$$\begin{cases} \text{find } u_\varepsilon = (u_{1\varepsilon}, u_{2\varepsilon}) \text{ in } L^2(0,T;\ V^\varepsilon) \times L^2(0,T;\ H^1(\Omega_{2\varepsilon})) \\ \text{such that } u'_{1\varepsilon} \in L^2(0,T; L^2(\Omega_{1\varepsilon})),\ u'_{2\varepsilon} \in L^2(0,T; L^2(\Omega_{2\varepsilon})) \text{ and} \\ \langle u''_{1\varepsilon}, v_1 \rangle_{(V^\varepsilon)',V^\varepsilon} + \langle u''_{2\varepsilon}, v_2 \rangle_{(H^1(\Omega_{2\varepsilon}))',H^1(\Omega_{2\varepsilon})} \\ + \displaystyle\int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla u_{1\varepsilon} \cdot \nabla v_1 \, dx + \int_{\Omega_{2\varepsilon}} A^\varepsilon \nabla u_{2\varepsilon} \cdot \nabla v_2 \, dx \\ + \varepsilon^\gamma \displaystyle\int_{\Gamma^\varepsilon} h^\varepsilon (u_{1\varepsilon} - u_{2\varepsilon})(v_1 - v_2) \, d\sigma_x = \int_{\Omega_{1\varepsilon}} f_{1\varepsilon} v_1 \, dx + \int_{\Omega_{2\varepsilon}} f_{2\varepsilon} v_2 \, dx \\ \text{for every } (v_1, v_2) \in V^\varepsilon \times H^1(\Omega_{2\varepsilon}) \text{ in } \mathcal{D}'(0,T), \\ u_{1\varepsilon}(0) = U^0_{1\varepsilon} \quad \text{in } \Omega_{1\varepsilon}, \qquad u_{2\varepsilon}(0) = U^0_{2\varepsilon} \quad \text{in } \Omega_{2\varepsilon}, \\ u'_{1\varepsilon}(0) = U^1_{\varepsilon\,|\Omega_{1\varepsilon}} \quad \text{in } \Omega_{1\varepsilon}, \qquad u'_{2\varepsilon}(0) = U^1_{\varepsilon\,|\Omega_{2\varepsilon}} \quad \text{in } \Omega_{2\varepsilon}. \end{cases} \tag{2.8}$$

The homogenization of this problem has been studied in [9] under more general assumptions than (2.7), obtaining different limit problems according to different values of γ. We prove here some corrector results for the two cases $-1 < \gamma < 1$ and $\gamma = 1$.

It is well known that (see, for instance, [2] and [18]) corrector results for the wave equation need stronger assumptions than that of the convergence results. In particular, we suppose that

$$\begin{cases} \text{(i) } (f_{1\varepsilon}, f_{2\varepsilon}) \to \left(\theta_1^{-1} f_1, \theta_2^{-1} f_2\right) \text{ strongly in } \left[L^2(0,T;\ L^2(\Omega))\right]^2, \\ \text{(ii) } U^1_\varepsilon \to U^1 \text{ strongly in } L^2(\Omega) \end{cases} \tag{2.9}$$

and, concerning the initial condition U^0_ε, we assume that it is the unique solution of the problem

$$\begin{cases} -\mathrm{div}\left(A^\varepsilon \nabla U^0_{1\varepsilon}\right) = Q_1^{\varepsilon *}\left(-\mathrm{div}\ \left(A^0 \nabla U^0\right)\right) & \text{in } \Omega_{1\varepsilon}, \\ -\mathrm{div}\left(A^\varepsilon \nabla U^0_{2\varepsilon}\right) = 0 \quad \text{in } \Omega_{2\varepsilon}, \\ A^\varepsilon \nabla U^0_{1\varepsilon} \cdot n_{1\varepsilon} = -A^\varepsilon \nabla U^0_{2\varepsilon} \cdot n_{2\varepsilon} \quad \text{on } \Gamma^\varepsilon, \\ A^\varepsilon \nabla U^0_{1\varepsilon} \cdot n_{1\varepsilon} = -\varepsilon^\gamma h^\varepsilon \left(U^0_{1\varepsilon} - U^0_{2\varepsilon}\right) \quad \text{on } \Gamma^\varepsilon, \\ U^0_{1\varepsilon} = 0 \quad \text{on } \partial\Omega, \end{cases} \tag{2.10}$$

where U^0 is given in $H^1_0(\Omega)$ and $Q_1^{\varepsilon *}$ is the adjoint of a suitable extension operator Q_1^ε, defined in section 3.

Remark 2.2. The homogenization result proved in [8] for the elliptic case (recalled in section 3 for the reader's convenience) applies to (2.10) and gives (see the proof of Lemma 4.2 for details) the following convergences:

$$\begin{cases} \text{(i) } Q_1^\varepsilon U^0_{1\varepsilon} \rightharpoonup U^0 \quad \text{weakly in } H^1_0(\Omega), \\ \text{(ii) } \widetilde{A^\varepsilon \nabla U^0_{1\varepsilon}} \rightharpoonup A^0 \nabla U^0 \quad \text{weakly in } \left[L^2(\Omega)\right]^n, \\ \text{(iii) } \widetilde{A^\varepsilon \nabla U^0_{2\varepsilon}} \rightharpoonup 0 \quad \text{weakly in } \left[L^2(\Omega)\right]^n, \\ \text{(iv) } \left\|U^0_\varepsilon\right\|_{H^\varepsilon_\gamma} \le C \text{ with } C \text{ independent of } \varepsilon, \\ \text{(v) } \widetilde{U^0_{2\varepsilon}} \rightharpoonup \theta_2 U^0 \quad \text{weakly in } H^1_0(\Omega), \end{cases} \tag{2.11}$$

where $\widetilde{\ }$ denotes the zero extension to the whole of Ω and the homogenized matrix A^0 is defined by

$$A^0 \lambda = \frac{1}{|Y|} \int_{Y_1} A \nabla w_\lambda \, dy \tag{2.12}$$

with $w_\lambda \in H^1(Y_1)$ solution, for any $\lambda \in \mathbb{R}^n$, of

$$\begin{cases} -\mathrm{div}\ \ (A \nabla w_\lambda) = 0 \quad \text{in } Y_1, \\ (A \nabla w_\lambda) \cdot n_1 = 0 \quad \text{on } \Gamma, \\ w_\lambda - \lambda \cdot y \qquad Y\text{-periodic}, \\ \dfrac{1}{|Y_1|} \displaystyle\int_{Y_1} (w_\lambda - \lambda \cdot y)\, dy = 0. \end{cases} \tag{2.13}$$

Moreover, from (2.9) and (2.11)(i) and (v) one has

$$\begin{cases} \text{(i) } (\chi_{\Omega_{1\varepsilon}} f_{1\varepsilon}, \chi_{\Omega_{2\varepsilon}} f_{2\varepsilon}) \rightharpoonup (f_1, f_2) \text{ weakly in } \left[L^2(0,T;\ L^2(\Omega))\right]^2, \\ \text{(ii) } \left(\chi_{\Omega_{1\varepsilon}} U^1_\varepsilon, \chi_{\Omega_{2\varepsilon}} U^1_\varepsilon\right) \rightharpoonup \left(\theta_1 U^1, \theta_2 U^1\right) \text{ weakly in } L^2(\Omega) \times L^2(\Omega), \\ \text{(iii) } \left(\widetilde{U^0_{1\varepsilon}}, \widetilde{U^0_{2\varepsilon}}\right) \rightharpoonup \left(\theta_1 U^0, \theta_2 U^0\right) \quad \text{weakly in } L^2(\Omega) \times L^2(\Omega). \end{cases}$$

Let us describe first the case $-1 < \gamma < 1$, for which the homogenization result proved in [9] applies and, under the above assumptions, reads as follows.

THEOREM 2.3 (see [9]). *For $-1 < \gamma < 1$, let A^ε and h^ε be defined by* (2.4) *and* (2.5), *respectively, suppose that* (2.7), (2.9), *and* (2.10) *hold, and let u_ε be the solution of problem* (2.6). *Then, there exist a constant $C > 0$ (independent of ε) and an*

extension operator $P_1^\varepsilon \in \mathcal{L}(L^\infty(0,T;H^k(\Omega_{1\varepsilon}));L^\infty(0,T;H^k(\Omega)))$, *for* $k=1,2$, *such that*

$$\begin{cases} \text{(i) } P_1^\varepsilon u_{1\varepsilon} \rightharpoonup u_1 \quad \textit{weakly* in } L^\infty\left(0,T;H_0^1(\Omega)\right), \\ \text{(ii) } \widetilde{u_{2\varepsilon}} \rightharpoonup u_2 := \theta_2 u_1 \quad \textit{weakly* in } L^\infty\left(0,T;L^2(\Omega)\right), \\ \text{(iii) } \varepsilon^{\gamma/2}\|u_{1\varepsilon}-u_{2\varepsilon}\|_{L^\infty(0,T;L^2(\Gamma^\varepsilon))} < C, \end{cases} \tag{2.14}$$

$$\begin{cases} \text{(i) } P_1^\varepsilon u'_{1\varepsilon} \rightharpoonup u'_1 \quad \textit{weakly* in } L^\infty\left(0,T;L^2(\Omega)\right), \\ \text{(ii) } \widetilde{u'_{2\varepsilon}} \rightharpoonup u'_2 = \theta_2 u'_1 \quad \textit{weakly* in } L^\infty\left(0,T;L^2(\Omega)\right), \end{cases} \tag{2.15}$$

$$\begin{cases} \text{(i) } A^\varepsilon \widetilde{\nabla u_{1\varepsilon}} \rightharpoonup A^0\nabla u_1 \quad \textit{weakly* in } L^\infty\left(0,T;\left[L^2(\Omega)\right]^n\right), \\ \text{(ii) } A^\varepsilon \widetilde{\nabla u_{2\varepsilon}} \rightharpoonup 0 \quad \textit{weakly* in } L^\infty\left(0,T;\left[L^2(\Omega)\right]^n\right), \end{cases} \tag{2.16}$$

where θ_2 *is given by* (2.2) *and* u_1 *is the unique solution in* $L^2(0,T;H_0^1(\Omega))$, *with* u'_1 *in* $L^2(0,T;L^2(\Omega))$, *of the problem*

$$\begin{cases} u''_1 - \operatorname{div}\left(A^0\nabla u_1\right) = f_1+f_2 & \textit{in } \Omega\times]0,T[, \\ u_1 = 0 & \textit{on } \partial\Omega\times]0,T[, \\ u_1(0) = U^0 & \textit{in } \Omega, \\ u'_1(0) = U^1 & \textit{in } \Omega, \end{cases} \tag{2.17}$$

with A^0 *defined in* (2.12).

Let $(e_j)_{j=1,\dots,n}$ be the canonical basis and $w_j \in H^1(Y_1)$ be the solution of problem (2.13), written for $\lambda = e_j$, for $j=1,\dots,n$. The corrector matrix C^ε is defined, for any ε, by

$$C^\varepsilon(x) = \widetilde{C}\left(\frac{x}{\varepsilon}\right), \tag{2.18}$$

where

$$C_{ij}(y) := \frac{\partial w_j}{\partial y_i}(y), \quad \text{for } i,j=1,\dots,n,$$

and $\widetilde{\ }$ denotes the zero extension to the whole reference cell Y. Let us mention that, as in the elliptic case (see [8]), C^ε is the same corrector obtained in the case of a periodic perforated domain with an homogeneous Neumann condition on the holes studied in [7]. Here, due to the symmetry of A, the matrix C^ε is symmetric too.

Our first corrector result is as follows.

THEOREM 2.4 (correctors for $-1<\gamma<1$). *Let* A^ε *and* h^ε *be defined by* (2.4) *and* (2.5), *respectively, and suppose that* (2.7), (2.9), *and* (2.10) *hold. If* u_ε *is the solution of problem* (2.6) *with* $-1<\gamma<1$ *and* u_1 *is the solution of problem* (2.17), *then*

$$\begin{cases} \text{(i) } \widetilde{u'_{1\varepsilon}} + \widetilde{u'_{2\varepsilon}} \to u'_1 \quad \textit{strongly in } C^0\left(0,T;L^2(\Omega)\right), \\ \text{(ii) } \lim\limits_{\varepsilon\to 0}\|\nabla u_{1\varepsilon} - C^\varepsilon\nabla u_1\|_{C^0(0,T;[L^1(\Omega_{1\varepsilon})]^n)} = 0, \\ \text{(iii) } \lim\limits_{\varepsilon\to 0}\|\nabla u_{2\varepsilon}\|_{C^0(0,T;[L^2(\Omega_{2\varepsilon})]^n)} = 0. \end{cases} \tag{2.19}$$

This theorem will be proved in section 5.

Remark 2.5. Convergence (2.19)(i) is equivalent to

$$\lim_{\varepsilon\to 0}\|u'_{i\varepsilon} - u'_1\|_{C^0(0,T;L^2(\Omega_{i\varepsilon}))} = 0, \ i=1,2,$$

since

$$\int_\Omega |\widetilde{u'_{1\varepsilon}} + \widetilde{u'_{2\varepsilon}} - u'_1|^2\,dx = \int_{\Omega_{1\varepsilon}} |u'_{1\varepsilon} - u'_1|^2\,dx + \int_{\Omega_{2\varepsilon}} |u'_{2\varepsilon} - u'_1|^2\,dx,$$

$\Omega_{1\varepsilon}$ and $\Omega_{2\varepsilon}$ being disjoint sets.

We present now the more complicated case $\gamma = 1$, which is also the more interesting, since the limit function u_2 is not $\theta_2 u_1$ anymore and the limit problem satisfied by (u_1, u_2) is a coupled system consisting in a p.d.e. and an o.d.e. Indeed, we have the following theorem.

THEOREM 2.6 (see [9]). *For $\gamma = 1$, let A^ε and h^ε be defined by* (2.4) *and* (2.5), *respectively, suppose that* (2.7), (2.10), *and* (2.9) *hold, and let u_ε be the solution of the problem* (2.6). *Then, there exist a constant $C > 0$ (independent of ε) and an extension operator $P_1^\varepsilon \in \mathcal{L}(L^\infty(0,T;H^k(\Omega_{1\varepsilon}));L^\infty(0,T;H^k(\Omega)))$, for $k = 1, 2$, such that*

$$\begin{cases} \text{(i) } P_1^\varepsilon u_{1\varepsilon} \rightharpoonup u_1 \quad \textit{weakly* in } L^\infty\left(0,T;H_0^1(\Omega)\right), \\ \text{(ii) } \widetilde{u_{2\varepsilon}} \rightharpoonup u_2 \quad \textit{weakly* in } L^\infty\left(0,T;L^2(\Omega)\right), \\ \text{(iii) } \varepsilon^{1/2}\|u_{1\varepsilon} - u_{2\varepsilon}\|_{L^\infty(0,T;L^2(\Gamma^\varepsilon))} < C, \end{cases} \tag{2.20}$$

$$\begin{cases} \text{(i) } P_1^\varepsilon u'_{1\varepsilon} \rightharpoonup u'_1 \quad \textit{weakly* in } L^\infty\left(0,T;L^2(\Omega)\right), \\ \text{(ii) } \widetilde{u'_{2\varepsilon}} \rightharpoonup u'_2 \quad \textit{weakly* in } L^\infty\left(0,T;L^2(\Omega)\right), \end{cases} \tag{2.21}$$

$$\begin{cases} \text{(i) } A^\varepsilon \widetilde{\nabla u_{1\varepsilon}} \rightharpoonup A^0 \nabla u_1 \quad \textit{weakly* in } L^\infty\left(0,T;\left[L^2(\Omega)\right]^n\right), \\ \text{(ii) } A^\varepsilon \widetilde{\nabla u_{2\varepsilon}} \rightharpoonup 0 \quad \textit{weakly* in } L^\infty\left(0,T;\left[L^2(\Omega)\right]^n\right), \end{cases} \tag{2.22}$$

where the couple (u_1, u_2) is the unique solution $L^2(0,T;H_0^1(\Omega)) \times L^2(0,T;L^2(\Omega))$, with (u'_1, u'_2) in $L^2(0,T;L^2(\Omega)) \times L^2(0,T;L^2(\Omega))$, of the problem

$$\begin{cases} \theta_1 u''_1 - \text{div}\,\left(A^0 \nabla u_1\right) + c_h(\theta_2 u_1 - u_2) = f_1 & \textit{in } \Omega\times]0,T[, \\ u''_2 - c_h(\theta_2 u_1 - u_2) = f_2 & \textit{in }]0,T[\textit{ for a.e. } x \in \Omega, \\ u_1 = 0 & \textit{on } \partial\Omega\times]0,T[, \\ u_1(0) = U^0, \quad u_2(0) = \theta_2 U^0 & \textit{in } \Omega, \\ u'_1(0) = U^1, \quad u'_2(0) = \theta_2 U^1 & \textit{in } \Omega, \end{cases} \tag{2.23}$$

where θ_i, for $i = 1, 2$, are given by (2.2), *$c_h = \frac{1}{|Y_2|}\int_\Gamma h(y)d\sigma_y > 0$, and the homogenized matrix A^0 is defined by* (2.12).

Remark 2.7. (i) In [9], it is shown that u_1 is the solution of the equation

$$\theta_1 u''_1 - \text{div}\,\left(A^0 \nabla u_1\right) + c_h\theta_2 u_1 - c_h^2\theta_2 \int_0^t \mathcal{K}(t,s)u_1(s)\,ds = F \text{ in } \Omega\times]0,T[,$$

containing a periodic memory kernel $\mathcal{K}$; moreover, the limit solution u_2 and the function F are explicitly computed. In this paper we will need only to use the limit problem under the form (2.23), which is well adapted to the study of the energies.

(ii) Observe that convergences (2.14)–(2.15) and (2.20)–(2.21) imply that for $-1 < \gamma \le 1$

$$\chi_{\Omega_{1\varepsilon}} P_1^\varepsilon u'_{1\varepsilon} \rightharpoonup \theta_1 u'_1 \quad \text{weakly* in } L^\infty\left(0,T;L^2(\Omega)\right).$$

Moreover, from classical compactness results (see [14])

$$P_1^\varepsilon u_{1\varepsilon} \to u_1 \quad \text{strongly in } C^0\left(0,T;L^2(\Omega)\right).$$

Let us state the corrector result associated to the case $\gamma = 1$.

THEOREM 2.8 (correctors for $\gamma = 1$). *Let A^ε and h^ε be defined by* (2.4) *and* (2.5), *respectively, and suppose that* (2.7), (2.9), *and* (2.10) *hold. If u_ε is the solution of problem* (2.6) *with $\gamma = 1$ and (u_1, u_2) is the solution of problem* (2.23), *then*

$$\begin{cases} \text{(i) } \lim\limits_{\varepsilon\to 0} \|u'_{1\varepsilon} - u'_1\|_{C^0(0,T;L^2(\Omega_{1\varepsilon}))} = 0, \\ \text{(ii) } \lim\limits_{\varepsilon\to 0} \|u'_{2\varepsilon} - \theta_2^{-1}u'_2\|_{C^0(0,T;L^2(\Omega_{2\varepsilon}))} = 0, \\ \text{(iii) } \lim\limits_{\varepsilon\to 0} \|\nabla u_{1\varepsilon} - C^\varepsilon \nabla u_1\|_{C^0(0,T;[L^1(\Omega_{1\varepsilon})]^n)} = 0, \\ \text{(iv) } \lim\limits_{\varepsilon\to 0} \|\nabla u_{2\varepsilon}\|_{C^0(0,T;[L^2(\Omega_{2\varepsilon})]^n)} = 0. \end{cases} \tag{2.24}$$

Remark 2.9. Observe that in both cases, due to convergences (2.19)(iii) and (2.24)(iv), respectively, the additional assumptions (2.9) and (2.10) imply that convergences (2.16)(ii) and (2.22)(ii) are actually strong.

Theorem 2.4 will be proved in section 6. Its proof is more delicate than that of the case $-1 < \gamma < 1$, due to the particular form of the limit problem, and requires specific arguments (see Remark 6.3 for details).

3. Some preliminary results. In this section we will recall some technical results needed in the proofs of Theorems 2.4 and 2.8 as well as the homogenization result proved in [8] and [10] for the elliptic problem.

LEMMA 3.1 (see [7]). (i) *There exists a linear continuous extension operator Q_1 belonging to $\mathcal{L}(H^1(Y_1);H^1(Y)) \cap \mathcal{L}(L^2(Y_1);L^2(Y))$ such that, for some positive constant C,*

$$\|\nabla Q_1 v_1\|_{L^2(Y)} \le C\|\nabla v_1\|_{L^2(Y_1)}$$

for every $v_1 \in H^1(Y_1)$.

(ii) *There exists an extension operator Q_1^ε belonging to $\mathcal{L}(L^2(\Omega_{1\varepsilon});L^2(\Omega)) \cap \mathcal{L}(V^\varepsilon;H_0^1(\Omega))$ such that, for some positive constant C (independent of ε),*

$$\|Q_1^\varepsilon v_1\|_{L^2(\Omega)} \le C\|v_1\|_{L^2(\Omega_{1\varepsilon})}$$

and

$$\|\nabla Q_1^\varepsilon v_1\|_{L^2(\Omega)} \le C\|\nabla v_1\|_{L^2(\Omega_{1\varepsilon})}$$

for every $v_1 \in V^\varepsilon$.

LEMMA 3.2 (see [5]). *There exists a linear continuous extension operator P_1^ε belonging to $\mathcal{L}(L^\infty(0,T;H^k(\Omega_{1\varepsilon}));L^\infty(0,T;H^k(\Omega)))$, $k = 1, 2$, such that, for some positive constant C (independent of ε),*

$$\begin{cases} \text{(i) } P_1^\varepsilon\varphi = \varphi \text{ in } \Omega_{1\varepsilon}\times]0,T[, \\ \text{(ii) } P_1^\varepsilon\varphi' = (P^\varepsilon\varphi)' \text{in } \Omega\times]0,T[, \\ \text{(iii) } \|P_1^\varepsilon\varphi\|_{L^\infty(0,T;L^2(\Omega))} \le C\|\varphi\|_{L^\infty(0,T;L^2(\Omega_{1\varepsilon}))}, \\ \text{(iv) } \|P_1^\varepsilon\varphi'\|_{L^\infty(0,T;L^2(\Omega))} \le C\|\varphi'\|_{L^\infty(0,T;L^2(\Omega_{1\varepsilon}))}, \\ \text{(v) } \|\nabla(P_1^\varepsilon\varphi)\|_{L^\infty(0,T;[L^2(\Omega)]^n)} \le C\|\nabla\varphi\|_{L^\infty(0,T;[L^2(\Omega_{1\varepsilon})]^n)} \end{cases}$$

for any $\varphi \in L^\infty(0,T;H^k(\Omega_{1\varepsilon}))$.

The following homogenization result concerns the elliptic problem associated to problem (2.6).

THEOREM 3.3 (see [6] and [8]). *Let $-1 < \gamma \leq 1$, A^ε and h^ε be defined by* (2.4) *and* (2.5)*, respectively, and u_ε be the solution of problem*

$$\begin{cases} -\operatorname{div}(A^\varepsilon \nabla u_{1\varepsilon}) = b_1^\varepsilon + Q_1^{\varepsilon *}(g) & \text{in } \Omega_{1\varepsilon}, \\ -\operatorname{div}(A^\varepsilon \nabla u_{2\varepsilon}) = b_2^\varepsilon & \text{in } \Omega_{2\varepsilon}, \\ A^\varepsilon \nabla u_{1\varepsilon} \cdot n_{1\varepsilon} = -A^\varepsilon \nabla u_{2\varepsilon} \cdot n_{2\varepsilon} & \text{on } \Gamma^\varepsilon, \\ A^\varepsilon \nabla u_{1\varepsilon} \cdot n_{1\varepsilon} = -\varepsilon^\gamma h^\varepsilon (u_{1\varepsilon} - u_{2\varepsilon}) & \text{on } \Gamma^\varepsilon, \\ u_{1\varepsilon} = 0 & \text{on } \partial\Omega, \end{cases}$$

where $Q_1^\varepsilon \in \mathcal{L}(H^{-1}(\Omega); V^\varepsilon)$ is the adjoint of the extension operator given in Lemma 3.1(ii)*. Suppose that $b_1^\varepsilon \in L^2(\Omega_{1\varepsilon})$ and $b_2^\varepsilon \in L^2(\Omega_{2\varepsilon})$ satisfy*

$$\begin{cases} \widetilde{b_1^\varepsilon} \rightharpoonup \theta_1 b_1 & \text{weakly in } L^2(\Omega), \\ \widetilde{b_2^\varepsilon} \rightharpoonup \theta_2 b_2 & \text{weakly in } L^2(\Omega), \end{cases}$$

and let g be given in $L^2(\Omega)$. Then, there exists a positive constant C (independent of ε) such that

$$\begin{cases} Q_1^\varepsilon u_{1\varepsilon} \rightharpoonup u_1 & \text{weakly in } H_0^1(\Omega), \\ \widetilde{A^\varepsilon \nabla u_{1\varepsilon}} \rightharpoonup A^0 \nabla u_1 & \text{weakly in } [L^2(\Omega)]^n, \\ \|u_{1\varepsilon} - u_{2\varepsilon}\|_{L^2(\Gamma^\varepsilon)} < C\varepsilon^{-\gamma/2}, \end{cases}$$

and the following convergences hold:

$$\begin{cases} \widetilde{u_{2\varepsilon}} \rightharpoonup u_2 & \text{weakly in } L^2(\Omega), \\ \widetilde{A^\varepsilon \nabla u_{2\varepsilon}} \rightharpoonup 0 & \text{weakly in } [L^2(\Omega)]^n. \end{cases}$$

The function u_1 is the unique solution in $H_0^1(\Omega)$ of the problem

$$\begin{cases} -\operatorname{div}\left(A^0 \nabla u_1\right) = \theta_1 b_1 + \theta_2 b_2 + g & \text{in } \Omega, \\ u_1 = 0 & \text{on } \partial\Omega, \end{cases}$$

with θ_i, $i = 1, 2$, given by (2.2) *and A^0 by* (2.12)*.*

Moreover, for $-1 < \gamma < 1$, one has

$$\begin{cases} u_2 = \theta_2 u_1, \\ \|Q_1^\varepsilon u_{1\varepsilon} - u_{2\varepsilon}\|^2_{L^2(\Omega_{2\varepsilon})} \to 0, \end{cases}$$

while, for $\gamma = 1$,

$$u_2 = \theta_2 \left(u_1 + c_h^{-1} b_2\right),$$

where $c_h = \frac{1}{|Y_2|} \int_\Gamma h(y) d\sigma_y$.

The following lemma is a straightforward adaptation of Lemma 3.3 of [8] to the time-dependent case.

LEMMA 3.4. *Suppose that Γ is of class C^2. Let $g \in L^\infty(\Gamma)$, and set $c_g := \frac{1}{|Y_2|} \int_\Gamma g(y) d\sigma_y$.*

(i) *There exists* $\psi_g \in W^{1,\infty}(Y_2)$ *such that for every* $v_\varepsilon \in L^2(0,T;W^{1,1}(\Omega_{2\varepsilon}))$ *one has*

$$\varepsilon \int_{\Gamma^\varepsilon} g(x/\varepsilon) v_\varepsilon(x,t)\, d\sigma_x \ = c_g \int_{\Omega_{2\varepsilon}} v_\varepsilon(x,t)\, dx \ + \varepsilon \int_{\Omega_{2\varepsilon}} \nabla_y \psi_g(x/\varepsilon) \nabla_x v_\varepsilon(x,t)\, dx$$

for all $t \in [0,T]$.

(ii) *If for some positive constant* C *(independent of* ε*) one has*

$$||v_\varepsilon||_{L^2(0,T;W^{1,1}(\Omega_{2\varepsilon}))} \le C,$$

then

$$\liminf_{\varepsilon\to 0} \varepsilon \int_{\Gamma^\varepsilon} g(x/\varepsilon) v_\varepsilon(x,t)\, d\sigma_x \ = \liminf_{\varepsilon\to 0} c_g \int_{\Omega_{2\varepsilon}} v_\varepsilon(x,t)\, dx \ .$$

We will also need the following result.

LEMMA 3.5 (see [11]). *Let* $\mathcal{O}$ *be an open set of* $\mathbb{R}^n$ *and* $\{\mathcal{O}_\varepsilon\}_\varepsilon \subset \mathcal{O}$ *a sequence of open subsets of* $\mathcal{O}$. *Suppose that* $\{v_\varepsilon\}_\varepsilon \subset L^p(0,T;L^p(\mathcal{O}_\varepsilon))$, $p>1$, *is such that*

$$\begin{cases} \chi_{\mathcal{O}_\varepsilon} \rightharpoonup \chi_0 & \text{in } L^\infty(\mathcal{O}) \text{ weakly } *, \\ \widetilde{v_\varepsilon} \rightharpoonup \chi_0\, v & \text{weakly in } L^p\left(0,T;L^p(\mathcal{O})\right). \end{cases}$$

Then,

$$\liminf_{\varepsilon\to 0} \int_{\mathcal{O}_\varepsilon} |v_\varepsilon(t)|^p\, dx \ge \int_{\mathcal{O}} \chi_0 |v(t)|^p\, dx.$$

4. Asymptotic behavior of the energy. In this section we study the convergence of the energy associated to problem (2.6) which, for every ε, is defined by

(4.1)
$$E^\varepsilon(t) := \frac{1}{2}\Big[\int_{\Omega_{1\varepsilon}} |u'_{1\varepsilon}(t)|^2\, dx + \int_{\Omega_{2\varepsilon}} |u'_{2\varepsilon}(t)|^2\, dx + \int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla u_{1\varepsilon}(t) \nabla u_{1\varepsilon}(t)\, dx + \int_{\Omega_{2\varepsilon}} A^\varepsilon \nabla u_{2\varepsilon}(t) \nabla u_{2\varepsilon}(t)\, dx + \varepsilon^\gamma \int_{\Gamma^\varepsilon} h^\varepsilon |u_{1\varepsilon}(t) - u_{2\varepsilon}(t)|^2\, d\sigma_x \Big].$$

LEMMA 4.1. *For* $-1 < \gamma \le 1$, *let* A^ε *and* h^ε *be defined by* (2.4) *and* (2.5), *respectively, and suppose that* (2.7) *holds. If* u_ε *is the solution of problem* (2.6), *then*

$$\begin{aligned} E^\varepsilon(t) = \frac{1}{2}\Big[& \int_{\Omega_{1\varepsilon}} \left|U^1_\varepsilon\right|^2 dx + \int_{\Omega_{2\varepsilon}} \left|U^1_\varepsilon\right|^2 dx + \int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla U^0_{1\varepsilon} \nabla U^0_{1\varepsilon}\, dx \\ & + \int_{\Omega_{2\varepsilon}} A^\varepsilon \nabla U^0_{2\varepsilon} \nabla U^0_{2\varepsilon}\, dx + \varepsilon^\gamma \int_{\Gamma^\varepsilon} h^\varepsilon \left|U^0_{1\varepsilon} - U^0_{2\varepsilon}\right|^2 d\sigma_x \Big] \\ & + \int_0^t \int_{\Omega_{1\varepsilon}} f_{1\varepsilon} u'_{1\varepsilon}\, dx\, d\tau + \int_0^t \int_{\Omega_{2\varepsilon}} f_{2\varepsilon} u'_{2\varepsilon}\, dx\, d\tau \ \forall\, t \in [0,T]. \end{aligned} \tag{4.2}$$

Proof. If we take $(u'_{1\varepsilon}, u'_{2\varepsilon})$ as test functions in the variational formulation of problem (2.6) (actually a standard density argument has to be used, see, for instance,

[4] and [20]) we get

$$\begin{aligned}
&\int_0^t \langle u''_{1\varepsilon}, u'_{1\varepsilon}\rangle_{(V^\varepsilon)',V^\varepsilon}\, d\tau + \int_0^t \langle u''_{2\varepsilon}, u'_{2\varepsilon}\rangle_{(H^1(\Omega_{2\varepsilon}))',H^1(\Omega_{2\varepsilon})}\, d\tau \\
&+ \int_0^t \int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla u_{1\varepsilon} \nabla u'_{1\varepsilon}\, dx\, d\tau + \int_0^t \int_{\Omega_{2\varepsilon}} A^\varepsilon \nabla u_{2\varepsilon} \nabla u'_{2\varepsilon}\, dx\, d\tau \\
&\qquad + \varepsilon^\gamma \int_0^t \int_{\Gamma^\varepsilon} h^\varepsilon (u_{1\varepsilon} - u_{2\varepsilon})(u'_{1\varepsilon} - u'_{2\varepsilon})\, d\sigma_x\, d\tau \\
&\qquad = \int_0^t \int_{\Omega_{1\varepsilon}} f_{1\varepsilon} u'_{1\varepsilon}\, dx\, d\tau + \int_0^t \int_{\Omega_{2\varepsilon}} f_{2\varepsilon} u'_{2\varepsilon}\, dx\, d\tau.
\end{aligned} \tag{4.3}$$

Moreover,

$$\int_0^t \langle u''_{i\varepsilon}, u'_{i\varepsilon}\rangle_{(V^\varepsilon)',V^\varepsilon}\, d\tau = \frac{1}{2}\int_0^t \frac{d}{d\tau} \int_{\Omega_{i\varepsilon}} |u'_{i\varepsilon}|^2\, dx\, d\tau, i = 1, 2.$$

Similarly, since the matrix A is symmetric we get

$$\int_0^t \int_{\Omega_{i\varepsilon}} A^\varepsilon \nabla u_{i\varepsilon} \cdot \nabla u'_{i\varepsilon}\, dx\, d\tau = \frac{1}{2}\int_0^t \frac{d}{d\tau} \int_{\Omega_{i\varepsilon}} A^\varepsilon \nabla u_{i\varepsilon} \cdot \nabla u_{i\varepsilon}\, dx\, d\tau, \quad i = 1, 2.$$

On the other hand,

$$\varepsilon^\gamma \int_0^t \int_{\Gamma^\varepsilon} h^\varepsilon (u_{1\varepsilon} - u_{2\varepsilon})(u'_{1\varepsilon} - u'_{2\varepsilon})\, d\sigma_x\, d\tau = \frac{\varepsilon^\gamma}{2}\int_0^t \frac{d}{d\tau} \int_{\Gamma^\varepsilon} h^\varepsilon |u_{1\varepsilon} - u_{2\varepsilon}|^2\, d\sigma_x\, d\tau.$$

Therefore, identity (4.3) can be rewritten, using (4.1), as

$$E^\varepsilon(t) - E^\varepsilon(0) = \int_0^t \frac{dE^\varepsilon}{d\tau}\, d\tau = \int_0^t \int_{\Omega_{1\varepsilon}} f_{1\varepsilon} u'_{1\varepsilon}\, dx\, d\tau + \int_0^t \int_{\Omega_{2\varepsilon}} f_{2\varepsilon} u'_{2\varepsilon}\, dx\, d\tau.$$

Hence, again by (4.1) and (2.6), we have (4.2). ∎

LEMMA 4.2. *For $-1 < \gamma \le 1$, let A^ε and h^ε be defined by* (2.4) *and* (2.5), *respectively, and suppose that* (2.7), (2.9), *and* (2.10) *hold. If u_ε is the solution of problem* (2.6), *then*

$$\begin{aligned}
\lim_{\varepsilon\to 0} E^\varepsilon(t) = \frac{1}{2}\left[\int_\Omega \left|U^1\right|^2 dx + \int_\Omega A^0 \nabla U^0 \nabla U^0\, dx\right] \\
+ \int_0^t \int_\Omega f_1 u'_1\, dx\, d\tau + {\theta_2}^{-1} \int_0^t \int_\Omega f_2 u'_2\, dx\, d\tau \quad \forall t \in [0, T],
\end{aligned}$$

where we have $u'_2 = \theta_2 u'_1$, if $-1 < \gamma < 1$.

Proof. We make use of Lemma 4.1, passing to the limit in (4.2) for any fixed $t \in [0, T]$.

For the first two integrals, using (2.9), we have

$$\lim_{\varepsilon\to 0}\left(\int_{\Omega_{1\varepsilon}} \left|U^1_\varepsilon\right|^2 dx + \int_{\Omega_{2\varepsilon}} \left|U^1_\varepsilon\right|^2 dx\right) = \int_\Omega \left|U^1\right|^2 dx.$$

Observe now that (2.11) holds in both cases $-1 < \gamma < 1$ and $\gamma = 1$. Indeed, Theorem 3.3 written for $u_{1\varepsilon} = U^0_{1\varepsilon}$, $u_{2\varepsilon} = U^0_{2\varepsilon}$, $b_{1\varepsilon} = b_{2\varepsilon} = 0$, and $g = -\mathrm{div}\, A^0 \nabla U^0$

gives, by the uniqueness of the solution of the limit problem, $u_1 = U^0$. Hence, if we take $(U^0_{1\varepsilon}, U^0_{2\varepsilon})$ as test functions in (2.10), in view of (2.11)(i) we have

$$\lim_{\varepsilon\to 0}\left[\int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla U^0_{1\varepsilon}\nabla U^0_{1\varepsilon}\,dx + \int_{\Omega_{2\varepsilon}} A^\varepsilon \nabla U^0_{2\varepsilon}\nabla U^0_{2\varepsilon}\,dx + \varepsilon^\gamma \int_{\Gamma^\varepsilon} h^\varepsilon \left(U^0_{1\varepsilon} - U^0_{2\varepsilon}\right)^2 d\sigma_x\right]$$
$$= \lim_{\varepsilon\to 0}\left\langle -\operatorname{div}\left(A^0\nabla U^0\right), Q^\varepsilon_1 U^0_{1\varepsilon}\right\rangle = \int_\Omega A^0\nabla U^0\nabla U^0\,dx.$$

On the other hand, (2.9) and Remark 2.7(ii) imply that

$$\lim_{\varepsilon\to 0}\int_0^t\int_{\Omega_{1\varepsilon}} f_{1\varepsilon}u'_{1\varepsilon}\,dx\,d\tau + \int_0^t\int_{\Omega_{2\varepsilon}} f_{2\varepsilon}u'_{2\varepsilon}\,dx\,d\tau$$
$$= \int_0^t\int_\Omega f_1u'_1\,dx\,d\tau + {\theta_2}^{-1}\int_0^t\int_\Omega f_2u'_2\,dx\,d\tau,$$

where for $-1 < \gamma < 1$ and $\gamma = 1$ we used convergences (2.15) and (2.21), respectively. □

From now on, the convergence of the energy in the two cases $-1 < \gamma < 1$ and $\gamma = 1$ need to be studied separately.

THEOREM 4.3 (convergence of energy for $-1 < \gamma < 1$). *Let A^ε and h^ε be defined by* (2.4) *and* (2.5)*, respectively, and suppose that* (2.7), (2.9), *and* (2.10) *hold. If u_ε is the solution of problem* (2.6) *with $-1 < \gamma < 1$, then*

$$E^\varepsilon \to E \text{ in } C^0([0,T]), \tag{4.4}$$

where

$$E(t) := \frac{1}{2}\left[\int_\Omega |u'_1(t)|^2\,dx + \int_\Omega A^0\nabla u_1(t)\nabla u_1(t)\,dx\right] \tag{4.5}$$

is the energy associated to problem (2.17).

Proof. Taking u'_1 as test function in problem (2.17) and arguing as in the proof of Lemma 4.1, we obtain

$$E(t) = \frac{1}{2}\left[\int_\Omega \left|U^1\right|^2 dx + \int_\Omega A^0\nabla U^0\nabla U^0\,dx\right] + \int_0^t\int_\Omega (f_1+f_2)u'_1\,dx\,d\tau.$$

Hence, by Lemma 4.2 we obtain

$$\lim_{\varepsilon\to 0} E^\varepsilon(t) = E(t) \qquad \forall t\in[0,T], \tag{4.6}$$

since in this case $u'_2 = \theta_2 u'_1$.

Using Lemma 4.1, Theorem 2.3, (2.7), (2.9), and (2.10) we deduce that there exists a constant C (independent of ε) such that

$$|E^\varepsilon(t)| \le C \quad \forall\, t\ \in[0,T]$$

and, from the Hölder inequality,

$$|E^\varepsilon(t+\sigma) - E^\varepsilon(t)|$$
$$= \left|\int_t^{t+\sigma}\int_{\Omega_{1\varepsilon}} f_{1\varepsilon}u'_{1\varepsilon}\,dx\,d\tau + \int_t^{t+\sigma}\int_{\Omega_{2\varepsilon}} f_{2\varepsilon}u'_{2\varepsilon}\,dx\,d\tau\right| \le \sigma^{1/2}C.$$

Consequently, by the Ascoli–Arzelà theorem, there exist a subsequence, still denoted by E^ε, and a function ζ in $C^0([0,T])$ such that

$$E^\varepsilon \to \zeta \text{ in } C^0([0,T]). \tag{4.7}$$

Hence, from (4.6) and (4.7), by uniqueness, one has $\zeta = E$, which concludes the proof. ∎

THEOREM 4.4 (convergence of energy for $\gamma = 1$). *Let A^ε and h^ε be defined by* (2.4) *and* (2.5), *respectively, and suppose that* (2.7), (2.9), *and* (2.10) *hold. If u_ε is the solution of problem* (2.6) *with $\gamma = 1$, then*

$$E^\varepsilon \to \hat{E} \text{ in } C^0([0,T]),$$

where

$$\begin{aligned}\hat{E}(t) := \frac{1}{2}\Big[&\theta_1 \int_\Omega |u_1'(t)|^2\,dx + {\theta_2}^{-1}\int_\Omega |u_2'(t)|^2\,dx \\ &+ \int_\Omega A^0\nabla u_1(t)\nabla u_1(t)\,dx + c_h{\theta_2}^{-1}\int_\Omega |\theta_2 u_1(t) - u_2(t)|^2\,dx\Big]\end{aligned} \tag{4.8}$$

is the energy associated to problem (2.23).

Proof. Let us prove first that

$$\begin{aligned}\hat{E}(t) = \frac{1}{2}&\left[\int_\Omega \left|U^1\right|^2 dx + \int_\Omega A^0\nabla U^0\nabla U^0\,dx\right] \\ &+ \int_0^t\int_\Omega f_1u_1'\,dx\,d\tau + \theta_2^{-1}\int_0^t\int_\Omega f_2u_2'\,dx\,d\tau \quad \forall t\in[0,T].\end{aligned} \tag{4.9}$$

Let us take u_1' as test function in the first equation of (2.23). Multiplying the second equation by $\theta_2^{-1}u_2'$ and integrating over $\Omega\times[0,t]$ we have by summation

$$\begin{aligned}&\int_0^t \langle\theta_1u_1'', u_1'\rangle_{L^2(\Omega),L^2(\Omega)}\,d\tau + \int_0^t \langle u_2'', \theta_2^{-1}u_2'\rangle_{L^2(\Omega),L^2(\Omega)}\,d\tau \\ &\qquad + \int_0^t\int_\Omega A^0\nabla u_1\nabla u_1'\,dx\,d\tau + c_h\int_0^t\int_\Omega(\theta_2u_1 - u_2)u_1'\,dx\,d\tau \\ &\qquad - c_h\int_0^t\int_\Omega(\theta_2u_1 - u_2)\theta_2^{-1}u_2'\,dx\,d\tau \\ &\qquad = \int_0^t\int_\Omega f_1u_1'\,dx\,d\tau + {\theta_2}^{-1}\int_0^t\int_\Omega f_2u_2'\,dx\,d\tau \quad \forall t\in[0,T].\end{aligned} \tag{4.10}$$

Now, observe that

$$\begin{aligned}\int_0^t \langle\theta_1u_1'', u_1'\rangle_{L^2(\Omega),L^2(\Omega)}\,d\tau &= \frac{1}{2}\theta_1\int_0^t\frac{d}{d\tau}\int_\Omega |u_1'|^2\,dx\,d\tau, \\ \int_0^t \langle u_2'', \theta_2^{-1}u_2'\rangle_{L^2(\Omega),L^2(\Omega)}\,d\tau &= \frac{1}{2}\theta_2^{-1}\int_0^t\frac{d}{d\tau}\int_\Omega |u_2'|^2\,dx\,d\tau.\end{aligned}$$

Similarly, taking into account that the matrix A^0 is symmetric we get

$$\int_0^t\int_\Omega A^0\nabla u_1\nabla u_1'\,dx\,d\tau = \frac{1}{2}\int_0^t\frac{d}{d\tau}\int_\Omega A^0\nabla u_1\cdot\nabla u_1\,dx\,d\tau.$$

On the other hand,

$$c_h \int_0^t \int_\Omega (\theta_2 u_1 - u_2) u_1' \, dx \; d\tau - c_h \int_0^t \int_\Omega (\theta_2 u_1 - u_2) \theta_2^{-1} u_2' \, dx \; d\tau$$
$$= c_h \theta_2^{-1} \int_0^t \int_\Omega (\theta_2 u_1 - u_2)(\theta_2 u_1' - u_2') \, dx \, d\tau = \frac{c_h \theta_2^{-1}}{2} \int_0^t \frac{d}{d\tau} \int_\Omega (\theta_2 u_1 - u_2)^2 dx \, d\tau.$$

Therefore, taking into account (4.8) and identity (4.10) we obtain

$$\hat{E}(t) - \hat{E}(0) = \int_0^t \frac{d\hat{E}}{d\tau} \, d\tau = \int_0^t \int_\Omega f_1 u_1' \, dx \, d\tau + \theta_2{}^{-1} \int_0^t \int_\Omega f_2 u_2' \, dx \, d\tau \quad \forall t \in [0,T].$$

Using (2.23) and again (2.8), we deduce that

$$\begin{aligned} \hat{E}(0) &= \frac{1}{2} \left[\theta_1 \int_\Omega \left| U^1 \right|^2 dx + \theta_2^{-1} \int_\Omega \left| \theta_2 U^1 \right|^2 dx + \int_\Omega A^0 \nabla U^0 \nabla U^0 \, dx \right] \\ &\quad + c_h \theta_2^{-1} \int_\Omega \left| \theta_2 U^0 - \theta_2 U^0 \right|^2 dx \\ &= \frac{1}{2} \left[\int_\Omega \left| U^1 \right|^2 dx + \int_\Omega A^0 \nabla U^0 \nabla U^0 \, dx \right]. \end{aligned}$$

This gives (4.9) which, together with Lemma 4.2, implies that

$$\lim_{\varepsilon \to 0} E^\varepsilon(t) \to \hat{E}(t) \quad \forall t \in [0,T].$$

Now, arguing as in the proof of Theorem 4.3, but using here Theorem 2.6 instead of Theorem 2.3, we conclude the proof. □

5. Proof of the corrector result in the case $-1 < \gamma < 1$. Let Q_1 be defined by Lemma 3.1 and introduce the test functions associated to the solution w_λ of problem (2.13) by

$$\chi_{1\lambda} = \lambda \cdot y - w_\lambda(y), \;\; w_\lambda^\varepsilon(x) := \; \lambda \cdot x - \varepsilon(Q_1(\chi_{1\lambda})(x/\varepsilon)). \tag{5.1}$$

A simple change of scale gives that

$$\int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_\lambda^\varepsilon \cdot \nabla v_1 \, dx = 0 \tag{5.2}$$

for every $v_1 \in V^\varepsilon$ and (see [7]) the following convergences hold true:

$$\begin{cases} w_\lambda^\varepsilon \to \lambda \cdot x & \text{weakly in } H^1(\Omega), \\ w_\lambda^\varepsilon \to \lambda \cdot x & \text{strongly in } L^2(\Omega), \\ \chi_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_\lambda^\varepsilon \rightharpoonup A^0 \lambda & \text{weakly in } \; [L^2(\Omega)]^n, \end{cases} \tag{5.3}$$

where A^0 is given by (2.12).

From now on, we will adopt the Einstein summation convention. The proof of the corrector result is based on the following proposition.

PROPOSITION 5.1. *Suppose that the assumptions of Theorem* 2.4 *are fulfilled. Set for any* $\Phi \in C^\infty([0,T], \mathcal{D}(\Omega))$

$$X_\varepsilon(t) = \frac{1}{2} \Big[\int_\Omega \left| \widetilde{u_{1\varepsilon}'}(t) + \widetilde{u_{2\varepsilon}'}(t) - \Phi'(t) \right|^2 \, dx$$
$$+ \int_{\Omega_{1\varepsilon}} A^\varepsilon (\nabla u_{1\varepsilon}(t) - C^\varepsilon \nabla \Phi(t))(\nabla u_{1\varepsilon}(t) - C^\varepsilon \nabla \Phi(t)) \, dx + \int_{\Omega_{2\varepsilon}} A^\varepsilon \nabla u_{2\varepsilon}(t) \nabla u_{2\varepsilon}(t) \, dx \Big],$$

where C^ε is given in (2.18). *Then*

$$\limsup_{\varepsilon\to 0} \|X_\varepsilon\|_{C^0([0,T])} \le \|X\|_{C^0([0,T])}, \tag{5.4}$$

where

$$X(t) = \frac{1}{2}\left[\|u_1'(t) - \Phi'(t)\|^2_{L^2(\Omega)} + \int_\Omega A^0(\nabla u_1(t) - \nabla\Phi(t))(\nabla u_1(t) - \nabla\Phi(t))\,dx\right].$$

Remark 5.2. Observe that in general in literature (see, for instance, [5], [17], [18]) one can introduce suitable quantities X_ε and X such that

$$X_\varepsilon \to X \quad \text{in } C^0([0,T]).$$

Here, we can prove only (5.4), which is just an inequality on the upper limit of $\|X_\varepsilon\|_{C^0([0,T])}$. Nevertheless, this will be sufficient to prove the corrector result.

Proof of Proposition 5.1. Using the symmetry of A^ε and C^ε, one has

$$\begin{aligned} X_\varepsilon(t) = \frac{1}{2}\Bigg[&\int_\Omega \left|\widetilde{u_{1\varepsilon}'}(t) + \widetilde{u_{2\varepsilon}'}(t) - \Phi'(t)\right|^2 \\ &+ \int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla u_{1\varepsilon}(t)\nabla u_{1\varepsilon}(t)\,dx - 2\int_{\Omega_{1\varepsilon}} A^\varepsilon C^\varepsilon \nabla\Phi(t)\nabla u_{1\varepsilon}(t)\,dx \\ &+ \int_{\Omega_{1\varepsilon}} A^\varepsilon C^\varepsilon \nabla\Phi(t) C^\varepsilon\nabla\Phi(t)\,dx + \int_{\Omega_{2\varepsilon}} A^\varepsilon \nabla u_{2\varepsilon}(t)\nabla u_{2\varepsilon}(t)\,dx\Bigg]. \end{aligned}$$

Set, for $t\in[0,T]$,

$$\begin{aligned} X_{1\varepsilon}(t) &= \frac{1}{2}\Bigg[\int_\Omega \left|\widetilde{u_{1\varepsilon}'}(t) + \widetilde{u_{2\varepsilon}'}(t)\right|^2 + \int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla u_{1\varepsilon}(t)\nabla u_{1\varepsilon}(t)\,dx \\ &\qquad + \int_{\Omega_{2\varepsilon}} A^\varepsilon \nabla u_{2\varepsilon}(t)\nabla u_{2\varepsilon}(t)\,dx\Bigg], \\ X_{2\varepsilon}(t) &= \int_\Omega \left(\widetilde{u_{1\varepsilon}'}(t) + \widetilde{u_{2\varepsilon}'}(t)\right)\Phi'(t)\,dx + \int_{\Omega_{1\varepsilon}} A^\varepsilon C^\varepsilon\nabla\Phi(t)\nabla u_{1\varepsilon}(t)\,dx, \end{aligned}$$

and

$$X_{3\varepsilon}(t) = \frac{1}{2}\left[\int_\Omega |\Phi'(t)|^2 + \int_{\Omega_{1\varepsilon}} A^\varepsilon C^\varepsilon\nabla\Phi(t) C^\varepsilon\nabla\Phi(t)\,dx\right]$$

so that

$$X_\varepsilon = X_{1\varepsilon} - X_{2\varepsilon} + X_{3\varepsilon}.$$

For $X_{1\varepsilon}$, recalling (4.1), we have

$$X_{1\varepsilon}(t) \le E^\varepsilon(t) \quad \forall\, t\in[0,T]. \tag{5.5}$$

For $X_{2\varepsilon}$, taking into account (2.18), (5.1) written for $\lambda = e_i$, and (5.2) we obtain

$$\begin{aligned} X_{2\varepsilon}(t) &= \int_\Omega \left(\widetilde{u'_{1\varepsilon}}(t) + \widetilde{u'_{2\varepsilon}}(t)\right) \Phi'(t)\, dx + \int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_i^\varepsilon \frac{\partial \Phi}{\partial x_i}(t) \nabla u_{1\varepsilon}(t)\, dx \\ &= \int_\Omega \left(\widetilde{u'_{1\varepsilon}}(t) + \widetilde{u'_{2\varepsilon}}(t)\right) \Phi'(t)\, dx + \int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_i^\varepsilon \nabla \left[\frac{\partial \Phi}{\partial x_i}(t)\, u_{1\varepsilon}(t)\right] dx \\ &\quad - \int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_i^\varepsilon \nabla \left[\frac{\partial \Phi}{\partial x_i}(t)\right] u_{1\varepsilon}(t)\, dx \\ &= \int_\Omega \left(\widetilde{u'_{1\varepsilon}}(t) + \widetilde{u'_{2\varepsilon}}(t)\right) \Phi'(t)\, dx \\ &\quad - \int_\Omega \chi_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_i^\varepsilon \nabla \left[\frac{\partial \Phi}{\partial x_i}(t)\right] P_1^\varepsilon u_{1\varepsilon}(t)\, dx \ \forall\, t \in [0,T]. \end{aligned} \tag{5.6}$$

Hence, by (2.14), (2.15), and (5.3) we conclude that

$$\begin{aligned} X_{2\varepsilon} &\to \int_\Omega (\theta_1 u'_1 + \theta_2 u'_1)\Phi'\, dx - \int_\Omega A^0 e_i \nabla \left[\frac{\partial \Phi}{\partial x_i}\right] u_1\, dx \\ &= \int_\Omega u'_1 \Phi'\, dx + \int_\Omega A^0 \nabla \Phi \nabla u_1\, dx \text{ in } \mathcal{D}'(0,T). \end{aligned} \tag{5.7}$$

Moreover, taking into account (5.6), by Theorem 2.3, (5.2), and (5.3) we obtain that there exists a constant C (independent of ε) such that

$$\|X_{2\varepsilon}\|_{L^\infty(0,T)} \le C. \tag{5.8}$$

Consequently, to prove that convergence (5.7) takes place in $C^0([0,T])$ it is enough to show that

$$\left\| \frac{\partial X_{2\varepsilon}}{\partial t} \right\|_{L^2(0,T)} \le C. \tag{5.9}$$

Using the variational formulation (2.8), we have

$$\begin{aligned} \frac{\partial}{\partial t} \int_\Omega \left(\widetilde{u'_{1\varepsilon}}(t) + \widetilde{u'_{2\varepsilon}}(t)\right) \Phi'(t)\, dx &= \int_\Omega \left(\widetilde{u'_{1\varepsilon}}(t) + \widetilde{u'_{2\varepsilon}}(t)\right) \Phi''(t) \\ &\quad - \int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla u_{1\varepsilon}(t) \cdot \nabla \Phi'(t)\, dx - \int_{\Omega_{2\varepsilon}} A^\varepsilon \nabla u_{2\varepsilon}(t) \cdot \nabla \Phi'(t)\, dx \\ &\quad + \int_{\Omega_{1\varepsilon}} f_{1\varepsilon}(t)\Phi'(t)\, dx + \int_{\Omega_{2\varepsilon}} f_{2\varepsilon}(t)\Phi'(t)\, dx, \end{aligned}$$

which is bounded in $L^2(0,T)$ due to (2.15), (2.16), and (2.7).

Moreover, we have

$$\begin{aligned} \frac{\partial}{\partial t} \int_\Omega \chi_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_i^\varepsilon \nabla \left[\frac{\partial \Phi}{\partial x_i}(t)\right] P_1^\varepsilon u_{1\varepsilon}(t)\, dx &= \int_\Omega \chi_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_i^\varepsilon \nabla \left[\frac{\partial \Phi'}{\partial x_i}(t)\right] P_1^\varepsilon u_{1\varepsilon}(t)\, dx \\ &\quad + \int_\Omega \chi_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_i^\varepsilon \nabla \left[\frac{\partial \Phi}{\partial x_i}(t)\right] P_1^\varepsilon u'_{1\varepsilon}(t)\, dx, \end{aligned}$$

which is bounded in $L^2(0,T)$ as a consequence of (5.3) and Theorem 2.3.

Thus, from (5.6) we obtain (5.9). Due to classical compactness results, from this inequality and (5.8) it turns out that $X_{2\varepsilon}$ is relatively compact in $C^0([0,T])$. This, together with (5.7), gives

$$X_{2\varepsilon} \to X_2 := \int_\Omega u_1'\Phi'\,dx + \int_\Omega A^0\nabla\Phi\nabla u_1\,dx \text{ strongly in } C^0([0,T]). \tag{5.10}$$

For $X_{3\varepsilon}$, by the smoothness of Φ we have that it is bounded in $L^\infty(0,T)$ as well as its time derivative. Moreover, by (5.2) we deduce that

$$\begin{aligned}\int_{\Omega_{1\varepsilon}} A^\varepsilon C^\varepsilon\nabla\Phi(t)C^\varepsilon\nabla\Phi(t)\,dx &= \int_{\Omega_{1\varepsilon}} A^\varepsilon\nabla w_i^\varepsilon\frac{\partial\Phi}{\partial x_i}(t)\nabla w_j^\varepsilon\frac{\partial\Phi}{\partial x_j}(t)\,dx\\ &= -\int_{\Omega_{1\varepsilon}} A^\varepsilon\nabla w_i^\varepsilon w_j^\varepsilon\nabla\left[\frac{\partial\Phi}{\partial x_i}(t)\frac{\partial\Phi}{\partial x_j}(t)\right]\,dx.\end{aligned}$$

Thus, from (5.3)

$$\begin{aligned}\lim_{\varepsilon\to0} X_{3\varepsilon}(t) &= \lim_{\varepsilon\to0}\frac12\left[\|\Phi'(t)\|^2_{L^2(\Omega)} + \int_{\Omega_{1\varepsilon}} A^\varepsilon C^\varepsilon\nabla\Phi(t)C^\varepsilon\nabla\Phi(t)\,dx\right]\\ &= \frac12\left[\|\Phi'(t)\|^2_{L^2(\Omega)} - \int_\Omega A^0 e_i x_j\nabla\left[\frac{\partial\Phi}{\partial x_i}(t)\frac{\partial\Phi}{\partial x_j}(t)\right]\,dx\right]\\ &= \frac12\left[\|\Phi'(t)\|^2_{L^2(\Omega)} + \int_\Omega A^0\nabla\Phi(t)\nabla\Phi(t)\,dx\right]\ \forall\, t\in[0,T],\end{aligned}$$

which gives

$$X_{3\varepsilon} \to X_3 := \frac12\left[\|\Phi'\|^2_{L^2(\Omega)} + \int_\Omega A^0\nabla\Phi\nabla\Phi\,dx\right] \text{ strongly in } C^0([0,T]). \tag{5.11}$$

Convergence (5.11), together with (5.10), (4.4), and (4.5), gives

$$E^\varepsilon - X_{2\varepsilon} + X_{3\varepsilon} \to E - X_2 + X_3 = X \quad \text{strongly in } C^0([0,T]). \tag{5.12}$$

Since from (5.5) one has

$$0 \le X_\varepsilon(t) \le E^\varepsilon(t) - X_{2\varepsilon}(t) + X_{3\varepsilon}(t) \quad \forall\, t\in[0,T],$$

by (5.12) we conclude that

$$\limsup_{\varepsilon\to0}\|X_\varepsilon\|_{C^0([0,T])} \le \lim_{\varepsilon\to0}\|E^\varepsilon - X_{2\varepsilon} + X_{3\varepsilon}\|_{C^0([0,T])} = \|X\|_{C^0([0,T])}. \qquad \square$$

Remark 5.3. Let us point out that the main difficulty when proving Proposition 5.1 is due to the fact that, as a consequence of the presence of the boundary term in the energy, we have only $X_{1\varepsilon} \le E^\varepsilon$ and not $X_{1\varepsilon} = E^\varepsilon$ as in the classical cases.

Nevertheless, the fact that $E^\varepsilon - X_{2\varepsilon} + X_{3\varepsilon} \to X$ in $C^0([0,T])$ allows us to prove the result.

Proof of Theorem 2.4. The function $u_1 \in L^2(0,T;H^1_0(\Omega))\cap C^0([0,T];L^2(\Omega))$ and its derivative $u_1' \in C^0([0,T];L^2(\Omega))$; thus, from classical density results, for any $\delta>0$ there exists $\Phi\in C^\infty([0,T];\mathcal{D}(\Omega))$ such that

$$\begin{cases}\|u_1' - \Phi'\|_{C^0([0,T];L^2(\Omega))} \le \delta,\\ \|\nabla u_1 - \nabla\Phi\|_{L^2(0,T;L^2(\Omega))} \le \delta.\end{cases} \tag{5.13}$$

Therefore,

$$\begin{aligned}
&\left\|\widetilde{u'_{1\varepsilon}}+\widetilde{u'_{2\varepsilon}}-u'_1\right\|^2_{C^0(0,T;L^2(\Omega))}\\
&\qquad\le 2\Big(\left\|\widetilde{u'_{1\varepsilon}}+\widetilde{u'_{2\varepsilon}}-\Phi'\right\|^2_{C^0(0,T;L^2(\Omega))}+\|\Phi'-u'_1\|^2_{C^0(0,T;L^2(\Omega))}\Big)\\
&\qquad\le 2\left\|\widetilde{u'_{1\varepsilon}}+\widetilde{u'_{2\varepsilon}}-\Phi'\right\|^2_{C^0(0,T;L^2(\Omega))}+2\delta^2.
\end{aligned}\tag{5.14}$$

On the other hand, due to the Cauchy–Schwarz inequality, definition (2.18) of C^ε, and (5.13) there exist two constants C_1, C_2 such that

$$\begin{aligned}
&\|\nabla u_{1\varepsilon}-C^\varepsilon\nabla u_1\|^2_{C^0([0,T];[L^1(\Omega_{1\varepsilon})]^n)}+\|\nabla u_{2\varepsilon}\|^2_{C^0([0,T];[L^2(\Omega_{2\varepsilon})]^n)}\\
&\quad\le 2\|\nabla u_{1\varepsilon}-C^\varepsilon\nabla\Phi\|^2_{C^0([0,T];[L^1(\Omega_{1\varepsilon})]^n)}+\|\nabla u_{2\varepsilon}\|^2_{C^0([0,T];[L^2(\Omega_{2\varepsilon})]^n)}\\
&\qquad+2\|C^\varepsilon(\nabla\Phi-\nabla u_1)\|^2_{C^0([0,T];[L^1(\Omega_{1\varepsilon})]^n)}\\
&\quad\le 2C_1\|\nabla u_{1\varepsilon}-C^\varepsilon\nabla\Phi\|^2_{C^0([0,T];[L^2(\Omega_{1\varepsilon})]^n)}+\|\nabla u_{2\varepsilon}\|^2_{C^0([0,T];[L^2(\Omega_{2\varepsilon})]^n)}+2C_2\delta^2.
\end{aligned}\tag{5.15}$$

From properties (2.3) and definition (2.4) of A^ε, we have

$$\begin{aligned}
&\frac12\left\|\widetilde{u'_{1\varepsilon}}(t)+\widetilde{u'_{2\varepsilon}}(t)-\Phi'(t)\right\|^2_{L^2(\Omega)}\\
&\qquad+\frac{\alpha}{2}\left(\|\nabla u_{1\varepsilon}(t)-C^\varepsilon\nabla\Phi(t)\|^2_{[L^2(\Omega_{1\varepsilon})]^n}+\|\nabla u_{2\varepsilon}(t)\|^2_{[L^2(\Omega_{2\varepsilon})]^n}\right)\le X_\varepsilon(t)\quad\forall t\in[0,T];
\end{aligned}$$

moreover, there exists a constant C_3

$$\|X\|_{C^0([0,T])}\le C_3\delta^2,$$

where X_ε and X are defined in Proposition 5.1 and are applied to the function Φ, given by (5.13).

From this last inequality and by Proposition 5.1, we conclude that

$$\begin{aligned}
\limsup_{\varepsilon\to0}&\left\{\frac12\left\|\widetilde{u'_{1\varepsilon}}+\widetilde{u'_{2\varepsilon}}-\Phi'\right\|^2_{C^0([0,T];L^2(\Omega))}\right.\\
&\left.+\frac{\alpha}{2}\left(\|\nabla u_{1\varepsilon}-C^\varepsilon\nabla\Phi\|^2_{C^0([0,T];[L^2(\Omega_{1\varepsilon})]^n)}+\|\nabla u_{2\varepsilon}\|^2_{C^0([0,T];[L^2(\Omega_{2\varepsilon})]^n)}\right)\right\}\\
&\qquad\le\limsup_{\varepsilon\to0}\|X_\varepsilon\|_{C^0([0,T])}\le\|X\|_{C^0([0,T])}\le C_3\delta^2.
\end{aligned}$$

This, together with (5.14) and (5.15), gives convergences (2.19), δ being arbitrary. □

6. Proof of the corrector result in the case $\gamma = 1$. The proof is based on the result below, which is analogous to that shown for $-1<\gamma<1$ in Proposition 5.1. Let us emphasize that here the proof is more delicate and contains some technically specific parts.

PROPOSITION 6.1. *Suppose that the assumptions of Theorem* 2.8 *are fulfilled. Set for any* $\Phi, \Psi \in C^\infty([0,T], \mathcal{D}(\Omega))$

$$\begin{aligned}\hat{X}_\varepsilon(t) = \frac{1}{2}\int_{\Omega_{1\varepsilon}} |u'_{1\varepsilon}(t) - \Phi'(t)|^2\,dx + \int_{\Omega_{2\varepsilon}} |u'_{2\varepsilon}(t) - \Psi'(t)|^2\,dx \\ + \int_{\Omega_{1\varepsilon}} A^\varepsilon(\nabla u_{1\varepsilon}(t) - C^\varepsilon\nabla\Phi(t))(\nabla u_{1\varepsilon}(t) - C^\varepsilon\nabla\Phi(t))\,dx \\ + \int_{\Omega_{2\varepsilon}} A^\varepsilon\nabla u_{2\varepsilon}(t)\nabla u_{2\varepsilon}(t)\,dx\Big].\end{aligned}$$

Then,

$$\limsup_{\varepsilon\to 0} \big\|\hat{X}_\varepsilon\big\|_{C^0([0,T])} \le \big\|\hat{X}\big\|_{C^0([0,T])},$$

where

$$\begin{aligned}\hat{X}(t) = \frac{1}{2}\Big[\theta_1\|u'_1(t) - \Phi'(t)\|^2_{L^2(\Omega)} + \theta_2^{-1}\|u'_2(t) - \theta_2\Psi'(t)\|^2_{L^2(\Omega)} \\ + \int_\Omega A^0(\nabla u_1(t) - \nabla\Phi(t))(\nabla u_1(t) - \nabla\Phi(t))\,dx\Big].\end{aligned} \tag{6.1}$$

Remark 6.2. Here also (see Remark 5.2) we have only an inequality on the upper limit of $\|\hat{X}_\varepsilon\|_{C^0([0,T])}$. Due to the special form of the energy, to prove Proposition 6.1 we need to introduce more complex arguments than those used in the proof of Proposition 5.1.

Proof of Proposition 6.1. By the symmetry of A^ε and C^ε, one has

$$\begin{aligned}\hat{X}_\varepsilon(t) = \frac{1}{2}\Big[\int_{\Omega_{1\varepsilon}} |u'_{1\varepsilon}(t) - \Phi'(t)|^2\,dx + \int_{\Omega_{2\varepsilon}} |u'_{2\varepsilon}(t) - \Psi'(t)|^2\,dx \\ + \int_{\Omega_{1\varepsilon}} A^\varepsilon\nabla u_{1\varepsilon}(t)\nabla u_{1\varepsilon}(t)\,dx - 2\int_{\Omega_{1\varepsilon}} A^\varepsilon C^\varepsilon\nabla\Phi(t)\nabla u_{1\varepsilon}(t)\,dx \\ + \int_{\Omega_{1\varepsilon}} A^\varepsilon C^\varepsilon\nabla\Phi(t)C^\varepsilon\nabla\Phi(t)\,dx + \int_{\Omega_{2\varepsilon}} A^\varepsilon\nabla u_{2\varepsilon}(t)\nabla u_{2\varepsilon}(t)\,dx\Big].\end{aligned}$$

Decompose $\hat{X}_\varepsilon$ as

$$\hat{X}_\varepsilon = X_{1\varepsilon} - \hat{X}_{2\varepsilon} + \hat{X}_{3\varepsilon},$$

where, as in the previous case,

$$\begin{aligned}X_{1\varepsilon}(t) = \frac{1}{2}\Big[\int_{\Omega_{1\varepsilon}} |u'_{1\varepsilon}(t)|^2\,dx + \int_{\Omega_{2\varepsilon}} |u'_{2\varepsilon}(t)|^2\,dx \\ + \int_{\Omega_{1\varepsilon}} A^\varepsilon\nabla u_{1\varepsilon}(t)\nabla u_{1\varepsilon}(t)\,dx + \int_{\Omega_{2\varepsilon}} A^\varepsilon\nabla u_{2\varepsilon}(t)\nabla u_{2\varepsilon}(t)\,dx\Big],\end{aligned}$$

while

$$\begin{aligned}\hat{X}_{2\varepsilon}(t) = \int_{\Omega_{1\varepsilon}} u'_{1\varepsilon}(t)\Phi'(t)\,dx + \int_{\Omega_{2\varepsilon}} u'_{2\varepsilon}(t)\Psi'(t)\,dx \\ + \int_{\Omega_{1\varepsilon}} A^\varepsilon C^\varepsilon\nabla\Phi(t)\nabla u_{1\varepsilon}(t)\,dx\end{aligned}$$

and

$$\hat{X}_{3\varepsilon}(t) = \frac{1}{2}\left[\int_{\Omega_{1\varepsilon}} |\Phi'(t)|^2\, dx + \int_{\Omega_{2\varepsilon}} |\Psi'(t)|^2\, dx + \int_{\Omega_{1\varepsilon}} A^\varepsilon C^\varepsilon \nabla\Phi C^\varepsilon \nabla\Phi\, dx\right].$$

We proceed in several steps.

Step 1. Let us prove that

$$\begin{aligned}\limsup_{\varepsilon\to 0} X_{1\varepsilon}(t) \le \hat{X}_1 := \frac{1}{2}\Big[&\theta_1 \int_\Omega |u_1'(t)|^2\, dx + \theta_2^{-1}\int_\Omega |u_2'(t)|^2\, dx \\ &+ \int_\Omega A^0\nabla u_1(t)\nabla u_1(t)\, dx\Big] \quad \forall\, t\in[0,T].\end{aligned} \tag{6.2}$$

Since from (4.1) we have

$$X_{1\varepsilon} = E^\varepsilon - \frac{1}{2}\left(\varepsilon\int_{\Gamma^\varepsilon} h^\varepsilon |u_{1\varepsilon} - u_{2\varepsilon}|^2 d\sigma_x\right), \tag{6.3}$$

following the same ideas of [8] we show first that

$$\liminf_{\varepsilon\to 0}\left(\varepsilon\int_{\Gamma^\varepsilon} h^\varepsilon |u_{1\varepsilon}(t) - u_{2\varepsilon}(t)|^2 d\sigma_x\right) \ge c_h\theta_2^{-1}\int_\Omega |\theta_2 u_1(t) - u_2(t)|^2\, dx \tag{6.4}$$

for any $t\in[0,T]$.

To do that, we apply Lemma 3.4(ii) with $g = h$ and $v_\varepsilon = (P_1^\varepsilon u_{1\varepsilon} - u_{2\varepsilon})^2$ getting

$$\begin{aligned}&\liminf_{\varepsilon\to 0}\left(\varepsilon\int_{\Gamma^\varepsilon} h^\varepsilon |u_{1\varepsilon}(t) - u_{2\varepsilon}(t)|^2 d\sigma_x\right)\\ &\quad= \liminf_{\varepsilon\to 0}\left(\varepsilon\int_{\Gamma^\varepsilon} h^\varepsilon |P_1^\varepsilon u_{1\varepsilon}(t) - u_{2\varepsilon}(t)|^2 d\sigma_x\right)\\ &\quad= \liminf_{\varepsilon\to 0} c_h\int_{\Omega_{2\varepsilon}} |P_1^\varepsilon u_{1\varepsilon}(t) - u_{2\varepsilon}(t)|^2 dx \quad \forall\, t\in[0,T].\end{aligned} \tag{6.5}$$

Observe now that, thanks to (2.2), (2.20), and Remark 2.7(ii), we have

$$\widetilde{P_1^\varepsilon u_{1\varepsilon}}_{|\Omega_{2\varepsilon}}(t) - \widetilde{u_{2\varepsilon}}(t) = \chi_{|\Omega_{2\varepsilon}} P_1^\varepsilon u_{1\varepsilon}(t) - \widetilde{u_{2\varepsilon}}(t) \rightharpoonup \theta_2\left(u_1(t) - \theta_2^{-1}u_2(t)\right) \text{ weakly in } L^2(\Omega)$$

for any $t\in[0,T]$.

Hence, we can apply Lemma 3.5 with $p = 2$, $\mathcal{O}_\varepsilon = \Omega_{2\varepsilon}$, $\chi_0 = \theta_2$, $v_\varepsilon = P_1^\varepsilon u_{1\varepsilon}{}_{|\Omega_{2\varepsilon}} - u_{2\varepsilon}$, and $v = (u_1 - \theta_2^{-1}u_2)$. We have

$$\liminf_{\varepsilon\to 0} c_h\int_{\Omega_{2\varepsilon}} |P_1^\varepsilon u_{1\varepsilon}{}_{|\Omega_{2\varepsilon}}(t) - u_{2\varepsilon}(t)|^2 dx \;\ge c_h\int_\Omega \theta_2\left|u_1(t) - \theta_2^{-1}u_2(t)\right|^2\, dx\ \forall\, t\in[0,T],$$

which, together with (6.5), gives (6.4).

By (6.3), (6.4), and Theorem 4.4 we conclude that

$$\begin{aligned}\limsup_{\varepsilon\to 0} X_{1\varepsilon}(t) &= \limsup_{\varepsilon\to 0}\left[E^\varepsilon(t) - \frac{1}{2}\left(\varepsilon\int_{\Gamma^\varepsilon} h^\varepsilon |u_{1\varepsilon}(t)-u_{2\varepsilon}(t)|^2 d\sigma_x\right)\right]\\ &= \lim_{\varepsilon\to 0} E^\varepsilon(t) - \liminf_{\varepsilon\to 0}\left[\frac{1}{2}\left(\varepsilon\int_{\Gamma^\varepsilon} h^\varepsilon |u_{1\varepsilon}(t)-u_{2\varepsilon}(t)|^2 d\sigma_x\right)\right]\\ &\le \frac{1}{2}\Bigg[\theta_1\int_\Omega |u_1'(t)|^2\,dx + {\theta_2}^{-1}\int_\Omega |u_2'(t)|^2\,dx\\ &\quad + \int_\Omega A^0\nabla u_1(t)\nabla u_1(t)\,dx + c_h{\theta_2}^{-1}\int_\Omega |\theta_2 u_1(t)-u_2(t)|^2\,dx\\ &\quad - c_h{\theta_2}^{-1}\int_\Omega |\theta_2 u_1(t)-u_2(t)|^2\,dx\Bigg]\ \forall\, t\in[0,T],\end{aligned}$$

which proves (6.2).

Step 2. Observe now that, due to the presence of the boundary term in (6.3), we cannot have a priori estimates on the time derivative of $X_{1\varepsilon}$. Hence, we cannot deduce any compactness of $X_{1\varepsilon}$ in $C^0([0,T])$. To overcome this difficulty, we decompose $X_{1\varepsilon}$ as a sum of a compact part $E^\varepsilon - Y_\varepsilon$ and a rest $\hat{Y}_\varepsilon$, which goes to zero in $C^0([0,T])$ as $\varepsilon\to 0$. To do that we use Lemma 3.4(i) in (6.3) to obtain

$$X_{1\varepsilon} = E^\varepsilon - Y_\varepsilon - \hat{Y}_\varepsilon,$$

where

$$Y_\varepsilon(t) := c_h\int_{\Omega_{2\varepsilon}} |P_1^\varepsilon u_{1\varepsilon}(t) - u_{2\varepsilon}(t)|^2\,dx$$

and

$$\hat{Y}_\varepsilon(t) := \varepsilon\int_{\Omega_{2\varepsilon}} \nabla_y\psi_h(x/\varepsilon)\nabla_x |P_1^\varepsilon u_{1\varepsilon}(t) - u_{2\varepsilon}(t)|^2\,dx\ \forall\, t\ \in[0,T]. \tag{6.6}$$

Let us show first that

$$E^\varepsilon - Y_\varepsilon \text{ is compact in } C^0([0,T]). \tag{6.7}$$

Indeed, from Theorem 4.4 E^ε converges in $C^0([0,T])$. Moreover, Y_ε is bounded in $L^\infty(0,T)$ and

$$\left\|\frac{\partial Y_\varepsilon}{\partial t}\right\|_{L^\infty(0,T)} \le C\|P_1^\varepsilon u_{1\varepsilon}' - u_{2\varepsilon}'\|_{L^\infty(0,T;L^2(\Omega_{2\varepsilon}))}\|P_1^\varepsilon u_{1\varepsilon} - u_{2\varepsilon}\|_{L^\infty(0,T;L^2(\Omega_{2\varepsilon}))} \le C.$$

This gives (6.7).

To conclude this step, let us prove that

$$\hat{Y}_\varepsilon \to 0 \text{ in } C^0([0,T]). \tag{6.8}$$

Indeed,

$$\begin{aligned}&\varepsilon\left|\int_{\Omega_{2\varepsilon}} \nabla_y\psi_h(x/\varepsilon)\nabla_x |P_1^\varepsilon u_{1\varepsilon}(t) - u_{2\varepsilon}(t)|^2\,dx\right|\\ &\quad\le 2\varepsilon\|\nabla_y\psi_h\|_{L^\infty(\mathbb{R}^n)}\,\|\nabla(P_1^\varepsilon u_{1\varepsilon} - u_{2\varepsilon})\,(P_1^\varepsilon u_{1\varepsilon} - u_{2\varepsilon})\|_{L^\infty(0,T;L^1(\Omega_{2\varepsilon}))}\\ &\quad\le C_3\varepsilon\|P_1^\varepsilon u_{1\varepsilon} - u_{2\varepsilon}\|_{C^0(0,T;H^1(\Omega_{2\varepsilon}))} \le C\varepsilon\ \forall\, t\ \in[0,T]\end{aligned}$$

with C independent of ε and t. Therefore,

$$\varepsilon \left| \int_{\Omega_{2\varepsilon}} \nabla_y \psi_h(x/\varepsilon) \nabla_x (P_1^\varepsilon u_{1\varepsilon} - u_{2\varepsilon})^2 \, dx \right| \to 0 \text{ in } C^0([0,T]),$$

which gives (6.8).

Step 3. We prove here the convergences of $\hat{X}_{2\varepsilon}$ and $\hat{X}_{3\varepsilon}$ in $C^0([0,T])$.

Consider first $\hat{X}_{2\varepsilon}$. From (2.18), (5.1) written for $\lambda = e_i$, and (5.2) we have

(6.9)
$$\begin{aligned}
\hat{X}_{2\varepsilon}(t) &= \int_{\Omega_{1\varepsilon}} u'_{1\varepsilon}(t)\Phi'(t)\,dx + \int_{\Omega_{2\varepsilon}} u'_{2\varepsilon}(t)\Psi'(t)\,dx + \int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_i^\varepsilon \nabla u_{1\varepsilon}(t) \frac{\partial \Phi}{\partial x_i}(t)\,dx \\
&= \int_\Omega \widetilde{u'_{1\varepsilon}}(t)\Phi'(t)\,dx + \int_\Omega \widetilde{u'_{2\varepsilon}}(t)\Psi'(t)\,dx + \int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_i^\varepsilon \nabla \left[u_{1\varepsilon}(t) \frac{\partial \Phi}{\partial x_i}(t) \right] dx \\
&\quad - \int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_i^\varepsilon \nabla \left[\frac{\partial \Phi}{\partial x_i}(t) \right] u_{1\varepsilon}(t)\,dx = \int_\Omega \widetilde{u'_{1\varepsilon}}(t)\Phi'(t)\,dx + \int_\Omega \widetilde{u'_{2\varepsilon}}(t)\Psi'(t)\,dx \\
&\quad - \int_\Omega \chi_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_i^\varepsilon \nabla \left[\frac{\partial \Phi}{\partial x_i}(t) \right] P_1^\varepsilon u_{1\varepsilon}(t)\,dx.
\end{aligned}$$

Due to Theorem 2.6, Remark 2.7(ii), and (5.3) one concludes that

(6.10)
$$\begin{aligned}
\hat{X}_{2\varepsilon} &\to \int_\Omega \theta_1 u'_1 \Phi'\,dx + \int_\Omega u'_2 \Psi'\,dx - \int_\Omega A^0 e_i \nabla \left[\frac{\partial \Phi}{\partial x_i} \right] u_1\,dx \\
&= \int_\Omega \theta_1 u'_1 \Phi'\,dx + \int_\Omega u'_2 \Psi'\,dx + \int_\Omega A^0 \nabla \Phi \nabla u_1\,dx \text{ in } \mathcal{D}'(0,T).
\end{aligned}$$

We have to prove that this convergence takes place in $C^0([0,T])$. From (6.9), Theorem 2.6, (5.2), and (5.3) there exists a constant C (independent of ε) such that

$$\|\hat{X}_{2\varepsilon}\|_{L^\infty(0,T)} \le C. \tag{6.11}$$

Let us show that

$$\left\| \frac{\partial \hat{X}_{2\varepsilon}}{\partial t} \right\|_{L^2(0,T)} \le C. \tag{6.12}$$

The variational formulation (2.8) written for $v_1 = \Phi$ and $v_2 = \Psi$ reads

$$\begin{aligned}
&\frac{\partial}{\partial t} \left(\int_\Omega u'_{1\varepsilon}(t)\Phi'(t)\,dx + \int_\Omega u'_{2\varepsilon}(t)\Psi'(t)\,dx \right) \\
&\quad = \int_\Omega \widetilde{u'_{1\varepsilon}}(t)\Phi''(t) + \int_\Omega \widetilde{u'_{2\varepsilon}}(t)\Psi''(t) - \int_{\Omega_{1\varepsilon}} A^\varepsilon \nabla u_{1\varepsilon}(t) \cdot \nabla \Phi'(t)\,dx \\
&\qquad - \int_{\Omega_{2\varepsilon}} A^\varepsilon \nabla u_{2\varepsilon}(t) \nabla \Psi'(t)\,dx - \varepsilon \int_{\Gamma^\varepsilon} h^\varepsilon (u_{1\varepsilon}(t) - u_{2\varepsilon}(t))(\Phi'(t) - \Psi'(t))\,d\sigma_x \\
&\qquad + \int_{\Omega_{1\varepsilon}} f_{1\varepsilon}(t)\Phi'(t)\,dx + \int_{\Omega_{2\varepsilon}} f_{2\varepsilon}(t)\Psi'(t)\,dx,
\end{aligned}$$

which is bounded in $L^2(0,T)$ due to Theorems 2.6 and (2.9)(i).

Moreover, we have

$$\frac{\partial}{\partial t}\int_\Omega \chi_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_i^\varepsilon \nabla \left[\frac{\partial \Phi}{\partial x_i}(t)\right] P_1^\varepsilon u_{1\varepsilon}(t)\,dx = \int_\Omega \chi_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_i^\varepsilon \nabla \left[\frac{\partial \Phi'}{\partial x_i}(t)\right] P_1^\varepsilon u_{1\varepsilon}(t)\,dx + \int_\Omega \chi_{\Omega_{1\varepsilon}} A^\varepsilon \nabla w_i^\varepsilon \nabla \left[\frac{\partial \Phi}{\partial x_i}(t)\right] P_1^\varepsilon u'_{1\varepsilon}(t)\,dx,$$

and the right-hand side of this equality is bounded in $L^2(0,T)$ in view of (5.3) and Theorem 2.6. Hence (6.12) holds; this, together with (6.11), shows that $\hat{X}_{2\varepsilon}$ is relatively compact in $C^0([0,T])$ so that from (6.10) we obtain

(6.13)
$$\hat{X}_{2\varepsilon} \to \hat{X}_2 := \int_\Omega \theta_1 u_1' \Phi'\,dx + \int_\Omega u_2' \Psi'\,dx + \int_\Omega A^0 \nabla\Phi\nabla u_1\,dx \text{ strongly in } C^0([0,T]).$$

Concerning $\hat{X}_{3\varepsilon}$, a similar argument to that used in the proof of Proposition 5.1 to show (5.11) gives

$$\hat{X}_{3\varepsilon} \to \hat{X}_3 := \frac{1}{2}\left[\theta_1\|\Phi'\|^2_{L^2(\Omega)} + \theta_2\|\Psi'\|^2_{L^2(\Omega)} + \int_\Omega A^0\nabla\Phi\nabla\Phi\,dx\right] \text{ strongly in } C^0([0,T]). \tag{6.14}$$

Step 4. Observe first that from (6.2), (6.13), and (6.14) we have

$$0 \le \limsup_{\varepsilon\to 0} \hat{X}_\varepsilon(t) \le \hat{X}_1(t) - \hat{X}_2(t) + \hat{X}_3(t) = \hat{X}(t) \quad \forall\, t\in[0,T], \tag{6.15}$$

where $\hat{X}$ is given by (6.1).

On the other hand, if we write $\hat{X}_\varepsilon$ as

$$\hat{X}_\varepsilon = Z_\varepsilon - \hat{Y}_\varepsilon, \tag{6.16}$$

where

$$Z_\varepsilon := E^\varepsilon - Y_\varepsilon - \hat{X}_{2\varepsilon} + \hat{X}_{3\varepsilon} \tag{6.17}$$

and $\hat{Y}_\varepsilon$ is given by (6.6), due to (6.8) we have

$$\limsup_{\varepsilon\to 0} \left\|\hat{X}_\varepsilon\right\|_{C^0([0,T])} \le \limsup_{\varepsilon\to 0} \|Z_\varepsilon\|_{C^0([0,T])} + \lim_{\varepsilon\to 0}\left|\hat{Y}_\varepsilon\right| = \limsup_{\varepsilon\to 0}\|Z_\varepsilon\|_{C^0([0,T])}. \tag{6.18}$$

Consequently, to conclude, it is enough to prove that

$$\limsup_{\varepsilon\to 0}\|Z_\varepsilon\|_{C^0([0,T])} \le \left\|\hat{X}\right\|_{C^0([0,T])}, \tag{6.19}$$

which together with (6.18) will give the claimed result.

Let $\{\varepsilon'\}$ be a subsequence such that

$$\limsup_{\varepsilon\to 0}\|Z_\varepsilon\|_{C^0([0,T])} = \lim_{\varepsilon'\to 0}\|Z_{\varepsilon'}\|_{C^0([0,T])}. \tag{6.20}$$

From (6.7), (6.13), and (6.14) it follows that Z_ε is compact in $C^0([0,T])$. Therefore, there exists a subsequence (still denoted $\{\varepsilon'\}$) such that

$$Z_{\varepsilon'} \to Z \text{ strongly in } C^0([0,T]). \tag{6.21}$$

But, from (6.16), (6.15), and (6.8) we have

$$0 \le Z(t) = \lim_{\varepsilon' \to 0} \left[\hat{X}_{\varepsilon'}(t) + \hat{Y}_{\varepsilon'}(t) \right] = \lim_{\varepsilon' \to 0} \hat{X}_{\varepsilon'}(t) \le X(t) \quad \forall\, t \ \in [0,T]$$

so that from (6.21) one has

$$\lim_{\varepsilon' \to 0} \|Z_{\varepsilon'}\|_{C^0([0,T])} = \|Z\|_{C^0([0,T])} \le \left\|\hat{X}\right\|_{C^0([0,T])},$$

which together with (6.20) gives (6.19) and ends the proof. □

Remark 6.3. Let us emphasize the main difficulties in the proof of Proposition 6.1. First, as in the previous case (see Remark 5.3), due to the presence of the boundary term in the energy, we have only $X_{1\varepsilon} \le E^\varepsilon$ and not $X_{1\varepsilon} = E^\varepsilon$, as usual. Moreover, here the limit of $E^\varepsilon - \hat{X}_{2\varepsilon} + \hat{X}_{3\varepsilon}$ is bigger than $\hat{X}$ so that we cannot conclude as in the previous case. On the other hand, since we have no estimates for the time derivative of the boundary term of $X_{1\varepsilon}$, we cannot derive any compactness of $X_{1\varepsilon}$ in $C^0([0,T])$. This is why we introduced in Step 4 of the proof a more technical argument, which relies on the decomposition (6.17) of $\hat{X}_\varepsilon$ as a sum of a compact term $Z_\varepsilon - Y_\varepsilon$ and a rest $\hat{Y}_\varepsilon$, which goes to zero in $C^0([0,T])$ as $\varepsilon \to 0$.

Proof of Theorem 2.8. Since $u_1 \in L^2(0,T;H_0^1(\Omega)) \cap C^0([0,T];L^2(\Omega))$, $u_1' \in C^0([0,T];L^2(\Omega))$, and $u_2' \in C^0([0,T];L^2(\Omega))$, from classical density results, we have that for any $\delta > 0$ there exist $\Phi, \Psi \in C^\infty([0,T];\mathcal{D}(\Omega))$ such that

$$\begin{cases} \text{(i)} \ \|u_1' - \Phi'\|_{C^0([0,T];L^2(\Omega))} \le \delta, \\ \text{(ii)} \ \left\|\theta_2^{-1} u_2' - \Psi'\right\|_{C^0([0,T];L^2(\Omega))} \le \delta, \\ \text{(iii)} \ \|\nabla u_1 - \nabla \Phi\|_{L^2(0,T;L^2(\Omega))} \le \delta. \end{cases} \tag{6.22}$$

Therefore,

$$\begin{aligned} &\|u_{1\varepsilon}' - u_1'\|^2_{C^0(0,T;L^2(\Omega_{1\varepsilon}))} + \left\|u_{2\varepsilon}' - \theta_2^{-1} u_2'\right\|^2_{C^0(0,T;L^2(\Omega_{2\varepsilon}))} \\ &\le 2 \Big(\|u_{1\varepsilon}' - \Phi'\|^2_{C^0(0,T;L^2(\Omega_{1\varepsilon}))} + \|\Phi' - u_1'\|^2_{C^0(0,T;L^2(\Omega_{1\varepsilon}))} \\ &\quad + \|u_{2\varepsilon}' - \Psi'\|^2_{C^0(0,T;L^2(\Omega_{2\varepsilon}))} + \left\|\Psi' - \theta_2^{-1} u_2'\right\|^2_{C^0(0,T;L^2(\Omega_{2\varepsilon}))} \Big) \\ &\le 2 \Big(\|u_{1\varepsilon}' - \Phi'\|^2_{C^0(0,T;L^2(\Omega_{1\varepsilon}))} + \|u_{2\varepsilon}' - \Psi'\|^2_{C^0(0,T;L^2(\Omega_{2\varepsilon}))} \Big) + 2\delta^2. \end{aligned} \tag{6.23}$$

The same argument used to prove (5.15) gives that there exists a constant C_1 such that

$$\begin{aligned} &\left(\|\nabla u_{1\varepsilon} - C^\varepsilon \nabla u_1\|^2_{C^0([0,T];[L^1(\Omega_{1\varepsilon})]^n)} + \|\nabla u_{2\varepsilon}\|^2_{C^0([0,T];[L^2(\Omega_{2\varepsilon})]^n)} \right) \\ &\le C_1 \left(\|\nabla u_{1\varepsilon} - C^\varepsilon \nabla \Phi\|^2_{C^0([0,T];[L^2(\Omega_{1\varepsilon})]^n)} + \|\nabla u_{2\varepsilon}\|^2_{C^0([0,T];[L^2(\Omega_{2\varepsilon})]^n)} + \delta^2 \right). \end{aligned} \tag{6.24}$$

On the other hand, from the properties of A^ε,

$$\begin{aligned} \frac{1}{2} \Big[&\|u_{1\varepsilon}'(t) - \Phi'(t)\|^2_{L^2(\Omega_{1\varepsilon})} + \|u_{2\varepsilon}'(t) - \Psi'(t)\|^2_{L^2(\Omega_{2\varepsilon})} \\ &+ \alpha \left(\|\nabla u_{1\varepsilon} - C^\varepsilon \nabla \Phi\|^2_{[L^2(\Omega_{1\varepsilon})]^n} + \|\nabla u_{2\varepsilon}\|^2_{[L^2(\Omega_{2\varepsilon})]^n} \right) \Big] \le \hat{X}_\varepsilon \quad \forall\, t \in [0,T] \end{aligned}$$

and there exists a constant C_2 such that

$$\left\|\hat{X}\right\|_{C^0([0,T])} \le C_2 \delta^2,$$

where $\hat{X}_\varepsilon$ and $\hat{X}$, defined in Proposition 6.1, are applied to the function Φ and Ψ, given by (6.22).

Therefore, from Proposition 6.1 we conclude

$$\begin{aligned}\limsup_{\varepsilon\to 0}\ &\left\{\frac{1}{2}\left[\|u'_{1\varepsilon}-\Phi'\|^2_{C^0([0,T];[L^2(\Omega_{1\varepsilon})])}+\|u'_{2\varepsilon}-\Psi'\|^2_{C^0([0,T];[L^2(\Omega_{2\varepsilon})])}\right]\right.\\ &\left.+\frac{\alpha}{2}\left(\|\nabla u_{1\varepsilon}-C^\varepsilon\nabla\Phi\|^2_{C^0([0,T];[L^2(\Omega_{1\varepsilon})]^n)}+\|\nabla u_{2\varepsilon}\|^2_{C^0([0,T];[L^2(\Omega_{2\varepsilon})]^n)}\right)\right\}\\ &\le\limsup_{\varepsilon\to 0}\left\|\hat{X}_\varepsilon\right\|_{C^0([0,T])}\le\left\|\hat{X}\right\|_{C^0([0,T])}\le C_2\delta^2,\end{aligned}$$

which, together with (6.23) and (6.24), gives (2.24), since δ is arbitrary. □

RELAXATION-TIME LIMIT IN THE ISOTHERMAL HYDRODYNAMIC MODEL FOR SEMICONDUCTORS*

JIANG XU†

Abstract. This work is concerned with the relaxation-time limit in the multidimensional isothermal hydrodynamic model for semiconductors in the critical Besov space. As the initial data are sufficiently close to equilibrium, the uniform (global) classical solutions are constructed by the high- and low-frequency decomposition methods. Furthermore, it is shown that the scaled classical solutions strongly converge towards that of a drift-diffusion model, as the relaxation time tends to zero.

Key words. relaxation-time limit, isothermal hydrodynamic model, semiconductors

AMS subject classifications. 35L45, 35B25, 35M20

DOI. 10.1137/080721893

1. Introduction and main results. In this work, we are interested in the isothermal hydrodynamic model for semiconductors, which is of the form

$$\begin{cases} n_t + \nabla \cdot (n\mathbf{u}) = 0, \\ (n\mathbf{u})_t + \nabla \cdot (n\mathbf{u} \otimes \mathbf{u}) + a^2 \nabla n = n \nabla \Phi - \frac{n\mathbf{u}}{\tau}, \\ \Delta \Phi = n - \bar{n}, \quad \Phi \to 0 \ \text{ as } \ |x| \to +\infty \end{cases} \tag{1.1}$$

for $(t, x) \in [0, +\infty) \times \mathbf{R}^N (N \geq 2)$. Here $n, \mathbf{u} = (u^1, u^2, \ldots, u^N)^\top (\top$ transpose), and Φ stand for the electron density, the electron velocity, and the electrostatic potential, respectively; $a > 0$ is the sound speed; and $0 < \tau \leq 1$ is the (small) momentum relaxation time for electrons. The symbols ∇, Δ, and $\otimes$ are the gradient operator, Laplacian operator, and the tensor products of two vectors, respectively. The positive constant $\bar{n}$ stands for the density of positively charged background ions.

The system (1.1) is supplemented with the initial data

$$(n, \mathbf{u})(x, 0) = (n_0, \mathbf{u}_0)(x), \quad x \in \mathbf{R}^N. \tag{1.2}$$

Concerning the small relaxation-time analysis, we define the scaled variables as in [12]:

$$(n^\tau, \mathbf{u}^\tau, \mathbf{e}^\tau)(x, s) = \Big(n, \frac{1}{\tau}\mathbf{u}, \mathbf{e}\Big)\Big(x, \frac{s}{\tau}\Big), \quad (\mathbf{e} = \nabla \Phi). \tag{1.3}$$

Then the new variables satisfy the equations

$$\begin{cases} n_s^\tau + \nabla \cdot (n^\tau \mathbf{u}^\tau) = 0, \\ \tau^2 \mathbf{u}_s^\tau + \tau^2 (\mathbf{u}^\tau \cdot \nabla)\mathbf{u}^\tau + \mathbf{u}^\tau = \mathbf{e}^\tau - a^2 \frac{\nabla n^\tau}{n^\tau}, \\ \nabla \cdot \mathbf{e}^\tau = n^\tau - \bar{n}, \end{cases} \tag{1.4}$$

with the initial data

$$(n^\tau, \tau \mathbf{u}^\tau)(x, 0) = (n_0, \mathbf{u}_0). \tag{1.5}$$

Let $\tau \to 0$; then, formally, we arrive at the classical drift-diffusion model

$$\begin{cases} \mathcal{N}_s + \nabla \cdot (\mathcal{N}\mathcal{E} - a^2 \nabla \mathcal{N}) = 0, \\ \nabla \cdot \mathcal{E} = \mathcal{N} - \bar{n}, \\ \mathcal{N}(x, 0) = n_0. \end{cases} \tag{1.6}$$

This relaxation-time limit for the system (1.1)–(1.2) was first studied by Marcati and Natalini [12]. They obtained the uniform weak solutions with respect to τ and proved that the scaled weak solutions converged towards that of the drift-diffusion model (1.6). Subsequently, some rigorous results related to the relaxation limit have appeared (we refer the reader to [1, 3, 7, 8, 9, 10]); however, these results are restricted to one space dimension. Physically, it is more important and more interesting to study this asymptotic limit in several space dimensions; unfortunately, due to the serious difficulties in establishing the global existence of weak or smooth solutions to (1.1)–(1.2), up to now, only partial relaxation limit results are available in several space dimensions. In [11], Lattanzio and Marcati considered the three-dimensional isentropic hydrodynamic model, assuming the existence of L^∞-solutions in an τ-independent time interval, and justified the relaxation limit. Inspired by the Maxwell iteration, Yong [15] dealt with the periodic initial-value problem for the multidimensional isentropic hydrodynamic model in the Sobolev space $H^\ell(\mathbf{T}^N)$; however, the regularity index is required to be high ($\ell > 1 + N/2$, an integer).

Recently, in [6], we first established the global existence and exponential stability of classical solutions to the (isentropic and isothermal) hydrodynamic model for semiconductors in the critical Besov space $B^{1+N/2}_{2,1}(\mathbf{R}^N)$, but it is not clear whether the results are independent of the relaxation time τ. In this paper, we construct the uniform classical solutions (close to equilibrium) to the *isothermal* hydrodynamic model (1.1)–(1.2) and justify the above formal limit rigorously. For the proof of the global result, different from that in [6], we add some "new" ideas. More concretely speaking, we take full advantage of the special structure (skew-symmetry) of (1.1)–(1.2), which can help us avoid differentiating the system with respect to variable t once, and develop some "new" frequency-localization estimates; for details, see Lemmas 4.3, 4.4, and 4.5. In this sense, the proof of the global result is shortened heavily. Here, we first state the main results as follows.

THEOREM 1.1. *Let $\bar{n} > 0$ be a constant reference density. Suppose that $n_0 - \bar{n}, \boldsymbol{u}_0$, and $\boldsymbol{e}_0 \in B^\sigma_{2,1}(\mathbf{R}^N)(\sigma = 1 + N/2)$. There exists a positive constant δ_0 independent of τ, such that if*

$$\|(n_0 - \bar{n}, \boldsymbol{u}_0, \boldsymbol{e}_0)\|_{B^\sigma_{2,1}(\mathbf{R}^N)} \le \delta_0,$$

then the system (1.1)–(1.2) *admits a unique global solution $(n, \boldsymbol{u}, \boldsymbol{e})$ satisfying*

$$(n - \bar{n}, \boldsymbol{u}, \boldsymbol{e}) \in \mathcal{C}([0, \infty), B^\sigma_{2,1}(\mathbf{R}^N)).$$

Moreover, the uniform energy estimate holds:

$$\begin{aligned} &\sup_{t \ge 0} \Big(\|(n - \bar{n}, \boldsymbol{u}, \boldsymbol{e})(\cdot, t)\|_{B^\sigma_{2,1}(\mathbf{R}^N)} \Big) \\ &+ \mu_0 \int_0^\infty \Big(\tau \|(n - \bar{n}, \boldsymbol{e})(\cdot, t)\|_{B^\sigma_{2,1}(\mathbf{R}^N)} + \|\boldsymbol{u}(\cdot, t)\|_{B^\sigma_{2,1}(\mathbf{R}^N)} \Big) dt \\ &\le C_0 \|(n_0 - \bar{n}, \boldsymbol{u}_0, \boldsymbol{e}_0)\|_{B^\sigma_{2,1}(\mathbf{R}^N)}, \end{aligned} \tag{1.7}$$

where μ_0, C_0 are the positive constants independent of τ, and $\boldsymbol{e}_0 := \nabla \Delta^{-1}(n_0 - \bar{n})$.

Remark 1.1. From the energy estimate (1.7) and the smallness of τ $(0 < \tau \le 1)$, we can obtain the uniform exponential decay of classical solution $(n, \mathbf{u}, \mathbf{e})$ near to equilibrium $(\bar{n}, 0, 0)$ in [6]:

$$\|(n-\bar{n}, \mathbf{u}, \mathbf{e})(\cdot, t)\|_{B^{\sigma}_{2,1}(\mathbf{R}^N)} \le C_0 \|(n_0-\bar{n}, \mathbf{u}_0, \mathbf{e}_0)\|_{B^{\sigma}_{2,1}(\mathbf{R}^N)} \exp(-\mu_0 \tau t),\ t \ge 0.$$

Remark 1.2. To our knowledge, Theorem 1.1 cannot directly be applied to the generally isentropic hydrodynamic model for semiconductors. As a matter of fact, for the isentropic model, we can establish a similar relaxation-limit result in stronger Besov space $B^{\sigma+\epsilon}_{2,2}(\mathbf{R}^N)(\epsilon > 0)$.

Then, by considering an "$\mathcal{O}(1/\tau)$ time scale" in (1.3), we justify the following convergence to the drift-diffusion model (1.6) by the standard weak convergence methods and the application of the compactness theorem in [14].

THEOREM 1.2. *Let* $(n, \boldsymbol{u}, \boldsymbol{e})$ *be the global solution of* (1.1)–(1.2) *given by Theorem* 1.1. *Then there exists some function* $(\mathcal{N}, \mathcal{E})$ *which is a global weak solution to* (1.6) *satisfying* $(\mathcal{N}-\bar{n}, \mathcal{E}) \in \mathcal{C}([0,\infty), B^{\sigma}_{2,1}(\mathbf{R}^N))$ *such that as* $\tau \to 0$, *it yields the following* $(1 \le p < +\infty,\ \sigma' < \sigma)$*:*

$$(n, \boldsymbol{e})\Big(x, \frac{s}{\tau}\Big) \to (\mathcal{N}, \mathcal{E})(x, s) \quad \textit{strongly in}\ \ L^p(0, T; (B^{\sigma'}_{2,1}(\mathbf{R}^N))_{\mathrm{loc}}) \quad \textit{for any}\ T > 0.$$

Remark 1.3. Let us mention that this strong convergence result is *weaker* than that obtained in [1, 4], which can be regarded as a supplement to the theory of diffusive limit for hyperbolic problems.

The rest of this paper is organized as follows. In section 2, we present some definitions and basic facts on the Littlewood–Paley decomposition theory and Besov space. In section 3, we rewrite the isothermal hydrodynamic model as a symmetric hyperbolic system and recall the local existence result of classical solutions. Then in section 4, we establish the uniform a priori estimate, which is used to derive the global existence of uniform classical solutions. Finally, in section 5, we perform the relaxation-time limit.

Throughout this paper, $f \approx g$ means that $f \le Cg$ and $g \le Cf$, where $C > 0$ is a uniform constant with respect to τ. All functional spaces are considered in $\mathbf{R}^N$, so we may omit the space dependence for simplicity.

2. Littlewood–Paley analysis. In this section, we review briefly the Littlewood–Paley decomposition theory and the characterization of Besov space; see also, e.g., [2] or [6].

Let $\mathcal{S}$ be the Schwarz class. (φ, χ) is a couple of smooth functions valued in [0,1] such that φ is supported in the shell $\mathbf{C}(0, \frac{3}{4}, \frac{8}{3}) = \{\xi \in \mathbf{R}^N | \frac{3}{4} \le |\xi| \le \frac{8}{3}\}$, χ is supported in the ball $\mathbf{B}(0, \frac{4}{3}) = \{\xi \in \mathbf{R}^N | |\xi| \le \frac{4}{3}\}$, and

$$\chi(\xi) + \sum_{q=0}^{\infty} \varphi(2^{-q}\xi) = 1, \quad q \in \mathbf{Z},\ \ \xi \in \mathbf{R}^N.$$

For $f \in \mathcal{S}'$(denote the set of temperate distributions which is the dual of $\mathcal{S}$), one can define the nonhomogeneous dyadic blocks as follows:

$$\Delta_{-1} f := \chi(D) f = \tilde{h} * f \quad \text{with}\ \ \tilde{h} = \mathcal{F}^{-1}\chi,$$

$$\Delta_q f := \varphi(2^{-q}D) f = 2^{qN} \int h(2^q y) f(x-y) dy \quad \text{with}\ \ h = \mathcal{F}^{-1}\varphi\ \ \text{if}\ \ q \ge 0,$$

where $*$, $\mathcal{F}^{-1}$ represent the convolution operator and the inverse Fourier transform, respectively. The nonhomogeneous Littlewood–Paley decomposition is

$$f = \sum_{q\geq -1} \Delta_q f \quad \text{in} \quad \mathcal{S}'.$$

Define the low-frequency cut-off by

$$S_q f := \sum_{p\leq q-1} \Delta_p f.$$

Of course, $S_0 f = \Delta_{-1} f$. The above Littlewood–Paley decomposition is almost orthogonal in L^2.

PROPOSITION 2.1. *For any $f, g \in \mathcal{S}'$, the following properties hold:*

$$\Delta_p \Delta_q f \equiv 0 \quad \textit{if} \quad |p-q| \geq 2,$$

$$\Delta_q (S_{p-1} f \Delta_p g) \equiv 0 \quad \textit{if} \quad |p-q| \geq 5.$$

Besov space can be characterized in virtue of the Littlewood–Paley decomposition.

DEFINITION 2.2. *Let $1 \leq p \leq \infty$ and $s \in \mathbf{R}$. For $1 \leq r < \infty$, the Besov spaces $B^s_{p,r}$ are defined by*

$$f \in B^s_{p,r} \Leftrightarrow \left(\sum_{q\geq -1} (2^{qs} \|\Delta_q f\|_{L^p})^r \right)^{\frac{1}{r}} < \infty$$

and $B^s_{p,\infty}$ are defined by

$$f \in B^s_{p,\infty} \Leftrightarrow \sup_{q\geq -1} 2^{qs} \|\Delta_q f\|_{L^p} < \infty.$$

LEMMA 2.3 (Bernstein's inequality). *Let $k \in \mathbf{N}$ and $0 < R_1 < R_2$. There exists a constant C depending only on R_1, R_2, and N such that for all $1 \leq a \leq b \leq \infty$ and $f \in L^a$, we have*

$$\text{Supp } \mathcal{F} f \subset \boldsymbol{B}(0, R_1\lambda) \Rightarrow \sup_{|\alpha|=k} \|\partial^\alpha f\|_{L^b} \leq C^{k+1} \lambda^{k+N(\frac{1}{a}-\frac{1}{b})} \|f\|_{L^a},$$

$$\text{Supp } \mathcal{F} f \subset \boldsymbol{C}(0, R_1\lambda, R_2\lambda) \Rightarrow C^{-k-1}\lambda^k \|f\|_{L^a} \leq \sup_{|\alpha|=k} \|\partial^\alpha f\|_{L^a} \leq C^{k+1}\lambda^k \|f\|_{L^a}.$$

Here, $\mathcal{F} f$ (or $\widehat{f} = \int_{\mathbf{R}^N} f(x) \exp(-ix\cdot\xi) dx$) represents the Fourier transform on f.

There is a compactness result in Besov space, which we show in the following proposition.

PROPOSITION 2.4. *Let $1 \leq p, r \leq \infty$, $s \in \mathbf{R}$, and $\varepsilon > 0$. For all $\phi \in C^\infty_c$, the map $f \mapsto \phi f$ is compact from $B^{s+\varepsilon}_{p,r}$ to $B^s_{p,r}$.*

Finally, we state a result of continuity for the composition to end this section.

PROPOSITION 2.5. *Let $1 \leq p, r \leq \infty$, and I be an open interval of $\mathbf{R}$. Let $s > 0$ and let n be the smallest integer such that $n \geq s$. Let $F : I \to \mathbf{R}$ satisfy $F(0) = 0$ and $F' \in W^{n,\infty}(I; \mathbf{R})$. Assume that $v \in B^s_{p,r}$ takes values in $J \subset\subset I$. Then $F(v) \in B^s_{p,r}$ and there exists a constant C depending only on s, I, J, and N such that*

$$\|F(v)\|_{B^s_{p,r}} \leq C(1 + \|v\|_{L^\infty})^n \|F'\|_{W^{n,\infty}(I)} \|v\|_{B^s_{p,r}}.$$

3. Reformulation and local existence. Let us introduce the enthalpy $\mathcal{H}(\varrho) = a^2 \ln \varrho$ $(\varrho > 0)$, and set

$$m(t,x) = (\mathcal{H}(n(t,x)) - \mathcal{H}(\bar{n}))/a. \tag{3.1}$$

Then (1.1) can be transformed into the symmetric hyperbolic form

$$\partial_t U + \sum_{j=1}^{N} A_j(\mathbf{u}) \partial_{x_j} U = \begin{pmatrix} 0 \\ -\frac{1}{\tau}\mathbf{u} + \mathbf{e} \end{pmatrix}, \tag{3.2}$$

coupled with the dynamic electron field equation

$$\mathrm{div}\mathbf{e} = h(m), \tag{3.3}$$

where

$$U = \begin{pmatrix} m \\ \mathbf{u} \end{pmatrix}, \qquad A_j(\mathbf{u}) = \begin{pmatrix} u^j & ae_j^\top \\ ae_j & u^j I_N \end{pmatrix}$$

(I_N denotes the unit matrix of order N),

and $h(m) = \bar{n}\{\exp(m/a) - 1\}$ is a smooth function on the domain $\{m | -\infty < m < +\infty\}$ satisfying $h(0) = 0$. The initial data (1.2) become

$$(m, \mathbf{u}, \mathbf{e})|_{t=0} = (a(\ln n_0 - \ln \bar{n}), \mathbf{u}_0, \mathbf{e}_0). \tag{3.4}$$

Remark 3.1. The variable change is from the open set $\{(n, \mathbf{u}, \mathbf{e}) \in (0, +\infty) \times \mathbf{R}^N \times \mathbf{R}^N\}$ to the whole space $\{(m, \mathbf{u}, \mathbf{e}) \in \mathbf{R} \times \mathbf{R}^N \times \mathbf{R}^N\}$. It is easy to show that for classical solutions $(n, \mathbf{u}, \mathbf{e})$ away from the vacuum, (1.1)–(1.2) is equivalent to (3.2)–(3.4).

Now, we recall a local existence and uniqueness result of the classical solutions to (3.2)–(3.4) which has been established in [6].

PROPOSITION 3.1. *For any fixed relaxation time $\tau > 0$, assume that $(m_0, \boldsymbol{u}_0, \boldsymbol{e}_0) \in B^\sigma_{2,1}$; then, there exist a time $T_0 > 0$ (depending only on the initial data) and a unique solution $(m, \boldsymbol{u}, \boldsymbol{e})$ to (3.2)–(3.4) such that $(m, \boldsymbol{u}, \boldsymbol{e}) \in \mathcal{C}^1([0, T_0] \times \mathbf{R}^N)$ and $(m, \boldsymbol{u}, \boldsymbol{e}) \in \mathcal{C}([0, T_0], B^\sigma_{2,1}) \cap \mathcal{C}^1([0, T_0], B^{\sigma-1}_{2,1})$.*

4. A uniform estimate and global existence. In this section, we shall establish a uniform a priori estimate, which is used to derive the global existence of classical solutions to (3.2)–(3.4).

PROPOSITION 4.1. *There exist three positive constants δ_1, C_1, and μ_1 independent of τ such that for any $T > 0$, if*

$$\sup_{0 \le t \le T} \|(m, \boldsymbol{u}, \boldsymbol{e})(\cdot, t)\|_{B^\sigma_{2,1}} \le \delta_1, \tag{4.1}$$

then

$$\begin{aligned} &\|(m, \boldsymbol{u}, \boldsymbol{e})(\cdot, t)\|_{B^\sigma_{2,1}} + \mu_1 \int_0^t \Big(\tau \|(m, \boldsymbol{e})(\cdot, \varsigma)\|_{B^\sigma_{2,1}} + \|\boldsymbol{u}(\cdot, \varsigma)\|_{B^\sigma_{2,1}}\Big) d\varsigma \\ &\le C_1 \|(m, \boldsymbol{u}, \boldsymbol{e})(\cdot, 0)\|_{B^\sigma_{2,1}}, \qquad t \in [0, T]. \end{aligned} \tag{4.2}$$

The main ingredients in the proof of Proposition 4.1 are the high-frequency ($q \ge 0$) estimates and low-frequency ($q = -1$) estimates on $(m, \mathbf{u}, \mathbf{e})$. To do this, we need to establish some lemmas.

LEMMA 4.2. *If* $(m, \boldsymbol{u}, \boldsymbol{e}) \in \mathcal{C}([0,T], B^{\sigma}_{2,1}) \cap \mathcal{C}^1([0,T], B^{\sigma-1}_{2,1})$ *is a solution of* (3.2)–(3.4) *for any given* $T > 0$*, then the following estimate holds* ($q \geq -1$)*:*

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\Big(\|\Delta_q m\|_{L^2}^2 + \|\Delta_q \boldsymbol{u}\|_{L^2}^2 + \frac{1}{\bar{n}}\|\Delta_q \boldsymbol{e}\|_{L^2}^2\Big) + \frac{1}{\tau}\|\Delta_q \boldsymbol{u}\|_{L^2}^2 \\
&\leq \frac{1}{2}\|\nabla \boldsymbol{u}\|_{L^\infty}(\|\Delta_q m\|_{L^2}^2 + \|\Delta_q \boldsymbol{u}\|_{L^2}^2) + \|[\boldsymbol{u}, \Delta_q]\cdot\nabla m\|_{L^2}\|\Delta_q m\|_{L^2} \\
&\quad + \|[\boldsymbol{u}, \Delta_q]\cdot\nabla \boldsymbol{u}\|_{L^2}\|\Delta_q \boldsymbol{u}\|_{L^2} + \frac{1}{\bar{n}}\|\Delta_q(h(m)\boldsymbol{u})\|_{L^2}\|\Delta_q \boldsymbol{e}\|_{L^2}, \qquad (4.3)
\end{aligned}$$

where the commutator $[f, g] = fg - gf$*.*

Remark 4.1. By applying the operator Δ_q to (3.2), then multiplying the resulting equations by the conjugator of $\Delta_q m(\overline{\Delta_q m})$ and $\overline{\Delta_q \mathbf{u}}$, respectively, we can directly achieve (4.3) without extra trouble; see [6].

Below, we formulate an important skew-symmetry lemma which was developed in [4, 13, 16].

LEMMA 4.3 (Shizuta–Kawashima). *For all* $\xi \in \mathbf{R}^N$, $\xi \neq 0$*, the system* (3.2) *admits a real skew-symmetric smooth matrix* $K(\xi)$ *which is defined in the unit sphere* $\boldsymbol{S}^{N-1}$*:*

$$K(\xi) = \begin{pmatrix} 0 & \frac{\xi^\top}{|\xi|} \\ -\frac{\xi}{|\xi|} & 0 \end{pmatrix}, \qquad (4.4)$$

and then

$$K(\xi)\sum_{j=1}^{N}\xi_j A_j(0) = \begin{pmatrix} a|\xi| & 0 \\ 0 & -a\frac{\xi\otimes\xi}{|\xi|} \end{pmatrix}. \qquad (4.5)$$

Thanks to the skew-symmetry of the system (3.2), we can develop some "new" frequency-localization estimates and avoid performing the t-derivative to (3.2), which is different from the estimates in [6].

LEMMA 4.4. *If* $(m, \boldsymbol{u}, \boldsymbol{e}) \in \mathcal{C}([0,T], B^{\sigma}_{2,1}) \cap \mathcal{C}^1([0,T], B^{\sigma-1}_{2,1})$ *is a solution of* (3.2)–(3.4) *for any given* $T > 0$*, then the following estimates hold:*

$$\begin{aligned}
&\frac{\tau}{2}\frac{d}{dt}\mathrm{Im}\int|\xi|\Big((\widehat{\Delta_q U})^* K(\xi)\widehat{\Delta_q U}\Big)d\xi + \tau\frac{a}{2}2^{2q}\|\Delta_q m\|_{L^2}^2 \\
&\leq \frac{C}{\tau}2^{2q}\|\Delta_q \boldsymbol{u}\|_{L^2}^2 + C\tau 2^q\|\Delta_q U\|_{L^2}\|\Delta_q \mathcal{G}\|_{L^2} \\
&\quad + C\tau\|\Delta_q(\tilde{h}(m)m)\|_{L^2}\|\Delta_q m\|_{L^2}\ (q \geq 0); \qquad (4.6)
\end{aligned}$$

$$\begin{aligned}
&\frac{\tau}{2}\frac{d}{dt}\mathrm{Im}\int|\xi|\Big((\widehat{\Delta_{-1} U})^* K(\xi)\widehat{\Delta_{-1} U}\Big)d\xi + \tau\frac{\bar{n}}{a}\|\Delta_{-1} m\|_{L^2}^2 \\
&\leq \frac{C}{\tau}\|\Delta_{-1}\boldsymbol{u}\|_{L^2}^2 + C\tau\|\Delta_{-1} U\|_{L^2}\|\Delta_{-1}\mathcal{G}\|_{L^2} \\
&\quad + C\tau\|\Delta_{-1}(\tilde{h}(m)m)\|_{L^2}\|\Delta_{-1} m\|_{L^2}, \qquad (4.7)
\end{aligned}$$

where the function $\mathcal{G}$ *is given in* (4.9)*,* $\tilde{h}(m) = \int_0^1 h'(\varsigma m)d\varsigma - \frac{\bar{n}}{a}$ *is a smooth function on* $\{m| -\infty < \varsigma m < \infty,\ \varsigma \in [0,1]\}$ *satisfying* $\tilde{h}(0) = 0$*, and* $C > 0$ *is a uniform constant independent of* τ*.*

Proof. The system (3.2) can be written as the linearized form

$$\partial_t U + \sum_{j=1}^{N} A_j(0)\partial_{x_j} U = \mathcal{G} + \begin{pmatrix} 0 \\ -\frac{1}{\tau}\mathbf{u} + \mathbf{e} \end{pmatrix}, \tag{4.8}$$

where

$$\mathcal{G} = \sum_{j=1}^{N} \Big\{ A_j(0) - A_j(\mathbf{u}) \Big\} \partial_{x_j} U. \tag{4.9}$$

Applying the operator Δ_q to the system (4.8) gives

$$\partial_t \Delta_q U + \sum_{j=1}^{N} A_j(0)\partial_{x_j} \Delta_q U = \Delta_q \mathcal{G} + \begin{pmatrix} 0 \\ -\frac{1}{\tau}\Delta_q \mathbf{u} + \Delta_q \mathbf{e} \end{pmatrix}. \tag{4.10}$$

By performing the Fourier transform with respect to the space variable x for (4.10) and multiplying the resulting equation by $-i\tau(\widehat{\Delta_q U})^* K(\xi)$(* represents transpose and conjugator), then taking the real part of each term in the equality, we can obtain

$$\begin{aligned} &\tau \mathrm{Im}\Big((\widehat{\Delta_q U})^* K(\xi) \frac{d}{dt} \widehat{\Delta_q U} \Big) + \tau (\widehat{\Delta_q U})^* K(\xi) \Big(\sum_{j=1}^{N} \xi_j A_j(0) \Big) \widehat{\Delta_q U} \\ &= \tau \mathrm{Im}\Big((\widehat{\Delta_q U})^* K(\xi) (\widehat{\Delta_q \mathcal{G}}) \Big) - \mathrm{Im}\Big((\overline{\widehat{\Delta_q m}}) \frac{\xi^\top}{|\xi|} \widehat{\Delta_q \mathbf{u}} \Big) + \tau \mathrm{Im}\Big((\overline{\widehat{\Delta_q m}}) \frac{\xi^\top}{|\xi|} \widehat{\Delta_q \mathbf{e}} \Big). \end{aligned} \tag{4.11}$$

Using the skew-symmetry of $K(\xi)$, we have

$$\mathrm{Im}\Big((\widehat{\Delta_q U})^* K(\xi) \frac{d}{dt} \widehat{\Delta_q U} \Big) = \frac{1}{2} \frac{d}{dt} \mathrm{Im}\Big((\widehat{\Delta_q U})^* K(\xi) \widehat{\Delta_q U} \Big). \tag{4.12}$$

Substituting (4.5) into the second term on the left-hand side of (4.11), it is not difficult to get

$$\begin{aligned} &\tau \mathrm{Im}\Big((\widehat{\Delta_q U})^* K(\xi) \frac{d}{dt} \widehat{\Delta_q U} \Big) + \tau (\widehat{\Delta_q U})^* K(\xi) \Big(\sum_{j=1}^{N} \xi_j A_j(0) \Big) \widehat{\Delta_q U} \\ &\geq \frac{\tau}{2} \frac{d}{dt} \mathrm{Im}\Big((\widehat{\Delta_q U})^* K(\xi) \widehat{\Delta_q U} \Big) + a\tau |\xi| |\widehat{\Delta_q U}|^2 - 2a\tau |\xi| |\widehat{\Delta_q \mathbf{u}}|^2. \end{aligned} \tag{4.13}$$

With the help of Young's inequality, the right-hand side of (4.11) can be estimated as

$$\begin{aligned} &\tau \mathrm{Im}\Big((\widehat{\Delta_q U})^* K(\xi) (\widehat{\Delta_q \mathcal{G}}) \Big) - \mathrm{Im}\Big((\overline{\widehat{\Delta_q m}}) \frac{\xi^\top}{|\xi|} \widehat{\Delta_q \mathbf{u}} \Big) + \tau \mathrm{Im}\Big((\overline{\widehat{\Delta_q m}}) \frac{\xi^\top}{|\xi|} \widehat{\Delta_q \mathbf{e}} \Big) \\ &\leq \tau \frac{a}{2} |\xi| |\widehat{\Delta_q U}|^2 + \frac{C}{\tau |\xi|} |\widehat{\Delta_q \mathbf{u}}|^2 + \tau |\widehat{\Delta_q U}| |\widehat{\Delta_q \mathcal{G}}| + \tau \mathrm{Im}\Big((\overline{\widehat{\Delta_q m}}) \frac{\xi^\top}{|\xi|} \widehat{\Delta_q \mathbf{e}} \Big), \end{aligned} \tag{4.14}$$

where we have used the uniform boundedness of the matrix $K(\xi)(\xi \neq 0)$; the positive constant C is independent of τ. Combining this with the equality (4.11) and the inequality (4.13)–(4.14), we deduce that

$$\begin{aligned} &\frac{\tau}{2} \frac{d}{dt} \mathrm{Im}\Big((\widehat{\Delta_q U})^* K(\xi) \widehat{\Delta_q U} \Big) + \tau \frac{a}{2} |\xi| |\widehat{\Delta_q U}|^2 \\ &\leq \frac{C}{\tau} \Big(|\xi| + \frac{1}{|\xi|} \Big) |\widehat{\Delta_q \mathbf{u}}|^2 + \tau |\widehat{\Delta_q U}| |\widehat{\Delta_q \mathcal{G}}| + \tau \mathrm{Im}\Big((\overline{\widehat{\Delta_q m}}) \frac{\xi^\top}{|\xi|} \widehat{\Delta_q \mathbf{e}} \Big). \end{aligned} \tag{4.15}$$

Multiplying (4.15) by $|\xi|$ and integrating it over $\mathbf{R}^N$, from Plancherel's theorem, we obtain

$$\begin{aligned}&\frac{\tau}{2}\frac{d}{dt}\mathrm{Im}\int|\xi|\Big((\widehat{\Delta_q U})^*K(\xi)\widehat{\Delta_q U}\Big)d\xi+\tau\frac{a}{2}\|\Delta_q\nabla U\|_{L^2}^2\\ &\le\frac{C}{\tau}2^{2q}\|\Delta_q\mathbf{u}\|_{L^2}^2+C\tau 2^q\|\Delta_q U\|_{L^2}\|\Delta_q\mathcal{G}\|_{L^2}+\tau\mathrm{Im}\int\Big((\overline{\widehat{\Delta_q m}})\xi^\top\widehat{\Delta_q\mathbf{e}}\Big)d\xi.\end{aligned}\tag{4.16}$$

For the third term on the right-hand side of (4.16), we have

$$\tau\mathrm{Im}\int\Big((\overline{\widehat{\Delta_q m}})\xi^\top\widehat{\Delta_q\mathbf{e}}\Big)d\xi=\tau\Big(J+\bar J\Big),\tag{4.17}$$

where

$$\begin{aligned}J+\bar J&=-\frac{i}{2}\int\Big((\overline{\widehat{\Delta_q m}})\xi^\top\widehat{\Delta_q\mathbf{e}}\Big)d\xi+\frac{i}{2}\int\Big((\widehat{\Delta_q m})\xi^\top\overline{\widehat{\Delta_q\mathbf{e}}}\Big)d\xi\\ &=\frac{1}{2}\int(\overline{\widehat{\Delta_q\nabla m}})\cdot\widehat{\Delta_q\mathbf{e}}d\xi+\frac{1}{2}\int(\widehat{\Delta_q\nabla m})\cdot\overline{\widehat{\Delta_q\mathbf{e}}}d\xi\\ &=\frac{1}{2}(2\pi)^N\Big(\int\overline{\Delta_q\nabla m}\cdot\Delta_q\mathbf{e}dx+\int\Delta_q\nabla m\cdot\overline{\Delta_q\mathbf{e}}dx\Big)\\ &=-\frac{1}{2}(2\pi)^N\Big(\int\overline{\Delta_q m}\Delta_q\mathrm{div}\mathbf{e}dx+\int\Delta_q m\overline{\Delta_q\mathrm{div}\mathbf{e}}dx\Big)\\ &=-\frac{1}{2}(2\pi)^N\Big(\int\overline{\Delta_q m}\Delta_q(h(m)-h(0))dx+\int\Delta_q m\overline{\Delta_q(h(m)-h(0))}dx\Big)\\ &=-\frac{(2\pi)^N\bar n}{a}\|\Delta_q m\|_{L^2}^2-\frac{(2\pi)^N}{2}\Big(\int\overline{\Delta_q m}\Delta_q(\tilde h(m)m)dx\\ &\qquad+\int\Delta_q m\overline{\Delta_q(\tilde h(m)m)}dx\Big).\end{aligned}\tag{4.18}$$

Here, $\tilde h(m)=\int_0^1 h'(\varsigma m)d\varsigma-\bar n/a$ is a smooth function on $\{m|-\infty<\varsigma m<\infty,\ \varsigma\in[0,1]\}$ satisfying $\tilde h(0)=0$. Therefore, from (4.16)–(4.18), we arrive at

$$\begin{aligned}&\frac{\tau}{2}\frac{d}{dt}\mathrm{Im}\int|\xi|\Big((\widehat{\Delta_q U})^*K(\xi)\widehat{\Delta_q U}\Big)d\xi+\tau\frac{a}{2}\|\Delta_q\nabla U\|_{L^2}^2+\tau\frac{(2\pi)^N\bar n}{a}\|\Delta_q m\|_{L^2}^2\\ &\le\frac{C}{\tau}2^{2q}\|\Delta_q\mathbf{u}\|_{L^2}^2+C\tau 2^q\|\Delta_q U\|_{L^2}\|\Delta_q\mathcal{G}\|_{L^2}+C\tau\|\Delta_q(\tilde h(m)m)\|_{L^2}\|\Delta_q m\|_{L^2}.\end{aligned}\tag{4.19}$$

In view of Lemma 2.3,

$$\|\Delta_q\nabla m\|_{L^2}\approx 2^q\|\Delta_q m\|_{L^2}\ (q\ge 0)$$

follows, so we get the estimates (4.6) and (4.7) immediately. □

From the proof of Lemma 4.4, we see that the Poisson equation remedies the low-frequency estimate on $\|\Delta_{-1}m\|_{L^2}^2$, which plays a key role in the uniform exponential decay of classical solutions (see Remark 1.1). This is essentially different from the Euler equations studied in [5]. On the electron field $\mathbf{e}$, we also have some "new" a priori estimates.

LEMMA 4.5. *If $(m,\boldsymbol{u},\boldsymbol{e})\in\mathcal{C}([0,T],B^\sigma_{2,1})\cap\mathcal{C}^1([0,T],B^{\sigma-1}_{2,1})$ is a solution of (3.2)–(3.4) for any given $T>0$, then*

$$2^q\|\Delta_q\boldsymbol{e}\|_{L^2}^2\le C\Big(\frac{\bar n}{a}\|\Delta_q m\|_{L^2}+\|\Delta_q(\tilde h(m)m)\|_{L^2}\Big)\|\Delta_q\boldsymbol{e}\|_{L^2}\ (q\ge 0);\tag{4.20}$$

$$
\begin{aligned}
&-\frac{d}{dt}\int \Delta_{-1}\boldsymbol{e}\cdot\overline{\Delta_{-1}\boldsymbol{u}}dx+\|\Delta_{-1}\boldsymbol{e}\|_{L^2}^2\\
&\le C(\bar n\|\Delta_{-1}\boldsymbol{u}\|_{L^2}+\|\Delta_{-1}(h(m)\boldsymbol{u})\|_{L^2})\|\Delta_{-1}\boldsymbol{u}\|_{L^2}+C\Big(a\|\Delta_{-1}\nabla m\|_{L^2}\\
&+\frac{1}{\tau}\|\Delta_{-1}\boldsymbol{u}\|_{L^2}+\|\boldsymbol{u}\|_{L^\infty}\|\Delta_{-1}\nabla\boldsymbol{u}\|_{L^2}+\|[\boldsymbol{u},\Delta_{-1}]\cdot\nabla\boldsymbol{u}\|_{L^2}\Big)\|\Delta_{-1}\boldsymbol{e}\|_{L^2},
\end{aligned}
\tag{4.21}
$$

where $C>0$ is a uniform constant independent of τ.

Proof. (I) By applying the operator Δ_q to both sides of div$\mathbf{e}=h(m)$ $(q\ge 0)$, integrating it over $\mathbf{R}^N$ after multiplying $\Delta_q$div$\mathbf{e}$, and noticing the irrotationality of $\mathbf{e}$, we can obtain (4.20) in virtue of Hölder's inequality.
(II) From (1.1) and (3.1), we get

$$
\mathbf{e}_t=-\nabla\Delta^{-1}\nabla\cdot\{h(m)\mathbf{u}+\bar n\mathbf{u}\},
\tag{4.22}
$$

where the nonlocal term $\nabla\Delta^{-1}\nabla\cdot f$ is the product of Riesz transforms on f. From (3.2) and (4.22), we have

$$
\begin{aligned}
&-\frac{d}{dt}\int\Delta_q\mathbf{e}\cdot\overline{\Delta_q\mathbf{u}}dx\\
&=-\int\Delta_q\mathbf{e}_t\overline{\Delta_q\mathbf{u}}dx-\int\Delta_q\mathbf{e}\overline{\Delta_q\mathbf{u}_t}dx\\
&=\int\nabla\Delta^{-1}\nabla\cdot\Delta_q\{h(m)\mathbf{u}+\bar n\mathbf{u}\}\overline{\Delta_q\mathbf{u}}dx\\
&-\int\Delta_q\mathbf{e}\cdot\Big(-a\overline{\Delta_q\nabla m}-\frac{1}{\tau}\overline{\Delta_q\mathbf{u}}-\mathbf{u}\overline{\Delta_q\nabla\mathbf{u}}+\overline{[\mathbf{u},\Delta_q]\cdot\nabla\mathbf{u}}+\overline{\Delta_q\mathbf{e}}\Big)dx.
\end{aligned}
\tag{4.23}
$$

Using the L^2-boundedness of the Riesz transform and Hölder's inequality, we derive (4.21) immediately. □

For those estimates of the commutators in (4.3) and (4.21), we have the following fact.

LEMMA 4.6 (see [6]). *Let $s>0$ and $1<p<\infty$; then the following inequalities are true:*

$$
\begin{aligned}
&2^{qs}\|[f,\Delta_q]\mathcal{A}g\|_{L^p}\\
&\le\begin{cases}
Cc_q\|f\|_{B^s_{p,1}}\|g\|_{B^s_{p,1}}, & f,g\in B^s_{p,1},\ s=1+N/p,\\
Cc_q\|f\|_{B^s_{p,1}}\|g\|_{B^{s+1}_{p,1}}, & f\in B^s_{p,1},\ \ g\in B^{s+1}_{p,1},\ s=N/p,\\
Cc_q\|f\|_{B^{s+1}_{p,1}}\|g\|_{B^s_{p,1}}, & f\in B^{s+1}_{p,1},\ \ g\in B^s_{p,1},\ s=N/p.
\end{cases}
\end{aligned}
\tag{4.24}
$$

In particular, if $f=g$, then

$$
2^{qs}\|[f,\Delta_q]\mathcal{A}g\|_{L^p}\le Cc_q\|\nabla f\|_{L^\infty}\|g\|_{B^s_{p,1}},\ s>0,
\tag{4.25}
$$

where the operator $\mathcal{A}=\operatorname{div}$ or ∇, C is a harmless constant, and c_q denotes a sequence such that $\|(c_q)\|_{l^1}\le 1$.

In addition, in the proof of Proposition 4.1, an elementary algebra inequality will be used. For clarity, we put it into a lemma.

LEMMA 4.7. *Assume that $f,g,h>0$ and $0<\tau\le 1$; then the following inequality is true:*

$$
f+\tau g+\tau h\le C\frac{\frac{1}{\tau}f^2+\tau g^2+\tau h^2}{(f^2+g^2+h^2)^{1/2}},
\tag{4.26}
$$

where $C>0$ is a uniform constant independent of τ.

Proof. Note that

$$(f^2+g^2+h^2)^{1/2}\approx f+g+h. \tag{4.27}$$

We need only show

$$\Big(f+\tau g+\tau h\Big)(f+g+h)\le C\bigg(\frac{1}{\tau}f^2+\tau g^2+\tau h^2\bigg), \tag{4.28}$$

which is obvious in virtue of the smallness of $\tau(0<\tau\le 1)$ and Young's inequality. □

Proof of Proposition 4.1. From the a priori estimate assumption (4.1), we have

$$\sup_{0\le t\le T}(\|(m,\mathbf{u},\mathbf{e})(\cdot,t)||_{W^{1,\infty}})\le C\delta_1. \tag{4.29}$$

In what follows, we are going to divide the proof into some lemmas.

LEMMA 4.8 ($q\ge 0$). *There exist some positive constants K_1,K_2,μ_2 independent of τ such that the following estimate holds:*

$$\begin{aligned}
&2^{q(\sigma-1)}\frac{d}{dt}\bigg\{\frac{K_1}{2}2^{2q}\bigg(\|\Delta_q m\|_{L^2}^2+\|\Delta_q\boldsymbol{u}\|_{L^2}^2+\frac{1}{\bar n}\|\Delta_q\boldsymbol{e}\|_{L^2}^2\bigg)\\
&+\frac{K_2\tau}{2}\mathrm{Im}\int|\xi|\Big((\widehat{\Delta_q U})^*K(\xi)\widehat{\Delta_q U}\Big)d\xi\bigg\}^{1/2}\\
&+\mu_2 2^{q\sigma}\Big(\tau\|\Delta_q m\|_{L^2}+\|\Delta_q\boldsymbol{u}\|_{L^2}+\tau\|\Delta_q\boldsymbol{e}\|_{L^2}\Big)\\
&\le C\{2^{q\sigma}\|\nabla\boldsymbol{u}\|_{L^\infty}(\|\Delta_q m\|_{L^2}+\|\Delta_q\boldsymbol{u}\|_{L^2})+c_q\|\boldsymbol{u}\|_{B^\sigma_{2,1}}(\|m\|_{B^\sigma_{2,1}}+\|\boldsymbol{u}\|_{B^\sigma_{2,1}})\\
&+\tau 2^{q(\sigma-1)}\|\Delta_q\mathcal{G}\|_{L^2}+2^{q\sigma}(\|\Delta_q(h(m)\boldsymbol{u})\|_{L^2}+\tau\|\Delta_q(\tilde h(m)m)\|_{L^2})\},
\end{aligned} \tag{4.30}$$

where K_1,K_2 are given in (4.32)*, and $C>0$ is a uniform constant independent of τ.*

Proof. Combining (4.3), (4.6), and (4.20), we have

$$\begin{aligned}
&\frac{d}{dt}\bigg\{\frac{K_1}{2}2^{2q}\bigg(\|\Delta_q m\|_{L^2}^2+\|\Delta_q\mathbf{u}\|_{L^2}^2+\frac{1}{\bar n}\|\Delta_q\mathbf{e}\|_{L^2}^2\bigg)\\
&+\frac{K_2\tau}{2}\mathrm{Im}\int|\xi|\Big((\widehat{\Delta_q U})^*K(\xi)\widehat{\Delta_q U}\Big)d\xi\bigg\}\\
&+\frac{K_1}{\tau}2^{2q}\|\Delta_q\mathbf{u}\|_{L^2}^2+\tau\frac{a}{2}K_2 2^{2q}\|\Delta_q m\|_{L^2}^2+K_3\tau 2^{2q}\|\Delta_q\mathbf{e}\|_{L^2}^2\\
&\le K_1 2^{2q}\bigg\{\frac{1}{2}\|\nabla\mathbf{u}\|_{L^\infty}(\|\Delta_q m\|_{L^2}^2+\|\Delta_q\mathbf{u}\|_{L^2}^2)\\
&+\|[\mathbf{u},\Delta_q]\cdot\nabla m\|_{L^2}\|\Delta_q m\|_{L^2}+\|[\mathbf{u},\Delta_q]\cdot\nabla\mathbf{u}\|_{L^2}\|\Delta_q\mathbf{u}\|_{L^2}\\
&+\frac{1}{\bar n}\|\Delta_q(h(m)\mathbf{u})\|_{L^2}\|\Delta_q\mathbf{e}\|_{L^2}\bigg\}+K_2\bigg\{\frac{C}{\tau}2^{2q}\|\Delta_q\mathbf{u}\|_{L^2}^2\\
&+C\tau 2^q\|\Delta_q U\|_{L^2}\|\Delta_q\mathcal{G}\|_{L^2}+C\tau\|\Delta_q(\tilde h(m)m)\|_{L^2}\|\Delta_q m\|_{L^2}\bigg\}\\
&+K_3 2^q\tau C\bigg\{\bigg(\frac{\bar n}{a}\|\Delta_q m\|_{L^2}+\|\Delta_q(\tilde h(m)m)\|_{L^2}\bigg)\|\Delta_q\mathbf{e}\|_{L^2}\bigg\},
\end{aligned} \tag{4.31}$$

where these positive constants K_1,K_2, and K_3 (independent of τ) satisfy

$$K_2=\frac{K_1}{4C},\quad K_3=\frac{a^3}{2C^2\bar n^2}K_2. \tag{4.32}$$

We introduce them in order to ensure that

$$\begin{aligned}&\frac{K_1}{2}2^{2q}\Big(\|\Delta_q m\|_{L^2}^2+\|\Delta_q \mathbf{u}\|_{L^2}^2+\frac{1}{\bar{n}}\|\Delta_q \mathbf{e}\|_{L^2}^2\Big)\\&+\frac{K_2\tau}{2}\mathrm{Im}\int|\xi|\Big((\widehat{\Delta_q U})^* K(\xi)\widehat{\Delta_q U}\Big)d\xi\\&\approx 2^{2q}\Big(\|\Delta_q m\|_{L^2}^2+\|\Delta_q \mathbf{u}\|_{L^2}^2+\|\Delta_q \mathbf{e}\|_{L^2}^2\Big),\end{aligned}\tag{4.33}$$

since

$$\left|\frac{K_2\tau}{2}\mathrm{Im}\int|\xi|\Big((\widehat{\Delta_q U})^* K(\xi)\widehat{\Delta_q U}\Big)d\xi\right|\le\frac{CK_2}{2}2^{2q}(\|\Delta_q m\|_{L^2}^2+\|\Delta_q \mathbf{u}\|_{L^2}^2),\tag{4.34}$$

and we eliminate the quadratic term $\frac{C}{\tau}2^{2q}\|\Delta_q \mathbf{u}\|_{L^2}^2$, $K_3 2^q\tau C\frac{\bar{n}}{a}\|\Delta_q m\|_{L^2}\|\Delta_q \mathbf{e}\|_{L^2}$ in the right-hand side of (4.31) with the aid of Young's inequality; for similar details, see [6]. Then, dividing the resulting inequality by

$$\left\{\frac{K_1}{2}2^{2q}\Big(\|\Delta_q m\|_{L^2}^2+\|\Delta_q \mathbf{u}\|_{L^2}^2+\frac{1}{\bar{n}}\|\Delta_q \mathbf{e}\|_{L^2}^2\Big)+\frac{K_2}{2}\mathrm{Im}\int|\xi|\Big((\widehat{\Delta_q U})^* K(\xi)\widehat{\Delta_q U}\Big)d\xi\right\}^{1/2}$$

and after eliminating the quadratic terms and multiplying the factor $2^{q(\sigma-1)}$ on both sides of the inequality, we arrive at (4.30) immediately with the help of Lemmas 4.6 and 4.7. □

Similarly, for the case of low frequency ($q=-1$), we have the following a priori estimate.

LEMMA 4.9 ($q=-1$). *There exist some positive constants $\bar{K}_1,\bar{K}_2,\bar{K}_3$, and μ_3 independent of τ such that the following estimate holds:*

$$\begin{aligned}&2^{-(\sigma-1)}\frac{d}{dt}\left\{\frac{\bar{K}_1}{2}2^{-2}\Big(\|\Delta_{-1} m\|_{L^2}^2+\|\Delta_{-1}\boldsymbol{u}\|_{L^2}^2+\frac{1}{\bar{n}}\|\Delta_{-1}\boldsymbol{e}\|_{L^2}^2\Big)\right.\\&\left.+\frac{\bar{K}_2\tau}{2}\mathrm{Im}\int|\xi|\Big((\widehat{\Delta_{-1}U})^* K(\xi)\widehat{\Delta_{-1}U}\Big)d\xi-\bar{K}_3\tau\int\Delta_{-1}\boldsymbol{e}\cdot\overline{\Delta_{-1}\boldsymbol{u}}dx\right\}^{1/2}\\&+\mu_3 2^{-\sigma}\Big(\tau\|\Delta_{-1} m\|_{L^2}+\|\Delta_{-1}\boldsymbol{u}\|_{L^2}+\tau\|\Delta_{-1}\boldsymbol{e}\|_{L^2}\Big)\\&\le C\{2^{-\sigma}(\|\nabla\boldsymbol{u}\|_{L^\infty}+\|\boldsymbol{u}\|_{L^\infty})(\|\Delta_{-1} m\|_{L^2}+\|\Delta_{-1}\boldsymbol{u}\|_{L^2})\\&+c_{-1}\|\boldsymbol{u}\|_{B^\sigma_{2,1}}(\|m\|_{B^\sigma_{2,1}}+\|\boldsymbol{u}\|_{B^\sigma_{2,1}})+\tau 2^{-(\sigma-1)}\|\Delta_{-1}\mathcal{G}\|_{L^2}\\&+2^{-\sigma}(\|\Delta_{-1}(h(m)\boldsymbol{u})\|_{L^2}+\tau\|\Delta_{-1}(\tilde{h}(m)m)\|_{L^2})\},\end{aligned}\tag{4.35}$$

where $C>0$ is a uniform constant independent of τ.

Remark 4.2. Similar to the proof of Lemma 4.8, the constants $\bar{K}_1,\bar{K}_2,\bar{K}_3$ are used to ensure that

$$\begin{aligned}&\frac{\bar{K}_1}{2}2^{-2}\Big(\|\Delta_{-1} m\|_{L^2}^2+\|\Delta_{-1}\mathbf{u}\|_{L^2}^2+\frac{1}{\bar{n}}\|\Delta_{-1}\mathbf{e}\|_{L^2}^2\Big)\\&+\frac{\bar{K}_2\tau}{2}\mathrm{Im}\int|\xi|\Big((\widehat{\Delta_{-1}U})^* K(\xi)\widehat{\Delta_{-1}U}\Big)d\xi-\bar{K}_3\tau\int\Delta_{-1}\mathbf{e}\cdot\overline{\Delta_{-1}\mathbf{u}}dx\\&\approx 2^{-2}\Big(\|\Delta_{-1} m\|_{L^2}^2+\|\Delta_{-1}\mathbf{u}\|_{L^2}^2+\|\Delta_{-1}\mathbf{e}\|_{L^2}^2\Big)\end{aligned}\tag{4.36}$$

and to eliminate some quadratic terms in the right-hand side of inequality (4.35).

Summing (4.30) on $q \in \mathbf{N} \cup \{0\}$ and adding with (4.35), then, according to the smallness of $\tau(0 < \tau \le 1)$, a priori assumption (4.1), (4.29), and Moser's estimates (Proposition 2.5), we obtain the following differential inequality:

$$\begin{aligned} &\frac{d}{dt}Q + \mu_4\Big(\tau\|m\|_{B^\sigma_{2,1}} + \|\mathbf{u}\|_{B^\sigma_{2,1}} + \tau\|\mathbf{e}\|_{B^\sigma_{2,1}}\Big) \\ &\le C\delta_1\Big(\tau\|m\|_{B^\sigma_{2,1}} + \|\mathbf{u}\|_{B^\sigma_{2,1}} + \tau\|\mathbf{e}\|_{B^\sigma_{2,1}}\Big), \end{aligned} \tag{4.37}$$

where

$$\begin{aligned} Q = \sum_{q\ge 0} 2^{q(\sigma-1)} \Bigg\{ &\frac{K_1}{2}2^{2q}\Big(\|\Delta_q m\|^2_{L^2} + \|\Delta_q \mathbf{u}\|^2_{L^2} + \frac{1}{\bar n}\|\Delta_q \mathbf{e}\|^2_{L^2}\Big) \\ &+ \frac{K_2\tau}{2}\mathrm{Im}\int |\xi|\Big((\widehat{\Delta_q U})^* K(\xi)\widehat{\Delta_q U}\Big)d\xi\Bigg\}^{1/2} \\ &+ \Bigg\{\frac{\bar K_1}{2}2^{-2}\Big(\|\Delta_{-1} m\|^2_{L^2} + \|\Delta_{-1}\mathbf{u}\|^2_{L^2} + \frac{1}{\bar n}\|\Delta_{-1}\mathbf{e}\|^2_{L^2}\Big) \\ &+ \frac{\bar K_2\tau}{2}\mathrm{Im}\int |\xi|\Big((\widehat{\Delta_{-1} U})^* K(\xi)\widehat{\Delta_{-1} U}\Big)d\xi - \bar K_3\tau\int \Delta_{-1}\mathbf{e}\cdot\overline{\Delta_{-1}\mathbf{u}}dx\Bigg\}^{1/2} \end{aligned} \tag{4.38}$$

and $\mu_4 > 0$ is a uniform constant independent of τ. Note that

$$Q \approx \|(m, \mathbf{u}, \mathbf{e})(\cdot, t)\|_{B^\sigma_{2,1}}, \quad t \ge 0, \tag{4.39}$$

and by choosing $\delta_1 = \frac{\mu_4}{2C}, \mu_1 = \frac{\mu_4}{2}$, we conclude the proof of Proposition 4.1.

Based on Propositions 3.1 and 4.1, we establish the global existence of classical solutions to the system (3.2)–(3.4) by virtue of the standard continuation argument. Using the imbedding property in Besov space $B^\sigma_{2,1}$, $(m, \mathbf{u}, \mathbf{e}) \in \mathcal{C}^1([0,\infty)\times\mathbf{R}^N)$ solves (3.2)–(3.4). From Remark 3.1, we know $(n, \mathbf{u}, \mathbf{e}) \in \mathcal{C}^1([0,\infty)\times\mathbf{R}^N)$ is a solution of (1.1)–(1.2) with $n > 0$. Furthermore, we attain Theorem 1.1.

5. Relaxation-time limit. In this section, we give the proof of Theorem 1.2.

Proof. From the uniform energy estimate (1.7) in Theorem 1.1 and the scaled variables (1.3), we have

$$\begin{aligned} &\sup_{s\ge 0}\Big(\|(n^\tau - \bar n, \tau\mathbf{u}^\tau, \mathbf{e}^\tau)(\cdot, s)\|_{B^\sigma_{2,1}}\Big) + \mu_0\int_0^\infty \Big(\|(n^\tau - \bar n, \mathbf{u}^\tau, \mathbf{e}^\tau)(\cdot, s)\|_{B^\sigma_{2,1}}\Big)ds \\ &\le C_0\|(n_0 - \bar n, \mathbf{u}_0, \mathbf{e}_0)\|_{B^\sigma_{2,1}}. \end{aligned} \tag{5.1}$$

According to Proposition 2.4 and the compactness theorem in [14], there exists a function $(\mathcal{N}, \mathcal{E}) \in \mathcal{C}([0,\infty), \bar n + B^\sigma_{2,1}) \times \mathcal{C}([0,\infty), B^\sigma_{2,1})$ such that, for any $T > 0$, the sequence (up to a subsequence)

$$\{n^\tau\} \to \mathcal{N} \quad \text{strongly in} \quad L^p(0, T; (B^{\sigma'}_{2,1})_{\mathrm{loc}})(1 \le p < +\infty,\ \sigma' < \sigma),$$

$$\{\mathbf{e}^\tau\} \to \mathcal{E} \quad \text{strongly in} \quad L^p(0, T; (B^{\sigma'}_{2,1})_{\mathrm{loc}})(1 \le p < +\infty,\ \sigma' < \sigma),\ \text{as}\ \ \tau \to 0.$$

From (5.1), we can derive that

$$\begin{aligned} &\mathbf{u}^\tau \ \text{ is uniformly bounded in } \ L^1(0, T; B^\sigma_{2,1}) \\ &\text{and} \quad \tau(\mathbf{u}^\tau\cdot\nabla)\mathbf{u}^\tau \quad \text{is uniformly bounded in } \ L^1(0, T; B^{\sigma-1}_{2,1}). \end{aligned}$$

Hence, in the system (1.4)–(1.5), the above convergence properties allow us to pass to the limit $\tau \to 0$ in the sense of distributions, which implies that $(\mathcal{N}, \mathcal{E})$ is a global weak solution to the drift-diffusion model (1.6). ∎

Acknowledgments. The author thanks his adviser, Professor Daoyuan Fang, for his constant support and encouragement. He also thanks the anonymous referees for their useful comments and suggestions.

EXISTENCE AND STABILITY RESULTS FOR PERIODIC STOKESIAN HELE–SHAW FLOWS*

JOACHIM ESCHER† AND BOGDAN-VASILE MATIOC†

Abstract. We consider here a 2π-periodic and two-dimensional Hele–Shaw flow modelling the motion of a viscous and incompressible fluid. The free surface is moving under the influence of gravity and is modelled by a modified Darcy law for Stokesian fluids. The bottom of the cell is assumed to be impermeable. We prove the existence of a unique classical solution if the initial data is near a constant, identify the equilibria of the flow, and study their stability.

Key words. quasi-linear elliptic equation, nonlinear parabolic equation, Hele–Shaw flow, non-Newtonian fluid, Oldroyd-B fluid, power law fluid

1. Introduction.

1.1. The mathematical model. Using a fluid model with a shear-rate dependent viscosity, the authors in [12] derive a Darcy law coupling the pressure p and the velocity field v of the bulk fluid situated between the parallel plates of a Hele–Shaw cell:

$$v = -\frac{Dp}{\overline{\mu}(|Dp|^2)}. \tag{1}$$

Here $\overline{\mu}$ is the so-called *effective viscosity*. In the situation studied in [12] the cell is horizontal and the gap d between the plates is small in relation to the other two dimensions of the cell. Having averaged over the gap d they consider (1) for a two-dimensional fluid. From the conservation of mass one concludes that the pressure p of a finite patch Ω of fluid with boundary Γ must solve the Dirichlet problem

$$\operatorname{div}\left(\frac{Dp}{\overline{\mu}(|Dp|^2)}\right) = 0 \quad \text{in} \quad \Omega, \qquad p = -\sigma\kappa \quad \text{on} \quad \Gamma, \tag{2}$$

where σ is the surface tension parameter and κ the curvature of Γ. The solvability of (2) is discussed in terms of the monotonicity of $\overline{\mu}$. It should be emphasized that in [12] only problems on temporal fixed domains are rigorously investigated. However, the full problem describing the more complex situation in which the boundary Γ moves and which is obtained by coupling (2) with an evolution equation describing the motion of the fluid molecules situated on Γ is not addressed by the authors in [12].

In this paper we study the general Cauchy problem of the full system describing the flow of a non-Newtonian fluid in a vertical Hele–Shaw cell with an impermeable bottom and laterals (see Figure 1). Hence, effects caused by gravity must be incorporated into our setting. As in [12] the gap d is again small compared to the height and length of the cell. In order to avoid the contact angle problem a two-dimensional,

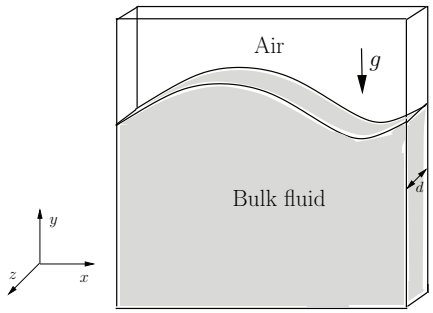

FIG. 1.

strip-like geometry will be considered. Given a positive function $f \in C^1(\mathbb{R})$, bounded away from 0, we define the set

$$\widetilde{\Omega}_f := \{(x,y) \in \mathbb{R}^2 \,:\, 0 < y < f(x)\},$$

identified as the fluid domain, and denote the components of its boundary $\partial\widetilde{\Omega}_f$ by

$$\widetilde{\Gamma}_f := \{(x, f(x)) \,:\, x \in \mathbb{R}\}, \quad \widetilde{\Gamma}_0 := \mathbb{R} \times \{0\}.$$

We denote by ν the outward-pointing normal of $\partial\widetilde{\Omega}_f$. The motion of the fluid is modelled using the Darcy law (1):

$$v = -\frac{Du}{\overline{\mu}(|Du|^2)},$$

with p replaced by the *velocity potential* u defined by

$$u(x,y) = \frac{p(x,y)}{g \cdot \rho} + y, \quad (x,y) \in \widetilde{\Omega}_f.$$

Here g is the gravity acceleration constant, ρ is the density constant, and $Du = (\partial_1 u, \partial_2 u)$ is the gradient of u. Also called *piezometric head*, u expresses the mechanical energy due to gravity and pressure of the fluid, per unit weight of fluid (see [3]).

The viscosity $\mu \in C^\infty([0,\infty),(0,\infty))$ is assumed to satisfy $\mu(r) + 2r\mu'(r) > 0$ for $r \geq 0$. Particularly, this implies that the mapping $[0,\infty) \ni r \longmapsto h(r) := r\mu^2(r)$ is invertible. The effective viscosity $\overline{\mu}$ (see [12]) is defined by

$$\frac{1}{\overline{\mu}(r)} := c \int_{-1}^{1} \frac{s^2}{\widetilde{\mu}(rs^2)}\, ds,$$

where c is a positive constant and $\widetilde{\mu} := \mu \circ h^{-1}$. The free surface $\widetilde{\Gamma}_f$ separating the fluid from air, at pressure normalized to be zero, is moving under the influence of gravity. Surface tension effects are neglected. Consequently, $p = 0$ on $\widetilde{\Gamma}_f$ and

$$u = f \quad \text{on} \quad \widetilde{\Gamma}_f.$$

On the fixed boundary $\widetilde{\Gamma}_0$ we have no flux, i.e.,

$$\partial_\nu u = 0 \quad \text{on} \quad \widetilde{\Gamma}_0.$$

Furthermore, the interface $\widetilde{\Gamma}_f$ is implicitly given by $F(t,z)=0$, where $z=(x,y)$ and $F(t,z)=y-f(t,x)$. Assuming that a particle located on the interface remains there, we obtain by differentiating this equation with respect to t the relation

$$0=\frac{d}{dt}F(t,z)=-f_t(t,x)+(-f_x,1)z'.$$

Finally, we shall make the following periodicity requirement on f and u:

$$\begin{aligned} f(t,x+2\pi) &= f(t,x) \qquad \forall x\in\mathbb{R},\, t\geq 0,\\ u(x+2\pi,y) &= u(x,y) \qquad \forall (x,y)\in\widetilde{\Omega}_{f(t)},\, t\geq 0. \end{aligned}$$

Summarizing, we arrive at the following system:

$$\begin{aligned} \operatorname{div}\left(\tfrac{Du}{\overline{\mu}(|Du|^2)}\right) &= 0 \quad \text{in} \quad \Omega_{f(t)}, \quad t\geq 0,\\ \partial_\nu u &= 0 \quad \text{on} \quad \Gamma_0, \quad t\geq 0,\\ u &= f \quad \text{on} \quad \Gamma_{f(t)}, \quad t\geq 0,\\ \partial_t f(t,\cdot)+\tfrac{\sqrt{1+\partial_x f^2(t,\cdot)}}{\overline{\mu}(|Du(\cdot,f(t,\cdot))|^2)}\partial_\nu u(\cdot,f(t,\cdot)) &= 0 \quad \text{on} \quad \mathbb{S}^1, \quad t>0,\\ f(0,\cdot) &= f_0 \quad \text{on} \quad \mathbb{S}^1, \end{aligned} \tag{3}$$

where, given $t\geq 0$, we use the notation

$$\begin{aligned} \Omega_{f(t)} &:= \{(x,y)\in\mathbb{S}^1\times\mathbb{R}\,:\,0<y<f(t,x)\},\\ \Gamma_{f(t)} &:= \{(x,f(t,x))\,:\,x\in\mathbb{S}^1\},\quad \Gamma_0=\mathbb{S}^1\times\{0\}, \end{aligned}$$

and where $\mathbb{S}^1$ stands for the unit circle. For the sake of simplicity, we identify periodic functions on $\mathbb{R}$ with functions on $\mathbb{S}^1$, and periodic functions in the x variable in $\widetilde{\Omega}_f$ with functions in Ω_f, for positive functions f on $\mathbb{S}^1$, respectively. Given $k\in\mathbb{N}$ and $\alpha\in(0,1)$, we define the so-called little Hölder spaces $h^{k+\alpha}(\mathbb{S}^1)$ as the closure of $C^\infty(\mathbb{S}^1)$ in $C^{k+\alpha}(\mathbb{S}^1)$.

For our analysis we fix $\alpha\in(0,1)$ and define

$$\mathcal{U}:=\Big\{f\in C^{2+\alpha}(\mathbb{S}^1)\,:\,\min_{x\in\mathbb{S}^1}f(x)>0\Big\},$$

respectively, $\mathcal{V}:=\mathcal{U}\cap h^{2+\alpha}(\mathbb{S}^1)$. For $f\in\mathcal{U}$ we denote by $buc^{k+\alpha}(\Omega_f)$ the closure of $BUC^\infty(\Omega_f)$ in the Hölder space $BUC^{k+\alpha}(\Omega_f)$.

A pair (u,f) is called a *classical Hölder solution* of (3) on $[0,T]$, with $T>0$, if

$$f\in C([0,T],\mathcal{V})\cap C^1([0,T],h^{1+\alpha}(\mathbb{S}^1)),$$

$$u(\cdot,t)\in buc^{2+\alpha}(\Omega_{f(t)}),\, t\in[0,T],$$

and if (u,f) satisfies the equations in (3) pointwise.

For simplicity we denote

$$\mathcal{Q}u:=\operatorname{div}\left(\frac{Du}{\overline{\mu}(|Du|^2)}\right).$$

Then $\mathcal{Q}u = a_{ij}(Du)u_{ij}$, with

$$a_{ij}(q_1,q_2) = \frac{\delta_{ij}}{\overline{\mu}(|q|^2)} - \frac{2q_iq_j\overline{\mu}'(|q|^2)}{\overline{\mu}^2(|q|^2)}, \quad 1 \le i,\, j \le 2,\, q = (q_1,q_2) \in \mathbb{R}^2.$$

The eigenvalues of the matrix $[a_{ij}(q)]_{1\le i,\,j\le 2}$, $q \in \mathbb{R}^2$, are

$$\lambda_1(q) = \frac{1}{\overline{\mu}(|q|^2)}, \qquad \lambda_2(q) = \frac{1}{\overline{\mu}(|q|^2)} - \frac{2|q|^2\overline{\mu}'(|q|^2)}{\overline{\mu}^2(|q|^2)},$$

and we have

$$c|\xi|^2 \le a_{ij}(q_1,q_2)\xi_i\xi_j \le C|\xi|^2 \quad \forall \xi = (\xi_1,\xi_2) \in \mathbb{R}^2,\, (q_1,q_2) \in \mathbb{R}^2,$$

if we assume that there exist positive constants c and C such that

$$(\mathrm{A}_1) \quad c \le \frac{1}{\overline{\mu}(r)} \le C \quad \forall\, r \ge 0,$$

$$(\mathrm{A}_2) \quad c \le \frac{1}{\overline{\mu}(r)} - \frac{2r\overline{\mu}'(r)}{\overline{\mu}^2(r)} \le C \quad \forall\, r \ge 0.$$

It can be shown (cf. [6]) that (A_1) and (A_2) hold true, provided the viscosity μ satisfies

$$(\mathrm{V}_1) \quad m \le \mu(r) \le M,$$

$$(\mathrm{V}_2) \quad m \le \mu(r) + 2r\mu'(r) \le M,$$

for all $r \ge 0$, where m and M are positive constants. If the viscosity μ is constant, then the fluid is called Newtonian. Results regarding this situation can be found in [4] and [7], [8], [9], [10]. The class of Stokesian, sometimes also called non-Newtonian, fluids satisfying (V_1) and (V_2) is quite large; see [6]. This class includes particularly numerous Oldroyd-B and power law fluids.

Under the above assumptions $\mathcal{Q}$ is a uniformly elliptic operator in $\mathbb{R}^2$. Consider now the problem

$$\begin{aligned}
\operatorname{div}\left(\tfrac{Du}{\overline{\mu}(|Du|^2)}\right) &= 0 \quad \text{in} \quad G_{f(t)}, && t \ge 0,\\
u &= f \quad \text{on} \quad \partial G_{f(t)}, && t \ge 0,\\
\partial_t f(t,\cdot) + \tfrac{\sqrt{1+\partial_x f^2(t,\cdot)}}{\overline{\mu}(|Du(\cdot,f(t,\cdot))|^2)}\partial_\nu u(\cdot, f(t,\cdot)) &= 0 \quad \text{on} \quad \mathbb{S}^1, && t > 0,\\
f(0,\cdot) &= f_0 \quad \text{on} \quad \mathbb{S}^1,
\end{aligned} \tag{4}$$

where

$$G_{f(t)} := \{(x,y) \in \mathbb{S}^1 \times \mathbb{R} : -f(t,x) < y < f(t,x)\},$$

for $t \ge 0$. A pair (u,f) is called a *classical Hölder solution* of (4) on $[0,T]$ if

$$f \in C([0,T],\mathcal{V}) \cap C^1([0,T],h^{1+\alpha}(\mathbb{S}^1)),$$

$$u(\cdot\,,t) \in buc^{2+\alpha}(G_{f(t)}),\, t \in [0,T],$$

and if (u,f) satisfies the equations in (4) pointwise.

Given $f \in \mathcal{V}$, let $u \in buc^{2+\alpha}(G_f)$ be the unique solution (existence will be discussed later) of the quasi-linear Dirichlet problem

$$\begin{aligned} \mathcal{Q}u &= 0 \quad \text{in} \quad G_f, \\ u &= f \quad \text{on} \quad \partial G_f. \end{aligned} \tag{5}$$

Because of the symmetry of the domain G_f and of the boundary conditions we obtain

$$u(x,-y) = u(x,y)$$

for all $(x,y) \in G_f$. Consequently, $\partial_\nu u = 0$ on Γ_0; thus the restriction of u to Ω_f is the unique solution of

$$\begin{aligned} \mathcal{Q}u &= 0 \quad \text{in} \quad \Omega_f, \\ \partial_\nu u &= 0 \quad \text{on} \quad \Gamma_0, \\ u &= f \quad \text{on} \quad \Gamma_f. \end{aligned} \tag{6}$$

We deduce that there exists a one-to-one correspondence between solutions to (3) and (4). Namely, if (u,f) is a solution to (3) on the interval $[0,T]$, $T>0$, then for each $t \in [0,T]$ the velocity potential $u(\cdot\,,t) \in buc^{2+\alpha}(\Omega_{f(t)})$ can be extended by reflection on the entire domain $G_{f(t)}$. We obtain in this manner a solution to (4). Moreover, if $(\widetilde{u},f)$ is a solution to (4) on the interval $[0,T]$, $T>0$, then we can restrict for $t \in [0,T]$ the function $\widetilde{u}(\cdot\,,t)$ to $\Omega_{f(t)}$, and so obtain a solution to (3).

It is more convenient to treat (4), because we have in this case a Dirichlet problem for the velocity potential, which can be solved using the techniques presented in [11].

We state now the first main result of this work.

THEOREM 1.1. *Assume that* (A_1) *and* (A_2) *hold true.*

(a) *Let c be a positive constant. Then we find an open neighborhood $\mathcal{O}$ of c in $\mathcal{V}$ such that for each $f_0 \in \mathcal{O}$, problem* (3) *has a classical Hölder solution (u,f) on an interval $[0,T]$ with $T>0$. Moreover, there exists a constant $\gamma \in (0,1)$ such that $f \in C^\gamma_\gamma((0,T],h^{2+\alpha}(\mathbb{S}^1))$.*

(b) *Let (u_1,f_1) and (u_2,f_2) be solutions of* (3) *with $f_1 \in C^\gamma_\gamma((0,T],h^{2+\alpha}(\mathbb{S}^1))$, $\gamma \in (0,1)$, and $f_2 \in C^\delta_\delta((0,T],h^{2+\alpha}(\mathbb{S}^1))$, $\delta \in (0,1)$. If $f_1([0,T]) \subset \mathcal{O}$ and $f_2([0,T]) \subset \mathcal{O}$, then $(u_1,f_1)=(u_2,f_2)$.*

For a definition of the weighted Hölder spaces $C^\gamma_\gamma((0,T],h^{2+\alpha}(\mathbb{S}^1))$, $\gamma \in (0,1)$, see [13].

In section 3 we prove that each pair $(c,c) \in buc^{2+\alpha}(\Omega_c) \times \mathcal{V}$, with $c>0$, is a stationary solution of the flow (3). Furthermore, we prove that if the initial data $f_0 \in \mathcal{O}$ is close enough to c in $h^{2+\alpha}(\mathbb{S}^1)$ and if Ω_{f_0} and Ω_c enclose the same fluid volume, then the solution corresponding to f_0 exists globally in time and is attracted at an exponential rate by c (see Theorem 3.3).

1.2. The transformed problem. In order to solve the problem we transform it on a fixed reference manifold $G := \mathbb{R} \times (0,2)$. In order to do so we define for each $f \in \mathcal{U}$ a diffeomorphism $\phi_f \in \mathit{Diff}^{\,2+\alpha}(G,G_f)$ by

$$\phi_f(x,y) := (x,(1-y)f(x)),\ (x,y) \in G,$$

and the push-forward and pull-back operators induced by ϕ_f:

$$\phi_f^* : BUC(G_f) \to BUC(G), \quad u \longmapsto u \circ \phi_f,$$

$$\phi_*^f : BUC(G) \to BUC(G_f), \quad v \longmapsto v \circ \phi_f^{-1}.$$

The transformed operators $\mathcal{A}(f)$ and $\mathcal{B}$, acting on $BUC^2(G)$, respectively, $\mathcal{U}\times BUC^{2+\alpha}(G)$, are defined by

$$\mathcal{A}(f) := \phi_f^* \circ \mathcal{Q} \circ \phi_*^f,$$
$$\mathcal{B}(f,v)(x) := \frac{D(\phi_*^f v)}{\overline{\mu}(|D(\phi_*^f v)|^2)}(x, f(x)) \cdot n(x), \quad x \in \mathbb{S}^1,$$

with $n(x) := (-f'(x), 1)$, $x \in \mathbb{S}^1$. Transformation of (4) to G yields

$$\begin{aligned} \mathcal{A}(f)v &= 0 \quad \text{in} \quad G \times [0,\infty), \\ v &= f \quad \text{on} \quad \partial G \times [0,\infty), \\ \partial_t f + \mathcal{B}(f,v) &= 0 \quad \text{on} \quad \mathbb{S}^1 \times (0,\infty), \\ f(0) &= f_0, \end{aligned} \tag{7}$$

where $v := \phi_f^* u$. A pair (v, f) is called a *classical Hölder solution* of (7) on $[0, T]$, with $T > 0$, if

$$f \in C([0,T], \mathcal{V}) \cap C^1([0,T], h^{1+\alpha}(\mathbb{S}^1)),$$
$$v(\cdot\,, t) \in buc^{2+\alpha}(G),\ t \in [0,T],$$

and if (v, f) satisfies the equations in (7) pointwise. It is obvious that problems (4) and (7) are equivalent in the following sense.

LEMMA 1.2. *Let $f_0 \in \mathcal{V}$ be given.*

(a) *If (u, f) is a classical Hölder solution of* (4)*, then $(\phi_f^* u, f)$ is a classical Hölder solution of* (7).

(b) *If (v, f) is a classical Hölder solution of* (7)*, then $(\phi_*^f v, f)$ is a classical Hölder solution of* (4).

Proof. See, for example, [6]. □

LEMMA 1.3. *Given $f \in \mathcal{U}$, we have*

$$\mathcal{A}(f)v = b_{ij}(y, f, Dv)v_{ij} + b(y, f, Dv)v_2 \quad \text{for} \quad v \in BUC^2(G),$$

where, using the notation $D_f v := (v_1 + \frac{(1-y)f'}{f} v_2, -\frac{1}{f} v_2)$ for $f \in \mathcal{U}$, $v \in BUC^2(G)$, and $y \in [0,2]$, we have

$$b_{11}(y, f, Dv) = a_{11}(D_f v),$$

$$b_{12}(y, f, Dv) = b_{21}(y, f, Dv) = \frac{(1-y)f'}{f} a_{11}(D_f v) - \frac{1}{f} a_{12}(D_f v),$$

$$b_{22}(y, f, Dv) = \frac{(1-y)^2 f'^2}{f^2} a_{11}(D_f v) - \frac{2(1-y)f'}{f^2} a_{12}(D_f v) + \frac{1}{f^2} a_{22}(D_f v),$$

$$b(y, f, Dv) = (1-y)\left(\frac{f''}{f} - \frac{2f'^2}{f^2}\right) a_{11}(D_f v) + \frac{2f'}{f^2} a_{12}(D_f v).$$

Proof. This follows by direct computation. □

We have the following existence and uniqueness theorem. The proof is similar to that of Lemma 2.2 in [6].

THEOREM 1.4. *Let $f \in \mathcal{V}$ be given. There exists a unique solution $v \in buc^{2+\alpha}(G)$ of the quasi-linear Dirichlet problem*

$$\begin{aligned} \mathcal{A}(f)v &= 0 \quad in \quad G, \\ v &= f \quad on \quad \partial G. \end{aligned} \tag{8}$$

Given $f \in \mathcal{V}$, we denote by $\mathcal{T}(f) \in buc^{2+\alpha}(G)$ the solution to (8). The mapping $[\mathcal{V} \ni f \mapsto \mathcal{T}(f) \in buc^{2+\alpha}(G)]$ is smooth.

2. The nonlinear Cauchy problem. Due to Theorem 1.4 we can reduce problem (4) to an abstract, fully nonlinear Cauchy problem on $\mathbb{S}^1$:

$$\partial_t f + \Phi(f) = 0, \qquad f(0) = f_0, \tag{9}$$

where

$$\Phi(f) := \mathcal{B}(f, \mathcal{T}(f)).$$

Note that the mapping $f \longmapsto \Phi(f)$ is a nonlinear and nonlocal operator of first order. It carries also a fully nonlinear structure in the sense that there is no leading linear part in $\mathcal{Q}$. We solve the Cauchy problem (9) by applying the theory of maximal regularity; cf. [13]. Further on we verify that the assumption in Theorem 8.1.1 in [13] are satisfied.

We first restrict our attention to the operator $\mathcal{B}$. Let $(f, v) \in \mathcal{V} \times buc^{2+\alpha}(G)$ be given. The function $\mathcal{B}(f, v)$ is given by

$$\mathcal{B}(f, v) = -\frac{1}{\overline{\mu}(|\gamma_0 D_f v|^2)} \left(f' \gamma_0 v_1 + \frac{1}{f}(1 + f'^2)\gamma_0 v_2 \right),$$

with γ_0 denoting the trace operator on Γ_0. Together with the relation

$$|\gamma_0 D_f v|^2 = \gamma_0 v_1^2 + 2\frac{f'}{f}\gamma_0 v_1 v_2 + \frac{1 + f'^2}{f^2}\gamma_0 v_2^2$$

we obtain that the operator $\mathcal{B}$ defined above is smooth.

LEMMA 2.1. *The mapping $\mathcal{B} : \mathcal{V} \times buc^{2+\alpha}(G) \to h^{1+\alpha}(\mathbb{S}^1)$ is smooth. Given $(f, v) \in \mathcal{V} \times buc^{2+\alpha}(G)$, we have*

$$\begin{aligned} \partial\mathcal{B}(f, v)[h, u] = &- \frac{1}{\overline{\mu}} \left(|\gamma_0 D_f v|^2\right) \Big[f' \gamma_0 u_1 + h' \gamma_0 v_1 + \frac{1}{f}(1 + f'^2)\gamma_0 u_2 \\ &- \left(\frac{h}{f^2} - \frac{2f'h'}{f} + \frac{hf'^2}{f^2} \right) \gamma_0 v_2 \Big] \\ &- 2 \left(\frac{1}{\overline{\mu}} \right)' \left(|\gamma_0 D_f v|^2\right) \left(f' \gamma_0 v_1 + \frac{1}{f}(1 + f'^2)\gamma_0 v_2 \right) \Big[\gamma_0 v_1 u_1 \\ &+ \frac{h'}{f}\gamma_0 v_1 v_2 + \frac{f'}{f}\gamma_0 u_1 v_2 + \frac{f'}{f}\gamma_0 v_1 u_2 - \frac{f'h}{f^2}\gamma_0 v_1 v_2 + \frac{f'h'}{f^2}\gamma_0 v_2^2 \\ &+ \frac{f'^2}{f^2}\gamma_0 v_2 u_2 - \frac{hf'^2}{f^3}\gamma_0 v_2^2 + \frac{1}{f^2}\gamma_0 v_2 u_2 - \frac{h}{f^3}\gamma_0 v_2^2 \Big] \end{aligned}$$

for all $[h, u] \in h^{2+\alpha}(\mathbb{S}^1) \times buc^{2+\alpha}(G)$.

LEMMA 2.2. *Given $f \in \mathcal{V}$ and $h \in h^{2+\alpha}(\mathbb{S}^1)$, the function $\partial\mathcal{T}(f)[h]$ is the unique solution of the linear Dirichlet problem*

$$
\begin{aligned}
&b_{ij}w_{ij} + bw_2 + D_f w \left[u_{11}\partial a_{11}(D_f u) + 2u_{12}\left(\frac{(1-y)f'}{f}\partial a_{11}(D_f u) - \frac{1}{f}\partial a_{12}(D_f u)\right)\right.\\
&+ u_{22}\left(\frac{(1-y)^2 f'^2}{f^2}\partial a_{11}(D_f u) - 2\frac{(1-y)f'}{f^2}\partial a_{12}(D_f u) + \frac{1}{f^2}\partial a_{22}(D_f u)\right)\\
&\left.+ u_2\left((1-y)\left(\frac{f''}{f} - 2\frac{f'^2}{f^2}\right)\partial a_{11}(D_f u) + 2\frac{f'}{f^2}\partial a_{12}(D_f u)\right)\right]\\
&\qquad = -u_2\left((1-y)\frac{fh' - f'h}{f^2}, \frac{h}{f^2}\right)\cdot\left[u_{11}\partial a_{11}(D_f u)\right.\\
&+ 2u_{12}\left(\frac{(1-y)f'}{f}\partial a_{11}(D_f u) - \frac{1}{f}\partial a_{12}(D_f u)\right) + u_{22}\left(\frac{(1-y)^2 f'^2}{f^2}\partial a_{11}(D_f u)\right.\\
&- 2\frac{(1-y)f'}{f^2}\partial a_{12}(D_f u) + \frac{1}{f^2}\partial a_{22}(D_f u)\Big) + u_2\left((1-y)\left(\frac{f''}{f} - 2\frac{f'^2}{f^2}\right)\partial a_{11}(D_f u)\right.\\
&\left.\left.+ 2\frac{f'}{f^2}\partial a_{12}(D_f u)\right)\right] - 2u_{12}\left((1-y)\frac{fh' - f'h}{f^2}a_{11}(D_f u) + \frac{h}{f^2}a_{12}(D_f u)\right)\\
&- 2u_{22}\left(\frac{(1-y)^2(ff'h' - f'^2 h)}{f^3}a_{11}(D_f u) - (1-y)\frac{fh' - 2f'h}{f^3}a_{12}(D_f u)\right.\\
&\left.- \frac{h}{f^3}a_{22}(D_f u)\right) - u_2\left((1-y)\left(\frac{fh'' - f''h}{f^2} - 4\frac{ff'h' - f'^2 h}{f^3}\right)a_{11}(D_f u)\right.\\
&\left.+ 2\frac{fh' - 2f'h}{f^3}a_{12}(D_f u)\right) \qquad \text{in} \quad G,
\end{aligned}
$$

$$
w = h \quad \text{on} \quad \partial G,
$$

where $u := \mathcal{T}(f)$ and $b_{ij} = b_{ij}(y, f, Du)$, $b = b(y, f, Du)$ are the coefficients computed in Lemma 1.3.

Proof. The proof follows using standard arguments and we omit it. □

Consequently, we obtain from Lemma 2.1 and Theorem 1.4 that the operator Φ is smooth. We can use the chain rule to compute its derivative. More precisely, we have the following result.

THEOREM 2.3. *The map Φ belongs to $C^\infty(\mathcal{V}, h^{1+\alpha}(\mathbb{S}^1))$ and*

$$
\partial\Phi(f) = \partial\mathcal{B}(f, \mathcal{T}(f)) \circ (\mathrm{id}_{h^{2+\alpha}(\mathbb{S}^1)}, \partial\mathcal{T}(f)) \quad \forall f \in \mathcal{V}.
$$

Our goal is to show that for $c \in \mathbb{R}_{>0}$ the Fréchet derivative $-\partial\Phi(c)$ generates a strongly continuous analytic semigroup in $\mathcal{L}(h^{1+\alpha}(\mathbb{S}^1))$. Then, using general results from the theory of maximal regularity (cf. [13]), we can prove Theorem 1.1. It is clear that we consider here $-\partial\Phi(c)$ as an unbounded operator in $h^{1+\alpha}(\mathbb{S}^1)$ with domain $h^{2+\alpha}(\mathbb{S}^1)$.

Let $c \in \mathbb{R}_{>0}$ be given. The solution $\mathcal{T}(c)$ to (8) is the constant function c on G. Given $h \in h^{2+\alpha}(\mathbb{S}^1)$, the map $\partial\mathcal{T}(c)[h]$ is the solution of the Dirichlet problem

$$\begin{aligned} c^2 w_{11} + w_{22} &= 0 \quad \text{in} \quad G, \\ w &= h \quad \text{on} \quad \partial G. \end{aligned} \tag{10}$$

Consequently,

$$-\partial\Phi(c)[h](x) = \frac{\zeta}{c} w_2(x,0), \quad x \in \mathbb{S}^1,$$

where $\zeta := 1/\overline{\mu}(0)$.

We expand h and w in the following way:

$$h(x) = \sum_{k\in\mathbb{Z}} c_k e^{ikx}, \qquad w(x,y) = \sum_{k\in\mathbb{Z}} C_k(y) e^{ikx},$$

and we substitute these expressions into (10). Comparing the coefficients of e^{ikx}, $k \in \mathbb{Z}$, we get the following equations for C_k:

$$\begin{aligned} C_k'' - c^2k^2 C_k &= 0, \quad 0 < y < 2, \\ C_k(0) &= c_k, \\ C_k(2) &= c_k, \end{aligned} \tag{11}$$

for $k \in \mathbb{Z} \setminus \{0\}$, and

$$\begin{aligned} C_0'' &= 0, \quad 0 < y < 2, \\ C_0(0) &= c_0, \\ C_0(2) &= c_0. \end{aligned} \tag{12}$$

The solution to (12) is the constant function $C_0 = c_0$, and for $k \in \mathbb{Z} \setminus \{0\}$ we have

$$C_k(y) = c_k d_k(y), \quad 0 \le y \le 2,$$

where

$$d_k(y) := \frac{e^{2ck}-1}{e^{4ck}-1} e^{cky} + \frac{e^{4ck}-e^{2ck}}{e^{4ck}-1} e^{-cky}, \quad 0 \le y \le 2.$$

Summarizing, we obtain

$$-\partial\Phi(c)\left[\sum_{k\in\mathbb{Z}} c_k e^{ikx}\right] = \sum_{k\in\mathbb{Z}} \lambda_k c_k e^{ikx}, \tag{13}$$

for all $h = \sum_{k\in\mathbb{Z}} c_k e^{ikx} \in h^{2+\alpha}(\mathbb{S}^1)$, with

$$\lambda_k := -\zeta \frac{e^{2ck}-1}{e^{2ck}+1} k, \quad k \in \mathbb{Z}. \tag{14}$$

The multiplying coefficients λ_k satisfy $\lambda_k = \lambda_{-k}$ for all $k \in \mathbb{Z}$. Furthermore,

$$0 = \lambda_0 > \lambda_{\pm 1} > \lambda_{\pm 2} > \cdots > \lambda_{\pm k} > \lambda_{\pm(k+1)} > \cdots .$$

For the purpose of proving that $-\partial\Phi(c)$ generates a strongly continuous analytic semigroup in $\mathcal{L}(h^{1+\alpha}(\mathbb{S}^1))$, i.e., $\partial\Phi(c) \in \mathcal{H}(h^{2+\alpha}(\mathbb{S}^1), h^{1+\alpha}(\mathbb{S}^1))$, it is enough (cf. [1]) to find constants $\omega > 0$ and $\kappa \geq 1$ such that

$$\lambda + \partial\Phi(c) \in \mathcal{L}is(h^{2+\alpha}(\mathbb{S}^1), h^{1+\alpha}(\mathbb{S}^1)), \tag{15}$$

$$|\lambda| \cdot \|R(\lambda, -\partial\Phi(c))\|_{\mathcal{L}(h^{1+\alpha}(\mathbb{S}^1))} \leq \kappa \tag{16}$$

for all $\operatorname{Re}\lambda \geq \omega$.

For $r \geq 0$ we introduce the Sobolev space

$$H^r(\mathbb{S}^1) := \left\{ f \in L^2(\mathbb{S}^1) \,:\, \sum_{n\in\mathbb{Z}} (1+n^2)^r |\widehat{f}(n)|^2 < \infty \right\},$$

endowed with the scalar product

$$\langle f \,,\, g \rangle := \sum_{n\in\mathbb{Z}} (1+n^2)^r \widehat{f}(n)\overline{\widehat{g}(n)}.$$

The smooth functions are dense in $H^r(\mathbb{S}^1)$ and the Sobolev embedding $H^{k+r}(\mathbb{S}^1) \hookrightarrow C^k(\mathbb{S}^1)$ holds for all $k \in \mathbb{N}$, provided $r > 1/2$. Therefore we have

$$H^{k+s}(\mathbb{S}^1) \overset{d}{\hookrightarrow} h^{k+\beta}(\mathbb{S}^1)$$

for all $k \in \mathbb{N}$, $\beta \in [0,1]$, and $s > 3/2$.

We choose $\omega = 1$ and prove that relations (15) and (16) hold.

LEMMA 2.4. *Given $r \geq 0$ and $\operatorname{Re}\lambda \geq \omega$, we have*

$$\lambda + \partial\Phi(c) \in \mathcal{L}is(H^{r+1}(\mathbb{S}^1), H^r(\mathbb{S}^1)).$$

Proof. The proof is just a consequence of the fact that

$$\lim_{k\to\infty} \frac{\lambda_k}{k} = -\zeta.$$

Given $r \geq 0$ and $\operatorname{Re}\lambda \geq \omega$, the inverse of $\lambda + \partial\Phi(c)$ is the operator $R(\lambda, -\partial\Phi(c)) \in \mathcal{L}is(H^r(\mathbb{S}^1), H^{r+1}(\mathbb{S}^1))$ defined by

$$R(\lambda, -\partial\Phi(c)) \left[\sum_{k\in\mathbb{Z}} c_k e^{ikx} \right] = \sum_{k\in\mathbb{Z}} \frac{1}{\lambda - \lambda_k} c_k e^{ikx} \tag{17}$$

for all $h := \sum_{k\in\mathbb{Z}} c_k e^{ikx} \in H^r(\mathbb{S}^1)$. □

In view of the above-mentioned facts, the multiplying operator $R(\lambda, -\partial\Phi(c))$ belongs to $\mathcal{L}(h^{1+\alpha}(\mathbb{S}^1), h^{k+\alpha}(\mathbb{S}^1))$, $k \in \{1,2\}$, if it belongs to $\mathcal{L}(C^{1+\alpha}(\mathbb{S}^1), C^{k+\alpha}(\mathbb{S}^1))$, $k \in \{1,2\}$. In the next proposition we show that, with our choice of ω, relation (15) holds; i.e., for $\operatorname{Re}\lambda \geq \omega$ it follows that λ belongs to the resolvent set $\varrho(-\partial\Phi(c))$ of the operator $-\partial\Phi(c)$.

PROPOSITION 2.5.

$$\{\lambda \in \mathbb{C} \,:\, \operatorname{Re}\lambda \geq \omega\} \subset \varrho(-\partial\Phi(c)).$$

Proof. It is sufficient to prove that $R(\lambda, -\partial\Phi(c)) \in \mathcal{L}(C^{1+\alpha}(\mathbb{S}^1), C^{2+\alpha}(\mathbb{S}^1))$ for all $\operatorname{Re}\lambda \geq \omega$. Let $\operatorname{Re}\lambda \geq \omega$. Then $R(\lambda, -\partial\Phi(c)) \in \mathcal{L}(C^{1+\alpha}(\mathbb{S}^1), C^{2+\alpha}(\mathbb{S}^1))$, if we have

$$\text{(i)} \quad \sup_{k\in\mathbb{Z}} |k||M_k| < \infty,$$

$$\text{(ii)} \quad \sup_{k\in\mathbb{Z}} |k|^2|M_{k+1} - M_k| < \infty,$$

$$\text{(iii)} \quad \sup_{k\in\mathbb{Z}} |k|^3|M_{k+2} - 2M_{k+1} + M_k| < \infty,$$

where $M_k := 1/(\lambda - \lambda_k)$ (see, e.g., [2] and [14]). The relation

$$\lim_{k\to\infty} \frac{k}{\lambda - \lambda_k} = \frac{1}{\zeta}$$

implies (i). For $k \geq 1$ we have

$$k^2|M_{k+1} - M_k| = \frac{k}{\lambda - \lambda_{k+1}} \frac{k}{\lambda - \lambda_k} |\lambda_{k+1} - \lambda_k| \underset{k\to\infty}{\longrightarrow} \frac{1}{\zeta},$$

because of $\lambda_k - \lambda_{k+1} \to \zeta$. Also

$$k^3|M_{k+2} - 2M_{k+1} + M_k| = \frac{k}{\lambda - \lambda_{k+2}} \frac{k}{\lambda - \lambda_{k+1}} \frac{k}{\lambda - \lambda_k} |\lambda(\lambda_{k+2} - 2\lambda_{k+1} + \lambda_k) + \lambda_k(\lambda_{k+1} - \lambda_{k+2}) + \lambda_{k+2}(\lambda_{k+1} - \lambda_k)|,$$

and $\lambda_{k+2} - 2\lambda_{k+1} + \lambda_k \to 0$, respectively, $\lambda_k(\lambda_{k+1} - \lambda_{k+2}) + \lambda_{k+2}(\lambda_{k+1} - \lambda_k) \to 2\zeta^2$. This completes the proof. □

PROPOSITION 2.6. *There exists $\kappa \geq 1$ such that*

$$|\lambda| \cdot \|R(\lambda, -\partial\Phi(c))\|_{\mathcal{L}(h^{1+\alpha}(\mathbb{S}^1))} \leq \kappa$$

for all $\operatorname{Re}\lambda \geq \omega$.

Proof. Given $h = \sum_{k\in\mathbb{Z}} \widehat{h}(k)e^{ikx} \in h^{1+\alpha}(\mathbb{S}^1)$, we have

$$|\lambda| R(\lambda, -\partial\Phi(c)) \left[\sum_{k\in\mathbb{Z}} \widehat{h}(k)e^{ikx}\right] = \sum_{k\in\mathbb{Z}} M_k^\lambda \widehat{h}(k)e^{ikx},$$

where

$$M_k^\lambda = \frac{|\lambda|}{\lambda - \lambda_k} \quad \forall\, k \in \mathbb{Z},\ \operatorname{Re}\lambda \geq \omega.$$

It suffices to prove (see [2], [14]) that there exist positive constants s_1, s_2, and s_3 such that

$$\text{(i)} \quad \sup_{k\in\mathbb{Z}} |M_k^\lambda| \leq s_1,$$

$$\text{(ii)} \quad \sup_{k\in\mathbb{Z}} |k||M_{k+1}^\lambda - M_k^\lambda| \leq s_2,$$

$$\text{(iii)} \quad \sup_{k\in\mathbb{Z}} |k|^2|M_{k+2}^\lambda - 2M_{k+1}^\lambda + M_k^\lambda| \leq s_3$$

for all $\operatorname{Re}\lambda \geq \omega$. For $\operatorname{Re}\lambda \geq \omega$ and $k \in \mathbb{Z}$ we have $\operatorname{Re}(\lambda - \lambda_k) \geq 1$ and $|\lambda - \lambda_k| \geq |\lambda|$. Thus, (i) holds with $s_1 = 1$. Moreover, for $k \neq 0$, we have $|\lambda - \lambda_k| \geq |\lambda_k|$ for all $\operatorname{Re}\lambda \geq \omega$; hence

$$|k||M_{k+1}^{\lambda} - M_k^{\lambda}| = \frac{|\lambda|}{|\lambda - \lambda_{k+1}|}\frac{|k|}{|\lambda - \lambda_k|}|\lambda_{k+1} - \lambda_k| \leq \frac{|k|}{|\lambda_k|}|\lambda_{k+1} - \lambda_k|,$$

and (ii) holds. For $k \geq 1$ we further have

$$\begin{aligned} k^2|M_{k+2} - 2M_{k+1} + M_k| &= \frac{|\lambda|}{|\lambda - \lambda_{k+2}|}\frac{k}{|\lambda - \lambda_{k+1}|}\frac{k}{|\lambda - \lambda_k|}|\lambda(\lambda_{k+2} - 2\lambda_{k+1} + \lambda_k) \\ &\quad + \lambda_k(\lambda_{k+1} - \lambda_{k+2}) + \lambda_{k+2}(\lambda_{k+1} - \lambda_k)| \\ &\leq \frac{k}{|\lambda_k|}|k(\lambda_{k+2} - 2\lambda_{k+1} + \lambda_k)| \\ &\quad + \frac{k}{|\lambda_k|}\frac{k}{|\lambda_{k+1}|}|\lambda_k(\lambda_{k+1} - \lambda_{k+2}) + \lambda_{k+2}(\lambda_{k+1} - \lambda_k)|. \end{aligned}$$

Taking into account

$$k(\lambda_{k+2} - 2\lambda_{k+1} + \lambda_k) \underset{k\to\infty}{\longrightarrow} 0,$$

and using the symmetry of the coefficients λ_k, we have (iii). ∎

In conclusion, given $c \in \mathbb{R}_{>0}$, we have proved that $-\partial\Phi(c)$ generates a strongly continuous analytic semigroup in $\mathcal{L}(h^{1+\alpha}(\mathbb{S}^1))$. The proof of Theorem 1.1 is similar to that of Theorem 8.1.1 in [13], and the assumptions of this theorem are all satisfied (see also Theorem 2.3).

3. Stability of the equilibria. We want to identify the steady states of this moving boundary problem, i.e., solutions which do not depend on time, and to study their stability. A pair $(u, f) \in buc^{2+\alpha}(\Omega_f) \times \mathcal{V}$ is a stationary solution of the flow (3) iff it is a solution of the free boundary problem

$$\begin{aligned} \operatorname{div}\left(\tfrac{Du}{\overline{\mu}(|Du|^2)}\right) &= 0 \quad \text{in} \quad \Omega_f, \\ \partial_\nu u &= 0 \quad \text{on} \quad \Gamma_0, \\ u &= f \quad \text{on} \quad \Gamma_f, \\ \partial_\nu u &= 0 \quad \text{on} \quad \Gamma_f. \end{aligned} \tag{18}$$

If $f \in \mathcal{V}$ is known, then $u \in buc^{2+\alpha}(\Omega_f)$ is a solution of the Neumann problem

$$\begin{aligned} \operatorname{div}\left(\tfrac{Du}{\overline{\mu}(|Du|^2)}\right) &= 0 \quad \text{in} \quad \Omega_f, \\ \partial_\nu u &= 0 \quad \text{on} \quad \partial\Omega_f. \end{aligned} \tag{19}$$

Thus there exists a constant $c \in \mathbb{R}$ such that $u = c$. The condition $u = f$ on Γ_f, together with $f \in \mathcal{V}$, implies $c \in \mathbb{R}_{>0}$. In conclusion, $(c, c) \in buc^{2+\alpha}(\Omega_c) \times \mathcal{V}$, $c > 0$, are the stationary solutions of the flow (3), or, equivalently, $(c, c) \in buc^{2+\alpha}(G) \times \mathcal{V}$, $c > 0$, are the stationary solutions of the flow (7).

Let $c \in \mathbb{R}_{>0}$ be given. We want to identify the spectrum of the operator $-\partial\Phi(c)$. Of course, we have

$$\{\lambda_k \,:\, k \in \mathbb{N}\} \subset \sigma_p(-\partial\Phi(c)) \subset \sigma(-\partial\Phi(c)).$$

Using a similar argument as in Proposition 2.5, one can in fact show that

$$\{\lambda_k \,:\, k \in \mathbb{N}\} = \sigma_p(-\partial\Phi(c)) = \sigma(-\partial\Phi(c)).$$

Thus, the spectrum of $-\partial\Phi(c)$ contains just eigenvalues. The largest eigenvalue is $\lambda_0 = 0$. This eigenvalue is simple and has a one-dimensional eigenspace consisting of constant functions. All other eigenvalues λ_k, $k \geq 1$, have a two-dimensional eigenspace spanned by $\{e^{ikx}, e^{-ikx}\}$. Compared to [5], the analysis is more involved here, since we have to take the eigenvalue $\lambda_0 = 0$ into consideration.

In order to prove the stability we transfer problem (9) into a neighborhood of the origin in $h^{2+\alpha}(\mathbb{S}^1)$. Let $\mathcal{V}_c := \mathcal{V} - c$. Then $\mathcal{V}_c$ is an open neighborhood of the origin in $h^{2+\alpha}(\mathbb{S}^1)$. We define $\psi : \mathcal{V}_c \to h^{1+\alpha}(\mathbb{S}^1)$ by $\psi(f) := -\Phi(f + c)$ and consider the following Cauchy problem:

$$\partial_t f = \psi(f), \qquad f(0) = f_0. \tag{20}$$

We have $\psi(0) = -\Phi(c) = 0$ and $\partial\psi(0) = -\partial\Phi(c)$. Thus, 0 is a stationary solution of (20), and there exists a one-to-one correspondence between solutions to (9) and (20). Namely, if f is a solution to (20) corresponding to the initial data $f_0 \in \mathcal{V}_c$, then $f + c$ is the solution to (9) corresponding to $f_0 + c \in \mathcal{V}$. Conversely, if f is a solution to (9) corresponding to the initial data $f_0 \in \mathcal{V}$, then $f - c$ is the solution to (20) corresponding to $f_0 - c \in \mathcal{V}_c$.

Hence, instead of studying the stability of the steady state c for (9), we study the stability of 0 for (20). Note that 0 is an eigenvalue of the derivative $\partial\psi(0)$. Moreover, the null solution is not asymptotically stable because each neighborhood of 0 in $\mathcal{V}_c$ contains constants, which are also steady states of this flow.

However, it is inappropriate to pose the problem in this way because, as the next lemma shows, we have conservation of the fluid volume.

We introduce first some notation. Define by $\widetilde{h}^{k+\alpha}(\mathbb{S}^1)$, $k \in \{1, 2\}$, the closure of the set of all smooth functions on $\mathbb{S}^1$ with mean 0 in $C^{k+\alpha}(\mathbb{S}^1)$. We have defined in this way closed subspaces of the little Hölder spaces. It is obvious that

$$\widetilde{h}^{2+\alpha}(\mathbb{S}^1) \overset{d}{\hookrightarrow} \widetilde{h}^{1+\alpha}(\mathbb{S}^1) \quad \text{and} \quad \widetilde{h}^{k+\alpha}(\mathbb{S}^1) = \left\{ f \in h^{k+\alpha}(\mathbb{S}^1) \,:\, \int_{\mathbb{S}^1} f\,dx = 0 \right\},\ k \in \{1, 2\}.$$

Further, let $\widetilde{\mathcal{V}} := \mathcal{V}_c \cap \widetilde{h}^{2+\alpha}(\mathbb{S}^1)$.

LEMMA 3.1 (conservation of volume). *Given $g \in \widetilde{\mathcal{V}}$, we have $\psi(g) \in \widetilde{h}^{1+\alpha}(\mathbb{S}^1)$.*

Proof. Let $g + c = f \in \mathcal{V}$ and denote by u the solution of (6). We have

$$\begin{aligned}
\int_{\mathbb{S}^1} \psi(g)dx &= -\int_{\mathbb{S}^1} \Phi(f)dx = -\int_{\mathbb{S}^1} \mathcal{B}(f, \mathcal{T}(f))dx \\
&= -\int_{\mathbb{S}^1} \frac{Du}{\overline{\mu}(|Du|^2)}(x, f(x)) \cdot n(x)\, dx = -\int_{\Gamma_f} \frac{\partial_\nu u}{\overline{\mu}(|Du|^2)}\, d\sigma \\
&= -\int_{\Omega_f} \operatorname{div}\left(\frac{Du}{\overline{\mu}(|Du|^2)}\right) dx + \int_{\Gamma_0} \frac{\partial_\nu u}{\overline{\mu}(|Du|^2)}\, d\sigma = 0. \qquad \square
\end{aligned}$$

We consider now the restriction $\widetilde{\psi}$ of ψ to $\widetilde{\mathcal{V}}$. From Lemma 3.1 and Theorem 2.3 we conclude that $\widetilde{\psi} \in C^\infty(\widetilde{\mathcal{V}}, \widetilde{h}^{1+\alpha}(\mathbb{S}^1))$. Given $h = \sum_{k\in\mathbb{Z}} \widehat{h}(k)e^{ikx} \in \widetilde{h}^{2+\alpha}(\mathbb{S}^1))$ we have

$$\partial\widetilde{\psi}(0)\left[\sum_{k\in\mathbb{Z}} \widehat{h}(k)e^{ikx}\right] = \sum_{k\in\mathbb{Z}} \lambda_k \widehat{h}(k)e^{ikx},$$

where the coefficients (λ_k) are given by (14).

THEOREM 3.2. *Consider $\partial\widetilde{\psi}(0)$ as an unbounded operator in $\widetilde{h}^{1+\alpha}(\mathbb{S}^1)$ with dense domain $\widetilde{h}^{2+\alpha}(\mathbb{S}^1)$. Then*

$$\sigma(\partial\widetilde{\psi}(0)) = \{\lambda_k \,:\, k \geq 1\}, \tag{21}$$

$$|\lambda| \cdot \|R(\lambda, -\partial\widetilde{\psi}(0))\|_{\mathcal{L}(\widetilde{h}^{1+\alpha}(\mathbb{S}^1))} \leq \kappa \quad \forall\, \mathrm{Re}\,\lambda \geq \omega, \tag{22}$$

where κ and ω are the constants from Proposition 2.6.

Proof. Given $\lambda \in \varrho(\partial\psi(0))$ and $h = \sum_{k\in\mathbb{Z}} \widehat{h}(k)e^{ikx} \in \widetilde{h}^{1+\alpha}(\mathbb{S}^1)$ there exists a unique

$$u = \sum_{k\in\mathbb{Z}} \frac{1}{\lambda - \lambda_k}\widehat{h}(k)e^{ikx} \in h^{2+\alpha}(\mathbb{S}^1),$$

such that $(\lambda - \partial\psi(0))u = h$. Since $\widehat{h}(0) = 0$ we conclude that $\widehat{u}(0) = 0$; thus $u \in \widetilde{h}^{2+\alpha}(\mathbb{S}^1)$ and $\lambda \in \varrho(\partial\widetilde{\psi}(0))$. Moreover, $\partial\widetilde{\psi}(0) \in \mathcal{L}is(\widetilde{h}^{2+\alpha}(\mathbb{S}^1), \widetilde{h}^{1+\alpha}(\mathbb{S}^1))$ and (21) holds. Relation (22) follows from Proposition 2.6, using the fact that

$$(\lambda - \partial\psi(0))[h] = (\lambda - \partial\widetilde{\psi}(0))[h],$$

for all $h \in \widetilde{h}^{2+\alpha}(\mathbb{S}^1)$ and $\mathrm{Re}\,\lambda \geq \omega$. □

In conclusion $-\partial\widetilde{\psi}(0)$ belongs to $\mathcal{H}(\widetilde{h}^{2+\alpha}(\mathbb{S}^1), \widetilde{h}^{1+\alpha}(\mathbb{S}^1)$, and therefore, if the initial value f_0 in (20) belongs to $\widetilde{h}^{2+\alpha}(\mathbb{S}^1)$, then the evolution takes place in $\widetilde{h}^{2+\alpha}(\mathbb{S}^1)$. We have the following stability result for the flow (3).

THEOREM 3.3 (exponential stability). *For any $\omega < -\lambda_1 = \tanh c/\overline{\mu}(0)$, there are positive constants r and C such that for any $f_0 \in c + \widetilde{h}^{2+\alpha}(\mathbb{S}^1)$ with $\|f_0 - c\|_{C^{2+\alpha}(\mathbb{S}^1)} \leq r$ the solution to* (3) *exists globally in time and the estimate*

$$\|f(t) - c\|_{C^{2+\alpha}(\mathbb{S}^1)} + \|f'(t)\|_{C^{1+\alpha}(\mathbb{S}^1)} \leq Ce^{-\omega t}\|f_0 - c\|_{C^{2+\alpha}(\mathbb{S}^1)} \quad \forall t \geq 0$$

holds.

Proof. Transferring problem (9) into a neighborhood of 0 in $\widetilde{h}^{2+\alpha}(\mathbb{S}^1)$ we find that all of the assumptions of Theorem 9.1.2 in [13] are satisfied (cf. Theorem 3.2). The result follows directly from this theorem. □

CONVERGENCE TO EQUILIBRIUM FOR PARABOLIC-HYPERBOLIC TIME-DEPENDENT GINZBURG–LANDAU–MAXWELL EQUATIONS*

MAURIZIO GRASSELLI†, HAO WU‡, AND SONGMU ZHENG§

Abstract. We consider a Ginzburg–Landau–Maxwell model which describes the behavior of a two-dimensional superconducting material. The state variables are the complex-valued order parameter ψ, the magnetic potential $\tilde{\mathbf{A}}$, and the electric potential Φ. Under the choice of Coulomb (i.e., London) gauge, the resulting system is a parabolic-hyperbolic coupled system of nonlinear partial differential equations subject to suitable boundary and initial conditions. Global well-posedness results were proved in [M. Tsutsumi and H. Kasai, *Nonlinear Anal.*, 37 (1999), pp. 187–216], while the existence of global attractor and exponential attractors was proved in [V. Berti and S. Gatti, *Quart. Appl. Math.*, 64 (2006), pp. 617–639]. In this paper we use an extended Łojasiewicz–Simon approach to show that for any initial datum in certain phase space, the corresponding global solution converges to an equilibrium as time goes to infinity. Besides, we also provide an estimate on the convergence rate with respect to the phase space metric.

Key words. Ginzburg–Landau–Maxwell equations, superconductivity, Coulomb gauge, convergence to equilibrium, Łojasiewicz–Simon inequality

1. Introduction.

This paper is concerned with the asymptotic behavior of solutions to a two-dimensional Ginzburg–Landau–Maxwell model of superconductivity proposed in [27] (see also [2, 13, 32]). When a superconducting material is kept close to a certain critical temperature, its behavior can be macroscopically described, within the Ginzburg–Landau phase transition theory (see [18] and its references, cf. also [8, Chapter 11]), by the state variables $(\psi, \tilde{\mathbf{A}}, \Phi)$. Here ψ is the complex order parameter, whose squared modulus represents the concentration of the superconducting electrons, while $\tilde{\mathbf{A}}$ and Φ are the magnetic and the electric potentials, respectively.

On account of [32], we introduce the equations governing the evolution of $(\psi, \tilde{\mathbf{A}}, \Phi)$. Suppose that the material occupies a bounded domain $\Omega \subset \mathbb{R}^2$ with smooth boundary Γ for any time $t \geq 0$. Then the state variables $\psi : \Omega \times (0,\infty) \to \mathbb{C}$, $\tilde{\mathbf{A}} : \Omega \times (0,\infty) \to \mathbb{R}^2$ and $\Phi : \Omega \times (0,\infty) \to \mathbb{R}$ satisfy the following equations:

$$\psi_t - i\Phi\psi - D_{\tilde{\mathbf{A}}}^2\psi - \lambda^2\left(1 - |\psi|^2\right)\psi = 0, \tag{1.1}$$

$$\varepsilon\left(\tilde{\mathbf{A}}_t - \nabla\Phi\right)_t + \sigma\left(\tilde{\mathbf{A}}_t - \nabla\Phi\right) + \mathrm{curl}^2\tilde{\mathbf{A}} + \frac{i}{2}\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi - \psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right) + \mathrm{curl}\mathbf{H}_{ext} = 0, \tag{1.2}$$

in $\Omega \times (0,\infty)$, subject to the boundary conditions

$$D_{\tilde{\mathbf{A}}}\psi\cdot\mathbf{n} = 0, \quad \left(\mathrm{curl}\tilde{\mathbf{A}} + \mathbf{H}_{ext}\right)\times\mathbf{n} = 0, \quad \left(\tilde{\mathbf{A}}_t - \nabla\Phi\right)\cdot\mathbf{n} = 0, \quad \text{on } \Gamma\times(0,\infty), \tag{1.3}$$

where

$$D_{\tilde{\mathbf{A}}}\psi = \nabla\psi - i\tilde{\mathbf{A}}\psi, \quad D^2_{\tilde{\mathbf{A}}}\psi = \Delta\psi - 2i\tilde{\mathbf{A}}\cdot\nabla\psi - i\psi\nabla\cdot\tilde{\mathbf{A}} - |\tilde{\mathbf{A}}|^2\psi. \tag{1.4}$$

Here $\mathbf{H}_{ext}$ is the external magnetic field, which is assumed to be time independent for the sake of simplicity throughout this paper; the positive constants λ, ε, and σ represent the Ginzburg–Landau parameter, the dielectric coefficient, and the electric conductivity, respectively, and $\mathbf{n}$ denotes the unit outward normal to the boundary Γ.

We recall that (1.2) is derived from Maxwell's equations. In the so-called quasi-steady approximation, namely, when the displacement current $\varepsilon(\tilde{\mathbf{A}}_t - \nabla\Phi)_t$ is negligible, we obtain the well-known system proposed by Gor'kov and Èliashberg [13], which has been widely studied in the literature (see, e.g., [7, 9, 11, 18, 19, 22, 23, 24, 26, 27, 29, 30, 33] and reference therein). However, if surface charge must be taken into account, then the displacement current cannot be neglected (see [2]).

Similarly to the classical time-dependent Ginzburg–Landau equations, the evolution equations (1.1)–(1.2) and the boundary conditions (1.3) are invariant under the gauge transformation:

$$\mathcal{T}_\chi : \left(\psi, \tilde{\mathbf{A}}, \Phi\right) \longmapsto \left(\psi e^{i\chi}, \tilde{\mathbf{A}} + \nabla\chi, \Phi + \chi_t\right). \tag{1.5}$$

The gauge χ can be any (smooth) real scalar-valued function depending on x and t. In [3, 32], the authors choose the Coulomb gauge (also known as the London gauge). This choice entails that the following identities hold:

$$\mathrm{div}\tilde{\mathbf{A}} = 0 \quad \text{in } \Omega, \quad \int_\Omega \Phi dx = 0, \tag{1.6}$$

$$\tilde{\mathbf{A}}\cdot\mathbf{n} = 0, \quad \partial_{\mathbf{n}}\Phi = 0, \quad \text{on } \Gamma. \tag{1.7}$$

For the existence of the gauge χ corresponding to (1.6) and (1.7), one may refer, e.g., to [23, Lemma 2.2, Remark 2.4] where even more general cases have been discussed (see also [18, section 1.4.4]). Using the Coulomb gauge, $\tilde{\mathbf{A}}$ is a solenoidal vector field so that

$$D^2_{\tilde{\mathbf{A}}}\psi = \Delta\psi - 2i\tilde{\mathbf{A}}\cdot\nabla\psi - \left|\tilde{\mathbf{A}}\right|^2\psi. \tag{1.8}$$

Moreover, system (1.1)–(1.2) is subject to the boundary conditions (cf. (1.3), (1.7))

$$\partial_{\mathbf{n}}\psi = 0, \quad \tilde{\mathbf{A}}\cdot\mathbf{n} = 0, \quad \left(\mathrm{curl}\tilde{\mathbf{A}} + \mathbf{H}_{ext}\right)\times\mathbf{n} = 0, \quad \text{on } \Gamma\times(0,\infty). \tag{1.9}$$

It will be more convenient to treat problem (1.1), (1.2), (1.9) in a homogeneous form. For this purpose, we consider the following boundary value problem:

$$\begin{cases} \mathrm{curl}^{\,2}\mathbf{A}_{ext} = \mathrm{curl}\mathbf{H}_{ext}, & \mathrm{div}\mathbf{A}_{ext} = 0, & \text{in } \Omega, \\ \mathbf{A}_{ext}\cdot\mathbf{n} = 0, & (\mathrm{curl}\mathbf{A}_{ext} - \mathbf{H}_{ext})\times\mathbf{n} = 0, & \text{on } \Gamma. \end{cases} \tag{1.10}$$

Throughout this paper we always assume that $\mathbf{H}_{ext} \in H^1$. Then, it is easy to see that the convex quadratic functional

$$J(\mathbf{A}) = \int_\Omega |\mathrm{curl}\mathbf{A} - \mathbf{H}_{ext}|^2 dx \tag{1.11}$$

on the domain

$$\mathcal{D} := \left\{\mathbf{A}\in\mathbf{H}^{\,1}(\Omega) :\ \mathrm{div}\mathbf{A} = 0 \ \text{ in } \Omega, \ \ \mathbf{A}\cdot\mathbf{n}|_\Gamma = 0\right\} \tag{1.12}$$

admits a unique minimizer $\mathbf{A}_{ext} \in \mathcal{D}$, which is the (unique) solution to (1.10). The linear mapping $\mathbf{H}_{ext} \to \mathbf{A}_{ext}$ is continuous from $\mathbf{H}^{\alpha}(\Omega)$ to $\mathbf{H}^{\alpha+1}(\Omega)$ for $0 \le \alpha \le 1$ (see [11, Lemma 3, Lemma 4]; cf. also [9]).

