{1}\|\mathcal{J}^j u(t)\|_{H^{3-j}} + (1+t)^{1/2}\|u(t)\|_{W^{2,\infty}}\right\}$$

with $\delta \in (0, 1/8]$ fixed. Here and later on as well, $W^{k,p}$ denotes an L^p-based Sobolev space of order k. What we are going to show is the following.

LEMMA 3.1. *Let $K \ge 1$ and assume $E_\delta(T) \le K\varepsilon$, where $\varepsilon = \|u_0\|_{H^{2,1}} + \|u_0\|_{H^3}$. Then we have*

$$E_\delta(T) \le C_1 e^{C_2K^2\varepsilon^2}(1 + K^3\varepsilon^2 + K^5\varepsilon^4)\varepsilon,$$

where C_1, C_2 are positive constants independent of ε, K, and T, but possibly dependent on δ.

Once this lemma is established, global existence follows immediately. Indeed, when we put $\varepsilon_0 = K^{-2}$ and choose K so large that $C_1 e^{C_2 K^{-2}}(1+K^{-1}+K^{-3}) \le K/2$, it follows from the above lemma that $E_\delta(T) \le K\varepsilon$ implies $E_\delta(T) \le K\varepsilon/2$ for any $\varepsilon \in (0, \varepsilon_0]$. Then, by the continuity argument (see, e.g., [12]), we see that $E_\delta(T) \le K\varepsilon$ must hold as long as the solution exists. Therefore the local solution can be extended to the global one.

Now, we turn to the proof of Lemma 3.1. It will be divided into two parts, i.e., L^∞ and L^2 estimates. The argument below is a refinement of section 2 of [9].

3.1. L^∞ estimates. In this part, we consider the estimate of $(1+t)^{1/2}\|u(t)\|_{W^{2,\infty}}$. We set

$$\alpha(t,\xi) = \mathcal{F}\big(\mathcal{U}^{-1}u(t)\big)(\xi)$$

and $\alpha_k(t,\xi) = (i\xi)^k\alpha(t,\xi)$ so that $\partial_x^k u = \mathcal{M}\mathcal{D}\mathcal{W}\alpha_k$. Using the inequality (2.7) for $t \in [1,T]$ and the Sobolev imbedding for $t \in [0,1]$, we can see that the problem is reduced to getting the bound of $\|\alpha_k(t)\|_{L^\infty}$ for $t \in [1,T]$, $0 \le k \le 2$, under the assumption $E_\delta(T) \le K\varepsilon$. More precisely, our objective here is to obtain the following estimate:

$$\sup_{t\in[1,T]} \|\alpha_k(t)\|_{L^\infty} \le C(\varepsilon + K^3\varepsilon^3), \qquad k = 0,1,2.$$

Let us first consider the case of $k = 0$. Applying the operator $\mathcal{F}\mathcal{U}^{-1}$ to the equation, we have

$$\begin{aligned} i\partial_t\alpha &= \mathcal{F}\mathcal{U}^{-1}N(u,u_x) \\ &= \mathcal{W}^{-1}\mathcal{D}^{-1}\mathcal{M}^{-1}N(\mathcal{M}\mathcal{D}\mathcal{W}\alpha, \mathcal{M}\mathcal{D}\mathcal{W}\alpha_1) \\ &= \frac{1}{t}\mathcal{W}^{-1}N(\mathcal{W}\alpha, \mathcal{W}\alpha_1) \\ &= \frac{1}{t}N(1,i\xi)|\alpha|^2\alpha + \rho_0, \end{aligned}$$

where

$$\rho_0 = \frac{1}{t}\Big\{\mathcal{W}^{-1}N(\mathcal{W}\alpha, \mathcal{W}\alpha_1) - N(\alpha,\alpha_1)\Big\}.$$

Observe that (1.4) implies

$$\begin{aligned} \partial_t\big(|\alpha|^2\big) &= 2\,\mathrm{Im}\big(\overline{\alpha}\, i\partial_t\alpha\big) \\ &= \frac{2}{t}\,\mathrm{Im}N(1,i\xi)|\alpha|^4 + 2\,\mathrm{Im}\big(\overline{\alpha}\rho_0\big) \\ &\le 2|\alpha||\rho_0| \end{aligned}$$

and that (2.5) yields

$$\begin{aligned} \|\rho_0\|_{L^\infty} &\le t^{-1}\|(\mathcal{W}^{-1}-1)N(\mathcal{W}\alpha,\mathcal{W}\alpha_1)\|_{L^\infty} \\ &\quad + t^{-1}\|N(\mathcal{W}\alpha,\mathcal{W}\alpha_1) - N(\alpha,\alpha_1)\|_{L^\infty} \\ &\le CK^3\varepsilon^3 t^{-5/4}. \end{aligned} \tag{3.1}$$

So we deduce that

$$\|\alpha(t)\|_{L^\infty} \le \|\alpha(1)\|_{L^\infty} + \int_1^t \|\rho_0(\tau)\|_{L^\infty} d\tau \le C\varepsilon + CK^3\varepsilon^3.$$

Next we turn to the case of $k = 1, 2$. We split $N(u, u_x)$ into $g_0(u, u_x)u + g_1(u, u_x)u_x$, where $g_0(u, q) = \lambda_1|u|^2 + \lambda_2 u\overline{q} + \lambda_3|q|^2$, $g_1(u, q) = \lambda_4|u|^2 + \lambda_5 q\overline{u} + \lambda_6|q|^2$ with complex constants $\lambda_1, \dots, \lambda_6$, and we set

$$h_k = \partial_x^k\big(N(u, u_x)\big) - \sum_{j=0}^{1} g_j(u, u_x)\partial_x^{j+k}u$$

so that

$$i\partial_t\alpha_k = \mathcal{F}\mathcal{U}^{-1}\sum_{j=0}^{1} g_j(u, u_x)\partial_x^{j+k}u + \mathcal{F}\mathcal{U}^{-1}h_k.$$

To find out the leading term of the right-hand side, we analyze the action of $\mathcal{F}\mathcal{U}^{-1}$ to $g_j(u, u_x)\partial_x^{j+k}u$ carefully. For $j = 0$, we have

$$\begin{aligned}\mathcal{F}\mathcal{U}^{-1}\Big(g_0(u, u_x)\partial_x^k u\Big) &= \mathcal{W}^{-1}\mathcal{D}^{-1}\mathcal{M}^{-1}\Big(g_0(\mathcal{M}\mathcal{D}\mathcal{W}\alpha, \mathcal{M}\mathcal{D}\mathcal{W}\alpha_1)\mathcal{M}\mathcal{D}\mathcal{W}\alpha_k\Big)\\ &= \frac{1}{t}\mathcal{W}^{-1}\Big(g_0(\mathcal{W}\alpha, \mathcal{W}\alpha_1)\mathcal{W}\alpha_k\Big)\\ &= \frac{1}{t}g_0(\alpha, \alpha_1)\alpha_k + \sigma_k,\end{aligned}$$

where

$$\sigma_k = \frac{1}{t}\Big\{\mathcal{W}^{-1}\big(g_0(\mathcal{W}\alpha, \mathcal{W}\alpha_1)\mathcal{W}\alpha_k\big) - g_0(\alpha, \alpha_1)\alpha_k\Big\}.$$

For $j = 1$, let us introduce

$$\tilde{h}_k = g_1(u, u_x)\partial_x^{1+k}u + (\lambda_4 u\overline{u}_x + \lambda_5|u_x|^2 + \lambda_6 u_x\overline{u}_{xx})\partial_x^k u.$$

Then, noting the relation $\lambda_4\alpha\overline{\alpha_1} + \lambda_5|\alpha_1|^2 + \lambda_6\alpha_1\overline{\alpha_2} = -i\xi g_1(1, i\xi)|\alpha|^2$, we see that

$$\begin{aligned}&\mathcal{F}\mathcal{U}^{-1}\Big(g_1(u, u_x)\partial_x^{1+k}u\Big)\\ &= -\mathcal{F}\mathcal{U}^{-1}\big\{(\lambda_4 u\overline{u}_x + \lambda_5|u_x|^2 + \lambda_6 u_x\overline{u}_{xx})\partial_x^k u\big\} + \mathcal{F}\mathcal{U}^{-1}\tilde{h}_k\\ &= -\frac{1}{t}\mathcal{W}^{-1}\Big\{\big(\lambda_4(\mathcal{W}\alpha)(\overline{\mathcal{W}\alpha_1}) + \lambda_5|\mathcal{W}\alpha_1|^2 + \lambda_6(\mathcal{W}\alpha_1)(\overline{\mathcal{W}\alpha_2})\big)\mathcal{W}\alpha_k\Big\} + \mathcal{F}\mathcal{U}^{-1}\tilde{h}_k\\ &= -\frac{1}{t}(\lambda_4\alpha\overline{\alpha_1} + \lambda_5|\alpha_1|^2 + \lambda_6\alpha_1\overline{\alpha_2})\alpha_k + \tilde{\sigma}_k + \mathcal{F}\mathcal{U}^{-1}\tilde{h}_k\\ &= \frac{1}{t}i\xi g_1(1, i\xi)|\alpha|^2\alpha_k + \tilde{\sigma}_k + \mathcal{F}\mathcal{U}^{-1}\tilde{h}_k,\end{aligned}$$

where

$$\begin{aligned}\tilde{\sigma}_k = &-\frac{\lambda_4}{t}\Big\{\mathcal{W}^{-1}\big((\mathcal{W}\alpha)(\overline{\mathcal{W}\alpha_1})\mathcal{W}\alpha_k\big) - (\alpha\overline{\alpha_1})\alpha_k\Big\}\\ &-\frac{\lambda_5}{t}\Big\{\mathcal{W}^{-1}\Big(|\mathcal{W}\alpha_1|^2\mathcal{W}\alpha_k\Big) - |\alpha_1|^2\alpha_k\Big\}\\ &-\frac{\lambda_6}{t}\Big\{\mathcal{W}^{-1}\big((\mathcal{W}\alpha_1)(\overline{\mathcal{W}\alpha_2})\mathcal{W}\alpha_k\big) - \alpha_1\overline{\alpha_2}\alpha_k\Big\}.\end{aligned}$$

Summing up, we have

$$\begin{aligned} i\partial_t\alpha_k &= \big(g_0(1,i\xi)+i\xi g_1(1,i\xi)\big)|\alpha|^2\alpha_k+\sigma_k+\tilde\sigma_k+\mathcal{FU}^{-1}(h_k+\tilde h_k)\\ &= N(1,i\xi)|\alpha|^2\alpha_k+\rho_k, \end{aligned}$$

where $\rho_k=\sigma_k+\tilde\sigma_k+\mathcal{FU}^{-1}(h_k+\tilde h_k)$. Thus we deduce as in the previous case that

$$\|\alpha_k(t)\|_{L^\infty}\le\|\alpha_k(1)\|_{L^\infty}+\int_1^t\|\rho_k(\tau)\|_{L^\infty}\,d\tau\le C\varepsilon+CK^3\varepsilon^3,$$

provided that the estimate $\|\rho_k\|_{L^\infty}\le CK^3\varepsilon^3t^{-5/4}$ is verified. So the remaining task is to check this for $k=1,2$. In order to estimate $\|\mathcal{FU}^{-1}(h_k+\tilde h_k)\|_{L^\infty}$, we rewrite h_k as

$$\sum_{j=0}^1\sum_{l=1}^k\begin{pmatrix}k\\ l\end{pmatrix}\partial_x^{l-1}\Big(\partial_x\big(g_j(u,u_x)\big)\Big)\partial_x^{j+k-l}u$$

and apply (2.2) to $\partial_x\big(g_j(u,u_x)\big)$. Also we express $\tilde h_k$ as

$$\lambda_4u\partial_x\big(\overline{u}\partial_x^ku\big)+\lambda_5u_x\partial_x\big(\overline{u}\partial_x^ku\big)+\lambda_6u_x\partial_x\big(\overline{u}_x\partial_x^ku\big)$$

and use (2.2). Then we see that $h_k+\tilde h_k$ can be written as a linear combination of

$$\frac1t\big(\mathcal{J}\partial_x^{k_1}u\big)\big(\partial_x^{k_2}u\big)\overline{\big(\partial_x^{k_3}u\big)}\quad\text{or}\quad\frac1t\overline{\big(\mathcal{J}\partial_x^{k_1}u\big)}\big(\partial_x^{k_2}u\big)\big(\partial_x^{k_3}u\big)$$

with $k_1,k_2,k_3\le2$. Hence it follows from (2.8) that

$$\|\mathcal{FU}^{-1}(h_k+\tilde h_k)\|_{L^\infty}\le CK^3\varepsilon^3t^{-3/2+2\delta}. \tag{3.2}$$

On the other hand, we deduce as the derivation of (3.1) that

$$\|\sigma_k+\tilde\sigma_k\|_{L^\infty}\le CK^3\varepsilon^3t^{-5/4}. \tag{3.3}$$

From (3.2) and (3.3), it follows that

$$\|\rho_k\|_{L^\infty}\le CK^3\varepsilon^3t^{-5/4}+CK^3\varepsilon^3t^{-3/2+2\delta}\le CK^3\varepsilon^3t^{-5/4} \tag{3.4}$$

for $k=1,2$, as desired.

3.2. L^2 estimates. In the remainder of this section, we consider the bound of $(1+t)^{-\delta}\sum_{j=0}^1\|\mathcal{J}^ju(t)\|_{H^{3-j}}$. It is enough to show that

$$\sum_{j=0}^1\|\mathcal{J}^ju(t)\|_{L^2}\le C\varepsilon+CK^3\varepsilon^3(1+t)^\delta \tag{3.5}$$

and

$$\sum_{j=0}^1\|\partial_x^{3-j}\mathcal{J}^ju(t)\|_{L^2}\le Ce^{CK^2\varepsilon^2}(\varepsilon+K^3\varepsilon^3+K^5\varepsilon^5)(1+t)^\delta \tag{3.6}$$

for $t\in[0,T]$ under the assumption $E_\delta(T)\le K\varepsilon$.

First we consider the easier estimate (3.5). It follows from the standard energy method that

$$\frac{d}{dt}\|u(t)\|_{L^2} \le C\|u\|^2_{W^{1,\infty}}\|u\|_{H^1} \le CK^3\varepsilon^3(1+t)^{-1+\delta}.$$

Also, when we remember (2.1) and (2.3), we see that

$$\begin{aligned}&\left(i\partial_t + \frac{1}{2}\partial_x^2\right)\mathcal{J}u\\ &= \frac{\partial N}{\partial u}(u,u_x)\mathcal{J}u - \frac{\partial N}{\partial \overline{u}}(u,u_x)\overline{\mathcal{J}u} + \frac{\partial N}{\partial q}(u,u_x)\mathcal{J}\partial_x u - \frac{\partial N}{\partial \overline{q}}(u,u_x)\overline{\mathcal{J}\partial_x u},\end{aligned}$$

where the variable q is responsible for u_x, and $\partial/\partial u$, $\partial/\partial\overline{u}$, $\partial/\partial q$, $\partial/\partial\overline{q}$ are defined by

$$\begin{aligned}\frac{\partial}{\partial u} &= \frac{1}{2}\left(\frac{\partial}{\partial \operatorname{Re} u} - i\frac{\partial}{\partial \operatorname{Im} u}\right), \quad \frac{\partial}{\partial \overline{u}} = \frac{1}{2}\left(\frac{\partial}{\partial \operatorname{Re} u} + i\frac{\partial}{\partial \operatorname{Im} u}\right),\\ \frac{\partial}{\partial q} &= \frac{1}{2}\left(\frac{\partial}{\partial \operatorname{Re} q} - i\frac{\partial}{\partial \operatorname{Im} q}\right), \quad \frac{\partial}{\partial \overline{q}} = \frac{1}{2}\left(\frac{\partial}{\partial \operatorname{Re} q} + i\frac{\partial}{\partial \operatorname{Im} q}\right),\end{aligned}$$

respectively. Then the energy method again implies

$$\frac{d}{dt}\|\mathcal{J}u(t)\|_{L^2} \le C\|u\|^2_{W^{1,\infty}}(\|u\|_{H^1} + \|\mathcal{J}u\|_{H^1}) \le CK^3\varepsilon^3(1+t)^{-1+\delta},$$

which gives us (3.5).

Next we consider (3.6). To obtain this estimate, we use the gauge transformation technique since the standard energy estimate may cause a derivative loss, as we have just seen. The following energy inequality is established in section 2 of [13] (see also [1] and [11]).

LEMMA 3.2. *Let $\psi(t,x)$ be a smooth function satisfying*

$$i\partial_t\psi + \frac{1}{2}\partial_x^2\psi + b_1(t,x)\partial_x\psi + b_2(t,x)\partial_x\overline{\psi} = f(t,x)$$

for $(t,x) \in [0,T]\times\mathbf{R}$ with some smooth functions $b_1(t,x)$, $b_2(t,x)$, $f(t,x)$ and some $T>0$. Then we have

$$\frac{d}{dt}\|e^{P(t,\cdot)}\psi(t,\cdot)\|_{L^2} \le CB(t)\|e^{P(t,\cdot)}\psi(t,\cdot)\|_{L^2} + \|e^{P(t,\cdot)}f(t,\cdot)\|_{L^2}$$

for $t\in[0,T]$, where

$$P(t,x) = \int_{-\infty}^{x} \operatorname{Re} b_1(t,y)\,dy, \tag{3.7}$$

$$B(t) = \sum_{k=1}^{2}\left(\|\partial_x b_k(t,\cdot)\|_{L^\infty} + \|b_k(t,\cdot)\|^2_{L^\infty}\right) + \sup_{x\in\mathbf{R}}\left|\int_{-\infty}^{x}\partial_t b_1(t,y)\,dy\right|. \tag{3.8}$$

Since $\partial_x^{3-j}\mathcal{J}^j u$ satisfies

$$\begin{aligned}&\left(i\partial_t + \frac{1}{2}\partial_x^2\right)(\partial_x^{3-j}\mathcal{J}^j u)\\ &= \frac{\partial N}{\partial q}(u,u_x)\partial_x(\partial_x^{3-j}\mathcal{J}^j u) + (-1)^j\frac{\partial N}{\partial \overline{q}}(u,u_x)\partial_x(\overline{\partial_x^{3-j}\mathcal{J}^j u}) + R_j\end{aligned}$$

with

$$\|R_j\|_{L^2} \le CK^3\varepsilon^3(1+t)^{-1+\delta} \tag{3.9}$$

for $j = 0, 1$, we can apply Lemma 3.2 to obtain

$$\frac{d}{dt}\|e^{P(t)}\partial_x^{3-j}\mathcal{J}^j u(t)\|_{L^2} \le CB(t)\|e^{P(t)}\partial_x^{3-j}\mathcal{J}^j u(t)\|_{L^2} + \|e^{P(t)}R_j(t)\|_{L^2}, \tag{3.10}$$

where $P(t,x)$ and $B(t)$ are given by (3.7) and (3.8) with

$$b_1 = -\frac{\partial N}{\partial q}(u, u_x), \quad b_2 = (-1)^{j+1}\frac{\partial N}{\partial \overline{q}}(u, u_x).$$

Note that

$$\begin{aligned}
\|u(t)\|_{H^1_x} &= \|\langle\xi\rangle\mathcal{F}\mathcal{U}^{-1}u(t)\|_{L^2_\xi} \\
&= \Big\|\langle\xi\rangle^{-1}\big(\alpha(t) + \xi^2\alpha(t)\big)\Big\|_{L^2_\xi} \\
&\le \left(\int_{-\infty}^{\infty}\frac{d\xi}{1+\xi^2}\right)^{1/2}\big(\|\alpha(t)\|_{L^\infty_\xi} + \|\alpha_2(t)\|_{L^\infty_\xi}\big) \\
&\le CK\varepsilon,
\end{aligned}$$

whence

$$e^{\pm P(t,x)} \le e^{C\|u(t)\|^2_{H^1}} \le e^{CK^2\varepsilon^2}. \tag{3.11}$$

As for the estimate of $B(t)$, we observe that the identity

$$\partial_t\big(\phi\overline{\psi}\big) = -\frac{i}{2}\partial_x\big(\phi\overline{\psi_x} - \phi_x\overline{\psi}\big) + i\phi\overline{\left(i\partial_t + \frac{1}{2}\partial_x^2\right)\psi} - i\overline{\psi}\left(i\partial_t + \frac{1}{2}\partial_x^2\right)\phi$$

adapted to $b_1 = \sum_{j,k=0}^1 \lambda_{jk}(\partial_x^j u)\overline{(\partial_x^k u)}$. Then we have

$$\begin{aligned}
B(t) &\le C\|u\|^2_{W^{2,\infty}} + C\|u\|^4_{W^{1,\infty}} + C\sum_{j,k=0}^{1}\int_{\mathbf{R}}|\partial_x^j u|\,|\partial_x^k N(u,u_x)|\,dx \\
&\le C\|u\|^2_{W^{2,\infty}} + C\|u\|^4_{W^{1,\infty}} + C\|u\|^2_{W^{2,\infty}}\|u\|^2_{H^1} \\
&\le C(K^2\varepsilon^2 + K^4\varepsilon^4)(1+t)^{-1}.
\end{aligned} \tag{3.12}$$

By (3.9)–(3.12) we obtain

$$\begin{aligned}
\frac{d}{dt}\|e^{P(t)}\partial_x^{3-j}\mathcal{J}^j u(t)\|_{L^2} &\le C(K^2\varepsilon^2 + K^4\varepsilon^4)(1+t)^{-1}e^{CK^2\varepsilon^2}\|\partial_x^{3-j}\mathcal{J}^j u(t,\cdot)\|_{L^2} \\
&\quad + Ce^{CK^2\varepsilon^2}K^3\varepsilon^3(1+t)^{-1+\delta} \\
&\le Ce^{CK^2\varepsilon^2}(K^3\varepsilon^3 + K^5\varepsilon^5)(1+t)^{-1+\delta},
\end{aligned}$$

whence

$$\sum_{j=0}^{1}\|\partial_x^{3-j}\mathcal{J}^j u(t)\|_{L^2} \le e^{CK^2\varepsilon^2}\sum_{j=0}^{1}\|e^{P(t)}\partial_x^{3-j}\mathcal{J}^j u(t)\|_{L^2}$$
$$\le e^{CK^2\varepsilon^2}\left\{C\varepsilon + Ce^{CK^2\varepsilon^2}(K^3\varepsilon^3+K^5\varepsilon^5)\int_0^t(1+\tau)^{-1+\delta}\,d\tau\right\}$$
$$\le Ce^{CK^2\varepsilon^2}(\varepsilon+K^3\varepsilon^3+K^5\varepsilon^5)(1+t)^{\delta}.$$

The proof of Lemma 3.1 is complete. □

4. Large time asymptotics. Now we are in a position to show the asymptotic expression (1.5). In view of (2.6), it suffices to find the asymptotics of $\alpha(t,\xi)$. The following lemma is essentially due to [7], [8], [14], [19], though we shall state a slightly refined version here. For the convenience of the readers, the proof will be provided in the appendix.

LEMMA 4.1. *Let $\beta_0(\xi)$, $\kappa(\xi)$ be bounded continuous functions and suppose that $\operatorname{Im}\kappa(\xi)\le 0$ for all $\xi\in\mathbf{R}$. Let $r(t,\xi)$ satisfy*

$$\sup_{\xi\in\mathbf{R}}|r(t,\xi)| = O(t^{-1-\lambda}) \qquad (t\to+\infty)$$

with some constant $\lambda>0$. If $\beta(t,\xi)$ solves the differential equation

$$i\frac{\partial\beta}{\partial t} = \varepsilon^2\frac{\kappa(\xi)}{t}|\beta|^2\beta + \varepsilon^2 r(t,\xi), \quad \beta(1,\xi)=\beta_0(\xi) \tag{4.1}$$

for sufficiently small ε, then there exist continuous functions $\beta_\infty(\xi)$ and $\gamma(\xi)$, which satisfy $|\beta_\infty(\xi)|\le C$ and $|\gamma(\xi)|\le C\varepsilon^2$, such that

$$\beta(t,\xi) = \frac{\beta_\infty(\xi)\exp\left\{-i\varepsilon^2|\beta_\infty(\xi)|^2\operatorname{Re}\kappa(\xi)\int_0^{\log t}\frac{d\sigma}{1-2\varepsilon^2\operatorname{Im}\kappa(\xi)(|\beta_\infty(\xi)|^2\sigma+\gamma(\xi))}\right\}}{\sqrt{1-2\varepsilon^2\operatorname{Im}\kappa(\xi)(|\beta_\infty(\xi)|^2\log t+\gamma(\xi))}}$$
$$+O\big(t^{-\lambda+\mu}\big)$$

as $t\to+\infty$ uniformly in $\xi\in\mathbf{R}$, where μ is an arbitrarily small number.

Now, we set $\beta(t,\xi)=\varepsilon^{-1}\langle\xi\rangle^2\alpha(t,\xi)$, $\kappa(\xi)=\langle\xi\rangle^{-4}N(1,i\xi)$, and

$$r(t,\xi) = \frac{1}{\varepsilon^2}\left(i\frac{\partial\beta}{\partial t} - \varepsilon^2\frac{\kappa(\xi)}{t}|\beta|^2\beta\right).$$

Then, since

$$r(t,\xi) = \frac{1}{\varepsilon^3}\left\{\left(i\frac{\partial\alpha}{\partial t}-\frac{1}{t}N(1,i\xi)|\alpha|^2\alpha\right)+\left(i\frac{\partial\alpha_2}{\partial t}-\frac{1}{t}N(1,i\xi)|\alpha|^2\alpha_2\right)\right\}$$
$$= \frac{1}{\varepsilon^3}\Big(\rho_0(t,\xi)+\rho_2(t,\xi)\Big),$$

we deduce from (3.1) and (3.4) that

$$\sup_{\xi\in\mathbf{R}}|r(t,\xi)| \le \frac{1}{\varepsilon^3}(\|\rho_0(t)\|_{L^\infty}+\|\rho_2(t)\|_{L^\infty}) \le Ct^{-5/4}.$$

Therefore we can apply Lemma 4.1 with $\lambda = 1/4$ to get the asymptotics of β as $t \to +\infty$. Putting $a(\xi) = e^{-i\pi/4}\varepsilon\langle\xi\rangle^{-2}\beta_\infty(\xi)$ and $b(\xi) = \varepsilon^2\langle\xi\rangle^{-4}\gamma(\xi)$, we have

$$\alpha(t,\xi) = \frac{a(\xi)\exp\left\{i\pi/4 - i|a(\xi)|^2\,\mathrm{Re}N(1,i\xi)\int_0^{\log t}\frac{d\sigma}{1-2\,\mathrm{Im}N(1,i\xi)(|a(\xi)|^2\sigma+b(\xi))}\right\}}{\sqrt{1-2\,\mathrm{Im}N(1,i\xi)(|a(\xi)|^2\log t + b(\xi))}} + O\big(t^{-1/4+\mu}\big)$$

as $t \to +\infty$. Finally, using (2.6), we arrive at the desired asymptotic expression for $u(t,x)$. □

Remark 4.1. We can also deduce the L^2-decay of $u(t)$ because

$$\|u(t)\|_{L^2_x} = \varepsilon\|\langle\xi\rangle^{-2}\beta(t)\|_{L^2_\xi} \le C\varepsilon\|\beta(t)\|_{L^\infty_\xi}$$

and

$$\|\beta(t)\|_{L^\infty_\xi} = O((\log t)^{-1/2}) \quad \text{as} \quad t \to +\infty$$

if $\sup_{\xi\in\mathbf{R}} \mathrm{Im}\,N(1,i\xi) < 0$.

Remark 4.2. It is possible to weaken (1.2) to a certain extent, but impossible to remove it completely. In fact, when (1.2) is replaced by

$$N(e^{i\theta},0) = e^{i\theta}N(1,0) \quad \text{for} \quad \theta \in \mathbf{R}, \tag{4.2}$$

we can modify the above argument combining the idea of [5], [6] (see also the appendix of [19]) to show that Theorem 1.1 is still valid if $N(1,i\xi)$ in the statement is replaced by

$$\frac{1}{2\pi}\int_0^{2\pi} N(e^{i\theta}, i\xi e^{i\theta})e^{-i\theta}\,d\theta.$$

Note that (4.2) is just what excludes u^3, $\overline{u}^3$, $u\overline{u}^2$ from all possible cubic nonlinear terms, but it is not a technical assumption because for these three nonlinearities we can find a class of initial data for which the solution has another kind of asymptotic profile than (1.5) (see [7] and [8] for details).

Appendix. We give a proof of Lemma 4.1 following [19] and [14] with some modifications. Because of the uniqueness for (4.1), $\beta(t,\xi)$ admits the decomposition

$$\beta(t,\xi) = \frac{p(t,\xi)}{\sqrt{q(t,\xi)}},$$

where $p(t,\xi)$ and $q(t,\xi)$ satisfy

$$\begin{cases} \partial_t p(t,\xi) = -i\varepsilon^2\dfrac{\mathrm{Re}\,\kappa(\xi)}{t}\dfrac{\big|p(t,\xi)\big|^2}{q(t,\xi)}p(t,\xi) - i\varepsilon^2\sqrt{q(t,\xi)}r(t,\xi), \\ \partial_t q(t,\xi) = -2\varepsilon^2\dfrac{\mathrm{Im}\,\kappa(\xi)}{t}\big|p(t,\xi)\big|^2, \\ p(1,\xi) = \beta_0(\xi), \quad q(1,\xi) = 1. \end{cases} \tag{A.1}$$

Note that $p(t,\xi)$ is complex-valued, while $q(t,\xi)$ is real and strictly positive. In order to obtain the desired conclusion, it is sufficient to get the asymptotics of $p(t,\xi)$ and $q(t,\xi)$ as $t \to +\infty$.

We first show that there exists a positive constant A such that

$$\sup_{(t,\xi)\in[1,\infty)\times\mathbf{R}} |p(t,\xi)| < A. \tag{A.2}$$

We shall argue by contradiction: Suppose that for any $A > \sup_{\xi\in\mathbf{R}} |\beta_0(\xi)|$ there exists a finite time $T_A \in (1,\infty)$ such that

$$\sup_{(t,\xi)\in[1,T_A)\times\mathbf{R}} |p(t,\xi)| \le A \quad \text{and} \quad \sup_{\xi\in\mathbf{R}} |p(T_A,\xi)| = A.$$

Then, from the second equation of (A.1), we have

$$1 \le q(t,\xi) \le 1 - 2\varepsilon^2 \operatorname{Im}\kappa(\xi) A^2 \log t$$

for $t \in [1, T_A]$. On the other hand, it follows from the first equation of (A.1) that

$$\begin{aligned}
\partial_t\Big(|p(t,\xi)|^2\Big) &= 2\operatorname{Re}\Big(\overline{p(t,\xi)}\partial_t p(t,\xi)\Big) \\
&= 2\varepsilon^2 \operatorname{Re}\Big(\overline{p(t,\xi)}\sqrt{q(t,\xi)}r(t,\xi)\Big) \\
&\le 2\varepsilon^2 \big|p(t,\xi)\big|\,\big|\sqrt{q(t,\xi)}r(t,\xi)\big|.
\end{aligned}$$

So we have

$$\begin{aligned}
|p(T_A,\xi)| &\le |\beta_0(\xi)| + \int_1^{T_A} \varepsilon^2 \big|\sqrt{q(\tau,\xi)}r(\tau,\xi)\big|\,d\tau \\
&\le C + \int_1^{\infty} C\varepsilon^2 (1 + A^2\varepsilon^2 \log\tau)^{1/2} \tau^{-1-\lambda} d\tau \\
&\le C(1 + A\varepsilon).
\end{aligned}$$

When we choose $A = 4C$ and $\varepsilon_1 = 1/A$, we have

$$\sup_{\xi\in\mathbf{R}} |p(T_A,\xi)| \le \frac{A}{2} < A$$

for $\varepsilon \in (0, \varepsilon_1]$, which is the desired contradiction. Hence (A.2) must hold for some A. Also we have

$$1 \le q(t,\xi) \le 1 - 2\varepsilon^2 \operatorname{Im}\kappa(\xi) A^2 \log t$$

for any $t \ge 1$. Next we define

$$\Theta(t,\xi) = \int_1^t \frac{\operatorname{Re}\kappa(\xi)|p(\tau,\xi)|^2}{q(\tau,\xi)} \frac{d\tau}{\tau}$$

so that $\partial_t(p(t,\xi)e^{i\varepsilon^2\Theta(t,\xi)}) = -i\varepsilon^2\sqrt{q(t,\xi)}r(t,\xi)e^{i\varepsilon^2\Theta(t,\xi)}$. Since

$$\sup_{\xi\in\mathbf{R}} \Big|\sqrt{q(t,\xi)}r(t,\xi)\Big| \le C(1+\varepsilon^2\log t)^{1/2} t^{-1-\lambda} \le C t^{-1-\lambda+\mu},$$

we obtain

$$\sup_{\xi\in\mathbf{R}} |p(t,\xi) - p_\infty(\xi) e^{-i\varepsilon^2\Theta(t,\xi)}| \le C\varepsilon^2 t^{-\lambda+\mu},$$

where

$$p_\infty(\xi) = \beta_0(\xi) - i\varepsilon^2 \int_1^\infty \sqrt{q(\tau,\xi)} r(\tau,\xi) e^{i\varepsilon^2 \Theta(\tau,\xi)}\, d\tau.$$

We also set $q_\infty(t,\xi) = 1 - 2\varepsilon^2 \operatorname{Im}\kappa(\xi)\big(|p_\infty(\xi)|^2 \log t + \gamma(\xi)\big)$ with

$$\gamma(\xi) = \int_1^\infty \big(|p(\tau,\xi)|^2 - |p_\infty(\xi)|^2\big)\frac{d\tau}{\tau}.$$

Noting that

$$\begin{aligned}\big||p(t,\xi)|^2 - |p_\infty(\xi)|^2\big| &\le \big|p(t,\xi) - p_\infty(\xi) e^{-i\varepsilon^2\Theta(t,\xi)}\big|\big(|p(t,\xi)| + |p_\infty(\xi)|\big)\\ &\le C\varepsilon^2 t^{-\lambda+\mu},\end{aligned}$$

we can see that

$$|q(t,\xi) - q_\infty(t,\xi)| \le 2\varepsilon^2 |\operatorname{Im}\kappa(\xi)| \int_t^\infty \big||p(\tau,\xi)|^2 - |p_\infty(\xi)|^2\big|\frac{d\tau}{\tau} \le C\varepsilon^4 t^{-\lambda+\mu}.$$

Let us also introduce

$$\Phi(t,\xi) = \frac{\operatorname{Re}\kappa(\xi)}{t}\left(\frac{|p(t,\xi)|^2}{q(t,\xi)} - \frac{|p_\infty(\xi)|^2}{q_\infty(t,\xi)}\right).$$

Then we have

$$i\varepsilon^2\Theta(t,\xi) = i\varepsilon^2 |p_\infty(\xi)|^2 \operatorname{Re}\kappa(\xi) \int_1^t \frac{d\tau}{q_\infty(\tau,\xi)} + i\varepsilon^2 \int_1^\infty \Phi(\tau,\xi)\, d\tau - i\varepsilon^2 \int_t^\infty \Phi(\tau,\xi)\, d\tau$$

and

$$\begin{aligned}\int_t^\infty |\Phi(\tau,\xi)|\, d\tau &\le C\int_t^\infty \left(\frac{\big||p(\tau,\xi)|^2 - |p_\infty(\xi)|^2\big|}{q(\tau,\xi)} + \frac{|p_\infty(\xi)|^2\big|q(\tau,\xi) - q_\infty(\tau,\xi)\big|}{q(\tau,\xi) q_\infty(\tau,\xi)}\right)\frac{d\tau}{\tau}\\ &\le C\varepsilon^2 \int_t^\infty \frac{d\tau}{\tau^{1+\lambda-\mu}}\\ &\le C\varepsilon^2 t^{-\lambda+\mu}.\end{aligned}$$

Therefore, putting $\beta_\infty(\xi) = p_\infty(\xi)\exp\big(-i\varepsilon^2\int_1^\infty \Phi(\tau,\xi)\, d\tau\big)$, we obtain

$$\begin{aligned}p(t,\xi) &= p_\infty(\xi) e^{-i\varepsilon^2\Theta(t,\xi)} + O(t^{-\lambda+\mu})\\ &= \beta_\infty(\xi)\exp\left(-i\varepsilon^2 |p_\infty(\xi)|^2 \operatorname{Re}\kappa(\xi)\int_1^t \frac{d\tau}{q_\infty(\tau,\xi)}\right) + O(t^{-\lambda+\mu})\\ &= \beta_\infty(\xi)\exp\left(-i\varepsilon^2 |\beta_\infty(\xi)|^2 \operatorname{Re}\kappa(\xi)\int_0^{\log t} \frac{d\sigma}{1 - 2\varepsilon^2 \operatorname{Im}\kappa(\xi)\big(|\beta_\infty(\xi)|^2\sigma + \gamma(\xi)\big)}\right)\\ &\quad + O(t^{-\lambda+\mu})\end{aligned}$$

as well as

$$\begin{aligned}\frac{1}{\sqrt{q(t,\xi)}} &= \frac{1}{\sqrt{q_\infty(t,\xi)}} + \frac{q_\infty(t,\xi) - q(t,\xi)}{\sqrt{q(t,\xi)q_\infty(t,\xi)}\big(\sqrt{q(t,\xi)} + \sqrt{q_\infty(t,\xi)}\big)}\\ &= \frac{1}{\sqrt{1 - 2\varepsilon^2 \operatorname{Im}\kappa(\xi)\big(|\beta_\infty(\xi)|^2 \log t + \gamma(\xi)\big)}} + O(t^{-\lambda+\mu}),\end{aligned}$$

whence

$$\begin{aligned}\beta(t,\xi) &= \frac{p(t,\xi)}{\sqrt{q(t,\xi)}}\\ &= \frac{\beta_\infty(\xi)\exp\left(-i\varepsilon^2|\beta_\infty(\xi)|^2\operatorname{Re}\kappa(\xi)\int_0^{\log t}\frac{d\sigma}{1-2\varepsilon^2\operatorname{Im}\kappa(\xi)\left(|\beta_\infty(\xi)|^2\sigma+\gamma(\xi)\right)}\right)}{\sqrt{1-2\varepsilon^2\operatorname{Im}\kappa(\xi)\left(|\beta_\infty(\xi)|^2\log t+\gamma(\xi)\right)}}\\ &\quad + O(t^{-\lambda+\mu})\end{aligned}$$

as $t\to+\infty$. □

QUASILINEAR PARABOLIC SYSTEMS WITH MIXED BOUNDARY CONDITIONS ON NONSMOOTH DOMAINS*

MATTHIAS HIEBER† AND JOACHIM REHBERG‡

Abstract. In this paper we investigate quasilinear systems of reaction-diffusion equations with mixed Dirichlet–Neumann boundary conditions on nonsmooth domains. Using techniques from maximal regularity and heat-kernel estimates we prove the existence of a unique solution to systems of this type.

Key words. quasilinear parabolic system, mixed Dirichlet–Neumann conditions, L^∞-coefficients

DOI. 10.1137/070683829

1. Introduction.

The theory of quasilinear parabolic systems has many applications to evolution problems in natural sciences, see, e.g., [2], [1], [5], [6], [20], [10], [16], [30], and [41]. In this paper we investigate in particular systems of reaction-diffusion equations with *mixed* Dirichlet–Neumann boundary conditions on nonsmooth domains $\Omega \subset \mathbb{R}^n$ for $n = 2, 3$ of the form

$$\begin{aligned} u_k' - \operatorname{div}(G_k(v)\mu_k \nabla v_k) &= R_k(t,v), \qquad t \in]T_0, T[, x \in \Omega, \\ u_k &= b_k\, F_k(v_k), \qquad t \in [T_0, T[, x \in \Omega, \\ \nu \cdot \mu_k \nabla v_k &= 0, \qquad t \in [T_0, T[, x \in \Gamma_N, \\ v_k &= \phi_k, \qquad t \in [T_0, T[, x \in \Gamma_D, \\ v_k(T_0) &= v_{0k}, \qquad x \in \Omega. \end{aligned} \tag{1.1}$$

Here $v = (v_1, \dots, v_m)$, $\mu_k \in L^\infty(\Omega, M_{n\times n})$ are diffusion coefficients, $b_k \in L^\infty(\Omega)$ are reference densities, and R_k, G_k, F_k denote the reaction, diffusion, and superposition terms for $k \in \{1, \dots, m\}$.

In many concrete problems which are described as a system of the form (1.1), the underlying domain is nonsmooth and the coefficient functions b_k and μ_k are discontinuous. We therefore aim for minimal smoothness assumptions on the boundary $\partial\Omega$ of Ω, the coefficient functions b_k and μ_k, as well as on the interface between the Neumann boundary part Γ_N of $\partial\Omega$ and the Dirichlet boundary part $\Gamma_D = \partial\Omega \setminus \Gamma_N$. More precisely, we generally assume that $\Omega \subset \mathbb{R}^n$ is a Lipschitz domain and $\Omega \cup \Gamma_N$ is regular in the sense of Gröger (see the definition below). Note that the situation where the boundary of Ω is smooth and consists of two *separated* parts, one with Dirichlet and the other with Neumann boundary conditions, has been studied before by Amann in [2].

Our setting includes even nonlocal diffusion terms as occurring in models describing the diffusion of bacteria (see [7], [8] and the references therein). In detail, the velocity at which the motion takes place is given by Fourier's law and the (relative)

diffusion coefficient $G = G_k$ depends on the solution v in the form

$$G(v) = \eta\left(\int_\Omega z(x)v(x)\,dx\right),$$

where η is a (strictly) positive, continuously differentiable function on $\mathbb{R}$.

Our approach includes reaction terms R_k depending discontinously on time t, which is important in many examples (see [41], [26], [30]), in particular in the control theory of parabolic equations. Alternatively, the reader should think, e.g., of a manufacturing process for semiconductors, where at a certain moment light is switched on/off and, of course, parameters in the chemical process change abruptly.

An interesting example for a reaction term stems from the thermistor problem (see [38], [3] and the references therein, see also [6]) which describes the combined processes of heat conduction and electrical conduction in a body. This is of importance in the industrially important process of electrical welding. To be precise, the reaction term is of the form $\sigma(v)|\nabla\varphi|^2$, where φ is the solution of an auxiliary elliptic problem, into which v enters as a parameter (see details in section 4.2). Observe that the quadratic gradient term is a critical one and in general not easy to handle (see [38]), while in our context it does not cause additional difficulties.

Note that the original formulation of the evolution equation in terms of balance laws takes the form (see [39, Ch. 21], see also [5])

$$\frac{\partial}{\partial t}\int_{\Omega'} u_k\,dx + \int_{\partial\Omega'} \nu\cdot j_k\,d\sigma = \int_{\Omega'} R_k\,dx; \quad j_k = j_k(v) = G_k(v)\mu_k\nabla v_k, \tag{1.2}$$

where Ω' stands for any (Lipschitzian) subdomain of Ω. Within the variational theory of weak solutions, however, the indicator functions of the subdomains are not admissible test functions. Therefore the integral formulation (1.2) is equivalent to the above evolution equation only if the weak solutions have some additional regularity. It is the main advantage of the present concept that the divergence of the corresponding current $j_k(v)$ indeed is a function, not only a distribution. In a strict sense, only this justifies the application of Gauss' theorem to calculate the normal components of the currents over boundaries of suitable subdomains. Moreover, the fact $\operatorname{div} j_k \in L^p$ is also of importance for the numerical treatment of (1.1), as the formulation (1.2) is the basis of finite volume methods (see [18])—namely in the sense of local balances. Global existence results for (1.1) cannot be expected within such a general approach (see, e.g., [17] or [6] and the references therein).

In contrast to many papers where existence and uniqueness results for quasilinear parabolic systems are based on the construction of an appropriate evolution operator (see, e.g., [1]), our approach relies heavily on maximal L^p-estimates for the linear part of (1.1). In fact, after rewriting (1.1) as an abstract evolution equation in $L^p(\Omega)^m$ of the form

$$\begin{aligned} w' - H(t,w)\big(\operatorname{div}(\mu\nabla w)\big) &= S(t,w),\\ w(T_0) &= v_0 - \phi(T_0), \end{aligned} \tag{1.3}$$

our strategy to solve (1.3) follows the approach of Clément and Li [10] and Prüss [34]. The advantage of the given situation (1.1) is that subtle techniques from harmonic analysis as well as heat-kernel methods can be used to prove the central L^p-estimates of the linear part. In order to apply these methods in our situation, one needs embedding properties of certain interpolation spaces between the domain of the L^p-realization of

the underlying elliptic operators and $L^p(\Omega)$ into $W^{1,2p}(\Omega)$. This embedding property rests on the assumption that the operators formally defined by

$$-\nabla \cdot \mu_k \nabla + 1 : W^{1,q}_{\Gamma_N}(\Omega) \to W^{-1,q}_{\Gamma_N}(\Omega)$$

provide topological isomorphisms for some $q > n$. Note that this assumption restricts the physical dimension of the problems to two and three, because one knows that the solution for a mixed boundary value problem generically has singularities, precisely, one cannot expect that its gradient lies in L^4; see Shamir's famous counterexample [37]. On the other hand, in two and three dimensions the assumption is fulfilled for many geometric constellations and (even discontinuous) coefficient functions; see section 4.

2. Preliminaries. Let $\Omega \subset \mathbb{R}^n$ be a bounded Lipschitz domain and assume that $n = 2$ or $n = 3$. (Concerning the notions "Lipschitz domain" and "domain with Lipschitz boundary" we follow [23, section 1.2.1].) Denote by $\Gamma_N \subset \partial\Omega$ an open subset of $\partial\Omega$. For $1 < q < \infty$ we define $W^{1,q}_{\Gamma_N}(\Omega)$ as the closure of

$$\{\psi|_\Omega : \psi \in C_c^\infty(\mathbb{R}^n),\ \operatorname{supp}\psi \cap (\partial\Omega \backslash \Gamma_N) = \emptyset\}$$

in the Sobolev space $W^{1,q}(\Omega)$. If $q = 2$, we write $H^1(\Omega)$ or $H^1_{\Gamma_N}(\Omega)$ instead of $W^{1,2}(\Omega)$ or $W^{1,2}_{\Gamma_N}(\Omega)$. Of course, if $\Gamma_N = \emptyset$, then $W^{1,q}_{\Gamma_N}(\Omega) = W^{1,q}_0(\Omega)$. Moreover, throughout this work we always suppose that $\Omega \cup \Gamma_N$ is regular in the sense of Gröger (see [24]), this means that, for all $x \in \partial\Omega$ there exist open sets $U_x, V_x \subset \mathbb{R}^n$ and a bi-Lipschitz transform Ψ_x from U_x onto V_x such that $x \in U_x, \Psi_x(x) = 0$ and $\Psi_x(U_x \cap (\Omega \cup \Gamma_N))$ coincides with one of the sets

$$\begin{aligned}
E_1 &:= \{x \in \mathbb{R}^n : \max_{l=1\ldots,n} |x_l| < 1, x_n < 0\},\\
E_2 &:= \{x \in \mathbb{R}^n : \max_{l=1,\ldots,n} |x_l| < 1, x_n \le 0\},\\
E_3 &:= \{x \in E_2 : x_n < 0 \text{ or } x_1 > 0\}.
\end{aligned}$$

It is not hard to see that every Lipschitz domain, and also its closure, is regular in the sense of Gröger, the corresponding model sets are then E_1 or E_2, respectively; see [23]. Moreover, if $\Omega \subset \mathbb{R}^2$ is a bounded Lipschitz domain and $\partial\Omega \setminus \Gamma_N$ is the finite union of (nondegenerate) closed arc pieces from the boundary, then $\Omega \cup \Gamma_N$ is regular in the sense of Gröger.

Finally, for $k \in \{1, \ldots, m\}$, let $\mu_k \in L^\infty(\Omega, M_{n\times n})$, where $M_{n\times n}$ denotes the set of all real, symmetric $n \times n$ matrices. Suppose that additionally

$$\inf_{x\in\Omega} \inf_{|\varsigma|=1} \mu_k(x)\varsigma \cdot \varsigma > 0. \tag{2.1}$$

For a closed subspace $V \subseteq H^1(\Omega)$ such that $H^1_0(\Omega) \subseteq V$ we define the form $a_k : V \times V \to \mathbb{R}$ by

$$a_k(u, v) := -\int_\Omega \mu_k \nabla u \cdot \nabla v \, \mathrm{d}x, \quad u, v \in V.$$

The form induces a continuous mapping $\mathcal{A}_k : V \to V'$ such that

$$a_k(u, v) = (\mathcal{A}_k u | v), \quad u, v \in V. \tag{2.2}$$

Here, for $v \in L^2(\Omega)$, $f_v(u) := (v|u)_{L^2}$ defines an element $f_v \in V'$ and $v \mapsto f_v : L^2(\Omega) \to V'$ defines a continuous injection. In the following, we identify v with f_v. We then define the operator A_k as

$$D(A_k) := \{u \in V : \exists f \in L^2(\Omega), a_k(u,\phi) = (f|\phi)\ \forall \phi \in V\}, \tag{2.3}$$

$$A_k u := f. \tag{2.4}$$

It is well known that A_k generates an analytic semigroup on $L^2(\Omega)$ which is positivity preserving. Furthermore, this semigroup extends to a C_0-semigroup of contractions on $L^p(\Omega)$ for all $1 < p < \infty$; see, [22, Thm. 4.9]. The realization of its generator in L^p is denoted by A_k^p.

3. Main result. We start this section by giving precise assumptions on the coefficients and functions being involved in problem (1.1). In order to do so, let $0 \le T_0 < T_1$ and set $J :=]T_0, T_1[$. For $k \in \{1, \dots, m\}$ let $\mu_k \in L^\infty(\Omega, M_{n\times n})$ and assume that (2.1) is satisfied.

Moreover, let for every $k \in \{1, \dots, m\}$ the functions $b_k \in L^\infty(\Omega; \mathbb{R})$ be bounded from below by some positive constant.

We assume the following for all $k \in \{1, \dots, m\}$.

(Op) There exists $p > \frac{n}{2}$ such that each $\mathcal{A}_k - Id$ is a topological isomorphism from $W^{1,2p}_{\Gamma_N}(\Omega)$ onto $W^{-1,2p}_{\Gamma_N}(\Omega)$. For all what follows we fix a number $r > \frac{4p}{2p-n}$.

(Su) There exists $f_k \in C^2(\mathbb{R})$, positive, with strictly positive derivative, such that F_k is the superposition operator induced by f_k; i.e., $F_k(v)(x) = (f_k \circ v)(x) = f_k(v(x))$, $x \in \Omega$.

(Ga) The mapping $G_k : \left(W^{1,2p}(\Omega)\right)^m \to W^{1,2p}(\Omega)$ is locally Lipschitz.

(Gb) For any ball in $\left(W^{1,2p}(\Omega)\right)^m$ there exists $\delta > 0$ such that $G_k(u) \ge \delta$ for all u from this ball.

(Ra) The function $R_k : J \times \left(W^{1,2p}(\Omega)\right)^m \to L^p(\Omega)$ is of Carathéodory type, i.e., $R_k(\cdot, u)$ is measurable for all $u \in \left(W^{1,2p}(\Omega)\right)^m$ and $R_k(t, \cdot)$ is continuous for a.a. $t \in J$.

(Rb) $R_k(\cdot, 0) \in L^r(J, L^p(\Omega))$ and for $\beta > 0$ there exists $g_\beta \in L^r(J)$ such that

$$\|R_k(t,u) - R_k(t,\tilde{u})\|_{L^p} \le g_\beta(t)\|u - \tilde{u}\|_{W^{1,2p}}, \quad t \in J,$$

provided $\max(\|u\|_{W^{1,2p}}, \|\tilde{u}\|_{W^{1,2p}}) \le \beta$.

(BC) $\phi_k \in C(\overline{J}; W^{1,2p}(\Omega)) \cap W^{1,r}(J; L^p(\Omega))$ and $A_k\phi_k(t) = 0$ for all $t \in J$.

(IC) $v_{0k} - \phi_k(T_0) \in (L^p(\Omega), D(A_k^p))_{1-\frac{1}{r},r}$.

The assumptions imply that the system (1.1) may be (formally) rewritten as a quasilinear system of the form

$$\begin{aligned} w_k' - H_k(t,w)A_k w_k &= T_k(t,w), \quad k = 1, \dots, m, \\ w(T_0) &= v_0 - \phi(T_0), \end{aligned} \tag{3.1}$$

where

(3.2)

$$T_k(t,w) := (b_k f_k'(w_k+\phi_k(t)))^{-1}[\nabla G_k(w+\phi(t))\cdot[\mu_k \nabla(w_k+\phi_k(t))]] + Q_k(t,w) - \frac{\partial \phi_k}{\partial t}(t)$$

with

$$H_k(t,z) := \frac{G_k(z+\phi(t))}{b_k\ f_k'(z_k+\phi_k(t))}, \quad t \in J,\ z \in \left(W^{1,2p}(\Omega)\right)^m, \tag{3.3}$$

$$Q_k(t,z) := \frac{R_k(t,z+\phi(t))}{b_k\ f_k'(z_k+\phi_k(t))}, \quad t \in J,\ z \in \left(W^{1,2p}(\Omega)\right)^m. \tag{3.4}$$

We are now in the position to state the main result of this paper.

THEOREM 3.1. *Let $1 < r, p < \infty$ such that $r > \frac{4p}{2p-n}$, where $n \in \{2, 3\}$. Assume that the assumptions* (Op), (Su), (Ga), (Gb), (Ra), (Rb), (BC), *and* (IC) *are satisfied. Then there exists a unique local solution $w = (w_1, \dots, w_m)$ for* (3.1) *on an interval $I =]T_0, T[$ satisfying*

$$w_k \in W^{1,r}(I; L^p(\Omega)) \cap L^r(I; D(A_k)), \quad k \in \{1, \dots, m\}. \tag{3.5}$$

COROLLARY 3.2. *Each w_k is Hölder-continuous simultaneously in space and time.*

Some remarks at this point are in order.

Remark 3.3.

(a) We refer the reader to section 4 for precise geometric and smoothness conditions implying the validity of assumption (Op).

(b) Besides the exponential, a typical example for a function f satisfying assumption (Su) is the Fermi–Dirac distribution function

$$f(t) := \frac{2}{\sqrt{\pi}} \int_0^\infty \frac{\sqrt{s}}{1 + e^{s-t}} \, \mathrm{d}s.$$

(c) Suppose that v_k coincides on Γ_D with a function $\phi \in C^1(J, W^{1,2p}(\Omega))$. Then there exists ϕ_k satisfying assumption (BC).

(d) Note that condition (BC) implies $\nu \cdot \mu_k \nabla \phi_k = 0$ on Γ_N. This, together with the property (3.5), yields the Neumann boundary condition for v_k on Γ_N; see [19, section II.2], [9, section 1.2].

4. Examples. Consider Ω and Γ_N, the subset of $\partial\Omega$ on which the Neumann boundary condition is prescribed. In this section we describe geometric configurations and coefficient functions for which Theorem 3.1 holds true. Furthermore, we present concrete examples of mappings G_k and reaction terms R_k fitting in our framework.

4.1. Geometric configurations and coefficients. In this subsection we will give a list of examples in order to show that (Op) is not an unjustified ad hoc assumption but fulfilled in many cases, even if the geometry is nonsmooth, the boundary conditions are mixed, and the coefficients may jump. Notice that for—realistic—nonsmooth situations a (strict) upper bound for the integrability index for the gradient of the solution is (at most) 4. That means in detail that, this limitation may be caused only by nonsmoothness of the domain (see [28, Thm. A]), only by the occurrence of mixed boundary conditions (despite smooth data, see [37]), or only by nonsmooth coefficients (see [33] or [14]).

We start with a result, due to Gröger [24], which completely covers the two-dimensional case.

PROPOSITION 4.1. *Assume that $\Omega \cup \Gamma_N$ is regular in the sense of Gröger and that the coefficient function satisfies the assumptions made in section* 2. *Then there exists $q > 2$ such that $\mathcal{A}_k - Id$ is a topological isomorphism from $W^{1,q}_{\Gamma_N}(\Omega)$ onto $W^{-1,q}_{\Gamma_N}(\Omega)$.*

In what follows we present three-dimensional settings, here always supposing that the domain Ω is a domain with Lipschitz boundary. We begin with the case where the coefficient function is continuous at least in a neighborhood of the boundary.

PROPOSITION 4.2. *Assume that $\Gamma_N = \emptyset$ or $\Gamma_N = \partial\Omega$ (pure Dirichlet or pure Neumann case). $\Omega_\circ \subset \Omega$ is another domain which is C^1 and which does not touch the boundary of Ω. $\mu_k|_{\Omega_\circ} \in BUC(\Omega_\circ)$ and $\mu_k|_{\Omega \setminus \bar{\Omega}_\circ} \in BUC(\Omega \setminus \bar{\Omega}_\circ)$. Then (Op) holds.*

Remark 4.3. The proposition is one of the main results from [15] and rests heavily on regularity results for the Dirichlet/Neumann Laplacian (see [28], [42]) and nontrivial estimates around points from $\partial\Omega_\circ$. In particular, the reader should carefully notice that the C^1 property of $\Omega_\circ$ is not dispensable without completely losing the result; see Elschner's counterexample in [15], see also [14].

The next proposition describes two cases with pure Dirichlet conditions ($\Gamma_N = \emptyset$), where the discontinuities of the coefficient function are located also near the boundary.

PROPOSITION 4.4. *There exists $q > 3$ such that $\mathcal{A}_k - Id$ is a topological isomorphism from $W^{1,q}_{\Gamma_N}(\Omega)$ onto $W^{-1,q}_{\Gamma_N}(\Omega)$ if one of the following conditions is satisfied.*

(i) *Ω is a polyhedron. There are hyperplanes $\mathcal{H}_1, \dots, \mathcal{H}_n$ in $\mathbb{R}^3$ which meet at most in a vertex of the polyhedron such that the coefficient function μ_k is constantly a real, symmetric, positive definite 3×3 matrix on each of the connected components of $\Omega \setminus \cup_{l=1}^n \mathcal{H}_l$. Moreover, for every edge on the boundary, induced by a hyperplane $\mathcal{H}_l$, the angles between the outer boundary plane and the hyperplane $\mathcal{H}_l$ do not exceed π.*

(ii) *$\Omega_\circ \subset \Omega$ is a Lipschitz domain such that $\partial\Omega_\circ \cap \Omega$ is a C^1 surface. Moreover, $\partial\Omega$ and $\partial\Omega_\circ$ meet suitably, this means that for any point x from the boundary of $\partial\Omega \cap \partial\Omega_\circ$ whithin $\partial\Omega$ there is an open neighborhood $\mathcal{U}_x$ of x in $\mathbb{R}^3$ and a C^1 diffeomorphism Φ_x from $\mathcal{U}_x$ onto an open subset of $\mathbb{R}^3$ such that*
- *$\Phi_x(\mathcal{U}_x \cap \Omega)$ equals a convex polyhedron $\mathcal{K}_x$,*
- *$\Phi_x(\mathcal{U}_x \cap \Omega \cap \partial\Omega_\circ) = \mathcal{K}_x \cap \mathcal{H}_x$, where $\mathcal{H}_x$ is a plane which contains $\Phi_x(x)$ and an inner point of $\mathcal{K}_x$. $\mu_k|_{\Omega_\circ} \in BUC(\Omega_\circ)$ and $\mu_k|_{\Omega\setminus\bar{\Omega}_\circ} \in BUC(\Omega \setminus \bar{\Omega}_\circ)$.*

The constellation (i) is treated in [14], the second in [15].

The last cases we present really affect the case of mixed boundary conditions.

PROPOSITION 4.5. *Assumption* (Op) *is also satisfied in any of the following two cases.*

(i) *Ω is a convex polyhedron, $\overline{\Gamma_N} \cap (\partial\Omega\setminus\Gamma_N)$ is a finite union of line segments, $\mu_k \equiv 1$.*

(ii) *Ω is a three-dimensional prismatic domain with triangular basis. Γ is half of one of its upright sides. Ξ is a plane that intersects the (relative) boundary of Γ within $\partial\Omega$ in only finitely many points. The coefficient function is constant on both components of $\Omega \setminus \Xi$.*

Remark 4.6. The assertion for (i) is shown in [11] (see Corollary 3.12), while the proof for (ii) is given in [25]. Notice that (ii) is by no means artificial: $\Omega \cup \Gamma$ may (alternatively) be taken as Gröger's third local model set in the description of geometric settings including mixed boundary conditions; see section 2 or [24] for further details. Additionally, it is the first three-dimensional constellation treated in the literature—in view of (Op)—which includes mixed boundary conditions and a discontinuous coefficient function, which is necessary, e.g., in the modeling of heterogeneous semiconductors [36]. (See [25] for other settings and further details.)

Remark 4.7. The operator $\mathcal{A}_k - Id$ also fulfills (Op) if the following condition is satisfied: there is a covering of $\bar{\Omega}$ by open sets $\mathcal{U}_1, \dots, \mathcal{U}_l$ such that for every $j \in \{1, \dots, l\}$ the setting $\Omega_j := \Omega \cap \mathcal{U}_j$, $\Gamma_j := \Gamma_N \cap \mathcal{U}_j$, and the restriction of μ_k to $\Omega \cap \mathcal{U}_j$ satisfy one of the conditions of the foregoing propositions; compare [24, Lemma 2]. Additionally, one can show by perturbation arguments (as, e.g., carried out in [15]) that in many cases admissible constellations are preserved under C^1 diffeomorphisms.

In the following we illustrate two admissible three-dimensional settings. On the left-hand side of Figure 4.1 one assumes Neumann conditions on the top of the upper cuboid, otherwise Dirichlet conditions. On the right-hand side of the figure, the

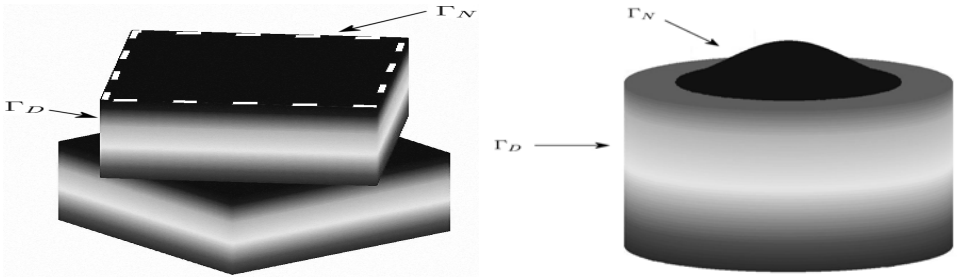

FIG. 4.1.

boundary of the cylinder is subject to Dirchlet conditions exept for the upper "hat," where Neumann conditions are prescribed.

4.2. Examples for the nonlinearities G_k and the reaction terms R_k. Next we give two examples for the operators G_k.

Example 4.8. Let $g_k : \mathbb{R}^m \mapsto]0, \infty[$ be a twice continuously differentiable function and define $G_k(z)(x) = g_k(z(x))$ if $z \in \left(W^{1,2p}\right)^m$ and $x \in \Omega$.

In many applications g_k depends only on one variable and is a multiple of the exponential function.

As the second example we present a nonlocal operator arising in the diffusion of bacteria; see [7], [8], and the references therein.

Example 4.9. Let η be a continuously differentiable function on $\mathbb{R}$ which is bounded from above and below by positive constants. Assume $\varphi \in L^2(\Omega)$ and define

$$G_k(z) := \eta\left(\int_\Omega z_k \varphi dx\right), \quad z = (z_1, \dots, z_m) \in \left(W^{1,2p}\right)^m.$$

Now we give two examples for mappings R_k.

Example 4.10. Assume that $[T_0, T_1[= \cup_{l=1}^{j} [t_l, t_{l+1}[$ is a (disjoint) decomposition of $[T_0, T_1[$ and let for $l \in \{1, \dots, j\}$

$$S_l : \mathbb{R}^m \times \mathbb{R}^{nm} \mapsto \mathbb{R}$$

be a function which satisfies the following condition: for any compact set $K \subset \mathbb{R}^m$ there is a constant L_K such that for any $a, \tilde{a} \in K$ and $b, \tilde{b} \in \mathbb{R}^{nm}$ the inequality

$$\begin{aligned} |S_l(a,b) - S_l(\tilde{a},\tilde{b})| \le\, & L_K |a - \tilde{a}|_{\mathbb{R}^m} \left(|b|^2_{\mathbb{R}^{nm}} + |\tilde{b}|^2_{\mathbb{R}^{nm}}\right) \\ & + L_K |b - \tilde{b}|_{\mathbb{R}^{nm}} \left(|b|_{\mathbb{R}^{nm}} + |\tilde{b}|_{\mathbb{R}^{nm}}\right) \end{aligned}$$

holds. We define a mapping $S : [T_0, T_1[\times \mathbb{R}^m \times \mathbb{R}^{nm} \mapsto \mathbb{R}$ by setting

$$S(t, a, b) := S_l(a, b) \quad \text{if} \quad t \in [t_l, t_{l+1}[.$$

The function S defines a mapping R in the following way: if z is the restriction of an $\mathbb{R}^m$-valued, continuously differentiable function on $\mathbb{R}^n$ to Ω, then we put

$$R(t, z, \nabla z)(x) = S(t, z(x), (\nabla z)(x)) \quad \text{for } x \in \Omega \tag{4.1}$$

and afterwards extend R by continuity to the whole set $[T_0, T_1[\times \left(W^{1,2p}(\Omega)\right)^m$.

Example 4.11 (electrical and heat conduction). Assume that $\sigma : \mathbb{R} \mapsto]0, \infty[$ is a continuously differentiable function. Further, let $\mathcal{S} : W^{1,2p} \mapsto W^{1,2p}$ be the mapping which assigns to $z \in W^{1,2p}$ the solution φ of the elliptic problem

$$-\nabla \cdot \sigma(z)\nabla\varphi = 0$$

(including boundary conditions, see [38], [3], [6]). If one defines

$$R(z) = \sigma(z)|\nabla(\mathcal{S}(z))|^2,$$

then, under a reasonable supposition on the domain and the boundary conditions, the mapping R satisfies assumption (Ra).

5. Tools for the proof of Theorem 3.1. Let $1 < s < \infty$ and let B be a densely defined sectorial operator in a Banach space X. Let again $J =]T_0, T_1[$ for some $T_0, T_1 > 0$. We say that the linear evolution equation

$$\begin{aligned} u' + Bu &= f, \\ u(T_0) &= 0 \end{aligned} \tag{5.1}$$

admits maximal L^s-regularity on J if for any $f \in L^s(J; X)$ there exists a unique function $u \in W^{1,s}(J; X) \cap L^s(J; D(B))$ satisfying (5.1) in the L^s-sense. In that case, we write $B \in MR(s, X)$. Observe that

$$W^{1,s}(J; X) \cap L^s(J; D(B)) \hookrightarrow C(\overline{J}; X_s), \tag{5.2}$$

where X_s is the real interpolation space $(X, D(B))_{1-\frac{1}{s},s}$. Consider now the quasilinear problem

$$\begin{aligned} u'(t) + \mathcal{B}(t, u(t))u(t) &= F(t, u(t)), \quad t \in J, \\ u(T_0) &= u_0. \end{aligned} \tag{5.3}$$

Here $u_0 \in X_s$, $B := \mathcal{B}(T_0, u_0)$, and $\mathcal{B} : J \times X_s \to \mathcal{L}(D(B); X)$ is continuous. $F : J \times X_s \to X$ is a Carathéodory map. We assume the following Lipschitz conditions on $\mathcal{B}$ and F.

(B) For each $R > 0$ there exists a constant $C_R > 0$, such that

$$\begin{aligned} &\|\mathcal{B}(t, u)v - \mathcal{B}(t, \tilde{u})v\|_X \\ &\quad \le C_R \, ||u - \tilde{u}||_{X_s} ||v||_{D(B)}, \ t \in J, u, \tilde{u} \in X_s, ||u||_s, \ ||\tilde{u}||_s \le R, \ v \in D(B). \end{aligned} \tag{5.4}$$

(F) $F(\cdot, 0) \in L^s(J; X)$ and for each $R > 0$ there is a function $\eta_R \in L^s(J)$ such that

$$\|F(t, u) - F(t, \tilde{u})\|_X \le \eta_R(t) \, \|u - \tilde{u}\|_s \text{ a.a. } t \in J, \ u, \tilde{u} \in X_s, \ ||u||_s, \|\tilde{u}\|_s \le R. \tag{5.5}$$

Then the following existence and uniqueness result due to Clément and Li [10] and Prüss [34] holds true.

THEOREM 5.1. *Assume that* (B) *and* (F) *are satisfied and that* $B := \mathcal{B}(T_0, u_0)$ *has the property of maximal* L^s*-regularity. Then there exists* $T \in]T_0, T_1[$ *such that* (5.3) *admits a unique solution* u *on* $I :=]T_0, T[$ *satisfying*

$$u \in W^{1,s}(I; X) \cap \ L^s(I; D(B)).$$

In order to verify the crucial condition that $B = \mathcal{B}(T_0, u_0)$ has maximal L^s-regularity in our situation, we need the following results on traces, heat kernels, their multiplicative perturbations, and maximal L^s-regularity.

Consider a closed subspace V of $H^1(\Omega)$ which includes $H^1_0(\Omega)$. Let $\varrho \in L^\infty(\Omega, M_{n\times n})$ and assume that it is elliptic in the sense of (2.1). Define a bilinear form $a : V \times V \to \mathbb{R}$ on V by

$$a(u,v) = -\int_\Omega \varrho \nabla u \cdot \nabla u \, \mathrm{d}x, \quad u, v \in V.$$

Let A be the operator associated with a in $L^2(\Omega)$ and let $(e^{tA})_{t\geq 0}$ be the semigroup on $L^2(\Omega)$ generated by A. The following result gives sufficient conditions on the subspace V such that $(e^{tA})_{t\geq 0}$ satisfies an upper Gaussian bound. More precisely, the following Proposition holds; see, [4, Ch. 4].

PROPOSITION 5.2. *Assume that V is a closed subspace of $H^1(\Omega)$ satisfying*
(a) $H^1_0(\Omega) \subseteq V$,
(b) *V has the L^1-H^1 extension property,*
(c) $u \in V$ *implies* $|u|,\ \inf(|u|, 1) \in V$,
(d) $u \in V,\ v \in H^1(\Omega),\ |v| \leq u$ *implies* $v \in V$.
Then e^{tA} satisfies an upper Gaussian estimate, i.e.,

$$(e^{tA} f)(x) = \int_\Omega K_t(x,y) f(y) \mathrm{d}y \quad \text{a.a. } x \in \Omega,\ f \in L^2(\Omega)$$

for some measurable function $K_t : \Omega \times \Omega \to \mathbb{R}_+$ and there exists constants $M, a > 0$ and $\omega \in \mathbb{R}$ such that

$$0 \leq K_t(x,y) \leq \frac{M}{t^{\frac{n}{2}}} \, e^{\frac{-a|x-y|^2}{t}} \, e^{\omega t}, \quad t > 0,\ \text{a.a. } x, y \in \Omega. \tag{5.6}$$

LEMMA 5.3. *Let $H^1_{\Gamma_N}(\Omega)$ be defined as above. Then $V := H^1_{\Gamma_N}(\Omega)$ satisfies the assumptions* (a)–(d) *of Proposition* 5.2.

Proof. We will not give a detailed proof—which is given in [4] in the case of domains with Lipschitz boundary. Let us only notice that assertion (a) is obvious and that (b) is assured by the fact that Lipschitz domains are extensions domains for $H^{1,2}$; see [21, Thm. 3.10] or [32, section 1.1.16]. Inspecting the corresponding proofs (which are given via localization, Lipschitz diffeomorphism, and reflection), one recognizes that the extension mapping simultaniously extends continuously to L^1. The assertions (c) and (d) may be proved essentially as in [4] (see Example 4.3). In fact, the continuity results for the mappings $u \to \inf(u, v)$ and $u \to |u|$ given in [31] are stated without any restriction on the regularity of the domain Ω. ∎

Consider the semigroup e^{tA_k} on $L^2(\Omega)$ generated by A_k associated with the form a_k defined in (2.2) with $V = H^1_{\Gamma_N}(\Omega)$. It follows from Proposition 5.2 and Lemma 5.3 that e^{tA_k} is a positive semigroup on $L^2(\Omega)$ satisfying an upper Gaussian bound. Hence, $(e^{tA_k})_{t\geq 0}$ extends to a positive C_0-semigroup of contractions on $L^q(\Omega)$ for all $1 \leq q < \infty$.

PROPOSITION 5.4. *Let $b \in L^\infty(\Omega, \mathbb{R})$ such that $\inf_{x\in\Omega} |b(x)| \geq \delta$ for some $\delta > 0$. Let $1 < s, q < \infty$. Then $bA_k \in MR(s, L^q(\Omega))$ for all $k \in \{1, \dots, m\}$.*

Proof. Let $k \in \{1, \dots, m\}$. By the above remark, e^{tA_k} is a positive contraction semigroup on $L^q(\Omega)$ satisfying an upper Gaussian bound. Hence, the kernel K_t of $e^{t(A_k - \alpha Id)})_{t\geq 0}$ satisfies (5.6) with $\omega = 0$ for suitable $\alpha \in \mathbb{R}$. Moreover, $A_k - \alpha Id$ is self-adjoint in $L^2(\Omega)$. By a result due to Duong and Ouhabaz [13], the semigroup on

$L^2(\Omega)$ generated by $b(A_k - \alpha Id)$ satisfies an upper Gaussian bound with $\omega = 0$ as well. Thus $b(A_k - \alpha Id) \in MR(s, L^q(\Omega))$ by a result of Hieber and Prüss (see [27] or [12, Thm. 4.8]). Finally, $bA_k \in MR(s, L^q(\Omega))$ due to the lower order perturbation result of maximal regularity; see [12, Prop. 4.3]. ∎

PROPOSITION 5.5. *Let $p > \frac{n}{2}$ be the number from Assumption* (Op) *and assume that $\theta \in (\frac{1}{2} + \frac{n}{4p}, 1]$. Then*

$$[L^p, D(A_k^p)]_\theta \hookrightarrow W^{1,2p}_{\Gamma_N}(\Omega).$$

A proof for the three-dimensional case is given in [35]; the two-dimensional case requires only obvious modifications. A complete, but technically more involved, proof for the two-dimensional case is contained in [29], see Thm. 5.2.

COROLLARY 5.6. *Let $r > \frac{4p}{2p-n}$. Then*

$$(L^p, D(A_k^p))_{1-\frac{1}{r},r} \hookrightarrow W^{1,2p}_{\Gamma_N}(\Omega).$$

Proof. Let θ be any number from the interval $]\frac{1}{2} + \frac{n}{4p}, 1 - \frac{1}{r}[$. By interpolation

$$(L^p, D(A_k^p))_{1-\frac{1}{r},r} \hookrightarrow (L^p, D(A_k^p))_{\theta,1} \hookrightarrow [L^p, D(A_k^p)]_\theta.$$

Then the assertion follows from the embedding property of the complex interpolation space into $W^{1,2p}_{\Gamma_N}(\Omega)$ established in Proposition 5.5. ∎

6. Proof of the main result. We first set $X := \big(L^p(\Omega)\big)^m$, $\mathcal{D} := \times_{k=1}^m D(A_k^p)$, and $X_r := (X, \mathcal{D})_{1-\frac{1}{r},r}$ for r as above. By assumption (IC), $w_0 \in X_r$. Further, for every pair $(t, z) \in [T_0, T_1) \times W^{1,2p}(\Omega)^m$ we define the mapping $H(t, z) : X \mapsto X$ via

$$\varphi := (\varphi_1, \dots, \varphi_m) \mapsto \big(H_1(t, z)\varphi_1, \dots, H_m(t, z)\varphi_m\big). \tag{6.1}$$

Since $H_k(t, z) \in L^\infty(\Omega)$ and since H_k possesses a strictly positive lower bound, it follows that

$$D(H_k(t, z)A_k^p) = D(A_k^p).$$

In particular, $D(H_k(T_0, w_0)A_k^p))$ is dense in $L^p(\Omega)$ (see [22, Thms. 4.5 and 4.7]).

Consider the mapping $\mathcal{B} : J \times X_r \to \mathcal{L}(\mathcal{D}; X)$ given by

$$\mathcal{B}(t, z)\varphi := H(t, z)(A_1^p\varphi_1, \dots, A_m^p\varphi_m), \quad \varphi = (\varphi_1, \dots, \varphi_m) \in \mathcal{D}.$$

By Corollary 5.6 and Morrey's theorem we have

$$X_r \hookrightarrow \big(W^{1,2p}_{\Gamma_N}(\Omega)\big)^m \hookrightarrow \big(C^\alpha(\Omega)\big)^m$$

for some $\alpha > 0$. Thus, the assumed properties on F_k, G_k, and ϕ_k imply that

$$\mathcal{B} : J \times X_r \to \mathcal{L}(\mathcal{D}; X)$$

is continuous. Moreover, for $\beta > 0$ there exists $C_\beta > 0$ such that

$$\|H(t, z) - H(t, \tilde{z})\|_\infty \le C_\beta \|z - \tilde{z}\|_{W^{1,2p}}$$

provided $t \in J$ and $\|z\|_{X_r}$ and $\|\tilde{z}\|_{X_r} \le \beta$. Hence, (5.4) from assertion (B) is fulfilled.

Furthermore, (5.5) from assertion (F) holds due to the assumed properties of F_k, G_k, ϕ, R_k and Corollary 5.6. It remains to verify the key condition of Theorem 5.1, namely that $B := \mathcal{B}(T_0, w_0)$ has the property of maximal regularity. To this end, recall that $H(T_0, w_0) \in \big(L^\infty(\Omega)\big)^m$ with a strictly positive lower bound in each component. Thus, $B \in MR(r, X)$ by Proposition 5.4. Finally, an application of Theorem 5.1 ends the proof of Theorem 3.1.

It remains to show that if w is a solution of (3.1), then $v := w + \phi$ provides a solution of (1.1). This will be done in the appendix. ∎

We now give a proof of Corollary 3.2; in fact we prove the following sharper result.

LEMMA 6.1. *There exists $\beta > 0$ such that each component w_k of the solution w of (3.1) belongs to the space $C^\beta(]T_0, T[; W^{1,2p}_\Gamma(\Omega)) \hookrightarrow C^\beta(]T_0, T[; C^\alpha(\Omega))$.*

Proof. We write for short $D_k = D(A_k)$ and $I =]T_0, T[$. Then

$$W^{1,r}(I; L^p) \cap L^r(I; D_k) \hookrightarrow C(\bar{I}; (L^p, D_k)_{1-\frac{1}{r},r}) \hookrightarrow C(\bar{I}; [L^p, D_k]_\theta)$$

if $\theta \in]0, 1 - \frac{1}{r}[$.

Moreover, we have the embedding

$$W^{1,r}(I; L^p) \hookrightarrow C^\delta(I; L^p) \quad \text{with} \quad \delta = 1 - \frac{1}{r}.$$

Fix $\theta \in]\frac{1}{2} + \frac{n}{4p}, 1 - \frac{1}{r}[$ and let $\lambda \in (0, 1)$ be given such that

$$\theta\lambda > \frac{1}{2} + \frac{n}{4p}.$$

In view of Proposition 5.5 and the reiteration theorem for complex interpolation (see [40, Ch. 1.9.3]) we obtain

$$\begin{aligned}
\frac{\|w_k(t) - w_k(s)\|_{W^{1,2p}}}{|t-s|^{\delta(1-\lambda)}} &\le c\, \frac{\|w_k(t) - w_k(s)\|_{[L^p, D_k]_{\theta\lambda}}}{|t-s|^{\delta(1-\lambda)}} \sim \frac{\|w_k(t) - w_k(s)\|_{\left[L^p, [L^p, D_k]_\theta\right]_\lambda}}{|t-s|^{\delta(1-\lambda)}} \\
&\le \hat{c}\, \frac{\|w_k(t) - w_k(s)\|^{1-\lambda}_{L^p}}{|t-s|^{\delta(1-\lambda)}} \|w_k(t) - w_k(s)\|^\lambda_{[L^p, D_k]_\theta} \\
&= \hat{c} \left(\frac{\|w_k(t) - w_k(s)\|_{L^p}}{|t-s|^\delta}\right)^{1-\lambda} \left(2 \sup_{s \in \bar{I}} \|w_k(s)\|_{[L^p, D_k]_\theta}\right)^\lambda. \qquad ∎
\end{aligned}$$

7. Appendix. It remains to show that if w is a solution of (3.1), then $v := w + \phi$ provides a solution of (1.1). One easily recognizes that all the manipulations which transfrom (1.1) into (3.1) are straightforward to justify within the distributional calculus, except one. Therefore, we will give a strict justification of this point in the following lemma. Throughout this appendix, $f : \mathbb{R} \mapsto \mathbb{R}$ is always assumed to be twice continuously differentiable.

LEMMA 7.1. *Assume $p, r \in]1, \infty[$ and $v \in W^{1,r}(]T_0, T[; L^p) \cap C([T_0, T]; C(\bar{\Omega}))$. Then the function $]T_0, T[\ni t \mapsto f(v(t))$ belongs to $W^{1,r}(]T_0, T[; L^p)$ and its distributional derivative is the function $]T_0, T[\ni t \mapsto f'(v(t))v'(t) \in L^r(]T_0, T[; L^p)$.*

Remark 7.2. We denote by $C^1(]T_0, T[; L^p)$ the space of all L^p-valued, continuously differentiable functions on $]T_0, T[$ with bounded derivatives on $]T_0, T[$.

In order to give a proof of Lemma 7.1 we use the following result.

LEMMA 7.3. *Let $[T_0, T] \ni t \mapsto \psi(t, \cdot)$ be a mapping belonging to $C([T_0, T]; C(\bar{\Omega})) \cap C^1(]T_0, T[; L^p)$. Then the mapping*

$$]T_0, T[\ni t \mapsto f(\psi(t, \cdot)) \tag{7.1}$$

takes its values in $C(\bar{\Omega}) \hookrightarrow L^p$. It is continuously differentiable when regarded as L^p-valued and its derivative in a point $s \in]T_0, T[$ is equal to the L^p-function $f'(\psi(s, \cdot))\psi'(s)$.

Proof. The first assertion is obvious. Concerning the second one, the set $\{\psi(t,x)/ x \in \Omega, t \in [T_0,T]\}$ is bounded. Since f is twice continuously differentiable, for $s,t \in]T_0,T[$ and $x \in \Omega$ one may apply Taylor's formulae:

$$\frac{f(\psi(t,x)) - f(\psi(s,x))}{t-s} = f'(\psi(s,x))\frac{[\psi(t,x)-\psi(s,x)]}{t-s} \tag{7.2}$$

$$+\int_0^1 (1-\tau)f''((1-\tau)\psi(t,x)+\tau\psi(s,x))\,d\tau \quad \frac{[\psi(t,x)-\psi(s,x)]^2}{t-s}. \tag{7.3}$$

The family $\{f'(\psi(s,\cdot))\frac{[\psi(t,\cdot)-\psi(s,\cdot)]}{t-s}\}_t$ converges by the supposition on the differentiablity of the mapping $t \mapsto \psi(t,\cdot)$ in L^p to $f'(\psi(s,\cdot))\psi'(s)$ if t approaches s . It remains to show that the expression in (7.3) approaches zero in L^p. This follows easily from the uniform boundedness of the values $f''((1-\tau)\psi(t,x)+\tau\psi(s,x))$, the boundedness of $\{\frac{[\psi(t,\cdot)-\psi(s,\cdot)]}{t-s}\}_t$ in L^p, and the convergence of $[\psi(t,\cdot)-\psi(s,\cdot)]$ to zero in $C(\bar\Omega)$ for t approaching s. The continuity of the derivative follows from the continuity of ψ' and the continuity of the function $t \mapsto f'(\psi(t,\cdot))$ in $C(\bar\Omega)$. ∎

LEMMA 7.4. *Let $v \in W^{1,r}(]T_0,T[;L^p) \cap C([T_0,T];C(\bar\Omega))$. Then there is a sequence $\{\psi_l\}_l$ in $C([T_0,T];C(\bar\Omega)) \cap C^1(]T_0,T[;L^p(\Omega))$ such that $\psi_l \mapsto v$ in $C([T_0,T];C(\bar\Omega))$ and $\psi_l' \mapsto v'$ in $L^r(]T_0,T[;L^p)$.*

Proof. Let us define a continuous extension $\tilde v$ to all of $\mathbb{R}$ which additionally has compact support as follows: we put

$$\hat v(t) := \begin{cases} v(T_0+(T_0-t)) & \text{if} \quad t \in]T_0-(T-T_0),T_0[, \\ v(t) & \text{if} \quad t \in [T_0,T], \\ v(T-(t-T) & \text{if} \quad t \in]T,T+(T-T_0)[\end{cases} \tag{7.4}$$

(reflection at T_0, T, respectively). Afterwards we multiply $\hat v$ by a real-valued, continuously differentiable function which is identical 1 on $[T_0,T]$ and which has its support in $]T_0-(T-T_0)/2, T+(T-T_0)/2[$. We define this product as $\tilde v$ and identify $\tilde v$ with its extension by zero to whole $\mathbb{R}$. Oviously, $\tilde v|_{[T_0,T]} = v$; further one verifies the property $\tilde v \in W^{1,r}(\mathbb{R};L^p) \cap C(\mathbb{R};C(\bar\Omega))$. Let ϑ be the usual mollifier function

$$\vartheta(s) = \begin{cases} \frac{1}{\int e^{-\frac{1}{1-s^2}}ds} e^{-\frac{1}{1-s^2}} & \text{if} \quad |s|<1, \\ 0 & \text{else on } \mathbb{R} \end{cases}$$

and $\vartheta_l(s) := l\vartheta(l\,s)$. Now we put

$$\psi_l(t) := \begin{cases} \int_{T_0}^t (\tilde v' * \vartheta_l)(s)\,ds + (\tilde v * \vartheta_l)(T_0) & \text{if} \quad t \ge T_0, \\ -\int_t^{T_0} (\tilde v' * \vartheta_l)(s)\,ds + (\tilde v * \vartheta_l)(T_0) & \text{if} \quad t < T_0. \end{cases} \tag{7.5}$$

Then ψ_l is nothing else but $\tilde v * \vartheta_l$. This yields $\psi_l \mapsto v$ in $C([T_0,T];C(\bar\Omega))$. On the other hand, (7.5) immediately gives $\psi_l' = \tilde v' * \vartheta_l$. This means that $\psi_l' \mapsto \tilde v'$ in $L^r(\mathbb{R};L^p)$, which implies $\psi_l'|_{]T_0,T[} \mapsto v'$ in $L^r(]T_0,T[;L^p)$. ∎

We now turn to the proof of Lemma 7.1. Let $\{\psi_l\}_l$ be the sequence from the previous lemma and $\varphi \in C_0^\infty(]T_0,T[)$. Then, considering the function $]T_0,T[\ni t \mapsto f(v(t))$ as an L^p-valued distribution, one gets by the definition of the weak derivative

$$\big(f(v)\big)'(\varphi) = -f(v)(\varphi') = -\int_{T_0}^T f(v(s))\varphi'(s)\,ds = -\int_{T_0}^T \lim_{l\mapsto\infty} f(\psi_l(s))\varphi'(s)\,ds$$

$$= \lim_{l\mapsto\infty} -\int_{T_0}^T f(\psi_l(s))\varphi'(s)\,ds.$$

By Lemma 7.3, each $f(\psi_l)$ even has a strong (time) derivative which equals $f'(\psi_l)\psi_l'$. From this and integrating by parts one gets

$$-\int_{T_0}^{T} f(\psi_l(s))\varphi'(s)\,ds = \int_{T_0}^{T} f'(\psi_l(s))\psi_l'(s)\varphi(s)ds.$$

By construction, $\psi_l \mapsto v$ in $C([T_0,T];C(\bar{\Omega}))$, $\psi_l' \mapsto v'$ in $L^r(]T_0,T[;L^p)$, which implies $f'(\psi_l(\cdot))\psi_l'\varphi \mapsto f'(v(\cdot))v'\varphi$ in $L^r(]T_0,T[;L^p)$. But the integral is a continuous mapping from $L^r(]T_0,T[;L^p)$ into L^p; this finally gives

$$\begin{aligned}\int_{T_0}^{T} f'(v(s))v'(s)\varphi(s)\,ds &= \int_{T_0}^{T} \lim_{l\mapsto\infty} f'(\psi_l(s))\psi_l'(s)\varphi(s)ds \\ &= \lim_{l\mapsto\infty}\int_{T_0}^{T} f'(\psi_l(s))\psi_l'(s)\varphi(s)ds \\ &= \lim_{l\mapsto\infty} -\int_{T_0}^{T} f(\psi_l(s))\varphi'(s)\,ds = \big(f(v)\big)'(\varphi).\end{aligned}$$

Thus, Lemma 7.1 is proved.

Acknowlegments. The second author would like to thank K. Gröger and J. Griepentrog for stimulating discussions on the subject of the paper.

A VARIATIONAL INEQUALITY ARISING FROM EUROPEAN INSTALLMENT CALL OPTIONS PRICING*

FAHUAI YI†, ZHOU YANG†, AND XIAOHUA WANG‡

Abstract. In this paper we consider a parabolic variational inequality arising from European continuous installment call options pricing and prove the existence and uniqueness of the solution to the problem. Moreover, we obtain C^∞ regularity and the bounds of the free boundary, as well as the limit of the free boundary as $\tau = T - t \to +\infty$. Eventually we show its numerical result by the binomial method.

Key words. free boundary, variational inequality, option pricing, European installment call options

1. Introduction.

In this paper we consider a parabolic variational inequality arising from the model of European continuous installment call options pricing. More precisely, we will find $C(S,t)$ satisfying

$$
\begin{cases}
\partial_t C + \frac{\sigma^2}{2} S^2 \partial_{SS} C + (r-q) S \partial_S C - rC = L^* \\
\qquad\qquad \text{if } C > 0 \text{ and } (S,t) \in (0,+\infty) \times (0,T\,], \\
\partial_t C + \frac{\sigma^2}{2} S^2 \partial_{SS} C + (r-q) S \partial_S C - rC \le L^* \\
\qquad\qquad \text{if } C = 0 \text{ and } (S,t) \in (0,+\infty) \times (0,T\,], \\
C(S,T) \ = (S-K)^+, \qquad\qquad S \in [\,0,+\infty),
\end{cases}
\tag{1.1}
$$

where σ, r, L^*, and K are positive constants and q is a nonnegative constant.

In the appendix we present the financial and stochastic background of this problem.

If $L^* = 0$ in problem (1.1), it is standard European call option, which has an explicit analytic formula of solution and does not have free boundary at all (see [11]). We will find that the case $L^* > 0$ is more complicated than the case $L^* = 0$.

There are some papers in the field of install options, such as [7], [8], [1], [6], in which the authors developed the models and numerical analysis. Particularly, Alobaidi, Mallier, and Deakin showed the behavior of the free boundary $S_s(\tau)$ in (1.1) close to expire by Laplace transforms in [1], that is,

$$
S_s(\tau) \sim K \exp\{-\sigma(-\tau \ln \tau)^{1/2}(1 + o(1))\} \quad \text{as } \tau = T - t \to 0^+. \tag{1.2}
$$

Since (1.1) is a degenerate backward parabolic problem, we transform it into a familiar forward nondegenerate parabolic variational inequality problem. Thus, letting

$$V(x,\tau) = C(S,t)/K, \qquad \tau = T - t, \qquad x = \ln(S/K), \qquad L = L^*/K, \tag{1.3}$$

then we have

$$\begin{cases} \partial_\tau V - \mathcal{L}_x V = -L & \text{if } V > 0 \quad \text{and} \quad (x,\tau) \in \mathbb{R} \times (0,T\,], \\ \partial_\tau V - \mathcal{L}_x V \geq -L & \text{if } V = 0 \quad \text{and} \quad (x,\tau) \in \mathbb{R} \times (0,T\,], \\ V(x,0) \ = (e^x - 1)^+, & \qquad\qquad\quad\ \ x \in \mathbb{R}, \end{cases} \tag{1.4}$$

where

$$\mathcal{L}_x V = \frac{\sigma^2}{2}\partial_{xx} V + \left(r - q - \frac{\sigma^2}{2}\right)\partial_x V - rV. \tag{1.5}$$

We focus our attention on the monotonicity, regularity, and bounds of the free boundary as well as the limit of the free boundary as $\tau \to +\infty$ in problem (1.4).

As we know, the behavior $\partial_\tau V \geq 0$ is quite important for investigation of the regularity properties of the free boundary. Based on this behavior it can be deduced that $\partial_\tau V$ is continuous across the free boundary and C^∞ regularity of the free boundary follows (for the one-dimensional case, see [9], and for higher dimensions, see [4]). In the absence of condition $\partial_\tau V \geq 0$, the latest development is that $\partial_\tau V$ is continuous for almost all time (see [3]) and the free boundary possesses C^∞ regularity locally around some points which are energetically characterized (see [5]). Those results manifest that the analysis for regularity of the free boundary is not thoroughly solved.

In our case $V(x,0) = e^x - 1$ if $x \geq 0$; combining Lemma 4.4 in this paper, we see that

$$\partial_\tau V(x,0) = \mathcal{L}_x(e^x - 1) - L = r - qe^x - L \quad \text{if } \ x > 0.$$

It is clear that $\partial_\tau V(x,0) < 0$ if $q > 0$ and x is large enough.

In the next section, we will construct a transformation (2.1) and deduce a new unknown function $v(y,\tau)$ satisfying the variational inequality (2.2), which is important to the property $\partial_\tau v \geq 0$; then we prove the existence and uniqueness of the $W^{2.1}_{p,\,loc}$ solution to the new parabolic variational inequality (2.2). The main work is in sections 3 and 4. In section 3 we prove that the new free boundary is monotonic and C^∞-smooth based on the results in section 2. Moreover, we will show the starting point, the bounds of the free boundary, and the limit behavior of the free boundary as $\tau \to +\infty$. In section 4, we come back to consider the behavior of the free boundary of problem (1.4): it is C^∞-smooth on $(0,+\infty)$, and its monotonicity depends on the relationship of parameters σ, r, q, and L in the problem. In section 5, we focus our attention on the monotonicity of free boundary with respect to the parameters r, q, and L. In the last section, we provide numerical result applying the binomial method.

2. Existence and uniqueness of $W^{2,1}_{p,\,loc}$ solution of problem (1.4). As mentioned in the previous section, applying the transformation

$$y = x + (r - q - p^*)\tau, \quad p^* = \max\{r,\, L\}, \quad v(y,\tau) = V(x,\tau), \tag{2.1}$$

problem (1.4) then becomes

$$\begin{cases} \partial_\tau v - \mathcal{L}_y v = -L & \text{if } v > 0 \quad \text{and} \quad (y,\tau) \in \mathbb{R} \times (0,T\,], \\ \partial_\tau v - \mathcal{L}_y v \geq -L & \text{if } v = 0 \quad \text{and} \quad (y,\tau) \in \mathbb{R} \times (0,T\,], \\ v(y,0) \ = (e^y - 1)^+, & \qquad\qquad\quad\ \ y \in \mathbb{R}, \end{cases} \tag{2.2}$$

where

$$\mathcal{L}_y v = \frac{\sigma^2}{2}\partial_{yy} v + \left(p^* - \frac{\sigma^2}{2}\right)\partial_y v - rv. \tag{2.3}$$

Since the problem lies in the unbounded domain $\Omega_T = \mathbb{R}\times(0,T\,]$, we first consider the problem in the bounded domain $\Omega_T^n = (-n,n)\times(0,T\,],\ n \in \mathbb{Z}^+$:

$$\begin{cases} \partial_\tau v_n - \mathcal{L}_y v_n = -L & \text{if } v_n > 0 \quad \text{and} \quad (y,\tau) \in \Omega_T^n, \\ \partial_\tau v_n - \mathcal{L}_y v_n \geq -L & \text{if } v_n = 0 \quad \text{and} \quad (y,\tau) \in \Omega_T^n, \\ v_n(-n,\tau) = 0, \qquad \partial_y v_n(n,\tau) = e^{n+(p^*-r)\tau}, & \qquad\qquad\quad\ \ \tau \in [\,0,T\,], \\ v_n(y,0) \ = (e^y - 1)^+, & \qquad\qquad\quad\ \ y \in [\,-n,n\,]. \end{cases} \tag{2.4}$$

LEMMA 2.1. *For any fixed $n \in \mathbb{Z}^+$, there exists a unique solution $v_n \in C(\overline{\Omega_T^n}) \cap W_p^{2,1}(\Omega_T^n \backslash B_\delta(P_0))$ to problem (2.4), where $\forall\ 1 < p < +\infty$, and $\delta > 0$, $P_0 = (0,0)$, $B_\delta(P_0) = \{(y,\tau) : y^2 + \tau^2 \leq \delta^2\}$. Moreover, if n is large enough, we have*

$$(e^y - 1)^+ \leq v_n \leq e^{y+(p^*-r)\tau}, \tag{2.5}$$

$$\partial_\tau v_n \geq 0, \tag{2.6}$$

$$\partial_y v_n \geq 0. \tag{2.7}$$

Proof. As usual we define a penalty function $\beta_\varepsilon(t)$ (see Figure 1), which satisfies

$$\varepsilon > 0 \text{ and small enough}, \quad \beta_\varepsilon(t) \in C^\infty(-\infty,+\infty),$$
$$\beta_\varepsilon(t) \leq 0, \qquad 0 \leq \beta_\varepsilon'(t) \leq 2L/\varepsilon, \qquad \beta_\varepsilon'' \leq 0,$$

and

$$\beta_\varepsilon(t) = \begin{cases} 0, & t \geq 2\varepsilon, \\ \frac{2L}{\varepsilon}t - 3L - r\varepsilon, & t \leq 3\varepsilon/2. \end{cases} \tag{2.8}$$

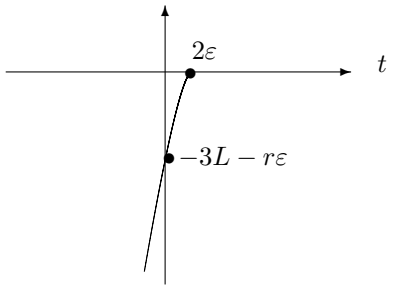

FIG. 1.

Then

$$\beta_\varepsilon(\varepsilon) = -L - r\varepsilon, \qquad \beta_\varepsilon(0) = -3L - r\varepsilon. \tag{2.9}$$

Since $(e^y-1)^+$ is not smooth enough, we need to smooth it. Define $\pi_\varepsilon(t)$ (see Figure 2):

$$\pi_\varepsilon(t) = \begin{cases} t, & t \geq \varepsilon, \\ 0, & t \leq -\varepsilon, \end{cases} \tag{2.10}$$

$\pi_\varepsilon(t) \in C^\infty$, $0 \leq \pi'_\varepsilon(t) \leq 1$, $\pi''_\varepsilon(t) \geq 0$, $\lim_{\varepsilon\to 0^+} \pi_\varepsilon(t) = t^+$.

Following the idea in [10], construct an approximation of problem (2.4):

$$\begin{cases} \partial_\tau v_{\varepsilon,n} - \mathcal{L}_y v_{\varepsilon,n} + \beta_\varepsilon(v_{\varepsilon,n}) = -L & \text{in } \Omega_T^n, \\ v_{\varepsilon,n}(-n,\tau) = 0, \qquad \partial_y v_{\varepsilon,n}(n,\tau) = e^{n+(p^*-r)\tau}, & \tau \in [\,0,T\,], \\ v_{\varepsilon,n}(y,0) = \pi_\varepsilon(e^y-1), & y \in [\,-n,n\,]. \end{cases} \tag{2.11}$$

Applying Schauder's fixed point theorem, it is not difficult to get the existence of the $W_p^{2,1}$ solution to problem (2.11). The proof of uniqueness is standard as well, so we omit the details.

If we can prove that, as ε is small enough,

$$\pi_\varepsilon(e^y-1) \leq v_{\varepsilon,n} \leq e^{y+(p^*-r)\tau}, \tag{2.12}$$

then

$$-3L - r\varepsilon \leq \beta_\varepsilon(v_{\varepsilon,n}) \leq 0.$$

This means that $\beta_\varepsilon(v_{\varepsilon,n})$ is a bounded function and its bound is independent of ε. It is deduced that, by $W_p^{2,1}$ and C^α $(0<\alpha<1)$ estimates of the parabolic problem,

$$|v_{\varepsilon,n}|_{W_p^{2,1}(\Omega_T^n \setminus B_\delta(P_0))} \leq C,$$
$$|v_{\varepsilon,n}|_{C^\alpha(\overline{\Omega_T^n})} \leq C,$$

where C is independent of ε. It is not difficult to derive that, as $\varepsilon \to 0^+$,

$$v_{\varepsilon,n} \to v_n \ \text{ in } \ W_p^{2,1}(\Omega_T^n \setminus B_\delta(P_0)) \text{ weakly} \qquad \text{and} \qquad v_{\varepsilon,n} \to v_n \ \text{ in } \ C(\overline{\Omega_T^n}),$$

where v_n is the solution of problem (2.4).

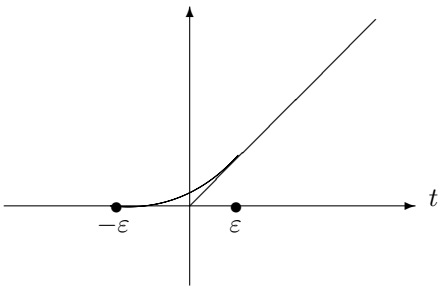

FIG. 2.

Next we prove (2.12). In the first, if ε is small enough, the properties of β_ε, π_ε, and (2.9) imply that

$$\begin{aligned}
&\partial_\tau \pi_\varepsilon(e^y-1) - \mathcal{L}_y\,\pi_\varepsilon(e^y-1) + \beta_\varepsilon(\pi_\varepsilon(e^y-1)) + L\\
&= -\frac{\sigma^2}{2}\pi_\varepsilon''(e^y-1)e^{2y} - \max\{r,\,L\}\pi_\varepsilon'(e^y-1)e^y + r\pi_\varepsilon(e^y-1) + \beta_\varepsilon(\pi_\varepsilon(e^y-1)) + L\\
&\le \begin{cases} r\pi_\varepsilon(e^y-1) + \beta_\varepsilon(\pi_\varepsilon(e^y-1)) + L \le r\varepsilon + \beta_\varepsilon(\varepsilon) + L \le 0, & e^y-1 \le \varepsilon,\\ -\max\{r,\,L\}e^y + r(e^y-1) + L \le 0, & e^y-1 > \varepsilon. \end{cases}
\end{aligned}$$

Furthermore, from the initial and boundary conditions in (2.11), we deduce that if ε is small enough,

$$\begin{cases} \pi_\varepsilon(e^y-1) = 0 = v_{\varepsilon,\,n}(y,\tau), & y=-n,\\ \partial_y\pi_\varepsilon(e^y-1) = \partial_y(e^y-1) = e^n \le e^{n+(p^*-r)\tau} = \partial_y v_{\varepsilon,\,n}(y,\tau), & y=n,\\ \pi_\varepsilon(e^y-1) = v_{\varepsilon,\,n}(y,0), & \tau=0. \end{cases}$$

From the comparison principle, we deduce $\pi_\varepsilon(e^y-1) \le v_{\varepsilon,\,n}$.

On the other hand, if $2\varepsilon < e^{-n}$, it is not difficult to check $\beta_\varepsilon(e^{y+(p^*-r)\tau}) \ge \beta_\varepsilon(e^{-n}) \ge \beta_\varepsilon(2\varepsilon) = 0$; hence, from (2.3),

$$\begin{aligned}
&\partial_\tau e^{y+(p^*-r)\tau} - \mathcal{L}_y e^{y+(p^*-r)\tau} + \beta_\varepsilon(e^{y+(p^*-r)\tau}) + L\\
&\ge e^{y+(p^*-r)\tau}\left(p^* - r - \frac{\sigma^2}{2} - \left(p^* - \frac{\sigma^2}{2}\right) + r\right) + 0 + L = L \ge 0 \quad \forall\,(y,\tau)\in\Omega_T^n.
\end{aligned}$$

Moreover, if $2\varepsilon < e^{-n}$, there holds

$$e^y = \pi_\varepsilon(e^y) \ge \pi_\varepsilon(e^y-1).$$

From the initial and boundary conditions in (2.11), we see that if $2\varepsilon < e^{-n}$,

$$\begin{cases} e^{y+(p^*-r)\tau} \ge 0 = v_{\varepsilon,\,n}(y,\tau), & y=-n,\\ \partial_y e^{y+(p^*-r)\tau} = e^{n+(p^*-r)\tau} = \partial_y v_{\varepsilon,\,n}(y,\tau), & y=n,\\ e^{y+(p^*-r)\tau} = e^y \ge \pi_\varepsilon(e^y-1) = v_{\varepsilon,\,n}(y,0), & \tau=0. \end{cases}$$

Then the comparison principle implies $e^{y+(p^*-r)\tau} \ge v_{\varepsilon,\,n}$; hence, we obtain (2.12), and (2.5) is a consequence of (2.12).

In the following, we prove (2.6). In fact, for any small $\delta > 0$, $v_{\varepsilon,\,n}(x,\tau+\delta)$ satisfies, by (2.11),

$$\begin{cases} \partial_\tau v_{\varepsilon,\,n}(y,\tau+\delta) - \mathcal{L}_y v_{\varepsilon,\,n}(y,\tau+\delta) + \beta_\varepsilon(v_{\varepsilon,\,n}(y,\tau+\delta)) = -L, & \\ \qquad\qquad (y,\tau)\in(-n,n)\times(0,T-\delta\,], & \\ v_{\varepsilon,\,n}(-n,\tau+\delta) = 0 = v_{\varepsilon,\,n}(-n,\tau), & \tau\in[\,0,T-\delta\,],\\ \partial_y v_{\varepsilon,\,n}(n,\tau+\delta) = e^{n+(p^*-r)(\tau+\delta)} \ge \partial_y v_{\varepsilon,\,n}(n,\tau), & \tau\in[\,0,T-\delta\,],\\ v_{\varepsilon,\,n}(y,0+\delta)\ \ge \pi_\varepsilon(e^y-1) = v_{\varepsilon,\,n}(y,0), & y\in[\,-n,n\,]. \end{cases}$$

Applying the comparison principle for solutions of PDEs with respect to initial and boundary values, we obtain

$$v_{\varepsilon,\,n}(y,\tau+\delta) \ge v_{\varepsilon,\,n}(y,\tau) \quad \forall\,(y,\tau)\in(-n,n)\times[\,0,T-\delta\,] \qquad \text{and} \qquad \partial_\tau v_{\varepsilon,\,n} \ge 0.$$

Take $\varepsilon \to 0^+$ in the above inequalities. Then (2.6) follows.

For proving (2.7), derive (2.11) with respect to y, and denote $W = \partial_y v_{\varepsilon,n}$; then

$$\begin{cases} \partial_\tau W - \mathcal{L}_y W + \beta'_\varepsilon(v_{\varepsilon,n})W = 0, & (y,\tau) \in \Omega_T^n, \\ W(-n,\tau) = \partial_y v_{\varepsilon,n}(-n,\tau), & \tau \in [\,0,T\,], \\ W(n,\tau) = e^{n+(p^*-r)\tau} \geq 0, & \tau \in [\,0,T\,], \\ W(y,0) = \pi'_\varepsilon(e^y-1)e^y \geq 0, & y \in [\,-n,n\,]. \end{cases} \tag{2.13}$$

Since $v_{\varepsilon,n}(x,\tau)$ achieves its minimum 0 at each point of $x=-n$, so $\partial_y v_{\varepsilon,n}(-n,\tau) \geq 0$, then the minimum principle implies

$$\partial_y v_{\varepsilon,n} = W \geq 0. \tag{2.14}$$

Take $\varepsilon \to 0^+$. Then we obtain (2.7).

At last, we prove uniqueness. Suppose v_1 and v_2 are two $W^{2.1}_{p,loc}(\Omega_T^n) \bigcap C(\overline{\Omega_T^n})$ solutions to problem (2.4), and denote

$$\mathcal{N} = \{(y,\tau) : v_1(y,\tau) < v_2(y,\tau),\ -n < y < n,\ 0 < \tau \leq T\}.$$

Suppose it is not empty; then if $(y,\tau) \in \mathcal{N}$,

$$v_2(y,\tau) > 0, \quad \partial_\tau v_2 - \mathcal{L}_y v_2 = -L.$$

Denote $W = v_2 - v_1$. Then W satisfies

$$\begin{cases} \partial_\tau W - \mathcal{L}_y W \leq 0, & (y,\tau) \in \mathcal{N}, \\ W(y,0) = 0 & \text{on } \partial_p\mathcal{N} \setminus (\{n\} \times [\,0,T\,]), \\ \partial_y W(y,0) = 0 & \text{on } \partial_p\mathcal{N} \cap (\{n\} \times [\,0,T\,]), \end{cases}$$

where $\partial_p\mathcal{N}$ is the parabolic boundary of the domain $\mathcal{N}$. Applying the A-B-P maximum principle (see [13]), we have $W \leq 0$ in $\mathcal{N}$, which contradicts the definition of $\mathcal{N}$. □

THEOREM 2.2. *There exists a unique solution $v \in C(\overline{\Omega_T}) \cap W^{2,1}_p(\Omega_T^R \backslash B_\delta(P_0))$ to problem* (2.2), *where $\forall\ R > 0,\ \delta > 0,\ 1 < p < +\infty$. And $\partial_y v \in C(\Omega_T)$,*

$$(e^y - 1)^+ \leq v \leq e^{y+(p^*-r)\tau}, \tag{2.15}$$

$$\partial_\tau v \geq 0, \tag{2.16}$$

$$\partial_y v \geq 0. \tag{2.17}$$

Proof. Applying

$$(\partial_\tau - \mathcal{L}_y)\, 0 = 0,$$

we rewrite problem (2.4) as

$$\begin{cases} \partial_\tau v_n - \mathcal{L}_y v_n = f(y,\tau) & \text{in } \Omega_T^n, \\ v_n(-n,\tau) = 0, \qquad \partial_y v_n(n,\tau) = e^{y+(p^*-r)\tau}, & \tau \in [\,0,T\,], \\ v_n(y,0) = (e^y-1)^+, & y \in [\,-n,n\,]. \end{cases} \tag{2.18}$$

$v_n \in W^{2.1}_{p,loc}(\,\Omega_T^n)$ implies $f(y,\tau) \in L^p_{loc}(\,\Omega_T^n)$ and

$$f(y,\tau) = I_{\{v_n>0\}}(-L) \qquad \text{a.e. in } \Omega_T^n, \tag{2.19}$$

where I_A denotes the indicator function of the set A.

Hence, for any fixed $R > \delta > 0$, if $n > R$, combining (2.5), we have the following $W_p^{2.1}$ uniform interior estimates in the domain $\Omega_T^R \backslash B_\delta(P_0)$:

$$\|v_n\|_{W_p^{2.1}(\Omega_T^R \backslash B_\delta(P_0))} \leq C(\|v_n\|_{L^\infty(\Omega_T^R)} + \|(e^y - 1)^+\|_{C^2([-R,-\delta]\cup[\delta,R])} + \|f(y,\tau)\|_{L^\infty(\Omega_T^R)}) \leq C,$$

where C depends on R but is independent of n. Let $n \to \infty$; then we have, possibly a subsequence,

$$v_n \rightharpoonup v_R \text{ in } W_p^{2.1}(\Omega_T^R \backslash B_\delta(P_0)) \text{ weakly} \qquad \text{as} \quad n \to +\infty.$$

Moreover, the Sobolev imbedding theorem implies

$$\partial_y v_n \to \partial_y v_R \text{ in } C(\Omega_T^R \backslash B_\delta(P_0)) \quad \text{as} \quad n \to +\infty.$$

Define $v = v_R$ if $y \in [-R, R]$. It is clear that v is reasonably defined and v is the solution of problem (2.2); moreover, $\partial_y v \in C(\Omega_T)$ and the C^α estimate implies $v \in C(\overline{\Omega_T})$.

Inequalities (2.15), (2.16), (2.17) are a consequence of (2.5), (2.6), (2.7), respectively. The proof of the uniqueness is the same as in the proof of Lemma 2.1. □

From the transformation (2.1), it is not difficult to see the following.

THEOREM 2.3. *There exists a unique solution* $V \in C(\overline{\Omega_T}) \cap W_p^{2,1}(\Omega_T^R \backslash B_\delta(P_0))$ *to problem* (1.4), *where* $\forall\ R > 0,\ \delta > 0,\ 1 < p < +\infty$. *And* $\partial_x V \in C(\Omega_T)$,

$$(e^{x+(r-q-p^*)\tau} - 1)^+ \leq V \leq e^{x-q\tau}, \tag{2.20}$$

$$\partial_x V \geq 0, \tag{2.21}$$

$$\partial_\tau V \geq (r - q - p^*)\, \partial_x V. \tag{2.22}$$

3. Characterizations of the free boundary of problem (2.2). In this section, we consider the behavior of the free boundary of problem (2.2). Denote

$$\mathbf{NR}_y = \{(y,\tau) :\ v(y,\tau) > 0\} \qquad \text{(nontransaction region)},$$
$$\mathbf{SR}_y = \{(y,\tau) :\ v(y,\tau) = 0\} \qquad \text{(stop region)}.$$

Applying (2.17), v is monotonic increasing with respect to y, so we can define the free boundary

$$y_s(\tau) = \sup\{y :\ v(y,\tau) = 0\}, \quad \tau > 0, \qquad \text{between } \mathbf{NR}_y \text{ and } \mathbf{SR}_y.$$

THEOREM 3.1. $y_s(\tau) \in C[0,T] \cap C^\infty(0,T]$ *and is strictly decreasing with* $y_s(0) = 0$ *(see Figure* 3*).*

Proof. We divide the proof into four steps.

Step 1. From (2.16) and (2.17), we see that $y_s(\tau)$ is decreasing in $[0,T]$.

Step 2. Prove $y_s(\tau)$ is continuous in $[0,T]$ and $y_s(0) = 0$.

In the first we prove $y_s(\tau)$ is continuous in $[0,T]$. Otherwise, there exists a domain $(y_1, y_2) \times (\tau_0, T)$ $(y_1 < y_2,\ 0 \leq \tau_0 < T)$ such that

$$\begin{cases} \partial_\tau v - \mathcal{L}_y v = -L, & (y,\tau) \in (y_1,y_2) \times (\tau_0, T), \\ v(y,\tau_0) = 0, & y \in (y_1, y_2). \end{cases}$$

Then we have $\partial_\tau v(y,\tau_0) = -L < 0$ for any $y_1 < y < y_2$, which contradicts (2.16).

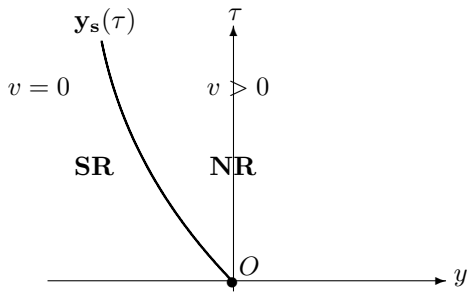

FIG. 3.

In the same way we can prove $y_s(0) \geq 0$; moreover, since $v(y,0) = (e^y - 1)^+ > 0$ if $y > 0$, we have $y_s(0) = 0$.

Step 3. Prove $y_s(\tau)$ is strictly decreasing in $[\,0, T\,]$.

Otherwise there exists a domain $(y_0, 1) \times (\tau_1, \tau_2)$ $(y_0 \leq 0,\ 0 < \tau_1 < \tau_2 \leq T)$ such that

$$\text{(3.1)} \qquad \begin{cases} \partial_\tau v - \mathcal{L}_y v = -L, & (x,\tau) \in (y_0, 1) \times (\tau_1, \tau_2), \\ v(y_0, \tau) = 0, & \tau \in (\tau_1, \tau_2). \end{cases}$$

Then $W = \partial_\tau v$ satisfies

$$\begin{cases} \partial_\tau W - \mathcal{L}_y W = 0, & (x,\tau) \in (y_0, 1) \times (\tau_1, \tau_2), \\ W(y_0, \tau) = 0, & \tau \in (\tau_1, \tau_2). \end{cases}$$

Since $W = \partial_\tau v \geq 0$, W achieves its nonpositive minimum at $y = y_0$. Applying the maximum principle, we have $\partial_y W(y_0, \tau) > 0$ for any $\tau \in (\tau_1, \tau_2)$. On the other hand, we can deduce that $\partial_y v(y_0, \tau) = 0$ for any $\tau \in (\tau_1, \tau_2)$ by $\partial_y v \in C(\Omega_T)$. So, $\partial_y W(y_0, \tau) = \partial_{\tau y} v(y_0, \tau) = 0$ for any $\tau \in (\tau_1, \tau_2)$; thus we get a contradiction. Hence $y_s(\tau)$ is strictly decreasing in $(0, T\,]$.

Step 4. Since $\partial_\tau v \geq 0$ and 0 is the lower obstacle, it can be proved that $y_s(\tau) \in C^{0,1}(0, T\,]$ by the method developed by Friedman in [9]. Moreover $y_s(\tau) \in C^\infty(0, T\,]$ by a bootstrap argument. □

THEOREM 3.2. *The free boundary $y_s(\tau)$ satisfies*

$$\text{(3.2)} \quad \ln\left[\frac{2L}{2r+\sigma^2}\left(1 - \frac{1}{1+r\tau}\right)\right] \leq y_s(\tau) + (p^* - r)\tau \leq \ln\left[\frac{2L}{2r+\sigma^2}\left(1 + \frac{1}{L\tau}\right)\right].$$

Proof. We divide the proof into four steps.

Step 1. In the first, we give a transformation

$$\text{(3.3)} \qquad z = y + (p^* - r)\tau, \qquad v^*(z,\tau) = v(y,\tau) = V(x,\tau).$$

Then we have

$$\text{(3.4)} \quad \begin{cases} \partial_\tau v^* - \mathcal{L}_z v^* = -L & \text{if } v^* > 0 \quad \text{and} \quad (z,\tau) \in \mathbb{R} \times (0, T\,], \\ \partial_\tau v^* - \mathcal{L}_z v^* \geq -L & \text{if } v^* = 0 \quad \text{and} \quad (z,\tau) \in \mathbb{R} \times (0, T\,], \\ v^*(z,0) = (e^z - 1)^+, & z \in \mathbb{R}, \end{cases}$$

where

$$\mathcal{L}_z v^* = \frac{\sigma^2}{2}\partial_{zz} v + \left(r - \frac{\sigma^2}{2}\right)\partial_z v - rv. \tag{3.5}$$

Denote the free boundary of problem (3.4) as $z_s(\tau)$, which is the counterpart of $y_s(\tau)$ and $z_s(\tau) = y_s(\tau) + (p^* - r)\tau$.

Step 2. We prove that for any $\tau > 0$, there holds

$$z_s(\tau) \geq z_1(\tau) = \ln\left[\frac{2L}{2r+\sigma^2}\left(1 - \frac{1}{1+r\tau}\right)\right]. \tag{3.6}$$

In fact, for any $T_0 > 0$, we will prove $z_s(T_0) \geq z_1(T_0)$.

Since $z_1(T_0) = \ln[\frac{2L}{2r+\sigma^2}(1 - \frac{1}{1+rT_0})]$, we define z_1 by

$$e^{z_1} = \frac{2L}{2r+\sigma^2}\left(1 - \frac{1}{1+rT_0}\right).$$

It follows that

$$e^{z_1} = \frac{2L}{2r+\sigma^2}\,\frac{rT_0}{1+rT_0} \leq \frac{LT_0}{1+rT_0}. \tag{3.7}$$

We define

$$W(z,\tau) = \begin{cases} \frac{L}{1+rT_0}(T_0 - \tau), & (z,\tau) \in (-\infty, z_1\,] \times [\,0, T_0\,], \\ e^z - \frac{1}{\alpha}e^{\alpha(z-z_1)+z_1} - \frac{L}{1+rT_0}\tau, & (z,\tau) \in (z_1, +\infty) \times [\,0, T_0\,], \end{cases} \tag{3.8}$$

where $\alpha = -\frac{2r}{\sigma^2}$.

We claim that $W(x,\tau)$ possesses the following four properties:

(I) $W \in W^{2,1}_{p,\,loc}(\mathbb{R} \times (0,T_0)) \cap C(\mathbb{R} \times [\,0,T_0\,])$.

(II) $W \geq 0 \ \ \forall (z,\tau) \in \mathbb{R} \times (0,T_0\,]$.

(III) $W(z,0) \geq (e^z - 1)^+$.

(IV) $\partial_\tau W - \mathcal{L}_z W \geq -L$, $(z,\tau) \in \mathbb{R} \times [\,0,T_0\,]$.

Indeed, since

$$W(z_1 + 0, \tau) = e^{z_1}\left(1 - \frac{1}{\alpha}\right) - \frac{L}{1+rT_0}\tau = \frac{L}{1+rT_0}(T_0 - \tau), \tag{3.9}$$

$$\partial_z W(z_1 + 0, \tau) = e^{z_1} - e^{z_1} = 0. \tag{3.10}$$

Then property (I) follows. Next, we prove properties (II) and (III).

It is clear that $W(z,\tau) \geq 0$ for $(z,\tau) \in (-\infty, z_1\,] \times [\,0,T_0\,]$. Moreover, it can be seen that if $z > z_1$,

$$\partial_{zz} W = e^z - \alpha e^{\alpha(z-z_1)+z_1} \geq e^z > 0.$$

Combining (3.9) and (3.10), we know that for any $(z,\tau) \in (z_1, +\infty) \times [\,0,T_0\,]$, there hold

$$\partial_z W(z,\tau) > 0, \qquad W(z,\tau) > \frac{L}{1+rT_0}(T_0 - \tau) \geq 0.$$

Thus we get property (II). On the other hand, applying (3.7), we obtain

$$W(z,0)=\begin{cases} \frac{LT_0}{1+rT_0}\geq e^{z_1}>(e^z-1)^+, & z\leq z_1,\\ e^z-\frac{1}{\alpha}e^{\alpha(z-z_1)+z_1}>e^z>(e^z-1)^+, & z>z_1. \end{cases}$$

Then we have property (III). In the following, we prove property (IV).

In fact, notice that 1 and α are the characteristic roots of the ODE $\mathcal{L}_z W=0$. Then we see that for any $(z,\tau)\in(z_1,+\infty)\times(0,T_0]$,

$$\partial_\tau W-\mathcal{L}_z W=-\frac{L}{1+rT_0}-\frac{rL}{1+rT_0}\tau=-L\frac{1+r\tau}{1+rT_0}\geq -L.$$

On the other hand, for any $(z,\tau)\in(-\infty,z_1)\times(0,T_0]$, as above, we have

$$\partial_\tau W-\mathcal{L}_z W=-\frac{L}{1+rT_0}+\frac{rL}{1+rT_0}(T_0-\tau)\geq -\frac{L}{1+rT_0}-\frac{rL}{1+rT_0}\tau\geq -L.$$

Hence we have property (IV).

Properties (I)–(IV) indicate that W is a supersolution of problem (3.4). Hence $W\geq v^*$ in $\mathbb{R}\times[\,0,T\,]$, especially

$$0\leq v^*(z,T_0)\leq W(z,T_0)=0,\qquad z\leq z_1,$$

meaning that $z_s(T_0)\geq z_1(T_0)$. Then (3.6) follows.

Step 3. We prove that for any $\tau>0$,

$$z_s(\tau)\leq z_2(\tau)=\ln\left[\frac{2L}{2r+\sigma^2}\left(1+\frac{1}{L\tau}\right)\right]. \tag{3.11}$$

In fact, for any $T_0>0$, denote

$$w(z,\tau)=\begin{cases} -1+\frac{\tau}{T_0}, & (z,\tau)\in(-\infty,z_2\,]\times[\,0,T_0\,],\\ e^z-\frac{1}{\alpha}e^{\alpha(z-z_2)+z_2}-A+(-1+\frac{\tau}{T_0}), & (z,\tau)\in(z_2,+\infty)\times[\,0,T_0\,], \end{cases} \tag{3.12}$$

where $\alpha=-\frac{2r}{\sigma^2}$ and

$$e^{z_2}=\frac{2L+2/T_0}{2r+\sigma^2},\qquad\qquad A=\frac{\alpha-1}{\alpha}e^{z_2}=\frac{L+1/T_0}{r}.$$

We claim that $w(z,\tau)$ satisfies the following three properties:

(I) $w\in W^{2,1}_{p,\,loc}(\mathbb{R}\times(0,T))\cap C(\mathbb{R}\times[\,0,T\,])$.

(II) $w(z,0)\leq(e^z-1)^+$.

(III) $\partial_\tau w-\mathcal{L}_z w\leq -L$ if $w>0$ and $(z,\tau)\in\mathbb{R}\times(0,T_0\,]$.

Indeed, as in the previous step, property (I) is obvious. Next, we prove properties (II) and (III). Considering

$$w(z,0)=\begin{cases} -1<0<(e^z-1)^+, & z\leq z_2,\\ (e^z-1)-(\frac{1}{\alpha}e^{\alpha(z-z_2)+z_2}+A)<(e^z-1)-(\frac{1}{\alpha}e^{z_2}+A) & \\ \qquad =(e^z-1)-e^{z_2}<(e^z-1)\leq(e^z-1)^+, & z>z_2, \end{cases}$$

property (II) follows.

In the following, we prove property (Ⅲ). It is clear that $w(z,\tau) \le 0$ for any $(z,\tau) \in (-\infty, z_2\,] \times [\,0, T_0\,]$. On the other hand, for any $(z,\tau) \in (z_2, +\infty) \times (0, T_0]$, by the method in Step 2, we see that

$$\partial_\tau w - \mathcal{L}_z w = \frac{1}{T_0} - rA + r\left(-1 + \frac{\tau}{T_0}\right) \le \frac{1}{T_0} - rA = \frac{1}{T_0} - r\frac{L + 1/T_0}{r} = -L.$$

Hence we have property (Ⅲ).

Based on properties (I)–(Ⅲ), as in the proof of the uniqueness in Lemma 2.1, we can prove $w \le v^*$ in $\mathbb{R} \times [\,0, T\,]$. Moreover, for $z > z_2$,

$$w(z, T_0) = (e^z - e^{z_2}) - \frac{1}{\alpha} e^{z_2}(e^{\alpha(z - z_2)} - 1) > 0.$$

Thus $v^*(z, T_0) > 0$ for any $z > z_2$, and (3.11) follows.

Step 4. From (3.6) and (3.11), we see that

$$\ln\left[\frac{2L}{2r + \sigma^2}\left(1 - \frac{1}{1 + r\tau}\right)\right] \le z_s(\tau) \le \ln\left[\frac{2L}{2r + \sigma^2}\left(1 + \frac{1}{L\tau}\right)\right].$$

Since $z_s(\tau) = y_s(\tau) + (p^* - r)\tau$, then (3.2) follows. □

Remark. Let $\tau \to +\infty$ in (3.2). We can deduce that

$$y_s(\tau) + (p^* - r)\tau = z_s(\tau) \to \ln\left(\frac{2L}{2r + \sigma^2}\right) \qquad \text{as} \qquad \tau \to +\infty.$$

Moreover, combining $z_s(\tau) = y_s(\tau) + (p^* - r)\tau$ is continuous in $[\,0, T\,]$. We see that there exist two constants M_1 and M_2 such that $M_1 \le z_s(\tau) \le M_2$, which are independent of T.

4. Characterizations of the free boundary of problem (1.4). We have obtained some properties (Theorems 3.1 and 3.2) about the free boundary $y_s(\tau)$ of the new problem (2.2). In the following, we come back to consider the free boundary of the original problem (1.4).

Denote $x_s(\tau)$ as the free boundary between $\mathbf{NR}_x$ and $\mathbf{SR}_x$, which are, respectively, the counterparts of $\mathbf{NR}_y$ and $\mathbf{SR}_y$ in the transformation (2.1). From the transformation (2.1), we have

$$V(x,\tau) = v(x + (r - q - p^*)\tau, \tau), \qquad x_s(\tau) = y_s(\tau) + (q + p^* - r)\tau.$$

Theorems 3.1 and 3.2 imply Theorem 4.1

THEOREM 4.1. (1) $x_s(\tau) \in C[\,0, T\,] \cap C^\infty(0, T\,]$ *with* $x_s(0) = 0$ *and satisfies*

$$\ln\left[\frac{2L}{2r + \sigma^2}\left(1 - \frac{1}{1 + r\tau}\right)\right] \le x_s(\tau) - q\tau \le \ln\left[\frac{2L}{2r + \sigma^2}\left(1 + \frac{1}{L\tau}\right)\right]. \tag{4.1}$$

(2) *If* $q = 0$ *and* $r \ge L$, $x_s(\tau) = y_s(\tau)$ *is strictly decreasing (see Figure* 4*).*

(3) *If* $q > 0$, $x_s(\tau) \to +\infty$ *as* $\tau \to +\infty$ *(see Figure* 5*).*

LEMMA 4.2. *If* $q = 0$ *and* $r < L \le r + \sigma^2/2$ *(see Figure* 6*), then*

$$x_s(\tau) \le 0.$$

Proof. Denote

$$w(x,\tau) = \begin{cases} 0, & (x,\tau) \in (-\infty, 0\,] \times [\,0, T\,], \\ C_1 e^x + C_2 e^{\alpha x} - \frac{L}{r}, & (x,\tau) \in (0, +\infty) \times [\,0, T\,], \end{cases} \tag{4.2}$$

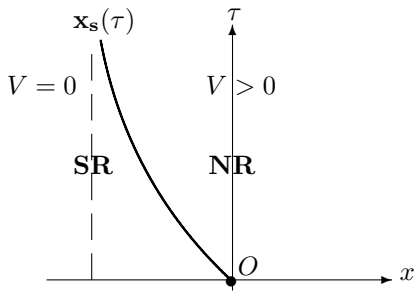

FIG. 4. $q = 0$ *and* $r \geq L$.

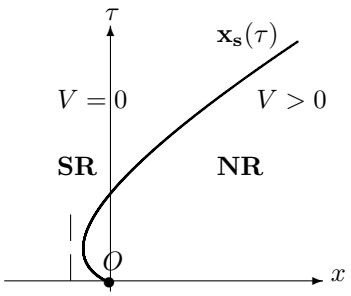

FIG. 5. $q > 0$.

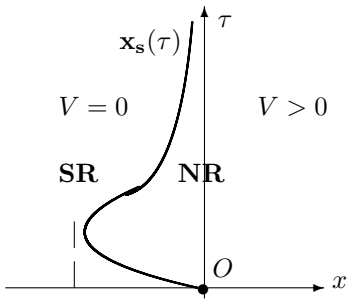

FIG. 6. $q = 0$ *and* $r < L \leq r + \sigma^2/2$.

where

$$\alpha = -2r/\sigma^2, \qquad C_1 = \frac{-\alpha L}{r(1-\alpha)} = \frac{2L}{2r+\sigma^2} \leq 1, \qquad C_2 = \frac{L}{r(1-\alpha)}. \tag{4.3}$$

We claim that $w(x,\tau)$ satisfies the following three properties:

$$\begin{cases} \text{(I) } w \in W^{2,1}_{p,\,loc}(\mathbb{R}\times(0,T)) \cap C(\mathbb{R}\times[\,0,T\,]), \\ \text{(II) } 0 \leq w(x,0) \leq (e^x-1)^+, \\ \text{(III) } \partial_\tau w - \mathcal{L}_x w = -L \quad \text{if } w > 0 \text{ and } (x,\tau) \in \mathbb{R}\times(0,T\,]. \end{cases} \tag{4.4}$$

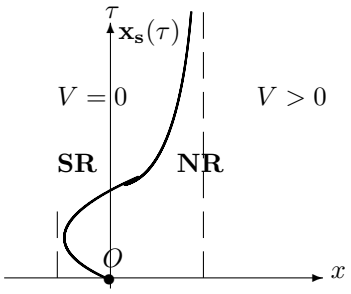

FIG. 7. $q = 0$ *and* $L > r + \sigma^2/2$.

Indeed, from (4.2) and (4.3), we have

$$w(0+0,\tau) = C_1 + C_2 - \frac{L}{r} = 0, \qquad \partial_x w(0+0,\tau) = C_1 + \alpha C_2 = 0. \tag{4.5}$$

Then we get property (I). Next, we prove property (II). Indeed, from (4.2), we have

$$\partial_{xx} w(x,\tau) = C_1 e^x + C_2 \alpha^2 e^{\alpha x} > 0 \qquad \forall x > 0.$$

This fact and (4.5) imply $\partial_x w(x,\tau) \geq 0$ and $w(x,\tau) \geq 0$ for any $x > 0$. Moreover, since as $x > 0$, there hold, by $C_1 \leq 1$,

$$\partial_x w(x,\tau) - \partial_x (e^x - 1) = C_1 e^x + C_2 \alpha e^{\alpha x} - e^x < 0 \qquad \text{and} \qquad w(0,0) = 0,$$

we have $w(x,\tau) < e^x - 1$ for any $x > 0$. Then, combining this result with (4.2), we get conclusion (II).

In the following, we prove property (III). Notice that 1 and α are the characteristic roots of ODE $\mathcal{L}_x w = 0$; then we have, if $(x,\tau) \in (0,+\infty) \times [\,0, T_0\,]$,

$$\partial_\tau w - \mathcal{L}_x w = -r\frac{L}{r} = -L.$$

Based on properties (I)–(III), as in the proof of the uniqueness in Lemma 2.1, we can prove $w \leq V$. Since $w > 0$ for any $x > 0$, so $V > 0$ for any $x > 0$; therefore, $x_s(\tau) \leq 0$. □

LEMMA 4.3. *If* $q = 0$ *and* $L > r + \sigma^2/2$, *then* $x_s(\tau) \leq \ln \frac{2L}{2r+\sigma^2}$ *(see Figure* 7*).*

Proof. Denote

$$w(x,\tau) = \begin{cases} 0, & (x,\tau) \in (-\infty, x_0\,] \times [\,0, T\,], \\ e^x - \frac{1}{\alpha} e^{\alpha(x-x_0)+x_0} - \frac{L}{r}, & (x,\tau) \in (x_0, +\infty) \times [\,0, T\,], \end{cases} \tag{4.6}$$

where

$$\alpha = \frac{-2r}{\sigma^2}, \qquad e^{x_0} = \frac{\alpha L}{r(\alpha - 1)} = \frac{2L}{2r + \sigma^2} > 1. \tag{4.7}$$

The proof is analogous to that of Lemma 4.2. We claim that $w(x,\tau)$ still satisfies the three properties in (4.4). Indeed, from (4.6) and (4.7), we have

$$w(x_0+0,\tau) = \frac{\alpha - 1}{\alpha} e^{x_0} - \frac{L}{r} = 0, \quad \partial_x w(x_0+0,\tau) = e^{x_0} - \alpha \frac{e^{x_0}}{\alpha} = 0. \tag{4.8}$$

Then we get property (I).

Next, from (4.6), we have

$$\partial_{xx} w(x,\tau) = e^x - \alpha e^{\alpha(x-x_0)+x_0} > 0 \qquad \forall\, (x,\tau) \in (x_0, +\infty) \times [\,0, T\,],$$

which, combined with (4.8), implies $\partial_x w(x,\tau) > 0$ and $w(x,\tau) > 0$ for any $x > x_0$. Moreover, since $x_0 > 0$ by $e^{x_0} > 1$, there hold, if $x > x_0$,

$$\partial_x w(x,\tau) - \partial_x (e^x - 1) = -e^{\alpha(x-x_0)+x_0} < 0 \qquad \text{and} \qquad w(x_0, 0) = 0 < e^{x_0} - 1;$$

hence, $w(x,\tau) < e^x - 1$ for any $x > x_0$. Combining this result with (4.6), we get conclusion (II).

Finally, as in the proof of Lemma 4.2, we can check

$$\partial_\tau w - \mathcal{L}_x w = -r\frac{L}{r} = -L, \qquad \forall\, (x,\tau) \in (x_0, +\infty) \times [\,0, T_0\,];$$

hence $w \le V$. Since $w > 0$ for any $x > x_0$, then $V > 0$ for any $x > x_0$; therefore $x_s(\tau) \le x_0 = \ln \frac{2L}{2r+\sigma^2}$. □

LEMMA 4.4. *There exists a $\tau_0 > 0$ such that $V(0,\tau) > 0$ for any $0 < \tau < \tau_0$ (see Figures 4–7), i.e.,*

$$\{x = 0,\ 0 < \tau < \tau_0\} \subset \mathbf{NR}, \qquad\qquad x_s(\tau) < 0 \quad \textit{for} \quad 0 < \tau < \tau_0.$$

Proof. The solution $V(x,t)$ of (1.4) satisfies

$$\text{(4.9)} \quad \begin{cases} \partial_\tau V - \mathcal{L}_x V \ge -L, & (x,\tau) \in \mathbb{R} \times (0, T\,], \\ V(x,0) \ = (e^x - 1)^+, & x \in \mathbb{R}. \end{cases}$$

Consider the Cauchy problem

$$\text{(4.10)} \quad \begin{cases} \partial_\tau V - \mathcal{L}_x V = -L, & (x,\tau) \in \mathbb{R} \times (0, T\,], \\ V_1(x,0) \ = (e^x - 1)^+, & x \in \mathbb{R}. \end{cases}$$

Applying the comparison principle to problems (4.9) and (4.10), we see that $V(x,\tau) \ge V_1(x,\tau)$. If we can prove that there exists a $\tau_0 > 0$ such that $V_1(0,\tau) > 0$ for $0 < \tau < \tau_0$, then the result of the theorem is an immediate result. To do this we define

$$V_1(x,\tau) = V_2(x,\tau) + \frac{L}{r}(e^{-r\tau} - 1).$$

Then $V_2(x,\tau)$ satisfies

$$\text{(4.11)} \qquad \begin{cases} \partial_\tau V_2 - \mathcal{L}_x V_2 = 0, & (x,\tau) \in \mathbb{R} \times (0, T\,], \\ V_2(x,0) \ = (e^x - 1)^+, & x \in \mathbb{R}. \end{cases}$$

This is a Cauchy problem which the price of the standard European call option satisfies. Its solution has an explicit formula (see [11]):

$$\text{(4.12)} \qquad V_2(x,\tau) = e^{x-q\tau} N(\widehat{d_1}) - e^{-r\tau} N(\widehat{d_2})\ ,$$

where

$$N(\widehat{d_1}) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\widehat{d_1}} e^{-\eta^2/2} d\eta,$$

$$\widehat{d_1} = \frac{x + (r - q + \sigma^2/2)\tau}{\sigma\sqrt{\tau}}, \quad \widehat{d_2} = \frac{x + (r - q - \sigma^2/2)\tau}{\sigma\sqrt{\tau}}.$$

Now we check

$$\partial_\tau V_2(0,\tau) = -qe^{-q\tau}N(d_1) + e^{-q\tau}n(d_1)\frac{r-q+\sigma^2/2}{2\sigma\sqrt{\tau}} + re^{-r\tau}N(d_2)$$
$$- e^{-r\tau}n(d_2)\frac{r-q-\sigma^2/2}{2\sigma\sqrt{\tau}} \geq -q + e^{-q\tau}n(d_1)\frac{\sigma}{2\sqrt{\tau}},$$

where

$$n(d_1) = e^{-d_1^2/2}/\sqrt{2\pi}, \qquad d_1 = \frac{(r-q+\sigma^2/2)\sqrt{\tau}}{\sigma}, \qquad d_2 = \frac{(r-q-\sigma^2/2)\sqrt{\tau}}{\sigma},$$

and we had utilized the equality $e^{-q\tau}n(d_1) = e^{-r\tau}n(d_2)$. As $\tau \to 0^+$, we have

$$d_1 \to 0, \quad n(d_1) \to 1, \quad \partial_\tau V_2(0,\tau) \to +\infty.$$

It follows that $\partial_\tau V_1(0,\tau) \to +\infty$ as $\tau \to 0^+$. Since $V_1(0,0) = 0$ and $V_1 \in C(\mathbb{R}\times[\,0,T\,])$, then we see that there exists a $\tau_0 > 0$ such that $V_1(0,\tau) > 0$ for any $0 < \tau < \tau_0$. ∎

From Theorem 4.1 and Lemmas 4.2–4.4, we can conclude the following theorem.

THEOREM 4.5. (1) *If $q > 0$, then $x_s(\tau)$ is not monotonic; moreover, $x_s(\tau)$ changes its sign (see Figure* 5*) and*

$$\lim_{\tau\to+\infty}[x_s(\tau) - q\tau] = \ln\frac{2L}{2r+\sigma^2}.$$

(2) *If $q = 0$ and $r < L \leq r + \sigma^2/2$, then $x_s(\tau) \leq 0$ (see Figure* 6*) and*

$$\lim_{\tau\to+\infty} x_s(\tau) = \ln\frac{2L}{2r+\sigma^2}.$$

(3) *If $q = 0$ and $L > r + \sigma^2/2$, then $x_s(\tau)$ is not monotonic; moreover, $x_s(\tau)$ changes its sign (see Figure* 7*) and $x_s(\tau) \leq \ln\frac{2L}{2r+\sigma^2}$ with*

$$\lim_{\tau\to+\infty} x_s(\tau) = \ln\frac{2L}{2r+\sigma^2}.$$

Proof. (1) From Theorem 4.1, we see that $x_s(0) = 0$ and $x_s(\tau) \to +\infty$ as $\tau \to +\infty$; moreover, by Lemma 4.4, there exists a $\tau_0 > 0$ such that $x_s(\tau) < 0$ for any $0 < \tau < \tau_0$, and hence $x_s(\tau)$ is not monotonic and changes sign. Inequality (4.1) implies

$$\lim_{\tau\to+\infty}(x_s(\tau) - q\tau) = \ln\frac{2L}{2r+\sigma^2}.$$

(2) and (3) are easily obtained as above, so we omit their proofs. ∎

Remark on the monotonicity of $x_s(\tau)$ in (2) *of Theorem* 4.5. According to the result of asymptotic expansion of $S_s(\tau) = e^{x_s(\tau)}$ close to expire in (1.2), we know that

$$x_s(\tau) \sim -\sigma(-\tau\ln\tau)^{1/2}(1+o(1)); \quad x_s'(\tau) \sim -\infty \qquad \text{as } \tau = T - t \to 0^+.$$

So if τ is small enough, $x_s(\tau)$ is monotonic decreasing. Combining this result with (4.1), we guess that $x_s(\tau)$ should not be monotonic. But we cannot prove this conjecture.

5. The monotonicity of the free boundary $x_s(\ )$ with respect to the parameters r, q, and L. In this section, we have the following theorem.

THEOREM 5.1. *$x_s(\tau)$ is decreasing with respect to r and increasing with respect to q and L.*

Proof. We divide the proof into three steps.

Step 1. We prove

$$\partial_x V - V \geq 0. \tag{5.1}$$

For the proof of (5.1), we come back to the approximation problem (2.11) and denote

$$W^* = \partial_y v_{\varepsilon,n} - v_{\varepsilon,n} + 2\varepsilon.$$

We claim that $W^* \geq 0$; otherwise, we suppose W^* achieves its negative minimum at $(x_0, \tau_0) \in \overline{\Omega_T^n}$.

If n is large enough, from the definition of π_ε and the initial and boundary values in (2.11) and (2.13), we have

$$\begin{cases} W^*(-n,\tau) \geq 0 - 0 + 2\varepsilon > 0 & \text{(by (2.14))}, \\ W^*(n,\tau) \geq e^{n+(p^*-r)\tau} - e^{n+(p^*-r)\tau} + 2\varepsilon > 0 & \text{(by (2.12))}, \\ W^*(y,0) = \partial_y \pi_\varepsilon(e^y - 1) - \pi_\varepsilon(e^y - 1) + \varepsilon \geq 0 - \varepsilon + 2\varepsilon > 0 & \text{if } e^y - 1 \leq \varepsilon, \\ W^*(y,0) > e^y - (e^y - 1) + 2\varepsilon > 0 & \text{if } e^y - 1 > \varepsilon. \end{cases}$$

Hence, from (2.3), we deduce that

$$(x_0,\tau_0) \in \Omega_T^n \qquad \text{and} \qquad \partial_\tau W^*(x_0,\tau_0) - \mathcal{L}_y W^*(x_0,\tau_0) \leq 0. \tag{5.2}$$

On the other hand, (2.14) and $W^*(x_0,\tau_0) < 0$ imply $v_{\varepsilon,n}(x_0,\tau_0) > 2\varepsilon$. Then

$$\beta_\varepsilon(v_{\varepsilon,n}(x_0,\tau_0)) = 0, \qquad\qquad \beta'_\varepsilon(v_{\varepsilon,n}(x_0,\tau_0)) = 0.$$

Combining (2.11) and (2.13), we see that at the point (x_0,τ_0)

$$\partial_\tau W^* - \mathcal{L}_y W^* = L + 2r\varepsilon > 0,$$

which contradicts (5.2). Hence,

$$W^* \geq 0 \qquad \text{and} \qquad \partial_y v_{\varepsilon,n} - v_{\varepsilon,n} \geq -2\varepsilon.$$

Taking $\varepsilon \to 0^+$ and $n \to \infty$, we obtain

$$\partial_y v - v \geq 0.$$

Eventually, the transformation (2.1) implies (5.1).

Step 2. Suppose that V_1 is the solution to (1.4), where r is r_1, and that V_2 is the solution to (1.4), where r is r_2 and $r_1 > r_2$. By (5.1), we deduce $\partial_x V_1 - V_1 \geq 0$. Then V_1 satisfies

$$\begin{cases} \partial_\tau V_1 - \frac{\sigma^2}{2}\partial_{xx} V_1 - (r_2 - q - \frac{\sigma^2}{2})\partial_x V_1 + r_2 V_1 = -L + (r_1 - r_2)(\partial_x V_1 - V_1) \geq -L \\ \qquad\qquad \text{if } V_1 > 0 \quad \text{and} \quad (x,\tau) \in \mathbb{R} \times (0,T\,], \\ \partial_\tau V_1 - \frac{\sigma^2}{2}\partial_{xx} V_1 - (r_2 - q - \frac{\sigma^2}{2})\partial_x V_1 + r_2 V_1 \geq -L + (r_1 - r_2)(\partial_x V_1 - V_1) = -L \\ \qquad\qquad \text{if } V_1 = 0 \quad \text{and} \quad (x,\tau) \in \mathbb{R} \times (0,T\,], \\ V_1(x,0) = (e^x - 1)^+, \qquad\qquad x \in \mathbb{R}. \end{cases}$$

By the comparison principle for the solution of variational inequalities with respect to nonhomogeneous terms, we have $V_1 \geq V_2$. If we denote $\mathbf{NR_1}$, $\mathbf{NR_2}$ to be the nontransaction region of V_1, V_2, respectively, then $\mathbf{NR_1} \supset \mathbf{NR_2}$. Hence $x_s(\tau)$ is decreasing with respect to r.

Step 3. As in Step 2, from (2.21), we can deduce that $x_s(\tau)$ is increasing with respect to q and L. □

6. Numerical methods and results. Starting from problem (1.4), we have

$$\begin{cases} \min\{\ \partial_\tau V - \frac{\sigma^2}{2}\partial_{xx}V - (r-q-\frac{\sigma^2}{2})\partial_x V + rV + LV\ \} = 0, & x \in \mathbb{R},\ \tau \in (0,T\,], \\ V(x,0)\ = (e^x-1)^+, & x \in \mathbb{R}. \end{cases} \tag{6.1}$$

Given mesh size $\triangle x,\ \triangle\tau > 0,\ V_j^n = V(j\triangle x, n\triangle\tau)$ represents the value of numerical approximation at $(j\triangle x,\ n\triangle\tau)$. Then the PDE is changed into the following difference equation:

$$\begin{cases} \min\left\{ \frac{V_j^n - V_j^{n-1}}{\triangle\tau} - \frac{\sigma^2}{2}\frac{V_{j+1}^{n-1} - 2V_j^{n-1} + V_{j-1}^{n-1}}{\triangle x^2} \right. \\ \qquad \left. - (r-q-\frac{\sigma^2}{2})\frac{V_{j+1}^{n-1} - V_{j-1}^{n-1}}{2\triangle x} + rV_j^n + L, V_j^n \right\} = 0, \\ V_j^0\ = (e^{j\triangle x}-1)^+. \end{cases} \tag{6.2}$$

This means

$$\begin{cases} V_j^n = \max\left\{ \frac{1}{1+r\triangle\tau}[(1 - \frac{\sigma^2\triangle\tau}{\triangle x^2})V_j^{n-1} + \frac{\sigma^2 + (r-q-\sigma^2/2)\triangle x}{2\triangle x^2}\triangle\tau V_{j+1}^{n-1} \right. \\ \qquad\qquad \left. + \frac{\sigma^2 - (r-q-\sigma^2/2)\triangle x}{2\triangle x^2}\triangle\tau V_{j-1}^{n-1} - L\triangle\tau],\ 0 \right\}, \\ V_j^0\ = \max\{0,\ e^{j\triangle x} - 1\}. \end{cases} \tag{6.3}$$

Choosing $\sigma^2\triangle\tau(\triangle x)^{-2} = 1$, we have

$$\begin{cases} V_j^n = \max\left\{ \frac{1}{1+r\triangle\tau}[(\frac{1}{2} + \frac{r-q-\sigma^2/2}{2\sigma}\sqrt{\triangle\tau})V_{j+1}^{n-1} \right. \\ \qquad\qquad \left. + (\frac{1}{2} - \frac{r-q-\sigma^2/2}{2\sigma}\sqrt{\triangle\tau})V_{j-1}^{n-1} - L\triangle\tau], 0 \right\}, \\ V_j^0 = \max\{0,\ e^{j\triangle x} - 1\}. \end{cases} \tag{6.4}$$

Denote $u = e^{\sigma\sqrt{\triangle\tau}}$, $d = u^{-1}$, $\rho = e^{r\triangle\tau}$, $p = (\rho e^{-q\triangle\tau} - d)(u-d)^{-1}$.

Then it is clear, as $\triangle\tau \to 0^+$, that the following hold:

$$\frac{1}{2} + \frac{r-q-\sigma^2/2}{2\sigma}\sqrt{\triangle\tau} = p + o(\triangle\tau), \qquad \frac{1}{1+r\triangle\tau} = \frac{1}{\rho} + O(\triangle\tau^2).$$

Neglecting a higher order of $\sqrt{\triangle\tau}$, we obtain

$$\begin{cases} V_j^n = \max\{\ \frac{1}{\rho}[\ pV_{j+1}^{n-1} + (1-p)V_{j-1}^{n-1} - L\triangle\tau],\ 0\ \}, \\ V_j^0\ = \max\{\ 0,\ u^j - 1\}. \end{cases} \tag{6.5}$$

Consider the point $(x,\tau) = (j\triangle x, n\triangle\tau)$. Then

$$V_j^n = V(x,\tau), \quad V_j^{n-1} = V(x, \tau - \triangle\tau),$$
$$V_{j+1}^{n-1} = V(x+\triangle x, \tau - \triangle\tau), \quad V_{j-1}^{n-1} = V(x-\triangle x, \tau - \triangle\tau).$$

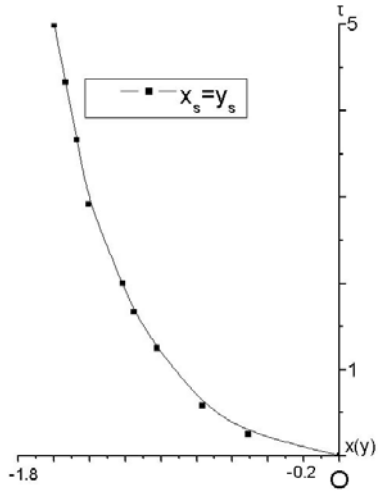

FIG. 8. $q = 0$ *and* $r \geq L$.

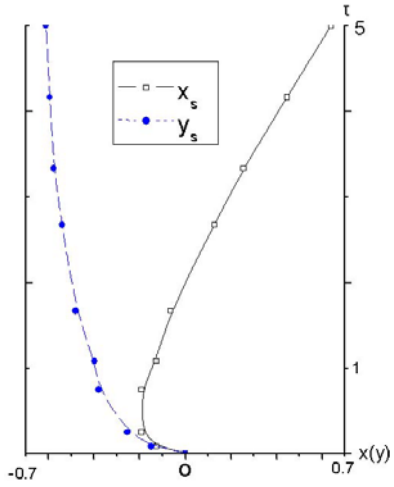

FIG. 9. $q > 0$.

Then we get Figures 8–11.

Figure 8 shows a plot of the optimal stop boundaries $x_s(\tau)$ $(y_s(\tau))$ as a function of time τ when $q = 0,\ r \geq L$. The parameter values used in the calculations are $r = 0.4,\ q = 0,\ \sigma = 0.7,\ L = 0.1,\ T = 5,\ n = 600$. $x_s(\tau),\ y_s(\tau)$ are the free boundaries of problems (1.4) and (2.2), respectively. Observe that $x_s(0) = y_s(\tau) = 0,\ -1.587 \leq x_s(\tau) = y_s(\tau) \leq 0$, and $x_s(\tau), y_s(\tau)$ are strictly decreasing with respect to τ. The numerical result is consistent with that of our proof (see Figure 8).

Figure 9 shows a plot of the optimal stop boundaries $x_s(\tau)$ $(y_s(\tau))$ as a function of time τ when $q > 0$. The parameter values used in the calculations are $r = 0.25,\ q = 0.2,\ \sigma = 0.7,\ L = 0.3,\ T = 5,\ n = 600$. $x_s(\tau),\ y_s(\tau)$ are the free boundaries of problems (1.4) and (2.2), respectively. Observe that $x_s(0) = y_s(\tau) = 0,\ x_s(\tau) \geq -0.1917$, and $x_s(\tau)$ is not monotonic and $y_s(\tau)$ is decreasing. The numerical result is consistent with that of our proof (see Figure 9).

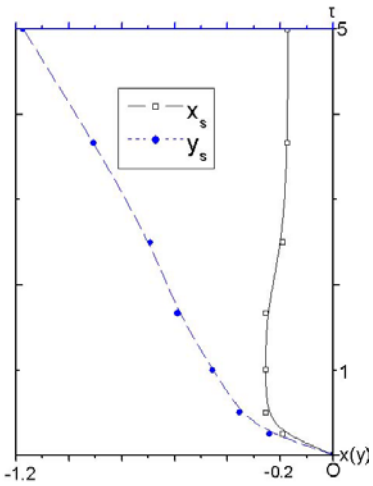

FIG. 10. $q = 0$ *and* $r < L \le r + \sigma^2/2$.

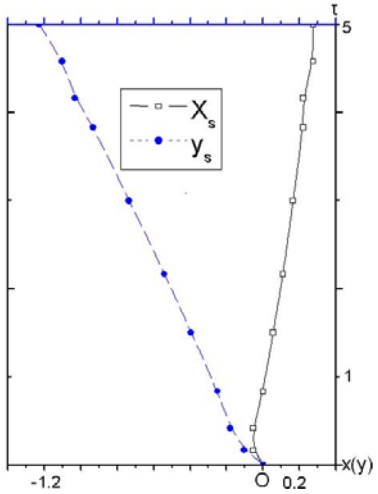

FIG. 11. $q = 0$ *and* $L > r + \sigma^2/2$.

Figure 10 shows a plot of the optimal stop boundaries $x_s(\tau)$ $(y_s(\tau))$ as a function of time τ when $q = 0$ and $r < L \le r + \sigma^2/2$. The parameter values used in the calculations are $r = 0.1,\ q = 0,\ \sigma = 0.7,\ L = 0.3,\ T = 5,\ n = 600$. $x_s(\tau),\ y_s(\tau)$ are the free boundaries of problems (1.4) and (2.2), respectively. Observe that $x_s(0) = y_s(\tau) = 0,\ -0.2556 \le x_s(\tau) \le -0.1278$, and $y_s(\tau)$ is decreasing. The numerical result is consistent with that of our proof (see Figure 10).

Figure 11 shows a plot of the optimal stop boundaries $x_s(\tau)$ $(y_s(\tau))$ as a function of time τ when $q = 0$ and $L > r+\sigma^2/2$. The parameter values used in the calculations are $r = 0.2,\ q = 0,\ \sigma = 0.6,\ L = 0.5,\ T = 5,\ n = 600$. $x_s(\tau),\ y_s(\tau)$ are the free boundaries of problems (1.4) and (2.2), respectively. Observe that $x_s(0) = y_s(\tau) = 0,\ -0.0548 \le x_s(\tau) \le 0.2739$, and $x_s(\tau)$ is not monotonic and $y_s(\tau)$ is decreasing. The numerical result is consistent with that of our proof (see Figure 11).

Appendix. Formulation of the model. A European call option is a contract which gives the owner the right but not the obligation to buy an asset at a fixed price K at the expiry date T. Because the holder of the option stands to make a profit without risking a loss, the holder must pay some premium for the option.

In a conventional European call option contract (see [2]), the holder pays the premium entirely up front and acquires the right. In a continuous installment European call option contract, the holder pays a smaller up-front premium and then a constant stream of installments at a certain rate per unit time. However, the holder can choose at any time to stop making installment payments by stopping the option contract.

There are some papers about install options, such as [7], [8], [1], [6]. Particularly, there are a variational inequality model in [7] and some numerical results about the model. In the following, we deduce a parabolic variational inequality model using their idea.

We consider a standard model for perfect market, continuous trading, no-arbitrage opportunity, a constant interest rate $r > 0$, and an asset with constant continuous dividend yield $q \geq 0$ with price S following a geometric Brownian motion

$$dS = \mu S dt + \sigma S dB, \tag{A.1}$$

where B is a Wiener process on a risk neutral probability space, $\mu > 0$ is the expected return rate, and $\sigma > 0$ is the constant volatility.

Let $C(S, t)$ denote the value of a European continuous installment call option and let L^* be the continuous install rate. Applying Itô's formula to $C(S, t)$ and combining (A.1), we obtain the dynamics

$$dC = \left(\frac{\partial C}{\partial t} + \frac{\sigma^2}{2} S^2 \frac{\partial C}{\partial S^2} + \mu S \frac{\partial C}{\partial S} \right) dt + \sigma S \frac{\partial C}{\partial S} dB. \tag{A.2}$$

We construct the $\triangle$-hedging portfolio consisting of one continuous installment option and an amount $-\triangle$ asset. The value of this portfolio is

$$\Pi = C - \triangle S. \tag{A.3}$$

Then its dynamics is given by

$$d\Pi = dC - \triangle S q dt - \triangle dS - L^* dt \leq r \Pi dt = r(C - \triangle S) dt. \tag{A.4}$$

Combining (A.1) and (A.3), we get

$$\begin{aligned} 0 &\geq d\Pi - r(C - \triangle S) dt \\ &= \left(\frac{\partial C}{\partial t} + \frac{\sigma^2}{2} S^2 \frac{\partial C}{\partial S^2} + \mu S \left(\frac{\partial C}{\partial S} - \triangle \right) + (r - q) \triangle S - rC - L^* \right) dt \\ &\quad + \sigma S \left(\frac{\partial C}{\partial S} - \triangle \right) dB. \end{aligned} \tag{A.5}$$

Setting $\triangle = \partial_S C$ the coefficient of dB vanishes. The portfolio is instantaneously riskless; then we see that $C(S, t)$ satisfies

$$\partial_t C + \frac{\sigma^2}{2} S^2 \partial_{SS} C + (r - q) S \partial_S C - rC \leq L^*. \tag{A.6}$$

Moreover, in the nontransaction region, $C(S, t)$ satisfies

$$\partial_t C + \frac{\sigma^2}{2} S^2 \partial_{SS} C + (r - q) S \partial_S C - rC = L^*. \tag{A.7}$$

At expiry date T, if $S > K$, the holder of the option will buy the asset with price S at K and can make a profit $S - K$. On the other hand, if $S \le K$, he will not exercise the option and stand any loss. Hence, the value of the option is $(S-K)^+$ at expiry date T, that is,

$$C(S, T) = (S - K)^+. \tag{A.8}$$

Because the owner must keep paying premiums to keep the option alive, if S is small enough at some t, the present value of the expected pay-off may be less than the present value of the remaining installments; then the holder would allow the option to lapse and stop paying installment payments. Hence, the value of the option is 0 in the case in which (S, τ) lies in the stop region.

It is clear that $C(S, t) \ge 0$ in nontransaction region. Otherwise, he can choose to stop the option for increased profit; hence we have

$$C(S, t) \ge 0. \tag{A.9}$$

From the above deduction, we see that the following equality holds in the stop region and the nontransaction region:

$$\left[\partial_t C + \frac{\sigma^2}{2} S^2 \partial_{SS} C + (r - q) S \partial_S C - rC - L^*\right] C(S, \tau) = 0. \tag{A.10}$$

Then we see that the value of the European continuous installment call option $C(S, t)$ satisfies (A.6), (A.8)–(A.10), that is, (1.1). Moreover, from the smooth fit conditions [12], we know that C, $\partial_S C$ are continuous.

DETERMINATION OF THE SPECTRAL GAP IN THE KAC MODEL FOR PHYSICAL MOMENTUM AND ENERGY-CONSERVING COLLISIONS*

ERIC A. CARLEN†, JEFFREY S. GERONIMO†, AND MICHAEL LOSS†

Abstract. The Kac model describes the local evolution of a gas of N particles with *three*-dimensional velocities by a random walk in which the steps correspond to binary collisions that conserve momentum as well as energy. The state space of this walk is a sphere of dimension $3N-4$. The Kac conjecture concerns the spectral gap in the one-step transition operator Q for this walk. In this paper, we compute the exact spectral gap. As in previous work by Carlen, Carvalho, and Loss, where a lower bound on the spectral gap was proved, we use a method that relates the spectral properties of Q to the spectral properties of a simpler operator P, which is simply an average of certain noncommuting projections. The new feature is that we show how to use a knowledge of certain eigenfunctions and eigenvalues of P to determine spectral properties of Q, instead of simply using the spectral gap for P to bound the spectral gap for Q, inductively in N, as in previous work. The methods developed here can be applied to many other high-dimensional stochastic process, as we shall explain. We also use some deep results on Jacobi polynomials to obtain the required spectral information on P, and we show how the identity through which Jacobi polynomials enter our problem may be used to obtain new bounds on Jacobi polynomials.

Key words. Kac model, orthogonal polynomials, spectral gap

1. The Markov transition operator Q for the Kac walk.

Let X_N be the N particle state space consisting of N-tuples $\vec{v} = (v_1, \dots, v_N)$ of vectors v_j in $\mathbb{R}^3$ with

$$\sum_{j=1}^{N} |v_j|^2 = 1 \qquad \text{and} \qquad \sum_{j=1}^{N} v_j = 0.$$

We think of a point $\vec{v}$ as specifying the velocities of N particles and shall consider a random walk on X_N that was introduced by Kac [7]. At each step of this random walk, $\vec{v}$ is updated due to the effect of a binary collision that conserves energy and momentum—hence the constraints defining X_N.

To specify this walk in more detail, we consider a collision in which particles i and j collide. Suppose that v_i^* and v_j^* are the postcollisional velocities, while v_i and v_j are the precollisional velocities. Then by momentum conservation, the center of mass velocity is conserved; i.e.,

$$v_i^* + v_j^* = v_i + v_j.$$

Furthermore, by energy conservation, i.e., $|v_i^*|^2 + |v_j^*|^2 = |v_i|^2 + |v_j|^2$, and the parallelogram law, it follows that

$$|v_i^* - v_j^*| = |v_i - v_j|.$$

The second author's work was partially supported by U.S. National Science Foundation grant DMS-0500641.

This leads to a natural parameterization of all of the possible binary collision outcomes that conserve energy and momentum: The parameter σ is a unit vector in S^2, and, when particles i and j collide, one updates $\vec{v} \to \vec{v}^* = R_{i,j,\sigma}(\vec{v})$, where

$$\begin{aligned} v_i^* &= \frac{v_i + v_j}{2} + \frac{|v_i - v_j|}{2}\sigma, \\ v_j^* &= \frac{v_i + v_j}{2} - \frac{|v_i - v_j|}{2}\sigma, \\ v_k^* &= v_k \quad \text{for } k \neq i, j. \end{aligned} \tag{1.1}$$

The *Kac walk* on X_N is a random walk in which the steps are such binary collisions between pairs of particles. At each step, one picks a pair (i, j), $i < j$ uniformly at random, and also a unit vector σ in S^2. One then makes the update described in (1.1). Of course it remains to specify the probabilistic rule according to which σ should be selected. In the physics being modeled here, the likelihood of selecting a particular σ will depend only on the resulting *scattering angle* θ, which is the angle between $v_i^* - v_j^*$ and $v_i - v_j$. In the parameterization above, this is the angle between σ and $v_i - v_j$. That is,

$$\cos(\theta) = \sigma \cdot \frac{v_i - v_j}{|v_i - v_j|}.$$

The *scattering rate function* b is a nonnegative integrable function on $[-1, 1]$ with

$$\frac{1}{2}\int_{-1}^{1} b(u)\mathrm{d}u = 1.$$

Then for any $v_i \neq v_j$, and with $\mathrm{d}\sigma$ being the uniform probability measure on S^2,

$$\int_{S^2} b\left(\sigma \cdot \frac{v_i - v_j}{|v_i - v_j|}\right)\mathrm{d}\sigma = 1. \tag{1.2}$$

(If $v_i = v_j$, the collision has no effect and can be ignored.) One selects σ according to the probability density that is integrated in (1.2).

There are several choices of b of particular interest. One is the *uniform redirection model*, given by $b(x) = 1$ for all $-1 \leq x \leq 1$. In this case, the new direction of the relative velocity σ is chosen uniformly from S^2.