Set now

$$\mathbf{A} = \tilde{\mathbf{A}} + \mathbf{A}_{ext}. \tag{1.13}$$

Then the Ginzburg–Landau–Maxwell equations (1.1) and (1.2) can be reduced to the following homogeneous form in terms of ψ and $\mathbf{A}$ (cf. [3,32]):

$$\psi_t - i\Phi\psi - D^2_{\tilde{\mathbf{A}}}\psi - \lambda^2\left(1 - |\psi|^2\right)\psi = 0, \tag{1.14}$$

$$\varepsilon(\mathbf{A}_t - \nabla\Phi)_t + \sigma(\mathbf{A}_t - \nabla\Phi) + \mathrm{curl}^2\mathbf{A} + \frac{i}{2}\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi - \psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right) = 0. \tag{1.15}$$

By applying the spatial divergence operator to (1.15) and taking (1.14) into account, we obtain the evolution equation for Φ, namely,

$$-\varepsilon\Delta\Phi_t - \sigma\Delta\Phi + \frac{i}{2}\left(\overline{\psi}\psi_t - \psi\overline{\psi}_t\right) + |\psi|^2\Phi = 0. \tag{1.16}$$

Moreover, we have (see (1.5))

$$\mathrm{div}\mathbf{A} = 0 \quad \text{in } \Omega, \quad \int_{\Omega}\Phi dx = 0, \tag{1.17}$$

and (1.14)–(1.17) are subject to the homogeneous boundary conditions (cf. (1.7)–(1.10))

$$\partial_{\mathbf{n}}\psi = 0, \quad \mathbf{A}\cdot\mathbf{n} = 0, \quad \mathrm{curl}\mathbf{A}\times\mathbf{n} = 0, \quad \partial_{\mathbf{n}}\Phi = 0, \quad \text{on } \Gamma\times(0,\infty), \tag{1.18}$$

as well as to the initial conditions

$$\psi|_{t=0} = \psi_0, \quad \mathbf{A}|_{t=0} = \mathbf{A}_0, \quad \mathbf{A}_t|_{t=0} = \mathbf{A}_1, \quad \Phi|_{t=0} = \Phi_0, \quad \text{in } \Omega \tag{1.19}$$

for some given initial data.

The main concern of this paper is the convergence to equilibrium of the solution to problem (1.14)–(1.19) as time goes to infinity. In what follows we recall related results in the literature on problem (1.14)–(1.19). The global well-posedness of problem (1.14)–(1.19) has been carefully investigated in [32] in both two and three dimensions, even though, physically speaking, the present model is essentially two-dimensional (see [18, sections 1.5, 1.6, 1.8]; cf. also [5,23]). The results of [32] are also concerned with the case $\varepsilon = 0$, which has been studied by many other authors (see, e.g., [18,23, 26,29,30,33] and references therein). Regarding the large time behavior of solutions, problem (1.14)–(1.19) has recently been analyzed in [3] within the theory of infinite-dimensional dissipative dynamical systems. In that paper the authors show that the quoted problem generates a strongly continuous semigroup which possesses the global attractor and an exponential attractor. However, the issue of convergence to equilibrium for single solutions to problem (1.14)–(1.19) has not been studied in [3]. This is the goal of the present contribution. More precisely, we will prove that, for any initial datum in the phase space introduced in [3], the corresponding global solution to (1.14)–(1.19) converges to a single equilibrium as time goes to infinity. Besides, an estimate of the convergence rate in the phase space metric will also be given. The key ingredients of the present paper can be summarized as follows:

(I) Since (1.15) is hyperbolic, we can no longer take advantage of the smoothing effects for solutions to parabolic equations like, e.g., in [9] where the Lorentz gauge is used. Instead, we will use a result proved in [3] to show the precompactness of solutions.

(II) We need to develop an extended Łojasiewicz–Simon approach for which it is necessary to establish a suitable Łojasiewicz–Simon-type inequality. Such an inequality is a suitable adaptation of the one proved in [9] for a problem similar to ours with $\varepsilon = 0$ but subject to the Lorentz gauge $\Phi = -\omega(\nabla \cdot \mathbf{A})$, with ω being a nonnegative constant (for $\omega = 0$, see also [24]).

(III) Due to the hyperbolic nature of (1.15), the standard Łojasiewicz–Simon approach used in the parabolic case must be modified by introducing an appropriate auxiliary functional $\mathfrak{F}$ (see section 5), which usually depends on the problem under consideration (see, e.g., [15, 19, 35] and references therein for similar problems).

(IV) In the existing literature the convergence rate in a (lower order) norm is usually obtained directly by using the Łojasiewicz–Simon approach (see, e.g., [9, 17, 36]). Then, estimates in higher order norms can be deduced by means of interpolation inequalities (cf. [17]) and, consequently, the decay exponent deteriorates. On the contrary, in this paper and some earlier papers by the authors, using the original equations and suitable energy estimates and constructing proper differential inequalities, we are able to preserve the original convergence rate when we estimate the convergence with respect to the phase space metric. This technique has been successfully applied to other equations as well (see, e.g., [14, 34, 35, 36]).

In [9] (see also [19]) the convergence to single equilibria for the case $\varepsilon = 0$ has been investigated in detail in the hypothesis of a time-dependent applied magnetic field and using the Lorentz gauge. The present contribution is a first step towards a more comprehensive analysis of the case $\varepsilon > 0$. The corresponding results for other widely used gauges (e.g., the Lorentz gauge) as well as for the case of a time-dependent applied magnetic field will be considered in the near future. We recall that the choice of the gauge plays an important role in the mathematical treatment of these models (see [10] and references therein).

This paper is organized as follows. In section 2 we introduce the notation and state the main results of this paper. Section 3 contains some preliminary results on the time-dependent Ginzburg–Landau–Maxwell model. In section 4 we state a suitable version of a Łojasiewicz–Simon-type inequality. The last two sections are devoted to the proof of our main results. More precisely, in section 5 we prove the convergence to a single equilibrium, while in section 6, we establish the convergence rate estimate.

2. Notation and main results. We use the notation introduced in [32] (see also [3]). As usual, $L^p(\Omega)$ and $W^{k,p}(\Omega)$ stand for the Lebesgue and the Sobolev spaces of real-valued functions, with the convention that $H^k(\Omega) = W^{k,2}(\Omega)$. We denote by bold letters the spaces of vector-valued functions, whereas a subscript $\mathbb{C}$ characterizes those of complex-valued functions. Without further specifications, $\|\cdot\|$ stands for the norm in $L^2_{\mathbb{C}}(\Omega), \mathbf{L}^2(\Omega)$, or $L^2(\Omega)$, according to the context. This norm is always induced by the scalar inner product

$$\langle u, v\rangle = \int_\Omega u(x)\overline{v}(x)dx,$$

where for a vector-valued function, the product $u\overline{v}$ is replaced by the Euclidean inner product $\mathbf{u}\cdot\overline{\mathbf{v}}$. Next, we introduce the function spaces

$$\mathbf{X} = \left\{\mathbf{u} \in \mathbf{H}^2(\Omega) :\ \mathrm{div}\mathbf{u} = 0 \text{ in } \Omega,\ \ \mathbf{u}\cdot\mathbf{n}|_\Gamma = 0,\ \ \mathrm{curl}\mathbf{u}\times\mathbf{n}|_\Gamma = \mathbf{0}\right\} \tag{2.1}$$

equipped with the usual $\mathbf{H}^2(\Omega)$ norm. Let $\mathbf{X}_0$ be the completion of $\mathbf{X}$ in $\mathbf{H}^1(\Omega)$ and

$$H^1_{0m}(\Omega) = \left\{ u \in H^1(\Omega) : \int_\Omega u dx = 0 \right\},$$
$$H^2_{0m}(\Omega) = \left\{ u \in H^2(\Omega) : \partial_{\mathbf{n}} u|_\Gamma = 0, \int_\Omega u dx = 0 \right\}.$$

We can thus define the phase space we shall work with:

$$\mathbb{X}^0_\infty = \left\{ \psi \in H^2_{\mathbb{C}}(\Omega) : \partial_{\mathbf{n}} \psi|_\Gamma = 0, \ \|\psi\|_{L^\infty_{\mathbb{C}}(\Omega)} \le 1 \right\} \times \mathbf{X} \times \mathbf{X}_0 \times H^2_{0m}(\Omega), \tag{2.2}$$

which is a closed subset of the Banach space

$$\mathbb{X}^0 = \left\{ \psi \in H^2_{\mathbb{C}}(\Omega) : \partial_{\mathbf{n}} \psi|_\Gamma = 0 \right\} \times \mathbf{X} \times \mathbf{X}_0 \times H^2_{0m}(\Omega). \tag{2.3}$$

The norm on $\mathbb{X}^0$ is defined by

$$\|z\|_0^2 = \|z_1\|^2_{H^2_{\mathbb{C}}(\Omega)} + \|\mathbf{z}_2\|^2_{\mathbf{H}^2(\Omega)} + \|\mathbf{z}_3\|^2_{\mathbf{H}^1(\Omega)} + \|z_4\|^2_{H^2(\Omega)} \tag{2.4}$$

for any $z = (z_1, \mathbf{z}_2, \mathbf{z}_3, z_4) \in \mathbb{X}^0$. We also introduce the Banach space

$$\mathbb{X}^{-1} = H^1_{\mathbb{C}}(\Omega) \times \mathbf{X}_0 \times \mathbf{L}^2(\Omega) \times H^1_{0m} \supset \mathbb{X}^0, \tag{2.5}$$

endowed with the norm

$$\|z\|_{-1}^2 = \|z_1\|^2_{H^1_{\mathbb{C}}(\Omega)} + \|\mathbf{z}_2\|^2_{\mathbf{H}^1(\Omega)} + \|\mathbf{z}_3\|^2_{\mathbf{L}^2(\Omega)} + \|z_4\|^2_{H^1(\Omega)} \tag{2.6}$$

for any $z = (z_1, \mathbf{z}_2, \mathbf{z}_3, z_4) \in \mathbb{X}^{-1}$.

In what follows, we will make use of the Gagliardo–Nirenberg inequalities in dimension two, namely,

$$\|u\|^2_{L^4(\Omega)} \le C\|u\|\|u\|_{H^1(\Omega)} \qquad \forall\ u \in H^1(\Omega), \tag{2.7}$$

$$\|u\|^2_{L^\infty(\Omega)} \le C\|u\|\|u\|_{H^2(\Omega)} \qquad \forall\ u \in H^2(\Omega), \tag{2.8}$$

where $C > 0$ depends only on Ω.

We also recall that there exist constants $\kappa > 0$ and $c > 0$ depending only on Ω such that (see, e.g., [25, Corollary 3.51])

$$\|\mathbf{A}\| \le \kappa \|\mathrm{curl}\mathbf{A}\| \qquad \forall\ \mathbf{A} \in \mathbf{X}_0, \tag{2.9}$$

and (cf. [12, Chapter I, (5.45), p. 92] also [32, section 2])

$$\|\mathbf{A}\|_{\mathbf{H}^1(\Omega)} \le c\|\mathrm{curl}\mathbf{A}\| \qquad \forall\ \mathbf{A} \in \mathbf{X}_0. \tag{2.10}$$

In the remaining part of the paper, we always assume that

$$\mathbf{A}_{ext} \in \mathbf{X}_0 \cap \mathbf{H}^2(\Omega). \tag{2.11}$$

We now recall the following result.

PROPOSITION 2.1 ([3, Theorem 2.1, Proposition 3.1]). *Denote* $z_0 = (\psi_0, \mathbf{A}_0, \mathbf{A}_1, \Phi_0) \in \mathbb{X}^0$. *Problem* (1.14)–(1.19) *generates a strongly continuous semigroup* $\{S(t)\}_{t\ge 0}$

on the space $\mathbb{X}^0$. *If* $z_0 = (\psi_0, \mathbf{A}_0, \mathbf{A}_1, \Phi_0) \in \mathbb{X}^0_\infty$, *then* $S(t)z_0 \in \mathbb{X}^0_\infty$. *Moreover, there exists a positive constant* C *depending only on* $\|z_0\|_0$ *such that*

$$\|S(t)z_0\|_0 \le C \qquad \forall\ t \ge 0. \tag{2.12}$$

The stationary problem corresponding to (1.14)–(1.19) is

$$-(\nabla - i(\mathbf{A}_\infty - \mathbf{A}_{ext}))^2\psi_\infty - \lambda^2\left(1 - |\psi_\infty|^2\right)\psi_\infty = 0, \tag{2.13}$$

$$\mathrm{curl}^2\mathbf{A}_\infty + \frac{i}{2}\left(\overline{\psi}_\infty\nabla\psi_\infty - \psi_\infty\nabla\overline{\psi}_\infty\right) + |\psi|^2(\mathbf{A}_\infty - \mathbf{A}_{ext}) = 0, \tag{2.14}$$

$$\mathrm{div}\mathbf{A}_\infty = 0, \tag{2.15}$$

$$\partial_{\mathbf{n}}\psi_\infty = 0, \quad \mathbf{A}_\infty\cdot\mathbf{n} = 0, \quad \mathrm{curl}\mathbf{A}_\infty\times\mathbf{n} = 0, \quad \text{on } \Gamma, \tag{2.16}$$

$$\Phi_\infty = 0. \tag{2.17}$$

Set now

$$\mathbf{A}_\infty = \tilde{\mathbf{A}}_\infty + \mathbf{A}_{ext}. \tag{2.18}$$

Then problem (2.13)–(2.17) becomes

$$-\left(\nabla - i\tilde{\mathbf{A}}_\infty\right)^2\psi_\infty - \lambda^2\left(1 - |\psi_\infty|^2\right)\psi_\infty = 0, \tag{2.19}$$

$$\mathrm{curl}^2\tilde{\mathbf{A}}_\infty + \frac{i}{2}\left(\overline{\psi}_\infty\nabla\psi_\infty - \psi_\infty\nabla\overline{\psi}_\infty\right) + |\psi_\infty|^2\tilde{\mathbf{A}}_\infty + \mathrm{curl}\mathbf{H}_{ext} = 0, \tag{2.20}$$

$$\mathrm{div}\tilde{\mathbf{A}}_\infty = 0, \tag{2.21}$$

$$\partial_{\mathbf{n}}\psi_\infty = 0, \quad \tilde{\mathbf{A}}_\infty\cdot\mathbf{n} = 0, \quad \left(\mathrm{curl}\tilde{\mathbf{A}}_\infty + \mathbf{H}_{ext}\right)\times\mathbf{n} = 0, \quad \text{on } \Gamma, \tag{2.22}$$

and

$$\Phi_\infty = 0. \tag{2.23}$$

Define the functional

$$\begin{aligned}\mathcal{E}_0\left(\psi_\infty, \tilde{\mathbf{A}}_\infty\right) = \int_\Omega \Bigg[&\frac{\lambda^2}{4}\left(1 - |\psi_\infty|^2\right)^2 + \frac{1}{2}\left|\left(\nabla - i\tilde{\mathbf{A}}_\infty\right)\psi_\infty\right|^2 \\ &+ \frac{1}{2}\left|\mathrm{curl}\tilde{\mathbf{A}}_\infty + \mathbf{H}_{ext}\right|^2\Bigg]dx,\end{aligned} \tag{2.24}$$

on $H^1_{\mathbb{C}}\times\mathbf{X}_0$. It is easy to see that a critical point $(\psi_\infty, \tilde{\mathbf{A}}_\infty)$ of $\mathcal{E}_0$ is a weak solution of (2.19)–(2.22). This stationary problem embodies the macroscopic quantum-mechanical nature of the superconducting state. There are many works on the stationary Ginzburg–Landau equations. For instance, the existence of vortex-like solutions to the time-independent Ginzburg–Landau equations was proved in [24]. An existence result for the stationary problem of the Ginzburg–Landau–Maxwell equations with Coulomb gauge in the L^p framework was recently given in [1]. An equivalence relation between solutions of the time-independent and time-dependent Ginzburg–Landau equations that describe the same physical state of a superconductor was established in [21].

We are now in a position to state our main theorem.

THEOREM 2.1. *For any initial datum* $z_0 = (\psi_0, \mathbf{A}_0, \mathbf{A}_1, \Phi_0) \in \mathbb{X}^0_\infty$, *the global solution* $z(t) = (\psi(t), \mathbf{A}(t), \mathbf{A}_t(t), \Phi(t))$ *to problem* (1.14)–(1.19) *converges in* $\mathbb{X}^0$ *to a unique equilibrium* $z_\infty = (\psi_\infty, \mathbf{A}_\infty, \mathbf{0}, 0)$, *where* $(\psi_\infty, \mathbf{A}_\infty)$ *satisfies* (2.13)–(2.16). *Moreover, the following estimate holds:*

$$\|z(t) - z_\infty\|_0 \le C(1+t)^{-\theta/(1-2\theta)} \qquad \forall\ t \ge 0, \tag{2.25}$$

where $C > 0$ *is a constant depending only on* $\|z_0\|_0$ *and* $\theta \in (0, \frac{1}{2})$ *depends on* z_∞.

Remark 2.1. We recall that θ is the so-called Łojasiewicz exponent (see Lemma 4.2 below). Note that the convergence rate is estimated in the same norm where convergence takes place. This requires some work (see section 6).

3. Preliminaries. In this section we first recall the basic results proven in [3], which entail the precompactness of the trajectory originated from an initial datum in $\mathbb{X}^0_\infty$.

Let

$$\mathbb{X}^1 = H^3_{\mathbb{C}}(\Omega) \times \left[\mathbf{X} \cap \mathbf{H}^3(\Omega)\right] \times \mathbf{X} \times \left[H^2_{0m}(\Omega) \cap H^3(\Omega)\right], \tag{3.1}$$

with the standard norm defined by

$$\|z\|_1^2 = \|z_1\|^2_{H^3_{\mathbb{C}}(\Omega)} + \|\mathbf{z}_2\|^2_{\mathbf{H}^3(\Omega)} + \|\mathbf{z}_3\|^2_{\mathbf{H}^2(\Omega)} + \|z_4\|^2_{H^3(\Omega)} \tag{3.2}$$

for any $z = (z_1, \mathbf{z}_2, \mathbf{z}_3, z_4) \in \mathbb{X}^1$.

For any given $z_0 \in \mathbb{X}^0_\infty$, let $z(t) = S(t)z_0$ be the solution to problem (1.14)–(1.19). Following [3, section 4], in order to prove the precompactness of $z(t)$, we make a decomposition of the solution z into a uniformly stable part z_d which decays to zero and a compact part z_c, that is,

$$z(t) = z_d(t) + z_c(t). \tag{3.3}$$

Here $z_d(t) = (\psi^d(t), \mathbf{A}^d(t), \mathbf{A}^d_t(t), \Phi^d(t))$ solves

$$\begin{cases} \psi^d_t - \Delta\psi^d + \psi^d = 0, \\ \varepsilon\left(\mathbf{A}^d_t - \nabla\Phi^d\right)_t + \sigma\left(\mathbf{A}^d_t - \nabla\Phi^d\right) + \operatorname{curl}^2\mathbf{A}^d = 0, \\ -\varepsilon\Delta\Phi^d_t - \sigma\Delta\Phi^d = 0, \\ \operatorname{div}\mathbf{A}^d = 0, \quad \int_\Omega \Phi^d = 0, \\ \partial_{\mathbf{n}}\psi^d\big|_\Gamma = 0, \quad \mathbf{A}^d\cdot\mathbf{n}\big|_\Gamma = 0, \ \operatorname{curl}\mathbf{A}^d\times\mathbf{n}\big|_\Gamma = 0, \quad \partial_{\mathbf{n}}\Phi^d\big|_\Gamma = 0, \\ \psi^d(0) = \psi_0, \quad \mathbf{A}^d(0) = \mathbf{A}_0, \quad \mathbf{A}^d_t(0) = \mathbf{A}_1, \quad \Phi^d(0) = \Phi_0, \end{cases} \tag{3.4}$$

and $z_c(t) = (\psi^c(t), \mathbf{A}^c(t), \mathbf{A}^c_t(t), \Phi^c(t))$ is the solution to

$$\begin{cases} \psi^c_t - \Delta\psi^c + \psi^c = F\left(\psi, \tilde{\mathbf{A}}, \Phi\right), \\ \varepsilon\left(\mathbf{A}^c_t - \nabla\Phi^c\right)_t + \sigma\left(\mathbf{A}^c_t - \nabla\Phi^c\right) + \operatorname{curl}^2\mathbf{A}^c = \mathbf{G}\left(\psi, \tilde{\mathbf{A}}\right), \\ -\varepsilon\Delta\Phi^c_t - \sigma\Delta\Phi^c = H(\psi, \Phi), \\ \operatorname{div}\mathbf{A}^c = 0, \quad \int_\Omega \Phi^c = 0, \\ \partial_{\mathbf{n}}\psi^c|_\Gamma = 0, \quad \mathbf{A}^c\cdot\mathbf{n}|_\Gamma = 0, \ \operatorname{curl}\mathbf{A}^c\times\mathbf{n}|_\Gamma = 0, \quad \partial_{\mathbf{n}}\Phi^c|_\Gamma = 0, \\ \psi^c(0) = 0, \quad \mathbf{A}^c(0) = \mathbf{0}, \quad \mathbf{A}^c_t(0) = \mathbf{0}, \quad \Phi^c(0) = 0, \end{cases} \tag{3.5}$$

where, in (3.5), we have set

$$F\left(\psi,\tilde{\mathbf{A}},\Phi\right)=i\Phi\psi-\left|\tilde{\mathbf{A}}\right|^2\psi-2i\tilde{\mathbf{A}}\cdot\nabla\psi+\lambda^2\left(1-|\psi|^2\right)\psi+\psi, \tag{3.6}$$

$$\mathbf{G}\left(\psi,\tilde{\mathbf{A}}\right)=\frac{i}{2}\left(\psi\nabla\overline{\psi}-\overline{\psi}\nabla\psi\right)-\tilde{\mathbf{A}}|\psi|^2, \tag{3.7}$$

$$H(\psi,\Phi)=-\frac{i}{2}\left(\overline{\psi}\psi_t-\psi\overline{\psi}_t\right)-|\psi|^2\Phi. \tag{3.8}$$

Then the following lemmas show that the $\mathbb{X}^0$-norm of $z_d(t)$ exponentially decays to zero as time goes to infinity, while $z_c(t)$ remains in a bounded set of $\mathbb{X}^1$ which is compact in $\mathbb{X}^0$.

LEMMA 3.1 (cf. [3, Lemma 4.2]). *There exist constants $\gamma>0$ and $\nu>0$ independent of $\|z_0\|_0$ such that*

$$\|z_d(t)\|_0^2\le\gamma^2e^{-2\nu t}\|z_0\|_0^2\qquad\forall\ t\ge0. \tag{3.9}$$

LEMMA 3.2 (cf. [3, Lemma 4.3]). *There exists a constant $C>0$ depending on $\|z_0\|_0$ such that*

$$\|z_c(t)\|_1\le C\qquad\forall\ t\ge0. \tag{3.10}$$

Let us define

$$\begin{aligned}\mathcal{E}\left(\psi,\tilde{\mathbf{A}},\tilde{\mathbf{A}}_t,\Phi\right)&=\frac{1}{2}\left\|D_{\tilde{\mathbf{A}}}\psi\right\|^2+\frac{\lambda^2}{4}\left\|1-|\psi|^2\right\|^2+\frac{1}{2}\left\|\mathrm{curl}\tilde{\mathbf{A}}+\mathbf{H}_{ext}\right\|^2\\&\quad+\frac{\varepsilon}{2}\|\tilde{\mathbf{A}}_t\|^2+\frac{\varepsilon}{2}\|\nabla\Phi\|^2.\end{aligned} \tag{3.11}$$

It is easy to see that $\mathcal{E}$ is well defined and continuous on $\mathbb{X}^{-1}$ (cf. (2.5)). In addition, we have what follows.

LEMMA 3.3. *$\mathcal{E}$ is a global Lyapunov functional for the dynamical system $(\mathbb{X}^0_\infty,S(t))$.*

Proof. We only need to prove that $\mathcal{E}$ decreases along any given trajectory $z(t)=S(t)z_0$. Here and in what follows, we will sometimes use formal arguments which can be rigorously justified, e.g., by using a Galerkin approximation scheme (see [32]).

Multiplying (1.1) by $\overline{\psi}_t$ and its conjugate by ψ_t, respectively, integrating on Ω and adding the results together, we get

$$\begin{aligned}&\frac{d}{dt}\left(\frac{1}{2}\|D_{\tilde{\mathbf{A}}}\psi\|^2+\frac{\lambda^2}{4}\left\|1-|\psi|^2\right\|^2\right)+\|\psi_t\|^2+\frac{i}{2}\left\langle\Phi,\overline{\psi}\psi_t-\psi\overline{\psi}_t\right\rangle\\&\quad-\left\langle\tilde{\mathbf{A}}\cdot\tilde{\mathbf{A}}_t,|\psi|^2\right\rangle-\frac{i}{2}\left\langle\tilde{\mathbf{A}}_t,\overline{\psi}\nabla\psi-\psi\nabla\overline{\psi}\right\rangle=0.\end{aligned} \tag{3.12}$$

On the other hand, multiplying (1.2) by $\tilde{\mathbf{A}}_t$ in $\mathbf{L}^2(\Omega)$, we have

$$\begin{aligned}&\frac{d}{dt}\left(\frac{1}{2}\left\|\mathrm{curl}\tilde{\mathbf{A}}+\mathbf{H}_{ext}\right\|^2+\frac{\varepsilon}{2}\left\|\tilde{\mathbf{A}}_t\right\|^2\right)+\sigma\left\|\tilde{\mathbf{A}}_t\right\|^2+\left\langle\tilde{\mathbf{A}}\cdot\tilde{\mathbf{A}}_t,|\psi|^2\right\rangle\\&\quad+\frac{i}{2}\left\langle\overline{\psi}\nabla\psi-\psi\nabla\overline{\psi},\tilde{\mathbf{A}}_t\right\rangle=0.\end{aligned} \tag{3.13}$$

Moreover, taking the inner product of (1.16) with Φ in $L^2(\Omega)$ yields

$$\frac{\varepsilon}{2}\frac{d}{dt}\|\nabla\Phi\|^2+\sigma\|\nabla\Phi\|^2+\left\langle\Phi^2,|\psi|^2\right\rangle+\frac{i}{2}\left\langle\overline{\psi}\psi_t-\psi\overline{\psi}_t,\Phi\right\rangle=0. \tag{3.14}$$

Hence, we infer from (3.12)–(3.14) that, for all $t \geq 0$,

$$\begin{aligned}
&\frac{d}{dt}\mathcal{E}\left(\psi, \tilde{\mathbf{A}}, \tilde{\mathbf{A}}_t, \Phi\right) \\
&= -\|\psi_t\|^2 - i\left\langle \Phi, \overline{\psi}\psi_t - \psi\overline{\psi}_t\right\rangle - \sigma\left\|\tilde{\mathbf{A}}_t\right\|^2 - \sigma\left\|\nabla\Phi\right\|^2 - \left\langle \Phi^2, |\psi|^2\right\rangle \\
&= -\|\psi_t - i\Phi\psi\|^2_{L^2_{\mathbb{C}}(\Omega)} - \sigma\left\|\tilde{\mathbf{A}}_t\right\|^2 - \sigma\|\nabla\Phi\|^2 \\
&\leq 0, \qquad (3.15)
\end{aligned}$$

and the assertion follows. □

Due to the above lemmas, we can see that $(S(t), \mathbb{X}^0_\infty)$ is a gradient system. Furthermore, on account of Lemmas 3.1, 3.2, 3.3, and some well-known results in dynamical systems (see, for instance, [4, Chapter 9]), we deduce the following.

LEMMA 3.4. *For any $z_0 \in \mathbb{X}^0_\infty$, the ω-limit set of z_0 is a nonempty compact connected subset of $\mathbb{X}^0$. Furthermore, we have*

(i) $dist_{\mathbb{X}^0}(S(t)z_0, \omega(z_0)) \to 0$ *as* $t \to \infty$;
(ii) $\omega(z_0)$ *consists of equilibria of the form* $z_\infty = (\psi_\infty, \mathbf{A}_\infty, \mathbf{0}, 0)$, *where* $(\psi_\infty, \mathbf{A}_\infty)$ *satisfies* (2.13)–(2.16);
(iii) $S(t)\omega(z_0) = \omega(z_0)\ \forall\ t \geq 0$;
(iv) $\mathcal{E}$ *is constant on* $\omega(z_0)$.

Remark 3.1. If the set of equilibria were discrete, then we could conclude immediately that each solution converges to a single equilibrium (see (i) of Lemma 3.4). However, as is well known, in more than one spatial dimension, the set of stationary solutions can be a continuum for physically reasonable nonlinearity. The reader is referred, for instance, to [16, Remark 2.3.13]), where the following two-dimensional equation $-\Delta u + u^3 - \lambda u = 0$, $\lambda > 0$, endowed with a standard Dirichlet homogeneous boundary condition, is considered.

Remark 3.2. Lemmas 3.1 and 3.2 play a basic role in [3]. In particular, they enable the authors to prove that $(S(t), \mathbb{X}^0_\infty)$ has the global attractor $\mathcal{A}_\varepsilon$ bounded in $\mathbb{X}^1$. In addition, due to Lemma 3.3, we infer that $\mathcal{A}_\varepsilon$ coincides with the unstable manifold of the set of equilibria (see, e.g., [31, Chapter 7, section 4]).

4. Extended Łojasiewicz–Simon inequality. Let us set $\psi = \psi_1 + i\psi_2$, where $\psi_1, \psi_2 : \Omega \times \mathbb{R}^+ \to \mathbb{R}$, and define $\overrightarrow{\psi} = (\psi_1, \psi_2)$. Recalling (2.24), we rewrite the functional $\mathcal{E}_0$ in the real form E_0:

$$\begin{aligned}
&E_0\left[(\psi_1, \psi_2), \tilde{\mathbf{A}}\right] = \mathcal{E}_0\left(\psi, \tilde{\mathbf{A}}\right) \\
&= \int_\Omega \left[\frac{\lambda^2}{4}\left(1 - |\psi|^2\right)^2 + \frac{1}{2}\left|\left(\nabla - i\tilde{\mathbf{A}}\right)\psi\right|^2 + \frac{1}{2}\left|\mathrm{curl}\tilde{\mathbf{A}} + \mathbf{H}_{ext}\right|^2\right] dx \\
&= \int_\Omega \left[\frac{\lambda^2}{4}\left(1 - \psi_1^2 - \psi_2^2\right)^2 + \frac{1}{2}\left|\nabla\psi_1 + \tilde{\mathbf{A}}\psi_2\right|^2 + \frac{1}{2}\left|\nabla\psi_2 - \tilde{\mathbf{A}}\psi_1\right|^2\right. \\
&\qquad \left. + \frac{1}{2}\left|\mathrm{curl}\tilde{\mathbf{A}} + \mathbf{H}_{ext}\right|^2\right] dx. \qquad (4.1)
\end{aligned}$$

In analogy to [9, Lemma 5.1], we can see that the functional E_0 is analytic on

$$\mathcal{X} = \left[H^1(\Omega)\right]^2 \times \mathbf{X}_0 \qquad (4.2)$$

in the sense of Deimling (see [6, Definition 15.1, pp. 150]). Then a direct calculation shows what follows.

LEMMA 4.1. *The Fréchet derivative DE_0 of E_0 is an analytic mapping from $\mathcal{X}$ to its dual $\mathcal{X}'$, and it is given by*

$$\left\langle DE_0[(\psi_1,\psi_2),\tilde{\mathbf{A}}],[(v_1,v_2),\mathbf{V}]\right\rangle = \langle \partial_{\psi_1}E_0, v_1\rangle + \langle \partial_{\psi_2}E_0, v_2\rangle + \langle \partial_{\tilde{\mathbf{A}}}E_0, \mathbf{V}\rangle, \tag{4.3}$$

for any $[(\psi_1,\psi_2),\tilde{\mathbf{A}}],[(v_1,v_2),\mathbf{V}]\in\mathcal{X}$, where

$$\begin{aligned}&\left\langle \partial_{\psi_1}E_0\left[(\psi_1,\psi_2),\tilde{\mathbf{A}}\right], v_1\right\rangle \\ &= \int_\Omega \left[\left(\nabla\psi_1+\tilde{\mathbf{A}}\psi_2\right)\cdot\nabla v_1 - \left(\nabla\psi_2-\tilde{\mathbf{A}}\psi_1\right)\cdot\tilde{\mathbf{A}}v_1\right]dx - \lambda^2\int_\Omega\left(1-|\psi|^2\right)\psi_1 v_1 dx,\end{aligned} \tag{4.4}$$

$$\begin{aligned}&\left\langle \partial_{\psi_2}E_0\left[(\psi_1,\psi_2),\tilde{\mathbf{A}}\right], v_2\right\rangle \\ &= \int_\Omega \left[\left(\nabla\psi_2-\tilde{\mathbf{A}}\psi_1\right)\cdot\nabla v_2 + \left(\nabla\psi_1+\tilde{\mathbf{A}}\psi_2\right)\cdot\tilde{\mathbf{A}}v_2\right]dx - \lambda^2\int_\Omega\left(1-|\psi|^2\right)\psi_2 v_2 dx,\end{aligned} \tag{4.5}$$

$$\begin{aligned}&\left\langle \partial_{\tilde{\mathbf{A}}}E_0\left[(\psi_1,\psi_2),\tilde{\mathbf{A}}\right], \mathbf{V}\right\rangle \\ &= \int_\Omega \left(\operatorname{curl}\tilde{\mathbf{A}}+\mathbf{H}_{ext}\right)\cdot(\operatorname{curl}\mathbf{V})\,dx + \int_\Omega\left[-\left(\psi_1\nabla\psi_2-\psi_2\nabla\psi_1\right)+\tilde{\mathbf{A}}|\psi|^2\right]\cdot\mathbf{V}dx.\end{aligned} \tag{4.6}$$

Let us introduce now the quadratic form $\mathcal{J}:\mathcal{X}\times\mathcal{X}\to\mathbb{R}$ given by

$$\mathcal{J}\left([(v_1,v_2),\mathbf{V}],[(w_1,w_2),\mathbf{W}]\right) := \int_\Omega(\nabla\overrightarrow{v}\cdot\nabla\overrightarrow{w}+\overrightarrow{v}\cdot\overrightarrow{w})dx + \int_\Omega(\operatorname{curl}\mathbf{V})\cdot(\operatorname{curl}\mathbf{W})dx, \tag{4.7}$$

$\forall\ [(v_1,v_2),\mathbf{V}],[(w_1,w_2),\mathbf{W}]\in\mathcal{X}$.

It follows from (2.10) that $(\mathcal{J}([(v_1,v_2),\mathbf{V}],[(v_1,v_2),\mathbf{V}]))^{1/2}$ defines an equivalent norm of $[(v_1,v_2),\mathbf{V}]$ on $\mathcal{X}$. Based on this fact, we can retrace the steps of [9, section 6] to prove the following version of the Łojasiewicz–Simon inequality, which is a slight modification of [9, Proposition 6.1]. We thus omit the details. This lemma can be viewed as an extended version of Simon's result [28] for the scalar case under the use of L^2 norm.

LEMMA 4.2 (extended Łojasiewicz–Simon inequality). *Let $[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty]\in\mathcal{X}$ be a critical point of E_0. Then there exist constants $\beta>0$ and $\theta\in(0,\frac{1}{2})$ depending on $[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty]$ such that, for any $[(\psi_1,\psi_2),\tilde{\mathbf{A}}]\in\mathcal{X}$ satisfying*

$$\left\|\left[(\psi_1,\psi_2),\tilde{\mathbf{A}}\right]-\left[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty\right]\right\|_{\mathcal{X}}<\beta, \tag{4.8}$$

we have

$$\left|E_0\left[(\psi_1,\psi_2),\tilde{\mathbf{A}}\right]-E_0\left[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty\right]\right|^{1-\theta}\le\left\|DE_0\left[(\psi_1,\psi_2),\tilde{\mathbf{A}}\right]\right\|_{\mathcal{X}'}. \tag{4.9}$$

5. Convergence to equilibrium. In this section we prove the convergence to equilibrium for the global solutions to our Ginzburg–Landau–Maxwell equations. First, we show the convergence for $\tilde{\mathbf{A}}_t(t)$ and $\Phi(t)$ to 0, which is given by the following lemma.

LEMMA 5.1. *We have*

$$\lim_{t\to+\infty}\left\|\tilde{\mathbf{A}}_t(t)\right\|_{\mathbf{X}_0}=0, \tag{5.1}$$

$$\lim_{t\to+\infty}\|\Phi(t)\|_{H^2(\Omega)}=0. \tag{5.2}$$

Proof. Integrating (3.15) from 0 to t, we obtain

$$\mathcal{E}(t) + \int_0^t \|\psi_t(\tau) - i\Phi(\tau)\psi(\tau)\|^2 d\tau + \sigma \int_0^t \left\|\tilde{\mathbf{A}}_t(\tau)\right\|^2 d\tau + \sigma \int_0^t \|\nabla\Phi(\tau)\|^2 d\tau$$
$$\leq \mathcal{E}(0) < \infty. \tag{5.3}$$

Since $\mathcal{E}$ is nonnegative, we deduce

$$\int_0^\infty \left\|\tilde{\mathbf{A}}_t(\tau)\right\|^2 d\tau < \infty, \quad \int_0^\infty \|\nabla\Phi(\tau)\|^2 d\tau < \infty, \tag{5.4}$$

and

$$\int_0^\infty \|\psi_t(\tau) - i\Phi(\tau)\psi(\tau)\|^2 d\tau < \infty. \tag{5.5}$$

From (1.16), we infer that

$$\begin{aligned} \varepsilon\|\Delta\Phi_t\| &\leq \sigma\|\Delta\Phi\| + \left\|\frac{i}{2}\left(\overline{\psi}\psi_t - \psi\overline{\psi}_t\right)\right\| + \||\psi|^2\Phi\| \\ &\leq \sigma\|\Delta\Phi\| + C\left(\|\psi_t\| + \|\nabla\Phi\|\right) \end{aligned} \tag{5.6}$$

and, on account of (1.17), $\int_\Omega \Phi_t dx = 0$. Thus we have

$$\|\nabla\Phi_t\| \leq \|\Phi_t\|_{H^2(\Omega)} \leq C\|\Delta\Phi_t\| \leq C\left(\|\Delta\Phi\| + \|\psi_t\| + \|\nabla\Phi\|\right). \tag{5.7}$$

On the other hand, from (1.1), (1.8), and the Sobolev embedding theorem, we have

$$\begin{aligned} \|\psi_t\| &\leq C\left(\|\Phi\psi\| + \|\Delta\psi\| + \left\|\tilde{\mathbf{A}}\cdot\nabla\psi\right\| + \left\|\left|\tilde{\mathbf{A}}\right|^2\psi\right\| + \left\|\left(1 - |\psi|^2\right)\psi\right\|\right) \\ &\leq C\left(\|\Phi\|\|\psi\|_{L^\infty_{\mathbb{C}}(\Omega)} + \|\psi\|_{H^2_{\mathbb{C}}(\Omega)} + \left\|\tilde{\mathbf{A}}\right\|_{\mathbf{H}^2(\Omega)}\|\nabla\psi\| + \left\|\tilde{\mathbf{A}}\right\|^2_{\mathbf{H}^2(\Omega)}\|\psi\|\right. \\ &\qquad \left. + \|\psi\|^3_{H^1_{\mathbb{C}}(\Omega)}\right). \end{aligned} \tag{5.8}$$

Then, it follows from (5.7), (5.8), and the uniform estimate (2.12) that

$$\|\nabla\Phi_t(t)\| \leq C \qquad \forall\ t \geq 0. \tag{5.9}$$

Similarly, it follows from (1.15) and estimates (2.12) and (5.9) that

$$\begin{aligned} \left\|\tilde{\mathbf{A}}_{tt}\right\| &\leq C\left(\|\nabla\Phi_t\| + \left\|\tilde{\mathbf{A}}_t\right\| + \|\nabla\Phi\| + \left\|\mathrm{curl}^2\tilde{\mathbf{A}}\right\| + \left\|\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi - \psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right)\right\|\right) \\ &\leq C\left(\|\nabla\Phi_t\| + \left\|\tilde{\mathbf{A}}_t\right\| + \|\nabla\Phi\| + \left\|\mathrm{curl}^2\tilde{\mathbf{A}}\right\| + \|\psi\|_{L^\infty_{\mathbb{C}}(\Omega)}\|\nabla\psi\|\right. \\ &\qquad \left. + \|\psi\|^2_{L^\infty_{\mathbb{C}}(\Omega)}\left\|\tilde{\mathbf{A}}\right\|\right) \leq C. \end{aligned} \tag{5.10}$$

Let $h(t) = \|\tilde{\mathbf{A}}_t(t)\|^2$. Then we have

$$\left|\frac{dh}{dt}\right| = 2\left|\left\langle\tilde{\mathbf{A}}_t, \tilde{\mathbf{A}}_{tt}\right\rangle\right| \leq 2\left\|\tilde{\mathbf{A}}_t\right\|\left\|\tilde{\mathbf{A}}_{tt}\right\| \leq C. \tag{5.11}$$

From (5.4) and (5.11), we infer that $h \in L^1(0,\infty)$, and it is globally Lipschitz on $(0,\infty)$. Hence we have

$$\lim_{t\to+\infty}\left\|\tilde{\mathbf{A}}_t(t)\right\| = 0. \tag{5.12}$$

Thus, on account of Lemmas 3.1 and 3.2, we deduce (5.1).

We recall that $\|\psi_0\|_{L^\infty_{\mathbb{C}}(\Omega)} \le 1$. Therefore, Proposition 2.1 implies

$$\|\psi(t)\|_{L^\infty_{\mathbb{C}}(\Omega)} \le 1 \qquad \forall\, t \ge 0. \tag{5.13}$$

Thus, recalling (1.6), the Poincaré inequality for Φ combined with (5.4) and (5.13) implies that

$$\int_0^\infty \| - i\Phi(\tau)\psi(\tau)\|^2 d\tau \le C \int_0^\infty \|\nabla \Phi(\tau)\|^2 d\tau < \infty. \tag{5.14}$$

This, together with (5.5), yields

$$\int_0^\infty \|\psi_t(\tau)\|^2 d\tau < \infty. \tag{5.15}$$

Observe now that

$$|i\langle \overline{\psi}\psi_t - \psi\overline{\psi}_t, \Phi\rangle| \le 2\,\|\psi\Phi\|\|\psi_t\| \le \left\langle \Phi^2, |\psi|^2\right\rangle + \|\psi_t\|^2. \tag{5.16}$$

Hence, from (3.14), the Hölder inequality, and the Cauchy–Schwarz inequality, we get

$$\begin{aligned} &\frac{\varepsilon}{2}\frac{d}{dt}\|\nabla\Phi\|^2 + \sigma\|\nabla\Phi\|^2 + \left\langle \Phi^2, |\psi|^2\right\rangle \\ &\le \left| \frac{i}{2}\left\langle \overline{\psi}\psi_t - \psi\overline{\psi}_t, \Phi\right\rangle\right| \le \|\psi\Phi\|\|\psi_t\| \le \frac{1}{2}\left\langle \Phi^2, |\psi|^2\right\rangle + \frac{1}{2}\|\psi_t\|^2. \end{aligned} \tag{5.17}$$

Setting $h_1(t) = \|\nabla\Phi(t)\|^2$, it follows from (5.4), (5.15), (5.17), and [36, Lemma 6.2.1] that

$$\lim_{t\to+\infty} h_1(t) = 0, \tag{5.18}$$

which entails

$$\lim_{t\to+\infty} \|\Phi(t)\|_{H^1(\Omega)} = 0. \tag{5.19}$$

Hence, (5.2) is a consequence of Lemma 3.1, Lemma 3.2, and (5.19). ∎

To establish the convergence for ψ and $\tilde{\mathbf{A}}$ (or $\mathbf{A}$), it is convenient to rewrite $\mathcal{E}$ in the real form. As before, we denote $\psi = \psi_1 + i\psi_2$, with ψ_1, ψ_2 being real functions. Then we have (cf. (3.11) and (4.1))

$$\begin{aligned} E\left[(\psi_1,\psi_2), \tilde{\mathbf{A}}, \Phi\right] &:= \mathcal{E}\left(\psi, \tilde{\mathbf{A}}, \tilde{\mathbf{A}}_t, \Phi\right) \\ &= E_0\left[(\psi_1,\psi_2), \tilde{\mathbf{A}}\right] + \frac{\varepsilon}{2}\left\|\tilde{\mathbf{A}}_t\right\|^2 + \frac{\varepsilon}{2}\|\nabla\Phi\|^2 \end{aligned} \tag{5.20}$$

and accordingly, (3.15) becomes

$$\frac{d}{dt}E\left[(\psi_1,\psi_2), \tilde{\mathbf{A}}, \Phi\right] = -\left\|\psi_{1t} + \Phi\psi_2\right\|^2 - \left\|\psi_{2t} - \Phi\psi_1\right\|^2 - \sigma\left\|\tilde{\mathbf{A}}_t\right\|^2 - \sigma\|\nabla\Phi\|^2 \le 0 \tag{5.21}$$

$\forall\, t \ge 0$.

It follows from (2.12) and the Poincaré inequality that

$$\|\psi_{1t}\|^2 \le 2\left(\|\psi_{1t} + \Phi\psi_2\|^2 + \|\Phi\psi_2\|^2\right) \le C_1\left(\|\psi_{1t} + \Phi\psi_2\|^2 + \|\nabla\Phi\|^2\right), \tag{5.22}$$

$$\|\psi_{2t}\|^2 \le 2\left(\|\psi_{2t}-\Phi\psi_1\|^2+\|\Phi\psi_1\|^2\right) \le C_1\left(\|\psi_{2t}-\Phi\psi_1\|^2+\|\nabla\Phi\|^2\right), \tag{5.23}$$

where $C_1>0$ is a constant. By choosing

$$C_2 \in \left(0, \min\left\{\frac{\sigma}{4C_1}, \frac{1}{2C_1}\right\}\right), \tag{5.24}$$

we infer from (5.21) that

$$\frac{d}{dt}E\left[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi\right] \le -C_2\|\psi_{1t}\|^2 - C_2\|\psi_{2t}\|^2 - \frac{\sigma}{2}\|\tilde{\mathbf{A}}_t\|^2 - \frac{\sigma}{2}\|\nabla\Phi\|^2. \tag{5.25}$$

Next, we introduce the following auxiliary functional:

$$\mathcal{G}\left[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi\right] = \left\langle \mathrm{curl}^2\tilde{\mathbf{A}} + \frac{i}{2}\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi - \psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right) + \mathrm{curl}\mathbf{H}_{ext},\ \tilde{\mathbf{A}}_t - \nabla\Phi\right\rangle_{\mathbf{X}_0'}. \tag{5.26}$$

Then we have what follows.

LEMMA 5.2. *The following inequality holds for all $t\ge 0$:*

$$\begin{aligned}
&\frac{d}{dt}\mathcal{G}\left[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi\right]\\
&\le -\frac{1}{2\varepsilon}\left\|\mathrm{curl}^2\tilde{\mathbf{A}} + \frac{i}{2}\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi - \psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right) + \mathrm{curl}\mathbf{H}_{ext}\right\|^2_{\mathbf{X}_0'}\\
&\quad + C_3\left(\|\psi_{1t}\|^2+\|\psi_{2t}\|^2+\|\nabla\psi_{1t}\|^2+\|\nabla\psi_{2t}\|^2+\|\tilde{\mathbf{A}}_t\|^2+\|\nabla\Phi\|^2\right).
\end{aligned} \tag{5.27}$$

Proof. By direct calculation and (1.2), we get

$$\begin{aligned}
&\frac{d}{dt}\mathcal{G}\left[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi\right]\\
&= \left\langle\left(\mathrm{curl}^2\tilde{\mathbf{A}} + \frac{i}{2}\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi - \psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right) + \mathrm{curl}\mathbf{H}_{ext}\right)_t,\ \tilde{\mathbf{A}}_t - \nabla\Phi\right\rangle_{\mathbf{X}_0'}\\
&\quad -\frac{1}{\varepsilon}\left\|\mathrm{curl}^2\tilde{\mathbf{A}} + \frac{i}{2}\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi - \psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right) + \mathrm{curl}\mathbf{H}_{ext}\right\|^2_{\mathbf{X}_0'}\\
&\quad -\frac{\sigma}{\varepsilon}\left\langle \mathrm{curl}^2\tilde{\mathbf{A}} + \frac{i}{2}\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi - \psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right) + \mathrm{curl}\mathbf{H}_{ext},\ \tilde{\mathbf{A}}_t - \nabla\Phi\right\rangle_{\mathbf{X}_0'}\\
&:= I_1 + I_2 + I_3.
\end{aligned} \tag{5.28}$$

Let us estimate the right-hand side term by term. Observe first that

$$\left|\left\langle \mathrm{curl}^2\tilde{\mathbf{A}}_t, \tilde{\mathbf{A}}_t - \nabla\Phi\right\rangle_{\mathbf{X}_0'}\right| = \left|\left\langle\tilde{\mathbf{A}}_t,\tilde{\mathbf{A}}_t\right\rangle - \left\langle\tilde{\mathbf{A}}_t,\nabla\Phi\right\rangle\right| \le \frac{3}{2}\|\tilde{\mathbf{A}}_t\|^2 + \frac{1}{2}\|\nabla\Phi\|^2. \tag{5.29}$$

Recalling that we are in dimension two, it follows from a well-known Sobolev embedding theorem that

$$\mathbf{X}_0 \subset \mathbf{H}^1(\Omega) \hookrightarrow \mathbf{L}^p(\Omega) \quad \forall\ p>1, \tag{5.30}$$

$$\mathbf{L}^q(\Omega) \hookrightarrow (\mathbf{H}^1(\Omega))' \subset \mathbf{X}_0' \quad \forall\ q>1. \tag{5.31}$$

Therefore, using (2.12) and taking $q = \frac{4}{3}$ in (5.31), we have

$$\begin{aligned}
&\left| \left\langle \frac{i}{2} \left(\overline{\psi} D_{\tilde{\mathbf{A}}} \psi - \psi \overline{D_{\tilde{\mathbf{A}}} \psi} \right)_t, \tilde{\mathbf{A}}_t - \nabla \Phi \right\rangle_{\mathbf{X}_0'} \right| \\
&\leq \left\| \left[-(\psi_1 \nabla \psi_2 - \psi_2 \nabla \psi_1) + \tilde{\mathbf{A}} |\psi|^2 \right]_t \right\|_{\mathbf{X}_0'} \left\| \tilde{\mathbf{A}}_t - \nabla \Phi \right\|_{\mathbf{X}_0'} \\
&\leq \Big(\|\psi_{1t} \nabla \psi_2\|_{\mathbf{L}^{\frac{4}{3}}(\Omega)} + \|\psi_1 \nabla \psi_{2t}\| + \|\psi_{2t} \nabla \psi_1\|_{\mathbf{L}^{\frac{4}{3}}(\Omega)} + \|\psi_2 \nabla \psi_{1t}\| \\
&\quad + \left\| \tilde{\mathbf{A}}_t |\psi|^2 \right\| + 2 \left\| \tilde{\mathbf{A}} (\psi_1 \psi_{1t} + \psi_2 \psi_{2t}) \right\| \Big) \left(\left\| \tilde{\mathbf{A}}_t \right\| + \|\nabla \Phi\| \right) \\
&\leq \Big(\|\nabla \psi_2\|_{\mathbf{L}^4(\Omega)} \|\psi_{1t}\| + \|\nabla \psi_1\|_{\mathbf{L}^4(\Omega)} \|\psi_{2t}\| + C \|\nabla \psi_{1t}\| + C \|\nabla \psi_{2t}\| \\
&\quad + C \left\| \tilde{\mathbf{A}}_t \right\| + C \|\psi_{1t}\| + C \|\psi_{2t}\| \Big) \left(\left\| \tilde{\mathbf{A}}_t \right\| + \|\nabla \Phi\| \right) \\
&\leq C \left(\|\psi_{1t}\|^2 + \|\psi_{2t}\|^2 + \|\nabla \psi_{1t}\|^2 + \|\nabla \psi_{2t}\|^2 + \left\| \tilde{\mathbf{A}}_t \right\|^2 + \|\nabla \Phi\|^2 \right). \qquad (5.32)
\end{aligned}$$

As a result, we get

$$I_1 \leq C \left(\|\psi_{1t}\|^2 + \|\psi_{2t}\|^2 + \|\nabla \psi_{1t}\|^2 + \|\nabla \psi_{2t}\|^2 + \left\| \tilde{\mathbf{A}}_t \right\|^2 + \|\nabla \Phi\|^2 \right). \qquad (5.33)$$

On the other hand, thanks to the Cauchy–Schwarz inequality, we obtain

(5.34)

$$I_3 \leq \frac{1}{2\varepsilon} \left\| \mathrm{curl}^2 \tilde{\mathbf{A}} + \frac{i}{2} \left(\overline{\psi} D_{\tilde{\mathbf{A}}} \psi - \psi \overline{D_{\tilde{\mathbf{A}}} \psi} \right) + \mathrm{curl} \mathbf{H}_{ext} \right\|_{\mathbf{X}_0'}^2 + C \left(\left\| \tilde{\mathbf{A}}_t \right\|^2 + \|\nabla \Phi\|^2 \right).$$

Thus, (5.27) follows from (5.28), (5.33), and (5.34). ∎

Let

$$\mathcal{G}_1[(\psi_1, \psi_2), \Phi] = \frac{1}{2} \|\psi_{1t}\|^2 + \frac{1}{2} \|\psi_{2t}\|^2 + \frac{\varepsilon}{2} \|\Delta \Phi\|^2 + \frac{\sigma}{2} \|\nabla \Phi\|^2. \qquad (5.35)$$

Then we have the following.

LEMMA 5.3. *The following inequality holds for all $t \geq 0$:*

$$\begin{aligned}
\frac{d}{dt} \mathcal{G}_1[(\psi_1, \psi_2), \Phi] &\leq -\frac{1}{2} \|\nabla \psi_{1t}\|^2 - \frac{1}{2} \|\nabla \psi_{2t}\|^2 - \frac{\sigma}{2} \|\Delta \Phi\|^2 - \frac{\varepsilon}{2} \|\nabla \Phi_t\|^2 \\
&\quad + C_4 \left(\|\psi_{1t}\|^2 + \|\psi_{2t}\|^2 + \left\| \tilde{\mathbf{A}}_t \right\|^2 + \|\nabla \Phi\|^2 \right). \qquad (5.36)
\end{aligned}$$

Proof. Differentiating (1.14) with respect to time, adding the resulting equation multiplied by $\overline{\psi}_t$ to its conjugate multiplied by ψ_t, then integrating on Ω yield

$$\begin{aligned}
\frac{1}{2} \frac{d}{dt} \|\psi_t\|^2 &= -\|\nabla \psi_t\|^2 + \frac{i}{2} \left\langle \Phi_t, \psi \overline{\psi}_t - \overline{\psi} \psi_t \right\rangle + \lambda^2 \left\langle \left(1 - 2|\psi|^2 \right), |\psi_t|^2 \right\rangle \\
&\quad - \frac{\lambda^2}{2} \left(\left\langle \psi^2, \overline{\psi}_t^2 \right\rangle + \left\langle \overline{\psi}^2, \psi_t^2 \right\rangle \right) - \left\langle \left| \tilde{\mathbf{A}} \right|^2, |\psi_t|^2 \right\rangle + i \left\langle \mathbf{A}_t, \psi \nabla \overline{\psi}_t - \overline{\psi} \nabla \psi_t \right\rangle \\
&\quad - \left\langle \tilde{\mathbf{A}} \cdot \mathbf{A}_t, \psi \overline{\psi}_t + \overline{\psi} \psi_t \right\rangle - i \left\langle \tilde{\mathbf{A}}, \overline{\psi}_t \nabla \psi_t - \psi_t \nabla \overline{\psi}_t \right\rangle. \qquad (5.37)
\end{aligned}$$

It follows from (2.12), standard Sobolev embeddings, and the Poincaré inequality that the terms on the right-hand side of (5.37) can be estimated as follows:

$$\begin{aligned}
&\frac{i}{2} \left\langle \Phi_t, \psi \overline{\psi}_t - \overline{\psi} \psi_t \right\rangle + \lambda^2 \left\langle \left(1 - 2|\psi|^2 \right), |\psi_t|^2 \right\rangle - \frac{\lambda^2}{2} \left(\left\langle \psi^2, \overline{\psi}_t^2 \right\rangle + \left\langle \overline{\psi}^2, \psi_t^2 \right\rangle \right) \qquad (5.38) \\
&\leq \frac{\varepsilon}{4} \|\nabla \Phi_t\|^2 + C \|\psi_t\|^2
\end{aligned}$$

$$
\begin{aligned}
&-\left\langle \left|\tilde{\mathbf{A}}\right|^2, |\psi_t|^2\right\rangle + i\left\langle \mathbf{A}_t, \psi\nabla\overline{\psi}_t - \overline{\psi}\nabla\psi_t\right\rangle - \left\langle \tilde{\mathbf{A}}\cdot\mathbf{A}_t, \psi\overline{\psi}_t + \overline{\psi}\psi_t\right\rangle \\
&-i\left\langle \tilde{\mathbf{A}}, \overline{\psi}_t\nabla\psi_t - \psi_t\nabla\overline{\psi}_t\right\rangle \\
&\le \frac{1}{2}\|\nabla\psi_t\|^2 + C\|\psi_t\|^2 + C\left\|\tilde{\mathbf{A}}_t\right\|^2.
\end{aligned} \tag{5.39}
$$

Multiplying now (1.16) by $-\Delta\Phi + \Phi_t$ and integrating on Ω yield

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\left(\varepsilon\|\Delta\Phi\|^2 + \sigma\|\nabla\Phi\|^2\right) \\
&= -\sigma\|\Delta\Phi\|^2 - \varepsilon\|\nabla\Phi_t\|^2 - \frac{i}{2}\left\langle \overline{\psi}\psi_t - \psi\overline{\psi}_t, -\Delta\Phi\right\rangle - \left\langle |\psi|^2\Phi, -\Delta\Phi\right\rangle \\
&-\frac{i}{2}\left\langle \overline{\psi}\psi_t - \psi\overline{\psi}_t, \Phi_t\right\rangle - \left\langle |\psi|^2\Phi, \Phi_t\right\rangle \\
&\le -\sigma\|\Delta\Phi\|^2 - \varepsilon\|\nabla\Phi_t\|^2 + \frac{\sigma}{2}\|\Delta\Phi\|^2 + \frac{\varepsilon}{4}\|\nabla\Phi_t\|^2 + C\|\psi_t\|^2 + C\|\nabla\Phi\|^2.
\end{aligned} \tag{5.40}
$$

Then from (5.37)–(5.40), it follows that

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\left(\|\psi_t\|^2 + \varepsilon\|\Delta\Phi\|^2 + \sigma\|\nabla\Phi\|^2\right) \\
&\le -\frac{1}{2}\|\nabla\psi_t\|^2 - \frac{\sigma}{2}\|\Delta\Phi\|^2 - \frac{\varepsilon}{2}\|\nabla\Phi_t\|^2 + C\left(\|\psi_t\|^2 + \left\|\tilde{\mathbf{A}}_t\right\|^2 + \|\nabla\Phi\|^2\right),
\end{aligned} \tag{5.41}
$$

which gives (5.36). ∎

We are now able to prove that ψ_t vanishes at infinity.

LEMMA 5.4. *There holds*

$$
\lim_{t\to+\infty}\|\psi_t(t)\| = 0. \tag{5.42}
$$

Proof. It follows from (5.41) that

$$
\frac{1}{2}\frac{d}{dt}\left(\|\psi_t\|^2 + \varepsilon\|\Delta\Phi\|^2 + \sigma\|\nabla\Phi\|^2\right) + \frac{\sigma}{2}\|\Delta\Phi\|^2 \le C\left(\|\psi_t\|^2 + \left\|\tilde{\mathbf{A}}_t\right\|^2 + \|\nabla\Phi\|^2\right). \tag{5.43}
$$

Since $z_0 = (\psi_0, \mathbf{A}_0, \mathbf{A}_1, \Phi_0) \in \mathbb{X}^0_\infty$, from (1.1) and the Sobolev embedding theorem we infer that $\|\psi_t|_{t=0}\| \le C$, where C is a constant depending on $\|z_0\|_0$. Therefore, (5.4), (5.15), and (5.43) yield

$$
\|\psi_t(t)\| \le C \quad \forall\ t \ge 0, \tag{5.44}
$$

$$
\int_0^\infty \|\Delta\Phi(\tau)\|^2 d\tau < \infty. \tag{5.45}
$$

Denote $h_2(t) = \|\psi_t\|^2 + \varepsilon\|\Delta\Phi\|^2 + \sigma\|\nabla\Phi\|^2$. Then (5.43), Lemma 5.1, and (5.44) imply

$$
\frac{d}{dt}h_2 \le C \quad \forall\ t \ge 0. \tag{5.46}
$$

On the other hand, we deduce $h_2(t) \in L^1(0,\infty)$ from (5.4), (5.15), and (5.45). As a consequence of [36, Lemma 6.2.1],

$$
\lim_{t\to+\infty} h_2(t) = 0. \tag{5.47}
$$

The proof is complete. ∎

As we mentioned in the Introduction, due to the hyperbolic nature of the equation for $\tilde{\mathbf{A}}$, a key point in the proof of convergence result is to construct an appropriate auxiliary functional in order to implement the Łojasiewicz–Simon approach. For this purpose, we introduce the following functional $\mathfrak{F}:\mathbb{X}^0\to\mathbb{R}$:

$$\mathfrak{F}\left[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi\right]:=E\left[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi\right]+\eta\mathcal{G}\left[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi\right]+\eta_1\mathcal{G}_1[(\psi_1,\psi_2),\Phi], \tag{5.48}$$

where η and η_1 are positive constants to be specified later.

Furthermore, it follows from (5.25), Lemma 5.2, and Lemma 5.3 that

$$\begin{aligned}
&\frac{d}{dt}\mathfrak{F}\left[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi\right]\\
&\leq -(C_2-C_3\eta-C_4\eta_1)\left(\|\psi_{1t}\|^2+\|\psi_{2t}\|^2\right)\\
&\quad-\left(\frac{\sigma}{2}-C_3\eta-C_4\eta_1\right)\left(\left\|\tilde{\mathbf{A}}_t\right\|^2+\|\nabla\Phi\|^2\right)\\
&\quad-\left(\frac{\eta_1}{2}-C_3\eta\right)\left(\|\nabla\psi_{1t}\|^2+\|\nabla\psi_{2t}\|^2\right)-\frac{\eta_1\sigma}{2}\|\Delta\Phi\|^2-\frac{\eta_1\varepsilon}{2}\|\nabla\Phi_t\|^2\\
&\quad-\frac{\eta}{2\varepsilon}\left\|\mathrm{curl}^2\tilde{\mathbf{A}}+\frac{i}{2}\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi-\psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right)+\mathrm{curl}\mathbf{H}_{ext}\right\|^2_{\mathbf{X}_0'}.
\end{aligned} \tag{5.49}$$

Taking

$$\eta=\frac{\min\{C_2,\sigma\}}{4C_3(1+4C_4)},\quad \eta_1=4C_3\eta=\frac{\min\{C_2,\sigma\}}{(1+4C_4)}, \tag{5.50}$$

we can deduce that

$$\begin{aligned}
&\frac{d}{dt}\mathfrak{F}\left[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi\right]\\
&\leq -C\Bigg(\|\psi_{1t}\|^2_{H^1}+\|\psi_{2t}\|^2_{H^1}+\left\|\tilde{\mathbf{A}}_t\right\|^2+\|\nabla\Phi\|^2+\|\Delta\Phi\|^2+\|\nabla\Phi_t\|^2\\
&\qquad+\left\|\mathrm{curl}^2\tilde{\mathbf{A}}+\frac{i}{2}\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi-\psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right)+\mathrm{curl}\mathbf{H}_{ext}\right\|^2_{\mathbf{X}_0'}\Bigg)\\
&\leq 0
\end{aligned} \tag{5.51}$$

for some $C>0$.

Thanks to Lemma 3.1, Lemma 3.2, and Lemma 3.4, we can find an increasing unbounded sequence $\{t_n\}_{n=1}^{\infty}$ and a pair $(\psi_\infty,\tilde{\mathbf{A}}_\infty)$ satisfying (2.19)–(2.22) such that

$$\lim_{t_n\to+\infty}\left\|\tilde{\mathbf{A}}(t_n)-\tilde{\mathbf{A}}_\infty\right\|_{\mathbf{H}^2(\Omega)}=0, \tag{5.52}$$

$$\lim_{t_n\to+\infty}\|\psi(t_n)-\psi_\infty\|_{H^2_{\mathbb{C}}(\Omega)}=0. \tag{5.53}$$

Thus, it follows from (5.52), (5.53), Lemma 5.1, and Lemma 5.4 that

$$\lim_{t_n\to+\infty}\mathfrak{F}(t_n)=E_0\left[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty\right]. \tag{5.54}$$

Since $\mathfrak{F}$ is decreasing in time (see (5.51)), we have

$$\mathfrak{F}(t)\geq E_0\left[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty\right]\quad\forall\, t\geq 0. \tag{5.55}$$

After these preparations, we proceed to prove the convergence result following a simple argument introduced in [20]. The key observation is that, after a certain time t_0, the solution $[(\psi_1(t),\psi_2(t)),\tilde{\mathbf{A}}(t)]$ always satisfies the condition of Lemma 4.2, that is, it falls in a neighborhood of $[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty]$, where (4.9) holds.

We now consider all the possible cases.

(1) If there is a $t_0>0$ such that at this time $\mathfrak{F}[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi]=E_0[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty]$, then $\forall\ t>t_0$, we deduce from (5.51) that $[(\psi_1(t),\psi_2(t)),\tilde{\mathbf{A}}(t)]$ is independent of t. We obtain the convergence for ψ and $\tilde{\mathbf{A}}$ from (5.52) and (5.53).

(2) If $\mathfrak{F}[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi]>E_0[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty]\ \forall\ t\geq 0$ and there is $t_0>0$ such that $\forall\ t\geq t_0$, $[(\psi_1,\psi_2),\tilde{\mathbf{A}}]$ satisfies the condition of Lemma 4.2, i.e.,

$$\left\|\left[(\psi_1,\psi_2),\tilde{\mathbf{A}}\right]-\left[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty\right]\right\|_{\mathcal{X}}<\beta, \tag{5.56}$$

then, for the Łojasiewicz exponent $\theta\in(0,\frac{1}{2})$ (see Lemma 4.2), we calculate

$$\begin{aligned}&\frac{d}{dt}\left(\mathfrak{F}\left[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi\right]-E_0\left[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty\right]\right)^{\theta}\\ &=\theta\left(\mathfrak{F}\left[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi\right]-E_0\left[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty\right]\right)^{\theta-1}\frac{d}{dt}\mathfrak{F}\left[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi\right].\end{aligned} \tag{5.57}$$

Recalling (5.20) and the definitions of $\mathcal{G}[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi]$ and $\mathcal{G}_1[(\psi_1,\psi_2),\Phi]$, we have

$$\begin{aligned}&\left(\mathfrak{F}\left[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi\right]-E_0\left[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty\right]\right)^{1-\theta}\\ &\leq C\left(\left|E_0\left[(\psi_1,\psi_2),\tilde{\mathbf{A}}\right]-E_0\left[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty\right]\right|^{1-\theta}+\left\|\tilde{\mathbf{A}}_t\right\|^{2(1-\theta)}\right.\\ &\quad+\|\nabla\Phi\|^{2(1-\theta)}+\|\Delta\Phi\|^{2(1-\theta)}+\|\psi_{1t}\|^{2(1-\theta)}+\|\psi_{2t}\|^{2(1-\theta)}\\ &\quad\left.+\left\|\mathrm{curl}^2\tilde{\mathbf{A}}+\frac{i}{2}\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi-\psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right)+\mathrm{curl}\mathbf{H}_{ext}\right\|_{\mathbf{X}_0'}^{2(1-\theta)}\right).\end{aligned} \tag{5.58}$$

On the other hand, on account of (4.9), Lemma 4.1 (cf. the explicit form of DE_0), Proposition 2.1, and the Poincaré inequality, we deduce that

$$\begin{aligned}&\left|E_0\left[(\psi_1,\psi_2),\tilde{\mathbf{A}}\right]-E_0\left[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty\right]\right|^{1-\theta}\leq\left\|DE_0\left[(\psi_1,\psi_2),\tilde{\mathbf{A}}\right]\right\|_{\mathcal{X}'}\\ &\leq C\left(\|\psi_{1t}+\Phi\psi_2\|+\|\psi_{2t}-\Phi\psi_1\|+\left\|\mathrm{curl}^2\tilde{\mathbf{A}}+\frac{i}{2}\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi-\psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right)+\mathrm{curl}\mathbf{H}_{ext}\right\|_{\mathbf{X}_0'}\right)\\ &\leq C\left(\|\psi_{1t}\|+\|\psi_{2t}\|+\|\nabla\Phi\|+\left\|\mathrm{curl}^2\tilde{\mathbf{A}}+\frac{i}{2}\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi-\psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right)+\mathrm{curl}\mathbf{H}_{ext}\right\|_{\mathbf{X}_0'}\right).\end{aligned} \tag{5.59}$$

Since $\theta\in(0,\frac{1}{2})$, thanks to (5.1) and (5.2), it follows that

$$\begin{aligned}&\left(\mathfrak{F}\left[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi\right]-E_0\left[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty\right]\right)^{1-\theta}\\ &\leq C\left(\|\psi_{1t}\|+\|\psi_{2t}\|+\left\|\tilde{\mathbf{A}}_t\right\|+\|\nabla\Phi\|+\|\Delta\Phi\|\right.\\ &\quad\left.+\left\|\mathrm{curl}^2\tilde{\mathbf{A}}+\frac{i}{2}\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi-\psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right)+\mathrm{curl}\mathbf{H}_{ext}\right\|_{\mathbf{X}_0'}\right).\end{aligned} \tag{5.60}$$

Hence, combining (5.51), (5.57), and (5.60), we infer that, for all $t \geq t_0$,

$$\frac{d}{dt}\left(\mathfrak{F}\left[(\psi_1,\psi_2),\tilde{\mathbf{A}},\Phi\right]-E_0\left[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty\right]\right)^\theta + C_5\Bigg(\|\psi_{1t}\|+\|\psi_{2t}\|+\left\|\tilde{\mathbf{A}}_t\right\| + \|\nabla\Phi\|+\|\Delta\Phi\|+\|\nabla\Phi_t\|+\left\|\mathrm{curl}^2\tilde{\mathbf{A}}+\frac{i}{2}\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi-\psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right)+\mathrm{curl}\mathbf{H}_{ext}\right\|_{\mathbf{X}_0'}\Bigg) \leq 0. \tag{5.61}$$

As a result, we can deduce that

$$\int_{t_0}^{t}\left\|\tilde{\mathbf{A}}_t(\tau)\right\|d\tau<\infty, \tag{5.62}$$

$$\int_{t_0}^{t}\left(\|\psi_{1t}(\tau)\|+\|\psi_{2t}(\tau)\|\right)\,d\tau<\infty \tag{5.63}$$

$\forall\ t\geq t_0$. This yields

$$\lim_{t\to+\infty}\left\|\tilde{\mathbf{A}}(t)-\tilde{\mathbf{A}}_\infty\right\|=0,\qquad \lim_{t\to+\infty}\|\psi(t)-\psi_\infty\|=0.$$

From Lemmas 3.1 and 3.2, owing to the uniqueness of the limit, we infer that

$$\lim_{t\to+\infty}\left\|\tilde{\mathbf{A}}(t)-\tilde{\mathbf{A}}_\infty\right\|_{\mathbf{H}^2(\Omega)}=0,\qquad \lim_{t\to+\infty}\|\psi(t)-\psi_\infty\|_{H^2_{\tilde{\mathbb{C}}}(\Omega)}=0.$$

Recalling Lemma 5.1, we conclude that $(\psi(t),\tilde{\mathbf{A}}(t),\tilde{\mathbf{A}}_t(t),\Phi(t))$ converges to $(\psi_\infty,\tilde{\mathbf{A}}_\infty,\mathbf{0},0)$ in $\mathbb{X}^0$ as t goes to infinity.

(3) Combining (5.52), (5.53), and Lemma 5.1, we obtain that, for any $\rho\in(0,\beta)$, there exists an integer $N=N(\rho)$ such that, when $n\geq N$,

$$\|\psi_1(t_n)-\psi_{1\infty}\|_{H^2(\Omega)}<\frac{\rho}{4},\quad \|\psi_2(t_n)-\psi_{2\infty}\|_{H^2(\Omega)}<\frac{\rho}{4}, \tag{5.64}$$

$$\left\|\tilde{\mathbf{A}}(t_n)-\tilde{\mathbf{A}}_\infty\right\|_{\mathbf{H}^2(\Omega)}<\frac{\rho}{4}, \tag{5.65}$$

$$\frac{1}{C_5}\left(\mathfrak{F}\left[(\psi_1(t_n),\psi_2(t_n)),\tilde{\mathbf{A}}(t_n),\Phi(t_n)\right]-E_0\left[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty\right]\right)^\theta<\frac{\rho}{4}. \tag{5.66}$$

We now define

$$\bar{t}_n=\sup_{t>t_n}\Big\{\ |\ \|\psi_1(s)-\psi_{1\infty}\|_{H^2(\Omega)}+\|\psi_2(s)-\psi_{2\infty}\|_{H^2(\Omega)} +\left\|\tilde{\mathbf{A}}(s)-\tilde{\mathbf{A}}_\infty\right\|_{\mathbf{H}^2(\Omega)}<\beta,\quad \forall s\in[t_n,t]\Big\}, \tag{5.67}$$

and we note that it follows from (5.64), (5.65), and the continuity of the orbit in $\mathbb{X}^0$ that $\bar{t}_n>t_n\forall\ n\geq N$. Then there are two possibilities, namely,

(i) There exists $n_0\geq N$ such that $\bar{t}_{n_0}=+\infty$, then arguing as in (1) and (2), the convergence result can be obtained.

(ii) Otherwise, for all $n\geq N$, we have $t_n<\bar{t}_n<+\infty$, and, for all $t\in[t_n,\bar{t}_n]$, we have

$$\mathfrak{F}\left[(\psi_1(t),\psi_2(t)),\tilde{\mathbf{A}}(t),\Phi(t)\right]>E_0\left[(\psi_{1\infty},\psi_{2\infty}),\tilde{\mathbf{A}}_\infty\right].$$

Hence, we deduce from (5.61) that

$$\begin{aligned}
&\int_{t_n}^{\bar{t}_n} \left(\|\psi_{1t}(\tau)\| + \|\psi_{2t}(\tau)\| + \|\tilde{\mathbf{A}}_t(\tau)\| \right) d\tau \\
&\leq \frac{1}{C_5} \left(\mathfrak{F}\left[(\psi_1(t_n), \psi_2(t_n)), \tilde{\mathbf{A}}(t_n), \Phi(t_n) \right] - E_0\left[(\psi_{1\infty}, \psi_{2\infty}), \tilde{\mathbf{A}}_\infty \right] \right)^\theta \\
&< \frac{\rho}{4}. \qquad (5.68)
\end{aligned}$$

Noticing that $\rho > 0$ is arbitrary in the above argument, we are able to conclude that for any $\rho > 0$, there exist $N = N(\rho) \in \mathbb{N}$ such that, for all $n \geq N$, there holds

$$\begin{aligned}
&\|\psi_1(\bar{t}_n) - \psi_{1\infty}\| + \|\psi_2(\bar{t}_n) - \psi_{2\infty}\| + \|\tilde{\mathbf{A}}(\bar{t}_n) - \tilde{\mathbf{A}}_\infty\| \\
&\leq \|\psi_1(t_n) - \psi_{1\infty}\| + \|\psi_2(t_n) - \psi_{2\infty}\| + \|\tilde{\mathbf{A}}(t_n) - \tilde{\mathbf{A}}_\infty\| \\
&\quad + \int_{t_n}^{\bar{t}_n} \left(\|\psi_{1t}(\tau)\| + \|\psi_{2t}(\tau)\| + \|\tilde{\mathbf{A}}_t(\tau)\| \right) d\tau \\
&< \rho. \qquad (5.69)
\end{aligned}$$

This implies

$$\lim_{n\to+\infty} \left(\|\psi_1(\bar{t}_n) - \psi_{1\infty}\| + \|\psi_2(\bar{t}_n) - \psi_{2\infty}\| + \|\tilde{\mathbf{A}}(\bar{t}_n) - \tilde{\mathbf{A}}_\infty\| \right) = 0. \qquad (5.70)$$

Therefore, due to Lemmas 3.1 and 3.2, there exists a subsequence of $\{\bar{t}_n\}$, denoted by $\{\bar{t}_{n_k}\}$ such that

$$\lim_{n_k\to+\infty} \left(\|\psi_1(\bar{t}_{n_k}) - \psi_{1\infty}\|_{H^2(\Omega)} + \|\psi_2(\bar{t}_{n_k}) - \psi_{2\infty}\|_{H^2(\Omega)} + \|\tilde{\mathbf{A}}(\bar{t}_{n_k}) - \tilde{\mathbf{A}}_\infty\|_{\mathbf{H}^2(\Omega)} \right) = 0, \qquad (5.71)$$

which contradicts the definition of $\bar{t}_n$.

Summing up, we conclude that

$$\lim_{t\to+\infty} \|z(t) - z_\infty\|_0 = 0. \qquad (5.72)$$

6. Convergence rate. In this section we demonstrate estimate (2.25) on convergence rate. Let us begin by noting that a combination of (5.60) and (5.61) implies, for all $t \geq t_0$, that

$$\begin{aligned}
&\frac{d}{dt} \left(\mathfrak{F}\left[(\psi_1, \psi_2), \tilde{\mathbf{A}}, \Phi \right] - E_0\left[(\psi_{1\infty}, \psi_{2\infty}), \tilde{\mathbf{A}}_\infty \right] \right) \\
&+ C \left(\mathfrak{F}\left[(\psi_1, \psi_2), \tilde{\mathbf{A}}, \Phi \right] - E_0\left[(\psi_{1\infty}, \psi_{2\infty}), \tilde{\mathbf{A}}_\infty \right] \right)^{2(1-\theta)} \leq 0. \qquad (6.1)
\end{aligned}$$

Keeping in mind that $\theta \in (0, \frac{1}{2})$, we deduce

$$\mathfrak{F}\left[(\psi_1(t), \psi_2(t)), \tilde{\mathbf{A}}(t), \Phi(t) \right] - E_0\left[(\psi_{1\infty}, \psi_{2\infty}), \tilde{\mathbf{A}}_\infty \right] \leq C(1+t)^{-1/(1-2\theta)}, \qquad (6.2)$$

for all $t \geq 0$ and for a suitable $C > 0$, because for $t \in [0, t_0]$, the term on the left-hand side is bounded by a constant depending only on initial data (cf. (2.12)). Hence, it

follows from (5.61) that

$$\begin{aligned}&\int_t^\infty \left(\|\psi_{1t}\| + \|\psi_{2t}\| + \|\nabla\Phi\| + \|\nabla\Phi_t\| + \left\|\tilde{\mathbf{A}}_t\right\|\right) d\tau\\ &+ \int_t^\infty \left(\left\|\mathrm{curl}^2\tilde{\mathbf{A}} + \frac{i}{2}\left(\overline{\psi}D_{\tilde{\mathbf{A}}}\psi - \psi\overline{D_{\tilde{\mathbf{A}}}\psi}\right) + \mathrm{curl}\mathbf{H}_{ext}\right\|_{\mathbf{X}_0'}\right) d\tau\\ &\leq C(1+t)^{-\theta/(1-2\theta)}, \qquad \forall\ t \geq 0,\end{aligned} \tag{6.3}$$

and, as a consequence (cf. (1.2)),

$$\int_t^\infty \left\|\tilde{\mathbf{A}}_{tt}(\tau)\right\|_{\mathbf{X}_0'} d\tau \leq C(1+t)^{-\theta/(1-2\theta)} \qquad \forall\ t \geq 0. \tag{6.4}$$

Therefore, from (6.3) and (6.4), we deduce the following preliminary convergence rate estimate:

$$\begin{aligned}&\|\psi(t) - \psi_\infty\| + \left\|\tilde{\mathbf{A}}(t) - \tilde{\mathbf{A}}_\infty\right\| + \left\|\tilde{\mathbf{A}}_t(t)\right\|_{\mathbf{X}_0'} + \|\nabla\Phi\|\\ &\leq \int_t^\infty \left(\|\psi_t(\tau)\| + \left\|\tilde{\mathbf{A}}_t(\tau)\right\| + \left\|\tilde{\mathbf{A}}_{tt}(\tau)\right\|_{\mathbf{X}_0'} + \|\nabla\Phi_t(\tau)\|\right) d\tau\\ &\leq C(1+t)^{-\theta/(1-2\theta)} \qquad \forall\ t \geq 0.\end{aligned} \tag{6.5}$$

In order to get higher order estimates, we first subtract the stationary equations from the time-dependent equations. This gives

$$\begin{aligned}&\psi_t - i\Phi\psi - \Delta(\psi - \psi_\infty) + 2i\left(\tilde{\mathbf{A}}\cdot\nabla\psi - \tilde{\mathbf{A}}_\infty\cdot\nabla\psi_\infty\right) + \tilde{\mathbf{A}}^2\psi - \tilde{\mathbf{A}}_\infty^2\psi_\infty\\ &-\lambda^2\left(1 - |\psi|^2\right)\psi + \lambda^2\left(1 - |\psi_\infty|^2\right)\psi_\infty = 0,\end{aligned} \tag{6.6}$$

$$\begin{aligned}&\varepsilon\left(\tilde{\mathbf{A}}_t - \nabla\Phi\right)_t + \sigma\left(\tilde{\mathbf{A}}_t - \nabla\Phi\right) + \mathrm{curl}^2\tilde{\mathbf{A}} - \mathrm{curl}^2\tilde{\mathbf{A}}_\infty + |\psi|^2\tilde{\mathbf{A}} - |\psi_\infty|^2\tilde{\mathbf{A}}_\infty\\ &\qquad + \frac{i}{2}\left(\overline{\psi}\nabla\psi - \psi\nabla\overline{\psi}\right) - \frac{i}{2}\left(\overline{\psi}_\infty\nabla\psi_\infty - \psi_\infty\nabla\overline{\psi}_\infty\right) = 0,\end{aligned} \tag{6.7}$$

$$-\varepsilon\Delta\Phi_t - \sigma\Delta\Phi + \frac{i}{2}\left(\overline{\psi}\psi_t - \psi\overline{\psi}_t\right) + |\psi|^2\Phi = 0, \tag{6.8}$$

in $\Omega\times(0,\infty)$, with boundary conditions

$$\partial_{\mathbf{n}}(\psi - \psi_\infty) = 0, \quad \left(\tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty\right)\cdot\mathbf{n} = 0, \quad \left(\mathrm{curl}\tilde{\mathbf{A}} - \mathrm{curl}\tilde{\mathbf{A}}_\infty\right)\times\mathbf{n} = 0, \ \ \partial_{\mathbf{n}}\Phi = 0, \tag{6.9}$$

on $\Gamma\times(0,\infty)$.

Multiplying (6.6) by $\overline{\psi}_t$ and its conjugate by ψ_t, respectively, then integrating on Ω and adding the results together, we have

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\|\nabla\psi - \nabla\psi_\infty\|^2 + \|\psi_t\|^2 + \frac{i}{2}\left\langle\Phi, \overline{\psi}\psi_t - \psi\overline{\psi}_t\right\rangle\\ &+ i\left\langle\tilde{\mathbf{A}}\cdot\nabla\psi - \tilde{\mathbf{A}}_\infty\cdot\nabla\psi_\infty,\ \overline{\psi}_t\right\rangle - i\left\langle\tilde{\mathbf{A}}\cdot\nabla\overline{\psi} - \tilde{\mathbf{A}}_\infty\cdot\nabla\overline{\psi}_\infty,\ \psi_t\right\rangle\\ &+ \frac{1}{2}\left\langle\tilde{\mathbf{A}}^2\psi - \tilde{\mathbf{A}}_\infty^2\psi_\infty,\ \overline{\psi}_t\right\rangle + \frac{1}{2}\left\langle\tilde{\mathbf{A}}^2\overline{\psi} - \tilde{\mathbf{A}}_\infty^2\overline{\psi}_\infty,\ \psi_t\right\rangle\\ &- \frac{\lambda^2}{2}\int_\Omega\left[\left(1 - |\psi|^2\right)\psi - \left(1 - |\psi_\infty|^2\right)\psi_\infty\right]\overline{\psi}_t dx\\ &- \frac{\lambda^2}{2}\int_\Omega\left[\left(1 - |\psi|^2\right)\overline{\psi} - \left(1 - |\psi_\infty|^2\right)\overline{\psi}_\infty\right]\psi_t dx = 0.\end{aligned} \tag{6.10}$$

It follows from inequalities (2.7), (2.8), and bound (2.12) that

$$
\begin{aligned}
I_4 &:= \left| i \left\langle \tilde{\mathbf{A}} \cdot \nabla \psi - \tilde{\mathbf{A}}_\infty \cdot \nabla \psi_\infty,\ \overline{\psi}_t \right\rangle \right| \\
&\leq \left| \left\langle \tilde{\mathbf{A}} \cdot \nabla \psi - \tilde{\mathbf{A}}_\infty \cdot \nabla \psi,\ \overline{\psi}_t \right\rangle \right| + \left| \left\langle \tilde{\mathbf{A}}_\infty \cdot \nabla \psi - \tilde{\mathbf{A}}_\infty \cdot \nabla \psi_\infty,\ \overline{\psi}_t \right\rangle \right| \\
&\leq \|\nabla \psi\|_{\mathbf{L}^4} \left\| \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\|_{\mathbf{L}^4} \|\psi_t\| + \left\| \tilde{\mathbf{A}}_\infty \right\|_{\mathbf{L}^\infty} \|\nabla \psi - \nabla \psi_\infty\| \|\psi_t\| \\
&\leq C \left\| \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\|^{\frac{1}{2}} \left\| \mathrm{curl} \tilde{\mathbf{A}} - \mathrm{curl} \tilde{\mathbf{A}}_\infty \right\|^{\frac{1}{2}} \|\psi_t\| + C \|\nabla \psi - \nabla \psi_\infty\| \|\psi_t\| \\
&\leq \frac{1}{16} \|\psi_t\|^2 + \frac{\alpha}{8} \left\| \mathrm{curl} \tilde{\mathbf{A}} - \mathrm{curl} \tilde{\mathbf{A}}_\infty \right\|^2 + C \|\tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty\|^2 \\
&\quad + C_6 \|\nabla \psi - \nabla \psi_\infty\|^2. \qquad (6.11)
\end{aligned}
$$

Similarly, we deduce

$$
\begin{aligned}
I_5 &:= \left| -i \left\langle \tilde{\mathbf{A}} \cdot \nabla \overline{\psi} - \tilde{\mathbf{A}}_\infty \cdot \nabla \overline{\psi}_\infty,\ \psi_t \right\rangle \right| \\
&\leq \frac{1}{16} \|\psi_t\|^2 + \frac{\alpha}{8} \left\| \mathrm{curl} \tilde{\mathbf{A}} - \mathrm{curl} \tilde{\mathbf{A}}_\infty \right\|^2 + C \left\| \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\|^2 \\
&\quad + C_6 \|\nabla \psi - \nabla \psi_\infty\|^2. \qquad (6.12)
\end{aligned}
$$

Next, we have

$$
\begin{aligned}
I_6 &:= \frac{1}{2} \left| \left\langle \tilde{\mathbf{A}}^2 \psi - \tilde{\mathbf{A}}_\infty^2 \psi_\infty,\ \overline{\psi}_t \right\rangle \right| \\
&\leq \frac{1}{2} \left| \left\langle \tilde{\mathbf{A}}^2 \psi - \tilde{\mathbf{A}}^2 \psi_\infty,\ \overline{\psi}_t \right\rangle \right| + \frac{1}{2} \left| \left\langle \tilde{\mathbf{A}}^2 \psi_\infty - \tilde{\mathbf{A}}_\infty^2 \psi_\infty,\ \overline{\psi}_t \right\rangle \right| \\
&\leq \frac{1}{16} \|\psi_t\|^2 + C \left(\left\| \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\|^2 + \|\psi - \psi_\infty\|^2 \right). \qquad (6.13)
\end{aligned}
$$

In the same manner, we get

$$
I_7 := \frac{1}{2} \left| \left\langle \tilde{\mathbf{A}}^2 \overline{\psi} - \tilde{\mathbf{A}}_\infty^2 \overline{\psi}_\infty,\ \psi_t \right\rangle \right| \leq \frac{1}{16} \|\psi_t\|^2 + C \left(\left\| \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\|^2 + \|\psi - \psi_\infty\|^2 \right). \qquad (6.14)
$$

Moreover, we have

$$
\begin{aligned}
I_8 &:= \frac{\lambda^2}{2} \left| \int_\Omega \left[\left(1 - |\psi|^2\right) \psi - \left(1 - |\psi_\infty|^2\right) \psi_\infty \right] \overline{\psi}_t dx \right| \\
&\leq \frac{\lambda^2}{2} \left| \int_\Omega |\psi|^2 (\psi - \psi_\infty) \overline{\psi}_t dx \right| + \frac{\lambda^2}{2} \left| \int_\Omega \psi_\infty \left(|\psi|^2 - |\psi_\infty|^2 \right) \overline{\psi}_t dx \right| \\
&\quad + \frac{\lambda^2}{2} \left| \int_\Omega (\psi - \psi_\infty) \overline{\psi}_t dx \right| \\
&\leq \frac{1}{32} \left\| \overline{\psi}_t \right\|^2 + C \|\psi - \psi_\infty\|^2 + C \left\| \psi_1^2 + \psi_2^2 - \psi_{1\infty}^2 - \psi_{2\infty}^2 \right\| \left\| \overline{\psi}_t \right\| \\
&\leq \frac{1}{32} \left\| \overline{\psi}_t \right\|^2 + C \|\psi - \psi_\infty\|^2 + C \left\| \overline{\psi}_t \right\| (\|\psi_1 - \psi_{1\infty}\| + \|\psi_2 - \psi_{2\infty}\|) \\
&\leq \frac{1}{32} \left\| \overline{\psi}_t \right\|^2 + C \|\psi - \psi_\infty\|^2 + C \left\| \overline{\psi}_t \right\| \|\psi - \psi_\infty\| \\
&\leq \frac{1}{16} \|\psi_t\|^2 + C \|\psi - \psi_\infty\|^2, \qquad (6.15)
\end{aligned}
$$

(6.16)
$$I_9 := \frac{\lambda^2}{2}\left|\int_\Omega \left[\left(1-|\psi|^2\right)\overline{\psi}-\left(1-|\psi_\infty|^2\right)\overline{\psi}_\infty\right]\psi_t dx\right| \le \frac{1}{16}\|\psi_t\|^2 + C\|\psi-\psi_\infty\|^2.$$

Multiplying (6.6) by $\overline{\psi}-\overline{\psi}_\infty$ and its conjugate by $\psi-\psi_\infty$, respectively, then integrating on Ω and adding the results together, we obtain

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\psi-\psi_\infty\|^2 + \|\nabla\psi-\nabla\psi_\infty\|^2 + \frac{i}{2}\left\langle \Phi,\ \psi\overline{\psi}_\infty - \overline{\psi}\psi_\infty\right\rangle \\
&\quad + i\left\langle \tilde{\mathbf{A}}\cdot\nabla\psi - \tilde{\mathbf{A}}_\infty\cdot\nabla\psi_\infty,\ \overline{\psi}-\overline{\psi}_\infty\right\rangle - i\left\langle \tilde{\mathbf{A}}\cdot\nabla\overline{\psi} - \tilde{\mathbf{A}}_\infty\cdot\nabla\overline{\psi}_\infty,\ \psi-\psi_\infty\right\rangle \\
&\quad + \frac{1}{2}\left\langle \tilde{\mathbf{A}}^2\psi - \tilde{\mathbf{A}}_\infty^2\psi_\infty,\ \overline{\psi}-\overline{\psi}_\infty\right\rangle + \frac{1}{2}\left\langle \tilde{\mathbf{A}}^2\overline{\psi} - \tilde{\mathbf{A}}_\infty^2\overline{\psi}_\infty,\ \psi-\psi_\infty\right\rangle \\
&\quad + \frac{1}{2}\left\langle -\lambda^2\left(1-|\psi|^2\right)\psi + \lambda^2\left(1-|\psi_\infty|^2\right)\psi_\infty,\ \overline{\psi}-\overline{\psi}_\infty\right\rangle \\
&\quad + \frac{1}{2}\left\langle -\lambda^2\left(1-|\psi|^2\right)\overline{\psi} + \lambda^2\left(1-|\psi_\infty|^2\right)\overline{\psi}_\infty,\ \psi-\psi_\infty\right\rangle = 0. \qquad (6.17)
\end{aligned}$$

Then, arguing as before, we infer the following estimates:

$$\begin{aligned}
I_{10} &:= \frac{1}{2}\left|i\left\langle \Phi,\ \psi\overline{\psi}_\infty - \overline{\psi}\psi_\infty\right\rangle\right| \\
&\le \frac{1}{2}\left|\left\langle \Phi,\ \psi\overline{\psi}_\infty - \psi_\infty\overline{\psi}_\infty\right\rangle\right| + \frac{1}{2}\left|\left\langle \Phi,\ \psi_\infty\overline{\psi}_\infty - \psi_\infty\overline{\psi}\right\rangle\right| \\
&\le \|\Phi\|_{L^4}\left\|\overline{\psi}_\infty\right\|_{L^4}\|\psi-\psi_\infty\| + \|\Phi\|_{L^4}\|\psi_\infty\|_{L^4}\left\|\overline{\psi}-\overline{\psi}_\infty\right\| \\
&\le \|\nabla\Phi\|^2 + C\|\psi-\psi_\infty\|^2, \qquad (6.18)
\end{aligned}$$

$$\begin{aligned}
I_{11} &:= \left|i\left\langle \tilde{\mathbf{A}}\cdot\nabla\psi - \tilde{\mathbf{A}}_\infty\cdot\nabla\psi_\infty,\ \overline{\psi}-\overline{\psi}_\infty\right\rangle\right| \\
&\le \left|\left\langle \tilde{\mathbf{A}}\cdot\nabla\psi - \tilde{\mathbf{A}}_\infty\cdot\nabla\psi,\ \overline{\psi}-\overline{\psi}_\infty\right\rangle\right| + \left|\left\langle \tilde{\mathbf{A}}_\infty\cdot\nabla\psi - \tilde{\mathbf{A}}_\infty\cdot\nabla\psi_\infty,\ \overline{\psi}-\overline{\psi}_\infty\right\rangle\right| \\
&\le \|\nabla\psi\|_{\mathbf{L}^4}\left\|\tilde{\mathbf{A}}-\tilde{\mathbf{A}}_\infty\right\|_{\mathbf{L}^4}\|\psi-\psi_\infty\| + \left\|\tilde{\mathbf{A}}_\infty\right\|_{\mathbf{L}^\infty}\|\nabla\psi-\nabla\psi_\infty\|\|\psi-\psi_\infty\| \\
&\le \frac{\epsilon\alpha}{16}\left\|\mathrm{curl}\tilde{\mathbf{A}}-\mathrm{curl}\tilde{\mathbf{A}}_\infty\right\|^2 + \frac{1}{16}\|\nabla\psi-\nabla\psi_\infty\|^2 + C\|\psi-\psi_\infty\|^2, \qquad (6.19)
\end{aligned}$$

$$\begin{aligned}
I_{12} &:= \left|i\left\langle \tilde{\mathbf{A}}\cdot\nabla\overline{\psi} - \tilde{\mathbf{A}}_\infty\cdot\nabla\overline{\psi}_\infty,\ \psi-\psi_\infty\right\rangle\right| \\
&\le \frac{\epsilon\alpha}{16}\left\|\mathrm{curl}\tilde{\mathbf{A}}-\mathrm{curl}\tilde{\mathbf{A}}_\infty\right\|^2 + \frac{1}{16}\|\nabla\psi-\nabla\psi_\infty\|^2 + C\|\psi-\psi_\infty\|^2, \qquad (6.20)
\end{aligned}$$

$$\begin{aligned}
I_{13} &:= \left|\frac{1}{2}\left\langle \tilde{\mathbf{A}}^2\psi - \tilde{\mathbf{A}}_\infty^2\psi_\infty,\ \overline{\psi}-\overline{\psi}_\infty\right\rangle\right| \\
&\le \left|\frac{1}{2}\left\langle \tilde{\mathbf{A}}^2\psi - \tilde{\mathbf{A}}_\infty^2\psi,\ \overline{\psi}-\overline{\psi}_\infty\right\rangle\right| + \left|\frac{1}{2}\left\langle \tilde{\mathbf{A}}_\infty^2\psi - \tilde{\mathbf{A}}_\infty^2\psi_\infty,\ \overline{\psi}-\overline{\psi}_\infty\right\rangle\right| \\
&\le C\|\psi\|_{L^\infty}\left\|\tilde{\mathbf{A}}+\tilde{\mathbf{A}}_\infty\right\|_{\mathbf{L}^\infty}\left\|\tilde{\mathbf{A}}-\tilde{\mathbf{A}}_\infty\right\|\|\psi-\psi_\infty\| + C\left\|\tilde{\mathbf{A}}_\infty^2\right\|_{\mathbf{L}^\infty}\|\psi-\psi_\infty\|^2 \\
&\le C\left(\left\|\tilde{\mathbf{A}}-\tilde{\mathbf{A}}_\infty\right\|^2 + \|\psi-\psi_\infty\|^2\right), \qquad (6.21)
\end{aligned}$$

$$I_{14} := \left|\frac{1}{2}\left\langle \tilde{\mathbf{A}}^2\overline{\psi} - \tilde{\mathbf{A}}_\infty^2\overline{\psi}_\infty,\ \psi-\psi_\infty\right\rangle\right| \le C\left(\left\|\tilde{\mathbf{A}}-\tilde{\mathbf{A}}_\infty\right\|^2 + \|\psi-\psi_\infty\|^2\right), \qquad (6.22)$$

$$I_{15} := \left|\frac{1}{2}\left\langle -\lambda^2\left(1-|\psi|^2\right)\psi + \lambda^2\left(1-|\psi_\infty|^2\right)\psi_\infty,\ \overline{\psi}-\overline{\psi}_\infty\right\rangle\right| \le C\|\psi-\psi_\infty\|^2, \qquad (6.23)$$

$$I_{16} := \left| \frac{1}{2} \left\langle -\lambda^2 \left(1 - |\psi|^2\right) \overline{\psi} + \lambda^2 \left(1 - |\psi_\infty|^2\right) \overline{\psi}_\infty,\ \psi - \psi_\infty \right\rangle \right| \le C \|\psi - \psi_\infty\|^2. \tag{6.24}$$

In the above estimates, $\alpha > 0$ and $\epsilon > 0$ are constants to be chosen later.

We now consider (6.7) and take the inner product with $\tilde{\mathbf{A}}_t + \alpha(\tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty)$ in $\mathbf{L}^2(\Omega)$. We thus have

$$\begin{aligned}
&\frac{d}{dt}\left(\frac{1}{2} \|\mathrm{curl}\tilde{\mathbf{A}} - \mathrm{curl}\tilde{\mathbf{A}}_\infty\|^2 + \frac{\varepsilon}{2} \|\tilde{\mathbf{A}}_t\|^2 + \alpha\varepsilon \left\langle \tilde{\mathbf{A}}_t, \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\rangle \right. \\
&\qquad \left. + \frac{\alpha\sigma}{2} \|\tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty\|^2 \right) \\
&+ \alpha \|\mathrm{curl}\tilde{\mathbf{A}} - \mathrm{curl}\tilde{\mathbf{A}}_\infty\|^2 + (\sigma - \alpha\varepsilon) \|\tilde{\mathbf{A}}_t\|^2 \\
&+ \left\langle \tilde{\mathbf{A}} \cdot \tilde{\mathbf{A}}_t, |\psi|^2 \right\rangle - \left\langle \tilde{\mathbf{A}}_\infty \cdot \tilde{\mathbf{A}}_t, |\psi_\infty|^2 \right\rangle \\
&+ \frac{i}{2} \left\langle \overline{\psi}\nabla\psi - \psi\nabla\overline{\psi}, \tilde{\mathbf{A}}_t \right\rangle - \frac{i}{2} \left\langle \overline{\psi}_\infty \nabla\psi_\infty - \psi_\infty \nabla\overline{\psi}_\infty, \tilde{\mathbf{A}}_t \right\rangle \\
&+ \alpha \left\langle |\psi|^2 \tilde{\mathbf{A}} - |\psi_\infty|^2 \tilde{\mathbf{A}}_\infty,\ \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\rangle \\
&+ \frac{\alpha i}{2} \left\langle \overline{\psi}\nabla\psi - \psi\nabla\overline{\psi}, \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\rangle - \frac{\alpha i}{2} \left\langle \overline{\psi}_\infty \nabla\psi_\infty - \psi_\infty \nabla\overline{\psi}_\infty, \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\rangle = 0.
\end{aligned} \tag{6.25}$$

Let us estimate some of the terms in (6.25). We have

$$\begin{aligned}
I_{17} &:= \left| \left\langle \tilde{\mathbf{A}} \cdot \tilde{\mathbf{A}}_t, |\psi|^2 \right\rangle - \left\langle \tilde{\mathbf{A}}_\infty \cdot \tilde{\mathbf{A}}_t, |\psi_\infty|^2 \right\rangle \right| \\
&\le \left| \left\langle \tilde{\mathbf{A}} \cdot \tilde{\mathbf{A}}_t, |\psi|^2 \right\rangle - \left\langle \tilde{\mathbf{A}}_\infty \cdot \tilde{\mathbf{A}}_t, |\psi|^2 \right\rangle \right| \\
&\quad + \left| \left\langle \tilde{\mathbf{A}}_\infty \cdot \tilde{\mathbf{A}}_t, |\psi|^2 \right\rangle - \left\langle \tilde{\mathbf{A}}_\infty \cdot \tilde{\mathbf{A}}_t, |\psi_\infty|^2 \right\rangle \right| \\
&\le \frac{\sigma}{16} \|\tilde{\mathbf{A}}_t\|^2 + C \left(\|\tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty\|^2 + \|\psi - \psi_\infty\|^2 \right),
\end{aligned} \tag{6.26}$$

$$\begin{aligned}
I_{18} &:= \left| \frac{i}{2} \left\langle \overline{\psi}\nabla\psi - \psi\nabla\overline{\psi}, \tilde{\mathbf{A}}_t \right\rangle - \frac{i}{2} \left\langle \overline{\psi}_\infty \nabla\psi_\infty - \psi_\infty \nabla\overline{\psi}_\infty, \tilde{\mathbf{A}}_t \right\rangle \right| \\
&\le \left| \left\langle \overline{\psi}\nabla\psi - \overline{\psi}_\infty \nabla\psi, \tilde{\mathbf{A}}_t \right\rangle \right| + \left| \left\langle \overline{\psi}_\infty \nabla\psi - \overline{\psi}_\infty \nabla\psi_\infty, \tilde{\mathbf{A}}_t \right\rangle \right| \\
&\quad + \left| \left\langle \psi\nabla\overline{\psi} - \psi_\infty \nabla\overline{\psi}, \tilde{\mathbf{A}}_t \right\rangle \right| + \left| \left\langle \psi_\infty \nabla\overline{\psi} - \psi_\infty \nabla\overline{\psi}_\infty, \tilde{\mathbf{A}}_t \right\rangle \right| \\
&\le \frac{\sigma}{16} \|\tilde{\mathbf{A}}_t\|^2 + C_7 \|\nabla\psi - \nabla\psi_\infty\|^2 + C\|\psi - \psi_\infty\|^2,
\end{aligned} \tag{6.27}$$

$$\begin{aligned}
I_{19} &:= \left| \alpha \left\langle |\psi|^2 \tilde{\mathbf{A}} - |\psi_\infty|^2 \tilde{\mathbf{A}}_\infty,\ \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\rangle \right| \\
&\le \alpha \left| \left\langle |\psi|^2 \tilde{\mathbf{A}} - |\psi|^2 \tilde{\mathbf{A}}_\infty,\ \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\rangle \right| + \alpha \left| \left\langle |\psi|^2 \tilde{\mathbf{A}}_\infty - |\psi_\infty|^2 \tilde{\mathbf{A}}_\infty,\ \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\rangle \right| \\
&\le C\alpha \left(\|\tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty\|^2 + \|\psi - \psi_\infty\|^2 \right),
\end{aligned} \tag{6.28}$$

$$\begin{aligned}
I_{20} &:= \left| \frac{\alpha i}{2} \left\langle \overline{\psi}\nabla\psi - \psi\nabla\overline{\psi}, \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\rangle - \frac{\alpha i}{2} \left\langle \overline{\psi}_\infty \nabla\psi_\infty - \psi_\infty \nabla\overline{\psi}_\infty, \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\rangle \right| \\
&\le \alpha \left| \left\langle \overline{\psi}\nabla\psi - \overline{\psi}_\infty \nabla\psi, \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\rangle \right| + \alpha \left| \left\langle \overline{\psi}_\infty \nabla\psi - \overline{\psi}_\infty \nabla\psi_\infty, \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\rangle \right| \\
&\quad + \alpha \left| \left\langle \psi\nabla\overline{\psi} - \psi_\infty \nabla\overline{\psi}, \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\rangle \right| + \alpha \left| \left\langle \psi_\infty \nabla\overline{\psi} - \psi_\infty \nabla\overline{\psi}_\infty, \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\rangle \right| \\
&\le \frac{\alpha}{16} \|\nabla\psi - \nabla\psi_\infty\|^2 + C\alpha \left(\|\psi - \psi_\infty\|^2 + \|\tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty\|^2 \right).
\end{aligned} \tag{6.29}$$

On the other hand, recalling (3.14) and (6.10), we observe that

$$I_{21} := \left| i \left\langle \Phi, \overline{\psi}\psi_t - \psi\overline{\psi}_t \right\rangle \right| \leq \frac{1}{16}\|\psi_t\|^2 + C\|\nabla\Phi\|^2. \tag{6.30}$$

Thus, adding (6.10), the product of (6.17) by constant $M > 0$, (6.25) and (3.14) together, using the above estimates of I_j $(j = 4, \ldots, 21)$, and taking

$$\alpha \in \left(0, \frac{\sigma}{2\varepsilon}\right), \quad M \geq \frac{\sigma}{\varepsilon} + 4C_6 + 2C_7, \quad \epsilon \in \left(0, \frac{3}{M}\right), \tag{6.31}$$

we can find two positive constants C and γ such that

$$\begin{aligned} &\frac{d}{dt}\left(\frac{1}{2}\|\nabla\psi - \nabla\psi_\infty\|^2 + \frac{M}{2}\|\psi - \psi_\infty\|^2 + \frac{1}{2}\left\|\mathrm{curl}\tilde{\mathbf{A}} - \mathrm{curl}\tilde{\mathbf{A}}_\infty\right\|^2\right. \\ &\left. + \frac{\varepsilon}{2}\left\|\tilde{\mathbf{A}}_t\right\|^2 + \alpha\varepsilon\left\langle \tilde{\mathbf{A}}_t, \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\rangle + \frac{\alpha\sigma}{2}\left\|\tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty\right\|^2 + \frac{\varepsilon}{2}\|\nabla\Phi\|^2\right) \\ &+ \gamma\left(\|\psi_t\|^2 + \|\nabla\psi - \nabla\psi_\infty\|^2 + \left\|\mathrm{curl}\tilde{\mathbf{A}} - \mathrm{curl}\tilde{\mathbf{A}}_\infty\right\|^2 + \left\|\tilde{\mathbf{A}}_t\right\|^2 + \|\nabla\Phi\|^2\right) \\ &\leq C\left(\left\|\tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty\right\|^2 + \|\psi - \psi_\infty\|^2 + \|\nabla\Phi\|^2\right). \end{aligned} \tag{6.32}$$

Let us now set

$$\begin{aligned} y := &\frac{1}{2}\|\nabla\psi - \nabla\psi_\infty\|^2 + \frac{M}{2}\|\psi - \psi_\infty\|^2 + \frac{1}{2}\left\|\mathrm{curl}\tilde{\mathbf{A}} - \mathrm{curl}\tilde{\mathbf{A}}_\infty\right\|^2 \\ &+ \frac{\varepsilon}{2}\left\|\tilde{\mathbf{A}}_t\right\|^2 + \alpha\varepsilon\left\langle \tilde{\mathbf{A}}_t, \tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty \right\rangle + \frac{\alpha\sigma}{2}\left\|\tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty\right\|^2 + \frac{\varepsilon}{2}\|\nabla\Phi\|^2. \end{aligned} \tag{6.33}$$

Choosing α small enough, by the Cauchy–Schwarz inequality, we get

$$c_1 y \leq \|\psi_t\|^2 + \|\nabla\psi - \nabla\psi_\infty\|^2 + \left\|\mathrm{curl}\tilde{\mathbf{A}} - \mathrm{curl}\tilde{\mathbf{A}}_\infty\right\|^2 + \left\|\tilde{\mathbf{A}}_t\right\|^2 + \|\nabla\Phi\|^2 \leq c_2 y. \tag{6.34}$$

Therefore, recalling (6.5), we have

$$\frac{d}{dt}y(t) + \hat{\gamma}y(t) \leq C(1+t)^{-2\theta/(1-2\theta)} \qquad \forall\, t \geq 0 \tag{6.35}$$

for some constant $\hat{\gamma} > 0$. Thus, it follows that (see also [14, 34, 35])

$$y(t) \leq C(1+t)^{-2\theta/(1-2\theta)} \qquad \forall\, t \geq 0. \tag{6.36}$$

Furthermore, on account of (6.34), we obtain the estimate of convergence rate in $\mathbb{X}^{-1}$-norm (cf. (2.5)), namely,

$$\|z(t) - z_\infty\|_{-1} \leq C(1+t)^{-\theta/(1-2\theta)} \qquad \forall\, t \geq 0. \tag{6.37}$$

To get (2.25), a further step is needed. We adapt a higher order estimate derived in [3, section 3]. Let us set

$$\begin{aligned} y_1 := &\alpha_1\|\psi_t\|^2 + \left\|\mathrm{curl}\tilde{\mathbf{A}}_t\right\|^2 + \varepsilon\left\|\tilde{\mathbf{A}}_{tt}\right\|^2 + 2\alpha_2\varepsilon\left\langle \tilde{\mathbf{A}}_t,\ \tilde{\mathbf{A}}_{tt} \right\rangle + \alpha_2\sigma\left\|\tilde{\mathbf{A}}_t\right\|^2 \\ &+ \varepsilon\|\Delta\Phi\|^2 + \sigma\|\nabla\Phi\|^2 \end{aligned} \tag{6.38}$$

and choose $\alpha_1, \alpha_2 > 0$ such that (cf. also (2.9))

$$\alpha_1 \geq \max\left\{\frac{\sigma}{\varepsilon}, \frac{1}{\sigma\kappa}\right\} + \frac{24}{\sigma}, \qquad 0 < \alpha_2 \leq \min\left\{\frac{\sigma}{4\varepsilon}, \frac{1}{4\sigma\kappa}\right\}. \tag{6.39}$$

Then we observe that (see [3, equations (3.7) and (3.8)])

$$\frac{1}{2}\left(\alpha_1\|\psi_t\|^2 + \left\|\mathrm{curl}\tilde{\mathbf{A}}_t\right\|^2 + \varepsilon\left\|\tilde{\mathbf{A}}_{tt}\right\|^2 + \varepsilon\|\Delta\Phi\|^2 + \sigma\|\nabla\Phi\|^2\right) \leq y_1, \tag{6.40}$$

$$y_1 \leq \frac{3}{2}\left(\alpha_1\|\psi_t\|^2 + \left\|\mathrm{curl}\tilde{\mathbf{A}}_t\right\|^2 + \varepsilon\left\|\tilde{\mathbf{A}}_{tt}\right\|^2 + \varepsilon\|\Delta\Phi\|^2 + \sigma\|\nabla\Phi\|^2\right). \tag{6.41}$$

Furthermore, a refinement of the argument used in [3, section 3, p. 628] yields

$$\frac{d}{dt}y_1 + \gamma_1 y_1 + \frac{\alpha_1}{2}\|\nabla\psi_t\|^2 + \varepsilon\|\nabla\Phi_t\|^2 \leq C\left(\|\psi_t\|^2 + \|\nabla\Phi\|^2 + \left\|\tilde{\mathbf{A}}_t\right\|^2\right), \tag{6.42}$$

for some $\gamma_1 > 0$, provided that α_1 and α_2 satisfy (6.39).

Hence, on account of (6.37), it follows that

$$\frac{d}{dt}y_1(t) + \gamma_1 y_1(t) \leq C(1+t)^{-2\theta/(1-2\theta)}, \tag{6.43}$$

which gives, using (6.40),

$$\|\psi_t(t)\| + \left\|\mathrm{curl}\tilde{\mathbf{A}}_t(t)\right\| + \left\|\tilde{\mathbf{A}}_{tt}(t)\right\| + \|\Delta\Phi(t)\| \leq C(1+t)^{-\theta/(1-2\theta)} \qquad \forall\, t \geq 0. \tag{6.44}$$

On the other hand, we infer from (6.6) that

$$\begin{aligned}\|\Delta(\psi-\psi_\infty)\| &\leq \|\psi_t\| + C\|\Phi\| + C\left\|\tilde{\mathbf{A}}\cdot\nabla\psi - \tilde{\mathbf{A}}_\infty\cdot\nabla\psi_\infty\right\| + \left\|\tilde{\mathbf{A}}^2\psi - \tilde{\mathbf{A}}_\infty^2\psi_\infty\right\| \\ &\quad + \left\|-\lambda^2\left(1-|\psi|^2\right)\psi + \lambda^2\left(1-|\psi_\infty|^2\right)\psi_\infty\right\|, \end{aligned} \tag{6.45}$$

$$\begin{aligned}\left\|\tilde{\mathbf{A}}\cdot\nabla\psi - \tilde{\mathbf{A}}_\infty\cdot\nabla\psi_\infty\right\| &\leq \left\|\tilde{\mathbf{A}}\cdot\nabla\psi - \tilde{\mathbf{A}}_\infty\cdot\nabla\psi\right\| + \left\|\tilde{\mathbf{A}}_\infty\cdot\nabla\psi - \tilde{\mathbf{A}}_\infty\cdot\nabla\psi_\infty\right\| \\ &\leq \left\|\tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty\right\|_{\mathbf{L}^4}\|\nabla\psi\|_{\mathbf{L}^4} + \left\|\tilde{\mathbf{A}}_\infty\right\|_{\mathbf{L}^\infty}\|\nabla\psi - \nabla\psi_\infty\| \\ &\leq C\left(\left\|\mathrm{curl}\tilde{\mathbf{A}} - \mathrm{curl}\tilde{\mathbf{A}}_\infty\right\| + \|\nabla\psi - \nabla\psi_\infty\|\right), \end{aligned} \tag{6.46}$$

$$\begin{aligned}\left\|\tilde{\mathbf{A}}^2\psi - \tilde{\mathbf{A}}_\infty^2\psi_\infty\right\| &\leq \left\|\tilde{\mathbf{A}}^2\psi - \tilde{\mathbf{A}}^2\psi_\infty\right\| + \left\|\tilde{\mathbf{A}}^2\psi_\infty - \tilde{\mathbf{A}}_\infty^2\psi_\infty\right\| \\ &\leq \left\|\tilde{\mathbf{A}}^2\right\|_{\mathbf{L}^\infty}\|\psi - \psi_\infty\| + \left\|\tilde{\mathbf{A}} + \tilde{\mathbf{A}}_\infty\right\|_{\mathbf{L}^\infty}\left\|\tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty\right\|\|\psi_\infty\|_{L^\infty_{\mathbb{C}}} \\ &\leq C\left(\left\|\tilde{\mathbf{A}} - \tilde{\mathbf{A}}_\infty\right\| + \|\psi - \psi_\infty\|\right), \end{aligned} \tag{6.47}$$

$$\left\|-\lambda^2\left(1-|\psi|^2\right)\psi + \lambda^2\left(1-|\psi_\infty|^2\right)\psi_\infty\right\| \leq C\|\psi - \psi_\infty\|. \tag{6.48}$$

Therefore, due to (6.37), we deduce

$$\|\Delta(\psi(t) - \psi_\infty)\| \leq C(1+t)^{-\theta/(1-2\theta)} \qquad \forall\, t \geq 0. \tag{6.49}$$

Similarly, from (6.7), we obtain

$$\begin{aligned}&\left\|\mathrm{curl}^2\tilde{\mathbf{A}} - \mathrm{curl}^2\tilde{\mathbf{A}}_\infty\right\| \\ &\leq \varepsilon\left\|\tilde{\mathbf{A}}_{tt}\right\| + \varepsilon\|\nabla\Phi_t\| + \sigma\left\|\tilde{\mathbf{A}}_t\right\| + \sigma\|\nabla\Phi\| + \left\||\psi|^2\tilde{\mathbf{A}} - |\psi_\infty|^2\tilde{\mathbf{A}}_\infty\right\| \\ &\quad + \left\|\frac{i}{2}\left(\overline{\psi}\nabla\psi - \psi\nabla\overline{\psi}\right) - \frac{i}{2}\left(\overline{\psi}_\infty\nabla\psi_\infty - \psi_\infty\nabla\overline{\psi}_\infty\right)\right\|. \end{aligned} \tag{6.50}$$

Besides, the following estimates hold:

$$\left\||\psi|^2\tilde{\mathbf{A}} - |\psi_\infty|^2\tilde{\mathbf{A}}_\infty\right\| \le C\left(\|\psi-\psi_\infty\| + \left\|\tilde{\mathbf{A}}-\tilde{\mathbf{A}}_\infty\right\|\right), \tag{6.51}$$

$$\left\|\frac{i}{2}\left(\overline{\psi}\nabla\psi - \psi\nabla\overline{\psi}\right) - \frac{i}{2}\left(\overline{\psi}_\infty\nabla\psi_\infty - \psi_\infty\nabla\overline{\psi}_\infty\right)\right\| \le C\left(\|\psi-\psi_\infty\| + \|\nabla\psi-\nabla\psi_\infty\|\right). \tag{6.52}$$

As a result, owing to (6.37), we infer from (5.7) and (6.50)–(6.52) that

$$\left\|\mathrm{curl}^2\tilde{\mathbf{A}}(t) - \mathrm{curl}^2\tilde{\mathbf{A}}_\infty\right\| \le C(1+t)^{-\theta/(1-2\theta)} \qquad \forall\, t \ge 0. \tag{6.53}$$

Finally, (2.25) follows from (6.37), (6.44), (6.49), and (6.53).

The proof of Theorem 2.1 is now complete.

Acknowledgments. This paper was conceived on occasion of a first author's visit to the Institute of Mathematics in Fudan University, whose hospitality is gratefully acknowledged.

ON A FOURTH ORDER NONLINEAR ELLIPTIC EQUATION WITH NEGATIVE EXPONENT*

ZONGMING GUO† AND JUNCHENG WEI‡

Abstract. We consider the following nonlinear fourth order equation: $T\Delta u - D\Delta^2 u = \frac{\lambda}{(L+u)^2}$, $-L < u < 0$, in Ω, $u = 0$, $\Delta u = 0$ on $\partial\Omega$, where $\lambda > 0$ is a parameter. This nonlinear equation models the deflection of charged plates in electrostatic actuators under the pinned boundary condition (Lin and Yang [*Proc. R. Soc. Lond. Ser. A Math. Phys. Eng. Sci.*, 463 (2007), pp. 1323–1337]). Lin and Yang proved that there exists a $\lambda_c > 0$ such that for $\lambda > \lambda_c$ there is no solution, while for $\lambda < \lambda_c$ there is a branch of maximal solutions. In this paper, we show that in the physical domains (two or three dimensions) the maximal solution is unique and regular at $\lambda = \lambda_c$. In a two-dimensional (2D) convex smooth domain, we also establish the existence of a second mountain-pass solution for $\lambda \in (0, \lambda_c)$. The asymptotic behavior of the second solution is also studied. The main difficulty is the analysis of the touch-down behavior.

Key words. fourth order, electrostatic actuation, touch-down, pull-in threshold

1. Introduction.

We consider the structure of solutions to the problem

$$(P_\lambda) \qquad \begin{cases} T\Delta u - D\Delta^2 u = \frac{\lambda}{(L+u)^2} & \text{in } \Omega, \\ -L < u \le 0 & \text{in } \Omega, \\ u = 0, \quad \Delta u = 0 & \text{on } \partial\Omega, \end{cases}$$

where $\lambda > 0$ is a parameter, $T > 0$, $D > 0$, and $L > 0$ are fixed constants, and $\Omega \subset \boldsymbol{R}^N$ $(N \ge 2)$ is a bounded smooth domain.

When $D = 0$, problem (P_λ) becomes

$$(Q_\lambda) \qquad \begin{cases} T\Delta u = \frac{\lambda}{(L+u)^2} & \text{in } \Omega, \\ -L < u \le 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

which models a simple electrostatic microelectromechanical system (MEMS) device consisting of a thin dielectric elastic membrane with boundary supported at 0 above a rigid plate located at $-L$. Here $L + u$ represents the distance from the membrane to the plate. Recently there have been many studies on (Q_λ). See, for example, [9], [14], [15], [16], [10], [11], [12], [7], [8], [17], [25], [24], and the references therein. These papers deal only with second order semilinear elliptic equations with singular nonlinearities. Equation (Q_λ) also appears in the study of thin film; see, for example, [2], [3], [5], [19], [20], [21], [18], and the references therein.

In a recent paper [22], Lin and Yang derived the fourth order equation (P_λ) in the study of the deflection of charged plates in electrostatic actuators. Here $\lambda = aV^2$, where V is the electric voltage and a is positive constant. Associated with (P_λ) is the energy functional

$$E(u) = \int_\Omega \left\{ \frac{T}{2}|\nabla u|^2 + \frac{D}{2}|\Delta u|^2 - \frac{\lambda}{L+u} \right\}, \tag{1.1}$$

where $P = \int_\Omega \frac{T}{2}|\nabla u|^2 dx$ is the stretching energy, $Q = \int_\Omega \frac{D}{2}|\Delta u|^2 dx$ corresponds to the bending energy, and $W = -\int_\Omega \frac{\lambda}{L+u(x)} dx$ is the electric potential energy.

Lin and Yang [22] considered two kinds of boundary conditions: the pinned boundary condition

$$u = \Delta u = 0 \text{ on } \partial\Omega$$

and the clamped boundary condition

$$u = \frac{\partial u}{\partial n} = 0 \text{ on } \partial\Omega.$$

For the pinned boundary condition problem (P_λ), they found that there exists $0 < \lambda_c < \infty$ such that for $\lambda \in (0, \lambda_c)$, (P_λ) has a maximal regular solution u_λ, which can be obtained from an iterative scheme. (By a regular solution u_λ of (P_λ), we mean that $u_\lambda \in C^4(\Omega) \cap C^3(\overline{\Omega})$ satisfies (P_λ).) For $\lambda > \lambda_c$, (P_λ) does not have any regular solution. Moreover, if λ', $\lambda'' \in (0, \lambda_c)$ and $\lambda' < \lambda''$, then the corresponding maximal solutions $u_{\lambda'}$ and $u_{\lambda''}$ satisfy

$$u_{\lambda'} > u_{\lambda''} \quad \text{in } \Omega.$$

Physically, this is a natural relation because a higher supply voltage results in a greater elastic deformation or deflection.

The number λ_c, which determines the pull-in voltage, is called the pull-in threshold. It is known from [22] that, for $\lambda \in (0, \lambda_c)$, $\min_\Omega(L + u_\lambda) > 0$. Let $\Sigma_\lambda = \{x \in \Omega : L + u_\lambda(x) = 0\}$ be the singular set of (P_λ). An interesting question is to study the limit of u_λ as $\lambda \nearrow \lambda_c$. The monotonicity of u_λ with respect to λ implies that there is a well-defined function U so that

$$U(x) = \lim_{\lambda \to \lambda_c^-} u_\lambda(x); \quad -L \le U(x) < 0, \quad x \in \Omega.$$

However, $U(x)$ may touch down to $-L$ and cease to be a regular solution to (P_{λ_c}). (By [22], $U \in W^{2,2}_{loc}(\Omega)$.) For the one-dimensional case, Lin and Yang showed that U is a regular solution; that is, the set $\Sigma_{\lambda_c} = \emptyset$.

In this paper, we will show that *for two dimensions and three dimensions, U is a regular solution*. Moreover, we also show that there is a *unique solution for* (P_λ) *at* $\lambda = \lambda_c$. To obtain our results, we first prove that the solutions u_λ for $\lambda \in (0, \lambda_c)$ obtained in [22] are stable in some sense. Furthermore, we also obtain the structure of solutions of (P_λ) in the two-dimensional (2D) case. Our main results of this paper are as follows.

THEOREM 1.1. *For dimension $N = 2$ or 3, there exists a constant $0 < C := C(N, L)$ independent of λ such that for any $0 < \lambda < \lambda_c$, the maximal solution u_λ of (P_λ) satisfies* $\min_\Omega(L + u_\lambda) \ge C$.

Consequently, $u_{\lambda_c} = \lim_{\lambda \nearrow \lambda_c} u_\lambda$ *exists in the topology of* $C^4(\Omega)$. *It is the unique regular solution to* (P_{λ_c}).

THEOREM 1.2. *Let* $N = 2$ *and* Ω *be a bounded, smooth, and convex domain in* $\boldsymbol{R}^2$. *For* $\lambda \in (0, \lambda_c]$, *any solution of the problem* (P_λ) *is regular and the following hold.*

(i) *For* $0 < \lambda < \lambda_c$, *problem* (P_λ) *admits two solutions: the maximal solution and a mountain-pass solution.*

(ii) *For* $\lambda = \lambda_c$, *problem* (P_λ) *admits a unique regular solution.*

(iii) *For* $\lambda > \lambda_c$, *problem* (P_λ) *admits no regular solution.*

Furthermore, the mountain-pass solution V_λ *has the following asymptotic behavior as* $\lambda \to 0$*:*

$$\max_\Omega V_\lambda \to L \ \text{ as } \lambda \to 0, \quad \lim_{\lambda \to 0^+} \frac{[\min_\Omega (L - V_\lambda)]^3}{\lambda} = 0. \tag{1.2}$$

Remark. Theorem 1.2 shows that the bifurcation diagram of (P_λ) changes drastically when $D > 0$. In a nice 2D domain (see [16]), it has been proved in [16] that for λ small, the maximal solution is *unique*, and there exists $0 < \lambda_* < \lambda_c$ such that the solutions to (Q_λ) undergo infinitely many turning points. An interesting question is the asymptotic behavior as $D \to 0$. When $\Omega = B_1 \subset \boldsymbol{R}^2$, the complete bifurcation picture as well as the asymptotic behavior when $D \to 0$ has been considered in [23].

The organization of the paper is as follows: in section 2, we present some preliminary results on the first eigenvalue and the corresponding eigenfunction of the problem

$$-T\Delta\phi + D\Delta^2\phi = \sigma\phi \ \text{ in } \Omega, \quad \phi = \Delta\phi = 0 \ \text{ on } \partial\Omega.$$

In section 3, we derive a key L^1 bound for $\frac{1}{(L+u)^2}$. In section 4, we show the stability of the maximal solutions of (P_λ). In section 5, we show that the solution at the pull-in threshold is regular for $N = 2$ or 3. In section 6, we show that any weak solution at the pull-in threshold is unique. In section 7, we present the structure of the solutions of (P_λ) for the 2D case. We show that for $0 < \lambda < \lambda_c$, (P_λ) admits at least two solutions: the maximal solution and a mountain-pass solution. Finally in section 8, we give some asymptotic behaviors of the mountain-pass solution as $\lambda \to 0^+$.

2. The first eigenfunction. In this section, we study the following eigenvalue problem:

$$-T\Delta\phi + D\Delta^2\phi = \sigma\phi \ \text{ in } \Omega, \quad \phi = \Delta\phi = 0 \ \text{ on } \partial\Omega, \tag{2.1}$$

where T, $D > 0$. We will show that (2.1) has the least eigenvalue σ_1 and the corresponding eigenfunction $\phi_1 > 0$ in Ω. Moreover, ϕ_1 is simple; i.e., all the eigenfunctions corresponding to σ_1 assume the forms of $C\phi_1$ with $C \in \boldsymbol{R}$.

PROPOSITION 2.1. *Problem* (2.1) *has the least eigenvalue* σ_1 *such that all the eigenfunctions corresponding to* σ_1 *assume the forms of* $C\phi_1$, *where* $\phi_1 \in C^\infty(\Omega)$ *and* $\phi_1 > 0$ *in* Ω.

Proof. This proposition may be known, but we cannot find the reference. We give a proof here for completeness.

Consider the following minimization problem:

$$\sigma_1 := \inf \left\{ \int_\Omega [T|\nabla\phi|^2 + D|\Delta\phi|^2]dx : \ \phi \in \mathcal{H}, \ \ \|\phi\|_{L^2(\Omega)} = 1 \right\}, \tag{2.2}$$

where $\mathcal{H} = H^2(\Omega) \cap H_0^1(\Omega)$ is the function space obtained by taking the completion under the norm of $H^2(\Omega) \cap H_0^1(\Omega)$ (i.e., $\|\psi\| = (\int_\Omega [T|\nabla\psi|^2 + D|\Delta\psi|^2]dx)^{1/2}$) for the set of smooth functions that satisfy the boundary condition $\phi = \Delta\phi = 0$ on $\partial\Omega$. Since the Sobolev embedding $\mathcal{H} \hookrightarrow L^2(\Omega)$ is compact, by the standard direct method of calculus of variations, we have at least one minimizer ϕ_1 for the problem (2.2), where $\phi_1 \in \mathcal{H}$, $\|\phi_1\|_{L^2(\Omega)} = 1$. Furthermore, ϕ_1 is a weak solution to (2.1); namely,

$$\int_\Omega [T\nabla\phi_1\nabla\phi + D\Delta\phi_1\Delta\phi] = \sigma_1 \int_\Omega \phi_1\phi dx \quad \forall\phi \in \mathcal{H}. \tag{2.3}$$

Using the L^p-estimates due to Agmon, Douglis, and Nirenberg [1], we conclude that

$$\|\phi_1\|_{W^{4,p}(\Omega)} \le C\|\phi_1\|_{L^p(\Omega)}$$

for any $p > 1$. Thus we have $\phi_1 \in C^4(\Omega) \cap C^3(\bar\Omega)$, and hence $\Delta\phi_1 = 0$ on $\partial\Omega$, and ϕ_1 satisfies (2.1). (See a similar argument in Lemma B.3 of [27].)

It is clear that

$$\sigma_1 = \frac{\int_\Omega [T|\nabla\phi_1|^2 + D|\Delta\phi_1|^2]dx}{\int_\Omega \phi_1^2 dx} = \inf_{\phi\in\mathcal{H}\setminus\{0\}} \frac{\int_\Omega [T|\nabla\phi|^2 + D|\Delta\phi|^2]dx}{\int_\Omega \phi^2 dx}.$$

In order to show that ϕ_1 is of fixed sign, we consider the following new problem:

$$-T\Delta\psi_1 + D\Delta^2\psi_1 = \sigma_1|\phi_1| \ \text{ in } \Omega, \quad \psi_1 = \Delta\psi_1 = 0 \ \text{ on } \partial\Omega. \tag{2.4}$$

By the maximum principle, $\psi_1 > 0$, $-D\Delta\psi_1 + T\psi_1 > 0$ in Ω. Furthermore, we have $\psi_1 \ge \phi_1, \psi_1 \ge -\phi_1$, and hence $\psi_1 \ge |\phi_1|$ in Ω.

On the other hand, from (2.4) we obtain

$$\int_\Omega [T|\nabla\psi_1|^2 + D|\Delta\psi_1|^2]dx = \sigma_1 \int_\Omega \psi_1|\phi_1|dx \le \sigma_1 \int_\Omega |\psi_1|^2 dx. \tag{2.5}$$

By the minimality of σ_1, we have

$$\sigma_1 = \frac{\int_\Omega [T|\nabla\psi_1|^2 + D|\Delta\psi_1|^2]dx}{\int_\Omega |\psi_1|^2 dx}. \tag{2.6}$$

Thus ψ_1 also attains σ_1, and hence the inequality of (2.5) is actually an equality. This implies that $\psi_1 = |\phi_1|$ in Ω. Since $\psi_1 > 0$ in Ω, we conclude that ϕ_1 is of fixed sign in Ω.

The above argument actually proves that any nonzero eigenfunction corresponding to σ_1 must be of fixed sign in Ω. So if ϕ_1 and ϕ_2 are two eigenfunctions corresponding to σ_1, we may choose $\phi_1 > 0, \phi_2 > 0$. Let $x_0 \in \Omega$ and $C = \frac{\phi_1(x_0)}{\phi_2(x_0)}$. Then the function $\phi_1 - C\phi_2$ is again an eigenfunction corresponding to σ_1. By the previous argument, we see that $\phi_1 \equiv C\phi_2$ in Ω. This completes the proof. □

3. A uniform L^1 bound. In this section, we establish a key uniform L^1 bound for $\frac{1}{(L-v)^2}$, where v satisfies

$$(T_\lambda) \qquad \begin{cases} -T\Delta v + D\Delta^2 v = \frac{\lambda}{(L-v)^2} & \text{in } \Omega, \\ 0 < v < L & \text{in } \Omega, \\ v = 0, \quad \Delta v = 0 & \text{on } \partial\Omega \end{cases}$$

(which is equivalent to (P_λ) by taking $u = -v$). Note that $v \in C^4(\Omega)\cap C^2(\overline{\Omega})$ provided that v satisfies (T_λ).

THEOREM 3.1. *Let Ω be a bounded, smooth, and convex domain. Then there exists a constant C (independent of λ) such that for any solution v to (T_λ) we have*

$$\int_\Omega \frac{1}{(L-v)^2} \le \frac{C}{\lambda}. \tag{3.1}$$

As a consequence, we have

$$\int_\Omega (D|\Delta v|^2 + T|\nabla v|^2) \le C. \tag{3.2}$$

Proof. Let ϕ_1 be as given in Proposition 2.1. Multiplying (T_λ) by ϕ_1 and integrating over Ω, we obtain

$$\lambda \int_\Omega \frac{1}{(L-v)^2}\phi_1 = \sigma_1 \int_\Omega v\phi_1 \le C, \tag{3.3}$$

which implies that

$$\int_{\Omega'} \frac{1}{(L-v)^2} \le \frac{C_{\Omega'}}{\lambda} \tag{3.4}$$

for any $\Omega' \subset\subset \Omega$, where $C_{\Omega'}$ is independent of λ.

We write (T_λ) as

$$\begin{cases} \Delta v + \frac{1}{D}w - \frac{T}{D}v = 0 & \text{in } \Omega, \\ \Delta w + \frac{\lambda}{(L-v)^2} = 0 & \text{in } \Omega, \\ v = w = 0 & \text{on } \partial\Omega. \end{cases}$$

If we denote $f_1(v,w) = -\frac{T}{D}v + \frac{1}{D}w$, $f_2(v,w) = \frac{\lambda}{(L-v)^2}$, we see that $\frac{\partial f_1}{\partial w} = \frac{1}{D} > 0$ and $\frac{\partial f_2}{\partial v} = \frac{2\lambda}{(L-v)^3} > 0$. Therefore, the convexity of Ω, Lemma 5.1 of [26], and the moving plane method near $\partial\Omega$ as in the appendix of [13] imply that there exist $t_0 > 0$ and $\alpha > 0$ depending only on the domain Ω, such that *$v(x - t\nu)$ and $w(x - t\nu)$ are nondecreasing for $t \in [0, t_0]$, $\nu \in R^N$ satisfying $|\nu| = 1$ and $(\nu, n(x)) \ge \alpha$ and $x \in \partial\Omega$.* Therefore, we can find $\gamma, \delta > 0$ such that for any $x \in \Omega_\delta := \{z \in \bar{\Omega} : d(z, \partial\Omega) < \delta\}$ there exists a fixed-sized cone Γ_x (with x as its vertex) with

(i) $meas(\Gamma_x) \ge \gamma$,

(ii) $\Gamma_x \subset \{z \in \Omega : d(z, \partial\Omega) < \delta\}$, and

(iii) $v(y) \ge v(x)$ for any $y \in \Gamma_x$.

Then, for any $x \in \Omega_\delta$, we have

$$\frac{1}{(L-v(x))^2} \le \frac{1}{meas(\Gamma_x)} \int_{\Gamma_x} \frac{1}{(L-v)^2} \le \frac{1}{\gamma} \int_{\Omega_\delta} \frac{1}{(L-v)^2} \le \frac{C}{\lambda}.$$

This implies that $\frac{1}{(L-v)^2} \in L^\infty(\Omega_\delta)$ and there is $C > 0$ independent of λ such that

$$\sup_{x\in\Omega_\delta} v < L - C\sqrt{\lambda}. \tag{3.5}$$

Next, we derive estimates for w near $\partial\Omega$. Multiplying the second equation of the equivalent system of (T_λ) by φ_0, the first eigenfunction of $-\Delta$, and integrating over Ω, we obtain

$$\lambda \int_\Omega \frac{1}{(L-v)^2}\varphi_0 = \lambda_1 \int_\Omega \varphi_0 w, \tag{3.6}$$

where λ_1 is the first eigenvalue of $-\Delta$. By (3.3), we have that

$$\lambda_1 \int_\Omega \varphi_0 w = \lambda \int_\Omega \frac{1}{(L-v)^2}\varphi_0 \le \lambda C \int_\Omega \frac{1}{(L-v)^2}\phi_1 \le C, \tag{3.7}$$

and hence

$$\int_{\Omega'} w \le C_{\Omega'}$$

for any $\Omega' \subset\subset \Omega$. To see the second inequality of (3.7), we notice that there exist $\ell_i > 0$ $(i = 1, 2, 3, 4)$ such that

$$\ell_1 d(x) \le \varphi_0(x) \le \ell_2 d(x), \quad \ell_3 d(x) \le \phi_1(x) \le \ell_4 d(x),$$

where $d(x) = \operatorname{dist}(x, \partial\Omega)$. Hence $\varphi_0(x) \le C\phi_1(x)$. The same reason as above shows that $w \le C(\Omega_\delta)$.

By elliptic regularity applied to the system (T_λ) (noting that $v, w, and\ \frac{1}{(L-v)^2}$ are all bounded in Ω_δ), we have $v \in C^3(\Omega_\delta)$, and hence

$$\lambda \int_\Omega \frac{1}{(L-v)^2} = D \int_{\partial\Omega} \frac{\partial \Delta v}{\partial n} - T \int_\Omega \frac{\partial v}{\partial n} \le C.$$

To prove the inequality (3.2), we multiply (T_λ) by v and integrate over Ω to obtain

$$T \int_\Omega |\nabla v|^2 + D \int_\Omega |\Delta v|^2 = \lambda \int_\Omega \frac{Lv}{(L-v)^2} \le C. \qquad \square$$

4. Stability of the maximal solutions of (P_λ). In this section, we show that the maximal solutions u_λ to (P_λ) obtained in [22] for $\lambda \in (0, \lambda_c)$ are stable in some sense. Let $v_\lambda = -u_\lambda$. Then, from [22], for each $\lambda \in (0, \lambda_c)$, (T_λ) has a minimal positive solution v_λ.

We call v_λ stable if the first eigenvalue $\sigma_{1,\lambda}(v_\lambda)$ of the problem

$$-T\Delta h + D\Delta^2 h = \frac{2\lambda}{(L-v_\lambda)^3}h + \sigma h \ \text{ in } \Omega, \quad h = \Delta h = 0 \ \text{ on } \partial\Omega \tag{4.1}$$

is nonnegative. By arguments similar to those in the proof of Proposition 2.1, we see that the first eigenvalue $\sigma_{1,\lambda}(v_\lambda)$ exists and every eigenfunction corresponding to $\sigma_{1,\lambda}(v_\lambda)$ is of fixed sign if $\sigma_{1,\lambda}(v_\lambda) \ge 0$.

LEMMA 4.1. *Suppose that v is a regular solution of (T_λ), and u is a regular supersolution of (T_λ); that is,*

$$\begin{cases} -T\Delta u + D\Delta^2 u \ge \frac{\lambda}{(L-u)^2} & \text{in } \Omega, \\ 0 < u < L & \text{in } \Omega, \\ u = 0, \ \ \Delta u = 0 & \text{on } \partial\Omega. \end{cases}$$

If $\sigma_{1,\lambda}(v) > 0$, then $u \geq v$ in Ω, and if $\sigma_{1,\lambda}(v) = 0$, then $u = v$ in Ω.

Proof. For a given λ and $x \in \Omega$, by the fact that $s \to (L-s)^{-2}$ is convex on $(0, L)$, we see that

$$-T\Delta(v+\tau(u-v)) + D\Delta^2(v+\tau(u-v)) - \frac{\lambda}{[L-(v+\tau(u-v))]^2} \geq 0 \text{ in } \Omega \tag{4.2}$$

for $\tau \in [0,1]$. Note that (4.2) is an identity at $\tau = 0$, which means that the first derivative of the left-hand side of (4.2) with respect to τ is nonnegative at $\tau = 0$, i.e.,

$$\begin{cases} -T\Delta(u-v) + D\Delta^2(u-v) - \frac{2\lambda}{(L-v)^3}(u-v) \geq 0 & \text{in } \Omega, \\ u - v = 0, \ \ \Delta(u-v) = 0 & \text{on } \partial\Omega. \end{cases} \tag{4.3}$$

Thus, the fact $\sigma_{1,\lambda}(v) > 0$ implies that $u \geq v$ in Ω. Indeed, on the contrary, we see that $0 \not\equiv (u-v)^- \in H^2(\Omega) \cap H_0^1(\Omega)$. Multiplying $(u-v)^-$ on both the sides of (4.3) and integrating it on Ω, we see that

$$\begin{aligned} &\sigma_{1,\lambda}(v) \int_\Omega [(u-v)^-]^2 dx \\ &\quad \leq T \int_\Omega |\nabla(u-v)^-|^2 dx + D \int_\Omega |\Delta(u-v)^-|^2 dx - \int_\Omega \frac{2\lambda}{(L-v)^3}[(u-v)^-]^2 dx \\ &\quad \leq 0. \end{aligned}$$

This contradicts $\sigma_{1,\lambda}(v) > 0$.

If $\sigma_{1,\lambda}(v) = 0$, we have

$$-T\Delta(u-v) + D\Delta^2(u-v) - \frac{2\lambda}{(L-v)^3}(u-v) = 0 \text{ in } \Omega.$$

Moreover, the second derivative of the left-hand side of (4.2) with respect to τ at $\tau = 0$ is

$$-6\lambda(L-v)^{-4}(u-v)^2 \geq 0,$$

which implies that $u \equiv v$ in Ω. This completes the proof. □

PROPOSITION 4.2. *For each $\lambda \in (0, \lambda_c)$, the minimal positive solution v_λ of (T_λ) is stable.*

Proof. Since $\sigma_1 > 0$, we easily see that the first eigenvalue $\sigma_{1,\lambda}(v_\lambda)$ of problem (4.1) is positive provided that λ is sufficiently small. Now we prove that $\sigma_{1,\lambda}(v_\lambda) > 0$ for $\lambda \in (0, \lambda_c)$.

We define

$$\lambda^* = \sup\{\rho : \ v_\lambda \text{ is a stable solution for } \lambda \in (0, \rho)\}.$$

It is clear that $\lambda^* \leq \lambda_c$. To show $\lambda^* = \lambda_c$, it suffices to prove that there is no regular minimal solution for (T_λ) with $\lambda > \lambda^*$. For that, suppose w is a regular minimal solution of $(T_{\lambda^*+\delta})$ with $\delta > 0$; then we would have for $\lambda \leq \lambda^*$

$$-T\Delta w + D\Delta^2 w = \frac{\lambda^* + \delta}{(L-w)^2} \geq \frac{\lambda}{(L-w)^2} \text{ in } \Omega.$$

Since for $0 < \lambda < \lambda^*$ the minimal solution v_λ is stable, it follows from Lemma 4.1 that $L > w \geq v_\lambda$. Consequently, $\overline{v} = \lim_{\lambda \nearrow \lambda^*} v_\lambda$ exists in $C^4(\Omega)$, and it is a regular solution to (T_{λ^*}). Now, from the definition of λ^* and the implicit function theorem, we necessarily have $\sigma_{1,\lambda^*}(\overline{v}) = 0$. By Lemma 4.1 again, we obtain that $w \equiv \overline{v}$ in Ω and hence $\delta = 0$. This is a contradiction. Therefore, $\lambda^* = \lambda_c$. This completes the proof. □

5. The regularity of the minimal solution of (T_λ) at $\lambda = \lambda_c$. In this section, we are concerned with the regularity of the minimal solutions of (T_λ) at $\lambda = \lambda_c$. Normally, the minimal solution v_λ at $\lambda = \lambda_c$ may have a singular set in Ω; i.e., there exists a set $\Sigma_{\lambda_c} \subset \Omega$ such that $v_{\lambda_c}(x) = L$ for $x \in \Sigma_{\lambda_c}$. But we will see that for the lower dimensional case, $v_{\lambda_c} < L$ in Ω.

By a weak solution $v \in \mathcal{H}$ of (T_λ) we mean $0 < v \le L$ in Ω and $(L-v)^{-2} \in L^1(\Omega)$ such that for any $\varphi \in \mathcal{H}$,

$$\int_\Omega [T\nabla v \cdot \nabla\varphi + D\Delta v\Delta\varphi]dx = \lambda \int_\Omega (L-v)^{-2}\varphi dx.$$

LEMMA 5.1. *If $v \in \mathcal{H}$ is a weak solution to (T_λ), then there exists $C := C(\lambda) > 0$ such that*

$$\int_\Omega \frac{dx}{(L-v)^2} \le C.$$

For $N \ge 2$, any solution v satisfying $(L-v)^{-2} \in L^p(\Omega)$ with $p = N/2$ is a classical solution.

Proof. For the first conclusion, we see that, since $v \in \mathcal{H}$ is a solution of (T_λ),

$$\int_\Omega \frac{v}{(L-v)^2}dx = \frac{1}{\lambda}\left[\int_\Omega (|\nabla v|^2 + |\Delta v|^2)dx\right] \le C. \tag{5.1}$$

On the other hand, we see that

$$\frac{v}{(L-v)^2} = \frac{L}{(L-v)^2} - \frac{1}{(L-v)}.$$

Thus, (5.1) implies that

$$\int_\Omega \frac{L}{(L-v)^2}dx = \int_\Omega \frac{1}{(L-v)}dx + \int_\Omega \frac{v}{(L-v)^2}dx. \tag{5.2}$$

By Young's inequality, we have that

$$\int_\Omega \frac{1}{(L-v)}dx \le \epsilon L \int_\Omega \frac{1}{(L-v)^2}dx + C(\epsilon, L)|\Omega|, \tag{5.3}$$

where $0 < \epsilon < 1/4$ and $C(\epsilon, L) > 0$ is a constant. Our first conclusion can be obtained from (5.1), (5.2), and (5.3).

For $N = 2$, suppose that v is a weak solution such that $\frac{1}{(L-v)^2} \in L^1(\Omega)$. Thus,

$$-D\Delta^2 v = \lambda(L-v)^{-2} - T\Delta v \in L^1(\Omega).$$

This and the Sobolev embedding imply that $\nabla^3 v \in L^q(\Omega)$ for any $1 < q < 2$. In particular, $\nabla v \in C^{2-\frac{2}{q}}(\Omega)$ for any $1 < q < 2$. This and the fact that $(L-v)^{-2} \in L^1(\Omega)$ clearly imply that $v < L$ in Ω. In fact, on the contrary, suppose that there exists $x_0 \in \Omega$ such that $v(x_0) = \max_\Omega v = L$. Then, $\nabla v(x_0) = 0$ and

$$v(x) - v(x_0) = \nabla v(\xi) \cdot (x - x_0) \text{ for } x \in \Omega \text{ near } x_0,$$

where $\xi = tx_0 + (1-t)x$ with $t \in (0,1)$. Moreover, since $\nabla v \in C^{2-\frac{2}{q}}(\Omega)$, we see that

$$|\nabla v(\xi) - \nabla v(x_0)| \le M|\xi - x_0|^{2-\frac{2}{q}} \le M|x - x_0|^{2-\frac{2}{q}},$$

and thus

$$|v(x)-v(x_0)| \le M|x-x_0|^{3-\frac{2}{q}} \text{ for } x\in\Omega \text{ near } x_0.$$

This inequality shows that

$$\infty > \int_\Omega \frac{1}{(L-v)^2}dx \ge M^{-2}\int_\Omega |x-x_0|^{-(6-\frac{4}{q})}dx = \infty,$$

which is a contradiction, which implies that we must have $\|v\|_{C(\overline{\Omega})} < L$.

For $N \ge 3$, suppose that v is a weak solution such that $\frac{1}{(L-v)^2} \in L^p(\Omega)$ with $p = \frac{N}{2}$. By the regularity of Δ^2, we see that $v \in W^{4,p}(\Omega)$. The Sobolev embedding theorem then implies that $v \in C^{1,\alpha}(\Omega)$ with $\alpha < 1$ since $4 - \frac{N}{p} = 2$. To show that v is a classical solution, it suffices to show that $v < L$ in Ω. Indeed, on the contrary, there exists $x_0 \in \Omega$ such that $v(x_0) = \max_\Omega v = L$. Then, $\nabla v(x_0) = 0$ and

$$v(x)-v(x_0) = \nabla v(\xi)\cdot(x-x_0) \text{ for } x\in\Omega \text{ near } x_0, \tag{5.4}$$

where $\xi = tx_0 + (1-t)x$ with $t \in (0,1)$. Moreover, since $v \in C^{1,1}(\Omega)$, we see that $|\nabla v(\xi) - \nabla v(x_0)| \le M|\xi - x_0| \le M|x-x_0|$. This and (5.4) imply that

$$|v(x)-v(x_0)| \le M|x-x_0|^{1+\alpha} \text{ for } x\in\Omega. \tag{5.5}$$

This inequality shows that

$$\infty > \int_\Omega \left(\frac{1}{(L-v)^2}\right)^p dx \ge M^{-2p}\int_\Omega |x-x_0|^{-2(1+\alpha)p}dx = \infty,$$

which is a contradiction, which implies that we must have $\|v\|_{C(\overline{\Omega})} < L$. This completes the proof. □

PROPOSITION 5.2. *There exists a constant $C := C(L,\lambda) > 0$ such that for each $\lambda \in (0,\lambda_c)$, the minimal solution v_λ satisfies $\|(L-v_\lambda)^{-2}\|_{L^{3/2}(\Omega)} \le C$.*

Proof. Since the minimal solutions v_λ are stable, we have

$$\int_\Omega \frac{2\lambda}{(L-v_\lambda)^3}w^2dx \le \int_\Omega [T|\nabla w|^2 + D|\Delta w|^2]dx \tag{5.6}$$

for all $0 < \lambda < \lambda_c$ and nonnegative $w \in \mathcal{H}$.

Let $w = v_\lambda$; we then have

$$\int_\Omega \frac{2\lambda}{(L-v_\lambda)^3}v_\lambda^2dx \le \int_\Omega [T|\nabla v_\lambda|^2 + D|\Delta v_\lambda|^2]dx = \int_\Omega \frac{\lambda v_\lambda}{(L-v_\lambda)^2}. \tag{5.7}$$

Since $v_\lambda < L$, this implies that

$$\int_\Omega \frac{v_\lambda^2}{(L-v_\lambda)^3}dx \le C \tag{5.8}$$

and

$$\int_\Omega \frac{L^2}{(L-v_\lambda)^3}dx \le \int_\Omega \frac{v_\lambda^2}{(L-v_\lambda)^3}dx + \int_\Omega \frac{(L-v_\lambda)^2}{(L-v_\lambda)^3}dx \le C + \int_\Omega \frac{1}{L-v_\lambda}dx. \tag{5.9}$$

Hence

$$\int_\Omega \frac{1}{(L-v_\lambda)^3}dx \le C. \tag{5.10}$$

This completes the proof. □

Now we obtain the following theorem, from which our Theorem 1.1 can be obtained.

THEOREM 5.3. *For dimension $N = 2$ or 3, there exists a constant $0 < C := C(N, L) < L$ independent of λ such that for any $0 < \lambda < \lambda_c$, the minimal solution v_λ of (T_λ) satisfies $\|v_\lambda\|_{C(\Omega)} \le C$.*

Consequently, $v_{\lambda_c} = \lim_{\lambda \nearrow \lambda_c} v_\lambda$ exists in the topology of $C^4(\Omega)$. It is the unique classical solution to (T_{λ_c}).

Proof. By Proposition 5.2 and (3.2), we see that there is $C > 0$ independent of λ such that

$$\|v_\lambda\|_{H^2(\Omega)} \le C.$$

Since the mapping $\lambda \mapsto v_\lambda$ is increasing for $\lambda \in (0, \lambda_c)$, we see that there is a function $v_{\lambda_c} \in H^2(\Omega)$ such that

$$\lim_{\lambda \nearrow \lambda_c} v_\lambda = v_{\lambda_c} \text{ weakly in } H^2(\Omega).$$

Consequently, v_{λ_c} is a weak solution of the equation (T_λ) at the critical parameter λ_c,

$$-T\Delta v_{\lambda_c} + D\Delta^2 v_{\lambda_c} = \frac{\lambda_c}{(L-v_{\lambda_c})^2} \text{ in } \Omega,$$

and in the sense of weak solutions, the critical value λ_c is attainable.

Now we show that v_{λ_c} is a classical solution. The implicit function theorem implies that the mapping $\lambda \mapsto v_\lambda$ from $(0, \lambda_c)$ to $C(\overline{\Omega})$ is continuous. Thus, we see that $\sigma_{1,\lambda_c} = 0$. (Otherwise, the implicit function theorem implies that v_λ will exist for $\lambda > \lambda_c$.) By arguments similar to those in the proof of Proposition 5.2, we see that

$$\|(L-v_{\lambda_c})^{-2}\|_{L^{3/2}(\Omega)} \le C(L).$$

Note that (5.6) holds with the inequality replaced by an equality. Then Lemma 5.1 implies that for $N = 2$ and 3, v_{λ_c} is a classical solution. Thus, there exists $C < L$ such that $\|v_{\lambda_c}\|_{C(\overline{\Omega})} \le C$. Note that $\|v_\lambda\|_{C(\overline{\Omega})} \le \|v_{\lambda_c}\|_{C(\overline{\Omega})} \le C < L$ for $\lambda \in (0, \lambda_c)$. The uniqueness of v_{λ_c} of (T_λ) at $\lambda = \lambda_c$ follows from Lemma 4.1. This completes the proof. □

6. Uniqueness of the solution of (T_λ) at $\lambda = \lambda_c$. We first note that the monotonicity with respect to λ and the uniform boundedness of the branch of the minimal solutions imply that the extremal function defined by $v_{\lambda_c} = \lim_{\lambda \nearrow \lambda_c} v_\lambda$ always exists and can always be considered as a solution for (T_{λ_c}) in a weak sense. On the other hand, if there is a $0 < C < L$ such that $\|v_\lambda\|_{C(\overline{\Omega})} \le C$ for each $\lambda < \lambda_c$, just as in the case $N = 2$ or 3, then we see from Theorem 5.3 that v_{λ_c} is the unique classical solution.

In the following, we consider only the case that v_{λ_c} is a weak solution (i.e., $v_{\lambda_c} \in W^{2,2}_{loc}(\Omega)$; note that we can obtain $v_{\lambda_c} \in \mathcal{H}$ provided that $v_{\lambda_c} \in W^{2,2}_{loc}(\Omega)$ by the moving plane argument) but with the possibility that $\|v_{\lambda_c}\|_{L^\infty(\Omega)} = L$.

THEOREM 6.1. *For $\lambda > 0$, assume that $v \in \mathcal{H}$ is a weak solution to (T_λ) such that $\|v\|_{L^\infty(\Omega)} = L$. The following assertions are equivalent:*

(i) $\sigma_{1,\lambda}(v) \geq 0$*; that is, v satisfies*

$$2\lambda \int_\Omega (L-v)^{-3}\phi^2 \leq \int_\Omega [T|\nabla\phi|^2 + D|\Delta\phi|^2]dx \quad \forall \phi \in \mathcal{H}.$$

(ii) $\lambda = \lambda_c$ *and* $v \equiv v_{\lambda_c}$ *in* Ω.

Theorem 6.1 can be easily obtained from the following proposition.

PROPOSITION 6.2. *Let v_1, v_2 be two $\mathcal{H}$-weak solutions of (T_λ) so that $\sigma_{1,\lambda}(v_i) \geq 0$ for $i = 1, 2$. Then $v_1 = v_2$ a.e. in Ω.*

Proof. For any $\theta \in [0,1]$ and $\phi \in \mathcal{H}$, $\phi \geq 0$, we have that

$$\begin{aligned} I_{\theta,\phi} :&= T\int_\Omega \nabla(\theta v_1 + (1-\theta)v_2)\nabla\phi dx + D\int_\Omega \Delta(\theta v_1 + (1-\theta)v_2)\Delta\phi dx \\ &\quad - \lambda\int_\Omega [L - (\theta v_1 + (1-\theta)v_2)]^{-2}\phi dx \\ &= \lambda\int_\Omega \Big[[\theta(L-v_1)^{-2} + (1-\theta)(L-v_2)^{-2}] - [(L-(\theta v_1 + (1-\theta)v_2))^{-2}]\Big]dx \\ &\geq 0 \end{aligned}$$

due to the convexity of $(L-s)^{-2}$ with respect to $s \in (0, L)$. Since $I_{0,\phi} = I_{1,\phi} = 0$, the derivative of $I_{\theta,\phi}$ at $\theta = 0, 1$ provides

$$\begin{aligned} \int_\Omega [T\nabla(v_1-v_2)\nabla\phi + D\Delta(v_1-v_2)\Delta\phi] - 2\lambda\int_\Omega (L-v_2)^{-3}(v_1-v_2)\phi \geq 0, \\ \int_\Omega [T\nabla(v_1-v_2)\nabla\phi + D\Delta(v_1-v_2)\Delta\phi] - 2\lambda\int_\Omega (L-v_1)^{-3}(v_1-v_2)\phi \leq 0 \end{aligned}$$

for any $\phi \in \mathcal{H}$ with $\phi \geq 0$. Testing the first inequality on $\phi = (v_1-v_2)^-$ and the second one on $(v_1-v_2)^+$, we obtain that

$$\begin{aligned} \int_\Omega \Big[T|\nabla(v_1-v_2)^-|^2 + D|\Delta(v_1-v_2)^-|^2\Big] - 2\lambda\int_\Omega (L-v_2)^{-3}((v_1-v_2)^-)^2 \leq 0, \\ \int_\Omega \Big[T|\nabla(v_1-v_2)^+|^2 + D|\Delta(v_1-v_2)^+|^2\Big] - 2\lambda\int_\Omega (L-v_1)^{-3}((v_1-v_2)^+)^2 \leq 0. \end{aligned}$$

Since $\sigma_{1,\lambda}(v_1) \geq 0$, we have the following:

(1) If $\sigma_{1,\lambda}(v_1) > 0$, then $v_1 \leq v_2$ a.e. in Ω.

(2) If $\sigma_{1,\lambda}(v_1) = 0$, then

$$\int_\Omega \Big[T\nabla(v_1-v_2)\nabla\overline{\varphi} + D\Delta(v_1-v_2)\Delta\overline{\varphi}\Big] - 2\lambda\int_\Omega (L-v_1)^{-3}(v_1-v_2)\overline{\varphi} = 0,$$

where $\overline{\varphi} = (v_1-v_2)^+$. Since $I_{\theta,\overline{\varphi}} \geq 0$ for any $\theta \in [0,1]$ and $I_{1,\overline{\varphi}} = \partial I_{1,\overline{\varphi}} = 0$, we get that $\partial^2_{\theta\theta} I_{1,\overline{\varphi}} = -\int_\Omega \frac{6\lambda}{(L-v_1)^4}((v_1-v_2)^+)^3 \geq 0$. Thus, $(v_1-v_2)^+ = 0$ a.e. in Ω. Hence, $v_1 \leq v_2$ a.e. in Ω. The same argument applies to prove the reversed inequality, and the proof of the proposition is complete. ∎

7. Structure of solutions of (T_λ) in the 2D case. In this section we obtain the structure of positive solutions of (T_λ) in the 2D case. The main theorem of this section is the following theorem. Our Theorem 1.2 can be obtained from this theorem and Theorem 8.2.

THEOREM 7.1. *Let Ω be a convex smooth domain in $\boldsymbol{R}^2$. For $\lambda \in (0, \lambda_c]$, any solution of the problem (T_λ) is regular and the following hold.*

(i) *For $0 < \lambda < \lambda_c$, problem (T_λ) admits two solutions: the minimal solution and a mountain-pass solution.*

(ii) *For $\lambda = \lambda_c$, problem (T_λ) admits a unique regular solution.*

(iii) *For $\lambda > \lambda_c$, problem (T_λ) admits no regular solution.*

To prove this theorem, we first show the following lemma.

LEMMA 7.2. *For any fixed $\lambda > 0$, if $v_\lambda \in \mathcal{H}$ is a positive solution of (T_λ), then there exists $0 < \tau_\lambda < L$ such that $v_\lambda \le L - \tau_\lambda$ in Ω. This also implies that v_λ is regular.*

Proof. The embedding theorem implies that $v_\lambda \in C^\alpha(\overline{\Omega})$ for any $0 < \alpha < 1$, and thus the moving plane arguments as in the proof of Theorem 3.1 imply that if $v_\lambda(x_\lambda) = \max_\Omega v_\lambda$, then $x_\lambda \in \Omega_0$, where $\Omega_0 \subset\subset \Omega$. Moreover, by Theorem 3.1, we have

$$\int_\Omega (L - v_\lambda)^{-2} \le \frac{C}{\lambda} \tag{7.1}$$

and

$$\int_\Omega [T|\nabla v_\lambda|^2 + D(\Delta v_\lambda)^2]dx \le C. \tag{7.2}$$

Suppose that there is $\lambda_0 > 0$ and sequences $\{\lambda_i\}$ and $\{v_i\}$ with $\max_\Omega v_i = L - \epsilon_i$ such that $\lambda_i \to \lambda_0$, $\epsilon_i \to 0$ as $i \to \infty$. Making the transformation $w_i = L - v_i$, we see that w_i with $\min_\Omega w_i = \epsilon_i$ satisfies the problem

$$T\Delta w_i - D\Delta^2 w_i = \lambda_i w_i^{-2} \text{ in } \Omega, \quad w_i = L, \Delta w_i = 0 \text{ on } \partial\Omega.$$

Define $z_i = \Delta w_i$; then

$$-D\Delta z_i + T z_i = \lambda_i w_i^{-2} \text{ in } \Omega, \ \ z_i = 0 \text{ on } \partial\Omega. \tag{7.3}$$

It is known from (7.3) that $z_i(x) = \lambda_i \int_\Omega G_{T,D}(x,y) w_i^{-2}(y)dy$, where $G_{T,D}(x,y)$ is the Green's function of the operator $-D\Delta + TId$. Let $w_i(x_i) = \min_\Omega w_i$. Then $x_i \in \Omega_0 \subset\subset \Omega$. Setting $\tilde{w}_i(y) = \frac{w_i}{\epsilon_i}$ and $y = \lambda_i^{1/4}\epsilon_i^{-3/4}(x - x_i)$, we see that $\tilde{w}_i$ with $\tilde{w}_i(0) = \min_{\Omega_i} \tilde{w}_i = 1$ and $\tilde{w}_i$ satisfies the problem

$$\lambda_i^{-1/2}\epsilon_i^{3/2} T\Delta_y \tilde{w}_i - D\Delta_y^2 \tilde{w}_i = \tilde{w}_i^{-2} \text{ in } \Omega_i, \quad \tilde{w}_i = \frac{L_i}{\epsilon_i}, \ \ \Delta_y \tilde{w}_i = 0 \text{ on } \partial\Omega_i, \tag{7.4}$$

where $\Omega_i = \{y = \lambda_i^{1/4}\epsilon_i^{-3/4}(x - x_i) : \ x \in \Omega\}$. On the other hand,

$$\Delta_y \tilde{w}_i = \lambda_i^{-1/2}\epsilon_i^{1/2}\Delta_x w_i = \lambda_i^{1/2}\epsilon_i^{1/2}\int_\Omega G_{T,D}(x,\xi) w_i^{-2}(\xi)d\xi.$$

Note that $N = 2$ and $w_i \geq \epsilon_i$ in Ω. The Hölder inequality implies that

$$\begin{aligned}|\Delta_y \tilde{w}_i| &\leq C\epsilon_i^{1/2}\left(\int_\Omega [G_{T,D}(x,\xi)]^p d\xi\right)^{1/p}\left(\int_\Omega w_i^{-2} w_i^{2-2q}(\xi)d\xi\right)^{1/q}\\ &\leq C\epsilon_i^{1/2}\epsilon_i^{-2/p}\left(\int_\Omega [G_{T,D}(x,\xi)]^p d\xi\right)^{1/p}\left(\int_\Omega w_i^{-2}(\xi)d\xi\right)^{1/q}\\ &\leq C\epsilon_i^{\frac{1}{2}-\frac{2}{p}},\end{aligned}$$

where we have applied (7.1). Choosing p sufficiently large, we see that

$$|\Delta_y \tilde{w}_i(y)| \to 0 \ \text{ for } y \in \Omega_i \text{ a.e. as } i \to \infty. \tag{7.5}$$

On the other hand, it follows from (7.4), (7.5), and the regularity of the operator $T\Delta - D\Delta^2$ that $\tilde{w}_i \to W$ in $C^4_{loc}(\boldsymbol{R}^2)$ as $i \to \infty$, where W with $W(0) = 1$ and $W \geq 1$ in $\boldsymbol{R}^2$ satisfies the equation

$$-D\Delta^2 W = W^{-2} \ \text{ in } \boldsymbol{R}^2, \quad W(0) = 1. \tag{7.6}$$

Meanwhile, (7.5) implies that $\Delta W = 0$ in $\boldsymbol{R}^2$. This contradicts (7.6) and completes the proof of this lemma. □

In the remainder of this section, we establish the existence of the second solution. Note that in the energy functional (1.1), the integral $\int_\Omega \frac{1}{L+u(x)}dx$ is not well defined for $u \in H^2(\Omega)$. Therefore, we do not have a good energy functional to work with. Our idea is to modify the nonlinearity so that the mountain-pass lemma works, and then show that the resulting solution has no singularity.

We first modify the nonlinearity. Since the nonlinearity $g(v) = \frac{1}{(L-v)^2}$ is singular at $v = L$, we need to consider a regularized C^1 nonlinearity $g_\epsilon(v)$, $0 < \epsilon < L$, of the following form:

$$g_\epsilon(v) = \begin{cases} \frac{1}{(L-v)^2}, & v \leq L-\epsilon,\\ \frac{1}{\epsilon^2} - \frac{(L-\epsilon)}{\epsilon^3} + \frac{1}{\epsilon^3(L-\epsilon)}v^2, & v > L-\epsilon.\end{cases}$$

For $\lambda \in (0, \lambda_c)$, we study the regularized semilinear elliptic problem:

$$-T\Delta v + D\Delta^2 v = \lambda g_\epsilon(v) \ \text{ in } \Omega, \quad v = \Delta v = 0 \ \text{ on } \partial\Omega. \tag{7.7}$$

From a variational viewpoint, the action functional associated to (7.7) is

$$J_{\epsilon,\lambda}(v) = \frac{1}{2}\int_\Omega [T|\nabla v|^2 + D(\Delta v)^2]dx - \lambda\int_\Omega G_\epsilon(v)dx, \quad v \in \mathcal{H},$$

where $G_\epsilon(v) = \int_{-\infty}^v g_\epsilon(s)ds$.

Fix now $0 < \epsilon < \tau_\lambda/4$, where τ_λ is as given in Lemma 7.2. The minimal solution $\underline{v}_\lambda$ of (T_λ) is still a solution of (7.7) so that $\sigma_{1,\lambda}(\underline{v}_\lambda) > 0$. In order to motivate the choice of $g_\epsilon(v)$, we briefly sketch the proof of Theorem 7.1. First, we prove that $\underline{v}_\lambda$ is a local minimum for $J_{\epsilon,\lambda}(v)$. Then, by the well-known mountain-pass theorem, we show the existence of a second solution $V_{\epsilon,\lambda}$ for (7.7). (A similar idea has been used in [6].) The subcritical growth

$$0 \leq g_\epsilon(v) \leq C_\epsilon(1 + |v|^2) \tag{7.8}$$

and the inequality

$$3G_\epsilon(v) \le v g_\epsilon(v) \ \text{ for } v \ge L-\theta, \tag{7.9}$$

for some sufficiently small $\theta > 10\epsilon$ independent of ϵ, $C_\epsilon > 0$, will yield that $J_{\epsilon,\lambda}$ satisfies the Palais–Smale condition.

In order to complete the details of the proof of Theorem 7.1, we first need to show the following lemma.

LEMMA 7.3. *The minimal solution $\underline{v}_\lambda$ of (T_λ) is a local minimum of $J_{\epsilon,\lambda}$ on $\mathcal{H}$.*

Proof. Since $\mathcal{H} \hookrightarrow C^\alpha(\overline{\Omega})$ for any $0 < \alpha < 1$, we need only to show that $\underline{v}_\lambda$ is a local minimum of $J_{\epsilon,\lambda}$ in $C^\alpha(\overline{\Omega})$ for some $0 < \alpha < 1$. Indeed, since $\sigma_{1,\lambda}(\underline{v}_\lambda) > 0$, we have the following inequality:

$$\int_\Omega [T|\nabla\varphi|^2 + D(\Delta\varphi)^2]dx - 2\lambda \int_\Omega \frac{1}{(L-\underline{v}_\lambda)^3}\varphi^2 dx \ge \sigma_{1,\lambda}\int_\Omega \varphi^2 dx \tag{7.10}$$

for any $\varphi \in \mathcal{H}$, since $\underline{v}_\lambda \le L - \tau_\lambda < L - \epsilon$ (see Lemma 7.2). Now, take any $\varphi \in \mathcal{H} \cap C^\alpha(\overline{\Omega})$ such that $\|\varphi\|_{C^\alpha} \le \delta_\lambda$. Since $\underline{v}_\lambda \le L - \tau_\lambda$, if $\delta_\lambda \le \epsilon$, then $\underline{v}_\lambda + \varphi \le L - \epsilon$, and we have that

$$\begin{aligned}
&J_{\epsilon,\lambda}(\underline{v}_\lambda + \varphi) - J_{\epsilon,\lambda}(\underline{v}_\lambda) \\
&\quad = \frac{1}{2}\int_\Omega [T|\nabla\varphi|^2 + D(\Delta\varphi)^2]dx + \int_\Omega [T\nabla\underline{v}_\lambda\cdot\nabla\varphi + D\Delta\underline{v}_\lambda\Delta\varphi]dx \\
&\qquad\quad - \lambda\int_\Omega \left(\frac{1}{L-\underline{v}_\lambda-\varphi} - \frac{1}{L-\underline{v}_\lambda}\right) \\
&\quad \ge \frac{\sigma_{1,\lambda}}{2}\int_\Omega \varphi^2 - \lambda\int_\Omega \left(\frac{1}{L-\underline{v}_\lambda-\varphi} - \frac{1}{L-\underline{v}_\lambda} - \frac{\varphi}{(L-\underline{v}_\lambda)^2} - \frac{\varphi^2}{(L-\underline{v}_\lambda)^3}\right),
\end{aligned}$$

where we have used (7.10). Since now

$$\left|\frac{1}{L-\underline{v}_\lambda-\varphi} - \frac{1}{L-\underline{v}_\lambda} - \frac{\varphi}{(L-\underline{v}_\lambda)^2} - \frac{\varphi^2}{(L-\underline{v}_\lambda)^3}\right| \le C|\varphi|^3$$

for some $C > 0$, we have that

$$J_{\epsilon,\lambda}(\underline{v}_\lambda + \varphi) - J_{\epsilon,\lambda}(\underline{v}_\lambda) \ge \left(\frac{\sigma_{1,\lambda}}{2} - C\lambda\delta_\lambda\right)\int_\Omega \varphi^2 > 0$$

provided δ_λ is small enough. This proves that $\underline{v}_\lambda$ is a local minimum of $J_{\epsilon,\lambda}$ in the C^α topology and completes the proof of this lemma. ∎

Fix some ball $B_{2r} \subset \Omega$ of radius $2r$, $r > 0$. Take a cut-off function χ so that $\chi = 1$ on B_r and $\chi = 0$ outside B_{2r}. Let $w_\epsilon = (L-\epsilon)\chi \in \mathcal{H}$. We have that

$$J_{\epsilon,\lambda}(w_\epsilon) \le \frac{(L-\epsilon)^2}{2}\int_\Omega [T|\nabla\chi|^2 + D(\Delta\chi)^2]dx - \frac{\lambda}{\epsilon^2}|B_r| \to -\infty$$

as $\epsilon \to 0$. Moreover, we can find for $\epsilon > 0$ small the inequality

$$J_{\epsilon,\lambda}(w_\epsilon) < J_{\epsilon,\lambda}(\underline{v}_\lambda). \tag{7.11}$$

Now fix $\epsilon > 0$ small enough in order that (7.11) holds, and define

$$c_{\epsilon,\lambda} = \inf_{\gamma\in\Gamma}\max_{v\in\gamma} J_{\epsilon,\lambda}(v),$$

where $\Gamma = \{\gamma : [0,1] \to \mathcal{H}; \gamma \text{ continuous and } \gamma(0) = \underline{v}_\lambda,\ \gamma(1) = w_\epsilon\}$. We can then apply the mountain-pass theorem to get a solution $V_{\epsilon,\lambda}$ of (7.7), provided the Palais–Smale condition holds at level $c_{\epsilon,\lambda}$. The embedding theorem and the maximum principle imply that $V_{\epsilon,\lambda} > 0$ in Ω.

LEMMA 7.4. *Assume that $\{v_n\} \subset \mathcal{H}$ satisfies*

$$J_{\epsilon,\lambda_n}(v_n) \le C, \quad J'_{\epsilon,\lambda_n}(v_n) \to 0 \ \text{ in } \mathcal{H}' \tag{7.12}$$

for $\lambda_n \to \lambda > 0$. Then the sequence $(v_n)_n$ is uniformly bounded in $\mathcal{H}$ and therefore admits a convergent subsequence in $\mathcal{H}$.

Proof. By (7.12) we have that

$$\int_\Omega [T|\nabla v_n|^2 + D(\Delta v_n)^2]dx = \lambda_n \int_\Omega g_\epsilon(v_n)v_n dx + o(\|v_n\|_{\mathcal{H}})$$

as $n \to +\infty$, and then

$$\begin{aligned}
C &\ge \frac{1}{2}\int_\Omega [T|\nabla v_n|^2 + D(\Delta v_n)^2]dx - \lambda_n \int_\Omega G_\epsilon(v_n)dx \\
&= \frac{1}{6}\int_\Omega [T|\nabla v_n|^2 + D(\Delta v_n)^2]dx + \lambda_n \int_\Omega \left(\frac{1}{3}v_n g_\epsilon(v_n) - G_\epsilon(v_n)\right)dx + o(\|v_n\|_{\mathcal{H}}) \\
&\ge \frac{1}{6}\int_\Omega [T|\nabla v_n|^2 + D(\Delta v_n)^2]dx + \lambda_n \int_{\{v_n \ge L-\theta\}} \left(\frac{1}{3}v_n g_\epsilon(v_n) - G_\epsilon(v_n)\right)dx \\
&\quad + o(\|v_n\|_{\mathcal{H}}) - C(\theta) \\
&\ge \frac{1}{6}\int_\Omega [T|\nabla v_n|^2 + D(\Delta v_n)^2]dx + o(\|v_n\|_{\mathcal{H}}) - C(\theta)
\end{aligned}$$

in view of (7.9), where $C(\theta) > 0$ depends on θ but is independent of ϵ. Hence, $\sup_{n\in\mathbf{N}} \|v_n\|_{\mathcal{H}} < +\infty$.

The compactness of the embedding $\mathcal{H} \hookrightarrow C^\alpha(\overline{\Omega})$ for any $0 < \alpha < 1$ provides that, up to a subsequence, $v_n \to v$ weakly in $\mathcal{H}$ and strongly in $C^\alpha(\overline{\Omega})$ for some $0 < \alpha < 1$ and some $v \in \mathcal{H}$. By (7.12) we get that $\int_\Omega [T|\nabla v|^2 + D(\Delta v)^2]dx = \lambda \int_\Omega g_\epsilon(v)v$, and then

$$\begin{aligned}
&\int_\Omega [T|\nabla(v_n - v)|^2 + D(\Delta(v_n - v))^2]dx \\
&\quad = T\left[\int_\Omega |\nabla v_n|^2 - \int_\Omega |\nabla v|^2\right] + D\left[\int_\Omega (\Delta v_n)^2 - \int_\Omega (\Delta v)^2\right] + o(1) \\
&\quad = \lambda_n \int_\Omega g_\epsilon(v_n)v_n - \lambda \int_\Omega g_\epsilon(v)v + o(1) \to 0
\end{aligned}$$

as $n \to +\infty$. This completes the proof. □

Proof of Theorem 7.1. We need only to show (i), and it is enough to show that for any fixed $\lambda > 0$, the mountain-pass solution $V_{\epsilon,\lambda}$ satisfies $V_{\epsilon,\lambda} \le L - \epsilon$ in Ω.

Since $V_{\epsilon,\lambda} \in \mathcal{H}$, by the same argument as in Theorem 3.1, we easily see that

$$\int_\Omega g_\epsilon(V_{\epsilon,\lambda})dx \le C/\lambda, \tag{7.13}$$

where C is independent of ϵ. In fact, we see that

$$J_{\epsilon,\lambda}(V_{\epsilon,\lambda}) \le \max_{v\in\gamma_0} J_{\epsilon,\lambda}(v),$$

where $\gamma_0 : [0,1] \to \mathcal{H}$; $\gamma_0(v) = t\underline{v}_\lambda + (1-t)w_\epsilon$ for $t \in [0,1]$. Thus,

$$J_{\epsilon,\lambda}(V_{\epsilon,\lambda}) \le C,$$

where $C > 0$ is independent of ϵ. On the other hand, we see that

$$\begin{aligned} C &\ge \frac{1}{2}\int_\Omega [T|\nabla V_{\epsilon,\lambda}|^2 + D(\Delta V_{\epsilon,\lambda})^2]dx - \lambda_n \int_\Omega G_\epsilon(V_{\epsilon,\lambda})dx \\ &= \frac{1}{6}\|V_{\epsilon,\lambda}\|^2_{\mathcal{H}} + \lambda\int_\Omega \left(\frac{1}{3}V_{\epsilon,\lambda}g_\epsilon(V_{\epsilon,\lambda}) - G_\epsilon(V_{\epsilon,\lambda})\right)dx \\ &\ge \frac{1}{6}\int_\Omega \|V_{\epsilon,\lambda}\|^2_{\mathcal{H}} + \lambda\int_{\{V_{\epsilon,\lambda}\ge L-\theta\}} \left(\frac{1}{3}V_{\epsilon,\lambda}g_\epsilon(V_{\epsilon,\lambda}) - G_\epsilon(V_{\epsilon,\lambda})\right)dx - C(\theta) \\ &\ge \frac{1}{6}\|V_{\epsilon,\lambda}\|^2_{\mathcal{H}}dx - C(\theta). \end{aligned}$$

Thus,

$$\|V_{\epsilon,\lambda}\|_{\mathcal{H}} \le C,$$

where $C > 0$ is independent of ϵ. The embedding $\mathcal{H} \hookrightarrow C^0(\overline{\Omega})$ implies $V_{\epsilon,\lambda} \le C$ in Ω. By the moving plane argument, as in the proof of Theorem 3.1, we have that $V_{\epsilon,\lambda} \le L - \theta$ in Ω_δ, where Ω_δ is as given in the proof of Theorem 3.1 and θ is as given by (7.9). This implies that (7.13) holds.

Let $W_\epsilon = \Delta V_{\epsilon,\lambda}$. Then W_ϵ satisfies the equation

$$-TW_\epsilon + D\Delta W_\epsilon = \lambda g_\epsilon(V_{\epsilon,\lambda}) \in L^1(\Omega).$$

Since $N = 2$, the Brezis–Merle inequality [4] implies that

$$\int_\Omega |W_\epsilon|^q dx \le C \quad \forall q > 1,$$

where C is independent of ϵ. This also yields that

$$\|V_{\epsilon,\lambda}\|_{W^{2,q}(\Omega)} \le C.$$

By choosing $q > 3$ sufficiently large, we see from the embedding $W^{2,q}_0(\Omega) \hookrightarrow C^{1+\frac{1}{2}}(\Omega)$ that $V_{\epsilon,\lambda} \le C$ in Ω.

Now we show that $V_{\epsilon,\lambda} < L$ in Ω for ϵ sufficiently small. On the contrary, we suppose that there is a sequence $\{\epsilon_i\}$ with $\epsilon_i \to 0$ as $i \to \infty$ such that $\max_\Omega V_{\epsilon_i,\lambda} \ge L$. Denote $V_{\epsilon_i,\lambda}(x_i) = \max_\Omega V_{\epsilon_i,\lambda}$. By arguments similar to those in the proof of Lemma 5.1, we see that

$$V_{\epsilon_i,\lambda}(x_i) - V_{\epsilon_i,\lambda}(x) \le C|x - x_i|^{3/2}.$$

Thus,

$$V_{\epsilon_i,\lambda}(x) \ge V_{\epsilon_i,\lambda}(x_i) - C|x - x_i|^{3/2} > L - \epsilon_i$$

provided that $|x - x_i| < (\epsilon_i/C)^{2/3}$. But

$$C \ge \int_\Omega g_{\epsilon_i}(V_{\epsilon_i,\lambda})dx \ge \epsilon_i^{-2}\int_{\{|x-x_i|\le(\epsilon_i/C)^{2/3}\}} dx = C\epsilon_i^{-2/3} \to \infty$$

as $i \to \infty$. This is a contradiction.

Now we claim that there exists $\delta > 0$ independent of ϵ such that

$$V_{\epsilon,\lambda} \le L - \delta \ \text{ in } \Omega$$

for ϵ sufficiently small. On the contrary, there are sequences $\{\epsilon_i\}$ and $\{V_i\} \equiv \{V_{\epsilon_i,\lambda}\}$ with $\epsilon_i \to 0$ as $i \to \infty$ such that $\max_\Omega V_i = L - \xi_i$ and $\xi_i \to 0$ as $i \to \infty$. Set $Z_i = L - V_i$. Then $Z_i(x_i) := \min_\Omega Z_i = \xi_i$ and Z_i satisfies

$$T\Delta Z_i - D\Delta^2 Z_i = \lambda h_i(Z_i) \ \text{ in } \Omega, \quad Z_i = T, \ \ \Delta Z_i = 0 \ \text{ on } \partial\Omega,$$

where

$$h_i(Z_i) = \begin{cases} \frac{1}{Z_i^2}, & Z_i \ge \epsilon_i, \\ \frac{1}{\epsilon_i^2} + \frac{2(\epsilon_i - Z_i)}{\epsilon_i^3} + \frac{(\epsilon_i - Z_i)^2}{\epsilon_i^3(L-\epsilon_i)}, & Z_i < \epsilon_i. \end{cases}$$

Making the transformations $\tilde{Z}_i(y) = Z_i/\xi_i$ and $y = \xi_i^{-3/4}(x - x_i)$, we see that $\tilde{Z}_i(0) = \min_\Omega \tilde{Z}_i = 1$ and $\tilde{Z}_i$ satisfies the problem

$$\xi_i^{3/2}\Delta_y \tilde{Z}_i - D\Delta_y^2 \tilde{Z}_i = \lambda \tilde{h}_i(\tilde{Z}_i) \ \text{ in } \tilde{\Omega}_i, \quad \tilde{Z}_i = T/\xi_i, \ \ \Delta_y \tilde{Z}_i = 0 \ \text{ on } \partial\tilde{\Omega}_i, \tag{7.14}$$

where $\tilde{\Omega}_i = \{y = \xi_i^{-3/4}(x - x_i) : \ x \in \Omega\}$ and

$$\tilde{h}_i(\tilde{Z}_i) = \begin{cases} \frac{1}{\tilde{Z}_i^2}, & \tilde{Z}_i \ge \frac{\epsilon_i}{\xi_i}, \\ 3\Big(\frac{\xi_i}{\epsilon_i}\Big)^2 - 2\Big(\frac{\xi_i}{\epsilon_i}\Big)^3 \tilde{Z}_i + \frac{\xi_i^2}{\epsilon_i(L-\epsilon_i)} - 2\Big(\frac{\xi_i^3}{\epsilon_i^2(L-\epsilon_i)}\Big)\tilde{Z}_i + \Big(\frac{\xi_i^4}{\epsilon_i^3(L-\epsilon_i)}\Big)\tilde{Z}_i^2, & \tilde{Z}_i < \frac{\epsilon_i}{\xi_i}. \end{cases}$$

We consider two cases for $\{\frac{\epsilon_i}{\xi_i}\}$ (we can choose subsequences if necessary):

(i) There is $0 < A < \infty$ such that $\frac{\epsilon_i}{\xi_i} \le A$ for all i,

(ii) $\frac{\epsilon_i}{\xi_i} \to \infty$ as $i \to \infty$.

For the first case, we have that there is $0 \le A_1 \le A$ such that $\lim_{i\to\infty} \frac{\epsilon_i}{\xi_i} = A_1$. If $A_1 < 1$, since $\tilde{Z}_i \ge 1$, we have that $\tilde{h}_i = \tilde{Z}_i^{-2} \le 1$ in $\tilde{\Omega}_i$ for i sufficiently large. If $1 \le A_1 \le A$, we also have that $\tilde{h}_i \le C$ in $\tilde{\Omega}_i$ for i sufficiently large, where $0 < C < \infty$ is independent of i. Moreover, for $q > 3$,

$$\begin{aligned} \int_{\tilde{\Omega}_i} |\Delta_y \tilde{Z}_i|^q dy &= \xi_i^{q/2} \int_{\tilde{\Omega}_i} |\Delta_x Z_i|^q dy \\ &= \xi^{\frac{q-3}{2}} \int_\Omega |\Delta_x Z_i|^q dx \to 0 \end{aligned}$$

as $i \to \infty$. Thus, the regularity of Δ^2 implies that $\tilde{Z}_i \to \tilde{Z}$ in $C^3_{loc}(\boldsymbol{R}^2)$ with $\tilde{Z}(0) = \min_{\mathbf{R}^2} \tilde{Z} = 1$, and $\tilde{Z}$ satisfies the equation

$$-D\Delta^2 \tilde{Z} = \lambda \tilde{Z}^{-2} \ \text{ in } \boldsymbol{R}^2$$

provided $A_1 \le 1$ and the equation

$$D\Delta^2 \tilde{Z} = \lambda \tilde{h}(\tilde{Z}) \ \text{ in } \boldsymbol{R}^2$$

provided $1 < A_1 \le A$, where

$$\tilde{h}(\tilde{Z}) = \begin{cases} \tilde{Z}^2, & \tilde{Z} \ge A_1, \\ \frac{3}{A_1^2} - \frac{2}{A_1^3}\tilde{Z}, & \tilde{Z} < A_1. \end{cases}$$

Moreover, for any large ball B_R of $\boldsymbol{R}^2$, $\int_{B_R} |\Delta \tilde{Z}|^q(y)dy = 0$. This is impossible.

For the second case, we see that $\xi_i = o(\epsilon_i)$ for i sufficiently large. Thus, $Z_i(x_i) = \xi_i = o(\epsilon_i)$. Noting that $\int_\Omega |\Delta Z_i|^q dx \le C$, we see that $Z_i \in W_0^{2,q}(\Omega)$. The embedding $W_0^{2,q}(\Omega) \hookrightarrow C^{1+\frac{1}{2}}(\Omega)$ gives

$$|Z_i(x)| \le Z_i(x_i) + C|x - x_i|^{3/2} < \epsilon_i$$

provided $|x - x_i| \le (\frac{\epsilon_i}{2C})^{2/3}$. Thus

$$C \ge \int_\Omega h_i(Z_i)dx \ge \frac{1}{\epsilon_i^2} \int_{Z_i < \epsilon_i} dx \ge C\epsilon_i^{-2/3} \to \infty$$

as $i \to \infty$. This is also a contradiction. Therefore,

$$V_{\epsilon,\lambda} \le L - \delta \ \text{ in } \Omega,$$

where $\delta > 0$ is independent of ϵ. This also implies that $V_{\epsilon,\lambda}$ is a solution of (T_λ). This completes the proof of (i) of Theorem 7.1. □

8. The asymptotic behavior of the mountain-pass solution as $\lambda \to 0$. In this section we will study the asymptotic behavior of the mountain-pass solution V_λ obtained in Theorem 7.1 as $\lambda \to 0$.

LEMMA 8.1.

$$\sigma_{1,\lambda}(V_\lambda) < 0 \ \textit{for } 0 < \lambda < \lambda_c.$$

Proof. Let $\underline{v}_\lambda$ be the minimal solution of (T_λ) so that $V_\lambda \ge \underline{v}_\lambda$. If the linearization around V_λ had nonnegative first eigenvalue, then Lemma 4.1 would also yield $V_\lambda \le \underline{v}_\lambda$ so that $\overline{v}_\lambda$ and V_λ would necessarily coincide, which would be a contradiction. □

THEOREM 8.2.

$$\max_\Omega V_\lambda \to L \ \textit{ as } \lambda \to 0. \tag{8.1}$$

Moreover,

$$\lim_{\lambda \to 0^+} \frac{[\min_\Omega (L - V_\lambda)]^3}{\lambda} = 0. \tag{8.2}$$

Proof. Suppose that there are sequences $\{\lambda_i\}$ and $\{V_i\} \equiv \{V_{\lambda_i}\}$ such that $\lambda_i \to 0$ as $i \to \infty$ and $\max_\Omega V_i \le L - \delta$, where $0 < \delta < L$ is independent of i. Then it follows from the equation of V_i that $V_i \to 0$ in $C^0(\overline{\Omega})$ as $i \to \infty$ (we can choose subsequences if necessary). This contradicts the fact that $\sigma_{1,\lambda_i}(V_i) < 0$ for all i. Thus, (8.1) holds.

By Theorem 3.1, we see that

$$\lambda \int_\Omega (L - V_\lambda)^{-2} dx + \int_\Omega |\Delta V_\lambda|^2 \le C$$

for any λ sufficiently small, where C is independent of λ. Since ΔV_λ satisfies

$$-D\Delta(\Delta V_\lambda) = D\Delta V_\lambda + \frac{\lambda}{(L - V_\lambda)^2} \in L^1(\Omega), \quad \Delta V_\lambda = 0 \text{ on } \partial\Omega,$$

by the Brezis–Merle inequality [4], we have, for any $q > 1$,

$$\int_\Omega |\Delta V_\lambda|^q dx \le C \tag{8.3}$$

for any λ sufficiently small.

Let $V_\lambda(x_\lambda) = \max_\Omega V_\lambda$. Setting $W_\lambda = L - V_\lambda$, we see that $\xi_\lambda := W_\lambda(x_\lambda) = \min_\Omega W_\lambda$ and $\xi_\lambda \to 0$ as $\lambda \to 0$. Now we claim that

$$\lim_{\lambda\to 0} \frac{\xi_\lambda^3}{\lambda} = 0. \tag{8.4}$$

Suppose not; there are sequences $\{\lambda_i\}$ and $\{\xi_i\}$ with $\lambda_i \to 0$ as $i \to \infty$ such that $\frac{\xi_i^3}{\lambda_i} \to C > 0$ or $\frac{\xi_i^3}{\lambda_i} \to \infty$ as $i \to \infty$.

We first consider the case that $\frac{\xi_i^3}{\lambda_i} \to \infty$ as $i \to \infty$. Then, defining $\hat{W}_i = W_i/\xi_i$, we see that $\hat{W}_i$ satisfies the problem

$$T\Delta\hat{W}_i - D\Delta^2\hat{W}_i = \frac{\lambda_i}{\xi_i^3}\hat{W}_i^{-2} \text{ in } \Omega, \quad \hat{W}_i = L/\xi_i, \ \Delta W_i = 0 \text{ on } \partial\Omega.$$

Since $\hat{W}_i \geq 1$, we see that $\hat{W}_i \to \hat{W}$ in $C^3_{loc}(\Omega)$ as $i \to \infty$ and $\hat{W}$ with $\hat{W}(0) = \min_\Omega \hat{W} = 1$ satisfies the equation

$$T\Delta\hat{W} - D\Delta^2\hat{W} = 0 \text{ in } \Omega, \quad \hat{W} = \infty, \ \Delta\hat{W} = 0 \text{ on } \partial\Omega. \tag{8.5}$$

Setting $Z = \Delta\hat{W}$, we see from (8.5) that

$$TZ - D\Delta Z = 0 \text{ in } \Omega, \quad Z = 0 \text{ on } \partial\Omega.$$

The strong maximum principle then implies that $Z \equiv 0$ in Ω and hence $\Delta\hat{W} \equiv 0$ in Ω. The maximum principle then implies that $\hat{W} \equiv 1$ in Ω, which is a contradiction.

Now we consider the case that $\lim_{i\to\infty} \frac{\xi_i^3}{\lambda_i} \to C > 0$. Defining $\hat{W}_i = W_i/\xi_i$ again, we see that $\hat{W}_i$ satisfies the problem

$$T\Delta\hat{W}_i - D\Delta^2\hat{W}_i = \frac{\lambda_i}{\xi_i^3}\hat{W}_i^{-2} \text{ in } \Omega, \quad \hat{W}_i = L/\xi_i, \ \Delta\hat{W}_i = 0 \text{ on } \partial\Omega. \tag{8.6}$$

Setting $\hat{Z}_i = \Delta\hat{W}_i$, we see that $\hat{Z}_i$ satisfies the problem

$$T\hat{Z}_i - D\Delta\hat{Z}_i = \frac{\lambda_i}{\xi_i^3}\hat{W}_i^{-2} \text{ in } \Omega, \quad \hat{Z}_i = 0 \text{ on } \partial\Omega. \tag{8.7}$$

Therefore,

$$\hat{Z}_i = \frac{\lambda_i}{\xi_i^3}\int_\Omega G_{T,D}(x,y)\hat{W}_i^{-2}(y)dy,$$

and hence $|\hat{Z}_i| \leq C$, where $C > 0$ is independent of i. We now obtain from the regularity of Δ^2 and (8.6) that $\hat{W}_i \to \hat{W}$ in $C^3_{loc}(\Omega)$ and $\hat{W}$ satisfies the equation

$$T\Delta\hat{W} - D\Delta^2\hat{W} = \frac{1}{C}\hat{W}^{-2} \text{ in } \Omega, \quad \hat{W} = \infty, \ \Delta\hat{W} = 0 \text{ on } \partial\Omega.$$

On the other hand, we see from (8.7) that $\hat{Z}_i \to \hat{Z}$ in $C^1(\overline{\Omega})$ as $i \to \infty$ and $\hat{Z} \equiv \Delta\hat{W}$ satisfies the problem

$$T\hat{Z} - D\Delta\hat{Z} = \frac{1}{C}\hat{W}^{-2} \text{ in } \Omega, \quad \hat{Z} = 0 \text{ on } \partial\Omega.$$

Since we easily know that $\Delta\hat{W} \leq C$ on $\overline{\Omega}$ and hence $\Delta(\hat{W} - C\rho) \leq 0$ in Ω, where $-\Delta\rho = 1$ in Ω and $\rho = 0$ on $\partial\Omega$, the maximum principle implies that $\hat{W}$ cannot be ∞ on $\partial\Omega$. Thus, (8.2) holds. This completes the proof of Theorem 8.2. ∎

STABILITY AND SYMMETRY IN THE NAVIER PROBLEM FOR THE ONE-DIMENSIONAL WILLMORE EQUATION*

KLAUS DECKELNICK† AND HANS-CHRISTOPH GRUNAU†

Abstract. We consider the one-dimensional Willmore equation subject to Navier boundary conditions; i.e., the position and the curvature are prescribed on the boundary. In a previous work, explicit symmetric solutions to symmetric data have been constructed. Within a certain range of boundary curvatures one has precisely two symmetric solutions, while for boundary curvatures outside the closure of this range there are none. The solutions are ordered; one is "small," and the other is "large." In the first part of this paper we address the stability problem and show that the small solution is (linearized) stable in the whole open range of admissible boundary curvatures, while the large one is unstable and has Morse index 1. A second goal is to investigate whether the small solution is minimal for the corresponding Willmore functional. It turns out that for a certain subrange of admissible boundary curvatures the small solution is the unique minimum, while for curvatures outside that range the minimum is not attained. As a byproduct of our argument we show that for any admissible function there exists a symmetric function with smaller Willmore energy.

1. Introduction.

Recently, Willmore surfaces (see [19]) and the related flow have attracted quite some attention; see, e.g., [1, 8, 9, 10, 13, 17, 18], [3] for numerical studies, and [15, 5] for elastic curves, which are the one-dimensional analogues. The mentioned work is concerned with closed surfaces and curves, while only very few results concerning boundary value problems are available. Quite recently, Schätzle [16] considered Willmore surfaces with a boundary, which are subject to the constraint to be submanifolds of $\mathbb{S}^n$ and which satisfy Dirichlet-type boundary conditions.

In order to gain some more insight into general boundary conditions for the "free" Willmore equation, in [4] we had a look at the one-dimensional case, where, in some situations, almost explicit solutions can be found for suitable boundary value problems. For further background information and references, see [4] and also [14]. In [4], we were interested in Willmore graphs and studied among others the *Navier boundary value problem* with symmetric data $\alpha \in \mathbb{R}$ for the *one-dimensional Willmore equation*:

$$\begin{cases} \frac{1}{\sqrt{1+u'(x)^2}} \frac{d}{dx} \left(\frac{\kappa'(x)}{\sqrt{1+u'(x)^2}} \right) + \frac{1}{2}\kappa^3(x) = 0, \quad x \in (0,1), \\ u(0) = u(1) = 0, \quad \kappa(0) = \kappa(1) = -\alpha. \end{cases} \tag{1.1}$$

Here

$$\kappa(x) = \frac{d}{dx} \left(\frac{u'(x)}{\sqrt{1+u'(x)^2}} \right) = \frac{u''(x)}{(1+u'(x)^2)^{3/2}} \tag{1.2}$$

denotes the curvature of the graph of u at the point $(x, u(x))$. Solutions of (1.1) are critical points of the modified one-dimensional Willmore functional

(1.3)
$$\tilde{W}_\alpha(u) = \int_{\mathrm{graph}(u)} \big(\kappa(x)^2 + 2\alpha\kappa(x)\big)\, ds(x) = \int_0^1 \big(\kappa(x)^2 + 2\alpha\kappa(x)\big)\, \sqrt{1+u'(x)^2}\, dx,$$

with $u \in H^2(0,1) \cap H_0^1(0,1)$; see [4, section 2]. The boundary conditions $u(0) = u(1) = 0$ are formulated by working in the space H_0^1, while the curvature boundary conditions $\kappa(0) = \kappa(1) = -\alpha$ arise as natural boundary conditions since also the admissible testing functions have only to be in $H^2 \cap H_0^1$. By reflection it is sufficient to consider

$$\alpha \geq 0.$$

Our first results are concerned with solutions of (1.1) which are symmetric about $x = 1/2$. This class is particularly important for two reasons: on the one hand, it is possible to associate with each function in $H^2 \cap H_0^1$ a symmetric function with the same or smaller Willmore energy. The corresponding construction is nontrivial and will be described in the proof of Theorem 1.5. Moreover, exploiting an observation due to Euler [6, p. 234, line 13], we can give symmetric solutions more or less in closed form. This issue was discussed in detail in [4], where, among other things, the following result was proved.

PROPOSITION 1.1 (see [4, Theorem 1]). *There exists* $\alpha_{\max} = 1.343799725\ldots$ *such that for* $0 < \alpha < \alpha_{\max}$, *the Navier boundary value problem* (1.1) *has precisely two smooth (graph) solutions* u *in the class of smooth functions that are symmetric around* $x = \frac{1}{2}$. *If* $\alpha = \alpha_{\max}$, *one has precisely one such solution, for* $\alpha = 0$ *one has only the trivial solution, and for* $\alpha > \alpha_{\max}$ *no such solutions exist.*

Both solutions are positive, and one of these solutions is larger than the other. The small solutions are ordered with respect to α, while the large ones become smaller for increasing α; see Figure 1.1. For the bifurcation diagram, see Figure 1.2.

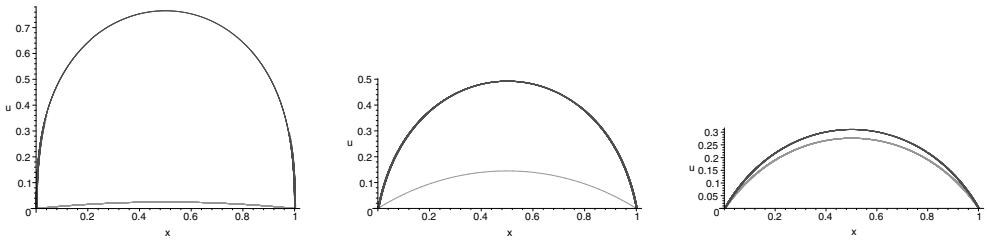

FIG. 1.1. *Solutions of the Navier boundary value problem* (1.1) *for* $\alpha = 0.2$, $\alpha = 1$, *and* $\alpha = 1.34$ *(left to right). See* [4, *Figure* 1].

It is an obvious conjecture that for $0 \leq \alpha < \alpha_{\max}$ the small solutions are (linearized) stable. This property was left open in [4], and to prove it is the first goal of this paper.

THEOREM 1.2. *Assume that* $0 \leq \alpha < \alpha_{\max}$ *and that* u *is the symmetric* small solution *of the Navier boundary value problem* (1.1). *Then, this solution is linearized stable; i.e., the spectrum of the (self-adjoint) linearization of* (1.1) *around* u *is contained in* $(0, \infty)$.

That these linearizations are the second variation of the functional $\tilde{W}_\alpha$ proves that the small solution is a local minimum of the functional $\tilde{W}_\alpha$ in $H^2 \cap H_0^1(0,1)$.

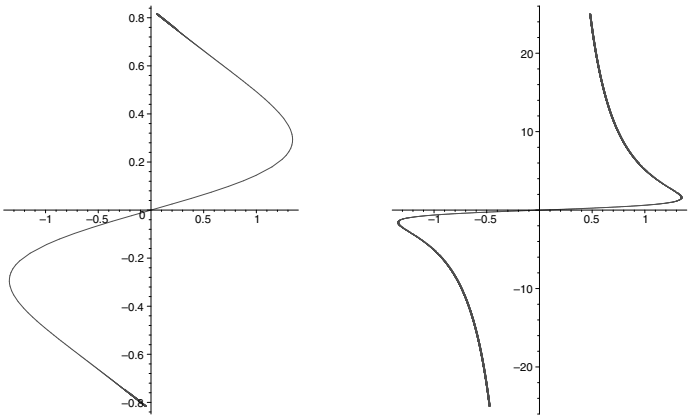

FIG. 1.2. *Bifurcation diagram for* (1.1)*: The extremals value of the solution* $u(1/2)$ *(left) and of the derivative* $u'(0)$ *(right) plotted over* α*. See* [4, *Figure* 2].

Furthermore, we will show that on $0 < \alpha < \alpha_{\max}$, the large solutions are unstable. More precisely, we prove that the following holds.

THEOREM 1.3. *Assume that* $0 < \alpha < \alpha_{\max}$ *and that* u *is the symmetric* large solution *of the Navier boundary value problem* (1.1)*. Then, this solution is unstable and has Morse index* 1*; i.e., one eigenvalue of the (self-adjoint) linearization of* (1.1) *is negative, while the remaining spectrum is contained in* $(0, \infty)$.

We emphasize that no symmetry assumptions are made in the discussion of the linearizations of (1.1).

A further important question is whether the small solutions are not only a local but also a global minimum of the functional $\tilde{W}_\alpha$.

THEOREM 1.4. *There exists* $\alpha^* = 1.132372323\ldots \in (0, \alpha_{\max})$ *such that for* $0 \le \alpha \le \alpha^*$ *the small solution* u *is the unique global minimum of the functional* $\tilde{W}_\alpha$ *in the class* $H^2 \cap H_0^1(0,1)$*. If* $\alpha^* < \alpha \le \alpha_{\max}$*, the infimum of* $\tilde{W}_\alpha$ *in* $H^2 \cap H_0^1(0,1)$ *is not attained, and in that case*

$$\inf_{v \in H^2 \cap H_0^1(0,1)} \tilde{W}_\alpha(v) = \left(\int_{\mathbb{R}} \frac{1}{(1+\tau^2)^{5/4}}\, d\tau \right)^2 - 2\alpha\pi.$$

The main idea of proving Theorem 1.4 consists in reducing the minimization of $\tilde{W}_\alpha$ over $H^2 \cap H_0^1(0,1)$ to the minimization of a function of two variables. As a byproduct of this approach we shall see that the infimum of the Willmore energy in $H^2 \cap H_0^1(0,1)$ coincides with the infimum in the subspace M of functions that are symmetric about $x = 1/2$; i.e., for every function in $H^2 \cap H_0^1(0,1)$, there exists a symmetric function with the same or smaller Willmore energy. This is remarkable since we deal with a fourth order problem and the well-known symmetrization procedures do not apply.

THEOREM 1.5. *Let* M *be the class of functions in* $H^2 \cap H_0^1(0,1)$*, which are symmetric about* $x = 1/2$*. Then we have*

$$\inf_{v \in H^2 \cap H_0^1(0,1)} \tilde{W}_\alpha(v) = \inf_{v \in M} \tilde{W}_\alpha(v).$$

2. Linearized stability. To prove Theorem 1.2 we describe in more detail how the symmetric solutions to (1.1) were obtained in [4].

In what follows, the function

$$G : \mathbb{R} \to \left(-\frac{c_0}{2}, \frac{c_0}{2}\right), \qquad G(s) := \int_0^s \frac{1}{(1+\tau^2)^{5/4}}\, d\tau, \tag{2.1}$$

$$c_0 = \int_{\mathbb{R}} \frac{1}{(1+\tau^2)^{5/4}}\, d\tau = \mathcal{B}\left(\frac{1}{2}, \frac{3}{4}\right) = 2.396280469\ldots,$$

plays a crucial role. It is straightforward to see that G is strictly increasing and bijective with $G'(s) > 0$. So, also the inverse function

$$G^{-1} : \left(-\frac{c_0}{2}, \frac{c_0}{2}\right) \to \mathbb{R} \tag{2.2}$$

is strictly increasing, bijective, and smooth with $G^{-1}(0) = 0$.

LEMMA 2.1 (see [4, Lemma 4]). *Let $u \in C^4([0,1])$ be a function symmetric about $x = 1/2$. Then u solves the Willmore equation in (1.1) iff there exists $c \in (-c_0, c_0)$ such that*

$$\forall x \in [0,1] : \qquad u'(x) = G^{-1}\left(\frac{c}{2} - cx\right). \tag{2.3}$$

For the curvature, one has that

$$\kappa(x) = -\frac{c}{\sqrt[4]{1 + G^{-1}\left(\frac{c}{2} - cx\right)^2}}. \tag{2.4}$$

Moreover, if we additionally assume that $u(0) = u(1) = 0$, then one has

$$u(x) = \frac{2}{c\sqrt[4]{1 + G^{-1}\left(\frac{c}{2} - cx\right)^2}} - \frac{2}{c\sqrt[4]{1 + G^{-1}\left(\frac{c}{2}\right)^2}} \quad (c \neq 0). \tag{2.5}$$

In order to solve the Navier boundary value problem (1.1), in [4], we had to study the function

$$h : (-c_0, c_0) \to \mathbb{R}, \qquad h(c) = \frac{c}{\sqrt[4]{1 + G^{-1}\left(\frac{c}{2}\right)^2}} \tag{2.6}$$

and the equation $h(c) = \alpha$. See Figure 2.1. The range of h is precisely the set of α, for which the Navier boundary value problem (1.1) has a smooth symmetric graph solution. The number of solutions c of the equation $\alpha = h(c)$ is the number of such solutions of the boundary value problem.

LEMMA 2.2 (see [4, Lemma 6]). *We have $h > 0$ in $(0, c_0)$, $h < 0$ in $(-c_0, 0)$, $\lim_{c \nearrow c_0} h(c) = \lim_{c \searrow -c_0} h(c) = 0$. The function h is odd and has precisely one local maximum in $c_{\max} = 1.840428142\ldots$ and one local minimum in $c_{\min} = -c_{\max}$. The corresponding value is $\alpha_{\max} = h(c_{\max}) = 1.343799725\ldots$.*

The small solutions correspond precisely to $c \in (0, c_{\max})$ and the large ones to $c \in (c_{\max}, c_0)$. Let us fix $c \in (0, c_0)$ with corresponding $\alpha = h(c)$ and solution u given by (2.5). First we have to calculate the linearization of (1.1) around u, i.e., the second variation of the modified Willmore functional $\tilde{W}_\alpha$ in u.

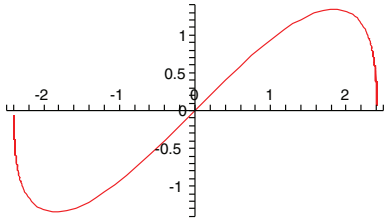

FIG. 2.1. *The function $c \mapsto h(c)$. According to* [4, *Lemma* 4], *solutions to* (1.1) *are given by solving $h(c) = \alpha$.*

LEMMA 2.3. *We have*

$$D^2\tilde{W}_\alpha(u)(\varphi,\eta) = 2\int_0^1 \frac{\varphi''(x)\eta''(x)}{(1+u'(x)^2)^{5/2}}\,dx + 5\int_0^1 \frac{1-u'(x)^2}{(1+u'(x)^2)^{3/2}}\kappa(x)^2\varphi'(x)\eta'(x)\,dx + 6\alpha\left[\frac{u'(x)\varphi'(x)\eta'(x)}{(1+u'(x)^2)^2}\right]_0^1, \quad \varphi,\eta \in H^2 \cap H_0^1(0,1).$$

Proof. According to [4, Lemma 2 and Corollary 1], the first variation of $\tilde{W}_\alpha(u)$ is given by

$$D\tilde{W}_\alpha(u)(\varphi) = 2\int_0^1 \frac{u''(x)\varphi''(x)}{(1+u'(x)^2)^{5/2}}\,dx - 5\int_0^1 \frac{u'(x)u''(x)^2\varphi'(x)}{(1+u'(x)^2)^{7/2}}\,dx + 2\alpha\left[\frac{\varphi'(x)}{1+u'(x)^2}\right]_0^1, \qquad \varphi \in H^2 \cap H_0^1(0,1).$$

In order to obtain the second derivative, we also consider $\eta \in H^2 \cap H_0^1(0,1)$ and differentiate the previous expression with respect to this direction:

$$\begin{aligned}
D^2\tilde{W}_\alpha(u)(\varphi,\eta) &= \frac{d}{dt}D\tilde{W}_\alpha(u+t\eta)(\varphi)|_{t=0} \\
&= 2\int_0^1 \frac{\varphi''(x)\eta''(x)}{(1+u'(x)^2)^{5/2}}\,dx - 10\int_0^1 \frac{u'(x)u''(x)\varphi''(x)\eta'(x)}{(1+u'(x)^2)^{7/2}}\,dx \\
&\quad - 10\int_0^1 \frac{u'(x)u''(x)\varphi'(x)\eta''(x)}{(1+u'(x)^2)^{7/2}}\,dx - 5\int_0^1 \frac{u''(x)^2\varphi'(x)\eta'(x)}{(1+u'(x)^2)^{7/2}}\,dx \\
&\quad + 35\int_0^1 \frac{u'(x)^2u''(x)^2\varphi'(x)\eta'(x)}{(1+u'(x)^2)^{9/2}}\,dx - 4\alpha\left[\frac{u'(x)\varphi'(x)\eta'(x)}{(1+u'(x)^2)^2}\right]_0^1 \\
&= 2\int_0^1 \frac{\varphi''(x)\eta''(x)}{(1+u'(x)^2)^{5/2}}\,dx - 5\int_0^1 \frac{\kappa(x)^2\varphi'(x)\eta'(x)}{\sqrt{1+u'(x)^2}}\,dx \\
&\quad - 10\int_0^1 \kappa(x)\cdot\frac{u'(x)}{\sqrt{1+u'(x)^2}}\cdot\frac{1}{(1+u'(x)^2)^{3/2}}\cdot\frac{d}{dx}\left(\varphi'(x)\eta'(x)\right)dx \\
&\quad + 35\int_0^1 \frac{u'(x)^2\kappa(x)^2\varphi'(x)\eta'(x)}{(1+u'(x)^2)^{3/2}}\,dx - 4\alpha\left[\frac{u'(x)\varphi'(x)\eta'(x)}{(1+u'(x)^2)^2}\right]_0^1.
\end{aligned}$$

To proceed further we would like to integrate the third term by parts. Here we will exploit that u is a solution to (1.1). In particular, u is smooth and satisfies the Navier

boundary data $\kappa(x) = -\alpha$, $x \in \{0,1\}$.

$$\begin{aligned}
D^2\tilde{W}_\alpha(u)(\varphi,\eta) &= 2\int_0^1 \frac{\varphi''(x)\eta''(x)}{(1+u'(x)^2)^{5/2}}\,dx - 5\int_0^1 \frac{\kappa(x)^2\varphi'(x)\eta'(x)}{\sqrt{1+u'(x)^2}}\,dx \\
&\quad + 35\int_0^1 \frac{u'(x)^2\kappa(x)^2\varphi'(x)\eta'(x)}{(1+u'(x)^2)^{3/2}}\,dx - 4\alpha\left[\frac{u'(x)\varphi'(x)\eta'(x)}{(1+u'(x)^2)^2}\right]_0^1 \\
&\quad - 10\left[\kappa(x)\frac{u'(x)\varphi'(x)\eta'(x)}{(1+u'(x)^2)^2}\right]_0^1 + 10\int_0^1 \frac{\kappa'(x)u'(x)\varphi'(x)\eta'(x)}{(1+u'(x)^2)^2}\,dx \\
&\quad + 10\int_0^1 \frac{\kappa(x)^2\varphi'(x)\eta'(x)}{(1+u'(x)^2)^{3/2}}\,dx - 30\int_0^1 \frac{\kappa(x)u'(x)^2u''(x)\varphi'(x)\eta'(x)}{(1+u'(x)^2)^3}\,dx \\
&= 2\int_0^1 \frac{\varphi''(x)\eta''(x)}{(1+u'(x)^2)^{5/2}}\,dx - 5\int_0^1 \frac{\kappa(x)^2\varphi'(x)\eta'(x)}{\sqrt{1+u'(x)^2}}\,dx \\
&\quad + 5\int_0^1 \frac{u'(x)^2\kappa(x)^2\varphi'(x)\eta'(x)}{(1+u'(x)^2)^{3/2}}\,dx + 6\alpha\left[\frac{u'(x)\varphi'(x)\eta'(x)}{(1+u'(x)^2)^2}\right]_0^1 \\
&\quad + 10\int_0^1 \frac{\kappa'(x)u'(x)\varphi'(x)\eta'(x)}{(1+u'(x)^2)^2}\,dx + 10\int_0^1 \frac{\kappa(x)^2\varphi'(x)\eta'(x)}{(1+u'(x)^2)^{3/2}}\,dx.
\end{aligned}$$

We infer from (2.3) and (2.4) that

$$\forall x \in [0,1], \qquad \kappa(x)\left(1+u'(x)^2\right)^{1/4} = -c,$$

and hence

$$\forall x \in [0,1], \quad \kappa'(x)\left(1+u'(x)^2\right)^{1/4} + \frac{1}{2}u'(x)\kappa(x)^2\left(1+u'(x)^2\right)^{3/4} = 0.$$

Consequently,

$$\begin{aligned}
D^2\tilde{W}_\alpha(u)(\varphi,\eta) &= 2\int_0^1 \frac{\varphi''(x)\eta''(x)}{(1+u'(x)^2)^{5/2}}\,dx - 5\int_0^1 \frac{\kappa(x)^2\varphi'(x)\eta'(x)}{\sqrt{1+u'(x)^2}}\,dx \\
&\quad + 6\alpha\left[\frac{u'(x)\varphi'(x)\eta'(x)}{(1+u'(x)^2)^2}\right]_0^1 + 10\int_0^1 \frac{\kappa(x)^2\varphi'(x)\eta'(x)}{(1+u'(x)^2)^{3/2}}\,dx.
\end{aligned}$$

This proves our claim. □

Looking at $\eta \in H^2(0,1) \cap H_0^1(0,1)$ as a test function, we now obtain the linearization from the second variation with the help of integration by parts. Note that the first integral gives rise to a further boundary term $2\left[\frac{\varphi''(x)\eta'(x)}{(1+u'(x)^2)^{5/2}}\right]_0^1$. Expressing u and α in terms of c according to Lemmas 2.1 and 2.2, the linearization of (1.1) around u reads as follows:

(2.7)

$$\begin{cases}
\left(\frac{\varphi''(x)}{\left(1+G^{-1}\left(\frac{c}{2}-cx\right)^2\right)^{5/2}}\right)'' + \frac{5}{2}c^2\left(\frac{G^{-1}\left(\frac{c}{2}-cx\right)^2-1}{\left(1+G^{-1}\left(\frac{c}{2}-cx\right)^2\right)^2}\varphi'(x)\right)' = 0, \quad x \in (0,1), \\
\varphi(0) = \varphi(1) = 0, \\
\frac{\varphi''(0)}{\left(1+G^{-1}\left(\frac{c}{2}\right)^2\right)^{5/2}} + 3\frac{c\,G^{-1}\left(\frac{c}{2}\right)\varphi'(0)}{\left(1+G^{-1}\left(\frac{c}{2}\right)^2\right)^{9/4}} = 0, \quad \frac{\varphi''(1)}{\left(1+G^{-1}\left(\frac{c}{2}\right)^2\right)^{5/2}} - 3\frac{c\,G^{-1}\left(\frac{c}{2}\right)\varphi'(1)}{\left(1+G^{-1}\left(\frac{c}{2}\right)^2\right)^{9/4}} = 0.
\end{cases}$$

For $c = 0$, the small solution of (1.1) is $u(x) \equiv 0$, and $D^2\tilde{W}_0(u)(\varphi,\varphi) = \int_0^1 \varphi''(x)^2\,dx$ is positive definite in $H^2 \cap H_0^1(0,1)$ with respect to the $L^2(0,1)$-norm. The spectrum of the linearization as a regular elliptic operator on a bounded interval together with suitable boundary conditions consists only of eigenvalues. Since these eigenvalues depend smoothly on u and u depends smoothly on c, $D^2\tilde{W}_\alpha(u)(\varphi,\varphi)$ remains positive definite for c increasing from 0 as long as (2.7) has only the trivial solution $\varphi(x) \equiv 0$.

We assume that (2.7) has a solution φ and put

$$\chi(x) := \varphi'(x).$$

Then, there exists a constant $A \in \mathbb{R}$ such that χ solves the second order differential equation

$$\left(\frac{\chi'(x)}{\left(1+G^{-1}\left(\frac{c}{2}-cx\right)^2\right)^{5/2}}\right)' + \frac{5}{2}c^2\left(\frac{G^{-1}\left(\frac{c}{2}-cx\right)^2-1}{\left(1+G^{-1}\left(\frac{c}{2}-cx\right)^2\right)^2}\chi\right) = c^2A.$$

We introduce more suitable variables,

$$\begin{aligned} y &= G^{-1}\left(\frac{c}{2}-cx\right) \in \left[-G^{-1}\left(\frac{c}{2}\right), G^{-1}\left(\frac{c}{2}\right)\right], \quad x = \frac{1}{2} - \frac{G(y)}{c}, \\ \psi(y) &:= \chi(x) = \chi\left(\frac{1}{2}-\frac{G(y)}{c}\right), \qquad \chi(x) = \psi\left(G^{-1}\left(\frac{c}{2}-cx\right)\right), \\ \chi'(x) &= -c\left(1+G^{-1}\left(\frac{c}{2}-cx\right)^2\right)^{5/4}\psi'\left(G^{-1}\left(\frac{c}{2}-cx\right)\right), \end{aligned}$$

and conclude that ψ solves the following boundary value problem:

$$\text{(2.8)} \qquad \begin{cases} \psi''(y) - \frac{5y}{2(1+y^2)}\psi'(y) + \frac{5(y^2-1)}{2(1+y^2)^2}\psi(y) = A, \quad y \in (-y_0, y_0), \\ \psi'(-y_0) + \frac{3y_0}{1+y_0^2}\psi(-y_0) = 0, \qquad \psi'(y_0) - \frac{3y_0}{1+y_0^2}\psi(y_0) = 0. \end{cases}$$

Here, we denote

$$\text{(2.9)} \qquad y_0 := G^{-1}\left(\frac{c}{2}\right).$$

To simplify the boundary conditions we make a last change of variables and put

$$\text{(2.10)} \qquad \Phi(y) := \frac{\psi(y)}{(1+y^2)^{3/2}}, \qquad y \in [-y_0, y_0],$$

and finally consider the following boundary value problem:

$$\text{(2.11)} \qquad \begin{cases} (1+y^2)^{3/2}\Phi''(y) + \frac{7}{2}y(1+y^2)^{1/2}\Phi'(y) \\ \qquad\qquad + \left(y^2+\frac{1}{2}\right)(1+y^2)^{-1/2}\Phi(y) = A, \quad y \in (-y_0, y_0), \\ \Phi'(-y_0) = \Phi'(y_0) = 0. \end{cases}$$

We recall the definition of $G(y) := \int_0^y \frac{1}{(1+\tau^2)^{5/4}}\,d\tau$ and put

$$\text{(2.12)} \qquad \Phi_0(y) := -2\frac{1}{\sqrt{1+y^2}}, \qquad \Phi_1(y) := \frac{1}{\sqrt[4]{1+y^2}}, \qquad \Phi_2(y) := \frac{G(y)}{\sqrt[4]{1+y^2}}.$$

Then, one directly verifies that the general solution of the differential equation in (2.11) is given by

$$\Phi(y) := A \cdot \Phi_0(y) + \gamma_1 \cdot \Phi_1(y) + \gamma_2 \cdot \Phi_2(y) \tag{2.13}$$

with $\gamma_1, \gamma_2 \in \mathbb{R}$. Since $A \cdot \Phi_0(y) + \gamma_1 \cdot \Phi_1(y)$ is even and $\gamma_2 \cdot \Phi_2(y)$ is odd, the boundary conditions in (2.11) are equivalent to

$$A \cdot \Phi_0'(y_0) + \gamma_1 \cdot \Phi_1'(y_0) = 0 \text{ and } \gamma_2 \cdot \Phi_2'(y_0) = 0, \tag{2.14}$$

which in turn are equivalent to

$$\gamma_1 = \frac{4A}{\sqrt[4]{1+y_0^2}} \text{ and } (\gamma_2 = 0 \text{ or } \Phi_2'(y_0) = 0)\,. \tag{2.15}$$

A beautiful coincidence between these solutions and the functions involved in the proof of Theorem 1.1 can be observed, namely,

$$\Phi_2(y) = \frac{1}{2} h(2G(y)), \qquad \Phi_2'(y) = \frac{h'(2G(y))}{(1+y^2)^{5/4}}. \tag{2.16}$$

With the help of these observations we are now ready to conclude the following lemma.

LEMMA 2.4. *For $c \in [0, c_0) \setminus \{c_{\max}\}$, the boundary value problem (2.7) has only the trivial solution $\varphi(x) \equiv 0$. For $c = c_{\max}$, it has a one-dimensional null space which is spanned by*

$$\varphi(x) = \frac{1}{c} \int_{G^{-1}(\frac{c}{2} - cx)}^{G^{-1}(\frac{c}{2})} G(\eta)\, d\eta.$$

If $c = c_{\max}$, $\alpha = \alpha_{\max}$, instabilities will occur first from the corresponding solution u in direction of this function φ; see Figure 2.2.

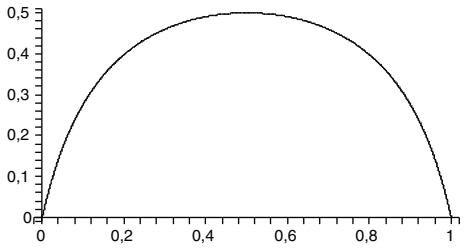

FIG. 2.2. *Profile of the unstable direction in $c = c_{\max}$.*

Proof. The case $c = 0$ is obvious, and we consider only $c \in (0, c_0)$. We denote

$$\tilde{\Phi}_1(y) := \Phi_0(y) + \frac{4}{\sqrt[4]{1+y_0^2}} \cdot \Phi_1(y) = \frac{2}{\sqrt[4]{1+y^2} \cdot \sqrt[4]{1+y_0^2}} \left(2 - \frac{\sqrt[4]{1+y_0^2}}{\sqrt[4]{1+y^2}} \right).$$

According to (2.13), we have to study

$$\Phi(y) = A\tilde{\Phi}_1(y) + \gamma_2 \Phi_2(y)$$

with some suitable $A, \gamma_2 \in \mathbb{R}$. Let φ be the corresponding solution of (2.7) which is obtained from Φ by tracing back the changes of variables and integrating χ. We want to show first that necessarily $A = 0$ for any $c \in [0, c_0)$:

$$\begin{aligned}
0 = \varphi(1) - \varphi(0) &= \int_0^1 \chi(x)\,dx = \int_0^1 \psi\left(G^{-1}\left(\frac{c}{2} - cx\right)\right) dx \\
&= \frac{1}{c}\int_{-G^{-1}\left(\frac{c}{2}\right)}^{G^{-1}\left(\frac{c}{2}\right)} \psi(y)(1+y^2)^{-5/4}\,dy = \frac{1}{c}\int_{-G^{-1}\left(\frac{c}{2}\right)}^{G^{-1}\left(\frac{c}{2}\right)} \Phi(y)(1+y^2)^{1/4}\,dy \\
&= \frac{A}{c}\int_{-G^{-1}\left(\frac{c}{2}\right)}^{G^{-1}\left(\frac{c}{2}\right)} \tilde{\Phi}_1(y)(1+y^2)^{1/4}\,dy + \frac{\gamma_2}{c}\int_{-G^{-1}\left(\frac{c}{2}\right)}^{G^{-1}\left(\frac{c}{2}\right)} \Phi_2(y)(1+y^2)^{1/4}\,dy \\
&= \frac{A}{c}\int_{-G^{-1}\left(\frac{c}{2}\right)}^{G^{-1}\left(\frac{c}{2}\right)} \tilde{\Phi}_1(y)(1+y^2)^{1/4}\,dy
\end{aligned}$$

since Φ_2 is odd. Hence we may conclude that

$$\begin{aligned}
0 &= \frac{A}{c}\int_{-G^{-1}\left(\frac{c}{2}\right)}^{G^{-1}\left(\frac{c}{2}\right)} \tilde{\Phi}_1(y)(1+y^2)^{1/4}\,dy \\
&= \frac{2A}{c}\int_{-G^{-1}\left(\frac{c}{2}\right)}^{G^{-1}\left(\frac{c}{2}\right)} \left(\frac{2}{\left(1+G^{-1}\left(\frac{c}{2}\right)^2\right)^{1/4}} - \frac{1}{(1+y^2)^{1/4}}\right) dy \\
&= \frac{4A}{c} F\left(G^{-1}\left(\frac{c}{2}\right)\right),
\end{aligned}$$

where F is defined by

$$F(\eta) := \frac{2\eta}{(1+\eta^2)^{1/4}} - \int_0^\eta \frac{1}{(1+s^2)^{1/4}}\,ds.$$

Since $F(0) = 0$ and

$$\begin{aligned}
F'(\eta) &= \frac{2}{(1+\eta^2)^{1/4}} - \frac{\eta^2}{(1+\eta^2)^{5/4}} - \frac{1}{(1+\eta^2)^{1/4}} \\
&= \frac{1}{(1+\eta^2)^{1/4}} - \frac{\eta^2}{(1+\eta^2)^{5/4}} = \frac{1}{(1+\eta^2)^{5/4}} > 0,
\end{aligned}$$

we have

$$F\left(G^{-1}\left(\frac{c}{2}\right)\right) > 0.$$

As a consequence, $A = 0$, and hence $\gamma_1 = 0$ by (2.15), and we are left with considering $\gamma_2\Phi_2$. We have that $h'(c) > 0$ for $c \in (0, c_{\max})$ and $h'(c) < 0$ for $c \in (c_{\max}, c_0)$. By making use of

$$\Phi_2'(y) = \frac{h'(2G(y))}{(1+y^2)^{5/4}}$$

and the boundary condition $\gamma_2\Phi_2'(G^{-1}(c/2)) = 0$, we conclude that $\gamma_2 = 0$ provided $c \in (0, c_0) \setminus \{c_{\max}\}$. If $c = c_{\max}$, then Φ_2 is a nontrivial solution of (2.11). For the

corresponding nontrivial solution φ of (2.7) we derive

$$\begin{aligned}\varphi(x) &= \gamma_2 \frac{c_{\max}}{2} \int_0^x \left(1 + G^{-1}\left(\frac{c_{\max}}{2} - c_{\max}\xi\right)^2\right)^{5/4} (1-2\xi)\, d\xi \\ &= \frac{\gamma_2}{c_{\max}} \int_{G^{-1}(\frac{c_{\max}}{2} - c_{\max}x)}^{G^{-1}(\frac{c_{\max}}{2})} G(\eta)\, d\eta,\end{aligned}$$

where we made use of the boundary conditions $\varphi(0) = \varphi(1) = 0$. □

Proof of Theorem 1.2. The proof is now immediate. By the preceding lemma we have that on $[0, c_{\max})$, 0 is not an eigenvalue of (2.7). Since $D^2\tilde{W}_0(u)(\varphi,\varphi)$ is positive definite in $H^2 \cap H_0^1(0,1)$ with respect to the $L^2(0,1)$-norm, by continuity, the same holds true for $D^2\tilde{W}_\alpha(u)(\varphi,\varphi)$ for $c \in [0, c_{\max})$, which is the stated linearized stability of the corresponding small solutions of (1.1). □

As an immediate consequence of Theorem 1.2 we obtain a global existence result for the geometric flow associated with (1.1), namely,

$$V = -\kappa_{ss} - \frac{1}{2}\kappa^3 \quad \text{on } \Gamma(t).$$

Here, V denotes the upward normal velocity of the evolving graphs

$$\Gamma(t) = \{(x, v(x,t)) \mid x \in [0,1]\}.$$

The above evolution law then leads to the parabolic initial-boundary value problem (2.18) below. The principle of linearized stability as it was proved in great generality by Latushkin, Prüss, and Schnaubelt [11, Proposition 16] can be applied to our situation and allows us to obtain global existence and asymptotic stability for initial data close to a small solution to (1.1).

COROLLARY 2.5. *Assume that* $c \in [0, c_{\max})$, *and let* $\alpha = h(c) = \frac{c}{\sqrt[4]{1+G^{-1}(\frac{c}{2})^2}}$ *and*

$$u(x) = \frac{2}{c\sqrt[4]{1 + G^{-1}\left(\frac{c}{2} - cx\right)^2}} - \frac{2}{c\sqrt[4]{1 + G^{-1}\left(\frac{c}{2}\right)^2}} \tag{2.17}$$

be the corresponding small solution of (1.1). *We fix some* $p > 5$. *Then, there exist* $\delta, \rho, C > 0$ *such that for* $v_0 \in W^{4,p}(0,1)$ *with* $v_0(0) = v_0(1) = 0$, $\kappa_{v_0}(0) = \kappa_{v_0}(1) = -\alpha$, *and*

$$\|v_0 - u\|_{W^{4,p}(0,1)} \le \delta,$$

there exists a global solution $v \in L^p(0,\infty, W^{4,p}(0,1)) \cap W^{1,p}(0,\infty, L^p(0,1))$ *of the initial Navier boundary value problem*

(2.18)
$$\begin{cases} \frac{v_t(t,x)}{\sqrt{1+v_x(t,x)^2}} + \frac{1}{\sqrt{1+v_x(t,x)^2}} \frac{d}{dx}\left(\frac{\kappa_{v,x}(t,x)}{\sqrt{1+v_x(t,x)^2}}\right) + \frac{1}{2}\kappa_v^3(t,x) = 0, & (t,x) \in [0,\infty) \times [0,1], \\ v(t,0) = v(t,1) = 0, \quad \kappa_v(t,0) = \kappa_v(t,1) = -\alpha, & t \in [0,\infty), \\ v(0,x) = v_0(x), & x \in [0,1]. \end{cases}$$

One has exponential convergence toward the steady state u:

$$\|v(t,\,.\,) - u(\,.\,)\|_{W^{4,p}(0,1)} \le C\exp(-\rho t) \qquad (t \ge 1). \tag{2.19}$$

With similar but simpler techniques and calculations one finds that the unique solution (cf. [4, Theorem 2]), being symmetric about $x = 1/2$ of the Dirichlet problem

$$\begin{cases} \frac{1}{\sqrt{1+u_x(x)^2}} \frac{d}{dx} \left(\frac{\kappa_x(x)}{\sqrt{1+u_x(x)^2}} \right) + \frac{1}{2}\kappa^3(t,x) = 0, & x \in [0,1], \\ u(0) = u(1) = 0, \quad u_x(0) = -u_x(1) = \beta, \end{cases} \tag{2.20}$$

$\beta \in \mathbb{R}$, is (linearized) stable. Analogously, a global existence result follows for the initial Dirichlet boundary value problem

$$\begin{cases} \frac{v_t(t,x)}{\sqrt{1+v_x(t,x)^2}} + \frac{1}{\sqrt{1+v_x(t,x)^2}} \frac{d}{dx} \left(\frac{\kappa_{v,x}(t,x)}{\sqrt{1+v_x(t,x)^2}} \right) + \frac{1}{2}\kappa_v^3(t,x) = 0, & (t,x) \in [0,\infty) \times [0,1], \\ v(t,0) = v(t,1) = 0, \quad v_x(t,0) = -v_x(t,1) = \beta, & t \in [0,\infty), \\ v(0,x) = v_0(x), & x \in [0,1], \end{cases} \tag{2.21}$$

provided the initial datum v_0 obeys the same boundary data and is sufficiently close to the stationary solution u of (2.20) with respect to the $W^{4,p}$-norm ($p > 5$).

3. Morse index of the large solution. For $c \in (0, c_0)$ we consider as in (2.5)

$$u_c(x) = \frac{2}{c\sqrt[4]{1 + G^{-1}\left(\frac{c}{2} - cx\right)^2}} - \frac{2}{c\sqrt[4]{1 + G^{-1}\left(\frac{c}{2}\right)^2}}.$$

In order to prove Theorem 1.3, we have to show that exactly one eigenvalue of the quadratic form

$$\varphi \mapsto D^2\tilde{W}_\alpha(u_c)(\varphi,\varphi), \qquad \alpha = h(c),$$

passes through 0 when c passes through $c_{\max}$ and that for $c \in (c_{\max}, c_0)$, 0 is not an eigenvalue of $D^2\tilde{W}_\alpha(u_c)$, i.e., of (2.7). The latter was already done in Lemma 2.4. Moreover, its proof yields that there is at most one eigenvalue, which crosses 0 in $c = c_{\max}$. It remains to show that for $c > c_{\max}$ and suitable $\varphi \in H^2 \cap H_0^1(0,1)$, one indeed has $D^2\tilde{W}_\alpha(u_c)(\varphi,\varphi) < 0$. Making use of the same transformations and notations of section 2 and restricting ourselves to symmetric φ, we find

$$\begin{aligned} D^2\tilde{W}_\alpha(u_c)(\varphi,\varphi) &= 2\int_0^1 \frac{\chi'(x)^2}{\left(1 + G^{-1}\left(\frac{c}{2} - cx\right)^2\right)^{5/2}}\,dx \\ &\quad - 5c^2 \int_0^1 \frac{G^{-1}\left(\frac{c}{2} - cx\right)^2 - 1}{\left(1 + G^{-1}\left(\frac{c}{2} - cx\right)^2\right)^2}\,\chi(x)^2\,dx - 12h(c)\frac{G^{-1}\left(\frac{c}{2}\right)}{\left(1 + G^{-1}\left(\frac{c}{2}\right)^2\right)^2}\chi(1)^2 \\ &= 2c\int_{-G^{-1}\left(\frac{c}{2}\right)}^{G^{-1}\left(\frac{c}{2}\right)} \frac{\psi'(y)^2}{(1+y^2)^{5/4}}\,dy - 5c\int_{-G^{-1}\left(\frac{c}{2}\right)}^{G^{-1}\left(\frac{c}{2}\right)} \frac{(y^2-1)}{(1+y^2)^{13/4}}\psi(y)^2\,dy \\ &\quad - 12\frac{c\,G^{-1}\left(\frac{c}{2}\right)}{\left(1 + G^{-1}\left(\frac{c}{2}\right)^2\right)^{9/4}}\psi\left(G^{-1}\left(\frac{c}{2}\right)\right)^2. \end{aligned}$$

We choose

$$\psi_c(y) := (1+y^2)^{3/2}\Phi_2(y) = (1+y^2)^{5/4}G(y)$$

and obtain for the corresponding $\varphi_c \in H^2 \cap H_0^1(0,1)$

$$\begin{aligned}&\frac{1}{4c} D^2\tilde{W}_\alpha(u_c)(\varphi_c,\varphi_c)\\ &= \int_0^{G^{-1}(\frac{c}{2})} \left(\left((1+y^2)^{-1/4} + \frac{5}{2} y G(y) \right)^2 - \frac{5}{2}(y^2-1)G(y)^2 \right) \frac{dy}{(1+y^2)^{3/4}}\\ &\quad - \frac{3}{4} c^2 G^{-1}\left(\frac{c}{2}\right) \left(1 + G^{-1}\left(\frac{c}{2}\right)^2 \right)^{1/4}. \end{aligned} \tag{3.1}$$

According to Theorem 1.2, we know that this expression is equal to 0 for $c = c_{\max}$. Writing $c = 2G(d)$, we see that the asymptotic behavior of the right-hand side is dominated by

$$\frac{c_0^2}{4}\left(\frac{25}{4}\cdot\frac{2}{3} - \frac{5}{2}\cdot\frac{2}{3} - 3 \right) d^{3/2} = -\frac{c_0^2}{8} d^{3/2} \to -\infty$$

for $d \to \infty$, i.e., $c \nearrow c_0$. This shows, together with Lemma 2.4, that $D^2\tilde{W}_\alpha(u_c)(\varphi_c,\varphi_c) < 0$ for $c \in (c_{\max}, c_0)$ and concludes the proof of Theorem 1.3.

The right-hand side of (3.1) is plotted in Figure 3.1. Since $\varphi_c \to 0$ for $c \searrow 0$, the curve starts in $(0,0)$, although there, $D^2\tilde{W}_\alpha(u_0)$ is positive definite.

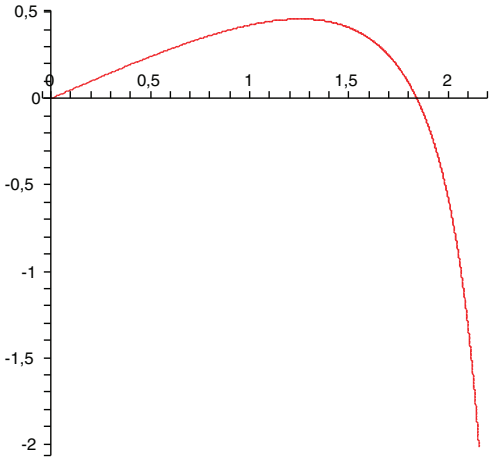

FIG. 3.1. $c \mapsto \frac{1}{4c} D^2\tilde{W}_\alpha(u_c)(\varphi_c,\varphi_c)$.

4. Global minima and symmetry. The aim of this section is to examine whether the small solutions which were found to be local minima in section 2 are also global minima for the functional $\tilde{W}_\alpha$. In what follows it will be convenient to write

$$\begin{aligned}\tilde{W}_\alpha(v) &= \int_0^1 \left(\kappa(x)^2 + 2\alpha\kappa(x)\right)\sqrt{1+v'(x)^2}\,dx,\\ &= \int_0^1 \kappa(x)^2\sqrt{1+v'(x)^2}\,dx + 2\alpha\left[\arctan(v'(x))\right]_0^1 =: W(v) + BC_\alpha(v).\end{aligned}$$

We remark that all quantities are geometric and so are invariant under rotation. Moreover, when stretching a curve by a factor k, W is multiplied by a factor $1/k$ while BC_α remains unchanged.

We shall see that the task of minimizing $\tilde{W}_\alpha$ can be reduced to a minimization problem for a function of two variables. As a byproduct of the analysis of this function we find that in order to determine $\inf_{v\in H^2\cap H_0^1}\tilde{W}_\alpha(v)$ it is sufficient to minimize over all symmetric functions. The reduction to a two-dimensional problem is achieved in two steps. We begin by showing that it is enough to consider concave functions.

LEMMA 4.1. *Suppose that $u\in H^2\cap H_0^1(0,1)$ is not concave. Then there exists a concave function $v\in H^2\cap H_0^1(0,1)$ with $\tilde{W}_\alpha(v)<\tilde{W}_\alpha(u)$.*

Proof. It is natural to think of v as the concave envelope of u, so that we are led to consider the following obstacle problem: find $v\in K$ such that

$$\forall \eta\in K,\qquad \int_0^1 v'(\eta'-v')\geq 0, \tag{4.1}$$

where $K=\{\eta\in H_0^1(0,1)\mid \eta\geq u \text{ a.e. in } (0,1)\}$. It is shown in Chapter IV of [7] that v can be obtained as the limit of a sequence $(v_\varepsilon)_{\varepsilon>0}$, where $v_\varepsilon\in H^2\cap H_0^1(0,1)$ solves

$$-v_\varepsilon''=(-u'')^+\,\vartheta_\varepsilon(v_\varepsilon-u)\quad \text{in } (0,1). \tag{4.2}$$

Here, $\vartheta_\varepsilon:\mathbb{R}\to\mathbb{R}$ satisfies

$$\vartheta_\varepsilon(t)=\begin{cases}1, & t<0,\\ 1-\frac{t}{\varepsilon}, & 0\leq t\leq\varepsilon,\\ 0, & t>\varepsilon.\end{cases}$$

It follows from the analysis in [7] that $v_\varepsilon\to v$ in $H^1(0,1)$ and $v_\varepsilon''\rightharpoonup v''$ in $L^2(0,1)$ as $\varepsilon\to 0$, so that $v\in H^2\cap H_0^1(0,1)$ and $v''\leq 0$ a.e. in $(0,1)$; in particular, v is concave. Denoting by $I=\{x\in[0,1]\mid v(x)=u(x)\}$ the coincidence set, we have that $v''=0$ a.e. in $[0,1]\setminus I$. Furthermore, using (4.2)

$$\begin{aligned}W(v)&=\int_0^1\frac{|v''|^2}{(1+(v')^2)^{\frac{5}{2}}}=\int_I\frac{|v''|^2}{(1+(u')^2)^{\frac{5}{2}}}\leq\liminf_{\varepsilon\to 0}\int_I\frac{|v_\varepsilon''|^2}{(1+(u')^2)^{\frac{5}{2}}}\\&\leq\int_I\frac{|(-u'')^+|^2}{(1+(u')^2)^{\frac{5}{2}}}\leq\int_0^1\frac{|(-u'')^+|^2}{(1+(u')^2)^{\frac{5}{2}}}\leq\int_0^1\frac{|u''|^2}{(1+(u')^2)^{\frac{5}{2}}}=W(u).\end{aligned}$$

If we had $W(v)=W(u)$, then the above argument would imply that $(-u'')^-=0$ a.e. in $(0,1)$ and therefore $u''\leq 0$ a.e. in $(0,1)$, contradicting our assumption that u is not concave. Hence $W(v)<W(u)$; since $v\geq u$ we have that $u'(0)\leq v'(0)$ and $u'(1)\geq v'(1)$, and therefore $\tilde{W}_\alpha(v)<\tilde{W}_\alpha(u)$. ∎

In what follows we shall make use of the prototype solution

$$U_0(x)=\frac{2}{c_0\sqrt[4]{1+G^{-1}\left(\frac{c_0}{2}-c_0x\right)^2}}. \tag{4.3}$$

Formally, it is the large solution of the Navier boundary value problem (1.1) for $\alpha=0$. However, one should observe that this solution is no longer smooth as a graph near $x=0$ and $x=1$, and for this reason, it was not included in Proposition 1.1.

Suppose that $0\leq x_0<x_1\leq 1$ are two points with $x_1-x_0<1$. Then $U_{0|[x_0,x_1]}$ can be written as a graph over the segment connecting $(x_0,U_0(x_0))$ and $(x_1,U_0(x_1))$. We denote by $u_{x_0,x_1}:[0,1]\to\mathbb{R}$ the strictly concave function which is obtained by translating, rotating, and rescaling the above graph to the unit interval $[0,1]$. Note

that $u_{x_0,x_1} \in H^2 \cap H_0^1(0,1)$. Our next lemma essentially reduces the minimization of $\tilde{W}_\alpha$ to a two-dimensional minimization problem.

LEMMA 4.2. *Suppose that $u \in H^2 \cap H_0^1(0,1) \setminus \{0\}$ is concave. Then there exist $0 \le x_0 < x_1 \le 1$, $x_1 - x_0 < 1$ such that $v = u_{x_0,x_1}$ satisfies $BC_\alpha(u) = BC_\alpha(v)$ and either $W(v) \le W(u)$, $u'(0) = v'(0)$, or $W(v) < W(u)$, $u'(0) \ne v'(0)$.*

Proof. Let us denote by β_ℓ and β_r the boundary angles of graph(u) on the left and on the right, respectively. Since u is assumed to be concave and nontrivial we have $\beta_\ell, \beta_r \in (0, \frac{\pi}{2})$. Consider

$$\mathcal{K} := \text{graph}(U_0) \cup \{(0,y) : y \le 0\} \cup \{(1,y) : y \le 0\}.$$

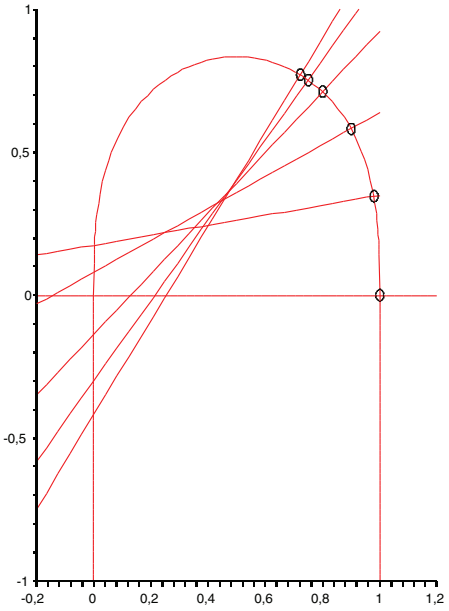

FIG. 4.1. *Left angle β_ℓ; right angle $\pi/2$.*

This is neither a graph nor a solution of the Willmore equation. However, it is a regular H^2-curve, locally an H^2-graph over the x- or the y-axis, respectively, and it has minimal Willmore energy c_0^2 among all concave curves connecting any point from $\{(0,y) : y \le 0\}$ with any point from $\{(1,y) : y \le 0\}$ with tangential directions $(0,1)$ and $(0,-1)$, respectively. This minimality follows similarly as in [4, end of section 5].

Claim. There exist two points $P = (x_P, y_P)$, $Q = (x_Q, y_Q) \in \mathcal{K}$, $P \ne Q$, such that the segment $[P,Q]$ intersects $\mathcal{K}$ under the angles β_ℓ at P and β_r at Q.

To see this, we start with the point $(x_1, y_1) = (1,0)$ and the orthogonal straight line through this point. This line intersects the left part of $\mathcal{K}$ in (x_0, y_0) under a right angle. Now we move the point (x_1, y_1) and the corresponding orthogonal straight line counterclockwise. The corresponding (x_0, y_0) finally moves down, and the intersection angle (at least finally) decreases and becomes arbitrarily small. In particular, the left angle β_ℓ is attained. See Figure 4.1. Now we keep this angle fixed and move the point (x_0, y_0) clockwise. We consider (x_1, y_1) on the right part of $\mathcal{K}$ as an intersection point with the straight line building the angle β_ℓ with $\mathcal{K}$ in (x_0, y_0). At the beginning this right angle is $\pi/2$, while it becomes arbitrarily small when (x_0, y_0) moves clockwise. In particular, β_r is attained as the angle on the right and the claim is proved.

In view of the above-mentioned minimality property of $\mathcal{K}$, $\mathcal{K}'$ enjoys a similar minimality among those arcs with boundary angles β_ℓ, β_r. We infer that

$$W(\mathcal{K}') \le \frac{1}{|P-Q|} W(u), \tag{4.4}$$

where $\mathcal{K}'$ denotes the subarc of $\mathcal{K}$ between P and Q. Observing that by construction y_P and y_Q cannot both be negative, we may distinguish two cases.

Case 1. $y_P \ge 0$ and $y_Q \ge 0$. Setting $x_0 = x_P$, $x_1 = x_Q$, we have $x_1 - x_0 < 1$ since $\beta_\ell, \beta_r \in (0, \frac{\pi}{2})$. The function $v = u_{x_0,x_1}$ then satisfies

$$W(v) = |P-Q| W(\mathcal{K}') \le W(u)$$

as well as $v'(0) = u'(0)$ and $v'(1) = u'(1)$.

Case 2. Either $y_P < 0$ or $y_Q < 0$. If $y_P < 0$, then $y_Q > 0$ since $\beta_r < \frac{\pi}{2}$, and we let $x_0 = 0$, $x_1 = x_Q$, and $v = u_{x_0,x_1}$. Denoting by $L(x_0, x_1)$ the length of the segment connecting $(x_0, U_0(x_0))$ and $(x_1, U_0(x_1))$, we have

$$W(v) = L(x_0,x_1) W(\mathcal{K}') \le \frac{L(x_0,x_1)}{|P-Q|} W(u) < W(u)$$

since $u \neq 0$ and by construction any point on $\mathrm{graph}(U_0)$ is strictly closer to $(0,0)$ than to any other point on $\{(0,y) \mid y < 0\}$. A similar argument applies if $y_Q < 0$. Finally note that while $BC_\alpha(u) = BC_\alpha(v)$, we have $u'(0) \neq v'(0)$ in this case. ∎

We deduce from Lemmas 4.1 and 4.2 that when determining $\inf \tilde{W}_\alpha$ over $H^2 \cap H_0^1(0,1)$ it is sufficient to calculate the Willmore energy for functions $v = u_{x_0,x_1}$ with $0 \le x_0 < x_1 \le 1$ and $x_1 - x_0 < 1$. The integrand for W on $[x_0, x_1]$ is c_0^2, so the integral is $c_0^2 \cdot (x_1 - x_0)$. The length of the base line is $\big((x_1-x_0)^2 + (U_0(x_1) - U_0(x_0))^2\big)^{1/2}$. As for BC_α, we have $2\alpha(\arctan(U_0'(x_1)) - \arctan(U_0'(x_0)))$. After rotation and rescaling we come up with

$$\begin{aligned}
\tilde{W}_\alpha(u_{x_0,x_1}) &= c_0^2 \cdot (x_1 - x_0) \left((x_1-x_0)^2 + (U_0(x_1) - U_0(x_0))^2\right)^{1/2} \\
&\quad + 2\alpha(\arctan(U_0'(x_1)) - \arctan(U_0'(x_0))) \\
&= c_0^2 \cdot (x_1 - x_0) \\
&\quad \cdot \left((x_1-x_0)^2 + \frac{4}{c_0^2} \left(\frac{1}{\sqrt[4]{1 + G^{-1}(c_0/2 - c_0 x_1)^2}} - \frac{1}{\sqrt[4]{1 + G^{-1}(c_0/2 - c_0 x_0)^2}} \right)^2 \right)^{1/2} \\
&\quad + 2\alpha(\arctan(G^{-1}(c_0/2 - c_0 x_1)) - \arctan(G^{-1}(c_0/2 - c_0 x_0))).
\end{aligned}$$

We now introduce the new variables

$$d_0 := G^{-1}(c_0/2 - c_0 x_0), \qquad d_1 := -G^{-1}(c_0/2 - c_0 x_1), \qquad d_1 > -d_0, \tag{4.5}$$

so that

$$x_0 = \frac{1}{2} - \frac{1}{c_0} G(d_0), \qquad x_1 = \frac{1}{2} + \frac{1}{c_0} G(d_1).$$

Defining

$$\hat{W}_\alpha(d_0, d_1) := \tilde{W}_\alpha(u_{x_0,x_1})$$

(see Figure 4.2), we end up with

$$\begin{aligned}&\hat W_\alpha(d_0,d_1)\\&= (G(d_0)+G(d_1))\left((G(d_0)+G(d_1))^2+4((1+d_0^2)^{-1/4}-(1+d_1^2)^{-1/4})^2\right)^{1/2}\\&\qquad -2\alpha(\arctan(d_0)+\arctan(d_1)).\end{aligned}$$

The following result summarizes what we have achieved so far.

THEOREM 4.3. *Let $\alpha \ge 0$. Then*

$$\inf_{v\in H^2\cap H_0^1(0,1)} \tilde W_\alpha(v) = \inf_{(d_0,d_1)\in\mathbb{R}^2,\, d_1\ge -d_0} \hat W_\alpha(d_0,d_1).$$

Let us remark that ideas similar to those employed to obtain Theorem 4.3 were used in [2] in order to prove an existence result for axially symmetric Willmore surfaces satisfying Dirichlet boundary conditions. The corresponding Navier problem, however, is still open.

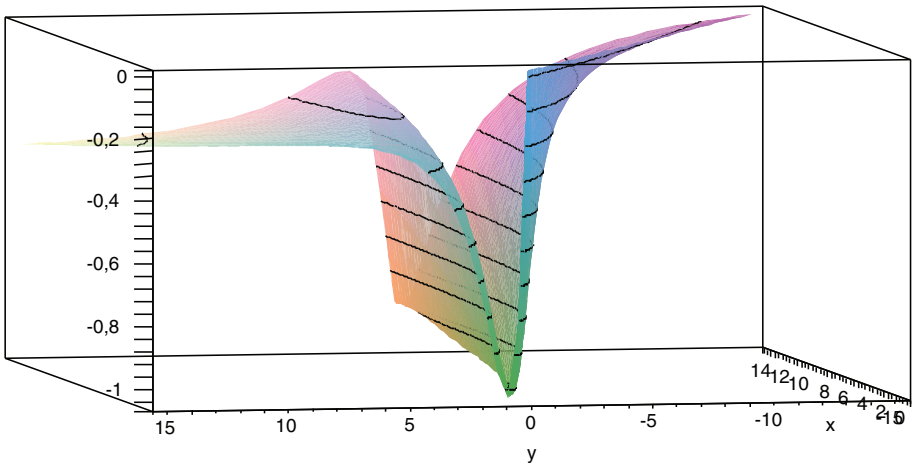

FIG. 4.2. *Cross section of the graph of $\hat W_1$ along the axis $d_0 = d_1$.*

It remains to discuss the two-dimensional function $\hat W_\alpha(d_0,d_1)$, $(d_1 \ge -d_0)$. Here, the key step is proving positivity for the following expression.

LEMMA 4.4. *For $d_1 > -d_0$ we have that*

$$\begin{aligned}&(G(d_0)+G(d_1))\cdot\left(\frac{d_0}{\sqrt[4]{1+d_0^2}}+\frac{d_1}{\sqrt[4]{1+d_1^2}}\right)-(G(d_0)+G(d_1))^2\\&\qquad -2\left(\frac{1}{\sqrt[4]{1+d_0^2}}-\frac{1}{\sqrt[4]{1+d_1^2}}\right)^2>0.\end{aligned}$$

Proof. By the fundamental theorem of calculus and since G is odd, we have

$$G(d_0)+G(d_1) = G(d_0)-G(-d_1) = \int_{-d_1}^{d_0} \frac{1}{(1+\tau^2)^{5/4}}\,d\tau,$$

$$\frac{d_0}{\sqrt[4]{1+d_0^2}}+\frac{d_1}{\sqrt[4]{1+d_1^2}} = \left[\frac{\tau}{(1+\tau^2)^{1/4}}\right]_{-d_1}^{d_0} = \int_{-d_1}^{d_0}\frac{1+\frac12\tau^2}{(1+\tau^2)^{5/4}}\,d\tau,$$

$$\frac{1}{\sqrt[4]{1+d_0^2}} - \frac{1}{\sqrt[4]{1+d_1^2}} = \left[\frac{1}{(1+\tau^2)^{1/4}}\right]_{-d_1}^{d_0} = -\frac{1}{2}\int_{-d_1}^{d_0} \frac{\tau}{(1+\tau^2)^{5/4}}\,d\tau.$$

One may observe that $d_1 > -d_0$ is equivalent to $-d_1 < d_0$. The first two terms in the expression under consideration combine as follows:

$$\begin{aligned}&(G(d_0)+G(d_1))\cdot\left(\frac{d_0}{\sqrt[4]{1+d_0^2}} + \frac{d_1}{\sqrt[4]{1+d_1^2}}\right) - (G(d_0)+G(d_1))^2\\ &= \frac{1}{2}\left(\int_{-d_1}^{d_0} \frac{1}{(1+\tau^2)^{5/4}}\,d\tau\right)\cdot\left(\int_{-d_1}^{d_0} \frac{\tau^2}{(1+\tau^2)^{5/4}}\,d\tau\right).\end{aligned}$$

We now apply the Cauchy–Schwarz inequality and make use of $\tau \mapsto \frac{1}{(1+\tau^2)^{5/8}}$ and $\tau \mapsto \frac{\tau}{(1+\tau^2)^{5/8}}$ being linearly independent to obtain

$$\begin{aligned}2\left(\frac{1}{\sqrt[4]{1+d_0^2}} - \frac{1}{\sqrt[4]{1+d_1^2}}\right)^2 &= \frac{1}{2}\left(\int_{-d_1}^{d_0} \frac{\tau}{(1+\tau^2)^{5/4}}\,d\tau\right)^2\\ &< \frac{1}{2}\left(\int_{-d_1}^{d_0} \frac{1}{(1+\tau^2)^{5/4}}\,d\tau\right)\cdot\left(\int_{-d_1}^{d_0} \frac{\tau^2}{(1+\tau^2)^{5/4}}\,d\tau\right)\\ &= (G(d_0)+G(d_1))\cdot\left(\frac{d_0}{\sqrt[4]{1+d_0^2}} + \frac{d_1}{\sqrt[4]{1+d_1^2}}\right) - (G(d_0)+G(d_1))^2,\end{aligned}$$

thereby proving the claim. □

Next we show that in the open interior of the domain of definition of the two-dimensional energy function $\hat{W}_\alpha$, critical points may occur at most on the diagonal, i.e., on symmetric graphs in the original context.

LEMMA 4.5. *Let $\alpha \geq 0$ and assume that*

$$\begin{aligned}&(d_0,d_1) \mapsto \hat{W}_\alpha(d_0,d_1)\\ &= (G(d_0)+G(d_1))\cdot\left((G(d_0)+G(d_1))^2 + 4\left((1+d_0^2)^{-1/4} - (1+d_1^2)^{-1/4}\right)^2\right)^{1/2}\\ &\quad - 2\alpha\left(\arctan(d_0)+\arctan(d_1)\right)\end{aligned}$$

has a critical point (d_0,d_1) with $d_1 > -d_0$. Then

$$d_0 = d_1.$$

Proof. In a critical point of $\hat{W}_\alpha$, we have that

$$\begin{aligned}0 &= \frac{\partial}{\partial d_0}\hat{W}_\alpha(d_0,d_1)\\ &= \frac{1}{2}\left(G(d_0)+G(d_1)\right)\cdot\left((G(d_0)+G(d_1))^2 + 4\left((1+d_0^2)^{-1/4} - (1+d_1^2)^{-1/4}\right)^2\right)^{-1/2}\\ &\quad\cdot\left(2(G(d_0)+G(d_1))(1+d_0^2)^{-5/4} - 4d_0(1+d_0^2)^{-5/4}\left((1+d_0^2)^{-1/4} - (1+d_1^2)^{-1/4}\right)\right)\\ &\quad + (1+d_0^2)^{-5/4}\left((G(d_0)+G(d_1))^2 + 4\left((1+d_0^2)^{-1/4} - (1+d_1^2)^{-1/4}\right)^2\right)^{1/2} - \frac{2\alpha}{1+d_0^2};\end{aligned}$$

$$
\begin{aligned}
0 &= \frac{\partial}{\partial d_1}\hat{W}_\alpha(d_0,d_1)\\
&= \frac{1}{2}\,(G(d_0)+G(d_1))\cdot\left((G(d_0)+G(d_1))^2+4\left((1+d_0^2)^{-1/4}-(1+d_1^2)^{-1/4}\right)^2\right)^{-1/2}\\
&\quad\cdot\left(2(G(d_0)+G(d_1))(1+d_1^2)^{-5/4}+4d_1(1+d_1^2)^{-5/4}\left((1+d_0^2)^{-1/4}-(1+d_1^2)^{-1/4}\right)\right)\\
&\quad+(1+d_1^2)^{-5/4}\left((G(d_0)+G(d_1))^2+4\left((1+d_0^2)^{-1/4}-(1+d_1^2)^{-1/4}\right)^2\right)^{1/2}\\
&\quad-2\alpha\frac{1}{1+d_1^2}.
\end{aligned}
\tag{4.6}
$$

Equivalently,

$$
\begin{aligned}
0 &= (G(d_0)+G(d_1))\cdot\left((G(d_0)+G(d_1))^2+4\left((1+d_0^2)^{-1/4}-(1+d_1^2)^{-1/4}\right)^2\right)^{-1/2}\\
&\quad\cdot\left((G(d_0)+G(d_1))(1+d_0^2)^{-1/4}-2d_0(1+d_0^2)^{-1/4}\left((1+d_0^2)^{-1/4}-(1+d_1^2)^{-1/4}\right)\right)\\
&\quad+(1+d_0^2)^{-1/4}\left((G(d_0)+G(d_1))^2+4\left((1+d_0^2)^{-1/4}-(1+d_1^2)^{-1/4}\right)^2\right)^{1/2}-2\alpha;\\
0 &= (G(d_0)+G(d_1))\cdot\left((G(d_0)+G(d_1))^2+4\left((1+d_0^2)^{-1/4}-(1+d_1^2)^{-1/4}\right)^2\right)^{-1/2}\\
&\quad\cdot\left((G(d_0)+G(d_1))(1+d_1^2)^{-1/4}+2d_1(1+d_1^2)^{-1/4}\left((1+d_0^2)^{-1/4}-(1+d_1^2)^{-1/4}\right)\right)\\
&\quad+(1+d_1^2)^{-1/4}\left((G(d_0)+G(d_1))^2+4\left((1+d_0^2)^{-1/4}-(1+d_1^2)^{-1/4}\right)^2\right)^{1/2}-2\alpha.
\end{aligned}
$$

Subtracting both equations yields

$$
\begin{aligned}
0 &= \left((1+d_0^2)^{-1/4}-(1+d_1^2)^{-1/4}\right)\\
&\quad\cdot\left((G(d_0)+G(d_1))^2+4\left((1+d_0^2)^{-1/4}-(1+d_1^2)^{-1/4}\right)^2\right)^{-1/2}\\
&\quad\cdot\left\{(G(d_0)+G(d_1))^2-2(G(d_0)+G(d_1))\left(\frac{d_0}{\sqrt[4]{1+d_0^2}}+\frac{d_1}{\sqrt[4]{1+d_1^2}}\right)\right.\\
&\qquad\left.+\left((G(d_0)+G(d_1))^2+4\left((1+d_0^2)^{-1/4}-(1+d_1^2)^{-1/4}\right)^2\right)\right\}.
\end{aligned}
$$

By Lemma 4.4, the curly bracket is strictly negative, since we assume that $d_1 > -d_0$. We conclude that

$$
0 = \left((1+d_0^2)^{-1/4}-(1+d_1^2)^{-1/4}\right),
$$

which yields that $d_0 = d_1$. □

We are now in position to solve the two-dimensional minimization problem.

PROPOSITION 4.6. *Let $0 < \alpha \le \alpha_{\max}$. There exists $\alpha^* = 1.132372323\ldots \in (0,\alpha_{\max})$ such that*

$$\inf_{(d_0,d_1)\in\mathbb{R}^2,\, d_1\geq -d_0} \hat{W}_\alpha(d_0,d_1) = \begin{cases} \hat{W}_\alpha(G^{-1}(\frac{c}{2}), G^{-1}(\frac{c}{2})), & 0<\alpha\leq\alpha^*, \\ c_0^2 - 2\alpha\pi, & \alpha^*<\alpha\leq\alpha_{\max}, \end{cases}$$

where $c\in(0,c_{\max})$ solves $h(c)=\alpha$. In the first case $d_0=d_1=G^{-1}(\frac{c}{2})$ is the only point for which the minimum is attained, while it is not attained for $\alpha^*<\alpha\leq\alpha_{\max}$.

Proof. In view of Lemma 4.5 and the symmetry of $\hat{W}_\alpha$,

$$\inf_{(d_0,d_1)\in\mathbb{R}^2,\, d_1\geq -d_0} \hat{W}_\alpha(d_0,d_1)$$

is the minimum between

$$\inf_{d\in(0,\infty)} \hat{W}_\alpha(d,d), \tag{4.7}$$

$$\inf_{d\in\mathbb{R}} \hat{W}_\alpha(d,-d) = 0, \tag{4.8}$$

and

$$\inf_{d\in\mathbb{R}} \hat{W}_\alpha(d,\infty). \tag{4.9}$$

Since

$$\hat{W}_\alpha(d,d) = 4G(d)^2 - 4\alpha\arctan(d)$$

is certainly negative for $d>0$ close to 0, we see that $\inf_{d\in(0,\infty)}\hat{W}_\alpha(d,d)<0$, so we need not consider (4.8). As for (4.9) we have

$$\hat{W}_\alpha(d,\infty) = \Big(G(d)+\frac{c_0}{2}\Big)\cdot\left(\Big(G(d)+\frac{c_0}{2}\Big)^2 + 4(1+d^2)^{-1/2}\right)^{1/2} - 2\alpha\Big(\arctan(d)+\frac{\pi}{2}\Big).$$

It is sufficient to discuss local mimima, since $\hat{W}_\alpha(\infty,\infty)$ is already covered by (4.7) and $\hat{W}_\alpha(-\infty,\infty)=0$ by (4.8). Passing to the $c=2G(d)$-variable, we see that $\hat{W}_\alpha$ attains its minimum on $\{(d_0,d_1): d_0\in[-\infty,\infty],\, d_1\in[-d_0,\infty]\}$. For fixed $d_0\in\mathbb{R}$, we infer from (4.6) that for d_1 large enough, $\frac{\partial\hat{W}_\alpha}{\partial d_1}>0$. This follows since the slowest term $4d_1(1+d_1^2)^{-5/4}(1+d_0^2)^{-1/4}$ decays of order $-3/2$ and has a positive coefficient. Hence, the minimum is not attained on $\mathbb{R}\times\{\infty\}$ but either in (∞,∞) or in the interior of our domain. This proves that

$$\inf_{(d_0,d_1)\in\mathbb{R}^2,\, d_1\geq -d_0} \hat{W}_\alpha(d_0,d_1) = \inf_{d\in(0,\infty)} \hat{W}_\alpha(d,d). \tag{4.10}$$

It remains to evaluate the right-hand side of (4.10). Let

$$\phi(d) := \hat{W}_\alpha(d,d) = 4G(d)^2 - 4\alpha\arctan(d).$$

We have

$$\phi'(d) = \frac{8G(d)}{(1+d^2)^{\frac{5}{4}}} - \frac{4\alpha}{1+d^2} = \frac{4}{1+d^2}\big(h(2G(d))-\alpha\big),$$

with h defined in (2.6). Thus, $\phi'(d)=0$ iff $d=G^{-1}(\frac{c}{2})$, where c is one of the solutions of $h(c)=\alpha$. Only the solution $c\in(0,c_{\max})$ is a local minimum so that

$$\inf_{d\in(0,\infty)}\phi(d) = \min\left(c^2 - 4\alpha\arctan\left(G^{-1}\left(\frac{c}{2}\right)\right), c_0^2 - 2\alpha\pi\right);$$

we take into account that $\phi(0) = 0$ and $\phi(d) < 0$ for small $d > 0$. In order to calculate the last minimum we introduce the following auxiliary function $f : [0, c_{\max}] \to \mathbb{R}$:

$$f(c) := c_0^2 - 2h(c)\pi - c^2 + 4h(c) \arctan G^{-1}\left(\frac{c}{2}\right).$$

We find that $f(0) = c_0^2 > 0$ and $f(c_{\max}) = -0.6674542140\ldots < 0$, and a short calculation shows that

$$f'(c) = \left(4 \arctan G^{-1}\left(\frac{c}{2}\right) - 2\pi\right) h'(c) < 0, \quad c \in (0, c_{\max}),$$

so that f has a unique zero

$$c^* = 1.274998908\ldots \in [0, c_{\max}] \text{ with } \alpha^* := h(c^*) = 1.132372323\ldots.$$

This proves the formula for $\inf_{(d_0,d_1)\in\mathbb{R}^2,\, d_1 \geq -d_0} \hat{W}_\alpha(d_0, d_1)$. The uniqueness of the minimum for $0 \leq \alpha \leq \alpha^*$ follows from Lemma 2.2. □

We are now in position to prove Theorems 1.4 and 1.5. The second result is an immediate consequence of (4.10) and Theorem 4.3. As for Theorem 1.4, we focus on the case $0 < \alpha \leq \alpha^*$. Let $c \in (0, c_{\max})$ be the unique solution of $h(c) = \alpha$ with corresponding small solution u_c. Clearly,

$$\begin{aligned}\tilde{W}_\alpha(u_c) = \hat{W}_\alpha\left(G^{-1}\left(\frac{c}{2}\right), G^{-1}\left(\frac{c}{2}\right)\right) &= \inf_{(d_0,d_1)\in\mathbb{R}^2,\, d_1 \geq -d_0} \hat{W}_\alpha(d_0, d_1) \\ &= \inf_{v \in H^2 \cap H_0^1(0,1)} \tilde{W}_\alpha(v)\end{aligned}$$

by Proposition 4.6 and Lemma 4.2. It remains to show that u_c is the only function in $H^2 \cap H_0^1(0, 1)$ for which the minimum is attained. Suppose that $u \in H^2 \cap H_0^1(0, 1)$ satisfies $\tilde{W}_\alpha(u) = \inf_{v\in H^2\cap H_0^1(0,1)} \tilde{W}_\alpha(v)$. In view of Lemma 4.1, u is necessarily concave. Let $v = u_{x_0,x_1} \in H^2 \cap H_0^1(0, 1)$ be the function appearing in Lemma 4.2 with d_0, d_1 given by (4.5). Using the minimality of u, Proposition 4.6, and Lemma 4.2, we obtain

$$\tilde{W}_\alpha(u) \leq \tilde{W}_\alpha(u_c) = \hat{W}_\alpha\left(G^{-1}\left(\frac{c}{2}\right), G^{-1}\left(\frac{c}{2}\right)\right) \leq \hat{W}_\alpha(d_0, d_1) = \tilde{W}_\alpha(v) \leq \tilde{W}_\alpha(u).$$

This implies that $\hat{W}_\alpha(G^{-1}(\frac{c}{2}), G^{-1}(\frac{c}{2})) = \hat{W}_\alpha(d_0, d_1)$ and hence by Proposition 4.6 that $d_0 = d_1 = G^{-1}(\frac{c}{2})$ so that $v = u_c$. In particular, we infer with the help of Lemma 4.2 that $u'(0) = v'(0) = u_c'(0)$ and $u'(1) = v'(1) = u_c'(1)$. As a consequence we have $BC_\alpha(u) = BC_\alpha(u_c)$, and therefore $W(u) = W(u_c)$. However, in view of Theorem 2 in [4], u_c is the *unique* minimum of W in the class $M_\beta = \{w \in H^2 \cap H_0^1(0, 1) \mid w'(0) = -w'(1) = \beta\}$ ($\beta = u_c'(0)$) so that we must have $u = u_c$. This completes the proof of Theorem 1.4. □

For selected values of α, Figure 4.3 shows plots of the function $c \mapsto \tilde{W}_\alpha(u_c)$ on the interval $[0, c_0)$.

The uniqueness part of Theorem 1.4 guarantees that a global minimizer of $\tilde{W}_\alpha$ is symmetric. A more difficult question is whether any solution of (1.1) is necessarily symmetric. The following example (see also [12, p. 461]) shows that such a result certainly does not hold if one extends the class of admissible functions to include graphs with singularities in their first derivatives. Let

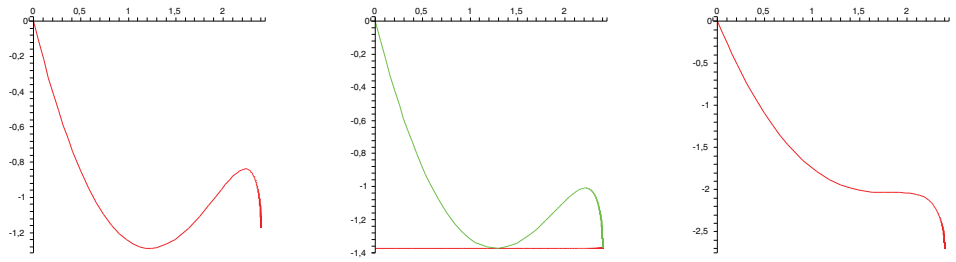

FIG. 4.3. *Graphs of the function* $c \mapsto \tilde{W}_\alpha(u_c)$ *for* $\alpha = 1.1$, $\alpha = \alpha^*$, *and* $\alpha = 1.34$ *(left to right).*

$$u(x) := \begin{cases} \frac{1}{2}U_0(2x), & 0 \le x \le \frac{1}{2}, \\ -\frac{1}{2}U_0(2-2x), & \frac{1}{2} \le x \le 1, \end{cases}$$

where the function U_0 was defined in (4.3). Clearly, as a curve in $\mathbb{R}^2$, the graph of u is a nonsymmetric solution of (1.1) for $\alpha = 0$. Note, however, that $u \notin H^2(0,1) \cap H_0^1(0,1)$ so that u is not a smooth solution of (1.1).

Acknowledgment. The authors thank N. Masel (Minsk) for pointing out an error in an earlier version of Lemma 2.3.

ON THE ENERGY OF SUPERCONDUCTORS IN LARGE AND SMALL DOMAINS*

MATTHIAS KURZKE† AND DANIEL SPIRN‡

Abstract. We study the Ginzburg–Landau energy functional for superconductors in an applied magnetic field. We focus on asymptotically large or small domains and establish the asymptotic behavior of the energy as a function of the Ginzburg–Landau parameter, applied magnetic field, and domain size. For a large class of domain sizes, we calculate the critical field strength where vortex nucleation becomes energetically favorable, and describe the vorticity of minimizers. For supercritical magnetic field strengths, we recover the energy of a classical Abrikosov vortex lattice. Our findings generalize several known results of Sandier and Serfaty for domains of fixed size.

Key words. Ginzburg–Landau, vortices, asymptotics, critical field

AMS subject classifications. 82D55, 35B25, 35J60

DOI. 10.1137/070687992

1. Introduction.

In the widely studied Ginzburg–Landau model, superconducting materials are modeled via the free energy functional

(1.1)
$$G_{phys}(\psi, \hat{A}) = G_0 + \int_\Omega \frac{|\operatorname{curl} \hat{A} - H_{ex}|^2}{8\pi} + \frac{1}{2m_*} \left| \left(\hbar \nabla - \frac{ie_* \hat{A}}{c} \right) \psi \right|^2 + \alpha |\psi|^2 + \frac{\beta}{2} |\psi|^4,$$

where Ω is the region occupied by the superconductor, ψ a complex-valued order parameter, $\hat{A}$ the vector potential of the magnetic field, H_{ex} an applied magnetic field, e_* and m_* physical constants corresponding to the charge and mass of superconducting carriers, c the speed of light, and $\hbar$ the Planck constant. G_0 is the energy of the normal state and independent of $(\psi, \hat{A})$. The quantities α and β are temperature-dependent constants. We will assume subcritical temperatures, so $\alpha < 0$ and $\beta > 0$. An introduction to the physics of (1.1) explaining the meaning of these constants can be found in [26].

We will work with only two-dimensional domains (corresponding to cylindrical symmetry in the x_3-direction) and will assume that the domain size is s. As we want to study regimes in which the domain size becomes small or large, we renormalize by assuming that $U = \frac{\Omega}{s}$ is a fixed domain of size $O(1)$.

Setting $u(x) = \sqrt{\frac{\beta}{|\alpha|}} \psi(sx)$, $A(x) = \frac{e_* s}{\hbar c} \hat{A}(sx)$, and $h_{ex} = \frac{e_*}{\hbar c} H_{ex}$, we rewrite the energy as

$$G_0 + K \left(\frac{1}{2} \int_U \frac{1}{\ell^2} |\operatorname{curl} A - h_{ex}|^2 + \frac{1}{2\varepsilon^2} (1 - |u|^2)^2 + |(\nabla - iA)u|^2 \right), \tag{1.2}$$

where $K = \frac{\hbar^2 |\alpha|}{2m_* \beta}$, $\ell^2 = \frac{2\pi s^2 e_*^2 |\alpha|}{m_* \beta c^2}$, and $\varepsilon^2 = \frac{\hbar^2}{4m_* |\alpha| s^2}$.

Dropping K and G_0 by an affine transformation of the energy, we arrive at the functional

$$G_\varepsilon(u,A) = \frac{1}{2}\int_U |\nabla_A u|^2 + \frac{1}{\ell^2}\,|\operatorname{curl} A - h_{ex}|^2 + \frac{1}{2\varepsilon^2}\left(1-|u|^2\right)^2 dx. \tag{1.3}$$

Using the commonly used comparison length scales of *penetration depth*,

$$\lambda = \sqrt{\frac{m_*\beta c^2}{4\pi|\alpha|e_*^2}}, \tag{1.4}$$

and *coherence length*,

$$\xi = \frac{\hbar}{\sqrt{2m_*|\alpha|}}, \tag{1.5}$$

we find that our dimensionless parameters ε and ℓ can be expressed as

$$\varepsilon = \frac{\xi}{\sqrt{2}s}, \quad \ell = \frac{s}{\sqrt{2}\lambda}. \tag{1.6}$$

We will consider ε small (i.e., domains of size $s \gg \xi$) and various scalings of ℓ.

We will study *type II* superconductors, those where the Ginzburg–Landau parameter $\kappa = \frac{\lambda}{\xi}$ is large, so the coherence length will be the smallest of the three physical length scales. This corresponds to $\ell \ll \frac{1}{\varepsilon}$, which will be implied by other assumptions throughout this article. Under this limit minimizers will start to energetically favor the formation of vortices once the applied magnetic field grows large enough.

The asymptotics of (1.3) with $\ell \equiv 1$, i.e.,

$$\frac{1}{2}\int_U |\nabla_A u|^2 + |\operatorname{curl} A - h_{ex}|^2 + \frac{1}{2\varepsilon^2}\left(1-|u|^2\right)^2 dx \tag{1.7}$$

under the asymptotic limit $\varepsilon \to 0$, has been widely studied in the past decade and a half.

1.1. Background results. In the last 15 years, there has been considerable progress made in the mathematical understanding of the Ginzburg–Landau model. A major step has been the groundbreaking work of Bethuel, Brezis, and Hélein [5] on the related functional without gauge term, the so-called BBH functional

$$E_\varepsilon(u) = \frac{1}{2}\int_U |\nabla u|^2 + \frac{1}{2\varepsilon^2}(1-|u|^2)^2, \tag{1.8}$$

and much of the analysis for the full gauge-invariant functional G_ε is based on analysis of E_ε. We can only sketch some of the developments for the static Ginzburg–Landau model with magnetic field, and refer the reader to the recent monograph [18] by Sandier and Serfaty, which contains a thorough treatment of vortex solutions and critical fields for vortex nucleation for (1.7).

We mention some works that are of particular relevance to the topic of this article. The first rigorous treatment of (1.7) in the $\varepsilon \to 0$ limit can be found in Bethuel and Riviere [6], who discovered many important features of the standard Ginzburg–Landau functional. Serfaty [22, 23] built on this work and gave the first rigorous treatment of the critical field question by a study of local minimizers close to the critical field.

The technique used assumptions on the BBH energy (1.8) to obtain an a priori bound on the number of vortices. Using the "vortex ball construction" of Sandier [17] and Jerrard [10], a key ingredient in most of the later research, Sandier and Serfaty [21] were then able to show that the global minimizer below the critical field is indeed vortex-free and $|u_\varepsilon|$ is bounded away from zero.

The structure of global minimizers with an unbounded number of vortices and with external field of order $h_{ex} = O(|\log \varepsilon|)$ was analyzed by Sandier and Serfaty in [20]. This result, combined with a Jacobian compactness theorem [11], was rephrased by Jerrard and Soner [12] in the framework of Γ-convergence. The limit problem is equivalent to a certain obstacle problem, and the limiting vorticity (after rescaling with $|\log \varepsilon|$) is constant in the set where the obstacle is active.

For asymptotically larger applied magnetic fields ($|\log \varepsilon| \ll h_{ex} \ll \frac{1}{\varepsilon^2}$), the vortices fill the whole domain as an Abrikosov-type lattice with uniform limiting density of vortices. This was established by Sandier and Serfaty in [19].

There are few results as of yet on the influence of the domain size on the behavior of the functional. The asymptotic expansion results of Chapman et al. [8] contain a scaling argument similar to ours above, and then study domains of size $s = O(\xi)$ with $\kappa \gg 1$, which corresponds to very small domains.

Aftalion and Dancer [1] studied critical points of the Ginzburg–Landau energy. For small domains ($\ell < C \min(1, \frac{C}{\kappa})$), they showed that any solution that is not the normal solution (where $u \equiv 0$) will be bounded away from zero, regardless of the external field. For the special case where the domain is a ball, $U_\ell = B_\ell(0)$, they showed that solutions in small domains are necessarily radially symmetric, and there exists a critical field of order $O(\frac{1}{\ell})$ such that, above this field, only the normal solution exists, while a unique superconducting solution exists below this threshold.

A numerical study was performed by Aftalion and Du [2], who studied the response of a superconductor to the raising and lowering of the external field depending on Ginzburg–Landau parameter κ and domain size. They found bifurcation diagrams in several distinct regimes, including a critical line separating type I and type II behavior.

Recently, there have been results by Aydi [3] and Aydi and Sandier [4] on minimizing sequences of the Ginzburg–Landau energy in periodic boxes. In these papers the authors establish a detailed description of the critical field strength for vortex nucleation; vortices are located at minimizers of an explicit renormalized energy. Furthermore, the limiting induced magnetic field satisfies a periodic London equation with point sources at the vortex locations. These results can be understood as a study of the interior behavior of an Abrikosov lattice in the large domain limit.

There have also been a few results that study (1.7) with applied magnetic fields and domain-dependence between h_{c_2} and h_{c_3}, the regime associated with surface superconductivity. However, we restrict ourselves to field strengths asymptotically below h_{c_2}; hence we do not attempt to review results within this class of field strengths.

There are similarities between the Ginzburg–Landau energy (1.3) and the Chern–Simons–Higgs energy

$$G_{csh}(u, A) = \frac{1}{2} \int_U |\nabla_A u|^2 + \frac{\mu^2}{4} \frac{|\operatorname{curl} A - h_{ex}|^2}{|u|^2} + \frac{1}{\varepsilon^2} |u|^2 \left(1 - |u|^2\right)^2 dx \tag{1.9}$$

for an applied magnetic field, h_{ex}, and a bounded simply connected domain, $U \subset \mathbb{R}^2$. The Chern–Simons–Higgs model is an anyon theory that is of interest in connection with high-temperature superconductors and the quantum Hall effect. For an overview

of the study in the self-dual case $\mu = \varepsilon$, see Yang [27].

In [14, 15] the authors proved several results of a similar nature to those found here: For $h_{ex} = H|\log\varepsilon|$ and $G_{csh}(u_\varepsilon, A_\varepsilon) = O(|\log\varepsilon|^2)$, we were able to show Γ-convergence results for the cases $\mu = \mu_\varepsilon \to \mu_0 \in (0, \infty]$. These enabled us to calculate the critical field for vortex nucleation. The main ingredient in these results is a compactness proof that relates the Jacobian of u, $J(u) = \det \nabla u$, to the energy

$$E_{csh}(u) = \frac{1}{2}\int_U |\nabla u|^2 + \frac{1}{\varepsilon^2}|u|^2(1-|u|^2).$$

Using this compactness result from [14] and an energy decomposition, we showed Γ-convergence for finite μ in [14] and for $\mu \to \infty$ in [15]. For $\mu \to 0$, we gave an explicit counterexample that illustrates why this method, using a decomposition and bounds for E_{csh}, fails in this case. However, we were later able to show that for h_{ex} much larger than the critical field, and under certain restrictions on μ, the energy of minimizers scales in the same fashion as the energy of an Abrikosov-type lattice just as for the Ginzburg–Landau energy (1.7); see [16].

All of our results here carry over from the Chern–Simons–Higgs energy (1.9) under the assumptions above. In particular, we can extend the results of [14, 15, 16, 25] and understand vortices in non–self-dual Chern–Simons–Higgs for a wider range of parameters and in more detail. Results for (1.3) in the next subsection can be related to results for (1.9) by simply setting $\ell = \frac{2}{\mu}$.

1.2. Main results. In this subsection, we list our main theorems on the behavior of minimizers for various parameter regimes. These results, most of which are generalizations of known results from the last section, provide a partial solution to Open Problem 1 of [18].

Our first result is the calculation of the first critical field where minimizers of the Ginzburg–Landau energy start to have vortices. This field is $O(|\log\varepsilon|)$ if the domains stay bounded and $O(\ell^2|\log\varepsilon|)$ if the domains are unbounded and ℓ is bounded by a power of $|\log\varepsilon|$.

THEOREM 1.1. *There exists a sequence of critical fields $h_{c_1}(\varepsilon)$ such that any minimizer of the Ginzburg–Landau functional with $h_{ex} < h_{c_1}(\varepsilon) - o(|\log\varepsilon|)$ is vortex-free, while any minimizer with $h_{ex} > h_{c_1}(\varepsilon) + o(|\log\varepsilon|)$ has vortices.*

As $\varepsilon \to 0$, the critical field $h_{c_1}(\varepsilon)$ satisfies the following expansion: If $\ell_\varepsilon \to \ell_0$ with $0 \le \ell_0 < \infty$, then

$$\frac{h_{c_1}(\varepsilon)}{|\log\varepsilon|} \to H_1(\ell_0), \tag{1.10}$$

where

$$H_1(\ell_0) = \frac{1}{2\max_{\overline{U}} |y_{\ell_0}|}, \tag{1.11}$$

where y_{ℓ_0} is the solution of

$$-\Delta y_{\ell_0} + \ell_0^2 y_{\ell_0} + 1 = 0$$

with Dirichlet boundary conditions $y_{\ell_0} = 0$ on ∂U.

Finally, if $\ell_\varepsilon \to \infty$ and $\ell_\varepsilon \le |\log\varepsilon|^\gamma$ for any fixed $\gamma > 0$, then

$$\frac{h_{c_1}(\varepsilon)}{\ell_\varepsilon^2|\log\varepsilon|} \to \frac{1}{2} \tag{1.12}$$

as $\varepsilon \to 0$. Therefore, the critical field scales as $h_{c_1} = \frac{\ell_\varepsilon^2 |\log \varepsilon|}{2}$ in this regime of domain sizes.

For small or bounded domains Theorem 1.1 follows from adapting the proof of Sandier and Serfaty [21], where $\ell \equiv 1$. Formally examining the resulting critical field (1.11), one finds $H_1(\ell_0) \to \frac{\ell_0^2}{2}$ as $\ell_0 \to \infty$, so we expect that $h_{c_1} = \frac{\ell_\varepsilon^2 |\log \varepsilon|}{2}$ for any $\ell_\varepsilon \to +\infty$ and $\ell_\varepsilon \ll \frac{1}{\sqrt{\varepsilon |\log \varepsilon|}}$; see the discussion before Lemma 2.7. We give a proof for the case of large (but not too large) domains in section 2; see Proposition 2.1 for details.

The following results can be used to characterize the minimizers of $(u_\varepsilon, A_\varepsilon)$ for external fields of order $O(|\log \varepsilon|)$ and small or bounded domains. The first step is a Γ-convergence result that relates $G_\varepsilon(u_\varepsilon, A_\varepsilon)$ to a simpler functional that no longer involves ε. We skip some of the detailed convergence statements for ease of presentation. The full statement is given in Theorem 3.1.

THEOREM 1.2. *As $\varepsilon \to 0$, the functional $\frac{1}{|\log \varepsilon|^2} G_\varepsilon$ is Γ-convergent to $G(v, a)$, where the limit functional G is given by*

(1.13)
$$G(v,a) := \begin{cases} \frac{1}{2}\int_U |v-a|^2 + \frac{1}{\ell_0^2} |\operatorname{curl} a - H|^2 + \frac{1}{2} \|\operatorname{curl} v\|_{\mathscr{M}} & \text{if } \ell_0 > 0, \\ \frac{1}{2}\int_U |v-a|^2 + \frac{1}{2} \|\operatorname{curl} v\|_{\mathscr{M}} & \text{if } \ell_0 = 0 \text{ and } \operatorname{curl} a = H, \\ +\infty & \text{otherwise,} \end{cases}$$

under a convergence that includes $\left(\frac{1}{|\log \varepsilon|}(iu_\varepsilon, \nabla u_\varepsilon) - \frac{1}{|\log \varepsilon|}|u|^2 A_\varepsilon\right) \rightharpoonup (v - a)$ and $\frac{1}{|\log \varepsilon|} A_\varepsilon \rightharpoonup \operatorname{curl} a$ in L^2.

Since Γ-convergence and the compactness we have here imply that minimizers of G_ε and of G approximate each other, we study minimizers of G to gain insight into the structure of minimizers of G_ε.

THEOREM 1.3. *If (v_0, a_0) is a minimizer of (1.13) and $\ell_0 > 0$, then $z_0 = \ell_0^{-2}(\operatorname{curl} a_0 - H)$ is the unique minimizer of the following obstacle problem: Minimize*

$$F_{\ell_0, H}(z) = \frac{1}{2}\int_U |\nabla z|^2 + \ell_0^2 z^2 + 2zH \tag{1.14}$$

in the admissible class

$$\mathscr{K} = \left\{ z \in H_0^1(U) : z \geq -\frac{1}{2} \text{ a.e. in } U \right\}. \tag{1.15}$$

The limit (v_0, a_0) satisfies the following additional properties:

$$\begin{aligned} \ell_0^{-2} \operatorname{curl}(\operatorname{curl} a_0 - H) + a_0 &= v_0 \quad \text{in } U, \\ \operatorname{curl} a_0 - H &= 0 \quad \text{on } \partial U, \\ -\frac{1}{2} \leq z_0 &\leq 0, \\ \operatorname{curl} v_0 &\geq 0, \\ \operatorname{spt}(\operatorname{curl} v_0) &\subset \left\{ z_0 = -\frac{1}{2} \right\}. \end{aligned}$$

In the case where $\ell_0 = 0$, we have $\operatorname{curl} a_0 = H$ and obtain a slightly different obstacle problem: Let y_0 be the solution of $-\Delta y_0 = \operatorname{curl} v_0 - H$ with zero boundary conditions. Then y_0 is the unique minimizer of

$$F_{0,H}(y) = \frac{1}{2}\int_U |\nabla y|^2 + 2yH \tag{1.16}$$

in the admissible class

$$\mathscr{K} = \left\{ y \in H^1_0(U) : y \geq -\frac{1}{2} \text{ a.e. in } U \right\}. \tag{1.17}$$

Moreover, $\operatorname{curl} v_0 \geq 0$ *and* $\operatorname{spt}(\operatorname{curl} v_0) \subset \{y_0 = -\frac{1}{2}\}$.

This theorem, proved later in section 3, implies again the results on the first critical field: When the obstacle is not active, the minimizer satisfies $\operatorname{curl} v = 0$. This happens if and only if $H < H_1(\ell_0)$ with the same fields as above. However, since we rescaled the vorticity to obtain convergence, this only shows that an approximating sequence $(u_\varepsilon, A_\varepsilon)$ has at most $o(|\log \varepsilon|)$ vortices, a result that is weaker than the "no vortices below the critical field" obtained in Theorem 1.1.

Finally, we study minimizers of the Ginzburg–Landau functional with a very large (supercritical) applied external magnetic field and obtain energy asymptotics of a uniform vortex lattice, as follows.

THEOREM 1.4. *Assume that*

$$\max\{1, \ell^2\} |\log \varepsilon| \ll h_{ex} \ll \frac{1}{\varepsilon^2}; \tag{1.18}$$

then minimizing sequence $\{u_\varepsilon, A_\varepsilon\}$ *satisfies*

$$G_\varepsilon(u_\varepsilon, A_\varepsilon) = \frac{1}{2} |U| \, h_{ex} \log \frac{1}{\varepsilon \sqrt{h_{ex}}} \left(1 - o_\varepsilon(1)\right). \tag{1.19}$$

Furthermore, the vortex density is uniform in the limit; see Proposition 5.2 *for a precise statement.*

The proof of Theorem 1.4 is given in Proposition 5.2 and relies on the upper bound Proposition 4.1. For the lower bound, we have followed the simple proof of Sandier and Serfaty [18] and reduced the theorem by a well-chosen rescaling to the lower bound part of the Γ-convergence theorem in the $|\log \varepsilon|^2$ scaling.

For the upper bound, we use a simple approach with Fourier series (Proposition 4.1). A refined version of the upper bound, (4.2), motivates our conjecture on the behavior close to the critical field for large domains.

Remark 1.5. For $\ell_\varepsilon \to \infty$ and $h_{ex} = O(\ell^2 |\log \varepsilon|)$, we do not yet have a rigorous result on the structure of minimizers. However, we expect from formal calculations that a uniform lattice, such as those constructed in section 4, should be minimizing. This is further supported by the analysis of Aydi [3], who showed such a result in the periodic setting. Aydi's upper bound and ours are essentially equivalent.

1.3. Discussion. We conclude the introduction with several unresolved questions regarding asymptotics of (1.3). There is still work to do to complete the answer to Problem 1 in [18]. In particular, a complete phase diagram for the minimizing behavior depending on κ, ℓ, and h_{ex} should be given, including the cross-over between type I and type II behavior that happens for $\kappa\ell = O(1)$, and the results of Aftalion and Du [2] should be made fully rigorous. For such a study, it would also be necessary to understand local minimizers and hysteresis phenomena for slowly changing fields.

It is an interesting problem to further study beginning vortex nucleation close to the critical field in the large domain limit, $\ell \to +\infty$. Based on the construction of Proposition 4.1 and the structure of the Meissner state, we expect that minimizers exhibit a uniform vortex lattice that fills the whole domain. However, vortices will be far apart and interact only weakly, making this a subtle problem. Finally, it would

be interesting to study (1.3) with applied fields in the "intermediate range," recently undertaken for (1.7) in [18]. For states with few vortices in large domains, we similarly expect very slow motion for the gradient flow, as vortices will move in an almost flat potential.

2. Critical field calculation. In this section we establish Theorem 1.1. The proof of Theorem 1.1 for $\ell \to [0, +\infty)$ follows from a direct insertion of ℓ^{-2} into the magnetic field term of (1.7) and following the proof found in [22, 21]. However, when $\ell \to +\infty$, a simple scaling argument fails, and we need to be more careful. In the following we show that for a substantial class of large-domain asymptotics, the critical field strength is indeed

$$h_{c_1} = \frac{\ell^2}{2}|\log \varepsilon| + o(|\log \varepsilon|),$$

as suggested by the formal analysis of the scaled renormalized energy.

PROPOSITION 2.1. *Let $\ell \to +\infty$ with $\ell \le C|\log \varepsilon|^{\gamma}$ for any fixed $\gamma \in \mathbb{R}^+$, and suppose that (u, A) is a minimizer of the Ginzburg–Landau energy* (1.3). *Then the first critical field for vortex nucleation is $h_{c_1} = \frac{\ell^2}{2}|\log \varepsilon| = \frac{1}{2}|\log \varepsilon|^{2\gamma+1}$. In particular for $h_{ex} < \frac{\ell^2}{2}|\log \varepsilon|$, any minimizer will satisfy $|u| \ge \frac{3}{4}$ for all ε sufficiently small, and for $h_{ex} > \frac{\ell^2}{2}|\log \varepsilon|$ any minimizer must have a vortex.*

Remark 2.2. Although we establish the conjectured critical field for $\ell = |\log \varepsilon|^{\gamma}$, we believe the critical field should be true over length scales up to $\ell \le \frac{C}{\sqrt{\varepsilon}|\log \varepsilon|}$. In particular, the more refined vortex ball estimates found in [13, 18] should be powerful enough to handle larger domains, but in the interest of brevity we consider only ℓ's that satisfy $1 \ll \ell \le C|\log \varepsilon|^{\gamma}$. We establish Proposition 2.1 by using the explicit vortex structure that exists for these intermediate-sized domains.

The Euler–Lagrange equations of (1.3),

$$\begin{aligned} 0 &= \nabla_A^2 u + \frac{1}{\varepsilon^2} u\left(1 - |u|^2\right), \\ 0 &= \operatorname{curl}\operatorname{curl} A + \ell^2 j_A(u), \end{aligned} \tag{2.1}$$

in U and $n \cdot \nabla_A u = 0$ and $\operatorname{curl} A = h_{ex}$ on ∂U. Setting the Coulomb gauge, we see that

$$\operatorname{div} A = 0 \text{ in } U, \qquad n \cdot A = 0 \text{ on } \partial U.$$

Solutions to (2.1) satisfy the maximum principle

$$\|u\|_{L^\infty(U)} \le 1, \tag{2.2}$$

the proof of which can be found in [6, 19].

The key to establishing Proposition 2.1 is a good energy decomposition. In order to establish this decomposition we use the following result of Sandier and Serfaty that supplies the vortex structure for our range of ℓ's. Their result, based on the method of Jerrard [10] and Jerrard and Soner [11] is the following.

PROPOSITION 2.3 (see Sandier and Serfaty[21]). *Let $u : U \to \mathbb{C}$ be such that $|\nabla u| \le \frac{C}{\varepsilon}$ and that $E_\varepsilon(u) \le C|\log \varepsilon|^M$ for $M \ge 2$ a fixed number. Then, for any $\alpha > 0$ there exist disjoint balls $\{B_{r_i}\}_{i \in I}$ of radii r_i such that for sufficiently small ε,*

1. $\{|u| < \frac{3}{4}\} \subset \cup_{i \in I} B_{r_i}$,

2. $\operatorname{card} I \leq C|\log\varepsilon|^M$,
3. $r_i \leq \frac{C}{|\log\varepsilon|^\alpha}$,
4. *if* $\overline{B_{r_i}} \subset U$ *and* $d_i = \deg(u, \partial B_{r_i})$, *then*

$$\int_{B_{r_i}} e_\varepsilon(u)dx \geq \pi\,|d_i|\,(|\log\varepsilon| - O(\log|\log\varepsilon|))\,. \tag{2.3}$$

Remark 2.4. The result in [21] is restricted to energies of the size $E_\varepsilon(u) \leq K|\log\varepsilon|^2$; however, the same proof holds for the higher energies in the assumptions found in Proposition 2.1.

We now state our energy decomposition, in the spirit of Bethuel and Riviere [6], Serfaty [22], and Sandier and Serfaty [19].

PROPOSITION 2.5. *Let* (u, A) *be a minimizer, where* A *satisfies the Coulomb gauge and* $1 \ll \ell \leq C|\log\varepsilon|^\gamma$. *Let* $A = h_{ex}\nabla^\perp\xi_\ell + \nabla^\perp\zeta$, *where* ξ_ℓ *satisfies*

$$\begin{aligned} -\frac{1}{\ell^2}\Delta^2\xi_\ell + \Delta\xi_\ell &= 0 \text{ in } U,\\ \Delta\xi_\ell &= 1 \text{ on } \partial U,\\ \xi_\ell &= 0 \text{ on } \partial U. \end{aligned} \tag{2.4}$$

Then

$$\begin{aligned} G_\varepsilon(u, A) \geq \sum_{i\in I}\int_{B_{r_i}} e_\varepsilon(u)dx + \frac{1}{\ell^2}\int_U |\Delta\zeta|^2 + G^0\\ + 2\pi h_{ex}\sum_{i\in I} d_i\xi_\ell(a_i) - \frac{C}{|\log\varepsilon|}, \end{aligned} \tag{2.5}$$

where $G^0 = G_\varepsilon(1, h_{ex}\nabla^\perp\xi_\ell)$. *Here the vortex balls* B_{r_i} *and degrees* d_i *are defined via Proposition* 2.3

We prove several intermediate lemmas before attempting the proof of Proposition 2.5. The first facts we establish are on the scaled London equation. This limiting equation for the stream function of the magnetic field potential is the expected Meissner solution.

LEMMA 2.6. *Let* ξ_ℓ *be the solution of* (2.4) *with* $\ell \gg 1$; *then*

$$-\frac{1}{\ell^2} \leq \xi_\ell \leq 0 \tag{2.6}$$

and

$$\sup_{x\in\overline{U}} |\xi_\ell| = \frac{1}{\ell^2}\,(1 - o_\ell(1))\,. \tag{2.7}$$

Further,

$$\|\xi_\ell\|_{H^2} \leq C \quad \text{and} \quad \|\nabla\xi_\ell\|_{L^\infty} \leq C, \tag{2.8}$$

where C *depends only on* U.

Proof. These results are similar to results found in [6, 22, 24] for $\ell \equiv 1$. If $\Delta\xi_\ell = h_\ell$ in U and $\xi_\ell = 0$ on ∂U, then h_ℓ satisfies

$$\begin{aligned} -\frac{1}{\ell^2}\Delta h_\ell + h_\ell &= 0 \text{ in } U,\\ h_\ell &= 1 \text{ on } \partial U. \end{aligned} \tag{2.9}$$

If we let $\chi = \xi_\ell - \frac{1}{\ell^2}(h_\ell - 1)$, then $\Delta\chi = \Delta\xi_\ell - \frac{1}{\ell^2}\Delta(h_\ell - 1) = h_\ell - \frac{1}{\ell^2}\Delta h_\ell = 0$ in U and $\chi = 0$ on ∂U. Therefore, $\chi \equiv 0$, and thus

$$\xi_\ell = \frac{1}{\ell^2}(h_\ell - 1). \tag{2.10}$$

Applying the maximum principle to (2.9) yields $0 < h_\ell < 1$. In particular, if a minimum occurs at a point x_m in the interior of U, then $0 < \frac{1}{\ell^2}\Delta h_\ell(x_m) = h_\ell(x_m)$, and by the boundary condition we see $h_\ell \geq 0$. On the other hand, if the maximum occurs at a point x_M in the interior of U, then $0 > \frac{1}{\ell^2}\Delta h_\ell(x_M) = h_\ell(x_M)$, and by the boundary condition $h_\ell \leq 1$. Applying this to (2.10) yields (2.6).

Next, using the boundary conditions on ξ_ℓ,

$$\begin{aligned} 0 &= \int_U \xi_\ell \left[-\frac{1}{\ell^2}\Delta^2\xi_\ell + \Delta\xi_\ell\right] = \int_U \frac{1}{\ell^2}\nabla\xi_\ell \cdot \nabla\Delta\xi_\ell - |\nabla\xi_\ell|^2 \\ &= \int_{\partial U} \frac{1}{\ell^2}\partial_n\xi - \int_U \left[\frac{1}{\ell^2}|\Delta\xi_\ell|^2 + |\nabla\xi_\ell|^2\right]. \end{aligned}$$

Thus by (2.9), (2.10), and the bound on h_ℓ,

$$\int_U \frac{1}{\ell^2}|\Delta\xi_\ell|^2 + |\nabla\xi_\ell|^2 = \frac{1}{\ell^2}\int_U \Delta\xi_\ell = \frac{1}{\ell^2}\int_U h_\ell \leq \frac{1}{\ell^2}|U|.$$

This implies $\|\xi_\ell\|_{H^2(U)} \leq 2\sqrt{|U|}$. Since $0 < \Delta\xi_\ell < 1$, then $\|\xi_\ell\|_{W^{2,p}} \leq C_p$ for any chosen $p > 2$. Therefore, by Sobolev embedding, we have (2.8).

Set $z_\ell = \partial_\ell h_\ell$; then z_ℓ satisfies

$$\Delta z_\ell - \ell^2 z_\ell = 2\ell h_\ell \geq 0$$

in U and $z_\ell = 0$ on ∂U. By the maximum principle $z_\ell \leq 0$; hence, h_ℓ is monotonically decreasing in ℓ for all $x \in U$. Since h_ℓ is bounded below by -1, then $h_\ell(x) = -1 + o_\ell(1)$ for all $x \in U' \Subset U$. Thus $\max|\xi_\ell| = \frac{1}{\ell^2}(1 - o_\ell(1))$ by (2.10). ∎

In order to use Proposition 2.3 we need to establish a bound on $E_\varepsilon(u)$; see (1.8). As we see below, the BBH energy can be much larger than the Ginzburg–Landau energy $G_\varepsilon(u, A)$, since the magnetic field term in the energy can absorb large induced fields generated by a large number of vortices. We have the following result.

LEMMA 2.7. *Let (u, A) be a minimizer of the Ginzburg–Landau energy. Suppose $h_{ex} \leq C\ell^2|\log\varepsilon| \leq \frac{C}{\varepsilon}$ and $G_\varepsilon(u, A) \leq K\ell^2|\log\varepsilon|^2$; then*

$$E_\varepsilon(u) \leq C\ell^4|\log\varepsilon|^2 \tag{2.11}$$

and

$$\|A\|_{H^1(U)} \leq C\ell^2|\log\varepsilon| \quad \text{and} \quad \|A\|_{H^2(U)} \leq C\ell^3|\log\varepsilon|. \tag{2.12}$$

Proof. We first establish a uniform H^1 estimate on A. From the assumption on the energy,

$$\int |h - h_{ex}|^2 \leq K\ell^4|\log\varepsilon|^2,$$

and hence from the bound on h_{ex} we see that

$$\|h\|_{L^2(U)} \leq C\ell^2|\log\varepsilon|.$$

Since $\operatorname{div} A = 0$ and $n \cdot A = 0$ on ∂U, there exists ξ such that $\nabla^\perp \xi = A$ and $\xi = 0$ on ∂U. From standard elliptic estimates we get $\|\xi\|_{H^2(U)} \le C\ell^2 |\log\varepsilon|$. Thus

$$\|A\|_{H^1(U)} \le C\ell^2 |\log\varepsilon|.$$

Decomposing $\frac{1}{2}|\nabla_A u|^2 = \frac{1}{2}|\nabla u|^2 - A \cdot j(u) + \frac{1}{2}A^2 |u|^2$, we control the cross term via

$$\begin{aligned} A \cdot j(u) &\le \frac{1}{4}\left|\frac{j(u)}{|u|}\right|^2 + A^2 |u|^2 \\ &\le \frac{1}{4}\left|\frac{j(u)}{|u|}\right|^2 + A^2 + 2\varepsilon^2 A^4 + \frac{1}{8\varepsilon^2}\left(1-|u|^2\right)^2. \end{aligned}$$

Therefore, from the algebraic bounds, the estimate on A, and Sobolev embedding,

$$\begin{aligned} G_\varepsilon(u,A) &\ge E_\varepsilon + \frac{1}{2\ell^2}\|h - h_{ex}\|^2 - \left[\frac{1}{2}E_\varepsilon(u) + \int_U A^2 + 2\varepsilon^2 A^4\right] \\ &\ge \frac{1}{2}E_\varepsilon(u) - C\left[\|A\|^2_{H^1(U)} + \varepsilon^2 \|A\|^4_{H^1(U)}\right] \\ &\ge \frac{1}{2}E_\varepsilon(u) - C\ell^4 |\log\varepsilon|^2 - C\varepsilon^2\ell^8 |\log\varepsilon|^4. \end{aligned}$$

The upper bound on $E_\varepsilon(u)$ follows.

In order to establish higher bounds on A we use the Euler–Lagrange equation $-\nabla^\perp h = \ell^2 j_A(u)$. Therefore,

$$\|\nabla h\|_{L^2(U)} \le \ell^2 \|\nabla_A u\|_{L^2(U)} \|u\|_{L^\infty(U)} \le C\ell^3 |\log\varepsilon|,$$

and hence (2.8). ∎

The fact that $E_\varepsilon(u)$ can have a much larger energy than $G_\varepsilon(u,A)$ is an essential difference in the large-ℓ asymptotics. It implies a more complicated global vortex structure. Given the energy bound on $E_\varepsilon(u)$, we can split apart the full Ginzburg–Landau energy into its chief components. We start with an initial energy splitting.

LEMMA 2.8. *We can decompose* $G_\varepsilon(u,A) = G_\varepsilon(u, \nabla^\perp\xi) = G_\varepsilon(u, h_{ex}\nabla^\perp\xi_\ell + \nabla^\perp\zeta)$ *as*

$$\begin{aligned} G_\varepsilon(u,A) \ge{}& \frac{1}{2}\int_U \left|\nabla u - iu\nabla^\perp\xi\right|^2 + \frac{1}{2\varepsilon^2}\left(1-|u|^2\right)^2 + \frac{1}{2\ell^2}\int_U |\Delta\xi|^2 \\ &+ \int_U \left(\nabla u, -ih_{ex}\nabla^\perp\xi_\ell u\right) + G^0 - \frac{C}{|\log\varepsilon|}. \end{aligned} \tag{2.13}$$

Proof. We decompose the energy in a series of steps.

Our first step is to compute the approximate energy of the Meissner state via the method of Serfaty [22]. Since $\operatorname{div} A = 0$ and $n \cdot A = 0$ in ∂U, we can write $A = \nabla^\perp\xi$ with $\xi = 0$ on ∂U and so $\Delta\xi = h$. We further decompose $\nabla^\perp\xi$ as $\nabla^\perp\xi = h_{ex}\nabla^\perp\xi_\ell + \nabla^\perp\zeta$, where $\zeta = \Delta\zeta = 0$ on ∂U and where ξ_ℓ satisfies (2.4). Consider now the Meissner energy associated with $G^0 = G_\varepsilon(1, h_{ex}\nabla^\perp\xi_\ell)$. We compute the form of the Meissner energy, setting $(u_0, A_0) = (1, h_{ex}\nabla^\perp\xi_\ell)$. Then

$$\begin{aligned} G_\varepsilon(u_0,A_0) &= \frac{1}{2}\int_U |\nabla_{A_0}u_0|^2 + \frac{1}{\ell^2}|\operatorname{curl} A_0 - h_{ex}|^2 + \frac{1}{2\varepsilon^2}\left(1-|u_0|^2\right)^2 \\ &= \frac{h_{ex}^2}{2}\int_U |\nabla\xi_\ell|^2 + \frac{1}{\ell^2}|\Delta\xi_\ell - 1|^2. \end{aligned}$$

Multiplying ξ_ℓ against $-\frac{1}{\ell^2}\Delta^2\xi_\ell + \Delta\xi_\ell$ and integrating over U yields

$$\int_U |\nabla\xi_\ell|^2 + \frac{1}{\ell^2}|\Delta\xi_\ell|^2\,dx = \frac{1}{\ell^2}\int_U \Delta\xi_\ell.$$

We use the above identity to rewrite the Meissner energy as

$$\begin{aligned} G^0 &= \frac{1}{2}\int_U h_{ex}^2|\nabla\xi_\ell|^2 + \frac{h_{ex}^2}{\ell^2}|\Delta\xi_\ell|^2 + \frac{h_{ex}^2}{\ell^2} - 2\frac{h_{ex}^2}{\ell^2}\Delta\xi_\ell \\ &= -\frac{h_{ex}^2}{2}\int_U \left[|\nabla\xi_\ell|^2 + \frac{1}{\ell^2}|\Delta\xi_\ell|^2\right] + \frac{h_{ex}^2}{2\ell^2}|U|. \end{aligned} \tag{2.14}$$

Therefore the Meissner energy is of order $O(\frac{h_{ex}^2}{\ell^2})$.

Next we write

$$\begin{aligned} \frac{1}{2}\int_U |\nabla_A u|^2 &= \frac{1}{2}\int_U \left|\nabla u - ih_{ex}\nabla^\perp\xi_\ell u - i\nabla^\perp\zeta u\right|^2 \\ &= \frac{1}{2}\int_U \left|\nabla u - i\nabla^\perp\zeta u\right|^2 + \frac{h_{ex}^2}{2}\int_U |u|^2\left|\nabla^\perp\xi_\ell\right|^2 \\ &\quad + \int_U \left(\nabla u - i\nabla^\perp\zeta u, -ih_{ex}\nabla^\perp\xi_\ell u\right) \end{aligned}$$

and

$$\begin{aligned} &\int_U \left(\nabla u - i\nabla^\perp\zeta u, -ih_{ex}\nabla^\perp\xi_\ell u\right) \\ &\quad = \int_U \left(\nabla u, -ih_{ex}\nabla^\perp\xi_\ell u\right) + h_{ex}\int_U |u|^2\nabla\xi_\ell\cdot\nabla\zeta. \end{aligned}$$

Therefore, we can write the Ginzburg–Landau energy as

$$\begin{aligned} G_\varepsilon(u,A) &= \frac{1}{2}\int_U \left|\nabla u - i\nabla^\perp\zeta u\right|^2 + \frac{1}{2\varepsilon^2}\left(1-|u|^2\right)^2 \\ &\quad + \int_U \left(\nabla u, -ih_{ex}\nabla^\perp\xi_\ell u\right) \\ &\quad + \frac{h_{ex}^2}{2}\int_U \left(|u|^2-1\right)\left|\nabla^\perp\xi_\ell\right|^2 + h_{ex}\int_U \left(|u|^2-1\right)\nabla\xi_\ell\cdot\nabla\zeta \\ &\quad + \frac{1}{2\ell^2}\int_U |h-h_{ex}|^2 + \frac{h_{ex}^2}{2}\int_U \left|\nabla^\perp\xi_\ell\right|^2 + h_{ex}\int_U \nabla\xi_\ell\cdot\nabla\zeta. \end{aligned} \tag{2.15}$$

The terms in the third line of (2.15) are small since

$$\begin{aligned} h_{ex}^2\int_U \left(|u|^2-1\right)|\nabla\xi_\ell|^2 &\le Ch_{ex}^2\|\nabla\xi_\ell\|_{L^\infty}^2\left\|1-|u|^2\right\|_{L^2} \le C\varepsilon h_{ex}^2 E_\varepsilon^{\frac{1}{2}}(u) \\ &\le C\varepsilon\ell^6|\log\varepsilon|^3 \le C\varepsilon|\log\varepsilon|^{6\gamma+3} \le \frac{C}{|\log\varepsilon|} \end{aligned}$$

and

$$\begin{aligned} h_{ex}\int_U \left(|u|^2-1\right)\nabla\xi_\ell\cdot\nabla\zeta &\le Ch_{ex}\|\nabla\xi_\ell\|_{L^\infty}\|\nabla\zeta\|_{L^2}\left\|1-|u|^2\right\|_{L^2} \\ &\le C\varepsilon h_{ex}\left\|A - h_{ex}\nabla^\perp\xi_\ell\right\|_{L^2} E_\varepsilon^{\frac{1}{2}}(u) \\ &\le C\varepsilon\ell^2|\log\varepsilon|\left(\ell^2|\log\varepsilon| + \ell^2|\log\varepsilon|\right)\ell^2|\log\varepsilon| \\ &\le C\varepsilon|\log\varepsilon|^{6\gamma+3} \le \frac{C}{|\log\varepsilon|}. \end{aligned}$$

For the fourth line of (2.15) we have

$$\begin{aligned}
&\frac{1}{2\ell^2}\int_U |h-h_{ex}|^2 + \frac{h_{ex}^2}{2}\int_U \left|\nabla^\perp \xi_\ell\right|^2 + h_{ex}\int_U \nabla\xi_\ell\cdot\nabla\zeta \\
&\quad = \frac{1}{2\ell^2}\int_U |h_{ex}\Delta\xi_\ell - h_{ex} + \Delta\zeta|^2 + \frac{h_{ex}^2}{2}\int_U |\nabla\xi_\ell|^2 + h_{ex}\int_U \nabla\xi_\ell\cdot\nabla\zeta \\
&\quad = \frac{h_{ex}^2}{2\ell^2}\int |\Delta\xi_\ell - 1|^2 + \frac{h_{ex}^2}{2}\int |\nabla\xi_\ell|^2 + \frac{1}{2\ell^2}\int |\Delta\zeta|^2 \\
&\qquad + \frac{h_{ex}}{\ell^2}\int (\Delta\xi_\ell - 1)\,\Delta\zeta + h_{ex}\int \nabla\xi_\ell\cdot\nabla\zeta.
\end{aligned}$$

Multiplying ζ against (2.4) and integrating over U, we have

$$0 = -\frac{1}{\ell^2}\int_U \Delta\zeta\,(\Delta\xi_\ell - 1) - \int_U \nabla\xi_\ell\cdot\nabla\zeta,$$

and then

$$\begin{aligned}
&\frac{1}{2\ell^2}\int_U |h-h_{ex}|^2 + \frac{h_{ex}^2}{2}\int_U \left|\nabla^\perp \xi_\ell\right|^2 + h_{ex}\int_U \nabla\xi_\ell\cdot\nabla\zeta \\
&\qquad = G^0 + \frac{1}{2\ell^2}\int_U |\Delta\zeta|^2 .
\end{aligned} \tag{2.16}$$

Combining (2.15), the bounds on the third line, and (2.16) yields (2.13). ∎

We can now prove Proposition 2.5 by carefully extracting the concentration of the Ginzburg–Landau energy against the magnetic field potential ξ_ℓ. Note that there are potentially an unbounded number of vortices, so we need to extract good decay on each vortex ball.

Proof of Proposition 2.5. We follow the approach in [21] for $\ell \equiv 1$. The first step is to establish the concentration in the cross term $\int \nabla^\perp\xi_\ell \cdot j(u)$. In particular, we claim

$$\left|\int_U \left(\nabla u, -ih_{ex}\nabla^\perp\xi_\ell u\right) - 2\pi h_{ex}\sum_{i\in I} d_i\xi_\ell(a_i)\right| \le \frac{C}{|\log\varepsilon|}, \tag{2.17}$$

where a_j is the center of the vortex ball B_{r_i} and I is the vortex ball collection.

Step 1. Since $E_\varepsilon(u) \le C\ell^4|\log\varepsilon|^2 \le C|\log\varepsilon|^{4\gamma+2}$ and $h_{ex} = C\ell^2|\log\varepsilon| = C|\log\varepsilon|^{2\gamma+1}$, then by Proposition 2.3 we have balls $\{B_{r_i}\}_{i\in I}$ such that

$$\left\{|u| < \frac{3}{4}\right\} \subset \cup_{i\in I} B_{r_i}, \qquad \operatorname{card} I \le C|\log\varepsilon|^{4\gamma+2}, \qquad r_i \le \frac{C}{|\log\varepsilon|^{10\gamma+6}},$$

$$\text{if } \overline{B_{r_i}} \subset U \text{ and } d_i = \deg(u,\partial B_{r_i}), \text{ then } \int_{B_{r_i}} e_\varepsilon(u)dx \ge \pi\,|d_i|\,(|\log\varepsilon| - O(\log|\log\varepsilon|)),$$

where we chose $\alpha = 10\gamma + 6$ in Proposition 2.3. Therefore,

$$\begin{aligned}
\left|\int_{\cup_I B_{r_i}} \left(\nabla u, -ih_{ex}\nabla^\perp\xi_\ell u\right)\right| &\le (\operatorname{card} I)\,h_{ex}\,\|\nabla u\|_{L^2}\max_{i\in I} r_i \\
&\le C|\log\varepsilon|^{8\gamma+4-\alpha} \le \frac{C}{|\log\varepsilon|}.
\end{aligned}$$

Setting $\widetilde{U} = U \setminus \cup_{i\in I} B_{r_i}$, for $v = \frac{u}{|u|}$ we have

$$\int_{\widetilde{U}} \left(\nabla u, -ih_{ex}\nabla^{\perp}\xi_\ell u\right) = h_{ex}\int_{\widetilde{U}} \nabla\xi_\ell \times j(v) + h_{ex}\int_{\widetilde{U}} \nabla\xi_\ell \times (j(u) - j(v)).$$

The second term is small, using (2.8) and (2.11), since

$$\begin{aligned} h_{ex}\int_{\widetilde{U}} \nabla\xi_\ell \times (j(u) - j(v)) &\le h_{ex}\left\|\nabla^{\perp}\xi_\ell\right\|_{L^\infty}\int_{\widetilde{U}}\left|j(u) - \frac{j(u)}{|u|^2}\right| \\ &\le Ch_{ex}\int_{\widetilde{U}} \frac{|j(u)|}{|u|}\frac{\left||u|^2-1\right|}{|u|} \le C\varepsilon h_{ex}E_\varepsilon(u) \\ &\le C\varepsilon|\log\varepsilon|^{6\gamma+3} = \frac{C}{|\log\varepsilon|}, \end{aligned}$$

where we used $|u| \ge \frac{1}{2}$ in $\widetilde{U}$ in the second line. Therefore,

$$\left|\int_{\widetilde{U}} \left(\nabla u, -ih_{ex}\nabla^{\perp}\xi_\ell u\right) - h_{ex}\int_{\widetilde{U}} \nabla\xi_\ell \times j(v)\right| \le \frac{C}{|\log\varepsilon|}. \tag{2.18}$$

Next for $J = \{i \text{ such that } \overline{B_{r_i}} \subset U\}$ we claim we can extract the following bound:

$$\left|h_{ex}\int_{B_{r_i}} \nabla\xi_\ell \times j(v) - 2\pi h_{ex}d_i\xi_\ell(a_i)\right| \le \frac{C}{|\log\varepsilon|^{4\gamma+3}}. \tag{2.19}$$

For $\Omega_i = B_{r_i} \cap \{x \in U \text{ such that } |u| \le \frac{1}{2}\}$, $\Omega_i \cap \partial B_{r_i} = \varnothing$. Since $|u| \ge \frac{1}{2}$ in Ω_i, by Stokes' theorem,

$$\begin{aligned} &h_{ex}\left|\int_{\partial B_{r_i}} (\xi_\ell - \xi_\ell(a_i))\, j(v)\cdot\tau - \int_{\partial U_i} (\xi_\ell - \xi_\ell(a_i))\, j(v)\cdot\tau\right| \\ &\quad = h_{ex}\left|\int_{B_i\setminus U_i} \nabla\xi_\ell \times j(u)\right| \le Ch_{ex}\left\|\nabla\xi_\ell\right\|_{L^\infty}\left\|\nabla u\right\|_{L^2} r_i \\ &\quad \le C|\log\varepsilon|^{4\gamma+2-\alpha} \le \frac{C}{|\log\varepsilon|^{4\gamma+3}}; \end{aligned}$$

thus

$$\begin{aligned} h_{ex}\left|\int_{\partial B_{r_i}} (\xi_\ell - \xi_\ell(a_i))\, j(v)\cdot\tau - \int_{\partial\Omega_i} (\xi_\ell - \xi_\ell(a_i))\, j(v)\cdot\tau\right| \\ \le \frac{C}{|\log\varepsilon|^{4\gamma+3}}. \end{aligned} \tag{2.20}$$

On the other hand, since $|u| = \frac{1}{2}$ on $\partial\Omega_i$ we find

$$\begin{aligned}
&h_{ex}\left|\int_{\partial\Omega_i}(\xi_\ell - \xi_\ell(a_i))\, j(v)\cdot\tau\right| \\
&\quad= h_{ex}\left|\int_{\partial\Omega_i}(\xi_\ell - \xi_\ell(a_i))\,\frac{j(u)}{|u|^2}\cdot\tau\right| = 4h_{ex}\left|\int_{\partial\Omega_i}(\xi_\ell - \xi_\ell(a_i))\, j(u)\cdot\tau\right| \\
&\quad= 4h_{ex}\left|\int_{\Omega_i}\operatorname{curl}\left[(\xi_\ell - \xi_\ell(a_i))\, j(u)\right]\right| \\
&\quad\le 4h_{ex}\left|\int_{\Omega_i}\nabla\xi_\ell\times j(u)\right| + 8h_{ex}\left|\int_{\Omega_i}(\xi_\ell - \xi_\ell(a_i))\, J(u)\right| \\
&\quad\le Ch_{ex}\left\|\nabla\xi_\ell\right\|_{L^\infty}\left\|\nabla u\right\|_{L^2} r_i + Ch_{ex}\left\|\nabla\xi_\ell\right\|_{L^\infty}\left\|\nabla u\right\|_{L^2}^2 r_i \\
&\quad\le C|\log\varepsilon|^{4\gamma+2-\alpha} + C|\log\varepsilon|^{6\gamma+3-\alpha} \le \frac{C}{|\log\varepsilon|^{4\gamma+3}},
\end{aligned}$$

and consequently, since $\operatorname{card} I \le C|\log\varepsilon|^{4\gamma+2}$ and $\int_{\partial B_{r_i}}\xi_\ell(a_i)j(v)\cdot\tau = 2\pi d_i$,

$$\sum_{i\in J}\left|h_{ex}\int_{\partial B_{r_i}}\xi_\ell j(v)\cdot\tau - h_{ex}\int_{\partial B_{r_i}}\xi_\ell(a_i)j(v)\cdot\tau\right| \le \frac{C}{|\log\varepsilon|}. \tag{2.21}$$

Finally, for the balls that intersect ∂U, $I\backslash J$. Since $\xi_\ell = 0$ on ∂U, then for $\Omega_i = B_i\cap\{x\in U \text{ such that } |u|\le\frac{1}{2}\}$ we follow the above argument and see

$$\begin{aligned}
\left|h_{ex}\int_{\partial B_{r_i}\cap U}\xi_\ell j(v)\cdot\tau\right| &\le \left|h_{ex}\int_{\partial(\Omega_i\cap U)}\xi_\ell j(v)\cdot\tau\right| + \frac{C}{|\log\varepsilon|^{4\gamma+3}} \\
&\le 4h_{ex}\left|\int_{\Omega_i\cap U}\nabla\xi_\ell\times j(v) + 2\xi_\ell J(v)\right| + \frac{C}{|\log\varepsilon|^{4\gamma+3}} \\
&\le \frac{C}{|\log\varepsilon|^{4\gamma+3}}.
\end{aligned}$$

Combining this estimate along with $\operatorname{card} I \le C|\log\varepsilon|^{4\gamma+2}$ and (2.21) yields estimate (2.17).

Step 2. We bound $\int_U\left|\nabla u - i\nabla^\perp\zeta u\right|^2 \ge \int_{\cup_{i\in I}B_{r_i}}|\nabla u|^2 - \frac{C}{|\log\varepsilon|}$. In particular,

$$\begin{aligned}
\int_U\left|\nabla u - i\nabla^\perp\zeta u\right|^2 &\ge \int_{\cup_{i\in I}B_{r_i}}\left|\nabla u - i\nabla^\perp\zeta u\right|^2 \\
&= \int_{\cup_{i\in I}B_{r_i}}|\nabla u|^2 - 2\nabla^\perp\zeta\cdot j(u) + |\nabla\zeta|^2\,|u|^2.
\end{aligned}$$

From (2.12) we see $\|A\|_{L^\infty(U)} \le C\|A\|_{H^2(U)} \le C|\log\varepsilon|^{3\gamma+2}$, and thus

$$\begin{aligned}
\left|\int_{\cup_{i\in I}B_{r_i}}\nabla^\perp\zeta\cdot j(u)\right| &\le (\operatorname{card} I)\left\|A - h_{ex}\nabla^\perp\xi_\ell\right\|_{L^\infty}\left\|\nabla u\right\|_{L^2}\max_{i\in I} r_i \\
&\le C|\log\varepsilon|^{4\gamma+2}\left(|\log\varepsilon|^{3\gamma+2} + |\log\varepsilon|^{2\gamma+1}\right)|\log\varepsilon|^{2\gamma+1}|\log\varepsilon|^{-\alpha} \\
&\le C|\log\varepsilon|^{9\gamma+5-\alpha} \le \frac{C}{|\log\varepsilon|},
\end{aligned}$$

and so

$$\int_U \left|\nabla u - i\nabla^\perp \zeta u\right|^2 \geq \int_{\cup_{i\in I} B_{r_i}} |\nabla u|^2 . \tag{2.22}$$

Combining (2.13) with (2.17) and (2.22) yields (2.5). ∎

We are finally in the position to establish the next claim.

Proof of Proposition 2.1. The first part of the proof establishes that a minimizing sequence must be in the Meissner state when $h_{ex} < \frac{\ell^2 |\log\varepsilon|}{2}$.

Step 1. From Proposition 2.5 and the minimality of (u, A)

$$\begin{aligned} G^0 &\geq G_\varepsilon(u, A) \\ &\geq \sum_{i\in I} \int_{B_{r_i}} e_\varepsilon(u)dx + \frac{1}{2\ell^2}\int_U |\Delta\zeta|^2 + G^0 + 2\pi h_{ex}\sum_{i\in I} d_i \xi_\ell(a_i) - \frac{C}{|\log\varepsilon|}. \end{aligned}$$

Therefore, since $\xi_\ell \leq 0$, we use (2.7) and lower bound in Proposition 2.3.4 to get

$$\begin{aligned} \pi \sum_{i\in I} |d_i| \left(|\log\varepsilon| + O(\log|\log\varepsilon|)\right) &\leq 2\pi h_{ex} \sum_{i\in I} d_i \left|\xi_\ell(a_i)\right| \\ &\leq 2\pi h_{ex} \left(\sum_{i\in I} |d_i|\right) \max|\xi_\ell| \\ &\leq \left(\sum_{i\in I} |d_i|\right) 2\pi \frac{h_{ex}}{\ell^2} \left(1 - o_\ell\right). \end{aligned}$$

So if $\sum_{i\in I} |d_i| \neq 0$, then

$$h_{ex} \geq \frac{\ell^2}{2}\left(|\log\varepsilon| + O(\log|\log\varepsilon|)\right).$$

Hence, for $h_{ex} < \frac{\ell^2}{2}|\log\varepsilon|$, either $\deg(u, \partial B_{r_i}) = 0$ or $B_{r_i} \cap U \neq \varnothing$. It is straightforward to show from this point that $|u| \geq \frac{3}{4}$ in U; see [5, 6].

Step 2. We now complete the proof of the critical field strength. In particular, we show that if $h_{ex} > \frac{\ell^2|\log\varepsilon|}{2}$, then there must be a vortex. We prove this by contradiction. Let $(u_\varepsilon, A_\varepsilon)$ be a minimizing sequence with $\sum_{j\in J} |d_j| = 0$; then we claim $G_\varepsilon(u, A) \geq G_\varepsilon(1, h_{ex}\nabla^\perp\xi_\ell) - \frac{C}{|\log\varepsilon|}$.

In order to get better bounds on $\nabla^\perp\zeta = A - h_{ex}\nabla^\perp\xi_\ell$, we replace lower bound (2.22) with

$$\frac{1}{2}\int_U \left|\nabla u - i\nabla^\perp\zeta u\right|^2 \geq \frac{1}{2}\int_U |\nabla u|^2 - 2j(u)\cdot\nabla^\perp\zeta + |\nabla\zeta|^2 - \frac{C}{|\log\varepsilon|},$$

where we used the argument for the estimate of the third line of (2.15) in the proof of Lemma 2.8. By (2.8) and (2.12) we see that ζ is continuous. Since there are no nontrivial-degree vortex balls, then by an argument identical to the proof of (2.17) we have the lower bound

$$G_\varepsilon(u, A) \geq E_\varepsilon(u) + G^0 + \frac{1}{2}\int_U |\nabla\zeta|^2 + \frac{1}{\ell^2}|\Delta\zeta|^2 - \frac{C}{|\log\varepsilon|}.$$

Since (u,A) is an energy minimizer, $G^0 \geq G_\varepsilon(u,A)$, and so $E_\varepsilon(u)+\frac{1}{2}\int_U |\nabla\zeta|^2 \leq \frac{C}{|\log\varepsilon|}$. Even more so, the boundary condition $\zeta = 0$ implies $\zeta \to 0$ and $E_\varepsilon(u) \to 0$ as $\varepsilon \to 0$. We see that

$$G_\varepsilon(u,A) \geq G^0 - \frac{C}{|\log\varepsilon|} \tag{2.23}$$

when $\sum_{j\in J}|d_j| = 0$.

To prove that $G_\varepsilon(u,A)$ is no longer the Meissner state, we construct a sequence of functions $(u_\varepsilon, A_\varepsilon)$ which have lower energy than the Meissner energy when $h_{ex} > \frac{\ell^2|\log\varepsilon|}{2}$. Set $A_\varepsilon = h_{ex}\nabla^\perp\xi_\ell + \nabla^\perp\zeta$, where ξ_ℓ is defined in (2.4) and

$$-\frac{1}{\ell^2}\Delta^2\zeta + \Delta\zeta = 2\pi\delta_a \text{ in } U, \qquad \Delta\zeta = \xi_\ell = 0 \text{ on } \partial U. \tag{2.24}$$

To define $u_\varepsilon = \rho_\varepsilon e^{i\varphi_\varepsilon}$ we set $\nabla\varphi_\varepsilon = A_\varepsilon + \frac{1}{\ell^2}\nabla^\perp \operatorname{curl} A_\varepsilon$ and

$$\rho_\varepsilon = \begin{cases} 0 & |x-a| \leq \frac{\varepsilon}{2}, \\ 1 & |x-a| \geq \varepsilon. \end{cases}$$

Then for any $B_R \supset \{a\}$, $\int_{\partial B_R}\partial_\tau\varphi_\varepsilon = \int_{B_R} h_\varepsilon - \frac{1}{\ell^2}\Delta h_\varepsilon = 2\pi$, which correctly quantizes the phase. A straightforward calculation shows that $E_\varepsilon(u_\varepsilon) \leq \pi\log\frac{\operatorname{diam} U}{\varepsilon} + C \leq \pi|\log\varepsilon| + C$, where C is a fixed constant. The arguments in section 4 contain more refined upper bound calculations; however, they are similar in spirit.

Following Step 1 of the proof of Proposition 2.5 yields

$$\begin{aligned}
&\frac{1}{2}\int_U A_\varepsilon^2 |u_\varepsilon|^2 + \frac{1}{\ell^2}|\operatorname{curl} A_\varepsilon - h_{ex}|^2 \\
&\leq \frac{h_{ex}^2}{2}\int_U |\nabla\xi_\ell|^2 + \frac{1}{\ell^2}|\Delta\xi_\ell - h_{ex}|^2 + \frac{1}{2}\int_U |\nabla\zeta|^2 + \frac{1}{\ell^2}|\Delta\zeta|^2 + \frac{C}{|\log\varepsilon|}.
\end{aligned}$$

Again we decompose $\|\nabla u - i\nabla^\perp\zeta u\|^2_{L^2(U)} = \|\nabla u\|^2_{L^2(U)} - 2\int j(u)\cdot\nabla^\perp\zeta + \|\nabla^\perp\zeta u\|^2_{L^2(U)}$, and a similar calculation as in Step 1 shows

$$\begin{aligned}
G_\varepsilon(u_\varepsilon, A_\varepsilon) &\leq E_\varepsilon(u_\varepsilon) - \int_U j(u_\varepsilon)\cdot\nabla^\perp(h_{ex}\xi_\ell + \zeta) + G^0 \\
&\quad + \frac{1}{2}\int_U |\nabla\zeta|^2 + \frac{1}{\ell^2}|\Delta\zeta|^2 + \frac{C}{|\log\varepsilon|} \\
&\leq G^0 + \pi|\log\varepsilon| - \frac{2\pi h_{ex}}{\ell^2}(1 - o_\ell(1)) + C \\
&\quad + \frac{1}{2}\int_U |\nabla\zeta|^2 + \frac{1}{\ell^2}|\Delta\zeta|^2 + 2\pi\zeta(a),
\end{aligned}$$

where we used (2.7) in the last inequality. Multiplying (2.24) by ζ and integrating over U shows $2\pi\zeta(a) = -\int_U |\nabla\zeta|^2 + \frac{1}{\ell^2}|\Delta\zeta|^2 < 0$; hence $\frac{1}{2}\int_U |\nabla\zeta|^2 + \frac{1}{\ell^2}|\Delta\zeta|^2 + 2\pi\zeta(a) < 0$. Therefore,

$$G_\varepsilon(u_\varepsilon, A_\varepsilon) \leq G^0 + \pi|\log\varepsilon| - \frac{2\pi h_{ex}}{\ell^2}(1 - o_\ell(1)) + C.$$

Since $h_{ex} > \frac{\ell^2|\log\varepsilon|}{2}$, there exists $\delta > 0$, bounded away from zero, such that $\pi|\log\varepsilon| - \frac{2\pi h_{ex}}{\ell^2}(1 - o_\ell(1)) + C < C - \delta|\log\varepsilon| < -\frac{|C|}{2}$ for ε small enough; thus

$$G_\varepsilon(u_\varepsilon, A_\varepsilon) < G^0 - \frac{|C|}{2} < G_\varepsilon(u_\varepsilon, A_\varepsilon).$$

Therefore, a vortex-less configuration *cannot* be minimizing in the $h_{ex} > \frac{\ell^2|\log\varepsilon|}{2}$ regime. □

Remark 2.9. For values of h_{ex} well above the critical field, we expect the minimizers to be similar to the functions constructed in the proof of (4.2) in section 4.

Remark 2.10. The proof of the critical field for $\ell_0 \in [0,+\infty)$ proceeds in the same way as for the proof of Proposition 2.1 and can be done by a suitable modification of the method in [21]. Since we handled the more difficult case $\ell \to +\infty$ such that $\ell_\varepsilon = |\log\varepsilon|^\gamma$ for some $\gamma \in \mathbb{R}^+$, we leave out the proof for the case $\ell_\varepsilon \to \ell_0 \in [0,+\infty)$.

3. Obstacle problem for small and bounded domains. In this section, we study the functional (1.3) where $\ell_\varepsilon \to \ell_0 \in [0,\infty)$, i.e., for domain sizes s that are smaller than or comparable with the penetration depth ($s \ll \lambda$ or $s = O(\lambda)$), in the critical scaling of energy and magnetic field.

The following result is a generalization of Theorem 1.3 in [12] (where it is proved for $\ell = 1$). Closely related results in the context of the Chern–Simons–Higgs energy were shown by the authors in [14, Theorem 1.3] and [15, Theorem 3]. We state the theorem in its gauge-invariant form.

THEOREM 3.1. *Let $(u_\varepsilon, A_\varepsilon)$ be a sequence with $G_\varepsilon(u_\varepsilon, A_\varepsilon) \le K|\log\varepsilon|^2$ and assume that h_{ex} satisfies $\frac{h_{ex}}{|\log\varepsilon|} \to H$ for some $H \ge 0$ and $\ell_\varepsilon \to \ell_0 \in [0,\infty)$. Define the following rescaled quantities:*

$$a_\varepsilon := \frac{1}{|\log\varepsilon|}A_\varepsilon,$$
$$v_\varepsilon := \frac{1}{|\log\varepsilon|}(iu_\varepsilon, \nabla u_\varepsilon),$$
$$w_\varepsilon := v_\varepsilon - |u_\varepsilon|^2 a_\varepsilon.$$

Then $\operatorname{curl} a_\varepsilon$ is weakly compact in $L^2(U)$, and w_ε is weakly compact in L^p for $1 \le p < 2$. Furthermore, $\frac{w_\varepsilon}{|u_\varepsilon|}$ converges weakly in L^2 if and only if w_ε converges weakly, and the weak limits are equal.

Any weak limit of $(w_\varepsilon, \operatorname{curl} a_\varepsilon)$ can be expressed in the form $(v-a, \operatorname{curl} a)$ for some $(v,a) \in L^2(U;\mathbb{R}^2) \times H^1(U;\mathbb{R}^2)$ such that $\operatorname{curl} v$ is a Radon measure. In addition, we have the following $\Gamma - \liminf$ inequality:

$$\liminf_{\varepsilon\to 0} \frac{1}{|\log\varepsilon|^2} G_\varepsilon(u_\varepsilon, A_\varepsilon) \ge G(v,a),$$

where the limit functional G is given by

(3.1)
$$G(v,a) := \begin{cases} \frac{1}{2}\int_U |v-a|^2 + \frac{1}{\ell_0^2}|\operatorname{curl} a - H|^2 + \frac{1}{2}\|\operatorname{curl} v\|_{\mathscr{M}} & \text{if } \ell_0 > 0, \\ \frac{1}{2}\int_U |v-a|^2 + \frac{1}{2}\|\operatorname{curl} v\|_{\mathscr{M}} & \text{if } \ell_0 = 0 \text{ and } \operatorname{curl} a = H, \\ +\infty & \text{otherwise.} \end{cases}$$

Conversely, for every $(v,a) \in L^2(U;\mathbb{R}^2) \times H^1(U;\mathbb{R}^2)$ such that $\operatorname{curl} v$ is a Radon measure there exist approximating sequences $(\tilde{u}_\varepsilon, \tilde{A}_\varepsilon)$ such that the convergences above hold and such that

$$\lim_{\varepsilon\to 0} \frac{1}{|\log\varepsilon|^2} G_\varepsilon(\tilde{u}_\varepsilon, \tilde{A}_\varepsilon) = G(v,a). \tag{3.2}$$

Proof. It suffices to check the theorem for sequences $(u_\varepsilon, A_\varepsilon)$ that satisfy the Coulomb gauge condition $\operatorname{div} A_\varepsilon = 0$ in U, $A \cdot \nu = 0$ on ∂U, since $G(u_\varepsilon, A_\varepsilon) =$

$G(u_\varepsilon e^{i\chi}, A_\varepsilon + \nabla\chi)$ and the quantities w_ε and $\operatorname{curl} a_\varepsilon$ are invariant under this gauge transformation. The limit functional $G(v,a)$ also has the gauge invariance $G(v + \nabla\chi, a + \nabla\chi) = G(v,a)$.

From the energy bound $G_\varepsilon(u_\varepsilon, A_\varepsilon) \le K|\log\varepsilon|^2$ we infer that

$$\int_U |\operatorname{curl} a_\varepsilon - H|^2 \le 2K\ell_\varepsilon^2 \le C,$$

since ℓ_ε is bounded, and together with $\operatorname{div} a_\varepsilon = 0$ this implies $\|a_\varepsilon\|_{H^1(U)} \le C$, and via Sobolev embedding $\|A_\varepsilon\|_{L^p(U)} \le C_p|\log\varepsilon|$ for $p \ge 1$.

We can now establish that the BBH energy $E_\varepsilon(u_\varepsilon)$ is bounded, using the following decomposition:

$$|\nabla_A u|^2 = |\nabla u|^2 - 2j(u)\cdot A + |u|^2|A|^2,$$

which implies that

$$E_\varepsilon(u_\varepsilon) \le G_\varepsilon(u_\varepsilon, A_\varepsilon) + \int_U |j(u_\varepsilon)\cdot A_\varepsilon|.$$

As in [12], we can estimate the cross term via

$$\begin{aligned}
|j(u_\varepsilon)\cdot A_\varepsilon| &\le \frac{1}{4}|\nabla u_\varepsilon|^2 + |u_\varepsilon|^2|A_\varepsilon|^2 \\
&\le \frac{1}{4}|\nabla u_\varepsilon|^2 + \left(|u_\varepsilon|^2 - 1\right)|A_\varepsilon|^2 + |A_\varepsilon|^2 \\
&\le \frac{1}{4}|\nabla u_\varepsilon|^2 + \frac{1}{8\varepsilon^2}\left(1 - |u_\varepsilon|^2\right)^2 + 2\varepsilon^2|A_\varepsilon|^4 + |A_\varepsilon|^2 \\
&\le \frac{1}{2}E_\varepsilon(u_\varepsilon) + C\varepsilon^2|\log\varepsilon|^4 + C|\log\varepsilon|^2,
\end{aligned}$$

and it follows that $E_\varepsilon(u_\varepsilon) \le C|\log\varepsilon|^2$. We are therefore able to use the compactness results of [12] that show compactness for v_ε and the estimate

$$\liminf_{\varepsilon\to 0} E_\varepsilon(u_\varepsilon) \ge \frac{1}{2}\int_U |v|^2 + \frac{1}{2}\|\operatorname{curl} v\|_{\mathscr{M}}.$$

It is then not difficult to show the lower bound for the full energy using the same decomposition as above and the weak convergence of a_ε implied by the bounds.

The Γ-limsup property (3.2) can be shown as follows: Given a limit (v,a) with $\operatorname{div} a = 0$, we set $\tilde{A}_\varepsilon = a|\log\varepsilon|$ and construct $\tilde{u}_\varepsilon$ as in [12, section 7]. It is then easy to see that the claimed convergence holds, using the Γ-convergence result for E_ε from [12] and the same decomposition as above. □

Remark 3.2. Note that compactness for v_ε only holds due to our choice of gauge. The representative $\tilde{u}_\varepsilon = u_\varepsilon e^{i\chi_\varepsilon}$ corresponds to $\tilde{v}_\varepsilon = v_\varepsilon + \frac{1}{|\log\varepsilon|}\nabla\chi_\varepsilon$, and so v_ε and $\tilde{v}_\varepsilon$ need not have the same compactness properties. The limit functional $G(v,a)$ also has the gauge invariance $G(v + \nabla\chi, a + \nabla\chi) = G(v,a)$. If $\ell_\varepsilon \to \infty$, the compactness argument for a_ε fails, since we only know that $\int_U |\operatorname{curl} a_\varepsilon - H|^2 \le K\ell_\varepsilon^2$, so this sequence need not be bounded. The example given (for $H = 0$) in [15, Theorem 5], which can be used for (1.3), shows that v_ε also need not be compact in this case, even if $\operatorname{div} A_\varepsilon = 0$. In fact we construct a sequence of $(v_\varepsilon, a_\varepsilon)$ with bounded energy but $\|v_\varepsilon\|_{L^2(U)} \gtrsim \log(\ell_\varepsilon \wedge \frac{1}{\varepsilon|\log\varepsilon|^{1/2}}) \to +\infty$ by constructing a set of vortices that

concentrate about a single point. Therefore, the energy splitting approach of [12] is insufficient to treat the case of large domains.

As in [20], we can characterize the minimizers of the limit functional. We obtain, following the presentation of [12], Theorem 1.3.

Proof of Theorem 1.3. We prove only the part for $\ell_0 = 0$; the first half can be shown by a completely straightforward insertion of ℓ^{-2} into the argument of [12]. Our proof of the second half also follows the structure of their argument.

For a Radon measure $\mu \in H^{-1}$, define the vector field $v^\mu \in L^2(U;\mathbb{R}^2)$ by $\operatorname{curl} v^\mu = \mu$ and $\operatorname{div} v^\mu = 0$. We decompose μ as $\mu^{ac} + \mu^{sing}$ into an absolutely continuous and a singular part. Setting $g(t,\mu) = G(v_0 + tv_\mu, a)$, we calculate

$$0 \le \lim_{t\to 0^+} \frac{g(t,\mu) - g(0,\mu)}{t} = \int_U (v_0 - a_0, v^\mu) + \frac{1}{2}\int_U \operatorname{sgn}(\mu_0) d\mu^{ac} + \frac{1}{2}\left\|\mu^{sing}\right\|(U).$$

Integrating by parts and using the definition of y_0, we see that

$$\int_U (v_0 - a_0, v^\mu) = \int_U y_0 \mu,$$

so we obtain

$$0 \le \int_U \left(y_0 + \frac{1}{2}\operatorname{sgn}(\mu_0)\right) d\mu^{ac} + \int_U \left(y_0 + \frac{1}{2}\operatorname{sgn}(\mu)\right) d\mu^{sing} \tag{3.3}$$

and similarly by one-sided differentiation in the opposite direction,

$$0 \ge \int_U \left(y_0 + \frac{1}{2}\operatorname{sgn}(\mu_0)\right) d\mu^{ac} + \int_U \left(y_0 - \frac{1}{2}\operatorname{sgn}(\mu)\right) d\mu^{sing}. \tag{3.4}$$

Together, (3.3) and (3.4) imply, due to the arbitrariness of μ^{ac} and μ^{sing}, that $|y_0| \le \frac{1}{2}$ everywhere and $y_0 = -\frac{1}{2}\operatorname{sgn}(\mu_0)$ in $\operatorname{spt}\mu_0$. It follows that for any smooth function φ with $\varphi(z) = 0$ for $z \le 0$ and $\varphi'(z) \ge 0$ there holds

$$\int_U \varphi(y_0) d\mu_0 = -\varphi\left(\frac{1}{2}\right)\mu_0^-(U),$$

where μ_0^- denotes the negative part in the Hahn decomposition of μ_0. Since $\mu_0 = -\Delta y_0 + H$, we can integrate by parts and obtain

$$\int_U \varphi(y_0) d\mu_0 = \int_U \varphi'(y_0)|\nabla y_0|^2 + \varphi(y_0)H \ge 0,$$

and we conclude that $\mu_0^-(U) = 0$ and so $\mu_0 \ge 0$.

To see that y_0 is a solution of the obstacle problem, we take any $y \in \mathscr{K}$ and compare using $|v|^2 - |w|^2 \ge 2(v-w)\cdot w$ and integration by parts:

$$F_{0,H}(y) - F_{0,H}(y_0) \ge \int_U \nabla(y - y_0)\cdot\nabla y_0 + (y - y_0)H = \int_U (y - y_0) d\mu_0.$$

Now $y_0 = -\frac{1}{2}$ on $\operatorname{spt}(\mu_0)$, so $(y - y_0) \ge 0$ on $\operatorname{spt}(\mu_0)$ for all $y \in \mathscr{K}$. It follows that y_0 is a minimizer of the obstacle problem. Standard theory [9] can now be used to show uniqueness of y_0. □

Remark 3.3. Another proof of Theorem 1.3 can be given in the framework of Brezis and Serfaty [7], who examine the obstacle problem arising from (1.7).

COROLLARY 3.4. *Let (v_0, a_0) be a minimizer of $G(v,a)$. Then* $\operatorname{curl} v_0 = 0$ *for* $H < H_1(\ell_0)$ *and* $\operatorname{curl} v_0 \neq 0$ *for* $H > H_1(\ell_0)$*, where $H_1(\ell_0)$ is given by*

$$H_1(\ell_0) = \frac{1}{2\max_{\overline{U}} |y_{\ell_0}|}, \tag{3.5}$$

where y_{ℓ_0} is the solution of

$$-\Delta y_{\ell_0} + \ell_0^2 y_{\ell_0} + 1 = 0$$

with Dirichlet boundary conditions $y_{\ell_0} = 0$ on ∂U.

Remark 3.5. We reiterate that the function H_1 in (3.5) satisfies $\frac{2H_1(\ell_0)}{\ell_0^2} \to 1$ as $\ell_0 \to \infty$.

Remark 3.6. In the case where $U = B_1(0)$ is a ball, the function H_1 can be written down explicitly since the solutions of $-\Delta y + \alpha y + 1 = 0$ with Dirichlet boundary conditions are given by known special functions. Denoting by I_0 the modified Bessel function of zeroth order, we have that

$$H_1(\ell_0) = \frac{\ell_0^2 I_0(\ell_0)}{2(I_0(\ell_0) - 1)}.$$

Since $I_0(x) \sim \frac{e^x}{\sqrt{2\pi x}}$ as $x \to \infty$ and $I_0(x) = 1 + \frac{x^2}{4} + O(x^4)$ as $x \to 0$, it is easy to see that this matches the claimed behavior at zero and infinity.

4. Upper bound for vortex lattices. In this section, we construct good comparison sequences that correspond to vortex lattices and calculate their energy.

PROPOSITION 4.1. *Assume $\varepsilon < \frac{C}{\sqrt{h_{ex}}}$ and $\varepsilon \to 0$. There exists a sequence of functions $(u_\varepsilon, A_\varepsilon)$ such that the Ginzburg–Landau energy satisfies*

$$G_\varepsilon(u_\varepsilon, A_\varepsilon) \leq h_{ex}\frac{|U|}{2}\left(\log\frac{1}{\sqrt{h_{ex}}\varepsilon} + C\right). \tag{4.1}$$

If $h_{ex} - \frac{\ell^2|\log\varepsilon|}{2} = S \gg 1$ and $h_{ex} \leq \frac{1}{\varepsilon^2}$, then there exists a sequence of functions with Ginzburg–Landau energy

$$G_\varepsilon(u_\varepsilon, A_\varepsilon) \leq \frac{|U|}{2}\left(S\left(\left|\log\left(\varepsilon\max(\sqrt{S}, \ell)\right)\right| + C\right) + \frac{\ell^2}{4}|\log\varepsilon|^2\right). \tag{4.2}$$

Remark 4.2. The bound given in (4.2) is better than that of (4.1). It is essentially equivalent to the one given for $\ell = 1$ in Proposition 5.8 of Aydi's thesis [3]. Aydi's upper bound, adapted to our setting, reads as

$$G_\varepsilon(u_\varepsilon, A_\varepsilon) \leq \frac{|U|}{2}\left(\left(\frac{1}{2}|\log\varepsilon| + S\right)^2 - \frac{1}{2}S^2\right),$$

and, expanding the square, this is essentially (4.2).

Remark 4.3. If $\ell^2 \geq Kh_{ex}$, then

$$G_\varepsilon(1,0) \leq h_{ex}\frac{|U|}{2K}.$$

In particular, there is a constant $K > 0$ such that our vortex lattice construction is not minimizing for $\ell^2 \geq Kh_{ex}$.

Remark 4.4. Under the assumptions for the upper bound (4.2), the trivial Meissner-like state $(u, A) = (1, 0)$ has the energy

$$\frac{|U|}{2}\left(\frac{S^2}{\ell^2} + S|\log\varepsilon| + \frac{\ell^2}{4}|\log\varepsilon|^2\right).$$

Since $|\log(\varepsilon\max(\ell, \sqrt{S}))| \leq |\log\varepsilon| - C$, the vortex lattice state with $O(S)$ vortices is energetically favorable compared to $(u, A) = (1, 0)$. Consult Proposition 2.1 for a more detailed statement regarding the first critical field for vortex nucleation.

We now turn to the proof of Proposition 4.1. We present a new elementary approach using Fourier series to estimate the energy of a vortex lattice. This approach shows the cross-over that happens at $L = \ell^{-1}$; this is related to the decay properties of the Bessel function–type solutions. On the unit cell of our lattice, we investigate solutions of

$$-\alpha\Delta h + h = 2\pi\delta_\varepsilon \quad \text{in } K_L \tag{4.3}$$

with homogeneous Neumann boundary conditions. Here $K_L = \left(-\frac{L}{2}, \frac{L}{2}\right)^2$ for some $L > 0$. This is equivalent to looking at $L\mathbb{Z}^2$-periodic solutions in $\mathbb{R}^2$. For δ_ε we use the Dirac sequence

$$\delta_\varepsilon(x) = \frac{1}{4\varepsilon^2}\chi_{(-\varepsilon,\varepsilon)}(x_1)\chi_{(-\varepsilon,\varepsilon)}(x_2),$$

where χ_A is the characteristic function of a set $A \subset \mathbb{R}$. We assume $2\varepsilon < L$. We obtain the following results on the lattice.

PROPOSITION 4.5. *There exists a $C > 0$ such that for any L, ε with $\varepsilon < \frac{L}{2}$ there exists a periodic function h such that $-\ell^{-2}\Delta h + h = 2\pi\delta_\varepsilon$ and*

$$\int_{K_L} \ell^{-4}|\nabla h|^2 + \ell^{-2}|h - h_{ex}|^2 \leq 2\pi\log\frac{1}{\max(\ell, L^{-1})\varepsilon} + C + L^2\left(h_{ex} - \frac{2\pi}{L^2}\right)^2. \tag{4.4}$$

Proof. We calculate the energy

$$\int_{K_L} \alpha^2|\nabla h|^2 + \ell^{-2}|h - h_{ex}|^2.$$

It will become apparent later that we should use $\alpha = \ell^{-2}$.

We use double Fourier series as follows. For $f \in L^2(K_L)$ and $k \in \mathbb{Z}^2$, set

$$a_k = \frac{1}{L^2}\int_{K_L} f(x)e^{-i\gamma k\cdot x},$$

where $\gamma = \frac{2\pi}{L}$. Then f can be reconstructed as

$$f(x) = \sum_{k\in\mathbb{Z}^2} a_k e^{i\gamma k\cdot x}.$$

By Plancherel's theorem we have

$$\int_{K_L} |f|^2 = L^2\sum_{k\in\mathbb{Z}^2} |a_k|^2.$$

It is standard that ∇f corresponds to the series $(i\gamma k a_k)$, and Δf to the series $(-\gamma^2|k|^2 a_k)$. Solving (4.3) therefore corresponds to

$$(\alpha\gamma^2|k|^2+1)a_k = b_k,$$

where b_k are the Fourier coefficients for δ_ε.

We calculate these coefficients. Set $k=(k_1,k_2)$. If $k_1k_2\neq 0$, then

$$b_k = \frac{2\pi}{4\varepsilon^2L^2}\frac{4\sin(\gamma k_1\varepsilon)\sin(\gamma k_2\varepsilon)}{\gamma^2 k_1k_2}.$$

In other cases we have

$$b_{(m,0)} = b_{(0,m)} = \frac{2\pi}{4\varepsilon^2L^2}\frac{4\varepsilon\sin(\gamma m\varepsilon)}{\gamma m}$$

and finally $b_0 = \frac{2\pi}{L^2}$ corresponding to $\int_{K_L} h = 2\pi$.

To simplify notation we write this using $\operatorname{sinc}(x)$, the continuous continuation of $\frac{\sin x}{x}$, which yields

$$b_k = \frac{2\pi}{L^2}\operatorname{sinc}(\gamma k_1\varepsilon)\operatorname{sinc}(\gamma k_2\varepsilon).$$

Since $a_0 = b_0 = \frac{2\pi}{L^2}$, we have that

$$\int |h-h_{ex}|^2 = L^2\sum_{k\neq 0}|a_k|^2 + L^2\left(\frac{2\pi}{L^2}-h_{ex}\right)^2.$$

We want to calculate

$$E = L^2\sum_{k\in\mathbb{Z}^2\setminus 0}(\alpha^2\gamma^2|k|^2+\alpha)|a_k|^2 + L^2\left(\frac{2\pi}{L^2}-h_{ex}\right)^2.$$

Using the expressions obtained for b_k above, it follows that we have

$$E = \frac{4\pi^2}{L^2}\sum_{k\in\mathbb{Z}^2\setminus 0}\frac{\alpha}{\alpha|\gamma|^2|k|^2+1}\operatorname{sinc}^2(\gamma\varepsilon k_1)\operatorname{sinc}^2(\gamma\varepsilon k_2) + L^2\left(\frac{2\pi}{L^2}-h_{ex}\right)^2.$$

We split up the double sum as follows. First, consider $k=(k_1,k_2)$ with $1\leq|k|\leq\frac{1}{\gamma\varepsilon}$. For these terms we estimate $|\operatorname{sinc}|\leq 1$. We label this part of the energy E_1, and so

$$E_1 \leq \frac{4\pi^2}{L^2}\sum_{K_1}\frac{\alpha}{\alpha\gamma^2|k|^2+1}.$$

Now we compare the sum with an integral. For any decreasing function f, we have

$$\sum_{1\leq|k|\leq A} f(|k|) \leq \int_{1-\frac{1}{\sqrt{2}}}^{A+\frac{1}{\sqrt{2}}} f(r)2\pi r\,dr$$

and so

$$E_1 \leq \frac{4\pi^2}{L^2}\int_{1-c}^{\frac{1}{\gamma\varepsilon}+c}\frac{2\pi\alpha r}{1+\alpha\gamma^2r^2}dr = \frac{4\pi^2}{L^2\gamma^2}\left(\frac{2\pi}{2}\log(\alpha\gamma^2x^2+1)\right)\Bigg|_{x=1-c}^{x=\frac{1}{\gamma\varepsilon}+c},$$

where $c = \frac{1}{\sqrt{2}}$. As $\frac{4\pi^2}{L^2\gamma^2} = 1$, we obtain

$$E_1 \le \frac{2\pi}{2} \log \frac{\frac{\alpha}{\varepsilon^2} + \frac{2c\alpha\gamma}{\varepsilon} + c^2 + 1}{\alpha\gamma^2(1-c)^2 + 1}.$$

We distinguish two cases. If $\alpha\gamma^2 \le 1$, we estimate the denominator as ≥ 1 and obtain

$$E_1 \le \frac{2\pi}{2} \log \frac{\alpha}{\varepsilon^2} + C \le 2\pi \log \frac{\sqrt{\alpha}}{\varepsilon} + C.$$

In the case where $\alpha\gamma^2 \ge 1$, we estimate the denominator as $\ge C\alpha\gamma^2$ and obtain

$$E_1 \le \frac{2\pi}{2} \log \frac{1}{\gamma^2\varepsilon^2} + C \le 2\pi \log \frac{1}{\gamma\varepsilon} + C$$

if $\alpha\gamma > \varepsilon$.

We still need to deal with the frequencies k with $|k| \ge \frac{1}{\gamma\varepsilon}$. For this we use that $\operatorname{sinc}^2(x)\operatorname{sinc}^2(y) \le \frac{2}{r^2}$, which can be seen as follows. Assume without loss of generality that $|x| \le |y|$. Then $r^2 = x^2 + y^2 \le 2y^2$. Estimating $|\operatorname{sinc}(x)| \le 1$ and $|\operatorname{sinc}(y)| \le \frac{1}{y}$, we see that $\operatorname{sinc}^2(x)\operatorname{sinc}^2(y) \le \frac{1}{y^2} \le \frac{2}{r^2}$, as claimed.

To calculate the energy contribution E_2 of those k with $|k| \ge \frac{1}{\gamma\varepsilon}$, we again replace the sum by an integral. Using the sinc bound, we see that

$$E_2 \le \frac{4\pi^2}{L^2} \int_{\frac{1}{\gamma\varepsilon}-c}^{\infty} \frac{4\pi\alpha r}{(\alpha r^2\gamma^2 + 1)\gamma^2 r^2 \varepsilon^2}.$$

We estimate this using $4\pi^2 L^{-2}\gamma^{-2} = 1$ as

$$E_2 \le C \int_{\frac{1}{\gamma\varepsilon}-c}^{\infty} \frac{1}{\gamma^2\varepsilon^2 r^3} dr \le \frac{C}{\gamma^2\varepsilon^2} \cdot \frac{1}{(\frac{1}{\gamma\varepsilon} - c)^2},$$

and for $\frac{1}{\gamma\varepsilon} > 2c$ we obtain that $E_2 \le C$. The claim then follows using the definitions. ∎

Choosing $L = \frac{2\pi}{h_{ex}}$ in (4.4) implies the following upper bound.

COROLLARY 4.6. *If $\varepsilon < \frac{1}{2\sqrt{h_{ex}}}$, then there exists a periodic function h with period $L = \sqrt{\frac{2\pi}{h_{ex}}}$ such that $-\ell^{-2}\Delta h + h = \delta_\varepsilon$ and*

$$\int_{K_L} \ell^{-4}|\nabla h|^2 + \ell^{-2}|h - h_{ex}|^2 \le 2\pi \log \frac{1}{\max(\ell, \sqrt{h_{ex}})\varepsilon} + C.$$

Furthermore, for any $L > 2\varepsilon$ there exists h with $-\ell^{-2}\Delta h + h = \delta_\varepsilon$ and

$$\int_{K_L} \ell^{-4}|\nabla h|^2 + \ell^{-2}|h - h_{ex}|^2 \le 2\pi \log \frac{1}{\max(\ell, \sqrt{h_{ex}})\varepsilon} + C + L^2\ell^{-2}\left(\frac{2\pi}{L^2} - h_{ex}\right)^2.$$

Remark 4.7. This can be easily extended to $\varepsilon \le \frac{C}{\sqrt{h_{ex}}}$ for any C that is bounded independently of ε, ℓ, and h_{ex} by choosing $\tilde{\varepsilon} = \frac{2\varepsilon}{C}$ and constructing with $\tilde{\varepsilon}$ instead of ε.

To construct a pair (u, A) from h, we do the following. To define the modulus ρ, we set

$$\rho(r) = \begin{cases} 0, & r < \varepsilon\sqrt{2}, \\ \frac{r-\varepsilon\sqrt{2}}{\varepsilon}, & \varepsilon\sqrt{2} < r < \varepsilon(1+\sqrt{2}), \\ 1, & r > \varepsilon(1+\sqrt{2}). \end{cases}$$

We take any A with $\operatorname{curl} A = h$. Outside $B_{\varepsilon\sqrt{2}}$, we define u as $\rho e^{i\varphi}$, where $\nabla\varphi - A = \alpha\nabla^\perp h$. This is possible since for any simple closed curve $\Gamma \subset K_L \setminus B_{\varepsilon\sqrt{2}}$ with $\Gamma = \partial G$ we have

$$\int_\Gamma \frac{\partial\varphi}{\partial\tau} = \int_\Gamma A\cdot\tau - \alpha\frac{\partial h}{\partial\nu} = \int_G(-\Delta h + h) = \begin{cases} 2\pi & \text{if } G \supset B_{\varepsilon\sqrt{2}}, \\ 0 & \text{otherwise.} \end{cases} \tag{4.5}$$

On K_L, we can therefore estimate

$$\begin{aligned} \frac{1}{2}\int_{K_L} |(\nabla - iA)u|^2 + \ell^{-2}|h - h_{ex}|^2 + \frac{1}{2\varepsilon^2}(1-\rho^2)^2 \\ \le \frac{1}{2}\int_{K_L} \rho^2\ell^{-4}|\nabla h|^2 + \ell^{-2}|h-h_{ex}|^2 + |\nabla\rho|^2 + \frac{1}{2\varepsilon^2}(1-\rho^2)^2 \\ \le C + \pi\log\frac{1}{\max(\ell,\sqrt{h_{ex}})\varepsilon}. \end{aligned} \tag{4.6}$$

We are now in the position to establish the following argument.

Proof of Proposition 4.1. This will be done in two steps.

Step 1. We use the above construction to build an h in $\mathbb{R}^2$ and to define a periodic ρ_ε corresponding to the lattice. As the equivalent of (4.5) holds in all of $\mathbb{R}^2$, we can define (u, A) in all of $\mathbb{R}^2$ such that (4.6) holds on every cell of the lattice. All we need to do is choose a proper origin for our lattice: For any $a \in K_L$ we can set $(u^a(z), A^a(z)) = (u(z-a), A(z-a))$, which has energy density $gl^a(z) = gl(z-a)$, where $gl(z) = \frac{1}{2}|(\nabla - iA)u|^2(z) + \ell^{-2}|\operatorname{curl} A(z) - h_{ex}|^2 + \frac{1}{2\varepsilon^2}(1-|u(z)|^2)^2$. Integrating over the unit cell, we see that

$$\int_{K_L} G_\varepsilon(u_\varepsilon^a, A_\varepsilon^a; U)da = \int_{K_L}\int_U gl^a(z)dzda = |U|G_\varepsilon(u, A; K_L).$$

The mean value theorem shows that there exists some a such that $G(u^a, A^a; U) \le \frac{|U|}{|K_L|}G(u, A; K_L)$, and since $|K_L| = \frac{h_{ex}}{2\pi}$, this finishes the proof of (4.1).

Step 2. We follow the argument in Step 1; however, we choose a lattice of size $L = \sqrt{\frac{2\pi}{S}}$, which is optimal up to logarithmic terms. Since $h_{ex} \le \varepsilon^{-2}$ and $S \gg 1$, we have $2\varepsilon \le L \ll 1$, and we can follow the same construction as above and obtain for the energy after choosing a suitable origin

$$\begin{aligned} G(u_\varepsilon, A_\varepsilon; U) &\le \frac{|U|}{2|K_L|}\left(2\pi\log\frac{1}{\max(\sqrt{S},\ell)\varepsilon} + C + L^2\ell^{-2}\left|h_{ex} - \frac{2\pi}{L^2}\right|\right) \\ &= \frac{|U|}{2}\left(\frac{S}{2\pi}\left(2\pi\log\frac{1}{\max(\sqrt{S},\ell)\varepsilon} + C\right) + \ell^{-2}\left(\frac{1}{2}\ell^2|\log\varepsilon|\right)^2\right) \\ &= \frac{|U|}{2}\left(S\log\frac{1}{\max(\sqrt{S},\ell)\varepsilon} + C + \frac{1}{4}\ell^2|\log\varepsilon|^2\right) \end{aligned}$$

since $h_{ex} - \frac{2\pi}{L^2} = h_{ex} - S = \frac{1}{2}\ell^2|\log\varepsilon|$. This completes the proof of (4.2). ∎

5. Lower bound for vortex lattices. The lower bound counterpart to Proposition 4.1 can be obtained similarly to the calculation in [18] (see also [19]). We can actually get a uniform vortex density estimate.

The heart of the lower bound argument is the following blow-up estimate.

PROPOSITION 5.1. *Assume that* $\ell^2|\log\varepsilon| \ll h_{ex} \ll \frac{1}{\varepsilon^2}$, *and let* $(u_\varepsilon, A_\varepsilon)$ *be a minimizer of the Ginzburg–Landau energy* (1.3). *Then for every* $H > 0$ *we can find* λ *with* $\ell \ll \lambda \ll \frac{1}{\varepsilon}$ *such that for every* x *such that the ball* $B(x, \frac{1}{\lambda}) \subset U$ *there holds*

$$G_\varepsilon\left(u_\varepsilon, A_\varepsilon; B\left(x, \frac{1}{\lambda}\right)\right) \geq \frac{\alpha_H |B(x, \frac{1}{\lambda})|}{2} h_{ex} \log \frac{1}{\varepsilon\sqrt{h_{ex}}}(1 - o_\varepsilon(1)), \tag{5.1}$$

where α_H *satisfies* $\alpha_H \to 1$ *for* $H \to \infty$.

Proof. We follow the proof of Proposition 8.2 in [18] and rescale by λ. Setting $u(x) = u'(\lambda x)$, $A'(x) = \lambda A(\lambda x)$, $\varepsilon' = \lambda\varepsilon$, and $h'_{ex} = \frac{h_{ex}}{\lambda^2}$, the claim is equivalent to proving for a ball B_1 of radius 1 that

$$\frac{1}{2}\int_{B_1} |(\nabla - iA')u'|^2 + \frac{\lambda^2}{\ell^2}|\operatorname{curl} A' - h'_{ex}|^2 + \frac{1}{2\varepsilon'^2}(1 - |u'|^2)^2 \geq \frac{\alpha_H |B_1|}{2} h'_{ex} \log \frac{1}{\varepsilon\sqrt{h_{ex}}}(1 - o_\varepsilon(1)). \tag{5.2}$$

Since $\varepsilon^2\ell^2|\log\varepsilon| \ll \varepsilon^2 h_{ex} \ll 1$ and using the asymptotic behavior of the function $x \mapsto Hx^2 \log\frac{1}{x}$ near 0, we can find λ such that $\varepsilon^2 h_{ex} = H(\varepsilon\lambda)^2 \log\frac{1}{\varepsilon\lambda}$. It also follows that λ satisfies $\ell \ll \lambda \ll \frac{1}{\varepsilon}$.

With this choice of λ, we have $\varepsilon' \to 0$ and $h'_{ex} = H|\log\varepsilon'|$. We also have $\log\frac{1}{\varepsilon\sqrt{h_{ex}}} = |\log\varepsilon'|(1 - o_\varepsilon(1))$, and so it suffices to prove that (dropping some ε's)

$$G'_{\varepsilon'}(u', A'; x) = \frac{1}{2}\int_{B_1(x)} |(\nabla - iA')u'|^2 + \frac{\lambda^2}{\ell^2}|\operatorname{curl} A' - h'_{ex}|^2 + \frac{1}{2\varepsilon'^2}(1 - |u'|^2)^2 \geq \frac{H\alpha_H |B_1|}{2}|\log\varepsilon'|^2(1 - o_\varepsilon(1)) \tag{5.3}$$

for some α_H with $\alpha_H \to 1$ as $H \to \infty$.

Depending on the blow-up origin x, we distinguish two cases. Either $G'_{\varepsilon'}(u', A'; x) \gg |\log\varepsilon'|^2$ (in which case (5.3) is true trivially) or $G'_{\varepsilon'}(u', A'; x) \leq K|\log\varepsilon'|^2$. In the latter case we can use the Gamma-convergence result Theorem 3.1 to see that $\frac{1}{|\log\varepsilon'|}(iu'_\varepsilon, \nabla u'_\varepsilon) \rightharpoonup v$ and $\frac{1}{|\log\varepsilon'|}A'_\varepsilon \rightharpoonup a$. As $\lambda \gg \ell$, we are in the case $\ell_0 = 0$.

Letting (v_0, a_0) denote the minimizer of the functional G defined in (3.1), we now use the characterization of the limit in Theorem 1.3. It follows that $\operatorname{curl} a_0 = H$. Using Lemma 5.3 below, $\operatorname{curl} v_0 = H$ on $B_{r_0(H)}$ with $r_0(H) \to 1$ for $H \to \infty$. As $\operatorname{curl} v_0 \geq 0$ by Theorem 1.3, it follows that

$$\liminf_{\varepsilon\to 0} \frac{1}{|\log\varepsilon'|^2} G'_{\varepsilon'}(u', A'; x) \geq G(v, a) \geq G(v_0, a_0) \geq \frac{1}{2}\|\operatorname{curl} v_0\|_{\mathscr{M}} \geq H\frac{|B_{r_0(H)}|}{2} = H\alpha_H\frac{|B_1|}{2}, \tag{5.4}$$

and $\alpha_H \to 1$ by Lemma 5.3. ∎

Combining this with the result of the previous section, we obtain the following claim.

PROPOSITION 5.2. *Assume that* $\ell^2|\log\varepsilon| \ll h_{ex} \ll \frac{1}{\varepsilon^2}$, *and let* $(u_\varepsilon, A_\varepsilon)$ *be a minimizer of the Ginzburg–Landau energy* (1.3). *Then the energy density*

$$g_\varepsilon = \frac{1}{2}\left(|\nabla_{A_\varepsilon} u_\varepsilon|^2 + \frac{1}{\ell^2}|\operatorname{curl} A_\varepsilon - h_{ex}|^2 + \frac{1}{2\varepsilon^2}(1-|u_\varepsilon|^2)^2\right)$$

satisfies

$$\frac{g_\varepsilon}{h_{ex}\log\frac{1}{\varepsilon\sqrt{h_{ex}}}} \rightharpoonup \mathscr{L}^2$$

in the sense of measures, and the energy satisfies

$$G_\varepsilon(u_\varepsilon, A_\varepsilon) = \frac{1}{2}\,|U|\,h_{ex}\log\frac{1}{\varepsilon\sqrt{h_{ex}}}\,(1-o_\varepsilon(1))\,. \tag{5.5}$$

Proof. As in [18], this follows by integrating (5.1) over the domain. If $W \subset\subset U$ is a compactly contained subdomain, then we can use Fubini's theorem and estimate

$$\begin{aligned}\int_W G_\varepsilon\left(u_\varepsilon, A_\varepsilon; B\left(x,\frac{1}{\lambda}\right)\cap W\right)dx &= \int_{x\in W}\int_{y\in B(x,\frac{1}{\lambda})\cap W} g_\varepsilon\,dy\,dx \\ = \int_{y\in B(x,\frac{1}{\lambda})\cap W}\int_{x\in W} g_\varepsilon\,dx\,dy &= \int_{y\in W}\left|B\left(y,\frac{1}{\lambda}\right)\cap W\right| g_\varepsilon\,dy \le \frac{\pi}{\lambda^2}G_\varepsilon(u_\varepsilon, A_\varepsilon; W).\end{aligned} \tag{5.6}$$

Using now (5.1) and Fatou's lemma, we continue to estimate

$$\begin{aligned}\liminf_{\varepsilon\to0}\frac{G_\varepsilon(u_\varepsilon, A_\varepsilon; W)}{h_{ex}\log\frac{1}{\varepsilon\sqrt{h_{ex}}}} &\ge \liminf_{\varepsilon\to0}\int_{x\in W}\frac{\lambda^2 G_\varepsilon(u_\varepsilon, A_\varepsilon; B(x,\frac{1}{\lambda}\cap W))}{\pi h_{ex}\log\frac{1}{\varepsilon\sqrt{h_{ex}}}} \\ &\ge \int_{x\in W}\liminf_{\varepsilon\to0}\left(\chi_{\{x:B(x,\frac{1}{\lambda})\subset W\}}\frac{G_\varepsilon(u_\varepsilon, A_\varepsilon; B(x,\frac{1}{\lambda}))}{|B(x,\frac{1}{\lambda})|h_{ex}\log\frac{1}{\varepsilon\sqrt{h_{ex}}}}\right) \ge \frac{1}{2}|W|.\end{aligned} \tag{5.7}$$

Using the upper bound of the previous section, we can deduce the existence of a weak limit g of $\frac{g_\varepsilon}{h_{ex}\log\frac{1}{\varepsilon\sqrt{h_{ex}}}}$. Using an approximation result, we see from (5.7) that $g \ge \frac{1}{2}\mathscr{L}^2$, and by the upper bound, equality follows. ∎

LEMMA 5.3. *For the domain* $U = B_1(0)$, *the unique minimizer* y_0 *of*

$$F_{0,H}(y) = \frac{1}{2}\int_{B_1(0)} |\nabla y|^2 + 2yH$$

in the admissible class

$$\mathscr{K} = \left\{y \in H^1_0(B_1(0)) : y \ge -\frac{1}{2} \text{ a.e. in } B_1(0)\right\}$$

satisfies $y_0 \equiv -\frac{1}{2}$ *in* $B_{r_0(H)}$ *with* $r_0(H) \to 1$ *as* $H\to\infty$. *Furthermore, the minimizer* (v_0, a_0) *of the functional* G *given in* (3.1) *satisfies* $\operatorname{curl} v_0 = H$ *on* $B_{r_0}(0)$, *and* $\alpha_H = \frac{\|\operatorname{curl} v_0\|_{\mathscr{M}}}{H|B_1(0)|} \to 1$ *as* $H\to\infty$.

Proof. Using the uniqueness and regularity properties [9], we can calculate the solution of the obstacle problem explicitly: It is given by

$$y_0(r) = \max\left\{H\left(\frac{r^2}{4} - \frac{1}{4} + \frac{r_0^2}{2}\log r\right), -\frac{1}{2}\right\},$$

where r_0 is chosen such that

$$H\left(\frac{r_0^2}{4}-\frac{1}{4}+\frac{r_0^2}{2}\log r_0\right)=-\frac{1}{2},$$

which we rewrite as

$$1-\frac{2}{H}=r_0^2(1+2\log r_0). \tag{5.8}$$

From (5.8), it is easy to see that $r_0\to 1$ as $H\to\infty$.

In B_{r_0}, $y_0\equiv -\frac{1}{2}$, so $\Delta y_0=0$, and from Theorem 1.3 we infer $\operatorname{curl} v_0=H$ in B_{r_0}, and $\operatorname{curl} v_0\geq 0$ elsewhere, which shows the claim. □

Acknowledgments. The authors wish to thank the referees for many helpful suggestions, including the approach to Proposition 5.2, that significantly improved the paper.

INVERSE SPECTRAL AND SCATTERING THEORY FOR THE HALF-LINE LEFT-DEFINITE STURM–LIOUVILLE PROBLEM*

C. BENNEWITZ†, B. M. BROWN‡, AND R. WEIKARD§

Abstract. The problem of integrating the Camassa–Holm equation leads to the scattering and inverse scattering problem for the Sturm–Liouville equation $-u'' + \frac{1}{4}u = \lambda w u$, where w is a weight function which may change sign but where the left-hand side gives rise to a positive quadratic form so that one is led to a left-definite spectral problem. In this paper the spectral theory and a generalized Fourier transform associated with the equation $-u'' + \frac{1}{4}u = \lambda w u$ posed on a half-line are investigated. An inverse spectral theorem and an inverse scattering theorem are established. A crucial ingredient of the proofs of these results is a theorem of Paley–Wiener type which is shown to hold true. Additionally, the accumulation properties of eigenvalues are investigated.

Key words. inverse scattering problems, inverse spectral problems, left-definite problems, Sturm–Liouville, Camassa–Holm equation

1. Introduction.

Standard Sturm–Liouville theory deals with the eigenvalue problem

$$-(pu')' + qu = \lambda w u, \tag{1.1}$$

together with appropriate boundary conditions, in the space L^2_w of functions square integrable with respect to the weight w, *i.e.*, the norm-square of the space is $\|u\|^2 = \int |u|^2 w$. A basic assumption for this to be possible is that $w \geq 0$. In some situations of interest this is not the case, but instead one has $p > 0$, $q \geq 0$. One may then use as a norm-square the integral $\int (p|u'|^2 + q|u|^2)$, and a problem of this type is usually called *left-definite*. A left-definite problem of current interest is the spectral problem associated with the Camassa–Holm equation, which is of the form

$$-u'' + \tfrac{1}{4}u = \lambda w u. \tag{1.2}$$

The Camassa–Holm equation is an integrable system in a similar sense as the Korteweg–de Vries (KdV) equation. It was first derived as an abstract bi-Hamiltonian system by Fuchssteiner and Fokas [22]. Subsequently, it was shown by Camassa and Holm [11] that it may serve as an integrable model for shallow water waves. In that paper Camassa and Holm also showed that the solitons are peaked and called them peakons (see also Fokas and Liu [21] and Johnson [23]). In contrast to the KdV equation the Camassa–Holm equation may model breaking waves, *i.e.*, smooth

initial data may develop singularities in finite time; cf. Constantin and Escher [15] and Constantin [13] (see also Bressan and Constantin [10] for a way to resolve the singularities due to wave breaking). This, however, happens only when w changes sign and it is this fact which motivates us to consider (1.2) without the assumption that w is positive. The well developed theory of scattering and inverse scattering for the Schrödinger equation is of crucial importance to the theory of the KdV equation. In the same way scattering/inverse scattering theory for (1.2) is important for dealing with the Camassa–Holm equation. Unfortunately, no such theory is available unless $w \geq 0$, and even then current theory requires more smoothness of w than is convenient to assume, in view of the lack of smoothness for the corresponding peakons.

The problem of inverse scattering for (1.2) is considerably more difficult than for the Schrödinger equation, which may be viewed as a rather mild perturbation of the equation $-u'' = \lambda u$. In case of (1.2) the perturbation is of the equation $-u''+\frac{1}{4}u = \lambda u$, and thus changes the coefficient containing the eigenvalue parameter λ. It appears that the methods used so far for dealing with the Schrödinger equation are no longer applicable.

In this paper we will prove some uniqueness results for inverse spectral theory and inverse scattering for the left-definite case which apply to (1.2) posed on a half-line. One would also like to have results for the full-line, but this appears to be more difficult. One exception is the case of odd initial data for the Camassa–Holm equation on the full-line because the problem can be reduced to one on a half-line. We mention here that the half-line case was also investigated by Boutet de Monvel and Shepelsky [8], [9], who employ Riemann–Hilbert techniques but assume that w is positive. Our approach is via the inverse spectral theory for the left-definite problem, which also is not very well developed. Even the spectral theory for left-definite problems is not widely known (but see for example [1]), in the level of detail necessary for dealing with the inverse problem. We will therefore start by presenting a reasonably comprehensive spectral theory, then prove some uniqueness theorems for the inverse spectral problem, and finally a uniqueness theorem for inverse half-line scattering.

Spectral theory for left-definite Sturm–Liouville problems seems to have been initiated by Weyl [28], who called such problems *polar*. Later many authors have dealt with more or less general left-definite problems. In particular we mention a series of papers by Niessen, Schneider, and their collaborators on singular left-definite so-called S-hermitian systems; see, *e.g.*, [26]. See also [1] and the references cited there. For a more recent contribution, see Kong, Wu, and Zettl [24]. However, papers in inverse spectral theory for left-definite problems are much more scarce; one example is Binding, Browne, and Watson [7].

Because of the connection with the Camassa–Holm equation the inverse scattering problem for (1.2) has attracted some attention. From the physical point of view the full-line case where w decays at infinity and the periodic case are most interesting. The former was treated by Fokas [20] and Constantin and various co-authors, for example in [14], [16], and [17]. The latter was addressed by Constantin and McKean [18], Constantin [12], and Vaninsky [27]. The full-line case with odd initial data reduces to a half-line case, but the half-line case is also of interest independently.

It will be convenient to deal only with the equation

$$-u'' + qu = \lambda wu. \tag{1.3}$$

There is no loss of generality in doing this, since the change of variable $t = \int_0^x 1/p$ will, as is readily seen, turn (1.1) into an equation of this form.

The plan of the paper is as follows. In section 2 we give a general spectral theory for left-definite problems on intervals with at least one regular endpoint, modelled on standard Titchmarsh–Weyl theory. One may extend this to intervals with two singular endpoints, in the same way as one can extend the right-definite theory, but since we will have no use of it here we have abstained from this.

In section 3 we deal with the generalized Fourier transform associated with a left-definite problem. To simplify the discussion we have restricted ourselves to one case, when so-called finite functions are dense in the Hilbert space associated with the equation. There are no fundamental difficulties involved in dealing with the general situation, but again we have no need of it in the applications we are thinking of.

Section 4 discusses uniqueness of the inverse spectral problem. Unfortunately we have neither a characterization nor a reconstruction algorithm, but the fundamental uniqueness theorem is quite general.

In section 5 we prove a theorem of Paley–Wiener type which is crucial for our approach to the inverse spectral theory, and section 6 deals with the uniqueness theorem for the half-line inverse scattering of a left-definite problem. Section 7 is devoted to some results about the number of eigenvalues for a left-definite problem under scattering conditions. Some elementary, but rather lengthy, calculations needed in section 4 have been relegated to the appendix.

2. Spectral theory. We shall consider (1.3) on an interval $[0, b)$ and assume that q and w are real-valued and integrable on compact subsets of $[0, b)$, that $q \geq 0$, and that neither q nor w vanish a.e. Let $\mathcal{H}_1$ be the set of locally absolutely continuous functions u defined in $[0, b)$ such that $u' \in L^2(0, b)$ and $q|u|^2 \in L^1(0, b)$. As we shall see presently $\mathcal{H}_1$ is a Hilbert space with scalar product

$$\langle u, v\rangle = \int_0^b (u'\overline{v'} + qu\overline{v})$$

and norm $\|u\| = \sqrt{\langle u, u\rangle}$. In order to show completeness of $\mathcal{H}_1$ and discuss how to find self-adjoint realizations corresponding to (1.3) we first note the following simple result.

LEMMA 2.1. *For any $a \in [0, b)$ there exists a constant C_a such that*

$$|u(x)| \leq C_a\|u\| \tag{2.1}$$

for any $x \in [0, a]$ and any $u \in \mathcal{H}_1$.

Proof. By the fundamental theorem of calculus and the Cauchy–Schwarz inequality $|u(x)| \leq |u(y)| + |y - x|^{1/2}\big(\int_0^b |u'|^2\big)^{1/2}$. If $c \in [a, b)$ is such that $\int_0^c q > 0$, multiplication by $q(y)$ and integrating with respect to y gives

$$|u(x)| \int_0^c q \leq \int_0^c q|u| + c^{1/2} \int_0^c q \left(\int_0^b |u'|^2\right)^{1/2}.$$

Using Cauchy–Schwarz again we obtain (2.1) with $C_a = \big(c + 1/\int_0^c q\big)^{1/2}$. □

PROPOSITION 2.2. *The space $\mathcal{H}_1$ is complete.*

Proof. By (2.1) a Cauchy sequence $u_1, u_2, \ldots$ in $\mathcal{H}_1$ converges locally uniformly to a continuous function u. Furthermore, $\sqrt{q}u_j$ and u_j' converge in $L^2[0, b)$ to $\sqrt{q}u$ and, say, v, respectively. Now

$$u_j(x) - u_j(0) = \int_0^x u_j'.$$

Letting $j \to \infty$ we obtain $u(x) = u(0) + \int_0^x v$. Thus u is absolutely continuous with derivative v and u_j converges to u in $\mathcal{H}_1$. □

Denote the set of integrable functions with compact support in $(0,b)$ by L_0. Then, if $u \in \mathcal{H}_1$ and $v \in L_0$, it follows that $|\int u\overline{v}| \le C_a \int |v|\,\|u\|$ if $\operatorname{supp} v \subset [0,a]$, so that the linear form $\mathcal{H}_1 \ni u \mapsto \int u\overline{v}$ is bounded. By Riesz's representation theorem we may therefore find a unique $v^* \in \mathcal{H}_1$ so that $\int u\overline{v} = \langle u, v^*\rangle$. Clearly v^* depends linearly on v, so we obtain a (bounded) operator $G_0 : L_0 \to \mathcal{H}_1$ such that

$$\langle u, G_0 v\rangle = \int_0^b u\overline{v} \quad \text{for} \quad u \in \mathcal{H}_1,\ v \in L_0.$$

The operator G_0 is central for the left-definite spectral theory of (1.3).

PROPOSITION 2.3. *The operator G_0 is an integral operator $G_0u(x) = \int u\, g_0(x,\cdot)$, it is injective, and its restriction to $L_0 \cap \mathcal{H}_1$ is symmetric with range dense in $\mathcal{H}_1$.*

Proof. By (2.1) the map $\mathcal{H}_1 \ni u \mapsto u(x)$ is for each fixed $x \in [0,b)$ a bounded linear form, so there exists an element $g_0(x,\cdot) \in \mathcal{H}_1$ so that $u(x) = \langle u, \overline{g_0(x,\cdot)}\rangle$ for $u \in \mathcal{H}_1$, and therefore $G_0v(x) = \langle G_0v, \overline{g_0(x,\cdot)}\rangle = \int_0^b v\, g_0(x,\cdot)$ for any $v \in L_0$. Thus G_0 is an integral operator with kernel $g_0(x,y)$ (actually, as we shall see in Proposition 2.7, g_0 is real-valued). If u and $v \in L_0 \cap \mathcal{H}_1$, then

$$\langle G_0u, v\rangle = \overline{\langle v, G_0u\rangle} = \int_0^b u\overline{v} = \langle u, G_0v\rangle,$$

so the restriction of G_0 to $L_0 \cap \mathcal{H}_1$ is symmetric.

Let $[c,d] \subset (0,b)$ and $u_j(x) = \min(1, j(x-c), j(d-x))$ for $x \in [c,d]$ and $u_j(x) = 0$ otherwise. Then $u_j \in L_0 \cap \mathcal{H}_1$ and tends boundedly to the characteristic function of $[c,d]$ as $j \to \infty$, so if $G_0v = 0$, it follows from $0 = \langle G_0v, u_j\rangle = \int v\overline{u_j}$ that $\int_c^d v = 0$ for all $[c,d] \subset (0,b)$. Thus $v = 0$ a.e. so that G_0 is injective. On the other hand, if $u \in \mathcal{H}_1$ is orthogonal to G_0v for all $v \in L_0 \cap \mathcal{H}_1$, we may put $v = u_j$, so that $0 = \langle u, G_0u_j\rangle \to \int_c^d u$. It follows that $u = 0$ so the range of G_0 restricted to $L_0 \cap \mathcal{H}_1$ is dense and the proof is complete. □

We shall have to briefly use the theory of symmetric relations as presented in [1, section 1], and define maximal and minimal relations corresponding to (1.3). We start by setting

$$T_c = \{(G_0(wv), v) \mid v \in L_0 \cap \mathcal{H}_1\}.$$

Then, since w is real-valued, T_c is a symmetric relation in $\mathcal{H}_1$ for

$$\langle G_0(wu), v\rangle = \overline{\langle v, G_0(wu)\rangle} = \int_0^b wu\overline{v} = \langle u, G_0(wv)\rangle.$$

Proposition 2.3 implies that T_c is the graph of a densely defined symmetric operator in $\mathcal{H}_1$ if $\operatorname{supp} w = [0,b)$, but at this point we do not want to exclude the possibility of w vanishing on an open set. We define the *minimal relation* T_0 as the closure (in $\mathcal{H}_1 \oplus \mathcal{H}_1$) of T_c, and the *maximal relation* T_1 as the adjoint of this, *i.e.*,

$$T_1 = \{(u,f) \in \mathcal{H}_1 \oplus \mathcal{H}_1 \mid \langle u, v\rangle = \langle f, G_0(wv)\rangle \text{ for all } v \in L_0 \cap \mathcal{H}_1\}.$$

We must show that T_1 is a differential relation.

PROPOSITION 2.4. *We have $(u,f) \in T_1$ if and only if u and $f \in \mathcal{H}_1$, u' is locally absolutely continuous, and $-u'' + qu = wf$.*

Proof. First note that if u and $f \in \mathcal{H}_1$, then the definition of G_0 shows that

$$\langle u, v\rangle - \langle f, G_0(wv)\rangle = \int_0^b (u'\overline{v'} + qu\overline{v} - wf\overline{v}) \tag{2.2}$$

for any $v \in L_0 \cap \mathcal{H}_1$. If in addition u' is locally absolutely continuous and satisfies $-u'' + qu = wf$, integrating by parts gives

$$\langle u, v\rangle - \langle f, G_0(wv)\rangle = \int_0^b (-u'' + qu - wf)\overline{v} = 0.$$

This proves one direction of the proposition.

In proving the other direction the assumption is that the quantity (2.2) is zero. But since $C_0^\infty(0,b) \subset \mathcal{H}_1$ this means that the distributional derivative of u' is $qu - wf$ so that u' is locally absolutely continuous and u satisfies the differential equation.

To give a proof without the use of distribution theory we prove a variant of the classical du Bois-Reymond lemma. If $v \in L_0 \cap \mathcal{H}_1$, integration by parts in (2.2) gives

$$\int_0^b \left\{ u' - \int_0^x (qu - wf) - C \right\} \overline{v'} = 0 \tag{2.3}$$

for any constant C. Now let $[c,d] \subset (0,b)$ and choose $C = \frac{1}{d-c}\int_c^d \{u' - \int_0^x (qu - wf)\}$. Put $v(y) = 0$ for $y \notin [c,d]$ and

$$v(y) = \int_c^y \left\{ u'(x) - \int_0^x (qu - wf) - C \right\} dx$$

for $y \in [c,d]$. Then $v \in L_0 \cap \mathcal{H}_1$ and (2.3) gives

$$\int_c^d \left| u' - \int_0^x (qu - wf) - C \right|^2 = 0$$

so that $u' - \int_0^x (qu - wf)$ is constant in $[c,d]$. Thus u' is locally absolutely continuous, and differentiation gives $-u'' + qu = wf$. ∎

Let $\mathcal{D}_\lambda = \{(u, \lambda u) \in T_1\}$ and let D_λ be the projection of $\mathcal{D}_\lambda$ onto its first components, *i.e.*, $u \in D_\lambda$ means that $u \in \mathcal{H}_1$ and u satisfies $-u'' + qu = \lambda wu$. We then have

$$T_1 = T_0 \dotplus \mathcal{D}_\lambda \dotplus \mathcal{D}_{\overline{\lambda}}$$

as a direct sum for any nonreal λ. Here $\dim \mathcal{D}_\lambda = \dim D_\lambda$ is constant in each of the upper and lower half-planes, and these dimensions will be called the *deficiency indices* of T_1. See [1, Theorem 1.4] for this simple generalization of the von Neumann formula for symmetric operators and its consequences. It is clear that $\dim D_\lambda \le 2$, and that $\dim D_{\overline{\lambda}} = \dim D_\lambda$, since $\overline{u} \in D_{\overline{\lambda}}$ if and only if $u \in D_\lambda$. Thus deficiency indices are always equal, and there are always self-adjoint extensions of T_0, which will at the same time be restrictions of T_1, and therefore realizations of (1.3). It is of course of interest to have criteria in terms of the coefficients q and w for different values of the deficiency indices $\dim D_\lambda$. In surprising contrast to the right-definite case, we have the following simple and explicit criteria.

THEOREM 2.5. *Suppose* $\operatorname{Im}\lambda \neq 0$ *and let* W *be an antiderivative of* w. *Then* $\dim D_\lambda = 2$ *if* $b < \infty$ *and* $q + W^2 \in L^1[0,b)$. *Otherwise* $\dim D_\lambda = 1$ *for* $\operatorname{Im}\lambda \neq 0$.

The theorem is a special case of [2, Theorem 2.3]. See also [5]. In the right-definite case a simple variation of constants argument shows that if $\dim D_\lambda = 2$ for one real or nonreal value of λ, then this holds for all $\lambda \in \mathbb{C}$. A similar argument shows that this remains true in the left-definite case, with the exception that it is possible that $\dim D_0 = 2$ even if $\dim D_\lambda < 2$ for all $\lambda \neq 0$. This is to be expected, since D_0 does not depend on the choice of w. We characterize $\dim D_0$ completely in the following theorem, which also brings out the significance of the space D_0. We use the expression *finite function* in $\mathcal{H}_1$ to denote a function which vanishes near b.

THEOREM 2.6.

(1) *The set D_0 is the orthogonal complement in $\mathcal{H}_1$ of $L_0 \cap \mathcal{H}_1$ and has dimension 1 or 2.*
(2) $\dim D_0 = 2$ *if and only if* $b < \infty$ *and* $q \in L^1[0, b)$.
(3) *If $b < \infty$ and $q \in L^1[0, b)$, then v and v' have finite limits at b for all $v \in D_0$, and these limits uniquely determine v.*
(4) *If $b < \infty$ and $q \in L^1[0, b)$, then every $u \in \mathcal{H}_1$ has a limit at b which is a bounded linear form on $\mathcal{H}_1$.*
(5) *If $\dim D_0 = 1$ and $D_0 \ni v \not\equiv 0$, then $v(0)\overline{v'(0)} < 0$ and $u(x)\overline{v'(x)} \to 0$ as $x \to b$ for any $u \in \mathcal{H}_1$.*
(6) *Finite functions are dense in $\mathcal{H}_1$ if and only if* $\dim D_0 = 1$.

Most of this is also a special case of the results of [2] and [5], but we give a simple proof, an elaboration of which can also prove Theorem 2.5.

Proof. We have $u \in D_0$ precisely if $(u, 0) \in T_1$, which holds precisely if $\langle u, v\rangle = \langle u, v\rangle - \langle 0, G_0(wv)\rangle = 0$ for all $v \in L_0 \cap \mathcal{H}_1$, proving the first claim. Since there are elements $v \in \mathcal{H}_1$ with $v(0) \neq 0$, and since $u(0) = 0$ for every $u \in L_0 \cap \mathcal{H}_1$, it follows from (2.1) for $x = 0$ that $\dim D_0 \geq 1$ and we have proved (1).

If b is finite and q integrable, standard existence and uniqueness theorems show that all solutions of $-v'' + qv = 0$ are continuously differentiable with absolutely continuous derivative in $[0, b]$, and thus in $\mathcal{H}_1$, and that they are uniquely determined by the values of v and v' at b. In this case the proof of Lemma 2.1 clearly also works for $a = b$, so we have proved (3), (4), and one direction of (2).

Now let $u \in \mathcal{H}_1$ and $v \in D_0$. Integration by parts gives

$$\int_0^x (u'\overline{v'} + qu\overline{v}) + u(0)\overline{v'(0)} = u(x)\overline{v'(x)}. \tag{2.4}$$

Thus $u(x)\overline{v'(x)}$ has a limit at b. If this is not 0, then $(u(x)\overline{v'(x)})^{-1}$ is bounded close to b. Therefore $u'/u = u'\overline{v'}/(u\overline{v'})$ is integrable near b, so that u has a nonzero limit at b. Since $q|u|^2$ is integrable it follows that $q \in L^1(0, b)$. Similarly, $v''/v' = qv/v' = qv\overline{u}/(v'\overline{u})$ is integrable near b, so v' has a nonzero limit at b. Since $|v'|^2$ is integrable it follows that b is finite.

Now, setting $u = v \not\equiv 0$ in (2.4) the integral is increasing, ≥ 0, and not constant, so if $v(0)\overline{v'(0)} \geq 0$, then $v(x)\overline{v'(x)}$ cannot tend to 0 at b. However, if $\dim D_0 = 2$, we may choose $v \in D_0$ with $v'(0) = 0$, so it follows that $q \in L^1(0, b)$ and b finite, completing the proof of (2).

On the other hand, if $\dim D_0 = 1$, then $u(x)\overline{v'(x)}$ must tend to zero for any $u \in \mathcal{H}_1$. In particular, for $u = v$ one therefore has $v(0)\overline{v'(0)} < 0$ for any nonzero $v \in D_0$ which proves (5).

Finally, if $u \in \mathcal{H}_1$ is finite and $v \in D_0$, integration by parts shows that $\langle u, v\rangle = -u(0)\overline{v'(0)}$, so the orthogonal complement of the finite functions consists of those

$v \in D_0$ for which $v'(0) = 0$. According to (5) this implies $v = 0$ if $\dim D_0 = 1$ and the proof is complete. □

It is now possible to give a detailed description of the kernel g_0.

PROPOSITION 2.7. *The kernel $g_0(x, y)$ is real-valued and symmetric in x, y. As a function of y it satisfies* (1.3) *with $\lambda = 0$ for $y \neq x$, and there are real-valued functions ψ_0 and φ_0 which solve* (1.3) *with $\lambda = 0$, such that if $u \in \mathcal{H}_1$, then*

(1) $\psi_0 \in \mathcal{H}_1$, $\psi_0'(0) = 1$ *and* $\psi_0'(x)u(x) \to 0$ *as* $x \to b$,

(2) $\varphi_0(0) = -1$, $\varphi_0'(0) = 0$,

(3) $g_0(x, y) = \varphi_0(\min(x, y))\psi_0(\max(x, y))$.

Proof. The existence of the solution φ_0 is not in question, and if a solution with the properties of ψ_0 exists, it is easy to verify that the kernel $\varphi_0(\min(x, y))\psi_0(\max(x, y))$ has the properties required of $g_0(x, y)$.

The existence of ψ_0 follows from Theorem 2.6. Indeed, if $\dim D_0 = 2$, the element $v \in D_0$ with $v(b) = 1$, $v'(b) = 0$ is real-valued and must have $v(0)v'(0) < 0$ by (2.4), so $v'(0) \neq 0$, and an appropriate multiple will have the properties required of ψ_0.

On the other hand, if $\dim D_0 = 1$, any nonzero $v \in D_0$ satisfies $v(0)\overline{v'(0)} < 0$ so $v'(0) \neq 0$, and an appropriate multiple will satisfy the requirements for ψ_0. Note that this solution is real-valued, since its real and imaginary parts also are in D_0, and are thus proportional, and the initial condition guarantees that the imaginary part vanishes. □

Now let T be a self-adjoint restriction of T_1 and assume that (u, f) and $(v, g) \in T$. Integrating by parts we then obtain

$$\int_0^x (u'\overline{g'} + qu\overline{g}) - \int_0^x (f'\overline{v'} + qf\overline{v}) = (u'\overline{g} - f\overline{v'})\big|_0^x. \tag{2.5}$$

As $x \to b$ this vanishes, since the left-hand side tends to $\langle u, g\rangle - \langle f, v\rangle$. Thus the condition for symmetry is that

$$(u'\overline{g} - f\overline{v'})\big|_0^b = 0.$$

Comparing this with $(u'\overline{v} - u\overline{v'})\big|_0^b = 0$, which is the similar condition in the right-definite case, we see that only exceptionally would self-adjoint boundary conditions in the left-definite case also be self-adjoint boundary conditions in the right-definite case.

Separated boundary conditions are those that make $u'\overline{g} - f\overline{v'}$ vanish at each endpoint separately, and are thus at 0 of the form

$$f(0)\cos\alpha + u'(0)\sin\alpha = 0, \tag{2.6}$$

for some $\alpha \in [0, \pi)$. Again comparing with the right-definite case, where the condition is $u(0)\cos\alpha + u'(0)\sin\alpha = 0$, the conditions coincide only in the case $\alpha = \pi/2$, the Neumann boundary condition. However, for eigenfunctions, where $f = \lambda u$, it is clear that also $\alpha = 0$, the Dirichlet boundary condition, gives the same spectra outside of $\lambda = 0$.

We shall not need a detailed description of self-adjoint boundary conditions at a singular endpoint. However, one may always impose the condition (2.6) at 0. It is easy to see that the corresponding restriction of T_1 has a symmetric adjoint, which is a strict extension of T_0. If the deficiency indices of T_0 equal 1, this is sufficient to obtain a self-adjoint restriction T of T_1, and all self-adjoint realizations are of this form. Otherwise, a condition needs to be imposed also at b. From (2.5) it follows

immediately that every $(u,f) \in T_1$ satisfying such a condition at b must satisfy $\mathrm{Im}(u'(x)\overline{f(x)}) \to 0$ as $x \to b$.

Assuming now that we have a self-adjoint relation T, the spectral theorem looks as follows (see [1, Theorem 1.15]). Consider the set $\mathcal{H}_\infty = \{u \in \mathcal{H}_1 \mid (0,u) \in T\}$. Then $\mathcal{H}_\infty$ is a subspace of $\mathcal{H}_1$, and setting $\mathcal{H} = \mathcal{H}_1 \ominus \mathcal{H}_\infty$ the *domain* D_T of T (*i.e.*, the set of first components of T) is a dense subset of $\mathcal{H}$, and $T \cap \mathcal{H} \oplus \mathcal{H}$ is the graph of a self-adjoint operator in $\mathcal{H}$. We will denote this operator by T as well, and may now apply the usual spectral theorem to T. If the resolution of the identity for the operator T is $\{E_t\}_{t\in\mathbb{R}}$, we extend the domain of the projection E_t to all of $\mathcal{H}_1$ by setting $E_t\mathcal{H}_\infty = 0$. Clearly one may view $\mathcal{H}_\infty$ as an eigenspace for the relation T belonging to the eigenvalue ∞, so adjoining the orthogonal projection onto $\mathcal{H}_\infty$ to $\{E_t\}_{t\in\mathbb{R}}$ gives a resolution of the identity in $\mathcal{H}_1$ for the relation T. In the present case one may give a rather complete description of $\mathcal{H}_\infty$.

PROPOSITION 2.8. *The space $\mathcal{H}_\infty$ consists of those elements $g \in \mathcal{H}_1$ for which $wg = 0$ a.e., and for which $(0,g)$ satisfies the boundary conditions that define T. In particular, if $wg = 0$ a.e. and $g \in L_0 \cap \mathcal{H}_1$, then $g \in \mathcal{H}_\infty$.*

Proof. Now $g \in \mathcal{H}_\infty$ means that $(0,g) \in T$, which therefore satisfies the boundary conditions defining T. In particular, $0 = \langle g, G_0(wf)\rangle - \langle 0, f\rangle = \langle g, G_0(wf)\rangle = \int g\overline{f}w$ for any $f \in L_0 \cap \mathcal{H}_1$. It follows, as in the proof of Proposition 2.3, that $wg = 0$ a.e.

Conversely, if $(0,g)$ satisfies the boundary conditions and $gw = 0$ a.e., then if $(u,f) \in T$, an integration by parts gives

$$\langle u, g\rangle - \langle f, 0\rangle = \lim_{x\to b}(u'\overline{g} - f\cdot 0)\big|_0^x = 0,$$

i.e., $(0,g) \in T$, so the proof is complete. □

We remark that if an endpoint is regular, then the boundary condition implied by $u \in \mathcal{H}_\infty$ is in most cases the vanishing of u in that endpoint. For separated boundary conditions an exception occurs when the boundary condition is of Neumann type (*i.e.*, when $\alpha = \pi/2$ in (2.6)). If we have Neumann conditions at both ends, or at one end when deficiency indices equal 1, there are *no* boundary conditions for elements of $\mathcal{H}_\infty$.

We will base our derivation of the expansion theorem for the operator T on a detailed description of the resolvent $R_\lambda = (T-\lambda)^{-1}$. Thus R_λ is defined on $\mathcal{H}$, but we extend its domain to $\mathcal{H}_1$ by setting $R_\lambda\mathcal{H}_\infty = 0$. The range of R_λ is of course D_T, which is a dense set in $\mathcal{H}$. Using the kernel g_0 for the evaluation operator on $\mathcal{H}_1$ introduced in the proof of Proposition 2.3, we have $R_\lambda u(x) = \langle R_\lambda u, \overline{g_0(x,\cdot)}\rangle = \langle u, R_{\overline{\lambda}}g_0(x,\cdot)\rangle$, since the adjoint of R_λ is $R_{\overline{\lambda}}$. Thus we may view $G(x,\cdot,\lambda) = \overline{R_{\overline{\lambda}}g_0(x,\cdot)}$ as Green's function for our operator; note, however, that G is not the kernel of a standard integral operator. It will turn out to be convenient to introduce the kernel $g(x,y,\lambda) = G(x,y,\lambda) + g_0(x,y)/\lambda$, so that we obtain

$$R_\lambda u(x) = \langle u, \overline{g(x,\cdot,\lambda)}\rangle - u(x)/\lambda. \tag{2.7}$$

Note that $G(x,\cdot,\lambda) \in \mathcal{H}$ but this is not true of $g(x,\cdot,\lambda)$ unless $\mathcal{H}_\infty = \{0\}$. We shall need a precise description of $g(x,y,\lambda)$. To do this we must introduce solutions of (1.3) satisfying initial conditions at 0, so let $\varphi(x,\lambda)$, $\theta(x,\lambda)$ be solutions of (1.3) for $\lambda \neq 0$ satisfying

$$\begin{cases}\lambda\varphi(0,\lambda) = -\sin\alpha\\ \varphi'(0,\lambda) = \cos\alpha\end{cases}, \quad \begin{cases}\lambda\theta(0,\lambda) = \cos\alpha\\ \theta'(0,\lambda) = \sin\alpha\end{cases}. \tag{2.8}$$

This means that φ satisfies the boundary condition (2.6) and θ another similar boundary condition at 0. We have the following theorem.

THEOREM 2.9. *Suppose T is a self-adjoint realization of* (1.3) *given by* (2.6) *and, if needed, an appropriate condition at b. Then there exists a function $m(\lambda)$ defined for* $\operatorname{Im}\lambda \neq 0$, *the* Titchmarsh–Weyl m-function for T, *depending only on λ and such that $\psi(x,\lambda) = \theta(x,\lambda) + m(\lambda)\varphi(x,\lambda)$, called the* Weyl solution *for T, is in $\mathcal{H}_1$ and satisfies the boundary condition at b, if any. Furthermore*

$$g(x,y,\lambda) = \varphi(\min(x,y),\lambda)\psi(\max(x,y),\lambda).$$

Proof. For nonreal λ neither φ nor θ can be in $\mathcal{H}_1$ and satisfy the boundary condition at b, since that would make λ a nonreal eigenvalue for a self-adjoint problem. Thus there is a solution $\psi(x,\lambda) = \theta(x,\lambda) + m(\lambda)\varphi(x,\lambda)$ in $\mathcal{H}_1$ which also satisfies the boundary condition at b, since if $\dim D(\lambda) = 2$, one linear, homogeneous condition still leaves a one-dimensional space, whereas if $\dim D(\lambda) = 1$, no boundary condition is imposed at b.

Define, for fixed x and $\lambda \notin \mathbb{R}$, the function

$$F(y) = \varphi(\min(x,y),\lambda)\psi(\max(x,y),\lambda) - \lambda^{-1}g_0(x,y).$$

Since $\psi(\cdot,\lambda)$ and ψ_0 are in $\mathcal{H}_1$ so is F. We claim that $F \in D_T$. In fact, one easily checks that F' is locally absolutely continuous and that F satisfies $-F'' + qF = \lambda wF + wg_0(x,\cdot)$. It is also easy to check that F satisfies the boundary condition (2.6).

Finally, for $y > x$ the function F is a linear combination of $\psi(\cdot,\lambda)$ and ψ_0. The former satisfies the boundary condition at b by construction, and ψ_0 satisfies the boundary condition at b by Theorem 2.6(5), since if $(u,f) \in T$, then $\psi_0'\overline{f} - 0\overline{u'} = \psi_0'\overline{f} \to 0$ at b. All this means that $F = R_\lambda g_0(x,\cdot) = \overline{R_{\overline{\lambda}} g_0(x,\cdot)} = G(x,\cdot,\lambda)$ so that $g(x,y,\lambda)$ is as claimed. ∎

THEOREM 2.10. *The function m is analytic outside $\mathbb{R}$, it maps the upper half plane into itself, and it satisfies $\overline{m(\lambda)} = m(\overline{\lambda})$.*

Proof. Since R_λ is analytic outside $\mathbb{R}$ in the strong operator topology $R_\lambda u(x)$ is, by (2.1), pointwise analytic. It follows that $g(x,\cdot,\lambda)$ is weakly analytic for each x, and thus, again by (2.1), $g(x,y,\lambda)$ is analytic outside $\mathbb{R}$ for each x and y. Since $\varphi(x,\lambda)$ and $\theta(x,\lambda)$ also are analytic and since an integration by parts shows that they are nonzero for $x > 0$ and $\lambda \notin \mathbb{R}$, it follows that $m(\lambda)$ is analytic in $\mathbb{C} \setminus \mathbb{R}$.

If (v,g) defines a boundary condition at b, then so does either its real part or its imaginary part, which is easily seen. Therefore, since $\psi(x,\lambda)$ satisfies (1.3) and the boundary condition at b, so does $\overline{\psi(x,\overline{\lambda})}$, and is thus a multiple of $\psi(x,\lambda)$. Now $\overline{\varphi(x,\overline{\lambda})} = \varphi(x,\lambda)$, $\overline{\theta(x,\overline{\lambda})} = \theta(x,\lambda)$ and $\psi(x,\lambda) = \theta(x,\lambda) + m(\lambda)\varphi(x,\lambda)$ so it follows that $m(\overline{\lambda}) = \overline{m(\lambda)}$.

Integrating by parts we have

$$\operatorname{Im}\lambda \int_0^x (|\psi'(\cdot,\lambda)|^2 + q|\psi(\cdot,\lambda|^2) = \operatorname{Im}(\overline{\psi'(\cdot,\lambda)}\lambda\psi(\cdot,\lambda))\big|_0^x.$$

Since ψ satisfies a boundary condition at b, the integrated term vanishes as $x \to b$. At 0 the integrated term evaluates to $-\operatorname{Im} m(\lambda)$, so we obtain

$$\|\psi(\cdot,\lambda)\|^2 = \operatorname{Im} m(\lambda)/\operatorname{Im}\lambda. \tag{2.9}$$

Thus m maps the upper and lower half-planes into themselves. ∎

A function with the properties of m is a so-called Nevanlinna or Herglotz function, and has a unique representation

$$m(\lambda) = A + B\lambda + \int_{\mathbb{R}} \left(\frac{1}{t-\lambda} - \frac{t}{t^2+1} \right) d\rho, \tag{2.10}$$

where $A \in \mathbb{R}$, $B \geq 0$, and $d\rho$ is a positive measure with $\int_{\mathbb{R}} \frac{d\rho(t)}{1+t^2} < \infty$. We will call the measure $d\rho$ the *spectral measure* for T, for reasons that will become clear presently.

We finally note the following proposition.

PROPOSITION 2.11. *Unless $\alpha = \pi/2$ and $0 \notin \operatorname{supp} w$ the functions ψ_0 and $\psi(\cdot, \lambda)$ are in $\mathcal{H}$.*

Proof. Suppose $g \in \mathcal{H}_\infty$. An integration by parts then gives

$$\langle g, \psi \rangle = -g(0)\overline{\psi'(0)},$$

where $\psi = \psi_0$ or $\psi(\cdot, \lambda)$. The boundary condition at 0 requires $g(0) = 0$ unless $\alpha = \pi/2$, and even then $g(0) = 0$ unless $w = 0$ in a neighbourhood of 0. ∎

3. The Fourier transform. We shall call functions that vanish near b *finite* and from now on make the following simplifying assumption.

Assumption 3.1. Assume that finite functions are dense in $\mathcal{H}_1$.

According to Theorem 2.6 this means exactly that either $q \notin L^1(0, b)$ or else $b = \infty$. Note that, according to Theorem 2.5, the assumption implies that the deficiency indices of T_1 equal 1.

The spectral measure introduced in the previous section gives rise to a Hilbert space L^2_ρ with scalar product $\langle \hat{u}, \hat{v} \rangle_\rho = \int_{-\infty}^{\infty} \hat{u}\overline{\hat{v}}\, d\rho$. We shall define a generalized Fourier transform $\mathcal{F} : \mathcal{H}_1 \to L^2_\rho$ with the following properties.

THEOREM 3.2.

(1) *The map $u \mapsto \int_0^b (u'\varphi'(\cdot, t) + qu\varphi(\cdot, t))$, defined for finite $u \in \mathcal{H}_1$, extends by continuity to a map $\mathcal{F} : \mathcal{H}_1 \to L^2_\rho$ called the* generalized Fourier transform. *The image of $u \in \mathcal{H}_1$ is denoted by $\mathcal{F}(u)$ or $\hat{u}$. We write this as $\hat{u}(t) = \langle u, \varphi(\cdot, t) \rangle$ although the integral in general does not converge pointwise.*

(2) *The mapping $\mathcal{F} : \mathcal{H}_1 \to L^2_\rho$ has kernel $\mathcal{H}_\infty$ and is unitary between $\mathcal{H}$ and L^2_ρ so that* Parseval's formula *$\langle u, v \rangle = \langle \hat{u}, \hat{v} \rangle_\rho$ holds if at least one of u and v is in $\mathcal{H}$.*

(3) *If $u \in D_T$, then $\mathcal{F}(Tu)(t) = t\hat{u}(t)$. Conversely, if $\hat{u}$ and $t\hat{u}(t)$ are in L^2_ρ, then $\mathcal{F}^{-1}(\hat{u}) \in D_T$.*

(4) *Suppose $\alpha \neq 0$ in (2.6). Then $\varphi(x, \cdot) \in L^2_\rho$ for each x and $\int_{-\infty}^{\infty} \hat{u}\varphi(x, \cdot)\, d\rho = \langle \hat{u}, \varphi(x, \cdot) \rangle_\rho$ converges in $\mathcal{H}$, and hence locally uniformly in x, for $\hat{u} \in L^2_\rho$. This is the adjoint of $\mathcal{F} : \mathcal{H}_1 \to L^2_\rho$ and thus the inverse of $\mathcal{F}$ restricted to $\mathcal{H}$. If M is a Borel set in $\mathbb{R}$, then*

$$E_M u(x) = \int_M \hat{u}\varphi(x, \cdot)\, d\rho. \tag{3.1}$$

If $\alpha = 0$, the same is true, except that we must replace $\varphi(\cdot, t)$ for $t = 0$ by the function ψ_0 of Proposition 2.7. Note that ψ_0 is the eigenfunction for the eigenvalue 0 in this case.

We first consider the Fourier transform for finite functions $u \in \mathcal{H}_1$, for every $\lambda \in \mathbb{C}$ setting

$$\hat{u}(\lambda) = \langle u, \varphi(\cdot, \overline{\lambda}) \rangle.$$

It is clear that $\hat{u}$ is an entire function, since integration by parts shows that

$$\hat{u}(\lambda) = \langle u, \varphi(\cdot, \overline{\lambda})\rangle = \int_0^b u\lambda\varphi(\cdot,\lambda)w - u(0)\cos\alpha,$$

and by (2.8) $\lambda\varphi(x,\lambda)$ is an entire function of λ, locally uniformly in x.

LEMMA 3.3. *For finite u and $v \in \mathcal{H}_1$ we have $\hat{u}$ and $\hat{v} \in L^2_\rho$. If E_Δ is the spectral projection for T associated with an interval Δ, then $\langle E_\Delta u, v\rangle = \int_\Delta \hat{u}\overline{\hat{v}}\, d\rho$.*

Proof. We have $\langle R_\lambda u, v\rangle = \hat{u}(\lambda)\overline{\hat{v}(\overline{\lambda})}m(\lambda) + g(\lambda)$, where g is entire, as is easily verified by direct calculation. Integrating around a rectangle γ with corners at $c \pm i$ and $d \pm i$ we therefore have $\int_\gamma \langle R_\lambda u, v\rangle\, d\lambda = \int_\gamma \hat{u}(\lambda)\overline{\hat{v}(\overline{\lambda})}m(\lambda)\, d\lambda$ whenever one of the integrals exists. By the spectral theorem the first integral equals $\int_\gamma \int_{\mathbb{R}} \frac{d\langle E_t u, v\rangle}{t-\lambda}\, d\lambda$, so if the integral is absolutely convergent, changing the order of integration gives $-2\pi i\langle E_{(c,d)}u, v\rangle$ if c and d are points of continuity for $\langle E_t u, v\rangle$.

Similarly, using the Nevanlinna representation (2.10), the other integral equals $-2\pi i \int_c^d \hat{u}(t)\overline{\hat{v}(t)}\, d\rho(t)$ if it is absolutely convergent and c, d are points of continuity for ρ.

The absolute convergence of the double integrals is ensured if $\langle E_t u, v\rangle$ and ρ are differentiable at c and d as is easily seen. For more details of the identical calculation carried out for the right-definite case, see [6, Lemmas 14.3, 14.4].

As functions of bounded variation $\langle E_t u, v\rangle$ and ρ are both differentiable a.e., so the second claim of the lemma is true if the endpoints of Δ belong to this dense set of points, and so in general by continuity. In particular, letting $c \to -\infty$, $d \to \infty$ through such points it follows that $\langle E_{\mathbb{R}} u, u\rangle = \langle \hat{u}, \hat{u}\rangle_\rho$, so that $\hat{u}, \hat{v} \in L^2_\rho$. ∎

Since finite functions are dense in $\mathcal{H}_1$, and since $E_{\mathbb{R}}$ has kernel $\mathcal{H}_\infty$, we now obtain Theorem 3.2(1) by continuity and also (2) except for the surjectivity of $\mathcal{F}$. To prove this we need the following lemmas.

LEMMA 3.4. *The transform of $R_\lambda u$ is $\hat{u}(t)/(t-\lambda)$.*

Proof. According to the spectral theorem we have $\langle R_\lambda u, v\rangle = \int_{\mathbb{R}} \frac{d\langle E_t u, v\rangle}{t-\lambda}$ and by Lemma 3.3 we have $\langle E_t u, v\rangle = \int_{-\infty}^t \hat{u}\overline{\hat{v}}\, d\rho$ so that

$$\langle R_\lambda u, v\rangle = \int_{\mathbb{R}} \frac{\hat{u}(t)}{t-\lambda}\,\overline{\hat{v}(t)}\, d\rho(t).$$

We also have $R_\lambda - R_{\overline{\lambda}} = (\lambda - \overline{\lambda})R_{\overline{\lambda}}R_\lambda$ and $\langle R_\lambda u, R_\lambda u\rangle = \langle R_{\overline{\lambda}}R_\lambda u, u\rangle$ so

$$\langle R_\lambda u, R_\lambda u\rangle = \frac{1}{\lambda - \overline{\lambda}}(\langle R_\lambda u, u\rangle - \langle R_{\overline{\lambda}}u, u\rangle) = \left\| \frac{\hat{u}(t)}{t-\lambda}\right\|_\rho^2.$$

Expanding $\|\frac{\hat{u}(t)}{t-\lambda} - \mathcal{F}(R_\lambda u)\|_\rho^2$ and using Parseval's formula and the above yields 0, thus proving the lemma. ∎

LEMMA 3.5. *The operator T has eigenvalue 0 if and only if $\alpha = 0$, in which case the eigenfunction is ψ_0, and for any $u \in \mathcal{H}_1$ we then have $\hat{u}(0) = -u(0)$.*

Furthermore, the measure $d\rho$ has mass at 0 ($\{0\}$ is not a nullset with respect to $d\rho$) precisely if $\alpha = 0$. In this case $\hat{\psi}_0 = \chi_{\{0\}}/\rho\{0\}$, where $\chi_{\{0\}}$ is the characteristic function of the singleton $\{0\}$ and $\rho\{0\}$ the spectral measure of this set.

Proof. According to Theorem 2.6 the only nontrivial solutions of (1.3) for $\lambda = 0$ in $\mathcal{H}_1$ are multiples of a solution u for which $u'(0)\overline{u(0)} < 0$, so that $u'(0) \neq 0$. These solutions satisfy the boundary condition (2.6) precisely if $\alpha = 0$, which proves the first

claim. If u is any finite function, integrating by parts gives $\hat{u}(0) = \langle u, \varphi(\cdot,0)\rangle = -u(0)$. This holds in general by continuity, $u(0)$ being a bounded linear form on $\mathcal{H}_1$ by (2.1), and $\hat{u}(0)$ on L^2_ρ since $d\rho$ has mass at 0, as we shall see presently.

Now $u \in D_T$ and $Tu = 0$ precisely if $u + \lambda R_\lambda u = 0$, and the Fourier transform of $u + \lambda R_\lambda u$ is $(1 + \frac{\lambda}{t-\lambda})\hat{u}(t) = \frac{t\hat{u}(t)}{t-\lambda}$. If this is 0, then $\hat{u} = 0$ a.e. with respect to $d\rho$ except possibly at $t = 0$. Thus, if $\alpha = 0$, then $\{0\}$ cannot be a nullset with respect to $d\rho$. It also follows that $\hat{\psi}_0$ is a multiple of the characteristic function of the set $\{0\}$. On the other hand, since $\dim D_\lambda = 1$, Weyl solutions for different α are proportional so it immediately follows that

$$m_0(\lambda) = \frac{\psi'(0,\lambda)}{\lambda\psi(0,\lambda)} = \frac{\sin\alpha + m_\alpha(\lambda)\cos\alpha}{\cos\alpha - m_\alpha(\lambda)\sin\alpha}, \tag{3.2}$$

where m_α denotes the m-function associated with the boundary condition parameter α. Now $m_0(i\nu) \to \infty$ as $\nu \downarrow 0$, as a consequence of the mass at 0, so that $m_\alpha(i\nu) \to \cot\alpha$ for $\alpha \neq 0$. For $\alpha \neq 0$ the spectral measure therefore has no mass at 0.