Another is the *Morgenstern model* [10], [11], or the *uniform reflection model*: For any unit vector $\omega \in S^2$, let H_ω be the reflection given by

$$H_\omega(v) = v - 2(v \cdot \omega)\omega.$$

In the uniform reflection model, one updates the relative velocity according to

$$v_i - v_j \to H_\omega(v_i - v_j) = v_i^* - v_j^*,$$

with ω chosen uniformly. The relation between ω and σ is given by $\sigma = H_\omega((v_i - v_j)/|v_i - v_j|)$, and, by computing the Jacobian of the map $\omega \to \sigma$, one finds

$$b(x) = \frac{1}{\sqrt{2}\sqrt{1 - x}}.$$

Both of these belong to the one-parameter family

$$b_\alpha(x) = (1-\alpha)2^\alpha(1-x)^{-\alpha}. \tag{1.3}$$

By leaving the particular choice of b open, this completes the specification of the steps in the Kac walk. For more detail and background, see [7] and [3].

The main object of study here is the spectrum of the one-step transition operator Q for this random walk, and the manner in which this spectrum depends on N. Q is defined as follows: Let $\vec{v}_n$ be the state of the process after the nth step. The one-step Markov transition operator Q is given by taking the conditional expectation

$$Q\phi(\vec{v}) = \mathrm{E}(\phi(\vec{v}_{n+1}) \mid \vec{v}_n = \vec{v})$$

for any continuous function ϕ on X_N.

From the above description, one deduces the formula

$$Q\phi(\vec{v}) = \begin{pmatrix} N \\ 2 \end{pmatrix}^{-1} \sum_{i<j} \int_{S^2} \phi(R_{i,j,\sigma}(\vec{v}))b\left(\sigma \cdot \frac{v_i - v_j}{|v_i - v_j|}\right) \mathrm{d}\sigma. \tag{1.4}$$

Let σ_N denote the uniform probability measure on X_N, which is the normalized measure induced on X_N as a manifold embedded in $\mathbb{R}^{3N}$.

For any two unit vectors σ and ω, one sees from (1.1) that

$$R_{i,j,\sigma}(R_{i,j,\omega}\vec{v}) = R_{i,j,\sigma}\vec{v}.$$

From this and the fact that the measure $\mathrm{d}\sigma_N$ is invariant under $\vec{v} \mapsto R_{i,j,\sigma}\vec{v}$, it follows that, for any continuous functions ϕ and ψ on X_N,

$$\int_{X_N} \psi(\vec{v})Q\phi(\vec{v})\mathrm{d}\sigma_N = \int_{X_N}\int_{S^2}\int_{S^2} \psi(R_{i,j,\omega}\vec{v})\phi(R_{i,j,\sigma}\vec{v})b(\omega\cdot\sigma)\mathrm{d}\omega\mathrm{d}\sigma\mathrm{d}\sigma_N.$$

It follows that Q is a self-adjoint Markov operator on $L^2(X_N, \sigma_N)$. Moreover, it is clearly a Markov operator; that is, in addition to being self-adjoint, Q is positivity preserving and $Q1 = 1$.

The motivation for considering the spectral properties of Q stems from a theorem of Kac [7] that relates the continuous time version of the Kac walk to the nonlinear Boltzmann equation. For the details, see [7] or [3]. Let $\vec{v}(t)$ denote the random variable giving the state of the system at time t for the process run in continuous time with the jumps taking place in a Poisson stream with the mean time between jumps being $1/N$. Then the equation describing the evolution of the probability law of $\vec{v}(t)$ is called the *Kac master equation*: If the initial law on X_N has a density F_0, then the law at time t has a density $F(\vec{v}, t)$ satisfying

$$\frac{\partial}{\partial t}F(\vec{v},t) = N(Q-I)F(\vec{v},t), \qquad \text{with} \qquad F(\vec{v},0) = F_0(\vec{v}).$$

The solution $F(\vec{v}, t)$ is of course given by

$$F(\vec{v},t) = e^{t\mathcal{L}}F_0(\vec{v}),$$

where

$$\mathcal{L} = N(Q-I).$$

Since Q is a self-adjoint Markov operator, its spectrum lies in the interval $[-1,1]$, and since $Q1 = 1$, the constant function is an eigenfunction with eigenvalue 1. It is easily seen that, as long as $b(x)$ is strictly positive on a neighborhood of $x = 1$, the eigenvalue 1 of Q has multiplicity one. It then follows that the spectrum of $\mathcal{L}$ lies in $[-2N, 0]$ and that 0 is an eigenvalue of multiplicity one. We impose this assumption on b throughout what follows.

The Kac conjecture for this stochastic process pertains to the spectral gap

$$\Delta_N = \inf\left\{ -\int_{X_N} \phi(\vec{v})\mathcal{L}\phi(\vec{v})\mathrm{d}\sigma_N \;\middle|\; \int_{X_N} \phi^2(\vec{v})\mathrm{d}\sigma_N = 1,\ \int_{X_N} \phi(\vec{v})\mathrm{d}\sigma_N = 0 \right\}$$

and states that

$$\liminf_{N\to\infty} \Delta_N > 0.$$

This was proved by Carlen, Carvalho, and Loss [3], but without an explicit lower bound. Kac also made a similar conjecture for a simplified model with one-dimensional velocities and no conservation of momentum. For this model, the conjecture was first proved by Janvresse [6], though her approach provided no explicit lower bound. The sharp bound for the simplified model was first established in [2]. See Maslen [9] for a representation theoretic approach.

The main goal of the present paper is to compute *exactly* $\liminf_{N\to\infty} \Delta_N$. We shall be able to do this under an easily checked condition relating Δ_2 and the quantities

$$B_1 = \frac{1}{2}\int_{-1}^{1} xb(x)\mathrm{d}x \qquad \text{and} \qquad B_2 = \frac{1}{2}\int_{-1}^{1} x^2 b(x)\mathrm{d}x. \tag{1.5}$$

The condition, given in (1.6) below, will turn out to be satisfied when b is given by b_α, as in (1.3), for all $0 \le \alpha \le 7/9$.

THEOREM 1.1. *Suppose that $B_2 > B_1$ and that*

$$\Delta_2 \ge \frac{20}{9}(1 - B_2). \tag{1.6}$$

Then for all $N \ge 3$,

$$\Delta_N = (1 - B_2)\frac{N}{(N-1)}. \tag{1.7}$$

Moreover, the eigenspace is three-dimensional and is spanned by the functions

$$\phi(\vec{v}) = \sum_{j=1}^{N} |v_j|^2 v_j^\alpha, \qquad \alpha = 1, 2, 3, \tag{1.8}$$

where v_j^α denotes the αth component of v_j.

As we shall see in the next section, for many choices of b, including the b_α, there is a simple monotonicity of the eigenvalues of Q for $N = 2$ which ensures that the eigenfunction providing the gap comes from a first degree polynomial and thus that

$$\Delta_2 = 2(1 - B_1). \tag{1.9}$$

When (1.9) is satisfied, the condition (1.6) reduces to $(1 - B_1)/(1 - B_2) > 10/9$.

Next, notice that the eigenfunctions listed in (1.8) are symmetric under permutation of the particle indices. Indeed, the operator Q commutes with such permutations, so that the subspace of functions with this symmetry is invariant. As explained in [7] and [3], it is the spectrum of Q on this subspace that is relevant for the study of the Boltzmann equation.

Moreover, notice that, in the collision rules (1.1), exchanging v_i^* and v_j^* has the same effect as changing σ to $-\sigma$. For this reason, if one's primary object of interest is the Boltzmann equation, one may freely assume that b is a symmetric function on $[-1,1]$, since then replacing $b(x)$ by $(b(x)+b(-x))/2$ will have no effect on the spectrum of Q on the invariant subspace of symmetric functions or on the corresponding Boltzmann equation. (See the introduction of [4] for more discussion of this point in the context of the Boltzmann equation.) If B is symmetric, then $B_1 = 0$, and we do have $B_1 < B_2$.

However, it is interesting that the Kac conjecture holds without restriction to the symmetric subspace and that the methods developed here can be used to determine the spectral gap even when b is not symmetric, and the eigenfunctions corresponding to the gap eigenvalue are not symmetric.

When b is not symmetric, it may happen that $B_1 \le B_2$. We shall give examples of this below. The next theorem gives the spectral gap and the eigenfunctions whenever $\Delta_2 = 2(1-B_1)$, regardless of whether $B_1 < B_2$ or $B_2 < B_1$. However, it gives the exact value of Δ_N only for $N \ge 7$. Since we are interested in large values of N, this is fully satisfactory. Indeed, it is remarkable that the two theorems show that already at relatively small values of N, the behavior of the system is very close, qualitatively and quantitatively to the behavior in the large N limit.

THEOREM 1.2. *Suppose that $\Delta_2 = 2(1-B_1)$. Then, for all $N \ge 7$,*

$$\Delta_N = \min\{\ (1-B_1),\ (1-B_2)\ \}\frac{N}{(N-1)}. \tag{1.10}$$

Moreover, if $B_2 > B_1$, the eigenspace is three-dimensional and is spanned by the functions

$$\phi(\vec{v}) = \sum_{j=1}^{N} |v_j|^2 v_j^\alpha, \qquad \alpha = 1,2,3, \tag{1.11}$$

where v_j^α denotes the αth component of v_j.

On the other hand, if $B_2 < B_1$, the eigenspace is spanned by the functions of the form

$$|v_i|^2 - |v_j|^2 \qquad \textit{and} \qquad v_i^\alpha - v_j^\alpha, \quad \alpha = 1,2,3, \tag{1.12}$$

for all $i < j$.

Finally, if $B_1 = B_2$, the eigenspace is spanned by both of the sets of functions listed in (1.8) *and* (1.12) *together.*

For the family of collision rates introduced so far, the b_α, one may apply Theorem 1.1, as we have indicated, but only for $\alpha \le 7/9$. As we shall see in section 2, Theorem 1.2 applies for all $0 \le \alpha < 1$ and in this case gives $\Delta_N = (N/N-1)(1-B_2)$ for $N \ge 7$. In order to illustrate the case in which Theorem 1.2 yields the gap $\Delta_N = (N/N-1)(1-B_1)$, we introduce

$$\widetilde{b}_\alpha(x) = 2(\alpha+1)1_{[0,1]}(x)x^\alpha, \qquad \alpha \ge 0. \tag{1.13}$$

Since $x^2 < x$ on $(0,1)$, it is clear that $B_2 < B_1$ for all α in this case. We show at the end of section 2 that, at least for $0 \le \alpha \le 1$, $\Delta_2 = 2(1 - B_1)$, so that Theorem 1.2 applies in these cases.

The method of proof is quite robust, and in section 10 we shall describe how it may be extended to determine the spectral gap of Q for still other choices of b that are not covered by Theorems 1.1 and 1.2.

The method of proof of these theorems relies on a basic strategy introduced in [3] but which is extended significantly here. The strategy consists of exploiting an inductive link between the spectral gap of Q and the one of an operator P, an average over projections introduced in section 3. In fact,

$$\Delta_N \ge \frac{N}{N-1}(1-\mu_N)\Delta_{N-1}, \tag{1.14}$$

where $1 - \mu_N$ is the gap of P. The eigenvalues of P are much easier to compute than the ones of Q since the range of P consists of sums of functions of single variables v_j.

In the case of the original model treated by Kac, one is in the happy circumstance that Q has a single gap eigenfunction ϕ which is also the gap eigenfunction of P for all N, *and*, when this is used as a trial function in the derivation of (1.14), one sees that (1.14) actually holds with equality, giving an identity relating Δ_N and Δ_{N-1}. Thus, starting at $N = 2$, where the gap can be easily calculated, the above formula yields a lower bound on Δ_N that turns out to be exact. The model treated in this paper does not have this simplifying feature, even when the gap eigenfunctions of Q are also the gap eigenfunctions of P. Nevertheless, the ideas that lead to (1.14) can be used in such a way that we can still calculate the gap of Q exactly. Very briefly, here is how.

Let $\mu_N^* < \mu_N$ be any number, and assume that there are finitely many eigenvalues $\mu_N^* \le \mu_N^{(m)} \le \cdots \le \mu_N^{(1)} \le \mu_N$ of P. Denote the corresponding eigenspaces by E_j. Let V_j be the smallest invariant subspace of Q that contains E_j. Lemma 4.1 in section 4 provides us with the following dichotomy: *Either*

$$\Delta_N \ge \frac{N}{N-1}(1-\mu_N^*)\Delta_{N-1} \tag{1.15}$$

or else

$$\text{the gap of } Q \text{ is the same as the gap of } Q \text{ restricted to } \oplus_{j=1}^m V_j. \tag{1.16}$$

If the threshold has been chosen so that the lower bound on Δ_N provided by (1.15) is at least as large as the upper bound on Δ_N provided by some trial function in $\oplus_{j=1}^m V_j$, then Δ_N is the gap of Q restricted to $\oplus_{j=1}^m V_j$. As we shall see, the V_j are finite-dimensional, so determining the gap of Q on $\oplus_{j=1}^m V_j$ is a tractable problem. In this case we have determined the exact value of Δ_N.

To proceed to the determination of Δ_N for all large N, one needs a strategy for choosing the threshold $\mu_N^\star$. The lower the value of $\mu_N^\star$ that is chosen, the stronger the bound (1.15) will be, but also the higher the value of m will be. The basis for the choice of $\mu_N^\star$ is a trial function calculation, providing a guess $\widetilde{\Delta}_N$ for the value of Δ_N. Indeed, natural trial functions can often be chosen on the basis of physical considerations. (The spectrum of the linearized Boltzmann equation is the source in the case at hand.) To show that the guess is correct, so that $\widetilde{\Delta}_N = \Delta_N$, we are led to choose $\mu_N^\star$ so that

$$\widetilde{\Delta}_N \le \frac{N}{N-1}(1-\mu_N^*)\widetilde{\Delta}_{N-1}. \tag{1.17}$$

Since $\widetilde{\Delta}_{N-1} \geq \Delta_{N-1}$, this forces us into the second alternative in the dichotomy discussed above, so that the gap eigenfunction for N particles lies in $\oplus_{j=1}^{m} V_j$. Indeed, if the physical intuition behind the guess was correct, the trial function leading to $\widetilde{\Delta}_N$ will lie in $\oplus_{j=1}^{m} V_j$ and yield the gap.

Choosing $\mu_N^\star$ small enough that (1.17) is satisfied might in principle lead to a value of m that depends on N. However, in the case at hand, we are fortunate and can work with a choice of $\mu_N^\star$ that leads to a fixed and small value of m but for which (1.17) is satisfied for all sufficiently large values of N—hence the restriction to $N \geq 7$ in Theorem 1.2.

As will be clear from this summary of the strategy, the determination of the spectrum of P is the main technical step that must be accomplished. As we mentioned before, this is relatively simple, compared to the determination of the spectrum of Q, since the range of P consists of functions that are a sum of functions of a single variable.

For this reason, we can reduce the study of the spectrum of P to that of a much simpler Markov operator K acting on functions on the unit ball B in $\mathbb{R}^3$. In the analysis of K, we shall draw on some deep results on Jacobi polynomials [8], [12]. In fact, it turns out that the connection between our eigenvalue problems and pointwise bounds on Jacobi polynomials is through a simple identity, and applications of this identity can be made in both directions: We not only use bounds on Jacobi polynomials to bound eigenvalues, we shall use simple eigenvalue estimates to sharpen certain best known bounds on Jacobi polynomials, as we briefly discuss in section 11.

First, however, we deal with a simpler technical problem, the computation of the spectral gap of Q for $N = 2$.

2. The spectral gap for $N = 2$. For $N = 2$, the state space X_2 consists of pairs $(v, -v)$, with $v \in \mathbb{R}^3$ satisfying $|v|^2 = 1/2$. Note that for $N = 2$ the collision rules (1.1) reduce to

$$v_1^* = \sigma/\sqrt{2} \qquad \text{and} \qquad v_2^* = -\sigma/\sqrt{2},$$

since $v_1 + v_2 = 0$.

The map $(v, -v) \mapsto \sqrt{2}v$ identifies X_2 with the unit sphere S^2, and the measure $\mathrm{d}\sigma_2$ on X_2 with $\mathrm{d}\sigma$ on S^2. Thus, we may think of Q as operating on functions on S^2. In this representation, we have the formula

$$Q\phi(u) = \int_{S^2} \phi(\sigma) b(u \cdot \sigma) \mathrm{d}\sigma.$$

Notice that if R is any rotation of $\mathbb{R}^3$

$$\begin{aligned}(Q\phi)(Ru) &= \int_{S^2} \phi(\sigma) b(Ru \cdot \sigma) \mathrm{d}\sigma \\ &= \int_{S^2} \phi(R\sigma) b(Ru \cdot R\sigma) \mathrm{d}\sigma \\ &= \int_{S^2} \phi(R\sigma) b(u \cdot \sigma) \mathrm{d}\sigma = Q(\phi \circ R)(u).\end{aligned}$$

That is, $(Q\phi) \circ R = Q(\phi \circ R)$, and this means that for each n the space of spherical harmonics of degree n is an invariant subspace of Q, contained in an eigenspace of Q. In turn, this means that we can determine the spectrum of Q by computing its

action on the zonal spherical harmonics, i.e., those of the form $P_n(e \cdot u)$, where e is any fixed unit vector in $\mathbb{R}^3$ and P_n is the nth degree Legendre polynomial. Now, for any function $\phi(u)$ of the form $\phi(u) = f(e \cdot u)$,

$$Q\phi(u) = \int_{S^2} \phi(\sigma \cdot e) b(\sigma \cdot u) \mathrm{d}\sigma.$$

We choose coordinates in which u and e span the x, z plane with

$$u = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} \qquad \text{and} \qquad e = \begin{bmatrix} \sqrt{1-t^2} \\ 0 \\ t \end{bmatrix},$$

so that $t = u \cdot e$. Then with

$$\sigma = \begin{bmatrix} \sin\theta\cos\psi \\ \sin\theta\sin\psi \\ \sin\theta \end{bmatrix},$$

$$Q\phi(u) = \mathcal{Q}f(e \cdot u),$$

where

$$\begin{aligned} \mathcal{Q}f(t) &= \frac{1}{4\pi} \int_0^\pi \int_0^{2\pi} f(t\cos\theta + \sqrt{1-t^2}\sin\theta\cos\varphi) b(\cos\theta) \sin\theta \mathrm{d}\theta \mathrm{d}\varphi \\ &= \frac{1}{4\pi} \int_0^\pi \int_{-1}^1 f(ts + \sqrt{1-t^2}\sqrt{1-s^2}\cos\varphi) b(s) \mathrm{d}s \mathrm{d}\varphi. \end{aligned} \tag{2.1}$$

Now, if f is any eigenfunction of $\mathcal{Q}$, with $\mathcal{Q}f = \lambda f$, then by evaluating both sides at $t = 1$, we have $\lambda f(1) = \frac{1}{2}\int_0^\pi \int_{-1}^1 f(s) b(s) \mathrm{d}s$. Thus, the eigenvalue is given by

$$\lambda = \frac{1}{2} \int_{-1}^1 \frac{f(s)}{f(1)} b(s) \mathrm{d}s.$$

As we have observed above, the eigenfunctions of $\mathcal{Q}$ are the Legendre polynomials. Thus, if P_n is the Legendre polynomial of nth degree with the standard normalization $P_n(1) = 1$, and λ_n is the corresponding eigenvalue,

$$\lambda_n = \frac{1}{2} \int_{-1}^1 P_n(s) b(s) \mathrm{d}s. \tag{2.2}$$

This explicit formula enables one to easily compute Δ_2. For example, we can now easily prove the following.

LEMMA 2.1. *When $b(x) = b_\alpha(x)$, as in* (1.3)*, then $1 - B_2 < 1 - B_1$ for all $\alpha < 1$, and moreover*

$$\Delta_2 = 2(1 - \lambda_1) = \frac{4(1-\alpha)}{2-\alpha} = (1 - B_2)(3 - \alpha), \tag{2.3}$$

so that (1.6) *is satisfied for all α with $0 \le \alpha \le 7/9$.*

Proof. By using Rodrigues's formula [13, equation 4.3.1]

$$P_n(x) = \frac{1}{2^n n!} \frac{\mathrm{d}^n}{\mathrm{d}x^n}(x^2 - 1)$$

and integration by parts, one computes

$$\lambda_n = (1-\alpha)\frac{(\alpha)_n}{(1-\alpha)_{n+1}} = \frac{(\alpha)_n}{(2-\alpha)_n},$$

where $(\alpha)_n = \alpha(\alpha+1)(\alpha+2)\dots(\alpha+n-1)$. Notice that, for all $0 \le \alpha < 1$, λ_n decreases as n increases, so with the collision rate given by b_α,

$$\Delta_2 = 2(1-\lambda_1) = \frac{4(1-\alpha)}{2-\alpha}. \tag{2.4}$$

Next, one computes

$$1 - B_1 = \frac{2(1-\alpha)}{(2-\alpha)} \qquad \text{and} \qquad 1 - B_2 = \frac{4(1-\alpha)}{(2-\alpha)(3-\alpha)}.$$

Since $2 > 4/(3-\alpha)$ for $\alpha < 1$, $1 - B_2 < 1 - B_1$ for all $\alpha < 1$. Moreover, from this computation, one readily obtains (2.3) and the statement concerning (1.6). □

In particular, the condition (1.6) is satisfied in both the uniform redirection model ($\alpha = 0$) and the Morgenstern model ($\alpha = 1/2$). Thus in these cases we have the exact spectral gaps

$$\begin{aligned} \Delta_N &= \frac{2}{3}\frac{N}{N-1} \qquad \text{for the uniform redirection model,} \\ \Delta_N &= \frac{8}{15}\frac{N}{N-1} \qquad \text{for the Morgenstern model.} \end{aligned} \tag{2.5}$$

We close this section with a remark that may provide a useful perspective on what follows. In determining the spectral gap of Q for $N = 2$, general symmetry conditions told us right away what all of the eigenfunctions were. A less obvious, though still simple, argument then provided us with the explicit formula (2.2) for all of the eigenvalues. There is one last hurdle to cross: There are infinitely many eigenvalues given by (2.2), and for a general b, we cannot determine which is the second largest by computing them all explicitly. What was particularly nice about b_α is that in this case the eigenvalues of Q were monotone-decreasing:

$$\lambda_{n+1} \le \lambda_n.$$

For other choices of b, this need not be the case. However, there are ways to use pointwise bounds on Legendre polynomials to reduce the problem of determining Δ_2 to the computation of a *finite* number of eigenvalues by using (2.2). For example, one has the classical bound (see [13, Theorem 7.3.3]):

$$|P_n(x)|^2 < \frac{2}{n\pi}\frac{1}{\sqrt{1-x^2}}. \tag{2.6}$$

As long as $b(x)(1-x^2)^{-1/4}$ is integrable, this gives an upper bound on λ_n that is proportional to $n^{-1/2}$: Define

$$\tilde{\lambda}_n = \left(\frac{1}{8\pi n}\right)^{1/2} \int_{-1}^{1} b(x)(1-x^2)^{-1/4}\mathrm{d}x.$$

Then let n_0 be the least value of n such that $\tilde{\lambda}_n \le \lambda_1$. Then the second largest eigenvalue of Q is

$$\max_{1 \le n \le n_0} \lambda_n.$$

We illustrate this by showing that, for the rate function $\widetilde{b}_\alpha$ introduced in (1.13), $\Delta_2 = 2(1 - B_1)$ at least for $0 \le \alpha \le 1$. (Of course, the integrals in (2.2) can be computed exactly in this case; see [5, section 7.231, page 822]. However, we prefer to illustrate the use of (2.6).)

By (2.6) and (2.2),

$$\begin{aligned} |\lambda_n| &\le (\alpha+1)\left(\int_0^1 x^{2\alpha}\mathrm{d}x\right)^{1/2}\left(\int_0^1 P_n(x)^2\mathrm{d}x\right)^{1/2} \\ &< \frac{\alpha+1}{\sqrt{2\alpha+1}}\frac{1}{\sqrt{n}}. \end{aligned} \tag{2.7}$$

Also, by (2.2), $\lambda_1 = B_1 = (\alpha+1)/(\alpha+2)$. Comparison of the formulas shows that, for $0 \le \alpha \le 1$, $\lambda_n < \lambda_1$ for all $n > 4$. Thus it suffices to check that $\lambda_j < \lambda_1$ for $j = 2, 3$, and 4 by direct computation with (2.2). By doing so, one finds that this is the case. Hence, Theorem 1.2 applies and yields $\Delta_N = (N/N-1)(1-B_1)$ for $N \ge 7$.

Further calculation would extend this result to higher values of α. Notice that, as α tends to infinity, $\widetilde{b}_\alpha(x)$ is more and more concentrated at $x = 1$, which corresponds to $\theta = 0$. Thus, for large values of α, $\widetilde{b}_\alpha$ represents a "grazing collision model."

For $N > 2$, the operator Q is much more complicated, and direct determination of the spectrum is not feasible. Instead, we use an inductive procedure involving an auxiliary operator that we now introduce.

3. The average of projections operator P and its relation to Q. A simple convexity argument shows that, for each j,

$$\sup\{|v_j|^2 \ : \ \vec{v} \in X_N\} = \frac{N-1}{N}.$$

For each j, define $\pi_j(\vec{v})$ by

$$\pi_j(\vec{v}) = \sqrt{\frac{N}{N-1}}v_j,$$

so that π_j maps X_N onto the unit ball B in $\mathbb{R}^3$.

For any function ϕ in $L^2(X_N, \mathrm{d}\sigma_N)$, and any j with $1 \le j \le N$, define $P_j(\phi)$ to be the orthogonal projection of ϕ onto the subspace of $L^2(X_N, \mathrm{d}\sigma_N)$ consisting of square integrable functions that depend on $\vec{v}$ through v_j alone. That is, $P_j(\phi)$ is the unique element of $L^2(X_N, \mathrm{d}\sigma_N)$ of the form $f(\pi_j(\vec{v}))$ such that

$$\int_{X_N} \phi(\vec{v})g(\pi_j(\vec{v}))\mathrm{d}\sigma_N = \int_{X_N} f(\pi_j(\vec{v}))g(\pi_j(\vec{v}))\mathrm{d}\sigma_N$$

for all continuous functions g on B.

The *average of projections operator* P is then defined through

$$P = \frac{1}{N}\sum_{j=1}^{N} P_j.$$

If the individual projections P_j all commuted with one another, then the spectrum of P would be very simple: The eigenvalues of each P_j are 0 and 1. Moreover, $P_j\phi = \phi$ if and only if ϕ depends only on v_j so that it cannot then also satisfy $P_k\phi = \phi$ for

$k \neq j$, unless ϕ is constant. It would then follow that the eigenvalues of P would be 0, $1/N$, and 1, with the last having multiplicity one.

However, the individual projections P_j do not commute with one another, due to the nature of the constraints defining X_N.

We now define

$$\mu_N = \sup\left\{ \int_{X_N} \phi(\vec{v}) P\phi(\vec{v}) \mathrm{d}\sigma_N \;\middle|\; \int_{X_N} \phi^2(\vec{v}) \mathrm{d}\sigma_N = 1,\ \int_{X_N} \phi(\vec{v}) \mathrm{d}\sigma_N = 0 \right\}. \tag{3.1}$$

The P operator is simpler than the Q operator in that if ϕ is any eigenfunction of P with a nonzero eigenvalue, then clearly ϕ has the form

$$\phi = \sum_{j=1}^{N} f_j \circ \pi_j$$

for some functions $f_1, \ldots, f_N$ on B. For $N \geq 4$, most of the eigenfunctions of Q have a more complicated structure. Nonetheless, there is a close relation between the spectra of Q and P, as we now explain.

To do this, we need a more explicit formula for P, such as the formula (1.4) that we have for Q. The key to computing $P_j\phi$ is a factorization formula [3] for the measure σ_N. Define a map $T_N : X_{N-1} \times B \to X_N$ as follows:

$$T_N(\vec{y}, v) = \left(\alpha(v) y_1 - \frac{1}{\sqrt{N^2 - N}} v, \ldots, \alpha(v) y_{N-1} - \frac{1}{\sqrt{N^2 - N}} v, \sqrt{\frac{N-1}{N}} v \right), \tag{3.2}$$

where

$$\alpha^2(v) = 1 - |v|^2.$$

This map induces coordinates $(\vec{y}, v)$ on X_N, and, in terms of these coordinates, one has the integral factorization formula

$$\int_{X_N} \phi(\vec{v}) \mathrm{d}\sigma_N = \frac{|S^{3N-7}|}{|S^{3N-4}|} \int_B \left[\int_{X_{N-1}} \phi(T_N(\vec{y}, v)) \mathrm{d}\sigma_{N-1} \right] (1 - |v|^2)^{(3N-8)/2} \mathrm{d}v.$$

It follows from this and the definition of P_N that

$$P_N \phi(\vec{v}) = f \circ \pi_N(\vec{v}),$$

where

$$f(v) = \int_{X_{N-1}} \phi(T_N(\vec{y}, v)) \mathrm{d}\sigma_{N-1}.$$

For $j < N$, one has analogous formulas for T_j and P_j, except the roles of v_N and v_j are interchanged.

Next, we make the definition for Q that is analogous to (3.1) for P: Define λ_N by

$$\lambda_N = \sup\left\{ \int_{X_N} \phi(\vec{v}) Q\phi(\vec{v}) \mathrm{d}\sigma_N \;\middle|\; \int_{X_N} \phi^2(\vec{v}) \mathrm{d}\sigma_N = 1,\ \int_{X_N} \phi(\vec{v}) \mathrm{d}\sigma_N = 0 \right\}. \tag{3.3}$$

With this explicit formula in hand, and the definitions of μ_N and λ_N, we come to the fundamental fact relating P and Q.

LEMMA 3.1. *For any square integrable function ϕ on X_N that is orthogonal to the constants,*

$$\langle \phi, Q\phi \rangle \leq \lambda_{N-1} \|\phi\|_2^2 + (1 - \lambda_{N-1}) \langle \phi, P\phi \rangle, \tag{3.4}$$

where $\langle \cdot, \cdot \rangle$ denotes the inner product on $L^2(X_N, \sigma_N)$.

Proof. To bound $\langle \phi, Q\phi \rangle$ in terms of λ_{N-1}, define, for $1 \leq k \leq N$, the operator $Q^{(k)}$ by

$$Q^{(k)}\phi(\vec{v}) = \begin{pmatrix} N-1 \\ 2 \end{pmatrix}^{-1} \sum_{i<j, i\neq k, j\neq k} \int_{S^2} \phi(R_{i,j,\sigma}(\vec{v})) \mathrm{d}\sigma.$$

That is, we leave out collisions involving the kth particle and average over the rest. Clearly,

$$Q = \frac{1}{N} \sum_{k=1}^{N} Q^{(k)}.$$

Therefore, for any ϕ in $L^2(X_N, \sigma_N)$,

$$\langle \phi, Q\phi \rangle = \frac{1}{N} \sum_{k=1}^{N} \langle \phi, Q^{(k)}\phi \rangle.$$

By using the coordinates $(\vec{y}, v)$ induced by the map $T_k : X_{N-1} \times B \to X_N$, it is easy to see that, for $i \neq k, j \neq k$, $R_{i,j,\sigma}$ acts only on the $\vec{y}$ variable. That is, for such i and j,

$$R_{i,j,\sigma}(T_k(\vec{y}, v)) = T_k(R_{i,j,\sigma}(\vec{y}), v).$$

Thus, if we hold v fixed as a parameter, we can think of $(Q^{(k)}\phi)(T_k(\vec{y}, v))$ as resulting from applying the $N-1$ dimensional version of Q to ϕ with v_k held fixed.

To estimate λ_N, we need to estimate $\langle \phi, Q\phi \rangle$ when ϕ is orthogonal to the constants. When ϕ is orthogonal to the constants, and we fix v, the function

$$\vec{y} \mapsto \phi(T_k(\vec{y}, v))$$

is not, in general, orthogonal to the constants on X_{N-1}. However, we can correct for that by adding and subtracting $P_k\phi$. Therefore

$$\begin{aligned} \langle (\phi - P_k\phi), Q^{(k)}(\phi - P_k\phi) \rangle &\leq \lambda_{N-1} \|\phi - P_k\phi\|_2^2 \\ &= \lambda_{N-1}(\|\phi\|_2^2 - \|P_k\phi\|_2^2) \\ &= \lambda_{N-1}(\|\phi\|_2^2 - \langle \phi, P_k\phi \rangle). \end{aligned} \tag{3.5}$$

Then since $Q^{(k)}P_k\phi = P_k\phi$ and since $P_k\phi$ is orthogonal to $\phi - P_k\phi$,

$$\begin{aligned} \langle \phi, Q^{(k)}\phi \rangle &= \langle ((\phi - P_k\phi) + P_k\phi) Q^{(k)} ((\phi - P_k\phi) + P_k\phi) \rangle \\ &= \langle (\phi - P_k\phi), Q^{(k)}(\phi - P_k\phi) \rangle + \langle P_k\phi, P_k\phi \rangle \\ &= \langle (\phi - P_k\phi), Q^{(k)}(\phi - P_k\phi) \rangle + \langle \phi, P_k\phi \rangle \\ &\leq \lambda_{N-1}(\|\phi\|_2^2 - \langle \phi P_k\phi \rangle) + \langle \phi P_k\phi \rangle . \end{aligned} \tag{3.6}$$

By averaging over k, we have (3.4). ∎

Lemma 3.1 was used as follows in [3]: Any trial function ϕ for λ_N is a valid trial function for μ_N, so that

$$\lambda_N \leq \lambda_{N-1} + (1 - \lambda_{N-1})\mu_N. \tag{3.7}$$

Then since $\Delta_N = N(1 - \lambda_N)$, we have

$$\Delta_N \geq \frac{N}{N-1}(1 - \mu_N)\Delta_{N-1}. \tag{3.8}$$

Therefore, with $a_N = \frac{N}{N-1}(1 - \mu_N)$, for all $N \geq 3$,

$$\Delta_N \geq \left(\prod_{j=3}^{N} a_j \right) \Delta_2.$$

Thus, one route to proving a lower bound on Δ_N is to prove an upper bound on μ_N and hence a lower bound on a_N. This route led to a sharp lower bound for Δ_N—the exact value—for the one dimension Kac model investigated in [2]. However, it would not lead to a proof of Theorem 1.1. The reasons for this are worth pointing out before we proceed.

As we shall see below, the eigenspace of P with the eigenvalue μ_N—the gap eigenspace of P—is spanned by the functions specified in (1.8). Granted this, and granted Theorem 1.1, whenever condition (1.6) is satisfied:

$$\text{For } (1 - B_2) < (1 - B_1), \quad Q\phi = \lambda_N \phi \quad \Rightarrow \quad P\phi = \mu_N \phi,$$

while

$$\text{for } (1 - B_1) < (1 - B_2), \quad Q\phi = \lambda_N \phi \quad \Rightarrow \quad P\phi \neq \mu_N \phi.$$

In the second case $(1-B_1) < (1-B_2)$, the mismatch between the gap eigenspaces for Q and P means that equality cannot hold in (3.7), and hence the recursive relation (3.8) cannot possibly yield exact results in this case.

Moreover, even in the first case $(1 - B_2) < (1 - B_1)$, where there is a match between the gap eigenspaces of Q and P, there *still* will not be equality in (3.7). The reasons for this are more subtle: The inequality (3.7) comes from the key estimate (3.6). By considering (3.6), one sees that equality will hold there if and only if

$$Q^{(k)}(\phi - P_k\phi) = \lambda_{N-1}(\phi - P_k\phi)$$

for each k, where $(\phi - P_k\phi)$ is regarded as a function on X_{N-1} through the change of variables $T_k : (X_{N-1}, B) \to X_N$ that was introduced just before Lemma 3.1.

However, if ϕ is in the gap eigenspace for Q on X_N, Theorem 1.1 tells us that it is a linear combination of the three functions specified in (1.8), all of which are homogeneous of degree 3 in v. Because of the translation in (3.2), which is due to momentum conservation, $(\phi - P_k\phi)$ is regarded as a function on X_{N-1} that will *not* be homogeneous of degree 3—it will contain lower order terms. Hence $(\phi - P_k\phi)$ will not be in the gap eigenspace for $Q^{(k)}$.

The main result of the next section provides a way to use more detailed spectral information about P to sharpen the recursive estimate so that we do obtain the exact results announced in Theorem 1.1.

4. How to use more detailed spectral information on P to determine the spectral gap of Q. The following lemma is the key to using (3.4) to obtain sharp results for the model considered here.

LEMMA 4.1. *For any $N \geq 3$, let $\mu_N^\star$ be a number with*

$$\mu_N^\star < \mu_N$$

such that there are only finitely eigenvalues of P between $\mu_N^\star$ and μ_N:

$$\mu_N^\star \leq \mu_N^{(m)} < \cdots < \mu_N^{(1)} < \mu_N.$$

Let $\mu_N^{(0)}$ denote μ_N, and then, for $j = 0, \ldots, m$, let E_j denote the eigenspace of P corresponding to $\mu_N^{(j)}$. Let V_j denote the smallest invariant subspace of Q that contains E_j. Let ν_j be the largest eigenvalue of Q on V_j.

Then either

$$\lambda_N = \max\{\nu_0, \ldots, \nu_m\} \tag{4.1}$$

or else

$$\Delta_N \geq \frac{N}{N-1}(1 - \mu_N^\star)\Delta_{N-1}. \tag{4.2}$$

If $\mu_N^\star = \mu_N^{(m)}$, then we have the same alternative except with strict inequality in (4.2).

Proof. If $\lambda_N > \max\{\nu_0, \ldots, \nu_m\}$, then in the variational principle for λ_N we need only consider functions ϕ that are orthogonal to the constants and also in the orthogonal complement of each of the V_j. This means also that ϕ belongs to the orthogonal complement of each of the E_j. But then

$$\langle \phi, P\phi \rangle \leq \mu_N^\star \|\phi\|_2^2.$$

By using this estimate in (3.4), we have (4.2). Moreover, if $\mu_N^\star = \mu_N^{(m)}$, then strict inequality must hold in the last inequality. □

Lemma 4.1 gives us the dichotomy between (1.15) and (1.16) that plays a key role in the strategy described in the introduction. To put this strategy into effect, we must first carry out a more detailed investigation of the spectrum of P. The main result of the next section reduces the investigation of the spectrum of P to the study of a simpler operator—the *correlation operator* K, which is a Markov operator on functions on the unit ball B in $\mathbb{R}^3$.

5. The correlation operator K and its relation to P. While Q and P are both operators on spaces of functions of a large number of variables, the problem of computing the eigenvalues of P reduces to the problem of computing the eigenvalues of an operator on functions on B, the unit ball in $\mathbb{R}^3$.

First, define the measure ν_N on B to be the "push forward" of σ_N under the map π_j. That is, for any continuous function f on B,

$$\int_B f(v)\mathrm{d}\nu_N = \int_{X_N} f(\pi_j(\vec{v}))\mathrm{d}\sigma_N.$$

By the permutation invariance of σ_N, this definition does not depend on the choice of j. By direct calculation [3], one finds that

$$\mathrm{d}\nu_N(v) = \frac{|S^{3N-7}|}{|S^{3N-4}|}(1 - |v|^2)^{(3N-8)/2}\mathrm{d}v. \tag{5.1}$$

Now define the self-adjoint operator K on $L^2(B, \mathrm{d}\nu_N)$ through the following quadratic form:

$$\langle f, Kf\rangle_{L^2(\nu)} = \int_{X_N} f(\pi_1(\vec{v}))f(\pi_2(\vec{v}))\mathrm{d}\sigma_N \tag{5.2}$$

for all f in $L^2(B, \mathrm{d}\nu_N)$. Equivalently,

$$(Kf)\circ\pi_1 = P_1(f\circ\pi_2). \tag{5.3}$$

Note that, by the permutation invariance of σ_N, one can replace the pair $(1,2)$ of indices by any other pair of distinct indices without affecting the operator K defined by (5.3). This is the *correlation operator*.

To see the relation between the spectra of P and the spectra of K, suppose that ϕ is an eigenfunction of P that is symmetric under permutation of the particle indices. (These symmetric eigenfunctions are the ones that are significant in the physical application.) Then since any vector in the image of P has the form $\sum_{j=1}^N f_j\circ\pi_j$ for functions $f_1,\dots,f_N$ on B, we must have, for ϕ symmetric,

$$\phi = \sum_{j=1}^N f\circ\pi_j. \tag{5.4}$$

Now we ask: For which choices of f will ϕ given by (5.4) be an eigenfunction of P? To answer this, note that, by (5.3),

$$P_k\phi = f\circ\pi_k + \sum_{j=1, j\neq k}^N P_k(f\circ\pi_j). \tag{5.5}$$

Therefore, from (5.5) and the definition of K, $P_k\phi = f\circ\pi_k + (N-1)(Kf)\circ\pi_k$. Thus, by averaging over k,

$$P\phi = \frac{1}{N}\phi + \frac{N-1}{N}\sum_{j=1}^N (Kf)\circ\pi_j. \tag{5.6}$$

In the case $Kf = \kappa f$, this reduces to

$$P\phi = \frac{1}{N}(1+(N-1)\kappa)\phi,$$

and thus eigenfunctions of K yield eigenfunctions of P. It turns out that all symmetric eigenfunctions arise in exactly this way and that all eigenfunctions, symmetric or not, arise in a similar way, specified in the next lemma.

LEMMA 5.1. *Let V be the orthogonal complement in $L^2(X_N, \sigma_N)$ of the kernel of P. There is a complete orthonormal basis of V consisting of eigenfunctions ϕ of P of one of the two forms:*

(i) *For some eigenfunction f of K, $\phi = \sum_{k=1}^N f\circ\pi_k$. In this case, if $Kf = \kappa f$, then $P\phi = \mu\phi$, where*

$$\mu = \frac{1}{N}\left(1+(N-1)\kappa\right). \tag{5.7}$$

(ii) *For some eigenfunction f of K, and some pair of indices $i < j$, $\phi = f \circ \pi_i - f \circ \pi_j$. In this case, if $Kf = \kappa f$, then $P\phi = \mu\phi$, where*

$$\mu = \frac{1-\kappa}{N}. \tag{5.8}$$

Proof. Suppose that ϕ is an eigenfunction of P with nonzero eigenvalue μ, and ϕ is orthogonal to the constants. By the permutation invariance we may assume that either ϕ is invariant under permutations or that there is some pair permutation, which we may as well take to be $\sigma_{1,2}$, such that $\phi \circ \sigma_{1,2} = -\phi$. We will treat these two cases separately.

First, suppose that ϕ is symmetric. We have already observed that, in this case, the recipe $\phi = \sum_{j=1}^{N} f \circ \pi_j$, with f an eigenfunction of K, yields symmetric eigenfunctions of P. We now show that all symmetric eigenfunctions of P on V have this form.

First, simply because such a ϕ is in the image of P and is symmetric, ϕ must have the form (5.4). It remains to show that f must be an eigenfunction of K. Then by (5.6), $\mu\phi = P\phi$ becomes

$$\mu \sum_{k=1}^{N} f \circ \pi_k = \frac{1}{N} \sum_{k=1}^{N} (f + (N-1)Kf) \circ \pi_k.$$

Apply P_1 to both sides to obtain

$$\frac{1}{N} \left([f + (N-1)Kf] + (N-1)K \left[f + (N-1)Kf \right] \right) = \mu(f + (N-1)Kf),$$

which is

$$\frac{1}{N} \left(I + (N-1)K \right)^2 f = \mu(I + (N-1)K)f. \tag{5.9}$$

Since $\mu \neq 0$, f is not in the null space of either $I + (N-1)K$ or $(I + (N-1)K)^2$. It then follows from (5.9) that

$$\frac{1}{N} \left(I + (N-1)K \right) f = \mu f.$$

Thus, when ϕ is symmetric, there is an eigenfunction f of K with eigenvalue κ such that $\phi = \sum_{k=1}^{N} f \circ \pi_k$ and

$$\mu = \frac{1}{N} \left(1 + (N-1)\kappa \right).$$

We next consider the case in which

$$\phi \circ \sigma_{1,2} = -\phi.$$

Note that

$$P_k(\phi \circ \sigma_{1,2}) = P_k\phi = 0$$

whenever k is different from both 1 and 2. It follows that

$$\frac{1}{N} \sum_{k=1}^{N} P_k\phi = \frac{1}{N} \left(P_1\phi + P_2\phi \right).$$

The right-hand side is of the form $f(v_1) - f(v_2)$, and hence ϕ must have this form if it is an eigenvector. By taking $\phi = f \circ \pi_1 - f \circ \pi_2$ we have

$$\frac{1}{N}\sum_{k=1}^{N} P_k\phi = \frac{1}{N}\left((f - Kf)\circ\pi_1 - (f - Kf)\circ\pi_2\right).$$

Hence when $P\phi = \mu\phi$ and ϕ is antisymmetric as above, there is an eigenvalue κ of K such that

$$\mu = \frac{1-\kappa}{N}.$$

This proves the second part. □

Lemma 5.1 reduces the computation of the spectrum of P to the computaton of the spectrum of K. We undertake this in the next three sections.

6. Explicit form of the correlation operator K. For any two functions f and g on B that are square integrable with respect to ν_N, consider the bilinear form $\int_{X_N} f(\pi_1(\vec{v}))g(\pi_2(\vec{v}))\mathrm{d}\sigma_N$. It is easily seen from (5.3) that

$$\langle f, Kg\rangle = \int_{X_N} f(\pi_1(\vec{v}))g(\pi_2(\vec{v}))\mathrm{d}\sigma_N,$$

where $\langle\cdot,\cdot\rangle$ is the inner product on $L^2(B,\nu_N)$.

By computing the right-hand side using the factorization formula (3.2), but for T_1 instead of T_N, one finds, for $N > 3$:

$$Kg(v) = \frac{|S^{3N-10}|}{|S^{3N-7}|}\int_B g\left(\frac{\sqrt{N^2-2N}}{N-1}\sqrt{1-|v|^2}y - \frac{1}{N-1}v\right)(1-|y|^2)^{(3N-11)/2}\mathrm{d}y.$$

The explicit form of K is slightly different for $N = 3$. We can see this different form as a limiting case, if we make the dimension a continuous fact. The following way of doing this will be convenient later on.

For $\alpha > -1$, define the constant C_α by

$$C_\alpha = \left(\int_B (1-|y|^2)^\alpha \mathrm{d}y\right)^{-1},$$

so that, for

$$\alpha = \frac{3N-8}{2},$$

$$\mathrm{d}\nu_N(v) = C_\alpha(1-|y|^2)^\alpha\mathrm{d}y,$$

and then

$$Kg(v) = C_{\alpha-3/2}\int_B g\left(\frac{\sqrt{N^2-2N}}{N-1}\sqrt{1-|v|^2}y - \frac{1}{N-1}v\right)(1-|y|^2)^{\alpha-3/2}\mathrm{d}y.$$

Now, as N approaches 3, $\alpha - 3/2$ approaches -1. Then the measure $C_\alpha(1-|y|^2)^\alpha\mathrm{d}y$ concentrates more and more on the boundary of the ball B, so that, in the limit, it becomes the uniform measure on S^2. Understood in this way, the formula remains valid at $\alpha = 1/2$, i.e., at $N = 3$.

It is clear that K is a self-adjoint Markov operator on $L^2(B,\nu_N)$ and that 1 is an eigenvalue of multiplicity one. With more effort, there is much more that can be said; the spectrum of K can be completely determined.

7. The spectrum of K and ratios of Jacobi polynomials. In studying the spectrum of the correlation operator, it is in fact natural and useful to study a wider family of operators of this type. Fix any $\alpha > 1/2$ and any numbers a and b such that

$$a^2 + b^2 = 1.$$

Then define the generalized correlation operator, still simply denoted by K, through

$$Kg(v) = C_{\alpha-3/2} \int_B g\left(a\sqrt{1-|v|^2}y + bv\right)(1-|y|^2)^{\alpha-3/2}\mathrm{d}y. \tag{7.1}$$

Notice that, as v and y range over B, the maximum of $|a\sqrt{1-|v|^2}y + bv|$ occurs when ay and bv are parallel. In that case,

$$|a\sqrt{1-|v|^2}y+bv| = |a||y|\sqrt{1-|v|^2}+|b||v| \le (a^2+b^2)^{1/2}((1-|v|^2)|y|^2+|v|^2)^{1/2} \le 1.$$

Thus, as v and y range over B, so does

$$u(y,v) = a\sqrt{1-|v|^2}y + bv, \tag{7.2}$$

and $g(a\sqrt{1-|v|^2}y + bv)$ is well defined for any function g on B. Thus, K is well defined.

Now when

$$a = \frac{\sqrt{N^2-2N}}{N-1} \qquad \text{and} \qquad b = -\frac{1}{N-1}, \tag{7.3}$$

we know that K is self-adjoint because in that case it is defined in terms of a manifestly symmetric bilinear form. We shall show here that K is always self-adjoint for all $a^2 + b^2 = 1$ and that the eigenvalues of K are given by an explicit formula involving ratios of Jacobi polynomials.

To explain this, we fix some terminology and notation. For any numbers $\alpha > -1$ and $\beta > -1$, $P_n^{(\alpha,\beta)}$ denotes the nth degree polynomial in the sequence of orthogonal polynomials on $[-1,1]$ for the measure

$$(1-x)^\alpha(1+x)^\beta\mathrm{d}x$$

and is referred to as the nth degree Jacobi polynomial for (α,β). As is well known, $\{P_n^{(\alpha,\beta)}\}_{n\ge0}$ is a complete orthogonal basis for $L^2([-1,1],(1-x)^\alpha(1+x)^\beta\mathrm{d}x)$.

Of course, what we have said so far specifies $P_n^{(\alpha,\beta)}$ only up to a multiplicative constant. One common normalization is given by Rodrigues's formula

$$P_n^{(\alpha,\beta)}(x) = \frac{(-1)^n}{2^n n!}(1-x)^{-\alpha}(1+x)^{-\beta}\frac{\mathrm{d}^n}{\mathrm{d}x^n}\left((1-x)^{\alpha+n}(1+x)^{\beta+n}\right).$$

For this normalization,

$$P_n^{(\alpha,\beta)}(1) = \begin{pmatrix} n+\alpha \\ n \end{pmatrix} \qquad \text{and} \qquad P_n^{(\alpha,\beta)}(-1) = \begin{pmatrix} n+\beta \\ n \end{pmatrix}. \tag{7.4}$$

LEMMA 7.1. *Fix any $\alpha > 1/2$ and any numbers a and b such that $a^2+b^2 = 1$, and define K through the formula* (7.1). *Then K is a self-adjoint Markov operator, and*

the spectrum of K consists of eigenvalues $\kappa_{n,\ell}$ enumerated by nonnegative integers n and ℓ; these eigenvalues are given by the explicit formula

$$\kappa_{n,\ell} = \frac{P_n^{(\alpha,\beta)}(-1+2b^2)}{P_n^{(\alpha,\beta)}(1)} b^\ell, \tag{7.5}$$

where $\beta = \ell + 1/2$ and α is the parameter α entering into the definition of K.

Proof. To see that K is self-adjoint, we write it as a bilinear form and change variables to reveal the symmetry. The change of variable that we make is naturally $(y,v) \to (u,v)$, with $u(y,v)$ given by (7.2). From (7.2), one computes $y = (u - bv)/(a\sqrt{1-|v|^2})$, so that

$$\begin{aligned} 1 - |y|^2 &= \frac{a^2 - a^2|v|^2 - |u|^2 - b^2|v|^2 + 2bu\cdot v}{a^2(1-|v|^2)} \\ &= \frac{b^2 - (|u|^2 + |v|^2) + 2bu\cdot v}{a^2(1-|v|^2)}. \end{aligned} \tag{7.6}$$

The Jacobian is easy to work out, and one finds that $\mathrm{d}u\mathrm{d}v = a^3(1-|v|^2)^{3/2}\mathrm{d}y\mathrm{d}v$, so that

$$\begin{aligned} &\int_B f(v) K g(v) C_\alpha (1-|v|^2)^\alpha \mathrm{d}v \\ &= \int_B \int_B f(v) g(u) a^{-2\alpha} \left[a^2 - (|u|^2 + |v|^2) + 2bu\cdot v\right]_+^{\alpha - 3/2} C_{\alpha-3/2} \mathrm{d}u\mathrm{d}v. \end{aligned} \tag{7.7}$$

This shows that the operator K is self-adjoint on $L^2(B, C_\alpha(1-|v|^2)^\alpha)$ for all $\alpha \geq 1/2$ and all a and b with $a^2 + b^2 = 1$.

Our next goal is to prove the eigenvalue formula (7.5). This shall follow from several simple properties of K.

First, K commutes with rotations in $\mathbb{R}^3$. That is, if R is a rotation on $\mathbb{R}^3$, it is evident that

$$K(g \circ R) = (Kg) \circ R.$$

Hence we may restrict our search for eigenfunctions g of K to functions of the form

$$g(v) = h(|v|)|v|^\ell \mathcal{Y}_{\ell,m}(v/|v|)$$

for some function h on $[0,\infty)$ and some spherical harmonic $\mathcal{Y}_{\ell,m}$.

Second, for each $n \geq 0$, K preserves the space of polynomials of degree n. To see this, notice that any monomial in $\sqrt{1-|v|^2}y$ that is of odd degree is annihilated when integrated against $(1-|y|^2)^{\alpha-3/2}\mathrm{d}y$, and any even monomial in $\sqrt{1-|v|^2}y$ is a polynomial in v.

By combining these two observations, we see that K has a complete basis of eigenfunctions of the form

$$g_{n,\ell,m}(v) = h_{n,\ell}(|v|^2)|v|^\ell \mathcal{Y}_{\ell,m}(v/|v|),$$

where $h_{n,\ell}$ is a polynomial of degree n.

To determine these polynomials, we use the fact that K is self-adjoint, so that the eigenfunctions $g_{n,\ell,m}$ can be taken to be orthogonal. In particular, for any two

distinct positive integers n and p, the eigenfunctions $g_{n,\ell,m}$ and $g_{p,\ell,m}$ are orthogonal in $L^2(B, C_\alpha(1-|v|^2)^\alpha)$. Hence for each ℓ, and for $n \neq p$,

$$\int_{|v|\leq 1} h_{n,\ell}(|v|^2) h_{p,\ell}(|v|^2)(1-|v|^2)^\alpha |v|^{2\ell} \mathrm{d}v = 0.$$

By taking $r = |v|^2$ as a new variable, we have

$$\int_0^1 h_{n,\ell}(r) h_{p,\ell}(r)(1-r)^\alpha r^{\ell+1/2} \mathrm{d}r = 0.$$

This is the orthogonality relation for a family of Jacobi polynomials in one standard form, and this identifies the polynomials $h_{n,\ell}$. A more common standard form, and one that is used in the sources to which we shall refer, is obtained by the change of variable $t = 2r - 1$, so that the variable t ranges over the interval $[-1, 1]$. Then for $\alpha, \beta > -1$, $P_n^{(\alpha,\beta)}(t)$ is the nth degree orthogonal polynomial for the weight $(1-t)^\alpha(1+t)^\beta$. With the variables t and $|v|^2$ related as above, i.e.,

$$t = 2|v|^2 - 1,$$

$$h_{n,\ell}(|v|^2) = P_n^{(\alpha,\beta)}(t)$$

for

$$\beta = \ell + \frac{1}{2}.$$

Now that we have all of the eigenfunctions determined, a further observation gives us a simple formula for the eigenvalues. Consider any eigenfunction g with eigenvalue κ, so that $Kg(v) = \kappa g(v)$. Let $\hat{e}$ be any unit vector in R^3. Then since g is a polynomial and hence continuous,

$$\begin{aligned} \lim_{t\to 1} Kg(t\hat{e}) &= \lim_{t\to 1} \int_B g\left(a\sqrt{1-t^2}y + bt\hat{e}\right) C_{\alpha-3/2}(1-|y|)^{\alpha-3/2}\mathrm{d}y \\ &= g\left(b\hat{e}\right), \end{aligned} \tag{7.8}$$

since $K1 = 1$. By combining this with $Kg(v) = \kappa g(v)$, we have

$$g\left(b\hat{e}\right) = \kappa g(\hat{e}).$$

Now consider any eigenfunction $g_{n,\ell,m}$ of the form given above, and let $\kappa_{n,\ell}$ be the corresponding eigenvalue, which will not depend on m. Then by taking any $\hat{e}$ so that $\mathcal{Y}_{\ell,m}(\hat{e}) \neq 0$, we have

$$\kappa_{n,\ell} = \frac{h_{n,\ell}(b^2)}{h_{n,\ell}(1)} b^\ell. \tag{7.9}$$

By changing variables as above to express this as a ratio of Jacobi polynomials, we finally have proved (7.5). □

One might expect the largest eigenvalues of K to correspond to eigenfunctions that are polynomials of low degree. After all, in a system of orthogonal polynomials, those with high degree will have many changes of sign, and one might expect considerable

cancellation when applying an averaging operator, such as K, to them. Therefore, let us compute the $\kappa_{n,\ell}$ for low values of n and ℓ. We find from (7.5), by using the value $b = -1/(N-1)$ from (7.3), that

$$\kappa_{0,1} = \kappa_{1,0} = \frac{-1}{N-1}, \tag{7.10}$$

so that $\kappa_{n,\ell}$ is negative for $n + \ell = 1$. For $n + \ell = 2$, we find from (7.5) that

$$\begin{aligned} \kappa_{1,1}(N) &= \frac{5N-3}{3(N-1)^3}, \\ \kappa_{2,0}(N) &= \frac{(N-3)(15N^2-15N+4)}{3(3N-4)(N-1)^4}, \\ \kappa_{0,2}(N) &= \frac{1}{(N-1)^2}. \end{aligned} \tag{7.11}$$

Evidently, for large N,

$$\kappa_{0,2}(N) = \frac{1}{N^2} + \mathcal{O}\left(\frac{1}{N^3}\right),$$

while

$$\kappa_{1,1}(N) = \frac{5}{3N^2} + \mathcal{O}\left(\frac{1}{N^3}\right) \qquad \text{and} \qquad \kappa_{0,2}(N) = \frac{5}{3N^2} + \mathcal{O}\left(\frac{1}{N^3}\right).$$

Thus, one might expect that, at least for large values of N, 1, $\kappa_{1,1}(N)$, $\kappa_{2,0}(N)$, and $\kappa_{0,2}(N)$ are the four largest eigenvalues of K and that $\kappa_{0,1} = \kappa_{1,0}$ is the most negative, with all other eigenvalues of K lying strictly between these. We shall show in the next section that this is indeed the case for all $N \geq 4$ and that 1 and $\kappa_{1,1}$ are the two largest eigenvalues of K for all $N \geq 3$.

When we use Lemma 5.1 to convert this to spectral information on P, we find that $\kappa_{0,1}$, $\kappa_{1,0}$, and $\kappa_{0,2}$ all correspond to the same eigenvalues of P, namely,

$$\frac{1}{N}\left(1 + \frac{1}{N-1}\right) = \frac{1}{N}\left(1 + (N-1)\frac{1}{(N-1)^2}\right) = \frac{1}{N-1}.$$

This is the eigenvalue of P that shall play the role of $\mu_N^{(m)}$ in our application of Lemma 4.1.

Let us conclude this section by recording a number of useful calculations that can be made by using (7.5).

For $N = 3$, we have

$$\kappa_{1,1}(3) = \frac{1}{2} > \kappa_{2,2}(3) = \frac{13}{40} > \kappa_{0,2}(3) = \frac{1}{4} > \kappa_{2,0}(3) = 0. \tag{7.12}$$

For $N = 4$, we have

$$\kappa_{1,1}(4) = \frac{17}{81} > \kappa_{0,2}(4) = \frac{1}{9} > \kappa_{2,0}(4) = \frac{23}{243}. \tag{7.13}$$

For $N = 5$, we have

$$\kappa_{1,1}(5) = \frac{11}{96} > \kappa_{2,0}(5) = \frac{19}{264} > \kappa_{0,2}(5) = \frac{1}{16}. \tag{7.14}$$

In each case, the second largest eigenvalue after 1, among the ones listed, is $\kappa_{1,1}$. In the next section we shall see that the list is not misleading: $\kappa_{1,1}$ is the gap eigenvalue. However, note that the third largest eigenvalue comes from different values of n and ℓ for each of $N = 3$, $N = 4$, and $N = 5$. As we shall see, things do settle down for $N \geq 5$; the third largest eigenvalue does turn out to be $\kappa_{2,0}$ in all such cases.

LEMMA 7.2. *For all $N \geq 5$, $\kappa_{1,1}(N) > \kappa_{2,0}(N) > \kappa_{0,2}(N)$.*

Proof. From (7.11),

$$\kappa_{2,0}(N) - \kappa_{0,2}(N) = \frac{2N(3N^2 - 15N + 8)}{3(3N-4)(N-1)^4}.$$

A simple calculation shows that the roots of the polynomial in the numerator are less than 5, so that $\kappa_{2,0}(N) > \kappa_{0,2}(N)$ for $N \geq 5$. A similar argument applied to $\kappa_{1,1}(N) - \kappa_{2,0}(N)$ yields the conclusion of the lemma. □

Our goal in the next section is to show that, for all $N \geq 4$, there are no eigenvalues $\kappa_{n,\ell}$ with $n + \ell > 2$ that are larger than the ones listed above and that, for $N = 3$, the three largest eigenvalues are $1 = \kappa_{0,0} > 1/2 = \kappa_{1,1} > 13/40 = \kappa_{2,2}$. However, since there is no simple monotonicity in $n + \ell$, this shall require some detailed estimate on ratios of Jacobi polynomials.

We shall also need to know that in all cases $\kappa_{0,1} = \kappa_{1,0} = -1/(N-1)$ is the most negative eigenvalue. This will tell us the four largest eigenvalues of P for $N \geq 4$ and the three largest for $n = 3$, and this shall turn out to be enough to prove the main result, Theorem 1.1.

Finally, the value of $\kappa_{2,2}(N)$ will play an important role in the proof of Theorem 1.2, and so we record the expression here:

$$\kappa_{2,2}(N) = \frac{21N^3 - 60N^2 + 27N - 4}{(3N-4)(N-1)^6}. \tag{7.15}$$

8. The determination of the spectrum of K. The main result in this section is the following theorem.

THEOREM 8.1. *For $N \geq 5$ and all n and ℓ with $n + \ell > 2$,*

$$-\frac{1}{N-1} \leq \kappa_{n,\ell}(N) < \kappa_{0,2}(N). \tag{8.1}$$

For $N = 4$ and all n and ℓ with $n + \ell > 2$,

$$-\frac{1}{N-1} \leq \kappa_{n,\ell}(4) < \kappa_{2,0}(4). \tag{8.2}$$

For $N = 3$ and all n and ℓ with $n + \ell > 0$, except for $n = 1, \ell = 1$,

$$-\frac{1}{N-1} \leq \kappa_{n,\ell}(3) \leq \kappa_{2,2}(3) = \frac{13}{40}. \tag{8.3}$$

We present the proof at the end of this section after a number of preparatory lemmas. These lemmas rest on two deep results about Jacobi polynomials. One is a formula due to Koornwinder [8] (see also [1, p. 31]) that was already applied in [3].

For all $-1 \leq x \leq 1$, all n, and all $\alpha > \beta$,

$$\frac{J_n^{(\alpha,\beta)}(x)}{J_n^{(\alpha,\beta)}(1)} = \int_0^\pi \int_0^1 \left[\frac{1 + x - (1-x)r^2}{2} + i\sqrt{1-x^2}\, r\cos(\theta)\right]^n \mathrm{d}m_{\alpha,\beta}(r,\theta), \tag{8.4}$$

where

$$m_{\alpha,\beta}(r,\theta) = c_{\alpha,\beta}(1-r^2)^{\alpha-\beta-1} r^{2\beta+1} (\sin\theta)^{2\beta}\, \mathrm{d}r\mathrm{d}\theta,$$

and $c_{\alpha,\beta}$ is a normalizing constant that makes $\mathrm{d}m_{\alpha,\beta}$ a probability measure.

Koornwinder's bound is very useful for obtaining uniform control in n for given ℓ and N. But since in Lemma 7.1

$$\alpha = \frac{3N-8}{2} \quad \text{and} \qquad \beta = \ell + \frac{1}{2}, \tag{8.5}$$

we can apply (8.4) only when

$$\ell < \ell^\star = \frac{3N-9}{2}. \tag{8.6}$$

As in [3], one may use this formula to show the following.

LEMMA 8.2. *For all ℓ with $2 \le \ell < \ell^\star$, and all $n > 0$ and $N \ge 3$,*

$$|\kappa_{n,\ell}(N)| < \frac{1}{(N-1)^2} = \kappa_{0,2}(N).$$

Note that, while this lemma does not address the case $n = 0$, this is not a problem: We have the explicit formula

$$\kappa_{0,\ell} = \left(\frac{-1}{N-1}\right)^\ell. \tag{8.7}$$

To handle large values of ℓ, we need another deep result, which is a uniform pointwise bound on the *orthonormal* Jacobi polynomials that was obtained by Nevai, Erdelyi, and Magnus [12]. Let $p_n^{\alpha,\beta}$ be the orthonormal Jacobi polynomial of degree n with a positive leading coefficient for the weight $w(x) = (1-x)^\alpha(1+x)^\beta$. It was shown in [12] that, for all $\alpha \ge -1/2$ and $\beta \ge -1/2$ and all nonnegative integers n,

$$\max_{x\in[-1,1]} \sqrt{1-x^2}\, w(x) p_n^{\alpha,\beta}(x)^2 \le \frac{2e(2+\sqrt{\alpha^2+\beta^2})}{\pi}. \tag{8.8}$$

Of course, we could use the orthonormal Jacobi polynomials in the ratio formula (7.5), since any normalization factor would cancel out in the ratio. However, the exact formula (7.4) for the denominator in (7.5) is simplest in the other normalization. Hence we need the relation between $p_n^{\alpha,\beta}$ and $P_n^{\alpha,\beta}$, which is given by $p_n^{\alpha,\beta} = l_n P_n^{\alpha,\beta}$, where

$$l_n = \left(\frac{2n+\alpha+\beta+1}{2^{\alpha+\beta+1}} \frac{\Gamma(n+1)\Gamma(n+\alpha+\beta+1)}{\Gamma(n+\alpha+1)\Gamma(n+\beta+1)}\right)^{1/2}.$$

Therefore

$$\frac{P_n^{\alpha,\beta}(x)^2}{P_n^{\alpha,\beta}(1)^2} \le \frac{1}{l_n^2} \frac{2e\Gamma(n+1)^2\Gamma(\alpha+1)^2(2+\sqrt{\alpha^2+\beta^2})}{\sqrt{1-x^2}\, w(x)\pi\Gamma(n+\alpha+1)^2}. \tag{8.9}$$

At this point it is perhaps worth noting that, since the spectrum of K lies in $[-1,1]$, any upper bound on its eigenvalues by a number larger than one is vacuous. This implies that for certain regions the identity (7.9) will provide a stronger bound than (8.9). We shall return to this point at the end of the paper.

Substituting $x = -1 + \frac{2}{(N-1)^2}$, $\beta = \ell + \frac{1}{2}$, and $\alpha = \frac{3}{2}N - 4$ in (8.9) and then multiplying by $\frac{1}{(N-1)^{2l}}$ yields

$$\kappa_{n,\ell}(N) \le \tilde{\kappa}_{n,\ell}(N), \tag{8.10}$$

where

$$\tilde{\kappa}^2_{n,\ell}(N) = \frac{2e}{\pi} g_1(n,\ell,N) g_2(N) g_3(n,N) g_4(n,\ell,N), \tag{8.11}$$

with

$$\begin{aligned} g_1(n,\ell,N) &= \left(\frac{4 + \sqrt{9N^2 - 48N + 65 + 4\ell^2 + 4\ell}}{3N + 4n + 2\ell - 5} \right), \\ g_2(N) &= \left(\frac{(N-1)^2}{N(N-2)} \right)^{(3N-7)/2}, \\ g_3(n,N) &= \frac{\Gamma(n+1)\Gamma\left(\frac{3}{2}N - 3\right)}{\Gamma\left(n + \frac{3}{2}N - 3\right)}, \\ g_4(n+\ell,N) &= \frac{(N-1)^2 \Gamma\left(n + \ell + \frac{3}{2}\right) \Gamma\left(\frac{3}{2}N - 3\right)}{\Gamma\left(n + \ell + \frac{3}{2}N - \frac{5}{2}\right)}. \end{aligned} \tag{8.12}$$

Our goal now is to extract a reasonably tight upper bound for $\tilde{\kappa}_{n,\ell}(N)$ with as much monotonicity in n, ℓ, and N as possible. The next lemmas address this goal.

LEMMA 8.3. *For $\ell \ge 0$, $N \ge 3$, and $n \ge 0$,*

$$g_1(n,\ell,N) \le \left(\frac{4}{3N + 4n + 2\ell - 5} + 1 \right), \tag{8.13}$$

where the right-hand side is clearly decreasing in n, ℓ, and N.

Proof. Note that, for $n \ge 0$, $\ell \ge 0$, and $N \ge 3$,

$$\frac{\sqrt{9N^2 - 48N + 65 + 4\ell^2 + 4\ell}}{3N + 4n + 2\ell - 5} \le 1 \tag{8.14}$$

since then

$$\begin{aligned} &(3N + 4n + 2\ell - 5)^2 - (9N^2 - 48N + 65 + 4\ell^2 + 4\ell) \\ &\quad = (24N - 40)n + (12N - 24)\ell + 16n^2 + 16n\ell + 18N - 40 > 0. \end{aligned} \tag{8.15}$$

∎

LEMMA 8.4. *For $N \ge 4$, $g_2(N)$ is a decreasing function of N.*

Proof. Let $h(x) = (1 - 1/x^2)^{2-3x/2}$, so that $g_2(N) = h(N-1)$. By computing the derivative of $\ln(h(x))$, one finds that it is negative for $x \ge 3$. ∎

LEMMA 8.5. *For $n \ge 0$ and $N \ge 3$, $g_3(n,N)$ is a decreasing function of n and N.*

Proof. For n a nonzero integer

$$\frac{\Gamma(n+1)\Gamma\left(\frac{3}{2}N - 3\right)}{\Gamma\left(n + \frac{3}{2}N - 3\right)} = \frac{n}{n + \frac{3}{2}N - 4} \, \frac{n-1}{n + \frac{3}{2}N - 5} \cdots \frac{1}{\frac{3}{2}N - 3}. \tag{8.16}$$

Since each factor is less than 1 for $N \ge 3$ and is a decreasing function of N, the assertion follows. ∎

LEMMA 8.6. *For $N \geq 3$, $g_4(n+\ell, N)$ is a decreasing function of $n+\ell$, with*

$$\lim_{n+\ell\to\infty} g_4(n+\ell, N) = 0. \tag{8.17}$$

Moreover, for $n+\ell \geq \ell^\star = 3(N-3)/2$,

$$g_4(n,\ell,N) \leq \frac{(N-1)^2\Gamma\left(\frac{3}{2}N-3\right)^2}{\Gamma(3N-7)} \leq f(N), \tag{8.18}$$

where

$$f(N) = \frac{(N-1)^2\sqrt{\pi}(\frac{3}{2}N-4)}{2^{3N-8}}. \tag{8.19}$$

Finally, for $N \geq 5$, $(N-1)^4 f(N)$ is a decreasing function of N.

Proof. Since

$$\frac{\Gamma\left(n+\ell+\frac{5}{2}\right)}{\Gamma\left(n+\ell+\frac{3}{2}N-\frac{3}{2}\right)}\,\frac{\Gamma\left(n+\ell+\frac{3}{2}N-\frac{5}{2}\right)}{\Gamma\left(n+\ell+\frac{3}{2}\right)} = \frac{\left(n+\ell+\frac{3}{2}\right)}{n+\ell+\frac{3}{2}N-\frac{5}{2}} < 1 \tag{8.20}$$

for $N \geq 3$, it follows that, for fixed nonnegative integers N,

$$\frac{\Gamma\left(n+\ell+\frac{3}{2}\right)}{\Gamma\left(n+\ell+\frac{3}{2}N-\frac{5}{2}\right)} \tag{8.21}$$

is a decreasing function of $n+\ell$. Hence, for $n+\ell \geq 3(N-3)/2$,

$$\frac{\Gamma\left(n+\ell+\frac{3}{2}\right)}{\Gamma\left(n+\ell+\frac{3}{2}N-\frac{5}{2}\right)} \leq \frac{\Gamma\left(\frac{3}{2}N-3\right)}{\Gamma\left(3N-7\right)}.$$

This together with the definition of g_4 proves the first inequality in (8.18). Use of the duplication formula for the Γ function yields

$$\frac{\Gamma\left(\frac{3}{2}N-3\right)^2}{\Gamma(3N-7)} = \frac{\sqrt{\pi}\Gamma\left(\frac{3}{2}N-3\right)}{2^{3N-8}\Gamma\left(\frac{3}{2}N-\frac{7}{2}\right)} = \frac{\sqrt{\pi}\left(\frac{3}{2}N-4\right)\Gamma\left(\frac{3}{2}N-4\right)}{2^{3N-8}\Gamma\left(\frac{3}{2}N-\frac{7}{2}\right)} < \frac{\sqrt{\pi}\left(\frac{3}{2}N-4\right)}{2^{3N-8}}.$$

This implies the second inequality in (8.18). A check of the logarithmic derivative of $(N-1)^4 f(N)$ shows that it is negative for $N \leq 5$. ∎

Now, by combining the results in the last four lemmas, we have, for $N \geq 3$ and $n+\ell \geq \ell^\star = 3(N-3)/2$,

$$\tilde{\kappa}^2_{n,\ell}(N) \leq \hat{\kappa}^2_{n,l}(N) \leq \kappa^2(N), \tag{8.22}$$

where

$$\hat{\kappa}^2_{n,l}(N) = \frac{2e}{\pi}\left(\frac{4}{3N+4n+2\ell-5}+1\right) g_2(N)g_3(n,N)g_4(n,l,N) \tag{8.23}$$

and

$$\kappa^2(N) = \frac{2e}{\pi}\left(\frac{4}{6N-14}+1\right) g_2(N)f(N), \tag{8.24}$$

where g_2, g_3, and f are given by (8.12) and (8.19).

We are now ready to prove the main theorem of this section.

Proof of Theorem 8.1. First, we take care of large values of N. By Lemmas 8.4 and 8.6, $(N-1)^4\kappa(N)$ is a decreasing function of N for $N \geq 5$. Direct computation shows that at $N = 12$ this quantity is less than one. Hence for $N \geq 12$, $\kappa(N) \leq (N-1)^{-4} = \kappa_{0,2}^2$. For $\ell \geq \ell^\star$, so that (8.22) is satisfied, this proves (8.1) for $N \geq 12$. On the other hand, if $2 \leq \ell < \ell^\star$, we have this from Lemma 8.2 or (8.7). Thus, in any case, (8.1) is valid for $N \geq 12$.

For $4 \leq N \leq 11$, we again use Lemma 8.2 or (8.7) for $2 \leq \ell < \ell^*$ and computation of $\hat{\kappa}_{n,\ell}$. By (8.17), for each such N there is a finite value $k(N)$ so that we need only consider values of $n + \ell < k(N)$. By checking these cases, we obtain (8.1) and (8.2).

We finally turn to $N = 3$, which requires the greatest amount of computation. First for $n = 0$, we have from (8.7)

$$\kappa_{0,\ell}(3) = \left(\frac{-1}{2}\right)^\ell$$

so $\kappa_{0,1}(3) = -1/2$ and $|\kappa_{0,\ell}(3)| < 1/3$ for $\ell \geq 2$.

The exact forms of the eigenvalues are simple enough to be useful for $n = 1$ and 2 as well. We have

$$\kappa_{1,\ell}(N) = \frac{(-1)^{\ell+1}}{3}\frac{[2\ell N + 3(N-1)]}{(N-1)^{\ell+2}}$$

and

$$\kappa_{2,\ell}(N) = \frac{(-1)^\ell((4\ell^2+16\ell+15)N^3 - (8\ell^2+44\ell+60)N^2 + (49+16\ell)N - 12)}{3(3N-4)(N-1)^{\ell+4}}.$$

By specializing to $N = 3$,

$$\kappa_{1,\ell}(3) = (-1)^{\ell+1}\frac{\ell+1}{2^{\ell+1}}$$

so that $|\kappa_{1,\ell}(3)| \leq 3/8$ for $\ell \geq 2$. Likewise, for $N = 3$,

$$\kappa_{2,\ell}(3) = \frac{\ell}{20}\frac{(7+3\ell)}{2^\ell}(-1)^\ell,$$

which implies that

$$|\kappa_{2,\ell}(3)| \leq |\kappa_{22}(3)| = \frac{13}{40}. \tag{8.25}$$

For higher values of n, we estimate $\kappa_{n,\ell}^2$ by means of $\hat{\kappa}_{n,\ell}^2$. Since $\ell^\star = 0$ for $N = 3$, we may use Lemma 8.6 for all ℓ, and then by (8.17), for each fixed n, there is a maximal value $\ell(n)$ that needs to be considered and a maximum value of n that needs to be considered. Table 1 gives the values of n, ℓ, and $\hat{\kappa}_{n,\ell}^2, (3)$ when $\tilde{\kappa}_{n,\ell}^2(3) < 1/4$. The monotonicity of $\kappa_{n,\ell}^2(3)$ in n and l shows that $\hat{\kappa}_{n,\ell}^2(3) \leq \hat{\kappa}_{n_0,\ell_0}^2(3)$ for $n \geq n_0$ and $\ell \geq \ell_0$ where (n_0, ℓ_0) is chosen from the table. The remaining values can be computed

from the exact formula for $\kappa_{n,\ell}(3)$ from (7.1), and the results are all consistent with (8.3). □

9. The determination of the spectrum of P. For given values of N, n, and ℓ, let $\mu_{n,\ell}(N)$ be the eigenvalue of P corresponding to the eigenvalue $\kappa_{n,\ell}(N)$ of K through Theorem 8.1, where we use (5.7) if $\kappa_{n,\ell}(N) > 0$ and use (5.8) if $\kappa_{n,\ell}(N) < 0$. (This is the relevant choice, as we are concerned with the largest eigenvalues of P.)

By consulting the calculations in (7.10) for $n + \ell = 1$, and in (7.12), (7.13), and (7.14) for $n + \ell = 2$, and finally the bounds in Theorem 8.1 for $n + \ell > 2$, we see that for all $N \geq 3$ the largest eigenvalues of K is $\kappa_{1,1}$, and the least (most negative) is $\kappa_{0,1} = \kappa_{1,0}$. Thus, by turning to Lemma 5.1 and using the positive eigenvalue in (5.7) and the negative one in (5.8), we see that the positive one yields the greater value for each N. Thus, the gap eigenvalue of P, μ_N, is given by

$$\mu_N = \mu_{1,1}(N) = \frac{3N-1}{3(N-1)^2}. \tag{9.1}$$

Use of this result in (3.8) would yield a strictly positive lower bound on Δ_N, uniform in N, but, as we have said above, it would not yield the exact lower bound. To obtain this, we now carry out the strategy outlined in the introduction.

First, we combine Lemma 5.1 and Theorem 8.1 to produce the information necessary for the application of Lemma 4.1. We must now make a choice of the thresholds $\mu^\star_N$ that appear in Lemma 4.1. The choice we shall make is based on trial function computations with Q that suggest that the gap eigenfunctions are the ones specified in Theorem 1.1.

Notice that in Theorem 1.1 the formula given for Δ_N is of the form $C\frac{N}{N-1}$ for some constant C. This value can be guessed by computing the eigenvalues of Q on the invariant subspace of polynomials of degree 4 or less in the v_j. If we are to prove this guess correct by using (4.2) of Lemma 4.1, we require a value of $\mu_N^\star$ such that

$$\frac{N}{N-1}(1-\mu_N^\star)\frac{N-1}{N-2} \geq \frac{N}{N-1}, \tag{9.2}$$

at least for $N \geq 4$. (The guess is valid only for $N-1 \geq 3$. For $N-1=2$, there is a different value of Δ_2 which has been determined already in section 2.)

The largest value of $\mu_N^\star$ that will satisfy (9.2) is

$$\mu_N^\star = \frac{1}{N-1} \qquad \text{for} \qquad N \geq 4. \tag{9.3}$$

This turns out to be an eigenvalue of P: Indeed, we have found in (7.11) that $\kappa_{0,2} = 1/(N-1)^2$. Furthermore, we have found in (7.10) that $\kappa_{0,1} = \kappa_{1,0} = -1/(N-1)$. By using the first of these results in (5.7) of Lemma 5.1 and the second in (5.8), we find that

$$\mu_{0,2} = \mu_{1,0} = \mu_{0,1} = \frac{1}{N-1}.$$

For $N=3$ we need to make a different choice, as the spectrum of Q is quite different for $N=2$ and for $N \geq 3$. The choice that will work is $\mu_3^\star = \mu_{2,2}(3)$. Since $\kappa_{2,2}(3) = 13/40$, we have from Lemma 5.1 that $\mu_{2,2}(3) = \frac{1}{3}(1+2(13/40)) = \frac{11}{20}$. Thus,

$$\mu_3^\star = \frac{11}{20}. \tag{9.4}$$

Now, to apply Lemma 4.1, we need the eigenspaces of P for the eigenvalues μ satisfying $1 > \mu > \mu_N^\star$. By Theorem 8.1 and (7.13), for $N=3$ and $N=4$, there is just one such eigenvalue, namely, $\mu_{1,1}(4)$, the gap eigenvalue, and for $N \geq 5$, there are two: $\mu_{1,1}(N)$ and $\mu_{2,0}(N)$.

Let $E_{n,\ell}$ be the eigenspace of P corresponding to the eigenvalue $\mu_{n,\ell}(N)$. For all values of n and ℓ with $n+\ell \leq 2$, we have determined the corresponding eigenfunctions of K and thus, through Lemma 5.1, the corresponding eigenfunctions of P. Thus, we have the following explicit descriptions of the $E_{n,\ell}$ for $n+\ell \leq 2$.

First, for $n+\ell = 1$, the eigenvalues of K are negative, and so by Lemma 5.1, the eigenfunctions are antisymmetric. If we are concerned only with the spectrum of Q on the subspace of symmetric functions (which is all that is of significance for Kac's application to the Boltzmann equation), we can ignore these eigenspaces. However, they turn out to be very simple. The $n=0, \ell=1$ eigenfunctions of K are degree one spherical harmonics, and the $n=1, \ell=0$ eigenfunctions of K are degree one Jacobi polynomials in $|v|^2$. Hence

$$E_{0,1} \quad \text{is spanned by the functions} \quad v_i^\alpha - v_j^\alpha, \alpha = 1,2,3, \quad \text{and } i<j, \tag{9.5}$$

while

$$E_{1,0} \quad \text{is spanned by the functions} \quad |v_i|^2 - |v_j|^2, i<j. \tag{9.6}$$

Next, for $n+\ell = 2$, the eigenvalues of K are positive, and so by Lemma 5.1, the eigenfunctions are symmetric. The $n=0, \ell=2$ eigenfunctions of K are degree two spherical harmonics and so have the form

$$f_{0,2}(v) = \sum_{\alpha,\beta=1}^{3} A_{\alpha,\beta} v^\alpha v^\beta$$

for some traceless symmetric 3×3 matrix A. Hence, by Lemma 5.1,

$$E_{0,2} \quad \text{is spanned by the functions} \quad \sum_{j=1}^{N} f_{0,2}(v_j), \tag{9.7}$$

with $f_{0,2}$ given as above.

For $n = 1$, $\ell = 1$, the eigenfunctions of K are the product of a degree one spherical harmonic and a degree one Jacobi polynomial in $|v|^2$. When we sum over the particles, the constant term in the Jacobi polynomial drops out due to the momentum constraint, and we see that

$$E_{1,1} \quad \text{is spanned by the functions} \quad \sum_{j=1}^{N} f_{1,1}(v_j), \tag{9.8}$$

where

$$f_{1,1}(v) = |v|^2 v^\alpha, \quad \alpha = 1, 2, 3.$$

Finally, for $n = 2$, $\ell = 0$, the eigenfunction of K is a degree two Jacobi polynomial in $|v|^2$. After summing on the particles, the linear term can be absorbed into the constant by the energy constraint, and so we see that

$$E_{2,0} \quad \text{is spanned by the function} \quad \sum_{j=1}^{N} f_{2,0}(v_j), \tag{9.9}$$

where

$$f_{2,0}(v) = |v|^4 - \int_B |v|^4 \mathrm{d}\nu_N.$$

We close this section with a lemma that we shall need to prove Theorem 1.2. There we shall need to know the next largest eigenvalue of P below $\max_{n+\ell \leq 2} \mu_{n,\ell}(N)$. One might guess that this occurs for some values of n and ℓ with $n + \ell = 3$, but this is not the case: By (8.3) of Theorem 8.1, and (7.12), we see that for $N = 3$ the most negative eigenvalue of K is $-1/2$, and by Lemma 5.1, this corresponds to the eigenvalue $1/2$ of P. On the other hand, the largest eigenvalue of K apart from $\kappa_{1,1}(3)$ is $\kappa_{2,2}(3) = 13/40$. This corresponds to the eigenvalue $11/20$ of P. Since $11/20 > 1/2$, we do indeed have

$$\sup_{n+\ell>2} \mu_n, \ell(3) = \mu_{2,2}(3) = \frac{11}{20}.$$

It seems likely, on the basis of computations that we have made, that in fact

$$\sup_{n+\ell>2} \mu_n, \ell(N) = \mu_{2,2}(N) \tag{9.10}$$

for all $N \geq 3$. However, for the proof of Theorem 1.2, all that we require is the following.

LEMMA 9.1. *For $N = 3, 4, 5, 6$, and 7, (9.10) is true.*

Proof. Note that the case $N = 3$ has already been proved in the remarks above. To deal with the other cases, we proceed essentially as in the proof of Theorem 8.1, using (8.23) to reduce the number of cases to be checked to a finite number and then checking these. We will therefore be brief in our remarks on the remaining cases.

Perhaps the most important point to recall is that (8.23) is valid for $n + \ell \geq 3(N-3)/2$. Since the right-hand side evaluates to zero for $N = 3$, we could use it without restriction. For $N = 7$, though, $3(N-3)/2$ evaluates to 6, and so we may use (8.23) only for $n + \ell \geq 6$. So these cases must be checked by direct computation of the eigenvalues by using 7.1 and then converting these to eigenvalues of P by using Lemma 5.1.

Then, by using (8.23) for $n + \ell > 6$, one finds that

$$\kappa^2_{n,\ell}(7) < \kappa^2_{2,2}(7)$$

unless $0 \leq n \leq 6$ and $0 \leq \ell \leq 27$. By computing the rest of the eigenvalues of P in this 6 by 27 rectangle, we find that the stated result is true for $N = 7$.

A similar analysis takes care of $N = 4$, $N = 5$, and $N = 6$. □

We shall not need to know the corresponding eigenfunctions in our application of Lemma 9.1, since we will be concerned only with the eigenspaces of eigenvalues lying strictly above $\mu_{2,2}(N)$, and those have been determined already in this section.

10. The spectrum of Q on invariant subspaces containing eigenspaces of P. For each n and ℓ, let $V_{n,\ell}$ be the smallest invariant subspace of Q containing $E_{n,\ell}$. As we shall see, for $n + \ell \leq 2$, $V_{n,\ell} = E_{n,\ell}$ except for $n = 2$, $\ell = 0$, in which case $V_{2,0}$ is two-dimensional, while $E_{1,0}$ is one-dimensional. This is established in the next lemma, which also specifies the spectrum of Q on these invariant subspaces. The eigenvalues of course depend on the particular choice of b in the definition of Q, but in a very simple way: The dependence on b is only through the quantities $(1 - B_1)$ and $(1 - B_2)$, where B_j is the jth moment of b, as defined in (1.5).

LEMMA 10.1. *Every nonzero function in $E_{0,1}$ and in $E_{1,0}$ is an eigenfunction of Q with eigenvalue*

$$\lambda^Q_{0,1} = \lambda^Q_{1,0} = 1 - (1 - B_1)\frac{1}{N-1}, \tag{10.1}$$

so that $V_{0,1} = E_{0,1}$ and $V_{1,0} = E_{1,0}$.

Every nonzero function in $E_{1,1}$ is an eigenfunction of Q with the eigenvalue

$$\lambda^Q_{1,1} = 1 - (1 - B_2)\frac{1}{(N-1)}, \tag{10.2}$$

so that $V_{1,1} = E_{1,1}$.

Furthermore, every nonzero function in $E_{0,2}$ is an eigenfunction of Q with the eigenvalue

$$\lambda^Q_{0,2} = 1 - (1 - B_2)\frac{3}{2(N-1)}, \tag{10.3}$$

so that $V_{0,2} = E_{0,2}$.

Finally, while $V_{2,0}$ is larger than $E_{2,0}$, there are only two eigenvalues of Q in $V_{2,0}$. These are

$$1 - (1 - B_2)\left(\frac{1}{N(N-1)}\left[(2N-1) \pm \sqrt{N^2 - 3N + 1}\right]\right). \tag{10.4}$$

For all $N \geq 3$, the largest of these eigenvalues is $\lambda^Q_{1,1}$.

Before beginning the proof, we note that, if $(1/2)b(x)\mathrm{d}x$ is a Dirac mass at $x = 1$, the collisions are all trivial (zero scattering angle), and thus $Q = I$ in this case. But also in this case $(1 - B_1) = (1 - B_2) = 0$, so all of the eigenvalues $\lambda^Q_{n,\ell}$ listed above are 1—as they must be for $Q = I$.

Proof. We begin with the last case, $n = 2$, $\ell = 0$, which is the most involved. Consider the function

$$\phi = \sum_{i=1}^{N} |v_i|^4, \tag{10.5}$$

and note that $\phi - \int_{X_N} \phi \mathrm{d}\sigma_N$ spans $E_{2,0}$, as we have noted above.

One simple way to calculate $Q\phi$ is to take advantage of the permutation symmetry of Q: Define the symmetrization operator $\mathcal{S}$ by

$$\mathcal{S}f(v_1, \ldots, v_N) = \frac{1}{N!} \sum_{\pi} f(v_{\pi(1)}, \ldots, v_{\pi(N)}),$$

where the sum runs over all permutations π of $\{1, \ldots, N\}$. Then it is easy to see that

$$\mathcal{S}(|v_1|^4) = \frac{1}{N}\phi.$$

Thus, since $\mathcal{S}Q = Q\mathcal{S}$,

$$Q\phi = N\mathcal{S}Q(|v_1|^4).$$

One now directly calculates $Q(|v_1|^4)$ and then symmetrizes. In carrying out the calculation, we make use of the following.

LEMMA 10.2. *Let c and d be any two vectors in $\mathbb{R}^3$, and let e be any unit vector in $\mathbb{R}^3$. Then with B_1 and B_2 defined as in* (1.5)*, we have the following identities:*

$$\int_{S^2} (c \cdot \sigma) b(e \cdot \sigma) \mathrm{d}\sigma = (c \cdot e) B_1$$

and

$$\int_{S^2} (c \cdot \sigma)(d \cdot \sigma) b(e \cdot \sigma) \mathrm{d}\sigma = (c \cdot d) \frac{1 - B_2}{2} + (e \cdot c)(e \cdot d) \frac{3B_2 - 1}{2}.$$

Proof. We choose coordinates in which c and e span the x, z plane with

$$e = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} \qquad \text{and} \qquad c = \begin{bmatrix} c^1 \\ 0 \\ c^3 \end{bmatrix}.$$

Then with

$$\sigma = \begin{bmatrix} \sin\theta \cos\psi \\ \sin\theta \sin\psi \\ \sin\theta \end{bmatrix},$$

the computations are easily accomplished. □

Now to compute $Q\phi$, go back to the definition of Q given in (1.4), and note first of all that with $\eta(\vec{v}) = |v_1|^4$, unless $i = 1$,

$$\eta(R_{i,j,\sigma}(\vec{v})) = \eta(\vec{v}).$$

Hence

$$Q\eta(\vec{v}) = \left(1 - \frac{2}{N}\right)\eta(\vec{v}) + \frac{2}{N(N-1)}\sum_{j=2}^{N}\int_{S^2}\eta(R_{1,j,\sigma}(\vec{v}))b\left(\sigma\cdot\frac{v_i - v_j}{|v_i - v_j|}\right)\mathrm{d}\sigma.$$

Then from (1.1),

$$\begin{aligned}\eta(R_{1,j,\sigma}(\vec{v})) &= \left|\frac{v_1 + v_j}{2} + \frac{|v_1 - v_j|}{2}\sigma\right|^4 \\ &= \frac{1}{8}\left||v_1|^2 + |v_j|^2 + |v_1 - v_j|(v_1 + v_j)\cdot\sigma\right|^2 \\ &= \frac{1}{8}\Big((|v_1|^2 + |v_j|^2)^2 + 2(|v_1|^2 + |v_j|^2)|v_1 - v_j|(v_1 + v_j)\cdot\sigma \\ &\qquad + |v_1 - v_j|^2((v_1 + v_j)\cdot\sigma)^2\Big). \end{aligned} \tag{10.6}$$

Integrating over S^2 using Lemma 10.2 yields

$$\begin{aligned}\int_{S^2}\eta(R_{1,j,\sigma}(\vec{v}))b\left(\sigma\cdot\frac{v_i - v_j}{|v_i - v_j|}\right)\mathrm{d}\sigma &= \frac{1}{8}(|v_1|^2 + |v_j|^2)^2 \\ &\quad + \frac{1}{4}(|v_1|^2 + |v_j|^2)B_1(|v_1|^2 - |v_j|^2) \\ &\quad + |v_1 - v_j|^2|v_1 + v_j|^2\frac{1 - B_2}{16} \\ &\quad + ((v_1 - v_j)\cdot(v_1 + v_j))^2\frac{3B_2 - 1}{16}. \end{aligned} \tag{10.7}$$

The right-hand side simplifies to

$$\begin{aligned}&\frac{1}{8}(|v_1|^4 + |v_j|^4 + 2|v_1|^2|v_j|^2) + \frac{B_1}{4}(|v_1|^4 - |v_j|^4) \\ &\quad + (|v_1|^4 + |v_j|^4 + 2|v_1|^2|v_j|^2 - 4(v_1\cdot v_j)^2)\frac{1 - B_2}{16} \\ &\quad + (|v_1|^4 + |v_j|^4 - 2|v_1|^2|v_j|^2)\frac{3B_2 - 1}{16}. \end{aligned} \tag{10.8}$$

It is now a simple matter to carry out the sum on $j \geq 2$. By using the identities

$$\sum_{j=2}^{N}|v_j|^4 = \phi(\vec{v}) - |v_1|^4 \qquad \text{and} \qquad \sum_{j=2}^{N}|v_j|^2 = \phi(\vec{v}) - |v_1|^2$$

and the symmetrizing, one finds that

$$Q\phi = \phi - \frac{1 - B_2}{N}\left[\frac{N+1}{N-1}\phi + \frac{1}{(N-1)}\psi - \frac{2}{(N-1)}\right], \tag{10.9}$$

where

$$\psi = \sum_{i\neq j}(v_i\cdot v_j)^2. \tag{10.10}$$

For $N \geq 4$, the two functions ϕ and ψ are linearly independent, although for $N = 3$ they are not. In fact for $N = 3$, one has the identity

$$\psi = 2\phi - \frac{1}{2}. \tag{10.11}$$

Evidently, for $N \geq 4$, $\phi - \int_{X_N} \phi \mathrm{d}\sigma_N$ is not an eigenfunction of Q, so that $E_{0,2}$ is not an eigenspace of Q. We are required to compute $Q\psi$.

We again take advantage of the permutation symmetry and note that

$$\mathcal{S}((v_1 \cdot v_2)^2) = \frac{2}{N(N-1)}\psi \qquad \text{and} \qquad Q\psi = \frac{N(N-1)}{2}\mathcal{S}(Q(v_1 \cdot v_2)^2).$$

We carry out the calculation in the same way that we calculated $Q\phi$ and find that

$$Q\psi = \psi - \frac{1 - B_2}{N}\left[3\psi + \frac{(N-3)}{(N-1)}\phi - \frac{1}{N}\right]. \tag{10.12}$$

We see that the subspace spanned by $\phi - \int_{X_N} \phi \mathrm{d}\sigma_N$ and $\psi - \int_{X_N} \phi \mathrm{d}\sigma_N$ is invariant under Q. By using (10.12) and (10.9) we easily find that the two eigenvalues of $N(I - Q)$ on the two-dimensional space $V_{2,0}$ are the eigenvalues of

$$\frac{1 - B_2}{N-1}\begin{bmatrix} N+1 & 1 \\ N-3 & 3N-3 \end{bmatrix},$$

which are

$$\frac{1 - B_2}{N-1}\left[(2N-1) \pm \sqrt{N^2 - 3N + 1}\right].$$

The minus sign clearly gives the lesser of these and gives the gap for $N(I - Q)$ on $V_{2,0}$. From here, one easily deduces (10.4).

A further, much simpler calculation shows that the three functions

$$\psi^\alpha_{1,1} = \sum_{k=1}^{N} |v_k|^2 v^\alpha_k, \tag{10.13}$$

where α indexes the components, are also eigenfunctions of Q; more precisely,

$$Q\psi^\alpha_{1,1} = \left(1 - \frac{1 - B_2}{N-1}\right)\psi^\alpha_{1,1}. \tag{10.14}$$

Thus the unique eigenvalue of A on $V_{1,1}$ is

$$\lambda^Q_{1,1} = 1 - \frac{1 - B_2}{N-1}.$$

For $E_{0,2}$, a simple computation shows that the functions

$$\psi^{\alpha,\beta}_{0,2} = \sum_k v^\alpha_k v^\beta_k, \tag{10.15}$$

where $\alpha \neq \beta$ are indices for the components, are also eigenfunctions for Q; in fact,

$$Q\psi^{\alpha,\beta}_{0,2} = \left(1 - \frac{3(1 - B_2)}{2(N-1)}\right)\psi^{\alpha,\beta}_{0,2}. \tag{10.16}$$

Thus, $V_{0,2} = E_{0,2}$, and the unique eigenvalue of Q on this subspace is

$$\lambda^Q_{0,2} = 1 - \frac{1}{N-1}.$$

Finally, we consider the spectrum on Q on the eigenspaces of P corresponding to $n + \ell = 1$. In this case, as noted above, the eigenfunctions are antisymmetric, so that if we are concerned only with the spectrum of Q on the subspace of symmetric functions (which is all that is of significance for Kac's application to the Boltzmann equation), we can ignore these eigenspaces. However, if we define $\eta_{0,1}(\vec{v}) = v_1 - v_2$ and $\eta_{1,0}(\vec{v}) = |v_1|^2 - |v_2|^2$, we find, as above, that

$$Q\eta_{1,0} = \left(1 - (1 - B_1)\frac{1}{N-1}\right)\eta_{1,0} \qquad \text{and} \tag{10.17}$$

$$Q\eta_{0,1} = \left(1 - (1 - B_1)\frac{1}{N-1}\right)\eta_{0,1}. \qquad \square \tag{10.18}$$

Now that we have all of our eigenvalues, we need to order them. By a simple comparison, we determine that for all N the largest eigenvalue of Q on our three invariant subspaces with $n + \ell = 2$ is $\lambda^Q_{1,1}$. This is true for all choices of b, since the only dependence on b in these eigenvalues is a common factor of $(1 - B_2)$.

It is worth noting, however, that for large N

$$\lambda^Q_{1,1} = 1 - (1 - B_2)\frac{1}{N} + \mathcal{O}\left(\frac{1}{N^2}\right) \qquad \text{and} \qquad \lambda^Q_{2,0} = 1 - (1 - B_2)\frac{1}{N} + \mathcal{O}\left(\frac{1}{N^2}\right),$$

so that these eigenvalues merge as N tends to infinity. Still, for all finite N,

$$\lambda^Q_{1,1} = 1 - (1 - B_2)\frac{1}{N-1}$$

is strictly larger.

Next, the invariant subspaces of Q with $n + \ell = 1$ are also eigenspaces of Q with the eigenvalue

$$\lambda^Q_{0,1} = \lambda^Q_{1,0} = 1 - (1 - B_1)\frac{1}{N-1}.$$

In summary, the largest eigenvalue of Q on the invariant subspaces $V_{n,\ell}$ in $L^2(X_N, \mathrm{d}\sigma_N)$ with $n + \ell = 1, 2$ and $N \geq 3$ is either

$$1 - (1 - B_2)\frac{1}{N-1} \qquad \text{or} \qquad 1 - (1 - B_1)\frac{1}{N-1},$$

depending on which of these is larger. In particular,

$$\Delta_3 \leq \min\{(1 - B_2), (1 - B_1)\}\frac{3}{2}. \tag{10.19}$$

With the above arguments we have all of the ingredients needed to prove Theorem 1.1.

Proof of Theorem 1.1. First, we wish to apply Lemma 4.1 to estimate Δ_3 in terms of Δ_2. In (9.4), we have set $\mu^\star_3 = 11/20$, and with this choice of the threshold, we have seen that there is just one eigenvalue of P between $\mu^\star_3$ and 1, namely, the gap

eigenvalue $\mu_3 = \mu_{1,1}(3) = \mu_{0,1}(3) = \mu_{1,0}(3)$. Thus, from Lemma 4.1 and the eigenvalue computations in Lemma 10.1, either the gap eigenvalue of Q for $N = 3$ is

$$\max\left\{\ 1-(1-B_2)\frac{1}{N-1},\ 1-(1-B_1)\frac{1}{N-1}\ \right\} \tag{10.20}$$

or else

$$\Delta_3 \geq \frac{3}{2}\left(1-\frac{11}{20}\right)\Delta_2 = \frac{27}{40}\Delta_2. \tag{10.21}$$

If (10.20) does give the gap eigenvalue of Q for $N = 3$, then

$$\Delta_3 = \min\{\ (1-B_1),\ (1-B_2)\ \}\frac{3}{2}. \tag{10.22}$$

Since, according to Lemma 4.1, at least one of (10.21) and (10.22) is true, the condition

$$\frac{27}{40}\Delta_2 \geq \frac{3}{2}\min\{\ (1-B_1),\ (1-B_2)\ \} \tag{10.23}$$

and (10.19) ensure that (10.22) is true and thus give us the gap eigenvalue for $N = 3$. Note that the condition (10.23) is equivalent to the condition (1.6) in Theorem 1.1.

Now we proceed by induction. For any $n \geq 4$, assume that

$$\Delta_{N-1} = \min\{\ (1-B_1),\ (1-B_2)\ \}\frac{N-1}{N-2}. \tag{10.24}$$

In (9.3) we have set

$$\mu_N^\star = \frac{1}{N-1}$$

for all $N \geq 4$, and we have seen that the only eigenvalues μ of P with $1 > \mu \geq \mu_N^\star$ are the gap eigenvalue $\mu_N = \mu_{1,1}(N) = \mu_{0,1}(N) = \mu_{1,0}(N)$, and for $N > 4$, $\mu_{2,0}(N)$. Thus, by Lemma 4.1 and the eigenvalue computations in Lemma 10.1, either the gap eigenvalue of Q for N is

$$\max\left\{\ 1-(1-B_2)\frac{1}{N-1},\ 1-(1-B_1)\frac{1}{N-1}\ \right\} \tag{10.25}$$

or else

$$\Delta_N > \frac{N}{N-1}\left(1-\frac{1}{N-1}\right)\Delta_{N-1}. \tag{10.26}$$

There is strict inequality in (10.26) since all remaining eigenvalues of P not taken into account in (10.25) are strictly less than $\mu_N^\star$. By the inductive hypothesis (10.24) yields

$$\Delta_N > \min\{\ (1-B_1),\ (1-B_2)\ \}\frac{N}{N-1}.$$

This is impossible, as the trial functions leading to (10.25) yield the upper bound

$$\Delta_N \leq \min\{\ (1-B_1),\ (1-B_2)\ \}\frac{N}{N-1}. \tag{10.27}$$

Thus equality holds in (10.27), which completes the proof of the inductive step. Because of the strict inequality in (10.26), the only eigenfunctions with the gap eigenvalue are found in the invariant subspaces considered here, i.e., in the $V_{n,\ell}$ with $0 < n+\ell \leq 2$. By the results of Lemma 10.1, this yields the statement in Theorem 1.1 concerning the gap eigenfunctions of Q. □

Proof of Theorem 1.2. We proceed as in the previous proof except that, for low values of N, we shall use a different choice for the threshold $\mu_N^\star$, namely,

$$\mu_N^\star = \mu_{2,2}(N). \tag{10.28}$$

We know from Lemma 9.1 that for all $N \leq 7$

$$\mu_{n,\ell}(N) \leq \mu_{2,2}(N) \quad \text{for all} \quad n+\ell > 2.$$

Thus, at least for such N, the only eigenvalues μ of P with $\mu > \mu_N^\star = \mu_{2,2}(N)$ are those with $n+\ell \leq 2$. We have already computed the gap for Q on the invariant subspaces containing these eigenvalues, and we have found that the gap in these subspaces is

$$\widetilde{\Delta}_N = \min\{\ (1-B_1),\ (1-B_2)\ \}\frac{N}{N-1}.$$

If for any $N_0 \geq 3$ it turns out that $\widetilde{\Delta}_{N_0} = \Delta_{N_0}$, the gap on the whole space, then we can switch from that point onwards to the use of $\mu_N^\star = \mu_{0,2}(N)$ as in the proof of Theorem 1.1 to show that $\widetilde{\Delta}_N = \Delta_N$ for all $N \geq N_0$ and that the eigenfunctions are exactly as claimed for all $N > N_0$.

We now show that it is always the case that $\widetilde{\Delta}_{N_0} = \Delta_{N_0}$ for some $N_0 \leq 7$. To do this, pick any value $N_1 \geq 4$, and suppose that for $3 \leq j \leq N_1$ we have

$$\Delta_j < \min\{\ (1-B_1),\ (1-B_2)\ \}\frac{j}{j-1}. \tag{10.29}$$

Then by Lemmas 4.1 and 9.1, by using the value $\mu_j^\star = \mu_{2,2}(j)$, for $3 \leq j \leq N_1$, we have

$$\Delta_{N_1} \geq \frac{N_1}{2}\prod_{j=3}^{N_1}(1-\mu_{2,2}(j))\Delta_2.$$

By using the hypothesis $\Delta_2 = 2(1-B_1)$, we have

$$\Delta_{N_1} \geq \frac{N_1}{2}\prod_{j=3}^{N_1}(1-\mu_{2,2}(j))2(1-B_1).$$

Of course we can rewrite this as

$$\Delta_{N_1} \geq \frac{N_1}{2}\left(\prod_{j=4}^{N_1}(1-\mu_{0,2}(j))\right)(1-\mu_{2,2}(3))\left(\prod_{j=4}^{N_1}\frac{(1-\mu_{2,2}(j))}{(1-\mu_{0,2}(j))}\right)2(1-B_1)$$

$$= \frac{N_1}{N_1-1}\left(\prod_{j=4}^{N_1}\frac{(1-\mu_{2,2}(j))}{(1-\mu_{0,2}(j))}\right)\frac{9}{10}(1-B_1), \tag{10.30}$$

since, as in the last proof, $(1-\mu_{2,2}(3)) = 9/20$, and

$$\frac{N_1}{2}\prod_{j=4}^{N_1}(1-\mu_{0,2}(j)) = \frac{N_1}{N_1-1}.$$

Now, by direct computation, we find that

$$\prod_{j=4}^{7}\frac{(1-\mu_{2,2}(j))}{(1-\mu_{0,2}(j))} = \frac{558018643}{495720000} > \frac{10}{9}.$$

For $N_1 \geq 7$, this would lead to

$$\Delta_{N_1} > \frac{N_1}{N_1-1}(1-B_1),$$

and this is impossible, since we have a trial function showing that the gap cannot be so large. Hence it must be that (10.29) is false for some $j \leq 7$. By what we have said above, from this point onward, we can proceed as in the proof of Theorem 1.1, and we obtain Theorem 1.2. □

While the results presented here cover a very wide range of models, it is possible to come up with choices of b for which $\Delta_2 \neq 2(1-B_1)$. If one found a need to deal with such an example, one might have to go deeper into the spectrum of P. It is very likely that Lemma 9.1 holds for all $N \geq 3$, based on extensive computations. These computations also show that, as N increases, $\mu_{2,1}(N)$ comes very close to $\mu_{2,2}(N)$, so that to get much more leverage one would need to compute all of the eigenvalues of Q on the smallest invariant subspaces of Q that contain both of these eigenspaces of P. This could be done by using the methods illustrated above, but the computations would be considerably more involved than the ones we have presented in this section. Thus, having treated a wide range of models, we shall conclude our discussion of Q here. In the brief final section, we discuss a point we raised earlier concerning bounds on Jacobi polynomials.

11. Bounds on Jacobi polynomials. As alluded to in section 8, the identity (7.9), together with the trivial bound on the $|\kappa_{n,\ell}| \leq 1$, which comes from the fact that K is a Markov operator, will for certain regions provide a stronger bound than (8.8), the bound of Nevai, Erdelyi, and Magnus. We close this section by showing how (7.9) can be used to obtain better bounds.

To begin, write

$$\begin{aligned} & b^{2\beta-1}\frac{P_n^{\alpha,\beta}(-1+2b^2)}{P_n^{\alpha,\beta}(1)} \\ & \leq \frac{2e}{\pi}\frac{\Gamma(n+1)}{b(1-b^2)^{\alpha+1/2}}\frac{2+\sqrt{\alpha^2+\beta^2}}{2n+\alpha+\beta+1}\frac{\Gamma(n+\beta+1)}{\Gamma(n+\alpha+\beta+1)}\frac{\Gamma(\alpha+1)^2}{\Gamma(n+\alpha+1)}, \end{aligned} \tag{11.1}$$

where $\beta = l+1/2$, with l an integer. In regions where the right-hand side of the above equation becomes larger than one, the simple bound

$$b^{2\beta-1}\frac{P_n^{\alpha,\beta}(-1+2b^2)}{P_n^{\alpha,\beta}(1)} \leq 1$$

becomes stronger. In the region $2n+1 < \alpha < \beta$, we find $\frac{2+\sqrt{\alpha^2+\beta^2}}{2n+\alpha+\beta+1} > \frac{1}{4}$. This plus Stirling's formula with the remainder yields

$$\frac{2e}{\pi}\frac{\Gamma(n+1)}{b(1-b^2)^{\alpha+1/2}}\frac{2+\sqrt{\alpha^2+\beta^2}}{2n+\alpha+\beta+1}\frac{\Gamma(n+\beta+1)}{\Gamma(n+\alpha+\beta+1)}\frac{\Gamma(\alpha+1)^2}{\Gamma(n+\alpha+1)}$$
$$> \frac{e^n}{\sqrt{2\pi}}\frac{\Gamma(n+1)}{b(1-b^2)^{\alpha+1/2}}\frac{\alpha^{\alpha+1/2-n}\beta^{-\alpha}}{(1+\frac{\alpha}{\beta})^{n+\alpha+\beta+1}}\frac{(1+\frac{1}{\alpha})^{2\alpha+1}}{(1+\frac{n+1}{\alpha})^{n+\alpha+1/2}(1+\frac{n+1}{\alpha+\beta})^{\beta}} * r$$
$$> \frac{e^n}{\sqrt{2\pi}}\frac{\Gamma(n+1)}{b(1-b^2)^{\alpha+1/2}}\frac{\alpha^{\alpha+1/2-n}\beta^{-\alpha}}{2^{2n+2\alpha+2\beta+3/2}}r,$$

where $r = (1-\frac{1}{12(n+\alpha+\beta+1)})(1-\frac{1}{12(n+\alpha+1)})$ and n is assumed to be fixed. Choosing $b(1-b^2)^{\alpha+1/2}$ so that the last inequality is greater than one provides a region where the combination of (7.9) and $|\kappa_{n,\ell}| \le 1$ does better than (7.9). It would be interesting to obtain better bounds on $|\kappa_{n,\ell}|$ by direct analysis of K and to use these to sharpen the argument just made.

Acknowledgment. We thank Doron Lubinsky for valuable discussions concerning (8.8), the bound of Nevai, Erdelyi, and Magnus, and related results.

ORBITAL STABILITY OF BOUND STATES OF SEMICLASSICAL NONLINEAR SCHRÖDINGER EQUATIONS WITH CRITICAL NONLINEARITY*

TAI-CHIA LIN† AND JUNCHENG WEI‡

Abstract. We consider the orbital stability of single-spike bound states of semiclassical nonlinear Schrödinger equations with critical nonlinearity and a trap potential. Due to the effect of the trap potential, we derive the asymptotic expansion formulas and obtain the necessary conditions for orbital stability and instability of single-spike bound states. Our argument is applied to two-component systems of nonlinear Schrödinger equations with a common trap potential, cubic nonlinearity in two spatial dimensions. The orbital stability of bound states with spikes of these systems is investigated. Our results show the existence of stable spikes in two-dimensional Bose–Einstein condensates.

Key words. orbital stability, spike, trap potential

1. Introduction.

The nonlinear Schrödinger (NLS) equation with a trap potential is central to the understanding of many physical phenomena. For example, it has become a well-known model referred to as the Gross–Pitaevskii equation governing the evolution of Bose–Einstein condensates (BEC) given by

$$-i\hbar\frac{\partial\psi}{\partial t} = \frac{\hbar^2}{2m}\triangle\psi - V_{trap}\psi - \mu|\psi|^2\psi \tag{1.1}$$

for $x \in \mathbb{R}^N$, $N \leq 3$, and $t > 0$, where $\psi = \psi(x,t) \in \mathbb{C}$ is the wavefunction of BEC and $V_{trap} = V_{trap}(x)$ is the trap potential. Also, $\hbar$ is the Planck constant, m is the atom mass, and $\mu \sim 4\pi\frac{\hbar^2}{2m}a$, where a denotes the s-wave scattering length.

In BEC, spikes may occur when the s-wave scattering length is negative and large. Due to Feshbach resonance, the s-wave scattering length of a single condensate can be tuned over a very large range by adjusting the externally applied magnetic field. As the s-wave scattering length of a single condensate is negative and large enough, the interactions of atoms are strongly attractive and the associated condensate tends to increase its density at the center of the trap potential in order to lower the interaction energy (cf. [28]). Under the effect of trap potentials, spikes of BEC are observable by physical experiments (cf. [10]) so there must be stability to ensure spikes appearing in the condensate wavefunction (cf. [7]). In [24], stable bright solitons (spikes) of BEC can be observed by numerical simulations, provided that the strength of the trap potential exceeds a threshold value. Here we want to develop mathematical theorems to support the existence of stable spikes in BEC.

To get spikes in BEC, we may assume the s-wave scattering length a, i.e., μ is negative and large. Setting $h^2 = \hbar^2/(2m\mu)$, $V_{trap}(x) = \mu^{-1} V(x)$, and suitable time scale, (1.1) with negative and large μ can be equivalent to a semiclassical NLS given by

$$-ih\frac{\partial \psi}{\partial t} = h^2 \triangle \psi - V\psi + |\psi|^2\psi, \quad x \in \mathbb{R}^N,\ t > 0, \tag{1.2}$$

where $0 < h \ll 1$ is a small parameter (semiclassical limit) and $V = V(x)$ is a smooth nonnegative function. We may generalize (1.2) to an NLS equation having the form

$$-ih\frac{\partial \psi}{\partial t} = h^2 \triangle \psi - V\psi + |\psi|^{p-1}\psi, \quad x \in \mathbb{R}^N,\ t > 0, \tag{1.3}$$

with critical nonlinearity

$$p = 1 + \frac{4}{N}\,, \quad N \geq 1. \tag{1.4}$$

In particular, when $N = 2$, (1.3) is exactly the same as (1.2).

Bound states of (1.3) are of the form $\psi(x,t) = e^{i\lambda t/h}u(x)$, where $\lambda > 0$ and u satisfies the following nonlinear elliptic equation:

$$h^2 \triangle u - (V + \lambda)u + u^p = 0\,, \quad u \in H^1(\mathbb{R}^N)\,, \quad u > 0 \quad \text{in} \quad \mathbb{R}^N\,, \tag{1.5}$$

with zero Dirichlet boundary condition, i.e., $u(x) \to 0$ as $|x| \to \infty$.

In the case when $V(x) \equiv 0$, for any $\lambda > 0$, problem (1.5) admits a unique radially symmetric ground state, which is stable for any $\lambda > 0$ if $p < 1 + \frac{4}{N}$ and unstable for any $\lambda > 0$ if $p \geq 1 + \frac{4}{N}$ (see [5], [6], and [36]).

When $V(x) \not\equiv 0$, the existence of single- or multiple-spike solutions of (1.5) was first established by Floer and Weinstein [11] in the one-dimensional case, i.e., $N = 1$ and $1 < p < 5$, and later extended by Oh [25], [26] to the higher-dimensional case, i.e., $N \geq 2$ and $1 < p < \frac{N+2}{N-2}$ under the condition that the trap potential V has nondegenerate critical points. When the trap potential V becomes degenerate, there have been many works in recent years. The reader may refer to [1], [3], [17], [8], [9] [19], [29], [30], [32], [33], and the references therein.

The trap potential V may also play a crucial role in the orbital (dynamic) stability of single-spike bound states. As the trap potential V is switched off, it is well known that all bound states of (1.3) with the condition (1.4) are orbitally unstable if the dimension $N = 2$ (cf. [37]). To stabilize bound states, one has to turn on the trap potential. However, in general, some nonzero trap potentials may still cause dynamic instability in BEC. For instance, one may find bending-wave instability of vortex ring dynamics under some nonzero trap potentials (cf. [18]). Consequently, to get the dynamic stability of single-spike bound states, we have to choose trap potentials properly. For suitable trap potentials, Oh [26] and Grillakis, Shatah, and Strauss [14] proved that when $N = 1$, the single-spike bound state (concentrating at local nondegenerate minimum of the trap potential V) is stable if $1 < p < 1 + \frac{4}{N}$ and unstable if $p > 1 + \frac{4}{N}$. Generically, the case of $p = 1 + \frac{4}{N}$ is left open and referred to as a critical case in the literature. In this paper, we give an affirmative answer for such a case by studying the orbital stability and instability of single-spike bound states when the trap potential V has nondegenerate critical points.

In [25] and [26], a single-spike bound state solution u_h of (1.5) can be obtained, provided the trap potential V is of class $(V)_a$ and fulfills other conditions. Hereafter,

we set u_h as a single-spike bound state constructed in [25] and [26] and satisfying (1.5). Of course, the trap potential V is also of class $(V)_a$ and fulfills other conditions in [25] and [26]. Hence $\psi_h(x,t) = e^{i\lambda t/h}u_h(x)$ may form an orbit of (1.3). From [14], the orbital stability of ψ_h's is defined as follows: For all $\epsilon > 0$, there exists $\delta > 0$ such that if $\|\psi_0 - u_h\|_{H^1} < \delta$ and ψ is a solution of (1.3) in some interval $[0, t_0)$ with $\psi|_{t=0} = \psi_0$, then $\psi(t,\cdot)$ can be extended to a solution in $0 \le t < \infty$ and

$$\sup_{0<t<\infty} \inf_{s\in\mathbb{R}} \|\psi(\cdot,t) - \psi_h(\cdot,s)\|_{H^1} < \epsilon\,.$$

Otherwise, the orbit ψ_h is called orbitally unstable. To check the orbital stability of ψ_h, we use the linearized operator defined by

$$L_h = h^2\triangle - (V+\lambda) + pu_h^{p-1}, \quad p = 1 + \frac{4}{N}\,. \tag{1.6}$$

Observe that u_h may depend on the variable λ. Moreover, we assume u_h to be nondegenerate due to [16]. Let $n(L_h)$ be the number of positive eigenvalues of L_h and

$$d(\lambda) = \int_{\mathbb{R}^N} \left[\frac{h^2}{2}|\nabla u_h|^2 + \frac{1}{2}(V+\lambda)u_h^2 - \frac{1}{p+1}u_h^{p+1}\right]. \tag{1.7}$$

Assume that d is nondegenerate, i.e., $d'' \neq 0$. Let $p(d'') = 1$ if $d'' > 0$ and $p(d'') = 0$ if $d'' < 0$. According to the general theory of orbital stability of bound states (cf. [14], [15]), u_h is orbitally stable if $n(L_h) = p(d'')$ and orbitally unstable if $n(L_h) - p(d'')$ is odd (see page 309 of [15]).

It is worth noting that if $V \equiv C$ and $p = 1 + \frac{4}{N}$, then $d''(\lambda) = 0$, i.e., the function d becomes degenerate, where C is a positive constant. Consequently, we may assume that the trap potential V has nondegenerate critical points in order to derive the asymptotic expansion formulas for the operator L_h and the function d as the parameter h goes to zero. These formulas are crucial to obtaining the orbital stability and instability of single-spike bound states as follows.

THEOREM 1.1. *Let N be a positive integer and $p = 1 + \frac{4}{N}$. For $0 < h < 1$, let u_h be a bound state of* (1.3) *concentrated at a nondegenerate critical point x_0 of the potential V such that $\Delta V(x_0) \neq 0$. Let m denote the number of negative eigenvalues of the matrix $(\nabla^2 V(x_0))$. Suppose the parameter h is sufficiently small. Then u_h is orbitally stable if x_0 is a nondegenerate local minimum point of the potential V. Furthermore, u_h is orbitally unstable if $m - \frac{1}{2}(1 + \frac{\Delta V(x_0)}{|\Delta V(x_0)|})$ is even.*

Remark. In [12], Fukuizumi considered the orbital stability of the standing wave solution to (1.3) in the critical case $p = 1 + \frac{4}{N}$ under the following conditions:

$$h = 1, \quad V(x) = V(|x|), u(x,t) = u(|x|,t). \tag{1.8}$$

He studied the stability of the standing wave solution $e^{i\lambda t}u(x)$ for λ large (*in the radially symmetric class*). After suitable scaling, the standing wave solution satisfies

$$\epsilon^2\Delta u - (1 + \epsilon^2 V(|x|))u + u^p = 0, u > 0, \quad \text{where } \epsilon^2 = \frac{1}{\lambda}. \tag{1.9}$$

There is a slightly subtle difference between (1.5) and (1.9). However, the main difference is that we consider the *full functional space* here. The method of proving Theorem 1.1 can also be applied to obtain a more general result to Fukuizumi's problem for general $V(x)$.

Another motivation of studying (1.3) in the critical case may come from two-component systems of NLS equations which describe a double condensate, i.e., a binary mixture of BEC (cf. [28]). To get stable spikes of a double condensate with two spatial dimensions, we study orbitally stable bound states with spikes of a two-component system of NLS equations given by

$$\begin{cases} -ih\dfrac{\partial \Phi}{\partial t} = h^2\triangle\Phi - V\Phi + |\Phi|^2\Phi + \beta|\Psi|^2\Phi\,, \\ -ih\dfrac{\partial \Psi}{\partial t} = h^2\triangle\Psi - V\Psi + |\Psi|^2\Psi + \beta|\Phi|^2\Psi \end{cases} \tag{1.10}$$

for $x \in \mathbb{R}^2$ and $t > 0$, where $V = V(x)$ is a smooth nonnegative function, $\beta \in \mathbb{R}$ is a nonzero constant, and $0 < h \ll 1$ is a small parameter. Bound states of (1.10) are of the form $\Phi(x,t) = e^{i\lambda t/h}u(x)$ and $\Psi(x,t) = e^{i\lambda t/h}v(x)$, where (u,v) satisfies the following nonlinear elliptic system:

$$\begin{cases} h^2\triangle u - (V+\lambda)u + u^3 + \beta uv^2 = 0, & x \in \mathbb{R}^2, \\ h^2\triangle v - (V+\lambda)v + v^3 + \beta u^2 v = 0, & x \in \mathbb{R}^2, \\ u(x), v(x) > 0, & u, v \in H^1(\mathbb{R}^2). \end{cases} \tag{1.11}$$

Note that in $\mathbb{R}^2$, the nonlinearity u^3, v^3 are a critical nonlinearity by the simple algebra $p = 3 = 1 + \frac{4}{N}$ with $N = 2$. The system (1.11) admits a bound state solution $(\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h)$, where $\beta > -1$ and u_h satisfies (1.5). Generically, such a solution may be neither a unique positive solution nor a ground state solution of the system (1.11). Thus the stability problem is nontrivial. Here we want to get the orbital stability of such a solution using suitable trap potentials V's. To study the orbital stability of such a bound state solution, we set the linearized operator of (1.10) around $(\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h)$ given by

$$\mathbb{L}_h \begin{pmatrix} \phi \\ \psi \end{pmatrix} = \begin{pmatrix} h^2\triangle\phi - (V+\lambda)\phi + \frac{3+\beta}{1+\beta}u_h^2\phi + \frac{2\beta}{1+\beta}u_h^2\psi \\ h^2\triangle\psi - (V+\lambda)\psi + \frac{3+\beta}{1+\beta}u_h^2\psi + \frac{2\beta}{1+\beta}u_h^2\phi \end{pmatrix}. \tag{1.12}$$

Furthermore, we also need a function defined as follows:

$$\begin{aligned} d(\lambda_1,\lambda_2) = &\int_{\mathbb{R}^2} \frac{h^2}{2}|\nabla u_{h,\lambda_1,\lambda_2}|^2 + \frac{V(x)+\lambda+\lambda_1}{2}u_{h,\lambda_1,\lambda_2}^2 - \frac{1}{4}\int_{\mathbb{R}^2} u_{h,\lambda_1,\lambda_2}^4 \\ &+ \int_{\mathbb{R}^2} \frac{h^2}{2}|\nabla v_{h,\lambda_1,\lambda_2}|^2 + \frac{V(x)+\lambda+\lambda_2}{2}v_{h,\lambda_1,\lambda_2}^2 - \frac{1}{4}\int_{\mathbb{R}^2} v_{h,\lambda_1,\lambda_2}^4 \\ &- \frac{\beta}{2}\int_{\mathbb{R}^2} u_{h,\lambda_1,\lambda_2}^2 v_{h,\lambda_1,\lambda_2}^2\,, \end{aligned} \tag{1.13}$$

where $(u_{h,\lambda_1,\lambda_2}, v_{h,\lambda_1,\lambda_2})$ is the solution of

$$\begin{cases} h^2\triangle u - (V+\lambda+\lambda_1)u + u^3 + \beta uv^2 = 0 \quad \text{in } \mathbb{R}^2\,, \\ h^2\triangle v - (V+\lambda+\lambda_2)v + v^3 + \beta u^2 v = 0 \quad \text{in } \mathbb{R}^2\,, \end{cases} \tag{1.14}$$

such that $(u_{h,\lambda_1,\lambda_2}, v_{h,\lambda_1,\lambda_2}) \to (\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h)$ as $|\lambda_1| + |\lambda_2| \to 0$.

Suppose the solution $(\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h)$ is nondegenerate, i.e., the operator $\mathbb{L}_h$ has no zero eigenvalue. Let $n(\mathbb{L}_h)$ denote the positive eigenvalues of $\mathbb{L}_h$, and set p as the number of positive eigenvalues of the Hessian matrix $(\nabla^2 d(0,0))$. From [14] and [15], we know that the solution $(\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h)$ is orbitally stable if $n(\mathbb{L}_h) = p$ and orbitally unstable if $n(\mathbb{L}_h) - p$ is odd. The parameter β may affect the orbital stability of the solution $(\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h)$. Now we state our result as follows.

THEOREM 1.2. *For $0 < h < 1$, let u_h be a single-spike solution concentrated at a local minimum point of the function V. Suppose the parameter h is sufficiently small. Then $(\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h)$ is an orbitally stable solution to* (1.10) *if $0 < \beta \neq 1$.*

Remark. The orbital instability of $(\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h)$ for $-1 < \beta < 0$ can also be investigated. However, the condition is quite complicated so we may omit it here. On the other hand, as $\beta = 1$, the system (1.11) may have infinitely many solutions with the form $(u, v) = (w, \eta w)$ for $\eta \neq 0$, where w is the solution of $h^2 \triangle w - (V + \lambda)w + (1 + \eta^2)w^3 = 0$ in $\mathbb{R}^2$. This may provide a reason to ignore the case $\beta = 1$ in Theorem 1.2.

For the existence of other bound states to the system (1.11), the reader may refer to [2], [4], [13], [20], [21], [23], [31], and the references therein. Our result here seems to be the first in studying the orbital stability of (1.11) with a trapping potential.

The argument of Theorem 1.2 is applicable to studying another two-component system of NLS equations having symbiotic bright solitons (cf. [22] and [27]) given by

$$\begin{cases} -ih\dfrac{\partial \Phi}{\partial t} = h^2 \triangle \Phi - V\Phi - |\Phi|^2\Phi + \beta|\Psi|^2\Phi\,, \\ -ih\dfrac{\partial \Psi}{\partial t} = h^2 \triangle \Psi - V\Psi - |\Psi|^2\Psi + \beta|\Phi|^2\Psi \end{cases} \tag{1.15}$$

for $x \in \mathbb{R}^2$ and $t > 0$, where $V = V(x)$ is a smooth nonnegative function, $\beta \in \mathbb{R}$ is a nonzero constant, and $0 < h \ll 1$ is a small parameter. It is remarkable that the coefficients of the terms $|\Phi|^2\Phi$ and $|\Psi|^2\Psi$ of the system (1.15) have opposite sign to those of the system (1.10). As for the system (1.11), bound states of (1.15) are of the form $\Phi(x,t) = e^{i\lambda t/h}u(x)$ and $\Psi(x,t) = e^{i\lambda t/h}v(x)$, where (u, v) satisfies the following nonlinear elliptic system:

$$\begin{cases} h^2 \triangle u - (V + \lambda)u - u^3 + \beta u v^2 = 0, & x \in \mathbb{R}^2, \\ h^2 \triangle v - (V + \lambda)v - v^3 + \beta u^2 v = 0, & x \in \mathbb{R}^2, \\ u(x), v(x) > 0, & u, v \in H^1(\mathbb{R}^2). \end{cases} \tag{1.16}$$

It is easy to check that the system (1.16) has a solution $(\frac{1}{\sqrt{\beta-1}}u_h, \frac{1}{\sqrt{\beta-1}}u_h)$ for $\beta > 1$. As for Theorem 1.2, we may have the following corollary.

COROLLARY 1.3. *For $0 < h < 1$, let u_h be a single-spike solution concentrated at a local minimum point of the function V. Suppose the parameter h is sufficiently small. Then $(\frac{1}{\sqrt{\beta-1}}u_h, \frac{1}{\sqrt{\beta-1}}u_h)$ is an orbitally stable solution to* (1.15) *if $\beta > 1$.*

The proof of Corollary 1.3 is quite similar to that of Theorem 1.2 so we may neglect the detailed proof here.

The rest of this paper is organized as follows. In section 2, we figure out the properties of u_h and the spectrum of the linearized operator L_h as the parameter h goes to zero. Then we state the proof of Theorem 1.1 in section 3. Finally, we provide the proof of Theorem 1.2 in section 4.

2. Properties of u_h. In this section, we study the properties of u_h, which is a single-spike solution concentrated at a nondegenerate critical point x_0 of $V(x)$. Let x_h be the unique local maximum point of u_h. So $x_h \to x_0$. Let us recall the following results of Grossi [16].

LEMMA 2.1.

(1) $x_h = x_0 + \mathrm{o}(h)$;

(2) u_h *is unique and nondegenerate, i.e.,* L_h *has no zero eigenvalue.*

Proof. (1) follows from Lemma 5.4 of [16], while (2) follows from Theorem 1.1 of [16]. □

We need the following two lemmas. The first one is an asymptotic behavior of u_h.

LEMMA 2.2.

$$u_h(x_h + hy) = (V(x_h) + \lambda)^{\frac{1}{p-1}}\, w(\sqrt{V(x_h) + \lambda}\, y) + h^2\phi_0 + \mathrm{o}(h^2), \tag{2.1}$$

where w *is the unique positive solution of*

$$\triangle w - w + w^p = 0, w(0) = \max_{y\in\mathbb{R}^N} w(y), w > 0 \quad in \quad \mathbb{R}^N, w \to 0 \ as \ |y| \to +\infty, \tag{2.2}$$

ϕ_0 *satisfies*

$$\triangle\phi_0 - (V(x_h) + \lambda)\phi_0 + pw_{x_h}^{p-1}\phi_0 - \frac{1}{2}\sum_{i,j} V_{ij}(x_0) y_i y_j w_{x_h} = 0 \tag{2.3}$$

with

$$w_{x_h}(y) := (V(x_h) + \lambda)^{\frac{1}{p-1}}\, w(\sqrt{V(x_h) + \lambda}\, y). \tag{2.4}$$

Proof. Note that for fixed s, $w_s(y)$ satisfies

$$\triangle w_s - (V(s) + \lambda)w_s + w_s^p = 0. \tag{2.5}$$

Let $\phi_h(y) = u_h(x_h + hy) - w_{x_h}(y)$. Then $|\phi_h| \to 0$ uniformly and ϕ_h satisfies

$$\triangle\phi_h - (V(x_h + hy) + \lambda)\phi_h + pw_{x_h}^{p-1}\phi_h + N(\phi_h) - (V(x_h + hy) - V(x_h))w_{x_h} = 0, \tag{2.6}$$

where $N(\phi_h) = (w_{x_h} + \phi_h)^p - w_{x_h}^p - pw_{x_h}^{p-1}\phi_h$. Note that $\nabla\phi_h(0) = 0$ and

$$\begin{aligned}(V(x_h + hy) - V(x_h)) &= (\nabla V(x_h))hy + \frac{1}{2}\sum_{i,j} V_{ij}(x_h)h^2 y_i y_j + \mathrm{O}(h^3|y|^3)\\ &= \mathrm{o}(h^2)|y| + \frac{1}{2}\sum_{i,j} V_{ij}(x_0)h^2 y_i y_j + \mathrm{o}(h^2|y|^2).\end{aligned} \tag{2.7}$$

Here we have used Lemma 2.1(1).

Now we claim that $|\phi_h| \le ch^2$. In fact, suppose not. We may assume that $|\phi_h|_{L^\infty} h^{-2} \to \infty$. Let $\widetilde{\phi}_h = \frac{\phi_h}{|\phi_h|_{L^\infty}}$. Then $\widetilde{\phi}_h$ satisfies

$$\triangle\widetilde{\phi}_h - (V + \lambda)\widetilde{\phi}_h + pw_{x_h}^{p-1}\widetilde{\phi}_h + \frac{N(\phi_h)}{|\phi_h|_{L^\infty}} - \frac{(V(x_h + hy) - V(x_h))w_{x_h}}{|\phi_h|_{L^\infty}} = 0. \tag{2.8}$$

Note that by (2.7),

$$\frac{|V(x_h+hy)-V(x_h)||w_{x_h}|}{|\phi_h|_{L^\infty}} \le \frac{h^2|y|^2|w_{x_h}|}{|\phi_h|_{L^\infty}} \le o(1)|y|^2|w_{x_h}| \tag{2.9}$$

for $|y| \ge 1$. Let y_h be the global maximum point of $\widetilde{\phi}_h$, i.e., $\widetilde{\phi}_h(y_h) = \max_y \frac{\phi_h(y)}{|\phi_h|_{L^\infty}} = 1$. Then by (2.8) and (2.9) and the maximum principle, we have $|y_h| \le C$. Here we have used the fact that $V \ge 0$ and $\lambda > 0$.

By the usual elliptic regularity theory, we may take a subsequence $\widetilde{\phi}_h \to \overline{\phi}_0$, where $\overline{\phi}_0$ satisfies

$$\triangle\overline{\phi}_0 - (V(x_0)+\lambda)\overline{\phi}_0 + pw_{x_0}^{p-1}\overline{\phi}_0 = 0,\ \nabla\overline{\phi}_0(0) = 0. \tag{2.10}$$

Since $\nabla\overline{\phi}_0(0) = 0$, we see that $\overline{\phi}_0 = \sum_{j=1}^N c_j \frac{\partial w_{x_0}}{\partial y_j}$, and hence $c_j = 0$. Consequently, $\overline{\phi}_0 \equiv 0$. This may contradict the fact that $1 = \widetilde{\phi}_h(y_h) \to \overline{\phi}_0(y_0)$ for some y_0. Therefore $|\phi_h| \le ch^2$. Now we let $\phi_h = h^2\phi_0 + h^2\overline{\phi}_h$. Then, as for the previous argument, we may have $\overline{\phi}_h = o(1)$ and complete the proof of Lemma 2.2. □

As in Proposition 3.6 of [19], one may get two lemmas, as follows.

LEMMA 2.3. *For each $s \in \mathbb{R}^N$, the map*

$$L_s\phi := \triangle\phi - (V(s)+\lambda)\phi + pw_s^{p-1}\phi \tag{2.11}$$

is invertible from $K_s^\perp$ to $C_s^\perp$, where

$$K_s^\perp = \left\{\phi \in H^2(\mathbb{R}^N) \,\middle|\, \int_{\mathbb{R}^N} \phi\frac{\partial w_s}{\partial y_j}(y)\,dy = 0\,, j = 1,\dots,N\right\} \subset H^2(\mathbb{R}^N),$$

$$C_s^\perp = \left\{\phi \in L^2(\mathbb{R}^N) \,\middle|\, \int_{\mathbb{R}^N} \phi\frac{\partial w_s}{\partial y_j}(y)\,dy = 0\,, j = 1,\dots,N\right\} \subset L^2(\mathbb{R}^N).$$

LEMMA 2.4. *The map*

$$L_0\phi := \triangle\phi - (V(x_0)+\lambda)\phi + pw_{x_0}^{p-1}\phi \tag{2.12}$$

admits the following eigenvalues:

$$\lambda_1 > 0\,,\ \lambda_2 = \cdots = \lambda_{N+1} = 0\,,\ \lambda_{N+2} < 0,$$

where the kernel of L_0 is spanned by $\frac{\partial w_{x_0}}{\partial y_j}$, $j = 1,\dots,N$.

Our main result in this section is the following.

THEOREM 2.5. *The eigenvalue problem*

$$L_h\psi_h = \lambda_h\psi_h \tag{2.13}$$

admits eigenvalues

$$\lambda_{h,1} > \lambda_{h,2} > \cdots > \lambda_{h,N+1} > \lambda_{h,N+2}, \tag{2.14}$$

satisfying, as $h \to 0$, $\lambda_{h,1} \to \lambda_1 > 0$, $\lambda_{h,N+2} \to \lambda_{N+2} < 0$, and

$$\frac{\lambda_{h,j}}{h^2} \to c_0\nu_{j-1},\ j = 2,\dots,N+1, \tag{2.15}$$

where c_0 is a negative constant and ν_j's are eigenvalues of the Hessian matrix $(\nabla^2 V(x_0))$.

Proof. We follow the proofs given in section 5 of [35]. Assume that $\|\psi_h\|_{L^2} = 1$. It is easy to see that for eigenvalues $\lambda_h \in [\frac{1}{2}\lambda_{N+2}, \frac{1}{2}\lambda_1]$, as $h \downarrow 0$, $\lambda_h \to \lambda_j$ for some j, where λ_j's are given in Lemma 2.4. Now we focus on the case $\lambda_{h,j} \to 0$, i.e., $\lambda_h \to 0$ as $h \downarrow 0$. Then the corresponding eigenfunctions can be written as

$$\psi_h(x_h + hy) = \sum_{j=1}^{N} c_j \frac{\partial w_{x_h}}{\partial y_j}(y) + \psi_h^{\perp}(y), \tag{2.16}$$

where $\int_{\mathbb{R}^N} \frac{\partial w_{x_h}}{\partial y_j}\psi_h^{\perp}(y)\,dy = 0$, $j = 1, 2, \ldots, N$. Hence by (2.13) and (2.16), $\psi_h^{\perp}$ may satisfy

(2.17)

$$\begin{aligned}&\triangle\psi_h^{\perp} - (V(x_h + hy) + \lambda)\psi_h^{\perp} + pw_{x_h}^{p-1}(y)\psi_h^{\perp} + p(u_h^{p-1}(x_h + hy) - w_{x_h}^{p-1}(y))\psi_h^{\perp}\\ &\quad + \sum_j c_j L_h \frac{\partial w_{x_h}}{\partial y_j} = \lambda_h \left(\sum_j c_j \frac{\partial w_{x_h}}{\partial y_j} + \psi_h^{\perp}\right).\end{aligned}$$

Using (2.1) and (2.7) of Lemma 2.2, we have

$$\begin{aligned}L_h \frac{\partial w_{x_h}}{\partial y_j} &= \triangle\left(\frac{\partial w_{x_h}}{\partial y_j}\right) - (V(x_h + hy) + \lambda)\frac{\partial w_{x_h}}{\partial y_j} + pu_h^{p-1}(x_h + hy)\frac{\partial w_{x_h}}{\partial y_j}\\ &= (V(x_h) - V(x_h + hy))\frac{\partial w_{x_h}}{\partial y_j} + p(u_h^{p-1}(x_h + hy) - w_{x_h}^{p-1}(y))\frac{\partial w_{x_h}}{\partial y_j}\\ &= O(h^2). \qquad (2.18)\end{aligned}$$

From Lemma 2.3, the map $L_{x_h} = \triangle - (V(x_h) + \lambda) + pw_{x_h}^{p-1}$ is invertible in the space $K_{x_h}^{\perp}$. Thus by (2.1), (2.7), and (2.18), (2.17) may give

$$||\psi_h^{\perp}||_{H^2} \le c(h^2 + |\lambda_h|)\sum_j |c_j|\,. \tag{2.19}$$

Now we set $z_j(y) = \frac{\partial w_{x_h}}{\partial y_j}(y)$ for $j = 1, \ldots, N$. Then multiplying (2.17) by z_k and integrating over $\mathbb{R}^N$, it is obvious that

(2.20)

$$\int_{\mathbb{R}^N} \left(L_h\psi_h^{\perp}\right) z_k\,dy + \sum_j c_j \int_{\mathbb{R}^N} \left(L_h \frac{\partial w_{x_h}}{\partial y_j}\right) z_k\,dy = \lambda_h \left(\sum_j c_j \int_{\mathbb{R}^N} z_j z_k\right) dy\,.$$

Here we have used the fact that $\psi_h^{\perp} \in K_{x_h}^{\perp}$. Using (2.18), (2.19), $\lambda_h = \mathrm{o}(1)$, and integration by parts, we obtain

$$\int_{\mathbb{R}^N} \left(L_h\psi_h^{\perp}\right) z_k = \int_{\mathbb{R}^N} \psi_h^{\perp} L_h z_k = \mathrm{o}(h^2) \tag{2.21}$$

and

$$\int_{\mathbb{R}^N} (L_h z_j)\, z_k = \int_{\mathbb{R}^N} (V(x_h) - V(x_h + hy)) z_j z_k + p \int_{\mathbb{R}^N} \left(u_h^{p-1} - w_{x_h}^{p-1} \right) z_j z_k$$

$$:= I_1 + I_2, \tag{2.22}$$

where

$$I_1 = \int_{\mathbb{R}^N} (V(x_h) - V(x_h + hy)) z_j z_k$$

$$= \mathrm{o}(h^2) - \frac{h^2}{2} \sum_{l,m} V_{lm}(x_h) \int_{\mathbb{R}^N} y_l y_m z_j z_k$$

$$= -\frac{h^2}{2} V_{jk}(x_h) \int_{\mathbb{R}^N} y_j z_j y_k z_k \,. \tag{2.23}$$

Here we have used (2.7) to get (2.23). For I_2, we use Lemma 2.2:

$$I_2 = p(p-1)h^2 \int_{\mathbb{R}^N} \phi_0 w_{x_h}^{p-2} z_j z_k + \mathrm{o}(h^2)$$

$$= -h^2 \int_{\mathbb{R}^N} L_0 \left(\frac{\partial^2 w}{\partial y_j \partial y_k} \right) \phi_0 + \mathrm{o}(h^2)$$

$$= -h^2 \int_{\mathbb{R}^N} (L_0 \phi_0) \frac{\partial^2 w}{\partial y_j \partial y_k} + \mathrm{o}(h^2)$$

$$= -\frac{h^2}{2} \sum_{l,m} V_{lm}(x_h) \int_{\mathbb{R}^N} y_l y_m w_{x_h} \frac{\partial^2 w}{\partial y_j \partial y_k} + \mathrm{o}(h^2)$$

$$= \frac{h^2}{2} \sum_{l,m} V_{lm}(x_h) \int_{\mathbb{R}^N} \frac{\partial}{\partial y_j} (y_l y_m w_{x_h}) z_k + \mathrm{o}(h^2)$$

$$= \frac{h^2}{2} V_{jk}(x_h) \int_{\mathbb{R}^N} y_j y_k z_j z_k - \frac{h^2}{2} V_{jk}(x_h) \int_{\mathbb{R}^N} w_{x_h}^2 + \mathrm{o}(h^2)\,. \tag{2.24}$$

Here we have used the following identity:

$$\int_{\mathbb{R}^N} \frac{\partial}{\partial y_j} (y_l y_m w_{x_h}) z_k = \int_{\mathbb{R}^N} \delta_{jl} y_m w_{x_h} z_k + \int_{\mathbb{R}^N} \delta_{jm} y_l w_{x_h} z_k + \int_{\mathbb{R}^N} y_l y_m z_j z_k$$

$$= \frac{1}{2} \int_{\mathbb{R}^N} \delta_{jl} y_m \frac{\partial}{\partial y_k} (w_{x_h}^2)$$

$$+ \frac{1}{2} \int_{\mathbb{R}^N} \delta_{jm} y_l \frac{\partial}{\partial y_k} (w_{x_h}^2) + \int_{\mathbb{R}^N} y_l y_m z_j z_k$$

$$= -(\delta_{jl}\delta_{km} + \delta_{jm}\delta_{lk}) \frac{1}{2} \int_{\mathbb{R}^N} w_{x_h}^2 + \int_{\mathbb{R}^N} y_l y_m z_j z_k.$$

Combining (2.23) and (2.24), we have

$$I_1 + I_2 = -\frac{h^2}{2} V_{jk}(x_h) \int_{\mathbb{R}^N} w_{x_0}^2 + \mathrm{o}(h^2). \tag{2.25}$$

Substituting (2.21) and (2.25) into (2.20), we may obtain $\lambda_j/h^2 \to c_0\nu_j$ for $j = 1, \ldots, N$, where $c_0 = -\frac{\int_{\mathbb{R}^N} w_{x_0}^2\, dy}{\int_{\mathbb{R}^N} z_j^2\, dy}$ is a negative constant. The rest of the proof follows from a perturbation result, similar to pages 1473–1474 of [35]. We may omit the details here. □

From Theorem 2.5, we may deduce the following.

THEOREM 2.6. *u_h is smooth in λ. Moreover, let $R_h = \frac{\partial u_h}{\partial \lambda}$. Then R_h satisfies*

$$L_h R_h - u_h = 0 \tag{2.26}$$

and

$$R_h = \sum_{j=1}^{N} c_j^h z_j + R_0 + \mathrm{o}(1)\,, \tag{2.27}$$

where $R_0 = \frac{\partial}{\partial \lambda} w_{x_h} = (V(x_h) + \lambda)^{-1}(\frac{1}{p-1} w_{x_h} + \frac{1}{2} y \cdot \nabla w_{x_h})$ and $|c_j^h| = \mathrm{O}(1)$ for $j = 1, \ldots, N$.

Proof. Since u_h is unique and L_h is invertible, it is easy to see that u_h is smooth in λ and R_h satisfies (2.26). Now we decompose R_h as

$$R_h = \sum_{j=1}^{N} c_j^h z_j + R_0 + \overline{R}_h,$$

where $\int_{\mathbb{R}^N} z_j \overline{R}_h = 0,\ j = 1, \ldots, N$. Then $\overline{R}_h$ satisfies

$$L_h \overline{R}_h - u_h + L_h R_0 + \sum_{j=1}^{N} c_j^h L_h z_j = 0. \tag{2.28}$$

As for the proof of Theorem 2.5, we have

$$\|\overline{R}_h\|_{H^2} \le c \left(|c_j^h| h^2 + \|L_h R_0 - u_h\|_{L^2} \right). \tag{2.29}$$

From (2.4) and (2.5), it is easy to check that $R_0 = \frac{\partial}{\partial \lambda} w_{x_h} = (V(x_h) + \lambda)^{-1}(\frac{1}{p-1} w_{x_h} + \frac{1}{2} y \cdot \nabla w_{x_h})$ and $L_{x_h} R_0 = w_{x_h}$ by differentiating (2.5) with respect to λ. Hence

$$L_h R_0 - u_h = p(u_h^{p-1}(x_h + hy) - w_{x_h}^{p-1}(y)) R_0 - (V(x_h + hy) - V(x_h))\, R_0 + w_{x_h} - u_h\,.$$

Consequently, by Lemma 2.2 and (2.7), we obtain

$$\|L_h R_0 - u_h\|_{L^2} = \mathrm{O}(h^2)\,, \tag{2.30}$$

and then by (2.29),

$$\|\overline{R}_h\|_{H^2} = (1 + |c_j^h|)\mathrm{O}(h^2)\,. \tag{2.31}$$

To estimate c_j^h's, we may multiply (2.28) by z_k and integrate over $\mathbb{R}^N$. Then

$$\sum_{j=1}^{N} c_j^h \int_{\mathbb{R}^N} (L_h z_j) z_k + \int_{\mathbb{R}^N} (L_h R_0 - u_h) z_k + \int_{\mathbb{R}^N} (L_h \overline{R}_h) z_k = 0\,. \tag{2.32}$$

Hence by (2.22) and (2.25), (2.32) may imply

$$|c_j^h| \le \frac{C}{h^2} \left(\left| \int_{\mathbb{R}^N} (L_h R_0 - u_h) z_k \right| + \left| \int_{\mathbb{R}^N} (L_h \overline{R}_h) z_k \right| \right). \tag{2.33}$$

Using integration by parts and (2.18), we have

$$\int_{\mathbb{R}^N} (L_h \overline{R}_h) z_k = \int_{\mathbb{R}^N} (L_h z_k) \overline{R}_h = \|\overline{R}_h\|_{L^2}\, \mathrm{O}(h^2)\,. \tag{2.34}$$

Therefore by (2.30), (2.31), (2.33), and (2.34), we may obtain $|c_j^h| = \mathrm{O}(1)$ and complete the proof. □

3. Proof of Theorem 1.1. Let $p = 1 + \frac{4}{N}$. By Theorem 2.5, L_h has $m+1$ positive eigenvalues and no zero eigenvalue, where m is the number of negative eigenvalues of the matrix $(\nabla^2 V(x_0))$. Let us now compute $d''(\lambda)$.

From (1.7), it is easy to get

$$d'(\lambda) = \frac{1}{2} \int_{\mathbb{R}^N} u_h^2$$

and hence

$$d''(\lambda) = \int_{\mathbb{R}^N} \frac{\partial u_h}{\partial \lambda} u_h = \int_{\mathbb{R}^N} R_h u_h.$$

By direct computations,

$$L_h \left(\frac{1}{p-1} u_h + \frac{1}{2} hy \cdot \nabla u_h \right) = \frac{1}{2} hy \cdot \nabla V(x_h + hy) u_h + (V(x_h + hy) + \lambda) u_h. \tag{3.1}$$

Consequently,

$$\begin{aligned}
(V(x_h) + \lambda) \int_{\mathbb{R}^N} R_h u_h &= \int_{\mathbb{R}^N} R_h (V(x_h) - V(x_h + hy)) u_h \\
&\quad + \int_{\mathbb{R}^N} R_h (V(x_h + hy) + \lambda) u_h \\
&= \int_{\mathbb{R}^N} R_h \left(V(x_h) - V(x_h + hy) - \frac{1}{2} hy \cdot \nabla V(x_h + hy) \right) u_h \\
&\quad + \int_{\mathbb{R}^N} R_h L_h \left(\frac{1}{p-1} u_h + \frac{1}{2} hy \cdot \nabla u_h \right). \qquad (3.2)
\end{aligned}$$

Using integration by parts and (2.26), we may obtain

$$\begin{aligned}
\int_{\mathbb{R}^N} R_h L_h \left(\frac{1}{p-1} u_h + \frac{1}{2} hy \cdot \nabla u_h \right) &= \int_{\mathbb{R}^N} (L_h R_h) \left(\frac{1}{p-1} u_h + \frac{1}{2} hy \cdot \nabla u_h \right) \\
&= \int_{\mathbb{R}^N} u_h \left(\frac{1}{p-1} u_h + \frac{1}{2} hy \cdot \nabla u_h \right) \\
&= \left(\frac{1}{p-1} - \frac{N}{4} \right) \int_{\mathbb{R}^N} u_h^2 = 0\,, \qquad (3.3)
\end{aligned}$$

since $p = 1 + \frac{4}{N}$. So by (2.7), (3.2), (3.3), Lemma 2.2, and Theorem 2.6, we have

$$
\begin{aligned}
d''(\lambda) &= \frac{1}{V(x_h)+\lambda}\int_{\mathbb{R}^N} R_h\left(V(x_h) - V(x_h+hy) - \frac{1}{2}hy\cdot\nabla V(x_h+hy)\right)u_h \\
&= \frac{h^2}{V(x_h)+\lambda}\int_{\mathbb{R}^N} R_h\left[\sum_{i,j} -V_{ij}(x_h)y_iy_j\right]u_h + \mathrm{o}(h^2) \\
&= \frac{h^2}{V(x_h)+\lambda}\int_{\mathbb{R}^N} \left(\sum_l c_l^h z_l + R_0 + \mathrm{o}(1)\right)\left(\sum_{i,j} -V_{ij}(x_h)y_iy_j\right) \\
&\quad (w_{x_h} + \mathrm{O}(h^2)) + \mathrm{o}(h^2) \\
&= -\frac{h^2}{V(x_h)+\lambda}\sum_i V_{ii}(x_h)\int_{\mathbb{R}^N} R_0 y_i^2 w_{x_h} + \mathrm{o}(h^2) \\
&= -\frac{h^2}{(V(x_h)+\lambda)^2}\sum_i V_{ii}(x_h)\int_{\mathbb{R}^N}\left(\frac{1}{p-1}w_{x_h} + \frac{1}{2}y\cdot\nabla w_{x_h}\right)y_i^2 w_{x_h} + \mathrm{o}(h^2) \\
&= -\frac{h^2}{(V(x_h)+\lambda)^2}\left(\frac{1}{p-1} - \frac{N+2}{4}\right)\sum_i V_{ii}(x_h)\int_{\mathbb{R}^N} y_i^2 w_{x_h}^2 + \mathrm{o}(h^2) \\
&= \frac{h^2}{2(V(x_0)+\lambda)^2}\Delta V(x_0)\int_{\mathbb{R}^N} y_i^2 w_{x_0}^2 + \mathrm{o}(h^2) \quad \left(\text{because } p = 1+\frac{4}{N}\right). \qquad (3.4)
\end{aligned}
$$

If x_0 is a local minimum point, then $m = 0$ and $n(L_h) = 1$. Since the Hessian matrix $(\nabla^2 V(x_0))$ is positive definite, then

$$
d''(\lambda) > 0, \quad p(d''(\lambda)) = 1, \qquad (3.5)
$$

which implies that u_h is orbitally unstable by the orbital stability criteria of [14] and [15].

If x_0 is not a local minimum, then $m \geq 1$ and $n(L_h) \geq 2$. In this case, by the formula (3.4), $p(d''(\lambda)) = \frac{1}{2}(1 + \frac{\Delta V(x_0)}{|\Delta V(x_0)|})$. By the instability criteria of [15], we conclude that u_h is orbitally unstable if $m - \frac{1}{2}(1 + \frac{\Delta V(x_0)}{|\Delta V(x_0)|})$ is even. This completes the proof of Theorem 1.1.

4. Proof of Theorem 1.2. Let $(\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h)$ be a solution of (1.11). The linearized operator of (1.10) around $(\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h)$ is

$$
\mathbb{L}_h\begin{pmatrix}\phi\\ \psi\end{pmatrix} = \begin{pmatrix} h^2\triangle\phi - (V(x)+\lambda)\phi + \frac{3+\beta}{1+\beta}u_h^2\phi + \frac{2\beta}{1+\beta}u_h^2\psi \\ h^2\triangle\psi - (V(x)+\lambda)\psi + \frac{3+\beta}{1+\beta}u_h^2\psi + \frac{2\beta}{1+\beta}u_h^2\phi \end{pmatrix}. \qquad (4.1)
$$

We first define a sequence of numbers $\beta_j \in (-1, 0)$. By Lemma 4.2 of [34], the eigenvalue problem

$$
\triangle\psi - (V(x_0)+\lambda)\psi + \mu w_{x_0}^2\psi = 0 \qquad (4.2)
$$

admits eigenvalues

$$\mu_1 = 1,\ \mu_2 = \cdots = \mu_{N+1} = 3,\ \mu_{N+2} > 3. \tag{4.3}$$

We then define β_j by

$$\beta_j = \frac{3-\mu_j}{1+\mu_j}, \quad j = 1, 2, \ldots . \tag{4.4}$$

The following lemma shows the nondegeneracy of $\mathbb{L}$.

LEMMA 4.1. *$\mathbb{L}_h$ has no zero eigenvalue if $\beta \neq \beta_j, j = 1, 2, \ldots$.*

Proof. Let $\mathbb{L}_h \binom{\phi}{\psi} = \binom{0}{0}$. Then by an orthonormal transformation it is equivalent to

$$L_{h,1}\widetilde{\phi} = 0, \tag{4.5}$$

$$L_{h,2}\widetilde{\psi} = 0, \tag{4.6}$$

where $L_{h,1} = L_h$, $L_{h,2} = h^2\triangle - (V(x_h + hy) + \lambda) + \frac{3-\beta}{1+\beta}u_h^2$. By Theorem 2.5, we may conclude that $\widetilde{\phi} = 0$. It remains to consider (4.6). As $h \to 0$, (4.6) may tend to the limiting equation given by

$$\triangle\psi - (V(x_0) + \lambda)\psi + \frac{3-\beta}{1+\beta}w_{x_0}^2\psi = 0. \tag{4.7}$$

Since $\beta \neq \beta_j$, i.e., $\frac{3-\beta}{1+\beta} \neq \mu_j$, then by Lemma 4.2 of [34], (4.7) has only a trivial solution. Therefore, $\widetilde{\psi} = 0$ and we may complete the proof. ∎

The next lemma computes the Morse index of $(\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h)$. Here the Morse index is defined to be the number of positive eigenvalues of $\mathbb{L}_h$, which is just $n(\mathbb{L}_h)$.

LEMMA 4.2. *If $-1 < \beta < 0$ and $\beta \notin \{\beta_2, \ldots, \beta_j, \ldots\}$, then the Morse index of $(\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h)$ is at least $N+2$. If $0 < \beta < 1$, then the Morse index of $(\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h)$ is two. If $\beta > 1$, then the Morse index of $(\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h)$ is one.*

Proof. The eigenvalue problem $\mathbb{L}_h \binom{\phi}{\psi} = \bar{\lambda}\binom{\phi}{\psi}$ can be decomposed to

$$L_{h,1}\widetilde{\phi} = \bar{\lambda}\widetilde{\phi}, \tag{4.8}$$

$$L_{h,2}\widetilde{\psi} = \bar{\lambda}\widetilde{\psi}. \tag{4.9}$$

By Theorem 2.5, $L_{h,1}$ has only one positive eigenvalue. It remains to consider the spectrum of $L_{h,2}$. If $\beta < 0$, then the eigenvalue problem

$$\triangle\psi - (V(x_0) + \lambda)\psi + \frac{3-\beta}{1+\beta}w_{x_0}^2\psi = \bar{\lambda}\psi \tag{4.10}$$

has at least $N+1$ positive eigenvalues. We may define a space of functions by

$$\mathbf{V} = \operatorname{span}\left\{ w_{x_0}, \frac{\partial w_{x_0}}{\partial y_j},\ j = 1, \ldots, N, \right\}.$$

Since $-1 < \beta < 0$, we have $\frac{3-\beta}{1+\beta} > 3$. Hence

$$\int_{\mathbb{R}^N} \left[|\nabla\phi|^2 + (V(x_0) + \lambda)\phi^2 - \frac{3-\beta}{1+\beta}w_{x_0}^2\phi^2 \right] < 0 \quad \forall \phi \in \mathbf{V}. \tag{4.11}$$

Thus by the variational characterization of the eigenvalues of (4.10), we see that $\lambda_{N+1} > 0$. Moreover, by the perturbation argument, (4.9) has at least $N+1$ positive eigenvalues.

So when $\beta < 0$, $\mathbb{L}_h$ has at least $N+2$ positive eigenvalues.

When $0 < \beta < 1$, $1 < \frac{3-\beta}{1+\beta} < 3$, (4.10) has only one positive eigenvalue. So the Morse index is two.

When $\beta > 1$, (4.10) has no positive eigenvalue. So the Morse index is one. □

Since $\mathbb{L}_h$ is invertible, $(\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h)$ is nondegenerate. Thus the system

$$\begin{cases} h^2\triangle u - (V(x)+\lambda+\lambda_1)u + u^3 + \beta u v^2 = 0 & \text{in } \mathbb{R}^N, \\ h^2\triangle v - (V(x)+\lambda+\lambda_2)v + v^3 + \beta u^2 v = 0 & \text{in } \mathbb{R}^N \end{cases} \tag{4.12}$$

has a solution $(u_{h,\lambda_1,\lambda_2}, v_{h,\lambda_1,\lambda_2})$ satisfying

$$(u_{h,\lambda_1,\lambda_2}, v_{h,\lambda_1,\lambda_2}) = \left(\frac{1}{\sqrt{1+\beta}}u_h, \frac{1}{\sqrt{1+\beta}}u_h\right) + \mathrm{O}\left((|\lambda_1|+|\lambda_2|)h^{-2}\right) \tag{4.13}$$

as $|\lambda_1| + |\lambda_2| \ll 1$.

Let us define

$$\begin{aligned} d(\lambda_1,\lambda_2) = &\int_{\mathbb{R}^N} \frac{h^2}{2}|\nabla u_{h,\lambda_1,\lambda_2}|^2 + \frac{V(x)+\lambda+\lambda_1}{2}u_{h,\lambda_1,\lambda_2}^2 - \frac{1}{4}\int_{\mathbb{R}^N} u_{h,\lambda_1,\lambda_2}^4 \\ &+ \int_{\mathbb{R}^N} \frac{h^2}{2}|\nabla v_{h,\lambda_1,\lambda_2}|^2 + \frac{V(x)+\lambda+\lambda_2}{2}v_{h,\lambda_1,\lambda_2}^2 - \frac{1}{4}\int_{\mathbb{R}^N} v_{h,\lambda_1,\lambda_2}^4 \\ &- \frac{\beta}{2}\int_{\mathbb{R}^N} u_{h,\lambda_1,\lambda_2}^2 v_{h,\lambda_1,\lambda_2}^2. \end{aligned} \tag{4.14}$$

It is easy to see that

$$\frac{\partial d}{\partial \lambda_1} = \frac{1}{2}\int_{\mathbb{R}^N} u_{h,\lambda_1,\lambda_2}^2, \quad \frac{\partial^2 d}{\partial \lambda_1^2} = \int_{\mathbb{R}^N} u_{h,\lambda_1,\lambda_2}\frac{\partial u_{h,\lambda_1,\lambda_2}}{\partial \lambda_1},$$

$$\frac{\partial d}{\partial \lambda_2} = \frac{1}{2}\int_{\mathbb{R}^N} v_{h,\lambda_1,\lambda_2}^2, \quad \frac{\partial^2 d}{\partial \lambda_2^2} = \int_{\mathbb{R}^N} v_{h,\lambda_1,\lambda_2}\frac{\partial v_{h,\lambda_1,\lambda_2}}{\partial \lambda_2},$$

$$\frac{\partial^2 d}{\partial \lambda_1 \partial \lambda_2} = \int_{\mathbb{R}^N} u_{h,\lambda_1,\lambda_2}\frac{\partial u_{h,\lambda_1,\lambda_2}}{\partial \lambda_2}.$$

Now we may define functions as

$$\Phi_1 = \left.\frac{\partial u_{h,\lambda_1,\lambda_2}}{\partial \lambda_1}\right|_{(\lambda_1,\lambda_2)=(0,0)} \quad \text{and} \quad \Psi_1 = \left.\frac{\partial u_{h,\lambda_1,\lambda_2}}{\partial \lambda_2}\right|_{(\lambda_1,\lambda_2)=(0,0)}.$$

Then by (4.12), $\binom{\Phi_1}{\Psi_1}$ satisfies

$$\mathbb{L}_h \begin{pmatrix} \Phi_1 \\ \Psi_1 \end{pmatrix} = \begin{pmatrix} u_{h,0,0} \\ 0 \end{pmatrix}. \tag{4.15}$$

Similarly, if we set $\Phi_2 = \frac{\partial v_{h,\lambda_1,\lambda_2}}{\partial \lambda_1}|_{(\lambda_1,\lambda_2)=(0,0)}$ and $\Psi_2 = \frac{\partial v_{h,\lambda_1,\lambda_2}}{\partial \lambda_2}|_{(\lambda_1,\lambda_2)=(0,0)}$, then by (4.12), we have

$$\Psi_2 = \Phi_1, \quad \Phi_2 = \Psi_1. \tag{4.16}$$

Let $\mathbb{B} = \left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right)$. Then (4.15) is equivalent to

$$\mathbb{B}\mathbb{L}_h \begin{pmatrix} \Phi_1 \\ \Psi_1 \end{pmatrix} = \begin{pmatrix} L_{h,1}(\Phi_1 + \Psi_1) \\ L_{h,2}(\Phi_1 - \Psi_1) \end{pmatrix} = \begin{pmatrix} u_{h,0,0} \\ u_{h,0,0} \end{pmatrix}. \tag{4.17}$$

So

$$\Phi_1 + \Psi_1 = R_{h,1} \quad \text{and} \quad \Phi_1 - \Psi_1 = R_{h,2}, \tag{4.18}$$

where

$$R_{h,1} = \frac{1}{\sqrt{1+\beta}} R_h \quad \text{and} \quad R_{h,2} = L_{h,2}^{-1}\left(\frac{1}{\sqrt{1+\beta}} u_h\right). \tag{4.19}$$

Now we compute the Hessian matrix

$$(\nabla^2 d)\big|_{(\lambda_1,\lambda_2)=(0,0)} = \begin{pmatrix} \frac{1}{\sqrt{1+\beta}} \int_{\mathbb{R}^N} u_h \Phi_1 & \frac{1}{\sqrt{1+\beta}} \int_{\mathbb{R}^N} u_h \Psi_1 \\ \frac{1}{\sqrt{1+\beta}} \int_{\mathbb{R}^N} u_h \Psi_1 & \frac{1}{\sqrt{1+\beta}} \int_{\mathbb{R}^N} u_h \Phi_1 \end{pmatrix},$$

$$\begin{aligned} \mathbb{B}\,(\nabla^2 d)\big|_{(\lambda_1,\lambda_2)=(0,0)}\,\mathbb{B}^T &= \begin{pmatrix} \frac{1}{\sqrt{1+\beta}} \int_{\mathbb{R}^N} u_h R_{h_1} & \frac{1}{\sqrt{1+\beta}} \int_{\mathbb{R}^N} u_h R_{h_1} \\ \frac{1}{\sqrt{1+\beta}} \int_{\mathbb{R}^N} u_h R_{h_2} & -\frac{1}{\sqrt{1+\beta}} \int_{\mathbb{R}^N} u_h R_{h_2} \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \\ &= \begin{pmatrix} \frac{2}{\sqrt{1+\beta}} \int_{\mathbb{R}^N} u_h R_{h_1} & 0 \\ 0 & \frac{2}{\sqrt{1+\beta}} \int_{\mathbb{R}^N} u_h R_{h_2} \end{pmatrix}. \end{aligned}$$

By the results in section 3, $\frac{2}{\sqrt{1+\beta}} \int_{\mathbb{R}^N} u_h R_{h_1} = \frac{2}{1+\beta} \int_{\mathbb{R}^N} u_h R_h > 0$. It is enough to compute $\sqrt{1+\beta} \int_{\mathbb{R}^N} u_h R_{h_2} = \int_{\mathbb{R}^N} u_h L_{h,2}^{-1}(u_h)$. Note that as $h \to 0^+$,

$$\int_{\mathbb{R}^N} u_h L_{h,2}^{-1}(u_h) \to \int_{\mathbb{R}^N} w_{x_0} L_\mu^{-1}(w_{x_0}),$$

where

$$L_\mu \phi = \triangle \phi - (V(x_0) + \lambda)\phi + \mu w_{x_0}^2 \phi \tag{4.20}$$

with $\mu = \frac{3-\beta}{1+\beta}$.