It only remains to prove the formula for $\hat{\psi}_0$. By Parseval's formula (note that $\psi_0 \in \mathcal{H}$ by Proposition 2.11) we have $\hat{\psi}_0(0) = -\psi_0(0) = \|\psi_0\|^2 = \|\hat{\psi}_0\|^2_\rho = |\hat{\psi}_0(0)|^2\rho\{0\}$. Hence $-\psi_0(0) = \hat{\psi}_0(0) = 1/\rho\{0\}$. □

It is now easy to prove that $\mathcal{F}$ is surjective.

LEMMA 3.6. *The Fourier transform $\mathcal{H} \to L^2_\rho$ is surjective.*

Proof. Suppose that $\hat{u} \in L^2_\rho$ is orthogonal to all Fourier transforms $\hat{v}$. Since $\hat{v}(t)/(t-\lambda)$ is also a transform, for any nonreal λ, we have $\int \frac{1}{t-\lambda}\hat{u}(t)\overline{\hat{v}(t)}\,d\rho(t) = 0$ for all nonreal λ. Thus the Stieltjes transform of the measure $\hat{u}\overline{\hat{v}}\,d\rho$ is 0, so by the uniqueness of the Stieltjes transform it follows that this measure is the zero measure.

Now, if $\hat{v}$ is the transform of a finite function in $\mathcal{H}_1$, then it is an entire function, so to prove that t is outside the support of $\hat{u}\,d\rho$ it is enough to show that there is such a $\hat{v}$ for which $\hat{v}(t) \neq 0$. If $t \neq 0$ and $\hat{v}(t) = 0$ for all compactly supported $v \in \mathcal{H}_1$, then as in the proof of Proposition 2.4 it follows that $\varphi(\cdot,t)$ satisfies (1.3) both for $\lambda = 0$ and $\lambda = t$, so that $\varphi(\cdot,t)w = 0$ a.e., which is not possible since it implies that $\varphi(\cdot,t) = 0$ in a set of positive Lebesgue measure. It therefore follows that $\hat{u}\,d\rho$ vanishes outside 0. But according to Lemma 3.5 this proves that the measure is zero, unless $\alpha = 0$. However, also in this case $\hat{u} = 0$ since otherwise $\hat{u}$ would be the transform of an eigenfunction. □

We next turn to Theorem 3.2(3).

LEMMA 3.7. *If $u \in D_T$, then $\mathcal{F}(Tu)(t) = t\hat{u}(t)$. Conversely, if $\hat{u}$ and $t\hat{u}(t)$ are in L^2_ρ, then $\mathcal{F}^{-1}(\hat{u}) \in D_T$.*

Proof. We have $u \in D_T$ if and only if for some $v \in \mathcal{H}_1$ we have $u = R_\lambda(v - \lambda u)$, *i.e.*, if and only if $\hat{u}(t) = (\hat{v}(t) - \lambda\hat{u}(t))/(t-\lambda)$ or $t\hat{u}(t) = \hat{v}(t)$ for some $\hat{v} \in L^2_\rho$. □

We obtain the following corollary which will be useful later on.

COROLLARY 3.8. *If $u \in D_T$, then $\hat{u}$ is integrable with respect to $d\rho$.*

Proof. The functions $t\hat{u}(t)$, $\hat{u}$, and $1/(t-i)$ are all in L^2_ρ, so that $\hat{u}(t) = (t\hat{u}(t) - i\hat{u}(t))/(t-i)$ is integrable with respect to $d\rho$. □

To finish the proof of Theorem 3.2 it only remains to consider the inverse transform.

LEMMA 3.9. *If $\alpha \neq 0$, the integral $\langle \hat{u}, \varphi(x,\cdot)\rangle_\rho$ converges in $\mathcal{H}$ and locally uniformly for every $\hat{u} \in L^2_\rho$. If $\hat{u} = \mathcal{F}(u)$ for some $u \in \mathcal{H}_1$, then the integral is the orthogonal projection of u onto $\mathcal{H}$.*

If $\alpha = 0$, the same statement is true if one replaces $\varphi(\cdot,0)$ by ψ_0 in the integral.

Remark 3.10. A simple integration by parts shows that every finite function is orthogonal to φ_0. Now suppose $\alpha = 0$ and let $\theta_0 = \varphi(\cdot, 0)$ so that θ_0 solves (1.3) for $\lambda = 0$ with initial data $\theta_0(0) = 0$, $\theta_0'(0) = 1$. Then, when calculating the Fourier transform at 0 we may replace $\varphi(\cdot, 0)$ by any function $\theta_0 + A\varphi_0$ for A constant, with no change to the Fourier transform.

In particular we may choose $A = -\psi_0(0) = 1/\rho\{0\}$, according to Lemma 3.5, so that $\theta_0 + A\varphi_0 = \psi_0$. This might seem a more natural choice of kernel for the Fourier transform, in view of the fact that it must be used for the inverse transform, and that ψ_0 is an eigenfunction to the eigenvalue 0, but would thus not actually change the Fourier transform.

Proof of Lemma 3.9. We have $u(x) = \langle u, g_0(x, \cdot)\rangle = \langle \hat{u}, e(x, \cdot)\rangle_\rho$ for $u \in \mathcal{H}$, where $e(x,t) = \mathcal{F}(g_0(x,\cdot))(t)$. If $u \in \mathcal{H}_1$, we instead get the projection of u onto $\mathcal{H}$, so that the integral operator $\hat{u} \mapsto \langle \hat{u}, e(x,\cdot)\rangle_\rho$ is the adjoint of $\mathcal{F}$. We must prove that $e(x,t) = \varphi(x,t)$, so suppose $\hat{u}$ has compact support and consider $\tilde{u}(x) = \langle \hat{u}, \varphi(x,\cdot)\rangle_\rho$ which satisfies the equation $-\tilde{u}'' + q\tilde{u} = w(x)\langle \hat{u}, t\varphi(x,\cdot)\rangle_\rho$, differentiating under the integral sign. Since $\hat{u}$ has compact support $u \in D_T$, so that $-u'' + qu = w(x)\langle t\hat{u}(t), e(x,t)\rangle_\rho$. Thus $u_1 = u - \tilde{u}$ satisfies $-u_1'' + qu_1 = w(x)\langle t\hat{u}(t), e(x,t) - \varphi(x,t)\rangle_\rho$.

Now, if v is finite, then

$$\langle \tilde{u}, v\rangle = \iint \hat{u}(t)(\varphi'(\cdot,t)\overline{v'} + q\varphi(\cdot,t)\overline{v})\, d\rho(t) = \langle \hat{u}, \hat{v}\rangle_\rho = \langle u, v\rangle,$$

since the double integral is absolutely convergent. Hence u_1 is orthogonal to all finite v so it satisfies $-u_1'' + qu_1 = 0$. It follows that $w(x)\langle t\hat{u}(t), e(x,t) - \varphi(x,t)\rangle_\rho = 0$ a.e., so that $\langle t\hat{u}(t), e(x,t) - \varphi(x,t)\rangle_\rho = 0$ on a set of positive measure. But this function also satisfies (1.3) for $\lambda = 0$, as is seen by replacing $\hat{u}$ by $t\hat{u}(t)$ in the previous calculations. It follows that $t(e(x,t) - \varphi(x,t)) = 0$ for a.a. t with respect to $d\rho$, so that $e(x,t) = \varphi(x,t)$ except possibly if $t = 0$ and $\alpha = 0$.

However, 0 is an eigenvalue for $\alpha = 0$ and the eigenfunction ψ_0 has transform $\chi_{\{0\}}/\rho\{0\}$ according to Lemma 3.5, so we must choose $e(x,0) = \psi_0(x)$. □

The proof of Theorem 3.2 is now complete if we note that from $\langle E_t u, v\rangle = \int_{-\infty}^t \hat{u}\overline{\hat{v}}$ follows that the transform of $E_t u$ is $\hat{u}$ multiplied by the characteristic function of $(-\infty, t]$. The formula $E_M u(x) = \int_M \hat{u}\varphi(x,\cdot)\, d\rho$ therefore follows from the inversion formula.

In Lemma 3.5 we calculated the Fourier transform of ψ_0 in the case $\alpha = 0$. We shall need to find a few more Fourier transforms.

LEMMA 3.11. *If $\lambda \notin \mathbb{R}$, the Fourier transform of $\psi(\cdot,\lambda)$ is $\hat{\psi}(t,\lambda) = 1/(t-\lambda)$. Furthermore, the Fourier transform of ψ_0 equals $\hat{\psi}_0(t) = \sin\alpha/t$ for $\alpha \neq 0$ and $1/\rho\{0\}$ times the characteristic function of the set $\{0\}$ for $\alpha = 0$.*

Proof. We have already calculated $\hat{\psi}_0$ for $\alpha = 0$ in Lemma 3.5. If $\alpha \neq 0$, we note that $\psi_0(x) = -g_0(0,x)$ so its Fourier transform is $-e(0,t) = -\varphi(0,t) = \sin\alpha/t$.

According to (2.7), Theorem 2.9, and Lemma 3.9, for $u \in \mathcal{H}$ we have

$$-\sin\alpha\langle \hat{u}, \hat{\psi}(\cdot,\lambda)\rangle_\rho = \overline{\lambda}\varphi(0,\overline{\lambda})\langle u, \psi(\cdot,\lambda)\rangle$$

$$= \overline{\lambda}R_{\overline{\lambda}}u(0) + u(0) = \left\langle \left(\frac{\overline{\lambda}}{t-\overline{\lambda}} + 1\right)\hat{u}(t), e(0,t)\right\rangle_\rho$$

$$= \left\langle \hat{u}(t), \frac{t\, e(0,t)}{t-\lambda}\right\rangle_\rho = -\sin\alpha\left\langle \hat{u}(t), \frac{1}{t-\lambda}\right\rangle_\rho$$

so that we have $\hat{\psi}(t,\lambda) = 1/(t-\lambda)$ if $\alpha \neq 0$. If $\alpha = 0$, we assume $\hat{u}$ has compact support so that we may differentiate $u(x) = \langle \hat{u}, e(x,\cdot)\rangle_\rho$ under the integral sign to obtain

$$\langle \hat{u}, \hat{\psi}(\cdot,\lambda)\rangle_\rho = \varphi'(0,\overline{\lambda})\langle u, \psi(\cdot,\lambda)\rangle = (R_{\overline{\lambda}}u)'(0)$$
$$= \left\langle \frac{\hat{u}(t)}{t-\overline{\lambda}}, e'_x(0,t)\right\rangle_\rho = \left\langle \hat{u}(t), \frac{e'_x(0,t)}{t-\lambda}\right\rangle_\rho = \left\langle \hat{u}(t), \frac{1}{t-\lambda}\right\rangle_\rho .$$

Thus, also in this case we obtain $\hat{\psi}(t,\lambda) = 1/(t-\lambda)$. □

COROLLARY 3.12. *Suppose $u \in \mathcal{H}$. Then $\langle u, \psi(\cdot,t\lambda)\rangle \to 0$ as $t \to \infty$, locally uniformly for $\lambda \notin \mathbb{R}$. By (2.1) this means that $\psi(x,t\lambda) \to 0$ as $t \to \infty$, locally uniformly in x and $\lambda \notin \mathbb{R}$.*

In fact, unless $0 \notin \operatorname{supp} w$ and $\alpha = \pi/2$ we have $\psi(\cdot,t\lambda) \to 0$ in $\mathcal{H}$, locally uniformly in $\lambda \notin \mathbb{R}$ as $t \to \infty$.

Proof. We have $\langle u, \psi(\cdot,\lambda)\rangle = \langle \hat{u}, \hat{\psi}(\cdot,\lambda\rangle_\rho$. With the extra assumptions Proposition 2.11 shows that $\psi(\cdot,\lambda) \in \mathcal{H}$ so that $\|\psi(\cdot,\lambda)\| = \|\hat{\psi}(\cdot,\lambda)\|_\rho$.

It follows immediately by dominated convergence from Lemma 3.11 that the claims are true. □

Remark 3.13. All of the theory of sections 2 and 3 extends with no essential change to the case when w is just a measure, or even an element of $H^{-1}_{\mathrm{loc}}(0,b)$.

4. Uniqueness of the inverse problem. We shall here deal with the following question: *To what extent is the operator T,* i.e.*, the interval $[0,b)$, the coefficients q and w, and the boundary condition parameter α, determined by the spectral measure $d\rho$?* To answer this question we introduce the concept of a *Liouville transform* as a map $v \mapsto u$ given by $u(x) = f(x)v(g(x))$, where f and g are fixed functions. We suppose that g is strictly increasing and continuous, and that f is never 0. It is then easy to see that the inverse of a Liouville transform is also a Liouville transform, as is the composition of two Liouville transforms.

Now consider another relation $\breve{T}$ of the same type as T, with Hilbert space $\breve{\mathcal{H}}_1$, interval $[0,\breve{b})$, boundary condition parameter $\breve{\alpha}$, and coefficients $\breve{q}$ and $\breve{w}$. We will assume, as we do for $\mathcal{H}_1$, that finite functions are dense in $\breve{\mathcal{H}}_1$.

THEOREM 4.1. *Suppose that $\alpha = \breve{\alpha}$, or $0 < \alpha = \pi/2 - \breve{\alpha} < \pi/2$, or $\pi/2 < \alpha = 3\pi/2 - \breve{\alpha} < \pi$ and that there is a continuously differentiable bijection g from $[0,b)$ to $[0,\breve{b})$ with the following properties: g, g', and g'' are locally absolutely continuous, $g' > 0$, $g(0) = g''(0) = 0$, $g'(0) = (\sin\breve{\alpha}/\sin\alpha)^2$ if $\alpha \neq 0 \neq \breve{\alpha}$, $g'(0) = 1$ if $\alpha = \breve{\alpha} = 0$, and the coefficients of T and $\breve{T}$ satisfy $\breve{q}(g(x)) = (-f(x)f''(x) + q(x)f(x)^2)/g'(x)$ and $\breve{w}(g(x)) = w(x)/g'(x)^2$, where $f(x) = g'(x)^{-1/2}$.*

Then the spectral measures associated with T and $\breve{T}$ are identical.

Proof. The functions g and f give rise to Liouville transform $\mathcal{L}$ from functions defined on $[0,\breve{b})$ to functions defined on $[0,b)$, in particular to a transform from $\breve{\mathcal{H}}_1$ to $\mathcal{H}_1$. We will first show that this latter transform is unitary. To that end assume that $\breve{u}$ and $\breve{v}$ are in $\breve{\mathcal{H}}_1$ and that at least one of them is a finite function. Obviously $\mathcal{L}\breve{u}$ and $\mathcal{L}\breve{v}$ are locally absolutely continuous. Furthermore we obtain after a partial integration

$$\langle \mathcal{L}\breve{u}, \mathcal{L}\breve{v}\rangle_{\mathcal{H}_1} = \int_0^b (g'(\breve{u}'\overline{\breve{v}'}) \circ g + (-ff'' + qf^2)(\breve{u}\overline{\breve{v}}) \circ g)$$
$$= \int_0^{\breve{b}} (\breve{u}'\overline{\breve{v}'} + \breve{q}\breve{u}\overline{\breve{v}}) = \langle \breve{u}, \breve{v}\rangle_{\breve{\mathcal{H}}_1}.$$

This proves first that $\mathcal{L}\breve{u} \in \mathcal{H}_1$ whenever $\breve{u}$ is a finite function in $\breve{\mathcal{H}}_1$ and second that $\mathcal{L}$ is an isometry from the finite functions in $\breve{\mathcal{H}}_1$ onto the finite functions in $\mathcal{H}_1$. As an isometry $\mathcal{L}$ can be extended to a unitary operator from $\breve{\mathcal{H}}_1$ to $\mathcal{H}_1$.

Next, a straightforward computation, using that $2f'g' + fg'' = 0$, shows that $-u'' + qu = wr$ if $u = \mathcal{L}\breve{u}$, $r = \mathcal{L}\breve{r}$, and $-\breve{u}'' + \breve{q}\breve{u} = \breve{w}\breve{r}$. In particular, $(\breve{u}, \breve{r}) \in \breve{T}$ implies that $(\mathcal{L}\breve{u}, \mathcal{L}\breve{r}) \in T$ and $\mathcal{L}\breve{\psi}(\cdot, \lambda)$ must be a multiple of $\psi(\cdot, \lambda)$.

Also, since $\breve{\varphi}(\cdot, \lambda)$ satisfies the differential equation $-\breve{u}'' + \breve{q}\breve{u} = \lambda\breve{w}\breve{u}$ the function $\mathcal{L}\breve{\varphi}(\cdot, \lambda)$ satisfies $-u'' + qu = \lambda wu$. Our assumptions on α, $\breve{\alpha}$, $g'(0)$, and $g''(0)$ imply that $f(0) = \sin\alpha / \sin\breve{\alpha} = \cos\breve{\alpha} / \cos\alpha$ and that $f'(0) = 0$. Therefore we find $\lambda(\mathcal{L}\breve{\varphi}(\cdot, \lambda))(0) = \lambda f(0)\breve{\varphi}(0, \lambda) = -\sin\alpha$ and $(\mathcal{L}\breve{\varphi}(\cdot, \lambda))'(0) = \breve{\varphi}'(0, \lambda)/f(0) = \cos\alpha$ which shows that $\varphi(\cdot, \lambda) = \mathcal{L}\breve{\varphi}(\cdot, \lambda)$. The situation is a little more complicated for the relationship between θ and $\breve{\theta}$ where one finds that

$$\mathcal{L}\breve{\theta}(\cdot, \lambda) = \theta(\cdot, \lambda) + (\tan\breve{\alpha} - \tan\alpha)\varphi(\cdot, \lambda).$$

By the linearity of $\mathcal{L}$ we have

$$\mathcal{L}\breve{\psi}(\cdot, \lambda) = \theta(\cdot, \lambda) + (\tan\breve{\alpha} - \tan\alpha + \breve{m})\varphi(\cdot, \lambda) = \psi(\cdot, \lambda).$$

This proves that $\breve{m} + \tan\breve{\alpha} = m + \tan\alpha$ and hence that $\breve{\rho} = \rho$. □

In the rest of this section we will make the following additional assumption about (1.3).

Assumption 4.2. The coefficients w and $\breve{w}$ satisfy $\operatorname{supp} w = [0, b)$, $\operatorname{supp}\breve{w} = [0, \breve{b})$.

Note that this does not mean that $w \neq 0$ a.e.; w could vanish on a nowhere dense set of strictly positive measure. However, it does mean that $\mathcal{H}_\infty = \{0\}$, $\mathcal{H} = \mathcal{H}_1$.

Remark 4.3. One may also allow w to be an arbitrary measure. However, then in the definition of the function h below, and in the statement of Lemma 5.1, w should be replaced by the density of the absolutely continuous part of the measure w, and Assumption 4.2 will have to be made on this density. If this is done, the results in the rest of the paper are still true, *mutatis mutandis*, with essentially the same proofs.

Now define the functions $h(x) = \int_0^x \sqrt{|w|}$ on $[0, b)$ and $\breve{h}(x) = \int_0^x \sqrt{|\breve{w}|}$ on $[0, \breve{b})$, respectively. By Assumption 4.2 these are strictly increasing, locally absolutely continuous functions.

Our main theorem is the following.

THEOREM 4.4. *Suppose that T and $\breve{T}$ have the same spectral measure $d\rho$. Then there is a unitary Liouville transform $\mathcal{U}$ taking $\breve{T}$ into T, in the sense that $\mathcal{H} \ni u \mapsto \mathcal{U}u \in \breve{\mathcal{H}}$ through $u(x) = f(x)\mathcal{U}u(g(x))$ and $\mathcal{U}T = \breve{T}\mathcal{U}$. Here $g(x) = \breve{h}^{-1} \circ h(x)$ and $f(x) = (g'(x))^{-1/2}$.*

The functions f and g are continuously differentiable, f is strictly positive, and f' is locally absolutely continuous with $f'(0) = 0$. Also $\alpha = \breve{\alpha}$, in which case $f(0) = 1$, or else $0 < \alpha = \pi/2 - \breve{\alpha} < \pi/2$ or $\pi/2 < \alpha = 3\pi/2 - \breve{\alpha} < \pi$, in which case $f(0) = |\tan\alpha|$.

The relations between the coefficients are $\breve{w}(g(x)) = w(x)/(g'(x))^2$ and $\breve{q}(g(x)) = (-f''(x) + q(x)f(x))/(f(x)(g'(x))^2)$.

It is clear from Theorem 4.1 that Theorem 4.4 is optimal in the sense that it is not possible to deduce more about the relation between T and $\breve{T}$ from the equality of their spectral measures than is done in Theorem 4.4. Sufficient additional information, however, will imply that T and $\breve{T}$ are identical. We give two corollaries of this type.

COROLLARY 4.5. *Suppose T and $\breve{T}$ have the same spectral measure and that $|w| = |\breve{w}|$ in $[0, \min(b, \breve{b}))$. Then $T = \breve{T}$,* i.e., *$b = \breve{b}$, $\alpha = \breve{\alpha}$, $q = \breve{q}$, and $w = \breve{w}$.*

Proof. The assumptions together with Theorem 4.4 show that $g(x) = x$ so that $b = \breve{b}$, and that $f(x) = 1$, so that T and $\breve{T}$ are identical. □

Note that only the absolute value of w need be known, so that all information about sign changes in w is encoded in the spectral measure. Also note that if $|w| = |\breve{w}|$ only in $[0,a)$, where $0 < a < \min(b,\breve{b})$, we still have $\alpha = \breve{\alpha}$ and $q = \breve{q}$, $w = \breve{w}$ in $[0,a)$.

COROLLARY 4.6. *Suppose T and $\breve{T}$ have the same spectral measure, that $q = \breve{q}$ on $[0, \min(b,\breve{b}))$, and that either $b = \breve{b}$ or $\alpha = \breve{\alpha}$. Then $T = \breve{T}$,* i.e., *$b = \breve{b}$, $\alpha = \breve{\alpha}$, $q = \breve{q}$, and $w = \breve{w}$.*

We will postpone the proof and first prove Theorem 4.4. To do this we will use a theorem of Paley–Wiener type. For its statement it will be convenient to introduce a special class of entire functions.

DEFINITION 4.7. *Let $\mathcal{A}$ be the set of entire functions $\hat{u}$ of order $\le 1/2$ which satisfy*

$$\limsup_{t\to\infty} t^{-1} \ln|\hat{u}(t^2\lambda)| \le \int_0^a \operatorname{Re}\sqrt{-\lambda w} \tag{4.1}$$

for some $a \in (0,b)$ and all $\lambda \in \mathbb{C}\setminus\mathbb{R}$. Here the branch of the square root is that with a positive real part.

THEOREM 4.8. *Let $\hat{u}$ be the generalized Fourier transform of $u \in \mathcal{H}$. Then $\hat{u}$ has at most one entire continuation in $\mathcal{A}$, and if* $\sup\operatorname{supp} u = a < b$, *such a continuation is given by*

$$\hat{u}(\lambda) = \int_0^a (u'\varphi'(\cdot,\lambda) + qu\varphi(\cdot,\lambda))$$

in which case (4.1) *holds with equality for all $\lambda \in \mathbb{C}$.*

Conversely, if $\hat{u}$ has an entire continuation of order $\le 1/2$ satisfying (4.1) *for λ on at least two different rays from the origin, then* $\operatorname{supp} u \subset [0,a]$.

We will postpone the proof of Theorem 4.8 to the next section and instead turn to the proof of Theorem 4.4.

LEMMA 4.9. *Let $g : [0,b) \to [0,\breve{b})$ be increasing and $g(0) = 0$. Suppose $\mathcal{U} : \mathcal{H}_1 \to \breve{\mathcal{H}}_1$ is linear with the properties that $(\mathcal{U}u)(0) = 0$ if $u(0) = 0$, that* $\operatorname{supp}\mathcal{U}u \subset [0,g(x)]$ *if* $\operatorname{supp} u \subset [0,x]$, *and that* $\operatorname{supp}\mathcal{U}u \subset [g(x),\breve{b})$ *if* $\operatorname{supp} u \subset [x,b)$. *Then there exists a function f such that $(\mathcal{U}u)(g(x)) = f(x)u(x)$ for all $u \in \mathcal{H}_1$.*

Proof. Fix $x \in [0,b)$. Suppose $u, v \in \mathcal{H}_1$ and that $u(x) = v(x)$. We will first show that $(\mathcal{U}(u-v)(g(x)) = 0$. If $x = 0$, this is by assumption.

For $x > 0$ we define[1] $u_- = \chi_{[0,x]}(u-v)$ and $u_+ = \chi_{[x,b)}(u-v)$. These are elements of $\mathcal{H}$. Thus $\operatorname{supp}\mathcal{U}u_- \subset [0,g(x)]$ and $\operatorname{supp}\mathcal{U}u_+ \subset [g(x),b)$ so that the functions $\mathcal{U}u_\pm$ vanish in $g(x)$. Adding them gives $\mathcal{U}(u-v)(g(x)) = 0$ as desired.

It follows that the value of $\mathcal{U}u$ at $g(x)$ only depends on the value of u at x. Thus, for each fixed $x \in [0,b)$, the map $u(x) \mapsto \mathcal{U}u(g(x))$ is well-defined and linear on $\mathbb{C}$, so we may find $f(x)$ so that $\mathcal{U}u(g(x)) = f(x)u(x)$. □

We will also need the following lemma.

LEMMA 4.10. *Put $m(x,\lambda) = \psi'(x,\lambda)/(\lambda\psi(x,\lambda))$. Then $m(x,\lambda) \to 0$ and $\lambda m(x,\lambda) \to \infty$ for every $x \in [0,b)$ as $\lambda \to \infty$ along any nonreal ray starting from the origin.*

Proof. First note that $m(x,\lambda)$ is the m-function for (1.3) on the interval $[x,b)$, with the Dirichlet boundary condition ($\alpha = 0$) at x. The first claim is then an immediate consequence of [3, Theorem 3.6].

[1] χ_I denotes the characteristic function of an interval I.

To prove the second claim, first assume that q does not have compact support, so that it does not vanish identically on $[x,b)$. Now note that, according to (3.2), $\tilde{m}(\lambda) = -1/m(x,\lambda)$ is the m-function for the Neumann boundary condition ($\alpha = \pi/2$) at x, so we need to show this to be $o(|\lambda|)$. Now, in the Nevanlinna representation (2.10) it is easy to see that the integral is always $o(|\lambda|)$, so we simply need to prove that $B = 0$ in the representation of $\tilde{m}$. Denote the corresponding Weyl solution by $\tilde{\psi}$ and the spectral measure by $d\tilde{\rho}$. Using (2.9) and Lemma 3.11 we obtain

$$\|\tilde{\psi}(\cdot,\lambda)\|^2_{[x,b)} = \frac{\operatorname{Im}\tilde{m}(\lambda)}{\operatorname{Im}\lambda} = B + \int_{-\infty}^{\infty} \frac{d\tilde{\rho}(t)}{|t-\lambda|^2} = B + \|\hat{\tilde{\psi}}(\cdot,\lambda)\|^2_{\tilde{\rho}}.$$

However, by Proposition 2.11, Parseval's formula is correct for $\tilde{\psi}$, so that $B = 0$ and we are done in the case when q does not have compact support.

Now suppose q vanishes identically in $[x,b)$. Consider an auxiliary equation for which q does not have compact support, but which has the same coefficients as (1.3) up to some point c, $x < c < b$. For this equation the above proof of the lemma is valid. Moreover, let $\tilde{\theta}$ and $\tilde{\varphi}$ denote functions analogous to θ and φ for $\alpha = 0$, but with initial data given in the point x. In view of (2.9) both the original $m(x,\lambda)$ and the corresponding function for the auxiliary equation are in the "Weyl disk" defined by

$$\int_x^c |\tilde{\theta}' + m\tilde{\varphi}'|^2 \le \frac{\operatorname{Im} m}{\operatorname{Im}\lambda},$$

so their distance is bounded by the diameter of the disk, which is exponentially small as λ becomes large (see [3, Theorem 6.3] for this result). Since $m(x,\lambda)$ is a nontrivial Nevanlinna function it cannot tend to 0 faster than a multiple of $1/|\lambda|$ for large $|\lambda|$, so that asymptotically $m(x,\lambda)$ is the same as the corresponding function for the auxiliary equation. Thus the lemma is actually valid in all cases. □

Proof of Theorem 4.4. Note first that by Lemma 3.5 we must have either $\alpha = \breve{\alpha} = 0$ or else $\alpha \neq 0 \neq \breve{\alpha}$.

Let $\mathcal{H}$ and $\breve{\mathcal{H}}$ denote the Hilbert spaces and $\mathcal{F}$ and $\breve{\mathcal{F}}$ the generalized Fourier transforms associated with the two equations, and put $\mathcal{U} = \breve{\mathcal{F}}^{-1} \circ \mathcal{F} : \mathcal{H} \to \breve{\mathcal{H}}$, which is unitary since the target space is L^2_ρ for both $\mathcal{F}$ and $\breve{\mathcal{F}}$. By Lemma 3.11 we have $\mathcal{U}\psi_0 = \breve{\psi}_0$ if $\alpha = \breve{\alpha}$, and if $\alpha \neq 0 \neq \breve{\alpha}$, we have $\mathcal{U}\psi_0 = \frac{\sin\alpha}{\sin\breve{\alpha}}\breve{\psi}_0$. Since $\langle u, \psi_0\rangle = -u(0)$ it follows that

$$u(0) = -\langle u, \psi_0\rangle = -\langle \mathcal{U}u, \mathcal{U}\psi_0\rangle = \frac{\sin\alpha}{\sin\breve{\alpha}}\mathcal{U}u(0), \tag{4.2}$$

where the quotient of the sines is to be read as 1 for $\alpha = \breve{\alpha} = 0$. In particular, $\mathcal{U}u(0) = 0$ if and only if $u(0) = 0$.

Now, applying Theorem 4.8 for the rays generated by $\pm i$, it is clear that if $\breve{a} \in (0,\breve{b})$ and $u \in \mathcal{H}$, then $\sup\operatorname{supp} u = a$ if $\sup\operatorname{supp}\mathcal{U}u = \breve{a}$, where $h(a) = \breve{h}(\breve{a})$, provided there is such an $a \in (0,b)$[2] (see [4, p. 29] for more details). This will certainly be the case if $\breve{a}$ is sufficiently close to 0. Suppose for some $\breve{a} \in (0,\breve{b})$ we have $h(b) \le \breve{h}(\breve{a})$. Then, since compactly supported functions are dense in $\mathcal{H}$, the range of $\mathcal{U}$ would be orthogonal to all elements of $\breve{\mathcal{H}}$ with supports in $(\breve{a},\breve{b})$, contradicting the fact that $\mathcal{U}$ is unitary.

A similar reasoning applied to $\mathcal{U}^{-1}$ shows that the mapping

$$g : [0,b) \ni a \mapsto \breve{a} \in [0,\breve{b})$$

[2]Note that $\operatorname{Re}\sqrt{\pm iw} = \sqrt{|w|/2}$.

is bijective, and that $\sup\operatorname{supp}\mathcal{U}u = \breve{a}$ if $\sup\operatorname{supp} u = a$. It follows that $\sup\operatorname{supp} u = a$ if and only if $\sup\operatorname{supp}\mathcal{U}u = g(a)$.

We also have $\inf\operatorname{supp} u = a$ if and only if $\inf\operatorname{supp}\mathcal{U}u = g(a)$. To see this, note that what we have already proved implies that if $\inf\operatorname{supp} u = a > 0$, then $\mathcal{U}u$ is orthogonal to all elements of $\breve{\mathcal{H}}$ with support in $[0, g(a)]$. This means that in this interval $\mathcal{U}u$ is a multiple of $\breve{\varphi}_0$. However, since $u(0) = 0$ we also have $\mathcal{U}u(0) = 0$, so that the multiple is 0, and thus $\inf\operatorname{supp}\mathcal{U}u \geq g(a)$. A similar reasoning applied to $\mathcal{U}^{-1}$ proves the other direction.

We have now verified that $\mathcal{U}$ and $\mathcal{U}^{-1}$ both have the properties required in Lemma 4.9. This implies that there is a nonvanishing function f so that

$$u(x) = f(x)\mathcal{U}u(g(x)). \tag{4.3}$$

We must have f real-valued since $\mathcal{F}$ and $\breve{\mathcal{F}}^{-1}$, and thus $\mathcal{U}$, map real-valued functions to real-valued functions. We note that (4.2) implies that $f(0) = 1$ if $\alpha = \breve{\alpha} = 0$ and $f(0) = \frac{\sin\alpha}{\sin\breve{\alpha}} > 0$ if $\alpha \neq 0 \neq \breve{\alpha}$. Now choose $\mathcal{U}u = 1$ in a neighborhood of $g(x)$. We then have $u = f$ in a neighborhood of x. Since $u \in \mathcal{H}$ is locally absolutely continuous, so is f. This also implies that f is strictly positive, since it cannot change sign and $f(0) > 0$. Similarly, choosing $\mathcal{U}u$ linear in a neighborhood of $g(x)$ it follows that also g is locally absolutely continuous.

According to Lemma 3.11 $\mathcal{U}\psi(\cdot,\lambda) = \breve{\psi}(\cdot,\lambda)$, so we have $\psi(x,\lambda) = f(x)\breve{\psi}(g(x),\lambda)$. Taking the logarithmic derivative we obtain

$$\frac{\psi'(x,\lambda)}{\psi(x,\lambda)} = \frac{f'(x)}{f(x)} + g'(x)\frac{\breve{\psi}'(g(x),\lambda)}{\breve{\psi}(g(x),\lambda)}.$$

Here the left member and the coefficient for $g'(x)$ are locally absolutely continuous, and the coefficient for $g'(x)$ is not independent of λ by Lemma 4.10. It follows that g' and f' are locally absolutely continuous, and differentiating, using the differential equations, we obtain

$$-\frac{f''}{f} + q - (g')^2\breve{q}\circ g - \lambda(w - (g')^2\breve{w}\circ g) = \frac{(f^2g')'}{f^2}\,\frac{\breve{\psi}'(g(\cdot),\lambda)}{\breve{\psi}(g(\cdot),\lambda)}.$$

Here the right member is $o(|\lambda|)$ according to Lemma 4.10 so the coefficient of λ to the left vanishes. On the other hand, the right member is not independent of λ unless $(f^2g')' = 0$, so that we obtain

$$\breve{q}\circ g = \frac{1}{f(g')^2}(-f'' + qf),$$

$$\breve{w}\circ g = (g')^{-2}w,$$

$$f^2g' = C$$

for some constant C. Evaluating (4.3) and its derivative at 0 for $u = \psi(\cdot,\lambda)$ elementary calculations now shows[3] that $C = 1$ and $f'(0) = 0$. One also deduces that either $\alpha = \breve{\alpha}$ or else $0 < \alpha = \pi/2 - \breve{\alpha} < \pi/2$ or $\pi/2 < \alpha = 3\pi/2 - \breve{\alpha} < \pi$. In these calculations one uses that $\breve{m}$ is not a Möbius transform, which is clear since this would give

[3]See the appendix.

a transform space of dimension 1. This can only happen if w, and $d\rho$, is a point mass. □

Finally we have to prove Corollary 4.6.

Proof of Corollary 4.6. The function $\tilde{f} = -\varphi_0$ solves $-\tilde{f}'' + q\tilde{f} = 0$ with initial data $\tilde{f}(0) = 1$, $\tilde{f}'(0) = 0$. Since $q \geq 0$ this solution is strictly positive on $[0, b)$, so we may put $\tilde{g}(x) = \int_0^x 1/\tilde{f}^2$. The pair of functions $\tilde{f}$, $\tilde{g}$ gives us a Liouville transform F_0 mapping $[0, b)$ onto some interval $[0, c)$ and $[0, \breve{b})$ onto $[0, \breve{c})$, and transforming the equations into $-u_0'' = \lambda w_0 u_0$ and $-\breve{u}_0'' = \lambda \breve{w}_0 \breve{u}_0$, respectively. Thus $F_0 F F_0^{-1}$, where F is the Liouville transform of Theorem 4.4, transforms one of these equations into the other.

Being a composition of Liouville transforms this is itself a Liouville transform given, say, by $u_0(x) = f_1(x)\breve{u}_0(g_1(x))$. By construction we obtain $f_1(0) = f(0)$, $f_1'(0) = 0$, and $f_1^2 g_1' \equiv 1$. Since both potentials are identically 0 it follows that $f_1'' = 0$. This means that $f_1 \equiv f(0)$ and $g_1(x) = x/(f(0))^2$.

If $\alpha = \breve{\alpha}$, then by Theorem 4.4 $f(0) = 1$ so that $F_0 F F_0^{-1}$ is the identity, implying that also F is the identity. Similarly, if $b = \breve{b}$, then $c = \breve{c}$ so that $f(0) = 1$, unless $c = \breve{c} = \infty$. We will show that c is always finite, and then it again follows that F is the identity.

Now $c = \int_0^b 1/\tilde{f}^2$, so we need to show that this integral is finite. Put $H = \tilde{f}'\tilde{f}$ which will be strictly positive sufficiently close to b by (2.4).

Differentiating $H' = (\tilde{f}')^2 + \tilde{f}''\tilde{f} = (\tilde{f}')^2 + q\tilde{f}^2 \geq (\tilde{f}')^2$. Thus $1/\tilde{f}^2 = (\tilde{f}')^2/H^2 \leq H'/H^2$ so that $\int_d^b 1/\tilde{f}^2 \leq 1/H(d) < \infty$ if d is sufficiently close to b. This completes the proof. □

5. The Paley–Wiener theorem. The proof of Theorem 4.8 relies on the following lemma, which is taken from [3, Theorem 6.1, Corollary 6.2].

LEMMA 5.1. *The following asymptotic formulas hold, locally uniformly for* $\lambda \in \mathbb{C} \setminus \mathbb{R}$ *and* $x > 0$. *The square root refers to the branch with positive real part:*

$$\lim_{t\to\infty} t^{-1} \ln \varphi(x, t^2\lambda) = \int_0^x \sqrt{-\lambda w},$$

$$\lim_{t\to\infty} t^{-1} \ln \psi(x, t^2\lambda) = -\int_0^x \sqrt{-\lambda w}.$$

The next lemma implies the simple direction of Theorem 4.8.

LEMMA 5.2. *Suppose* $u \in \mathcal{H}$ *and* $\operatorname{supp} u \subset [0, a]$. *Then* $\hat{u}(\lambda)$ *is entire of order* $\leq 1/2$ *and* $\hat{u}(\lambda) = o(|\lambda\varphi(a + \varepsilon, \lambda)|)$ *for every* $\varepsilon > 0$ *as* $\lambda \to \infty$ *along any nonreal ray originating at the origin.*

Proof. For finite u we have $\langle u, \varphi(\cdot, \overline{\lambda})\rangle = -u(0)\cos\alpha + \int_0^b u\lambda\varphi(\cdot, \lambda)w$. Now write

$$\hat{u}(\lambda) = -u(0)\cos\alpha + \lambda\varphi(a + \varepsilon, \lambda)\int_0^a u\varphi(\cdot, \lambda)w/\varphi(a + \varepsilon, \lambda).$$

The function $\varphi(x, \lambda)/\varphi(a + \varepsilon, \lambda)$ tends to zero uniformly for $x \in [0, a]$ and $\lambda\varphi(a + \varepsilon, \lambda) \to \infty$ according to Lemma 5.1 as $\lambda \to \infty$ along a nonreal ray. The lemma follows. □

The hard direction of Theorem 4.8 follows from the next lemma.

LEMMA 5.3. *Suppose* $u \in \mathcal{H}$, *that* $\hat{u}$ *has an entire continuation of order* $\leq 1/2$, *and that* $\hat{u}(\lambda) = \mathcal{O}(1/|\psi(a, \lambda)|)$ *as* $\lambda \to \infty$ *along two different nonreal rays originating at the origin. Then* $\operatorname{supp} u \subset [0, a]$ *and* $\hat{u}(\lambda) = \langle u, \overline{\varphi(\cdot, \lambda)}\rangle$.

Proof. Let $\varepsilon > 0$ and consider $F(\lambda) = \langle R_\lambda u, v\rangle - \hat{u}(\lambda)\langle\psi(\cdot,\lambda), v\rangle$, where $v = G_0(wf)$ and $f \in \mathcal{H}$ has compact support in $(a+\varepsilon, b)$. In particular $v \in D_T$. We shall show that F has an entire continuation of order $\leq 1/2$ which tends to 0 along the given rays. By the Phragmén–Lindelöf principle it follows that F is bounded everywhere and is therefore constant by Liouville's theorem, thus actually identically 0.

Now $F(\lambda) = \int_0^b (R_\lambda u - \hat{u}(\lambda)\psi(\cdot,\lambda))\overline{f}w$ so, arguing like in the proof of Proposition 2.3, it follows that $R_\lambda u - \hat{u}(\lambda)\psi(\cdot,\lambda)$ has support in $[0, a+\varepsilon]$. Applying the differential equation it follows that also u has support in $[0, a+\varepsilon]$. Since $\varepsilon > 0$ is arbitrary, in fact u has support in $[0,a]$. For $x > a$ the formula (2.7) gives $R_\lambda u(x) = \psi(x,\lambda)\langle u, \overline{\varphi(\cdot,\lambda)}\rangle$ so that $\psi(x,\lambda)(\hat{u}(\lambda) - \langle u, \overline{\varphi(\cdot,\lambda)}\rangle) = 0$. The lemma follows from this.

To prove that F is entire, Parseval's formula and Lemma 3.11 show that

$$F(\lambda) = \int_{-\infty}^{\infty} \frac{\hat{u}(t) - \hat{u}(\lambda)}{t-\lambda}\,\overline{\hat{v}(t)}\,d\rho(t).$$

It is obvious that this is an entire function, at least if we can bound the integrand properly. To do this and see that the order is at most $1/2$, note that for $|t-\lambda| \leq 1$ we may estimate the integrand by $\sup_{|z|\leq 1}|\hat{u}'(\lambda+z)||\hat{v}(t)|$. For $|t-\lambda| > 1$ we may estimate the integrand by $|\hat{u}(t)\hat{v}(t)| + |\hat{u}(\lambda)||\hat{v}(t)|$. Hence we have locally uniformly dominated convergence of the integral and

$$|F(\lambda)| \leq \|u\|\|v\| + (\sup_{|z|\leq 1}|\hat{u}'(\lambda+z)| + |\hat{u}(\lambda)|)\int_{-\infty}^{\infty}|\hat{v}|d\rho,$$

which is the required estimate, the integral being finite by Corollary 3.8 and $\hat{u}$ and therefore $\hat{u}'$ being of order $\leq 1/2$.

Finally, to show that F tends to 0 along the rays, we first note that $\psi(x,\lambda)/\psi(a,\lambda)$ converges to 0 uniformly for $x \in [a+\varepsilon, b)$, according to Lemma 5.1. Assuming f has compact support in $[a+\varepsilon, b)$ we obtain $\int_0^b \psi(\cdot,\lambda)\overline{f}w = o(|\psi(a,\lambda)|)$. Since $R_\lambda \to 0$ strongly as $\operatorname{Im}\lambda \to \infty$, it follows that F tends to 0 along the given rays. This finishes the proof. □

Theorem 4.8 is a simple consequence of these lemmas.

Proof of Theorem 4.8. If $\operatorname{supp} u \subset [0,a]$, it follows from Lemmas 5.2 and 5.1 that $\hat{u}(\lambda) = \langle u, \varphi(\cdot,\overline{\lambda})\rangle$ is an entire continuation of $\hat{u}$ of order $\leq 1/2$ such that

$$\limsup_{t\to\infty} t^{-1}\ln|\hat{u}(t^2\lambda)| \leq \lim_{t\to\infty} t^{-1}\ln|\varphi(a+\varepsilon, t^2\lambda)| = \int_0^{a+\varepsilon} \operatorname{Re}\sqrt{-\lambda w}$$

for nonreal λ and all $\varepsilon > 0$.

On the other hand, suppose there is an entire continuation of $\hat{u}$ of order $\leq 1/2$ and such that

$$\limsup_{t\to\infty} t^{-1}\ln|\hat{u}(t^2\lambda)| \leq \int_0^a \operatorname{Re}\sqrt{-\lambda w}$$

for λ on two different rays from the origin. If one or both of these are real, an immediate application of the Phragmén–Lindelöf principle shows this to be true for all other rays as well, so we may assume them nonreal. By Lemma 5.1 this implies that $\hat{u}(\lambda) = \mathcal{O}(|\psi(a+\varepsilon,\lambda)|^{-1})$ for large λ on these rays if $0 < \varepsilon < b-a$. Lemma 5.3 now shows that $\operatorname{supp} u \subset [0, a+\varepsilon]$ for small $\varepsilon > 0$ and thus for $\varepsilon = 0$. The uniqueness

of the continuation also follows from Lemma 5.3. If we have strict inequality on one ray, a simple argument using the Phragmén–Lindelöf principle (see [4, Lemma 3.6]) shows this to hold on all nearby rays as well, so that in fact $\sup \operatorname{supp} u < a$. The proof is now complete. □

6. Inverse scattering on the half-line. In this section we will show that scattering data for the half-line problem determines the coefficient w if q is known. We will of course have to assume that our equation is sufficiently close to a model equation, which, as usual, has constant coefficients.

Thus we consider (1.3) on $[0,\infty)$ with the following additional assumption, which will be in force throughout this section.

Assumption 6.1. There is a constant $q_0 \geq 0$ such that $q(x) - q_0$ and $w(x) - 1$ are both in $L^1(0,\infty)$.

Note that according to Theorems 2.5 and 2.6 finite functions are dense in $\mathcal{H}_1$ and, given the boundary condition (2.6), there is a unique self-adjoint realization T of (1.3) in $\mathcal{H}_1$.

We will need the following standard result.

PROPOSITION 6.2. *For* $\operatorname{Im} k \geq 0$, $k \neq 0$, *there exists a solution* $f(\cdot,k)$ *of* (1.3) *with* $\lambda = k^2 + q_0$ *having the following properties:* (1) $f(x,\cdot)$ *and* $f'(x,\cdot)$ *are analytic for* $\operatorname{Im} k > 0$ *and continuous for* $\operatorname{Im} k \geq 0$, $k \neq 0$; (2) $f(x,k) \sim e^{ikx}$ *and* $f'(x,k) \sim ike^{ikx}$ *as* $x \to \infty$.

This is standard. It is easily proved by first writing the equation for $g(x,k) = f(x,k)e^{-ikx}$ as $g'' + 2ikg' = (q - q_0 - (k^2 + q_0)(w-1))g$ and then solving this equation by successive approximations from its desired initial values $g(\infty) = 1$, $g'(\infty) = 0$ at ∞ using the estimate $|e^{2ik(t-x)} - 1| \leq 2$. See, for instance, Deift and Trubowitz [19].

If $\operatorname{Im} k > 0$, then $f(\cdot,k) \in \mathcal{H}_1$. Thus, if $\lambda \notin \mathbb{R}$ (*i.e.*, also $\operatorname{Re} k \neq 0$), then

$$f(x,k) = F(k)\psi(x,\lambda)$$

for some function F defined in $\operatorname{Im} k > 0$, $\operatorname{Re} k \neq 0$.

Let $[u,v] = u'v - uv'$ denote the Wronskian of the functions u and v and recall that Wronskians of solutions to (1.3) are independent of x. Since

$$[\lambda\varphi(\cdot,\lambda), f(\cdot,k)] = F(k)[\lambda\varphi(\cdot,\lambda), \psi(\cdot,\lambda)] = F(k) \tag{6.1}$$

is analytic for $\operatorname{Im}(k) > 0$ we find that F is analytic and can be extended analytically to the positive imaginary axis. Moreover, since $[\lambda\varphi(\cdot,\lambda), f(\cdot,k)]$ is continuous in $\operatorname{Im}(k) \geq 0$, $k \neq 0$, the function F extends continuously to the positive and negative real line. The zeros of F are located exactly where φ and f are linearly dependent, *i.e.*, when $\lambda = q_0 + k^2$ is an eigenvalue.

Equation (6.1) gives also that $F(-k) = \overline{F(k)}$ for real $k \neq 0$ and that F has no zeros on either the positive or the negative real line since $\varphi(\cdot,\lambda)$ is real for real λ and the real and imaginary parts of $f(x,k) \sim e^{ikx}$ are linearly independent.

For $k > 0$ and thus $\lambda = k^2 + q_0 > q_0$ define

$$\psi_\pm(\cdot,\lambda) = \lim_{\epsilon \to 0} \psi(\cdot, (\pm k + i\epsilon)^2 + q_0)$$

and

$$m_\pm(\lambda) = \lim_{\epsilon \to 0} m((\pm k + i\epsilon)^2 + q_0).$$

Since $\overline{m(\lambda)} = m(\overline{\lambda})$ when λ is not real we find that $m_+(\lambda) = \overline{m_-(\lambda)}$ when λ is real. Therefore

$$\frac{2ik\lambda}{|F(k)|^2} = \lambda[\psi_+(\cdot,\lambda), \psi_-(\cdot,\lambda)] = m_+(\lambda) - m_-(\lambda) = 2i \operatorname{Im} m_+(\lambda)$$

when $k > 0$ so that $\lambda > q_0$. This in turn implies

$$\pi\rho'(\lambda) = \operatorname{Im} m(\lambda + i0) = \frac{k\lambda}{|F(k)|^2}$$

for $\lambda > q_0$. Thus the restriction of F to the positive real line determines the spectral measure on the interval (q_0, ∞). It follows from this that the spectrum of T is absolutely continuous[4] in (q_0, ∞).

In the interval $(-\infty, q_0)$, where λ corresponds to the positive half of the imaginary axis for k, the spectrum is discrete since F is analytic there. There might also be an eigenvalue for $k = 0$, $\lambda = q_0$. Suppose $\lambda \neq 0$ is an eigenvalue. Then $\varphi(\cdot,\lambda)$ is a corresponding eigenfunction, and its Fourier transform $\hat{\varphi}(\lambda)$ is a multiple of the characteristic function of the set $\{\lambda\}$. The inversion formula (3.1) gives $\varphi(x,\lambda) = \hat{\varphi}(\lambda)\varphi(x,\lambda)\rho\{\lambda\}$, where $\rho\{\lambda\}$ is the spectral measure of the set $\{\lambda\}$. Thus $\hat{\varphi}(\lambda) = 1/\rho\{\lambda\}$. Parseval's formula gives $\|\varphi(\cdot,\lambda)\|^2 = |\hat{\varphi}(\lambda)|^2\rho\{\lambda\} = 1/\rho\{\lambda\}$. On the interval $(-\infty, q_0]$ we therefore know the spectral measure if we know all eigenvalues λ and the corresponding *normalization constants* $\|\varphi(\cdot,\lambda)\|^2$. Similarly, if $\alpha = 0$, then by Lemma 3.5 also $\lambda = 0$ is an eigenvalue, and $1/\rho\{0\}$ is the normalization constant for the eigenfunction ψ_0. We obtain the following theorem.

THEOREM 6.3. *Given the absolute value of the coefficient $F(k)$ for positive k, all eigenvalues, the corresponding normalization constants, and either q or $|w|$, the coefficients q and w and the boundary value parameter α are uniquely determined.*

Proof. We have already seen that the given data determine the spectral measure, and may now apply Corollaries 4.5 and 4.6 to draw the desired conclusion. □

7. Eigenvalues. This section is devoted to the proof of the following theorem. Part of the proof is an adaptation of Marchenko [25].

THEOREM 7.1. *Assume that q and w satisfy Assumption* 6.1. *Then we have the following:*

(1) *The eigenvalues of T are isolated and can accumulate only at q_0 or negative infinity.*
(2) *There will be infinitely many negative eigenvalues if and only if w is negative on a set of positive measure.*

If in addition we have $\int_0^\infty t|q(t) - q_0 w(t)|dt < \infty$, we also have the following:

(3) *Eigenvalues will not accumulate at q_0.*
(4) *q_0 is not an eigenvalue unless $q_0 = 0$ and $\alpha = 0$.*

To prove this we need the following strengthening of Proposition 6.2.

PROPOSITION 7.2. *Suppose q and w satisfy Assumption* 6.1 *and the integral $\int_0^\infty t|q(t) - q_0 w(t)|dt$ is finite. Then, for every $x \in [0,\infty)$, the function $f(x,\cdot)$ and its x-derivative, which were previously defined for $\operatorname{Im}(k) \geq 0$, $k \neq 0$, extend continuously to $k = 0$.*

The additional assumption and the improved estimate

$$|e^{2ik(t-x)} - 1| \leq \min(2|k|t, 2)$$

[4] For $q_0 < s < t$ we have $\int_s^t \operatorname{Im} m(\mu + i\varepsilon)\, d\mu \to \pi(\rho(t) - \rho(s))$ as $\varepsilon \downarrow 0$. But the left-hand side converges to $\int_s^t \operatorname{Im} m(\mu + i0)\, d\mu$ so ρ is absolutely continuous.

allow us to perform the successive approximations also near $k = 0$. The proposition follows from this.

Proof of Theorem 7.1. If $\mu = k^2 + q_0 < q_0$ is an eigenvalue of T, then, since F is analytic in the upper half-plane, eigenvalues are isolated and hence cannot accumulate at any point in $(-\infty, q_0)$. This proves (1).

To prove the second statement we make first the assumption that $q_0 > 0$ and $\alpha \neq 0$. By Lemma 3.5 zero is then not in the spectrum of T so that the range of T is $\mathcal{H}$ and we may define a bilinear form Q on $\mathcal{H}$ by setting

$$Q(u, v) = \int_{\mathbb{R}} \frac{1}{t} \hat{u}(t)\overline{\hat{v}(t)} d\rho(t).$$

Note that $Q(u, v) = 0$ if the supports of $\hat{u}$ and $\hat{v}$ do not intersect, which happens, for instance, if u and v are eigenvectors for different eigenvalues. Furthermore, by Lemma 3.7 $Q(u, Tv) = \int_{\mathbb{R}} \hat{u}(t)\overline{\hat{v}(t)} d\rho(t) = \langle u, v\rangle$. An integration by parts gives

$$\int_0^x (u'\overline{v'} + qu\overline{v}) = u(x)\overline{v'(x)} - u(0)\overline{v'(0)} + \int_0^x wu\overline{Tv}$$

for $u \in \mathcal{H}$ and $v \in D_T$. Hence if v is in the range of T and u is finite, or if u and v are exponentially decaying eigenfunctions, then we obtain

$$Q(u, v) = \int_0^\infty wu\overline{v} + \cot(\alpha) u(0)\overline{v(0)} \tag{7.1}$$

taking into account the boundary condition satisfied by $(T^{-1}v, v)$.

Now assume that $w \geq 0$. If $\cot(\alpha) \geq 0$, there can be no negative eigenvalue since $Tv = \lambda v$, $\lambda < 0$, $\|v\| \neq 0$ would imply that

$$0 \leq \int_0^\infty w|v|^2 + \cot\alpha |v(0)|^2 = \frac{1}{\lambda} Q(v, Tv) = \frac{1}{\lambda}\|v\|^2 < 0,$$

giving a contradiction. If $\cot\alpha < 0$, there can be at most one negative eigenvalue as we shall show now. If there were two distinct negative eigenvalues λ_1 and λ_2 with associated eigenvectors v_1 and v_2, we could assume that $v_1(0) = v_2(0)$. This would entail that

$$0 \leq \int_0^\infty w|v_1 - v_2|^2 = Q(v_1 - v_2, v_1 - v_2) = Q(v_1, v_1) + Q(v_2, v_2) < 0$$

since eigenfunctions decay exponentially so that we are allowed to employ (7.1).

Next assume $w < 0$ on a set of positive Lebesgue measure. We shall show that there are infinitely many negative eigenvalues. For any integer n one can choose elements $u_1, \ldots, u_n$ in $\mathcal{H}$, compactly supported in $(0, \infty)$, such that $Q(u_j, u_j) < 0$ and $Q(u_j, u_k) = 0$ if $j \neq k$. To achieve this one may for instance choose first bounded sets $A_1, \ldots, A_n$ of positive measure and positive distances from zero and each other on which w is negative. Then one lets u_j be a suitable mollification of the characteristic function of A_j. Equation (7.1) now guarantees that they have the desired properties.

Thus $Q(u, u) < 0$ whenever u is in the linear span B of $u_1, \ldots, u_n$. Let P be the orthogonal projection of B into the negative spectral subspace of $\mathcal{H}$, *i.e.*, $Pu = \mathcal{F}^{-1}(u\chi)$, where χ is the characteristic function of $(-\infty, 0)$. Suppose now that n is

larger than the number of negative eigenvalues. Then the kernel of P cannot be trivial so that there is a nontrivial $u \in B$ such that $\hat{u}$ is supported in $[0, \infty)$. Hence

$$0 > Q(u,u) = \int_{\mathbb{R}} \frac{1}{t} |\hat{u}(t)|^2 d\rho(t) \geq 0.$$

Since this is impossible the number of negative eigenvalues must be infinite.

If we only have $q_0 \geq 0$, but still $\alpha \neq 0$, then Q remains defined for functions u, v with Fourier transforms bounded near 0, since in this case $1/t \in L^2_\rho$ by Lemma 3.11. But the Fourier transforms of eigenfunctions to nonzero eigenvalues are supported away from 0, and the Fourier transform of a finite function is entire and thus locally bounded. Also, u_j is in the range of T. To see this, solve $-y'' + qy = wu_j$ with 0 initial data at a point to the right of $\operatorname{supp} u_j$ which yields a finite function y. Adding an appropriate multiple of ψ_0 (Proposition 2.7) gives a function in D_T. Thus the proof applies also in this case.

Allowing also $\alpha = 0$ the form Q is still defined if $\hat{u}(t)\overline{\hat{v}(t)}/t$ is continuous at 0. This is the case if u and v are eigenfunctions to negative eigenvalues. Also, if u is a finite function orthogonal to the eigenfunction ψ_0, then $\hat{u}(0) = 0$; so Q is defined for such functions. This last condition is just one linear condition on the space B, so the remainder can still have arbitrarily large dimension. All of the u_j are in the range of T, since the boundary condition now reads $u_j(0) = 0$. Thus the proof applies also in this case, and the proof of (2) is finished.

Now assume that $\int_0^\infty t|q(t) - q_0 w(t)|dt$ is finite, and that, contrary to our claim, there is a sequence $\mu_n = k_n^2 + q_0 < q_0$ of eigenvalues converging to q_0. Since eigenfunctions are orthogonal and satisfy the boundary condition an integration by parts shows

$$\int_0^\infty w f(\cdot, k_n)\overline{f(\cdot, k_m)} = -f(0, k_n)\overline{f(0, k_m)} \cot \alpha \tag{7.2}$$

if $n \neq m$. If $\alpha = 0$, the right-hand side has to be replaced by zero.

Since $\int_0^\infty t|q(t) - q_0 w(t)|dt < \infty$, our construction of f shows that $f(x,k) \sim e^{ikx}$ as $x \to \infty$, uniformly for $k \in i[0,1]$. This shows first that (7.2) is bounded as n and m tend to infinity, and second that we may find a positive c such that $|f(x,k) - e^{ikx}| \leq e^{-|k|x}/4$ if $x \geq c$, $k \in i[0,1]$. Simple estimates then show that

$$\frac{7}{16} e^{-(|k_n| + |k_m|)x} \leq \operatorname{Re}(f(x,k_n)\overline{f(x,k_m)}) \leq \frac{25}{16} e^{-(|k_n| + |k_m|)x}$$

if n and m are large. Since $w - 1$ is integrable this shows that the integral

$$\int_c^\infty \operatorname{Re}(f(x,k_n)\overline{f(x,k_m)}) w \to +\infty$$

as n, m tend to infinity. Now, since $f(x,k)$ is uniformly continuous on $[0,c] \times i[0,1]$ it follows that the integral over $[0,c]$ is bounded, so the integral over $[0,\infty)$ tends to infinity, contradicting the previously established boundedness and proving (3).

Finally, if $q_0 = 0$, we already know q_0 is an eigenvalue if and only if $\alpha = 0$. On the other hand, if $q_0 > 0$, then $f(\cdot, q_0)$ is asymptotic to 1, and any other solution to (1.3) is asymptotically linear, as is easily seen from the well-known reduction of order method. Thus no such solution is in $\mathcal{H}$ and there is no eigenfunction with eigenvalue q_0. This proves (4). □

Remark 7.3. If we allow w to be a general measure, then the negative part of w could be a finite sum of Dirac measures. In this case one may in the same way show that the number of negative eigenvalues is equal to the number of these Dirac measures if $\alpha \neq 0$, $\cot\alpha \geq 0$, and $q_0 > 0$, with suitable modifications in the other cases.

8. Appendix. Here we present some calculations which were omitted from the proof of Theorem 4.4.

For $x = 0$ the relation $\psi(x,\lambda) = f(x)\breve{\psi}(g(x),\lambda)$ gives

$$\cos\alpha - m(\lambda)\sin\alpha = f(0)\{\cos\breve{\alpha} - \breve{m}(\lambda)\sin\breve{\alpha}\}, \tag{8.1}$$

while $\psi'(x,\lambda) = f'(x)\breve{\psi}(g(x),\lambda) + f(x)g'(x)\breve{\psi}'(g(x),\lambda)$ for $x = 0$ gives

$$\sin\alpha + m(\lambda)\cos\alpha = \frac{f'(0)}{\lambda}\{\cos\breve{\alpha} - \breve{m}(\lambda)\sin\breve{\alpha}\} + \frac{C}{f(0)}\{\sin\breve{\alpha} + \breve{m}(\lambda)\cos\breve{\alpha}\}. \tag{8.2}$$

From (8.1), (8.2) we obtain

$$1 = \left\{f(0)\cos\alpha + \frac{f'(0)}{\lambda}\sin\alpha\right\}\{\cos\breve{\alpha} - \breve{m}(\lambda)\sin\breve{\alpha}\} + \frac{C\sin\alpha}{f(0)}\{\sin\breve{\alpha} + \breve{m}(\lambda)\cos\breve{\alpha}\}$$

and

$$m(\lambda) = \left\{-f(0)\sin\alpha + \frac{f'(0)}{\lambda}\cos\alpha\right\}\{\cos\breve{\alpha} - \breve{m}(\lambda)\sin\breve{\alpha}\} + \frac{C\cos\alpha}{f(0)}\{\sin\breve{\alpha} + \breve{m}(\lambda)\cos\breve{\alpha}\},$$

which after rearranging gives

$$\begin{aligned} 1 - \left(f(0)\cos\alpha + \frac{f'(0)}{\lambda}\sin\alpha\right)\cos\breve{\alpha} - \frac{C\sin\alpha\sin\breve{\alpha}}{f(0)} \\ = \breve{m}(\lambda)\left\{-\left(f(0)\cos\alpha + \frac{f'(0)}{\lambda}\sin\alpha\right)\sin\breve{\alpha} + \frac{C\sin\alpha\cos\breve{\alpha}}{f(0)}\right\} \end{aligned} \tag{8.3}$$

and

$$\begin{aligned} \left(f(0)\sin\alpha - \frac{f'(0)}{\lambda}\cos\alpha\right)\cos\breve{\alpha} - \frac{C\cos\alpha\sin\breve{\alpha}}{f(0)} \\ = \breve{m}(\lambda)\left\{\left(f(0)\sin\alpha - \frac{f'(0)}{\lambda}\cos\alpha\right)\sin\breve{\alpha} + \frac{C\cos\alpha\cos\breve{\alpha}}{f(0)}\right\} - m(\lambda). \end{aligned} \tag{8.4}$$

In (8.3) the left member and the coefficient of $\breve{m}$ are linear in $1/\lambda$, while $\breve{m}(\lambda)$ is not constant or a Möbius transform (this would give a one-dimensional transform space). From (8.3) we therefore obtain

$$\left(f(0)\cos\alpha + \frac{f'(0)}{\lambda}\sin\alpha\right)\cos\breve{\alpha} = 1 - \frac{C\sin\alpha\sin\breve{\alpha}}{f(0)},$$

$$\left(f(0)\cos\alpha + \frac{f'(0)}{\lambda}\sin\alpha\right)\sin\breve{\alpha} = \frac{C\sin\alpha\cos\breve{\alpha}}{f(0)},$$

which gives

$$f(0)\cos\alpha + \frac{f'(0)}{\lambda}\sin\alpha = \cos\breve{\alpha},$$

$$\frac{C\sin\alpha}{f(0)} = \sin\breve{\alpha}.$$

From this it is (again) clear that $\sin\alpha = 0$ if and only if $\sin\breve{\alpha} = 0$, so that we have two cases.

- $\alpha = \breve{\alpha} = 0$. We obtain $f(0) = 1$, and insertion in (8.4) shows that $\frac{f'(0)}{\lambda} = m(\lambda) - C\breve{m}(\lambda)$. The right member is $(1-C)m(\lambda)$ since $m(i\nu)$ and $\breve{m}(i\nu) \to 0$ as $\nu \to +\infty$ by Lemma 4.10, and m, $\breve{m}$ have the same spectral measure. Again by Lemma 4.10 it follows that $C = 1$, and thus $f'(0) = 0$.
- $\alpha \neq 0 \neq \breve{\alpha}$. We obtain $f'(0) = 0$, $f(0) = C\sin\alpha/\sin\breve{\alpha}$, and $C\sin(2\alpha) = \sin(2\breve{\alpha})$. But we know that $f(0) = \sin\alpha/\sin\breve{\alpha}$ so that $C = 1$. Insertion in (8.4) gives $m(\lambda) - \breve{m}(\lambda) = \cot\alpha - \cot\breve{\alpha}$.
  Since $\sin(2\alpha) = \sin(2\breve{\alpha})$ we have either $\alpha = \breve{\alpha}$ or $0 < \alpha = \pi/2 - \breve{\alpha} < \pi/2$ or $\pi/2 < \alpha = 3\pi/2 - \breve{\alpha} < \pi$. If $\alpha = \breve{\alpha}$, we obtain $f(0) = 1$ and $m(\lambda) = \breve{m}(\lambda)$. In the other cases we obtain $f(0) = |\tan\alpha|$ and $m(\lambda) - \breve{m}(\lambda) = 2\cot(2\alpha)$.

ABSOLUTELY CONTINUOUS LAWS OF JUMP-DIFFUSIONS IN FINITE AND INFINITE DIMENSIONS WITH APPLICATIONS TO MATHEMATICAL FINANCE*

BARBARA FORSTER†, EVA LÜTKEBOHMERT‡, AND JOSEF TEICHMANN†

Abstract. In mathematical Finance calculating the Greeks by Malliavin weights has proved to be a numerically satisfactory procedure for finite-dimensional Itô-diffusions. The existence of Malliavin weights relies on absolute continuity of laws of the projected diffusion process and a sufficiently regular density. In this article we first prove results on absolute continuity for laws of projected jump-diffusion processes in finite and infinite dimensions and a general result on the existence of Malliavin weights in finite dimension. In both cases we assume Hörmander conditions and hypotheses on the invertibility of the so-called linkage operators. The purpose of this article is to show that for the construction of numerical procedures for the calculation of the Greeks in fairly general jump-diffusion cases one can proceed as in a pure diffusion case. We also show how the given results apply to infinite-dimensional questions in mathematical Finance. There we start from the Vasiček model, and add—by pertaining no arbitrage—a jump-diffusion component. We prove that we can obtain in this case an interest rate model, where the law of any projection is absolutely continuous with respect to Lebesgue measure on $\mathbb{R}^M$.

1. Introduction.

We shall consider in this article the question of whether the law of $\mathbf{l}(X_t^x)$, for a finite-dimensional projection $\mathbf{l} : H \to \mathbb{R}^M$, is absolutely continuous with respect to Lebesgue measure on $\mathbb{R}^M$, where X_t^x is the solution of the stochastic (partial) differential equation (SPDE)

$$dX_t^x = (AX_{t^-}^x + \alpha(X_{t^-}^x))dt + \sum_{i=1}^{d} V_i(X_{t^-}^x)dB_t^i + \sum_{j=1}^{m} \delta_j(X_{t^-}^x)dL_t^j, \tag{1.1}$$

$$X_0^x = x \in H \tag{1.2}$$

and H is a possibly infinite-dimensional separable Hilbert space. We refer to the previous equation loosely speaking as a jump-diffusion on the Hilbert space H, pointing out that the involved Lévy processes are of finite type. For sake of simplicity we shall always work with the cadlag integrand $t \mapsto X_{t^-}^x$, even though for the dt and dB_t integrals this is superfluous. In the infinite-dimensional setting we are not aware of results on absolute continuity of the projected process in the jump-diffusion case.

Related work has been done in [5] for the construction of first variation processes. In the diffusion case we refer the reader to the work [3] and the references therein and in particular to the recently published inspiring results of Jonathan Mattingly; see, for instance [1]. We point out that we deal here with SPDEs and stochastic differential equations (SDEs) at the same time, where the latter case appears in this setting when the state (Hilbert) space H is finite-dimensional.

Very satisfying results in the finite-dimensional setting with Lévy processes of infinite type have been obtained in [11] through a generalization of the Norris lemma to Lévy processes. These results have been built upon our results presented in this work for the finite activity case (see section 7). Substantial work with respect to absolute continuity and smoothness of the density has already been published in the 1980s, the most prominent being [7] and [6]. Therein several questions of extension of hypoellipticity results (and Malliavin Calculus) to jump-processes are discussed and completely solved; however, the problem of a hypoelliptic diffusion together with a finite-activity jump-structure remained open. It has to be pointed out here that—in contrast to [6]—we do not need any extension of Malliavin Calculus to jump-processes for our results (see also the discussion in Remark 5). This gap was filled by the announced results of [27], but several proofs therein are extremely short. Recently, motivated by questions from financial mathematics (see section 8 for an outline of the problem), there has been increasing interest in those results; see the works [2], [13], [14], and the references therein. This article aims to work out the most general finite activity case under Hörmander conditions on the diffusion part.

From the point of view of existence and uniqueness for jump-diffusions in infinite dimensions, our main reference is [15] and the references therein. Since we consider jump-diffusions as concatenated diffusions on Hilbert space, we mention [12] as the main reference for existence and uniqueness results but also [4] and [10] for many interesting constructions and ideas.

There are two applications added to this work. The first is the Heath–Jarrow–Morton (HJM) equation (as presented in [15]), where we show that the innocent Vasiček model (see, for instance, the seminal work [9]) with a certain jump-structure triggered by a one-dimensional Poisson process yields, under no-arbitrage assumptions, a model where not only do no finite-dimensional realizations exist but also where every projection into a finite-dimensional subspace admits a density (compare with the notion of generic interest rate evolutions from [3]). The second application is concerned with concrete formulas for the calculation of Malliavin weights. There our message is that one can think Poisson-trajectory–wise; i.e., the results from [18] or [17] can be literally applied by replacing the diffusion process by the respective jump-diffusion process.

When we analyze jump-diffusions with values in Hilbert spaces, loosely speaking the following facts hold true:

- Between two consecutive jumps of the jump-diffusion we are given an ordinary diffusion.
- At a jump we add to the left limit the jump size (which usually depends on the left limit, too). In [25, Chapter V.10, Hypothesis (H3)], this operation is formalized by the so-called *linkage operators* $x \mapsto x + \mu\delta^j(x)$, which encode what happens at a jump of size μ at x. We shall apply this notion here, too.

Hence the following picture arises:

- In order to obtain absolute continuity of the projected diffusion process, we need the Hörmander condition to be in force. Otherwise we cannot expect—

conditioned on the event of positive probability that no jump occurs—that the law of $\mathbf{l}(X_t^x)$ is absolutely continuous with respect to Lebesgue measure.
- In order to preserve absolute continuity we need the linkage operators to be invertible in a proper sense.

Remark 1. Both conditions are "sine qua non," since it is easy to imagine counterexamples.

In section 2 we fix the general setting of this article. We shall deal with Lévy processes of finite type as drivers of the SDEs, even though we believe that one should be able to prove similar results in the case of many small jumps, too. We also state the main assumptions of this work in section 2 for later use.

In section 3 we state a "folklore" decomposition theorem, which tells that solving a jump-diffusion S(P)DE is the same as solving associated diffusion S(P)DEs and concatenating the solutions by linkage operators at jumps. In section 4 we show that we can also prove results on first variation processes in the spirit of the decomposition theorem. We prove that under our analytic requirements there is in fact a sufficiently regular first variation process.

In section 5 we show by means of Malliavin calculus for a d-dimensional Brownian motion that the law of a projected jump-diffusion is absolutely continuous with respect to Lebesgue measure. In section 6 we introduce a class of examples from mathematical Finance, where we see very directly the phenomenon of absolute continuity arising from the introduction of jumps and the no-arbitrage condition. This shows again that finite-dimensional realizations, as constructed, for instance, in [8], are a rare case in infinite dimensions. In section 7 we restrict our attention to the finite-dimensional setting to show that the density of the absolutely continuous law is in fact smooth by proving that the inverse of the covariance matrix has pth moments for all $p \geq 1$. In section 8 we apply the invertibility of the covariance matrix to the calculation of Greeks. The appendix shows an important estimate implicitly present in the Norris lemma as presented in Nualart's book [24]. A similar result (which could be directly used in section 7 for the proof of the main theorem) can be found in [21, Corollary 3.25]. The article [21] is most likely the source of the first appearance of the precise polynomial time-dependence in the estimate of the L^p-norm of the inverse of the covariance matrix. We have been choosing here the path via the Norris lemma; we explain the estimate by redoing its proof in the appendix.

2. Setting and assumptions. Let $(\Omega, \mathcal{F}, P, (\mathcal{F}_t)_{t\geq 0})$ be a filtered probability space where the filtration $(\mathcal{F}_t)_{t\geq 0}$ satisfies the usual conditions. Let $(B_t)_{t\geq 0}$ be a d-dimensional Brownian motion and $(L_t^j)_{t\geq 0}$, $j = 1, \ldots, m$, be m independent compound Poisson processes given by

$$L_t^j := \sum_{k=1}^{N_t^j} Z_k^j,$$

where N_t^j denotes a Poisson process with jump intensity $\widetilde{\lambda_j} > 0$ and $Z^j = (Z_k^j)_{k\geq 1}$ is an independently and identically distributed sequence of random variables with distribution μ_j for $j = 1, \ldots, m$ such that each μ_j admits all moments. The compensated compound Poisson process reads as

$$L_t^j - E(L_t^j) = L_t^j - \lambda_j t,$$

where $\lambda_j = E(Z_1^j)\widetilde{\lambda_j}$ is the average jump size times the jump rate.

We could equally take an $\mathbb{R}^m$-valued Lévy process of finite type, i.e., introduce a dependence structure between the jumps of the components, and all theorems would equally hold true with slightly modified proofs, but we believe that this generalization does not bring further insight.

We assume that all sources of randomness are mutually independent and that the filtration $(\mathcal{F}_t)_{t\geq 0}$ is the natural filtration with respect to $(B_t, L_t^1, \ldots, L_t^m)_{t\geq 0}$. Let H be a separable Hilbert space. We fix furthermore a strongly continuous semigroup S on H with generator A. Let $\alpha, V_1, \ldots, V_d$, the diffusion vector fields, and $\delta_1, \ldots, \delta_m$, the jump vector fields, be C^∞-bounded on H; that is, the vector fields are infinitely often differentiable with bounded partial derivatives of all proper orders $n \geq 1$. We consider the mild cadlag solution $(X_t^x)_{t\geq 0}$ of an SDE

$$dX_t^x = (AX_{t^-}^x + \alpha(X_{t^-}^x))dt + \sum_{i=1}^{d} V_i(X_{t^-}^x)dB_t^i + \sum_{j=1}^{m} \delta_j(X_{t^-}^x)dL_t^j, \tag{2.1}$$

$$X_0^x = x \in H. \tag{2.2}$$

See [15] for all necessary details on existence and uniqueness of the previous equation.

The previous conditions are slightly more than standard for existence and uniqueness of mild solutions; i.e., in [15] the authors need Lipschitz conditions on the vector fields, whereas we assume them to be C^∞-bounded. In order to speak about absolute continuity of projections to $\mathbb{R}^M$ we shall need more assumptions; in particular, for conclusions drawn from the geometry of the given vector fields $\alpha, V_1, \ldots, V_d, \delta_1, \ldots, \delta_m$ several quite strong analytic requirements are necessary. We group the assumptions into three groups and indicate in each section which assumptions we shall need.

Let $\mathbf{l} : H \to \mathbb{R}^M$ be a projection; then we want to know whether the law of $\mathbf{l}(X_t^x)$ is absolutely continuous with respect to Lebesgue measure and if the density is smooth. Following the short discussion in the introduction, we need the Hörmander conditions to be in force, and we need to suppose invertibility on linkage operators.

We apply the following notation for Hilbert spaces $\mathrm{dom}(A^k)$:

$$\begin{aligned} \mathrm{dom}(A^k) &:= \left\{h \in H \,|\, h \in \mathrm{dom}(A^{k-1}) \text{ and } A^{k-1}h \in \mathrm{dom}(A)\right\}, \\ ||h||^2_{\mathrm{dom}(A^k)} &:= \sum_{i=0}^{k} ||A^i h||^2, \\ \mathrm{dom}(A^\infty) &= \bigcap_{k\geq 0} \mathrm{dom}(A^k), \end{aligned}$$

which we need in order to specify the analytic conditions.

ASSUMPTION 1. *We assume that the generator A of S generates a* strongly continuous group. *We assume furthermore that $\alpha, V_1, \ldots, V_d$, the diffusion vector fields, and $\delta_1, \ldots, \delta_m$, the jump vector fields, are C^∞-bounded on the Hilbert spaces* $\mathrm{dom}(A^k)$ *for $k \geq 0$; that is, the vector fields are infinitely often differentiable with bounded partial derivatives of all proper orders $n \geq 1$ on the Hilbert space* $\mathrm{dom}(A^k)$ *for $k \geq 0$.*

ASSUMPTION 2. *We take Assumption* 1 *for granted; i.e., we can consider all vector fields on the space* $\mathrm{dom}(A^k)$ *for $k = 0, \ldots, \infty$. For a proper statement of the Hörmander condition we apply the "geometrically relevant" drift*

$$V_0(x) = Ax + \alpha(x) - \frac{1}{2}\sum_{i=1}^{d} \mathrm{T}\, V_i(x) \cdot V_i(x)$$

for $x \in \mathrm{dom}(A)$ and call V_0 the Stratonovich drift of the diffusion. Recall the (tangent) directional derivative operator T *defined through*

$$\mathrm{T}\,V(x)\cdot v = \frac{d}{d\epsilon}\Big|_{\epsilon=0} V(x+\epsilon v).$$

Lie brackets can only be calculated on the Fréchet space $\mathrm{dom}(A^\infty)$ and there we formulate the Hörmander condition. We assume that the distribution $\mathcal{D}(x)$ generated by the vector fields

$$\begin{aligned} &V_1(x),\dots,V_d(x), \quad [V_i(x),V_j(x)]\ (i,j=0,1,\dots,d),\\ &[V_i(x),[V_j(x),V_k(x)]]\ (i,j,k=0,1,\dots,d),\dots \end{aligned} \tag{2.3}$$

is dense in H for one $x \in \mathrm{dom}(A^\infty)$.

ASSUMPTION 3. *We assume that the inverse of $x \mapsto x + z\delta_j(x)$ exists and is C^∞-bounded on each $\mathrm{dom}(A^k)$ for $z \in \mathrm{supp}(\mu_j)$, $j = 1,\dots,m$, and $k \geq 0$ (recall that μ_j was the distribution of the random variable Z_j).*

Remark 2. As far as Assumption 1 is concerned, we do believe that the assertions of this paper also hold true for (most) strongly continuous semigroups. A proof based on an application of the Szőkefalvi–Nagy theorem can be found in the recent preprint [26]; therefore, we could replace the assumption that A generates a strongly continuous group by the assumption that A generates a pseudocontractive, strongly continuous semigroup. This includes most of the second order partial differential operators. However, for this paper we do always assume the group property for the sake of simplicity.

Remark 3. The Hörmander condition could not be formulated without the analytic part of Assumption 1.

Example 1. In order to show examples of vector fields, which are C^∞-bounded on $\mathrm{dom}(A^k)$, consider the following structure. Let H be a separable Hilbert space and A the generator of a strongly continuous semigroup. We know that $\mathrm{dom}(A^\infty)$ is a Fréchet space and an injective limit of the Hilbert spaces $\mathrm{dom}(A^k)$ for $k \geq 0$. Following the analysis as developed in [16] (see also [20] and [19], where the analytic concepts have been originally developed), we can consider vector fields $V : U \subset H \to \mathrm{dom}(A^\infty)$. If V is smooth in the sense explained in [16] and has the property that its derivatives of proper order $n \geq 1$ are bounded on $U \subset H$, then V is obviously a C^∞-bounded vector field, and additionally $V|_{\mathrm{dom}(A^\infty)}$ is a Banach map-vector field in the sense of [16]. Such vector fields constitute a class, where Assumptions 1–3 can be readily checked.

3. Decomposition theorem for jump-diffusions on Hilbert spaces. In order to properly understand how to apply the Malliavin calculus, we state the following rather obvious structure theorem on jump-diffusions, which simply takes into account that stochastic integration with respect to the Poisson process follows the rules of Lebesgue–Stieltjes integration (see, for instance, [25] for a general exposition). Here we need only that the vector fields are C^∞-bounded on H in order to guarantee existence and uniqueness of the respective equations.

THEOREM 1. *Let $(\Omega,\mathcal{F},P,(\mathcal{F}_t)_{t\geq 0})$ be a filtered probability space, $(B_t)_{t\geq 0}$ be a d-dimensional Brownian motion, and $(L_t^j)_{t\geq 0}$ be m independent compound Poisson processes for $j = 1,\dots,m$, such that the filtration is the natural filtration with respect to $(B_t, L_t^1,\dots,L_t^m)_{t\geq 0}$. Let S be a strongly continuous semigroup with generator A on H. Let $\alpha, V_1,\dots,V_d$, the diffusion vector fields, and $\delta_1,\dots,\delta_m$, the jump vector fields,*

be C^∞-bounded on H, and consider the cadlag solution $(X_t^x)_{0\le t\le T}$ of an SPDE

$$dX_t^x = (AX_{t^-}^x + \alpha(X_{t^-}^x))dt + \sum_{i=1}^{d} V_i(X_{t^-}^x)dB_t^i + \sum_{j=1}^{m} \delta_j(X_{t^-}^x)dL_t^j, \tag{3.1}$$

$$X_0^x = x. \tag{3.2}$$

Let η denote a piecewise constant cadlag trajectory $\eta : \mathbb{R}_{\ge 0} \to \mathbb{R}^m$ of the compound Poisson process L with finitely many jumps on compact intervals and starting at 0. We consider

$$\begin{aligned} dY_{s,t}^{x,\eta} = &\Big(AY_{s,t^-}^{x,\eta} + \alpha(Y_{s,t^-}^{x,\eta})\Big)dt + \sum_{i=1}^{d} V_i(Y_{s,t^-}^{x,\eta})dB_t^i \\ &+ \sum_{j=1}^{m} \delta_j(Y_{s,t^-}^{x,\eta})d\eta^j(t), \end{aligned} \tag{3.3}$$

$$Y_{s,s}^{x,\eta} = x. \tag{3.4}$$

Then $(Y_{s,t}^{x,\eta})_{s\ge 0}$ can be given explicitly in terms of the jump times τ_n of η for $n \ge 0$ and the diffusion process between two consecutive jumps:

$$\begin{aligned} Y_t^{x,\eta} &:= Y_{0,t}^{x,\eta} \text{ for } 0 \le t < \tau_1, \\ Y_t^{x,\eta} &:= Y_{\tau_1,t}^{y,\eta}\big|_{y = Y_{0,\tau_1^-}^{x,\eta} + \sum_{j=1}^m \delta_j(Y_{0,\tau_1^-}^{x,\eta})\Delta\eta^j(\tau_1)} \text{ for } \tau_1 \le t < \tau_2 \\ &\vdots \\ Y_t^{x,\eta} &:= Y_{\tau_{n-1},t}^{y,\eta}\big|_{y = Y_{0,\tau_{n-1}^-}^{x,\eta} + \sum_{j=1}^m \delta_j(Y_{0,\tau_{n-1}^-}^{x,\eta})\Delta\eta^j(\tau_{n-1})} \text{ for } \tau_{n-1} \le t < \tau_n. \end{aligned}$$

Here we write $\Delta\eta(t) := \eta(t) - \eta(t^-)$ for $t \ge 0$. We define the process $(Y_t^{x,L})_{t\ge 0}$ by inserting the compound Poisson process L for η into $(Y_t^{x,\eta})_{t\ge 0}$. The resulting process $(Y_t^{x,L})_{t\ge 0}$ is then indistinguishable from $(X_t^x)_{t\ge 0}$.

Proof. For the proof we refer the reader to [25, Chapter V.10, Theorem 57], particularly with respect to the conditioning on the jump part. The proof remains unchanged in the infinite-dimensional setting; see [15] for the existence and uniqueness proof on separable Hilbert spaces. □

Remark 4. For future use we shall always assume that the first jumping time of η is strictly positive, $\tau_1 > 0$, and that each time corresponds to the jump of exactly one coordinate process L^j, which is true for almost all trajectories of the compound Poisson process L. Notice that the dependence of $(Y_t^{x,\eta})_{t\ge 0}$ on the jump times of η is continuous but certainly not smooth since the jump times are inserted instead of the time of a hypoelliptic diffusion process.

Remark 5. Notice that one can also interpret the result in the following way: consider the solution $(X_t^x)_{t\ge 0}$ of (3.1) as an element of $L^2(\Omega_1 \times \Omega_2; H)$, where Ω_1 carries the Brownian motion part (with natural filtration), Ω_2 carries the Poisson part (with natural filtration), and $\Omega_1 \times \Omega_2$ is equipped with the respective product σ-algebra. Then we know by Fubini's theorem that

$$L^2(\Omega_1 \times \Omega_2; H) = L^2(\Omega_2; L^2(\Omega_1; H)).$$

The previous theorem only clarifies the jump-diffusion structure of the dependence on Ω_2. In other words, between jumps we have ordinary diffusions, and at a jump we link by linkage operators.

4. First variation processes. In order to calculate Malliavin derivatives, which is crucial for arguments on absolute continuity, we need precise statements on first variation processes of jump-diffusions. For later purposes, but also in order to see results on the inverse of the first variation process easily, we write our equations in the Stratonovich notation. This is not innocent in infinite dimensions, since mild solutions are in general *not* semimartingales, and therefore the Stratonovich notation fails to be applicable in general. However, by Assumption 1 we are able to determine whether we are given a semimartingale, or not, by analyzing the initial value of the process. Indeed, for fixed $k \geq 0$, if $x \in \mathrm{dom}(A^{k+1})$, then there is a mild solution taking values in $\mathrm{dom}(A^{k+1})$ of the Itô SDE. However, this solution process has to coincide, by uniqueness, with the solution process obtained by considering the same equation on $\mathrm{dom}(A^k)$ with an initial value in $\mathrm{dom}(A^{k+1})$. Therefore, the mild solution in $\mathrm{dom}(A^{k+1})$ is a strong solution in $\mathrm{dom}(A^k)$. Therefore, we assume Assumptions 1 and 3 to be in force in this section.

By the previous arguments for the given SDE (3.1), we can switch to Stratonovich notation for $x \in \mathrm{dom}(A)$ and obtain

$$dX_t^x = V_0(X_{t^-}^x)dt + \sum_{i=1}^{d} V_i(X_{t^-}^x) \circ dB_t^i + \sum_{j=1}^{m} \delta_j(X_{t^-}^x)dL_t^j$$

with the Stratonovich drift given by

$$V_0(x) := Ax + \alpha(x) - \frac{1}{2}\sum_{i=1}^{d} \mathrm{T}\, V_i(x) \cdot V_i(x)$$

for $x \in \mathrm{dom}(A)$. Recall the tangent (derivative) operator T:

$$\mathrm{T}\, V(x) \cdot v = \frac{d}{d\epsilon}\Big|_{\epsilon=0} V(x + \epsilon v).$$

We do also consider the SDE (3.3) with respect to one trajectory η and switch to Stratonovich notation there, too. The following theorem states the result on the first variation process along one trajectory η, which yields in what follows the same result by inserting the compound Poisson process L for η. Notice that the trajectory η is such that the first jumping time is strictly positive and that at each jumping time τ_n for $n \geq 1$ only one coordinate jumps.

THEOREM 2. *Assume Assumptions* 1 *and* 3 *hold. We fix* $k \geq 0$. *The* first variation process $(J_{s\to t}(x,\eta))_{t\geq s}$ *associated with* $(Y_t^{x,\eta})_{t\geq 0}$ *on* $\mathrm{dom}(A^k)$ *is well defined and satisfies the SDE*

$$\begin{aligned} dJ_{s\to t}(x,\eta)\cdot h &= \Big(AJ_{s\to t-}(x,\eta)\cdot h + \mathrm{T}\,\alpha(Y_{s,t^-}^{x,\eta})\cdot J_{s\to t^-}(x,\eta)\cdot h\Big)dt \\ &\quad + \sum_{i=1}^{d}\Big(\mathrm{T}\, V_i(Y_{s,t^-}^{x,\eta})\cdot J_{s\to t^-}(x,\eta)\cdot h\Big)dB_t^i \\ &\quad + \sum_{j=1}^{m}\Big(\mathrm{T}\,\delta_j(Y_{s,t^-}^{x,\eta})\cdot J_{s\to t^-}(x,\eta)\cdot h\Big)d\eta^j(t), \end{aligned}$$

$$J_{s\to s}(x,\eta)\cdot h = h \tag{4.1}$$

for $h, x \in \mathrm{dom}(A^k)$ *and* $t \geq s$. *The Itô equation has a unique global mild solution for* $h, x \in \mathrm{dom}(A^k)$, *and* $J_{s\to t}(x,\eta)$ *defines a continuous linear operator on* $\mathrm{dom}(A^k)$, *which is invertible if* $x \in \mathrm{dom}(A^{k+1})$.

The Stratonovich equation on $\mathrm{dom}(A^k)$ *in turn is well defined only for* $h, x \in \mathrm{dom}(A^{k+1})$. *We apply the (formal) notation here:*

$$\mathrm{T}\, V_0(x)v = Av + \mathrm{T}\, \alpha(x)v - \frac{1}{2}\mathrm{T}\left(x \mapsto \sum_{i=1}^{d} \mathrm{T}\, V_i(x) \cdot V_i(x)\right) v$$

for $x \in \mathrm{dom}(A)$ *and* $v \in \mathrm{dom}(A)$.

$$\begin{aligned} dJ_{s\to t}(x,\eta)\cdot h &= \Big(\mathrm{T}\, V_0(Y^{x,\eta}_{s,t^-})\cdot J_{s\to t^-}(x,\eta)\cdot h\Big)dt \\ &\quad + \sum_{i=1}^{d}\Big(\mathrm{T}\, V_i(Y^{x,\eta}_{s,t^-})\cdot J_{s\to t^-}(x,\eta)\cdot h\Big)\circ dB^i_t \\ &\quad + \sum_{j=1}^{m}\Big(\mathrm{T}\, \delta_j(Y^{x,\eta}_{s,t^-})\cdot J_{s\to t^-}(x,\eta)\cdot h\Big)d\eta^j(t), \\ J_{s\to s}(x,\eta)\cdot h &= h \end{aligned} \tag{4.2}$$

for $h, x \in \mathrm{dom}(A^{k+1})$ *and* $t \geq s$. *The adjoint of the inverse*

$$Z^{x,h}_t := \left(J_{s\to t}(x,\eta)^{-1}\right)^* \cdot h,$$

if it exists, should satisfy the following Stratonovich equation at the point x *in direction* h*:*

$$\begin{aligned} dZ^{x,h}_t &= -\Big(\mathrm{T}\, V_0(Y^{x,\eta}_{s,t^-})^*\cdot Z^{x,h}_{t^-}\Big)dt - \sum_{i=1}^{d}\Big(\mathrm{T}\, V_i(Y^{x,\eta}_{s,t^-})^*\cdot Z^{x,h}_{t^-}\Big)\circ dB^i_t \\ &\quad - \sum_{j=1}^{m}\Big(\mathrm{T}\, \delta_j(Y^{x,\eta}_{s,t^-})^*\cdot Z^{x,h}_{t^-}\Big)d\eta^j(t) \\ &\quad + \sum_{j=1}^{m}\Bigg(\Big(\mathrm{T}\, \delta_j(Y^{x,\eta}_{s,t^-})^2\Big)^*\cdot\Big(\Big(id_H + \Delta\eta^j(t)\,\mathrm{T}\, \delta_j(Y^{x,\eta}_{s,t^-})\Big)^{-1}\Big)^* \\ &\qquad \cdot Z^{x,h}_{t^-}(\Delta\eta^j(t))^2\Bigg) \end{aligned} \tag{4.3}$$

for $h, x \in \mathrm{dom}(A^{k+1})$ *and* $t \geq s \geq 0$ *(here we applied the notions of* [25]*).*

Remark 6. The completely analogous theorem holds when we replace η by a compound Poisson process L. We do not state this theorem again, but we point out that we even have moment estimates for the respective processes, which is the only additional relevant information. To be precise, the first variation process $J_{s\to t}(x)\cdot h$, which equals $J_{s\to t}(x, L)$ by construction, has bounded second moments by [15].

Proof. Under our Assumption 1, the regularity in the initial values is clear by well-known results from [12] and the chain rule on Hilbert spaces (recall that the linkage operators are smooth). We are allowed to pass to the Stratonovich decomposition since we integrate semimartingales by Itô's formula on Hilbert spaces for $x, h \in \mathrm{dom}(A^{k+1})$ due to the arguments of [3]: the core assertion here is that we can replace H by each $\mathrm{dom}(A^k)$ for some $k \geq 0$, which means in turn if we start in $\mathrm{dom}(A^{k+1})$ and obtain a mild solution there, it is indeed a strong solution considered on $\mathrm{dom}(A^k)$ for $k \geq 0$. It remains to show the invertibility results on the respective first variation processes.

Left invertibility of the first variation $J_{s\to t}(y,.)$ follows by Itô's formula since we have cadlag trajectories with finitely many jumps. Calculating the semimartingale decomposition of $(Z_t^{y,\cdot})^* \cdot J_{0\to t}(x,\eta)$ given by (4.2) and (4.3) yields the result

$$(Z_t^{x,\cdot})^* J_{0\to t}(x,\eta) = id_{\mathrm{dom}(A^k)}.$$

Thus, the solution of (4.3) is the left inverse of $J_{s\to t}$.

We prove that the left inverse is also the right inverse by the same reasoning as in the proof of Proposition 2 in [3]. Therefore, we choose an orthonormal basis $(g_i)_{i\geq 1}$ of $\mathrm{dom}(A^k)$ which lies in $\mathrm{dom}(A^{k+1})$. Then we can compute the semimartingale decomposition of

$$\begin{aligned}&\sum_{i=1}^N \langle (Z_t^{x,h_1})^*, g_i\rangle_{\mathrm{dom}(A^k)} \langle g_i, J_{s\to t}(x,\eta)^* \cdot h_2\rangle_{\mathrm{dom}(A^k)}\\ &= \sum_{i=1}^N \langle h_1, Z_t^{x,g_i}\rangle_{\mathrm{dom}(A^k)} \langle J_{s\to t}(x,\eta)\cdot g_i, h_2\rangle_{\mathrm{dom}(A^k)}\end{aligned}$$

for $h_1, h_2 \in \mathrm{dom}(A^{k+1})$ and $N \geq 1$. Applying the Stratonovich decomposition and by adjoining, we can free the g_i's and pass to the limit, which yields the vanishing finite variation and martingale part. Hence

$$\begin{aligned}&\langle J_{s\to t}(x,\eta)(Z_t^{x,h_1})^*, h_2\rangle_{\mathrm{dom}(A^k)}\\ &= \lim_{N\to\infty} \sum_{i=1}^N \langle (Z_t^{x,h_1})^*, g_i\rangle_{\mathrm{dom}(A^k)} \langle g_i, J_{s\to t}(x,\eta)^* \cdot h_2\rangle_{\mathrm{dom}(A^k)}\\ &= \langle h_1, h_2\rangle_{\mathrm{dom}(A^k)},\end{aligned}$$

which is what a right inverse should satisfy. □

5. Absolutely continuous laws in finite and infinite dimensions. In this section we assume Assumptions 1, 2, and 3. We want to determine by means of Malliavin calculus whether the law of $\mathbf{l}(Y_t^{x,\eta})$ is absolutely continuous with respect to Lebesgue measure for $t > 0$.

For details on Malliavin calculus see [22] and [24], where in particular the derivative operator and the Skorohod integral for Malliavin calculus with respect to a d-dimensional Brownian motion are defined. Notice that we do not need a Malliavin calculus with respect to the Poissonian trajectories, since we calculate Poisson-trajectory–wise.

Our first task is the calculation of the Malliavin derivative for a fixed cadlag path η. In a second step, we consider the composed problem, where we replace η by a compound Poisson process L as outlined before. Therefore, we first fix a piecewise constant cadlag trajectory $\eta : \mathbb{R}_{\geq 0} \to \mathbb{R}^m$ of the process $(L_t^1, \dots, L_t^m)_{t\geq 0}$ with finitely many jumps on compact intervals starting at 0.

THEOREM 3. *We take Assumptions* 1, 2, *and* 3 *for granted, where* $x \in \mathrm{dom}(A^\infty)$ *denotes the point where the Hörmander condition* (2.3) *holds true. Let* $(Y_t^x)_{t\geq 0}$ *denote the unique cadlag solution of* (3.3). *Then for projections* $\mathbf{l} : H \to \mathbb{R}^M$ *the law of* $\mathbf{l}(Y_t^x)$ *is absolutely continuous with respect to Lebesgue measure on* $\mathbb{R}^M$ *for* $t > 0$.

Proof. Fix $t > 0$. We are able to write the Malliavin derivative of Y_t^x for each Poissonian trajectory η:

$$D_s^i(\mathbf{l}\circ Y_t^{x,\eta}) = \mathbf{l}\circ J_{0\to t}(x) J_{0\to s}(x)^{-1} V_i(Y_{s^-}^{x,\eta}) 1_{[0,t]}(s).$$

We can calculate the *Malliavin covariance matrix* γ as

$$\langle \gamma(\mathbf{l} \circ Y_t^{x,\eta})\xi, \xi\rangle := \sum_{i=1}^{d} \int_0^t \langle \mathbf{l} \circ J_{0\to t}(x) J_{0\to s}(x)^{-1} V_i(Y_{s^-}^{x,\eta}), \xi\rangle^2 ds.$$

Consequently, the covariance matrix $\gamma(\mathbf{l} \circ Y_t^{x,\eta})$ can be calculated in the usual way via the reduced covariance matrix

$$\langle C_t\xi, \xi\rangle := \sum_{i=1}^{d} \int_0^t \left\langle J_{0\to s}(x)^{-1} V_i(Y_{s^-}^{x,\eta}), \xi\right\rangle^2 ds$$

through the relation

$$\gamma(\mathbf{l} \circ Y_t^{x,\eta}) = (\mathbf{l} \circ J_{0\to t}(x)) C_t (\mathbf{l} \circ J_{0\to t}(x))^*,$$

where $*$ denotes the adjoint operator with respect to the Hilbert space structures on H and $\mathbb{R}^M$. We assume n jumps of η on $[0,t]$, and we denote by $0 = \tau_0 < \tau_1 < \cdots < \tau_n \le t$ the sequence of jump times of η. For convenience, we denote the last point in time t by τ_{n+1}, even if $\tau_{n+1} = \tau_n$, which can in principle happen. Hence we can decompose:

$$\langle C_t\xi, \xi\rangle := \sum_{k=0}^{n} \sum_{i=1}^{d} \int_{\tau_k}^{\tau_{k+1}} \left\langle J_{0\to s}(x)^{-1} V_i(Y_{s^-}^{x,\eta}), \xi\right\rangle^2 ds = \sum_{k=0}^{n} \langle C_t^k \xi, \xi\rangle.$$

Each of the summands determines a symmetric matrix C_t^k and can be interpreted as a reduced covariance matrix coming from a diffusion between τ_k and τ_{k+1} with initial value $Y_{\tau_k^-}^x$ for $k = 0, \ldots, n$. We do not know whether the Hörmander condition is true everywhere. Therefore, we do not know whether C_t^k is a positive definite operator for each $k \ge 0$. From [3], Theorem 1, we do know, however, that C_t^0 is a positive definite operator and there exist null sets N_0 such that on N_0^c the matrix C_t^0 is invertible. Hence the law of $(\mathbf{l} \circ Y_t^{x,\eta})$ is absolutely continuous with respect to the Lebesgue measure on $\mathbb{R}^M$, since $J_{0\to t}(x)$ is invertible and therefore $\gamma(\mathbf{l} \circ Y_t^{x,\eta})$ has empty kernel (Theorem 2.1.2 in [24, p. 86]). □

Remark 7. The same conclusions hold for $Y_{t^-}^{x,\eta}$: notice that $Y_t^{x,\eta} = Y_{t^-}^{x,\eta}$ if there is no jump at t. Otherwise, $Y_t^{x,\eta} = Y_{t^-}^{x,\eta} + \sum_{j=1}^{m} \delta_j(Y_{0,t^-}^{x,\eta}) \Delta\eta^j(t)$, but invertible diffeomorphisms transform absolutely continuous laws into absolutely continuous ones.

Now we extend this theorem to the jump-diffusion process $(X_t^x)_{t\ge 0}$, which is easy since, conditioned on one trajectory η, we do have an absolutely continuous law and this property is not perturbed by integration due to Fubini's theorem.

THEOREM 4. *We take Assumptions* 1, 2, *and* 3 *for granted, where* $x \in \mathrm{dom}(A^\infty)$ *denotes the point where the Hörmander condition* (2.3) *holds true. Let* $(X_t^x)_{t\ge 0}$ *denote the unique cadlag solution of* (3.1). *Then for projections* $\mathbf{l} = (l_1, \ldots, l_k) : H \to \mathbb{R}^M$ *the law of* $\mathbf{l}(X_t^x)$ *is absolutely continuous with respect to the Lebesgue measure on* $\mathbb{R}^M$ *for* $t > 0$. *Notice that* $\mathbf{l}(X_t^x)$ *and* $\mathbf{l}(X_{t^-}^x)$ *have the same distribution.*

Proof. The proof applies the following simple corollary of Fubini's theorem on $\mathbb{R}^M$ with Lebesgue measure λ and a probability space $(\Omega, \mathcal{F}, P)$: let ν be a probability measure on $\mathbb{R}^M \times \Omega$ such that there is random density $p : \mathbb{R}^M \times \Omega \to \mathbb{R}_{\ge 0}$ with

$$\int_{\mathbb{R}^M \times \Omega} f(x,\eta) p(x,\eta) (\lambda \otimes P)(dx, d\eta) = \int_{\mathbb{R}^M \times \Omega} f(x,\eta) \nu(dx, d\eta);$$

then the marginal of ν on $\mathbb{R}^M$ is absolutely continuous with respect to Lebesgue measure λ with density

$$p(x) = \int_\Omega p(x,\eta) P(d\eta)$$

for almost all $x \in \mathbb{R}^M$. In our case we know that the law of $(\mathbf{l}(X_t^x)$ is absolutely continuous for almost all trajectories η of the compound Poisson processes L (precisely those where $\tau_1 > 0$, where only one coordinate jumps at each jumping time, and finitely many jumps occur on compact intervals); the probability measure ν corresponds to the distribution of $(\mathbf{l}(X_t^x), L)$, where we choose Ω as the space of cadlag trajectories on $\mathbb{R}_{\geq 0}$ with values in $\mathbb{R}^m$. Finally, we have that the law of $(\mathbf{l}(X_t^x)$ is $p(x)\lambda(dx)$. □

6. Applications of the infinite-dimensional result to interest rate theory. In mathematical Finance, the theory of interest rates deals with the market of interest rate related products like swaps, bonds, bills, etc. If one considers default-free products one can crystallize from the data of real markets the prices of default-free zero-coupon bonds for any maturity. A zero-coupon bond contract with maturity T (a calendar date) can be entered at calendar time $t \leq T$ and (certainly) pays 1 unit of currency at maturity time T. Therefore, bonds reflect the level of interest rate between time t and maturity time T. No coupons are paid between t and T, which explains the notion of "zero-coupon bond." We denote the price of a default-free zero-coupon bond with maturity T at time $t \leq T$ by $P(t,T)$. Commonly one assumes that bond prices are at least C^1 with respect to T, i.e.,

$$P(t,T) = \exp\left(-\int_t^T f(t,r)dr\right)$$

for $0 \leq t \leq T$, where $f(t,T)$ denotes the forward rate. This leads to the concept of the short rate

$$R_t = f(t,t)$$

for $t \geq 0$, which corresponds to the level of interest rate for instantaneous transactions from t to $t + dt$. As usual in mathematical Finance, discounted default-free zero-coupon bonds are modeled by semimartingales, and one assumes the existence of an equivalent martingale measure for discounted price processes. This leads to the following fundamental formula with respect to the martingale measure

$$E\left(\exp\left(-\int_t^T R_s ds\right)|\mathcal{F}_t\right) = P(t,T) = \exp\left(-\int_t^T f(t,r)dr\right).$$

The formula simply expresses the fact that the expected value of discounted value of the payoff $P(T,T) = 1$ conditional on today's information equals today's price with respect to the martingale measure. Assuming a jump-diffusion model for $(f(t,T)_{0\leq t\leq T}$ for $T \geq 0$ for the forward rates together with Musiela's parametrization $r(t,T-t) = f(t,T)$ for $0 \leq t \leq T$ leads to the famous Heath–Jarrow–Morton (HJM) equation of interest rate theory, which is an SDE taking values in a Hilbert space of forward rate curves H (and therefore an SPDE). We quote here as leading reference [15], where the no-arbitrage conditions for the HJM equation are discussed in all necessary detail. A

very readable introduction can also be found in [8], particularly for HJM equations with jumps.

The HJM equation has been analyzed from different points of view:

- The question of which HJM equations driven by finitely many Brownian motions admit finite-dimensional realizations has been treated in detail in [16]. This research was inspired by [9], where the geometric approach was introduced. The satisfying answer is that, under quite natural restrictions, finite-dimensional realizations do exist if and only if the corresponding factor processes are affine processes. This is the case, for instance, for Vasiček's model or for the Cox–Ingersoll–Ross model of interest rate theory. In both cases the finite-dimensional realizations are, in fact, two-dimensional. In [8] finite-dimensional realizations are treated for HJM equations with jumps but under the strong restriction that the vector fields do not depend on the forward rate. In this case one can solve the HJM equation explicitly by variation of constants and read off the respective geometric properties of the solution process.
- The question of whether the solution process of an HJM equation always admits a density with respect to Lebesgue measure when projected to a finite-dimensional subspace has been treated in [3] and could be answered affirmatively under Hörmander-type conditions.

We ask here the question—having the theory of the previous sections in mind—of whether a structure of finite-dimensional realizations, such as for Vasiček's model, can be perturbed so strongly through the introduction of jumps that the resulting HJM evolution is "hypoelliptic," i.e., the assumptions of Theorem 3 are fulfilled. We can answer this question affirmatively in the case of a Vasiček model. In contrast to [8], we allow the vector fields to be state-dependent (therefore, we cannot hope for explicit solutions of the HJM equation, and we have to apply local methods from differential geometry to conclude).

We consider the HJM model with jumps

$$\begin{cases} dr_t &= \left(\dfrac{d}{dx}r_{t^-} + \alpha_{HJM}(r_{t^-}) + \beta_{HJM}(r_{t^-})\right)dt + \sigma(r_{t^-})dB_t + \delta(r_{t^-})dN_t, \\ r_0 &= r^* \in H, \end{cases}$$

on some Hilbert space H of forward rate curves as constructed in [3] and [15]. Here $(B_t)_{t\geq 0}$ is a standard Brownian motion, and $(N_t)_{t\geq 0}$ is a standard Poisson process with intensity $\widetilde{\lambda} > 0$ and jump measure $\mu = \delta_1$ (hence $\widetilde{\lambda} = \lambda$). Define

$$\begin{aligned} \Psi_1(z) &\equiv \ln \mathbb{E}\left[e^{zW_1}\right] = \ln\left(e^{\frac{z^2}{2}}\right) = \frac{z^2}{2} \quad \text{and} \\ \Psi_2(z) &\equiv \ln \mathbb{E}\left[e^{zN_1}\right] = \ln\left(\exp\left(\lambda\left(e^z - 1\right)\right)\right) = \lambda\left(e^z - 1\right). \end{aligned}$$

Then we know from [15, equation (2.4)], that

$$\begin{aligned} \alpha_{HJM}(r)(x) &= -\sigma(r)(x)\Psi_1'\left(-\int_0^x \sigma(r)(y)dy\right) \\ &= \sigma(r)(x)\int_0^x \sigma(r)(y)dy \end{aligned}$$

and

$$\begin{aligned}\beta_{HJM}(r)(x) &= -\delta(r)(x)\Psi_2'\left(-\int_0^x \delta(r)(y)dy\right)\\ &= -\lambda\delta(r)(x)\exp\left(-\int_0^x \delta(r)(y)dy\right).\end{aligned}$$

For an explicit example we choose

$$\sigma(r)(x) = \sigma(x) > 0 \quad \text{and} \quad \delta(r)(x) = -\frac{d}{dx}\ln(B(r)(x)),$$

where the vector field B will be determined later. Then we have

$$\alpha_{HJM}(r)(x) = \sigma(x)\int_0^x \sigma(y)dy$$

and

$$\beta_{HJM}(r)(x) = \lambda\frac{d}{dx}\ln(B(r)(x))\frac{(B(r)(x))}{(B(r)(0))} = \lambda\frac{\frac{d}{dx}(B(r)(x))}{(B(r)(0))}.$$

We choose B such that $(B(r)(x))$ is positive on H for $x \in \mathbb{R}$ and $B(r)(0) = 1$ for all $r \in H$, whence δ is well defined. Thus, for such $r \in U$ we have

$$\beta_{HJM}(r)(x) = \lambda\frac{d}{dx}(B(r)(x))$$

and

$$\delta(r)(x) = -\frac{d}{dx}\ln(B(r)(x)).$$

A particular choice in the spirit of Remark 1 is given through

$$B(r)(x) = \psi(x, l(r)),$$

where the maps $y \mapsto \frac{d}{dx}\psi(.,y)$ and $y \mapsto \frac{1}{\psi(.,y)}$ from $\mathbb{R}$ to $\mathrm{dom}(A^\infty) \subset H$ are supposed to be C^∞-bounded with $\psi(0,y) = 1$ for all $y \in \mathbb{R}$. The map l denotes here a non-vanishing linear functional $l : H \to \mathbb{R}$. Hence δ and β are well defined C^∞-bounded vector fields on the whole Hilbert space, and we have global existence of mild solutions.

The Vasiček model is defined by

$$\sigma(r) = \rho\exp(-ax)$$

for $\rho, a > 0$ without any jump component. By [9] and [16] we know that the Vasiček model admits finite-dimensional realizations, as for

$$V_0(r)(x) = \frac{d}{dx}r(x) + \alpha_{HJM}(r)(x)$$

we have

$$\dim(\{V_0, \sigma\}_{LA}(r)) \leq 2,$$

at any point $r \in \mathrm{dom}((\frac{d}{dx})^\infty)$. Here the index LA stands for the Lie algebra generated by the vector fields V_0, σ on $\mathrm{dom}(A^\infty)$. If we add a jump structure as described above and if we choose ψ generic, the two-dimensional structure (a regular finite-dimensional realization in the sense of [16]) is destroyed, since then the drift changes due to no-arbitrage. We obtain a dense Lie algebra if we choose the vector field B generically.

These results might be of interest for recent works in interest rate theory; see, for instance, [23], where under diffusion assumptions hypoellipticity is tested empirically. If one allows for jumps in an HJM model, the phenomenon of hypoellipticity seems to be more generic.

7. Smooth densities for the law X_T^x on $\mathbb{R}^M$. In the what folllows we consider the cases $\dim H = M$ and $\mathbf{l} = \mathrm{id}$, and we choose a coordinate representation $H = \mathbb{R}^M$. We then want to show that the pth power of the inverse of the Malliavin covariance matrix of X_t^x for $t > 0$ can be integrated even with respect to Poisson trajectory η. We therefore need an extension of the Hörmander condition which is called the uniform Hörmander condition.

Following [24], we define

$$\Sigma_0' := \{V_1, \dots, V_d\},$$
$$\Sigma_n' := \left\{ [V_k, V], k = 1, \dots, d, V \in \Sigma_{n-1}'; [V_0, V] + \frac{1}{2}\sum_{i=1}^d [V_i, [V_i, V]], V \in \Sigma_{n-1}' \right\}$$

for $n \geq 1$. We assume that there exist j_0 and $c > 0$ such that

$$\inf_{\xi \in S^{M-1}} \sum_{j=0}^{j_0} \sum_{V \in \Sigma_j'} \langle V(x), \xi \rangle^2 \geq c \tag{7.1}$$

uniformly in $x \in \mathbb{R}^M$.

THEOREM 5. *Assume that* $\dim H < \infty$. *We take Assumptions* 2 *and* 3 *for granted but assume that the Hörmander condition* (2.3) *holds true uniformly on* $\mathbb{R}^M$ *in the sense of* (7.1). *Let* $(X_t^x)_{t \geq 0}$ *denote the unique cadlag solution of* (3.1), *and fix* $t > 0$. *Then the random variable* X_t^x *admits a smooth density with respect to Lebesgue measure on* $\mathbb{R}^M$. *Furthermore, the covariance matrix of* X_t^x *is invertible with p-integrable inverse for all* $p \geq 1$.

Proof. We write the Malliavin derivative of X_t^x,

$$D_s^i X_t^x = J_{0 \to t}(x) J_{0 \to s}(x)^{-1} V_i(X_{s^-}^x) \mathbf{1}_{[0,t]}(s),$$

and calculate the reduced covariance matrix

$$\langle C_t \xi, \xi \rangle = \sum_{i=1}^d \int_0^t \left\langle J_{0 \to s}(x)^{-1} V_i(X_{s^-}^x), \xi \right\rangle^2 ds.$$

We now apply the result from Theorem 1 and the condition on the trajectories of the compound Poisson process (2)

$$\begin{aligned} &\sup_{\xi \in S^{M-1}} P(\langle C_t \xi, \xi \rangle < \epsilon) \\ &= \sup_{\xi \in S^{M-1}} \sum_{n_1, \dots, n_m \geq 0} \left[\prod_{k=1}^m P(N_t^k = n_k) \right] P(\langle C_t \xi, \xi \rangle < \epsilon | N_t^j = n_j \text{ for } j = 1, \dots, m). \end{aligned} \tag{7.2}$$

As in the proof of Theorem 3, we can decompose $\langle C_t\xi,\xi\rangle$ into

$$\langle C_t\xi,\xi\rangle = \sum_{k=0}^{\infty}\sum_{i=1}^{d}\int_{\tau_k\wedge t}^{\tau_{k+1}\wedge t}\left\langle J_{0\to s}(x)^{-1}V_i(X_{s^-}^x),\xi\right\rangle^2 ds,$$

where $\tau_0 = 0 < \tau_1 < \cdots < \tau_n \le \dots$ denotes the sequence of jump times of $(N_t)_{0\le t\le T}$. Hence, we obtain for $n = n_1 + \cdots + n_m$

$$\begin{aligned}&\sup_{\xi\in S^{M-1}} P(\langle C_t\xi,\xi\rangle < \epsilon | N_t^j = n_j,\ j=1,\dots,m)\\ &\le \sup_{\xi\in S^{M-1}} P\left(\sum_{i=1}^{d}\int_{\tau_k\wedge t}^{\tau_{k+1}\wedge t}\left\langle J_{0\to s}(x)^{-1}V_i(X_{s^-}^x),\xi\right\rangle^2 ds < \epsilon \,\middle|\, N_t^j = n_j,\ j=1,\dots,m\right)\end{aligned}$$

for all $0\le k\le n$. Observing that $\max_{0\le k\le n}(\tau_{k+1}-\tau_k)^{K(p)} \ge (\frac{t}{n})^{K(p)}$ (after all, we have only n jumps, so the maximal distance between two consecutive jumps is bigger than $\frac{t}{n}$), we finally obtain

$$P(\langle C_t\xi,\xi\rangle < \epsilon | N_t^j = n_j \text{ for } j=1,\dots,m) \le \epsilon^p$$

for $0\le\epsilon\le(\frac{t}{n})^{K(p)}\epsilon_0(p)$ due to the calculations outlined in the appendix. Note that we can apply the calculations from the appendix, since $J_{0\to s}(x)^{-1}$ is well defined and bounded due to boundedness of $(id + zd\delta_j)^{-1}$ for $z\in\operatorname{supp}(\mu_j)$ and $j=1,\dots,m$. Hence integration with respect to the measures μ_j is possible and yields finite bounds. Recall also that μ_j has moments of all orders; hence X_t^x is L^p, and so is $J_{0\to s}(x)^{-1}$ (see [25] for all necessary details on SDEs).

Let $\Lambda = \inf_{\xi\in S^{M-1}}\langle C_t\xi,\xi\rangle$ be the smallest eigenvalue of the reduced covariance matrix C_t. Following the steps of [24, Lemma 2.3.1], we know that

$$P(\Lambda < \epsilon \mid N_t^j = n_j \text{ for } j=1,\dots,m) \le \text{const}\cdot\epsilon^p$$

for any $p\ge 2$ and $0\le\epsilon\le\left(\frac{t}{n}\right)^{K(p+2M)}\epsilon_0(p+2M) =: \epsilon_{max}$, where the constant depends on the p-norm of C_t. In what follows we shall denote any constant of this type by D. We denote by ρ the law of Λ conditioned on $N_t^j = n_j$ for $j=1,\dots,m$. Consequently, for $j=1,\dots,m$, we have by Fubini's theorem

$$\begin{aligned}E\left(\frac{1}{\Lambda^{p-1}}\,\middle|\, N_t^j = n_j\right) &= E\left(\frac{1}{\Lambda^{p-1}}\cdot\mathbf{1}_{\{\Lambda>\epsilon_{max}\}}\,\middle|\, N_t^j = n_j\right)\\ &\quad + E\left(\frac{1}{\Lambda^{p-1}}\cdot\mathbf{1}_{\{\Lambda\le\epsilon_{max}\}}\,\middle|\, N_t^j = n_j\right)\\ &\le \frac{1}{\epsilon_{max}^{p-1}} + \int_0^{\epsilon_{max}}\frac{1}{z^{p-1}}\rho(dz)\\ &= \frac{1}{\epsilon_{max}^{p-1}} + \int_0^{\epsilon_{max}}(p-1)\int_z^{\infty}\frac{1}{t^p}dt\rho(dz)\\ &= \frac{1}{\epsilon_{max}^{p-1}} + (p-1)\int_0^{\epsilon_{max}}\frac{1}{z^p}\int_0^z\rho(dt)dz\end{aligned}$$

$$
\begin{aligned}
&+ (p-1)\int_{\epsilon_{max}}^{\infty} \frac{1}{z^p}\int_0^{\epsilon_{max}} \rho(dt)dz \\
&\leq \frac{D}{\epsilon_{max}^{p-1}} + D\underbrace{\int_0^{\epsilon_{max}} \frac{1}{z^p}\, z^p dz}_{=\epsilon_{max}} \\
&\leq D\left(\frac{t}{n}\right)^{K(p+2M)} \epsilon_0(p+2M) \\
&+ \frac{D}{[(\frac{t}{n})^{K(p+2M)}\epsilon_0(p+2M)]^{p-1}}.
\end{aligned}
$$

Here we applied $\int_0^z \rho(dt) \leq D \times z^p$ as previously proved. Hence, through the decomposition (7.2),

$$
\begin{aligned}
E\left(\frac{1}{\Lambda^{p-1}}\right) \leq &\sum_{n_1,\ldots,n_m>0} \prod_{k=1}^{m} P(N_t^k = n_k) \\
&\cdot D \cdot \left[\left(\frac{t}{n}\right)^{K(p+2M)} \epsilon_0(p+2M) + \frac{1}{[(\frac{t}{n})^{K(p+2M)}\epsilon_0(p+2M)]^{p-1}}\right] < \infty;
\end{aligned}
$$

the result follows by $n = n_1 + \cdots + n_m$ and by the following fact for any real number K:

$$
\sum_{n_1,\ldots,n_m>0} \frac{\widetilde{\lambda}_1^{n_1}\cdots\widetilde{\lambda}_m^{n_m}}{n_1!\cdots n_m!} e^{-t\tilde{\lambda}_1 n_1 - \cdots - t\tilde{\lambda}_m n_m} t^n (n_1+\cdots+n_m)^K < \infty. \qquad \square
$$

Remark 8. We could have also applied the beautiful results of [21, Corollary 3.25] to evaluate the L^p-norm of the inverse of the covariance matrix between two jumps. Both methods lead to the same result. We have been choosing our approach since we can root it as much as possible in the standard reference [24].

8. Calculating the Greeks in finite dimension. In what follows we consider the case $\dim H = M$ and $\mathbf{l} = \mathrm{id}$ as in the previous section. Once we are given an invertible Malliavin covariance matrix with p-integrable inverse such as in Theorem 5, we can easily calculate derivatives with respect to initial values and obtain explicit formulas for so-called Malliavin weights (see [17] for successful applications of this method in mathematical Finance). We quickly sum up the main idea: in mathematical Finance the gradient of the function $x \mapsto E(f(X_t^x))$ has the meaning of hedging ratios, which control the hedging portfolios away from jumps. Hence for any hedging portfolio corresponding to prices $E(f(X_t^x))$ of a certain derivative at maturity $t > 0$ it is crucial to know $\nabla E(f(X_t^x))$ to perform hedging off jumps.

Very often pricing results in the applications of a weak approximation scheme for the process X, for instance, the Euler–Maruyama scheme. For the calculation of $\nabla E(f(X_t^x))$ in the direction of some vector $v \in H$, basically three methods can be applied:

- a finite difference method to approximate $\nabla E(f(X_t^x)) \cdot v$, resulting in the calculation of $\frac{E(f(X_t^{x+\epsilon v})) - E(f(X_t^x))}{\epsilon}$ ($v \in H$ denotes some vector) for small $\epsilon > 0$;
- a pathwise method applying the formula

$$
\nabla E(f(X_t^x)) \cdot v = E(df(X_t^x) J_{0\to t}(x) \cdot v),
$$

resulting in the weak numerical approximation of $(X_t^x, J_{0\to t}(x))$; and

- the method of Malliavin weights applying the formula

$$\nabla E(f(X_t^x)) \cdot v = E(f(X_t^x)\pi^v),$$

resulting in the weak numerical approximation of (X_t^x, π^v).

The first method is the most robust in the sense that it can be applied under very weak assumptions both on X_t^x and on the payoff f, but the rate of convergence might be very slow since the errors of Monte Carlo evaluations are amplified. The second method works for all reasonable jump-diffusion processes, but one needs Lipschitz conditions on the payoff f. The third method needs the assumptions of Theorem 5 on X_t^x, but no restrictions on the payoff f, which makes the third method attractive for several problems from mathematical Finance, where measurable, non-Lipschitz payoffs (e.g., digital options) are quite usual and hypoellipticity assumptions as in Theorem 5 are common, too.

The implementation of procedures for all three methods has been outlined in [18] in the pure diffusion case. We shall not work on this issue here, since our main message is that one can implement precisely the same methods in pure diffusion cases as in jump-diffusion cases. The important point is that the formulas have the same structure in both cases, a fact we shall point out in this section on several occasions.

We denote in what follows the Skorohod integral (resp., the divergence operator) by δ and its domain by $\mathrm{dom}(\delta)$.

DEFINITION 1. *Assume that $H = \mathbb{R}^M$ and fix $t > 0$ and a direction $v \in \mathbb{R}^M$. We define a set of Skorohod-integrable processes*

$$\mathbb{A}_{t,x,v} = \left\{ a \in \mathrm{dom}(\delta) \text{ such that } \sum_{i=1}^{d} \int_0^t J_{0\to s}(x)^{-1} V_i(X_{s-}^x) a_s^i ds = v \right\}$$

and call it the set of path-perturbations with target-value v.

Remark 9. In the previous definition, as in the whole section, assertions on Skorohod-integrability are meant Poissonian-trajectory–wise.

PROPOSITION 1. *Assume that $H = \mathbb{R}^M$. We take Assumption 3 for granted. Fix $t > 0$ and a direction $v \in \mathbb{R}^M$. Assume furthermore uniform ellipticity; i.e., $M = d$ and there is $c > 0$ such that*

$$\inf_{\xi \in S^{M-1}} \sum_{k=1}^{M} \langle V_k(x), \xi \rangle^2 \geq c.$$

Then $\mathbb{A}_{t,x,v} \neq \emptyset$ and there exists an integrable, real valued random variable π^v (which depends linearly on v) such that for all bounded random variables f we obtain

$$\frac{d}{d\epsilon}|_{\epsilon=0} E(f(X_t^{x+\epsilon v})) = E(f(X_t^x)\pi^v).$$

Such a random variable π^v is called a Malliavin weight and can be obtained through an Itô integral.

Remark 10. The assertion of this theorem corresponds to Assumption (E) in [18] and to the assumptions of [17]. The assumptions are seen as too restrictive since not every problem in mathematical Finance has an elliptic volatility matrix. The formulas of [18] and [17] correspond precisely to the formulas obtained here, which

leads to the assertion that even in the presence of jumps one can apply the same (numerical) methods for the calculation of Greeks as in the pure diffusion cases.

Proof. Here the proof is particularly simple, since we can take a matrix $\sigma(x) := (V_1(x), \dots, V_M(x))$, which is uniformly invertible with bounded inverse. We define

$$a_s := \frac{1}{t}\sigma(X^x_{s^-})^{-1} \cdot J_{0\to s}(x) \cdot v$$

for $0 \le s \le t$ and obtain that $a \in \mathbb{A}_{t,x,v}$. Furthermore, as in [17] and [13], we obtain

$$\pi^v = \sum_{i=1}^{M} \int_0^t a^i_s dB^i_s,$$

since the Skorohod-integrable process a is in fact adapted, left-continuous, and hence Itô-integrable. □

THEOREM 6. *Assume that $H = \mathbb{R}^M$. We take Assumptions 2 and 3 for granted but assume that the Hörmander condition (2.3) holds true uniformly on $\mathbb{R}^M$ (see section 7). Fix $t > 0$ and a direction $v \in \mathbb{R}^M$. Then $\mathbb{A}_{t,x,v} \neq \emptyset$ and there exists an integrable, real valued random variable π^v (which depends linearly on v) such that for all bounded random variables f we obtain*

$$\frac{d}{d\epsilon}|_{\epsilon=0} E(f(X^{x+\epsilon v}_t)) = E(f(X^x_t)\pi^v).$$

We can choose π^v to be the Skorohod integral of any element $a \in \mathbb{A}_{t,x,v} \neq \emptyset$ and call it a Malliavin weight. Moreover, by the explicit construction of a in the proof, we can assert that π^v is the sum of an Itô integral and an integral with respect to Lebesgue measure; see, for instance, [18].

Remark 11. The assertion of this theorem corresponds to Assumption (E′) in [18]. The assumptions (E) and (E′) are fundamental for the third method in [18]. Again the formulas of [18] correspond to the formulas obtained here.

Proof. We take f bounded with bounded first derivative; then we obtain

$$\frac{d}{d\epsilon}|_{\epsilon=0} E(f(X^{x+\epsilon v}_t)) = E(df(X^x_t)J_{0\to t}(x) \cdot v).$$

If there is $a \in \mathbb{A}_{t,x,v}$, we obtain

$$\begin{aligned}
E(df(X^x_t)J_{0\to t}(x) \cdot v) &= E\left(df(X^x_t)\sum_{i=1}^{d}\int_0^t J_{0\to t}(x)J_{0\to s}(x)^{-1}V_i(X^x_{s^-})a^i_s ds\right)\\
&= E\left(\sum_{i=1}^{d}\int_0^t df(X^x_t)J_{0\to t}(x)J_{0\to s}(x)^{-1}V_i(X^x_{s^-})a^i_s ds\right)\\
&= E\left(\sum_{i=1}^{d}\int_0^t D^i_s f(X^x_t)a^i_s ds\right)\\
&= E(f(X^x_t)\delta(a)).
\end{aligned}$$

Here we cannot assert that the strategy is Itô-integrable, since it will be anticipative in general. In order to see that $\mathbb{A}_{t,x,v} \neq \emptyset$, we construct an element, namely,

$$a^i_s := \left\langle J_{0\to s}(x)^{-1}V_i(X^x_{s^-}), (C_t)^{-1}v\right\rangle,$$

where C_t denotes the reduced covariance matrix from Theorem 5. Indeed,

$$\begin{aligned}
&\sum_{i=1}^{d} \left\langle \int_0^t J_{0\to s}(x)^{-1} V_i(X_{s-}^x) a_s^i ds, \xi \right\rangle \\
&= \sum_{i=1}^{d} \int_0^t \left\langle J_{0\to s}(x)^{-1} V_i(X_{s-}^x), \xi \right\rangle \left\langle J_{0\to s}(x)^{-1} V_i(X_{s-}^x), (C_t)^{-1} v \right\rangle ds \\
&= \left\langle \xi, C_t (C_t)^{-1} v \right\rangle = \langle \xi, v \rangle
\end{aligned}$$

for all $\xi \in \mathbb{R}^M$, since C_t is a symmetric random operator defined via

$$\langle \xi, C_t \xi \rangle = \sum_{i=1}^{d} \int_0^t \left\langle J_{0\to s}(x)^{-1} V_i(X_{s-}^x), \xi \right\rangle^2 ds$$

for $\xi \in \mathbb{R}^M$. ∎

For any other derivative with respect to parameters ϵ, we consider a modified set, namely,

$$\mathbb{B}_{t,x,v} = \left\{ b \in \operatorname{dom}(\delta) \,\middle|\, \sum_{i=1}^{d} \int_0^t J_{0\to s}(x)^{-1} V_i(X_{s-}^x) b_s^i ds = J_{0\to t}(x)^{-1} \frac{d}{d\epsilon}\bigg|_{\epsilon=0} X_t^{x,\epsilon} \right\}.$$

Here we are given a parameter-dependent process $X_t^{x,\epsilon}$, where all derivatives with respect to ϵ can be calculated nicely. Also in this case we can construct—if the reduced covariance matrix is invertible and regular enough—an element, namely,

$$b_s^i := \left\langle J_{0\to s}(x)^{-1} V_i(X_{s-}^x), (C_t)^{-1} J_{0\to t}(x)^{-1} \frac{d}{d\epsilon}|_{\epsilon=0} X_t^{x,\epsilon} \right\rangle.$$

This is a consequence of the reasoning

$$\begin{aligned}
&\sum_{i=1}^{d} \left\langle \int_0^t J_{0\to s}(x)^{-1} V_i(X_{s-}^x) b_s^i ds, \xi \right\rangle = \sum_{i=1}^{d} \int_0^t \left\langle J_{0\to s}(x)^{-1} V_i(X_{s-}^x), \xi \right\rangle \cdot \\
&\quad \cdot \left\langle J_{0\to s}(x)^{-1} V_i(X_{s-}^x), (C_t)^{-1} J_{0\to t}(x)^{-1} \frac{d}{d\epsilon}|_{\epsilon=0} X_t^{x,\epsilon} \right\rangle ds \\
&= \left\langle \xi, C_t (C_t)^{-1} J_{0\to t}(x)^{-1} \frac{d}{d\epsilon}|_{\epsilon=0} X_t^{x,\epsilon} \right\rangle = \left\langle \xi, J_{0\to t}(x)^{-1} \frac{d}{d\epsilon}|_{\epsilon=0} X_t^{x,\epsilon} \right\rangle,
\end{aligned}$$

due to the symmetry of C_t.

Appendix.

THEOREM 7. *Let $(\Omega, \mathcal{F}, P, (\mathcal{F}_t)_{t\geq 0})$ be a filtered probability space, and let $(B_t)_{t\geq 0}$ be a d-dimensional Brownian motion adapted to the filtration (which is not necessarily generated by the Brownian motion). Let $V, V_1, \ldots, V_d$, the diffusion vector fields, be C^∞-bounded on $\mathbb{R}^M$, and consider the continuous solution $(X_t^x)_{0\leq t\leq T}$ of an SDE (in Stratonovich notation). V_0 denotes the Stratonovich corrected drift term,*

$$dX_t^x = V_0(X_t^x)dt + \sum_{i=1}^{d} V_i(X_t^x) \circ dB_t^i, \tag{A.1}$$

$$X_0^x = x. \tag{A.2}$$

Assume that the uniform Hörmander condition holds true (see the proof for the precise statement). Then for any $p \geq 1$ there exist numbers $\epsilon_0(p) > 0$ and an integer $K(p) \geq 1$ such that for each $0 < t < T$

$$\sup_{\xi \in S^{M-1}} P(\langle C_t \xi, \xi \rangle < \epsilon) \leq \epsilon^p$$

holds true for $0 \leq \epsilon \leq t^{K(p)} \epsilon_0(p)$. The result holds uniformly in x.

Remark 12. The time-dependence of the estimate $0 \leq \epsilon \leq t^{K(p)} \epsilon_0(p)$ is best explained by redoing the proof. It is heavily applied in section 7 and the main technical ingredient of the given proof. We could have also directly used the results from [21].

Proof. The proof of the theorem is a careful rereading of the Norris lemma and the classical proof of the Hörmander theorem in probability theory (see [22] or [24]). We shall sketch this path in what follows (see [24, pp. 120–123]).

1. Consider the random quadratic form

$$\langle C_t \xi, \xi \rangle = \sum_{i=1}^{d} \int_0^t \left\langle J_{0 \to s}(x)^{-1} V_i(X_s^x), \xi \right\rangle^2 ds.$$

Following [24], we define

$$\Sigma_0' := \{V_1, \ldots, V_d\},$$
$$\Sigma_n' := \left\{ [V_k, V], k = 1, \ldots, d, V \in \Sigma_{n-1}'; [V_0, V] + \frac{1}{2} \sum_{i=1}^{d} [V_i, [V_i, V]], V \in \Sigma_{n-1}' \right\}$$

for $n \geq 1$. We assume that there exist j_0 and $c > 0$ such that

$$\inf_{\xi \in S^{M-1}} \sum_{j=0}^{j_0} \sum_{V \in \Sigma_j'} \langle V(x), \xi \rangle^2 \geq c$$

uniformly in $x \in \mathbb{R}^M$.

2. We define $m(j) := 2^{-4j}$ for $0 \leq j \leq j_0$ and the sets

$$E_j := \left\{ \sum_{V \in \Sigma_j'} \int_0^t \left\langle J_{0 \to s}(x)^{-1} V(X_s^x), \xi \right\rangle^2 ds \leq \epsilon^{m(j)} \right\}.$$

We consider the decomposition

$$E_0 = \{\langle C_t \xi, \xi \rangle \leq \epsilon\} \subset (E_0 \cap E_1^c) \cup (E_1 \cap E_2^c) \cup \cdots \cup (E_{j_0 - 1} \cap E_{j_0}^c) \cup F,$$
$$F = E_0 \cap \cdots \cap E_{j_0}$$

and proceed with

$$P(F) \leq C \epsilon^{\frac{q\beta}{2}}$$

for $\epsilon \leq \epsilon_1$ and any $q \geq 2$ with a constant C depending on q and the norms of the derivatives of the vector fields $V_0, \ldots, V_d$. Furthermore, $0 < \beta < m(j_0)$. The number ϵ_1 is determined by the following two (!) equations:

$$(j_0 + 1) \epsilon_1^{m(j_0)} < \frac{c \epsilon_1^\beta}{4},$$
$$\epsilon_1^\beta < t.$$

Hence ϵ_1 depends on j_0, c, t, and the choice of β via

$$\epsilon_1 < \min\left(t^{\frac{1}{\beta}}, \left(\frac{c}{4(j_0+1)}\right)^{\frac{1}{m(j_0)-\beta}}\right).$$

This little observation, in addition to the proof in [24], is key for our proof.

3. We obtain furthermore that

$$\begin{aligned}
P(E_j \cap E_{j+1}^c) = P\Bigg(& \sum_{V\in\Sigma_j'} \int_0^t \langle J_{0\to s}(x)^{-1} V(X_s^x), \xi\rangle^2 ds \le \epsilon^{m(j)}, \\
& \sum_{V\in\Sigma_{j+1}'} \int_0^t \langle J_{0\to s}(x)^{-1} V(X_s^x), \xi\rangle^2 ds > \epsilon^{m(j+1)} \Bigg) \\
\le \sum_{V\in\Sigma_j'} P\Bigg(& \int_0^t \left\langle J_{0\to s}(x)^{-1} V(X_s^x), \xi\right\rangle^2 ds \le \epsilon^{m(j)}, \\
& \sum_{k=1}^d \int_0^t \left\langle J_{0\to s}(x)^{-1} [V_k, V](X_s^x), \xi\right\rangle^2 ds \\
& + \int_0^t \left\langle J_{0\to s}(x)^{-1} \left([V_0, V] + \frac{1}{2}\sum_{i=1}^d [V_i, [V_i, V]]\right)(X_s^x), \xi \right\rangle^2 ds > \frac{\epsilon^{m(j+1)}}{n(j)} \Bigg),
\end{aligned}$$

where $n(j) = \#\Sigma_j'$. Since we can find the bounded variation and the quadratic variation parts of the martingale $(\langle J_{0\to s}(x)^{-1} V(X_s^x), \xi\rangle)_{0\le s\le t}$ in the above expression, we are able to apply the Norris lemma (see [24, Lemma 2.3.2]). We observe that $8m(j+1) < m(j)$; hence we can apply it with $q = \frac{m(j)}{m(j+1)}$.

4. We obtain for $p \ge 2$—still by the Norris lemma—the estimate

$$P(E_j \cap E_{j+1}^c) \le d_1 \left(\frac{\epsilon^{m(j+1)}}{n(j)}\right)^{rp} + d_2 \exp\left(-\left(\frac{\epsilon^{m(j+1)}}{n(j)}\right)^{-\nu}\right)$$

for $\epsilon \le \epsilon_2$. Furthermore, $r, \nu > 0$ with $18r + 9\nu < q - 8$, and the numbers d_1, d_2 depend on the vector fields $V_0, \dots, V_d$, and on p, T. The number ϵ_2 can be chosen as $\epsilon_2 = \epsilon_3 t^{k_1}$, where ϵ_3 does not depend on t anymore.

5. Putting all this together, we take the minimum of ϵ_1 and ϵ_2 to obtain the desired dependence on t. □

Acknowledgment. The authors are grateful to two unknown referees who helped to considerably improve the presentation and contents of this paper. In particular, we are grateful that they pointed out Corollary 3.25 of [21].

BILLIARD SCATTERING ON ROUGH SETS: TWO-DIMENSIONAL CASE*

ALEXANDER PLAKHOV†

Abstract. The notion of a rough two-dimensional (convex) body is introduced, and to each rough body there is assigned a measure on $\mathbb{T}^3$ describing billiard scattering on the body. The main result is characterization of the set of measures generated by rough bodies. This result can be used to solve various problems of least aerodynamical resistance.

Key words. billiards, scattering on rough surfaces, Monge–Kantorovich optimal mass transportation, problems of minimal and maximal resistance, shape optimization

AMS subject classifications. 37N05, 49K30, 49Q10

1. Definition of a rough set and statement of main theorem.

1.1. Introductory remarks and review of literature. In this paper the notion of a rough two-dimensional (convex) body is given and some properties of rough bodies are established.

Let $B \subset \mathbb{R}^2$ be a convex bounded set with nonempty interior, that is, a bounded convex body. Consider the "set" obtained from B by moving off a set of "very small" area. Such a (heuristically defined) set is called a *rough body*: from the "macroscopic" point of view, it almost coincides with B, and, from the "microscopic" point of view, it contains some "flaws." (One can imagine a detail of a mechanism that, after a period of exploitation, has some defects.) If the removed set adjoins the boundary ∂B, then one can expect that a flow of point particles incident on the rough body is reflected in another way as compared to reflection from B.

The notion of rough body arises naturally when studying Newton-like problems of the body of least resistance. The first problem of such kind was considered by Newton himself [1]. Recently there were several works made concerning the problem of least resistance in various classes of admissible bodies; see, e.g., [2], [3], [4], [5], [6], [7], [8], [9], [10], [11], [12], [13], [15]. The solution of a minimization problem for the case of *rotating bodies* can be naturally identified with a rough body [14]; see also the concluding remarks to this paper.

There are many papers on particle scattering by rough bodies (see, e.g., [16], [17], [18]); they describe bodies and flows of particles that occur in nature. On the contrary, we assume that a rough structure can be "manufactured," and our aim is to describe all possible rough structures.

1.2. Definition of a rough body. It is supposed that the "microscopic structure" of the boundary of a rough body can be detected from observations of particle

scattering on the body. From this point of view, two rough bodies are considered equal if they scatter flows of particles in an identical manner. Having these observations in mind, we give the definition of a rough body.

Let B be a bounded convex body. Denote by $n(\xi)$ the unit outer normal vector to ∂B at a regular point $\xi \in \partial B$, and denote by $(\partial B \times S^1)_+$ the set of pairs $(\xi, v) \in \partial B \times S^1$ such that $\langle n(\xi), v\rangle \geq 0$. Here and in what follows, $\langle \cdot, \cdot \rangle$ means the standard scalar product in $\mathbb{R}^2$. The set $(\partial B \times S^1)_+$ is equipped with the measure μ which is defined by $d\mu(\xi, v) = \langle n(\xi), v\rangle \, d\xi \, dv$, where $d\xi$ and dv are the one-dimensional Lebesgue measures on ∂B and S^1, respectively.

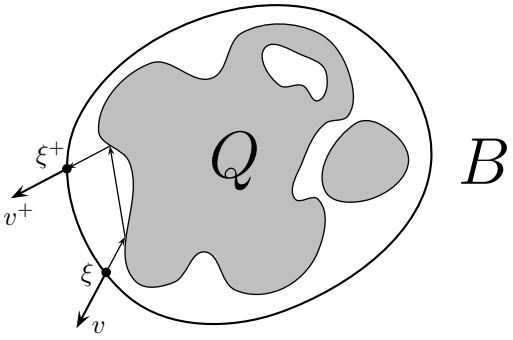

FIG. 1. *A billiard trajectory in* $\mathbb{R}^2 \setminus Q$.

Let Q be a set with piecewise smooth boundary contained in B; consider the billiard in $\mathbb{R}^2 \setminus Q$. Note that Q is not necessarily connected. For $(\xi, v) \in (\partial B \times S^1)_+$, consider a billiard particle starting at the point ξ with the velocity $-v$. After several (maybe none) reflections from $\partial Q \setminus \partial B$, the particle will intersect ∂B again, at a point $\xi^+ = \xi^+_{Q,B}(\xi, v) \in \partial B$; denote by $v^+ = v^+_{Q,B}(\xi, v)$ the velocity at this point (see Figure 1). It may happen that the initial point ξ belongs to ∂Q; in that case we have $\xi^+ = \xi$ and the vector v^+ is symmetric to v with respect to $n(\xi)$. It may also happen that at some moment the particle either gets into a singular point of ∂Q, or touches ∂Q at a regular point, or stays in $B \setminus Q$ forever and does not intersect ∂B again, or makes an infinite number of reflections in finite time. The set of corresponding points (ξ, v) has zero measure, and the corresponding values $\xi^+_{Q,B}(\xi, v)$ and $v^+_{Q,B}(\xi, v)$ are not defined.

Thus, there is defined the one-to-one mapping $T_{Q,B} : (\xi, v) \mapsto (\xi^+_{Q,B}(\xi, v), v^+_{Q,B}(\xi, v))$ of a full measure subset of $(\partial B \times S^1)_+$ onto itself. It has the following properties:

T1. $T_{Q,B}$ preserves the measure μ.
T2. $T^{-1}_{Q,B} = T_{Q,B}$.

The mapping $T_{Q,B}$ induces the measure $\nu_{Q,B}$ on $\mathbb{T}^3 = S^1 \times S^1 \times S^1$ in the following way. Let $A \subset \mathbb{T}^3$ be a Borel set; by definition,

$$\nu_{Q,B}(A) = \mu\left(\{(\xi, v) \in (\partial B \times S^1)_+ : (v, v^+_{Q,B}(\xi, v), n(\xi)) \in A\}\right).$$

In fact, the measure $\nu_{Q,B}$ contains information about particle scattering on Q. Imagine that an observer has no means to track the trajectory of particles inside B. Instead, for each incident particle there is registered the triple of vectors: the initial and final

velocities (measured at the points of first and second intersection with ∂B), and the normal vector to ∂B at the point of first intersection with ∂B. The normal vector at the second point of intersection is not registered; as will be seen later (Lemma 1), if the area of $B \setminus Q$ is small, then the difference between the normal vectors at these two points is also small. The measure $\nu_{Q,B}$ describes the distribution of triples.

DEFINITION 1. *We say that a sequence of sets* $\{Q_m,\ m = 1, 2, \ldots\}$ *represents a* rough body *if it has the following properties:*

M1. $Q_m \subset B$ *and* $\operatorname{Area}(B \setminus Q_m) \to 0$ *as* $m \to \infty$.

M2. *The sequence of measures* $\nu_{Q_m,B}$ *weakly converges.*

Two sequences of such sets are called equivalent if the corresponding limiting measures coincide. An equivalence class is called a body obtained by roughening B*, or simply* rough body*, and denoted by* $\mathcal{B}$*, and the corresponding limiting measure is denoted by* $\nu_{\mathcal{B}}$.

Note that the sets Q_m in this definition are not necessarily connected.

Remark. Since $\mathbb{T}^3$ is compact and the full measure of $\mathbb{T}^3$ satisfies $\nu_{Q,B}(\mathbb{T}^3) \le 2\pi\,|\partial B|$, one concludes that the set of measures $\{\nu_{Q,B}\}$, with fixed B, is weakly precompact. That is, any sequence of measures $\{\nu_{Q_m,B}\}$ contains a weakly converging subsequence. In this sense one can say that a sequence, satisfying only condition M1, can represent more than one rough body.

We would also like to mention that, first, two rough bodies obtained one from another by translation are identified, according to our definition. Second, particle scattering on $\mathcal{B}$ in a small neighborhood of $\xi \in \partial B$ can be detected if ξ is an extreme point of B, and cannot otherwise. Indeed, if ξ is an extreme point of B, then the scattering is described by the restriction of $\nu_{\mathcal{B}}$ on $\mathbb{T}^2 \times \mathcal{N}_{n(\xi)}$, with $\mathcal{N}_{n(\xi)}$ being a small neighborhood of $n(\xi)$ in S^1. If, otherwise, ξ is not an extreme point of B, that is, belongs to an open linear segment contained in ∂B, the scattering can be determined only on the whole segment.

Actually, from the viewpoint of applications to the problems of optimal resistance in *homogeneous* and *rarefied* media (see section 4, containing concluding remarks and applications), these drawbacks are not so serious. Indeed, resistance of a body is invariant under translations (due to homogeneity). Besides, if the boundary of a body contains a linear segment, then one does not need to know scattering at each point of the segment; it suffices to know it on the whole segment (due to homogeneity and rarefaction).

The definition of a rough body could be made in a slightly different way, basing it on measures defined on $S^1 \times S^1 \times \partial B$. In that case the triple (v, v^+, ξ) should be registered, with ξ being the point of first intersection with ∂B. That definition would allow one to register particle scattering at each point of ∂B and to distinguish between bodies obtained by translation one from another. However, we prefer to adopt the former definition, since it seems to us mathematically more transparent and makes the arguments a bit easier.

1.3. Examples. Sometimes it is convenient to use another representation of the measure $\nu_{\mathcal{B}}$. Namely, consider the change of coordinates $(v, v^+, n) \mapsto (\varphi, \varphi^+, n)$, where $\varphi = \operatorname{Arg} v - \operatorname{Arg} n$, $\varphi^+ = \operatorname{Arg} v^+ - \operatorname{Arg} n$. Here $\operatorname{Arg} v$ is the angle between a fixed vector and v measured, say, clockwise from this vector to v. If $(v, v^+, n) \in \operatorname{spt} \nu_{\mathcal{B}}$, then φ and φ^+ belong to $[-\pi/2, \pi/2]$ modulo 2π. Introduce the shorthand notation $\square := [-\pi/2, \pi/2] \times [-\pi/2, \pi/2]$ and define the mapping $\varpi : \square \times S^1 \to \mathbb{T}^3$ by $\varpi(\varphi, \varphi^+, n) = (v, v^+, n)$. One has $\operatorname{spt} \nu_{\mathcal{B}} \subset \varpi(\square \times S^1)$. Denote $\breve{\nu}_{\mathcal{B}} := (\varpi^{-1})^{\#} \nu_{\mathcal{B}}$. Sometimes this measure can be factorized: $\breve{\nu}_{\mathcal{B}} = \eta_{\mathcal{B}} \otimes \tau_B$, where $\eta_{\mathcal{B}}$ is defined on $\square$

and τ_B is the surface measure on B; so to say, the "roughness" is "homogeneous" along the body's boundary. Consider several examples.

Example 1 ("smooth body"). The rough body represented by the sequence $Q_m = B$ is identified with B itself. The corresponding measure is $\breve{\nu}_B = \eta_0 \otimes \tau_B$, where the measure η_0 has the density $\cos\varphi \cdot \delta(\varphi + \varphi^+)$; the support of η_0 is shown in Figure 2(b). In Figure 2(a), B is taken to be an ellipse.

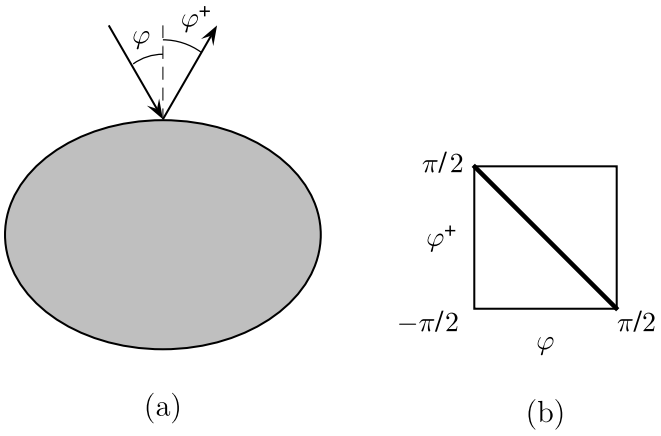

FIG. 2. *A smooth body* (a) *and the support of the corresponding measure* η_0 (b).

Example 2 (roughness formed by triangular hollows). Q_m is a $2m$-polygon; the 270° angles alternate with the angles that are slightly smaller than 90°. All vertices corresponding to the angles smaller than 90° belong to ∂B. Any two sides that form a 270° angle are equal. The largest side length tends to zero as $m \to \infty$. Thus, the set Q_m is obtained by moving off m "hollows" from its convex hull, each of the hollows being an isosceles right triangle.

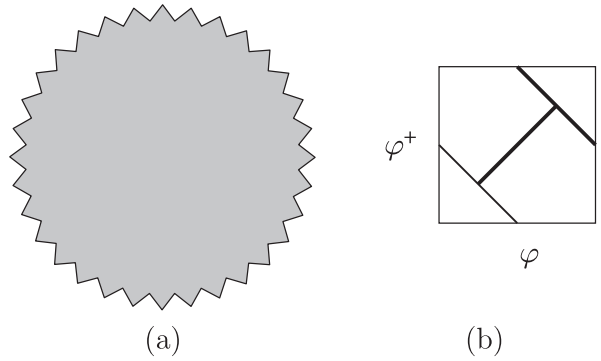

FIG. 3. *A rough body with hollows being isosceles right triangles* (a) *and the support of the corresponding measure* $\eta_\triangledown$ (b).

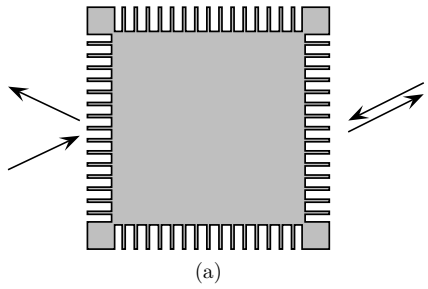
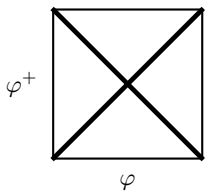
The corresponding measure is $\breve{\nu}_{\mathcal{B}} = \eta_\triangledown \otimes \tau_B$, where the measure $\eta_\triangledown$ has the density $\cos\varphi \cdot [\chi_{[-\pi/2,-\pi/4]}(\varphi)\,\delta(\varphi+\varphi^+ + \frac{\pi}{2}) + \chi_{[-\pi/4,\pi/4]}(\varphi)\,\delta(\varphi-\varphi^+) + \chi_{[\pi/4,\pi/2]}(\varphi)\,\delta(\varphi+\varphi^+ - \frac{\pi}{2})] + |\sin\varphi| \cdot [\chi_{[-\pi/4,0]}(\varphi)\,\delta(\varphi+\varphi^+ + \frac{\pi}{2}) - \chi_{[-\pi/4,\pi/4]}(\varphi)\,\delta(\varphi-\varphi^+) + \chi_{[0,\pi/4]}(\varphi)\,\delta(\varphi+\varphi^+ - \frac{\pi}{2})]$. Thus, the support of $\eta_\triangledown$ is the union of three segments; see Figure 3(b). The

middle segment $\varphi^+ = \varphi$ corresponds to double reflections, and the lateral segments, $\varphi^+ = -\varphi - \pi/2$ and $\varphi^+ = -\varphi + \pi/2$, correspond to single reflections, from the right or from the left side of a triangular hollow. In Figure 3(a), B is a circle.

Example 3 (roughness formed by rectangular hollows). The sets Q_m are obtained by removing a finite number of "rectangular hollows" from B. In other words, one has $Q_m = B \setminus (\cup_n \Omega_{m,n})$, where the removed sets $\Omega_{m,n}$ do not mutually intersect and each set $\partial\Omega_{m,n} \setminus \partial B$ is the union of three sides of a rectangle. The ratio (width)/(depth) of a hollow depends only on m and is denoted by h_m. Denote by $l_m = |\partial B \setminus \cup_n(\partial\Omega_{m,n})|/|\partial B|$ the relative length of the part of boundary ∂B not covered by hollows. We assume that $\lim_{m\to\infty} h_m = 0 = \lim_{m\to\infty} l_m$. In Figure 4(a), B is a square.



(a)



(b)

FIG. 4. *A rough body where hollows are "thin rectangles"* (a)*; the support of the corresponding measure* $\eta_\square$ (b).

The measure $\breve{\nu}_{\mathcal{B}}$ equals $\breve{\nu}_{\mathcal{B}} = \eta_\square \otimes \tau_B$. The density of the measure $\eta_\square$ equals $\frac{1}{2}\cos\varphi \cdot (\delta(\varphi + \varphi^+) + \delta(\varphi - \varphi^+))$, and the support is the union of two diagonals, $\varphi^+ = \varphi$ and $\varphi^+ = -\varphi$; see Figure 4(b). The particles with an even (odd) number of reflections contribute to the first (second) diagonal.

1.4. Main theorem. According to Definition 1, each rough body is identified with a measure on $\mathbb{T}^3$. The question is, What is the set of these measures? The following definition and theorem give the answer.

Let us first introduce some notation: $\pi_{v,n} : \mathbb{T}^3 \to \mathbb{T}^2$, $\pi_n : \mathbb{T}^3 \to S^1$, etc., are projections onto the corresponding subspaces: $\pi_{v,n}(v, v^+, n) = (v, n)$, $\pi_n(v, v^+, n) = n$, etc.; $\pi_d : \mathbb{T}^3 \to \mathbb{T}^3$ is the symmetry with respect to the plane $v = v^+$, that is, $\pi_d(v, v^+, n) = (v^+, v, n)$; $z_+ = \max\{0, z\}$ is the positive part of $z \in \mathbb{R}$; and u means Lebesgue measure on S^1. Recall that τ_B is the surface measure on B and is defined on S^1.

DEFINITION 2. *We denote by* $\mathcal{M}_B$ *the set of measures* ν *on* $\mathbb{T}^3$ *such that the following properties hold:*

A1. *The marginal measures* $\pi^{\#}_{v,n}\nu$ *and* $\pi^{\#}_{v^+,n}\nu$ *are*

$$\pi^{\#}_{v,n}\nu = \langle v, n\rangle_+ \cdot u \otimes \tau_B, \qquad \pi^{\#}_{v^+,n}\nu = \langle v^+, n\rangle_+ \cdot u \otimes \tau_B.$$

A2. $\pi^{\#}_d \nu = \nu$.

Denote also $\mathcal{M} = \cup_B \mathcal{M}_B$*, the union being taken over all bounded convex bodies* B.

Taking into account the Alexandrov theorem on characterization of surface measures, one concludes that $\mathcal{M}$ is the set of measures ν on $\mathbb{T}^3$ such that

(1) the marginal measure $\pi^{\#}_{n}\nu =: \tau$ satisfies the conditions
  1a. $\int_{S^1} n\, d\tau(n) = 0$;
  1b. for any $v \in S^1$ it holds that $\int_{S^1} \langle n, v\rangle^2\, d\tau(n) \neq 0$;
(2) the marginal measures $\pi^{\#}_{v,n}\nu$ and $\pi^{\#}_{v^+,n}\nu$ satisfy the conditions
  2a. $\pi^{\#}_{v,n}\nu = \langle v, n\rangle_+ \cdot u \otimes \tau$;
  2b. $\pi^{\#}_{v^+,n}\nu = \langle v^+, n\rangle_+ \cdot u \otimes \tau$.

Thus, these marginal measures coincide; the only difference is in the notation for the variables: v, n in case 2a and v^+, n in case 2b.

Now we can state the main theorem.

THEOREM. *The set of measures $\{\nu_{\mathcal{B}}\}$, with $\mathcal{B}$ being all possible bodies obtained by roughening B, coincides with $\mathcal{M}_B$. Therefore, $\{\nu_{\mathcal{B}}$, $\mathcal{B}$ is a rough body$\} = \mathcal{M}$.*

In section 2, we formulate two auxiliary lemmas and using them prove the theorem. In section 3, the lemmas are proved. Section 4 contains concluding remarks and applications of the theorem to problems of optimal aerodynamic resistance. Appendices A and B contain proofs of some auxiliary technical results.

2. Statement of auxiliary lemmas and proof of theorem.

2.1. Statement of Lemma 1. Fix a bounded convex body B. Two points $\xi_1, \xi_2 \in \partial B$, $\xi_1 \neq \xi_2$, divide the curve ∂B into two arcs. Denote by $l(\xi_1, \xi_2)$ the length of the smallest arc and denote

$$c = c_B := \inf_{\substack{\xi_1,\xi_2\in\partial B\\ \xi_1\neq\xi_2}} \frac{|\xi_1 - \xi_2|}{l(\xi_1, \xi_2)};$$

one obviously has $0 < c < 1$.

Let $Q \subset B$; denote

$$\overline{|\xi - \xi^+|}_{Q,B} := \iint_{(\partial B\times S^1)_+} |\xi - \xi^+_{Q,B}(\xi, v)|\, d\mu(\xi, v)$$

and

$$\overline{|n - n^+|}_{Q,B} := \iint_{(\partial B\times S^1)_+} |n(\xi) - n(\xi^+_{Q,B}(\xi, v))|\, d\mu(\xi, v).$$

LEMMA 1. (a) *The following holds true:*

$$\overline{|\xi - \xi^+|}_{Q,B} \leq 2\pi \cdot \mathrm{Area}(B \setminus Q).$$

(b) *For sufficiently small* $\mathrm{Area}(B \setminus Q)$,[1] *one has*

$$\overline{|n - n^+|}_{Q,B} \leq \frac{2\pi\sqrt{8\pi}}{\sqrt{c}} \sqrt{\mathrm{Area}(B \setminus Q)}.$$

2.2. Statement of Lemma 2. Let us first introduce the notion of a hollow.

DEFINITION 3. *Let $\Omega \subset \mathbb{R}^2$ be a closed bounded set with piecewise smooth boundary and $I \subset \partial\Omega$, where the following hold:*

(i) *I is an interval contained in a straight line $\langle x, n\rangle = a$.*

(ii) *$\Omega \setminus I$ is contained in the open half-plane $\langle x, n\rangle < a$. Here n is a fixed unit vector.*

Then the pair (Ω, I) is called a hollow oriented by n, or just an n-hollow.

[1] That is, it is smaller than a positive value depending only on B.

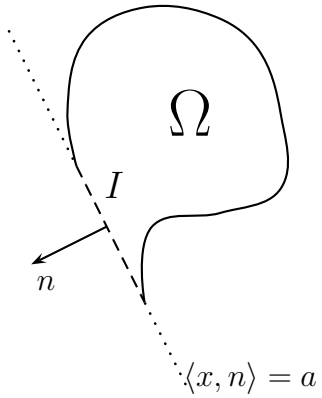


FIG. 5. *A hollow.*

In Figure 5 and in what follows, I is shown by a dashed line, and $\partial\Omega \setminus I$ is shown by a solid line.

Define the measure $\tilde{\mu}_I$ on $I \times S^1$ by $d\tilde{\mu}_I(\xi, v) = \frac{\langle n,v\rangle_+}{|I|}\, d\xi\, dv$, where $|I|$ means the length of I. Obviously, $\tilde{\mu}_I$ is supported on the set $(I \times S^1)_+ := \{(\xi, v) \in I \times S^1 : \langle n, v\rangle \geq 0\}$. Define the one-to-one mapping $(\xi, v) \mapsto (\Xi^+_{\Omega,I}(\xi, v), V^+_{\Omega,I}(\xi, v))$ of a full measure subset of $(I \times S^1)_+$ onto itself. Namely, consider the billiard in Ω. Let $(\xi, v) \in (I \times S^1)_+$; consider the billiard particle starting at the point ξ with the velocity $-v$. It makes several reflections from $\partial\Omega \setminus I$ and then reflects from I again, at a point $\Xi^+ = \Xi^+_{\Omega,I}(\xi, v)$. The velocity immediately before this reflection is denoted by $V^+ = V^+_{\Omega,I}(\xi, v)$. The mapping so defined preserves the measure $\tilde{\mu}_I$ and is an involution, that is, coincides with its inverse.

One can give an equivalent definition based on the mapping $\xi^+_{Q,B}(\xi, v), v^+_{Q,B}(\xi, v)$ just defined in section 1.2. Take a set Q such that Ω is a connected component of $\operatorname{conv} Q \setminus Q$ and I is a connected component of $\partial(\operatorname{conv} Q) \setminus \partial Q$. For $(\xi, v) \in (I \times S^1)_+$, let by definition $(\Xi^+_{\Omega,I}(\xi, v), V^+_{\Omega,I}(\xi, v)) := (\xi^+_{Q,\operatorname{conv} Q}(\xi, v), v^+_{Q,\operatorname{conv} Q}(\xi, v))$. This definition does not depend on the choice of Q.

DEFINITION 4. *Let (Ω, I) be a hollow. The measure $\eta_{\Omega,I}$ on $\mathbb{T}^2 = S^1 \times S^1$ is defined as follows. For a Borel set $A \subset \mathbb{T}^2$, put*

$$\eta_{\Omega,I}(A) := \tilde{\mu}_I(\{(\xi, v) \in (I \times S^1)_+ : (v, V^+_{\Omega,I}(\xi, v)) \in A\}).$$

We shall say that $\eta_{\Omega,I}$ is the measure generated by the hollow (Ω, I).

Here we use the notation $\pi_v, \pi_{v^+} : \mathbb{T}^2 \to S^1$ for the projections onto the subspaces $\{v\}$ and $\{v^+\}$, respectively; $\pi_v(v, v^+) = v$, $\pi_{v^+}(v, v^+) = v^+$. We also denote by π_d the symmetry with respect to the diagonal $v = v^+$; $\pi_d(v, v^+) = (v^+, v)$.

DEFINITION 5. *Denote by Λ_n the set of measures η on $\mathbb{T}^2$ such that*

(i) $d\pi^{\#}_v \eta(v) = \langle v, n\rangle_+\, dv$, $d\pi^{\#}_{v^+}\eta(v^+) = \langle v^+, n\rangle_+\, dv^+$;

(ii) $\pi^{\#}_d \eta = \eta$.

Any measure $\eta_{\Omega,I}$ generated by an n-hollow belongs to Λ_n. Indeed, for any $A \subset S^1$ one has $\pi^{\#}_v \eta_{\Omega,I}(A) = \eta_{\Omega,I}(A \times S^1) = \tilde{\mu}_I(\{(\xi, v) \in (I \times S^1)_+ : v \in A\}) = \frac{1}{|I|} \iint_{I\times A} \langle n, v\rangle_+\, d\xi\, dv = \int_A \langle n, v\rangle_+\, dv$. This proves the first equality in (i).

Similarly, one has $\pi^{\#}_{v^+}\eta_{\Omega,I}(A) = \eta_{\Omega,I}(S^1 \times A) = \tilde{\mu}_I(\{(\xi, v) \in (I \times S^1)_+ : V^+_{\Omega,I}(\xi, v) \in A\})$. Since the mapping $(\xi, v) \mapsto (\Xi^+_{\Omega,I}, V^+_{\Omega,I})$ preserves the measure, one gets the

value $\tilde{\mu}_I(\{(\xi,v)\in(I\times S^1)_+ : v\in A\})$, which in turns equals $\int_A \langle n,v\rangle_+\,dv$. This proves the second equality in (i). Finally, the relation (ii) for $\eta_{\Omega,I}$ is a simple consequence of involutive and measure preserving properties of the mapping $(\xi,v)\mapsto(\Xi^+_{\Omega,I},V^+_{\Omega,I})$.

LEMMA 2. *The set of measures generated by n-hollows is weakly dense in* Λ_n.

2.3. Proof of the direct statement of theorem. Here we prove that for any body $\mathcal{B}$ obtained by roughening B it holds that $\nu_{\mathcal{B}}\in\mathcal{M}_B$.

Let $Q\subset B$; define the measure $\nu'_{Q,B}$ on $\mathbb{T}^3$ by

$$\nu'_{Q,B}(A):=\mu\left(\{(\xi,v)\in(\partial B\times S^1)_+ : (v,v^+_{Q,B}(\xi,v),n(\xi^+_{Q,B}(\xi,v)))\in A\}\right),$$

where A is an arbitrary Borel subset of $\mathbb{T}^3$. Thus, the definition of both $\nu_{Q,B}$ and $\nu'_{Q,B}$ is based on observations of vector triples (v,v^+,n) and (v,v^+,n^+), respectively. Here n and n^+ are the outer normals to ∂B at the points where the particle *gets in* B and *gets out* of B. The measures $\nu_{Q,B}$ and $\nu'_{Q,B}$ have the following properties:

$$\pi^{\#}_{v,n}\nu_{Q,B}=\langle v,n\rangle_+\cdot u\otimes\tau_B, \tag{1}$$

$$\pi^{\#}_{v^+,n^+}\nu'_{Q,B}=\langle v^+,n^+\rangle_+\cdot u\otimes\tau_B, \tag{2}$$

$$\pi^{\#}_{d}\nu_{Q,B}=\nu'_{Q,B}. \tag{3}$$

Consider a sequence $\{Q_m\}$ representing $\mathcal{B}$; let us show that $\nu_{Q_m,B}-\nu'_{Q_m,B}$ weakly converges to zero as $m\to\infty$. It is enough to prove that for any continuous function f on $\mathbb{T}^3$ it holds that

$$\int_{\mathbb{T}^3} f(v,v^+,n)\,d\nu_{Q_m,B}(v,v^+,n)-\int_{\mathbb{T}^3} f(v,v^+,n^+)\,d\nu'_{Q_m,B}(v,v^+,n^+)\to_{m\to\infty}0. \tag{4}$$

Taking into account the formulas for a change of variables

$$\int_{\mathbb{T}^3} f(v,v^+,n)\,d\nu_{Q,B}(v,v^+,n)=\int_{(\partial B\times S^1)_+} f(v,v^+_{Q,B}(\xi,v),n(\xi))\,d\mu(\xi,v)$$

and

$$\int_{\mathbb{T}^3} f(v,v^+,n^+)\,d\nu'_{Q,B}(v,v^+,n^+)=\int_{(\partial B\times S^1)_+} f(v,v^+_{Q,B}(\xi,v),n(\xi^+_{Q,B}(\xi,v)))\,d\mu(\xi,v),$$

formula (4) takes the form

$$\lim_{m\to\infty}\int_{(\partial B\times S^1)_+}\left[f(v,v^+_{Q_m,B}(\xi,v),n(\xi^+_{Q_m,B}(\xi,v)))-f(v,v^+_{Q_m,B}(\xi,v),n(\xi))\right]d\mu(\xi,v)=0. \tag{5}$$

According to Lemma 1, the difference $n(\xi^+_{Q_m,B}(\xi,v))-n(\xi)$ converges to zero in mean, and hence it converges to zero in measure; therefore the difference

$$f(v,v^+_{Q_m,B}(\xi,v),n(\xi^+_{Q_m,B}(\xi,v)))-f(v,v^+_{Q_m,B}(\xi,v),n(\xi))$$

also converges to zero in measure. It follows that formula (5) is true.

Thus, both $\nu_{Q_m,B}$ and $\nu'_{Q_m,B}$ weakly converge to $\nu_{\mathcal{B}}$. Substituting $Q = Q_m$ into formulas (1)–(3) and passing to limit as $m \to \infty$, one gets

$$\pi^{\#}_{v,n}\nu_{\mathcal{B}} = \langle v, n\rangle_+ \cdot u \otimes \tau_B,$$
$$\pi^{\#}_{v^+,n}\nu_{\mathcal{B}} = \langle v^+, n\rangle_+ \cdot u \otimes \tau_B,$$
$$\pi^{\#}_{d}\nu_{\mathcal{B}} = \nu_{\mathcal{B}},$$

that is, $\nu_{\mathcal{B}} \in \mathcal{M}_B$.

2.4. Proof of the inverse statement of theorem. Here it is proved that for any $\nu \in \mathcal{M}_B$ there exists a body $\mathcal{B}$ obtained by roughening B such that $\nu_{\mathcal{B}} = \nu$. The proof is based on two statements.

STATEMENT 1. *Let B be a convex polygon. Then for any measure $\nu \in \mathcal{M}_B$ there exists a body $\mathcal{B}$ obtained by roughening B such that $\nu_{\mathcal{B}} = \nu$.*

Proof. Let us enumerate the sides of the polygon B and denote by c_i the length of the ith side and by n_i the outer unit normal to this side. By δ_n, denote the probabilistic atomic measure on S^1 concentrated at $n \in S^1$, that is, $\delta_n(n) = 1$. The surface measure of B is $\tau_B = \sum c_i\delta_{n_i}$; this implies that any measure $\nu \in \mathcal{M}_B$ has the form $\nu = \sum c_i\eta_i \otimes \delta_{n_i}$, where $\eta_i \in \Lambda_{n_i}$.

According to Lemma 2, any measure η_i is the weak limit as $m \to \infty$ of measures $\eta_{\Omega_i^m, I_i^m}$ generated by a sequence of n_i-hollows (Ω_i^m, I_i^m). Now take a sequence of sets Q_m such that $\operatorname{conv} Q_m = B$ and each connected component of $B\setminus Q_m$ is the image of a set Ω_i^m under the composition of a homothety with positive ratio and a translation; additionally, the image of I_i^m under this transformation belongs to (ith side of B)$\setminus \partial Q_m$. We also require that $\operatorname{Area}(B \setminus Q_m) \to 0$ and $|(i\text{th side of } B) \setminus \partial Q_m| =: c_i^m \to c_i$ as $m \to \infty$. In Appendix A it is shown how to construct such a sequence Q_m. The measure $\nu_{Q_m,B} = \tilde\nu_m + \sum_i \nu_i^m$ is the sum of the measure $\tilde\nu_m$ corresponding to reflections from $\partial B \cap \partial Q_m$ and the measures ν_i^m corresponding to particles getting into the "hollows on the ith side." One has $\tilde\nu_m = \sum_i (c_i - c_i^m)\cdot\eta_0 \otimes \delta_{n_i}$ and $\nu_i^m = c_i^m \cdot \eta_{\Omega_i^m, I_i^m} \otimes \delta_{n_i}$. The norm of $\tilde\nu_m$ goes to zero and ν_i^m weakly converges to $c_i\,\eta_i \otimes \delta_{n_i}$ for any i; it follows that $\nu_{Q_m,B}$ weakly converges to ν as $m \to \infty$. Therefore, the sequence Q_m represents a body $\mathcal{B}$ obtained by roughening B, and $\nu_{\mathcal{B}} = \nu$. □

STATEMENT 2. *For any measure $\nu \in \mathcal{M}_B$ there exist a sequence of convex polygons $B_k \subset B$ with $\operatorname{Area}(B \setminus B_k) \to 0$ and a sequence of measures $\nu_k \in \mathcal{M}_{B_k}$ weakly converging to ν as $k \to \infty$.*

Proof. Consider a partition of the circumference S^1 into a finite number of arcs, $S^1 = \cup_i \mathcal{S}^i$. It induces the partition of ∂B into arcs $\partial B^i = \{\xi \in \partial B : n(\xi) \in \mathcal{S}^i\}$. Consider the polygon $\check B$ inscribed into ∂B whose vertices are separation points of this partition. Denote by n_i the outer normal to the ith side of this polygon. Denote by s_{v_1,v_2} the operator of rotation on S^1 that takes v_1 to v_2, and define the mapping $\Upsilon_i : \mathbb{T}^2 \times \mathcal{S}^i \to \mathbb{T}^2$ by $\Upsilon_i(v, v^+, n) = (s_{n,n_i}v, s_{n,n_i}v^+)$. Finally, consider the measure $\check\nu = \sum_i |b^i|\,\eta_i \otimes \delta_{n_i}$, where $|b^i|$ is the length of the ith side of the polygon, and the measure η_i on $\mathbb{T}^2$ is defined by $\eta_i(A) = \frac{1}{|\partial B^i|}\,\nu(\Upsilon_i^{-1}(A))$ for arbitrary Borel set $A \subset \mathbb{T}^2$. Here $|\partial B^i|$ is the length of the arc ∂B^i. One easily verifies that $\check\nu$ belongs to $\mathcal{M}_{\check B}$.

Now take a sequence of partitions of S^1, $\{\mathcal{S}_k^i\}_i$, $k = 1, 2, \dots$, where the maximum arc length of a partition goes to zero as $k \to \infty$. Denote by $\{\partial B_k^i\}_i$, $k = 1, 2, \dots$, the sequence of induced partitions of ∂B, and take the sequence of polygons B_k generated by these partitions. One clearly has $\operatorname{Area}(B \setminus B_k) \to 0$ and

$$\max_i \frac{|b_k^i|}{|\partial B_k^i|} \to 1 \qquad \text{as} \quad k \to \infty, \tag{6}$$

where $|b_k^i|$ is the length of the ith side of B_k. In the same way as above, one defines the mappings $\Upsilon_{ik} : \mathbb{T}^2 \times \mathcal{S}_k^i \to \mathbb{T}^2$ and the measures $\nu_k = \sum_i |b_k^i|\, \eta_{ik} \otimes \delta_{n_{ik}} \in \mathcal{M}_{B_k}$, where η_{ik} is given by $\eta_{ik}(A) := \frac{1}{|\partial B_k^i|}\, \nu(\Upsilon_{ik}^{-1}(A))$ and n_{ik} is the outer unit normal to the ith side of B_k.

It remains to show that ν_k weakly converges to ν. For any continuous function f on $\mathbb{T}^3$ one has

$$\iiint_{\mathbb{T}^3} f(v, v^+, n)\, d\nu_k(v, v^+, n) = \sum_i |b_k^i| \iint_{\mathbb{T}^2} f(v, v^+, n_{ik})\, d\eta_{ik}(v, v^+)$$

$$= \sum_i \frac{|b_k^i|}{|\partial B_k^i|} \iiint_{\mathbb{T}^2 \times \mathcal{S}_k^i} f(\Upsilon_{ik}(v, v^+, n), n_{ik})\, d\nu(v, v^+, n). \tag{7}$$

For each k define the mapping from $\mathbb{T}^3$ to $\mathbb{T}^3$ by the relations $(v, v^+, n) \mapsto (\Upsilon_{ik}(v, v^+, n), n_{ik})$ if $n \in \mathcal{S}_k^i$. It uniformly converges to the identity mapping as $k \to \infty$; hence the function $\tilde{f}_k$, defined by the relations $\tilde{f}_k(v, v^+, n) := f(\Upsilon_{ik}(v, v^+, n), n_{ik})$ if $n \in \mathcal{S}_k^i$, uniformly converges to f as $k \to \infty$. From here and from (6) it follows that the right-hand side in (7) converges to $\iiint_{\mathbb{T}^3} f(v, v^+, n)\, d\nu(v, v^+, n)$ as $k \to \infty$. Thus, the convergence $\int f\, d\nu_k \to \int f\, d\nu$ is proved. □

The inverse statement of the theorem follows from Statements 1 and 2. Indeed, let $\nu \in \mathcal{M}_B$. Using Statement 2, find a sequence of convex polygons $B_k \subset B$ and a sequence $\nu_k \in \mathcal{M}_{B_k}$ weakly converging to ν. According to Statement 1, each measure ν_k is generated by a rough body. Consider the sequence of sets $Q_{kl} \subset B_k$, $l = 1, 2, \ldots$, representing this body, and then from all of these sequences choose a diagonal sequence $\tilde{Q}_k = Q_{kl_k}$ such that the corresponding sequence of measures $\nu_{\tilde{Q}_k, B}$ weakly converges to ν and $\mathrm{Area}(B \setminus \tilde{Q}_k)$ goes to zero as $k \to \infty$. The sequence $\tilde{Q}_k$ represents a body $\mathcal{B}$ obtained by roughening B and $\nu_{\mathcal{B}} = \nu$.

3. Proof of the lemmas.

3.1. Proof of Lemma 1. Consider the billiard in $\mathbb{R}^2 \setminus Q$. For $(\xi, v) \in (\partial B \times S^1)_+$, denote by $\tau(\xi, v)$ the time the billiard trajectory with the initial data $\xi, -v$ spends in $B \setminus Q$. In particular, if $\xi \in \partial B \cap \partial Q$, then one has $\tau(\xi, v) = 0$.

Denote by D the set of points $(x, w) \in (B \setminus Q) \times S^1$ that are accessible from $(\partial B \times S^1)_+$; that is, there exists $(\xi, v) \in (\partial B \times S^1)_+$ such that the billiard particle with the data $\xi, -v$ at the zero moment of time at some moment $0 \le t \le \tau(\xi, v)$ will pass through x with the velocity w. This description defines the change of coordinates in $D : (\xi, v, t) \mapsto (x, w)$; $(\xi, v) \in (\partial B \times S^1)_+$, $t \in [0, \tau(\xi, v)]$, and the element of phase volume $d^2x\, dw$ in the new coordinates takes the form $d\mu(\xi, v)\, dt$. Hence, the phase volume of D equals $\iiint_D d^2x\, dw = \iint_{(\partial B \times S^1)_+} \tau(\xi, v)\, d\mu(\xi, v)$. Taking into account that $D \subset (B \setminus Q) \times S^1$ and the phase volume of $(B \setminus Q) \times S^1$ equals $2\pi \cdot \mathrm{Area}(B \setminus Q)$, one gets

$$\iint_{(\partial B \times S^1)_+} \tau(\xi, v)\, d\mu(\xi, v) \le 2\pi \cdot \mathrm{Area}(B \setminus Q). \tag{8}$$

This is in fact a simple modification of the well-known *mean free path* formula (see, e.g., [19]).

One has $\tau(\xi, v) \ge |\xi - \xi^+_{Q,B}(\xi, v)|$: the time the particle spends in $B \setminus Q$ exceeds the distance between the initial and final points of the trajectory. This inequality and (8) imply (a).

The points ξ and $\xi^+_{Q,B}(\xi,v)$ divide the curve ∂B into two arcs; denote by $\gamma(\xi,v)$ the shortest one. One has $|\gamma(\xi,v)| = l(\xi,\xi^+_{Q,B}(\xi,v))$, and therefore $|\xi - \xi^+_{Q,B}(\xi,v)| \geq c\,|\gamma(\xi,v)|$. It follows that

(9)
$$c\iint_{(\partial B\times S^1)_+} |\gamma(\xi,v)|\,d\mu(\xi,v) \leq \iint_{(\partial B\times S^1)_+} |\xi-\xi^+_{Q,B}(\xi,v)|\,d\mu(\xi,v) \leq 2\pi\cdot\mathrm{Area}(B\setminus Q).$$

Let $\varrho(y)$ be a natural parametrization of the curve ∂B, $\varrho : [0,|\partial B|] \to \partial B$. By $f(y)$ denote the measure of the values (ξ,v) such that the interval $\gamma(\xi,v)$ contains the point $\varrho(y)$; that is, $f(y) := \iint_{(\partial B\times S^1)_+} \mathbb{I}(\varrho(y)\in\gamma(\xi,v))\,d\mu(\xi,v)$. Making a change of variables in the integral in the left-hand side of (9), one gets

$$\iint_{(\partial B\times S^1)_+} |\gamma(\xi,v)|\,d\mu(\xi,v) = \int_0^{|\partial B|} f(y)\,dy,$$

and therefore

$$\int_0^{|\partial B|} f(y)\,dy \leq \frac{2\pi}{c}\,\mathrm{Area}(B\setminus Q). \tag{10}$$

One easily sees that $|f(y_1)-f(y_2)| \leq 4\,|y_1-y_2|$ for any y_1 and y_2 and $f(y)\geq 0$. From here and from (10) it follows that for sufficiently small $\mathrm{Area}(B\setminus Q)$ (namely, for $\mathrm{Area}(B\setminus Q) \leq c|\partial B|^2/(2\pi)$) it holds that $f(y) \leq \sqrt{8\pi/c}\,\sqrt{\mathrm{Area}(B\setminus Q)}$.

Recall that $\mathrm{Arg}(v)$ is the angle the vector $v\neq 0$ forms with a fixed vector v_0; the angle is measured clockwise from v_0 to v and is defined modulo 2π. Introduce the shorthand notation $\xi^+ := \xi^+_{Q,B}(\xi,v)$, and denote by $\Delta\,\mathrm{Arg}(\xi,v)$ the smallest in modulus of the values $\mathrm{Arg}(n(\xi^+)) - \mathrm{Arg}(n(\xi))$. In other words, $\Delta\,\mathrm{Arg}(\xi,v)$ equals the smallest of the values

$$\int_{\gamma(\xi,v)} |d\,\mathrm{Arg}(n_{\xi'})|, \qquad \int_{\partial B\setminus\gamma(\xi,v)} |d\,\mathrm{Arg}(n_{\xi'})|.$$

Taking into account that $|n(\xi^+)-n(\xi)| \leq |\Delta\,\mathrm{Arg}(\xi,v)|$, one gets that

$$|n(\xi^+)-n(\xi)| \leq \int_{\gamma(\xi,v)} |d\,\mathrm{Arg}(n_{\xi'})|,$$

and therefore

$$\overline{|n-n^+|}_{Q,B} \leq \iint_{(\partial B\times S^1)_+} \left(\int_{\gamma(\xi,v)} |d\,\mathrm{Arg}(n_{\xi'})|\right) d\mu(\xi,v).$$

Making a change of variables in this integral, one obtains

$$\overline{|n-n^+|}_{Q,B} \leq \int_0^{|\partial B|} f(y)\,|d\,\mathrm{Arg}(n_{\varrho(y)})| \leq 2\pi\,\sqrt{8\pi/c}\,\sqrt{\mathrm{Area}(B\setminus Q)}.$$

Thus, (b) is also proved.

3.2. Proof of Lemma 2. Fix $n \in S^1$ and $m \in \mathbb{N}$. Let σ be an involutive permutation of $\{1,\dots,m\}$, that is, $\sigma^2 = \mathrm{id}$. Divide the half-circumference $S^1_n := \{v \in S^1 : \langle v, n\rangle \geq 0\}$ into m arcs $\mathcal{S}^1_{n,m} = \mathcal{S}^1_n$, …, $\mathcal{S}^m_{n,m} = \mathcal{S}^m_n$ numbered clockwise such that, for any i, $\int_{\mathcal{S}^i_n} \langle v, n\rangle\, dv = 2/m$. For the sake of brevity we omit the subscript m when no confusion can arise.

Definition 6. *A measure η is called a (σ, n)-measure if $\eta \in \Lambda_n$ and $\operatorname{spt}\eta \subset \cup_{i=1}^m \left(\mathcal{S}^i_n \times \mathcal{S}^{\sigma(i)}_n\right)$, and therefore, for any i it holds that $\eta\left(\mathcal{S}^i_n \times \mathcal{S}^{\sigma(i)}_n\right) = 2/m$.*

Proposition 1. *For any measure $\eta \in \Lambda_n$ there exists a sequence of involutive permutations σ_k on $\{1,\dots,m_k\}$, $k = 1, 2, \dots$, such that m_k tends to infinity and any sequence of (σ_k, n)-measures weakly converges to η as $k \to \infty$.*

Proposition 2. *Let σ be an involutive permutation on $\{1,\dots,m\}$. Then the distance (in variation) between the set of measures generated by n-hollows and the set of (σ, n)-measures does not exceed $16/m$. In other words, whatever $\varepsilon > 0$, there exist a (σ, n)-measure η and an n-hollow (Ω, I) such that $\|\eta_{\Omega,I} - \eta\| < 16/m + \varepsilon$; here the norm means variation of measure.*

This distance actually equals zero, but we need only the (weaker) claim of Proposition 2.

Lemma 2 follows from Propositions 1 and 2. Indeed, let $\eta \in \Lambda_n$. First, choose the sequence of permutations σ_k, according to Proposition 1, and then, using Proposition 2, for every k choose an an n-hollow (Ω_k, I_k) such that the distance from η_{Ω_k,I_k} to the set of (σ_k, n)-measures does not exceed $17/m_k$. The sequence of chosen measures η_{Ω_k,I_k} weakly converges to η.

3.3. Proof of Proposition 1. Introduce on S^1_n the angular coordinate $\varphi = \operatorname{Arg} v - \operatorname{Arg} n$; that is, φ changes between $-\pi/2$ and $\pi/2$ and increases clockwise. With this notation, to the arcs $\mathcal{S}^i_{n,m}$ correspond the segments $J^i_m = [\arcsin(-1+2(i-1)/m), \arcsin(-1+2i/m)]$. Define the measure λ on $[-\pi/2, \pi/2]$ by $d\lambda(\varphi) = \cos\varphi\, d\varphi$, and denote by Λ the set of measures η on $\square := [-\pi/2, \pi/2] \times [-\pi/2, \pi/2]$ such that (a) $\pi^{\#}_{\varphi}\eta = \lambda = \pi^{\#}_{\varphi^+}\eta$ and (b) $\pi^{\#}_d\eta = \eta$. Here π_φ, π_{φ^+}, and π_d are defined by $\pi_\varphi(\varphi, \varphi^+) = \varphi$, $\pi_{\varphi^+}(\varphi, \varphi^+) = \varphi^+$, and $\pi_d(\varphi, \varphi^+) = (\varphi^+, \varphi)$. Reformulating Definition 6, we shall say that η is a σ-measure if $\eta \in \Lambda$ and $\operatorname{spt}\eta \subset \cup_{i=1}^m \left(J^i_m \times J^{\sigma(i)}_m\right)$. Notice that in the new notation the objects no longer depend on n: we write Λ instead of Λ_n, σ-measure instead of (σ, n)-measure, and hollow instead of n-hollow.

In this notation, Proposition 1 can be reformulated as follows: for any measure $\eta \in \Lambda$ there exists a sequence of involutive permutations σ_k on $\{1,\dots,m_k\}$, $k = 1, 2, \dots$, such that m_k tends to infinity and any sequence of σ_k-measures weakly converges to η as $k \to \infty$.

The idea of the proof is as follows. First, η is approximated by means of a rational matrix, and then this matrix is approximated by means of a larger matrix generated by a permutation.

Consider the partition of $\square$ into smaller rectangles $\square^{ij}_k = J^i_k \times J^j_k$, $i, j = 1, \dots, k$. Choose rational nonnegative numbers c^{ij}_k such that $c^{ij}_k = c^{ji}_k$, $\sum_j c^{ij}_k = 2/k$ for any i, and $\left|\eta(\square^{ij}_k) - c^{ij}_k\right| \leq k^{-3}$ for any i and j. To do so, it suffices to take positive rational values c^{ij}_k such that $\eta(\square^{ij}_k) - k^{-4} \leq c^{ij}_k \leq \eta(\square^{ij}_k)$ for $i > j$ and put $c^{ij}_k = c^{ji}_k$ for $i < j$ and $c^{ii}_k = 2/k - \sum_{j\neq i} c^{ij}_k$ for $i = j$. One has $\eta\left(J^i_k \times [-\pi/2, \pi/2]\right) = \sum_{j=1}^k \eta(\square^{ij}_k) = 2/k$; hence $c^{ii}_k - \eta(\square^{ii}_k) = \sum_{j\neq i}\left(\eta(\square^{ij}_k) - c^{ij}_k\right) \in [0, (k-1)\cdot k^{-4}] \subset [0, k^{-3}]$.

Any sequence of measures η_k satisfying the conditions $\eta_k(\square^{ij}_k) = c^{ij}_k$, $1 \leq i, j \leq k$, weakly converges to η. Indeed, for any continuous function f on $\square$ it holds that

$$\int_{\square} f\,d\eta_k - \int_{\square} f\,d\eta = \sum_{i,j=1}^{k} \int_{\square_k^{ij}} f\,(d\eta_k - d\eta) \le k^{-1} \max f \to 0$$

as $k \to \infty$.

To complete the proof, it suffices to find an integer $m_k > k$ and an involutive permutation σ_k of $\{1, \dots, m_k\}$ such that any σ_k-measure, η_k, satisfies the equalities $\eta_k(\square_k^{ij}) = c_k^{ij}$, $i, j = 1, \dots, k$. Choose a positive integer N such that all of the values $a_{ij} := N \cdot c_k^{ij}$ are integer. The obtained matrix $A = (a_{ij})_{i,j=1}^{k}$ is symmetric, and for any i the value $\sum_{j=1}^{k} a_{ij} = 2N/k$ is a fixed positive integer. In Appendix B it is shown that there exist square matrices $B_{ij} = (b_{ij}^{\mu\nu})_{\mu,\nu}$ of size $2N/k$ such that $B_{ij}^T = B_{ji}$, the sum of elements in any matrix B_{ij} equals a_{ij}, and the block matrix $D = (B_{ij})$ composed of these matrices has exactly one unit in each row and each column, and other elements are zeros.

D is a symmetric square matrix of size $2N$; denote its elements by d_{ij}. Put $m_k = 2N$, and define the mapping σ_k on $\{1, \dots, 2N\}$ in such a way that $d_{i\sigma_k(i)} = 1$ for any i. The so defined mapping σ_k is a permutation; it is involutive since the matrix D is symmetric. Moreover, if η_k is a σ_k-measure, then for any i and j it holds that $\eta_k(\square_k^{ij}) = N^{-1} \sum_{\mu,\nu} b_{ij}^{\mu\nu} = c_k^{ij}$. The proposition is proved.

3.4. Proof of Proposition 2.

1. Whatever the n-hollow (Ω, I), one introduces the reference system (x_1, x_2) in such a way that n coincides with $(0, -1)$, and the interval I belongs to the straight line $x_2 = 0$ and contains the origin $O = (0, 0)$. Like in the proof of Proposition 1, introduce the coordinate $\varphi = \operatorname{Arg} v - \operatorname{Arg} n$ on S_n^1. One has $v = -(\sin\varphi, \cos\varphi)$, $\varphi \in [-\pi/2, \pi/2]$. The definitions of the segments $J_m^i = J^i$, the measure λ, the set of measures Λ, and the σ-measure are seen in the beginning of the previous subsection. The mapping $(\xi, v) \mapsto V_{\Omega,I}^+(\xi, v)$ in the new coordinates ξ, φ is written as $(\xi, \varphi) \mapsto \varphi_{\Omega,I}^+(\xi, \varphi)$. Finally, define the measure μ_I on $I \times [-\pi/2, \pi/2]$ by $d\mu_I(\xi, \varphi) = \frac{\cos\varphi}{|I|}\,d\xi\,d\varphi$.

Denote $\square' = \left(\cup_{i=2}^{m-1} J^i\right) \times \left(\cup_{i=2}^{m-1} J^i\right)$, $\square_1 = J^1 \times [-\pi/2, \pi/2]$, $\square_2 = J^m \times [-\pi/2, \pi/2]$, $\square_3 = \left(\cup_{i=2}^{m-1} J^i\right) \times J^1$, and $\square_4 = \left(\cup_{i=2}^{m-1} J^i\right) \times J^m$. Thus, one has $\square \setminus \square' = \square_1 \cup \square_2 \cup \square_3 \cup \square_4$; see Figure 6.

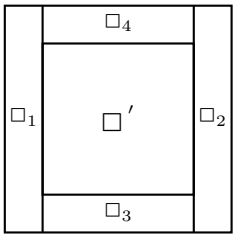

FIG. 6. *Partition of the square into rectangles.*

It suffices to construct a sequence of hollows $(\Omega_\varepsilon, I_\varepsilon)$, $\varepsilon > 0$, such that

(P) *for any* $i \ne 1, m, \sigma(1), \sigma(m)$ *the measure of the set of values* $(\xi, \varphi) \in I_\varepsilon \times J^i$ *such that* $\varphi_{\Omega_\varepsilon, I_\varepsilon}^+(\xi, \varphi) \notin J^{\sigma(i)}$ *goes to zero as* $\varepsilon \to 0$.

Then, speaking of restrictions of measures on the subset $\square'$, one gets that the distance from the restrictions of measures $\eta_{\Omega_\varepsilon, I_\varepsilon}$ to the set of restrictions of σ-measures goes to zero as $\varepsilon \to 0$. On the other hand, for any measure $\eta \in \Lambda$ one has $\eta(\square_1) =$

$\eta(\square_2) = 2/m$, $\eta(\square_3) \le 2/m$, $\eta(\square_4) \le 2/m$, and hence $\eta(\square \setminus \square') \le 8/m$; therefore the distance between the restrictions on $\square \setminus \square'$ of any two measures η_1 and η_2 from Λ does not exceed $16/m$: $\| \eta_1 \rfloor_{\square \setminus \square'} - \eta_2 \rfloor_{\square \setminus \square'} \| \le 16/m$. It follows that the upper limit of distances from $\eta_{\Omega_\varepsilon, I_\varepsilon}$ to the set of σ-measures does not exceed $16/m$, and so Proposition 2 is proved.

2. The rest of this subsection is dedicated to the detailed description of the sequence of hollows $(\Omega_\varepsilon, I_\varepsilon)$ and to the proof of property (P) for them.

First, consider an auxiliary construction (see Figure 7). Take two different points F and F' above the line $l = \{x_2 = 0\}$, with $|OF| = 2 = |OF'|$. Denote by Φ and Φ' the angles the rays OF and OF', respectively, formed with the vector $(0, 1)$. The angles are counted clockwise from $(0, 1)$. Thus, $F = 2(\sin\Phi, \cos\Phi)$ and $F' = 2(\sin\Phi', \cos\Phi')$. Assume, for further convenience, that F is situated on the left of F'; thus, one has $-\pi/2 < \Phi < \Phi' < \pi/2$. (The case where F is situated on the right of F' is completely similar.) Select three positive numbers λ, λ', and δ, and define two ellipses $\mathcal{E}$ and $\mathcal{E}$' and two parabolas $\mathcal{P}$ and $\mathcal{P}$'. The first ellipse has the foci O and F, the length of its large semiaxis is $\sqrt{1+\lambda}$, of the small semiaxis, $\sqrt{\lambda}$, and the focal distance equals 2. The second ellipse has the foci O and F', the lengths of its large and small semiaxes are $\sqrt{1+\lambda'}$ and $\sqrt{\lambda'}$, respectively, and the focal distance is also 2. The parabolas $\mathcal{P}$ and $\mathcal{P}$' have the foci F and F', respectively, the common axis FF', and the same focal distance δ. Thus, the parabolas are symmetric to each other with respect to the bisectrix of the triangle OFF'. The parameter δ is chosen sufficiently small, so that the point O lies in the exterior of both parabolas.

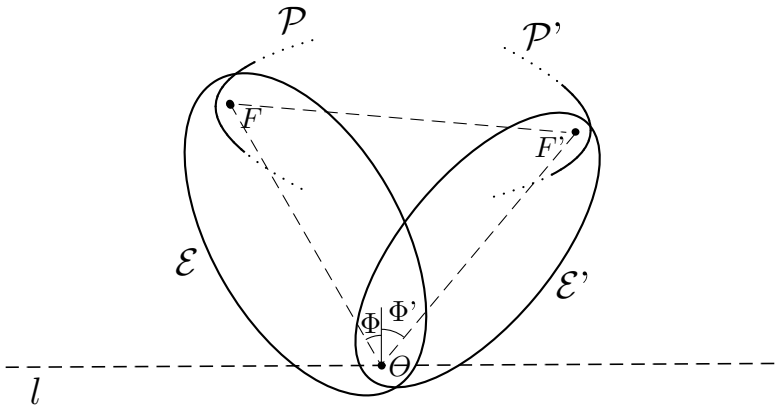

FIG. 7. *Auxiliary construction.*

In what follows, we shall distinguish between the billiard and *pseudobilliard* dynamics. The pseudobilliard dynamics is defined as follows. A particle starts at a point $(\xi, 0) \in l$ and moves with a velocity $(\sin\varphi, \cos\varphi)$ until it reflects from the interior side of $\mathcal{E}$. (Before the reflection it can intersect other curves $\mathcal{E}', \mathcal{P}, \mathcal{P}'$, or even intersect $\mathcal{E}$ from the outer side, without changing the velocity.) Then it moves again with constant velocity until it reflects from the interior side of $\mathcal{P}$. Then, in the same way, it reflects from the interior side of $\mathcal{P}'$, and then from the interior side of $\mathcal{E}'$, and, finally, it intersects l from above to below. Denote by $(\xi', 0)$ the point of intersection and by $-(\sin\varphi', \cos\varphi')$ the velocity at this point.

Consider the admissible set: the set of 7-tuples $(\varphi, \xi, \Phi, \Phi', \lambda, \lambda', \delta)$ such that all of the indicated reflections occur in the prescribed order. This set is open and nonempty.

Indeed, let $\delta(\Phi, \Phi')$ be the least of the values δ such that one of the parabolas (in fact, both of them simultaneously) passes through O. Put $\varphi = \Phi$, $\xi = 0$, and take arbitrary values $\lambda > 0$, $\lambda' > 0$, $-\pi/2 < \Phi < \Phi' < \pi/2$, $0 < \delta < \delta(\Phi, \Phi')$. The particle with initial data $\varphi = \Phi$, $\xi = 0$ first passes along the large semiaxis of $\mathcal{E}$, reflects from $\mathcal{E}$, returns along the same semiaxis, and reflects from $\mathcal{P}$. Then it moves with the velocity parallel to FF', reflects from $\mathcal{P}'$, moves the large semiaxis of the ellipse $\mathcal{E}'$, reflects from it, and returns to O along the same semiaxis. Thus, the admissible set is nonempty. Under a small perturbation of the parameters $\varphi, \xi, \Phi, \Phi', \lambda, \lambda', \delta$, all of the reflections are maintained and the order of reflections remains the same. This implies that the admissible set is open.

This description determines the mapping $\varphi' = \varphi'(\varphi, \xi, \Phi, \Phi', \lambda, \lambda', \delta)$, $\xi' = \xi'(\varphi, \xi, \Phi, \Phi', \lambda, \lambda', \delta)$[2] from the admissible set to $\mathbb{R}^2$. This mapping is infinitely differentiable. For $\varphi = \Phi$ and $\xi = 0$ one has

$$\varphi'(\Phi, 0, \Phi, \Phi', \lambda, \lambda', \delta) = \Phi'. \tag{11}$$

For $\xi = 0$ with arbitrary φ one has

$$\xi'(\varphi, 0, \Phi, \Phi', \lambda, \lambda', \delta) = 0, \tag{12}$$

and

$$\varphi'(\varphi, 0, \Phi, \Phi', \lambda, \lambda', \delta) \quad \text{does not depend on} \quad \delta.$$

Indeed, a particle starting at O, after the reflection from $\mathcal{E}$ passes through F, after reflecting from $\mathcal{P}$ moves in parallel to FF', after the reflection from $\mathcal{P}'$ passes through F', and, finally, after the reflection from $\mathcal{E}'$ returns to O (see Figure 8). The initial and final velocities of the particle are, respectively, $(\sin\varphi, \cos\varphi)$ and $-(\sin\varphi', \cos\varphi')$. Denoting by α and α' the angles the second and fourth segments of the (5-segment) trajectory form, respectively, with OF and OF', one has $\alpha = \alpha'$. The angle α is a function of φ, and φ' is a function of α'; these functions depend only on the parameters of the ellipses $\mathcal{E}$ and $\mathcal{E}'$, respectively, and do not depend on the parameter δ determining the shape of parabolas.

Using properties of ellipses, one derives the formulas connecting φ, α, and $\varphi' = \varphi'(\varphi, 0, \Phi, \Phi', \lambda, \lambda', \delta)$:

$$\sin(\varphi - \Phi) = \frac{\lambda \sin\alpha}{2 + \lambda - 2\cos\alpha\sqrt{1+\lambda}}, \qquad \sin(\varphi' - \Phi') = -\frac{\lambda' \sin\alpha}{2 + \lambda' - 2\cos\alpha\sqrt{1+\lambda'}}. \tag{13}$$

It follows that

$$\left.\frac{\partial\varphi'}{\partial\varphi}\right|_{\substack{\varphi=\Phi \\ \xi=0}} = -\left(\frac{\sqrt{\lambda'}}{1+\sqrt{\lambda'}}\frac{1+\sqrt{\lambda}}{\sqrt{\lambda}}\right)^2. \tag{14}$$

With fixed Φ, Φ', λ, λ', and δ the mapping $\varphi'(\varphi, \xi)$, $\xi'(\varphi, \xi)$ preserves the measure, $\cos\varphi\, d\varphi\, d\xi = \cos\varphi'\, d\varphi'\, d\xi'$, and hence

$$\cos\varphi = \pm\cos\varphi' \begin{vmatrix} \frac{\partial\varphi'}{\partial\varphi} & \frac{\partial\varphi'}{\partial\xi} \\ \frac{\partial\xi'}{\partial\varphi} & \frac{\partial\xi'}{\partial\xi} \end{vmatrix}.$$

[2]Note that throughout this paper the sign ' (prime) never means derivation.

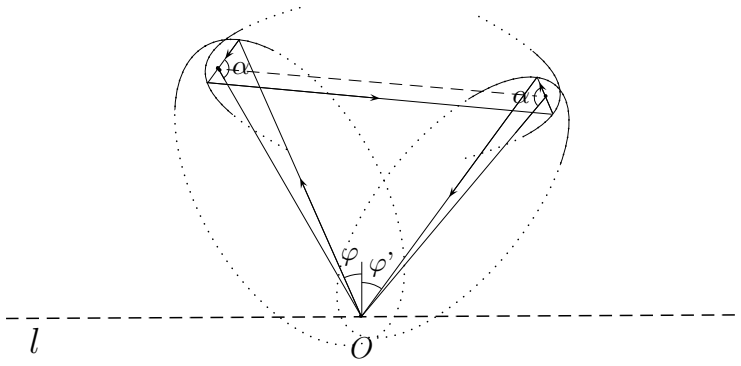

FIG. 8. *Pseudobilliard dynamics.*

Using (12), one gets that $\frac{\partial\xi'}{\partial\varphi}\big\rfloor_{\xi=0} = 0$, and hence

$$\begin{vmatrix} \frac{\partial\varphi'}{\partial\varphi} & \frac{\partial\varphi'}{\partial\xi} \\ \frac{\partial\xi'}{\partial\varphi} & \frac{\partial\xi'}{\partial\xi} \end{vmatrix}_{\xi=0} = \frac{\partial\varphi'}{\partial\varphi}\,\frac{\partial\xi'}{\partial\xi}\Big\rfloor_{\xi=0};$$

therefore

$$\cos\varphi = \pm\cos\varphi'\,\frac{\partial\varphi'}{\partial\varphi}\,\frac{\partial\xi'}{\partial\xi}\Big\rfloor_{\xi=0}. \tag{15}$$

Putting $\varphi = \Phi$ and $\xi = 0$, and taking into account (11), (14), and (15), one gets

$$\cos\Phi = \pm\cos\Phi'\left(\frac{\sqrt{\lambda'}}{1+\sqrt{\lambda'}}\,\frac{1+\sqrt{\lambda}}{\sqrt{\lambda}}\right)^2 \frac{\partial\xi'}{\partial\xi}\Big\rfloor_{\substack{\varphi=\Phi\\ \xi=0}}. \tag{16}$$

Define the positive continuous functions $\lambda(\Phi')$ and $\lambda'(\Phi)$ by the relations

$$\left(\frac{\sqrt{\lambda}}{1+\sqrt{\lambda}}\right)^2 = \frac{1}{2}\cos\Phi', \qquad \left(\frac{\sqrt{\lambda'}}{1+\sqrt{\lambda'}}\right)^2 = \frac{1}{2}\cos\Phi; \tag{17}$$

then one has

$$\left|\frac{\partial\xi'}{\partial\xi}\Big\rfloor_{\substack{\varphi=\Phi;\ \lambda=\lambda(\Phi')\\ \xi=0;\ \lambda'=\lambda'(\Phi)}}\right| = 1. \tag{18}$$

Additionally, taking into account (14) and (17), one gets

$$\frac{\cos\Phi'}{\cos\Phi}\,\frac{\partial\varphi'}{\partial\varphi}\Big\rfloor_{\substack{\varphi=\Phi;\ \lambda=\lambda(\Phi')\\ \xi=0;\ \lambda'=\lambda'(\Phi)}} = -1. \tag{19}$$

Recall that $\varphi' = \varphi'(\varphi, 0, \Phi, \Phi', \lambda, \lambda')$; that is, the restriction of the function φ' to the subspace $\xi = 0$ does not depend on δ. Hence the function $\frac{\partial\varphi'}{\partial\varphi}\big\rfloor_{\xi=0}$ and, by formula (15), the function $\frac{\partial\xi'}{\partial\xi}\big\rfloor_{\xi=0}$ also do not depend on δ. Put $\Phi_0 = \arcsin(1 - 2/m)$,

so that $J^1 = [-\pi/2, -\Phi_0]$ and $J^m = [\Phi_0, \pi/2]$, and put $\Delta\Phi = 2/m$. The set $\{(\Phi, 0, \Phi, \Phi', \lambda(\Phi'), \lambda'(\Phi)) : -\Phi_0 \le \Phi, \Phi' \le \Phi_0,\ \Phi' - \Phi \ge \Delta\Phi\}$ is compact and belongs to the (open) domain of the function φ'. Choose a sufficiently large integer value $k = k(\varepsilon)$, so that for

$$|\sin\varphi - \sin\Phi| < 2/(km), \qquad \xi = 0, \qquad -\Phi_0 \le \Phi, \Phi' \le \Phi_0, \tag{20}$$
$$\Phi' - \Phi \ge \Delta\Phi, \qquad \lambda = \lambda(\Phi'), \qquad \lambda' = \lambda'(\Phi)$$

it holds true that

$$-\frac{\cos\Phi'}{\cos\Phi}\frac{\partial\varphi'}{\partial\varphi} \in [(1+\varepsilon)^{-1}, 1+\varepsilon]. \tag{21}$$

Formulas (21) and (11) mean that, under conditions (20), φ' is also close to Φ'. Increasing k if necessary, ensure (under the same conditions) that

$$\frac{\cos\Phi'}{\cos\Phi}\frac{\cos\varphi}{\cos\varphi'} \in [(1+\varepsilon)^{-1}, 1+\varepsilon]. \tag{22}$$

Taking into account (15), (21), and (22), one obtains that under conditions (20) it holds true that

$$\left|\frac{\partial\xi'}{\partial\xi}\right| \in [(1+\varepsilon)^{-2}, (1+\varepsilon)^2]. \tag{23}$$

3. Now we proceed to the description of the hollow $(\Omega_\varepsilon, I_\varepsilon)$.

(a) If $2 \le i \ne \sigma(i) \le m-1$, then divide the interval J^i into k subintervals $J^{i,j}$ of equal measure λ, going in increasing order: $J^i = \cup_{j=1}^k J^{i,j}$, $\lambda(J^{i,j}) = 2/(km)$ for any $j = 1, \dots, k$. Recall that $d\lambda(\varphi) = \cos\varphi\, d\varphi$ and the value $k = k(\varepsilon)$ is defined above. Without loss of generality assume that $k(\varepsilon) \to \infty$ as $\varepsilon \to 0$.

To each pair of intervals, $J^{i,j}$ and $J^{\sigma(i),j}$, we apply the construction described above; see Figure 9. Namely, draw arcs of ellipses $\mathcal{E}_{i,j} = \overset{\smile}{AB}$, $\mathcal{E}'_{i,j} = \overset{\smile}{A'B'}$ and arcs of parabolas $\mathcal{P}_{i,j}$, $\mathcal{P}'_{i,j}$. Without loss of generality suppose that $i < \sigma(i)$. The angles AOB and $A'OB'$ correspond to the angular intervals $J^{i,j}$ and $J^{\sigma(i),j}$, respectively. The foci $\bar F = F_{i,j}$ and $\bar F' = F'_{i,j}$ belong to the intervals OA and OA', respectively. The endpoints of the arcs $\mathcal{P}_{i,j}$ and $\mathcal{P}'_{i,j}$ also belong to the intervals OA and OA', respectively. The angle corresponding to the ray OA (and therefore to the left endpoint of the interval $J^{i,j}$) will be denoted by $\bar\Phi = \Phi_{i,j}$, and the angle corresponding to the ray OA' (and therefore to the right endpoint of the interval $J^{\sigma(i),j}$) will be denoted by $\bar\Phi' = \Phi'_{i,j}$. Denote $\bar\lambda = \lambda_{i,j} := \lambda(\bar\Phi')$ and $\bar\lambda' = \lambda'_{i,j} := \lambda'(\bar\Phi)$, according to formula (17). Next, select a value $\bar\delta = \delta_{i,j}$ and draw two curves (*lateral reflectors*) in such a way that (i) each of the curves contains an arc of parabola (the first curve contains $\mathcal{P}_{i,j}$ and the second one $\mathcal{P}'_{i,j}$), an arc of circumference centered at O, and three radial segments; (ii) these curves do not intersect the intervals whose endpoints belong to the set $\{F_{\alpha,\beta}, F'_{\gamma,\delta} : (\alpha,\beta) \ne (i,j),\ (\gamma,\delta) \ne (\sigma(i), j)\}$: this will guarantee free passage of particles from one parabola to another; and (iii) the λ-measure of the angular interval occupied by each lateral reflector does not exceed $\varepsilon/(km)$. In Figure 9, the angular reflectors are the curves joining the points A and C, and the points A' and C'.

Notice that $-\Phi_0 \le \bar\Phi, \bar\Phi' \le \Phi_0$, and $\bar\Phi' - \bar\Phi \ge \Delta\Phi$. Indeed, $\bar\Phi$ and $\bar\Phi'$ do not belong to the intervals $J^1 = [-\pi/2, -\Phi_0]$ and $J^m = [\Phi_0, \pi/2]$. On the other hand, one has $\bar\Phi' - \bar\Phi \ge \sin\bar\Phi' - \sin\bar\Phi = \lambda([\bar\Phi, \bar\Phi']) \ge 2/m = \Delta\Phi$.

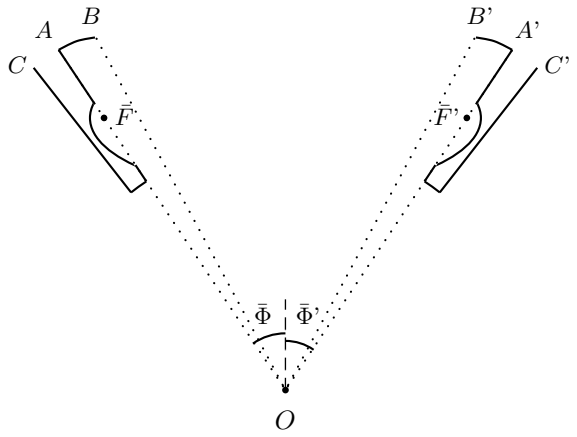

FIG. 9. *Part of the hollow corresponding to the angular intervals $J^{i,j}$ and $J^{\sigma(i),j}$.*

Introduce the shorthand notation $\varphi'(\varphi,\xi)=\varphi'(\varphi,\xi,\Phi_{i,j},\Phi'_{i,j},\lambda_{i,j},\lambda'_{i,j},\delta_{i,j})$. According to (21) and (23), for $\varphi\in J^{i,j}$ it holds true that

$$-\frac{\cos\bar\Phi'}{\cos\bar\Phi}\frac{\partial\varphi'}{\partial\varphi}(\varphi,0)\in[(1+\varepsilon)^{-1},1+\varepsilon] \tag{24}$$

and

$$\left|\frac{\partial\xi'}{\partial\xi}(\varphi,0)\right|\in[(1+\varepsilon)^{-2},(1+\varepsilon)^2]. \tag{25}$$

According to (11), one has $\varphi'(\bar\Phi,0)=\bar\Phi'$; this equality and formula (24) imply that for $\varphi\in J^{i,j}$ and $\varphi'=\varphi'(\varphi,0)$ one has

$$-\frac{\cos\bar\Phi'}{\cos\bar\Phi}\frac{\varphi'-\bar\Phi'}{\varphi-\bar\Phi}\in[(1+\varepsilon)^{-1},1+\varepsilon]. \tag{26}$$

On the other hand, one has

$$\cos\bar\Phi\,|J^{i,j}|=\frac{2}{km}\,(1+o(1)), \tag{27}$$

$$\cos\bar\Phi'\,|J^{\sigma(i),j}|=\frac{2}{km}\,(1+o(1)), \tag{28}$$

with $o(1)$ being uniformly small over all i,j as $\varepsilon\to0$, and $|J|$ being the Lebesgue measure of J. (Recall that the parameters $\bar\Phi,\bar\Phi',k$ and the intervals $J^{i,j}$ implicitly depend on ε.)

Choose closed intervals $\tilde J^{i,j}\subset J^{i,j}$ and $\tilde J^{\sigma(i),j}\subset J^{\sigma(i),j}$ satisfying the following conditions: (i) $\varphi'(\tilde J^{i,j}\times\{0\})=\tilde J^{\sigma(i),j}$; (ii) some neighborhoods of $\tilde J^{i,j}$ and $\tilde J^{\sigma(i),j}$ belong to $J^{i,j}$ and $J^{\sigma(i),j}$, respectively; and (iii) the pseudobilliard trajectory with the initial data $(\varphi,0)$, $\varphi\in\tilde J^{i,j}$ does not intersect the neighbor lateral reflectors (that is, the lateral reflectors corresponding to the intervals $\tilde J^{i,j+1}$ and $\tilde J^{\sigma(i),j-1}$ if $j\ne1,k$; if $j=1$, then $\tilde J^{\sigma(i),j-1}$ should be replaced with $\tilde J^{\sigma(i)-1,k}$, and if $j=k$, then $\tilde J^{i,j+1}$ should be replaced with $\tilde J^{i+1,1}$). Note in this regard that the neighbor lateral reflectors occupy a small part of the angular intervals $J^{i,j}$ and $J^{\sigma(i),j}$ (represented in the figure

by the arcs AB and $B'A'$). Other lateral reflectors will not be intersected by the choice of lateral reflectors.

By virtue of (26), (27), (28) and because of smallness of the angular intervals occupied by the lateral reflectors, $\tilde{J}^{i,j}$ and $\tilde{J}^{\sigma(i),j}$ may be chosen in such a way that the ratios $\lambda(\tilde{J}^{i,j})/\lambda(J^{i,j})$ and $\lambda(\tilde{J}^{\sigma(i),j})/\lambda(J^{\sigma(i),j})$ uniformly (with respect to i, j) tend to 1 as $\varepsilon \to 0$. Thus, a billiard particle going from O in a direction $\varphi \in \tilde{J}^{i,j}$ makes the same reflections and in the same order as under the pseudobilliard dynamics: first, reflection from $\mathcal{E}_{i,j}$, from $\mathcal{P}_{i,j}$, from $\mathcal{P}'_{i,j}$, and from $\mathcal{E}'_{i,j}$; finally, the particle goes back to O in the direction $\varphi'(\varphi, 0) \in \tilde{J}^{\sigma(i),j}$.

Choose $a_{i,j}$ in such a way that the following conditions are fulfilled: if $(\xi, \varphi) \in [-a_{i,j}, a_{i,j}] \times \tilde{J}^{i,j}$, then (i) the corresponding billiard trajectory does not intersect the lateral reflectors and the indicated order of reflections is preserved; (ii) $\varphi'(\varphi, \xi) \in J^{\sigma(i),j}$; (iii) $\left|\frac{\partial \xi'}{\partial \xi}(\varphi, \xi)\right| \in [(1+\varepsilon)^{-3}, (1+\varepsilon)^3]$. Analogously, choose $a_{\sigma(i),j}$ in such a way that the conditions are fulfilled: if $(\xi, \varphi) \in [-a_{\sigma(i),j}, a_{\sigma(i),j}] \times \tilde{J}^{\sigma(i),j}$, then (i) the billiard trajectory does not intersect the lateral reflectors and the order of its reflections is reversed; (ii) $\varphi'(\varphi, \xi) \in J^{i,j}$; (iii) $\left|\frac{\partial \xi'}{\partial \xi}(\varphi, \xi)\right| \in [(1+\varepsilon)^{-3}, (1+\varepsilon)^3]$. Note that the values $a_{i,j}$ and $a_{\sigma(i),j}$ implicitly depend on ε.

Select $a_\varepsilon \le \min_{i,j} a_{ij}$ in such a way that $a_\varepsilon \to 0$ as $\varepsilon \to 0$, and denote $I_\varepsilon = (-a_\varepsilon, a_\varepsilon) \times \{0\}$, $\tilde{I}_\varepsilon = (-a_\varepsilon(1+\varepsilon)^{-3}, a_\varepsilon(1+\varepsilon)^{-3}) \times \{0\}$, and $\tilde{J}^i_\varepsilon = \tilde{J}^i := \cup_j \tilde{J}^{i,j}_\varepsilon$. The part of the boundary of Ω_ε related to the angular intervals $J^{i,j}$ and $J^{\sigma(i),j}$ under consideration is formed by the arcs of ellipses $\mathcal{E}_{i,j}$, $\mathcal{E}'_{i,j}$ and the corresponding lateral reflectors. Then a billiard particle with initial conditions $(\xi, \varphi) \in \tilde{I}_\varepsilon \times \tilde{J}^{i,j}$ after making four reflections will intersect l at a point $(\xi', 0) \in I_\varepsilon$, and the angle at the point of intersection will be $\varphi^+_{\Omega_\varepsilon, I_\varepsilon}(\xi, \varphi) = \varphi'(\varphi, \xi) \in J^{\sigma(i),j} \subset J^{\sigma(i)}$. Thus, the set of values $(\xi, \varphi) \in I_\varepsilon \times J^i$ such that $\varphi^+_{\Omega_\varepsilon, I_\varepsilon}(\xi, \varphi) \notin J^{\sigma(i)}$ is contained in the set $\big(I_\varepsilon \times J^i\big) \setminus \big(\tilde{I}_\varepsilon \times \tilde{J}^i_\varepsilon\big)$, whose measure is vanishing as $\varepsilon \to 0$.

(b) If $2 \le i = \sigma(i) \le m-1$, then the corresponding part of the boundary is the arc of circumference of radius 2 with the center at O occupying the angular interval J^i, that is, the set $\{2(\sin\varphi, \cos\varphi),\ \varphi \in J^i\}$. Next, we will show that for all values $(\xi, 0) \in I_\varepsilon$, $\varphi \in J^i$, except for a portion of order $o(1)$, the corresponding billiard particle makes one reflection from the arc and then goes back to I_ε in the direction $\varphi' \in J^i$.

For all values $\varphi \in J^i$, except for the union of two intervals of vanishing length (each of the intervals is contained in J^i, has the length $2\arctan(a_\varepsilon/4)$, and contains an endpoint of J^i), the particle starting at $(\xi, 0) \in I_\varepsilon$ in the direction φ will reflect from the indicated arc of circumference. Let $\psi \in J^i$ be the angular coordinate of the reflection point. By $(\xi', 0)$ denote the point at which the reflected particle intersects the straight line l. One easily verifies that

$$\frac{1}{\xi} + \frac{1}{\xi'} = \cos\psi. \tag{29}$$

One has

$$|\xi| < a_\varepsilon, \tag{30}$$

and hence

$$\frac{1}{|\xi'|} = \left|\cos\psi - \frac{1}{\xi}\right| > \frac{1}{a_\varepsilon} - 1. \tag{31}$$

From (29) it follows that $|\xi + \xi'|/|\xi\xi'| = |\cos\psi| \le 1$, and, taking into account (30) and (31), one finds that $|\xi + \xi'| < a_\varepsilon^2/(1 - a_\varepsilon)$. This implies that for all values $(\xi, 0) \in I_\varepsilon$, except for a set of measure $O(a_\varepsilon^2)$, the second point of intersection of the billiard trajectory belongs to I_ε; moreover, the velocity at this point, $\varphi^+_{\Omega_\varepsilon, I_\varepsilon}(\xi, \varphi)$, belongs to $\mathcal{N}_{2\arctan(a_\varepsilon/4)}(J^i)$, the neighborhood of J^i of radius $2\arctan(a_\varepsilon/4)$. This finally implies that for all $(\xi, \varphi) \in I_\varepsilon \times J^i$, except for a portion of order $O(a_\varepsilon)$, it holds that $\varphi^+_{\Omega_\varepsilon, I_\varepsilon}(\xi, \varphi) \in J^i$.

(c) The parts of the hollow's boundary, corresponding to J^1 and J^m, are formed by smooth curves joining the corresponding endpoints of I_ε and the points $2(\sin\Phi_0, -\cos\Phi_0)$ and $2(\sin\Phi_0, \cos\Phi_0)$, respectively. The unique condition on these curves is that they can be parametrized by the monotonically increasing angular coordinate. For those values $\sigma(1), \sigma(m)$ that coincide with neither 1 nor m take just the arcs of circumference of radius 2 corresponding to the angular intervals $J^{\sigma(1)}, J^{\sigma(m)}$.

Consider the union of all of the elliptic arcs $\mathcal{E}_{i,j}, \mathcal{E}'_{i,j}$ introduced in item (a), all of the arcs of circumference defined in items (a) and (b), and the two curves introduced in this item (c). Let us call this union the *main element*. Each lateral reflector is a curve; select it in such a way that both its endpoints belong to the main element. Finally, the curve $\partial\Omega_\varepsilon \setminus I_\varepsilon$ is the union of all of the lateral reflectors and the part of the main element visible from O (that is, which is not shielded by the adjacent lateral reflectors). Thus, the definition of the hollow $(\Omega_\varepsilon, I_\varepsilon)$ is complete.

In Figure 10, there is shown a particular hollow $(\Omega_\varepsilon, I_\varepsilon)$ corresponding to the permutation $\sigma = \left(\begin{smallmatrix} 1 & 2 & 3 & 4 & 5 \\ 5 & 4 & 3 & 2 & 1 \end{smallmatrix}\right)$. The angular intervals $J^1, \dots, J^5$ are separated by dotted lines. The family of hollows $(\Omega_\varepsilon, I_\varepsilon)$, with vanishingly small ε, has the following property: for almost all particles with the initial direction from J^2 (resp. J^3, J^4), the final direction will belong to J^4 (resp. J^3, J^2). In the figure, there is shown the trajectory of a particle with the initial direction $\varphi \in J^2$ and the final direction $\varphi^+ \in J^4$. The particle makes a reflection from an elliptic arc, then two reflections from (very small) parabolic arcs, and, finally, again from an elliptic arc. According to our notation, these arcs are $\mathcal{E}_{2,2}$, $\mathcal{P}_{2,2}$, $\mathcal{P}'_{2,2}$, and $\mathcal{E}'_{2,2}$.

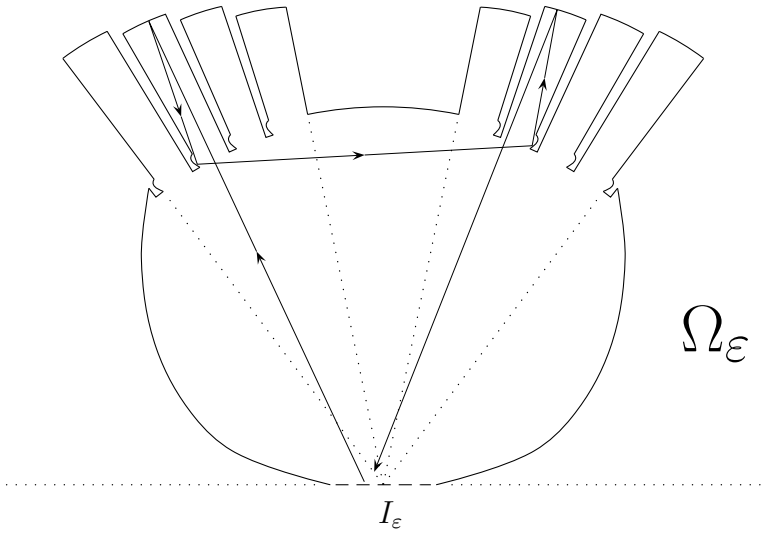

FIG. 10. *A hollow* $(\Omega_\varepsilon, I_\varepsilon)$ *approximating a* σ*-measure.*

4. Concluding remarks and applications. Physical bodies in the real world have atomic structure and therefore are disconnected. This is a reason for using (generally) disconnected sets Q_m in the definition of a rough body. In the future we intend to turn to propose and study the notion of a three-dimensional rough body, where the connectivity assumption is absolutely useless; this is another reason. By removing this assumption, the consideration in two dimensions (namely, the proof of Lemma 1) is made somewhat more difficult, but at the same time prerequisites for passing to the three-dimensional case are created.

In fact, the notions of "disconnected" (as everywhere in this paper) and "connected" rough bodies are equivalent. There is a natural one-to-one correspondence between the equivalence classes in the connected and disconnected cases,[3] the former classes being subclasses of the latter ones under this correspondence.

Let us now consider applications of the main theorem to problems of the body of minimal or maximal aerodynamic resistance. A two-dimensional convex body B moves, at constant velocity, through a rarefied homogeneous medium in $\mathbb{R}^2$, and at the same time it slowly rotates. The rotation is generally nonuniform; we assume that, during a sufficiently long observation period, in a reference system connected with the body the body's velocity is distributed in S^1 according to a given density function ρ, with $\int_{S^1} \rho(v)\,dv = 1$. The medium particles do not mutually interact, and collisions of the particles with the body are absolutely elastic. The resistance of the medium to the motion of the body is a vector-valued function of time. After averaging it over a sufficiently long period of time, one gets a vector. We are interested in the projection of this vector onto the direction of motion; for the sake of brevity, it will be called mean resistance, or just resistance. The problem is as follows: given B, determine the roughness on it in such a way that the main resistance of the resulting rough body is minimal or maximal.

A prototype of such a mechanical system is an artificial satellite of the Earth on relatively low altitudes ($100 \div 200$ km), with restricted capacity of rotation angle control. The satellite's motion is slowing down by the rest of the atmosphere; the problem is to minimize or maximize the effect of slowing down. The problems of resistance *maximization* may also arise when considering solar sail: a spacecraft driven by the pressure of solar photons.

The initial velocity of an incident particle (in the reference system connected with the body) is $-v$, and the final velocity is v^+; therefore, the momentum transmitted by the particle to the body is $v + v^+$. The projection of the transmitted momentum onto the direction of motion of the body equals $1 + \langle v, v^+\rangle$. Averaging this value over all particles incident on the body within a sufficiently long time interval, one gets the mean resistance. The averaging amounts to integration over $\rho(v)\,d\nu_{\mathcal{B}}(v, v^+, n)$; that is, the mean resistance of the rough body equals

$$R(\nu_{\mathcal{B}}) = \iiint_{\mathbb{T}^3} (1 + \langle v, v^+\rangle)\,\rho(v)\,d\nu_{\mathcal{B}}(v, v^+, n).$$

Using the main theorem and Fubini's theorem, one rewrites this formula in the form

$$R(\nu_{\mathcal{B}}) = \int_{S^1} d\tau_B(n) \iint_{\mathbb{T}^2} (1 + \langle v, v^+\rangle)\,\rho(v)\,d\eta_{\mathcal{B},n}(v, v^+), \tag{32}$$

[3]More precisely, we mean equivalence classes formed by sequences of connected/disconnected sets.

where $\eta_{\mathcal{B},n} \in \Lambda_n$. Thus, the minimization problem for $R(\nu_{\mathcal{B}})$ reduces to minimization, for any n, of the functional $\iint_{\mathbb{T}^2} (1+\langle v, v^+\rangle)\,\rho(v)\,d\eta(v,v^+)$ over all $\eta \in \Lambda_n$. Using the notation introduced in section 3.3, one comes to the problem:

$$\inf_{\eta\in\Lambda} \iint_{\square} (1+\cos(\varphi-\varphi^+))\,\varrho(\varphi)\,d\eta(\varphi,\varphi^+), \tag{33}$$

where $\varrho(\varphi) = \rho(v)$ for $\varphi = \operatorname{Arg} v - \operatorname{Arg} n$. This problem, in turn, by symmetrization of the cost function reduces to a particular Monge–Kantorovich problem:

$$\inf_{\eta\in\Lambda_{\lambda,\lambda}} \mathcal{F}(\eta), \quad \text{where} \quad \mathcal{F}(\eta) = \iint_{\square} c(\varphi,\varphi^+)\,d\eta(\varphi,\varphi^+), \tag{34}$$

where $c(\varphi,\varphi^+) = (1+\cos(\varphi-\varphi^+))\,\frac{\varrho(\varphi)+\varrho(\varphi^+)}{2}$ and $\Lambda_{\lambda,\lambda}$ is the set of measures η on $\square$ having both marginal measures equal to λ: $\pi^{\#}_{\varphi}\eta = \lambda = \pi^{\#}_{\varphi^+}\eta$. Recall that λ is defined by $d\lambda(v) = \cos\varphi\,d\varphi$.

Problem (34) can be exactly solved in several particular cases. Consider the case of uniform motion, where the function ρ, and therefore ϱ, is constant, and thus one can take $c(\varphi,\varphi^+) = \frac{3}{8}\,(1+\cos(\varphi-\varphi^+))$.[4] Note that $\mathcal{F}(\eta_0) = 1$ and therefore resistance of the smooth body is equal to its perimeter: $R(\nu_B) = \int_{S^1} d\tau_B(n)\,\mathcal{F}(\eta_0) = |\partial B|$. (Recall that the measure η_0 belongs to Λ and is supported on the diagonal $\varphi^+ = -\varphi$.) The minimization problem (34) for constant ϱ was solved in [14]: one has $\inf_{\mathcal{B}} R(\nu_{\mathcal{B}}) = 0.9878\ldots\cdot|\partial B|$, the infimum being taken over all roughenings of B.

Note that the corresponding *maximization* problem for (34) has the trivial solution, which does not depend on the function ϱ: $\eta = \eta_\star$, the measure $\eta_\star \in \Lambda$ being supported on the diagonal $\varphi^+ = \varphi$. One has $\sup_{\mathcal{B}} R(\nu_{\mathcal{B}}) = \kappa\,|\partial B|$, where $\kappa = \bigl(\int_{-\pi/2}^{\pi/2} \varrho(\varphi)\cos\varphi\,d\varphi\bigr)\big/\bigl(\int_{-\pi/2}^{\pi/2} \varrho(\varphi)\,\cos^3\varphi\,d\varphi\bigr) > 1$; in the case of uniform rotation one has $\kappa = 1.5$. The maximization problem was studied in more detail in [20].

Appendix A. The construction below is simple (see Figure 11), but its description is a bit cumbersome.

Take a point in the interior of B and connect it by segments with all vertices. The polygon is thus divided into several triangles; fix i and m and consider the triangle with the base $\mathfrak{b}_i$, the ith side of B. Denote by $d(\Omega_i^m)$ the diameter of the orthogonal projection of Ω_i^m onto the straight line containing I_i^m; one obviously has $d(\Omega_i^m) \geq |I_i^m|$. Fix a positive number $\kappa < |I_i^m|/d(\Omega_i^m)$.

Take a rectangle Π^1 contained in the triangle and such that one side of Π^1 belongs to $\mathfrak{b}_i$. By δ_1 denote the total length of the part of $\mathfrak{b}_i$ which is not occupied by this side.

For the sake of brevity, the image of a set under the composition of a homothety with positive ratio and a translation will be called a copy of this set. Take several copies of Ω_i^m (copies of first order) that do not mutually interact, that belong to Π^1, whose corresponding copies of I_i^m belong to $\mathfrak{b}_i$, and whose portion of the side of Π^1 occupied by them is more than κ.

Next, take several rectangles that do not mutually intersect and do not intersect with the chosen copies of Ω_i^m, belong to Π^1, and have one side contained in $\mathfrak{b}_i$. Denote by Π^2 the union of these rectangles and by δ_2 the total length of the part of the side of Π^1 which is not occupied by the rectangles from Π^2 and by the copies of I_i^m. Next,

[4] The normalization constant 3/8 is taken for further convenience.

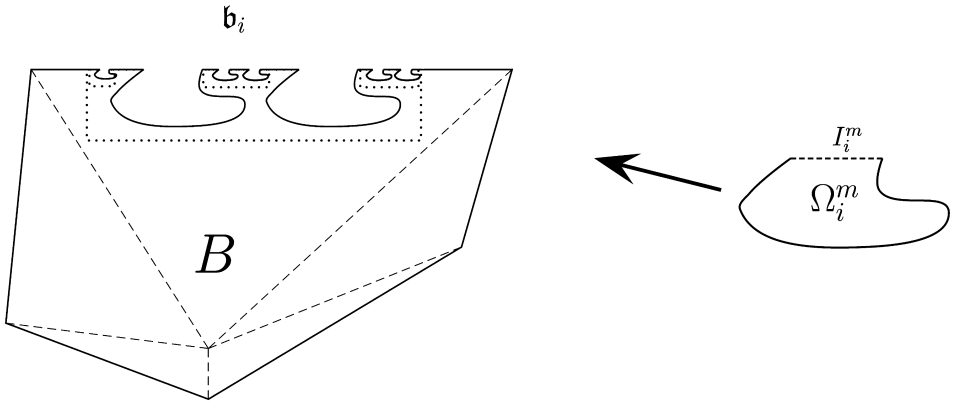

FIG. 11. *Making hollows on the ith side of a polygon.*

for each rectangle from Π^2 choose several copies of Ω_i^m (copies of second order) in the way completely similar to the described above (see Figure 11).

Continuing this process, one obtains a sequence $\Pi^1, \Pi^2, \dots$ of unions of rectangles and collections of copies of Ω_i^m of first, second, ... order. Choose the rectangles in such a way that $\delta_1 + \delta_2 + \dots < 1/m$ and $\mathrm{Area}(\Pi^1) < 1/m$. Finally, choose k such that the total length of sides of rectangles from Π^{k+1} contained in $\mathfrak{b}_i$ is less than $1/m$, and take the collection of copies of Ω_i^m of order $1, 2, \dots, k$ (we shall call it full collection). The total length of the part of $\mathfrak{b}_i$ not occupied by the corresponding copies of I_i^m is less than $2/m$, and therefore it goes to zero as $m \to \infty$.

By definition, the desired set Q_m is B minus the union of full collections of copies of Ω_i^m over all i.

Appendix B. We prove here slightly more than needed.

STATEMENT 3. *Let $A = (a_{ij})_{i,j=1}^k$ be a symmetric matrix, with a_{ij} being non-negative integers. Denote $n_i = \sum_{j=1}^k a_{ij}$. Then there exist matrices $B_{ij} = (b_{ij}^{\mu\nu})_{\mu,\nu}$ of size $n_i \times n_j$ such that $b_{ij}^{\mu\nu} \in \{0, 1\}$, $B_{ij}^T = B_{ji}$, the sum of elements in B_{ij} equals a_{ij}, and the block matrix $D = (B_{ij})$ contains exactly one unit in each row and each column.*

Note that for some values $i = i_1, i_2, \dots$ it may happen that $n_i = 0$, that is, $a_{ij} = 0$ for all $j = 1, \dots, k$. Then the corresponding matrices B_{ij} have the size $0 \times n_j$, that is, are empty. In this case D coincides with the block matrix $D' = (B_{ij})$ having the rows $i_1, i_2, \dots$ and columns $i_1, i_2, \dots$ crossed out.

Proof. The proof is by induction on k. Let the statement be true for $k-1$; prove it for k. Take the matrix $\tilde{A} = (a_{ij})_{i,j=2}^k$; there exists a block matrix $\tilde{B} = (\tilde{B}_{ij})_{i,j=2}^k$ satisfying the statement. Note that the order of $\tilde{B}_{ij}$ is $\tilde{n}_i \times \tilde{n}_j$, where $\tilde{n}_i = \sum_{j=2}^k a_{ij} = n_i - a_{i1}$. Define the matrices B_{ij} as follows.

(a) Put $B_{11} = \mathrm{diag}\{\underbrace{1, \dots, 1}_{a_{11}}, 0, \dots, 0\}$.

(b) Put $b_{12}^{a_{11}+1,1} = \dots = b_{12}^{a_{11}+a_{12},a_{12}} = 1$; $b_{13}^{a_{11}+a_{12}+1,1} = \dots = b_{13}^{a_{11}+a_{12}+a_{13},a_{13}} = 1$; $\dots$; $b_{1k}^{a_{11}+\dots+a_{1,k-1}+1,1} = \dots = b_{1k}^{a_{11}+\dots+a_{1k},a_{1k}} = 1$; the other elements of the matrices B_{1j}, $j = 2, \dots, k$, are zeros. Thus, on the diagonal of B_{1j} starting from the element at the first column and the $(a_{11} + a_{12} + \dots + a_{1,j-1} + 1)$th row, the first a_{1j} elements equal 1, and the remaining elements on this diagonal and all of the elements

off the diagonal are zeros. This defines the matrices B_{1j}, $j = 2, \dots, k$. The matrices B_{i1}, $i = 2, \dots, k$, are determined by the condition $B_{i1} = B_{1i}^T$.

(c) For $i \geq 2$, $j \geq 2$ define the matrix B_{ij} as follows. For $\mu \leq a_{1i}$ or $\nu \leq a_{1j}$, put $b_{ij}^{\mu\nu} = 0$, and for $\mu \geq a_{1i} + 1$, $\nu \geq a_{1j} + 1$, put $b_{ij}^{\mu\nu} = \tilde{b}_{ij}^{\mu - a_{1i}, \nu - a_{1j}}$. Thus, in the obtained matrix B_{ij}, the right lower corner coincides with the matrix $\tilde{B}_{ij}$, and all of the remaining elements are equal to zero. The number of rows of this matrix equals $a_{1i} + \tilde{n}_i = n_i$, and the number of columns equals $a_{1j} + \tilde{n}_j = n_j$. One obviously has $B_{ij}^T = B_{ji}$.

One easily verifies that $\sum_{\mu\nu} b_{ij}^{\mu\nu} = a_{ij}$ and that each row and each column of the obtained block matrix $D = (B_{ij})_{i,j=1}^k$ contains precisely one unit. □

PERMANENCE AND ASYMPTOTICALLY STABLE COMPLETE TRAJECTORIES FOR NONAUTONOMOUS LOTKA–VOLTERRA MODELS WITH DIFFUSION*

JOSÉ A. LANGA†, JAMES C. ROBINSON‡, ANÍBAL RODRÍGUEZ-BERNAL§, AND ANTONIO SUÁREZ¶

Abstract. Lotka–Volterra systems are the canonical ecological models used to analyze population dynamics of competition, symbiosis, or prey-predator behavior involving different interacting species in a fixed habitat. Much of the work on these models has been within the framework of infinite-dimensional dynamical systems, but this has frequently been extended to allow explicit time dependence, generally in a periodic, quasiperiodic, or almost periodic fashion. The presence of more general nonautonomous terms in the equations leads to nontrivial difficulties which have stalled the development of the theory in this direction. However, the theory of nonautonomous dynamical systems has received much attention in the last decade, and this has opened new possibilities in the analysis of classical models with general nonautonomous terms. In this paper we use the recent theory of attractors for nonautonomous PDEs to obtain new results on the permanence and the existence of forwards and pullback asymptotically stable global solutions associated to nonautonomous Lotka–Volterra systems describing competition, symbiosis, or prey-predator phenomena. We note in particular that our results are valid for prey-predator models, which are not order-preserving: even in the "simple" autonomous case the uniqueness and global attractivity of the positive equilibrium (which follows from the more general results here) is new.

Key words. Lotka–Volterra competition, symbiosis and prey-predator systems, nonautonomous dynamical systems, permanence, attracting complete trajectories

1. Introduction.

Partial differential equations have proved a very useful tool in the modelling of many ecological phenomena related to the dynamics between species interacting in a given habitat. Many authors have allowed explicit dependence on both space and time in the parameters of the equation, a natural way to take into account the spatial and temporal variations that influence real species interactions.

In this paper we consider a nonautonomous model for two species (u and v), evolving within a habitat Ω that is a bounded domain in $\mathbf{R}^N$, $N \geq 1$, with a smooth

boundary $\partial\Omega$, of the following type:

$$\begin{cases} u_t - d_1\Delta u = uf(t,x,u,v) & x\in\Omega,\ t>s \\ v_t - d_2\Delta v = vg(t,x,u,v) & x\in\Omega,\ t>s \\ \mathcal{B}_1 u = 0,\ \mathcal{B}_2 v = 0 & x\in\partial\Omega,\ t>s \\ u(s)=u_s,\ v(s)=v_s, \end{cases} \tag{1.1}$$

where f and g are regular functions, d_1, d_2 are positive constants, and $\mathcal{B}_i$ denotes one of the boundary operators

$$\mathcal{B}u = u, \quad \text{or} \quad \mathcal{B}u = \frac{\partial u}{\partial \vec{n}}, \quad \text{or} \quad \mathcal{B}u = d\frac{\partial u}{\partial \vec{n}} + \sigma(x)u, \tag{1.2}$$

for the Dirichlet, Neumann, or Robin case, respectively, $\vec{n}$ is the outward normal vector-field to $\partial\Omega$, and $\sigma(x)$ a C^1 function. Note that we take diffusion coefficient d_i and boundary potential $\sigma_i(x)$ for the case of Robin boundary condition $\mathcal{B}_i$. Also note that we allow all of the nine possible combinations of boundary conditions in (1.1).

A particularly interesting class of models of the form (1.1) are the nonautonomous Lotka–Volterra models:

$$\begin{cases} u_t - d_1\Delta u = u(\lambda(t,x) - a(t,x)u - b(t,x)v) & x\in\Omega,\ t>s \\ v_t - d_2\Delta v = v(\mu(t,x) - c(t,x)u - d(t,x)v) & x\in\Omega,\ t>s \\ \mathcal{B}_1 u = 0,\ \mathcal{B}_2 v = 0 & x\in\partial\Omega,\ t>s \\ u(s)=u_s,\ v(s)=v_s. \end{cases} \tag{1.3}$$

We refer, for example, to [6] for the biological meaning of the parameters d_1, d_2, λ, μ, a, b, c, d involved in (1.3).

In line with the ecological interpretation of these models, we will consider only positive solutions, and in the light of this we note here that $u_s, v_s \geq 0$ implies that the solution of (1.1) satisfies $u, v \geq 0$.

Note that our hypotheses on b and c allow different models of population dynamics: competition if $b, c > 0$, symbiosis if $b, c < 0$, and prey-predator if $b > 0$ and $c < 0$, although we do not allow sign-changing coefficients.

Of course, it is an important problem to determine the asymptotic behavior of solutions of the system (1.1). Since in general this is a very complicated task, one may try to solve simpler problems; e.g., one can try to determine whether or not the two species will survive in the long term or if, on the contrary, one of them will be driven to extinction. Survival of the species has been formalized in the notion of *permanence*; see Hale and Waltman [15] or Hutson and Schmitt [20]. Loosely speaking, the system (1.1) is said to be *permanent* if for any positive initial data u_s and v_s, within a finite time the values of the solution $(u(t,s,x;u_s,v_s), v(t,s,x;u_s,v_s))$, for $x\in\Omega$, enter and remain within a compact set in $\mathbf{R}^2$ that is strictly bounded away from zero in each component. Note, however, that this is an imprecise statement in the presence of Dirichlet boundary conditions.

Note that permanence is a form of *coexistence* of the species, since none is extinguished at any part of the habitat domain at any time.

A related situation, which implies that the system is permanent but gives more detail since it also indicates the expected final state of the system, is when there exists a solution, bounded away from zero, to which all other solutions tend asymptotically.

These two are the main topics with which we are concerned in this paper.

Before going further observe that both (1.1) and (1.3) always possess the *trivial* solution $(0,0)$ and *semitrivial* solutions of the form $(u,0)$ and $(0,v)$. In the latter

case the nontrivial component satisfies a scalar parabolic problem, of logistic type in the case of (1.3). The dynamics of these solutions have a deep impact on the global dynamics of general solutions. Indeed, if the system is permanent, this implies that semitrivial solutions must be unstable in some sense. On the other hand, if semitrivial solutions are stable, then it can be expected that some solutions of the system exhibit *extinction*, that is, one of the species (or both) approaches asymptotically the value zero.

Some results are already known along these lines. For example, in the autonomous case, assume that all the coefficients in (1.3) are constants and consider, for example, the problem with Dirichlet boundary conditions. In this case results about permanence for problem (1.3) depend on the values of λ and μ with respect to the first eigenvalue of certain associated linear elliptic problems, which we now describe. Given $d \in \mathbf{R}$, $d > 0$, and $f \in L^\infty(\Omega)$, we denote by $\Lambda(d, f)$ (we write $\Lambda_0 := \Lambda(d, 0)$) the first eigenvalue of the problem

$$\begin{cases} -d\Delta w = \sigma w + f(x)w & \text{in } \Omega, \\ w = 0 & \text{on } \partial\Omega, \end{cases}$$

and given $\gamma, \alpha \in \mathbf{R}$ with $\alpha > 0$, we denote by $\omega_{[d,\gamma,\alpha]}$ the unique positive solution of

$$\begin{cases} -d\Delta w = \gamma w - \alpha w^2 & \text{in } \Omega, \\ w = 0 & \text{on } \partial\Omega. \end{cases}$$

If λ and μ satisfy

$$\lambda > \Lambda(d_1, -b\omega_{[d_2,\mu,d]}) \quad \text{and} \quad \mu > \Lambda(d_2, -c\omega_{[d_1,\lambda,a]}), \tag{1.4}$$

then the autonomous version of the competition or prey-predator cases of (1.3), with Dirichlet boundary conditions in both components, are permanent and moreover there exists a positive equilibrium solution (Cantrell et al. [4], [6], [7], [8] and López-Gómez [27]).

Although the case of symbiosis, $b, c < 0$, is not treated in these papers, a similar result holds provided that

$$bc < ad,$$

a condition which is used to obtain *a priori bounds* for the solutions (see, for instance, Pao [30] or Theorem 9.8 in Delgado et al. [12], where moreover the coefficients a, b, c, and d depend on x).

Note that (1.4) is a condition that expresses the instability of semitrivial solutions.

However, in the competition case it is well known that if $\lambda \le \Lambda_0$ or $\mu \le \Lambda_0$, then one of the two species (or both of them) will be driven to extinction (see López-Gómez and Sabina [29] for an improvement of this result). Similar results can be obtained in the other cases; see [6] and [30]. Note that, in contrast with (1.4), the condition above expresses the stability of either one of the semitrivial solutions.

When nonautonomous terms are allowed in the equations, this is usually done under the assumption of periodicity, quasiperiodicity, or almost periodicity, and in this case similar results can be obtained to those for autonomous equations (see Hess [17], Hess and Lazer [18], Hetzer and Shen [19], and references therein). For the case of periodic coefficients, the use of the Poincaré map implies that the system resembles an autonomous one in many respects.

Cantrell and Cosner [5] assume general nonautonomous terms that are bounded by periodic functions, and using a comparison method give conditions on λ and μ that guarantee that (1.3) is permanent.

Note that most of the references cited in the papers above are concerned (besides periodicity or almost periodicity) with some particular choice of boundary conditions (typically Neumann, or even Dirichlet, in both components) and one of the competition, symbiosis or prey-predator cases. In the first two cases a common tool in the references is the use of order-preserving properties of the Lotka–Volterra system.

For example, in the case of almost periodic time dependence, Hetzer and Shen [19] proved similar results for the competition case, assuming that $d_1 = d_2$ and $\lambda = \mu$ are constant and both components of the system satisfy Dirichlet boundary conditions (no such restrictions are required in the case of Neumann BCs). In that paper, the limitation to almost periodic cases is due to the use of skew-product techniques which require, some way or another, some sort of time recurrence in the coefficients of the system.

Note that in [25] Langa et al. studied permanence for the competition case with Dirichlet boundary conditions when only the coefficient a is allowed to depend on time.

In this paper we allow general nonautonomous terms and do not restrict ourselves to (for example) almost periodic time dependence. As said before, we also consider all nine possible choices of boundary conditions and treat competition, symbiosis, and prey-predator models, since we do not rely on monotonicity properties of the system. Note that the only restriction that we impose on the coefficients is that $d_1 = d_2$ in the symbiotic case, a condition that we assume only in order to have explicit upper bounds on the solutions, but not for the permanence results. Also note that as we employ for the solutions of (1.1) or (1.3) the approach of *nonautonomous processes* rather than skew-product techniques, we have to pay attention to both the initial time, s, and the observation time for the solutions, $t > s$. This implies that concepts like permanence, stability, instability, and attractivity can be defined and analyzed in both pullback and forwards senses; see section 2 for further details and also [24]. Observe also that while pullback properties (e.g., permanence, attraction) are usually the most one can expect for general nonautonomous terms, in this case we can also show results on permanence and attractivity forwards in time; see Langa et al. [25, 23] for cases of pullback but not forwards permanence or attraction in nonautonomous reaction-diffusion equations.

In section 3, using results for the scalar nonautonomous logistic equations from, e.g., [25, 34], which we compile in section 3.1, we make use of the theory of attractors for nonautonomous PDEs as developed by Chepyzhov and Vishik [9] (see also Crauel et al. [11] or Kloeden and Schmalfuss [21]). Thus, we prove in section 3.2 that under the assumptions

$$\inf_{\mathbf{R}\times\Omega} a(t,x) > 0 \quad \text{and} \quad \inf_{\mathbf{R}\times\Omega} d(t,x) > 0$$

the system (1.3) has a nonautonomous attractor; see Theorem 3.5. The existence of a nonautonomous attractor in this case implies the presence of bounded complete trajectories, i.e., solutions defined for all time.

From here we derive in section 3.3 some sufficient conditions for the extinction of one (or both) of the species of the system. These conditions are far from optimal but qualitatively describe the stability of semitrivial solutions; see Proposition 3.6.

Then, in section 3.4 we give sufficient conditions reflecting the instability of semitrivial solutions that guarantee that (1.3) is permanent both in a pullback and in

a forwards sense. We want to stress here that these sufficient conditions involve only information about the behavior of the coefficients of the system as either $t \to -\infty$ or $t \to \infty$. Also, they are given in such a way that the result is robust with respect to perturbations of the coefficients.

The rest of the paper is then devoted to a more detailed analysis of the asymptotic behavior of the solutions of (1.3). After some preparatory material in sections 4 and 5, we will prove in section 6 that under appropriate conditions on the parameters all nonsemitrivial solutions of (1.3) have the same asymptotic behavior as $t \to \infty$. In particular all bounded complete trajectories in the nonautonomous attractor have the same asymptotic behavior as $t \to \infty$. For this we make use of the permanence results in section 3.4 and impose a smallness condition on the product of the coupling parameters:

$$\limsup_{t\to\infty} \|b\|_{L^\infty(\Omega)} \limsup_{t\to\infty} \|c\|_{L^\infty(\Omega)} < \rho_0$$

for some suitable constant $\rho_0 > 0$; see Theorem 6.1.

Moreover we show that, under a similar smallness condition on the coupling coefficients, now as $t \to -\infty$, if one of the bounded complete trajectories of (1.3) (which exists from the existence of the nonautonomous attractor) is bounded away from zero at $-\infty$, it is the unique such trajectory, and it also describes the unique pullback asymptotic behavior of all nonsemitrivial solutions of (1.3); see Theorem 6.2. When these two theorems can be applied together, there is a unique bounded complete trajectory $(u^*(t), v^*(t))$ that is both forwards and pullback attracting for (1.3); i.e., (u^*, v^*) is a bounded trajectory such that, for any $s \in \mathbf{R}$ and for any positive solution $(u(t,s), v(t,s))$ of (1.3) defined for $t > s$, one has

$$(u(t,s) - u^*(t), v(t,s) - v^*(t)) \to (0,0) \qquad \text{as} \quad t \to \infty, \text{ or } \quad s \to -\infty. \tag{1.5}$$

To obtain these results we need some nontrivial machinery for the linear scalar case, section 4.1, and some perturbation results about the exponential decay for solutions of linear parabolic nonautonomous systems, section 4.2. In particular, we find conditions guaranteeing that any bounded solution of

$$\begin{cases} u_t - d_1 \Delta u = p(t,x)u \\ v_t - d_2 \Delta v = q(t,x)v \end{cases} \tag{1.6}$$

gives rise to a solution that tends to zero as $t \to \infty$, when (1.6) is perturbed in a certain way; see Theorem 4.6. It is because we are able to study the linear part of the system in detail that we can obtain results for the nonlinear system.

Since we are able to treat the difference of two solutions of problem (1.3) within this framework, as a consequence of this argument we can apply our results to the Lotka–Volterra model in all three standard cases: competition, symbiosis, and prey-predator. It is noteworthy that these different situations are usually studied separately in the literature, but since we do not make any use of monotonicity arguments (which do not apply in the prey-predator case) we are able to give a unified treatment.

We close this paper in section 7 with a discussion of our results and some possibilities for further developments.

In the case in which all the coefficients are autonomous or periodic, our results in section 6 that we described above in (1.5) imply the uniqueness of the asymptotic behavior of all nonsemitrivial solutions.

Hence, in the autonomous case our results agree with all the classical results of uniqueness and stability of the nonsemitrivial steady states of (1.3) for the three cases of competition, symbiosis, and prey-predator (see, for instance, Theorem 4.4 in Furter and López-Gómez [13] and Corollary 4.3 in López-Gómez and Sabina de Lis [29] in the competition case, and Corollary 9.5 in Delgado et al. [12] in the symbiosis case).

Moreover, in the prey-predator case, with (1.5) we are able to conclude the uniqueness and *global stability* of a steady state, solving (for particular ranges of parameter values) one of the most interesting open problems in this field. We emphasize that this result is new even in the autonomous case, where until now only local stability has been proved; see Theorem 4.1 in Leung [26], see also Lakos [22], López-Gómez and Pardo [28], and Yamada [36].

2. Some notations and preliminaries. In this section we introduce some basic notations and terminology that will be used throughout the rest of the paper. In particular, we make precise the way systems (1.1) or (1.3) are said to be permanent.

2.1. Asymptotic behavior and complete trajectories for nonlinear systems. Note that if the solutions of (1.1) are global, then we can define a nonautonomous nonlinear *process* in some Banach space X appropriate for the solutions, i.e., a family of mappings $\{S(t,s)\}_{t\geq s} : X \to X$, $t, s \in \mathbf{R}$ satisfying:

(a) $S(t,s)S(s,\tau)z = S(t,\tau)z$, for all $\tau \leq s \leq t$, $z \in X$,

(b) $S(t,\tau)z$ is continuous in $t > \tau$ and z, and

(c) $S(t,t)$ is the identity in X for all $t \in \mathbf{R}$.

$S(t,\tau)z$ arises as the value of the solution of our nonautonomous system at time t with initial condition z at initial time τ. For an autonomous system the solutions depend only on $t-\tau$, and we can write $S(t,\tau) = S(t-\tau,0)$.

In order to describe the asymptotic behavior of nonautonomous systems like (1.1) and (1.3), we rely on the concept of a nonautonomous pullback attractor (Chepyzhov and Vishik [9], Kloeden and Schmalfuss [21]), which is the sensible generalization of an attractor for nonautonomous systems. For $A, B \subset X$ we denote the Hausdorff semidistance between A and B by $\operatorname{dist}(A,B) = \sup_{a\in A} \inf_{b\in B} d(a,b)$.

DEFINITION 2.1. *We say that a family of compact sets $\{\mathcal{A}(t)\}_{t\in\mathbf{R}} \subset X$ is a pullback attractor associated to S if*

(a) *$S(t,\tau)\mathcal{A}(\tau) = \mathcal{A}(t)$, for all $t \geq \tau$ and*

(b) *for all $t \in \mathbf{R}$ and $D \subset X$ bounded*

$$\lim_{\tau\to-\infty} \mathit{dist}(S(t,\tau)D, \mathcal{A}(t))) = 0.$$

Observe that the attraction in (b) fixes the final time and moves the initial time backwards towards $-\infty$. We are not evolving one trajectory backwards in time, but rather we consider the current state of the system (at the fixed time t) which would result from the same initial condition starting at earlier and earlier times.

To guarantee the existence of such a pullback attractor, one is usually faced with the task of proving the existence of a pullback absorbing family, defined as follows.

DEFINITION 2.2. *Given $t_0 \in \mathbf{R}$, we say that $B(t_0) \subset X$ is pullback absorbing at time t_0 if for every bounded $D \subset X$ there exists a $T = T(t,D) \in \mathbf{R}$ such that*

$$S(t_0,\tau)D \subset B(t_0), \text{ for all } \tau \leq T.$$

A family $\{B(t)\}_{t\in\mathbf{R}}$ is pullback absorbing if $B(t_0)$ is pullback absorbing at time t_0, for all $t_0 \in \mathbf{R}$.

The general result on the existence of nonautonomous pullback attractors is a generalization of the abstract theory for autonomous dynamical systems (Temam [37], Hale [14]).

THEOREM 2.3 (Crauel et al. [11], Schmalfuss [35]). *Assume that there exists a family of compact pullback absorbing sets. Then, there exists a pullback attractor* $\{\mathcal{A}(t)\}_{t\in\mathbf{R}}$ *that is minimal in the sense that if* $\{C(t)\}_{t\in\mathbf{R}}$ *is another family of closed pullback attracting sets, then* $\mathcal{A}(t)\subset C(t)$ *for all* $t\in\mathbf{R}$.

To have a more precise description of the dynamical objects within the pullback attractor, we make the following definition:

DEFINITION 2.4. *Let* S *be a process. We call the continuous map* $w:\mathbf{R}\to X$ *a complete trajectory if, for all* $s\in\mathbf{R}$,

$$S(t,s)w(s)=w(t)\qquad \text{for all}\qquad t\geq s.$$

According to Chepyzhov and Vishik [9], when the family of absorbing sets is uniformly bounded, the pullback attractor can be characterized as

$$\mathcal{A}(t)=\{w(t):\ w(\cdot)\text{ is a bounded complete trajectory for } S\}. \tag{2.1}$$

2.2. Pullback and forwards permanence for nonautonomous systems. Consider the nonlinear system (1.1) and assume that f and g are regular functions. Hence, we can assume that for initial data $(u_s,v_s)\in C_{\mathcal{B}_1}(\overline{\Omega})\times C_{\mathcal{B}_2}(\overline{\Omega})$ there exists a unique (local) smooth solution such that $(u,v)\in C^1_{\mathcal{B}_1}(\overline{\Omega})\times C^1_{\mathcal{B}_2}(\overline{\Omega})$ for $t>s$, where, for $j=0,1$,

$$C^j_{\mathcal{B}}(\overline{\Omega})=\begin{cases} C^j_0(\overline{\Omega}) & \text{for Dirichlet BCs,}\\ C^j(\overline{\Omega}) & \text{for Neumann or Robin BCs,}\end{cases}$$

with $C^j_0(\overline{\Omega})$ denoting functions in $C^j(\overline{\Omega})$ that are zero on $\partial\Omega$ and $C^0(\overline{\Omega})=C(\overline{\Omega})$.

Note that in practice we will be interested only in nonnegative solutions and that if $u_s\geq 0$ and $v_s\geq 0$ in (1.1), then the local solution satisfies $u,v\geq 0$. In fact, the maximum principle implies that if both $u_s\geq 0$ and $v_s\geq 0$ are nontrivial, then u and v are strictly positive in Ω.

Although at this point we assume only local existence of solutions, it still makes sense to consider complete trajectories of (1.1), which roughly speaking are solutions defined for all times. These objects will play a central role in our analysis below, as can be seen from (2.1). More precisely, a restatement of Definition 2.4 gives the following.

DEFINITION 2.5. *A continuous function* $U=\binom{u}{v}:\mathbf{R}\to C_{\mathcal{B}_1}(\overline{\Omega})\times C_{\mathcal{B}_2}(\overline{\Omega})$ *is a complete trajectory of* (1.1)*, if for all* $s<t$ *in* $\mathbf{R}$, $(u(t),v(t))$ *is the solution of* (1.1) *with initial data* $u_s=u(s)$, $v_s=v(s)$.

Now we define several concepts that will help us in making precise the concepts of pullback and forwards permanence for the solutions of (1.1) or (1.3). Note that the concepts below are related to the spaces $C_{\mathcal{B}_i}(\overline{\Omega})$ above. We start with the following.

DEFINITION 2.6. *A set of nonnegative functions* $B\subset C(\overline{\Omega})$ *is bounded away from zero if there exists a nonnegative nontrivial continuous function* $\varphi_0(x)\geq 0$ *in* Ω *(vanishing on* $\partial\Omega$ *in case of Dirichlet boundary conditions) such that*

$$u(x)\geq\varphi_0(x)\quad \text{for all}\quad x\in\Omega,\quad u\in B.$$

The set B *is nondegenerate if the function* $\varphi_0(x)$ *above is in* $C^1(\overline{\Omega})$ *and* $\varphi_0(x)>0$ *in* Ω.

Note that φ_0 above can be a positive constant in the case of Neumann or Robin boundary conditions.

Then we have the following definitions for curves in the space of continuous functions.

DEFINITION 2.7. *A positive function with values in $C(\overline{\Omega})$ is nondegenerate at ∞ (respectively, $-\infty$) if there exists $t_0 \in \mathbf{R}$ such that u is defined in $[t_0, \infty)$ (respectively, $(-\infty, t_0]$) and*

$$\{u(t),\ t \geq t_0\} \quad \textit{is a nondegenerate set}$$

(respectively, for $t \leq t_0$), that is, there exists a $C^1(\overline{\Omega})$ function $\varphi_0(x) > 0$ in Ω, (vanishing on $\partial\Omega$ in case of Dirichlet boundary conditions), such that

$$u(t,x) \geq \varphi_0(x) \qquad \textit{for all} \quad x \in \Omega, \quad t \geq t_0$$

(respectively, for all $t \leq t_0$).

A family of curves in $C(\overline{\Omega})$, denoted $\{u_\sigma(t)\}_{\sigma\in\Sigma}$, is nondegenerate at ∞ if there exists $t_0 \in \mathbf{R}$ such that u_σ is defined in $[t_0, \infty)$ and

$$\{u_\sigma(t),\ t \geq t_0,\ \sigma \in \Sigma\} \quad \textit{is a nondegenerate set.}$$

Finally, a family of curves in $C(\overline{\Omega})$, denoted $\{u_\sigma(t,s)\}_{\sigma\in\Sigma}$, defined in the intervals $[s, \infty)$ is nondegenerate as $s \to -\infty$ if there exists $s_0 \in \mathbf{R}$ such that for all $s \leq s_0$

$$\{u_\sigma(t),\ s \leq t \leq s_0,\ \sigma \in \Sigma\} \quad \textit{is a nondegenerate set.}$$

For systems, analogously to Definition 2.6, a set $B \subset (C(\overline{\Omega}))^2$ is bounded away from zero if each projection of B is bounded away from zero in $C(\overline{\Omega})$. In a similar way, as in Definition 2.7, a family of curves $U_\sigma(x,\cdot) \in (C(\overline{\Omega}))^2$, $\sigma \in \Sigma$, is nondegenerate if both components are nondegenerate in $C(\overline{\Omega})$.

Now we can finally define when the system (1.1) or (1.3) is pullback permanent. Observe that we assume here that solutions are globally defined.

DEFINITION 2.8. *We say that system* (1.1) *is pullback permanent if for any bounded set of intial $B \subset (C(\overline{\Omega}))^2$ bounded away from zero, there exists $t_0 \in \mathbf{R}$ such that for any $t \leq t_0$ the family of solutions*

$$\{\big(u(t,s;u_0,v_0), v(t,s;u_0,v_0)\big),\ s \leq t,\ (u_0,v_0) \in B\} \tag{2.2}$$

is nondegenerate as $s \to -\infty$.

The system (1.1) *is uniformly pullback permanent if it is pullback permament and the functions φ_0 in Definition* 2.7 *are independent of B.*

Note that using the regularizing properties of the solutions of (1.1) or (1.3), if the system is pullback permanent, as defined above, then the set (2.2) is nondegenerate as $s \to -\infty$ for any fixed $t \in \mathbf{R}$.

In an analogous although subtly different way, we can define when system (1.1) or (1.3) is forwards permanent.

DEFINITION 2.9. *We say that system* (1.1) *is forwards permanent if for any bounded set of initial $B \subset (C(\overline{\Omega}))^2$ bounded away from zero, and for any $s \in \mathbf{R}$, the family of solutions*

$$\{\big(u(t,s;u_0,v_0), v(t,s;u_0,v_0)\big),\ s \leq t,\ (u_0,v_0) \in B\} \tag{2.3}$$

is nondegenerate at ∞.

The system (1.1) *is uniformly forwards permanent if it is forwards permanent and the functions* φ_0 *in Definition* 2.7 *are independent of* B.

Note that (1.1) always has the trivial solution $(0,0)$ as well as semitrivial solutions $(u,0)$ and $(0,v)$. Hence, if the system is permanent, as defined above, this implies that trivial and semitrivial solutions are unstable in the pullback or forwards sense; see, e.g., Langa, Robinson, and Suárez [24]. Also, note that permanence implies coexistence of the species, since the values of the solutions eventually remain far from zero in all points of the domain (except at the boundary in the case of Dirichlet boundary conditions).

In the next section we will give conditions on the coefficients of (1.3) for uniform permanence (both forwards and pullback), which will be moreover robust with respect to suitable perturbations on the coefficients.

3. Extinction and permanence for nonautonomous Lotka–Volterra equations: Competition, symbiosis, and prey-predator models. In this section we give results on extinction and pullback and forwards permanence for nonautonomous Lotka–Volterra systems of the type

$$\begin{cases} u_t - d_1\Delta u = u\big(\lambda(t,x) - a(t,x)u - b(t,x)v\big), & x\in\Omega,\ t>s \\ v_t - d_2\Delta v = v\big(\mu(t,x) - c(t,x)u - d(t,x)v\big), & x\in\Omega,\ t>s \\ \mathcal{B}_1 u = 0,\ \mathcal{B}_2 v = 0, & x\in\partial\Omega,\ t>s \\ u(s) = u_s \geq 0,\ v(s) = v_s \geq 0, \end{cases} \tag{3.1}$$

with $d_1, d_2 > 0$; $\lambda, \mu, a, b, c, d \in C^\theta(\overline{Q})$, and $\overline{Q} = \mathbf{R}\times\overline{\Omega}$. Given a function $e \in C^\theta(\overline{Q})$, we define

$$e_L := \inf_{\overline{Q}} e(t,x) \qquad e_M := \sup_{\overline{Q}} e(t,x).$$

We assume from now on that

$$a_L, d_L > 0, \tag{3.2}$$

and consider the three classical cases depending on the signs of b and c:

1. *Competition*: $b_L, c_L > 0$ in $\overline{Q}$.
2. *Symbiosis*: $b_M, c_M < 0$ in $\overline{Q}$.
3. *Prey-predator*: $b_L > 0$, $c_M < 0$ in $\overline{Q}$.

Also, note that we consider all nine possible choices for $\mathcal{B}_i$ as in (1.2).

Using standard techniques, see for instance Pao [30], it can be shown that given $0 \leq u_s \in C(\overline{\Omega})$, $0 \leq v_s \in C(\overline{\Omega})$ there exists, locally in time, a unique solution of (3.1) which is nonnegative, and which we will denote by

$$u = u(t,s,x;u_s,v_s) \geq 0, \quad v = v(t,s,x;u_s,v_s) \geq 0.$$

In fact, due to the strong maximum principle, if $u_s \geq 0$ and $v_s \geq 0$ are both nontrivial, then u and v are strictly positive in Ω. Furthermore, if we denote by $\mathcal{C}_i$ and $\operatorname{int}(\mathcal{C}_i)$ for $i = 1, 2$, respectively, the positive cones in $C^1_{\mathcal{B}_i}(\overline{\Omega})$ and their corresponding interior sets, we have

$$\operatorname{int}(\mathcal{C}_i) := \{u \in \mathcal{C}_i : u > 0 \quad \text{in } \Omega, \text{ and } \frac{\partial u}{\partial \vec{n}} < 0 \quad \text{on } \partial\Omega\} \quad \text{if } \mathcal{B}_i u = u$$

and

$$\operatorname{int}(\mathcal{C}_i) := \{u \in \mathcal{C}_i : u \geq \delta > 0, \quad \text{for some } \delta > 0 \quad \text{in } \overline{\Omega}\},$$

if $\mathcal{B}_i u = \frac{\partial u}{\partial \vec{n}}$ or $\mathcal{B}_i u = d_i \frac{\partial u}{\partial \vec{n}} + \sigma_i(x)u$.

Thus, if $u_s \geq 0$ and $v_s \geq 0$ are both nontrivial, then $(u,v) \in \operatorname{int}(\mathcal{C}_1) \times \operatorname{int}(\mathcal{C}_2)$ for $t > s$.

Note that (3.1) also admits semitrivial solutions of the form $(u,0)$ or $(0,v)$. As indicated in the Introduction, the stability properties of semitrivial solutions play an important role in the global dynamics of (3.1). In fact, extinction requires some semitrivial solution is stable whereas permanence is only possible if semitrivial solutions are somehow unstable.

Thus, we first review some results on the solutions of scalar logistic equations that will be used further below. These results will be used to prove that the local solutions of (3.1) above are, in fact, globally defined. Also, they will be crucially used to prove the existence of a pullback attractor as in section 2.1, and to obtain our results on extinction and permanence as well.

3.1. On the nonautonomous logistic equation. Note that (3.1) always admits semitrivial solutions of the form $(u,0)$ or $(0,v)$. In this case, when one species is not present, the other one satisfies the nonautonomous logistic equation

$$\begin{cases} u_t - d\Delta u = h(t,x)u - g(t,x)u^2 & \text{in } \Omega,\ t > s, \\ \mathcal{B}u = 0 & \text{on } \partial\Omega, \\ u(s) = u_s \geq 0 & \text{in } \Omega, \end{cases} \tag{3.3}$$

where $d > 0$ and $\mathcal{B}$ as in (1.2), $u_s \in C(\overline{\Omega})$, $h, g \in C^\theta(\overline{Q})$, and

$$g_L > 0 \quad \text{in} \quad \overline{Q}.$$

For $m \in L^\infty(\Omega)$ we denote by $\Lambda_{\mathcal{B}}(d,m)$ the first eigenvalue of

$$\begin{cases} -d\Delta u = \lambda u + m(x)u & \text{in } \Omega, \\ \mathcal{B}u = 0 & \text{on } \partial\Omega. \end{cases} \tag{3.4}$$

In particular, we denote by $\Lambda_{0,\mathcal{B}}(d) = \Lambda_{\mathcal{B}}(d,0)$ the first eigenvalue of the operator $-d\Delta$ with boundary conditions $\mathcal{B}$. It is well known that $\Lambda_{\mathcal{B}}(d,m)$ is a simple eigenvalue and a continuous and decreasing function of m. Also note that if m_1 is constant, then

$$\Lambda_{\mathcal{B}}(d, m_1 + m_2) = \Lambda_{\mathcal{B}}(d, m_2) - m_1. \tag{3.5}$$

We write $\varphi_{1,\mathcal{B}}(d,m)$ for the positive eigenfunction associated to $\Lambda_{\mathcal{B}}(d,m)$, normalized such that $\|\varphi_{1,\mathcal{B}}(d,m)\|_{L^\infty(\Omega)} = 1$.

If there is no possible confusion we will suppress the dependence on d and $\mathcal{B}$ in the notations above. When we need to distinguish these quantities with respect to $\mathcal{B}_i$, or d_i, $i = 1,2$, we will employ superscripts as $\Lambda^i(m)$ or Λ_0^i.

Finally, for $h, g \in L^\infty(\Omega)$ with $g_L > 0$ consider the elliptic equation

$$\begin{cases} -d\Delta u = h(x)u - g(x)u^2 & \text{in } \Omega, \\ \mathcal{B}u = 0 & \text{on } \partial\Omega. \end{cases} \tag{3.6}$$

The following result is well known (Cantrell and Cosner [6]).

PROPOSITION 3.1. *If $\Lambda(h) \geq 0$, the unique nonnegative solution of* (3.6) *is the trivial one, i.e., $\omega_{[h,g]}(x) = 0$. On the other hand, if $\Lambda(h) < 0$ there exits a unique positive solution of* (3.6)*, which we denote by $\omega_{[h,g]}(x)$. Moreover, $0 < \omega_{[h,g]}(x) \leq \Psi(x)$ in Ω, where*

$$\Psi(x) = \begin{cases} \dfrac{h_M}{g_L} & \textit{for Dirichlet or Neumann BCs,} \\ -\dfrac{\Lambda(h)}{\varphi_L g_L}\varphi(x) & \textit{for Robin BCs,} \end{cases}$$

with $\varphi = \varphi_{1,\mathcal{B}}(m)$.

The following result will be used in what follows.

LEMMA 3.2. *Assume that* $h_n \in L^\infty(\Omega)$ *and that*

$$h_n \to h_\infty \quad \text{in } L^\infty(\Omega),$$

with $\Lambda(h_\infty) < 0$. *Then, there exist* $n_0 \in \mathbb{N}$, *and* $\varphi \in int(\mathcal{C})$ *such that*

$$\varphi(x) \le \omega_{[h_n,g]}(x) \quad \text{in } \Omega, \quad \text{for all } n \ge n_0,$$

where $\omega_{[h_n,g]}(x)$ *is given by Proposition* 3.1.

Proof. Since $\Lambda(h_\infty) < 0$, we can take $\varepsilon > 0$ such that $0 < \varepsilon < -\Lambda(h_\infty)$. For this $\varepsilon > 0$, there exists $n_0 \in \mathbb{N}$ such that for $n \ge n_0$

$$-\varepsilon < h_n - h_\infty < \varepsilon \quad \text{for all } x \in \Omega.$$

Consider $\varphi_\infty \in \text{int}(\mathcal{C})$ the eigenfunction associated to $\Lambda(h_\infty)$ with $\|\varphi_\infty\|_{L^\infty(\Omega)} = 1$. It is not hard to show that $\delta\varphi_\infty$ is a subsolution of (3.6) with $h = h_n$ provided that

$$\delta \le -\frac{\varepsilon + \Lambda(h_\infty)}{g_M}.$$

So, $\delta\varphi_\infty(x) \le \omega_{[h_n,g]}(x)$ in Ω. This completes the proof. ∎

In [25] and [34] the following properties of (3.3) were proved.

THEOREM 3.3. *Assume that in* (3.3)

$$h_M < \infty \quad \text{and} \quad g_L > 0 \quad \text{in } \overline{Q}.$$

Then

1. *For every nontrivial* $u_s \in C(\overline{\Omega})$, $u_s \ge 0$, *there exists a unique positive solution of* (3.3) *denoted by* $\Theta_{[h,g]}(t,s,u_s)$. *Moreover,*

$$0 \le \Theta_{[h,g]}(t,s,u_s) \le K, \tag{3.7}$$

where

$$K := \begin{cases} \max\left\{(u_s)_M, \dfrac{h_M}{g_L}\right\} & \text{for Dirichlet or Neumann BCs,} \\ \max\left\{\left(\dfrac{u_s}{\varphi}\right)_M, \dfrac{-\Lambda(h_M)}{\varphi_L g_L}\right\} & \text{for Robin BCs,} \end{cases}$$

and φ *is the positive eigenfunction associated to* $\Lambda(h_M)$ *with* $\|\varphi\|_{L^\infty(\Omega)} = 1$.

2. *For fixed* $t > s$, u_s, *the map* $h \mapsto \Theta_{[h,g]}(t,s,u_s)$ *is increasing and* $g \mapsto \Theta_{[h,g]}(t,s,u_s)$ *is decreasing.*
   For fixed $t > s$, h *and* g, *the map* $u_s \mapsto \Theta_{[h,g]}(t,s,u_s)$ *is increasing.*
3. *Define, for* $x \in \Omega$,

$$h_0(x) := \inf_{t\in\mathbf{R}} h(t,x), \qquad H_0(x) := \sup_{t\in\mathbf{R}} h(t,x)$$

and

$$g_0(x) := \inf_{t\in\mathbf{R}} g(t,x), \qquad G_0(x) := \sup_{t\in\mathbf{R}} g(t,x).$$

Then, if $u_s \in int(\mathcal{C})$ and $\Lambda(h_0) < 0$ we have, for any $t > s$,

$$0 < \varepsilon\varphi_1(x) \le \Theta_{[h,g]}(t,s,x;u_s) \quad \text{in } \Omega, \tag{3.8}$$

where φ_1 is the positive eigenfunction associated to $\Lambda(h_0)$ and

$$\varepsilon = \varepsilon(u_s) := \min\left\{\left(\frac{u_s}{\varphi_1}\right)_L, \frac{-\Lambda(h_0)}{g_M}\right\}.$$

4. *If $\Lambda(H_0) > 0$, then for all initial data $u_s \ge 0$, $\Theta_{[h,g]}(t,s,u_s) \to 0$, in $C^1(\overline{\Omega})$, as $t - s \to \infty$. Moreover the convergence is exponential and uniform for bounded sets of initial data u_s.*
5. *If $\Lambda(h_0) < 0$, then there exists a unique bounded, complete, and nondegenerate trajectory at $\pm\infty$ of (3.3), $\varphi_{[h,g]}$, which moreover satisfies that for all s and any bounded set of nontrivial initial data $u_s \ge 0$, bounded away from 0,*

$$\Theta_{[h,g]}(t,s,u_s) - \varphi_{[h,g]}(t) \to 0 \quad \text{as } t \to \infty.$$

That is, $\varphi_{[h,g]}$ describes the forward behavior of all solutions. Also, $\varphi_{[h,g]}$ describes the pullback behavior of all nondegenerate solutions of (3.3), that is, for each t, if $s \mapsto u_s \ge 0$ is bounded and nondegenerate, then

$$\Theta_{[h,g]}(t,s,u_s) - \varphi_{[h,g]}(t) \to 0 \quad \text{as } s \to -\infty.$$

Both limits above are taken in $C^1(\overline{\Omega})$. Furthermore for all $t \in \mathbf{R}$, we have

$$\omega_{[h_0,G_0]}(x) \le \varphi_{[h,g]}(t,x) \le \omega_{[H_0,g_0]}(x) \quad \text{in } \Omega.$$

6. *If h, g are independent of t and are in $L^\infty(\Omega)$ with $g_L > 0$ and $\Lambda(h) < 0$, then $\varphi_{[h,g]}(t,x) = \omega_{[h,g]}(x)$ is the unique positive solution of (3.6) and for all $t > s$ and u_s*

$$\Theta_{[h,g]}(t,s,u_s) = \Theta_{[h,g]}(t-s,u_s) \to \omega_{[h,g]} \quad \text{in } C^1(\overline{\Omega}) \text{ as } t - s \to \infty$$

uniformly for bounded sets of initial data $u_s \ge 0$ bounded away from zero. In particular, there exist $m \le 1 \le M$ such that

$$m\omega_{[h,g]} \le \Theta_{[h,g]}(t,s,u_s) \le M\omega_{[h,g]},$$

for $t - s$ large.

Moreover in statements 4, 5, and 6 above the convergence as $t \to \infty$ is exponentially fast (see [33]).

3.2. Existence of the pullback attractor and complete trajectories for nonautonomous Lotka–Volterra systems. Our first purpose is to prove the existence of a nonautonomous pullback attractor for (3.1). To do this we will derive suitable estimates on the solutions of (3.1). In doing this we will use the following notation for the solutions of (3.3) with diffusion coefficients d_1 and d_2 and boundary conditions $\mathcal{B}_1$ and $\mathcal{B}_2$, respectively,

$$\xi_{[\lambda,a]}(t,s) = \Theta_{[\lambda,a]}(t,s,u_s), \quad \eta_{[\mu,d]}(t,s) = \Theta_{[\mu,d]}(t,s,v_s),$$

where $u_s \ge 0$ and $v_s \ge 0$ in Ω.

THEOREM 3.4. *Provided that $a_L, d_L > 0$, for any solution (u,v) of (3.1), with initial data $u_s \ge 0$, $v_s \ge 0$, the following lower and upper bounds hold:*

1. *Competition,* $b_L > 0, c_L > 0$*:*

$$\xi_{[\lambda - b\eta_{[\mu,d]},a]} \le u \le \xi_{[\lambda,a]}, \qquad \eta_{[\mu - c\xi_{[\lambda,a]},d]} \le v \le \eta_{[\mu,d]}.$$

2. *Symbiosis,* $b_M < 0, c_M < 0$*: Assume that*

$$b_L c_L < a_L d_L. \tag{3.9}$$

Then,

$$\xi_{[\lambda - b\eta_{[\mu,d]},a]} \le u, \quad \eta_{[\mu - c\xi_{[\lambda,a]},d]} \le v.$$

Assume furthermore that $d_1 = d_2$ *and define*

$$\gamma = \max\{\lambda_M, \mu_M\}, \quad M = \frac{a_L - c_L}{d_L - b_L} > 0, \quad K = \frac{a_L d_L - b_L c_L}{d_L - b_L} > 0,$$

and choose w_s *such that* $w_s \ge \max\{u_s, \frac{1}{M} v_s\}$*. Denote by* $\Theta_{[\gamma,K]}(t, s, w_s)$ *the solution of* (3.3) *with* $d = d_1$ *and a certain boundary condition that depends on* $\mathcal{B}_1$ *and* $\mathcal{B}_2$ *and that will be specified in the proof. Then, we have the upper bounds*

$$u \le \Theta_{[\gamma,K]}(t, s, w_s), \quad v \le M\Theta_{[\gamma,K]}(t, s, w_s).$$

3. *Prey-predator,* $b_L > 0, c_M < 0$*:*

$$\xi_{[\lambda - b\eta_{[\mu - c\xi_{[\lambda,a]},d]},a]} \le u \le \xi_{[\lambda - b\eta_{[\mu,d]},a]} \le \xi_{[\lambda,a]}, \qquad \eta_{[\mu,d]} \le v \le \eta_{[\mu - c\xi_{[\lambda,a]},d]}.$$

Proof. 1. Assume that $b_L, c_L > 0$. If we write the equation for u as

$$u_t - d_1 \Delta u = u(\lambda - bv) - au^2,$$

then using Theorem 3.3 we get

$$u = \xi_{[\lambda - bv,a]} \le \xi_{[\lambda,a]},$$

and similarly,

$$v \le \eta_{[\mu,d]}.$$

Hence, again by Theorem 3.3

$$u = \xi_{[\lambda - bv,a]} \ge \xi_{[\lambda - b\eta_{[\mu,d]},a]}.$$

2. Assume now that $b_M, c_M < 0$. To have the lower bounds it is enough to check that in the equation for u one has

$$\xi_{[\lambda - b\eta_{[\mu,d]},a]}(\lambda - a\xi_{[\lambda - b\eta_{[\mu,d]},a]} - b\eta_{[\mu,d]}) \le \xi_{[\lambda - b\eta_{[\mu,d]},a]}(\lambda - a\xi_{[\lambda - b\eta_{[\mu,d]},a]} - b\eta_{[\mu - c\xi_{[\lambda,a]},d]}),$$

or equivalently,

$$\eta_{[\mu - c\xi_{[\lambda,a]},d]} \ge \eta_{[\mu,d]},$$

which is true since $c < 0$. We treat the equation for v similarly.

On the other hand, assuming that $d_1 = d_2$, define

$$\overline{u} = \Theta_{[\gamma,K]}(t,s,w_s), \quad \overline{v} = M\Theta_{[\gamma,K]}(t,s,w_s)$$

with a suitable boundary condition, $\mathcal{B}$, to be described below. Then using the equations we get that $\overline{u}$ and $\overline{v}$ are supersolutions if

$$-K \geq -a - bM, \qquad -K \geq -dM - c,$$

which is satisfied with the choice of M and K. To compare the solutions with the uppersolutions on the boundary, if either u or v satisfies Dirchlet boundary conditions we take $\mathcal{B}$ the boundary condition of the other component. If both u and v satisfy Robin or Neumann (i.e., $\sigma_i = 0$ in the latter case) boundary conditions we define

$$\sigma = \min\{\sigma_1, \sigma_2\},$$

and $\mathcal{B}u = d_1 \frac{\partial u}{\partial \overline{n}} + \sigma(x)u$.

3. Assume finally that $b_L > 0$, $c_M < 0$, then

$$u \leq \xi_{[\lambda,a]} \quad \text{and} \quad \eta_{[\mu,d]} \leq v.$$

Hence

$$v = \eta_{[\mu - cu,d]} \leq \eta_{[\mu - c\xi_{[\lambda,a]},d]},$$

and then,

$$u = \xi_{[\lambda - bv,a]} \geq \xi_{[\lambda - b\eta_{[\mu - c\xi_{[\lambda,a]},d]},a]}. \qquad \square$$

With the upper bounds in Theorem 3.4 and using the results for scalar logistic equations in Theorem 3.3, we get the following result.

THEOREM 3.5. *Under the assumptions in cases* (1)–(3) *of Theorem* 3.4*, all solutions of* (3.1) *are global in time and moreover there exists a pullback attractor* $\mathcal{A}(t)$ *of* (3.1)*, which is bounded for all* $t \in \mathbf{R}$*. More precisely, we have*

$$\limsup_{t-s\to\infty} u(t,s;u_s,v_s) \leq M_\infty, \quad \limsup_{t-s\to\infty} v(t,s;u_s,v_s) \leq N_\infty,$$

uniformly in Ω *and for bounded sets of intial data* $u_s, v_s \geq 0$*, for some constants* $M_\infty \geq 0$ *and* $N_\infty \geq 0$ *that depend on the coefficients of* (3.1)*.*

In particular, there exists at least one complete bounded trajectory $(u^*(t), v^*(t))$*,* $t \in \mathbf{R}$*, for* (3.1)*. Furthermore, all complete bounded trajectories of* (3.1) *are uniformly bounded by* M_∞ *and* N_∞ *and for all* $t \in \mathbf{R}$*.*

Proof. Thanks to the upper bounds in Theorem 3.4, the positive solutions of (3.1) are always bounded by solutions of the logistic equation of the type (3.3). In particular, all solutions of (3.1) are globally defined.

Now we use that

$$0 \leq \Theta_{[\alpha,\beta]}(t,s;z) \leq \Theta_{[\alpha_M,\beta_L]}(t-s;z),$$

statements (4)–(6) in Theorem 3.3, and that $0 \leq \omega_{[\alpha_M,\beta_L]}(x) \leq \Psi_M$, with ω and $\Psi(x)$ as in Proposition 3.1, to get the estimates.

In particular, this implies the existence of bounded pullback absorbing sets for (3.1) in $C(\overline{\Omega}) \times C(\overline{\Omega})$.

Then following the proof of section 6 in Langa et al. [25], we can show the existence of a bounded pullback absorbing set in $C^1(\overline{\Omega}) \times C^1(\overline{\Omega})$, and so compact in $C(\overline{\Omega}) \times C(\overline{\Omega})$. Hence, we conclude using Theorem 2.3 as the existence of a bounded nonautonomous pullback attractor $\mathcal{A}(t)$, and thus the existence of at least one bounded complete trajectory $(u^*(t), v^*(t))$, $t \in \mathbf{R}$, follows. $\square$

3.3. Extinction for nonautonomous Lotka–Volterra systems. Note that with the arguments above there are some cases, when statement 4 in Theorem 3.3 can be used, in which one (or both) constants M_∞ and N_∞ are zero and we have then extinction of one of the species. This implies, in turn, that the semitrivial (or the trivial) solutions are stable in a forwards and pullback senses. More precisely, we have the following result. Observe that these sufficient conditions are far from optimal but qualitatively they describe the global stability of trivial or semitrivial solutions.

PROPOSITION 3.6. *With the notations in Theorems* 3.4 *and* 3.5*, we have*

1. *Competition,* $b_L > 0, c_L > 0$*. If*

$$\lambda_M < \Lambda_0^1, \quad \textit{then} \quad M_\infty = 0,$$

while if

$$\mu_M < \Lambda_0^2, \quad \textit{then} \quad N_\infty = 0.$$

2. *Symbiosis,* $b_M < 0, c_M < 0$*,* $d_1 = d_2$ *and* (3.9)*, that is* $b_L c_L < a_L d_L$*. If*

$$\gamma < \Lambda_0^1, \quad \textit{then} \quad M_\infty = 0,$$

while if

$$\gamma < \Lambda_0^2, \quad \textit{then} \quad N_\infty = 0.$$

3. *Prey-predator,* $b_L > 0, c_M < 0$*. If*

$$\lambda_M < \Lambda_0^1, \quad \textit{then} \quad M_\infty = 0,$$

and in this case, if

$$\mu_M < \Lambda_0^2, \quad \textit{then} \quad M_\infty = 0.$$

On the other hand, if

$$\Lambda_0^1 < \lambda_M, \quad \textit{and} \quad \mu_M - c_L \frac{\lambda_M}{a_L} < \Lambda_0^2, \quad \textit{then} \quad N_\infty = 0.$$

In all the cases, when $M_\infty = 0$ *the* u *component of the solutions of* (3.1) *extinguishes in pullback and forwards senses, while the* v *component of the solutions asymptotically follows the dynamics of the scalar logistic equation* (3.3) *with* $h(t,x) = \mu(t,x)$ *and* $g(t,x) = d(t,x)$ *as described in Theorem* 3.3*.*

The case when $N_\infty = 0$ *is analogous.*

Proof. In fact, in the case of competition we have $0 \le u \le \xi_{[\lambda_M, a_L]}$ and $0 \le v \le \eta_{[\mu_M, d_L]}$. Hence, from statement 4 in Theorem 3.3 and using (3.5), if $\Lambda^1(\lambda_M) = \Lambda_0^1 - \lambda_M > 0$, then $M_\infty = 0$, while $N_\infty = 0$ if $\Lambda^2(\mu_M) = \Lambda_0^2 - \mu_M > 0$.

In the case of symbiosis, assuming $d_1 = d_2$, we have $0 \le u \le \Theta_{[\gamma,K]}(t,s,w_s)$, $0 \le v \le M\Theta_{[\gamma,K]}(t,s,w_s)$. Hence, if $\Lambda^1(\gamma) = \Lambda_0^1 - \gamma > 0$, then $M_\infty = 0$, while $N_\infty = 0$ if $\Lambda^2(\gamma) = \Lambda_0^2 - \gamma > 0$.

Finally, in the case of prey-predator, we have $0 \le u \le \xi_{[\lambda_M, a_L]}$, $0 \le v \le \eta_{[\mu_M - c_L \xi_{[\lambda_M, a_L]}, d_L]}$. Hence, if $\Lambda^1(\lambda_M) = \Lambda_0^1 - \lambda_M > 0$, then $M_\infty = 0$. In this case, $N_\infty = 0$ if $\Lambda^2(\mu_M) = \Lambda_0^2 - \mu_M > 0$.

On the other hand, if $\Lambda_0^1 < \lambda_M$, then for large values of $t - s$ we have $v \le \eta_{[\mu_M - c_L(\omega_{[\lambda_M, a_L]} + \varepsilon), d_L]}$, and then $N_\infty = 0$ if $\Lambda^2(\mu_M - c_L \frac{\lambda_M}{a_L}) = \Lambda_0^2 - \mu_M + c_L \frac{\lambda_M}{a_L} > 0$.

The rest is immediate. ∎

As we are interested in the "permanence" problem for (3.1), we will consider in what follows only the cases in which $M_\infty > 0$ and $N_\infty > 0$. In particular, note that for sufficiently large values of $\lambda_M > 0$ and $\mu_M > 0$ we can take, for the case of Dirichlet or Neumann boundary conditions in either one of the components u or v,

$$M_\infty = \begin{cases} \dfrac{\lambda_M}{a_L} & \text{in the competition case,} \\ \dfrac{\gamma}{K} & \text{in the symbiosis case,} \\ \dfrac{\lambda_M}{a_L} & \text{in the prey-predator case,} \end{cases}$$

$$N_\infty = \begin{cases} \dfrac{\mu_M}{d_L} & \text{in the competition case,} \\ M\dfrac{\gamma}{K} & \text{in the symbiosis case,} \\ \dfrac{\mu_M - c_L \frac{\lambda_M}{a_L}}{d_L} & \text{in the prey-predator case,} \end{cases}$$

while for Robin boundary conditions we have

$$M_\infty = \begin{cases} \dfrac{\lambda_M - \Lambda_0^1}{(\varphi^1)_L a_L} & \text{in the competition case,} \\ \dfrac{\gamma - \Lambda_0^1}{(\varphi^1)_L K} & \text{in the symbiosis case,} \\ \dfrac{\lambda_M - \Lambda_0^1}{(\varphi^1)_L a_L} & \text{in the prey-predator case,} \end{cases}$$

$$N_\infty = \begin{cases} \dfrac{\mu_M - \Lambda_0^2}{(\varphi^2)_L d_L} & \text{in the competition case,} \\ M\dfrac{\gamma - \Lambda_0^2}{(\varphi^2)_L K} & \text{in the symbiosis case,} \\ \dfrac{\mu_M - c_L \frac{\lambda_M - \Lambda_0^1}{(\varphi^1)_L a_L} - \Lambda_0^2}{(\varphi^2)_L d_L} & \text{in the prey-predator case,} \end{cases}$$

where φ^i denotes the positive eigenfunction associated to Λ_0^i with $\|\varphi^i\|_{L^\infty(\Omega)} = 1$. Note that similar expressions can be given in the remaining five cases for the boundary conditions, although their explicit form becomes more cumbersome.

In fact, in the next section we will impose conditions on the coefficients to ensure that the pullback and forwards behavior of the solutions of (3.1), with nontrivial initial data, is far from the semitrivial and the trivial solutions.

3.4. Permanence for nonautonomous Lotka–Volterra systems: Nondegeneracy of solutions. Now, using the lower bounds in Theorem 3.4, we will give sufficient conditions for the system (3.1) to be uniformly permanent in pullback and forwards senses, as in section 2.2. For reasons that will become clear further below, we are interested in obtaining such nondegeneracy in a uniform way with respect to the coefficients λ, μ, a, b, c, d in the system. For this, recall the notations in (3.4) and that we always take nonnegative nontrivial initial data u_s, v_s.

Also note that in the results of this section we will use the quantities $\lambda_I \le \lambda_S$, $\mu_I \le \mu_S$, $a_I \le a_S$, $b_I \le b_S$, $c_I \le c_S$, and $d_I \le d_S$ to control the asymptotic sizes of

the coefficients λ, μ, a, b, c, d as $t \to \pm\infty$. As all the results will be given in terms of such quantities, the statements below show the robustness of the results with respect to perturbations in the coefficients of the system.

Finally, we stress here once again that the results below imply the instability of trivial and semitrivial solutions.

3.4.1. Competition.

PROPOSITION 3.7 (forwards permanence—competitive case). *Assume* (3.2) *and* $b_L, c_L > 0$. *Then:*

(i) *If* $\lambda_I > \Lambda^1(-b_S\omega_{[\mu_S,d_I]})$ *there exists* $\psi_{11} \in int(\mathcal{C}_1)$ *such that whenever*

$$\lambda(t,x) \geq \lambda_I,\ \mu(t,x) \leq \mu_S,\ b(t,x) \leq b_S,\ a(t,x) \leq a_S,\ \text{and}\quad d(t,x) \geq d_I > 0$$

for all $x \in \Omega$ *and* $t \geq t_0$, *for any* $u_s, v_s > 0$, *the solution for* $t > s \geq t_0$ *of* (3.1) *satisfies* $\psi_{11}(x) \leq u(t,s,x;u_s,v_s)$ *for* $t-s$ *large enough.*

(ii) *If* $\mu_I > \Lambda^2(-c_S\omega_{[\lambda_S,a_I]})$ *there exists* $\psi_{22} \in int(\mathcal{C}_2)$ *such that whenever*

$$\lambda(t,x) \leq \lambda_S,\quad \mu(t,x) \geq \mu_I,\quad a(t,x) \geq a_I > 0,\quad d(t,x) \leq d_S,\quad c(t,x) \leq c_S$$

for all $x \in \Omega$ *and* $t \geq t_0$, *for any* $u_s, v_s > 0$, *the solution for* $t > s \geq t_0$ *of* (3.1) *satisfies* $\psi_{22}(x) \leq v(t,s,x;u_s,v_s)$ *for* $t-s$ *large enough.*

Hence, if

$$\lambda_I > \Lambda^1(-b_S\omega_{[\mu_S,d_I]}) \qquad \text{and} \qquad \mu_I > \Lambda^2(-c_S\omega_{[\lambda_S,a_I]}), \tag{3.10}$$

then there exist $\psi_{11} \in int(\mathcal{C}_1)$ *and* $\psi_{22} \in int(\mathcal{C}_2)$ *such that for any choice of coefficients that satisfy*

$$\begin{aligned} &\lambda_I \leq \lambda(t,x) \leq \lambda_S, \qquad \mu_I \leq \mu(t,x) \leq \mu_S, \qquad 0 < a_I \leq a(t,x) \leq a_S,\\ &0 < b_I \leq b(t,x) \leq b_S, \quad 0 < c_I \leq c(t,x) \leq c_S, \quad 0 < d_I \leq d(t,x) \leq d_S, \end{aligned}$$

for all $x \in \Omega$ *and for all* $t \geq t_0$, *and for all nontrivial* $u_s \geq 0$, $v_s \geq 0$ *in a fixed bounded set of* $C(\overline{\Omega})$ *bounded away from* 0, *the solution* (u,v) *of* (3.1) *for* $t > s \geq t_0$ *is nondegenerate at* ∞ *and for all* $t-s$ *large enough,*

$$u(t,s,x;u_s,v_s) \geq \psi_{11}(x) \quad \text{and} \quad v(t,s,x;u_s,v_s) \geq \psi_{22}(x).$$

In particular, (3.1) *is uniformly forwards permanent.*

Proof. Since $\lambda_I > \Lambda^1(-b_S\omega_{[\mu_S,d_I]})$, by the continuity of $\Lambda^1(m)$ with respect to m, there exists $\varepsilon > 0$ such that

$$\lambda_I > \Lambda^1(-b_S(\omega_{[\mu_S,d_I]} + \varepsilon)) \quad \text{or equivalently by (3.5)} \quad \Lambda^1(\lambda_I - b_S(\omega_{[\mu_S,d_I]} + \varepsilon)) < 0.$$

Using Theorems 3.3 and 3.4, we get, for $t > s \geq t_0$,

$$u(t,s,u_s,v_s) \geq \xi_{[\lambda - b\eta_{[\mu,d]},a]}(t,s,u_s) \geq \Theta_{[\lambda_I - b_S\eta_{[\mu_S,d_I]},a_S]}(t-s,u_s).$$

Moreover, $\eta_{[\mu_S,d_I]}(t,s,v_s) \to \omega_{[\mu_S,d_I]}$ in $C^1(\overline{\Omega})$ and uniformly for v_s in bounded sets bounded away from zero, as $t-s \to \infty$, and so

$$u(t,s,u_s,v_s) \geq \Theta_{[\lambda_I - b_S(\omega_{[\mu_S,d_I]}+\varepsilon),a_S]}(t-s,u_s) \to \omega_{[\lambda_I - b_S(\omega_{[\mu_S,d_I]}+\varepsilon),a_S]} \tag{3.11}$$

in $C^1(\overline{\Omega})$ and uniformly for u_s in bounded sets bounded away from zero, as $t-s \to \infty$ by Theorem 3.3 and where we have used (3.10). Hence, the result follows for u.

On the other hand, we have analogously for the v component, for $t > s \geq t_0$,

$$v(t,s,u_s,v_s) \geq \eta_{[\mu - c\xi_{[\lambda,a]},d]}(t,s,v_s) \geq \Theta_{[\mu_I - c_S\xi_{[\lambda_S,a_I]},d_S]}(t-s,v_s).$$

Now, from (3.10), $\xi_{[\lambda_S,a_I]}(t,s,u_s) \to \omega_{[\lambda_S,a_I]}$ in $C^1(\overline{\Omega})$ and uniformly for u_s in bounded sets bounded away from zero, as $t-s \to \infty$, and so

$$v(t,s,u_s,v_s) \geq \Theta_{[\mu_I - c_S(\omega_{[\lambda_S,a_I]}+\varepsilon),d_S]}(t-s,v_s) \to \omega_{[\mu_I - c_S(\omega_{[\lambda_S,a_I]}+\varepsilon),d_S]} \tag{3.12}$$

in $C^1(\overline{\Omega})$ and uniformly for v_s in bounded sets bounded away from zero, as $t-s \to \infty$ by Theorem 3.3. ∎

The same arguments as above, carried out in all pullback sense lead to the following result. Note that, in particular, this proposition guarantees the uniform nondegeneracy at $-\infty$ of complete nondegenerate trajectories with respect to the coefficients in the system.

PROPOSITION 3.8 (pullback permanence—competitive case). *Assume* (3.2) *and* $b_L, c_L > 0$. *Then:*

(i) *If* $\lambda_I > \Lambda^1(-b_S\omega_{[\mu_S,d_I]})$ *there exists* $\psi_{11} \in int(\mathcal{C}_1)$ *such that whenever*

$$\lambda(t,x) \geq \lambda_I, \quad \mu(t,x) \leq \mu_S, \quad b(t,x) \leq b_S, \quad a(t,x) \leq a_S, \quad d(t,x) \geq d_I > 0$$

for all $x \in \Omega$ *and* $t \leq t_0$ *(for some* $t_0 \in \mathbf{R}$*), for any* $u_s, v_s > 0$, *the solution for* $s < t \leq t_0$ *of* (3.1) *satisfies* $\psi_{11}(x) \leq u(t,s,x;u_s,v_s)$ *for* $t-s$ *large enough. In particular, any complete trajectory of* (3.1) *that is nondegenerate at* $-\infty$ *satisfies* $u(t,x) \geq \psi_{11}(x)$ *for all* $x \in \Omega$ *and* $t \leq t_0$.

(ii) *If* $\mu_I > \Lambda^2(-c_S\omega_{[\lambda_S,a_I]})$ *there exists* $\psi_{22} \in int(\mathcal{C}_2)$ *such that whenever*

$$\lambda(t,x) \leq \lambda_S, \quad \mu(t,x) \geq \mu_I, \quad a(t,x) \geq a_I > 0, \quad d(t,x) \leq d_S, \quad c(t,x) \leq c_S$$

for all $x \in \Omega$ *and* $t \leq t_0$ *(some* $t_0 \in \mathbf{R}$*), for any* $u_s, v_s > 0$, *the solution for* $s < t \leq t_0$ *of* (3.1) *satisfies* $\psi_{22}(x) \leq v(t,s,x;u_s,v_s)$ *for* $t-s$ *large enough. In particular, any complete trajectory of* (3.1) *that is nondegenerate at* $-\infty$ *satisfies* $v(t,x) \geq \psi_{22}(x)$ *for all* $x \in \Omega$ *and* $t \leq t_0$.

Hence, if

$$\lambda_I > \Lambda^1(-b_S\omega_{[\mu_S,d_I]}) \qquad \text{and} \qquad \mu_I > \Lambda^2(-c_S\omega_{[\lambda_S,a_I]}) \tag{3.13}$$

there exist functions $\psi_{11} \in int(\mathcal{C}_1)$ *and* $\psi_{22} \in int(\mathcal{C}_2)$ *such that whenever*

$$\begin{aligned} &\lambda_I \leq \lambda(t,x) \leq \lambda_S, \qquad \mu_I \leq \mu(t,x) \leq \mu_S, \qquad 0 < a_I \leq a(t,x) \leq a_S, \\ &0 < b_I \leq b(t,x) \leq b_S, \quad 0 < c_I \leq c(t,x) \leq c_S, \quad 0 < d_I \leq d(t,x) \leq d_S, \end{aligned}$$

for all $x \in \Omega$ *and* $t \leq t_0$ *(for some* $t_0 \in \mathbf{R}$*), and for all nontrivial* $u_s \geq 0$, $v_s \geq 0$ *in a fixed bounded set,* B, *of* $C(\overline{\Omega})$ *bounded away from* 0, *the set of solutions of* (3.1) $\{(u,v),\ s < t \leq t_0,\ (u_s,v_s) \in B\}$ *is nondegenerate as* $s \to -\infty$ *and for all* $t-s$ *large enough*

$$u(t,s,x;u_s,v_s) \geq \psi_{11}(x) \quad \text{and} \quad v(t,s,x;u_s,v_s) \geq \psi_{22}(x).$$

In particular, (3.1) *is uniformly pullback permanent and any bounded complete trajectory that is nondegenerate at* $-\infty$ *satisfies*

$$u(t,x) \geq \psi_{11}(x) \quad \text{and} \quad v(t,x) \geq \psi_{22}(x) \quad \text{for all } x \in \Omega \text{ and } t \leq t_0.$$

Proof. The first part of the statements follow from (3.11) and (3.12), with $t-s \to \infty$ but now $s < t \le t_0$.

For a complete solution, arguing as in Proposition 3.7 we get for any $t_0 \ge t > s$,

$$u(t) \ge \xi_{[\lambda - b\eta_{[\mu,d]},a]}(t,s,u(s)) \ge \Theta_{[\lambda_I - b_S\eta_{[\mu_S,d_I]},a_S]}(t-s,u(s)).$$

As v is nondegenerate at $-\infty$, 5 in Theorem 3.3 implies $\eta_{[\mu_S,d_I]}(t,s,v(s)) \to \omega_{[\mu_S,d_I]}$ in $C^1(\overline{\Omega})$ as $s \to -\infty$. Thus, for sufficiently negative s,

$$u(t) \ge \Theta_{[\lambda_I - b_S(\omega_{[\mu_S,d_I]}+\varepsilon),a_S]}(t-s,u(s)) \to \omega_{[\lambda_I - b_S(\omega_{[\mu_S,d_I]}+\varepsilon),a_S]} \tag{3.14}$$

in $C^1(\overline{\Omega})$ as $s \to -\infty$, because u is nondegenerate at $-\infty$ and 5 in Theorem 3.3 again. Hence the result follows for u.

On the other hand, we have analogously for the v component for any $t_0 \ge t > s$,

$$v(t) \ge \eta_{[\mu - c\xi_{[\lambda,a]},d]}(t,s,v(s)) \ge \Theta_{[\mu_I - c_S\xi_{[\lambda_S,a_I]},d_S]}(t-s,v(s)).$$

Now, $\xi_{[\lambda_S,a_I]}(t,s,u(s)) \to \omega_{[\lambda_S,a_I]}$ in $C^1(\overline{\Omega})$ as $s \to -\infty$, because u is nondegenerate at $-\infty$, and so, for sufficiently negative s,

$$v(t) \ge \Theta_{[\mu_I - c_S(\omega_{[\lambda_S,a_I]}+\varepsilon),d_S]}(t-s,v(s)) \to \omega_{[\mu_I - c_S(\omega_{[\lambda_S,a_I]}+\varepsilon),d_S]} \tag{3.15}$$

in $C^1(\overline{\Omega})$ as $s \to -\infty$ by Theorem 3.3, because v is nondegenerate at $-\infty$. ∎

Results for the other cases can be proved analogously, as we now show.

3.4.2. Symbiosis. First for the case of symbiosis, we have the following result. Note that as we make no use here of the upper bound in Theorem 3.4, we do not assume below that $d_1 = d_2$.

PROPOSITION 3.9 (forwards permanence—symbiotic case). *Assume* (3.2), b_M, $c_M < 0$, *and* (3.9), *that is*

$$b_L c_L < a_L d_L.$$

Then:

(i) *If* $\lambda_I > \Lambda^1(-b_S\omega_{[\mu_I,d_S]})$ *there exists* $\psi_{11} \in int(\mathcal{C}_1)$ *such that whenever*

$$\lambda(t,x) \ge \lambda_I, \quad \mu(t,x) \ge \mu_I, \quad b(t,x) \le b_S < 0, \quad a(t,x) \le a_S, \quad d(t,x) \le d_S$$

for all $x \in \Omega$ *and* $t \ge t_0$ *(some* $t_0 \in \mathbf{R}$*), for any* $u_s, v_s > 0$ *the solution for* $t > s \ge t_0$ *of* (3.1) *satisfies* $\psi_{11}(x) \le u(t,s,x;u_s,v_s)$ *for* $t-s$ *large enough.*

(ii) *If* $\mu_I > \Lambda^2(-c_S\omega_{[\lambda_I,a_S]})$ *there exists* $\psi_{22} \in int(\mathcal{C}_2)$ *such that whenever*

$$\lambda(t,x) \ge \lambda_I, \quad \mu(t,x) \ge \mu_I, \quad a(t,x) \le a_S, \quad d(t,x) \le d_S, \quad c(t,x) \le c_S < 0$$

for all $x \in \Omega$ *and* $t \ge t_0$ *(some* $t_0 \in \mathbf{R}$*), for any* $u_s, v_s > 0$ *the solution for* $t > s \ge t_0$ *of* (3.1) *satisfies* $\psi_{22}(x) \le v(t,s,x;u_s,v_s)$ *for* $t-s$ *large enough.*

Hence, if

$$\lambda_I > \Lambda^1(-b_S\omega_{[\mu_I,d_S]}) \qquad \text{and} \qquad \mu_I > \Lambda^2(-c_S\omega_{[\lambda_I,a_S]}), \tag{3.16}$$

then there are functions $\psi_{11} \in int(\mathcal{C}_1)$ *and* $\psi_{22} \in int(\mathcal{C}_2)$ *such that whenever*

$$\begin{array}{lll} \lambda_I \le \lambda(t,x), & \mu_I \le \mu(t,x), & a(t,x) \le a_S, \\ b(t,x) \le b_S < 0, & c(t,x) \le c_S < 0, & d(t,x) \le d_S \end{array}$$

$x \in \Omega$ and $t \geq t_0$ (some $t_0 \in \mathbf{R}$), and for all $u_s > 0, v_s > 0$ in a fixed bounded set of $C(\overline{\Omega})$ bounded away from 0, the solution (u, v) of (3.1) for $t > s \geq t_0$ is nondegenerate at ∞, and for all $t - s$ large enough

$$u(t, s; u_s, v_s) \geq \psi_{11}(x) \qquad \text{and} \qquad v(t, s; u_s, v_s) \geq \psi_{22}(x).$$

In particular, (3.1) is uniformly forwards permanent.

Proof. We proceed as in the Proposition 3.7 using now that, as $t - s \to \infty$,

$$u \geq \xi_{[\lambda - b\eta_{[\mu,d]},a]} \geq \xi_{[\lambda_I - b_S \eta_{[\mu_I,d_S]},a_S]} \to \omega_{[\lambda_I - b_S \omega_{[\mu_I,d_S]},a_S]}$$

and

$$v \geq \eta_{[\mu - c\xi_{[\lambda,a]},d]} \geq \eta_{[\mu_I - c_S \xi_{[\lambda_I,a_S]},d_S]} \to \omega_{[\mu_I - c_S \omega_{[\lambda_I,a_S]},d_S]}. \qquad \square$$

On the other hand, for pullback permenence and for complete nondegenerate solutions, we have the following proposition along the same lines as that above.

PROPOSITION 3.10 (pullback permanence—symbiotic case). *Assume (3.2), b_M, $c_M < 0$, and (3.9), that is*

$$b_L c_L < a_L d_L.$$

Then

(i) *If $\lambda_I > \Lambda^1(-b_S \omega_{[\mu_I,d_S]})$ there exists $\psi_{11} \in int(\mathcal{C}_1)$ such that whenever*

$$\lambda(t, x) \geq \lambda_I, \quad \mu(t, x) \geq \mu_I, \quad b(t, x) \leq b_S < 0, \quad a(x, t) \leq a_S, \quad d(t, x) \leq d_S.$$

for all $x \in \Omega$ and $t \leq t_0$ (some $t_0 \in \mathbf{R}$), for any $u_s, v_s > 0$, the solution for $s < t \leq t_0$ of (3.1) satisfies $\psi_{11}(x) \leq u(t, s, x; u_s, v_s)$ for $t - s$ large enough.
In particular, any complete trajectory of (3.1) that is nondegenerate at $-\infty$ satisfies $u(t, x) \geq \psi_{11}(x)$ for all $x \in \Omega$ and $t \leq t_0$.

(ii) *If $\mu_I > \Lambda^2(-c_S \omega_{[\lambda_I,a_S]})$ there exists $\psi_{22} \in int(\mathcal{C}_2)$ such that whenever*

$$\lambda(t, x) \geq \lambda_I, \quad \mu(t, x) \geq \mu_I, \quad a(t, x) \leq a_S, \quad d(t, x) \leq d_S, \quad c(t, x) \leq c_S < 0,$$

$x \in \Omega$ and $t \leq t_0$ (some $t_0 \in \mathbf{R}$) for any $u_s, v_s > 0$, the solution for $s < t \leq t_0$ of (3.1) satisfies $\psi_{22}(x) \leq v(t, s, x; u_s, v_s)$ for $t - s$ large enough.
In particular, any complete trajectory of (3.1) that is nondegenerate at $-\infty$ satisfies $v(t, x) \geq \psi_{22}(x)$ for all $x \in \Omega$ and $t \leq t_0$.

Hence, if

$$\lambda_I > \Lambda^1(-b_S \omega_{[\mu_I,d_S]}) \qquad \text{and} \qquad \mu_I > \Lambda^2(-c_S \omega_{[\lambda_I,a_S]}), \tag{3.17}$$

there exist $\psi_{11} \in int(\mathcal{C}_1)$ and $\psi_{22} \in int(\mathcal{C}_2)$ such that whenever

$$\begin{aligned} &\lambda_I \leq \lambda(t, x), \qquad \mu_I \leq \mu(t, x), \qquad a(t, x) \leq a_S, \\ &b(t, x) \leq b_S < 0, \quad c(t, x) \leq c_S < 0, \quad d(t, x) \leq d_S, \end{aligned}$$

for all $x \in \Omega$ and $t \leq t_0$ (some $t_0 \in \mathbf{R}$), and for all nontrivial $u_s \geq 0$, $v_s \geq 0$ in a fixed bounded set, B, of $C(\overline{\Omega})$ bounded away from 0, the set of solutions of (3.1) $\{(u, v),\ s < t \leq t_0,\ (u_s, v_s) \in B\}$ is nondegenerate as $s \to -\infty$ and for all $t - s$ large enough

$$u(t, s, x; u_s, v_s) \geq \psi_{11}(x) \quad \text{and} \quad v(t, s, x; u_s, v_s) \geq \psi_{22}(x).$$

In particular, (3.1) is uniformly pullback permanent and any bounded complete trajectory that is nondegenerate at $-\infty$ satisfies

$$u(t, x) \geq \psi_{11}(x) \quad \text{and} \quad v(t, x) \geq \psi_{22}(x) \quad \text{for all } x \in \Omega \text{ and } t \leq t_0.$$

3.4.3. Prey-predator. We also have for the prey-predator case the following result.

PROPOSITION 3.11 (forwards permanence—prey-predator case). *Assume* (3.2) *and* $b_L > 0$ *and* $c_M < 0$. *Then:*

(i) *If* $\lambda_I > \Lambda^1(-b_S\omega_{[\mu_S - c_I\omega_{[\lambda_S,a_I]},d_I]})$, *there exists* $\psi_{11} \in int(\mathcal{C}_1)$ *such that whenever*

$$\begin{aligned} &\lambda_S \geq \lambda(t,x) \geq \lambda_I, && \mu(t,x) \leq \mu_S, && a_S \geq a(t,x) \geq a_I > 0,\\ &b(t,x) \leq b_S, && c(t,x) \geq c_I, && d(t,x) \geq d_I > 0 \end{aligned}$$

for all $x \in \Omega$ *and* $t \geq t_0$ *(some* $t_0 \in \mathbf{R}$*), for any* $u_s, v_s > 0$ *the solution for* $t > s \geq t_0$ *of* (3.1) *satisfies* $\psi_{11}(x) \leq u(t,s,x;u_s,v_s)$ *for* $t - s$ *large enough.*

(ii) *If* $\mu_I > \Lambda_0^2$, *there exists* $\psi_{22} \in int(\mathcal{C}_2)$ *such that whenever*

$$\mu(t,x) \geq \mu_I, \quad d(x,t) \leq d_S$$

for all $x \in \Omega$ *and* $t \geq t_0$ *(some* $t_0 \in \mathbf{R}$*), for any* $u_s, v_s > 0$ *the solution for* $t > s \geq t_0$ *of* (3.1) *satisfies* $\psi_{22}(x) \leq v(t,s,x;u_s,v_s)$ *for* $t - s$ *large enough.*

Hence, if

$$\lambda_I > \Lambda^1(-b_S\omega_{[\mu_S - c_I\omega_{[\lambda_S,a_I]},d_I]}) \qquad \text{and} \qquad \mu_I > \Lambda_0^2, \tag{3.18}$$

there are functions $\psi_{11} \in int(\mathcal{C}_1)$ *and* $\psi_{22} \in int(\mathcal{C}_2)$ *such that whenever*

$$\begin{aligned} &\lambda_I \leq \lambda(t,x) \leq \lambda_S, && \mu_I \leq \mu(t,x) \leq \mu_S, && a_S \geq a(t,x) \geq a_I > 0,\\ &0 < b_I \leq b(t,x) \leq b_S, && c_I \leq c(t,x) \leq c_S < 0, && d_S \geq d(t,x) \geq d_I > 0 \end{aligned}$$

for all $x \in \Omega$ *and* $t \geq t_0$ *(some* $t_0 \in \mathbf{R}$*), and for all* $u_s > 0, v_s > 0$ *in a fixed bounded set of* $C(\overline{\Omega})$ *bounded away from* 0, *the solution* (u,v) *of* (3.1) *for* $t > s \geq t_0$ *is nondegenerate at* ∞ *and for all* $t - s$ *large enough*

$$u(t,s,x;u_s,v_s) \geq \psi_{11}(x) \qquad \text{and} \qquad v(t,s,x;u_s,v_s) \geq \psi_{22}(x).$$

In particular, (3.1) *is uniformly forwards permanent.*

Proof. As before, we use now that as $t - s \to \infty$,

$$u \geq \xi_{[\lambda - b\eta_{[\mu - c\xi_{[\lambda,a]},d]},a]} \geq \xi_{[\lambda_I - b_S\eta_{[\mu_S - c_I\xi_{[\lambda_S,a_I]},d_I]},a_I]} \to \omega_{[\lambda_I - b_S\eta_{[\mu_S - c_I\omega_{[\lambda_S,a_I]},d_I]},a_I]}$$

and

$$v \geq \eta_{[\mu,d]} \geq \eta_{[\mu_I,d_S]} \to \omega_{[\mu_I,d_S]}. \qquad \square$$

PROPOSITION 3.12 (pullback permanence—prey-predator case). *Assume* (3.2) *and* $b_L > 0$ *and* $c_M < 0$. *Then:*

(i) *If* $\lambda_I > \Lambda^1(-b_S\omega_{[\mu_S - c_I\omega_{[\lambda_S,a_I]},d_I]})$, *there exists* $\psi_{11} \in int(\mathcal{C}_1)$ *such that whenever*

$$\begin{aligned} &\lambda_S \geq \lambda(t,x) \geq \lambda_I, && \mu(t,x) \leq \mu_S, && a_S \geq a(t,x) \geq a_I > 0,\\ &b(t,x) \leq b_S, && c(t,x) \geq c_I, && d(t,x) \geq d_I > 0 \end{aligned}$$

for all $x \in \Omega$ *and* $t \leq t_0$ *(some* $t \in \mathbf{R}$*), for any* $u_s, v_s > 0$, *the solution for* $s < t \leq t_0$ *of* (3.1) *satisfies* $\psi_{11}(x) \leq u(t,s,x;u_s,v_s)$ *for* $t - s$ *large enough. In particular, any complete trajectory of* (3.1) *that is nondegenerate at* $-\infty$ *satisfies* $u(t,x) \geq \psi_{11}(x)$ *for all* $x \in \Omega$ *and* $t \leq t_0$.

(ii) *If $\mu_I > \Lambda_0^2$, there exists $\psi_{22} \in int(\mathcal{C}_2)$ such that whenever*

$$\mu(t,x) \geq \mu_I, \quad d(x,t) \leq d_S$$

for all $x \in \Omega$ and $t \leq t_0$ (some $t_0 \in \mathbf{R}$), for any $u_s, v_s > 0$, the solution for $s < t \leq t_0$ of (3.1) satisfies $\psi_{22}(x) \leq v(t,s,x;u_s,v_s)$ for $t-s$ large enough. In particular, any complete trajectory of (3.1) that is nondegenerate at $-\infty$ satisfies $v(t,x) \geq \psi_{22}(x)$ for all $x \in \Omega$ and $t \leq t_0$.

Hence, if

$$\lambda_I > \Lambda^1(-b_S\omega_{[\mu_S - c_I\omega_{[\lambda_S,a_I]},d_I]}) \qquad \text{and} \qquad \mu_I > \Lambda_0^2, \tag{3.19}$$

there exist functions $\psi_{11} \in int(\mathcal{C}_1)$ and $\psi_{22} \in int(\mathcal{C}_2)$ such that whenever

$$\begin{aligned} &\lambda_I \leq \lambda(t,x) \leq \lambda_S, \qquad \mu_I \leq \mu(t,x) \leq \mu_S, \qquad a_S \geq a(t,x) \geq a_I > 0,\\ &0 < b_I \leq b(t,x) \leq b_S, \quad c_I \leq c(t,x) \leq c_S < 0, \quad d_S \geq d(t,x) \geq d_I > 0, \end{aligned}$$

for all $x \in \Omega$ and $t \leq t_0$ (some $t_0 \in \mathbf{R}$), and for all nontrivial $u_s \geq 0$, $v_s \geq 0$ in a fixed bounded set, B, of $C(\overline{\Omega})$ bounded away from 0, the set of solutions of (3.1) $\{(u,v),\ s < t \leq t_0,\ (u_s,v_s) \in B\}$ is nondegenerate as $s \to -\infty$ and for all $t-s$ large enough

$$u(t,s,x;u_s,v_s) \geq \psi_{11}(x) \quad \text{and} \quad v(t,s,x;u_s,v_s) \geq \psi_{22}(x).$$

In particular, (3.1) is uniformly pullback permanent and any bounded complete trajectory that is nondegenerate at $-\infty$ satisfies

$$u(t,x) \geq \psi_{11}(x) \quad \text{and} \quad v(t,x) \geq \psi_{22}(x) \quad \text{for all } x \in \Omega \text{ and } t \leq t_0.$$

Remark 3.13. Note that in order to apply the previous results one has to check that the assumptions in Propositions 3.7–3.12 are meaningful. Indeed, conditions (3.10), (3.16), and (3.18) must define nonempty sets of coefficients. Here we analyze only Dirichlet or Neumann boundary conditions; Robin ones can be treated in a similar way although the estimates are a little more involved.

In fact, (3.16) includes all coefficients such that

$$\lambda_I > \Lambda_0^1, \qquad \mu_I > \Lambda_0^2$$

since in this case $\lambda_I > \Lambda_0^1 > \Lambda^1(-b_S\omega_{[\mu_I,d_S]})$ and $\mu_I > \Lambda_0^2$ then $\mu_I > \Lambda^2(-c_S\omega_{[\lambda_I,a_S]})$; see also [12].

However, in order to show that (3.10) defines a nonempty set we must impose some conditions on b or c. If, for example, $b_S \to 0$, then $\Lambda^1(-b_S\omega_{[\mu_S,d_I]}) \to \Lambda_0^1$. Also, if $c_S \to 0$, then $\Lambda^2(-c_S\omega_{[\lambda_S,a_I]}) \to \Lambda_0^2$. Hence if b_S or c_S are small, the conditions in (3.10) can be met; see also [27] and [29].

We analyze condition (3.18) for the prey-predator case in more detail. From Proposition 3.1, in the case of Dirichlet or Neumann boundary conditions, we have $\omega_{[h,g]} \leq h_M/g_L$, and so

$$\omega_{[\lambda_S,a_I]} \leq \frac{\lambda_S}{a_I} \quad \text{and then} \quad \omega_{[\mu_S - c_I\omega_{[\lambda_S,a_I]},d_I]} \leq \frac{\mu_S - c_I\left(\frac{\lambda_S}{a_I}\right)}{d_I},$$

and then using the monotonicity of $\Lambda(m)$ with respect to m and (3.5), we get

$$\Lambda^1(-b_S\omega_{[\mu_S - c_I\omega_{[\lambda_S,a_I]},d_I]}) \leq \Lambda^1(-b_S\frac{(a_I\mu_S - c_I\lambda_S)}{a_Id_I}) = \Lambda_0^1 + b_S\frac{(a_I\mu_S - c_I\lambda_S)}{a_Id_I}.$$

Hence, if λ_I and μ_I satisfy

$$\lambda_I > \Lambda_0^1 + \frac{b_S\mu_S}{d_I} + \frac{-b_S c_I}{a_I d_I}\lambda_S, \qquad \mu_I > \Lambda_0^2,$$

then (3.18) defines a nonempty set of parameters.

Observe that the first condition above is a restriction on the oscillation of $\lambda(t,x)$ as $t \to \pm\infty$.

In particular, if $\Lambda_0^1 + \frac{b_S\mu_S}{d_I} > 0$, then a necessary condition is

$$a_I d_I + b_S c_I > 0.$$

In such a case the conditions above can be met.

Now, for reasons that will be apparent in the following sections, we are interested in some uniformity in the previous results with respect to the coefficients $b_I \le b_S$ and $c_I \le c_S$. More precisely, we are going to show that the functions $\psi_{11}(x)$ and $\psi_{22}(x)$ in all the previous propositions can be taken independent of $b(t,x)$ and $c(t,x)$, provided that one of the numbers $b_I \le b_S$ or $c_I \le c_S$ is sufficiently small. In fact we have the following:

THEOREM 3.14. (i) *The competitive case: $b_L, c_L > 0$. Assume either*

1. *$\lambda_I > \Lambda_0^1$, $\mu_I > \Lambda^2(-c_S\omega_{[\lambda_S,a_I]})$, and b_S is sufficiently small, or*
2. *$\lambda_I > \Lambda^1(-b_S\omega_{[\mu_S,d_I]})$, $\mu_I > \Lambda_0^2$, and c_S is sufficiently small, for $t-s$ large enough.*

Then the functions $\psi_{11}(x)$ and $\psi_{22}(x)$ in Propositions 3.7 *and* 3.8 *can be taken also independent of b_S and c_S.*

(ii) *The symbiotic case: $b_M, c_M < 0$ and $b_L c_L < a_L d_L$. Assume either*

1. *$\lambda_I > \Lambda_0^1$, $\mu_I > \Lambda^2(-c_S\omega_{[\lambda_I,a_S]})$, or*
2. *$\lambda_I > \Lambda^1(-b_S\omega_{[\mu_I,d_S]})$, $\mu_I > \Lambda_0^2$.*

Then the functions $\psi_{11}(x)$ and $\psi_{22}(x)$ in Propositions 3.9 *and* 3.10 *can be taken also independent of b_I and c_I.*

(iii) *The prey-predator case: $b_L > 0$, $c_M < 0$. Assume either*

1. *$\lambda_I > \Lambda_0^1$, $\mu_I > \Lambda_0^2$, and b_S is sufficiently small, or*
2. *$\lambda_I > \Lambda^1(-b_S\omega_{[\mu_S,d_I]})$, $\mu_I > \Lambda_0^2$, and $|c_I|$ is sufficiently small.*

Then the functions $\psi_{11}(x)$ and $\psi_{22}(x)$ in Propositions 3.11 *and* 3.12 *can be taken also independent of b_S and c_I.*

Proof. We analyze only the competitive case. By the proof of Proposition 3.7 and Theorem 3.3, statement 6 we get

$$\begin{aligned} u(t,s,u_s,v_s) &\ge \Theta_{[\lambda_I - b_S\eta_{[\mu_S,d_I]},a_S]}(t-s,u_s) \ge \\ &\ge \omega_{[\lambda_I - b_S(\omega_{[\mu_S,d_I]}+\varepsilon),a_S]} \ge m\omega_{[\lambda_I - b_S(\omega_{[\mu_S,d_I]}+\varepsilon),a_S]}. \end{aligned}$$

It suffices to apply Lemma 3.2 as $b_S \to 0$ where $m < 1$.

On the other hand,

$$v(t,s,u_s,v_s) \ge \Theta_{[\mu_I - c_S(\omega_{[\lambda_S,a_I]}+\varepsilon),d_S]}(t-s,v_s) \to \omega_{[\mu_I - c_S(\omega_{[\lambda_S,a_I]}+\varepsilon),d_S]},$$

and so taking ε small, the result follows.

The other cases can be studied in an analogous way by Propositions 3.9, 3.10, 3.11, and 3.12. ∎

4. Exponential decay for nonautonomous linear systems. Once the results on permanence of the previous section have been established, we turn now our

attention to determining ranges of parameters such that there exist some special asymptotically stable trajectories describing the asymptotic behavior of solutions of (3.1), either forwards or in a pullback sense. For this we have to develop some tools for linear systems.

Hence, in this section we give sufficient conditions for certain linear systems to have exponential decay. The results are of a perturbative nature and are based upon results in [33] for scalar equations.

4.1. Preliminary results for the scalar case. We start by recalling some results for the following scalar equation:

$$\begin{cases} u_t - d\Delta u = c(t,x)u & x \in \Omega,\ t > s \\ \mathcal{B}u = 0, & x \in \partial\Omega,\ t > s \\ u(s) = u_s. \end{cases} \tag{4.1}$$

Assume that $d > 0$, $c \in C^\theta(\mathbf{R}, L^p(\Omega))$, with $0 < \theta \le 1$ and some $p > \max(N/2, 1)$. Then for any $u_s \in X$, where $X = L^q(\Omega)$ with $1 \le q < \infty$, or $X = C(\overline{\Omega})$, (4.1) has a unique solution given by $u(t, s; u_s)$, which is a strong solution in $L^r(\Omega)$ for any $1 \le r < p$. This solution can be used to define an order-preserving evolution operator T_c in X via the definition $T_c(t,s)u_s = u(t,s;u_s)$.

Moreover for each q and r with $1 \le q \le r \le \infty$ and $R_0 > 0$ there exist $L_0 = L_0(R_0, r, q) > 0$ and $\delta_0 = \delta(R_0, r, q) > 0$ such that the evolution operator $T_c(t,s)$ satisfies

$$\|T_c(t,s)u_0\|_{L^r(\Omega)} \le L_0 \frac{\mathrm{e}^{\delta_0(t-s)}}{(t-s)^{\frac{N}{2}\left(\frac{1}{q}-\frac{1}{r}\right)}} \|u_0\|_{L^q(\Omega)}, \qquad t > s \tag{4.2}$$

for every $c \in C^\theta(\mathbf{R}, L^p(\Omega))$, with $0 < \theta \le 1$ and some $p > N/2$, such that

$$\|c\|_{L^\infty(\mathbf{R}, L^p(\Omega))} \le R_0.$$

Also, the evolution operator smooths the solutions. More precisely, for every $u_0 \in L^q(\Omega)$ and $t > s$, the map

$$(s, \infty) \ni t \longmapsto u(t,s;u_0) := T_c(t,s)u_0 \in \begin{cases} C^\nu_{\mathcal{B}}(\overline{\Omega}) & \text{if } p > N/2, \\ C^{1,\nu}_{\mathcal{B}}(\overline{\Omega}) & \text{if } p > N, \end{cases}$$

is continuous for some $\nu > 0$. Here

$$C^{j,\nu}_{\mathcal{B}}(\overline{\Omega}) = \begin{cases} C^{j,\nu}_0(\overline{\Omega}) & \text{for Dirichlet BCs,} \\ C^{j,\nu}(\overline{\Omega}) & \text{for Neumann or Robin BCs,} \end{cases}$$

see, e.g., Rodríguez-Bernal [32].

The following proposition is taken from Lemma 4.1 in Robinson et al. [31] and Lemma 2.1 in Rodríguez-Bernal [33]:

PROPOSITION 4.1. *Suppose that for some q with $1 \le q \le \infty$ there exist $M > 0$ and $\beta \in \mathbf{R}$ such that*

$$\|T_c(t,s)\|_{\mathcal{L}(L^q(\Omega))} \le M\mathrm{e}^{\beta(t-s)} \quad \textit{for all} \quad t > s. \tag{4.3}$$

Then for any $1 \le r \le \infty$ there exists a $K \ge 1$ such that

$$\|T_c(t,s)\|_{\mathcal{L}(L^r(\Omega))} \le K\mathrm{e}^{\beta(t-s)} \quad \textit{for all} \quad t > s. \tag{4.4}$$

The constant K can be taken as a continuous function of β, M.

Moreover, for each r with $1 \le r \le q \le \infty$ and for any $\varepsilon > 0$, we have

$$\|T_c(t,s)\|_{\mathcal{L}(L^q(\Omega),L^r(\Omega))} \le M(\beta,\varepsilon)\frac{\mathrm{e}^{(\beta+\varepsilon)(t-s)}}{(t-s)^\delta}, \quad t > s, \tag{4.5}$$

where $\delta = \frac{N}{2}\left(\frac{1}{r} - \frac{1}{q}\right)$,

$$M(\beta,\varepsilon) = \kappa(\beta,M)\begin{cases} \left(\frac{\delta}{\mathrm{e}}\right)^\delta \varepsilon^{-\delta} & \text{if } 0 < \varepsilon < \varepsilon_0 = \frac{\delta}{\mathrm{e}} \\ 1 & \text{if } \varepsilon \ge \varepsilon_0 = \frac{\delta}{\mathrm{e}} \end{cases} \tag{4.6}$$

and

$$\kappa(\beta,M) = L_0\varepsilon^{\delta_0}\max\{1, M\varepsilon^{-\beta}\}.$$

Note that the constants K and κ in the proposition also depend on q and r but we will not pay attention to this dependence.

Our main argument, further below in the paper, will rely on results of the following type. We start with an evolution operator $T_c(t,s)$ that satisfies the estimate

$$\|T_c(t,s)\|_{\mathcal{L}(L^q(\Omega))} \le M_1 \quad \text{for } t \ge s \text{ and } M_1 > 0$$

for either $s \ge s_0$ or for $t \le t_0$. Then, we add to $c(t,x)$ a perturbation $p(t,x)$ in the class $C^\theta(\mathbf{R}, L^p(\Omega))$, with $0 < \theta \le 1$ and some $p > \max(N/2, 1)$, and we want to guarantee that the solutions of the new evolution operator $T_{c+p}(t,s)$ decay exponentially. This means that we want to get estimates of the type

$$\|T_{c+p}(t,s)\|_{\mathcal{L}(L^q(\Omega))} \le M_1'\mathrm{e}^{\beta'(t-s)} \quad \text{for all} \quad t > s \quad \text{and some} \quad \beta' < 0 \tag{4.7}$$

and for either $s \ge s_0$ or for $t \le t_0$. Note also that we can always assume, without loss of generality, that the $L^\infty(\mathbf{R}, L^p(\Omega))$ norms of both $c(t,x)$ and $p(t,x)$ are bounded by R_0, so (4.2) holds for $T_c(t,s)$ and $T_{c+p}(t,s)$.

In this direction, the following important result is a particular case of Corollary 3.3 in Rodríguez-Bernal [33], and it provides sufficient conditions on $p(t,x)$ to ensure that (4.7) holds.

PROPOSITION 4.2. *Assume that*

$$\|T_c(t,s)\|_{\mathcal{L}(L^q(\Omega))} \le M_1 \quad \textit{for} \quad t \ge s \quad \textit{and} \quad M_1 > 0 \tag{4.8}$$

and for either $s \ge s_0$ or for $t \le t_0$.

Let $p \in C^\theta(\mathbf{R}, L^p(\Omega))$, for some $0 < \theta \le 1$ and $p > \max(N/2, 1)$, and assume that for $|t|$ sufficiently large, we have $p(t,x) \le -\varphi(x)$ where

$$\varphi \in C^1(\overline{\Omega}), \quad \varphi \ge 0, \quad \textit{and} \quad \nabla\varphi \ne 0 \quad \textit{at the points at which } \varphi = 0.$$

Then

$$\|T_{c+p}(t,s)\|_{\mathcal{L}(L^q(\Omega))} \le M_1'\mathrm{e}^{\beta'(t-s)} \quad \textit{for all} \quad t > s \quad \textit{and some} \quad \beta' < 0 \tag{4.9}$$

and for either $s \ge s_0$ or for $t \le t_0$, with $M_1' = M_1'(M_1,\varphi)$ and $\beta' = \beta'(M_1,\varphi)$.

The constants $M_1' = M_1'(M_1,\varphi)$ and $\beta' = \beta'(M_1,\varphi)$ depend continuously on M_1 and on $\varphi \in C^1(\overline{\Omega})$.

Note that the condition above holds, in particular if $p(t,x) \le -\delta < 0$ (in which case the constants M_1' and β' can be chosen so that they depend continuously on δ), or if $\varphi \in C_0^1(\overline{\Omega})$ is positive in Ω and $\frac{\partial \varphi}{\partial \vec{n}} < 0$ on $\partial\Omega$. The former is a common situation in the case of Neumann or Robin boundary conditions and the latter in the case of Dirichlet boundary conditions.

In order to apply the above result, we need to show first that (4.8) holds. The next result gives conditions for an evolution operator to have bounds of the type (4.8); see [34], [33]. For this recall the definitions of complete trajectory and of nondegeneracy in section 2.2, which we apply here to solutions of (4.1). Hence, according to [33], we have the following proposition.

PROPOSITION 4.3. (i) *If there exists a positive nondegenerate solution $u(t,s;u_s)$ of (4.1) defined for all $t > s \ge s_0$ such that for some $M > 0$ and some q with $1 \le q \le \infty$*

$$\|u(t,s;u_s)\|_{L^q(\Omega)} \le M,$$

then

$$0 < M_0 \le \|T_c(t,s)\|_{\mathcal{L}(L^q(\Omega))} \le M_1 \quad \text{for} \quad t \ge s \ge s_0, \tag{4.10}$$

where M_0, M_1 are independent of t and s and depend continuously on M and on $\varphi_0 \in C^1(\overline{\Omega})$.

(ii) *If there exists a positive, complete nondegenerate solution $u(t)$ of (4.1) that is bounded as $t \to -\infty$, i.e.,*

$$\|u(t)\|_{L^q(\Omega)} \le M \quad \text{for} \quad t \le t_0,$$

then

$$0 < M_0 \le \|T_c(t,s)\|_{\mathcal{L}(L^q(\Omega))} \le M_1 \quad \text{for} \quad s \le t \le t_0, \tag{4.11}$$

where M_0, M_1 are independent of t and s and depend continuously on M and $\varphi_0 \in C^1(\overline{\Omega})$.

4.2. Perturbation and decay of linear systems. In this section we generalize the perturbation result in the previous section to the case of a system of linear equations. The main theorem in this section will be crucial in the analysis of Lotka–Volterra models in the following sections.

Consider the linear coupled nonautonomous system

$$\begin{cases} u_t - d_1\Delta u = a_{11}(t,x)u + a_{12}(t,x)v, & x \in \Omega,\ t > s \\ v_t - d_2\Delta v = a_{21}(t,x)u + a_{22}(t,x)v, & x \in \Omega,\ t > s \\ \mathcal{B}_1 u = 0,\ \mathcal{B}_2 v = 0 \\ u(s) = u_s,\ v(s) = v_s, \end{cases} \tag{4.12}$$

in $L^q(\Omega, \mathbf{R}^2) \doteq [L^q(\Omega)]^2$. Then define

$$D = \operatorname{diag}(d_1, d_2) \qquad \text{and} \qquad A = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}$$

and note that setting $U = \binom{u}{v}$, (4.12) can be written as

$$U_t - D\Delta U = A(t,x)U$$

with boundary conditions $\mathcal{B}U = \binom{\mathcal{B}_1 u}{\mathcal{B}_2 v} = 0$ on the boundary of Ω.

If $A \in C^\theta(\mathbf{R}, L^p(\Omega, \mathbf{R}^4))$, with $0 < \theta \leq 1$, $p > N/2$, and $p > q \geq 1$, the existence of a unique solution $U(t, s; U_s)$ of (4.12), in $L^q(\Omega, \mathbf{R}^2)$, can be obtained from Theorems 11.2, 11.3, and 11.4 in Amann [1]. Thus, the time-dependent operator $-D\Delta - A(t, x)$ generates an evolution operator, $T_A(t, s)$, in $L^q(\Omega, \mathbf{R}^2)$ (Theorem 4.4.1 in Amann [2]) via the definition $T_A(t, s)U_s = U(t, s; U_s)$.

The following result, analogous to (4.2), can be proved along the lines of the scalar arguments in Rodríguez-Bernal [33], [32], and Robinson et al. [31].

PROPOSITION 4.4. *For any $1 \leq q \leq r \leq \infty$, and $R_0 > 0$ there exist $L_0 = L_0(R_0, r, q) > 0$ and $\delta_0 = \delta_0(R_0, r, q) > 0$ such that the evolution operator $T_A(t, s)$ satisfies*

$$\|T_A(t, s)U_s\|_{L^r(\Omega, \mathbf{R}^2)} \leq L_0 \frac{\mathrm{e}^{\delta_0(t-s)}}{(t-s)^{\frac{N}{2}\left(\frac{1}{q}-\frac{1}{r}\right)}} \|U_s\|_{L^q(\Omega, \mathbf{R}^2)}, \tag{4.13}$$

for every $\|A\|_{L^\infty(\mathbf{R}, L^p(\Omega, \mathbf{R}^4))} \leq R_0$. In particular, $T_A(t, s)$ extends to an evolution operator in $L^q(\Omega, \mathbf{R}^2)$ for every $1 \leq q < \infty$.

Furthermore, the results of Proposition 4.1 *for the scalar case remain true for system* (4.12).

Along the same lines as for scalar equations, we consider the linear uncoupled system

$$\begin{cases} u_t - d_1\Delta u = q_{11}(t, x)u, & x \in \Omega,\ t > s \\ v_t - d_2\Delta v = q_{22}(t, x)v, & x \in \Omega,\ t > s \\ \mathcal{B}_1 u = 0,\ \mathcal{B}_2 v = 0 \\ u(s) = u_s,\ v(s) = v_s. \end{cases} \tag{4.14}$$

Observe that with the notations above and setting

$$Q = \operatorname{diag}(q_{11}, q_{22}),$$

then the evolution operator $T_Q(t, s)$ is well defined in $L^q(\Omega, \mathbf{R}^2)$, $1 \leq q < \infty$.

Now we assume that each separate equation in (4.14) satisfies

$$\|T_{q_{ii}}(t, s)\|_{\mathcal{L}(L^q(\Omega))} \leq M_1, \quad t > s,$$

with M_1 independent of t and s and for either $t \leq t_0$ or $s \geq s_0$. Therefore the evolution operator $T_Q(t, s)$ satisfies (4.8).

Our goal is to give conditions on the coupling perturbations such that the solutions of the perturbed system

$$\begin{cases} u_t - d_1\Delta u = q_{11}(t, x)u + p_{11}(t, x)u + p_{12}(t, x)v, & x \in \Omega,\ t > s \\ v_t - d_2\Delta v = q_{22}(t, x)v + p_{21}(t, x)u + p_{22}(t, x)v, & x \in \Omega,\ t > s \\ \mathcal{B}_1 u = 0,\ \mathcal{B}_2 v = 0 \\ u(s) = u_s,\ v(s) = v_s, \end{cases}$$

decay exponentially. Note that the perturbed system can be written as

$$U_t - D\Delta U = Q(t, x)U + P(t, x)U \tag{4.15}$$

with

$$Q = \operatorname{diag}(q_{11}, q_{22}), \quad P = \begin{pmatrix} p_{11} & p_{12} \\ p_{21} & p_{22} \end{pmatrix}, \quad \text{and} \quad U = \begin{pmatrix} u \\ v \end{pmatrix},$$

with $Q, P \in C^\theta(\mathbf{R}, L^p(\Omega, \mathbf{R}^4))$, with $0 < \theta \leq 1$, $p > \max(N/2, 1)$.

Hence our goal is to obtain an estimate of the type

$$\|T_{Q+P}(t,s)\|_{\mathcal{L}(L^q(\Omega,\mathbf{R}^2))} \le M_1' \mathrm{e}^{\beta'(t-s)} \quad \text{for all} \quad t > s \text{ and some } \beta' < 0 \tag{4.16}$$

and for either $s \ge s_0$ or for $t \le t_0$.

Note that again we will assume, without loss of generality, that all the evolution operators considered satisfy (4.13) with the same constants L_0 and δ_0.

In what follows we will make use of the following singular Gronwall lemma (see Henry [16]):

LEMMA 4.5 (a singular Gronwall lemma). *Assume that $a \in L^\infty(\tau_0,\infty)$ with $\tau_0 \ge -\infty$ and that $z(t) \ge 0$ is a locally bounded function that for $t \ge s > \tau_0$ satisfies*

$$z(t) \le A + \int_s^t \frac{a(\tau)}{(t-\tau)^\delta} z(\tau)\,\mathrm{d}\tau \tag{4.17}$$

with $\delta < 1$. Then we have for $t \ge s > \tau_0$

$$0 \le z(t) \le A(\delta)\mathrm{e}^{\gamma(t-s)}$$

with $\gamma = \gamma(a,s,\delta) = (\|a\|_{L^\infty(s,\infty)}\Gamma(1-\delta))^{1/(1-\delta)}$ and $A(\delta)$ depends only on the constants A and δ but not on the function $a(\cdot)$ or on s, γ, or τ_0.

Our next result states that if the diagonal perturbing terms $p_{ii}(t,x)$ are sufficiently strong and the coupling terms $p_{ij}(t,x)$, $i \ne j$, are "small" at $\pm\infty$, then (4.16) is achieved.

THEOREM 4.6. *With the notations in* (4.15)*, assume that the scalar evolution operators $T_{q_{ii}}(t,s)$ satisfy*

$$\|T_{q_{ii}}(t,s)\|_{\mathcal{L}(L^q(\Omega))} \le M_1, \quad t > s, \tag{4.18}$$

with M_1 independent of t and s and for either $t \le t_0$ or $s \ge s_0$.

Assume also that $p_{ii}(t,x)$ satisfies $p_{ii}(t,x) \le -\varphi_{ii}(x)$ with $\varphi_{ii}(x)$ as in Proposition 4.2*.*

Then there exists a $\rho = \rho(M_1,\varphi_{11},\varphi_{22}) > 0$ such that if

$$\limsup_{|t|\to\infty} \|p_{12}(t)\|_{L^p(\Omega)} \limsup_{|t|\to\infty} \|p_{21}(t)\|_{L^p(\Omega)} \le \rho^2, \tag{4.19}$$

then

$$\|T_{Q+P}(t,s)\|_{\mathcal{L}(L^q(\Omega,\mathbf{R}^2))} \le M_1'' \mathrm{e}^{\beta''(t-s)} \quad \textit{for all } t > s \textit{ and some } \beta'' < 0 \tag{4.20}$$

and for either $s \ge s_0$ or for $t \le t_0$, where $M_1'' = M_1''(M_1,\varphi_{11},\varphi_{22})$ and $\beta'' = \beta''(M_1,\varphi_{11},\varphi_{22})$.

The constants ρ, M_1'', and β'' depend continuously on M_1 and $\varphi_{11},\varphi_{22}$ as in Proposition 4.2*.*

Proof. Note that, using Proposition 4.4, we just need to prove the result for some suitably chosen $1 \le q < \infty$. We proceed in several steps.

Step 1. If we define

$$P_1 = \begin{pmatrix} p_{11} & 0 \\ 0 & p_{22} \end{pmatrix},$$

then Proposition 4.2 applied to each separate equation gives the estimate

$$\|T_{Q+P_1}(t,s)\|_{\mathcal{L}(L^q(\Omega,\mathbf{R}^2))} \le M_1' \mathrm{e}^{\beta'(t-s)} \quad \text{for all } t > s \text{ and some } \beta' < 0 \tag{4.21}$$

and for either $s \geq s_0$ or for $t \leq t_0$, with $M_1' = M_1'(M_1, \varphi_{11}, \varphi_{22})$ and $\beta' = \beta'(M_1, \varphi_{11}, \varphi_{22})$.

Step 2. We will show that there exists a $\rho = \rho(M_1', \beta')$, which depends continuously on M_1', β', such that if

$$\|p_{12}\|_{L^\infty(\mathbf{R}, L^p(\Omega))} \leq \rho \quad \text{and} \quad \|p_{21}\|_{L^\infty(\mathbf{R}, L^p(\Omega))} \leq \rho,$$

then

$$\|T_{Q+P}(t,s)\|_{\mathcal{L}(L^q(\Omega,\mathbf{R}^2))} \leq M_1'' \mathrm{e}^{\beta''(t-s)} \quad \text{for all } t > s \text{ and some } \beta'' < 0 \tag{4.22}$$

and for either $s \geq s_0$ or for $t \leq t_0$, with

$$P = P_1 + P_2, \qquad P_2 = \begin{pmatrix} 0 & p_{12} \\ p_{21} & 0 \end{pmatrix},$$

where $M_1'' = M_1''(M_1', \beta', \rho)$ and $\beta'' = \beta''(M_1', \beta', \rho)$, depend continuously on M_1', β', ρ.

In fact, we have, by the variation of constants formula, that for every $U_0 \in L^q(\Omega, \mathbf{R}^2)$ the solution $U(t,s;U_0) = T_{Q+P}(t,s)U_0$ of (4.15) satisfies for $t \geq s$,

$$U(t,s;U_0) = T_{Q+P_1}(t,s)U_0 + \int_s^t T_{Q+P_1}(t,\tau)P_2(\tau)U(\tau,s;U_0)\,\mathrm{d}\tau.$$

Now we choose q such that $p \geq q'$, so that $1/p + 1/q \leq 1$. In what follows we will apply (4.5) with $\frac{1}{r} = \frac{1}{p} + \frac{1}{q}$, and so with $\delta = N/2p$. With this choice, we have (4.21) and from (4.5)

$$\|T_{Q+P_1}(t,s)\|_{\mathcal{L}(L^r(\Omega,\mathbf{R}^2), L^q(\Omega,\mathbf{R}^2))} \leq M(\beta', \varepsilon)\, \frac{\mathrm{e}^{(\beta'+\varepsilon)(t-s)}}{(t-s)^{\frac{N}{2p}}},$$

where $M(\beta', \varepsilon)$ is as in (4.6).

Since $P_2(\tau) \in L^p(\Omega, \mathbf{R}^2)$ and $U(\tau, s; U_0) \in L^q(\Omega, \mathbf{R}^2)$, then the term $P_2(\tau)U(\tau, s; U_0)$ can be estimated, using Hölder's inequality, in $L^r(\Omega, \mathbf{R}^2)$ with $\frac{1}{r} = \frac{1}{p} + \frac{1}{q}$. Thus,

$$\begin{aligned} \|U(t,s;U_0)\|_{L^q(\Omega,\mathbf{R}^2)} &\leq M_1' \mathrm{e}^{(\beta'+\varepsilon)(t-s)} \|U_0\|_{L^q(\Omega,\mathbf{R}^2)} \\ &+ M(\beta', \varepsilon) \int_s^t \frac{\mathrm{e}^{(\beta'+\varepsilon)(t-\tau)}}{(t-\tau)^{\frac{N}{2p}}} \|P_2(\tau)\|_{L^p(\Omega,\mathbf{R}^2)} \|U(\tau,s;U_0)\|_{L^q(\Omega,\mathbf{R}^2)}\,\mathrm{d}\tau. \end{aligned}$$

Then, multiplying by $\mathrm{e}^{-(\beta'+\varepsilon)(t-s)}$, and setting $A = M_1' \|U_0\|_{L^q(\Omega,\mathbf{R}^2)}$,

$$z(t) = \mathrm{e}^{-(\beta'+\varepsilon)(t-s)} \|U(t,s;U_0)\|_{L^q(\Omega,\mathbf{R}^2)}, \quad \text{and} \quad a(\tau) = M(\beta', \varepsilon)\|P_2(\tau)\|_{L^p(\Omega,\mathbf{R}^2)}$$

we get, for all $t \geq s$,

$$z(t) \leq A + \int_s^t \frac{a(\tau)}{(\tau - s)^{\frac{N}{2p}}} z(\tau)\,\mathrm{d}\tau.$$

We can apply the singular Gronwall lemma above with $\delta = \frac{N}{2p} < 1$, and we get

$$\|U(t,s;U_0)\|_{L^q(\Omega,\mathbf{R}^2)} \leq M_1'' \mathrm{e}^{(\beta'+\mu(\varepsilon))(t-s)} \|U_0\|_{L^q(\Omega,\mathbf{R}^2)}, \quad t \geq s, \tag{4.23}$$

where

$$\mu(\varepsilon) = \varepsilon + \left(M(\beta', \varepsilon)\Gamma(1-\delta)\|P_2\|_{L^\infty((s,\infty),L^p(\Omega,\mathbf{R}^2))}\right)^{\frac{1}{1-\delta}}.$$

Recalling (4.6), we get that

$$\mu(\varepsilon) = \begin{cases} \varepsilon + \varepsilon^{\frac{-\delta}{1-\delta}} A_0 \|P_2\|^{\frac{1}{1-\delta}}_{L^\infty((s,\infty),L^p(\Omega,\mathbf{R}^2))} & \text{if } 0 < \varepsilon < \varepsilon_0 = \frac{\delta}{\mathrm{e}} \\ \varepsilon + A_1 \|P_2\|^{\frac{1}{1-\delta}}_{L^\infty((s,\infty),L^p(\Omega,\mathbf{R}^2))} & \text{if } \varepsilon \geq \varepsilon_0, \end{cases}$$

where

$$A_1 = \left(L_0 \mathrm{e}^{\delta_0} \max\{1, M_1' \mathrm{e}^{-\beta'}\}\Gamma(1-\delta)\right)^{1/(1-\delta)}, \quad A_0 = A_1 \left(\frac{\delta}{e}\right)^{\delta/(1-\delta)},$$

and L_0 and δ_0 are the constants in (4.2).

Thus $\mu(0) = \mu(\infty) = \infty$. But the function

$$h(\varepsilon) = \varepsilon + \varepsilon^{\frac{-\delta}{1-\delta}} A_0 \|P_2\|^{\frac{1}{1-\delta}}_{L^\infty((s,\infty),L^p(\Omega,\mathbf{R}^2))}$$

has a unique minimum at

$$\varepsilon_1 = \left(A_0 \frac{\delta}{1-\delta}\right)^{1-\delta} \|P_2\|_{L^\infty((s,\infty),L^p(\Omega,\mathbf{R}^2))},$$

and

$$h(\varepsilon_1) = \frac{1}{\delta^\delta}\left(\frac{A_0}{1-\delta}\right)^{1-\delta} \|P_2\|_{L^\infty((s,\infty),L^p(\Omega,\mathbf{R}^2))}.$$

Therefore, comparing ε_0 and ε_1, and minimizing $\mu(\varepsilon)$ leads to

$$\|U(t,s;U_0)\|_{L^q(\Omega,\mathbf{R}^2)} \leq M_1'' \mathrm{e}^{\beta''(t-s)} \|U_0\|_{L^q(\Omega,\mathbf{R}^2)}, \quad t \geq s$$

with

$$\begin{aligned} \beta'' &= \beta' + \min_{\{\varepsilon>0\}} \mu(\varepsilon) \\ &= \beta' + \begin{cases} c_0 \|P_2\|_{L^\infty((s,\infty),L^p(\Omega,\mathbf{R}^2))}, & \text{if } \|P_2\|_{L^\infty((s,\infty),L^p(\Omega,\mathbf{R}^2))} \leq s^*, \\ c_1 + c_2 \|P_2\|^{\frac{1}{1-\delta}}_{L^\infty((s,\infty),L^p(\Omega,\mathbf{R}^2))}, & \text{if } \|P_2\|_{L^\infty((s,\infty),L^p(\Omega,\mathbf{R}^2))} \geq s^*, \end{cases} \end{aligned}$$

where

$$c_0 = \frac{1}{\delta^\delta}\left(\frac{A_0}{1-\delta}\right)^{1-\delta}, \quad c_1 = \frac{\delta}{e}, \quad c_2 = A_1, \quad s^* = \frac{\delta}{e}\left(\frac{1-\delta}{A_0\delta}\right)^{1-\delta}.$$

Thus, it is then clear that (4.22) follows, i.e., $\beta'' < 0$, provided that

$$\|P_2\|_{L^\infty((s,\infty),L^p(\Omega,\mathbf{R}^2))} < \min\left\{s^*, \frac{-\beta'}{c_0}\right\},$$

which reads

$$\|P_2\|_{L^\infty((s,\infty),L^p(\Omega,\mathbf{R}^2))} < \rho := \delta\left(\frac{1-\delta}{\delta A_0}\right)^{1-\delta} \min\left\{-\beta', \frac{1}{\mathrm{e}}\right\}. \tag{4.24}$$

Step 3. Now we show that the result in Step 2 above can be obtained only in terms of $\limsup_{|t|\to\infty} \|P_2(t)\|_{L^p(\Omega,\mathbf{R}^2)}$.

In fact, note that from (4.24), if we take $s \geq s_0$ sufficiently large, the conclusion with $\limsup_{t\to\infty} \|P_2(t)\|_{L^p(\Omega,\mathbf{R}^2)}$ is clear.

On the other hand, observe that we can set $P_2 = 0$ for $t \geq t_0$ and we still have (4.23) for $s \leq t \leq t_0$. Taking then t_0 very negative, (4.24) gives the result for $\limsup_{t\to-\infty} \|P_2(t)\|_{L^p(\Omega,\mathbf{R}^2)}$.

In particular, (4.22) follows, provided that

$$\limsup_{|t|\to\infty} \|P_2(t)\|_{L^p(\Omega,\mathbf{R}^2)} < \rho, \tag{4.25}$$

with ρ as in (4.24).

Step 4. The change of variables

$$U = \begin{pmatrix} u \\ v \end{pmatrix} \to V = \begin{pmatrix} \alpha u \\ \beta v \end{pmatrix}$$

with $\alpha, \beta > 0$, transforms the system (4.15) into

$$V_t - D\Delta V = Q(t,x)V + \tilde{P}(t,x)V$$

with

$$D = \operatorname{diag}(d_1, d_2),\ Q = \operatorname{diag}(q_{11}, q_{22}),\ \tilde{P} = \begin{pmatrix} p_{11} & \frac{\alpha}{\beta}p_{12} \\ \frac{\beta}{\alpha}p_{21} & p_{22} \end{pmatrix}.$$

Hence, we can apply Step 3 provided

$$\frac{\alpha}{\beta}\limsup_{|t|\to\infty} \|p_{12}(t)\|_{L^p(\Omega)} \leq \rho \quad \text{and} \quad \frac{\beta}{\alpha}\limsup_{|t|\to\infty} \|p_{21}(t)\|_{L^p(\Omega)} \leq \rho,$$

with $\rho > 0$ as in (4.24). We can choose α, β such that the above inequalities are satisfied if

$$\limsup_{|t|\to\infty} \|p_{12}(t)\|_{L^p(\Omega)} \limsup_{|t|\to\infty} \|p_{21}(t)\|_{L^p(\Omega)} \leq \rho^2$$

with $\rho > 0$ as in (4.24). □

Remark 4.7. Note that (4.24) gives a quantitative threshold for the size of the perturbation. In fact, from (4.24) and the expression of A_0, it can be deduced that

$$\rho = \rho(M_1', \beta') = \frac{\mathrm{e}^{\delta}(1-\delta)^{1-\delta}}{\Gamma(1-\delta)} \frac{\min\{-\beta', \frac{1}{\mathrm{e}}\}}{L_0 \mathrm{e}^{\delta_0} \max\{1, M_1' \mathrm{e}^{-\beta'}\}},$$

where M_1', β' are from Step 1.

Observe that Step 4 above is the only place where we used the fact that the system has only two components.

5. Attracting trajectories for general nonautonomous nonlinear systems. In this section we sketch out our approach to the existence of asymptotically stable complete trajectories for Lotka–Volterra systems. The key point is to write the equation satisfied by the difference of two solutions as a perturbation of an associated

linear system. Using then the permanence results in section 3, we can apply Theorem 4.6 to conclude that the difference of two solutions converges to zero as $t \to \infty$. A similar convergence result as the initial time $s \to -\infty$ will imply the uniqueness of complete nondegenerate solutions, which moreover describes the pullback behavior of the system.

First we treat the case of general nonautonomous nonlinear systems, before specializing to Lotka–Volterra models. Consider the general nonautonomous nonlinear system

$$\begin{cases} u_t - d_1\Delta u = uf(t,x,u,v) & x \in \Omega,\ t > s \\ v_t - d_2\Delta v = vg(t,x,u,v) & x \in \Omega,\ t > s \\ \mathcal{B}_1 u = 0,\ \mathcal{B}_2 v = 0 & x \in \partial\Omega,\ t > s \\ u(s) = u_s,\ v(s) = v_s. \end{cases} \tag{5.1}$$

We now sketch our strategy for analyzing the asymptotic behavior of solutions to (5.1). Consider two different pairs of nonnegative initial conditions (u_s^1, v_s^1) and (u_s^2, v_s^2) and consider the corresponding solutions of (5.1), $U_1 = \binom{u_1}{v_1}$ and $U_2 = \binom{u_2}{v_2}$, respectively. Write $y = u_2 - u_1$ and $z = v_2 - v_1$. Then, (y, z) satisfies

$$\begin{cases} y_t - d_1\Delta y = q_{11}(t,x)y + p_{11}(t,x)y + p_{12}(t,x)z & x \in \Omega,\ t > s \\ z_t - d_2\Delta z = q_{22}(t,x)z + p_{21}(t,x)y + p_{22}(t,x)z & x \in \Omega,\ t > s \\ \mathcal{B}_1 y = 0,\ \mathcal{B}_2 z = 0 & x \in \partial\Omega,\ t > s \\ y(s) = y_s,\ z(s) = z_s, \end{cases} \tag{5.2}$$

with $y_s = u_s^2 - u_s^1$, $z_s = v_s^2 - v_s^1$, and

$$\begin{aligned} q_{11}(t,x) &= f(t,x,u_2,v_2), \qquad q_{22}(t,x) = g(t,x,u_2,v_2) \\ p_{11}(t,x) &= u_1 \frac{f(t,x,u_2,v_1) - f(t,x,u_1,v_1)}{u_2 - u_1}, \\ p_{12}(t,x) &= u_1 \frac{f(t,x,u_2,v_2) - f(t,x,u_2,v_1)}{v_2 - v_1}, \\ p_{21}(t,x) &= v_1 \frac{g(t,x,u_2,v_1) - g(t,x,u_1,v_1)}{u_2 - u_1}, \\ p_{22}(t,x) &= v_1 \frac{g(t,x,u_2,v_2) - g(t,x,u_2,v_1)}{v_2 - v_1}. \end{aligned}$$

Most of the analysis that follows in the next section will be based on proving that the following results can be applied. The first one gives sufficient conditions to guarantee that two solutions have the same forwards asymptotic behavior, while the second gives a criterion to prove the coincidence of two complete trajectories and also describes the pullback behavior of solutions.

THEOREM 5.1 (forwards behavior). *Assume that both solutions of* (5.1), $U_1 = \binom{u_1}{v_1}$ *and* $U_2 = \binom{u_2}{v_2}$, *are globally defined and bounded in* $L^\infty(\Omega, \mathbf{R}^2)$ *for* $t > s > t_0$. *Moreover, suppose that* u_1, v_1 *are positive in* Ω *and* $U_2(t)$ *is positive, nondegenerate for* $t > t_0$ *and for some* $p > \max(N/2, 1)$ *and* $0 < \theta \le 1$, *the coefficients in* (5.2) *satisfy* $p_{ij}, q_{ii} \in C^\theta(\mathbf{R}, L^p(\Omega))$ *for* $i, j = 1, 2$ *and* $p_{ii}(t,x) \le -\varphi_{ii}(x)$, *for* $t > t_0$, *with* $\varphi_{ii}(x)$ *as in Proposition* 4.2.

Then there exists a $\rho > 0$ *such that if*

$$\limsup_{t\to\infty} \|p_{12}(t)\|_{L^p(\Omega)} \limsup_{t\to\infty} \|p_{21}(t)\|_{L^p(\Omega)} \le \rho^2, \tag{5.3}$$

both solutions have the same forwards asymptotic behavior, i.e.,

$$U_1(t) - U_2(t) \to 0 \quad \textit{exponentially in } C^1_{\mathcal{B}_1}(\overline{\Omega}) \times C^1_{\mathcal{B}_2}(\overline{\Omega}) \quad \textit{as} \quad t \to \infty.$$

In particular, $U_1(t)$ is also nondegenerate at $+\infty$.

Proof. Clearly, (5.2) can be written as

$$W_t - D\Delta W = QW + PW,$$

where

$$D = \operatorname{diag}(d_1, d_2),\ Q = \operatorname{diag}(q_{11}, q_{22}),\ P = \begin{pmatrix} p_{11} & p_{12} \\ p_{21} & p_{22} \end{pmatrix}, \quad W = \begin{pmatrix} y \\ z \end{pmatrix}. \tag{5.4}$$

Since $U_2 = \binom{u_2}{v_2}$ is a positive, bounded, and nondegenerate solution, for $t > s > t_0$, of the diagonal system

$$W_t - D\Delta W = QW,$$

it follows from Propositions 4.3 and 4.4 that for any $1 \le q < \infty$,

$$\|T_Q(t,s)\|_{\mathcal{L}(L^q(\Omega,\mathbf{R}^2))} \le M_1, \quad t > s > t_0, \tag{5.5}$$

with M_1 independent of t and s, $t > s > t_0$.

Then, we apply Theorem 4.6 to obtain that there exists $\rho > 0$ such that if (5.3) holds, then

$$\|T_{Q+P}(t,s)\|_{\mathcal{L}(L^q(\Omega,\mathbf{R}^2))} \le M_1'' \mathrm{e}^{\beta''(t-s)} \quad \text{for all} \quad t > s > t_0 \quad \text{and some} \quad \beta'' < 0.$$

Thus, from Proposition 4.4 (see also Proposition 4.1), we have, writing $W_s = (y_s, z_s)$ and for $t > s > t_0$,

$$\|W(t,s;W_s)\|_{L^\infty(\Omega,\mathbf{R}^2)} \le M_2 e^{\beta''(t-s)} \|W_s\|_{L^\infty(\Omega,\mathbf{R}^2)} \to 0, \quad t \to \infty. \tag{5.6}$$

The uniform forwards convergence of trajectories follows. Standard parabolic regularization implies the $C^1_{\mathcal{B}_1}(\overline{\Omega}) \times C^1_{\mathcal{B}_2}(\overline{\Omega})$ convergence. ∎

In the following result we use similar arguments to prove the coincidence of complete nondegenerate trajectories, and show that such a trajectory, when it exists, attracts (in the pullback sense) all bounded positive trajectories. In particular, the following results guarantee the uniqueness of complete nondegenerate solutions.

THEOREM 5.2 (coincidence of complete trajectories and pullback behavior). *Assume that $U_1 = \binom{u_1}{v_1}$ is a complete trajectory that is bounded in $L^\infty(\Omega, \mathbf{R}^2)$ at $-\infty$, and nondegenerate for $t \le t_0$. Suppose further that for some $p > \max(N/2, 1)$ and $0 < \theta \le 1$, the coefficients in (5.2) satisfy $p_{ij}, q_{ii} \in C^\theta(\mathbf{R}, L^p(\Omega))$ for $i, j = 1, 2$ and $p_{ii}(t,x) \le -\varphi_{ii}(x)$, for $t \le t_0$, with $\varphi_{ii}(x)$ as in Proposition 4.2.*

Then there exists a $\rho > 0$ such that if

$$\limsup_{t\to-\infty} \|p_{12}(t)\|_{L^p(\Omega)} \limsup_{t\to-\infty} \|p_{21}(t)\|_{L^p(\Omega)} \le \rho^2, \tag{5.7}$$

then

(i) *$U_1(t)$ is the unique complete trajectory that is bounded in $L^\infty(\Omega,\mathbf{R}^2)$ at $-\infty$, and*

(ii) *if $U_2(s)$ is a family of positive initial data which is bounded in $L^\infty(\Omega,\mathbf{R}^2)$ as $s\to-\infty$, then $U_1(\cdot)$ pullback attracts $S(t,s)U_2(s)$, i.e., for any $t\in\mathbf{R}$*

$$S(t,s)U_2(s)-U_1(t)\to 0 \quad \text{in } C^1_{\mathcal{B}_1}(\overline{\Omega})\times C^1_{\mathcal{B}_2}(\overline{\Omega}) \quad \text{as} \quad s\to-\infty.$$

Proof.

(i) Let $U_2(t)$ be a complete trajectory bounded in $L^\infty(\Omega,\mathbf{R}^2)$ at $-\infty$. We write (5.2) as

$$W_t - D\Delta W = QW + PW, \qquad W(s)=W_s=U_2(s)-U_1(s),$$

where Q, P, and W are defined as in (5.4). Since $U_1=(u_1,v_1)$ is a complete, positive, bounded, and nondegenerate solution of the diagonal system

$$W_t - D\Delta W = QW,$$

it follows from Proposition 4.3 that for any $1\le q<\infty$, and sufficiently negative t_0,

$$\|T_Q(t,s)\|_{\mathcal{L}(L^q(\Omega,\mathbf{R}^2))}\le M_1, \quad s<t\le t_0, \tag{5.8}$$

with M_1 independent of t and s.

Then, we apply Theorem 4.6 to obtain that there exists $\rho>0$ such that if (5.7) holds, then

$$\|T_{Q+P}(t,s)\|_{\mathcal{L}(L^q(\Omega,\mathbf{R}^2))}\le M_1''\mathrm{e}^{\beta''(t-s)} \quad \text{for all } s<t\le t_0 \quad \text{and some} \quad \beta''<0.$$

Thus,

$$\|U_1(t)-U_2(t)\|_{L^q(\Omega,\mathbf{R}^2)}=\|W(t,s;W_s)\|_{L^q(\Omega,\mathbf{R}^2)}\le M_1''\mathrm{e}^{\beta''(t-s)}\|W_s\|_{L^q(\Omega,\mathbf{R}^2)}. \tag{5.9}$$

The right-hand side tends to zero as $s\to-\infty$ since both complete trajectories are bounded, and the result follows.

(ii) Proceeding as above, we obtain

$$\|U_1(t)-S(t,s)U_2(s)\|_{L^q(\Omega,\mathbf{R}^2)}\le M_1''\mathrm{e}^{\beta''(t-s)}\|U_1(s)-U_2(s)\|_{L^q(\Omega,\mathbf{R}^2)}$$

for $s<t\le t_0$ and some $\beta''<0$.

Thus, from Proposition 4.4 (see also Proposition 4.1), we get for $s<t\le t_0$,

$$\|U_1(t)-S(t,s)U_2(s)\|_{L^\infty(\Omega,\mathbf{R}^2)}\le M_2\mathrm{e}^{\beta''(t-s)}\|U_1(s)-U_2(s)\|_{L^q(\Omega,\mathbf{R}^2)}\to 0$$

as $s\to-\infty$. Standard parabolic regularization implies the convergence in $C^1_{\mathcal{B}_1}(\overline{\Omega})\times C^1_{\mathcal{B}_2}(\overline{\Omega})$.

Now for every $\tau\ge t_0$, using the continuity of the nonlinear evolution process, we get, as $s\to-\infty$,

$$U_1(\tau,s)=S(\tau,t)U_1(t,s)\to S(\tau,t)U_2(t). \qquad \square$$

The theorems above may perhaps appear more general than they really are. To verify the assumptions involved one must restrict the nonlinearities of the system and carefully choose the classes of solutions being considered. For example, the conditions $p_{ii}(t,x)\le-\varphi_{ii}(x)$ and the smallness conditions on $p_{ij}(t,x)$, $i\ne j$ depend on the particular solutions considered.

Nevertheless, in the next section we will show that the assumptions required can be verified for our example of a general nonautonomous Lotka–Volterra system.

6. Attracting trajectories for nonautonomous Lotka–Volterra systems. As (5.1) is far too general to apply Theorems 5.1 and 5.2 in a straightforward manner, in this section we apply these results to the solutions of (3.1). Note that we handle the three cases, competition, symbiosis, and prey-predator, in a unified way.

Then, for the difference of two solutions the coefficients in (5.2) are given by

(6.1)
$$q_{11}(t,x) = \lambda(t,x) - a(t,x)u_2 - b(t,x)v_2, \quad q_{22}(t,x) = \mu(t,x) - c(t,x)u_2 - d(t,x)v_2,$$
$$p_{11}(t,x) = -a(t,x)u_1, \qquad p_{12}(t,x) = -b(t,x)u_1,$$
$$p_{21}(t,x) = -c(t,x)v_1, \qquad p_{22}(t,x) = -d(t,x)v_1.$$

Hence, to apply Theorems 5.1 or 5.2, since $a_L, d_L > 0$ and $u_1, v_1 \geq 0$, in order to find positive functions $\varphi_{ii}(x)$ such that $p_{ii}(t,x) \leq -\varphi_{ii}(x)$, $i = 1, 2$ we need positive functions $\psi_{ii}(x)$ such that $\psi_{11}(x) \leq u_1(t,x)$ and $\psi_{22}(x) \leq v_1(t,x)$, that is, we must consider nondegenerate solutions. The results in section 3.4 guarantee then that all solutions are nondegenerate.

On the other hand we must show that the product of the coupling terms

$$p_{12}(t,x)p_{21}(t,x)$$

is small at $\pm\infty$. Having obtained bounds on u_1, v_1 this will be achieved by a smallness condition on the coefficients $b(t,x)$ or $c(t,x)$.

But note that the nondegeneracy of solutions above depends on the functions $b(t,x)$ and $c(t,x)$ themselves. Therefore, we will use the results in section 3.4 which guarantee that solutions of (3.1) are nondegenerate for all sufficiently small "coupling" coefficients $b(t,x)$ or $c(t,x)$ and that the functions $\psi_{ii}(x)$, $i = 1, 2$ do not converge to zero as b or c vanish.

We first start with the forwards behavior in Theorem 5.1. Then we can prove the following theorem.

THEOREM 6.1. *There exists $\rho_0(M_\infty, N_\infty) > 0$, where M_∞ and N_∞ are given in Theorem* 3.5*, such that if*

$$\limsup_{t\to\infty} \|b\|_{L^\infty(\Omega)} \limsup_{t\to\infty} \|c\|_{L^\infty(\Omega)} < \rho_0(M_\infty, N_\infty),$$

and for some t_0 the coefficients of (3.1) *satisfy for $t \geq t_0$ the assumptions of Theorem* 3.14*, then for any bounded set of positive initial data bounded away from zero, all solutions of* (3.1) *that start at a sufficiently large $s > t_0$ have the same asymptotic behavior as $t \to \infty$.*

In particular, all complete positive trajectories in the pullback attractor have the same asymptotic behavior as $t \to \infty$.

Proof. Note that Theorem 3.14 implies that all forward solutions of (3.1) that start at $s \geq t_0$ are uniformly nondegenerate with respect to a bounded set of initial data $u_s > 0$, $v_s > 0$, bounded away from zero, and the coefficients. In particular, from Propositions 4.2 and 4.4 the constant M_1 in (5.5) can be taken independent of such $u_s > 0$, $v_s > 0$ and the coefficients.

Moreover, for such initial data and $t > s \geq t_0$, we have in (6.1)

$$p_{11}(t,x) = -a(t,x)u_1 \leq -a_L\psi_{11}(x) = -\varphi_{11}(x),$$
$$p_{22}(t,x) = -d(t,x)v_1 \leq -d_L\psi_{22}(x) = -\varphi_{22}(x)$$

with $\psi_{11}(x)$ and $\psi_{22}(x)$ independent $u_s > 0$, $v_s > 0$, and of the coefficients. In particular $\varphi_{11}(x)$ and $\varphi_{22}(x)$ satisfy the assumptions in Proposition 4.2.

Hence the threshold value $\rho > 0$ in Theorem 5.1 is also uniform for $u_s > 0$, $v_s > 0$, and of the coefficients as in Theorem 3.14.

Now we have in (6.1) $p_{12}(t,x) = -b(t,x)u_1$, $p_{21}(t,x) = -c(t,x)v_1$, and hence (5.3) is satisfied if

$$\limsup_{t\to\infty} \|b\|_{L^\infty(\Omega)} \limsup_{t\to\infty} \|c\|_{L^\infty(\Omega)} < \rho^2(p,\Omega,M_\infty,N_\infty) = \rho_0,$$

where M_∞ and N_∞ are given in Theorem 3.5.

Therefore, from Theorem 5.1, all solutions have the same forwards behavior. □

Our next result proves that if there is a complete trajectory that is nondegenerate at $-\infty$, then it must be unique and be pullback attracting, as in Theorem 5.2.

THEOREM 6.2. *Assume that there exists a complete, bounded solution of* (3.1) *that is nondegenerate at* $-\infty$, $U^*(t)$, $t \in \mathbf{R}$.

Then there exists $\rho_0(M_\infty, N_\infty) > 0$, *where* M_∞ *and* N_∞ *are given in Theorem* 3.5, *such that if*

$$\limsup_{t\to-\infty} \|b\|_{L^\infty(\Omega)} \limsup_{t\to-\infty} \|c\|_{L^\infty(\Omega)} < \rho_0(M_\infty, N_\infty),$$

and for some t_0 *the coefficients of* (3.1) *satisfy for* $t \le t_0$ *the assumptions of Theorem* 3.14, *then* $U^*(t)$ *is the unique bounded complete solution of* (3.1) *that is nondegenerate at* $-\infty$. *Moreover, for every* $t \in \mathbf{R}$, $U^*(t)$ *pullback attracts solutions* $U_1(t,s)$ *such that* $U_1(s)$ *are positive and bounded as* $s \to -\infty$.

If, in addition,

$$\limsup_{t\to\infty} \|b\|_{L^\infty(\Omega)} \limsup_{t\to\infty} \|c\|_{L^\infty(\Omega)} < \rho_0(M_\infty, N_\infty),$$

and for some t_1 *the coefficients of* (3.1) *satisfy for* $t \ge t_1$ *the assumptions of Theorem* 3.14, *then for any* $s \in \mathbf{R}$ *and for any positive solution* $U(t,s)$ *of* (3.1) *we have*

$$U(t,s) - U^*(t) \to 0 \qquad as \quad t \to \infty.$$

Proof. Assume there exists a complete, bounded nondegenerate solution at $-\infty$. Then Theorem 3.14 implies that all bounded nondegenerate solutions at $-\infty$ are uniformly nondegenerate with respect to the coefficients. In particular, from Propositions 4.2 and 4.4 the constant M_1 in (5.5) can be taken independent of the complete nondegenerate solution under consideration and of the coefficients. Moreover, we have in (6.1)

$$\begin{aligned} p_{11}(t,x) = -a(t,x)u_1 \le -a_L\psi_{11}(x) = -\varphi_{11}(x), \\ p_{22}(t,x) = -d(t,x)v_1 \le -d_L\psi_{22}(x) = -\varphi_{22}(x) \end{aligned}$$

with $\psi_{11}(x)$ and $\psi_{22}(x)$ independent of the complete nondegenerate solution and of the coefficients. In particular $\varphi_{11}(x)$, $\varphi_{22}(x)$ satisfy the assumptions in Proposition 4.2.

Hence the threshold value $\rho > 0$ in Theorem 5.2 is also independent of the complete nondegenerate solution and of the coefficients.

Now we have in (6.1) $p_{12}(t,x) = -b(t,x)u_1$, $p_{21}(t,x) = -c(t,x)v_1$, and hence (5.7) is satisfied if

$$\limsup_{t\to-\infty} \|b\|_{L^\infty(\Omega)} \limsup_{t\to-\infty} \|c\|_{L^\infty(\Omega)} < \rho^2(p,\Omega,M_\infty,N_\infty) = \rho_0.$$

Therefore, from Theorem 5.2, there exists at most a complete nondegenerate solution at $-\infty$.

To show that $U^*(t)$ is pullback attracting, observe that for sufficiently negative t_0 we can proceed as in the proof of Theorem 5.2 to conclude that $U^*(t)$ pullback attracts solutions $U_1(t,s)$ such that $U_1(s)$ is positive and bounded as $s \to -\infty$.

The rest follows from Theorem 6.1. □

7. Conclusions. We have obtained some results on permanence in nonautonomous Lotka–Volterra models without the assumption of any kind of periodicity. In particular we have found conditions under which there exists at least one complete trajectory, and for which all trajectories converge together as $t \to +\infty$. The key argument is a perturbation result for an associated linear system satisfied by the difference between two solutions, and using this we have been able to treat all the different classical cases – competition, symbiosis, and prey-predator – in a unified way. While this unified approach has its advantages, our method requires at least one of the coupling parameters in the system to be sufficiently small. Hence, we hope that a more detailed study of each particular situation could lead to some improvements in the conditions imposed on the nonautonomous terms while still using similar techniques.

It is a very interesting open problem to prove, for this Lotka–Volterra example, the existence of a complete trajectory that is nondegenerate at $-\infty$. Given this nondegeneracy one would get the uniqueness of such a trajectory, and its pullback attracting property. We believe that use of the concepts of sub- and super-trajectories (cf. Arnold and Chueshov [3] and Chueshov [10]), along with the sub- and supersolutions technique (cf. for example Pao [30]) should be able to provide this, and we intend to pursue this direction in a future paper.

However, it is certainly the case that the hypothesis that the time-dependent terms are bounded is important throughout the literature, as this assumption implies the existence of bounded global solutions, and in particular of bounded attracting trajectories. As the analysis in Langa et al. [23] shows, different kinds of forwards asymptotic behavior, such as the nonexistence of asymptotically stable trajectories, is possible if solutions are allowed to be unbounded.

AN ENTIRE SOLUTION TO THE LOTKA–VOLTERRA COMPETITION-DIFFUSION EQUATIONS*

YOSHIHISA MORITA† AND KOICHI TACHIBANA‡

Abstract. We deal with a system of Lotka–Volterra competition-diffusion equations on $\mathbb{R}$, which is a competing two species model with diffusion. It is known that the equations allow traveling waves with monotone profile. In this article we prove the existence of an entire solution which behaves as two monotone waves propagating from both sides of the x-axis, where an entire solution is meant by a classical solution defined for all space and time variables. The global dynamics for this entire solution exhibits the extinction of the inferior species by the superior one invading from both sides. The proof is carried out by applying the comparison principle for the competition-diffusion equations, that is, using an appropriate pair of a subsolution and a supersolution.

Key words. Lotka–Volterra, competition-diffusion, entire solution, traveling wave

1. Introduction.

In the field of population biology Lotka–Volterra competition equations are well accepted as a physiological model describing competing interaction of multiple species. Here we restrict our attention to a two species model. Taking random movement of the species into account, we get to the Lotka–Volterra competition-diffusion equations that are obtained by coupling diffusion terms to the Lotka–Volterra equations. In this article we are dealing with the following Lotka–Volterra competition-diffusion equations on $\mathbb{R}$:

$$\begin{cases} u_t = u_{xx} + (1 - u - k_1 v)u, \\ v_t = dv_{xx} + a(1 - v - k_2 u)v \end{cases} \quad (x \in \mathbb{R}), \tag{1.1}$$

where k_1, k_2, a, and d are positive constants. The variables $u(x,t)$ and $v(x,t)$ stand for the population density of two competing species. Thus we consider nonnegative $u(x,t), v(x,t)$. We note that the above system is normalized so that it has the equilibrium solutions $(u,v) = (1,0), (0,1)$, set as

$$\boldsymbol{e}_u := (1,0), \qquad \boldsymbol{e}_v := (0,1).$$

In the diffusion-free case we can classify the asymptotic behavior of the solution as $t \to \infty$, depending on k_1, k_2:

(i) $(u(t), v(t)) \to \boldsymbol{e}_u$ (u always wins) if $0 < k_1 < 1 < k_2$.
(ii) Depending on the initial condition, $(u,v) \to \boldsymbol{e}_u$ or $(u(t), v(t)) \to \boldsymbol{e}_v$ in general if $1 < k_1, k_2$.
(iii) $(u(t), v(t)) \to \boldsymbol{e}_v$ (v always wins) if $0 < k_2 < 1 < k_1$.

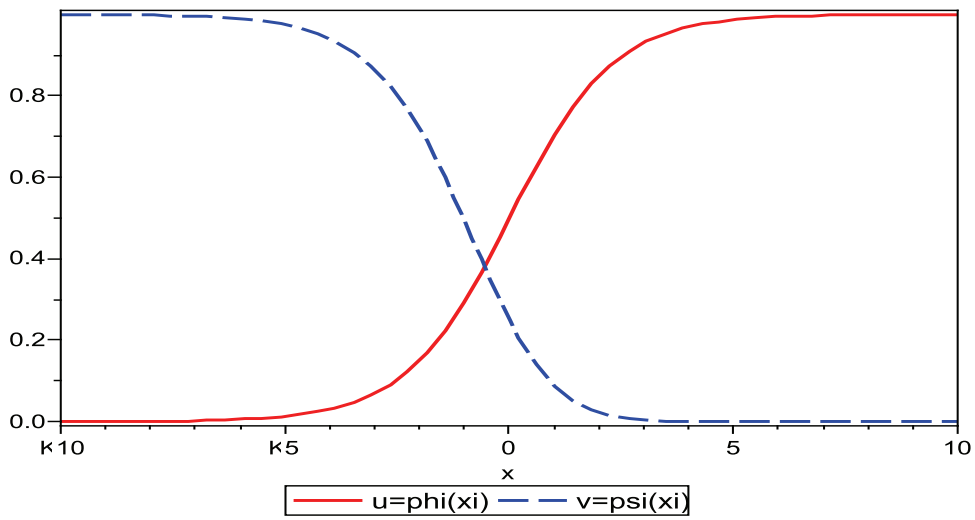

FIG. 1. *The profile of a monotone traveling wave solution of* (1.1). *Monotone increasing and decreasing curves correspond to* $u = \phi(\xi)$ *and* $v = \psi(\xi)$, *respectively. Parameter values are given by* $a = 3/2$, $d = 1/3$, $k_1 = 3/2$, *and* $k_2 = 2$.

(iv) $(u(t), v(t))$ converges to a positive equilibrium (u and v coexist) if $0 < k_1, k_2 < 1$.

Here we do not treat case (iv). Then we may assume $k_2 > 1$ because the third case (iii) is obtained by exchanging the roles of u and v.

The above equations (1.1) are used for describing the invasion of the superior species. As a matter of fact, by virtue of the diffusion, we can observe behavior such as the superior species propagating from one side of the x-axis to the other side, pushing back the inferior species. This dynamics of the propagation is mathematically characterized by a traveling wave solution $(u, v) = (\phi(x + ct), \psi(x + ct))$ satisfying

$$\begin{cases} \phi'' - c\phi' + (1 - \phi - k_1\psi)\phi = 0, \\ d\psi'' - c\psi' + a(1 - \psi - k_2\phi)\psi = 0, \end{cases} \tag{1.2}$$

with

$$\lim_{\xi \to -\infty} (\phi(\xi), \psi(\xi)) = \boldsymbol{e}_v, \quad \lim_{\xi \to \infty} (\phi(\xi), \psi(\xi)) = \boldsymbol{e}_u, \tag{1.3}$$

$$\phi(\xi), \quad \psi(\xi) > 0, \qquad \phi'(\xi) > 0, \quad \psi'(\xi) < 0, \tag{1.4}$$

where $' = d/d\xi$, $'' = d^2/d\xi^2$. A solution to (1.2) with (1.3) and (1.4) gives a profile of the traveling wave. Here we assume the monotonicity of (1.4) which arises in most cases. A traveling wave with the monotonicity is called a monotone wave or a wave front.

We note that for a traveling wave solution $(\phi(\xi), \psi(\xi)) = (\phi(x + ct), \psi(x + ct))$ to (1.2)–(1.4), the reflected $(\phi(-x + ct), \psi(-x + ct))$ also gives a traveling wave with opposite speed. Then $(\tilde{\phi}(\xi), \tilde{\psi}(\xi)) = (\phi(-x + ct), \psi(-x + ct))$ satisfies

$$\lim_{\xi \to -\infty} (\tilde{\phi}(\xi), \tilde{\psi}(\xi)) = \boldsymbol{e}_u, \quad \lim_{\xi \to \infty} (\tilde{\phi}(\xi), \tilde{\psi}(\xi)) = \boldsymbol{e}_v.$$

Thus we obtain traveling wave solutions with opposite speeds simultaneously if we obtain a solution satisfying (1.3)–(1.4).

As for the study of traveling wave solutions, there are various works, including [3], [4], [15], and [7]. In particular, see [8], [9], [10], [11], [12], and the references therein.

Although the study for a traveling wave is a central issue of the Lotka–Volterra competition-diffusion equations, it is not enough for mathematical understanding of the dynamical structure of solutions to (1.1). In fact, as seen in the recent development of the study for entire solutions to a scalar reaction-diffusion equation, some combination of two traveling waves yields characteristic dynamics for the equation (see [6], [16], [2], [5], [1], [13]), where the entire solution is meant by a classical solution which is defined for every x and t. Those results revealed that the equation allows types of entire solutions other than equilibrium solutions and traveling wave solutions. For example, in [6], [16], [2], [5], it is shown that there exists an entire solution which behaves as two wave fronts propagating from both sides of the x-axis and then annihilating, while [13] shows entire solutions which behave as two wave fronts merging.

In this article, motivated by the work of [2] and [5], we consider the entire solution which behaves like two monotone traveling waves propagating from both sides of the x-axis. As t goes forward, this solution converges to the equilibrium $\boldsymbol{e}_u$ when u is superior. Namely, we are interested in the entire solution $(u(x,t), v(x,t))$ which behaves like $(\phi(x+ct),\ \psi(x+ct))$ for $x \in (0,\infty)$ and $(\phi(-x+ct),\ \psi(-x+ct))$ for $x \in (-\infty, 0)$ as $t \to -\infty$ and converges to a uniform state as $t \to \infty$. This solution corresponds to the phenomenon that the superior species invades from both sides and causes the extinction of the inferior species.

We prepare some notation for stating the main result. We assume that u is always superior so that the traveling wave solution of (1.2) with (1.3) and (1.4) has a positive speed $c > 0$. In addition, we allow the equations to have solutions with different speeds (corresponding to case (i)). As a matter of fact, we have traveling waves of the Fisher type for the case (i); that is, there is a minimum speed $c_{min} > 0$ so that the equations allow a family of monotone traveling wave solutions for $c \geq c_{min} > 0$ (see [10]). Thus we set a pair of traveling wave solutions

$$(\phi_j(\xi), \psi_j(\xi)) \quad (j = 1, 2)$$

satisfying

$$\begin{cases} \phi_j'' - c_j\phi_j' + (1 - \phi_j - k_1\psi_j)\phi_j = 0, \\ d\psi_j'' - c_j\psi_j' + a(1 - \psi_j - k_2\phi_j)\psi_j = 0 \end{cases} \qquad (j = 1, 2), \tag{1.5}$$

with

$$\lim_{\xi \to -\infty} (\phi_j(\xi), \psi_j(\xi)) = \boldsymbol{e}_v, \quad \lim_{\xi \to \infty} (\phi_j(\xi), \psi_j(\xi)) = \boldsymbol{e}_u, \tag{1.6}$$

$$\phi_j(\xi), \quad \psi_j(\xi) > 0, \qquad \phi_j'(\xi) > 0, \quad \psi_j'(\xi) < 0, \tag{1.7}$$

where c_j $(j = 1, 2)$ are positive. Note that we consider the case when they coincide, namely, $(\phi_1(\xi), \psi_1(\xi))$ identically equals $(\phi_2(\xi), \psi_2(\xi))$ up to a phase shift.

We assume that there is a positive constant η_0 such that

$$\eta_0 \leq \frac{\phi_j(\xi)}{1 - \psi_j(\xi)} \qquad (\xi \leq 0) \tag{1.8}$$

holds. Then we obtain the following theorem, which is the main result in this article.

THEOREM 1.1. *Assume $k_1 \neq 1$ and $k_2 > 1$ in* (1.1). *Let (ϕ_j, ψ_j) be a solution to* (1.5) *with* (1.6), (1.7), *and $c_j > 0$ $(j = 1, 2)$. If the condition* (1.8) *holds, then there exists a solution $(u(x,t), v(x,t))$ $((x,t) \in \mathbb{R} \times \mathbb{R})$ of* (1.1) *satisfying*

$$\lim_{t\to-\infty} \sup_{x\geq(c_2-c_1)t/2} \{|u(x,t) - \phi_1(x + c_1t)| + |v(x,t) - \psi_1(x + c_1t)|\} = 0,$$
$$\lim_{t\to-\infty} \sup_{x\leq(c_2-c_1)t/2} \{|u(x,t) - \phi_2(-x + c_2t)| + |v(x,t) - \psi_2(-x + c_2t)|\} = 0,$$

and

$$\lim_{t\to\infty} \sup_{x\in\mathbb{R}} \{|u(x,t) - 1| + |v(x,t)|\} = 0.$$

Remark 1.1. If $k_1 > 1$, the monotone traveling wave is unique up to translation (for instance, see [8]). Hence, when $k_1 > 1$, $(\phi_1, \psi_1) = (\phi_2, \psi_2)$ in the theorem.

Considering the fact that the equations (1.1) are invariant under the translation in x and the time shift, we easily see the following result from the above theorem.

COROLLARY 1.2. *Let $(u(x,t), v(x,t))$ be an entire solution to* (1.1) *given in Theorem* 1.1. *Given θ_1, θ_2, there exist ξ and τ such that*

$$\lim_{t\to-\infty} \sup_{x\geq(c_2-c_1)t/2} \{|u(x+\xi,t+\tau) - \phi_1(x + c_1t + \theta_1)| + |v(x+\xi,t+\tau) - \psi_1(x + c_1t + \theta_1)|\} = 0,$$
$$\lim_{t\to-\infty} \sup_{x\leq(c_2-c_1)t/2} \{|u(x+\xi,t+\tau) - \phi_2(-x + c_2t + \theta_2)| + |v(x+\xi,t+\tau) - \psi_2(-x + c_2t + \theta_2)|\} = 0,$$

and

$$\lim_{t\to\infty} \sup_{x\in\mathbb{R}} \{|u(x+\xi,t+\tau) - 1| + |v(x+\xi,t+\tau)|\} = 0.$$

The condition (1.8) is crucial in our argument, though it might be a technical condition. Here we give a sufficient condition for (1.8), which is easier to check. Let $\lambda_3^{(j)}$ be a positive root of

$$d\lambda^2 - c_j\lambda - a = 0. \tag{1.9}$$

For $k_1 > 1$, we have a unique positive root $\lambda_4^{(j)}$ of

$$\lambda^2 - c_j\lambda - (k_1 - 1) = 0, \tag{1.10}$$

while for $0 < k_1 < 1$, there is another positive root $\lambda_5^{(j)}$ $(\leq \lambda_4^{(j)})$ of (1.10) under the condition

$$c_j \geq c_{min} \geq 2\sqrt{1 - k_1}, \tag{1.11}$$

where $\lambda_4^{(j)} = \lambda_5^{(j)}$ if $c_j = 2\sqrt{1 - k_1}$. Those roots $\lambda_k^{(j)}$ $(k = 3, 4, 5)$ are related to the convergence rate of the traveling waves as $(\phi_j(\xi), \psi_j(\xi)) \to (0, 1)$ $(\xi \to -\infty)$. We notice that

$$d\frac{\psi_j''}{1-\psi_j} - c_j\frac{\psi_j'}{1-\psi_j} + a\psi_j\left(1 - k_2\frac{\phi_j}{1-\psi_j}\right) = 0 \tag{1.12}$$

by the second equation of (1.5). We can prove the limit of $\psi_j'(\xi)/(1-\psi_j(\xi))$ as $\xi \to -\infty$ exists. In fact, we have the next lemma.

LEMMA 1.3. *Assume the same assumption of Theorem* 1.1. *Then* (1.8) *holds if*

$$\lim_{\xi \to -\infty} \frac{-\psi_j'(\xi)}{1-\psi_j(\xi)} \neq \lambda_3^{(j)}. \tag{1.13}$$

Moreover, the condition (1.13) *is realized for* $\lambda_4^{(j)} < \lambda_3^{(j)}$ $(j = 1, 2)$.

Remark 1.2. The condition $\lambda_4^{(j)} < \lambda_3^{(j)}$ $(j = 1, 2)$ is clear and easily checked. However, there are cases which break this condition but allow (1.13). For example, (1.13) is verified by the condition $\lambda_5^{(j)} < \lambda_3^{(j)} \leq \lambda_4^{(j)}$ together with a generic condition for the asymptotic behavior of the traveling wave as $t \to -\infty$. We discuss this in section 2.

We briefly sketch an outline of the proof of Theorem 1.1. We will use the following functions to approximate the entire solution as $t \approx -\infty$:

$$\begin{cases} \underline{u} = \max\{\phi_1(x + c_1 t), \phi_2(-x + c_2 t)\}, \\ \overline{v} = \min\{\psi_1(x + c_1 t), \psi_2(-x + c_2 t)\}, \end{cases} \tag{1.14}$$

and

$$\begin{cases} \overline{u} = \phi_1(x + p_1(t)) + \phi_2(-x + p_2(t)) - \phi_1(x + p_1(t))\phi_2(-x + p_2(t)), \\ \underline{v} = \psi_1(x + p_1(t))\psi_2(-x + p_2(t)), \end{cases} \tag{1.15}$$

where

$$p_j(t) \approx c_j t \qquad (t \approx -\infty).$$

Note that $(\underline{u}, \overline{v})$ and $(\overline{u}, \underline{v})$ certainly have the profile we are supposing as $t \to -\infty$. Since the comparison principle does work in the present competition-diffusion system, we prove that (1.14) and (1.15) are a subsolution and a supersolution with suitable $p_j(t)$, respectively, if $t < 0$. This yields a solution sandwiched by the subsolution and the supersolution, defined for every negative t. Then such a solution can be extended for any positive time. In what follows, we obtain the desired entire solution.

Although our idea for the proof of the main result is based on the previous work of [5], [1], and [13], we encounter a difficulty when we prove that the pairing of (1.15) is a supersolution. Fortunately, noticing the identity

$$\begin{aligned} &(u_1 + u_2 - u_1 u_2)v_1 v_2 - (1 - u_2)u_1 v_1 - (1 - u_1)u_2 v_2 \\ &\quad = -u_1(1 - u_2)v_1(1 - v_2) - (1 - u_1)u_2(1 - v_1)v_2 + u_1 u_2 v_1 v_2, \end{aligned} \tag{1.16}$$

we can overcome the difficulty (see section 4 for the details).

In the above theorem we obtain an entire solution characterized by the asymptotic behavior as $t \to -\infty$. Once we obtain such a solution, it is easy to prove the asymptotic behavior as $t \to \infty$ stated in the theorem, since the subsolution is defined globally in time. However, we have only the one side estimated by the subsolution; hence precise transient behavior for positive t is not described yet. Here, using an exact expression for the traveling wave solution, we show the entire behavior of the solution for specific parameter values. In the paper [14], traveling wave solutions are

exactly given in terms of the hyperbolic tangent function under a constraint of the parameters. We use one of them, which is given by

$$\phi(\xi) = \frac{1}{2}\left\{1 + \tanh\left(\frac{\sqrt{k_1}\xi}{2\sqrt{2}}\right)\right\}, \quad \psi(\xi) = \frac{1}{4}\left\{1 - \tanh\left(\frac{\sqrt{k_1}\xi}{2\sqrt{2}}\right)\right\}^2, \tag{1.17}$$

where

$$d = \frac{a}{3k_1}, \quad a = \frac{6 - 3k_1}{3k_2 - 5}, \quad c = \frac{2 - k_1}{\sqrt{2k_1}}, \tag{1.18}$$

with the condition

$$0 < k_1 < 2, \quad 5/3 < k_2. \tag{1.19}$$

It is a lengthy but simple computation to verify that (1.17) with (1.18) and (1.19) is a traveling wave of (1.1) satisfying (1.2)–(1.4). Moreover, this solution satisfies (1.13) as well as (1.8). Indeed, we can compute the corresponding positive roots of (1.9) and (1.10) as

$$\lambda_3 = \frac{1}{2}\sqrt{\frac{k_1}{2}}\{3k_2 - 5 + \sqrt{(3k_2 - 5)^2 + 24}\} > \sqrt{3k_1},$$

$$\lambda_4 = \begin{cases} \sqrt{k_1/2} & (2/3 \le k_1), \\ \sqrt{2}(1 - k_1)/\sqrt{k_1} & (0 < k_1 < 2/3) \end{cases}$$

and

$$\lambda_5 = \begin{cases} \sqrt{2}(1 - k_1)/\sqrt{k_1} & (2/3 < k_1 < 1), \\ \sqrt{k_1/2} & (0 < k_1 \le 2/3), \end{cases}$$

respectively.

We rewrite (1.17) as

$$\phi(\xi) = 1 - \frac{1}{1 + \exp(\xi\sqrt{k_1/2})}, \quad \psi(\xi) = \frac{1}{\{1 + \exp(\xi\sqrt{k_1/2})\}^2}.$$

Modify this expression as

$$u_*(x,t) := 1 - \frac{1}{1 + \Phi(x,t)}, \qquad v^*(x,t) = \frac{1}{(1 + \Phi(x,t))^2} \tag{1.20}$$

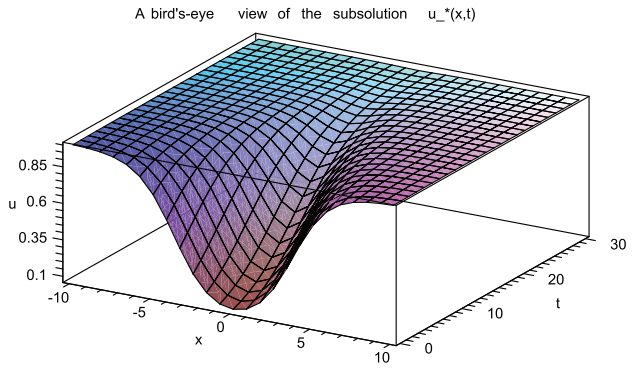
with

$$\Phi = \cosh\left(\frac{x\sqrt{k_1}}{\sqrt{2}}\right)\exp(\omega_0 t), \quad \omega_0 := 1 - \frac{k_1}{2}. \tag{1.21}$$

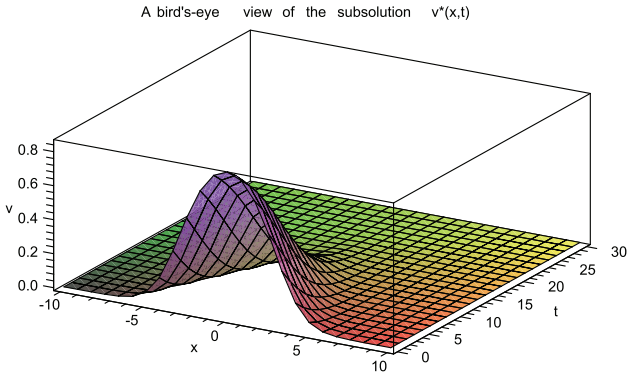
As for a profile of the functions of (1.20), see Figure 2.

We also define

$$u^*(x,t) := 1 - \frac{1}{1 + \Psi(x,t)}, \qquad v_*(x,t) = \frac{1}{(1 + \Psi(x,t))^2} \tag{1.22}$$



(a) A bird's eye view of $u_*(x, t-20)$



(b) A bird's eye view of $v^*(x, t-20)$

FIG. 2. *Bird's eye views of the functions* $u_*(x, t-20)$ *and* $v^*(x, t-20)$ $(0 \le t \le 30, -10 \le x \le 10)$*, respectively, which are defined by* (1.20) *and* (1.21)*. Parameter values are given by* (1.18) *with* $k_1 = 3/2$ *and* $k_2 = 2$*.*

with

$$\Psi = \cosh\left(\frac{x\sqrt{k_1}}{\sqrt{2}}\right)\exp(p(t)), \tag{1.23}$$

where $p(t)$ is given by a solution to

$$\dot{p}(t) = \omega_0 + \frac{L_0\exp(p(t))}{1+\exp(p(t))}, \quad p(0) = p_0, \tag{1.24}$$
$$L_0 := \max\{k_1, a/2\}.$$

Note that the solution $p(t)$ is a monotone increasing function satisfying

$$\lim_{t\to-\infty} p(t) = -\infty, \qquad \lim_{t\to\infty} p(t) = \infty.$$

The next result shows that the above functions give an approximation globally in time together with the existence of an entire solution.

PROPOSITION 1.4. *In addition to* (1.18) *and* (1.19)*, assume that the solution* $p(t)$ *of* (1.24) *satisfies* $p(t_0) = \omega_0 t_0$ *for an arbitrarily given* t_0*. Then a solution*

$(u(x,t),v(x,t))$ to (1.1) with the initial condition

$$(u(x,t_0),v(x,t_0))=(u_*(x,t_0),v^*(x,t_0))=(u^*(x,t_0),v_*(x,t_0))$$

satisfies

$$\begin{cases} u_*(x,t)\le u(x,t)\le u^*(x,t), \\ v_*(x,t)\le v(x,t)\le v^*(x,t) \end{cases} \quad ((t,x)\in(t_0,\infty)\times\mathbb{R}). \tag{1.25}$$

Moreover, if p_0 is a solution of

$$p_0=\frac{L_0}{L_0+\omega_0}\log\left(1+\frac{L_0+\omega_0}{\omega_0}\exp(p_0)\right), \tag{1.26}$$

then the asymptotics

$$\lim_{t\to-\infty}\sup_{x\in\mathbb{R}}[|u^*(x,t)-u_*(x,t)|+|v^*(x,t)-v_*(x,t)|]=0$$

hold; hence there is an entire solution $(u(x,t),v(x,t))$ satisfying (1.25) with $t_0=-\infty$.

We organize the paper as follows: In the next section we classify the asymptotic behavior of the traveling wave solutions as $\xi\to\pm\infty$. This result is given by investigating the linearized equations at the equilibrium points $\boldsymbol{e}_u$ and $\boldsymbol{e}_v$. Then Lemma 1.3 is proved. Although the result is already established, we give a proof in the appendix for the reader's convenience. In section 3 we give crucial estimates for the terms consisting of the traveling wave solutions. By virtue of the estimates we prove Theorem 1.1 together with Proposition 1.4 in section 4. The paper concludes with the appendix.

2. Asymptotic behavior of traveling front waves. All the results in Lemmas 2.1, 2.2, and 2.3 stated below were already obtained in [8] and [12]. For completeness of the present paper we give a proof in the appendix. We let $\lambda_1^{(j)}$ and $\lambda_2^{(j)}$ be negative roots of

$$\lambda^2-c_j\lambda-1=0 \tag{2.1}$$

and

$$d\lambda^2-c_j\lambda-a(k_2-1)=0, \tag{2.2}$$

respectively. The first lemma is on the asymptotic behavior of the traveling wave solutions as $\xi\to\infty$.

LEMMA 2.1. *Let $(\phi_j(\xi),\psi_j(\xi))$ be traveling wave solutions to (1.5)–(1.7) with $c_j>0$ $(j=1,2)$, and let $\lambda_1^{(j)}$ and $\lambda_2^{(j)}$ be negative roots of (2.1) and (2.2), respectively. Then the solution exhibits the asymptotic behavior as $\xi\to\infty$ as follows:*

(i) *If $\lambda_2^{(j)}<\lambda_1^{(j)}$, then*

$$\begin{aligned} 1-\phi_j(\xi)&=\alpha_j\exp(\lambda_1^{(j)}\xi)-\beta_j s_1^{(j)}\exp(\lambda_2^{(j)}\xi)+h.o.t., \\ \psi_j(\xi)&=\beta_j\exp(\lambda_2^{(j)}\xi)+h.o.t. \end{aligned} \tag{2.3}$$

hold for some numbers $\alpha_j\ge0$ and $\beta_j>0$, where

$$s_1^{(j)}:=\frac{k_1}{(\lambda_2^{(j)})^2-c_j\lambda_2^{(j)}-1}=\begin{cases}>0 & (\lambda_2^{(j)}<\lambda_1^{(j)}),\\ <0 & (\lambda_2^{(j)}>\lambda_1^{(j)}).\end{cases} \tag{2.4}$$

(ii) *If* $\lambda_1^{(j)} < \lambda_2^{(j)}$, *then*

$$\begin{aligned} 1-\phi_j(\xi) &= -\beta_j s_1^{(j)} \exp(\lambda_2^{(j)}\xi) + h.o.t., \\ \psi_j(\xi) &= \beta_j \exp(\lambda_2^{(j)}\xi) + h.o.t. \end{aligned} \tag{2.5}$$

for some $\beta_j > 0$, *where* $s_1^{(j)}$ *is as in* (2.4).

(iii) *If* $\lambda_1^{(j)} = \lambda_2^{(j)}$, *then*

$$\begin{aligned} 1-\phi_j(\xi) &= \beta_j \xi \exp(\lambda_1^{(j)}\xi) + h.o.t., \\ \psi_j(\xi) &= -\beta_j \tau_1^{(j)} \exp(\lambda_1^{(j)}\xi) + h.o.t. \end{aligned} \tag{2.6}$$

for some $\beta_j > 0$, *where*

$$\tau_1^{(j)} = \frac{2\lambda_1^{(j)} - c_j}{k_1} < 0.$$

The second lemma is related to the asymptotic behavior of the traveling wave solution as $\xi \to -\infty$ for $k_1 > 1$, namely, the bistable case (ii) stated in the introduction.

LEMMA 2.2. *Let* $(\phi_j(\xi), \psi_j(\xi))$ *be traveling wave solutions to* (1.5)–(1.7) *with* $c_j > 0$ $(j = 1, 2)$ *for* $k_1 > 1$, *and let* $\lambda_3^{(j)}$ *and* $\lambda_4^{(j)}$ *be positive roots of* (1.9) *and* (1.10), *respectively. Then the solution exhibits the asymptotic behavior as* $\xi \to -\infty$ *as follows:*

(i) *If* $\lambda_3^{(j)} < \lambda_4^{(j)}$, *then*

$$\begin{aligned} \phi_j(\xi) &= \beta_j \exp(\lambda_4^{(j)}\xi) + h.o.t., \\ 1-\psi_j(\xi) &= \alpha_j \exp(\lambda_3^{(j)}\xi) - \beta_j s_2^{(j)} \exp(\lambda_4^{(j)}\xi) + h.o.t. \end{aligned} \tag{2.7}$$

hold for some numbers $\alpha_j \geq 0$ *and* $\beta_j > 0$, *where*

$$s_2^{(j)} := \frac{ak_2}{d(\lambda_4^{(j)})^2 - c_j\lambda_4^{(j)} - a} = \begin{cases} > 0 & (\lambda_3^{(j)} < \lambda_4^{(j)}), \\ < 0 & (\lambda_3^{(j)} > \lambda_4^{(j)}). \end{cases} \tag{2.8}$$

(ii) *If* $\lambda_4^{(j)} < \lambda_3^{(j)}$, *then*

$$\begin{aligned} \phi_j(\xi) &= \beta_j \exp(\lambda_4^{(j)}\xi) + h.o.t., \\ 1-\psi_j(\xi) &= -\beta_j s_2^{(j)} \exp(\lambda_4^{(j)}\xi) + h.o.t. \end{aligned} \tag{2.9}$$

for some $\beta_j > 0$, *where* $s_2^{(j)}$ *is defined as in* (2.8).

(iii) *If* $\lambda_3^{(j)} = \lambda_4^{(j)}$, *then*

$$\begin{aligned} \phi_j(\xi) &= \beta_j \tau_2^{(j)} \exp(\lambda_3^{(j)}\xi) + h.o.t., \\ 1-\psi_j(\xi) &= -\beta_j \xi \exp(\lambda_3^{(j)}\xi) + h.o.t. \end{aligned} \tag{2.10}$$

as $\xi \to -\infty$ *for some* β_j, *where*

$$\tau_2^{(j)} := \frac{2d\lambda_3^{(j)} - c_j}{k_1} > 0. \tag{2.11}$$

The next lemma is related to the asymptotic behavior as $\xi \to -\infty$ when $0 < k_1 < 1$, namely, the monostable case (i) stated in the introduction.

LEMMA 2.3. *Let $(\phi_j(\xi), \psi_j(\xi))$ be traveling wave solutions to (1.5)–(1.7) with $c_j > 0$ $(j = 1, 2)$ for $k_1 \in (0, 1)$, and let $\lambda_5^{(j)}$ be a positive root of (1.10) with $\lambda_5^{(j)} \le \lambda_4^{(j)}$, where $c_j \ge 2\sqrt{1-k_1}$. Then the solution behaves as $\xi \to -\infty$ in the following way:*

(i) *$\lambda_5^{(j)} < \lambda_4^{(j)}$, $\lambda_4^{(j)}, \lambda_5^{(j)} \ne \lambda_3^{(j)}$: there are numbers α_j, β_j, and nonnegative γ_j such that*

(2.12)
$$\begin{aligned} \phi_j(\xi) &= \beta_j \exp(\lambda_4^{(j)}\xi) + \gamma_j \exp(\lambda_5^{(j)}\xi) + h.o.t., \\ 1 - \psi_j(\xi) &= \alpha_j \exp(\lambda_3^{(j)}\xi) - \beta_j s_2^{(j)} \exp(\lambda_4^{(j)}\xi) - \gamma_j s_3^{(j)} \exp(\lambda_5^{(j)}\xi) + h.o.t. \end{aligned}$$

with

$$\gamma_j \ge 0, \qquad \beta_j > 0 \quad (\gamma_j = 0), \qquad \alpha_j > 0 \quad (\lambda_3^{(j)} < \lambda_5^{(j)})$$

hold, where

$$s_3^{(j)} = \frac{ak_2}{d(\lambda_5^{(j)})^2 - c_j\lambda_5^{(j)} - a} = \begin{cases} > 0 & (\lambda_5^{(j)} > \lambda_3^{(j)}), \\ < 0 & (\lambda_5^{(j)} < \lambda_3^{(j)}). \end{cases} \tag{2.13}$$

(ii) *$\lambda_5^{(j)} = \lambda_4^{(j)} < \lambda_3^{(j)}$: there are β_j and γ_j such that*

$$\begin{aligned} \phi_j(\xi) &= \beta_j \xi \exp(\lambda_4^{(j)}\xi) + \gamma_j \exp(\lambda_4^{(j)}\xi) + h.o.t., \\ 1 - \psi_j(\xi) &= -\beta_j s_2^{(j)} \xi \exp(\lambda_4^{(j)}\xi) - \gamma_j s_2^{(j)} \exp(\lambda_4^{(j)}\xi) + h.o.t. \end{aligned} \tag{2.14}$$

with $\beta_j \ge 0$ and $\gamma_j > 0$ $(\beta_j = 0)$, where $s_2^{(j)}$ is defined as in (2.8).

(iii) *$\lambda_5^{(j)} < \lambda_3^{(j)} = \lambda_4^{(j)}$: there are β_j and γ_j such that*

$$\begin{aligned} \phi_j(\xi) &= \beta_j \tau_2^{(j)} \exp(\lambda_3^{(j)}\xi) + \gamma_j \exp(\lambda_5^{(j)}\xi) + h.o.t., \\ 1 - \psi_j(\xi) &= -\beta_j \xi \exp(\lambda_3^{(j)}\xi) - \gamma_j s_3^{(j)} \exp(\lambda_5^{(j)}\xi) + h.o.t. \end{aligned} \tag{2.15}$$

with $\gamma_j \ge 0$ and $\beta_j > 0$ $(\gamma_j = 0)$, where $\tau_2^{(j)}$ is defined as in (2.11).

(iv) *$\lambda_5^{(j)} = \lambda_3^{(j)} < \lambda_4^{(j)}$: there are α_j, β_j, and γ_j such that*

(2.16)
$$\begin{aligned} \phi_j(\xi) &= \gamma_j \tau_2^{(j)} \exp(\lambda_3^{(j)}\xi) + \beta_j \exp(\lambda_4^{(j)}\xi) + h.o.t., \\ 1 - \psi_j(\xi) &= \alpha_j \exp(\lambda_3^{(j)}\xi) - \gamma_j \xi \exp(\lambda_3^{(j)}\xi) - \beta_j s_2^{(j)} \exp(\lambda_4^{(j)}\xi) + h.o.t. \end{aligned}$$

with $\gamma_j \ge 0$ and

$$\alpha_j \ge 0, \quad \beta_j > 0 \qquad (\gamma_j = 0).$$

(v) *$\lambda_5^{(j)} = \lambda_4^{(j)} = \lambda_3^{(j)}$: there are β_j and γ_j such that*

$$\begin{aligned} \phi_j(\xi) &= \beta_j \tau_2^{(j)} \exp(\lambda_3^{(j)}\xi) - \gamma_j \tau_2 \xi \exp(\lambda_3^{(j)}\xi) + h.o.t., \\ 1 - \psi_j(\xi) &= -\beta_j \xi \exp(\lambda_3^{(j)}\xi) + \gamma_j (\xi^2/2) \exp(\lambda_3^{(j)}\xi) + h.o.t. \end{aligned} \tag{2.17}$$

with $\gamma_j \ge 0$ and $\beta_j > 0$ $(\gamma_j = 0)$.

The next lemma immediately follows from the above lemmas.

LEMMA 2.4. *There are positive constants r_1, r_2, η_1, η_2, ω_1, ω_2, and M such that*

$$r_1 \le \frac{\phi_j'(\xi)}{1-\phi_j(\xi)} \le r_2 \ (\xi \ge 0), \tag{2.18}$$

$$r_1 \le \frac{1-\phi_j(\xi)}{\psi_j(\xi)} \qquad (\xi \ge 0), \tag{2.19}$$

$$r_1 \le \frac{|\psi_j'(\xi)|}{\psi_j(\xi)} \qquad (\xi \ge 0) \tag{2.20}$$

and

$$0 < 1-\psi_j(\xi) \le M\exp(\omega_1\xi) \ (\xi \le 0), \tag{2.21}$$

$$\eta_1 \le \frac{|\psi_j'(\xi)|}{1-\psi_j(\xi)} \le \eta_2 \qquad (\xi \le 0), \tag{2.22}$$

$$0 \le \phi_j(\xi) \le M\exp(\omega_2\xi) \quad (\xi \le 0), \tag{2.23}$$

$$\eta_1 \le \frac{\phi_j'(\xi)}{\phi_j(\xi)} \le \eta_2 \qquad (\xi \le 0). \tag{2.24}$$

The following lemma is clear from Lemmas 2.2 and 2.3.

LEMMA 2.5. *Inequality* (1.8) *holds provided that one of the following conditions is satisfied:*

(1) $\lambda_4^{(j)} < \lambda_3^{(j)}$,

(2) $\lambda_5^{(j)} < \lambda_3^{(j)} \le \lambda_4^{(j)}, \quad \gamma_j > 0$,

(3) $\lambda_5^{(j)} \le \lambda_3^{(j)} < \lambda_4^{(j)}, \quad \alpha_j = \gamma_j = 0$,

where α_j, β_j, and γ_j are the numbers corresponding to each condition of (i)–(v) *for $\lambda_k^{(j)}$ $(k = 3, 4, 5)$ in Lemma* 2.3.

Proof of Lemma 1.3. By Lemmas 2.2 and 2.3, the limit

$$\lim_{\xi\to-\infty} \frac{-\psi_j'(\xi)}{1-\psi_j(\xi)} = \lim_{\xi\to-\infty} \frac{\psi_j''(\xi)}{\psi_j'(\xi)}$$

exists. Then the condition (1.13) implies that this limit is $\lambda_4^{(j)}$ or $\lambda_5^{(j)}$. Hence $\beta_j > 0$ or $\gamma_j > 0$. We assert that one of the conditions (1), (2), and (3) of Lemma 2.5 holds. This proves the first part of the assertion. The latter part is trivial by Lemma 2.5. □

3. Key estimates. In this section we prove two lemmas which will play a crucial role in the argument for the proof of Theorem 1.1.

LEMMA 3.1. *Let (ϕ_j, ψ_j) be traveling wave solutions of* (1.5)–(1.7) *satisfying* (1.8). *Define*

$$A_1(z,p) := (1-\phi_2(-z+p))\phi_1'(z+p) + (1-\phi_1(z+p))\phi_2'(-z+p), \tag{3.1}$$

and put $\omega = \min\{\omega_1, \omega_2\}$. Then there exist $L_1, L_2 > 0$ such that, given $p < 0$,

$$\frac{\phi_1'(z+p)\phi_2'(-z+p)}{A_1(z,p)} \le L_1\exp(\omega p), \tag{3.2}$$

$$\frac{\phi_1(z+p)(1-\phi_2(-z+p))\psi_1(z+p)(1-\psi_2(-z+p))}{A_1(z,p)} \le L_2\exp(\omega p), \tag{3.3}$$

and

$$\frac{\phi_2(-z+p)(1-\phi_1(z+p))\psi_2(-z+p)(1-\psi_1(z+p))}{A_1(z,p)} \le L_2\exp(\omega p) \tag{3.4}$$

hold.

Proof. We first prove (3.2). With the aid of (2.23) and (2.24), for $z \le 0$,

$$\begin{aligned}\frac{\phi_1'(z+p)\phi_2'(-z+p)}{A_1(z,p)} &\le \frac{\phi_1'(z+p)}{1-\phi_1(z+p)}\\ &\le \frac{\eta_2 M\exp(\omega_2(z+p))}{1-\phi_1(0)}\\ &\le \frac{\eta_2 M\exp(\omega_2 p)}{1-\phi_1(0)},\end{aligned}$$

while, for $z \ge 0$,

$$\begin{aligned}\frac{\phi_1'(z+p)\phi_2'(-z+p)}{A_1(z,p)} &\le \frac{\phi_2'(-z+p)}{1-\phi_2(-z+p)}\\ &\le \frac{\eta_2 M\exp(\omega_2(-z+p))}{1-\phi_2(0)}\\ &\le \frac{\eta_2 M\exp(\omega_2 p)}{1-\phi_2(0)}.\end{aligned}$$

Thus we can take $L_1 = \eta_2 M\max\{1/(1-\phi_1(0)),\, 1/(1-\phi_2(0))\}$ to prove (3.2).

Next we show (3.3) and (3.4). Put

$$B_1(z,p) := \phi_1(z+p)\psi_1(z+p)(1-\phi_2(-z+p))(1-\psi_2(-z+p)), \tag{3.5}$$

$$\tilde{B}_1(z,p) := \phi_2(-z+p)\psi_2(-z+p)(1-\phi_1(z+p))(1-\psi_1(z+p)). \tag{3.6}$$

First we prove (3.3). Let $z \le p$. By (2.18) we have

$$r_1 \le \frac{\phi_2'(-z+p)}{1-\phi_2(-z+p)} \quad (z \le p);$$

hence

$$\begin{aligned}\frac{B_1(z,p)}{A_1(z,p)} &\le \frac{\phi_1(z+p)}{r_1(1-\phi_1(z+p))}\\ &\le \frac{M\exp(\omega_2(z+p))}{r_1(1-\phi_1(0))}\\ &\le \frac{M\exp(\omega_2 p)}{r_1(1-\phi_1(0))}.\end{aligned} \tag{3.7}$$

As for the case $p \le z \le 0$, noticing that

$$\eta_0\eta_1 \le \frac{\phi_2'(-z+p)}{1-\psi_2(-z+p)} \quad (p \le z),$$

from (2.24) and (1.8) we have

$$\begin{aligned}\frac{B_1(z,p)}{A_1(z,p)} &\le \frac{\phi_1(z+p)}{\eta_0\eta_1(1-\phi_1(z+p))}\\ &\le \frac{M\exp(\omega_2(z+p))}{\eta_0\eta_1(1-\phi_1(0))}\\ &\le \frac{M\exp(\omega_2 p)}{\eta_0\eta_1(1-\phi_1(0))}. \end{aligned} \tag{3.8}$$

We let $0 \le z \le -p$. With the aid of

$$\eta_1 \le \frac{\phi_1'(z+p)}{\phi_1(z+p)} \quad (z \le -p),$$

we obtain

$$\begin{aligned}\frac{B_1(z,p)}{A_1(z,p)} &\le \frac{(1-\phi_2(-z+p))(1-\psi_2(-z+p))}{\eta_1(1-\phi_2(-z+p))}\\ &\le \frac{1-\psi_2(-z+p)}{\eta_1}\\ &\le \frac{M\exp(\omega_1(-z+p))}{\eta_1}\\ &\le \frac{M\exp(\omega_1 p)}{\eta_1}. \end{aligned} \tag{3.9}$$

Since

$$r_1^2 \le \frac{\phi_1'(z+p)}{\psi_1(z+p)} \quad (-p \le z),$$

by (2.18) and (2.19), we see that for $-p \le z$,

$$\begin{aligned}\frac{B_1(z,p)}{A_1(z,p)} &\le \frac{(1-\phi_2(-z+p))(1-\psi_2(-z+p))}{r_1^2(1-\phi_2(-z+p))}\\ &\le \frac{M\exp(\omega_1(-z+p))}{r_1^2}\\ &\le \frac{M\exp(\omega_1 p)}{r_1^2}. \end{aligned} \tag{3.10}$$

Combining (3.7), (3.8), (3.9), and (3.10) leads to (3.3).

We go to the case (3.4). In the above argument for (3.5), we replace $\phi_1(z+p)$, $\phi_2(-z+p)$, $\psi_1(z+p)$, and $\psi_2(-z+p)$ by $\phi_2(-z+p)$, $\phi_1(z+p)$, $\psi_2(-z+p)$, and $\psi_1(z+p)$, respectively, and change z to $-z$. Then for (3.6) we similarly obtain the desired estimate. We will leave the details to the reader. □

LEMMA 3.2. *Let*

$$A_2(z,p) := \psi_2(-z+p)\psi_1'(z+p) + \psi_1(z+p)\psi_2'(-z+p) \quad (<0). \tag{3.11}$$

Then there exist $L_3, L_4 > 0$ such that, given $p < 0$,

$$\frac{\psi_1'(z+p)\psi_2'(-z+p)}{|A_2(z,p)|} \le L_3\exp(\omega p) \tag{3.12}$$

and

$$\frac{\psi_1(z+p)\psi_2(-z+p)(1-\psi_1(z+p))(1-\psi_2(-z+p))}{|A_2(z,p)|} \le L_4 \exp(\omega p) \tag{3.13}$$

hold.