Let $\rho(\mu) = \int_{\mathbb{R}^N} w_{x_0} L_\mu^{-1}(w_{x_0})$ and ϕ_μ the unique solution of $\triangle \phi_\mu - (V(x_0)+\lambda)\phi_\mu + \mu w_{x_0}^2 \phi_\mu = w_{x_0}$, i.e., $L_\mu \phi_\mu = w_{x_0}$ for $\mu \neq \mu_j, j = 1, 2, \ldots$. Then $\frac{\partial \phi_\mu}{\partial \mu}$ satisfies

$$L_\mu\left(\frac{\partial \phi_\mu}{\partial \mu}\right) = -w_{x_0}^2 \phi_\mu, \quad \text{i.e.,} \quad \frac{\partial \phi_\mu}{\partial \mu} = -L_\mu^{-1}(w_{x_0}^2 \phi_\mu).$$

Hence

$$\begin{aligned} \rho'(\mu) &= \int_{\mathbb{R}^N} w_{x_0} \frac{\partial \phi_\mu}{\partial \mu} = -\int_{\mathbb{R}^N} w_{x_0} L_\mu^{-1}(w_{x_0}^2 \phi_\mu) \\ &= -\int_{\mathbb{R}^N} (L_\mu^{-1} w_{x_0})(w_{x_0}^2 \phi_\mu) \\ &= -\int_{\mathbb{R}^N} w_{x_0}^2 \phi_\mu^2 < 0 \quad \text{for} \quad \mu \neq \mu_j\,, j = 1, 2, \ldots, \end{aligned}$$

i.e.,

$$\rho'(\mu) < 0 \quad \text{for} \quad \mu \neq \mu_j\,, j = 1, 2, \dots. \tag{4.21}$$

Due to (4.3), ρ is smooth on $(-\infty, 1) \cup (1, 3) \cup (3, \infty) \setminus \{\mu_j : j = N + 2, N + 3, \dots\}$. On the other hand, as $\mu \to 3$,

$$\phi_\mu \to L_0^{-1} w_{x_0} = \frac{1}{2} w_{x_0} + \frac{1}{2} y \cdot \nabla w_{x_0}, \tag{4.22}$$

$$\rho(\mu) \to \int_{\mathbb{R}^2} w_{x_0} \left(\frac{1}{2} w_{x_0} + \frac{1}{2} y \cdot \nabla w_{x_0} \right) = 0. \tag{4.23}$$

Here we have used the fact that $N = 2$ and $p = 3$. Thus for $1 < \mu < 3$, $\rho(\mu) > 0$. This implies that for $0 < \beta < 1$, $\int_{\mathbb{R}^2} u_h R_{h,2} > 0$ and thus $(\nabla^2 d(0, 0))$ has *two* positive eigenvalues.

Now we consider $\mu \in (-\infty, 1)$, i.e., $\beta > 1$. By the standard maximal principle, $\phi_\mu < 0$ in $\mathbb{R}^2$ for $\mu < 0$. Consequently, $\rho(\mu) < 0$ for $\mu < 0$. Hence by (4.21), $\rho(\mu) < 0$ for $\mu \in (-\infty, 1)$, i.e., $\beta > 1$. This implies that $\int_{\mathbb{R}^2} u_h R_{h,2} < 0$ and thus $(\nabla^2 d(0, 0))$ has only *one* positive eigenvalue.

In conclusion, we see that the matrix $(\nabla^2 d(0, 0))$ has two positive eigenvalues when $0 < \beta < 1$ and one positive eigenvalue when $\beta > 1$. That is $p = 2$ when $0 < \beta < 1$ and $p = 1$ when $\beta > 1$. By Lemmas 4.1 and 4.2, we also deduce that $n(\mathbb{L}_h) = 2$ when $0 < \beta < 1$ and $n(\mathbb{L}_h) = 1$ when $\beta > 1$. Hence for $\beta > 0, \beta \neq 1$, we have $n(\mathbb{L}_h) = p$. Therefore, we conclude that $(u_{h,0,0}, v_{h,0,0}) = (\frac{1}{\sqrt{1+\beta}} u_h, \frac{1}{\sqrt{1+\beta}} v_h)$ is orbitally stable if $0 < \beta,\ \beta \neq 1$. This completes the proof of Theorem 1.2.

Acknowledgment. We thank the referees for bringing our attention to [12] and [13] and for many helpful suggestions.

FORCED VIBRATIONS OF A NONHOMOGENEOUS STRING*

PIETRO BALDI† AND MASSIMILIANO BERTI‡

Abstract. We prove existence of vibrations of a nonhomogeneous string under a nonlinear time periodic forcing term in the case in which the forcing frequency avoids resonances with the vibration modes of the string (nonresonant case). The proof relies on a Lyapunov–Schmidt reduction and a Nash–Moser iteration scheme.

Key words. nonlinear wave equations, periodic solutions, small divisors, Nash–Moser iteration scheme

1. Introduction.

In this paper we study forced vibrations of a nonhomogeneous string,

$$\begin{cases} \rho(x)u_{tt} - (p(x)u_x)_x = \mu f(x, \omega t, u), \\ u(0,t) = u(\pi,t) = 0, \end{cases} \tag{1}$$

where $\rho(x) > 0$ is the mass per unit length, $p(x) > 0$ is the modulus of elasticity multiplied by the cross-sectional area (see [15, p. 291]), $\mu > 0$ is a parameter, and the nonlinear forcing term $f(x, \omega t, u)$ is $(2\pi/\omega)$-periodic in time (i.e., $f(x, \cdot, u)$ is 2π-periodic).

Equation (1) is a nonlinear model also for propagation of waves in nonisotropic media describing seismic phenomena; see, e.g., [2].

We look for $(2\pi/\omega)$-time periodic solutions $u(x,t)$ of (1).

This problem has received wide attention since the pioneering paper of Rabinowitz [26] dealing with the weakly nonlinear homogeneous string with $\rho(x) = p(x) = 1$, μ small, and $\omega = 1$. In this case the forcing frequency ω enters in resonance with the proper eigenfrequencies $\omega_j = j \in \mathbb{N}$ of the string.

For functions 2π-periodic in time and satisfying spatial Dirichlet boundary conditions, the spectrum $\{-l^2 + j^2,\ l \in \mathbb{Z},\ j \geq 1\}$ of the D'Alembertian operator $\partial_{tt} - \partial_{xx}$ possesses the zero eigenvalue with infinite multiplicity (for $|l| = j$), but the other eigenvalues are well separated. The corresponding infinite-dimensional bifurcation problem is solved in [26] for nonlinearities f which are monotone in u; see [7] for nonmonotone f.

Subsequently many other results, both of bifurcation and of a global nature ($\mu = 1$), have been obtained, still for rational forcing frequencies $\omega \in \mathbb{Q}$, relying on the separation properties of the spectrum; see, e.g., [27, 28, 14, 31, 4].

When the forcing frequency $\omega \in \mathbb{R}\backslash\mathbb{Q}$ is irrational (nonresonant case) the situation is completely different. Indeed the wave operator $\omega^2\partial_{tt} - \partial_{xx}$ does not possess the

*Received by the editors July 13, 2006; accepted for publication (in revised form) September 14, 2007; published electronically April 25, 2008. This work was supported by MURST under the national project "Variational Methods and Nonlinear Differential Equations."

†SISSA, via Beirut 2-4, 34014 Trieste, Italy (baldi@sissa.it).
‡Dipartimento di Matematica e Applicazioni "R. Caccioppoli," Università di Napoli "Federico II," via Cintia, 80126 Napoli, Italy (m.berti@unina.it).

zero eigenvalue, but its spectrum $\{-\omega^2 l^2 + j^2,\ l \in \mathbb{Z},\ j \geq 1\}$ accumulates to zero for almost every ω. This is a "small divisors problem."

We underline that this "small divisors" phenomenon arises naturally for more realistic model equations like (1) where the density $\rho(x)$ and the modulus of elasticity $p(x)$ are not constant. Indeed in this case the eigenfrequencies ω_j of the string are no longer integer numbers, having the asymptotic expansion

$$\omega_j^2 = \frac{j^2}{c^2} + b + O\Big(\frac{1}{j}\Big) \tag{2}$$

with suitable constants c, b depending on ρ, p; see (66).

If $\omega = m/n \in \mathbb{Q}$, good separation properties of the spectrum can be recovered when $p(x) = \rho(x)$ (so $c = 1$) and assuming the extra condition $b \neq 0$; see [3, 29]. Indeed in this case the linear spectrum

$$-\omega^2 l^2 + \omega_j^2 = -\omega^2 l^2 + j^2 + b + O\Big(\frac{1}{j}\Big)$$

possesses at most finitely many zero eigenvalues and the remaining part of the spectrum is far away from zero. On the other hand, if $b = 0$, the eigenvalues with $(l, j) \in (n, m)\mathbb{N}$ tend to zero (also in the case $\omega \in \mathbb{Q}$!).

Existence of weak solutions in the nonresonant case was proved by Acquistapace [1] for $\rho = 1$, μ small, and for a zero measure set of forcing frequencies ω for which the eigenvalues $-\omega^2 l^2 + \omega_j^2$ are far away from zero. These frequencies are essentially the numbers whose continued fraction expansion is bounded; see [30].

For a similar zero measure set of frequencies, McKenna [23] has obtained some result when $\mu = 1$, $\rho = p = 1$, and $f(x, t, u) = g(u) + h(x, t)$ with g uniformly Lipschitz, via a fixed point argument; see also [5]; for related results using variational methods see [18, 10].

Existence of classical solutions of (1) for a positive measure set of frequencies was proved by Plotnikov and Yungerman [24] for the homogeneous string $\rho = p = 1$, μ small, and f monotone in u. This monotonicity condition allows one to control the constant coefficient in the asymptotic expansion of the eigenvalues (like b in (2)) of some perturbed linearized operator.

Recently Fokam [19] has proved existence of classical periodic solutions for large frequencies ω in a set of asymptotically full measure for the homogeneous string $\rho = p = 1$ plus a potential, $\mu = 1$ and $f = u^3 + h(x, t)$ with h a trigonometric polynomial odd in time and space.

In the present paper we prove existence of classical solutions of the nonhomogeneous string (1) for every $\rho(x)$, $p(x) > 0$ for general nonlinear terms $f(x, \omega t, u)$, and for (μ, ω) belonging to a large measure Cantor set B_γ, when the ratio μ/ω is small. Our Theorem 1 covers both the case $\mu \to 0$ (weak forcing) and the case $\omega \to +\infty$ (rapid forcing).

In the limit $\mu/\omega \to 0$ the solution we find tends to a static equilibrium $v(x)$ with smaller, zero average oscillations $w(x, t)$ of amplitude $O(\mu/\omega)$; see (13), (14), and Figure 1. The nonlinearity f selects such v through the infinite-dimensional bifurcation equation (10), which possesses nondegenerate solutions under natural assumptions on f; see Hypothesis (V). This problem is not present in [19], where, thanks to the symmetry assumptions on f, there is no bifurcation equation.

Considering the structure of the expected solution, it is natural to attack the problem via a Lyapunov–Schmidt decomposition.

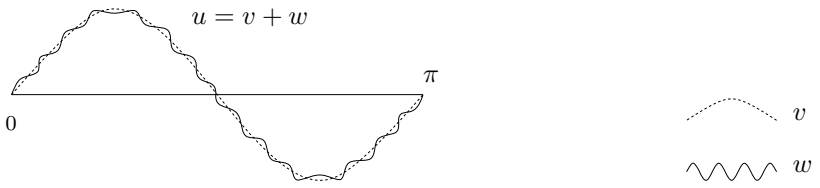

FIG. 1. *The solution* $u(x,t) = v(x) + w(x,t)$ *of* (1).

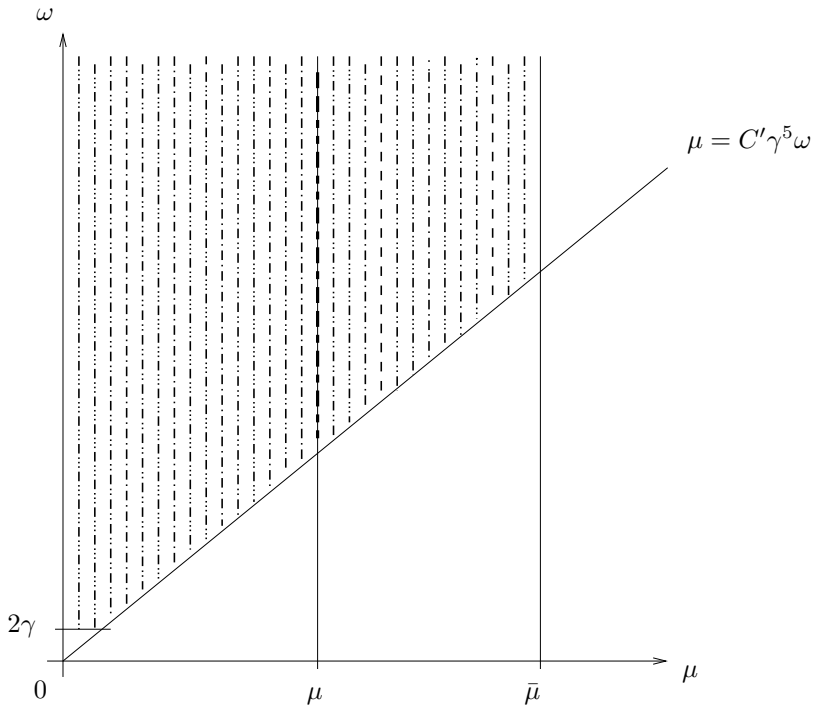

FIG. 2. *The Cantor set* B_γ.

In the range equation (to find w) a small divisors problem arises, and we solve it with a Nash–Moser-type iterative scheme. The inversion of the "linearized operators"—which is the core of any Nash–Moser scheme—is obtained adapting the techniques of [8] to the present time-dependent case (section 6). This method is also reminiscent of the approach of Kuksin (unpublished) explained by Bourgain in [13, pp. 90–94]. See also the works of Craig and Wayne [16, 17] and Bourgain [11, 12] for related techniques.

It is in the solution of the range equation where the interaction between the forcing frequency ω and the normal modes of oscillations of the string linearized at different positions (approximating better and better the final string configuration) appears.

The set B_γ of "nonresonant" parameters (μ, ω) for which we find a solution of the range equation (and then of (1)) is constructed avoiding these primary resonances. In particular the forcing frequency ω must not enter in resonance with the normal frequencies of oscillations of the string linearized at the limit solution; see (15). At the end of the construction we obtain a large measure Cantor set B_γ which looks like Figure 2. Outside this set the effect of resonance phenomena shall in general destroy the existence of periodic solutions like those found in Theorem 1.

Finally we recall that related existence results of periodic and quasi-periodic solutions for autonomous Hamiltonian PDEs have been obtained via KAM-type techniques since the pioneering works of Kuksin [21] and Wayne [32]; see also [22] and the references therein.

We now present rigorously our results.

1.1. Main result. After a time rescaling we look for 2π-periodic solutions of

$$\begin{cases} \omega^2\rho(x)u_{tt} - (p(x)u_x)_x = \mu f(x,t,u), \\ u(0,t) = u(\pi,t) = 0, \end{cases} \tag{3}$$

where $\mu \in [0,\bar\mu]$ for some given $\bar\mu > 0$, under the 2π-periodic forcing term

$$f(x,t,u) = \sum_{l\in\mathbb{Z}} f_l(x,u)e^{ilt} = f_0(x,u) + \bar f(x,t,u), \tag{4}$$

where

$$\bar f(x,t,u) := \sum_{l\neq 0} f_l(x,u)e^{ilt}\,.$$

We suppose that f is analytic in (t,u); more precisely,

$$f(x,t,u) = \sum_{l\in\mathbb{Z},\, k\in\mathbb{N}} f_{lk}(x)\, u^k\, e^{ilt},$$

where $f_{lk}(x) \in H^1((0,\pi);\mathbb{C})$, $f_{-l,k} = f_{lk}^*$ (the symbol z^* denotes the complex conjugate of $z\in\mathbb{C}$), and we assume the following hypothesis on the decay of the coefficients $\|f_{lk}\|_{H^1}$.

Hypothesis (F). *There exist* $2\sigma_0 > 0$, $r > 0$ *such that*

$$\sum_{l\in\mathbb{Z}} \|f_{lk}\|_{H^1}^2 (1+l^2)e^{(2\sigma_0)2|l|} := C_k^2(f) < \infty \quad \textit{and} \quad \sum_{k=0}^{+\infty} C_k(f)\, r^k < \infty\,.$$

For example, trigonometric polynomials in t and polynomials in u, namely,

$$f(x,t,u) = \sum_{|l|\le L, 0\le k\le K} f_{lk}(x)\, u^k\, e^{ilt} \tag{5}$$

for some $L, K \in \mathbb{N}$, satisfy Hypothesis (F) for every σ_0, r.

Remark 1. We notice that if $f(x,t,0) = \sum_{l\in\mathbb{Z}} f_{l0}(x)\, e^{ilt} \neq 0$, then (3) does not possess the trivial solution $u = 0$.

We look for periodic solutions of (3) in the Hilbert space

$$X_{\sigma,s} := \Big\{ u : \mathbb{T} \to H_0^1((0,\pi);\mathbb{R}),\ u(x,t) = \sum_{l\in\mathbb{Z}} u_l(x)\, e^{ilt}, \quad u_l \in H_0^1((0,\pi);\mathbb{C}),$$

$$u_{-l} = u_l^*, \quad \|u\|_{\sigma,s}^2 := \sum_{l\in\mathbb{Z}} \|u_l\|_{H^1}^2 (1+l^{2s})e^{2\sigma|l|} < \infty \Big\}$$

of 2π-periodic-in-time functions valued in $H^1((0,\pi);\mathbb{R})$ which have a bounded analytic extension on the complex strip $|\mathrm{Im}\, t| < \sigma$ with trace function on $|\mathrm{Im}\, t| = \sigma$ belonging to $H^s(\mathbb{T}; H^1((0,\pi);\mathbb{C}))$.

For $s > 1/2$, $X_{\sigma,s}$ is a multiplicative Banach algebra:

$$\|uv\|_{\sigma,s} \le c_s \|u\|_{\sigma,s} \|v\|_{\sigma,s} \quad \forall\, u, v \in X_{\sigma,s} \tag{6}$$

with

$$c_s := 2^s \Big(\sum_{n \in \mathbb{Z}} \frac{1}{1+n^{2s}} \Big)^{1/2}; \tag{7}$$

see, e.g., [6]. We shall use the notation X_σ, resp., $\| \, \|_\sigma$, for $X_{\sigma,1}$, resp., $\| \, \|_{\sigma,1}$.

1.2. The Lyapunov–Schmidt reduction. To find solutions of (3) we implement the Lyapunov–Schmidt reduction according to the decomposition

$$X_{\sigma,s} = V \oplus (W \cap X_{\sigma,s}),$$

where

$$V := H^1_0(0,\pi)\,, \qquad W := \Big\{ w = \sum_{l \neq 0} w_l(x)\, e^{ilt} \in X_{0,s} \Big\},$$

writing every $u \in X_{\sigma,s}$ as $u = u_0(x) + \sum_{l \neq 0} u_l(x)\, e^{ilt}$.

Projecting (3) with

$$u = v + w\,, \quad v \in V,\ w \in W\,,$$

yields

$$\begin{cases} -(pv')' = \mu \Pi_V f(v+w) & \text{(bifurcation equation)}, \\ L_\omega w = \mu \Pi_W f(v+w) & \text{(range equation)}, \end{cases} \tag{8}$$

where Π_V, Π_W denote the projectors, $f(u)(x,t) := f(x,t,u(x,t))$, and

$$L_\omega u := \omega^2 \rho(x) u_{tt} - (p(x) u_x)_x\,.$$

We shall find solutions of (8) when μ/ω is small. In this limit w tends to 0 and the bifurcation equation reduces to the time-independent equation

$$-(pv')' = \mu f_0(v) \tag{9}$$

because, by (4), for $w = 0$

$$\Pi_V f(v) = \Pi_V f_0(x, v(x)) + \Pi_V \bar f(x,t,v(x)) = f_0(v)\,.$$

The infinite-dimensional "0th order bifurcation equation" (9) is a second order ODE, which, under natural conditions on f_0, possesses nondegenerate solutions satisfying the boundary conditions $v(0) = v(\pi) = 0$.

Hypothesis (V). *The problem*

$$\begin{cases} -(p(x)v'(x))' = \mu f_0(x, v(x)), \\ v(0) = v(\pi) = 0 \end{cases} \tag{10}$$

admits a solution $\bar v \in H^1_0(0,\pi)$ which is nondegenerate, namely, the linearized equation

$$-(ph')' = \mu\, f_0'(\bar v) h$$

possesses in $H^1_0(0,\pi)$ only the trivial solution $h = 0$.

We note that, for $\mu = 0$, the trivial solution $\bar{v} = 0$ is nondegenerate, so, by the implicit function theorem, Hypothesis (V) is automatically satisfied for μ small. We deal also with the case μ not small; see, for example, Lemmas 2 and 3.

By the implicit function theorem, Hypothesis (V) implies the existence of a smooth map

$$(\mu, w) \mapsto v(\mu, w) \in V$$

such that $v(\mu, w)$ solves the bifurcation equation in (8); see Lemma 4.

Remark 2. For a discussion about the difficulties caused by a degenerate solution, we refer to [9].

Let λ_j denote the eigenvalues of the Sturm–Liouville problem

$$\begin{cases} -(p(x)y'(x))' = \lambda\rho(x)y(x), \\ y(0) = y(\pi) = 0 \end{cases} \tag{11}$$

and $\omega_j := \sqrt{\lambda_j}$. These are the frequencies of the free vibrations of the string (note that all the eigenvalues λ_j are positive). Physically, it is the sequence of the fundamental tone ω_1 and all its overharmonics $\omega_2, \omega_3, \dots$ which compose the musical note of the string.

For $\gamma \in (0, 1)$ we define

$$A_\gamma := \Big\{(\mu,\omega) \in (\mu_1,\mu_2) \times (\gamma, +\infty) \ : \ \frac{\mu}{\omega} < C'\gamma^5, \quad |\omega l - \omega_j| > \frac{\gamma}{l^\tau} \quad \forall\, l = 1, \dots, N_0, \quad j \geq 1\Big\}, \tag{12}$$

where ω_j are given by (11), and (μ_1, μ_2), $N_0 \in \mathbb{N}$, $C' > 0$ shall be fixed in the next theorem.

THEOREM 1 (existence). *Suppose $p(x), \rho(x) > 0$ are of class $H^3(0, \pi)$, f satisfies Hypothesis* (F)*, and Hypothesis* (V) *holds for some $\mu_0 \in [0, \bar{\mu}]$.*

Fix $\tau \in (1, 2)$, $\gamma \in (0, 1)$. There exist a neighborhood (μ_1, μ_2) of μ_0, $N_0 \in \mathbb{N}$, positive constants C, C' (depending on $\rho, p, f, \bar{\mu}, \bar{v}, \tau$), a map

$$\tilde{w} \in C^\infty(A_\gamma, X_{\sigma_0/2} \cap W),$$

and a Cantor set $B_\gamma \subset A_\gamma$ of positive measure such that, for all $(\mu, \omega) \in B_\gamma$,

$$\tilde{u}(\mu, \omega) := v(\mu, \tilde{w}(\mu, \omega)) + \tilde{w}(\mu, \omega) \in V \oplus (W \cap X_{\sigma_0/2}) \tag{13}$$

is a classical solution of (3) *and satisfies*

$$\tilde{u}(\cdot, t) \in H^3(0, \pi) \cap H^1_0(0, \pi) \quad \forall t \in \mathbb{R}\,.$$

The Cantor set B_γ is defined in (15) *and satisfies the measure estimate* (56)*.*

Furthermore, for all $(\mu, \omega) \in A_\gamma$ the following estimates hold:

$$\|\tilde{w}(\mu, \omega)\|_{\sigma_0/2} \leq C\frac{\mu}{\gamma\omega}\,, \quad \|v(\mu, \tilde{w}(\mu, \omega)) - v(\mu, 0)\|_{H^1} \leq C\frac{\mu}{\gamma\omega}, \tag{14}$$

and $\|v(\mu, 0) - \bar{v}\|_{H^1} \leq C|\mu - \mu_0|$.

The neighborhood (μ_1, μ_2) of μ_0 is fixed in Lemma 4, the integer N_0 is fixed in Lemma 9, and the constant C' is fixed in Lemma 13.

Estimate (14) shows how close the solution $\tilde u$ is to the static configuration $v(\mu,0)$; see Figure 1.

Remark 3. We underline that the function $\tilde w(\mu,\omega)$, as well as $\tilde u(\mu,\omega)$, is defined for all the values of the parameters $(\mu,\omega)\in A_\gamma$ and not only on the Cantor set B_γ ($\tilde w(\mu,\omega)$ is introduced in Lemma 11). What is true is that if $(\mu,\omega)\in B_\gamma$, then $\tilde w(\mu,\omega)$ solves the range equation; see Theorem 3. As a consequence, if $(\mu,\omega)\in B_\gamma$, then $\tilde u(\mu,\omega)$ solves (3).

The Cantor set B_γ is explicitly defined by

$$B_\gamma := \Big\{(\mu,\omega)\in(\mu_1,\mu_2)\times(2\gamma,+\infty)\,:\,|\omega l-\omega_j|>\frac{2\gamma}{l^\tau}\quad\forall\, l=1,\dots,N_0,\quad j\geq 1,$$

$$\frac{\mu}{\omega}<C'\gamma^5,\quad \Big|\omega l-\frac{j}{c}\Big|>\frac{2\gamma}{l^\tau},\quad |\omega l-\tilde\omega_j(\mu,\omega)|>\frac{2\gamma}{l^\tau}\quad\forall\, l,j\geq 1\Big\},\tag{15}$$

where

$$c:=\frac{1}{\pi}\int_0^\pi\Big(\frac{\rho(x)}{p(x)}\Big)^{1/2}dx\tag{16}$$

and $\tilde\lambda_j(\mu,\omega):=\tilde\omega_j^2(\mu,\omega)$ denote the eigenvalues of the Sturm–Liouville problem

$$\begin{cases}-(py')'-\mu\Pi_V f'(\tilde u(\mu,\omega))\,y=\lambda\rho y,\\ y(0)=y(\pi)=0\,.\end{cases}\tag{17}$$

Note that B_γ is constructed by means of the function $\tilde u(\mu,\omega)$, which is defined for all $(\mu,\omega)\in A_\gamma$; see Remark 3.

Remark 4. If some $\tilde\lambda_j(\mu,\omega)$ is negative, then $\tilde\omega_j(\mu,\omega)=i\sqrt{|\tilde\lambda_j(\mu,\omega)|}$ is a purely imaginary complex number and the nonresonance conditions in (15) are trivially satisfied.

The Cantor set B_γ is large in a measure theoretical sense; see section 4.3. In particular, for all $\mu\in(\mu_1,\mu_2)$,

$$S(\mu):=\big\{\omega:(\mu,\omega)\in\cup_{\gamma\in(0,1)}B_\gamma\big\}$$

has asymptotically full measure at $\omega\to+\infty$, i.e.,

$$\lim_{\omega\to+\infty}|S(\mu)\cap(\omega,\omega+1)|=1\,.\tag{18}$$

Analogously,

$$S(\omega):=\big\{\mu:(\mu,\omega)\in\cup_{\gamma\in(0,1)}B_\gamma\big\}$$

satisfies, for all $\omega'>0$ and for all $\gamma'\in(0,1)$,

$$\lim_{\mu\to0}\Big|\Big\{\omega\in(\omega',\omega'+1):\ \frac{|S(\omega)\cap(0,\mu)|}{\mu}\ \geq 1-\gamma'\Big\}\Big|=1\,.\tag{19}$$

Finally we discuss the regularity of the solution $\tilde u(x,t)$ found in Theorem 1 with respect to x (by construction $\tilde u$ is analytic with respect to t).

THEOREM 2 (regularity). *Assume the hypotheses of Theorem* 1. *In addition, suppose that, for some* $m\geq 3$,

$$\rho(x)\in H^m(0,\pi)\,,\quad p(x)\in H^{m+1}(0,\pi)\,,\quad f_{lk}(x)\in H^m(0,\pi)\ \ \forall\, l,k\tag{20}$$

and, for some $r_m > 0$,

$$\sum_{l\in\mathbb{Z},\, k\geq 0} \|f_{lk}\|_{H^m} r_m^k < +\infty\,. \tag{21}$$

If $\|\tilde u(\cdot\,,t)\|_{H^1} r_m^{-1}$ *is small enough, then*

$$\tilde u(\cdot\,,t) \in H^{m+2}(0,\pi)\cap H_0^1(0,\pi)\,. \tag{22}$$

This conclusion holds true, for example, when $f_0(x,0) = d_u f_0(x,0) = 0$ *and* $\mu/\gamma\omega$ *is small enough.*

Note that the regularity (22) requires no skewsymmetry assumptions on f and requires just a smallness condition for the H^1 norm of $\tilde u(\cdot\,,t)$.

Remark 5. If $f(x,t,u)$ is a trigonometric polynomial in t and a polynomial in u as in (5), then the series in (21) is a finite sum. Therefore the conclusion (22) is true without smallness conditions for $\tilde u$.

In particular, if $\rho(x)$, $p(x)$, $f_{lk}(x)$ are C^∞ (for example, $f = \cos x \cos t\,(1+u^2)$), then the solution $\tilde u$ is C^∞ also in the variable x (the above f does not satisfy the skewsymmetry assumption (24)).

The subtle problem to prove Theorem 2 is that, because of Dirichlet boundary conditions, the Sobolev regularity of a function with respect to x is *not* characterized by the rapid decaying properties of the Fourier coefficients (unless we assume skewsymmetry assumptions on the nonlinearity and restrict solutions to $u(x,t)$ odd in x; see Remark 6). Theorem 2 is proved in section 5 via bootstrap arguments.

1.3. Outline of the proof. In section 2 we prove that, under assumption (F), the composition operator induced by the nonlinearity f on $X_{\sigma,s}$ is an analytic map.

In section 3, we find a solution $v(\mu,w)$ of the infinite-dimensional bifurcation equation in (8). Thanks to assumption (V) (which is verified on several examples in Lemmas 2 and 3), $v(\mu,w)$ is obtained in Lemma 4 by a standard implicit function theorem.

In section 4 we solve the range equation by means of an iterative Nash–Moser implicit function theorem. The final theorem, Theorem 3, is proved in several steps.

In section 4.1 we find inductively a sequence of approximate solutions $w_n(\mu,\omega)$ defined on smaller and smaller subsets A_n of the parameters (μ,ω) (see (39)). The reason for these "excisions" is to avoid resonance phenomena in order to prove the invertibility of the linearized operators obtained at each step of the iteration; see conditions (33)–(34) in Lemma 7.

In section 4.2 we extend these approximate solutions $w_n(\mu,\omega)$ to C^∞-functions $\tilde w_n(\mu,\omega)$ defined for all the values of the parameters (μ,ω) and converging (superexponentially fast) to a C^∞ map $\tilde w$ defined for all (μ,ω); see Lemma 11. It is in proving the regularity of w_n with respect to the parameters (μ,ω) that we find it convenient to define the approximate solutions w_n as exact solutions of (41) (with $k=n$); see Remark 9.

In Lemma 12, we prove that the Cantor set B_γ, defined in (15) by means of $\tilde w$, is contained in A_n (which depends on w_{n-1}) for each n. This is a consequence of the superexponentially fast convergence of $\tilde w_n$ to $\tilde w$; see (52).

In section 4.3 we prove that B_γ is a large set in a measure theoretical sense.

In all the previous steps we have to assume smallness conditions for μ/ω. The most restrictive one is $\mu/\omega < C'\gamma^5$ in the definition (12) of A_γ.

In section 5 we conclude the proof of the existence Theorem 1, and we prove the regularity Theorem 2.

In section 6 we study the key step for the inversion of the linearized operators. Lemma 7 is obtained by a variant of the techniques developed in [8]. In particular, the key estimate on the small divisors of Lemma 18 is reminiscent of the method of Kuksin explained in [13, pp. 90–94].

Notation. The symbols K, K_i, K_i' shall denote positive constants depending only on $\rho, p, f, \bar\mu, \bar v, \tau$.

2. Regularity of the composition operator. We first prove the analyticity of the composition operator

$$u(x,t) \mapsto f(x,t,u(x,t))$$

induced by f on $X_{\sigma,s}$.

By the Banach algebra property (6) of $X_{\sigma,s}$ the composition operator

$$u \mapsto u^k \qquad \forall k \in \mathbb{N}$$

is an analytic map from $X_{\sigma,s}$ into itself. Thanks to the rapid decay of the coefficients $\|f_{lk}\|_{H^1}$ assumed in Hypothesis (F), this property holds true also for the composition operator $f(u)$.

LEMMA 1. *Let f satisfy assumption* (F). *For every $\sigma \in [0,\sigma_0]$, $s > 1/2$, the composition operator f is analytic on the ball $\{u \in X_{\sigma,s} : \|u\|_{\sigma,s} < r/c_s\}$, where c_s is defined in* (7).

Proof. First note that

$$\sum_{l\in\mathbb{Z}} \|u_l\|_\infty \le \sqrt{\frac{\pi}{2}} \sum_{l\in\mathbb{Z}} \|u_l\|_{H^1} \le \sqrt{\frac{\pi}{2}} \Big(\sum_{l\in\mathbb{Z}} \|u_l\|_{H^1}^2 (1+l^{2s}) \Big)^{1/2} \Big(\sum_{l\in\mathbb{Z}} \frac{1}{1+l^{2s}} \Big)^{1/2}$$

so $\|u\|_\infty \le c_s \|u\|_{\sigma,s}$ for all $u \in X_{\sigma,s}$, $\sigma \ge 0$, $s > 1/2$, and $f(x,t,u(x,t))$ is well-defined.

By definition of the norm $\|\cdot\|_{\sigma,s}$, there exists $C := C(\sigma_0, s) > 0$ such that for all $\sigma \in [0,\sigma_0]$ and for all $k \in \mathbb{N}$,

$$\big\| \sum_{l\in\mathbb{Z}} f_{lk}(x) e^{ilt} \big\|_{\sigma,s} \le C \, \big\| \sum_{l\in\mathbb{Z}} f_{lk}(x) e^{ilt} \big\|_{2\sigma_0,1} .$$

Next

$$\big\| \sum_{l\in\mathbb{Z}} f_{lk}(x) e^{ilt} \big\|_{2\sigma_0,1}^2 = \sum_{l\in\mathbb{Z}} \|f_{lk}\|_{H^1}^2 (1+l^2) e^{(2\sigma_0)2|l|} =: C_k^2(f) < +\infty$$

by assumption (F). Therefore $\sum_{l\in\mathbb{Z}} f_{lk}(x) e^{ilt} \in X_{\sigma,s}$ and

$$\big\| \sum_{l\in\mathbb{Z}} f_{lk}(x) e^{ilt} \big\|_{\sigma,s} \le C \, C_k(f) . \tag{23}$$

Using the algebra property (6) of $X_{\sigma,s}$ and (23)

$$\begin{aligned} \|f(u)\|_{\sigma,s} &\le \sum_{k=0}^\infty \big\| \big(\sum_{l\in\mathbb{Z}} f_{lk}(x) e^{ilt} \big) u^k \big\|_{\sigma,s} \\ &\le \sum_{k=0}^\infty c_s \big\| \sum_{l\in\mathbb{Z}} f_{lk}(x) e^{ilt} \big\|_{\sigma,s} \, \|u^k\|_{\sigma,s} \\ &\le C \sum_{k=0}^\infty C_k(f) \, (c_s \|u\|_{\sigma,s})^k < C \sum_{k=0}^\infty C_k(f) \, r^k < +\infty \end{aligned}$$

for $c_s\|u\|_{\sigma,s} < r$, by (F) again.

The analyticity of the composition operator f with respect to $\|\cdot\|_{\sigma,s}$ follows from the properties of the power series as explained in [25, Appendix A]. □

We emphasize that the analyticity of f as a map in $X_{\sigma,s}$ is not an assumption but follows from (F).

Remark 6. If $f(x,t,u)$ admits an analytic extension, which is 2π-periodic in x and skewsymmetric, namely,

$$f(-x,t,-u) = -f(x,t,u)\,, \tag{24}$$

then the Dirichlet problem on $[0,\pi]$ is equivalent to the 2π-periodic problem within the space of all functions odd in x. In this case also the spatial regularity is characterized by the decay properties of the Fourier coefficients. Therefore we could look for analytic solutions of (3),

$$u(x,t) = \sum_{l\in\mathbb{Z}} u_l(x)e^{ilt},$$

which are periodic and odd in x, more precisely with

$$u_l(x) \in Y := \Big\{ y(x) = \sum_{j\geq 1} y_j \sin(jx) \;:\; \sum_{j\geq 1} |y_j|^2 j^{2b} e^{2aj} < +\infty \Big\}$$

for some $a \geq 0$, $b > 1/2$. Without the oddness assumption (24) the composition operator f does not map this subspace into itself. It is for this reason that we consider the space $X_{\sigma,s}$ of functions valued in $H^1_0(0,\pi)$: also without (24), f sends $X_{\sigma,s}$ into itself (Lemma 1).

Throughout this paper we shall use spaces $X_{\sigma,s}$ with $\sigma \in [\sigma_0/2, \sigma_0]$ and $s \in \mathcal{S} := \{1,\, 1-\frac{\tau-1}{2},\, 1+\frac{(\tau-1)\tau}{2-\tau}\}$. So we choose $\bar{c} := \max_{s\in\mathcal{S}} c_s$ as a multiplicative algebra constant for all spaces $X_{\sigma,s}$.

By Lemma 1, f is analytic in the ball

$$\Big\{ u \in X_{\sigma,s} : \|u\|_{\sigma,s} < R_0 := \frac{r}{\bar{c}} \Big\}$$

and $f, f', f'', \ldots$ are bounded, uniformly in σ, s.

3. The bifurcation equation. Now we give some examples in which Hypothesis (V) holds.

LEMMA 2. *Suppose $f_0(x,u) = u^m$ for $m \geq 3$ odd and $p(x) \equiv 1$. Then, for all μ, there exists an unbounded sequence of nondegenerate solutions v_n of* (10).

Proof. All the solutions of the autonomous equation $-v'' = \mu v^m$ are periodic and can be parametrized by their energy

$$E = \frac{1}{2}\, v'^2 + \frac{\mu}{m+1}\, v^{m+1}\,.$$

Let T_E denote the period of the solution v_E. We can suppose $v_E(0) = 0$, so $v'_E(0) = \sqrt{2E}$. The other boundary condition $v_E(\pi) = 0$ is satisfied iff

$$k\frac{T_E}{2} = \pi \quad \text{for some } \; k \in \mathbb{N}\,. \tag{25}$$

By symmetry and energy conservation $v_E(T_E/4) = [(m+1)E/\mu]^{\frac{1}{m+1}}$. So

$$T_E = 4\int_0^{\left[\frac{(m+1)E}{\mu}\right]^{\frac{1}{m+1}}} \Big[2\Big(E - \frac{\mu\, x^{m+1}}{m+1}\Big)\Big]^{-1/2} dx$$

$$= \frac{4(m+1/\mu)^{\frac{1}{m+1}}}{E^{\frac{1}{2}-\frac{1}{m+1}}} \int_0^1 \frac{dy}{\sqrt{2(1-y^{m+1})}} =: \frac{C(m,\mu)}{E^{\frac{1}{2}-\frac{1}{m+1}}}$$

by the change of variable $y = x\,[E(m+1)/\mu]^{-\frac{1}{m+1}}$, and (25) is satisfied at infinitely many energy levels. Let $\bar E > 0$ such that $T_{\bar E} = 2\pi/k$ and denote the solution $\bar v := v_{\bar E}$.

Let us prove that $\bar v$ is nondegenerate. Any solution h of the linearized equation at $\bar v$,

$$-h''(x) = \mu m\, \bar v^{\,m-1}(x)\, h(x)\,, \tag{26}$$

can be written as $h = A\bar v' + B\beta$, $A, B \in \mathbb{R}$, because $\bar v'(x)$ and $\beta(x) := (\partial_E v_E)_{|E=\bar E}(x)$ are solutions of (26); they are independent because $\bar v'(0) \neq 0$ while $\beta(0) = 0$. If $h(0) = 0$, then $A = 0$. We claim that $\beta(\pi) \neq 0$; as a consequence, if $h(\pi) = 0$, then $B = 0$, and so $h = 0$, i.e., $\bar v$ is nondegenerate. To prove that $\beta(\pi) \neq 0$, we differentiate at $\bar E$ the identity $v_E(kT_E/2) = 0$,

$$\beta(\pi) + \bar v'(\pi)(\partial_E T_E)_{|E=\bar E} = 0\,.$$

Since $\bar v'(\pi) = (-1)^k\sqrt{2E} \neq 0$ and $\partial_E T_E \neq 0$, we get $\beta(\pi) \neq 0$. □

LEMMA 3. *If $f_0(x,0) = d_u f_0(x,0) = 0$, then $\bar v = 0$ is a nondegenerate solution of (10) for every μ.*

Proof. The linearized equation $-(ph')' = 0$, $h(0) = h(\pi) = 0$ has only the trivial solution. □

When Hypothesis (V) holds at some $(\mu_0, \bar v)$, we solve first the bifurcation equation in (8) using the standard implicit function theorem. We find, for every w small enough and μ in a neighborhood of μ_0, a unique solution $v(\mu, w)$ of the bifurcation equation.

LEMMA 4 (solution of the bifurcation equation). *There exist $0 < R < R_0$, a neighborhood $[\mu_1, \mu_2]$ of μ_0, and a C^∞ map*

$$[\mu_1, \mu_2] \times \big\{w \in W \cap X_{\sigma,s} \,:\, \|w\|_{\sigma,s} < R\big\} \to V, \quad (\mu, w) \mapsto v(\mu, w)$$

such that $v(\mu, w)$ solves the bifurcation equation in (8).

Proof. The linear operator

$$h \mapsto -(ph')' - \mu_0 d_v \Pi_V f(v)[h] = -(ph')' - \mu_0\, f_0'(v)\, h$$

is invertible on $H^1_0(0,\pi)$ by Hypothesis (V). Then we apply the implicit function theorem. □

Remark 7. The solutions of the 0th order bifurcation equation (10) found in Lemmas 2 and 3 are nondegenerate for every μ, so, in that case, we can continue $v(\mu, w)$ for all $[\mu_1, \mu_2] = [0, \bar\mu]$.

We denote by $\lambda_j(\mu, w) := \omega_j^2(\mu, w)$ the eigenvalues of the Sturm–Liouville problem

$$\begin{cases} -(py')' - \mu \Pi_V f'(v(\mu, w) + w)\, y = \lambda \rho y, \\ y(0) = y(\pi) = 0\,. \end{cases} \tag{27}$$

LEMMA 5. *The eigenvalues of* (27) *satisfy the continuity property*

$$|\lambda_j(\mu,w)-\lambda_j(\mu',w')|\le K\big(|\mu-\mu'|+\|w-w'\|_{\sigma,s}\big) \tag{28}$$

for some constant $K>0$ *independent of* j.

Proof. For the proof of the lemma, see the appendix. □

The nondegeneracy of $\bar v=v(\mu_0,0)$ means that $\lambda_j(\mu_0,0)\neq 0$ for all j. By (28),

$$\delta_0:=\inf\Big\{\big|\lambda_j(\mu,w)\big|:\ j\ge 1,\ \ \mu\in[\mu_1,\mu_2],\ \ \|w\|_{\sigma_0/2}\le R\Big\}>0, \tag{29}$$

taking, if necessary, $|\mu_2-\mu_1|$ and R smaller in Lemma 4.

Note also that the index j_0 of the smallest positive eigenvalue is constant, independently of (μ,w).

4. Solution of the range equation. It remains to solve the range equation

$$L_\omega w=\mu\Pi_W\mathcal{F}(\mu,w), \tag{30}$$

where

$$\mathcal{F}(\mu,w):=f(v(\mu,w)+w)\,.$$

By Lemmas 1 and 4, $\mathcal{F}$ is C^∞ and bounded, together with its derivatives, on $[\mu_1,\mu_2]\times B_R$, where $B_R:=\{w\in W\cap X_{\sigma,s}\ :\ \|w\|_{\sigma,s}<R\}$.

4.1. The Nash–Moser recursive scheme. We define the sequence of finite-dimensional subspaces

$$W^{(n)}:=\Big\{w=\sum_{1\le|l|\le N_n}w_l(x)e^{ilt}\Big\}\subset W,$$

where

$$N_n:=N_0 2^n$$

and $N_0\in\mathbb{N}$ will be fixed in Lemma 9. We also set

$$W^{(n)\perp}:=\Big\{w=\sum_{|l|>N_n}w_l(x)e^{ilt}\in W\Big\}$$

and denote by P_n, resp., $P_n^\perp$, the projection on $W^{(n)}$, resp., $W^{(n)\perp}$. Note that $P_n\circ\Pi_W=P_n$.

LEMMA 6 (smoothing estimate). *For* $w\in W^{(n)\perp}$, *if* $0<\sigma''<\sigma'$,

$$\|w\|_{\sigma'',s}\le\exp[-(\sigma'-\sigma'')N_n]\,\|w\|_{\sigma',s}\,. \tag{31}$$

Proof. It follows from the definition of the norms $\|\cdot\|_{\sigma,s}$ and $W^{(n)\perp}$; see, e.g., [16, 8]. □

The key property for the construction of the iterative sequence is the invertibility of the linear operator

$$\begin{aligned}\mathcal{L}_n(w)h&:=-L_\omega h+\mu P_n[d_w\mathcal{F}(\mu,w)h]\\&=-L_\omega h+\mu P_n\big[f'(v(\mu,w)+w)\big(h+d_wv(\mu,w)[h]\big)\big]\quad\forall\,h\in W^{(n)}\,.\end{aligned} \tag{32}$$

LEMMA 7 (inversion of the linear problem). *Let $\omega > 0$, $\tau \in (1,2)$, $\gamma \in (0,1)$, $\gamma < \omega$, and $\sigma \in (0, \sigma_0]$. Assume the "Melnikov" nonresonance conditions*

$$\left|\omega l - \frac{j}{c}\right| > \frac{\gamma}{l^\tau} \qquad \forall\, l = 1, 2, \dots, N_n, \quad \forall\, j \geq 1, \tag{33}$$

where c is defined in (16)*, and*

$$|\omega^2 l^2 - \lambda_j(\mu, w)| > \frac{\gamma\omega}{l^{\tau-1}} \qquad \forall\, l = 1, 2, \dots, N_n,\ j \geq 1, \tag{34}$$

where $\lambda_j(\mu, w)$ are the eigenvalues of (27)*.*

Let $u := v(\mu, w) + w$. There exist K_1, K_1' such that if

$$\frac{\mu}{\gamma^3\omega} \left\| \Pi_W f'(u) \right\|_{\sigma, 1+\frac{\tau(\tau-1)}{2-\tau}} < K_1' \,, \tag{35}$$

then $\mathcal{L}_n(w)$ is invertible and

$$\|\mathcal{L}_n(w)^{-1} h\|_\sigma \leq \frac{K_1 N_n^{\tau-1}}{\gamma\omega} \|h\|_\sigma \qquad \forall\, h \in W^{(n)} \,. \tag{36}$$

Proof. For the proof of the lemma, see section 6. □

Remark 8. The condition $\omega > 0$ means that (1) is nonautonomous. Indeed, if $\omega = 0$, the nonlinearity $f(x, \omega t, u) = f(x, 0, u)$ is independent of t.

For $\vartheta := 3\sigma_0/\pi^2$ we define the sequence

$$\sigma_{n+1} := \sigma_n - \frac{\vartheta}{(n+1)^2} \,, \qquad \sigma_0 > \sigma_1 > \sigma_2 > \cdots > \frac{\sigma_0}{2} \,. \tag{37}$$

Let A_0 denote the open set

$$A_0 := \Big\{ (\mu, \omega) \in (\mu_1, \mu_2) \times (\gamma, +\infty) \ :\ |\omega l - \omega_j| > \frac{\gamma}{l^\tau} \ \ \forall\, l = 1, \dots, N_0,\ j \geq 1 \Big\},$$

where ω_j are defined by (11).

LEMMA 8 (approximate solution). *There exist K_2, K_2' such that if $(\mu, \omega) \in A_0$ and $\mu N_0^{\tau-1}/\gamma\omega < K_2'$, then there exists a solution $w_0 := w_0(\mu, \omega) \in W^{(0)}$ of*

$$L_\omega w_0 = \mu P_0 \mathcal{F}(\mu, w_0)$$

satisfying $\|w_0\|_{\sigma_0} \leq \mu K_2 N_0^{\tau-1}/\gamma\omega$.

Proof. By definition of A_0, the eigenvalues of $(1/\rho)L_\omega$ satisfy

$$|\omega^2 l^2 - \lambda_j| > \frac{\gamma\omega}{l^{\tau-1}} \qquad \forall\, l = 1, 2, \dots, N_0, \quad j \geq 1 \,,$$

so L_ω is invertible on $W^{(0)}$ and, for some K,

$$\|L_\omega^{-1} h\|_{\sigma_0} \leq \frac{K N_0^{\tau-1}}{\gamma\omega} \|h\|_{\sigma_0} \qquad \forall\, h \in W^{(0)} \,. \tag{38}$$

Then we look for a solution $w_0 \in W^{(0)}$ of $w_0 = \mu L_\omega^{-1} P_0 \mathcal{F}(\mu, w_0)$. The right-hand side term is a contraction in $\{\|w_0\|_{\sigma_0} < R\}$ if $\mu N_0^{\tau-1}/\gamma\omega$ is sufficiently small. □

Given $w_n \in W^{(n)}$, $\|w_n\|_{\sigma_n} < R$, and $A_n \subseteq A_0$, we define

$$A_{n+1} := \Big\{ (\mu,\omega) \in A_n \,:\, \big|\omega l - \omega_j(\mu,w_n)\big| > \frac{\gamma}{l^\tau}\,, \quad \Big|\omega l - \frac{j}{c}\Big| > \frac{\gamma}{l^\tau} \qquad \forall\, l = 1,2,\dots,N_{n+1},\ \ j \ge 1 \Big\} \subseteq A_n, \tag{39}$$

where $\lambda_j(\mu,w_n) = \omega_j^2(\mu,w_n)$ are defined in (27) with $w = w_n$.

In Lemma 8 we have constructed $h_0 := w_0$ for $(\mu,\omega) \in A_0$. Next, we proceed by induction. By means of w_0 we define the set A_1 as above, and we find $w_1 := h_0 + h_1 \in W^{(1)}$ for every $(\mu,\omega) \in A_1$ by Lemma 9 below. Then we define A_2, we find $w_2 \in W^{(2)}$, and so on. The main goal of the construction is to prove that, at the end of the recurrence, the set of parameters $(\mu,\omega) \in \cap_n A_n$ is actually a large set (see Lemmas 12 and 13).

LEMMA 9 (inductive step). *Fix $\chi := 3/2$. There exist $N_0 \in \mathbb{N}$ (depending only on $\rho, p, f, \bar\mu, \bar v, \tau$) and $K_3' \le K_2'/N_0^{\tau-1}$ with the following property.*

Suppose that $h_i \in W^{(i)}$ for all $i = 0,\dots,n$ satisfy

$$\|h_i\|_{\sigma_i} < \frac{\mu K_3 N_0^{\tau-1}}{\gamma\omega} \exp(-\chi^i), \tag{40}$$

where $K_3 := eK_2$ and K_2 is the constant in Lemma 8; for all $k = 0,\dots,n$, let $w_k := h_0 + \cdots + h_k$ satisfy $\|w_k\|_{\sigma_k} < R$ and

$$L_\omega w_k = \mu P_k \mathcal{F}(\mu, w_k) \tag{41}$$

and suppose that $(\mu,\omega) \in A_n$, where A_{i+1} is constructed by means of w_i as shown above.

If $(\mu,\omega) \in A_{n+1}$ and $\mu/\gamma^3\omega < K_3'$, then there exists $h_{n+1} \in W^{(n+1)}$ satisfying

$$\|h_{n+1}\|_{\sigma_{n+1}} < \frac{\mu K_3 N_0^{\tau-1}}{\gamma\omega}\, \exp(-\chi^{n+1}) \tag{42}$$

such that $w_{n+1} = w_n + h_{n+1}$ verifies $\|w_{n+1}\|_{\sigma_{n+1}} < R$ and

$$L_\omega w_{n+1} = \mu P_{n+1} \mathcal{F}(\mu, w_{n+1})\,. \tag{43}$$

Proof. In short $\mathcal{F}(w) := \mathcal{F}(\mu,w)$ and $D\mathcal{F}(w) := d_w\mathcal{F}(\mu,w)$. Equation (43) for $w_{n+1} = w_n + h_{n+1}$ is $L_\omega[w_n + h_{n+1}] = \mu P_{n+1}\mathcal{F}(w_n + h_{n+1})$.

By assumption, w_n satisfies (41) for $k = n$, namely, $L_\omega w_n = \mu P_n \mathcal{F}(w_n)$, so the equation for h_{n+1} can be written as

$$\mathcal{L}_{n+1}(w_n)h_{n+1} + \mu(P_{n+1} - P_n)\mathcal{F}(w_n) + \mu P_{n+1} Q = 0, \tag{44}$$

where, as defined in (32), $\mathcal{L}_{n+1}(w_n)h_{n+1} := -L_\omega h_{n+1} + \mu P_{n+1} D\mathcal{F}(w_n)h_{n+1}$, and Q denotes the quadratic remainder

$$Q = Q(w_n, h_{n+1}) := \mathcal{F}(w_{n+1}) - \mathcal{F}(w_n) - D\mathcal{F}(w_n)h_{n+1}\,.$$

Step 1. *Inversion of $\mathcal{L}_{n+1}(w_n)$.* We verify the assumptions of Lemma 7. By definition of A_{n+1}, ω satisfies (33). If $\lambda_j(\mu,w_n) < 0$, then $|\omega^2 l^2 - \lambda_j(\mu,w_n)| \ge \omega^2 l^2 > \gamma\omega/l^{\tau-1}$ because $\omega > \gamma$. If $\lambda_j(\mu,w_n) > 0$, we have

$$|\omega^2 l^2 - \lambda_j(\mu,w_n)| \ge |\omega l - \omega_j(\mu,w_n)|\omega l > \frac{\gamma\omega}{l^{\tau-1}} \qquad \forall\, l = 1,\dots,N_{n+1}$$

because $(\mu,\omega) \in A_{n+1}$. In both cases the nonresonance condition (34) holds.

To verify (35) we need an estimate for w_n. Let $\eta := \tau(\tau-1)/(2-\tau)$ and $\alpha > 0$. Using the elementary inequality

$$\frac{1+l^{2(1+\eta)}}{1+l^2}\cdot\frac{e^{2(\sigma-\alpha)|l|}}{e^{2\sigma|l|}} \le \frac{2l^{2\eta}}{e^{2\alpha|l|}} \le 2\max_{y>0}(y^{2\eta}e^{-2\alpha y}) = 2\Big(\frac{\eta}{\alpha e}\Big)^{2\eta} \quad \forall\, l\neq 0\,,$$

we deduce

$$\|h_i\|_{\sigma_{n+1},1+\eta} \le \frac{C_\eta}{(\sigma_i-\sigma_{n+1})^\eta}\,\|h_i\|_{\sigma_i},$$

where $C_\eta := \sqrt{2}(\eta/e)^\eta$. Since $\sigma_i-\sigma_{n+1} \ge \sigma_i-\sigma_{i+1}$ for every $i \le n$,

$$\|w_n\|_{\sigma_{n+1},1+\eta} \le \sum_{i=0}^{n}\|h_i\|_{\sigma_{n+1},1+\eta} \le C_\eta\sum_{i=0}^{n}\frac{\|h_i\|_{\sigma_i}}{(\sigma_i-\sigma_{i+1})^\eta} \le S_\eta\,\frac{\mu K_3 N_0^{\tau-1}}{\gamma\omega},$$

using (40) where $S_\eta := (C_\eta/\vartheta^\eta)\sum_{i=0}^{+\infty}(i+1)^{2\eta}\exp(-\chi^i) < +\infty$. If

$$\frac{S_\eta\,\mu K_3 N_0^{\tau-1}}{\gamma\omega} < R,$$

then

$$\|f'(u_n)\|_{\sigma_{n+1},1+\eta} \le K$$

for some K, where $u_n := v(\mu,w_n)+w_n$. Hence Hypothesis (35) is verified for $\mu/\gamma^3\omega$ sufficiently small.

Analogously we get $\|w_n\|_{\sigma_n} < R$ if $\mu N_0^{\tau-1}/\gamma\omega$ is small enough.

By Lemma 7 the operator $\mathcal{L}_{n+1}(w_n)$ is invertible on $W^{(n+1)}$ and

$$\|\mathcal{L}_{n+1}(w_n)^{-1}h\|_{\sigma_{n+1}} \le \frac{K_1 N_{n+1}^{\tau-1}}{\gamma\omega}\,\|h\|_{\sigma_{n+1}} \quad \forall h\in W^{(n+1)}\,. \tag{45}$$

Equation (44) amounts to the fixed point problem

$$h_{n+1} = -\mu\mathcal{L}_{n+1}(w_n)^{-1}\big[(P_{n+1}-P_n)\mathcal{F}(w_n)+P_{n+1}Q\big] := \mathcal{G}(h_{n+1})$$

for $h_{n+1}\in W^{(n+1)}$.

Step 2. $\mathcal{G}$ *is a contraction.* We prove that $\mathcal{G}$ is a contraction on the ball $B_{n+1} := \{\|h\|_{\sigma_{n+1}} < r_{n+1}\}$, where $r_{n+1} := (\mu K_3 N_0^{\tau-1}/\gamma\omega)\exp(-\chi^{n+1})$, implying (42). By (31)

$$\|(P_{n+1}-P_n)\mathcal{F}(w_n)\|_{\sigma_{n+1}} \le \|\mathcal{F}(w_n)\|_{\sigma_n}\exp[-(\sigma_n-\sigma_{n+1})N_n]\,.$$

Since $\|w_n\|_{\sigma_n} < R$, we have $\|Q\|_{\sigma_{n+1}} \le K\|h_{n+1}\|^2_{\sigma_{n+1}}$. Hence, by (45),

$$\|\mathcal{G}(h_{n+1})\|_{\sigma_{n+1}} \le K\,\frac{\mu N_{n+1}^{\tau-1}}{\gamma\omega}\Big(\exp[-(\sigma_n-\sigma_{n+1})N_n] + \|h_{n+1}\|^2_{\sigma_{n+1}}\Big)\,.$$

Therefore $\mathcal{G}(B_{n+1}) \subseteq B_{n+1}$ if

$$\frac{\mu K N_{n+1}^{\tau-1}}{\gamma\omega}\,\exp[-(\sigma_n-\sigma_{n+1})N_n] < \frac{r_{n+1}}{2}\,, \qquad \frac{\mu K N_{n+1}^{\tau-1}}{\gamma\omega}\,r_{n+1}^2 < \frac{r_{n+1}}{2}\,. \tag{46}$$

By the definition of σ_n in (37) and $N_n := N_0 2^n$, the first inequality is verified for every $n \geq 0$ if $\sigma_0 N_0$ is greater than a constant depending only on χ, K, K_3. The second inequality is verified for every $n \geq 0$ if $\mu N_0^{\tau-1}/\gamma\omega$ is small enough.

The estimate for $\|\mathcal{G}h - \mathcal{G}k\|$, $h, k \in B_{n+1}$ is similar. The lemma now follows from the contraction mapping theorem. □

Remark 9. In the previous scheme h_{n+1} is found as an exact solution of (44). We find this convenient to prove the regularity of h_{n+1} with respect to the parameters (μ, ω) in Lemma 10. However, other schemes are possible. For example, we could define h_{n+1} as a solution of the linearized equation $\mathcal{L}_{n+1}(w_n)h + \mu(P_{n+1} - P_n)\mathcal{F}(w_n) = 0$.

COROLLARY 1 (existence). *Suppose* $A_\infty := \cap_{n\geq 0} A_n \neq \emptyset$. *If* $(\mu, \omega) \in A_\infty$ *and* $\mu/\gamma^3\omega < K_3'$, *then*

$$w_\infty(\mu, \omega) := \sum_{n\geq 0} h_n(\mu, \omega) \in W \cap X_{\sigma_0/2}$$

is a solution of the range equation (30) *satisfying* $\|w_\infty\|_{\sigma_0/2} \leq K_\infty \mu/\gamma\omega$ *for some* K_∞.

Proof. Since w_n solves (41) for $k = n$,

$$-L_\omega w_n + \mu \Pi_W f(u_n) = \mu P_n^\perp f(u_n) \in W^{(n)\perp},$$

where $u_n := v(\mu, w_n) + w_n$. By (31)

$$\lim_{n\to+\infty} \| - L_\omega w_n + \mu f(u_n)\|_{\sigma_0/2} \leq \lim_{n\to+\infty} K \exp[-(\sigma_n - \sigma_0/2)N_n] = 0\,.$$

Since $w_n \to w_\infty$ in $\|\cdot\|_{\sigma_0/2}$ also $f(u_n) \to f(u_\infty)$ in the same norm, while $L_\omega w_n \to L_\omega w_\infty$ in the sense of distributions. So w_∞ is a weak solution of the range equation (30). □

Remark 10. We shall prove, as a consequence of Lemma 12 and section 4.3, that A_∞ is actually a positive measure set. One possible way to prove it uses the Whitney extension of w_∞ of section 4.2.

4.2. Whitney C^∞ extension. The functions h_n constructed in Lemmas 8 and 9 depend smoothly on the parameters (μ, ω).

LEMMA 10. *There exist* K_4 *and* $K_4' \leq K_3'$ *such that the maps*

$$h_i : A_i \cap \{\mu/\gamma^3\omega < K_4'\} \to W^{(i)}$$

are C^∞ *and*

$$\|\partial_\omega h_i(\mu, \omega)\|_{\sigma_i} \leq \frac{K_4 \mu}{\gamma^2 \omega} \exp(-\chi_0^i), \quad \|\partial_\mu h_i(\mu, \omega)\|_{\sigma_i} \leq \frac{K_4}{\gamma\omega} \exp(-\chi_0^i),$$

where $\chi_0 := (1 + \chi)/2 = 5/4$.

Proof. Since $w_0 = \mu L_\omega^{-1} P_0 \mathcal{F}(\mu, w_0)$, by the implicit function theorem the map w_0 is C^∞. Differentiating the identity $L_\omega(L_\omega^{-1}h) = h$ with respect to ω, by (38) we get $\|\partial_\omega L_\omega^{-1} h\|_{\sigma_0} \leq (K/\gamma^2\omega)\,\|h\|_{\sigma_0}$. For $\mu/\gamma\omega$ small,

$$\|\partial_\omega w_0\|_{\sigma_0} \leq \frac{K\mu}{\gamma^2\omega}\,.$$

Differentiating with respect to μ we get $\|\partial_\mu w_0\|_{\sigma_0} \leq K'/\gamma\omega$ for some K'.

By induction, suppose that h_i depends smoothly on $(\mu,\omega)\in A_i$ for every $i=0,\dots,n$. For $(\mu,\omega)\in A_{n+1}$, by (43), h_{n+1} is a solution of

$$-L_\omega h_{n+1}+\mu P_{n+1}[\mathcal{F}(w_n+h_{n+1})-\mathcal{F}(w_n)]+\mu(P_{n+1}-P_n)\mathcal{F}(w_n)=0\,. \tag{47}$$

By the implicit function theorem $h_{n+1}\in C^\infty$ once we prove that

$$\mathcal{L}_{n+1}(w_{n+1})[z]:=-L_\omega z+\mu P_{n+1}D\mathcal{F}(w_n+h_{n+1})[z]$$

is invertible. By (45), $\mathcal{L}_{n+1}(w_n)$ is invertible. Hence it is sufficient that

$$\Big\|\mathcal{L}_{n+1}^{-1}(w_n)(\mathcal{L}_{n+1}(w_{n+1})-\mathcal{L}_{n+1}(w_n))\Big\|_{\sigma_{n+1}}<\frac{1}{2}\,,$$

which holds true for $\mu^2/\gamma\omega$ small enough; indeed, by (42),

$$\|\mathcal{L}_{n+1}(w_{n+1})-\mathcal{L}_{n+1}(w_n)\|_{\sigma_{n+1}}\le K\mu\|h_{n+1}\|_{\sigma_{n+1}}\le\frac{\mu^2K'N_0^{\tau-1}}{\gamma\omega}\,\exp(-\chi^{n+1})\,.$$

Finally (45) implies

$$\|\mathcal{L}_{n+1}(w_{n+1})^{-1}\|_{\sigma_{n+1}}\le\frac{2K_1N_{n+1}^{\tau-1}}{\gamma\omega}\,. \tag{48}$$

Differentiating (47) with respect to ω

$$\begin{aligned}\mathcal{L}_{n+1}(w_{n+1})[\partial_\omega h_{n+1}]&=2\omega\rho(x)(h_{n+1})_{tt}-\mu(P_{n+1}-P_n)D\mathcal{F}(w_n)\partial_\omega w_n\\&\quad-\mu P_{n+1}\big[D\mathcal{F}(w_n+h_{n+1})-D\mathcal{F}(w_n)\big]\partial_\omega w_n\end{aligned} \tag{49}$$

and, using (48) and (31),

$$\begin{aligned}\|\partial_\omega h_{n+1}\|_{\sigma_{n+1}}\le\frac{KN_{n+1}^{\tau-1}}{\gamma\omega}\Big(&\omega N_{n+1}^2\|h_{n+1}\|_{\sigma_{n+1}}+\frac{\mu\|\partial_\omega w_n\|_{\sigma_n}}{\exp[(\sigma_n-\sigma_{n+1})N_n]}\\&+\mu\|h_{n+1}\|_{\sigma_{n+1}}\|\partial_\omega w_n\|_{\sigma_n}\Big)\,.\end{aligned}$$

We note that $\|\partial_\omega w_n\|_{\sigma_n}\le\sum_{i=0}^n\|\partial_\omega h_i\|_{\sigma_i}$. Using (46) the sequence $a_n:=\|\partial_\omega h_n\|_{\sigma_n}$ satisfies

$$\begin{aligned}a_{n+1}&\le\frac{KN_{n+1}^{\tau-1}}{\gamma\omega}\Big(\omega N_{n+1}^2r_{n+1}+\frac{\omega\gamma r_{n+1}}{N_{n+1}^{\tau-1}}\sum_{i=0}^n a_i+\mu r_{n+1}\sum_{i=0}^n a_i\Big)\\&\le b_{n+1}\Big(1+\sum_{i=0}^n a_i\Big),\quad\text{where }\ b_{n+1}:=\frac{K\mu}{\gamma^2\omega}\,N_{n+1}^{\tau+1}\,\exp(-\chi^{n+1}),\end{aligned}$$

recalling that $r_{n+1}=(\mu K/\gamma\omega)\exp(-\chi^{n+1})$. By induction, for $K\mu/\omega\gamma^2<1$, we have $a_n\le 2b_n$ and

$$\|\partial_\omega h_{n+1}\|_{\sigma_{n+1}}\le\frac{K\mu}{\gamma^2\omega}\,N_{n+1}^{\tau+1}\exp(-\chi^{n+1})\le\frac{K'\mu}{\gamma^2\omega}\,\exp(-\chi_0^{n+1}),$$

where $\chi_0:=(1+\chi)/2$. It follows that $\|\partial_\omega w_{n+1}\|_{\sigma_{n+1}}\le K\mu/\gamma^2\omega$.

Differentiating (47) with respect to μ we obtain the estimate for $\partial_\mu h_{n+1}$. □

Define, for $\nu_0 > 0$,

$$A_n^* := \Big\{(\mu,\omega) \in A_n \,:\, \mathrm{dist}\big((\mu,\omega),\, \partial A_n\big) > \frac{\nu_0\gamma^4}{N_n^3}\Big\}, \tag{50}$$

$$\tilde{A}_n := \Big\{(\mu,\omega) \in A_n \,:\, \mathrm{dist}\big((\mu,\omega),\, \partial A_n\big) > \frac{2\nu_0\gamma^4}{N_n^3}\Big\} \subset A_n^* .$$

LEMMA 11 (Whitney extension). *There exists a C^∞ map*

$$\tilde{w} : A_0 \cap \Big\{(\mu,\omega) : \frac{\mu}{\gamma^3\omega} < K_4^{'}\Big\} \to W \cap X_{\sigma_0/2}$$

satisfying

$$\|\tilde{w}(\mu,\omega)\|_{\sigma_0/2} \le \frac{K_5\mu}{\gamma\omega}, \tag{51}$$

$$\|\partial_\omega\tilde{w}(\mu,\omega)\|_{\sigma_0/2} \le \frac{C(\nu_0)\mu}{\gamma^5\omega}, \quad \|\partial_\mu\tilde{w}(\mu,\omega)\|_{\sigma_0/2} \le \frac{C(\nu_0)}{\gamma^5\omega}$$

for some K_5 and for some $C(\nu_0) > 0$, such that, for $(\mu,\omega) \in \tilde{A}_\infty := \cap_{n\ge 0}\tilde{A}_n$, $\tilde{w}(\mu,\omega)$ solves the range equation (30).

Moreover there exists a sequence of C^∞ maps

$$\tilde{w}_n : A_0 \cap \Big\{(\mu,\omega) : \frac{\mu}{\gamma^3\omega} < K_4^{'}\Big\} \to W^{(n)}$$

such that $\tilde{w}_n(\mu,\omega) = w_n(\mu,\omega)$ for $(\mu,\omega) \in \tilde{A}_n$, and

$$\|\tilde{w}(\mu,\omega) - \tilde{w}_n(\mu,\omega)\|_{\sigma_0/2} \le \frac{K_5\mu}{\gamma\omega}\,\exp(-\chi^n). \tag{52}$$

Proof. Let $\varphi : \mathbb{R}^2 \to \mathbb{R}^+$ be a C^∞-function supported in the open ball $B(0,1)$ of center 0 and radius 1 and with $\int_{\mathbb{R}^2}\varphi = 1$. Let $\varphi_n : \mathbb{R}^2 \to \mathbb{R}^+$ be the mollifier

$$\varphi_n(x) := \frac{N_n^6}{\nu_0^2\gamma^8}\,\varphi\Big(\frac{N_n^3}{\nu_0\gamma^4}\,x\Big).$$

$\mathrm{Supp}\,(\varphi_n) \subset B(0,\nu_0\gamma^4/N_n^3)$ and $\int_{\mathbb{R}^2}\varphi_n = 1$. We define $\psi_n : \mathbb{R}^2 \to \mathbb{R}$ as

$$\psi_n(x) := \big(\varphi_n * \chi_{A_n^*}\big)(x) = \int_{\mathbb{R}^2}\varphi_n(y-x)\chi_{A_n^*}(y)\,dy,$$

where $\chi_{A_n^*}$ is the characteristic function of the set A_n^*. ψ_n is C^∞,

$$|D\psi_n(x)| \le \int_{\mathbb{R}^2}|D\varphi_n(x-y)|\,\chi_{A_n^*}(y)\,dy \le \frac{N_n^3}{\nu_0\gamma^4}\,C, \tag{53}$$

where $C := \int_{\mathbb{R}^2}|D\varphi|\,dy$,

$$0 \le \psi_n(x) \le 1, \qquad \mathrm{supp}(\psi_n) \subset A_n, \qquad \psi_n(x) = 1 \;\; \forall\, x \in \tilde{A}_n .$$

We define, for $(\mu,\omega)\in A_0$, the C^∞-functions

$$\tilde h_n(\mu,\omega):=\begin{cases}\psi_n(\mu,\omega)h_n(\mu,\omega) & \text{if } (\mu,\omega)\in A_n,\\ 0 & \text{if } (\mu,\omega)\notin A_n,\end{cases}$$

and

$$\tilde w_n(\mu,\omega):=\sum_{i=0}^{n}\tilde h_i\,,\qquad \tilde w(\mu,\omega):=\sum_{i\ge 0}\tilde h_i,$$

which is a series if $(\mu,\omega)\in A_\infty:=\cap_{n\ge0}A_n$.

The estimate for $\|\tilde w\|_{\sigma_0/2}$ follows by $\|\tilde h_i\|_{\sigma_i}\le\|h_i\|_{\sigma_i}$ (because $0\le\psi_i\le1$) and (40). The estimates for the derivatives in (51) follow by differentiating the product $\tilde h_i=\psi_i h_i$ and using (53), (40), and Lemma 10. Similarly it follows that $\tilde w$ is in C^∞; see [8] for details.

For $(\mu,\omega)\in\tilde A_n$, $\psi_n(\mu,\omega)=1$, implying $\tilde w_n=w_n$. As a consequence, for $(\mu,\omega)\in\tilde A_\infty:=\cap_{n\ge0}\tilde A_n$, by Corollary 1, $\tilde w=w_\infty$ solves (30).

Finally, using (40),

$$\|\tilde w-\tilde w_n\|_{\sigma_0/2}\le\sum_{i\ge n+1}\|\tilde h_i\|_{\sigma_i}\le\sum_{i\ge n+1}\frac{K\mu}{\gamma\omega}\exp(-\chi^i)\le\frac{K'\mu}{\gamma\omega}\exp(-\chi^n)\,.\qquad\square$$

In the next lemma we fix the constant ν_0 introduced in (50).

LEMMA 12. *There exist $\nu_0>0$ and $K_5'\le K_4'$ such that if $\mu/\gamma^3\omega<K_5'$, then*

$$B_\gamma\subseteq\tilde A_n\subset A_n\quad\forall\, n\ge0,$$

where B_γ is defined in (15) *taking $C'\le K_5'$.*

Proof. The proof is by induction. Let $(\mu,\omega)\in B_\gamma$. Then $(\mu,\omega)\in\tilde A_0$ if A_0 contains the closed ball of center (μ,ω) and radius $2\nu_0\gamma^4/N_0^3$. Let (ω',μ') belong to such a ball. Then, for all $l=1,\dots,N_0$,

$$|\omega' l-\omega_j|\ge|\omega l-\omega_j|-|\omega-\omega'|l>\frac{2\gamma}{l^\tau}-\frac{2\nu_0\gamma^4}{N_0^3}\,l\ge\frac{\gamma}{l^\tau}$$

if $\nu_0\le1/2$.

Suppose now that $B_\gamma\subseteq\tilde A_n$ and let $(\mu,\omega)\in B_\gamma$. To prove that $(\mu,\omega)\in\tilde A_{n+1}$, we have to show that the closed ball of center (μ,ω) and radius $2\nu_0\gamma^4/N_{n+1}^3$ is contained in A_{n+1}. Let (μ',ω') belong to such a ball. The nonresonance condition on $|\omega' l-j/c|$ is verified, as above, for $\nu_0\le1/2$. For the other condition, we denote in short $\omega_j^n(\mu',\omega'):=\omega_j(\mu',w_n(\mu',\omega'))$ (see (27) for the definition of $\omega_j(\mu,w)$). It results, for all $l=1,\dots,N_{n+1}$, in

$$\begin{aligned}|\omega' l-\omega_j^n(\mu',\omega')|&\ge|\omega l-\tilde\omega_j(\mu,\omega)|-|\omega-\omega'|l-|\omega_j^n(\mu',\omega')-\tilde\omega_j(\mu,\omega)|\\&>\frac{2\gamma}{l^\tau}-\frac{2\nu_0\gamma^4 l}{N_{n+1}^3}-|\omega_j^n(\mu',\omega')-\tilde\omega_j(\mu,\omega)|\\&>\frac{3\gamma}{2l^\tau}-|\omega_j^n(\mu',\omega')-\tilde\omega_j(\mu,\omega)|\end{aligned}\tag{54}$$

if $\nu_0 \le 1/4$. Now we estimate the last term

$$|\omega_j^n(\mu',\omega') - \tilde\omega_j(\mu,\omega)| = \frac{|\lambda_j^n(\mu',\omega') - \tilde\lambda_j(\mu,\omega)|}{|\tilde\omega_j(\mu,\omega)| + |\omega_j^n(\mu',\omega')|} \le \frac{|\lambda_j^n(\mu',\omega') - \tilde\lambda_j(\mu,\omega)|}{\sqrt{\delta_0}}$$

by (29), both for $j < j_0$ and for $j \ge j_0$. By the comparison principle (28)

$$\delta_0^{-1/2}|\lambda_j^n(\mu',\omega') - \tilde\lambda_j(\mu,\omega)| \le K|\mu-\mu'| + K\|w_n(\mu',\omega') - \tilde w(\mu,\omega)\|_{\sigma_0/2}\,.$$

By Lemma 10, $\|\partial_\omega w_n\|_{\sigma_0/2}$, $\|\partial_\mu w_n\|_{\sigma_0/2} \le K/\gamma^2\omega$ for some other K, and being $\omega,\omega' > \gamma$,

$$K\|w_n(\mu',\omega') - w_n(\mu,\omega)\|_{\sigma_0/2} \le \frac{K'}{\gamma^3}\,\frac{\nu_0\gamma^4}{N_{n+1}^3} < \frac{\gamma}{8l^\tau} \quad \forall l = 1,\dots,N_{n+1}$$

if ν_0 is small enough ($1 < \tau < 2$). On the other hand, since $(\mu,\omega) \in \tilde A_n$ we have $w_n(\mu,\omega) = \tilde w_n(\mu,\omega)$ (Lemma 11) and, by (52),

$$K\|w_n(\mu,\omega) - \tilde w(\mu,\omega)\|_{\sigma_0/2} \le \frac{K'\mu}{\gamma\omega}\,\exp(-\chi^n) < \frac{\gamma}{8l^\tau} \quad \forall l = 1,\dots,N_{n+1}$$

for $\mu/\gamma^2\omega$ sufficiently small. By (54), collecting the previous estimates,

$$|\omega' l - \omega_j^n(\mu',\omega')| > \frac{\gamma}{l^\tau} \quad \forall l = 1,\dots,N_{n+1}$$

and (μ',ω') belongs to A_{n+1}. □

4.3. Measure of the Cantor set B_γ. In the following $R := (\mu',\mu'') \times (\omega',\omega'')$ denotes a rectangle contained in the region $\{(\mu,\omega) \in [\mu_1,\mu_2] \times (2\gamma,+\infty) : \mu < K_6'\gamma^5\omega\}$. Furthermore we consider $\omega'' - \omega'$ as a fixed quantity ("of order 1").

LEMMA 13. *There exist K_6 and $K_6' \le K_5'$ such that, taking $C' \le K_6'$ in the definition* (15) *of B_γ, for all $\mu \in (\mu_1,\mu_2)$ the section*

$$S_\gamma(\mu) := \{\omega : (\mu,\omega) \in B_\gamma\}$$

satisfies the measure estimate

$$|S_\gamma(\mu) \cap (\omega',\omega'')| \ge (1 - K_6\gamma)(\omega'' - \omega')\,. \tag{55}$$

As a consequence, for every $R := (\mu',\mu'') \times (\omega',\omega'')$

$$|B_\gamma \cap R| \ge |R|\,(1 - K_6\gamma)\,. \tag{56}$$

Proof. We consider the inequalities $|\omega l - \tilde\omega_j(\mu,\omega)| > 2\gamma/l^\tau$ in the definition of B_γ. The analogous inequalities for $|\omega l - \omega_j|$ and $|\omega l - j/c|$ are simpler because j/c and ω_j do not depend on (μ,ω).

The complementary set we have to estimate is

$$\mathcal{C} := \bigcup_{l,j\ge 1} \mathcal{R}_{lj},$$

where $\mathcal{R}_{lj} := \{\omega \in (\omega',\omega'') : |l\omega - \tilde\omega_j(\mu,\omega)| \le 2\gamma/l^\tau\}$.

We claim that

$$\left|\partial_\omega \tilde\omega_j(\mu,\omega)\right| \le \frac{K\mu}{\gamma^5\omega}\,. \tag{57}$$

Indeed, by the same arguments as in the proof of Lemma 12 and the comparison principle (28), we have

$$|\tilde\omega_j(\mu,\omega)-\tilde\omega_j(\mu,\omega')| \le K\|\tilde w(\mu,\omega)-\tilde w(\mu,\omega')\|_{\sigma_0/2} \le \frac{K\mu}{\gamma^5\omega}\,|\omega-\omega'|$$

using (51). As a consequence of (57)

$$\partial_\omega\big(l\omega-\tilde\omega_j(\mu,\omega)\big) \ge l-\frac{K\mu}{\gamma^5\omega} \ge \frac{l}{2} \qquad \forall l\ge 1$$

for $\mu/\gamma^5\omega$ small enough; we deduce $|\mathcal{R}_{lj}| \le 4\gamma/l^{\tau+1}$.

Furthermore the set $\mathcal{R}_{lj}$ is nonempty only if

$$\omega' l-\frac{2\gamma}{l^\tau} < \tilde\omega_j(\mu,\omega) < \omega'' l+\frac{2\gamma}{l^\tau}\,.$$

So, for every fixed l, the number of indices j such that $\mathcal{R}_{lj}\neq\emptyset$ is

$$\sharp\{j\} \le \frac{1}{\delta}\left(l(\omega''-\omega')+\frac{4\gamma}{l^\tau}\right)+1 \le Kl(\omega''-\omega'),$$

where

$$\delta := \inf\Big\{\,|\tilde\omega_{j+1}(\mu,\omega)-\tilde\omega_j(\mu,\omega)|\,:\,j\ge 1,\ (\mu,\omega)\in B_\gamma\Big\}\,.$$

For $\|\tilde w\|_{\sigma_0/2} \le K'\mu/\gamma\omega < R$ we have $\delta\ge\delta_1$, where

$$\delta_1 := \inf\Big\{\big|\omega_{j+1}(\mu,w)-\omega_j(\mu,w)\big|\,:\,j\ge 1\,,\ \mu\in[\mu_1,\mu_2],\ \|w\|_{\sigma_0/2}\le R\Big\} > 0, \tag{58}$$

as proved in the appendix.

In conclusion, the measure of the complementary set is

$$|\mathcal{C}| \le \sum_{l=1}^{+\infty}\frac{4\gamma}{l^{\tau+1}}\,K\,l(\omega''-\omega') \le K'(\omega''-\omega')\gamma$$

and (55) is proved. Integrating on (μ',μ'') we obtain (56). □

By Fubini's theorem also the section $S_\gamma(\omega)$ is large for ω in a large set.

LEMMA 14. *Let*

$$S_\gamma(\omega) := \{\mu\,:\,(\mu,\omega)\in B_\gamma\}\,.$$

For every $R := (\mu',\mu'')\times(\omega',\omega'')$, $\gamma'\in(0,1)$ *we obtain*

$$\left|\left\{\omega\in(\omega',\omega'')\,:\,\frac{|S_\gamma(\omega)\cap(\mu',\mu'')|}{\mu''-\mu'}\ge 1-\gamma'\right\}\right| \ge (\omega''-\omega')\Big(1-K_6\frac{\gamma}{\gamma'}\Big)\,. \tag{59}$$

Proof. Consider

$$\Omega^+ := \big\{\omega\in(\omega',\omega'')\,:\,|S_\gamma(\omega)\cap(\mu',\mu'')|\ge(\mu''-\mu')(1-\gamma')\big\}\,,$$

$$\Omega^- := \big\{\omega\in(\omega',\omega'')\,:\,|S_\gamma(\omega)\cap(\mu',\mu'')|<(\mu''-\mu')(1-\gamma')\big\}\,.$$

Using Fubini's theorem

$$|B_\gamma \cap R| = \int_{\omega'}^{\omega''} |S_\gamma(\omega) \cap (\mu', \mu'')|\, d\omega$$

$$= \int_{\Omega^+} |S_\gamma(\omega) \cap (\mu', \mu'')|\, d\omega + \int_{\Omega^-} |S_\gamma(\omega) \cap (\mu', \mu'')|\, d\omega$$

$$\leq (\mu'' - \mu')|\Omega^+| + (\mu'' - \mu')(1 - \gamma')|\Omega^-|\,. \tag{60}$$

By (56), $|B_\gamma \cap R| \geq (\omega'' - \omega')(\mu'' - \mu')(1 - K_6\gamma)$ and therefore, by (60),

$$(\omega'' - \omega')(1 - K_6\gamma) \leq |\Omega^+| + (1 - \gamma')|\Omega^-| = (\omega'' - \omega') - \gamma'|\Omega^-| \tag{61}$$

because $|\Omega^+| + |\Omega^-| = \omega'' - \omega'$. Then

$$|\Omega^-| \leq (\omega'' - \omega')K_6 \frac{\gamma}{\gamma'}$$

and, by the first inequality in (61), $|\Omega^+| \geq (\omega'' - \omega')(1 - K_6\gamma/\gamma')$, which is (59). ∎

Inequalities (55) and (59) imply the measure estimates (18)–(19).

The main conclusions of this section are summarized in the following theorem, which follows by Lemmas 11, 12, and 13.

THEOREM 3 (solution of the range equation). *There exist* $\tilde{w} \in C^\infty(A_\gamma,\ W \cap X_{\sigma_0/2})$ *satisfying* (51) *and the large (see* (56)*) Cantor set* B_γ *defined in* (15) *such that, for every* $(\mu, \omega) \in B_\gamma$*, the function* $\tilde{w}(\mu, \omega)$ *solves the range equation* (30)*.*

5. Proof of Theorems 1 and 2.

Proof of Theorem 1. By Theorem 3 for all $(\mu, \omega) \in B_\gamma$ the function $\tilde{w}(\mu, \omega) \in X_{\sigma_0/2}$ solves the range equation (30). By Lemma 4, $v(\mu, \tilde{w}(\mu, \omega))$ solves the bifurcation equation in (8), and therefore

$$\tilde{u} := v(\mu, \tilde{w}(\mu, \omega)) + \tilde{w}(\mu, \omega) \in X_{\sigma_0/2}$$

is a solution of (3). Estimates (14) follow by (51).

Since $\tilde{u}$ solves

$$-(p(x)\tilde{u}_x)_x = \mu f(x, t, \tilde{u}) - \omega^2 \rho(x)\tilde{u}_{tt} \tag{62}$$

we deduce

$$-(p(x)\tilde{u}_x(t, x))_x \in H^1(0, \pi) \qquad \forall t \in \mathbb{R}\,.$$

This implies, since $p(x) \in H^3(0, \pi)$, that

$$\tilde{u}(t, x) \in H^3(0, \pi) \cap H_0^1(0, \pi) \subset C^2(0, \pi) \quad \forall t \in \mathbb{R}\,. \qquad ∎$$

Proof of Theorem 2. For every fixed t, by the algebra property of H^m

$$\big\|f(x, t, u(x, t))\big\|_{H^m} \leq \sum_{l,k} \|f_{lk}(x)u^k(x)\|_{H^m} \leq K \sum_{l,k} \|f_{lk}\|_{H^m}\, \|u^k\|_{H^m}$$

for some $K > 0$.

Using the Gagliardo–Nirenberg-type inequality

$$\|u^k\|_{H^m} \le (C_m\|u\|_{H^1})^{k-1}\|u\|_{H^m}$$

valid for every $u \in H^1_0 \cap H^m$ (see, e.g., [26, 20]), we get

$$\big\|f(x,t,u(x,t))\big\|_{H^m} \le K\|u\|_{H^m}\sum_{l,k}\|f_{lk}\|_{H^m}\big(C_m\|u\|_{H^1}\big)^{k-1}, \tag{63}$$

which is convergent for $\|u\|_{H^1} < r_m/C_m$ by (21).

The solution $\tilde u$ satisfies (62) and $\tilde u(\cdot\,,t) \in H^3(0,\pi)$ for all t.

By assumption $\|\tilde u\|_{H^1} < r_m/C_m$. By induction, assume $\tilde u(\cdot\,,t) \in H^k$ for $k = 3,\dots,m$. Hence $\tilde u_{tt}(\cdot\,,t) \in H^k$ and $\rho(x)\tilde u_{tt}(\cdot\,,t) \in H^k$ because $\rho \in H^m$. Furthermore, by (63), $f(x,t,\tilde u) \in H^k$. We deduce, by (62), that $p(x)\tilde u_x \in H^{k+1}$. Finally $\tilde u \in H^{k+2}$ because $p \in H^{m+1}$.

If $f_0(x,0) = d_u f_0(x,0) = 0$, then, by Lemma 3, we can take $v(\mu,0) = 0$ for all μ. Therefore, by (14),

$$\|\tilde u(t,\cdot)\|_{H^1} \le \|\tilde u\|_{\sigma_0/2} \le \frac{2C\mu}{\gamma\omega} \quad \forall t\,,$$

and, for $\mu/\gamma\omega$ small enough, we deduce the regularity in (22). □

6. Inversion of the linearized problem. Here we prove Lemma 7. Decomposing in Fourier series

$$f'(u) = \sum_{k\in\mathbb{Z}} a_k(x)e^{ikt}$$

we write, for all $h = \sum_{1\le|l|\le N_n} h_l(x)e^{ilt} \in W^{(n)}$,

$$\begin{aligned}
-L_\omega h + \mu P_n[f'(u)h] &= \sum_{1\le|l|\le N_n}\big[\omega^2 l^2\rho h_l + \partial_x\big(p\,\partial_x h_l\big)\big]e^{ilt} \\
&\quad + \mu P_n\Big[\Big(\sum_{k\in\mathbb{Z}} a_k e^{ikt}\Big)\Big(\sum_{1\le|l|\le N_n} h_l e^{ilt}\Big)\Big] \\
&= \sum_{1\le|l|\le N_n}\big[\omega^2 l^2\rho h_l + \partial_x\big(p\,\partial_x h_l\big) + \mu a_0 h_l\big]e^{ilt} \\
&\quad + \mu \sum_{|l|,|k+l|\in\{1,\dots,N_n\},\,k\neq 0} a_k\,h_l\,e^{i(k+l)t}\,.
\end{aligned}$$

Hence $\mathcal{L}_n(w)$ defined in (32) can be decomposed as

$$\mathcal{L}_n(w)h = \rho\,\big(Dh + M_1 h + M_2 h\big), \tag{64}$$

where

$$\begin{aligned}
Dh &:= \frac{1}{\rho}\sum_{|l|=1}^{N_n}\big[\omega^2 l^2\rho\,h_l + \big(p\,h_l'\big)' + \mu a_0\,h_l\big]e^{ilt}, \\
M_1 h &:= \frac{\mu}{\rho}\sum_{|l|,|k|\in\{1,\dots,N_n\},\,l\neq k} a_{k-l}\,h_l\,e^{ikt}, \qquad (65)\\
M_2 h &:= \frac{\mu}{\rho}\,P_n\big[f'(u)\,d_w v(\mu,w)[h]\big]\,.
\end{aligned}$$

Note that D is a diagonal operator in time Fourier basis. To study the eigenvalues of D, we use Sturm–Liouville-type techniques.

LEMMA 15 (Sturm–Liouville). *The eigenvalues $\lambda_j(\mu,w)$ of the Sturm–Liouville problem* (27) *form a strictly increasing sequence which tends to $+\infty$. Every $\lambda_j(\mu,w)$ is simple and the following asymptotic formula holds:*

$$\lambda_j(\mu,w)=\frac{j^2}{c^2}+b+M(\mu,w)+r_j(\mu,w),\qquad |r_j(\mu,w)|\le\frac{K}{j} \tag{66}$$

for all $j\ge 1$, $(\mu,w)\in[\mu_1,\mu_2]\times B_R$, where

$$c:=\frac{1}{\pi}\int_0^\pi\Big(\frac{\rho}{p}\Big)^{1/2}dx,\qquad b:=\frac{1}{4\pi c}\int_0^\pi\left[\frac{(\rho p)'}{\rho\sqrt[4]{\rho p}}\right]'\frac{1}{\sqrt[4]{\rho p}}\,dx,$$

$$M(\mu,w):=-\frac{\mu}{c\pi}\int_0^\pi\frac{\Pi_V f'(v(\mu,w)+w)}{\sqrt{\rho p}}\,dx\,.$$

The eigenfunctions $\varphi_j(\mu,w)$ of (27) *form an orthonormal basis of $L^2(0,\pi)$ with respect to the scalar product $(y,z)_{L^2_\rho}:=c^{-1}\int_0^\pi yz\rho\,dx$. For K big enough*

$$(y,z)_{\mu,w}:=\frac{1}{c}\int_0^\pi p\,y'z'+\big[K\rho-\mu\Pi_V f'(v(\mu,w)+w)\big]\,yz\,dx$$

defines an equivalent scalar product on $H^1_0(0,\pi)$ and

$$K'\|y\|_{H^1}\le\|y\|_{\mu,w}\le K''\,\|y\|_{H^1}\quad\forall y\in H^1_0\,. \tag{67}$$

$\varphi_j(\mu,w)$ is also an orthogonal basis of $H^1_0(0,\pi)$ with respect to the scalar product $(\cdot,\cdot)_{\mu,w}$ and, for $y=\sum_{j\ge1}\hat y_j\,\varphi_j(\mu,w)$,

$$\|y\|^2_{L^2_\rho}=\sum_{j\ge1}\hat y_j^2\,,\qquad \|y\|^2_{\mu,w}=\sum_{j\ge1}\hat y_j^2\big(\lambda_j(\mu,w)+K\big)\,. \tag{68}$$

Proof. For the proof of the lemma, see the appendix. □

We develop

$$Dh=\sum_{1\le|l|\le N_n}D_l h_l e^{ilt},$$

where

$$D_l z:=\frac{1}{\rho}\left[\omega^2l^2\rho z+\big(p\,z'\big)'+\mu a_0 z\right]\quad\forall\,z\in H^1_0(0,\pi)$$

and $a_0=\Pi_V f(v(\mu,w)+w)$.

By Lemma 15 each D_l is diagonal with respect to the basis $\varphi_j(\mu,w)$:

$$z=\sum_{j=1}^{+\infty}\hat z_j\,\varphi_j(\mu,w)\in H^1_0(0,\pi)\quad\Rightarrow\quad D_l z=\sum_{j=1}^{+\infty}\big(\omega^2l^2-\lambda_j(\mu,w)\big)\hat z_j\,\varphi_j(\mu,w)\,.$$

LEMMA 16. *Suppose all the eigenvalues $\omega^2l^2-\lambda_j(\mu,w)$ are not zero. Then*

$$|D_l|^{-1/2}z:=\sum_{j=1}^{+\infty}\frac{\hat z_j\,\varphi_j(\mu,w)}{\sqrt{|\omega^2l^2-\lambda_j(\mu,w)|}}$$

satisfies

$$\big\| |D_l|^{-1/2} z \big\|_{H^1} \leq \frac{K}{\sqrt{\alpha_l}} \|z\|_{H^1} \quad \forall z \in H^1_0(0,\pi), \tag{69}$$

where $\alpha_l := \min_{j\geq 1} |\omega^2 l^2 - \lambda_j(\mu, w)| > 0$.

Proof. By (68) $\| |D_l|^{-1/2} z\|^2_{\mu,w} \leq (1/\alpha_l) \|z\|^2_{\mu,w}$. Hence (69) follows by the equivalence of the norms (67). □

LEMMA 17 (inversion of D). *Assume the nonresonance condition* (34). *Then* $|D|^{-1/2} : W^{(n)} \to W^{(n)}$ *defined by*

$$|D|^{-1/2} h := \sum_{1\leq |l|\leq N_n} |D_l|^{-1/2} h_l \, e^{ilt}$$

satisfies

$$\| |D|^{-1/2} h\|_{\sigma,s} \leq \frac{K}{\sqrt{\gamma\omega}} \|h\|_{\sigma, s+\frac{\tau-1}{2}} \leq \frac{K N_n^{\frac{\tau-1}{2}}}{\sqrt{\gamma\omega}} \|h\|_{\sigma,s} \quad \forall\, h \in W^{(n)}\,.$$

Proof. By (69) and $\alpha_{-l} = \alpha_l \geq \gamma\omega/|l|^{\tau-1}$

$$\begin{aligned}
\| |D|^{-1/2} h\|^2_{\sigma,s} &= \sum_{1\leq |l|\leq N_n} \| |D_l|^{-1/2} h_l\|^2_{H^1} (1+l^{2s}) e^{2\sigma|l|} \\
&\leq \sum_{1\leq |l|\leq N_n} \frac{K^2 |l|^{\tau-1}}{\gamma\omega} \|h_l\|^2_{H^1} (1+l^{2s}) e^{2\sigma|l|} \\
&\leq \frac{K'}{\gamma\omega} \|h\|^2_{\sigma, s+\frac{\tau-1}{2}}
\end{aligned}$$

because $|l|^{\tau-1}(1+l^{2s}) < 2(1+|l|^{2s+\tau-1})$ for all $|l| \geq 1$. □

To prove the invertibility of $\mathcal{L}_n(w)$ we write (64) as

$$\mathcal{L}_n(w) = \rho |D|^{1/2} \big(U + T_1 + T_2\big) |D|^{1/2}, \tag{70}$$

where

$$\begin{cases} U := |D|^{-1/2}\, D\, |D|^{-1/2}, \\ T_i := |D|^{-1/2}\, M_i\, |D|^{-1/2}\,, \quad i = 1,2\,. \end{cases} \tag{71}$$

With respect to the basis $\varphi_j(\mu, w)\, e^{ilt}$ the operator U is diagonal and its (l,j)th eigenvalue is $\mathrm{sign}(\omega^2 l^2 - \lambda_j(\mu,w)) \in \{\pm 1\}$, implying that the operator norm is

$$\|U\|_\sigma := \sup_{\|h\|_\sigma \leq 1} \|Uh\|_\sigma = 1\,. \tag{72}$$

The smallness of T_1 requires an analysis of the small divisors. Formula (66) implies, by Taylor expansion, the asymptotic dispersion relation

$$\Big| \omega_j(\mu, w) - \frac{j}{c} \Big| \leq \frac{K}{j}, \tag{73}$$

and there exists K such that, for every $x \geq 0$,

$$|x^2 - \lambda_{j^*}(\mu, w)| = \min_{j \geq 1} |x^2 - \lambda_j(\mu, w)| \quad \Rightarrow \quad j^* \geq Kx\,. \tag{74}$$

LEMMA 18 (analysis of the small divisors). *Assume the nonresonance conditions* (33)–(34) *and* $\omega > \gamma$. *Then for all* $|k|, |l| \in \{1, \dots, N_n\}$, $k \neq l$,

$$\alpha_l \alpha_k \geq \left(\frac{K\gamma^3 \omega}{|k-l|^{\frac{\tau(\tau-1)}{2-\tau}}} \right)^2,$$

where $\alpha_l := \min_{j \geq 1} |\omega^2 l^2 - \lambda_j(\mu, w)|$.

Proof. Since $\alpha_{-l} = \alpha_l$ for all l, we can suppose $l, k \geq 1$.

We distinguish two cases, if k, l are close to or far from each other. Let $\beta := (2-\tau)/\tau \in (0,1)$.

Case 1. Let $2|k-l| > (\max\{k,l\})^\beta$. By (34)

$$\alpha_k \alpha_l \geq \frac{(\gamma\omega)^2}{(kl)^{\tau-1}} \geq \frac{(\gamma\omega)^2}{(\max\{k,l\})^{2(\tau-1)}} \geq \frac{C(\gamma\omega)^2}{|k-l|^{\frac{2(\tau-1)}{\beta}}}\,.$$

Case 2. Let $0 < 2|k-l| \leq (\max\{k,l\})^\beta$. In this case $2k \geq l \geq k/2$. Indeed, if $k > l$, then $2(k-l) \leq k^\beta$, so $2l \geq 2k - k^\beta \geq k$ because $\beta \in (0,1)$—analogously if $l > k$.

Let i, resp., j, be an integer which realizes the minimum α_k, resp., α_l, and write in short $\lambda_j(\mu) := \lambda_j(\mu, w)$, $\omega_j(\mu) := \omega_j(\mu, w)$.

If both $\lambda_i(\mu), \lambda_j(\mu) \leq 0$, then $\alpha_l \geq \omega^2 l^2$, $\alpha_k \geq \omega^2 k^2$, $\alpha_l \alpha_k \geq \omega^4 > \gamma^2 \omega^2$.

If only $\lambda_j(\mu) \leq 0$, then $\alpha_l \alpha_k \geq \gamma \omega^3 l^2 / k^{\tau-1} \geq 2^{1-\tau} \gamma \omega^3 \geq 2^{1-\tau} \gamma^2 \omega^2$.

The really resonant cases happen if $\lambda_i(\mu), \lambda_j(\mu) > 0$. Suppose, for example, that $\max\{k,l\} = k$. By (73), $|\omega_j(\mu) - (j/c)| \leq K/j$, and, by (74), $i \geq K\omega k$, $j \geq K\omega l$. Hence, using also (33),

$$\begin{aligned} |(\omega k - \omega_i(\mu)) - (\omega l - \omega_j(\mu))| &= \big|\omega(k-l) - (\omega_i(\mu) - \omega_j(\mu))\big| \\ &\geq \Big|\omega(k-l) - \frac{i-j}{c}\Big| - \frac{K}{\omega l} - \frac{K}{\omega k} \\ &\geq \frac{\gamma}{(k-l)^\tau} - \frac{3K}{\omega k} \geq \frac{2^\tau \gamma}{k^{\beta\tau}} - \frac{3K}{\omega k} \end{aligned}$$

because $2(k-l) \leq k^\beta$, $2l \geq k$. Since $\beta\tau < 1$ and $k \leq 2l$,

$$\big|(\omega k - \omega_i(\mu)) - (\omega l - \omega_j(\mu))\big| \geq \frac{1}{2}\Big(\frac{\gamma}{k^{\beta\tau}} + \frac{\gamma}{l^{\beta\tau}}\Big) \quad \forall\, k \geq \Big(\frac{K}{\omega\gamma}\Big)^{\frac{1}{1-\beta\tau}} =: k^*\,.$$

We reach the same conclusion if $\max\{k,l\} = l$. It follows that, for $\max\{k,l\} \geq k^*$, there holds $|\omega k - \omega_i(\mu)| \geq \gamma/2k^{\beta\tau}$ or $|\omega l - \omega_j(\mu)| \geq \gamma/2l^{\beta\tau}$. Suppose $|\omega k - \omega_i(\mu)| \geq \gamma/2k^{\beta\tau}$. Then

$$\alpha_k = |\omega^2 k^2 - \omega_i^2(\mu)| \geq |\omega k - \omega_i(\mu)| \omega k \geq \frac{\gamma\omega}{2}\, k^{1-\beta\tau}\,.$$

Since $l \leq 2k$, for α_l we can use (34),

$$\alpha_k \alpha_l \geq \frac{\gamma\omega k^{1-\beta\tau}}{2} \frac{\gamma\omega}{l^{\tau-1}} \geq \frac{\gamma^2\omega^2}{2^\tau}\, k^{2-\tau-\beta\tau} = \frac{\gamma^2\omega^2}{2^\tau}$$

because $2 - \tau - \beta\tau = 0$.

On the other hand, if $\max\{k,l\} < k^* = (K/\omega\gamma)^{1/(\tau-1)}$, we can use (34) for both k, l:

$$\alpha_k\alpha_l \geq \frac{(\gamma\omega)^2}{(kl)^{\tau-1}} > \frac{(\gamma\omega)^2}{(k^*)^{2(\tau-1)}} = (\gamma\omega)^2 \left(\frac{\omega\gamma}{K}\right)^{\frac{1}{\tau-1}\,2(\tau-1)} > \frac{\gamma^6\omega^2}{K^2}$$

(using $\omega > \gamma$). Since $\gamma < 1$, taking the minimum for all these cases concludes the proof. □

LEMMA 19 (estimate of T_1). *Assume the nonresonance conditions* (33)–(34), $\omega > \gamma$, *and* $\Pi_W f'(u) = \sum_{l\neq 0} a_l(x)e^{ilt} \in X_{\sigma,1+\frac{\tau(\tau-1)}{2-\tau}}$. *There exists* K *such that*

$$\|T_1 h\|_\sigma \leq \frac{K\mu}{\gamma^3\omega}\,\|\Pi_W f'(u)\|_{\sigma,1+\frac{\tau(\tau-1)}{2-\tau}}\,\|h\|_\sigma \quad \forall h \in W^{(n)}\,.$$

Proof. For all $h \in W^{(n)}$, $T_1 h = \sum_{1\leq|k|\leq N_n} (T_1 h)_k\, e^{ikt}$, where

$$\begin{aligned}(T_1 h)_k &= |D_k|^{-1/2}\big(M_1|D|^{-1/2}h\big)_k \\ &= |D_k|^{-1/2}\left[\sum_{1\leq|l|\leq N_n,\, l\neq k} \mu\,\frac{a_{k-l}}{\rho}\,|D_l|^{-1/2}h_l\right].\end{aligned}$$

Setting $A_m := \|a_m/\rho\|_{H^1}$, using (69) and Lemma 18, we obtain

$$\|(T_1 h)_k\|_{H^1} \leq K\,\mu \sum_{1\leq|l|\leq N_n,\, l\neq k} \frac{A_{k-l}}{\sqrt{\alpha_k}\sqrt{\alpha_l}}\,\|h_l\|_{H^1} \;\leq\; \frac{K\mu}{\gamma^3\omega}\,S_k, \tag{75}$$

where

$$S_k := \sum_{|l|\leq N_n,\, l\neq k} A_{k-l}\,|k-l|^{\frac{\tau(\tau-1)}{2-\tau}}\|h_l\|_{H^1}\,.$$

By (75) we get, defining $S(t) := \sum_{|k|=1}^{N_n} S_k\, e^{ikt}$,

$$\begin{aligned}\|T_1 h\|_\sigma^2 &= \sum_{|k|=1}^{N_n} \|(T_1 h)_k\|_{H^1}^2 (1+k^2)e^{2\sigma|k|} \\ &\leq \left(\frac{K\mu}{\gamma^3\omega}\right)^2 \sum_{|k|=1}^{N_n} S_k^2(1+k^2)e^{2\sigma|k|} = \left(\frac{K\mu}{\gamma^3\omega}\right)^2 \|S\|_\sigma^2\,.\end{aligned}$$

Since $S = P_n(\varphi\psi)$ with $\varphi(t) := \sum_{l\in\mathbb{Z}} A_l|l|^{\frac{\tau(\tau-1)}{2-\tau}}\, e^{ilt}$ and $\psi(t) := \sum_{|l|=1}^{N_n} \|h_l\|_{H^1}\, e^{ilt}$

$$\|T_1 h\|_\sigma \leq \frac{K\mu}{\gamma^3\omega}\,\|\varphi\|_\sigma\|\psi\|_\sigma \leq \frac{K\mu}{\gamma^3\omega}\,\Big\|\Pi_W f'(u)\Big\|_{\sigma,1+\frac{\tau(\tau-1)}{2-\tau}}\,\|h\|_\sigma$$

because $\|\varphi\|_\sigma \leq 2\|\Pi_W f'(u)\|_{\sigma,1+\frac{\tau(\tau-1)}{2-\tau}}$ and $\|\psi\|_\sigma = \|h\|_\sigma$. □

LEMMA 20 (estimate of T_2). *Suppose that* $\Pi_W f'(u) \in X_{\sigma,1+\frac{\tau-1}{2}}$. *Then*

$$\|T_2 h\|_\sigma \leq \frac{K\mu}{\gamma\omega}\,\|\Pi_W f'(u)\|_{\sigma,1+\frac{\tau-1}{2}}\,\|h\|_\sigma \qquad \forall\, h \in W^{(n)}$$

for some K.

Proof. By the definitions (71) and (65) and by Lemma 17,

$$\begin{aligned}\|T_2h\|_\sigma &\le \frac{K}{\sqrt{\gamma\omega}}\,\|M_2|D|^{-1/2}h\|_{\sigma,1+\frac{\tau-1}{2}}\\ &\le \frac{K'\mu}{\sqrt{\gamma\omega}}\,\|\Pi_W f'(u)\|_{\sigma,1+\frac{\tau-1}{2}}\,\big\|d_w v(\mu,w)\big[\,|D|^{-1/2}h\big]\,\big\|_{\sigma,1+\frac{\tau-1}{2}}\\ &= \frac{K'\mu}{\sqrt{\gamma\omega}}\,\|\Pi_W f'(u)\|_{\sigma,1+\frac{\tau-1}{2}}\,\big\|d_w v(\mu,w)\big[\,|D|^{-1/2}h\big]\,\big\|_{H^1}\end{aligned}$$

because $d_w v(\mu,w)[|D|^{-1/2}h] \in V$. By Lemmas 4 and 17

$$\big\|d_w v(\mu,w)\big[\,|D|^{-1/2}h\big]\,\big\|_{H^1} \le K\,\|\,|D|^{-1/2}h\|_{\sigma,1-\frac{\tau-1}{2}} \le \frac{K}{\sqrt{\gamma\omega}}\,\|h\|_{\sigma,1},$$

implying the thesis. □

Proof of Lemma 7. By (72), $\|U\|_\sigma = 1$. If

$$\|T_1+T_2\|_\sigma < \frac{1}{2}\,, \tag{76}$$

then by Neumann series $U+T_1+T_2$ is invertible in $(W^{(n)},\|\ \|_\sigma)$ and

$$\|(U+T_1+T_2)^{-1}\|_\sigma < 2\,.$$

By Lemmas 19 and 20, condition (76) is verified if

$$\|T_1\|_\sigma \le \frac{K\mu}{\gamma^3\omega}\,\|\Pi_W f'(u)\|_{\sigma,1+\frac{\tau(\tau-1)}{2-\tau}} < \frac{1}{4} \tag{77}$$

and

$$\|T_2\|_\sigma \le \frac{K\mu}{\gamma\omega}\,\|\Pi_W f'(u)\|_{\sigma,1+\frac{\tau-1}{2}} \le \frac{K\mu}{\gamma^3\omega}\,\|\Pi_W f'(u)\|_{\sigma,1+\frac{\tau(\tau-1)}{2-\tau}} < \frac{1}{4} \tag{78}$$

(we recall that $\gamma \in (0,1)$ and $(\tau-1)/2 < \tau(\tau-1)/(2-\tau)$ because $\tau > 1$). Both conditions (77) and (78) are satisfied if

$$\frac{\mu}{\gamma^3\omega}\,\|\Pi_W f'(u)\|_{\sigma,1+\frac{\tau(\tau-1)}{2-\tau}} < \frac{1}{4K} =: K_1'\,,$$

which is condition (35). Hence, inverting (70)

$$\mathcal{L}_n(w)^{-1}h = |D|^{-1/2}\big(U+T_1+T_2\big)^{-1}|D|^{-1/2}\Big(\frac{h}{\rho}\Big)\,,$$

which, using Lemma 17, yields (36). □

7. Appendix.

Proof of Lemma 15. Let $a(x) \in L^2(0,\pi)$. Under the "Liouville change of variable"

$$x = \psi(\xi) \;\Leftrightarrow\; \xi = g(x), \qquad g(x) := \frac{1}{c}\int_0^x \Big(\frac{\rho(s)}{p(s)}\Big)^{1/2} ds\,, \tag{79}$$

we have that $(\lambda, y(x))$ satisfies

$$\begin{cases} -(p(x)y'(x))' + a(x)y(x) = \lambda\rho(x)y(x), \\ y(0) = y(\pi) = 0 \end{cases} \tag{80}$$

iff $(\nu, z(\xi))$ satisfies

$$\begin{cases} -z''(\xi) + [q(\xi) + \alpha(\xi)]\, z(\xi) = \nu z(\xi), \\ z(0) = z(\pi) = 0, \end{cases} \tag{81}$$

where

$$\nu = c^2\lambda, \qquad r(x) = \sqrt[4]{p(x)\,\rho(x)}, \qquad z(\xi) = y(\psi(\xi))\, r(\psi(\xi)),$$
$$\alpha(\xi) = c^2\, \frac{a(\psi(\xi))}{\rho(\psi(\xi))}\,, \qquad q(\xi) = c^2 Q(\psi(\xi)), \qquad Q = \frac{p}{\rho}\,\frac{r''}{r} + \frac{1}{2}\left(\frac{p}{\rho}\right)'\frac{r'}{r}\,.$$

By [25, Theorem 4 in Chapter 2, p. 35], the eigenvalues of (81) form an increasing sequence ν_j satisfying the asymptotic expansion

$$\nu_j = j^2 + \frac{1}{\pi}\int_0^\pi (q+\alpha)\, d\xi \; - \frac{1}{\pi}\int_0^\pi \cos(2j\xi)\big(q(\xi)+\alpha(\xi)\big)\, d\xi + r_j, \quad |r_j| \le \frac{C}{j},$$

where $C := C(\|q+\alpha\|_{L^2})$ is a positive constant. Moreover every ν_j is simple [25, Theorem 2, p. 30].

Since p, ρ are positive and belong to H^3, if $a \in H^1$, then $q, \alpha \in H^1$. Integrating by parts, $|\int_0^\pi \cos(2j\xi)(q+\alpha)\, d\xi| \le \|q+\alpha\|_{H^1}/j$ and so

$$\nu_j = j^2 + \frac{1}{\pi}\int_0^\pi (q+\alpha)\, d\xi + r_j', \quad |r_j'| \le \frac{C'}{j}$$

for some $C' := C'(\|q+\alpha\|_{H^1})$. Dividing by c^2 and using the inverse Liouville change of variable, we obtain the formula for the eigenvalues $\lambda_j(a)$ of (80),

$$\lambda_j(a) = \frac{j^2}{c^2} \; + \; \frac{1}{\pi c}\int_0^\pi \frac{Q\sqrt{\rho}}{\sqrt{p}}\, dx \; + \; \frac{1}{\pi c}\int_0^\pi \frac{a}{\sqrt{\rho p}}\, dx \; + \; r_j(a), \quad |r_j(a)| \le \frac{C}{j} \tag{82}$$

for some $C(\rho, p, \|a\|_{H^1}) > 0$. Formula (66) follows for $a(x) = -\mu\Pi_V f'(v(\mu, w) + w)(x)$ and some algebra.

By [25, Theorem 7, p. 43], the eigenfunctions of (81) form an orthonormal basis for L^2. Applying the Liouville change of variable (79) in the integrals, the eigenfunctions $\varphi_j(a)$ of (80) form an orthonormal basis for L^2 with respect to the scalar product $(\cdot\,,\cdot\,)_{L^2_\rho}$.

Finally, since $\varphi_j := \varphi_j(a)$ solves

$$-(p\varphi_j')' + (K\rho + a)\varphi_j = (\lambda_j(a) + K)\rho\varphi_j\,,$$

multiplying by φ_i and integrating by parts gives

$$(\varphi_j, \varphi_i)_{\mu,w} = \delta_{i,j}(\lambda_j(a) + K),$$

and (68) follows (note that $\lambda_j(a) + K > 0$ for all j and for K large enough). □

Proof of Lemma 5. Let $a, b \in H^1(0,\pi)$ and consider $\alpha := c^2 a(\psi)/\rho(\psi)$, $\beta := c^2 b(\psi)/\rho(\psi)$ constructed as above via the Liouville change of variable (79). By [25, p. 34], for every j

$$|\lambda_j(a) - \lambda_j(b)| = \frac{1}{c^2}|\nu_j(\alpha) - \nu_j(\beta)| \le \frac{1}{c^2}\|\alpha - \beta\|_\infty \le K\|a - b\|_{H^1}, \tag{83}$$

and (28) follows by the mean value theorem because $\mu\Pi_V f(v(\mu, w) + w)$ has bounded derivatives on bounded sets. □

Proof of (58). By the asymptotic formula (73)

$$\min_{j\ge 1} |\omega_{j+1}(\mu, w) - \omega_j(\mu, w)| \ge \frac{1}{c} - \frac{2K}{j} > \frac{1}{2c}$$

if $j > 4Kc$, uniformly in $\mu \in [\mu_1, \mu_2]$, $w \in B_R$. For $1 \le j \le 4Kc$ the minimum

$$m_j := \min_{(\mu,w)\in[\mu_1,\mu_2]\times B_R} |\omega_{j+1}(\mu, w) - \omega_j(\mu, w)|$$

is attained because $a \mapsto \lambda_j(a)$ is a compact function on H^1 by the compact embedding $H^1(0,\pi) \hookrightarrow L^\infty(0,\pi)$ and by (83) (see also [25, Theorem 3, pp. 31 and 34]). Each $m_j > 0$ because all the eigenvalues λ_j are simple. □

NORMAL FORMS, QUASI-INVARIANT MANIFOLDS, AND BIFURCATIONS OF NONLINEAR DIFFERENCE-ALGEBRAIC EQUATIONS*

R. BEARDMORE† AND K. WEBSTER†

Abstract. We study the existence of quasi-invariant manifolds in a neighborhood of a fixed point of the *difference*-algebraic equation (ΔAE) $F(z_n, z_{n+1}) = 0$, where $F : \mathbb{R}^{2m} \to \mathbb{R}^m$ is a smooth map satisfying $F(0,0) = 0$. We demonstrate the existence of quasi-invariant manifolds on which one can define forward and backward orbits of the ΔAE under mild assumptions on its linearization at the fixed point $z = 0$. Indeed, by assuming this linearization to be a regular matrix pencil, one obtains a functional equation satisfied by invariant manifolds which can be solved using an extension of the contraction mapping to spaces that satisfy an interpolation property. If the ΔAE under study is permitted to depend smoothly on a parameter, we then obtain a Neimark–Sacker bifurcation theorem as a corollary that can be deduced from the existence of a normal form for nonlinear ΔAEs.

Key words. invariant manifolds, bifurcations, difference-algebraic equations

AMS subject classifications. 39B72, 39A11, 37G99

DOI. 10.1137/050638618

1. Introduction.

The purpose of this paper is to provide an analysis of the invariant manifolds and bifurcations found in a class of *difference*-algebraic equations (ΔAEs) of the form

$$F(z_n, z_{n+1}) = 0; \tag{1.1}$$

the nomenclature and chosen acronym for (1.1) have been taken from [4, 22]. We assume that $F(= F(z, \bar{z})) : \mathbb{R}^{2m} \to \mathbb{R}^m$ is a smooth map satisfying $F(0,0) = 0$ and say that (1.1) is *singular* because the partial derivative $d_{\bar{z}}F(0,0)$ is not an isomorphism from $\mathbb{R}^m$ to itself. The purpose of the first part of this paper is to provide conditions under which (1.1) has suitably defined invariant manifolds that contain the fixed point $z = 0$, where the main difficulty to overcome in this analysis is the fact that forward orbits of (1.1) are not necessarily uniquely defined in a neighborhood of the fixed point.

The second part of the paper utilizes the existence of the aforementioned invariant manifolds to investigate the presence of bifurcations in ΔAEs in the sense that by extending F to be a C^k-mapping of the form $F : \mathbb{R}^{2m} \times \mathbb{R} \to \mathbb{R}^{2m}$, where $k \geq 5$, we examine the structure of invariant sets in the family of ΔAEs

$$F(z_n, z_{n+1}, \mu) = 0. \tag{1.2}$$

Our rationale is taken from bifurcation theory for maps which leads to the following question. If $F(0,0,\mu) = 0$ for all μ in some interval and the one-parameter family of matrix pencils

$$\mathcal{P}(\mu) := (A(\mu), B(\mu)) := (d_{\bar{z}}F(0,0,\mu), d_z F(0,0,\mu)),$$

where F has $(z, \overline{z}, \mu)$ as its argument, is such that $\mathcal{P}(\mu_0)$ has a finite eigenvalue of unit modulus in the complex plane, does an invariant set of (1.2) bifurcate from the fixed point $z = 0$ at $\mu = \mu_0$?

Due to the lack of forward uniqueness we modify what we mean by the term *invariant*, which we do by using the prefixed *quasi-invariant*, and say that a set $\mathcal{Q} \subset F^{-1}\{0\}$ is quasi-invariant for (1.1) if, for $(z, \overline{z}) \in \mathcal{Q}$, there is a subsequent iterate $(\overline{z}, \overline{\overline{z}}) \in \mathcal{Q}$ for some $\overline{\overline{z}} \in \mathbb{R}^m$.

The paper is organized in the following way: The remainder of section 1 briefly covers the linear prerequisites for (1.1). Section 2 then provides some motivating applications. Section 3 presents the basic definitions of how (1.1) defines a local dynamical system and gives the invariant manifold equation of fixed points of (1.1). Section 4 provides a reformulation of the invariant manifold equation from section 3 as a nonlinear fixed-point problem in suitable Banach spaces which then is shown to have a solution in section 4.3. Section 5 gives a normal form for (1.1) with and without the presence of a bifurcation parameter. This section concludes with theorems that can be deduced using these normal forms, giving bifurcation results for (1.1) when that parameter is included. Finally, section 6 finishes the paper with a series of examples.

1.1. The linear case: Kronecker normal form. As a precursor to the analysis of the nonlinear problem (1.1), consider the linear case

$$Bz_n + Az_{n+1} = 0, \tag{1.3}$$

where $A, B : \mathbb{R}^m \to \mathbb{R}^m$ are linear maps and A is singular. In order to discuss the behavior of (1.3) we first introduce a normal form for matrix pencils.

When A is singular, the matrix pencil (A, B) is said to be *regular* if there is an $\omega \in \mathbb{C}$ such that $\det(\omega A + B) \neq 0$. The following result is well known for regular matrix pencils (see [7, 3]): There are complementary subspaces $K_1 \simeq \mathbb{R}^p, K_2 \simeq \mathbb{R}^q \subset \mathbb{R}^m$ such that $p + q = m$ and nonsingular linear mappings P, Q on $\mathbb{R}^m$, $L : K_1 \to K_1$, and $N : K_2 \to K_2$ such that

$$PAQ = \begin{pmatrix} I_p & 0 \\ 0 & N \end{pmatrix}, \quad PBQ = \begin{pmatrix} L & 0 \\ 0 & I_q \end{pmatrix}; \tag{1.4}$$

I_p and I_q are identities on K_1 and K_2, respectively. Moreover, there is a $\nu \geq 1$ such that $N^\nu = 0$, and ν is said to be the Kronecker index of (A, B).

The Kronecker normal form (KNF) in (1.4) can be used to rewrite (1.3) as a coupled system of difference equations

$$Lu_n + u_{n+1} = 0, \quad v_n + Nv_{n+1} = 0, \tag{1.5}$$

which has the solution $u_n = (-L)^n u_0$ and $v_n \equiv 0$ for all n, and thus (1.3) *has* a quasi-invariant subspace that arises from the quasi-invariant space $\{(u, v) : v = 0\}$ associated with (1.5). It is the presence of the former that we shall exploit in the remainder of the paper to study nonlinear perturbations of (1.5) that arise from a consideration of problems of the form (1.1).

1.2. Notation. If we define the spectrum of a matrix pencil to be

$$\sigma(A, B) = \{\lambda \in \mathbb{C} : \det(\lambda A + B) = 0\},$$

then $\sigma(A, B) = -\sigma(L)$ (*note the minus sign*), and p as defined within the KNF above coincides with the number of finite eigenvalues of (A, B), where eigenvalues are

counted according to their algebraic multiplicity. The matrix pencil (A, B) is said to be *hyperbolic* if $\sigma(A, B)$ is nonempty and contains no elements of unit modulus; otherwise, it is said to be *elliptic*. We shall also write $\rho(A, B) = \sup\{|\lambda| : \lambda \in \sigma(A, B)\}$ and denote the spectral radius of any linear mapping L by $\rho(L)$. Throughout we shall use # to denote the cardinality of a set of eigenvalues, counted according to algebraic multiplicity.

We shall use $BL(X, Y)$ to denote the space of continuous linear maps from one normed linear space X to another Y, even when X and Y are finite-dimensional. We shall use $B_\epsilon(x)$ for the open ball of radius ϵ about x, and $B_\epsilon(x; X)$ will specify that this ball is contained in the space X. If $L \in BL(X, Y)$, we shall denote the usual operator norm by $\|L\|_{BL(X,Y)}$, which is given by $\sup\{\|Lx\|_Y : x \in X, \|x\|_X = 1\}$. If the context is clear, we shall simply write $\|L\|$, and $BL(X)$ is also used for $BL(X, X)$. Throughout, if $F : X \to Y$ is a nonlinear mapping, then $dF(x) \in BL(X, Y)$ shall denote the Fréchet derivative, and when acting on $h \in X$ it will be written with square brackets, as in $dF(x)[h]$. Similarly, $d^2F(x)[h, k]$ denotes the second derivative, and this is bilinear in $[h, k]$.

If n is a positive integer, we shall use $\mathcal{O}_n(x)$ on occasion to denote any mapping, H, say, with the property that $\lim_{x\to 0} \|H(x)\|/\|x\|^n$ exists.

2. Motivation. There are several problems from control theory and numerical analysis that lead to discrete systems where the relationship between the current and future states of a system are not explicit; see [12, 10, 6, 14] for examples.

2.1. Discretized differential-algebraic equations. In [11] the authors apply a Runge–Kutta method to solve a differential-algebraic boundary-value problem arising from an optimal control problem, yielding a nonlinear *difference-algebraic equation* where the control plays the role of an implicit variable. For example, using a forward-Euler method to discretize the differential-algebraic equation (DAE)

$$\dot{x} = f(x, y), 0 = g(x, y) \qquad ((x(0), y(0)) \text{ given})$$

yields the ΔAE

$$x_{n+1} = x_n + hf(x_n, y_n), 0 = g(x_n, y_n) \qquad ((x_0, y_0) \text{ given}),$$

where h is a small parameter. A singularity in this context occurs when the partial derivative $d_y g(x, y)$ is singular on some subset of $g^{-1}\{0\}$.

Over the past decade a great deal of attention has been devoted to singular DAEs

$$F(z, \dot{z}) = 0, \tag{2.1}$$

where $d_{\dot{z}} F(z, \dot{z})$ changes rank on some set, and our study of (1.1) can be viewed as an extension of the work undertaken on (2.1) to the discrete-time case.

It is well known that (2.1) supports a range of singular and regular behavior, including *impasse points* and *pseudoequilibria* [16, 19, 17, 20]. However, not a great deal of the current literature is devoted to the study of *bifurcations* of DAEs nor to the unfolding of singularities in DAEs, such as the image and kernel singularities defined in [23]. One reason for this is the difficulty of proving a suitable center manifold theorem that can cope with the kind of singularities peculiar to DAE. We do note, however, that a Hopf bifurcation theorem is presented in [9] for systems of the form $\dot{x} = f(x, \dot{x}, \alpha)$, where α is a bifurcation parameter, $x \in \mathbb{R}^m$, and f is *nonexpansive* with respect to $\dot{x}$, a case that does include certain DAE singularities; a Hopf bifurcation

theorem for regular DAEs can be found in [15]. We also note that there are results in the DAE literature that yield the existence of an invariant manifold containing an equilibrium point; for regular DAEs see [18], and for singular DAEs see [24, 2].

2.2. Output-nulling control. Take a discrete dynamical system of the form

$$x_{n+1} = f(x_n, u_n),\ y_n = g(x_n, u_n), \tag{2.2}$$

where (x_n) is a sequence of states, (u_n) are controls, and (y_n) is a sequence of outputs. One may ask whether there is an admissible control that nullifies or fixes the outputs: Given (y_n), does there exist a sequence pair $((x_n),(u_n))$ satisfying (2.2)? The resulting equation is an infinite-dimensional system of equations that has a structure reminiscent of the semiexplicit, index-1 DAE (for terminology, see [3]).

2.3. Optimal control. The preprint [14] is relevant to the present work as it presents an invariant manifold result which leads to the existence of a control for the following variational problem with an infinite horizon:

$$\min_{(u_k)} \left\{ \sum_{k=0}^{\infty} \ell(x_k, u_k) : x_{k+1} = f(x_k, u_k), x_0 \in \mathbb{R}^m, u_k \in B_\epsilon(0; \mathbb{R}^p) \right\}$$

such that $f(0,0) = 0$ and $\ell(0,0) = 0$. An optimal orbit satisfies the first-order optimality conditions given by the quasi-linear, *implicit* difference equation

$$x_{k+1} = f(x_k, u_k), \tag{2.3}$$

$$\frac{\partial H}{\partial x}(x_k, u_k, \lambda_{k+1}) = \lambda_k, \tag{2.4}$$

$$0 = \frac{\partial H}{\partial u}(x_k, u_k, \lambda_{k+1}), \tag{2.5}$$

where H is the Hamiltonian $H(x,u,\lambda) = \lambda^T f(x,u) + \ell(x,u)$. In [14] the author demonstrates the existence of a *stable manifold* associated with (2.3)–(2.5) which has a dimension that coincides with the number of eigenvalues of the linearization about its fixed point, and the existence of this stable manifold then provides the necessary optimal control. The obstacle treated in [14] is the existence of a zero closed-loop eigenvalue which is analogous to the type of singularity treated in this paper. One can see the resemblance of (2.3)–(2.5) to (1.5) in that state variables (x_k) propagate forwards in time in (2.3)–(2.5), whereas adjoint variables (λ_k) propagate backwards, a property shared by (1.5).

3. A functional equation for quasi-invariant manifolds. Let us now define in what sense we expect (1.1) to induce a dynamical system. An element $z \in \mathbb{R}^m$ is said to be a *fixed point* of (1.1) if $F(z,z) = 0$. If z denotes the first argument of F and $\overline{z}$ the second, as in $F(z,\overline{z})$, then we define the following conditions:

(A1) $z = 0$ is a fixed point of (1.1): $F(0,0) = 0$,
(A2) $\det(d_{\overline{z}} F(0,0)) = 0$, and
(A3) there is a $\xi \in \mathbb{C}$ such that $\det(d_z F(0,0) + \xi d_{\overline{z}} F(0,0)) \neq 0$.

Throughout we make use of the matrix pencil (A,B), where

$$A := d_{\overline{z}} F(0,0) \quad \text{and} \quad B := d_z F(0,0), \tag{3.1}$$

and (A3) is the condition that (A,B) is regular. We shall assume that $F \in C^k(\mathbb{R}^{2m}, \mathbb{R}^m)$ for $k > 3$ and seek *local* and *global orbits* of the ΔAE (1.1) in the following sense.

DEFINITION 1. *A sequence* $(z_n)_{j=0}^{J}$ *is said to be a* J-orbit *of* (1.1) *for* $J \in \mathbb{N}$ *if*

$$F(z_j, z_{j+1}) = 0 \quad \textit{for} \quad 0 \le j \le J-1 \quad \textit{and} \quad 2 \le J < \infty,$$

and a local orbit *is a* J*-orbit for some* $J \ge 2$. *If there is a* $z_2 \in \mathbb{R}^m$ *such that* $(z_0, z_1; z_2)$ *is a local* 2*-orbit, then we say that the initial condition* (z_0, z_1) supports *this orbit. A sequence* $(z_n)_{j=0}^{\infty}$ *is said to be a* global orbit *of* (1.1) *as it is a* J*-orbit for each* $J \ge 2$.

Following the terminology used for DAEs, a pair (z_0, z_1) such that $F(z_0, z_1) = 0$ is said to be *consistent*, and if this pair supports some orbit, then it is said to be a consistent initial condition. We could also have analogously defined backward orbits for $J \le -2$, but we omit this for brevity. Note that initial conditions lie in $\mathbb{R}^{2m}$ and not $\mathbb{R}^m$, a property that is analogous to DAEs whereby initial positions *and* certain initial derivatives must be provided in order to obtain the existence of solutions.

We now give the definition which stipulates how we expect (1.1) to induce a dynamical system.

DEFINITION 2. (1.1) *induces a local dynamical system on a manifold* $\mathcal{M} \subset F^{-1}\{0\} \subset \mathbb{R}^{2m}$ *which contains the origin of* $\mathbb{R}^{2m}$ *if there is a ball* $\mathcal{M}_r := \mathcal{M} \cap B_r(0; \mathbb{R}^{2m})$ *such that for each* $(z, \overline{z}) \in \mathcal{M}_r$ *there is a* unique $(\overline{z}, \overline{\overline{z}}) \in \mathcal{M}$. *If these conditions hold,* $\mathcal{M}$ *is said to be* a solution manifold of (1.1).

This definition ensures that every point $(z, \overline{z}) \in \mathcal{M}_r$ supports the nontrivial 3-orbit $(z, \overline{z}; \overline{\overline{z}})$ and that the point $\overline{\overline{z}} \in \mathbb{R}^m$ is uniquely determined if we are to impose the requirement that $(\overline{z}, \overline{\overline{z}}) \in \mathcal{M}$.

DEFINITION 3. *A set* $\mathcal{Q} \subset F^{-1}\{0\} \subset \mathbb{R}^{2m}$ *is said to be* quasi-*invariant if, for each* $(z, \overline{z}) \in \mathcal{Q}$, there exists *a* $\overline{\overline{z}} \in \mathbb{R}^m$ *such that* $(\overline{z}, \overline{\overline{z}}) \in \mathcal{Q}$.

As an aside, note that (1.1) induces a trivial dynamical system on the quasi-invariant set $\{(0,0)\}$ by virtue of (A1), even if assumption (A3) fails. Note also that a solution manifold $\mathcal{M}$ is not necessarily unique; it is the local orbit within $\mathcal{M}$ that must be uniquely determined. Indeed, there may well be many possible choices for $\overline{\overline{z}}$ in order to keep the orbit on $F^{-1}\{0\}$, many of which may not be elements of $\mathcal{M}$.

3.1. The functional equation. Our strategy for locating quasi-invariant manifolds of (1.1) is to study a functional equation obtained in an analogous manner to the center-manifold equation from the theory of invariant manifolds for maps. The solution of this equation then provides the manifold $\mathcal{M}$ needed to form a local dynamical system for (1.1). We shall show in Theorem 1 that one can find a linear space $K_1 \subset \mathbb{R}^{2m}$ with an associated locally defined, differentiable map $\varphi : K_1 \to K_1$, a manifold $\mathcal{M} \subset F^{-1}\{0\}$, and a local diffeomorphism $\theta : K_1 \to \mathcal{M}$ such that

$$F(\theta(u)) = 0 \Longrightarrow F(\theta(\varphi(u))) = 0.$$

As a result, we will be able to ensure that (1.1) induces a local dynamical system on $\mathcal{M}$ essentially by iterating the map φ. This simply means that if $(z, \overline{z}) = \theta(u)$ is a consistent initial condition, then $(\overline{z}, \overline{\overline{z}}) = \theta(\varphi(u))$ and $(\overline{\overline{z}}, \overline{\overline{\overline{z}}}) = \theta(\varphi(\varphi(u)))$ provide subsequent iterates of (1.1).

Returning to (1.1), let us change the form of the problem by setting $w_n = z_{n+1}$, so that along an orbit of (1.1) we have

$$z_{n+1} = w_n, \tag{3.2}$$

$$0 = Bz_n + Aw_n + \Phi(w_n, z_n), \tag{3.3}$$

where Φ is the C^k function which satisfies $\Phi(0,0) = 0, d\Phi(0,0) = 0$ and which is defined by

$$F(z,w) - Bz - Aw := \Phi(w,z).$$

The problem of finding an initial condition which is consistent, (z_0, w_0), say, is of an algebraic nature, whereas the problem of finding an orbit which is supported by this initial condition is a *dynamic* problem. This means that the problem of finding a manifold of orbits of a ΔAE will lead not to an algebraic equation that one could tackle using an elementary version of the implicit function theorem but instead to a functional equation.

Let us now obtain this functional equation. By applying the condition that (A, B) is a regular matrix pencil (condition (A3)), it follows that

$$(\mathcal{A}, \mathcal{B}) := \left(\begin{pmatrix} I & 0 \\ 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & I \\ B & A \end{pmatrix} \right) \tag{3.4}$$

is also a regular matrix pencil. If we define the vector $W_n = (z_n, w_n) \in \mathbb{R}^{2m}$, using (3.2)–(3.3), (1.1) can be written in the semilinear form

$$\mathcal{A}W_{n+1} = \mathcal{B}W_n + \Psi(W_n),$$

where Ψ is the C^k-mapping $\Psi(W) := (0, \Phi(W))$, so that $\Psi(0) = 0$ and $d\Psi(0) = 0$. There are mappings P and Q that put $(\mathcal{A}, \mathcal{B})$ in Kronecker normal form, and, by setting $W_n = QX_n$, we may write (3.2)–(3.3) in the form

$$[P\mathcal{A}Q]\, X_{n+1} = [P\mathcal{B}Q]\, X_n + P\Psi(QX_n), \tag{3.5}$$

where the terms in square brackets are in normal form:

$$\begin{bmatrix} I & 0 \\ 0 & N \end{bmatrix} X_{n+1} = \begin{bmatrix} C & 0 \\ 0 & I \end{bmatrix} X_n + P\Psi(QX_n).$$

Consequently, there are linear spaces $K_1 \simeq R^p$ and $K_2 \simeq \mathbb{R}^q$ such that $K_1 \oplus K_2 \simeq \mathbb{R}^{2m}$ and $X_n = (u_n, v_n) \in K_1 \oplus K_2$, where (u_n, v_n) satisfies the difference equation in normal form

$$\text{(NF)} \qquad \begin{cases} u_{n+1} &= Cu_n + f(u_n, v_n), \\ Nv_{n+1} &= \quad v_n - g(u_n, v_n). \end{cases}$$

We now ask that there is a manifold given by the graph of some function h on which one can solve (NF) uniquely in a neighborhood of the fixed point $(u, v) = (0, 0)$ in the sense that $v_n = h(u_n)$ holds along orbits. This imposes the two conditions

$$u_{n+1} = Cu_n + f(u_n, h(u_n)) \quad \text{and} \quad Nh(u_{n+1}) = h(u_n) - g(u_n, h(u_n))$$

on h, and it follows that the local orbit (u_n, v_n) of (NF) can be found if h satisfies the functional equation

$$h(u) = Nh(Cu + f(u, h(u))) + g(u, h(u)), \qquad h(0) = 0,\ dh(0) = 0, \tag{3.6}$$

for all u in some neighborhood of the origin in $\mathbb{R}^p$. The boundary conditions in (3.6) ask first that the fixed point $(u, v) = (0, 0)$ of (NF) lies on the graph of h and then that this graph is tangent to the quasi-invariant subspace obtained on setting $f = 0$ and $g = 0$ in (NF).

3.2. Further preliminaries.

3.2.1. Perturbation of eigenvalues. For completeness we have included the following two preliminary results regarding the spectra of one-parameter families of matrix pencils, which are mappings of the form

$$\mathcal{P} : (-1, 1) \to BL(\mathbb{R}^m) \times BL(\mathbb{R}^m); \mu \mapsto (A(\mu), B(\mu)).$$

If we define the family of analytic functions

$$f_\mu(\omega) = \det(\omega A(\mu) + B(\mu)),$$

the multiplicity of an eigenvalue of a matrix pencil is then the multiplicity of the corresponding zero of $f_\mu(\cdot)$, which is at most m. The identity

$$\frac{d}{d\omega} f_\mu(\omega) = f_\mu(\omega) \mathrm{tr}[(\omega A(\mu) + B(\mu))^{-1} A(\mu)], \tag{3.7}$$

whenever this inverse is defined, can be used to obtain the following two lemmas.

LEMMA 1 (C^1-dependence of eigenvalues). *Suppose that $\mathcal{P}(\mu) := (A(\mu), B(\mu))$ is a C^1-parameterized family of real matrix pencils, with $\mu \in (-1, 1)$, such that $\mathcal{P}(0)$ is a regular matrix pencil. An element $\lambda_0 \in \sigma(\mathcal{P}(0))$ is said to be an* algebraically simple eigenvalue *of $\mathcal{P}(0)$ if*

$$\ker(\lambda_0 A(0) + B(0)) = \langle x_0 \rangle \quad \text{and} \quad x_0 \notin \mathrm{ran}(\lambda_0 A(0) + B(0)).$$

If λ_0 is an algebraically simple eigenvalue of $\mathcal{P}(0)$, then there is a C^1-parameter family of algebraically simple eigenvalues $\lambda(\mu) \in \mathbb{C}$ of $\mathcal{P}(\mu)$ such that $\lambda(0) = \lambda_0$, with a corresponding C^1 family of unit eigenvectors $x(\mu)$, with $x(0) = x_0$.

Proof. This follows from the implicit function theorem applied to the system $F(\lambda, x, \mu) = (0, 0)$, where $F(\lambda, x, \mu) := \big[(\lambda A(\mu) + B(\mu))x, \|x\|_2^2 - 1\big]$. ∎

LEMMA 2 (C^0-dependence of eigenvalues). *Suppose that $\mathcal{P}(\mu) := (A(\mu), B(\mu))$ is a C^0-parameterized family of real matrix pencils, with $\mu \in (-1, 1)$, such that $\mathcal{P}(0)$ is regular. If λ_0 is an eigenvalue of $\mathcal{P}(0)$ of algebraic multiplicity l, then it is isolated in the complex plane, and for each $\epsilon > 0$ there is a $\delta > 0$ such that if $|\mu| < \delta$, then $\mathcal{P}(\mu)$ has l eigenvalues (counted according to algebraic multiplicity) in the disk $D(\lambda_0, \epsilon)$.*

Proof. As $f_0(\cdot)$ does not vanish identically because $\mathcal{P}(0)$ is regular by assumption, neither can $f_\mu(\cdot)$ for sufficiently small μ. The *isolatedness* of eigenvalues of $\mathcal{P}(\mu)$ is a consequence of the fact that analytic functions have isolated zeros. Now by using (3.7) we integrate around a closed circle in the complex plane with center $\omega = \lambda_0$ and radius ϵ, from where

$$\#\{\sigma(\mathcal{P}(\mu)) \cap D(\lambda_0, \epsilon)\} = \frac{1}{2\pi i} \oint_{\partial D(\lambda_0, \epsilon)} \mathrm{tr}[(\omega A(\mu) + B(\mu))^{-1} A(\mu)] d\omega,$$

where $D(\lambda_0, \epsilon)$ is an open disk of radius ϵ about λ_0 in the complex plane. This quantity is integer-valued and depends continuously on μ, and the result now follows. ∎

3.2.2. Notation. From this point we shall identify the linear space K_1 from the KNF with $\mathbb{R}^p$ and K_2 with $\mathbb{R}^q$; now let $|\cdot|_p$ and $|\cdot|_q$ denote norms on $\mathbb{R}^p$ and $\mathbb{R}^q$, and let $\Omega_\delta = \{u \in \mathbb{R}^p : |u|_p < \delta\}$. We also assume that the unit sphere $\partial\Omega_1$ is a C^∞ manifold.

Let $C^0(\overline{\Omega}_\delta, \mathbb{R}^q)$ be the Banach space of continuous maps on $\overline{\Omega}_\delta$ with norm $\|h\|_{C^0} = \sup_{u\in\overline{\Omega}_\delta} |h(u)|_q$. Similarly, let $C^j(\overline{\Omega}_\delta, \mathbb{R}^q)$ be the space of all j-times continuously differentiable functions on $\overline{\Omega}_\delta$ with norm $\|h\|_{C^j} = \max_{0\le i\le j} \sup_{u\in\overline{\Omega}_\delta} \|d^i h(u)\|_{C^0}$, where d^i denotes the ith (Fréchet) derivative, so that $d^j h(u)$ is a j-linear form which we denote $[k_1, \dots, k_j] \to d^j h(u)[k_1, \dots, k_j]$. Consequently, we have the norm of a higher derivative given by the formula

$$\|d^j h\|_{C^0} = \sup_{u\in\overline{\Omega}_\delta} \sup_{|k_i|_p\le 1} |d^j h(u)[k_1, \dots, k_j]|_q. \tag{3.8}$$

If M is any multilinear form on a linear space Z and $z \in Z$, then $M[z]^{(k)}$ is shorthand for $M[z, z, \dots, z]$.

From the smoothness of the unit sphere $\partial\Omega_1$, it follows that the embedding of $C^{j+1}(\overline{\Omega}_\delta)$ into $C^j(\overline{\Omega}_\delta)$ is compact, so that if $(h_n) \subset C^{j+1}(\overline{\Omega}_\delta)$ is bounded in the norm of the latter space, there is a subsequence (h_{n_k}) which converges in $C^j(\overline{\Omega}_\delta)$ to some element of $C^j(\overline{\Omega}_\delta)$. We shall also make limited use of the Hölder spaces, which we denote by $C^{j+\alpha}(\overline{\Omega}_\delta)$ whenever j is an integer and $0 < \alpha < 1$, recalling the compact embedding $C^{j+\alpha}(\overline{\Omega}_\delta) \subset C^{j+\beta}(\overline{\Omega}_\delta)$ if $\alpha > \beta$.

It can be somewhat notationally cumbersome to include all of the references to the underlying spaces in all of the norms that we use, so we shall limit their use and expect that the precise meaning can be taken from context.

4. Solving the fixed-point problem (3.6). It is not (NF) that we shall seek to solve directly, but we make the substitution

$$u = \epsilon\tilde{u}, v = \epsilon\tilde{v}$$

in (NF) to give (after removal of the tildes for clarity)

$$\left\{ \begin{array}{rl} u_{n+1} & = Cu_n + \epsilon^{-1} f(\epsilon u_n, \epsilon v_n), \\ Nv_{n+1} & = \quad v_n - \epsilon^{-1} g(\epsilon u_n, \epsilon v_n). \end{array} \right. \tag{NF}_\epsilon$$

As the functions f and g are higher than linear order at the origin, $(\mathrm{NF})_\epsilon$ is in fact smooth with respect to variations in ϵ.

Let us define the one-parameter family of C^k functions f_ϵ and g_ϵ (with C^{k-1} dependence on ϵ) by

$$\mathsf{f}_\epsilon(u, v) = \epsilon^{-1} f(\epsilon u, \epsilon v) \quad \text{and} \quad \mathsf{g}_\epsilon(u, v) = \epsilon^{-1} g(\epsilon u, \epsilon v),$$

respectively. For $j \in \mathbb{N}$ we also have

$$d^j \mathsf{f}_\epsilon(u, v) = \epsilon^{j-1} d^j f(\epsilon u, \epsilon v) \quad \text{and} \quad d^j \mathsf{g}_\epsilon(u, v) = \epsilon^{j-1} d^j g(\epsilon u, \epsilon v), \tag{4.1}$$

whenever these derivatives are defined.

Now seek an invariant manifold $\mathcal{M}$ of $(\mathrm{NF})_\epsilon$ given by a graph on which

$$v_n = h(u_n),$$

and then $\mathcal{M}$ can be realized as such a graph if there is a solution of the nonlinear functional equation

$$\left\{ \begin{array}{l} h(u) = Nh(Cu + \mathsf{f}_\epsilon(u, h(u))) + \mathsf{g}_\epsilon(u, h(u)), \\ h(0) = 0, dh(0) = 0. \end{array} \right. \tag{4.2}$$

4.1. Preliminary estimates. The following are simple but essential estimates on the derivatives of f and g. By the mean-value inequality and the fact that the mapping $(u,v) \mapsto (f(u,v), g(u,v))$ and its derivative vanish at $(u,v) = (0,0)$, there exists an ℓ $(= \ell(\delta, r)) > 0$ such that

$$|f(u,v)|_p \le \ell \|(u,v)\|^2, \quad |g(u,v)|_q \le \ell \|(u,v)\|^2, \tag{4.3}$$

and

$$\|df(u,v)\| \le \ell \|(u,v)\|, \quad \|dg(u,v)\| \le \ell \|(u,v)\|, \tag{4.4}$$

whenever $|u|_p \le \delta, |v|_q \le r$, where here and throughout we use the norm

$$\|(u,v)\| = \max(|u|_p, |v|_q) \qquad (\forall (u,v) \in \mathbb{R}^p \times \mathbb{R}^q).$$

Here $\|df(u,v)\|$ and $\|dg(u,v)\|$ both refer to induced operator norms, treating $df(u, v)$ and $dg(u,v)$ as linear mappings. By using the mean-value inequality we obtain

$$\|d^2 g(u,v) - d^2 g(0,0)\| \le \sup_{|u|_p \le \delta, |v|_q \le r} \|d^3 g(u,v)\| \|(u,v)\|,$$

and the triangle inequality gives

$$\|d^2 g(u,v)\| \le \|d^2 g(0,0)\| + \overline{\ell} \|(u,v)\| \qquad (|u|_p \le \delta, |v|_q \le r),$$

where $\overline{\ell}$ $(= \overline{\ell}(\delta, r)) = \sup_{|u|_p \le \delta, |v|_q \le r} \|d^3 g(u,v)\|$, whence

$$\|d^2 \mathsf{g}_\epsilon(u,v)\| \le \epsilon \left(\|d^2 g(0,0)\| + \epsilon \overline{\ell} \|(u,v)\| \right) \qquad (|u|_p \le \delta, |v|_q \le r). \tag{4.5}$$

An analogous inequality holds for f and f_ϵ:

$$\|d^2 \mathsf{f}_\epsilon(u,v)\| \le \epsilon \left(\|d^2 f(0,0)\| + \epsilon \overline{\ell} \|(u,v)\| \right) \qquad (|u|_p \le \delta, |v|_q \le r). \tag{4.6}$$

It is the $O(\epsilon)$ size of these quantities that will be important later.

4.2. Introducing a cutoff function. It is not (4.2) that we shall seek to solve directly, but we must employ a cutoff function to rewrite (4.2) in a fixed-point form that is amenable to a Picard iteration. This is not the case at present because if we were to define a nonlinear operator acting on h by the right-hand side of (4.2), there is no reason for it or its iterates to be well-defined on a suitable function space.

For any $\delta > 0$, there is a cutoff function $\psi \in C^\infty(\mathbb{R}^p)$ such that

$$\psi(u) = \begin{cases} u & \text{if} \quad |u|_p \le \delta/2, \\ 0 & \text{if} \quad |u|_p \ge 3\delta/2 \end{cases}$$

and such that $|\psi(u)|_p \le \delta$. By using this cutoff we define a Nemitskii operator π as follows:

$$\pi(h)(u) = \psi(Cu + \mathsf{f}_\epsilon(u, h(u))) \qquad (\forall u \in \overline{\Omega}_\delta, h : \overline{\Omega}_\delta \subset \mathbb{R}^p \to \mathbb{R}^q), \tag{4.7}$$

so that

$$\pi : C^0(\overline{\Omega}_\delta, \mathbb{R}^q) \to C^0(\overline{\Omega}_\delta, \mathbb{R}^p),$$

and the inequality $|\pi(h)(u)|_p \leq \delta$ holds pointwise. Moreover, by the C^k-regularity of f, it follows that π is itself a C^k-mapping for each $\epsilon > 0$ fixed, with Fréchet derivative

$$d\pi(h)[k](\cdot) = d\psi(C\cdot + \mathsf{f}_\epsilon(\cdot, h))[d_v \mathsf{f}_\epsilon(\cdot, h)[k]] \qquad (\forall h, k \in C^0(\overline{\Omega}_\delta, \mathbb{R}^q)). \tag{4.8}$$

Also note the following estimate, which will be important later.

LEMMA 3. *Suppose that $h \in C^0(\overline{\Omega}_\delta, \mathbb{R}^q)$ satisfies $\|h\|_{C^0} \leq r$, then*

$$\|d\pi(h)\|_{BL(C^0)} \leq \epsilon \ \cdot \|\psi\|_{C^1} \ell \max(\delta, r), \tag{4.9}$$

and there are constants $\kappa_1, \kappa_2 > 0$, depending on ℓ, δ, and r, but not on ϵ, such that

$$\|d^2\pi(h)\|_{BL(C^0)\times BL(C^0)} \leq \epsilon \|\psi\|_{C^2} \left(\kappa_1(\ell, \delta, r) + \epsilon\kappa_2(\ell, \delta, r)\right). \tag{4.10}$$

Proof. By using (4.8) we obtain

$$\begin{aligned}
\sup_{k\in C^0, \|k\|_{C^0}=1} \|d\pi(h)[k]\|_{C^0} &= \sup_{k\in C^0, \|k\|_{C^0}=1} \|d\psi(C\cdot + \mathsf{f}_\epsilon(\cdot, h))[d_v \mathsf{f}_\epsilon(\cdot, h)[k]]\|_{C^0} \\
&\leq \|\psi\|_{C^1} \cdot \sup_{k\in C^0, \|k\|_{C^0}=1} \|d_v \mathsf{f}_\epsilon(\cdot, h)[k]\|_{C^0} \\
&\leq \|\psi\|_{C^1} \cdot \sup_{|u|_p\leq\delta, |v|_q\leq r} \|d_v \mathsf{f}_\epsilon(u, v)\| \\
&\leq \|\psi\|_{C^1} \cdot \ell \cdot \sup_{|u|_p\leq\delta, |v|_q\leq r} \|(\epsilon u, \epsilon v)\| \text{ (by (4.1) and (4.3))},
\end{aligned}$$

and the first part follows. The second part follows from

$$d^2\pi(h)[k_1, k_2] = d^2\psi(C\cdot + \mathsf{f}_\epsilon(\cdot, h))[d_v \mathsf{f}_\epsilon[k_1], d_v \mathsf{f}_\epsilon[k_2]] + d\psi[d^2_{vv} \mathsf{f}_\epsilon(\cdot, h)[k_1, k_2]],$$

so that, for $i = 1, 2$,

$$\begin{aligned}
\sup_{k_i\in C^0, \|k_i\|_{C^0}=1} \|d^2\pi(h)[k_1, k_2]\|_{C^0} &\leq \sup_{u\in\mathbb{R}^p} \|d\psi(u)\| \cdot \|d^2_{vv} \mathsf{f}_\epsilon(\cdot, h)\| \\
&\quad + \sup_{u\in\mathbb{R}^p} \|d^2\psi(u)\| \cdot \|d_v \mathsf{f}_\epsilon(\cdot, h)\|^2 \\
&\leq \|\psi\|_{C^2} \left(\sup_{|u|_p\leq\delta, |v|_q\leq r} \|d^2_{vv} \mathsf{f}_\epsilon(u, v)\| + \sup_{|u|_p\leq\delta, |v|_q\leq r} \|d_v \mathsf{f}_\epsilon(u, v)\|^2 \right) \\
&\leq \|\psi\|_{C^2} \left(\epsilon\|d^2 f(0, 0)\| + \epsilon^2\overline{\ell} \max(\delta, r) + \sup_{|u|_p\leq\delta, |v|_q\leq r} \|d_v f(\epsilon u, \epsilon v)\|^2 \right) \quad \text{(by (4.5))} \\
&\leq \|\psi\|_{C^2} \left(\epsilon\|d^2 f(0, 0)\| + \epsilon^2\overline{\ell} \max(\delta, r) + \sup_{|u|_p\leq\delta, |v|_q\leq r} \|(\epsilon u, \epsilon v)\|^2 \ell^2 \right) \quad \text{(by (4.3))},
\end{aligned}$$

and the result follows directly from here. ∎

In order to solve (4.2), we now tackle the following nonlinear fixed-point problem:

$$h = Nh(\pi(h)) + \mathsf{G}_\epsilon(h), \tag{4.11}$$

where $\mathsf{G}_\epsilon : C^0(\overline{\Omega}_\delta, \mathbb{R}^q) \to C^0(\overline{\Omega}_\delta, \mathbb{R}^q)$ is the Nemitskii operator

$$\mathsf{G}_\epsilon(h)(u) := \mathsf{g}_\epsilon(u, h(u)).$$

Notice that the cutoff ψ has been used in (4.11), but, because ψ coincides with the identity on some balls around the origin, solutions of (4.11) will satisfy (4.2) on this ball.

This construction ensures that $h(\pi(h)) \in C^0(\overline{\Omega}_\delta, \mathbb{R}^q)$ whenever $h \in C^0(\overline{\Omega}_\delta, \mathbb{R}^q)$, and we may, as a result, define the operator

$$T : C^0(\overline{\Omega}_\delta, \mathbb{R}^q) \to C^0(\overline{\Omega}_\delta, \mathbb{R}^q); \quad h \mapsto h(\pi(h)),$$

noting that the operators $T : C^1(\overline{\Omega}_\delta, \mathbb{R}^q) \to C^1(\overline{\Omega}_\delta, \mathbb{R}^q)$ and $T : C^2(\overline{\Omega}_\delta, \mathbb{R}^q) \to C^2(\overline{\Omega}_\delta, \mathbb{R}^q)$ are also well-defined as the restrictions of T to various subspaces of $C^0(\overline{\Omega}_\delta, \mathbb{R}^q)$ as f and g are C^3 functions.

However, it is not (4.11) that we shall solve, but we exploit the nilpotency of N to bring the *functional part* of (4.2) and (4.11), that is, $Nh(\pi(h))$, into a higher-order contribution to the problem. However, because $g(u, v)$ is a second-, or possibly higher-order function, the operator G_ϵ contains no linear terms, and this will help us to obtain a contractive sequence by iterating T.

By way of example, let us suppose that $N \neq 0$ but $N^2 = 0$. If there exists a solution of $h = Nh(\pi(h)) + \mathsf{G}_\epsilon(h)$, there results $Nh = N\mathsf{G}_\epsilon(h)$, and therefore $Nh(\pi(h)) = N\mathsf{G}_\epsilon(h(\pi(h)))$. In this case we find that h must satisfy

$$h = N\mathsf{G}_\epsilon(h(\pi(h))) + \mathsf{G}_\epsilon(h), \tag{4.12}$$

and one observes that the *functional part* of the equation (that is, $h(\pi(h))$) now sits inside a higher-order term (and not a linear one as in (4.11)). Conversely, if h satisfies (4.12), then $Nh = N\mathsf{G}_\epsilon(h)$, so that $N\mathsf{G}_\epsilon(h(\pi(h))) = Nh(\pi(h))$ because $N^2 = 0$, and $h = Nh(\pi(h)) + \mathsf{G}_\epsilon(h)$ follows.

When the nilpotency index of the map N is arbitrary we extend this idea in the following lemma, where here and in the remainder we shall write

$$\mathcal{G}_\epsilon(h) = \sum_{j=0}^{\nu-1} N^j \mathsf{G}_\epsilon(T^j(h)),$$

and

$$T^{j+1} = T(T^j), \qquad \text{where} \qquad T^0 = I,$$

and the latter denotes the identity on $C^0(\overline{\Omega}_\delta, \mathbb{R}^q)$.

LEMMA 4. *Suppose that $N^\nu = 0$ but $N^{\nu-1} \neq 0$; then h is a solution of* (4.11) *if it is a solution of the fixed-point problem*

$$h = \mathcal{G}_\epsilon(h). \tag{4.13}$$

Proof. Let us suppose that h is a solution of (4.13); then

$$Nh = N\mathcal{G}_\epsilon(h) = N\left[\sum_{j=0}^{\nu-1} N^j \mathsf{G}_\epsilon(T^j(h))\right] = \sum_{j=0}^{\nu-1} N^{j+1} \mathsf{G}_\epsilon(T^j(h)),$$

and so, because $N^\nu = 0$, we obtain

$$\begin{aligned} Nh(\pi(h)) &= \sum_{j=0}^{\nu-1} N^{j+1} \mathsf{G}_\epsilon(T^j(h(\pi(h)))) \\ &= \sum_{j=0}^{\nu-1} N^{j+1} \mathsf{G}_\epsilon(T^{j+1}(h)) = \sum_{j=1}^{\nu-1} N^j \mathsf{G}_\epsilon(T^j(h)) = \mathcal{G}_\epsilon(h) - \mathsf{G}_\epsilon(h) = h - \mathsf{G}_\epsilon(h), \end{aligned}$$

which therefore provides a solution of (4.11) as required. ∎

4.3. The main result. Our strategy for solving (4.13), and hence (4.2), is to show that $\mathcal{G}_\epsilon$ satisfies a *refined* Banach contraction theorem of the type given in [26, p. 286]. The idea that we employ several times is encapsulated in the following idea. Consider Banach spaces $(X, \|\cdot\|_X)$ and $(Y, \|\cdot\|_Y)$ such that $x_0 \in Y$ and $Y \subset X$, and moreover $\mathcal{T}$ is a mapping satisfying $\mathcal{T} : Y \to Y$ and $\mathcal{T} : X \to X$. Now, if there is an $r > 0$ and a $\kappa \in [0, 1)$ such that

1. $\mathcal{T} : \overline{B}_r(x_0; X) \to \overline{B}_r(x_0; X)$,
2. $\|\mathcal{T}(y) - \mathcal{T}(y')\|_X \leq \kappa \|y - y'\|_X$ for all $y, y' \in Y \cap \overline{B}_r(x_0; X)$,

then $\mathcal{T}$ has a fixed point $y^* \in \overline{B}_r(x_0; X)$. In addition, if

3. $\mathcal{T} : \overline{B}_\rho(x_0; Y) \to \overline{B}_\rho(x_0; Y)$ and
4. there is an interpolating Banach space Z such that $Y \subset Z$ with compact embedding and $Z \subset X$ with continuous embedding,

then $y^* \in Z$.

The point here is that we cannot ensure that $y^* \in Y$, although one still obtains a fixed point in some space from the standard iteration scheme. By using this idea one can prove an existence and regularity result for (4.2), where we have in mind $x_0 = 0, \mathcal{T} = \mathcal{G}_\epsilon, Y = C^{k+1}, Z = C^{k+\alpha}$, and $X = C^k$, where $\alpha \in (0, 1)$. We begin by providing the details to cover the cases $k = 0$ and $k = 1$.

The following theorem is the main result of this paper from which the invariant manifold and bifurcation theorems are deduced.

THEOREM 1. *Let $\alpha \in [0, 1)$. There exists an $\epsilon_0 > 0$ such that, for each $\epsilon \in (0, \epsilon_0)$,* (4.13) *has a solution $h \in C^{1+\alpha}(\overline{\Omega}_\delta, \mathbb{R}^q)$; moreover $h(0) = 0$ and $dh(0) = 0$.*

Proof. Let X_r be the C^0-closed ball of radius r about zero in $C^0(\overline{\Omega}_\delta, \mathbb{R}^q)$ and Y_r the C^1-closed ball of radius r about zero in $C^1(\overline{\Omega}_\delta, \mathbb{R}^q)$. Let $h_0 \in Y_r$, and define a sequence

$$h_{n+1} := \mathcal{G}_\epsilon(h_n).$$

We shall show that we can choose ϵ such that (h_n) is well-defined, contractive, and hence Cauchy in X_r, and it therefore converges. Throughout the remainder of the proof we shall use the positive constant

$$n_* := \sum_{j=0}^{\nu-1} \|N\|^j_{BL(\mathbb{R}^q)}.$$

We now give a proof of Theorem 1 in four short steps, each placing a stronger restriction on ϵ relative to the fixed choice of δ and r to ensure that $\mathcal{G}_\epsilon$ contracts when acting on C^1 functions, measured in the C^0 norm.

Step 1. If $\epsilon < r(\ell n_* \max(\delta, r)^2)^{-1} =: \epsilon_1$, then $\mathcal{G}_\epsilon : X_r \to X_r$.

Proof. Suppose that $h \in X_r$, and then $T(h) = h(\pi(h))$ is continuous as h is. Moreover if $\|h\|_{C^0} \leq r$, then $\|T(h)\|_{C^0} = \|h(\pi(h))\|_{C^0} \leq r$; similarly $\|T^j(h)\|_{C^0} \leq r$ for all $0 \leq j \leq \nu - 1$. By definition,

$$\begin{aligned}\|\mathcal{G}_\epsilon(h)\|_{C^0} &\leq \sum_{j=0}^{\nu-1} \|N\|^j \|\mathsf{G}_\epsilon(T^j(h))\|_{C^0} \leq \sum_{j=0}^{\nu-1} \|N\|^j \sup_{\|\overline{h}\|_{C^0} \leq r} \|\mathsf{G}_\epsilon(\overline{h})\|_{C^0} \\ &\leq n_* \sup_{|u|_p \leq \delta, |v|_q \leq r} |\mathsf{g}_\epsilon(u, v)|_q = n_* \sup_{|u|_p \leq \delta, |v|_q \leq r} \epsilon^{-1} |g(\epsilon u, \epsilon v)|_q.\end{aligned}$$

From (4.3) it follows that

$$\|\mathcal{G}_\epsilon(h)\|_{C^0} \leq \epsilon\, \ell n_* \sup_{|u|_p \leq \delta, |v|_q \leq r} \|(u, v)\|^2 = \epsilon\, \ell n_* \max(\delta, r)^2.$$

By assumption, $\epsilon \ell n_* \max(\delta, r)^2 < r$, and Step 1 is complete. ∎

Step 2. If $\epsilon < \min\{\epsilon_1, [r\ell \max(\delta, r)\|\psi\|_{C^1}]^{-1}, r[n_*(1+r)\ell \max(\delta, r)]^{-1}\} =: \epsilon_2$, then $\mathcal{G}_\epsilon : Y_r \to Y_r$.

Proof. Suppose that $h \in Y_r$ so that $h \in X_r$, then $T^j(h)$ is differentiable on $\overline{\Omega}_\delta$ as h is; moreover throughout the remainder of the proof of Step 2 we shall write $H := \mathcal{G}_\epsilon(h)$ for brevity. It then follows that

$$dH(u) = \sum_{j=0}^{\nu-1} N^j \left[d_u \mathbf{g}_\epsilon(u, T^j(h)(u)) + d_v \mathbf{g}_\epsilon(u, T^j(h)(u))[d_u(T^j(h))(u)] \right], \tag{4.14}$$

and we now need to estimate $\|dH(u)\|_{C^0}$. By using the fact that $\|h\|_{C^0} \le r$, since $T : X_r \to X_r$ from Step 1, we obtain $|T^j(h)(u)|_q = |h(\pi(h(\ldots))\ldots)|_q \le r$, and therefore

$$\begin{aligned}
\sup_{|u|_p \le \delta} \|dH(u)\|_{BL(\mathbb{R}^p, \mathbb{R}^q)} &\le \sum_{j=0}^{\nu-1} \|N\|^j \left(\|d_u \mathbf{g}_\epsilon(u, T^j(h)(u))\| \right. \\
&\qquad \left. + \|d_v \mathbf{g}_\epsilon(u, T^j(h)(u))\| \|d_u(T^j(h))(u)\| \right) \\
&\le n_* \sup_{0 \le j \le \nu-1} \left(\|d_u \mathbf{g}_\epsilon(u, T^j(h)(u))\| + \|d_v \mathbf{g}_\epsilon(u, T^j(h)(u))\| \|d_u(T^j(h))(u)\| \right) \\
&\le n_* \sup_{\substack{0 \le j \le \nu-1 \\ |u|_p \le \delta, |v|_q \le r}} \left(\|d_u \mathbf{g}_\epsilon(u, v)\| + \|d_v \mathbf{g}_\epsilon(u, v)\| \|d_u(T^j(h))(u)\| \right) \\
&\le \epsilon\ n_* \ell \max(r, \delta) \left(1 + \sup_{0 \le j \le \nu-1, |u|_p \le \delta} \|d_u(T^j(h))(u)\| \right).
\end{aligned}$$

Now we estimate the final bracketed term in the latter expression. The linear mapping obtained from differentiating $T^j(h)(u)$ with respect to u is

$$d_u(T^j(h))(u) = d_u(h(\pi(h(\ldots \pi(h) \ldots)))),$$

which can be written as the recurrence

$$d_u(T^j(h))(u) = dh(\pi(T^{j-1}(h))(u)) d\pi(T^{j-1}(h)(u)) \cdot d_u(T^{j-1}(h)(u)), \tag{4.15}$$

where, by definition, $d_u(T^0(h))(u) = d_u(h)(u) = dh(u)$. By taking C^0 norms and setting

$$\xi_j := \|d_u(T^j(h))(u)\|_{BL(\mathbb{R}^p, \mathbb{R}^q)},$$

we obtain the relation

$$\xi_j \le \|dh\|_{C^0} \sup_{\|\overline{h}\|_{C^0} \le r} \|d\pi(\overline{h})\|_{BL(C^0)} \cdot \xi_{j-1},$$

where $\xi_0 = \|dh\|_{C^0} \le \|h\|_{C^1} \le r$. From (4.9) of Lemma 3, we find that

$$\xi_j \le \epsilon \ell r \max(\delta, r) \|\psi\|_{C^1} \cdot \xi_{j-1} \le (\epsilon \ell r \max(\delta, r) \|\psi\|_{C^1})^j\ \xi_0 \le r$$

because $\epsilon \ell r \max(\delta, r) \|\psi\|_{C^1} < 1$ by assumption. As a result, the inequality

$$\begin{aligned}
\sup_{|u|_p \le \delta} \|dH(u)\|_{BL(\mathbb{R}^p, \mathbb{R}^q)} &\le \epsilon\ n_* \ell \max(r, \delta) \left(1 + \sup_{0 \le j \le \nu-1} \xi_j \right) \\
&\le \epsilon n_* \ell \max(r, \delta)(1 + r) \le r
\end{aligned}$$

also now follows from the assumption of the claim, and we have proven that $h \in Y_r$, as required. ∎

Step 3. If $\epsilon < \epsilon_2$ and we define the $O(\epsilon)$ quantity $\kappa(\epsilon)$ by

$$\kappa(\epsilon) := \epsilon \cdot \ell \max(\delta, r) \sum_{i=0}^{\nu-1} (r\epsilon \cdot \|\psi\|_{C^1} \ell \max(\delta, r))^i,$$

then $\|h_{n+1} - h_n\|_{C^0} \le \kappa(\epsilon)\|h_n - h_{n-1}\|_{C^0}$. As a result, (h_n) is Cauchy in X_r if ϵ is further restricted so that $\kappa(\epsilon) < 1$, and so (h_n) converges in X_r.

Proof. For brevity, let us write h in place of h_{n+1} and k for h_n after setting $h_0 = 0 \in Y_r$ and $h_{n+1} = \mathcal{G}_\epsilon(h_n)$. Now

$$\begin{aligned}\|\mathcal{G}_\epsilon(h) - \mathcal{G}_\epsilon(k)\|_{C^0} &\le \sum_{j=0}^{\nu-1} \|N\|^j \|\mathsf{G}_\epsilon(T^j(h)) - \mathsf{G}_\epsilon(T^j(k))\|_{C^0} \\ &\le n_* \sup_{0\le j\le \nu-1} \|\mathsf{g}_\epsilon(u, T^j(h)(u)) - \mathsf{g}_\epsilon(u, T^j(k)(u))\|_{C^0}.\end{aligned}$$

The mean-value inequality yields

$$\begin{aligned}&|\mathsf{g}_\epsilon(u, T^j(h)(u)) - \mathsf{g}_\epsilon(u, T^j(k)(u))|_q \\ &\qquad \le \sup_{z\in[T^j(h)(u), T^j(k)(u)]} \|d_v \mathsf{g}_\epsilon(u, z)\| \|T^j(h) - T^j(k)\|_{C^0} \\ &\qquad \le \sup_{|u|_p\le\delta, |v|_q\le r} \|d_v \mathsf{g}_\epsilon(u, v)\| \|T^j(h) - T^j(k)\|_{C^0} \qquad \text{(using Step 1)} \\ &\qquad \le \epsilon\ell \max(r, \delta) \cdot \|T^j(h) - T^j(k)\|_{C^0} \qquad \text{(by (4.3))},\end{aligned} \tag{4.16}$$

where, for any $z_1, z_2 \in \mathbb{R}^p$, the generalized interval from z_1 to z_2 is given by

$$[z_1, z_2] := \{\lambda z_1 + (1-\lambda) z_2 : 0 \le \lambda \le 1\}.$$

So let us define $\chi_j := \|T^j(h) - T^j(k)\|_{C^0}$, and we estimate χ_j as follows:

$$\begin{aligned}|T^j(h)(u) - T^j(k)(u)|_q &= |h(\pi(T^{j-1}(h))) - k(\pi(T^{j-1}(k)))|_q \\ &\le |h(\pi(T^{j-1}(h))) - k(\pi(T^{j-1}(h)))|_q \\ &\qquad + |k(\pi(T^{j-1}(h))) - k(\pi(T^{j-1}(k)))|_q \\ \implies \qquad \chi_j &\le \|h - k\|_{C^0} + \|k(\pi(T^{j-1}(h))) - k(\pi(T^{j-1}(k)))\|_{C^0}.\end{aligned}$$

However, from Step 2 we have $\|k\|_{C^1} \le r$, and therefore

$$|k(u) - k(u')|_q \le r|u - u'|_p \qquad \forall u, u' \in \overline{\Omega}_\delta.$$

Using the fact that π is a Fréchet differentiable mapping on $C^0(\overline{\Omega}_\delta, \mathbb{R}^q)$ with norm bounded according to (4.9), an application of the mean-value inequality gives

$$\chi_j \le \|h - k\|_{C^0} + r \sup_{\|\overline{h}\|_{C^1}\le r} \|d\pi(\overline{h})\|_{BL(C^0)} \cdot \chi_{j-1},$$

so that $\chi_j \le \|h - k\|_{C^0} + \epsilon \cdot r\|\psi\|_{C^1} \ell \max(\delta, r)\chi_{j-1}$, where $\chi_0 = \|h - k\|_{C^0}$. The discrete Gronwall inequality now gives

$$\chi_j \le \|h - k\|_{C^0} \sum_{i=0}^{\nu-1} (r\epsilon \|\psi\|_{C^1} \ell \max(\delta, r))^i,$$

and with (4.16) we have the desired inequality

$$\|\mathcal{G}_\epsilon(h) - \mathcal{G}_\epsilon(k)\|_{C^0} \le \kappa(\epsilon) \cdot \|h - k\|_{C^0}.$$

The standard contraction argument now shows that $(h_n) \subset Y_r$ is Cauchy in X_r as claimed, and there therefore exists an $h \in X_r$ such that $h_n \overset{C^0}{\to} h$ as $n \to \infty$. ∎

Since $(h_n) \subset Y_r$, it follows that there is a subsequence (n_j) such that $h_{n_j} \overset{C^\alpha}{\to} \overline{h}$ as $j \to \infty$ for some $\overline{h} \in X_r \cap C^\alpha(\overline{\Omega}_\delta)$, and we deduce that $\overline{h} = h \in C^\alpha(\overline{\Omega}_\delta)$. By restricting ϵ further we can actually ensure that h is differentiable, as follows.

Step 4. There is an $\epsilon_3 > 0$ such that $h \in C^{1+\alpha}(\overline{\Omega}_\delta)$ whenever $\epsilon < \min(\epsilon_2, \epsilon_3)$ and $\kappa(\epsilon) < 1$.

Proof. Let $h \in C^2(\overline{\Omega}_\delta)$ satisfy $\|h\|_{C^2} \le r$, and recall that $H := \mathcal{G}_\epsilon(h)$. From (4.14) we obtain

$$\begin{aligned} d^2H(u) = \sum_{j=0}^{\nu-1} N^j \{ & d^2_{uu}\mathrm{g}_\epsilon(u, T^j(h)(u)) + 2d^2_{uv}\mathrm{g}_\epsilon(u, T^j(h)(u))[I, d_u(T^j(h)(u))] \\ & + d^2_{vv}\mathrm{g}_\epsilon(u, T^j(h)(u))[d_u(T^j(h)(u)), d_u(T^j(h)(u))] \\ & + d_v\mathrm{g}_\epsilon(u, T^j(h)(u))[d^2_{uu}(T^j(h)(u))]\}. \end{aligned}$$

In seeking a bound on $\|H\|_{C^2}$, we now examine the term $d^2_{uu}(T^j(h)(u))$ more closely as bounds on the remaining elements of d^2H can be obtained from Steps 1 and 2. By applying the chain rule (4.15) we obtain the recurrence

$$\begin{aligned} d^2_{uu}(T^j(h)(u)) &= d_u\left\{dh(\pi(T^{j-1}(h))(u))d\pi(T^{j-1}(h)(u)) \cdot d_u(T^{j-1}(h)(u))\right\} \\ &= d^2h(\pi(T^{j-1}(h))(u))[d\pi(T^{j-1}(h)(u)) \cdot d_u(T^{j-1}(h)(u))]^{(2)} \\ &\quad + dh(\pi(T^{j-1}(h))(u))[d^2\pi(T^{j-1}(h)(u))[d_u(T^{j-1}(h)(u))]^{(2)}] \\ &\quad + dh(\pi(T^{j-1}(h))(u))[d\pi(T^{j-1}(h)(u))[d^2_{uu}(T^{j-1}(h)(u))]], \end{aligned}$$

and taking norms gives

$$\begin{aligned} \|d^2_{uu}(T^j(h)(u))\|_{C^0} \le & \|d^2h\|_{C^0}\|d\pi(h)\|^2\|d_u(T^j(h)(u))\|_{C^0} \\ & + \|dh\|_{C^0}\|d^2\pi(h)\|\|d_u(T^j(h)(u))\|^2_{C^0} \\ & + \|dh\|_{C^0}\|d\pi(h)\|\|d^2_{uu}(T^j(h)(u))\|_{C^0}. \end{aligned}$$

If we write

$$\eta_j := \|d^2_{uu}(T^j(h)(u))\|_{C^0},$$

and use the fact that $\xi_j = \|d_u(T^j(h))(u)\|_{BL(\mathbb{R}^p,\mathbb{R}^q)} \le r$ for all $0 \le j \le \nu - 1$, which was established in Step 2, we obtain the difference inequality

$$\eta_j \le r^3\|d\pi(h)\|^2_{C^0} + r^2\|d^2\pi(h)\|_{C^0} + r\|d\pi\|_{C^0} \cdot \eta_{j-1}$$

such that $\eta_0 \le r$ by definition. There results, for $j \ge 1$,

$$\eta_j \le (r\|d\pi(h)\|_{C^0})^j\,\eta_0 + \left(r^3\|d\pi(h)\|^2_{C^0} + r^2\|d^2\pi(h)\|_{C^0}\right)\sum_{i=0}^{j-1}(r\|d\pi(h)\|_{C^0})^i,$$

and the bounds (4.9) and (4.10) show that $\eta := \max_{0\le j\le\nu-1}\eta_j$ has an $O(1)$ dependence on ϵ in the sense that there is an $M > 0$ such that $\eta \le M$ whenever $0 \le \epsilon \le 1$. (In fact, one can choose M to be less than r if ϵ is sufficiently small.)

We now obtain

$$\begin{aligned}\|d^2H\|_{C^0} &\leq n_* \sup_{0\leq j\leq \nu-1} \big\{ \|d^2_{uu}\mathsf{g}_\epsilon(u,T^j(h)(u))\|_{C^0} + 2\xi_j\|d^2_{uv}\mathsf{g}_\epsilon(u,T^j(h)(u))\|_{C^0} \\ &\qquad + \xi_j^2\|d^2_{vv}\mathsf{g}_\epsilon(u,T^j(h)(u))\|_{C^0} + \eta_j\|d_v\mathsf{g}_\epsilon(u,T^j(h)(u))\|_{C^0}\big\} \\ &\leq n_* \sup_{\|\overline{h}\|_{C^0}\leq r, 0\leq j\leq \nu-1} \big\{ \|d^2_{uu}\mathsf{g}_\epsilon(u,\overline{h})\|_{C^0} + 2r\|d^2_{uv}\mathsf{g}_\epsilon(u,\overline{h})\|_{C^0} \\ &\qquad + r^2\|d^2_{vv}\mathsf{g}_\epsilon(u,\overline{h})\|_{C^0} + \eta\|d_v\mathsf{g}_\epsilon(u,\overline{h})\|_{C^0}\big\}, \end{aligned} \tag{4.17}$$

where η has been used to bound the last term in (4.17). By using (4.5) to estimate the second derivative terms we find that

$$\begin{aligned}\|d^2H\|_{C^0} \leq \epsilon\cdot n_* \sup_{0\leq j\leq \nu-1} \big\{ &\|d^2g(0,0)\| + \epsilon\overline{\ell}\max(r,\delta) \\ &+ 2r(\|d^2g(0,0)\| + \epsilon r\overline{\ell}\max(r,\delta)) \\ &+ r^2(\|d^2g(0,0)\| + \epsilon\overline{\ell}\max(r,\delta)) + \eta\ell\max(r,\delta)\big\}. \end{aligned} \tag{4.18}$$

It is immediate from (4.18) and Steps 1 and 2 that a suitably small choice of ϵ ensures that $\|H\|_{C^2}\leq r$ whenever $\|h\|_{C^2}\leq r$. As a result, if we impose the following restriction on the initial guess for a fixed point of $\mathcal{G}_\epsilon$:

$$h_0 \in Z_r := \{h\in C^2(\overline{\Omega}_\delta,\mathbb{R}^q) : \|h\|_{C^2}\leq r\},$$

then the C^0-convergent sequence from Step 3 also satisfies $(h_n)\subset Z_r$. This means that a $C^{1+\alpha}$-convergent subsequence can now be extracted from (h_n), so that the convergence of h_n to h actually occurs in $C^{1+\alpha}$ and h therefore lies in this smoother space. □

We have shown that there is a differentiable solution of (4.2) on a sufficiently small ball around the origin, but there remains to prove the last part of Theorem 1 regarding the behavior of h at the origin. So let h be a C^1 solution of (4.2) on some ball $\overline{\Omega}_\delta$, and put $\zeta = h(0)$. It follows that ζ is a solution of the algebraic equation

$$-\zeta + Nh(\mathsf{f}_\epsilon(0,\zeta)) + \mathsf{g}_\epsilon(0,\zeta) = 0, \tag{4.19}$$

and (4.19) has solution $\zeta = 0$. As the linearization of the left-hand side of (4.19) at $\zeta = 0$ is a multiple of the identity, the inverse function theorem ensures that $\zeta = 0$ is the only solution of (4.19) in some neighborhood of zero, and this ensures that $h(0) = 0$. Since any solution of (4.13) provides one of (4.2), we can differentiate (4.2) with respect to u and set $u = 0$; this gives

$$dh(0) = Ndh(0)[C],$$

but then we can continue in an inductive manner to deduce that

$$Ndh(0)[C] = N^2dh(0)[C^2] = \cdots = N^\nu dh(0)[C^\nu] = 0,$$

as N is nilpotent. We find that $dh(0) = 0$, and this concludes the proof of Theorem 1. □

The question of maximal regularity of a solution of (4.2), or equivalently (4.13), is not addressed, although the method of proof used in Theorem 1 can be continued by restricting ϵ further as required to show that $\mathcal{G}_\epsilon$ maps the ball of radius r in $C^j(\overline{\Omega}_\delta,\mathbb{R}^p)$

into itself. This ensures that the sequence (h_n) constructed in the proof of Theorem 1 converges to h in as strong a C^j norm as we like, provided that f and g are sufficiently smooth. We cannot, however, be sure that the resulting solution h lies in $C^\infty(\overline{\Omega}_\delta, \mathbb{R}^p)$ because the interval in which ϵ must reside so as to obtain a C^j fixed point of $\mathcal{G}_\epsilon$ could shrink indefinitely as j grows.

Theorem 1 does not ensure the existence of a continuous fixed point of (4.2) which is not C^α for some $0 < \alpha < 1$. If we take a continuous initial guess for a solution, $h_0 \in C^0(\overline{\Omega}_\delta, \mathbb{R}^q)$, say, then, although there is a sequence of continuous functions defined by $h_{n+1} = \mathcal{G}_\epsilon(h_n)$, there is no reason to suspect that the sequence of iterates (h_n) will satisfy the property of being a C^0-contractive sequence. On the other hand, a suitably small C^1 initial guess will lead to C^α convergence of the resulting iterates for any $\alpha \in [0, 1)$.

4.4. Stability implies uniqueness. There are some simple cases where uniqueness and smoothness can be easily established. The most obvious is where $N = 0$, and then Theorem 1 can be proven using the elementary implicit function theorem. Another occurs when the matrix denoted C that arises from the Kronecker normal form of $(\mathcal{A}, \mathcal{B})$ in (3.5) satisfies $\|C\| < 1$ in the norm induced by $|\cdot|_p$. In this case the cutoff function ψ used above is not needed in order to obtain a well-defined operator π. If we define the Nemitskii operator

$$\pi(h)(u) = Cu + \mathsf{f}_\epsilon(u, h(u)),$$

and $h \in C^0(\overline{\Omega}_\delta, \mathbb{R}^q)$ satisfies $\|h\|_{C^0} \le r$, then $|Cu + \mathsf{f}_\epsilon(u, h(u))|_p \le \|C\||u|_p + |\mathsf{f}_\epsilon(u, h(u))|_p \le \|C\|\delta + \epsilon \cdot \ell \max(\delta, r)^2$. In order for $h(\pi(h))$ to be well-defined, we now need only to choose ϵ such that $\|C\|\delta + \epsilon \cdot \ell \max(\delta, r)^2 \le \delta$, which can be done. The proof of Theorem 1 then goes through with this minor modification, and the resulting fixed point of $\mathcal{G}_\epsilon$ is unique in the space of continuously differentiable functions.

4.5. Polynomial approximation. Let us remove the dependence of (4.2) on ϵ for clarity and return to the fixed-point problem (3.6) directly, which we recall defines a nonlinear operator G via

$$h(u) = Nh(Cu + f(u, h(u))) + g(u, h(u)) =: (Gh)(u), \quad \text{where } h(0) = 0, dh(0) = 0. \tag{4.20}$$

PROPOSITION 1. *Suppose that $h \in C^k(\overline{\Omega}_\delta, \mathbb{R}^q)$ is a solution of* (4.20), *and suppose that $\overline{h} \in C^k(\overline{\Omega}_\delta, \mathbb{R}^q)$ satisfies*

$$\overline{h}(u) - G(\overline{h})(u) = e(u), \quad \overline{h}(0) = 0,$$

where e is a given C^k function that satisfies $e(0) = 0, de(0) = 0, \ldots, d^k e(0) = 0$. Then

$$|h(u) - \overline{h}(u)|_q = o(|u|_p^k) \text{ as } u \to 0.$$

Proof. If we define the function $\Delta := h - \overline{h}$, then we have to prove that

$$\Delta(0) = 0, d\Delta(0) = 0, \ldots, d^k\Delta(0) = 0,$$

and the result then follows from the basic properties of the derivative. Clearly $\Delta(0) = 0$, and differentiating (4.20) with respect to u gives

$$\begin{aligned} dh(u) = Ndh(Cu + f(u, h(u)))[C + d_u f(u, h(u)) + d_v f(u, h(u))[dh(u)]] \\ + d_u g(u, h(u)) + d_v g(u, h(u))[dh(u)], \end{aligned}$$

and similarly,

$$d\overline{h}(u) = Nd\overline{h}(Cu + f(u, \overline{h}(u)))[C + d_u f(u, \overline{h}(u)) + d_v f(u, \overline{h}(u))[d\overline{h}(u)]] \\ + d_u g(u, \overline{h}(u)) + d_v g(u, \overline{h}(u))[d\overline{h}(u)] + de(u).$$

As a result, because $h(0) = \overline{h}(0) = 0$, we find that

$$d\Delta(0) = Nd\Delta(0)[C] + de(0) = Nd\Delta(0)[C],$$

by the assumption that $de(0) = 0$, so that

$$d\Delta(0) = Nd\Delta(0)[C] = N^2 d\Delta(0)[C^2] = \cdots = N^\nu d\Delta(0)[C^\nu] = 0.$$

Continuing in a similar vein, we obtain

$$d^2h(u) = Nd^2h(Cu + f(u, h(u)))[C + d_u f(u, h(u)) \\ + d_v f(u, h(u))[dh(u)]]^{(2)} + d^2_{uu} g(u, h(u)) + 2d^2_{uv} g(u, h(u))[I, dh(u)] \\ + d^2_{vv} g(u, h(u))[dh(u), dh(u)] + d_v g(u, h(u))[d^2h(u)],$$

with a similar expression for $d^2\overline{h}(u)$, with the additional presence of the term $d^2e(u)$. We find that

$$d^2h(0) = Nd^2h(0)[C, C] + d^2_{uu} g(0, 0), \tag{4.21}$$

and, because $d^2e(0) = 0$, (4.21) also holds with $h(0)$ replaced by $\overline{h}(0)$. We deduce that the bilinear form $d^2\Delta(0)$ satisfies

$$d^2\Delta(0)[X, Y] = Nd^2\Delta(0)[CX, CY] \qquad (\forall X, Y \in \mathbb{R}^p),$$

so that

$$d^2\Delta(0)[X, Y] = N^\nu d^2\Delta(0)[C^\nu X, C^\nu Y] = 0 \qquad (\forall X, Y \in \mathbb{R}^p).$$

We omit the details, but by continuing inductively and assuming $d^j e(0) = 0$, one obtains the result that the j-linear form $d^j\Delta(0)$ satisfies

$$d^j\Delta(0)[X_1, X_2, \ldots, X_j] = Nd^j\Delta(0)[CX_1, CX_2, \ldots, CX_j]$$

for all $X_1, \ldots, X_j \in \mathbb{R}^p$. The nilpotency of N now ensures that the latter quantity is zero. □

A simple corollary to Proposition 1 is that if (4.20) has two infinitely differentiable solutions h and $\overline{h}$ defined on some neighborhood of zero, then they agree beyond all orders at zero:

$$\lim_{u \to 0} \frac{|h(u) - \overline{h}(u)|_q}{|u|_p^k} = 0 \qquad (\forall k \geq 1).$$

5. Applications.

5.1. Nonlinear normal form. The first application of Theorem 1 is the following result, which says that (1.1) induces a local dynamical system on a manifold in the sense of Definition 2. Recall the definition of the matrix pencil (A, B) via

$$(A, B) := (d_{\overline{z}}F(0,0), d_z F(0,0)),$$

where F has $(z, \overline{z})$ as its argument, and note that the following matrix pencil defined on $\mathbb{R}^{2m}$:

$$(\mathcal{A}, \mathcal{B}) := \left(\begin{pmatrix} I & 0 \\ 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & I \\ B & A \end{pmatrix} \right),$$

satisfies $\sigma(\mathcal{A}, \mathcal{B}) = -\sigma(A, B)$.

THEOREM 2 (nonlinear Kronecker normal form). *Let $\alpha \in [0, 1)$, and suppose that* (A1)–(A3) *hold; then there is a linear space K_1 and a $C^{1+\alpha}$-manifold $\mathcal{M}$ modeled on K_1 such that* $\dim(K_1) = \#\sigma(A, B)$ *and*

1. *for all $(z, w) \in \mathcal{M}$ there results $F(z, w) = 0$,*
2. *there is an r' such that for each $(z, w) \in \mathcal{M}$, with $\|(z, w)\| < r'$, there is a unique $(\overline{z}, \overline{w}) \in \mathcal{M}$ such that $w = \overline{z}$, and*
3. *there is a $C^{1+\alpha}$-diffeomorphism $\theta : K_1 \to \mathcal{M}$ such that if $(z, w) = \theta(u)$ for some $u \in K_1$, then $(\overline{z}, \overline{w}) = \theta(\varphi(u))$, where*

$$\varphi(u) = Cu + p(u)$$

for some linear map $C : K_1 \to K_1$ that satisfies $\sigma(C) = \sigma(A, B)$. Moreover, $p : B_\delta(0; K_1) \to K_1$ satisfies $p(0) = 0$ and $d_u p(0) = 0$.

Proof. From Theorem 1, first identify the linear space K_1 from the KNF of $(\mathcal{A}, \mathcal{B})$ with $\mathbb{R}^p$ and K_2 with $\mathbb{R}^q$. Now define the $C^{1+\alpha}$-graph

$$\hat{\mathcal{M}} := \{(u, h(u)) \in \mathbb{R}^p \oplus \mathbb{R}^q : u \in \Omega_\delta\},$$

and let the r-neighborhood of zero in $\hat{\mathcal{M}}$ be $\hat{\mathcal{M}}_r := \{(u, h(u)) \in \mathbb{R}^p \oplus \mathbb{R}^q : |u|_p < r\}$ whenever $r < \delta$.

As a consequence of Theorem 1, there is an $r > 0$ such that for each $(u, v) = (u, h(u)) \in \hat{\mathcal{M}}_r$ we can find a pair $(\overline{u}, \overline{v})$ given by $(\overline{u}, h(\overline{u})) \in \hat{\mathcal{M}}$ such that (NF) is satisfied:

$$\overline{u} = Cu + f(u, v), \quad N\overline{v} = v - g(u, v),$$

where C is obtained from the KNF of $(\mathcal{A}, \mathcal{B})$ so that $\sigma(C) = -\sigma(\mathcal{A}, \mathcal{B}) = \sigma(A, B)$.

Let $\varphi(u) := Cu + f(u, h(u))$, and for each $u \in \mathbb{R}^p$ of sufficiently small norm set

$$\theta(u) := Q(u, h(u)) \qquad \text{and} \qquad \mathcal{M} \equiv Q(\hat{\mathcal{M}}), \quad \mathcal{M}_r \equiv Q(\hat{\mathcal{M}}_r),$$

where the linear map Q is taken from the KNF of $(\mathcal{A}, \mathcal{B})$ from the discussion that immediately follows (3.4). The map θ then provides a local diffeomorphism between Ω_δ and $\mathcal{M}$; moreover both

$$F(\theta(u)) = 0 \qquad \text{and} \qquad F(\theta(\varphi(u))) = 0$$

follow by the construction of h. The following diagram illustrates how a map is induced on $\mathcal{M}$ in this way:

$$\begin{array}{ccc} \mathcal{M}_r & \longrightarrow & \mathcal{M} \\ \theta^{-1}\downarrow & & \uparrow\theta \\ \Omega_r & \xrightarrow{\varphi} & \Omega_\delta \end{array},$$

where $\theta^{-1}(Q(u,h(u))) = u$, and this concludes the proof. ∎

The following immediate corollaries of Theorem 1 provide some information regarding the stable and unstable behavior of orbits in a neighborhood of a fixed point of (1.1).

COROLLARY 1. *Suppose that F satisfies* (A1)–(A3) *and (A,B) is a regular matrix pencil with $\rho(A,B)<1$; then there is a $C^{1+\alpha}$-solution manifold $\mathcal{M}$ of* (1.1) *containing* 0 *such that each $(z,\overline{z})\in\mathcal{M}$ supports a global orbit $(z_n)_{n=0}^{\infty}$ with $(z_n,z_{n+1})\in\mathcal{M}$, $z_0=z$, $z_1=\overline{z}$, and $\lim_{n\to\infty} z_n = 0$.*

Proof. The orbit is constructed by iterating the map $\varphi(u) = Cu + p(u)$ given in part 3 of Theorem 2: Because $\rho(A,B)<1$ we have $\rho(C)<1$ so that φ is a contraction near the origin in some norm, and the result follows. ∎

The following are the natural definitions of stable and unstable sets associated with fixed points of (1.1); note that they are subsets of $\mathbb{R}^{2m}$ and not $\mathbb{R}^m$.

DEFINITION 4. *The set*

$$W^s_{\mathrm{loc}}(0) := \{(z,\overline{z})\in\mathbb{R}^{2m} : \exists \text{ global orbit } (z_n)_{n=0}^{\infty}, z_0=z, z_1=\overline{z}, \lim_{n\to\infty} z_n = 0\}$$

is the local stable set associated with the zero fixed point of (1.1), *and*

$$W^u_{\mathrm{loc}}(0) := \{(z,\overline{z})\in\mathbb{R}^{2m} : \exists \text{ global orbit } (z_n)_{n=0}^{-\infty}, z_{-1}=z, z_0=\overline{z}, \lim_{n\to-\infty} z_n = 0\}$$

is the local unstable set.

In case $\sigma(A,B)$ contains elements outside the unit disk, one can apply the stable manifold theorem for maps to φ in Theorem 2 to give the following result.

COROLLARY 2. *Suppose that* (A1)–(A3) *are satisfied and (A,B) possesses n_s eigenvalues in the open unit disk; then* (1.1) *possesses a subset of the local stable set which is a differentiable manifold of dimension n_s.*

There is an analogous corollary to show that the unstable set is nonempty and contains a manifold of dimension n_u, where n_u is the number of elements of $\sigma(A,B)$ lying outside the closed unit disk. This result is obtained by applying Corollary 2 to (1.1) but with time running *backwards*.

COROLLARY 3. *Suppose that* (A1)–(A3) *are satisfied and (B,A) possesses n_u eigenvalues in the open unit disk; then* (1.1) *possesses a subset of the local unstable set which is a differentiable manifold of dimension n_u.*

Proof. Let us rewrite (1.1) in the form

$$F(z_{n-1}, z_n) = 0 \tag{5.1}$$

to emphasize the fact that we are seeking an orbit that propagates backwards in time, with (z_{-1}, z_0) given. The linearization of (5.1) is of the form

$$Bz_{n-1} + Az_n$$

and if $\det B \neq 0$, then we may locally solve (5.1) for $z_{n-1} = f(z_n)$, and then one can apply the stable manifold theorem for maps to this.

On the other hand if $\det B = 0$, then conditions (A1)–(A3), appropriately modified by exchanging the roles of z and $\overline{z}$ because time is flowing backwards, still apply to (5.1) because (B, A) is a regular matrix pencil due to the fact that (A, B) is regular. The result then follows from Corollary 2. ∎

As A is a singular mapping it follows that the finite spectrum of (B, A) satisfies

$$\sigma(B, A) = (\sigma(A, B)\backslash\{0\})^{-1} \cup \{0\},$$

whether or not B is singular, and hence $\sigma(B, A)$ contains zero so that $n_u \geq 1$. An unstable manifold therefore always exists for (1.1) under conditions (A1)–(A3).

5.2. Bifurcation theorems. We now consider a C^k-mapping $F : \mathbb{R}^{2m} \times \mathbb{R} \to \mathbb{R}^{2m}$, where $k \geq 5$, and examine the family of difference equations

$$F(z_n, z_{n+1}, \mu) = 0. \tag{5.2}$$

Define the one-parameter family of matrix pencils

$$\mathcal{P}(\mu) := (A(\mu), B(\mu)) := (d_{\overline{z}}F(0, 0, \mu), d_z F(0, 0, \mu)),$$

where F has $(z, \overline{z}, \mu)$ as its argument.

THEOREM 3 (parameterized nonlinear KNF). *Suppose that* $(0, 0)$ *is a fixed point of* (5.2) *for all* $\mu \in \mathbb{R}$ *and that* $\mathcal{P}(0)$ *is a regular matrix pencil. Then there is a linear space* K_1 *and a* $C^{1+\alpha}$*-parameter family of* $C^{1+\alpha}$*-manifolds* $\mathcal{M}_\mu$ *modeled on* K_1 *such that* $\dim(K_1) = \#\sigma(\mathcal{P}(0))$ *and*

1. *for all* $(z, w) \in \mathcal{M}_\mu$ *there results* $F(z, w, \mu) = 0$,
2. *there is an* r' *(independent of* μ*) such that for each* $(z, w) \in \mathcal{M}_\mu$*, with* $\|(z, w)\| < r'$*, there is a unique* $(\overline{z}, \overline{w}) \in \mathcal{M}_\mu$ *such that* $w = \overline{z}$*, and*
3. *there is a* $C^{1+\alpha}$*-parameter family of* $C^{1+\alpha}$*-diffeomorphisms* $\theta_\mu : K_1 \to \mathcal{M}_\mu$ *such that if* $(z, w) = \theta_\mu(u)$ *for some* $u \in K_1$*, then* $(\overline{z}, \overline{w}) = \theta_\mu(\varphi(u, \mu))$*, where*

$$\varphi(u, \mu) = C(\mu)u + p(u, \mu).$$

Moreover, $C(\cdot)$ *is a* $C^{1+\alpha}$*-parameter family of maps in* $BL(K_1)$ *and, for some* $\delta > 0$*,* $p : B_\delta(0; K_1) \times B_\delta(0; \mathbb{R}) \to K_1$ *satisfies*

$$p(0, \mu) \equiv 0, \;\; d_u p(0, \mu) \equiv 0.$$

4. *If* $\lambda : [-\delta, \delta] \to \mathbb{C}$ *is a continuous (and so bounded) curve, then* $\lambda(\mu) \in \sigma(\mathcal{P}(\mu))$ *for all* $\mu \in [-\delta, \delta]$ *if and only if* $\lambda(\mu) \in \sigma(C(\mu))$ *for all* $\mu \in [-\delta, \delta]$.

Proof. Consider the suspended difference equation

$$\text{(S)} \qquad \begin{cases} \mu_{n+1} = \mu_n, \\ z_{n+1} = w_n, \\ 0 = F(z_n, w_n, \mu_n). \end{cases}$$

Let us write

$$F(z, w, \mu) = A(\mu)w + B(\mu)z + \mathcal{F}(z, w, \mu),$$

where $F(0, 0, \mu) = 0$, $d_z F(0, 0, \mu) = B(\mu)$, and $d_w F(0, 0, \mu) = A(\mu)$, and then consider the following matrix pencil on $\mathbb{R}^{2m}$:

$$(\mathcal{A}, \mathcal{B}(\mu)) := \left(\begin{pmatrix} I & 0 \\ 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & I \\ B(\mu) & A(\mu) \end{pmatrix} \right).$$

This satisfies $\sigma(\mathcal{A}, \mathcal{B}(\mu)) = -\sigma(\mathcal{P}(\mu))$ and is a regular matrix pencil when $\mu = 0$, and we can exploit this fact using the resulting Kronecker normal form to put (S) into a normal form. If we set $\mathbf{z} = (z, w)$, then we may write (S) as

$$\begin{aligned} \overline{\mu} &= \mu, \\ \mathcal{A}\overline{\mathbf{z}} &= \mathcal{B}(\mu)\mathbf{z} + \mathcal{F}(\mathbf{z}, \mu), \end{aligned}$$

where an overbar is used to denote a forward iterate. Now there is a matrix pair (P, Q) such that $P\mathcal{A}Q = \left(\begin{smallmatrix} I_{K_1} & 0 \\ 0 & N \end{smallmatrix}\right)$ and $P\mathcal{B}(0)Q = \left(\begin{smallmatrix} C & 0 \\ 0 & I_{K_2} \end{smallmatrix}\right)$, where $Q : \mathbb{R}^{2m} \to K_1 \oplus K_2 = \mathbb{R}^{p+q}$ and N is nilpotent. With $(u, v) := \mathbf{w} = Q\mathbf{z} \in K_1 \oplus K_2$, we obtain

$$\overline{\mu} = \mu, \tag{5.3}$$

$$\overline{u} = \alpha(\mu)u + \beta(\mu)v + \mathcal{G}_1(u, v, \mu), \tag{5.4}$$

$$N\overline{v} = \gamma(\mu)u + \delta(\mu)v + \mathcal{G}_2(u, v, \mu), \tag{5.5}$$

where

$$\alpha : K_1 \to K_1, \quad \beta : K_2 \to K_1, \quad \gamma : K_1 \to K_2, \quad \text{and} \quad \delta : K_2 \to K_2$$

are differentiable linear maps in μ, and

$$\alpha(0) = C, \quad \beta(0) = 0, \quad \gamma(0) = 0, \quad \text{and} \quad \delta(0) = I_{K_2},$$

where $C \in BL(K_1)$ is provided by the KNF of $\mathcal{P}(0)$ and $\sigma(C) = -\sigma(\mathcal{A}, \mathcal{B}(0)) = \sigma(\mathcal{P}(0))$. Moreover, $\mathcal{G}_1$ and $\mathcal{G}_2$ represent $\mathcal{O}_2(u, v)$-functions parameterized by μ.

Seeking an invariant manifold on which $v = h(u, \mu)$, we put (5.3)–(5.5) into the form

$$\overline{\mu} = \mu, \tag{5.6}$$

$$\overline{u} = Cu + \mathcal{O}_2(u, v, \mu), \tag{5.7}$$

$$N\overline{v} = v + \mathcal{O}_2(u, v, \mu), \tag{5.8}$$

where $\mathcal{O}_2(u, v, \mu)$ denotes a function of (u, v, μ) which vanishes to second or higher order at the origin. From Theorem 1 we obtain a local invariant manifold of (5.6)–(5.7) on which $v = h(u, \mu)$. Moreover $h(0, 0) = 0, dh(0, 0) = 0$, and we may assume that h is C^1.

It follows that $h(u, \mu)$ satisfies the functional equation

$$Nh(\alpha u + \beta h(u, \mu) + \mathcal{G}_1(u, h(u, \mu), \mu)) = \gamma(\mu)u + \delta h(u, \mu) + \mathcal{G}_2(u, h(u, \mu), \mu),$$

and if we set $x = h(0, \mu)$, then x satisfies the equation

$$Nh(\beta x + \mathcal{G}_1(0, x, \mu), \mu) = \delta(\mu)x + \mathcal{G}_2(0, x, \mu).$$

The latter is an algebraic equation for x which we denote $a(x, \mu) = 0$; moreover $a(0, \mu) = 0$ holds for all μ near 0, whence $h(0, \mu) \equiv 0$. In addition, a short calculation shows that

$$d_x a(0, \mu) = \delta(\mu) - N d_u h(0, \mu)[\beta(\mu)],$$

which is an identity mapping when $\mu = 0$. The implicit function theorem now ensures that $x = 0$ is the only solution of $a(x, \mu) = 0$ for all μ near 0.

The functional equation satisfied by $d_u h(u,\mu)$ is then

$$-Nd_u h(\alpha u+\beta h+\mathcal{G}_1(u,h,\mu))[\alpha+\beta d_u h+d_u\mathcal{G}_1+d_v\mathcal{G}_1\cdot d_u h] \\ +\gamma+\delta d_u h+d_u\mathcal{G}_2+d_v\mathcal{G}_2\cdot d_u h=0,$$

where various arguments have been omitted for brevity. If we write τ for the linear map $d_u h(0,\mu)$, then

$$\gamma(\mu)+\delta(\mu)\tau=N\tau\cdot[\alpha(\mu)+\beta(\mu)\tau].$$

This is a Riccati equation for τ that can be solved near $\mu=0$ for τ as a function of μ using the implicit function theorem and the properties of α,β,γ, and δ. The result that $\tau(0)=0$ then follows because N is nilpotent and $\tau(0)=N\tau(0)[C]$.

We are now in a position to define the one-parameter family of matrices, denoted by $C(\mu)$ in the statement of the theorem, namely,

$$C(\mu):=\alpha(\mu)+\beta(\mu)\tau(\mu),$$

so that $C(0)=C$. If $C(\mu)$ has an eigenvalue λ, say, then

$$(\alpha+\beta\tau)w=\lambda w \implies \gamma+\delta\tau=N\tau\cdot[\lambda w],$$

whence

$$\begin{bmatrix}\alpha & \beta\\ \gamma & \delta\end{bmatrix}\begin{bmatrix}w\\ \tau w\end{bmatrix}=\lambda\begin{bmatrix}w\\ N\cdot\tau w\end{bmatrix},$$

and therefore

$$-\lambda\in\sigma\left(\begin{bmatrix}I & 0\\ 0 & N\end{bmatrix},\begin{bmatrix}\alpha & \beta\\ \gamma & \delta\end{bmatrix}\right)=\sigma(\mathcal{A},\mathcal{B}(\mu))=-\sigma(\mathcal{P}(\mu)).$$

We have deduced that

$$\sigma(\alpha(\mu)+\beta(\mu)\tau(\mu))\subseteq\sigma(\mathcal{P}(\mu)),$$

but the left-hand side of this inclusion has $\dim(K_1)$ elements counted according to algebraic multiplicity, whereas the right-hand side may have more unless, that is, $\mu=0$, in which case the inclusion is replaced by an equality because $\sigma(\alpha(0))=\sigma(C)=\sigma(\mathcal{P}(0))$.

As a result, if $\lambda(\mu)\in C([-\delta,\delta],\mathbb{C})$ is a continuous path of eigenvalues of $\mathcal{P}(\mu)$, then by virtue of the fact that $\lambda(0)\in\sigma(\alpha(\mu)+\beta(\mu)\tau(\mu)|_{\mu=0})$, it follows by the continuous dependence of eigenvalues on μ and by counting their location in the complex plane that $\lambda(\mu)\in\sigma(\alpha(\mu)+\beta(\mu)\tau(\mu)|_{\mu\neq 0})$. □

Conclusion 4 of Theorem 3 is not equivalent to saying that a locus of eigenvalues of $\mathcal{P}(\mu)$ is necessarily a locus of eigenvalues of $C(\mu)$. This is because $\mathcal{P}(\mu)$ may have other eigenvalues for small μ which become unbounded as μ tends to zero, and such curves cannot correspond to eigenvalues of $C(\mu)$. This happens, for instance, in the singularity-induced bifurcation theorem from [1] because an eigenvalue has a pole with respect to the bifurcation parameter.

5.2.1. Existence of bifurcations for (1.1). One can easily prove a period-doubling bifurcation theorem for (1.1) without having recourse to the nonlinear normal form given in Theorem 2, but we now include this result for completeness.

THEOREM 4. *Suppose that* (5.2) *satisfies the following hypotheses:*

1. $1 \notin \sigma(\mathcal{P}(0))$ *and* $F(0,0,\mu) \equiv 0$,
2. $\ker(-A(0)+B(0)) = \langle k \rangle$, *so that* $-1 \in \sigma(\mathcal{P}(0))$, *and*
3. $B'(0)k \notin \mathrm{im}(-\mathrm{A}(0)+\mathrm{B}(0))$.

Then $\mu = 0$ *is a period-doubling bifurcation point for* (5.2) *from the trivial solution* $z = 0$.

Proof. Consider the algebraic equation $G(z,w,\mu) = 0$, where $G : \mathbb{R}^{2m+1} \to \mathbb{R}^{2m}$ is given by

$$G(z,w,\mu) := \begin{bmatrix} F(z,w,\mu) \\ F(w,z,\mu) \end{bmatrix},$$

and moreover G has the trivial solution branch. Also define $\overline{G}(z,\mu) := F(z,z,\mu)$, so that

$$d_{(z,w)}G(0,0,\mu) = \begin{bmatrix} A(\mu) & B(\mu) \\ B(\mu) & A(\mu) \end{bmatrix},$$

and $d_z\overline{G}(0,\mu) = A(\mu)+B(\mu)$. By assumption, $A(0)+B(0)$ is invertible, and therefore $d_z\overline{G}(0,\mu)$ is an invertible map for small $|\mu|$, so that if $G(z,w,\mu) = 0$ near $\mu = 0$, then $z \neq w$ unless $z = w = 0$. The theorem now follows from the simple eigenvalue bifurcation theorem applied to G at $\mu = 0$, noting that the kernel of $d_{(z,w)}G(0,0,0)$ is $(k,-k)^T$. ∎

One can of course formulate a similarly straightforward fold bifurcation for (1.1) in an entirely analogous fashion. However, the following theorem relies on Theorem 3 in a nontrivial way.

THEOREM 5 (Neimark–Sacker bifurcation). *Suppose that* (5.2) *has the fixed point* $z = 0$ *for all* $\mu \in \mathbb{R}$ *and that* $\lambda(\mu) \in \sigma(\mathcal{P}(\mu))$ *is a curve which satisfies the following:*

1. $\mathcal{P}(0)$ *is a regular matrix pencil;*
2. $|\lambda(0)| = 1$, *and* $\lambda(0)$ *is an algebraically simply eigenvalue of* $\mathcal{P}(0)$*;*
3. $\lambda(0)^n \neq 1$ *for* $n \in \{1,2,3,4\}$*;*
4. $\frac{d}{d\mu}|\lambda(\mu)|\big|_{\mu=0} \neq 0$.

Then modulo a further nonresonance condition[1] *there is a half-interval* $J \subset \mathbb{R}$ *containing* 0 *in its closure such that* (5.2) *possesses a quasi-invariant circle* $\Gamma_\mu \subset \mathbb{R}^{2m}$ *for all* $\mu \in J$. *Moreover, if* $\mathrm{diam}(\Gamma_\mu) = \sup\{\|z-w\| : z,w \in \Gamma_\mu\}$, *then* $\lim_{\mu\to 0} \mathrm{diam}(\Gamma_\mu) = 0$.

Proof. Theorem 5 follows immediately from the Neimark–Sacker bifurcation for maps applied to $\varphi(u,\mu)$ from Theorem 3 (part 3). ∎

6. Examples. *Example* 1 (output-nulling control problem). The results in this paper give sufficient conditions for a positive answer to the following question:

(Q) *Given* $f(= f(x,u)) : \mathbb{R}^{n+m} \to \mathbb{R}^n, g(= g(x)) : \mathbb{R}^n \to \mathbb{R}^m$ *such that* $f(0,0) = 0, g(0) = 0$, *does there exist a sequence of states* (x_n) *given by the iterates of* f *and controls* (u_n) *such that* $g(x_n) \equiv 0$ *and* $x_n \to 0$ *as* $n \to \infty$*?*

Thus, we seek a global orbit of the ΔAE

$$x_{n+1} = f(x_n,u_n),\ g(x_n) = 0.$$

[1] See [21] or [25, p. 376], where the open condition "$a \neq 0$" is given, and this requires the computation of third-order terms in the normal form for this bifurcation.

A necessary condition for the existence of such a solution can be obtained by substituting the dynamic part of the problem into the constraint, to give the hidden constraint

$$g(f(x_n, u_n)) = 0 \qquad (\forall n \geq 1).$$

Hence, provided the function $g(f(x,u))$ has an invertible partial u-derivative at $(x,u) = (0,0)$, by the stable manifold theorem the response to (**Q**) is affirmative if the spectrum of the x-derivative of $f(x, U(x))$, also evaluated at $(x,u) = (0,0)$, contains an element of the open unit disk. Here $U(x)$ denotes the solution of the equation $g(f(x,U)) = 0$ given locally by the implicit function theorem. Note for a moment that if the stated u-derivative $dg(0)d_uf(0,0)$ is invertible, it follows that the matrix pencil

$$(A,B) := \left(\begin{pmatrix} I_x & 0 \\ 0 & 0 \end{pmatrix}, \begin{pmatrix} d_xf & d_uf \\ dg & 0 \end{pmatrix} \right)\Bigg|_{(x,u)=(0,0)}$$

is regular, and thus (A1)–(A3) hold for this problem.

However, by using Theorem 1 one can dispense with the condition that $dg(0)d_uf(0,0)$ is invertible. In fact, let us assume that $K := \ker(dg(0)d_uf(0,0)) \neq \{0\}$. In this case, the matrix $\lambda A + B$ is invertible if $-\lambda \notin \sigma(d_xf(0,0))$ and $dg(\lambda I_x + d_xf)^{-1}d_uf$ is also invertible at $(x,u) = (0,0)$. However, for λ large we have

$$\begin{aligned} \lambda^2 dg(\lambda I_x + d_xf)^{-1}d_uf &= \lambda dg(I_x + \lambda^{-1}d_xf)^{-1}d_uf \\ &= \lambda dg(I_x - \lambda^{-1}d_xf + O(\lambda^{-2}))d_uf \\ &= \lambda\ dg \cdot d_uf - dg \cdot d_xf \cdot d_uf + O(\lambda^{-1}), \end{aligned}$$

evaluating all of the stated derivatives at $(x,u) = (0,0)$. As a result, if the weaker condition holds that the pencil $(dg \cdot d_uf, dg \cdot d_xf \cdot d_uf)$ is regular, then (A,B) is regular and (A1)–(A3) still apply. The response to (Q) is again affirmative if $\sigma(A,B)$ contains at least one member of the open unit disk.

In fact one can show that output-nulling control problems are well-posed in sequence spaces as follows. First consider the linear problem

$$Az_{n+1} + Bz_n = \Gamma_n, \tag{6.1}$$

where $n \in \mathbb{N}$ and (Γ_n) is a given sequence in

$$\ell^\infty_{\mathbb{N}}(\mathbb{R}^m) = \left\{ (z_n)_{n\in\mathbb{N}} : z_n \in \mathbb{R}^m, \sup_{n\in\mathbb{N}} \|z_n\|_{\mathbb{R}^m} < \infty \right\},$$

but $\det A = 0$. If (A,B) is a regular matrix pencil with index ν, the KNF allows us to write (6.1) in the form

$$u_{n+1} = Cu_n + \alpha_n, \tag{6.2}$$

$$Nv_{n+1} = v_n + \beta_n, \tag{6.3}$$

where $(u_n, v_n) \in \mathbb{R}^{p+q}$. In order to solve (6.1), let us consider the linear operator $I - N\sigma$ on a space of sequences $\ell^\infty_{\mathbb{N}}(\mathbb{R}^q)$. We take linear maps $T \in BL(\mathbb{R}^q)$ to act pointwise on $\ell^\infty_{\mathbb{N}}(\mathbb{R}^q)$, so

$$T(w_n)_{n\in\mathbb{N}} = (Tw_n)_{n\in\mathbb{N}} \qquad (\forall (w_n)_{n\in\mathbb{N}} \in \ell^\infty_{\mathbb{N}}(\mathbb{R}^q)),$$

and we define σ the forward-shift map by

$$\sigma(w_n)_{n\in\mathbb{N}} = (w_{n+1})_{n\in\mathbb{N}} \qquad (\forall (w_n)_{n\in\mathbb{N}} \in \ell^\infty_{\mathbb{N}}(\mathbb{R}^q)).$$

Any such T will commute with σ, and one can see by a direct multiplication that

$$(I - N\sigma)\sum_{i=0}^{\nu-1} N^i\sigma^i = I,$$

where I denotes the identity on $\ell^\infty_{\mathbb{N}}(\mathbb{R}^q)$.

One can solve (6.2) in a suitably weighted sequence space if no restrictions are to be placed on the spectrum of (A, B). Equation (6.3) can also be solved:

$$\mathbf{v} = -(I - N\sigma)^{-1}\beta = -\sum_{i=0}^{\nu-1} N^i\sigma^i\beta,$$

where $\mathbf{v} = (v_i)_{i\in\mathbb{N}}$ and $\beta = (\beta_i)_{i\in\mathbb{N}}$, whence

$$v_n = -\sum_{i=0}^{\nu-1} N^i\beta_{n+i}.$$

So from a temporal point of view the current values of the state depend on future values of the input, but (6.1) is still well-posed in a sequence space as $\mathbf{v}$ depends continuously on β.

This means that a second- or higher-order nonlinear perturbation of (6.1),

$$Az_{n+1} + Bz_n + \mathcal{F}(z_n) = \Gamma_n, \tag{6.4}$$

say, where $\mathcal{F}(0) = 0, d\mathcal{F}(0) = 0$, can be written as an infinite-dimensional problem

$$(A\sigma + B)\mathbf{z} + \mathcal{F}(\mathbf{z}) = \mathbf{\Gamma} \tag{6.5}$$

in $\ell^\infty_{\mathbb{N}}(\mathbb{R}^m)$, and one can apply the inverse function theorem to solve locally for small-norm solutions of the form $\mathbf{z} = \mathbf{z}(\mathbf{\Gamma})$, where $\mathbf{z}(\mathbf{0}) = \mathbf{0}$.

This solution can be found via the Picard iteration $\mathbf{z}(\mathbf{\Gamma}) = \lim_{n\to\infty} \mathbf{y}^{(n)}$, where $\mathbf{y}^{(0)} = \mathbf{0}$ and

$$\mathbf{y}^{(n+1)} = -(A\sigma + B)^{-1}[\mathcal{F}(\mathbf{y}^{(n)}) - \mathbf{\Gamma}].$$

As a result, writing the solution sequence $\mathbf{z}(\mathbf{\Gamma})$ as $(z_n(\mathbf{\Gamma}))_{n\in\mathbb{N}}$, it is clear that the nonlinear perturbation will have the effect of making each z_n depend on infinitely many elements of the sequence $\mathbf{\Gamma}$, unless ν happens to equal 1.

This effect has been observed before in the literature in the context of delay DAEs [5, 13], where it is noted in the former reference that linear systems of delay DAEs can act like advanced systems when their index is two or higher. The problem (6.5) is displaying exactly this behavior.

Example 2. This example serves to illustrate how we can use Theorem 1 to deduce qualitative similarities between a DAE and its discrete counterpart. Take the DAE

$$\dot{x} = f(x, y), \tag{6.6}$$

$$g(x, y) = 0, \tag{6.7}$$

subject to $x \in \mathbb{R}^n, y \in \mathbb{R}^m$ with an equilibrium at the origin, so that $f(0,0) = 0, g(0,0) = 0$. Let us impose a singularity of the form

$$\ker(d_y g(0,0)) = \langle k \rangle \quad \text{such that} \quad d_y f(0,0) d_x g(0,0) k \notin \operatorname{im}(d_y g(0,0)), \tag{6.8}$$

and the equilibrium solution is isolated:

$$\det \begin{pmatrix} d_x f(0,0) & d_y f(0,0) \\ d_x g(0,0) & d_y g(0,0) \end{pmatrix} \neq 0.$$

From [2] it is known that (6.6)–(6.7) has an invariant manifold W of dimension $n-1$ that contains the origin and intersects the singularity in an $n-2$-dimensional manifold of pseudoequilibria.

Now consider the forward-Euler method in state-space form [8, p. 375] applied to (6.6)–(6.7), resulting in the difference equation

$$x_{i+1} - x_i = h f(x_i, y_i), \tag{6.9}$$

$$g(x_{i+1}, y_{i+1}) = 0. \tag{6.10}$$

Using Theorem 1, in order to to show that (6.9)–(6.10) possesses a quasi-invariant manifold of solutions W_h that contains the origin and has dimension $n-1$, we need only show that (A1)–(A3) hold, which entails showing that the derivative at the origin of (6.9)–(6.10) is a regular matrix pencil. Hence we seek a $\xi \in \mathbb{C}$ such that

$$\det \left(\xi \begin{bmatrix} I & 0 \\ d_x g & d_y g \end{bmatrix} + \begin{bmatrix} I + h d_x f & h d_y f \\ 0 & 0 \end{bmatrix} \right) \Bigg|_{(x,y)=(0,0)} \neq 0.$$

However, the conditions in (6.8) ensure the existence of such a ξ for any fixed $h \neq 0$, and the existence of W_h follows. The dimension of W_h comes from counting the number of finite eigenvalues of the linearization of (6.9)–(6.10) which is given in [1] as $n-1$.

Example 3. Consider again (6.6)–(6.7) but now with a parameter α

$$\dot{x} = f(x, y, \alpha), g(x, y, \alpha) = 0, \tag{6.11}$$

and suppose that $(x, y) = (0, 0)$ is an equilibrium locus for all $\alpha \in \mathbb{R}$. Now suppose that the conditions for a Hopf bifurcation are formally satisfied by (6.11) at $\alpha = \alpha_0$: $\omega(\alpha) \in \sigma(M, -L(\alpha))$ is a locus of algebraically simple eigenvalues, where

$$M = \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix}, \; L(\alpha) = \begin{bmatrix} d_x f(0,0,\alpha) & d_y f(0,0,\alpha) \\ d_x g(0,0,\alpha) & d_y g(0,0,\alpha) \end{bmatrix};$$

and $\omega(\alpha_0) = i\omega_0$ is an eigenvalue of $(M, -L(\alpha))$ such that $\frac{d}{d\alpha} \Re(\omega(\alpha)) \big|_{\alpha=\alpha_0}$ is nonzero. Also, no other eigenvalues of the regular matrix pencil $(M, -L(\alpha_0))$ have a zero real part.

Then, modulo an open condition on the third-order derivatives of the smooth functions f and g, we can show that the backward-Euler method

$$x_{i+1} - x_i = h f(x_{i+1}, y_{i+1}), \tag{6.12}$$

$$-h \cdot g(x_{i+1}, y_{i+1}) = 0, \tag{6.13}$$

satisfies the conditions of the Neimark–Sacker bifurcation theorem for all sufficiently small $h > 0$. Note that $(M - hL(\alpha), -M)$ is the linearization of (6.12)–(6.13) about the zero fixed point and is a regular matrix pencil for $h > 0$ and $\alpha \approx \alpha_0$ such that

$$(1 - h\omega(\alpha))^{-1} \in \sigma(M - hL(\alpha), -M) \qquad (\forall \alpha).$$

In order to apply Theorem 5 to (6.12)–(6.13) we first note that the eigenvalue locus $(1 - h\omega(\alpha))^{-1}$ has unit length if and only if $1 - h\omega(\alpha)$ has unit length. If we define functions $R(\alpha)$ and $I(\alpha)$ by $\omega(\alpha) = R(\alpha) + iI(\alpha)$, then $|1 - h\omega(\alpha)| = 1$ if and only if $(1 - hR(\alpha))^2 + h^2 I(\alpha)^2 = 1$, which holds when

$$h\left(-R(\alpha) + \frac{h}{2}(R(\alpha)^2 + I(\alpha)^2)\right) = 0. \tag{6.14}$$

As a result, we define the function $b(\alpha, h) := -R(\alpha) + \frac{h}{2}(R(\alpha)^2 + I(\alpha)^2)$ and note that $b(\alpha, h) = 0$ for $h > 0$ ensures that the linearization of (6.12)–(6.13) at $(0, 0)$ has an eigenvalue of unit modulus. Now $b(\alpha_0, 0) = 0$ and $\frac{\partial b}{\partial \alpha}(\alpha_0, 0) = -R'(\alpha_0) \neq 0$ by assumption, and, as a result, one may solve $b(\alpha, h) = 0$ locally using the implicit function theorem for $\alpha = \alpha(h)$ such that $\alpha(0) = \alpha_0$.

From this calculation one can show that the numerical scheme (6.12)–(6.13) has a quasi-invariant circle for α in some half-neighborhood of $\alpha(h) = \alpha_0 + \frac{h\omega_0^2}{R'(\alpha)} + O(h^2)$ provided $h > 0$ is sufficiently small.

Note that no assumption is made regarding the invertibility of $d_y g(0, 0, 0)$. If this mapping were invertible in addition to the formal conditions given above for Hopf bifurcation, then the existence of a locus of periodic solutions of (6.11) could be deduced. However, without the invertibility of $d_y g(0, 0, 0)$, it is not known whether a Hopf bifurcation occurs in (6.11), but (6.12)–(6.13) has a locus of invariant circles nevertheless.

6.1. Concluding remark. The results in this paper can be used to show that second-order problems of the form

$$F(z_n, z_{n+1}, z_{n+2}) = 0 \tag{6.15}$$

have quasi-invariant manifolds provided that the appropriate matrix pencil is regular simply by rewriting (6.15) as a first-order problem. However, the methods of this paper do not easily extend to the study of invariant manifolds of the system that one would like to study if (1.1) had a period-2 orbit $(z, w, z, w, \ldots)$, namely, the system

$$F(z_n, z_{n+1}) = 0, \tag{6.16}$$

$$F(z_{n+1}, z_{n+2}) = 0, \tag{6.17}$$

where $F(z, w) = 0$ and $F(w, z) = 0$, with $w \neq z$. Another approach is needed to answer the question of whether overdetermined systems of this type have any invariant manifolds associated with them.

ON THE WELL-POSEDNESS FOR THE VISCOUS SHALLOW WATER EQUATIONS*

QIONGLEI CHEN†, CHANGXING MIAO†, AND ZHIFEI ZHANG‡

Abstract. In this paper, we prove the existence and uniqueness of the solutions for the two-dimensional viscous shallow water equations with low regularity assumptions on the initial data as well as the initial height bounded away from zero.

Key words. shallow water equations, well-posedness, Bony's paraproduct decomposition, weight Besov space

AMS subject classifications. 35Q35, 76D

DOI. 10.1137/060660552

1. Introduction.

In this paper, we study the two-dimensional (2D) viscous shallow water equations with a more general diffusion,

$$\begin{cases} h_t + \operatorname{div}(hu) = 0, \\ h(u_t + u\cdot\nabla u) - \nu\nabla\cdot(hD(u)) - \nu\nabla(h\operatorname{div}(u)) + h\nabla h = 0, \\ u(0,\cdot) = u_0,\ h(0,\cdot) = h_0, \end{cases} \tag{1.1}$$

where $h(t,x)$ is the height of fluid surface, $u(t,x) = (u_1(t,x), u_2(t,x))$ is the horizontal velocity vector field, $D(u) = \frac{1}{2}(\nabla u + \nabla u^t)$ is the deformation tensor, and $\nu > 0$ is the viscous coefficient.

Recently, the viscous shallow water equations have been widely studied by mathematicians; see the review paper [4]. Bui [5] proved the local existence and uniqueness of classical solutions to the Cauchy–Dirichlet problem for shallow water equations with initial data h_0, u_0 in Hölder spaces as well as h_0 bounded away from a vacuum. Kloeden [17] and Sundbye [20] independently proved global existence and uniqueness of classical solutions to the Cauchy–Dirichlet problem in Sobolev spaces. Later, Sundbye [21] also proved global existence and uniqueness of classical solutions to the Cauchy problem. However, for all of the above results (except those of [5]), the authors only consider the case when the initial data h_0 is a small perturbation of some positive constant $\bar{h}_0$ and u_0 is small in some sense. Very recently, Wang and Xu [23] proved the local well-posedness of the Cauchy problem in Sobolev spaces for the large data u_0 and h_0 closing to $\bar{h}_0$. More precisely, they obtained the following result.

THEOREM 1.1 (see [23]). *Let $\bar{h}_0$ be a strictly positive constant and $s > 2$. Assume that*

(i) $(u_0, h_0 - \bar{h}_0) \in H^s(\mathbb{R}^2) \otimes H^s(\mathbb{R}^2)$;

(ii) $\|h_0 - \bar{h}_0\|_{H^s} \ll \bar{h}_0$.

‡School of Mathematical Science, Peking University, Beijing 100871, People's Republic of China (zfzhang@math.pku.edu.cn). This author's research was supported by the NSF of China (grant 10601002).

Then there exist a positive time T and a unique solution (u,h) of (1.1) such that

$$u,\ h-\bar{h}_0\in L^\infty([0,T],H^s),\quad \nabla u\in L^2([0,T];H^s). \tag{1.2}$$

Moreover, there exists a strictly positive constant c such that if

$$\|u_0\|_{H^s}+\|h_0-\bar{h}_0\|_{H^s}\leq c, \tag{1.3}$$

then we can choose $T=+\infty$.

One purpose of this paper is to study the well-posedness of (1.1) for the initial data with the minimal regularity. For the incompressible Navier–Stokes equations, such research has been initiated by Fujita and Kato [16]; see also [6, 7, 18] for other relevant results. They proved local well-posedness for the incompressible Navier–Stokes equations in the scaling invariant space. The scaling invariance means that if (u,p) is a solution of the incompressible Navier–Stokes equations with initial data $u_0(x)$, then

$$u_\lambda(t,x)\triangleq\lambda u(\lambda^2t,\lambda x),\quad p_\lambda(t,x)\triangleq\lambda^2p(\lambda^2t,\lambda x) \tag{1.4}$$

is also a solution of the incompressible Navier–Stokes equations with $u_{0,\lambda}\triangleq\lambda u_0(\lambda x)$. Obviously, $\dot{H}^{\frac{d}{2}-1}(\mathbb{R}^d)$ is a scaling invariant space under the scaling of (1.4), i.e.,

$$\|u_\lambda\|_{\dot{H}^{\frac{d}{2}-1}}=\|u\|_{\dot{H}^{\frac{d}{2}-1}}.$$

Equations (1.1) have no scaling invariance like the incompressible Navier–Stokes equations. However, due to the similarity of the structure between (1.1) and the incompressible Navier–Stokes equations, we still solve (1.1) for initial data whose regularity fits the scaling of (1.4). It should be pointed out that Danchin was the first to consider the same problem for the compressible Navier–Stokes equations, and some ideas of this paper are motivated by [11].

The second purpose of this paper is to prove the local well-posedness of (1.1) under the more natural assumption that the initial height is bounded away from zero. For the initial data with slightly higher regularity, this can be easily obtained by modifying the argument of Danchin [13]. However, for the initial data with low regularity, his method is not applicable anymore, since the proof of [13] relies on the fact that some profits can be gained from the inclusion map $B^s\hookrightarrow L^\infty$ in the case of $s>\frac{d}{2}$. For this reason, we have to introduce some kind of weighted Besov space E^s_T (see section 3), which is crucial to eliminating the condition that the initial height h_0 is close to $\bar{h}_0$. One important observation is that the E^s_T norm of the solution is small for small time T.

Before stating our main result, let us first introduce some notations and definitions. Choose a radial function $\varphi\in\mathcal{S}(\mathbb{R}^d)$ such that

$$\operatorname{supp}\varphi\subset\left\{\xi\in\mathbb{R}^d;\frac{5}{6}\leq|\xi|\leq\frac{12}{5}\right\},\quad \sum_{k\in\mathbb{Z}}\varphi(2^{-k}\xi)=1,\quad \xi\in\mathbb{R}^d\setminus\{0\}.$$

Here $\varphi_k(\xi)=\varphi(2^{-k}\xi)$, $k\in\mathbb{Z}$.

Definition 1.1. *Let $k\in\mathbb{Z}$. The Littlewood–Paley projection operators Δ_k and S_k are defined as follows:*

$$\Delta_kf=\varphi(2^{-k}D)f,\quad S_kf=\sum_{j\leq k-1}\Delta_jf\quad \textit{for}\quad f\in\mathcal{S}'(\mathbb{R}^d).$$

We denote the space $\mathcal{Z}'(\mathbb{R}^d)$ by the dual space of $\mathcal{Z}(\mathbb{R}^d) = \{f \in \mathcal{S}(\mathbb{R}^d);\ D^\alpha \hat{f}(0) = 0; \forall \alpha \in \mathbb{N}^d \text{ multi-index}\}$; it also can be identified by the quotient space of $\mathcal{S}'(\mathbb{R}^d)/\mathcal{P}$ with the polynomials space $\mathcal{P}$. The formal equality

$$f = \sum_{k\in\mathbb{Z}} \Delta_k f$$

holds true for $f \in \mathcal{Z}'(\mathbb{R}^d)$ and is called the homogeneous Littlewood–Paley decomposition. It has nice properties of quasi-orthogonality: with our choice of φ,

$$\Delta_j\Delta_k f = 0 \quad \text{if} \quad |j-k| \geq 2 \quad \text{and} \quad \Delta_j(S_{k-1}\Delta_k f) = 0 \quad \text{if} \quad |j-k| \geq 4. \tag{1.5}$$

DEFINITION 1.2. *Let $s \in \mathbb{R}$, $1 \leq p, r \leq +\infty$. The homogeneous Besov space $\dot{B}^s_{p,r}$ is defined by*

$$\dot{B}^s_{p,r} = \{f \in \mathcal{Z}'(\mathbb{R}^d) :\ \|f\|_{\dot{B}^s_{p,r}} < +\infty\},$$

where

$$\|f\|_{\dot{B}^s_{p,r}} = \begin{cases} \displaystyle\Big(\sum_{k\in\mathbb{Z}} 2^{ksr}\|\Delta_k f\|_p^r\Big)^{\frac{1}{r}} & \text{for} \quad r < +\infty, \\ \displaystyle\sup_{k\in\mathbb{Z}} 2^{ks}\|\Delta_k f\|_p & \text{for} \quad r = +\infty. \end{cases}$$

If $p = r = 2$, $\dot{B}^s_{2,2} = \dot{H}^s$, and if $d = 2$, we have $\dot{B}^1_{2,1} \hookrightarrow L^\infty$ and

$$\|f\|_\infty \leq C\|f\|_{\dot{B}^1_{2,1}}.$$

We refer to [8, 22] for more details.

In addition to the general time-space space such as $L^\rho(0,T;\dot{B}^s_{p,r})$, we introduce a useful mixed time-space homogeneous Besov space $\widetilde{L}^\rho_T(\dot{B}^s_{p,r})$, which was initiated in [10] and will be used in the proof of the uniqueness.

DEFINITION 1.3. *Let $s \in \mathbb{R}$, $1 \leq p, r, \rho \leq +\infty$, $0 < T \leq +\infty$. The mixed time-space homogeneous Besov space $\widetilde{L}^r_T(\dot{B}^s_{p,q})$ is defined by*

$$\widetilde{L}^\rho_T(\dot{B}^s_{p,r}) = \{f \in \mathcal{Z}'(\mathbb{R}^{d+1}) :\ \|f\|_{\widetilde{L}^\rho_T(\dot{B}^s_{p,r})} < +\infty\},$$

where

$$\|f\|_{\widetilde{L}^\rho_T(\dot{B}^s_{p,r})} = \Big\|2^{ks}\Big(\int_0^T \|\Delta_k f(t)\|_p^\rho dt\Big)^{\frac{1}{\rho}}\Big\|_{\ell^r}.$$

Using the Minkowski inequality, it is easy to verify that

$$L^\rho_T(\dot{B}^s_{p,r}) \subseteq \widetilde{L}^\rho_T(\dot{B}^s_{p,r}) \quad \text{if} \quad \rho \leq r \quad \text{and} \quad \widetilde{L}^\rho_T(\dot{B}^s_{p,r}) \subseteq L^\rho_T(\dot{B}^s_{p,r}) \quad \text{if} \quad \rho \geq r.$$

Next, we introduce a hybrid-index Besov space which plays an important role in the study of compressible fluids and was initiated in [11, 12].

DEFINITION 1.4. *Let s, $\sigma \in \mathbb{R}$, and set*

$$\|f\|_{\widetilde{B}^{s,\sigma}_2} \triangleq \sum_{k\leq 0} 2^{ks}\|\Delta_k f\|_2 + \sum_{k>0} 2^{k\sigma}\|\Delta_k f\|_2.$$

Let $m=-[\frac{d}{2}+1-s]$; we define

$$\widetilde{B}_2^{s,\sigma}(\mathbb{R}^d)=\{f\in\mathcal{S}'(\mathbb{R}^d):\|f\|_{\widetilde{B}_2^{s,\sigma}}<+\infty\}\quad \textit{if}\quad m<0,$$

$$\widetilde{B}_2^{s,\sigma}(\mathbb{R}^d)=\{f\in\mathcal{S}'(\mathbb{R}^d)/\mathcal{P}_m:\|f\|_{\widetilde{B}_2^{s,\sigma}}<+\infty\}\quad \textit{if}\quad m\geq 0,$$

where $\mathcal{P}_m$ denotes the set of polynomials of degree $\leq m$.

Throughout this paper, we will denote $\dot{B}^s_{2,1}$ by B^s and $\widetilde{B}^{s,\sigma}_2$ by $\widetilde{B}^{s,\sigma}$. The following facts can be easily verified by using the definition of $\widetilde{B}^{s,\sigma}$:

(i) $\widetilde{B}^{s,s}=\dot{B}^s_{2,1}$.

(ii) If $s\leq\sigma$, then $\widetilde{B}^{s,\sigma}=\dot{B}^s_{2,1}\cap\dot{B}^\sigma_{2,1}$. Otherwise, $\widetilde{B}^{s,\sigma}=\dot{B}^s_{2,1}+\dot{B}^\sigma_{2,1}$.

Now we state our main result as follows.

THEOREM 1.2. *Let $\bar{h}_0$ be a positive constant. Assume that*

(i) $(u_0,h_0-\bar{h}_0)\in B^0(\mathbb{R}^2)\otimes\widetilde{B}^{0,1}(\mathbb{R}^2)$;

(ii) $h_0\geq\bar{h}_0$.

Then there exist a positive time T and a unique solution (u,h) of (1.1) such that

$$\begin{aligned}&u\in C([0,T];B^0)\cap L^1(0,T;B^2),\\ &h-\bar{h}_0\in C([0,T];\widetilde{B}^{0,1})\cap L^1(0,T;\widetilde{B}^{2,1}),\quad h\geq\frac{1}{2}\bar{h}_0.\end{aligned}\tag{1.6}$$

Moreover, there exists a strictly positive constant c such that if

$$\|u_0\|_{B^0}+\|h_0-\bar{h}_0\|_{\widetilde{B}^{0,1}}\leq c,\tag{1.7}$$

then we can choose $T=+\infty$.

The structure of this paper is as follows. In section 2, we recall some useful multilinear estimates in the Besov spaces. In section 3, we prove the existence of the solution. In section 4, we prove the uniqueness of the solution. Finally, in the appendix, we prove some multilinear estimates in the weighted Besov spaces.

Throughout the paper, C denotes various "harmless" large finite constants, and c denotes various "harmless" small constants. We shall sometimes use $X\lesssim Y$ to denote the estimate $X\leq CY$ for some constant C. We denote $\|\cdot\|_p$ by the L^p norm of a function.

2. Multilinear estimates in the Besov spaces. Let us first recall Bony's paraproduct decomposition.

DEFINITION 2.1. *We shall use the following Bony paraproduct decomposition (see* [1, 3]*):*

$$fg=T_fg+T_gf+R(f,g),\tag{2.1}$$

with

$$T_fg=\sum_{k\in\mathbb{Z}}S_{k-1}f\Delta_kg\quad\textit{and}\quad R(f,g)=\sum_{k\in\mathbb{Z}}\sum_{|k'-k|\leq1}\Delta_kf\Delta_{k'}g.\tag{2.2}$$

Next, let us recall some useful lemmas and multilinear estimates in the Besov spaces.

LEMMA 2.1 (Bernstein's inequality). *Let $1\leq p\leq q\leq+\infty$. Assume that $f\in\mathcal{S}'(\mathbb{R}^d)$; then for any $\gamma\in\mathbb{Z}^d$, there exist constants C_1, C_2 independent of f, j*

such that

$$\mathrm{supp}\hat{f} \subseteq \{|\xi| \le A_0 2^j\} \Rightarrow \|\partial^\gamma f\|_q \le C_1 2^{j|\gamma|+jd(\frac{1}{p}-\frac{1}{q})}\|f\|_p,$$

$$\mathrm{supp}\hat{f} \subseteq \{A_1 2^j \le |\xi| \le A_2 2^j\} \Rightarrow \|f\|_p \le C_2 2^{-j|\gamma|} \sup_{|\beta|=|\gamma|} \|\partial^\beta f\|_p.$$

The proof can be found in [8].

PROPOSITION 2.2. *If $s > 0$, $f, g \in B^s \cap L^\infty$, then $fg \in B^s \cap L^\infty$ and*

$$\|fg\|_{B^s} \le C(\|f\|_\infty \|g\|_{B^s} + \|g\|_\infty \|f\|_{B^s}). \tag{2.3}$$

If s_1, $s_2 \le \frac{d}{2}$ such that $s_1 + s_2 > 0$, $f \in B^{s_1}$, and $g \in B^{s_2}$, then $fg \in B^{s_1+s_2-\frac{d}{2}}$ and

$$\|fg\|_{B^{s_1+s_2-\frac{d}{2}}} \le C\|f\|_{B^{s_1}}\|g\|_{B^{s_2}}. \tag{2.4}$$

If $|s| < \frac{d}{2}$, $1 \le r \le +\infty$, $f \in \dot{B}^s_{2,r}$, and $g \in B^{\frac{d}{2}}$, then $fg \in \dot{B}^s_{2,r}$ and

$$\|fg\|_{\dot{B}^s_{2,r}} \le C\|f\|_{\dot{B}^s_{2,r}}\|g\|_{B^{\frac{d}{2}}}. \tag{2.5}$$

If $s \in (-\frac{d}{2}, \frac{d}{2}]$, $f \in B^s$, and $g \in \dot{B}^{-s}_{2,\infty}$, then $fg \in \dot{B}^{-\frac{d}{2}}_{2,\infty}$ and

$$\|fg\|_{\dot{B}^{-\frac{d}{2}}_{2,\infty}} \le C\|f\|_{B^s}\|g\|_{\dot{B}^{-s}_{2,\infty}}. \tag{2.6}$$

If $1 \le \rho_1, \rho_2, \rho \le \infty, s \in (-\frac{d}{2}, \frac{d}{2}]$, $f \in \widetilde{L}^{\rho_1}_T(B^s)$, and $g \in \widetilde{L}^{\rho_2}_T(\dot{B}^{-s}_{2,\infty})$, then there holds

$$\|fg\|_{\widetilde{L}^\rho_T(\dot{B}^{-\frac{d}{2}}_{2,\infty})} \le C\|f\|_{\widetilde{L}^{\rho_1}_T(B^s)}\|g\|_{\widetilde{L}^{\rho_2}_T(\dot{B}^{-s}_{2,\infty})}, \tag{2.7}$$

where $\frac{1}{\rho_1} + \frac{1}{\rho_2} = \frac{1}{\rho}$.

Proof. For the sake of simplicity, we present only the proof of (2.4); the others can be deduced in the same way (see also [14, 19]). By Bony's paraproduct decomposition and the property of quasi-orthogonality (1.5), for fixed $j \in \mathbb{Z}$, we write

$$\begin{aligned}\Delta_j(fg) &= \sum_{|k-j|\le 3} \Delta_j(S_{k-1}f\Delta_k g) + \sum_{|k-j|\le 3} \Delta_j(S_{k-1}g\Delta_k f) \\ &\quad + \sum_{k\ge j-2}\sum_{|k-k'|\le 1} \Delta_j(\Delta_k f \Delta_{k'} g) \\ &\triangleq I + II + III.\end{aligned}$$

Thanks to the definition of Besov space B^s, we have

$$\begin{aligned}\|fg\|_{B^{s_1+s_2-\frac{d}{2}}} &\le \Big(\sum_{j\in\mathbb{Z}} 2^{(s_1+s_2-\frac{d}{2})j}\|I\|_2\Big) + \cdots + \Big(\sum_{j\in\mathbb{Z}} 2^{(s_1+s_2-\frac{d}{2})j}\|III\|_2\Big) \\ &\triangleq I' + II' + III'. \end{aligned} \tag{2.8}$$

It suffices to estimate the above three terms separately. Using Young's inequality and Lemma 2.1, we have

$$\begin{aligned}\|\Delta_j(S_{k-1}f\Delta_k g)\|_2 &\lesssim \|S_{k-1}f\|_\infty\|\Delta_k g\|_2 \lesssim \sum_{k'\leq k-2}\|\Delta_{k'}f\|_\infty\|\Delta_k g\|_2\\ &\lesssim \sum_{k'\leq k-2}2^{k's_1}\|\Delta_{k'}f\|_2 2^{k'(\frac{d}{2}-s_1)}\|\Delta_k g\|_2\\ &\lesssim \|f\|_{B^{s_1}}\|\Delta_k g\|_2 2^{k(\frac{d}{2}-s_1)},\end{aligned}$$

where we have used the fact $s_1 \leq \frac{d}{2}$ in the last inequality. Hence, we get

$$\begin{aligned}I' &\lesssim \|f\|_{B^{s_1}}\sum_{j\in\mathbb{Z}}2^{(s_1+s_2-\frac{d}{2})j}\sum_{|k-j|\leq 3}2^{k(\frac{d}{2}-s_1)}\|\Delta_k g\|_2\\ &\lesssim \|f\|_{B^{s_1}}\sum_{|\ell|\leq 3}2^{-(s_1+s_2-\frac{d}{2})\ell}\sum_{j\in\mathbb{Z}}2^{s_2(j+\ell)}\|\Delta_{j+\ell}g\|_2 \lesssim \|f\|_{B^{s_1}}\|g\|_{B^{s_2}}. \qquad (2.9)\end{aligned}$$

Similarly, using the fact $s_2 \leq \frac{d}{2}$, we can obtain

$$II' \lesssim \|f\|_{B^{s_1}}\|g\|_{B^{s_2}}. \qquad (2.10)$$

Now we turn to estimate III'. From Lemma 2.1 and the Hölder inequality, it follows that

$$\|\Delta_j(\Delta_k f\Delta_{k'}g)\|_2 \lesssim 2^{j\frac{d}{2}}\|\Delta_k f\Delta_{k'}g\|_1 \lesssim 2^{j\frac{d}{2}}\|\Delta_k f\|_2\|\Delta_{k'}g\|_2.$$

So, we get by the Minkowski inequality that for $s_1+s_2>0$

$$\begin{aligned}III' &\lesssim \sum_{j\in\mathbb{Z}}2^{(s_1+s_2-\frac{d}{2})j}2^{j\frac{d}{2}}\Big(\sum_{k\geq j-2}\sum_{|k-k'|\leq 1}\|\Delta_k f\|_2\|\Delta_{k'}g\|_2\Big)\\ &\lesssim \sum_{\ell\geq -2}2^{-(s_1+s_2)\ell}\sum_{j\in\mathbb{Z}}2^{s_1(j+\ell)}\|\Delta_{j+\ell}f\|_2\|g\|_{B^{s_2}} \lesssim \|f\|_{B^{s_1}}\|g\|_{B^{s_2}}. \qquad (2.11)\end{aligned}$$

Summing up (2.8)–(2.11), we get the desired inequality (2.4). □

PROPOSITION 2.3. (1) *Let $s>0$. Assume that $F\in W^{[s]+2,\infty}_{loc}(\mathbb{R}^d)$ such that $F(0)=0$. Then there exists a constant $C(s,d,F)$ such that if $u\in B^s\cap L^\infty$, it holds that*

$$\|F(u)\|_{B^s} \leq C(1+\|u\|_\infty)^{[s]+1}\|u\|_{B^s}; \qquad (2.12)$$

and if $u\in \dot{B}^s_{2,\infty}\cap L^\infty$, it holds that

$$\|F(u)\|_{\dot{B}^s_{2,\infty}} \leq C(1+\|u\|_\infty)^{[s]+1}\|u\|_{\dot{B}^s_{2,\infty}}. \qquad (2.13)$$

(2) *Assume that $G\in W^{[\frac{d}{2}]+3,\infty}_{loc}(\mathbb{R}^d)$ such that $G'(0)=0$. Then there exists a functions $C(s,d,G)$ such that if $-\frac{d}{2}<s\leq\frac{d}{2}$, $u,v\in B^{\frac{d}{2}}\cap L^\infty$ and $u-v\in B^s$, it holds that*

$$\|G(u)-G(v)\|_{B^s} \leq C(\|u\|_\infty,\|v\|_\infty)(\|u\|_{B^{\frac{d}{2}}}+\|v\|_{B^{\frac{d}{2}}})\|u-v\|_{B^s}; \qquad (2.14)$$

and if $|s| < \frac{d}{2}$, $u, v \in B^{\frac{d}{2}} \cap L^\infty$ *and* $u - v \in \dot{B}^s_{2,\infty}$, *it holds that*

$$\|G(u) - G(v)\|_{\dot{B}^s_{2,\infty}} \le C(\|u\|_\infty, \|v\|_\infty)(\|u\|_{B^{\frac{d}{2}}} + \|v\|_{B^{\frac{d}{2}}})\|u - v\|_{\dot{B}^s_{2,\infty}}. \tag{2.15}$$

Proof. We can refer to [2, 19] for the proof of (1). For (2), we refer to [11, 15]. For example, we write

$$G(u) - G(v) = (u - v)\int_0^1 G'(v + \tau(u - v))d\tau.$$

Then it follows from (2.5) that for $|s| < \frac{d}{2}$

$$\|G(u) - G(v)\|_{\dot{B}^s_{2,\infty}} \le C\|u - v\|_{\dot{B}^s_{2,\infty}}\|G'(v + \tau(u - v))\|_{B^{\frac{d}{2}}},$$

which together with (2.12) implies (2.15). □

PROPOSITION 2.4. *Let* A *be a homogeneous smooth function of degree* m. *Assume that* $-\frac{d}{2} < s_1, t_1, s_2, t_2 \le 1 + \frac{d}{2}$. *Then it holds that if* $k \ge 1$,

$$\begin{aligned} &|(A(D)\Delta_k(v \cdot \nabla f), A(D)\Delta_k f)| \\ &\lesssim \alpha_k 2^{-k(s_2 - m)}\|v\|_{B^{\frac{d}{2}+1}}\|f\|_{\widetilde{B}^{s_1,s_2}}\|A(D)\Delta_k f\|_2; \end{aligned} \tag{2.16}$$

if $k \le 0$,

$$\begin{aligned} &|(A(D)\Delta_k(v \cdot \nabla f), A(D)\Delta_k f)| \\ &\lesssim \alpha_k 2^{-k(s_1 - m)}\|v\|_{B^{\frac{d}{2}+1}}\|f\|_{\widetilde{B}^{s_1,s_2}}\|A(D)\Delta_k f\|_2; \end{aligned} \tag{2.17}$$

if $k \ge 1$,

$$\begin{aligned} &|(A(D)\Delta_k(v \cdot \nabla f), \Delta_k g) + (\Delta_k(v \cdot \nabla g), A(D)\Delta_k f)| \\ &\lesssim \alpha_k\|v\|_{B^{\frac{d}{2}+1}}(2^{-kt_2}\|g\|_{\widetilde{B}^{t_1,t_2}}\|A(D)\Delta_k f\|_2 + 2^{-k(s_2 - m)}\|f\|_{\widetilde{B}^{s_1,s_2}}\|\Delta_k g\|_2); \end{aligned} \tag{2.18}$$

and if $k \le 0$,

$$\begin{aligned} &|(A(D)\Delta_k(v \cdot \nabla f), \Delta_k g) + (\Delta_k(v \cdot \nabla g), A(D)\Delta_k f)| \\ &\lesssim \alpha_k\|v\|_{B^{\frac{d}{2}+1}}(2^{-kt_1}\|g\|_{\widetilde{B}^{t_1,t_2}}\|A(D)\Delta_k f\|_2 + 2^{-k(s_1 - m)}\|f\|_{\widetilde{B}^{s_1,s_2}}\|\Delta_k g\|_2), \end{aligned} \tag{2.19}$$

where $\sum_{k\in\mathbb{Z}} \alpha_k \le 1$.

For the proof we refer to [12].

3. Existence. In this section, we prove the existence of the solution for the 2D viscous shallow water equations. Without loss of generality, we assume that $\bar{h}_0 = 1$ and $\nu = 1$. Replacing h by $h + 1$ in (1.1), we rewrite (1.1) as

$$\begin{cases} h_t + \mathrm{div} u + \mathrm{div}(hu) = 0, \\ u_t - (\nabla \cdot D(u) + \nabla \mathrm{div}\, u) + u \cdot \nabla u - \frac{\nabla h}{1+h}(D(u) + \mathrm{div}\, u) + \nabla h = 0, \\ u(0, \cdot) = u_0, \quad h(0, \cdot) = h_0. \end{cases} \tag{3.1}$$

3.1. The linearized system. In this subsection, we consider the linearized system of (3.1):

$$\begin{cases} h_t + v\cdot\nabla h + \mathrm{div} u = \mathcal{H}, \\ u_t - (\nabla\cdot D(u) + \nabla \mathrm{div}\, u) + v\cdot\nabla u + \nabla h = \mathcal{G}, \\ u(0,\cdot) = u_0, \quad h(0,\cdot) = h_0. \end{cases} \tag{3.2}$$

Let us first introduce some definitions. Set

$$e_k^r(t) \triangleq (1 - e^{-cr2^{2k}t})^{\frac{1}{r}}, \quad \omega_k(t) = \sum_{\widetilde{k}\geq k} 2^{-(\widetilde{k}-k)}(e_{\widetilde{k}}^1(t) + e_{\widetilde{k}}^2(t)),$$

where c is a positive constant which will be determined later. We remark that

$$\omega_k(t) \leq C \quad \text{for any } k\in\mathbb{Z},$$

which will be constantly used in the following.

Definition 3.1. *Let $s\in\mathbb{R}$ and $T>0$. The function space E_T^s is defined by*

$$E_T^s = \{f\in\mathcal{Z}'((0,T)\times\mathbb{R}^d) : \|f\|_{E_T^s} < +\infty\},$$

where

$$\|f\|_{E_T^s} \triangleq \sum_{k\in Z} 2^{ks}\omega_k(T)\|\Delta_k f\|_{L_T^\infty(L^2)}.$$

Definition 3.2. *Let $s_1, s_2\in\mathbb{R}$ and $T>0$. The function space $\widetilde{E}_T^{s_1,s_2}$ is defined by*

$$\widetilde{E}_T^{s_1,s_2} = \{f\in\mathcal{Z}'((0,T)\times\mathbb{R}^d) : \|f\|_{\widetilde{E}_T^{s_1,s_2}} < +\infty\},$$

where

$$\|f\|_{\widetilde{E}_T^{s_1,s_2}} \triangleq \sum_{k\leq 0} 2^{ks_1}\omega_k(T)\|\Delta_k f\|_{L_T^\infty(L^2)} + \sum_{k\geq 1} 2^{ks_2}\omega_k(T)\|\Delta_k f\|_{L_T^\infty(L^2)}.$$

Remark 3.1. If $s_1\leq s_2$, then $\widetilde{E}_T^{s_1,s_2} = E_T^{s_1}\cap E_T^{s_2}$. Otherwise, $\widetilde{E}_T^{s_1,s_2} = E_T^{s_1} + E_T^{s_2}$.

Let (u,h) be a smooth solution of (3.2). We want to establish the following a priori estimates for (h,u):

$$\begin{aligned} &\|u\|_{L_T^1(B^2)} + \|u\|_{L_T^2(B^1)} + \|h\|_{\widetilde{E}_T^{0,1}} \\ &\quad\leq C\sum_{k\in\mathbb{Z}}\omega_k(T)E_k(0) + C\sum_{k\in\mathbb{Z}}\omega_k(T)\|\Delta_k\mathcal{G}(t)\|_{L_T^1(L^2)} \\ &\qquad + C\sum_{k\geq 1}\omega_k(T)\|\nabla\Delta_k\mathcal{H}(t)\|_{L_T^1(L^2)} + C\sum_{k<1}\omega_k(T)\|\Delta_k\mathcal{H}(t)\|_{L_T^1(L^2)} \\ &\qquad + C\|u\|_{L_T^2(B^1)}\|v\|_{L_T^2(B^1)} + C\|h\|_{\widetilde{E}_T^{0,1}}\|v\|_{L_T^1(B^2)} \end{aligned} \tag{3.3}$$

and

$$\begin{aligned} &\|u\|_{L_T^\infty(B^0)} + \|h\|_{L_T^\infty(\widetilde{B}^{0,1})} + \|h\|_{L_T^1(\widetilde{B}^{2,1})} \\ &\leq E_0 + C\left(\|\mathcal{H}\|_{L_T^1(\widetilde{B}^{0,1})} + \|\mathcal{G}\|_{L_T^1(B^0)} + \int_0^T V'(t)(\|u(t)\|_{B^0} + \|h(t)\|_{\widetilde{B}^{0,1}})dt\right), \end{aligned} \tag{3.4}$$

where $V(t) = \|v(t')\|_{L^1_t(B^2)}$ and

$$E_0 = \sum_{k\in\mathbb{Z}} E_k(0), \quad E_k(t) = \begin{cases} E_{hk}(t), & k \geq 1, \\ E_{lk}(t), & k < 1, \end{cases}$$

with

$$E^2_{hk}(t) = \frac{1}{2}\|u_k(t)\|^2_2 + \|\nabla h_k(t)\|^2_2 + (u_k(t), \nabla h_k(t)),$$

$$E^2_{lk}(t) = \frac{1}{2}\|u_k(t)\|^2_2 + \frac{1}{2}\|h_k(t)\|^2_2 + \frac{1}{8}(u_k(t), \nabla h_k(t)).$$

Let us begin with the proof of (3.3) and (3.4). Set

$$u_k = \Delta_k u, \quad h_k = \Delta_k h, \quad \mathcal{H}^k = \Delta_k \mathcal{H}, \quad \mathcal{G}^k = \Delta_k \mathcal{G}.$$

Then we get by applying the operator Δ_k to (3.2) that

$$\text{(3.5)} \qquad \begin{cases} \partial_t h_k + \Delta_k(v \cdot \nabla h) + \mathrm{div} u_k = \mathcal{H}_k, \\ \partial_t u_k - (\nabla \cdot D(u_k) + \nabla \mathrm{div}\, u_k) + \Delta_k(v \cdot \nabla u) + \nabla h_k = \mathcal{G}_k, \\ u_k(0, \cdot) = \Delta_k u_0, \quad h_k(0, \cdot) = \Delta_k h_0. \end{cases}$$

Multiplying the second equation of (3.5) by u_k, and integrating the resulting equation over $\mathbb{R}^2$, we obtain

$$\text{(3.6)} \quad \frac{1}{2}\frac{d}{dt}\|u_k\|^2_2 + \frac{1}{2}\|\nabla u_k\|^2_2 + \frac{3}{2}\|\mathrm{div} u_k\|^2_2 + (\nabla h_k, u_k) = (\mathcal{G}_k, u_k) - (\Delta_k(v \cdot \nabla u), u_k).$$

In the following, we will deal with the high frequency and the low frequency of h in a different manner.

High frequencies: $k \geq 1$. First, applying ∇ to the first equation of (3.5) and multiplying it by ∇h_k, then integrating the resulting equation over $\mathbb{R}^2$, we obtain

$$\text{(3.7)} \quad \frac{1}{2}\frac{d}{dt}\|\nabla h_k\|^2_2 + (\nabla \mathrm{div} u_k, \nabla h_k) = (\nabla \mathcal{H}_k, \nabla h_k) - (\nabla \Delta_k(v \cdot \nabla h), \nabla h_k).$$

Second, applying the operator ∇ to the first equation of (3.5) and taking the L^2 product of the resulting equation with u_k, then taking the L^2 product of the second equation of (3.5) with ∇h_k, we get by summing them up that

$$\begin{aligned} &\frac{d}{dt}(u_k, \nabla h_k) - \|\mathrm{div} u_k\|^2_2 - 2(\nabla \mathrm{div} u_k, \nabla h_k) + \|\nabla h_k\|^2_2 \\ &\text{(3.8)} \qquad = (\nabla \mathcal{H}_k, u_k) + (\mathcal{G}_k, \nabla h_k) - (\nabla \Delta_k(v \cdot \nabla h), u_k) - (\Delta_k(v \cdot \nabla u), \nabla h_k), \end{aligned}$$

where we used the fact that

$$(\nabla \cdot D(u_k) + \nabla \mathrm{div}\, u_k, \nabla h_k) = 2(\nabla \mathrm{div} u_k, \nabla h_k).$$

Then we get by summing up (3.6), (3.7)×2, and (3.8) that

$$\begin{aligned}
&\frac{d}{dt}\left[\frac{1}{2}\|u_k\|_2^2+\|\nabla h_k\|_2^2+(u_k,\nabla h_k)\right]\\
&\qquad+\left[\|\nabla h_k\|_2^2+\frac{1}{2}\|\nabla u_k\|_2^2+\frac{1}{2}\|\mathrm{div}u_k\|_2^2+(\nabla h_k,u_k)\right]\\
&=\Big[(\nabla\mathcal{H}_k,u_k)+2(\nabla\mathcal{H}_k,\nabla h_k)+(\mathcal{G}_k,u_k)+(\mathcal{G}_k,\nabla h_k)\Big]\\
&\quad-(\Delta_k(v\cdot\nabla u),u_k)-2(\nabla\Delta_k(v\cdot\nabla h),\nabla h_k)\\
&\quad-\Big[(\nabla\Delta_k(v\cdot\nabla h),u_k)+(\Delta_k(v\cdot\nabla u),\nabla h_k)\Big]\\
&\triangleq I+II+III+IV. \qquad (3.9)
\end{aligned}$$

Note that

$$(u_k,\nabla h_k)\le\frac{1}{3}\|u_k\|_2^2+\frac{3}{4}\|\nabla h_k\|_2^2;$$

hence, we get by the definition of E_{hk} that

$$\frac{1}{6}(\|u_k\|_2^2+\|\nabla h_k\|_2^2)\le E_{hk}^2\le 2(\|u_k\|_2^2+\|\nabla h_k\|_2^2). \qquad (3.10)$$

Similarly, using the fact that $\frac{5}{6}2^k\ge\frac{5}{3}$ and (3.10), we have

$$\|\nabla h_k\|_2^2+\frac{1}{2}\|\nabla u_k\|_2^2+\frac{1}{2}\|\mathrm{div}u_k\|_2^2+(\nabla h_k,u_k)\ge\frac{1}{8}E_{hk}^2. \qquad (3.11)$$

By summing up (3.9)–(3.11), we obtain

$$\frac{d}{dt}E_{hk}^2+cE_{hk}^2\le C|I+II+III+IV|. \qquad (3.12)$$

In order to obtain (3.3), we use Lemma 5.1 to deal with the right-hand terms of (3.12). First, we get by using the Cauchy–Schwarz inequality and (3.10) that

$$|I|\le C(\|\nabla\mathcal{H}_k(t)\|_2+\|\mathcal{G}_k(t)\|_2)E_{hk}. \qquad (3.13)$$

From Lemma 5.1 and (3.10), it follows that

$$|II+III+IV|\le C(\|\mathcal{F}_k^1(t)\|_2+\|\widetilde{\mathcal{F}}_k^0(t)\|_2)E_{hk}. \qquad (3.14)$$

By summing up (3.12), and (3.13)–(3.14), we obtain

$$\frac{d}{dt}E_{hk}+cE_{hk}\le C\Big(\|\nabla\mathcal{H}_k(t)\|_2+\|\mathcal{G}_k(t)\|_2+\|\mathcal{F}_k^1(t)\|_2+\|\widetilde{\mathcal{F}}_k^0(t)\|_2\Big), \qquad (3.15)$$

which implies that

$$\begin{aligned}
\|E_{hk}(t)\|_{L_T^\infty}\le&E_{hk}(0)+C\Big(\|\nabla\mathcal{H}_k(t)\|_{L_T^1(L^2)}+\|\mathcal{G}_k(t)\|_{L_T^1(L^2)}\\
&+\|\mathcal{F}_k^1(t)\|_{L_T^1(L^2)}+\|\widetilde{\mathcal{F}}_k^0(t)\|_{L_T^1(L^2)}\Big). \qquad (3.16)
\end{aligned}$$

Furthermore, by (5.4) and (5.5), it holds that

$$\sum_{k\in\mathbb{Z}}\omega_k(T)\Big(\|\mathcal{F}^1_k(t)\|_{L^1_T(L^2)}+\|\widetilde{\mathcal{F}}^0_k(t)\|_{L^1_T(L^2)}\Big)$$
$$\leq C\Big(\|u\|_{L^2_T(B^1)}\|v\|_{L^2_T(B^1)}+\|h\|_{E^1_T}\|v\|_{L^1_T(B^2)}\Big).$$

Multiplying $\omega_k(T)$ on both sides of (3.16), then summing up the resulting equation over $k\geq 1$, we obtain

$$\begin{aligned}\sum_{k\geq1}\omega_k(T)\|E_{hk}(t)\|_{L^\infty_T}\leq&\sum_{k\geq1}\omega_k(T)E_{hk}(0)\\&+C\sum_{k\geq1}\omega_k(T)\Big(\|\nabla\mathcal{H}_k(t)\|_{L^1_T(L^2)}+\|\mathcal{G}_k(t)\|_{L^1_T(L^2)}\Big)\\&+C\Big(\|u\|_{L^2_T(B^1)}\|v\|_{L^2_T(B^1)}+\|h\|_{E^1_T}\|v\|_{L^1_T(B^2)}\Big).\end{aligned}\tag{3.17}$$

Next, we use the decay effect of the parabolic operators to estimate $\|u\|_{L^2_T(B^1)\cap L^1_T(B^2)}$. It follows from (3.6) and Lemma 5.1 that

$$\frac{d}{dt}\|u_k\|_2+c2^{2k}\|u_k\|_2\leq C(\|\nabla h_k(t)\|_2+\|\mathcal{G}_k(t)\|_{L^2}+\|\widetilde{\mathcal{F}}^0_k(t)\|_{L^2}),$$

which implies that

$$\|u_k\|_2\leq e^{-ct2^{2k}}\|u_k(0)\|_2+Ce^{-ct2^{2k}}*_t\Big(\|\nabla h_k(t)\|_2+\|\mathcal{G}_k(t)\|_2+\|\widetilde{\mathcal{F}}^0_k(t)\|_2\Big),$$

where the sign $*$ denotes the convolution of functions defined in $\mathbb{R}^+$; more precisely,

$$e^{-ct2^{2k}}*_t f\triangleq\int_0^t e^{-c(t-\tau)2^{2k}}f(\tau)d\tau.$$

Taking the L^r norm for $r=1,2$ with respect to t, we get by using Young's inequality that

$$\|u_k\|_{L^r_T(L^2)}\leq C2^{-2k/r}e^r_k(T)\Big(\|u_k(0)\|_2+\|\nabla h_k\|_{L^1_T(L^2)}+\|\mathcal{G}_k\|_{L^1_T(L^2)}+\|\widetilde{\mathcal{F}}^0_k\|_{L^1_T(L^2)}\Big),$$

which together with (5.5) implies that

$$\begin{aligned}\sum_{k\geq1}\Big(2^{2k}\|u_k\|_{L^1_T(L^2)}+2^k\|u_k\|_{L^2_T(L^2)}\Big)\leq&C\sum_{k\geq1}\omega_k(T)\|u_k(0)\|_2\\&+C\sum_{k\geq1}\omega_k(T)\Big(\|\nabla h_k\|_{L^1_T(L^2)}+\|\mathcal{G}_k\|_{L^1_T(L^2)}\Big)+C\|u\|_{L^2_T(B^1)}\|v\|_{L^2_T(B^1)},\end{aligned}\tag{3.18}$$

where we used the fact that

$$e^1_k(T)+e^2_k(T)\leq\omega_k(T).$$

On the other hand, it follows from (3.15) that

$$\|E_{hk}\|_2\leq e^{-ct}E_{hk}(0)+Ce^{-ct}*_t\Big(\|\nabla\mathcal{H}_k(t)\|_2+\|\mathcal{G}_k(t)\|_2+\|\mathcal{F}^1_k(t)\|_2+\|\widetilde{\mathcal{F}}^0_k(t)\|_2\Big).$$

Taking the L^1 norm with respect to t, we get by using Young's inequality that

$$\|E_{hk}\|_{L^1_T} \leq C(1-e^{-cT})E_{hk}(0) + C(1-e^{-cT})\Big(\|\nabla\mathcal{H}_k(t)\|_{L^1_T(L^2)} + \|\mathcal{G}_k(t)\|_{L^1_T(L^2)}$$

$$+ \|\mathcal{F}^1_k(t)\|_{L^1_T(L^2)} + \|\widetilde{\mathcal{F}}^0_k(t)\|_{L^1_T(L^2)}\Big). \tag{3.19}$$

Note that for $k \geq 1$

$$1 - e^{-ct} \leq 1 - e^{-ct2^{2k}} \leq \omega_k(t),$$

which together with (3.19) and Lemma 5.1 gives

$$\sum_{k\geq 1}\|E_{hk}\|_{L^1_T} \leq C\sum_{k\geq 1}\omega_k(T)E_{hk}(0) + C\sum_{k\geq 1}\omega_k(T)\Big(\|\nabla\mathcal{H}_k(t)\|_{L^1_T(L^2)} + \|\mathcal{G}_k(t)\|_{L^1_T(L^2)}\Big)$$

$$+ C\Big(\|u\|_{L^2_T(B^1)}\|v\|_{L^2_T(B^1)} + \|h\|_{E^1_T}\|v\|_{L^1_T(B^2)}\Big). \tag{3.20}$$

Plugging (3.20) into (3.18), we obtain

$$\sum_{k\geq 1}\Big(2^{2k}\|u_k\|_{L^1_T(L^2)} + 2^k\|u_k\|_{L^2_T(L^2)}\Big)$$

$$\leq C\sum_{k\geq 1}\omega_k(T)E_{hk}(0) + C\sum_{k\geq 1}\omega_k(T)\Big(\|\nabla\mathcal{H}_k(t)\|_{L^1_T(L^2)} + \|\mathcal{G}_k(t)\|_{L^1_T(L^2)}\Big)$$

$$+ C\Big(\|u\|_{L^2_T(B^1)}\|v\|_{L^2_T(B^1)} + \|h\|_{E^1_T}\|v\|_{L^1_T(B^2)}\Big). \tag{3.21}$$

On the other hand, in order to obtain (3.4), we use Proposition 2.4 to deal with the right-hand terms of (3.12). Applying (2.16) with $s_1 = s_2 = 0$ to II, (2.16) with $s_1 = 0, s_2 = 1$ to III, and (2.18) with $t_1 = t_2 = 0, s_1 = 0, s_2 = 1$ to IV, we obtain

$$|II + III + IV| \leq CE_{hk}\alpha_k V'(t)(\|u\|_{B^0} + \|h\|_{\widetilde{B}^{0,1}}), \tag{3.22}$$

with $\sum_{k\in\mathbb{Z}}\alpha_k \leq 1$ and $V(t) = \|v(t')\|_{L^1_t(B^2)}$. From (3.13) and (3.22), it follows that

$$\frac{d}{dt}E_{hk} + cE_{hk} \leq C\Big(\|\nabla\mathcal{H}_k(t)\|_2 + \|\mathcal{G}_k(t)\|_2 + \alpha_k V'(t)(\|u\|_{B^0} + \|h\|_{\widetilde{B}^{0,1}})\Big),$$

from which a similar proof of (3.21) ensures that

$$\sum_{k\geq 1}\Big(\|E_{hk}\|_{L^1_T} + \|E_{hk}\|_{L^\infty_T}\Big) \leq C\sum_{k\geq 1}E_{hk}(0)$$

$$+C\Big(\|\mathcal{H}\|_{L^1_T(\widetilde{B}^{0,1})} + \|\mathcal{G}\|_{L^1_T(B^0)} + \int_0^T V'(t)(\|u(t)\|_{B^0} + \|h(t)\|_{\widetilde{B}^{0,1}})dt\Big). \tag{3.23}$$

Low frequencies: $k < 1$. Multiplying the first equation of (3.5) by h_k, we get by integrating the resulting equation over $\mathbb{R}^2$ that

$$\frac{1}{2}\frac{d}{dt}\|h_k\|_2^2 + (\mathrm{div}u_k, h_k) = (\mathcal{H}_k, h_k) - (\Delta_k(v\cdot\nabla h), h_k). \tag{3.24}$$

Summing up (3.6), (3.8) $\times \frac{1}{8}$, and (3.24), we obtain

$$\begin{aligned}
&\frac{d}{dt}\left[\frac{1}{2}\|u_k\|_2^2+\frac{1}{2}\|h_k\|_2^2+\frac{1}{8}(u_k,\nabla h_k)\right]\\
&\qquad+\left[\frac{1}{8}\|\nabla h_k\|_2^2+\frac{1}{2}\|\nabla u_k\|_2^2+\frac{11}{8}\|\mathrm{div} u_k\|_2^2-\frac{1}{4}(\nabla \mathrm{div}\, u_k,\nabla h_k)\right]\\
&=\left[\frac{1}{8}(\nabla\mathcal{H}_k,u_k)+(\mathcal{H}_k,h_k)+(\mathcal{G}_k,u_k)+\frac{1}{8}(\mathcal{G}_k,\nabla h_k)\right]\\
&\quad-(\Delta_k(v\cdot\nabla u),u_k)-(\Delta_k(v\cdot\nabla h),h_k)\\
&\quad-\frac{1}{8}\Big[(\nabla\Delta_k(v\cdot\nabla h),u_k)+(\Delta_k(v\cdot\nabla u),\nabla h_k)\Big]\\
&\triangleq I+II+III+IV. \qquad (3.25)
\end{aligned}$$

Note that $2^k\le 1$. We get by the Cauchy–Schwarz inequality that

$$\frac{1}{8}(u_k,\nabla h_k)\le\frac{3}{10}\|u_k\|_2\|h_k\|_2\le\frac{1}{4}\|u_k\|_2^2+\frac{1}{4}\|h_k\|_2^2;$$

hence, we get by the definition of E_{lk} that

$$\frac{1}{4}(\|u_k\|_2^2+\|h_k\|_2^2)\le E_{lk}^2\le 2(\|u_k\|_2^2+\|h_k\|_2^2). \qquad (3.26)$$

Similarly, we can prove

$$\frac{1}{4}(\nabla\mathrm{div}\, u_k,\nabla h_k)\le\frac{3}{5}\|\mathrm{div} u_k\|_2\|\nabla h_k\|_2\le\frac{9}{10}\|\nabla u_k\|_2^2+\frac{1}{10}\|\nabla h_k\|_2^2,$$

which together with (3.26) implies that

$$\begin{aligned}
&\frac{1}{8}\|\nabla h_k\|_2^2+\frac{1}{2}\|\nabla u_k\|_2^2+\frac{11}{8}\|\mathrm{div} u_k\|_2^2-\frac{1}{4}(\nabla\mathrm{div}\, u_k,\nabla h_k)\\
&\qquad\ge\frac{1}{160}2^{2k}(\|u_k\|_2^2+\|h_k\|_2^2)\ge\frac{1}{320}2^{2k}E_{lk}^2. \qquad (3.27)
\end{aligned}$$

By summing up (3.25)–(3.27), we obtain

$$\frac{d}{dt}E_{lk}^2+c2^{2k}E_{lk}^2\le C|I+II+III+IV|. \qquad (3.28)$$

In order to obtain (3.3), we use Lemma 5.1 to estimate the right-hand terms of (3.28). Using the fact that $2^k\le 1$, we get by the Cauchy–Schwarz inequality and (3.26) that

$$|I|\le C(\|\mathcal{H}_k(t)\|_2+\|\mathcal{G}_k(t)\|_2)E_{lk}. \qquad (3.29)$$

Using Lemma 5.1 and (3.26), we have

$$|II+III+IV|\le C(\|\mathcal{F}_k^1(t)\|_2+\|\mathcal{F}_k^0(t)\|_2+\|\widetilde{\mathcal{F}}_k^0(t)\|_2)E_{lk}. \qquad (3.30)$$

By summing up (3.28)–(3.30), we obtain

$$\frac{d}{dt}E_{lk}+c2^{2k}E_{lk}\leq C\Big(\|\mathcal{H}_k(t)\|_2+\|\mathcal{G}_k(t)\|_2+\|\mathcal{F}^1_k(t)\|_2+\|\mathcal{F}^0_k(t)\|_2+\|\widetilde{\mathcal{F}}^0_k(t)\|_2\Big),$$

which implies that

$$\begin{aligned}E_{lk}&\leq e^{-c2^{2k}t}E_{lk}(0)\\&\quad+Ce^{-c2^{2k}t}*_t\Big(\|\mathcal{H}_k(t)\|_2+\|\mathcal{G}_k(t)\|_2+\|\mathcal{F}^1_k(t)\|_2+\|\mathcal{F}^0_k(t)\|_2+\|\widetilde{\mathcal{F}}^0_k(t)\|_2\Big).\end{aligned}$$

Taking the L^r norm with respect to t, we get by using Young's inequality that

$$\begin{aligned}\|E_{lk}\|_{L^r_T}&\leq C2^{-2k/r}e^r_k(T)\Big(E_{lk}(0)+\|\mathcal{H}_k(t)\|_{L^1_T(L^2)}+\|\mathcal{G}_k(t)\|_{L^1_T(L^2)}\\&\qquad+\|\mathcal{F}^1_k(t)\|_{L^1_T(L^2)}+\|\mathcal{F}^0_k(t)\|_2+\|\widetilde{\mathcal{F}}^0_k(t)\|_{L^1_T(L^2)}\Big),\end{aligned}$$

from which, together with Lemma 5.1, it follows that

$$\begin{aligned}&\sum_{k<1}\omega_k(T)\|E_{lk}\|_{L^\infty_T}\\&\quad\leq C\sum_{k<1}\omega_k(T)E_{lk}(0)+\sum_{k<1}\omega_k(T)(\|\mathcal{H}_k(t)\|_{L^1_T(L^2)}+\|\mathcal{G}_k(t)\|_{L^1_T(L^2)})\\&\quad\quad+C\Big(\|u\|_{L^2_T(B^1)}\|v\|_{L^2_T(B^1)}+\|h\|_{\widetilde{E}^{0,1}_T}\|v\|_{L^1_T(B^2)}\Big)\end{aligned}\tag{3.31}$$

and

$$\begin{aligned}&\sum_{k<1}(2^{2k}\|E_{lk}\|_{L^1_T}+2^k\|E_{lk}\|_{L^2_T})\\&\quad\leq C\sum_{k<1}\omega_k(T)E_{lk}(0)+\sum_{k<1}\omega_k(T)(\|\mathcal{H}_k(t)\|_{L^1_T(L^2)}+\|\mathcal{G}_k(t)\|_{L^1_T(L^2)})\\&\quad\quad+C\Big(\|u\|_{L^2_T(B^1)}\|v\|_{L^2_T(B^1)}+\|h\|_{\widetilde{E}^{0,1}_T}\|v\|_{L^1_T(B^2)}\Big).\end{aligned}\tag{3.32}$$

On the other hand, in order to obtain (3.4), we use Proposition 2.4 to deal with the right-hand terms of (3.28). Applying (2.17) with $s_1=s_2=0$ to II, (2.17) with $s_1=0,s_2=1$ to III, and (2.19) with $t_1=t_2=0,s_1=0,s_2=1$ to IV, we obtain

$$|II+III+IV|\leq CE_{lk}\alpha_kV'(t)(\|u\|_{B^0}+\|h\|_{\widetilde{B}^{0,1}}),\tag{3.33}$$

with $\sum_{k\in\mathbb{Z}}\alpha_k\leq 1$ and $V(t)=\|v(t')\|_{L^1_t(B^2)}$. From (3.32) and (3.36), it follows that

$$\frac{d}{dt}E_{lk}+c2^{2k}E_{lk}\leq C\Big(\|\mathcal{H}_k(t)\|_2+\|\mathcal{G}_k(t)\|_2+\alpha_kV'(t)(\|u\|_{B^0}+\|h\|_{\widetilde{B}^{0,1}})\Big),$$

which, together with a similar proof of (3.21), ensures that

$$\begin{aligned}&\sum_{k<1}\big(2^{2k}\|E_{lk}\|_{L^1_T}+\|E_{lk}\|_{L^\infty_T}\big)\leq\sum_{k<1}E_{hk}(0)\\&\quad+C\left(\|\mathcal{H}\|_{L^1_T(\widetilde{B}^{0,1})}+\|\mathcal{G}\|_{L^1_T(B^0)}+\int_0^T V'(t)(\|u(t)\|_{B^0}+\|h(t)\|_{\widetilde{B}^{0,1}})dt\right).\end{aligned}\tag{3.34}$$

The completion of the a priori estimates. First, adding up (3.17), (3.21), (3.31), and (3.32) yields that

$$\begin{aligned}
&\|u\|_{L^1_T(B^2)} + \|u\|_{L^2_T(B^1)} + \|h\|_{\widetilde{E}^{0,1}_T} \\
&\quad \leq C\sum_{k\in\mathbb{Z}} \omega_k(T)E_k(0) + C\sum_{k\in\mathbb{Z}} \omega_k(T)\|\mathcal{G}_k(t)\|_{L^1_T(L^2)} \\
&\qquad + C\sum_{k\geq 1} \omega_k(T)\|\nabla\mathcal{H}_k(t)\|_{L^1_T(L^2)} + C\sum_{k<1} \omega_k(T)\|\mathcal{H}_k(t)\|_{L^1_T(L^2)} \\
&\qquad + C\|u\|_{L^2_T(B^1)}\|v\|_{L^2_T(B^1)} + C\|h\|_{\widetilde{E}^{0,1}_T}\|v\|_{L^1_T(B^2)}, \qquad (3.35)
\end{aligned}$$

where we used the fact that

$$\|h\|_{E^1_T} \leq C\|h\|_{\widetilde{E}^{0,1}_T}.$$

On the other hand, adding up (3.23) and (3.34) gives rise to

$$\begin{aligned}
&\|u\|_{L^\infty_T(B^0)} + \|h\|_{L^\infty_T(\widetilde{B}^{0,1})} + \|h\|_{L^1_T(\widetilde{B}^{2,1})} \\
&\leq E_0 + C\Big(\|\mathcal{H}\|_{L^1_T(\widetilde{B}^{0,1})} + \|\mathcal{G}\|_{L^1_T(B^0)} + \int_0^T V'(t)(\|u\|_{B^0} + \|h\|_{\widetilde{B}^{0,1}})dt\Big), \qquad (3.36)
\end{aligned}$$

which, together with the Gronwall inequality, implies that

$$\begin{aligned}
&\|u\|_{L^\infty_T(B^0)} + \|h\|_{L^\infty_T(\widetilde{B}^{0,1})} + \|h\|_{L^1_T(\widetilde{B}^{2,1})} \\
&\leq Ce^{C\|v\|_{L^1_T(B^2)}}\Big(E_0 + \|\mathcal{H}\|_{L^1_T(\widetilde{B}^{0,1})} + \|\mathcal{G}\|_{L^1_T(B^0)}\Big). \qquad (3.37)
\end{aligned}$$

Finally, let us remark that

$$E_0 \approx (\|h_0\|_{\widetilde{B}^{0,1}} + \|u_0\|_{B^0}).$$

3.2. The uniform estimate of the approximate sequence of solutions. In this subsection, we will construct the approximate solutions of (3.1) and present the uniform estimate of the approximate solutions. Let us first define the approximate sequence $(h^n, u^n)_{n\in\mathbb{N}}$ of (3.1) by the following system:

$$\begin{cases}
\partial_t h^{n+1} + u^n\cdot\nabla h^{n+1} + \mathrm{div}u^{n+1} = \mathcal{H}^n, \\
\partial_t u^{n+1} - (\nabla\cdot D(u^{n+1}) + \nabla\mathrm{div}\, u^{n+1}) + u^n\cdot\nabla u^{n+1} + \nabla h^{n+1} = \mathcal{G}^n, \\
(h^{n+1}, u^{n+1})|_{t=0} = \displaystyle\sum_{|k|\leq n+N} \Delta_k(h_0, u_0),
\end{cases} \qquad (3.38)$$

where

$$\mathcal{H}^n \triangleq -h^n\mathrm{div}u^n, \qquad \mathcal{G}^n \triangleq \frac{\nabla h^n}{1+h^n}\widetilde{\nabla}u^n, \quad \text{with} \quad \widetilde{\nabla}u^n = D(u^n) + \mathrm{div}u^n,$$

and N is a fixed large integer such that

$$1 + h^n(0) \geq \frac{3}{4} \qquad \text{for} \quad n \geq 1.$$

Set $(h^0,u^0)=(0,0)$ and solve the linear system. We can define $(h^n,u^n)_{n\in\mathbb{N}_0}$ by the induction. Next, we are going to prove by the induction that there exist positive constants η, K, and T such that the following bounds hold for all $n\in\mathbb{N}_0$:

$$1+h^n\geq\frac{1}{2}, \tag{3.39}$$

$$\|u^n\|_{L^1_T(B^2)\cap L^2_T(B^1)}+\|h^n\|_{\widetilde{E}^{0,1}_T}\leq\eta, \tag{3.40}$$

$$\|u^n\|_{L^\infty_T(B^0)}+\|h^n\|_{L^\infty_T(\widetilde{B}^{0,1})\cap L^1_T(\widetilde{B}^{2,1})}\leq KE_0. \tag{3.41}$$

Assume that (3.39)–(3.41) hold for (h^n,u^n). We need to prove that (3.39)–(3.41) also hold for (h^{n+1},u^{n+1}). Applying the a priori estimates (3.35) and (3.37) to (h^{n+1},u^{n+1}), we obtain

$$\begin{aligned}
&\|u^{n+1}\|_{L^1_T(B^2)}+\|u^{n+1}\|_{L^2_T(B^1)}+\|h^{n+1}\|_{\widetilde{E}^{0,1}_T}\\
&\quad\leq C\mathcal{Q}_0(T)+C\sum_{k\in\mathbb{Z}}\omega_k(T)\|\mathcal{G}^n_k(t)\|_{L^1_T(L^2)}+C\sum_{k\geq1}\omega_k(T)\|\nabla\mathcal{H}^n_k(t)\|_{L^1_T(L^2)}\\
&\qquad+C\sum_{k<1}\omega_k(T)\|\mathcal{H}^n_k(t)\|_{L^1_T(L^2)}+C\|u^{n+1}\|_{L^2_T(B^1)}\|u^n\|_{L^2_T(B^1)}\\
&\qquad+C\|h^{n+1}\|_{\widetilde{E}^{0,1}_T}\|u^n\|_{L^1_T(B^2)}
\end{aligned} \tag{3.42}$$

and

$$\begin{aligned}
&\|u^{n+1}\|_{L^\infty_T(B^0)}+\|h^{n+1}\|_{L^\infty_T(\widetilde{B}^{0,1})}+\|h^{n+1}\|_{L^1_T(\widetilde{B}^{2,1})}\\
&\qquad\leq Ce^{C\|u^n\|_{L^1_T(B^2)}}\Big(E_0+\|\mathcal{H}^n\|_{L^1_T(\widetilde{B}^{0,1})}+\|\mathcal{G}^n\|_{L^1_T(B^0)}\Big),
\end{aligned} \tag{3.43}$$

with

$$\mathcal{Q}_0(T)\triangleq\sum_{k\in\mathbb{Z}}\omega_k(T)E_k(0).$$

Thanks to (2.4), we have

$$\|\mathcal{H}^n\|_{B^0}\leq C\|h^n\|_{B^0}\|u^n\|_{B^2}\quad\text{and}\quad\|\mathcal{H}^n\|_{B^1}\leq C\|h^n\|_{B^1}\|u^n\|_{B^2},$$

which, together with the fact that $\widetilde{B}^{0,1}=B^0\cap B^1$, yields

$$\|\mathcal{H}^n\|_{L^1_T(\widetilde{B}^{0,1})}\leq C\|h^n\|_{L^\infty_T(\widetilde{B}^{0,1})}\|u^n\|_{L^1_T(B^2)}\leq CKE_0\eta. \tag{3.44}$$

We rewrite $\mathcal{G}^n$ as

$$\frac{\nabla h^n}{1+h^n}\widetilde{\nabla}u^n=(1+h^n)\nabla\bigg(\frac{h^n}{1+h^n}\bigg)\widetilde{\nabla}u^n.$$

Using (2.4) and (2.12), we get

$$\begin{aligned}
\|\mathcal{G}^n\|_{L^1_T(B^0)}&\leq C\bigg\|\nabla\bigg(\frac{h^n}{1+h^n}\bigg)\bigg\|_{L^\infty_T(B^0)}\|(1+h^n)\widetilde{\nabla}u^n\|_{L^1_T(B^1)}\\
&\leq C(1+\|h^n\|_{L^\infty_T(L^\infty)})^2\|h^n\|_{L^\infty_T(B^1)}(1+\|h^n\|_{L^\infty_T(B^1)})\|u^n\|_{L^1_T(B^2)}\\
&\leq C(1+\|h^n\|_{L^\infty_T(\widetilde{B}^{0,1})})^3\|h^n\|_{L^\infty_T(B^1)}\|u^n\|_{L^1_T(B^2)}\\
&\leq CKE_0(1+KE_0)^3\eta.
\end{aligned} \tag{3.45}$$

Plugging (3.44) and (3.45) into (3.43) yields

$$\begin{aligned}&\|u^{n+1}\|_{L^\infty_T(B^0)}+\|h^{n+1}\|_{L^\infty_T(\widetilde{B}^{0,1})}+\|h^{n+1}\|_{L^1_T(\widetilde{B}^{2,1})}\\&\leq Ce^{C\eta}\Big(E_0+KE_0(1+KE_0)^3\eta\Big).\end{aligned}\tag{3.46}$$

We take $\eta>0$ small enough and $K=4C$ such that

$$e^{C\eta}\leq 2,\quad K(1+KE_0)^3\eta\leq 1,\tag{$\Re_1$}$$

from which, together with (3.46), it follows that

$$\|u^{n+1}\|_{L^\infty_T(B^0)}+\|h^{n+1}\|_{L^\infty_T(\widetilde{B}^{0,1})}+\|h^{n+1}\|_{L^1_T(\widetilde{B}^{2,1})}\leq KE_0.$$

This proves (3.41) for (u^{n+1},h^{n+1}).

Next, we prove (3.40) for (u^{n+1},h^{n+1}). Applying Lemma 5.2 with $s_1=0$ and $s_2=1$, (2.4) with $s_1=s_2=1$, and Lemma 5.4 with $s=1$, we obtain

$$\begin{aligned}\sum_{k\in\mathbb{Z}}\omega_k(T)\|\mathcal{G}^n_k(t)\|_{L^1_T(L^2)}&\leq C\Big\|\nabla\Big(\frac{h^n}{1+h^n}\Big)\Big\|_{E^0_T}\|(1+h^n)\widetilde{\nabla}u^n\|_{L^1_T(B^1)}\\&\leq C(1+\|h^n\|_{L^\infty_T(L^\infty)})^3\|h^n\|_{E^1_T}(1+\|h^n\|_{L^\infty_T(B^1)})\|u^n\|_{L^1_T(B^2)}\\&\leq C(1+\|h^n\|_{L^\infty_T(\widetilde{B}^{0,1})})^4\|h^n\|_{\widetilde{E}^{0,1}_T}\|u^n\|_{L^1_T(B^2)}\\&\leq C(1+KE_0)^4\eta^2.\end{aligned}\tag{3.47}$$

On the other hand, we apply Lemma 5.2 with $s_1=0,s_2=1$ to get

$$\begin{aligned}&\sum_{k\geq1}\omega_k(T)\|\nabla\mathcal{H}^n_k(t)\|_{L^1_T(L^2)}+\sum_{k<1}\omega_k(T)\|\mathcal{H}^n_k(t)\|_{L^1_T(L^2)}\\&\leq C\sum_{k\in\mathbb{Z}}\omega_k(T)(\|\nabla h^n_k\|_{L^\infty_T(L^2)}+\|h^n_k\|_{L^\infty_T(L^2)})\|\mathrm{div}u^n\|_{L^1_T(B^1)}\\&\quad+C\sum_{k\in\mathbb{Z}}\omega_k(T)2^{2k}\|u^n_k\|_{L^1_T(L^2)}\|h^n\|_{L^\infty_T(\widetilde{B}^{0,1})}\\&\triangleq I+II.\end{aligned}$$

Obviously, we have

$$I\leq C\|h^n\|_{\widetilde{E}^{0,1}_T}\|u^n\|_{L^1_T(B^2)}\leq C\eta^2.\tag{3.48}$$

In order to estimate II, we first fix $k_0\geq1$ such that

$$\sum_{k\geq k_0}\|u_k(0)\|_2\leq\frac{\eta}{16CKE_0}.\tag{3.49}$$

Then we write

$$\begin{aligned}II&=C\sum_{k\geq k_0}\omega_k(T)2^{2k}\|u^n_k\|_{L^1_T(L^2)}\|h^n\|_{L^\infty_T(\widetilde{B}^{0,1})}+C\sum_{k\leq k_0}\omega_k(T)2^{2k}\|u^n_k\|_{L^1_T(L^2)}\|h^n\|_{L^\infty_T(\widetilde{B}^{0,1})}\\&\triangleq II_1+II_2.\end{aligned}$$

Using (3.18), (3.47), and (3.49), we obtain

$$\begin{aligned} II_1 &\leq CKE_0\Big[\sum_{k\geq k_0}\omega_k(T)\|u_k(0)\|_2+\sum_{k\geq k_0}\omega_k(T)\Big(\|\nabla h_k^n\|_{L^1_T(L^2)}+\|\mathcal{G}_k^{n-1}\|_{L^1_T(L^2)}\Big)\\ &\quad+\|u^n\|_{L^2_T(B^1)}\|u^{n-1}\|_{L^2_T(B^1)}\Big]\\ &\leq CKE_0\Big[\frac{\eta}{16CKE_0}+\sum_{k\geq k_0}\omega_k(T)\|\nabla h_k^n\|_{L^1_T(L^2)}+(1+KE_0)^4\eta^2\Big]. \end{aligned} \tag{3.50}$$

On the other hand, thanks to (3.19) and Lemma 5.1, we have

$$\begin{aligned} \sum_{k\geq k_0}\omega_k(T)\|\nabla h_k^n\|_{L^1_T(L^2)} &\leq C(1-e^{-cT})\sum_{k\geq k_0}\omega_k(T)E_{hk}(0)\\ &\quad+C(1-e^{-cT})\sum_{k\geq k_0}\omega_k(T)\\ &\quad\Big(\|\nabla\mathcal{H}_k^{n-1}(t)\|_{L^1_T(L^2)}+\|\mathcal{G}_k^{n-1}(t)\|_{L^1_T(L^2)}\Big)\\ &\quad+C\|u^n\|_{L^2_T(B^1)}\|u^{n-1}\|_{L^2_T(B^1)}+C\|h^n\|_{E^1_T}\|u^{n-1}\|_{L^2_T(B^1)}\\ &\leq C(1-e^{-cT})E_0+C(1-e^{-cT})KE_0\eta+C(1+KE_0)^4\eta^2, \end{aligned}$$

where we used (3.44) and (3.47) in the second inequality. Plugging the above inequality into (3.50) yields

$$II_1\leq CKE_0\Big[\frac{\eta}{16CKE_0}+(1-e^{-cT})(E_0+KE_0\eta)+(1+KE_0)^4\eta^2\Big]. \tag{3.51}$$

Note that for $k\leq k_0$, we can choose $T>0$ small enough such that

$$\omega_k(T)\leq\frac{1}{16CKE_0}, \tag{$\Re_2$}$$

so we get

$$|II_2|\leq\frac{\eta}{16}. \tag{3.52}$$

Plugging (3.47), (3.48), (3.51), and (3.52) into (3.42), we get

$$\begin{aligned} &\|u^{n+1}\|_{L^1_T(B^2)}+\|u^{n+1}\|_{L^2_T(B^1)}+\|h^{n+1}\|_{\widetilde{E}^{0,1}_T}\\ &\quad\leq C\mathcal{Q}_0(T)+\frac{\eta}{8}+C(1+KE_0)^5\eta^2+CKE_0(1-e^{-cT})(E_0+KE_0\eta)\\ &\quad\quad+C\eta(\|u^{n+1}\|_{L^2_T(B^1)}+\|h^{n+1}\|_{\widetilde{E}^{0,1}_T}). \end{aligned} \tag{3.53}$$

Note that $\mathcal{Q}_0(0)=0$. We can take T,η small enough such that

$$C\eta\leq\frac{1}{2},\quad C\mathcal{Q}_0(T)\leq\frac{\eta}{8},\quad C(1+KE_0)^5\eta<\frac{1}{8},\quad\text{and}$$

$$CKE_0(1-e^{-cT})(E_0+KE_0\eta)\leq\frac{\eta}{8}, \tag{$\Re_3$}$$

which, together with (3.53), gives

$$\|u^{n+1}\|_{L^1_T(B^2)} + \|u^{n+1}\|_{L^2_T(B^1)} + \|h^{n+1}\|_{\widetilde{E}^{0,1}_T} \leq \eta.$$

Finally, let us prove (3.39) for h^{n+1}. We rewrite the first equation of (3.38) as

$$\partial_t(1+h^{n+1}) + u^n \cdot \nabla(1+h^{n+1}) + \mathrm{div} u^{n+1} - \mathcal{H}^n = 0.$$

Then $1+h^{n+1}$ can be represented as

$$\begin{aligned}(1+h^{n+1})(t,x) = (1+h_0^{n+1})((\psi^n)_t^{-1}(x)) + \int_0^t \mathrm{div}\, u^{n+1}(\tau, \psi^n_\tau((\psi^n)_t^{-1}(x)))d\tau \\ + \int_0^t \mathcal{H}^n(\tau, \psi^n_\tau((\psi^n)_t^{-1}(x)))d\tau, \end{aligned} \tag{3.54}$$

where the flow map ψ^n_t is defined by

$$\begin{cases} \partial_t \psi^n_t(x) = u^n(t, \psi^n_t(x)), \\ \psi^n_t|_{t=0} = x. \end{cases}$$

Thanks to the inclusion map $B^1 \hookrightarrow L^\infty$ and (2.4), we get

$$\begin{aligned} &\int_0^t \|\mathrm{div}\, u^{n+1}(\tau, \psi^n_\tau((\psi^n)_t^{-1}(x)))\|_\infty d\tau \leq \|u^{n+1}\|_{L^1_t(B^2)} \leq \eta, \\ &\int_0^t \|\mathcal{H}^n(\tau, \psi_\tau(\psi_t^{-1}(x)))\|_\infty d\tau \leq \|h^n \mathrm{div} u^n\|_{L^1_t(B^1)} \\ &\qquad\qquad \leq C\|h^n\|_{L^\infty_t(\widetilde{B}^{0,1})}\|u^n\|_{L^1_t(B^2)} \leq CKE_0\eta, \end{aligned}$$

from which, together with (3.54), it follows that

$$1 + h^{n+1} \geq \frac{3}{4} - (1+CKE_0)\eta. \tag{3.55}$$

We take η small enough such that

$$(1+CKE_0)\eta \leq \frac{1}{4}, \tag{$\Re_4$}$$

which, together with (3.55), ensures that

$$1 + h^{n+1} \geq \frac{1}{2}.$$

So far, we have shown that T, η can be chosen small enough such that the assumptions ($\Re_1$)–($\Re_4$) hold, under which the approximate solutions $(u^n, h^n)_{n\in\mathbb{N}_0}$ are uniformly bounded in

$$\mathcal{E}_T \triangleq \Big(L^\infty_T(B^0) \cap L^1_T(B^2)\Big) \times \Big(L^\infty_T(\widetilde{B}^{0,1}) \cap L^1_T(\widetilde{B}^{2,1})\Big).$$

It should be pointed out that if $\|u_0\|_{B^0} + \|h_0\|_{\widetilde{B}^{0,1}}$ is small enough, we can take $T = +\infty$ such that the assumptions ($\Re_1$)–($\Re_4$) hold.

3.3. The existence of the solution. Now let us turn to prove the existence of the solution, and the standard compact arguments will be used. We should point out that in order to obtain the convergence of the terms $u^n\cdot\nabla u^{n+1}$ and $u^n\cdot\nabla h^{n+1}$ in (3.38), we need to show that both (u^n,h^n) and (u^{n+1},h^{n+1}) have the same limit. Indeed, following the argument in the proof of uniqueness (section 4), it can be proved that $(u^n,h^n)_n$ is a Cauchy sequence in some weak topology which particularly ensures the uniqueness of the limit for any subsequence of $(u^n,h^n)_n$. In section 3.2, we have showed that the approximate solutions $(h^n,u^n)_{n\in\mathbb{N}}$ satisfy (3.39)–(3.41), and without loss of generality, we can assume the following:

$$1+h^n\geq\frac{1}{2}, \tag{3.56}$$

$$\|u^n\|_{L^\infty_T(B^0)\cap L^1_T(B^2)}+\|h^n\|_{L^\infty_T(\widetilde{B}^{0,1})\cap L^1_T(\widetilde{B}^{2,1})}\leq KE_0. \tag{3.57}$$

Using the interpolation and the fact that $B^0\cap B^1=\widetilde{B}^{0,1}$, we have

$$\|h^n\|_{L^2_T(B^1)}\lesssim\|h^n\|^{\frac12}_{L^\infty_T(\widetilde{B}^{0,1})}\|h^n\|^{\frac12}_{L^1_T(\widetilde{B}^{2,1})},\quad \|u^n\|_{L^2_T(B^1)}\lesssim\|u^n\|^{\frac12}_{L^\infty_T(B^0)}\|u^n\|^{\frac12}_{L^1_T(B^2)},$$

$$\|h^n\|_{L^4_T(B^{\frac12})}\lesssim\|h^n\|^{\frac12}_{L^\infty_T(\widetilde{B}^{0,1})}\|h^n\|^{\frac12}_{L^2_T(B^1)},\quad \|u^n\|_{L^{\frac43}_T(B^{\frac32})}\lesssim\|u^n\|^{\frac14}_{L^\infty_T(B^0)}\|u^n\|^{\frac34}_{L^1_T(B^2)},$$

from which, together with (3.57), it follows that

$$\|h^n\|_{L^2_T(B^1)}+\|u^n\|_{L^2_T(B^1)}+\|h^n\|_{L^4_T(B^{\frac12})}+\|u^n\|_{L^{\frac43}_T(B^{\frac32})}\lesssim KE_0. \tag{3.58}$$

Now, we show that (h^n,u^n) is uniformly bounded in $C^{\frac12}_{loc}(B^0)\times C^{\frac14}_{loc}(B^{-\frac12})$. Using (2.4), (3.57), and (3.58), it is easy to verify that

$$\|u^n\cdot\nabla h^{n+1}\|_{L^2_T(B^0)}\lesssim\|u^n\|_{L^2_T(B^1)}\|h^{n+1}\|_{L^\infty_T(\widetilde{B}^{0,1})}\lesssim(KE_0)^2,$$

$$\|h^n\mathrm{div}u^n\|_{L^2_T(B^0)}\lesssim\|u^n\|_{L^2_T(B^1)}\|h^n\|_{L^\infty_T(\widetilde{B}^{0,1})}\lesssim(KE_0)^2,$$

from which, together with the first equation of (3.38), it follows that $\partial_t h^n$ is uniformly bounded in $L^2_T(B^0)$, which implies that h^n is uniformly bounded in $C^{\frac12}_{loc}(B^0)$. On the other hand, thanks to (2.4), (3.58), and (2.12), we have

$$\|u^n\cdot\nabla u^{n+1}\|_{L^{\frac43}_T(B^{-\frac12})}\lesssim\|u^n\|_{L^\infty_T(B^0)}\|u^{n+1}\|_{L^{\frac43}_T(B^{\frac32})}\lesssim(KE_0)^2,$$

$$\left\|\frac{\nabla h^n}{1+h^n}\widetilde{\nabla}u^n\right\|_{L^{\frac43}_T(B^{-\frac12})}\lesssim C(1+\|h^n\|_{L^\infty_T(B^1)})^3\|u^n\|_{L^{\frac43}_T(B^{\frac32})}\lesssim C(1+KE_0)^3KE_0,$$

from which, together with the second equation of (3.38), it follows that $\partial_t u^n$ is uniformly bounded in $L^{\frac43}_T(B^{-\frac12})$, which implies that u^n is uniformly bounded in $C^{\frac14}_{loc}(B^{-\frac12})$.

Next, we claim that the inclusions $B^0\cap B^1\hookrightarrow L^2$ and $B^{-\frac12}\cap B^0\hookrightarrow\dot{H}^{-\frac12}$ are locally compact. Indeed, these can be proved by noting that for $s'<s$, $\dot{H}^{s'}\cap\dot{H}^s\hookrightarrow\dot{H}^{s'}$ is locally compact and for $s\in\mathbb{R}$, $B^s\hookrightarrow\dot{H}^s$. Then, by the Arzelà–Ascoli theorem and

Cantor's diagonal process, there exist a subsequence (u^{n_k}, h^{n_k}) and a function (u, h) such that

$$(u^{n_k}, h^{n_k}) \to (u, h) \qquad \text{in} \quad C_{loc}(\dot{H}^{-\frac{1}{2}}_{loc}) \times C_{loc}(L^2_{loc}), \tag{3.59}$$

as $n_k \to \infty$. On the other hand, (u^{n_k}, h^{n_k}) is uniformly bounded in $\mathcal{E}_T$. Then there exists a subsequence (which is still denoted by (u^{n_k}, h^{n_k})) such that

$$(u^{n_k}, h^{n_k}) \rightharpoonup (u, h) \quad \text{in} \quad \mathcal{E}_T,$$

where "$\rightharpoonup$" denotes weak* convergence.

Finally, let us prove that (u, h) solves (1.1) in the sense of distribution. We need only prove that the nonlinear terms such as $u^n \cdot \nabla h^n$, $\frac{\nabla h^n}{1+h^n}\widetilde{\nabla} u^n$, etc., tend to the corresponding nonlinear terms in the sense of distribution. This can be done by using the uniform estimates of (u^n, h^n), (u, h) in $\mathcal{E}_T$ and the convergence result (3.59). Here, we show only the case of the term $Y(h^n)\widetilde{\nabla} u^n$ (where $Y(z) \triangleq \nabla z/(1+z)$); the other terms can be treated in the same way. For any test function $\theta \in C_0^\infty([0, T^*) \times \mathbb{R}^2)$, we write

$$\begin{aligned}
&\big\langle Y(h^n)\widetilde{\nabla} u^n - Y(h)\widetilde{\nabla} u,\, \theta\big\rangle \\
&\quad = \Big\langle (1+h^n)\nabla\Big(\frac{h^n}{1+h^n} - \frac{h}{1+h}\Big)\widetilde{\nabla} u^n,\, \theta\Big\rangle \\
&\qquad + \Big\langle (h^n - h)\nabla\Big(\frac{h}{1+h}\Big)\widetilde{\nabla} u^n,\, \theta\Big\rangle + \Big\langle (1+h)\nabla\Big(\frac{h}{1+h}\Big)\widetilde{\nabla}(u^n - u),\, \theta\Big\rangle \\
&\quad \triangleq I_1 + I_2 + I_3.
\end{aligned}$$

Thanks to (2.4) and (3.56), we have

$$\begin{aligned}
I_1 &\le \Big\| \frac{\psi(h^n - h)}{(1+h^n)(1+h)} \Big\|_2 \|\nabla((1+h^n)\widetilde{\nabla} u^n \theta)\|_2 \lesssim \|\psi(h^n - h)\|_2 \|(1+h^n)\widetilde{\nabla} u^n\|_{B^1} \\
&\lesssim \|\psi(h^n - h)\|_2 (1 + \|h^n\|_{\widetilde{B}^{0,1}}) \|u^n\|_{B^2},
\end{aligned}$$

where $\psi \in C_0^\infty([0, T^*) \times \mathbb{R}^2)$, and $\psi = 1$ on $\operatorname{supp}\theta$. For I_2, we have

$$\begin{aligned}
I_2 &\le \|\theta(h^n - h)\|_2 \Big\| \nabla\Big(\frac{h}{1+h}\Big)\widetilde{\nabla} u^n \Big\|_2 \lesssim \|\theta(h^n - h)\|_2 \|\nabla h\|_2 \|\nabla u^n\|_{L^\infty} \\
&\lesssim \|\theta(h^n - h)\|_2 \|h\|_{\widetilde{B}^{0,1}} \|u^n\|_{B^2}.
\end{aligned}$$

Using (3.56) and the interpolation, we get

$$\begin{aligned}
I_3 &\le \Big\| (1+h)\nabla\Big(\frac{h}{1+h}\Big) \Big\|_2 \|\widetilde{\nabla}(u^n - u)\theta\|_2 \lesssim (1 + \|h\|_\infty) \|\nabla h\|_2 \|(u^n - u)\theta\|_{\dot{H}^1} \\
&\lesssim (1 + \|h\|_{\widetilde{B}^{0,1}}) \|h\|_{B^1} \|u^n - u\|^{\frac{3}{5}}_{H^2} \|(u^n - u)\theta\|^{\frac{2}{5}}_{\dot{H}^{-\frac{1}{2}}}.
\end{aligned}$$

Thus, by (3.59), we get as $n \to 0$

$$\big\langle Y(h^n)\widetilde{\nabla} u^n - Y(h)\widetilde{\nabla} u,\, \theta\big\rangle \longrightarrow 0.$$

Following the argument in [11], we can also prove that (u, h) is continuous in time with values in $B^0 \times \widetilde{B}^{0,1}$.

4. Uniqueness. In this section, we will prove the uniqueness of the solution. First, let us recall some known results.

LEMMA 4.1 (Osgood's lemma). *Let ρ be a measurable positive function and γ a positive locally integrable function, each defined on the domain $[t_0, t_1]$. Let $\mu : [0,\infty) \to [0,\infty)$ be a continuous nondecreasing function, with $\mu(0) = 0$. Let $a \geq 0$, and assume that for all t in $[t_0, t_1]$,*

$$\rho(t) \leq a + \int_{t_0}^{t} \gamma(\tau)\mu(\rho(\tau))d\tau.$$

If $a > 0$, then

$$-\mathcal{M}(\rho(t)) + \mathcal{M}(a) \leq \int_{t_0}^{t} \gamma(\tau)d\tau, \quad \text{where} \quad \mathcal{M}(x) = \int_{x}^{1} \frac{d\tau}{\mu(\tau)}.$$

If $a = 0$ and $\mathcal{M} = \infty$, then $\rho \equiv 0$.

This lemma can be understood as a generalization of the classical Gronwall lemma and can be found in [8].

PROPOSITION 4.2. *Let $s \in (-\frac{d}{p}, 1 + \frac{d}{p})$ and $1 \leq p, r \leq +\infty$. Let v be a vector field such that $\nabla v \in L^1_T(\dot{B}^{\frac{d}{p}}_{p,r} \cap L^\infty)$. Assume that $f_0 \in \dot{B}^s_{p,r}$, $g \in L^1_T(\dot{B}^s_{p,r})$ and $f \in L^\infty_T(\dot{B}^s_{p,r}) \cap C([0,T]; \mathcal{S}')$ is the solution of*

$$\begin{cases} \partial_t f + v \cdot \nabla f = g, \\ f(0,x) = f_0. \end{cases}$$

Then there exists a constant $C(s,p,d)$ such that for $t \in [0,T]$

$$\|f\|_{\widetilde{L}^\infty_t(\dot{B}^s_{p,r})} \leq Ce^{CV(t)}\Big(\|f_0\|_{\dot{B}^s_{p,r}} + \int_0^t e^{-CV(\tau)}\|g(\tau)\|_{\dot{B}^s_{p,r}}d\tau\Big), \tag{4.1}$$

where $V(t) \triangleq \int_0^t \|\nabla v(\tau)\|_{\dot{B}^{\frac{d}{p}}_{p,r}\cap L^\infty} d\tau$. If $r < +\infty$, then f belongs to $C([0,T]; \dot{B}^s_{p,r})$.

The proof can be found in [15].

PROPOSITION 4.3. *Let $T > 0$, $s \in \mathbb{R}$, and $1 \leq q, r \leq +\infty$. Assume that $u_0 \in \dot{B}^s_{2,q}$, $g \in \widetilde{L}^1_T(\dot{B}^s_{2,q})$, and u is the solution of*

$$\begin{cases} \partial_t u - \nu\widetilde{\Delta}u = g, \\ u(0,x) = u_0, \end{cases}$$

where $\widetilde{\Delta}u = \nabla \cdot D(u) + \nabla \mathrm{div}\, u$. Then there exists a constant $C(s,d,\nu)$ such that

$$\begin{aligned}(r\nu)^{\frac{1}{r}}\|u\|_{\widetilde{L}^r_T(\dot{B}^{s+\frac{2}{r}}_{2,q})} \leq \Big(\sum_{k\in\mathbb{Z}}\big(1 - e^{-r\nu 2^{2k}T}\big)^{\frac{q}{r}} 2^{qks}\|\Delta_k u_0\|_2^q\Big)^{\frac{1}{q}} \\ + C\Big(\sum_{k\in\mathbb{Z}}\big(1 - e^{-r\nu 2^{2k}T}\big)^{\frac{q}{r}} 2^{qks}\|\Delta_k g\|^q_{L^1_T(L^2)}\Big)^{\frac{1}{q}}.\end{aligned} \tag{4.2}$$

If $q < +\infty$, then u belongs to $C([0,T]; \dot{B}^s_{2,q})$.

The proof is similar to the case when the diffusion term $\widetilde{\Delta}u$ is replaced by Δu. We refer the reader to [9] for details.

Now we introduce the logarithmic interpolation inequality (see [14]).

PROPOSITION 4.4. *For any* $1 \leq p, \rho \leq +\infty$, $s \in \mathbb{R}$, *and* $0 < \epsilon \leq 1$, *we have*

$$\|f\|_{\widetilde{L}^\rho_T(\dot{B}^s_{p,1})} \leq C\frac{\|f\|_{\widetilde{L}^\rho_T(\dot{B}^s_{p,\infty})}}{\epsilon}\log\left(e + \frac{\|f\|_{\widetilde{L}^\rho_T(\dot{B}^{s-\epsilon}_{p,\infty})} + \|f\|_{\widetilde{L}^\rho_T(\dot{B}^{s+\epsilon}_{p,\infty})}}{\|f\|_{\widetilde{L}^\rho_T(\dot{B}^s_{p,\infty})}}\right). \tag{4.3}$$

Now, let us prove the uniqueness of the solution of (3.1). Let (u_1, h_1), (u_2, h_2) $\in \big(L^\infty_T(B^0)\cap L^1_T(B^2)\big)\times L^\infty_T(\widetilde{B}^{0,1})$ be two solutions of (3.1) with the same initial data. The difference $\vartheta \triangleq h_2 - h_1$, $w \triangleq u_2 - u_1$ satisfies the following system:

$$\begin{cases} \partial_t\vartheta + u_2\cdot\nabla\vartheta = -\mathrm{div}w - w\nabla h_1 - \vartheta\mathrm{div}u_2 - h_1\mathrm{div}w, \\ \partial_t w - \nu\widetilde{\Delta}w = -\nabla\vartheta - u_2\cdot\nabla w - w\cdot\nabla u_1 + \nu(1+h_1)\nabla\Big(\dfrac{h_1}{1+h_1}\Big)\widetilde{\nabla}w \\ \qquad\qquad + \nu(1+h_1)\nabla\Big(\dfrac{h_2}{1+h_2} - \dfrac{h_1}{1+h_1}\Big)\widetilde{\nabla}u_2 + \nu\vartheta\nabla\Big(\dfrac{h_2}{1+h_2}\Big)\widetilde{\nabla}u_2, \\ \vartheta(0,x) = 0, \quad w(0,x) = 0. \end{cases} \tag{4.4}$$

Without loss of generality, we assume that there holds for sufficiently small T

$$1 + h_1 \geq \frac{1}{2}, \tag{4.5}$$

$$\|h_1\|_{\widetilde{E}^{0,1}_T} \leq \varepsilon, \tag{4.6}$$

where $\varepsilon > 0$ is small enough. Applying Proposition 4.2 to the first equation of (4.4) yields

$$\|\vartheta(t)\|_{\dot{B}^0_{2,\infty}} \lesssim \int_0^t e^{C(V_2(t)-V_2(\tau))}\|w\cdot\nabla h_1 + \vartheta\mathrm{div}u_2 + h_1\mathrm{div}w + \mathrm{div}w\|_{\dot{B}^0_{2,\infty}}d\tau, \tag{4.7}$$

with $V_2(t) \triangleq \int_0^t \|\nabla u_2\|_{\dot{B}^1_{2,\infty}\cap L^\infty}d\tau$. It follows from (2.5) with $s = 0$ that

$$\begin{aligned} \|w\cdot\nabla h_1\|_{\dot{B}^0_{2,\infty}} &\lesssim \|\nabla h_1\|_{\dot{B}^0_{2,\infty}}\|w\|_{B^1} \lesssim \|w\|_{B^1}\|h_1\|_{B^1}, \\ \|\vartheta\mathrm{div}u_2\|_{\dot{B}^0_{2,\infty}} &\lesssim \|\vartheta\|_{\dot{B}^0_{2,\infty}}\|u_2\|_{B^2}, \\ \|h_1\mathrm{div}w\|_{\dot{B}^0_{2,\infty}} &\lesssim \|\mathrm{div}w\|_{\dot{B}^0_{2,\infty}}\|h_1\|_{B^1} \lesssim \|w\|_{B^1}\|h_1\|_{B^1}, \end{aligned}$$

where we have used $B^1 \hookrightarrow \dot{B}^1_{2,\infty}$. Plugging the above estimates into (4.7), we get

$$\|\vartheta(t)\|_{\dot{B}^0_{2,\infty}} \lesssim \int_0^t e^{C(V_2(t)-V_2(\tau))}\Big[\|w\|_{B^1}(1+\|h_1\|_{B^1}) + \|\vartheta\|_{\dot{B}^0_{2,\infty}}\|u_2\|_{B^2}\Big]d\tau. \tag{4.8}$$

Recalling that $u^i \in L^1_T(B^2)$, we can take a $T \in (0,\infty)$ small enough so that

$$C\|u_2\|_{L^1_T(B^2)} \leq \frac{1}{4},$$

which together with (4.8) implies that for $t \leq T$

$$\|\vartheta\|_{L^\infty_t(\dot{B}^0_{2,\infty})} \lesssim \|w\|_{L^1_t(B^1)}(1 + \|h_1\|_{L^\infty_t(B^1)}). \tag{4.9}$$

Applying (4.3) to the term $\|w\|_{L^1_t(B^1)}$ yields

(4.10)
$$\|\vartheta\|_{L^\infty_t(\dot B^0_{2,\infty})} \lesssim \|w\|_{\widetilde L^1_t(\dot B^1_{2,\infty})} \log\left(e + \frac{\|w\|_{\widetilde L^1_t(\dot B^0_{2,\infty})} + \|w\|_{\widetilde L^1_t(\dot B^2_{2,\infty})}}{\|w\|_{\widetilde L^1_t(\dot B^1_{2,\infty})}}\right)(1 + \|h_1\|_{L^\infty_t(B^1)}).$$

Thanks to $B^s \hookrightarrow \dot B^s_{2,\infty}$ and $\widetilde B^{0,1} \hookrightarrow B^1$, we have

$$\|\vartheta\|_{L^\infty_t(\dot B^0_{2,\infty})} \lesssim \|w\|_{\widetilde L^1_t(\dot B^1_{2,\infty})} \log\left(e + \frac{W(t)}{\|w\|_{\widetilde L^1_t(\dot B^1_{2,\infty})}}\right) \tag{4.11}$$

with

$$W(t) \triangleq \sum_{i=1}^{2} \|u^i\|_{\widetilde L^1_t(B^0)} + \|u^i\|_{\widetilde L^1_t(B^2)},$$

and for finite t, $W(t) < +\infty$.

Next, we deal with the second equation of (4.4). We get by applying (2.7) with $s = 1$, $s = 0$, respectively, that

$$\|u_2 \cdot \nabla w\|_{\widetilde L^1_t(\dot B^{-1}_{2,\infty})} \lesssim \|u_2\|_{L^2_t(B^1)} \|w\|_{\widetilde L^2_t(\dot B^0_{2,\infty})}, \tag{4.12}$$

$$\|w \cdot \nabla u_1\|_{\widetilde L^1_t(\dot B^{-1}_{2,\infty})} \lesssim \|u_1\|_{L^2_t(B^1)} \|w\|_{\widetilde L^2_t(\dot B^0_{2,\infty})}. \tag{4.13}$$

We can deduce $h_i \in C(0,T;\mathbb{R}^2)$ $(i = 1, 2)$ from the fact $B^1 \hookrightarrow C$. Moreover, due to (4.5), we can assume $h_1(t,x) + 1 \geq \frac{1}{2}$ for all $t \leq T$, $x \in \mathbb{R}^2$. Since h_1, h_2 have the same initial data, from the continuity of h_2, there exists a $\widetilde T \leq T$ such that

$$h_2(x,t) + 1 \geq \frac{1}{4} \quad \text{for all} \quad t \in [0, \widetilde T], \quad x \in \mathbb{R}^2.$$

It follows from (2.6) with $s = 1$, (2.15), and $B^1 \hookrightarrow \dot B^1_{2,\infty} \cap L^\infty$ that

$$\begin{aligned}
&\Big\|(1+h_1)\nabla\Big(\frac{h_2}{1+h_2} - \frac{h_1}{1+h_1}\Big)\widetilde\nabla u_2\Big\|_{\dot B^{-1}_{2,\infty}} \\
&\quad\lesssim \Big\|(1+h_1)\nabla\Big(\frac{h_2}{1+h_2} - \frac{h_1}{1+h_1}\Big)\Big\|_{\dot B^{-1}_{2,\infty}} \|\widetilde\nabla u_2\|_{B^1} \\
&\quad\lesssim (1 + \|h_1\|_{B^1})\Big\|\frac{h_2}{1+h_2} - \frac{h_1}{1+h_1}\Big\|_{\dot B^0_{2,\infty}} \|u_2\|_{B^2} \\
&\quad\lesssim (1 + \|h_1\|_{B^1})(\|h_1\|_{B^1} + \|h_2\|_{B^1})\|\vartheta\|_{\dot B^0_{2,\infty}} \|u_2\|_{B^2},
\end{aligned}$$

which, together with $L^1_t(\dot B^{-1}_{2,\infty}) \subset \widetilde L^1_t(\dot B^{-1}_{2,\infty})$, yields

$$\begin{aligned}
&\Big\|(1+h_1)\nabla\Big(\frac{h_2}{1+h_2} - \frac{h_1}{1+h_1}\Big)\widetilde\nabla u_2\Big\|_{\widetilde L^1_t(\dot B^{-1}_{2,\infty})} \\
&\quad\lesssim \int_0^t (1 + \|h_1\|_{B^1})(\|h_1\|_{B^1} + \|h_2\|_{B^1})\|\vartheta\|_{\dot B^0_{2,\infty}} \|u_2\|_{B^2} d\tau.
\end{aligned} \tag{4.14}$$

Thanks to (2.6), (2.12), and $L^1_t(\dot B^{-1}_{2,\infty}) \subset \widetilde L^1_t(\dot B^{-1}_{2,\infty})$, we get

$$\Big\|\vartheta\nabla\Big(\frac{h_2}{1+h_2}\Big)\widetilde\nabla u_2\Big\|_{\widetilde L^1_t(\dot B^{-1}_{2,\infty})} \lesssim \int_0^t \|\vartheta\|_{\dot B^0_{2,\infty}}\|h_2\|_{B^1}\|u_2\|_{B^2}d\tau. \tag{4.15}$$

Thanks to Lemma 5.3 with $s_1 = s_2 = 0$, Lemma 5.4 with $s = 1$, and (2.5) with $s = 0$, we have

$$\begin{aligned}
&\sup_{k\in\mathbb{Z}}\omega_k(t)2^{-k}\Big\|\Delta_k\Big((1+h_1)\nabla\Big(\frac{h_1}{1+h_1}\Big)\widetilde\nabla w\Big)\Big\|_{L^1_t(L^2)}\\
&\quad\lesssim \Big\|\nabla\Big(\frac{h_1}{1+h_1}\Big)\Big\|_{E^0_t}\|(1+h_1)\widetilde\nabla w\|_{\widetilde L^1_t(\dot B^0_{2,\infty})}\\
&\quad\lesssim \Big\|\frac{h_1}{1+h_1}\Big\|_{E^1_t}(1+\|h_1\|_{L^\infty_t(B^1)})\|\nabla w\|_{\widetilde L^1_t(\dot B^0_{2,\infty})}\\
&\quad\lesssim \|h_1\|_{\widetilde E^{0,1}_t}(1+\|h_1\|_{L^\infty_t(\widetilde B^{0,1})})^4\|w\|_{\widetilde L^1_t(\dot B^1_{2,\infty})}.
\end{aligned}\tag{4.16}$$

In terms of Proposition 4.3, (4.12)–(4.16), and $\widetilde B^{0,1} \hookrightarrow B^1$, we finally obtain

$$\begin{aligned}
&\|w\|_{\widetilde L^1_t(\dot B^1_{2,\infty})} + \|w\|_{\widetilde L^2_t(\dot B^0_{2,\infty})}\\
&\lesssim \|u_2\|_{L^2_t(B^1)}\|w\|_{\widetilde L^2_t(\dot B^0_{2,\infty})} + \|u_1\|_{L^2_t(B^1)}\|w\|_{\widetilde L^2_t(\dot B^0_{2,\infty})}\\
&\quad + \|h_1\|_{\widetilde E^{0,1}_t}\big(1+\|h_1\|_{L^\infty_t(\widetilde B^{0,1})}\big)^4\|w\|_{\widetilde L^1_t(B^1_{2,\infty})}\\
&\quad + \int_0^t (1+\|h_1\|_{\widetilde B^{0,1}})(1+\|h_1\|_{\widetilde B^{0,1}}+\|h_2\|_{\widetilde B^{0,1}})(1+\|u_2\|_{B^2})\|\vartheta\|_{\dot B^0_{2,\infty}}d\tau.
\end{aligned}\tag{4.17}$$

Let us define

$$Z(t) \triangleq \|w\|_{\widetilde L^1_t(\dot B^1_{2,\infty})} + \|w\|_{\widetilde L^2_t(\dot B^0_{2,\infty})}.$$

Due to (4.6), if T is chosen small enough, then the first three terms on the right side of (4.17) can be absorbed by the left side $Z(t)$. Noting that $r\log(e+\frac{W(T)}{r})$ is increasing, from (4.11) and (4.17), it follows that

$$\begin{aligned}
Z(t) &\lesssim \int_0^t (1+W'(\tau))Z(\tau)\log\Big(e+\frac{W(\tau)}{Z(\tau)}\Big)d\tau\\
&\lesssim \int_0^t (1+W'(\tau))Z(\tau)\log\Big(e+\frac{W(T)}{Z(\tau)}\Big)d\tau.
\end{aligned}\tag{4.18}$$

It is easy to verify that

$$1+W'(\tau)\in L^1_{loc}(\mathbb{R}^+) \quad\text{and}\quad \int_0^1 \frac{dr}{r\log(e+\frac{W(T)}{r})} = +\infty.$$

Hence by the Osgood lemma, we have $Z \equiv 0$ on $[0,\widetilde T]$, i.e., $w \equiv 0$; then from (4.9), $\vartheta = h_2 - h_1 \equiv 0$. Then a standard continuous argument gives the uniqueness.