Proof. For $z \ge 0$, by (2.21) and (2.22) we have

$$\begin{aligned}\frac{\psi_1'(z+p)\psi_2'(-z+p)}{|A_2(z,p)|} &\le \frac{|\psi_2'(-z+p)|}{\psi_2(-z+p)} \\ &\le \frac{\eta_2 M \exp(\omega_1(-z+p))}{\psi_2(0)} \le \frac{\eta_2 M \exp(\omega_1 p)}{\psi_2(0)}.\end{aligned}$$

Similarly, we obtain that, for $z \le 0$,

$$\frac{\psi_1'(z+p)\psi_2'(-z+p)}{|A_2(z,p)|} \le \frac{\eta_2 M \exp(\omega_1 p)}{\psi_1(0)}.$$

This proves (3.12).

We show (3.13). Put

$$B_2(z,p) := \psi_1(z+p)\psi_2(-z+p)(1-\psi_1(z+p))(1-\psi_2(-z+p)). \tag{3.14}$$

First let $0 \le z \le -p$. By (2.22),

$$\begin{aligned}\frac{B_2(z,p)}{|A_2(z,p)|} &\le \frac{\psi_1(z+p)\psi_2(-z+p)(1-\psi_2(-z+p))}{\eta_1 \psi_2(-z+p)} \\ &\le \frac{1-\psi_2(-z+p)}{\eta_1} \le \frac{M \exp(\omega_1 p)}{\eta_1}.\end{aligned}$$

Next we consider the case $-p \le z$. By (2.20)

$$\begin{aligned}\frac{B_2(z,p)}{|A_2(z,p)|} &\le \frac{\psi_2(-z+p)(1-\psi_1(z+p))(1-\psi_2(-z+p))}{r_1 \psi_2(-z+p)} \\ &\le \frac{1-\psi_2(-z+p)}{r_1} \le \frac{M \exp(\omega_1 p)}{r_1}.\end{aligned}$$

As for $p \le z \le 0$ and $z \le p$, we use the above argument similarly to obtain

$$\frac{B_2(z,p)}{|A_2(z,p)|} \le \frac{M \exp(\omega_1 p)}{\eta_1} \quad (p \le z \le 0),$$

$$\frac{B_2(z,p)}{|A_2(z,p)|} \le \frac{M \exp(\omega_1 p)}{r_1} \quad (z \le p).$$

This concludes the proof of (3.13). ∎

4. Existence of the entire solution. Let $(\phi_j(\xi), \psi_j(\xi))$ $(j = 1, 2)$ be the traveling wave solutions as in Theorem 1.1. To prove the theorem, we consider the combination of the solutions $(\phi_1(x + c_1 t), \psi_1(x + c_1 t))$ and $(\phi_2(-x + c_2 t), \psi_2(-x + c_2 t))$.

By the change of variables

$$(U(z,t), V(z,t)) = (u(x,t), v(x,t)), \quad z = x + \frac{c_1 - c_2}{2} t,$$

(1.1) is transformed into

$$\begin{cases} U_t = U_{zz} - \dfrac{c_1 - c_2}{2} U_z + U(1 - U - k_1 V), \\ V_t = dV_{zz} - \dfrac{c_1 - c_2}{2} V_z + aV(1 - V - k_2 U) \end{cases} \quad (x \in \mathbb{R}). \tag{4.1}$$

Then $(U, V) = (\phi_1(z + c_m t),\ \psi_1(z + c_m t))$ and $(\phi_2(-z + c_m t),\ \psi_2(-z + c_m t))$ give traveling wave solutions of (4.1) with speed $c_m = (c_1 + c_2)/2$ and the opposite speed $-c_m$, respectively. The latter has the profile such that the U component is monotone decreasing while the V component is monotone increasing.

We define supersolutions and subsolutions to (1.1) and (4.1). Put

$$\begin{cases} \mathcal{F}_1(u, v) := u_t - u_{xx} + \beta u_x - f(u, v), \\ \mathcal{F}_2(u, v) := v_t - dv_{xx} + \beta v_x - ag(u, v), \end{cases}$$

and consider the equations

$$\mathcal{F}_1(u, v) = 0, \quad \mathcal{F}_2(u, v) = 0, \tag{4.2}$$

where

$$f(u, v) := (1 - u - k_1 v)u, \qquad g(u, v) := (1 - v - k_2 u)v,$$
$$\beta := \frac{c_1 - c_2}{2}.$$

We call $(\underline{u}(x, t), \overline{v}(x, t))$, $(x, t) \in \mathbb{R} \times [T_1, T_2]$ a subsolution if

$$\mathcal{F}_1(\underline{u}, \overline{v}) \le 0, \qquad \mathcal{F}_2(\underline{u}, \overline{v}) \ge 0 \qquad ((x, t) \in \mathbb{R} \times [T_1, T_2])$$

hold. We say that $(\overline{u}(x, t), \underline{v}(x, t))$, $(x, t) \in \mathbb{R} \times [T_1, T_2]$ is a supersolution to (4.2) if

$$\mathcal{F}_1(\overline{u}, \underline{v}) \ge 0, \qquad \mathcal{F}_2(\overline{u}, \underline{v}) \le 0 \qquad ((x, t) \in \mathbb{R} \times [T_1, T_2]).$$

We note that any solutions $(u(x, t), v(x, t))$ of (4.2) are not only subsolutions but also supersolutions. Let $(u(x, t), v(x, t))$ be solutions to (4.2) in $t \in [T_1, T_2]$. The maximal principle for the competition-diffusion system yields that if

$$\begin{cases} \underline{u}(x, T_1) \le u(x, T_1) \le \overline{u}(x, T_1), \\ \underline{v}(x, T_1) \le v(x, T_1) \le \overline{v}(x, T_1) \end{cases}$$

hold, then these orders are preserved for all $t \in [T_1, T_2]$.

If $(u_1(x, t), v_1(x, t))$ and $(u_1(x, t), v_1(x, t))$ are subsolutions in $t \in (T_1, T_2)$, then the pairing of

$$\underline{u}(x, t) := \max_{x \in \mathbb{R}} \{u_1(x, t), u_2(x, t)\}, \quad \overline{v}(x, t) := \min_{x \in \mathbb{R}} \{v_1(x, t), v_2(x, t)\}$$

is a subsolution in $t \in (T_1, T_2)$. Similarly, if $(u_1(x, t), v_1(x, t))$ and $(u_1(x, t), v_1(x, t))$ are supersolutions, then the pairing of

$$\overline{u}(x, t) := \min_{x \in \mathbb{R}} \{u_1(x, t), u_2(x, t)\}, \quad \underline{v}(x, t) := \max_{x \in \mathbb{R}} \{v_1(x, t), v_2(x, t)\}$$

is a supersolution.

We define a subsolution of (4.1) by the pairing

$$\begin{cases} \underline{U}(z,t) := \max_{z\in\mathbb{R}}\{\phi_1(z+c_mt+q), \phi_2(-z+c_mt+q)\}, \\ \overline{V}(z,t) := \min_{z\in\mathbb{R}}\{\psi_1(z+c_mt+q), \psi_2(-z+c_mt+q)\}, \end{cases} \tag{4.3}$$

where q is an arbitrarily given number.

Next we construct a supersolution. We first notice the following identities:

$$\begin{aligned} &f(u_1+u_2-u_1u_2, v_1v_2) - (1-u_2)f(u_1,v_1) - (1-u_1)f(u_2,v_2) \\ &\quad = -(1-u_1)(1-u_2)u_1u_2 \\ &\qquad - k_1\{(u_1+u_2-u_1u_2)v_1v_2 - (1-u_2)u_1v_1 - (1-u_1)u_2v_2\}, \\ &g(u_1+u_2-u_1u_2, v_1v_2) - v_2g(u_1,v_1) - v_1g(u_2,v_2) \\ &\quad = -v_1v_2(1-v_1)(1-v_2) + k_2u_1u_2v_1v_2. \end{aligned}$$

With the aid of (1.16), we obtain the inequalities

$$\begin{aligned} &f(u_1+u_2-u_1u_2, v_1v_2) - (1-u_2)f(u_1,v_1) - (1-u_1)f(u_2,v_2) \\ &\qquad \le k_1\{u_1(1-u_2)v_1(1-v_2) + (1-u_1)u_2(1-v_1)v_2\}, \end{aligned} \tag{4.4}$$

$$\begin{aligned} &g(u_1+u_2-u_1u_2, v_1v_2) - v_2g(u_1,v_1) - v_1g(u_2,v_2) \\ &\qquad \ge -v_1v_2(1-v_1)(1-v_2) \end{aligned} \tag{4.5}$$

for $0 \le u_1, u_2 \le 1$, and $0 \le v_1, v_2$.

We introduce the following ordinary differential equation:

$$\begin{cases} \dot{p} = c_m + Le^{\omega p} \qquad (t \le 0), \\ p(0) = p_0 < 0. \end{cases} \tag{4.6}$$

A simple computation yields a solution to (4.6) as

$$p(t) = c_mt - \frac{1}{\omega}\log\left\{e^{-\omega p_0} + \frac{L(1-e^{\omega c_m t})}{c_m}\right\} < 0 \quad (t<0) \tag{4.7}$$

having the asymptotics

$$\lim_{t\to-\infty}(p(t) - c_mt) = -\frac{1}{\omega}\log\left(e^{-\omega p_0} + \frac{L}{c_m}\right). \tag{4.8}$$

LEMMA 4.1. *Let* $(\phi_j(x+c_jt), \psi_j(x+c_jt))$ $(j=1,2)$ *be traveling wave solutions to* (1.1) *satisfying* (1.5), (1.6), (1.7), *and* (1.8). *Let* $p(t)$ *be a solution to* (4.6) *with* $L \ge \max\{2L_1 + 2k_1L_2,\ 2dL_3 + aL_4\}$. *Then the pairing of*

$$\begin{cases} \overline{U}(z,t) := \phi_1(z+p(t)) + \phi_2(-z+p(t)) - \phi_1(z+p(t))\phi_2(-z+p(t)), \\ \underline{V}(z,t) := \psi_1(z+p(t))\psi_2(-z+p(t)) \end{cases} \tag{4.9}$$

is a supersolution of (4.1).

Proof. First note that $\phi_1 = \phi_1(\xi)$, $\psi_1 = \psi_1(\xi)$ $(\xi = z + c_mt)$ satisfy

$$\begin{cases} \phi_1'' - c_1\phi_1' + f(\phi_1,\psi_1) = 0, \\ d\psi_1'' - c_1\psi_1' + ag(\phi_1,\psi_1) = 0, \end{cases}$$

while $\phi_2 = \phi_2(\xi)$, $\psi_2 = \psi_2(\xi)$ ($\xi = -z + c_m t$) satisfy

$$\begin{cases} \phi_2'' - c_2\phi_2' + f(\phi_2, \psi_2) = 0, \\ d\psi_2'' - c_2\psi_2' + ag(\phi_2, \psi_2) = 0, \end{cases}$$

where $' = d/d\xi$, $'' = d^2/d\xi^2$. Substituting $(\overline{U}, \underline{V})$ into

$$\begin{cases} \mathcal{F}_1(U,V) = U_t - U_{zz} + \dfrac{c_1 - c_2}{2} U_z - f(U,V), \\ \mathcal{F}_2(U,V) = V_t - dV_{zz} + \dfrac{c_1 - c_2}{2} V_z - ag(U,V) \end{cases}$$

yields

$$\begin{aligned} \mathcal{F}_1(\overline{U}, \underline{V}) &= \dot{p}\{(1-\phi_2)\phi_1' + (1-\phi_1)\phi_2'\} - (\phi_1'' + \phi_2'' - \phi_1''\phi_2 + 2\phi_1'\phi_2' - \phi_1\phi_2'') \\ &\quad + \frac{c_1 - c_2}{2}\{(1-\phi_2)\phi_1' - (1-\phi_1)\phi_2'\} - f(\phi_1 + \phi_2 - \phi_1\phi_2, \psi_1\psi_2) \\ &= \dot{p}\{(1-\phi_2)\phi_1' + (1-\phi_1)\phi_2'\} - (1-\phi_2)\left(\phi_1'' - \frac{c_1 - c_2}{2}\phi_1'\right) \\ &\quad - (1-\phi_1)\left(\phi_2'' + \frac{c_1 - c_2}{2}\phi_2'\right) - 2\phi_1'\phi_2' - f(\phi_1 + \phi_2 - \phi_1\phi_2, \psi_1\psi_2) \\ &= (\dot{p} - c_m)\{(1-\phi_2)\phi_1' + (1-\phi_1)\phi_2'\} - 2\phi_1'\phi_2' \\ &\quad - \{f(\phi_1 + \phi_2 - \phi_1\phi_2, \psi_1\psi_2) - (1-\phi_2)f(\phi_1, \psi_1) - (1-\phi_1)f(\phi_2, \psi_2)\}. \end{aligned}$$

Using (4.4), we obtain

$$\begin{aligned} \mathcal{F}_1(\overline{U}, \underline{V}) &\geq A_1(z,p)(\dot{p} - c_m) - 2\phi_1'\phi_2' - k_1(B_1(z,p) + \tilde{B}_1(z,p)) \\ &= A_1(z,p)\left\{L\exp(\omega p) - \frac{2\phi_1'\phi_2'}{A_1(z,p)} - k_1\frac{B_1(z,p) + \tilde{B}_1(z,p)}{A_1(z,p)}\right\}, \end{aligned} \tag{4.10}$$

where $A_1(z,p)$, $B_1(z,p)$, and $\tilde{B}_1(z,p)$ are defined in (3.1), (3.5), and (3.6), respectively. By Lemma 3.1 we obtain

$$\mathcal{F}_1(\overline{U}, \underline{V}) \geq 0 \qquad ((z,t) \in \mathbb{R} \times (-\infty, 0])$$

for $L \geq 2L_1 + 2k_1L_2$.

Similarly,

$$\begin{aligned} \mathcal{F}_2(\overline{U}, \underline{V}) &= (\psi_1'\psi_2 + \psi_1\psi_2')\dot{p} - d(\psi_1''\psi_2 + \psi_1\psi_2'') + 2d\psi_1'\psi_2' \\ &\quad + \frac{c_1 - c_2}{2}(\psi_1'\psi_2 - \psi_1\psi_2') - ag(\phi_1 + \phi_2 - \phi_1\phi_2, \psi_1\psi_2) \\ &= (\psi_1'\psi_2 + \psi_1\psi_2')\dot{p} + \psi_2\{-c_1\psi_1' + ag(\phi_1, \psi_1)\} \\ &\quad + \psi_1\{-c_2\psi_2' + ag(\phi_2, \psi_2)\} + 2d\psi_1'\psi_2' \\ &\quad + \frac{c_1 - c_2}{2}(\psi_1'\psi_2 - \psi_1\psi_2') - ag(\phi_1 + \phi_2 - \phi_1\phi_2, \psi_1\psi_2) \\ &= (\psi_1'\psi_2 + \psi_1\psi_2')(\dot{p} - c_m) + 2d\psi_1'\psi_2' \\ &\quad - a\{g(\phi_1 + \phi_2 - \phi_1\phi_2, \psi_1\psi_2) - \psi_2 g(\phi_1, \psi_1) - \psi_1 g(\phi_2, \psi_2)\}. \end{aligned}$$

Applying (4.5) to the right-hand side of this equality yields

$$\mathcal{F}_2(\overline{U},\underline{V}) \le A_2(z,p)\left\{L\exp(\omega p) + \frac{2d\psi_1'\psi_2'}{A_2(z,p)} + \frac{aB_2(z,p)}{A_2(z,p)}\right\}, \tag{4.11}$$

where $A_2(z,p)$ and $B_2(z,p)$ are defined as in (3.11) and (3.14), respectively (recall $A_2(z,p) < 0$). By Lemma 3.2 we obtain

$$\mathcal{F}_2(\overline{U},\underline{V}) \le 0 \qquad ((z,t) \in \mathbb{R}\times(-\infty,0])$$

for $L \ge 2dL_3 + aL_4$. This implies that $(\overline{U},\underline{V})$ is a supersolution. □

Proof of Theorem 1.1. We use the subsolution (4.3) with

$$q = -\frac{1}{\omega}\log\left(e^{-\omega p_0} + \frac{L}{c_m}\right)$$

and the supersolution (4.9). For this q we have

$$\lim_{t\to-\infty} |p(t) - (c_m+q)t| = 0,$$

$$\begin{cases} \underline{U}(z,t) < \overline{U}(z,t), \\ \underline{V}(z,t) < \overline{V}(z,t) \end{cases} \qquad (t<0,\ z\in\mathbb{R}),$$

and

$$\lim_{t\to-\infty}[\sup_{z\in\mathbb{R}}(\overline{U}(z,t) - \underline{U}(z,t)) + \sup_{z\in\mathbb{R}}(\overline{V}(z,t) - \underline{V}(z,t))] = 0.$$

Applying the same argument in [2] (see also [1]) with the aid of the comparison theorem yields that there is a solution $(U(z,t),V(z,t))$ satisfying

$$\begin{cases} \underline{U}(z,t) \le U(z,t) \le \overline{U}(z,t), \\ \underline{V}(z,t) \le V(z,t) \le \overline{V}(z,t) \end{cases} \qquad ((z,t)\in\mathbb{R}\times(-\infty,0]). \tag{4.12}$$

Since (1.1) (or (4.1)) has the invariance with time shift, we obtain the asymptotic behavior as $t\to-\infty$ in the statement in Theorem 1.1.

On the other hand, to prove the asymptotic behavior as $t\to\infty$ of the theorem, we recall that $\underline{U}(z,t), \overline{V}(z,t)$ in (4.3) are defined every t. By the asymptotic behavior

$$\lim_{t\to\infty}\sup_{z\in\mathbb{R}}(1-\underline{U}(z,t)) = 0, \quad \lim_{t\to\infty}\sup_{z\in\mathbb{R}}\overline{V}(z,t) = 0$$

and the fact that the solution can be continued for positive t, we obtain the desired behavior as $t\to\infty$. □

Proof of Corollary 1.2. Since the equation is invariant under phase shift and time shift, the desired result follows from Theorem 1.1. For the details of the argument, see [5]. □

Proof of Proposition 1.4. A straightforward computation yields

$$\mathcal{F}_1(u_*,v^*) = -\frac{k_1\exp(2\omega_0 t)}{(1+\Phi)^3} < 0,$$

$$\mathcal{F}_2(u_*,v^*) = \frac{a\exp(2\omega_0 t)}{(1+\Phi)^4} > 0.$$

On the other hand,

$$\begin{aligned}\mathcal{F}_1(u^*, v_*) &= \frac{\Psi}{(1+\Psi)^2}\left\{\dot{p} - \omega_0 - \frac{k_1 \exp(2p)}{\Psi(1+\Psi)}\right\} \\ &\geq \frac{\Psi}{(1+\Psi)^2}\left\{\frac{L_0 \exp(p)}{1+\exp(p)} - \frac{k_1 \exp(p)}{1+\exp(p)}\right\} \geq 0,\end{aligned}$$

$$\begin{aligned}\mathcal{F}_2(u^*, v_*) &= -\frac{2\Psi}{(1+\Psi)^3}\left\{\dot{p} - \omega_0 - \frac{a \exp(2p)}{2\Psi(1+\Psi)}\right\} \\ &\leq -\frac{2\Psi}{(1+\Psi)^3}\left\{\frac{L_0 \exp(p)}{1+\exp(p)} - \frac{a \exp(p)}{2(1+\exp(p))}\right\} \leq 0,\end{aligned}$$

where we used $\Psi(x,t) \geq \Psi(0,t) = \exp(p)$. Hence the first assertion of the proposition is true.

By integration we obtain

$$p(t) - \omega_0 t = \frac{L_0}{L_0 + \omega_0} \log\{\omega_0 + (L_0 + \omega_0)\exp(p(t))\} + q,$$

where

$$q := p_0 - \frac{L_0}{L_0 + \omega_0} \log\{\omega_0 + (L_0 + \omega_0)\exp(p_0)\}.$$

As $t \to -\infty$,

$$p(t) - \omega_0 t \to \frac{L_0}{L_0 + \omega_0} \log \omega_0 + q.$$

Hence, if we take p_0 as a solution of

$$\frac{L_0}{L_0 + \omega_0} \log \omega_0 + q = 0,$$

namely, a solution of (1.26), then

$$\lim_{t \to -\infty} (p(t) - \omega_0 t) = 0.$$

This yields

$$u_*(x,t) < u^*(x,t), \quad v_*(x,t) < v^*(x,t) \qquad ((x,t) \in \mathbb{R} \times \mathbb{R}),$$

and

$$\lim_{t \to -\infty} [\sup_{x \in \mathbb{R}}(u^*(x,t) - u_*(x,t)) + \sup_{x \in \mathbb{R}}(v^*(x,t) - v_*(x,t))] = 0.$$

The existence of the entire solution satisfying (1.25) is proven by the same argument found in [2] (see also [5] or [1]), which is left to the reader. □

Appendix. In this section we prove Lemmas 2.1, 2.2, and 2.3. We investigate the asymptotic behavior as $\xi \to \pm\infty$. For simplicity we will not specify the dependence on j in the notation as long as there is no confusion.

We put

$$(u, w, v, y) = (\phi_j(\xi), \phi_j'(\xi), \psi_j(\xi), \psi_j'(\xi)).$$

Then the equations of (1.5) are written as

$$\begin{pmatrix} u' \\ w' \\ v' \\ y' \end{pmatrix} = \begin{pmatrix} w \\ c_j w - f(u,v) \\ y \\ (c_j/d)y - (a/d)g(u,v) \end{pmatrix}, \tag{A.1}$$

where

$$f(u,v) := u(1-u-k_1 v), \qquad g(u,v) := v(1-v-k_2 u).$$

Proof of Lemma 2.1. We first consider the linearized equations of (A.1) at $(u,w,v,y) = (1,0,0,0)$:

$$\begin{pmatrix} W_1' \\ W_2' \\ Y_1' \\ Y_2' \end{pmatrix} = A_1 \begin{pmatrix} W_1 \\ W_2 \\ Y_1 \\ Y_2 \end{pmatrix}, \tag{A.2}$$

$$A_1 := \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & c_j & k_1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -(a/d)(1-k_2) & c_j/d \end{pmatrix}. \tag{A.3}$$

All the eigenvalues of A_1 consist of roots to (2.1) and (2.2). There is a negative eigenvalue satisfying (2.1) and a corresponding eigenvector, which are given by

$$\lambda_1 = -\frac{\sqrt{c_j^2+4}-c_j}{2}, \qquad \begin{pmatrix} 1 \\ \lambda_1 \\ 0 \\ 0 \end{pmatrix}. \tag{A.4}$$

We recall $k_2 > 1$. Since (2.2) has a negative root, A_1 has another negative eigenvalue and a corresponding eigenvector

$$\lambda_2^{(j)} = -\frac{\sqrt{c_j^2+4ad(k_2-1)}-c_j}{2d}, \qquad \begin{pmatrix} s_1 \\ s_1\lambda_2 \\ 1 \\ \lambda_2 \end{pmatrix}, \quad s_1 := \frac{k_1}{\lambda_2^2 - c_j\lambda_2 - 1}. \tag{A.5}$$

When $\lambda_1 = \lambda_2$, A_1 has a generalized eigenvector

$$\begin{pmatrix} 0 \\ 1 \\ \tau_1 \\ \lambda_1\tau_1 \end{pmatrix}, \quad \tau_1 := \frac{2\lambda_1 - c_j}{k_1}.$$

Thus every solution of (A.2), which converges to zeros as $\xi \to \infty$, is given by

$$\begin{pmatrix} W_1 \\ W_2 \\ Y_1 \\ Y_2 \end{pmatrix} = C_1 \begin{pmatrix} 1 \\ \lambda_1 \\ 0 \\ 0 \end{pmatrix} e^{\lambda_1\xi} + C_2 \begin{pmatrix} s_1 \\ s_1\lambda_2 \\ 1 \\ \lambda_2 \end{pmatrix} e^{\lambda_2\xi} \quad (\lambda_1 \neq \lambda_2)$$

or

$$\begin{pmatrix} W_1 \\ W_2 \\ Y_1 \\ Y_2 \end{pmatrix} = C_1 \begin{pmatrix} 1 \\ \lambda_1 \\ 0 \\ 0 \end{pmatrix} e^{\lambda_1 \xi} + C_2 \left\{ \begin{pmatrix} 1 \\ \lambda_1 \\ 0 \\ 0 \end{pmatrix} \xi + \begin{pmatrix} 0 \\ 1 \\ \tau_1 \\ \lambda_1 \tau_1 \end{pmatrix} \right\} e^{\lambda_1 \xi} \quad (\lambda_1 = \lambda_2),$$

where C_1, C_2 are arbitrarily given real numbers.

Applying the stable manifold theorem to (A.1) yields that as $\xi \to \infty$, there are α and β such that

$$\begin{cases} \phi(\xi) = 1 - \alpha \exp(\lambda_1 \xi) + \beta s_1 \exp(\lambda_2 \xi) + h.o.t., \\ \psi(\xi) = \beta \exp(\lambda_2 \xi) + h.o.t. \end{cases} \tag{A.6}$$

for $\lambda_1 \neq \lambda_2$, while there are $\tilde{\alpha}$ and $\tilde{\beta}$ such that

$$\begin{cases} \phi(\xi) = 1 - \tilde{\alpha} \exp(\lambda_1 \xi) - \tilde{\beta} \xi \exp(\lambda_1 \xi) + h.o.t., \\ \psi(\xi) = -\tilde{\beta} \tau_1 \exp(\lambda_1 \xi) + h.o.t. \end{cases} \tag{A.7}$$

for $\lambda_1 = \lambda_2$.

We show $\beta \neq 0$. Equation (A.1) allows a solution of the form $(u, w, 0, 0)$, which corresponds to a solution to

$$u' = w, \qquad w' = cw - f(u, 0) = cw - u(1 - u). \tag{A.8}$$

There is a stable manifold for the equilibrium $(u, w) = (1, 0)$ of (A.8). The stable manifold for $(u, w, v, y) = (1, 0, 0, 0)$ contains this dynamics that is obtained by putting $\beta = 0$ in (A.6). By this observation we can assert that $\beta \neq 0$ in (A.6) for the present traveling wave.

Since λ_1 is a negative root of (2.1), we notice that

$$s_1 > 0 \quad (\lambda_2 < \lambda_1 < 0), \qquad s_1 < 0 \quad (\lambda_1 < \lambda_2 < 0).$$

Recall that $\phi(\xi)$ and $\psi(\xi)$ are monotone increasing and decreasing, respectively. Thus for $\lambda_2 < \lambda_1$, $\alpha > 0$ and $\beta > 0$ follow from (A.6), while for $\lambda_1 < \lambda_2$, $\beta > 0$ follows.

When $\lambda_1 = \lambda_2$, we can let $\tilde{\beta} \neq 0$ in the same argument above. Since $\tau_1 < 0$ holds, $\tilde{\beta}$ must be positive in (A.7). This concludes the proof of the lemma. □

Next we consider the linearized equation at $(u, w, v, y) = (0, 0, 1, 0)$:

$$\boldsymbol{W}' = A_2 \boldsymbol{W}, \tag{A.9}$$

$$A_2 := \begin{pmatrix} 0 & 1 & 0 & 0 \\ k_1 - 1 & c_j & 0 & 0 \\ 0 & 0 & 0 & 1 \\ ak_2/d & 0 & a/d & c_j/d \end{pmatrix}, \qquad \boldsymbol{W} := \begin{pmatrix} W_1 \\ W_2 \\ Y_1 \\ Y_2 \end{pmatrix}. \tag{A.10}$$

In this case eigenvalues of A_2 are given by the roots of (1.9) and (1.10). We easily see from (1.9) that there is a positive eigenvalue and a corresponding eigenvector

$$\lambda_3 = \frac{c_j + \sqrt{c_j^2 + 4ad}}{2d}, \qquad \begin{pmatrix} 0 \\ 0 \\ 1 \\ \lambda_3 \end{pmatrix}. \tag{A.11}$$

Proof of Lemma 2.2. This corresponds to the bistable case (ii) stated in the introduction. In addition to the positive eigenvalue λ_3, there is a positive eigenvalue

$$\lambda_4 = \frac{c_j + \sqrt{c_j^2 + 4(k_1 - 1)}}{2}, \qquad \begin{pmatrix} 1 \\ \lambda_4 \\ s_2 \\ s_2\lambda_4 \end{pmatrix}, \quad s_2 := \frac{ak_2}{d\lambda_4^2 - c_j\lambda_4 - a} \tag{A.12}$$

unless λ_4 satisfies (1.9). When $\lambda_3 = \lambda_4$, we have a generalized eigenvector

$$\begin{pmatrix} \tau_2 \\ \tau_2\lambda_3 \\ 0 \\ 1 \end{pmatrix}, \quad \tau_2 := \frac{2d\lambda_3 - c_j}{ak_2}.$$

Hence every solution which converges to zeros as $\xi \to -\infty$ is given by

$$\boldsymbol{W}(\xi) = C_1\boldsymbol{p}_1 e^{\lambda_3\xi} + C_2\boldsymbol{p}_4 e^{\lambda_4\xi}$$

or

$$\boldsymbol{W}(\xi) = C_1\boldsymbol{p}_1 e^{\lambda_3\xi} + C_2(\boldsymbol{p}_1\xi + \boldsymbol{p}_2) e^{\lambda_3\xi},$$

where we put

$$\boldsymbol{p}_1 := \begin{pmatrix} 0 \\ 0 \\ 1 \\ \lambda_3 \end{pmatrix}, \quad \boldsymbol{p}_2 := \begin{pmatrix} \tau_2 \\ \tau_2\lambda_3 \\ 0 \\ 1 \end{pmatrix}, \quad \boldsymbol{p}_4 := \begin{pmatrix} 1 \\ \lambda_4 \\ s_2 \\ s_2\lambda_4 \end{pmatrix}.$$

Applying the unstable manifold theorem yields that as $\xi \to -\infty$, there exist α and β such that

$$\begin{cases} \phi_j(\xi) = \beta \exp(\lambda_4\xi) + h.o.t., \\ \psi_j(\xi) = 1 - \alpha \exp(\lambda_3\xi) + \beta s_2 \exp(\lambda_4\xi) + h.o.t. \end{cases} \tag{A.13}$$

for $\lambda_3 \neq \lambda_4$, while there are $\tilde{\alpha}$ and $\tilde{\beta}$ such that

$$\begin{cases} \phi_j(\xi) = \tilde{\beta}\tau_2 \exp(\lambda_3\xi) + h.o.t., \\ \psi_j(\xi) = 1 - \tilde{\alpha} \exp(\lambda_3\xi) + \tilde{\beta}\xi \exp(\lambda_3\xi) + h.o.t. \end{cases} \tag{A.14}$$

for $\lambda_3 = \lambda_4$. In this case we have an unstable manifold for the equilibrium $(v, y) = (1, 0)$ of

$$v' = y, \qquad y' = c_j y - ag(0, v),$$

which corresponds to $\beta = 0$ and $\tilde{\beta} = 0$ in (A.13) and (A.14), respectively. Thus we may assume that $\beta \neq 0$, $\tilde{\beta} \neq 0$. By a similar argument applying to the behavior as $\xi \to \infty$, we obtain the assertion in Lemma 2.2. □

Proof of Lemma 2.3. This corresponds to the monostable case (i) in the introduction. There is a family of traveling waves for $c_j \geq c_{min}^{(j)} \geq 2\sqrt{1 - k_1}$.

In addition to λ_3 and λ_4, we have a positive eigenvalue and a corresponding eigenvector,

$$\lambda_5 = \frac{c_j - \sqrt{c_j^2 - 4(1-k_1)}}{2}, \qquad \begin{pmatrix} 1 \\ \lambda_5 \\ s_3 \\ s_3\lambda_5 \end{pmatrix}, \quad s_3 := \frac{ak_2}{d\lambda_5^2 - c_j\lambda_5 - a}, \tag{A.15}$$

unless λ_5 satisfies (1.9). We note that $\lambda_5 \le \lambda_4$. If $\lambda_5 < \lambda_4$ and $\lambda_4, \lambda_5 \neq \lambda_3$, any solution converging to zeros as $\xi \to -\infty$ is given as

$$\boldsymbol{W}(\xi) = C_1\boldsymbol{p}_1 e^{\lambda_3\xi} + C_2\boldsymbol{p}_4 e^{\lambda_4\xi} + C_3\boldsymbol{p}_5 e^{\lambda_5\xi},$$

where

$$\boldsymbol{p}_5 := \begin{pmatrix} 1 \\ \lambda_5 \\ s_3 \\ s_3\lambda_5 \end{pmatrix}.$$

Applying the unstable manifold theorem, we obtain

$$\begin{cases} \phi_j(\xi) = \beta\exp(\lambda_4\xi) + \gamma\exp(\lambda_5\xi) + h.o.t., \\ \psi_j(\xi) = 1 - \alpha\exp(\lambda_3\xi) + \beta s_2\exp(\lambda_4\xi) + \gamma s_3\exp(\lambda_5\xi) + h.o.t. \end{cases}$$

By the same reason as in the previous case, we can assert $(\beta,\gamma) \neq (0,0)$. This leads to (2.12).

When $\lambda_5 = \lambda_4 < \lambda_3$, we obtain

$$\boldsymbol{W}(\xi) = C_1\boldsymbol{p}_1 e^{\lambda_3\xi} + C_2(\boldsymbol{p}_4\xi + \tilde{\boldsymbol{p}}_4)e^{\lambda_4\xi} + C_3\boldsymbol{p}_4 e^{\lambda_4\xi},$$

where

$$\tilde{\boldsymbol{p}}_4 := \begin{pmatrix} 0 \\ 1 \\ \tau_4 \\ \tau_5 \end{pmatrix}, \quad \begin{pmatrix} \tau_4 \\ \tau_5 \end{pmatrix} := \frac{s_2}{d\lambda_4^2 - c_j\lambda_4 - a}\begin{pmatrix} c_j - 2d\lambda_4 \\ -d\lambda_4^2 - a \end{pmatrix} \quad (\lambda_4 = \lambda_5 = c_j/2).$$

Applying the unstable manifold theorem to this case yields

$$\begin{cases} \phi_j(\xi) = \beta\exp(\lambda_4\xi) + \gamma\exp(\lambda_4\xi) + h.o.t., \\ \psi_j(\xi) = 1 - \alpha\exp(\lambda_3\xi) + \beta(s_2\xi + \tau_4)\exp(\lambda_4\xi) + \gamma s_2\exp(\lambda_4\xi) + h.o.t., \end{cases}$$

where we again see that $(\beta,\gamma) \neq (0,0)$. This leads to (2.14).

For the cases $\lambda_5 < \lambda_3 = \lambda_4$ and $\lambda_5 = \lambda_3 < \lambda_4$ all the solutions converging to zeros as $\xi \to -\infty$ are given by

$$\boldsymbol{W}(\xi) = C_1\boldsymbol{p}_1 e^{\lambda_3\xi} + C_2(\boldsymbol{p}_1\xi + \boldsymbol{p}_2)e^{\lambda_3\xi} + C_3\boldsymbol{p}_5 e^{\lambda_5\xi}$$

and

$$\boldsymbol{W}(\xi) = C_1\boldsymbol{p}_1 e^{\lambda_3\xi} + C_2(\boldsymbol{p}_1\xi + \boldsymbol{p}_2)e^{\lambda_3\xi} + C_3\boldsymbol{p}_4 e^{\lambda_4\xi},$$

respectively. When $\lambda_3 = \lambda_4 = \lambda_5 = c_j/2$, we obtain one more generalized eigenvector so that the solution is given by

$$\boldsymbol{W}(\xi) = C_1\boldsymbol{p}_1 e^{\lambda_3\xi} + C_2(\boldsymbol{p}_1\xi + \boldsymbol{p}_2)e^{\lambda_3\xi} + C_3(\boldsymbol{p}_1\xi^2/2 + \boldsymbol{p}_2\xi + \boldsymbol{p}_3)e^{\lambda_3\xi},$$

where

$$\boldsymbol{p}_3 := \begin{pmatrix} d/ak_2 \\ \lambda_3(3d-2)/ak_2 \\ 0 \\ 0 \end{pmatrix}.$$

By those solutions it is not so difficult to prove the remaining cases (iii), (iv), and (v) of Lemma 2.3. Completing the proof is left to the reader. □

Acknowledgments. The authors would like to express their sincere thanks to Professor Yukio Kan-on for valuable comments on the asymptotic behavior of the monotone traveling wave to the Lotka–Volterra competition-diffusion equations. Their thanks also go to the referees for the useful comments on the revision of the paper.

HIGHER ORDER APPROXIMATIONS IN THE HEAT EQUATION AND THE TRUNCATED MOMENT PROBLEM*

YONG JUNG KIM† AND WEI-MING NI‡

Abstract. In this paper, we employ linear combinations of n heat kernels to approximate solutions to the heat equation. We show that such approximations are of order $O(t^{(\frac{1}{2p}-\frac{2n+1}{2})})$ in L^p-norm, $1 \le p \le \infty$, as $t \to \infty$. For positive solutions of the heat equation such approximations are achieved using the theory of truncated moment problems. For general sign-changing solutions these type of approximations are obtained by simply adding an auxiliary heat kernel. Furthermore, inspired by numerical computations, we conjecture that such approximations converge geometrically as $n \to \infty$ for any fixed $t > 0$.

Key words. heat equation, moments, asymptotics convergence rates, approximation of an integral formula, heat kernel

1. Introduction.

It is well known that

$$u(x,t) = \int \frac{u_0(c)}{\sqrt{4\pi t}}\, e^{\frac{-(x-c)^2}{4t}}\, dc \tag{1.1}$$

is the physically meaningful solution to the heat equation

$$u_t = u_{xx}, \quad u(x,0) = u_0(x) \in L^1(\boldsymbol{R}), \qquad x, u \in \boldsymbol{R}, \quad t > 0, \tag{1.2}$$

where, for simplicity, the initial value $u_0(x)$ is assumed to be continuous. In this paper, we shall refer to (1.1) as the solution of the heat equation (1.2) for the sake of brevity. If a general L^1 initial value is considered, no asymptotic convergence order to a fundamental solution is expected in L^1-norm. Hence, the asymptotic convergence order is usually studied under suitable restrictions on its initial value $u_0(x)$ for $|x|$ large.

Since the analysis of this paper is based on the *moments* of the solution, the initial value $u_0(x)$ is required to have finite moments up to certain order, say, $2n$. We set $x^{2n}u_0(x) \in L^1(\boldsymbol{R})$ and the moments of the initial value $u_0(x)$ as

$$\gamma_k := \int x^k u_0(x)dx < \infty, \qquad k = 0, 1, \ldots, 2n. \tag{1.3}$$

For example, if the initial value has an algebraic decay order higher than $2n+1$ for $|x|$ large, i.e., for $\varepsilon > 0$,

$$u_0(x) = O\left(|x|^{-(2n+1+\varepsilon)}\right) \quad \text{as} \quad |x| \to \infty, \tag{1.4}$$

then the moments are well defined up to order $2n$. In the study of asymptotics the initial value is frequently assumed to have the order that a fundamental solution has for $|x|$ large. For the heat equation case the fundamental solution is the Gaussian and the corresponding decay order is $u_0(x) = O(e^{-x^2})$ as $|x| \to \infty$. Hence, the moment γ_k is defined for all order $k \geq 0$.

One may do the integration in the explicit formula (1.1) only approximately, even though the integration gives the exact value of the solution. In numerical computations finding an efficient way to compute such an integration has been an important issue. From this point of view, it seems useful to consider its approximation in a simpler form. Duoandikoetxea and Zuazua [9] showed that the following linear combination of derivatives of the Gaussian

$$\psi_{2n}(x,t) \equiv \sum_{i=0}^{2n-1} \frac{(-1)^i \gamma_i}{(i!)\sqrt{4\pi t}}\, \partial_x^i \left(e^{\frac{-x^2}{4t}} \right) \tag{1.5}$$

approaches to the solution u with a convergence order of

$$\|u(t) - \psi_{2n}(t)\|_p = O\left(t^{\left(\frac{1}{2p} - \frac{2n+1}{2}\right)} \right) \quad \text{as} \quad t \to \infty \ \text{ for } \ 1 \leq p \leq \infty, \tag{1.6}$$

where $\|\cdot\|_p$ denotes the L^p-norm in the whole space $\boldsymbol{R}$ and ∂_x^i the ith order partial differentiation with respect to x. Note that the original multidimensional result is written in a one-dimensional (1D) version for an easier comparison. This asymptotic convergence order indicates that ψ_{2n} is a good approximation of the solution $u(x,t)$ for t large. However, it does not necessarily mean that ψ_{2n} is a good approximation as $n \to \infty$ with a fixed $t > 0$. In fact, Table 7.3 shows that this L^p-norm difference may diverge geometrically as $n \to \infty$ if the fixed time $t > 0$ is not large enough. This is not surprising since the high order derivatives of the Gaussian in (1.5) diverge as their orders increase.

In this article we consider a linear combination of "n" heat kernels

$$\phi_n(x,t) \equiv \sum_{i=1}^{n} \frac{\rho_i}{\sqrt{4\pi t}}\, e^{\frac{-(x-c_i)^2}{4t}} \tag{1.7}$$

as an approximation to the solution $u(x,t)$. One may regard this summation as a discrete version of the integration in (1.1) by considering c_i's as grid points and ρ_i's as approximations of $u_0(c)dc$ in the interval (c_{i-1}, c_i). However, we employ these $2n$ degrees of freedom, ρ_i's and c_i's, to match the first $2n$ initial moments, i.e., to satisfy the following $2n$ moment equations:

$$\lim_{t \to 0} \int x^k \phi_n(x,t)dx = \gamma_k, \qquad k = 0, 1, \ldots, 2n-1. \tag{1.8}$$

If the initial value is positive, the theory of truncated moment problems [3] gives the solvability of this problem. Then ϕ_n and u share identical first $2n$ moments for all $t \geq 0$. Note that ψ_{2n} in (1.5) also has the same property, and Duoandikoetxea and Zuazua obtained the convergence order in (1.6) based on it. Hence, we may obtain the same convergence order for the approximation $\phi_n(x,t)$. In this paper, we actually go a little bit further and obtain the limit of $t^{\frac{2n+1}{2} - \frac{1}{2p}} \|u(t) - \phi_n(t)\|_p$ as $t \to \infty$. This convergence order is then improved in Lemma 2.3 for the case that this limit becomes zero. A multidimensional extension of this approach requires a theory of

multidimensional truncated moment problems. One may find one from a recent work by Curto and Fialkow [4].

From a practical point of view, it is desirable if the solution u can be approximated by ϕ_n as $n \to \infty$ for a fixed $t > 0$. Indeed, our numerical examples in section 7.2 indicate the following geometric convergence order:

$$\frac{\|u(t) - \phi_n(t)\|_\infty}{\|u(t) - \phi_{n+1}(t)\|_\infty} \to 1 + 4\frac{t}{v} \quad \text{as} \quad n \to \infty, \tag{1.9}$$

where the constant $v > 0$ depends on the initial value $u_0(x)$. However, its proof has, thus far, eluded us; nevertheless, we will include a discussion of (1.9) in section 6.

This paper is organized as follows. First, in section 2, we compute the limit of $t^{(\frac{2n+1}{2}-\frac{1}{2p})}\|u(t) - \phi_n(t)\|_p$ as $t \to \infty$ under the assumption (1.8), which gives the convergence order in (1.6). A short introduction to the theory of truncated moment problems is given in section 3, which provides the existence and the uniqueness of ρ_i's and c_i's that solve (1.8). We remark that the theory is applicable for nonnegative initial values only (see [1, 3]). For general sign-changing solutions the existence and the uniqueness of such ρ_i's and c_i's do not hold. In section 4 we discuss this issue in detail for three cases with $n = 1, 2$, and 3. In section 5 we construct approximations for general sign-changing cases by adding an auxiliary heat kernel or by assigning c_i's independently. The conjectured geometric convergence order for large $n > 0$ is discussed in section 6. The asymptotic convergence orders as $t \to \infty$ or $n \to \infty$ are numerically tested in sections 7.1 and 7.2. The convergence of the alternative approach using ψ_{2n} and the conjectured statements in section 6 are numerically tested in sections 7.3 and 7.4.

In the study of nonlinear diffusion or convection, fundamental solutions which have the Dirac measure as their initial value, i.e., $u_0(x) = \delta(x)$, often serve as canonical solutions. The Barenblatt solutions, the diffusion waves, and the N-waves are well-known examples (see [23]). In the study of porous medium equations, the Barenblatt solution is used as an asymptotic profile and the convergence order of general solutions to this special one has been studied in various cases (see [2, 6] and references therein). The diffusion wave and the Gaussian are the asymptotics of convection-diffusion equations for diffusion dominant cases (see [10, 11, 12, 16]). For convection dominant cases (see [14]) and inviscid convection equations (see [5, 8, 13, 20]) or hyperbolic systems (see [7, 17, 18]), N-waves represent the asymptotic behavior, where N-waves can be understood as a special solution with initial value $u_0(x) = \lim_{\varepsilon\to 0}[a\delta(x-\varepsilon) - b\delta(x+\varepsilon)]$ with $a, b > 0$. Placing the Dirac measure at the center of mass, the optimal convergence order of $O(t^{\frac{1}{2p}-\frac{3}{2}})$ in L^p-norm (or of $O(t^{-1})$ in L^1-norm) has been obtained in several cases (see [2, 13, 15]). Therefore, the result of this paper can be viewed as an extreme case that exploits all of the moments of the initial value.

The approach in this paper can be directly employed to approximate the solutions to the Burgers equation via the Cole–Hopf transformation. To obtain the rigorous convergence order for the Burgers case it is required to check the well definedness of the transformed solutions as is done in Lemmas 3.1–3.2 and Theorem 3.3 in [15] for the special case $n = 1$. Considering that the Burgers equation has been used as a tool to study the asymptotic structure of the viscous systems of conservation laws (see, e.g., [19]), we hope the approach in this article may be useful for other general models.

2. Asymptotic convergence order. In this section, we show that the decay rate of a derivative of a solution is naturally transferred to the convergence order

of our approximation. This connection will be made by assigning the moments of a solution to its approximation. Let $\gamma_k(t)$ be the kth order moment of a solution $u(x,t)$ at time $t \geq 0$, i.e.,

$$\gamma_k(t) = \int x^k u(x,t)dx, \qquad k = 0, 1, 2, \ldots, t \geq 0.$$

(Notice that we are slightly abusing the notation γ_k in (1.3) in the following couple of paragraphs.) We can easily show how the moment $\gamma_k(t)$ evolves as $t \to \infty$.

LEMMA 2.1. *Let $u(x,t)$ be the solution to the heat equation and $\gamma_k(t)$ be its kth order moment at time $t \geq 0$. Then*

$$\frac{d}{dt}\gamma_k(t) = \begin{cases} 0\ , & k = 0 \text{ or } 1, \\ k(k-1)\gamma_{k-2}(t), & k \geq 2. \end{cases}$$

Proof. For $k = 0$, the lemma is equivalent to the conservation of mass. For $k = 1$, since $u_t = u_{xx}$, the integration by parts gives

$$\gamma_1'(t) = \int x u_t dx = \int x u_{xx} dx = [x u_x - u]_{-\infty}^{\infty} = 0.$$

Similarly, for $k \geq 2$, we obtain

$$\begin{aligned} \gamma_k'(t) &= \int x^k u_t dx = \int x^k u_{xx} dx \\ &= \left[x^k u_x - k x^{k-1} u\right]_{-\infty}^{\infty} + \int k(k-1)x^{k-2} u dx = k(k-1)\gamma_{k-2}(t). \end{aligned}$$ ∎

This lemma shows that even numbered moments and odd numbered ones evolve independently. One may explicitly write

$$\begin{aligned} \gamma_{2n}(t) &= \sum_{k=0}^{n} \frac{(2n)!}{(n-k)!(2k)!} t^{n-k} \gamma_{2k}(0), \\ \gamma_{2n+1}(t) &= \sum_{k=0}^{n} \frac{(2n+1)!}{(n-k)!(2k+1)!} t^{n-k} \gamma_{2k+1}(0). \end{aligned} \tag{2.1}$$

If $\gamma_k(0) = 0$ for all $0 \leq k \leq n$, then $\gamma_k(t) = 0$ for all $0 \leq k \leq n$, $\gamma_k(t) = \gamma_k(0)$ for $k = n+1, n+2$, $\gamma_k(t)$ is linear for $k = n+3, n+4$, $\gamma_k(t)$ is quadratic for $k = n+5, n+6$, and so on.

Let $v(x,t)$ be an approximation solution of the exact one $u(x,t)$. Since the difference $E(x,t) = v(x,t) - u(x,t)$ is also a solution to the heat equation, the moments of $E(x,t)$ will be always zero up to certain order if they are initially zero. Hence, it is natural to expect a higher convergence order by matching the moments of the approximation solution to those of the exact one. We proceed with our discussion in this respect.

LEMMA 2.2. *If $x^m E_0(x) \in L^1(\boldsymbol{R})$ and*

$$\int_{-\infty}^{\infty} x^k E_0(x)dx = 0 \quad \textit{for all} \quad 0 \leq k < m, \tag{2.2}$$

then there exists $E_m \in W^{m,1}(\boldsymbol{R})$ such that

$$\partial_x^m E_m(x) = E_0(x). \tag{2.3}$$

Proof. The proof was given by Duoandikoetxea and Zuazua [9] for the multidimensional case. Here we provide its 1D counterpart. Consider a sequence of functions defined inductively by

$$E_k(x) = \int_{-\infty}^{x} E_{k-1}(y)dy, \quad 0 < k \le m. \tag{2.4}$$

First, we show that E_k's are well defined,

$$\int_{-\infty}^{\infty} E_k(x)dx = 0 \qquad \text{and} \qquad E_k(x) \to 0 \ \text{ as } |x| \to \infty \tag{2.5}$$

for $k = 0, 1, \dots, m-1$. It suffices to show (2.5) for $k = l < m$ under the assumption that (2.5) holds for all $k = 0, 1, \dots, l-1$. Note that it is clearly satisfied for $k = 0$. Since $\int_{-\infty}^{\infty} E_{l-1}(x)dx = 0$, the integral $E_l(x)$ also decays to zero as $|x| \to \infty$. Using the fact that E_k decays to zero as $|x| \to \infty$ for all $0 \le k \le l$, we obtain

$$\int_{-\infty}^{\infty} E_l(x)dx = (-1)^l \int_{-\infty}^{\infty} \frac{x^l}{l!} E_0(x)dx = 0$$

using the integration by parts and then (2.2). Therefore, (2.5) holds for $k = l$ and, hence, for all $0 \le k \le m-1$. Since $x^m E_0(x) \in L^1(\boldsymbol{R})$, $E_m \in W^{m,1}(\boldsymbol{R})$ and (2.3) is satisfied. ∎

The existence of E_m satisfying (2.3) is the key observation to obtain the asymptotic convergence order. We now continue our discussion under the assumption that the initial value $E_0(x)$ satisfies (2.2) and $E_m(x)$ is its mth order antiderivative given in Lemma 2.2. However, the following discussions about the decay rate of derivatives of a solution can be considered independently. Let $E_m(x,t)$ be the solution to the heat equation with initial value $E_m(x,0) = E_m(x) \in W^{m,1}(\boldsymbol{R})$, i.e.,

$$E_m(x,t) = \frac{1}{\sqrt{4\pi t}} \int e^{-(x-y)^2/(4t)} E_m(y)dy.$$

The dissipation of the solution can be easily shown by introducing similarity variables:

$$\xi = \frac{x}{\sqrt{t}}, \quad \zeta = \frac{y}{\sqrt{t}}, \quad \tilde{E}_m(\xi, t) = E_m(x,t).$$

Then $E_m(x,t)$ is transformed to

$$\tilde{E}_m(\xi,t) = \frac{1}{\sqrt{4\pi}} \int e^{-(\xi-\zeta)^2/4} E_m(\sqrt{t}\zeta)d\zeta,$$

and its mth order derivative is given by

$$\partial_\xi^m \tilde{E}_m(\xi,t) = \partial_x^m E_m(x,t)(\partial_\xi x)^m = \partial_x^m E_m(x,t)\big(\sqrt{t}\big)^m.$$

Now consider the decay order of the mth order derivative of the solution $E_m(x,t)$. First, let $C_m := |\int E_m(y)dy|$ and consider the case $C_m \neq 0$. Then

$$\big(\sqrt{t}\big)^{m+1} |\partial_x^m E_m(x,t)| = \sqrt{t}\left|\partial_\xi^m \tilde{E}_m(\xi,t)\right| = \frac{C_m}{\sqrt{4\pi}}\left|\int f(\zeta) g_t(\xi-\zeta)d\zeta\right|, \tag{2.6}$$

where

$$g_t(\xi) = \sqrt{t}E_m\big(\sqrt{t}\xi\big)/C_m, \ f(\xi) = \partial_\xi^m\left(e^{-\xi^2/4}\right). \tag{2.7}$$

After taking the supremum on both sides of (2.6), one obtains that

$$\left(\sqrt{t}\right)^{m+1}\|\partial_x^m E_m(t)\|_\infty \le \frac{C_m}{\sqrt{4\pi}}\left\|\partial_\xi^m\left(e^{-\xi^2/4}\right)\right\|_\infty.$$

If one takes $t\to\infty$ limit to (2.6), then

$$\lim_{t\to\infty}\left(\sqrt{t}\right)^{m+1}|\partial_x^m E_m(x,t)| = \frac{C_m}{\sqrt{4\pi}}|f(\xi)|.$$

Therefore, after taking the supremum on both sides again, we obtain

$$\lim_{t\to\infty}\left(\sqrt{t}\right)^{m+1}\|\partial_x^m E_m(t)\|_\infty = \frac{C_m}{\sqrt{4\pi}}\left\|\partial_\xi^m\left(e^{-\xi^2/4}\right)\right\|_\infty.$$

On the other hand, if $1\le p<\infty$, then

$$\begin{aligned} t^{\left(\frac{m+1}{2}-\frac{1}{2p}\right)}\ &\|\partial_x^m E_m(t)\|_p \\ &= \left(\sqrt{t}\right)^{m+1}\left(\frac{1}{\sqrt{t}}\right)^{1/p}\left(\int|\partial_x^m E_m(x,t)|^p dx\right)^{1/p} \\ &= \left(\int\left|\left(\sqrt{t}\right)^{m+1}\partial_x^m E_m(x,t)\right|^p d\left(\frac{x}{\sqrt{t}}\right)\right)^{1/p} \\ &= \left(\int\left|\sqrt{t}\partial_\xi^m\tilde{E}_m(\xi,t)\right|^p d\xi\right)^{1/p} \\ &= \frac{C_m}{\sqrt{4\pi}}\left(\int\left|\int f(\zeta)g_t(\xi-\zeta)d\zeta\right|^p d\xi\right)^{1/p} = \frac{C_m}{\sqrt{4\pi}}\|f*g_t\|_p. \end{aligned} \tag{2.8}$$

Standard arguments imply that $\|f*g_t\|_p\to\|f\|_p$ as $t\to\infty$ (see [21, p. 62]). Therefore,

$$\lim_{t\to\infty} t^{\left(\frac{m+1}{2}-\frac{1}{2p}\right)}\|\partial_x^m E_m(t)\|_p = \frac{C_m}{\sqrt{4\pi}}\left\|\partial_\xi^m\left(e^{-\xi^2/4}\right)\right\|_p.$$

Now we consider the case that $C_m=0$. Then one can easily show that this limit is zero. In fact, we will improve the convergence order by working with higher order antiderivatives. Let

$$E_k(x) = \int_{-\infty}^x E_{k-1}(y)dy, \qquad k>m. \tag{2.9}$$

We can easily show that $\int_{-\infty}^\infty E_{k_0}(x)dx(=\lim_{x\to\infty}E_{k_0+1}(x))\neq 0$ for some $k_0>m$. Suppose that $\int_{-\infty}^\infty E_k(x)dx=0$ for all $k>m$. Then $|E_k(x)|$ decays to zero for $|x|$ large, and, therefore, after integrating by parts k times with proper inductive arguments, one obtains

$$(-1)^k k!\int_{-\infty}^\infty E_k(x)dx = \int_{-\infty}^\infty x^k E_0(x)dx = 0.$$

On the other hand, by the Weierstrass approximation theorem, there exists a sequence of polynomials P_n such that

$$P_n(x)\to E_0(x) \qquad \text{as} \qquad n\to\infty$$

uniformly on any bounded domain $[-L, L]$. Therefore, we obtain

$$\|E_0\|_2^2 = \int_{-L}^{L} E_0^2(x)dx = \lim_{n\to\infty} \int_{-L}^{L} P_n(x)E_0(x)dx = 0.$$

Hence, if the initial value E_0 is not a trivial one, there exists $k_0 > m$ such that $\lim_{x\to\infty} E_k(x) = 0$ for all $0 \le k \le k_0$ and $C_{k_0} := |\lim_{x\to\infty} E_{k_0+1}(x)| \neq 0$. If $E_0(x)$ decays with an algebraic order $k_0+1+\varepsilon$, $\varepsilon > 0$, for $|x|$ large, then $C_{k_0} < \infty$. However, C_{k_0} can be unbounded in general.

Let $E_{k_0}(x,t)$ be the solution with $E_{k_0}(x)$ as its initial value. Then, clearly, $\partial_x^m E_m = \partial_x^{k_0} E_{k_0} = E_0$ and, hence,

$$\lim_{t\to\infty} t^{\left(\frac{k_0+1}{2}-\frac{1}{2p}\right)} \|\partial_x^m E_m\|_p = \lim_{t\to\infty} t^{\left(\frac{k_0+1}{2}-\frac{1}{2p}\right)} \left\|\partial_x^{k_0} E_{k_0}\right\|_p = \frac{C_{k_0}}{\sqrt{4\pi}} \left\|\partial_\xi^{k_0} e^{\frac{-\xi^2}{4}}\right\|_p .$$

Therefore, if $C_m := |\int E_m(y)dy| = 0$, one obtains a higher decay order. Summing up, we obtain the following lemma.

LEMMA 2.3. *Let $E_m(x,t)$ be the solution to the heat equation with a nontrivial initial value $E_m(x) \in W^{m,1}(\boldsymbol{R})$ and E_k's be given inductively by* (2.9). *Then there exists $k_0 \ge m$ such that $\lim_{x\to\infty} E_k(x) = 0$ for $0 \le k \le k_0$ and $0 \neq |\lim_{x\to\infty} E_{k_0+1}(x)|$, and, for $m \le k \le k_0$,*

$$\lim_{t\to\infty} t^{\left(\frac{k+1}{2}-\frac{1}{2p}\right)} \|\partial_x^m E_m(t)\|_p = \frac{\left\|\partial_\xi^k e^{-\xi^2/4}\right\|_p}{\sqrt{4\pi}} \left|\int E_k(x)dx\right| , \ 1 \le p \le \infty. \tag{2.10}$$

If $\int E_m(x)dx = 0$, then the limit in (2.10) implies that $\lim_{t\to\infty} t^{\left(\frac{m+1}{2}-\frac{1}{2p}\right)} \|\partial_x^m E_m\|_p = 0$. Hence, we may simply say that

$$\lim_{t\to\infty} t^{\left(\frac{m+1}{2}-\frac{1}{2p}\right)} \|\partial_x^m E_m(t)\|_p = \frac{\left\|\partial_\xi^m \left(e^{-\xi^2/4}\right)\right\|_p}{\sqrt{4\pi}} \left|\int E_m(x)dx\right| , \quad 1 \le p \le \infty, \tag{2.11}$$

which is a weaker statement than (2.10) is. Note that one may obtain the upper bound of the term $t^{\left(\frac{m+1}{2}-\frac{1}{2p}\right)} \|\partial_x^m E_m(t)\|_p$ using Young's inequality. In fact, the corresponding upper bound for the estimate ψ_{2n} was obtained in [9].

In the following, we take the convergence order in (2.11) for simplicity. If an optimal convergence order is concerned and $\int E_m(x)dx = 0$, then one may refer to (2.10). It is well known that an L^1 solution to the heat equation decays to zero with order $O(t^{-1/2})$. Lemma 2.3 says that the decay order of its derivative is increased by $\frac{1}{2}$ after each differentiation. The asymptotic convergence order between two solutions is now obtained as a corollary of previous lemmas.

THEOREM 2.4. *Let $u(x,t)$ and $v(x,t)$ be solutions of the heat equation with initial values $u_0(x)$ and $v_0(x)$, respectively. Suppose that the initial difference $E_0(x) := u_0(x) - v_0(x)$ satisfies the assumptions in Lemma* 2.2. *Then, for $1 \le p \le \infty$,*

$$\lim_{t\to\infty} t^{\left(\frac{m+1}{2}-\frac{1}{2p}\right)} \|u(t) - v(t)\|_p = \frac{\left\|\partial_\xi^m \left(e^{-\frac{1}{4}\xi^2}\right)\right\|_p}{\sqrt{4\pi}} \left|\int E_m(x)dx\right| , \tag{2.12}$$

where $E_m \in W^{m,1}(\boldsymbol{R})$ is the one that satisfies $\partial_x^m E_m(x) = E_0(x)$.

Proof. Let $E_m(x,t)$ be the solution to the heat equation with initial value $E_m(x)$. Then $\partial_x^m E_m(x,t)$ is the solution to the heat equation with initial value $\partial_x^m E_m(x) = E_0(x)$. Hence, $\partial_x^m E_m(x,t)(= E(x,t)) = u(x,t) - v(x,t)$ and (2.12) follows from (2.11). □

Remark 2.5. In this section, we basically considered the convergence order of $\phi_n(x,t)$ ($\cong v(x,t)$) to $u(x,t)$ as $t \to \infty$ with a fixed $n > 0$. However, the relation (2.6), for example, provides certain convergence information as $n \to \infty$ with a fixed $t > 0$, too. To obtain a convergence order as $n \to \infty$ we need to specify $E_m(x)$ corresponding to our approximation $\phi_n(x,t)$, which will be considered in section 6.

3. Positive solutions and truncated moment problems. Consider a linear combination of heat kernels

$$\phi_n(x,t) := \sum_{i=1}^{n} \frac{\rho_i}{\sqrt{4\pi t}}\, e^{-(x-c_i)^2/(4t)}. \tag{3.1}$$

The $2n$ freedom of choices in ρ_i's and c_i's are used to control the first $2n$ moments of the approximation. Remember that γ_k is to denote the initial kth moment, i.e.,

$$\gamma_k := \int x^k u_0(x) dx, \qquad k = 0, 1, \ldots, 2n-1. \tag{3.2}$$

Let $\mathbf{r}_k$ be a column n-vector and $\mathbf{A}$ be the $n \times n$ Hankel matrix given by

$$\begin{array}{ll} \mathbf{r}_k = (\gamma_k, \gamma_{k+1}, \ldots, \gamma_{k+n-1})^t, & k = 0, 1, \ldots, n, \\ \mathbf{A} \equiv (a_{ij}) = (\gamma_{i+j}), & i, j = 0, 1, \ldots, n-1. \end{array} \tag{3.3}$$

Since $\phi_n(x,t) \to \sum_{i=1}^n \rho_i \delta_{c_i}(x)$ as $t \to 0$, the difference between the initial value and its approximation is

$$E_0(x) := u_0(x) - \sum_{i=1}^{n} \rho_i \delta_{c_i}(x),$$

where $\delta_{c_i}(x)$ is the Dirac measure centered at c_i, i.e., $\delta_{c_i}(x) = \delta(x - c_i)$. Hence, the zero moment conditions in (2.2) can be written as

$$\int \sum_{i=1}^{n} x^k \rho_i \delta_{c_i}(x)\, dx = \int x^k u_0(x)\, dx (\equiv \gamma_k), \qquad 0 \le k \le 2n-1, \tag{3.4}$$

or, in a matrix form, as

$$\begin{pmatrix} 1 & \cdots & 1 \\ c_1 & \cdots & c_n \\ \cdot & \cdots & \cdot \\ \cdot & \cdots & \cdot \\ \cdot & \cdots & \cdot \\ c_1^{2n-1} & \cdots & c_n^{2n-1} \end{pmatrix} \begin{pmatrix} \rho_1 \\ \cdot \\ \cdot \\ \rho_n \end{pmatrix} = \begin{pmatrix} \gamma_0 \\ \gamma_1 \\ \cdot \\ \cdot \\ \cdot \\ \gamma_{2n-1} \end{pmatrix}. \tag{3.5}$$

After eliminating all ρ_i's (see section 4.3), one may obtain n-equations involving c_i's only:

$$\mathbf{A}\Psi = \mathbf{r}_n, \tag{3.6}$$

where the column vector $\Psi = (\psi_0, \ldots, \psi_{n-1})^t$ is given by

$$\psi_0 = (-1)^{n+1} \prod_{i=1}^{n} c_i, \quad \psi_1 = (-1)^n \sum_{j=1}^{n} \prod_{i \neq j} c_i, \ldots, \psi_{n-1} = \sum_{i=1}^{n} c_i. \tag{3.7}$$

Consequently, we set

$$g_n(x) := x^n - \sum_{j=0}^{n-1} \psi_j x^j = (x - c_1)(x - c_2) \cdots (x - c_n). \tag{3.8}$$

(Note that the coefficient of the leading order term is 1 and, hence, $g_n(x) \to \infty$ as $x \to \infty$.) Hence, if the initial moments in (3.4) are satisfied, then c_i's are zero points of the polynomial $g_n(x)$, where its coefficients are given as a solution of (3.6).

To show the existence and the uniqueness of the approximation we should show that the Hankel matrix in (3.6) is nonsingular. Then there exists a unique column vector $\Psi = (\psi_0, \ldots, \psi_{n-1})^t$ that satisfies (3.6). The next thing to show is that the polynomial $g_n(x)$ in (3.8) has n distinct real zeros $c_1 < \cdots < c_n$. Then ρ_i's are given by solving the Vandermonde given by the first n-equations in (3.5), i.e.,

$$\begin{pmatrix} 1 & 1 & \cdots & 1 \\ c_1 & c_2 & \cdots & c_n \\ \cdot & \cdot & \cdots & \cdot \\ \cdot & \cdot & \cdots & \cdot \\ \cdot & \cdot & \cdots & \cdot \\ c_1^{n-1} & c_2^{n-1} & \cdots & c_n^{n-1} \end{pmatrix} \begin{pmatrix} \rho_1 \\ \rho_2 \\ \cdot \\ \cdot \\ \cdot \\ \rho_n \end{pmatrix} = \begin{pmatrix} \gamma_0 \\ \gamma_1 \\ \cdot \\ \cdot \\ \cdot \\ \gamma_{n-1} \end{pmatrix}. \tag{3.9}$$

It is well known that the Vandermonde matrix is nonsingular if c_i's are all different. Then we can easily check that c_i's and ρ_i's also satisfy the last n-equations in (3.5).

For a general sign-changing initial value $u_0(x)$ the Hankel matrix $\mathbf{A}$ can be singular, and examples are given in section 4. However, if the initial value $u_0(x)$ is nonnegative, then the uniqueness and the existence are resolved by the theory for the moment problem (see [1, 3]). In the following, we assume $u_0(x) \geq 0$ and introduce this technique briefly for the completeness and the later use in this paper. Consider

$$\Psi^t \mathbf{A} \Psi = \sum_{i,j=0}^{n-1} \psi_i \psi_j \gamma_{i+j} = \int \sum_{i,j=0}^{n-1} \psi_i x^i \psi_j x^j u_0(x) dx = \int \left(\sum_{k=0}^{n-1} \psi_k x^k \right)^2 u_0(x) dx.$$

Since the integrand $(\sum_{k=0}^{n-1} \psi_k x^k)^2 u_0(x)$ is nonnegative, we have $\Psi^t \mathbf{A} \Psi \geq 0$. Furthermore, $\Psi^t \mathbf{A} \Psi = 0$ if and only if $(\sum_{k=0}^{n-1} \psi_k x^k)^2 u_0(x) = 0$ for all $x \in \boldsymbol{R}$. For $\Psi \neq 0$, the polynomial $\sum_{k=0}^{n-1} \psi_k x^k$ has at most $n-1$ zeros and, therefore, $\Psi^t \mathbf{A} \Psi > 0$ if the support of the initial value u_0 consists of at least n points. Hence, we may conclude that the Hankel matrix $\mathbf{A} \equiv (\gamma_{i+j})_{i,j=0}^{n-1}$ is nonsingular. (The proof is originally done by Hamburger.)

To show that $g_n(x)$ has n-distinct real zeros, consider a linear functional S on the space of polynomials defined by

$$S(r) := \sum_{i=0}^{l} r_i \gamma_i = r_0 \gamma_0 + \cdots + r_l \gamma_l \quad \text{for} \quad r(x) = \sum_{i=0}^{l} r_i x^i.$$

Then, the same statements used for the positivity of $\Psi^t \mathbf{A} \Psi$ also show that

$$S(r^2) = S\left(\sum_{i,j=0}^{l} r_i r_j x^{i+j} \right) = \sum_{i,j=0}^{l} r_i r_j \gamma_{i+j} > 0.$$

Suppose that $r(x) \geq 0$. Then the degree of the polynomial $r(x)$ is even and there exist two polynomials p, q such that $r(x) = p^2(x) + q^2(x)$ (see [1, p. 2]). So $S(r) = S(p^2) + S(q^2) > 0$.

Since $\mathbf{A}$ is nonsingular, there exists an n-vector $\Psi = (\psi_0, \ldots, \psi_{n-1})$ uniquely so that $\mathbf{A}\Psi = \mathbf{r}_n$, i.e.,

$$\sum_{j=0}^{n-1} \psi_j \mathbf{r}_j = \mathbf{r}_n$$

or

$$\gamma_{n+k} - \sum_{j=0}^{n-1} \psi_j \gamma_{j+k} = 0, \quad k = 0, 1, \ldots, n-1. \tag{3.10}$$

Considering the polynomial $g_n(x)$ and the definition of the functional $S(r)$, we can easily check that (3.10) implies

$$S\left(g_n x^k\right) = 0, \qquad k = 0, 1, \ldots, n-1. \tag{3.11}$$

Suppose that $g_n(x)$ never changes its sign. Then $g_n(x) \geq 0$ and, hence, $S(g_n) > 0$, which contradicts (3.11) with $k = 0$. Suppose that $g_n(x)$ changes its sign at points $c_1, \ldots, c_l$ only. Then $g_n(x)(x - c_1) \cdots (x - c_l) \geq 0$ and $S(g_n(x)(x - c_1) \cdots (x - c_l)) > 0$. On the other hand, if $l < n$, then the linearity of the functional $S(r)$ together with (3.11) implies that $S(g_n(x)(x - c_1) \cdots (x - c_l)) = 0$. Hence, we obtain that $g_n(x)$ has n-distinct real roots, say, $c_1 < \cdots < c_n$.

Now we show that there exist ρ_i's that solve (3.5) in a unique way, i.e.,

$$\sum_{i=1}^{n} \rho_i c_i^l = \gamma_l, \quad l = 0, 1, \ldots, 2n-1. \tag{3.12}$$

Since c_i's are all different, there exists a unique solution for the Vandermonde (3.9); i.e., (3.12) is satisfied for all $0 \leq l < n$. Now we complete the proof using inductive arguments. Let $0 \leq k \leq n-1$. We will show that the identity in (3.12) holds for $l = n + k$ under the assumption that it holds for all $0 \leq l < n + k$. First, observe that, since c_i's are zero points of $x^k g_n(x), k \geq 0$,

$$c_i^{n+k} = \sum_{j=0}^{n-1} \psi_j c_i^{j+k} \qquad \text{for any} \quad 1 \leq i \leq n,\ k \geq 0.$$

Using the relations (3.10) and (3.12) for $l < n + k$, we obtain

$$\gamma_{n+k} = \sum_{j=0}^{n-1} \psi_j \gamma_{j+k} = \sum_{j=0}^{n-1} \psi_j \sum_{i=1}^{n} \rho_i c_i^{j+k} = \sum_{i=1}^{n} \rho_i \sum_{j=0}^{n-1} \psi_j c_i^{j+k} = \sum_{i=1}^{n} \rho_i c_i^{n+k}.$$

Hence, (3.12) holds by the induction.

In summary, the proof of the existence and the uniqueness of the solution to the problem (3.5) consists of three steps. The invertibility of the Hankel matrix $\mathbf{A}$ in (3.6) and the existence of n-distinct real roots c_i's of g_n are the first two. The latter depends on the positive definiteness of the matrix $\mathbf{A}$ which is easily proved for positive initial value $u_0(x)$. On the other hand, after obtaining c_i's, finding ρ_i's that satisfy (3.5) does not require the positivity. It depends only on the recursive structure of the problem. The following theorem is now clear from Theorem 2.4.

THEOREM 3.1. *Let $u(x,t)$ be the solution to the heat equation with initial value $u_0(x)$. If $u_0(x)$ is nonnegative (or nonpositive) and $x^{2n}u_0(x) \in L^1(\boldsymbol{R})$, then there exist $\rho_i, c_i, i = 1, \ldots, n$, such that, for $\phi_n(x,t) \equiv \sum_{i=1}^n \frac{\rho_i}{\sqrt{4\pi t}}\, e^{-(x-c_i)^2/(4t)}$,*

$$\lim_{t\to\infty} t^{\frac{2n+1}{2}-\frac{1}{2p}} \|u(t) - \phi_n(t)\|_p = \frac{\left\|\partial_\xi^{2n}\left(e^{-\frac{1}{4}\xi^2}\right)\right\|_p}{\sqrt{4\pi}} \left|\int E_{2n}(x)dx\right|, \tag{3.13}$$

where $1 \le p \le \infty$ and $E_{2n}(x) \in W^{2n,1}(R)$ is the $2n$th order antiderivative of $E_0(x) = u(x,0) - \phi_n(x,0)$. Furthermore, such a function $\phi_n(x,t)$ is unique.

Remark 3.2. The system (3.5) can be solved by commercial software such as Maple. However, since the problem is highly nonlinear, it takes a very long time even for small n. Therefore, even for the computational purpose, one needs to follow the steps of the proof to construct $\phi_n(x)$.

4. General initial value. In this section, we consider a general initial value which may change its sign. Then the existence and the uniqueness theory of the previous section is not applicable since it is for positive solutions only. In this section, we observe that the existence and uniqueness may fail for a general solution.

4.1. Approximation with a single heat kernel. For the case $n = 1$, the approximation $\phi_1(x,t) = \frac{\rho_1}{\sqrt{4\pi t}}\, e^{-(x-c_1)^2/(4t)}$ is obtained by solving

$$\rho_1 = \gamma_0, \qquad c_1\,\rho_1 = \gamma_1. \tag{4.1}$$

If $\gamma_0 \neq 0$, c_1 is uniquely decided by $c_1 = \gamma_1/\gamma_0$; i.e., c_1 is the *center of the mass* of the initial mass distribution u_0. The convergence order in Theorem 2.4 is written as

$$\lim_{t\to\infty} t^{\left(\frac{3}{2}-\frac{1}{2p}\right)} \|u(t) - \phi_1(t)\|_p = \frac{\left\|\partial_\xi^{2}\left(e^{-\frac{1}{4}\xi^2}\right)\right\|_p}{\sqrt{4\pi}} \left|\int_{-\infty}^{\infty} E_2(x)dx\right|, \quad 1 \le p \le \infty,$$

where $E_2(x)$ is the second order antiderivative of the initial error $E_0(x) := u_0(x) - \rho_1\delta_{c_1}(x)$ given by (2.4), i.e., $E_2(x) = \int_{-\infty}^x \int_{-\infty}^y (u_0(z) - \rho_1\delta_{c_1}(z))dzdy$.

Now consider the singular case $\gamma_0 = 0$. Then the approximation is simply $\phi_1 \equiv 0$. If $\gamma_1 = 0$, then the equation for the first moment is satisfied for any $c_1 \in \boldsymbol{R}$ and we obtain the above convergence order which is equivalent to the decay rate $u(x,t)$. If $\gamma_1 \neq 0$, (4.1) has no solution and we do not obtain a single heat kernel approximation ϕ_1 with the desirable convergence order $O(t^{(\frac{1}{2p}-\frac{3}{2})})$ for t large.

4.2. Approximation with two heat kernels. The double heat kernel solution $\phi_2(x,t) = \sum_{i=1}^2 \frac{\rho_i}{\sqrt{4\pi t}}\, e^{-(x-c_i)^2/(4t)}$ that approximates the solution $u(x,t)$ is obtained by solving

$$\begin{aligned} \rho_1 + \rho_2 &= \gamma_0, & \rho_1 c_1 + \rho_2 c_2 &= \gamma_1, \\ \rho_1 c_1^2 + \rho_2 c_2^2 &= \gamma_2, & \rho_1 c_1^3 + \rho_2 c_2^3 &= \gamma_3. \end{aligned} \tag{4.2}$$

We may simplify the equation by eliminating ρ_i's and obtain two equations of the form $\mathbf{A}\Psi = \mathbf{r}_2$, i.e.,

$$\begin{pmatrix} \gamma_0 & \gamma_1 \\ \gamma_1 & \gamma_2 \end{pmatrix} \begin{pmatrix} \psi_0 \\ \psi_1 \end{pmatrix} = \begin{pmatrix} \gamma_2 \\ \gamma_3 \end{pmatrix}.$$

First, we need to check the invertibility of the Hankel matrix. Its determinant is the variance of the initial value u_0 if it is a probability distribution, i.e.,

$$|\mathbf{A}| = \gamma_0\gamma_2 - \gamma_1^2.$$

If $|\mathbf{A}| \neq 0$, ψ_i's can be solved using Cramer's rule, and c_i's are zeros of a quadratic function

$$g_2(x) = x^2 + \frac{\gamma_1\gamma_2 - \gamma_0\gamma_3}{|\mathbf{A}|}x + \frac{\gamma_1\gamma_3 - \gamma_2^2}{|\mathbf{A}|}.$$

Hence, the centers c_1, c_2 are given by

$$c_{1,2} = \frac{(\gamma_0\gamma_3 - \gamma_1\gamma_2) \pm \sqrt{D}}{2|\mathbf{A}|}, \qquad c_1 < c_2, \tag{4.3}$$

under two assumptions

$$|\mathbf{A}| = \gamma_0\gamma_2 - \gamma_1^2 \neq 0,\ D := (\gamma_1\gamma_2 - \gamma_0\gamma_3)^2 - 4\left(\gamma_0\gamma_2 - \gamma_1^2\right)\left(\gamma_1\gamma_3 - \gamma_2^2\right) > 0. \tag{4.4}$$

After obtaining c_i's, the problem (3.5) is easily solved and gives

$$\rho_1 = \frac{\gamma_0 c_2 - \gamma_1}{c_2 - c_1}, \qquad \rho_2 = \frac{\gamma_0 c_1 - \gamma_1}{c_1 - c_2}. \tag{4.5}$$

From Theorem 2.4 we may conclude that if $D > 0$ and $|\mathbf{A}| \neq 0$, then

$$\lim_{t\to\infty} t^{\left(\frac{5}{2}-\frac{1}{2p}\right)}\|u(t) - \phi_2(t)\|_p \leq \frac{\left\|\partial_\xi^4\left(e^{-\frac{1}{4}\xi^2}\right)\right\|_p}{\sqrt{4\pi}}\left|\int_{-\infty}^{\infty} E_4(x)dx\right|,\ 1 \leq p \leq \infty, \tag{4.6}$$

where $E_4(x)$ is the fourth order antiderivative of the initial error $E_0(x) := u_0(x) - \sum_{i=1}^2 \rho_i\delta_{c_i}(x)$ given by (2.4).

Example 4.1. Consider an initial value

$$U_l(x) = \begin{cases} -1, & -2l - 0.5 < x < -l - 0.5,\ \ l + 0.5 < x < 2l + 0.5, \\ 1, & -l - 0.5 \leq x \leq l + 0.5, \\ 0, & \text{otherwise}, \end{cases} \tag{4.7}$$

where $l > 0$. Let $\gamma_{k,l}$ be the kth moments of the function $U_l(x)$, i.e.,

$$\gamma_{k,l} := \int x^k U_l(x)dx, \quad k = 0, 1, \ldots.$$

Then $\gamma_{0,l} = 1$ for all $l > 0$ and, since U_l is an even function, $\gamma_{k,l} = 0$ for $k = 1, 3, 5, \ldots$. Hence, $|A|$ and D in (4.4) are given by

$$|A| = \gamma_{2,l}, \qquad D = 4(\gamma_{2,l})^3.$$

One may easily check that $\gamma_{2,l} = 0$, if and only if

$$l = l_2 := 0.5\left(\sqrt[3]{2} - 1\right) / \left(2 - \sqrt[3]{2}\right),$$

and $D = 4(\gamma_{2,l})^3 > 0$, if and only if $l < l_2$. Hence, the moment problem (4.2) with the initial value $U_l(x)$ is solvable only for $l < l_2$. This example says that, even if the Hankel matrix is nonsingular, $\phi_2(x,t)$ that satisfies convergence order in (4.6) may not exist.

4.3. Approximation with three heat kernels. The derivation of (3.6) from (3.5) is not clear without some calculations. In the following, such a derivation is given for an example. For the case $n = 3$ the system (3.5) reads

$$\begin{array}{l} \rho_1 \quad + \rho_2 \quad + \rho_3 \quad = \gamma_0, \\ \rho_1 c_1 + \rho_2 c_2 + \rho_3 c_3 = \gamma_1, \\ \rho_1 c_1^2 + \rho_2 c_2^2 + \rho_3 c_3^2 = \gamma_2, \\ \rho_1 c_1^3 + \rho_2 c_2^3 + \rho_3 c_3^3 = \gamma_3, \\ \rho_1 c_1^4 + \rho_2 c_2^4 + \rho_3 c_3^4 = \gamma_4, \\ \rho_1 c_1^5 + \rho_2 c_2^5 + \rho_3 c_3^5 = \gamma_5. \end{array} \tag{4.8}$$

Multiply c_1 to the kth equation and subtract $(k+1)$th one from it for $k = 1, \ldots, 5$ and obtain five equations without ρ_1, i.e.,

$$\begin{array}{l} \rho_2(c_1 - c_2) \quad + \rho_3(c_1 - c_3) \quad = \gamma_0 c_1 - \gamma_1, \\ \rho_2(c_1 - c_2)c_2 + \rho_3(c_1 - c_3)c_3 = \gamma_1 c_1 - \gamma_2, \\ \rho_2(c_1 - c_2)c_2^2 + \rho_3(c_1 - c_3)c_3^2 = \gamma_2 c_1 - \gamma_3, \\ \rho_2(c_1 - c_2)c_2^3 + \rho_3(c_1 - c_3)c_3^3 = \gamma_3 c_1 - \gamma_4, \\ \rho_2(c_1 - c_2)c_2^4 + \rho_3(c_1 - c_3)c_3^4 = \gamma_4 c_1 - \gamma_5. \end{array}$$

Do the similar process two more times and obtain three equations without ρ_i's:

$$\begin{array}{l} 0 = \gamma_0 c_1 c_2 c_3 - \gamma_1(c_1 c_2 + c_2 c_3 + c_3 c_1) + \gamma_2(c_1 + c_2 + c_3) - \gamma_3, \\ 0 = \gamma_1 c_1 c_2 c_3 - \gamma_2(c_1 c_2 + c_2 c_3 + c_3 c_1) + \gamma_3(c_1 + c_2 + c_3) - \gamma_4, \\ 0 = \gamma_2 c_1 c_2 c_3 - \gamma_3(c_1 c_2 + c_2 c_3 + c_3 c_1) + \gamma_4(c_1 + c_2 + c_3) - \gamma_5, \end{array}$$

which are identical to (3.6)–(3.7) with $n = 3$, i.e.,

$$\begin{pmatrix} \gamma_0 & \gamma_1 & \gamma_2 \\ \gamma_1 & \gamma_2 & \gamma_3 \\ \gamma_2 & \gamma_3 & \gamma_4 \end{pmatrix} \begin{pmatrix} \psi_0 \\ \psi_1 \\ \psi_2 \end{pmatrix} = \begin{pmatrix} \gamma_3 \\ \gamma_4 \\ \gamma_5 \end{pmatrix},$$

where $\psi_0 = c_1 c_2 c_3, \psi_1 = -(c_1 c_2 + c_2 c_3 + c_3 c_1)$, and $\psi_2 = c_1 + c_2 + c_3$. The derivation is done for the case $n = 3$.

The determinant of the 3×3 Hankel matrix is given by

$$|\mathbf{A}| = \gamma_0\gamma_2\gamma_4 + 2\gamma_1\gamma_2\gamma_3 - \gamma_2^3 - \gamma_0\gamma_3^2 - \gamma_1^2\gamma_4.$$

If $|\mathbf{A}| \neq 0$, then ψ_i are given by Cramer's rule:

$$\begin{array}{l} \psi_0 = (2\gamma_3\gamma_2\gamma_4 + \gamma_3\gamma_1\gamma_5 - \gamma_3^3 - \gamma_2^2\gamma_5 - \gamma_4^2\gamma_1)/|\mathbf{A}|, \\ \psi_1 = (\gamma_2\gamma_5\gamma_1 + \gamma_0\gamma_4^2 + \gamma_3^2\gamma_2 - \gamma_3\gamma_1\gamma_4 - \gamma_4\gamma_2^2 - \gamma_0\gamma_3\gamma_5)/|\mathbf{A}|, \\ \psi_2 = (\gamma_0\gamma_2\gamma_5 + \gamma_3^2\gamma_1 + \gamma_2\gamma_4\gamma_1 - \gamma_0\gamma_3\gamma_4 - \gamma_3\gamma_2^2 - \gamma_1^2\gamma_5)/|\mathbf{A}|. \end{array}$$

The points c_i's are zeros of third order polynomial

$$g_3(x) = x^3 - \psi_2 x^2 - \psi_1 x - \psi_0. \tag{4.9}$$

Hence, the solvability of the problem (4.8) is equivalent to the existence of three distinct real roots $c_1 < c_2 < c_3$ of (4.9). The convergence order in Theorem 2.4 gives the asymptotic convergence order:

$$\lim_{t\to\infty} t^{\left(\frac{7}{2}-\frac{1}{2p}\right)} \|u(t) - \phi_3(t)\|_p \le \frac{\left\|\partial_\xi^6 \left(e^{-\frac{1}{4}\xi^2}\right)\right\|_p}{\sqrt{4\pi}} \left| \int_{-\infty}^{\infty} E_6(x)dx \right|, \quad 1 \le p \le \infty, \tag{4.10}$$

where $E_6(x)$ is the sixth order antiderivative of the initial error $E_0(x) := u_0(x) - \sum_{i=1}^3 \rho_i \delta_{c_i}(x)$ given by (2.4).

Consider the initial value given in Example 4.1. Since $\gamma_{1,l} = \gamma_{3,l} = \gamma_{5,l} = 0$ and $\gamma_{0,l} = 1$, we obtain

$$|A| = \gamma_{2,l}\left(\gamma_{4,l} - \gamma_{2,l}^2\right), \quad \psi_1 = \gamma_{4,l}/\gamma_{2,l}, \quad \psi_0 = \psi_2 = 0.$$

Hence, if

$$|\mathbf{A}| \neq 0 \quad \text{and} \quad \psi_1 > 0,$$

then $g_3(x)$ has three distinct real roots

$$c_1 = -\sqrt{\psi_1}, \quad c_2 = 0, \quad c_3 = \sqrt{\psi_1}.$$

One may show that $\gamma_{4,l} > 0$ if and only if $0 < l < l_4 := 0.5(\sqrt[5]{2} - 1)/(2 - \sqrt[5]{2})$. Therefore, if $l_4 < l < l_2$, then $\psi_1 < 0$ and the existence of $\phi_3(x,t)$ satisfying (4.10) is not guaranteed. This example shows that the solvability of (3.5) is not obvious for sign-changing initial values.

5. Approximation for sign-changing solutions. Now consider a general sign-changing initial value. First, consider the case that the initial value $u_0(x)$ decays for $|x|$ large with the order that the Gaussian has, i.e.,

$$u_0(x) = O\left(e^{-|x|^2}\right) \quad \text{as} \quad |x| \to \infty. \tag{5.1}$$

Then there exists $M > 0$ such that $v_0(x) := u_0(x) + \frac{M}{\sqrt{4\pi}} e^{-x^2/4} \ge 0$, and we may apply the theory in section 3 to the nonnegative function v_0. Let ρ_i's and c_i's be the solutions of the moment problem with initial value $v_0(x)$. Then the solution $u(x,t)$ can be approximated by

$$u(x,t) \sim \sum_{i=1}^n \frac{\rho_i}{\sqrt{4\pi t}} e^{-(x-c_i)^2/(4t)} - \frac{M}{\sqrt{4\pi(t+1)}} e^{-x^2/4(t+1)}. \tag{5.2}$$

Since the auxiliary part of the approximation is the exact solution with the extra initial value added to $u_0(x)$, the convergence order of this approximation is the same as the one in Theorem 3.1. This example shows that we may obtain the same convergence order for general sign-changing solutions by simply adding an extra term.

On the other hand, if the grid points are preassigned, say, $c_i = \bar{c}_i$, then we have the freedom in choosing the weights ρ_i's only. These ρ_i's are simply obtained by solving

the first n equations in (3.5), where the corresponding matrix is the Vandermonde matrix, i.e.,

$$\begin{pmatrix} 1 & 1 & \cdots & 1 \\ \bar{c}_1 & \bar{c}_2 & \cdots & \bar{c}_n \\ \cdot & \cdot & \cdots & \cdot \\ \cdot & \cdot & \cdots & \cdot \\ \cdot & \cdot & \cdots & \cdot \\ \bar{c}_1^{n-1} & \bar{c}_2^{n-1} & \cdots & \bar{c}_n^{n-1} \end{pmatrix} \begin{pmatrix} \rho_1 \\ \rho_2 \\ \cdot \\ \cdot \\ \cdot \\ \rho_n \end{pmatrix} = \begin{pmatrix} \gamma_0 \\ \gamma_1 \\ \cdot \\ \cdot \\ \cdot \\ \gamma_{n-1} \end{pmatrix}. \tag{5.3}$$

The Vandermonde determinant $\prod_{1\le i<j\le n}(\bar{c}_j - \bar{c}_i)$ is not zero if $\bar{c}_i$ are all different and, hence, (5.3) is solvable. Now construct a different kind of approximation:

$$\eta_n(x,t) := \sum_{i=1}^{n} \frac{\rho_i}{\sqrt{4\pi t}} e^{-(x-\bar{c}_i)^2/(4t)}. \tag{5.4}$$

Then $\eta_n(\cdot,t)$ converges to $u(\cdot,t)$ with the order

$$\|u(t) - \eta_n(t)\|_p = O\left(t^{\left(\frac{1}{2p} - \frac{n+1}{2}\right)}\right) \qquad \text{as} \quad t \to \infty,$$

since $\lim_{t\to 0}(\eta_n(x,t) - u_0(x))$ has zero moments up to $(n-1)$th order.

6. Convergence as $n \to \infty$ with fixed $t > 0$. In this section, we discuss the convergence of the approximation $\phi_n(x,t)$ to the solution $u(x,t)$ as $n \to \infty$ with a fixed $t > 0$. An interesting behavior of the approximation $\phi_n(x,t)$ that one may observe numerically is a geometric convergence order such as

$$\beta_n(t) := \frac{\|u(t) - \phi_n(t)\|_\infty}{\|u(t) - \phi_{n+1}(t)\|_\infty} \to 1 + 4\frac{t}{v}\left(\equiv \beta\left(\frac{t}{v}\right)\right) \quad \text{as} \quad n \to \infty, \tag{6.1}$$

where $v > 0$ depends on the initial value $u_0(x)$. (We do not have a proof of it. Hence, the statements here are rather conjectures.) This convergence order implies that the error decays to zero very fast as $n \to \infty$ for any fixed time $t > 0$. This convergence order is somewhat extreme. For example, if $t > v/4$, then the approximation error is reduced into half whenever just a single heat kernel is added.

Set the approximation error as

$$e_n(x,t) = u(x,t) - \phi_n(x,t).$$

Consider a sequence of functions

$$E_k^n(x) = \int_{-\infty}^{x} E_{k-1}^n(y)dy, \qquad k = 1, 2, \ldots, 2n,$$

where

$$E_0^n(x) := e_n(x,0) = u_0(x) - \sum_{i=1}^{n} \rho_i \delta(x - c_i).$$

Notice that the upper index n is to denote that E_k^n is related to the approximation $\phi_n(x,t)$ and the lower index k is to indicate that E_k^n is the kth order antiderivative of the initial approximation error $E_0^n(x)$. Then, from (2.6), one obtains

$$\left(\sqrt{t}\right)^{2n+1} \|e_n(t)\|_\infty = \frac{C_{2n}}{\sqrt{4\pi}} \sup_\xi \left| \int \partial_\xi^{2n}\left(e^{-\zeta^2/4}\right) \sqrt{t} E_{2n}^n \frac{\sqrt{t}(\xi - \zeta)}{C_{2n}} d\zeta \right|, \tag{6.2}$$

where $C_{2n} := \int_{-\infty}^{\infty} E_{2n}^n(x)dx < \infty$.

An interesting observation is that, for n large, $E_{2n}^n(x)$ has a Gaussian-like structure. The following has been observed numerically.

CONJECTURE 6.1. *Suppose that the initial value $u_0(x)$ is nonnegative and has finite moments up to any order. Then there exist $c \in \boldsymbol{R}$ and $v > 0$ such that*

$$\left\| \frac{1}{\sqrt{v\pi}} e^{\frac{-(x-c)^2}{v}} - \frac{1}{C_{2n}} E_{2n}^n(x) \right\|_\infty \to 0 \quad as \quad n \to \infty, \tag{6.3}$$

where $C_{2n} := \int_{-\infty}^{\infty} E_{2n}^n(x)dx < \infty$. Furthermore,

$$\frac{C_{2n}}{C_{2(n+1)}} \frac{\left\| D_x^{2n} e^{\frac{-x^2}{v}} \right\|_\infty}{\left\| D_x^{2n+2} e^{\frac{-x^2}{v}} \right\|_\infty} \to 1 \quad as \quad n \to \infty. \tag{6.4}$$

The $(2n-1)$th order derivative of $E_{2n}^n(x)$ is $E_1^n(x)$ which is, at most, of order $O(1/n)$, which does not make any difference in the geometric convergence order such as (6.1). Hence, we may treat it as of order $O(1)$. Note that C_{2n} is obtained after integrating $E_0^n(x)$ $2n$ times and, hence, its order should be the reciprocal of the order of $\|D_x^{2n}(e^{\frac{-x^2}{v}})\|_\infty$, which is the $2n$th derivative of the Gaussian. Hence, (6.4) is a natural conclusion if (6.3) is assumed. Furthermore, for $\xi = x/\sqrt{v}$,

$$\left\| D_x^{2n} \left(e^{\frac{-x^2}{v}} \right) \right\|_\infty = \left\| D_\xi^{2n} \left(e^{-\xi^2} \right) (\xi_x)^{2n} \right\|_\infty = \frac{1}{v^n} \left\| D_\xi^{2n} \left(e^{-\xi^2} \right) \right\|_\infty .$$

Under Conjecture 6.1, the right-hand side of (6.2) can be approximated using $A(n, v/t)$ given by

$$\begin{aligned} \sup_x \left| \int D_y^{2n} \left(e^{-y^2/4} \right) \sqrt{t} E_{2n}^n \frac{\sqrt{t}(x-y)}{C_{2n}} dy \right| & \\ \cong \frac{\sqrt{t}}{\sqrt{v\pi}} \sup_x \left| \int D_y^{2n} \left(e^{-y^2/4} \right) e^{-\frac{(x-y-c/\sqrt{t})^2}{v/t}} dy \right| & \\ = \frac{\sqrt{t}}{\sqrt{v\pi}} \left| \int D_y^{2n} \left(e^{-y^2/4} \right) e^{-\frac{y^2}{v/t}} dy \right| =: A(n, v/t). & \end{aligned}$$

Notice that due to the symmetry of $D_x^{2n}(e^{-x^2/4})$ and $e^{-\frac{x^2}{v/t}}$ the supremum of the second line is obtained at $x - c/\sqrt{t} = 0$. Then we obtain from the relations (6.2) and (6.4) that

$$t^{-1} \frac{\|e_n(t)\|_\infty}{\|e_{n+1}(t)\|_\infty} \cong \frac{C_{2n}}{C_{2(n+1)}} \frac{A(n, v/t)}{A(n+1, v/t)} \cong \frac{v^n}{v^{n+1}} \frac{\left\| D_x^{2n+2} \left(e^{-x^2} \right) \right\|_\infty}{\left\| D_x^{2n} \left(e^{-x^2} \right) \right\|_\infty} \frac{A(n, v/t)}{A(n+1, v/t)}.$$

One can easily check that

$$\frac{\left\| D_x^{2n+2} \left(e^{-x^2} \right) \right\|_\infty}{\left\| D_x^{2n} \left(e^{-x^2} \right) \right\|_\infty} = 4n + 2, \quad \frac{A(n, v/t)}{A(n+1, v/t)} = \frac{4 + v/t}{4n+2},$$

using a mathematical software such as Maple or by hand. Therefore, we obtain the convergence order in (6.1), i.e.,

$$\frac{\|e_n(t)\|_\infty}{\|e_{n+1}(t)\|_\infty} \cong t \frac{1}{v} (4n+2) \frac{4 + v/t}{4n+2} = 1 + 4\frac{t}{v} \quad \text{for } n \text{ large.}$$

Notice that $c \in \boldsymbol{R}$ in (6.3) does not make any difference in the convergence order. The factor that decides the geometric convergence rate is the variance factor v of the limit function $\frac{1}{\sqrt{v\pi}}e^{-x^2/v}$. It seems that the variance factor v depends on the initial value $u_0(x)$, and another discussion about it will be included in section 7.2.

Remark 6.2. For $n > 0$ small, $E^n_{2n}(x)/C_{2n}$ is not close enough to the Gaussian and the arguments above do not apply. Then it is natural to ask how large n should be. The answer depends on the initial value. Clearly, if $u_0(x)$ itself is like a Gaussian, then such an $n > 0$ can be relatively small. In other cases, the corresponding $n > 0$ could be larger.

7. Numerical examples. In this section, we test the convergence orders numerically for $t > 0$ large and for $n > 0$ large. These tests confirm the convergence orders obtained in the previous sections. This section consists of four subsections. The first two are for $t \to \infty$ and for $n \to \infty$ limits of the approximation $\phi_n(x,t)$. In the third one, we test the behavior of the alternative approach $\psi_{2n}(x,t)$ as $n \to \infty$. In the last one, we do numerical tests for Conjecture 6.1.

There are two difficulties in observing the theoretical convergence order for $t > 0$ large. First, the convergence rate for small time $0 < t \ll 1$ is lower than the theoretical one for $t > 0$ large. So we need to wait a certain amount of time to observe the theoretical convergence order. On the other hand, since the convergence order is so high, the approximation error at the right moment can be as small as of order 10^{-36} or 10^{-64} (see Tables 7.1 and 7.2). So we should employ enough precisions in the computation to obtain meaningful numerical results.

The second difficulty, which is more restrictive, is in computing the solution $u(x,t)$. To compute the decay order of $\|u(x,t) - \phi_n(x,t)\|_\infty$ accurately, we should obtain the exact value $u(x,t)$ or compute it with a smaller error than the actual approximation error. However, it seems impossible to do the integration in (1.1) numerically with such a small error. (In this sense, one may say that the approximation $\phi_n(x,t)$ is more exact than the exact formula in (1.1).) To avoid such a difficulty, we consider the following two examples with explicit solutions. In the following numerical tests we employ these examples.

Example 7.1 (example with a single hump). Consider the solution of

$$u_t = u_{xx}, \quad u(x,0) = K(x,t_0), \quad x \in \boldsymbol{R},\ t > 0, \tag{7.1}$$

where $K(x,t)$ is the heat kernel

$$K(x,t) = \frac{1}{\sqrt{4\pi t}}e^{-x^2/4t}.$$

Then the exact solution is simply $u(x,t) = K(x,t+t_0)$ and the variance of the initial value is $var = 2t_0$. This rather simple example illustrates certain convergence behavior very clearly.

Example 7.2 (example with double humps). Consider the solution of

$$u_t = u_{xx}, \quad u(x,0) = \frac{1}{2}[K(x+1,t_0) + K(x-1,t_0)], \quad x \in \boldsymbol{R},\ t > 0. \tag{7.2}$$

Then the solution is simply $u(x,t) = \frac{1}{2}[K(x+1,t+t_0) + K(x-1,t+t_0)]$ and the variance of the initial value is $var = 1 + 2t_0$.

TABLE 7.1

The error $e_n(x,t) = u(x,t) - \phi_n(x,t)$ and the convergence order α_n in (7.5) have been computed for Examples 7.1 and 7.2 with $n = 4, 8$ and $t_0 = 1$. We observe that $\alpha_n(t) \to -(n + \frac{1}{2})$ as $t \to \infty$. (The norms in this and the following tables are L^∞-norms.)

TABLE 7.2

The error $e_n(x,t) = u(x,t) - \phi_n(x,t)$ and the geometric convergence rate $\beta_n(t)$ in (6.1) have been computed for Examples 7.1 and 7.2 with $t = 1, 10$ and $t_0 = 1$. The ratio $\beta_n(t)$ converges to the limit in (6.1) quickly with $v = 2$ for Example 1 and slowly for Example 2.

7.1. Numerical tests for the long time asymptotics. The approximation

$$\phi_n(x,t) \equiv \sum_{i=1}^{n} \frac{\rho_i}{\sqrt{4\pi t}} e^{\frac{-(x-c_i)^2}{4t}} \tag{7.3}$$

constructed in section 3 converges to the exact solution $u(x,t)$ with order

$$\|u(t) - \phi_n(t)\|_\infty = O\left(t^{-\frac{2n+1}{2}}\right) \quad \text{as} \quad t \to \infty. \tag{7.4}$$

In Table 7.1 the error $e_n(x,t) = u(x,t) - \phi_n(x,t)$ and the convergence order α_n have been computed for $n = 4, 8$ as doubling the time from $t = 0.1$ to $t = 204.8$. The convergence order of the approximation has been measured by computing

$$\alpha_n(t) \sim \frac{\ln(\|e_n(t/2)\|_\infty / \|e_n(t)\|_\infty)}{\ln(1/2)}. \tag{7.5}$$

(Note that we measure the error in L^∞-norm in the following numerical examples and denote it by $\|\cdot\|$ in the tables to get it fitted in the tables.) From Table 7.1, one

clearly observes that the convergence order $\alpha_n(t)$ approaches the optimal convergence order in (7.4) as $t \to \infty$. Notice that these numerical tests for $t \to \infty$ limits show similar patterns of the convergence for both Examples 7.1 and 7.2.

7.2. Numerical tests for $n \to \infty$ limits. Now we are going to check the convergence order for n large with a fixed $t > 0$. Consider the ratio

$$\beta_n(t) := \|e_{n-1}(t)\|_\infty \Big/ \|e_n(t)\|_\infty.$$

(The ratio $r = a_n/a_{n-1}$ is usually considered for a geometric sequence. Here we consider its reciprocal for easier comparison.) In Table 7.2, the error $\|e_n(t)\|_\infty$ and this ratio are computed for Examples 7.1 and 7.2 at two instances $t = 1$ and $t = 10$ with increasing n from $n = 2$ to $n = 25$. One can clearly observe a certain geometric convergence order as in (6.1). In both examples, we can clearly see that $10(\beta_n(1) - 1) \sim (\beta_n(10) - 1)$, which indicates that the corresponding constant $v > 0$ in (6.1) which decides the geometric convergence ratio does not depend on the time $t > 0$.

From the test for Example 7.1, one can clearly see that $\beta_n(1) \to 3$ and $\beta_n(10) \to 21$ as $n \to \infty$. In both cases, the corresponding v is $v = 2$ which is the variance of the initial value. The convergence pattern for Example 7.2 is different. First, the convergence speed of the ratio $\beta_n(t)$ is slow. It seems due to the complexity of the structure of the initial value. At the moment $n = 49$ the index v corresponding to the geometric convergence rate $\beta = 19.74$ is $v = 2.15$ and seems still decreasing. This value is already smaller than the variance of the initial value which is 3 and looks likely to converge to $v = 2$. It seems that the factor that decides the geometric convergence rate is not the variance but the tail of the initial value for $|x|$ large.

7.3. Approximation using derivatives of the Gaussian. We may write $\psi_{2n}(x,t)$ in (1.5) as

$$\psi_{2n}(x,t) = \sum_{i=0}^{2n-1} \frac{-\gamma_i}{2(i!)} \left(\frac{-1}{2\sqrt{t}}\right)^{n+1} H_i\left(\frac{x}{2\sqrt{t}}\right) e^{-x^2/4t}, \tag{7.6}$$

where $H_i(x)$ is the Hermite polynomial of degree i. In Table 7.3, the approximation error and the geometric convergence ratio β_n are given for Example 7.1. To make the relation between the initial value and the convergence ratio more clear, we set

$$\beta_{2n}(t, t_0) := \|e_{2n-2}(t)\|_\infty \Big/ \|e_{2n}(t)\|_\infty, \tag{7.7}$$

where $e_{2n}(x,t) = u(x,t) - \psi_{2n}(x,t)$ and $u_0(x) = K(x,t_0)$ with $t_0 = 10$.

One may observe that $\beta_{2n}(1,10) \to 0.1$, $\beta_{2n}(10,10) \to 1$, and $\beta_{2n}(100,10) \to 10$ as $n \to \infty$. This observation leads us to a conjecture

$$\lim_{n\to\infty} \frac{\|u(t) - \psi_{2n}(t)\|_\infty}{\|u(t) - \psi_{2n+2}(t)\|_\infty} = \frac{t}{t_0}\ , \tag{7.8}$$

which indicates that the approximation error increases geometrically if $t < t_0$ and, hence, $\psi_{2n}(x,t)$ is meaningful for $t > t_0$ only. We may consider t_0 as the age of the initial value since $u_0(x) = K(x,t_0)$. This t_0 seems to be related to the time-shift t_* in [22]. Generally, one may call t_0 the age of a general initial value u_0 of the heat equation if $\lim_{n\to\infty} \frac{\|u(t_0) - \psi_{2n}(t_0)\|_\infty}{\|u(t_0) - \psi_{2n+2}(t_0)\|_\infty} = 1$.

TABLE 7.3

The error $e_n(x,t) = u(x,t) - \psi_{2n}(x,t)$ and the geometric convergence rate $\beta_n(t,t_0)$ in (7.7) have been computed numerically for Example 7.1 with $t_0 = 10$ and $t = 1, 10, 100$. We may observe the convergence rate in (7.8).

7.4. Numerical test for Conjecture 6.1. The geometric convergence rate (6.1) for n large has been obtained under Conjecture 6.1 and observed numerically in section 7.2. The conjecture itself is of an independent interest which has no direct relation with the heat equation. In this section, we test the limits (6.3) and (6.4) in the conjecture.

In Table 7.4, the uniform norm of the difference in (6.3) and the ratio in (6.4) are given for Examples 7.1 and 7.2. In both cases, we have taken $v = 2t_0$. The results for Example 7.1 show the convergence clearly. In particular, the test for (6.4) shows that the ratio is identically one if the initial value $u_0(x)$ is the Gaussian.

The columns for Example 7.2 also show similar convergence behavior. However, the speed of its convergence is a lot slower. In fact, it is not even clear that taking $v = 2t_0$ is the correct one for the case of Example 7.2. Since $2t_0$ is the variance of Example 7.1, one may also try $2t_0 + 1$, which is the variance of Example 7.2. However, one cannot obtain the convergence, and $v = 2t_0$ seems a better choice. The computation is done up to $n = 10$ and that was our best. If computations with higher n are performed, we conjecture that the convergence to the unity will be more clearly observed.

Acknowledgment. Authors would like to thank anonymous reviewers. Their comments and suggestions helped to improve this paper.

ON DIVERGENCE FORM SPDES WITH VMO COEFFICIENTS*

N. V. KRYLOV†

Abstract. We present several results on solvability in Sobolev spaces W_p^1 of SPDEs in divergence form in the whole space.

Key words. stochastic partial differential equations, divergence equations, Sobolev spaces

AMS subject classifications. 60H15, 35R60

DOI. 10.1137/080726902

1. Introduction.

The theory of (usual) partial differential equations has two rather different parts depending on whether the equations are written in divergence or nondivergence form. Quite often the starting point is the same: equations with constant coefficients, and then one uses different techniques to treat different types of equations.

By now, one can say that the L_p-theory of evolutional second-order SPDEs is quite well developed. The most advanced results of this theory can be found in the following papers and references therein: [1] (nondivergence type equations), [2] and [3] (divergence type equations). The results of the present paper are close to the corresponding results of [2]. However, unlike [2] we do not assume that the leading coefficients are continuous in the space variable. Instead we assume that the leading coefficients of the "deterministic" part of the equation are in VMO (the space of functions with vanishing mean oscillation), which is a much wider class than C. Still the leading coefficients of the "stochastic" part are assumed to be continuous in x.

The exposition in [2] and [3] is based on the theory of solvability in spaces $H_p^\gamma = (1-\Delta)^{-\gamma/2}L_p$ of SPDEs with coefficients independent of x. Then the method of "freezing" the coefficients is applied as in the general framework set out in [6]. This method does not work if the coefficients are only in VMO so we use a different technique based on recent results from [8] on deterministic parabolic equations with VMO coefficients. In addition, our technique allows us to avoid using the W_2^n theory of SPDEs, which is a starting point in the paper [6] and subsequent articles based on it.

One more difference of our approach from the one in [2] is that we represent the free term in the deterministic part in the form $D_i f^i + f^0$ with $f^j \in L_p$ (see (1.1) below). Of course, this is just a general form of a distribution from H_p^{-1}. However, the spaces H_p^γ are most appropriate for equations in nondivergence form. One general inconvenience of these spaces is that the space or space-time dilations affect the norms in a way which is hard to control. For divergence form equations with low regularity of coefficients the most important space is H_p^1. This space coincides with the Sobolev space W_p^1 and the effect of dilations on the norm or on $D_i f^i + f^0$ can be easily taken into account.

The exposition here is self-contained apart from references to some very basic results of [6], [8], and [12], and is much more elementary than in [2], employing the

†School of Mathematics, University of Minnesota, 127 Vincent Hall, Minneapolis, MN 55455 (krylov@math.umn.edu).

derivatives instead of the powers of the Laplacian, and yet gives more information. In particular, the author intends to use Corollary 5.5 in order to largely simplify the theory in [2] of divergence form SPDEs in domains. It turns out that to develop this theory one need not first develop the theory of SPDEs in domains with coefficient independent of x, which in itself required quite a bit of work.

The author's interest in divergence-type equations and in simplifying the theory of them appeared after he realized that the corresponding results can be applied to filtering theory of partially observable diffusion processes, given by stochastic Itô equations. It turns out that, under Lipschitz and nondegeneracy conditions only, the filtering density is almost Lipschitz in x and almost Hölder $1/2$ in time. This is proved in [10] on the basis of Theorems 2.2 through 2.6 of the present article. The filtering density satisfies an SPDE usually written in terms of the operators adjoint to operators in nondivergence form with Lipschitz continuous coefficients. Writing these adjoint operators in divergence form makes perfect sense and allows us to obtain the above-mentioned results (see [10]).

Our Theorem 2.2 is very close to Theorem 2.12 of [2]. Apart from weaker conditions on the coefficients, another important difference is the presence of the parameter λ in (2.10). One of differences in the proofs is that we avoid proving the solvability on small consecutive time intervals and then gluing together the results.

Let $(\Omega, \mathcal{F}, P)$ be a complete probability space with an increasing filtration $\{\mathcal{F}_t, t \geq 0\}$ of complete with respect to $(\mathcal{F}, P)$ σ-fields $\mathcal{F}_t \subset \mathcal{F}$. Denote by $\mathcal{P}$ the predictable σ-field in $\Omega \times (0, \infty)$ associated with $\{\mathcal{F}_t\}$. Let w_t^k, $k = 1, 2, \dots$, be independent one-dimensional Wiener processes with respect to $\{\mathcal{F}_t\}$.

We fix a stopping time τ and for $t \leq \tau$ in the Euclidean d-dimensional space R^d of points $x = (x^1, \dots, x^d)$ we consider the following equation

$$du_t = \left(L_t u_t - \lambda u_t + D_i f_t^i + f_t^0\right) dt + \left(\Lambda_t^k u_t + g_t^k\right) dw_t^k, \tag{1.1}$$

where $u_t = u_t(x) = u_t(\omega, x)$ is an unknown function,

$$L_t \psi(x) = D_j \left(a_t^{ij}(x) D_i \psi(x) + a_t^j(x) \psi(x)\right) + b_t^i(x) D_i \psi(x) + c_t(x) \psi(x),$$

$$\Lambda_t^k \psi(x) = \sigma_t^{ik}(x) D_i \psi(x) + \nu_t^k(x) \psi(x),$$

the summation convention with respect to $i, j = 1, \dots, d$ and $k = 1, 2, \dots$ is enforced and detailed assumptions on the coefficients and the free terms will be given later.

One can rewrite (1.1) in the nondivergence form assuming that the coefficients a_t^{ij} and a_t^j are differentiable in x and then one could apply the results from [6]. It turns out that the differentiability of a_t^{ij} and a_t^j is not needed for the corresponding counterparts of the results in [6] to be true and showing this and generalizing the corresponding results of [2] is one of the main purposes of the present article.

The author is sincerely grateful to Kyeong-Hun Kim who kindly pointed out a serious error in the first draft of the article. Doyoon Kim and the referees of the paper made many valuable suggestions and their impact is greatly appreciated.

2. Main results. Fix a number

$$p \geq 2,$$

and denote $L_p = L_p(\mathsf{R}^d)$. We use the same notation L_p for vector- and matrix-valued or else ℓ_2-valued functions such as $g_t = (g_t^k)$ in (1.1). For instance, if $u(x) =$

$(u^1(x),u^2(x),\dots)$ is an ℓ_2-valued measurable function on R^d, then

$$\|u\|_{L_p}^p=\int_{\mathsf{R}^d}|u(x)|_{\ell_2}^p\,dx=\int_{\mathsf{R}^d}\left(\sum_{k=1}^\infty\left|u^k(x)\right|^2\right)^{p/2}dx.$$

Introduce

$$D_i=\frac{\partial}{\partial x^i},\quad i=1,\dots,d,\quad \Delta=D_1^2+\cdots+D_d^2.$$

By Du we mean the gradient with respect to x of a function u on R^d.

As usual,

$$W_p^1=\{u\in L_p:Du\in L_p\},\quad \|u\|_{W_p^1}=\|u\|_{L_p}+\|Du\|_{L_p}.$$

Recall that τ is a stopping time and introduce

$$\mathbf{L}_p(\tau):=L_p(\llbracket 0,\tau\rrbracket,\mathcal{P},L_p),\quad \mathbf{W}_p^1(\tau):=L_p\left(\llbracket 0,\tau\rrbracket,\mathcal{P},W_p^1\right).$$

We also need the space $\mathcal{W}_p^1(\tau)$, which is the space of functions $u_t=u_t(\omega,\cdot)$ on $\{(\omega,t):0\le t\le\tau,t<\infty\}$ with values in the space of generalized functions on R^d and having the following properties:

(i) We have $u_0\in L_p(\Omega,\mathcal{F}_0,L_p)$;

(ii) We have $u\in\mathbf{W}_p^1(\tau)$;

(iii) There exist $f^i\in\mathbf{L}_p(\tau)$, $i=0,\dots,d$, and $g=(g^1,g^2,\dots)\in\mathbf{L}_p(\tau)$ such that for any $\varphi\in C_0^\infty=C_0^\infty(\mathsf{R}^d)$ with probability 1 for all $t\in[0,\infty)$ we have

$$\begin{aligned}(u_{t\wedge\tau},\varphi)=(u_0,\varphi)&+\sum_{k=1}^\infty\int_0^t I_{s\le\tau}\left(g_s^k,\varphi\right)\,dw_s^k\\&+\int_0^t I_{s\le\tau}\left(\left(f_s^0,\varphi\right)-\left(f_s^i,D_i\varphi\right)\right)\,ds.\end{aligned}\tag{2.1}$$

In particular, for any $\phi\in C_0^\infty$, the process $(u_{t\wedge\tau},\phi)$ is $\mathcal{F}_t$-adapted and (a.s.) continuous.

The reader can find in [6] a discussion of (ii) and (iii), in particular, the fact that the series in (2.1) converges uniformly in probability on every finite subinterval of $[0,\tau]$. On the other hand, it is worth saying that the above introduced space $\mathcal{W}_p^1$ is not quite the same as $\mathcal{H}_p^1(\tau)$ in [6] or in [2]. There are three differences. One is that there is an additional restriction on u_0 in [6] and [2]. But in the main part of the article we are going to work with $\mathcal{W}_{p,0}^1(\tau)$ which is the subset of $\mathcal{W}_p^1(\tau)$ consisting of functions with $u_0=0$. Another issue is that in [6] and [2] in place of $D_if^i+f^0$ we have just f such that

$$f\in\mathbf{H}_p^{-1}(\tau)=L_p\left(\llbracket 0,\tau\rrbracket,\mathcal{P},H_p^{-1}\right).$$

Actually, this difference is fictitious because one knows that any $f\in H_p^{-1}$

(a) has the form $D_if^i+f^0$ with $f^j\in L_p$ and

$$\|f\|_{H_p^{-1}}\le N\sum_{j=0}^d\|f^j\|_{L_p},$$

where N is independent of f,f^j, and on the other hand,

(b) for any $f \in H_p^{-1}$ there exist $f^j \in L_p$ such that $f = D_i f^i + f^0$ and

$$\sum_{j=0}^{d} \|f^j\|_{L_p} \leq N \|f\|_{H_p^{-1}},$$

where N is independent of f.

The third difference is that instead of (ii) the condition $D^2 u \in \mathbf{H}_p^{-1}(\tau)$ is required in [6] and [2]. However, as it follows from Theorem 3.7 of [6] and the boundedness of the operator $D : L_p \to H_p^{-1}$, this difference disappears if τ is a bounded stopping time.

To summarize, the spaces $\mathcal{W}^1_{p,0}(\tau)$ introduced above coincide with $\mathcal{H}^1_{p,0}(\tau)$ from [6] if τ is bounded, and we choose a particular representation of the deterministic part of the stochastic differential just for convenience. In the remainder of the article the spaces $\mathcal{H}^1_{p,0}(\tau)$ do not appear and none of their properties is used.

In case that property (iii) holds, we write

$$du_t = \left(D_i f_t^i + f_t^0\right) dt + g_t^k \, dw_t^k \tag{2.2}$$

for $t \leq \tau$ and this explains the sense in which equation (1.1) is understood. Of course, we still need to specify appropriate assumptions on the coefficients and the free terms in (1.1).

Assumption 2.1. (i) The coefficients a_t^{ij}, a_t^i, b_t^i, σ_t^{ik}, c_t, and ν_t^k are measurable with respect to $\mathcal{P} \times \mathcal{B}(\mathsf{R}^d)$, where $\mathcal{B}(\mathsf{R}^d)$ is the Borel σ-field on R^d.

(ii) There is a constant K such that for all values of indices and arguments

$$\left|a_t^i\right| + \left|b_t^i\right| + |c_t| + |\nu|_{\ell_2} \leq K, \quad c_t \leq 0.$$

(iii) There is a constant $\delta > 0$ such that for all values of the arguments and $\xi \in \mathsf{R}^d$

$$a_t^{ij} \xi^i \xi^j \leq \delta^{-1} |\xi|^2, \quad \left(a_t^{ij} - \alpha_t^{ij}\right) \xi^i \xi^j \geq \delta |\xi|^2, \tag{2.3}$$

where $\alpha_t^{ij} = (1/2)(\sigma^{i\cdot}, \sigma^{j\cdot})_{\ell_2}$. Finally, the constant $\lambda \geq 0$.

It is worth emphasizing that we do not require the matrix (a^{ij}) to be symmetric.

Assumption 2.1 guarantees that (1.1) makes perfect sense if $u \in \mathcal{W}^1_p(\tau)$. By the way, adding the term $-\lambda u_t$ with constant $\lambda \geq 0$ is one more technically convenient step. One can always introduce this term, if originally it is absent, by considering $v_t := u_t e^{\lambda t}$.

Let $\mathbf{B}$ denote the set of balls $B \subset \mathsf{R}^d$ and let $\rho(B)$ be the radius of $B \in \mathbf{B}$. For functions $h_t(x)$ on $[0, \infty) \times \mathsf{R}^d$ and $B \in \mathbf{B}$ introduce

$$h_{t(B)} = \frac{1}{|B|} \int_B h_t(x) \, dx,$$

where $|B|$ is the volume of B. Also let $\mathbf{Q}$ denote the set of all cylinders in $[0, \infty) \times \mathsf{R}^d$ of type $Q = (s, t) \times B$, where $B \in \mathbf{B}$ and $t - s = \rho^2(B)$. For such Q set $\rho(Q) = \rho(B)$. For $\rho \geq 0$, $s < t$, a continuous R^d-valued function $x_r, r \in [s, t]$, and a $Q = (s, t) \times B \in \mathbf{Q}$, introduce

$$\operatorname{osc}(h, Q, x.) = \frac{1}{t - s} \int_s^t \left(|h_r - h_{r(B + x_r)}|\right)_{(B + x_r)} dr,$$

$$\operatorname{Osc}(h, Q, \rho) = \sup_{|x.|_C \leq \rho} \operatorname{osc}(h, Q, x.), \quad \operatorname{osc}(h, Q) = \operatorname{osc}(h, Q, 0),$$

where $|x.|_C$ is the sup norm of $|x.|$.

Observe that $\operatorname{osc}(h, Q, x.) = 0$ if $h_t(x)$ is independent of x.

Denote by B_ρ the open ball with radius $\rho > 0$ centered at the origin, define $Q_\rho = (0, \rho^2) \times B_\rho$ and for $t \geq 0$ and $x \in \mathsf{R}^d$ set $B_\rho(x) = B_\rho + x$, $Q_\rho(t, x) = Q_\rho + (t, x)$.

In the remaining two assumptions we use constants $\beta > 0$ and $\beta_1 > 0$, the values of which will be specified later.

Let $t_0 \geq 0$, $x_0 \in \mathsf{R}^d$, and constants $\varepsilon \geq \varepsilon_1 > 0$. We say that the couple (a, σ) is $(\varepsilon, \varepsilon_1)$-regular at point (t_0, x_0) if (for any ω) either

(i) we have $\sigma_t^{nm}(x_0) = 0$ for $t \in (t_0, t_0 + \varepsilon_1^2)$ and all n, m and

$$\operatorname{osc}\left(a^{ij}, Q\right) \leq \beta, \quad \forall i, j, \tag{2.4}$$

for all $Q \in \mathbf{Q}$ such that $Q \subset Q_\varepsilon(t_0, x_0)$, or

(ii) for all $Q \in \mathbf{Q}$ such that $Q \subset Q_\varepsilon(t_0, x_0)$ we have

$$\operatorname{Osc}\left(a^{ij}, Q, \varepsilon\right) \leq \beta, \quad \forall i, j. \tag{2.5}$$

Note that (a, σ) is $(\varepsilon, \varepsilon_1)$-regular at any point (t_0, x_0) for any $\beta > 0$ if, for instance, a^{ij} depend only on x and are of class VMO.

Assumption 2.2. There exist $\varepsilon \geq \varepsilon_1 > 0$ such that (a, σ) is $(\varepsilon, \varepsilon_1)$-regular at any point (t_0, x_0) and

$$\left(a_t^{jk}(x) - \alpha_t^{jk}(y)\right) \xi^j \xi^k \geq \delta |\xi|^2$$

for all t, ξ, x, and y satisfying $|x - y| \leq \varepsilon$.

Assumption 2.3. There exists an $\varepsilon_2 > 0$ such that

$$\left|\sigma_t^{i\cdot}(x) - \sigma_t^{i\cdot}(y)\right|_{\ell_2} \leq \beta_1 \tag{2.6}$$

for all i, t, x, and y satisfying $|x - y| \leq \varepsilon_2$.

Needless to say that Assumptions 2.2 and 2.3 are satisfied with any $\beta, \beta_1 > 0$ and slightly reduced δ if (2.3) holds and $a_t^{ij}(x)$ and $\sigma_t^{i\cdot}(x)$ are uniformly continuous in x uniformly with respect to (ω, t).

Finally, we describe the space of initial data. Recall that for $p \geq 2$ the Slobodetskii space $W_p^{1-2/p} = W_p^{1-2/p}(\mathsf{R}^d)$ of functions $u_0(x)$ can be introduced as the space of traces on $t = 0$ of (deterministic) functions u such that

$$u \in L_p\left(\mathsf{R}_+, H_p^1\right), \quad \partial u / \partial t \in L_p\left(\mathsf{R}_+, H_p^{-1}\right),$$

where $\mathsf{R}_+ = (0, \infty)$. For such functions there is a (unique) modification denoted again u such that u_t is a continuous L_p-valued function on $[0, \infty)$ so that u_0 is well defined. Any such u_t is called an extension of u_0.

The norm in $W_p^{1-2/p}$ can be defined as the infimum of

$$\|u\|_{L_p\left(\mathsf{R}_+, H_p^1\right)} + \|\partial u / \partial t\|_{L_p\left(\mathsf{R}_+, H_p^{-1}\right)}$$

over all extensions u_t of elements u_0. It is also well known that an equivalent norm of u_0 can be introduced as

$$\|u\|_{L_p\left((0,1), W_p^1\right)},$$

where $u = u_t$ is defined as the (unique) solution of the heat equation $\partial u_t(x)/\partial t = \Delta u_t(x)$ with initial condition $u_0(x)$.

For $s \geq 0$ we introduce

$$\mathrm{tr}_s \mathcal{W}^1_p = L_p\left(\Omega, \mathcal{F}_s, W_p^{1-2/p}\right).$$

The following auxiliary result helps understand the role of $\mathrm{tr}_s \mathcal{W}^1_p$. We use spaces $\mathcal{W}^1_p([S,T))$ and $\mathbf{W}^1_p((S,T))$, which are introduced in the same way as $\mathcal{W}^1_p(\tau)$ and $\mathbf{W}^1_p(\tau)$, but the functions are considered only on $[S,T)$ and (S,T), respectively.

LEMMA 2.1. *Let $s \geq 0$ be a fixed number and let u_s be an $\mathcal{F}_s$-measurable function with values in the set of distributions over R^d.*

(i) *We have $u_s \in \mathrm{tr}_s \mathcal{W}^1_p$ if and only if there exists a $v \in \mathcal{W}^1_p([s,\infty))$ satisfying the equation*

$$\partial v/\partial t = \Delta v - v, \quad t \geq s, \tag{2.7}$$

(which is a particular case of (1.1) and is understood in the same sense) with initial data u_s. This v is unique and satisfies

$$\|v\|_{\mathbf{W}^1_p((s,\infty))} \leq N\|u_s\|_{\mathrm{tr}_s \mathcal{W}^1_p}, \quad \|u_s\|_{\mathrm{tr}_s \mathcal{W}^1_p} \leq N\|v\|_{\mathbf{W}^1_p((s,\infty))}, \tag{2.8}$$

where the constants N are independent of s, u_s, and v.

(ii) *We have $u_s \in \mathrm{tr}_s \mathcal{W}^1_p$ if and only if there exists a $v \in \mathcal{W}^1_p([s,s+1))$ such that $v_s = u_s$.*

(iii) *If such a v exists and $dv_t = (D_i f^i_t + f^0_t)\,dt + g^k_t\,dw^k_t$, $t \geq s$, then*

$$\|u_s\|_{\mathrm{tr}_s \mathcal{W}^1_p} \leq N\left(\|v\|_{\mathbf{W}^1_p((s,s+1))} + \sum_{j=0}^{d} \left\|f^j\right\|_{\mathbf{L}_p((s,s+1))} + \|g\|_{\mathbf{L}_p((s,s+1))}\right), \tag{2.9}$$

where the constant N is independent of s, u_s, and v.

(iv) *If $s > 0$ and we have a $u \in \mathcal{W}^1_p(s)$, then $u_s \in \mathrm{tr}_s \mathcal{W}^1_p$ and*

$$\|u_s\|_{\mathrm{tr}_s \mathcal{W}^1_p} \leq N\left(\|u\|_{\mathbf{W}^1_p(s)} + \sum_{j=0}^{d} \left\|f^j\right\|_{\mathbf{L}_p(s)} + \|g\|_{\mathbf{L}_p(s)}\right),$$

where N is independent of u, and f^j and g^k are taken from (2.2).

We prove this lemma in section 5.

Here are our main results concerning (1.1). The following theorem is very close to Theorem 2.12 of [2]. Important differences are the presence of the parameter λ in (2.10) and weaker assumptions on the coefficients of the deterministic part of the equation.

THEOREM 2.2. *Let the above assumptions be satisfied with $\beta = \beta(d,p,\delta) = \beta_0/3$, where β_0 is the constant from Lemma 5.1, and $\beta_1 = \beta_1(d,p,\delta,\varepsilon) > 0$ taken from the proof of Lemma 5.2. Let $\lambda \geq 0$, let $f^j, g \in \mathbf{L}_p(\tau)$, and let $u_0 \in \mathrm{tr}_0 \mathcal{W}^1_p$.*

(i) *Then equation (1.1) for $t \leq \tau \wedge T$ has a unique solution $u \in \mathcal{W}^1_p(\tau \wedge T)$ with initial data u_0 and any $T \in (0,\infty)$. Moreover, if*

$$\lambda \geq \lambda_0(d,p,\delta,K,\varepsilon,\varepsilon_1,\varepsilon_2) \geq 1,$$

then (1.1) for $t \leq \tau$ has a unique solution $u \in \mathcal{W}^1_p(\tau)$ with initial data u_0.

(ii) *Furthermore, if a* $v \in \mathcal{W}^1_p(\infty)$ *is defined by* (2.7) *with initial condition* u_0, *then the above solution* u *satisfies*

$$\lambda^{1/2}\|u\|_{\mathbf{L}_p(\tau)} + \|Du\|_{\mathbf{L}_p(\tau)} \le N\left(\sum_{i=1}^d \|f^i\|_{\mathbf{L}_p(\tau)} + \|g\|_{\mathbf{L}_p(\tau)} + \|Dv\|_{\mathbf{L}_p(\tau)}\right) + N\lambda^{-1/2}\|f^0\|_{\mathbf{L}_p(\tau)} + N\lambda^{1/2}\|v\|_{\mathbf{L}_p(\tau)}, \tag{2.10}$$

provided that $\lambda \ge \lambda_0$, *where the constants* $N, \lambda_0 \ge 1$ *depend only on* d, p, δ, K, ε, ε_1, *and* ε_2.

(iii) *Finally, there exists a set* $\Omega' \subset \Omega$ *of full probability such that* $u_{t\wedge\tau}I_{\Omega'}$ *is a continuous* $\mathcal{F}_t$*-adapted* L_p*-valued function of* $t \in [0,\infty)$.

Observe that estimate (2.10) shows one of good reasons for writing the free term in (1.1) in the form $D_i f^i + f^0$, because f^i, $i = 1, \dots, d$, and f^0 enter (2.10) differently.

Remark 2.3. As it follows from our proofs, if $p = 2$, Assumptions 2.2 and 2.3 are not needed for Theorem 2.2 to be true and mentioning ε, ε_1, and ε_2 can be dropped in the statement. Thus we provide a new way to prove the classical result on Hilbert space solvability of SPDEs (cf., for instance, [13]).

We prove Theorem 2.2 in section 6 after we prepare necessary tools in sections 3–5. In section 3 we prove uniqueness part of Theorem 2.2 on the basis of Itô's formula from [12]. Here Assumptions 2.2 and 2.3 are not used. In section 4 we treat the case of the heat equation with the random right-hand side and present a simplified version of the corresponding result from [6]. In section 5 we prove an auxiliary existence theorem and derive some a priori estimates.

Here is a result about continuous dependence of solutions on the data.

THEOREM 2.4. *Assume that for each* $n = 1, 2, \dots$ *we are given functions* a^{ij}_{nt}, a^i_{nt}, b^i_{nt}, c_{nt}, σ^{ik}_{nt}, ν^k_{nt}, f^j_{nt}, g^k_{nt}, *and* u_{n0} *having the same meaning as the original ones and satisfying the same assumptions as those imposed on the original ones in Theorem* 2.2 *(with the same* $\delta, K, \beta, \dots$*). Assume that for* $i, j = 1, \dots, d$ *and almost all* (ω, t, x) *we have*

$$\left(a^{ij}_{nt}, a^i_{nt}, b^i_{nt}, c_{nt}\right) \to \left(a^{ij}_t, a^i_t, b^i_t, c_t\right),$$

$$\left|\sigma^{i\cdot}_{nt} - \sigma^{i\cdot}_t\right|_{\ell_2} + |\nu_{nt} - \nu_t|_{\ell_2} \to 0,$$

as $n \to \infty$. *Also assume that*

$$\sum_{j=0}^d \left\|f^j_n - f^j\right\|_{\mathbf{L}_p(\tau)} + \|g_n - g\|_{\mathbf{L}_p(\tau)} + \|u_{n0} - u_0\|_{\mathrm{tr}_0\mathcal{W}^1_p} \to 0$$

as $n \to \infty$. *Take* $\lambda \ge \lambda_0$, *take the function* u *from Theorem* 2.2, *and let* $u_n \in \mathcal{W}^1_p(\tau)$ *be the unique solutions of* (1.1) *for* $t \le \tau$ *constructed from* a^{ij}_{nt}, a^i_{nt}, b^i_{nt}, c_{nt}, σ^{ik}_{nt}, ν^k_{nt}, f^j_{nt}, *and* g^k_{nt} *and having initial values* u_{n0}.

Then, as $n \to \infty$, *we have* $\|u_n - u\|_{\mathbf{W}^1_p(\tau)} \to 0$ *and for any finite* $T \in [0,\infty)$

$$E\sup_{t\le\tau\wedge T}\|u_{nt} - u_t\|^p_{L_p} \to 0. \tag{2.11}$$

Proof. Set $v_{nt} = u_{nt} - u_t$. Then

$$dv_{nt} = \left(L_{nt}v_{nt} - \lambda v_{nt} + D_i\tilde{f}^i_{nt} + \tilde{f}^0_{nt}\right)dt + \left(\Lambda^k_{nt}v_{nt} + \tilde{g}^k_{nt}\right)dw^k_t,$$

where L_{nt} and Λ^k_{nt} are the operators constructed from a^{ij}_{nt}, a^i_{nt}, b^i_{nt}, c_{nt}, and σ^{ik}_{nt}, ν^k_{nt}, respectively, and

$$\tilde{f}^i_{nt} = f^i_{nt} - f^i_t + \left(a^{ji}_{nt} - a^{ji}_t\right) D_j u_t + \left(a^i_{nt} - a^i_t\right) u_t,$$
$$\tilde{f}^0_{nt} = f^0_{nt} - f^0_t + \left(b^i_{nt} - b^i_t\right) D_i u_t + (c_{nt} - c_t) u_t,$$
$$\tilde{g}^k_{nt} = g^k_{nt} - g^k_t + \left(\sigma^{ik}_{nt} - \sigma^{ik}_t\right) D_i u_t + \left(\nu^k_{nt} - \nu^k_t\right) u_t.$$

By Theorem 2.2 we know that $u \in \mathbf{W}^1_p(\tau)$. This, along with our assumptions and the dominated convergence theorem, implies that

$$\sum_{j=0}^d \left\| \tilde{f}^j_n \right\|_{\mathbf{L}_p(\tau)} + \|\tilde{g}_n\|_{\mathbf{L}_p(\tau)} \to 0$$

as $n \to \infty$. After that by applying (2.10) to v_{nt} we immediately see that $\|u_n - u\|_{\mathbf{W}^1_p(\tau)} \to 0$.

Assertion (2.11) is, actually, a simple corollary of the above. Indeed, by introducing $\hat{f}^j_n$ and $\hat{g}^k_n$ in an obvious way, we can write

$$dv_{nt} = \left(D_i \hat{f}^i_{nt} + \hat{f}^0_{nt}\right) dt + \hat{g}^k_{nt}\, dw^k_t, \tag{2.12}$$

and

$$\sum_{j=0}^d \left\| \hat{f}^j_n \right\|_{\mathbf{L}_p(\tau)} + \|\hat{g}_n\|_{\mathbf{L}_p(\tau)} \to 0.$$

It is standard (see, for instance, our Theorem 3.1) to derive from here the estimate

$$E \sup_{t \le \tau \wedge T} \|u_{nt} - u_t\|^p_{L_p} \le N \left(\sum_{j=0}^d \left\| \hat{f}^j_n \right\|_{\mathbf{L}_p(\tau \wedge T)} + \|\hat{g}_n\|_{\mathbf{L}_p(\tau \wedge T)} + E\|u_{n0} - u_0\|^p_{L_p} \right),$$

where N is independent of n. It is also well known that $W^{1-2/p}_p \subset L_p$, that is

$$\|u_{n0} - u_0\|_{L_p} \le N \|u_{n0} - u_0\|_{W^{1-2/p}_p}.$$

By combining all this together we obtain (2.11) and the theorem is proved. □

The following result could be proved on the basis of Theorem 2.4 in the same way as Corollary 5.11 of [6], where the solutions are approximated by solutions of equations with smooth coefficients and then a stopping time technique was used. We give here a shorter proof based on a different idea.

THEOREM 2.5. *Let $p_1, p_2 \in [2, \infty)$, $p_1 < p_2$, and let the above assumptions be satisfied with $\beta \le \beta(d, p, \delta)$ for all $p \in [p_1, p_2]$ and $\beta_1 \le \beta_1(d, p, \delta, \varepsilon)$ for all $p \in [p_1, p_2]$. Let $\lambda \ge 0$, and suppose that for $p \in [p_1, p_2]$ we have $f^j, g \in \mathbf{L}_p(\tau)$, and $u_0 \in \mathrm{tr}_0 \mathcal{W}^1_p$.*

Then the solutions corresponding to $p = p_1$ and $p = p_2$ coincide, that is, there is a unique solution $u \in \mathcal{W}^1_{p_1}(\tau) \cap \mathcal{W}^1_{p_2}(\tau)$ of (1.1) with initial data u_0.

Proof. Obviously, it suffices to concentrate on bounded τ. As is explained above in that case we may assume that λ is as large as we like. We take it so large that one could use assertion (ii) of Theorem 2.2 with any $p \in [p_1, p_2]$.

Denote by u the solution corresponding to $p = p_2$ and observe that, owing to uniqueness of solutions in $\mathcal{W}^1_{p_1}(\tau)$, we need only show that $u \in \mathcal{W}^1_{p_1}(\tau)$.

Take a nonnegative $\zeta \in C_0^\infty$ such that $\zeta(0) = 1$, set $\zeta_n(x) = \zeta(x/n)$, and notice that $u^n := u\zeta_n$ satisfies

$$du^n_t = \left(L_t u^n_t - \lambda u^n_t + D_i f^i_{nt} + f^0_{nt}\right) dt + \left(\Lambda^k_t u^n_t + g^k_{nt}\right) dw^k_t,$$

where

$$\begin{aligned}
f^i_{nt} &= f^i_t \zeta_n - u a^{ji}_t D_j \zeta_n, \quad i \geq 1,\\
f^0_{nt} &= f^0_t \zeta_n - f^i_t D_i \zeta_n - \left(a^{ij}_t D_i u_t + a^j_t u\right) D_j \zeta_n - b^i_t u_t D_i \zeta_n,\\
g^k_{nt} &= g^k_t \zeta_n - \sigma^{ik}_t u_t D_i \zeta_n.
\end{aligned}$$

It follows that for $p_1 \leq p \leq p_2$ we have

$$\|u^n\|_{\mathbf{W}^1_p(\tau)} \leq N \left(\sum_{i=0}^d \left\|f^i_n\right\|_{\mathbf{L}_p(\tau)} + \|g_n\|_{\mathbf{L}_p(\tau)} + \|u_0\zeta_n\|_{\mathrm{tr}_0 \mathcal{W}^1_p} \right). \tag{2.13}$$

One knows that with constants N independent of n

$$\|u_0\zeta_n\|_{\mathrm{tr}_0\mathcal{W}^1_p} \leq N \left(\|u_0\zeta_n\|_{\mathrm{tr}_0\mathcal{W}^1_{p_1}} + \|u_0\zeta_n\|_{\mathrm{tr}_0\mathcal{W}^1_{p_2}} \right) \leq N \left(\|u_0\|_{\mathrm{tr}_0\mathcal{W}^1_{p_1}} + \|u_0\|_{\mathrm{tr}_0\mathcal{W}^1_{p_2}} \right).$$

Similarly, and by Hölder's inequality,

$$\left\|f^i_n\right\|_{\mathbf{L}_p(\tau)} \leq N + N\|uD\zeta_n\|_{\mathbf{L}_p(\tau)} \leq N + \|u\|_{\mathbf{L}_{p_2}(\tau)} \|D\zeta_n\|_{\mathbf{L}_q(\tau)},$$

where

$$q = \frac{pp_2}{p_2 - p}.$$

Similar estimates are available for other terms in the right-hand side of (2.13). Since

$$\|D\zeta_n\|_{\mathbf{L}_q(\tau)} = N n^{-1+(p_2-p)d/(p_2 p)} \to 0$$

as $n \to \infty$ if

$$\frac{1}{p} - \frac{1}{p_2} < \frac{1}{d}, \tag{2.14}$$

estimate (2.13) implies that $u \in \mathcal{W}^1_p(\tau)$.

Thus, knowing that $u \in \mathcal{W}^1_{p_2}(\tau)$ allowed us to conclude that $u \in \mathcal{W}^1_p(\tau)$ as long as $p \in [p_1, p_2]$ and (2.14) holds. We can now replace p_2 with a smaller p and keep going in the same way each time increasing $1/p$ by the same amount until p reaches p_1. Then we get that $u \in \mathcal{W}^1_{p_1}(\tau)$. The theorem is proved. □

In many situations the following maximum principle is useful.

THEOREM 2.6. *Let the above assumptions be satisfied with $\beta \leq \beta(d, q, \delta)$ for all $q \in [2, p]$ and $\beta_1 \leq \beta_1(d, q, \delta, \varepsilon)$ for all $q \in [2, p]$. Let $\lambda \geq 0$ and $f^0 \in \mathbf{L}_p(\tau)$, $u_0 \in \mathrm{tr}_0\mathcal{W}^1_p$, $f^i = 0$, $i = 1, \ldots, d$, $g = 0$ be such that $u_0 \geq 0$ and $f^0 \geq 0$. Then for the solution u almost surely we have $u_t \geq 0$ for all finite $t \leq \tau$.*

Proof. If $p = 2$ the result is proved in [9]. For general $p \geq 2$ take the same function ζ_n as in the preceding proof, introduce $f^{ni} = f^i\zeta_n$, $g^k_n = 0$, and call u^n the solution of (1.1) with so modified free terms and the initial data $u_0\zeta_n$. By Theorem 2.5 we have $u^n \in \mathcal{W}^1_p(\tau) \cap \mathcal{W}^1_2(\tau)$. By the above, $u^n \geq 0$ and it only remains to use Theorem 2.4. The theorem is proved. □

3. Itô's formula and uniqueness. The following two "standard" results are taken from [12].

THEOREM 3.1. *Let $u \in \mathcal{W}^1_p(\tau)$, $f^j \in \mathbf{L}_p(\tau)$, $g = (g^k) \in \mathbf{L}_p(\tau)$, and assume that* (2.2) *holds for $t \le \tau$ in the sense of generalized functions. Then there is a set $\Omega' \subset \Omega$ of full probability such that*

(i) *$u_{t\wedge\tau} I_{\Omega'}$ is a continuous L_p-valued $\mathcal{F}_t$-adapted function on $[0,\infty)$;*

(ii) *for all $t \in [0,\infty)$ and $\omega \in \Omega'$ Itô's formula holds:*

$$\begin{aligned}\int_{\mathbf{R}^d} |u_{t\wedge\tau}|^p\,dx &= \int_{\mathbf{R}^d} |u_0|^p\,dx + p\int_0^{t\wedge\tau}\int_{\mathbf{R}^d} |u_s|^{p-2}u_s g^k_s\,dx\,dw^k_s\\ &+ \int_0^{t\wedge\tau}\left(\int_{\mathbf{R}^d}\left[p|u_t|^{p-2}u_t f^0_t - p(p-1)|u_t|^{p-2}f^i_t D_i u_t\right.\right.\\ &\left.\left. + (1/2)p(p-1)|u_t|^{p-2}|g_t|^2_{\ell_2}\right]dx\right)dt.\end{aligned} \tag{3.1}$$

Furthermore, for any $T \in [0,\infty)$

$$\begin{aligned}E\sup_{t\le\tau\wedge T}\|u_t\|^p_{L_p} &\le 2E\|u_0\|^p_{L_p} + NT^{p-1}\left\|f^0\right\|^p_{\mathbf{L}_p(\tau)}\\ &+ NT^{(p-2)/2}\left(\sum_{i=1}^d \left\|f^i\right\|^p_{\mathbf{L}_p(\tau)} + \|g\|^p_{\mathbf{L}_p(\tau)} + \|Du\|^p_{\mathbf{L}_p(\tau)}\right),\end{aligned} \tag{3.2}$$

where $N = N(d,p)$.

Here is an "energy" estimate.

COROLLARY 3.2. *Under the conditions of Theorem* 3.1 *assume that $\tau < \infty$ (a.s.). Then*

$$\begin{aligned}E\int_{\mathbf{R}^d}|u_0|^p\,dx + E\int_0^\tau\left(\int_{\mathbf{R}^d}\left[p|u_t|^{p-2}u_t f^0_t - p(p-1)|u_t|^{p-2}f^i_t D_i u_t\right.\right.\\ \left.\left. + (1/2)p(p-1)|u_t|^{p-2}|g_t|^2_{\ell_2}\right]dx\right)dt \ge EI_{\tau<\infty}\int_{\mathbf{R}^d}|u_\tau|^p\,dx.\end{aligned} \tag{3.3}$$

Furthermore, if τ is bounded, then there is an equality instead of inequality in (3.3).

The next result implies, in particular, uniqueness in Theorem 2.2.

LEMMA 3.3. *Under Assumption* 2.1 *there exist $\lambda_0 \ge 0$ and N depending only on d, p, K, and δ such that, for any strictly positive $\lambda \ge \lambda_0$ and any solution $u \in \mathcal{W}^1_{p,0}(\tau)$ of* (1.1) *for $t \le \tau$, we have*

$$\lambda\|u\|_{\mathbf{L}_p(\tau)} \le N\lambda^{1/2}\left(\sum_{j=1}^d \left\|f^j\right\|_{\mathbf{L}_p(\tau)} + \|g\|_{\mathbf{L}_p(\tau)}\right) + N\left\|f^0\right\|_{\mathbf{L}_p(\tau)}. \tag{3.4}$$

Furthermore, if $a^i = b^i = \nu^k \equiv 0$, then one can take $\lambda_0 = 0$.

Proof. We may assume that $f^j \in \mathbf{L}_p(\tau)$, $g = (g^k) \in \mathbf{L}_p(\tau)$, since otherwise the right-hand side of (3.4) is infinite.

If (3.4) is true for $\tau\wedge T$ in place of τ and any $T \in (0,\infty)$, then it is obviously also true as is. Therefore, we may assume that τ is finite. An advantage of this assumption is that we can use Corollary 3.2. Write (3.3) with $\hat f^i_t$, $\hat f^0_t$, and $\hat g^k_t$ in place of f^i_t, f^0_t, and g^k_t, respectively, where

$$\begin{aligned}&\hat f^i_t = a^{ji}_t D_j u_t + a^i_t u_t + f^i_t,\\ &\hat f^0_t = b^i_t D_i u_t + (c_t - \lambda)u_t + f^0_t, \quad \hat g^k_t = \sigma^{ik}_t D_i u_t + \nu^k_t u_t + g^k_t.\end{aligned}$$

Then observe that inequalities like $(a+b)^2 \leq (1+\varepsilon)a^2 + (1+\varepsilon^{-1})b^2$ show that for any $\varepsilon \in (0,1]$ we have

$$|\hat{g}_t|^2_{\ell_2} \leq (1+\varepsilon)\left|\sum_{i=1}^d \sigma^i_t D_i u_t\right|^2_{\ell_2} + 2\varepsilon^{-1}|\nu_t u_t + g_t|^2_{\ell_2}$$
$$\leq 2(1+\varepsilon)\alpha^{ij}_t (D_i u_t) D_j u_t + N\varepsilon^{-1}\left(|u_t|^2 + |g_t|^2_{\ell_2}\right).$$

Owing to (2.3), for $\varepsilon = \varepsilon(\delta) > 0$ small enough

$$\begin{aligned} I_t &:= (1/2)|u_t|^{p-2}|\hat{g}_t|^2_{\ell_2} - |u_t|^{p-2}\hat{f}^i_t D_i u_t + (p-1)^{-1}|u_t|^{p-2}u_t b^i_t D_i u_t \\ &\leq -(\delta/2)|u_t|^{p-2}|Du_t|^2 \\ &\quad + N|u_t|^{p-2}\left(|u_t|^2 + |g_t|^2_{\ell_2} + |Du_t|\,|u_t| + |Du_t|\sum_{i=1}^d \left|f^i_t\right|\right). \end{aligned} \tag{3.5}$$

Next, we use that for any $\gamma > 0$

$$|u_t|^{p-1}|Du_t| = \left(|u_t|^{(p-2)/2}|Du_t|\right)|u_t|^{p/2} \leq \gamma|u_t|^{p-2}|Du_t|^2 + \gamma^{-1}|u_t|^p,$$
$$|u_t|^{p-2}|Du_t|\,\left|f^i_t\right| \leq \gamma|u_t|^{p-2}|Du_t|^2 + \gamma^{-1}|u_t|^{p-2}\left|f^i_t\right|^2,$$

and by choosing γ appropriately find from (3.5) that

$$I_t \leq N|u_t|^p + N|u_t|^{p-2}\left(\sum_{i=1}^d \left|f^i_t\right|^2 + |g_t|^2_{\ell_2}\right). \tag{3.6}$$

After that Hölder's inequality and (3.3), where the right-hand side is nonnegative, immediately lead to

$$(\lambda - N_1)\|u\|^p_{\mathbf{L}_p(\tau)} \leq N\|u\|^{p-2}_{\mathbf{L}_p(\tau)}\left(\sum_{i=1}^d \|f^i\|^2_{\mathbf{L}_p(\tau)} + \|g\|^2_{\mathbf{L}_p(\tau)}\right) + N\|u\|^{p-1}_{\mathbf{L}_p(\tau)}\left\|f^0\right\|_{\mathbf{L}_p(\tau)}.$$

Furthermore, simple inspection of the above argument shows that, if $a^i = b^i = \nu^k \equiv 0$, then the terms with $|u_t|^2$ and $|u_t|\,|Du_t|$ in (3.5) and the term with $|u_t|^p$ in (3.6) disappear, so that we can take $N_1 = 0$ in this case (recall that $c \leq 0$). Generally, for $\lambda \geq 2N_1$ we have $\lambda - N_1 \geq (1/2)\lambda$ and

$$\bar{U}^p \leq N\bar{U}^{p-2}\bar{G}^2 + N\bar{U}^{p-1}\bar{F},$$

where

$$\bar{U} = \lambda\|u\|_{\mathbf{L}_p(\tau)}, \quad \bar{G} = \lambda^{1/2}\left(\sum_{i=1}^d \left\|f^i\right\|_{\mathbf{L}_p(\tau)} + \|g\|_{\mathbf{L}_p(\tau)}\right), \quad \bar{F} = \left\|f^0\right\|_{\mathbf{L}_p(\tau)}.$$

It follows that $\bar{U} \leq N(\bar{G} + \bar{F})$, which is (3.4) and the lemma is proved. □

4. Case of the heat equation. To move further we need the following analytic fact established in [4] (see also [7] for a complete proof).

LEMMA 4.1. *Denote by T_t the heat semigroup in R^d and let $p \geq 2$, $-\infty \leq a < b \leq \infty$, $g \in L_p((a,b)\times\mathsf{R}^d, \ell_2)$. Then*

$$\int_{\mathsf{R}^d}\int_a^b \left[\int_a^t |DT_{t-s}g_s(x)|^2_{\ell_2}\,ds\right]^{p/2} dtdx \leq N(d,p)\int_{\mathsf{R}^d}\int_a^b |g_t(x)|^p_{\ell_2}\,dtdx.$$

In this section we deal with the following model equation

$$du_t = \Delta u_t\,dt + g_t^k\,dw_t^k. \tag{4.1}$$

LEMMA 4.2. *Assume that $\tau \le T$, where the constant $T \in [0,\infty)$. Then for any $g = (g^1, g^2, \dots) \in \mathbf{L}_p(\tau)$ there exists a unique $u \in \mathcal{W}^1_{p,0}(\tau)$ satisfying (4.1) for $t \le \tau$. Furthermore, for this solution we have*

$$E\sup_{t\le\tau}\|u_t\|_{L_p}^p \le N(d,p)T^{(p-2)/2}\|g\|^p_{\mathbf{L}_p(\tau)}, \tag{4.2}$$

$$\|Du\|_{\mathbf{L}_p(\tau)} \le N(d,p)\|g\|_{\mathbf{L}_p(\tau)}. \tag{4.3}$$

Proof. By replacing the unknown function u_t with $v_t e^{\lambda t}$ we see that v_t satisfies

$$dv_t = (\Delta v_t - \lambda v_t)\,dt + e^{-\lambda t}g_t^k\,dw_t^k.$$

Since τ is bounded, the inclusions $u \in \mathcal{W}^1_{p,0}(\tau)$ and $v \in \mathcal{W}^1_{p,0}(\tau)$ are equivalent and our assertion about uniqueness follows from Lemma 3.3.

In the proof of existence we borrow part of the proof of Theorem 4.2 of [6]. As we have pointed out in the Introduction, the beginning of the theory of divergence and nondivergence type equations is the same. The main difference with that proof is that here we take $f \equiv 0$.

We take an integer $m \ge 1$, some stopping times $\tau_0 \le \tau_1 \le \cdots \le \tau_m \le T$, and some (nonrandom) functions $g^{ij} \in C_0^\infty$, $i,j = 1,\dots,m$. Then we define

$$g_t^k(x) = \sum_{i=1}^m g^{ik}(x) I_{(\tau_{i-1},\tau_i]}(t),$$

$$v_t(x) = \sum_{k=1}^m \int_0^t g_s^k(x)\,dw_s^k = \sum_{i,k=1}^m g^{ik}(x)\left(w^k_{t\wedge\tau_i} - w^k_{t\wedge\tau_{i-1}}\right), \quad t \ge 0.$$

Obviously, for any ω, the function $v_t(x)$ is continuous and bounded in (t,x) along with any derivative in x. Furthermore, the function and its derivative in x are Hölder $1/3$ continuous in t uniformly with respect to x (for almost any ω). Also, $v_t(x)$ has compact support in x.

These properties of $v_t(x)$ imply that for any ω there exists a unique classical solution of the heat equation

$$\frac{\partial}{\partial t}\bar{u}_t = \Delta\bar{u}_t + \Delta v_t, \quad t > 0,$$

with zero initial data. Furthermore,

$$\bar{u}_t(x) = \int_0^t T_{t-s}\Delta v_s(x)\,ds. \tag{4.4}$$

This formula shows, in particular, that $\bar{u}_t(x)$ is $\mathcal{F}_t$-adapted. Adding the fact that $\bar{u}_t$ is continuous in t proves that $\bar{u}_t(x)$ is predictable. The same holds for

$$(\bar{u}_t,\phi) = \int_0^t (T_{t-s}\Delta v_s,\phi)\,ds$$

with any $\phi \in C_0^\infty$. The following corollary of Minkowski's inequality

$$\|\bar{u}_t\|_{L_p} \leq \int_0^t \|\Delta v_s\|_{L_p}\, ds \tag{4.5}$$

shows that $\bar{u}_t$ is L_p-valued. Since $(\bar{u}_t, \phi)$ is predictable for any $\phi \in C_0^\infty$, $\bar{u}_t$ is weakly and, hence, strongly predictable as an L_p-valued process.

One can differentiate (4.4) with respect to x as many times as one wants and get similar statements about the derivatives of $\bar{u}_t$. In particular, (4.5) implies that for any multi-index α

$$E\int_0^T \int_{\mathsf{R}^d} |D^\alpha \bar{u}_t|^p\, dxdt \leq T^p E \int_0^T \int_{\mathsf{R}^d} |D^\alpha \Delta v_t|^p\, dxdt < \infty,$$

so that $\bar{u}_t \in \mathcal{W}^1_{p,0}(T)$.

Now, it is easily seen that

$$u_t(x) := \bar{u}_t(x) + v_t(x)$$

satisfies (4.1) pointwisely and by the above $u_t \in \mathcal{W}^1_{p,0}(T)$. The (deterministic) Fubini's theorem also shows that u_t satisfies (4.1) in the sense of distributions.

Next, we use the same simple transformation as in the proof of Lemma 4.1 of [6] and conclude that for any t and x almost surely

$$Du_t(x) = \sum_{k=1}^m \int_0^t T_{t-s} D g_s^k(x)\, dw_s^k.$$

Hence, by Burkholder–Davis–Gundy inequality

$$E|Du_t(x)|^p \leq NE\left[\int_0^t |T_{t-s} D g_s(x)|_{\ell_2}^2\, ds\right]^{p/2},$$

which along with Lemma 4.1 proves (4.3) for our particular g. Theorem 3.1 shows that (4.2) follows from (4.3) and (4.1).

The rest is trivial since the set of g's like the one above is dense in $\mathbf{L}_p(T)$ by Theorem 3.10 of [6]. The lemma is proved. □

Next we introduce the parameter λ into (4.1).

LEMMA 4.3. *Assume that $\tau \leq T$, where the constant $T \in [0, \infty)$. Let $\lambda > 0$. Then for any $g = (g^1, g^2, \dots) \in \mathbf{L}_p(\tau)$ there exists a unique $u \in \mathcal{W}^1_{p,0}(\tau)$ satisfying*

$$du_t = (\Delta u_t - \lambda u_t)\, dt + g_t^k\, dw_t^k \tag{4.6}$$

for $t \leq \tau$. Furthermore, for this solution we have

$$\lambda^{p/2}\|u\|^p_{\mathbf{L}_p(\tau)} \leq N(d,p)\|g\|^p_{\mathbf{L}_p(\tau)}, \tag{4.7}$$

$$\|Du\|_{\mathbf{L}_p(\tau)} \leq N(d,p)\|g\|_{\mathbf{L}_p(\tau)}. \tag{4.8}$$

Proof. Uniqueness and estimate (4.7) follow from Lemma 3.3. The existence immediately follows from Lemma 4.2 and the result of transformation described in the beginning of its proof. To establish (4.8) consider the heat equation

$$\frac{\partial}{\partial t} v_t = \Delta v_t - \lambda u_t. \tag{4.9}$$

Since $u \in \mathbf{L}_p(\tau)$, for almost any ω we have $u \in L_p((0,\tau)\times \mathsf{R}^d)$ and by a classical result (see, for instance, [11]) for almost any ω equation (4.9) with zero initial data has a unique solution in the class of functions such that along with derivatives in x up to the second order they belong to $L_p((0,\tau)\times \mathsf{R}^d)$. Furthermore, after writing the term $-\lambda u_t$ as $-\lambda v_t - \lambda z_t$, where $z_t = u_t - v_t$, differentiating the equation once with respect to x and using the contraction property of the heat semigroup we find

$$\|Dv\|^p_{L_p((0,\tau)\times\mathsf{R}^d)} \le \|Dz\|^p_{L_p((0,\tau)\times\mathsf{R}^d)}. \tag{4.10}$$

The solution v_t can be given by an integral formula, which implies that v_t is $\mathcal{F}_t$-adapted. It is also continuous as an L_p-valued process, and hence, is a predictable L_p-valued process. Taking expectations of both parts of (4.10) shows that $v \in \mathcal{W}^1_p(\tau)$ if $z \in \mathcal{W}^1_p(\tau)$.

Now observe that

$$dz_t = \Delta z_t\,dt + g^k_t\,dw^k_t,$$

which by Lemma 4.2 implies that $z \in \mathcal{W}^1_p(\tau)$ and

$$\|Dz\|^p_{\mathbf{L}_p(\tau)} \le N\|g\|^p_{\mathbf{L}_p(\tau)}.$$

Upon combining this with (4.10) and using the fact that $u = v + z$, we come to (4.8). The lemma is proved. □

5. A priori estimates in the general case. First we deal with the case when $\sigma = \nu = 0$.

LEMMA 5.1. *Suppose that $\sigma^{ik} \equiv \nu^k \equiv 0$. Also suppose that Assumptions* 2.1 *and* 2.2 *are satisfied with $\beta \le \beta_0$, where the way to estimate the constant $\beta_0(d,p,\delta) > 0$ is described in the proof. Let $f^j \in \mathbf{L}_p(\tau)$ and $g \in \mathbf{L}_p(\tau)$.*

Then there exist constants $\lambda_0 \ge 1$ and N, depending only on d, p, δ, K, and ε, such that for any $\lambda \ge \lambda_0$ there exists a unique $u \in \mathcal{W}^1_{p,0}(\tau)$ satisfying (1.1) *for $t \le \tau$. Furthermore, this solution satisfies the estimate*

$$\lambda^{1/2}\|u\|_{\mathbf{L}_p(\tau)} + \|Du\|_{\mathbf{L}_p(\tau)} \le N\left(\sum_{i=1}^d \left\|f^i\right\|_{\mathbf{L}_p(\tau)} + \|g\|_{\mathbf{L}_p(\tau)}\right) + N\lambda^{-1/2}\left\|f^0\right\|_{\mathbf{L}_p(\tau)}. \tag{5.1}$$

Proof. Uniqueness and part of estimate (5.1) follow from Lemma 3.3. In the rest of the proof we may assume that τ is bounded and split our argument into two parts.

Case $g^k \equiv 0$. First assume that the coefficients and f^j are nonrandom. We extend the coefficients of L following the example $a^{ij}_t(x) = \delta^{ij}$, $t < 0$, and extend f^j_t beyond $(0,\tau)$ arbitrary only requiring $f^j \in L_p(\mathsf{R}^{d+1})$.

Then by Theorem 4.5 and Remark 2.4 of [8] the equation

$$\frac{\partial}{\partial t}u_t = L_t u_t - \lambda u_t + D_i f^i_t + f^0_t \tag{5.2}$$

in R^{d+1} has a unique solution with finite norms

$$\|u\|_{L_p(\mathsf{R}^{d+1})} \quad \text{and} \quad \|Du\|_{L_p(\mathsf{R}^{d+1})}$$

provided that $\lambda \ge \lambda_0$. By Theorem 4.4 of [8]

(5.3)
$$\lambda^{1/2}\|u\|_{L_p(\mathsf{R}^{d+1})}+\|Du\|_{L_p(\mathsf{R}^{d+1})}\leq N\left(\sum_{i=1}^d\left\|f^i\right\|_{L_p(\mathsf{R}^{d+1})}+\lambda^{-1/2}\left\|f^0\right\|_{L_p(\mathsf{R}^{d+1})}\right).$$

By Theorem 3.1 the function u_t is a continuous L_p-valued function.

The proof of Theorem 4.4 of [8] is achieved on the basis of the a priori estimate (5.3) and the method of continuity by considering the family of equations

$$\frac{\partial}{\partial t}u_t=(\theta L_t+(1-\theta)\Delta)u_t-\lambda u_t+D_if_t^i+f_t^0, \tag{5.4}$$

where the parameter θ changes in $[0,1]$. We remind briefly the method of continuity because we want to show that certain properties of (5.4) which we know for $\theta=0$ propagate from $\theta=0$ to $\theta=1$.

We fix a $\theta_0\in[0,1]$ and to solve (5.4) for given f^j define a sequence of $u^n\in L_p(\mathsf{R},W_p^1)$ by solving the equation

$$\begin{aligned}\frac{\partial}{\partial t}u_t^{n+1}&=(\theta_0L_t+(1-\theta_0)\Delta)u_t^{n+1}-\lambda u_t^{n+1}\\&\quad+D_if_t^i+f_t^0+(\theta-\theta_0)(L_t-\Delta)u^n,\quad n\geq1,\quad u^0=0.\end{aligned} \tag{5.5}$$

If we know that (5.4) is uniquely solvable with θ_0 in place of θ for arbitrary $f^j\in L_p(\mathsf{R}^{d+1})$, then the sequence u^n is well defined. Furthermore, estimate (5.3) easily shows that for θ sufficiently close to θ_0 the $L_p(\mathsf{R},W_p^1)$ norm of $u^{n+1}-u^n$ goes to zero geometrically as $n\to\infty$. In this way, passing to the limit in (5.5), we obtain the solution of (5.4) for θ close to θ_0. Then we can repeat the procedure and starting from $\theta=0$ and moving step by step eventually reach $\theta=1$.

For $\theta=0$ we are dealing with solvability of the heat equation which is proved by giving the solution explicitly by means of the heat semigroup. This representation formula has two important implications:

(i) For any constant $T\in\mathsf{R}$, changing f_t^j for $t\geq T$ does not affect u_t for $t\leq T$;

(ii) If f^j are $L_p(\mathsf{R}^{d+1})$-valued measurable functions of a parameter, say ω from a measurable space, say $(\Omega,\mathcal{F}_T)$, then the solution $u\in L_p(\mathsf{R},W_p^1)$, which now depends on ω is also $\mathcal{F}_T$-measurable.

Property (i) is obtained by inspecting the representation formula. Property (ii) is true because the mapping $L_p(\mathsf{R}^{d+1})\ni f^j\to u\in L_p(\mathsf{R},W_p^1)$ is continuous and, hence, Borel measurable.

Obviously, both properties propagate from $\theta=0$ to $\theta=1$ by the above method of continuity. In particular, solutions of (5.2) on the time interval $(-\infty,T]$ depend only on the values of f_t^j for $t\in(-\infty,T]$. It follows that with the same λ and N, for any $T\in\mathsf{R}$,

$$\begin{aligned}&\lambda^{1/2}\|u\|_{L_p((-\infty,T),L_p)}+\|Du\|_{L_p((-\infty,T),L_p)}\\&\qquad\leq N\left(\sum_{i=1}^d\|f^i\|_{L_p((-\infty,T),L_p)}+\lambda^{-1/2}\|f^0\|_{L_p((-\infty,T),L_p)}\right).\end{aligned} \tag{5.6}$$

From now on, we allow the coefficients and f^j to be random, continue f^j as zero for $t<0$, and solve (5.2) for each ω. By (5.6) with $T=0$ we have that $u_t=0$ for $t\leq0$, and it makes sense considering (5.2) on $(0,T)$ for each $T\in(0,\infty)$ with zero initial condition. In such situation properties (i) and (ii) still hold.

In particular, if f^j are measurable $L_p((0,T),L_p)$-valued functions of a parameter, say ω from a measurable space, say $(\Omega,\mathcal{F}_T)$, then the solution $u\in L_p((0,T),W^1_p)$ is also $\mathcal{F}_T$-measurable. Then, from the equation itself, it follows that (u_T,ϕ) is $\mathcal{F}_T$-measurable for any $\phi\in C_0^\infty$. Since u_T takes values in L_p, it is an L_p-valued $\mathcal{F}_T$-measurable function.

If f^i_t are predictable L_p-valued functions, the above conclusions are valid for any $T\in[0,\infty)$. In particular, u_t is $\mathcal{F}_t$-adapted as an L_p-valued function and since it is continuous, u_t is a predictable L_p-valued function.

These properties and the fact that (5.6) holds for any $T\in(0,\infty)$ and ω prove the lemma in the particular case under consideration.

General case. By Lemma 4.3 there is a unique solution $v\in\mathcal{W}^1_{p,0}(\tau)$ of (4.6). Observe that

$$(L_t-\Delta)v_t=D_i\hat{f}^i_t+\hat{f}^0_t,$$

where $\hat{f}^j_t$ are functions of class $\mathbf{L}_p(\tau)$ defined by

$$\hat{f}^j_t=\left(a^{ij}_t-\delta^{ij}\right)D_iv_t+a^j_tv_t,\quad j=1,\dots,d,$$
$$\hat{f}^0_t=b^i_tD_iv_t+c_tv_t.$$

By the above there is a unique solution $u\in\mathcal{W}^1_{p,0}(\tau)$ of

$$\frac{\partial}{\partial t}u_t=L_tu_t-\lambda u_t+(L_t-\Delta)v_t+D_if^i_t+f^0_t.$$

Obviously, v_t+u_t is a solution of class $\mathcal{W}^1_{p,0}(\tau)$ of (1.1). By the particular case

$$\lambda^{1/2}\|u\|_{\mathbf{L}_p(\tau)}+\|Du\|_{\mathbf{L}_p(\tau)}\le N\sum_{i=1}^d\left(\left\|f^i\right\|_{\mathbf{L}_p(\tau)}+\left\|\hat{f}^i\right\|_{\mathbf{L}_p(\tau)}\right)$$
$$+N\lambda^{-1/2}\left(\left\|f^0\right\|_{\mathbf{L}_p(\tau)}+\left\|\hat{f}^0\right\|_{\mathbf{L}_p(\tau)}\right)$$

and to obtain (5.1), it remains only to use the estimates of v_t provided by Lemma 4.3. The lemma is proved. □

Now we allow $\sigma\neq0$.

LEMMA 5.2. (i) *Suppose that Assumption* 2.1 *is satisfied with* $K=0$ *and take* $\varepsilon\ge\varepsilon_1>0$, $\varepsilon_2\in(0,\varepsilon/4]$, $t_0\ge0$, *and* $x_0\in\mathsf{R}^d$.

(ii) *Let* $f^j\in\mathbf{L}_p(\tau)$, $g\in\mathbf{L}_p(\tau)$, *and* $u\in\mathcal{W}^1_{p,0}(\tau)$ *be such that* (1.1) *holds for* $t\le\tau$. *Assume that* $u_t(x)=0$ *if*

$$(t,x)\notin\Gamma:=(t_0,t_0+\varepsilon_1^2)\times B_{\varepsilon_2}(x_0).$$

(iii) *Assume that the couple* (a,σ) *is* $(\varepsilon,\varepsilon_1)$*-regular at* (t_0,x_0) *with* $\beta=\beta_0/3$ *in* (2.4) *and* (2.5), *where* β_0 *is the constant from Lemma* 5.1. *Also assume that*

$$|\sigma^{i\cdot}_t(x)-\sigma^{i\cdot}_t(x_0)|_{\ell_2}\le\beta_1,\quad(a^{jk}_t(y)-\alpha^{jk}_t(x_0))\xi^j\xi^k\ge\delta|\xi|^2$$

for all values of indices and arguments such that $(t,x)\in\Gamma$ *and* $(t,y)\in Q_\varepsilon(t_0,x_0)$, *where* $\beta_1=\beta_1(d,\delta,p,\varepsilon)>0$ *is a constant an estimate from below for which can be obtained from the proof.*

Then there exist constants $\lambda_0 \geq 1$ and N, depending only on d, p, δ, and ε, such that estimate (5.1) *holds provided that $\lambda \geq \lambda_0$.*

Proof. Without loss of generality we may and will assume that $x_0 = 0$. Also we modify, if necessary, a and σ in such a way that $\sigma_t^{ik}(x) = 0$ if $t \notin (t_0, t_0 + \varepsilon_1^2)$, and $a_t^{ij}(x) = \delta^{-1}\delta^{ij}$ if $t \notin (t_0, t_0 + \varepsilon_1^2)$. Obviously, under this modification assumption (iii) is preserved and (1.1) remains unaffected due to assumption (ii). The rest of the proof we split into two cases.

Case $\sigma_t^{ik}(x) = \sigma_t^{ik}(0)$ for $|x| \leq \varepsilon_2$ and $t \geq 0$. We want to apply Lemma 5.1 and for that, even if $\sigma \equiv 0$, we need a^{ij} to satisfy at least the condition $\operatorname{osc}(a^{ij}, Q) \leq \beta$ for *all* $Q \in \mathbf{Q}$ with $\rho(Q) \leq \varepsilon$. To achieve this we modify $a_t^{ij}(x)$ for $|x| \geq \varepsilon/4$ using the fact that such modifications have no effect on (1.1) since $u_t(x) = 0$ for $|x| \geq \varepsilon_2$ and $\varepsilon_2 \leq \varepsilon/4$.

Take a $\xi \in C_0^\infty(\mathsf{R}^d)$ with support lying in the ball of radius $\varepsilon/2$ centered at the origin and such that $\xi(x) = 1$ for $|x| \leq \varepsilon/4$ and $0 \leq \xi \leq 1$. Set

$$\hat{a}_t^{ij} := \xi a_t^{ij} + \delta^{-1}(1 - \xi)\delta^{ij}.$$

We can use $\hat{a}$ in place of a in (1.1). It follows by Lemma 4.7 of [6] (Itô–Wentzell formula) that the function $v_t(x) := u_t(x + x_t)$ satisfies the equation

$$dv_t(x) = \left(\bar{L}_t v_t(x) - \lambda v_t + D_i \bar{f}_t^i + \bar{f}_t^0\right) dt + \bar{g}_t^k(x + x_t)\, dw_t^k, \tag{5.7}$$

where

$$\begin{aligned}
\bar{L}_t\phi &= D_j\left(\bar{a}_t^{ij} D_i \phi\right), \quad \bar{a}_t^{ij}(x) = \hat{a}_t^{ij}(x + x_t) - \alpha_t^{ij}(0), \\
\bar{f}_t^i(x) &:= f_t^i(x + x_t) - \sigma_t^{ik}(0) g_t^k(x + x_t), \quad i = 1, \ldots, d, \\
\bar{f}_t^0(x) &:= f_t^0(x + x_t), \quad \bar{g}_t^k(x) = g_t^k(x + x_t),
\end{aligned}$$

and the process $x_t = (x_t^1, \ldots, x_t^d)$ is defined by

$$x_t^i = -\int_0^t \sigma_s^{ik}(0)\, dw_s^k.$$

This fact shows that the assertion of the present lemma is a direct consequence of Lemma 5.1 in case the latter is applicable to (5.7).

As is easy to see we will be able to apply Lemma 5.1 to (5.7) if we can find $\varepsilon' = \varepsilon'(d, \delta, \varepsilon, p) > 0$ such that

$$\frac{1}{t - s}\int_s^t \left(\left|\bar{a}_r^{ij} - \bar{a}_{r(B)}^{ij}\right|\right)_{(B)} dr \leq \beta_0, \tag{5.8}$$

whenever $(s, t) \times B \in \mathbf{Q}$ and $\rho(B) \leq \varepsilon'$.

Denote by N, with or without subscripts, various (large) constants depending only on d, δ, and ε and observe that $|D\xi| \leq N$. It follows easily that for $B \in \mathbf{B}$ we have

(5.9)

$$\begin{aligned}
\left(\left|\bar{a}_r^{ij} - \bar{a}_{r(B)}^{ij}\right|\right)_{(B)} &\leq \left(\left|\xi a_r^{ij} - (\xi a_r^{ij})_{(B+x_r)}\right|\right)_{(B+x_r)} + \delta^{-1}\delta^{ij}(|\xi - \xi_{(B+x_r)}|)_{(B+x_r)} \\
&\leq \left(\left|\xi a_r^{ij} - (\xi a_r^{ij})_{(B+x_r)}\right|\right)_{(B+x_r)} + N_1\rho =: I_r + N_1\rho,
\end{aligned}$$

where and below $\rho = \rho(B)$.

Let z be the center of B and set

$$y_r = (z + x_r)(\rho + \varepsilon/2)|z + x_r|^{-1}$$

if $|z + x_r| \geq \rho + \varepsilon/2$ and $y_r = z + x_r$ otherwise. Observe that y_r is continuous in r and

$$|y_r| \leq \rho + \varepsilon/2. \tag{5.10}$$

Next we claim that

$$I_r \leq 2\left(\left|a_r^{ij} - a_{r(B_\rho + y_r)}^{ij}\right|\right)_{(B_\rho + y_r)} + N_2\rho. \tag{5.11}$$

If (5.11) is true, then by combining it with (5.9) and using (5.10) we find that the left-hand side of (5.8) is less than

$$(N_1 + N_2)\rho + 2 \sup_{|y| \leq \rho + \varepsilon/2} \operatorname{osc}\left(a^{ij}, Q_\rho + (0, y), 0\right)$$

if $\sigma_t^{nm}(0) = 0$ for all t, n, m or, in general, less than

$$(N_1 + N_2)\rho + 2\operatorname{Osc}\left(a^{ij}, Q_\rho, \rho + \varepsilon/2\right),$$

where $Q_\rho = (s, t) \times B_\rho$. Now (2.4) and (2.5) imply that (5.8) is satisfied for $\rho \leq \varepsilon'$ if we choose $\varepsilon' > 0$ so that

$$(N_1 + N_2)\varepsilon' \leq \beta_0/3, \quad \varepsilon' \leq \varepsilon/4.$$

Therefore, it remains only to prove the claim. Obviously, if $|z + x_r| \geq \rho + \varepsilon/2$, then $I_r = 0$ and (5.11) holds.

In case $|z + x_r| < \rho + \varepsilon/2$ the estimates

$$(|h_r - h_{r(B')}|)_{(B')} \leq \frac{1}{|B'|^2} \int_{B'} \int_{B'} |h_r(y) - h_r(z)|\, dydz \leq 2(|h_r - h_{r(B')}|)_{(B')},$$

$$\left|\xi(y)a_r^{ij}(y) - \xi(z)a_r^{ij}(z)\right| \leq \xi(y)\left|a_r^{ij}(y) - a_r^{ij}(z)\right| + N|\xi(y) - \xi(z)|$$

show that

$$I_r \leq 2\left(\left|a_r^{ij} - a_{r(B + x_r)}^{ij}\right|\right)_{(B + x_r)} + N\rho,$$

which is equivalent to (5.11). This proves the lemma in the particular case under consideration.

General case. We rewrite the term $\Lambda_t^k u_t + g_t^k$ in (1.1) as $\sigma_t^{ik}(0)D_i u_t + \bar{g}_t^k$ with $\bar{g}_t^k = g_t^k + (\sigma_t^{ik} - \sigma_t^{ik}(0))D_i u_t$ and use the above result to conclude that estimate (5.1) holds with $N = N_1 = N_1(d, p, \delta, \varepsilon)$ if we add to its right-hand side

$$N_2(d, p, \delta, \varepsilon)\beta_1 \|Du\|_{\mathbf{L}_p(\tau)}.$$

By choosing $\beta_1 = \beta_1(d, p, \delta, \varepsilon)$ so that $N_2\beta_1 \leq 1/2$, we get (5.1) with $2N_1$ in place of N_1. The lemma is proved. □

Remark 5.3. If Assumption 2.1 is satisfied with $K = 0$ and a_t^{ij} and σ_t^{ik} depend only on ω and t, then the assertion of Lemma 5.2 is true with $\lambda_0 = 0$ and $N = N(d, p, \delta)$ and without requiring u to have compact support. This fact can be obtained

by following the arguments in section 4.3 of [6]. Even though those arguments are much longer, they allow one to prove a very general result that, roughly speaking, "whatever estimate can be established for solutions of the heat equation in Banach function spaces with norms that are invariant under time dependent shifting of the x coordinate, the same estimate with the same constant also holds for solutions of the parabolic equations with no lower order terms and with the matrix of the second order coefficients depending only on t and dominating (in the matrix sense) the unit matrix" (see [5]).

The next step is to consider equations with lower order terms. The following lemma and its corollary are stated in a slightly more general form than it is needed in the present article. The point is that we intend to use them in a subsequent article about equations in half spaces.

LEMMA 5.4. *Let $G \subset \mathsf{R}^d$ be a domain (perhaps, $G = \mathsf{R}^d$) and take $\varepsilon \geq \varepsilon_1 > 0$ and $\varepsilon_2 \in (0, \varepsilon/4]$.*

(i) *Let $f^j, g \in \mathbf{L}_p(\tau)$ and let $u \in \mathcal{W}^1_{p,0}(\tau)$ satisfy (1.1) for $t \leq \tau$ and be such that $u_t(x) = 0$ if $x \notin G$.*

(ii) *Suppose that Assumption 2.1 is satisfied.*

(iii) *Suppose that assumption (iii) of Lemma 5.2 is satisfied for any $t_0 \geq 0$ and x_0 such that $\operatorname{dist}(x_0, G) \leq \varepsilon_2$.*

Then there exist constants $N, \lambda_0 \geq 0$, depending only on d, p, K, δ, ε, ε_1, and ε_2, such that estimate (5.1) holds true whenever $\lambda \geq \lambda_0$.

Proof. As usual we will use partitions of unity. Take a nonnegative $\xi \in C_0^\infty(B_{\varepsilon_2})$ with unit L_p-norm and take a nonnegative $\eta \in C_0^\infty((0, \varepsilon_1^2))$ with unit L_p-norm. For $s \in \mathsf{R}$ and $y \in \mathsf{R}^d$ introduce

$$\zeta(t,x) = \xi(x)\eta(t), \quad \zeta^{s,y}(t,x) = \zeta(t-s, x-y), \quad u_t^{s,y}(x) = \zeta^{s,y}(t,x)u_t(x)$$

so that, in particular,

$$|u_t(x)|^p = \int_{\mathsf{R}^{d+1}} |u_t^{s,y}(x)|^p \, dyds. \tag{5.12}$$

Observe that, for each s, y,

$$\begin{aligned} du_t^{s,y} = &\left(\sigma_t^{ik} D_i u_t^{s,y} + \hat{g}_t^{s,y,k}\right) dw_t^k \\ &+ \left(D_j\left(a_t^{ij} D_i u_t^{s,y}\right) - \lambda u_t^{s,y} + D_j \hat{f}_t^{s,y,j} + \hat{f}_t^{s,y,0}\right) dt \end{aligned} \tag{5.13}$$

for $t \leq \tau$, where we dropped the argument x (and ω) and

$$\begin{aligned} \hat{g}_t^{s,y,k} &= \zeta^{s,y}\left(\nu_t^k u_t + g_t^k\right) - u_t \sigma_t^{ik} D_i \zeta^{s,y}, \\ \hat{f}_t^{s,y,j} &= \zeta^{s,y}\left(a_t^j u_t + f_t^j\right) - a_t^{ij} u_t D_i \zeta^{s,y}, \quad j = 1, \dots, d, \\ \hat{f}_t^{s,y,0} &= \zeta^{s,y}\left(f_t^0 + b_t^i D_i u_t + c_t u_t\right) - f_t^j D_j \zeta^{s,y} - \left(a_t^{ij} D_i u_t + a_t^j u_t\right) D_j \zeta^{s,y} + \zeta_t^{s,y} u_t, \end{aligned}$$

and $\zeta_t^{s,y}(t,x) = \xi(x-y)\eta'(t-s)$.

As is easy to see $u^{s,y}(t,x) = 0$ for $(t,x) \notin (s_+, s_+ + \varepsilon_1^2) \times B_{\varepsilon_2}(y)$. Therefore, by Lemma 5.2 if $\operatorname{dist}(y, G) \leq \varepsilon_2$, then

$$\begin{aligned} &\lambda^{p/2} \|u^{s,y}\|^p_{\mathbf{L}_p(\tau)} + \|Du^{s,y}\|^p_{\mathbf{L}_p(\tau)} \\ &\qquad \leq N\left(\sum_{j=1}^d \left\|\hat{f}^{s,y,j}\right\|^p_{\mathbf{L}_p(\tau)} + \|\hat{g}^{s,y}\|^p_{\mathbf{L}_p(\tau)}\right) + N\lambda^{-p/2}\left\|\hat{f}^{s,y,0}\right\|^p_{\mathbf{L}_p(\tau)} \end{aligned} \tag{5.14}$$

provided that $\lambda \geq \lambda_0$, where N and λ_0 depend only on d, δ, p, and ε. This estimate also, obviously, holds if $\operatorname{dist}(y, G) > \varepsilon_2$ since then $u_t^{s,y} \equiv 0$.

Next,

$$\begin{aligned}
&\left|\hat{f}_t^{s,y,j}\right| \leq N\bar{\zeta}^{s,y}|u_t| + \zeta^{s,y}\left|f_t^j\right|, \quad j = 1, \dots, d,\\
&\left|\hat{f}_t^{s,y,0}\right| \leq N\bar{\zeta}^{s,y}(|Du_t| + |u_t|) + N\bar{\zeta}^{s,y}\sum_{j=0}^{d}|f_t^j|,\\
&|\hat{g}_t^{s,y}|_{\ell_2} \leq N\bar{\zeta}^{s,y}|u_t| + \zeta^{s,y}|g_t|_{\ell_2},
\end{aligned}$$

where $\bar{\zeta} = \zeta + |D\zeta| + |\zeta_t|$, $\bar{\zeta}^{s,y}(t,x) = \bar{\zeta}(t-s, x-y)$, and here and below we allow the constants N to depend only on d, p, δ, K, ε, ε_1, and ε_2.

We also notice that $|\zeta^{s,y}Du_t| \leq |D(\zeta^{s,y}u_t)| + \bar{\zeta}^{s,y}|u_t|$. Then we find that

$$\begin{aligned}
&\lambda^{p/2}\|\zeta^{s,y}u\|_{\mathbf{L}_p(\tau)}^p + \|\zeta^{s,y}Du\|_{\mathbf{L}_p(\tau)}^p\\
&\leq N\left(\sum_{i=1}^{d}\left\|\bar{\zeta}^{s,y}f^i\right\|_{\mathbf{L}_p(\tau)}^p + \|\zeta^{s,y}g\|_{\mathbf{L}_p(\tau)}^p + \left\|\bar{\zeta}^{s,y}u\right\|_{\mathbf{L}_p(\tau)}^p\right)\\
&\quad + N\lambda^{-p/2}\left(\left\|\bar{\zeta}^{s,y}f^0\right\|_{\mathbf{L}_p(\tau)}^p + \left\|\bar{\zeta}^{s,y}Du\right\|_{\mathbf{L}_p(\tau)}^p\right).
\end{aligned}$$

We integrate through this estimate and use formulas like (5.12). Then we obtain

$$\begin{aligned}
&\lambda^{p/2}\|u\|_{\mathbf{L}_p(\tau)}^p + \|Du\|_{\mathbf{L}_p(\tau)}^p\\
&\leq N_1\left(\sum_{i=1}^{d}\left\|f^i\right\|_{\mathbf{L}_p(\tau)}^p + \|g\|_{\mathbf{L}_p(\tau)}^p + \|u\|_{\mathbf{L}_p(\tau)}^p\right) + N_1\lambda^{-p/2}\left(\left\|f^0\right\|_{\mathbf{L}_p(\tau)}^p + \|Du\|_{\mathbf{L}_p(\tau)}^p\right).
\end{aligned}$$

Finally, we increase $\lambda_0 \geq 0$, if necessary, in such a way that $N_1\lambda^{-p/2} \leq 1/2$ for $\lambda \geq \lambda_0$. Then we obviously arrive at (5.1) with $N = 2N_1$. The lemma is proved. □

To the best of the author's knowledge, the following multiplicative estimate is new even in the deterministic case.

COROLLARY 5.5. *Let $\lambda = 0$. Then under the assumptions of Lemma 5.4 we have*

$$\|Du\|_{\mathbf{L}_p(\tau)} \leq N\left(\sum_{i=1}^{d}\left\|f^i\right\|_{\mathbf{L}_p(\tau)} + \|g\|_{\mathbf{L}_p(\tau)} + \left\|f^0\right\|_{\mathbf{L}_p(\tau)}^{1/2}\|u\|_{\mathbf{L}_p(\tau)}^{1/2} + \|u\|_{\mathbf{L}_p(\tau)}\right),$$

where N depends only on d, p, K, δ, ε, ε_1, and ε_2.

Indeed, take $\lambda > 0$ and add and subtract the term $(\lambda_0 + \lambda)u_t\,dt$ on the right in (1.1), thus introducing λ into the equation and modifying f_t^0 by including into it one of $(\lambda_0 + \lambda)u_t$. Then after applying (5.1), we see that

$$\begin{aligned}
\|Du\|_{\mathbf{L}_p(\tau)} \leq N\Bigg(&\sum_{i=1}^{d}\left\|f^i\right\|_{\mathbf{L}_p(\tau)} + \|g\|_{\mathbf{L}_p(\tau)}\\
&+ (\lambda_0 + \lambda)^{-1/2}\left\|f^0\right\|_{\mathbf{L}_p(\tau)} + (\lambda_0 + \lambda)^{1/2}\|u\|_{\mathbf{L}_p(\tau)}\Bigg).
\end{aligned}$$

Now it remains only to take the inf with respect to $\lambda > 0$.

Proof of Lemma 2.1. By bearing in mind an obvious shifting of time, we see that in the proof of assertions (i)–(iii) we may assume that $s = 0$.

(i) First of all observe that uniqueness of solution of (2.7) is well known even in a much wider class than $\mathcal{W}^1_p(\infty)$.

Let $u_0 \in \mathrm{tr}_0 \mathcal{W}^1_p$, then $u_0 \in W^{1-2/p}$ for almost each ω and there is a unique solution of the heat equation

$$dv_t = \Delta v_t \, dt$$

of class $L_p((0,1), W^1_p)$ with initial condition u_0. Furthermore,

$$\|v\|_{L_p((0,1),W^1_p)} \sim \|u_0\|_{W^{1-2/p}_p}.$$

Next, take a $\zeta \in C_0^\infty(\mathsf{R})$ such that $\zeta_0 = 1$ and $\zeta_t = 0$ for $t \geq 1/2$ and define $\psi_t(x) = e^{-t} v_t(x) \zeta_t$ for $t \in [0,1]$ and as zero if $t \geq 1/2$. Notice that (a.s.)

$$\psi \in L_p\left(\mathsf{R}_+, W^1_p\right),$$

and

$$\frac{\partial}{\partial t} \psi_t = \Delta \psi_t - \psi_t + e^{-t} \zeta_t' v_t.$$

Then it is a classical result that there exists a unique $\phi \in L_p(\mathsf{R}_+, W^2_p)$ which solves the equation

$$d\phi_t = \left(\Delta \phi_t - \phi_t + e^{-t} \zeta_t' v_t\right) dt$$

with *zero* initial condition. In addition,

$$\|\phi\|_{L_p(\mathsf{R}_+,W^2_p)} \leq N \|\zeta' v\|_{L_p(\mathsf{R}_+,L_p)} \leq N \|u_0\|_{W^{1-2/p}_p},$$

where the constants N depend only on d and p. Owing to these estimates and uniqueness, the operators mapping u_0 into v and ϕ are continuous (and nonrandom). Since u_0 is $\mathcal{F}_0$-measurable, the same is true for ψ, ϕ, and $u = \psi - \phi$, which is of class $L_p(\mathsf{R}_+, W^1_p)$, satisfies (2.7), and equals u_0 for $t = 0$. Also, for each ω

$$\|u\|_{L_p(\mathsf{R}_+,W^1_p)} \leq \|\psi\|_{L_p(\mathsf{R}_+,W^1_p)} + \|\phi\|_{L_p(\mathsf{R}_+,W^1_p)} \leq N \|u_0\|_{W^{1-2/p}_p},$$

where N depends only on d and p. By raising the extreme terms to the pth power and taking expectations we get the first inequality in (2.8) and also finish proving the "only if" part of (i).

To prove the "if" part assume that we have a $v \in \mathcal{W}^1_p(\infty)$ satisfying (2.7) and equal u_0 at $t = 0$. Then $u_t = v_t e^t$ satisfies $\partial u_t / \partial t = \Delta u_t$ and is of class $\mathcal{W}^1_p(1)$. It follows that almost all ω we have $u \in L_p((0,1), W^1_p)$, $u_0 \in W^{1-2/p}_p$, and

$$\|u_0\|_{W^{1-2/p}_p} \leq N \|u\|_{L_p((0,1),W^1_p)} \leq N \|v\|_{L_p(\mathsf{R}_+,W^1_p)}.$$

By raising all expressions to the power p and taking expectations we arrive at the second estimate in (2.8). Assertion (i) is proved.

The "only if" part in (ii) is, actually, proved above. To prove the "if" part write

$$dv_t = \left(D_i f^i_t + f^0_t\right) dt + g^k_t \, dw^k_t = \left(\Delta v_t - \lambda v_t + D_i \hat{f}^i_t + \hat{f}^0_t\right) dt + g^k_t \, dw^k_t,$$

where the constant $\lambda > 0$ will be chosen later, $\hat{f}^i_t = f^i_t - D_i v_t$, $i = 1, \dots, d$, $\hat{f}^0_t = f^0_t + \lambda v_t$, and $\hat{f}^j, g \in \mathbf{L}_p(1)$. Next, take the function ζ as above, set $u = v\zeta$, and observe that

$$du_t = \left(\Delta u_t - \lambda u_t + D_i \check{f}^i_t + \check{f}^0_t\right) dt + \check{g}^k_t \, dw^k_t, \tag{5.15}$$

where $\check{f}^0 = \zeta \hat{f}^0 + v\zeta'$, $\check{f}^i_t = \zeta \hat{f}^i_t$, $i = 1, \dots, d$, $\check{g}^k = \zeta g^k$, and $\check{f}^j, \check{g} \in \mathbf{L}_p(\infty)$ and $u \in \mathcal{W}^1_p(\infty)$.

By Lemma 5.1, for λ fixed and large enough (actually, one can take $\lambda = 1$, which is shown by using dilations), (5.15) with zero initial condition admits a unique solution $\psi \in \mathcal{W}^1_p(\infty)$ and

$$\begin{aligned} \|\psi\|_{\mathbf{W}^1_p(\infty)} &\le N \left(\sum_{j=0}^d \left\| \check{f}^j \right\|_{\mathbf{L}_p(\infty)} + \|\check{g}\|_{\mathbf{L}_p(\infty)} \right) \\ &\le N \left(\sum_{j=0}^d \left\| f^j \right\|_{\mathbf{L}_p(1)} + \|g\|_{\mathbf{L}_p(1)} + \|v\|_{\mathbf{W}^1_p(1)} \right). \end{aligned}$$

Then the difference $\phi = u - \psi$ satisfies (2.7), is of class $\mathcal{W}^1_p(\infty)$, and $\phi_0 = u_0$. By assertion (i) we have $u_0 \in \mathrm{tr}_0 \mathcal{W}^1_p$, which proves the "if" part in (ii). Furthermore,

$$\begin{aligned} \|u_0\|_{\mathrm{tr}_0 \mathcal{W}^1_p} &\le N \|\phi\|_{\mathbf{W}^1_p(\infty)} \le N \|u\|_{\mathbf{W}^1_p(\infty)} + N \|\psi\|_{\mathbf{W}^1_p(\infty)} \\ &\le N \|v\|_{\mathbf{W}^1_p(1)} + N \|\psi\|_{\mathbf{W}^1_p(\infty)} \\ &\le N \left(\sum_{j=0}^d \left\| f^j \right\|_{\mathbf{L}_p(1)} + \|g\|_{\mathbf{L}_p(1)} + \|v\|_{\mathbf{W}^1_p(1)} \right). \end{aligned}$$

This proves assertion (iii).

To prove (iv) observe that obvious dilations of the t axis allow us to assume that $s = 1$. Then write (2.2) for $t \in [0, 1]$ and notice that tu_t admits representation (2.2) with new f^j and g^k having simple relations with u_t and the original f^j and g^k. It follows that in the rest of the proof we may assume that $u_0 = 0$.

In that case, take a sufficiently large $\lambda > 0$ and consider the equation

$$dv_t = \left(\Delta v_t - \lambda v_t + D_i \bar{f}^i_t + \bar{f}^0_t\right) dt + \bar{g}^k_t \, dw^k_t$$

for $t \ge 0$ with zero initial condition, where

$$\begin{aligned} \bar{f}^i_t &= f^i_t I_{(0,1)}(t) - D_i u_t I_{(0,1)}(t), \quad i = 1, \dots, d, \\ \bar{f}^0_t &= \left(f^0_t + \lambda u_t\right) I_{(0,1)}(t), \quad \bar{g}^k_t = g^k_t I_{(0,1)}(t). \end{aligned}$$

By uniqueness, $v_t = u_t$ for $t \in [0, 1]$ and by assertion (iii) we have $v_1 \in \mathrm{tr}_1 \mathcal{W}^1_p$. This fact combined with already known estimates of v proves assertion (iv). The lemma is proved. □

6. Proof of Theorem 2.2. Owing to Lemma 2.1 we may assume that we are given a v as in assertion (i) of the lemma. By introducing a new unknown function $\bar{u} = u - v$ we see that u satisfies (1.1) and $u_0 = v_0$ if and only if $\bar{u}_0 = 0$ and

$$d\bar{u}_t = \left(L_t \bar{u}_t - \lambda \bar{u}_t + D_j \bar{f}^j_t + \bar{f}^0_t \right) dt + \left(\Lambda^k_t \bar{u}_t + \bar{g}^k_t \right) dw^k_t,$$

where

$$\bar{f}^j_t = f^j_t - D_j v_t + a^{ij}_t D_i v_t + a^j_t v_t, \quad j = 1, \dots, d,$$
$$\bar{f}^0_t = f^0_t + b^i_t D_i v_t + (c_t - \lambda + 1) v_t,$$
$$\bar{g}^k_t = g^k_t + \sigma^{ik}_t D_i v_t + \nu^k_t v_t.$$

By Lemma 2.1 we have $\bar{f}^j, \bar{g} \in \mathbf{L}_p(\tau)$ and the problem of finding solutions of (1.1) with initial data u_0 is thus reduced to the same problem but with zero initial data.

Furthermore, if estimate (2.10) holds for solutions with zero initial condition, then (for $\lambda \geq \lambda_0$)

$$\begin{aligned}
\lambda^{1/2}\|u\|_{\mathbf{L}_p(\tau)} + \|Du\|_{\mathbf{L}_p(\tau)} - \lambda^{1/2}\|v\|_{\mathbf{L}_p(\tau)} - \|Dv\|_{\mathbf{L}_p(\tau)} & \\
&\leq \lambda^{1/2}\|\bar{u}\|_{\mathbf{L}_p(\tau)} + \|D\bar{u}\|_{\mathbf{L}_p(\tau)} \\
&\leq N\left(\sum_{i=1}^d \|\bar{f}^i\|_{\mathbf{L}_p(\tau)} + \|\bar{g}\|_{\mathbf{L}_p(\tau)}\right) + N\lambda^{-1/2}\left\|\bar{f}^0\right\|_{\mathbf{L}_p(\tau)} \\
&\leq N\left(\sum_{i=1}^d \left\|f^i\right\|_{\mathbf{L}_p(\tau)} + \|g\|_{\mathbf{L}_p(\tau)} + \|v\|_{\mathbf{W}^1_p(\tau)}\right) \\
&\quad + N\lambda^{-1/2}\left(\left\|f^0\right\|_{\mathbf{L}_p(\tau)} + \|v\|_{\mathbf{W}^1_p(\tau)}\right) + N\lambda^{1/2}\|v\|_{\mathbf{L}_p(\tau)},
\end{aligned}$$

which yields (2.10) in full generality.

It follows that while proving (2.10) we may also assume that $u_0 = 0$. Therefore, in the rest of the proof of assertions (i) and (ii) we assume that $u_0 = 0$. Having in mind the substitution $u_t = v_t e^{-\mu t}$, we see that while proving assertion (i) it suffices to concentrate on large λ and prove only the second part of the assertion.

We recall that we suppose that Assumption 2.2 is satisfied with $\beta = \beta_0/3$ and β_0 from Lemma 5.1 and Assumption 2.3 is satisfied with β_1 defined in Lemma 5.2. It follows that assumption (iii) of Lemma 5.2 is satisfied for any (t_0, x_0).

Now we take λ_0 larger than the one in Lemma 3.3 and the one in Lemma 5.4. In that case uniqueness follows from Lemma 3.3. In the proof of existence we will rely on the method of continuity and the a priori estimate (5.1) which is established in Lemma 5.4. For $\lambda \geq \lambda_0$ and $\theta \in [0,1]$ we consider the equation

$$du_t = [(\theta L_t + (1-\theta)\Delta)u_t - \lambda u_t + D_i f^i_t + f^0_t]\,dt + \left(\theta \Lambda^k_t u_t + g^k_t\right)\,dw^k_t. \tag{6.1}$$

We call a $\theta \in [0,1]$ "good" if the assertions of the theorem hold for (6.1). Observe that 0 is a "good" point by Lemma 5.1. Now to prove the theorem it suffices to show that there exists a $\gamma > 0$ such that if θ_0 is a good point, then all points of the interval $[\theta_0 - \gamma, \theta_0 + \gamma] \cap [0,1]$ are "good". So fix a "good" θ_0 and for any $v \in \mathbf{W}^1_p(\tau)$ consider the equation

$$\begin{aligned}
du_t = [(\theta_0 L_t + (1-\theta_0)\Delta)u_t - \lambda u_t + (\theta - \theta_0)(L_t - \Delta)v_t + D_i f^i_t + f^0_t]\,dt & \\
+ \left(\theta_0 \Lambda^k_t u_t + (\theta - \theta_0)\Lambda^k v_t + g^k_t\right)\,dw^k_t. &
\end{aligned} \tag{6.2}$$

Observe that

$$(L_t - \Delta)v_t = D_j\left(\left(a^{ij} - \delta^{ij}\right)D_i v_t + a^j_t v_t\right) + b^i_t D_i v_t + c v_t$$

and recall that $v \in \mathbf{W}^1_p(\tau)$. It follows by assumption that (6.2) has a unique solution $u \in \mathcal{W}^1_{p,0}(\tau)$ $(\subset \mathbf{W}^1_p(\tau))$.

In this way, for f^j and g being fixed, we define a mapping $v \to u$ in the space $\mathbf{W}^1_p(\tau)$. It is important to keep in mind that the image u of $v \in \mathbf{W}^1_p(\tau)$ is always in $\mathcal{W}^1_{p,0}(\tau)$. Take $v', v'' \in \mathbf{W}^1_p(\tau)$ and let u', u'' be their corresponding images. Then $u := u' - u''$ satisfies

$$du_t = [(\theta_0 L_t + (1-\theta_0)\Delta)u_t - \lambda u_t + (\theta - \theta_0)(L_t - \Delta)v_t)]\,dt + \left(\theta_0 \Lambda^k_t u_t + (\theta - \theta_0)\Lambda^k v_t\right)\,dw^k_t,$$

where $v = v' - v''$. It follows by Lemma 5.4 that

$$\|u\|_{\mathbf{W}^1_p(\tau)} \leq N|\theta - \theta_0|\,\|v\|_{\mathbf{W}^1_p(\tau)}$$

with a constant N independent of f, g, v', v'', θ_0, and θ. For θ sufficiently close to θ_0, our mapping is a contraction and, since $\mathbf{W}^1_p(\tau)$ is a Banach space, it has a fixed point. This fixed point is in $\mathcal{W}^1_{p,0}(\tau)$ and, obviously, satisfies (6.1). This proves assertion (i) of the theorem.

Estimate (2.10) is proved above in Lemma 5.4 and assertion (iii) follows from Theorem 3.1. The theorem is proved. □

SEMILINEAR STOCHASTIC EQUATIONS IN A HILBERT SPACE WITH A FRACTIONAL BROWNIAN MOTION*

T. E. DUNCAN†, B. MASLOWSKI‡, AND B. PASIK-DUNCAN†

Abstract. The solutions of a family of semilinear stochastic equations in a Hilbert space with a fractional Brownian motion are investigated. The nonlinear term in these equations has primarily only a growth condition assumption. An arbitrary member of the family of fractional Brownian motions can be used in these equations. Existence and uniqueness for both weak and mild solutions are obtained for some of these semilinear equations. The weak solutions are obtained by a measure transformation that verifies absolute continuity with respect to the measure for the solution of the associated linear equation. Some examples of stochastic differential and partial differential equations are given that satisfy the assumptions for the solutions of the semilinear equations.

Key words. semilinear stochastic equations, fractional Brownian motion, stochastic partial differential equations, absolute continuity of measures

1. Introduction.

Fractional Brownian motion denotes a family of Gaussian processes with continuous sample paths that are indexed by the Hurst parameter $H \in (0,1)$ and that have properties that appear empirically in a wide variety of physical phenomena, such as hydrology, economic data, telecommunications, and medicine. Since some physical phenomena are naturally modeled by stochastic partial differential equations and the randomness can be described by a fractional Gaussian noise, it is important to study the problems of the solutions of stochastic differential equations in a Hilbert space with a fractional Brownian motion. A significant family of these stochastic equations is the set of semilinear equations, so it is important to investigate the existence and the uniqueness of the solutions of the equations and the sample path properties of the solutions. If primarily only some growth assumptions are made on the nonlinear terms in the semilinear equations, then it is natural to investigate weak solutions, especially those that arise by an absolutely continuous transformation of the measure of the solution of the associated linear stochastic equation.

The study of the solutions of stochastic equations in an infinite-dimensional space with a (cylindrical) fractional Brownian motion (for example, stochastic partial differential equations) has been relatively limited. For the Hurst parameter $H \in (1/2,1)$, linear and semilinear equations with an additive fractional Gaussian noise, the formal derivative of a fractional Brownian motion, are considered in [8, 13, 15, 28]. Random dynamical systems described by such stochastic equations and their fixed points are studied in [22]. A pathwise (or nonprobabilistic) approach is used in [21] to study a parabolic equation with a fractional Gaussian noise where the stochastic term is a nonlinear function of the solution. Strong solutions of bilinear evolution equations

with a fractional Brownian motion are considered in [11, 12], and the same type of equation is studied in [33], where a fractional Feynman–Kac formula is obtained. A stochastic wave equation with a fractional Gaussian noise is considered in [2], and a stochastic heat equation with a multiparameter fractional Gaussian noise is studied in [16, 18].

One facet of the motivation for the study of weak solutions in an infinite-dimensional space follows from some results [7, 27] for weak solutions in finite-dimensional spaces that use an absolutely continuous transformation of measures which generalize the result of Girsanov [14] for Brownian motion.

In this paper, a similar analysis is made for infinite-dimensional state spaces. While the structure of the infinite-dimensional Girsanov theorem is analogous to the finite-dimensional case, significant distinct difficulties arise when the application of this theorem is used for stochastic equations in infinite-dimensional spaces. First the driving process is only cylindrical, so the Girsanov theorem can only be used to transform the semilinear equation to a linear equation that is a fractional Ornstein–Uhlenbeck process. Since there is no classical strong solution to the linear equation, the mild solution must be used, making the analysis of the transformation of the measures by the Radon–Nikodým derivative more difficult because a suitable sample path regularity of the Ornstein–Uhlenbeck process must be verified. Unlike the finite-dimensional case, this regularity is not immediate and some assumptions on the coefficients in the linear equation must be made which are known for the case of Brownian motion. The sample regularity requirement increases as the Hurst parameter H increases. Dually the operators that appear in the Radon–Nikodým derivative are less regular as H increases. Thus the applicability of the Girsanov theorem is not immediate in this case and some conditions must be determined for the whole procedure to succeed. Furthermore, for $H > \frac{1}{2}$ in the finite-dimensional case it is assumed that the nonlinear term in the semilinear equation satisfies a global Hölder condition, but this assumption is not satisfied in many typical examples in infinite-dimensional spaces, such as reaction-diffusion equations. Thus this Hölder condition is relaxed here as well.

In section 2, some results from fractional calculus are given, and these results are used to describe a kernel function for an integral operator that provides an isometry of the second moment of Wiener-type stochastic integrals with respect to a fractional Brownian motion and the Lebesgue space of square integrable functions. Furthermore, some recent results for the solution of a linear stochastic equation in a Hilbert space [28] are described. In section 3, semilinear stochastic equations in a Hilbert space are studied. Initially, an absolute continuity of measures result for transforming the solution of a linear stochastic equation is verified that can be viewed as an analogue of the result of Girsanov [14] for a transformation of a finite-dimensional standard Brownian motion. For a semilinear stochastic equation where the nonlinear term satisfies a linear growth condition and some additional conditions are satisfied, it is shown that there is one and only one weak solution. The weak solution is obtained by verifying an absolute continuity of the measure of the solution with respect to the measure of the solution of the associated linear equation. The cases $H \in (0, 1/2)$ and $H \in (1/2, 1)$ are treated separately. Absolute continuity of the above measures is verified when the nonlinearity satisfies a power growth condition and some additional assumptions are made. In section 4, some examples of stochastic differential and partial differential equations are given that satisfy the assumptions of the theorems.

2. Preliminaries. In this section, a cylindrical fractional Brownian motion in a separable Hilbert space is introduced, a Wiener-type stochastic integral with respect to this process is defined, and some basic properties of this integral are noted. Initially, some facts from the theory of fractional integration (cf. [31]) are described. Let $(V, \|\cdot\|, \langle\cdot,\cdot\rangle)$ be a separable Hilbert space. If $\varphi \in L^1([0,T],V)$, then for $\alpha > 0$ the left-side and the right-side fractional (Riemann–Liouville) integrals of φ are defined (for almost all $t \in [0,T]$) by

$$\left(I^{\alpha}_{0+}\varphi\right)(t) = \frac{1}{\Gamma(\alpha)} \int_0^t (t-s)^{\alpha-1}\,\varphi(s)\,ds$$

and

$$\left(I^{\alpha}_{T-}\varphi\right)(t) = \frac{1}{\Gamma(\alpha)} \int_t^T (s-t)^{\alpha-1}\varphi(s)\,ds,$$

respectively, where $\Gamma(\cdot)$ is the gamma function. For $\alpha \in (0,1)$ the inverse operators of these fractional integrals are called fractional derivatives and can be given by their respective Weyl representations

$$\left(D^{\alpha}_{0+}\psi\right)(t) = \frac{1}{\Gamma(1-\alpha)} \left(\frac{\psi(t)}{t^{\alpha}} + \alpha \int_0^t \frac{\psi(t)-\psi(s)}{(t-s)^{\alpha+1}}\,ds\right)$$

and

$$\left(D^{\alpha}_{T-}\psi\right)(t) = \frac{1}{\Gamma(1-\alpha)} \left(\frac{\psi(t)}{(T-t)^{\alpha}} + \alpha \int_t^T \frac{\psi(s)-\psi(t)}{(s-t)^{\alpha+1}}\,ds\right),$$

where $\psi \in I^{\alpha}_{0+}\left(L^1([0,T],V)\right)$ and $\psi \in I^{\alpha}_{T-}\left(L^1([0,T],V)\right)$, respectively.

Let $K_H(t,s)$ for $0 \le s \le t \le T$ be the real-valued kernel function

$$K_H(t,s) = \frac{\tilde{c}_H (t-s)^{H-\frac{1}{2}}}{\Gamma\left(H+\frac{1}{2}\right)} + \frac{\tilde{c}_H\left(\frac{1}{2}-H\right)}{\Gamma\left(H+\frac{1}{2}\right)} \int_s^t (u-s)^{H-\frac{3}{2}} \left(1-\left(\frac{s}{u}\right)^{\frac{1}{2}-H}\right) du \tag{2.1}$$

for $H \in (0,1/2)$. If $H \in (1/2,1)$, then K_H has a simpler form as

$$K_H(t,s) = \frac{\hat{c}_H}{\Gamma\left(H-\frac{1}{2}\right)} s^{\frac{1}{2}-H} \int_s^t (u-s)^{H-\frac{3}{2}} u^{H-\frac{1}{2}}\,du. \tag{2.2}$$

The terms $\tilde{c}_H$ and $\hat{c}_H$ are constants that depend only on H.

Define the integral operator $\mathbb{K}_H$ induced from the kernel K_H by

$$\mathbb{K}_H\varphi(t) = \int_0^t K_H(t,s)h(s)\,ds \tag{2.3}$$

for $h \in L^2([0,T],V)$. It is well known [31] that

$$\mathbb{K}_H \colon L^2([0,T],V) \to I^{H+\frac{1}{2}}_{0+}\left(L^2([0,T],V)\right)$$

is a bijection and $\mathbb{K}_H$ can be described as

$$\mathbb{K}_H h(s) = \overline{c}_H I^{2H}_{0+}\left(u_{\frac{1}{2}-H} I^{\frac{1}{2}-H}_{0+}\left(u_{H-\frac{1}{2}}h\right)\right)(s) \tag{2.4}$$

for $H \in (0, 1/2]$ and

$$\mathbb{K}_H h(s) = c_H I_{0+}^1 \left(u_{H-\frac{1}{2}} I_{0+}^{H-\frac{1}{2}} \left(u_{\frac{1}{2}-H} h \right) \right)(s) \tag{2.5}$$

for $H \in [1/2, 1)$, where

$$c_H = \left[\frac{2H\Gamma\left(H+\frac{1}{2}\right)\Gamma\left(\frac{3}{2}-H\right)}{\Gamma(2-2H)} \right]^{\frac{1}{2}}, \tag{2.6}$$

$$\overline{c}_H = c_H \Gamma(2H),$$

and

$$u_a(s) = s^a I$$

for $s \geq 0$ and $a \in \mathbb{R}$. The inverse operator

$$\mathbb{K}_H^{-1} \colon I_{0+}^{H+\frac{1}{2}} \left(L^2([0,T],V) \right) \to L^2([0,T],V)$$

is given by

$$\mathbb{K}_H^{-1} \varphi(s) = \overline{c}_H^{-1} s^{\frac{1}{2}-H} D_{0+}^{\frac{1}{2}-H} \left(u_{H-\frac{1}{2}} D_{0+}^{2H} \varphi \right)(s) \tag{2.7}$$

for $H \in (0, 1/2]$ and

$$\mathbb{K}_H^{-1} \varphi(s) = c_H^{-1} s^{H-\frac{1}{2}} D_{0+}^{H-\frac{1}{2}} \left(u_{\frac{1}{2}-H} D\varphi \right)(s) \tag{2.8}$$

for $H \in [1/2, 1)$ and $\varphi \in I_{0+}^{H+\frac{1}{2}} \left(L^2([0,T],V) \right)$. Note that if $\varphi \in H^1([0,T],V)$, the Sobolev space, then

$$\mathbb{K}_H^{-1} \varphi(s) = \overline{c}_H^{-1} s^{H-\frac{1}{2}} I_{0+}^{\frac{1}{2}-H} \left(u_{\frac{1}{2}-H} \varphi' \right)(s) \tag{2.9}$$

for $H \in (0, 1/2]$.

Since the operator $\mathbb{K}_H^{-1}$ plays an important role in what follows, it is desirable to have some information about its domain $I_{0+}^{H+\frac{1}{2}}\left(L^2([0,T],V)\right)$. It is straightforward that $I_{0+}^{H+\frac{1}{2}} \left(L^2([0,T],V) \right) \subset C^\beta([0,T],V)$ for $\beta > \frac{1}{2} - H$ and $H \in (0, 1/2)$. However, in section 3, a more refined result is needed. If $H \in (1/2, 1)$, then $I_{0+}^{H+\frac{1}{2}} \left(L^2([0,T],V) \right) \subset L^2([0,T],V)$.

A definition of the stochastic integral of a deterministic V-valued function with respect to a scalar fractional Brownian motion $(\beta(t), t \geq 0)$ is given. This definition uses the methods in [1, 6, 11, 30]. An alternative, equivalent method is given in [10].

A family of linear operators $(\mathcal{K}_H^*, H \in (0,1))$ is defined which provides an isometry between Wiener-type integrals of a fractional Brownian motion and $L^2([0,T],V)$. It is written as an adjoint because the linear operator $\mathcal{K}_H$ occurs naturally in the factorization of the covariance for a fractional Brownian motion in L^2.

Let $\mathcal{K}_H^* \colon \mathcal{E} \to L^2([0,T],V)$ be the linear map given by

$$\mathcal{K}_H^* \varphi(t) = \varphi(t) K_H(T,t) + \int_t^T (\varphi(s) - \varphi(t)) \frac{\partial K_H}{\partial s}(s,t)\, ds \tag{2.10}$$

for $\varphi \in \mathcal{E}$ and K_H given by (2.1), where $\mathcal{E}$ is the linear space of V-valued step functions on $[0,T]$, that is, $\varphi \in \mathcal{E}$ if

$$\varphi(t) = \sum_{i=1}^{n-1} x_i \mathbb{1}_{[t_i,t_{i+1})}(t),$$

where $x_i \in V$ for $i \in \{1,\dots,n-1\}$ and $0 = t_1 < t_2 < \cdots < t_n = T$.

Define the stochastic integral as

$$\int_0^T \varphi \, d\beta := \sum_{i=1}^{n} x_i \left(\beta(t_{i+1}) - \beta(t_i)\right).$$

It follows directly that

$$\mathbb{E}\left\| \int_0^T \varphi \, d\beta \right\|^2 = |\mathcal{K}_H^* \varphi|^2_{L^2([0,T],V)}, \tag{2.11}$$

where $|\cdot|_{L^2([0,T],V)}$ is the norm in $L^2([0,T],V)$ induced by the inner product. Let $(\mathcal{H}, |\cdot|_{\mathcal{H}}, \langle\cdot,\cdot\rangle_{\mathcal{H}})$ be the Hilbert space obtained by the completion of the pre-Hilbert space $\mathcal{E}$ with the inner product

$$\langle \varphi, \psi \rangle_{\mathcal{H}} := \langle \mathcal{K}_H^* \varphi, \mathcal{K}_H^* \psi \rangle_{L^2([0,T],V)} \tag{2.12}$$

for $\varphi, \psi \in \mathcal{E}$. The stochastic integral is extended to an arbitrary $\varphi \in \mathcal{H}$ by the isometry (2.11). Thus $\mathcal{H}$ is a linear space of integrable functions, and it is useful to obtain some more specific information about $\mathcal{H}$. If $H \in (1/2,1)$, then it is easily verified that $\mathcal{H} \supset \tilde{\mathcal{H}}$, where $\tilde{\mathcal{H}}$ is the Banach space of Borel measurable functions with the norm $|\cdot|_{\tilde{\mathcal{H}}}$ given by

$$|\varphi|^2_{\tilde{\mathcal{H}}} := \int_0^T \int_0^T \|\varphi(u)\| \, \|\varphi(v)\| \, \phi_H(u-v) \, du \, dv, \tag{2.13}$$

where $\phi_H(u) = H(2H-1)|u|^{2H-2}$, and it can be verified that $\tilde{\mathcal{H}} \supset L^{\frac{1}{H}}([0,T],V)$ and, in particular, $\tilde{\mathcal{H}} \supset L^2([0,T],V)$ (cf. [12]). If $\varphi \in \tilde{\mathcal{H}}$ and $H > 1/2$, then

$$\mathbb{E}\left\| \int_0^T \varphi \, d\beta \right\|^2 = \int_0^T \int_0^T \langle \varphi(u), \varphi(v) \rangle \, \phi_H(u-v) \, du \, dv. \tag{2.14}$$

If $H \in (0,1/2)$, then the space of integrable functions is smaller than for $H \in (1/2,1)$. For $H \in (0,1/2)$ it is known that $\mathcal{H} \supset H^1([0,T],V)$ (cf. [17, Theorem 5.20]) and $\mathcal{H} \supset C^\beta([0,T],V)$ for each $\beta > 1/2 - H$ (a more specific result is given in the next section). If $H \in (0,1/2)$, then the linear operator $\mathcal{K}_H^*$ can be described by a fractional derivative

$$\mathcal{K}_H^* \varphi(t) = c_H t^{\frac{1}{2}-H} D_{T-}^{\frac{1}{2}-H} \left(u_{H-\frac{1}{2}} \varphi \right)(t), \tag{2.15}$$

where its domain is $\mathcal{H} = I_{T-}^{\frac{1}{2}-H}\left(L^2([0,T],V)\right)$ (cf. [1, Proposition 6]). If $H \in (1/2,1)$, then

$$\mathcal{K}_H^* \varphi(t) = c_H t^{\frac{1}{2}-H} I_{T-}^{H-\frac{1}{2}} \left(u_{H-\frac{1}{2}} \varphi \right)(t). \tag{2.16}$$

A standard cylindrical fractional Brownian motion is defined now.

DEFINITION 2.1. *Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a complete probability space. A cylindrical process $\langle B, \cdot\rangle \colon \Omega \times \mathbb{R}_+ \times V \to \mathbb{R}$ on $(\Omega, \mathcal{F}, \mathbb{P})$ is called a standard cylindrical fractional Brownian motion with the Hurst parameter $H \in (0,1)$ if*

(1) *for each $x \in V \setminus \{0\}$, $\frac{1}{\|x\|}\langle B(\cdot), x\rangle$ is a standard scalar fractional Brownian motion with the Hurst parameter H;*
(2) *for $\alpha, \beta \in \mathbb{R}$ and $x, y \in V$*

$$\langle B(t), \alpha x + \beta y\rangle = \alpha\langle B(t), x\rangle + \beta\langle B(t), y\rangle \quad \text{a.s. } \mathbb{P}.$$

Note that $\langle B(t), x\rangle$ has the interpretation of the evaluation of the functional $B(t)$ at x though the process $B(\cdot)$ does not take values in V.

For $H = 1/2$, this definition is the usual one for a standard cylindrical Wiener process in V. For a complete orthonormal basis $(e_n, n \in \mathbb{N})$ of V, letting $\beta_n(t) = \langle B(t), e_n\rangle$ for $n \in \mathbb{N}$, the sequence of scalar processes $(\beta_n, n \in \mathbb{N})$ is independent and B can be represented by the formal series

$$B(t) = \sum_{n=1}^{\infty} \beta_n(t) e_n \tag{2.17}$$

that does not converge a.s. in V.

Naturally associated with a standard cylindrical fractional Brownian motion is a standard cylindrical Wiener process $(W(t), t \geq 0)$ in V such that, formally, $\dot{B}(t) = \mathcal{K}_H \dot{W}(t)$. For $x \in V \setminus \{0\}$, let $\beta_x(t) = \langle B(t), x\rangle$. It is elementary to verify from (2.1) that there is a scalar Wiener process $(w_x(t), t \geq 0)$ such that

$$\beta_x(t) = \int_0^t K_H(t,s)\, dw_x(s) \tag{2.18}$$

for $t \in \mathbb{R}_+$. Dually, $w_x(t) = \beta_x\big((\mathcal{K}_H^*)^{-1} \mathbb{1}_{[0,t)}\big)$, where $\mathcal{K}_H^*$ is given by (2.15) or (2.16) and $V = \mathbb{R}$. Thus there is a formal expansion of W,

$$W(t) = \sum_{n=1}^{\infty} w_n(t) e_n, \tag{2.19}$$

where $(e_n, n \in \mathbb{N})$ is a complete orthonormal basis for V and $w_n = \langle W, e_n\rangle$ for $n \in \mathbb{N}$.

Now, the stochastic integral $\int_0^T G\, dB$ is defined for a suitable operator-valued function $G \colon [0,T] \to \mathcal{L}(V)$ so that the integral is a V-valued random variable.

DEFINITION 2.2. *Let $G \colon [0,T] \to \mathcal{L}(V)$ be Borel measurable, let $(e_n, n \in \mathbb{N})$ be a complete orthonormal basis in V, let $G(\cdot)e_n \in \mathcal{H}$ for each $n \in \mathbb{N}$, and let B be a standard cylindrical fractional Brownian motion for some fixed $H \in (0,1)$. The stochastic integral $\int_0^T G\, dB$ is defined as*

$$\int_0^T G\, dB := \sum_{n=1}^{\infty} \int_0^T G e_n\, d\beta_n, \tag{2.20}$$

provided the infinite series converges in $L^2(\Omega, V)$.

It is elementary to verify that this definition does not depend on the complete orthonormal basis that is used.

The following proposition describes some $\mathcal{L}(V)$-valued functions G that can be used as integrands in Definition 2.2.

PROPOSITION 2.3. *Let $G\colon [0,T] \to \mathcal{L}(V)$ be Borel measurable and let $G(\cdot)x \in \mathcal{H}$ for each $x \in V$. Let $\Gamma_T\colon V \to L^2([0,T],V)$ be given as*

$$(\Gamma_T x)(t) = (\mathcal{K}_H^* G x)(t) \tag{2.21}$$

for $t \in [0,T]$ and $x \in V$. If $\Gamma_T \in \mathcal{L}_2\left(V, L^2([0,T],V)\right)$, the linear space of Hilbert–Schmidt operators, then the stochastic integral (2.20) is a centered Gaussian V-valued random variable with the covariance operator $\tilde{Q}_T$ given by

$$\tilde{Q}_T x = \int_0^T \sum_{n=1}^{\infty} \langle (\Gamma_T e_n)(s), x\rangle (\Gamma_T e_n)(s)\, ds. \tag{2.22}$$

This integral does not depend on the choice of the complete orthonormal basis $(e_n, n \in \mathbb{N})$ in V.

Proof. Substituting G in the definition of the stochastic integral (2.20), it is clear that the terms of the summation on the right-hand side are V-valued Gaussian random variables by the construction of the integral for a scalar fractional Brownian motion, and the sequence of random variables $\left(\int_0^T G e_n\, d\beta_n, n \in \mathbb{N}\right)$ is independent. Computing the second moment of the tail of the series in (2.20) yields

$$\begin{aligned}\mathbb{E}\left\|\sum_{k=m}^{\infty} G e_k\, d\beta_k\right\|^2 &= \sum_{k=m}^{\infty} \mathbb{E}\left\|\int_0^T G e_k\, d\beta_k\right\|^2 = \sum_{k=m}^{\infty} \int_0^T \left\|(\mathcal{K}_H^* G e_k)(s)\right\|^2 ds \\ &= \sum_{k=m}^{\infty} \int_0^T \left\|(\Gamma_T e_k)(s)\right\|^2 ds = \sum_{k=m}^{\infty} \left|\Gamma_T e_k\right|^2_{L^2([0,T],V)}.\end{aligned}$$

It is clear that this final series tends to zero as m tends to infinity. Thus there is convergence in $L^2(\Omega, V)$ of the partial sums of the infinite series in (2.20).

To verify that (2.20) is a Gaussian random variable and the form of the covariance $\tilde{Q}_T$, initially note that for any $\varphi \in \mathcal{H}$ and $x \in V$, there is the equality

$$\int_0^T \varphi\, d\beta_x = \int_0^T \mathcal{K}_H^* \varphi\, dw_x, \tag{2.23}$$

where w_x is the Wiener process given by (2.18). The terms in the infinite series on the right-hand side of (2.20) are V-valued, independent centered Gaussian random variables with the sequence of covariance operators $\left(\tilde{Q}_T^{(n)}, n \in \mathbb{N}\right)$

$$\tilde{Q}_T^{(n)} x = \int_0^T \langle (\mathcal{K}_H^* G e_n)(s), x\rangle (\mathcal{K}_H^* G e_n)(s)\, ds \tag{2.24}$$

for each $n \in \mathbb{N}$ and $x \in V$. Thus

$$\begin{aligned}\tilde{Q}_T x &= \sum_{n=1}^{\infty} \int_0^T \langle (\mathcal{K}_H^* G e_n)(s), x\rangle (\mathcal{K}_H^* G e_n)(s)\, ds \\ &= \int_0^T \sum_{n=1}^{\infty} \langle (\Gamma_T e_n)(s), x\rangle (\Gamma_T e_n)(s)\, ds.\end{aligned} \tag{2.25}$$

The summability of the infinite series on the right-hand side follows from the Hilbert–Schmidt property of Γ_T. The independence of the stochastic integral from the choice of the complete orthonormal basis follows from (2.23) and the analogous property for stochastic integrals with respect to a standard cylindrical Wiener process. □

Since for almost all $t \in [0,T]$ the linear operator $\Gamma_T(\cdot)(t) : V \to V$ is Hilbert–Schmidt, so we denote for almost all $t \in [0,T]$ the adjoint of $\Gamma_T(\cdot)(t)$ as $\Gamma_T^*(\cdot)(t) : V \to V$. It follows by (2.25) that for $x, y \in V$,

$$\begin{aligned}\left\langle \tilde{Q}_T x, y \right\rangle &= \int_0^T \sum_{n=1}^{\infty} \langle (\Gamma_T e_n)(s), x\rangle \langle (\Gamma_T e_n)(s), y\rangle \, ds \\ &= \int_0^T \sum_{n=1}^{\infty} \langle e_n, (\Gamma_T^* x)(s)\rangle \langle e_n, (\Gamma_T^* y)(s)\rangle \, ds \\ &= \int_0^T \langle (\Gamma_T^* x)(s), (\Gamma_T^* y)(s)\rangle \, ds \\ &= \int_0^T \langle \Gamma_T \Gamma_T^* x(s), y\rangle \, ds.\end{aligned}$$

If $H \in (1/2, 1)$, then $\tilde{Q}_T$ satisfies

$$\tilde{Q}_T = \int_0^T \int_0^T G(u) G^*(v) \phi_H(u-v) \, du \, dv,$$

where $\phi_H(u) = H(2H-1)|u|^{2H-2}$ and G is assumed to satisfy

$$\int_0^T \int_0^T |G(u)|_{\mathcal{L}_2(V)} |G(v)|_{\mathcal{L}_2(V)} \phi_H(u-v) \, du \, dv < \infty$$

(cf. [13, Proposition 2.2]).

The next proposition shows that some densely defined linear operators commute with the stochastic integration.

PROPOSITION 2.4. *If $\tilde{A}$: $\mathrm{Dom}(\tilde{A}) \to V$ is a closed linear operator,* $\mathrm{Dom}(\tilde{A}) \subset V$, *and G: $[0,T] \to \mathcal{L}(V)$ is Borel measurable such that $G([0,T]) \subset \mathrm{Dom}(\tilde{A})$ and both G and $\tilde{A}G$ satisfy the conditions for G in Proposition* 2.3, *then*

$$\int_0^T G \, dB \subset \mathrm{Dom}(\tilde{A}) \quad \textit{a.s. } \mathbb{P}$$

and

$$\tilde{A} \int_0^T G \, dB = \int_0^T \tilde{A} G \, dB \quad \textit{a.s. } \mathbb{P}. \tag{2.26}$$

Proof. By the assumptions on G and $\tilde{A}G$, it follows that $Ge_n \in \mathcal{H}$ and $\tilde{A}Ge_n \in \mathcal{H}$ for $n \in \mathbb{N}$, so by a standard argument using a sequence of step function integrands, the following equality is satisfied:

$$\tilde{A} \int_0^T Ge_n \, d\beta_n = \int_0^T \tilde{A} G e_n \, d\beta_n.$$

Since the sequence of integrals that are obtained from a complete orthonormal basis $(e_n, n \in \mathbb{N})$ are Gaussian random variables it follows that

$$\lim_{m\to\infty} \sum_{n=1}^{m} \int_0^T Ge_n \, d\beta_n = \int_0^T G \, dB \quad \text{a.s. } \mathbb{P} \tag{2.27}$$

and

$$\lim_{m\to\infty} \tilde{A} \left(\sum_{n=1}^{m} \int_0^T Ge_n \, d\beta_n \right) = \lim_{m\to\infty} \sum_{n=1}^{m} \int_0^T \tilde{A}Ge_n \, d\beta_n = \int_0^T \tilde{A}G \, dB \quad \text{a.s. } \mathbb{P}.$$

Since $\tilde{A}$ is a closed linear operator it follows that $\int_0^T G \, dB \in \mathrm{Dom}(\tilde{A})$ a.s. $\mathbb{P}$ and equality (2.26) is satisfied. □

Some results are reviewed for a linear stochastic differential equation with a cylindrical fractional Brownian motion whose solution is often called a fractional Ornstein–Uhlenbeck process. This process is a mild solution of the linear stochastic equation

$$\begin{aligned} dZ(t) &= AZ(t) \, dt + \Phi \, dB(t), \\ Z(0) &= x, \end{aligned} \tag{2.28}$$

where $Z(t)$, $x \in V$, $(B(t), t \geq 0)$ is a standard cylindrical fractional Brownian with $H \in (0,1)$, $\Phi \in \mathcal{L}(V)$, A: $\mathrm{Dom}(A) \to V$, $\mathrm{Dom}(A) \subset V$, and A is the infinitesimal generator of a strongly continuous semigroup $(S(t), t \geq 0)$ on V. A mild solution of (2.28) is

$$\begin{aligned} Z(t) &= S(t)x + \int_0^t S(t-r)\Phi \, dB(r) \\ &= S(t)x + \hat{Z}(t), \end{aligned} \tag{2.29}$$

where the stochastic integral in (2.29) is given by Definition 2.2.

Typically it is assumed that $(S(t), t \geq 0)$ is an analytic semigroup. In this case, there is a $\hat{\beta} \in \mathbb{R}$ such that the operator $\hat{\beta}I - A$ is uniformly positive on V; that is, the resolvent set contains $\{\lambda \in \mathbb{C}; |\arg \lambda| < \pi/2 + \delta\} \cup U$, where $\delta > 0$ and U is a neighborhood of zero.

For each $\delta \geq 0$, $(V_\delta, \|\cdot\|_\delta)$ is a Hilbert space where $V_\delta = \mathrm{Dom}\left((\hat{\beta}I - A)^\delta\right)$ with the graph norm topology so that

$$\|x\|_\delta = \left\| \left(\hat{\beta}I - A\right)^\delta x \right\|.$$

For the mild solution of (2.28), the cases $H \in (0, 1/2)$ and $H \in (1/2, 1)$ have been treated separately [13, 28] because the conditions for similar results are somewhat different. The case $H = 1/2$ (Brownian motion) has been studied extensively (cf. [4]).

For $H \in (1/2, 1)$, the following sample path property of the solution is described in [13].

PROPOSITION 2.5. *If $H \in (1/2, 1)$, $S(t)\Phi \in \mathcal{L}_2(V)$ for each $t > 0$ and*

$$\int_0^{T_0} \int_0^{T_0} u^{-\alpha} v^{-\alpha} |S(u)\Phi|_{\mathcal{L}_2(V)} |S(v)\Phi|_{\mathcal{L}_2(V)} \phi_H(u-v) \, du \, dv < \infty \tag{2.30}$$

for some $T_0 > 0$ and $\alpha > 0$, then there is a Hölder continuous V-valued version of the process $(\hat{Z}(t), t \geq 0)$ with Hölder exponent $\beta < \alpha$, where $\hat{Z}$ is the stochastic convolution in (2.29) and ϕ_H is given in (2.13). If $(S(t), t \geq 0)$ is an analytic semigroup, then there is a version of the process $(\hat{Z}(t), t \in [0,T])$ with $C^{\beta}([0,T], V_{\delta})$ sample paths for each $T > 0$ and $\beta + \delta < \alpha$.

For each $H \in (0,1)$, there are the following results for the sample path behavior of the mild solution [28].

PROPOSITION 2.6. *Let $(S(t), t \geq 0)$ be an analytic semigroup, let $H \in (0,1)$, and let*

$$|S(t)\Phi|_{\mathcal{L}_2(V)} \leq ct^{-\gamma} \tag{2.31}$$

for $t \in [0,T]$, some $c > 0$, and $\gamma \in [0, H)$. Let $\alpha \geq 0$ and $\delta \geq 0$ satisfy

$$\alpha + \delta + \gamma < H. \tag{2.32}$$

Then there is a version of the process $(\hat{Z}(t), t \in [0,T])$ with $C^{\alpha}([0,T], V_{\delta})$ sample paths. If it is assumed instead of (2.31) and (2.32) that $\Phi \in \mathcal{L}_2(V)$ and $\alpha + \delta < H$, then the process $\left(\hat{Z}(t), t \in [0,T]\right)$ has a $C^{\alpha}([0,T], V_{\delta})$ version. In particular, there is a $C^{\alpha}([0,T], V)$ version for $0 < \alpha < H$.

3. Semilinear stochastic equations. In this section, both weak and mild solutions are obtained for various semilinear stochastic equations with a fractional Brownian motion. The cases $H \in (0, 1/2)$ and $H \in (1/2, 1)$ are treated separately as in the case of the linear stochastic equations (Propositions 2.5 and 2.6). The weak solution of a semilinear equation is obtained by an absolutely continuous transformation of the measure for the solution of the associated linear equation. The absolute continuity methods given here are an analogue of the results for the measure of a finite-dimensional fractional Brownian motion [7, 9, 25, 26] and the results for Wiener measure [3,14]. For a fixed $H \in (0,1)$ and $T > 0$, let $(\mathcal{F}_t, t \in [0,T])$ be the filtration for the standard cylindrical fractional Brownian motion $(B(t), t \in [0,T])$ with the Hurst parameter H. The sub-σ-algebra $\mathcal{F}_t \subset \mathcal{F}$ can be generated by $\sigma(\beta_n(s), s \in [0,t], n \in \mathbb{N})$, where $(\beta_n, n \in \mathbb{N})$ is a sequence of independent scalar fractional Brownian motions with the Hurst parameter H that is given in the definition of a standard cylindrical fractional Brownian motion (Definition 2.1).

The following result describes an absolute continuity for a transformation of a standard cylindrical fractional Brownian motion.

THEOREM 3.1. *Let $H \in (0,1)$ and $T > 0$ be fixed and let $(u(t), t \in [0,T])$ be a V-valued, $(\mathcal{F}_t)$-adapted process such that*

1.
$$\int_0^T \|u(t)\| \, dt < \infty \quad \text{a.s. } \mathbb{P}$$

and

2.
$$U(\cdot) := \int_0^{\cdot} u(s) \, ds \in I_{0+}^{H+\frac{1}{2}}\left(L^2([0,T], V)\right) \quad \text{a.s. } \mathbb{P}.$$

Furthermore, it is assumed that

$$\mathbb{E}\xi(T) = 1,$$

where

$$\xi(T) = \exp\left[\int_0^T \left\langle \mathbb{K}_H^{-1}(U)(t), dW(t)\right\rangle - \frac{1}{2}\int_0^T \left\|\mathbb{K}_H^{-1}(U)(t)\right\|^2 dt\right], \tag{3.1}$$

where $(W(t), t \in [0,T])$ *is a standard cylindrical Wiener process in* V *given by* (2.19) *and* $\mathbb{K}_H^{-1}$ *is the inverse of the integral operator* $\mathbb{K}_H$ *in* (2.3). *Then the process* $\left(\tilde{B}(t), t \in [0,T]\right)$ *given by*

$$\tilde{B}(t) := B(t) - U(t)$$

is a standard cylindrical fractional Brownian motion in V *with the Hurst parameter* H *on the probability space* $\left(\Omega, \mathcal{F}, \tilde{\mathbb{P}}\right)$, *where*

$$\frac{d\tilde{\mathbb{P}}}{d\mathbb{P}} = \xi(T) \quad a.s. \tag{3.2}$$

Proof. Initially, it is noted that for an $(\mathcal{F}_t)$-adapted process, $(\eta(t), t \in [0,T])$ with $\eta \in L^2([0,T], V)$ a.s. $\mathbb{P}$, $\int_0^T \langle \eta, dW\rangle$ is defined by

$$\int_0^T \langle \eta, dW\rangle = \sum_{n=1}^{\infty} \int_0^T \langle \eta, e_n\rangle \, dw_n,$$

where the sequences $(\beta_n, n \in \mathbb{N})$ and $(w_n, n \in \mathbb{N})$ are related by (2.18). It is shown that $\mathbb{K}_H^{-1}U$ satisfies the conditions of η so that the stochastic integral in (2.20) is well-defined. Recall that the linear operator $\mathbb{K}_H$ given in (2.3) is a bijection

$$\mathbb{K}_H \colon L^2([0,T], V) \to I_{0+}^{H+\frac{1}{2}}\left(L^2([0,T], V)\right),$$

so by assumption 1 in Theorem 3.1, $\mathbb{K}_H^{-1}(U) \in L^2([0,T], V)$ a.s. $\mathbb{P}$. From the definition of $\mathbb{K}_H$, it follows that $\left(\mathbb{K}_H^{-1}(U)(t), t \in [0,T]\right)$ is an $(\mathcal{F}_t)$-adapted process because U is $(\mathcal{F}_t)$-adapted. By the construction of the standard cylindrical Wiener process W, it is a Wiener process with respect to $(\mathcal{F}_t)$ so ξ_T is a well-defined random variable. By a Girsanov theorem for Wiener processes in infinite dimensions (cf. [4, 24]), equality (3.2) defines a probability $\tilde{\mathbb{P}}$ on $(\Omega, \mathcal{F})$ such that

$$\tilde{W}(t) := W(t) - \int_0^t \mathbb{K}_H^{-1}(U)(s)\, ds$$

is a standard cylindrical Wiener process in V. Let

$$\tilde{\beta}_n(t) := \langle B(t), e_n\rangle - \langle U(t), e_n\rangle$$

and

$$\tilde{w}_n(t) = \langle W(t), e_n\rangle - \left\langle \int_0^t \mathbb{K}_H^{-1}(U)(s)\, ds, e_n \right\rangle.$$

It follows that

$$\begin{aligned}
\int_0^t K_H(t,s)\, d\tilde{w}_n(s) &= \int_0^t K_H(t,s)\, dw_n(s) - \int_0^t K_H(t,s)\left\langle \mathbb{K}_H^{-1}(U)(s), e_n\right\rangle ds \\
&= \beta_n(t) - \left\langle \int_0^t K_H(t,s)\left(\mathbb{K}_H^{-1}(U)(s)\right) ds, e_n \right\rangle \\
&= \beta_n(t) - \left\langle \mathbb{K}_H\mathbb{K}_H^{-1}(U)(t), e_n\right\rangle \\
&= \beta_n(t) - \langle U(t), e_n\rangle = \tilde{\beta}_n(t).
\end{aligned} \tag{3.3}$$

Thus $(\tilde{B}(t), t \in [0,T])$ is a standard cylindrical fractional Brownian motion in V with the Hurst parameter H on $\big(\Omega, \mathcal{F}, \tilde{\mathbb{P}}\big)$. □

In this section, the following semilinear stochastic equation is considered:

$$dX(t) = (AX(t) + F(X(t)))\, dt + \Phi\, dB(t), \tag{3.4}$$

where $t \in \mathbb{R}_+$, $X(t)$, $X_0 \in V$ is nonrandom, $(B(t), t \geq 0)$ is a standard cylindrical fractional Brownian motion with the Hurst parameter $H \in (0,1)$, $\Phi \in \mathcal{L}(V)$, $A\colon \mathrm{Dom}(A) \to V$, $\mathrm{Dom}(A) \subset V$, and A is the infinitesimal generator of a strongly continuous semigroup $(S(t), t \geq 0)$ on V. The function $F\colon V \to V$ is nonlinear, and for the applications to stochastic partial differential equations it is more useful to assume that F is defined only on a (dense) subspace of V. So, let $(E, \|\cdot\|_E)$ be a separable Banach space that is continuously embedded in V and $F\colon E \to E$ with $X_0 \in E$. Subsequently, it is assumed that $F\colon E \to E$ is Borel measurable, $\mathrm{Im}(F) \subset \mathrm{Im}(\Phi)$, for $G := \Phi^{-1}F$, $G\colon E \to V$, and

$$\|G(x)\| \leq \hat{k}\,(1 + \|x\|_E^{\rho}) \tag{3.5}$$

and

$$\|F(x)\|_E \leq \hat{k}\,(1 + \|x\|_E^{\rho}) \tag{3.6}$$

for each $x \in E$ and some $\rho \geq 1$. Furthermore, it is assumed that there is a constant $\bar{K}$ such that for each pair (x,y) in $\mathrm{Dom}(A)$, there is a $z^* \in \partial\|z\|_E$ such that

$$\langle Ax - Ay + F(x) - F(y), z^* \rangle_{E,E^*} \leq \bar{K}\|x - y\|_E, \tag{3.7}$$

where $\partial\|z\|_E$ is the subdifferential of the norm $\|z\|_E$ at the point $z = x - y$ and $\langle \cdot, \cdot, \rangle_{E,E^*}$ is the pairing between E and E^*. The basic results on subdifferentials can be found in [32]. Inequality (3.7) is a one-sided growth condition that ensures the absence of explosions of solutions of (3.4) in a finite time. Some subsequent examples should clarify its interpretation.

The notions of a weak and a mild solution of (3.4) are given now.

Definition 3.2. *A weak solution of* (3.4) *is a triple* $(X(t), B(t), (\tilde{\Omega}, \tilde{\mathcal{F}}, (\tilde{\mathcal{F}}_t), \tilde{\mathbb{P}}), t \geq 0)$, *where* $(B(t), t \geq 0)$ *is a standard cylindrical fractional Brownian motion in* V *that is defined on the probability space* $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}})$, $(B(t), t \geq 0)$ *and* $(X(t), t \geq 0)$ *are adapted to the filtration* $(\tilde{\mathcal{F}}_t)$, *and* $(X(t), t \geq 0)$ *is an* E*-valued process satisfying*

$$X(t) = S(t)X_0 + \int_0^t S(t-r)F(X(r))\, dr + \int_0^t S(t-r)\Phi\, dB(r). \tag{3.8}$$

A mild solution, $(X(t), t \geq 0)$ *of* (3.4), *is an* E*-valued process on a fixed probability space* $(\Omega, \mathcal{F}, (\mathcal{F}_t), \mathbb{P})$ *with a given standard cylindrical fractional Brownian motion that is the fractional Brownian motion in* (3.8), $(B(t), t \geq 0)$ *and* $(X(t), t \geq 0)$ *are adapted to the filtration* $(\mathcal{F}_t)$, *and the process* $(X(t), t \geq 0)$ *satisfies* (3.8).

Equation (3.8) *has a unique weak solution if, for any two weak solutions* $(X(t), B(t), (\Omega, \mathcal{F}, (\mathcal{F}_t), \mathbb{P}), t \geq 0)$ *and* $(\tilde{X}(t), \tilde{B}(t), (\tilde{\Omega}, \tilde{\mathcal{F}}, (\tilde{\mathcal{F}}_t), \tilde{\mathbb{P}}), t \geq 0)$, *the processes* $(X(t), t \geq 0)$ *and* $(\tilde{X}(t), t \geq 0)$ *have the same probability law.*

The equation has a unique mild solution if, for any two processes $(X_1(t), t \geq 0)$ *and* $(X_2(t), t \geq 0)$ *that satisfy* (3.8) *on the same probability space* $(\Omega, \mathcal{F}, (\mathcal{F}_t), \mathbb{P})$ *with the same standard cylindrical fractional Brownian motion,* $\mathbb{P}\,(X_1(t) = X_2(t), t \geq 0) = 1$.

A primary goal in this section is to verify weak existence and weak uniqueness of a solution of (3.4). Note that (H1) alone is not sufficient to ensure that the stochastic convolution has values in E. While the assumption (H2) is given in a rather general form, it is verified for particular examples in section 4. Since the cases $H \in (0, 1/2)$ and $H \in (1/2, 1)$ require different methods, they are treated separately.

The following three assumptions are made to construct a solution of (3.4):

(H1) The semigroup $(S(t), t \geq 0)$ generated by A is analytic on V and for each $t \geq 0$, $S(t)|_E \in \mathcal{L}(E)$ and $\| S(t)|_E \|_{\mathcal{L}(E)}$ is bounded on compact time intervals.

(H2) $\Phi \in \mathcal{L}(V)$ is injective and for $T > 0$ the stochastic convolution process

$$\left(\int_0^t S(t-r)\Phi \, dB(r), t \in [0,T] \right)$$

has a version with $C([0,T], E)$ sample paths.

(H3) The function $F\colon E \to V$ in (3.4) is Borel measurable, $\mathrm{Im}(F) \subset \mathrm{Im}(\Phi)$, and the function $G = \Phi^{-1}F\colon E \to V$ satisfies

$$\|G(x)\| \leq k\,(1 + \|x\|_E) \tag{3.9}$$

for some $k > 0$ and all $x \in E$.

The following result verifies a weak solution for $H \in (0, 1/2)$.

THEOREM 3.3. *If $H \in (0, 1/2)$ and the conditions* (H1)–(H3) *are satisfied, then the semilinear equation* (3.4) *has a weak solution. If additionally $F\colon E \to E$ and*

$$\|F(x)\|_E \leq k_1\,(1 + \|x\|_E) \tag{3.10}$$

for some $k_1 > 0$ and all $x \in E$, then the weak solution is unique.

Proof. Initially, existence of a weak solution is verified. By a standard method that has been used for equations of the form (3.4) with a standard cylindrical Brownian motion (cf. [4, 24]), it suffices to verify that the cylindrical process

$$\tilde{B}(t) = B(t) - \int_0^t G(Z(s))\, ds$$

is a standard cylindrical fractional Brownian motion in a suitable probability space where

$$Z(t) = S(t)X_0 + \tilde{Z}(t)$$

satisfies the associated linear equation. To use Theorem 3.1 it is necessary to verify that $G = \Phi^{-1}F$ satisfies the conditions of U in this theorem, that is,

$$\int_0^{\cdot} G(Z(s))\, ds \in I_{0+}^{H+\frac{1}{2}} \left(L^2([0,T], V) \right) \tag{3.11}$$

and

$$\mathbb{E} \exp\left[\rho(Z)\right] = 1, \tag{3.12}$$

where

$$\rho(Z) = \int_0^T \left\langle \mathbb{K}_H^{-1} \left(\int_0^{\cdot} G(Z) \right))(t), dW(t) \right\rangle - \frac{1}{2} \int_0^T \left\| \mathbb{K}_H^{-1} \left(\int_0^{\cdot} G(Z) \right)(t) \right\|^2 dt, \tag{3.13}$$

$\mathbb{K}_H^{-1}$ is the inverse of $\mathbb{K}_H$ in (2.3), and $(W(t), t \geq 0)$ is a standard cylindrical Wiener process in V by (2.19).

From (2.9), it follows that

$$
\begin{aligned}
(3.14)\qquad & \left| \mathbb{K}_H^{-1} \left(\int_0^{\cdot} G(Z) \right) \right|^2_{L^2([0,T],V)} \\
&= \bar{c}_H^{-2} \left| u_{H-\frac{1}{2}} I_{0+}^{\frac{1}{2}-H} \left(u_{\frac{1}{2}-H} G(Z) \right) \right|^2_{L^2([0,T],V)} \\
&= \hat{c}_H \int_0^T \left(s^{H-\frac{1}{2}} \left\| \int_0^s r^{\frac{1}{2}-H} (s-r)^{-\frac{1}{2}-H} G(Z(r))\, dr \right\| \right)^2 ds \\
&\leq \hat{c}_H k^2 \left(1 + |\tilde{Z}|_{C([0,T],E)} + \sup_{t\in[0,T]} \|S(t)X_0\|_E \right)^2 \int_0^T s^{2H-1} \\
&\quad \cdot \left(\int_0^s r^{\frac{1}{2}-H} (s-r)^{-\frac{1}{2}-H}\, dr \right)^2 ds \\
&\leq c_T \left(1 + |\tilde{Z}|^2_{C([0,T],E)} \right)
\end{aligned}
$$

for some $c_T > 0$ that depends only on T. This inequality verifies (3.11). By (3.14) it follows directly that

$$
(3.15)\qquad \mathbb{E} \exp \left[\hat{k} \int_0^T \left\| K_H^{-1} \left(\int_0^{\cdot} G(Z) \right)(t) \right\|^2 dt \right] \leq c \mathbb{E} \exp \left[\hat{k} c_T |\tilde{Z}|^2_{C([0,T],E)} \right]
$$

for some $c > 0$. Substituting $v = \frac{r}{s}$ in the integral with respect to r on the right-hand side of (3.14), it easily follows that $c_T \downarrow 0$ as $T \downarrow 0$. Since $\tilde{Z}$ is a $C([0,T],E)$-valued Gaussian random variable, it follows that

$$
(3.16)\qquad \mathbb{E} \exp \left[\hat{k} c_T |\tilde{Z}|^2_{C([0,T],E)} \right] < \infty
$$

is satisfied for $T > 0$ sufficiently small by the Fernique inequality. Clearly, (3.16) is the Novikov condition [19] which implies the equality (3.12) for $T > 0$ sufficiently small. For arbitrary $T > 0$, a simple iteration verifies the result, that is,

$$
(3.17)\qquad \mathbb{E} \exp \left[\hat{k} \int_{T_{m-1}}^{T_m} \left\| K_H^{-1} \left(\int_0^{\cdot} G(Z) \right)(t) \right\|^2 dt \right] < \infty
$$

for a sufficiently fine partition $0 = T_0 < T_1 < \cdots < T_n = T$. Using a downward induction procedure from the well-known proofs of the martingale property for the Radon–Nikodým derivative in (3.12) for an arbitrary $T > 0$ (see, e.g., [20, Example 6.2.3]), the verification of the equality in (3.12) is obtained.

Now, uniqueness of the weak solution is verified. Uniqueness in law can be proved in a standard way by removing the term F in (3.4) by absolute continuity of measures, which is a suitable inverse of the above construction of a weak solution.

Let $(\tilde{X}(t), t \in [0,T])$ be a solution to the equation

$$
(3.18)\qquad \tilde{X}(t) = S(t)x_0 + \int_0^t S(t-r)F(X(r))\, dr + \tilde{Z}(t),
$$

where $\tilde{Z}(t) = \int_0^t S(t-r)\Phi\, dB(r)$ and $(B(t), t \in [0,T])$ is some standard cylindrical fractional Brownian motion on a probability space $\left(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}}\right)$.

The process $(\tilde{X}(t), t \in [0,T])$ is defined on the same probability space as $(B(t), t \in [0,T])$. Let $(W(t), t \in [0,T])$ be the Wiener process associated with $(B(t), t \in [0,T])$ by (2.18). It suffices to show that

(3.19)

$$\exp\left[\tilde{\rho}(\tilde{X})\right] := \exp\left[-\int_0^T \left\langle \mathbb{K}_H^{-1}\left(\int_0^{\cdot} G(\tilde{X})\right)(t), dW(t)\right\rangle - \frac{1}{2}\int_0^T \left\|\mathbb{K}_H^{-1}\left(\int_0^{\cdot} G(\tilde{X})\right)(t)\right\|^2 dt\right]$$

is a Radon–Nikodým derivative on $\left(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}}\right)$, so $\tilde{\mathbb{P}}$ is the measure for a fractional Ornstein–Uhlenbeck process and uniqueness in law follows. Thus it is necessary to show that

$$\int_0^{\cdot} G\left(\tilde{X}(s)\right) ds \in I_{0+}^{H+\frac{1}{2}}\left(L^2([0,T], V)\right) \tag{3.20}$$

and

$$\tilde{\mathbb{E}} \exp\left[\tilde{\rho}(\tilde{X})\right] = 1, \tag{3.21}$$

where $\tilde{E}$ is integration with respect to $\tilde{\mathbb{P}}$. The verifications of (3.20) and (3.21) are analogous to the verifications of (3.11) and (3.12), respectively. However, since $\tilde{X}$ is not a Gaussian process, the Fernique inequality cannot be used directly. Initially, it is verified that there is a $c > 0$ such that

$$|\tilde{X}|_{C([0,T],E)} \le c\left(1 + \|X_0\|_E + |\tilde{Z}|_{C([0,T],E)}\right), \tag{3.22}$$

where $\tilde{Z}$ is the stochastic process described in (H2). Let

$$\begin{aligned} u(t) &= \tilde{X}(t) - \tilde{Z}(t) \\ &= S(t)X_0 + \int_0^t S(t-r)F\left(u(r) + \tilde{Z}(r)\right) dr. \end{aligned}$$

Thus

$$\|u(t)\|_E \le c_1\|X_0\| + c_2\int_0^t \left(1 + \|u(r)\|_E + \|\tilde{Z}(r)\|_E\right) dr \tag{3.23}$$

for some positive constants c_1 and c_2. By the Gronwall lemma it follows that

$$\|u(t)\|_E \le c_1\left(1 + \|X_0\|_E + |\tilde{Z}|_{C([0,T],E)}\right) \tag{3.24}$$

for $t \in [0,T]$, so the inequality (3.22) is verified. The exponential that usually occurs in the Gronwall inequality is bounded by $e^{c_2 T}$. Making the analogous computations in (3.14), it follows that

(3.25)

$$\left|\mathbb{K}_H^{-1}\left(\int_0^{\cdot} G(Z)\right)(s)\right|^2_{L^2([0,T],V)} \le c_T\left(1 + |X|^2_{C([0,T],E)}\right) \le \tilde{c}_T\left(1 + |\tilde{Z}|^2_{C([0,T],E)}\right),$$

where $\tilde{c}_T \downarrow 0$ as $T \downarrow 0$, so (3.20) is satisfied. Thus the method in (3.15)–(3.17) can be used to verify (3.21).

The random variable $\exp(\tilde{\rho}(\tilde{X}))$ in (3.19) is a Radon–Nikodým derivative and it defines a probability measure $\mathbb{Q}$ on $\tilde{\Omega}$. By this Girsanov-type theorem the process defined by $\tilde{B}(t) = B(t) + \int_0^t u(s)ds$, where $u(s) = G(\tilde{X}(s))$, is a standard cylindrical fractional Brownian motion with respect to the measure $\mathbb{Q}$. Let $(\tilde{W}(t), t \in [0,T])$ be the Wiener process associated with $(\tilde{B}(t), t \in [0,T])$. Let $U(s) = \mathbb{K}_H^{-1}(\int_0^{\cdot} G(\tilde{X}))(s)$ for $s \in [0,T]$ and let $\mathbb{E}$ and $\mathbb{E}_{\mathbb{Q}}$ denote the expectations with respect to the measures $\tilde{\mathbb{P}}$ and $\mathbb{Q}$, respectively. For a bounded measurable function Ψ on $C([0,T],V)$ it follows that

$$\begin{aligned}
\mathbb{E}[\Psi(\tilde{X})] &= \int_{\tilde{\Omega}} \Psi \frac{d\tilde{\mathbb{P}}}{d\mathbb{Q}} d\mathbb{Q} = \mathbb{E}_{\mathbb{Q}}[\Psi(\tilde{X}) \exp(-\tilde{\rho}(\tilde{X}))] \\
&= \mathbb{E}_{\mathbb{Q}} \left[\Psi(\tilde{X}) \exp\left(\int_0^T \langle U(r), d\tilde{W}(r) \rangle - \frac{1}{2} \int_0^T \|U(r)\|^2 dr \right) \right] \\
&= \mathbb{E}_{\mathbb{Q}} \left[\Psi(S(\cdot)X_0 + \int_0^{\cdot} S(\cdot - r) d\tilde{B}(r)) \exp\left(\int_0^T \left\langle \mathbb{K}_H^{-1} \left(\int_0^{\cdot} G\left(S(\cdot)X_0 \right.\right.\right.\right. \\
&\qquad \left.\left.\left.\left. + \int_0^{\cdot} S(\cdot - r)\Phi d\tilde{B}(r) \right) \right)(s), d\tilde{W}(s) \right\rangle \right. \\
&\quad \left. - \frac{1}{2} \int_0^T \left\| \mathbb{K}_H^{-1} \left(\int_0^{\cdot} G\left(S(\cdot)X_0 + \int_0^{\cdot} S(\cdot - r)\Phi d\tilde{B}(r) \right) \right)(s) \right\|^2 ds \right) \right].
\end{aligned}$$

Since the processes $\tilde{W}$ and $\tilde{B}$ are standard cylindrical Brownian motions and standard cylindrical fractional Brownian motions, respectively, the final expectation on the right-hand side above does not depend on the realization of $\tilde{X}$, so the uniqueness in law is verified. □

Now the existence and the uniqueness of a weak solution of (3.4) is verified for $H \in (1/2, 1)$.

THEOREM 3.4. *If $H \in (1/2,1)$,* (H1)–(H3) *are satisfied, and*

$$\|G(x) - G(y)\| \le k_G \|x - y\|^{\gamma} \tag{3.26}$$

for all $x, y \in E$, some $\gamma \in (0,1]$, $k_G > 0$, and $\tilde{Z} \in C^{\beta}([0,T],V)$ for some β satisfying

$$\beta > \frac{H - \frac{1}{2}}{\gamma}, \tag{3.27}$$

where $\tilde{Z}$ is the stochastic convolution process in (H2)*, then* (3.4) *has a weak solution. If, additionally,* (3.10) *is satisfied, then the weak solution is unique.*

Proof. Initially, the existence of a solution is verified as in the proof of Theorem 3.3. It is shown that

$$\int_0^{\cdot} G(Z(s))\, ds \in I_{0+}^{H+\frac{1}{2}} \left(L^2([0,T],V) \right) \quad \text{a.s.} \tag{3.28}$$

and

$$\mathbb{E} \exp[\rho(Z)] = 1, \tag{3.29}$$

where ρ is given by (3.13). By (2.8) it follows that

$$
\begin{aligned}
(3.30)\qquad & \left|\mathbb{K}_H^{-1}\left(\int_0^{\cdot} G(Z)\right)\right|^2_{L^2([0,T],V)} \\
&= c_H^{-2}\left|u_{H-\frac{1}{2}} D_{0+}^{H-\frac{1}{2}}\left(u_{\frac{1}{2}-H} G(Z)\right)\right|^2_{L^2([0,T],V)} \\
&= c_H^{-2}\int_0^T \left\| \frac{s^{H-\frac{1}{2}}}{\Gamma\left(\frac{3}{2}-H\right)}\left(\frac{s^{\frac{1}{2}-H}G(Z(s))}{s^{H-\frac{1}{2}}}\right)\right. \\
&\quad \left. + \left(H-\frac{1}{2}\right)\int_0^s \frac{s^{\frac{1}{2}-H}G(Z(s)) - r^{\frac{1}{2}-H}G(Z(r))}{(s-r)^{H+\frac{1}{2}}}\,dr\right\|^2 ds \\
&\le c\int_0^T \left(s^{\frac{1}{2}-H}\,\|G(Z(s))\| + s^{H-\frac{1}{2}}\int_0^s \frac{s^{\frac{1}{2}-H} - r^{\frac{1}{2}-H}}{(s-r)^{H+\frac{1}{2}}}\|G(Z(r))\|\,dr\right. \\
&\quad \left. + \int_0^s \frac{\|G(Z(s)) - G(Z(r))\|}{(s-r)^{H+\frac{1}{2}}}\,dr\right)^2 ds.
\end{aligned}
$$

Using (3.9) and (3.26), the analyticity of the semigroup $S(\cdot)$ on V, and the inequality

$$
\int_0^s \frac{s^{\frac{1}{2}-H} - r^{\frac{1}{2}-H}}{(s-r)^{H+\frac{1}{2}}}\,dr \le cs^{1-2H},
$$

where c is a generic constant, it follows that

(3.31)

$$
\begin{aligned}
&\left|\mathbb{K}_H^{-1}\left(\int_0^{\cdot} G(Z)\right)\right|_{L^2([0,T],V)} \\
&\quad \le c_T\left(1 + \|X_0\|_E^2 + |\tilde{Z}|^2_{C([0,T],E)}\right) \\
&\quad + c_T\int_0^T \left[\left(\int_0^s \frac{\|S(s)X_0 - S(r)X_0\|^\gamma}{(s-r)^{H+\frac{1}{2}}}\,dr\right)^2 + \left(\int_0^s \frac{\|\tilde{Z}(s) - \tilde{Z}(r)\|^\gamma}{(s-r)^{H+\frac{1}{2}}}\,dr\right)^2\right] ds \\
&\quad \le c_T\left(1 + \|X_0\|_E^2 + |\tilde{Z}|^2_{C([0,T],E)}\right) + c_T\int_0^T \left(\|X_0\|^\gamma \int_0^s \frac{(s-r)^{\gamma\lambda}}{r^{\gamma\lambda}(s-r)^{H+\frac{1}{2}}}\,dr\right)^2 \\
&\quad + c_T\int_0^T |\tilde{Z}|^2_{C^\beta([0,T],V)}\left(\int_0^s \frac{(s-r)^{\gamma\beta}}{(s-r)^{H+\frac{1}{2}}}\,dr\right)^2 ds,
\end{aligned}
$$

where $\lambda > 0$ satisfies $\gamma\lambda < 1$ and $H + 1/2 - \gamma\lambda < 1$. The first integral term in the initial inequality in (3.31) is obtained by the analyticity of the semigroup $S(.)$ on V, which implies that

$$
||(S(s) - S(r))x|| \le c(s-r)^\lambda r^\lambda\ ||x||, \quad x \in V,\ \lambda \ge 0,\ 0 < r < s \le T,
$$

for some $c = c(\lambda)$. It follows that

(3.32)
$$\left|\mathbb{K}_H^{-1}\left(\int_0^{\cdot} G(Z)\right)\right|^2_{L^2([0,T],V)} \leq c_T\left(1 + \|X_0\|_E^2 + \|\tilde{Z}\|^2_{C([0,T],E)} + |\tilde{Z}|^2_{C^\beta([0,T],V)}\right),$$

where $c_T \downarrow 0$ as $T \downarrow 0$, so (3.28) is verified and by the Fernique inequality (3.29) is also verified.

Now the uniqueness of the weak solution is verified. Let $(\tilde{X}(t), t \in [0,T])$ be the solution to (3.4) on a probability space $(\tilde{\Omega}, \tilde{\mathcal{F}}.\tilde{\mathbb{P}})$. As in the proof of Theorem 3.3, it is shown that

$$\int_0^{\cdot} G(\tilde{X})\, ds \in I_{0+}^{H+\frac{1}{2}}\left(L^2([0,T],V)\right) \quad \text{a.s.} \tag{3.33}$$

and

$$\tilde{\mathbb{E}} \exp\left[\tilde{\rho}(\tilde{X})\right] = 1, \tag{3.34}$$

where $\tilde{\rho}$ is given by (3.13). It is necessary to obtain inequality (3.22), used in the proof of Theorem 3.3. Inequality (3.22) is verified by verifying the inequality

$$\|\hat{X}\|_{C^\beta([0,T],V)} \leq L\left(1 + \|X_0\|_E + |\tilde{Z}|_{C([0,T],E)} + |\tilde{Z}|_{C^\beta([0,T],V)}\right), \tag{3.35}$$

where $\hat{X}(t) = \tilde{X}(t) - S(t)X_0$ and $L > 0$. Let $w(t) = \tilde{X}(t) - S(t)X_0 - \tilde{Z}(t)$ for $t \geq 0$. The process w satisfies

$$w(t) = \int_0^t S(t-r)\psi(r)\, dr \tag{3.36}$$

for $t \in [0,T]$, where

$$\psi(t) = F(w(t) + S(t)X_0 + \tilde{Z}(t)).$$

By inequalities (3.10) and (3.35) it follows that $\psi \in L^\infty([0,T],V)$ a.s. $\mathbb{P}$. Since the semigroup $S(\cdot)$ is analytic on V, w is α-Hölder continuous for each $\alpha \in (0,1)$, and using the method of proof of [29, Theorem 4.3.1] there are constants $c_i > 0$ for $i = 1,2$ such that

(3.37)
$$|w|_{C^\beta([0,T],V)} \leq c_1|\psi|_{L^\infty([0,T],V)} \leq c_2\left(|w|_{L^\infty([0,T],E)} + \|X_0\|_E + |\tilde{Z}|_{C([0,T],E)}\right).$$

Thus

$$\begin{aligned} |\tilde{X}|_{C^\beta([0,T],V)} &\leq |w|_{C^\beta([0,T],V)} + |\tilde{Z}|_{C^\beta([0,T],V)} \\ &\leq c_2\left(|w|_{L^\infty([0,T],E)} + \|X_0\|_E + |\tilde{Z}|_{C([0,T],E)} + |\tilde{Z}|_{C^\beta([0,T],V)}\right). \end{aligned} \tag{3.38}$$

Using (3.22) again to bound $|w|_{L^\infty([0,T],E)}$, inequality (3.35) follows.

Now, using the methods for inequalities (3.30)–(3.32), where $Z(t)$ is replaced by $\tilde{X}(t) = S(t)X_0 + \hat{X}(t)$, it follows that

(3.39)
$$\left| \mathbb{K}_H^{-1} \left(\int_0^{\cdot} G(Z) \right) \right|^2_{L^2([0,T],V)} \leq c_T \left(1 + \|X_0\|_E^2 + |\tilde{X}|^2_{C([0,T],V)} + |\tilde{X}|^2_{C^\beta([0,T],V)} \right),$$

where $c_T \downarrow 0$ as $T \downarrow 0$, which by (3.22) and (3.35) verifies (3.33). Equality (3.34) is obtained from (3.39) by the Fernique inequality as in the proof of Theorem 3.3. ∎

Remark 3.5. The proofs of Theorems 3.3 and 3.4 have verified, in addition to weak existence and uniqueness of a solution to (3.4), the mutual absolute continuity (equivalence) of the probability laws of the solution to (3.4) and the solution of (3.4) with $F \equiv 0$ (the fractional Ornstein–Uhlenbeck process) in the path space.

The next objective is to relax the linear growth conditions (3.9) and (3.10) and the Hölder continuity (3.26). The linear growth condition is replaced by a dissipativity condition of the drift term of (3.4), but some other conditions are also imposed so that there is existence and (strong) uniqueness of a mild solution. The main contribution of the following two theorems is a mutual absolute continuity of the probability laws of the solutions of (3.4) with a nonzero F and (3.4) with $F \equiv 0$.

Initially, the case $H \in (0, 1/2)$ is considered.

THEOREM 3.6. *Let $H \in (0, 1/2)$ and let* (H1) *and* (H2) *be satisfied. Let $\Phi \in \mathcal{L}(V)$ be injective, let $\Phi^{-1} \in \mathcal{L}(E, V)$, and let $(S(t)|_E, t \geq 0)$ be a strongly continuous semigroup on E such that*

$$|S(t)|_E|_{\mathcal{L}(E)} \leq e^{\tilde{w}t} \tag{3.40}$$

for $t \geq 0$ and some $\tilde{w} \in \mathbb{R}$. Let $F\colon E \to E$ be continuous and satisfy

$$\|F(x)\|_E \leq k_1 \left(1 + \|x\|_E^\rho\right) \tag{3.41}$$

for $x \in E$ for some $k_1 \geq 0$ and $\rho \geq 1$, and for each pair $x, y \in E$, there is a $z^* \in \partial\|x - y\|_E$ where $\partial\|z\|_E$ is the subdifferential of the norm $\|\cdot\|_E$ at $z \in E$ such that

$$\langle F(x) - F(y), z^* \rangle_{E,E^*} \leq k_2 \|x - y\|_E \tag{3.42}$$

for some $k_2 \in \mathbb{R}$; that is, $F - k_2 I$ is dissipative on E. Then there is one and only one mild solution of (3.4)*, and its probability law on the Borel σ-algebra of $\breve{\Omega} = C([0,T], E)$ is mutually absolutely continuous with respect to the probability law of the fractional Ornstein–Uhlenbeck process* (3.24) *on Ω.*

Proof. Let $(F_\lambda, \lambda > 0)$ be a family of Lipschitz continuous functions from E to E such that each F_λ satisfies inequalities (3.41) and (3.42) for F with the same constants ρ, k_1, k_2. It is shown that there is a $\bar{k} > 0$ depending only on $\tilde{w}$, k_1, and k_2 such that

$$\|v_\lambda(t)\|_E \leq \bar{k} \left(1 + \|X_0\|_E + \|\phi\|^\rho_{C([0,T],E)} \right) \tag{3.43}$$

for $t \in [0,T]$ is satisfied for each $\lambda > 0$ and $\phi \in C([0,T], E)$, where v_λ is a solution of the equation

$$v_\lambda(t) = S(t)X_0 + \int_0^t S(t-r) F_\lambda \left(v_\lambda(r) + \phi(r) \right) dr \tag{3.44}$$

for $t \in [0,T]$.

To verify inequality (3.43), it can be assumed by translation that $k_2 = 0$ in (3.42) (replace F_λ and A by $F_\lambda - k_2 I$ and $A + k_2 I$, respectively). Thus F_λ is dissipative on E for each $\lambda > 0$ and by the assumptions

$$\langle A_E z, z^* \rangle_{E,E^*} \leq \tilde{w} \|z\|_E^2 \tag{3.45}$$

for each $z \in \mathrm{Dom}(A_E)$ and $z^* \in \partial \|z\|_E$, where A_E is the restriction of A to E that generates the semigroup $S(\cdot)|_E$. For each pair $x, y \in \mathrm{Dom}(A_E)$ and $\lambda > 0$, there is a $z_\lambda^* \in \partial \|x - y\|_E$ such that

$$\langle A_E(x-y) + F_\lambda(x) - F_\lambda(y), z_\lambda^* \rangle_{E,E^*} \leq \tilde{w} \|x - y\|_E.$$

By [5, Proposition 5.5.6], there is a sequence $(v_\lambda^n, n \in \mathbb{N})$ such that $v_\lambda^n \in C^1([0,T], E) \cap C([0,T], \mathrm{Dom}(A_E))$ such that $v_\lambda^n \to v_\lambda$ and $\delta_\lambda^n = \frac{d}{dt} v_\lambda^n - A_E v_\lambda^n - F_\lambda\left(v_\lambda^n + \phi\right) \to 0$ in $C([0,T], E)$ as $n \to \infty$. It follows that

$$\begin{aligned}
\frac{d^-}{dt} \left\| v_\lambda^n(t) \right\|_E &\leq \left\langle A_E v_\lambda^n(t) + F_\lambda\left(v_\lambda^n(t) + \phi(t)\right), (v_\lambda^n(t))^* \right\rangle_{E,E^*} + \left\| \delta_\lambda^n(t) \right\|_E \\
&= \left\langle A_E v_\lambda^n(t) + F_\lambda\left(v_\lambda^n(t) + \phi(t)\right) - F_\lambda(\phi(t)), (v_\lambda^n(t))^* \right\rangle \\
&\qquad + \left\langle F_\lambda(\phi(t)), (v_\lambda^n(t))^* \right\rangle_{E,E^*} + \left\| \delta_x^n(t) \right\|_E \\
&\leq \bar{w} \left\| v_\lambda^n(t) \right\|_E + k_2 \left(1 + |\phi|_{C([0,T],E)}^\rho + \left\| \delta_\lambda^n(t) \right\|_E\right)
\end{aligned} \tag{3.46}$$

for $t \in [0,T]$. Using the Gronwall lemma, and letting $n \to \infty$, verifies inequality (3.43).

The mild solution to (3.4) can be expressed as $X(t) = v(t) + \tilde{Z}(t)$, where v satisfies the equation

$$v(t) = S(t)X_0 + \int_0^t S(t-r) F(v(r) + \tilde{Z}(r))\, dr \tag{3.47}$$

for $t \in [0,T]$. Thus the existence and the uniqueness of a mild solution follows from the corresponding pathwise deterministic result (cf. [5, Proposition 5.5.6]).

The equivalence of the probability laws is shown by application of Theorem 3.1. As in the proof of Theorem 3.3, it suffices to show that

$$\int_0^\cdot G(Z(s))\, ds \in I_{0+}^{H+\frac{1}{2}} \left(L^2([0,T], V)\right) \tag{3.48}$$

and

$$\mathbb{E} \exp\left[\rho(Z)\right] = 1, \tag{3.49}$$

where ρ is given by (3.13). While G is not assumed to have at most linear growth as in Theorem 3.3, there is the growth condition

$$\|G(x)\| \leq \hat{k}\left(1 + \|x\|_E^\rho\right) \tag{3.50}$$

for all $x \in E$ and a constant $\hat{k}$. Proceeding as in (3.14), it follows that

(3.51)
$$\begin{aligned}
&\left|\mathbb{K}_H^{-1}\left(\int_0^{\cdot} G(Z)\right)\right|^2_{L^2([0,t],V)} \\
&\quad \le c_1 \int_0^T \left(s^{H-\frac{1}{2}} \left\| \int_0^s r^{\frac{1}{2}-H}(s-r)^{-\frac{1}{2}-H} G(Z(r))\, dr \right\|\right)^2 ds \\
&\quad \le c_2 \left(1 + |\tilde{Z}|^{\rho}_{C([0,T],E)} + \sup_{t\in[0,T]} \|S(t)X_0\|^{\rho}_E\right) \int_0^T s^{2H-1} \\
&\quad \cdot \left(\int_0^s r^{\frac{1}{2}-H}(s-r)^{-\frac{1}{2}-H}\, dr\right)^2 ds \\
&\quad \le c_3 \left(1 + \|X_0\|^{2\rho}_E + |\tilde{Z}|^{2\rho}_{C([0,T],E)}\right)
\end{aligned}$$

for suitable constants c_1, c_2, c_3. This inequality verifies (3.48). To verify equality (3.49), it suffices to assume that F is dissipative (that is, $k_2 = 0$ in (3.42)). Recall that m-dissipative mapping F is defined as a dissipative mapping satisfying $Range(I - \lambda F) = E$ for each $\lambda > 0$; cf. [22]. Since F is continuous, it is m-dissipative (cf. [23]), so the family $(F_\lambda, \lambda > 0)$ of Yosida approximations of F is defined as

$$F_\lambda(x) = F\left(R_\lambda(x)\right) = \frac{1}{\lambda}\left(R_\lambda(x) - x\right) \tag{3.52}$$

for $x \in E$, where

$$R_\lambda(x) = (I - \lambda F)^{-1}(x). \tag{3.53}$$

It is well known that $F_\lambda \colon E \to E$ for $\lambda > 0$ is Lipschitz continuous, so by Theorem 3.3, there is the equality

$$\mathbb{E} \exp\left[\rho_\lambda(Z)\right] = 1 \tag{3.54}$$

for $\lambda > 0$, where

(3.55)
$$\rho_\lambda(Z) = \int_0^T \left\langle \mathbb{K}_H^{-1}\left(\int_0^{\cdot} G_\lambda(Z)\right)(t), dW(t)\right\rangle - \frac{1}{2}\int_0^T \left\|\mathbb{K}_H^{-1}\left(\int_0^{\cdot} G_\lambda(Z)\right)(t)\right\|^2 dt$$

and $G_\lambda := \Phi^{-1} F_\lambda$. As in (3.51), it follows that

(3.56)
$$\begin{aligned}
&\mathbb{E}\left|\mathbb{K}_H^{-1}\left(\int_0^{\cdot} (G_\lambda(Z) - G(Z))\right)\right|_{L^2([0,T],V)} \\
&\quad \le c_T \mathbb{E} \int_0^T \left(s^{H-\frac{1}{2}} \int_0^s r^{\frac{1}{2}-H}(s-r)^{-\frac{1}{2}-H} \left\|G_\lambda(Z(r)) - G(Z(r))\right\| dr\right)^2 ds.
\end{aligned}$$

By some well-known properties of the Yosida approximations and for $x \in E$,

$$\left\|G_\lambda(x) - G(x)\right\| \le \left|\Phi^{-1}\right|_{\mathcal{L}(E,V)} \left\|F_\lambda(x) - F(x)\right\|, \tag{3.57}$$

it follows that $F_\lambda \to F$ as $\lambda \to 0$ and the right-hand side of (3.57) tends to zero as $\lambda \downarrow 0$, and

$$\begin{aligned} \|G_\lambda(x)\| &\le \left|\Phi^{-1}\right|_{\mathcal{L}(E,V)} \|F_\lambda(x)\|_E \\ &\le \left|\Phi^{-1}\right|_{\mathcal{L}(E,V)} \|F(x)\|_E \\ &\le \left|\Phi^{-1}\right|_{\mathcal{L}(E,V)} k_1 \left(1 + \|x\|_E^\rho\right), \end{aligned} \tag{3.58}$$

so the right-hand side of (3.56) tends to zero as $\lambda \downarrow 0$. For a sequence $(\lambda_n, n \in \mathbb{N})$ that decreases to zero, it follows that

$$\lim_{n\to\infty} \exp\left[\rho_{\lambda_n}(Z)\right] = \exp\left[\rho(Z)\right] \quad \text{a.s. } \mathbb{P}. \tag{3.59}$$

To obtain equality (3.54) from equality (3.59) for $\lambda_n, n \in \mathbb{N}$, it is necessary and sufficient to show that the sequence $(\exp\left[\rho_{\lambda_n}(Z)\right], n \in \mathbb{N})$ is uniformly integrable. A sufficient condition for this uniform integrability is to verify that

$$\sup_n \mathbb{E}\left[\left(\exp\left[\rho_{\lambda_n}(Z)\right]\right) \left|\log\left(\exp\left[\rho_{\lambda_n}(Z)\right]\right)\right|\right] = \sup_n \mathbb{E}\left[\left(\exp\left[\rho_{\lambda_n}(Z)\right]\right) \rho_{\lambda_n}(Z)\right] < \infty. \tag{3.60}$$

By Theorem 3.3,

$$\mathbb{E}\left[\rho_{\lambda_n}(Z) \exp\left[\rho_{\lambda_n}(Z)\right]\right] \le \tilde{\mathbb{E}}_{\lambda_n}\left[2\int_0^T \left\|\mathbb{K}_H^{-1}\left(\int_0^\cdot G_{\lambda_n}(Z)\right)(t)\right\|^2 dt\right], \tag{3.61}$$

where $\tilde{\mathbb{E}}_{\lambda_n}$ is the expectation with respect to $\tilde{\mathbb{P}}_{\lambda_n}$ and

$$\frac{d\tilde{\mathbb{P}}_{\lambda_n}}{d\mathbb{P}} = \exp\left[\rho_{\lambda_n}(Z)\right],$$

and $Z(\cdot)$ satisfies (2.28). On the probability space with the measure $\mathbb{P}_{\lambda_n}$, $Z(\cdot)$ satisfies the following semilinear equation, where $B(\cdot)$ is a fractional Brownian motion with respect to $\mathbb{P}_{\lambda_n}$:

$$\begin{aligned} dX_{\lambda_n}(t) &= \left(AX(t) + F_{\lambda_n}(X(t))\right) dt + \Phi\, dB(t), \\ X_{\lambda_n}(0) &= X_0. \end{aligned} \tag{3.62}$$

Since F_{λ_n} is Lipschitz continuous, there is a unique mild solution on a given probability space, so it suffices to show

$$\mathbb{E}\int_0^T \left\|\mathbb{K}_H^{-1}\left(\int_0^\cdot G_{\lambda_n}\left(X_{\lambda_n}\right)\right)(t)\right\|^2 dt \le c \tag{3.63}$$

for some $c \in \mathbb{R}_+$ that does not depend on λ_n. Repeating inequalities (3.51), where G and Z are replaced by G_{λ_n} and X_{λ_n}, respectively, and using inequality (3.58), it follows that

$$\int_0^T \left\|\mathbb{K}_H^{-1}\left(\int_0^\cdot G_{\lambda_n}\left(X_{\lambda_n}\right)\right)(t)\right\|^2 dt \le c_5\left(1 + \|X_0\|_E^{2\rho} + \left|\tilde{X}_{\lambda_n}\right|^{2\rho}_{C([0,T],E)}\right) \tag{3.64}$$

for a constant c_5 that does not depend on $n \in \mathbb{N}$ where $\tilde{X}_{\lambda_n}(t) = X_{\lambda_n}(t) - S(t)X_0$. By inequality (3.43) there is a constant c_6 that does not depend on n such that

(3.65)
$$\mathbb{E}\int_0^T \left\| \mathbb{K}_H^{-1}\left(\int_0^{\cdot} G_{\lambda_n}\left(X_{\lambda_n}\right)\right)(t)\right\|^2 dt \le c_6\left(1 + \|X_0\|_E^{2\rho} + \mathbb{E}\,|Z|^{4\rho^2}_{C([0,T],E)}\right) = C < \infty.$$

This inequality verifies (3.60). Thus the sequence $(\exp[\rho_{\lambda_n}(Z)], n \in \mathbb{N})$ converges in L^1 and equality (3.54) is satisfied. □

Now the case $H \in (1/2, 1)$ is considered.

THEOREM 3.7. *Let $H \in (1/2, 1)$ and the other assumptions in Theorem 3.6 be satisfied. Let $\Phi^{-1} \in \mathcal{L}(V)$, $\tilde{Z} \in C^\beta([0,T], V)$ for some $\beta \in (0,1)$,*

$$\langle F(x) - F(y), x - y\rangle \le k_2 \|x - y\|^2 \tag{3.66}$$

for each pair $x, y \in E$ and a $k_2 \in \mathbb{R}_+$ (that is, $F - k_2 I$ is dissipative on E with respect to the norm on V) and

$$\|F(x) - F(y)\| \le k_3\left(1 + \|x\|_E^q + \|y\|_E^q\right)\|x - y\|^\gamma \tag{3.67}$$

for each $x, y \in E$, with some $k_3 > 0$, $q \ge 1$, and $\gamma \in (0,1]$ such that

$$\gamma\beta > H - \frac{1}{2}. \tag{3.68}$$

Then there is one and only one mild solution to (3.4), and its probability law is mutually absolutely continuous with respect to the probability law of the fractional Ornstein–Uhlenbeck process (2.28) on $\check{\Omega}$.

Proof. As in the proof of Theorem 3.6, it is shown that

$$\int_0^{\cdot} G(Z(s))\,ds \in I_{0+}^{H+\frac{1}{2}}\left(L^2([0,T], V)\right) \tag{3.69}$$

and

$$\mathbb{E}\exp[\rho(Z)] = 1. \tag{3.70}$$

The methods to verify (3.69) and (3.70) are similar to those used in the proof of Theorem 3.6, but now the operator $\mathbb{K}_H^{-1}$ has a different form. Using inequality (3.41) and the Hölder continuity condition (3.67), it follows that

$$\begin{aligned}
&\left|\mathbb{K}_H^{-1}\left(\int_0^{\cdot} G(Z)\right)\right|^2_{L^2([0,T],V)} \\
&\quad\le c_1\int_0^T\left(s^{\frac{1}{2}-H}\|G(Z(s))\| + s^{H-\frac{1}{2}}\int_0^s \frac{s^{\frac{1}{2}-H} - r^{\frac{1}{2}-H}}{(s-r)^{H+\frac{1}{2}}}\|G(Z(r))\|\,dr\right. \\
&\quad\left. + \int_0^s \frac{\|G(Z(s)) - G(Z(r))\|}{(s-r)^{H+\frac{1}{2}}}\,dr\right)^2 ds \\
&\quad\le c_2\left[1 + |Z|^{2\rho}_{C([0,T],E)} + c_3\left(1 + |Z|^{2q}_{C([0,T],E)}\right)\right. \\
&\quad\left.\cdot\int_0^T\left(\int_0^s \frac{\|S(s)X_0 - S(r)X_0\|^\gamma + \left\|\tilde{Z}(s) - \tilde{Z}(r)\right\|^\gamma}{(s-r)^{H+\frac{1}{2}}}\,dr\right)^2 ds\right]
\end{aligned} \tag{3.71}$$

for some constants c_1, c_2, c_3. By the analyticity of the semigroup $S(\cdot)$ on V, it follows that

$$\begin{aligned}(3.72)\qquad &\left|\mathbb{K}_H^{-1}\left(\int_0^{\cdot} G(Z)\right)\right|^2_{L^2([0,T],V)}\\ &\quad\le c_4\left[1+\|X_0\|_E^{2\rho}\right.\\ &\quad+\left.\left(\|X_0\|_E^{2q}+|Z|^{2q}_{C([0,T],V)}+1\right)\left(\|X_0\|_E^{2\gamma}+|Z|^{2\gamma}_{C^\beta([0,T],V)}\right)\right]\\ &\quad\le c_5\left(1+\|X_0\|_E^m+|Z|^m_{C([0,T],V)}+|Z|^m_{C^\beta([0,T],V)}\right)\end{aligned}$$

for some constants c_4 and c_5 and m sufficiently large. Thus (3.69) is verified. To verify equality (3.70) consider the family of Yosida approximations $(F_\lambda, \lambda>0)$ of F as in the proof of Theorem 3.6. By the dissipativity of F in the norm on V, $F_\lambda\colon V\to V$ is Lipschitz continuous for each $\lambda>0$ and has at most polynomial growth, so F_λ satisfies the assumptions of Theorem 3.4 so that

$$(3.73)\qquad \mathbb{E}\exp\left[\rho_\lambda(Z)\right]=1,$$

where ρ_λ is given by (3.55). By the method used to obtain inequality (3.71), it follows that

$$\begin{aligned}(3.74)\quad &\mathbb{E}\left|\mathbb{K}_H^{-1}\left(\int_0^{\cdot}\left(G_\lambda(Z)-G(Z)\right)\right)\right|^2_{L^2([0,T],V)}\\ &\qquad\le c_6\mathbb{E}\int_0^T\left[s^{\frac12-H}\left\|G_\lambda(Z(s))-G(Z(s))\right\|\right.\\ &\quad+s^{H-\frac12}\int_0^s\frac{s^{\frac12-H}-r^{\frac12-H}}{(s-r)^{H+\frac12}}\left\|G_\lambda(Z(r))-G(Z(r))\right\|\,dr\\ &\qquad\left.+\int_0^s\frac{\left\|G_\lambda(Z(s))-G(Z(s))-G_\lambda(Z(r))+G(Z(r))\right\|}{(s-r)^{H+\frac12}}\,dr\right]^2 ds.\end{aligned}$$

By inequalities (3.57) and (3.58), it follows that $\|G_\lambda(x)-G(x)\|\to 0$ as $\lambda\downarrow 0$ for each $x\in E$ and the family $(G_\lambda,\lambda>0)$ satisfies the growth condition

$$(3.75)\qquad \|G_\lambda(x)\|\le c_7\left(1+\|x\|_E^\rho\right)$$

for $x\in E$ and some $c_7>0$. From the V-dissipativity of F, it follows by [5, Proposition 5.5.3] that

$$\|R_\lambda(x)-R_\lambda(y)\|\le\|x-y\|$$

for $x,y\in E$, so that

$$\begin{aligned}(3.76)\qquad \|F_\lambda(x)-F_\lambda(y)\|&=\|F\left(R_\lambda(x)\right)-F\left(R_\lambda(y)\right)\|\\ &\le k_3\left(1+\|R_\lambda(x)\|_E^q+\|R_\lambda(y)\|_E^q\right)\|x-y\|^\gamma\end{aligned}$$

for $x,y\in E$. Since

$$\|R_\lambda(x)\|_E\le\|x\|_E+\lambda\|F(x)\|_E\le c_8\left(1+\|x\|_E^\rho\right)$$

for $x \in E$, $c_8 \in \mathbb{R}_+$, and $\lambda \in (0,1]$, there is the inequality

$$\|F_\lambda(x) - F_\lambda(y)\| \le c_9 \left(1 + \|x\|_E^m + \|y\|_E^m\right) \|x - y\|^\gamma \tag{3.77}$$

for $x, y \in E$, $c_0 \in \mathbb{R}_+$, $m \ge 1$, and $\lambda \in (0,1]$. So F_λ and G_λ satisfy inequality (3.67) uniformly in $\lambda \in (0,1]$. Thus the right-hand side of inequality (3.74) tends to zero as $\lambda \downarrow 0$ by the dominated convergence theorem where a majorizing function is provided by the estimates (3.75) and (3.77), whose integrability is shown in (3.71) and (3.72), and there is a decreasing sequence $(\lambda_n, n \in \mathbb{N})$ whose limit is zero such that

$$\lim_{n\to\infty} \exp\left[\rho_{\lambda_n}(Z)\right] = \exp\left[\rho(Z)\right] \quad \text{a.s. } \mathbb{P}. \tag{3.78}$$

The uniform integrability of the sequence $(\exp\left[\rho_{\lambda_n}(Z)\right], n \in \mathbb{N})$ is shown by verifying the analogue of (3.60). Equivalently,

$$\sup_n \mathbb{E} \int_0^T \left\| \mathbb{K}_H^{-1} \left(\int_0^\cdot G_{\lambda_n}\left(X_{\lambda_n}\right) \right)(t) \right\|^2 dt \le c < \infty, \tag{3.79}$$

where $X_{\lambda_n}(\cdot)$ is the unique mild solution to (3.62). The analogous inequalities (3.71)–(3.74) are obtained by replacing G by G_λ using the polynomial growth bound and the local Hölder continuity that are uniform in $(\lambda_n, n \in \mathbb{N})$, and $Z(\cdot)$ is replaced by $X_{\lambda_n}(\cdot)$. For some constants c_{10} and $m \ge 1$,

$$\begin{aligned} &\left| \mathbb{K}_H^{-1} \left(\int_0^\cdot G_{\lambda_n}\left(X_{\lambda_n}\right) \right) \right|_{L^2([0,T],V)}^2 \\ &\qquad \le c_{10} \left(1 + \|X_0\|_E^m + \left|\tilde{X}_{\lambda_n}\right|_{C([0,T],E)}^m + \left|\tilde{X}_{\lambda_n}\right|_{C^\beta([0,T],V)}^m \right), \end{aligned} \tag{3.80}$$

where $\tilde{X}_{\lambda_m}(t) = X_{\lambda_m}(t) - S(t)X_0$. By inequality (3.43), it follows that

$$\left|\tilde{X}_{\lambda_n}\right|_{C([0,T],E)} \le c_{11} \left(1 + \|X_0\| + |Z|_{C(0,T],E)}^\rho \right) \tag{3.81}$$

for some $c_{11} > 0$. Let $w_{\lambda_n}(t) = \tilde{X}_{\lambda_n}(t) - \tilde{Z}(t)$ so that

$$w_{\lambda_n}(t) = \int_0^t S(t-r) F_{\lambda_n} \left(w_{\lambda_n}(s) + S(s)X_0 + \tilde{Z}(s) \right) ds \tag{3.82}$$

for $t \in [0,T]$. Inequality (3.81) provides a uniform bound on $|w_{\lambda_n}|_{C([0,T],E)}$, so by repeating the arguments for inequalities (3.37) and (3.38), it follows that

$$|X_{\lambda_n}|_{C^\beta([0,T],V)} \le c_{12} \left(1 + \|X_0\| + |\tilde{Z}|_{C([0,T],E)}^\rho + |\tilde{Z}|_{C^\beta([0,T],V)} \right) \tag{3.83}$$

for some $c_{12} > 0$. Inequalities (3.80) and (3.81) verify inequality (3.79), so the sequence $(\exp\left[\rho_{\lambda_n}(Z)\right], n \in \mathbb{N})$ is uniformly integrable and equality (3.73) is verified. □

4. Some examples. The first example is a finite-dimensional stochastic equation with a nonlinear drift. Consider the equation

$$dX(t) = f(X(t))\, dt + \Phi\, dB(t), \tag{4.1}$$

where $f\colon \mathbb{R}^n \to \mathbb{R}^n$, $\Phi \in \mathcal{L}(\mathbb{R}^n)$, and $(B(t), t \geq 0)$ is an $\mathbb{R}^n$-valued standard fractional Brownian motion with Hurst parameter $H \in (0,1)$. This case can be subsumed in the infinite-dimensional results given here, though some of the assumptions and the results simplify significantly. Let $E = V = \mathbb{R}^n$, $S(t) = I$ for $t \in \mathbb{R}_+$, and assume that $Q = \Phi\Phi^*$ is positive definite. The process

$$\left(\int_0^t \Phi \, dB, t \in [0,T] \right)$$

has sample paths in $C^\beta([0,T], \mathbb{R}^n)$ for $0 < \beta < H$. If $f\colon \mathbb{R}^n \to \mathbb{R}^n$ is Borel measurable and

$$\|f(x)\| \leq k_1(1 + \|x\|) \tag{4.2}$$

for some $k_1 > 0$ and all $x \in \mathbb{R}^n$, then for $H \in (0, 1/2)$ there is one and only one weak solution of (4.1) by Theorem 3.3. If, additionally, it is assumed that

$$\|f(x) - f(y)\| \leq k\|x - y\|^\gamma \tag{4.3}$$

for all $x, y \in \mathbb{R}^n$ and some $\gamma > 1 - \frac{1}{2H}$, then for $H \in (1/2, 1)$ there is one and only one weak solution. In each of these cases, the probability measure of the solution is mutually absolutely continuous with respect to the probability measure of the process $(\Phi B(t), t \in [0,T])$.

Now, replace the inequality in (4.2) by

$$\|f(x)\| \leq k_1(1 + \|x\|^\rho) \tag{4.4}$$

for some $\rho \geq 1$ and $k_1 > 0$. Assume that $f\colon \mathbb{R}^n \to \mathbb{R}^n$ is continuous and satisfies

$$\langle f(x) - f(y), x - y \rangle \leq k_3\|x - y\|^2 \tag{4.5}$$

for some $k_3 > 0$ and all $x, y \in \mathbb{R}^n$. If $H \in (1/2, 1)$, then assume that

$$\|f(x) - f(y)\| \leq k_4 \left(1 + \|x\|^q + \|y\|^q\right) \|x - y\|^\gamma \tag{4.6}$$

for some $q \geq 1$, $k_4 > 0$, $\gamma > 1 - \frac{1}{2H}$. For $H \in (0, \frac{1}{2})$ Theorem 3.6 can be used to verify that the probability law of the solution of (4.1) is mutually absolutely continuous with respect to the probability law of $(\Phi B(t), t \in [0,T])$. Furthermore, there is one and only one mild solution of (4.1); in fact, since the state space is finite-dimensional, the mild solution is a strong solution. For $H \in (\frac{1}{2}, 1)$ Theorem 3.7 can be used to verify mutual absolute continuity and one and only one mild solution as for the case $H \in (0, \frac{1}{2})$. Note that inequalities (4.4)–(4.6) are satisfied for the important case of models where f is a polynomial of odd degree with a negative leading coefficient.

The second example is a stochastic parabolic equation of $2m$th order:

$$\frac{\partial u}{\partial t}(t, \xi) = [L_{2m}u](t, \xi) + f(u(t, \xi)) + \eta(t, \xi) \tag{4.7}$$

for $(t, \xi) \in [0,T] \times \mathcal{O}$ with the initial condition

$$u(0, \xi) = x(\xi) \tag{4.8}$$

for $\xi \in \mathcal{O}$ and the Dirichlet boundary condition

$$\frac{\partial^k u}{\partial v^k}(t, \xi) = 0 \tag{4.9}$$

for $(t,\xi) \in [0,T] \times \partial\mathcal{O}$, $k \in \{0,\dots,m-1\}$, with $\frac{\partial}{\partial v}$ denoting the conormal derivative, $\mathcal{O}$ a bounded domain in $\mathbb{R}^d$ with a smooth boundary, and L_{2m} a $2m$th order uniformly elliptic operator

$$L_{2m} = \sum_{|\alpha| \le 2m} a_\alpha(\xi) D^\alpha \tag{4.10}$$

with $a_\alpha \in C_b^\infty(\mathcal{O})$. For example, if $m = 1$, then this equation is called the stochastic heat equation. The process η denotes a space-dependent noise process that is fractional in time with the Hurst parameter $H \in (0,1)$ and, possibly, in space. The system (4.7)–(4.9) is modeled as

$$\begin{aligned} dX(t) &= AX(t)dt + F(X(t))dt + \Phi dB(t), \\ X(0) &= x \end{aligned} \tag{4.11}$$

in the space $V = L^2(\mathcal{O})$, where $A = L_{2m}$,

$$\mathrm{Dom}(A) = \left\{ \varphi \in H^{2m}(\mathcal{O}) \Big| \frac{\partial^k}{\partial v^k}\varphi = 0 \text{ on } \partial D \text{ for } k \in \{0,\dots,m-1\} \right\},$$

$F : V \to V$ is the operator, $F(x)(\xi) = f(x(\xi)), x \in V, \xi \in \mathcal{O}$, $\Phi \in \mathcal{L}(V)$ defines the space correlation of the noise process, and $(B(t), t \ge 0)$ is a cylindrical standard fractional Brownian motion in V (formally, $\eta(t,\cdot) = \Phi(\partial/\partial t)B(t,\cdot)$). For $\Phi = I$, the noise process is uncorrelated in space. It is well known that A generates an analytic semigroup $(S(t), t \ge 0)$. Furthermore

$$|S(t)\Phi|_{\mathcal{L}_2(V)} \le |S(t)|_{\mathcal{L}_2(V)} |\Phi|_{\mathcal{L}(V)} \le c t^{-\frac{d}{4m}} \tag{4.12}$$

for $t \in [0,T]$, so if

$$H > \frac{d}{4m}, \tag{4.13}$$

then the conditions of Proposition 2.6 are satisfied with $\gamma = \frac{d}{4m}$. Therefore, for any $\Phi \in \mathcal{L}(V)$, the stochastic convolution process

$$\left(\int_0^t S(t-r)\Phi \, dB(r), t \in [0,T] \right)$$

is well-defined and has a version with $C^\beta([0,T],V)$ sample paths for $\beta \ge 0$ satisfying

$$\beta < H - \frac{d}{4m}. \tag{4.14}$$

Note that the condition (4.13) extends the well-known result for a standard Wiener process ($H = \frac{1}{2}$).

Theorems 3.3 and 3.4 are applied to the present example. Assume inequality (4.13) and let Φ be boundedly invertible on V. Furthermore, let $f : \mathbb{R} \to \mathbb{R}$ be measurable and satisfy

$$|f(\xi)| \le k_1(1 + |\xi|), \qquad \xi \in \mathbb{R}. \tag{4.15}$$

By the preceding part of this example, conditions (H1)–(H3) are satisfied for $E = V = L^2(\mathcal{O})$ and the map $F : V \to V$ has at most linear growth. Thus by Theorem 3.3 if $H < \frac{1}{2}$, then there exists a unique weak solution to (4.11).

If $H > \frac{1}{2}$, some additional conditions are required. Assume that

$$\frac{d}{4m} < \frac{1}{2} \tag{4.16}$$

(which is more restrictive than (4.13)) and suppose that

$$|f(\xi) - f(\lambda)| \le k|\xi - \lambda|^\gamma, \qquad \xi, \lambda \in \mathbb{R}, \tag{4.17}$$

for some $k > 0$ and $\gamma > 0$,

$$\frac{H - 1/2}{H - d/4m} < \gamma \le 1. \tag{4.18}$$

Then, letting β be such that $\beta < H - \frac{d}{4m}$ and $\gamma\beta > H - \frac{1}{2}$, it is clear that all of the conditions of Theorem 3.4 are verified so there is a unique weak solution to (4.11).

The third example is a one-dimensional stochastic equation of reaction-diffusion type. Consider the equation

$$\frac{\partial u}{\partial t}(t,\xi) = \frac{\partial^2 u}{\partial \xi^2}(t,\xi) + f(u(t,\xi)) + \eta(t,\xi) \tag{4.19}$$

for $(t,\xi) \in (0,T) \times (0,1)$ and

$$u(0,\xi) = x_0(\xi),$$
$$\frac{\partial u}{\partial \xi}(t,0) = \frac{\partial u}{\partial \xi}(t,1) = 0$$

for $(t,\xi) \in (0,T) \times (0,1)$, where f and η are given in the previous example (with $\mathcal{O} = (0,1)$). The above formal equation can be rewritten in the form (4.11) with $V = L^2([0,1])$, $A = \frac{\partial^2}{\partial \xi^2}$,

$$\mathrm{Dom}(A) = \left\{ \phi \in H^2([0,1]) : \frac{\partial}{\partial \xi}\phi(0) = \frac{\partial}{\partial \xi}\phi(1) = 0 \right\},$$

where $\Phi \in \mathcal{L}(V)$ and F is as given in the preceding example. The semigroup generated by A satisfies the estimate (4.12) (with $m = d = 1$), so if f satisfies the conditions of the previous example, the same conclusions on existence and uniqueness of the weak solution are obtained.

However, it is desirable to relax condition (4.15) of the linear growth of the function f, which is very restrictive in view of reaction-diffusion models, where f is often a polynomial. Let $H > 1/2$ and assume that

$$|f(\xi)| \le k(1 + |\xi|^\rho), \tag{4.20}$$

$$(f(\xi) - f(\lambda))\,\mathrm{sgn}(\xi - \lambda) \le k(\xi - \lambda), \tag{4.21}$$

$$|f(\xi) - f(\lambda)| \le k(1 + |\xi|^q + |\lambda|^q|\xi - \lambda|^\gamma \tag{4.22}$$

for all $\xi, \lambda \in \mathbb{R}$ and some universal constants $\rho > 0, q > 0, k > 0$ and γ satisfying

$$\frac{H - 1/2}{H - 1/4} < \gamma \leq 1. \tag{4.23}$$

Note that these conditions are satisfied if f is Lipschitz or if f is a polynomial of odd degree with a negative leading coefficient.

The conditions of Theorem 3.7 are verified now. Take the state space $E = C([0,1])$. It is well known that the restriction of A to E generates a strongly continuous semigroup of contractions on E. By Proposition 2.6 the stochastic convolution

$$\left(\int_0^t S(t-r)\Phi dB(r), t \in [0,T] \right) \tag{4.24}$$

has $C^\beta([0,T], V_\delta)$ sample paths for $\beta + \delta < H - 1/4$, and, hence, by the Sobolev embedding theorem, in the space $C([0,T], E) \cap C^\beta([0,T], V)$ for $0 < \beta < H - 1/4$ (by (4.23) β can be chosen such that $\beta\gamma > H - 1/2$). It remains to verify the conditions imposed on F. The polynomial growth condition (3.41), the "dissipativity of $F - kI$ on V" (3.66), and the local Hölder continuity of the form (3.67) follow easily from the corresponding conditions on f, that is, (4.20), (4.21), and (4.22). The dissipativity of $F - kI$ on E (3.42) is a well-known consequence of (4.21) by the characterization of the subdifferential of the norm on $E = C([0,1])$ (cf. [32]). The characterization of the subdifferentials for this example is as follows: Given $x \in E$, let $M_x = \{\xi \in [0,1]; |x(\xi)| = ||x||_E\}$. Then $\mu \in \delta||x||_E$ if and only if the following three conditions are satisfied: (i) μ is a Radon measure on $[0,1]$ with $||\mu|| = 1$; (ii) the support of μ is contained in M_x; and (iii) $\int_\Gamma sgn\ x(\xi)\mu(d\xi) \geq 0$ for each Borel set Γ in $[0,1]$. In particular if $x \in E$ has the property that $M_x = \{\xi_0\}$, then $\delta||x||_E = \delta_{\xi_0}$ for $x(\xi_0) = ||x||_E$ and $\delta||x||_E = -\delta_{\xi_0}$ for $x(\xi_0) = -||x||_E$, where δ_{ξ_0} is the Dirac distribution at ξ_0. The family of $x \in E$ with this latter property is dense in E. Therefore, all of the conditions of Theorem 3.7 are satisfied, and it follows that there is a unique weak solution in the present case.

ON THE EXISTENCE OF SOLUTIONS OF EQUILIBRIA IN LUBRICATED JOURNAL BEARINGS*

I. CIUPERCA†, M. JAI‡, AND J. I. TELLO§

Abstract. In this paper we study a system of equations concerning equilibrium positions of journal bearings. The problem consists of two surfaces in relative motion separated by a small distance filled with a lubricant. The shape of the inlet surface is circular, while the other surface has a more general shape. Our result shows the existence of at least one equilibrium by using degree theory.

Key words. Reynolds variational inequality, inverse problem, existence of solutions, degree theory

1. Introduction.

We consider in this paper a lubricated system called a journal bearing consisting of two cylinders in relative motion. An incompressible fluid, the lubricant, is introduced in the narrow space between the cylinders. An exterior force $F = (F_1, F_2) \in \mathbb{R}^2$ is applied on the inner cylinder (shaft) which turns with a given velocity ω.

The wedge between the two cylinders is assumed to satisfy the thin-film hypothesis, so that the pressure (assumed time-independent) does not depend on the normal coordinate to the bodies and obeys the Reynolds equation.

In order to introduce the Reynolds equation we need to describe the geometry and the dynamic of the system. We suppose that the interior cylinder has a circular form of constant radius (assumed 1) which rotates with known velocity. The transversal axis of the shaft is assumed to have only two degrees of freedom in the transversal plane, i.e., parallel to the exterior cylinder (bush) which is fixed and not necessarily of constant radius.

Let us consider (O, y_1, y_2) a reference system in the transversal plane to the cylinders, and suppose that the distance between O and the surface of the bush is larger than the radius of the shaft (see Figure 1.1). We also assume that the representation in polar coordinates (r, θ) of the bush is given by

$$r = 1 + \delta\rho(\theta), \tag{1.1}$$

where $\rho : [0, 2\pi] \to [1, +\infty[$ is a known function and $\delta > 0$ (the clearance) is a small parameter, representing the distance between the two cylinders when O and the center of the shaft coincide.

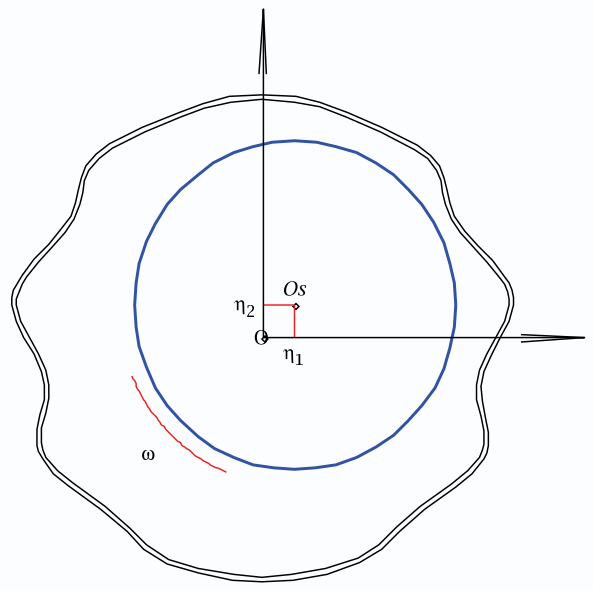

FIG. 1.1. *Scheme of the journal bearing.*

Remark 1.1. The particular case $\rho \equiv 1$ corresponds to a circular bush with radius $1+\delta$ and O the center of the bush.

Let us now denote by O_s the center of the shaft. The position of O_s is given in cartesian coordinates by $(\delta\eta_1, \delta\eta_2)$ and in polar coordinates by $(\delta\eta, \alpha)$, that is,

$$\begin{aligned} \eta_1 &= \eta\cos\alpha, \\ \eta_2 &= \eta\sin\alpha. \end{aligned} \tag{1.2}$$

It is well known (see, for instance, [5]) that the distance between the two cylinders is given by $\delta h(\theta,\eta,\alpha) + O(\delta^2)$ with

$$h(\theta,\eta,\alpha) = \rho(\theta) - \eta\cos(\theta-\alpha) = \rho(\theta) - \eta_1\cos\theta - \eta_2\sin\theta. \tag{1.3}$$

The formulation of the problem is complete when the distance between the surfaces is of order δ (i.e., $h \in O(1)$) and second order terms are neglected. Admissible forces in that case are of order $\frac{1}{\delta^2}$ or smaller. If the distance becomes smaller (i.e., $h \ll 1$) or forces are large (larger than $O(\frac{1}{\delta^2})$), second order terms cannot be neglected and the formulation loses its physical meaning.

Now, the problem will be posed in a fixed domain $\Omega =]0, 2\pi[\times]0,1[$ which parametrizes the space between shaft and bush. In fact the gap is approximated by the following domain given in cylindrical coordinates by (r,θ,x) with respect to O_s:

$$1 \le r \le 1 + \delta h(\theta,\eta,\alpha), \quad \theta \in [0,2\pi[, \quad x \in [0,1],$$

where $O_s = (\delta\eta\cos(\alpha), \delta\eta\sin(\alpha))$.

Since the wedge between the two cylinders satisfies the thin-film hypothesis, the pressure of the lubricant fluid (assumed time-independent) does not depend on the

normal coordinate to the bodies and obeys the Reynolds equation (see [9]). We also consider that there is an alimentation region along the circles $\{x = 0\}$ and $\{x = 1\}$, respectively, where the pressure in the fluid equals the atmospheric pressure supposed to be 0 by translation. Then the pressure $p : (\theta, x) \in \Omega \to \mathbb{R}$ satisfies the following problem written in nondimensional form:

$$\begin{cases} \nabla \cdot (h^3 \nabla p) = \frac{\partial h}{\partial \theta} & \text{on } \Omega, \\ p & \text{is } 2\pi\text{-periodic in } \theta, \\ p = 0 & \text{on }]0, 2\pi[\times \{0\} \cup]0, 2\pi[\times \{1\}. \end{cases} \tag{1.4}$$

In general the solution of (1.4) is not always nonnegative and we must replace (1.4) by the corresponding variational inequality.

In this work we are interested in an equilibrium problem which entails finding the position (η_1, η_2) of the shaft such that the hydrodynamic force (load) created by the pressure film equilibrates the exterior force F. Thus the problem is formulated as follows:

$$\text{Find } p \in K, (\eta_1, \eta_2) \in A \text{ such that}$$

$$\int_\Omega h^3 \nabla p \cdot \nabla(\varphi - p) \geq \int_\Omega h \frac{\partial}{\partial \theta}(\varphi - p) \quad \forall \varphi \in K, \tag{1.5}$$

$$\int_\Omega p \cos\theta \, d\theta dx = F_1, \tag{1.6}$$

$$\int_\Omega p \sin\theta \, d\theta dx = F_2, \tag{1.7}$$

where h is given in (1.3),

$$K = \left\{ \varphi \in H_0^1(\Omega) : \varphi \geq 0 \right\},$$

and $A \subset \mathbb{R}^2$. The set of admissible positions of the shaft (to be defined later) is such that $h(\theta, \eta, \alpha) > 0 \ \ \forall \theta \in [0, 2\pi]$.

As far as we know, very few works can be found in the literature concerning existence of equilibrium in the lubricated devices in spite of a larger number of references to numerical simulations; see, for instance, [3] or [4].

Some results exist in the case of sliders, that is, mechanisms consisting of an almost plane surface sliding above a horizontal plane surface.

Exact solutions for the case in which the upper surface is an inclined plane of angle θ and infinite width have been known for a long time, since the problem becomes one-dimensional and is easily integrated [7].

For more general shapes of the upper surfaces an existence result is obtained in [1] for the equation case and in [2] for the variational inequality in the one-dimensional case.

The content of the paper is as follows: In section 2 we give the main result. In section 3 we recall some elements of the degree theory which will be used. In section 4 some preliminary results are given, and section 5 is devoted to the proof of the main result.

2. Main results and assumptions. For the rest of the paper we assume that

$$\rho \in C^3(\mathbb{R}), \quad \rho,\ \rho',\ \text{and } \rho'' \text{ are } 2\pi\text{-periodic}, \tag{2.1}$$

$$\rho''(\theta) + \rho(\theta) > 0 \qquad \forall\, \theta \in \mathbb{R}, \tag{2.2}$$

$$\min_{0\le\theta\le 2\pi} \rho(\theta) = 1. \tag{2.3}$$

We denote the following:

$$\begin{aligned} \rho_M &= \max_{0\le\theta\le 2\pi} \rho(\theta), \\ m &= \min_{0\le\theta\le 2\pi} (\rho''(\theta) + \rho(\theta)) > 0, \\ M &= \max_{0\le\theta\le 2\pi} (\rho''(\theta) + \rho(\theta)) > 0. \end{aligned} \tag{2.4}$$

Remark 2.1. All these assumptions are clearly satisfied in the particular case of a circular bush, corresponding to $\rho \equiv 1$.

Remark 2.2. Assumption (2.2) is the most restrictive of the assumptions. It is introduced for technical reasons and guarantees that in the limit case the set where $h = 0$ is a single line.

Let us introduce the function $a(\alpha) : \mathbb{R} \to \mathbb{R}_+$ given by

$$a(\alpha) := \min_{\alpha-\frac{\pi}{2}<\theta<\alpha+\frac{\pi}{2}} \left\{ \frac{\rho(\theta)}{\cos(\theta-\alpha)} \right\}. \tag{2.5}$$

The fact that

$$\lim_{\theta\to\alpha\pm\frac{\pi}{2}} \frac{\rho(\theta)}{\cos(\theta-\alpha)} = \infty$$

and the continuity and boundedness of ρ guarantee the existence of at least one minimum.

Now we define the set A by

$$A = \Big\{ (\eta_1, \eta_2) \in \mathbb{R}^2 : 0 \le \eta < a(\alpha) \Big\},$$

where (η, α) are given by (1.2).

It is clear that $h(\theta) > 0\ \forall \theta \in [0, 2\pi]$ if and only if $(\eta_1, \eta_2) \in A$.

For any fixed $(\eta_1, \eta_2) \in A$, problem (1.5) has been studied by several authors. The existence and uniqueness of solutions can be obtained by using the direct methods in the calculus of variations along with strict convexity of the associated functional. Then (1.5) admits a unique classical solution $p \in K$; see, for instance, Kinderlehrer and Stampacchia [6].

Thus problem (1.5)–(1.7) is equivalent to the following problem:

$$\begin{cases} \text{Find } (\eta_1, \eta_2) \in A & \text{such that} \\ G(\eta_1, \eta_2) = (0, 0), \end{cases} \tag{2.6}$$

where $G = (G_1, G_2) : A \to \mathbb{R}^2$ is given by

$$G_1(\eta_1, \eta_2) = \int_\Omega p \cos\theta \, d\theta \, dx - F_1, \tag{2.7}$$

$$G_2(\eta_1, \eta_2) = \int_\Omega p \sin\theta \, d\theta \, dx - F_2, \tag{2.8}$$

where p (depending on η_1, η_2) is the unique solution of (1.5).

The main result of the paper is presented in the following theorem.

THEOREM 2.1. *Under assumptions* (2.1)–(2.3) *and for any* $F \in \mathbb{R}^2$ *there exists at least one solution* $(\eta_1, \eta_2) \in A$ *of* (2.6).

3. Known results on degree theory. In order to prove Theorem 2.1 we use the topological degree theory, which is rapidly recalled in the following.

The topological degree for continuous mappings between n-dimensional Euclidean spaces was first introduced by L. E. J. Brouwer in 1912. We first introduce the definition of degree for C^1 maps.

Let S be a bounded open subset of $\mathbb{R}^n$ and a $C^1(S)$ function $f : S \to \mathbb{R}^n$. Let $y_0 \in \mathbb{R}^n$ such that $y_0 \notin f(\partial S)$, and suppose that $f \in C^1(S)$ and that $Df(x)$ is invertible for all $x \in f^{-1}(y_0)$. Then $f(x) = y_0$ has either no solutions in S or a finite number r of solutions, say $x_1, x_2, \ldots, x_r$ and $\det(Df(x_i)) \neq 0$ for $i = 1, 2, \ldots, r$.

DEFINITION 3.1. *We define the degree of* f *in* S *at* y_0 *as follows:*

If $r = 0$, *then* $d(f, S, y_0) := 0$; *else*

$$d(f, S, y_0) := \sum_{i=1}^{r} sign(\det(Df(x_i))).$$

Remark 3.1. In the particular case where f is a linear function, i.e., $f(x) = Ax$, where A is an invertible matrix, the general formula for calculating the degree of linear functions is the following:

$$deg(Ax, S, 0) = sgn(\det A) \quad \text{if} \quad 0 \text{ is contained in } S.$$

The definition of degree can be extended to continuous maps; see [8, Extension Lemma, p. 60]. For the reader's convenience we state the following result (see, for instance, [8, Corollary 4 to Theorem 1.12, p. 81]) adapted to the finite-dimensional case.

THEOREM 3.1. *Let* S *be a bounded open set in* $\mathbb{R}^n$. *Let* f_0 *and* f_1 *be two continuous functions from* $\overline{S}$ *to* $\mathbb{R}^n$. *We assume moreover that* S *is a star domain with respect to the point* $y_0 \in S$ *and that*

$$[f_0(x) - y_0] \cdot [f_1(x) - y_0] > 0 \text{ for any } \ x \in \partial S.$$

Then

$$d(f_0, S, y_0) = d(f_1, S, y_0).$$

Remark 3.2. It is clear that if $d(f, S, y_0) \neq 0$, then there exists at least a solution $x \in S$ of the equation $f(x) = y_0$.

4. Preliminary results.

LEMMA 4.1. *Let* $a(\alpha)$ *be the function defined in* (2.5). *Then*

$$1 = \min_{0 \leq \theta \leq 2\pi} \rho \leq a(\alpha) \leq \max_{0 \leq \theta \leq 2\pi} \rho = \rho_M.$$

Proof. Since

$$\min_{0 \leq \theta \leq 2\pi} \rho \leq \rho \leq \max_{0 \leq \theta \leq 2\pi} \rho$$

we have that

$$\min_{0\le\theta\le 2\pi}\{\rho\}\ \min_{\alpha-\frac{\pi}{2}<\theta<\alpha+\frac{\pi}{2}}\left\{\frac{1}{\cos(\theta-\alpha)}\right\}\le a(\alpha)$$

and

$$a(\alpha)\le\max_{0\le\theta\le 2\pi}\{\rho\}\ \min_{\alpha-\frac{\pi}{2}<\theta<\alpha+\frac{\pi}{2}}\left\{\frac{1}{\cos(\theta-\alpha)}\right\}.$$

The fact that

$$\min_{\alpha-\frac{\pi}{2}<\theta<\alpha+\frac{\pi}{2}}\left\{\frac{1}{\cos(\theta-\alpha)}\right\}=1$$

implies

$$\min\{\rho\}\le a(\alpha)\le\max\{\rho\},$$

and the proof is complete. □

LEMMA 4.2. *There exists s with $0<s<\frac{\pi}{2}$ such that*

$$|\tilde{\theta}_\alpha-\alpha|<s$$

for any $\alpha\in\mathbb{R}$ and for any $\tilde{\theta}_\alpha\in]\alpha-\frac{\pi}{2},\ \alpha+\frac{\pi}{2}[$ satisfying

$$\frac{\rho(\tilde{\theta}_\alpha)}{\cos(\tilde{\theta}_\alpha-\alpha)}=a(\alpha).$$

Proof. From Lemma 4.1 we deduce

$$\cos(\tilde{\theta}_\alpha-\alpha)\ge\frac{1}{\rho_M},$$

which implies

$$|\tilde{\theta}_\alpha-\alpha|\le\arccos\frac{1}{\rho_M}<\frac{\pi}{2}. \tag{4.1}$$

Now taking $s=\frac{1}{2}(\frac{\pi}{2}+\arccos\frac{1}{\rho_M})$ we obtain the result. □

LEMMA 4.3. *Under assumptions (2.1)–(2.3), for any $\alpha\in\mathbb{R}$, the set of $\theta\in]\alpha-\frac{\pi}{2},\alpha+\frac{\pi}{2}[$, which minimizes the function $\theta\mapsto\frac{\rho(\theta)}{\cos(\theta-\alpha)}$, is a single point which we denote by θ_α satisfying*

$$\frac{\rho(\theta_\alpha)}{\cos(\theta_\alpha-\alpha)}=a(\alpha)$$

and

$$\rho'(\theta_\alpha)\cos(\theta_\alpha-\alpha)+\rho(\theta_\alpha)\sin(\theta_\alpha-\alpha)=0.$$

Moreover the function $\alpha\mapsto\theta_\alpha$ belongs to $C^1(\mathbb{R})$.

Proof. Let α be a fixed value of $\mathbb{R}$ and consider the critical points of the function $\theta\in]\alpha-\frac{\pi}{2},\alpha+\frac{\pi}{2}[\mapsto\frac{\rho(\theta)}{\cos(\theta-\alpha)}$, which satisfies

$$\left(\frac{\rho(\theta)}{\cos(\theta-\alpha)}\right)'=\frac{\rho'(\theta)}{\cos(\theta-\alpha)}+\frac{\rho(\theta)\sin(\theta-\alpha)}{\cos(\theta-\alpha)^2}=0. \tag{4.2}$$

Consider

$$f(\theta,\alpha) := \rho' \cos(\theta-\alpha) + \rho \sin(\theta-\alpha).$$

Notice that if θ is a minimum of

$$\frac{\rho(\theta)}{\cos(\theta-\alpha)},$$

then $f(\theta,\alpha)=0$. We now have that

$$\frac{\partial f}{\partial \theta} = (\rho'' + \rho)\cos(\theta-\alpha),$$

which is positive in $|\theta-\alpha| < \frac{\pi}{2}$ (by hypothesis (2.2)). The assertion follows using also the implicit function theorem on the open set $(\theta,\alpha) \in]-s,s[\times \mathbb{R}$ with s given in Lemma 4.2. □

We now introduce the function $h_0 : \mathbb{R}^2 \to \mathbb{R}$ defined by

$$h_0(\theta,\alpha) = h(\theta, a(\alpha), \alpha) = \rho(\theta) - a(\alpha)\cos(\theta-\alpha).$$

Remark 4.1. We have from Lemma 4.3

$$h_0(\theta_\alpha,\alpha) = \frac{\partial h_0}{\partial \theta}(\theta_\alpha,\alpha) = 0, \tag{4.3}$$

$$\frac{\partial^2 h_0}{\partial \theta^2}(\theta_\alpha,\alpha) = \rho''(\theta_\alpha) + \rho(\theta_\alpha). \tag{4.4}$$

LEMMA 4.4. *Let us denote for any* $\alpha \in [0,2\pi]$ *and* $\epsilon > 0$ *small enough*

$$I_{\alpha,\epsilon} := [\theta_\alpha - 2\sqrt{\epsilon}, \theta_\alpha - \sqrt{\epsilon}].$$

Then for any $\alpha \in [0,2\pi]$ *and* $\theta \in I_{\alpha,\epsilon}$ *we have*

(i) $h(\theta, a(\alpha)-\epsilon, \alpha) \le (2M+2)\epsilon$,

(ii) $-\frac{\partial h}{\partial \theta}(\theta, a(\alpha)-\epsilon,\alpha) \ge \frac{m}{2}\sqrt{\epsilon}$,

with m *and* M *defined in* (2.4).

Proof.

(i) We have

$$h(\theta, a(\alpha)-\epsilon,\alpha) = h_0(\theta,\alpha) + \epsilon\cos(\theta-\alpha).$$

From Taylor development of h_0 at $\theta=\theta_\alpha$, using (4.3) and (4.4) we have (i).

(ii) We have

$$-\frac{\partial h}{\partial \theta}(\theta, a(\alpha)-\epsilon,\alpha) = -\frac{\partial h_0}{\partial \theta}(\theta,\alpha) + \epsilon\sin(\theta-\alpha).$$

Using the Taylor development of $\frac{\partial h_0}{\partial \theta}$ at $\theta=\theta_\alpha$ we obtain

$$-\frac{\partial h}{\partial \theta}(\theta, a(\alpha)-\epsilon,\alpha) = \frac{\partial^2 h_0}{\partial \theta^2}(\hat{\theta},\alpha)(\theta_\alpha-\theta) + \epsilon\sin(\theta-\alpha)$$

with $\hat{\theta} \in I_{\alpha,\epsilon}$.

From (4.4), the uniform continuity of $\frac{\partial^2 h_0}{\partial\theta^2}$, and (2.4) we deduce

$$\frac{\partial^2 h_0}{\partial\theta^2}(\hat{\theta},\alpha) \geq \frac{2}{3}m.$$

Since $\theta_\alpha - \theta \geq \sqrt{\epsilon}$, we obtain for ϵ small enough

$$-\frac{\partial h}{\partial\theta}(\theta, a(\alpha)-\epsilon, \alpha) \geq \frac{2}{3}m\sqrt{\epsilon} - \epsilon,$$

which ends the proof. □

LEMMA 4.5. *Let ϵ be small enough and $\eta := a(\alpha) - \epsilon$. There exists a constant $c > 0$ independent of ϵ and α such that*

$$\inf_{0\leq\alpha\leq 2\pi} \int_\Omega h^3(\theta,\eta,\alpha)|\nabla p|^2 d\theta dx > c\epsilon^{-\frac{1}{2}} \qquad \text{as } \epsilon \to 0.$$

Proof. We take in (1.5) $\phi := p + \varphi$ with $\varphi \in K$ arbitrary. Then

$$\int_\Omega h\frac{\partial\varphi}{\partial\theta} d\theta dx \leq \int_\Omega h^3 \nabla p \nabla\varphi d\theta dx.$$

By the Cauchy–Schwarz inequality we have

$$\int_\Omega h\frac{\partial\varphi}{\partial\theta} d\theta dx \leq \left|\int_\Omega h^3|\nabla p|^2 d\theta dx\right|^{\frac{1}{2}} \left|\int_\Omega h^3|\nabla\varphi|^2 d\theta dx\right|^{\frac{1}{2}}$$

and we deduce

$$\left|\int_\Omega h^3|\nabla p|^2 d\theta dx\right|^{\frac{1}{2}} \geq \sup_{\varphi\in K,\varphi\neq 0} \frac{-\int_\Omega \varphi\frac{\partial h}{\partial\theta} d\theta dx}{\left|\int_\Omega h^3|\nabla\varphi|^2 d\theta dx\right|^{\frac{1}{2}}}. \tag{4.5}$$

Let m be given by (2.4) and $\psi \in C^2(\mathbb{R})$ such that

(i) $\operatorname{supp}(\psi) \subset [-2,-1]$;
(ii) $\psi \geq 0$;
(iii) $\int_{\mathbb{R}} \psi > 0$.

As a consequence of (i)–(iii) we have

$$\frac{\int_{\mathbb{R}} \psi}{\left|\int_{\mathbb{R}} |\psi'|^2\right|^{\frac{1}{2}}} = c_1 > 0. \tag{4.6}$$

Let

$$\varphi_\epsilon(\theta, x) := \psi\left(\frac{\theta-\theta_\alpha}{\sqrt{\epsilon}}\right) x(1-x)$$

with θ_α defined in Lemma 4.3.

It is clear that $\operatorname{supp}(\varphi_\epsilon) = I_{\alpha,\epsilon} \times [0,1]$ with $I_{\alpha,\epsilon}$ as in Lemma 4.4. Using Lemma 4.4 (ii) we deduce

$$\begin{aligned} -\int_\Omega \frac{\partial h}{\partial\theta}\varphi_\epsilon d\theta dx &\geq \min_{\theta\in I_{\alpha,\epsilon}} \left(-\frac{\partial h}{\partial\theta}\right) \int_\Omega \varphi_\epsilon d\theta dx \\ &\geq \frac{m}{2}\epsilon \int_{\mathbb{R}} \psi dy \int_0^1 x(1-x)dx = \frac{m}{12}\epsilon\int_{\mathbb{R}}\psi dy. \end{aligned} \tag{4.7}$$

On the other hand, using Lemma 4.4 (i) we have

$$\left|\int_\Omega h^3|\nabla\varphi_\epsilon|^2 d\theta dx\right|^{\frac{1}{2}} \le \max_{I_{\alpha,\epsilon}}\{h^3\}^{\frac{1}{2}}\left|\int_\Omega |\nabla\varphi_\epsilon|^2 d\theta dx\right|^{\frac{1}{2}}$$
$$\le ((2M+2)\epsilon)^{3/2}\left|\int_\Omega |\nabla\varphi_\epsilon|^2 d\theta dx\right|^{\frac{1}{2}}.$$

A simple calculation gives

$$\int_\Omega |\nabla\varphi_\epsilon|^2 d\theta dx \le c_3\epsilon^{-1/2}.$$

We then have

$$\left|\int_\Omega h^3|\nabla\varphi_\epsilon|^2 d\theta dx\right|^{\frac{1}{2}} \le c_4\epsilon^{5/4}, \tag{4.8}$$

which, also using (4.7), gives us

$$\frac{-\int_\Omega \varphi_\epsilon \frac{\partial h}{\partial\theta} d\theta dx}{\left|\int_\Omega h^3|\nabla\varphi_\epsilon|^2 d\theta dx\right|^{1/2}} \ge c_5\epsilon^{-\frac{1}{4}}. \tag{4.9}$$

Finally from (4.5) and (4.9) we have the result. □

We now introduce for any ϵ small the function $\tilde{h}:\mathbb{R}^2\to\mathbb{R}$ defined by

$$\tilde{h}(\theta,\alpha) := h(\theta_\alpha, a(\alpha)-\epsilon,\alpha) + [\rho''(\theta_\alpha)+\rho(\theta_\alpha)](1-\cos(\theta-\theta_\alpha)). \tag{4.10}$$

Notice that

$$\begin{cases} h(\theta_\alpha, a(\alpha)-\epsilon,\alpha) = \tilde{h}(\theta_\alpha,\alpha) = \epsilon\cos(\theta_\alpha-\alpha), \\ \frac{\partial h}{\partial\theta}(\theta_\alpha, a(\alpha)-\epsilon,\alpha) - \frac{\partial\tilde{h}}{\partial\theta}(\theta_\alpha,\alpha) = \frac{\partial h}{\partial\theta}(\theta_\alpha, a(\alpha)-\epsilon,\alpha) = -\epsilon\sin(\theta_\alpha-\alpha), \\ \frac{\partial^2 h}{\partial\theta^2}(\theta_\alpha, a(\alpha)-\epsilon,\alpha) - \frac{\partial^2\tilde{h}}{\partial\theta^2}(\theta_\alpha,\alpha) = -\epsilon\cos(\theta_\alpha-\alpha). \end{cases} \tag{4.11}$$

LEMMA 4.6. *There exists a constant c independent of ϵ and α such that*

$$\int_0^{2\pi} \frac{\Big(h(\theta,a(\alpha)-\epsilon,\alpha)-\tilde{h}(\theta,\alpha)\Big)^2}{h^3(\theta,a(\alpha)-\epsilon,\alpha)} d\theta \le c.$$

Proof. By the Taylor polynomial of $h-\tilde{h}$ and h at θ_α and (4.11) we have

$$|h(\theta,a(\alpha)-\epsilon,\alpha)-\tilde{h}(\theta,\alpha)| \le \epsilon|\theta-\theta_\alpha| + \epsilon|\theta-\theta_\alpha|^2 + c|\theta-\theta_\alpha|^3 \tag{4.12}$$

and

$$\begin{aligned} h(\theta,a(\alpha)-\epsilon,\alpha) &= \epsilon\cos(\theta_\alpha-\alpha) - \epsilon\sin(\theta_\alpha-\alpha)(\theta-\theta_\alpha) \\ &+\frac{1}{2}\Big(\rho''(\theta_\alpha)+\rho(\theta_\alpha)-\epsilon\cos(\theta_\alpha-\alpha)\Big)(\theta-\theta_\alpha)^2 \\ &+\frac{1}{6}\frac{\partial^3 h}{\partial\theta^3}(\hat{\theta},a(\alpha)-\epsilon,\alpha)(\theta-\theta_\alpha)^3 \end{aligned} \tag{4.13}$$

with $\hat{\theta}\in\mathbb{R}$.

From Lemma 4.2, (4.13), and (2.2) there exists m_1, m_2, and m_3 positive and independent of ϵ and α such that

$$h(\theta, a(\alpha) - \epsilon, \alpha) \geq m_1\epsilon + m_2(\theta - \theta_\alpha)^2 \tag{4.14}$$

$\forall\ \theta$ such that $|\theta - \theta_\alpha| \leq m_3$.

We have from (4.12)

$$\int_0^{2\pi} \frac{(h - \tilde{h})^2}{h^3} d\theta \leq 2(\epsilon^2 I_1 + \epsilon^2 I_2 + c^2 I_3)$$

with $I_k = \int_0^{2\pi} \frac{(\theta - \theta_\alpha)^{2k}}{h^3} d\theta, k = 1, 2, 3$.

Now from (4.14) it is clear that I_3 is bounded uniformly in ϵ and α.

We will prove the uniform estimate for $\epsilon^2 I_1$. For $\epsilon^2 I_2$ the proof is similar.

We have

$$I_1 = I_1^1 + I_1^2 + I_1^3,$$

where I_1^1, I_1^2, I_1^3 are the subintegrals, respectively, in the intervals $|\theta - \theta_\alpha| \geq m_3, \epsilon^{1/3} \leq |\theta - \theta_\alpha| \leq m_3$, and $0 \leq |\theta - \theta_\alpha| \leq \epsilon^{1/3}$.

It is clear that $\epsilon^2 I_1^1$ is bounded uniformly in ϵ and α since h is lower bounded by a positive constant on the interval $|\theta - \theta_\alpha| \geq m_3$.

From (4.14) we have

$$I_1^2 \leq m_2^{-3} \int_{\epsilon^{1/3} \leq |\theta - \theta_\alpha| \leq m_3} \frac{d\theta}{|\theta - \theta_\alpha|^4} \leq c\epsilon^{-4/3}$$

and

$$I_1^3 \leq m_1^{-3}\epsilon^{-3} \int_{0 \leq |\theta - \theta_\alpha| \leq \epsilon^{1/3}} |\theta - \theta_\alpha|^2 d\theta \leq m_1^{-3}\epsilon^{-2},$$

which proves the lemma. □

5. Proof of Theorem 2.1. We apply the degree theory recalled in section 3 to the function G.

Since G is not defined on $\bar{A}$ we introduce for any $\epsilon > 0$ small enough the domain

$$A_\epsilon = \Big\{(\eta_1, \eta_2) : 0 \leq \eta \leq a(\alpha) - \epsilon\Big\}.$$

Let us now introduce the vector field

$$W : (\eta_1, \eta_2) \in A \to (\eta \sin\theta_\alpha, -\eta \cos\theta_\alpha) \in \mathbb{R}^2$$

with (η, α) defined in (1.2) and θ_α as in Lemma 4.3.

We observe that

$$W \cdot (-\eta_2, \eta_1) = -\eta^2 \cos(\theta_\alpha - \alpha).$$

From Lemmas 4.2 and 4.3 we have that

$$W \cdot (-\eta_2, \eta_1) < 0 \quad \forall (\eta_1, \eta_2) \in A.$$

From Theorem 3.1 we deduce that

$$deg(W, A_\epsilon, 0) = deg((-\eta_2, \eta_1), A_\epsilon, 0) = 1.$$

Notice that $deg(f, S, 0) = (-1)^n deg(-f, S, 0)$, where n is the dimension of the domain (for the application here, $n = 2$, so the sign does not change).

It suffices now to prove the inequality

$$G(\eta_1, \eta_2) \cdot W(\eta_1, \eta_2) > 0 \quad \forall (\eta_1, \eta_2) \in \partial A_\epsilon, \tag{5.1}$$

and the proof is finished using again Theorem 3.1.

We have, $\forall (\eta_1, \eta_2) \in \partial A_\epsilon$, $\eta = a(\alpha) - \epsilon$. Then

$$G(\eta_1, \eta_2) \cdot W(\eta_1, \eta_2) = -\eta \int_\Omega p \sin(\theta - \theta_\alpha) d\theta dx + \eta(-F_1 \sin\theta_\alpha + F_2 \cos\theta_\alpha). \tag{5.2}$$

Now taking $\varphi = 0$ and $\varphi = 2p$, respectively, in (1.5) we obtain

$$\int_\Omega h^3 |\nabla p|^2 d\theta dx = -\int_\Omega \frac{\partial h}{\partial \theta} p d\theta dx. \tag{5.3}$$

Notice that

$$\int_\Omega \frac{\partial h}{\partial \theta} p d\theta dx = \int_\Omega \frac{\partial}{\partial \theta}(h - \tilde{h}) p d\theta dx + \int_\Omega \frac{\partial \tilde{h}}{\partial \theta} p d\theta dx \tag{5.4}$$

with $\tilde{h}$ given by (4.10).

We now have

$$\begin{aligned} \int_\Omega \frac{\partial}{\partial \theta}(h - \tilde{h}) p d\theta dx &= -\int_\Omega (h - \tilde{h}) \frac{\partial p}{\partial \theta} d\theta dx \\ &\geq -\int_\Omega \frac{|h - \tilde{h}|}{h^{3/2}} h^{3/2} |\nabla p| d\theta dx \\ &\geq -\frac{1}{2} \int_\Omega \frac{|h - \tilde{h}|^2}{h^3} d\theta dx - \frac{1}{2} \int_\Omega h^3 |\nabla p|^2 d\theta dx. \end{aligned} \tag{5.5}$$

Since

$$\frac{\partial \tilde{h}}{\partial \theta} = (\rho''(\theta_\alpha) + \rho(\theta_\alpha)) \sin(\theta - \theta_\alpha)$$

we obtain from (5.3) and (5.5)

$$\begin{aligned} \int_\Omega h^3 |\nabla p|^2 d\theta dx \leq \frac{1}{2} \int_\Omega \frac{|h - \tilde{h}|^2}{h^3} + \frac{1}{2} \int_\Omega h^3 |\nabla p|^2 d\theta dx \\ - (\rho''(\theta_\alpha) + \rho(\theta_\alpha)) \int_\Omega \sin(\theta - \theta_\alpha) p d\theta dx, \end{aligned}$$

which implies, using also hypotheses (2.2),

$$-\int_\Omega \sin(\theta - \theta_\alpha) p d\theta dx \geq \frac{\int_\Omega h^3 |\nabla p|^2 d\theta dx - \int_\Omega \frac{|h - \tilde{h}|^2}{h^3} d\theta dx}{2(\rho''(\theta_\alpha) + \rho(\theta_\alpha))}.$$

Since ρ is in C^2 and from Lemmas 4.5 and 4.6, we obtain for ϵ small enough

$$-\int_\Omega \sin(\theta-\theta_\alpha)p \geq c(\epsilon^{-1/2}-1)$$

with $c>0$ a constant independent of ϵ and α.

Since $\eta = a(\alpha)-\epsilon$ and thanks to (5.2) we deduce

$$G(\eta_1,\eta_2)\cdot W(\eta_1,\eta_2) \geq \eta\Big(c(\epsilon^{-1/2}-1)-\|F\|\Big).$$

Taking ϵ small enough, we prove the theorem.

Remark 5.1. In the same manner we can prove the existence of at least one equilibrium solution for some other similar problems in this context. For instance, the case of Dirichlet boundary conditions on every boundary of Ω, or the case of a one-dimensional domain with Dirichlet boundary conditions.

Acknowledgments. The third author thanks INSA-Lyon and Institut Camille Jordan at University of Lyon for their hospitality.

POINTWISE GREEN FUNCTION BOUNDS AND LONG-TIME STABILITY OF LARGE-AMPLITUDE NONCHARACTERISTIC BOUNDARY LAYERS*

SHANTIA YARAHMADIAN† AND KEVIN ZUMBRUN†

Abstract. Using pointwise semigroup techniques of Zumbrun–Howard and Mascia–Zumbrun, we obtain sharp global pointwise Green function bounds for noncharacteristic boundary layers of arbitrary amplitude. These estimates allow us to analyze linearized and nonlinearized stability of noncharacteristic boundary layers of one-dimensional systems of conservation laws, showing that both follow from (and linearized stability is equivalent to) a numerically checkable Evans function condition. Our results extend to the large-amplitude case results obtained for small amplitudes by Matsumura, Nishihara, and others using energy estimates.

Key words. boundary layer stability, Evans function, pointwise Green function bounds

1. Introduction.

Boundary layers appear in many physical settings, such as gas dynamics, MHD, and rotating fluids; see, for example, the physical discussion in [34]. In this paper, we study the stability of boundary layers assuming that the boundary layer solution is noncharacteristic, which means that signals are transmitted into or out of, but not along the boundary. Specifically, we consider a boundary layer, or stationary solution,

$$u = \bar{u}(x), \quad \lim_{x\to+\infty} \bar{u}(x) = u_+, \quad \bar{u}(0) = u_0 \tag{1.1}$$

of a system of conservation laws on the quarter-plane

$$u_t + f(u)_x = (B(u)u_x)_x, \quad x, t > 0, \tag{1.2}$$

$u, f \in \mathbb{R}^n$, $B \in \mathbb{R}^{n\times n}$, with initial data $u(x,0) = g(x)$ and Dirichlet boundary condition

$$u(0,t) = h(t). \tag{1.3}$$

A fundamental question is whether or not such boundary layer solutions are *stable* in the sense of PDE, i.e., whether or not a sufficiently small perturbation of $\bar{u}$ remains close to $\bar{u}$, or converges time-asymptotically to $\bar{u}$, under the evolution of (1.2).

Long-time stability of boundary layers has been considered for scalar equations in [24, 25] and for the equations of isentropic gas dynamics in [26, 23]. The latter results, obtained by energy estimates, apply to arbitrary amplitude layers of "expansive inflow" type analogous to rarefaction waves, but only to small-amplitude layers of "compressive inflow or outflow" type analogous to shock waves or "expansive outflow" type. For general symmetric hyperbolic-parabolic systems, stability of small-amplitude noncharacteristic boundary layers has been shown in multidimensions for

strictly parabolic systems in [11], and in one dimension for partially parabolic ("real viscosity") systems in [30].

Here, in the spirit of results obtained for shock waves in [37, 27, 28], we show for general strictly parabolic systems of conservation laws that linearized and nonlinear stability follow from and linearized stability is equivalent to a generalized spectral stability condition phrased in terms of the Evans function associated with the linearized equations about the wave, *independent of the amplitude of the boundary layer in question.* The Evans function, introduced for boundary layers in [32], is described further in section 2; for its origins in the study of stability of traveling waves, see for example, [1, 10] and references therein.

The Evans condition is readily checkable numerically, and in some cases analytically; see [3, 4, 5, 6, 20, 2, 17]. In particular, stability of small-amplitude uniformly noncharacteristic boundary layers has been shown for general hyperbolic–parabolic systems in multidimensions in [13] using elementary Evans function arguments (convergence to the constant layer). An exhaustive numerical study for isentropic gas layers in one dimension has been carried out in [7], with the conclusion of stability for arbitrary amplitudes. Results of instability in some cases have been shown in [32, 33] using a mod two stability index in the spirit of [10].

Our method of analysis [35] is by pointwise Green function methods like those used in [37, 27, 28], and especially [16], to analyze the stability of viscous shock layers. Similar results have been obtained for the related small-viscosity-limit problem in [12, 29, 14]. In particular, we point to the analysis of Grenier and Rousset [12] as using pointwise Green function estimates very similar to those that we use here, though adapted for different purposes.

1.1. Equations and assumptions. Consider a *viscous boundary layer*, a standing-wave solution (1.1) of a general parabolic system of conservation laws (1.2).

Assume, similarly, as in the treatment of the viscous shock case in [16]:

(H0) $f, B \in C^3$.

(H1) $Re\,\sigma(B) > 0$.

(H2) $\sigma(f'(u_+))$ real, distinct, and nonzero.

(H3) $Re\,\sigma(-ikf'(u_+) - k^2 B(u_+)) < -\theta k^2$ for all real k and $\theta > 0$.

LEMMA 1.1 ([27, 36]). *Assuming* (H0)–(H3), *a solution* $\bar u$ *of* (1.1) *if it exists is also unique; moreover,*

$$\big|(d/dx)^k(\bar u - u_+)\big| \le Ce^{-\theta x}, \quad k = 0, \dots, 4, \tag{1.4}$$

as $x \to +\infty$, *for some* $\theta > 0$.

Proof. As in the shock case [28, 36], (1.4) follows by the observation that, under hypotheses (H0)–(H3), u_+ is a hyperbolic rest point of the layer profile ODE. Uniqueness follows by the observation [27] that the standing-wave ODE may be integrated from x to $+\infty$ and rearranged to yield

$$B(u)u' = f(u) - f(u_+) \tag{1.5}$$

together with the boundary conditions at $x = 0$, thus determining a unique solution for all $x \ge 0$. ∎

1.2. Linearized stability and the Evans function. After linearizing (1.2) about the stationary solution $\bar u$, we obtain the linearized equation

$$u_t = Lu := -(Au)_x + (Bu_x)_x, \quad A, B \in C^2, \tag{1.6}$$

where

$$B := B(\bar{u}) \tag{1.7}$$

and

$$Au := dF(\bar{u})u - dB(\bar{u})(u, \bar{u}_x). \tag{1.8}$$

DEFINITION 1.2. *The boundary layer $\bar{u}$ is said to be linearly asymptotically stable if $u(\cdot,t)$ approaches 0 as $t \to \infty$, for any solution u of (1.6) with initial data bounded in some specified norm.*

We define the following *stability criterion*, where $D(\lambda)$, described below, denotes the Evans function associated with the linearized operator L about the layer, an analytic function analogous to the characteristic polynomial of a finite-dimensional operator, whose zeroes away from the essential spectrum agree in location and multiplicity with the eigenvalues of L:

(1.9) There exist no zeroes of $D(\cdot)$ in the nonstable half-plane $Re\lambda \geq 0$.

As discussed, e.g., in [31], under assumptions (H0)–(H3), this is equivalent to *strong spectral stability*, $\sigma(L) \subset \{Re\lambda < 0\}$, *transversality* of $\bar{u}$ as a solution of the connection problem in the associated standing-wave ODE, and *hyperbolic stability* of an associated boundary value problem obtained by formal matched asymptotics. Here, and elsewhere, σ denotes spectrum of a linearized operator or matrix.

Our first main result is as follows.

THEOREM 1.3. *Assuming* (H0)–(H3), *linearized asymptotic $L^1 \cap L^p \to L^p$ stability, $p > 1$, is equivalent to* (1.9).

Theorem 1.3 is obtained as a consequence of the following detailed, pointwise bounds on the Green function $G(x,t;y)$ of the linearized evolution equations (1.6) with homogeneous boundary conditions (more properly speaking, a distribution), defined by:

(i) $(\partial_t - L_x)G = 0$ in the distributional sense, for all $x, y, t > 0$;
(ii) $G(x,t;y) \to \delta(x-y)$ as $t \to 0$;
(iii) $G(0,t;y) \equiv 0$, for all $y, t > 0$.

Denote by

$$a_1^+ < a_2^+ < \cdots < a_n^+ \tag{1.10}$$

the eigenvalues of of the limiting convection matrix $A_+ := df(u_+)$.

Then, our second main result is as follows.

THEOREM 1.4. *Assuming* (H0)–(H3) *and stability condition* (1.9),

$$\begin{aligned} |\partial_x^\gamma \partial_y^\alpha G(x,t;y)| &\leq Ce^{-\eta(|x-y|+t)} \\ &+ C\left(t^{-|\alpha|/2} + |\alpha|e^{-\eta|y|} + |\gamma|e^{-\eta|x|}\right)\left(\sum_{k=1}^{n} t^{-1/2} e^{-(x-y-a_k^- t)^2/Mt}\right. \\ &\left. + \sum_{a_k^+<0,\, a_j^+>0} \chi_{\{|a_k^+ t| \geq |y|\}} t^{-1/2} e^{-\left(x-a_j^+\left(t-|y/a_k^+|\right)\right)^2/Mt}\right), \end{aligned} \tag{1.11}$$

$0 \leq |\alpha|, |\gamma| \leq 1$, *for some η, C, $M > 0$, where x^+ denotes the positive/negative part of x, indicator function $\chi_{\{|a_k^- t| \geq |y|\}}$ is 1 for $|a_k^- t| \geq |y|$ and 0 otherwise.*

1.3. Nonlinear stability.

DEFINITION 1.5. *The boundary layer $\bar u$ is said to be nonlinearly asymptotically stable if $\tilde u(\cdot,t)$ exists for all $t\geq 0$ and approaches $\bar u$ as $t\to\infty$, for any solution $\tilde u$ of* (1.2) *with initial data sufficiently close in some norm to the original layer $\bar u$.*

Denoting by

$$a_1^+ < a_2^+ < \cdots < a_n^+ \tag{1.12}$$

the eigenvalues of of the limiting convection matrix $A_+ := df(u_+)$, define

$$\theta(x,t) := \sum_{a_j^+>0} (1+t)^{-1/2} e^{-|x-a_j^+ t|^2/Lt}, \tag{1.13}$$

$$\psi_1(x,t) := \chi(x,t) \sum_{a_j^+>0} (1+|x|+t)^{-1/2} \left(1+\left|x-a_j^+ t\right|\right)^{-1/2}, \tag{1.14}$$

and

$$\psi_2(x,t) := (1-\chi(x,t)) \left(1+\left|x-a_n^+ t\right|+t^{1/2}\right)^{-3/2}, \tag{1.15}$$

where $\chi(x,t)=1$ for $x\in[0,a_n^+ t]$ and $\chi(x,t)=0$ otherwise and $L>0$ is a sufficiently large constant. For simplicity, take B identically constant. Then, our third and final main result is as follows.

THEOREM 1.6. *Assuming* (H0)–(H3), *$B\equiv$ constant, and the linear stability condition* (1.9), *the profile $\bar u$ is nonlinearly asymptotically stable with respect to perturbations g, h in initial and boundary data satisfying*

$$|g(x)|\leq E_0(1+|x|)^{-3/2}, \quad |h(t)|\leq E_0(1+|t|)^{-3/2}, \quad |h'(t)|\leq E_0(1+|t|)^{-1}$$

for E_0 sufficiently small. More precisely,

$$|\tilde u(x,t)-\bar u(x)| \leq CE_0(\theta+\psi_1+\psi_2)(x,t), \tag{1.16}$$

where $\tilde u$ denotes the solution of (1.2) *with initial data $\tilde g=\bar u+g$ and boundary data $\tilde h = u_0+h$.*

Remark 1.7. Pointwise bound (1.16) yields as a corollary the sharp L^p decay rate

$$|\tilde u(x,t)-\bar u(x)|_{L^p} \leq CE_0(1+t)^{-\frac12(1-\frac1p)}, \quad 1\leq p\leq\infty. \tag{1.17}$$

1.4. Discussion and open problems. The case of boundary layers is quite analogous to the undercompressive shock case; in particular, pointwise estimates as in [16] appear to be necessary to close the one-dimensional analysis by a linearized semigroup approach suitable for large-amplitude layers. (On the other hand, small-amplitude stability has been established using energy estimates in, e.g., [26, 11].) A new feature of the present analysis as compared to those of [16, 18, 19] is the admission of perturbations in boundary as well as initial data. Open problems are extensions to systems with physical (partial) or quasilinear viscosity and to multidimensional boundary layers.

2. The Evans function. Before starting the analysis, we review the basic Evans function methods and gap/conjugation lemma.

2.1. The gap/conjugation lemma. Consider a family of first-order ODE systems on the half-line:

$$\begin{aligned} W' &= \mathbb{A}(x,\lambda)W, \quad \lambda \in \Omega \quad \text{and} \quad x > 0, \\ \mathbb{B}(\lambda)W &= 0, \quad \lambda \in \Omega \quad \text{and} \quad x = 0. \end{aligned} \tag{2.1}$$

These systems of ODEs should be considered as a generalized eigenvalue equation, with λ representing frequency. We assume that the boundary matrix $\mathbb{B}$ is analytic in λ and that the coefficient matrix $\mathbb{A}$ is analytic in λ as a function from Ω into $L^\infty(x)$, C^K in x, and approaches exponentially to a limit $\mathbb{A}_+(\lambda)$ as $x \to \infty$, with uniform exponentially decay estimates

$$\left|(\partial/\partial x)^k(\mathbb{A} - \mathbb{A}_+)\right| \le C_1 e^{-\theta|x|/C_2}, \quad \text{for } x > 0,\ 0 \le k \le K, \tag{2.2}$$

C_j, $\theta > 0$, on compact subsets of Ω. Now we can state a refinement of the "Gap Lemma" of [10, 21], relating solutions of the variable-coefficient ODE to the solutions of its constant-coefficient limiting equations

$$Z' = \mathbb{A}_+(\lambda)Z \tag{2.3}$$

as $x \to +\infty$.

LEMMA 2.1 (conjugation Lemma [29]). *Under assumption* (2.2)*, there exists locally to any given $\lambda_0 \in \Omega$ a linear transformation $P_+(x,\lambda) = I + \Theta_+(x,\lambda)$ on $x \ge 0$, Φ_+ analytic in λ as functions from Ω to $L^\infty[0,+\infty)$, such that:*

(i) *$|P_+|$ and their inverses are uniformly bounded, with*

$$\left|(\partial/\partial\lambda)^j(\partial/\partial x)^k\Theta_+\right| \le C(j)C_1C_2e^{-\theta|x|/C_2} \quad \text{for } x > 0,\ 0 \le k \le K+1, \tag{2.4}$$

$j \ge 0$, where $0 < \theta < 1$ is an arbitrary fixed parameter, and $C > 0$ and the size of the neighborhood of definition depend only on θ, j, the modulus of the entries of $\mathbb{A}$ at λ_0, and the modulus of continuity of $\mathbb{A}$ on some neighborhood of $\lambda_0 \in \Omega$.

(ii) *The change of coordinates $W := P_+Z$ reduces* (2.1) *on $x \ge 0$ to the asymptotic constant-coefficient equations* (2.3)*. Equivalently, solutions of* (2.1) *may be conveniently factorized as*

$$W = (I + \Theta_+)Z_+, \tag{2.5}$$

where Z_+ are solutions of the constant-coefficient equations, and Θ_+ satisfy (2.4)*.*

Proof. As described in [27], for $j = k = 0$ this is a straightforward corollary of the gap lemma as stated in [Z.3], applied to the "lifted" matrix-valued ODE

$$P' = \mathbb{A}_+P - P\mathbb{A} + (\mathbb{A} - \mathbb{A}_+)P$$

for the conjugating matrices P_+. The x-derivative bounds $0 < k \le K+1$ then follow from the ODE and its first K derivatives. Finally, the λ-derivative bounds follow from standard interior estimates for analytic functions. ∎

DEFINITION 2.2. *Following* [1]*, we define the* domain of consistent splitting *for the ODE system $W' = \mathbb{A}(x,\lambda)W$ as the (open) set of λ such that the limiting matrix $\mathbb{A}_+$ is hyperbolic (has no center subspace) and the boundary matrix $\mathbb{B}$ is full rank, with* $\dim S_+ = \operatorname{rank}\mathbb{B}$.

LEMMA 2.3. *On any simply connected subset of the domain of consistent splitting, there exists an analytic basis $\{v_1,\dots,v_k\}$ for the subspace S_+ defined in Definition* 2.2.

Proof. By spectral separation of S_+ from the complementary unstable subspace U_+, the associated (group) eigenprojection is analytic. The existence of an analytic eigenbasis then follows by a standard result of Kato; see [22], pp. 99–102. ∎

COROLLARY 2.4. *By the Conjugation Lemma, on the domain of consistent splitting, the stable manifold of solutions decaying as $x \to +\infty$ of* (2.1) *is*

$$\mathcal{S}^+ := \text{span}\left\{P_+v_1^+, \dots, P_+v_k^+\right\}, \tag{2.6}$$

where $W_+^j := P_+v_j^+$ are analytic in λ and C^{K+1} in x for $\mathbb{A} \in C^K$.

2.2. Definition of the Evans function. On any simply connected subset of the domain of consistent splitting, let $W_1^+, \dots, W_k^+ = P_+v_1^+, \dots, P_+v_k^+$ be the analytic basis described in Corollary 2.4 of the subspace $\mathcal{S}^+$ of solutions W of (2.1) satisfying the boundary condition $W \to 0$ at $+\infty$. Then, the *Evans function* for the ODE systems $W' = \mathbb{A}(x,\lambda)W$ associated with this choice of limiting bases is defined as the $k \times k$ Gramian determinant

$$\begin{aligned} D(\lambda) &:= \det\left(\mathbb{B}W_1^+, \dots, \mathbb{B}W_k^+\right)_{|x=0,\lambda} \\ &= \det\left(\mathbb{B}P_+v_1^+, \dots, \mathbb{B}P_+v_k^+\right)_{|x=0,\lambda}. \end{aligned} \tag{2.7}$$

Remark 2.5. Note that D is independent of the choice of P_+ as, by uniqueness of stable manifolds, the exterior products (minors) $P_+v_1^+ \wedge \cdots \wedge P_+v_k^+$ are uniquely determined by their behavior as $x \to +\infty$.

PROPOSITION 2.6. *Both the Evans function and the subspace $\mathcal{S}^+$ are analytic on the entire simply connected subset of the domain of consistent splitting on which they are defined. Moreover, for λ within this region, equation* (2.1) *admits a nontrivial solution $W \in L^2(x > 0)$ if and only if $D(\lambda) = 0$.*

Proof. Analyticity follows by uniqueness, and local analyticity of P_+, v_k^+. Noting that the first $P_+v_j^+$ are a basis for the stable manifold of (2.1) at $x \to +\infty$, we find that the determinant of $\mathbb{B}P_+v_j^+$ vanishes if and only if $\mathbb{B}(\lambda)$ has nontrivial kernel on $\mathcal{S}_+(\lambda, 0)$, whence, the second assertion follows. ∎

Remark 2.7. In the case that the ODE system describes an eigenvalue equation associated with an ordinary differential operator L, Proposition 2.6 implies that eigenvalues of L agree in location with zeroes of D. (Indeed, they agree also in multiplicity; see [8, 9]; Lemma 6.1, [37]; or Proposition 6.15 of [27].)

When $\ker \mathbb{B}$ has an analytic basis $v_{k+1}^0, \dots, v_{N-k}^0$, for example, in the commonly occurring case, as here, that $\mathbb{B} \equiv$ constant, we have the following useful alternative formulation. This is the version that we will use in our analysis of the Green function and resolvent kernel.

PROPOSITION 2.8. *Let $v_{k+1}^0, \dots, v_{N-k}^0$ be an analytic basis of $\ker \mathbb{B}$, normalized so that $\det(\mathbb{B}^*, v_{k+1}^0, \dots v_N^0) \equiv 1$. Then, the solutions W_j^0 of* (2.1) *determined by initial data $W_j^0(\lambda, 0) = v_j^0$ are analytic in λ and C^{K+1} in x, and*

$$D(\lambda) := \det\left(W_1^+, \dots, W_k^+, W_{k+1}^0, \dots, W_N^0\right)_{|x=0,\lambda}. \tag{2.8}$$

Proof. Analyticity/smoothness follow by analytic/smooth dependence on initial data/parameters. By the chosen normalization, and standard properties of Grammian determinants, $D(\lambda) = \det(W_1^+, \dots, W_k^+, v_{k+1}^0, \dots, v_N^0)_{|x=0,\lambda}$, yielding (2.8). ∎

3. Construction of the resolvent kernel. In this section we construct the explicit form of the resolvent kernel, which is nothing more than the Green function

$G_\lambda(x,y)$ associated with the elliptic operator $(L-\lambda I)$, where

$$(L-\lambda I)G_\lambda(.,y)=\delta_y I,\quad G_\lambda(0,y)\equiv 0. \tag{3.1}$$

Let Λ be the region of consistent splitting for L. It is an established fact (see [15]) that the resolvent $(L-\lambda I)^{-1}$ and the Green function $G_\lambda(x,y)$ are meromorphic in λ on Λ, with isolated poles of finite order. G_λ, in fact, admits a meromorphic extension to a sector

$$\Omega_\theta=\{\lambda : Re(\lambda)\geq -\theta_1-\theta_2|Im(\lambda)|\},\quad \theta_1,\theta_2>0. \tag{3.2}$$

Writing the associated eigenvalue equation in the form of a first-order system (2.1), we obtain

$$W'=\mathbb{A}(\lambda,x)W,\quad \mathbb{B}W(0)=0, \tag{3.3}$$

where

$$W=\begin{pmatrix} w\\ w'\end{pmatrix}\in\mathbb{C}^{2n},\qquad \mathbb{A}=\begin{pmatrix} 0 & I\\ \lambda B^{-1}+A'B^{-1} & AB^{-1}-B'B^{-1}\end{pmatrix},$$

and $\mathbb{B}\equiv$ constant is the rank-n projection onto the first coordinate w of W, with kernel spanned by the constant basis $v^0_{n+j}=e_{n+j}$, $j=1,\dots,n$ and e_j the jth standard basis element.

Denote by

$$\Phi^0=\begin{pmatrix}\phi^0_1(x;\lambda) & \cdots & \phi^0_n(x;\lambda)\end{pmatrix}=\begin{pmatrix}W^0_1 & \cdots & W^0_n\end{pmatrix} \tag{3.4}$$

and

$$\Phi^+=\begin{pmatrix}\phi^+_1(x;\lambda) & \cdots & \phi^+_n(x;\lambda)\end{pmatrix}=\begin{pmatrix}W^+_{n+1} & \cdots & W^+_{2n}\end{pmatrix}=\begin{pmatrix}P_+v^+_1 & \cdots & P_+v^+_k\end{pmatrix} \tag{3.5}$$

the matrices whose columns span the subspaces of solutions of (2.1) decaying at $x=0,+\infty$, respectively, denoting (analytically chosen) complementary subspaces by

$$\Psi^0=\begin{pmatrix}\psi^0_1(x;\lambda) & \cdots & \psi^0_n(x;\lambda)\end{pmatrix}=\begin{pmatrix}W^0_{n+1} & \cdots & W^0_{2n}\end{pmatrix} \tag{3.6}$$

and

$$\Psi^+=\begin{pmatrix}\psi^+_1(x;\lambda) & \cdots & \psi^+_n(x;\lambda)\end{pmatrix}=\begin{pmatrix}W^+_1 & \cdots & W^+_n\end{pmatrix}. \tag{3.7}$$

As described in the previous subsection, eigenfunctions decaying at both $0,+\infty$ occur precisely when the subspaces span Φ^0 and span Φ^+ intersect, i.e., at zeros of the Evans function defined in (2.8):

$$D_L(\lambda):=\det\left(\Phi^0,\Phi^+\right)_{|x=0}=\left(\phi^0_1\wedge\cdots\wedge\phi^0_n\wedge\phi^+_1\wedge\cdots\wedge\phi^+_n\right)_{|x=0}. \tag{3.8}$$

LEMMA 3.1 ([10, 37]). *For $\theta_1,\theta_2>0$ sufficiently small, D_L is locally analytic on sector Ω_θ as defined in* (3.2).

Proof. Direct calculation showing that the domain Λ of consistent splitting is contained in $\Omega_\theta - B(0,r)$ for $r>0$ arbitrary and θ sufficiently small, with v^+_j extending analytically to $B(0,r)$. ∎

LEMMA 3.2. *Let $H_\lambda(x,y)$ denote the Green function for the adjoint operator $(L-\lambda I)^*$ on the half-plane $x \geq 0$. Then $G_\lambda(x,y) = H^*_\lambda(x,y)$. In particular, for $x \neq y$, the matrix $z = G_\lambda(x,.)$ satisfies*

$$(z'B)' = -z'A + z\lambda. \tag{3.9}$$

Proof. Standard duality argument; see [37] for operators on the whole line. ∎

Considering (3.9) as an ODE system for the vector $Z = (z, z')$, it becomes

$$Z' = Z\tilde{\mathbb{A}}(\lambda, x), \tag{3.10}$$

where

$$\tilde{\mathbb{A}} = \begin{pmatrix} 0 & \lambda B^{-1} - A'B^{-1} \\ I & -AB^{-1} - B'B^{-1} \end{pmatrix}. \tag{3.11}$$

LEMMA 3.3 ([37]). *Z is a solution of (3.11) if and only if $Z\mathcal{S}W \equiv$ constant for any solution W of (2.1), where $\mathcal{S} = \begin{pmatrix} -A & B \\ -B & 0 \end{pmatrix}$.*

Proof. Direct computation/comparison with 0 of $(Z\mathcal{S}W)'$; see [37]. ∎

Using Lemma 3.3, we can define dual bases $\tilde{W}^0_j$ and $\tilde{W}^+_j$ by the relations

$$\tilde{W}^{0,+}_j \mathcal{S} W^{0,+}_k = \delta^j_k. \tag{3.12}$$

Likewise, $\tilde{\mathbb{A}}_{0,+}$ can be defined as

$$\tilde{\mathbb{A}}_{0,+} = \begin{pmatrix} 0 & \lambda B^{-1}_{0,+} \\ I & -A_{0,+}B^{-1}_{0,+} \end{pmatrix}. \tag{3.13}$$

We define also the dual subspaces

$$\tilde{\Phi}^0 = \begin{pmatrix} \tilde{\phi}^0_1(x;\lambda) & \cdots & \tilde{\phi}^0_n(x;\lambda) \end{pmatrix} = \begin{pmatrix} \tilde{W}^0_{n+1} & \cdots & \tilde{W}^0_{2n} \end{pmatrix}, \tag{3.14}$$

$$\tilde{\Phi}^+ = \begin{pmatrix} \tilde{\phi}^+_1(x;\lambda) & \cdots & \tilde{\phi}^+_n(x;\lambda) \end{pmatrix} = \begin{pmatrix} \tilde{W}^+_1 & \cdots & \tilde{W}^+_n \end{pmatrix}, \tag{3.15}$$

$$\tilde{\Psi}^0 = \begin{pmatrix} \tilde{\psi}^0_1(x;\lambda) & \cdots & \tilde{\psi}^+_n(x;\lambda) \end{pmatrix} = \begin{pmatrix} \tilde{W}^0_1 & \cdots & \tilde{W}^0_n \end{pmatrix}, \tag{3.16}$$

$$\tilde{\Psi}^+ = \begin{pmatrix} \tilde{\psi}^+_1(x;\lambda) & \cdots & \tilde{\psi}^0_n(x;\lambda) \end{pmatrix} = \begin{pmatrix} \tilde{W}^+_{n+1} & \cdots & \tilde{W}^+_{2n} \end{pmatrix}. \tag{3.17}$$

With these preparations, the construction of the resolvent kernel goes exactly as in the construction performed in [37, 27] on the whole line.

LEMMA 3.4. *We have the the representation*

$$\begin{pmatrix} G_\lambda & G_{\lambda_y} \\ G_{\lambda_x} & G_{\lambda_{xy}} \end{pmatrix} = \begin{cases} \Phi^+(\lambda,x)M^+(\lambda)\tilde{\Psi}^0(\lambda,y) & \text{for} \quad x > y, \\ \Phi^0(\lambda,x)M^0(\lambda)\tilde{\Psi}^+(\lambda,y) & \text{for} \quad x < y, \end{cases} \tag{3.18}$$

where $M^{0,+}$ are to be determined.

Proof. See [37] Lemma 4.6. ∎

Using Lemma 3.4, we find the explicit coordinate-free representation for $x > y$:

$$\begin{pmatrix} G_\lambda & G_{\lambda_y} \\ G_{\lambda_x} & G_{\lambda_{xy}} \end{pmatrix} = \mathcal{F}^{z\to x}\Pi_+(z)\mathcal{S}^{-1}(z)\tilde{\Pi}_0(z)\tilde{\mathcal{F}}^{z\to y}, \tag{3.19}$$

where

$$\Pi_+(y) = \big(\Phi^+(y), 0\big)\big(\Phi^+(y), \Phi^-(y)\big)^{-1}, \tag{3.20}$$

$$\tilde{\Pi}_0(y) = \begin{pmatrix} \tilde{\Psi}^0(y) \\ \tilde{\Psi}^+(y) \end{pmatrix}^{-1} \begin{pmatrix} \tilde{\Psi}^0(y) \\ 0 \end{pmatrix}, \tag{3.21}$$

$$\mathcal{F}^{z\to x} = \big(\Phi^+(x), \Phi^0(x)\big)\big(\Phi^+(z), \Phi^0(z)\big)^{-1}, \tag{3.22}$$

$$\tilde{\mathcal{F}}^{z\to y} = \begin{pmatrix} \tilde{\Psi}^0(z) \\ \Phi^+(z) \end{pmatrix} \begin{pmatrix} \Psi^0(y) \\ \Psi^+(y) \end{pmatrix}^{-1}, \tag{3.23}$$

and similarly for $x < y$.

COROLLARY 3.5. *The resolvent kernel may be expressed as*

$$G_\lambda(x,y) = \begin{cases} (I_n, 0)\Phi^+(x;\lambda)M^+(\lambda)\tilde{\Psi}^{0*}(y;\lambda)(I_n,0)^{tr} & x > y, \\ -(I_n,0)\Phi^0(x;\lambda)M^0(\lambda)\tilde{\Psi}^{+*}(y;\lambda)(I_n,0)^{tr} & x < y, \end{cases} \tag{3.24}$$

where

$$M(\lambda) := \operatorname{diag}\big(M^+(\lambda), M^0(\lambda)\big) = \Phi^{-1}(z;\lambda)\bar{\mathcal{S}}^{-1}(z)\tilde{\Psi}^{-1*}(z;\lambda). \tag{3.25}$$

4. Low-frequency bounds. Our goal in this section is the estimation of the resolvent kernel in the critical regime $|\lambda| \to 0$, i.e., the large time behavior of the Green function G, or global behavior in space and time. We are basically following the same treatment as that carried out for viscous shock waves of strictly parabolic conservation laws in [37, 27]; we refer to those references for details. In the low frequency case the behavior is essentially governed by the equation

$$U_t = L_+U := -A_+U_x + B_+U_{xx}. \tag{4.1}$$

PROPOSITION 4.1. *Assuming* (H0)–(H3), *let K be the order of the pole of G_λ at $\lambda = 0$ and r be sufficiently small that there are no other poles in $B(0,r)$. Then for $\lambda \in \Omega_\theta$ such that $|\lambda| \le r$ and for $x > y > 0$ we have*

$$\begin{pmatrix} G_\lambda & G_{\lambda_y} \\ G_{\lambda_x} & G_{\lambda_{xy}} \end{pmatrix} = \sum_{j,k} d_{jk}(\lambda)\phi_j^+(x)\tilde{\psi}_k^+(y) + \sum_k \phi_k^+(x)\tilde{\phi}_k^+(y), \tag{4.2}$$

where $d_{jk}(\lambda) = \mathcal{O}(\lambda^{-K})$ is a scalar meromorphic function, moreover, $K \le$ order of vanishing of the Evans function $D(\lambda)$ at $\lambda = 0$.

Proof. See [37], Proposition 7.1 for the first statement and Theorem 6.3 for the second statement linking order K of the pole to multiplicity of the zero of the Evans function. ∎

LEMMA 4.2. *Assuming* (H0)–(H3), *for $|\lambda|$ sufficiently small, the eigenvalue equation $(L_+ - \lambda)W = 0$ associated with the limiting, constant-coefficient operator L_+ has a basis of $2n$ solutions $\bar{W}_j^+ = e^{\mu_j^+(\lambda)x}V_j(\lambda)$ where μ_j^+ and V_j^+ are analytic in λ, consisting of n fast modes*

$$\begin{aligned} \mu_j^+ &= \gamma_j^+ + \mathcal{O}(\lambda), \\ V_j^+ &= S_j^+ + \mathcal{O}(\lambda), \end{aligned} \tag{4.3}$$

where γ_j^+, S_j^+ are eigenvalues and associated right eigenvectors of $B_+^{-1}A_+$, and n slow modes

$$\begin{aligned}\mu_{r+j}^+(\lambda) &:= -\lambda/a_j^+ + \lambda^2\beta_j^+/{a_j^+}^3 + \mathcal{O}\left(\lambda^3\right),\\ V_{r+j}^+(\lambda) &:= r_j^+ + \mathcal{O}(\lambda),\end{aligned} \tag{4.4}$$

where a_j^+, l_j^+, r_j^+ are eigenvalues and left and right eigenvectors of $A_+ := dF(u_+)$, and $\beta_j^+ := l_j^+ B_+ r_j^+ > 0$ with $B_+ := B(u_+)$. The same is true for the adjoint eigenvalue equation

$$\left(L^+ - \lambda\right)^* Z = 0;$$

i.e, it has a basis of solutions

$$\bar{\tilde{W}}_j^+ = e^{-\mu_j^+(\lambda)x}\tilde{V}_j(\lambda)$$

with

$$\tilde{V}_j^+(\lambda) = \tilde{T}_j^+ + \mathcal{O}(\lambda), \tag{4.5}$$

$$\tilde{V}_{r+j}^+(\lambda) = l_j^+ + \mathcal{O}(\lambda), \tag{4.6}$$

$\tilde{V}^+$ analytic in λ.

Proof. See [27]. □

PROPOSITION 4.3. *Assume* (H0)–(H3) *and* (1.9), *then, for $r > 0$ sufficiently small, the resolvent kernel G_λ associated with the linearized evolution equation*

$$U_t = L_+U := -A_+U_x + B_+U_{xx} \tag{4.7}$$

satisfies, for $0 \le y \le x$:

(4.8)

$$\begin{aligned}|\partial_x^\gamma\partial_y^\alpha G_\lambda(x,t;y)| \le C\left(|\lambda|^\gamma + e^{-\theta|x|}\right)\left(|\lambda|^\alpha + e^{-\theta|y|}\right)\Bigg(&\sum_{a_k^+>0}\left|e^{\left(-\lambda/a_k^+ + \lambda^2\beta_k^+/{a_k^+}^3\right)(x-y)}\right|\\ &+ \sum_{a_k^+<0,\, a_j^+>0}\left|e^{\left(-\lambda/a_j^+ + \lambda^2\beta_j^+/{a_j^+}^3\right)x + \left(\lambda/a_k^+ - \lambda^2\beta_k^+/{a_k^+}^3\right)y}\right|\Bigg),\end{aligned}$$

$0 \le |\alpha|, |\gamma| \le 1$, $\theta > 0$, with similar bounds for $0 \le x \le y$. Moreover, each term in the summation on the right-hand side of (4.8) *bounds a separately analytic function.*

Proof. By 1.8 D does not vanish on $Re(\lambda) \ge 0$, hence, by continuity, on $|\lambda| \le r$. Thus, according to (4.2), all $|d_{jk}(\lambda)|$ are uniformly bounded on $|\lambda| \le r$, and so it is enough to find estimates for fast and slow modes ϕ_j^+, $\tilde{\phi}_j^+$, ψ_j^+, and $\tilde{\psi}_j^+$. By using (3.5) we find:

$$\begin{pmatrix}\phi_j^+\\ \partial_x\phi_j^+\end{pmatrix} = e^{\mu_j(\lambda)x}P^+\begin{pmatrix}V_j\\ \mu_jV_j\end{pmatrix} = e^{\mu_j(\lambda)x}(I+\Theta)\begin{pmatrix}V_j\\ \mu_jV_j\end{pmatrix} \tag{4.9}$$

and similarly for $\tilde{\phi}_j^+$, ψ_j^+, and $\tilde{\psi}_j^+$. Now using (2.4) and the fact, by (4.4), that $e^{\mu_j(\lambda)x}$ is of order $e^{-|\theta x|}$ for fast modes and order $e^{-\lambda/a_j^+ + \lambda^2\beta_j^+/{a_j^+}^3 + \mathcal{O}(\lambda^3)}$ for slow modes, substituting this and corresponding dual estimates in (4.9) and grouping terms, we obtain the result. □

5. High frequency bounds. To analyze the high frequency behavior of the Green function of the boundary layer, we first establish some bounds for the projection terms in the Green function, using the symmetric formula

$$\begin{pmatrix} G_\lambda(x,y) & \partial_y G_\lambda(x,y) \\ \partial_x G_\lambda(x,y) & \partial_x\partial_y G_\lambda(x,y) \end{pmatrix} = \begin{cases} \mathcal{F}^{y\to x}\Pi_+(x)\mathcal{S}^{-1}(y) & if \quad x>y, \\ \tilde{\mathcal{F}}^{x\to y}\tilde{\Pi}_+(x)\mathcal{S}^{-1}(x) & if \quad x<y. \end{cases} \tag{5.1}$$

By setting $\bar{x} = |\lambda^{\frac{1}{2}}|x$, $\bar{\lambda} = \frac{\lambda}{|\lambda|}$, $\bar{B}(\bar{x}) = B(\frac{\bar{x}}{\lambda^{\frac{1}{2}}})$, $\bar{w}(\bar{x}) = w(\frac{x}{\lambda^{\frac{1}{2}}})$ in the eigenvalue equation $Lw = \lambda w$ associated with (1.6) we obtain

$$\bar{W}' = \bar{\mathbb{B}}\bar{W} + \mathcal{O}\left(\left|\lambda^{-\frac{1}{2}}\right|\right)\bar{W} \tag{5.2}$$

where

$$\mathbb{B} = \begin{pmatrix} 0 & I \\ \bar{\lambda}\bar{B} & 0 \end{pmatrix} \tag{5.3}$$

and $\mathbb{B}' = \mathcal{O}(|\lambda^{-\frac{1}{2}}|)$ and $|\bar{\lambda}| = 1$. Since $\mathbb{B}(\lambda, \bar{x})$ varies within a compact set, then there are C^1 eigenprojections P_0 and P_+ with property $|P'_+| = \mathcal{O}(|\lambda^{-\frac{1}{2}}|)$ and $|P'_0| = \mathcal{O}(|\lambda^{-\frac{1}{2}}|)$ taking $\bar{W}$ onto the stable and unstable subspaces. By using the two new coordinates $Y_+ = P_+\bar{W}$ and $Y_0 = P_0\bar{W}$, we obtain

$$\begin{pmatrix} Y_+ \\ Y_0 \end{pmatrix}' = \begin{pmatrix} A_+ & 0 \\ 0 & A_0 \end{pmatrix}\begin{pmatrix} Y_+ \\ Y_0 \end{pmatrix} + \mathcal{O}\left(\left|\lambda^{-\frac{1}{2}}\right|\right)\begin{pmatrix} y \\ y \end{pmatrix}. \tag{5.4}$$

Equivalently, we can find continuous invertible transformations Q_+, Q_0 such that $E_+ = Q_+A_+Q_+^{-1}$ and $E_0 = Q_0A_0Q_0^{-1}$, where

$$Re(E) := \frac{1}{2}(E_+ + E_+^*) < -\beta^{-\frac{1}{2}}I \tag{5.5}$$

in the sense of quadratic forms.

Again, by coordinate change $Z_+ = Q_+Y_+$, $Z_0 = Q_0Y_0$, we find

$$\begin{pmatrix} z_+ \\ z_0 \end{pmatrix}' = \begin{pmatrix} E_+ & 0 \\ 0 & E_0 \end{pmatrix}\begin{pmatrix} z_+ \\ z_0 \end{pmatrix} + \mathcal{O}\left(\left|\lambda^{-\frac{1}{2}}\right|\right)\begin{pmatrix} z \\ z \end{pmatrix}, \tag{5.6}$$

where

$$\frac{|\bar{w}|}{C} \le |z| \le C|\bar{w}|. \tag{5.7}$$

From this we find by energy estimate that

$$\left(|z_+|^2\right)' < -2\beta^{-\frac{1}{2}}|z_+|^2 \tag{5.8}$$

and, hence,

$$\frac{|z_+(x)|}{|z_+(y)|} \le e^{-\tilde{\beta}^{-\frac{1}{2}}|(x-y)|} \tag{5.9}$$

for any solution z_+ decaying at ∞, where $\tilde{\beta} < \beta$ and, thus,

$$\frac{|z_(x)|}{|z_(y)|} \le e^{-\beta^{-\frac{1}{2}}|(x-y)|} \tag{5.10}$$

for $x > y$, provided that $|\lambda|$ is sufficiently large. From this we obtain

$$\frac{\left|\bar{W}(x)\right|}{\left|\bar{W}(y)\right|} \leq C^2 e^{-\beta^{-\frac{1}{2}}|(x-y)|} \tag{5.11}$$

where C is as in (5.7).

Applying a symmetric argument for the adjoint equation, we obtain the following lemma.

LEMMA 5.1. *On the manifolds Φ_+ and $\tilde{\Psi}_+$ defined in* (3.5) *and* (3.17)*, for λ sufficiently large, within the sector $\Omega_\theta = \{\lambda : Re(\lambda) \geq -\theta_1 - \theta_2 |Im(\lambda)|\}$, $\theta_1, \theta_2 > 0$, we have in rescaled coordinates $\bar{x}$, for some uniform $C > 0$,*

$$|\mathcal{F}^{y\to x}|, \left|\tilde{\mathcal{F}}^{x\to y}\right| \leq Ce^{-\frac{|y-x|}{C}} \tag{5.12}$$

for $x > y$ and $x < y$, respectively.

LEMMA 5.2. *In rescaled coordinates $\bar{x}$, $\bar{\lambda}$, for the projection terms $\Pi_+(y)$ and $\tilde{\Pi}_+(x)$, the projection along Φ_0 onto Φ_+, for λ sufficiently large,*

$$|\Pi_+(y)|, \left|\tilde{\Pi}_+(x)\right| < C \tag{5.13}$$

for some uniform $C > 0$.

Proof. Choosing the coordinates $\begin{pmatrix} W_1 \\ W_2 \end{pmatrix} \in \mathbb{C}^{2n}$ where $W^j = \begin{pmatrix} W_1^j \\ W_2^j \end{pmatrix}$, we show for small enough ϵ and fixed $c > 0$ such that $\frac{|W_2^j|}{|W_1^j|} \leq c\epsilon$ and $\frac{|W_1^j|}{|W_2^j|} < c$ the projection along $E = \operatorname{span}(W^1, \ldots, W^n)$ onto $F = \operatorname{span}(W^{n+1}, \ldots, W^{2n})$

$$\Pi := \left(w^1, \ldots, w^{2n}\right)(O_n, I_n)\left(w^1, \ldots, w^{2n}\right)^{-1} \tag{5.14}$$

satisfies

$$|\Pi| \leq C_2(c, \epsilon). \tag{5.15}$$

To show this without loss of generality we assume that

$$\left(w^{n+1}, \ldots, w^{2n}\right) = \begin{pmatrix} I_n \\ \mathcal{O}(\epsilon) \end{pmatrix}\left(w^1, \ldots, w^n\right) = \begin{pmatrix} \mathcal{O}(1) \\ I_n \end{pmatrix}. \tag{5.16}$$

Now it is sufficient to show that

$$\left|\left(w^1, \ldots, w^{2n}\right)\right| \leq C_2(c, \epsilon). \tag{5.17}$$

However, this amounts to showing that

$$\left|\begin{pmatrix} M & I_n \\ I_n & O \end{pmatrix} + \mathcal{O}(\epsilon))^{-1}\right| \leq C, \tag{5.18}$$

which amounts to showing that

$$\left|\begin{pmatrix} M & I_n \\ I_n & O \end{pmatrix}^{-1}\right| \leq C_2(c), \tag{5.19}$$

where $|M| \leq c$. However, this is easy to show because

$$\begin{pmatrix} M & I_n \\ I_n & O \end{pmatrix}^{-1} = \begin{pmatrix} I_n & -M \\ O & I_n \end{pmatrix},$$

and so

$$\left| \begin{pmatrix} M & I_n \\ I_n & O \end{pmatrix}^{-1} \right| \leq 1 + |M| \leq C. \qquad \square$$

PROPOSITION 5.3. *Assume* (H0)–(H3) *and* (1.9). *Then, for* $R > 0$ *sufficiently large, the resolvent kernel* G_λ *associated with the linearized evolution equation* (4.7) *satisfies, for* $c, C > 0$ *and* $0 \leq |\alpha|, |\gamma| \leq 1$*:*

$$|\partial_x^\gamma \partial_y^\alpha G_\lambda(x,y)| \leq C|\lambda|^{\left(\frac{|\alpha|+|\gamma|-1}{2}\right)} e^{-\sqrt{\lambda}\frac{|y-x|}{c}}. \tag{5.20}$$

Proof. Recalling the coordinate-free representation (5.1) and combining with (5.12) and (5.13), we find that the Green function $\bar{G}_{\bar{\lambda}}$ in rescaled coordinates $\bar{x}$, $\bar{\lambda}$ satisfies

$$\left|\partial_x^\gamma \partial_y^\alpha \bar{G}_{\bar{\lambda}}(\bar{x},\bar{y})\right| \leq C e^{-\frac{|y-x|}{C}}, \tag{5.21}$$

whence, (5.20) follows in the original coordinates. $\square$

Remark 5.4. The argument of Lemma 5.2 is the key new ingredient in the resolvent estimates for the boundary layer case as compared to the analysis on the whole line carried out for viscous shock layers in [37], making essential use of compatibility of the boundary condition with high-frequency behavior. On the whole line, there is no such requirement and high-frequency stability is automatic.

6. Pointwise Green function bounds. With the pointwise bounds established on the resolvent kernel G_λ, we obtain pointwise bounds on the Green function through the inverse Laplace transform formula by a simplified version of the stationary-phase arguments used in [37] for the shock case, repeated here for completeness.

Proof of Theorem 1.4. By sectoriality of L, we have the inverse Laplace transform representation (see [37]):

$$G(t;x,y) = \int_\Gamma e^{\lambda t} G_\lambda(x,y) d\lambda. \tag{6.1}$$

Let $\theta_1 > 0$, $\theta_2 > 0$ be chosen sufficiently small, in particular so small as to satisfy the hypotheses of all previous assertions. By assumption (1.9), the large-$|\lambda|$ bounds on the resolvent kernel, and analyticity of the Evans function $D_L(\lambda)$, it follows that G_λ has finitely many poles in Ω_θ (corresponding to roots of D_L), each with strictly negative real part. Choosing θ_1, θ_2 still smaller, if necessary, we can, thus, arrange that G_λ *is analytic on* Ω_θ. It follows from Cauchy's Theorem that

$$G(x,t;y) = \int_\Gamma e^{\lambda t} G_\lambda(x,y)\, d\lambda \tag{6.2}$$

for any contour Γ that can be expressed as $\Gamma = \partial(\Omega_\theta \setminus \mathcal{S})$ for $\mathcal{S} \subset \mathbb{C}$ open.

Case I. $|x-y|/t$ *large.* We first treat the trivial case that $|x-y|/t \geq S$, S sufficiently large, the regime in which standard short-time parabolic theory applies. Set

$$\bar{\alpha} := \frac{|x-y|}{2\beta t}, \quad R := \beta \bar{\alpha}^2, \tag{6.3}$$

where β is as in (5.5), and consider again the representation of G, that is

$$G(x,t;y) = \int_{\Gamma_1\cup\Gamma_2} e^{\lambda t} G_\lambda(x,y)\, d\lambda, \tag{6.4}$$

where $\Gamma_1 := \partial B(0,R) \cap \bar\Omega_\theta$ and $\Gamma_2 := \partial\Omega_\theta \setminus B(0,R)$. Note that the intersection of Γ with the real axis is $\lambda_{min} = R = \beta\bar\alpha^2$. □

By the large $|\lambda|$ estimates of Proposition 5.3, we have for all $\lambda \in \Gamma_1 \cup \Gamma_2$ that

$$|G_\lambda(x,y)| \le C \frac{e^{-\sqrt{|\lambda|}\frac{|y-x|}{c}}}{\sqrt{|\lambda|}}.$$

Further, we have

$$Re\lambda \le R\left(1-\eta\omega^2\right), \quad \lambda\in\Gamma_1, Re\lambda \quad \le Re\lambda_0 - \eta(|Im\lambda| - |Im\lambda_0|), \quad \lambda\in\Gamma_2 \tag{6.5}$$

for R sufficiently large, where ω is the argument of λ and λ_0 and λ_0^* are the two points of intersection of Γ_1 and Γ_2, for some $\eta > 0$ independent of $\bar\alpha$. Combining these estimates, we obtain

$$\begin{aligned}\left|\int_{\Gamma_1} e^{\lambda t} G_\lambda d\lambda\right| &\le \int_{\Gamma_1} C|\lambda|^{-\frac12}\, e^{Re\lambda t - \beta^{-\frac12}|\lambda|^{-\frac12}|x-y|}\, d\lambda \\ &\le Ce^{-\beta\bar\alpha^2 t}\int_{-L}^{+L} R^{-\frac12} e^{-\beta R\eta\omega^2 t}\, Rd\omega \qquad \le Ct^{-\frac12}e^{-\beta\bar\alpha^2 t}.\end{aligned} \tag{6.6}$$

Likewise,

$$\begin{aligned}\left|\int_{\Gamma_2} e^{\lambda t} G_\lambda d\lambda\right| &\le \int_{\Gamma_2} C|\lambda|^{-\frac12}\, Ce^{Re\lambda t - \beta^{-\frac12}|\lambda|^{-\frac12}|x-y|} d\lambda \\ &\le Ce^{Re(\lambda_0)t - |\beta|^{-\frac12}|\lambda_0|^{-\frac12}|x-y|}\int_{\Gamma_2} |\lambda|^{-\frac12} e^{(Re\lambda - Re\lambda_0)t}\ |d\lambda| \\ &\le Ce^{-\beta\bar\alpha^2 t}\int_{\Gamma_2} |Im\,\lambda|^{-\frac12} e^{-\eta|Im\,\lambda - Im\,\lambda_0|t}\ |d\,Im\lambda| \\ &\le Ct^{-\frac12}e^{-\beta\bar\alpha^2 t}.\end{aligned} \tag{6.7}$$

Combining these last two estimates, we have

$$|G(x,t;y)| \le Ct^{-\frac12} e^{\frac{-\beta\bar\alpha^2 t}{2}} e^{\frac{-(x-y)^2}{8\beta t}} \le Ct^{-\frac12} e^{-\eta t} e^{\frac{-(x-y)^2}{8\beta t}}, \tag{6.8}$$

for $\eta > 0$ independent of $\bar\alpha$. Observing that $\frac{|x-at|}{2t} \le \frac{|x-y|}{t} \le \frac{2|x-at|}{t}$ for any bounded a, for $\frac{|x-y|}{t}$ sufficiently large, we find that this contribution may be absorbed in any summand $t^{\frac{-1}{2}} e^{\frac{-(x-y-a_k^+ t)^2}{Mt}}$.

Case II. $|x-y|/t$ *bounded.* We now turn to the critical case that $|x-y|/t \le S$. A few remarks are in order at the outset. Our goal is to bound $|G|$ by terms of form $Ct^{-1/2}e^{-\bar\alpha^2 t/M}$, where $\bar\alpha := (x - a_j^+(t - |y/a_k^+|))/2t$ or $\bar\alpha := (x-y-a_k^+ t)/2t$ are now *uniformly bounded*, by

$$|x-y|/2t + \max_j \left\{\left|a_j^+\right|\right\}/2 \le S/2 + \max\left|a_j^+\right|/2. \tag{6.9}$$

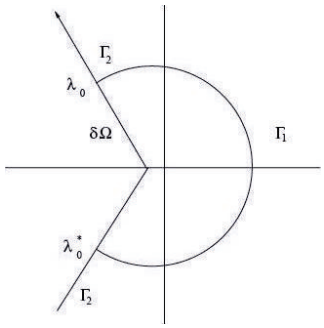

FIG. 1.

Thus, in particular, *contributions of order* $t^{-1/2}e^{-\eta t}$, $\eta > 0$, *can be absorbed in any summand* $t^{-1/2}e^{-(x-y-a_k^+ t)^2/Mt}$) if we take M sufficiently large. Likewise, for G_x and G_y, contributions of order $t^{-1}e^{-\eta t}$ can be absorbed. We will use this observation repeatedly.

In contrast to the previous case of large characteristic speed $|x-y|/t \geq S$, we are not trying to show rapid time-exponential decay. Rather, we are trying to show that the rate of exponential decay of the solution does not degrade too rapidly as $\bar{\alpha} \to 0$: precisely, that it vanishes to order $\bar{\alpha}^2$ and no more. Thus, the crucial part of our analysis will be for small $\bar{\alpha}$. All other situations can be estimated crudely as described just above.

Let r be sufficiently small that the small-$|\lambda|$ bounds hold on $B(0,r)$. Next, choose θ_1 and θ_2 still smaller than before, if necessary, so that $\Omega_\theta \setminus B(0,r) \subset \Lambda$. This implies that $\partial\Omega_\theta \cap B(0,r) \neq \emptyset$, giving the configuration pictured in Figure 1. Similarly as in the previous case, define $\Gamma = \Gamma_1 \cup \Gamma_2$, where Γ_1 is the portion of the circle $\partial B(0,r)$ contained in $\bar{\Omega}_\theta$, and Γ_2 is the portion of $\partial\Omega_\theta$ outside $B(0,r)$.

$$G(x,t;y) = \int_{\Gamma_1} e^{\lambda t} G_\lambda(x,y)\, d\lambda + \int_{\Gamma_2} e^{\lambda t} G_\lambda(x,y)\, d\lambda. \tag{6.10}$$

We separately estimate the terms $\int_{\Gamma_1}$ and $\int_{\Gamma_2}$.

Large- and medium-λ *estimates.* The $\int_{\Gamma_2}$ term is straightforward. The points λ_0, λ_0^* where Γ_1 meets Γ_2 satisfy $Re(\lambda_0) = -\eta < 0$. Moreover, combining the results low-frequency case, we have the bound $|G_\lambda| \leq C|\lambda|^{-\frac{1}{2}}$ for $\lambda \in \Gamma_2$. Thus, we have

$$\begin{aligned} \left| \int_{\Gamma_2} e^{\lambda t} G_\lambda d\lambda \right| &\leq C e^{-Re\,\lambda_0 t} \int_{\Gamma_2} |Im\,\lambda|^{-\frac{1}{2}} e^{-\eta |Im\,\lambda - Im\,\lambda_0| t}\, |d\,Im\lambda| \\ &\leq C t^{-\frac{1}{2}} e^{-\eta t}. \end{aligned} \tag{6.11}$$

This contribution can be absorbed as described above. An analogous computation using $|G_{\lambda_x}|$, $|G_{\lambda_x}| \leq C|\lambda|^{-1}$ shows that the Γ_2 contribution to G_x and G_y is $O(t^{-1}e^{-\eta t})$, and can likewise be absorbed.

Small $|\lambda|$ *estimates.* It remains to estimate the critical term $\int_{\Gamma_1} e^{\lambda t} G_\lambda d\lambda$. This we will estimate in different ways, depending on the size of t.

Bounded time. For t bounded, we can use the medium-λ bounds $|G_\lambda|$, $|G_{\lambda_x}|$, $|G_{\lambda_y}| \leq C$ to obtain $|\int_{\Gamma_1} e^{\lambda t} G_\lambda d\lambda| \leq C_2 |\Gamma_1|$. This contribution is order $Ce^{-\eta t}$ for bounded time, and hence can be absorbed.

Large time. For t large, we must instead estimate $\int_{\Gamma_1} e^{\lambda t} G_\lambda d\lambda$ using the small-$|\lambda|$ expansions. First, observe that all coefficient functions $d_{jk}(\lambda)$ are uniformly bounded (since $|\lambda|$ is bounded in this case).

Expanding $G = \int_\Gamma e^{\lambda t} G_\lambda(x,y) d\lambda$ as

$$\begin{pmatrix} G & G_x \\ G_y & G_{xy} \end{pmatrix} = \int_\Gamma e^{\lambda t} \begin{pmatrix} G_\lambda & G_{\lambda_x} \\ G_{\lambda_y} & G_{\lambda_{xy}} \end{pmatrix} d\lambda,$$

we estimate the $\int_{\Gamma_1}$ contributions to G, G_x, and G_y simultaneously.

Case II(i). $(0 < y < x)$. By our low-frequency estimates, we have

$$\begin{aligned} \int_\Gamma e^{\lambda t} \begin{pmatrix} G_\lambda & G_{\lambda_x} \\ G_{\lambda_y} & G_{\lambda_{xy}} \end{pmatrix} d\lambda &= \int_\Gamma \sum_{j,k} e^{\lambda t} \phi_j^+(x) d_{jk} \tilde{\psi}_k^+(y) d\lambda \\ &\quad + \int_\Gamma \sum_{j,k} e^{\lambda t} \psi_k^+(x) \tilde{\psi}_k^+(y) d\lambda, \end{aligned} \tag{6.12}$$

where each d_{jk} is analytic and, hence, bounded. We estimate separately each of the terms

$$\int_{\Gamma_1} e^{\lambda t} \phi_j^+(x) d_{jk} \tilde{\psi}_k^+(y) d\lambda$$

on the right-hand side of (6.12). Estimates for terms

$$\int_\Gamma \sum_{j,k} e^{\lambda t} \psi_k^+(x) \tilde{\psi}_k^+(y) d\lambda$$

go similarly.

Case II(ia). First, consider the critical case $a_j^+ > 0$, $a_k^+ < 0$. For this case,

$$\left| \phi_{j(x)}^+ d_{jk} \tilde{\psi}_k^+(y) \right| \le C e^{Re\left(\rho_j^+ x - \nu_k^+ y\right)},$$

where

$$\begin{cases} \nu_k^+(\lambda) = -\lambda/a_k^+ + \lambda^2 \beta_k^+ / \left(a_k^+\right)^3 + \mathcal{O}\left(\lambda^3\right) \\ \rho_j^+(\lambda) = -\lambda/a_j^+ + \lambda^2 \beta_j^+ / \left(a_j^+\right)^3 + \mathcal{O}\left(\lambda^3\right). \end{cases}$$

Set

$$\bar{\alpha} = \frac{a_k^+ x/a_j^+ - y - a_k^+ t}{2t}, \quad p := \frac{\beta_j^+ a_k^+ x/\left(a_j^+\right)^3 - \beta_k^+ y/\left(a_k^+\right)^2}{t} > 0.$$

Define Γ'_{1a} to be the portion contained in Ω_θ of the hyperbola

(6.13)

$$\begin{aligned} &Re\left(\rho_j^+ x - \nu_k^+ y\right) + \mathcal{O}\left(\lambda^3\right)(|x| + |y|) \\ &\quad = \left(1/a_k^+\right) Re\left[\lambda\left(-a_k^+ x/a_j^+ + y\right) + \lambda^2\left(x\beta_j^+ a_k^+/\left(a_j^+\right)^3 - y\beta_k^-/\left(a_k^+\right)^2\right)\right] \\ &\quad \equiv \text{constant} \\ &\quad = \left(1/a_k^-\right)\left[\lambda_{min}\left(-a_k^- x/a_j^+ + y\right) + \lambda_{min}^2\left(x\beta_j^+ a_k^+/\left(a_j^+\right)^3 - y\beta_k^+/\left(a_k^+\right)^2\right)\right], \end{aligned}$$

where

$$\lambda_{min} := \begin{cases} \frac{\bar\alpha}{p} & if \quad \left|\frac{\bar\alpha}{p}\right| \le \epsilon, \\ \pm\epsilon & if \quad \frac{\bar\alpha}{p} \gtrless \epsilon. \end{cases} \tag{6.14}$$

Denoting by λ_1, λ_1^* the intersections of this hyperbola with $\partial\Omega_\theta$, define Γ'_{1_b} to be the union of $\lambda_1\lambda_0$ and $\lambda_0^*\lambda_1^*$, and define $\Gamma'_1 = \Gamma'_{1_a} \cup \Gamma'_{1_b}$. Note that $\lambda = \bar\alpha/p$ minimizes the left-hand side of (6.13) for λ real. Note also that p is bounded for $\bar\alpha$ sufficiently small, since $\bar\alpha \le \epsilon$ implies that

$$\left(\left|a_k^+ x/a_j^+\right| + |y|\right)/t \le 2\left|a_k^+\right| + 2\epsilon;$$

i.e., $(|x| + |y|)/t$ is controlled by $\bar\alpha$.

With these definitions, we readily obtain that

$$\begin{aligned} Re\left(\lambda t + \rho_j^+ x - \nu_k^+ y\right) &\le -\left(t/a_k^-\right)\left(\bar\alpha^2/4p\right) - \eta Im(\lambda)^2 t \\ &\le -\bar\alpha^2 t/M - \eta Im(\lambda)^2 t, \end{aligned} \tag{6.15}$$

for $\lambda \in \Gamma'_{1_a}$ (note: here, we have used the crucial fact that $\bar\alpha$ controls $(|x| + |y|)/t$, in bounding the error term $\mathcal{O}(\lambda^3)(|x| + |y|)/t$ arising from expansion). Likewise, we obtain for any q that

$$\int_{\Gamma'_{1_a}} |\lambda|^q e^{Re\left(\lambda t + \rho_j^+ x - \nu_k^- y\right)} d\lambda \le C t^{-\frac{1}{2}-\frac{q}{2}} e^{-\bar\alpha^2 t/M}, \tag{6.16}$$

for suitably large C, $M > 0$ (depending on q). Observing that

$$\bar\alpha = \left(a_k^+/a_j^+\right)\left(x - a_j^+\left(t - \left|y/a_k^+\right|\right)\right)/2t,$$

we find that the contribution of (6.16) can be absorbed in the described bounds for $t \ge |y/a_k^-|$. At the same time, we find that $\bar\alpha \ge x > 0$ for $t \le |y/a_k^+|$, whence,

$$\bar\alpha \ge \left(x - y - a_j^+ t\right)/Mt + |x|/M,$$

for some $\epsilon > 0$ sufficiently small and $M > 0$ sufficiently large.

This gives

$$e^{-\bar\alpha^2/p} \le e^{-\left(x-y-a_k^+ t\right)^2/Mt} e^{-\eta|x|}$$

provided $|x|/t > a_j^+$, a contribution which can again be absorbed. On the other hand, if $t \le |x/a_j^+|$, we can use the dual estimate

$$\begin{aligned} \bar\alpha &= \left(-y - a_k^+\left(t - \left|x/a_j^+\right|\right)\right)/2t \\ &\ge \left(x - y - a_k^+ t\right)/Mt + |y|/M, \end{aligned} \tag{6.17}$$

together with $|y| \ge |a_k^- t|$, to obtain

$$e^{-\bar\alpha^2/p} \le e^{-\left(x-y-a_j^+ t\right)^2/Mt} e^{-\eta|y|},$$

a contribution that can likewise be absorbed.

Case II(ib). In case $a_j^+ < 0$ or $a_k^+ > 0$, terms $|\varphi_j^+| \le Ce^{-\eta|x|}$ and $|\tilde\psi_j^+| \le Ce^{-\eta|y|}$ are strictly smaller than those already treated in Case II(ia), so may be absorbed in previous terms.

Case II(ii) $(0 < x < y)$. The case $0 < x < y$ can be treated very similarly to the previous one; see [37] for details. This completes the proof of Case II, and the theorem.

7. Nonlinear analysis. Introducing the perturbation variable

$$u(x,t) := \tilde{u}(x,t) - \bar{u}(x), \tag{7.1}$$

we obtain

$$u_t - Lu = Q(u)_x, \tag{7.2}$$

where the second-order Taylor remainder satisfies

$$Q(u) := f(\bar{u}+u) - f(\bar{u}) - df(\bar{u})u = \mathcal{O}\left(|u|^2\right) \tag{7.3}$$

so long as $|u|$ remains bounded.

LEMMA 7.1 (integral formulation). *Under the assumptions of Theorem* 1.6, *there exists a classical solution of* (7.2) *for* $0 < t \le T$, $T > 0$, *continuous in* $L^\infty(x)$ *at* $t = 0$, *extending for all* $t > 0$ *such that* $u(\cdot,t)$ *remains sufficiently small in* $L^1 \cap L^\infty$, *given by*

$$\begin{aligned} u(x,t) = &\int_0^\infty G(x,t;y)g(y)\,dy + \int_0^t G_y(x,t-s;0)Bh(s)\,ds \\ &- \int_0^t \int_0^\infty G_y(x,t-s;y)Q(u)(y,s)\,dy\,ds. \end{aligned} \tag{7.4}$$

Proof. From Lemma 3.2 and the inverse Laplace representation (6.1) we find that $G(x,t-s;y)$ considered as a function of y,s satisfies the adjoint equation

$$(\partial_s - L_y)^* G^*(x,t-\cdot;\cdot) = 0, \tag{7.5}$$

or

$$-G_s - (GA)_y + GA_y = (G_y B)_y. \tag{7.6}$$

Likewise, reviewing the construction of the resolvent, we find $G_\lambda(x,0) \equiv 0$, yielding

$$G(x,t-s;0) \equiv 0. \tag{7.7}$$

That is, $G^*(x,t-\cdot;\cdot)$ is the Green function for the adjoint equation, as may alternatively be seen directly by a duality argument analogous to the proof of Lemma 3.2.

Thus, integrating G against (7.2), integrating by parts, and using the fact that $G = 0$ and $u = h$ on the boundary $y = 0$, we obtain for any classical solution of (7.2) that

$$\begin{aligned} &\int_0^t \int_0^\infty G(x,t-s;y)Q(u(y,s))_y\,dy\,ds = \\ &\qquad \int_0^t \int_0^\infty G(x,t-s;y)(\partial_s - L_y)u(y,s)\,dy\,ds \\ &\qquad = \int_0^t \int_0^\infty ((\partial_s - L_y)^* G^*)^*(x,t-s;y)u(y,s)\,dy\,ds \\ &\qquad + u(x,t) - \int_0^\infty G(x,t;y)g(y)\,dy - \int_0^t G_y(x,t-s;0)Bh(s)\,ds, \end{aligned} \tag{7.8}$$

from which we obtain (7.4) by rearranging and integrating by parts the term $\int_0^t \int_0^\infty G(x,t-s;y)Q(u(y,s))_y\,dy\,ds$.

Indeed, (7.4) may be taken as the definition of a weak solution in $L^\infty(x,t)$. (One can see using convolution identities that this agrees with the usual definition in terms of integration against test functions $\phi \in C_0^\infty(\mathbb{R}\times\mathbb{R})$.) Existence of weak solutions can be obtained by a standard contraction mapping/continuation argument using the convolution bounds of Lemmas 7.2–7.4 below; we omit the details, since we shall carry out quite similar but more difficult estimates in the proof of stability. Smoothness of solutions may then be obtained by a bootstrapping argument as sketched in Appendix A. ∎

To establish stability, we use the following lemmas proved in [16].

LEMMA 7.2 (linear estimates [16]). *Under the assumptions of Theorem* 1.6,

$$\int_0^{+\infty} |G(x,t;y)|(1+|y|)^{-3/2}\,dy \le C(\theta+\psi_1+\psi_2)(x,t), \tag{7.9}$$

for $0\le t\le+\infty$, *some* $C>0$.

LEMMA 7.3 (nonlinear estimates [16]). *Under the assumptions of Theorem* 1.6,

$$\int_0^t\int_0^{+\infty} |G_y(x,t-s;y)|\Psi(y,s)\,dyds \le C(\theta+\psi_1+\psi_2)(x,t), \tag{7.10}$$

for $0\le t\le+\infty$, *some* $C>0$, *where*

$$\begin{aligned}\Psi(y,s) := {}& (1+s)^{1/2}s^{-1/2}(\theta+\psi_1+\psi_2)^2(y,s)\\ &+(1+s)^{-1}(\theta+\psi_1+\psi_2)(y,s).\end{aligned} \tag{7.11}$$

We require also the following estimate accounting boundary effects.

LEMMA 7.4 (boundary estimate). *Under the assumptions of Theorem* 1.6,

$$\left|\int_0^t G_y(x,t-s;0)Bh(s)\,ds\right| \le CE_0(\theta+\psi_1+\psi_2)(x,t), \tag{7.12}$$

for $0\le t\le+\infty$, *some* $C>0$.

Proof. The estimate on $\int_0^{t-1}$, where $G_y(x,t-s;0)$ is nonsingular, follows readily by estimates similar to but somewhat simpler than those of Lemma (7.3), which we, therefore, omit.

To bound the singular part $\int_{t-1}^t$, we integrate (7.6) in y from 0 to $+\infty$, recalling that $G(x,t-s;0)\equiv 0$, to obtain

$$G_yB = -\int_0^{+\infty} A_y(y)G(x,t-s;y)\,dy - \int_0^{+\infty} G_s(x,t-s;y)\,dy. \tag{7.13}$$

Substituting in the left-hand side of (7.12), and integrating by parts in s, we obtain

$$\begin{aligned}\int_{t-1}^t G_yBh(s)\,ds = {}& \int_0^1\left(\int_0^{+\infty} A_y(y)G(x,\tau;y)\,dy\right)h(t-\tau)\,d\tau\\ &-\int_0^1\left(\int_0^{+\infty} G(x,\tau;y)\,dy\right)h'(t-\tau)\,d\tau\\ &+\left(\int_0^{+\infty} G(x,1;y)\,dy\right)h(t-1),\end{aligned} \tag{7.14}$$

which, by $\int |G|dy\le C$, has norm bounded by $\max_{0\le\tau\le1}(|h|+|h'|)(t-\tau)$.

Combining this with the more straightforward estimate

$$\begin{aligned}\left|\int_{t-1}^{t} G_y(x,t;0)Bh(s)\,ds\right| &\le \int_0^1 |G_y(x,\tau;0)|Bh(s)\,ds\\ &\le C\max_{0\le\tau\le1}|h(t-\tau)|\int_0^1 \tau^{-1}e^{-|x|^2/C\tau}\,d\tau\\ &= C|x|^{-2}\max_{0\le\tau\le1}|h(t-\tau)|\\ &\quad\times\int_0^1 \left(|x|^2/\tau\right)e^{-|x|^2/C\tau}\,d\tau\\ &\le C\max_{0\le\tau\le1}|h(t-\tau)||x|^{-2},\end{aligned}\tag{7.15}$$

we find that the contribution from $\int_{t-1}^{t}$ has norm bounded by

$$\max_{0\le\tau\le1}(|h|+|h'|)(t-\tau)(1+|x|)^{-2}.$$

Combining this estimate with the one for $\int_0^{t-1}$, we obtain (7.12). □

With these preparations, the proof of stability is straightforward.

Proof of Theorem 1.6. Define

$$\zeta(t) := \sup_{y,0\le s\le t}|u|(\theta+\psi_1+\psi_2)^{-1}(y,t).\tag{7.16}$$

We will establish:

Claim. For all $t\ge 0$ for which a solution exists with ζ uniformly bounded by some fixed, sufficiently small constant, there holds

$$\zeta(t)\le C_2\left(E_0+\zeta(t)^2\right).\tag{7.17}$$

From this result, provided $E_0 < 1/4C_2^2$, we have that $\zeta(t)\le 2C_2E_0$ implies $\zeta(t) < 2C_2E_0$, and so we may conclude by continuous induction that

$$\zeta(t) < 2C_2E_0\tag{7.18}$$

for all $t\ge 0$. (By Lemma 7.1 and standard short-time estimates, $u\in C^0(x)$ exists and ζ remains continuous so long as ζ remains bounded by some uniform constant; hence (7.18) is an open condition.) From (7.18) and the definition of ζ in (7.16) we then obtain the bounds of (1.16). Thus, it remains only to establish the claim above.

Proof of Claim. We must show that $u(\theta+\psi_1+\psi_2)^{-1}$ is bounded by $C(E_0+\zeta(t)^2)$, for some $C>0$, all $0\le s\le t$, so long as ζ remains sufficiently small. By (7.16), we have for all $t\ge 0$ and some $C>0$ that

$$|u(x,t)|\le\zeta(t)(\theta+\psi_1+\psi_2)(x,t),\tag{7.19}$$

and, therefore,

$$|Q(u)(y,s)|\le C\zeta(t)^2\Psi(y,s)\tag{7.20}$$

with Ψ as defined in (7.11), for $0\le s\le t$. Combining (7.20) with representation (7.4)

and applying Lemmas 7.2–7.4, we obtain

$$
\begin{aligned}
|u(x,t)| &\le \int_0^\infty \left|\tilde G(x,t;y)\right| |g(y)|\,dy + \left|\int_0^t G_y(x,t-s;0)Bh(s)\,ds\right| \\
&\quad + \int_0^t \int_0^\infty \left|\tilde G_y(x,t-s;y)\right| |(Q(u))(y,s)|dy\,ds \\
&\le E_0 \int_0^\infty \left|\tilde G(x,t;y)\right| (1+|y|)^{-3/2}\,dy \\
&\quad + \left|\int_0^t G_y(x,t-s;0)Bh(s)\,ds\right| \\
&\quad + C\zeta(t)^2 \int_0^t \int_0^\infty \left|\tilde G_y(x,t-s;y)\right| \Psi(y,s)dy\,ds \\
&\le C\left(E_0+\zeta(t)^2\right)(\theta+\psi_1+\psi_2)(x,t).
\end{aligned}
\tag{7.21}
$$

Dividing by $(\theta+\psi_1+\psi_2)(x,t)$, we obtain (7.17) as claimed. This completes the proof of the claim, and the theorem. ∎

Appendix A. Smoothness of solutions.

In this appendix, we briefly sketch the proof that weak solutions defined by (7.4) are necessarily smooth, classical solutions as well, by indicating how to get the necessary derivative bounds.

Time-derivative. Rewriting the second boundary term on the right-hand side of (7.4) using its convolution structure, as

$$
\int_0^t G_y(x,\tau;0)Bh(t-\tau)\,d\tau,
$$

and differentiating in t, we obtain

$$
G_y(x,t;0)Bh(0) + \int_0^t G_y(x,\tau;0)Bh'(t-\tau)\,d\tau,
$$

for which the first term is bounded and smooth for $x,t>0$, and the second by the same estimate as in (7.15) is bounded by

$$
C|x|^{-2}\int_0^t |h'(t-\tau)|\,d\tau \le C|x|^{-2}\log(1+t).
$$

Differentiating the first and third terms, with respect to t and integrating the third term by parts in y, yields

$$
\begin{aligned}
&\int_0^\infty G(x,t;y)g(y)\,dy - \int_{t/2}^t \int_0^\infty G_y(x,t-s;y)Q(u)_s(y,s)\,dy\,ds \\
&\qquad - \int_0^{t/2}\int_0^\infty G_{yt}(x,t-s;y)Q(u)(y,s)\,dy\,ds,
\end{aligned}
\tag{A.1}
$$

from which, in combination with the boundary estimate already performed, we may readily obtain a short-time bound $|u_t| \le C|x|^{-2}t^{-1}$ by Picard iteration.

Spatial-derivatives. Likewise, differentiating (7.14) with respect to x, we may bound the x-derivative of the boundary term $\int_0^t G_y B\,ds$ by

$$
C\int_0^t \tau^{-1/2}(|h'|+|h|)(t-\tau)|\,d\tau \le C\log(1+t).
$$

Differentiating the first and third terms of the right-hand side of (7.4), with respect to x and integrating the third term by parts in y, yields

$$\int_0^\infty G(x,t;y)g(y)\,dy - \int_{t/2}^t \int_0^\infty G_x(x,t-s;y)Q(u)_y(y,s)\,dy\,ds - \int_0^{t/2}\int_0^\infty G_{yx}(x,t-s;y)Q(u)(y,s)\,dy\,ds, \tag{A.2}$$

from which, in combination with the boundary estimate already performed, we obtain a short-time bound $|u_x| \le Ct^{-1/2}$ by Picard iteration. From the bounds on $|u_t|$ and $|u_x|$, finally, we obtain bounds on $|u_{xx}|$ by the equation satisfied by u.

A HIGHER ORDER MODEL FOR IMAGE RESTORATION: THE ONE-DIMENSIONAL CASE*

G. DAL MASO†, I. FONSECA‡, G. LEONI‡, AND M. MORINI†

Abstract. The higher order total variation-based model for image restoration proposed by Chan, Marquina, and Mulet in [*SIAM J. Sci. Comput.*, 22 (2000), pp. 503–516] is analyzed in one dimension. A suitable functional framework in which the minimization problem is well posed is being proposed, and it is proved analytically that the higher order regularizing term prevents the occurrence of the *staircase effect*. The generalized version of the model considered here includes, as particular cases, some curvature dependent functionals.

Key words. image segmentation, total variation models, staircase effect, higher order regularization, relaxation, curvature dependent functionals

1. Introduction.

Deblurring and denoising of images are fundamental problems in image processing and gave rise in the past few years to a vast variety of techniques and methods touching different fields of mathematics. Among them, variational methods based on the minimization of some energy functional have been successfully employed to treat a fairly general class of image restoration problems. Typically, such functionals present a *fidelity term*, which penalizes the distance between the reconstructed image u and the noisy image g with respect to a suitable metric, and a regularizing term, which makes high frequency noise energetically unfavorable.

When the fidelity term is given by the squared L^2 distance multiplied by a parameter $\lambda > 0$ and the regularizing term is represented by the total variation, we are led to the following minimization problem:

$$\min\left\{|Du|(\Omega) + \lambda \int_\Omega |u-g|^2\,dx : u \in BV(\Omega)\right\}, \tag{1.1}$$

which was proposed by Rudin, Osher, and Fatemi in [13]. Here Ω is an open bounded domain in one or two dimensions, $BV(\Omega)$ denotes the space of functions of bounded variations in Ω, and $|Du|(\Omega)$ stands for the total variation of u in Ω. The main feature of the total variation-based image restoration is perhaps represented by the tendency to yield (almost) piecewise constant solutions or, in other words, "blocky" images. Typically, one observes that *ramps* (i.e., affine regions) in the original image give rise to staircase-like structures in the reconstructed image, a phenomenon which is often referred to as the *staircase effect*. This means that the original edges are well preserved by this method but also that many artificial discontinuities can be generated by the presence of noise, while the finer details of the objects contained in the image may not be properly recovered.

Several variants of (1.1) have been subsequently proposed in order to fix these drawbacks. In this paper we follow the approach of Chan, Marquina, and Mulet [6]:

*Received by the editors July 9, 2007; accepted for publication (in revised form) October 10, 2008; published electronically February 25, 2009.

Since the total variation does not distinguish between jumps and smooth transitions, their idea is to consider an additional penalization of the discontinuities by taking second derivatives into account. More precisely, they propose a regularizing term of the form

$$\int_\Omega |\nabla u|\,dx + \int_\Omega \psi(|\nabla u|)h(\Delta u)\,dx, \tag{1.2}$$

where ψ is a function that must satisfy suitable conditions at infinity in order to allow jumps.

In this paper we consider the following one-dimensional (1D) version of (1.2):

$$\mathcal{F}_p(u) := \int_a^b |u'|\,dx + \int_a^b \psi(|u'|)|u''|^p\,dx, \tag{1.3}$$

where $a < b$ are real numbers, $p \in [1, +\infty)$, and $\psi : \mathbb{R} \to]0, +\infty[$ is a bounded Borel function satisfying suitable integrability assumptions (see (2.1) and (3.1)). We remark that by taking

$$\psi(t) := \frac{1}{(1+t^2)^{\frac{1}{2}(3p-1)}}$$

the functional (1.3) takes the form

$$\int_a^b |u'|\,dx + \int_{\text{Graph } u} |k|^p\,d\mathcal{H}^1,$$

where k denotes the curvature of the graph of u and $\mathcal{H}^1$ stands for the 1D Hausdorff measure. This seems to suggest a broader applicability of our results: Functionals of this kind are often encountered in many computer vision and graphics applications, such as, among the others, corner preserving geometry denoising and segmentation with depth (see, e.g., [3], [15], and the references contained therein).

Our main analytical objective is twofold:

(i) to set up a proper functional framework where the minimization problem corresponding to

$$\mathcal{F}_p(u) + \lambda \int_a^b |u-g|^2\,dx$$

is well posed;

(ii) to give an analytical proof of the fact that the higher order regularizing term eliminates the staircase effect.

We carry out the first part of this program in sections 2 and 3 by using the theory of relaxation (see [7] for a general introduction): We regard $\mathcal{F}_p$ as defined for all functions in the Sobolev space $W^{2,p}(]a,b[)$, we extend it to $L^1(]a,b[)$ by setting $\mathcal{F}_p(u) := +\infty$ if $u \in L^1(]a,b[) \setminus W^{2,p}(]a,b[)$, and then we identify its lower semicontinuous envelope with respect to the strong L^1 convergence. The two cases $p = 1$ and $p > 1$ require a different treatment, and, in fact, the analysis turns out to be considerably more delicate in the case $p = 1$. Moreover, the domains of the relaxed functionals are quite peculiar (see Definitions 2.1 and 3.1) and display properties that are qualitatively different in the two cases. In particular, it turns out that piecewise constant functions corresponding to images with genuine edges are approximable by sequences with bounded energy

only for $p = 1$. The extension of these relaxation results to higher dimensions will be the subject of a subsequent paper.

The second part of the program is carried out in section 4. We start by exhibiting an analytical example of staircasing for the Rudin–Osher–Fatemi model (Theorem 4.3). More precisely, we show that if g has the form $g = g_1 + h$, with g_1 an affine function (which represents the original "clean" signal) and h a highly oscillating noise, then, for certain choices of h, the reconstructed signal u may display a stairlike or piecewise constant structure, even if h is uniformly small. In particular, we note that

(a) the discontinuity set of u is much larger than the discontinuity set of the original signal g_1,

(b) the derivatives of u and u_1 are very far apart,

where u_1 denotes the solution to the Rudin–Osher–Fatemi minimization problem corresponding to the datum g_1. Although we do not attempt to give a formal definition of staircasing, we consider the presence/absence of (a) and (b) as a way to detect the presence/absence of the staircase effect. In Theorems 4.5 and 4.8 we prove that the new model eliminates the effect by showing that (a) and (b) do not occur. More precisely, we show that whenever the datum g is of the form $g = g_1 + h$, with g_1 a regular signal and h a highly oscillating noise close to 0 in the L^∞-weak* topology, the reconstructed image u is regular as well (in particular, no new artificial discontinuities are created) and u and u_1 are close in some strong norm ($W^{1,q}$-norm for every $q > 1$ or C^1-norm, depending on whether $p = 1$ or $p > 1$), where u_1 is the solution corresponding to the clean signal g_1.

For completeness we conclude by mentioning that other approaches have been considered to avoid staircasing: The works by Geman and Reynolds [9] and Chambolle and Lions [5] contain a different use of higher order derivatives as regularizing terms; in [2], Blomgren, Chan, and Mulet propose a BV-H^1 interpolation approach, while Kindermann, Osher, and Jones avoid in [11] the use of second derivatives by considering a sort of nonlocal total variation.

2. The case $p = 1$. We start by studying the compactness properties and the relaxation of (1.3) in the case $p = 1$. Throughout this section $\psi\colon \mathbb{R} \to]0, +\infty[$ will be a bounded Borel function such that

$$M := \int_{-\infty}^{+\infty} \psi(t)\, dt < +\infty \tag{2.1}$$

and

$$\inf_{t\in K} \psi(t) > 0 \quad \text{for every compact set } K \subset \mathbb{R}. \tag{2.2}$$

Let $\Psi_1\colon \overline{\mathbb{R}} \to [0, M]$ be the increasing function defined by

$$\Psi_1(t) := \int_{-\infty}^{t} \psi(s)\, ds,$$

and let $\Psi_1^{-1}\colon [0, M] \to \overline{\mathbb{R}}$ be its inverse function.

Given a bounded open interval $]a, b[$ in $\mathbb{R}$, we let $\mathcal{F}_1\colon L^1(]a, b[) \to [0, +\infty]$ be the functional defined by

$$\mathcal{F}_1(u) := \begin{cases} \displaystyle\int_a^b |u'|\, dx + \int_a^b \psi(u')|u''|\, dx & \text{if } u \in W^{2,1}(]a, b[), \\ +\infty & \text{otherwise.} \end{cases} \tag{2.3}$$

The first step in the study of (2.3) will consist in identifying the subspace of L^1 functions which can be approximated by energy bounded sequences. In order to do so, we need to introduce some notation and recall some basic facts about BV functions of one variable. This will be the content of the next subsection.

2.1. *BV* functions of one variable. We recall that a function $u \in L^1(]a,b[)$ belongs to $BV(]a,b[)$ if and only if

$$\sup\left\{\int_a^b u\varphi'\,dx : \varphi \in C_c^1(]a,b[),\ |\varphi| \le 1\right\} < +\infty. \tag{2.4}$$

Note that this implies that the distributional derivative u' of u is a bounded Radon measure in $]a,b[$. We will often consider the Lebesgue decomposition

$$u' = (u')^a\mathcal{L}^1 + (u')^s,$$

where $(u')^a$ is the density of the absolutely continuous part of u' with respect to the Lebesgue measure $\mathcal{L}^1$ on $]a,b[$ while $(u')^s$ is its singular part. We will denote the total variation measure of u' by $|u'|$. In particular, $|u'|(]a,b[)$ equals the value of the supremum in (2.4). For every function $u \in BV(]a,b[)$ the following left and right approximate limits

$$u_-(y) := \lim_{\varepsilon\to 0+}\frac{1}{\varepsilon}\int_{y-\varepsilon}^{y} u(x)\,dx, \qquad u_+(y) := \lim_{\varepsilon\to 0+}\frac{1}{\varepsilon}\int_{y}^{y+\varepsilon} u(x)\,dx,$$

respectively, are well defined at every point $y \in]a,b[$. In fact, $u_-(y)$ is well defined also at $y = b$ while $u_+(y)$ exists also at $y = a$. The functions u_- and u_+ coincide $\mathcal{L}^1$-a.e. with u and are left and right continuous, respectively. Moreover, it turns out that the set $S_u := \{y \in]a,b[: u_-(y) \ne u_+(y)\}$ is at most countable. The set S_u is often referred to as the set of essential discontinuities or *jump points* of u.