5. Appendix. In this appendix, we prove some multilinear estimates in the weighted Besov space.

LEMMA 5.1. *Let A be a homogeneous smooth function of degree m. Assume that $-\frac{d}{2} < \rho \leq \frac{d}{2}$. Then it holds that*

$$\Big|\big(A(D)\Delta_k(v\cdot\nabla h), A(D)\Delta_k h\big)\Big| \leq C\|\mathcal{F}_k^m(t)\|_2\|A(D)\Delta_k h\|_2, \tag{5.1}$$

$$\Big|\big(A(D)\Delta_k(v\cdot\nabla u), A(D)\Delta_k u\big)\Big| \leq C\|\widetilde{\mathcal{F}}_k^m(t)\|_2\|A(D)\Delta_k u\|_2, \tag{5.2}$$

and

$$\begin{aligned}&\Big|\big(A(D)\Delta_k(v\cdot\nabla h), \Delta_k u\big) + \big(\Delta_k(v\cdot\nabla u), A(D)\Delta_k h\big)\Big|\\ &\qquad\leq C\big(\|\mathcal{F}_k^m(t)\|_2 + \|\widetilde{\mathcal{F}}_k^0(t)\|_2\big)\big(\|\Delta_k u\|_2 + \|A(D)\Delta_k h\|_2\big),\end{aligned} \tag{5.3}$$

where $\mathcal{F}_k^m(t)$ and $\widetilde{\mathcal{F}}_k^m(t)$ satisfy

$$\sum_{k\in\mathbb{Z}}\omega_k(T)2^{k(\rho-m)}\|\mathcal{F}_k^m(t)\|_{L^1_T(L^2)} \leq C\|h\|_{E^\rho_T}\|v\|_{L^1_T(B^{\frac{d}{2}+1})}, \tag{5.4}$$

$$\sum_{k\in\mathbb{Z}}2^{k(\rho-m)}\|\widetilde{\mathcal{F}}_k^m(t)\|_{L^1_T(L^2)} \leq C\|u\|_{L^2_T(B^{\rho+1})}\|v\|_{L^2_T(B^{\frac{d}{2}})}. \tag{5.5}$$

Proof. Let us first prove (5.1). Using Bony's paraproduct decomposition, we write

$$\big(A(D)\Delta_k(v\cdot\nabla h), A(D)\Delta_k h\big) = \big(A(D)\Delta_k(T'_{\partial_j h}v^j), A(D)\Delta_k h\big) + J_k, \tag{5.6}$$

where

$$\begin{aligned}&T'_f g = T_f g + R(f,g), \quad \text{and}\\ &J_k = \sum_{|k'-k|\leq 3}([A(D)\Delta_k, S_{k'-1}v^j]\Delta_{k'}\partial_j h, A(D)\Delta_k h)\\ &\qquad + \sum_{|k'-k|\leq 3}((S_{k'-1}-S_{k-1})v^j A(D)\Delta_k\Delta_{k'}\partial_j h, A(D)\Delta_k h)\\ &\qquad + (S_{k-1}v^j A(D)\Delta_k\partial_j h, A(D)\Delta_k h).\end{aligned}$$

We get by integration by parts that

$$(S_{k-1}v^j A(D)\Delta_k\partial_j h, A(D)\Delta_k h) = -\frac{1}{2}\big(S_{k-1}\mathrm{div}\, vA(D)\Delta_k h, A(D)\Delta_k h\big).$$

Let us set

$$\begin{aligned}&\mathcal{F}^m_{k,0}(t) = A(D)\Delta_k(T'_{\partial_j h}v^j),\\ &\mathcal{F}^m_{k,1}(t) = \sum_{|k'-k|\leq 3}[A(D)\Delta_k, S_{k'-1}v^j]\Delta_{k'}\partial_j h,\\ &\mathcal{F}^m_{k,2}(t) = \sum_{|k'-k|\leq 3}(S_{k'-1}-S_{k-1})v^j A(D)\Delta_k\Delta_{k'}\partial_j h,\\ &\mathcal{F}^m_{k,3}(t) = -\frac{1}{2}S_{k-1}\mathrm{div}\, vA(D)\Delta_k h.\end{aligned}$$

By the Cauchy–Schwarz inequality, we get

$$\big(A(D)\Delta_k(v\cdot\nabla h), A(D)\Delta_k h\big) \le \|\mathcal{F}_k^m(t)\|_2 \|A(D)\Delta_k h\|_2,$$

with $\mathcal{F}_k^m(t) = \sum_{i=0}^3 \mathcal{F}_{k,i}^m(t)$. So, it remains to prove that $\mathcal{F}_k^m(t)$ satisfies (5.4). For the simplicity, we set

$$\widetilde{\Delta}_k = \sum_{|k'-k|\le 1} \Delta_{k'}, \quad \widetilde{\widetilde{\Delta}}_k = \sum_{|k'-k|\le 3} \Delta_{k'}.$$

Thanks to the definition of $\mathcal{F}_{k,0}^m(t)$ and Lemma 2.1, we have

$$\begin{aligned}\|\mathcal{F}_{k,0}^m(t)\|_{L^1_T(L^2)} &\le \sum_{|k'-k|\le 3} 2^{km}\|S_{k'-1}\partial_j h\|_{L^\infty_T(L^\infty)}\|\Delta_{k'}v^j\|_{L^1_T(L^2)} \\ &\quad + \sum_{k'\ge k-2} 2^{(m+\frac{d}{2})k}\|\Delta_k(\Delta_{k'}\partial_j h\widetilde{\Delta}_{k'}v^j)\|_{L^1_T(L^1)} \\ &\triangleq I + II.\end{aligned}$$

Thanks to Lemma 2.1, we have

$$\begin{aligned}2^{k(\rho-m)}I &\lesssim 2^{k\rho}\sum_{k'\le k+1} 2^{k'(1+\frac{d}{2})}\|\Delta_{k'}h\|_{L^\infty_T(L^2)}\|\widetilde{\widetilde{\Delta}}_k v\|_{L^1_T(L^2)} \\ &\lesssim \sum_{k'\le k+1} 2^{(k'-k)(1+\frac{d}{2}-\rho)}2^{k'\rho}\|\Delta_{k'}h\|_{L^\infty_T(L^2)}2^{k(1+\frac{d}{2})}\|\widetilde{\widetilde{\Delta}}_k v\|_{L^1_T(L^2)},\end{aligned}$$

from which, together with the definition of $\omega_k(T)$, it follows that

$$\begin{aligned}&\sum_{k\in\mathbb{Z}}\omega_k(T)2^{k(\rho-m)}I \\ &\lesssim \sum_{k'\in\mathbb{Z}} 2^{k'\rho}\|\Delta_{k'}h\|_{L^\infty_T(L^2)}\sum_{k\ge k'-1}\omega_k(T)2^{(k'-k)(1+\frac{d}{2}-\rho)}2^{k(1+\frac{d}{2})}\|\widetilde{\widetilde{\Delta}}_k v\|_{L^1_T(L^2)} \\ &\lesssim \sum_{k'\in\mathbb{Z}}\omega_{k'}(T)2^{k'\rho}\|\Delta_{k'}h\|_{L^\infty_T(L^2)}\sum_{k\ge k'-1}2^{(k'-k)(\frac{d}{2}-\rho)}2^{k(1+\frac{d}{2})}\|\widetilde{\widetilde{\Delta}}_k v\|_{L^1_T(L^2)} \\ &\lesssim \|h\|_{E^\rho_T}\|v\|_{L^1_T(B^{\frac{d}{2}+1})}, \qquad (5.7)\end{aligned}$$

where we used the assumption $\rho \le \frac{d}{2}$ in the last inequality. Set $e_k(T) = e_k^1(T)+e_k^2(T)$. Using Lemma 2.1, we also have

$$\begin{aligned}\omega_k(T)2^{k(\rho-m)}II &\lesssim \omega_k(T)2^{k(\rho+\frac{d}{2})}\sum_{k'\ge k-2}2^{k'}\|\Delta_{k'}h\|_{L^\infty_T(L^2)}\|\widetilde{\Delta}_{k'}v\|_{L^1_T(L^2)} \\ &\lesssim 2^{k(\rho+\frac{d}{2})}\sum_{k'\ge k-2}2^{k'}\|\Delta_{k'}h\|_{L^\infty_T(L^2)}\|\widetilde{\Delta}_{k'}v\|_{L^1_T(L^2)}\sum_{k'\ge\widetilde{k}\ge k}2^{-(\widetilde{k}-k)}e_{\widetilde{k}}(T) \\ &\quad + 2^{k(\rho+\frac{d}{2})}\sum_{k'\ge k-2}2^{k'}\|\Delta_{k'}h\|_{L^\infty_T(L^2)}\|\widetilde{\Delta}_{k'}v\|_{L^1_T(L^2)} \\ &\qquad \sum_{\widetilde{k}\ge k,\widetilde{k}\ge k'}2^{-(\widetilde{k}-k)}e_{\widetilde{k}}(T) \\ &\triangleq II_1 + II_2.\end{aligned}$$

Note that for $\widetilde{k} \leq k'$

$$e_{\widetilde{k}}(T) \leq e_{k'}(T) \leq \omega_{k'}(T),$$

from which, together with $\rho > -\frac{d}{2}$, we deduce that

$$\sum_{k\in Z} II_1 \lesssim \sum_{k'\in Z} \omega_{k'}(T)2^{k'\rho}\|\Delta_{k'}h\|_{L^\infty_T(L^2)}2^{k'(\frac{d}{2}+1)}\|\widetilde{\Delta}_{k'}v\|_{L^1_T(L^2)} \sum_{k\leq k'+2} 2^{(k-k')(\rho+\frac{d}{2})}$$

$$\lesssim \|h\|_{E^\rho_T}\|v\|_{L^1_T(B^{\frac{d}{2}+1})}. \tag{5.8}$$

Similarly, we can obtain

$$\begin{aligned}\sum_{k\in\mathbb{Z}} II_2 &\lesssim \sum_{k'\in\mathbb{Z}} 2^{k'\rho}\|\Delta_{k'}h\|_{L^\infty_T(L^2)} \sum_{k\leq k'+2} 2^{(k-k')(\frac{d}{2}+\rho)} \sum_{\widetilde{k}\geq k'} 2^{-(\widetilde{k}-k)}e_{\widetilde{k}}(T)\|v\|_{L^1_T(B^{\frac{d}{2}+1})}\\ &\lesssim \sum_{k'\in\mathbb{Z}} \omega_{k'}(T)2^{k'\rho}\|\Delta_{k'}h\|_{L^\infty_T(L^2)} \sum_{k\leq k'+2} 2^{(k-k')(\frac{d}{2}+\rho+1)}\|v\|_{L^1_T(B^{\frac{d}{2}+1})}\\ &\lesssim \|h\|_{E^\rho_T}\|v\|_{L^1_T(B^{\frac{d}{2}+1})}. \end{aligned} \tag{5.9}$$

By summing up (5.7)–(5.9), we obtain

$$\sum_{k\in\mathbb{Z}} \omega_k(T)2^{k(\rho-m)}\|\mathcal{F}^m_{k,0}(t)\|_{L^1_T(L^2)} \lesssim \|h\|_{E^\rho_T}\|v\|_{L^1_T(B^{\frac{d}{2}+1})}. \tag{5.10}$$

Note that $A(D)\Delta_k = 2^{km}\widetilde{\varphi}(2^{-k}D)$ with $\widetilde{\varphi}(\xi) = A(\xi)\varphi(\xi)$. Setting $\tilde{\theta} = \mathcal{F}^{-1}\tilde{\varphi}$, we get by using Taylor's formula that

$$\begin{aligned}\mathcal{F}^m_{k,1}(t) = \sum_{|k'-k|\leq 3} 2^{k(m-1)} \int_{\mathbb{R}^d}\int_0^1 \tilde{\theta}(y)\\ (y\cdot S_{k'-1}\nabla v^j(x-2^{-k}\tau y))\Delta_{k'}\partial_j h(x-2^{-k}y)d\tau dy,\end{aligned}$$

from which, together with Lemma 2.1, it follows that

$$\begin{aligned}\|\mathcal{F}^m_{k,1}(t)\|_{L^1_T(L^2)} &\lesssim 2^{k(m-1)} \sum_{|k'-k|\leq 3} \|S_{k'-1}\nabla v^j\|_{L^1_T(L^\infty)}\|\Delta_{k'}\partial_j h\|_{L^\infty_T(L^2)}\\ &\lesssim 2^{km} \sum_{|k'-k|\leq 3} \|\Delta_{k'}h\|_{L^\infty_T(L^2)}\|v\|_{L^1_T(B^{\frac{d}{2}+1})};\end{aligned}$$

thus, we get

$$\sum_{k\in\mathbb{Z}} \omega_k(T)2^{k(\rho-m)}\|\mathcal{F}^m_{k,1}(t)\|_{L^1_T(L^2)} \lesssim \|h\|_{E^\rho_T}\|v\|_{L^1_T(B^{\frac{d}{2}+1})}. \tag{5.11}$$

Thanks to the fact $|k'-k| \leq 3$ and Lemma 2.1, we have

$$\|(S_{k'-1}-S_{k-1})v^j A(D)\Delta_k\Delta_{k'}\partial_j h\|_{L^1_T(L^2)} \lesssim 2^{km}\|\Delta_k h\|_{L^\infty_T(L^2)}\|v\|_{L^1_T(B^{\frac{d}{2}+1})},$$

from which it follows that

$$\sum_{k\in\mathbb{Z}}\omega_k(T)2^{k(\rho-m)}\big(\|\mathcal{F}^m_{k,2}(t)\|_{L^1_T(L^2)}+\|\mathcal{F}^m_{k,3}(t)\|_{L^1_T(L^2)}\big)\lesssim\|h\|_{E^\rho_T}\|v\|_{L^1_T(B^{\frac{d}{2}+1}_)},\tag{5.12}$$

which, together with (5.10) and (5.11), yields (5.4).

Using the decomposition (5.6), with h instead of u, and Lemma 2.1, (5.2) can be easily proved. We omit the proof here. In order to prove (5.3), we use the decomposition

$$\big(A(D)\Delta_k(v\cdot\nabla h),\Delta_k u\big)+\big(\Delta_k(v\cdot\nabla u),A(D)\Delta_k h\big)=I_k+J_k,$$

with

$$\begin{aligned}
I_k&=\big(A(D)\Delta_k(T'_{\partial_j h}v^j),\Delta_k u\big)+\big(\Delta_k(T'_{\partial_j u}v^j),A(D)\Delta_k h\big)\\
&\triangleq\big(\mathcal{F}^m_{k,0}(t),\Delta_k u\big)+\big(\widetilde{\mathcal{F}}^0_{k,0}(t),A(D)\Delta_k h\big),\\
J_k&=\sum_{|k'-k|\le3}\Big([A(D)\Delta_k,S_{k'-1}v^j]\Delta_{k'}\partial_j h,\Delta_k u\Big)\\
&\quad+\Big((S_{k'-1}-S_{k-1})v^jA(D)\Delta_k\Delta_{k'}\partial_j h,\Delta_k u\Big)\\
&\quad+\sum_{|k'-k|\le3}\Big([\Delta_k,S_{k'-1}v^j]\Delta_{k'}\partial_j u,A(D)\Delta_k h\Big)\\
&\quad+\Big((S_{k'-1}-S_{k-1})v^j\Delta_k\Delta_{k'}\partial_j u,A(D)\Delta_k h\Big)\\
&\quad-\Big(S_{k-1}\mathrm{div}vA(D)\Delta_k h,\Delta_k u\Big)\\
&\triangleq\big(\mathcal{F}^m_{k,1}(t),\Delta_k u\big)+\big(\mathcal{F}^m_{k,2}(t),\Delta_k u\big)+\big(\widetilde{\mathcal{F}}^0_{k,1}(t),A(D)\Delta_k h\big)\\
&\quad+\big(\widetilde{\mathcal{F}}^0_{k,2},A(D)\Delta_k h\big)+\big(\mathcal{F}^m_{k,3}(t),\Delta_k u\big),
\end{aligned}$$

from which, using a similar proof of (5.4), we obtain (5.3). This completes the proof of Lemma 5.1. □

LEMMA 5.2. *Let $s_1\le\frac{d}{2}-1$, $s_2\le\frac{d}{2}$, and $s_1+s_2>0$. Then it holds that*

$$\sum_{k\in\mathbb{Z}}\omega_k(T)2^{k(s_1+s_2-\frac{d}{2})}\|\Delta_k(fg)\|_{L^1_T(L^2)}\le C\sum_{k\in\mathbb{Z}}\omega_k(T)2^{ks_1}\|\Delta_k f\|_{L^{r_1}_T(L^2)}\|g\|_{L^{r_2}_T(B^{s_2})},\tag{5.13}$$

where $1\le r_1,r_2\le\infty$ and $\frac{1}{r_1}+\frac{1}{r_2}=1$.

Proof. Using Bony's paraproduct decomposition, we write

$$\begin{aligned}
\Delta_k(fg)&=\sum_{|k'-k|\le3}\Delta_k(S_{k'-1}f\Delta_{k'}g)+\sum_{|k'-k|\le3}\Delta_k(S_{k'-1}g\Delta_{k'}f)\\
&\quad+\sum_{k'\ge k-2}\Delta_k(\Delta_{k'}f\widetilde{\Delta}_{k'}g)\triangleq I+II+III.
\end{aligned}$$

A similar proof of (5.7) ensures that for $s_1 \leq \frac{d}{2} - 1$

$$\sum_{k\in\mathbb{Z}} \omega_k(T) 2^{k(s_1+s_2-\frac{d}{2})} \|I\|_{L^1_T(L^2)} \lesssim \sum_{k\in\mathbb{Z}} \omega_k(T) 2^{ks_1} \|\Delta_k f\|_{L^{r_1}_T(L^2)} \|g\|_{L^{r_2}_T(B^{s_2})},$$

while II can be directly deduced for $s_2 \leq \frac{d}{2}$. On the other hand, a similar proof of (5.8) and (5.9) gives for $s_1 + s_2 > 0$

$$\sum_{k\in\mathbb{Z}} \omega_k(T) 2^{k(s_1+s_2-\frac{d}{2})} \|III\|_{L^1_T(L^2)} \lesssim \sum_{k\in\mathbb{Z}} \omega_k(T) 2^{ks_1} \|\Delta_k f\|_{L^{r_1}_T(L^2)} \|g\|_{L^{r_2}_T(B^{s_2})}.$$

This completes the proof of Lemma 5.2. □

Similarly, we can also prove the following lemma.

LEMMA 5.3. *Let $s_1 \leq \frac{d}{2} - 1$, $s_2 < \frac{d}{2}$, and $s_1 + s_2 \geq 0$. Then it holds that*

$$\sup_{k\in\mathbb{Z}} \omega_k(T) 2^{k(s_1+s_2-\frac{d}{2})} \|\Delta_k(fg)\|_{L^1_T(L^2)} \leq C\|f\|_{E^{s_1}_T} \|g\|_{\widetilde{L}^1_T(\dot{B}^{s_2}_{2,\infty})}. \tag{5.14}$$

LEMMA 5.4. *Let $s > 0$. Assume that $F \in W^{[s]+3,\infty}_{loc}(\mathbb{R}^d)$ with $F(0) = 0$. Then it holds that*

$$\|F(f)\|_{E^s_T} \leq C(1 + \|f\|_{L^\infty_T(L^\infty)})^{[s]+2} \|f\|_{E^s_T}. \tag{5.15}$$

Proof. We decompose $F(f)$ as

$$\begin{aligned} F(f) = \sum_{k'\in\mathbb{Z}} F(S_{k'+1}f) - F(S_{k'}f) &= \sum_{k'\in\mathbb{Z}} \Delta_{k'} f \int_0^1 F'(S_{k'}f + \tau\Delta_{k'}f) d\tau \\ &\triangleq \sum_{k'\in\mathbb{Z}} \Delta_{k'} f \, m_{k'}, \end{aligned}$$

where $m_{k'} = \int_0^1 F'(S_{k'}f + \tau\Delta_{k'}f)d\tau$. Furthermore, we write

$$\Delta_k F(f) = \sum_{k'<k} \Delta_k(\Delta_{k'} f \, m_{k'}) + \sum_{k'\geq k} \Delta_k(\Delta_{k'} f \, m_{k'}) \triangleq I + II.$$

By Lemma 2.1, we have

$$\begin{aligned} \|I\|_{L^\infty_T(L^2)} &\leq \sum_{k'<k} \|\Delta_k(\Delta_{k'} f \, m_{k'})\|_{L^\infty_T(L^2)} \\ &\leq \sum_{k'<k} 2^{-k|\alpha|} \sup_{|\gamma|=|\alpha|} \|D^\gamma \Delta_k(\Delta_{k'} f \, m_{k'})\|_{L^\infty_T(L^2)}, \end{aligned} \tag{5.16}$$

with α to be determined later. Note that for $|\gamma| \geq 0$, we have

$$\|D^\gamma m_{k'}\|_\infty \lesssim 2^{k'|\gamma|}(1 + \|f\|_\infty)^{|\gamma|} \|F'\|_{W^{|\gamma|,\infty}},$$

from which, together with (5.16), it follows that

$$2^{ks}\|I\|_{L^\infty_T(L^2)} \lesssim 2^{k(s-|\alpha|)} \sum_{k'<k} 2^{k'|\alpha|} \|\Delta_{k'} f\|_{L^\infty_T(L^2)} (1 + \|f\|_{L^\infty_T(L^\infty)})^{|\alpha|} \|F'\|_{W^{|\alpha|,\infty}}.$$

Thus, if we take $|\alpha| = [s] + 2$, we get

$$\begin{aligned}
&\sum_{k\in\mathbb{Z}} \omega_k(T) 2^{ks} \|I\|_{L^\infty_T(L^2)} \\
&\quad \lesssim \sum_{k'\in\mathbb{Z}} 2^{k's} \omega_{k'}(T) \|\Delta_{k'} f\|_{L^\infty_T(L^2)} \sum_{k>k'} 2^{(k-k')(s-|\alpha|+1)} (1 + \|f\|_{L^\infty_T(L^\infty)})^{|\alpha|} \|F'\|_{W^{|\alpha|,\infty}} \\
&\quad \lesssim (1 + \|f\|_{L^\infty_T(L^\infty)})^{[s]+2} \|F'\|_{W^{[s]+2,\infty}} \|f\|_{E^s_T}. \qquad (5.17)
\end{aligned}$$

Next, let us turn to the proof of II. We get by using Lemma 2.1 that

$$\|II\|_{L^\infty_T(L^2)} \lesssim \sum_{k'\geq k} \|\Delta_{k'} f\|_{L^\infty_T(L^2)}.$$

Then we write

$$\begin{aligned}
\sum_{k\in\mathbb{Z}} \omega_k(T) 2^{ks} \|II\|_{L^\infty_T(L^2)} &\lesssim \sum_{k\in\mathbb{Z}} 2^{ks} \sum_{k'\geq k} \|\Delta_{k'} f\|_{L^\infty_T(L^2)} \sum_{k'\geq \widetilde{k}\geq k} 2^{-(\widetilde{k}-k)} e_{\widetilde{k}}(T) \\
&\quad + \sum_{k\in\mathbb{Z}} 2^{ks} \sum_{k'\geq k} \|\Delta_{k'} f\|_{L^\infty_T(L^2)} \sum_{\widetilde{k}\geq k', \widetilde{k}\geq k} 2^{-(\widetilde{k}-k)} e_{\widetilde{k}}(T),
\end{aligned}$$

from which a similar proof of (5.8) and (5.9) ensures that

$$\sum_{k\in\mathbb{Z}} \omega_k(T) 2^{ks} \|II\|_{L^\infty_T(L^2)} \lesssim \|f\|_{E^s_T}. \qquad (5.18)$$

By summing up (5.17) and (5.18), we deduce the inequality (5.15). This completes the proof of Lemma 5.4. □

BLOW-UP AND DECAY OF THE SOLUTION OF THE WEAKLY DISSIPATIVE DEGASPERIS–PROCESI EQUATION*

SHUYIN WU† AND ZHAOYANG YIN†

Abstract. In this paper, we mainly study several problems on the weakly dissipative Degasperis–Procesi equation. We first establish the local well-posedness of the equation, derive a precise blow-up scenario, and present two blow-up criteria for strong solutions to the equation. We then give the precise blow-up rate of blow-up solutions to the equation. We finally prove that the equation has global strong solutions and these global solutions decay to zero as time goes to infinity provided the potentials associated with their initial data are of one sign.

Key words. the weakly dissipative Degasperis–Procesi equation, blow-up, blow-up rate, global strong solutions, decay of solutions

1. Introduction.

Recently, Degasperis and Procesi [20] studied the following family of third-order dispersive conservation laws:

$$u_t + c_0 u_x + \gamma u_{xxx} - \alpha^2 u_{txx} = (c_1 u^2 + c_2 u_x^2 + c_3 u u_{xx})_x, \tag{1.1}$$

where α, c_0, c_1, c_2, and c_3 are real constants. They found [20] that there are only three equations that satisfy the asymptotic integrability condition within this family: the KdV equation, the Camassa–Holm equation, and the Degasperis–Procesi equation.

If $\alpha = c_2 = c_3 = 0$, then (1.1) becomes the well-known KdV equation which describes the unidirectional propagation of waves at the free surface of shallow water under the influence of gravity. In this model $u(t, x)$ represents the wave's height above a flat bottom, x is proportional to the distance in the direction of propagation, and t is proportional to the elapsed time. The KdV equation is completely integrable, and its solitary waves are solitons [21, 39]. The Cauchy problem of the KdV equation has been the subject of a number of studies, and a satisfactory local or global (in time) existence theory is now in hand (for example, see [31, 43]). It is shown that the KdV equation is globally well-posed for $u_0 \in L^2(\mathbb{R})$; cf. [43]. It is observed that the KdV equation does not accommodate wave breaking (by wave breaking we mean that the wave remains bounded, but its slope becomes unbounded in finite time [45]).

For $c_1 = -\frac{3}{2}c_3/\alpha^2$ and $c_2 = c_3/2$, (1.1) becomes the Camassa–Holm equation, modeling the unidirectional propagation of shallow water waves over a flat bottom. Again $u(t, x)$ stands for the fluid velocity at time t in the spatial x direction, and c_0 is a nonnegative parameter related to the critical shallow water speed [3, 22, 30]. The Camassa–Holm equation is also a model for the propagation of axially symmetric waves in hyperelastic rods [15, 18]. It has a bi-Hamiltonian structure [33, 27] and is completely integrable [3, 8]. Its solitary waves are smooth if $c_0 > 0$ and peaked in the limiting case $c_0 = 0$; see [4]. The orbital stability of the peaked solitons is proved

in [16] and that of the smooth solitons in [17]. The explicit interaction of the peaked solitons is given in [1].

The Cauchy problem of the Camassa–Holm equation has been studied extensively. It has been shown that this equation is locally well-posed [9, 34, 42] for initial data $u_0 \in H^s(\mathbb{R})$, $s > \frac{3}{2}$. More interestingly, it has global strong solutions [7, 9] and also finite time blow-up solutions [7, 9, 10, 13]. On the other hand, it has global weak solutions in $H^1(\mathbb{R})$ [2, 11, 14, 47]. It is also known that if u is the solution of the Camassa–Holm equation with the initial data u_0 in $H^1(\mathbb{R})$, then we have the following a priori estimate:

$$\|u(t,\cdot)\|_{L^\infty(\mathbb{R})} \le \sqrt{2}\|u(t,\cdot)\|_{H^1(\mathbb{R})} \le \sqrt{2}\|u_0(\cdot)\|_{H^1(\mathbb{R})}$$

for all $t > 0$. The advantage of the Camassa–Holm equation in comparison with the KdV equation lies in the fact that the Camassa–Holm equation has peaked solitons and models wave breaking [4].

If $c_1 = -2c_3/\alpha^2$ and $c_2 = c_3$ in (1.1), then after rescaling, shifting the dependent variable, and applying a Galilean boost [19], we find the Degasperis–Procesi equation of the form

$$u_t - u_{txx} + 4uu_x = 3u_xu_{xx} + uu_{xxx}, \quad t > 0, \quad x \in \mathbb{R}. \tag{1.2}$$

The integrability of (1.2) was proved in [19] by constructing a Lax pair. It was also shown in [19] that (1.2) has a bi-Hamiltonian structure and admits exact peakon solutions which are analogous to the Camassa–Holm peakons.

The Degasperis–Procesi equation can be regarded as a model for the motion of shallow water waves, and its asymptotic accuracy is the same as for the Camassa–Holm shallow water equation [23, 29]. An inverse scattering approach for computing n-peakon solutions to (1.2) was presented in [37]. The traveling wave solutions to (1.2) were investigated in [44, 32]. The multisoliton solutions to (1.2) and their peakon limits were studied in [38].

The Cauchy problem of the Degasperis–Procesi equation is locally well-posed [48] for initial data $u_0 \in H^s(\mathbb{R})$ with $s > \frac{3}{2}$. Analogous to the Camassa–Holm equation, it not only has global strong solutions [35, 51] but also blow-up solutions in finite time [35, 48]. Meanwhile, the Degasperis–Procesi equation also has global weak solutions with initial data $u_0 \in H^1(\mathbb{R})$ (cf. [50, 51]) and global entropy weak solutions in the class of $L^1(\mathbb{R}) \cap BV(\mathbb{R})$ and the class of $L^2(\mathbb{R}) \cap L^4(\mathbb{R})$; cf. [5].

Despite the similarities to the Camassa–Holm equation, we would like to point out that these two equations are truly different. One of the important features of the Degasperis–Procesi equation is that it not only has peakon solitons [19] and periodic peakons [49] but also shock peakons [6, 36] and periodic shock waves [25]. On the other hand, the isospectral problem for the Degasperis–Procesi equation is the third-order equation in the Lax pair [19], while the isospectral problem for the Camassa–Holm equation is the second-order equation [3]. Another indication of the fact that there is no simple transformation of the Degasperis–Procesi equation into the Camassa–Holm equation is the entirely different form of conservation laws for these two equations [3, 19]. Furthermore, the Camassa–Holm equation is a reexpression of geodesic flow on the diffeomorphism group [12] or on the Bott–Virasoro group [40]. Up to now, no geometric derivation of the Degasperis–Procesi equation has been available.

Recently, several new global existence and blow-up results for strong solutions to the Degasperis–Procesi equation were presented in [35]. It is proved that the first blow-up must occur as wave breaking and shock waves possibly appear afterward [35].

Global weak solution and blow-up structure for this equation were investigated in [24]. Initial boundary value problems for the Degasperis–Procesi equation were also discussed in [26].

In general, it is quite difficult to avoid energy dissipation mechanisms in a real world. Ott and Sudan [41] ever investigated how the KdV equation was modified by the presence of dissipation and the effect of such dissipation on the solitary solution of the KdV equation. Ghidaglia [28] studied the long time behavior of solutions to the weakly dissipative KdV equation as a finite-dimensional dynamical system. Recently, Wu and Yin [46] discussed the blow-up, blow-up rate, and decay of the solution of the weakly dissipative periodic Camassa–Holm equation.

In this paper, we would like to consider the following dissipative Degasperis–Procesi equation:

$$u_t - u_{txx} + 4uu_x + L(u) = 3u_x u_{xx} + uu_{xxx}, \quad t > 0, \quad x \in \mathbb{R},$$

where $L(u)$ is a dissipative term, and L can be a differential operator or a quasi-differential operator according to different physical situations. We are interested in the effect of the weakly dissipative term on the Degasperis–Procesi equation. In particular, we study the following weakly dissipative Degasperis–Procesi equation:

$$\begin{cases} y_t + uy_x + 3u_x y + \lambda y = 0, \quad t > 0, \quad x \in \mathbb{R}, \\ y = u - u_{xx}, \quad t > 0, \quad x \in \mathbb{R}, \\ u(0,x) = u_0(x), \qquad x \in \mathbb{R}, \end{cases} \tag{1.3}$$

where $\lambda y = \lambda(1 - \partial_x^2)u$ is the weakly dissipative term, and $\lambda > 0$ is a constant.

We find that the behaviors of (1.3) are similar to the Degasperis–Procesi equation in a finite interval of time, such as the local well-posedness and the blow-up phenomena. But there are considerable differences between (1.3) and the Degasperis–Procesi equation in their long time behaviors. Global solution of (1.3) decays to zero as time goes to infinity provided the potential $y_0 = (1 - \partial_x^2)u_0$ is of one sign. This long time behavior is an important feature that the Degasperis–Procesi equation does not possess. It is known that the Degasperis–Procesi equation has peaked traveling wave solutions [19]. Theorem 4.1 in what follows shows that any global solution decays in the H^1-norm. This means that there are no traveling wave solutions of (1.3). This is also another considerable difference between (1.3) and the Degasperis–Procesi equation (1.2) in their long time behaviors.

It is very interesting that (1.3) has the same blow-up rate as the Degasperis–Procesi equation does when the blow-up occurs. This fact shows that the blow-up rate of the Degasperis–Procesi equation is not affected by the weakly dissipative term. But the occurrence of blow-up of (1.2) is affected by the dissipative parameter.

It should be noticed that the weakly dissipative term breaks the conservation laws of the following Degasperis–Procesi equation [19]:

$$E_1(u) = \int_{\mathbb{R}} y dx, \quad E_2(u) = \int_{\mathbb{R}} yv dx, \quad E_3(u) = \int_{\mathbb{R}} u^3 dx,$$

where $y = (1 - \partial_x^2)u$ and $v = (4 - \partial_x^2)^{-1}u$, which play an important role in the study of the Degasperis–Procesi equation [5, 24, 25, 35, 48, 49, 50, 51].

Notation. As above and henceforth, we denote by $*$ the convolution. We write $\hat{f}$ as the Fourier transform of f. We also use $(\ ,\ )$ to represent the standard inner product in $L^2(\mathbb{R})$. For $1 \le p \le \infty$, the norm in the Lebesgue space L^p will be written $\|\cdot\|_{L^p}$, while $\|\cdot\|_r$, $r \ge 0$, will stand for the norm in the classical Sobolev spaces $H^r(\mathbb{R})$.

2. Local well-posedness and blow-up. In this section, we establish the local well-posedness of (1.3), derive a precise blow-up scenario, and present two blow-up criteria for strong solutions to (1.3).

Note that if $p(x) = \frac{1}{2}e^{-|x|}$, $x \in \mathbb{R}$, then $(1-\partial_x^2)^{-1}f = p * f$ for all $f \in L^2(\mathbb{R})$ and $p * y = u$. Using this identity, we can rewrite (1.3) as follows:

$$\begin{cases} u_t + uu_x + \partial_x p * (\frac{3}{2}u^2) + \lambda u = 0, & t > 0, \quad x \in \mathbb{R}, \\ u(0,x) = u_0(x), & x \in \mathbb{R}. \end{cases} \tag{2.1}$$

Using Kato's semigroup approach along lines very similar to [48], one obtains the local well-posedness of (1.3) or (2.1).

THEOREM 2.1. *Given $u_0 \in H^r(\mathbb{R})$, $r > \frac{3}{2}$, there exist a maximal $T = T(\lambda, \|u_0\|_r) > 0$, and a unique solution u to* (1.3) *(or* (2.1)*), such that*

$$u = u(\cdot, u_0) \in C([0,T); H^r(\mathbb{R})) \cap C^1([0,T); H^{r-1}(\mathbb{R})),$$

and the solution depends continuously on the initial data; i.e., the mapping $u \to u(\cdot, u_0) : H^r(\mathbb{R}) \to C([0,T); H^r(\mathbb{R})) \cap C^1([0,T); H^{r-1}(\mathbb{R}))$ is continuous. Moreover, T may be chosen independent of r in the following sense. If

$$u = u(\cdot, u_0) \in C([0,T); H^r(\mathbb{R})) \cap C^1([0,T); H^{r-1}(\mathbb{R}))$$

to (1.3) *(or* (2.1)*), and if $u_0 \in H^{r'}(\mathbb{R})$ for some $r' \neq r, r' > \frac{3}{2}$, then*

$$u \in C([0,T); H^{r'}(\mathbb{R})) \cap C^1([0,T); H^{r'-1}(\mathbb{R}))$$

with the same T.

The following results are proved only with regard to $r = 3$, since we can obtain the same conclusion for the general case $r > \frac{3}{2}$ by using Theorem 2.1 and a simple density argument.

We now present a precise blow-up scenario for strong solutions to (1.3).

THEOREM 2.2. *Given $u_0 \in H^r(\mathbb{R})$, $r > \frac{3}{2}$, the solution of* (1.3) *(or* (2.1)*) blows up in a finite time $T > 0$ if and only if*

$$\liminf_{t \to T} \{\inf_{x \in \mathbb{R}} u_x(t,x)\} = -\infty.$$

Proof. Let $T > 0$ be the maximal time of existence of the solution u to (1.3) (or (2.1)) with initial data $u_0 \in H^3(\mathbb{R})$. By (1.3), we have

$$\begin{aligned} \frac{d}{dt}\int_{\mathbb{R}} y^2 dx &= 2\int_{\mathbb{R}} yy_t dx \\ &= -2\int_{\mathbb{R}} uyy_x dx - 6\int_{\mathbb{R}} u_x y^2 dx - 2\lambda \int_{\mathbb{R}} y^2 dx \\ &= -5\int_{\mathbb{R}} u_x y^2 dx - 2\lambda \int_{\mathbb{R}} y^2 dx. \end{aligned} \tag{2.2}$$

If $u_0 \in H^4(\mathbb{R})$, then we can obtain by (1.3)

$$\begin{aligned}(2.3)\quad \frac{d}{dt}\int_{\mathbb{R}} y_x^2 dx &= 2\int_{\mathbb{R}} y_x y_{xt} dx \\ &= -8\int_{\mathbb{R}} u_x y_x^2 dx - 2\int_{\mathbb{R}} u y_x y_{xx} dx - 6\int_{\mathbb{R}} u_{xx} y y_x dx - 2\lambda\int_{\mathbb{R}} y_x^2 dx \\ &= -7\int_{\mathbb{R}} u_x y_x^2 dx + 3\int_{\mathbb{R}} u_x y^2 dx - 2\lambda\int_{\mathbb{R}} y_x^2 dx.\end{aligned}$$

As for $u_0 \in H^3(\mathbb{R})$, we will show that (2.3) still holds. In fact, we can approximate u_0 in $H^3(\mathbb{R})$ by function $u_0^n \in H^4(\mathbb{R})$. Moreover, we write $u^n = u^n(\cdot, u_0^n)$ for the solution of (1.3) with initial data u_0^n.

By Theorem 2.1, we know that

$$u^n \in C([0,T_n); H^4(\mathbb{R})) \cap C^1([0,T_n); H^3(\mathbb{R})), \qquad n \geq 1,$$

$$y^n = u^n - u_{xx}^n \in C([0,T_n); H^2(\mathbb{R})) \cap C^1([0,T_n); H^1(\mathbb{R})), \qquad n \geq 1,$$

$u^n \to u$ in $H^3(\mathbb{R})$, and $T_n \to T$ as $n \to \infty$.

Due to $u_0^n \in H^4(\mathbb{R})$, we have by (2.3)

$$\frac{d}{dt}\int_{\mathbb{R}} (y_x^n)^2 dx = -7\int_{\mathbb{R}} u_x^n (y_x^n)^2 dx + 3\int_{\mathbb{R}} u_x^n (y^n)^2 dx - 2\lambda\int_{\mathbb{R}} (y_x^n)^2 dx.$$

Since $u^n \to u$ in $H^3(\mathbb{R})$ as $n \to \infty$, it follows that $u_x^n \to u_x$ in $L^\infty(\mathbb{R})$ as $n \to \infty$. Also note that $y^n \to y$ in $H^1(\mathbb{R})$ and $y_x^n \to y_x$ in $L^2(\mathbb{R})$ as $n \to \infty$. Letting n go to infinity in the above equation, we can easily deduce that (2.3) holds for $u_0 \in H^3(\mathbb{R})$.

Adding (2.2) and (2.3), we get

$$\begin{aligned}\frac{d}{dt}\left(\int_{\mathbb{R}} y^2 dx + \int_{\mathbb{R}} y_x^2 dx\right) &= -7\int_{\mathbb{R}} u_x y_x^2 dx - 2\int_{\mathbb{R}} u_x y^2 dx \\ &\quad - 2\lambda\left(\int_{\mathbb{R}} y^2 dx + \int_{\mathbb{R}} y_x^2 dx\right).\end{aligned} \tag{2.4}$$

If u_x is bounded from below on $[0,T)$, then there exists a positive constant k such that $u_x \geq -k$ on $[0,T)$. Thus, we get by (2.4) and Gronwall's inequality

$$\|y\|_1^2 \leq \exp\{(7k - 2\lambda)t\}\|y(0)\|_1^2.$$

The above inequality implies that the H^3-norm of the solution u of (1.3) does not blow up in finite time. □

Next, we present two blow-up criteria for (1.3) guaranteeing the occurrence of this phenomenon. Let us first prove several useful lemmas.

Consider the following differential equation:

$$\begin{cases} q_t = u(t,q), & t \in [0,T), \\ q(0,x) = x, & x \in \mathbb{R}. \end{cases} \tag{2.5}$$

The system (2.5) is essential in deriving invariance properties for solutions of the Degasperis–Procesi equation [25, 35, 51] and the Camassa–Holm equation [7, 9, 13]. It is thus natural to expect it would also be useful in the present context.

Applying classical results in the theory of ordinary differential equations, one can obtain the following two results on q which are crucial in the proof of global existence and blow-up solutions.

LEMMA 2.1 (see [51]). *Let $u_0 \in H^r(\mathbb{R})$, $r \geq 3$, and let $T > 0$ be the maximal existence time of the corresponding solution u to (1.3). Then (2.5) has a unique solution $q \in C^1([0,T) \times \mathbb{R}, \mathbb{R})$. Moreover, the map $q(t,\cdot)$ is an increasing diffeomorphism of $\mathbb{R}$ with*

$$q_x(t,x) = \exp\left(\int_0^t u_x(s,q(s,x))ds\right) > 0 \quad \forall (t,x) \in [0,T) \times \mathbb{R}.$$

LEMMA 2.2. *Let $u_0 \in H^r(\mathbb{R})$, $r \geq 3$, and let $T > 0$ be the maximal existence time of the corresponding solution u to (1.3). Setting $y := u - u_{xx}$, we have*

$$y(t,q(t,x))q_x^3(t,x) = y_0(x)\exp\{-\lambda t\} \quad \forall (t,x) \in [0,T) \times \mathbb{R}.$$

Proof. Differentiation of the system (2.5) with respect to x yields

$$\begin{cases} \frac{d}{dt}q_x = u_x(t,q)q_x, & t \in (0,T), \\ q_x(0,x) = 1, & x \in \mathbb{R}. \end{cases}$$

Let $g(t,x) = y(t,q(t,x))q_x^3(t,x)$. By Lemma 2.1, we infer from (1.3) and (2.5) that

$$\frac{d}{dt}g(t,x) = -\lambda g(t,x).$$

Integrating the above relation with respect to $t < T$ on $[0,t]$ yields the desired result. ∎

LEMMA 2.3. *If $u_0 \in H^r(\mathbb{R})$, $r > \frac{3}{2}$, then as long as the solution $u(t,x)$ given by Theorem 2.1 exists, we have*

$$\int_{\mathbb{R}} y(t,x)v(t,x)dx = \exp\{-2\lambda t\}\int_{\mathbb{R}} y_0(x)v_0(x)dx,$$

where $y(t,x) = u(t,x) - u_{xx}(t,x)$ and $v(t,x) = (4 - \partial_x^2)^{-1}u$. Moreover, we have

$$\|u(t)\|_{L^2}^2 \leq 4\exp\{-2\lambda t\}\|u_0\|_{L^2}^2.$$

Proof. Let $T > 0$ be the maximal time of existence of the solution u to (1.3) (or (2.1)) with initial data $u_0 \in H^3(\mathbb{R})$. By (1.3), we have

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}} yv\,dx &= \frac{1}{2}\int_{\mathbb{R}} y_t v\,dx + \frac{1}{2}\int_{\mathbb{R}} yv_t dx = \int_{\mathbb{R}} y_t\, v\,dx \\ &= -\int_{\mathbb{R}} vy_x u\,dx - 3\int_{\mathbb{R}} vyu_x dx - \lambda\int_{\mathbb{R}} yv\,dx \\ &= -\int_{\mathbb{R}} v(yu)_x\,dx - 2\int_{\mathbb{R}} vyu_x dx - \lambda\int_{\mathbb{R}} yv\,dx. \end{aligned}$$

Using the relations $y = u - u_{xx}$ and $4v - v_{xx} = u$, it yields

$$\begin{aligned}
\int_{\mathbb{R}} v(yu)_x\,dx &= -\int_{\mathbb{R}} v_x yu\,dx = -\int_{\mathbb{R}} v_x u^2\,dx + \int_{\mathbb{R}} v_x u u_{xx} dx \\
&= -\int_{\mathbb{R}} v_x u^2\,dx - \int_{\mathbb{R}} (v_x u)_x\, u_x\,dx \\
&= -\int_{\mathbb{R}} v_x u^2\,dx - \int_{\mathbb{R}} v_{xx} u u_x\,dx - \int_{\mathbb{R}} v_x u_x^2 dx \\
&= -\int_{\mathbb{R}} v_x u^2\,dx + \frac{1}{2}\int_{\mathbb{R}} v_{xxx} u^2\,dx - \int_{\mathbb{R}} v_x u_x^2 dx \\
&= -\int_{\mathbb{R}} v_x u^2\,dx + \frac{1}{2}\int_{\mathbb{R}} (4v_x - u_x) u^2\,dx - \int_{\mathbb{R}} v_x u_x^2 dx \\
&= \int_{\mathbb{R}} v_x u^2\,dx - \int_{\mathbb{R}} v_x u_x^2 dx.
\end{aligned}$$

On the other hand,

$$\begin{aligned}
2\int_{\mathbb{R}} v\, y\, u_x\,dx &= 2\int_{\mathbb{R}} v u u_x\,dx - 2\int_{\mathbb{R}} v u_{xx} u_x dx \\
&= -\int_{\mathbb{R}} v_x\, u^2\,dx + \int_{\mathbb{R}} v_x u_x^2\,dx.
\end{aligned}$$

Combining the above three relations, we deduce that

$$\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}} yv\,dx = -\lambda\int_{\mathbb{R}} yv dx.$$

Consequently, this implies the first desired result. In view of the proved equality, it then follows that

$$\begin{aligned}
\|u(t)\|_{L^2}^2 = \|\hat{u}(t)\|_{L^2}^2 &\le 4\int_{\mathbb{R}} \frac{1+\xi^2}{4+\xi^2}|\hat{u}(t,\xi)|^2\,d\xi \\
&= 4(\hat{y}(t),\ \hat{v}(t)) = 4(y(t),\ v(t)) \\
&= 4\exp\{-2\lambda t\}(y_0,\ v_0) = 4\exp\{-2\lambda t\}(\hat{y}_0,\ \hat{v}_0) \\
&\le 4\exp\{-2\lambda t\}\int_{\mathbb{R}} \frac{1+\xi^2}{4+\xi^2}|\hat{u}_0(\xi)|^2\,d\xi \\
&\le 4\exp\{-2\lambda t\}\|\hat{u}_0\|_{L^2}^2 = 4\exp\{-2\lambda t\}\|u_0\|_{L^2}^2.
\end{aligned}$$

This completes the proof of the lemma. □

LEMMA 2.4. *Assume $u_0 \in H^r(\mathbb{R})$, $r > \frac{3}{2}$. Let T be the maximal existence time of the solution u to* (1.3) *guaranteed by Theorem* 2.1. *Then we have*

$$\|u(t)\|_{L^\infty} \le \exp\{-\lambda t\}\left(\frac{3}{\lambda}\|u_0\|_{L^2}^2 + \|u_0\|_{L^\infty}\right) \quad \forall t \in [0,T].$$

Proof. Let $T > 0$ be the maximal time of existence of the solution u to (1.3) with the initial data $u_0 \in H^3(\mathbb{R})$. By (2.5), we get

$$\begin{aligned}\frac{du(t,q(t,x))}{dt} &= u_t(t,q(t,x)) + u_x(t,q(t,x))\frac{dq(t,x)}{dt}\\ &= (u_t + uu_x)(t,q(t,x)).\end{aligned}$$

By (2.1), we have

$$u_t + uu_x = -3p * (uu_x) - \lambda u.$$

Note that

$$\begin{aligned}-3p * (uu_x) &= -\frac{3}{2}\int_{-\infty}^{+\infty} e^{-|x-\eta|}uu_\eta d\eta\\ &= -\frac{3}{2}\int_{-\infty}^{x} e^{-x+\eta}uu_\eta d\eta - \frac{3}{2}\int_{x}^{+\infty} e^{x-\eta}uu_\eta d\eta\\ &= \frac{3}{4}\int_{-\infty}^{x} e^{-|x-\eta|}u^2 d\eta - \frac{3}{4}\int_{x}^{+\infty} e^{-|x-\eta|}u^2 d\eta.\end{aligned}$$

It then follows that

$$-\frac{3}{4}\int_{q(t,x)}^{+\infty} e^{-|q(t,x)-\eta|}u^2 d\eta \le \frac{du(t,q(t,x))}{dt} + \lambda u(t,q(t,x)) \le \frac{3}{4}\int_{-\infty}^{q(t,x)} e^{-|q(t,x)-\eta|}u^2 d\eta.$$

It thus transpires that

$$\left|\frac{du(t,q(t,x))}{dt} + \lambda u(t,q(t,x))\right| \le \frac{3}{4}\int_{-\infty}^{+\infty} e^{-|q(t,x)-\eta|}u^2 d\eta \le \frac{3}{4}\|u(t)\|_{L^2}^2.$$

In view of Lemma 2.3, we have

$$\left|\frac{du(t,q(t,x))}{dt} + \lambda u(t,q(t,x))\right| \le 3\exp\{-2\lambda t\}\|u_0\|_{L^2}^2.$$

Integrating the above inequality with respect to $t < T$ on $[0,t]$ yields

$$|\exp\{\lambda t\}u(t,q(t,x)) - u_0(x)| \le \frac{3}{\lambda}\|u_0\|_{L^2}^2.$$

Thus,

$$\begin{aligned}|u(t,q(t,x))| &\le \|u(t,q(t,x))\|_{L^\infty}\\ &\le \exp\{-\lambda t\}\left(\frac{3}{\lambda}\|u_0\|_{L^2}^2 + \|u_0\|_{L^\infty}\right).\end{aligned} \tag{2.6}$$

Using the Sobolev embedding to ensure the uniform boundedness of $u_x(s,\eta)$ for $(s,\eta) \in [0,t]\times\mathbb{R}$ with $t \in [0,T)$, in view of Lemma 2.1, we get for every $t \in [0,T)$ a constant $C(t) > 0$ such that

$$e^{-C(t)} \le q_x(t,x) \le e^{C(t)}, \qquad x \in \mathbb{R}.$$

We deduce from the above equation that the function $q(t,\cdot)$ is strictly increasing on $\mathbb{R}$ with $\lim_{x\to\pm\infty} q(t,x) = \pm\infty$ as long as $t \in [0,T)$. Thus, by (2.6) we can obtain

$$\|u(t,x)\|_{L^\infty} = \|u(t,q(t,x))\|_{L^\infty} \le \exp\{-\lambda t\}\left(\frac{3}{\lambda}\|u_0\|_{L^2}^2 + \|u_0\|_{L^\infty}\right).$$

This completes the proof of Lemma 2.4. □

We are now in the position to present the first blow-up result.

THEOREM 2.3. *Let $u_0 \in H^r(\mathbb{R})$, $r > \frac{3}{2}$, and assume that there exists $x_0 \in \mathbb{R}$ such that*

$$u_0'(x_0) < -\frac{1}{2}\lambda - \frac{1}{2}\sqrt{\lambda^2 + 6\left(\frac{3}{\lambda}\|u_0\|_{L^2}^2 + \|u_0\|_{L^\infty}\right)^2}.$$

Then the corresponding solution of (1.3) *blows up in finite time.*

Proof. Let $T > 0$ be the existence time of the solution $u(t,\cdot)$ of (1.3) (or (2.1)) with the initial data $u_0 \in H^3(\mathbb{R})$. Differentiating (2.1) with respect to x, in view of $\partial_x^2 p * f = p * f - f$, we get

$$u_{tx} = -u_x^2 - uu_{xx} + \frac{3}{2}u^2 - p * \left(\frac{3}{2}u^2\right) - \lambda u_x. \tag{2.7}$$

Note that

$$\begin{aligned}\frac{du_x(t,q(t,x))}{dt} &= u_{xt}(t,q(t,x)) + u_{xx}(t,q(t,x))\frac{dq(t,x)}{dt}\\ &= u_{tx}(t,q(t,x)) + u(t,q(t,x))u_{xx}(t,q(t,x)).\end{aligned}$$

Thus, we have

$$\begin{aligned}\frac{du_x(t,q(t,x))}{dt} =& -u_x^2(t,q(t,x)) + \frac{3}{2}u^2(t,q(t,x))\\ &- p * \left(\frac{3}{2}u^2(t,q(t,x)\right) - \lambda u_x(t,q(t,x)).\end{aligned} \tag{2.8}$$

In view of $p * \left(\frac{3}{2}u^2\right)(t,q(t,x)) \ge 0$, we infer from (2.8) and Lemma 2.4 that

$$\begin{aligned}\frac{du_x(t,q(t,x))}{dt} &\le -u_x^2(t,q(t,x)) - \lambda u_x(t,q(t,x)) + \frac{3}{2}u^2(t,q(t,x))\\ &\le -u_x^2(t,q(t,x)) - \lambda u_x(t,q(t,x)) + \frac{3}{2}\left(\frac{3}{\lambda}\|u_0\|_{L^2}^2 + \|u_0\|_{L^\infty}\right)^2.\end{aligned}$$

Set $m(t) = u_x(t,q(t,x_0))$ and

$$\alpha^2 = \frac{3}{2}\left(\frac{3}{\lambda}\|u_0\|_{L^2}^2 + \|u_0\|_{L^\infty}\right)^2.$$

Then we obtain

$$\begin{aligned}\frac{dm(t)}{dt} &\le -m^2(t) - \lambda m(t) + \alpha^2\\ &= -\frac{1}{4}\left(2m(t) + \lambda - \sqrt{\lambda^2 + 4\alpha^2}\right)\left(2m(t) + \lambda + \sqrt{\lambda^2 + 4\alpha^2}\right).\end{aligned}$$

From the hypothesis, we have $m(0) < -\frac{1}{2}\lambda - \frac{1}{2}\sqrt{\lambda^2+4\alpha^2}$, and thus $\frac{dm}{dt}|_{t=0} < 0$. By continuity with respect to t of $m(t)$, we have $\frac{dm}{dt} < 0$ for all $t \in [0,T)$. Therefore, $m(t) < -\frac{1}{2}\lambda - \frac{1}{2}\sqrt{\lambda^2+4\alpha^2}$ for all $t \in [0,T)$. Thus, we can solve the above inequality to obtain

$$\frac{2m(0)+\lambda+\sqrt{\lambda^2+4\alpha^2}}{2m(0)+\lambda-\sqrt{\lambda^2+4\alpha^2}}\exp\{\sqrt{\lambda^2+4\alpha^2}\,t\}-1 \le \frac{2\sqrt{\lambda^2+4\alpha^2}}{2m(t)+\lambda-\sqrt{\lambda^2+4\alpha^2}} \le 0.$$

Since

$$0 < \frac{2m(0)+\lambda+\sqrt{\lambda^2+4\alpha^2}}{2m(0)+\lambda-\sqrt{\lambda^2+4\alpha^2}} < 1,$$

there exists T satisfying

$$T \le \frac{1}{\sqrt{\lambda^2+4\alpha^2}}\ln\left(\frac{2m(0)+\lambda-\sqrt{\lambda^2+4\alpha^2}}{2m(0)+\lambda+\sqrt{\lambda^2+4\alpha^2}}\right)$$

such that $\lim_{t\uparrow T} m(t) = -\infty$. Hence, the above theorem is proved according to Theorem 2.2. □

We give the second criterion that guarantees the blow-up of the solutions of (1.3).

THEOREM 2.4. *Assume that $u_0 \in H^r(\mathbb{R})$ $\left(r > \frac{3}{2}\right)$ is odd, and $u_0'(0) < -\lambda$. Then the corresponding solution of* (1.3) *blows up in finite time.*

Proof. Let $T > 0$ be the maximal time of existence of the solution u to (1.3) (or (2.1)) with initial data $u_0 \in H^3(\mathbb{R})$. As one can check, the function

$$v(t,x) := -u(t,-x), \quad t \in [0,T), \quad x \in \mathbb{R},$$

is also a solution of (1.3) in $C([0,T);H^3(\mathbb{R})\bigcap C^1([0,T);H^2(\mathbb{R})$ with initial data u_0. By uniqueness we conclude that $v \equiv u$, and therefore $u(t,\cdot)$ is odd for any $t \in [0,T)$. In particular, by continuity with respect to the spatial variable of u and u_{xx}, we get

$$u(t,0) = u_{xx}(t,0) = 0, \qquad t \in [0,T).$$

Define $h(t) := u_x(t,0)$ for $t \in [0,T)$. Note that $h \in C^1([0,T),\mathbb{R})$. From (2.7), we get

$$\begin{aligned}\frac{dh}{dt}(t) &= -h^2(t) - \lambda h(t) - p * \left(\frac{3}{2}u^2\right)\\ &\le -\left(h(t)+\lambda\right)h(t), \qquad t \in [0,T).\end{aligned}$$

From the hypothesis, we have $h(0) < -\lambda$. Therefore, $h(t) < -\lambda$ for all $t \in [0,T)$. Solving the above inequality, we get

$$1 - \frac{h(0)}{h(0)+\lambda}\exp\{-\lambda t\} \le \frac{\lambda}{h(t)+\lambda} \le 0.$$

Since

$$\frac{h(0)}{h(0)+\lambda} > 1,$$

we conclude that there exists T and

$$T \le \frac{1}{\lambda}\ln\frac{h(0)}{h(0)+\lambda}$$

such that $\lim_{t\uparrow T} h(t) = -\infty$. We complete the proof of the theorem by Theorem 2.2. □

3. Blow-up rate. In this section, we give more insight into the blow-up mechanism for the wave-breaking solutions to (1.3).

LEMMA 3.1 (see [10]). *Let $T > 0$ and $v \in C^1([0,T); H^2(\mathbb{R}))$; then for every $t \in [0,T)$ there exists at least one point $\xi(t) \in \mathbb{R}$ with*

$$m(t) := \inf_{x\in\mathbb{R}} v_x(t,x) = v_x(t,\xi(t)).$$

The function $m(t)$ is a.e. differentiable on $(0,T)$ with

$$\frac{dm}{dt} = v_{tx}(t,\xi(t)) \text{ a.e. on } (0,T).$$

THEOREM 3.1. *Let $u_0 \in H^r(\mathbb{R})$, $r > \frac{3}{2}$, and let $T > 0$ be the maximal existence time of the corresponding solution to (1.3). If T is finite, we have*

$$\lim_{t\to T}(T-t)\inf_{x\in\mathbb{R}} u_x(t,x) = -1.$$

Proof. Let $T > 0$ be the maximal time of existence of the solution u to (1.3) (or (2.1)) with initial data $u_0 \in H^3(\mathbb{R})$. We already know by Theorem 2.2 that

$$\lim_{t\to T}\inf\{\inf_{x\in\mathbb{R}} u_x(t,x)\} = -\infty. \tag{3.1}$$

We know that $u(x,t) \in C^1([0,T); H^2(\mathbb{R}))$ by Theorem 2.1; then we infer from Lemma 3.1 that, for every $t \in [0,T)$, there exists at least one point $\xi(t) \in \mathbb{R}$ with $u_x(t,\xi(t)) = \inf_{x\in\mathbb{R}} u_x(t,x)$. Let

$$m(t) = u_x(t,\xi(t)) = \inf_{x\in\mathbb{R}} u_x(t,x);$$

then $u_{xx}(t,\xi(t)) = 0$ for all $t \in [0,T)$. From (2.7) we have

$$\frac{dm}{dt} + m^2(t) + \lambda m(t) = \frac{3}{2}u^2(t,\xi(t)) - p * \left(\frac{3}{2}u^2(t,\xi(t))\right) \text{ a.e. on } (0,T). \tag{3.2}$$

By Lemmas 2.3–2.4, we have for $t \in [0,T)$ that

$$\begin{aligned}
&\left|\frac{3}{2}u^2(t,\xi(t)) - p * \left(\frac{3}{2}u^2(t,\xi(t))\right)\right| \\
\le &\left|\frac{3}{2}u^2(t,\xi(t))\right| + \left|\frac{3}{4}\int_{\mathbb{R}} e^{-|\xi(t)-\eta|}u^2(t,\eta)d\eta\right| \\
\le &\frac{3}{2}\|u\|_{L^\infty}^2 + \frac{3}{4}\|u\|_{L^2}^2 \\
\le &\frac{3}{2}\left(\frac{3}{\lambda}\|u_0\|_{L^2}^2 + \|u_0\|_{L^\infty}\right)^2 + 3\|u_0\|_{L^2}^2.
\end{aligned}$$

Set

$$\beta = \frac{3}{2}\left(\frac{3}{\lambda}\|u_0\|_{L^2}^2 + \|u_0\|_{L^\infty}\right)^2 + 3\|u_0\|_{L^2}^2.$$

We infer from (3.2) that

$$\left|\frac{dm}{dt}+m^2(t)+\lambda m(t)\right|\le\beta \text{ a.e. on } (0,T).$$

Hence,

$$-\beta-\frac{1}{4}\lambda^2\le\frac{dm}{dt}+\left(m(t)+\frac{1}{2}\lambda\right)^2\le\beta+\frac{1}{4}\lambda^2 \text{ a.e. on } (0,T). \tag{3.3}$$

Let $\varepsilon\in(0,1)$. Since $\lim_{t\to T}\inf(m(t)+\frac{1}{2}\lambda)=-\infty$ (by (3.1)), there is some $t_0\in(0,T)$ with $m(t_0)+\frac{1}{2}\lambda<0$ and

$$\left(m(t_0)+\frac{1}{2}\lambda\right)^2>\frac{1}{\varepsilon}\left(\beta+\frac{1}{4}\lambda^2\right).$$

We claim that

$$\left(m(t)+\frac{1}{2}\lambda\right)^2>\frac{1}{\varepsilon}\left(\beta+\frac{1}{4}\lambda^2\right),\qquad t\in[t_0,T). \tag{3.4}$$

In fact, since $m(t)$ is locally Lipschitz (it belongs to $W^{1,\infty}_{loc}(\mathbb{R})$ by Theorem 2.1), there is some $\delta>0$ such that

$$\left(m(t)+\frac{1}{2}\lambda\right)^2>\frac{1}{\varepsilon}\left(\beta+\frac{1}{4}\lambda^2\right),\qquad t\in(t_0,t_0+\delta).$$

From (3.3), we have

$$\frac{dm}{dt}<(\varepsilon-1)\left(m(t)+\frac{1}{2}\lambda\right)^2<0,\qquad t\in(t_0,t_0+\delta) \text{ a.e. on } (0,T).$$

Being locally Lipschitz, the function $m(t)$ is absolutely continuous. Therefore, by integrating the above relation on $[t_0,t_0+\delta]$, we obtain that $m(t_0+\delta)\le m(t_0)$. Thus,

$$m(t_0+\delta)+\frac{1}{2}\lambda\le m(t_0)+\frac{1}{2}\lambda<0.$$

By the above inequality, we have

$$\left(m(t_0+\delta)+\frac{1}{2}\lambda\right)^2\ge\left(m(t_0)+\frac{1}{2}\lambda\right)^2>\frac{1}{\varepsilon}\left(\beta+\frac{1}{4}\lambda^2\right).$$

The relation (3.4) is proved by a continuous extension.

A combination of (3.3) with (3.4) enables us to infer that

$$-1-\varepsilon<\frac{\frac{dm}{dt}}{\left(m(t)+\frac{1}{2}\lambda\right)^2}<-1+\varepsilon \text{ a.e. on } (t_0,T). \tag{3.5}$$

For $t\in(t_0,T)$, integrating (3.5) on (t,T), we obtain

$$-1-\varepsilon<\frac{1}{\left(m(t)+\frac{1}{2}\lambda\right)(T-t)}<-1+\varepsilon,\qquad t\in(t_0,T).$$

Letting ε go to zero, we obtain

$$\lim_{t\to T}\left[\left(m(t)+\frac{1}{2}\lambda\right)(T-t)\right]=-1,$$

that is,

$$\lim_{t\to T}(T-t)m(t)=-1.$$

This completes the proof of the theorem. □

Remark 3.1. Although the occurrence of blow-up of strong solutions to (1.3) is affected by the dissipative parameter (see Theorems 2.3–2.4), Theorem 3.1 shows that the blow-up rate of strong solutions to the Degasperis–Procesi equation [24] is not affected by the weakly dissipative term.

4. Global solution and its decay. In this section we will show that there exist global strong solutions to (1.3) and these global solutions decay to zero as time goes to infinity provided the initial data u_0 satisfy certain sign conditions.

THEOREM 4.1. *Assume $u_0\in H^r(\mathbb{R})$, $r>\frac{3}{2}$. If $y_0=u_0-u_{0,xx}$ does not change sign on $\mathbb{R}$, then* (1.3) *(or* (2.1)*) has a global strong solution*

$$u=u(\cdot,u_0)\in C([0,\infty);H^r(\mathbb{R}))\cap C^1([0,\infty);H^{r-1}(\mathbb{R})).$$

Moreover, the global solution decays to 0 *in the H^1-norm and the H^3-norm as time goes to infinity.*

Proof. Let $T>0$ be the maximal time of existence of the solution u to (1.3) (or (2.1)) with initial data $u_0\in H^3(\mathbb{R})$. We first consider the case where $y_0\geq 0$ on $\mathbb{R}$. If $y_0\geq 0$, then Lemmas 2.1–2.2 ensure that $y\geq 0$ for all $t\in[0,T)$. Using $u=p*y$ and the positivity of p, we infer that $u(t,\cdot)\geq 0$ for all $t\geq 0$. Note that

$$u(t,x)=\frac{e^{-x}}{2}\int_{-\infty}^{x}e^{\eta}y(t,\eta)d\eta+\frac{e^{x}}{2}\int_{x}^{\infty}e^{-\eta}y(t,\eta)d\eta$$

and

$$u_x(t,x)=-\frac{e^{-x}}{2}\int_{-\infty}^{x}e^{\eta}y(\eta)d\eta+\frac{e^{x}}{2}\int_{x}^{\infty}e^{-\eta}y(\eta)d\eta.$$

From the above two equations, we deduce that

$$\begin{aligned}u(t,x)+u_x(t,x)&=e^{x}\int_{x}^{\infty}e^{-\eta}y(t,\eta)d\eta,\\ u(t,x)-u_x(t,x)&=e^{-x}\int_{-\infty}^{x}e^{\eta}y(t,\eta)d\eta.\end{aligned}\tag{4.1}$$

By (4.1) and $y\geq 0$ for all $t\in[0,T)$, we obtain, for $t\in[0,T)$,

$$|u_x(t,x)|\leq u(t,x)\quad\forall(t,x)\in[0,T)\times\mathbb{R}.\tag{4.2}$$

By Lemma 2.4, we have

$$\begin{aligned}|u_x(t,x)|&\leq u(t,x)\\ &\leq\exp\{-\lambda t\}\left(\frac{3}{\lambda}\|u_0\|_{L^2}^2+\|u_0\|_{L^\infty}\right)\quad\forall(t,x)\in[0,T)\times\mathbb{R}.\end{aligned}\tag{4.3}$$

The above inequality and Theorem 2.2 imply that $T = \infty$. This proves that the solution u exists globally in time.

Multiplying (1.3) by u and integrating by parts, in view of (4.2) and Lemmas 2.3–2.4, we get

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}}\left(u^2+u_x^2\right)dx+\lambda\int_{\mathbb{R}}\left(u^2+u_x^2\right)dx\\
=&-4\int_{\mathbb{R}}u^2u_xdx+3\int_{\mathbb{R}}uu_xu_{xx}dx+\int_{\mathbb{R}}u^2u_{xxx}dx\\
=&-\frac{1}{2}\int_{\mathbb{R}}u_x^3dx\le\frac{1}{2}\int_{\mathbb{R}}u^3dx\le\frac{1}{2}\|u\|_{L^\infty}\int_{\mathbb{R}}u^2dx\\
\le&2\exp\{-3\lambda t\}\left(\frac{3}{\lambda}\|u_0\|_{L^2}^2+\|u_0\|_{L^\infty}\right)\|u_0\|_{L^2}^2.
\end{aligned}$$

Integrating the above inequality with respect to t, we have

$$\|u(t)\|_1^2\le\exp\{-2\lambda t\}\left(\frac{12}{\lambda^2}\|u_0\|_{L^2}^4+\frac{4}{\lambda}\|u_0\|_{L^2}^2\|u_0\|_{L^\infty}+\|u_0\|_1^2\right).$$

This shows that the corresponding global solution with $y_0\ge 0$ decays to 0 in the H^1-norm.

By (4.3), we obtain that $-u_x\le\frac{\lambda}{7}$ for sufficiently large t. This yields, in combination with (2.4) and Gronwall's inequality,

$$\|y\|_1^2\le e^{-\lambda t}\|y_0\|_1^2$$

for large t. The above inequality implies that the corresponding global solution with $y_0\ge 0$ decays to 0 in the H^3-norm. This completes the proof of the theorem with the assumption $y_0\ge 0$ on $\mathbb{R}$. In the case when $y_0(x)\le 0$ on $\mathbb{R}$, one can repeat the above proof to get the desired result. □

Remark 4.1. Note that the global solution to the Degasperis–Procesi equation does not generally decay to zero as time goes to infinity [35]. Theorem 4.1 shows that there is a considerable difference between (1.3) and the Degasperis–Procesi equation in their long time behaviors. More precisely, the energy dissipation will affect the long time behavior of global solutions to the Degasperis–Procesi equation.

Remark 4.2. It is well known that the Degasperis–Procesi equation has peaked traveling wave solutions. Theorem 4.1 shows that global H^3-solutions with y_0 of one sign decay in the H^1-norm and the H^3-norm. Lemma 2.4 shows that any global solution decays in the L^∞-norm. This means that there are no traveling wave solutions of the dissipative equation (1.3). This is also another considerable difference between (1.3) and the Degasperis–Procesi equation in their long time behaviors.

Acknowledgment. The authors thank the referees for their valuable comments and suggestions.

NONLINEAR STABILITY OF STATIONARY SOLUTIONS FOR SURFACE DIFFUSION WITH BOUNDARY CONDITIONS*

HARALD GARCKE†, KAZUO ITO‡, AND YOSHIHITO KOHSAKA§

Abstract. The volume-preserving fourth order surface diffusion flow has constant mean curvature hypersurfaces as stationary solutions. We show nonlinear stability of certain stationary curves in the plane which meet an exterior boundary with a prescribed contact angle. Methods include semigroup theory, energy arguments, geometric analysis, and variational calculus.

Key words. surface diffusion, nonlinear stability, energy method, variational calculus

1. Introduction.

The surface diffusion flow

$$V = -\Delta_S \kappa \tag{1.1}$$

is a geometrical evolution law which describes the surface dynamics for phase interfaces, when mass diffusion occurs only within the interface. Here V is the normal velocity of the evolving surface, Δ_S is the surface Laplacian, and κ is the mean curvature of the surface. The flow (1.1) was first proposed by Mullins [20] in works concerned with thermal grooving. A derivation of (1.1) within rational thermodynamics was given by Davi and Gurtin [7]. In [22], Cahn and Taylor showed that (1.1) is the H^{-1}-gradient flow of the area functional, and in [5], Cahn, Elliott, and Novick-Cohen used formal asymptotics to derive (1.1) as the sharp interface limit of the Cahn–Hilliard equation with degenerate mobility. Further, the motion given by (1.1) has the significant geometrical properties that for closed embedded hypersurfaces the enclosed volume is preserved and surface area decreases in time (see, e.g., [10, 12]). The evolution law (1.1) leads to a fourth order parabolic equation which is in contrast to the second order mean curvature flow $V = \kappa$. We remark that the mean curvature flow is also area decreasing but changes the enclosed volume.

In this paper we study the motion by surface diffusion for curves in cases where the interface intersects an external boundary. More precisely, we consider the following problem. Let Ω be an open bounded domain in $\mathbb{R}^2$. We look for evolving curves $\Gamma = \{\Gamma_t\}_{t\geq 0}$ lying in Ω with $\partial\Gamma \subset \partial\Omega$ and satisfying

$$V = -\kappa_{ss} \tag{1.2}$$

for all points on Γ_t with the boundary conditions

$$\begin{cases} \Gamma_t \perp \partial\Omega & (90^\circ\text{-angle condition}), \\ \kappa_s = 0 & (\text{no-flux condition}) \end{cases} \tag{1.3}$$

at $\Gamma_t \cap \partial\Omega$, where a subscript s denotes differentiation with respect to the arc-length parameter of the evolving curve Γ_t. The boundary conditions (1.3) are the natural boundary conditions when viewing the flow as the H^{-1}-gradient flow of the length functional. It is not difficult to show that under the surface diffusion flow (1.2) with the boundary conditions (1.3) the areas enclosed by Γ_t and $\partial\Omega$ are preserved and the length of Γ_t decreases in time. We also find that an arc of a circle or a line segment is stationary under (1.2) and (1.3). Our goal in this paper is to show a nonlinear stability result for stationary solutions to (1.2) and (1.3). A proof of such a result is difficult due to the area-preserving property and due to the fact that highly nonlinear boundary conditions appear. We remark that for nonlinear boundary conditions satisfactory stability results are not available within the context of semigroup theory. We also remark that it is not possible to use methods based on maximum or comparison principles which have been used for mean curvature flow; see [8, 9].

For closed curves evolving by surface diffusion, Elliott and Garcke [10] showed a global existence result in the case that the initial curve is close to a circle. In addition, they proved nonlinear stability of circles under surface diffusion. Escher, Mayer, and Simonett [12] generalized the result in [10] to the higher-dimensional case. For evolving curves which come into contact with the outer boundary, Garcke, Ito, and Kohsaka [13] studied the linearized stability of stationary curves for (1.2) and (1.3). They derived a linearized stability criterion by extending the work for mean curvature flow of [8, 9, 15] to motion by surface diffusion. For three evolving curves with a triple junction in the case that the outer boundary $\partial\Omega$ is a rectangle [11, 16] or a triangle [17], global existence results when the initial curve is a small perturbation of a certain stationary curve have been shown. Also, nonlinear stability of this stationary curve can be shown.

Since the proof of nonlinear stability will depend heavily on the linear stability criterion derived in [13], we will now state it in detail. Let Γ^* be a stationary curve parameterized by X^* such that

$$\Gamma^* = \{X^*(\sigma) \mid \sigma \in [l_-, l_+]\},$$

where σ is the arc-length parameter along Γ^* and $X^*(l_\pm) \in \partial\Omega$. Further, we denote by κ^* the curvature of Γ^* and by $h^*_\pm$ the curvature of $\partial\Omega$ at $X^*(l_\pm)$, where we assume the sign convention that $h^*_\pm$ is negative if Ω is convex. Then the linearized stability criterion requires that

$$I^*[w,w] = \int_{l_-}^{l_+} \left\{ w_\sigma^2 - (\kappa^*)^2 w^2 \right\} d\sigma + h^*_+(w^2|_{\sigma=l_+}) + h^*_-(w^2|_{\sigma=l_-}) \tag{1.4}$$

is positive for all $w \in H^1(\Gamma^*)$ with mean value zero. In [13] this criterion was derived by studying the stability of the linearized problem. The same bilinear form also appears if one computes the second variation of the length functional taking boundary contacts into account; see, e.g., Vogel [23]. We refer the reader to section 7 of [13] for several examples in which the linearized stability criterion has been applied. In the papers [2, 3] numerical results on the stability of stationary solutions for surface diffusion are presented.

Our methods to obtain a nonlinear stability result are the following. First we introduce new curvilinear coordinates in order to derive an appropriate parameterization for which we can formulate (1.2) and (1.3) in a PDE setting. We then prove a local existence result, where the local existence time depends only on the $C^{2+\alpha}$-norm

$(0 < \alpha < 1)$ of the initial curve. This is very helpful for a global existence result because we need a priori estimates only up to two spatial derivatives. In fact, by applying an energy method as in [6, 10, 16, 17] to a resulting evolution equation for the curvature, we can derive an a priori estimate of the L^2-norm of κ_s, which implies the boundedness of the $C^{2+\alpha}$-norm $(0 < \alpha < 1/2)$ of the solution for $t > 0$. In the derivation of this a priori estimate, the linearized stability criterion developed in [13] is used. In addition, we need to understand the set of stationary solutions. We can use a result by Vogel [23] which guarantees that linearly stable stationary solutions are strict local minimizers of the length functional under an area constraint. We also show that in the neighborhood of the linearly stable stationary solution other stationary solutions can be represented as a one parameter family, where the parameter is the enclosed area. This implies that the linearly stable stationary solution is isolated, a fact which will be important in order to study the long time behavior of solutions.

This paper proceeds as follows. In section 2, a parameterization established in [13] is employed for the geometric evolution equation (1.2) with boundary conditions (1.3). As a consequence, we obtain a nonlinear fourth order parabolic PDE with nonlinear boundary conditions. We show a local existence result for this nonlinear parabolic problem. For the reader's convenience we show an essential part of the proof of the local existence result in Appendix A. In section 3, an evolution equation for the curvature is derived together with some geometric identities. The evolution equation for the curvature allows it to apply an energy method as in [6, 10, 16, 17]. In section 4, we first derive a priori estimates for the length of Γ_t and the L^2-norm of κ_s when Γ_t is close to a linearly stable stationary curve. These estimates imply the boundedness of the $C^{2+\alpha}$-norm $(0 < \alpha < 1/2)$ of the solution for $t > 0$, so that the global existence result is proven when the initial curve is close to a linearly stable stationary curve. Finally, in section 5, we show nonlinear stability of linearly stable stationary curves.

2. Local existence and uniqueness. In order to derive local existence and uniqueness for the geometric evolution equation (1.2) with the boundary conditions (1.3), we employ a parameterization which was established in [13]. We remark that our parameterization describes the curves close to a stationary curve by a modified distance function over a fixed interval and leads to a single PDE in contrast to parameterizations used, e.g., in Bronsard and Reitich [4] which involve vector-valued functions and lead to a system of PDEs. We also want to avoid arc-length parameterizations, as they lead to time-dependent parameter intervals, which is less convenient for semigroup theory. For the reader's convenience, we give a detailed derivation of our parameterization in the following.

Let $\Omega \subset \mathbb{R}^2$ be a domain such that

$$\Omega = \{x \in \mathbb{R}^2 \mid \psi(x) < 0\}, \quad \partial\Omega = \{x \in \mathbb{R}^2 \mid \psi(x) = 0\}$$

with a smooth function $\psi : \mathbb{R}^2 \to \mathbb{R}$ fulfilling $\nabla\psi(x) \neq 0$ for x with $\psi(x) = 0$.

Also, let Γ^* be a stationary curve under the flow (1.2) and (1.3); i.e., Γ^* has constant curvature κ^*. We now introduce an arc-length parameterization of Γ^* in the form

$$\Gamma^* = \{\Phi^*(\sigma) \mid \sigma \in [l_-, l_+]\},$$

where Φ^* is a mapping from $[l_-, l_+]$ to $\mathbb{R}^2$ and $l_+ - l_-$ is the total length of Γ^*. Note that we can extend Γ^* naturally either to the full circle when Γ^* is an arc of a circle

or to a straight line when Γ^* is a line segment. We set

$$\bar{l} := \begin{cases} \pi/|\kappa^*| & \text{if } \kappa^* \neq 0, \\ +\infty & \text{if } \kappa^* = 0; \end{cases}$$

i.e., $\bar{l}$ is the length of the extension of Γ^* to a half circle if $\kappa_* \neq 0$. Without loss of generality, we can assume $[l_-, l_+] \subset (-\bar{l}, \bar{l})$. Define

$$\begin{cases} \xi_+(q) := \max\{\sigma \in (-\bar{l}, \bar{l}) \mid \Phi^*(\sigma) + qN^*(\sigma) \in \Omega\}, \\ \xi_-(q) := \min\{\sigma \in (-\bar{l}, \bar{l}) \mid \Phi^*(\sigma) + qN^*(\sigma) \in \Omega\}, \end{cases}$$

where $N^*(\sigma)$ is a unit normal vector of Γ^* at σ and is obtained by rotating the unit tangent vector $T^*(\sigma)$ of Γ^* by $\pi/2$. Above, q is a parameter with $q \in (-\bar{d}, \bar{d})$ for a small and given $\bar{d} > 0$. It holds that $\psi(\Phi^*(\xi_\pm(q)) + qN^*(\xi_\pm(q))) = 0$ and $\xi_\pm(0) = l_\pm$. Using the implicit function theorem, we see that $\xi_+(q)$ and $\xi_-(q)$ are smooth. Let

$$\Psi(\sigma, q) := \Phi^*(\xi(\sigma, q)) + qN^*(\xi(\sigma, q))$$

with

$$\xi(\sigma, q) := \xi_-(q) + \frac{\sigma - l_-}{l_+ - l_-}(\xi_+(q) - \xi_-(q)).$$

It is not difficult to check that $\xi(l_\pm, q) = \xi_\pm(q)$ and $\xi(\sigma, 0) = \sigma$.

In addition, one derives that $\Psi : (l_-, l_+) \times (-\bar{d}, \bar{d}) \to \Omega$ parameterizes the intersection W of a tubular neighborhood around the extended Γ^* with Ω. We now consider functions $\rho : [l_-, l_+] \to (-\bar{d}, \bar{d})$ and obtain $\Psi(\sigma, \rho(\sigma)) \in W$ for $\sigma \in (l_-, l_+)$. Then we define $\Phi(\sigma) := \Psi(\sigma, \rho(\sigma))$ for $\sigma \in [l_-, l_+]$, which is a parameterization of a curve Γ. An evolving curve is now given by

$$\Gamma_t := \{\Phi(\sigma, t) \mid \sigma \in [l_-, l_+]\} \tag{2.1}$$

with $\Phi(\sigma, t) := \Psi(\sigma, \rho(\sigma, t))$ for a function $\rho = \rho(\sigma, t)$. We note that $|\rho(\sigma, t)| < \bar{d}$ guarantees that $\Phi(\sigma, t) = \Psi(\sigma, \rho(\sigma, t)) \in W$ for $\sigma \in (l_-, l_+)$ and $t > 0$. We remark that $\rho \equiv 0$ corresponds to the stationary curve Γ^*.

Let us now express (1.2) and (1.3) with the help of parameterizations which have the form (2.1). For the arc-length parameter s of Γ_t, we have

$$\frac{ds}{d\sigma} = |\Phi_\sigma| = \sqrt{|\Psi_\sigma|^2 + 2(\Psi_\sigma, \Psi_q)_{\mathbb{R}^2}\rho_\sigma + |\Psi_q|^2\rho_\sigma^2} \ =: J(\rho). \tag{2.2}$$

By $|\cdot|$ and $(\cdot, \cdot)_{\mathbb{R}^2}$ we denote the norm and the inner product in $\mathbb{R}^2$, respectively. Then we find

$$T = \frac{1}{J(\rho)}\Phi_\sigma, \quad N = \frac{1}{J(\rho)}R\Phi_\sigma,$$

where T and N are the unit tangent and unit normal to Γ_t, respectively, and R is the rotation by the angle $\pi/2$. The normal velocity V of Γ_t is given by

$$V = (\Phi_t, N)_{\mathbb{R}^2} = \frac{1}{J(\rho)}(\Phi_t, R\Phi_\sigma)_{\mathbb{R}^2} = \frac{1}{J(\rho)}(\Psi_q, R\Psi_\sigma)_{\mathbb{R}^2}\rho_t.$$

Further, the Laplace–Beltrami operator $\Delta(\rho)$ on Γ_t is given via (2.2) as

$$\Delta(\rho) = \partial_s^2 = \frac{1}{J(\rho)}\partial_\sigma\left(\frac{1}{J(\rho)}\partial_\sigma\right) = \frac{1}{(J(\rho))^2}\partial_\sigma^2 + \frac{1}{J(\rho)}\left(\partial_\sigma\frac{1}{J(\rho)}\right)\partial_\sigma. \tag{2.3}$$

Then the curvature κ of Γ_t can be derived by using $\Delta(\rho)$ as

$$\begin{aligned}\kappa(\rho) &= (\Delta(\rho)\Phi, N)_{\mathbb{R}^2} = \frac{1}{(J(\rho))^3}(\Phi_{\sigma\sigma}, R\Phi_\sigma)_{\mathbb{R}^2} \\ &= \frac{1}{(J(\rho))^3}\Big[(\Psi_q, R\Psi_\sigma)_{\mathbb{R}^2}\rho_{\sigma\sigma} + \big\{2(\Psi_{\sigma q}, R\Psi_\sigma)_{\mathbb{R}^2} + (\Psi_{\sigma\sigma}, R\Psi_q)_{\mathbb{R}^2}\big\}\rho_\sigma \\ &\quad + \big\{(\Psi_{qq}, R\Psi_\sigma)_{\mathbb{R}^2} + 2(\Psi_{\sigma q}, R\Psi_q)_{\mathbb{R}^2} + (\Psi_{qq}, R\Psi_q)_{\mathbb{R}^2}\rho_\sigma\big\}\rho_\sigma^2 \\ &\quad + (\Psi_{\sigma\sigma}, R\Psi_\sigma)_{\mathbb{R}^2}\Big].\end{aligned} \tag{2.4}$$

Furthermore, we note that the Neumann boundary condition $(\Phi_\sigma, T_{\partial\Omega})_{\mathbb{R}^2} = 0$ on $\partial\Omega$ is equivalent to the condition $(R\Phi_\sigma, \nabla\psi(\Phi))_{\mathbb{R}^2} = 0$ on $\partial\Omega$. Then we compute that the parameterization of the Neumann boundary condition is

$$(R\Psi_\sigma + R\Psi_q\rho_\sigma, \nabla\psi(\Psi))_{\mathbb{R}^2} = 0 \ \text{ at } \ \sigma = l_\pm.$$

As a consequence, we conclude that the problem (1.2) and (1.3) is represented by

$$\begin{cases} \rho_t = -L(\rho)\Delta(\rho)\kappa(\rho) & \text{for} \quad \sigma \in (l_-, l_+),\ t > 0, \\ (R\Psi_\sigma + R\Psi_q\rho_\sigma, \nabla\psi(\Psi))_{\mathbb{R}^2} = 0 & \text{at} \quad \sigma = l_\pm, \\ \partial_\sigma\kappa(\rho) = 0 & \text{at} \quad \sigma = l_\pm. \end{cases} \tag{2.5}$$

Here $L(\rho) := J(\rho)/(\Psi_q, R\Psi_\sigma)_{\mathbb{R}^2}$; $\Delta(\rho)$ and $\kappa(\rho)$ are given by (2.3) and (2.4), respectively.

Let $\mathcal{I} = [l_-, l_+]$ and $\mathcal{Q}_{t_0,t_1} = \mathcal{I}\times(t_0, t_1]$ for $0 \le t_0 < t_1 < \infty$. For $0 < \alpha < 1$, we define the function space

$$\mathcal{Y}(\overline{\mathcal{Q}_{t_0,t_1}}) = \{\rho \in C^{2+\alpha,0}(\overline{\mathcal{Q}_{t_0,t_1}}) \cap C^{4+\alpha,1}(\mathcal{Q}_{t_0,t_1}) \mid \|\rho\|_{\mathcal{Y}(\overline{\mathcal{Q}_{t_0,t_1}})} < \infty\}$$

with the norm

$$\begin{aligned}\|\rho\|_{\mathcal{Y}(\overline{\mathcal{Q}_{t_0,t_1}})} &= \sup_{t_0\le t\le t_1}\|\rho(\cdot,t)\|_{C^{2+\alpha}(\mathcal{I})} + \sup_{t_0<t\le t_1}(t-t_0)^{1/2}\|\partial_\sigma^4\rho(\cdot,t)\|_{C^\alpha(\mathcal{I})} \\ &\quad + \sup_{t_0<t\le t_1}(t-t_0)^{1/2}\|\rho_t(\cdot,t)\|_{C^\alpha(\mathcal{I})},\end{aligned}$$

where $\overline{\mathcal{Q}_{t_0,t_1}}$ is the closure of $\mathcal{Q}_{t_0,t_1}$.

Now we are ready to state a local existence theorem.

THEOREM 2.1 (local existence). *Let $\alpha \in (0,1)$ and let us assume that $\rho_0 \in C^{2+\alpha}(\mathcal{I})$ with $\|\rho_0\|_{C^0(\mathcal{I})} < \bar{d}$ fulfills*

$$(R\Psi_\sigma + R\Psi_q\rho_\sigma, \nabla\psi(\Psi))_{\mathbb{R}^2} = 0 \ \text{ at } \ \sigma = l_\pm.$$

Then there exists a $T_0 = T_0(1/\|\rho_0\|_{C^{2+\alpha}(\mathcal{I})}) > 0$ such that the problem (2.5) with $\rho(\cdot,0) = \rho_0$ has a unique solution in $\mathcal{Y}(\overline{\mathcal{Q}_{0,T_0}})$.

This theorem is proved by applying similar arguments as in [16]. Since we have to take care of the boundary conditions in a different way, we will sketch the proof in Appendix A.

Remark 2.2. Applying the local existence results used in [4] directly, we obtain solutions for $C^{4+\alpha}$-initial curves. But this makes it difficult to derive a global existence result because we need a priori estimates for higher order derivatives. Thus our local existence result is an improvement of the one obtained in [4].

Remark 2.3. By using a bootstrapping argument as in [16, Theorem 3.6, Remark 3.7], it can be shown that the solution ρ established in Theorem 2.1 is smooth for $t \in (0, T_0]$.

3. An evolution equation for curvature. In order to show nonlinear stability of solutions for which the linearized stability criterion of [13] is fulfilled, we apply an energy method similar to the one used in [6, 10, 16, 17]. For this approach it is important to derive an evolution equation for the curvature. Such an equation will be useful for the derivation of a priori estimates with the help of the linearized stability criterion.

For the above-mentioned purpose, we employ a parameterization of the evolving curve Γ_t by arc length contrary to the one stated in section 2. Let X be a smooth mapping so that $X(\cdot, t)$ is an arc-length parameterization of Γ_t, i.e.,

$$\Gamma_t := \{X(s,t) \,|\, s \in [r_-(t), r_+(t)]\}$$

for any $t > 0$, where r_+ and r_- are smooth in t. In particular, $X(r_\pm(t), t) \in \partial\Omega$ and $r_+(t) - r_-(t) = L[\Gamma_t]$, where $L[\Gamma_t]$ denotes the total length of Γ_t. Let $N\,(= N(s,t))$ be the unit normal vector of Γ_t, which is represented as

$$N(s,t) = \begin{pmatrix} \cos\theta(s,t) \\ \sin\theta(s,t) \end{pmatrix}.$$

Also, let $T\,(= T(s,t))$ and $\kappa\,(= \kappa(s,t))$ be the unit tangent vector of Γ_t and the curvature of Γ_t, respectively. Note that the unit tangent vector T is obtained by rotating the unit normal vector N by $-\pi/2$. Then, using $\theta_s = \kappa$, we have

$$\begin{cases} N_s = -\kappa T, \quad T_s = \kappa N, \\ N_t = -\theta_t T, \quad T_t = \theta_t N. \end{cases} \tag{3.1}$$

In addition, set

$$V := (X_t, N)_{\mathbb{R}^2}, \quad v := (X_t, T)_{\mathbb{R}^2}.$$

Note that V and v are the normal velocity and the tangent velocity of X, respectively. Then it follows that

$$X_t = VN + vT. \tag{3.2}$$

Differentiating (3.2) with respect to s and using (3.1), we have

$$\begin{aligned} X_{ts} &= V_s N + V N_s + v_s T + v T_s \\ &= (V_s + \kappa v) N + (-\kappa V + v_s) T. \end{aligned}$$

This implies the following lemma.

LEMMA 3.1. *Let X be a smooth arc-length parameterization as above. Then*

$$\theta_t = V_s + \kappa v, \quad v_s = \kappa V.$$

Proof. Since $X_{ts} = X_{st}$ and $X_s = T$, it follows from (3.1) that

$$\theta_t N = (V_s + \kappa v)N + (-\kappa V + v_s)T.$$

Thus we obtain the desired results. ∎

By Lemma 3.1, we have the following formula for the time derivative of curvature.

LEMMA 3.2. *Let X be a smooth arc-length parameterization as above. Then*

$$\kappa_t = V_{ss} + \kappa^2 V + \kappa_s v.$$

Proof. By $\theta_s = \kappa$ and Lemma 3.1, we derive

$$\kappa_t = \theta_{st} = \theta_{ts} = (V_s + \kappa v)_s = V_{ss} + \kappa v_s + \kappa_s v = V_{ss} + \kappa^2 V + \kappa_s v.$$

This completes the proof. ∎

By the assumption that Γ_t touches $\partial\Omega$ with the angle $\pi/2$, we have

$$\psi(X(r_\pm(t), t)) = 0, \quad (\nabla\psi(X), N)_{\mathbb{R}^2} = 0 \quad \text{at } s = r_\pm(t).$$

Then we derive the following lemma.

LEMMA 3.3. *Let X be a smooth arc-length parameterization as above. Then*

$$v(r_\pm(t), t) + r'_\pm(t) = 0.$$

Proof. Differentiating $\psi(X(r_\pm(t), t)) = 0$ with respect to t and using $(\nabla\psi(X), N)_{\mathbb{R}^2} = 0$ at $s = r_\pm(t)$, we have at $s = r_\pm(t)$

$$\begin{aligned} 0 &= (\nabla\psi(X), X_s r'_\pm + X_t)_{\mathbb{R}^2} = (\nabla\psi(X), X_s r'_\pm + VN + vT)_{\mathbb{R}^2} \\ &= (v + r'_\pm)(\nabla\psi(X), T)_{\mathbb{R}^2} = \pm\,(v + r'_\pm)|\nabla\psi(X)|. \end{aligned}$$

The last identity is derived with the help of $T = \pm\,\nabla\psi(X)/|\nabla\psi(X)|$ at $s = r_\pm(t)$. Since $|\nabla\psi(X)| \neq 0$, we obtain the desired result. ∎

Now we can present an evolution equation for the curvature.

PROPOSITION 3.4 (evolution equation for the curvature). *Let evolving curves $\Gamma = \{\Gamma_t\}_{t\geq 0}$ be lying in Ω with $\partial\Gamma \subset \partial\Omega$. Then a smooth solution of*

$$V = -\kappa_{ss} \quad \text{on} \quad \Gamma_t \tag{3.3}$$

with the boundary conditions

$$\begin{cases} \sphericalangle(\Gamma_t, \partial\Omega) = \pi/2 & \text{at} \quad \Gamma_t \cap \partial\Omega, \\ \kappa_s = 0 & \text{at} \quad \Gamma_t \cap \partial\Omega \end{cases} \tag{3.4}$$

fulfills for $t > 0$

$$\kappa_t = -\kappa_{ssss} - \kappa^2\kappa_{ss} + \kappa_s v \quad \text{on} \quad \Gamma_t \tag{3.5}$$

and

$$\begin{cases} \kappa_s = 0 & \text{at} \quad \Gamma_t \cap \partial\Omega, \\ (\partial_s \pm h_\pm)\kappa_{ss} = 0 & \text{at} \quad \Gamma_t \cap \partial\Omega. \end{cases} \tag{3.6}$$

Here $h_\pm$ is the curvature of $\partial\Omega$ at the points $X(r_\pm(t),t) \in \Gamma_t \cap \partial\Omega$ with the sign convention that $h_\pm \le 0$ if Ω is convex.

Proof. We immediately obtain (3.5) from (3.3) and Lemma 3.2. Next we show (3.6). Differentiating $(\nabla\psi(X), N)_{\mathbb{R}^2} = 0$ at $s = r_\pm(t)$ with respect to t and using (3.1), (3.2), Lemma 3.1, and Lemma 3.3, we have at $s = r_\pm(t)$

$$\begin{aligned}
0 &= ([D^2\psi(X)](X_s r'_\pm + X_t), N)_{\mathbb{R}^2} + (\nabla\psi(X), N_s r'_\pm + N_t)_{\mathbb{R}^2} \\
&= (v + r'_\pm)([D^2\psi(X)]T, N)_{\mathbb{R}^2} + V([D^2\psi(X)]N, N)_{\mathbb{R}^2} \\
&\quad - \kappa r'_\pm(\nabla\psi(X), T)_{\mathbb{R}^2} - \theta_t(\nabla\psi(X), T)_{\mathbb{R}^2} \\
&= V([D^2\psi(X)]T_{\partial\Omega}(X), T_{\partial\Omega}(X))_{\mathbb{R}^2} - V_s(\nabla\psi(X), T)_{\mathbb{R}^2} \\
&\quad - \kappa(v + r'_\pm)(\nabla\psi(X), T)_{\mathbb{R}^2} \\
&= V([D^2\psi(X)]T_{\partial\Omega}(X), T_{\partial\Omega}(X))_{\mathbb{R}^2} \mp V_s|\nabla\psi(X)|.
\end{aligned}$$

Here $D^2\psi$ is the Hessian matrix of ψ. Then we observe that

$$\kappa_{\partial\Omega}(X) = -\frac{1}{|\nabla\psi(X)|}([D^2\psi(X)]T_{\partial\Omega}(X), T_{\partial\Omega}(X))_{\mathbb{R}^2},$$

so that

$$V_s \pm h_\pm V = 0 \quad \text{at } \ s = r_\pm(t),$$

where $h_\pm$ are given by $h_\pm := \kappa_{\partial\Omega}(X(r_\pm(t),t))$. This completes the proof. ∎

4. A priori estimates and global existence. We now derive basic evolution formulas for length and $\int_{\Gamma_t} \kappa_s^2\, ds$.

LEMMA 4.1. *A smooth solution of* (3.3)–(3.4) *fulfills*

(i) $\dfrac{d}{dt}L[\Gamma_t] = -\displaystyle\int_{\Gamma_t} \kappa_s^2\, ds,$

(ii) $$\frac{d}{dt}\int_{\Gamma_t} \kappa_s^2\, ds = -2\left\{\int_{\Gamma_t} V_s^2\, ds - \int_{\Gamma_t} \kappa^2 V^2\, ds + h_+(V^2|_{s=r_+(t)}) + h_-(V^2|_{s=r_-(t)})\right\} + \int_{\Gamma_t} \kappa_s^2 \kappa V\, ds,$$

where $h_\pm$ is evaluated at $X(r_\pm(t),t)$.

Proof. Recalling $L[\Gamma_t] = r_+(t) - r_-(t)$ and using Lemmas 3.1 and 3.3, we have

$$\begin{aligned}
\frac{d}{dt}L[\Gamma_t] = r'_+(t) - r'_-(t) &= -v(r_+(t),t) + v(r_-(t),t) = -\int_{\Gamma_t} v_s\, ds \\
&= -\int_{\Gamma_t} \kappa V\, ds = \int_{\Gamma_t} \kappa\kappa_{ss}\, ds = -\int_{\Gamma_t} \kappa_s^2\, ds.
\end{aligned}$$

The last term is derived using integration by parts and $\kappa_s = 0$ at $\Gamma_t \cap \partial\Omega$.

In order to prove (ii), we compute

$$\int_{\Gamma_t} \kappa_s(\kappa_t)_s\, ds = \int_{\Gamma_t} \kappa_s(-\kappa_{ssss} - \kappa^2\kappa_{ss} + \kappa_s v)_s\, ds. \tag{4.1}$$

Since $\kappa_{ts} = \kappa_{st}$ and $\kappa_s = 0$ at $\Gamma_t \cap \partial\Omega$, we have

$$\text{(left-hand side of (4.1))} = \int_{\Gamma_t} \kappa_s \kappa_{st}\, ds = \frac{1}{2}\int_{\Gamma_t} (\kappa_s^2)_t\, ds = \frac{1}{2}\frac{d}{dt}\int_{\Gamma_t} \kappa_s^2\, ds.$$

On the other hand, by means of integration by parts and using (3.6), we derive

$$\begin{aligned}\text{(right-hand side of (4.1))} &= -\int_{\Gamma_t} \kappa_{ss}(-\kappa_{ssss} - \kappa^2\kappa_{ss} + \kappa_s v)\, ds \\ &= \int_{\Gamma_t} \kappa_{ss}\kappa_{ssss}\, ds + \int_{\Gamma_t} \kappa^2\kappa_{ss}^2\, ds - \int_{\Gamma_t} \kappa_{ss}\kappa_s v\, ds \\ &= -h_+(\kappa_{ss}^2|_{s=r_+(t)}) - h_-(\kappa_{ss}^2|_{s=r_-(t)}) - \int_{\Gamma_t} \kappa_{sss}^2\, ds \\ &\quad + \int_{\Gamma_t} \kappa^2\kappa_{ss}^2\, ds + \frac{1}{2}\int_{\Gamma_t} \kappa_s^2 v_s\, ds.\end{aligned}$$

Thus it follows from $V = -\kappa_{ss}$ and $v_s = \kappa V$ that

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_{\Gamma_t} \kappa_s^2\, ds &= -\left\{\int_{\Gamma_t} V_s^2\, ds - \int_{\Gamma_t} \kappa^2 V^2\, ds + h_+(V^2|_{s=r_+(t)}) + h_-(V^2|_{s=r_-(t)})\right\} \\ &\quad + \frac{1}{2}\int_{\Gamma_t} \kappa_s^2 \kappa V\, ds.\end{aligned}$$

This completes the proof. □

Let us define the bilinear form I as

$$I[w,w] = \int_{r_-}^{r_+} (w_s^2 - \kappa_{av}^2 w^2)\, ds + h_+(w^2|_{s=r_+}) + h_-(w^2|_{s=r_-}) \tag{4.2}$$

for $w \in H^1(\Gamma_t)$ with

$$\int_{r_-}^{r_+} w\, ds = 0.$$

Here s is the arc-length parameter along Γ_t, which belongs to the interval $[r_-, r_+]$ with $L[\Gamma_t] = r_+ - r_-$; $h_\pm$ is the curvature of $\partial\Omega$ at $\Gamma_t \cap \partial\Omega$; and κ_{av} is the averaged curvature of Γ_t defined as

$$\kappa_{av} = \frac{1}{L[\Gamma_t]}\int_{r_-}^{r_+} \kappa\, ds.$$

Since $V = -\kappa_{ss}$ and $\kappa_s = 0$ at $\Gamma_t \cap \partial\Omega$, it holds that

$$\int_{\Gamma_t} V\, ds = 0. \tag{4.3}$$

Then we can rewrite Lemma 4.1(ii) as

$$\frac{d}{dt}\int_{\Gamma_t} \kappa_s^2\, ds + 2I[V,V] = -2\int_{\Gamma_t} (\kappa_{av}^2 - \kappa^2)V^2\, ds + \int_{\Gamma_t} \kappa_s^2 \kappa V\, ds. \tag{4.4}$$

Remark 4.2. Although the 90°-angle condition in (1.3) is the natural boundary condition when considering the gradient flow of the length functional, we can also consider the case where the prescribed angle is not 90°. In this case, the angle condition is represented as

$$(\nabla\psi(X), N)_{\mathbb{R}^2} = |\nabla\psi(X)| \cos\Theta_\pm \quad \text{at } \ s = r_\pm(t)$$

for $\Theta_\pm \in (0, \pi)$. Then the identity in Lemma 3.3 is replaced by

$$v + r'_\pm = \mp V \cot\Theta_\pm \quad \text{at } \ s = r_\pm(t),$$

and the second boundary condition of (3.6) is replaced by

$$\big\{\partial_s + (\pm h_\pm \csc\Theta_\pm \mp \kappa \cot\Theta_\pm)\big\}\kappa_{ss} = 0 \quad \text{at } \ s = r_\pm(t).$$

Further, setting

$$I_\Theta[w, w] = \int_{r_-}^{r_+} (w_s^2 - \kappa_{av}^2 w^2)\, ds + \big\{h_+ \csc\Theta_+ - (\kappa|_{s=r_+}) \cot\Theta_+\big\}(w^2|_{s=r_+}) + \big\{h_- \csc\Theta_- - (\kappa|_{s=r_-}) \cot\Theta_-\big\}(w^2|_{s=r_-})$$

instead of I in (4.2), we have

$$\frac{d}{dt}\int_{\Gamma_t} \kappa_s^2\, ds + 2I_\Theta[V, V] = -2\int_{\Gamma_t} (\kappa_{av}^2 - \kappa^2) V^2\, ds + \int_{\Gamma_t} \kappa_s^2 \kappa V\, ds.$$

We remark that for the non-90°-angle condition the stationary solutions with the property that I_Θ is positive are strict local minimizers of an energy also involving a wetting energy at the boundary if one takes an area constraint into account (see Vogel [23]). On the other hand,

$$\frac{d}{dt} L[\Gamma_t] = -\int_{\Gamma_t} \kappa_s^2\, ds - (V|_{s=r_+(t)}) \cot\Theta_+ - (V|_{s=r_-(t)}) \cot\Theta_-,$$

so that the monotonicity of $L[\Gamma_t]$ with respect to t is no longer fulfilled.

The following lemmas will be crucial in order to derive an a priori estimate.

LEMMA 4.3. *A smooth solution of* (3.3)–(3.4) *fulfills*

(i) $\displaystyle\left|\int_{\Gamma_t} \kappa_s^2 \kappa \kappa_{ss}\, ds\right| \le \frac{1}{3} L[\Gamma_t] \|\kappa_s\|_{L^2(\Gamma_t)}^2 \|\kappa_{ss}\|_{L^2(\Gamma_t)}^2,$

(ii) $\|\kappa - \kappa_{av}\|_{C^0(\Gamma_t)} \le L[\Gamma_t]^{1/2} \|\kappa_s\|_{L^2(\Gamma_t)}.$

Proof. We first prove (i). Since $\kappa_s = 0$ at $\Gamma_t \cap \partial\Omega$, we get

$$\int_{\Gamma_t} \kappa_s^2 \kappa \kappa_{ss}\, ds = -\frac{1}{3}\int_{\Gamma_t} \kappa_s^4\, ds.$$

Then it follows that

$$\left|\int_{\Gamma_t} \kappa_s^4\, ds\right| \le \|\kappa_s\|_{L^2(\Gamma_t)}^2 \|\kappa_s\|_{L^\infty(\Gamma_t)}^2 \le L[\Gamma_t] \|\kappa_s\|_{L^2(\Gamma_t)}^2 \|\kappa_{ss}\|_{L^2(\Gamma_t)}^2.$$

The last term is derived by using a Poincaré inequality since $\kappa_s = 0$ at $\Gamma_t \cap \partial\Omega$.

Next we prove (ii). Since

$$\int_{\Gamma_t} (\kappa - \kappa_{av})\, ds = 0,$$

for each $t > 0$, there is a $r_0\,(= r_0(t)) \in (r_-(t), r_+(t))$ such that $\kappa(r_0, t) - \kappa_{av}(t) = 0$. This implies that

$$|\kappa(s,\cdot) - \kappa_{av}| = \left| \int_{r_0}^{s} (\kappa - \kappa_{av})_s \, ds \right| = \left| \int_{r_0}^{s} \kappa_s \, ds \right| \le \int_{\Gamma_t} |\kappa_s| \, ds \le L[\Gamma_t]^{1/2} \|\kappa_s\|_{L^2(\Gamma_t)}.$$

Thus we have the desired result. □

We remind the reader that for functions w_1, w_2 with mean values zero we can define the H^{-1}-inner product via

$$(w_1, w_2)_{-1} = \int_{l_-}^{l_+} u_{1,\sigma} u_{2,\sigma} \, d\sigma,$$

where u_i is the solution of $-u_{i,\sigma\sigma} = w_i$ in (l_-, l_+) and $u_{i,\sigma} = 0$ at $\sigma = l_\pm$. According to [13], the bilinear form I^* as stated in the introduction (see (1.4)) is positive, provided that the maximal eigenvalue λ for the linearized problem to (1.2) and (1.3) is negative. In [13] it was shown that $I^*[w, w] \ge (-\lambda)(w, w)_{-1}$ for all $w \in H^1(\Gamma^*)$ with mean value zero. We now want to derive a perturbation of this result. Let us denote $L = L[\Gamma]$ and $L^* = L[\Gamma^*]\,(= l_+ - l_-)$. Then we have the following lemma, which implies a lower bound for I when the parameters κ_{av}, $h_\pm$, and L are close to κ^*, $h_\pm^*$, and L^*, respectively.

LEMMA 4.4. (i) *Let λ be the maximal eigenvalue of the linearized problem. For $\varepsilon > 0$ there exists $\delta > 0$ such that*

$$I[w, w] > (-\lambda - \varepsilon)(w, w)_{-1}$$

for $w \in H^1(\Gamma)$ with mean value zero, provided that

$$|\kappa_{av} - \kappa^*| < \delta, \quad |h_\pm - h_\pm^*| < \delta, \quad |L - L^*| < \delta.$$

(ii) *There exists $\mu > 0$ such that*

$$\mu \|w_s\|^2_{L^2(\Gamma)} \le I[w, w] + (w, w)_{-1}$$

for $w \in H^1(\Gamma)$ with mean value zero.

Proof. The largest eigenvalue λ corresponding to the bilinear form I depends continuously on L, κ_{av}, and $h_\pm$. In the case that $L = L^*$, $\kappa_{av} = \kappa^*$, and $h_\pm = h_\pm^*$ we obtain (i) with $\varepsilon = 0$, and hence (i) follows from a straightforward perturbation argument; compare [13] for similar arguments. Arguing as in the proof of Lemma 5.3 in [13], we obtain (ii). □

It is significant to obtain a positive lower bound of $L[\Gamma]$ in terms of ρ. The following lemma implies that L^* is a local minimum of $L[\Gamma]$, provided that I^* is positive.

LEMMA 4.5. *Let Γ^* be a stationary curve such that the bilinear form I^* is positive and let $\rho \in C^1(\mathcal{I})$ be a function describing a curve Γ close to Γ^* as in section 2. Assume that a curve Γ encloses the same area as Γ^*. Then there exist constants $\bar{c}$, $\gamma^* > 0$ such that*

$$L[\Gamma] \ge L^* + \bar{c} \|\rho\|^2_{H^1(\mathcal{I})}$$

if $\|\rho\|_{C^1(\mathcal{I})} < \gamma^*$.

Proof. This follows as in the proof of Theorem 2.1 of Vogel [23] (see (2.14) and the inequality after (2.19) in [23]). ∎

By virtue of Lemma 4.5, we have an a priori estimate of $L[\Gamma_t]$ and can derive useful estimates concerning κ_{av} and $h_\pm$.

LEMMA 4.6. *Let the assumptions of Lemma* 4.5 *hold for a stationary curve* Γ^* *and all curves* Γ_t, $t \in [0,T]$, *described by* $\rho(t) \in C^1(\mathcal{I})$ *for the parameterization in section* 2. *Assume in particular that* $\|\rho(t)\|_{C^1(\mathcal{I})} < \gamma^*$ *for* $t \in [0,T]$, *where* γ^* *is as in Lemma* 4.5. *We then obtain the following:*

(i) $L[\Gamma_0] \geq L[\Gamma_t] \geq L^*$ *for all* $t \in [0,T]$.

(ii) *There exist* $K_1, K_2 > 0$ *such that for* $t \in [0,T]$

$$|\kappa_{av}(t) - \kappa^*| \leq K_1 |L[\Gamma_t] - L^*|, \quad |h_\pm(t) - h_\pm^*| \leq K_2 |L[\Gamma_t] - L^*|.$$

Proof. (i) follows from Lemma 4.1(i) and Lemma 4.5. To prove (ii), we compute

$$\kappa_{av} = \frac{1}{L[\Gamma_t]} \int_{\Gamma_t} \kappa \, ds = \frac{1}{L[\Gamma_t]} \int_{\Gamma_t} \theta_s \, ds = \frac{1}{L[\Gamma_t]} (\theta_+ - \theta_-).$$

A similar computation gives

$$\kappa^* = \frac{1}{L^*} (\theta_+^* - \theta_-^*).$$

Then we have

$$\begin{aligned} |\kappa_{av} - \kappa^*| &= \left| \frac{1}{L[\Gamma_t]} (\theta_+ - \theta_-) - \frac{1}{L^*} (\theta_+^* - \theta_-^*) \right| \\ &= \frac{1}{L[\Gamma_t] L^*} |L^* (\theta_+ - \theta_-) - L[\Gamma_t] (\theta_+^* - \theta_-^*)| \\ &\leq \left(\frac{1}{L^*} \right)^2 \Big\{ |L^* (\theta_+ - \theta_- - (\theta_+^* - \theta_-^*))| + |L^* - L[\Gamma_t]| |\theta_+^* - \theta_-^*| \Big\}. \end{aligned}$$

By means of the mean value theorem, the smoothness of $\partial\Omega$, and the $\pi/2$ angle condition, we see that the quantity $|\theta_+ - \theta_+^*| + |\theta_-^* - \theta_-|$ is estimated by $\|\rho\|_{C^0(\mathcal{I})}$. Using Lemma 4.5 and an embedding result, we obtain the first inequality in (ii).

Recall that $\kappa_{\partial\Omega}(X)$ is represented by

$$\kappa_{\partial\Omega}(X) = -\frac{1}{|\nabla\psi(X)|} ([D^2\psi(X)] T_{\partial\Omega}(X), T_{\partial\Omega}(X))_{\mathbb{R}^2}.$$

Since this expression does not depend on derivatives of ρ, the mean value theorem implies that the quantity $|h_\pm - h_\pm^*|$ is estimated by $\|\rho\|_{C^0(\mathcal{I})}$. Using Lemma 4.5 and an embedding result, we derive the second inequality in (ii). ∎

Using Lemma 4.4, we obtain the existence of constants $\delta^* > 0$ and $\mu^* > 0$ such that

$$I[w,w] > -\frac{\lambda}{2} (w,w)_{-1} + \mu^* \|w_s\|_{L^2(\Gamma_t)}^2 \tag{4.5}$$

for $w \in H^1(\Gamma_t)$ with mean value zero, provided that

$$|\kappa_{av}(t) - \kappa^*| < \delta^*, \quad |h_\pm(t) - h_\pm^*| < \delta^*, \quad |L[\Gamma_t] - L^*| < \delta^*. \tag{4.6}$$

We are now in a position to derive a priori estimates for solutions of (2.5) if the solution is close to Γ^*.

PROPOSITION 4.7. *Let the assumptions of Lemma* 4.5 *hold for a stationary curve* Γ^* *and a curve* Γ_t *described by* $\rho(t) \in C^1(\mathcal{I})$ *for the parameterization in section* 2. *Assume that for* $t \in (0, T]$

$$\|\rho(t)\|_{C^1(\mathcal{I})} < \gamma^* \quad \text{and} \quad |L[\Gamma_t] - L^*| \le \frac{\delta^*}{1 + K_1 + K_2} \,(=: \delta_1^*), \tag{4.7}$$

where γ^* *is as in Lemma* 4.5, K_1 *and* K_2 *are as in Lemma* 4.6, *and* δ^* *is as in* (4.6). *Then there is a constant* $\delta_1 > 0$ *such that, if* $\|\kappa_s(t)\|^2_{L^2(\Gamma_t)} < \delta_1$ *for* $t \in (0, T]$, *it holds that*

$$\|\kappa_s(t)\|^2_{L^2(\Gamma_t)} + \mu^* \int_{t_0}^t \|V_s(\tau)\|^2_{L^2(\Gamma_t)}\, d\tau \le \|\kappa_s(t_0)\|^2_{L^2(\Gamma_t)}$$

for $t \in [t_0, T]$ *with* $t_0 > 0$, *where* μ^* *is as in* (4.5).

Proof. By (4.4), we have

$$\begin{aligned}
&\frac{d}{dt}\|\kappa_s\|^2_{L^2(\Gamma_t)} + 2I[V, V] \\
&= -2\int_{\Gamma_t} (\kappa_{av}^2 - \kappa^2) V^2\, ds + \int_{\Gamma_t} \kappa_s^2 \kappa V\, ds \\
&= 2\int_{\Gamma_t} (\kappa - \kappa_{av})^2 V^2\, ds + 4\kappa_{av}\int_{\Gamma_t} (\kappa - \kappa_{av}) V^2\, ds + \int_{\Gamma_t} \kappa_s^2 \kappa V\, ds.
\end{aligned}$$

By virtue of (4.7) and Lemma 4.6(ii), we also see that $\kappa_{av}(t)$, $h_\pm(t)$, and $L[\Gamma_t]$ satisfy (4.6). Then it follows from Lemma 4.3, Lemma 4.6(i), and (4.5) that there exist $C_1, C_2 > 0$ such that

$$\begin{aligned}
&\frac{d}{dt}\|\kappa_s\|^2_{L^2(\Gamma_t)} + (-\lambda)\,(V, V)_{-1} + 2\mu^*\|V_s\|^2_{L^2(\Gamma_t)} \\
&\le C_1\|V\|^2_{L^2(\Gamma_t)}\|\kappa_s\|^2_{L^2(\Gamma_t)} + C_2(\delta^* + |\kappa^*|)\|V\|^2_{L^2(\Gamma_t)}\|\kappa_s\|_{L^2(\Gamma_t)}.
\end{aligned}$$

Since $\|V\|_{L^\infty(\Gamma_t)} \le C\|V_s\|_{L^2(\Gamma_t)}$ by virtue of (4.3), we derive $\|V\|_{L^2(\Gamma_t)} \le \widetilde{C}\|V_s\|_{L^2(\Gamma_t)}$. By means of this fact and $(-\lambda)\,(V, V)_{-1} \ge 0$, we are led to

$$\frac{d}{dt}\|\kappa_s\|^2_{L^2(\Gamma_t)} + \{2\mu^* - \widetilde{C}_1\|\kappa_s\|^2_{L^2(\Gamma_t)} - \widetilde{C}_2(\delta^* + |\kappa^*|)\|\kappa_s\|_{L^2(\Gamma_t)}\}\|V_s\|^2_{L^2(\Gamma_t)} \le 0. \tag{4.8}$$

Then we choose δ_1 such that

$$0 < \delta_1 < \min\left\{ \frac{\mu^*}{2\,\widetilde{C}_1}\,,\ \left(\frac{\mu^*}{2\,\widetilde{C}_2(\delta^* + |\kappa^*|)} \right)^2 \right\}.$$

Assuming $\|\kappa_s(t)\|^2_{L^2(\Gamma_t)} < \delta_1$ for $t \in (0, T]$, it follows that

$$\frac{d}{dt}\|\kappa_s(t)\|^2_{L^2(\Gamma_t)} + \mu^*\|V_s(t)\|^2_{L^2(\Gamma_t)} \le 0. \tag{4.9}$$

Integrating (4.9) with respect to t in the interval $[t_0, t]$, we derive the desired result. ∎

Now we arrive at the main result in this section.

THEOREM 4.8 (global existence). *Let Γ^* be a stationary curve such that the bilinear form I^* is positive. Also, let $\rho_0 \in C^{2+\alpha}(\mathcal{I})$ be a function describing a curve Γ_0, which is close to Γ^* as in section 2 and satisfies $\Gamma_0 \perp \partial\Omega$. Assume that a curve Γ_0 includes the same area as Γ^*. Then there exist constants $\gamma_0 > 0$ and $\delta_0 > 0$ such that if $\|\rho_0\|_{C^1(\mathcal{I})} < \gamma_0$ and $L[\Gamma_0] - L^* < \delta_0$, the problem (2.5) admits a unique global-in-time solution ρ with*

$$\|\rho(t)\|_{C^1(\mathcal{I})} < \gamma_0 \quad \text{and} \quad L[\Gamma_t] - L^* < \delta_0 \quad \text{for} \quad t \geq 0,$$

where Γ_t is the curve parameterized by $\Psi(\sigma, \rho(\sigma, t))$ in section 2.

Proof. Choose γ_0 and δ_0 satisfying

$$0 < \gamma_0 < \frac{\gamma^*}{2}, \quad 0 < \delta_0 < \frac{\delta_1^*}{2}, \tag{4.10}$$

where γ^* is as in Lemma 4.5 and δ_1^* is as in (4.7). Assume that the initial curve Γ_0 satisfies $\|\rho_0\|_{C^1(\mathcal{I})} < \gamma_0$ and $L[\Gamma_0] - L^* < \delta_0$. Then Lemma 4.5 and an embedding result imply that

$$\|\rho_0\|_{C^0(\mathcal{I})} \leq C(L[\Gamma_0] - L^*) < C\delta_0. \tag{4.11}$$

Further, Lemma 4.6(i) implies that for $t > 0$

$$L[\Gamma_t] - L^* \leq L[\Gamma_0] - L^* < \delta_0. \tag{4.12}$$

We now prove that $\|\kappa_s(t)\|^2_{L^2(\Gamma_t)} < \delta_1$ for each time t in the existence interval of the solution, where δ_1 is as in Proposition 4.7. Let $0 < \beta < \alpha < 1/2$. By Theorem 2.1, we can construct a unique local-in-time solution for $\rho_0 \in C^{2+\beta}(\mathcal{I})$ and obtain the estimate

$$\|\rho\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T_0}})} \leq K_0, \tag{4.13}$$

where K_0 is a constant, which depends on $\|\rho_0\|_{C^{2+\beta}(\mathcal{I})}$ increasingly, and T_0 is the local existence time, which depends on $1/\|\rho_0\|_{C^{2+\beta}(\mathcal{I})}$ increasingly (for details, see Appendix B). According to the interpolation inequality for Hölder spaces and (4.11), we have

$$\|\rho_0\|_{C^{2+\beta}(\mathcal{I})} \leq C(\|\rho_0\|_{C^0(\mathcal{I})})^{\frac{\alpha-\beta}{2+\alpha}}(\|\rho_0\|_{C^{2+\alpha}(\mathcal{I})})^{\frac{2+\beta}{2+\alpha}} \leq \widetilde{C}\delta_0^{\frac{\alpha-\beta}{2+\alpha}}. \tag{4.14}$$

Set $t_0 := \delta_0^{\frac{\alpha-\beta}{2+\alpha}} > 0$. Then it follows from (4.13), (4.14), and the definition of $\mathcal{Y}(\overline{\mathcal{Q}_{0,T_0}})$ that there exist $C > 0$ and $\nu > 0$ such that

$$\|\kappa_s(t_0)\|^2_{L^2(\Gamma_t)} \leq C\delta_0^\nu.$$

Since $\|\rho(t)\|_{C^1(\mathcal{I})}$ is continuous for $t \in [0, T_0]$, we see that $\|\rho(t)\|_{C^1(\mathcal{I})} < \gamma^*$ for $t \in [0, T]$ with a $T \in (0, T_0]$. Further, by (4.10) and (4.12), we have $L[\Gamma_t] - L^* < \delta_1^*$ for $t > 0$. Choose δ_0 such that $t_0 < T$ and $C\delta_0^\nu < \delta_1$. Then, by applying a similar argument to [10, Proof of Theorem 6.1] together with Proposition 4.7, we obtain that $\|\kappa_s(t)\|^2_{L^2(\Gamma_t)} < \delta_1$ for $t \in [t_0, T]$.

Next we prove that $\|\rho(t)\|_{C^1(\mathcal{I})} < \gamma_0$ for $t \in [t_0, T]$. By Lemma 4.5 and (4.12), it holds that for $t \in [0, T]$

$$\bar{c}\|\rho(t)\|_{H^1(\mathcal{I})} \le L[\Gamma_t] - L^* < \delta_0. \tag{4.15}$$

Then, by the embedding inequality and (4.15), we see that $\|\rho(t)\|_{C^0(\mathcal{I})} \le C\delta_0$ for $t \in [0, T]$. On the other hand, it follows from Lemma 4.3(ii) and Lemma 4.6(ii) that there exists $C > 0$ such that for $t \in [t_0, T]$

$$\|\kappa(t)\|_{C^0(\Gamma_t)} \le \|\kappa(t) - \kappa_{av}(t)\|_{C^0(\Gamma_t)} + |\kappa_{av}(t) - \kappa^*| + |\kappa^*| \le C(\delta_1 + \delta_0) + |\kappa^*|. \tag{4.16}$$

Thus, by virtue of (4.15), (4.16), and $\|\kappa_s(t)\|^2_{L^2(\Gamma_t)} < \delta_1$ for $t \in [t_0, T]$, we derive the boundedness of $\|\rho(t)\|_{H^3(\mathcal{I})}$ for $t \in [t_0, T]$, which implies the boundedness of $\|\rho(t)\|_{C^{2+\alpha}(\mathcal{I})}$ for $\alpha \in (0, 1/2)$. Then, by the interpolation inequality for Hölder spaces, we have

$$\|\rho(t)\|_{C^1(\mathcal{I})} \le C(\|\rho(t)\|_{C^0(\mathcal{I})})^{\frac{1+\alpha}{2+\alpha}}(\|\rho(t)\|_{C^{2+\alpha}(\mathcal{I})})^{\frac{1}{2+\alpha}} \le \widetilde{C}\delta_0^{\frac{1+\alpha}{2+\alpha}}$$

for $t \in [t_0, T]$. Choosing δ_0 such that $\widetilde{C}\delta_0^{\frac{1+\alpha}{2+\alpha}} < \gamma_0$, we obtain $\|\rho(t)\|_{C^1(\mathcal{I})} < \gamma_0$ for $t \in [t_0, T]$.

Finally, let us derive the existence of a unique global-in-time solution. Repeating the above argument until the local existence time T_0, we see that Γ_t satisfies

$$\|\rho(t)\|_{C^1(\mathcal{I})} < \gamma_0, \quad L[\Gamma_t] - L^* < \delta_0, \quad \|\kappa_s(t)\|^2_{L^2(\Gamma_t)} < \delta_1 \tag{4.17}$$

for $t \in [t_0, T_0]$. This implies that Γ_{T_0} satisfies the same conditions as those fulfilled by Γ_0 and the boundedness of $\|\rho(T_0)\|_{C^{2+\alpha}(\mathcal{I})}$ for $\alpha \in (0, 1/2)$ is guaranteed. Thus, due to Theorem 2.1, the solution of (2.5) can be extended over $t = T_0$ by a fixed amount of time. Further, by applying the same argument as we did in the first half of this proof, we have the estimates (4.17) for each time t in the extended existence interval of the solution. This procedure can be iterated as many times as we want, so that a unique global-in-time solution of (2.5) with $\rho(\cdot, 0) = \rho_0$ can be obtained. ∎

5. Stability of stationary curves. The following theorem shows nonlinear stability of the stationary curve Γ^* when the bilinear form I^* is positive.

THEOREM 5.1 (nonlinear stability). *Let the assumption of Theorem* 4.8 *hold. Then*

$$\|\rho(t)\|_{H^3(\mathcal{I})} \to 0 \quad \textit{as} \quad t \to \infty\,.$$

Proof. We apply a method similar to the one used in [10, Proof of Theorem 6.4]. By Lemma 4.1(i), we see that

$$\int_0^\infty \|\kappa_s(\tau)\|^2_{L^2(\Gamma_\tau)}\, d\tau \le L[\Gamma_0].$$

This implies that for any $\varepsilon \in (0, \delta_1)$ there exists a sufficiently large $t_\varepsilon > 0$ such that

$$\|\kappa_s(t_\varepsilon)\|^2_{L^2(\Gamma_t)} < \varepsilon.$$

According to the proof of Theorem 4.8, it holds that $\|\kappa_s(t)\|^2_{L^2(\Gamma_t)} < \delta_1$ as long as the solution exists. Thus, applying Proposition 4.7 for $t \in [t_\varepsilon, \infty)$, we have

$$\|\kappa_s(t)\|^2_{L^2(\Gamma_t)} + \mu^* \int_{t_\varepsilon}^t \|V_s(\tau)\|^2_{L^2(\Gamma_t)}\, d\tau \le \|\kappa_s(t_\varepsilon)\|^2_{L^2(\Gamma_t)} < \varepsilon.$$

This means that

$$\|\kappa_s(t)\|^2_{L^2(\Gamma_t)} \to 0 \quad \text{as} \quad t \to \infty. \tag{5.1}$$

By (5.1) and Lemma 4.3(ii), we also see that

$$\|\kappa(\cdot,t) - \kappa_{av}(t)\|_{C^0(\Gamma_t)} \to 0 \quad \text{as} \quad t \to \infty. \tag{5.2}$$

On the other hand, by virtue of Lemma 4.5 and Lemma 4.6(i), we obtain the boundedness of $\|\rho(t)\|_{H^1(\mathcal{I})}$. Using Lemma 4.6 and (5.2), we also have the boundedness of $\|\kappa(t)\|_{L^2(\Gamma_t)}$. Then the boundedness of $\|\rho(t)\|_{H^1(\mathcal{I})}$ and $\|\kappa(t)\|_{L^2(\Gamma_t)}$ imply the boundedness of $\|\rho(t)\|_{H^2(\mathcal{I})}$. Since it follows from the boundedness of $\|\rho(t)\|_{H^2(\mathcal{I})}$ and (5.1) that $\|\rho(t)\|_{H^3(\mathcal{I})}$ is bounded, there exists a sequence $\{t_n\}_{n\in\mathbb{N}}$ and $\widetilde{\rho}$ such that

$$\rho(t_n) \to \widetilde{\rho} \quad \text{in} \quad C^{2+\alpha}(\mathcal{I}) \quad \text{as} \quad n \to \infty.$$

By virtue of (5.2), $\widetilde{\rho}$ satisfies $\widetilde{\kappa} - \widetilde{\kappa}_{av} = 0$. The solution of the problem

$$\kappa = \kappa_{av}, \quad \sphericalangle(\Gamma, \partial\Omega) = \pi/2, \quad \text{Area}\,[\Gamma] = \text{Area}\,[\Gamma^*]$$

is unique in the C^0-neighborhood of Γ^* and given by $\rho \equiv 0$ (see Theorem 5.2). Since $\widetilde{\rho}$ is a solution of this problem, we obtain $\widetilde{\rho} \equiv 0$. In particular, we get

$$L[\Gamma_{t_n}] \to L[\Gamma^*] = L^* \quad \text{as} \quad n \to \infty.$$

We remark that Γ_{t_n} and Γ^* are the curves described by $\rho = \rho(t_n)$ and $\rho \equiv 0$ for the parameterization in section 2, respectively. Then, by the fact that $L[\Gamma_t]$ decreases in time, we obtain that

$$L[\Gamma_t] \to L^* \quad \text{as} \quad t \to \infty.$$

Applying Lemma 4.5, we have

$$\|\rho(t)\|^2_{H^1(\mathcal{I})} \to 0 \quad \text{as} \quad t \to \infty.$$

Hence, using this fact together with both (5.1) and (5.2), we obtain the desired result. □

It remains to prove the following result. We refer the reader to Grosse-Brauckmann [14] for a similar proof in the case of a different boundary condition.

THEOREM 5.2. *Let Γ^* be a stationary curve such that the bilinear form I^* is positive and let Γ be a curve described by ρ for the parameterization in section 2. Then there exists a C^2-neighborhood of Γ^* such that $\rho \equiv 0$ is the unique solution of the problem*

$$\kappa = \kappa_{av}\,, \quad \sphericalangle(\Gamma, \partial\Omega) = \pi/2\,, \quad \text{Area}\,[\Gamma] = \text{Area}\,[\Gamma^*]. \tag{5.3}$$

Proof. We use the following implicit function theorem (see Zeidler [24, Theorem 4.B]).

Suppose that the following hold:

(i) *The mapping $F : U(x_0, y_0) \subset X \times Y \to Z$ is defined on an open neighborhood $U(x_0, y_0)$ of (x_0, y_0), and $F(x_0, y_0) = 0$, where X, Y, and Z are Banach spaces over $\mathbb{R}$.*

(ii) *F_y exists as the partial Fréchet derivative on $U(x_0, y_0)$ and*

$$F_y(x_0, y_0) : Y \to Z$$

is bijective.

(iii) *F and F_y are continuous at (x_0, y_0).*

Then the following holds true: There exist positive numbers r_0 and r such that, for every $x \in X$ satisfying $\|x - x_0\| < r_0$, there is exactly one $y(x) \in Y$ for which $\|y(x) - y_0\| \le r$ and $F(x, y(x)) = 0$.

We use this theorem for

$$X := \{\rho \in C^2(\mathcal{I}) \mid \rho = \text{const.}\},$$

$$Y := \left\{\rho \in C^2(\mathcal{I}) \;\middle|\; \int_{l_-}^{l_+} \rho \, d\sigma = 0\right\},$$

$$Z := \left\{\rho \in C^0(\mathcal{I}) \;\middle|\; \int_{l_-}^{l_+} \rho \, d\sigma = 0\right\} \times \mathbb{R}^2$$

and

$$F(m, u) := \left(\kappa - \kappa_{av},\ \sphericalangle(\partial\Omega, \Gamma_t)_+ - \frac{\pi}{2},\ \sphericalangle(\partial\Omega, \Gamma_t)_- - \frac{\pi}{2}\right),$$

where κ is computed for the curve that we get by taking $\rho = u + m$ in section 2. The expression $\sphericalangle(\partial\Omega, \Gamma_t)_\pm$ denotes the angles with the outer boundary at the two boundary points. The derivative $F_u(0, 0)$ is (by a similar computation as in [13]) given by

$$F_u(0,0)(v)$$

$$= \left((\partial_\sigma^2 + \kappa^2)v - \frac{1}{l_+ - l_-}\int_{l_-}^{l_+} (\partial_\sigma^2 + \kappa^2)v \, d\sigma,\ (\partial_\sigma + h_+)v(l_+),\ (\partial_\sigma - h_-)v(l_-)\right).$$

The fact that I^* is positive implies that $F_u(0, 0)$ is invertible (using regularity theory for ODEs). Straightforward computations show that F and F_u are continuous at $(0, 0)$.

Hence, for $m \in X$ small, we find exactly one $u(m)$ such that

$$F(m, u(m)) = 0.$$

Let us define

$$\rho_m = u(m) + m$$

and let Γ_m be a curve described by ρ_m for the parameterization in section 2. Then we have

$$\text{Area}[\Gamma_m] = \text{Area}[\Gamma^*] + \int_{l_-}^{l_+} (u(m) + m) \, d\sigma + \mathcal{O}(\|u(m) + m\|^2_{C^2(\mathcal{I})})$$

$$= \text{Area}[\Gamma^*] + (l_+ - l_-)m + \mathcal{O}(\|u(m) + m\|^2_{C^2(\mathcal{I})}).$$

This implies that for $m \neq 0$

$$|\,\mathrm{Area}[\Gamma_m] - \mathrm{Area}[\Gamma^*]\,| \neq 0 \tag{5.4}$$

if $\|(m, u(m))\|_{C^2(\mathcal{I})}$ is small enough. We now represent a solution ρ of (5.3) with $\|\rho\|_{C^2(\mathcal{I})}$ small as $\rho = u + m$, where $u = \rho - \rho_{av}$ and $m = \rho_{av}$ with

$$\rho_{av} = \frac{1}{l_+ - l_-} \int_{l_-}^{l_+} \rho \, d\sigma.$$

Then we see that $F(m, u) = 0$. Due to the area-preserving property and (5.4), we obtain $m = 0$ and $u \equiv 0$, which implies that $\rho \equiv 0$. This proves the theorem. □

Appendix A. Proof of Theorem 2.1. The problem (2.5) is an initial boundary value problem for a quasi-linear parabolic PDE which has the form

$$\begin{cases} \rho_t = -\dfrac{1}{(J(\rho))^4}\,\partial_\sigma^4\rho + a(\rho, \partial_\sigma\rho, \partial_\sigma^2\rho)\,\partial_\sigma^3\rho + f(\rho, \partial_\sigma\rho, \partial_\sigma^2\rho) & \text{in} \quad \mathcal{Q}_{0,T}, \\ b_1(\rho)\partial_\sigma\rho + g_1(\rho) = 0 & \text{at} \quad \sigma = l_\pm, \\ b_2(\rho, \partial_\sigma\rho)\,\partial_\sigma^3\rho + g_2(\rho, \partial_\sigma\rho, \partial_\sigma^2\rho) = 0 & \text{at} \quad \sigma = l_\pm, \\ \rho|_{t=0} = \rho_0 & \text{in} \quad \mathcal{I}, \end{cases} \tag{A.1}$$

where a, f, b_i, and g_i $(i = 1, 2)$ are smooth functions with respect to ρ, $\partial_\sigma\rho$, and $\partial_\sigma^2\rho$; and g_i $(i = 1, 2)$ satisfy $\|g_1(t)\|_{C^0(\mathcal{I})} = \mathcal{O}(\|\rho(t)\|_{C^0(\mathcal{I})})$ and $\|g_2(t)\|_{C^0(\mathcal{I})} = \mathcal{O}(\|\rho(t)\|_{C^{2+\alpha}(\mathcal{I})})$ when $\|\rho\|_{C^{2+\alpha}(\mathcal{I})} \to 0$. In order to prove Theorem 2.1, we apply a fixed point argument. Let

$$\mathcal{D} := \{\rho \in \mathcal{Y}(\overline{\mathcal{Q}_{0,T}}) \mid \rho(\cdot, 0) = \rho_0,\ \|\rho\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})} \leq K\}$$

for positive constants K and T, and define a mapping $\mathcal{P}$ as

$$\mathcal{P} : \mathcal{D} \ni \bar{\rho} \mapsto \rho \in \mathcal{Y}(\overline{\mathcal{Q}_{0,T}}),$$

where ρ is the unique solution of the linearized problem

$$\begin{cases} \rho_t = \mathcal{A}\rho + F(\sigma, t) & \text{for} \quad (\sigma, t) \in \mathcal{Q}_{0,T}, \\ \mathcal{B}_1\rho = G_1(\sigma, t) & \text{at} \quad \sigma = l_\pm,\ t \in (0, T], \\ \mathcal{B}_2\rho = G_2(\sigma, t) & \text{at} \quad \sigma = l_\pm,\ t \in (0, T], \\ \rho(\sigma, 0) = \rho_0 & \text{for} \quad \sigma \in \mathcal{I}. \end{cases} \tag{A.2}$$

Here the linearized operators $\mathcal{A}$, $\mathcal{B}_1$, and $\mathcal{B}_2$ around the initial data $\rho_0 \in C^{2+\alpha}(\mathcal{I})$ are given by

$$\mathcal{A} = -\frac{1}{(J(\rho_0))^4}\,\partial_\sigma^4 + a(\rho_0, \partial_\sigma\rho_0, \partial_\sigma^2\rho_0)\,\partial_\sigma^3\,,$$
$$\mathcal{B}_1 = b_1(\rho_0)\,\partial_\sigma, \quad \mathcal{B}_2 = b_2(\rho_0, \partial_\sigma\rho_0)\,\partial_\sigma^3\,,$$

and for given $\bar{\rho} \in \mathcal{D}$

$$\begin{aligned}
F(\sigma,t) &= -\left\{ \frac{1}{(J(\bar{\rho}))^4} - \frac{1}{(J(\rho_0))^4} \right\} \partial_\sigma^4 \bar{\rho} \\
&\quad + \left\{ a(\bar{\rho}, \partial_\sigma \bar{\rho}, \partial_\sigma^2 \bar{\rho}) - a(\rho_0, \partial_\sigma \rho_0, \partial_\sigma^2 \rho_0) \right\} \partial_\sigma^3 \bar{\rho} \\
&\quad + f(\bar{\rho}, \partial_\sigma \bar{\rho}, \partial_\sigma^2 \bar{\rho}), \\
G_1(\sigma,t) &= -\left\{ b_1(\bar{\rho}) - b_1(\rho_0) \right\} \partial_\sigma \bar{\rho} - g_1(\bar{\rho}), \\
G_2(\sigma,t) &= -\left\{ b_2(\bar{\rho}, \partial_\sigma \bar{\rho}) - b_2(\rho_0, \partial_\sigma \rho_0) \right\} \partial_\sigma^3 \bar{\rho} - g_2(\bar{\rho}, \partial_\sigma \bar{\rho}, \partial_\sigma^2 \bar{\rho}).
\end{aligned}$$

The existence of a unique solution for the linearized problem (A.2) in $\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})$ is proved by applying the optimal regularity theory for analytic semigroups to the linearized problem (A.2) (see [18]). If the mapping $\mathcal{P}$ is a contraction on $\mathcal{D}$ for suitable constants K and T depending on $\|\rho_0\|_{C^{2+\alpha}(\mathcal{I})}$, $\mathcal{P}$ has a unique fixed point in $\mathcal{D}$ which is a unique solution of the nonlinear problem (A.1). Thus we show that the mapping $\mathcal{P}$ is a contraction on $\mathcal{D}$. In order to prove this fact, the following lemma is crucial.

LEMMA A.1. (i) *Assume that $\bar{\rho} \in \mathcal{D}$ and that ρ is a solution of the linearized problem* (A.2). *Then there exist positive constants M_0 and N such that*

$$\|\rho\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})} \le M_0 + NT^{\frac{\alpha}{4}}.$$

In particular, M_0 depends on $\|\rho_0\|_{C^{2+\alpha}(\mathcal{I})}$ increasingly, and N depends on K increasingly.

(ii) *Assume that $\bar{\rho}_1, \bar{\rho}_2 \in \mathcal{D}$ and that ρ_1, ρ_2 are solutions of the linearized problem* (A.2). *Then there exists a positive constant N such that*

$$\|\rho_1 - \rho_2\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})} \le NT^{\frac{\alpha}{4}} \|\bar{\rho}_1 - \bar{\rho}_2\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})}.$$

In particular, N depends on K increasingly.

A method to prove this lemma is to use the optimal regularity theory of analytic semigroups as in [18]. We prove this lemma in the next section.

Lemma A.1 implies that if we take

$$K = 2M_0, \quad T_0 = \min\left\{ \left(\frac{K}{2N} \right)^{4/\alpha}, \left(\frac{1}{2N} \right)^{4/\alpha} \right\},$$

it follows that for $T \le T_0$

$$\|\rho\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})} \le K, \quad \|\rho_1 - \rho_2\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})} \le \frac{1}{2} \|\bar{\rho}_1 - \bar{\rho}_2\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})}.$$

This means that $\mathcal{P}$ maps $\mathcal{D}$ into itself and is a contraction on $\mathcal{D}$ for $T \le T_0$. Thus the proof of Theorem 2.1 is completed.

Appendix B. Proof of Lemma A.1. We prove only Lemma A.1(i). Applying a similar argument, we can also derive Lemma A.1(ii). It is convenient to introduce the following estimate without proof.

LEMMA B.1 (see [18, section 2]). *For $k \in \mathbb{N}$, β_1, $\beta_2 \in (0,1)$, and a sectorial operator A, there exists a constant $C = C(k, \beta_1, \beta_2, A)$ such that*

$$\|t^{k-\beta_1+\beta_2} A^k e^{tA}\|_{L(D_A(\beta_1,\infty), D_A(\beta_2,\infty))} \le C \quad \text{for} \quad 0 < t \le 1. \tag{B.1}$$

The statement also holds for $k = 0$, provided that $\beta_1 \le \beta_2$.

Define $X := C(\mathcal{I})$ and

$$D(A) := \{u \in C^4(\mathcal{I}) \mid \mathcal{B}_1 u(l_\pm) = \mathcal{B}_2 u(l_\pm) = 0\}.$$

Then $A : X \supset D(A) \ni u \mapsto \mathcal{A}u \in X$ is the realization of $\mathcal{A}$ in X. It is known that A is a sectorial operator in X (see [21]).

Let ρ be a unique solution of the linearized problem (A.2). In order to reduce the inhomogeneous problem to a homogeneous problem at the boundaries, we introduce an auxiliary function ζ defined as

$$\zeta(\sigma,t) := \left\{ \frac{(\sigma - l_-)G_1(l_-,t)}{b_1(\rho_0)\big|_{\sigma=l_-}} + \frac{(\sigma-l_-)^3 G_2(l_-,t)}{3!\, b_2(\rho_0, \partial_\sigma \rho_0)\big|_{\sigma=l_-}} \right\} \eta(\sigma)$$

$$+ \left\{ \frac{(\sigma - l_+)G_1(l_+,t)}{b_1(\rho_0)\big|_{\sigma=l_+}} + \frac{(\sigma-l_+)^3 G_2(l_+,t)}{3!\, b_2(\rho_0, \partial_\sigma \rho_0)\big|_{\sigma=l_+}} \right\} \hat{\eta}(\sigma),$$

where η, $\hat{\eta} \in C^\infty(\mathcal{I})$ are cut-off functions satisfying

$$\begin{cases} \eta'(\sigma) < 0, \quad \hat{\eta}'(\sigma) > 0 & \text{for} \quad \sigma \in (l_- + L^*/4, l_+ - L^*/4), \\ \eta(\sigma) \equiv 1, \quad \hat{\eta}(\sigma) \equiv 0 & \text{for} \quad \sigma \in [l_-, l_- + L^*/4], \\ \eta(\sigma) \equiv 0, \quad \hat{\eta}(\sigma) \equiv 1 & \text{for} \quad \sigma \in [l_+ - L^*/4, l_+]. \end{cases}$$

Then it follows that $\rho - \zeta$ fulfills homogeneous boundary conditions. Since A is sectorial, we represent $\rho - \zeta$ with the help of a variant of the variation of constants formula and the analytic semigroup e^{tA}. By a simple computation, we obtain for $0 \le t \le T$

$$\rho(\cdot,t) = \rho_1(\cdot,t) + \rho_2(\cdot,t) + \rho_3(\cdot,t),$$

where

$$\rho_1(\cdot,t) = e^{tA}\{\rho_0 - \zeta(\cdot,0)\},$$

$$\rho_2(\cdot,t) = \int_0^t e^{(t-r)A}\{F(\cdot,r) + \mathcal{A}\zeta(\cdot,r)\}\, dr,$$

$$\rho_3(\cdot,t) = -A\int_0^t e^{(t-r)A}\{\zeta(\cdot,r) - \zeta(\cdot,0)\}\, dr + \zeta(\cdot,0).$$

Applying the theory of analytic semigroups as in [18], we have (see below)

$$\text{(B.2)} \qquad \begin{cases} \|\rho_1\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})} \le C_0 \, \|\rho_0 - \zeta(\cdot,0)\|_{D_A(\frac{2+\alpha}{4},\infty)}, \\ \|\rho_2\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})} \le C_0 \sup\limits_{0<\delta<T} \delta^{\frac{1}{2}} \sup\limits_{t\in[\delta,T]} \|F(\cdot,t) + \mathcal{A}\zeta(\cdot,t)\|_{D_A(\frac{\alpha}{4},\infty)}, \\ \|\rho_3\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})} \le C_0 + C_{0,K} T^{\frac{1}{4}}. \end{cases}$$

In particular, it is verified that a constant C_0 increases with $\|\rho_0\|_{C^{2+\alpha}(\mathcal{I})}$ and that a constant $C_{0,K}$ increases with $\|\rho_0\|_{C^{2+\alpha}(\mathcal{I})}$ and K. Once (B.2) is proven, it follows from characterization of interpolation spaces $D_A(\beta,\infty)$ (see, e.g., [1, 18, 19]) and

the definition of F that

$$\begin{aligned}\|\rho\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})} &\le \|\rho_1\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})} + \|\rho_2\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})} + \|\rho_3\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})}\\ &\le \widetilde{C}_0\|\rho_0 - \zeta(\cdot,0)\|_{C^{2+\alpha}(\mathcal{I})}\\ &\quad + \widetilde{C}_0 \sup_{0<\delta<T} \delta^{\frac{1}{2}} \sup_{t\in[\delta,T]} \|F(\cdot,t) + \mathcal{A}\zeta(\cdot,t)\|_{C^{\alpha}(\mathcal{I})}\\ &\quad + \widetilde{C}_0 + \widetilde{C}_{0,K}T^{\frac{1}{4}}\\ &\le M_0 + N_{0,K}T^{\frac{\alpha}{4}} + N_{0,K}T^{\frac{1}{4}},\end{aligned}$$

where $\widetilde{C}_0$ and M_0 depend on $\|\rho_0\|_{C^{2+\alpha}(\mathcal{I})}$ increasingly, and $\widetilde{C}_{0,K}$ and $N_{0,K}$ depend on $\|\rho_0\|_{C^{2+\alpha}(\mathcal{I})}$ and K increasingly. This completes the proof of Lemma A.1(i). Thus we give the proof of (B.2) in detail.

First let us explain about the estimates for ρ_1 and ρ_2. Using (B.1) with $k = 0$ and $\beta_1 = \beta_2 = (2+\alpha)/4$ to ρ_1, and with $k = 1$, $\beta_1 = (2+\alpha)/4$, and $\beta_2 = \alpha/4$ to $\partial\rho_1/\partial t = A\rho_1$, we are led to the estimate of ρ_1 easily. Since $F + \mathcal{A}\zeta \in L^\infty((0,T]; D_A(\frac{\alpha}{4},\infty))$, applying the same argument as [18, section 4.3.2] to ρ_2 in $[\varepsilon, T]$ ($\varepsilon \in (0,T)$), we have an estimate for ρ_2. Let us consider the estimate for ρ_3. Since ζ is less regular, we cannot derive the desired estimate for ρ_3 if we use only (B.1) to ρ_3 directly. Set

$$z(t) = \int_0^t e^{(t-r)A}\{\zeta(\cdot,r) - \zeta(\cdot,0)\}\,dr. \tag{B.3}$$

Then z satisfies

$$\rho_3(\cdot,t) = -Az(t) + \zeta(\cdot,0) = -\frac{d}{dt}z(t) + \zeta(\cdot,t),$$

$$\frac{d}{dt}\rho_3(\cdot,t) = -A\frac{d}{dt}z(t) = A\{\rho_3(\cdot,t) - \zeta(\cdot,t)\}.$$

This means that if we obtain the estimates for dz/dt, we have the desired estimates for ρ_3. In fact, the estimate for $\|\rho_3\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})}$ is given by

$$\begin{aligned}\|\rho_3\|_{\mathcal{Y}(\overline{\mathcal{Q}_{0,T}})} &\le \|\zeta(\cdot,0)\|_{C^{2+\alpha}(\overline{\mathcal{Q}_{0,T}})} + \|\zeta(\cdot,t) - \zeta(\cdot,0)\|_{C^{2+\alpha}(\overline{\mathcal{Q}_{0,T}})}\\ &\quad + \sum_{i=1}^{3} \sup_{0<t<T} t^{\frac{1}{2}}\|\mathcal{A}\zeta(\cdot,t)\|_{C^{\alpha}(\overline{\mathcal{Q}_{0,T}})}\\ &\quad + \widetilde{C}\Big(\|\dot{z}(t)\|_{D_A(\frac{2+\alpha}{4},\infty)} + \sup_{0<\delta<T}\delta^{\frac{1}{2}} \sup_{t\in[\delta,T]}\|A\dot{z}(t)\|_{D_A(\frac{\alpha}{4},\infty)}\Big).\end{aligned}$$

Here and hereafter we use $\dot{z}$ instead of dz/dt to simplify the notation. For the function z, we have the following estimates.

LEMMA B.2. *Let z be a function represented by* (B.3). *Then there exists a constant N, which depends on $\|\rho_0\|_{C^{2+\alpha}(\mathcal{I})}$, α, and K, such that*

$$\begin{cases} \|\dot{z}(t)\|_{D_A(\frac{2+\alpha}{4},\infty)} \le NT^{\frac{1}{4}},\\ \sup\limits_{0<\delta<T}\delta^{\frac{1}{2}} \sup\limits_{t\in[\delta,T]}\|A\dot{z}(t)\|_{D_A(\frac{\alpha}{4},\infty)} \le NT^{\frac{1}{4}}. \end{cases} \tag{B.4}$$

Proof. The proof of the first estimate of (B.4) is similar to arguments in [16, Appendix]. We prove only the second estimate of (B.4). For $t \geq \varepsilon$ with $\varepsilon \in (0,T)$, we have

$$\dot{z}(t) = e^{(t-\varepsilon/2)A}\dot{z}(\varepsilon/2) + \int_{\varepsilon/2}^{t} Ae^{(t-r)A}\{\zeta(\cdot,r) - \zeta(\cdot,t)\}\,dr + e^{(t-\varepsilon/2)A}\{\zeta(\cdot,t) - \zeta(\cdot,\varepsilon/2)\}.$$

This implies that

$$\begin{aligned}\|A\dot{z}(t)\|_{D_A(\frac{\alpha}{4},\infty)} \leq\ & \|Ae^{(t-\varepsilon/2)A}\dot{z}(\varepsilon/2)\|_{D_A(\frac{\alpha}{4},\infty)} \\ & + \left\| \int_{\varepsilon/2}^{t} A^2 e^{(t-r)A}\{\zeta(\cdot,r) - \zeta(\cdot,t)\}\,dr \right\|_{D_A(\frac{\alpha}{4},\infty)} \\ & + \|Ae^{(t-\varepsilon/2)A}\{\zeta(\cdot,t) - \zeta(\cdot,\varepsilon/2)\}\|_{D_A(\frac{\alpha}{4},\infty)} \\ =:\ & I_1(t) + I_2(t) + I_3(t).\end{aligned}$$

Let us first derive the estimate of $I_1(t)$. It follows that for $t \geq \varepsilon$

$$I_1(t) \leq C_0(t-\varepsilon/2)^{-\frac{\alpha}{4}}\|A\dot{z}(\varepsilon/2)\| \leq C_0(\varepsilon/2)^{-\frac{\alpha}{4}}\|A\dot{z}(\varepsilon/2)\|. \tag{B.5}$$

Thus it is necessary to obtain an estimate of $\|A\dot{z}(t)\|$. Since $\dot{z}(0) = 0$, we see that

$$\|A\dot{z}(t)\| \leq \int_0^t \|A^2 e^{(t-r)A}\{\zeta(\cdot,r) - \zeta(\cdot,t)\}\|\,dr + \|Ae^{tA}\{\zeta(\cdot,t) - \zeta(\cdot,0)\}\|.$$

We now recall the definition of ζ. Then we have to estimate each term. We show the estimate only for the term including the function

$$\hat{\zeta}(\sigma,t) := (\sigma - l_-)^3 G_2(l_-,t)\eta(\sigma).$$

The idea for the estimation of the other terms is similar. Set

$$J_1(t) := \int_0^t \|A^2 e^{(t-r)A}\{\hat{\zeta}(\cdot,\sigma) - \hat{\zeta}(\cdot,t)\}\|\,dr,$$

$$J_2(t) := \|Ae^{tA}\{\hat{\zeta}(\cdot,t) - \hat{\zeta}(\cdot,0)\}\|.$$

Let us derive the estimate of $J_1(t)$. For $t > r$ we have

$$\begin{aligned}&|G_2(\cdot,t) - G_2(\cdot,r)| \\ &\leq |b_2(\bar{\rho}(\cdot,t),\partial_\sigma\bar{\rho}(\cdot,t)) - b_2(\rho_0,\partial_\sigma\rho_0)||\partial_\sigma^3\bar{\rho}(\cdot,t) - \partial_\sigma^3\bar{\rho}(\cdot,r)| \\ &\quad + |b_2(\bar{\rho}(\cdot,t),\partial_\sigma\bar{\rho}(\cdot,t)) - b_2(\bar{\rho}(\cdot,r),\partial_\sigma\bar{\rho}(\cdot,r))||\partial_\sigma^3\bar{\rho}(\cdot,r)| \\ &\quad + |g_2(\bar{\rho}(\cdot,t),\partial_\sigma\bar{\rho}(\cdot,t),\partial_\sigma^2\bar{\rho}(\cdot,t)) - g_2(\bar{\rho}(\cdot,r),\partial_\sigma\bar{\rho}(\cdot,r),\partial_\sigma^2\bar{\rho}(\cdot,r))| \\ &\leq C_K\big\{t^{\frac{1+\alpha}{4}}\cdot r^{-\frac{1}{2}}(t-r)^{\frac{1+\alpha}{4}} + r^{-\frac{1}{2}}(t-r)^{\frac{3+\alpha}{4}}\cdot r^{-\frac{1}{4}} + r^{-\frac{1}{2}}(t-r)^{\frac{2+\alpha}{4}}\big\}.\end{aligned}$$

This fact and characterization of interpolation spaces $D_A(\beta,\infty)$ imply that

$$\begin{aligned}
J_1(t) &\le C_0 \int_0^t (t-r)^{\frac{3}{4}-2} \|(\sigma - l_-)^3 \eta\|_{D_A(\frac{3}{4},\infty)} |G_2(l_-,t) - G_2(l_-,r)|\, dr \\
&\le C_{0,K} \int_0^t (t-r)^{\frac{3}{4}-2} \big\{ t^{\frac{1+\alpha}{4}} \cdot r^{-\frac{1}{2}} (t-r)^{\frac{1+\alpha}{4}} \\
&\qquad + r^{-\frac{1}{2}} (t-r)^{\frac{3+\alpha}{4}} \cdot r^{-\frac{1}{4}} + r^{-\frac{1}{2}} (t-r)^{\frac{2+\alpha}{4}} \big\}\, dr \\
&\le C_{0,K,\alpha} \, (t^{\frac{1+\alpha}{4}} + t^{\frac{1}{4}} + t^{\frac{1}{4}})\, t^{\frac{\alpha}{4}-\frac{1}{2}} \\
&\le \widetilde{C}_{0,K,\alpha} \, (t^{\frac{1+\alpha}{4}} + t^{\frac{1}{4}})\, t^{\frac{\alpha}{4}-\frac{1}{2}}.
\end{aligned}$$

Applying the similar argument to $J_2(t)$, we are led to

$$\begin{aligned}
J_2(t) &\le C_0\, t^{\frac{3}{4}-1} \|(\sigma - l_-)^3 \eta\|_{D_A(\frac{3}{4},\infty)} |G_2(l_-,t) - G_2(l_-,0)| \\
&\le C_{0,K}\, t^{\frac{3}{4}-1} \, (t^{\frac{1+\alpha}{4}} \cdot K t^{-\frac{1}{4}} + t^{\frac{\alpha}{4}}) \\
&\le \widetilde{C}_{0,K}\, t^{\frac{1}{4}} \cdot t^{\frac{\alpha}{4}-\frac{1}{2}}.
\end{aligned}$$

Since the estimates for the other terms are also obtained similarly, we have

$$\|A\dot{z}(t)\| \le C_{0,K,\alpha} T^{\frac{1}{4}} \cdot t^{\frac{\alpha}{4}-\frac{1}{2}}.$$

It follows from (B.5) that

$$I_1(t) \le C_{0,K,\alpha} T^{\frac{1}{4}} \cdot (\varepsilon/2)^{-\frac{1}{2}}.$$

Let us derive the estimate for $I_2(t)$. Set

$$w(t) := \int_{\varepsilon/2}^t A^2 e^{(t-r)A} \{\zeta(\cdot,r) - \zeta(\cdot,t)\}\, dr.$$

In order to obtain the estimate of $\|w\|_{D_A(\frac{\alpha}{4},\infty)}$, we recall the definition of $\|\cdot\|_{D_A(\frac{\alpha}{4},\infty)}$. Since the estimate of $\|w\|$ is similar to that of $J_1(t)$, we consider only the estimate of the seminorm. According to the definition, we see that

$$\begin{aligned}
[w]_{D_A(\frac{\alpha}{4},\infty)} &= \sup_{0<\tau<1} \|\tau^{1-\frac{\alpha}{4}} A e^{\tau A} w\| \\
&\le \sup_{0<\tau<1} \tau^{1-\frac{\alpha}{4}} \int_{\varepsilon/2}^t \|A^3 e^{(t+\tau-r)A} \{\zeta(\cdot,r) - \zeta(\cdot,t)\}\|\, dr.
\end{aligned}$$

We show the estimate only for the term including $\hat{\zeta}(\sigma,t)$. In fact we obtain

$$
\begin{aligned}
&\tau^{1-\frac{\alpha}{4}} \int_{\varepsilon/2}^{t} \|A^3 e^{(t+\tau-r)A}\{\hat{\zeta}(\cdot,r)-\hat{\zeta}(\cdot,t)\}\|\,dr \\
&\le C_0\,\tau^{1-\frac{\alpha}{4}} \int_{\varepsilon/2}^{t} (t+\tau-r)^{\frac{3}{4}-3}\|(\sigma-l_-)^3\eta\|_{D_A(\frac{3}{4},\infty)}|G_2(l_-,t)-G_2(l_-,r)|\,dr \\
&\le C_{0,K}\,\tau^{1-\frac{\alpha}{4}} \int_{\varepsilon/2}^{t} (t+\tau-r)^{\frac{3}{4}-3}\{t^{\frac{1+\alpha}{4}}\cdot(\varepsilon/2)^{-\frac{1}{2}}(t-r)^{\frac{1+\alpha}{4}} \\
&\qquad\qquad + (\varepsilon/2)^{-\frac{1}{2}}(t-r)^{\frac{3+\alpha}{4}}\cdot r^{-\frac{1}{4}} + (\varepsilon/2)^{-\frac{1}{2}}(t-r)^{\frac{2+\alpha}{4}}\}\,dr \\
&\le C_{0,K}\,\tau^{1-\frac{\alpha}{4}} \int_{\varepsilon/2}^{t} (t+\tau-r)^{\frac{\alpha}{4}-2}\,dr\cdot(t^{\frac{1+\alpha}{4}}+t^{\frac{1}{4}})\cdot(\varepsilon/2)^{-\frac{1}{2}} \\
&\quad + C_{0,K}\,\tau^{1-\frac{\alpha}{4}} \int_{\varepsilon/2}^{t} (t+\tau-r)^{\frac{\alpha}{4}-2}\,(r-\varepsilon/2)^{-\frac{1}{4}}\,dr\cdot(t-\varepsilon/2)^{\frac{1}{2}}\cdot(\varepsilon/2)^{-\frac{1}{2}} \\
&\le C_{0,K,\alpha}\,\tau^{1-\frac{\alpha}{4}}\cdot\tau^{\frac{\alpha}{4}-1}\{T^{\frac{1}{4}}+(t-\varepsilon/2)^{\frac{1}{4}}\}\cdot(\varepsilon/2)^{-\frac{1}{2}} \\
&\le C_{0,K,\alpha}\,T^{\frac{1}{4}}\cdot(\varepsilon/2)^{-\frac{1}{2}}.
\end{aligned}
$$

As a consequence, we are led to

$$I_2(t) \le C_{0,K,\alpha}\,T^{\frac{1}{4}}\cdot(\varepsilon/2)^{-\frac{1}{2}}.$$

The estimate of $I_3(t)$ is omitted, since we can readily obtain it by using (B.1) together with the estimate of $|G_2(\cdot,t)-G_2(\cdot,r)|$.

Consequently, we have

$$\|A\dot{z}(t)\|_{D_A(\frac{\alpha}{4},\infty)} \le C_{0,K,\alpha}T^{\frac{1}{4}}\cdot\varepsilon^{-\frac{1}{2}} \quad \text{for} \quad \varepsilon \le t \le T.$$

This completes the proof of the second estimate of (B.4). □

DECAY ASYMPTOTICS OF THE VISCOUS CAMASSA–HOLM EQUATIONS IN THE PLANE*

CLAYTON BJORLAND†

Abstract. We consider the vorticity formulation of the two-dimensional viscous Camassa–Holm equations in the whole space. We establish global existence for solutions corresponding to initial data in L^1 and describe the large time behavior of solutions with sufficiently small and localized initial data. We calculate the rate at which such solutions approach an "unfiltered" Oseen vortex by computing the rate at which the solution of a scaled vorticity problem approaches the solution to a corresponding linearized equation.

1. Introduction.

The viscous Camassa–Holm equations (VCHE) are commonly written

$$\begin{aligned} v_t + u \cdot \nabla v + v \cdot (\nabla u)^T + \nabla p &= \triangle v, \\ H_\alpha^{-1}(u) = u - \alpha^2 \triangle u &= v, \\ \nabla \cdot u &= 0, \\ v(0) &= v_0. \end{aligned} \tag{1.1}$$

Here H_α is the Helmholtz operator with constant α defined by solving the PDE $u - \alpha^2 \triangle u = v$. This will be referred to as the *filter* associated with the VCHE. For a derivation of these equations from variational principles see [11] or [15]; for a derivation based on modifying the Navier–Stokes system see [7]. The significance of these equations is in the combination of a close relation to the famous Navier–Stokes equations and easily computable bounds on solutions. In particular, in dimensions 2–4, the VCHE admit smooth global solutions which satisfy a modified Kelvin circulation theorem where circulation is conserved around "loops" moving with the filtered flow. The filter is responsible for the smoothing effect on solutions, and the nonlinear term $v \cdot (\nabla u)^T$ brings the solution into compliance with the Kelvin circulation theorem. These solutions are well suited for numerical and analytic calculations and retain many properties displayed by solutions of the Navier–Stokes equations. For proofs of global existence and uniqueness in dimensions 2–4 see [2], [7], [8], [13], and [15]. Decay of energy and higher norms is considered in [2]. Numerical literature is outside the scope of this paper, and the reader is referred to [12] for a survey of the VCHE role in computational turbulence models and a more complete bibliography.

The relation between the VCHE and the Navier–Stokes equations is particularly visible in the vorticity form of the equations found by taking the curl ($\nabla \times v = \tilde{v}$) of

(1.1). In two dimensions the vorticity form is

$$\tilde{v}_t + u \cdot \nabla \tilde{v} = \triangle \tilde{v}, \tag{1.2}$$

$$B(H_\alpha(\tilde{v})) = u,$$

$$\tilde{v}(0) = \tilde{v}_0.$$

In the above equation, B represents convolution with the well-known Biot–Savart kernel which reconstructs the velocity from the vorticity; see (2.1). The aim of this paper is to further explore the relationship between solutions of the Navier–Stokes equation and the VCHE by describing the way a solution of (1.2) approaches the fixed point *zero*, i.e., computing the first and second order decay asymptotics for solutions with small initial data.

Similar study of the asymptotic behavior of the two-dimensional (2-D) vorticity equation for the Navier–Stokes equation can be found in [5], [9], and [10]. In [9] the asymptotics are calculated by applying invariant manifold techniques to the semiflow governing the vorticity problem. Their approach is to scale the vorticity problem into coordinates which are particularly well suited for studying the large time behavior of the Navier–Stokes equation and then apply the invariant manifold theorem in [6] to construct an invariant manifold in the phase space of the scaled problem and foliate the phase space locally, near the fixed point *zero*. The manifolds constructed give insight into the behavior of solutions near the fixed point, and, among other results, the authors calculate the asymptotics through the interaction and properties of these manifolds.

The close relation of the Navier–Stokes equations and the VCHE gives hope that a similar program may be carried out for the 2-D VCHE, especially when comparing the vorticity equations. In fact, such attempts are met with resistance from the filter in the VCHE. In a functional setting the filter eases problems by smoothing the solution, but in a dynamical setting such as this the filter adds complication to the problem. In particular, the filter does not scale well with the other parts of the equation, and the resulting nonlinear term has dependence on the scaled time variable not present in the case of the Navier–Stokes equations. This time dependence carries through into the semigroups generated by the scaled equation and complicates the invariant manifold construction. Specifically, the theorem in [6] cannot be applied. It is possible to add another equation to the system to express it in an autonomous form (does not depend explicitly on the scaled time variable), but the semigroup generated is still dependent on time and does not commute ($\Theta(s+t) \neq \Theta(s)\Theta(t)$). It is not immediately clear how to construct invariant manifolds with such a time dependence or even if such a structure exists.

The invariant manifold theorem in [6] is based on solving Lyapunov–Perron-type equations which are generated through recursive application of the semiflow. To work around the time dependence of this system we construct an infinite family of systems by stepping the original system forward in time a fixed length and work with the corresponding semigroups. These semigroups do not commute but can be composed to reconstruct the flow of the solution. Following in spirit [6] the semiflow generated by these systems is decomposed into a linear term, a nonlinear term for which we can find uniform Lipschitz bounds, and a forcing function which decays sufficiently fast. Applying this decomposition recursively we find a discrete Lyapunov–Perron-type system which is solvable in a rapidly decaying space. The existence of a solution to this discrete system implies decay properties of the difference system which in turn allow

us to compute the asymptotics we desire. Although the notion of invariant manifolds is lost we still retain enough structure to complete the asymptotic calculations. In essence we rework part of [6] with weaker hypotheses reflecting our situation. To calculate the decay of solutions we linearize the scaled VCHE around a fixed point sufficiently close to zero and determined by the initial data considered, subtract the linearized equation from the scaled one to get a system which measures distance from the linear solution, and apply the newly constructed decay theorem. This procedure, in theory, can be continued to arbitrary orders of asymptotics by considering sufficiently localized data. We consider only the cases where the governing ODEs are linear.

The work is based in large part on the work in [6] and [9]; this is reflected in the notation we use and the statements of many theorems. Following this introduction we introduce the majority of our notation and a few useful lemmas relating to the VCHE. Section 3 is dedicated to proving the existence and uniqueness of solutions to the vorticity problem in two dimensions. This section is somewhat based on the work in [1], where similar results were proved for the Navier–Stokes equations, but for us the work is simplified thanks to the smoothing properties of the filter in functional settings. In section 4 we introduce the scaled variables, prove bounds for solutions with these variables in weighted spaces, and discuss other properties of the scaled system. In this section we also discuss the linearized system and the action of the linear operator $\mathcal{L}$ (the scaled form of $\triangle$) on the weighted spaces. Section 5 contains the decay theorems based on the invariant manifold structure. Sections 6 and 7 hold the theorems and computations involving the first and second order asymptotic, respectively. The theorems in section 7 are very similar to section 6, and many are stated with little or no proof when they have nearly identical analogues in section 6. To end this introduction we state the main conclusions of this paper; proofs are contained in sections 3, 6, and 7, respectively. The spaces $L^2(m)$ are weighted spaces; see (2.2) below.

THEOREM 1.1. *Given initial conditions $\tilde{v}_0 \in L^1(\mathbb{R}^2)$, there exists a unique global solution $\tilde{v} \in L^\infty([0,\infty); L^1(\mathbb{R}^2))$ to the PDE* (1.2). *This solution satisfies the decay bound*

$$|\tilde{v}(t)|_q \leq Ct^{-(1-\frac{1}{q})}|\tilde{v}(0)|_1.$$

THEOREM 1.2. *For any $\mu \in (0, \frac{1}{2})$, there exists a $r_0 > 0$ so that for any initial data $\tilde{v}_0 \in L^2(2)$ with $\|\tilde{v}_0\|_2 \leq r_0$ the solution of* (1.2) *satisfies*

$$|\tilde{v}(\cdot,t) - a(\Omega(\cdot,t))|_p \leq C(1+t)^{-1-\mu+\frac{1}{p}},$$

where $a = \int_{\mathbb{R}^2} \tilde{v}_0\, dx$ and

$$\Omega(x,t) = \frac{1}{4\pi(1+t)} e^{\frac{-|x|^2}{4(1+t)}}.$$

THEOREM 1.3. *For any $\mu \in (\frac{1}{2}, 1)$, there exists a $r_0 > 0$ so that for any initial data $\tilde{v}_0 \in L^2(3)$ with $\|\tilde{v}_0\|_3 \leq r_0$ the solution of* (1.2) *satisfies*

$$|\tilde{v}(\cdot,t) - a(\Omega(\cdot,t) - \sum_{i=1,2} b_i(\partial_i \Omega(x,t)))|_p \leq C(1+t)^{-1-\mu+\frac{1}{p}},$$

where $b_i = \int x_i \tilde{v}_0\, dx$ and a, Ω are as in the previous theorem.

2. Notation and preliminaries. Throughout this paper we use $\mathbb{N}$ to refer to the natural numbers including 0. Standard Lebesgue spaces will be denoted $L^p(\mathbb{R}^2)$ or (L^p for short) with the norm $|\cdot|_p = (\int |\cdot|^p\,dx)^{1/p}$. Other Banach spaces defined within will use the norm $\|\cdot\|_X$.

To denote the curl of a vector field we use the tilde. For example, the curl of a vector field v is given by $\nabla \times v = \tilde{v}$. For a divergence-free vector field the curl can be undone through convolution with the well-known Biot–Savart kernel $x^\perp/(2\pi|x|^2)$, $x^\perp = (-x_2, x_1)^T$. We denote this convolution as

$$B(\tilde{w}) = \frac{1}{2\pi}\int_{\mathbb{R}^2} \frac{(x-y)^\perp}{|x-y|^2}\tilde{w}(y)\,dy \tag{2.1}$$

so that $B(\tilde{v}) = v$ for divergence-free vector fields.

We define $\langle\xi\rangle = (1+|\xi|^2)^{1/2}$ and make frequent use of the weighted Hilbert spaces $L^2(m)$ defined by

$$L^2(m) = \{f \in L^2(\mathbb{R}^2)|\ \|f\|_m < \infty \text{ and } \nabla\cdot f = 0\}, \tag{2.2}$$

$$\|f\|_m^2 = \int_{\mathbb{R}^2} \langle\xi\rangle^{2m}(\xi)|f(\xi)|^2\,d\xi.$$

The remaining part of this section contains bounds that will be useful later in the paper. To begin we recall a lemma from [9] concerning the Biot–Savart operator B defined by (2.1) and the curl of divergence-free vector fields.

LEMMA 2.1. *Let*

$$v = B(\tilde{v}) = \frac{1}{2\pi}\int_{\mathbb{R}^2} \frac{(x-y)^\perp}{|x-y|^2}\tilde{v}(y)\,dy.$$

(i) *If* $1 < p < 2 < q < \infty$, $\frac{1}{q} = \frac{1}{p} - \frac{1}{2}$, *and* $\tilde{v} \in L^p(\mathbb{R}^2)$, *then there exists a* $C > 0$ *such that* $|v|_q \le C|\tilde{v}|_p$.

(ii) *If* $1 \le p < 2 < q \le \infty$, $\frac{1}{2} = \frac{\alpha}{p} + \frac{(1-\alpha)}{q}$, *where* $\alpha \in (0,1)$, *and* $\tilde{v} \in L^p \cap L^q(\mathbb{R}^2)$, *then there exists a* $C > 0$ *such that* $|v|_\infty \le C|\tilde{v}|_p^\alpha|\tilde{v}|_q^{1-\alpha}$.

(iii) *If* $1 < p < \infty$ *and* $\tilde{v} \in L^p(\mathbb{R}^2)$, *then there exists a* $C > 0$ *such that* $|\nabla v|_p \le C|\tilde{v}|_p$

Proof. This is Lemma 2.1 in [9]. □

The following bounds for the heat kernel will also be useful in proving the existence of solutions in section 3.

LEMMA 2.2. *Let* Φ *be the fundamental solution to the heat equation. Then*

$$|\Phi(t)|_p \le \frac{C(n,p)}{t^{(1-\frac{1}{p})\frac{n}{2}}},$$

$$|\nabla\Phi(t)|_p \le \frac{C(n,p)}{t^{\frac{1}{2}+(1-\frac{1}{p})\frac{n}{2}}}.$$

Proof. By direct calculation

$$|\Phi(t)|_p^p = \frac{1}{(4\pi t)^{\frac{pn}{2}}}\int_{\mathbb{R}^n} e^{\frac{-p|x|^2}{4t}}\,dx = \frac{1}{p^{\frac{n}{2}}(4\pi t)^{\frac{(p-1)n}{2}}}.$$

This proves the first bound. For the second, start by differentiating the heat kernel and then take the L^p norm

$$|\nabla\Phi(t)|_p^p \leq \frac{C(n,p)}{t^{p(1+\frac{n}{2})}} \int_{\mathbb{R}^n} |x|^p e^{\frac{-p|x|^2}{4t}}\, dx.$$

A change of variables and integration now proves the second bound. □

We also recall some facts about the Helmholtz operator H_α.

LEMMA 2.3. *Let $v \in L^r(\mathbb{R}^n)$, $r \in [1,\infty)$. Then there exists a solution $u \in W^{1,r}(\mathbb{R}^n)$ to the Helmholtz equation*

$$H_\alpha^{-1}(u) = u - \alpha^2 \triangle u = v$$

which satisfies the bounds

$$|u|_p \leq |v|_p \ for\ p \in [1,\infty],$$

$$|u|_p \leq \frac{C(n,p,r)}{\alpha^{1+\gamma}} |v|_r \ for\ \gamma = \frac{n}{2}\left(\frac{1}{r} - \frac{1}{p}\right) < 1,$$

$$|\nabla u|_p \leq \frac{C(n,p,r)}{\alpha^{\frac{3}{2}+\gamma}} |v|_r \ for\ \gamma = \frac{n}{2}\left(\frac{1}{r} - \frac{1}{p}\right) < \frac{1}{2}.$$

Proof. This follows by standard elliptic theory. □

The last lemma in this section concerns the inclusion $L^2(m) \hookrightarrow L^1$ and will be useful in proving many estimates later in this paper.

LEMMA 2.4. *If $f \in L^2(m)$ for some $m > 1$, then $f \in L^q$ for $1 \leq q \leq 2$.*

Proof. The bound $|f|_2 \leq \|f\|_m$ is immediate from the definition of $L^2(m)$. Since $\langle\xi\rangle^{-m}$ is integrable in $\mathbb{R}^2$ if $m > 1$ we have $|f|_1 \leq C\|f\|_m$. Interpolation finishes the proof. □

3. Vorticity problem for the VCHE. This section contains proofs for the existence and uniqueness of solutions to the vorticity form of the VCHE (1.2) with data in $\tilde{v} \in L^1(\mathbb{R}^2)$. Decay of these solutions is provided by the optimal smoothing results in [4].

Instead of working directly with (1.2) we prove existence and uniqueness for the mild form of the PDE by solving the integral equation

$$\tilde{v}(t) = e^{\triangle t}\tilde{v}_0 - \int_0^t \nabla\Phi(t-s) * [B(H_\alpha(\tilde{v})) \otimes \tilde{v}](s)\, ds. \tag{3.1}$$

The corresponding result for the Navier–Stokes equation was proved in [1] using a fixed point argument in a subspace of L^1 and then extending the solution operator to L^1; see also [3] and [14]. This approach was necessary because it is difficult to write the Navier–Stokes equations such that a fixed point argument can be applied in L^1. In the case of the VCHE the filter provides enough leverage to apply a fixed point argument directly. We start by proving a bound on the bilinear term and then follow with the existence of a global solution.

LEMMA 3.1. *The bilinear form*

$$b(\tilde{v},\tilde{w}) : L^\infty([0,T],L^1(\mathbb{R}^2)) \times L^\infty([0,T],L^1(\mathbb{R}^2)) \to L^\infty([0,T],L^1(\mathbb{R}^2))$$

defined by

$$b(\tilde{v},\tilde{w}) = \int_0^t \nabla\Phi(t-s) * [B(H_\alpha(\tilde{v})) \otimes \tilde{w}](s)\, ds$$

satisfies the bound

$$\sup_{t\in[0,T]} |b(\tilde{v},\tilde{w})(t)|_1 \le C(T) \left(\sup_{t\in[0,T]} |\tilde{v}(t)|_1 \right) \left(\sup_{t\in[0,T]} |\tilde{w}(t)|_1 \right),$$

where $C(T) \to 0$ *as* $T \to 0$.

Proof. First apply Young's inequality and then Hölder's inequality to the bilinear form

$$|b(\tilde{v},\tilde{w})(t)|_1 \le \int_0^t |\nabla\Phi(t-s)|_1 |B(H_\alpha(\tilde{v}))(s)|_\infty |\tilde{w}(s)|_1\, ds.$$

Lemmas 2.1 and 2.3 give the bound $|B(H_\alpha(\tilde{v}))(s)|_\infty \le C|\tilde{v}(s)|_1$, so

$$|b(\tilde{v},\tilde{w})(t)|_1 \le C \int_0^t |\nabla\Phi(t-s)|_1\, ds \left(\sup_{s\in[0,t]} |\tilde{v}(t)|_1 \right) \left(\sup_{s\in[0,t]} |\tilde{w}(t)|_1 \right).$$

By Lemma 2.2, $|\nabla\Phi(t-s)|_1 \le C/\sqrt{t-s}$ and the right-hand side is integrable over finite intervals. Taking the supremum over $t \in [0,T]$ yields

$$\sup_{t\in[0,T]} |b(\tilde{v},\tilde{w})(t)|_1 \le CT^{\frac{1}{2}} \left(\sup_{t\in[0,T]} |\tilde{v}(t)|_1 \right) \left(\sup_{t\in[0,T]} |\tilde{w}(t)|_1 \right).$$

This estimate concludes the proof. □

THEOREM 3.2. *Given initial data* $\tilde{v}_0 \in L^1(\mathbb{R}^2)$ *there exists a unique global solution* $\tilde{v} \in L^\infty([0,\infty); L^1(\mathbb{R}^2))$ *to the integral equation* (3.1). *For any* $p \in [1,\infty]$, *this solution satisfies the decay bound*

$$|\tilde{v}(t)|_p \le Ct^{-(1-1/p)} |\tilde{v}(0)|_1. \tag{3.2}$$

Proof. Lemma 3.1 with a standard fixed point argument gives the existence of a mild solution in some possibly small time interval. The length of the time interval depends on the L^1 norm of the initial data. After applying the optimal smoothing results in [4] (see also [16]) the L^1 norm of the solution does not increase beyond the L^1 norm of the data which implies the existence of a global solution. Indeed, the vorticity equation for the VCHE is a viscously damped conservation law, so after applying Theorem 1 in [4] we establish (3.2). In particular, $|v(t)|_1 \le C|v(0)|_1$, which establishes global existence.

It remains to establish uniqueness. Let $\tilde{v}$ and $\tilde{w}$ be two solutions of (3.1) corresponding to the same initial data $\tilde{v}_0 \in L^1(\mathbb{R}^2)$. After adding and subtracting cross terms we see that

$$\begin{aligned}(\tilde{v}-\tilde{w})(t) = &- \int_0^t \nabla\Phi(t-s) * [B(H(\tilde{v},\alpha)) \otimes (\tilde{v}-\tilde{w})](s)\, ds \\ &+ \int_0^t \nabla\Phi(t-s) * [B(H((\tilde{v}-\tilde{w}),\alpha)) \otimes \tilde{w}](s)\, ds.\end{aligned}$$

Similar to the proof of Lemma 3.1, apply Lemmas 2.1 and 2.3 with Young's inequality:

$$|\tilde{v}(t)-\tilde{w}(t)|_1 \le C\int_0^t |\nabla\Phi(t-s)|_1(|\tilde{v}(s)|_1+|\tilde{w}(s)|_1)|\tilde{v}(s)-\tilde{w}(s)|_1\,ds.$$

Apply (3.2) to obtain

$$|\tilde{v}(t)-\tilde{w}(t)|_1 \le C|\tilde{v}_0|_1\int_0^t |\nabla\Phi(t-s)|_1|\tilde{v}(s)-\tilde{w}(s)|_1\,ds.$$

From here the Gronwall inequality with Lemma 2.2 is used to establish uniqueness and conclude the proof. □

This establishes Theorem 1.1.

4. The scaled equations. In this section we introduce scaled variables and rewrite the vorticity equation for the VCHE in these variables, preparing it for use with the theorems in section 5. An existence theorem for the scaled VCHE and related filter equations in the weighted spaces $L^2(m)$ is provided, and we discuss the action of the linear operator $\mathcal{L}$ (scaled Laplacian) on the weighted spaces $L^2(m)$.

The scaled variables are defined as

$$\xi = \frac{x}{\sqrt{1+t}}, \qquad \tau = \ln(1+t),$$

$$v(x,t) = \frac{1}{\sqrt{1+t}}w(\xi,\tau), \qquad u(x,t) = \frac{1}{\sqrt{1+t}}\omega(\xi,\tau),$$

$$\tilde{v}(x,t) = \frac{1}{1+t}\tilde{w}(\xi,\tau), \qquad \tilde{u}(x,t) = \frac{1}{1+t}\tilde{\omega}(\xi,\tau).$$

It has been shown in [5], [9], and [10] that these variables are very useful when studying the large time behavior of the Navier–Stokes equation in vorticity form. Under these variables the vorticity form of the VCHE (1.2) becomes

$$\tilde{w}_\tau = \mathcal{L}\tilde{w} - \omega\cdot\nabla_\xi\tilde{w}, \qquad \tilde{w}(0)=\tilde{w}_0, \tag{4.1}$$

$$\omega = B(\mathcal{H}_{\alpha,\tau}(\tilde{w})), \tag{4.2}$$

where B is again convolution with the Biot–Savart kernel as in (2.1), $\mathcal{L}$ is the linear operator $\mathcal{L}=\triangle_\xi+\frac{1}{2}\xi\cdot\nabla_\xi+I$, and $\mathcal{H}_{\alpha,\tau}$ is the operator defined by solving the scaled Helmholtz equation $\tilde{\omega}-\alpha^2e^{-\tau}\triangle_\xi\tilde{\omega}=\tilde{w}$.

The first goal of the section is to show how the filter $\mathcal{H}_{\alpha,\tau}$ acts on the weighted spaces $L^2(m)$; in particular we will show that the Helmholtz equation has a unique solution in these spaces.

LEMMA 4.1. *If $w\in L^2(m)$ and $\omega\in L^2(m)$ are related by the scaled Helmholtz equation $w=\omega-\alpha^2e^{-\tau}\triangle_\xi\omega$, then $\|\omega(\tau)\|_m^2\le C\|w(\tau)\|_m^2$. In the case $4m^2\alpha^2<1$, $C=1$; otherwise $C=2(1+2^{m-1}(4m^2\alpha^2)^m)$. This lemma shows how the operator $\mathcal{H}_{\alpha,\tau}:L^2(m)\to L^2(m)$ is bounded.*

Proof. The case of $m=0$ follows from the well-known linear elliptic theory; the bound is

$$\|w\|_0^2=\|\omega\|_0^2+2\alpha^2e^{-\tau}\|\nabla\omega\|_0^2+\alpha^4e^{-2\tau}\|\triangle\omega\|_0^2.$$

For $m > 0$ we proceed formally, noting that the following calculations can be applied to a dense set of smooth functions. First square the PDE and then multiply by $\langle\xi\rangle^{2m}$; after integration we have

$$\|w\|_m^2 = \|\omega\|_m^2 + \alpha^4 e^{-2\tau}\|\triangle\omega\|_m^2 - 2\alpha^2 e^{-\tau}\int_{\mathbb{R}^2}\langle\xi\rangle^{2m}\omega\triangle\omega\,d\xi.$$

Using integration by parts

$$\int_{\mathbb{R}^2}(1+|\xi|^2)^m\omega\triangle\omega\,d\xi = 2m\int_{\mathbb{R}^2}(\langle\xi\rangle^{2m-2} + (m-1)\langle\xi\rangle^{2m-4}|\xi|^2)\omega^2\,d\xi - \|\nabla\omega\|_m^2$$

leaves

$$\|w\|_m^2 = \|\omega\|_m^2 + \alpha^4 e^{-2\tau}\|\triangle\omega\|_m^2 + 2\alpha^2 e^{-\tau}\|\nabla\omega\|_m^2 - 4m\alpha^2 e^{-\tau}\|\omega\|_{m-1}^2 - 4m(m-1)\alpha^2 e^{-\tau}\||\xi|\omega\|_{m-2}^2.$$

The bound

$$-e^{-\tau}\langle\xi\rangle^{2m-4}(\langle\xi\rangle^2 + (m-1)|\xi|^2) \geq -2m\langle\xi\rangle^{2m}$$

shows that

$$\|w\|_m^2 \geq (1-4m^2\alpha^2)\|\omega\|_m^2 + \alpha^4 e^{-2\tau}\|\triangle\omega\|_m^2 + 2\alpha^2 e^{-\tau}\|\nabla\omega\|_m^2$$

and proves the result if $4m^2\alpha^2 < 1$.

If $4m^2\alpha^2 \geq 1$, set $\beta^2 = 8m^2\alpha^2 - 1$ so that for $|\xi| \geq \beta$ we have $\langle\xi\rangle^{2m} \geq 8m^2\alpha^2\langle\xi\rangle^{2m-2}$. If $B(\beta)$ is the ball with radius β,

$$-4m^2\alpha^2\int_{\mathbb{R}^2}\langle\xi\rangle^{2m-2}\omega^2\,d\xi \geq -4m^2\alpha^2(8m^2\alpha^2)^{m-1}\int_{B(\beta)}\omega^2\,d\xi - \frac{1}{2}\int_{B^C(\beta)}\langle\xi\rangle^{2m}\omega^2\,d\xi.$$

Applying the case $m = 0$ and the bound $\|\tilde{w}\|_2^2 \leq \|\tilde{w}\|_m^2$ allows

$$-\int_{B(\beta)}\omega^2\,d\xi \geq -\int_{\mathbb{R}^2}\omega^2\,d\xi \geq -\int_{\mathbb{R}^2}w^2\,d\xi \geq -\|w\|_m^2.$$

Also,

$$-\frac{1}{2}\int_{B^C(\beta)}\langle\xi\rangle^{2m}\omega^2\,d\xi \geq -\frac{1}{2}\|\omega\|_m^2.$$

Considering all of this leaves, in the case $4m^2\alpha^2 \geq 1$,

$$C\|w\|_m^2 \geq \frac{1}{2}\|\omega\|_m^2 + \alpha^4 e^{-2\tau}\|\triangle\omega\|_m^2 + 2\alpha^2 e^{-\tau}\|\nabla\omega\|_m^2, \tag{4.3}$$

where $C = 1 + 2^{m-1}(4m^2\alpha^2)^m$. □

The above proof is some indication that the filter is not well suited for the weighted spaces. There is still a smoothing effect, but as can be seen from (4.3) this effect decreases as τ becomes large.

THEOREM 4.2. *Given $w \in L^2(m)$, there exists a unique solution $\omega \in L^2(m)$ to the scaled Helmholtz equations $w = \omega - \alpha^2 e^{-\tau} \triangle_\xi \omega$. This proves that the operator $\mathcal{H}_{\alpha,\tau} : L^2(m) \to L^2(m)$ is well defined.*

Proof. The rough estimate $\langle \xi \rangle^{2m} > 1$ implies $L^2(m) \subset L^2(0)$, so if $w \in L^2(m)$, it is well known that there is a unique $\omega \in L^2(0)$ solving the equation. Lemma 4.1 shows that $\omega \in L^2(m)$. ∎

We now turn our attention to the scaled VCHE. Using the strongly continuous semigroup $e^{\tau \mathcal{L}}$ generated by $\mathcal{L}$ in $L^2(m)$ (see the appendix of [9]) we write the mild form of the scaled vorticity problem:

$$\tilde{w}(\tau) = e^{\tau \mathcal{L}} \tilde{w}_0 - \int_0^\tau e^{-\frac{1}{2}(\tau - s)} \nabla \cdot e^{(\tau - s)\mathcal{L}} (\omega(s) \tilde{w}(s))\, ds, \tag{4.4}$$

$$\tilde{\omega} = \mathcal{H}_{\alpha,\tau}(\tilde{w}).$$

The following lemma, based on Lemma 3.1 in [9], provides an estimate on the bilinear form which will be used to prove the existence of a local solution to (4.4).

LEMMA 4.3. *Given $\tilde{w}_1, \tilde{w}_2 \in C^0([0,T]; L^2(m))$, define*

$$R(\tilde{w}_1, \tilde{w}_2)(\tau) = \int_0^\tau e^{-\frac{1}{2}(\tau - s)} \nabla \cdot e^{(\tau - s)\mathcal{L}} (\omega_1(s) \tilde{w}_2(s))\, ds,$$

where $\omega_1 = w_1 - \alpha^2 e^{-\tau} \triangle w_1$ and w_1 is obtained from $\tilde{w}_1$ via the Biot–Savart law. Then $R \in C^0([0,T], L^2(m))$, and there exists $C_0 = C_0(m,T) > 0$ such that

$$\sup_{0 \le \tau \le T} \|R(\tilde{w}_1, \tilde{w}_2)(\tau)\|_m \le C_0 \left(\sup_{0 \le \tau \le T} \|\tilde{w}_1(\tau)\|_m \right) \left(\sup_{0 \le \tau \le T} \|\tilde{w}_2(\tau)\|_m \right).$$

Moreover, the constant C_0 becomes arbitrarily small as T tends to zero.

Proof. We rely on an estimate of the semigroup $e^{\tau \mathcal{L}}$ proved in the appendix of [9]; if $r \in (\frac{2}{m+1}, 2)$, then

$$|\langle \xi \rangle^m \nabla \cdot e^{\tau \mathcal{L}} u|_2 \le \frac{C}{a(\tau)^{(\frac{1}{r} - \frac{1}{2}) + \frac{1}{2}}} |\langle \xi \rangle^m u|_r,$$

where $a(\tau) = 1 - e^{-\tau}$. This allows

$$|\langle \xi \rangle^m R(\tilde{w}_1, \tilde{w}_2)(\tau)|_2 \le C \int_0^\tau \frac{1}{a(\tau - s)^{\frac{1}{r}}} |\langle \xi \rangle^m \omega_1(s) \tilde{w}_2(s)|_r\, ds.$$

Hölder's inequality, Lemma 2.1, and the inclusion $L^2(m) \hookrightarrow L^r(\mathbb{R}^2)$ provide the bound $|\langle \xi \rangle^m \omega_1(s) \tilde{w}_2(s)|_r \le C \|\tilde{w}_2\|_m \|\tilde{\omega}_1\|_m$. Apply Lemma 4.1 and note that $a(\tau - s)^{-1/r}$ is integrable from 0 to τ to finish the proof. ∎

In addition to providing existence and uniqueness the following theorem shows how we can control the $L^2(m)$ norm of a solution to the integral equation (4.4) by controlling the $L^2(m)$ norm of the initial data. Our proof is modeled after the proof of Theorem 3.2 in [9].

THEOREM 4.4. *Given $\tilde{w}_0 \in L^2(m)$ for some $m > 1$, there exists a global solution $\tilde{w} \in C^0([0,\infty), L^2(m))$ to the integral equation (4.4) with $\tilde{w}(0) = \tilde{w}_0$. Moreover, there exists a constant $C_1 = C_1(\|\tilde{w}_0\|_m)$ such that*

$$\|\tilde{w}(\tau)\|_m \le C_1 \tag{4.5}$$

and $C_1 \to 0$ as $\|\tilde{w}_0\|_m \to 0$.

Proof. The previous lemma and a fixed point argument give local in time existence of a unique solution. Moreover, there exists a $T > 0$ such that

$$\sup_{0\le\tau\le T} \|\tilde{w}(\tau)\|_m \le 2\|\tilde{w}_0\|_m. \tag{4.6}$$

By scaling (3.2) and using the fact that $L^2(m) \hookrightarrow L^1$ for $m > 1$ we see that this solution satisfies, for all $p \in [1,\infty]$,

$$|\tilde{w}(\tau)|_p \le \frac{C_p\|\tilde{w}(0)\|_m}{a(\tau)^{1-\frac{1}{p}}}. \tag{4.7}$$

We will now establish (4.5), which will imply global in time existence. Multiplying (4.1) by $\langle\xi\rangle^{2m}\tilde{w}$ and integrating we find that

$$\frac{1}{2}\frac{d}{d\tau}\int_{\mathbb{R}^2}\langle\xi\rangle^{2m}\tilde{w}^2\,d\xi = \int_{\mathbb{R}^2}\langle\xi\rangle^{2m}NL(\tilde{w})\,d\xi,$$

$$NL(\tilde{w}) = \tilde{w}\triangle\tilde{w} + \frac{\tilde{w}}{2}(\xi\cdot\nabla)\tilde{w} + \tilde{w}^2 - \tilde{w}(\omega\cdot\nabla)\tilde{w}.$$

Integration by parts and the bound $|\xi| \le \langle\xi\rangle$ give the following estimates:

$$\int_{\mathbb{R}^2}\langle\xi\rangle^{2m}\tilde{w}\triangle\tilde{w}\,d\xi \le -\int_{\mathbb{R}^2}\langle\xi\rangle^{2m}\nabla\tilde{w}^2\,d\xi + 2m^2\int_{\mathbb{R}^2}\langle\xi\rangle^{2m-2}\tilde{w}^2\,d\xi,$$

$$\frac{1}{2}\int_{\mathbb{R}^2}\langle\xi\rangle^{2m}\tilde{w}(\xi\cdot\nabla\tilde{w}) = -\frac{1}{2}\int_{\mathbb{R}^2}\langle\xi\rangle^{2m}\tilde{w}^2\,d\xi - \frac{1}{2}m\int_{\mathbb{R}^2}\langle\xi\rangle^{2m-2}|\xi|^2\tilde{w}^2\,d\xi$$

$$-\int_{\mathbb{R}^2}\langle\xi\rangle^{2m}\tilde{w}(\omega\cdot\nabla)\tilde{w}\,d\xi = m\int_{\mathbb{R}^2}\langle\xi\rangle^{2m-2}(\xi\cdot\omega)\tilde{w}^2\,d\xi.$$

Furthermore, given $\epsilon > 0$, there exists a $C_\epsilon > 0$ such that

$$\langle\xi\rangle^{2m-2} \le \epsilon\langle\xi\rangle^{2m} + C_\epsilon$$

and we can bound

$$2m^2\int_{\mathbb{R}^2}\langle\xi\rangle^{2m-2}\tilde{w}^2\,d\xi \le \epsilon\int_{\mathbb{R}^2}\langle\xi\rangle^{2m}\tilde{w}^2\,d\xi + C_\epsilon\int_{\mathbb{R}^2}\tilde{w}^2\,d\xi.$$

Similarly,

$$m\int_{\mathbb{R}^2}\langle\xi\rangle^{2m-2}(\xi\cdot\omega)\tilde{w}^2\,d\xi \le \epsilon\int_{\mathbb{R}^2}\langle\xi\rangle^{2m}\tilde{w}^2\,d\xi + C_\epsilon|\omega|_\infty^{2m}\int_{\mathbb{R}^2}\tilde{w}^2\,d\xi.$$

Putting these bounds together yields

$$\frac{1}{2}\frac{d}{d\tau}\int_{\mathbb{R}^2}\langle\xi\rangle^{2m}\tilde{w}^2\,d\xi \le -\left(\frac{1}{2}-2\epsilon\right)\int_{\mathbb{R}^2}\langle\xi\rangle^{2m}\tilde{w}^2\,d\xi + C_\epsilon(1+|\omega|_\infty^{2m})\int_{\mathbb{R}^2}\tilde{w}^2\,d\xi.$$

Write $\delta = \frac{1}{2} - 4\epsilon$; then

$$\frac{d}{d\tau}\left(e^{\delta\tau}\int_{\mathbb{R}^2}\langle\xi\rangle^{2m}\tilde{w}^2\,d\xi\right) \le C_\epsilon e^{\delta\tau}(1+|\omega|_\infty^{2m})\int_{\mathbb{R}^2}\tilde{w}^2\,d\xi.$$

This inequality implies (4.5), provided

$$\sup_{0\le\tau\le\infty}\left((1+|\omega|_\infty^{2m})\int_{\mathbb{R}^2}\tilde{w}^2\,d\xi\right) \le C(\|\tilde{w}_0\|_m), \tag{4.8}$$

where $C(\|\tilde{w}_0\|_m)\to 0$ as $\|\tilde{w}_m\|_m\to 0$. We now establish this estimate.

When T is such that (4.6) holds, estimate (4.7) with $p=\infty$ and then $p=2$ implies (4.8) when the supremum is taken over $\tau\in[T,\infty)$. When $\tau\le T$, Lemmas 2.1 and 2.3 provide the bound $|\omega(\tau)|_\infty \le C(T)|\tilde{w}(\tau)|_2$; with (4.6) this implies $(1+|\omega(\tau)|_\infty)\le C(T)\|\tilde{w}_0\|_m$ for all $\tau\le T$. In addition (4.6) implies $|\tilde{w}(\tau)|_2\le C(\|\tilde{w}_0\|_m)$ when $\tau\le T$. This concludes the proof. ∎

We spend the remaining portion of this section recalling facts about the operator on the spaces $L^2(m)$ useful to our discussion. The operator $\mathcal{L}$ is studied closely in the appendix of [9], and the reader is referred there for proofs of the statements which are not immediate.

The spectrum of $\mathcal{L}$ in the space $L^2(m)$ is

$$\sigma(\mathcal{L}) = \left\{\lambda\in\mathbb{C}|Re(\lambda)\le\frac{1-m}{2}\right\}\cup\left\{-\frac{k}{2}|k\in\mathbb{N}\right\}.$$

The operator $\mathcal{L}$ generates a strongly continuous semigroup $e^{\tau\mathcal{L}}$ on the space $L^2(m)$. The spectrum of $\mathcal{L}$ acting on $L^2(m)$ has $m-1$ isolated eigenvalues $\lambda_j=\frac{-j}{2}$ for $0\le j\le m-2$. This allows a spectral decomposition that we will use throughout the remaining parts.

Definition 4.5. *Let $X_1^m\subset L^2(m)$ be the finite subspace spanned by the eigenvectors associated with the eigenvalues λ_j, $0\le j\le m-2$, and $X_2^m = L^2(m)-X_1$. Define P_1^m as the spectral projection onto X_1^m and P_2^m the projection onto X_2^m.*

Note that P_1^m and P_2^m are guaranteed to exist because X_1^m and X_2^m are closed subspaces of the Hilbert space $L^2(m)$.

Lemma 4.6. *The projections P_1^m and P_2^m defined above satisfy the following bounds for $\tilde{w}\in L^2(m)$:*

$$\|(e^{\mathcal{L}}P_1^m)^{-j}w\|_m \le C_1 e^{\frac{j(m-2)}{2}}\|w\|_m,$$

$$\|(H_{\alpha,\tau}e^{\mathcal{L}}P_2^m)^j w\|_m \le C_2 e^{\frac{-j(m-1)}{2}}\|w\|_m.$$

Proof. This follows from the definitions of the projections. ∎

Of particular interest to us are the first two eigenvalues and the associated eigenvectors.

DEFINITION 4.7. *The first two eigenvalues of $\mathcal{L}$ acting on $L^2(m)$ are $\lambda_0 = 1$ and $\lambda_1 = \frac{-1}{2}$. For the single eigenvector associated with λ_0 we write $G(\xi) = \frac{1}{4\pi} e^{\frac{-|\xi|}{4}}$. For the two eigenvalues associated with λ_2 we write $F_i = \partial_i G(\xi) = -\frac{\xi}{2} G(\xi)$, $i = 1, 2$.*

The eigenvalue G is the scaled "Oseen vortex" and plays an important role in studying the Navier–Stokes system in two dimensions. It is a stationary solution of the scaled PDE, a fact that is easily checked by finding the associated velocity field (v^G) with the Biot–Savart kernel and computing $v^G \cdot \nabla G = 0$. For reference,

$$v^G(\xi) = \frac{1}{2\pi} \frac{1 - e^{\frac{-|\xi|^2}{4}}}{|\xi|^2} |\xi|^{-2} \begin{pmatrix} -\xi_2 \\ \xi_1 \end{pmatrix}.$$

In the scaled VCHE a similar statement is true when we consider G as the filtered and scaled vorticity; this suggests that in describing the behavior of solutions we will also need to consider the following "unfiltered" eigenvectors.

DEFINITION 4.8.

$$\Gamma(\xi, \tau) = G(\xi) - \alpha^2 e^{-\tau} \triangle G(\xi),$$

$$\Lambda_i(\xi, \tau) = F_i(\xi) - \alpha^2 e^{-\tau} \triangle F_i(\xi).$$

Through straightforward calculations one can check that

$$v^G \cdot \nabla \Gamma = 0, \qquad \partial_\tau \Gamma = \mathcal{L}\Gamma = \alpha^2 e^{-\tau} \triangle \Gamma.$$

It is then clear that Γ is a solution of the VCHE. This solution is stationary from the perspective of the filtered flow ω and plays a similar role as G in the Navier–Stokes equations.

By linearizing the PDE (4.1) about the "fixed" point $a\Gamma$ ($a \in \mathbb{R}$) we obtain

$$\tilde{\psi}_\tau = \mathcal{L}\tilde{\psi} - a\eta \cdot \nabla \Gamma - a v^G \cdot \nabla \tilde{\psi}, \qquad \tilde{\psi}(0) = \tilde{\psi}_0, \tag{4.9}$$

$$\eta = B(\mathcal{H}_{\alpha,\tau}(\tilde{\psi})).$$

This linear PDE has strong global solutions, a fact which can be established following the steps in Theorem 4.4; the proof will be omitted here. Note that $a\Gamma$ is a solution to (4.9).

Letting v^{F_i} denote the velocity field associated with F_i, two other important relations are

$$v^{F_i} \cdot \nabla \Gamma + v^G \cdot \nabla \Lambda_i = 0, \qquad \partial_t \Lambda_i - \mathcal{L}\Lambda_i + \frac{1}{2}\Lambda_i = 0.$$

The first is quickly checked by differentiating the relation $v^G \cdot \nabla \Gamma = 0$, and the second can be checked directly. Together, these show that $a\Gamma + b_1 e^{\frac{-\tau}{2}} \Lambda_1 + b_2 e^{\frac{-\tau}{2}} \Lambda_2$ is a solution to the linearized equation (4.9).

Subtracting (4.9) from (4.1) we find that

$$(\tilde{w} - \tilde{\psi})_\tau = \mathcal{L}(\tilde{w} - \tilde{\psi}) - \omega \cdot \nabla(\tilde{w} - \tilde{\psi}) - (\omega - a v^G) \cdot \nabla \tilde{\psi} + a\eta \cdot \nabla \Gamma. \tag{4.10}$$

This system will be studied in the final sections as the foundation for our asymptotic results.

5. Semigroup theorems. This section contains theorems on collections of semigroups which will be used in the following section to prove our decay results. These theorems are based on the Lyapunov–Perron approach of constructing invariant manifolds in [6] but uses relaxed hypotheses. In particular we allow for the treatment of semigroups which may be time dependent and therefore noncommutative. As our hypotheses are relaxed we are not able to fully construct invariant manifolds. This section instead culminates with a decay theorem.

Unless otherwise specified, in this section let X denote a Hilbert space with norm $\|\cdot\|_X$ and $\{\Theta_n(f,\tau)\}$ a collection of semigroups which map X into itself. That is, each $\Theta_n : X \times \mathbb{R}^+ \to X$ is a semigroup. The idea we will keep in the back of our mind is a noncommutative semigroup $\Theta(\cdot,t)$, where $\Theta_n(\cdot,\tau)$ is the action of the semigroup when $t = n + \tau$. The semigroup Θ can then be reconstructed by composing the semigroups Θ_n. Indeed, if $t = n + \tau$, then

$$\Theta(f,t) = \Theta_n(\Theta_{n-1}(\cdots\Theta_2(\Theta_1(f,1),1),1),\tau).$$

Conversely we make a definition for a natural flow through the collection.

DEFINITION 5.1. *If $\{\Theta_n(f,\tau)\}$ is a collection of semigroups which, for each $\tau \in [0,1]$, map X into itself, we call the function $\Theta : X \times \mathbb{R}^+ \to X$ defined by*

$$\Theta(f,t) = \Theta_n(\Theta_{n-1}(\cdots\Theta_2(\Theta_1(f,1),1),1),\tau),$$

where $t = n + \tau$ and $\tau \in [0,1)$, the natural flow *of the collection through f.*

That $\Theta(f,t)$ is well defined for each f follows from the well-defined properties of each Θ_n.

Throughout this section we assume the following uniform conditions on the collection of semigroups; these conditions are relaxations of (H.1)–(H.4) in [6].

(H.1) Define $Lip(\Theta(\cdot,t)) := \sup_n Lip(\Theta_n(\cdot,t))$. Each $\Theta_n(f,t)$ is continuous in $(f,t) \in X \times [0,1]$ and

$$\sup_{0\le t\le 1} Lip(\Theta(\cdot,t)) = D < \infty.$$

(H.2) Each $\Theta_n(f,1)$ can be decomposed as $\Theta_n(\cdot,1) = L + R_n + S_n$, where $L : X \to X$ is a bounded linear operator, each $R_n : X \to X$ is a global Lipschitz map satisfying $R_n(0) = 0$, and $S_n \in X$.

(H.3) There are subspaces X_i, $i = 1,2$, of X and continuous projections P_i, $i = 1,2$, such that $P_1 + P_2 = I$, $X_1 \oplus X_2 = X$. L leaves X_i invariant and commutes with P_i, $i = 1,2$. Denoting by $L_i : X_i \to X_i$ the restriction of L on X_i, L_1 has bounded inverse and there exist constants $\alpha_1 > \alpha_2 \ge 0$, C_1, and C_2 such that

$$|L_1^{-k}P_1| \le C_1\alpha_1^{-k},$$

$$|L_2^{k}P_1| \le C_1\alpha_1^{k}.$$

We will also write L_i for LP_i when there is no confusion.

(H.4) Define $Lip(R) := \sup_n Lip(R_n)$. Let α_1 and α_2 be as in (H.3); there exists $\alpha_1 > \gamma_1 > \gamma_2 > \alpha_2$ such that the R_n satisfy

$$\frac{C_1}{\alpha_1 - \gamma} + \frac{C_2}{\gamma - \alpha_2} < \frac{1}{Lip(R)}$$

for all $\gamma \in (\gamma_2, \gamma_1)$.

(H.5) With α_1 as in (H.3), S_n satisfies

$$\limsup_{n\to\infty} \frac{1}{n} \ln \|S_n\|_X < \ln \alpha_1.$$

DEFINITION 5.2. *We call a sequence* $\{f_n\}_{n\in\mathbb{N}} \subset X$ *a* discrete positive semiorbit *of* $\{\Theta_n\}$ *through* f_0 *if it satisfies the relation* $f_n = Lf_{n-1} + R_{n-1}(f_{n-1}) + S_{n-1}$ *for all* $n \geq 1$.

For a given initial position $f_0 \in X$ we find the discrete positive semiorbit $\{f_n\}_{n\in\mathbb{N}}$ it generates using this definition recursively:

$$f_n = L^n f_0 + \sum_{j=0}^{n-1} L^{n-j-1}(R_j(f_j) + S_j). \tag{5.1}$$

We now prove a lemma based on Lemma 3.3 from [6] which will provide a link between the semiflows $\{\Theta_n\}$ and a discrete Lyapunov–Perron system.

LEMMA 5.3. *We assume conditions* (H.1)–(H.5) *are satisfied. Let* $\{f_n\}_{n\in\mathbb{N}} \subset X$ *satisfy*

$$\limsup_{n\to\infty} \frac{1}{n} \ln \|f_n\|_X < \ln \alpha_1. \tag{5.2}$$

Then the sequence $\{f_n\}_{n\in\mathbb{N}}$ *is a positive semiorbit of* $\{\Theta_n\}$ *if and only if it satisfies, for all* $n \in \mathbb{N}$,

$$f_n = L_2^n f_0 - \sum_{n\leq j} L_1^{(n-j-1)}(R_j(f_j) + S_j) + \sum_{0\leq j<n} L_2^{(n-j-1)}(R_j(f_j) + S_j). \tag{5.3}$$

Proof. Using the iterative relation (5.1) with the projection P_2 shows that

$$P_2 f_n = L_2^n f_0 + \sum_{0\leq j<n} L_2^{(n-j-1)}(R_j(f_j) + S_j).$$

Likewise, if $m > n$, we can write (5.1) in the form

$$f_m = L^{n-m} f_n + \sum_{n\leq j<m} L_1^{(m-j-1)}(R_j(f_j) + S_j)$$

so that

$$P_1 f_n = L_1^{n-m} f_m - \sum_{n\leq j<m} L_1^{(n-j-1)}(R_j(f_j) + S_j).$$

We will show that the right-hand side of the above equation converges as $m \to \infty$; then it remains only to add these projections together to finish the proof. Condition (H.3) and the Lipschitz property of R_n allow

$$\left\| \sum_{n\leq j<m} L_1^{(n-j-1)}(R_j(f_j) + S_j) \right\|_X \leq C_1 \sum_{n\leq j<m} \alpha_1^{n-j-1}(Lip(R)\|f_j\|_X + \|S_j\|_X).$$

The bound (5.2) and assumption (H.5) give convergence of this sum as $m \to \infty$ as well as the following limit:

$$\limsup_{m\to\infty} \|L_1^{n-m} f_m\|_X \le C_1 \alpha_1^n \limsup_{m\to\infty} (\alpha_1^{-m} \|f_m\|_X)$$
$$= 0. \qquad \square$$

The next step is to show that for any initial data f_0 there exists a unique solution to the system (5.3) in a weighted space where all elements satisfy (5.2); then through the previous lemma we can deduce that this solution is a discrete positive semiorbit. Systems such as (5.3) are called Lyapunov–Perron equations and used in the Lyapunov–Perron approach to invariant manifolds. The existence theorem we prove uses a fixed point argument and is similar to Theorem 2.1 in [6].

DEFINITION 5.4. *Fix $\gamma \in (\gamma_2, \gamma_1)$, where γ_1 and γ_2 are as in* (H.4)*, and let E_n^γ be the Banach space equal to X as a vector space but equipped with the norm $\|\cdot\|_{E_n^\mu} = \gamma^{-n}\|\cdot\|_X$. E^γ is the sequence space $f = \{f_n\}_{n\in\mathbb{N}}$, $f_n \in E_n^\gamma$ equipped with the norm $\|f\|_{E^\gamma} = \sup_{n\in\mathbb{N}} \|f_n\|_{E_n^\gamma}$.*

As $\gamma_1 < \alpha_1$ by assumption this definition is compatible with (5.2).

THEOREM 5.5. *We assume conditions* (H.1)–(H.5) *are satisfied. Pick $\gamma \in (\gamma_2, \gamma_1)$. Given initial data $x \in X_2$, there exists a unique solution $\{f_n\} \in E^\mu$ to* (5.3).

Proof. Define $J : E^\gamma \to E^\gamma$ componentwise as

$$J_n(\{f_n\}) = L_2^n x + \sum_{0\le j<n} L_2^{(n-1-j)}(R_j(f_j) + S_j) - \sum_{n\le j} L_1^{(n-1-j)}(R_j(f_j) + S_j).$$

To apply a fixed point theorem we need to check that J is well defined and is a contraction map. In that direction we start with the bound

$$\|J_n(\{f_n\})\|_{E_n^\gamma} \le \|L_2^n x\|_{E_n^\gamma} + \sum_{0\le j<n} \|L_2^{(n-1-j)}(R_j(f_j) + S_j)\|_{E_n^\gamma}$$
$$- \sum_{n\le j} \|L_1^{(n-1-j)}(R_j(f_j) + S_j)\|_{E_n^\gamma}.$$

The first term on the right-hand side is bounded with the help of (H.3), the definition of the space E_n^γ, and the condition $\gamma > \alpha_2$:

$$\|L_2^n x\|_{E_n^\gamma} \le C_2 \alpha_2^n \gamma^{-n} \|x\|_X$$
$$\le C_2 \|x\|_X.$$

Assumption (H.5) and $\gamma < \alpha_1$ imply $\{S_n\} \in E^\gamma$; then the second term is bounded using the same ideas but adding the uniform Lipschitz constant of R_j:

$$\sum_{0\le j<n} \|L_2^{(n-1-j)}(R_j(f_j) + S_j)\|_{E_n^\gamma} \le C_2 \alpha_2^{-1} \sum_{0\le j<n} (\alpha_2/\gamma)^{n-j} \|(R_j(f_j) + S_j)\|_{E_j^\gamma}$$
$$\le \frac{C_2}{\gamma - \alpha_2} \left(Lip(R) \|\{f_n\}\|_{E^\gamma} + \|\{S_n\}\|_{E^\gamma} \right).$$

Similarly,

$$\sum_{n\le j} \|L_1^{(n-1-j)}(R_j(f_j) + S_j)\|_{E_n^\gamma} \le \frac{C_1}{\alpha_1 - \gamma} \left(Lip(R) \|\{f_n\}\|_{E^\gamma} + \|\{S_n\}\|_{E^\gamma} \right).$$

These bounds show that $\|J_n(\{f_n\})\|_{E_n^\gamma}$ is bounded independent of n and therefore J maps E^γ into itself. Given another sequence $g_n \in E^\gamma$, following nearly the same steps one finds the bound

$$\|J_n(\{f_n\}) - J_n(\{g_n\})\|_{E_n^\gamma} \leq \left(\frac{C_1}{\alpha_1 - \gamma} + \frac{C_2}{\gamma - \alpha_2}\right) Lip(R)\|\{f_n - g_n\}\|_{E^\gamma}.$$

Assumption (H.4) guarantees J is a contraction map, and a standard fixed point argument finishes the theorem. ∎

We would like to remark here that the system (5.3) does not "see" the component of the initial data in X_1 but instead picks out the correct component to form a solution which satisfies (5.2). Thus, by solving the system one creates a map $h : X_2 \to X_1$ defined $h(x) = P_1 f_0$ such that the *natural flow* through $x + h(x)$ decays rapidly. This map is important when constructing invariant manifolds and foliations through the Lyapunov–Perron approach (see, for example, [6]). This next corollary makes this remark precise.

COROLLARY 5.6. *Let $\{\Theta_n\}$ be a collection of semigroups satisfying* (H.1)–(H.5). *For each $x \in X_2$ there exists $h(x) \in X_1$ such that the discrete positive orbit through $x + h(x)$ satisfies* (5.2). *This defines a map $h : X_2 \to X_1$.*

Proof. Define h by using x as initial conditions in the previous theorem to find a sequence $\{f_n\}$; then let $h(x) = P_1 f_0$. As the solution is unique so h is well defined, the remaining properties follow quickly from Lemma 5.3. ∎

We are now in a position to prove the theorem, which is the goal of this section and will be the basis for decay estimates in the following sections.

THEOREM 5.7. *Let $\{\Theta_n\}$ be a collection of semigroups satisfying* (H.1)–(H.5) *and h as in the previous corollary. For each $\gamma \in (\gamma_2, \gamma_1)$ and initial condition $x \in X_2$ denote by $\Theta(x + h(x), t)$ the* natural flow *of $\{\Theta_n\}$ through $x + h(x)$. This satisfies*

$$\limsup_{t\to\infty} \frac{1}{t} \ln \|\Theta(x + h(x), t)\|_X < \gamma. \tag{5.4}$$

Proof. $\{\Theta(x+h(x), n)\}$ is a discrete positive orbit of $\{\Theta_n\}$ through $x+h(x)$. Using Theorem 5.5 and its corollary we obtain

$$\limsup_{n\to\infty} \frac{1}{n} \ln \|\Theta(x + h(x), n)\|_X < \gamma.$$

We now apply the Lipschitz property of the semiflows Θ_n given by (H.1). If $n \in \mathbb{N}$ and $0 \leq \sigma < 1$ are such that $t = n + \sigma$,

$$\begin{aligned}\frac{1}{t} \ln \|\Theta(x + h(x), t)\|_X &\leq \frac{1}{t} |\ln(D\|\Theta(x + h(x), n)\|_X) \\ &\leq \frac{1}{n} \ln \|\Theta(x + h(x), n)\|_X + \frac{1}{t} \ln D.\end{aligned}$$

Taking the limit superior first as $n \to \infty$ and then as $t \to \infty$ in the above expression finishes the proof. ∎

6. First order asymptotic behavior. For the first order calculations we work in the space $L^2(2)$ where the operator $\mathcal{L}$ has a single isolated eigenvalue 0 and corresponding eigenvector G (see Definition 4.7). This eigenvector spans the subspace X_1 as in Definition 4.5. The projection onto this subspace is defined as follows: let

$a = \int \tilde{w}_0 \, d\xi$; then $P_1(\tilde{w}_0) = aG$. Before we proceed it is important to remark that $\int \tilde{w} \, d\xi$ is a conserved quantity under the flow of (4.9), so $P_1(\tilde{w}(\tau)) = aG$. Indeed, since $\mathcal{L}\tilde{w} = \nabla \cdot (\nabla \tilde{w} + \frac{\xi}{2})$,

$$\frac{1}{2}\frac{d}{dt}\int \tilde{w} \, d\xi = \int \nabla \cdot \left(\nabla \tilde{w} + \frac{\xi}{2} \cdot \tilde{w} - \omega \tilde{w} \right) d\xi = 0. \tag{6.1}$$

Fix $\tilde{w}_0$ (we keep this fixed throughout the calculations) and consider the system (4.10) with initial data $\tilde{w}_0 - a\Gamma(\cdot, 0)$, where $a = \int \tilde{w}_0 \, d\xi$; later we will require $\|\tilde{w}_0\|_m$ to be sufficiently small. With these initial conditions $\tilde{\psi} = a\Gamma$ is a "stationary" solution of the linear system (4.9). Writing $\tilde{f} = \tilde{w} - a\Gamma$, $\phi = B\mathcal{H}_{\alpha,\tau}(\tilde{f})$, (4.10) becomes

$$\tilde{f}_\tau = \mathcal{L}\tilde{f} - \omega \cdot \nabla \tilde{f} - a\phi \cdot \nabla \Gamma. \tag{6.2}$$

The associated integral equation is

$$\tilde{f} = e^{\tau\mathcal{L}} P_2(\tilde{w}_0) - \int_0^\tau e^{\frac{-1}{2}(\tau-\sigma)\nabla} \cdot e^{(\tau-\sigma)\mathcal{L}} (\omega \tilde{f} + a\phi\Gamma)(\sigma) \, d\sigma. \tag{6.3}$$

Although it is not obvious at a quick glance, the above system changes with τ. The dependence on τ is buried in the ϕ term (in the filter relation) and destroys the commutative property of the generated semiflow. Commutativity is a very useful property when dealing with semiflows, but we are able to proceed in a fashion consistent with the Lyapunov–Perron approach to constructing invariant manifolds using the results of section 5. To make this work we need a collection of semiflows with uniform bounds which can be put together to reconstruct the original flow. The following system takes us in that direction, and we now change our focus to finding properties of $\tilde{f}_n$ which solve the following system, defined for all $n \in \mathbb{N}$:

$$\tilde{f}_n = e^{\tau\mathcal{L}} \tilde{f}_{n,0} - \int_0^\tau e^{\frac{-1}{2}(\tau-\sigma)\nabla} \cdot e^{(\tau-\sigma)\mathcal{L}} (\omega(n+\sigma)\tilde{f}_n(\sigma) + a\phi_m(\sigma)\Gamma(n+\sigma)) \, d\sigma, \tag{6.4}$$

$$\phi_n(\sigma) = B\mathcal{H}_{\alpha,\sigma+n}(\tilde{f}_n)(\sigma).$$

Note that this system has a global solution; existence can be proved analogously to Theorem 4.4. It should also be noted here that the above system, (6.2), (6.3), and therefore the flow Θ_n depend on $\tilde{w}_0$, which we consider fixed when we write down the system (a depends on $\tilde{w}_0$); this relation is suppressed in the notation. Most solutions of this equation will have no meaning, but by choosing $\tilde{f}_{0,0} = P_2(\tilde{w}_0)$ and then $\tilde{f}_{n,0} = \tilde{f}_{n-1}(1)$ we are able to recover information about the semiflow corresponding to $\tilde{w}_0$.

DEFINITION 6.1. *Throughout the remainder of this section let $\Theta_n(\tilde{f}_{n,0}, \tau)$ denote the global solution to the system* (6.4) *with initial data $\tilde{f}_{n,0}$.*

The parameter n allows us to keep track of our progress in time. For example, if $0 \le \sigma < 1$ is such that $\tau = n + \sigma$ and $\Theta(\tilde{f}_0, \tau)$ is the semiflow of (6.3), then

$$\Theta(\tilde{f}_0, \tau) = \Theta_n(\Theta_{n-1}(\Theta_{n-2}(\cdots \Theta_0(\tilde{f}_0, 1), 1), 1), \sigma). \tag{6.5}$$

We will now prove uniform properties of these semiflows.

LEMMA 6.2. *The semiflows $\Theta_n(\tilde{f}_0, \tau)$, $n \in \mathbb{N}$, are all C^1 in $L^2(2) \times \mathbb{R}^+$. There exist a constant $r_0 > 0$ (possibly small) and $D > 0$ such that for all $\|\tilde{w}_0\|_2 < r_0$ and $n \in \mathbb{N}$ the flow Θ_n satisfies the following Lipschitz property:*

$$\sup_{n\in\mathbb{N}} \sup_{0\le\tau<1} Lip(\Theta_n(\cdot, \tau)) = D < \infty. \tag{6.6}$$

This bound holds as $r_0 \to 0$.

Proof. Since the bound obtained in Lemma 4.1 is independent of τ we can prove this lemma for all $n \in \mathbb{N}$ at once. That the semiflow is C^1 is a classical result. Consider the semiflows $\tilde{f}(\tau) = \Theta_n(\tilde{f}_0, \tau)$ and $\tilde{g}(\tau) = \Theta_n(\tilde{g}_0, \tau)$ found from initial data $\tilde{f}_0$ and $\tilde{g}_0$, respectively, and the corresponding filtered flows ϕ and γ. Subtracting we have

$$\|\Theta_n(\tilde{f}, \tau) - \Theta_n(\tilde{g}, \tau)\|_2 \leq \|e^{\tau\mathcal{L}}(\tilde{f}_0 - \tilde{g}_0)\|_2 + I(\tau) + J(\tau),$$

where

$$I(\tau) = \left\| \int_0^\tau e^{-\frac{1}{2}(\tau-\sigma)} \nabla \cdot e^{(\tau-\sigma)\mathcal{L}} (\omega(n+\sigma)(\tilde{f}(\sigma) - \tilde{g}(\sigma)))\, d\sigma \right\|_2,$$

$$J(\tau) = \left\| \int_0^\tau e^{-\frac{1}{2}(\tau-\sigma)} \nabla \cdot e^{(\tau-\sigma)\mathcal{L}} ((\phi(\sigma) - \gamma(s)) a\Gamma(n+\sigma))\, ds \right\|_2.$$

Similar to the steps in Lemma 4.3 we obtain

$$I(\tau) + J(\tau) \leq C(\tau) \left(\sup_{0\leq\sigma<\tau} \|\tilde{f}(\sigma) - \tilde{g}(\sigma)\|_2 \right) \cdot \left(\sup_{0\leq\sigma<\tau} (\|\tilde{w}(n+\sigma)\|_m + a\|\Gamma(n+\sigma)\|_2) \right)$$

with $C(\tau)$ a continuous function and hence bounded on $\tau \in [0,1]$ by a constant C. The bound (4.5) combined with the definition of a ($a \leq \|\tilde{w}_0\|_2$) allows us to pick $r_0 > 0$ small enough so that, for all $\sigma > 0$,

$$\|\tilde{w}(n+\sigma)\|_2 + a\|\Gamma(n+\sigma)\|_2 < \frac{1}{2C}.$$

After taking the supremum over $\tau \in [0,1]$ we have

$$\sup_{0\leq\tau<1} \|\Theta_n(\tilde{f}, \tau) - \Theta_n(\tilde{g}, \tau)\|_2 \leq \sup_{0\leq\tau<1} \|e^{\tau\mathcal{L}}(\tilde{f}_0 - \tilde{g}_0)\|_2 \leq D\|\tilde{f}_0 - \tilde{g}_0\|_2.$$

This is the bound (6.6). □

LEMMA 6.3. *There exists a constant $r_0 > 0$ (possibly small) such that for all $\|\tilde{w}_0\|_2 < r_0$ and $n \in \mathbb{N}$ the flow Θ_n can be decomposed as $\Theta_n(\tilde{f}_0, 1) = e^{\mathcal{L}}\tilde{f}_0 + R_n(\tilde{f}_0)$, where $R_n(\cdot)$ is Lipschitz as a function from $L^2(2)$ to itself. The uniform Lipschitz constant $Lip(R) := \sup_{n\in\mathbb{N}} Lip(R_n(\cdot))$ satisfies the following conditions:*

(i) *For any $\mu \in (0, \frac{1}{2})$, r_0 may be chosen so that, for all $i \in \mathbb{N}$,*

$$\frac{C_1}{1 - e^{-\mu}} + \frac{C_2}{e^{-\mu} - e^{-1/2}} < \frac{1}{Lip(R)}. \tag{6.7}$$

(ii) *This bound holds as $r_0 \to 0$.*

Proof. As in the previous proof, consider the semiflows $\tilde{f}(\tau) = \Theta_n(\tilde{f}_0, \tau)$ and $\tilde{g}(\tau) = \Theta_n(\tilde{g}_0, \tau)$. Define

$$R_n(\tilde{f}_0) = \Theta_n(\tilde{f}_0, 1) - e^{\mathcal{L}}\tilde{f}_0 = -\int_0^1 e^{-1/2(1-\sigma)} \nabla \cdot e^{(1-\sigma)\mathcal{L}} (\omega(n+\sigma)\tilde{f}(\sigma) + a\phi(\sigma)\Gamma(n+\sigma))\, d\sigma.$$

As in Lemmas 4.3 or 6.2, after adding and subtracting cross terms,

$$\|R_n(\tilde{f}_0) - R_n(\tilde{g}_0)\|_2 \leq C \left(\sup_{0\leq\sigma<\tau} \|\tilde{f}(\sigma) - \tilde{g}(\sigma)\|_2 \right) \cdot \left(\sup_{0\leq\sigma<\tau} (\|\tilde{w}(n+\sigma)\|_2 + a\|\Gamma(n+\sigma)\|_2) \right).$$

Appealing to (6.6),

$$\|R_n(\tilde{f}_0) - R_n(\tilde{g}_0)\|_2 \leq CD \left(\sup_{0\leq\sigma<\tau} \|\tilde{f}_0 - \tilde{g}_0\|_2 \right) \cdot \left(\sup_{0\leq\sigma<\tau} (\|\tilde{w}(n+\sigma)\|_2 + a\|\Gamma(n+\sigma)\|_m) \right).$$

This shows that

$$Lip(R_i(\cdot)) \leq CD \left(\sup_{0\leq\sigma<\infty} (\|\tilde{w}(\sigma)\|_2 + a\|\Gamma(\sigma)\|_2) \right)$$

and, with the help of (4.5), satisfies the Lipschitz condition. The bound (6.7) is established by taking r_0 sufficiently small. □

For the remainder of this section we assume that r_0 is small enough so the conclusions of Lemma 6.2 and 6.3 hold.

THEOREM 6.4. *Pick $\mu \in (0, \frac{1}{2})$ and choose $r_0 > 0$ to satisfy the conclusions of Lemmas 6.2 and 6.3. Let P_i^2 and X_i^2, $i = 1, 2$, be as in Definition 4.5. Given $\tilde{w}_0$ such that $\|\tilde{w}_0\|_2 \leq r_0$ and initial data $\tilde{f}_0 \in X_2$, there exists a unique global solution $\Theta(\tilde{f}_0, \tau) \in C^0([0,\infty), L^2(2))$ of (6.3). This solution satisfies $P_1\Theta(\tilde{f}_0, \tau) = 0$ and*

$$\limsup_{\tau\to\infty} \frac{1}{t} \ln \|\Theta(\tilde{f}_0, \tau)\|_2 < -\mu. \tag{6.8}$$

Proof. The existence of a unique global solution can be argued as in Theorem 4.4; again let $\Theta_n(\tilde{f}_{n,0}, \tau)$ denote the global solution with initial data $\tilde{f}_{n,0}$. We now check the assumptions for Theorem 5.7. Lemma 6.2 shows that the collection $\{\Theta_n\}$ satisfies assumption (H.1) from section 6. Assumption (H.3) is satisfied by Lemma 4.6. As the left-hand side of (6.7) is continuous and the inequality is strict we can find a small neighborhood of μ, say $(\gamma_2, \gamma_1) \subset (0, \frac{1}{2})$, such that the inequality is satisfied for all numbers in this neighborhood. Taking $\alpha_1 = \frac{1}{2}$ and $\alpha_2 = 0$ and applying Lemma 6.3 shows that the collection $\{\Theta_n\}$ satisfies assumptions (H.2), (H.4), and (H.5) with $S_n = 0$.

Applying Theorem 5.7 gives the existence of an element $h(\tilde{f}_0) \in X_1$ such that

$$\limsup_{n\to\infty} \frac{1}{\tau} \ln \|\Theta(y, \tau)\|_2 < -\mu,$$

where $y = \tilde{f}_0 + h(\tilde{f}_0)$ and Θ is constructed as in (6.5); in other words it is the solution of (6.3). To finish the proof we need only argue that $h(\tilde{f}_0) = 0$, which can be inferred from the "conservation of mass" property of (6.2) and the decay implied by the above inequality. Indeed, using (6.2) we see that $\int \tilde{f}\, d\xi$ is a conserved property:

$$\frac{1}{2}\frac{d}{dt} \int \tilde{f}\, d\xi = \int \nabla \cdot (\nabla \tilde{f} + \xi \tilde{f} - \omega \tilde{f} - a\phi\Gamma)\, d\xi = 0. \tag{6.9}$$

The orthogonal relation $X_1^2 \perp X_2^2$ allows (again writing $y = \tilde{f}_0 + h(\tilde{f}_0)$)

$$\|P_1^2\Theta(y,\tau)\|_2 \le \|\Theta(y,\tau)\|_2$$

and, as $\|P_1\Theta(y,\tau)\|_2$, is constant for all $\tau > 0$; (6.9) implies that $P_1\Theta(y,\tau) = h(\tilde{f}_0) = 0$. ∎

We now prove the theorem, which is the goal of this section.

THEOREM 6.5. *Pick $\mu \in (0, \frac{1}{2})$ and choose $r_0 > 0$ to satisfy the conclusions of Lemmas* 6.2 *and* 6.3. *Given initial data $\tilde{w}_0$ such that $\|\tilde{w}_0\|_2 \le r_0$, the solution $\tilde{w}(\tau)$ of the scaled VCHE given by Theorem* 4.4 *is subject to the following decay estimate:*

$$\|\tilde{w}(\tau) - a\Gamma(\tau)\|_2 \le Ce^{-\mu\tau},$$

where $a = \int \tilde{w}_0\, d\xi$.

Proof. In the previous theorem take $\tilde{f}_0 = P_2\tilde{w}_0$; then $\tilde{f}(\tau) = \tilde{w}(\tau) - a\Gamma(\tau)$. The decay follows from (6.8). ∎

Finally, as a corollary to this theorem we prove the result listed as Theorem 1.2 in the introduction.

COROLLARY 6.6. *For any $\mu \in (0, \frac{1}{2})$, there exists a $r_0 > 0$ so that, for any initial data $\tilde{v}_0 \in L^2(2)$ such that $\|\tilde{v}_0\|_2 \le r_0$, the solution of* (1.2) *given by Theorem* 3.2 *satisfies*

$$|\tilde{v}(\cdot,t) - a(\Omega(\cdot,t) - \alpha^2\triangle\Omega(\cdot,t))|_p \le C(1+t)^{-1-\mu+\frac{1}{p}},$$

where $a = \int_{\mathbb{R}^2} \tilde{v}_0\, dx$ and

$$\Omega(x,t) = \frac{1}{4\pi(1+t)} e^{\frac{-|x|^2}{4(1+t)}}.$$

Proof. This is the result of the previous theorem in unscaled coordinates. Let

$$\Omega(x,t) = \frac{1}{(1+t)} G\left(\frac{x}{\sqrt{1+t}}\right) = \frac{1}{4\pi(1+t)} e^{\frac{-|x|^2}{4(1+t)}}; \tag{6.10}$$

then

$$\frac{1}{(1+t)}\Gamma\left(\frac{x}{\sqrt{1+t}}, \ln(1+t)\right) = \Omega(x,t) - \alpha^2\triangle\Omega(x,t).$$

Thanks to the above theorem and the inclusion $L^2(2) \hookrightarrow L^p$ for when $1 \le p \le 2$,

$$\begin{aligned}
&|\tilde{v}(\cdot,t) - a(\Omega(\cdot,t) - \alpha^2\triangle\Omega(\cdot,t))|_p \\
&\qquad \le (1+t)^{-1+\frac{1}{p}} |\tilde{w}(\cdot, \ln(1+t)) - a\Gamma(\cdot, \ln(1+t))|_p \\
&\qquad \le C(1+t)^{-1+\frac{1}{p}} \|\tilde{w}(\cdot, \ln(1+t)) - a\Gamma(\cdot, \ln(1+t))\|_2 \\
&\qquad \le C(1+t)^{-1-\mu+\frac{1}{p}}. \qquad ∎
\end{aligned}$$

As $\triangle\Omega$ decays faster than $(1+t)^{-1-\mu+1/p}$ we can include it on the right-hand side; this is how Theorem 1.2 is stated.

7. Second order asymptotic. This section is similar in spirit to the previous section, and many of the proofs are omitted because they are nearly the same as the proofs given in the previous section. We work in the space $L^2(3)$ where the operator $\mathcal{L}$ has two isolated eigenvalues, 0 and $\frac{-1}{2}$, and three corresponding eigenvectors, G and F_i, $i = 1, 2$ (see Definition 4.7). Together these eigenvalues span the subspace X_1^3 given by Definition 4.5. Any $\tilde{w}_0 \in L^2(3)$ can be written as $\tilde{w}_0 = aG + b_1F_1 + b_2F_2 + \tilde{g}$, where $a = \int \tilde{w}_0\, d\xi$, $b_i = \int \xi_i \tilde{w}_0\, d\xi$, and $\tilde{g} \in X_2$.

In addition to the "conservation of mass" property $\frac{d}{dt}\int \tilde{w}\, d\xi = 0$ used in the previous section (proof of Theorem 5.7), solutions to the scaled VCHE (4.1) also satisfy the scaled form of conservation of the first moments, $\frac{d}{dt}\int \xi_i \tilde{w}\, d\xi = -\frac{1}{2}\int \xi_i \tilde{w}\, d\xi$. Indeed, let $i = 1, 2$ and $j \neq i$; then

$$\xi_i \mathcal{L}\tilde{w} + \frac{1}{2}\xi_i \tilde{w} = \partial_j \left(\xi_i \partial_i \tilde{w} + \frac{1}{2}\xi_i^2 \tilde{w} - \tilde{w} \right) + \partial_j \left(\xi_i \partial_j \tilde{w} + \frac{1}{2}\xi_i \xi_j \tilde{w} \right),$$

and it is clear that $\int_{\mathbb{R}^2} \xi_i \mathcal{L}\tilde{w}\, d\xi = -\frac{1}{2}\int_{\mathbb{R}^2} \xi_i \tilde{w}\, d\xi$. For the nonlinear term, note that if $\nabla \cdot \omega = 0$ and $\tilde{\omega} = \partial_1\omega_2 - \partial_2\omega_1$, then

$$\xi_i \omega \cdot \nabla \tilde{\omega} = \partial_i(\xi_i \omega_i \tilde{\omega} - \omega_i \omega_j) + \partial_j \left(\xi_i \omega_j \tilde{\omega} + \frac{1}{2}(\omega_i^2 - \omega_j^2) \right).$$

Similarly,

$$\begin{aligned} \xi_i \omega \cdot \nabla \partial_i^2 \tilde{\omega} &= \partial_i(\xi_i \omega \cdot \nabla \partial_j \tilde{\omega}) - \omega \cdot \nabla \partial_i \tilde{\omega} - \xi_i \partial_i \omega \cdot \nabla \partial_i \tilde{\omega} \\ &= \partial_i(\xi_i \omega \cdot \nabla \partial_j \tilde{\omega}) - \nabla(\omega \partial_i \tilde{\omega}) - \partial_i(\xi_i \partial_i \omega_i \partial_i \tilde{\omega} - \partial_i \omega_i \partial_i \omega_j) \\ &\quad - \partial_j \left(\xi_i \partial_i \omega_j \partial_i \tilde{\omega} + \frac{1}{2}((\partial_i \omega_i)^2 - (\partial_i \omega_j)^2) \right) \end{aligned}$$

and

$$\begin{aligned} \xi_i \omega \cdot \nabla \partial_j^2 \tilde{\omega} &= \partial_j(\xi_i \omega \cdot \nabla \partial_j \tilde{\omega}) - \partial_i(\xi_i \partial_j \omega_i \partial_j \tilde{\omega} - \partial_j \omega_i \partial_j \omega_j) \\ &\quad - \partial_j \left(\xi_i \partial_j \omega_j \partial_j \tilde{\omega} + \frac{1}{2}((\partial_j \omega_i)^2 - (\partial_j \omega_j)^2) \right) \end{aligned}$$

so that $\int_{\mathbb{R}^2} \xi_i \omega \cdot \nabla \tilde{w}\, d\xi = 0$.

Fix $\tilde{w}_0 \in L^2(m)$ and consider the system (4.10) with initial data $P_2^m \tilde{w}_0$. Let $a = \int \tilde{w}_0\, d\xi$, $b_i = \int \xi_i \tilde{w}_0\, d\xi$; then $\tilde{\psi}(\tau) = a\Gamma + e^{\frac{-1}{2}}(b_1\Lambda_1 + b_2\Lambda_2)$ is the solution to the linear equation (4.9). Write $\tilde{f} = \tilde{w} - a\Gamma - e^{\frac{-1}{2}}(b_1\Lambda_1 + b_2\Lambda_2)$, $\phi = B\mathcal{H}_{\alpha,\tau}(\tilde{f})$, and after simplification,

$$\tilde{f}_\tau = \mathcal{L}\tilde{f} - \omega \cdot \nabla \tilde{f} - \phi \cdot \nabla \psi - e^{-\tau}(b_1 v^{F_1} \cdot \nabla \Lambda_1 - b_2 v^{F_2} \cdot \nabla \Lambda_2). \tag{7.1}$$

In mild form $\tilde{f}$ satisfies the integral equation

$$\begin{aligned} \tilde{f} = e^{\tau\mathcal{L}} \tilde{f}_0 - \int_0^\tau & e^{-1/2(\tau-\sigma)} \nabla \\ & \cdot e^{(\tau-\sigma)\mathcal{L}}(\omega \tilde{f} + \phi \cdot \nabla \psi + e^{-\tau}(b_1 v^{F_1} \cdot \nabla \Lambda_1 - b_2 v^{F_2} \cdot \nabla \Lambda_2))(\sigma)\, d\sigma. \end{aligned}$$

The key difference between this system and (6.3) of the previous section is the "forcing term" $e^{-\tau}(b_1 v^{F_1} \cdot \nabla \Lambda_1 - b_2 v^{F_2} \cdot \nabla \Lambda_2)$.

As in the previous section fix $\tilde{w}_0$ and for any $n \in \mathbb{N}$ consider the system

(7.2)
$$\tilde{f}_n = e^{\tau\mathcal{L}}\tilde{f}_{0,n} - \int_0^\tau e^{-1/2(\tau-\sigma)}\nabla\cdot e^{(\tau-\sigma)\mathcal{L}}(\omega(n+\sigma)\tilde{f}(\sigma) + a\phi(\sigma)\psi(n+\sigma))\,d\sigma$$
$$- \int_0^\tau e^{-1/2(\tau-\sigma)}\nabla\cdot e^{(\tau-\sigma)\mathcal{L}}(e^{-(n+\sigma)}(b_1 v^{F_1}\cdot\nabla\Lambda_1 - b_2 v^{F_2}\cdot\nabla\Lambda_2)(n+\sigma))\,d\sigma,$$
$$\phi(\sigma) = B\mathcal{H}_{\alpha,\sigma+\tau}(\tilde{f})(\sigma), \qquad \tilde{f}(0) = \tilde{f}_0 \in X_2.$$

We redefine Θ_n for this section.

DEFINITION 7.1. *Throughout the remainder of this section let $\Theta_n(\tilde{f}_{n,0},\tau)$ denote the global solution to the system* (7.2) *with initial data $\tilde{f}_{n,0}$.*

LEMMA 7.2. *For each $n \in \mathbb{N}$, the semiflows $\Theta_n(\tilde{f}_0,\tau)$ are C^1 in $L^2(2)\times\mathbb{R}^+$. There exist a constant $r_0 > 0$ (possibly small) and $D > 0$ such that for all $\|\tilde{w}_0\|_3 < r_0$ and $n \in \mathbb{N}$ the flow Θ_n satisfies the following Lipschitz property:*

$$\sup_{n\in\mathbb{N}}\sup_{0\le\tau<1} Lip(\Theta_n(\cdot)(\tau)) = D < \infty. \tag{7.3}$$

This bound holds as $r_0 \to 0$.

Proof. The proof is nearly identical to the proof of Lemma 6.2. □

LEMMA 7.3. *There exists a constant $r_0 > 0$ (possibly small) such that for all $\|\tilde{w}_0\|_3 < r_0$ and $n \in \mathbb{N}$ the flow Θ_n can be decomposed as $\Theta_n(\tilde{f}_0,1) = e^{\mathcal{L}}\tilde{f}_0 + R_n(\tilde{f}_0) + S_n$, where $R_n(\cdot)$ is Lipschitz as a function from $L^2(3)$ to itself and $S_n \in L^2(3)$ satisfies*

$$\limsup_{n\to\infty}\frac{1}{n}\ln\|S_n\|_3 < -1. \tag{7.4}$$

The Lipschitz constant $Lip(R) := \sup_{n\in\mathbb{N}} Lip(R_n(\cdot))$ can be made arbitrarily small and satisfies the following conditions:

(i) *For any $\mu \in (\frac{1}{2},1)$, r_0 may be chosen so that, for all $n \in \mathbb{N}$,*

$$\frac{C_1}{e^{-1/2}-e^{-\mu}} + \frac{C_2}{e^{-\mu}-e^{-1}} < \frac{1}{Lip(R)}. \tag{7.5}$$

(ii) *This bound holds as $r_0 \to 0$.*

Proof. Define

$$S_n = -\int_0^\tau e^{-1/2(\tau-\sigma)}\nabla\cdot e^{(\tau-\sigma)\mathcal{L}}(e^{-(n+\sigma)}(b_1^2 v^{F_1}\cdot\nabla\Lambda_1 - b_2^2 v^{F_2}\cdot\nabla\Lambda_2)(n+\sigma))\,d\sigma$$

and $R_n(\tilde{f}_0) = \Theta_n(\tilde{f}_0)(1) - e^{\mathcal{L}}\tilde{f}_0 - S_n$. Proving (7.4) is similar to the proof of Lemma 4.3:

$$\|S_n\|_3 \le e^{-n}(b_1\|v^{F_1}\|_3\|\Lambda_1\|_3 + b_2\|v^{F_2}\|_3\|\Lambda_2\|_3). \tag{7.6}$$

The remaining statements in this proof follow as in the proof of Lemma 6.3. □

THEOREM 7.4. *Pick $\mu \in (\frac{1}{2},1)$ and choose $r_0 > 0$ to satisfy the conclusions of Lemmas* 6.2 *and* 6.3. *Let P_i^3 and X_i^3, $i = 1,2$, be as in Definition* 4.5. *Given $\tilde{w}_0$ such that $\|\tilde{w}_0\|_3 \le r_0$ and initial data $\tilde{f}_0 \in X_2$, there exists a unique global solution $\Theta(\tilde{f}_0,\tau) \in C^0([0,\infty), L^2(2))$ of* (6.3). *This solution satisfies $P_1^3\Theta(\tilde{f}_0,\tau) = 0$ and*

$$\limsup_{\tau\to\infty}\frac{1}{t}\ln\|\Theta(\tilde{f}_0,\tau)\|_2 < -\mu. \tag{7.7}$$

Proof. The proof progresses similarly to the proof of Theorem 7.4. The main difference is in the argument for the statement $P_1^3\Theta(\tilde{f}_0,\tau)=0$. This is accomplished by decomposing $P_1\Theta(\tilde{f}_0,\tau)$ onto the first three eigenvectors of $\mathcal{L}$ using conservation of mass (discussed at the beginning of section 6) and conservation of first moments (discussed at the start of section 7):

$$P_1^3\Theta(\tilde{f}_0,\tau)=aG+e^{-\frac{1}{2}}(b_1F_1+b_2F_2).$$

That a and b_i must be zero follows by comparing this expression to the decay implied by (7.7). ∎

THEOREM 7.5. *Pick $\mu\in(\frac{1}{2},1)$ and choose $r_0>0$ to satisfy the conclusions of Lemmas* 7.2 *and* 7.3. *Given initial data $\tilde{w}_0$ such that $\|\tilde{w}_0\|_3\le r_0$, the solution $\tilde{w}(\tau)$ of the scaled VCHE given by Theorem* 4.4 *is subject to the following decay estimate:*

$$\|\tilde{w}(\tau)-a\Gamma(\tau)-e^{\frac{-\tau}{2}}(b_1\Lambda_1+b_2\Lambda_2)\|_2\le Ce^{-\mu\tau},$$

where $a=\int\tilde{w}_0\,d\xi$ and $b_i=\int\xi_i\tilde{w}_0\,d\xi$.

Proof. In the previous theorem take $\tilde{f}_0=P_2\tilde{w}_0$; then $\tilde{f}(\tau)=\tilde{w}(\tau)-a\Gamma(\tau)-e^{\frac{-\tau}{2}}(b_1\Lambda_1+b_2\Lambda_2)$. The decay then follows from (6.8). ∎

The following corollary proves Theorem 1.3, which was stated after removing the fast decaying term.

COROLLARY 7.6. *For any $\mu\in(\frac{1}{2},1)$, there exists a $r_0>0$ so that for any initial data $\tilde{v}_0\in L^2(3)$ with $\|\tilde{v}_0\|_3\le r_0$ the solution of* (1.2) *given by Theorem* 3.2 *satisfies*

$$|\tilde{v}(\cdot,t)-a(\Omega(\cdot,t)-\alpha^2\triangle\Omega(\cdot,t))-\sum_{i=1,2}b_i(\partial_i\Omega(x,t)-\alpha^2\triangle\partial_i\Omega(x,t))|_p\le C(1+t)^{-1-\mu+\frac{1}{p}},$$

where $a=\int\tilde{w}_0\,dx$ and $b_i=\int x_i\tilde{v}_0\,dx$ and Ω is defined by (6.10).

Proof. This is the result of the previous theorem in unscaled coordinates. Let $\Omega(x,t)=\frac{1}{(1+t)}G(\frac{x}{\sqrt{1+t}})$; then

$$\frac{1}{(1+t)}\Gamma\left(\frac{x}{\sqrt{1+t}},\ln(1+t)\right)=\Omega(x,t)-\alpha^2\triangle\Omega(x,t),$$

$$e^{-\frac{\tau}{2}}\frac{1}{(1+t)}\Lambda_i\left(\frac{x}{\sqrt{1+t}},\ln(1+t)\right)=\partial_i\Omega(x,t)-\alpha^2\triangle\partial_i\Omega(x,t).$$

The rest follows as in Corollary 6.6. ∎

Acknowledgments. The author would like to thank M. E. Schonbek for suggesting the problem and the anonymous referees for insightful suggestions and comments.

RIGOROUS DERIVATION OF INCOMPRESSIBLE e-MHD EQUATIONS FROM COMPRESSIBLE EULER–MAXWELL EQUATIONS*

YUE-JUN PENG† AND SHU WANG‡

Abstract. We derive incompressible e-MHD equations from compressible Euler–Maxwell equations via the quasi-neutral regime. Under the assumption that the initial data are well prepared for the electric density, electric velocity, and magnetic field (but not necessarily for the electric field), the convergence of the solutions of the compressible Euler–Maxwell equations in a torus to the solutions of the incompressible e-MHD equations is justified rigorously by studies on a weighted energy. One of the main ingredients for establishing uniform a priori estimates is to use the curl-div decomposition of the gradient and the wave-type equations of the Maxwell equations.

Key words. Euler–Maxwell equations, incompressible electron magnetohydrodynamics equations, quasi-neutral limit, weighted energy

1. Introduction.

Let n and u be the density and velocity vector of the electric particles in a plasma and E and B be, respectively, the electric field and magnetic field. They are vector functions of a three-dimensional position vector $x \in \mathbb{T}$ and of the time $t > 0$, where $\mathbb{T} = (\mathbb{R}/2\pi\mathbb{Z})^3$ is the torus. The fields E and B are coupled to the electron density through the Maxwell equations and act on the electrons via the Lorentz force. We assume that in the plasma the ions are nonmoving and become a uniform background with a fixed unit density. This implies that the density of ions is equal to 1 and the velocity of ions vanishes. Under these assumptions, the dynamics of the compressible electrons obey the (scaled) one-fluid Euler–Maxwell system:

$$\partial_t n + \operatorname{div}(nu) = 0, \tag{1.1}$$

$$\partial_t (nu) + \operatorname{div}(nu \otimes u) + \nabla p(n) = -n(E + \gamma u \times B), \tag{1.2}$$

$$\gamma\epsilon\partial_t E - \nabla \times B = \gamma n u, \quad \gamma\partial_t B + \nabla \times E = 0, \tag{1.3}$$

$$\epsilon \operatorname{div} E = 1 - n, \quad \operatorname{div} B = 0 \tag{1.4}$$

for $x \in \mathbb{T}$ and $t > 0$ subject to initial conditions

$$(n, u, E, B)(t = 0) = (n_0^\epsilon, u_0^\epsilon, E_0^\epsilon, B_0^\epsilon) \tag{1.5}$$

for $x \in \mathbb{T}$. In the above equations, $p = p(n)$ is the pressure, assumed to be smooth and strictly increasing for $n > 0$, $j = nu$ is the current density, and $E + \gamma u \times B$ represents

the Lorentz force. Equations (1.1)–(1.2) are the mass and momentum balance laws for the electrons, respectively, while (1.3)–(1.4) are the Maxwell equations. It is easy to see that equations (1.4) are redundant with equations (1.3) as soon as they are satisfied by the initial data. However, we keep them in the system because this redundancy may be lost in the asymptotic limit.

Equations (1.1)–(1.4) can be viewed as a fluid version of the Vlasov–Maxwell system for a plasma describing the evolution of the electron phase density [3]. Their form is similar to the two-fluid Euler–Maxwell system (see [1, 5, 19, 21]). However, the natures of the one-fluid and the two-fluid Euler–Maxwell systems are different. In the two-fluid model, the vanishing velocity of ions implies the vanishing electric field and the quasi neutrality of the plasma; i.e., the density of ions is equal to the density of electrons. Thus, the one-fluid equations (1.1)–(1.4) cannot be derived from the two-fluid equations.

The dimensionless parameters ϵ and γ can be chosen independently of each other, according to the desired scaling. Physically, ϵ and γ can be chosen to be proportional to the Debye length and $\frac{1}{c}$, where $c = (\epsilon_0\nu_0)^{-\frac{1}{2}}$ is the speed of light, with ϵ_0 and ν_0 being the vacuum permittivity and permeability (see [5, pp. 349–351]). The limit $\epsilon \to 0$ leads to $n = 1$, which is called the quasi neutrality of the plasma (here the constant 1 denotes the unit density of nonmoving ions). Thus, the limit $\epsilon \to 0$ is called the quasi-neutral limit. Also, the limit $\gamma \to 0$ is physically called the nonrelativistic limit. For the other physical meaning of the dimensionless parameters ϵ and γ, see [3, 10].

In the present paper, we concentrate on the so-called quasi-neutral regime. Hence here we consider only the following quasi-neutral scaling: $\gamma = O(1)$ and $\epsilon \ll 1$.

Now, setting formally $\epsilon = 0$ in the system (1.1)–(1.4), one can arrive at the so-called electron magnetohydrodynamics (e-MHD) equations as follows [3]:

$$\partial_t u + u \cdot \nabla u + E = -\gamma u \times B, \tag{1.6}$$

$$-\nabla \times B = \gamma u, \quad \mathrm{div} B = 0, \tag{1.7}$$

$$\gamma \partial_t B + \nabla \times E = 0, \quad n = 1. \tag{1.8}$$

The e-MHD system (1.6)–(1.8) is incompressible, i.e., $\mathrm{div} u = 0$, which is precisely the limit equation obtained from (1.1) by using the fact that $n = 1$ in (1.8). However, this incompressible condition need not be written separately since it can be obtained by the first equation in (1.7).

The main purpose of this paper is to prove rigorously the above formal limit for smooth solutions of the Euler–Maxwell system (1.1)–(1.4) on time intervals, on which a smooth solution of the incompressible e-MHD equations exists. The precise statement is given in section 2.

From the view of the singular perturbation theory, the quasi-neutral limit $\epsilon \to 0$ in the Euler–Maxwell system is a problem of singular perturbation for hyperbolic systems (see [8, 11, 12, 22]). However, it is very different from the theory of singular low Mach number limit for symmetrizable hyperbolic systems by Klainerman and Majda in [11, 12]. In the latter case, the essential singularity can be cancelled using a symmetrizer of hyperbolic systems. For the quasi-neutral limit in the Euler–Maxwell system, besides the singularities in the Maxwell equations, there exists an extra singularity caused by the coupling electromagnetic field (source term) in the Euler equations, which cannot be overcome by using the symmetric technique of hyperbolic systems. Hence the singular limit theory for symmetrizable hyperbolic systems developed by Klainerman

and Majda [11, 12] or extended further by Schochet [22] cannot be applied here to obtain the uniform a priori estimates of the solution with respect to ϵ.

In this paper, we control these singularities and then derive rigorously the e-MHD system from the Euler–Maxwell system by an elaborate energy method based on studies on an ϵ-weighted energy. Let $(n^\epsilon, u^\epsilon, E^\epsilon, B^\epsilon)$ be the solution to the Euler–Maxwell problem and (u^0, E^0, B^0) be the solution to the incompressible e-MHD equations. Our basic idea to establish the uniform a priori estimates is the need to obtain an estimate not just for $n^\epsilon - 1 - \epsilon \mathrm{div} E^0$ but also for $\frac{n^\epsilon - 1 - \epsilon \mathrm{div} E^0}{\sqrt{\epsilon}}$ and then for $\sqrt{\epsilon}(E^\epsilon - E^0)$. In particular, the order of derivatives that we need to estimate for the latter is one less than for the other main quantities $(n^\epsilon - 1 - \epsilon \mathrm{div} E^0, u^\epsilon - u^0, B^\epsilon - B^0)$. These estimates cannot be obtained by straightforward Sobolev energy estimates for which the same order of derivatives for both is needed. They are achieved due to the dissipation structure of the equation for $\frac{n^\epsilon - 1 - \epsilon \mathrm{div} E^0}{\sqrt{\epsilon}}$ (see (4.21)). Finally, the desired estimates are obtained through a priori estimates of vorticity and divergence (see Lemmas 4.2–4.3).

There have been a lot of studies on the Euler–Poisson equations and their asymptotic analysis contrarily to the study on the Euler–Maxwell equations. See [2, 4, 7, 8, 20, 23, 24, 25] and the references therein. The first mathematical study of the Euler–Maxwell equations with an extra relaxation term is due to Chen, Jerome, and Wang [6], where a global existence result to weak solutions in the one-dimensional case is established by the fractional step Godunov scheme together with a compensated compactness argument. Paper [6] also exhibits some applications of the model (1.1)–(1.4) in the semiconductor theory. Since then little progress has been made on the Euler–Maxwell equations. Recently the convergence of the Euler–Maxwell system to the compressible Euler–Poisson system has been proved in [17] via the nonrelativistic limit, in which general initial data are allowed by performing an initial layer analysis. This limit corresponds to $\gamma \to 0$ and $\epsilon > 0$ being fixed. The convergence of the compressible Euler–Maxwell equations to the incompressible Euler equations is justified as $\gamma = \epsilon \to 0$ (see [18]). Finally, we mention that a related asymptotic limit problem on the Vlasov–Maxwell system is discussed in [2, 3].

We stress that, in this paper, the convergence of the electron density, the current velocity vector, and the magnetic field vector of the Euler–Maxwell systems is strong, whereas the convergence of the electric field vector is only weak. That is why we do not need the assumption that the initial electric field of Euler–Maxwell systems tends to the initial value of the electric field of the limit system. The latter is not arbitrarily given but is determined by the initial data of the limit system (2.6)–(2.9) (see Proposition 2.1). This is different from the situation in [18], where the initial data are prepared. Also, by checking the proof in section 4, we see that it is possible to extend the results of this paper ($\gamma > 0$ being fixed and $\epsilon \to 0$) to the case $\gamma \to 0$ and $\epsilon \to 0$ without any relation between γ and ϵ. This limit is still governed by the incompressible Euler equations. To see this more clearly, the parameter γ is kept in the estimates.

Notation and preliminary results.

(1) Throughout this paper, $\nabla = \nabla_x$ is the gradient, $\nabla\cdot$ is the divergence operator, and $\alpha = (\alpha_1, \alpha_2, \alpha_3)$ and β, etc., are multi-indices. We denote by $H^s(\mathbb{T})$ the standard Sobolev space in torus $\mathbb{T}$, which is defined by Fourier transform, namely, $f \in H^s(\mathbb{T})$ if and only if

$$\|f\|_s^2 = (2\pi)^3 \sum_{k \in \mathbb{Z}^3} (1 + |k|^2)^s |(\mathcal{F}f)(k)|^2 < +\infty,$$

where $(\mathcal{F}f)(k) = \int_{\mathbb{T}} f(x)e^{-ikx}dx$ is the Fourier transform of $f \in H^s(\mathbb{T})$.

(2) Recall the following basic Moser-type calculus inequalities [11, 12]: for $f, g, v \in H^s$ and any nonnegative multi index $\alpha, |\alpha| \le s$,

(i) $\|D_x^\alpha(fg)\|_{L^2} \le C_s(\|f\|_{L^\infty}\|D_x^s g\|_{L^2} + \|g\|_{L^\infty}\|D_x^s f\|_{L^2}), \quad s \ge 0,$

(ii) $\|D_x^\alpha(fg) - fD_x^\alpha g\|_{L^2} \le C_s(\|D_x f\|_{L^\infty}\|D_x^{s-1} g\|_{L^2} + \|g\|_{L^\infty}\|D_x^s f\|_{L^2}), \quad s \ge 1.$

(3) The following vector analysis formulas will be repeatedly used (see [5]):

$$\mathrm{div}(f \times g) = \nabla \times f \cdot g - \nabla \times g \cdot f, \tag{1.9}$$

$$f \cdot \nabla g = (\nabla \times g) \times f + \nabla(f \cdot g) - \nabla f \cdot g, \tag{1.10}$$

$$f \cdot \nabla f = (\nabla \times f) \times f + \nabla\left(\frac{|f|^2}{2}\right), \tag{1.11}$$

$$\nabla \times (f \times g) = f\mathrm{div}g - g\mathrm{div}f + (g \cdot \nabla)f - (f \cdot \nabla)g. \tag{1.12}$$

2. Well-posedness of the e-MHD and main results. For smooth solutions of the Euler–Maxwell system (1.1)–(1.5) with $n > 0$, (1.2) is equivalent to

$$\partial_t u + (u \cdot \nabla)u + \nabla h(n) = -(E + \gamma u \times B),$$

where the enthalpy $h(n)$ is defined by

$$h(n) = \int_1^n \frac{p'(s)}{s} ds.$$

Thus, regarding ϵ as a singular perturbation parameter, we can rewrite the problem (1.1)–(1.5) as

$$\partial_t n^\epsilon + \mathrm{div}(n^\epsilon u^\epsilon) = 0, \tag{2.1}$$

$$\partial_t u^\epsilon + (u^\epsilon \cdot \nabla)u^\epsilon + \nabla h(n^\epsilon) = -(E^\epsilon + \gamma u^\epsilon \times B^\epsilon), \tag{2.2}$$

$$\gamma\epsilon\partial_t E^\epsilon - \nabla \times B^\epsilon = \gamma n^\epsilon u^\epsilon, \quad \gamma\partial_t B^\epsilon + \nabla \times E^\epsilon = 0, \tag{2.3}$$

$$\epsilon\mathrm{div}E^\epsilon = 1 - n^\epsilon, \quad \mathrm{div}B^\epsilon = 0, \tag{2.4}$$

$$(n^\epsilon, u^\epsilon, E^\epsilon, B^\epsilon)(t = 0) = (n_0^\epsilon, u_0^\epsilon, E_0^\epsilon, B_0^\epsilon), \tag{2.5}$$

where γ is a positive constant of order one. This means that the magnetic field does not vanish in the limiting process.

We also rewrite the limit system (1.6)–(1.8) as

$$\partial_t u^0 + u^0 \cdot \nabla u^0 + E^0 = -\gamma u^0 \times B^0, \tag{2.6}$$

$$-\nabla \times B^0 = \gamma u^0, \quad \mathrm{div}B^0 = 0, \tag{2.7}$$

$$\gamma\partial_t B^0 + \nabla \times E^0 = 0, \quad n^0 = 1. \tag{2.8}$$

Following the idea of [3], introduce the general vorticity

$$\omega^0 = \nabla \times (u^0 - \gamma A^0),$$

where A^0 is the magnetic potential such that

$$\nabla \times A^0 = B^0 \quad \text{and} \quad \mathrm{div} A^0 = 0.$$

Noting $\nabla \cdot u^0 = 0$ and using the identity (1.11), we can write the e-MHD equations (2.6)–(2.8) in a different way:

$$\partial_t \omega^0 + u^0 \cdot \nabla \omega^0 - \omega^0 \cdot \nabla u^0 = 0, \quad -\Delta u^0 + \gamma^2 u^0 = \nabla \times \omega^0.$$

Therefore the existence results are the same as for the incompressible Euler equations [14]. In particular, we have local smooth solutions of the e-MHD equations for the smooth initial data given by

$$u^0(t=0) = u_0^0, \quad B^0(t=0) = B_0^0. \tag{2.9}$$

PROPOSITION 2.1 (see [3]). *Assume that* $u_0^0, B_0^0 \in C^\infty(\mathbb{T})$ *satisfy*

$$-\nabla \times B_0^0 = \gamma u_0^0, \quad \mathrm{div} B_0^0 = 0. \tag{2.10}$$

Then there exist $0 < T_* \le \infty$ *(if* $d = 2$, $T_* = \infty$*), the maximal existence time, and a unique smooth solution* $(u^0, B^0, E^0) \in C^\infty(\mathbb{T} \times [0, T_*))$ *of the incompressible e-MHD equations* (2.6)–(2.9) *defined on* $[0, T_*)$.

For the convergence of the compressible Euler–Maxwell system (2.1)–(2.5), our main result is stated as follows.

THEOREM 2.1. *Let* $s_0 > \frac{3}{2} + 2$ *and* $\gamma > 0$ *be fixed. Let* $u_0^0, B_0^0 \in C^\infty(\mathbb{T})$ *satisfy* (2.10) *and* $n_0^\epsilon, E_0^\epsilon, B_0^\epsilon \in C^\infty(\mathbb{T})$ *satisfy*

$$\epsilon \mathrm{div} E_0^\epsilon = 1 - n_0^\epsilon, \quad \mathrm{div} B_0^\epsilon = 0.$$

Assume that

$$\|(n_0^\epsilon - 1, u_0^\epsilon - u_0^0, B_0^\epsilon - B_0^0)\|_{H^{s_0}(\mathbb{T})} + \|\sqrt{\epsilon} E_0^\epsilon\|_{H^{s_0}(\mathbb{T})} \le C\sqrt{\epsilon} \tag{2.11}$$

for some positive constant C *independent of* ϵ. *Let* T_*, $0 < T_* \le \infty$ $(d = 2, T_* = \infty)$, *be the maximal existence time of the smooth solution* $(u^0, B^0, E^0) \in C^\infty(\mathbb{T} \times [0, T_*))$ *of the incompressible e-MHD equations* (2.6)–(2.9). *Then, for any* $T_0 < T_*$, *there exist constants* $\epsilon_0(T_0) > 0$ *and* $\tilde{M}(T_0) > 0$, *depending only upon* T_0 *and the initial data, such that the Euler–Maxwell system* (2.1)–(2.5) *has a classical smooth solution* $(n^\epsilon, u^\epsilon, E^\epsilon, B^\epsilon)$, *defined on* $[0, T_0]$, *satisfying*

$$\|(n^\epsilon - 1, u^\epsilon - u^0, B^\epsilon - B^0)(\cdot, t)\|_{H^{s_0}(\mathbb{T})} + \|\sqrt{\epsilon} E^\epsilon(\cdot, t)\|_{H^{s_0 - 1}(\mathbb{T})} \le \tilde{M}(T_0)\sqrt{\epsilon} \tag{2.12}$$

for all $0 < \epsilon \le \epsilon_0$ *and* $0 \le t \le T_0$. *As a result, the sequence* $(n^\epsilon, u^\epsilon, B^\epsilon)_{\epsilon > 0}$ *converges strongly to* $(1, u^0, B^0)$ *in* $L^\infty(0, T_0; H^{s_0}(\mathbb{T}))$. *Furthermore, the sequence* $(E^\epsilon)_{\epsilon > 0}$ *converges to* E^0 *in* $W^{-1,\infty}(0, T_0; H^{s_0 - 1}(\mathbb{T}))$.

Remark 2.1. Condition (2.11) means that the initial data are well prepared for $(n^\epsilon, u^\epsilon, B^\epsilon)$ but not for E^ϵ, which are only bounded. This is sufficient to conclude the convergence of E^ϵ to E^0 in some weak sense. Since all the terms involving E^ϵ in the Euler–Maxwell system (2.1)–(2.5) are linear, we can pass to the limit in the system (in the sense of distributions, for instance). The fact that the electric field $E^\epsilon(\cdot, t)$ is bounded uniformly in ϵ for all time $t \in [0, T_0]$ is not surprising because, generally speaking, this property should be maintained over time when the initial electric field is bounded uniformly in ϵ and the density n^ϵ has a better convergence rate. As in

[8, 13, 22], some new techniques are required to study the strong convergence of the electric field when its initial value is also prepared. This is related to the initial layer analysis and will be discussed in the future.

Remark 2.2. The convergence rate $O(\sqrt{\epsilon})$ in Theorem 2.1 is probably not optimal. It should be possible to improve it by constructing better approximate solutions under the same assumption. Moreover, if the initial error for $(n^\epsilon, u^\epsilon, B^\epsilon)$ is better than $O(\sqrt{\epsilon})$, then so should the convergence rate. On the other hand, the convergence rate should be better in a weaker norm than $\|\cdot\|_{s_0}$. For example, the estimate (2.12) on E^ϵ and the first equation in (2.4) already give

$$\|n^\epsilon(\cdot,t)-1\|_{H^{s_0-2}(\mathbb{T})}=O(\epsilon).$$

Remark 2.3. The results of this paper hold in the whole space $\mathbb{R}^3$. Indeed, the key point of the proof of Theorem 2.1 is to establish the uniform a priori estimates (2.12) based on the study of a weighted energy combined with singular perturbation methods. This is dealt with in the same way as that of the papers [11, 12] by Klainerman and Majda. Here neither the compactness of $\mathbb{T}$ nor a Poincaré-type inequality is used.

3. Derivation of error equations and local existence. Let $(n^\epsilon, u^\epsilon, E^\epsilon, B^\epsilon)$ be the unknown solution to the problem (2.1)–(2.5) and (u^0, E^0, B^0) be the solution to the incompressible e-MHD equations defined on $[0, T_*)$ given by Proposition 2.1. Denote this by

$$(N^\epsilon, U^\epsilon, F^\epsilon, G^\epsilon)=(n^\epsilon-1+\epsilon\mathrm{div}E^0, u^\epsilon-u^0, E^\epsilon-E^0, B^\epsilon-B^0), \tag{3.1}$$

which satisfies the following problem:

(3.2)
$$\begin{cases}
\partial_t N^\epsilon+\mathrm{div}((N^\epsilon+1-\epsilon\mathrm{div}E^0)U^\epsilon+N^\epsilon u^0)=\epsilon(\partial_t\mathrm{div}E^0+\mathrm{div}(u^0\mathrm{div}E^0)),\\
\partial_t U^\epsilon+[(U^\epsilon+u^0)\cdot\nabla]U^\epsilon+(U^\epsilon\cdot\nabla)u^0+F^\epsilon+\nabla(h(N^\epsilon+1-\epsilon\mathrm{div}E^0)\\
\qquad\qquad -h(1-\epsilon\mathrm{div}E^0))\\
\qquad\qquad =-\gamma\big((U^\epsilon+u^0)\times G^\epsilon+U^\epsilon\times B^0\big)+\epsilon h'(1-\epsilon\mathrm{div}E^0)\nabla(\mathrm{div}E^0),\\
\epsilon\gamma\partial_t F^\epsilon-\nabla\times G^\epsilon=\gamma\big((N^\epsilon+1-\epsilon\mathrm{div}E^0)U^\epsilon+N^\epsilon u^0\big)-\epsilon\gamma\big(\partial_t E^0+u^0\mathrm{div}E^0\big),\\
\gamma\partial_t G^\epsilon+\nabla\times F^\epsilon=0,\\
\epsilon\mathrm{div}F^\epsilon=-N^\epsilon,\quad \mathrm{div}G^\epsilon=0,\\
(N^\epsilon, U^\epsilon, F^\epsilon, G^\epsilon)|_{t=0}\\
\qquad\qquad =\big(n_0^\epsilon-1+\epsilon\mathrm{div}E^0(t=0), u_0^\epsilon-u_0^0, E_0^\epsilon-E^0(t=0), B_0^\epsilon-B_0^0\big).
\end{cases}$$

Note that we use $1-\epsilon\mathrm{div}E^0$ as the approximate solution of the density n^ϵ instead of the formal approximate solution 1. This implies that the equation $\epsilon\mathrm{div}F^\epsilon=-N^\epsilon$ is homogeneous. This is a key point in the following convergence analysis. Otherwise, an extra term $\mathrm{div}E^0$ appears in the divergence equation (4.21), which is just bounded but does not converge to 0 as $\epsilon\to 0$. If so, by the techniques used in this paper, the desired convergence rate $O(\sqrt{\epsilon})$ cannot be obtained.

Set

$$W_I^\epsilon = \begin{pmatrix} N^\epsilon \\ U^\epsilon \end{pmatrix}, \quad W_{II}^\epsilon = \begin{pmatrix} F^\epsilon \\ G^\epsilon \end{pmatrix}, \quad W^\epsilon = \begin{pmatrix} W_I^\epsilon \\ W_{II}^\epsilon \end{pmatrix} = \begin{pmatrix} N^\epsilon \\ U^\epsilon \\ F^\epsilon \\ G^\epsilon \end{pmatrix},$$

$$W_0^\epsilon = \begin{pmatrix} N_0^\epsilon \\ U_0^\epsilon \\ F_0^\epsilon \\ G_0^\epsilon \end{pmatrix} = \begin{pmatrix} n_0^\epsilon - 1 + \epsilon \mathrm{div} E^0(t=0) \\ u_0^\epsilon - u_0^0 \\ E_0^\epsilon - E^0(t=0) \\ B_0^\epsilon - B_0^0 \end{pmatrix}, \ D_0^\epsilon = \begin{pmatrix} \mathbf{I}_{4\times 4} & \mathbf{0} \\ \mathbf{0} & \begin{pmatrix} \epsilon\gamma \mathbf{I}_{3\times 3} & \mathbf{0} \\ \mathbf{0} & \gamma \mathbf{I}_{3\times 3} \end{pmatrix} \end{pmatrix},$$

$$A_i(W^\epsilon) = \begin{pmatrix} \begin{pmatrix} (U^\epsilon + u^0)_i & (N^\epsilon + 1 - \epsilon \mathrm{div} E^0) e_i^T \\ h'(N^\epsilon + 1 - \epsilon \mathrm{div} E^0) e_i & (U^\epsilon + u^0)_i \mathbf{I}_{3\times 3} \end{pmatrix} & \mathbf{0} \\ \mathbf{0} & \begin{pmatrix} \mathbf{0} & B_i \\ B_i^T & \mathbf{0} \end{pmatrix} \end{pmatrix},$$

$$H_1(W_I^\epsilon) = \begin{pmatrix} -\epsilon U^\epsilon \cdot \nabla(\mathrm{div} E^0) \\ (U^\epsilon \cdot \nabla) u^0 - \epsilon (h'(N^\epsilon + 1 - \epsilon \mathrm{div} E^0) - h'(1 - \epsilon \mathrm{div} E^0)) \nabla(\mathrm{div} E^0) \\ 0 \\ 0 \end{pmatrix},$$

$$H_2(F^\epsilon) = \begin{pmatrix} 0 \\ F^\epsilon \\ 0 \\ 0 \end{pmatrix}, \quad H_3(W_I^\epsilon, G^\epsilon) = \begin{pmatrix} 0 \\ (U^\epsilon + u^0) \times G^\epsilon + U^\epsilon \times B^0 \\ -\big((N^\epsilon + 1 - \epsilon \mathrm{div} E^0) U^\epsilon + N^\epsilon u^0\big) \\ 0 \end{pmatrix}$$

and

$$R^\epsilon = \begin{pmatrix} R_n^\epsilon \\ R_u^\epsilon \\ R_E^\epsilon \\ R_B^\epsilon \end{pmatrix} = \begin{pmatrix} \partial_t \mathrm{div} E^0 + \mathrm{div}(u^0 \mathrm{div} E^0) \\ h'(1 - \epsilon \mathrm{div} E^0) \nabla(\mathrm{div} E^0) \\ -\gamma(\partial_t E^0 + u^0 \mathrm{div} E^0) \\ 0 \end{pmatrix},$$

where (e_1, e_2, e_3) is the canonical basis of $\mathbb{R}^3$, $\mathbf{I}_{d\times d}$ $(d = 3, 4)$ is a $d \times d$ unit matrix, y_i denotes the ith component of $y \in \mathbb{R}^3$, and

$$B_1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{pmatrix}, \quad B_2 = \begin{pmatrix} 0 & 0 & -1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad B_3 = \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

From $(3.2)_{1,3}$, the redundant equations $\epsilon \mathrm{div} F^\epsilon = -N^\epsilon$ and $\mathrm{div} G^\epsilon = 0$ in system (3.2) hold as soon as they are satisfied by the initial data. Thus the problem (3.2) for the

unknown W^ϵ can be rewritten as

(3.3)
$$\begin{cases} D_0^\epsilon \partial_t W^\epsilon + \sum_{i=1}^{3} A_i(W^\epsilon)\partial_{x_i} W^\epsilon + H_1(W_I^\epsilon) = H_2(F^\epsilon) + \epsilon R^\epsilon - \gamma H_3(W_I^\epsilon, G^\epsilon), \\ W^\epsilon|_{t=0} = W_0^\epsilon, \end{cases}$$

with

$$\epsilon \mathrm{div} F^\epsilon(x,0) = -N^\epsilon(x,0), \quad \mathrm{div} G^\epsilon(x,0) = 0,$$

which can be guaranteed by the assumptions on the initial data.

It is not difficult to see that the equations for W^ϵ in (3.3) are symmetrizable hyperbolic; i.e., if we introduce

$$A_0(W^\epsilon) = \begin{pmatrix} \begin{pmatrix} h'(N^\epsilon + 1 - \epsilon \mathrm{div} E^0) & 0 \\ 0 & (N^\epsilon + 1 - \epsilon \mathrm{div} E^0)\mathbf{I}_{3\times 3} \end{pmatrix} & \mathbf{0} \\ \mathbf{0} & \mathbf{I}_{6\times 6} \end{pmatrix},$$

which is positively definite when $N^\epsilon + 1 - \epsilon \mathrm{div} E^0 \geq M_0 > 0$ for $\epsilon \ll 1$ and $\|N^\epsilon\|_{L^\infty} \leq \frac{1}{2}$, then $A_0 D_0^\epsilon$ and $\tilde{A}_i(W^\epsilon) = A_0(W^\epsilon)A_i(W^\epsilon)$ are symmetric for all $1 \leq i \leq 3$. Note that, for smooth solutions, the Euler–Maxwell system (2.1)–(2.5) is equivalent to that of (3.2) or (3.3). Thus, by the standard existence theory of local smooth solutions for symmetrizable hyperbolic equations (see [9, 15, 16]), we have the following result.

PROPOSITION 3.1. *Let $M > 0$ and $u_0^0, B_0^0 \in C^\infty$ be given and W_0^ϵ satisfy $W_0^\epsilon \in H^s$, $s > \frac{3}{2} + 2$, and $\|N_0^\epsilon\|_{H^s(\mathbb{T})} \leq \delta$ for some given $\delta > 0$ (to be chosen sufficiently small so that $M\delta C_s \leq \frac{1}{2}$, where C_s is the Sobolev embedding constant). Then, for any fixed ϵ ($\ll 1$), there exist $0 < T_\epsilon(\delta) \leq \infty$, the maximal existence time, and a unique smooth solution $W^\epsilon \in \bigcap_{l=0}^{1} C^l([0,T_\epsilon); H^{s-l}(\mathbb{T}))$ of the system (3.2) or (3.3) on $[0,T_\epsilon)$ satisfying $\sup_{0<t<T_\epsilon} \|N^\epsilon(t)\|_{H^s(\mathbb{T})} \leq M\delta$. Moreover, if $T_\epsilon < \infty$, then, for any fixed ϵ (sufficiently small), we have*

$$\text{either } \lim_{t\to T_\epsilon} \|N^\epsilon(t)\|_{H^s(\mathbb{T})} = M\delta \text{ or } \lim_{t\to T_\epsilon} \|(U^\epsilon, F^\epsilon, G^\epsilon)(\cdot,t)\|_{H^s(\mathbb{T})} = +\infty. \tag{3.4}$$

Note that the error equations (3.2) or (3.3) from the Euler–Maxwell system are not in the form covered by the well-known Klainerman and Majda theory of singular limits of hyperbolic systems because of the extra singularity caused by the coupling source term $H_2(F^\epsilon)$ in the Euler equations. Hence the singular limit theory for symmetrizable hyperbolic systems developed by Klainerman and Majda [11, 12] or extended further by Schochet [22] cannot be applied here to obtain the uniform a priori estimates of the solution W^ϵ with respect to ϵ.

4. Proof of the main results. In this section, we justify rigorously the convergence of the Euler–Maxwell system to the incompressible e-MHD equations; namely, we prove Theorem 2.1 by using the asymptotic expansion of singular perturbations and careful classical energy methods.

4.1. Convergence rate and uniform a priori estimates. We first establish the convergence rate of the error function $(N^\epsilon, U^\epsilon, B^\epsilon)$ by obtaining the a priori estimates uniformly in ϵ. As a consequence, we obtain the existence of exact solutions

$(n^\epsilon, u^\epsilon, E^\epsilon, B^\epsilon)$ to (2.1)–(2.5) in a time interval independent of ϵ, and the convergence of $(n^\epsilon, u^\epsilon, E^\epsilon, B^\epsilon)$ to $(1, u^0, E^0, B^0)$ as $\epsilon \to 0$, where (u^0, E^0, B^0) is the solution of the incompressible e-MHD equations (2.6)–(2.9).

In order to justify rigorously the convergence, it suffices to obtain the uniform estimates of the smooth solutions to (3.2) or (3.3) with respect to the parameter ϵ. This is achieved by the elaborate energy method. Since the detailed estimates are very lengthy and involved, we would like to outline some main ingredients here. First, based on the L^2 energy conservation of the Euler–Maxwell system, an ϵ-weighted L^2 energy estimate is derived by noting that there exists a cancellation or some kind of balance between the Euler part and Maxwell part of the Euler–Maxwell system. Second, we introduce a general vorticity of the velocity and the magnetic field and give the corresponding equations of the vorticity and the divergence. Then high order Sobolev energy estimates on the vorticity and the divergence are established by the vector analysis techniques and an elaborate energy method. Next, based on the curl-div decomposition of the gradient, an ϵ-weighted high order Sobolev energy estimate on the density and velocity of the Euler part is derived. Finally, based on the wave-type equation of the Maxwell equations, an ϵ-weighted high order Sobolev energy estimate on the electric field and magnetic field is established. Combining these estimates, an entropy production integral inequality is derived by introducing an ϵ-weighted energy, which yields the desired estimates.

In the following, $(\cdot, \cdot)$ stands for the L^2 inner product of two scalar or vector functions in $\mathbb{T}$. Also, we denote $\int_{\mathbb{T}}$ by $\int$ and

$$\|\cdot\| = \|\cdot\|_{L^2(\mathbb{T})}, \quad \|\cdot\|_l = \|\cdot\|_{H^l(\mathbb{T})}, \quad l \in \mathbb{N}^*.$$

For convenience, we introduce the ϵ-weighted Sobolev norms

$$\|W^\epsilon(t)\|_{l,*} = \|(N^\epsilon, U^\epsilon, G^\epsilon)(t)\|_l,$$

$$|||W^\epsilon(t)|||_l = \left(\|W^\epsilon(t)\|_{l,*}^2 + \left\| \left(\frac{N^\epsilon}{\sqrt{\epsilon}}, \sqrt{\epsilon}\gamma F^\epsilon, \epsilon\gamma \partial_t F^\epsilon \right)(t) \right\|_{l-1}^2 \right)^{\frac{1}{2}},$$

$$|||W^\epsilon|||_{l,T} = \sup_{0<t<T} |||W^\epsilon(t)|||_l, \quad l \in \mathbb{N}^*.$$

Note that these norms are different from those used in [18] to prove the convergence of the compressible Euler–Maxwell equations to the incompressible Euler equations.

The key estimate of this paper is contained in the following result.

PROPOSITION 4.1. *Let l be an integer such that $l > \frac{3}{2} + 2$. Assume*

$$|||W_0^\epsilon|||_l \le D_1 \sqrt{\epsilon} \tag{4.1}$$

for sufficiently small ϵ and a constant $D_1 > 0$ independent of ϵ. Then, for any $T_0 \in (0, T_*)$, there are constants $D_2 > 0$ and $\epsilon_0 > 0$, depending upon T_0, such that, for all $\epsilon \le \epsilon_0$, it holds that $T_\epsilon \ge T_0$, and the solution $W^\epsilon(t)$ of (3.2), well defined in $[0, T_\epsilon)$, satisfies

$$|||W^\epsilon|||_{l,T_0} \le D_2 \sqrt{\epsilon}. \tag{4.2}$$

The remainder of section 4 is devoted to the proof of this result.

First, according to the assumption (4.1), using the local existence results in Proposition 3.1 and Sobolev's embedding lemma, we know that there exists an $\epsilon_0 > 0$ such

that, for all $\epsilon \le \epsilon_0$, there exists a smooth solution W^ϵ to the system (3.2) or (3.3), defined on $[0, T_\epsilon)$, satisfying

$$\sup_{0<t<T_\epsilon} \|N^\epsilon(t)\|_{L^\infty(\mathbb{T})} \le C_s \sup_{0<t<T_\epsilon} \|N^\epsilon(t)\|_{H^s(\mathbb{T})} \le MC_sD_1\sqrt{\epsilon} \le \frac{1}{2}. \tag{4.3}$$

Here we take $\delta = D_1\sqrt{\epsilon}$ in Proposition 3.1, and M will be chosen to be a sufficiently large constant independent of ϵ. Hence the rest involves establishing the a priori estimates uniformly with respect to ϵ so as to guarantee $T_\epsilon \ge T_0$ for any given $T_0 < T_*$ and sufficiently small ϵ. Of course, if $T_\epsilon = \infty$, it suffices to obtain the a priori estimates uniformly with respect to ϵ.

In the following, assuming the conditions of Proposition 4.1, we establish a priori estimates by the elaborate energy method in several steps.

For any $T_1 < 1$ independent of ϵ, denote by $T = T^\epsilon = \min\{T_1, T_\epsilon\}$ and by $C > 0$ a constant which depends upon T_0, D_1 but does not depend upon M, T_1, T, and ϵ.

4.2. L^2-estimates. Based on the L^2-conservation of solutions to the Euler–Maxwell system, we obtain L^2-estimates of the error function W^ϵ. Our basic idea is to control the electric field F^ϵ using the special structure between the Euler part and Maxwell part in the Euler–Maxwell system by introducing the extra singular term $\|\frac{N^\epsilon}{\sqrt{\epsilon}}\|$.

LEMMA 4.1. *For all $0 < t < T$ and sufficiently small ϵ, it holds that*

$$\begin{aligned}
&\int \left\{ |U^\epsilon|^2 + \int_0^{N^\epsilon} (h(1-\epsilon \mathrm{div}E^0 + s) - h(1-\epsilon \mathrm{div}E^0))ds + \epsilon|F^\epsilon|^2 + |G^\epsilon|^2 \right\}(t)dx \\
\le &\int \left\{ |U^\epsilon|^2 + \int_0^{N^\epsilon} (h(1-\epsilon \mathrm{div}E^0 + s) - h(1-\epsilon \mathrm{div}E^0))ds + \epsilon|F^\epsilon|^2 + |G^\epsilon|^2 \right\}(t=0)dx \\
&+ \int_0^t \left\{ \|\sqrt{\epsilon}F^\epsilon\|^2 + C(\|W^\epsilon\|_{l,*}^2 + \|W^\epsilon\|_{l,*} + 1) \left\| \left(N^\epsilon, U^\epsilon, \nabla U^\epsilon, \gamma G^\epsilon, \frac{N^\epsilon}{\sqrt{\epsilon}} \right) \right\|^2 \right\}(s)ds \\
&+ C\epsilon^2 + C\epsilon.
\end{aligned} \tag{4.4}$$

Proof. Taking the L^2 inner product of the second equation in the error system (3.2) for U^ϵ, by integration by parts, we get

$$\begin{aligned}
&\frac{d}{dt}(U^\epsilon, U^\epsilon) + 2(F^\epsilon, U^\epsilon) \\
&= \big(\mathrm{div}(U^\epsilon + u^0)U^\epsilon, U^\epsilon\big) + 2\big(h(1-\epsilon \mathrm{div}E^0 + N^\epsilon) - h(1-\epsilon \mathrm{div}E^0), \mathrm{div}U^\epsilon\big) \\
&\quad - 2\big(U^\epsilon \nabla u^0 + \gamma(U^\epsilon \times B^0 + (U^\epsilon + u^0) \times G^\epsilon) - \epsilon R_u^\epsilon, U^\epsilon\big).
\end{aligned} \tag{4.5}$$

Now we estimate each term on the right-hand side of (4.5).

For the first and third terms, using the property of the approximate solution (u^0, E^0, B^0), Cauchy–Schwarz's inequality, and Sobolev's lemma, we get

$$\big(\mathrm{div}(U^\epsilon + u^0)U^\epsilon, U^\epsilon\big) \le C(\|W^\epsilon(t)\|_{l,*} + 1)\|U^\epsilon\|^2 \tag{4.6}$$

and

$$-2\big(U^\epsilon\nabla u^0+\gamma(U^\epsilon\times B^0+(U^\epsilon+u^0)\times G^\epsilon)-\epsilon R_u^\epsilon,U^\epsilon\big)$$

$$\le C(\|W^\epsilon(t)\|_{l,*}+1)\|(U^\epsilon,\gamma G^\epsilon)\|^2+C\epsilon^2. \tag{4.7}$$

For the second term, noting that the first equation in (3.2) can be rewritten as

$$\mathrm{div}U^\epsilon=-(\partial_t N^\epsilon+\mathrm{div}(N^\epsilon(U^\epsilon+u^0)))+\epsilon(\mathrm{div}(\mathrm{div}E^0U^\epsilon)+R_n^\epsilon),$$

from (4.3) we have, for sufficiently small ϵ,

$$\begin{aligned}
&(h(1-\epsilon\mathrm{div}E^0+N^\epsilon)-h(1-\epsilon\mathrm{div}E^0),\mathrm{div}U^\epsilon)\\
&=-\int(h(1-\epsilon\mathrm{div}E^0+N^\epsilon)-h(1-\epsilon\mathrm{div}E^0))(\partial_t N^\epsilon+\mathrm{div}(N^\epsilon(U^\epsilon+u^0)))dx\\
&\quad+\epsilon\int(h(1-\epsilon\mathrm{div}E^0+N^\epsilon)-h(1-\epsilon\mathrm{div}E^0))(\mathrm{div}(\mathrm{div}E^0U^\epsilon)+R_n^\epsilon)dx\\
&=-\frac{d}{dt}\iint_0^{N^\epsilon}(h(1-\epsilon\mathrm{div}E^0+s)-h(1-\epsilon\mathrm{div}E^0))dsdx\\
&\quad+\iint_0^{N^\epsilon}(h'(1-\epsilon\mathrm{div}E^0+s)-h'(1-\epsilon\mathrm{div}E^0))\partial_t(1-\epsilon\mathrm{div}E^0)dsdx\\
&\quad-\int(h(1-\epsilon\mathrm{div}E^0+N^\epsilon)-h(1-\epsilon\mathrm{div}E^0))\mathrm{div}(N^\epsilon(U^\epsilon+u^0))dx\\
&\quad+\epsilon\int(h(1-\epsilon\mathrm{div}E^0+N^\epsilon)-h(1-\epsilon\mathrm{div}E^0))(\mathrm{div}(\mathrm{div}E^0U^\epsilon)+R_n^\epsilon)dx\\
&\le-\frac{d}{dt}\iint_0^{N^\epsilon}(h(1-\epsilon\mathrm{div}E^0+s)-h(1-\epsilon\mathrm{div}E^0))dsdx\\
&\quad+C(\|W^\epsilon(t)\|_{l,*}+1)\|(N^\epsilon,U^\epsilon,\nabla U^\epsilon)\|^2+C\epsilon^2.
\end{aligned}\tag{4.8}$$

Combining (4.5) with (4.6)–(4.8), we have

$$\begin{aligned}
&\frac{d}{dt}\left[(U^\epsilon,U^\epsilon)+\iint_0^{N^\epsilon}(h(1-\epsilon\mathrm{div}E^0+s)-h(1-\epsilon\mathrm{div}E^0))dsdx\right]+2(F^\epsilon,U^\epsilon)\\
&\le C(\|W^\epsilon(t)\|_{l,*}+1)\|(N^\epsilon,U^\epsilon,\nabla U^\epsilon,\gamma G^\epsilon)\|^2+C\epsilon^2.
\end{aligned}\tag{4.9}$$

Multiplying the first equation of the Maxwell system in the error system (3.2) by $\frac{1}{\gamma}F^\epsilon$ and the second one by $\frac{1}{\gamma}G^\epsilon$, by integration by parts, we get

$$\begin{aligned}
&\frac{d}{dt}(\epsilon\|F^\epsilon\|^2+\|G^\epsilon\|^2)+\frac{2}{\gamma}\int(\nabla\times F^\epsilon\cdot G^\epsilon-\nabla\times G^\epsilon\cdot F^\epsilon)dx-2(U^\epsilon,F^\epsilon)\\
&=2(N^\epsilon(U^\epsilon+u^0),F^\epsilon)-2(\epsilon\mathrm{div}E^0U^\epsilon,F^\epsilon)+\frac{2}{\gamma}(\epsilon R_E^\epsilon,F^\epsilon).
\end{aligned}\tag{4.10}$$

On one hand, using the vector analysis formulas (1.9), the term $O(\frac{1}{\gamma})$ appearing in Sobolev's energy estimates vanishes, i.e.,

$$\int(\nabla\times F^\epsilon\cdot G^\epsilon-\nabla\times G^\epsilon\cdot F^\epsilon)dx=\int \mathrm{div}(F^\epsilon\times G^\epsilon)dx=0. \tag{4.11}$$

On the other hand, using Young's inequality, we have

$$\begin{aligned}(N^\epsilon(U^\epsilon+u^0),F^\epsilon)&\le\epsilon\|F^\epsilon\|^2+\frac{1}{4\epsilon}\|N^\epsilon(U^\epsilon+u^0)\|^2\\&\le\epsilon\|F^\epsilon\|^2+C(\|U^\epsilon(t)\|_l^2+1)\left\|\frac{N^\epsilon}{\sqrt{\epsilon}}\right\|^2,\end{aligned} \tag{4.12}$$

where a singular term $\|\frac{N^\epsilon}{\sqrt{\epsilon}}\|$ appears, and

$$-2(\epsilon\mathrm{div}E^0U^\epsilon,F^\epsilon)+\frac{2}{\gamma}(\epsilon R_E^\epsilon,F^\epsilon)\le\epsilon\|F^\epsilon\|^2+C\epsilon\|U^\epsilon\|^2+C\epsilon. \tag{4.13}$$

Thus, combining (4.10) with (4.11)–(4.13), we get

$$\begin{aligned}&\frac{d}{dt}(\epsilon\|F^\epsilon\|^2+\|G^\epsilon\|^2)-2(U^\epsilon,F^\epsilon)\\&\le\epsilon\|F^\epsilon\|^2+C\epsilon\|U^\epsilon\|^2+C(\|U^\epsilon(t)\|_l^2+1)\left\|\frac{N^\epsilon}{\sqrt{\epsilon}}\right\|^2+C\epsilon.\end{aligned} \tag{4.14}$$

It follows from (4.9) and (4.14) that

$$\begin{aligned}&\frac{d}{dt}\int\left\{|U^\epsilon|^2+\int_0^{N^\epsilon}(h(1-\epsilon\mathrm{div}E^0+s)-h(1-\epsilon\mathrm{div}E^0))ds+\epsilon|F^\epsilon|^2+|G^\epsilon|^2\right\}(t)dx\\&\le\|\sqrt{\epsilon}F^\epsilon\|^2+C(\|W^\epsilon(t)\|_{l,*}^2+\|W^\epsilon(t)\|_{l,*}+1)\left\|\left(N^\epsilon,U^\epsilon,\nabla U^\epsilon,\gamma G^\epsilon,\frac{N^\epsilon}{\sqrt{\epsilon}}\right)\right\|^2\\&\quad+C\epsilon^2+C\epsilon.\end{aligned}$$

This completes the proof of Lemma 4.1. □

Note that it follows from the estimate (4.4) that our problem is the need to obtain an estimate not just for N^ϵ but also for $\frac{N^\epsilon}{\sqrt{\epsilon}}$. In particular, the order of derivatives that we need to estimate for the latter is one less than for the other main quantities $(N^\epsilon,U^\epsilon,G^\epsilon)$. However, straightforward Sobolev energy estimates of higher order would require the same number for both. Hence the above method cannot be generalized directly to the high order Sobolev energy estimates. Here the idea is to establish the uniform estimates for $\|\frac{N^\epsilon}{\sqrt{\epsilon}}(t)\|_{l-1}$ through a priori estimates of vorticity and divergence. To this end, we require the equations of vorticity and divergence.

4.3. Derivation of the vorticity and divergence equations. Taking *curl* on the momentum equation and using $\gamma\partial_tG^\epsilon+\nabla\times F^\epsilon=0$ of the magnetic field in the error system (3.2), we have

$$\begin{aligned}&\partial_t(\nabla\times U^\epsilon)+\nabla\times([(U^\epsilon+u^0)\cdot\nabla]U^\epsilon)+\nabla\times((U^\epsilon\cdot\nabla)u^0)-\gamma\partial_tG^\epsilon\\&=-\gamma\nabla\times\big((U^\epsilon+u^0)\times G^\epsilon+U^\epsilon\times B^0\big).\end{aligned} \tag{4.15}$$

Since $\mathrm{div}G^\epsilon = 0$, there exists a vector function $\mathcal{G}^\epsilon$ such that

$$G^\epsilon = \nabla \times \mathcal{G}^\epsilon. \tag{4.16}$$

Using the vector analysis formulas (1.10) and (1.11), we get

$$\nabla \times ([(U^\epsilon + u^0)\cdot\nabla]U^\epsilon) = \nabla \times \big((\nabla \times U^\epsilon) \times (U^\epsilon + u^0)\big) - \nabla \times \big(\nabla u^0 \cdot U^\epsilon\big). \tag{4.17}$$

Then, putting (4.16) and (4.17) into the equations (4.15), we obtain

$$\partial_t(\nabla \times (U^\epsilon - \gamma\mathcal{G}^\epsilon)) + \nabla \times ((\nabla \times (U^\epsilon - \gamma\mathcal{G}^\epsilon)) \times (U^\epsilon + u^0)) = \mathcal{J}_1^\epsilon, \tag{4.18}$$

where

$$\mathcal{J}_1^\epsilon = \nabla \times (\nabla u^0 \cdot U^\epsilon) - \nabla \times ((U^\epsilon \cdot \nabla)u^0) - \gamma\nabla \times (U^\epsilon \times B^0)$$

satisfies

$$\|\mathcal{J}_1^\epsilon\|_{l-1} \le C\|U^\epsilon\|_l. \tag{4.19}$$

Here we require $u^0 \in H^{l+1}$.

Next, introduce the general vorticity

$$\omega^\epsilon = \nabla \times (U^\epsilon - \gamma\mathcal{G}^\epsilon);$$

then it follows from (4.18) that ω^ϵ satisfies the following vorticity equation:

$$\partial_t\omega^\epsilon + (U^\epsilon + u^0)\cdot\nabla\omega^\epsilon - \omega^\epsilon \cdot \nabla(U^\epsilon + u^0) + \omega^\epsilon \mathrm{div}(U^\epsilon + u^0) = \mathcal{J}_1^\epsilon. \tag{4.20}$$

Here we have again used the vector formulas (1.12).

Taking *div* on the momentum equations in the error system (3.2) and using the equation $\epsilon\mathrm{div}F^\epsilon = -N^\epsilon$, we can obtain the following divergence equation:

$$\begin{aligned}&\partial_t \mathrm{div}U^\epsilon + \mathrm{div}([(U^\epsilon + u^0)\cdot\nabla]U^\epsilon) - \frac{N^\epsilon}{\epsilon} + \Delta(h(N^\epsilon + 1 - \epsilon\mathrm{div}E^0) - h(1 - \epsilon\mathrm{div}E^0))\\ &= -\gamma\mathrm{div}\big((U^\epsilon + u^0) \times G^\epsilon\big) + \mathcal{J}_2^\epsilon,\end{aligned} \tag{4.21}$$

where

$$\mathcal{J}_2^\epsilon = -\epsilon\mathrm{div}(R_u^\epsilon) - \mathrm{div}((U^\epsilon \cdot \nabla)u^0) - \gamma\mathrm{div}(U^\epsilon \times B^0)$$

satisfies

$$\|\mathcal{J}_2^\epsilon\|_{l-1} \le C\|U^\epsilon\|_l + C\epsilon. \tag{4.22}$$

4.4. Estimates of the vorticity and divergence. Now we control $\|\nabla \times U^\epsilon\|_{l-1}$ using the vorticity equations (4.20).

LEMMA 4.2. *For any $0 < t < T$ and $l > \frac{3}{2} + 2$, it holds that*

$$\begin{aligned}&\|\nabla \times U^\epsilon(t)\|_{l-1}^2\\ &\le C(\|\nabla \times U^\epsilon(t=0)\|_{l-1}^2 + \gamma^2\|G^\epsilon(t=0)\|_{l-1}^2) + C\gamma^2\|G^\epsilon(t)\|_{l-1}^2\\ &\quad + C\int_0^t (\|W^\epsilon(s)\|_{l,*} + 1)(\|\nabla \times U^\epsilon(s)\|_{l-1}^2 + \gamma^2\|G^\epsilon(s)\|_{l-1}^2)ds.\end{aligned} \tag{4.23}$$

Proof. Let $\alpha \in \mathbb{N}^3$ with $|\alpha| \le l-1$. Taking ∂_x^α on (4.20) and multiplying the resulting equation by $\partial_x^\alpha \omega^\epsilon$, by integration by parts, we have the basic Friedrich energy equation

$$\begin{aligned}\frac{d}{dt}\|\partial_x^\alpha \omega^\epsilon\|^2 &= \big(\mathrm{div}(U^\epsilon + u^0)\partial_x^\alpha \omega^\epsilon, \partial_x^\alpha \omega\big) + 2(H_\alpha^{(1)}, \partial_x^\alpha \omega)\\ &\quad + 2\Big(\partial_x^\alpha\big(\omega^\epsilon \cdot \nabla(U^\epsilon + u^0) - \omega^\epsilon \mathrm{div}(U^\epsilon + u^0) + \mathcal{J}_1^\epsilon\big), \partial_x^\alpha \omega^\epsilon\Big), \end{aligned} \tag{4.24}$$

where the commutator $H_\alpha^{(1)}$ is defined by

$$H_\alpha^{(1)} = -[\partial_x^\alpha((U^\epsilon + u^0)\cdot\nabla\omega^\epsilon) - (U^\epsilon + u^0)\cdot\nabla\partial_x^\alpha\omega^\epsilon],$$

which can be estimated as follows:

$$\begin{aligned}\|H_\alpha^{(1)}\| &\le C(\|\nabla(U^\epsilon + u^0)\|_{L^\infty}\|\partial_x^{l-2}\nabla\omega^\epsilon\| + \|\nabla\omega^\epsilon\|_{L^\infty}\|\partial_x^{l-1}(U^\epsilon + u^0)\|)\\ &\le C(\|\nabla(U^\epsilon + u^0)\|_{l-1}\|\partial_x^{l-2}\nabla\omega^\epsilon\| + \|\nabla\omega^\epsilon\|_{l-2}\|\partial_x^{s-1}(U^\epsilon + u^0)\|)\\ &\le C(\|W^\epsilon(t)\|_{l,*} + 1)\|\omega^\epsilon\|_{l-1}. \end{aligned} \tag{4.25}$$

Here we have used Sobolev's lemma and $l > \frac{3}{2} + 2$.

Using the estimates (4.25) for $H_\alpha^{(1)}$ and (4.19) for $\mathcal{J}_1^\epsilon$, we have, with the aid of Cauchy–Schwarz's inequality and Sobolev's lemma,

$$(\mathrm{div}(U^\epsilon + u^0)\partial_x^\alpha\omega^\epsilon, \partial_x^\alpha\omega) \le C(\|W^\epsilon(t)\|_{l,*} + 1)\|\omega^\epsilon\|_{l-1}^2, \tag{4.26}$$

$$2(H_\alpha^{(1)}, \partial_x^\alpha\omega) \le C(\|W^\epsilon(t)\|_{l,*} + 1)\|\omega^\epsilon\|_{l-1}^2 \tag{4.27}$$

and

$$\begin{aligned}&\Big(\partial_x^\alpha\big(\omega^\epsilon\cdot\nabla(U^\epsilon + u^0) - \omega^\epsilon\mathrm{div}(U^\epsilon + u^0) + \mathcal{J}_1^\epsilon\big), \partial_x^\alpha\omega^\epsilon\Big)\\ &\le C(\|W^\epsilon(t)\|_{l,*} + 1)\|\omega^\epsilon\|_{l-1}^2. \end{aligned} \tag{4.28}$$

Combining (4.24) with (4.26), (4.27), and (4.28), we get

$$\frac{d}{dt}\|\omega^\epsilon\|_{l-1}^2 \le C(\|W^\epsilon(t)\|_{l,*} + 1)\|\omega^\epsilon\|_{l-1}^2,$$

which yields, for any $0 < t < T$,

$$\|\omega^\epsilon(t)\|_{l-1}^2 \le C\|\omega^\epsilon(t=0)\|_{l-1}^2 + C\int_0^t (\|W^\epsilon(s)\|_{l,*} + 1)\|\omega^\epsilon(s)\|_{l-1}^2 ds. \tag{4.29}$$

Using the definition of ω^ϵ, we get

$$\|\nabla\times U^\epsilon\|_{l-1}^2 \le 2\|\omega^\epsilon\|_{l-1}^2 + 2\gamma^2\|G^\epsilon\|_{l-1}^2 \tag{4.30}$$

and

$$\|\omega^\epsilon(t)\|_{l-1}^2 \le 2\|\nabla\times U^\epsilon(t)\|_{l-1}^2 + 2\gamma^2\|G^\epsilon\|_{l-1}^2. \tag{4.31}$$

Then (4.29)–(4.31) give the estimate (4.23).

The proof of Lemma 4.2 is complete. ∎

Next, we estimate $\|\mathrm{div}U^\epsilon\|_{l-1}$ using the divergence equation (4.21). The estimate is contained in the following lemma, whose proof is long and is postponed to the appendix.

LEMMA 4.3. *Let $\alpha \in \mathbb{N}^3$ with $|\alpha| \le l-1$ and $l > \frac{3}{2}+2$. Then, for any $0 < t < T$, we have*

$$\begin{aligned}
&\left[\|\partial_x^\alpha \mathrm{div}U^\epsilon\|^2 + \frac{1}{\epsilon}\left(\frac{1}{1-\epsilon\mathrm{div}E^0}\partial_x^\alpha N^\epsilon, \partial_x^\alpha N^\epsilon\right)\right.\\
&\qquad \left. + \left(\frac{h'(N^\epsilon+1-\epsilon\mathrm{div}E^0)}{N^\epsilon+1-\epsilon\mathrm{div}E^0}\partial_x^\alpha \nabla N^\epsilon, \partial_x^\alpha \nabla N^\epsilon\right)\right](t)\\
&\le C\left[\|\partial_x^\alpha \mathrm{div}U^\epsilon\|^2 + \frac{1}{\epsilon}\left(\frac{1}{1-\epsilon\mathrm{div}E^0}\partial_x^\alpha N^\epsilon, \partial_x^\alpha N^\epsilon\right)\right.\\
&\qquad \left. + \left(\frac{h'(N^\epsilon+1-\epsilon\mathrm{div}E^0)}{N^\epsilon+1-\epsilon\mathrm{div}E^0}\partial_x^\alpha \nabla N^\epsilon, \partial_x^\alpha \nabla N^\epsilon\right)\right](t=0)\\
&\quad + C\int_0^t (\|W^\epsilon(s)\|_{l,*}+1)\|W^\epsilon(s)\|_{l,*}^2 ds\\
&\quad + C\gamma^2\int_0^t (\|U^\epsilon(s)\|_l^2+1)\|G^\epsilon(s)\|_l^2 ds + C\epsilon^2 + C\epsilon. \qquad (4.32)
\end{aligned}$$

4.5. High order energy estimates on the electromagnetic field. Finally, we derive the high order energy estimates on the electromagnetic field. For the electric field, we establish its estimates by using the wave formulas of the Maxwell equations as follows.

LEMMA 4.4. *For any $0 < t \le T$ and $l > \frac{3}{2}+2$, it holds that*

$$\begin{aligned}
&(\epsilon^2\gamma^2\|\partial_t F^\epsilon\|_{l-1}^2 + \epsilon\gamma^2\|F^\epsilon\|_{l-1}^2 + \epsilon\|\nabla\times F^\epsilon\|_{l-1}^2)(t)\\
&\le (\epsilon^2\gamma^2\|\partial_t F^\epsilon\|_{l-1}^2 + \epsilon\gamma^2\|F^\epsilon\|_{l-1}^2 + \epsilon\|\nabla\times F^\epsilon\|_{l-1}^2)(t=0)\\
&\quad + C(\gamma^2+1)\int_0^t (|||W^\epsilon(t)|||_l^4 + |||W^\epsilon(t)|||_l^2+1)|||W^\epsilon(t)|||_l^2(s)ds + C\gamma^2\epsilon^2. \qquad (4.33)
\end{aligned}$$

Proof. It follows from the Maxwell equation in the error equation (3.2) that F^ϵ satisfies the following wave-type equation:

$$\epsilon\gamma\partial_{tt}F^\epsilon - \frac{1}{\gamma}\Delta F^\epsilon + \frac{1}{\gamma}\nabla\mathrm{div}F^\epsilon + \gamma F^\epsilon = -\gamma N^\epsilon F^\epsilon + \gamma\epsilon\mathrm{div}E^0 F^\epsilon + \mathcal{J}_3^\epsilon, \qquad (4.34)$$

where

$$\begin{aligned}
\mathcal{J}_3 &= \gamma(N^\epsilon+1-\epsilon\mathrm{div}E^0)\Big(-[(U^\epsilon+u^0)\cdot\nabla]U^\epsilon - (U^\epsilon\cdot\nabla)u^0\\
&\quad - \nabla(h(N^\epsilon+1-\epsilon\mathrm{div}E^0) - h(1-\epsilon\mathrm{div}E^0)) - \gamma\big((U^\epsilon+u^0)\times G^\epsilon + U^\epsilon\times B^0\big)\\
&\quad + \epsilon h'(1-\epsilon\mathrm{div}E^0)\nabla(\mathrm{div}E^0)\Big) + \gamma\partial_t(N^\epsilon+1-\epsilon\mathrm{div}E^0)U^\epsilon\\
&\quad + \gamma u^0\partial_t N^\epsilon + \gamma\partial_t u^0 N^\epsilon + \epsilon\partial_t(\partial_t E^0 + u^0\mathrm{div}E^0) \qquad (4.35)
\end{aligned}$$

satisfies

$$\|\mathcal{J}_3\|_{l-1} \le C\gamma(|||W^\epsilon(t)|||_l^2 + |||W^\epsilon(t)|||_l + 1)|||W^\epsilon(t)|||_l + C\gamma\epsilon. \tag{4.36}$$

Let $\alpha \in \mathbb{N}^3$ with $|\alpha| \le l-1$. Taking ∂_x^α on (4.34), multiplying the resulting equation by $\partial_t \partial_x^\alpha F^\epsilon$, by integration by parts, we get

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int \left(\epsilon\gamma|\partial_t\partial_x^\alpha F^\epsilon|^2 + \gamma|\partial_x^\alpha F^\epsilon|^2 + \frac{1}{\gamma}|\partial_x^\alpha(\nabla\times F^\epsilon)|^2\right)dx \\
&= -\gamma\int \partial_x^\alpha(N^\epsilon F^\epsilon)\partial_t\partial_x^\alpha F^\epsilon dx + \gamma\epsilon\int \partial_x^\alpha(\mathrm{div}E^0F^\epsilon)\partial_t\partial_x^\alpha F^\epsilon dx \\
&\quad + \int \partial_x^\alpha \mathcal{J}_3\partial_t\partial_x^\alpha F^\epsilon dx.
\end{aligned} \tag{4.37}$$

In the following we control the right-hand side of (4.37) by $\gamma\|F^\epsilon\|_{l-1}^2$ and $\gamma\epsilon\|\partial_t F^\epsilon\|_{l-1}^2$. First, it holds that

$$\begin{aligned}
&-\gamma\int \partial_x^\alpha(N^\epsilon F^\epsilon)\partial_t\partial_x^\alpha F^\epsilon dx \\
&= -\gamma\int N^\epsilon\partial_x^\alpha F^\epsilon\partial_t\partial_x^\alpha F^\epsilon dx - \gamma\int \mathcal{H}_\alpha^{(10)}\partial_t\partial_x^\alpha F^\epsilon dx \\
&\le \frac{\gamma}{6}\int|\partial_x^\alpha F^\epsilon|^2dx + 6\gamma\|N^\epsilon\|_{L^\infty}^2\int|\partial_t\partial_x^\alpha F^\epsilon|^2dx + \gamma\|\mathcal{H}_\alpha^{(10)}\|\|\partial_t\partial_x^\alpha F^\epsilon\| \\
&\le \frac{\gamma}{6}\int|\partial_x^\alpha F^\epsilon|^2dx + C\gamma\|N^\epsilon\|_{l-1}^2\int|\partial_t\partial_x^\alpha F^\epsilon|^2dx + C\gamma\|N^\epsilon\|_{l-1}\|F^\epsilon\|_{l-1}\|\partial_t\partial_x^\alpha F^\epsilon\| \\
&\le \frac{\gamma}{3}\|F^\epsilon\|_{l-1}^2 + C\gamma\|N^\epsilon\|_{l-1}^2\|\partial_t F^\epsilon\|_{l-1}^2 \\
&= \frac{\gamma}{3}\|F^\epsilon\|_{l-1}^2 + C\left\|\frac{N^\epsilon}{\sqrt{\epsilon}}\right\|_{l-1}^2\epsilon\gamma\|\partial_t F^\epsilon\|_{l-1}^2,
\end{aligned} \tag{4.38}$$

where the commutator

$$\mathcal{H}_\alpha^{(10)} = \partial_x^\alpha(N^\epsilon F^\epsilon) - N^\epsilon\partial_x^\alpha F^\epsilon$$

can be estimated by

$$\begin{aligned}
\|\mathcal{H}_\alpha^{(10)}\| &\le C\|\nabla N^\epsilon\|_{L^\infty}\|\partial_x^{l-2}F^\epsilon\| + C\|F^\epsilon\|_{L^\infty}\|\partial_x^{l-1}N^\epsilon\| \\
&\le C\|\nabla N^\epsilon\|_{l-2}\|\partial_x^{l-2}F^\epsilon\| + C\|F^\epsilon\|_{l-1}\|\partial_x^{l-1}N^\epsilon\| \\
&\le C\|N^\epsilon\|_{l-1}\|F^\epsilon\|_{l-1}.
\end{aligned}$$

Then, as in the establishment of (4.38), we can get

$$\gamma\epsilon\int \partial_x^\alpha(\mathrm{div}E^0F^\epsilon)\partial_t\partial_x^\alpha F^\epsilon dx \le C\epsilon\gamma(\|F^\epsilon\|_{l-1}^2 + \|\partial_t F^\epsilon\|_{l-1}^2). \tag{4.39}$$

Finally, by Cauchy–Schwarz's inequality, we have

$$\int \partial_x^\alpha\mathcal{J}_3\partial_t\partial_x^\alpha F^\epsilon dx \le \frac{C}{\epsilon\gamma}\|\partial_x^\alpha\mathcal{J}_3\|^2 + C\epsilon\gamma\|\partial_x^\alpha\partial_t F^\epsilon\|^2. \tag{4.40}$$

Combining (4.37) with (4.38), (4.39), and (4.40), we get

$$\frac{1}{2}\frac{d}{dt}\int\left(\epsilon\gamma|\partial_t\partial_x^\alpha F^\epsilon|^2+\gamma|\partial_x^\alpha F^\epsilon|^2+\frac{1}{\gamma}|\partial_x^\alpha(\nabla\times F^\epsilon)|^2\right)dx$$

$$\le\frac{\gamma}{3}\|F^\epsilon\|_{l-1}^2+C\left\|\frac{N^\epsilon}{\sqrt{\epsilon}}\right\|_{l-1}^2\epsilon\gamma\|\partial_t F^\epsilon\|_{l-1}^2+C\epsilon\gamma(\|F^\epsilon\|_{l-1}^2+\|\partial_t F^\epsilon\|_{l-1}^2)$$

$$+\frac{C}{\epsilon\gamma}\|\partial_x^\alpha\mathcal{J}_3\|^2+C\epsilon\gamma\|\partial_x^\alpha\partial_t F^\epsilon\|^2, \tag{4.41}$$

from which we can easily obtain (4.33).

The proof of Lemma 4.4 is complete. □

We estimate the magnetic field by using the estimates on the electric field and the curl-div decomposition technique of the gradient for the magnetic field.

LEMMA 4.5. *For any* $0<t\le T$ *and* $l>\frac{3}{2}+2$, *it holds that*

$$\|\nabla G^\epsilon\|_{l-1}\le\|\epsilon\gamma\partial_t F^\epsilon\|_{l-1}+C\gamma(\|N^\epsilon\|_{l-1}+1)\|U^\epsilon\|_{l-1}+C\gamma\|N^\epsilon\|_{l-1}+C\gamma\epsilon. \tag{4.42}$$

Proof. Because $\mathrm{div}G^\epsilon=0$, by the curl-div decomposition formulas of the gradient for the magnetic field

$$\|\nabla G^\epsilon\|_{l-1}\le\|\nabla\times G^\epsilon\|_{l-1}+\|\mathrm{div}G^\epsilon\|_{l-1}, \tag{4.43}$$

it suffices to control $\|\nabla\times G^\epsilon\|_{l-1}$.

Using the third equation in the error system (3.2), we get

$$\|\nabla\times G^\epsilon\|_{l-1}\le\|\epsilon\gamma\partial_t F^\epsilon\|_{l-1}+\gamma\|(N^\epsilon+1-\epsilon\mathrm{div}E^0)U^\epsilon+N^\epsilon u^0\|_{l-1}+C\gamma\epsilon$$

$$\le\|\epsilon\gamma\partial_t F^\epsilon\|_{l-1}+C\gamma(\|N^\epsilon\|_{l-1}+1)\|U^\epsilon\|_{l-1}+C\gamma\|N^\epsilon\|_{l-1}+C\gamma\epsilon. \tag{4.44}$$

Combining (4.43) and (4.44), we obtain (4.42).

The proof of Lemma 4.5 is complete. □

4.6. The end of proof of Proposition 4.1. Introduce an ϵ-weighted Sobolev-type energy function

$$\Gamma^\epsilon(t)=\||W^\epsilon(t)\||_l^2.$$

Then it follows from (4.4), (4.23), (4.32), (4.33), and (4.42) that there exists an $\epsilon_0>0$, depending only upon T_0, such that, for any $0<\epsilon\le\epsilon_0$ and any $0<t<T$,

$$\Gamma^\epsilon(t)\le C\Gamma^\epsilon(t=0)+C\int_0^t((\Gamma^\epsilon+\sqrt{\Gamma^\epsilon}+1)\Gamma^\epsilon)(s)ds+C\epsilon. \tag{4.45}$$

Then, applying Gronwall's lemma and using Proposition 3.1 and (3.4), it follows from (4.45) and $\Gamma^\epsilon(t=0)\le C\epsilon$ that there exist a $0<T_1<1$ and an $\epsilon_0>0$ such that $T_\epsilon\ge T_1$ for all $0<\epsilon\le\epsilon_0$ and that there exists an ϵ_0 sufficiently small such that, for any $\epsilon\le\epsilon_0$ and $0<t<T$,

$$\Gamma^\epsilon(t)\le C\epsilon,$$

which gives the desired a priori estimate (4.2). Moreover, by the standard continuous induction method, we can extend $T_\epsilon\ge T_0$ for any $T_0<T_*$.

The proof of Proposition 4.1 is complete. □

4.7. Proof of Theorem 2.1. According to the definitions of the error functions $N^\epsilon, U^\epsilon, F^\epsilon, G^\epsilon$, the regularities of u^0, E^0, B^0, and the error system (3.2), it follows from the assumption (2.11) in Theorem 2.1 that

$$\|\sqrt{\epsilon}F^\epsilon(t=0)\|_{s_0-1} \le C\sqrt{\epsilon},$$

$$\left\|\frac{N^\epsilon}{\sqrt{\epsilon}}(t=0)\right\|_{s_0-1} = \sqrt{\epsilon}\|\mathrm{div}F^\epsilon(t=0)\|_{s_0-1} \le \sqrt{\epsilon}\|F^\epsilon(t=0)\|_{s_0} \le C\sqrt{\epsilon}.$$

Hence, the assumption (4.1) in Proposition 4.1 holds. Thus, the results of Proposition 4.1 imply (2.12). As a consequence, $(n^\epsilon, u^\epsilon, B^\epsilon)$ converges strongly to $(1, u^0, B^0)$ in $L^\infty(0,T_0;H^{s_0}(\mathbb{T}))$. It follows from (2.2), (2.6), and the uniqueness of solutions to the limit problem (2.6)–(2.9) that E^ϵ converges to E^0 in $W^{-1,\infty}(0,T_0;H^{s_0-1}(\mathbb{T}))$.

The proof of Theorem 2.1 is complete. ∎

Appendix A. Proof of Lemma 4.3. Taking ∂_x^α on (4.21) and taking the L^2 inner product of the resulting equation with $\partial_x^\alpha \mathrm{div}U^\epsilon$, by integration by parts, we have the following energy equation:

$$\begin{aligned}
(\mathrm{A}.1)\ & \frac{d}{dt}\|\partial_x^\alpha \mathrm{div}U^\epsilon\|^2 \\
&= (\mathrm{div}(U^\epsilon+u^0)\partial_x^\alpha \mathrm{div}U^\epsilon, \partial_x^\alpha \mathrm{div}U^\epsilon) + 2(\mathcal{H}_\alpha^{(2)}, \partial_x^\alpha \mathrm{div}U^\epsilon) \\
&\quad + \frac{2}{\epsilon}(\partial_x^\alpha N^\epsilon, \partial_x^\alpha \mathrm{div}U^\epsilon) - 2\big(\partial_x^\alpha \Delta(h(N^\epsilon+1-\epsilon \mathrm{div}E^0) - h(1-\epsilon \mathrm{div}E^0)), \partial_x^\alpha \mathrm{div}U^\epsilon\big) \\
&\quad - 2\gamma\Big(\partial_x^\alpha \mathrm{div}\big((U^\epsilon+u^0)\times G^\epsilon\big), \partial_x^\alpha \mathrm{div}U^\epsilon\Big) + 2(\partial_x^\alpha \mathcal{J}_2^\epsilon, \partial_x^\alpha \mathrm{div}U^\epsilon),
\end{aligned}$$

where the commutator is defined by

$$\mathcal{H}_\alpha^{(2)} = -\{\partial_x^\alpha \mathrm{div}([(U^\epsilon+u^0)\cdot\nabla]U^\epsilon) - [(U^\epsilon+u^0)\cdot\nabla]\partial_x^\alpha \mathrm{div}U^\epsilon\},$$

which can be estimated as follows:

$$\begin{aligned}
\|\mathcal{H}_\alpha^{(2)}\| &\le C\|\nabla(U^\epsilon+u^0)\|_{L^\infty}\|\partial_x^{l-1}\nabla U^\epsilon\| + C\|\nabla U^\epsilon\|_{L^\infty}\|\partial_x^l(U^\epsilon+u^0)\| \\
&\le C\|\nabla(U^\epsilon+u^0)\|_{l-1}\|\partial_x^{l-1}\nabla U^\epsilon\| + C\|\nabla U^\epsilon\|_{l-1}\|\partial_x^l(U^\epsilon+u^0)\| \\
&\le C(\|U^\epsilon\|_l+1)\|U^\epsilon\|_l.
\end{aligned}$$

Hence, by Cauchy–Schwarz's inequality, Sobolev's lemma, and using the estimate (4.22) for $\mathcal{J}_2^\epsilon$, we obtain

$$\begin{aligned}
&(\mathrm{div}(U^\epsilon+u^0)\partial_x^\alpha \mathrm{div}U^\epsilon, \partial_x^\alpha \mathrm{div}U^\epsilon) + 2(\mathcal{H}_\alpha^{(2)}, \partial_x^\alpha \mathrm{div}U^\epsilon) \\
&\le C(\|U^\epsilon\|_l+1)\|U^\epsilon\|_l^2 + C\|\mathcal{H}_\alpha^{(2)}\|\|\partial_x^\alpha \mathrm{div}U^\epsilon\| \\
&\le C(\|W^\epsilon(t)\|_{l,*}+1)\|U^\epsilon\|_l^2 \qquad (\mathrm{A}.2)
\end{aligned}$$

and

$$\begin{aligned}
&-2\gamma\Big(\partial_x^\alpha \mathrm{div}\big((U^\epsilon+u^0)\times G^\epsilon\big), \partial_x^\alpha \mathrm{div}U^\epsilon\Big) + 2(\partial_x^\alpha \mathcal{J}_2^\epsilon, \partial_x^\alpha \mathrm{div}U^\epsilon) \\
&\le C\gamma^2(\|U^\epsilon\|_l^2+1)\|G^\epsilon\|_l^2 + \|W^\epsilon(t)\|_{l,*}^2 + C\epsilon^2. \qquad (\mathrm{A}.3)
\end{aligned}$$

The rest involves dealing with the other two terms on the right-hand side of (A.1), which are more difficult to control. To do this, we rewrite the density equation in (3.2) into the following two formulations:

$$\mathrm{div}U^\epsilon = -\frac{\partial_t N^\epsilon + \mathrm{div}(N^\epsilon(U^\epsilon+u^0)) - \epsilon U^\epsilon\cdot\nabla(\mathrm{div}E^0) - \epsilon R_n^\epsilon}{1-\epsilon\mathrm{div}E^0} \tag{A.4}$$

and

$$\mathrm{div}U^\epsilon = -\frac{\partial_t N^\epsilon + (U^\epsilon+u^0)\cdot\nabla N^\epsilon + N^\epsilon\mathrm{div}u^0 - \epsilon U^\epsilon\cdot\nabla(\mathrm{div}E^0) - \epsilon R_n^\epsilon}{N^\epsilon+1-\epsilon\mathrm{div}E^0}. \tag{A.5}$$

In the following, we use the first formulation (A.4) to estimate the electric field term and the second one (A.5) to estimate the nonlinear pressure term integral in order to avoid the presence of the $(l+1)$th order derivative of the velocity because we are now in H^l energy estimates.

First, we control the singular term $O(\frac{1}{\epsilon})$ in (A.1). We have

$$\begin{aligned}
I_1 &= \frac{2}{\epsilon}(\partial_x^\alpha N^\epsilon, \partial_x^\alpha \mathrm{div}U^\epsilon)\\
&= -\frac{2}{\epsilon}\left(\partial_x^\alpha N^\epsilon, \partial_x^\alpha\left(\frac{\partial_t N^\epsilon + \mathrm{div}(N^\epsilon(U^\epsilon+u^0)) - \epsilon U^\epsilon\cdot\nabla(\mathrm{div}E^0) - \epsilon R_n^\epsilon}{1-\epsilon\mathrm{div}E^0}\right)\right)\\
&= -\frac{2}{\epsilon}\left(\partial_x^\alpha N^\epsilon, \partial_x^\alpha\left(\frac{\partial_t N^\epsilon}{1-\epsilon\mathrm{div}E^0}\right)\right) - \frac{2}{\epsilon}\left(\partial_x^\alpha N^\epsilon, \partial_x^\alpha\left(\frac{\mathrm{div}(N^\epsilon(U^\epsilon+u^0))}{1-\epsilon\mathrm{div}E^0}\right)\right)\\
&\quad + 2\left(\partial_x^\alpha N^\epsilon, \partial_x^\alpha\left(\frac{U^\epsilon\cdot\nabla(\mathrm{div}E^0)}{1-\epsilon\mathrm{div}E^0}\right)\right) + 2\left(\partial_x^\alpha N^\epsilon, \partial_x^\alpha\left(\frac{R_n^\epsilon}{1-\epsilon\mathrm{div}E^0}\right)\right)\\
&= \sum_{i=1}^4 I_1^{(i)},
\end{aligned} \tag{A.6}$$

in which each term can be estimated as follows.

For $I_1^{(1)}$, by Cauchy–Schwarz's inequality and using the fact that

$$\left\|\partial_t\left(\frac{1}{1-\epsilon\mathrm{div}E^0}\right)\right\|_{L^\infty} \le C\epsilon,$$

we have

$$\begin{aligned}
I_1^{(1)} &= -\frac{2}{\epsilon}\left(\partial_x^\alpha N^\epsilon, \partial_x^\alpha\left(\frac{\partial_t N^\epsilon}{1-\epsilon\mathrm{div}E^0}\right)\right)\\
&= -\frac{2}{\epsilon}\left(\frac{1}{1-\epsilon\mathrm{div}E^0}\partial_x^\alpha N^\epsilon, \partial_x^\alpha\partial_t N^\epsilon\right) - \frac{2}{\epsilon}(\mathcal{H}_\alpha^{(2)}, \partial_x^\alpha N^\epsilon)\\
&= -\frac{1}{\epsilon}\frac{d}{dt}\left(\frac{1}{1-\epsilon\mathrm{div}E^0}\partial_x^\alpha N^\epsilon, \partial_x^\alpha N^\epsilon\right) + \frac{1}{\epsilon}\left(\partial_t\left(\frac{1}{1-\epsilon\mathrm{div}E^0}\right)\partial_x^\alpha N^\epsilon, \partial_x^\alpha N^\epsilon\right)\\
&\quad - \frac{2}{\epsilon}(\mathcal{H}_\alpha^{(2)}, \partial_x^\alpha N^\epsilon)\\
&\le -\frac{1}{\epsilon}\frac{d}{dt}\left(\frac{1}{1-\epsilon\mathrm{div}E^0}\partial_x^\alpha N^\epsilon, \partial_x^\alpha N^\epsilon\right) + C\|\partial_x^\alpha N^\epsilon\|^2 + \frac{C}{\epsilon}\|\mathcal{H}_\alpha^{(3)}\|\|\partial_x^\alpha N^\epsilon\|,
\end{aligned} \tag{A.7}$$

where the commutator is defined by

$$\mathcal{H}_\alpha^{(3)} = \partial_x^\alpha\left(\frac{\partial_t N^\epsilon}{1-\epsilon \mathrm{div} E^0}\right) - \frac{1}{1-\epsilon \mathrm{div} E^0}\partial_x^\alpha \partial_t N^\epsilon,$$

which can be controlled as follows:

$$\begin{aligned}\|\mathcal{H}_\alpha^{(3)}\| &\le C\left\|\nabla\left(\frac{1}{1-\epsilon \mathrm{div} E^0}\right)\right\|_{L^\infty}\|\partial_x^{l-2}\partial_t N^\epsilon\| + C\|\partial_t N^\epsilon\|_{L^\infty}\left\|\partial_x^{l-1}\left(\frac{1}{1-\epsilon \mathrm{div} E^0}\right)\right\| \\ &\le C\epsilon\|\partial_t N^\epsilon\|_{l-2} \\ &\le C\epsilon\|(N^\epsilon, U^\epsilon)\|_{l-1} + C\epsilon(\|U^\epsilon\|_{l-1}+1)\|N^\epsilon\|_{l-1} + C\epsilon^2. \qquad \text{(A.8)}\end{aligned}$$

Here we have used $\|\nabla(\frac{1}{1-\epsilon \mathrm{div} E^0})\|_{L^\infty} \le C\epsilon$ and $l > \frac{3}{2} + 2$. Combining (A.7) and (A.8), we obtain

$$I_1^{(1)} \le -\frac{1}{\epsilon}\frac{d}{dt}\left(\frac{1}{1-\epsilon \mathrm{div} E^0}\partial_x^\alpha N^\epsilon, \partial_x^\alpha N^\epsilon\right) + C(\|U^\epsilon\|_{l-1}+1)\|W^\epsilon(t)\|_{l,*}^2 + C\epsilon^2. \qquad \text{(A.9)}$$

For $I_1^{(2)}$, a direct calculation yields

$$\begin{aligned} I_1^{(2)} &= -\frac{2}{\epsilon}\left(\partial_x^\alpha N^\epsilon, \partial_x^\alpha\left(\frac{\mathrm{div}(N^\epsilon(U^\epsilon+u^0))}{1-\epsilon \mathrm{div} E^0}\right)\right) \\ &= -\frac{2}{\epsilon}\left(\partial_x^\alpha N^\epsilon, \frac{1}{1-\epsilon \mathrm{div} E^0}\partial_x^\alpha\big(\mathrm{div}(N^\epsilon(U^\epsilon+u^0))\big)\right) - \frac{2}{\epsilon}(\partial_x^\alpha N^\epsilon, \mathcal{H}_\alpha^{(4)}) \\ &= -\frac{2}{\epsilon}\left(\partial_x^\alpha N^\epsilon, \frac{1}{1-\epsilon \mathrm{div} E^0}\partial_x^\alpha\big((U^\epsilon+u^0)\cdot\nabla N^\epsilon + N^\epsilon \mathrm{div}(U^\epsilon+u^0)\big)\right) \\ &\quad - \frac{2}{\epsilon}(\partial_x^\alpha N^\epsilon \mathcal{H}_\alpha^{(4)}) \\ &= \frac{1}{\epsilon}\left(\partial_x^\alpha N^\epsilon, \mathrm{div}\left(\frac{1}{1-\epsilon \mathrm{div} E^0}(U^\epsilon+u^0)\right)\partial_x^\alpha N^\epsilon\right) \\ &\quad - \frac{2}{\epsilon}\left(\partial_x^\alpha N^\epsilon, \frac{1}{1-\epsilon \mathrm{div} E^0}\partial_x^\alpha N^\epsilon \mathrm{div}(U^\epsilon+u^0)\right) \\ &\quad - \frac{2}{\epsilon}(\partial_x^\alpha N^\epsilon, \mathcal{H}_\alpha^{(4)}) - \frac{2}{\epsilon}\sum_{i=5}^{i=6}\left(\frac{1}{1-\epsilon \mathrm{div} E^0}\partial_x^\alpha N^\epsilon, \mathcal{H}_\alpha^{(i)}\right), \end{aligned} \qquad \text{(A.10)}$$

where the commutators $\mathcal{H}_\alpha^{(i)}, i = 4, 5, 6$, are defined by

$$\begin{aligned}\mathcal{H}_\alpha^{(4)} &= \partial_x^\alpha\left(\frac{\mathrm{div}(N^\epsilon(U^\epsilon+u^0))}{1-\epsilon \mathrm{div} E^0}\right) - \frac{1}{1-\epsilon \mathrm{div} E^0}\partial_x^\alpha\big(\mathrm{div}(N^\epsilon(U^\epsilon+u^0))\big), \\ \mathcal{H}_\alpha^{(5)} &= \partial_x^\alpha\big((U^\epsilon+u^0)\cdot\nabla N^\epsilon\big) - (U^\epsilon+u^0)\cdot\partial_x^\alpha\nabla N^\epsilon, \\ \mathcal{H}_\alpha^{(6)} &= \partial_x^\alpha(N^\epsilon \mathrm{div}(U^\epsilon+u^0)) - \partial_x^\alpha N^\epsilon \mathrm{div}(U^\epsilon+u^0),\end{aligned}$$

which, with the aid of Sobolev's lemma, can be estimated, respectively, as follows:

$$\begin{aligned}\|\mathcal{H}_\alpha^{(4)}\| &\le C\left\|\nabla\left(\frac{1}{1-\epsilon\mathrm{div}E^0}\right)\right\|_{L^\infty}\|\partial_x^{l-2}(\mathrm{div}(N^\epsilon(U^\epsilon+u^0)))\|\\ &\quad + C\|\mathrm{div}(N^\epsilon(U^\epsilon+u^0))\|_{L^\infty}\left\|\partial_x^{l-1}\left(\frac{1}{1-\epsilon\mathrm{div}E^0}\right)\right\|\\ &\le C\left\|\nabla\left(\frac{1}{1-\epsilon\mathrm{div}E^0}\right)\right\|_{L^\infty}\|\partial_x^{l-2}(\mathrm{div}(N^\epsilon(U^\epsilon+u^0)))\|\\ &\quad + C\|\mathrm{div}(N^\epsilon(U^\epsilon+u^0))\|_{l-2}\left\|\partial_x^{l-1}\left(\frac{1}{1-\epsilon\mathrm{div}E^0}\right)\right\|\\ &\le C\epsilon(\|U^\epsilon\|_l+1)\|N^\epsilon\|_{l-1}, \qquad \text{(A.11)}\end{aligned}$$

$$\begin{aligned}\|\mathcal{H}_\alpha^{(5)}\| &\le C\|\nabla(U^\epsilon+u^0)\|_{L^\infty}\|\partial_x^{l-2}\nabla N^\epsilon\| + C\|\nabla N^\epsilon\|_{L^\infty}\|\partial_x^{l-1}(U^\epsilon+u^0)\|\\ &\le C\|\nabla(U^\epsilon+u^0)\|_{l-1}\|\partial_x^{l-2}\nabla N^\epsilon\| + C\|\nabla N^\epsilon\|_{l-2}\|\partial_x^{l-1}(U^\epsilon+u^0)\|\\ &\le C(\|U^\epsilon\|_l+1)\|N^\epsilon\|_{l-1}, \qquad \text{(A.12)}\end{aligned}$$

$$\begin{aligned}\|\mathcal{H}_\alpha^{(6)}\| &\le C\|\nabla\mathrm{div}(U^\epsilon+u^0)\|_{L^\infty}\|\partial_x^{l-2}N^\epsilon\| + C\|N^\epsilon\|_{L^\infty}\|\partial_x^{l-1}\mathrm{div}(U^\epsilon+u^0)\|\\ &\le C\|\nabla\mathrm{div}(U^\epsilon+u^0)\|_{l-2}\|\partial_x^{l-2}N^\epsilon\| + C\|N^\epsilon\|_{l-1}\|\partial_x^{l-1}\mathrm{div}(U^\epsilon+u^0)\|\\ &\le C(\|U^\epsilon\|_l+1)\|N^\epsilon\|_{l-1}. \qquad \text{(A.13)}\end{aligned}$$

Here we have again used $\|\nabla(\frac{1}{1-\epsilon\mathrm{div}E^0})\|_{L^\infty}\le C\epsilon$ and $l>\frac{3}{2}+2$.

Thus, combining (A.10) together with (A.11)–(A.13), we get, with the aid of Cauchy–Schwarz's inequality, that

$$I_1^{(2)} \le \frac{C}{\epsilon}(\|U^\epsilon\|_l+1)\|N^\epsilon\|_{l-1}^2. \qquad \text{(A.14)}$$

Also, by Cauchy–Schwarz's inequality, $I_1^{(3)}$ can be estimated as follows:

$$I_1^{(3)} = 2\left(\partial_x^\alpha N^\epsilon, \partial_x^\alpha\left(\frac{U^\epsilon\cdot\nabla(\mathrm{div}E^0)}{1-\epsilon\mathrm{div}E^0}\right)\right) \le C\|W^\epsilon(t)\|_{l,*}^2. \qquad \text{(A.15)}$$

Finally, we estimate $I_1^{(4)}$. Since R_n^ϵ is not small with respect to ϵ (only uniformly bounded), we must use $\|\frac{N^\epsilon}{\sqrt{\epsilon}}\|_{l-1}$ to control $I_1^{(4)}$. Thus, we rewrite $I_1^{(4)}$ as

$$I_1^{(4)} = 2\left(\partial_x^\alpha N^\epsilon, \partial_x^\alpha\left(\frac{R_n^\epsilon}{1-\epsilon\mathrm{div}E^0}\right)\right) = 2\left(\frac{\partial_x^\alpha N^\epsilon}{\sqrt{\epsilon}}, \sqrt{\epsilon}\partial_x^\alpha\left(\frac{R_n^\epsilon}{1-\epsilon\mathrm{div}E^0}\right)\right).$$

By Cauchy–Schwarz's inequality and the uniform bound on R_n^ϵ, we have

$$I_1^{(4)} \le \frac{C}{\epsilon}\|N^\epsilon\|_{l-1}^2 + C\epsilon. \qquad \text{(A.16)}$$

Combining (A.6) with (A.9), (A.14), (A.15), and (A.16), we obtain

$$I_1 \le -\frac{1}{\epsilon}\frac{d}{dt}\left(\frac{1}{1-\epsilon\mathrm{div}E^0}\partial_x^\alpha N^\epsilon, \partial_x^\alpha N^\epsilon\right) + C(\|U^\epsilon\|_l+1)|||W^\epsilon(t)|||_l^2 + C\epsilon. \qquad \text{(A.17)}$$

Next, we control the pressure term I_2. It holds that

$$\begin{aligned}
I_2 &= -2(\partial_x^\alpha \Delta(h(N^\epsilon+1-\epsilon \mathrm{div}E^0)-h(1-\epsilon \mathrm{div}E^0)), \partial_x^\alpha \mathrm{div}U^\epsilon)\\
&= -2\Big(\partial_x^\alpha \mathrm{div}\big(h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)\nabla N^\epsilon\\
&\qquad -\epsilon(h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)-h'(1-\epsilon \mathrm{div}E^0))\nabla(\mathrm{div}E^0)\big), \partial_x^\alpha \mathrm{div}U^\epsilon\Big)\\
&= -2\Big(\mathrm{div}\big(h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)\partial_x^\alpha \nabla N^\epsilon\big), \partial_x^\alpha \mathrm{div}U^\epsilon\Big) - 2(\mathcal{H}_\alpha^{(7)}, \partial_x^\alpha \mathrm{div}U^\epsilon)\\
&\quad + 2\epsilon\Big(\partial_x^\alpha \mathrm{div}\big((h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)-h'(1-\epsilon \mathrm{div}E^0))\nabla(\mathrm{div}E^0)\big), \partial_x^\alpha \mathrm{div}U^\epsilon\Big)
\end{aligned}$$

$$(\text{A.18}) = I_2^{(1)} + I_2^{(2)} + I_2^{(3)},$$

where

$$\begin{aligned}
I_2^{(1)} &= -2\Big(\mathrm{div}\big(h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)\nabla \partial_x^\alpha N^\epsilon\big), \partial_x^\alpha \mathrm{div}U^\epsilon\Big),\\
I_2^{(2)} &= -2(\mathcal{H}_\alpha^{(7)}, \partial_x^\alpha \mathrm{div}U^\epsilon),\\
I_2^{(3)} &= 2\epsilon\Big(\partial_x^\alpha \mathrm{div}\big((h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)-h'(1-\epsilon \mathrm{div}E^0))\nabla(\mathrm{div}E^0)\big), \partial_x^\alpha \mathrm{div}U^\epsilon\Big)
\end{aligned}$$

and the commutator $\mathcal{H}_\alpha^{(7)}$ is defined by

$$\begin{aligned}
\mathcal{H}_\alpha^{(7)} &= \partial_x^\alpha \mathrm{div}\big(h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)\nabla N^\epsilon\big) - \mathrm{div}\big(h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)\partial_x^\alpha \nabla N^\epsilon\big)\\
&= \partial_x^\alpha\big(h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)\mathrm{div}\nabla N^\epsilon\big) - h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)\partial_x^\alpha \mathrm{div}\nabla N^\epsilon\\
&\quad + \partial_x^\alpha\big(\nabla h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)\nabla N^\epsilon\big) - \nabla h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)\partial_x^\alpha \nabla N^\epsilon.
\end{aligned}$$

Noting that $I_2^{(3)}$ does contain only the lth order derivatives of the error function W_I^ϵ, it can be easily estimated by

$$I_2^{(3)} \le \|U^\epsilon\|_l^2 + C\|N^\epsilon\|_l^2. \tag{A.19}$$

Here we have used the regularity of the limit system, i.e., $\|E^0\|_{l+2} \le C$. The estimate techniques of the commutator yield

$$\begin{aligned}
\|\mathcal{H}_\alpha^{(7)}\| &\le C\|\nabla h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)\|_{L^\infty}\|\partial_x^{l-2}\mathrm{div}\nabla N^\epsilon\|\\
&\quad + C\|\mathrm{div}\nabla N^\epsilon\|_{L^\infty}\|\partial_x^{l-1}h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)\|\\
&\quad + C\|\nabla^2 h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)\|_{L^\infty}\|\partial_x^{l-2}\nabla N^\epsilon\|\\
&\quad + C\|\nabla N^\epsilon\|_{L^\infty}\|\partial_x^{l-1}\nabla h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)\|\\
&\le C(\|N^\epsilon\|_l + 1)\|N^\epsilon\|_l,
\end{aligned}$$

which implies by Cauchy–Schwarz's inequality that

$$I_2^{(2)} \le C(\|N^\epsilon\|_l + 1)\|W^\epsilon(t)\|_{l,*}^2. \tag{A.20}$$

In the following, we estimate $I_2^{(1)}$. By the relation (A.5) between the density and the divergence, we have

$$
\begin{aligned}
I_2^{(1)} &= 2\bigg(\mathrm{div}\big(h'(N^\epsilon+1-\epsilon\mathrm{div}E^0)\partial_x^\alpha\nabla N^\epsilon\big),\\
&\qquad \partial_x^\alpha\bigg(\frac{\partial_t N^\epsilon+(U^\epsilon+u^0)\cdot\nabla N^\epsilon-\epsilon U^\epsilon\cdot\nabla(\mathrm{div}E^0)+N^\epsilon\mathrm{div}u^0-\epsilon R_n^\epsilon}{N^\epsilon+1-\epsilon\mathrm{div}E^0}\bigg)\bigg)\\
&= -2\bigg(h'(N^\epsilon+1-\epsilon\mathrm{div}E^0)\partial_x^\alpha\nabla N^\epsilon,\nabla\partial_x^\alpha\bigg(\frac{\partial_t N^\epsilon}{N^\epsilon+1-\epsilon\mathrm{div}E^0}\bigg)\bigg)\\
&\quad -2\bigg(h'(N^\epsilon+1-\epsilon\mathrm{div}E^0)\partial_x^\alpha\nabla N^\epsilon,\nabla\partial_x^\alpha\bigg(\frac{(U^\epsilon+u^0)\cdot\nabla N^\epsilon}{N^\epsilon+1-\epsilon\mathrm{div}E^0}\bigg)\bigg)\\
&\quad -2\bigg(h'(N^\epsilon+1-\epsilon\mathrm{div}E^0)\partial_x^\alpha\nabla N^\epsilon,\\
&\qquad \nabla\partial_x^\alpha\bigg(\frac{-\epsilon U^\epsilon\cdot\nabla(\mathrm{div}E^0)+N^\epsilon\mathrm{div}u^0-\epsilon R_n^\epsilon}{N^\epsilon+1-\epsilon\mathrm{div}E^0}\bigg)\bigg)\\
&= \sum_{i=1}^{3} I_{21}^{(i)}. \qquad \text{(A.21)}
\end{aligned}
$$

Now we estimate each term of $I_2^{(1)}$.

For $I_{21}^{(1)}$ and $I_{21}^{(2)}$, we have

$$
\begin{aligned}
I_{21}^{(1)} &= -2\bigg(h'(N^\epsilon+1-\epsilon\mathrm{div}E^0)\partial_x^\alpha\nabla N^\epsilon,\nabla\partial_x^\alpha\bigg(\frac{\partial_t N^\epsilon}{N^\epsilon+1-\epsilon\mathrm{div}E^0}\bigg)\bigg)\\
&= -\frac{d}{dt}\bigg(\frac{h'(N^\epsilon+1-\epsilon\mathrm{div}E^0)}{(N^\epsilon+1-\epsilon\mathrm{div}E^0)}\partial_x^\alpha\nabla N^\epsilon,\partial_x^\alpha\nabla N^\epsilon\bigg)\\
&\quad +\bigg(\partial_t\bigg(\frac{h'(N^\epsilon+1-\epsilon\mathrm{div}E^0)}{(N^\epsilon+1-\epsilon\mathrm{div}E^0)}\bigg)\partial_x^\alpha\nabla N^\epsilon,\partial_x^\alpha\nabla N^\epsilon\bigg)\\
&\quad -2\bigg(h'(N^\epsilon+1-\epsilon\mathrm{div}E^0)\partial_x^\alpha\nabla N^\epsilon,\mathcal{H}_\alpha^{(8)}\bigg)\\
&\le -\frac{d}{dt}\bigg(\frac{h'(N^\epsilon+1-\epsilon\mathrm{div}E^0)}{2(N^\epsilon+1-\epsilon\mathrm{div}E^0)}\partial_x^\alpha\nabla N^\epsilon,\partial_x^\alpha\nabla N^\epsilon\bigg)\\
&\quad +C(\|W^\epsilon(t)\|_{l,*}+1)\|W^\epsilon(t)\|_{l,*}^2 \qquad \text{(A.22)}
\end{aligned}
$$

and

$$I_{21}^{(2)} = -2\Big(h'(N^\epsilon+1-\epsilon\mathrm{div}E^0)\partial_x^\alpha\nabla N^\epsilon, \nabla\partial_x^\alpha\Big(\frac{(U^\epsilon+u^0)\cdot\nabla N^\epsilon}{N^\epsilon+1-\epsilon\mathrm{div}E^0}\Big)\Big)$$

$$= \Big(\mathrm{div}\Big(\frac{h'(N^\epsilon+1-\epsilon\mathrm{div}E^0)(U^\epsilon+u^0)}{(N^\epsilon+1-\epsilon\mathrm{div}E^0)}\Big)\partial_x^\alpha\nabla N^\epsilon, \partial_x^\alpha\nabla N^\epsilon\Big)$$

$$-2\Big(h'(N^\epsilon+1-\epsilon\mathrm{div}E^0)\partial_x^\alpha\nabla N^\epsilon, \mathcal{H}_\alpha^{(9)}\Big)$$

$$\le C(\|W^\epsilon(t)\|_{l,*}+1)\|W^\epsilon(t)\|_{l,*}^2 \tag{A.23}$$

because the commutators

$$\mathcal{H}_\alpha^{(8)} = \nabla\partial_x^\alpha\Big(\frac{\partial_t N^\epsilon}{N^\epsilon+1-\epsilon\mathrm{div}E^0}\Big) - \frac{\partial_t\nabla\partial_x^\alpha N^\epsilon}{N^\epsilon+1-\epsilon\mathrm{div}E^0}$$

and

$$\mathcal{H}_\alpha^{(9)} = \nabla\partial_x^\alpha\Big(\frac{(U^\epsilon+u^0)\cdot\nabla N^\epsilon}{N^\epsilon+1-\epsilon\mathrm{div}E^0}\Big) - \frac{(U^\epsilon+u^0)\cdot\nabla(\partial_x^\alpha\nabla N^\epsilon)}{N^\epsilon+1-\epsilon\mathrm{div}E^0}$$

can be estimated, respectively, by

$$\|\mathcal{H}_\alpha^{(8)}\| \le C\Big\|\nabla\Big(\frac{1}{N^\epsilon+1-\epsilon\mathrm{div}E^0}\Big)\Big\|_{L^\infty}\|\partial_x^{l-1}\partial_t N^\epsilon\|$$

$$+C\|\partial_t N^\epsilon\|_{L^\infty}\Big\|\partial_x^l\Big(\frac{1}{N^\epsilon+1-\epsilon\mathrm{div}E^0}\Big)\Big\|$$

$$\le C(\|W^\epsilon(t)\|_{l,*}+1)\|W^\epsilon(t)\|_{l,*}+C\epsilon^2$$

and

$$\|\mathcal{H}_\alpha^{(9)}\| \le C\Big\|\nabla\Big(\frac{U^\epsilon+u^0}{N^\epsilon+1-\epsilon\mathrm{div}E^0}\Big)\Big\|_{L^\infty}\|\partial_x^{l-1}\nabla N^\epsilon\|$$

$$+C\|\nabla N^\epsilon\|_{L^\infty}\Big\|\partial_x^l\Big(\frac{U^\epsilon+u^0}{N^\epsilon+1-\epsilon\mathrm{div}E^0}\Big)\Big\|$$

$$\le C(\|W^\epsilon(t)\|_{l,*}+1)\|W^\epsilon(t)\|_{l,*}+C\epsilon^2.$$

For $I_{21}^{(3)}$, by Cauchy–Schwarz's inequality and the regularities of u^0, E^0, we have

$$I_{21}^{(3)} = -2\Big(h'(N^\epsilon+1-\epsilon\mathrm{div}E^0)\partial_x^\alpha\nabla N^\epsilon,$$

$$\nabla\partial_x^\alpha\Big(\frac{-\epsilon U^\epsilon\cdot\nabla(\mathrm{div}E^0)+N^\epsilon\mathrm{div}u^0-\epsilon R_n^\epsilon}{N^\epsilon+1-\epsilon\mathrm{div}E^0}\Big)\Big)$$

$$\le C\|W^\epsilon(t)\|_{l,*}^3 + C\|W^\epsilon(t)\|_{l,*}^2 + C\epsilon^2. \tag{A.24}$$

Combining (A.21) with (A.22)–(A.24), we get

$$I_2^{(1)} \le -\frac{d}{dt}\left(\frac{h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)}{(N^\epsilon+1-\epsilon \mathrm{div}E^0)}, \partial_x^\alpha \nabla N^\epsilon, \partial_x^\alpha \nabla N^\epsilon\right)$$

$$+ C(\|W^\epsilon(t)\|_{l,*}+1)\|W^\epsilon(t)\|_{l,*}^2 + C\epsilon^2. \tag{A.25}$$

Similarly, combining (A.18) with (A.19), (A.20), and (A.25), we get

$$I_2 \le -\frac{d}{dt}\left(\frac{h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)}{(N^\epsilon+1-\epsilon \mathrm{div}E^0)}\partial_x^\alpha \nabla N^\epsilon, \partial_x^\alpha \nabla N^\epsilon\right)$$

$$+ C(\|W^\epsilon(t)\|_{l,*}+1)\|W^\epsilon(t)\|_{l,*}^2 + C\epsilon^2, \tag{A.26}$$

and combining (A.1) with (A.2), (A.3), (A.17), and (A.26), we get

$$\frac{d}{dt}\left[\|\partial_x^\alpha \mathrm{div}U^\epsilon\|^2 + \frac{1}{\epsilon}\left(\frac{1}{1-\epsilon \mathrm{div}E^0}\partial_x^\alpha N^\epsilon, \partial_x^\alpha N^\epsilon\right)\right.$$

$$\left. + \left(\frac{h'(N^\epsilon+1-\epsilon \mathrm{div}E^0)}{N^\epsilon+1-\epsilon \mathrm{div}E^0}\partial_x^\alpha \nabla N^\epsilon, \partial_x^\alpha \nabla N^\epsilon\right)\right]$$

$$\le C(\|W^\epsilon\|_{l,*}+1)\|W^\epsilon(t)\|_{l,*}^2 + C\gamma^2(\|U^\epsilon\|_l^2+1)\|G^\epsilon\|_l^2 + C\epsilon^2 + C\epsilon,$$

which yields (4.32).

This ends the proof of Lemma 4.3. □

Acknowledgments. The authors are very grateful to both referees for their constructive comments and helpful suggestions, which considerably improved the presentation of the paper. The second author would like to express his gratitude for the hospitality of the Laboratory of Mathematics at Blaise Pascal University, France, when he visited there in May through July 2006.

SYMMETRY-BREAKING BIFURCATION IN NONLINEAR SCHRÖDINGER/GROSS–PITAEVSKII EQUATIONS*

E. W. KIRR†, P. G. KEVREKIDIS‡, E. SHLIZERMAN§, AND M. I. WEINSTEIN¶

Abstract. We consider a class of nonlinear Schrödinger/Gross–Pitaeveskii (NLS-GP) equations, i.e., NLS with a linear potential. NLS-GP plays an important role in the mathematical modeling of nonlinear optical as well as macroscopic quantum phenomena (BEC). We obtain conditions for a symmetry-breaking bifurcation in a symmetric family of states as $\mathcal{N}$, the squared L^2 norm (particle number, optical power), is increased. The bifurcating asymmetric state is a "mixed mode" which, near the bifurcation point, is approximately a superposition of symmetric and antisymmetric modes. In the special case where the linear potential is a double well with well-separation L, we estimate $\mathcal{N}_{cr}(L)$, the symmetry breaking threshold. Along the "lowest energy" symmetric branch, there is an exchange of stability from the symmetric to the asymmetric branch as $\mathcal{N}$ is increased beyond $\mathcal{N}_{cr}$.

1. Introduction.

Symmetry breaking is a ubiquitous and important phenomenon which arises in a wide range of physical systems. In this paper, we consider a class of partial differential equations (PDEs), which are invariant under a symmetry group. For sufficiently small values of a parameter, $\mathcal{N}$, the preferred (dynamically stable) stationary state of the system is invariant under this symmetry group. However, above a critical parameter, $\mathcal{N}_{cr}$, although the group-invariant state persists, the new preferred state of the system is a state which (i) exists only for $\mathcal{N} > \mathcal{N}_{cr}$ and (ii) is no longer invariant. That is, symmetry is broken and there is an exchange of stability.

Physical examples of symmetry breaking include liquid crystals [31], quantum dots [34], semiconductor lasers [13], and pattern dynamics [28]. This article focuses on spontaneous symmetry breaking as a phenomenon in nonlinear optics [4, 20, 18], as well as in the macroscopic quantum setting of Bose–Einstein condensation (BEC) [1]. Here, the governing equations are PDEs of nonlinear Schrödinger/Gross–Pitaevskii (NLS-GP) type. Symmetry breaking has been observed experimentally in optics for two-component spatial optical vector solitons (i.e., for self-guided laser beams in Kerr media and focusing cubic nonlinearities) in [4], as well as for the electric field distribution between multiple wells of a photorefractive crystal in [20, 18]. In BECs,

an effective double well formed by a combined (parabolic) magnetic trapping and a (periodic) optical trapping of the atoms may have similar effects [1] and lead to "macroscopic quantum self-trapping."

Symmetry breaking in ground states of the three-dimensional NLS-GP equation, with an attractive nonlinearity of Hartree type and a symmetric double-well linear potential, was considered in Aschbacher et. al. [3]; see also Remark 2.2. An example of a double-well potential is the function $V_L(x)$, plotted for the one-dimensional case, in Figure 2b of Example 2.1. The spectral properties of $H_L = -\Delta + V_L(x)$ are discussed in the appendix in section 8. For L sufficiently large, H_L has (at least) two eigenpairs, (Ω_0, ψ_0) and (Ω_1, ψ_1). The normalized ground state eigenfunction ψ_0 is of even parity in x ("symmetric") and the normalized excited state ψ_1 is of odd parity in x ("antisymmetric"). Moreover, $\psi_0(x) \sim 2^{-\frac{1}{2}}(\psi_\omega(x+L) + \psi_\omega(x-L))$ and $\psi_1(x) \sim 2^{-\frac{1}{2}}(\psi_\omega(x+L) - \psi_\omega(x-L))$.

Ground states of NLS-GP are positive nonlinear bound states, arising as *minimizers* of $\mathcal{H}$, the NLS-GP Hamiltonian energy subject to fixed $\mathcal{N}$, the squared L^2 norm. For the class of equations considered in [3], ground states exist for any $\mathcal{N} > 0$. It is proved that for sufficiently large $\mathcal{N}$, any ground state is concentrated in only one of the wells, i.e., symmetry is broken. The analysis in [3] is an asymptotic study of a variational problem (see Remark 2.2) showing that if $\mathcal{N}$ is sufficiently large, then it is energetically preferable for the ground state to localize in a single well. In contrast, for small L^2 norm the ground state is even and bimodal having the symmetries of the ground state of the *linear* Schrödinger operator with symmetric double-well potential. For macroscopic quantum systems, the squared L^2 norm, denoted by $\mathcal{N}$, is the particle number, while in optics it is the optical power. An attractive nonlinearity corresponds to the case of negative scattering length in BEC and focusing Kerr nonlinearity in optics.

An alternative approach to symmetry breaking in NLS-GP is via bifurcation theory. It follows from [26, 25] that a family of "nonlinear ground states" bifurcates from the zero solution ($\mathcal{N} = 0$) at the ground state energy of the Schrödinger operator with a linear double-well potential. This nonlinear ground state branch consists of states having the same bimodal symmetry of the linear ground state. In this article we prove, under suitable conditions, that there is a secondary bifurcation to an asymmetric state at a critical $\mathcal{N} = \mathcal{N}_{cr} > 0$. The bifurcating asymmetric state is a "mixed mode" (see, for example, [8]) which, near the bifurcation point, is approximately a superposition of symmetric and antisymmetric modes. As $\mathcal{N}$ is increased beyond $\mathcal{N}_{cr}$, the asymmetric state tends to concentrate in only one of the two wells. Since the double-well potential is symmetric, the bifurcating state is doubly degenerate; there are two families of asymmetric states associated with energy concentration in each of the wells. Figure 1 shows a typical bifurcation diagram demonstrating symmetry breaking for the NLS-GP system with a double-well potential. At the bifurcation point $\mathcal{N}_{cr}$ (marked by a circle in Figure 1(a)), the symmetric (even with respect to coordinate x_1) ground state becomes unstable and a stable asymmetric (neither even nor odd parity) "mixed (degenerate) state" emanates from it. Further, we show that there is a transfer or exchange of stability which takes place at $\mathcal{N}_{cr}$; for $\mathcal{N} < \mathcal{N}_{cr}$ the symmetric state is stable, while for $\mathcal{N} > \mathcal{N}_{cr}$ the asymmetric state is stable. Since our method is based on local bifurcation analysis we do not require that the states we consider satisfy a minimization principle, as in [3]. Thus, quite generally, symmetry breaking occurs as a consequence of the (finite-dimensional) *normal form* arising in systems with certain symmetry properties. Although we can treat a large class of problems for which there is no minimization principle, our analysis, at present, is

FIG. 1. (a) *Bifurcation diagram for bound state solutions* $\psi(x,t) = e^{-i\Omega t}\Psi_\Omega(x)$ *of NLS-GP equation* (2.1), *with double-well potential* (6.1) *and cubic nonlinearity. Double-well parameters are* $s = 1, L = 6$. Ω *denotes the (nonlinear) frequency and* $\mathcal{N} = \mathcal{N}[\Psi_\Omega]$, *the squared* L^2 *norm of* Ψ_Ω *(optical power or particle number). The first bifurcation is from the zero state at the* ground state energy *of the double well. This state is an even function of* x *(symmetric). A secondary bifurcation, to an asymmetric state, at* $\mathcal{N} = \mathcal{N}_{cr}$, *is marked by a (red) circle. For* $\mathcal{N} < \mathcal{N}_{cr}$ *the symmetric state ((blue) solid line) is nonlinearly dynamically stable. For* $\mathcal{N} > \mathcal{N}_{cr}$ *the symmetric state is unstable ((blue) dashed line). The stable asymmetric state, appearing for* $\mathcal{N} > \mathcal{N}_{cr}$, *is marked by a (red) solid line. The (unstable) odd in* x *(antisymmetric) state is marked by a (green) dashed-dotted line.* (b) *Bound state solutions* $\Psi_\Omega(x)$ *plotted for a level set of* $\mathcal{N}[\Psi_\Omega] = 0.5$.

restricted to small norm. As we shall see, a bifurcation occurring at small norm can be ensured, for example, by taking the distance between wells in the double well to be sufficiently large.

In [14] the precise transition point to symmetry breaking, $\mathcal{N}_{cr}$, of the ground state and the transfer of its stability to an asymmetric ground state was considered (by geometric dynamical systems methods) in the exactly solvable NLS-GP, with a double-well potential consisting of two Dirac delta functions separated by a distance L. Additionally, the behavior of the function $\mathcal{N}_{cr}(L)$ was considered. Another solvable model was examined by numerical means in [23]. A study of dynamics for nonlinear double wells appeared in [27].

We study $\mathcal{N}_{cr}(L)$ in general. The value at which symmetry breaking occurs, $\mathcal{N}_{cr}(L)$, is closely related to the spectral properties of the linearization of NLS-GP

about the symmetric branch. Indeed, so long as the linearization of NLS-GP at the symmetric state has no nonsymmetric null space, the symmetric state is locally unique by the implicit function theorem [24]. The mechanism for symmetry breaking is the first appearance of an antisymmetric element in the null space of the linearization for some $\mathcal{N} = \mathcal{N}_{cr}$. This is demonstrated for a finite-dimensional Galerkin approximation of NLS-GP in [20, 17]. The present work extends and generalizes this analysis to the full infinite-dimensional problem using the Lyapunov–Schmidt method [24]. Control of the corrections to the finite-dimensional approximation requires small norm of the states considered. Since, as anticipated by the Galerkin approximation, $\mathcal{N}_{cr}$ is proportional to the distance between the lowest eigenvalues of the double well, which is exponentially small in L, our results apply to double wells with separation L, for L sufficiently large.

Our bifurcation results can be viewed as a very detailed study of a class of $O(2) \times \mathbb{Z}_2$ symmetric dynamical systems with four degrees of freedom in which there is a bifurcation of mixed states. We know of no classification of such systems. We show, under the nondegeneracy condition (4.3), that they are reducible to systems with two degrees of freedom and $\mathbb{Z}_2 \times \mathbb{Z}_2$ symmetry which have been classified in, for example, [8, 11]. In addition to being a self-contained treatment, our study of the nature of the solution set on the manifold of constant $\mathcal{N}$, as $\mathcal{N}$ is varied, shows the key role of $\mathcal{N}$, a physical NLS-GP time-invariant, in determining the bifurcation diagram, which encodes the dynamic stability properties.

The article is organized as follows. In section 2 we introduce the NLS-GP model and give a technical formulation of the bifurcation problem. In section 3 we study a finite-dimensional truncation of the bifurcation problem, identifying a relevant bifurcation point. In section 4, we prove the persistence of this symmetry-breaking bifurcation in the full NLS-GP problem for $\mathcal{N} \geq \mathcal{N}_{cr}$. Moreover, in section 5 we show that the lowest energy symmetric state becomes dynamically unstable at $\mathcal{N}_{cr}$ and the bifurcating asymmetric state is the dynamically stable ground state for $\mathcal{N} > \mathcal{N}_{cr}$.

The main results are stated in Theorem 4.1, Corollary 4.1, and Theorem 5.1. In particular, we obtain an asymptotic formula for the critical particle number (optical power) for symmetry breaking in NLS-GP,

$$\mathcal{N}_{cr} = \frac{\Omega_1 - \Omega_0}{\Xi[\psi_0, \psi_1]} \; + \; \mathcal{O}\left(\frac{(\Omega_1 - \Omega_0)^2}{\Xi[\psi_0, \psi_1]^3} \right). \tag{1.1}$$

Here, (Ω_0, ψ_0) and (Ω_1, ψ_1) are eigenvalue-eigenfunction pairs of the *linear* Schrödinger operator $H = -\Delta + V$, where Ω_0 and Ω_1 are separated from other spectrum and Ξ is a positive constant, given by (4.2), depending on ψ_0 and ψ_1. (Section 8 is an appendix where we discuss the basic spectral properties of $-\Delta + V$, where V is a double-well potential.) *The most important case is where* $\Omega_0 < \Omega_1$ *are the* lowest *two energies (linear ground and first excited states).* For double wells with separation L, we have $\mathcal{N}_{cr} = \mathcal{N}_{cr}(L)$, depending on the eigenvalue spacing $\Omega_0(L) - \Omega_1(L)$, which is exponentially small if L is large and Ξ is of order one. Thus, for large L, the bifurcation occurs at small L^2 norm. This is the weakly nonlinear regime in which the corrections to the finite-dimensional model can be controlled perturbatively. A local bifurcation diagram of this type will occur for *any* simple even-odd symmetric pair of simple eigenvalues of H in the weakly nonlinear regime, so long as the eigenfrequencies are separated from the rest of the spectrum of H; see Proposition 4.1 and the gap condition (4.13). Therefore, a similar phenomenon occurs for higher order, nearly degenerate pairs of eigenstates of the double wells, arising from isolated single

wells with multiple eigenstates. Section 6 contains numerical results validating our theoretical analysis.

2. Technical formulation. Consider the initial value problem for the time-dependent NLS-GP equation

$$i\partial_t\psi = H\psi \ + \ g(x)K[\psi\bar{\psi}]\ \psi, \quad \psi(x,0) \text{ given}, \tag{2.1}$$

$$H = -\Delta + V(x). \tag{2.2}$$

We assume the following.

(H1) The initial value problem for NLS-GP is well-posed in the space $C^0([0,\infty); H^1(\mathbb{R}^n))$.

(H2) The potential $V(x)$ is assumed to be real valued, smooth, and rapidly decaying as $|x| \to \infty$. We also assume symmetry with respect to a hyperplane which, without loss of generality, can be taken to be $\{x_1 = 0\}$:

$$V(x_1, x_2, \ldots, x_n) = V(-x_1, x_2, \ldots, x_n). \tag{2.3}$$

We assume the nonlinear term, $K[\psi\overline{\psi}]$, to be attractive, cubic (local or nonlocal), and symmetric with respect to the same hyperplane. Specifically, we assume the following hypotheses on the nonlinear term:

(H3) (a) $g(x_1, x_2, \ldots, x_n) = g(-x_1, x_2, \ldots, x_n)$ (symmetry).
(b) $g(x) < 0$ (attractive/focusing).
(c) $K[h] = \int K(x-y)h(y)dy$,
$K(x_1, x_2, \ldots, x_n) = K(-x_1, x_2, \ldots, x_n)$, $K > 0$.
(d) Consider the map $N : H^2 \times H^2 \times H^2 \mapsto L^2$ defined by

$$N(\phi_1, \phi_2, \phi_3) = gK[\phi_1\bar{\phi_2}]\phi_3. \tag{2.4}$$

We also write $N(u) = N(u,u,u)$ and note that $\partial_u N(u) = N(\cdot, u, u) + N(u, \cdot, u) + N(u, u, \cdot)$. We assume that there exists a constant $k > 0$ such that

$$\|N(\phi_0, \phi_1, \phi_2)\|_{L^2} \ \leq \ k\ \|\phi_1\|_{H^2}\|\phi_2\|_{H^2}\|\phi_3\|_{H^2}. \tag{2.5}$$

Remark 2.1. The symmetry restrictions in (H3) insure that the nonlinear term is equivariant with respect to the action of $O(2) \times \mathbb{Z}_2$, namely,

$$\begin{aligned} N(e^{i\theta}u) &= e^{i\theta}N(u), \qquad 0 \leq \theta < 2\pi, \\ N(\bar{u}) &= \overline{N(u)}, \\ N(Ru) &= RN(u), \end{aligned}$$

where R is the reflection with respect to the $x_1 = 0$ hyperplane. Although, the nonlinearity taken in (H3) is cubic, our analysis can be easily extended to more general cases satisfying the $O(2) \times \mathbb{Z}_2$ equivariance.

We now give several illustrative and important examples of NLS-GP.

Example 1. *GP equation for BECs with negative scattering* length $g(x) \equiv -1$, $K(x) = \delta(x)$.

Example 2. *NLS equation for optical media with a nonlocal kernel* $g(x) \equiv \pm 1$, $K(x) = A\exp(-x^2/\sigma^2)$ [22]. See also [6] for similar considerations in BECs.

Example 3. *Photorefractive (saturable) nonlinearities and optically induced potentials* [7]. The relevant symmetry breaking phenomenology is experimentally observable, as shown in [20]. Also contained therein is the finite-dimensional Galerkin approach of section 3.

Nonlinear bound states. Nonlinear bound states are solutions of NLS-GP of the form

$$\psi(x,t) = e^{-i\Omega t}\Psi_\Omega(x), \tag{2.6}$$

where $\Psi_\Omega \in H^1(\mathbb{R}^n)$ solves

$$H\ \Psi_\Omega\ +\ g(x)\ K[|\Psi_\Omega|^2]\ \Psi_\Omega\ -\ \Omega\Psi_\Omega = 0,\quad \Psi_\Omega \in H^1. \tag{2.7}$$

If the potential $V(x)$ is such that the operator $H = -\Delta + V(x)$ has a discrete eigenvalue, Ω_*, and a correspsonding eigenstate ψ_*, then for energies Ω near Ω_*, one expects small amplitude *nonlinear* bound states, which are to leading order small multiples of ψ_*. This is the standard setting of bifurcation from a simple eigenvalue [24], which follows from the implicit function theorem.

THEOREM 2.1 (see [21, 25, 26]). *Let $(\Psi,\Omega) = (\psi_*,\Omega_*)$ be a simple eigenpair of the eigenvalue problem $H\Psi = \Omega\Psi$, i.e., $dim\{\rho : (H-\Omega_*)\rho = 0\} = 1$. Then there exists a unique smooth curve of nontrivial solutions $\alpha \mapsto (\ \Psi(\cdot;\alpha),\Omega(\alpha)\ )$, defined in a neighborhood of $\alpha = 0$, such that*

$$\Psi_\Omega = \alpha\left(\ \psi_*\ +\ \mathcal{O}(|\alpha|^2)\ \right),\quad \Omega = \Omega_*\ +\ \mathcal{O}(|\alpha|^2),\quad \alpha \to 0. \tag{2.8}$$

Remark 2.2. For a large class of problems, a nonlinear ground state can be characterized variationally as a constrained minimum of the NLS-GP energy subject to fixed squared L^2 norm. Define the NLS-GP Hamiltonian energy functional

$$\mathcal{H}_{NLS-GP}[\Phi]\ \equiv\ \int |\nabla\Phi|^2\ +\ V|\Phi|^2\ dy\ +\ \frac{1}{2}\int\ g(y)|\Phi(y)|^2K[|\Phi|^2]\ dy \tag{2.9}$$

and the particle number (optical power)

$$\mathcal{N}[\Phi] = \int\ |\Phi|^2\ dy. \tag{2.10}$$

In particular, the following can be proved.

THEOREM 2.2. *Let $I_\lambda = \inf_{\mathcal{N}[f]=\lambda}\ \mathcal{H}[f]$. If $-\infty < I_\lambda < 0$, then the minimum is attained at a positive solution of* (2.7). *Here, $\Omega = \Omega(\lambda)$ is a Lagrange multiplier for the constrained variational problem.*

In [3] the nonlinear Hartree equation is studied; $K[h] = |y|^{-1} \star h$, $g \equiv -1$. It is proved that if $V(x)$ is a double-well potential, then for λ sufficiently large, the minimizer does not have the same symmetry as the linear ground state. By uniqueness, ensured by the implicit function theorem, for small $\mathcal{N}$, the minimizer has the same symmetry as that as the linear ground state and has the expansion (2.8); see [3] and section 4.

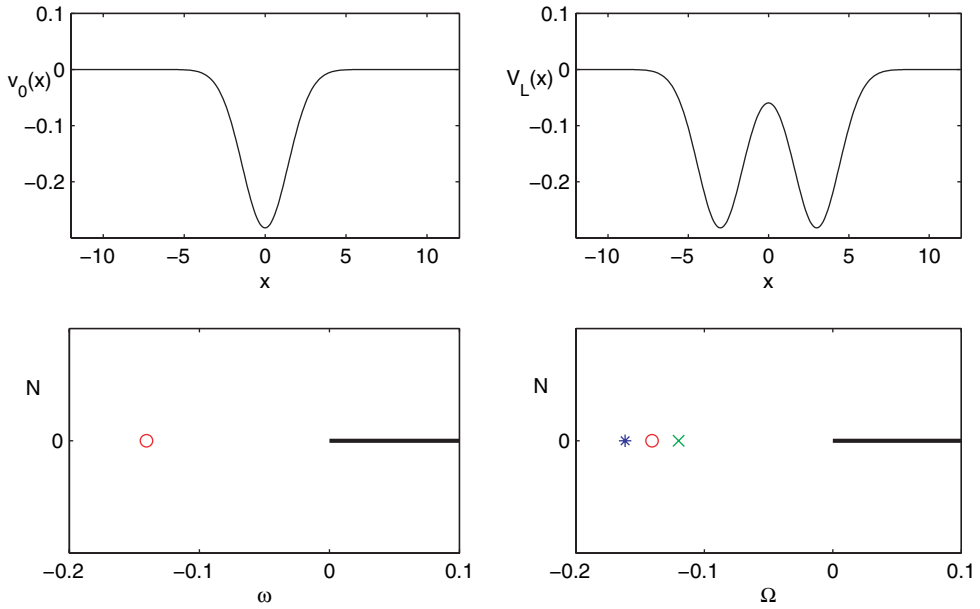
We make the following assumptions.

Spectral assumptions on H.

(H4) H has a pair of simple eigenvalues Ω_0 and Ω_1. ψ_0 and ψ_1, the corresponding (real-valued) eigenfunctions are, respectively, even (symmetric) and odd (antisymmetric) in x_1.

Example 2.1 (the basic example: *double-well potentials*). Our basic example of $V(x)$ is a double-well potential consisting of two identical potential wells and separated by a distance L. Thus, assume symmetry with respect to the hyperplane which, without loss of generality, can be taken to be $\{x_1 = 0\}$:

$$V(x_1,x_2,\ldots,x_n) = V(-x_1,x_2,\ldots,x_n). \tag{2.11}$$



(a) (b)

FIG. 2. *This figure demonstrates a single- and a double-well potential and the spectrum of H and H_L, respectively.* (a) *shows a single-well potential and under it the spectrum of H, with an eigenvalue marked by a (red) mark "o" at ω and continuous spectrum marked by a (black) line for energies $\omega \geq 0$.* (b) *shows the double well centered at $\pm L$ and the spectrum of H_L underneath. The eigenvalues Ω_0 and Ω_1 are each marked by a (blue) mark "*" and a (green) mark "x," respectively, on either side of the location ω—(red) mark "o." The continuous spectrum is marked by a (black) line for energies $\Omega \geq 0$.*

In the appendix, we discuss how spectral hypothesis (H4) is shown for a double wells with well-separation parameter L. The simplest example, in one space dimension, is obtained as follows. Start with a single potential well (rapidly decaying as $|x| \to \infty$), $v_0(x)$, having exactly one eigenvalue, ω, $H_0\psi_\omega = (-\Delta + v_0(x))\psi_\omega = \omega\psi_\omega$; see Figure 2(a). Center this well at $x = -L$ and place an identical well centered at $x = L$. Denote by $V_L(x)$ the resulting *double-well potential* and by H_L the Schrödinger operator:

$$H_L = -\Delta + V_L(x). \tag{2.12}$$

There exists $L > L_0$ such that for $L > L_0$, H_L has a pair of eigenvalues $\Omega_0 = \Omega_0(L)$ and $\Omega_1 = \Omega_1(L)$, $\Omega_0 < \Omega_1$, and corresponding eigenfunctions ψ_0 and ψ_1; see Figure 2(b). ψ_0 is symmetric with respect to $x = 0$ and ψ_1 is antisymmetric with respect to $x = 0$. Moreover, for L sufficiently large, $|\Omega_0 - \Omega_1| = \mathcal{O}(e^{-\kappa L})$, $\kappa > 0$; see [12] and see also the appendix.

The construction can be generalized. If $-\Delta + v_0(x)$ has m bound states, then forming a double well V_L with L sufficiently large, $H_L = -\Delta + V_L$ will have m pairs of eigenvalues: $(\Omega_{2j}, \Omega_{2j+1})$, $j = 0, \ldots, m-1$, eigenfunctions ψ_{2j} (symmetric), and ψ_{2j+1} antisymmetric.

By Theorem 2.1, for small $\mathcal{N}$, there exists a unique nontrivial nonlinear bound state bifurcating from the zero solution at the ground state energy, Ω_0, of H. By uniqueness, ensured by the implicit function theorem, these small amplitude nonlinear bound states have the same symmetries as the double well; they are bimodal. We also

know from [3] that for sufficiently large $\mathcal{N}$ the ground state has broken symmetry. We now seek to elucidate the transition from the regime of $\mathcal{N}$ small to $\mathcal{N}$ large.

We work in the general setting of hypotheses (H1)–(H4). Define spectral projections onto the bound and continuous spectral parts of H:

$$P_0 = (\psi_0, \cdot)\,\psi_0,\ P_1 = (\psi_1, \cdot)\,\psi_1,\quad \tilde{P} = I\ -\ P_0\ -\ P_1. \tag{2.13}$$

Here,

$$(f, g) = \int\ \bar{f} g\ dx. \tag{2.14}$$

We decompose the solutions of (2.7) according to

$$\Psi_\Omega = c_0\psi_0\ +\ c_1\psi_1\ +\ \eta,\quad \eta = \tilde{P}\eta. \tag{2.15}$$

We next substitute the expression (2.15) into (2.7) and then act with projections P_0, P_1, and $\tilde{P}$ on the resulting equation. Using the symmetry and antisymmetry properties of the eigenstates, we obtain three equations which are equivalent to the PDE (2.7):

$$\begin{aligned}(\Omega_0 - \Omega)\, c_0 + a_{0000}|c_0|^2 c_0 + (a_{0110} + a_{0011})\,|c_1|^2 c_0,\\ + a_{0011} c_1^2 \bar{c}_0 + (\psi_0 g, \mathcal{R}(c_0, c_1, \eta)) = 0,\end{aligned} \tag{2.16}$$

$$\begin{aligned}(\Omega_1 - \Omega)\, c_1 + a_{1111}|c_1|^2 c_1 + (a_{1010} + a_{1001})\,|c_0|^2 c_1\\ + a_{1010} c_0^2 \bar{c}_1 + (\psi_1 g, \mathcal{R}(c_0, c_1, \eta)) = 0,\end{aligned} \tag{2.17}$$

$$(H - \Omega)\ \eta = -\tilde{P}\ g\left[F(\cdot; c_0, c_1)\ +\ \mathcal{R}(c_0, c_1, \eta)\right], \tag{2.18}$$

where $F(\cdot, c_0, c_1)$ is independent of η and $\mathcal{R}(c_0, c_1, \eta)$ contains linear, quadratic, and cubic terms in η. The coefficients a_{klmn} are defined by

$$a_{klmn} = \left(\psi_k, gK[\psi_l \bar{\psi_m}]\psi_n\right). \tag{2.19}$$

We shall study the character of the set of solutions of the system (2.16)–(2.18) restricted to the level set

$$\int |\Psi_\Omega|^2 dx = \mathcal{N} \quad\Longleftrightarrow\quad |c_0|^2\ +\ |c_1|^2\ +\ \int |\eta|^2 dx = \mathcal{N} \tag{2.20}$$

as $\mathcal{N}$ varies.

Let Ω_0 and Ω_1 denote the two lowest eigenvalues of H_L. We prove (Theorem 4.1, Corollary 4.1, Theorem 5.1) the following.

- There exist two solution branches, parametrized by $\mathcal{N}$, which bifurcate from the zero solution at the eigenvalues Ω_0 and Ω_1.
- Along the branch (Ω, Ψ_Ω), emanating from the solution $(\Omega = \Omega_0, \Psi = 0)$, there is a symmetry-breaking bifurcation at $\mathcal{N} = \mathcal{N}_{crit} > 0$. In particular, let u_{crit} denote the solution of (2.7) corresponding to the value $\mathcal{N} = \mathcal{N}_{crit}$. Then, in a neighborhood u_{crit}, for $\mathcal{N} < \mathcal{N}_{crit}$ there is only one solution of (2.7), the symmetric ground state, while for $\mathcal{N} > \mathcal{N}_{crit}$ there are two solutions one symmetric and a second asymmetric.
- *Exchange of stability* at the bifurcation point: For $\mathcal{N} < \mathcal{N}_{crit}$ the symmetric state is dynamically stable, while for $\mathcal{N} > \mathcal{N}_{crit}$ the asymmetric state is stable and the symmetric state is exponentially unstable.

3. Bifurcations in a finite-dimensional approximation. It is illustrative to consider the finite-dimensional approximation to the system (2.16)–(2.18), obtained by neglecting the continuous spectral part, η. Let us first set $\eta = 0$, and therefore $\mathcal{R}(c_0, c_1, 0) = 0$. Under this assumption of no coupling to the continuous spectral part of H, we obtain the finite-dimensional system

$$(\Omega_0 - \Omega)\, c_0 + a_{0000}|c_0|^2 c_0 + (a_{0110} + a_{0011})\, |c_1|^2 c_0 + a_{0011} c_1^2 \bar{c}_0 = 0, \tag{3.1}$$

$$(\Omega_1 - \Omega)\, c_1 + a_{1111}|c_1|^2 c_1 + (a_{1010} + a_{1001})\, |c_0|^2 c_1 + a_{1010} c_0^2 \bar{c}_1 = 0. \tag{3.2}$$

Note that in this approximation the physically meaningful parameter $\mathcal{N}$ is given by

$$|c_0|^2 \ + \ |c_1|^2 = \mathcal{N}. \tag{3.3}$$

Our strategy is to first analyze the bifurcation problem for this approximate finite-dimensional system of *algebraic equations*. We then treat the corrections, coming from coupling to the continuous spectral part of H, η, perturbatively. In fact, the analysis in the next section indirectly shows that (3.1)-(3.2) is the universal unfolding of bifurcation problems with four degrees of freedom and $O(2) \times \mathbb{Z}_2$ symmetry; see [8] for related notions.[1]

Our point of view, however, is not the *general* theory of (3.1)-(3.2), its bifurcations and its structural stability, but rather what it implies for solutions of the NLS-GP system for given "data", e.g., spectral properties of the potential $V(x)$, the nonlinearity term defined in terms of $K[\cdot]$ and g. This data, together with structural properties of $NLS\text{-}GP$, such as its Hamiltonian structure and the second-order elliptic character of the nonlinear bound state equations, imply natural assumptions as well as constraints on the coefficients a_{jklm}. In this section, where we study the algebraic problem (3.1)-(3.2), we posit and comment briefly on these properties. The first are

$$a_{0000} - a_{1001} - 2a_{1010} > 0, \tag{3.4}$$

$$a_{1010} \neq 0. \tag{3.5}$$

Condition (3.4) will guarantee a symmetry-breaking bifurcation at small amplitude, while (3.5) is a nondegeneracy condition, easily seen to hold for generic assumptions on $V, K[\cdot]$ and g in NLS-GP.

Additional conditions are

$$a_{1001} - a_{0000} > 0 \tag{3.6}$$

and

$$a_{1111} - a_{0110} - 2a_{0011} > 0, \tag{3.7}$$

$$a_{1111} - a_{0110} > 0, \tag{3.8}$$

which we shall see are related to secondary bifurcations and the exchange of stability at the bifurcation point.

Note also that

$$a_{0000} < 0, \quad a_{1111} < 0 \tag{3.9}$$

since $K[\cdot]$ preserves positivity and $g < 0$; see (2.19) and hypothesis (H3).

[1] Since the full problem, with $\eta \neq 0$, adds higher order terms in (3.1)-(3.2), from singularity theory we expect that they will not qualitatively change the bifurcation diagram. We do not make use of results in singularity theory instead we prefer a self-contained treatment yielding a detailed understanding of the effect of the physically important unfolding parameter $\Omega_1 - \Omega_0$.

One can easily construct, using (3.9), the following two *pure mode solutions* of (3.1)-(3.2):

(1) *Approximate nonlinear symmetric branch:*
$c_1 = 0,\ c_0 = \sqrt{\frac{\Omega-\Omega_0}{a_{0000}}}e^{i\theta},\ 0 \le \theta < 2\pi,\ \Omega \le \Omega_0.$
In terms of the physical parameter $\mathcal{N}$: $c_1 = 0,\ c_0 = \sqrt{\mathcal{N}}e^{i\theta},\ \Omega = \Omega_0 + a_{0000}\mathcal{N}$, where $\mathcal{N} \ge 0,\ 0 \le \theta < 2\pi$.

(2) *Approximate nonlinear antisymmetric branch:*
$c_0 = 0,\ c_1 = \sqrt{\frac{\Omega-\Omega_1}{a_{1111}}}e^{i\theta},\ 0 \le \theta < 2\pi,\ \Omega \le \Omega_1.$
In terms of the physical parameter $\mathcal{N}$: $c_0 = 0,\ c_1 = \sqrt{\mathcal{N}}e^{i\theta},\ \Omega = \Omega_1 + a_{1111}\mathcal{N}$, where $\mathcal{N} \ge 0,\ 0 \le \theta < 2\pi$.

The above two solutions correspond to those of NLS-GP given by Theorem 2.1.

Under assumptions (3.4)–(3.8) the system (3.1)-(3.2) has exactly one more (secondary) branch of solutions which bifurcates from the symmetric branch at

$$\Omega^* = \Omega_0 + \frac{a_{0000}(\Omega_1 - \Omega_0)}{a_{0000} - a_{1001} - 2a_{1010}} < \Omega_0$$

or, equivalently, at

$$\mathcal{N}_{cr} = \frac{\Omega_1 - \Omega_0}{a_{0000} - a_{1001} - 2a_{1010}} > 0. \tag{3.10}$$

In terms of the physical parameter $\mathcal{N}$, these *mixed mode solutions of the approximate system* are given by

(3) *Approximate nonlinear asymmetric branch:* For $\mathcal{N} \ge \mathcal{N}_{cr},\ 0 \le \theta_0,\ \theta_1 < 2\pi,\ \theta_1 - \theta_0 \in \{0, \pi\}$,

$$\begin{aligned}
c_0 &= \sqrt{\frac{(a_{1111} - a_{0110} - 2a_{0011})\mathcal{N} + (\Omega_1 - \Omega_0)}{a_{1111} - a_{0110} - 2a_{0011} + a_{0000} - a_{1001} - 2a_{1010}}}e^{i\theta_0},\\
c_1 &= \sqrt{\frac{(a_{0000} - a_{1001} - 2a_{1010})\mathcal{N} - (\Omega_1 - \Omega_0)}{a_{1111} - a_{0110} - 2a_{0011} + a_{0000} - a_{1001} - 2a_{1010}}}e^{i\theta_1},\\
\Omega &= \Omega_0 + \\
&\frac{(a_{0000}a_{1111} - (a_{1001} + 2a_{1010})(a_{0110} + 2a_{0011}))\mathcal{N}}{a_{1111} - a_{0110} - 2a_{0011} + a_{0000} - a_{1001} - 2a_{1010}}\\
&\frac{- (a_{0000} - a_{1001} - 2a_{1010})(\Omega_1 - \Omega_0)}{a_{1111} - a_{0110} - 2a_{0011} + a_{0000} - a_{1001} - 2a_{1010}}.
\end{aligned} \tag{3.11}$$

To derive the above solutions, first introduce polar coordinates: $c_j = \rho_j e^{i\theta_j},\ j = 1, 2,\ \Delta\theta = \theta_1 - \theta_0$. Then, (3.1)-(3.2) becomes

$$\rho_0\ \left[\Omega_0 - \Omega\ +\ a_{0000}\rho_0^2\ +\ \left(a_{0110} + a_{0011} + a_{0011}e^{i2\Delta\theta}\right)\rho_1^2\right] = 0, \tag{3.12}$$

$$\rho_1\ \left[\Omega_1 - \Omega\ +\ a_{1111}\rho_1^2\ +\ \left(a_{1001} + a_{1010} + a_{1010}e^{-i2\Delta\theta}\right)\rho_0^2\right] = 0. \tag{3.13}$$

Taking the imaginary parts of both equations and using the fact that all coefficients are real, see (2.19), we get $a_{0011}\sin(2\Delta\theta) = 0 = a_{1010}\sin(2\Delta\theta)$. Because of (3.5), the latter are equivalent with $\Delta\theta \in \{0, \pi/2, \pi, 3\pi/2\}$ modulo 2π, note that $a_{0011} = a_{1010}$; see (2.19). The real parts of (3.12)-(3.13) become

$$\rho_0\ \left[\Omega_0 - \Omega\ +\ a_{0000}\rho_0^2\ +\ (a_{0110} + 2a_{0011})\,\rho_1^2\right] = 0, \tag{3.14}$$

$$\rho_1\ \left[\Omega_1 - \Omega\ +\ a_{1111}\rho_1^2\ +\ (a_{1001} + 2a_{1010})\,\rho_0^2\right] = 0 \tag{3.15}$$

for $\Delta\theta \in \{0, \pi\}$, while for $\Delta\theta \in \{\pi/2, 3\pi/2\}$,

$$\rho_0 \left[\Omega_0 - \Omega + a_{0000}\rho_0^2 + a_{0110}\rho_1^2\right] = 0, \tag{3.16}$$

$$\rho_1 \left[\Omega_1 - \Omega + a_{1111}\rho_1^2 + a_{1001}\rho_0^2\right] = 0. \tag{3.17}$$

Both systems (3.14)-(3.15) and (3.16)-(3.17), respectively, can be easily analyzed and even reduced to a linear system by the change of variables: $\mathcal{P}_0 = \rho_0^2$, $\mathcal{P}_1 = \rho_1^2$. The first one, under assumption (3.4), gives the mixed mode solution (3) in addition to the pure mode solutions (1) and (2), and no other solutions provided (3.7) holds. The second system gives no other solutions provided (3.6), (3.8) hold. Thus we have that the finite-dimensional Galerkin approximation yields the qualitative structure of the NLS-GP bifurcation diagram of Figure 3. Dynamic stability can also be addressed in the context of the Galerkin-truncated time-dependent Hamiltonian dynamics. We defer our study of stability to our considerations of the full PDE problem in the coming sections.

The study of the systems (3.14)-(3.15) and (3.16)-(3.17) can be put in the context of singularity theory and bifurcations in systems with symmetry [8]. These systems exhibit a $\mathbb{Z}_2 \oplus \mathbb{Z}_2$ symmetry. Actually the argument in the next section shows that under the nondegeneracy condition (3.5), bifurcation problems with four degrees of freedom and $O(2) \times \mathbb{Z}_2$ symmetry are reducible to two distinct systems each with two degrees of freedom and $\mathbb{Z}_2 \oplus \mathbb{Z}_2$ symmetry. The latter have been classified, for example, in [8, Chapter X]. Under assumptions (3.4), (3.7), our first system (3.14)-(3.15) falls in case A subcase (1) [8, Chapter X] while under (3.6), (3.8) our second system falls in their case A subcases (2) or (3). Note that the above-cited book uses $\lambda = \Omega_0 - \Omega$ as bifurcation parameter and $\sigma = \Omega_0 - \Omega_1$ as the unfolding parameter which explains the differences between our bifurcation diagram in Figure 1 and their Figure 4.3 in Chapter X.

Finally, the posited properties of a_{klmn} can be directly verified for general double-well problems with L sufficiently large; see the proof of Corollary 4.1.

4. Bifurcation/symmetry breaking analysis of the PDE. In this section we prove the following theorem.

THEOREM 4.1 (symmetry breaking for NLS-GP). *Consider NLS-GP with hypotheses* (H2)–(H4). *Let* a_{klmn} *be given by* (2.19) *and let*

$$\Xi[\psi_0, \psi_1, g] \equiv a_{0000} - a_{1001} - 2a_{1010} \tag{4.1}$$

$$= \left(\psi_0^2, gK[\psi_0^2]\right) - \left(\psi_1^2, gK[\psi_0^2]\right) - 2\left(\psi_0\psi_1, gK[\psi_0\psi_1]\right) > 0, \tag{4.2}$$

$$a_{1010} = \left(\psi_0\psi_1, gK[\psi_0\psi_1]\right) \neq 0. \tag{4.3}$$

Assume

$$\frac{\Omega_1 - \Omega_0}{\Xi[\psi_0, \psi_1, g]^2} \quad \textit{is sufficiently small.} \tag{4.4}$$

Then, there exists $\mathcal{N}_{cr} > 0$ *such that*

(i) *for any* $\mathcal{N} \leq \mathcal{N}_{cr}$, *there is (up to the symmetry* $u \mapsto u\, e^{i\gamma}$*) a locally unique symmetric state,* $u_{\mathcal{N}}^{sym}$.

(ii) $\mathcal{N} = \mathcal{N}_{cr}$, $u_{\mathcal{N}_{cr}}^{sym}$ *is a bifurcation point. For* $\mathcal{N} > \mathcal{N}_{cr}$, *there are, in a neighborhood of* $\mathcal{N} = \mathcal{N}_{cr}$, $u_{\mathcal{N}_{cr}}^{sym}$, *two branches of solutions:* (a) *a continuation of the symmetric branch and* (b) *a new asymmetric branch.*

(iii) *The critical* $\mathcal{N}$ *value for bifurcation is given approximately by*

$$\mathcal{N}_{cr} = \frac{\Omega_1 - \Omega_0}{\Xi[\psi_0, \psi_1, g]} \left[1 + \mathcal{O}\left(\frac{\Omega_1 - \Omega_0}{\Xi[\psi_0, \psi_1, g]^2} \right)\right].$$

(iv) *The bifurcation from the zero state at* $\Omega = \Omega_0$ *and the bifurcation described in* (i)–(iii) *are the only ones along this branch for* $\mathcal{N}$ *small.*

COROLLARY 4.1 (application to double wells, V_L, with separation L). *Fix a pair of eigenvalues,* (Ω_{2j}, ψ_{2j}), $(\Omega_{2j+1}, \psi_{2j+1})$, *of the linear double-well potential,* $V_L(x)$; *see Example* 2.1. *Assume that* $K(x) \to 0$ *as* $|x| \to 0$ *and* $\lim_{L\to\pm\infty} g(x_1 + L, x_2, \dots) = g_\pm(x_2, \dots) < 0$. *Then, for the NLS-GP with double-well potential of well-separation* L, *there exists* $\tilde{L} > 0$ *such that for all* $L \geq \tilde{L}$, *there is a symmetry-breaking bifurcation, as described in Theorem* 4.1, *with* $\mathcal{N}_{cr} = \mathcal{N}_{cr}(L; j)$.

Proof of Corollary 4.1. The crux is to verify the spectral properties (H4), the nondegeneracy condition (4.3), and the smallness condition (4.4). The spectral properties of $H_L = -\Delta + V_L$ are handled in Proposition 8.1 of the appendix. In what follows we show that

$$\lim_{L\to\infty} a_{0000} - a_{1001} = 0, \tag{4.5}$$

$$\lim_{L\to\infty} a_{1010} < 0. \tag{4.6}$$

These imply both (4.3) and (4.4) since $\Omega_0 - \Omega_1 \to 0$ as $L \to \infty$; see Proposition 8.1.

For (4.5), (4.6) we use the large L asymptotic behavior of the eigenfunctions of H_L, given in Proposition 8.1, together with the continuity of the nonlinearity (2.5), to rewrite them as

$$\lim_{L\to\infty} a_{0000} - a_{1001} = \lim_{L\to\infty} \frac{1}{2} \left(T_L\psi_\omega, gK[(T_L\psi_\omega + RT_L\psi_\omega)^2]RT_L\psi_\omega\right), \tag{4.7}$$

$$\lim_{L\to\infty} a_{1010} = \lim_{L\to\infty} \frac{1}{4} \left(T_L\psi_\omega^2 - RT_L\psi_\omega^2, gK[T_L\psi_\omega^2 - RT_L\psi_\omega^2]\right). \tag{4.8}$$

To obtain (4.5) approximate $\psi_\omega \in H^2$ by smooth functions with compact support ψ_ω^0. For sufficiently large L, $T_L\psi_\omega^0$ and $RT_L\psi_\omega^0$ have no common support and the scalar product in (4.7) is zero. The continuity of the nonlinearity (2.5) implies (4.5).

Now, the right-hand side in (4.8) has two types of similar terms:

$$\lim_{L\to\infty} \left(T_L\psi_\omega^2, gK[RT_L\psi_\omega^2]\right) = \lim_{L\to\infty} \left(\psi_\omega^2, (T_{-L}g)T_{-2L}K[R\psi_\omega^2]\right) = 0,$$

$$\lim_{L\to\infty} \left(T_L\psi_\omega^2, gK[T_L\psi_\omega^2]\right) = \lim_{L\to\infty} \left(\psi_\omega^2, (T_{-L}g)K[\psi_\omega^2]\right) = \left(\psi_\omega^2, g_-K[\psi_\omega^2]\right) < 0,$$

where we used the symmetries of g and K and their behavior as $x_1 \to \pm\infty$. This completes the proof of the corollary. □

To prove Theorem 4.1 we will establish that, under hypotheses (4.2)–(4.4), the character of the solution set (symmetry-breaking bifurcation) of the finite-dimensional

approximation (3.1)-(3.2) persists for the full (infinite-dimensional) problem:

$$(\Omega_0 - \Omega)\, c_0 + a_{0000}|c_0|^2 c_0 + (a_{0110} + a_{0011})\,|c_1|^2 c_0 + a_{0011} c_1^2 \bar{c}_0 + (\psi_0 g, \mathcal{R}(c_0, c_1, \eta)) = 0, \tag{4.9}$$

$$(\Omega_1 - \Omega)\, c_1 + a_{1111}|c_1|^2 c_1 + (a_{1010} + a_{1001})\,|c_0|^2 c_1 + a_{1010} c_0^2 \bar{c}_1 + (\psi_1 g, \mathcal{R}(c_0, c_1, \eta)) = 0, \tag{4.10}$$

$$(H - \Omega)\ \eta = -\tilde{P}\ g\,[F(\cdot; c_0, c_1)\ +\ \mathcal{R}(c_0, c_1, \eta)\ ]\,, \qquad \eta = \tilde{P}\eta, \tag{4.11}$$

$$|c_0|^2\ +\ |c_1|^2\ +\ \int |\eta|^2 = \mathcal{N}. \tag{4.12}$$

We analyze this system using the Lyapunov–Schmidt-type method. The strategy is to solve (4.11) for η as a functional of c_0, c_1, and Ω. Then, substituting $\eta = \eta[c_0, c_1, \Omega]$ into (4.9), (4.10), and (4.12), we obtain three closed equations, depending on a parameter $\mathcal{N}$, for c_0, c_1, and Ω. This system is a perturbation of the finite-dimensional (truncated) system: (3.1)–(3.3). We then show that under hypotheses (4.2)–(4.4) there is a symmetry-breaking bifurcation. Finally, we show that the terms perturbing the finite-dimensional model have a small and controllable effect on the character of the solution set for a range of $\mathcal{N}$, which includes the bifurcation point. As seen in the proof, the form of the nonlinearity implies analyticity. However, analyticity is not essential for the arguments, at the root of which is the implicit function theorem, and the methods can be adapted to situations where one has a finite degree of smoothness.

We begin with the following proposition, which characterizes $\eta = \eta[c_0, c_1, \Omega]$.

PROPOSITION 4.1. *Consider* (4.11) *for* η. *By* (H4) *we have the following:*

(4.13) Gap condition : $|\Omega_j - \tau|\ \geq\ 2d_*$ for $j = 0, 1$ and for all $\tau \in \sigma(H) \setminus \{\Omega_0, \Omega_1\}$.

Then there exist $n_*,\ r_* > 0$, *depending on* d_*, *such that in the open set*

$$|c_0| + |c_1| < r_*, \qquad \|c_0\psi_0 + c_1\psi_1 + \eta\|_{H^2} < n_*(d_*), \tag{4.14}$$

$$dist(\Omega, \sigma(H) \setminus \{\Omega_0, \Omega_1\}) > d_*, \tag{4.15}$$

the unique solution of (2.18) *is given by the real-analytic mapping*

$$(c_0, c_1, \Omega)\ \mapsto\ \ \eta[c_0, c_1, \Omega], \tag{4.16}$$

defined on the domain given by (4.14)-(4.15). *Moreover, there exists* $C_* > 0$ *such that*

$$\|\eta[c_0, c_1, \Omega]\|_{H^2} \leq C_*(|c_0| + |c_1|)^3. \tag{4.17}$$

Proof. Consider the map

$$N : H^2 \times H^2 \times H^2 \mapsto L^2,$$
$$N(\phi_0, \phi_1, \phi_2) = gK[\phi_1 \bar{\phi}_2]\phi_3.$$

By assumptions on the nonlinearity (see section 2), there exists a constant $k > 0$ such that

$$\|N(\phi_0, \phi_1, \phi_2)\|_{L^2} \leq k\|\phi_1\|_{H^2}\|\phi_2\|_{H^2}\|\phi_3\|_{H^2}. \tag{4.18}$$

Moreover, since the map is real linear in each component, it is real analytic.[2]

[2]The trilinearity follows from the implicit bilinearity of K in formulas (2.16)–(2.18).

Let c_0, c_1, and Ω be restricted according to (4.14)-(4.15). Equation (2.18) can be rewritten in the form

$$\eta + (H-\Omega)^{-1}\tilde{P}N[c_0\psi_0 + c_1\psi_1 + \eta] = 0. \tag{4.19}$$

Since the spectrum of $H\tilde{P}$ is bounded away from Ω by d_*, the resolvent

$$(H-\Omega)^{-1}\tilde{P} : L^2 \mapsto H^2$$

is a (complex) analytic map and bounded uniformly,

$$\|(H-\Omega)^{-1}\tilde{P}\|_{L^2\mapsto H^2} \le p(d_*^{-1}), \tag{4.20}$$

where $p(s) \to \infty$ as $s \to \infty$. Consequently the map $F : \mathbb{C}^2 \times \{\Omega \in \mathbb{C} \ : \ dist(\Omega, \sigma(H) \setminus \{\Omega_0, \Omega_1\}\ \} \ge d_*\} \times H^2 \mapsto H^2$ given by

$$F(c_0, c_1, \Omega, \eta) = \eta + (H-\Omega)^{-1}\tilde{P}N[c_0\psi_0 + c_1\psi_1 + \eta] \tag{4.21}$$

is real analytic. Moreover,

$$F(0,0,\Omega,0) = 0, \quad D_\eta F(0,0,\Omega,0) = I.$$

Applying the implicit function theorem to (4.19), we have that there exists $n_*(\Omega), r_*(\Omega)$ such that whenever $|c_0| + |c_1| < r_*$ and $\|c_0\psi_0 + c_1\psi_1 + \eta\|_{H^2} < n_*$, (4.19) has a unique solution:

$$\eta = \eta(c_0, c_1, \Omega) \in H^2$$

which depends analytically on the parameters $c_0,\ c_1,\ \Omega$. By applying the projection operator $\tilde{P}$ to (4.19), which commutes with $(H-\Omega)^{-1}$, we immediately obtain $\tilde{P}\eta = \eta$, i.e., $\eta \in \tilde{P}L^2$.

We now show that $n_*,\ r_*$ can be chosen independently of Ω, satisfying (4.15). The implicit function theorem can be applied in an open set for which

$$D_\eta F(c_0, c_1, \Omega, \eta) = I + (H-\Omega)^{-1}\tilde{P}D_\eta N[c_0\psi_0 + c_1\psi_1 + \eta]$$

is invertible. For this it suffices to have

$$\|(H-\Omega)^{-1}\tilde{P}D_\eta N[c_0\psi_0 + c_1\psi_1 + \eta]\|_{H^2} \le Lip < 1.$$

A direct application of (2.5) and (4.20) shows that

$$\|(H-\Omega)^{-1}\tilde{P}D_\eta N[c_0\psi_0 + c_1\psi_1 + \eta]\|_{H^2} \le 3k\ p(d_*^{-1})\|c_0\psi_0 + c_1\psi_1 + \eta\|_{H^2}^2. \tag{4.22}$$

Fix $Lip = 3/4$. Then, a sufficient condition for invertibility is

$$3k\ p(d_*^{-1})\ \|c_0\psi_0 + c_1\psi_1 + \eta\|_{H^2}^2 \le Lip = 3/4, \tag{4.23}$$

which allows us to choose $n_* = \frac{1}{2}\sqrt{\frac{1}{kp(d_*^{-1})}}$ independently of Ω.

But, if (4.23) holds, then, from (4.22), the H^2 operator

$$(H-\Omega)^{-1}\tilde{P}N[c_0\psi_0 + c_1\psi_1 + \cdot]$$

is Lipschitz with Lipschitz constant less than or equal to $Lip = 3/4$. The standard contraction principle estimate applied to (4.19) gives

$$\begin{aligned}\|\eta\|_{H^2} &\leq \frac{1}{1-Lip}\|(H-\Omega)^{-1}\tilde{P}N[c_0\psi_0+c_1\psi_1]\|_{H^2}\\ &\leq 4p(d_*^{-1})\ k\|c_0\psi_0+c_1\psi_1\|_{H^2}^3. \end{aligned} \tag{4.24}$$

Plugging the above estimate into (4.23) gives

$$\|c_0\psi_0+c_1\psi_1\|_{H^2}+4p(d_*^{-1})\ k\|c_0\psi_0+c_1\psi_1\|_{H^2}^3 \leq \frac{1}{2\sqrt{p(d_*^{-1})k}}.$$

Since the left-hand side is continuous in $(c_0,c_1)\in\mathbb{C}^2$ and zero for $c_0=c_1=0$, one can construct $r_*>0$ depending only on $d_*,\ k$ such that the above inequality, hence (4.23) and (4.24), all hold whenever $|c_0|+|c_1|\leq r_*$. Finally, (4.17) now follows from (4.24). ∎

In particular, for the double-well potential we have the following proposition.

PROPOSITION 4.2. *Let $V=V_L$ denote the double-well potential with well-separation L. There exist $L_*>0, \varepsilon(L_*)>0$, and $d_*(L_*)>0$ such that for $L>L_*$, we have that for (c_0,c_1,Ω) satisfying dist$(\Omega,\sigma(H)\setminus\{\Omega_0,\Omega_1\})\geq d_*(L_*)$ and $|c_0|+|c_1|<\varepsilon(L_*)$, $\eta[c_0,c_1,\Omega]$ is defined and analytic and satisfies the bound* (4.17) *for some $C_*>0$.*

Proof. Since Ω_0,Ω_1,ψ_0, and ψ_1 can be controlled uniformly in L large, both d_* and r_* in the previous proposition can be controlled uniformly in L large. ∎

Next we study the symmetries of $\eta(c_0,c_1,\Omega)$ and the properties of $\mathcal{R}(c_0,c_1,\eta)$ which we will use in analyzing (2.16)-(2.17). The following result is a direct consequence of the symmetries of (2.18) and Proposition 4.1.

PROPOSITION 4.3. *We have*

$$\eta(e^{i\theta}c_0,e^{i\theta}c_1,\Omega)=e^{i\theta}\eta(c_0,c_1,\Omega) \qquad \text{for } 0\leq\theta<2\pi, \tag{4.25}$$

$$\overline{\eta(c_0,c_1,\Omega)}=\eta(\overline{c_0},\overline{c_1},\overline{\Omega}), \tag{4.26}$$

in particular

$$\eta(e^{i\theta}c_0,c_1=0,\Omega)=e^{i\theta}\eta(c_0,c_1=0,\Omega), \tag{4.27}$$

$$\eta(c_0=0,e^{i\theta}c_1,\Omega)=e^{i\theta}\eta(c_0=0,c_1,\Omega), \tag{4.28}$$

$\eta(c_0,0,\Omega)$ is even in x_1, $\eta(0,c_1,\Omega)$ is odd in x_1, and if c_0,c_1, and Ω are real-valued, then $\eta(c_0,c_1,\Omega)$ is real-valued.

In addition

$$\langle\psi_0,\mathcal{R}(c_0,c_1,\eta)\rangle=c_0\ f_0\left(c_0,c_1,\Omega\right), \tag{4.29}$$

$$\langle\psi_1,\mathcal{R}(c_0,c_1,\eta)\rangle=c_1\ f_1\left(c_0,c_1,\Omega\right), \tag{4.30}$$

where, for any $0\leq\theta<2\pi$ and $j=0,1$,

$$f_j\left(e^{i\theta}c_0,e^{i\theta}c_1,\Omega\right)=f_j\left(c_0,c_1,\Omega\right), \tag{4.31}$$

$$\overline{f_j(c_0,c_1,\Omega\ )}=f_j\left(\overline{c_0},\overline{c_1},\overline{\Omega}\right), \tag{4.32}$$

$$|f_j\left(c_0,c_1,\Omega\right)|\leq C(|c_0|+|c_1|)^4 \tag{4.33}$$

for some constant $C > 0$. Moreover, both f_0 and f_1 can be written as absolutely convergent power series:

(4.34)
$$f_j(c_0, c_1, \Omega) = \sum_{\substack{k+l+m+n \geq 4,\\ k-l+m-n=0,\\ m+n=\text{even}}} b^j_{klmn}(\Omega) c_0^k\ \overline{c}_0^{\,l}\ c_1^m\ \overline{c}_1^{\,n}, \qquad j = 0, 1,$$

where $b^j_{klmn}(\Omega)$ are real valued when Ω is real valued. In particular, if $c_0,\ c_1$, and Ω are real valued, then $f_j(c_0, c_1, \Omega)$ is real valued and, in polar coordinates, for $c_0, c_1 \neq 0$, we have

$$f_j(|c_0|, |c_1|, \Delta\theta, \Omega) = \sum_{k+m\geq 2,\ p\in\mathbb{Z}} b^j_{kmp}(\Omega) e^{ip2\Delta\theta} |c_0|^{2k} |c_1|^{2m}, \qquad j = 0, 1, \tag{4.35}$$

where $\Delta\theta$ is the phase difference between $c_1 \in \mathbb{C}$ and $c_0 \in \mathbb{C}$.

Proof of Proposition 4.3. We start with (4.25) which clearly implies (4.27)-(4.28). We fix Ω and suppress dependence on it in subsequent notation. From (4.19) we have

$$\begin{aligned}
&\eta(e^{i\theta}c_0, e^{i\theta}c_1)\\
&\quad = -(H-\Omega)^{-1}\tilde{P}\\
&\qquad N(e^{i\theta}c_0\psi_0 + e^{i\theta}c_1\psi_1 + \eta, e^{i\theta}c_0\psi_0 + e^{i\theta}c_1\psi_1 + \eta, e^{i\theta}c_0\psi_0 + e^{i\theta}c_1\psi_1 + \eta)\\
&\quad = -(H-\Omega)^{-1}\tilde{P}\\
&\qquad e^{i\theta}N(c_0\psi_0 + c_1\psi_1 + e^{-i\theta}\eta, c_0\psi_0 + c_1\psi_1 + e^{-i\theta}\eta, c_0\psi_0 + c_1\psi_1 + e^{-i\theta}\eta),
\end{aligned}$$

where we used

$$N(a\phi_1, b\phi_2, c\phi_3) = a\overline{b}cN(\phi_1, \phi_2, \phi_3). \tag{4.36}$$

Consequently,

$$\begin{aligned}
e^{-i\theta}\eta(e^{i\theta}c_0, e^{i\theta}c_1) = -(H-\Omega)^{-1}\tilde{P}\\
N[c_0\psi_0 + c_1\psi_1 + e^{-i\theta}\eta, c_0\psi_0 + c_1\psi_1 + e^{-i\theta}\eta, c_0\psi_0 + c_1\psi_1 + e^{-i\theta}\eta]
\end{aligned}$$

which shows that both $e^{-i\theta}\eta(e^{i\theta}c_0, e^{i\theta}c_1)$ and $\eta(c_0, c_1)$ satisfy the same equation (4.19). From the uniqueness of the solution proved in Proposition 4.1 we have the relation (4.25).

A similar argument (and use of the complex conjugate) leads to (4.26) and to the parities of $\eta(c_0, 0)$ and $\eta(0, c_1)$.

To prove (4.29) and (4.30), recall that

$$\begin{aligned}
\mathcal{R}\left(c_0, c_1, \eta(c_0, c_1, \Omega)\right) &= N(c_0\psi_0 + c_1\psi_1 + \eta, c_0\psi_0 + c_1\psi_1 + \eta, c_0\psi_0 + c_1\psi_1 + \eta)\\
&\quad - N(c_0\psi_0 + c_1\psi_1, c_0\psi_0 + c_1\psi_1, c_0\psi_0 + c_1\psi_1).
\end{aligned} \tag{4.37}$$

Consider first the case $c_1 = \rho_1 \in \mathbb{R}$. Note that

$$\langle \psi_1 g, \mathcal{R}(c_0, \rho_1 = 0, \eta(c_0, 0))\rangle = 0.$$

Indeed, for $\rho_1 = 0$, all the functions in the arguments of $\mathcal{R}$ are even functions (in x_1) making $\mathcal{R}$ an even function. Since ψ_1 is odd we get that the above is the integral over the entire space of an odd function, and therefore equal to zero. Since

$\langle \psi_1, \mathcal{R}(c_0, \rho_1, \eta(c_0, \rho_1))\rangle$ is analytic in $\rho_1 \in \mathbb{R}$ by the composition rule and its Taylor series starts with zero, we get (4.30) for real $c_1 = \rho_1$. To extend the result for complex values c_1 we use the rotational symmetry of $\mathcal{R}$, namely from (4.25), (4.36), and (4.37) we have

$$\mathcal{R}\left(e^{i\theta}c_0, e^{i\theta}c_1, \eta(e^{i\theta}c_0, e^{i\theta}c_1, \Omega)\right) = e^{i\theta}\mathcal{R}\left(c_0, c_1, \eta(c_0, c_1, \Omega)\right), \qquad 0 \le \theta < 2\pi,$$

hence (4.30) holds for $c_1 = |c_1|e^{-i\theta}$ by extending f_1 via the equality (4.31).

A similar argument holds for (4.29). Identity (4.33) follows from the definition of $\mathcal{R}$ and (4.17) while identity (4.32) follows from (4.26).

We now turn to a proof of the expansions for f_j: (4.34) and (4.35). Note first that $\mathcal{R}$ is real analytic because in (4.37) N is real linear in each variable and η is real analytic by Proposition 4.1. Hence, both f_0 and f_1 given by (4.29)-(4.30) are real analytic in $c_0,\ c_1$ and can be written in power series of the type (4.34). Estimate (4.33) implies that $k + l + m + n \ge 4$, while the rotational invariance (4.31) implies $k-l+m-n = 0$. The following parity argument shows why $m+n$ hence $m-n = l-k$ and $k + l$ are all even. Assume $m + n$ is odd. Note that because of (4.29), b^0_{klmn} is the scalar product between an even function (in x_1) ψ_0 and the term in the power series of $\mathcal{R}$ in which ψ_1 is repeated $m+n$ times. The latter is an odd function (in x_1) because ψ_1 is an odd function and it is repeated an odd number of times. The scalar product and hence b^0_{klmn} for $m + n$ odd will be zero. A similar argument holds for $b^1_{klmn},\ m + n$ odd. Finally $b^j_{klmn}(\Omega)$ are real-valued when Ω is real because they are scalar products of real-valued functions.

The form (4.35) of the power series follows directly from (4.34) by expressing c_0 and c_1 in their polar forms: $c_0 = |c_0|e^{i\theta_0}$ and $c_1 = |c_1|e^{i\theta_1},\ \Delta\theta = \theta_1 - \theta_0$, and using that $m + n,\ k + l$, and $m - n = -(k - l)$ are all even. The proof of Proposition 4.3 is now complete. ∎

4.1. Ground state and excited state branches, prebifurcation. In this section we prove part (i) of Theorem 4.1 as well as a corresponding statement about the excited state. In particular, we show that for sufficiently small amplitude, the only nonlinear bound state families are those arising via bifurcation from the zero state at the eigenvalues Ω_0 and Ω_1. This is true for general potentials with two bound states. Here, however, we can determine threshold amplitude, $\mathcal{N}_{cr}$, above which the solution set changes.

A closed system of equations for c_0, c_1, and Ω, parametrized by $\mathcal{N}$, is obtained upon substitution of $\eta[c_0, c_1, \Omega]$ (Proposition 4.1) into (4.9)–(4.12). Furthermore, using the structural properties (4.29)-(4.30) of Proposition 4.3, we obtain

(4.38)
$$(\Omega_0 - \Omega)\, c_0 + a_{0000}|c_0|^2 c_0 + (a_{0110} + a_{0011})\,|c_1|^2 c_0 + a_{0011}c_1^2\bar{c}_0 + c_0 f_0(c_0, c_1, \Omega) = 0,$$

(4.39)
$$(\Omega_1 - \Omega)\, c_1 + a_{1111}|c_1|^2 c_1 + (a_{1010} + a_{1001})\,|c_0|^2 c_1 + a_{1010}c_0^2\bar{c}_1 + c_1 f_1(c_0, c_1, \Omega) = 0,$$

(4.40)
$$|c_0|^2 \ + \ |c_1|^2 \ + \mathcal{O}\left(|c_0|^2 + |c_1|^2\right)^3 = \mathcal{N}.$$

This system of equations is valid for $|c_0| + |c_1| < r_*$, independent of L (the distance between wells).

If we choose $c_1 = 0$, then the second equation in the system, (4.39), is satisfied. In this case, a nontrivial solution requires $c_0 \neq 0$. The first equation, (4.38), after

factoring out c_0 becomes

$$\Omega_0 - \Omega + a_{0000}|c_0|^2 + f_0(|c_0|, 0, \Omega) = 0, \tag{4.41}$$

where we used (4.31) to eliminate the phase of the complex quantity c_0. Since Ω is real, (4.41) becomes one equation with two real parameters $\Omega,\ |c_0|$. Since the right-hand side of (4.41) vanishes for $\Omega = \Omega_0$ and $|c_0| = 0$ and since the partial derivative of this function with respect to Ω, evaluated at this solution, is nonzero, we have by the implicit function theorem that there is a unique solution

$$\Omega = \Omega_g(|c_0|) = \Omega_0 + a_{0000}|c_0|^2 + \mathcal{O}(|c_0|^4). \tag{4.42}$$

By (4.40), for small amplitudes, the mapping from $|c_0|^2 + |c_1|^2$ to $\mathcal{N}$ is invertible. The family of solutions

$$|c_0| \ \mapsto\ \left(|c_0|e^{i\theta}, |c_1| = 0, \Omega = \Omega_g(|c_0|)\right), \quad \theta_0 \in [0, 2\pi),$$

defined for $|c_0|$ sufficiently small, corresponds to a family of symmetric nonlinear bound states, $u_{\mathcal{N}}$ with $\|u_{\mathcal{N}}\|_{L^2}^2 = \mathcal{N}$, bifurcating from the zero solution at the linear eigenvalue Ω_0

$$u_{\mathcal{N}} = (|c_0|\psi_0(x) \ +\ \eta[|c_0|, 0, \Omega_g(|c_0|)](x))\ e^{i\theta_0}, \quad \theta_0 \in [0, 2\pi);$$

see, for example, [21, 25, 26]. Since both ψ_0 and $\eta(|c_0|, 0, \Omega_g)$ are even (in x_1) we infer that $u_{\mathcal{N}}$ is symmetric (even).

Remark 4.1. A similar result holds for the case $c_0 = 0$ leading to the antisymmetric excited state branch.

PROPOSITION 4.4. *For $|c_0|+|c_1|$ sufficiently small, these two branches of solutions are the only nontrivial solutions of* (2.7).

Proof. Indeed, suppose the contrary. By local uniqueness of these branches, ensured by the implicit function theorem, a solution not already lying on one of these branches must have both c_0 and c_1 nonzero. Now, divide the first equation by c_0, the second equation by c_1, and subtract the results. Introducing polar coordinates

$$c_0 = \rho_0 e^{i\theta_0},\ c_1 = \rho_1 e^{i\theta_1},\ \Delta\theta = \theta_1 - \theta_0, \tag{4.43}$$

we obtain from (4.38)

$$\begin{aligned} \Omega_1 - \Omega_0 = a_{0000}\rho_0^2 \ +\ \left(a_{0110} + a_{0011} + a_{0011}e^{i2\Delta\theta}\right)\rho_1^2 \ +\ f_0\left(\rho_0, \rho_1, \Delta\theta, \Omega\right) \\ - a_{1111}\rho_1^2 \ -\ \left(a_{1001} + a_{1010} + a_{1010}e^{-i2\Delta\theta}\right)\rho_0^2 \ -\ f_1\left(\rho_0, \rho_1, \Delta\theta, \Omega\right). \end{aligned} \tag{4.44}$$

The left-hand side is nonzero while the right-hand side is continuous uniformly for Ω satisfying (4.15) and zero for $\rho_0 = 0 = \rho_1$. Equation (4.44) cannot hold for $|\rho_0|+|\rho_1| < \varepsilon$ where $\varepsilon > 0$ is independent of Ω. This completes the proof of Proposition 4.4. ∎

Note, however, that nothing can preclude validity of (4.44) for larger ρ_0 and ρ_1, possibly leading to a third branch of solutions of (2.7). In what follows, we show that this is indeed the case and the third branch bifurcates from the ground state one at a critical value of $\rho_0 = \rho_0^*$.

4.2. Symmetry-breaking bifurcation along the ground state/symmetric branch. A consequence of the previous section is that there are no bifurcations from the ground state branch for sufficiently small amplitude. We now seek a bifurcating

branch of solutions to (2.16), (4.40), along which $c_0 \cdot c_1 \neq 0$. As argued just above, along such a new branch one must have

$$\Omega_0 - \Omega + a_{0000}\rho_0^2 + \left(a_{0110} + a_{0011} + a_{0011}e^{i2\Delta\theta}\right)\rho_1^2 + f_0(\rho_0, \rho_1, \Delta\theta, \Omega) = 0, \tag{4.45}$$

$$\Omega_1 - \Omega + a_{1111}\rho_1^2 + \left(a_{1010} + a_{1001} + a_{1010}e^{-i2\Delta\theta}\right)\rho_0^2 + f_1(\rho_0, \rho_1, \Delta\theta, \Omega) = 0. \tag{4.46}$$

We first derive constraints on $\Delta\theta$. Consider the imaginary parts of the two equations and use the expansions (4.35) and the fact that Ω is real:

$$\begin{aligned} &a_{0011}\sin(2\Delta\theta)\rho_1^2 + \sum_{k,m\geq 1,\ p\in\mathbb{Z}} b^0_{kmp}(\Omega)\sin(p2\Delta\theta)\rho_0^{2k}\rho_1^{2m} \\ &\quad = \sin(2\Delta\theta)\rho_1^2(a_{0011} + \mathcal{O}(\rho_0^2 + \rho_1^2)) = 0, \\ &-a_{1010}\sin(2\Delta\theta)\rho_0^2 + \sum_{k,m\geq 1,\ p\in\mathbb{Z}} b^1_{kmp}(\Omega)\sin(p2\Delta\theta)\rho_0^{2k}\rho_1^{2m} \\ &\quad = \sin(2\Delta\theta)\rho_0^2(-a_{1010} + \mathcal{O}(\rho_0^2 + \rho_1^2)) = 0. \end{aligned}$$

Due to the nondegeneracy assumption (4.3) and $a_{0011} = a_{1010}$, see (2.19), both equations hold if and only if $\sin(2\Delta\theta) = 0$ or, equivalently,

$$\Delta\theta \in \left\{0, \frac{\pi}{2}, \pi, \frac{3\pi}{2}\right\}. \tag{4.47}$$

Case 1. $\Delta\theta \in \{0, \pi\}$: Here, the system (4.45)-(4.46) is equivalent to the same system of two real equations with three real parameters $\rho_0 \geq 0$, $\rho_1 \geq 0$, and Ω:

$$F_0(\rho_0, \rho_1, \Omega) \stackrel{def}{=} \Omega_0 - \Omega + a_{0000}\rho_0^2 + (a_{0110} + 2a_{0011})\rho_1^2 + f_0(\rho_0, \rho_1, \Omega) = 0, \tag{4.48}$$

$$F_1(\rho_0, \rho_1, \Omega) \stackrel{def}{=} \Omega_1 - \Omega + a_{1111}\rho_1^2 + (2a_{1010} + a_{1001})\rho_0^2 + f_1(\rho_0, \rho_1, \Omega) = 0. \tag{4.49}$$

We begin by seeking the point along the ground state branch $(\rho_0^*, 0, \Omega_g(\rho_0^*))$ from which a new family of solutions of (4.48)-(4.49), parametrized by $\rho_1 \geq 0$, bifurcates; see (4.42).

Recall first that for *any* $\rho_0 \geq 0$ sufficiently small, $F_0(\rho_0, 0, \Omega_g(\rho_0)) = 0$. A candidate for a bifurcation point is $\rho_0^* > 0$ for which, in addition,

$$F_1(\rho_0^*, 0, \Omega_g(\rho_0^*)) = 0. \tag{4.50}$$

Using (4.33) one can check that

$$F_1(\rho_0, 0, \Omega_g(\rho_0)) = \Omega_1 - \Omega_0 + \left(a_{1001} + 2a_{1010} - a_{0000} + \mathcal{O}(\rho_0^2)\right)\rho_0^2 = 0 \tag{4.51}$$

has a solution:

$$\rho_0^* = \sqrt{\frac{\Omega_1 - \Omega_0}{|a_{1001} + 2a_{1010} - a_{0000}|}}\ \left[1 + \mathcal{O}\left(\ \frac{\Omega_1 - \Omega_0}{|a_{1001} + 2a_{1010} - a_{0000}|^2}\ \right)\right]. \tag{4.52}$$

We now show that a new family of solutions bifurcates from the symmetric state at $(\rho_0^*, 0, \Omega_g(\rho_0^*))$. This is realized as a unique, one-parameter family of solutions

$$\rho_1 \mapsto (\rho_0(\rho_1), \rho_1, \Omega_{asym}(\rho_1)) \tag{4.53}$$

of the equations

$$F_0(\rho_0, \rho_1, \Omega) = 0, \quad F_1(\rho_0, \rho_1, \Omega) = 0. \tag{4.54}$$

To see this, note that by the preceding discussion we have $F_j(\rho_0^*, 0, \Omega_g(\rho_0^*)) = 0, j = 1, 2$. Moreover, the Jacobian

$$\left| \frac{\partial(F_0, F_1)}{\partial(\rho_0, \Omega)}(\rho_0^*, 0, \Omega_g(\rho_0^*)) \right| = 2\rho_0^*(a_{1001} + 2a_{1010} - a_{0000} + \mathcal{O}(\rho_0^{*2}))$$

is nonzero because $\rho_0^* > 0$ and

$$a_{1001} + 2a_{1010} - a_{0000} + \mathcal{O}(\rho_0^{*2}) < 0 \tag{4.55}$$

since ρ_0^* solves (4.51) and $\Omega_1 - \Omega_0 > 0$. Therefore, by the implicit function theorem, for small $\rho_1 > 0$, there is a unique solution of the system (4.48)-(4.49):

$$\rho_0 = \rho_0(\rho_1) = \rho_0^* + \frac{\rho_1^2}{2\rho_0^*}\left(\frac{a_{0110} + 2a_{0011} - a_{1111}}{a_{1001} + 2a_{1010} - a_{0000}} + \mathcal{O}(\rho_0^{*2})\right) + \mathcal{O}(\rho_1^4), \tag{4.56}$$

$$\Omega = \Omega_{asym}(\rho_1) = \Omega_g(\rho_0^*) + \rho_1^2\left(a_{1111} + (2a_{1010} + a_{1001})\frac{a_{0110} + 2a_{0011} - a_{1111}}{a_{1001} + 2a_{1010} - a_{0000}} + \mathcal{O}(\rho_0^{*2})\right) + \mathcal{O}(\rho_1^4). \tag{4.57}$$

Remark 4.2. (1) Due to the equivalence of $\mathcal{N}$ and $\rho_0^2 + \rho_1^2$ as parameters, for small amplitude, we have that symmetry is broken at

$$\mathcal{N}_{cr} \sim \frac{\Omega_1 - \Omega_0}{|a_{0000} - a_{1001} - 2a_{1010}|}. \tag{4.58}$$

(2) Note also that we have the family of solutions

$$e^{i\theta}\left(\rho_0(\rho_1)\psi_0 \pm \rho_1\psi_1 + \eta(\rho_0(\rho_1), \pm\rho_1, \Omega_{asym}(\rho_1))\right), \qquad 0 \le \theta < 2\pi,\ \rho_1 > 0. \tag{4.59}$$

Here the $\pm$ is present because the phase difference $\Delta\theta$ between c_0 and c_1 can be 0 or π; see (4.47) and immediately below it. Because $\rho_0 \neq 0 \neq \rho_1$ this branch is neither symmetric nor antisymmetric. Thus, symmetry breaking has taken place. In the case of the double well, the $\pm$ sign in (4.59) shows that the bound states on this asymmetric branch tend to localize in one of the two wells but not symmetrically in both; see also [3], [23], [14].

Case 2. $\Delta\theta \in \left\{\frac{\pi}{2}, \frac{3\pi}{2}\right\}$: In both cases the system (4.45)-(4.46) is equivalent to the system of two real equations, depending on three real parameters $\rho_0 \ge 0$, $\rho_1 \ge 0$, and Ω:

$$F_0(\rho_0, \rho_1, \Omega) \stackrel{def}{=} \Omega_0 - \Omega + a_{0000}\rho_0^2 + a_{0110}\rho_1^2 + f_0(\rho_0, \rho_1, \Omega) = 0, \tag{4.60}$$

$$F_1(\rho_0, \rho_1, \Omega) \stackrel{def}{=} \Omega_1 - \Omega + a_{1111}\rho_1^2 + a_{1001}\rho_0^2 + f_1(\rho_0, \rho_1, \Omega) = 0. \tag{4.61}$$

As before, in order to have a second bifurcation of the symmetric branch it is necessary to find a point, $(\rho_0^{**}, 0, \Omega_g(\rho_0^{**}))$, for which

$$F_1(\rho_0^{**}, 0, \Omega_g(\rho_0^{**}) = \Omega_1 - \Omega_0 + (a_{1001} - a_{0000})\,\rho_0^{**2} + \mathcal{O}(\rho_0^{**4}) = 0. \tag{4.62}$$

To preclude the existence of this bifurcation, one must have that there are no real solutions for ρ_0^{**} small. This is ensured by inequality (3.6): $a_{1001} - a_{0000} > 0$.

In fact (3.6) can be *deduced* from the following general argument and thus we need not hypothesize it. Let L_- and L_+ denote the second-order, self-adjoint Schrödinger operators, defined in section 5, and related to the real and imaginary parts of the linearized NLS-GP equation about a real-valued nonlinear bound state. Consider the full *complex* linearization of the nonlinear bound state equation for NLS-GP. A nontrivial solution of the type in question would correspond to a second element of the null space of L_-. Since zero is the lowest eigenvalue of L_- and the lowest eigenvalue of an elliptic second-order operator is nondegenerate, we have a contradiction. It follows that there is no bifurcation for small amplitude and therefore (3.6) holds.

Remark 4.3. A similar argument holds along the antisymmetric branch. We now denote $L_\pm$ as linearized operators associated with the *antisymmetric* (odd parity with respect to x_1) branch. A bifurcation would occur along it if and only if $\dim\ker L_- \geq 2$ (the antisymmetric nonlinear bound state is always in $\ker L_-$ along this branch) or $\dim\ker L_+ \geq 1$. In the regime in which the first two eigenvalues are still separated from the rest of the spectrum, the former means that the lowest eigenvalue of L_-, i.e., the one bifurcating from $\Omega_0 - \Omega_1$, crosses zero and becomes double. This contradicts the nondegeneracy of the ground state of the second-order elliptic operator L_-. Now, $\dim\ker L_+ \geq 1$ is also impossible. This follows from the fact that the nonlinearity is attractive, see (H3), which easily implies that, for the nonlinear antisymmetric bound state Ψ_Ω, we have $(\Psi_\Omega, L_+\Psi_\Omega) < 0$. Since L_+ is self-adjoint and its lowest eigenvalue has a symmetric eigenvector orthogonal on Ψ_Ω, we get that the first two eigenvalues must be strictly negative and none can become zero. A consequence of a lack of bifurcation along the antisymmetric branch are inequalities (3.7), (3.8).

In summary, there are no other bifurcations than those stated in Theorem 4.1 for NLS-GP, where our Lyapunov–Schmidt-type reduction applies, i.e., in the regime covered by Proposition 4.1.

5. Exchange of stability at the bifurcation point. In this section we consider the dynamic stability of the symmetric and asymmetric waves, associated with the branch bifurcating from the zero state at the *ground state frequency*, Ω_0, of the linear Schrödinger operator $-\Delta + V(x)$; see Figure 1.

The notion of stability with which we work is H^1-orbital Lyapunov stability.

DEFINITION 5.1. *The family of nonlinear bound states* $\{\Psi_\Omega\ e^{-i\Omega t} : \theta \in [0, 2\pi)\}$ *is* H^1*-orbitally Lyapunov stable if for every* $\varepsilon > 0$ *there is a* $\delta(\varepsilon) > 0$ *such that if the initial data* u_0 *satisfies*

$$\inf_{\theta\in[0,2\pi)} \|u_0(\cdot)\ -\ \Psi_\Omega(\cdot)e^{i\theta}\|_{H^1}\ <\ \delta,$$

then for all $t \neq 0$*, the solution* $u(x,t)$ *satisfies*

$$\inf_{\theta\in[0,2\pi)} \|u(\cdot,t)\ -\ \Psi_\Omega(\cdot)e^{i\theta}\|_{H^1}\ <\ \varepsilon.$$

In this section we prove the following theorem.

THEOREM 5.1. *Consider the bifurcations elucidated in Theorem* 4.1. *The symmetric branch is* H^1*-orbitally Lyapunov stable for* $0 \leq \rho_0 < \rho_0^*$ *or, equivalently,* $0 < \mathcal{N} < \mathcal{N}_{cr}$*. At the bifurcation point* $\rho_0 = \rho_0^*$ $(\mathcal{N} = \mathcal{N}_{cr})$*, there is an exchange of stability from the symmetric branch to the asymmetric branch. In particular, for* $\mathcal{N} > \mathcal{N}_{cr}$ *the asymmetric state is stable and the symmetric state is unstable.*

We summarize basic results on stability and instability. Introduce L_+ and L_-, real and imaginary parts, respectively, of the linearized operators about a real-valued state Ψ_Ω:

$$\begin{aligned} L_+ = L_+[\Psi_\Omega]\cdot &= (H-\Omega)\cdot\ + \partial_u N(u,u,u)\mid_{\Psi_\Omega} \\ &\equiv (H-\Omega)\cdot + D_u N[\Psi_\Omega](\cdot), \\ L_- = L_-[\Psi_\Omega]\cdot &= (H-\Omega)\cdot + N(\Psi_\Omega,\Psi_\Omega,\cdot). \end{aligned} \tag{5.1}$$

By (2.7) and (2.4), $L_-\Psi_\Omega = 0$.

We state a special case of known results on stability and instability, directly applicable to the symmetric branch which bifurcates from the zero state at the ground state frequency of $-\Delta + V$.

THEOREM 5.2 (see [32, 33, 10, 9, 15]).

(1) Stability: *Suppose L_+ has exactly one negative eigenvalue and L_- is nonnegative. Assume that*

$$\frac{d}{d\Omega}\int |\Psi_\Omega(x)|^2 dx < 0. \tag{5.2}$$

Then, Ψ_Ω is H^1-orbitally stable.

(2) Instability: *Suppose L_- is nonnegative. If $n_-(L_+) \geq 2$, then the linearized dynamics about Ψ_Ω has spatially localized solution which is exponentially growing in time. Moreover, Ψ_Ω is not H^1-orbitally stable.*

First we claim that along the branch of symmetric solutions bifurcating from the zero solution at frequency Ω_0, the hypothesis on L_- holds. To see that the operator $L_-[\Psi_\Omega]$ is always nonnegative, consider $L_-[\Psi_{\Omega_0}] = L_-[0] = -\Delta + V - \Omega_0$. Clearly, $L_-[0]$ is a nonnegative operator because Ω_0 is the lowest eigenvalue of $-\Delta + V$. Since clearly we have $L_-\Psi_\Omega = 0$, $0 \in spec(L_-[\Psi_\Omega])$. Since the lowest eigenvalue is necessarily simple, by continuity there cannot be any negative eigenvalues for Ω sufficiently close to Ω_0. Finally, if for some Ω, L_- has a negative eigenvalue, then by continuity there would be an Ω_* for which $L_-[\Psi_{\Omega_*}]$ would have a double eigenvalue at zero and no negative spectrum. But this contradicts that the ground state is simple. Therefore, it is the quantity $n_-(L_+)$ which controls whether or not Ψ_Ω is stable.

Next we discuss the slope condition (5.2). It is clear from the construction of the branch $\Omega \mapsto \Psi_\Omega$ that (5.2) holds for Ω near Ω_0. Suppose now that $\partial_\Omega \int |\Psi_\Omega|^2 = 0$. Then, $\langle \Psi_\Omega, \partial_\Omega \Psi_\Omega\rangle = 0$. As shown below, L_+ has exactly one negative eigenvalue for Ω sufficiently near Ω_0. It follows that $L_+ \geq 0$ on $\{\Psi_\Omega\}^\perp$ (see [32, 33]). Therefore, we have $(L_+^{\frac{1}{2}}\partial_\Omega\Psi_\Omega, L_+^{\frac{1}{2}}\partial_\Omega\Psi_\Omega) = (L_+\partial_\Omega\Psi_\Omega, \partial_\Omega\Psi_\Omega) = (\Psi_\Omega, \partial_\Omega\Psi_\Omega) = 0$. Therefore, $L_+^{\frac{1}{2}}\partial_\Omega\Psi_\Omega = 0$, implying $\Psi_\Omega = L_+\partial_\Omega\Psi_\Omega = 0$, which is a contradiction. It follows that (5.2) holds so long as $L_+ > 0$ on $\{\Psi_\Omega\}^\perp$ and when (5.2) first fails, it does so due to a nontrivial element of the nullspace of L_+.

Therefore, Ψ_Ω is stable so long as $n_-(L_+)$ does not increase. We shall now show that for $\mathcal{N} < \mathcal{N}_{cr}$, $n_-(L_+[\Psi_\Omega]) = 1$ but that along the symmetric branch for $\mathcal{N} > \mathcal{N}_{cr}$, $n_-(L_+[\Psi_\Omega]) = 2$. Furthermore, we show that along the bifurcating asymmetric branch, the hypotheses of Theorem 5.2 ensuring stability hold.

Remark 5.1. For simplicity we have considered the most important case where there is a transition from dynamical stability to dynamical instability along the symmetric branch, bifurcating from the ground state of H. However, our analysis which actually shows that along any symmetric branch, associated with any of the eigenvalues $\Omega_{2j}, j \geq 0$, of H, there is a critical $\mathcal{N} = \mathcal{N}_{cr}(j)$ such that as $\mathcal{N}$ is increased

through $\mathcal{N}_{cr}(j)$, the number of negative eigenvalues of the linearization about the symmetric state along the jth symmetric branch, $n_-(L_+^{(j)})$, increases by one. By the results in [15, 9, 19], this has implications for the number of unstable modes of higher order ($j \geq 1$) symmetric states.

Consider the spectral problem for $L_+ = L_+[\Psi_\Omega]$:

$$L_+[\Psi_\Omega]\phi = \mu\phi. \tag{5.3}$$

We now formulate a Lyapunov–Schmidt reduction of (5.3) and then relate it to our formulation for nonlinear bound states. We first decompose ϕ relative to the states $\psi_0,\ \psi_1$ and their orthogonal complement:

$$\phi = \alpha_0\psi_0 \ + \ \alpha_1\psi_1 \ + \ \xi, \quad (\psi_j, \xi) = 0,\ j = 0, 1.$$

Projecting (5.3) onto $\psi_0,\ \psi_1$ and onto the range of $\tilde{P}$ we obtain the system

$$\langle \psi_0, L_+[\Psi_\Omega](\alpha_0\psi_0 \ + \ \alpha_1\psi_1 \ + \ \xi)\rangle = \mu\alpha_0, \tag{5.4}$$

$$\langle \psi_1, L_+[\Psi_\Omega](\alpha_0\psi_0 \ + \ \alpha_1\psi_1 \ + \ \xi)\rangle = \mu\alpha_1, \tag{5.5}$$

$$(H - \Omega)\xi + D_u N[\Psi_\Omega](\alpha_0\psi_0 + \alpha_1\psi_1 + \xi) = \mu\xi. \tag{5.6}$$

The last equation can be rewritten in the form

$$\Big[I \ + \ (H - \Omega - \mu)^{-1}\tilde{P}D_u N[\Psi_\Omega]\Big]\,\xi = -(H - \Omega - \mu)^{-1}\tilde{P}D_u N[\Psi_\Omega](\alpha_0\psi_0 + \alpha_1\psi_1). \tag{5.7}$$

The operator on the right-hand side of (5.7) is essentially the Jacobian studied in the proof of Proposition 4.1, evaluated at $\Omega+\mu$. Hence, by the proof of Proposition 4.1, if $\Omega+\mu$ satisfies (4.15) and $\|\Psi_\Omega\|_{H^2} \leq \mathcal{N}_*$, then the operator $I+(H-\Omega-\mu)^{-1}\tilde{P}D_u N[\Psi_\Omega]$ is invertible on H^2 and (5.7) has a unique solution

$$\begin{aligned}
\xi \ &\stackrel{def}{=} \ \xi[\mu, \alpha_0, \alpha_1, \Omega] \\
&\equiv \ Q[\mu, \Psi_\Omega](\alpha_0\psi_0 + \alpha_1\psi_1) \\
&= \ -(I + (H - \Omega - \mu)^{-1}\tilde{P}D_u N[\Psi_\Omega])^{-1}(H - \Omega - \mu)^{-1}\tilde{P}D_u N[\Psi_\Omega](\alpha_0\psi_0 + \alpha_1\psi_1) \\
&= \ \mathcal{O}\left[(|\rho_0| + |\rho_1|)^2\right] \ [\alpha_0\psi_0 + \alpha_1\psi_1]\,.
\end{aligned} \tag{5.8}$$

The last relation follows from $D_u N[\psi]$ being a quadratic form in $\Psi_\Omega = \rho_0\psi_0 + \rho_1\psi_1 + \mathcal{O}((|\rho_0| + |\rho_1|)^3)$.

Substitution of the expression for ξ as a functional of α_j into (5.4) and (5.5) we get a closed system of two real equations:

$$\begin{aligned}
&(\Omega_0 - \Omega)\alpha_0 \ + \ \langle \psi_0, D_u N[\Psi_\Omega]\ (I + Q[\mu, \Psi_\Omega])\ (\alpha_0\psi_0 + \alpha_1\psi_1)\rangle = \mu\ \alpha_0, \\
&(\Omega_1 - \Omega)\alpha_1 \ + \ \langle \psi_1, D_u N[\Psi_\Omega]\ (I + Q[\mu, \Psi_\Omega])\ (\alpha_0\psi_0 + \alpha_1\psi_1)\rangle = \mu\ \alpha_1.
\end{aligned} \tag{5.9}$$

The system (5.9) is the Lyapunov–Schmidt reduction of the linear eigenvalue problem for L_+ with eigenvalue parameter μ. *Our next step will be to write it in a form relating it to the linearization of the Lyapunov–Schmidt reduction of the nonlinear problem.*

Remark 5.2. For $\|\Psi_\Omega\|_{H^2} \leq n_*$, the above system is equivalent to the eigenvalue problem for the operator $L_+[\Psi_\Omega]$ with eigenvalue parameter μ as long as (4.15) holds

with Ω replaced by $\Omega+\mu$. This restriction on the spectral parameter, μ, is in fact very mild and has no impact on the analysis. This is because we are primarily interested in μ near zero as we are interested in detecting the crossing of an eigenvalue of L_+ from positive to negative reals as $\mathcal{N}$ is increased beyond some $\mathcal{N}_{cr}$. The values of μ for which (4.15) does not hold do not play a role in any change of index, $n_-(L_+)$.

First rewrite (5.9) as

$$\begin{aligned}(\Omega_0-\Omega-\mu)\alpha_0 \;+\; &\langle\psi_0, D_uN[\Psi_\Omega]\;(I+Q[0,\Psi_\Omega])\;(\alpha_0\psi_0+\alpha_1\psi_1)\rangle\\ &+\;\langle\psi_0, D_uN[\Psi_\Omega]\;\Delta Q[\mu,\Psi_\Omega]\;(\alpha_0\psi_0+\alpha_1\psi_1)\rangle=0,\end{aligned}\tag{5.10}$$

$$\begin{aligned}(\Omega_1-\Omega-\mu)\alpha_1 \;+\; &\langle\psi_1, D_uN[\Psi_\Omega]\;(I+Q[0,\Psi_\Omega])\;(\alpha_0\psi_0+\alpha_1\psi_1)\rangle\\ &+\;\langle\psi_1, D_uN[\Psi_\Omega]\;\Delta Q[\mu,\Psi_\Omega]\;(\alpha_0\psi_0+\alpha_1\psi_1)\rangle=0.\end{aligned}\tag{5.11}$$

Here,

$$\Delta Q\left[\mu,\Psi_\Omega\right]=Q\left[\mu,\Psi_\Omega\right]\;-\;Q\left[0,\Psi_\Omega\right].\tag{5.12}$$

Note that terms involving ΔQ in (5.10), (5.11) are of size $\mathcal{O}[(\rho_0^2+\rho_1^2)\mu\alpha_j]$.

Proposition 5.1.

$$Q[0,\Psi_\Omega](\alpha_0\psi_0+\alpha_1\psi_1)=\partial_{\rho_0}\eta[\rho_0,\rho_1,\Omega]\;\alpha_0\;+\;\partial_{\rho_1}\eta[\rho_0,\rho_1,\Omega]\;\alpha_1.\tag{5.13}$$

Proof. Recall that η satisfies

$$F(\rho_0,\rho_1,\Omega,\eta)\;\equiv\;\eta+(H-\Omega)^{-1}\tilde{P}N[\rho_0\psi_0+\rho_1\psi_1+\eta]=0.\tag{5.14}$$

Differentiation with respect to $\rho_j,\;j=0,1$, yields

$$\Big(I\;+\;(H-\Omega)^{-1}\tilde{P}D_uN[\Psi_\Omega]\Big)\;\partial_{\rho_j}\eta=-\,(H-\Omega)^{-1}\,\tilde{P}D_uN[\Psi_\Omega]\psi_j,\tag{5.15}$$

where

$$\Psi_\Omega=\rho_0\psi_0+\rho_1\psi_1+\eta[\rho_0,\rho_1,\Omega].$$

Thus,

$$\partial_{\rho_j}\;\eta=Q[0,\Psi_\Omega]\;\psi_j,\tag{5.16}$$

from which Proposition 5.1 follows. ∎

We now use Proposition 5.1 to rewrite the first inner products in (5.10), (5.11). For $k=0,1$,

$$\begin{aligned}&\langle\psi_k, D_uN[\Psi_\Omega]\;(I+Q[0,\Psi_\Omega])\;(\alpha_0\psi_0+\alpha_1\psi_1)\rangle\\ &=\sum_{j=0}^{1}\langle\psi_k, D_uN[\rho_0\psi_0+\rho_1\psi_1+\eta](\psi_j+\partial_{\rho_j}\eta)\rangle\alpha_j\\ &=\;\sum_{j=0}^{1}\;\frac{\partial}{\partial\rho_j}\langle\psi_k, N[\Psi_\Omega]\rangle\;\alpha_j\\ &=\;\sum_{j=0}^{1}\;\partial_{\rho_j}\;\langle\psi_k, N[\rho_0\psi_0+\rho_1\psi_1]\rangle\;\alpha_j\;+\;\partial_{\rho_j}\;\left[\rho_k f_k(\rho_0,\rho_1,\Omega)\right],\end{aligned}\tag{5.17}$$

where $N[\psi_\Omega] = N[\rho_0\psi_0 + \rho_1\psi_1] + \mathcal{R}$; see (2.16)–(2.18) and (4.29), (4.30). Therefore, the Lyapunov–Schmidt reduction of the eigenvalue problem for L_+ becomes

$$(5.18)\quad (\Omega_0 - \Omega - \mu)\alpha_0 \;+\; \sum_{j=0}^{1} \partial_{\rho_j}\, \langle \psi_0, N[\rho_0\psi_0 + \rho_1\psi_1]\rangle\, \alpha_j \;+\; \partial_{\rho_j}\, [\rho_0 f_0(\rho_0, \rho_1, \Omega)] + \langle \psi_0, D_u N[\Psi_\Omega]\, \Delta Q[\mu, \Psi_\Omega]\, (\alpha_0\psi_0 + \alpha_1\psi_1)\rangle = 0,$$

$$(5.19)\quad (\Omega_1 - \Omega - \mu)\alpha_1 \;+\; \sum_{j=0}^{1} \partial_{\rho_j}\, \langle \psi_1, N[\rho_0\psi_0 + \rho_1\psi_1]\rangle\, \alpha_j \;+\; \partial_{\rho_j}\, [\rho_1 f_1(\rho_0, \rho_1, \Omega)] + \langle \psi_1, D_u N[\Psi_\Omega]\, \Delta Q[\mu, \Psi_\Omega]\, (\alpha_0\psi_0 + \alpha_1\psi_1)\rangle = 0.$$

This can be written succinctly in a matrix form as

$$(5.20)\qquad [M \;-\mu\; +\; \mathcal{C}(\mu)] \begin{pmatrix} \alpha_0 \\ \alpha_1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix},$$

where

(5.21)

$$M = M[\Omega, \rho_0, \rho_1] = \begin{pmatrix} \Omega_0 - \Omega + 3a_{0000}\rho_0^2 + (a_{0110} + 2a_{0011})\rho_1^2 + \partial_{\rho_0}(\rho_0 f_0) & 2(a_{0110} + 2a_{0011})\rho_0\rho_1 + \partial_{\rho_1}(\rho_0 f_0) \\ 2(2a_{1010} + a_{1001})\rho_0\rho_1 + \partial_{\rho_0}(\rho_1 f_1) & (\Omega_1 - \Omega) + 3a_{1111}\rho_1^2 + (2a_{1010} + a_{1001})\rho_0^2 + \partial_{\rho_1}(\rho_1 f_1) \end{pmatrix}$$

and

$$(5.22)\qquad \mathcal{C}(\mu)_{lm} = \langle \psi_l, D_u N[\Psi_\Omega]\Delta Q[\mu, \Psi_\Omega]\psi_m\rangle, \quad l, m = 0, 1.$$

Note that

$$(5.23)\qquad \mathcal{C}(\mu = 0) = 0.$$

Recall that μ is the spectral parameter for the eigenvalue problem L_+, (5.3), and we are interested in $n_-(L_+[\Psi_\Omega])$, the number of negative eigenvalues along a family of nonlinear bound states $\Omega \mapsto \Psi_\Omega$. By Theorem 5.2, $n_-(L_+)$ determines the stability or instability of a particular state. This question has now been mapped to the problem of following the roots of

$$(5.24)\qquad D(\mu, \rho_0, \rho_1) = \det(\mu I - M - \mathcal{C}(\mu)) = 0,$$

where ρ_0 and ρ_1 are parameters along the different branches of nonlinear bounds states. Since $\mathcal{C}(\mu)$, defined in (5.22), is small for small amplitude nonlinear bound states, we expect the roots, μ, to be small perturbations of the eigenvalues of the matrix M. We study these roots along the symmetric ($M = M(\Omega_g(\rho_0), \rho_0, 0)$) and asymmetric branch ($M = M(\Omega_{asym}(\rho_1), \rho_0(\rho_1), \rho_1)$) using the implicit function theorem.

Symmetric branch. Along the symmetric branch:

$$\rho_1 = 0, \quad \rho_0 \geq 0, \quad \Omega = \Omega_g = \Omega_0 + a_{0000}\rho_0^2 + \mathcal{O}(\rho_0^4),$$
$$\Psi_\Omega = \rho_0\psi_0 + \eta(\rho_0, 0, \Omega) = \text{symmetric}.$$

Thus, $D = D(\mu, \rho_0)$. Moreover, the system (5.20) is diagonal. This is because Q and hence ΔQ preserve parity at a symmetric Ψ_Ω; see their definitions (5.8) and (5.12). Therefore $\mathcal{C}_{01} = 0 = \mathcal{C}_{10}$, since each is the scalar product of an even and an odd function. Moreover, from (4.35) we get $\frac{\partial f_j}{\partial \rho_1}(\rho_0, 0, \Omega) = 0,\ j = 0, 1.$

Therefore, the matrix $\mu I - M - \mathcal{C}(\mu)$ is diagonal and μ is an eigenvalue of $L_+[\psi_{\Omega_g(\rho_0)}]$ if and only if μ is a root of either

$$P_0(\mu, \rho_0) \ \equiv \ \mu - M_{00}(\rho_0) - \mathcal{C}_{00}(\mu, \rho_0) = 0 \tag{5.25}$$

or

$$P_1(\mu, \rho_0) \ \equiv \ \mu - M_{11}(\rho_0) - \mathcal{C}_{11}(\mu, \rho_0) = 0. \tag{5.26}$$

Both P_0 and P_1 are analytic in μ and ρ_0 and it is easy to check that

$$P_0(0, 0) = 0, \qquad \partial_\mu P_0(0, 0) = 1$$

and

$$P_1(\Omega_1 - \Omega_0, 0) = 0, \qquad \partial_\mu P_1(\Omega_1 - \Omega_0, 0) = 1.$$

Formally differentiating (5.25) or (5.26) with respect to ρ_0 gives

$$\partial_{\rho_0} \mu_j = \frac{\partial_{\rho_0} M_{jj} + \partial_{\rho_0} C_{jj}}{1 - \partial_\mu C_{jj}}. \tag{5.27}$$

By the implicit function theorem (5.25) and (5.26) define, respectively, μ_0 and μ_1 as smooth functions of ρ provided

$$|\partial_\mu \mathcal{C}_{jj}| < 1, \qquad j = 0, 1. \tag{5.28}$$

A direct calculation using (5.8) and estimates (2.5), (4.20) shows that in the regime of interest: Ω satisfying (4.15), it suffices to have

$$\|\Psi_\Omega\|_{H^2} \leq n_* \left(9 \max(\|\psi_0\|_{H^2}, \|\psi_1\|_{H^2})\right)^{-\frac{1}{4}}, \tag{5.29}$$

where n_* is given by Proposition 4.1. The latter can be reduced to an estimate on ρ_0 via the above definition of Ψ_Ω and (4.24) as in the end of the proof of Proposition 4.1.

Therefore, under conditions (4.15) and (5.29), we have a unique solution μ_0, respectively μ_1, of (5.25), respectively (5.26). Moreover, the two solutions are analytic in ρ_0 and, for small ρ_0, we have the following estimates:

$$\mu_0 = 2a_{0000}\rho_0^2 + \mathcal{O}(\rho_0^4) < 0, \tag{5.30}$$

$$\mu_1 = \Omega_1 - \Omega_0 + \mathcal{O}(\rho_0^2) > 0, \tag{5.31}$$

where we used $a_{0000} \equiv g\langle \psi_0^2, K[\psi_0^2]\rangle < 0$ and $\mu_1(\rho_0 = 0) = \Omega_1 - \Omega_0 > 0$.

We claim that μ_1 changes sign for the first time at $\rho_0 = \rho_0^*$. Indeed, by continuity, the sign can only change when $\mu_1 = 0$, i.e., when (5.26) has a solution of the form $(0, \rho_0)$. Since $\mathcal{C}_{11}(0, \rho_0) = 0$ (see (5.23)) (5.26) becomes

$$0 = M_{11}(\rho_0) = \Omega_1 - \Omega_g(\rho_0) + (2a_{1010} + a_{1001})\rho_0^2 + f_1(\rho_0, 0, \Omega_g) = F_1(\rho_0, 0, \Omega_g(\rho_0));$$

see (5.21) and note that $\rho_1 = 0$. But this equation is the same as (4.50), which determines the bifurcation point ρ_0^*. Thus, as expected, $D(\mu, \rho_0) = 0$ has a root

$\rho_1(\rho_0^*) = 0$ or, equivalently, L_+ has a zero eigenvalue at the bifurcation point. Note that the associated null eigenfunction has odd parity in one space dimension and is, more generally, nonsymmetric and changes sign.

To see that $\mu_1(\rho_0)$ changes sign at $\rho_0 = \rho_0^*$ we differentiate (5.26) with respect to ρ_0 at $\rho_0 = \rho_0^*$ and obtain from (5.27) that

$$\partial_{\rho_0}\mu_1 = \frac{\partial_{\rho_0}M_{11} + \partial_{\rho_0}C_{11}}{1 - \partial_\mu C_{11}} < 0.$$

This follows because the denominator is positive, by (5.28), while direct calculation gives for the numerator

$$\partial_{\rho_0}M_{11}(\rho_0^*) + \partial_{\rho_0}C_{11}(\rho_0^*) = 2\rho_0^*\left(a_{1001} + 2a_{1010} - a_{0000} + \mathcal{O}(\rho_0^{*2})\right) < 0;$$

see (4.55). Therefore μ_1 becomes negative for $\rho_0 > \rho_0^*$ at least when $|\rho_0 - \rho_0^*|$ is small enough.

In conclusion, $L_+[\Omega_g(\rho_0)]$ has exactly one negative eigenvalue for $0 \le \rho_0 < \rho_0^*$ and two negative eigenvalues for $\rho_0 > \rho_0^*$ and $|\rho_0 - \rho_0^*|$ small. Therefore, following the criteria of [32, 33, 10, 15, 9, 16], the symmetric branch is stable for $0 \le \rho_0 < \rho_0^*$ and becomes unstable past the bifurcation point.

Asymmetric branch: Stability for $\mathcal{N} > \mathcal{N}_{cr}$. Finally, we study the behavior of the eigenvalue problem (5.20) on the asymmetric branch:

$$0 \le \rho_1 \ll 1,$$

$$\rho_0 = \rho_0(\rho_1) = \rho_0^* + \frac{\rho_1^2}{2\rho_0^*}\left(\frac{a_{0110} + 2a_{0011} - a_{1111}}{a_{1001} + 2a_{1010} - a_{0000}} + \mathcal{O}(\rho_0^{*2})\right) + \mathcal{O}(\rho_1^4),$$

$$\begin{aligned}\Omega = \Omega_{asym}(\rho_1) = \Omega_g(\rho_0^*) &\\ + \rho_1^2\left(a_{1111} + (2a_{1010} + a_{1001})\frac{a_{0110} + 2a_{0011} - a_{1111}}{a_{1001} + 2a_{1010} - a_{0000}} + \mathcal{O}(\rho_0^{*2})\right)&\\ + \mathcal{O}(\rho_1^4),&\end{aligned} \tag{5.33}$$

$$\Psi_\Omega = \rho_0(\rho_1)\psi_0 + \rho_1\psi_1 + \eta(\rho_0(\rho_1), \rho_1, \Omega_{asym}(\rho_1)).$$

The eigenvalues will be given by the zeros of the real-valued function

$$D(\mu, \rho_1) = \det(\mu I - M(\rho_1) - \mathcal{C}(\mu, \rho_1)), \tag{5.34}$$

which is analytic in μ and ρ_1 for $\Omega + \mu$ satisfying (4.15) and ρ_1 small. Note that at $\rho_1 = 0$ we are still on the symmetric branch at the bifurcation point $\rho_0 = \rho_0^*$. Hence, the matrix is diagonal and

$$D(\mu, 0) = P_0(\mu, \rho_0^*)P_1(\mu, \rho_0^*), \tag{5.35}$$

where $P_j,\ j = 0, 1$, are defined in (5.25)-(5.26). In the previous subsection we showed that each $P_j(\cdot, \rho_0^*)$ has exactly one zero, μ_j, on the interval $-\infty < \mu < d_* - \Omega_g(\rho_0^*) > 0$. The zeros were simple by our implicit function theorem application in which

$$\partial_\mu P_j(\mu_j, \rho_0^*) = 1 - \partial_\mu C_{jj} > 0; \tag{5.36}$$

see (5.28). In addition one can easily deduce that $\lim_{\mu\to-\infty} P_j(\mu, \rho_0^*) = -\infty$ by using the definitions (5.22), (5.12) and the fact that $\|(H - \Omega - \mu)^{-1}\|_{L^2\to H^2} \overset{\mu\to-\infty}{\to} 0$ which implies $\|Q[\mu, \Psi_\Omega]\|_{H^2\to H^2} \overset{\mu\to-\infty}{\to} 0$.

Consequently, $D(\cdot,0)$ has exactly two simple zeros $\mu_0 < 0$ and $\mu_1 = 0$ on the interval $-\infty < \mu \le (-d_* - \Omega_g(\rho_0^*))/2 > 0$, which are both simple and $\lim_{\mu\to-\infty} D(\mu,0) = \infty$. It is well known, and a consequence of continuity arguments and of the implicit function theorem, that the previous statement continues to hold for small perturbations. More precisely, there exists $\varepsilon > 0$ such that whenever $|\rho_1| < \varepsilon$, $D(\cdot,\rho_1)$ has exactly two zeros $\mu_0(\rho_1) < 0$ and $\mu_1(\rho_1)$ on the interval $-\infty < \mu \le (-d_* - \Omega_g(\rho_0^*))/2 > 0$, which are both simple and analytic in ρ_1.

Since we are interested in $n_-(L_+)$, the number of negative eigenvalues of L_+, we still need to determine the sign of $\mu_1(\rho_1)$. In what follows we will show that its derivatives satisfy

$$\partial_{\rho_1}\mu_1(0) = 0, \quad \partial_{\rho_1}^2\mu_1(0) > 0. \tag{5.37}$$

We can then conclude that for $0 < \rho_1 \ll 1$, $\mu_1(\rho_1) > 0$ and L_+ has exactly one (simple) negative eigenvalue, $\mu_0(\rho_1)$. Therefore, the asymmetric branch is stable.

We now prove (5.37). By differentiating

$$D(\mu_1(\rho_1),\rho_1) = 0 \tag{5.38}$$

once with respect to ρ_1 at $\rho_1 = 0$ we get

$$\partial_\mu D(0,0)\partial_{\rho_1}\mu_1(0) + \partial_{\rho_1} D(0,0) = 0.$$

Using (5.35) we obtain

$$\partial_\mu D(0,0) = P_0(0,\rho_0^*)\partial_\mu P_1(\mu_1 = 0,\rho_0^*) > 0, \tag{5.39}$$

where we used (5.36) and $P_0(0,\rho_0^*) = -M_{00}(\rho_0^*) > 0$. Using (5.34) and (5.23) we obtain

$$\partial_{\rho_1} D(0,0) = \frac{\partial \det(M)}{\partial\rho_1}(\rho_1 = 0) = \det 10 + \det 01, \tag{5.40}$$

where $\det ij$ is the determinant evaluated at $\rho_1 = 0$ of the matrix obtained from M by differentiating the first row i times, respectively the second row j times. $\det ij$ can be evaluated using (4.34), (4.50), and (5.33).

Note that the second row of $\det 10$ is zero and therefore $\det 10 = 0$. Furthermore, $\det 01$ is zero because its second column is zero. Therefore, by (5.40) we have $\partial_{\rho_1}\mu_1(0) = 0$.

We now calculate $\partial_{\rho_1}^2\mu_1(\rho_1 = 0)$. Differentiate (5.38) twice with respect to ρ_1 at $\rho_1 = 0$ and use $\partial_{\rho_1}\mu_1(0) = 0$ to obtain

$$\partial_\mu D(0,0)\partial_{\rho_1}^2\mu_1(0) + \partial_{\rho_1}^2 D(0,0) = 0$$

which implies, by (5.39),

$$\operatorname{sign}(\partial_{\rho_1}^2\mu_1(0)) = -\operatorname{sign}(\partial_{\rho_1}^2 D(0,0)).$$

But, as before, (5.34) and (5.23) imply

$$\partial_{\rho_1}^2 D(0,0) = \frac{\partial^2 \det(M)}{\partial\rho_1^2}(0) = \det 20 + 2\det 11 + \det 02 < 0.$$

The last inequality is a consequence of the following argument. First, $\det 20 = 0$, since its second row is zero. A direct calculation using the definition of M and relations (5.32) show

$$\det 11 = -4(a_{0110} + 2a_{0011})(2a_{1010} + a_{1001})\rho_0^{*2} + \mathcal{O}(\rho_0^{*4}),$$
$$\det 02 = 8a_{0000}a_{1111}\rho_0^{*2} + \mathcal{O}(\rho_0^{*4}).$$

By hypothesis (4.2) and by (3.7), shown in Remark 4.3, we have

$$a_{0000} > a_{1001} + 2a_{1010}, \quad a_{1111} > a_{0110} + 2a_{0011}.$$

This implies, for ρ_0^* sufficiently small, that

$$2\det 11 + \det 02 < 0.$$

Therefore, $\partial^2_{\rho_1}\mu_1(0) > 0$ and the proof of Theorem 5.1 is now complete.

Remark 5.3. We remark that, in the special case of $g < 0$ a constant and $V = V_L$ a double-well potential with well-separation parameter L, for L large all coefficients $a_{klmn} = a_{klmn}(L)$ converge to the same value $g\alpha^2 < 0$. This implies

$$2\det 11 + \det 02 = (-64g^2\alpha^4 + \mathcal{O}(e^{-\tau L}))\rho_0^{*2} + \mathcal{O}(\rho_0^{*4}) < 0.$$

6. Numerical study of symmetry breaking.

6.1. Symmetry-breaking bifurcation for fixed well-separation, *L*. In this section we numerically compute the bifurcation diagram for the lowest energy nonlinear bound state branch for NLS-GP equation (2.1) and compare these results to the predictions of the finite-dimensional approximation equations (3.12), (3.13). Specifically, we numerically compute the bifurcation structure of (2.1) for a double-well potential, $V_L(x)$, of the form

$$V(x) = V_0\left[\frac{1}{\sqrt{4\pi s^2}}\exp\left(-\frac{(x-L/2)^2}{4s^2}\right) + \frac{1}{\sqrt{4\pi s^2}}\exp\left(-\frac{(x+L/2)^2}{4s^2}\right)\right]. \tag{6.1}$$

The potential for $V_0 = -1$, $s = 1$, and $L = 6$ has two discrete eigenvalues $\Omega_0 = -0.1616$ and $\Omega_1 = -0.12$ and a continuous spectral part for $\Omega > 0$. The linear eigenstates can also be obtained and used to numerically compute the coefficients of the finite-dimensional decomposition of (3.12), (3.13) as $a_{0000} = -0.09397$, $a_{1111} = -0.10375$, $a_{0011} = a_{1010} = a_{1001} = a_{0110} = -0.08836$ (for $g = -1$). Then, using (3.10), we can compute the approximate threshold in $\mathcal{N}$ for bifurcation of an asymmetric branch (and the destabilization of the symmetric one):

$$\mathcal{N}_{cr} \sim \mathcal{N}_{cr}^{(0)} = 0.24331, \quad \Omega_{cr} \sim \Omega_{cr}^{(0)} \equiv \Omega_0 \ + \ a_{0000}\,\mathcal{N}_{cr}^{(0)} = -0.18447.$$

We expect good agreement because the values of s and L suggest the regime of large L, where our rigorous theory holds.

Using numerical fixed-point iterations (in particular Newton's method), we obtain the branches of the nonlinear eigenvalue problem (2.7). To study the stability of a solution, u_0, of (2.7), consider the evolution of a small perturbation of it:

$$u = e^{-i\Omega t}\left[u_0(x) + \left(p(x)e^{\lambda t} + q(x)e^{\bar{\lambda}t}\right)\right]. \tag{6.2}$$

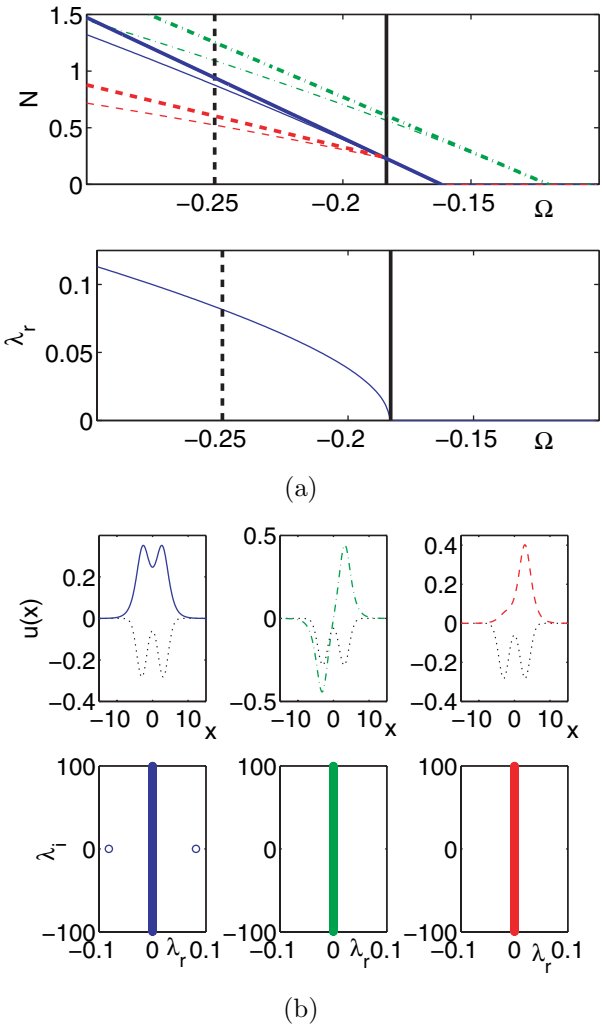


FIG. 3. *The figure shows the typical numerical bifurcation results for the cubic case and their comparison with the finite-dimensional analysis of section* 3. *Panel* (a) *shows the bifurcation diagram in the top subplot and the relevant real eigenvalues in the bottom subplot. In the top, the solid (blue) line represents the symmetric branch, the dashed-dotted (green) line represents the antisymmetric branch, while the dashed (red) line represents the bifurcating asymmetric branch. The thin lines indicate the numerical findings, while the thick ones show the corresponding finite-dimensional, weakly nonlinear predictions. The solid vertical (black) line indicates the critical point (of* $\Omega \approx -0.1835$*) obtained numerically. The dashed vertical (black) line is a guide to the eye for the case with* $\Omega = -0.25$*, whose detailed results are shown in panel* (b). *The bottom subplot of panel* (a) *shows the real eigenvalue (as a function of* Ω*) of the symmetric branch that becomes unstable for* $\Omega < -0.1835$. *Panel* (b) *shows, using the same symbolism as panel* (a)*, the symmetric (left), antisymmetric (middle), and asymmetric (right) branches and their linearization eigenvalues (bottom subplots) for* $\Omega = -0.25$. *The potential is shown by a dotted black line.*

Keeping only linear terms in p, q, we obtain a linear evolution equation, whose normal modes satisfy a linear eigenvalue problem with spectral parameter, which we denote by λ and eigenvector $(p(x), \bar{q}(x))^T$.

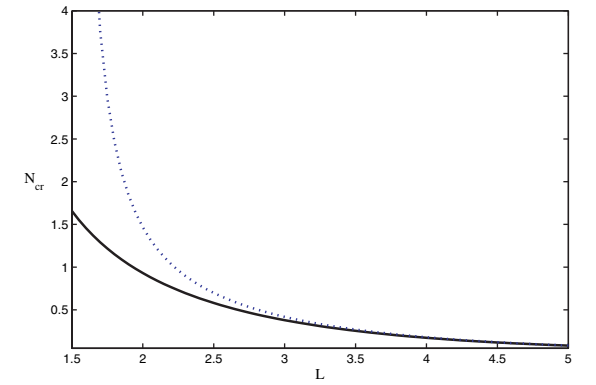
Our computations for the simplest case of the cubic nonlinearity with $K[\psi\bar{\psi}] = \psi\bar{\psi}$ are shown in Figure 3 (for $g(x) = -1$). In particular, the top subplot of panel (a) shows

the full numerical results by thin lines (solid for the symmetric solution, dashed for the bifurcating asymmetric, and dashed-dotted for the antisymmetric one) and compares them with the predictions based on the finite-dimensional truncation of (3.12)-(3.13) shown by the corresponding thick lines. The approximate threshold values $\mathcal{N}_{cr}$ and Ω_{cr} are found numerically to be $\Omega_{cr}^{(0)} \approx -0.1835$ and $\mathcal{N}_{cr}^{(0)} \approx 0.229$. This suggests a relative error in its evaluation by the finite-dimensional reduction of less than 1%. This critical point is indicated by a solid vertical line in panel (a). For $\Omega > \Omega_{cr}^{(0)}$, there exist two branches in the problem, namely the one that bifurcates from the symmetric linear state (this branch exists for $\Omega < \Omega_0$) and the one that bifurcates from the antisymmetric linear state (and, hence, exists for $\Omega < \Omega_1$). For $\Omega < \Omega_{cr}^{(0)}$, the symmetric branch becomes unstable due to a real eigenvalue (see bottom subplot of panel (a)), signalling the emergence of a new branch, namely the asymmetric one. All three branches are shown for $\Omega = -0.25$ (indicated by dashed vertical line in panel (a)) in panel (b) and their corresponding linearization spectrum (λ_r, λ_i) is shown for the eigenvalues $\lambda = \lambda_r + i\lambda_i$.

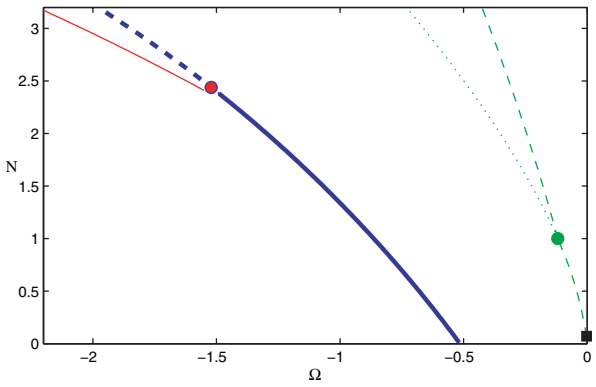
6.2. Symmetry-breaking threshold $\mathcal{N}_{cr}(L)$ as L varies. We now investigate the limits of validity of $\mathcal{N}_{cr}^{(0)}(L)$ as an approximation to $\mathcal{N}_{cr}(L)$ by varying the distance L between the potential wells (6.1). For L large, $\mathcal{N}_{cr}^{(0)}$, given by (3.10), is close to the actual $\mathcal{N}_{cr}(L)$, the exact threshold. In this case the eigenvalues of $-\partial_x^2 + V_L(x)$, $\Omega_0(L)$, and $\Omega_1(L)$ are close to each other; see Example 2.1. Therefore, the bifurcation occurs for small $\mathcal{N}$ and one is in the regime of validity of Theorem 4.1. In Figure 4 we display a comparison between the estimate for $\mathcal{N}_{cr}$ based on the finite-dimensional truncation, $\mathcal{N}_{cr}^{(0)}$, and the actual $\mathcal{N}_{cr}$. For large L the two values are close to each other. As L is decreased the wells approach one another and eventually, at $L = 0$, merge to form a single-well potential. As L is decreased, the eigenvalues of the linear bound states $\Omega_0(L)$ and $\Omega_1(L)$ move farther apart. For some value of L, L_d, the eigenvalue of the excited state, $\Omega_1(L)$, merges at $\Omega = 0$ into the continuous spectrum (and becomes a complex *scattering resonance*). For $L < L_d$ the estimate $\mathcal{N}_{cr}^{(0)}$ is not correct. In fact, $\mathcal{N}_{cr}^{(0)}(L) \to \infty$, while the actual value of $\mathcal{N}_{cr}(L)$ appears to remain finite. In Figure 4(a) we observe that for $L < 2$, $\mathcal{N}^{(0)}$ and $\mathcal{N}_{cr}$ diverge from one another and eventually the approximation $\mathcal{N}_{cr}^{(0)}(L)$ tends to infinity, while the actual $\mathcal{N}_{cr}(L)$ remains finite. In Figure 4(b) we show a bifurcation diagram for small L, in which a second discrete (excited state) eigenvalue of $-\partial_x^2 + V_L$, Ω_1, does not exist. Yet there exists a symmetry-breaking threshold, $\mathcal{N}_{cr}$, along the symmetric branch.

There are interesting observations to make with regard to antisymmetric solutions. Although there is no linear antisymmetric state, from which to bifurcate in the linear (zero amplitude) limit, we do observe a bifurcation of antisymmetric solutions. The black square in Figure 4(b) marks a *strictly positive* threshold value of the squared L^2 norm, $\mathcal{N}_{cr}^{excited} > 0$, at which an antisymmetric nonlinear bound state emerges from zero frequency. The linearization, L_+, about this *excited state branch* has two negative eigenvalues: with corresponding symmetric and antisymmetric eigenstates. The bifurcation along this antisymmetric branch at a larger value of $\mathcal{N}$ to an "asymmetric" state (see Figure 4(b)) is the result of a third eigenvalue of L_+ (with corresponding *even* parity eigenfunction) emerging from the continuous spectrum, as $\mathcal{N}$ is increased, and hitting zero at some critical value $\mathcal{N}_{cr}^{excited,asym} > \mathcal{N}_{cr}^{excited}$.

Finally, note that we expect, at least in the regime of weak nonlinearity, that branches of nonlinear bound states originating from nonground state eigenvalues to be unstable. There can be various mechanisms: linear [10, 15, 9, 16] as well as nonlinear.



(a)



(b)

FIG. 4. *The figure demonstrates the validity of* $\mathcal{N}_{cr}^{(0)}(L)$ *as an approximation to* $\mathcal{N}_{cr}(L)$. *Panel* (a) *compares the linear finite-dimensional estimation for the bifurcation point* $\mathcal{N}_{cr}^{(0)}(L)$ *and the actual numerical bifurcation point* $\mathcal{N}_{cr}$. *The computations are for the double-well potential* (6.1), $V_0 = -1$, *and* $s = 1/4$ *and cubic nonlinearity. The curve* $\mathcal{N}_{cr}(L)$ *is marked by a solid (black) line and the curve* $\mathcal{N}_{cr}^{(0)}(L)$ *is marked by a dotted (blue) line. Panel* (b) *shows a numerical bifurcation diagram for the double-well potential* (6.1), $V_0 = -1$, $s = 1/4$, *and* $L = 1.3$. *The bifurcation point* $\mathcal{N}_{cr}$ *is marked by a (red) circle. For* $\mathcal{N} < \mathcal{N}_{cr}$ *the ground state, marked by a thick (blue) solid line, is stable. For* $\mathcal{N} > \mathcal{N}_{cr}$ *the ground state is unstable and marked by a thick (blue) dashed line. The stable asymmetric state which appears for* $\mathcal{N} > \mathcal{N}_{cr}$ *is marked by a thin (red) solid line. The antisymmetric state* $\Omega_1^{\mathcal{N}}$ *is marked by a thin (light green) dashed line. The point* $\mathcal{N}$ *for which the antisymmetric state appears in the discrete spectrum is marked by a (black) square. Notice that in this bifurcation diagram there is also a bifurcation from the antisymmetric branch. The state which bifurcates from the antisymmetric state is marked by a (dark green) thin dotted line. See the text for remarks on the instability of these latter branches.*

Concerning the latter, if $2\Omega_1 - \Omega_0 > 0$, then it is known that the excited state is unstable due to resonant coupling to the radiation modes; see, for example, [29, 30]. Linearly this is manifested by an exponential instability, computed via perturbation theory of an embedded eigenvalue of the linearization about the excited state at the bifurcation point (zero amplitude) [5]. If $2\Omega_1 - \Omega_0 < 0$, which is the case in the example of Figure 1, the excited state is linearly stable for small amplitude, but it is nonlinearly unstable due to higher nonlinear order coupling to radiation modes [35].

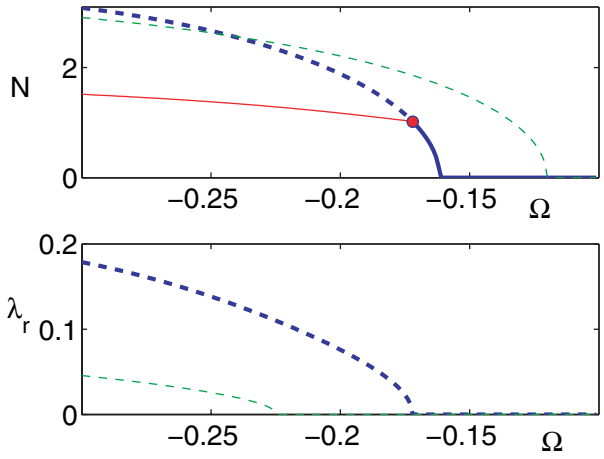


FIG. 5. *Same as panel* (a) *of Figure* 3 *but for the* quintic *nonlinearity. This serves to illustrate the analogies between the bifurcation pictures but also their differences (shifted critical point and also partial instability of the antisymmetric branch).*

6.3. More general nonlinearities. To simplify the analysis in this paper, we assumed a cubic nonlinearity in NLS-GP; see (H3). Our approach is quite general and more general nonlinearities can be treated. That is, a more general finite-dimensional Galerkin approximation can be derived and its normal form/symmetry/bifurcation theory can be developed.

In this subsection we present numerical computations for general power law nonlinearities such as $K[\psi\bar{\psi}] = (\psi\bar{\psi})^p$ and discuss phenomena analogous to the cubic case, $p = 1$.

Our numerical results for the case of $p = 2$, $K[\psi\bar{\psi}]\psi = |\psi|^4\psi$, are presented in Figure 5. The curves are analogous to those of panel (a) of Figure 3. The bifurcation diagram for this higher order nonlinearity is similar to that of the cubic case. However, the critical point for the emergence of the asymmetric branch is now shifted to $\Omega_{cr} \approx -0.1725$, closer to the linear limit. We have also examined the case of $p = 3$, $K[\psi\bar{\psi}]\psi = |\psi|^6\psi$, finding that the relevant critical point is further shifted toward the linear limit, $\Omega_{cr} = -0.168$. Using our methods one could identify, in the double-well case with large separation, $\Omega_{cr}(p; L)$ such that for all $\Omega < \Omega_{cr}(p; L)$, the symmetric branch is unstable. We also note in passing that bifurcation diagrams for higher values of p may also bear additional (to the shift in Ω_{cr}) differences from the cubic case; one such example in Figure 5 is given by the presence of a linear instability (due to a complex eigenvalue quartet emerging for $\Omega < -0.224$) for the antisymmetric branch. The latter was found to be linearly stable in the cubic case of Figure 3.

6.4. Nonlocal nonlinearities. Finally, we consider the case of nonlocal nonlinearities depending on a parameter ϵ, the range of the nonlocal interaction. In particular, consider the case of a nonlocal nonlinearity of the form

$$K[\psi\bar{\psi}] = \int_{-\infty}^{\infty} \mathcal{K}(x-y)\psi(y)\bar{\psi}(y)dy, \tag{6.3}$$

where

$$\mathcal{K}(x-y) = \frac{1}{2\pi\epsilon^2} e^{-\frac{(x-y)^2}{2\epsilon^2}}. \tag{6.4}$$

Here, $\epsilon > 0$ is a parameter controlling the range of the nonlocal interaction. As ϵ tends to 0, $\mathcal{K}(x-y) \to \delta(x-y)$ and we recover the "local" cubic limit. The form of the finite-dimensional reduction, of (3.12), (3.13), does not change; the only modification is that the coefficients a_{klmn} are now functions of the range of the interaction ϵ. The dependence of the coefficients a_{klmn} on ϵ is displayed in panel (a) of Figure 6. The solid (blue) line shows $|a_{0000}|$, the dashed (green) one corresponds to $|a_{1111}|$, the dashed-dotted (red) one corresponds to $|a_{1001}| = |a_{0110}|$ (g is constant, K even), while the thick solid (black) one corresponds to $|a_{0101}| = |a_{0011}| = |a_{1010}|$. Notice in the inset how the coefficients asymptote smoothly to their "local" limit. Additionally, note the expected asymptotic relation $a_{1001} = a_{0011}$. Also note the significant (decaying) dependence of the relevant coefficients on the range of the interaction. The nature of this dependence indicates that while the character of the bifurcation may be the same as in the case of local nonlinearities, its details (such as the location of the critical points) depend sensitively on the range of the nonlocal interaction. This is illustrated in panel (b) for the specific case of $\epsilon = 5$. In this panel (which is analogous to panel (a) of Figure 3, but for the nonlocal case) the critical point for emergence of the asymmetric branch/instability of the symmetric branch is shifted to $\Omega_{cr} = -0.2466$ (and the corresponding $\mathcal{N}_{cr} = 1.4353$) in comparison to the numerically obtained value of $\Omega_{cr} \approx -0.256$; the relative error in the identification of the critical point (by the finite-dimensional reduction) is in this case of the order of 3.7%. This can be attributed to the more nonlinear character (i.e., occurring for higher value of $\mathcal{N}_{cr}$) nature of the bifurcation. However, as the finite-dimensional approximation still yields a reliable estimate for the location of the critical point, in panel (c) we use it to obtain an approximation to the location of the critical point $(\Omega_{cr}, \mathcal{N}_{cr})$ as a function of the nonlocality parameter ϵ.

7. Concluding remarks. We have obtained rigorous results on the spontaneous symmetry-breaking bifurcation for a large class of NLS-GP equations and studied in detail the case of double-well potentials. Our analysis of the symmetry-breaking bifurcation and the exchange of stability is based on an expansion which, to leading order in amplitude, is a superposition of a symmetric-antisymmetric pair of eigenstates of the linear Hamiltonian, H, whose energies are separated (gap condition (4.13)) from all other spectra of H. This gap condition holds for double wells with sufficiently large L, but breaks down as L decreases. Nevertheless, numerical studies show the existence of a finite threshold for symmetry breaking; see the discussion above on the variation of $\mathcal{N}_{cr}(L)$ with L. A theory encompassing this phenomenon is of interest and is currently under investigation.

Finally, we remark that our analysis can be naturally extended to treat cases of general multi-wells, identical or not, since the methods involve a strategy for analysis of the weakly nonlinear regime, given spectral assumptions on the linear limit. An example is the case of a symmetric triple well, studied in [18], where the finite-dimensional Galerkin analysis has been implemented, revealing a rich bifurcation picture, but with no symmetry-breaking bifurcation in the symmetric branch. In such multi-well cases, naturally the dimension of the Galerkin approximation needs to be increased accordingly (e.g., 3-dimensional for 3-wells, 4-dimensional for 4-wells, etc.) introducing greater complexity into the global bifurcation structure. Formally, the derivation may be systematically extended to the case of infinitely many wells, constituting the so-called tight-binding approximation [2], although a rigorous derivation of such lattice equations may pose a considerable challenge.

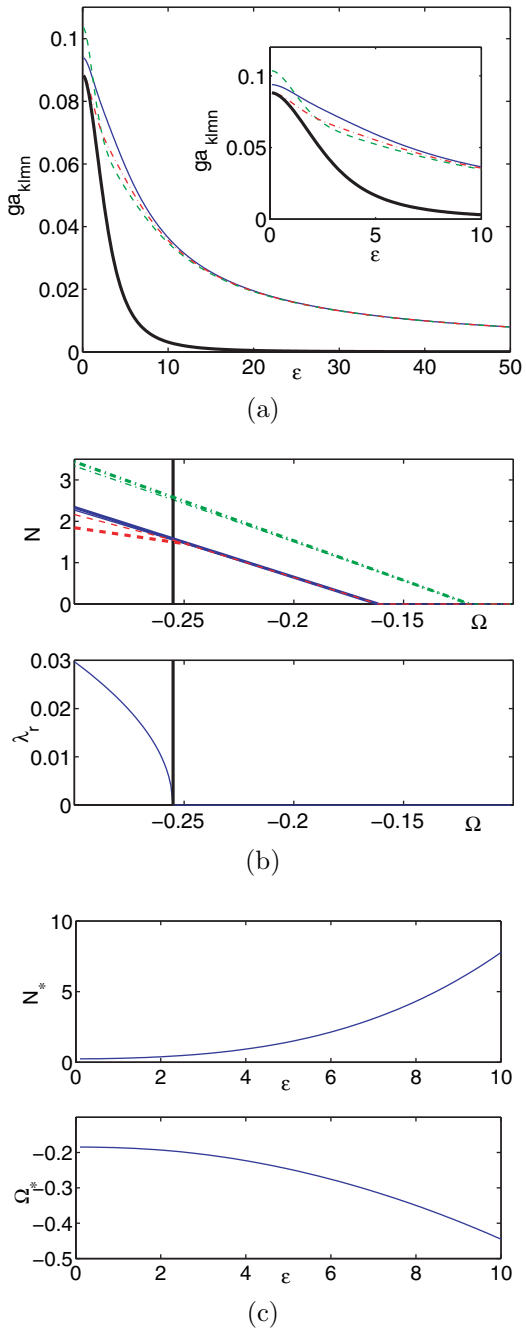

FIG. 6. *This figure shows the nonlocal analogue of Figure* 3. *Panel* (a) *shows the dependence of the (absolute value of the) coefficients of the finite-dimensional approximation on the nonlocality parameter* ϵ *(*$\epsilon = 0$ *denotes the "local" nonlinearity limit). The solid (blue) line denotes* a_{0000}*, the dashed (green) denotes* a_{1111}*, the dashed-dotted (red) denotes* a_{0110}*, while the thick solid (black) one denotes* a_{0101}*. Panel* (b) *is analogous to panel* (a) *of Figure* 3*, but now shown for the nonlocal case, with the nonlocality parameter* $\epsilon = 5$*. Finally, panel* (c) *shows the dependence of the critical point of the finite-dimensional bifurcation* $(N_\star, \Omega_\star)$ *on the nonlocality parameter* ϵ*.*

8. Appendix. Double wells. In this discussion, we are going to follow the analysis of [12]. Consider a (single-well) real-valued potential $v_0(x)$ on $\mathbb{R}^n$ such that $v_0(x) \in L^r + L^\infty_\varepsilon$ for all $1 \le r \le q$ where $q \ge \max(n/2, 2)$ for $n \ne 4$, $q > 2$ for $n = 4$. Then, multiplication by v_0 defines a compact operator from H^2 to L^2 and

$$H_0 = -\Delta + v_0(x)$$

is a self-adjoint operator on L^2 with domain H^2.

Consider now the double-well potential

$$V_L = T_L v_0 T_{-L} + R T_L v_0 T_{-L} R,$$

where T_L and R are the unitary operators

$$T_L g(x_1, x_2, \dots, x_n) = g(x_1 + L, x_2, \dots, x_n),$$
$$Rg(x_1, x_2, \dots, x_n) = g(-x_1, x_2, \dots, x_n),$$

and the self-adjoint operator

$$H_L = -\Delta + V_L(x).$$

PROPOSITION 8.1. *Assume that $\omega < 0$ is a nondegenerate eigenvalue of H_0 separated from the rest of the spectrum of H_0 by a distance greater than $2d_*$. Denote by ψ_ω its corresponding eigenvector, $\|\psi_\omega\|_{L^2} = 1$. Then there exists $L_0 > 0$ such that for $L \ge L_0$ the following are true.*

(i) *H_L has exactly two eigenvalues $\Omega_0(L)$ and $\Omega_1(L)$ nearer to ω than $2d_*$. Moreover, $\lim_{L\to\infty} \Omega_j(L) = \omega,\ j = 0, 1$.*

(ii) *One can choose the normalized eigenvectors $\psi_j(L),\ \|\psi_j(L)\|_{L^2} = 1$, corresponding to the eigenvalues $\Omega_j(L),\ j = 0, 1$, such that they satisfy*

$$\lim_{L\to\infty} \|\psi_j(L) - (T_L\psi_\omega + (-1)^j R T_L \psi_\omega)/\sqrt{2}\|_{H^2} = 0,\ j = 0, 1.$$

(iii) *If P^L_j are the orthogonal projections in L^2 onto $\psi_j(L),\ j = 0, 1$, and $\tilde{P}_L = Id - P^L_0 - P^L_1$, then there exists $d > 0$ independent of L such that*

$$\|(H_L - \Omega)^{-1}\tilde{P}_L\|_{L^2 \mapsto H^2} \ge d \quad \text{for all } L \ge L_0 \text{ and } |\Omega - \omega\| \le d_*.$$

Proof. For (i) we refer the reader to [12]. The L^2 convergence in (ii) has also been proved there. The H^2 convergence follows from the following compactness argument. Let

$$\psi^L_j = n_L \psi_j(L), \qquad j = 0, 1,$$

where n_L is such that $\|\psi^L_j\|_{H^2} = 1,\ j = 0, 1$. From the eigenvector equations: $(H_L - \Omega(L))\psi^L = 0$, where we dropped the index $j = 0, 1$ and the convergence $\Omega(L) \to \omega$, see part (i), we get

$$\lim_{L\to\infty} \|(-\Delta - \omega + V_L)\psi^L\|_{L^2} = 0. \tag{8.1}$$

Denote

$$g_L = (-\Delta - \omega)\psi^L \in L^2. \tag{8.2}$$

Since $-\Delta-\omega : H^2 \mapsto L^2$ is bounded, there exists a constant $C>0$ independent of L such that

$$\|g_L\|_{L^2} \leq C.$$

Since $\omega<0$, $-\Delta-\omega : H^2 \mapsto L^2$ has a continuous inverse, then (8.1) is equivalent to

$$g_L + V_L(-\Delta-\omega)^{-1}g_L \to 0 \text{ in } L^2.$$

By expanding V_L we get

$$g_L + T_L v_0(-\Delta-\omega)^{-1}T_{-L}g_L + RT_L v_0(-\Delta-\omega)^{-1}T_{-L}Rg_L \to 0. \tag{8.3}$$

But $v_0(-\Delta-\omega)^{-1} : L^2 \mapsto L^2$ is compact while the translation and reflection operators are unitary. These and the uniform boundedness of g_L lead to the existence of $\psi \in L^2$ and $\tilde{\psi} \in L^2$ and a subsequence of g_L, which we will redenote by g_L, such that

$$\lim_{L\to\infty} \|v_0(-\Delta-\omega)^{-1}T_{-L}g_L - \psi\|_{L^2} = 0 \text{ and } \lim_{L\to\infty} \|v_0(-\Delta-\omega)^{-1}T_{-L}Rg_L - \tilde{\psi}\|_{L^2} = 0. \tag{8.4}$$

By plugging in (8.3) and multiplying to the left by T_{-L} we get

$$\lim_{L\to\infty} \|T_{-L}g_L + \psi + RT_{2L}\tilde{\psi}\|_{L^2} = 0.$$

But $RT_{2L}\tilde{\psi}$ converges weakly to zero, hence $T_{-L}g_L$ converges weakly to $-\psi$. By plugging now in (8.4) and using compactness we get

$$\psi + v_0(-\Delta-\omega)^{-1}\psi = 0.$$

The latter shows that $(-\Delta-\omega)^{-1}\psi$ is an eigenvector of $-\Delta+v_0$ corresponding to the eigenvalue ω. By nondegeneracy of ω we get

$$\psi = -n(-\Delta-\omega)\psi_\omega, \tag{8.5}$$

where n is a constant. A similar argument shows that

$$\tilde{\psi} = -\tilde{n}(-\Delta-\omega)\psi_\omega, \tag{8.6}$$

where $\tilde{n}$ is a constant.

Combining (8.1)–(8.6) we get

$$\lim_{L\to\infty} \|(-\Delta-\omega)(\psi^L - nT_L\psi_\omega - \tilde{n}RT_L\psi_\omega)\|_{L^2} = 0 \tag{8.7}$$

which by the continuity of $(-\Delta-\omega)^{-1} : L^2 \mapsto H^2$ implies

$$\lim_{L\to\infty} \|\psi^L - nT_L\psi_\omega - \tilde{n}RT_L\psi_\omega\|_{H^2} = 0.$$

Using now that $\|\psi^L\|_{H^2} = 1$ and that the rescaled ψ_j^L, such that it has norm 1 in L^2, converges to $(T_L\psi_\omega + (-1)^j RT_L\psi_\omega)/\sqrt{2}$, we get the conclusion of part (ii) for a subsequence first, then, by uniqueness of the limit, for all $L\to\infty$.

For part (iii), it suffices to show that there are no sequences $(\Omega_L, \psi^L) \in [\omega - d_*, \omega + d_*] \times H^2$ with $\|\psi^L\|_{H^2} = 1$ and $\psi_L \perp \psi_j(L),\ j=0,1$, in L^2 such that

$$\lim_{L\to\infty} \|(H_L - \Omega_L)\psi^L\|_{L^2} = 0. \tag{8.8}$$

The spectral estimate

$$\|(H_L - \Omega_L)\psi^L\|_{L^2} \geq dist(\Omega_L, \sigma(H_L)\backslash\{\Omega_0(L), \Omega_1(L)\})\|\psi^L\|_{L^2} \geq d_*\|\psi^L\|_{L^2},$$

combined with (8.8), implies

$$\lim_{L\to\infty} \|\psi^L\|_{L^2} = 0. \tag{8.9}$$

In principle, we can now employ the compactness argument in part (ii) to get

$$\lim_{L\to\infty} \|\psi^L\|_{H^2} = 0 \tag{8.10}$$

which will contradict $\|\psi^L\|_{H^2} = 1$. More precisely, (8.8), (8.9) imply

$$\lim_{L\to\infty} \|(-\Delta - \omega - d_* + V_L)\psi^L\|_{L^2} = 0$$

which, by repeating the argument after (8.1) with ω replaced by $\omega + d_*$, gives

$$\lim_{L\to\infty} \|\psi^L + T_L\psi_{\omega+d_*} + RT_L\tilde{\psi}_{\omega+d_*}\|_{H^2} = 0,$$

where $\psi_{\omega+d_*}$ and $\tilde{\psi}_{\omega+d_*}$ are eigenvectors of $-\Delta + v_0$ corresponding to eigenvalue $\omega + d_*$. But the latter is not actually an eigenvalue, hence $\psi_{\omega+d_*} = 0$ and $\tilde{\psi}_{\omega+d_*} = 0$. These show (8.10) and finishes the proof of part (iii).

The proposition is now completely proven. ∎

ON 2×2 CONSERVATION LAWS AT A JUNCTION*

R. M. COLOMBO†, M. HERTY‡, AND V. SACHERS§

Abstract. This paper deals with 2×2 conservation laws at a junction. For the Cauchy problem, existence, uniqueness, and Lipschitz continuous dependence of the solution from the initial data as well as from the conditions at the junction are proved. The present construction comprehends the case of the p-system used to describe gas flow in networks and hereby unifies different approaches present in the literature. Furthermore, different models for water networks are considered.

Key words. hyperbolic systems of conservation laws, p-system, St. Venant equations

1. Introduction.

This paper studies the initial value problem consisting of

$$\partial_t u_l + \partial_{x_l} f(u_l) = 0, \qquad \text{with } l = 1, \dots, n,\ t \in [0, +\infty[\ ,\ x \in [0, +\infty[\ , \tag{1.1}$$

along n pipes together with

$$\Psi\left(u_1(t, 0+), u_2(t, 0+), \dots, u_n(t, 0+)\right) = 0 \tag{1.2}$$

at a junction. In other words, we deal with n initial boundary value problems for systems of 2×2 conservation laws, coupled through nonlinear boundary conditions. In this general setting, extending the results in [10], we derive conditions under which the Cauchy problem for (1.1) has a unique solution. Furthermore, the Lipschitz continuous dependence of the solution on initial data and coupling conditions is proved.

We model a junction connecting n rectilinear pipes by n pairwise distinct vectors $\nu_1, \dots, \nu_n$ parallel to the pipes and such that $\|\nu_l\|$ equals the cross section of the lth pipe. Furthermore, we assign a space coordinate $x_l > 0$ to each pipe. The transport of a specific quantity in the lth pipe is given by (1.1), where u_l is the vector of variables along the lth duct and f is a general nonlinear flux function. Condition (1.2) describes the interaction of the transported quantities at the intersection of the pipes; see [2, 3, 9, 10, 11, 19]. The standard situation of the Cauchy problem on a line is recovered in the case $n = 2$, $\nu_1 + \nu_2 = 0$, and $\Psi(u_1, u_2) = f(u_1) - f(u_2)$; see section 4.1. To simplify the notation, below we denote by x all the coordinates x_l along the various pipes.

Applications of the theoretical results are in the field of fluid flow in networks and in particular in high-pressure gas pipelines in open canals. In recent years, there has been intense research in flow problems on networks; see, e.g., the book on gas networks [23] and the publications of the Pipeline Simulation Interest Group [26]. Most of the proposed models [12, 14, 21, 23, 24, 25, 27, 22, 18] consider each pipe as a

one-dimensional domain and use balance laws to describe the dynamics. The validity of one-dimensional models is the subject of intense discussions; we refer the reader to [26] for more details.

In this context, the most challenging and interesting point is the coupling condition at pipe-to-pipe intersections. In an engineering context, this coupling is typically modeled through tables prescribing suitable relations depending on, e.g., the geometry of the pipe, the material, and flow conditions [12, 21]. Among the first mathematical treatments of this situation are [2, 3, 9, 10, 19]. The current presentation considers the *subsonic* case as in [2, 3, 9, 10, 11, 19] and typical physical conditions [14]. Extending the presentations in [4, 16, 20], we consider solutions possibly containing shocks.

Our purpose is to present a general framework for coupling conditions and prove well posedness. Indeed, we unify and extend the approaches [2, 3, 9, 10, 16, 19]. First, the present framework includes the currently used one-dimensional isothermal model for gas flow as well as the shallow-water equations for flows in open channels. In particular, we extend the results in [10] covering not only the isentropic Euler equations but a general 2×2 system. More importantly, the present result allows us to consider any coupling conditions specified through any (possibly nonlinear) function Ψ, the sole constraint being condition (2.2) below. Hence, the present results also extend previous works on open channel flow with gate control or pumps (see [16]), as well as the model for a kink in a pipe introduced in [19]. Finally, within this general setting, we also prove the Lipschitz continuous dependence of the solutions from the condition Ψ at the junction; see (3.2) in Theorem 3.2. As a consequence, in all the cases mentioned above, it is possible to prove the existence of an optimal control.

Numerically, we show that different one-dimensional coupling conditions lead to qualitatively different solutions. The comparison is in the context of the present theory, i.e., for one-dimensional models. Two-dimensional situations are considered, for instance, in [17, 18]. For a comparison with results of the engineering community we refer the reader to the pressure loss tables [12, 21].

The paper is organized as follows. Section 2 is devoted to the Riemann problem and extends [9]. In section 3, the well posedness of the Cauchy problem is stated. Applications of this result to gas flow in pipes as well as flow in open canals are collected in section 4. Section 5 contains the detailed constructions and proofs.

2. The Riemann problem at a junction. Throughout, we refer the reader to [6] for the general theory of hyperbolic systems of conservation laws. Let $\Omega \subseteq \mathbb{R}^2$ be a nonempty open set. Fix a flow $f \in \mathbf{C^4}(\Omega; \mathbb{R}^2)$ satisfying the following assumption:

(F) There exists a $\bar{u} \in \Omega$ such that $Df(\bar{u})$ admits a strictly negative eigenvalue $\lambda_1(\bar{u})$ and a strictly positive one $\lambda_2(\bar{u})$, the corresponding eigenvectors are linearly independent, and each characteristic field is either genuinely nonlinear or linearly degenerate.

Under this condition, (1.1) generates a standard Riemann semigroup; see [6, Chapter 8]. By *Riemann problem at the junction* we mean the problem

$$\begin{cases} \partial_t u_l + \partial_x f(u_l) = 0, & t \in \mathbb{R}^+, \quad l \in \{1, \dots, n\}, \\ u_l(0, x) = \bar{u}_l\,, & x \in \mathbb{R}^+, \quad u_l \in \Omega, \end{cases} \tag{2.1}$$

where $\bar{u}_1, \dots, \bar{u}_n$ are constant states in Ω. For $l = 1, \dots, n$, u_l has two components; i.e., $u_l = (u_{l,1}, u_{l,2})$ denotes the densities of the conserved quantities in the lth tube. Here and in what follows, $\mathbb{R}^+ = [0, +\infty[$.

DEFINITION 2.1. *Fix a map $\Psi \in \mathbf{C^1}(\Omega^n; \mathbb{R}^n)$. A* Ψ-solution *to the Riemann problem* (2.1) *is a function $u\colon \mathbb{R}^+ \times \mathbb{R}^+ \mapsto \Omega^n$ such that the following hold:*

(L) *For $l = 1, \dots, n$, the function $(t, x) \mapsto u_l(t, x)$ is self-similar and coincides with the restriction to $x \in \mathring{\mathbb{R}}^+$ of the Lax solution to the standard Riemann problem*

$$\begin{cases} \partial_t u_l + \partial_x f(u_l) = 0, \\ u_l(0, x) = \begin{cases} \bar{u}_l & \text{if } x > 0, \\ u_l(1, 0+) & \text{if } x < 0\,. \end{cases} \end{cases}$$

(Ψ) *The trace $u(t, 0+)$ of u at the junction satisfies* (1.2) *for a.e. $t > 0$.*

Given an entropy-entropy flux pair (E, F), the Ψ-solution is entropic at the junction if the following holds:

(E) *At the junction, entropy may not decrease; i.e., for a.e. $t > 0$*

$$\sum_{l=1}^{n} \|\nu_l\|\, F\left(u_l(t, 0+)\right) \leq 0\,.$$

For later use, with a slight abuse of notation, we denote

$$\begin{aligned} \|u\| &= \sum_{l=1}^{n} \|u_l\| && \text{for } u \in \Omega^n\,, \\ \|u\|_{\mathbf{L^1}} &= \int_{\mathbb{R}^+} \left\|u(x)\right\| dx && \text{for } u \in \mathbf{L^1}\left(\mathbb{R}^+; \Omega^n\right)\,, \\ \mathrm{TV}\,(u) &= \sum_{l=1}^{n} \mathrm{TV}\,(u_l) && \text{for } u \in \mathbf{BV}\left(\mathbb{R}^+; \Omega^n\right)\,. \end{aligned}$$

The following proposition yields the well posedness of the Riemann problem and the continuous dependence of the solution to the Riemann problem from the initial state and from the function Ψ. These results are used in section 3 to prove well posedness of the Cauchy problem by the wave tracking algorithm. The proofs are deferred to section 5.

PROPOSITION 2.2. *Let $n \in \mathbb{N}$ with $n \geq 2$. Fix the pairwise distinct vectors $\nu_1, \dots, \nu_n$ in $\mathbb{R}^3 \setminus \{0\}$ and an n-tuple of constant states $\hat{u} \in \Omega^n$ giving a stationary solution to the Riemann problem* (2.1) *in the sense of Definition* 2.1. *Assume that for $l = 1, \dots, n$,* **(F)** *holds in $\hat{u}_l$. If $\Psi \in \mathbf{C^1}(\Omega^n; \mathbb{R}^n)$ satisfies*

$$\det \left[\; D_1\Psi(\hat{u}) r_2(\hat{u}_1) \quad D_2\Psi(\hat{u}) r_2(\hat{u}_2) \quad \dots \quad D_n\Psi(\hat{u}) r_2(\hat{u}_n) \;\right] \neq 0, \tag{2.2}$$

where $D_l\Psi = D_{u_l}\Psi$, then there exist positive δ, K such that the following hold:

1. *For all $\bar{u} \in \Omega^n$ satisfying $\|\bar{u} - \hat{u}\| < \delta$, the Riemann problem* (2.1) *admits a unique self-similar solution $(t, x) \mapsto \left(\mathcal{R}^\Psi(\bar{u})\right)(t, x)$ in the sense of Definition* 2.1.
2. *If* (1.1) *admits an entropy-entropy flux pair (E, F), requiring that*

$$\sum_{l=1}^{n} \|\nu_l\|\, F(\hat{u}_l) < 0 \tag{2.3}$$

ensures that the solution $(t, x) \mapsto \left(\mathcal{R}^\Psi(\bar{u})\right)(t, x)$ is also entropic.

3. *If $\bar u, \bar w \in \Omega^n$ both satisfy $\|\bar u - \hat u\| < \delta$ and $\|\bar w - \hat u\| < \delta$, then the traces at the junction of the corresponding solutions to* (2.1) *satisfy*

$$\left\| \left((\mathcal{R}^\Psi(\bar u)) \right)(t, 0+) - \left((\mathcal{R}^\Psi(\bar w)) \right)(t, 0+) \right\| \leq K \cdot \|\bar u - \bar w\| \,. \tag{2.4}$$

4. *For any $\tilde\Psi \in \mathbf{C^1}(\Omega^n; \mathbb{R}^n)$ with $\|\tilde\Psi - \Psi\|_{\mathbf{C^1}} < \delta$, $\tilde\Psi$ also satisfies* (2.2) *and for all $\bar u \in \Omega^n$ satisfying $\|\bar u - \hat u\| < \delta$,*

$$\left\| \left(\mathcal{R}^{\tilde\Psi}(\bar u) \right)(t) - \left(\mathcal{R}^\Psi(\bar u) \right)(t) \right\|_{\mathbf{L^1}} \leq K \cdot \left\| \tilde\Psi - \Psi \right\|_{\mathbf{C^1}} \cdot t \,.$$

In the previous proposition, $r_2(\hat u)$ is the right eigenvector of $Df(\hat u)$ corresponding to the second characteristic field.

We remark that, for subsonic initial data, we obtain here a unique Ψ-solution, without any additional condition, such as **(E)**.

3. The Cauchy problem at an intersection. Next we consider the Cauchy problem at a junction. First, we give a definition of a solution which naturally extends Definition 2.1 to the Cauchy problem. Then we prove the existence of solutions for initial data with small total variation and the continuous dependence on the coupling condition Ψ.

DEFINITION 3.1. *Fix $\hat u \in \Omega^n$ and $T \in]0, +\infty]$. A weak Ψ-solution to*

$$\begin{cases} \partial_t u_l + \partial_x f(u_l) = 0, & t \in \mathbb{R}^+, & l \in \{1, \dots, n\}, \\ u(0, x) = u_o(x), & x \in \mathbb{R}^+, & u_o \in \hat u + \mathbf{L^1}(\mathbb{R}^+; \Omega^n) \end{cases} \tag{3.1}$$

on $[0, T]$ is a map $u \in \mathbf{C^0}\left([0, T]; \hat u + \mathbf{L^1}(\mathbb{R}^+; \Omega^n)\right)$ such that the following hold:

(W) *For all $\varphi \in \mathbf{C^\infty_c}\left(]-\infty, T[\times \mathbb{R}^+; \mathbb{R}\right)$ and for $l = 1, \dots, n$*

$$\int_0^T \int_{\mathbb{R}^+} \left(u_l \, \partial_t \varphi + f(u_l) \, \partial_x \varphi \right) dx \, dt + \int_{\mathbb{R}^+} u_{o,l}(x) \, \varphi(0, x) \, dx = 0 \,.$$

($\mathbf{\Psi}$) *The condition at the junction is met: for a.e. $t \in \mathbb{R}^+$, $\Psi\left(u(t, 0+)\right) = 0$.*

If (1.1) *admits an entropy-entropy flux pair (E, F), then the weak Ψ-solution u is entropic if for all $\varphi \in \mathbf{C^\infty_c}\left(]-\infty, T[\times \mathbb{R}^+; \mathbb{R}^+\right)$*

$$\sum_{l=1}^n \left(\int_0^T \int_{\mathbb{R}^+} \left(E(u_l) \, \partial_t \varphi + F(u_l) \, \partial_x \varphi \right) dx \, dt + \int_{\mathbb{R}^+} E(u_o) \, \varphi(0, x) \, dx \right) \|\nu_l\| \geq 0.$$

We are now ready to state the main result of this paper, namely the well posedness of the Cauchy problem for (3.1) at the junction.

THEOREM 3.2. *Let $n \in \mathbb{N}$, $n \geq 2$. Fix the pairwise distinct vectors $\nu_1, \dots, \nu_n$ in $\mathbb{R}^3 \setminus \{0\}$. Fix an n-tuple of states $\bar u \in \Omega^n$ such that f satisfies* **(F)** *at $\bar u$ and the Riemann problem* (2.1) *with initial datum $\bar u$ admits the stationary solution in the sense of Definition* 2.1. *Let $\Psi \in \mathbf{C^1}(\Omega^n; \mathbb{R}^n)$ satisfy* (2.2). *Then there exist positive δ, L and a map $S\colon [0, +\infty[\times \mathcal{D} \to \mathcal{D}$ such that*

1. *$\mathcal{D} \supseteq \left\{ u \in \bar u + \mathbf{L^1}(\mathbb{R}^+; \Omega^n) \colon \mathrm{TV}(u) \leq \delta \right\}$;*
2. *for $u \in \mathcal{D}$, $S_0 u = u$ and for $s, t \geq 0$, $S_s S_t u = S_{s+t} u$;*
3. *for $u, w \in \mathcal{D}$ and $s, t \geq 0$, $\|S_t u - S_s w\|_{\mathbf{L^1}} \leq L \cdot \left(\|u - w\|_{\mathbf{L^1}} + |t - s| \right)$;*

4. *if $u \in \mathcal{D}$ is piecewise constant, then for $t > 0$ sufficiently small, $S_t u$ coincides with the juxtaposition of the solutions to Riemann problems centered at the points of jumps or at the junction.*

Moreover, for every $u \in \mathcal{D}$, the map $t \mapsto S_t u$ is a Ψ-solution to the Cauchy problem (3.1) *according to Definition* 3.1.

For any $\tilde{\Psi} \in \mathbf{C^1}(\Omega^n; \mathbb{R}^n)$ with $\|\tilde{\Psi} - \Psi\|_{\mathbf{C^1}} < \delta$, $\tilde{\Psi}$ generates a semigroup of solutions on $\mathcal{D}$ and for $u \in \mathcal{D}$,

$$\left\| S_t^{\tilde{\Psi}} \bar{u} - S_t^{\Psi} \bar{u} \right\|_{\mathbf{L^1}} \leq L \cdot \left\| \tilde{\Psi} - \Psi \right\|_{\mathbf{C^1}} \cdot t \,. \tag{3.2}$$

If (1.1) *admits an entropy-entropy flux pair (E, F) and $\bar{u}$ is strictly entropic in the sense of* (2.3)*, then the Ψ-solution $t \mapsto S_t u$ is entropic at the junction.*

The proof is deferred to section 5.

4. Gas networks and open channels. A widely used model for gas flow in pipe networks is the system of isothermal Euler equations; see [23] and the references therein. In this section, we discuss the coupling conditions [2, 10] in the context of the presented theory in the case of a general p-system. By p-system we mean

$$\left\{ \begin{array}{l} \partial_t \rho_l + \partial_x q_l = 0, \\ \partial_t q_l + \partial_x \left(\dfrac{q_l^2}{\rho_l} + p(\rho_l) \right) = 0, \end{array} \right. \qquad \begin{array}{rcl} t & \in & \mathbb{R}^+, \\ x & \in & \mathbb{R}^+, \\ l & \in & \{1, \dots, n\}, \\ (\rho_l, q_l) & \in & \mathring{\mathbb{R}}^+ \times \mathbb{R}, \end{array} \tag{4.1}$$

where $\rho > 0$ is the mass density of a given fluid, q its linear momentum density, and $p = p(\rho)$ the pressure law, which we assume to satisfy the following:

(P) $p \in \mathbf{C^2}\left(\mathbb{R}^+; \mathbb{R}^+\right)$, $p(0) = 0$ and for all $\rho \in \mathbb{R}^+$, $p'(\rho) > 0$, $p''(\rho) \geq 0$.

In the context of gas pipelines, the pressure law typically chosen is $p(\rho) = a^2 \rho$, where the sound speed a depends on the gas type and temperature [23].

As is well known, (4.1) is equipped with the (mathematical) entropy-entropy flux pair

$$\begin{array}{rcll} E(\rho, q) & = & \dfrac{q^2}{2\rho} + \rho \displaystyle\int_{\rho_*}^{\rho} \frac{p(r)}{r^2}\, dr & \text{(total energy)}, \\ F(\rho, q) & = & \dfrac{q}{\rho} \cdot \big(E(\rho, q) + p(\rho) \big) & \text{(flow of the total energy)} \end{array}$$

for a $\rho_* > 0$. Choosing an initial datum $\bar{u} = (\bar{\rho}, \bar{q})$ in the *subsonic* region

$$\Omega = \Big\{ (\rho, q) \in \mathring{\mathbb{R}}^+ \times \mathbb{R} \colon \lambda_1(\rho, q) < 0 < \lambda_2(\rho, q) \Big\}$$

ensures that **(F)** holds at $\bar{u}$. Recall the standard relations

$$\begin{array}{rclcrcl} \lambda_1(\rho, q) & = & (q/\rho) - \sqrt{p'(\rho)}\,, & \qquad & \lambda_2(\rho, q) & = & (q/\rho) + \sqrt{p'(\rho)}, \\ r_1(\rho, q) & = & \begin{bmatrix} -1 \\ -\lambda_1(\rho, q) \end{bmatrix}, & & r_2(\rho, q) & = & \begin{bmatrix} 1 \\ \lambda_2(\rho, q) \end{bmatrix}. \end{array} \tag{4.2}$$

Below we consider different coupling conditions that appeared in the literature. Remark that the geometry of the junction implicitly enters into all the relations below

through the choice of the x_l coordinates. Explicitly, only the area $\|\nu_l\|$ of the cross section appears.

Below we consider the conditions presented in [3, 4, 10, 14, 16, 19, 23]. Any of them prescribes the conservation of mass, so that the first component in (1.2) reads

$$\sum_{l=1}^{n} \|\nu_l\| \, q_l = 0 \,. \tag{4.3}$$

With a slight abuse of notation, we use Ψ to denote the remaining $n-1$ conditions.

(a) We prescribe the equal momentum flow for all connected pipes; see [9] and in the case of open channels [16]:

$$P\left(\rho_i(t,0+), q_i(t,0+)\right) = P\left(\rho_j(t,0+), q_j(t,0+)\right) \qquad \forall\, i \neq j.$$

(b) We prescribe a single pressure at the pipe-to-pipe intersection; see [2, 3] and [14] in the engineering literature. For open canals, see [15]:

$$p\left(\rho_i(t,0+)\right) = p\left(\rho_j(t,0+)\right) \qquad \forall\, i \neq j.$$

(c) In case of only two connected pipes, a further coupling condition is proposed in [19] (see (4.7) for the definition of $k(\theta)$):

$$P\left(\rho_1(t,0+), q_1(t,0+)\right) + k(\theta) = P\left(\rho_2(t,0+), q_2(t,0+)\right).$$

Some remarks are in order. Most of the engineering literature uses (b) modified by so-called *minor loss* factors. These factors are listed in tables and depend on additional information; see [12, 21].

On the other hand, (a) is not so commonly used in the engineering literature but yields the $\mathbf{L^1}$ continuity across stationary transonic shocks (see [10, Example 2.3]), which does not hold when (b) or (c) is adopted. A numerical study of a two-dimensional situation for the p-system can be found in [18] and for the Euler system in [17].

4.1. Equal linear momentum flow for the *p*-system. We consider the setting in [10], i.e., a junction among n pipes, each modeled through the p-system (4.1) with a general pressure law and with the corresponding function Ψ in (1.2) given by (4.3) together with

$$\Psi(\rho, q) = \begin{bmatrix} P(\rho_1, q_1) & - & P(\rho_2, q_2) \\ \vdots & \vdots & \vdots \\ P(\rho_{n-1}, q_{n-1}) & - & P(\rho_n, q_n) \end{bmatrix}, \tag{4.4}$$

where $P(\rho, q) = q^2/\rho + p(\rho)$ is the flow of the linear momentum. The well posedness of the Cauchy problem for (4.1) at a junction was proved in [9, Theorem 3.3].

Remark that this choice of Ψ allows us to consider the problem at the junction as an extension of the standard Cauchy problem. Indeed, setting $n = 2$ and $\nu_1 + \nu_2 = 0$, then (4.1)–(4.4) reduces to the usual situation.

In the general case, the total linear momentum Q varies by

$$Q(t_2) - Q(t_1) = \int_{t_1}^{t_2} \sum_{l=1}^{n} P\left(\rho_l(t,0+), q_l(t,0+)\right) \nu_l dt = \left(\int_{t_1}^{t_2} P_*(t)\, dt \right) \sum_{l=1}^{n} \nu_l$$

(see [9, section 1]), where $P_*(t)$ is the trace of $P\left(\rho_l(t,0+), q_l(t,0+)\right)$, which is independent from l by (1.2)–(4.4). Note that the right-hand side in the equation above depends explicitly on the geometry of the junction.

4.2. Equal pressure for the *p*-system. In [3], the condition at the junction amounts to mass conservation and to pressure equality. Here we extend that approach to the case of n ducts with a general pressure law, so that (1.2) consists of (4.3) with

$$\Psi(\rho, q) = \begin{bmatrix} p(\rho_1) & - & p(\rho_2) \\ \vdots & \vdots & \vdots \\ p(\rho_{n-1}) & - & p(\rho_n) \end{bmatrix}. \tag{4.5}$$

Using [9, Lemma 4.4], the determinant in condition (2.2) evaluates to

$$(-1)^{n+1} \prod_{i=1}^{n} \lambda_2(\hat\rho_i, \hat q_i) \cdot \sum_{i=1}^{n} \prod_{j\neq i} \frac{p'(\hat\rho_j)}{\lambda_2(\hat\rho_j, \hat q_j)}\,. \tag{4.6}$$

Since $(\hat\rho, \hat q) \in \Omega^n$, we have $\lambda_2(\hat\rho_i, \hat q_i) > 0$, while the assumption **(P)** on the pressure law implies $p'(\hat\rho_i) > 0$. Thus, Theorem 3.2 applies, yielding well posedness in the case of n pipes with a general pressure law.

4.3. Two pipes with friction for the *p*-system. The case studied in [19] corresponds to (4.1) with $p(\rho) = \rho$, $n = 2$, $\nu_1 = [-1\ 0]$, and $\nu_2 = [\cos\theta\ \ \sin\theta]$. Here the angular dependence is modeled explicitly and taken into account in the coupling conditions. This situation mimics a kink forming an angle θ in a pipe. Due to the kink, the linear momentum is assumed to vary by a factor k such that

$$k = \sqrt{2(1 - \cos\theta)} \tag{4.7}$$

for $\theta \in [0, \pi/2]$. In the case of pipes possibly with different cross sections $\|\nu_l\|$ and a general pressure law satisfying **(P)**, at the junction we obtain condition (4.3) with

$$\Psi(\rho, q) = \left(\frac{q_1^2}{\rho_1} + p(\rho_1) + fkq_1\right) - \left(\frac{q_2^2}{\rho_2} - p(\rho_2)\right), \tag{4.8}$$

which reduces to the case considered in [19] when $p(\rho) = \rho$ and equal cross sections. The parameter f denotes a nonnegative empirical friction coefficient. The condition (2.2) is

$$\lambda_2(\hat\rho_2, \hat q_2)\, \lambda_2(\hat\rho_1, \hat q_1)\, \big(\lambda_2(\hat\rho_2, \hat q_2) + \lambda_2(\hat\rho_1, \hat q_1) + fk\big) \neq 0\,.$$

Hence, Theorem 3.2 applies, yielding well posedness for general pressure laws.

4.4. Equal momentum flow for open canals. The model presented in [20, formulae (2.3)–(2.7)] for a node among n open canals reads

$$\begin{cases} \partial_t A_l + \partial_x (A_l\, V_l) = 0, \\ \partial_t V_l + \partial_x \left(\dfrac{1}{2} {V_l}^2 + g\, h(A_l)\right) = 0, \end{cases} \qquad \begin{aligned} t &\in \mathbb{R}^+, \\ x &\in \mathbb{R}^+, \\ l &\in \{1, \dots, n\}, \\ (A_l, V_l) &\in \mathring{\mathbb{R}}^+ \times \mathbb{R}, \end{aligned} \tag{4.9}$$

where V_l is the water speed in the lth canal, A_l is the vertical cross section occupied by the water, g is gravity, and h is the water level. Here, differently from [20], we assume

that the canals' beds are all at the same height above sea level, which is acceptable in a neighborhood of the node among the pipes.

Other descriptions for the dynamics of open canals are found in the literature. In particular, [15, section 6.1] presents a different model, based on [13], that fits into our framework of section 4.2.

The coupling condition at the node is given by [20, formulae (2.9)–(2.16)]:

$$\Psi(A,V) = \begin{bmatrix} \displaystyle\sum_{l=1}^{n} A_l\, V_l \\ \displaystyle\frac{1}{2}{V_1}^2 + g\, h(A_1) - \frac{1}{2}{V_2}^2 - g\, h(A_2) \\ \vdots \qquad \vdots \qquad \vdots \\ \displaystyle\frac{1}{2}{V_{n-1}}^2 + g\, h(A_{n-1}) - \frac{1}{2}{V_n}^2 - g\, h(A_n) \end{bmatrix}.$$

The first component in Ψ ensures the conservation of water. For a motivation for the other components, we refer the reader to [20, formulae (2.9)–(2.16)].

This condition is analogous to the equal linear momentum flow condition (4.4) discussed in section 4.1.

Choosing an initial datum $\bar u = (\bar A, \bar V)$ such that $\bar V < \sqrt{\bar A g h'(\bar A)}$ ensures that **(F)** is fulfilled at $\bar u$. In the present case we have

$$\begin{aligned} \lambda_1(A,V) &= V - \sqrt{Agh'(A)}\,, & \lambda_2(\rho,q) &= V + \sqrt{Agh'(A)}\,, \\ r_1(A,V) &= \begin{bmatrix} \sqrt{A} \\ -\sqrt{gh'(A)} \end{bmatrix}, & r_2(A,V) &= \begin{bmatrix} \sqrt{A} \\ \sqrt{gh'(A)} \end{bmatrix}. \end{aligned}$$

The determinant in condition (2.2) evaluates therefore to

$$(-1)^{n+1} \left(\prod_{i=1}^{n} \lambda_2(\bar A_i, \bar V_i) \right) \cdot \sum_{i=1}^{n} \sqrt{\bar A_i} \prod_{j\neq i} \sqrt{gh'(\bar A_j)}\,.$$

Here $A > 0$ by assumption, as well as $\sqrt{gh'(A)} > 0$ by the monotonicity of $h(A)$, which ensures that $\lambda_2(A,V) > 0$. Thus, Theorem 3.2 can be applied, yielding the well posedness for a junction of n open canals.

4.5. Numerical examples for the *p*-system. This section is devoted to comparisons among the different coupling conditions at the junction in the case of the p-system (4.1). Throughout, we use the γ-law: $p(\rho) = p_* \cdot (\rho/\rho_*)^\gamma$ with $\gamma = 1.4$, $\rho_* = 1$, and $p_* = 1$, which clearly satisfies **(P)**. In the case of the coupling conditions (4.8), we set $f \equiv 1$.

In general, stationary solutions for (4.4) fail to be stationary solutions for (4.5) or (4.8). Therefore, we perturb below *static* solutions, which are stationary for all coupling conditions and allow the comparisons.

Below the initial data $u_l(x) = (\rho_l(x), q_l(x))$ along the lth duct attains at most two values, say $u_l^\infty = \lim_{x\to+\infty} u_l(x)$ and $u_l^0 = \lim_{x\to 0+} u_l(x)$. When waves hit the junction, we solve numerically condition (1.2) using Newton's method and obtain the traces u_l^+ of the solution at the junction. The solution to (2.1) is then computed

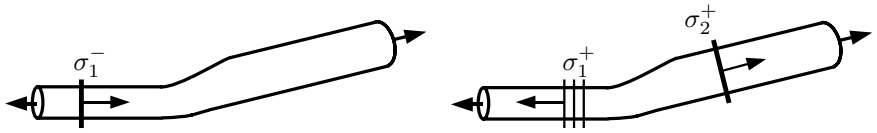

FIG. 1. *Kink with a small angle. Left: a shock approaches a kink with a small angle. Right: a rarefaction is reflected and a shock is refracted.*

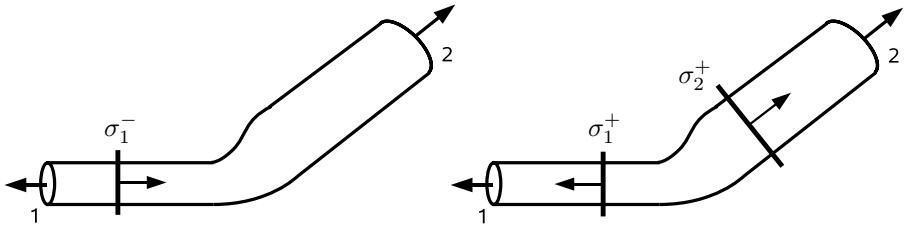

FIG. 2. *Kink with a large angle. Left: a shock approaches a kink. Right: according to condition* (4.8)*, a shock is reflected and a shock is refracted.*

solving a classical Riemann problem between the states u_l^+ (on the left) and u_l^∞ (on the right). Due to the chosen directions of the space variables, waves approaching the junction belong to the first family and those exiting it to the second.

We selected three different examples. In the case of the coupling conditions (4.4) and (4.5), only the cross section of the connected pipes appears explicitly. In the case of (4.8), the angular dependence is taken into account explicitly.

Remark that the numerical values provided in the tables below are expressed in the coordinates x_l adapted to the junction. In particular, the column *Wave speed* is the modulus of the propagation speed of the wave; its x and y components depend on the direction of the pipe. In case of rarefactions, the column *Wave speed* displays the minimal and maximal moduli of the propagation speeds.

4.5.1. Two pipes, different cross sections, possibly different angles. Consider a junction between $n = 2$ horizontal pipes having cross sections $\|\nu_1\| = 1$ and $\|\nu_2\| = 2$. The situation is depicted in Figures 1 and 2. We choose the cases $\theta = 0$, $\theta = \pi/4$, $\theta = \pi/16$, and $\theta = \pi/32$. In each of these cases, a shock with right state $u_1^0 = [1.1000, -0.1253]$ propagating along pipe 1 hits the junction. At first, we compare conditions (4.4) and (4.5). In Table 1, the first column refers to the coupling condition; in the case of (4.8), Table 2 displays the angle θ. The type of the resulting wave is in the fifth column, where S and R refer to 2-(Lax-)shocks and 2-rarefaction waves, respectively.

These numerical integrations suggest that, according to (4.8), there exists an angle θ_* at which no wave is reflected. Clearly, θ_* depends on the initial states, on the ducts' sections, and on the empirical factor f.

4.5.2. Three pipes, different cross sections. Consider $n = 3$ pipes identified by $\nu_1 = [-1 - \sqrt{2} \quad 0]^T$, $\nu_2 = [1 \; 1]^T$, and $\nu_3 = [1 \; 0]^T$ and having cross sections $\|\nu_l\|$. The situation is depicted in Figure 3. Again, we assume that the flow is initially at rest, i.e., $\hat{q}_l = 0$ for $l = 1, 2, 3$. We consider the case of a shock approaching the junction along pipe 1. Due to the choice of the initial data and to the geometry of the junction, the numerical solutions to both coupling conditions (4.4) and (4.5) in fact yield the same results. The final states and the corresponding waves are in Table 3.

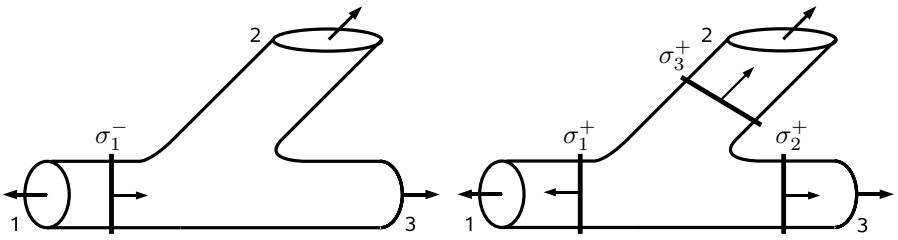

FIG. 3. *A shock hitting a T-junction.*

4.5.3. Four pipes, different cross sections. Finally, we consider a junction with $n = 4$ pipes defined by $\nu_1 = [-1\ 0]$, $\nu_2 = [0\ 1]$, $\nu_3 = [0\ -1]$, and $\nu_4 = [1\ 0]$. The situation is depicted in Figure 4. Initially the gas flow is at rest, i.e., $\hat{q}_l = 0$, and $\hat{\rho}_l = 1$ for $l = 1, \dots, 4$. We let three 1-Lax-shocks of different strengths collide simultaneously at the junction along pipes 1, 3, and 4.

It is remarkable that the two coupling conditions yield qualitatively different results. The wave reflected in tube 1 is a rarefaction according to (4.4) and a shock according to (4.5). However, the propagation speeds in the two cases are close to each other, coherently with the $\mathbf{L^1}$ continuous dependence.

Table 4 displays, for each duct, the type of wave arising after the interaction at the junction, and its speed is reported below for the two different coupling conditions (4.4) and (4.5).

5. Technical details. As a general reference on the theory of hyperbolic systems of conservation laws, we refer the reader to [6]. Denote by $\sigma \mapsto \mathcal{L}_i(u_o, \sigma)$ the ith Lax curve through u_o for $i = 1, 2$. As usual, $\mathcal{O}(1)$ denotes a sufficiently large constant dependent only on f restricted to a neighborhood of the initial states.

Proof of Proposition 2.2. It is sufficient to show that for all $\bar{u}$ sufficiently near $\hat{u}$ the nonlinear system $\Psi\left(\mathcal{L}_2(\bar{u}_1, \sigma_1), \dots, \mathcal{L}_2(\bar{u}_n, \sigma_n)\right) = 0$ admits a unique n-tuple of solution $\sigma_1, \dots, \sigma_n$. Indeed, condition (2.2) allows us to use the implicit function theorem.

The Lipschitz estimate (2.4) follows immediately from the regularity of the implicit function.

To prove the latter statement, it is sufficient to consider a single pipe, say the first one. Let u, respectively, $\tilde{u}$, be the solutions to (2.1) with condition Ψ, respectively, $\tilde{\Psi}$, at the junction. If u and $\tilde{u}$ contain a single shock, then

$$
\begin{aligned}
&\|u - \tilde{u}\| \\
&= \int_0^{\min\{\Lambda^1, \Lambda^2\}t} \|u(x) - \tilde{u}(x)\| \, dx \\
&\quad + \int_{\min\{\Lambda^1, \Lambda^2\}t}^{\max\{\Lambda^1, \Lambda^2\}t} \|u(x) - \tilde{u}(x)\| \, dx \\
&= \mathcal{O}(1) \cdot \|u(t, 0+) - \tilde{u}(t, 0+)\| \cdot t + \mathcal{O}(1) \cdot \left|\Lambda^2 - \Lambda^1\right| \cdot t \\
&= \mathcal{O}(1) \cdot \left\|\tilde{\Psi} - \Psi\right\|_{\mathbf{C^1}} \cdot t + \mathcal{O}(1) \cdot \|u(t, 0+) - \tilde{u}(t, 0+)\| \cdot t \\
&= \mathcal{O}(1) \cdot \left\|\tilde{\Psi} - \Psi\right\|_{\mathbf{C^1}} \cdot t \, .
\end{aligned}
$$

The case of one or both solutions containing a rarefaction is similar; see also the proof of [5, Corollary 2.5]. □

We now pass to the proof of Theorem 3.2. To do this, we first use wave front tracking to construct approximate solutions to the Cauchy problem (3.1) adapting the wave front tracking technique; see [6, Chapter 7].

Let $\hat{\delta} > 0$ be such that the closed sphere $\overline{B(\hat{u}_l, \hat{\delta})} \subset \Omega$ for $l = 1, \dots, n$, and introduce the compact set $\mathcal{B} = \prod_{l=1}^n \overline{B(\hat{u}_l, \hat{\delta})}$. We omit the proof of the following simple estimate.

LEMMA 5.1. *For all $u \in \overline{B(\hat{u}, \hat{\delta})}$ there exists $C > 0$ such that if $\|u - \hat{u}\| < \hat{\delta}$ and $\|\mathcal{L}_i(u; \sigma) - u\| \leq \hat{\delta}$, then*

$$
\frac{1}{C} \cdot |\sigma| \leq \|\mathcal{L}_i(u; \sigma) - u\| \leq C \cdot |\sigma| \, .
$$

Fix $\varepsilon > 0$. Approximate the initial datum u_o with a sequence $u_{o,\varepsilon}$ of piecewise constant initial data each having a finite number of discontinuities so that $\lim_{\varepsilon \to 0} \left\|u_{o,\varepsilon} - u_o\right\|_{\mathbf{L^1}} = 0$. Then, at the junction and at each point of jump in the approximate initial datum along the pipes, we solve the corresponding Riemann problem according to Definition 2.1. If the total variation of the initial datum is sufficiently small, then Proposition 2.2 ensures the existence and uniqueness of solutions to the Riemann problem. We approximate each rarefaction wave with a rarefaction fan,

i.e., by means of (nonentropic) shock waves traveling at the characteristic speed of the state to the right of the shock and with size at most ε.

This construction can be extended up to the first time $\bar{t}_1$ at which two waves interact in a pipe or a wave hits the junction. Clearly, at time $\bar{t}_1$ the functions so constructed are piecewise constant with a finite number of discontinuities. Hence, at any subsequent interaction or collision with the junction, we repeat the previous construction with the following provisions:

1. no more than two waves interact at the same point or at the junction;
2. a rarefaction fan of the ith family produced by the interaction between an ith rarefaction and any other wave is *not* split any further;
3. when the product of the strengths of two interacting waves falls below a threshold $\check{\varepsilon}$, then we let the waves cross each other, their size being unaltered, and introduce a *nonphysical* wave with speed $\hat{\lambda}$, with $\hat{\lambda} > \sup_u \lambda_2(u)$; see [6, Chapter 7] and the refinement [1].

In the present case, we have to complete the above algorithm stating how the Riemann problem at the junction is to be solved. At time $t = 0$ and whenever a physical wave with size greater than $\check{\varepsilon}$ hits the junction, the accurate solver is used; i.e., the exact solution as in Definition 2.1 is approximated by replacing rarefaction waves with rarefaction fans. When a wave with strength smaller than $\check{\varepsilon}$ hits the junction, then we let it be reflected into a nonphysical wave with speed $\hat{\lambda}$, and no wave in any other pipe is produced.

Repeating recursively this procedure, we construct a wave front tracking sequence of approximate solutions u_ε in the sense of [6, Definition 7.1].

At interactions of waves in a pipe, we have the following classical result.

LEMMA 5.2. *There exists a constant K with the following property.*

1. *If there is an interaction in a pipe between two waves σ_1^- and σ_2^-, respectively, of the first and second family, producing the waves σ_1^+ and σ_2^+ (see Figure 5, left), then*

$$\left|\sigma_1^+ - \sigma_1^-\right| + \left|\sigma_2^+ - \sigma_2^-\right| \leq K \cdot \left|\sigma_1^- \sigma_2^-\right|. \tag{5.1}$$

2. *If there is an interaction in a pipe between two waves σ_i' and σ_i'' of the same ith family producing waves of total size σ_1^+ and σ_2^+ (see Figure 5, right, for the case $i = 2$), then*

$$\left|\sigma_1^+ - (\sigma_1'' + \sigma_1')\right| + \left|\sigma_2^+\right| \leq K \cdot \left|\sigma_1' \sigma_1''\right| \qquad \text{if } i = 1,$$

$$\left|\sigma_1^+\right| + \left|\sigma_2^+ - (\sigma_2'' + \sigma_2')\right| \leq K \cdot \left|\sigma_2' \sigma_2''\right| \qquad \text{if } i = 2.$$

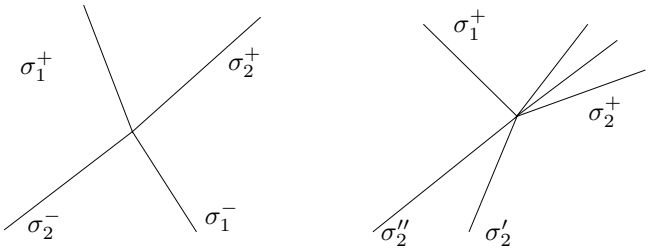

FIG. 5. *Notation for the standard interaction estimates in Lemma* 5.2.

3. *If there is an interaction in a pipe between two physical waves* σ_1^- *and* σ_2^- *producing a nonphysical wave* σ_3^+ *(see Figure* 6*, left), then*

$$\left|\sigma_3^+\right| \leq K \cdot \left|\sigma_1^- \sigma_2^-\right|.$$

4. *If there is an interaction in a pipe between a physical wave* σ *and a nonphysical wave* σ_3^- *producing a physical wave* σ *and a nonphysical wave* σ_3^+ *(see Figure* 6*, right), then*

$$\left|\sigma_3^+\right| - \left|\sigma_3^-\right| \leq K \cdot \left|\sigma\sigma_3^-\right|.$$

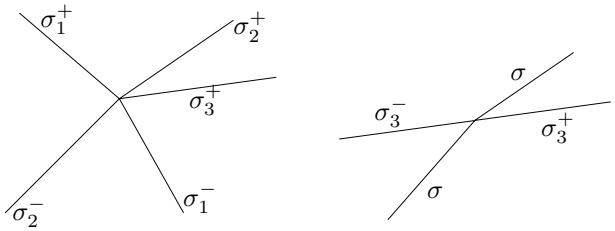

FIG. 6. *Left: a nonphysical wave arises. Right: a nonphysical wave hits a physical one.*

For a proof of this result see [6, Chapter 7]. By construction, nonphysical waves cannot interact with the junction or with other nonphysical waves. In the case of the junction, we have the following result, with notation as depicted in Figure 7.

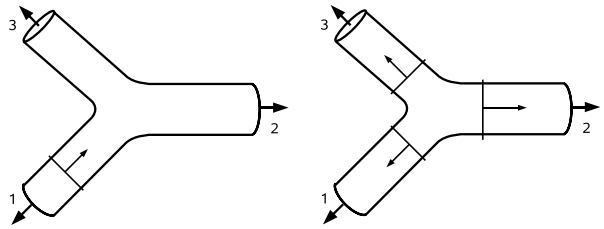

FIG. 7. *Notation for Proposition* 5.3*. Left: before the interaction. Right: after the interaction.*

PROPOSITION 5.3. *There exist* $\delta_J > 0$ *and* $K_J \geq 1$ *with the following property. For any* $\bar{u} \in \mathcal{B}$ *that yields a stationary solution to the Riemann problem* (2.1)*, and for any* 1*-waves* $\sigma_{\bar{l}}^- \in]-\delta_J, \delta_J[$ *hitting the junction and producing the* 2*-waves* σ_l^+*,*

$$\sum_{l=1}^{n} \left|\sigma_l^+\right| \leq K_J \cdot \left|\sigma_{\bar{l}}^-\right|. \tag{5.2}$$

The proof follows immediately from (2.4) and Lemma 5.1.

Define $\bar{K} = 2KK_J + 1$. Fix a wave front tracking approximate solution u_ε. For $t > 0$ and $l \in \{1, \ldots, n\}$, we denote with $\{x_{l,\alpha} : \alpha \in \mathcal{J}_l(u)\}$ the set of the positions of the discontinuities of the approximate solution u in the lth pipe and with $\sigma_{l,1,\alpha}$, $\sigma_{l,2,\alpha}$, $\sigma_{l,3,\alpha}$ the strengths of the waves, respectively, of the first family, of the second family, and of the nonphysical waves at $x_{l,\alpha}$. Introduce the Glimm-type functionals

$$V(t) = \sum_{l=1}^{n} \sum_{\alpha \in \mathcal{J}_l} \left(2\,K_J \cdot \left|\sigma_{l,1,\alpha}\right| + \left|\sigma_{l,2,\alpha}\right| + \left|\sigma_{l,3,\alpha}\right|\right), \tag{5.3}$$

$$Q(t) = \sum_{l=1}^{n} \sum \left\{ \left|\sigma_{l,i,\alpha}\, \sigma_{l,j,\beta}\right| : (\sigma_{l,i,\alpha}, \sigma_{l,j,\beta}) \in \mathcal{A}_l \right\},$$

$$\Upsilon(t) = V(t) + \check{K} \cdot Q(t)\,,$$

where $\mathcal{A}_l$ denotes the set of approaching waves in the lth pipe; see [6, section 7.3].

The functionals above are well defined for every $t > 0$ at which no interaction takes place. Now suppose that at a time $\tau > 0$ there is an interaction between the wave $\sigma_{\bar{l},1}$ of the first family and the junction. In general, this interaction produces n waves $\sigma^+_{l,2}$ of the second family. Thus

$$\Delta V(\tau) \le \left(\sum_{l=1}^{n} \left|\sigma^+_{l,2}\right| \right) - 2\, K_J \left|\sigma_{\bar{l},1}\right| \;\le\; -K_J \cdot \left|\sigma_{\bar{l},1}\right|,$$

$$\Delta Q(\tau) \le \sum_{l=1}^{n} \left(\left|\sigma^+_{l,2}\right| \sum_{i,\alpha} \left|\sigma_{l,i,\alpha}\right| \right) \;\le\; K_J \cdot V(\tau-) \cdot \left|\sigma_{\bar{l},1}\right|,$$

$$\Delta\Upsilon(\tau) \le K_J \cdot \left(\check{K} \cdot V(\tau-) - 1 \right) \cdot \left|\sigma_{\bar{l},1}\right|.$$

Now suppose an interaction between two waves $\sigma_{l,i,\alpha}$, $\sigma'_{l,j,\beta}$ happens in a pipe at time τ. By Lemma 5.2 we deduce that

$$\Delta V(\tau) \le 2 \cdot K \cdot K_J \cdot \left|\sigma_{l,i,\alpha}\sigma'_{l,j,\beta}\right|,$$

$$\Delta Q(\tau) \le K \cdot \left|\sigma_{l,i,\alpha}\sigma'_{l,j,\beta}\right| \cdot V(\tau-) - \left|\sigma_{l,i,\alpha}\sigma'_{l,j,\beta}\right|,$$

$$\Delta\Upsilon(\tau) \le \left|\sigma_{l,i,\alpha}\sigma'_{l,j,\beta}\right| \left(K \cdot (2 \cdot K_J + \check{K} \cdot V(\tau-)) - \check{K} \right).$$

We have thus proved the following basic result.

PROPOSITION 5.4. *Let* $\check{\delta} = \min\{1/(2\check{K}+1), 1/(2K\check{K}+1), \hat{\delta}, \delta_J\}$. *At any interaction time* $\tau > 0$, *if* $V(\tau-) < \check{\delta}$, *then* $\Delta\Upsilon(\tau) < 0$ *with* Υ *defined in* (5.4).

Proof of Theorem 3.2. Let $\check{\delta}$ be as in Proposition 5.4, and define

$$\tilde{\mathcal{D}} = \left\{ u \in \hat{u} + \mathbf{L^1}\left(\mathbb{R}^+; (\mathring{\mathbb{R}}^+ \times \mathbb{R})^n\right) : u \in \mathbf{PC} \text{ and } \Upsilon(u) \le \check{\delta} \right\};$$

here **PC** denotes the set of piecewise constant functions with finitely many jumps. It is immediate to prove that there exists a suitable $C_1 > 0$ such that $\frac{1}{C_1}\,\mathrm{TV}\,(u)(t,\cdot) \le V(t) \le C_1\,\mathrm{TV}\,(u)(t,\cdot)$ for all $u \in \tilde{\mathcal{D}}$. Any initial data in $\tilde{\mathcal{D}}$ yields an approximate solution to (1.1) attaining values in $\tilde{\mathcal{D}}$ by Proposition 5.4.

We now pass to the $\mathbf{L^1}$-Lipschitz continuous dependence of the approximate solutions from the initial datum. Consider two wave front tracking approximate solutions u_1 and u_2. Define the functional

$$\Phi\,(u_1, u_2) = \sum_{l=1}^{n} \sum_{i=1}^{2} \int_0^{+\infty} \left|s_{l,i}(x)\right| W_{l,i}(x)\, dx\,, \tag{5.4}$$

where $s_{l,i}(x)$ measures the strengths of the ith shock wave in the lth pipe at point x (see [6, Chapter 8]) and the weights $W_{l,i}$ are defined by

$$W_{l,1}(x) = \hat{K} \cdot \left(1 + \kappa_1 \, A_{l,i}(x) + \kappa_1 \, \kappa_2 \, \left(\Upsilon(u_1) + \Upsilon(u_2)\right)\right),$$
$$W_{l,2}(x) = 1 + \kappa_1 \, A_{l,i}(x) + \kappa_1 \, \kappa_2 \, \left(\Upsilon(u_1) + \Upsilon(u_2)\right)$$

for suitable positive constants κ_1, κ_2 chosen as in [6, formula (8.7)] and $\hat{K} = 1 + (\max_l W_{l,2}) \, K_j \, \hat{\lambda}/|\inf \lambda_1|$. Here Υ is the functional defined in (5.4), while the $A_{l,i}$ are defined by

$$A_{l,i}(x) = \sum \left\{ \left|\sigma_{l,k_\alpha,\alpha}\right| \colon \begin{array}{l} x_\alpha < x, \, i < k_\alpha \leq 2 \\ x_\alpha > x, \, 1 \leq k_\alpha < i \end{array} \right\}$$
$$+ \begin{cases} \displaystyle\sum \left\{ \left|\sigma_{l,i,\alpha}\right| \colon \begin{array}{l} x_\alpha < x, \, \alpha \in \mathcal{J}_l(u_1) \\ x_\alpha > x, \, \alpha \in \mathcal{J}_l(u_2) \end{array} \right\} & \text{if } s_{l,i}(x) < 0, \\ \displaystyle\sum \left\{ \left|\sigma_{l,i,\alpha}\right| \colon \begin{array}{l} x_\alpha < x, \, \alpha \in \mathcal{J}_l(u_2) \\ x_\alpha > x, \, \alpha \in \mathcal{J}_l(u_1) \end{array} \right\} & \text{if } s_{l,i}(x) \geq 0; \end{cases}$$

see [6, Chapter 8]. We first fix κ_1, κ_2, so that $\check{\delta}$ in the definition of $\tilde{\mathcal{D}}$ can be chosen to make $W_{l,i}(x) \geq 1$ and uniformly bounded for every $l \in \{1, \dots, n\}$, $i \in \{1, 2\}$, and $x \geq 0$. Hence the functional Φ is equivalent to $\mathbf{L^1}$ distance:

$$\frac{1}{C_2} \cdot \|u_1 - u_2\|_{\mathbf{L^1}} \leq \Phi\left(u_1, u_2\right) \leq C_2 \cdot \|u_1 - u_2\|_{\mathbf{L^1}}$$

for a positive constant C_2. The same calculations as in [6, Chapter 8] show that, at any time $t > 0$ when an interaction happens neither in u_1 nor in u_2,

$$\begin{aligned} &\frac{d}{dt} \Phi\left(u_1(t), u_2(t)\right) \\ &\leq C_3 \, \varepsilon + \sum_l \sum_i \left|s_{l,i}(0+)\right| W_{l,i} \, \lambda_{l,i}(0+) \\ &\leq C_3 \, \varepsilon - \left(\sum_l \left|s_{l,1}(0+)\right|\right) \hat{K} \left|\inf_l \lambda_{l,1}\right| + K_J \left(\sum_l \left|s_{l,1}(0+)\right|\right) \max_l W_{l,2} \, \hat{\lambda} \\ &\leq C_3 \, \varepsilon + \sum_l \left|s_{l,1}(0+)\right| \left(K_J \max_l W_{l,2} \, \hat{\lambda} - \hat{K} \left|\inf \lambda_{l,1}\right|\right) \\ &\leq C_3 \, \varepsilon \, , \end{aligned}$$

where C_3 is a suitable positive constant depending only on a bound on the total variation of the initial data. Above we used the analogue of Proposition 5.3 for shock curves, i.e., if $\Psi(S_2(S_1(u, q_{l,1}), q_{l,2})) = 0$, then $\sum_l \left|q_{l,2}\right| \leq K_J \sum_l \left|q_{l,1}\right|$, for a suitable K_J.

If $t > 0$ is an interaction time for u_1 or u_2, then, by Proposition 5.4, $\Delta[\Upsilon(u_1(t)) + (u_2(t))] < 0$ and, choosing κ_2 large enough, we obtain

$$\Delta \Phi\left(u_1(t), u_2(t)\right) < 0 \, .$$

Thus, $\Phi\left(u_1(t), u_2(t)\right) - \Phi\left(u_1(s), u_2(s)\right) \leq C_2\, \varepsilon\, (t-s)$ for every $0 \leq s \leq t$. The proof is now completed using the standard arguments in [6, Chapter 8].

The proof that the semigroup trajectory does indeed yield a solution to (3.1) and, in particular, that **(Ψ)** is satisfied on the traces is exactly as that of [7, Proposition 5.3].

We now pass to the stability estimate (3.2). Its proof is similar to those of [5, Theorem 2.1] or [8, Theorem 3.1] and is based on [6, Theorem 2.9], which we recall for convenience: for every Lipschitz map $w\colon [0,T] \to \mathcal{D}$ and every Lipschitz semigroup $S\colon [0,+\infty[\, \times \mathcal{D} \to \mathcal{D}$, the following estimate holds:

$$\|w(T) - S_T w(0)\|_{\mathbf{L^1}} \leq L \cdot \int_0^T \left(\liminf_{h \to 0+} \frac{1}{h} \|w(t+h) - S_h w(t)\|_{\mathbf{L^1}} \right) dt\,,$$

L being the Lipschitz constant of S. In the present case, we are led to

$$\left\| S^{\tilde\Psi}_t u - S^{\Psi}_t u \right\|_{\mathbf{L^1}} \leq L^{\Psi} \cdot \int_0^t \left(\liminf_{h \to 0+} \frac{1}{h} \left\| S^{\Psi}_h S^{\Psi}_\tau u - S^{\tilde\Psi}_h S^{\Psi}_\tau u \right\| \right) d\tau\,.$$

It remains to estimate $\|S^{\Psi}_h v - S^{\tilde\Psi}_h v\|_{\mathbf{L^1}}$ for $v = S^{\Psi}_\tau u$. We use the wave front tracking approximations $v^{\Psi,\varepsilon}(h,\cdot) = S^{\Psi,\varepsilon}_h u$ and $v^{\tilde\Psi,\varepsilon}(h,\cdot) = S^{\tilde\Psi,\varepsilon}_h u$. For $h > 0$ sufficiently small, we can assume that there is at most a single interaction of the waves of $u \in \mathcal{D}$ with the intersection. Then $S^{\Psi,\varepsilon}_h$ coincides with the Riemann solver of Proposition 2.2, and estimate (2.4) can be applied:

$$\left\| S^{\Psi}_h u - S^{\tilde\Psi}_h u \right\| \leq L^{\Psi} \|\Psi_1 - \Psi_2\|_{\mathbf{C^1}} h\,.$$

Since the right-hand side is independent of ε and since $S^{\Psi,\varepsilon}_h u$ converges in $\mathbf{L^1}$ to $S^{\Psi}_h u$, we obtain

$$\left\| S^{\Psi}_h u - S^{\tilde\Psi}_h u \right\|_{\mathbf{L^1}} \leq \int_0^t \left(\liminf_{h \to 0+} \frac{1}{h} \cdot \left\| \Psi - \tilde\Psi \right\|_{\mathbf{C^1}} \cdot h \right) d\tau \leq L^{\Psi} \cdot \left\| \Psi - \tilde\Psi \right\|_{\mathbf{C^1}} \cdot t,$$

completing the proof. □

A VARIATIONAL PRINCIPLE FOR HARDENING ELASTOPLASTICITY*

ULISSE STEFANELLI†

Abstract. We present a variational principle governing the quasi-static evolution of a linearized elastoplastic material. In the case of linear hardening, the novel characterization allows us to recover and partly extend some known results and proves itself to be especially well suited for discussing general approximation and convergence issues. In particular, the variational principle is exploited in order to prove in a novel setting the convergence of time and space-time discretizations as well as to provide some possible a posteriori error control.

Key words. variational principle, elastoplasticity, approximation

1. Introduction. The primal initial-boundary value problem of elastoplasticity consists in determining the generalized deformation state of a material subject to external mechanical actions. In particular, starting from some initial state and for a given load and traction, one shall determine the displacement u of the body from the reference configuration, the inelastic (plastic) part p of its strain, and, possibly, a vector of internal hardening variables ξ. In the small deformation regime and within the frame of associative elastoplasticity, the problem is classically formulated in a variational form as that of finding the absolutely continuous trajectory $t \in [0,T] \mapsto y(t) \in Y$ (Y is a Banach space) such that

$$\partial\psi(\dot{y}) + Ay \ni \ell \quad \text{a.e. in } (0,T), \quad y(0) = y_0, \tag{1.1}$$

where $y = (u, p, \xi)$ stands for the vector of unknown fields, $A : Y \to Y^*$ (dual) is linear, continuous, and symmetric, and $\psi : Y \to [0,\infty]$ is the positively 1-homogeneous and convex dissipation potential (∂ is the classical subdifferential in the sense of convex analysis; see below). Moreover, $\ell : [0,T] \to Y^*$ is a given and suitably smooth generalized load (possibly including surface tractions), and y_0 represents the initial state. The reader is referred to section 2 for some brief mechanical motivation as well as to the classical monographs by Duvaut and Lions [7], Han and Reddy [13], Lemaitre and Chaboche [18], and Simo and Hughes [42] for a comprehensive collection of results.

The aim of this paper is that of investigating a global-in-time variational formulation of problem (1.1). In particular, we shall introduce the functional $\mathcal{F} : W^{1,1}(0,T;Y) \to [0,\infty]$ on trajectories as

$$\mathcal{F}(y) = \int_0^T \big(\psi(\dot{y}) + \psi^*(\ell - Ay) - \langle \ell - Ay, \dot{y}\rangle\big),$$

where ψ^* stands for the conjugate $\psi^*(w) = \sup_{v\in Y}(\langle w, v\rangle - \psi(v))$ of ψ and $\langle\cdot,\cdot\rangle$ denotes the duality pairing between Y^* and Y. The starting point of this analysis relies on the fact that solutions of (1.1) and minimizers of $\mathcal{F}$ fulfilling the initial condition and making $\mathcal{F}$ zero coincide, namely (see Theorem 3.1),

$$y \text{ solves (1.1)} \quad \text{iff} \quad \mathcal{F}(y) = \min \mathcal{F} = 0 \ \text{ and } \ y(0) = y_0. \tag{1.2}$$

This variational characterization has a clear mechanical interpretation. Indeed, since ψ is positively 1-homogeneous, its conjugate ψ^* turns out to be the indicator function of the convex set $\partial\psi(0)$. Hence, $\min \mathcal{F}$ is actually a constrained minimization problem, and we have

$$\mathcal{F}(y) = 0 \quad \text{iff} \quad \begin{cases} \ell - Ay \in \partial\psi(0) \quad \text{a.e. in } \ (0,T), \\ \varphi(T, y(T)) + \displaystyle\int_0^T \psi(\dot{y}) = \varphi(0, y(0)) - \int_0^T \langle \dot{\ell}, y\rangle, \end{cases} \tag{1.3}$$

where we have used the notation $(t,y) \mapsto \varphi(t,y) = \frac{1}{2}\langle Ay, y\rangle - \langle \ell(t), y\rangle$. The first relation above expresses the so-called *local stability* [26] of the trajectory, whereas the second is nothing but the energy balance at time T. More precisely, $\varphi(t,y)$ denotes the complementary energy at time t for the state y, $\int_0^T \psi(\dot{y})$ represents the dissipation of the system on $[0,T]$, and $-\int_0^T \langle \dot{\ell}, y\rangle$ is related to external actions on $[0,T]$. Hence, minimizing $\mathcal{F}$ consists in selecting the (only) stable trajectory which conserves the energy. In this regards, the reader is referred to the pioneering papers by Moreau [33, 34, 35].

The interest of variational characterization (1.2) of the differential problem (1.1) relies on the possibility of exploiting the general tools from the calculus of variations. Some care is, however, required. Indeed, although $\mathcal{F}$ is convex and lower semicontinuous with respect to the weak topology of $W^{1,1}(0,T;Y)$, the functional generally fails to be coercive. Moreover, one is not just asked to minimize $\mathcal{F}$ but also to prove that the minimum is 0. These considerations suggest that the direct method is hardly applicable in order to get solutions to (1.1) via the characterization in (1.2).

The first issue of this paper is that of exploiting the variational principle in (1.2) in order to address general approximation procedures. Since solutions and minimizers coincide, a natural tool in order to frame an abstract approach to limiting procedures within (1.1) is that of considering the corresponding minimum problems via Γ-convergence [11]. As the value of the functional is directly quantified to be 0 on the minimizers, what is actually needed here for passing to limits are so-called Γ-lim inf inequalities only, and the latter are generally easily available. We shall specifically focus on the case of linear hardening elastoplasticity and apply the above-mentioned perspective in order to recover in a unified and more transparent frame and partly generalize some convergence results for conformal finite elements (Theorem 5.3), time discretizations (Theorem 6.5), and fully discrete space-time approximations (Theorem 7.1). In particular, for time discretization we develop a discrete version of the variational principle (1.2) in the same spirit of the theory of *variational integrators* [25] (see subsection 6.1). This connection entails also some generalized view at the classical discrete time schemes (see subsection 6.5).

A second novel point of the present variational approach consists in the possibility of exploiting $\mathcal{F}$ in order to estimate a posteriori some approximation error. By letting $\mathcal{F}(y) = 0$, we will check that (Corollary 4.5)

$$\max_{[0,T]} \frac{1}{2}\langle A(y-v), y-v\rangle \le \mathcal{F}(v) \quad \forall v \in W^{1,1}(0,T;Y), \quad v(0) = y_0.$$

If A shows some coercivity (which is precisely the case of linearized hardening; see subsection 2.4), and v is the outcome of some approximation procedure, the estimate above may serve as the basis for some a posteriori estimation procedure, possibly headed to adaptivity (see subsection 6.7). Let us stress that the latter and (1.3) entail that the distance of a (stable) trajectory from the solution to (1.1) can be uniformly estimated by means of its energy production along the path.

The variational characterization in (1.2) is strictly linked to the celebrated principle by Brezis, Ekeland, and Nayroles [3, 4, 38, 39] for the gradient flow of a convex functional $j : Y \to (-\infty, \infty]$ in a Hilbert space Y, namely,

$$\dot{y} + \partial j(y) \ni \ell \quad \text{a.e. in } (0,T). \tag{1.4}$$

In particular, by using the convexity of j (see details in section 3.1), this inclusion may be equivalently rewritten as the scalar relation

$$j(y) + j^*(\ell - \dot{y}) - \langle \ell - \dot{y}, y \rangle = 0 \quad \text{a.e. in } (0,T), \tag{1.5}$$

where j^* is the conjugate of j. As the above left-hand side is a.e. nonnegative for all trajectories y and it is 0 iff y solves (1.4), the latter is equivalent to minimize the global functional

$$\mathcal{I}(y) = \int_0^T \Big(j(y) + j^*(\ell - \dot{y}) - \langle \ell - \dot{y}, y \rangle \Big)$$

and check that $\mathcal{I}(y) = 0$. Since its introduction, the latter principle has continuously attracted attention. In particular, it has been exploited in the direction of proving the existence [40, 2, 41, 10, 9] (note that the above-mentioned obstructions to the application of the direct methods again appear) and the description of long-time dynamics [17]. Moreover, the Brezis–Ekeland–Nayroles approach has been adapted to the case of second order [21, 22] and doubly nonlinear equations [45] and to the study of variable time step discretizations of (1.4) [43] as well.

The variational characterization (1.2) stems basically from the same idea as in (1.5). Namely, the differential inclusion in (1.1) is equivalently rewritten by convexity of ψ as

$$\psi(\dot{y}) + \psi^*(\ell - Ay) - \langle \ell - Ay, \dot{y} \rangle = 0 \quad \text{a.e. in } (0,T),$$

and (1.2) follows by noting that the above left-hand side is a.e. nonnegative for all trajectories y and it is 0 iff y is fulfilling the inclusion in (1.1). On the other hand, apart from this conceptual analogy, one has indeed to mention that the characterization (1.2) has little in common with the original Brezis–Ekeland–Nayroles principle. In particular, the two principles turn out to be different even in the case of a quadratic functional ψ on a Hilbert space.

One has to mention that, of course, (1.2) is not the only possible global-in-time variational characterization of (1.1). Besides minimizing the L^2 space-time norm of the residual (which might be a little interesting since the order of the problem is doubled), one has at least to mention Visintin [48], where generalized solutions are obtained as minimal elements of a certain partial-order relation on the trajectories, and the recent contribution by Mielke and Ortiz [27], where the functional

$$y \mapsto e^{-T/\varepsilon} \varphi(T, y(T)) + \int_0^T e^{-t/\varepsilon} \left(\psi(\dot{y}) + \frac{1}{\varepsilon} \varphi(t, y) \right) \tag{1.6}$$

is minimized among trajectories with $y(0) = y_0$. Under extra-smoothness conditions on ψ (not fulfilled in the current frame), the Euler–Lagrange equations of the latter functional are

$$\begin{aligned} -\varepsilon \mathrm{D}^2\psi(\dot y)\ddot y + \mathrm{D}\psi(\dot y) + Ay = \ell,\\ y(0) = y_0, \qquad \mathrm{D}\psi(\dot y(T)) + Ay(T) = \ell(T). \end{aligned}$$

In particular, minimizing the functional in (1.6) consists in performing a suitable elliptic (in time) regularization of the problem. In the specific case of ψ positively 1-homogeneous, the limit $\varepsilon \to 0$ can be carried out, and the minimizers of the functional in (1.6) are proved to converge to the solution of (1.1). The latter approach is quite different from that of (1.2). On the one hand, it is much more general as it naturally applies to the nonsmooth case as well (no derivatives of ψ and ϕ are involved). The results of [27] have been recently extended in the direction of discretizations and relaxation in [31].

2. Mechanical model. Let us provide the reader with a brief introduction to the mechanical setting under consideration. Our aim is just that of recalling some essential features of the models as well as their variational formulation. In particular, we restrain from reporting here an extensive discussion on associative elastoplasticity as the latter can be easily recovered from the many contributions on the subject. The reader is particularly referred to the mentioned monographs for some comprehensive presentation.

2.1. Preliminaries. We will denote by $\mathbb{R}^{3\times 3}_{\mathrm{sym}}$ the space of symmetric 3×3 tensors endowed with the natural scalar product $a : b := \mathrm{tr}(ab) = a_{ij}b_{ij}$ (summation convention). The space $\mathbb{R}^{3\times 3}_{\mathrm{sym}}$ is orthogonally decomposed as $\mathbb{R}^{3\times 3}_{\mathrm{sym}} = \mathbb{R}^{3\times 3}_{\mathrm{dev}} \oplus \mathbb{R}\,1_2$, where $\mathbb{R}\,1_2$ is the subspace spanned by the identity 2-tensor 1_2 and $\mathbb{R}^{3\times 3}_{\mathrm{dev}}$ is the subspace of deviatoric symmetric 3×3 tensors. In particular, for all $a \in \mathbb{R}^{3\times 3}_{\mathrm{sym}}$, we have that $a = a_{\mathrm{dev}} + \mathrm{tr}(a)1_2/3$.

We shall assume the reference configuration Ω to be a nonempty, bounded, and connected open set in $\mathbb{R}^3$ with a Lipschitz continuous boundary. The space dimension 3 plays essentially no role throughout the analysis, and we would be in the position of reformulating our results in $\mathbb{R}^d$ with no particular intricacy. Our unknown variables are the displacement of the body $u \in \mathbb{R}^3$, the plastic strain $p \in \mathbb{R}^{3\times 3}_{\mathrm{dev}}$, and a vector of internal variables $\xi \in \mathbb{R}^m$ ($m \in \mathbb{N}$) which will describe the hardening of the material. We will denote by $\varepsilon(u)$ the standard symmetric gradient.

2.2. Constitutive relation. Moving within the small-strain regime, we additively decompose the linearized deformation $\varepsilon(u)$ into the elastic strain e and the inelastic (or plastic) strain p as

$$\varepsilon(u) = e + p.$$

Let $\mathbb{C}$ be the elasticity tensor. By regarding the latter as a symmetric positive definite linear map $\mathbb{C} : \mathbb{R}^{3\times 3}_{\mathrm{sym}} \to \mathbb{R}^{3\times 3}_{\mathrm{sym}}$, we shall assume that the orthogonal subspaces $\mathbb{R}^{3\times 3}_{\mathrm{dev}}$ and $\mathbb{R}\,1_2$ are invariant under $\mathbb{C}$. This amounts to saying that indeed

$$\mathbb{C}a = \mathbb{C}_{\mathrm{dev}}a_{\mathrm{dev}} + \kappa\,\mathrm{tr}(a)1_2$$

for a given $\mathbb{C}_{\mathrm{dev}} : \mathbb{R}^{3\times 3}_{\mathrm{dev}} \to \mathbb{R}^{3\times 3}_{\mathrm{dev}}$, a constant κ, and all $a \in \mathbb{R}^{3\times 3}_{\mathrm{sym}}$. The case of isotropic materials is given by $\mathbb{C}_{\mathrm{dev}} = 2G(1_4 - 1_2 \otimes 1_2/3)$, and G and κ are, respectively, the

shear and the bulk moduli. The latter decomposition is not exploited in our analysis, but it is clearly suggested by the mechanical application. Moreover, we shall introduce two linear symmetric positive semidefinite hardening moduli $\mathbb{H}_p : \mathbb{R}^{3\times3}_{\mathrm{dev}} \to \mathbb{R}^{3\times3}_{\mathrm{dev}}$ and $\mathbb{H}_\xi : \mathbb{R}^m \to \mathbb{R}^m$ (to be identified with a fourth order tensor and a matrix, respectively) and define the Helmholtz free energy $W : \mathbb{R}^{3\times3}_{\mathrm{sym}} \times \mathbb{R}^{3\times3}_{\mathrm{dev}} \times \mathbb{R}^m \to [0,\infty)$ of the material as

$$W(\varepsilon(u), p, \xi) := \frac{1}{2}(\varepsilon(u) - p) : \mathbb{C}(\varepsilon(u) - p) + \frac{1}{2}p : \mathbb{H}_p p + \frac{1}{2}\xi^T \cdot \mathbb{H}_\xi \xi.$$

The generalized stresses (σ, η) are conjugate to the above-defined generalized strains (e, ξ) via the energy W. In particular, the material is classically assumed to show elastic response,

$$\sigma = \frac{\partial W}{\partial e} = \mathbb{C}e = \mathbb{C}(\varepsilon(u) - p), \tag{2.1}$$

and the thermodynamic force η driving the evolution of the internal variables ξ is defined as

$$\eta = -\frac{\partial W}{\partial \xi} = -\mathbb{H}_\xi \xi. \tag{2.2}$$

Moreover, by moving within the frame of associative elastoplasticity, we assume the existence of a function $R : \mathbb{R}^{3\times3}_{\mathrm{dev}} \times \mathbb{R}^m \to [0,\infty]$ convex, positively 1-homogeneous, and lower semicontinuous such that

$$\partial R(\dot p, \dot\xi) \ni \begin{pmatrix} \sigma - \mathbb{H}_p p \\ \eta \end{pmatrix}. \tag{2.3}$$

In particular, R is asked to be the support function of a convex set $C^* \in \mathbb{R}^{3\times3}_{\mathrm{dev}} \times \mathbb{R}^m$, i.e., $R(p) = \sup_{q\in C^*} q : p$. We will indicate with R^* its conjugate, namely, the indicator function of C^* given by $R^*(q) = 0$ if $q \in C^*$ and $R^*(q) = \infty$ otherwise. Moreover, we let C be the domain of R, namely, $C = D(R) = \{(p,\xi) \in \mathbb{R}^{3\times3}_{\mathrm{dev}} \times \mathbb{R}^m : R(p,\xi) < \infty\}$.

Finally, the above material relations (2.1)–(2.3) can be condensed as the following constitutive material law:

$$\partial R(\dot p, \dot\xi) + \begin{pmatrix} (\mathbb{C} + \mathbb{H}_p)p \\ \mathbb{H}_\xi \xi \end{pmatrix} \ni \begin{pmatrix} \mathbb{C}\varepsilon(u) \\ 0 \end{pmatrix}, \tag{2.4}$$

which in turn can be rephrased in the form of (1.1) by letting

$$\begin{gathered} y = (p,\xi), \quad Y = \mathbb{R}^{3\times3}_{\mathrm{dev}} \times \mathbb{R}^m, \quad \psi = R, \\ A(p,\xi) = \big((\mathbb{C} + \mathbb{H}_p)p, \mathbb{H}_\xi \xi\big), \quad \ell = (\mathbb{C}\varepsilon(u), 0). \end{gathered} \tag{2.5}$$

Let us close this subsection by explicitly mentioning three classical linear hardening models [13, Ex. 4.8, p. 88]:

Linear kinematic hardening. Choose $\mathbb{H}_p = h_p 1_4$, where $h_p > 0$, and $\mathbb{H}_\xi = 0$. In this case the internal variable ξ is not evolving and shall be removed from the set of unknowns.

Linear isotropic hardening. Choose $\mathbb{H}_p = 0$, $m = 1$, and $\mathbb{H}_\xi = h_\xi > 0$. Moreover, let $D(R) = \{(p,\xi) \in \mathbb{R}^{3\times3}_{\mathrm{dev}} \times \mathbb{R} : |p| \le \xi\}$.

Linear combined kinematic-isotropic hardening. Let $\mathbb{H}_p = h_p 1_4$, $m = 1$, and $\mathbb{H}_\xi = h_\xi$, where $h_p, h_\xi > 0$. Moreover, let $D(R) = \{(p,\xi) \in \mathbb{R}^{3\times3}_{\mathrm{dev}} \times \mathbb{R} : |p| \le \xi\}$.

It is beyond the purpose of this introduction to discuss and justify the above-mentioned material models. The reader should check the cited references for comments on their relevance within applications and some mechanical motivation.

2.3. Variational formulation of the quasi-static evolution. Let us now move to the consideration of the full equilibrium problem. To this aim, we assume that the boundary $\partial\Omega$ is partitioned in two disjoint open sets $\Gamma_{\rm tr}$ and $\Gamma_{\rm Dir}$, with $\partial\Gamma_{\rm tr} = \partial\Gamma_{\rm Dir}$ (in $\partial\Omega$). We ask $\Gamma_{\rm Dir}$ to be such that there exists a positive constant $c_{\rm Korn}$ depending on $\Gamma_{\rm Dir}$ and Ω such that the Korn inequality

$$c_{\rm Korn}\|u\|^2_{H^1(\Omega;\mathbb{R}^3)} \le \|u\|^2_{L^2(\Gamma_{\rm Dir};\mathbb{R}^3)} + \|\varepsilon(u)\|^2_{L^2(\Omega;\mathbb{R}^{3\times 3}_{\rm sym})} \tag{2.6}$$

holds true for all $u \in H^1(\Omega;\mathbb{R}^3)$. It would indeed suffice to impose $\Gamma_{\rm Dir}$ to have a positive surface measure (see, e.g., [7, Thm. 3.1, p. 110]).

For the sake of simplicity, we will prescribe homogeneous Dirichlet boundary conditions on $\Gamma_{\rm Dir}$ (our analysis extends with little notational intricacy to the case of non-homogeneous Dirichlet boundary conditions as well). On $\Gamma_{\rm tr}$ some time-dependent traction will be prescribed instead.

As for the full quasi-static evolution of the material, we shall couple the constitutive relation (2.4) with the equilibrium equation

$$\operatorname{div}\sigma + f = 0 \quad \text{in } \ \Omega. \tag{2.7}$$

Here we assume to be given the body force $f : [0,T] \to L^2(\Omega;\mathbb{R}^3)$ and a surface traction $g : [0,T] \to L^2(\Gamma_{\rm tr};\mathbb{R}^3)$.

Then one can rephrase the problem into the form of (1.1) by choosing

$$y = (u,p,\xi), \tag{2.8}$$

$$Y = \Big\{(u,p,\xi) \in H^1(\Omega;\mathbb{R}^3) \times L^2(\Omega;\mathbb{R}^{3\times 3}_{\rm dev}) \times L^2(\Omega;\mathbb{R}^m) \tag{2.9}$$

$$\text{such that } \ u = 0 \ \text{ on } \ \Gamma_{\rm Dir}\Big\},$$

$$\langle A(u,p,\xi),(v,q,z)\rangle = \int_\Omega \Big((\varepsilon(u)-p) : \mathbb{C}(\varepsilon(v)-q) + p : \mathbb{H}_p q + \xi^T \cdot \mathbb{H}_\xi z\Big)$$

$$\forall (v,q,z) \in Y, \tag{2.10}$$

$$\psi(u,p,\xi) = \int_\Omega R(p,\xi) \tag{2.11}$$

and defining the total load $\ell : [0,T] \to Y^*$ as

$$\langle \ell(t),(u,p,\xi)\rangle = \int_\Omega f\cdot u + \int_{\Gamma_{\rm tr}} g\cdot u \ {\rm d}\mathcal{H}^2 \quad \forall u \in H^1(\Omega;\mathbb{R}^3),\ t\in[0,T],$$

where $\mathcal{H}^2$ is the 2-dimensional Hausdorff measure.

2.4. The coercivity of A. Let us close this introductory discussion by explicitly commenting on the coercivity of the bilinear form induced by A. We shall recall some sufficient conditions on $\mathbb{H}_p$, $\mathbb{H}_\xi$, and R in such a way that there exists a constant $\alpha > 0$ such that

$$\langle Ay, y\rangle \ge \alpha |y|^2 \quad \forall y \in D(\psi), \tag{2.12}$$

where $|\cdot|$ is the norm in Y. This issue is fairly classical [13, sec. 7.3, p. 167], and we discuss it here for the sake of completeness only.

Of course, (2.12) holds (and even for all $y \in Y$) whenever $\mathbb{H}_p$ and $\mathbb{H}_\xi$ are positive definite (this is the case of the above-mentioned linear combined kinematic-isotropic hardening).

As we have already observed, in the case $\mathbb{H}_\xi = 0$, the problem naturally reduces to the pair (u, p) only. Up to this reduction, (2.12) holds (again for all $y \in Y$) when $\mathbb{H}_p$ is positive definite. This is exactly the case of linear kinematic hardening.

On the other hand, in the case $\mathbb{H}_p = 0$, the plastic strain will still evolve, and one has (2.12) if $D(R)$ is bounded in the p-direction for all ξ, namely, if [13, eq. (7.51)]

(2.13)
$$D(R) \subset \{(p,\xi) \in \mathbb{R}^{3\times 3}_{\rm dev} \times \mathbb{R}^m \ : \ \beta|p|^2 \le \xi^T \cdot \mathbb{H}_\xi \xi \ \text{ for some constant } \ \beta > 0\},$$

which is clearly the case for linear isotropic hardening.

Some generalization of the latter condition could in principle be considered for the case when $\mathbb{H}_p$ and $\mathbb{H}_\xi$ are only semidefinite. In particular, (2.12) holds if one assumes (2.13) and

$$\xi \neq 0 \ \text{ and } \ \xi^T \cdot \mathbb{H}_\xi \xi = 0 \quad \Rightarrow \quad R(p,\xi) = \infty \ \ \forall p \in \mathbb{R}^{3\times 3}_{\rm dev}.$$

Let us mention that the most critical case in the class of (2.4) is $\mathbb{H}_p = 0$, $\mathbb{H}_\xi = 0$ where actually no hardening takes place. This is the situation of *perfect plasticity* for which the Sobolev space framework above is not appropriate, and one would consider the space $BD(\Omega)$ of functions of bounded deformations instead [6]. We shall make clear that, even if our variational characterization covers the case of perfect plasticity, the subsequent approximation results apply to the linear hardening situation only.

3. Characterization.

3.1. General assumptions. Let us start by recalling notation and enlisting the basic assumptions for the following. First of all, we will ask that

(3.1) $$Y \quad \text{is a separable and reflexive Banach space.}$$

We will use the symbols $|\cdot|$ for the norm of Y and $\langle\cdot,\cdot\rangle$ for the duality pairing between Y^* (dual) and Y. The norm in Y^* will be denoted by $|\cdot|_*$ instead.

We introduce the functional

(3.2) $$\psi : Y \to [0,\infty] \quad \text{proper, convex, lower semicontinuous, and positively 1-homogeneous.}$$

Equivalently, ψ is required to be the support function of a convex and closed set $C^* \subset Y^*$ containing 0, namely,

(3.3) $$\psi(y) = \sup\{\langle y^*, y\rangle \ : \ y^* \in C^*\}.$$

We shall define $C = D(\psi)$. Hence, the conjugate $\psi^* : Y^* \to [0,\infty]$, which is classically defined as $\psi^*(y^*) = \sup_{y\in Y}(\langle y^*, y\rangle - \psi(y))$, is the indicator function of the convex set C^*, namely, $\psi^*(y^*) = 0$ if $y^* \in C^*$ and $\psi^*(y^*) = \infty$ otherwise. Let us remark that ψ fulfills the triangle inequality $\psi(a) \le \psi(b) + \psi(c)$ whenever $a = b + c$.

We shall use the symbol ∂ in order to denote the usual subdifferential in the sense of convex analysis, namely,

$$y^* \in \partial\psi(y) \quad \text{iff} \quad y \in D(\psi) \ \text{ and } \ \langle y^*, w - y\rangle \le \psi(w) - \psi(y) \quad \forall w \in Y.$$

Similarly, we define

$$\begin{aligned} y \in \partial\psi^*(y^*) \quad &\text{iff} \quad y^* \in D(\psi^*) \ \text{ and } \ \langle w^* - y^*, y\rangle \le \psi^*(w^*) - \psi^*(y^*) \quad \forall w^* \in Y^* \\ &\text{iff} \quad y^* \in C^* \ \text{ and } \ \langle w^* - y^*, y\rangle \le 0 \quad \forall w^* \in C^*. \end{aligned}$$

Finally, we recall Fenchel's inequality

$$\psi(y) + \psi^*(y^*) \geq \langle y^*, y \rangle \quad \forall y \in Y,\ y^* \in Y^*,$$

and remark that equality holds iff $y^* \in \partial\psi(y)$ (or, equivalently, $y \in \partial^*\psi^*(y^*)$).

As for the operator A we require that

$$A : Y \to Y^* \quad \text{linear, continuous, and symmetric} \tag{3.4}$$

and define the function

$$y \to \phi(y) = \frac{1}{2}\langle Ay, y \rangle,$$

so that $A = \mathrm{D}\phi$. Moreover, we will ask ϕ to be coercive on $C = D(\psi)$; namely, we assume that there exists a positive constant α such that

$$\phi(y) \geq \frac{\alpha}{2}|y|^2 \quad \forall y \in C. \tag{3.5}$$

As we have already commented in subsection 2.4, the latter coercivity is fulfilled in the situation of elastoplastic evolution with linear kinematic, isotropic, or combined kinematic-isotropic hardening and will turn out to be sufficient for both of the forthcoming characterization results.

On the other hand, the following uniqueness-type results will be checked under some stronger coercivity frame, and we will ask for

$$\phi(y) \geq \frac{\alpha}{2}|y|^2 \quad \forall y \in C - C. \tag{3.6}$$

Clearly, condition (3.6) is fulfilled when ϕ happens to be coercive on the whole space Y. The latter applies in particular to the case of linear kinematic and combined kinematic-isotropic hardening elastoplasticity. In this case, ϕ defines an equivalent (squared) norm in Y.

We shall make use of the following notation:

$$\chi(y) = \phi(y) + |y|^2 \quad \forall y \in Y.$$

Indeed the latter choice is just motivated by simplicity and could be replaced as well by any other $\chi : Y \to [0, \infty)$ such that $\chi(y) = 0$ iff $y = 0$ and that $y \mapsto \chi(y) - \phi(y)$ is lower semicontinuous.

Finally, we shall fix data such that

$$\ell \in L^\infty(0, T; Y^*),\ y_0 \in C. \tag{3.7}$$

The restriction on the choice of the initial datum in C is motivated by the coercivity assumption on ϕ in (3.5). On the other hand, we shall explicitly mention that the usual choice for y_0 in elastoplasticity is $y_0 = 0$.

In what follows, the above assumptions (3.1)–(3.5) and (3.7) will be tacitly assumed (unless explicitly stated). It should be clear, however, that the above choice is motivated by the sake of simplicity. Indeed, most of the following results still hold under suitably weaker assumptions, as we shall comment.

3.2. The functional. Let the *Lagrangian* $L : (0,T)\times Y\times Y \to [0,\infty]$ be defined as

$$L(t,y,p) = \psi(p) + \psi^*(\ell(t) - Ay) - \langle \ell(t) - Ay, p\rangle \quad \text{for a.e. } t \in (0,T),\ \forall y,\ p \in Y, \tag{3.8}$$

and the functional $F : W^{1,1}(0,T;Y) \to [0,\infty]$ as

$$F(y) = \int_0^T L(t, y(t), \dot y(t))\ \mathrm{d}t + \chi(y(0) - y_0). \tag{3.9}$$

Now, by simply using the chain rule, we obtain

$$F(y) = \int_0^T \Big(\psi(\dot y) + \psi^*(\ell - Ay) - \langle \ell, \dot y\rangle\Big) + \phi(y(T)) - \phi(y(0)) + \chi(y(0) - y_0).$$

A first remark is that, by exploiting the particular form of χ,

$$F(y) = \int_0^T \Big(\psi(\dot y) + \psi^*(\ell - Ay) - \langle \ell, \dot y\rangle\Big) + \phi(y(T)) + \phi(y_0) - \langle Ay(0), y_0\rangle + |y(0) - y_0|^2. \tag{3.10}$$

In particular, F is clearly convex.

3.3. The characterization. Let us state here our variational principle.

THEOREM 3.1 (variational principle). *$y \in W^{1,1}(0,T;Y)$ solves (1.1) iff*

$$F(y) = 0 = \min F.$$

Proof. Owing to Fenchel's inequality we have

$$L(t,y,p) = 0 \quad \text{iff} \quad \ell(t) - Ay \in \partial\psi(p)$$

and, clearly, $\chi(y(0) - y_0) = 0$ iff $y(0) = y_0$. Hence, all solutions y of (1.1) are such that $F(y) = 0$ and vice versa. ∎

Let us remark that the latter variational characterization result holds in much greater generality. The proof made no use of the separability and reflexivity of Y nor of the linearity of A (besides its being single-valued and such that $t \mapsto Ay(t)$ is measurable). Moreover, the positive 1-homogeneity of ψ is unessential [44]. In particular, the variational approach of Theorem 3.1 can be directly extended to a variety of different dissipative systems possibly including viscous evolution as well. We shall address this perspective in a forthcoming contribution.

We have already observed that F is convex. Moreover, F is lower semicontinuous with respect to the weak topology of $W^{1,1}(0,T;Y)$, since all weakly convergent sequences in $W^{1,1}(0,T;Y)$ are pointwise weakly convergent as well. Hence, one could be tempted to use the direct method in order to get the existence of minimizers, i.e., solutions to (1.1). As we commented in the introduction, this seems to be no trivial task.

First of all, the functional F need not be coercive with respect to the weak topology of $W^{1,1}(0,T;Y)$. Indeed, the functional ψ may degenerate and hence not control the norm of its argument. Moreover, even in the case when ψ is nondegenerate, the homogeneity assumption just entails that the sublevels of F are bounded in $W^{1,1}(0,T;Y)$ and no weak compactness follows.

Second, even assuming coercivity in the weak topology of $W^{1,1}(0,T;Y)$, one would still need to prove that the minimum 0 is attained.

3.4. The variational principle for hardening elastoplasticity. By referring to the notations of section 2, let us now present the actual form of the functional F for the case of the constitutive relation for linearized elastoplastic materials with linear hardening (see (2.5)). In this case the functional reads

$$\begin{aligned}F(p,\xi) = &\int_0^T \Big(R(\dot p,\dot\xi) + R^*\big(\mathbb{C}(\varepsilon(u)-p) - \mathbb{H}_p p, -\mathbb{H}_\xi \xi\big)\Big)\\ &- \int_0^T \Big(\big(\mathbb{C}(\varepsilon(u)-p) - \mathbb{H}_p p\big) : \dot p - \xi^T \cdot \mathbb{H}_\xi \dot\xi\Big)\\ &+ \frac{1}{2}(p(0)-p_0) : (\mathbb{C}+\mathbb{H}_p)(p(0)-p_0) + \frac{1}{2}(\xi(0)-\xi_0)^T \cdot \mathbb{H}_\xi(\xi(0)-\xi_0)\\ &+ |(p(0),\xi(0)) - (p_0,\xi_0)|^2\end{aligned}$$

for some given initial datum $(p_0,\xi_0) \in \mathbb{R}^{3\times 3}_{\rm dev} \times \mathbb{R}^m$ and $\varepsilon(u) \in L^\infty(0,T;\mathbb{R}^{3\times 3}_{\rm sym})$.

In the situation of the quasi-static evolution, for some given initial datum $(u_0,p_0,\xi_0) \in Y$, a load $f \in L^\infty(0,T;L^2(\Omega;\mathbb{R}^3))$, and a traction $g \in L^\infty(0,T;L^2(\Gamma_{\rm tr};\mathbb{R}^3))$, the functional reads (see (2.8)–(2.11))

$$\begin{aligned}F(u,p,\xi) = &\int_0^T \int_\Omega \Big(R(\dot p,\dot\xi) + R^*\big(\mathbb{C}(\varepsilon(u)-p) - \mathbb{H}_p p, -\mathbb{H}_\xi \xi\big)\Big)\\ &- \int_0^T \int_\Omega f\cdot\dot u - \int_0^T \int_{\Gamma_{\rm tr}} g\cdot \dot u \,{\rm d}\mathcal{H}^2\\ &+ \int_0^T \int_\Omega \Big((\varepsilon(u)-p) : \mathbb{C}(\varepsilon(\dot u)-\dot p) + p : \mathbb{H}_p\dot p + \xi^T\cdot\mathbb{H}_\xi\dot\xi\Big)\\ &+ \frac{1}{2}\int_\Omega (\varepsilon(u(0)-u_0) - (p(0)-p_0)) : \mathbb{C}(\varepsilon(u(0)-u_0) - (p(0)-p_0))\\ &+ \frac{1}{2}\int_\Omega \Big((p(0)-p_0) : \mathbb{H}_p(p(0)-p_0) + (\xi(0)-\xi_0)^T\cdot\mathbb{H}_\xi(\xi(0)-\xi_0)\Big)\\ &+ \frac{1}{2}\int_\Omega |(u(0),p(0),\xi(0)) - (u_0,p_0,\xi_0)|^2\end{aligned}$$

for all points $(u,p,\xi) \in Y$ such that

$$\begin{aligned}&\int_\Omega (\varepsilon(u)-p) : \mathbb{C}\varepsilon(v) = \int_\Omega f\cdot v - \int_{\Gamma_{\rm tr}} g\cdot v\,{\rm d}\mathcal{H}^2\\ &\forall v \in H^1(\Omega;\mathbb{R}^3), \quad \text{with} \quad v = 0 \quad \text{on} \quad \Gamma_{\rm Dir}, \quad \text{a.e. in} \quad (0,T),\end{aligned}$$

and $F(u,p,\xi) = \infty$ otherwise.

4. Properties of the minimizers. For the sake of illustrating the variational principle of Theorem 3.1, we shall collect here some properties of the trajectories belonging to the domain of the functional F and, in particular, of the minimizers.

4.1. Trajectories are in C.

LEMMA 4.1. *Let $F(y) < \infty$. Then $y(t) \in C$ for all $t \in [0,T]$.*

Proof. Since $F(y) < \infty$ we have $\dot y \in C$ a.e. in $(0,T)$. Hence, for all $t \in [0,T]$, we have $\int_0^t \dot y \in C$ by Jensen's inequality. On the other hand, $y_0 \in C$ and $y(t) = y_0 + \int_0^t \dot y$. The assertion follows by recalling that C is a cone. ∎

4.2. Stability at regular points of ℓ. Assume that $\ell : [0,T] \to Y^*$ is given, and let the set of *stable* states $S(t) \subset Y$ for $t \in [0,T]$ be defined as

$$S(t) = \{y \in Y \ : \ \phi(y) - \langle \ell(t), y\rangle \le \phi(w) - \langle \ell(t), w\rangle + \psi(w-y) \ \ \forall w \in Y\}.$$

In particular, one has $y \in S(t)$ iff it minimizes the convex functional $G : w \mapsto \phi(w) - \langle \ell(t), w\rangle + \psi(w-y)$, namely,

$$y \in S(t) \quad \text{iff} \quad 0 \in \partial G(y) = Ay - \ell(t) + \partial\psi(0).$$

Let us now check that indeed $\partial\psi(0) = C^*$. To this end, owing to (3.3), given $y^* \in C^*$ one has $\langle y^*, w\rangle \le \psi(w)$ for all $w \in Y$. Namely, $C^* \subset \partial\psi(0)$. On the other hand, assume that there exists $\xi \in \partial\psi(0) \setminus C^*$. Hence, by the Hahn–Banach theorem one finds $y \in Y$, $\alpha \in \mathbb{R}$, and $\varepsilon > 0$ such that

$$\psi(y) \overset{\xi\in\partial\psi(0)}{\ge} \langle \xi, y\rangle \ge \alpha + \varepsilon > \alpha - \varepsilon \ge \langle y^*, y\rangle \quad \forall y^* \in C^*,$$

and, by passing to the supremum as $y^* \in C^*$, we obtain a contradiction. We may summarize this discussion as follows:

$$y \in S(t) \quad \text{iff} \quad \ell(t) - Ay \in C^*.$$

LEMMA 4.2 (stability of the minimizers). *Let ℓ be either left- or right-weakly continuous at some point $t \in [0,T]$ and $F(y) < \infty$. Then $y(t) \in S(t)$.*

Proof. Since $F(y) < \infty$, we have $\ell(t) - Ay(t) \in C^*$ for all $t \in (0,T) \setminus N$, where $|N| = 0$. Choose a sequence $t_k \in (0,T) \setminus N$ such that $t_k \to t$ (from the left or from the right) and $\ell(t_k) \to \ell(t)$ weakly in Y^*. Hence, $\ell(t_k) - Ay(t_k) \to \ell(t) - Ay(t)$ weakly in Y^* and $\ell(t) - Ay(t) \in C^*$. ∎

In particular, if ℓ happens to be right-continuous at 0, the functional F will not attain the minimum value 0 unless the initial datum y_0 is stable, namely, $y_0 \in S(0)$.

4.3. Equivalent formulations. Letting now $\ell \in W^{1,1}(0,T;Y^*)$, problem (1.1) admits some alternative equivalent formulations [26, sec. 2.1]. We explicitly mention that $y \in W^{1,1}(0,T;Y)$ is said to be an *energetic solution* if it solves the *energetic formulation* [32] of (1.1), namely,

$$y(t) \in S(t) \quad \forall t \in [0,T], \tag{4.1}$$

$$\phi(y(t)) - \langle \ell(t), y(t)\rangle + \int_0^t \psi(\dot y) = \phi(y(0)) - \langle \ell(0), y(0)\rangle - \int_0^t \langle \dot\ell, y\rangle \tag{4.2}$$

$$\forall t \in [0,T],$$

$$y(0) = y_0. \tag{4.3}$$

Mielke and Theil [32] proved that the latter is equivalent to (1.1) and hence, owing to the characterization of Theorem 3.1, to $F(y) = 0 = \min F$ (note that the analysis in [32] is much more general and is in particular allowing discontinuous in time evolutions by introducing the above notion of energetic solutions in the frame of functions of a bounded variation). For the aim of pointing out some features of our variational approach, we shall present here a direct proof of this fact.

LEMMA 4.3 (equivalence with the energetic formulation). *Let $\ell \in W^{1,1}(0,T;Y^*)$. Then $F(y) = 0 = \min F$ iff y fulfills* (4.1)–(4.3).

Proof. Owing to Lemma 4.2, we readily have that the stability condition (4.1) holds iff $\psi^*(\ell - Ay) = 0$ a.e.

Let y be such that $F(y)=0$. Then (4.1) and (4.3) hold and $L(t,y(t),\dot y(t))=0$ for a.e. $t\in(0,T)$. In particular, for all $t\in[0,T]$,

$$\begin{aligned}0=\int_0^t L(s,y(s),\dot y(s))\,\mathrm{d}s&=\int_0^t\Big(\psi(\dot y)-\langle\ell,\dot y\rangle\Big)+\phi(y)\Big|_0^t\\&=\big(\phi(y)-\langle\ell,y\rangle\big)\Big|_0^t+\int_0^t\psi(\dot y)+\int_0^t\langle\dot\ell,y\rangle,\end{aligned}$$

so that the energy equality (4.2) holds for all $t\in[0,T]$.

On the contrary, let $y\in W^{1,1}(0,T;Y)$ fulfill (4.1)–(4.3). Then $\chi(y(0)-y_0)=0$ and $\psi^*(\ell-Ay)=0$ a.e. (see above). Hence $F(y)=0$ follows from the energy equality (4.2) at time T and an integration by parts. □

Let us mention that the last lemma proves in particular that the energy equality (4.2) could be equivalently enforced *at the final time* T only. Moreover, it proves that, as already commented in the introduction, all *stable trajectories* $t\mapsto y(t)$ (i.e., trajectories such that $y(t)\in S(t)$ for all $t\in[0,T]$) are such that the following energy inequality holds:

$$\phi(y(t))-\langle\ell(t),y(t)\rangle+\int_0^t\psi(\dot y)\ge\phi(y(0))-\langle\ell(0),y(0)\rangle-\int_0^t\langle\dot\ell,y\rangle\quad\forall t\in[0,T].$$

Hence, we have provided a proof to [26, Prop. 5.7] (note that the referred result is, however, more general as it is concerned with the BV situation, the energy is implicitly depending on time, and no linear structure on Y is required).

Before closing this subsection, let us explicitly remark that the above inferred equivalence between formulations has been obtained for the absolutely continuous case $\ell\in W^{1,1}(0,T;Y^*)$ only, whereas the characterization of Theorem 3.1 holds more generally for bounded ℓ.

4.4. The functional controls the uniform distance: Uniqueness. So far, we have simply reformulated known results in a variational fashion. Here we present some novel results instead.

LEMMA 4.4 (uniform distance control via F). *We have*

$$\eta(1-\eta)\max_{t\in[0,T]}\phi\big(u(t)-v(t)\big)\le\eta F(u)+(1-\eta)F(v)\tag{4.4}$$
$$\forall u,\,v\in W^{1,1}(0,T;Y),\ \eta\in[0,1].$$

Proof. The statement follows from the quadratic character of ϕ. Fix $t\in[0,T]$, and define $F^t:W^{1,1}(0,t;Y)\to[0,\infty]$ as

$$\begin{aligned}F^t(y)&=\int_0^t L(s,y(s),\dot y(s))\,\mathrm{d}s+\chi(y(0)-y_0)\\&=\int_0^t\Big(\psi(\dot y)+\psi^*(\ell-Ay)-\langle\ell,\dot y\rangle\Big)\\&\quad+\phi(y(t))+\phi(y_0)-\langle Ay(0),y_0\rangle+|y(0)-y_0|^2.\end{aligned}$$

Then, clearly, $y\mapsto G^t(y)=F^t(y)-\phi(y(t))$ is convex. Hence, by letting $w=\eta u+(1-\eta)v$ we have

$$\begin{aligned}&0\le F^t(w)\\&\le\eta\big(G^t(u)+\phi(u(t))\big)+(1-\eta)\big(G^t(v)+\phi(v(t))\big)-\eta(1-\eta)\phi\big(u(t)-v(t)\big),\end{aligned}$$

whence the assertion follows. □

The latter lemma exploits the quadratic character of ϕ only. In particular, no coercivity for ϕ is assumed. It should, however, be clear that its application (as the title of the lemma indeed suggests) will always be referred to the situation where the stronger (3.6) is required, namely, when the left-hand side of (4.4) controls

$$\eta(1-\eta)\frac{\alpha}{2}\max_{[0,T]}|u-v|^2.$$

We now present two immediate corollaries of Lemma 4.4.

COROLLARY 4.5 (uniform distance from the minimizer). *Let $F(y)=0$. Then*

$$\max_{t\in[0,T]}\phi\big(y(t)-v(t)\big)\le F(v).$$

This corollary encodes an interesting novel feature of our variational approach, for it provides a possible a posteriori error estimator to be used within approximation procedures. It is interesting to remark that the uniform distance of any stable trajectory from the minimizer is controlled by means of its energy production along the path only. Again, although Corollary 4.5 holds under no coercivity assumptions of ϕ, let us mention that its application will be restricted to the frame of (3.6). Finally, we have uniqueness of the minimizers of F attaining the value 0.

COROLLARY 4.6 (uniqueness). *Assume* (3.6). *Then there exists at most one trajectory y such that $F(y)=0$.*

4.5. Lipschitz bound. Throughout the remainder of the paper we shall tacitly assume that

$$\ell\in W^{1,\infty}(0,T;Y^*),\quad y_0\in S(0). \tag{4.5}$$

As already commented after Lemma 4.2, the above restriction on the initial datum is mandatory whenever ℓ admits a weak right limit in 0.

As for ℓ, the extra Lipschitz continuity assumption is motivated by the rate independence of the problem (every absolutely continuous datum can be time-rescaled to a Lipschitz continuous datum) and the following well known result.

LEMMA 4.7 (Lipschitz bound). *Assume* (3.6), *and let $\ell\in W^{1,\infty}(0,T;Y^*)$ and $F(y)=0$. Then*

$$\|\dot y\|_{L^\infty(0,T;Y)}\le\frac{1}{\alpha}\|\dot\ell\|_{L^\infty(0,T;Y^*)}\quad \textit{a.e. in}\ \ (0,T). \tag{4.6}$$

The proof of the lemma is exactly the classical one [32, Thm. 7.5] but formulated by means of our variational arguments. We provide it for the sake of completeness.

Proof. Let $0\le s<t\le T$ be fixed. Since $L(y,\dot y)=0$ a.e. we have

$$\int_s^t\Big(\psi(\dot y)+\langle\dot\ell,y\rangle\Big)+\big(\phi(y)-\langle\ell,y\rangle\big)\Big|_s^t=0.$$

On the other hand, owing to the strong monotonicity of A and the fact that $y(s)\in S(s)$ (see Lemma 4.2), one obtains

$$\begin{aligned}\phi(y(t)-y(s))&\le\phi(y(t))-\langle\ell(s),y(t)\rangle+\psi(y(t)-y(s))-\phi(y(s))-\langle\ell(s),y(s)\rangle\\&=\big(\phi(y)-\langle\ell,u\rangle\big)\Big|_s^t+\int_s^t\langle\dot\ell(r),y(t)\rangle\,\mathrm{d}r+\psi(y(t)-y(s)).\end{aligned}$$

By taking the sum of these two relations and recalling that, by Jensen,

$$\psi(y(t)-y(s)) = \psi\left(\int_s^t \dot{y}\right) \le \int_s^t \psi(\dot{y}),$$

we get

$$\phi(y(t)-y(s)) \le \int_s^t \langle \dot{\ell}(r), y(t)-y(r)\rangle \,\mathrm{d}r.$$

Finally, an application of some extended Gronwall lemma (see [26, Thm. 3.4]) entails that

$$\frac{\alpha}{2}|y(t)-y(s)|^2 \le \frac{1}{2}\|\dot{\ell}\|_{L^\infty(0,T;Y^*)}|y(t)-y(s)|\,(t-s),$$

and the assertion follows. ∎

5. Space approximation and stability under data perturbation. We now apply the characterization results of Theorem 3.1 to the approximation of solutions of (1.1). As already commented in the introduction, we shall proceed via Γ-convergence [11]. The reader is referred to the monographs by Attouch [1] and Dal Maso [5] for some comprehensive discussion on this topic. Indeed, since Theorem 3.1 directly quantifies the value of the minimum to be 0, what is actually needed for passing to limits are Γ-lim inf inequalities only. We shall illustrate this fact by discussing the simple case of stability under data perturbation first.

LEMMA 5.1 (stability under data perturbation). *Assume* (3.6), *and let* $\ell_h \to \ell$ *strongly in* $L^1(0,T;Y^*)$ *being uniformly Lipschitz continuous and* $y_{0,h} \to y_0$. *Moreover, let* $F_h : W^{1,1}(0,T;Y) \to [0,\infty]$ *be defined as*

$$F_h(y) = \int_0^T \Big(\psi(\dot{y}) + \psi^*(\ell_h - Ay) - \langle \ell_h - Ay, \dot{y}\rangle\Big) + \chi(y(0)-y_{0,h}),$$

and let $F_h(y_h) = 0$. *Then* $y_h \to y$ *weakly star in* $W^{1,\infty}(0,T;Y)$ *and* $F(y) = 0$.

Proof. Owing to Lemma 4.7, we find a (not relabeled) subsequence y_h such that $y_h \to y$ weakly star in $W^{1,\infty}(0,T;Y)$. Hence, we have by lower semicontinuity

$$\begin{aligned} 0 \le F(y) &\le \liminf_{h\to 0} \left(\int_0^T \Big(\psi(\dot{y}_h) + \psi^*(\ell_h - Ay_h) - \langle \ell_h, \dot{y}_h\rangle\Big) \right. \\ &\qquad \left. + \phi(y_h(T)) + \phi(y_{0,n}) - \langle Ay_h(0), y_{0,h}\rangle + |y_h(0)-y_{0,h}|^2 \right) \\ &= \liminf_{h\to 0} F_h(y_h) = 0. \end{aligned}$$

Hence, $F(y) = 0$, y is unique, and the assertion follows from the fact that the whole sequence converges. ∎

5.1. Preliminaries on functional convergence. In order to move to more general approximation situations, we are forced to discuss a suitable functional convergence notion. We limit ourselves in introducing the relevant definitions, referring to the mentioned monographs for all of the necessary details.

Recall that Y is a real reflexive Banach space. Letting f_n, $f : Y \to (-\infty, \infty]$ be convex, proper, and lower semicontinuous, we say that $f_n \to f$ in the *Mosco sense in* Y [1, 36] iff, for all $y \in Y$,

$$f(y) \le \liminf_{n\to\infty} f_n(y_n) \quad \forall y_n \to y \ \text{ weakly in } \ Y,$$
$$\exists y_n \to y \ \text{ strongly in } \ Y \ \text{ such that } \ f(y) = \limsup_{n\to\infty} f_n(y_n).$$

In particular, $f_n \to f$ in the Mosco sense iff $f_n \to f$ in the sense of Γ-convergence with respect to both the weak and the strong topology in Y.

We will consider the situation of approximating functionals ψ_h. By [1, Thm. 3.18, p. 295], we have $\psi_h \to \psi$ in the Mosco sense in Y iff $\psi_h^* \to \psi^*$ in the Mosco sense in Y^*. By assuming the functionals ψ_h to be positively 1-homogeneous, it turns out that the Mosco convergence $\psi_h \to \psi$ in Y is equivalent to the Mosco convergence of sets $C_h^* \to C^*$ in Y^*, which reads

$$C_n^* \ni y_n^* \to y^* \quad \text{weakly in } Y^* \quad \Rightarrow \quad y^* \in C^*,$$
$$\forall y^* \in C^*, \quad \exists y_n^* \in C_n^* \ : \ y_n^* \to y^* \quad \text{strongly in } Y^*.$$

Finally, we repeatedly use a lemma from [45] which we report it here, for the sake of completeness.

LEMMA 5.2 ([45, Cor. 4.4]). *Let $p \in [1, \infty]$ and f_h, $f : Y \to (-\infty, \infty]$ be convex, proper, and lower semicontinuous such that*

$$f(y) \le \inf \left\{ \liminf_{h\to 0} f_h(y_h) \ : \ y_h \to y \ \text{ weakly in } \ Y \right\} \quad \forall y \in Y.$$

Moreover, let $y_h \to y$ weakly in $W^{1,p}(0, T; Y)$ (weakly star if $p = \infty$). Then we have

$$\int_0^T f(y(t))\ \mathrm{d}t \le \liminf_{h\to 0} \int_0^T f_h(y_h(t))\ \mathrm{d}t.$$

5.2. Space approximations. We now move to the analysis of some space approximation situation, indeed specifically tailored for the case of conformal finite elements. Let us list here our assumptions for the sake of later referencing.

We assume to be given

$$Y_h \subset Y \ \text{ closed subspaces such that } \ h \mapsto Y_h \ \text{ increases}$$
(5.1) $$\text{and } \ \cup_{h>0} Y_h \ \text{ is dense in } \ Y,$$
(5.2) $$\phi_h(y) = \phi(y) \ \text{ if } \ y \in Y_h \ \text{ and } \ \phi_h(y) = \infty \ \text{ otherwise.}$$
(5.3) $$\psi_h : Y \to (-\infty, \infty] \quad \text{convex, proper, and lower semicontinuous,}$$
(5.4) $$\psi_h \quad \text{positively 1-homogeneous,}$$
(5.5) $$\psi_h \to \psi \quad \text{in the Mosco sense in } Y,$$
(5.6) $$\phi(y) \ge \frac{\alpha}{2}|y|^2 \quad \forall y \in C_h - C_h \quad \text{where } \ C_h = D(\psi_h),$$
(5.7) $$\ell_h \to \ell \quad \text{pointwise strongly in } Y^*,$$
(5.8) $$\ell_h \quad \text{uniformly Lipschitz continuous,}$$
(5.9) $$y_{0,h} \in Y_h, \quad y_{0,h} \to y_0.$$

We shall mention that within the frame of conformal finite elements methods the subspaces Y_h are obviously taken to be finite-dimensional and that the approximating functionals ϕ_h and ψ_h are usually the restrictions of the functionals ϕ and ψ on the subspace Y_h. This is exactly our choice here for ϕ_h. In particular, one shall observe that $\phi_h \to \phi$ in the Mosco sense in Y, $D(\partial\phi_h) = Y_h$, and that

$$A_h y = \partial\phi_h(y) = \partial\phi(y) = D\phi(y) = Ay \quad \forall y \in Y_h. \tag{5.10}$$

As for ψ_h we are allowing some extra freedom (let us remark, however, that (5.6) follows from (3.6) as soon as ψ_h is the restriction of ψ to Y_h since, in this case, $C_h = C \cap Y_h$). On the other hand, we are asking ψ_h to be positively 1-homogeneous; namely, we are considering the case of some rate-independent approximation of (1.1) only. The reader is referred instead to Efendiev and Mielke [8], Mielke, Rossi, and Savaré [29, 28], Toader and Zanini [47], and Zanini [49] for some results in the direction of rate-dependent approximation of rate-independent processes.

Finally, we shall (re)define the approximating functionals as $F_h : W^{1,1}(0,T;Y) \to [0,\infty]$ as

$$F_h(y) = \int_0^T \Big(\psi_h(\dot y) + \psi_h^*(\ell_h - A_h y) - \langle \ell_h - A_h y, \dot y\rangle\Big) + \chi_h(y(0) - y_{0,h}),$$

where $A_h = \partial\phi_h$ and $\chi_h(\cdot) = \phi_h(\cdot) + |\cdot|^2$. We have the following.

THEOREM 5.3 (convergence of space approximations). *Assume* (5.1)–(5.9)*, and let* $F_h(y_h) = 0$*. Then* $y_h \to y$ *weakly star in* $W^{1,\infty}(0,T;Y)$ *and* $F(y) = 0$*.*

Proof. By Lemma 4.7, we find a (not relabeled) subsequence $y_n \to y$ weakly star in $W^{1,\infty}(0,T;Y)$ and weakly pointwise. Since $F_h(y_h) = 0$ we readily check that $y(t) \in Y_h$ for all $t \in [0,T]$. In particular, $A_h y_h = A y_h$ for all $t \in [0,T]$ owing to (5.10). Hence, by lower semicontinuity,

$$\begin{aligned}
0 \le F(y) &\le \liminf_{h\to 0} \bigg(\int_0^T \Big(\psi_h(\dot y_h) + \psi_h^*(\ell_h - A y_h) - \langle \ell_h, \dot y_h\rangle\Big) \\
&\qquad + \phi(y_h(T)) + \phi(y_{0,h}) - \langle A y_h(0), y_{0,h}\rangle + |y_h(0) - y_{0,h}|^2 \bigg) \\
&= \liminf_{h\to 0} \bigg(\int_0^T \Big(\psi_h(\dot y_h) + \psi_h^*(\ell_h - A_h y_h) - \langle \ell_h, \dot y_h\rangle\Big) \\
&\qquad + \phi_h(y_h(T)) - \phi_h(y_h(0)) \bigg) \\
&= \liminf_{h\to 0} F_h(y_h) = 0.
\end{aligned}$$

Note that the integral terms containing ψ and ψ^* pass to the lim inf by means of Lemma 5.2. ∎

By inspecting the proof of Theorem 5.3 (which of course generalizes Lemma 5.1), one realizes that, whenever the weak-star precompactness in $W^{1,\infty}(0,T;Y)$ of the sequence y_h is assumed, the convergence statement holds more generally in the case $F_h(y_h) \to 0$. Namely, by directly asking for the above-mentioned compactness, one could consider the convergence of some approximated solutions y_h such that, possibly, $F_h(y_h) > 0$. We rephrase this fact in the following statement.

LEMMA 5.4 (Γ-lim inf inequality for F_h). *Assume* (5.1)–(5.3), (5.5)–(5.7), *and* (5.9). *Then*

$$F(u) \le \inf\left\{ \liminf_{h\to 0} F_h(y_h) \ : \ y_h \to y \quad \textit{weakly star in} \ \ W^{1,\infty}(0,T;Y) \right\}.$$

Note that the homogeneity of ψ_h, the uniform convexity of ϕ_h, and the Lipschitz continuity of ℓ_h play no role here.

Finally, again by looking carefully to the proof of Theorem 5.3, one could wonder if the requirement on the Mosco convergence of ψ_h could be weakened. Indeed, what we are actually using is only that

$$\psi \le \Gamma\text{-}\liminf_{h\to 0} \psi_h \quad \text{and} \quad \psi^* \le \Gamma\text{-}\liminf_{h\to 0} \psi_h^* \tag{5.11}$$

with respect to the weak topologies of Y and Y^*, respectively. On the other hand, in our specific situation, [45, Lem. 4.1] entails that (5.11) and the fact that $\psi_h \to \psi$ in the Mosco sense in Y are equivalent.

This observation motivates once again the belief that Mosco convergence is the right frame in order to pass to limits within rate-independent problems. For the sake of completeness, let us recall that a first result in the direction of the approximation of the play operator (Y Hilbert and A coercive on Y) under the Hausdorff convergence of the characteristic sets $C_h^* = D(\psi_h^*)$ is contained in [16, Thm. 3.12, p. 34], whereas the extension of this result to the more general situation of Mosco converging sets as well as some application to parabolic PDEs with hysteresis is discussed in [46]. More recently, Mielke, Roubíček, and Stefanelli [30] addressed in full generality the issue of Γ-convergence and relaxation for the energetic solutions of rate-independent processes. An alternative convergence proof in the specific case of convex energies is obtained by means of the Brezis–Ekeland–Nayroles approach in [45].

6. Time discretization. Assume now that we are given the partitions $P_n = \{0 = t_n^0 < t_n^1 < \cdots < t_n^{N_n} = T\}$, and denote by $\tau_n^i = t_n^i - t_n^{i-1}$ the ith time step and by $\tau_n = \max_{1\le i\le N_n} \tau_n^i$ the diameter of the nth partition. No constraints are imposed on the possible choice of the time steps throughout this analysis besides $\tau_n \to 0$ as $n \to \infty$. Moreover, let the parameter $\theta \in [1/2, 1]$ be given.

In the following we will make extensive use of the following notation: Letting $v = (v^0, \dots, v^{N_n})$ be a vector, we will denote by $\widehat{v}_n$ and $\overline{v}_n$ two functions of the time interval $[0,T]$ which interpolate the values of the vector v piecewise linearly and backward constantly on the partition P_n, respectively. Namely,

$$\begin{aligned} \widehat{v}_n(0) = v^0, \ \ \widehat{v}_n(t) = \gamma_n^i(t) v^i + \big(1 - \gamma_n^i(t)\big) v^{i-1}, \\ \overline{v}_n(0) = v^0, \ \ \overline{v}_n(t) = v^i, \quad \text{for} \ \ t \in (t_n^{i-1}, t_n^i], \ \ i = 1, \dots, N_n \end{aligned}$$

where

$$\gamma_n^i(t) = (t - t_n^{i-1})/\tau_n^i \quad \text{for} \ \ t \in (t_n^{i-1}, t_n^i], \ \ i = 1, \dots, N_n.$$

Moreover, we let $\delta v^i = (v^i - v^{i-1})/\tau_n^i$ for $i = 1, \dots, N_n$ (so that $\dot{\widehat{v}}_n = \overline{\delta v_n}$) and denote by v_θ the vector with components $v_\theta^i = \theta v^i + (1-\theta) v^{i-1}$.

Recall that $\ell \in W^{1,\infty}(0,T;Y^*)$ and $y_0 \in S(0)$. We shall be concerned with the so-called θ-scheme for problem (1.1):

$$\partial\psi\left(\frac{y_n^i - y_n^{i-1}}{\tau_n^i}\right) + A(\theta y_n^i + (1-\theta)y_n^{i-1}) \ni \ell(\theta t_n^i + (1-\theta)t_n^{i-1})$$

$$\text{for } \ i = 1, \dots, N_n, \tag{6.1}$$

$$y_n^0 = y_0. \tag{6.2}$$

One usually refers to the latter as the backward or implicit Euler scheme for the choice $\theta = 1$ and as the Crank–Nicolson scheme for $\theta = 1/2$.

Owing to the above-introduced notation, the latter scheme can be equivalently rewritten as

$$\partial\psi\left(y_n^i - y_n^{i-1}\right) + Ay_{n,\theta}^i \ni \ell(t_{n,\theta}^i) \quad \text{for } \ i = 1, \dots, N_n, \quad y_n^0 = y_0. \tag{6.3}$$

Clearly, the θ-scheme (6.3) is rate-independent. Namely, no time step appears in (6.3), and the choice of the partition affects the solution via the values of the load ℓ only. In this concern, our focus on variable time-step partition could be simplified by considering proper rescaled loads ℓ instead. We shall, however, keep up with it, especially in order to underline the possibility of adapting the partition according to some a posteriori analysis (see subsection 6.7).

Before moving on, let us comment that, for all n, the latter scheme is a unique solution. Indeed, given $y_n^{i-1} \in C$, it suffices to (uniquely) solve iteratively the incremental problem

$$y_n^i \in \operatorname{Arg\,min}_{y\in Y}\Big(\theta\phi(y) - \langle \ell(t_{n,\theta}^i) - (1-\theta)Ay_n^{i-1}, y\rangle + \psi(y - y_n^{i-1})\Big). \tag{6.4}$$

Note that, since $y_n^{i-1} \in C$, the functional under minimization turns out to be uniformly convex. Hence, by (3.5), the minimum problem has a unique solution. In particular, exactly as in Lemma 4.1 we have the following.

LEMMA 6.1. *$y_n^i \in C$ for all $i = 0, 1, \dots, N_n$.*

A crucial observation is that, as in the continuous case, the discrete trajectories show some sort of stability as well.

LEMMA 6.2 (stability of the discrete trajectories). *We have*

$$y_n^i \in \operatorname{Arg\,min}_{y\in Y}\Big(\theta\phi(y) - \langle \ell(t_{n,\theta}^i) - (1-\theta)Ay_n^{i-1}, y\rangle + \psi(y - y_n^i)\Big)$$

$$\text{for } \ i = 1, \dots, N_n. \tag{6.5}$$

In particular, if $\theta = 1$, then $y_n^i \in S(t_n^i)$.

Proof. From the incremental formulation (6.4) and the triangle inequality for ψ, we get, for all $y \in Y$,

$$\begin{aligned}
&\theta\phi(y_n^i) - \langle \ell(t_{n,\theta}^i) - (1-\theta)Ay_n^{i-1}, y_n^i\rangle + \psi(y_n^i - y_n^{i-1}) \\
&\quad \le \theta\phi(y) - \langle \ell(t_{n,\theta}^i) - (1-\theta)Ay_n^{i-1}, y\rangle + \psi(y - y_n^{i-1}) \\
&\quad \le \theta\phi(y) - \langle \ell(t_{n,\theta}^i) - (1-\theta)Ay_n^{i-1}, y\rangle + \psi(y - y_n^i) + \psi(y_n^i - y_n^{i-1}),
\end{aligned}$$

whence the assertion follows. ∎

Again as in the continuous case, we readily check that

$$\text{(6.5) holds iff} \quad \ell(t_{n,\theta}^i) - Ay_{n,\theta}^i \in C^*. \tag{6.6}$$

6.1. The discrete variational principle. We shall now present a discrete version of the variational principle of Theorem 3.1.

We define $L_n^{\theta,i}(y,z) : Y \times Y \to [0,\infty]$ as

$$L_n^{\theta,i}(y,z) = \psi\left(\frac{y-z}{\tau_n^i}\right) + \psi^*\left(\ell(t_{n,\theta}^i) - A(\theta y + (1-\theta)z)\right) - \left\langle \ell(t_{n,\theta}^i) - A(\theta y + (1-\theta)z), \frac{y-z}{\tau_n^i}\right\rangle$$

and the functionals $F_n^\theta : Y^{N_n+1} \to [0,\infty]$ as

$$F_n^\theta(y_n^0,\dots,y_n^{N_n}) = \sum_{i=1}^{N_n} \tau_n^i L_n^{\theta,i}(y_n^i, y_n^{i-1}) + \chi(y_n^0 - y_0).$$

LEMMA 6.3 (discrete variational principle). $(y_n^0,\dots,y_n^{N_n})$ *solves* (6.3) *iff* $F_n^\theta(y_n^0, \dots, y_n^{N_n}) = 0 = \min F_n^\theta$.

Proof. Analogously to the continuous case, we have, for all $i = 1,\dots,N_n$,

$$\partial\psi\left(\delta y_n^i\right) + A y_{n,\theta}^i \ni \ell(t_{n,\theta}^i) \quad \text{iff} \quad L_n^{\theta,i}(y_n^i, y_n^{i-1}) = 0,$$

and $y_n^0 = y_0$ iff $\chi(y_n^0 - y_0) = 0$. ∎

Let us observe that the functional F_n^θ is convex and lower semicontinuous. Moreover, by the homogeneity of ψ (see (3.2)), F_n^θ is actually independent of the time steps. In fact, we have

$$F_n^\theta(y_n^0,\dots,y_n^{N_n}) = \sum_{i=1}^{N_n}\left(\psi\left(y_n^i - y_n^{i-1}\right) + \psi^*\left(\ell(t_{n,\theta}^i) - A y_{n,\theta}^i\right) - \langle \ell(t_{n,\theta}^i) - A y_{n,\theta}^i, y_n^i - y_n^{i-1}\rangle\right) + \chi(y_n^0 - y_0).$$

The idea of dealing with time discretizations via a discrete variational principle closely relates our analysis to the theory of so-called *variational integrators*. The latter are numerical schemes stemming from the approximation of the action functional in Lagrangian mechanics. By referring the reader to the monograph [12] and the survey [25], we shall restrain here from giving a detailed presentation of the subject and limit ourselves to some (necessarily sketchy) considerations. By letting $(t,y,p) \in [0,T] \times \mathbb{R}^m \times \mathbb{R}^m \mapsto \mathcal{L}(t,y,p)$ denote the Lagrangian of a (finite-dimensional, for simplicity) system, the Hamilton principle asserts that the actual trajectory $t \mapsto y(t)$ of the system minimizes the action functional

$$y \mapsto \int_0^T \mathcal{L}(t, y(t), \dot y(t))\ \mathrm{d}t$$

among all curves with prescribed end points, thus solving the Lagrange equations

$$\partial_{y_i}\mathcal{L} - \frac{\mathrm{d}}{\mathrm{d}t}\partial_{p_i}\mathcal{L} = 0 \quad \text{for } i = 1,\dots,m. \tag{6.7}$$

Hence, a natural idea is that of deriving numerical schemes for Lagrangian mechanics by applying some quadrature procedure to the action functional, i.e., discretizing

Hamilton's principle. The resulting discrete schemes show comparable performance with respect to other methods but generally enjoy some interesting extra (and often crucial) properties such as the conservation of suitable quantities [20]. Variational integrators have been intensively applied in finite-dimensional contexts and, more recently, to the situation of nonlinear wave equations [24] and nonequilibrium elasticity [19].

The present analysis may bear some resemblance to the above-mentioned theory. Indeed, the formulation of the θ-scheme in the case $\theta = 1/2$ stems exactly from the midpoint quadrature of the functional F as

$$\begin{aligned}
&\int_{t_n^{i-1}}^{t_n^i} L(t, \widehat{y}(t), \dot{\widehat{y}}(t))\, \mathrm{d}t \\
&= \tau_n^i L(t_{n,1/2}^i, \widehat{y}(t_{n,1/2}^i), \dot{\widehat{y}}(t_{n,1/2}^i)) \\
&= \psi\left(y^i - y^{i-1}\right) + \psi^*\left(\ell(t_{n,1/2}^i) - A\left(\frac{y^i + y^{i-1}}{2}\right)\right) \\
&- \left\langle \ell(t_{n,1/2}^i) - A\left(\frac{y^i + y^{i-1}}{2}\right), y_n^i - y_n^{i-1} \right\rangle,
\end{aligned}$$

where $\widehat{y}$ is taken to be piecewise affine on the partition P_n.

On the other hand, our focus here is quite different. First of all, we are not dealing with the Hamilton principle (end points are not fixed) as we are not aimed at solving the Euler–Lagrange equations for F (i.e., solving (6.7)). Second, we are specifically interested at infinite-dimensional situations, namely, PDEs. Finally, the only choice of θ which is directly related with a quadrature of F is $\theta = 1/2$, and we are not considering higher-order schemes.

Before closing this discussion, let us mention that some Γ-convergence techniques have been recently exploited in the (finite-dimensional) frame of variational integrators by Müller and Ortiz [37] (see also [23]).

6.2. Stability of the θ-scheme. It has been known since Han and Reddy [15, 13] that the choice $\theta < 1/2$ in (6.3) leads to an unconditionally unstable scheme and that, on the contrary, for $\theta \in [1/2, 1]$ the θ-scheme is stable in $H^1(0,T;Y)$ when Y is a Hilbert space and the partitions are chosen to be uniform.

Here we shall provide an alternative stability proof by taking into account the Banach-space frame.

LEMMA 6.4 (stability). *Assume* (3.6)*, and let* $\theta \in [1/2, 1]$. *Then the solution to the* θ*-scheme* (6.3) *fulfills*

$$\|\dot{\widehat{y}}_{n,\theta}\|_{L^\infty(0,T;Y)} \le \frac{1}{\alpha}\|\dot{\ell}\|_{L^\infty(0,T;Y^*)} \quad \text{if } \theta = 1 \text{ or } \theta = \frac{1}{2}. \tag{6.8}$$

Moreover, for constant time steps,

$$\|\dot{\widehat{y}}_{n,\theta}\|_{L^\infty(0,T;Y)} \le \frac{1}{\alpha(2\theta - 1)}\|\dot{\ell}\|_{L^\infty(0,T;Y^*)} \quad \text{if } \frac{1}{2} < \theta < 1. \tag{6.9}$$

Our argument coincides with that of [32, Thm. 4.4] in the case of the implicit Euler scheme, i.e., $\theta = 1$, and it is an extension of the latter for the case $1/2 < \theta < 1$. Here we do not play with the variational inequality by choosing suitable tests but use the scalar relations $L_n^{\theta,i}(y_n^i, y_n^{i-1}) = 0$ instead (this, however, makes no substantial

difference since the latter scalar relations are exactly the outcome of the test on the variational inequality in [32, Thm. 4.4]).

The stability proof for the Crank–Nicolson scheme $\theta = 1/2$ is quite different from former arguments and stems as a direct outcome of our variational approach. In both cases $\theta = 1$ and $\theta = 1/2$, the stability constant $1/\alpha$ is sharp (see Lemma 4.7).

We complement this analysis by providing the stability for the θ-scheme for $1/2 < \theta < 1$ in the case of constant time steps (likely with a nonoptimal, although explicit, stability constant).

Note that the stability estimates (6.8)–(6.9) do not hold in the classical parabolic situation (i.e., ψ quadratic on a Hilbert space) unless the very restrictive compatibility assumption $Ay_0 = \ell(0)$ is made (and in this case, the proof below just goes through). Evidence of this failure is available even in the simplest scalar situation ($Y = \mathbb{R}$) of problem $\dot{y}(t) + y(t) = 0$ for $t > 0$ and $y(0) = y_0$. Indeed, the corresponding θ-scheme fulfills (6.8)–(6.9) iff $y_0 = 0$ (and hence $y \equiv 0$). The current rate-independent situation turns out to be better behaved since the restriction $Ay_0 = \ell(0)$ of the parabolic case is replaced by the weaker $y_0 \in S(0)$ (see (4.5)).

Proof. Let us prove the stability of the Crank–Nicolson scheme $\theta = 1/2$ first. For this aim, it suffices to recall that

$$\begin{aligned} 0 &= F_n^{1/2}(y_n^0, \dots, y_n^{N_n}) \\ &= \int_0^T \Big(\psi(\dot{\widehat{y}}_n) + \psi^*(\widehat{\ell}_n - A\widehat{y}_n) - \langle \widehat{\ell}_n - A\widehat{y}_n, \dot{\widehat{y}}_n\rangle\Big) + \chi(\widehat{y}_n(0) - y_0). \end{aligned}$$

Hence $\widehat{y}_n$ minimizes the functional F where ℓ is replaced by $\widehat{\ell}_n$. The stability estimate follows from Lemma 4.7.

Let us now move to the case $1/2 < \theta \le 1$. Relation (6.5) applied at level $i-1$ for some $i = 2, \dots, N_n$ along with the choice $y = y_n^i$ entails that

$$\begin{aligned} &\theta\phi(y_n^i - y_n^{i-1}) + \theta\phi(y_n^{i-1}) - \langle \ell(t_{n,\theta}^{i-1}) - (1-\theta)Ay_n^{i-2}, y_n^{i-1}\rangle \\ &\quad \le \theta\phi(y_n^i) - \langle \ell(t_{n,\theta}^{i-1}) - (1-\theta)Ay_n^{i-2}, y_n^i\rangle + \psi(y_n^i - y_n^{i-1}), \end{aligned}$$

where the extra term $\theta\phi(y_n^i - y_n^{i-1})$ is obtained from the fact ϕ is quadratic. Hence, we have

$$\begin{aligned} &\theta\phi(y_n^i - y_n^{i-1}) + \theta\phi(y_n^{i-1}) - \theta\phi(y_n^i) \\ &\le \langle \ell(t_{n,\theta}^{i-1}), y_n^{i-1} - y_n^i\rangle + (1-\theta)\langle A(y_n^{i-2} - y_n^{i-1}), y_n^i - y_n^{i-1}\rangle + \psi(y_n^i - y_n^{i-1}) \\ &+(1-\theta)\langle Ay_n^{i-1}, y_n^i - y_n^{i-1}\rangle \\ &= \langle \ell(t_{n,\theta}^{i-1}), y_n^{i-1} - y_n^i\rangle + (1-\theta)\langle A(y_n^{i-2} - y_n^{i-1}), y_n^i - y_n^{i-1}\rangle + \psi(y_n^i - y_n^{i-1}) \\ &-(1-\theta)\Big(\phi(y_n^{i-1}) + \phi(y_n^i - y_n^{i-1}) - \phi(y_n^i)\Big), \end{aligned}$$

so that

$$\phi(e_n^i) + \phi(y_n^{i-1}) - \phi(y_n^i) \le -\langle \ell(t_{n,\theta}^{i-1}), e_n^i\rangle + (\theta-1)\langle Ae_n^{i-1}, e_n^i\rangle + \psi(e_n^i), \tag{6.10}$$

where we have used $e_n^i = y_n^i - y_n^{i-1}$ in order to shorten notations.

Next, from $L_n^{\theta,i}(y_n^i, y_n^{i-1}) = 0$ for $i = 1, \dots, N_n$, we obtain

$$\begin{aligned} 0 &= \psi(e_n^i) - \langle \ell(t_{n,\theta}^i) - Ay_{n,\theta}^i, e_n^i\rangle \\ &= \psi(e_n^i) - \langle \ell(t_{n,\theta}^i), e_n^i\rangle + \theta\Big(\phi(y_n^i) + \phi(e_n^i) - \phi(y_n^{i-1})\Big) \\ &\quad - (1-\theta)\Big(\phi(y_n^{i-1}) + \phi(e_n^i) - \phi(y_n^i)\Big). \end{aligned}$$

In particular, we have checked that

$$\psi(e_n^i) + \phi(y_n^i) - \phi(y_n^{i-1}) + (2\theta - 1)\phi(e_n^i) = \langle \ell(t_{n,\theta}^i), e_n^i \rangle. \tag{6.11}$$

We take the sum between the latter and (6.10) and get

$$2\theta\phi(e_n^i) \le \langle \ell(t_{n,\theta}^i) - \ell(t_{n,\theta}^{i-1}), e_n^i \rangle + (\theta - 1)\langle Ae_n^{i-1}, e_n^i \rangle$$

or, equivalently,

$$\langle Ae_{n,\theta}^i, e_n^i \rangle \le \langle \ell(t_{n,\theta}^i) - \ell(t_{n,\theta}^{i-1}), e_n^i \rangle. \tag{6.12}$$

Now, if $\theta = 1$, we conclude that

$$|e_n^i| \le \frac{1}{\alpha} |\ell(t_{n,\theta}^i) - \ell(t_{n,\theta}^{i-1})|_*,$$

and the assertion follows.

In case $1/2 \le \theta < 1$ and for a constant time-step partition, one proceeds from (6.12) by computing

$$\begin{aligned}
&\tau_n \|\dot{\widehat{\ell}}_n\|_{L^\infty(0,T;Y^*)} \sqrt{\frac{2}{\alpha}} \sqrt{\phi(e_n^i)} \\
&\ge \langle \ell(t_{n,\theta}^i) - \ell(t_{n,\theta}^{i-1}), e_n^i \rangle \\
&\ge \theta \langle Ae_n^i, e_n^i \rangle + (1-\theta)\langle Ae_n^{i-1}, e_n^i \rangle \\
&= (2\theta - 1)\langle Ae_n^i, e_n^i \rangle + (1-\theta)\langle A(e_n^i + e_n^{i-1}), e_n^i \rangle \\
&\ge 2(2\theta - 1)\phi(e_n^i) + (1-\theta)\Big(\phi(e_n^i) - \phi(e_n^{i-1})\Big).
\end{aligned}$$

Note that the coefficient $(2\theta - 1)$ is strictly positive as $\theta > 1/2$. By using the fact that $y_n^0 = y_0 \in S(0)$ (recall (4.5)), we readily check that

$$\phi(e_n^1) + \phi(y_n^0) - \langle \ell(0), y_n^0 \rangle \le \phi(y_n^1) - \langle \ell(0), y_n^1 \rangle + \psi(e_n^1), \tag{6.13}$$

and, by adding the latter to (6.11) for $i = 1$, we have

$$2\theta\phi(e_n^1) \le \langle \ell(t_{n,\theta}^1) - \ell(0), e_n^1 \rangle \le \tau_n \|\dot{\widehat{\ell}}_n\|_{L^\infty(0,T;Y^*)} \sqrt{\frac{2}{\alpha}} \sqrt{\phi(e_n^1)}. \tag{6.14}$$

Let us define

$$a_i^2 = \phi\left(\frac{y_n^i - y^{i-1}}{\tau_n}\right) = \phi(e_n^i)/\tau_n^2,$$

$$C_0 = \frac{2(2\theta - 1)}{1 - \theta}, \quad C_1 = \frac{1}{1-\theta}\sqrt{\frac{2}{\alpha}} \|\dot{\widehat{\ell}}_n\|_{L^\infty(0,T;Y^*)}, \quad C_2 = \frac{C_1}{C_0},$$

so that, owing to (6.13) and (6.14) and by using the fact that $2(2\theta - 1) < 2\theta$,

$$\begin{aligned}
&\big(C_0 + 1\big)a_i^2 - a_{i-1}^2 \le C_1 a_i \quad \text{for} \quad i = 2, \dots, N_n, \\
&\qquad a_1 \le \frac{1}{2\theta}\sqrt{\frac{2}{\alpha}} \|\dot{\widehat{\ell}}_n\|_{L^\infty(0,T;Y^*)} \le \frac{1}{2(2\theta - 1)}\sqrt{\frac{2}{\alpha}} \|\dot{\widehat{\ell}}_n\|_{L^\infty(0,T;Y^*)} \\
&\qquad\quad = \frac{1}{1-\theta}\sqrt{\frac{2}{\alpha}} \|\dot{\widehat{\ell}}_n\|_{L^\infty(0,T;Y^*)} \frac{1-\theta}{2(2\theta - 1)} \\
&\qquad\quad = \frac{C_1}{C_0} = C_2.
\end{aligned}$$

Now, since $(C_0+1)C_2^2 - C_1C_2 = C_2^2$, we easily prove by induction that $a_i \le C_2$, and the assertion follows. ∎

6.3. Convergence. We shall prove the weak-star $W^{1,\infty}(0,T;Y)$ convergence for the θ-method. This result has to be compared with that of Han and Reddy [14, Thm. 3.4], where the uniform convergence of the backward constant interpolations is obtained. Our result is weaker than that of [14, Thm. 3.4] since we are not providing strong convergence. On the other hand, we believe our half-page proof to be possibly more transparent than the long argument developed in [14]. Let us moreover mention that, in the Hilbertian case and for A coercive on Y, the strong convergence in $W^{1,p}(0,T;Y)$ for all $p<\infty$ of the Euler method $\theta = 1$ has been proved in [16, Prop. 3.9, p. 33].

THEOREM 6.5 (convergence for the θ-method). *Assume* (3.6)*, and let* $F_n^\theta(y_n^0,\dots,y_n^{N_n}) = 0$*. Then* $\widehat{y}_n \to y$ *weakly star in* $W^{1,\infty}(0,T;Y)$*, where* $F(y) = 0 = \min F$*.*

Proof. Owing to Lemma 6.4, we can extract a (not relabeled) subsequence such that $\widehat{y}_n \to y$ weakly star in $W^{1,\infty}(0,T;Y)$ and hence weakly pointwise in Y. Moreover, we clearly have that both $\overline{y}_n$ and $\overline{y}_{n,\theta}$ converge at the same limit weakly star in $L^\infty(0,T;Y)$. Finally, we directly check that $\overline{\ell}_{n,\theta} \to \ell$ strongly in $L^\infty(0,T;Y^*)$. By observing that, since $\theta \ge 1/2$,

$$\begin{aligned}\tau_n^i\langle A(\theta y_n^i + (1-\theta)y_n^{i-1}), \delta y_n^i\rangle &= \phi(y_n^i) + (2\theta-1)\phi(y_n^i - y_n^{i-1}) - \phi(y_n^{i-1})\\ &\ge \phi(y_n^i) - \phi(y_n^{i-1}),\end{aligned}$$

we compute that

$$\begin{aligned}0 &= F_n^\theta(y_n^0,\dots,y_n^{N_n})\\ &\ge \int_0^T \Big(\psi(\dot{\widehat{y}}_n) + \psi^*(\overline{\ell}_{n,\theta} - A\overline{y}_{n,\theta}) - \langle \overline{\ell}_{n,\theta}, \dot{\widehat{y}}_n\rangle\Big)\\ &\quad + \phi(\widehat{y}_n(T)) - \phi(\widehat{y}_n(0)) + \chi(\widehat{y}_n(0) - y_0)\\ &= \int_0^T \Big(\psi(\dot{\widehat{y}}_n) + \psi^*(\overline{\ell}_{n,\theta} - A\overline{y}_{n,\theta}) - \langle \overline{\ell}_{n,\theta}, \dot{\widehat{y}}_n\rangle\Big)\\ &\quad + \phi(\widehat{y}_n(T)) + \phi(y_0) - \langle A\widehat{y}_n(0), y_0\rangle + |\widehat{y}_n(0) - y_0|^2.\end{aligned}$$

Finally, it suffices to pass to the lim inf above as $n\to\infty$ and exploit lower semicontinuity and the stated convergences in order to obtain $F(y)\le 0$. Hence, by Theorem 3.1 and Corollary 4.6, y is the only solution to (1.1), and the whole sequence $\widehat{y}_n$ converges. ∎

6.4. The functional controls the uniform distance. We shall reproduce at the discrete level the results of subsection 4.6. We begin by showing how to possibly control the uniform distance of two vectors by means of the discrete functional F_n^θ.

LEMMA 6.6 (uniform distance control via F_n^θ). *Let the vectors* $u = (u^0,\dots,u^{N_n})$ *and* $v = (v^0,\dots,v^{N_n}) \in Y^{N_n+1}$ *be given. Then*

$$\begin{aligned}&\eta(1-\eta)\max_{1\le i\le N_n}\phi(u^i - v^i)\\ &\le \eta F_n^\theta(u^0,\dots,u^{N_n}) + (1-\eta)F_n^\theta(v^0,\dots,v^{N_n}) \quad \forall \eta\in[0,1].\end{aligned}$$

Proof. This proof follows the same lines as that of Corollary 4.4. Let $1 \le i \le N_n$ be fixed, and define $F_n^{\theta,i} : Y^{i+1} \to [0,\infty]$ as

$$\begin{aligned} &F_n^{\theta,i}(y^0,\dots,y^i) \\ &\quad= \sum_{j=1}^{i} \tau_n^j L_n^{\theta,j}(y^j, y^{j-1}) + \chi(y^0 - y_0) \\ &\quad= \sum_{j=1}^{i} \psi(y^j - y^{j-1}) + \psi^*(\ell(t_{n,\theta}^j) - Ay_\theta^j) - \langle \ell(t_{n,\theta}^j), y^j - y^{j-1}\rangle \\ &\qquad+ \phi(y^i) + (2\theta - 1)\sum_{j=1}^{i} \phi(y^j - y^{j-1}) + \phi(y_0) - \langle Ay^0, y_0\rangle + |y^0 - y_0|^2. \end{aligned}$$

Then, clearly, $y = (y^0,\dots,y^i) \mapsto G_n^{\theta,i}(y) = F_n^{\theta,i}(y) - \phi(y^i)$ is convex. Hence, by letting $w = \eta u + (1-\eta)v$ for some $\eta \in [0,1]$, we have

$$\begin{aligned} &0 \le F_n^{\theta,i}(w) \\ &\le \eta\big(G_n^{\theta,i}(u) + \phi(u^i)\big) + (1-\eta)\big(G_n^{\theta,i}(v) + \phi(v^i)\big) - \eta(1-\eta)\phi(u^i - v^i), \end{aligned}$$

whence the assertion follows. ∎

Again, note that the latter lemma controls the uniform norm of the distance only if the stronger (3.6) is required. The following corollary of Lemma 6.6 will be the starting point for some possible a posteriori error control procedure (see subsection 6.6).

COROLLARY 6.7 (uniform distance from the minimizer). *Let* $F_n^\theta(y^0,\dots,y^{N_n}) = 0$. *Then*

$$\max_{1\le i\le N_n} \phi(y^i - v^i) \le F_n^\theta(v^0,\dots,v^{N_n}) \quad \forall (v^0,\dots,v^{N_n}) \in Y^{N_n+1}.$$

Moreover, we reobtain a proof of the uniqueness of the solution of the θ-method.

COROLLARY 6.8 (uniqueness of the minimizer). *Assume* (3.6). *Then there exists at most one* $y = (y^0,\dots,y^{N_n})$ *such that* $F_n^\theta(y) = 0$.

6.5. The generalized θ-method. Although minimizers of F_n^θ and solutions of the θ-scheme (6.3) coincide, minimizing sequences of F_n^θ need not solve (6.3). This extra freedom allows the minimization formulation to capture the convergence of some generalized θ-method, where the relations in (6.3) are not solved exactly but rather are approximated. Namely, we shall look for vectors $u_n = (u_n^0,\dots,u_n^{N_n})$ such that

$$F_n^\theta(u_n) \to 0 \quad \text{as} \quad n \to \infty$$

instead of $F_n^\theta(u_n) = 0$ for all $n \in \mathbb{N}$.

From the computational viewpoint, note that the θ-scheme consists in solving N_n nonlinear equations in one unknown each, while checking for stationarity for F_n^θ implies the solution of a tridiagonal system of $N_n + 1$ nonlinear equations with (up to) three unknowns each. This entails in particular that minimizing F_n^θ instead of solving (6.3) could be of a scarce interest if one is merely concerned in reproducing the θ-scheme with no error. On the other hand, the issue of solving up to some tolerance turns out to be particularly relevant whenever one is aimed at implementing an optimization procedure for the solution of (6.3). Indeed, one should be prepared to run the algorithm (some descent method, say) until some given tolerance is reached.

Our starting point for a possible convergence analysis of the generalized θ-method is the following classical error control result.

THEOREM 6.9 (Mielke and Theil [32]). *Assume* (3.6). *Then* $\widehat{y}_n \to y$ *uniformly and* $F(y) = 0$. *In particular,*

$$\max_{t\in[0,T]} |(\widehat{y}_n - y)(t)| \le C_e\sqrt{\tau_n}, \tag{6.15}$$

where C_e *depends only on data and is independent of* n.

More precisely, in [32] solely the case of the Euler scheme $\theta = 1$ is discussed. However, an easy adaptation of the argument entails the result for $\theta \in [1/2, 1)$ as well.

By explicitly comparing the minimizing sequence $u_n = (u_n^0, \dots, u_n^{N_n})$ with the corresponding solution $(y_n^0, \dots, y_n^{N_n})$ of the θ-method, we have the following.

THEOREM 6.10 (convergence for the generalized θ-method). *Assume* (3.6), *and let* $F_n^\theta(u_n^0, \dots, u_n^{N_n}) \to 0$. *Then* $\widehat{u}_n \to y$ *uniformly, where* $F(y) = 0$. *In particular,*

$$\max_{t\in[0,T]} |(\widehat{u}_n - y)(t)| \le C_e\sqrt{\tau_n} + \left(\frac{2}{\alpha}F_n^\theta(u_n^0, \dots, u_n^{N_n})\right)^{1/2}. \tag{6.16}$$

Proof. We have

$$\begin{aligned}\max_{t\in[0,T]} |(y - \widehat{u}_n)(t)| &\le \max_{t\in[0,T]} |(y - \widehat{y}_n)(t)| + \max_{t\in[0,T]} |(\widehat{y}_n - \widehat{u}_n)(t)| \\ &\le C_e\sqrt{\tau_n} + \max_{1\le i\le N_n} |u_n^i - y_n^i| \\ &\le C_e\sqrt{\tau_n} + \left(\frac{2}{\alpha}\max_{1\le i\le N_n} \phi(u_n^i - y_n^i)\right)^{1/2},\end{aligned}$$

and we conclude by applying Corollary 6.7. ∎

6.6. A posteriori error control. Let us now exploit both Corollary 4.5 and Theorem 6.10 in order to provide some possible a posteriori estimates of the approximation error by means of solutions u_n of the generalized θ-method described above.

LEMMA 6.11 (a posteriori error control via F_n^θ). *Assume* (3.6), *and let* $F_n^\theta(u_n^0, \dots, u_n^{N_n}) \sim \tau_n^s$ *for some* $s > 0$ *and* $F(y) = 0$. *Then*

$$\max_{t\in[0,T]} |(\widehat{u}_n - y)(t)| \sim \tau_n^r, \quad \textit{where} \quad 2r = \max\{1, s\}.$$

LEMMA 6.12 (a posteriori error control via F). *Assume* (3.6), *and let* $F(\widehat{u}_n) \sim \tau_n^s$ *for some* $s > 0$ *and* $F(y) = 0$. *Then* $\max_{t\in[0,T]} |(\widehat{u}_n - y)(t)| \sim \tau_n^{s/2}$.

We are also in the position of proving the weak-star convergence of the time derivatives of solutions u_n of the generalized θ-method by comparing them with the corresponding derivatives of the exact solution of the θ-method.

LEMMA 6.13 (improved convergence for the generalized θ-method). *Assume* (3.6), *and let* $F_n^\theta(u_n^0, \dots, u_n^{N_n}) \sim \tau_n^2$. *Then* $\widehat{u}_n$ *is equibounded in* $W^{1,\infty}(0, T; Y)$. *In particular,* $\widehat{u}_n \to y$ *weakly star in* $W^{1,\infty}(0, T; Y)$.

Proof. Let $(y_n^0, \dots, y_n^{N_n})$ be the solution of the θ-scheme. By exploiting Lemma 6.7, we check that

$$\begin{aligned}|u_n^i - u_n^{i-1}| &\le \left|u_n^i - y_n^i\right| + \left|y_n^i - y_n^{i-1}\right| + \left|y_n^{i-1} - u_n^{i-1}\right| \\ &\le \tau_n^i\|\dot{\widehat{y}}_n\|_{L^\infty(0,T;Y)} + 2\left(\frac{2}{\alpha}F_n^\theta(u_n^0, \dots, u_n^{N_n})\right)^{1/2}.\end{aligned}$$

The uniform bound on $\|\widehat{u}_n\|_{W^{1,\infty}(0,T;Y)}$ follows by dividing the latter by τ_n^i, taking the maximum as $1 \le i \le N_n$, and recalling Lemma 6.4. ∎

6.7. Adaptivity. By assuming (3.6), the above-introduced a posteriori error estimators can be exploited in order to develop an adaptive strategy. In particular, the error control in the uniform norm up to a given tolerance $\mathrm{tol} > 0$

$$\max_{t\in[0,T]} |(y - \widehat{y}_n)(t)| \le \mathrm{tol}$$

for some piecewise approximation $\widehat{y}_n$, with $\chi(\widehat{y}_n(0) - y_0) \le \alpha\,\mathrm{tol}^2/4$, can be inferred, for instance, by choosing time steps in such a way that

$$\int_{t_n^{i-1}}^{t_n^i} L(t, \widehat{y}_n(t), \dot{\widehat{y}}_n(t)) \le \frac{\alpha\,\mathrm{tol}^2}{4N_n},$$

namely, by uniformly distributing the error along the partition.

Alternatively, one could develop an adaptive strategy by considering just computed quantities at the discrete level by asking for

$$\tau_n^i L_n^{\theta,i}(y_n^i, y_n^{i-1}) \le \frac{\alpha\,\mathrm{tol}^2}{32N_n} \quad \text{for} \quad \tau_n \le \frac{\mathrm{tol}^2}{16C_e^2}$$

and exploiting Theorem 6.10.

7. Space-time approximations. Let us combine the results of the previous sections (and use the corresponding notation) in order to state and prove a result on the convergence of full space-time approximations. Our results have to be compared with the former convergence analysis by Han and Reddy [13]. Our approach leads to a convergence proof with respect to a weaker topology. However, it is, on the one hand, slightly more general (some assumptions on the spaces and the functionals—see (H1)–(H2) [13, p. 264]—are not required) and, on the other hand, has a much simpler proof.

THEOREM 7.1 (convergence of space-time approximations). *Assuming* (5.1)–(5.9) *and that* $\theta \in [1/2, 1]$, *define* $L_{n,h}^{\theta,i}(y,z) : Y \times Y \to [0,\infty]$ *as*

$$L_{n,h}^{\theta,i}(y,z) = \psi_h\left(\frac{y-z}{\tau_n^i}\right) + \psi_h^*\left(\ell_h(t_{n,\theta}^i) - A_h(\theta y + (1-\theta)z)\right) - \left\langle \ell_h(t_{n,\theta}^i) - A_h(\theta y + (1-\theta)z), \frac{y-z}{\tau_n^i}\right\rangle,$$

where $A_h = \partial\phi_h$, *and let the functionals* $F_{n,h}^\theta : Y^{N_n+1} \to [0,\infty]$ *be defined as*

$$F_{n,h}^\theta(y^0, \dots, y^{N_n}) = \sum_{i=1}^{N_n} \tau_n^i L_{n,h}^{\theta,i}(y^i, y^{i-1}) + \chi_h(y^0 - y_0),$$

where $\chi_h(\cdot) = \phi_h(\cdot) + |\cdot|^2$ *(note that* $D(F_{n,h}^\theta) \subset Y_h^{N_n+1}$*). Finally, let* $F_{n,h}(y_h^0, \dots, y_h^{N_n}) = 0$. *We have the following:*

(a) $\widehat{y}_{n,h} \to y_h$ *weakly star in* $W^{1,\infty}(0,T;Y)$ *as* $(n,h) \to (\infty,h)$ *and* $F_h(y_h) = 0$.
(b) $\widehat{y}_{n,h} \to \widehat{y}_n$ *weakly star in* $W^{1,\infty}(0,T;Y)$ *as* $(n,h) \to (n,0)$ *and* $F_n^\theta(y_n) = 0$.
(c) $\widehat{y}_n \to y$ *weakly star in* $W^{1,\infty}(0,T;Y)$ *as* $(n,0) \to (\infty,0)$ *and* $F(y) = 0$.

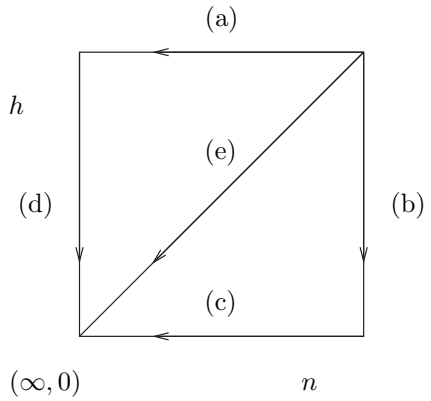

FIG. 1. *Convergences for space-time approximations (see Theorem* 7.1*).*

(d) $y_h \to y$ *weakly star* $W^{1,\infty}(0,T;Y)$ *as* $(\infty,h) \to (\infty,0)$ *and* $F(y)=0$.

(e) $\widehat{y}_{n,h} \to y$ *weakly star in* $W^{1,\infty}(0,T;Y)$ *as* $(n,h) \to (\infty,0)$ *and* $F(y)=0$.

The thesis of the theorem is illustrated in Figure 1. In particular, we aim at showing that the space (or data) and time limit can be taken in any order. Note that limit (c) has been already checked in Theorem 6.5 and that the very same argument yields limit (a) as well (recall that Y_h is closed). Moreover, limit (d) is discussed in Theorem 5.3. So what we are actually left to check are limits (b) and (e) only.

Proof. Limit (b). The assertion follows once we check that, for all $i = 1, \dots, N_n$, if $y^{i-1}_{n,h} \to y^{i-1}_n$ weakly in Y, one has the weak convergence $y^i_{n,h} \to y^i_n$ as well. Recall that

$$y^i_{n,h} \in \operatorname{Arg\,min}_{y\in Y}\Big(\theta\phi_h(y) - \langle \ell_h(t^i_{n,\theta}) - (1-\theta)A_h y^{i-1}_{n,h}, y\rangle + \psi_h(y - y^{i-1}_{n,h})\Big)$$

$$= \operatorname{Arg\,min}_{y\in Y_h}\Big(\theta\phi(y) - \langle \ell_h(t^i_{n,\theta}) - (1-\theta)A y^{i-1}_{n,h}, y\rangle + \psi_h(y - y^{i-1}_{n,h})\Big).$$

Hence, since we have (5.6), the sequence $y^i_{n,h}$ is weakly precompact, and, up to the extraction of a (not relabeled) subsequence, $y^i_{n,h} \to \tilde{y}$ weakly in Y. Let us prove that $\tilde{y}$ solves the incremental problem (6.4). Indeed, we have

$$\begin{aligned} 0 &\le L^{\theta,i}_n(\tilde{y}, y^{i-1}_n) \\ &\le \liminf_{h\to 0}\Big(\psi_h(y^i_{n,h} - y^{i-1}_{n,h}) + \psi^*_h(\ell_h(t^i_{n,\theta}) - A y^i_{n,h,\theta}) \\ &\quad - \langle \ell_h(t^i_{n,\theta}) - A y^i_{n,h,\theta}, y^i_{n,h} - y^{i-1}_{n,h}\rangle\Big) \\ &= \liminf_{h\to 0} L^{\theta,i}_{n,h}(y^i_{n,h}, y^{i-1}_{n,h}) = 0, \end{aligned}$$

where we have used the Mosco convergence in (5.5) and the pointwise convergence of ℓ_h (5.7). Since the only solution of (6.4) is y^i_n, we have $\tilde{y} = y^i_n$, and the whole sequence converges.

Let us mention that, if the functionals ψ_h are uniformly linearly bounded (which is quite common in practice), one could prove the latter convergence to be actually strong: Namely, $y^{i-1}_{n,h} \to y^{i-1}_n$ strongly in Y implies the strong convergence $y^i_{n,h} \to y^i_n$. Indeed, let w_h and $\tilde{w}_h$ be such that $w_h - y^i_{n,h} \to 0$ strongly in Y, $\psi_h(w_h - y^i_{n,h}) \to 0$,

$\tilde w_h \in Y_h$ and $\tilde w_h - w_h \to 0$ strongly in Y. Then

$$\theta\phi(y^i_{n,h}) - \langle \ell(t^i_{n,\theta}) - (1-\theta)A_h y^{i-1}_{n,h}, y^i_{n,h}\rangle + \psi_h(y^i_{n,h} - y^{i-1}_{n,h})$$

$$\le \theta\phi_h(\tilde w_h) - \langle \ell(t^i_{n,\theta}) - (1-\theta)A y^{i-1}_{n,h}, \tilde w_h\rangle + \psi_h(\tilde w_h - w_h) + \psi_h(w_h - y^i_{n,h}).$$

If ψ_h are uniformly linearly bounded above, then $\psi_h(\tilde w_h - w_h) \to 0$, with $h \to 0$. Then, by passing to the lim sup in the latter, we check that $\limsup_{h\to 0} \phi(y^i_{n,h}) \le \phi(y^i_n)$, which together with lower semicontinuity gives $\phi(y^i_{n,h}) \to \phi(y^i_n)$, and the strong convergence follows from the reflexivity of Y.

Limit (e). Lemma 6.4, the uniform Lipschitz continuity of ℓ_h (5.8), and the initial datum convergence (5.9) entail that $\widehat y_{n,h}$ are uniformly Lipschitz continuous as well. Hence, by extracting a (not relabeled) subsequence, $\widehat y_{n,h} \to y$ weakly star in $W^{1,\infty}(0,T;Y)$. In order to check that y solves (1.1), let us remark that, since $\ell^i_{n,h,\theta} = \ell_h(t^i_{n,\theta})$,

$$\overline\ell_{n,h,\theta} \to \ell \quad \text{strongly in} \quad L^1(0,T;Y^*)$$

and that, by [45, Cor. 4.4],

$$\int_0^T \psi(\dot y) \le \liminf_{h\to 0} \int_0^T \psi_h(\dot{\widehat y}_{n,h}),$$

$$\int_0^T \psi^*(\ell - Ay) \le \liminf_{h\to 0} \int_0^T \psi_h^*(\overline\ell_{n,h,\theta} - A\overline y_{n,h,\theta})$$

and compute that

$$\begin{aligned}
0 &\le F(y)\\
&\le \liminf_{h\to 0} \left(\int_0^T \big(\psi_h(\dot{\widehat y}_{n,h}) + \psi_h^*(\overline\ell_{n,h,\theta} - A\overline y_{n,h,\theta}) - \langle \overline\ell_{n,h,\theta}, \dot{\widehat y}_{n,h}\rangle\big)\right.\\
&\quad \left. + \phi(\widehat y_{n,h}(T)) + \phi(y_{0,h}) - \langle A\widehat y_{n,h}(0), y_{0,h}\rangle + |\widehat y_{n,h}(0) - y_{0,h}|^2 \right)\\
&\le \liminf_{h\to 0} F^\theta_{n,h}(y^0_{n,h}, \dots, y^{N_n}_{n,h}) = 0,
\end{aligned}$$

and we have $F(y) = 0$. □

We shall conclude by briefly mentioning some further results which can be obtained by suitably adapting to the current fully discretized situation the arguments developed above for time discretizations. First, in the same spirit of Lemma 6.6, one could consider the possibility of estimating the distance of a vector from the minimizer of $F^\theta_{n,h}$ by means of the functional itself. Second, the use of Corollary 4.5 would entail the possibility of an a posteriori error control, and some adaptive strategy along the lines of subsection 6.7 could be considered. Finally, by relying on the known convergence estimates for full space-time discretized problems [13], one could obtain a convergence and an a posteriori error control result for some generalized space-time approximated problem where $F^\theta_{n,h}$ are not exactly minimized and one considers minimizing sequences instead (see subsection 6.5). We shall develop these considerations elsewhere.