It is well known that, in turn, the singular part $(u')^s$ splits into the sum of an atomic measure concentrated on S_u and a singular diffuse measure $(u')^c$, called the *Cantor part* of u':

$$(u')^s = [u]\mathcal{H}^0 \llcorner S_u + (u')^c,$$

where we set $[u] := u_+ - u_-$ and $\mathcal{H}^0$ stands for the counting measure. Finally, we recall that every $u \in BV(]a,b[)$ is differentiable at $\mathcal{L}^1$-a.e. y in $]a,b[$ with derivative given by $(u')^a(y)$. In this case, we will often write, with a slight abuse of notation, $u'(y)$ instead of $(u')^a(y)$.

We say that a sequence $\{u_k\}$ of functions in $BV(]a,b[)$ *weakly star converges in* $BV(]a,b[)$ to a function $u \in BV(]a,b[)$ if $u_n \to u$ in $L^1(]a,b[)$ and $u_k' \rightharpoonup u'$ weakly* in $M_b(]a,b[)$, where $M_b(]a,b[)$ is the space of bounded Radon measures.

We will also need sometimes the notion of total variation for a function defined everywhere. We recall that $u\colon]a,b[\to \mathbb{R}$ has bounded *pointwise total variation* over the interval $]c,d[\subset]a,b[$ if

$$\mathrm{Var}\,(u;]c,d[) := \sup\sum_{i=1}^{k}|u(y_i) - u(y_{i-1})| < +\infty,$$

where the supremum is taken over all finite families $y_0, y_1, \dots, y_k$ such that $c < y_0 < y_1 < \cdots < y_k < d$, $k \in \mathbb{N}$. It is easy to see that if u has bounded pointwise total

variation in $]a,b[$, then it admits left and right limits at every point, it belongs to $BV(]a,b[)$, and $|u'|(]c,d[) \le \mathrm{Var}\,(u;]c,d[)$ for every interval $]c,d[\subset]a,b[$. Conversely, if $u \in BV(]a,b[)$, the *precise representatives* u_- and u_+ have bounded pointwise total variation and satisfy

$$|u'|(]c,d[) = \mathrm{Var}\,(u_-;]c,d[) = \mathrm{Var}\,(u_+;]c,d[)$$

for every interval $]c,d[\subset]a,b[$.

Finally, we recall the Helly theorem: For every bounded sequence of functions $u_k :]a,b[\to \mathbb{R}$ such that $\sup_k \mathrm{Var}\,(u_k;]a,b[) < +\infty$, there exist u, with pointwise total variation in $]a,b[$, and a subsequence (not relabeled) such that $u_k \to u$ pointwise.

We refer to [14] and [10] for an exhaustive exposition of the properties of BV functions of one variable.

2.2. Compactness. To define the subspace of L^1 functions that can be approximated by energy bounded sequences, for every function $u \in BV\,(]a,b[)$ we consider the sets

$$Z^+[(u')^a] := \left\{ x \in]a,b[: \lim_{\varepsilon\to 0+} \frac{1}{2\varepsilon} \int_{x-\varepsilon}^{x+\varepsilon} (u')^a \, dx = +\infty \right\}, \tag{2.5}$$

$$Z^-[(u')^a] := \left\{ x \in]a,b[: \lim_{\varepsilon\to 0+} \frac{1}{2\varepsilon} \int_{x-\varepsilon}^{x+\varepsilon} (u')^a \, dx = -\infty \right\}. \tag{2.6}$$

It is also convenient to define

$$Z[(u')^a] := Z^+[(u')^a] \cup Z^-[(u')^a].$$

Definition 2.1. *Let $X^1_\psi(]a,b[)$ be the set of all functions $u \in BV(]a,b[)$ such that $v := \Psi_1 \circ (u')^a$ belongs to $BV(]a,b[)$ and the positive part $((u')^c)^+$ and the negative part $((u')^c)^-$ of the measure $(u')^c$ are concentrated on $Z^+[(u')^a]$ and $Z^-[(u')^a]$, respectively.*

Remark 2.2. Note that if $u \in X^1_\psi(]a,b[)$, then the limits

$$(u')^a_-(y) := \lim_{\varepsilon\to 0+} \frac{1}{\varepsilon} \int_{y-\varepsilon}^{y} (u')^a \, dx, \qquad (u')^a_+(y) := \lim_{\varepsilon\to 0+} \frac{1}{\varepsilon} \int_{y}^{y+\varepsilon} (u')^a \, dx \tag{2.7}$$

exist in $\overline{\mathbb{R}}$ for every y. More precisely, $(u')^a_-$ exists also at $y = b$, while $(u')^a_+$ is well defined also at $y = a$. Indeed, since $v = \Psi_1 \circ (u')^a$ is a BV function, it admits a precise representative $\tilde v$ such that the right and left limits exist at every point, and the same property holds for $\Psi_1^{-1}(\tilde v)$. As $\Psi_1^{-1}(\tilde v) = (u')^a$ $\mathcal{L}^1$-a.e. in $]a,b[$, the limits considered in (2.7) are everywhere well defined. Moreover, the set $S_{(u')^a} := S_v$ is at most countable and

$$(u')^a_- = (u')^a_+ \quad \text{on }]a,b[\setminus S_{(u')^a}. \tag{2.8}$$

We also remark that $(u')^a_-$ and $(u')^a_+$ are left and right continuous, respectively, which, in turn, implies that the functions defined by

$$(u')^a_\vee(x) := \max\left\{(u')^a_+(x), (u')^a_-(x)\right\}, \ (u')^a_\wedge(x) := \min\left\{(u')^a_+(x), (u')^a_-(x)\right\}$$

if $x \in]a,b[$ and by

$$(u')^a_\vee(a) = (u')^a_\wedge(a) := (u')^a_+(a), \qquad (u')^a_\vee(b) = (u')^a_\wedge(b) := (u')^a_-(b)$$

are upper and lower semicontinuous in $[a,b]$, respectively. By (2.8) we have

$$Z^+[(u')^a] \setminus S_{(u')^a} = \{x \in]a,b[: (u')^a_\wedge(x) = +\infty\} \setminus S_{(u')^a},$$
$$Z^-[(u')^a] \setminus S_{(u')^a} = \{x \in]a,b[: (u')^a_\vee(x) = -\infty\} \setminus S_{(u')^a}.$$

Therefore, $((u')^c)^+$ is concentrated on the set $\{x \in]a,b[: (u')^a_\wedge(x) = +\infty\}$ and $((u')^c)^-$ is concentrated on the set $\{x \in]a,b[: (u')^a_\vee(x) = -\infty\}$.

Before we proceed we show that the space $X^1_\psi(]a,b[)$ contains functions with nontrivial Cantor part when ψ satisfies suitable decay estimates at infinity.

PROPOSITION 2.3. *Assume that* $\psi\colon \mathbb{R} \to]0,+\infty[$ *is a bounded Borel function satisfying* (2.1), (2.2), *and*

$$\psi(t) \le \frac{c}{t^\alpha} \tag{2.9}$$

for all $t \ge 1$ *and for some* $c > 0$, $\alpha > 1$. *Then there exists* $u \in X^1_\psi(]a,b[)$ *with* $(u')^c \neq 0$.

Proof. For simplicity we take $]a,b[=]0,1[$.

Step 1. We start by recalling the definition of the generalized Cantor set $\mathbb{D}_\delta$, where $\delta \in]0,\frac{1}{2}[$ (see, for instance, [8, Chapter 1, section 2.4]). The construction is entirely similar to the one of the (ternary) Cantor set with the only difference that the middle intervals removed at each step have length $1-2\delta$ times the length of the intervals remaining from the previous step. To be more precise, remove from $[0,1]$ the interval $I_{11} := (\delta, 1-\delta)$. At the second step remove from each of the remaining closed intervals $[0,\delta]$ and $[1-\delta,1]$ the middle intervals, denoted by I_{12} and I_{22}, of length $\delta(1-2\delta)$. Continuing in this fashion at each step n we remove 2^{n-1} middle intervals $I_{1n},\dots,I_{2^{n-1}n}$, each of length $\delta^{n-1}(1-2\delta)$. The *generalized Cantor set* $\mathbb{D}_\delta$ is defined as

$$\mathbb{D}_\delta := [0,1] \setminus \bigcup_{n=1}^{\infty} \bigcup_{k=1}^{2^{n-1}} I_{kn}.$$

The set $\mathbb{D}_\delta$ is closed (since its complement is given by a family of open intervals), and

$$\mathcal{L}^1(\mathbb{D}_\delta) = 1 - \sum_{n=1}^{\infty} \sum_{k=1}^{2^{n-1}} \mathcal{L}^1(I_{kn}) = 1 - \sum_{n=1}^{\infty} \sum_{k=1}^{2^{n-1}} \delta^{n-1}(1-2\delta)$$
$$= 1 - (1-2\delta) \sum_{n=1}^{\infty} (2\delta)^{n-1} = 0.$$

Next, we recall the definition of the corresponding Cantor function f_δ. Set

$$g_n := \frac{1}{(2\delta)^n} \left(1 - \sum_{j=1}^{n} \sum_{k=1}^{2^{j-1}} \chi_{I_{kj}} \right),$$

and define $f_n(x) := \int_0^x g_n(t)\,dt$. It can be shown that $\{f_n\}$ converges uniformly to a continuous nondecreasing function f_δ such that $f_\delta(0) = 0$, $f_\delta(1) = 1$, and $f'_\delta = (f'_\delta)^c$ is supported on $\mathbb{D}_\delta$.

Step 2. We claim that it is enough to find a constant $\delta \in]0,\frac{1}{2}[$ for which it is possible to construct a continuous integrable function $w_\delta :]0,1[\to [0,+\infty]$ such

that $\Psi_1 \circ w_\delta \in BV(]0,1[)$ and $w_\delta(x) = +\infty$ if and only if $x \in \mathbb{D}_\delta$. Indeed, setting $u_\delta(x) := \int_0^x w_\delta(t)\,dt + f_\delta(x)$, we have that $u_\delta \in BV(]0,1[)$, u_δ is continuous, and $(u'_\delta)^a = w_\delta$ so that $Z^+[(u'_\delta)^a] = Z[(u'_\delta)^a] = \mathbb{D}_\delta$ and $\Psi_1 \circ (u'_\delta)^a \in BV(]0,1[)$. Moreover, $(u'_\delta)^c = (f'_\delta)^c$ is supported on $\mathbb{D}_\delta = Z^+[(u'_\delta)^a]$. Hence, u_δ belongs to $X^1_\psi(]a,b[)$.

Step 3. It remains to construct w_δ for a suitable $\delta \in]0, \frac{1}{2}[$. Consider a convex function $\phi :]0,1[\to [0,+\infty)$ such that

$$\lim_{x\to 0^+} \phi(x) = \lim_{x\to 1^-} \phi(x) = +\infty, \quad \phi\left(\frac{1}{2}\right) = 0, \tag{2.10}$$

and

$$\int_0^1 \phi(x)\,dx = 1. \tag{2.11}$$

Choose $s > 0$ so large that

$$\alpha > \frac{s+1}{s}. \tag{2.12}$$

For $x \in I_{kn}$ (see Step 1) define

$$\phi_{kn}(x) := 2^{sn} + \phi\left(\frac{x - a_{kn}}{\delta^{n-1}(1-2\delta)} + \frac{1}{2}\right), \tag{2.13}$$

where a_{kn} is the midpoint of the interval I_{kn}. Finally, set

$$w_\delta := \sum_{n=1}^{\infty} \sum_{k=1}^{2^{n-1}} \phi_{kn}\chi_{I_{kn}} + I_{\mathbb{D}_\delta},$$

where $I_{\mathbb{D}_\delta}$ is the indicator function of the set $\mathbb{D}_\delta$, that is,

$$I_{\mathbb{D}_\delta}(x) := \begin{cases} +\infty & \text{if } x \in \mathbb{D}_\delta, \\ 0 & \text{otherwise.} \end{cases}$$

Using the fact that

$$\int_{I_{kn}} \phi_{kn}\,dx = (2^{sn}+1)\,\delta^{n-1}(1-2\delta),$$

which follows from (2.11) and a change of variables, we have

$$\int_0^1 w_\delta\,dx = \sum_{n=1}^{\infty} \sum_{k=1}^{2^{n-1}} (2^{sn}+1)\,\delta^{n-1}(1-2\delta) < \infty$$

for $\delta < \frac{1}{2^{s+1}}$. To estimate the total variation of $v := \Psi_1 \circ w_\delta$, we consider the approximating sequence

$$v_m(x) := \begin{cases} \Psi_1 \circ \phi_{kn}(x) & \text{if } x \in I_{kn},\ 1 \le k \le 2^{n-1},\ 1 \le n \le m, \\ M & \text{otherwise.} \end{cases}$$

By (2.9), (2.10), (2.13), and the convexity of ϕ, it can be seen that

$$\operatorname{Var}(v_m; I_{kn}) = 2(M - \Psi_1(2^{sn})) = 2\int_{2^{sn}}^{+\infty} \psi(t)\,dt \le \frac{2c}{\alpha - 1}\frac{1}{2^{sn(\alpha-1)}}.$$

It follows that

$$\mathrm{Var}\,(v_m;]0,1[) \le \frac{2c}{\alpha-1}\sum_{n=1}^{m}\sum_{k=1}^{2^{n-1}}\frac{1}{2^{sn(\alpha-1)}} \le \frac{2c}{\alpha-1}\sum_{n=1}^{\infty}\frac{1}{2^{sn(\alpha-1)-n+1}}.$$

The last series is finite, thanks to (2.12). Therefore, the v_m's have equibounded total variations, and, since $v_m \to v$ in $L^1(]0,1[)$, we conclude that $v \in BV(]0,1[)$. □

Energy bounded sequences are compact in $X^1_\psi(]a,b[)$, as made precise by the following theorem.

THEOREM 2.4. *Let $\{u_k\}$ be a sequence of functions bounded in $L^1(]a,b[)$ such that*

$$C := \sup_k \mathcal{F}_1(u_k) < +\infty. \tag{2.14}$$

Then there exist a subsequence (not relabeled) $\{u_k\}$ and a function $u \in X^1_\psi(]a,b[)$ such that

$$u_k \rightharpoonup u \quad \textit{weakly}^* \textit{ in } BV(]a,b[), \tag{2.15}$$

$$\Psi_1 \circ u_k' \rightharpoonup \Psi_1 \circ (u')^a \quad \textit{weakly}^* \textit{ in } BV(]a,b[), \tag{2.16}$$

$$u_k' \to (u')^a \quad \textit{pointwise } \mathcal{L}^1\textit{-a.e. in }]a,b[. \tag{2.17}$$

Proof. By (2.3) and (2.14) we have that each u_k belongs to $W^{2,1}(]a,b[)$ and

$$C_1 := \sup_k \int_a^b [\,|u_k| + |u_k'| + \psi(u_k')|u_k''|\,]\,dx < +\infty. \tag{2.18}$$

Let us define

$$v_k := \Psi_1 \circ u_k'. \tag{2.19}$$

As Ψ_1 is Lipschitz in $\mathbb{R}$, the functions v_k belong to $W^{1,1}(]a,b[)$ and

$$v_k' = \psi(u_k')u_k'' \qquad \mathcal{L}^1\text{-a.e. on }]a,b[. \tag{2.20}$$

It follows from (2.1) and (2.14) that

$$\int_a^b [\,|v_k| + |v_k'|\,]\,dx \le M(b-a) + C. \tag{2.21}$$

By (2.18) and (2.21) and the Helly theorem, passing to a subsequence if necessary, we may assume that

$$u_k \rightharpoonup u \quad \text{weakly}^* \text{ in } BV(]a,b[)$$

and

$$v_k(x) \to v(x) \quad \text{for all } x \in]a,b[\tag{2.22}$$

for some $u \in BV(]a,b[)$ and $v\colon]a,b[\to [0,M]$ with pointwise bounded variation. Note that (2.22) determines the values of v at every $x \in]a,b[$.

Since Ψ_1^{-1} is continuous, we obtain

$$u_k' \to w := \Psi_1^{-1}(v) \quad \text{pointwise in }]a,b[. \tag{2.23}$$

Since by (2.18) we have $\sup_k \|u_k'\|_1 < +\infty$, it follows from Fatou's lemma and (2.23) that w is integrable, and so

$$w \text{ is finite } \mathcal{L}^1\text{-a.e. in }]a,b[. \tag{2.24}$$

Moreover, w has left and right limits in $\overline{\mathbb{R}}$ at each point $x \in]a,b[$, denoted by $w_-(x)$ and $w_+(x)$, respectively, and

$$w(x) = w_-(x) = w_+(x) \quad \text{except for a countable set of points } x. \tag{2.25}$$

We now split the remaining part of the proof into two steps.

Step 1. We prove that

$$w = (u')^a \quad \mathcal{L}^1\text{-a.e. in }]a,b[. \tag{2.26}$$

If not, we have $\mathcal{L}^1(\{w \neq (u')^a\}) > 0$. By (2.24) there exists $t_0 > 0$ such that

$$\mathcal{L}^1(\{w \neq (u')^a\} \cap \{|w| < t_0\}) > 0,$$

and, in particular, we may find an infinite number of disjoint open intervals I such that

$$\mathcal{L}^1(\{w \neq (u')^a\} \cap \{|w| < t_0\} \cap I) > 0. \tag{2.27}$$

By a change of variables we obtain

$$\int_I \psi(u_k')|u_k''|\,dx \geq \int_{m_k}^{M_k} \psi(t)\,dt, \tag{2.28}$$

where

$$m_k := \inf_I u_k' \quad \text{and} \quad M_k := \sup_I u_k'.$$

We claim that at least one of the two sequences $\{m_k\}$ and $\{M_k\}$ is divergent. Indeed, if not, a subsequence of $\{u_k'\}$ would be bounded in $L^\infty(I)$. This implies that $u' \in L^\infty(I)$ and that $u_k' \rightharpoonup u'$ weakly* in $L^\infty(I)$. As $u_k' \to w$ pointwise $\mathcal{L}^1$-a.e. in I, we deduce that $u' = w$ $\mathcal{L}^1$-a.e. in I, which contradicts (2.27). Hence, the claim holds. If

$$\lim_{k\to\infty} M_k = +\infty, \tag{2.29}$$

then by (2.23) and (2.27)

$$\limsup_{k\to\infty} m_k < t_0. \tag{2.30}$$

From (2.28), (2.30), and (2.29) we obtain

$$\liminf_{k\to\infty} \int_I \psi(u_k')|u_k''|\,dx \geq \int_{t_0}^{+\infty} \psi(t)\,dt > 0.$$

Analogously, if $\lim_k m_k = -\infty$, then

$$\liminf_{k\to\infty} \int_I \psi(u_k')|u_k''|\,dx \geq \int_{-\infty}^{-t_0} \psi(t)\,dt > 0.$$

In any case, we can choose an arbitrarily large number m of disjoint intervals I satisfying (2.27). Adding the contributions of each interval we obtain

$$\liminf_{k\to\infty} \int_a^b \psi(u_k')|u_k''|\,dx \geq m \min\left\{\int_{t_0}^{+\infty} \psi(t)\,dx, \int_{-\infty}^{-t_0} \psi(t)\,dt\right\},$$

which contradicts (2.18) for m large enough. This concludes the proof of (2.26).

Step 2. To prove that $u \in X^1_\psi(]a,b[)$, it remains to show that the positive part $((u')^c)^+$ and the negative part $((u')^c)^-$ of the measure $(u')^c$ are concentrated on $Z^+[(u')^a]$ and $Z^-[(u')^a]$, respectively, that is,

$$((u')^c)^\pm (]a,b[\setminus Z^\pm[(u')^a]) = 0. \tag{2.31}$$

To this purpose we introduce the sets

$$E^+[u'] := \left\{x \in]a,b[: \lim_{\varepsilon\to 0+} \frac{(u')^+(]x-\varepsilon,x+\varepsilon[)}{2\varepsilon} = +\infty\right\}, \tag{2.32}$$

$$E^-[u'] := \left\{x \in]a,b[: \lim_{\varepsilon\to 0+} \frac{(u')^-(]x-\varepsilon,x+\varepsilon[)}{2\varepsilon} = +\infty\right\}, \tag{2.33}$$

$$E[u'] := \left\{x \in]a,b[: \lim_{\varepsilon\to 0+} \frac{|u'|(]x-\varepsilon,x+\varepsilon[)}{2\varepsilon} = +\infty\right\}.$$

Since $((u')^s)^+ = ((u')^+)^s$ is concentrated on $E^+[u']$ and $((u')^s)^- = ((u')^-)^s$ is concentrated on $E^-[u']$ (see, e.g., [1, Theorem 2.22]), to prove (2.31) it is enough to show that

$$E^+[u'] \setminus Z^+[(u')^a] \text{ and } E^-[u'] \setminus Z^-[(u')^a] \text{ are at most countable.} \tag{2.34}$$

We show only that $E^+[u'] \setminus Z^+[(u')^a]$ is at most countable, since the other property can be proved in a similar way. Assume, by contradiction, that $E^+[u'] \setminus Z^+[(u')^a]$ is not countable. Since by (2.5) and (2.26)

$$Z^+[(u')^a] \subset \{x \in]a,b[: \max\{w_-(x), w_+(x)\} = +\infty\},$$

by (2.25) there exists $t_0 > 0$ such that

$$(E^+[u'] \setminus Z^+[(u')^a]) \cap \{w < t_0\} \quad \text{is uncountable.}$$

Fix $t_1 > t_0$, and let $x_1, \dots, x_m$ be m distinct points in $(E^+[u'] \setminus Z^+[(u')^a]) \cap \{w < t_0\}$. By (2.32) there exists $\varepsilon > 0$ such that the intervals $I_j :=]x_j - \varepsilon, x_j + \varepsilon[$ are pairwise disjoint and

$$\frac{(u')^+(]x_j-\varepsilon,x_j+\varepsilon[)}{2\varepsilon} > t_1 \quad \text{for } i = 1,\dots,m. \tag{2.35}$$

By a change of variables we obtain

$$\int_{I_j} \psi(u_k')|u_k''|\,dx \geq \int_{m_{kj}}^{M_{kj}} \psi(t)\,dt, \tag{2.36}$$

where

$$m_{kj} := \inf_{I_j} u_k' \quad \text{and} \quad M_{kj} := \sup_{I_j} u_k'.$$

By (2.23) and the fact that $w(x_j) < t_0$, we deduce that

$$\limsup_{k\to\infty} m_{kj} < t_0 \tag{2.37}$$

for $j = 1, \dots, m$. On the other hand, (2.15) and (2.35) yield

$$\liminf_{k\to\infty} \frac{1}{2\varepsilon} \int_{x_j-\varepsilon}^{x_j+\varepsilon} (u_k')^+ \, dx \geq \frac{(u')^+(]x_j-\varepsilon, x_j+\varepsilon[)}{2\varepsilon} > t_1$$

(this can be seen as a particular case of the Reshetnyak lower semicontinuity theorem, with $f = (\cdot)^+$). This implies that $\liminf_{k\to\infty} M_{kj} > t_1$ for $j = 1, \dots, m$. Hence, also by (2.36) and (2.37) we obtain

$$\liminf_{k\to\infty} \sum_{j=1}^{m} \int_{I_j} \psi(u_k')|u_k''| \, dx \geq \sum_{j=1}^{m} \liminf_{k\to\infty} \int_{I_j} \psi(u_k')|u_k''| \, dx \geq m \int_{t_0}^{t_1} \psi(t) \, dt,$$

which contradicts (2.18) for m large enough. This shows (2.34) and concludes the proof of the theorem. ∎

2.3. Relaxation. The following theorem, which is the main result of the section, is devoted to the characterization of the relaxation of $\mathcal{F}_1$ with respect to strong convergence in $L^1(]a,b[)$.

THEOREM 2.5. *Let $\overline{\mathcal{F}}_1 \colon L^1(]a,b[) \to [0,+\infty]$ be defined by*

$$\overline{\mathcal{F}}_1(u) := \inf \left\{ \liminf_{k\to\infty} \mathcal{F}_1(u_k) : u_k \to u \text{ in } L^1(]a,b[) \right\}$$

for every $u \in L^1(]a,b[)$. Then

$$\overline{\mathcal{F}}_1(u) = \begin{cases} |u'|(]a,b[) + |v'|(]a,b[\setminus S_u) + \displaystyle\sum_{x\in S_u} \Phi(\nu_u, (u')^a_-, (u')^a_+) & \text{if } u \in X^1_\psi(]a,b[), \\ +\infty & \text{otherwise,} \end{cases} \tag{2.38}$$

where $v := \Psi_1 \circ (u')^a$, $\nu_u := \operatorname{sign}(u_+ - u_-)$, and

$$\begin{aligned} \Phi(1, t_1, t_2) &:= \int_{t_1}^{+\infty} \psi(t) \, dt + \int_{t_2}^{+\infty} \psi(t) \, dt, \\ \Phi(-1, t_1, t_2) &:= \int_{-\infty}^{t_1} \psi(t) \, dt + \int_{-\infty}^{t_2} \psi(t) \, dt. \end{aligned} \tag{2.39}$$

Remark 2.6. For every $x \in S_u$ we have

$$\Phi(\nu_u(x), (u')^a_-(x), (u')^a_+(x)) = |v'|(\{x\}) + \hat{\Phi}(\nu_u(x), (u')^a_-(x), (u')^a_+(x)),$$

where

$$\hat{\Phi}(1, t_1, t_2) := \int_{\max\{t_1,t_2\}}^{+\infty} \psi(t) \, dt \qquad \text{and} \qquad \hat{\Phi}(-1, t_1, t_2) := \int_{-\infty}^{\min\{t_1,t_2\}} \psi(t) \, dt.$$

In particular, for every Borel set $B \subset]a,b[$

$$\begin{aligned} &|v'|(B \setminus S_u) + \sum_{x\in S_u\cap B} \Phi(\nu_u, (u')^a_-, (u')^a_+) \\ &\quad = |v'|(B) + \sum_{x\in S_u\cap B} \hat{\Phi}(\nu_u, (u')^a_-, (u')^a_+) \geq |v'|(B). \end{aligned}$$

Proof of Theorem 2.5. Let $\mathcal{G}$ be the functional defined by the right-hand side of (2.38). We prove that, for every $u_k \to u$ in $L^1(]a,b[)$, we have

$$\mathcal{G}(u) \le \liminf_{k\to\infty} \mathcal{F}_1(u_k). \tag{2.40}$$

It is enough to consider sequences $\{u_k\}$ for which the liminf is a limit and has a finite value and $u_k \to u$ pointwise $\mathcal{L}^1$-a.e. in $]a,b[$. Then u_k belongs to $W^{2,1}(]a,b[)$ and (2.14) is satisfied. This implies that

$$|u'|(]a,b[) \le \liminf_{k\to\infty} \int_a^b |u_k'|\,dx. \tag{2.41}$$

Moreover, it follows from Theorem 2.4 that $u \in X^1_\psi(]a,b[)$ and that, up to a subsequence, $\{u_k'\}$ converges to $(u')^a$ pointwise $\mathcal{L}^1$-a.e. in $]a,b[$.

Let F be a finite subset of S_u. We want to prove that

$$|v'|(]a,b[\setminus F) + \sum_{x\in F} \Phi(\nu_u, (u')^a_-, (u')^a_+) \le \liminf_{k\to\infty} \int_a^b \psi(u_k')|u_k''|\,dx. \tag{2.42}$$

We write F as $\{x_1,\dots,x_m\}$, with $a < x_1 < \cdots < x_m < b$. For every $\varepsilon > 0$ there exists $\delta = \delta(\varepsilon) \in]0,\varepsilon[$ such that $a < x_1 - \delta < x_1 + \delta < x_2 - \delta < x_2 + \delta < \cdots < x_{m-1} - \delta < x_{m-1} + \delta < x_m - \delta < x_m + \delta < b$ and

$$|u(x_j-\delta) - u_-(x_j)| < \varepsilon, \quad |u(x_j+\delta) - u_+(x_j)| < \varepsilon, \tag{2.43}$$

$$|(u')^a(x_j-\delta) - (u')^a_-(x_j)| < \varepsilon, \quad |(u')^a(x_j+\delta) - (u')^a_+(x_j)| < \varepsilon, \tag{2.44}$$

$$u_k(x_j-\delta) \to u(x_j-\delta), \quad u_k(x_j+\delta) \to u(x_j+\delta) \quad \text{as} \quad k\to\infty, \tag{2.45}$$

$$u_k'(x_j-\delta) \to (u')^a(x_j-\delta), \quad u_k'(x_j+\delta) \to (u')^a(x_j+\delta) \quad \text{as} \quad k\to\infty, \tag{2.46}$$

$$|(u')^a(x_j-\delta)| + |(u')^a(x_j+\delta)| + \varepsilon < \frac{|[u](x_j)| - 4\varepsilon}{2\delta}$$

for $j = 1,\dots,m$.

Since $v_k \to v$ pointwise $\mathcal{L}^1$-a.e. in $]a,b[$ and $v_k' = \psi(u_k')u_k''$ $\mathcal{L}^1$-a.e. in $]a,b[$, we obtain

$$|v'|(]x_j+\delta, x_{j+1}-\delta[) \le \liminf_{k\to\infty} \int_{x_j+\delta}^{x_{j+1}-\delta} \psi(u_k')|u_k''|\,dx$$

for $j = 1,\dots,m-1$. A similar result holds for the intervals $]a,x_1-\delta[$ and $]x_m+\delta,b[$. Let F_δ be the union of the intervals $[x_j-\delta, x_j+\delta]$ for $j = 1,\dots,m$. Summing with respect to j and adding the contributions of the intervals $]a,x_1-\delta[$ and $]x_m+\delta,b[$, we obtain

$$|v'|(]a,b[\setminus F_\delta) \le \liminf_{k\to\infty} \int_{]a,b[\setminus F_\delta} \psi(u_k')|u_k''|\,dx. \tag{2.47}$$

We consider now the interval $I_j^\delta := [x_j-\delta, x_j+\delta]$, assuming that $[u](x_j) = u_+(x_j) - u_-(x_j) > 0$. By the mean value theorem there exists $y_{kj}^\delta \in]x_j-\delta, x_j+\delta[$ such that

$$u_k'(y_{kj}^\delta) = \frac{u_k(x_j+\delta) - u_k(x_j-\delta)}{2\delta} \ge \frac{[u](x_j) - 4\varepsilon}{2\delta}, \tag{2.48}$$

where the last inequality follows from (2.43) and (2.45) for k sufficiently large. By a change of variables we obtain

$$\int_{u_k'(x_j-\delta)}^{\frac{[u](x_j)-4\varepsilon}{2\delta}} \psi(t)\,dt \le \int_{x_j-\delta}^{y_{kj}^{\delta}} \psi(u_k')|u_k''|\,dx,$$
$$\int_{u_k'(x_j+\delta)}^{\frac{[u](x_j)-4\varepsilon}{2\delta}} \psi(t)\,dt \le \int_{y_{kj}^{\delta}}^{x_j+\delta} \psi(u_k')|u_k''|\,dx.$$

Adding these inequalities and taking the limit as $k\to\infty$ we obtain, thanks to (2.46),

$$\int_{(u')^a(x_j-\delta)}^{\frac{[u](x_j)-4\varepsilon}{2\delta}} \psi(t)\,dt + \int_{(u')^a(x_j+\delta)}^{\frac{[u](x_j)-4\varepsilon}{2\delta}} \psi(t)\,dt \le \liminf_{k\to\infty} \int_{x_j-\delta}^{x_j-\delta} \psi(u_k')|u_k''|\,dx. \tag{2.49}$$

Similarly, if $[u](x_j)<0$, then we have

$$\int_{\frac{[u](x_j)+4\varepsilon}{2\delta}}^{(u')^a(x_j-\delta)} \psi(t)\,dt + \int_{\frac{[u](x_j)+4\varepsilon}{2\delta}}^{(u')^a(x_j+\delta)} \psi(t)\,dt \le \liminf_{k\to\infty} \int_{x_j-\delta}^{x_j-\delta} \psi(u_k')|u_k''|\,dx. \tag{2.50}$$

From (2.47), (2.49), and (2.50) we deduce that

$$\begin{aligned}|v'|(]a,b[\setminus F_\delta) &+ \sum_{[u](x_j)>0}\left(\int_{(u')^a(x_j-\delta)}^{\frac{[u](x_j)-4\varepsilon}{2\delta}} \psi(t)\,dt + \int_{(u')^a(x_j+\delta)}^{\frac{[u](x_j)-4\varepsilon}{2\delta}} \psi(t)\,dt\right)\\ &+ \sum_{[u](x_j)<0}\left(\int_{\frac{[u](x_j)+4\varepsilon}{2\delta}}^{(u')^a(x_j-\delta)} \psi(t)\,dt + \int_{\frac{[u](x_j)+4\varepsilon}{2\delta}}^{(u')^a(x_j+\delta)} \psi(t)\,dt\right)\\ &\le \liminf_{k\to\infty}\int_a^b \psi(u_k')|u_k''|\,dx.\end{aligned}$$

Taking the limit as $\varepsilon\to 0$ (which implies $\delta(\varepsilon)\to 0$) we obtain (2.42), thanks to (2.44).

Since S_u is at most countable, (2.40) can be obtained from (2.42) by taking the supremum over all finite sets F contained in S_u.

Conversely, let $u\in X^1_\psi(]a,b[)$. We claim that there exists a sequence $\{u_k\}$ in $W^{2,1}(]a,b[)$ such that $u_k\to u$ in $L^1(]a,b[)$ and

$$\mathcal{G}(u) \ge \limsup_{k\to\infty} \mathcal{F}_1(u_k)\ . \tag{2.51}$$

It is clearly enough to consider the case $\mathcal{G}(u)<+\infty$.

We divide the proof into three steps.

Step 1. We prove (2.51) under the additional assumptions that $(u')^a$ is bounded and that $S_u=\{x_1,\dots,x_m\}$, with $x_1<\dots<x_m$. Note that, in this case, $Z[(u')^a]=\emptyset$ and, hence, $(u')^c=0$.

Construct a sequence $\{v_k\}$ in $W^{1,1}(]a,b[)$ such that $v_k\to v=\Psi_1\circ(u')^a$ pointwise $\mathcal{L}^1$-a.e. in $]a,b[$, $\Psi_1(-\|(u')^a\|_\infty)\le v_k\le\Psi_1(\|(u')^a\|_\infty)$, and

$$\int_a^b |v_k'(x)|\ dx \to |v'|(]a,b[)\,.$$

Setting $w_k:=\Psi_1^{-1}(v_k)$, we have $w_k\in W^{1,1}(]a,b[)$, thanks to (2.2),

$$w_k\to (u')^a \quad \text{pointwise } \mathcal{L}^1\text{-a.e. in }]a,b[, \tag{2.52}$$

and $\|w_k\|_\infty \le \left\|(u')^a\right\|_\infty$. Find $\delta_k \to 0^+$ such that

$$w_k\left(x_j-\delta_k\right) \to (u')^a_-\left(x_j\right), \quad w_k\left(x_j+\delta_k\right) \to (u')^a_+\left(x_j\right) \quad \text{for } j=1,\dots,m \tag{2.53}$$

and

$$\begin{gathered} \int_{x_{j-1}+\delta_k}^{x_j-\delta_k} |v_k'|\,dx \to |v'|(]x_{j-1},x_j[) \quad \text{for } j=2,\dots,m, \\ \int_a^{x_1-\delta_k} |v_k'|\,dx \to |v'|(]a,x_1[), \ \int_{x_m+\delta_k}^b |v_k'|\,dx \to |v'|(]x_m+\delta_k,b[). \end{gathered} \tag{2.54}$$

By (2.52) and by the dominated convergence theorem we have

$$u_+(x_{j-1}) + \int_{x_{j-1}+\delta_k}^{x_j-\delta_k} w_k(s)\,ds \longrightarrow u_+(x_{j-1}) + \int_{x_{j-1}}^{x_j} (u')^a\,ds = u_-(x_j) \tag{2.55}$$

for $j=2,\dots,m$, with the obvious changes for $j=1$ and $j=m+1$.

To deal with the jump point x_j, assume first that

$$u_+\left(x_j\right) - u_-\left(x_j\right) > 0. \tag{2.56}$$

In this case, we need to construct functions $f_{kj} \in C^2([x_j-\delta_k, x_j+\delta_k])$ that satisfy the following properties: There exists $y_{kj} \in]x_j-\delta_k, x_j+\delta_k[$ such that

$$f_{kj}\left(x_j-\delta_k\right) = u_+\left(x_{j-1}\right) + \int_{x_{j-1}+\delta_k}^{x_j-\delta_k} w_k\left(s\right)\,ds, \quad f_{kj}\left(x_j+\delta_k\right) = u_+\left(x_j\right), \tag{2.57}$$

$$f_{kj}'\left(x_j-\delta_k\right) = w_k\left(x_j-\delta_k\right), \quad f_{kj}'\left(x_j+\delta_k\right) = w_k\left(x_j+\delta_k\right), \tag{2.58}$$

$$f_{kj}''(x) > 0 \text{ for } x \in]x_j-\delta_k, y_{kj}[, \quad f_{kj}''(x) < 0 \text{ for } x \in]y_{kj}, x_j+\delta_k[, \tag{2.59}$$

$$\left|f_{kj}\left(x_j-\delta_k\right) - \min_{[x_j-\delta_k, y_{kj}]} f_{kj}\right| \le \tfrac{1}{k}, \quad \left|f_{kj}\left(x_j+\delta_k\right) - \max_{[y_{kj}, x_j+\delta_k]} f_{kj}\right| \le \tfrac{1}{k}, \tag{2.60}$$

where we replace x_{j-1} and $x_{j-1}-\delta_k$ by a in the case $j=1$.

We now discuss briefly the existence of such functions. We observe that the latter conditions in (2.57)–(2.59) imply that the graph of f_{kj} in the interval $[y_{kj}, x_j+\delta_k[$ lies below the straight line passing through the point $(x_j+\delta_k, u_+(x_j))$ with slope $w_k(x_j+\delta_k)$, i.e.,

$$f_{kj}(x) \le u_+(x_j) + w_k(x_j+\delta_k)(x-x_j-\delta_k)$$

for $x \in [y_{kj}, x_j+\delta_k[$. It is then easy to see that the inequality

$$u_+\left(x_j\right) - 2w_k\left(x_j+\delta_k\right)\delta_k - u_+\left(x_{j-1}\right) - \int_{x_{j-1}+\delta_k}^{x_j-\delta_k} w_k\left(s\right)\,ds > 0 \tag{2.61}$$

allows us to fulfill also the former conditions in (2.57)–(2.59), as well as (2.60). By (2.53), (2.55), and (2.56), inequality (2.61) is satisfied when δ_k is small enough.

If the left-hand side of (2.56) is negative, then we choose f_{kj} so that (2.57) and (2.58) hold, and there exists $y_{kj} \in]x_j-\delta_k, x_j+\delta_k[$ such that

$$\begin{gathered} f_{kj}''(x) < 0 \text{ for } x \in]x_j-\delta_k, y_{kj}[, \quad f_{kj}''(x) > 0 \text{ for } x \in]y_{kj}, x_j+\delta_k[, \\ \left|f_{kj}\left(x_j-\delta_k\right) - \max_{[x_j-\delta_k, x_j+\delta_k]} f_{kj}\right| \le \tfrac{1}{k}, \quad \left|f_{kj}\left(x_j+\delta_k\right) - \min_{[x_j-\delta_k, x_j+\delta_k]} f_{kj}\right| \le \tfrac{1}{k}. \end{gathered}$$

In the same way the construction is possible if δ_k is small enough.

We are now ready to define the approximating sequence

$$u_k(x) := \begin{cases} u_+(a) + \int_a^x w_k(s)\, ds & \text{if } a \le x < x_1 - \delta_k, \\ f_{kj}(x) & \text{if } x_j - \delta_k \le x < x_j + \delta_k,\ j = 1, \dots, m, \\ u_+(x_{j-1}) + \int_{x_{j-1}+\delta_k}^x w_k(s)\, ds & \text{if } x_{j-1} + \delta_k \le x < x_j - \delta_k,\ j = 2, \dots, m, \\ u_+(x_m) + \int_{x_m+\delta_k}^x w_k(s)\, ds & \text{if } x_m + \delta_k \le x < b. \end{cases}$$

Let us define $x_0 := a$ and $x_{m+1} := b$. Since $w_k \to (u')^a$ in $L^1(]a,b[)$, we have

$$u_k(x) \to u_+(x_{j-1}) + \int_{x_{j-1}}^x (u')^a(s)\, ds = u(x)$$

for every $x \in]x_{j-1}, x_j[$ and $j = 1, \dots, m+1$ and, in turn, $u_k \to u$ in $L^1(]a,b[)$. As

$$\begin{aligned} \int_{x_{j-1}+\delta_k}^{x_j-\delta_k} |u_k'|\, dx + \int_{x_{j-1}+\delta_k}^{x_j-\delta_k} \psi(u_k')\, |u_k''|\, dx &= \int_{x_{j-1}+\delta_k}^{x_j-\delta_k} |w_k|\, dx + \int_{x_{j-1}+\delta_k}^{x_j-\delta_k} \psi(w_k)\, |w_k'|\, dx \\ &\le \int_{x_{j-1}}^{x_j} |w_k|\, dx + \int_{x_{j-1}+\delta_k}^{x_j-\delta_k} |v_k'|\, dx, \end{aligned}$$

by (2.54) and the fact that $w_k \to (u')^a$ in $L^1(]a,b[)$ we have

$$\begin{aligned} &\limsup_{k\to\infty} \left(\int_{x_{j-1}+\delta_k}^{x_j-\delta_k} |u_k'|\, dx + \int_{x_{j-1}+\delta_k}^{x_j-\delta_k} \psi(u_k')\, |u_k''|\, dx \right) \\ &\qquad \le \int_{x_{j-1}}^{x_j} \left|(u')^a\right| dx + |v'|(]x_{j-1}, x_j[). \end{aligned} \tag{2.62}$$

Similarly,

$$\begin{aligned} &\limsup_{k\to\infty} \left(\int_a^{x_1-\delta_k} |u_k'|\, dx + \int_a^{x_1-\delta_k} \psi(u_k')\, |u_k''|\, dx \right) \\ &\qquad \le \int_a^{x_1} \left|(u')^a\right| dx + |v'|(]a, x_1[), \end{aligned} \tag{2.63}$$

$$\begin{aligned} &\limsup_{k\to\infty} \left(\int_{x_m+\delta_k}^{b} |u_k'|\, dx + \int_{x_m+\delta_k}^{b} \psi(u_k')\, |u_k''|\, dx \right) \\ &\qquad \le \int_{x_m}^{b} \left|(u')^a\right| dx + |v'|(]x_m, b[). \end{aligned} \tag{2.64}$$

Assume that $[u](x_j) = u_+(x_j) - u_-(x_j) > 0$. Then (2.56) holds for the functions u_k

if k is sufficiently large. By (2.58), (2.59), (2.60), and a change of variables we obtain

$$\begin{aligned}
&\int_{x_j-\delta_k}^{x_j+\delta_k} |u_k'|\ dx + \int_{x_j-\delta_k}^{x_j+\delta_k} \psi\left(u_k'\right) |u_k''|\ dx \\
&\qquad = \int_{x_j-\delta_k}^{x_j+\delta_k} |f_{kj}'|\, dx + \int_{x_j-\delta_k}^{x_j+\delta_k} \psi\left(f_{kj}'\right) \left|f_{kj}''\right|\ dx \\
&\qquad \le f_{kj}\left(x_j+\delta_k\right) - f_{kj}\left(x_j-\delta_k\right) + \int_{w_k(x_j-\delta_k)}^{f_{kj}'(y_{kj})} \psi\left(t\right)\ dt \\
&\qquad\quad + \int_{w_k(x_j+\delta_k)}^{f_{kj}'(y_{kj})} \psi\left(t\right)\ dt + \frac{2}{k}. \qquad (2.65)
\end{aligned}$$

By (2.59) we have

$$f_{kj}'\left(y_{kj}\right) = \max_{[x_j-\delta_k, x_j+\delta_k]} f_{kj}' \ge \frac{1}{2\delta_k}\left[f_{kj}\left(x_j+\delta_k\right) - f_{kj}\left(x_j-\delta_k\right)\right]. \qquad (2.66)$$

By (2.57) and the fact that $w_k \to (u')^a$ in $L^1\left(]a,b[\right)$ we obtain

$$f_{kj}\left(x_j+\delta_k\right) - f_{kj}\left(x_j-\delta_k\right) \to u_+\left(x_j\right) - \left(u_+\left(x_{j-1}\right) + \int_{x_{j-1}}^{x_j} \left(u'\right)^a\ ds\right) = [u]\left(x_j\right).$$

In turn, using (2.66), we get that $f_{kj}'\left(y_{kj}\right) \to \infty$. Thus, letting $k \to \infty$ in (2.65) and using (2.53), we infer

$$\begin{aligned}
&\limsup_{k\to\infty} \left(\int_{x_j-\delta_k}^{x_j+\delta_k} |u_k'|\ dx + \int_{x_j-\delta_k}^{x_j+\delta_k} \psi\left(u_k'\right) |u_k''|\ dx\right) \\
&\le [u]\left(x_j\right) + \int_{(u')_-^a\left(x_j\right)}^{+\infty} \psi\left(t\right)\ dt + \int_{(u')_+^a\left(x_j\right)}^{+\infty} \psi\left(t\right)\ dt. \qquad (2.67)
\end{aligned}$$

Similarly, if $[u]\left(x_j\right) = u_+\left(x_j\right) - u_-\left(x_j\right) < 0$, we find

$$\begin{aligned}
&\limsup_{k\to\infty} \left(\int_{x_j-\delta_k}^{x_j+\delta_k} |u_k'|\ dx + \int_{x_j-\delta_k}^{x_j+\delta_k} \psi\left(u_k'\right) |u_k''|\ dx\right) \\
&\le \left|[u]\left(x_j\right)\right| + \int_{-\infty}^{\left(u'\right)_-^a\left(x_j\right)} \psi\left(t\right)\ dt + \int_{-\infty}^{\left(u'\right)_+^a\left(x_j\right)} \psi\left(t\right)\ dt. \qquad (2.68)
\end{aligned}$$

Summing over j in (2.62), (2.67), and (2.68) and combining with (2.63) and (2.64), inequality (2.51) follows.

Step 2. Assume only that $u \in X_\psi^1(]a,b[)$ and that S_u is finite. We claim that there exists a sequence $\{u_k\}$ such that $u_k \to u$ in $L^1\left(]a,b[\right)$, each u_k satisfies the hypotheses of Step 1, and

$$\mathcal{G}\left(u\right) \ge \limsup_{k\to\infty} \mathcal{G}\left(u_k\right). \qquad (2.69)$$

Note that, if (2.69) holds, then, by applying Step 1 to each u_k, we may find a sequence $u_{km} \in W^{2,1}\left(]a,b[\right)$ converging to u_k in $L^1\left(]a,b[\right)$ and satisfying

$$\mathcal{G}\left(u_k\right) \ge \limsup_{m\to\infty} \mathcal{F}_1\left(u_{km}\right).$$

By (2.69) we then have

$$\mathcal{G}(u) \geq \limsup_{k\to\infty} \limsup_{m\to\infty} \mathcal{F}_1(u_{km}),$$

and a standard diagonalization argument now yields the existence of a sequence $m_k \to \infty$ such that $u_{km_k} \to u$ in $L^1(]a,b[)$ and

$$\mathcal{G}(u) \geq \limsup_{k\to\infty} \mathcal{F}_1(u_{km_k}).$$

In the construction of the sequence satisfying (2.69), we need to consider the precise representatives $(u')^a_\vee$ and $(u')^a_\wedge$ defined in Remark 2.2. We recall that $(u')^a_\vee$ is upper semicontinuous while $(u')^a_\wedge$ is lower semicontinuous, and so for each $k \in \mathbb{N}$ we may decompose the open sets $\{(u')^a_\wedge > k\}$ and $\{(u')^a_\vee < -k\}$ into the union of two finite sequences of pairwise disjoint open sets U^+_{kj} and U^-_{kj}, that is,

$$\bigcup_j U^+_{kj} = \{(u')^a_\wedge > k\}, \quad \bigcup_j U^-_{kj} = \{(u')^a_\vee < -k\},$$

such that

$$\text{diam}\left(U^+_{kj}\right) \leq \mathcal{L}^1(\{(u')^a_\wedge > k\}),\ \text{diam}\left(U^-_{kj}\right) \leq \mathcal{L}^1(\{(u')^a_\vee < -k\}) \tag{2.70}$$

for every j. Note that, setting $v_\vee := \Psi_1 \circ (u')^a_\vee$ and $v_\wedge := \Psi_1 \circ (u')^a_\wedge$, we have

$$|v'|(]c,d[) = \text{Var}(v_\vee;]c,d[) = \text{Var}(v_\wedge;]c,d[) \tag{2.71}$$

for every interval $]c,d[\subset]a,b[$.

For every set $U^\pm_{kj}$, we fix a nonnegative function $g^\pm_{kj} \in C^1_c(U^\pm_{kj})$ such that

$$\int_{U^\pm_{kj}} g^\pm_{kj}(x)\, dx = ((u')^c)^\pm\left(U^\pm_{kj}\right), \tag{2.72}$$

and $(g^\pm_{kj})'$ has only one zero in the interior of the support of $g^\pm_{kj}$. Then we define

$$g^+_k := \sum\nolimits_j g^+_{kj}, \quad g^-_k := \sum\nolimits_j g^-_{kj}, \quad g_k := g^+_k - g^-_k, \quad w_k := T^k_{-k} \circ (u')^a + g_k, \tag{2.73}$$

where, for any pair of constants $h < k$, the truncation function T^k_h is defined by

$$T^k_h(t) := \begin{cases} h & \text{for } t \leq h, \\ t & \text{for } h \leq t \leq k, \\ k & \text{for } t \geq k. \end{cases}$$

We claim that

$$w_k\, \mathcal{L}^1 \rightharpoonup (u')^a\, \mathcal{L}^1 + (u')^c \ \text{ weakly}^* \text{ in } M_b(]a,b[)\,. \tag{2.74}$$

Define

$$A_k := \left\{(u')^a_\wedge > k\right\} \cup \left\{(u')^a_\vee < -k\right\}.$$

Since by the Chebychev inequality

$$k\mathcal{L}^1(A_k) \to 0, \tag{2.75}$$

it suffices to show that

$$\left(\sum_j g_{kj}^{\pm}\right) \mathcal{L}^1 \rightharpoonup \left((u')^c\right)^{\pm} \text{ weakly}^* \text{ in } M_b\left(]a,b[\right). \tag{2.76}$$

Let $\varphi \in C_0\left(]a,b[\right)$ and $\varepsilon > 0$. By uniform continuity, there exists $\delta = \delta(\varepsilon) > 0$ such that $|\varphi(x) - \varphi(y)| \le \varepsilon$ for all $x,\ y \in]a,b[$ with $|x-y| \le \delta$. In view of (2.70) and (2.75), for all k sufficiently large and for all j we have that $\operatorname{diam}\left(U_{kj}^{\pm}\right) \le \delta$. Let us fix $y_{kj}^{\pm} \in U_{kj}^{\pm}$. Then by (2.72)

$$\begin{aligned}
&\Big| \int_{U_{kj}^{\pm}} \varphi(x)\, g_{kj}^{\pm}(x)\, dx - \int_{U_{kj}^{\pm}} \varphi(x)\, d\left((u')^c\right)^{\pm}(x) \Big| \\
&\qquad = \left| \int_{U_{kj}^{\pm}} \left[\varphi(x) - \varphi\left(y_{kj}^{\pm}\right)\right] g_{kj}^{\pm}(x)\, dx - \int_{U_{kj}^{\pm}} \left[\varphi(x) - \varphi\left(y_{kj}^{\pm}\right)\right]\, d\left((u')^c\right)^{\pm}(x) \right| \\
&\qquad \le \varepsilon \left(\int_{U_{kj}^{\pm}} g_{kj}^{\pm}(x)\, dx + \left((u')^c\right)^{\pm}\left(U_{kj}^{\pm}\right) \right) \le 2\varepsilon \left((u')^c\right)^{\pm}\left(U_{kj}^{\pm}\right).
\end{aligned}$$

Summing over j and using the fact that the measures $\left(\sum_j g_{kj}^{+}\right)\mathcal{L}^1$ and $\left((u')^c\right)^{+}$ are concentrated on $\{(u')_{\wedge}^a > k\}$, while the measures $\left(\sum_j g_{kj}^{-}\right)\mathcal{L}^1$ and $\left((u')^c\right)^{-}$ are concentrated on $\{(u')_{\vee}^a < -k\}$ (see Remark 2.2), we obtain (2.76).

Moreover, we claim that

$$\lim_{k\to\infty} \int_a^b |w_k|\, dx = \int_a^b |\,(u')^a\,|\, dx + |\,(u')^c\,|\,(]a,b[)\ . \tag{2.77}$$

Indeed, using (2.72), (2.73), and Remark 2.2, we deduce that

$$\begin{aligned}
\int_a^b |w_k|\, dx &\le \int_{\{|(u')^a| \le k\}} \left|(u')^a\right|\, dx + k\mathcal{L}^1(A_k) + \sum_j \int_{U_{kj}^{+}} g_{kj}^{+}\, dx + \sum_j \int_{U_{kj}^{-}} g_{kj}^{-}\, dx \\
&\le \int_a^b \left|(u')^a\right|\, dx + k\mathcal{L}^1(A_k) + \sum_j \left((u')^c\right)^{+}\left(U_{kj}^{+}\right) + \sum_j \left((u')^c\right)^{-}\left(U_{kj}^{-}\right) \\
&\le \int_a^b \left|(u')^a\right|\, dx + k\mathcal{L}^1(A_k) + \left|(u')^c\right|\left(]a,b[\right),
\end{aligned}$$

and the limit superior inequality follows from (2.75). The limit inferior inequality follows from (2.74) and the lower semicontinuity of the total variation.

Set

$$u_k(x) := u_+(a) + \int_a^x w_k(s)\, ds + \sum_{x_j < x,\, x_j \in S_u} [u](x_j) \tag{2.78}$$

and $v_k := \Psi_1 \circ (u_k')^a = \Psi_1 \circ w_k$.

We claim that $u_k \to u$ in $L^1(]a,b[)$. For $x \in]a,b[$ by (2.74) and (2.77) it follows that

$$\int_a^x w_k\,dy \to \int_a^x (u')^a\,dy + (u')^c(]a,x[),$$

and so u_k converges to u pointwise $\mathcal{L}^1$-a.e. and, in turn, in $L^1(]a,b[)$.

Next, we show that

$$\limsup_{k\to\infty} \mathcal{G}(u_k) \le \mathcal{G}(u). \tag{2.79}$$

From (2.77) we get

$$|u_k'|(]a,b[) \to |u'|(]a,b[)\ . \tag{2.80}$$

Moreover, as $v_k = T^{\Psi_1(k)}_{\Psi_1(-k)} \circ v$ $\mathcal{L}^1$-a.e. in the open set $V_k :=]a,b[\setminus \operatorname{supp} g_k$, we have $|v_k'| \le |v'|$ as measures in V_k. In particular, this yields $|v_k'|(]a,b[\setminus (A_k \cup S_u)) \le |v'|(]a,b[\setminus (A_k \cup S_u))$ and, hence,

$$|v_k'|(]a,b[\setminus (A_k \cup S_u)) \le |v'|(]a,b[\setminus (A_\infty \cup S_u))\ , \tag{2.81}$$

where

$$A_\infty := \bigcap_k A_k = \left\{(u')^a_\wedge = +\infty\right\} \cup \left\{(u')^a_\vee = -\infty\right\}.$$

Using the properties of g^+_{kj}, we have

$$\begin{aligned} |v_k'|\left(\left\{(u')^a_\wedge > k\right\} \setminus S_u\right) &= \sum_j \int_{U^+_{kj}} \psi\left(k + g^+_{kj}\right) \left|\left(g^+_{kj}\right)'\right| dx \\ &= 2\sum_j \int_k^{k+\sup g^+_{kj}} \psi(t)\,dt \le 2\mathcal{H}^0\left(\left\{j:\ ((u')^c)^+\left(U^+_{kj}\right) > 0\right\}\right) \int_k^\infty \psi(t)\ dt\,. \end{aligned} \tag{2.82}$$

We claim that

$$\begin{aligned} &2\mathcal{H}^0\left(\left\{j:\ ((u')^c)^+\left(U^+_{kj}\right) > 0\right\}\right) \int_k^\infty \psi(t)\ dt \\ &\qquad\qquad \le |v'|\left(\left\{(u')^a_\wedge > k\right\} \setminus S_u\right) + 4\int_k^\infty \psi(t)\ dt. \end{aligned}$$

Indeed, if $((u')^c)^+(U^+_{kj}) > 0$, then there exists a connected component $I^+_{kj} =]a_{kj}, b_{kj}[$ of $U^+_{kj} \setminus S_u$ such that $((u')^c)^+(I^+_{kj}) > 0$. Assume that $I^+_{kj} \subset\subset]a,b[$. Then by Remark 2.2 we may find $c_{kj} \in I^+_{kj}$ such that $(u')^a_\wedge(c_{kj}) = +\infty$, while $(u')^a_\wedge(a_{kj})$, $(u')^a_\wedge(b_{kj}) \le k$. Hence, by (2.71)

$$|v'|\left(U^+_{kj} \setminus S_u\right) \ge |v'|\left(I^+_{kj}\right) \ge 2\int_k^\infty \psi(t)\,dt.$$

Summing over all such intervals and adding the possible contribution of the intervals I^+_{kj} with at least one end point in $\{a,b\}$, we obtain the claim. In turn, by (2.82) we have

$$|v_k'|\left(\left\{(u')^a_\wedge > k\right\} \setminus S_u\right) \le |v'|\left(\left\{(u')^a_\wedge > k\right\} \setminus S_u\right) + 4\int_k^\infty \psi(t)\ dt.$$

A similar estimate holds for the set $\{(u')^a_\vee < -k\} \setminus S_u$, thus, yielding

$$\limsup_{k\to\infty} |v'_k|\,(A_k \setminus S_u) \le |v'|\,(A_\infty \setminus S_u)\ . \tag{2.83}$$

Combining (2.81) with (2.83) we obtain

$$\limsup_{k\to\infty} |v'_k|\,(]a,b[\setminus S_u) \le |v'|\,(]a,b[\setminus S_u)\ .$$

Next, we show that

$$\lim_{k\to\infty} \sum_{x\in S_{u_k}} \Phi\left(\nu_{u_k}, (u'_k)^a_-, (u'_k)^a_+\right) = \sum_{x\in S_u} \Phi\left(\nu_u, (u')^a_-, (u')^a_+\right). \tag{2.84}$$

Note that $S_{u_k} = S_u$ and $\nu_{u_k}(x) = \nu_u(x)$ for all k by (2.78). Moreover, for every $x \in S_u$ if $(u')^a_+(x) \in \mathbb{R}$, then $\left|(u')^a_+(y)\right| \le k_0$ for all y in a right neighborhood of x and for some integer k_0. Thus, by (2.73) and (2.78) we have that $(u'_k)^a(y) = (u')^a(y)$ for $k \ge k_0$ and for $\mathcal{L}^1$-a.e. y in the same right neighborhood. In turn, by (2.7) we infer $(u'_k)^a_+(x) = (u')^a_+(x)$ for all $k \ge k_0$. If $(u')^a_+(x) = \infty$, then for all k we have $(u')^a_+ > k$ in a right neighborhood of x by right continuity (see Remark 2.2). By construction this implies that $(u'_k)^a = w_k \ge k$ $\mathcal{L}^1$-a.e. in the same right neighborhood. Thus, $(u'_k)^a_+(x) \ge k \to (u')^a_+(x)$. Similarly, $(u'_k)^a_-(x) \to (u')^a_-(x)$ so that

$$\Phi\left(\nu_{u_k}(x), (u'_k)^a_-(x), (u'_k)^a_+(x)\right) \to \Phi\left(\nu_u(x), (u')^a_-(x), (u')^a_+(x)\right)\ .$$

Hence, (2.84) follows. This, together with (2.80) and (2.83), yields (2.79).

Step 3. Let now u be an arbitrary function in $X^1_\psi(]a,b[)$ such that $\mathcal{G}(u) < +\infty$. As in the previous step it suffices to construct $u_k \in X^1_\psi(]a,b[)$ satisfying the hypotheses of Step 2, converging to u in $L^1(]a,b[)$ and such that (2.79) holds. Write $S_u = \{x_j\}$, and for each k define $S^k_u := \{x_j : j \le k\}$ and

$$u_k(x) = u_+(a) + \int_a^x (u')^a\ dt + (u')^c(]a,x[) + \sum_{x_j<x,\, x_j\in S^k_u} [u](x_j)\,.$$

It is clear that $\{u_k\}$ converges to u in $L^1(]a,b[)$ and that $|u'_k|(]a,b[) \to |u'|(]a,b[)$. Moreover, $|v'_k|(]a,b[\setminus S_u) = |v'|(]a,b[\setminus S_u)$ and

$$\begin{aligned}\lim_{k\to\infty} \sum_{x\in S_{u_k}} \Phi\left(\nu_{u_k}, (u'_k)^a_-, (u'_k)^a_+\right) &= \lim_{k\to\infty} \sum_{x\in S^k_u} \Phi\left(\nu_u, (u')^a_-, (u')^a_+\right)\\ &= \sum_{x\in S_u} \Phi\left(\nu_u, (u')^a_-, (u')^a_+\right)\ .\end{aligned}$$

This concludes the proof of the theorem. □

We end the section with a compactness result for energy bounded sequences in $X^1_\psi(]a,b[)$.

COROLLARY 2.7. *Let $\{u_k\}$ be a sequence of functions in $X^1_\psi(]a,b[)$ bounded in $L^1(]a,b[)$ and such that*

$$C := \sup_k \overline{\mathcal{F}}_1(u_k) < +\infty. \tag{2.85}$$

Then there exist a subsequence (not relabeled) $\{u_k\}$ and a function $u \in X^1_\psi(]a,b[)$ such that

$$u_k \rightharpoonup u \quad \text{weakly}^* \text{ in } BV(]a,b[), \tag{2.86}$$

$$\Psi_1 \circ (u_k')^a \rightharpoonup \Psi_1 \circ (u')^a \quad \text{weakly}^* \text{ in } BV(]a,b[), \tag{2.87}$$

$$(u_k')^a \to (u')^a \quad \text{pointwise } \mathcal{L}^1\text{-a.e. in }]a,b[.$$

Proof. It is well known that convergence in measure is metrizable with the following metric:

$$d(u_1,u_2) := \int_a^b \frac{|u_1-u_2|}{1+|u_1-u_2|}\,dx,$$

where u_1 and u_2 are (equivalent classes of) measurable functions.

By Theorems 2.4 and 2.5, for every $k \in \mathbb{N}$ we may find $w_k \in W^{2,1}(]a,b[)$ such that

$$\int_a^b |u_k - w_k|\,dx \le \frac{1}{k}, \quad d((u_k')^a, w_k') \le \frac{1}{k}, \tag{2.88}$$

and

$$\mathcal{F}_1(w_k) \le C+1.$$

By Theorem 2.4 we may find a subsequence (not relabeled) of $\{w_k\}$ and a function $u \in X^1_\psi(]a,b[)$ such that (2.15), (2.16), and (2.17) hold (with w_k in place of u_k). It now follows from (2.88) that $u_k \to u$ in $L^1(]a,b[)$ and $(u_k')^a \to (u')^a$ in measure and, hence, pointwise $\mathcal{L}^1$-a.e. in $]a,b[$, up to a further subsequence. From the bound (2.85), the uniqueness of the limit, and the invertibility of Ψ_1, we deduce (2.86) and (2.87). ∎

3. The case $p > 1$. In this section we analyze the functional (1.3) in the case $p > 1$.

Let us state precisely the standing assumptions. Throughout this section p denotes any exponent in $]1,+\infty[$, $\psi\colon \mathbb{R} \to]0,+\infty[$ is a bounded Borel function satisfying

$$M := \int_{-\infty}^{+\infty} (\psi(t))^{1/p}\,dt < +\infty \tag{3.1}$$

in addition to (2.2), and $\Psi_p\colon \overline{\mathbb{R}} \to [0,M]$ denotes the antiderivative of $\psi^{1/p}$ defined by

$$\Psi_p(t) := \int_{-\infty}^{t} (\psi(s))^{1/p}\,ds. \tag{3.2}$$

The function $\Psi_p^{-1}\colon [0,M] \to \overline{\mathbb{R}}$ stands for the inverse function of Ψ_p.

We now consider the functional $\mathcal{F}_p\colon L^1(]a,b[) \to [0,+\infty]$ defined by

$$\mathcal{F}_p(u) := \begin{cases} \displaystyle\int_a^b |u'|\,dx + \int_a^b \psi(u')|u''|^p\,dx & \text{if } u \in W^{2,p}(]a,b[), \\ +\infty & \text{otherwise.} \end{cases} \tag{3.3}$$

It turns out that piecewise smooth functions with bounded derivative and nonempty discontinuity set cannot be approximated by sequences with equibounded energy. This is a consequence of Remark 3.2(i) and Theorem 3.3 below, and to this end we introduce a suitable space of functions. Recall that $Z^{\pm}[(u')^a]$ are the sets defined in (2.5) and (2.6), while $(u')^s$ denotes the singular part of the gradient measure u'.

DEFINITION 3.1. Let $X^p_\psi(]a,b[)$ be the set of all functions $u \in BV(]a,b[)$ such that $v := \Psi_p \circ (u')^a$ belongs to $W^{1,p}(]a,b[)$, and the positive part $((u')^s)^+$ and the negative part $((u')^s)^-$ of the measure $(u')^s$ are concentrated on $Z^+[(u')^a]$ and $Z^-[(u')^a]$, respectively.

Remark 3.2. (i) It follows immediately from the definition that if $u \in X^p_\psi(]a,b[)$, then $(u')^a = \Psi_p^{-1}(v)$ is continuous on $[a,b]$ with values in $\overline{\mathbb{R}}$. In particular, it turns out that

$$Z^{\pm}[(u')^a] = \{x \in]a,b[: (u')^a = \pm\infty\}.$$

By the hypothesis on the support of the singular part $(u')^s$, we have $\lim_{x\to x_0}(u')^a(x) = +\infty$ for every jump point x_0 with $u_+(x_0) - u_-(x_0) > 0$ and $\lim_{x\to x_0}(u')^a(x) = -\infty$ for every jump point x_0 with $u_+(x_0) - u_-(x_0) < 0$. This means that if S_u is nonempty, then u cannot have bounded derivative outside the discontinuity set. In particular, piecewise constant functions are not included in the class $X^p_\psi(]a,b[)$.

(ii) We observe that the function $(u')^a$ is differentiable $\mathcal{L}^1$-a.e. in $]a,b[$ with

$$v' = \psi^{\frac{1}{p}}\left((u')^a\right)\left((u')^a\right)'. \tag{3.4}$$

To see this, we consider the open set

$$A_k := \{x \in]a,b[: -k < (u')^a < k\}.$$

Since by (2.2) the function Ψ_p^{-1} is Lipschitz continuous in the interval $[\Psi_p(-k), \Psi_p(k)]$ and $v \in W^{1,p}(]a,b[)$, by the chain rule, we have that $(u')^a = \Psi_p^{-1} \circ v \in W^{1,p}(A_k)$ and, in particular, it is differentiable $\mathcal{L}^1$-a.e. in A_k, and (3.4) holds. Since $(u')^a$ is integrable, we have that

$$\mathcal{L}^1\left(]a,b[\setminus \bigcup_k A_k\right) = 0,$$

and the conclusion follows.

(iii) It is easy to check that $X^p_\psi(]a,b[)$ may contain discontinuous functions. An example is given by the following construction: Let $\psi\colon \mathbb{R} \to]0,+\infty[$ be defined by

$$\psi(t) := \begin{cases} 1 & \text{if } |t| \le 1, \\ \dfrac{1}{|t|^\alpha} & \text{if } |t| > 1, \end{cases}$$

where α is any number in $]1,+\infty[$, and let $p \in]1, \frac{\alpha+1}{2}[$. Consider now the discontinuous functions $u\colon]-1,1[\to \mathbb{R}$ given by

$$u(x) := \begin{cases} -|x|^\beta & \text{if } x \le 0, \\ 1 + x^\beta & \text{if } x > 0, \end{cases}$$

with

$$0 < \beta < 1 - \frac{p-1}{\alpha - p}.$$

A simple computation shows that the function $\Psi_p \circ (u')^a$ belongs to $W^{1,p}(]-1,1[)$, which in turn implies that $u \in X^p_\psi(]-1,1[)$.

(iv) Finally, the same construction of Proposition 2.3 shows that, for every admissible ψ satisfying (2.9), the space $X^p_\psi(]a,b[)$ contains a function with nontrivial Cantor part if p is sufficiently close to 1. We omit the details of this fact, which can be easily checked following step by step the proof of Proposition 2.3.

The next theorem is the counterpart of Theorem 2.4 for the case $p > 1$. It establishes that energy bounded sequences are relatively compact in $X^p_\psi(]a,b[)$. The proof is similar to the one of Theorem 2.4; nevertheless, since this is the main result of this section we reproduce it in full detail for the reader's convenience.

THEOREM 3.3. *Let $\{u_k\}$ be a sequence of functions bounded in $L^1(]a,b[)$ and such that*

$$C := \sup_k \mathcal{F}_p(u_k) < +\infty. \tag{3.5}$$

Then there exist a subsequence (not relabeled) $\{u_k\}$ and a function $u \in X^p_\psi(]a,b[)$ such that

$$u_k \rightharpoonup u \quad \textit{weakly}^* \textit{ in } BV(]a,b[), \tag{3.6}$$

$$\Psi_p \circ u_k' \rightharpoonup \Psi_p \circ (u')^a \quad \textit{weakly in } W^{1,p}(]a,b[),$$

$$u_k' \to (u')^a \quad \textit{pointwise in }]a,b[. \tag{3.7}$$

Proof. By (3.3) and (3.5) we may assume that each u_k belongs to $W^{2,p}(]a,b[)$ and that

$$C_1 := \sup_k \int_a^b [\,|u_k| + |u_k'| + \psi(u_k')|u_k''|^p\,]\,dx < +\infty. \tag{3.8}$$

Let us define

$$v_k := \Psi_p \circ u_k'. \tag{3.9}$$

As Ψ_p is Lipschitz in $\mathbb{R}$, the functions v_k belong to $W^{1,p}(]a,b[)$ and

$$v_k' = (\psi(u_k'))^{1/p} u_k'' \qquad \mathcal{L}^1\text{-a.e. on }]a,b[. \tag{3.10}$$

It follows from (3.1) and (3.5) that

$$\int_a^b [\,|v_k|^p + |v_k'|^p\,]\,dx \le M^p(b-a) + C_1. \tag{3.11}$$

By (3.8) and (3.11), passing to a subsequence (not relabeled), we may assume that

$$u_k \rightharpoonup u \quad \text{weakly}^* \text{ in } BV(]a,b[)$$

and

$$v_k \rightharpoonup v \quad \text{weakly in } W^{1,p}(]a,b[) \tag{3.12}$$

for some functions $u \in BV(]a,b[)$ and $v \in W^{1,p}(]a,b[;[0,M])$.

Since Ψ_p^{-1} is continuous, we obtain

$$u_k' = \Psi_p^{-1} \circ v_k \to w := \Psi_p^{-1} \circ v \quad \text{pointwise in }]a,b[. \tag{3.13}$$

Note, also, that w is continuous with values in $\overline{\mathbb{R}}$.

We now split the remaining part of the proof into two steps.

Step 1. We prove that

$$w = (u')^a \quad \mathcal{L}^1\text{-a.e. on }]a,b[. \tag{3.14}$$

If not, arguing as for (2.27), we may find $t_0 > 0$ and an infinite number of disjoint open intervals I such that

$$\mathcal{L}^1\left(\{w \neq (u')^a\} \cap \{|w| < t_0\} \cap I\right) > 0. \tag{3.15}$$

By Hölder's inequality and a change of variables, we obtain

$$\begin{aligned} \int_I \psi(u_k')|u_k''|^p\,dx &\geq \frac{1}{\mathcal{L}^1(I)^{p-1}} \left(\int_I (\psi(u_k'))^{1/p}|u_k''|\,dx\right)^p \\ &\geq \frac{1}{(b-a)^{p-1}} \left(\int_{m_k}^{M_k} (\psi(t))^{1/p}\,dt\right)^p, \end{aligned} \tag{3.16}$$

where $m_k := \inf_I u_k'$ and $M_k := \sup_I u_k'$.

Reasoning as in the first step of the proof of Theorem 2.4, we can show that at least one of the two sequences $\{m_k\}$ and $\{M_k\}$ is divergent. If $\lim_k M_k = +\infty$, then by (3.13) $\limsup_k m_k < t_0$ and, in turn, from (3.16) we obtain

$$\liminf_{k\to\infty} \int_I \psi(u_k')|u_k''|^p\,dx \geq \frac{1}{(b-a)^{p-1}} \left(\int_{t_0}^{+\infty} (\psi(t))^{1/p}\,dt\right)^p > 0.$$

Analogously, if $\lim_k m_k = -\infty$, then

$$\liminf_{k\to\infty} \int_I \psi(u_k')|u_k''|^p\,dx \geq \frac{1}{(b-a)^{p-1}} \left(\int_{-\infty}^{t_0} (\psi(t))^{1/p}\,dt\right)^p > 0.$$

In any case, for an arbitrarily large number m of disjoint intervals I satisfying (3.15), adding the contributions of each interval we obtain

$$\begin{aligned} &\liminf_{k\to\infty} \int_a^b \psi(u_k')|u_k''|^p\,dx \\ &\qquad \geq \frac{m}{(b-a)^{p-1}} \min\left\{\left(\int_{t_0}^{+\infty} (\psi(t))^{1/p}\,dt\right)^p, \left(\int_{-\infty}^{t_0} (\psi(t))^{1/p}\,dt\right)^p\right\}, \end{aligned}$$

which contradicts (3.8) for m large enough. This concludes the proof of (3.14) and, in turn, of (3.7).

Step 2. To prove that $u \in X_\psi^p(]a,b[)$, it remains to show that the positive part $((u')^s)^+$ and the negative part $((u')^s)^-$ of the measure $(u')^s$ are concentrated on $Z^+[(u')^a]$ and $Z^-[(u')^a]$, respectively.

Arguing as in Step 2 of the proof of Theorem 2.4, one can see that it is enough to show

$$E^+[u'] \setminus Z^+[(u')^a] \text{ and } E^-[u'] \setminus Z^-[(u')^a] \text{ are empty,} \tag{3.17}$$

where $E^+[u']$ and $E^-[u']$ are the sets introduced in (2.32) and (2.33). We show only that $E^+[u'] \setminus Z^+[(u')^a]$ is empty, since the other property can be proved in the same way.

Assume, by contradiction, that $E^+[u'] \setminus Z^+[(u')^a]$ contains a point x_0. Denote $t_0 := 2|w(x_0)|$, fix any $t_1 > t_0$, and choose $\varepsilon_0 > 0$ such that

$$\frac{1}{(2\varepsilon_0)^{p-1}} \left(\int_{t_0}^{t_1} (\psi(t))^{1/p}\, dt \right)^p > C, \tag{3.18}$$

where C is the constant appearing in (3.5). By (2.32) there exists $0 < \varepsilon < \varepsilon_0$ such that

$$\frac{(u')^+ (]x_0 - \varepsilon, x_0 + \varepsilon[)}{2\varepsilon} > t_1. \tag{3.19}$$

Set $I :=]x_0 - \varepsilon, x_0 + \varepsilon[$. By Hölder's inequality and a change of variables (see (3.16)), we obtain

$$\int_I \psi(u_k')|u_k''|^p\, dx \geq \frac{1}{(2\varepsilon_0)^{p-1}} \left(\int_{m_k}^{M_k} (\psi(t))^{1/p}\, dt \right)^p, \tag{3.20}$$

where $m_k := \inf_I u_k'$ and $M_k := \sup_I u_k'$. By (3.13) and the fact that $w(x_0) < t_0$, we deduce that

$$\limsup_{k\to\infty} m_k < t_0. \tag{3.21}$$

On the other hand, reasoning as at the end of the proof of Theorem 2.4, we deduce from (3.6) and (3.19) that

$$\liminf_{k\to\infty} \frac{1}{2\varepsilon} \int_{x_0-\varepsilon}^{x_0+\varepsilon} (u_k')^+\, dx \geq \frac{(u')^+ (]x_0 - \varepsilon, x_0 + \varepsilon[)}{2\varepsilon} > t_1,$$

which implies that

$$\liminf_{k\to\infty} M_k > t_1. \tag{3.22}$$

From (3.18), (3.20), (3.21), and (3.22) we obtain

$$\liminf_{k\to\infty} \int_I \psi(u_k')|u_k''|^p\, dx \geq \frac{1}{(2\varepsilon_0)^{p-1}} \left(\int_{t_0}^{t_1} (\psi(t))^{1/p}\, dt \right)^p > C,$$

which contradicts (3.8). This shows (3.17) and concludes the proof of the theorem. □

We next identify the relaxation of $\mathcal{F}_p$ with respect to strong convergence in $L^1(]a, b[)$.

THEOREM 3.4. *Let $\overline{\mathcal{F}}_p \colon L^1(]a, b[) \to [0, +\infty]$ be defined by*

$$\overline{\mathcal{F}}_p(u) := \inf \left\{ \liminf_{k\to\infty} \mathcal{F}_p(u_k) : u_k \to u \text{ in } L^1(]a, b[) \right\} \tag{3.23}$$

for every $u \in L^1(]a,b[)$. *Then*

$$\overline{\mathcal{F}}_p(u) = \begin{cases} |u'|(]a,b[) + \displaystyle\int_a^b |v'|^p \, dx & \text{if } u \in X^p_\psi(]a,b[), \\ +\infty & \text{otherwise,} \end{cases} \tag{3.24}$$

where $v := \Psi_p \circ (u')^a$.

Proof. We sketch the proof focusing only on the main changes with respect to the proof of Theorem 2.5. Let $\mathcal{G}_p$ be the functional defined by the right-hand side of (3.24).

We start by showing that

$$\mathcal{G}_p(u) \le \liminf_{k\to\infty} \mathcal{F}_p(u_k) \tag{3.25}$$

whenever $u_k \to u$ in $L^1(]a,b[)$. It is enough to consider sequences $\{u_k\}$ for which the liminf is a limit and has a finite value. Then u_k belongs to $W^{2,1}(]a,b[)$ and (3.5) is satisfied. Setting $v_k := \Psi_p \circ u_k'$, by Theorem 3.3, we have $v_k \rightharpoonup v$ weakly in $W^{1,p}(]a,b[)$. Using the fact that $|v_k'|^p = \psi(u_k')|u_k''|^p$, we deduce that

$$\int_a^b |v'|^p \, dx \le \liminf_{k\to\infty} \int_a^b \psi(u_k')|u_k''|^p \, dx. \tag{3.26}$$

Inequality (3.25) follows now from (3.26) and the lower semicontinuity of the total variation.

We split the proof of the limsup inequality into several steps.

Step 1. Let $u \in X^p_\psi(]a,b[)$ be such that $(u')^s = 0$. We claim that there exists a sequence $\{u_k\}$ in $W^{2,p}(]a,b[)$ such that $u_k \to u$ in $L^1(]a,b[)$ and

$$\limsup_{k\to\infty} \mathcal{F}_p(u_k) \le \mathcal{G}_p(u). \tag{3.27}$$

Define $w_k := ((u')^a \vee -k) \wedge k$. Using the fact that $(u')^a \in W^{1,p}(A_{2k})$, where

$$A_{2k} := \{x \in]a,b[: -2k < (u')^a < 2k\}$$

as observed in Remark 3.2(ii), one sees that $w_k \in W^{1,p}(]a,b[)$. Define

$$u_k(x) := u_+(a) + \int_a^x w_k(y) \, dy.$$

It is easy to see that $u_k \to u$ in $L^1(]a,b[)$ and (3.27) holds.

Step 2. Assume that $u \in X^p_\psi(]a,b[)$, $(u')^c = 0$, and S_u is finite. We claim that there exists a sequence $\{u_k\}$ of functions in $X^p_\psi(]a,b[)$, with $(u_k')^s = 0$, such that $u_k \to u$ in $L^1(]a,b[)$ and

$$\limsup_{k\to\infty} \mathcal{G}_p(u_k) \le \mathcal{G}_p(u). \tag{3.28}$$

Since the construction is local, it is enough to consider the case $S_u = \{x_0\}$ for some $x_0 \in]a,b[$ with $[u](x_0) > 0$. By the properties of $X^p_\psi(]a,b[)$, we can find two sequences $x_k \nearrow x_0$ and $y_k \searrow x_0$ such that

$$u(x_k) \to u_-(x_0), \quad u(y_k) \to u_+(x_0), \text{ and } (u')^a(x_k) = (u')^a(y_k) \to (u')^a(x_0) = +\infty.$$

Consider the affine functions $h_k(x) := u(x_k) + (u')^a(x_k)(x - x_k)$. For every k sufficiently large there exists $z_k \in]x_k, b[$ such that $h_k(z_k) = u_+(x_0)$. Since $(u')^a(x_k) \to +\infty$ and $x_k \to x_0$, we have that $z_k \to x_0$ as $k \to \infty$. Define

$$u_k(x) := \begin{cases} u(x) & \text{if } a < x \le x_k, \\ h_k(x) & \text{if } x_k < x \le z_k, \\ u(x + y_k - z_k) + u_+(x_0) - u(y_k) & \text{if } z_k < x < b. \end{cases}$$

Using the fact that $(u')^a(x_k) = (u')^a(y_k)$, it is easy to check that $u_k \in X^p_\psi(]a, b[)$, with $(u_k')^s = 0$, $u_k \to u$ in $L^1(]a, b[)$, and (3.28) holds.

Step 3. Assume that $u \in X^p_\psi(]a, b[)$ and $(u')^c = 0$. We claim that there exists a sequence of functions u_k in $X^p_\psi(]a, b[)$, with $(u_k')^c = 0$ and S_{u_k} finite, such that $u_k \to u$ in $L^1(]a, b[)$ and (3.28) holds.

To see this, it is enough to consider the same approximation constructed in Step 3 of the proof of Theorem 2.5.

Step 4. Assume that $u \in X^p_\psi(]a, b[)$. We claim that there exists a sequence of functions u_k in $X^p_\psi(]a, b[)$, with $(u_k')^c = 0$, such that $u_k \to u$ in $L^1(]a, b[)$ and (3.28) holds.

Since $(u')^a$ is continuous from $]a, b[$ into $\overline{\mathbb{R}}$ and integrable (see Remark 3.2), we have that $K := \{x \in]a, b[: |(u')^a| = +\infty\}$ is relatively closed in $]a, b[$ with zero $\mathcal{L}^1$ measure. Hence, we may find a sequence of open sets $A_k \subset]a, b[$ such that $A_k \searrow K$. Let $\{I_j^k\}_j$ be the collection of all connected components of A_k intersecting K. Let $c_j^k := (u')^s(I_j^k) > 0$. By the properties of $X^p_\psi(]a, b[)$, for every j we may choose $x_j^k \in I_j^k \cap K$ such that $(u')^a(x_j^k) = +\infty$ if $c_j^k > 0$ and $(u')^a(x_j^k) = -\infty$ if $c_j^k < 0$. Define

$$u_k(x) := u_+(a) + \int_a^x (u')^a(y)\, dy + \sum_{j:\, x_j^k \le x} c_j^k.$$

Using the definition of $X^p_\psi(]a, b[)$, one can check that

$$\sum_j c_j^k \delta_{x_j^k} \rightharpoonup (u')^s \quad \text{weakly}^* \text{ in } M_b(]a, b[)$$

and $|\sum_j c_j^k \delta_{x_j^k}|(]a, b[) \to |(u')^s|(]a, b[)$ as $k \to \infty$. Using this fact it is easy to see that the sequence $\{u_k\}$ meets all of the requirements.

By combining Steps 1–4 with a diagonal argument, one can finally prove that (3.27) holds for every u in $X^p_\psi(]a, b[)$. ∎

Corollary 3.5. *Let $\{u_k\}$ be a sequence of functions in $X^p_\psi(]a, b[)$ bounded in $L^1(]a, b[)$ and such that*

$$C := \sup_k \overline{\mathcal{F}}_p(u_k) < +\infty. \tag{3.29}$$

Then there exists a subsequence (not relabeled) $\{u_k\}$ and a function $u \in X^p_\psi(]a, b[)$ such that

$$u_k \rightharpoonup u \quad \textit{weakly}^* \textit{ in } BV(]a, b[), \tag{3.30}$$

$$\Psi_p \circ (u_k')^a \rightharpoonup \Psi_p \circ (u')^a \quad \textit{weakly in } W^{1,p}(]a, b[), \tag{3.31}$$

$$(u_k')^a \to (u')^a \quad \textit{pointwise in }]a, b[. \tag{3.32}$$

Proof. With an argument entirely similar to the one used in the proof of Corollary 2.7 we can extract a subsequence $\{u_k\}$ which satisfies (3.30) and (3.31). In turn, (3.31) and the continuity of Ψ_p^{-1} in $\overline{\mathbb{R}}$ imply (3.32). □

4. The staircase effect. The purpose of this section is to show analytically that the presence of the higher order term in the functional $\overline{\mathcal{F}}$ prevents the occurrence of the so-called *staircase effect*, as opposed to what happens in image reconstructions based on the total variation functional.

4.1. The Rudin–Osher–Fatemi model. We start by showing that staircase-like structures do appear in solutions to the Rudin–Osher–Fatemi problem, i.e., in minimizers for the functional $\mathrm{ROF}_{\lambda,g} : BV(]a,b[) \to \mathbb{R}$ defined by

$$\mathrm{ROF}_{\lambda,g}(w) := |w'|(]a,b[) + \lambda \int_a^b (w-g)^2\,dx,$$

where $\lambda > 0$ is the *fidelity parameter* and $g \in L^2(]a,b[)$ is the given "signal" to be processed. This fact is well known and numerically observed in many situations. We provide here a simple analytical example. A different example is provided in [12], and a more detailed analysis on the nature of the staircase effect in the Rudin–Osher–Fatemi model can be found in a recent paper of Caselles, Chambolle, and Novaga [4]. Our example will be constructed by means of the following proposition which deals with minimizers of $\mathrm{ROF}_{\lambda,g}$ when g is a monotone function.

PROPOSITION 4.1. *Let $g : [a,b] \to [0,1]$ be a nondecreasing function such that $g_+(a) = 0$ and $g_-(b) = 1$. Let g^{-1} denote the left-continuous generalized inverse of g, defined by*

$$g^{-1}(c) := \inf\{x \in [a,b] :\ g(x) \geq c\} \tag{4.1}$$

for every $c \in [0,1]$, and assume that there exist $0 < c_1 < c_2 < 1$ such that

$$2\lambda \int_a^{g^{-1}(c_1)} (c_1 - g(x))\,dx = 1 \qquad \text{and} \qquad 2\lambda \int_{g^{-1}(c_2)}^b (g(x) - c_2)\,dx = 1. \tag{4.2}$$

Then the function u, defined by

$$u(x) := \begin{cases} c_1 & \text{if } a \leq x \leq g^{-1}(c_1), \\ g(x) & \text{if } g^{-1}(c_1) < x \leq g^{-1}(c_2), \\ c_2 & \text{if } g^{-1}(c_2) < x \leq b, \end{cases}$$

is the unique minimizer of $\mathrm{ROF}_{\lambda,g}$ in $BV(]a,b[)$.

Remark 4.2. Since

$$\int_a^{g^{-1}(c)} (c - g(x))\,dx = \int_0^c g^{-1}(y)\,dy, \qquad \int_{g^{-1}(c)}^b (g(x) - c)\,dx = \int_c^1 g^{-1}(y)\,dy$$

for all $c \in [0,1]$, the continuity of the integral implies that condition (4.2) is satisfied for every λ sufficiently large.

Proof of Proposition 4.1. We split the proof into two steps.

Step 1. We assume first that u is absolutely continuous. In order to prove the minimality of u, by density it suffices to show that $\mathrm{ROF}_{\lambda,g}(u+\varphi) \geq \mathrm{ROF}_{\lambda,g}(u)$ for

every $\varphi \in C^1([a,b])$, which, in turn, due to the convexity of $\mathrm{ROF}_{\lambda,g}$, is equivalent to proving that

$$\frac{d^+}{d\varepsilon}\mathrm{ROF}_{\lambda,g}(u+\varepsilon\varphi)\Big|_{\varepsilon=0} \geq 0 \quad \text{for every } \varphi \in C^1([a,b]), \tag{4.3}$$

where $\frac{d^+}{d\varepsilon}$ denotes the right derivative. By a straightforward computation, we have

$$\frac{d^+}{d\varepsilon}\mathrm{ROF}_{\lambda,g}(u+\varepsilon\varphi)\Big|_{\varepsilon=0} = \int_{\{u'=0\}} |\varphi'|\,dx + \int_{\{u'>0\}} \varphi'\,dx + 2\lambda\int_a^b (u-g)\varphi\,dx. \tag{4.4}$$

Consider now the function $\theta : [a,b] \to [0,1]$ defined by $\theta(x) := 2\lambda\int_a^x (u-g)\,dt$. Using (4.2) and the definition of u, one can check that $\theta(a) = \theta(b) = 0$, $0 \leq \theta \leq 1$, and $\theta \equiv 1$ in $[g^{-1}(c_1), g^{-1}(c_2)]$. In particular, $\{u' > 0\} \subset [g^{-1}(c_1), g^{-1}(c_2)] \subset \{\theta = 1\}$ so that by (4.4)

$$\frac{d^+}{d\varepsilon}\mathrm{ROF}_{\lambda,g}(u+\varepsilon\varphi)\Big|_{\varepsilon=0} \geq \int_a^b \varphi'\theta\,dx + 2\lambda\int_a^b (u-g)\varphi\,dx = 0,$$

where the last equality is obtained by integrating by parts and by using the fact that $\theta' = 2\lambda(u-g)$ and $\theta(a) = \theta(b) = 0$. This shows (4.3) and concludes the proof of Step 1.

Step 2. In the general case, we construct a sequence $\{g_k\} \subset AC([g^{-1}(c_1), g^{-1}(c_2)])$ of nondecreasing functions such that $g_k(g^{-1}(c_1)) = c_1$, $g_k(g^{-1}(c_2)) = c_2$, and $g_k \to g$ in $L^2([g^{-1}(c_1), g^{-1}(c_2)])$. Let $\tilde{g}_k$ be the function coinciding with g_k in $[g^{-1}(c_1), g^{-1}(c_2)]$ and with g elsewhere in $[a,b]$, and, analogously, let u_k coincide with g_k in the interval $[g^{-1}(c_1), g^{-1}(c_2)]$ and with u elsewhere. For any $v \in BV(]a,b[)$, by applying the previous step we obtain

$$\mathrm{ROF}_{\lambda,\tilde{g}_k}(v) \geq \mathrm{ROF}_{\lambda,\tilde{g}_k}(u_k) = \mathrm{ROF}_{\lambda,g}(u).$$

The minimality of u follows by letting $k \to \infty$. Finally, uniqueness is a consequence of the strict convexity of $\mathrm{ROF}_{\lambda,g}$. ∎

As a corollary of the previous result, we can prove analytically the occurrence of the staircase effect in a very simple case. Let $g(x) := x$, $x \in [0,1]$, be the original 1D image to which we add the "noise"

$$h_n(x) := \frac{i}{n} - x \qquad \text{if } \frac{i-1}{n} \leq x < \frac{i}{n}, \ \ i = 1, \ldots, n,$$

where $n \in \mathbb{N}$, so that the resulting degraded 1D image is given by the staircase function

$$g_n(x) := \frac{i}{n} \qquad \text{if } \frac{i-1}{n} \leq x < \frac{i}{n}, \quad i = 1, \ldots, n. \tag{4.5}$$

Note that, even though $h_n \to 0$ uniformly, the reconstructed image u_n preserves the staircase structure of g_n. Indeed, we show that there exists a nondegenerate interval $I \subset [0,1]$ such that each u_n coincides with the degraded 1D image g_n in I for all $n \in \mathbb{N}$. More precisely, we have the following theorem.

THEOREM 4.3 (staircase effect). *Let $\lambda > 4$, let g_n be as in (4.5), and let u_n be the unique minimizer of $\mathrm{ROF}_{\lambda,g_n}$ in $BV(]0,1[)$. Then for all n sufficiently large there exist $0 < a_n < b_n < 1$, with*

$$a_n \to \frac{1}{\sqrt{\lambda}}, \quad b_n \to 1 - \frac{1}{\sqrt{\lambda}}$$

as $n \to \infty$, such that $u_n = g_n$ on $[a_n, b_n]$ and u_n is constant on each interval $[0, a_n)$ and $(b_n, 1]$.

Proof. Let g_n^{-1} denote the generalized inverse function of g_n defined by (4.1) with g replaced by g_n. As both $\{g_n\}$ and $\{g_n^{-1}\}$ converge uniformly to $g(x) = x$ and since $\lambda > 4$, one can check that for n large enough there exist $0 < c_1^{(n)} < c_2^{(n)} < 1$ satisfying

$$2\lambda \int_0^{g_n^{-1}\left(c_1^{(n)}\right)} \left(c_1^{(n)} - g_n\right) dx = 1 \qquad \text{and} \qquad 2\lambda \int_{g_n^{-1}\left(c_2^{(n)}\right)}^1 \left(g_n - c_2^{(n)}\right) dx = 1$$

with $c_1^{(n)} \to c_1$ and $c_2^{(n)} \to c_2$ as $n \to \infty$, where c_1 and c_2 are defined by

$$2\lambda \int_0^{c_1} (c_1 - x)\, dx = 1 \qquad \text{and} \qquad 2\lambda \int_{c_2}^1 (x - c_2)\, dx = 1. \tag{4.6}$$

By Proposition 4.1, the unique minimizer u_n of $\mathrm{ROF}_{\lambda, g_n}$ in $BV(]0,1[)$ takes the form

$$u_n(x) = \begin{cases} c_1^{(n)} & \text{if } 0 \le x \le g_n^{-1}\left(c_1^{(n)}\right), \\ g_n(x) & \text{if } g_n^{-1}\left(c_1^{(n)}\right) < x \le g_n^{-1}\left(c_2^{(n)}\right), \\ c_2^{(n)} & \text{if } g_n^{-1}\left(c_2^{(n)}\right) < x \le 1. \end{cases}$$

The conclusion follows by observing that $a_n := g_n^{-1}(c_1^{(n)}) \to c_1$ and $b_n := g_n^{-1}(c_2^{(n)}) \to c_2$ and that $c_1 = \frac{1}{\sqrt{\lambda}}$ and $c_2 = 1 - \frac{1}{\sqrt{\lambda}}$, thanks to (4.6). ∎

4.2. Absence of the staircase effect: The case $p = 1$. Next, we show that the presence of the higher order term in the functional $\overline{\mathcal{F}}_1$ prevents the occurrence of the staircase effect. We begin with the case $p = 1$. We consider the minimization problem

$$\min\left\{\overline{\mathcal{F}}_1(u) + \lambda \int_a^b (u - g)^2\, dx :\ u \in X^1_\psi(]a,b[)\right\}, \tag{4.7}$$

where $\overline{\mathcal{F}}_1$ is the relaxed functional given in (2.38). To prove the absence of the staircase effect we need the following auxiliary result that is of independent interest.

PROPOSITION 4.4. *Assume that $\psi\colon \mathbb{R} \to]0, +\infty[$ is a bounded Borel function satisfying* (2.1) *and* (2.2). *Let $g : [a,b] \to \mathbb{R}$ be Lipschitz continuous, and let $u \in X^1_\psi(]a,b[)$ be a solution of the minimization problem* (4.7). *Then u is Lipschitz continuous and $u' \in BV(]a,b[)$.*

Proof. The plan of the proof is the following. We will show that the discontinuity set S_u is empty and that the left and right limits $(u')^a_-$ and $(u')^a_+$, respectively, defined in (2.7), are finite everywhere on $]a,b]$ and on $[a,b[$, respectively. Note that this will imply that the sets $Z^{\pm}[(u')^a]$ (see (2.5) and (2.6)) are empty and, in turn, that $u \in W^{1,1}(]a,b[)$ by the properties of the space $X^1_\psi(]a,b[)$. Moreover, recalling that the functions $(u')^a_\vee$ and $(u')^a_\wedge$ defined in Remark 2.2 are upper and lower semicontinuous on $[a,b]$, it will also follow that both $(u')^a_-$ and $(u')^a_+$ are bounded, yielding the Lipschitz continuity of u. In turn, the fact that $u' \in BV(]a,b[)$ is a consequence of the local Lipschitz continuity of Ψ_1^{-1}.

Step 1. We start by showing that S_u is empty. We argue, by contradiction, assuming that S_u contains a point x_0. Without loss of generality, we may suppose that

$\nu_u(x_0) = 1$; i.e., $u_+(x_0) > u_-(x_0)$. We also assume that $\frac{1}{2}(u_+(x_0) + u_-(x_0)) \geq g(x_0)$. In the following, it is convenient to think of u as coinciding everywhere with its lower semicontinuous representative $u_\wedge := \min\{u_-, u_+\}$.

Find $\varepsilon > 0$ so small that

$$\sum_{\substack{x \in S_u \\ x \in]x_0, x_0+\varepsilon[}} |[u](x)| < \frac{[u](x_0)}{4}, \tag{4.8}$$

and let $C > 0$ satisfy

$$C > 2\|g'\|_\infty \quad \text{and} \quad \frac{1}{2}(u_+(x_0) + u_-(x_0)) + C\varepsilon > u_-(x_0 + \varepsilon). \tag{4.9}$$

For $t \in [0, 1]$ consider the affine function

$$h^t(x) := \frac{(1-t)}{2}(u_+(x_0) + u_-(x_0)) + t\left(\frac{1}{4}u_-(x_0) + \frac{3}{4}u_+(x_0)\right) + C(x - x_0)$$

and note that, by (4.9), there exists $x^t \in]x_0, x_0 + \varepsilon[$ such that

$$\left(x^t, h^t\left(x^t\right)\right) \in \Gamma_u \quad \text{and} \quad g < h^t < u \text{ in } \left]x_0, x^t\right[, \tag{4.10}$$

where Γ_u stands for the extended graph of u defined by

$$\Gamma_u := \{(x, t) \in]a, b[\times \mathbb{R} : \min\{u_-(x), u_+(x)\} \leq t \leq \max\{u_-(x), u_+(x)\}\}.$$

Let u^t be the function defined by

$$u^t(x) := \begin{cases} h^t(x) & \text{if } x \in]x_0, x^t[, \\ u(x) & \text{otherwise,} \end{cases} \tag{4.11}$$

and note that

$$\lambda\left(\int_a^b |u - g|^2\, dx - \int_a^b |u^t - g|^2\, dx\right) \geq \lambda\left(\int_a^b |u - g|^2\, dx - \int_a^b |u^1 - g|^2\, dx\right) =: \eta > 0 \tag{4.12}$$

for every $t \in [0, 1]$. Now it is convenient to approximate u with functions having only finitely many jump points. Hence, the following approximation procedure is needed only when S_u is infinite. In this case, write $S_u = \{x_0, x_1, \ldots, x_j, \ldots\}$, for each k define $S_u^k := \{x_j : 0 \leq j \leq k\}$, and for $x \in]a, b[$ set

$$u_k(x) = u_+(a) + \int_a^x (u')^a\, dt + (u')^c(]a, x[) + \sum_{x_j < x,\, x_j \in S_u^k} [u](x_j).$$

Note that, since $u_k \to u$ in $L^\infty(]a, b[)$, for k large enough it follows from (4.9) and (4.10) that for every $t \in [0, 1]$ there exists $x_k^t \in]x_0, x_0 + \varepsilon[$ such that

$$\left(x_k^t, h^t\left(x_k^t\right)\right) \in \Gamma_{u_k} \quad \text{and} \quad g < h^t < u_k \text{ in } \left]x_0, x_k^t\right[,$$

where Γ_{u_k} denotes the extended graph of u_k. For all such k, we consider the comparison function u_k^t defined as in (4.11), with u and x^t replaced by u_k and x_k^t, respectively. Using the uniform convergence of $\{u_k\}$ to u and (4.10), we have that $x^t \le \liminf_k x_k^t$, which yields $u^t \ge \limsup_k u_k^t$ $\mathcal{L}^1$-a.e. on $]a,b[$. Moreover, $u_k \to u$ in $\overline{\mathcal{F}}_1$ energy. Hence, also by (4.12) we may find k so large that for $t \in [0,1]$

$$\lambda\left(\int_a^b |u_k-g|^2\,dx-\int_a^b |u_k^t-g|^2\,dx\right) \ge \lambda\left(\int_a^b |u_k-g|^2\,dx-\int_a^b |u_k^1-g|^2\,dx\right) \ge \frac{\eta}{2}, \tag{4.13}$$

$$\overline{\mathcal{F}}_1(u_k) + \lambda\int_a^b |u_k-g|^2\,dx \le \overline{\mathcal{F}}_1(u) + \lambda\int_a^b |u-g|^2\,dx + \frac{\eta}{4}. \tag{4.14}$$

Let us fix k satisfying (4.13) and (4.14). We claim that there exists $\bar t \in [0,1]$ such that $x_k^{\bar t}$ is a continuity point for u_k. Indeed, if not, then for every $t \in [0,1]$ there exists a jump point x_j, with $1 \le j \le k$, such that $x_k^t = x_j$ and the point $(x_k^t, h^t(x_k^t))$ belongs to the corresponding vertical segment of the extended graph of u_k. Setting $I_j := \{t \in [0,1] : x_k^t = x_j\}$ and $\sigma_j := \{(x_j, h^t(x_j)) : t \in I_j\}$, it is clear that $[0,1] = \cup_{j=1}^k I_j$ and $\mathcal{H}^1(\sigma_j) = \mathcal{H}^1(\{(x_0, h^t(x_0)) : t \in I_j\})$. Thus,

$$\sum_{\substack{x\in S_u\\ x\in]x_0,x_0+\varepsilon[}} |[u](x)| \ge \sum_{j=1}^k \mathcal{H}^1(\sigma_j) = \mathcal{H}^1\big(\{(x_0,h^t(x_0)) : t\in[0,1]\}\big) = \frac{[u](x_0)}{4},$$

in contradiction with (4.8).

Since from now on $\bar t$ and k are fixed, to simplify the notation we set $\hat x := x_k^{\bar t}$, $\hat u := u_k^{\bar t}$, $\hat h := h^{\bar t}$, and $\hat v := \Psi_1 \circ (\hat u')^a$. By construction (see (4.11)) we have

$$|\hat u'|(]a,b[) \le |u_k'|(]a,b[). \tag{4.15}$$

Next, we claim that

$$(u')_-^a(\hat x) \le \hat h'(\hat x) = C. \tag{4.16}$$

If $(u')_-^a(\hat x) \le 0$, there is nothing to prove. If $(u')_-^a(\hat x) > 0$, then by left continuity $(u')_-^a(y) > 0$ for y sufficiently close to $\hat x$, which, in turn, implies $(u')^c(]y,\hat x[) \ge 0$ by the properties of $X_\psi^1(]a,b[)$. Since S_{u_k} is finite and $\hat x$ is a continuity point, for y in a left neighborhood of $\hat x$ we can write

$$\hat h(\hat x) = u_k(\hat x) = u_k(y) + \int_y^{\hat x} (u')^a(s)\,ds + (u')^c(]y,\hat x[) > \hat h(y) + \int_y^{\hat x} (u')^a(s)\,ds,$$

where we have used the fact that $u_k(\hat x) = \hat h(\hat x)$ and $\hat h < u_k$ in a left neighborhood of $\hat x$. Claim (4.16) follows.

Now, recalling that $\Phi(1,t_1,t_2) = 2\Psi_1(+\infty) - \Psi_1(t_1) - \Psi_1(t_2)$ for every t_1, $t_2 \in \overline{\mathbb{R}}$

by (2.39) and using Remark 2.6, we estimate

$$
\begin{aligned}
&|v'|([x_0,\hat{x}]\setminus S_u)+\sum_{x\in S_u\cap[x_0,\hat{x}]}\Phi\left(\nu_u,(u')^a_-,(u')^a_+\right)\\
&\quad\geq |v'|(]x_0,\hat{x}])+\Phi\left(1,(u')^a_-(x_0),(u')^a_+(x_0)\right)\\
&\quad\geq |\Psi_1\left((u')^a_+(x_0)\right)-\Psi_1\left((u')^a_-(\hat{x})\right)|+|\Psi_1\left((u')^a_+(\hat{x})\right)-\Psi_1\left((u')^a_-(\hat{x})\right)|\\
&\qquad+\Phi\left(1,(u')^a_-(x_0),(u')^a_+(x_0)\right)\\
&\quad= |\Psi_1\left((u')^a_+(x_0)\right)-\Psi_1\left((u')^a_-(\hat{x})\right)|+|\Psi_1\left((u')^a_+(\hat{x})\right)-\Psi_1\left((u')^a_-(\hat{x})\right)|\\
&\qquad+2\Psi_1(+\infty)-\Psi_1\left((u')^a_-(x_0)\right)-\Psi_1\left((u')^a_+(x_0)\right)\\
&\quad\geq -\Psi_1\left((u')^a_-(\hat{x})\right)+2\Psi_1(+\infty)-\Psi_1\left((u')^a_-(x_0)\right)\\
&\qquad+|\Psi_1\left((u')^a_+(\hat{x})\right)-\Psi_1\left((u')^a_-(\hat{x})\right)|\\
&\quad= \Psi_1(C)-\Psi_1\left((u')^a_-(\hat{x})\right)+2\Psi_1(+\infty)-\Psi_1\left((u')^a_-(x_0)\right)-\Psi_1(C)\\
&\qquad+|\Psi_1\left((u')^a_+(\hat{x})\right)-\Psi_1\left((u')^a_-(\hat{x})\right)|\\
&\quad\geq |\Psi_1(C)-\Psi_1\left((u')^a_+(\hat{x})\right)|+\Phi\left(1,(\hat{u}')^a_-(x_0),(\hat{u}')^a_+(x_0)\right)\\
&\quad= |\hat{v}'|\left([x_0,\hat{x}]\setminus S_{\hat{u}}\right)+\sum_{x\in S_{\hat{u}}\cap[x_0,\hat{x}]}\Phi\left(\nu_{\hat{u}},(\hat{u}')^a_-,(\hat{u}')^a_+\right),
\end{aligned}
\tag{4.17}
$$

where in the last inequality we have used (4.11) and (4.16). Collecting (4.13), (4.15), and (4.17) we deduce that

$$
\overline{\mathcal{F}}_1(\hat{u})+\lambda\int_a^b|\hat{u}-g|^2+\frac{\eta}{2}\leq\overline{\mathcal{F}}_1(u_k)+\lambda\int_a^b|u_k-g|^2
$$

and, in turn, by (4.14)

$$
\overline{\mathcal{F}}_1(\hat{u})+\lambda\int_a^b|\hat{u}-g|^2\,dx<\overline{\mathcal{F}}_1(u)+\lambda\int_a^b|u-g|^2\,dx,
\tag{4.18}
$$

which contradicts the minimality of u.

If $\frac{1}{2}(u_+(x_0)+u_-(x_0))<g(x_0)$, then we proceed in a similar manner: The comparison function $\hat{u}$ is now constructed by replacing u_k with an affine function (defined as before and with C and t properly chosen) in a left neighborhood of x_0. The argument is completely analogous to the previous one, and we omit the details.

Step 2. We finally show that $(u')^a_-$ and $(u')^a_+$ are finite everywhere in $]a,b]$ and in $[a,b[$, respectively. We give the details only for $(u')^a_-$, since one can argue for $(u')^a_+$ in an entirely similar way.

Recall that, by the previous step, u is continuous. Once again, we reason, by contradiction, by assuming that there exists $\bar{x}\in]a,b]$ such that $|(u')^a_-(\bar{x})|=+\infty$. Without loss of generality, we may suppose that $(u')^a_-(\bar{x})=+\infty$. Using Remark 2.2 and the differentiability properties of BV functions we may choose a point $x_1\in]a,\bar{x}[$ such that u is differentiable at x_1 and

$$
u(x_1)\neq g(x_1),\ u'(x_1)=(u')^a_-(x_1)=(u')^a_+(x_1),\ u'(x_1)>2\|g'\|_\infty,\ |v'|(]a,x_1])>0.
$$

The first condition is a consequence of the fact that g is Lipschitz and u cannot be Lipschitz in any left neighborhood of $\bar{x}$, since $|(u')^a_-(\bar{x})|=+\infty$. The last condition follows easily from the fact that $(u')^a$ cannot be constant $\mathcal{L}^1$-a.e. on $]a,\bar{x}[$. Assume

that $u(x_1) > g(x_1)$. Then, by our choice of x_1 and by the previous step, we can find $\varepsilon \in [0, \frac{1}{2}[$, with

$$\Psi_1(u'(x_1)) - \Psi_1((1-\varepsilon)u'(x_1)) < |v'|([x_1, b[), \tag{4.19}$$

such that the affine function $h(x) := u(x_1) + (1-\varepsilon)u'(x_1)(x - x_1)$ satisfies one of the following conditions: Either there exists a point $x_2 \in]x_1, b[$ for u such that

$$h(x_2) = u(x_2) \text{ and } g < h < u \text{ in }]x_1, x_2[\tag{4.20}$$

or

$$g < h < u \text{ in }]x_1, b[. \tag{4.21}$$

In the latter case, we set $x_2 := b$. We now consider the comparison function

$$\hat{u}(x) := \begin{cases} h(x) & \text{if } x \in]x_1, x_2[, \\ u(x) & \text{otherwise,} \end{cases}$$

and we denote $\hat{v} := \Psi_1 \circ (\hat{u}')^a$. We claim that (4.18) holds, contradicting the minimality of u. By (4.20) and (4.21) in any case we have

$$\lambda \int_a^b |\hat{u} - g|^2 \, dx < \lambda \int_a^b |u - g|^2 \, dx.$$

Moreover, if $x_2 < b$, we have $|\hat{u}'|([x_1, x_2]) = u(x_2) - u(x_1) \le |u'|([x_1, x_2])$, while if $x_2 = b$, we have $|\hat{u}'|([x_1, b[) = u_-(b) - u(x_1) \le |u'|([x_1, b[)$ so that in both cases $|\hat{u}'|([a, b[) \le |u'|(]a, b[)$. Hence, (4.18) will follow if we show that $|\hat{v}'|([x_1, x_2]) \le |v'|([x_1, x_2])$, where $[x_1, x_2]$ is replaced by $[x_1, b[$ if $x_2 = b$. To see this, we first assume that (4.20) holds. Arguing as for (4.16), we deduce $(u')^a_-(x_2) \le h'(x_2) = (1-\varepsilon)u'(x_1)$. Therefore, using the properties of x_1, we have

$$\begin{aligned} |v'|([x_1, x_2]) &= |v'|(]x_1, x_2[) + |v'|(\{x_2\}) \\ &\ge \Psi_1(u'(x_1)) - \Psi_1((u')^a_-(x_2)) + |\Psi_1((u')^a_-(x_2)) - \Psi_1((u')^a_+(x_2))| \\ &= \Psi_1(u'(x_1)) - \Psi_1((1-\varepsilon)u'(x_1)) + \Psi_1((1-\varepsilon)u'(x_1)) - \Psi_1((u')^a_-(x_2)) \\ &\quad + |\Psi_1((u')^a_-(x_2)) - \Psi_1((u')^a_+(x_2))| \\ &\ge \Psi_1(u'(x_1)) - \Psi_1((1-\varepsilon)u'(x_1)) + |\Psi_1((1-\varepsilon)u'(x_1)) - \Psi_1((u')^a_+(x_2))| \\ &= |\hat{v}'|([x_1, x_2]). \end{aligned}$$

If (4.21) holds, then by (4.19) we obtain

$$|v'|([x_1, b[) > \Psi_1(u'(x_1)) - \Psi_1((1-\varepsilon)u'(x_1)) = |\hat{v}'|([x_1, b[).$$

If $u(x_1) < g(x_1)$, we modify the previous argument in the following way. We now choose $\varepsilon \in [0, \frac{1}{2}[$ satisfying (4.19) with $|v'|([x_1, b[)$ replaced by $|v'|(]a, x_1])$ and such that the affine function $h(x)$ defined before satisfies one of the following conditions: Either there exists a point $x_2 \in]a, x_1[$ such that $h(x_2) = u(x_2)$ and $u < h < g$ in $]x_2, x_1[$ or $u < h < g$ in $]a, x_1[$. In the latter case, we set $x_2 := a$. We now consider the comparison function

$$\hat{u}(x) := \begin{cases} h(x) & \text{if } x \in]x_2, x_1[, \\ u(x) & \text{otherwise,} \end{cases}$$

and we proceed exactly as before to show (4.18). ∎

We now turn to the main theorem of this subsection.

THEOREM 4.5. *Assume that $\psi\colon \mathbb{R} \to]0,+\infty[$ is a bounded Borel function satisfying* (2.1) *and* (2.2)*, let $g : [a,b] \to \mathbb{R}$ be Lipschitz continuous, and let $\{h_n\}$ satisfy*

$$h_n \rightharpoonup 0 \quad \text{weakly}^* \text{ in } L^\infty(]a,b[)\,. \tag{4.22}$$

Define $\mathcal{A}_n$ as the class of all solutions to (4.7)*, with g replaced by $g_n := g + h_n$. Then for n large enough every solution $u_n \in \mathcal{A}_n$ is Lipschitz continuous. Moreover,*

$$\limsup_{n\to\infty} \sup_{w\in\mathcal{A}_n} \|w\|_{1,\infty} < +\infty \tag{4.23}$$

and for every sequence $\{u_n\} \subset \mathcal{A}_n$ there exists a subsequence (not relabeled) and a solution u to (4.7) *such that $u_n \to u$ in $W^{1,p}(]a,b[)$ for all $p \in [1,+\infty[$.*

Proof. It will be enough to prove that for any (sub)sequence $\{u_n\} \subset \mathcal{A}_n$ we may extract a further subsequence (not relabeled) and find a solution u to (4.7) such that u_n is Lipschitz continuous for n large enough,

$$\limsup_{n\to\infty} \|u_n\|_{1,\infty} < +\infty, \tag{4.24}$$

and $u_n \to u$ in $W^{1,p}(]a,b[)$ for all $p \in [1,+\infty[$. Since the sequence h_n is bounded in $L^\infty(]a,b[)$, for any $w \in X^1_\psi(]a,b[)$ we have

$$\sup_n \left(\overline{\mathcal{F}}_1(u_n) + \lambda \int_a^b (u_n - g_n)^2\,dx \right) \le \overline{\mathcal{F}}_1(w) + \lambda \int_a^b (w - g_n)^2\,dx \le C < \infty$$

for a suitable constant $C > 0$ independent of n. By Corollary 2.7 there exist a subsequence not relabeled and a function $u \in X^1_\psi(]a,b[)$ such that

$$u_n \rightharpoonup u \quad \text{weakly}^* \text{ in } BV(]a,b[) \tag{4.25}$$

and

$$u_n' \to (u')^a \quad \text{pointwise } \mathcal{L}^1\text{-a.e. in }]a,b[. \tag{4.26}$$

Moreover, since also the functions h_n^2 are equibounded, upon extracting a further subsequence we may find $f \in L^\infty(]a,b[)$ such that

$$h_n^2 \rightharpoonup f \quad \text{weakly}^* \text{ in } L^\infty(]a,b[). \tag{4.27}$$

It is convenient to "localize" the functional $\overline{\mathcal{F}}_1$: For every Borel set $B \subset]a,b[$ and for $w \in X^1_\psi(]a,b[)$ we set

$$\overline{\mathcal{F}}_1(w;B) := |w'|(B) + |v'|(B \setminus S_w) + \sum_{x\in S_w\cap B} \Phi\left(\nu_w, (w')^a_-, (w')^a_+\right), \tag{4.28}$$

where $v := \Psi_1 \circ (w')^a$. We divide the remaining part of the proof into two steps.

Step 1. We claim that u is a solution of the minimization problem (4.7) and that, for every open interval $I =]c,d[$, with $a \le c < d \le b$ and $c,\, d \in [a,b] \setminus S_{(u')^a}$,

$$\lim_{n\to\infty} \overline{\mathcal{F}}_1(u_n; I) = \overline{\mathcal{F}}_1(u; I)\,. \tag{4.29}$$

To see this, note that for each $n \in \mathbb{N}$

$$\lambda \int_I (u_n - g_n)^2 \, dx = \lambda \int_I (u_n - g)^2 \, dx - 2\lambda \int_I (u_n - g)\, h_n \, dx + \lambda \int_I h_n^2 \, dx.$$

By (4.22), (4.25), and (4.27) it follows that

$$\lim_{n\to\infty} \int_I (u_n - g_n)^2 \, dx = \int_I (u - g)^2 \, dx + \int_I f \, dx. \tag{4.30}$$

Recall, also, that by lower semicontinuity

$$\liminf_{n\to\infty} \overline{\mathcal{F}}_1 (u_n; A) \geq \overline{\mathcal{F}}_1 (u; A) \tag{4.31}$$

for every open set $A \subset]a, b[$.

By the minimality of u_n, for every $w \in X^1_\psi(]a, b[)$ we have

$$\begin{aligned} \overline{\mathcal{F}}_1 (w) &+ \lambda \int_a^b (w - g)^2 \, dx - 2\lambda \int_a^b (w - g)\, h_n \, dx + \lambda \int_a^b h_n^2 \, dx \\ &= \overline{\mathcal{F}}_1 (w) + \lambda \int_a^b (w - g_n)^2 \, dx \geq \overline{\mathcal{F}}_1 (u_n) + \lambda \int_a^b (u_n - g_n)^2 \, dx. \end{aligned}$$

Using (4.31) (with $A =]a, b[$) and once again (4.22) and (4.27), we get

$$\begin{aligned} \overline{\mathcal{F}}_1 (w) + \lambda \int_a^b (w - g)^2 \, dx + \lambda \int_a^b f \, dx &\geq \limsup_{n\to\infty} \left(\overline{\mathcal{F}}_1 (u_n) + \lambda \int_a^b (u_n - g_n)^2 \, dx \right) \\ &\geq \liminf_{n\to\infty} \left(\overline{\mathcal{F}}_1 (u_n) + \lambda \int_a^b (u_n - g_n)^2 \, dx \right) \\ &\geq \overline{\mathcal{F}}_1 (u) + \lambda \int_a^b (u - g)^2 \, dx + \lambda \int_a^b f \, dx. \end{aligned}$$

Given the arbitrariness of $w \in X^1_\psi(]a, b[)$ this implies that u is a solution of the minimization problem (4.7). Moreover, taking $w = u$ in the previous inequalities and using (4.30) we deduce (4.29) for $I =]a, b[$; i.e.,

$$\lim_{n\to\infty} \overline{\mathcal{F}}_1(u_n) = \overline{\mathcal{F}}_1(u). \tag{4.32}$$

It remains to prove (4.29) for every open interval of the form $I =]c, d[$, with c, $d \in [a, b] \setminus S_{(u')^a}$. To this end, fix one such interval and assume, by contradiction, that

$$\limsup_{n\to\infty} \overline{\mathcal{F}}_1 (u_n; I) > \overline{\mathcal{F}}_1 (u; I)\,. \tag{4.33}$$

As u is continuous by Proposition 4.4, our assumption on I implies that the end points c and d do not charge $\overline{\mathcal{F}}_1 (u; \cdot)$ so that $\overline{\mathcal{F}}_1 (u; I) = \overline{\mathcal{F}}_1 \left(u; \overline{I} \cap]a, b[\right)$. Therefore, combining (4.31), (4.32), and (4.33) we obtain

$$\begin{aligned} \overline{\mathcal{F}}_1(u) &= \overline{\mathcal{F}}_1 \left(u; \overline{I} \cap]a, b[\right) + \overline{\mathcal{F}}_1 \left(u;]a, b[\setminus \overline{I}\right) = \overline{\mathcal{F}}_1 (u; I) + \overline{\mathcal{F}}_1 \left(u;]a, b[\setminus \overline{I}\right) \\ &< \limsup_{n\to\infty} \overline{\mathcal{F}}_1 (u_n; I) + \liminf_{n\to\infty} \overline{\mathcal{F}}_1 \left(u_n;]a, b[\setminus \overline{I}\right) \leq \lim_{n\to\infty} \overline{\mathcal{F}}_1(u_n) = \overline{\mathcal{F}}_1(u), \end{aligned}$$

which is a contradiction. This concludes the proof of (4.29).

Step 2. We now show that u_n is Lipschitz continuous for n large enough and that (4.24) holds. Note that the convergence of u_n to u in $W^{1,p}(]a,b[)$ for all $p \in [1,+\infty[$ will then easily follow from (4.24) and (4.26). Assume, by contradiction, that the conclusion is false. Then, arguing as at the beginning of the proof of Proposition 4.4, we may find a subsequence (not relabeled) and points $x_n \in]a,b[$ such that one of the following two cases holds:

(i) $x_n \notin S_{(u_n')^a}$ and $|(u_n')^a(x_n)| \to +\infty$;

(ii) $x_n \in S_{u_n}$ for every $n \in \mathbb{N}$.

Assume that (i) holds and, without loss of generality, that $(u_n')^a(x_n) \to +\infty$. Upon extracting a further subsequence, we may also assume that $x_n \to x_0 \in [a,b]$. Recall that, by Proposition 4.4 and by the previous step, the function u is Lipschitz continuous. Hence, there are two cases: Either

$$\overline{\mathcal{F}}_1(u;\{x_0\}\cap]a,b[) = 0 \tag{4.34}$$

or

$$x_0 \in S_{(u')^a},\ (u')^a_{\pm}(x_0) \in \mathbb{R},\ \overline{\mathcal{F}}_1(u;\{x_0\}) = |\Psi_1((u')^a_+(x_0)) - \Psi_1((u')^a_-(x_0))|. \tag{4.35}$$

Assume first that (4.34) holds. Set $L := \|u'\|_\infty$ and fix ε so small that

$$\overline{\mathcal{F}}_1(u;I_\varepsilon) < \int_{L+1}^{+\infty} \psi(t)\,dt,$$

where $I_\varepsilon :=]x_0-\varepsilon, x_0+\varepsilon[\cap]a,b[$. By (4.29) we also have

$$\overline{\mathcal{F}}_1(u_n;I_\varepsilon) < \int_{L+1}^{+\infty} \psi(t)\,dt \tag{4.36}$$

for n large enough. On the other hand, by (4.26) there exists $y \in I_\varepsilon$ such that $(u_n')^a(y) < L+1$ for n large. Moreover, taking into account (i), we also have $(u_n')^a(x_n) > L+1$ for n large enough. Thus,

$$\overline{\mathcal{F}}_1(u_n;I_\varepsilon) \geq |v_n'|(I_\varepsilon) \geq |\Psi_1((u_n')^a(x_n)) - \Psi_1((u_n')^a(y))| \geq \Psi_1((u_n')^a(x_n)) - \Psi_1(L+1).$$

Passing to the limit as $n \to \infty$, we then obtain

$$\liminf_{n\to\infty} \overline{\mathcal{F}}_1(u_n;I_\varepsilon) \geq \Psi_1(+\infty) - \Psi_1(L+1) = \int_{L+1}^{+\infty} \psi(t)\,dt,$$

which contradicts (4.36).

In case (4.35) holds, then $x_0 \in]a,b[$. Set

$$\eta := 2\Psi_1(+\infty) - \Psi_1((u')^a_+(x_0)) - \Psi_1((u')^a_-(x_0)) - |\Psi_1((u')^a_+(x_0)) - \Psi_1((u')^a_-(x_0))| > 0, \tag{4.37}$$

and choose ε such that both $x_0-\varepsilon$ and $x_0+\varepsilon$ belong to $]a,b[\setminus S_{(u')^a}$ and

$$\overline{\mathcal{F}}_1(u;I_\varepsilon) < |\Psi_1((u')^a_+(x_0)) - \Psi_1((u')^a_-(x_0))| + \frac{\eta}{3}, \tag{4.38}$$

$$|\Psi_1((u')^a_\pm(y)) - \Psi_1((u')^a_\pm(x_0))| < \frac{\eta}{4} \quad \text{for } y \in I^\pm_\varepsilon, \tag{4.39}$$

where $I_\varepsilon :=]x_0-\varepsilon, x_0+\varepsilon[$, $I_\varepsilon^+ :=]x_0, x_0+\varepsilon[$, and $I_\varepsilon^- :=]x_0-\varepsilon, x_0[$. Note that by (4.29) and (4.38) we have

$$\overline{\mathcal{F}}_1(u_n; I_\varepsilon) < |\Psi_1((u')_+^a(x_0)) - \Psi_1((u')_-^a(x_0))| + \frac{\eta}{3} \tag{4.40}$$

for n large enough. Moreover, by (4.26) and (4.39) we may find y^-, $y^+ \in I_\varepsilon$, with $y^- < x_0 < y^+$, such that

$$y^\pm \notin S_{(u_n')^a} \quad \text{and} \quad \left|\Psi_1\left((u_n')^a\left(y^\pm\right)\right) - \Psi_1\left((u')_\pm^a(x_0)\right)\right| < \frac{\eta}{4} \tag{4.41}$$

for n large enough. As $y^- < x_n < y^+$ for n sufficiently large, we have

$$\begin{aligned}\overline{\mathcal{F}}_1(u_n; I_\varepsilon) &\geq |v_n'|(I_\varepsilon) \geq |\Psi_1((u_n')^a(x_n)) - \Psi_1((u_n')^a(y^-))| \\ &\quad + |\Psi_1((u_n')^a(x_n)) - \Psi_1((u_n')^a(y^+))| \\ &\geq |\Psi_1((u_n')^a(x_n)) - \Psi_1((u')_-^a(x_0))| + |\Psi_1((u_n')^a(x_n)) - \Psi_1((u')_+^a(x_0))| - \frac{\eta}{2},\end{aligned} \tag{4.42}$$

where the last inequality follows from (4.41). Letting $n \to \infty$ in (4.42) and recalling (4.37) we deduce

$$\begin{aligned}\liminf_{n\to\infty} \overline{\mathcal{F}}_1(u_n; I_\varepsilon) &\geq 2\Psi_1(+\infty) - \Psi_1((u')_+^a(x_0)) - \Psi_1((u')_-^a(x_0)) - \frac{\eta}{2} \\ &= |\Psi_1((u')_+^a(x_0)) - \Psi_1((u')_-^a(x_0))| + \frac{\eta}{2},\end{aligned}$$

which contradicts (4.40). This concludes the proof of (4.24) if (i) holds.

Assume now that (ii) holds, and let $x_0 \in [a,b]$ be the limit of a subsequence (not relabeled) of $\{x_n\}$. Passing to a further subsequence, we may also assume that $\nu_{u_n}(x_n)$ is constant, say, 1 (the other case is analogous). Again, either (4.34) or (4.35) holds. If (4.34) holds, we may choose, as before, ε so small that (4.36) holds. On the other hand, by (4.26) there exists $y \in I_\varepsilon$ such that $(u_n')^a(y) < L+1$ for n large, and, thus, taking into account (ii), we have

$$\begin{aligned}\overline{\mathcal{F}}_1(u_n; I_\varepsilon) &\geq |v_n'|(I_\varepsilon \setminus \{x_n\}) + \Phi(1, (u_n')_-^a(x_n), (u_n')_+^a(x_n)) \\ &\geq |\Psi_1((u_n')^a(y)) - \Psi_1(+\infty)| = \int_{(u_n')^a(y)}^{+\infty} \psi(t)\,dt > \int_{L+1}^{+\infty} \psi(t)\,dt,\end{aligned}$$

which contradicts (4.36). If (4.35) holds, then we may argue exactly as for case (i), with the only difference that (4.42) must be replaced by

$$\begin{aligned}\overline{\mathcal{F}}_1(u_n; I_\varepsilon) &\geq |v_n'|(I_\varepsilon \setminus \{x_n\}) + \Phi(1, (u_n')_-^a(x_n), (u_n')_+^a(x_n)) \\ &\geq |\Psi_1((u_n')_-^a(x_n)) - \Psi_1((u_n')^a(y^-))| + \left|\Psi_1((u_n')_+^a(x_n)) - \Psi_1\left((u_n')^a\left(y^+\right)\right)\right| \\ &\quad + \Phi(1, (u_n')_-^a(x_n), (u_n')_+^a(x_n)) \\ &\geq 2\Psi_1(+\infty) - \Psi_1((u')_-^a(x_0)) - \Psi_1((u')_+^a(x_0)) - \frac{\eta}{2} \\ &= |\Psi_1((u')_+^a(x_0)) - \Psi_1((u')_-^a(x_0))| + \frac{\eta}{2},\end{aligned}$$

where we have used (4.37) and (4.41). The last chain of inequalities contradicts (4.40) and concludes the proof of the theorem. ∎

4.3. Absence of the staircase effect: The case $p > 1$. We now turn to the case $p > 1$. We consider the minimization problem

$$\min\left\{\overline{\mathcal{F}}_p(u) + \lambda\int_a^b |u-g|^2\,dx :\ u \in X^p_\psi(]a,b[)\right\}, \tag{4.43}$$

where $\overline{\mathcal{F}}_p$ is the relaxed functional given in (3.24). We start with two auxiliary results.

PROPOSITION 4.6. *Let $p > 1$, and assume that $\psi\colon \mathbb{R} \to]0,+\infty[$ is a bounded Borel function satisfying* (2.2) *and* (3.1). *Let g be Lipschitz continuous, and let u_n be a sequence in $X^p_\psi(]a,b[)$ such that $\sup_n \overline{\mathcal{F}}_p(u_n) < +\infty$ and $u_n \to g$ in $L^2(]a,b[)$. Then $g \in C^1([a,b]) \cap X^p_\psi(]a,b[)$. Moreover, $u_n \in C^1([a,b])$ for n large enough and $u_n \to g$ in $C^1([a,b])$.*

Proof. By the assumptions and by Corollary 3.5 we deduce that $g \in X^p_\psi(]a,b[)$. The fact that $g \in C^1([a,b])$ now follows from Remark 3.2(i). To prove the last part of the statement we start by showing that $(u_n')^a \to g'$ uniformly in $]a,b[$. Again, by Corollary 3.5, the whole sequence u_n satisfies

$$\Psi_p \circ (u_n')^a \rightharpoonup \Psi_p \circ g' \quad \text{weakly in } W^{1,p}(]a,b[), \tag{4.44}$$

which implies, in particular, that

$$(\Psi_p \circ (u_n')^a)([a,b]) \subset [\Psi_p(-2\|g'\|_\infty), \Psi_p(2\|g'\|_\infty)] \quad \text{for } n \text{ large enough.} \tag{4.45}$$

Since by (2.2) Ψ_p^{-1} is Lipschitz continuous on $[\Psi_p(-2\|g'\|_\infty), \Psi_p(2\|g'\|_\infty)]$, it follows from (4.44) and (4.45) that $(u_n')^a \to g'$ uniformly in $]a,b[$. In turn, by Definition 3.1 we have that $u_n' = (u_n')^a$ in $]a,b[$. In particular, $u_n \in C^1([a,b])$ by Remark 3.2(i) and $u_n \to g$ in $C^1([a,b])$. ∎

PROPOSITION 4.7. *Let p and ψ be as in the previous proposition. Then, for every $C > 0$, there exists $\overline{\lambda} = \overline{\lambda}(C)$ with the following property: For all $g \in C^1([a,b]) \cap X^p_\psi(]a,b[)$, with $\|g\|_{C^1([a,b])} \le C$ and $\overline{\mathcal{F}}_p(g) \le C$, and for all $\lambda \ge \overline{\lambda}$, every solution u to* (4.43) *belongs to $C^1([a,b])$.*

Proof. Assume, by contradiction, that for every $n \in \mathbb{N}$ there exist $g_n \in C^1([a,b]) \cap X^p_\psi(]a,b[)$, with $\|g_n'\|_\infty \le C$ and $\overline{\mathcal{F}}_p(g_n) \le C$, and a solution u_n to

$$\min\left\{\overline{\mathcal{F}}_p(u) + n\int_a^b |u-g_n|^2\,dx :\ u \in X^p_\psi(]a,b[)\right\}$$

which does not belong to $C^1([a,b])$. Owing to Proposition 4.6 we may assume, without loss of generality, that $g_n \to g$ in $C^1([a,b])$ for a suitable function $g \in C^1([a,b]) \cap X^p_\psi(]a,b[)$. Moreover, by minimality, we have

$$\overline{\mathcal{F}}_p(u_n) + n\int_a^b |u_n - g_n|^2\,dx \le \overline{\mathcal{F}}_p(g_n) \le C.$$

It follows, in particular, that $\sup_n \overline{\mathcal{F}}_p(u_n) < +\infty$ and $u_n \to g$ in $L^2(]a,b[)$. By Proposition 4.6 we conclude that $u_n \in C^1([a,b])$ for n large enough, which gives a contradiction. ∎

The next theorem shows that also in the case $p > 1$ the staircase effect does not occur.

THEOREM 4.8. *Let ψ and p be as in Proposition* 4.6, *let $g \in C^1([a,b]) \cap X^p_\psi(]a,b[)$, and let h_n satisfy* (4.22). *For $\lambda > 0$ and $n \in \mathbb{N}$ let $\mathcal{A}_{\lambda,n} \subset X^p_\psi(]a,b[)$ be the class of the solutions to the minimization problem* (4.43), *with g replaced by $g_n := g + h_n$. Let $\overline{\lambda}$ be as in Proposition* 4.7, *with $C := \max\{\|g\|_{C^1([a,b])}, \overline{\mathcal{F}}_p(g)\}$. Then for all $\lambda \geq \overline{\lambda}$ we have $\mathcal{A}_{\lambda,n} \subset C^1([a,b])$ for n sufficiently large. Moreover,*

$$\lim_{\lambda\to\infty} \limsup_{n\to\infty} \sup_{u\in\mathcal{A}_{\lambda,n}} \|u - g\|_{C^1([a,b])} = 0. \tag{4.46}$$

Proof. We start by showing the second part of the statement. Assume, by contradiction, that (4.46) does not hold. Then there exist $\delta > 0$, a sequence of real numbers $\lambda_k \to +\infty$, and, for every k, a sequence of integers $n^k_j \to \infty$ as $j \to \infty$ such that for every k, j

$$\|u_{\lambda_k,n^k_j} - g\|_{C^1([a,b])} \geq \delta \tag{4.47}$$

for a suitable function $u_{\lambda_k,n^k_j} \in \mathcal{A}_{\lambda_k,n^k_j}$, with the understanding that

$$\|u_{\lambda_k,n^k_j} - g\|_{C^1([a,b])} = +\infty \text{ if } u_{\lambda_k,n^k_j} \notin C^1([a,b]).$$

Arguing exactly as in Step 1 of the proof of Theorem 4.5 we can show that for every k there exist a subsequence (still denoted by n^k_j) and a solution u_k to (4.43), with λ replaced by λ_k, such that

$$u_{\lambda_k,n^k_j} \rightharpoonup u_k \quad \text{weakly}^* \text{ in } BV(]a,b[) \qquad \text{and} \qquad \overline{\mathcal{F}}_p(u_{\lambda_k,n^k_j}) \to \overline{\mathcal{F}}_p(u_k) \tag{4.48}$$

as $j \to \infty$. Moreover, since $g \in C^1([a,b]) \cap X^p_\psi(]a,b[)$, we have, by minimality, that

$$\overline{\mathcal{F}}_p(u_k) + \lambda_k \int_a^b |u_k - g|^2\, dx \leq \overline{\mathcal{F}}_p(g), \tag{4.49}$$

which shows, in particular, that $u_k \to g$ in $L^2(]a,b[)$. Combining (4.48) and (4.49) and using a diagonal argument, we may find a subsequence $n^k_{j_k}$ such that

$$\sup_k \overline{\mathcal{F}}_p(u_{\lambda_k,n^k_{j_k}}) < +\infty \qquad \text{and} \qquad u_{\lambda_k,n^k_{j_k}} \to g \text{ in } L^2(]a,b[).$$

Proposition 4.6 then implies that $u_{\lambda_k,n^k_{j_k}} \to g$ in $C^1([a,b])$, which contradicts (4.47).

Finally, the first part of the statement follows from a similar argument, by contradiction, as a consequence of Propositions 4.6 and 4.7 and from the fact that if $u_n \in \mathcal{A}_{\lambda,n}$ then, up to subsequences, u_n converges to a solution of (4.43). ∎

ENTIRE SOLUTIONS IN DELAYED LATTICE DIFFERENTIAL EQUATIONS WITH MONOSTABLE NONLINEARITY*

ZHI-CHENG WANG†, WAN-TONG LI‡, AND JIANHONG WU§

Abstract. We construct new types of entire solutions for a class of monostable delayed lattice differential equations with global interaction by mixing a heteroclinic orbit of the spatially averaged ordinary differential equations with traveling wave fronts with different speeds. We also establish the uniqueness of entire solutions and the continuous dependence of such an entire solution on parameters, such as wave speeds, for the spatially discrete Fisher-KPP equation.

Key words. entire solution, traveling wave front, heteroclinic orbit, delayed lattice differential equation, monostable nonlinearity

DOI. 10.1137/080727312

1. Introduction.

We consider the following delayed lattice differential equations:

$$u_n'(t) = D \sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)\left[u_{n-i}(t) - u_n(t)\right] - du_n(t) + \sum_{i\in\mathbb{Z}} J(i)\, b\left(u_{n-i}(t-\tau)\right), \tag{1.1}$$

where $D > 0$ is a given constant, $\tau \geq 0$, $I(i) = I(-i) \geq 0$, $J(i) = J(-i) \geq 0$, $\sum_{i\in\mathbb{Z}\setminus\{0\}} I(i) = 1$, $\sum_{i\in\mathbb{Z}} J(i) = 1$, $\sum_{i\in\mathbb{Z}\setminus\{0\}} e^{\lambda|i|} I(i) < \infty$, and $\sum_{i\in\mathbb{Z}} e^{\lambda|i|} J(i) < \infty$ for every $\lambda \geq 0$. The birth function $b \in C^2(\mathbb{R})$, and we assume that there exists a constant $K > 0$ such that

$$b(0) = dK - b(K) = 0$$

and that

(H1) for $u \in (0, K)$, there hold $b(u) > du$, $b'(u) \geq 0$, and $b(u) \leq b'(0)u$;

(H2) $b'(K) < d < b'(0)$.

A specific function $b(u) = pue^{-\alpha u}$ with $p > 0$ and $\alpha > 0$, which has been widely used in the mathematical biology literature, satisfies the above conditions for a wide range of parameters p and α.

A special case when $I(i) = 0$ for $|i| \neq 1$ and $I(1) = \frac{1}{2}$ is

$$u_n' = \frac{D}{2}\left[u_{n+1} + u_{n-1} - 2u_n\right] - du_n + \sum_{i\in\mathbb{Z}} J(i)\, b\left(u_{n-i}(t-\tau)\right). \tag{1.2}$$

This work was partially supported by Canada Research Chairs Program, by Natural Sciences and Engineering Research Council of Canada, and by Mathematics for Information Technology and Complex Systems.

This system was derived by Weng, Huang, and Wu [40] for the dynamics of growth of a single species population with two age classes distributed over a patchy environment consisting of all integer nodes of a one-dimensional (1-D) lattice. Another special case when $\tau = 0$, $J(0) = 1$, and $J(i) = 0$ for $|i| > 0$ is

$$u_n'(t) = D \sum_{i \in \mathbb{Z} \setminus \{0\}} I(i) [u_{n-i}(t) - u_n(t)] + f(u_n(t)), \tag{1.3}$$

which was derived by Bates and Chmaj [1] as an l_2-gradient flow for a Helmholtz-free energy functional with general long range interactions. Both lattice systems include, as a special example, the following spatially discrete Fisher-KPP equation:

$$u_n'(t) = \frac{D}{2} [u_{n+1} + u_{n-1} - 2u_n] + f(u_n(t)). \tag{1.4}$$

It is shown in [25] that (1.1) admits a nondecreasing traveling wave front $\phi_c(n+ct)$ satisfying $\phi_c(-\infty) = 0$ and $\phi_c(+\infty) = K$ for every $c \geq c^* > 0$. Furthermore, $\lim_{\xi \to -\infty} \phi_c(\xi) e^{-\lambda_1(c)\xi} = 1$ and $\lim_{\xi \to -\infty} \phi_c'(\xi) e^{-\lambda_1(c)\xi} = \lambda_1(c)$ for $c > c^*$, where c and $\lambda_1(c)$ satisfy

$$\Delta(\lambda, c) = D \sum_{i \in \mathbb{Z} \setminus \{0\}} I(i) \left(e^{-\lambda i} - 1\right) - c\lambda - d + b'(0) e^{-\lambda c\tau} \sum_{i \in \mathbb{Z}} J(i) e^{-\lambda i} = 0 \tag{1.5}$$

and c^* is determined by $\Delta(\lambda, c) = 0$ and $\frac{\partial}{\partial \lambda} \Delta(\lambda, c) = 0$. More precisely, there exist $c^* > 0$ and $\lambda^* > 0$ such that

(D1) if $0 < c < c^*$ and $\lambda > 0$, then $\Delta(\lambda, c) > 0$;

(D2) if $c = c^*$, then the equation $\Delta(\lambda, c^*) = 0$ has a double real root $\lambda_1(c^*) = \lambda_2(c^*)$ with $0 < \lambda_1(c^*) = \lambda_2(c^*) = \lambda^*$ such that $\Delta(\lambda, c^*) > 0$ for $\lambda \neq \lambda^*$;

(D3) if $c > c^*$, then the equation $\Delta(\lambda, c) = 0$ has two positive real roots $\lambda_1(c)$ and $\lambda_2(c)$ with $0 < \lambda_1(c) < \lambda^* < \lambda_2(c)$ such that $\lambda_1'(c) < 0$, $\lambda_2'(c) > 0$, $\frac{d}{dc}\{c\lambda_1(c)\} < 0$, and

$$\Delta(\lambda, c) = \begin{cases} > 0 & \text{for } \lambda < \lambda_1(c), \\ < 0 & \text{for } \lambda \in (\lambda_1(c), \lambda_2(c)), \\ > 0 & \text{for } \lambda > \lambda_2(c). \end{cases}$$

We note that in [25] (see also [1], where bistable waves were considered) there is a further assumption on the kernel I; that is, *the support of I contains either $i = 1$ or two relatively prime integers*, to ensure $\phi_c'(\xi) > 0$ for every $c \geq c^*$. It is interesting to note that, for $c > c^*$, we can confirm $\phi_c'(\xi) > 0$ for any $\xi \in \mathbb{R}$ without this assumption. In fact, for a fixed $c > c^*$, their proof of the existence of nondecreasing traveling wave fronts ϕ_c with $\phi_c(-\infty) = 0$, $\phi_c(+\infty) = K$, and $\lim_{\xi \to -\infty} \phi_c(\xi) e^{-\lambda_1(c)\xi} = 1$ is independent of this assumption; so is the proof of $\lim_{\xi \to -\infty} \phi_c'(\xi) e^{-\lambda_1(c)\xi} = \lambda_1(c)$. We now note that $\phi_c'(\xi) \geq 0$ for $\xi \in \mathbb{R}$. Assume that there exists $\xi_0 \in \mathbb{R}$ such that $\phi_c'(\xi_0) = 0$. Then there must be $\phi_c''(\xi_0) = 0$. It is obvious that ϕ_c satisfies

$$\begin{aligned} c\phi_c''(\xi) = D &\sum_{i \in \mathbb{Z} \setminus \{0\}} I(i) [\phi_c'(\xi - i) - \phi_c'(\xi)] - d\phi_c'(\xi) \\ &+ \sum_{i \in \mathbb{Z}} J(i) b' (\phi_c(\xi - i - c\tau)) \phi_c'(\xi - i - c\tau), \end{aligned}$$

which implies that $\sum_{i \in \mathbb{Z} \setminus \{0\}} I(i) \phi_c'(\xi_0 - i) = 0$. By $\sum_{i \in \mathbb{Z} \setminus \{0\}} I(i) = 1$, there exists a $i_0 \in \mathbb{N}$ such that $I(i_0) > 0$ and $\phi_c'(\xi_0 - i_0) = 0$. Let $\xi_1 = \xi_0 - i_0$. A similar argument yields $\phi_c'(\xi_0 - 2i_0) = \phi_c'(\xi_1 - i_0) = 0$. Continuing this procedure, we have

$\phi_c'(\xi_0 - mi_0) = 0$ for all $m \in \mathbb{N}$, a contradiction to the fact $\lim_{\xi\to-\infty} \phi_c'(\xi)e^{-\lambda_1(c)\xi} = \lambda_1(c)$. Therefore, we have $\phi_c'(\xi) > 0$ for $\xi \in \mathbb{R}$. Of course, to prove $\phi_c'(\xi) > 0$ for the case $c = c^*$ the above assumption on the support of I seems necessary. Since in what follows in this paper we use only the traveling wave fronts ϕ_c with $c > c^*$, we shall not require this assumption.

In the remainder of this paper, we always normalize the traveling wave front $\phi_c(n + ct)$ so that $\phi_c(0) = \frac{K}{2}$. Then, for each $c \in (c^*, +\infty)$, we set

$$\alpha_c = \lim_{z\to-\infty} \phi_c(z)e^{-\lambda_1(c)z}. \tag{1.6}$$

Furthermore, we define $A_c > 0$ for each $c \in (c^*, +\infty)$ by

$$A_c = \inf\left\{A > 0 : A \geq \phi_c(z)e^{-\lambda_1(c)z} \quad \text{for any} \quad z \in \mathbb{R}\right\}. \tag{1.7}$$

It is easy to see that $A_c \geq \alpha_c$.

Our focus is on the so-called entire solutions; here an entire solution of (1.1) is a solution defined for all $(n, t) \in \mathbb{Z} \times \mathbb{R}$. In what follows, we say that a sequence of functions $\Phi_p(t) = \{\Phi_{n,p}(t)\}_{n\in\mathbb{Z}}$ converges to a function $\Phi_{p_0}(t) = \{\Phi_{n,p_0}(t)\}_{n\in\mathbb{Z}}$ in $\mathcal{T}$ if, for every compact set $S \subset \mathbb{Z} \times \mathbb{R}$, the functions $\Phi_{n,p}(t)$ and $\frac{d}{dt}\Phi_{n,p}(t)$ converge uniformly in $(n, t) \in S$ to $\Phi_{n,p_0}(t)$ and $\frac{d}{dt}\Phi_{n,p_0}(t)$ as $p \to p_0$.

One of our main results can be stated as follows.

THEOREM 1.1. *Let $\Gamma(t)$ be a heteroclinic orbit of the following functional differential equation:*

$$\frac{d}{dt}u(t) = -du(t) + b(u(t - \tau)),$$

which is increasing and satisfies $\Gamma(-\infty) = 0$, $\Gamma(+\infty) = K$, $\lim_{t\to-\infty} e^{-\lambda_* t}\Gamma(t) = K$, and $\Gamma(t) \leq Ke^{\lambda_* t}$ for all $t \in \mathbb{R}$, where $\lambda_* > 0$ is the unique real root of the equation $\lambda + d - b'(0)e^{-\lambda\tau} = 0$. Then for every $c_1, \ldots, c_m, c_1', \ldots, c_l' > c^*$, $\theta_0, \theta_1, \ldots, \theta_m, \theta_1', \ldots, \theta_l' \in \mathbb{R}$, and $\chi \in \{0, 1\}$, there exists an entire solution $\Phi(t) = \{\Phi_n(t)\}_{n\in\mathbb{Z}}$ of (1.1) such that

$$\begin{aligned} &\max\left\{\max_{1\leq i\leq m} \phi_{c_i}\left(n + c_i t + \theta_i\right), \max_{1\leq j\leq l} \phi_{c_j'}\left(-n + c_j' t + \theta_j'\right), \chi\Gamma\left(t + \theta_0\right)\right\} \\ &\quad \leq \Phi_n(t) \leq \min\left\{\vartheta_m^+(n, t), \vartheta_l^-(n, t), \vartheta^0(n, t)\right\} \end{aligned} \tag{1.8}$$

on $(n, t) \in \mathbb{Z} \times \mathbb{R}$, where

$$\begin{aligned} \vartheta_m^+(n, t) = \min_{1\leq i\leq m} \Bigg\{ &\phi_{c_i}\left(n + c_i t + \theta_i\right) + \chi K e^{\lambda_*(t+\theta_0)} \\ &+ \sum_{1\leq j\leq m, j\neq i} A_{c_j} e^{\lambda_1(c_j)(n+c_j t+\theta_j)} + \sum_{1\leq j\leq l} A_{c_j'} e^{\lambda_1\left(c_j'\right)\left(-n+c_j' t+\theta_j'\right)} \Bigg\}, \end{aligned}$$

$$\begin{aligned} \vartheta_l^-(n, t) = \min_{1\leq i\leq l} \Bigg\{ &\phi_{c_i'}\left(-n + c_i' t + \theta_i'\right) + \chi K e^{\lambda_*(t+\theta_0)} \\ &+ \sum_{1\leq j\leq m} A_{c_j} e^{\lambda_1(c_j)(n+c_j t+\theta_j)} + \sum_{1\leq j\leq l, j\neq i} A_{c_j'} e^{\lambda_1\left(c_j'\right)\left(-n+c_j' t+\theta_j'\right)} \Bigg\}, \end{aligned}$$

$$\vartheta^0(n, t) = \chi\Gamma\left(t + \theta_0\right) + \sum_{1\leq j\leq m} A_{c_j} e^{\lambda_1(c_j)(n+c_j t+\theta_j)} + \sum_{1\leq j\leq l} A_{c_j'} e^{\lambda_1\left(c_j'\right)\left(-n+c_j' t+\theta_j'\right)},$$

and $m, l \in \mathbb{N} \cup \{0\}$ with $\chi + m + l \geq 2$. Moreover, the following statements hold:

(i) *For any* $n \in \mathbb{Z}$, $\Phi_n'(t) > 0$ *for* $t \in \mathbb{R}$.

(ii) $\lim_{t\to\infty} \sup_{n\in\mathbb{Z}} |\Phi_n(t) - K| = 0$ *and* $\lim_{t\to-\infty} \sup_{|n|\le N_0} |\Phi_n(t)| = 0$ *for every given* $N_0 \in \mathbb{N}$.

(iii) *If* $m \ge 1$, *then* $\lim_{n\to\infty} \|\Phi_n(\cdot) - K\|_{L^\infty[a,+\infty)} = 0$ *for every* $a \in \mathbb{R}$; *if* $l \ge 1$, *then* $\lim_{n\to-\infty} \|\Phi_n(\cdot) - K\|_{L^\infty[a,+\infty)} = 0$ *for every* $a \in \mathbb{R}$.

(iv) *If* $\chi = 1$ *and* $m = 0$ ($l = 0$, *respectively*), *then* $\Phi_n(t)$ *converges uniformly on* $t \in [a,b]$ *to* $\Gamma(t+\theta_0)$ *as* $n \to +\infty$ ($n \to -\infty$, *respectively*) *for any* $a, b \in \mathbb{R}$ *with* $a < b$.

(v) *If* $\chi = 1$, *then* $\Phi_n(t) \sim Ke^{\lambda_*(t+\theta_0)}$ *as* $t \to -\infty$ *for every* $n \in \mathbb{Z}$.

(vi) *If* $\chi = 0$, *then, for every* $n \in \mathbb{Z}$, *there exist* $B_2(n) > B_1(n) > 0$ *such that*

$$B_1(n)e^{c_{\max}\lambda_1(c_{\max})t} < \Phi_n(t) < B_2(n)e^{c_{\max}\lambda_1(c_{\max})t} \quad \text{for every } t \ll -1,$$

where $c_{\max} = \max\{\max_{1\le i\le m} c_i, \max_{1\le j\le l} c_j'\}$.

(vii) *If we denote* $\Phi(t)$ *by* $\Phi_{c_1,\dots,c_m;c_1',\dots,c_l';\theta_1,\dots,\theta_m;\theta_1',\dots,\theta_l';\theta_0}(t)$ *when* $\chi = 1$ *and denote* $\Phi(t)$ *by* $\Phi_{c_1,\dots,c_m;c_1',\dots,c_l';\theta_1,\dots,\theta_m;\theta_1',\dots,\theta_l'}(t)$ *when* $\chi = 0$, *then*

$$\Phi_{c_1,\dots,c_m;c_1',\dots,c_l';\theta_1,\dots,\theta_m;\theta_1',\dots,\theta_l';\theta_0}(t)$$

converges to $\Phi_{c_1,\dots,c_m;c_1',\dots,c_l';\theta_1,\dots,\theta_m;\theta_1',\dots,\theta_l'}(t)$ *as* $\theta_0 \to -\infty$ *in* $\mathcal{T}$ *and uniformly on* $(n,t) \in \mathbb{Z}\times(-\infty,a]$ *for every* $a \in \mathbb{R}$; $\Phi_{c_1,\dots,c_m;c_1',\dots,c_l';\theta_1,\dots,\theta_m;\theta_1',\dots,\theta_l';\theta_0}(t)$ *converges to* K *as* $\theta_0 \to +\infty$ *in* $\mathcal{T}$ *and uniformly on* $(n,t) \in \mathbb{Z}\times[a,+\infty)$ *for every* $a \in \mathbb{R}$.

(viii) $\Phi_{c_1,\dots,c_m;c_1',\dots,c_l';\theta_1,\dots,\theta_m;\theta_1',\dots,\theta_l';\theta_0}(t)$ *converges to*

$$\Phi_{c_1,\dots,c_{i-1},c_{i+1},\dots,c_m;c_1',\dots,c_l';\theta_1,\dots,\theta_{i-1},\theta_{i+1},\dots,\theta_m;\theta_1',\dots,\theta_l';\theta_0}(t)$$

as $\theta_i \to -\infty$ *in* $\mathcal{T}$ *and uniformly on* $(n,t) \in \{n : n \le N_0, n \in \mathbb{Z}\}\times(-\infty,a]$ *for every* $N_0 \in \mathbb{Z}$ *and* $a \in \mathbb{R}$. $\Phi_{c_1,\dots,c_m;c_1',\dots,c_l';\theta_1,\dots,\theta_m;\theta_1',\dots,\theta_l';\theta_0}(t)$ *converges to*

$$\Phi_{c_1,\dots,c_m;c_1',\dots,c_{j-1}',c_{j+1}',\dots,c_l';\theta_1,\dots,\theta_m;\theta_1',\dots,\theta_{j-1}',\theta_{j+1}',\dots,\theta_l';\theta_0}(t)$$

as $\theta_j' \to -\infty$ *in* $\mathcal{T}$ *and uniformly on* $(n,t) \in \{n : n \ge N_0, n \in \mathbb{Z}\}\times(-\infty,a]$ *for every* $N_0 \in \mathbb{Z}$ *and* $a \in \mathbb{R}$. *Similar results hold for* $\Phi_{c_1,\dots,c_m;c_1',\dots,c_l';\theta_1,\dots,\theta_m;\theta_1',\dots,\theta_l'}(t)$.

(ix) $\Phi(t)$ *converges to* K *as* $\theta_i \to +\infty$ *in* $\mathcal{T}$ *and uniformly on* $(n,t) \in \{n : n \ge N_0, n \in \mathbb{Z}\}\times[a,+\infty)$ *for every* $N_0 \in \mathbb{Z}$ *and* $a \in \mathbb{R}$; $\Phi(t)$ *converges to* K *as* $\theta_j' \to +\infty$ *in* $\mathcal{T}$ *and uniformly on* $(n,t) \in \{n : n \le N_0, n \in \mathbb{Z}\}\times[a,+\infty)$ *for every* $N_0 \in \mathbb{Z}$ *and* $a \in \mathbb{R}$.

From (iv) and (v) of Theorem 1.1 and the fact $\lambda_* < c_{\max}\lambda_1(c_{\max})$, it follows that $\Phi_{c_1,\dots,c_m;c_1',\dots,c_l';\theta_1,\dots,\theta_m;\theta_1',\dots,\theta_l';\theta_0}(t)$ are completely different from

$$\Phi_{c_1,\dots,c_m;c_1',\dots,c_l';\theta_1,\dots,\theta_m;\theta_1',\dots,\theta_l'}(t).$$

Theorem 1.1 applies to the spatially discrete Fisher-KPP equation (1.4), where $f \in C^2$ satisfies $f(0) = f(1) = 0$, $f'(0) > 0$, $f'(1) < 0$, $f(u) > 0$, and $f(u) \le f'(0)u$ for $u \in (0,1)$. In this case, $K = 1$, $d = \max_{u\in[0,1]} |f'(u)|$, and $b(u) = du + f(u)$. The existence, uniqueness, and stability of traveling wave fronts of (1.4) were studied in Chen, Fu, and Guo [3], Chen and Guo [4, 5], and Zinner [44]; the entire solutions of (1.4) were studied by Guo and Morita [18] and Guo [19]. However, there seem to be no results on the uniqueness of entire solutions of (1.4) and the continuous dependence on parameters $c_1, \dots, c_m, c_1', \dots, c_l', \theta_0, \theta_1, \dots, \theta_m, \theta_1', \dots, c_l'$ given by Theorem 1.1. The following theorem is devoted to this topic and is a spatially discrete version of results of Hamel and Nadirashvili [20], where the reaction-diffusion Fisher-KPP equation was considered.

THEOREM 1.2. *For any $c, c' > c^*$, $\theta_0, \theta, \theta' \in \mathbb{R}$, and $\varrho, \varrho', \chi \in \{0,1\}$ with $\varrho + \varrho' + \chi \geq 2$, there exists a unique entire solution $\Phi(t) = \{\Phi_n(t)\}_{n\in\mathbb{Z}}$ of (1.4) such that* (i)–(ix) *of Theorem* 1.1 *hold and*

$$
\begin{aligned}
(1.9)\qquad & \max\left\{\varrho\phi_c\left(n+ct+\theta\right), \varrho'\phi_{c'}\left(-n+c't+\theta'\right), \chi\Gamma\left(t+\theta_0\right)\right\} \\
& \leq \Phi_n(t) \\
& \leq \min\Big\{\varrho\phi_c\left(n+ct+\theta\right) + \chi e^{f'(0)(t+\theta_0)} + \varrho' A_{c'} e^{\lambda_1(c')\left(-n+c't+\theta'\right)}, \\
& \qquad\qquad \varrho'\phi_{c'}\left(-n+c't+\theta'\right) + \chi e^{f'(0)(t+\theta_0)} + \varrho A_c e^{\lambda_1(c)(n+ct+\theta)}, \\
& \qquad\qquad \chi\Gamma\left(t+\theta_0\right) + \varrho A_c e^{\lambda_1(c)(n+ct+\theta)} + \varrho' A_{c'} e^{\lambda_1(c')\left(-n+c't+\theta'\right)}\Big\}
\end{aligned}
$$

on $(n,t) \in \mathbb{Z}\times\mathbb{R}$. In particular, when $\varrho = \varrho' = \chi = 1$, the entire solutions $\Phi = \Phi_{c,c',\theta,\theta',\theta_0}$ depend continuously on $(c,c',\theta,\theta',\theta_0) \in (c^*,+\infty)^2\times\mathbb{R}^3$ in $\mathcal{T}$; when $\varrho = \varrho' = 1$ and $\chi = 0$, the entire solutions $\Phi = \Phi_{c,c',\theta,\theta'}$ depend continuously on $(c,c',\theta,\theta') \in (c^*,+\infty)^2\times\mathbb{R}^2$ in $\mathcal{T}$; when $\varrho = \chi = 1$ and $\varrho' = 0$, the entire solutions $\Phi = \Phi_{c,\theta,\theta_0}$ depend continuously on $(c,\theta,\theta_0) \in (c^*,+\infty)\times\mathbb{R}^2$ in $\mathcal{T}$; when $\varrho' = \chi = 1$ and $\varrho = 0$, the entire solutions $\Phi = \Phi_{c',\theta',\theta_0}$ depend continuously on $(c',\theta',\theta_0) \in (c^*,+\infty)\times\mathbb{R}^2$ in $\mathcal{T}$.

We note that when $\varrho' = \chi = 0$ and $\varrho = 1$, $\Phi_n(t) = \Phi_{n;c,\theta}(t) = \phi(n+ct+\theta)$ for $(n,t) \in \mathbb{Z}\times\mathbb{R}$; when $\varrho = \chi = 0$ and $\varrho' = 1$, $\Phi_n(t) = \Phi_{n;c',\theta'}(t) = \phi(-n+c't+\theta')$ for $(n,t) \in \mathbb{Z}\times\mathbb{R}$; and when $\varrho = \varrho' = 0$ and $\chi = 1$, $\Phi_n(t) = \Phi_{n;\theta_0}(t) = \Gamma(t+\theta_0)$ for $(n,t) \in \mathbb{Z}\times\mathbb{R}$. Therefore, similarly to the discussions in Hamel and Nadirashvili [20], it follows from Theorems 1.1 and 1.2 that the functions $\Phi_{c,c',\theta,\theta',\theta_0}(t)$ ($\Phi_{c,c',\theta,\theta'}(t)$, $\Phi_{c,\theta,\theta_0}(t)$, $\Phi_{c',\theta',\theta_0}(t)$, respectively) established by Theorem 1.2 are the 5-D (4-D, 3-D, and 3-D, respectively) manifold of entire solutions of (1.4). In addition, (1.4) possesses two 2-D manifolds of entire solutions of traveling wave type, namely, $\Phi^+_{c,\theta}(t) = \{\phi_c(n+ct+\theta)\}_{n\in\mathbb{Z}}$ and $\Phi^-_{c',\theta'}(t) = \{\phi_{c'}(-n+c't+\theta')\}_{n\in\mathbb{Z}}$, and a 1-D manifold of spatially homogeneous entire solutions, namely, $\Gamma(t+\theta_0)$. Let $\mathcal{M}_5$ ($\mathcal{M}_4$, $\mathcal{M}_3^+$, $\mathcal{M}_3^-$, $\mathcal{M}_2^+$, $\mathcal{M}_2^-$, and $\mathcal{M}_1$, respectively) be the above 5-D (4-D, 3-D, 3-D, 2-D, 2-D, and 1-D, respectively) manifold of entire solutions. Then, from Theorems 1.1 and 1.2, it follows that $\mathcal{M}_4$ is on the boundary of $\mathcal{M}_5$ (via taking the limit $\theta_0 \to -\infty$) and $\mathcal{M}_3^+$ (or $\mathcal{M}_3^-$) is on the boundary of $\mathcal{M}_5$ (via taking the limit $\theta \to -\infty$) (or $\theta' \to -\infty$). $\mathcal{M}_2^+$ (or $\mathcal{M}_2^-$) is on the boundary of $\mathcal{M}_4$ (via taking the limit $\theta' \to -\infty$) (or $\theta \to -\infty$) and is also on the boundary of $\mathcal{M}_3^+$ (or $\mathcal{M}_3^-$) (via taking the limit $\theta_0 \to -\infty$). $\mathcal{M}_1$ is on the boundary of $\mathcal{M}_3^+$ (or $\mathcal{M}_3^-$) (via taking the limit $\theta \to -\infty$) (or $\theta' \to -\infty$). In particular, $\mathcal{M}_2^+$ (or $\mathcal{M}_2^-$) is on the boundary of $\mathcal{M}_5$ (via taking the limits $\theta' \to -\infty$ and $\theta_0 \to -\infty$) (or $\theta \to -\infty$ and $\theta_0 \to -\infty$), and $\mathcal{M}_1$ is on the boundary of $\mathcal{M}_5$ (via taking the limits $\theta \to -\infty$ and $\theta' \to -\infty$). We can also easily show that the functions $\Phi_{c,c',\theta,\theta',\theta_0}$ converge to $\Phi^+_{c,\theta}$ as $\theta' \to -\infty$ and $\theta_0 \to -\infty$ in $\mathcal{T}$ and to $\Phi^-_{c',\theta'}$ as $\theta \to -\infty$ and $\theta_0 \to -\infty$ in $\mathcal{T}$, and that $\Phi_{c,c',\theta,\theta',\theta_0}$ converge to Φ_{θ_0} as $\theta \to -\infty$ and $\theta' \to -\infty$ in $\mathcal{T}$.

Contrasting to [18, 20], we require only $f(u) \leq f'(0)u$ for any $u \in (0,1)$ other than $f'(u) \leq f'(0)$. We also note some differences on the uniqueness of entire solutions up to a spatial-temporal translation between a reaction-diffusion equation and its spatially discrete analogue (see a similar remark for the bistable nonlinearity reported by Wang, Li, and Ruan [39]). Namely, consider the reaction-diffusion KPP equation

$$
(1.10)\qquad \frac{d}{dt}u(x,t) = D\Delta u(x,t) + f(u),
$$

for which the existence of entire solutions was established by Hamel and Nadirashvili ([20, Theorems 1.1, 1.3, and 1.4 and Corollary 1.5]). For comparison, we consider only the entire solutions established by [20, Theorem 1.3], corresponding to the case $\chi = 0$ and $\varrho = \varrho' = 1$ in our Theorem 1.2. The entire solution $v_{c,c',h,h'}(x,t)$ of (1.10) established by [20, Theorem 1.3] and satisfying (1.4) of [20] is unique for each given $(c,c',h,h') \in (c^*,+\infty)^2 \times \mathbb{R}^2$. Consequently, it is easy to see that for any $(\bar{h},\bar{h}') \neq (h,h')$,

$$v_{c,c',\bar{h},\bar{h}'}(x,t) = v_{c,c',\bar{h},\bar{h}'}(x+x_0,t+t_0) \quad \text{for} \quad (x,t) \in \mathbb{R}^2,$$

where

$$x_0 = \frac{c\left(\bar{h}'-h'\right) - c'\left(\bar{h}-h\right)}{c+c'}, \quad t_0 = \frac{\left(\bar{h}'-h'\right)+\left(\bar{h}-h\right)}{c+c'}.$$

But for (1.4) if $(\bar{\theta},\bar{\theta}') \neq (\theta,\theta')$, then $\Phi_{n;c,c',\bar{\theta},\bar{\theta}'}(t) = \Phi_{n+n_0;c,c',\theta,\theta'}(t+t_0)$ for any $(n,t) \in \mathbb{Z} \times \mathbb{R}$ if and only if

$$\frac{c\left(\bar{h}'-h'\right) - c'\left(\bar{h}-h\right)}{c+c'} \in \mathbb{Z},$$

and, hence, $n_0 = \frac{c(\bar{h}'-h') - c'(\bar{h}-h)}{c+c'}$, $t_0 = \frac{(\bar{h}'-h')+(\bar{h}-h)}{c+c'}$. When $(\bar{c},\bar{c}') \neq (c,c')$, as proved by [24, Theorem 1.1], there exists no $(x_0,t_0) \in \mathbb{R}^2$ such that $v_{\bar{c},\bar{c}',h,h'}(\cdot,\cdot) = v_{c,c',h,h'}(\cdot + x_0, \cdot + t_0)$ on $\mathbb{R}^2$ for (1.10). Similarly, for (1.4), there exists no $(n_0,t_0) \in \mathbb{Z} \times \mathbb{R}$ such that $\Phi_{n;\bar{c},\bar{c}',h,h'}(t) = v_{n+n_0;c,c',h,h'}(t)$ for any $(n,t) \in \mathbb{Z} \times \mathbb{R}$.

There have been extensive studies about the dynamics of lattice delay systems (1.1), as reported in a recent survey by Gourley and Wu [16]. In particular, the asymptotic speed of propagation and the existence of monotone traveling waves were studied in [25, 40]. The existence, uniqueness, and stability of traveling wave solutions of (1.1) and (1.2) with monostable and bistable nonlinearities have henceforth been studied; see Ma and Zou [26] for the bistable case and Ma and coworkers [25, 27] for the monostable case. Also, Gourley and Wu [17] proved for (1.2) that if the birth rate is so small that a patch alone cannot sustain a positive equilibrium, then the whole population in the patchy environment will become extinct; and if the birth rate is large enough that each patch can sustain a positive equilibrium and if the maturation time is moderate, then the model exhibits nonlinear oscillations characterized by the occurrence of multiple periodic traveling waves. A stage-structured model for a single species on a finite 1-D spatial lattice was also studied in [22]. Related results on traveling waves of lattice differential equations (without delay) can be found in Cahn, Chow, and Van Vleck [2], Chen, Fu, and Guo [3], Chen and Guo [4, 5], Chow [10], Mallet-Paret [28], Wu and Zou [42], and references therein. We note that some progress has been made as well for 2-D lattice delay differential equations; see, for example, Cheng, Li, and Wang [8, 9], Shi, Li, and Cheng, [32], and Weng et al. [41]. In addition, Wang, Li, and Ruan [35, 36, 37] studied traveling wave solutions of reaction-diffusion equations with spatial-temporal delay.

The aforementioned studies also suggest that these wave solutions $\phi_c(n+ct)$ are defined for all $t \in \mathbb{R}$. They often determine the long time behavior of the solutions of Cauchy-type problems and constitute an important part of global attractors, which consist of *entire solutions*. However, the global attractors can be quite complicated, and recent studies for reaction-diffusion equations with continuous spatial variables have showed the existence of many new types of entire solutions arising from the

simple traveling wave fronts, and these entire solutions combined provide essential information about the global attractors; see Chen and Guo [6], Chen, Guo, and Nimomiya [7], Fukao, Morita, and Nimomiya [14], Guo and Morita [18], Hamel and Nadirashvili [20, 21], and Yagisita [43]. For the Fisher-KPP nonlinearity and bistable nonlinearity, these entire solutions behave as two (opposite) wave fronts of positive speed(s) approaching each other from both sides of the x-axis and then annihilate in a finite time. Similar results hold true for nonlocal reaction-diffusion equations with delayed monostable and bistable nonlinearities ([24, 38]). Morita and Ninomiya [30] and Guo [19] have constructed other types of entire solutions for reaction-diffusion equations and discrete diffusive equations with bistable nonlinearity, respectively, which are different from those obtained in [6, 7, 14, 18, 20, 21, 24, 38, 43]. In particular, Li, Liu, and Wang [23] established the existence of entire solutions for reaction-advection-diffusion equations in cylinders, where the ignition temperature nonlinearity has been studied. As reported in [30], entire solutions play also very important roles in some other areas, for example, transient dynamics, distinct history of two solutions, etc.

The remainder of this paper is organized as follows: In section 2, we show how systems (1.1) arise from some areas, such as population biology. In section 3, we establish some existence and comparison results, which are needed in what follows. In section 4, we show the existence of heteroclinic orbit $\Gamma(t)$ connecting two equilibria 0 and K. Section 5 is devoted to Theorem 1.1, and then Theorem 1.2 is proved in section 6.

2. Important particular cases. In this section, we derive from a structured population model a particular case of systems along with an explicit formula to calculate $J(i)$.

Consider a single species population with age structures distributed over a patchy environment consisting of all integer nodes of a 1-D lattice. Let $w_n(t)$ be the density of juvenile individuals in the nth patch and at time t, $v_n(t,a)$ be the density of individuals with age a in the nth patch and at time t, and $\tau > 0$ the length of a juvenile period. Then

$$w_n(t) = \int_0^\tau v_n(t,a)\, da.$$

Let $u_n(t)$ be the density of mature individuals in the nth patch and at time t. Assume that the spatial dispersal of juvenile individuals and mature individuals is isotropic and can be long range (see Murray [31]). Assume that the diffusion rate of juvenile individuals with age a is $\overline{D}(a) \geq 0$ and the diffusion rate of mature individuals is a constant $D > 0$. Let $K(n-i)$ and $I(n-i)$ be the probability distributions of juvenile individuals and mature individuals traveling from the ith patch to the nth patch, respectively. Then we have

$$K(i) \geq 0,\ I(i) \geq 0,\ K(i) = K(-i),\ I(i) = I(-i),\quad \sum_{i\in\mathbb{Z}\setminus\{0\}} K(i) = 1,\quad \sum_{i\in\mathbb{Z}\setminus\{0\}} I(i) = 1.$$

Since only the mature population can reproduce, we have

$$\begin{cases} \frac{\partial}{\partial t} v_n(t,a) + \frac{\partial}{\partial a} v_n(t,a) = \overline{D}(a) \sum_{i\in\mathbb{Z}\setminus\{0\}} K(n-i)\left[v_i(t,a) - v_n(t,a)\right] \\ \qquad\qquad -\mu(a)\, v_n(t,a), \quad 0 < a < \tau, \\ v_n(t,0) = \widehat{b}\left(u_n(t)\right), \\ \frac{d}{dt} u_n(t) = D \sum_{i\in\mathbb{Z}\setminus\{0\}} I(n-i)\left[u_i(t) - u_n(t)\right] - \widehat{d}\left(u_n(t)\right) + v_n(t,\tau), \end{cases} \tag{2.1}$$

where $\mu(a)$ denotes the death rate of the juvenile individuals with age $a \in (0,\tau)$, $\widehat{b}:\mathbb{R}_+ \to \mathbb{R}_+$ is the birth function, and $\widehat{d}:\mathbb{R}_+ \to \mathbb{R}_+$ is the death function of mature individuals.

For fixed $s \geq -\tau$, let $V_n^s(t) = v_n(t, t-s)$ for $s \leq t \leq s+\tau$. Then $V_n^s(s) = v_n(s,0) = \widehat{b}(u_n(s))$. From (2.1),

$$\begin{aligned}(2.2)\quad \frac{d}{dt}V_n^s(t) &= \frac{\partial}{\partial t}v_n(t,a)\Big|_{a=t-s} + \frac{\partial}{\partial a}v_n(t,a)\Big|_{a=t-s} \\ &= \overline{D}(t-s)\sum_{i\in\mathbb{Z}\setminus\{0\}} K(i)\left[V_{n-i}^s(t) - V_n^s(t)\right] - \mu(t-s)V_n^s(t).\end{aligned}$$

Note that the grid function $V_n^s(t)$ can be viewed as the discrete spectral of a periodic function $v^s(t,\omega)$ by discrete Fourier transform [15, 34]:

$$(2.3)\qquad v^s(t,\omega) = \frac{1}{\sqrt{2\pi}}\sum_{n=-\infty}^{\infty} e^{-i(n\omega)}V_n^s(t),$$

$$(2.4)\qquad V_n^s(t) = \frac{1}{\sqrt{2\pi}}\int_{-\pi}^{\pi} e^{i(n\omega)}v^s(t,\omega)\,d\omega,$$

where i is the imaginary unit. Applying (2.2) and (2.3) yields

$$\begin{aligned}\frac{\partial}{\partial t}v^s(t,\omega) &= \left[\overline{D}(t-s)\sum_{k\in\mathbb{Z}\setminus\{0\}} K(k)\left(e^{-ik\omega}-1\right) - \mu(t-s)\right]v^s(t,\omega) \\ &= \left[-2\overline{D}(t-s)\sum_{k\in\mathbb{Z}\setminus\{0\}} K(k)\sin^2\left(\frac{k\omega}{2}\right) - \mu(t-s)\right]v^s(t,\omega).\end{aligned}$$

Solving the equation, we get

$$\begin{aligned}v^s(t,\omega) = \exp&\left\{-2\sum_{k\in\mathbb{Z}\setminus\{0\}} K(k)\sin^2\left(\frac{k\omega}{2}\right)\int_s^t \overline{D}(z-s)\,dz - \int_s^t \mu(z-s)\,dz\right\} \\ &\times v^s(s,\omega).\end{aligned}$$

By the inverse discrete Fourier transform (2.4), we obtain

$$\begin{aligned}V_n^s(t) = &\frac{1}{\sqrt{2\pi}}e^{-\int_s^t \mu(z-s)dz} \\ &\times\int_{-\pi}^{\pi} e^{i(n\omega)}\exp\left\{-2\alpha_s\sum_{k\in\mathbb{Z}\setminus\{0\}} K(k)\sin^2\left(\frac{k\omega}{2}\right)\right\}v^s(s,\omega)\,d\omega,\end{aligned}$$

where $\alpha_{t-s} = \int_s^t \overline{D}(z-s)dz = \int_0^{t-s}\overline{D}(z)dz$. Noting that $V_n^s(s) = v_n(s,0) = \widehat{b}(u_n(s))$, by (2.3) we have

$$v_s(s,\omega) = \frac{1}{\sqrt{2\pi}}\sum_{j\in\mathbb{Z}} e^{-i(j\omega)}V_j^s(t) = \frac{1}{\sqrt{2\pi}}\sum_{j\in\mathbb{Z}} e^{-i(j\omega)}\widehat{b}(u_j(s)).$$

Hence,

$$V_n^s(t) = \frac{1}{2\pi} e^{-\int_s^t \mu(z-s)dz} \sum_{j\in\mathbb{Z}} \widehat{b}(u_j(s)) \times \int_{-\pi}^{\pi} e^{i((n-j)\omega)} \exp\left\{-2\alpha_s \sum_{k\in\mathbb{Z}\setminus\{0\}} K(k) \sin^2\left(\frac{k\omega}{2}\right)\right\} d\omega. \tag{2.5}$$

Let $t = s+\tau$, $\widehat{\mu} = e^{-\int_s^t \mu(z-s)dz} = e^{-\int_0^\tau \mu(z)dz}$, and $\alpha = \int_0^\tau \overline{D}(z)dz$. Then (2.5) yields

$$v_n(t,\tau) = \frac{\widehat{\mu}}{2\pi} \sum_{j\in\mathbb{Z}} \beta_\alpha(n-j)\widehat{b}(u_j(s)) = \frac{\widehat{\mu}}{2\pi} \sum_{j\in\mathbb{Z}} \beta_\alpha(n-j)\widehat{b}(u_j(t-\tau)),$$

where

$$\beta_\alpha(j) = \int_{-\pi}^{\pi} e^{i(j\omega)} \exp\left\{-2\alpha \sum_{k\in\mathbb{Z}\setminus\{0\}} K(k) \sin^2\left(\frac{k\omega}{2}\right)\right\} d\omega.$$

Thus, the last equality of (2.1) becomes

$$\frac{d}{dt}u_n(t) = D \sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)[u_{n-i}(t) - u_n(t)] - \widehat{d}(u_n(t)) + \frac{\widehat{\mu}}{2\pi} \sum_{j\in\mathbb{Z}} \beta_\alpha(n-j)\widehat{b}(u_j(t-\tau)), \quad t>0. \tag{2.6}$$

Let $\widehat{d}(u) = du$, $b(u) = \widehat{\mu}\widehat{b}(u)$, and $J(i) = \frac{1}{2\pi}\beta_\alpha(i)$; then (2.6) reduces to (1.1).

In particular, the case when $I(i) = K(i) = 0$ for $|i| \neq 1$ and $I(1) = K(1) = \frac{1}{2}$ was studied by Weng, Huang, and Wu [40]. In this case, (2.6) reduces to (1.2). When $\overline{D}(a) \equiv 0$, we have $\alpha = 0$, and it follows that (2.6) reduces to

$$\frac{d}{dt}u_n(t) = D \sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)[u_{n-i}(t) - u_n(t)] - \widehat{d}(u_n(t)) + \widehat{\mu}\widehat{b}(u_n(t-\tau)), \quad t>0.$$

When $\tau = 0$, $\alpha = 0$, and $\widehat{\mu} = 1$, we have

$$\frac{d}{dt}u_n(t) = D \sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)[u_{n-i}(t) - u_n(t)] - \widehat{d}(u_n(t)) + \widehat{b}(u_j(t)), \quad t>0,$$

which coincides with (1.3).

When the diffusion rate $\overline{D}(a)$ and death rate $\mu(a)$ of the juvenile individuals are independent of age a, namely, $D_0 \equiv \overline{D}(a)$ and $\gamma \equiv \mu(a)$ for $a \in [0,\tau]$, we have

$$\frac{d}{dt}w_n(t) = D_0 \sum_{i\in\mathbb{Z}\setminus\{0\}} K(i)[w_{n-i}(t) - w_n(t)] - \gamma u_n(t) + \widehat{b}(u_n(t)) - \frac{e^{-\gamma\tau}}{2\pi} \sum_{j\in\mathbb{Z}} \beta_\alpha(n-j)\widehat{b}(u_j(t-\tau)), \quad t>0. \tag{2.7}$$

We note that it is easy to prove that $\sum_{j\in\mathbb{Z}} \frac{1}{2\pi}\beta_\alpha(j) = 1$. It seems difficult to prove $\beta_\alpha(j) \geq 0$ for general kernel $\sum_{i\in\mathbb{Z}\setminus\{0\}} K(i) = 1$ though it was proved by Weng, Huang, and Wu [40] for the case when $K(i) = 0$ for $|i| \neq 1$ and $K(\pm 1) = \frac{1}{2}$. Nevertheless, in the remainder of this paper, we consider (1.1) for general kernel functions $I(i)$ and $J(i)$ satisfying the assumptions in section 1.

3. Preliminaries. Consider the initial value problem

$$\begin{cases} u_n'(t) = D\sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)\left[u_{n-i}(t) - u_n(t)\right] - du_n(t) + \sum_{i\in\mathbb{Z}} J(i)\, b\left(u_{n-i}(t-\tau)\right), \\ u_n(s) = \varphi_n(s), \end{cases} \tag{3.1}$$

where $n \in \mathbb{Z}$, $t > 0$, and $s \in [-\tau, 0]$.

DEFINITION 3.1. *A sequence of continuous differentiable functions $\{v_n(t)\}_{n\in\mathbb{Z}}$, $t \in [-\tau, l)$, $l > 0$, is called a supersolution (subsolution) of* (3.1) *on* $[0, l)$ *if*

$$\begin{aligned} v_n'(t) \geq (\leq)\, D \sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)\left[v_{n-i}(t) - v_n(t)\right] - dv_n(t) \\ + \sum_{i\in\mathbb{Z}} J(i)\, b\left(v_{n-i}(t-\tau)\right) \end{aligned} \tag{3.2}$$

for all $t \in [0, l)$.

LEMMA 3.2. *For any $\varphi = \{\varphi_n\}_{n\in\mathbb{Z}}$ with $\varphi_n \in C([-\tau, 0], [0, K])$,* (3.1) *admits a unique solution $u(t;\varphi) = \{u_n(t;\varphi)\}_{n\in\mathbb{Z}}$ on $[0, +\infty)$ satisfying $u_n(s) = \varphi_n(s)$ and $0 \leq u_n(t) \leq K$ for $s \in [-\tau, 0]$, $t \in [-\tau, +\infty)$, and $n \in \mathbb{Z}$. For any pair of supersolution $w_n^+(t)$ and subsolution $w_n^-(t)$ of* (3.1) *on $[0, +\infty)$ with $0 \leq w_n^-(t) \leq K$, $0 \leq w_n^+(t) \leq K$ for $t \in [-\tau, +\infty)$, $n \in \mathbb{Z}$, and $w_n^+(s) \geq w_n^-(s)$ for $s \in [-\tau, 0]$, $n \in \mathbb{Z}$, there holds $w_n^+(t) \geq w_n^-(t)$ for $t \geq 0$, $n \in \mathbb{Z}$.*

Note that (3.1) is equivalent to

$$\begin{cases} u_n(t) = \varphi_n(0)\, e^{-(D+d)t} + \int_0^t e^{(D+d)(s-t)} H_n[u](s)\, ds, & t > 0, \\ u_n(t) = \varphi_n(t), & t \in [-\tau, 0], \end{cases}$$

where $H_n[u](t) = D\sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)u_{n-i}(t) + \sum_{i\in\mathbb{Z}} J(i)b(u_{n-i}(t-\tau))$. Lemma 3.2 can be proved using an argument used in [26, Lemma 4.1].

Consider also the following linear initial value problem:

$$\begin{cases} u_n'(t) = D\sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)\left[u_{n-i}(t) - u_n(t)\right] - du_n(t) + b'(0)\sum_{i\in\mathbb{Z}} J(i)\, u_{n-i}(t-\tau), \\ u_n(s) = \varphi_n(s) \in C\left([-\tau, 0], \mathbb{R}\right), \end{cases} \tag{3.3}$$

where $n \in \mathbb{Z}$, $t > 0$, and $s \in [-\tau, 0]$.

Before stating the following theorem, we first define a Banach space l^∞ by

$$l^\infty = \left\{ \xi = \{\xi_i\}_{i\in\mathbb{Z}}, \xi_i \in \mathbb{R} : \sup_{i\in\mathbb{Z}} |\xi_i| < \infty \right\}$$

with the norm $\|\xi\|_{l^\infty} = \sup_{i\in\mathbb{Z}} |\xi_i|$.

THEOREM 3.3. *For any $\varphi = \{\varphi_n\}_{n\in\mathbb{Z}}$ with $\varphi \in C([-\tau, 0], l^\infty)$,* (3.3) *admits a unique solution $u(t) := u(t;\varphi) = \{u_n(t;\varphi)\}_{n\in\mathbb{Z}}$ on $[0, +\infty)$. Furthermore, if $\varphi^1, \varphi^2 \in C([-\tau, 0], l^\infty)$ satisfy $\varphi_n^1(s) \leq \varphi_n^2(s)$ for any $n \in \mathbb{Z}$ and $s \in [-\tau, 0]$, then $u_n(t;\varphi^1) \leq u_n(t;\varphi^2)$ holds for any $n \in \mathbb{Z}$ and $t > 0$.*

Proof. Let $X = l^\infty$. Set $X^+ = \{\xi \in l^\infty : \xi_i \geq 0 \text{ for each } i \in \mathbb{Z}\}$. Then it is easy to see that X^+ is a closed cone of X. Let $T(t) = e^{-(D+d)t}$; it is obvious that $\{T(t)\}$ is a strongly continuous semigroup on X. In particular, it is strongly positive. Now let $\mathcal{C} = C([-\tau, 0], X)$ be the Banach space of continuous functions from $[-\tau, 0]$ into X with the supremum norm. Set $\mathcal{C}^+ = \{\Phi \in \mathcal{C} : \Phi(s) \in X^+, s \in [-\tau, 0]\}$. Then $\mathcal{C}^+$ is a positive cone of $\mathcal{C}$. For any continuous function $w : [-\tau, +\infty) \to X$, define $w_t \in \mathcal{C}$,

$t \in [0, +\infty)$, by $w_t(s) = w(t+s)$, $s \in [-\tau, 0]$. Then the map $t \mapsto w_t$ is a continuous function from $[0, +\infty)$ to $\mathcal{C}$.

Define $f : \mathcal{C} \to X$ by

$$f(w) = \{f_i(w)\}_{i\in\mathbb{Z}}$$

for $w = \{w_i\}_{i\in\mathbb{Z}} \in \mathcal{C}$, where

$$f_i(w) = D \sum_{j\in\mathbb{Z}\setminus\{0\}} I(j)\, w_{i-j}(0) + b'(0) \sum_{k\in\mathbb{Z}} J(k)\, w_{i-k}(-\tau).$$

It is not difficult to verify that $f : \mathcal{C} \to X$ is globally Lipschitz continuous. Furthermore, since for any $v, w \in \mathcal{C}$ with $v \geq w$ in $\mathcal{C}$,

$$\begin{aligned} f_i(v) - f_i(w) &= D \sum_{j\in\mathbb{Z}\setminus\{0\}} I(j)\, v_{i-j}(0) - D \sum_{j\in\mathbb{Z}\setminus\{0\}} I(j)\, w_{i-j}(0) \\ &\quad + b'(0) \sum_{k\in\mathbb{Z}} J(k)\, v_{i-k}(-\tau) - b'(0) \sum_{k\in\mathbb{Z}} J(k)\, w_{i-k}(-\tau) \\ &\geq 0, \end{aligned}$$

it follows that $f(v) \geq f(w)$ in X for any $v, w \in \mathcal{C}$ with $v \geq w$, which implies that $f : \mathcal{C} \to X$ is quasi-monotone in the sense that

$$\lim_{h\to 0} \frac{1}{h} \operatorname{dist}\left((v(0) - w(0)) + h\left[f(v) - f(w)\right], X^+\right) = 0$$

for any $v, w \in \mathcal{C}$ with $v \geq w$.

Note that (3.3) is equivalent to

$$\begin{cases} u(t) = T(t)\, u(0) + \int_0^t T(t-s)\, f(u_s)\, ds, & t > 0, \\ u(t) = \varphi(t), & t \in [-\tau, 0]. \end{cases} \tag{3.4}$$

Take $M_0 = \max_{t\in[-\tau,0]} \|\varphi(t)\|_{l^\infty}$. Furthermore, define a vector-valued function $v^+(\cdot) = \{v_n^+(\cdot)\}_{n\in\mathbb{Z}} : [-\tau, +\infty) \to X$ by

$$\begin{cases} v_n^+(t) = M_0, & t \in [-\tau, 0], \\ v_n^+(t) = M_0 e^{(b'(0)-d)t}, & t > 0 \text{ for any } n \in \mathbb{Z}. \end{cases} \tag{3.5}$$

It is easy to verify that v^+ satisfies

$$v^+(t) \geq T(t)\, v^+(s) + \int_s^t T(t-r)\, f\left(v_r^+\right) dr \text{ for any } t > s \geq 0. \tag{3.6}$$

Define $v^-(\cdot) = \{v_n^-(\cdot)\}_{i\in\mathbb{Z}} : [-\tau, +\infty) \to X$ by $v^-(\cdot) = -v^+(\cdot)$. Then v^- satisfies

$$v^-(t) \leq T(t)\, v^-(s) + \int_s^t T(t-r)\, f\left(v_r^-\right) dr \text{ for any } t > s \geq 0. \tag{3.7}$$

Now we use the conclusions of [29]. By setting $S(t,s) = T(t,s) = T(t-s)$ for any $t \geq s \geq 0$ and $B(t, \Phi) = f(\Phi)$, the existence and uniqueness of the solution $u(t;\varphi)$ follows from [29, Corollary 5].

For any $\varphi^1, \varphi^2 \in \mathcal{C}$ with $\varphi^1 \le \varphi^2$ in $\mathcal{C}$, again applying [29, Corollary 5], we have

$$v^-(t) \le u\left(t;\varphi^1\right) \le u\left(t;\varphi^2\right) \le v^+(t) \text{ in } X \text{ for any } t \ge 0,$$

via letting

$$M_0 = \max\left\{ \max_{s\in[-\tau,0]} \left\|\varphi^1(s)\right\|_{l^\infty}, \max_{s\in[-\tau,0]} \left\|\varphi^2(s)\right\|_{l^\infty} \right\}$$

in (3.5). This implies the solution semiflow is order preserving. The proof is complete. □

Remark 3.1. Assume that the continuous functions $w^\pm = \{w_n^\pm\}_{n\in\mathbb{Z}} : [-\tau,+\infty) \to l^\infty$ satisfy (3.6) and (3.7), respectively, and $w_n^+(s) \ge w_n^-(s)$ for any $(n,s) \in \mathbb{Z}\times[-\tau,0]$; then we have $w_n^+(t) \ge w_n^-(t)$ for any $(n,t) \in \mathbb{Z}\times[0,+\infty)$.

THEOREM 3.4. *Assume that*

$$w_n^-(t) \in C\left([-\tau,\infty),(-\infty,K]\right) \quad \text{and} \quad w_n^+(t) \in C\left([-\tau,\infty),[0,\infty)\right)$$

satisfy $w_n^-(t) \le w_n^+(t)$ *for any* $t \in [-\tau,0]$ *and* $n \in \mathbb{Z}$ *and*

$$\begin{aligned} \frac{d}{dt}w_n^+(t) \ge D &\sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)\left[w_{n-i}^+(t) - w_n^+(t)\right] - dw_n^+(t) \\ &+ b'(0)\sum_{i\in\mathbb{Z}} J(i)\, w_{n-i}^+(t-\tau), \end{aligned} \tag{3.8}$$

$$\begin{aligned} \frac{d}{dt}w_n^-(t) \le D &\sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)\left[w_{n-i}^-(t) - w_n^-(t)\right] - dw_n^-(t) \\ &+ b'(0)\sum_{i\in\mathbb{Z}} J(i)\, w_{n-i}^-(t-\tau) \end{aligned} \tag{3.9}$$

for any $t > 0$ *and* $n \in \mathbb{Z}$. *Then there holds* $w_n^+(t) \ge w_n^-(t)$ *for any* $t > 0$ *and* $n \in \mathbb{Z}$.

Proof. Put $w_n(t) := w_n^-(t) - w_n^+(t)$, $n \in \mathbb{Z}$, $t \in [-\tau,+\infty)$. Then $w_n(t)$ is continuous and bounded from above by K, and $\overline{w}(t) := \sup_{n\in\mathbb{Z}} w_n(t)$ is continuous on $[-\tau,\infty)$. We use a contradiction argument to prove the assertion. Suppose that the assertion is not true. Let $M_0 > 0$ be such that $M_0 + d - b'(0)e^{-M_0\tau} > 0$. Then there exists $t_0 > 0$ such that $\overline{w}(t_0) > 0$ and

$$\overline{w}(t_0)\, e^{-M_0 t_0} = \sup_{t\ge-\tau}\left\{\overline{w}(t)\, e^{-M_0 t}\right\} > \overline{w}(s)\, e^{-M_0 s} \text{ for all } s \in [-\tau,t_0). \tag{3.10}$$

Let $\{n_j\}_{j\in\mathbb{N}}$ be a sequence so that $w_{n_j}(t_0) > 0$ for all $j \ge 1$ and $\lim_{j\to\infty} w_{n_j}(t_0) = \overline{w}(t_0)$. Let $\{t_j\}_{j\in\mathbb{N}} \subset (0,t_0]$ so that

$$w_{n_j}(t_j)\, e^{-M_0 t_j} = \max_{t\in[0,t_0]}\left\{w_{n_j}(t)\, e^{-M_0 t}\right\}. \tag{3.11}$$

Since

$$w_{n_j}(t_0)\, e^{-M_0 t_0} \le w_{n_j}(t_j)\, e^{-M_0 t_j} \le \overline{w}(t_j)\, e^{-M_0 t_j} \le \overline{w}(t_0)\, e^{-M_0 t_0},$$

we have $\lim_{j\to+\infty} \overline{w}(t_j)e^{-M_0 t_j} = \overline{w}(t_0)e^{-M_0 t_0}$. Then there must be $\lim_{j\to+\infty} t_j = t_0$ due to (3.10). In view of $w_{n_j}(t_0)e^{-M_0(t_0-t_j)} \le w_{n_j}(t_j) \le \overline{w}(t_0)e^{-M_0(t_0-t_j)}$, we obtain $\lim_{j\to+\infty} w_{n_j}(t_j) = \overline{w}(t_0)$.

Following (3.11), for each $j \geq 1$, we have

$$0 \leq \frac{d}{dt}\left\{w_{n_j}(t)\, e^{-M_0 t}\right\}_{t=t_j} = \left[w'_{n_j}(t_j) - M_0 w_{n_j}(t_j)\right] e^{-M_0 t_j},$$

and, hence, $w'_{n_j}(t_j) \geq M_0 w_{n_j}(t_j)$. Then it follows from (3.8) and (3.9) that

$$\begin{aligned}
0 &\geq w'_{n_j}(t_j) - D\sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)\left[w_{n_j-i}(t_j) - w_{n_j}(t_j)\right] + d w_{n_j}(t_j) \\
&\quad - b'(0)\sum_{i\in\mathbb{Z}} J(i)\left[w^-_{n_j-i}(t_j-\tau) - w^+_{n_j-i}(t_j-\tau)\right] \\
&\geq (M_0 + D + d)\, w_{n_j}(t_j) - D\sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)\, w_{n_j-i}(t_j) - b'(0)\,\overline{w}(t_j-\tau) \\
&\geq (M_0 + D + d)\, w_{n_j}(t_j) - D\overline{w}(t_j) - b'(0)\,\overline{w}(t_j-\tau).
\end{aligned}$$

Taking $j \to +\infty$, we have

$$\begin{aligned}
0 &\geq (M_0 + D + d)\,\overline{w}(t_0) - D\overline{w}(t_0) - b'(0)\, e^{M_0(t_0-\tau)}\left[\overline{w}(t_0-\tau)\, e^{-M_0(t_0-\tau)}\right] \\
&\geq (M_0 + d)\,\overline{w}(t_0) - b'(0)\, e^{M_0(t_0-\tau)}\overline{w}(t_0)\, e^{-M_0 t_0} \\
&= \left[M_0 + d - b'(0)\, e^{-M_0\tau}\right]\overline{w}(t_0).
\end{aligned}$$

In view of $M_0 + d - b'(0)e^{-M_0\tau} > 0$, we obtain that $\overline{w}(t_0) \leq 0$, which contradicts to $\overline{w}(t_0) > 0$. Consequently, we conclude that $w_n^+(t) \geq w_n^-(t)$ for all $n \in \mathbb{Z}$ and $t \in (0, +\infty)$. This completes the proof. □

4. Existence of heteroclinic orbits. In this section, we show the existence of a heteroclinic orbit connecting the equilibria $u \equiv 0$ and $u \equiv K$ for the following functional differential equation:

$$\frac{d}{dt}u(t) = -du(t) + b(u(t-\tau)). \tag{4.1}$$

There are now various methods developed to establish the existence of such a heteroclinic orbit, for example, Faria, Huang, and Wu [11], Faria and Trofimchuk [12, 13], Li, Wang, and Wu [24], and Smith [33]. However, except for Faria and Trofimchuk [13], these results do not give the exponential decay rate of the heteroclinic orbit connecting the equilibria $u \equiv 0$ and $u \equiv K$ at minus infinity. At the same time, the results in [13] are not directly applicable (see the condition (A1) of [13]) and do not ensure the monotonicity of the heteroclinic orbit.

Define

$$\Lambda(\lambda) = \lambda + d - b'(0)\, e^{-\lambda\tau};$$

then it is easy to prove that the equation $\Lambda(\lambda) = 0$ has one and only one real root $\lambda_* > 0$ such that $\Lambda(\lambda) < 0$ for any $\lambda < \lambda_*$ and $\Lambda(\lambda) > 0$ for any $\lambda > \lambda_*$.

Define an operator $S : C(\mathbb{R}, [0, K]) \to C(\mathbb{R}, [0, K])$ by

$$S(u)(t) = e^{-dt}\int_{-\infty}^{t} e^{ds} b(u(s-\tau))\, ds \text{ for any } u \in C(\mathbb{R}, [0, K]).$$

PROPOSITION 4.1.
(i) *If* $u \in C(\mathbb{R}, [0, K])$, *then* $S(u) \in C^1(\mathbb{R}, [0, K])$.
(ii) *For any* $u, v \in C(\mathbb{R}, [0, K])$ *with* $u \le v$, $S(u) \le S(v)$.
(iii) *For any* $u \in C(\mathbb{R}, [0, K])$, *if* $u(\cdot)$ *is increasing in* $\mathbb{R}$, *then so is* $S(u)(\cdot)$.
Let $b''_{\max} = \max_{u\in[0,K]} |b''(u)|$. Define

$$\overline{u}(t) = K \min\left\{e^{\lambda_* t}, 1\right\} \text{ and } \underline{u}(t) = \max\left\{Ke^{\lambda_* t}\left(1 - Me^{\epsilon t}\right), 0\right\},$$

where $\epsilon \in (0, \lambda_*)$ and $M > 1$ with

$$1 - \frac{(d+\lambda_*)\, e^{-\epsilon\tau}}{d+\lambda_*+\epsilon} - \frac{(d+\lambda_*)\, Ke^{-\lambda_*\tau} b''_{\max}}{Mb'(0)\,(d+2\lambda_*)} > 0.$$

LEMMA 4.2. *For any* $t \in \mathbb{R}$, $S(\overline{u})(t) \le \overline{u}(t)$ *and* $\underline{u}(t) \le S(\underline{u})(t)$.
Proof. First, we prove $S(\overline{u})(t) \le \overline{u}(t)$. When $t \ge 0$, $\overline{u}(t) = K$. Therefore,

$$\begin{aligned} S(\overline{u})(t) &= e^{-dt}\int_{-\infty}^{t} e^{ds} b(\overline{u}(s-\tau))\, ds \\ &\le e^{-dt}\int_{-\infty}^{t} e^{ds} b(K)\, ds = dKe^{-dt}\int_{-\infty}^{t} e^{ds} ds = K = \overline{u}(t). \end{aligned}$$

When $t < 0$, $\overline{u}(t) = Ke^{\lambda_* t}$. Noting that $d + \lambda_* = b'(0)e^{-\lambda_*\tau}$, we have

$$\begin{aligned} S(\overline{u})(t) &= e^{-dt}\int_{-\infty}^{t} e^{ds} b(\overline{u}(s-\tau))\, ds \le e^{-dt}\int_{-\infty}^{t} e^{ds} b'(0)\overline{u}(s-\tau)\, ds \\ &\le b'(0)\, Ke^{-dt}\int_{-\infty}^{t} e^{ds} e^{\lambda_*(s-\tau)} ds = \frac{b'(0)\, e^{-\lambda_*\tau} K}{d+\lambda_*} e^{\lambda_* t} = \overline{u}(t). \end{aligned}$$

Now we prove $\underline{u}(t) \le S(\underline{u})(t)$. Let $t_0 = \frac{1}{\epsilon}\ln\frac{1}{M} < 0$ such that $1 - Me^{\epsilon t_0} = 0$. When $t \ge t_0$, $\underline{u}(t) = 0$, and, hence, $\underline{u}(t) \le S(\underline{u})(t)$. When $t < t_0$, $\underline{u}(t) = Ke^{\lambda_* t}(1 - Me^{\epsilon t}) \le Ke^{\lambda_* t}$. In this case, we have

$$\begin{aligned} S(\underline{u})(t) &= e^{-dt}\int_{-\infty}^{t} e^{ds} b(\underline{u}(s-\tau))\, ds \\ &\ge e^{-dt}\int_{-\infty}^{t} e^{ds}\left[b'(0)\,\underline{u}(s-\tau) - b''_{\max}\underline{u}^2(s-\tau)\right] ds \\ &\ge e^{-dt}\int_{-\infty}^{t} e^{ds}\left[b'(0)\, Ke^{\lambda_*(s-\tau)}\left(1 - Me^{\epsilon(s-\tau)}\right) - b''_{\max}K^2 e^{2\lambda_*(s-\tau)}\right] ds \\ &= \frac{b'(0)\, Ke^{-\lambda_*\tau}}{d+\lambda_*} e^{\lambda_* t} - \frac{Mb'(0)\, Ke^{-(\lambda_*+\epsilon)\tau}}{d+\lambda_*+\epsilon} e^{(\lambda_*+\epsilon)t} - \frac{b''_{\max}K^2 e^{-2\lambda_*\tau}}{d+2\lambda_*} e^{2\lambda_* t} \\ &\ge \underline{u}(t) + \frac{Mb'(0)\, Ke^{-\lambda_*\tau}}{d+\lambda_*}\left[1 - \frac{(d+\lambda_*)\, e^{-\epsilon\tau}}{d+\lambda_*+\epsilon} - \frac{(d+\lambda_*)\, Ke^{-\lambda_*\tau} b''_{\max}}{Mb'(0)\,(d+2\lambda_*)}\right] e^{(\lambda_*+\epsilon)t} \\ &\ge \underline{u}(t). \end{aligned}$$

The proof is complete. □

THEOREM 4.3. *There exists a heteroclinic solution* $\Gamma(t)$ *of* (4.1)*, which is increasing on* $\mathbb{R}$ *and satisfies* $\lim_{t\to-\infty} e^{-\lambda_* t}\Gamma(t) = K$*,* $\Gamma(+\infty) = K$*,* $\Gamma(t) \le Ke^{\lambda_* t}$*, and* $\Gamma'(t) > 0$ *for every* $t \in \mathbb{R}$*.*

Proof. By an argument similar to that of [42, Theorem 3.1], we can get a nondecreasing solution $\Gamma(t)$ which meets the theorem except $\Gamma'(t) > 0$ for any $t \in \mathbb{R}$. Since $\Gamma'(t)$ satisfies

$$\Gamma''(t) = -d\Gamma'(t) + b'\left(\Gamma(t-\tau)\right)\Gamma'(t-\tau) \quad \forall t \in \mathbb{R},$$

we have

$$\Gamma'(t) = e^{-d(t-s)}\Gamma'(s) + \int_s^t e^{-d(t-r)} b'\left(\Gamma(t-\tau)\right)\Gamma'(r-\tau)dr \quad \text{for any} \quad s < t.$$

Note that $\Gamma'(t) \ge 0$ for any $t \in \mathbb{R}$. Then it is easy to see that if $\Gamma'(t_0) > 0$ for some $t_0 \in \mathbb{R}$, then $\Gamma'(t) > 0$ for all $t > t_0$. In view of $\lim_{t\to-\infty} e^{-\lambda_* t}\Gamma(t) = K$, we know that there exists a sequence $\{t_i\}$ with $t_i \to -\infty$ as $i \to +\infty$ such that $\Gamma(t_i) > 0$ for any $i \in \mathbb{N}$. Hence, we conclude $\Gamma'(t) > 0$ for any $t \in \mathbb{R}$. This completes the proof. □

5. Proof of Theorem 1.1. In this section, we prove Theorem 1.1.

LEMMA 5.1. *Suppose that* $u(t;\varphi) = \{u_n(t;\varphi)\}_{n\in\mathbb{Z}}$ *is a solution of* (1.1) *with initial value* $\varphi = \{\varphi_n\}_{n\in\mathbb{Z}}$ *with* $\varphi_n \in C([-\tau, 0], [0, K])$*; then there exists a positive constant* $M_* > 0$ *such that for any* $\varphi = \{\varphi_n\}_{n\in\mathbb{Z}}$ *with* $\varphi_n \in C([-\tau, 0], [0, K])$ *and* $t > \tau$*,* $|u_n'(t;\varphi)| \le M_*$ *and* $|u_n''(t;\varphi)| \le M_*$*.*

Proof. Denote $u_n(t;\varphi)$ by $u_n(t)$. Let $M' = 2DK + 2dK$. It is easy to see that $|u_n'(t;\varphi)| \le M'$ for any $t > 0$. For $t > \tau$, there is

$$\begin{aligned} u_n''(t) = {} & D\sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)\left[u_{n-i}'(t) - u_n'(t)\right] \\ & - du_n'(t) + \sum_{i\in\mathbb{Z}} J(i)\, b'\left(u_{n-i}(t-\tau)\right) u_{n-i}'(t-\tau). \end{aligned}$$

Set $M'' = 2DM' + dM' + M'b'(0)$. Then $|u_n''(t;\varphi)| \le M''$. Note that M' and M'' are independent of φ and $t > \tau$. Take $M_* = \max\{M', M''\}$. This completes the proof. □

LEMMA 5.2. *Let* $u^k(t;\varphi^k) = \{u_n^k(t;\varphi^k)\}_{n\in\mathbb{Z}}$ *be a solution of the following initial value problem:*

$$\begin{cases} \frac{d}{dt}u_n^k(t) = D\sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)\left[u_{n-i}(t) - u_n(t)\right] \\ \qquad\qquad -du_n(t) + \sum_{i\in\mathbb{Z}} J(i)\, b\left(u_{n-i}(t-\tau)\right), \ t > 0, \\ u_n^k(t) = \varphi_n^k(t), \ t \in [-\tau, 0], \end{cases}$$

where

$$\begin{aligned} \varphi_n^k(t) = \max\Big\{ & \max_{1\le i\le m} \phi_{c_i}\left(n + c_i(t-k) + \theta_i\right), \\ & \max_{1\le j\le l} \phi_{c_j'}\left(-n + c_j'(t-k) + \theta_j'\right), \chi\Gamma\left((t-k) + \theta_0\right)\Big\}. \end{aligned}$$

Then $v^k\left(t;\varphi^k\right)=\left\{u_n^k\left(t+k;\varphi^k\right)\right\}_{n\in\mathbb{Z}}$ *satisfies*

$$\begin{aligned}\limsup_{t>-k,k\to+\infty} v_n^k(t)\le{}&\phi_{c_i}(n+c_it+\theta_i)+\chi Ke^{\lambda_*(t+\theta_0)}+\sum_{1\le j\le m,j\ne i}A_{c_j}e^{\lambda_1(c_j)(n+c_jt+\theta_j)}\\&+\sum_{1\le j\le l}A_{c'_j}e^{\lambda_1\left(c'_j\right)\left(-n+c'_jt+\theta'_j\right)}\qquad \text{for } 1\le i\le m,\end{aligned}\tag{5.1}$$

$$\begin{aligned}\limsup_{t>-k,k\to+\infty} v_n^k(t)\le{}&\phi_{c'_i}(-n+c'_it+\theta'_i)+\chi Ke^{\lambda_*(t+\theta_0)}+\sum_{1\le j\le m}A_{c_j}e^{\lambda_1(c_j)(n+c_jt+\theta_j)}\\&+\sum_{1\le j\le l,j\ne i}A_{c'_j}e^{\lambda_1\left(c'_j\right)\left(-n+c'_jt+\theta'_j\right)}\qquad \text{for } 1\le i\le l,\end{aligned}\tag{5.2}$$

$$\begin{aligned}\limsup_{t>-k,k\to+\infty} v_n^k(t)\le{}&\chi\Gamma(t+\theta_0)+\sum_{1\le j\le m}A_{c_j}e^{\lambda_1(c_j)(n+c_jt+\theta_j)}\\&+\sum_{1\le j\le l}A_{c'_j}e^{\lambda_1\left(c'_j\right)\left(-n+c'_jt+\theta'_j\right)}.\end{aligned}\tag{5.3}$$

Proof. We prove only (5.1), because the proofs of (5.2) and (5.3) are similar to that of (5.1). Assume $m\ge 1$. Consider $i=1$. Let

$$w_n^k(t)=u_n^k(t)-\phi_{c_1}(n+c_1(t-k)+\theta_1).$$

Then $w_n^k(t)$ satisfies

$$\begin{aligned}\frac{d}{dt}w_n^k(t)&=D\sum_{i\in\mathbb{Z}\setminus\{0\}}I(i)\left[w_{n-i}(t)-w_n(t)\right]-dv_n(t)+\sum_{i\in\mathbb{Z}}J(i)\,b\left(u_{n-i}(t-\tau)\right)\\&\quad-\sum_{i\in\mathbb{Z}}J(i)\,b\left(\phi_{c_1}(n-i+c_1(t-\tau)+\theta_1)\right)\\&\le D\sum_{i\in\mathbb{Z}\setminus\{0\}}I(i)\left[w_{n-i}(t)-w_n(t)\right]-dw_n(t)+b'(0)\sum_{i\in\mathbb{Z}}J(i)\,w_{n-i}(t-\tau).\end{aligned}$$

Since

$$\chi Ke^{\lambda_*((t-k)+\theta_0)}+\sum_{2\le j\le m}A_{c_j}e^{\lambda_1(c_j)(n+c_j(t-k)+\theta_j)}+\sum_{1\le j\le l}A_{c'_j}e^{\lambda_1\left(c'_j\right)\left(-n+c'_j(t-k)+\theta'_j\right)}$$

is a solution of (3.3) with

$$\begin{aligned}\varphi_n(s)={}&\chi Ke^{\lambda_*((s-k)+\theta_0)}+\sum_{2\le j\le m}A_{c_j}e^{\lambda_1(c_j)(n+c_j(s-k)+\theta_j)}\\&+\sum_{1\le j\le l}A_{c'_j}e^{\lambda_1\left(c'_j\right)\left(-n+c'_j(s-k)+\theta'_j\right)}\end{aligned}$$

for any $s \in [-\tau, 0]$ and $n \in \mathbb{Z}$, then by Theorem 3.4 and

$$\begin{aligned}
&\chi K e^{\lambda_*((s-k)+\theta_0)} + \sum_{2\le j\le m} A_{c_j} e^{\lambda_1(c_j)(n+c_j(s-k)+\theta_j)} \\
&\quad + \sum_{1\le j\le l} A_{c'_j} e^{\lambda_1(c'_j)\left(-n+c'_j(s-k)+\theta'_j\right)} \\
&\ge \max\left\{ \max_{1\le i\le m} \phi_{c_i}\left(n + c_i\left(t-k\right) + \theta_i\right), \right. \\
&\qquad \left. \max_{1\le j\le l} \phi_{c'_j}\left(-n + c'_j\left(t-k\right) + \theta'_j\right), \chi\Gamma\left(\left(t-k\right)+\theta_0\right)\right\} \\
&\quad - \phi_{c_1}\left(n + c_1(s-k) + \theta_1\right)
\end{aligned}$$

for any $s \in [-\tau, 0]$ and $n \in \mathbb{Z}$, we have

$$\begin{aligned}
w_n^k\left(t\right) &\le \chi K e^{\lambda_*((t-k)+\theta_0)} + \sum_{2\le j\le m} A_{c_j} e^{\lambda_1(c_j)(n+c_j(t-k)+\theta_j)} \\
&\quad + \sum_{1\le j\le l} A_{c'_j} e^{\lambda_1(c'_j)\left(-n+c'_j(t-k)+\theta'_j\right)} \quad \text{for any } t > 0.
\end{aligned}$$

That is,

$$\begin{aligned}
u_n^k\left(t\right) &\le \phi_{c_1}\left(n + c_1(t-k) + \theta_1\right) + \chi K e^{\lambda_*((t-k)+\theta_0)} + \sum_{2\le j\le m} A_{c_j} e^{\lambda_1(c_j)(n+c_j(t-k)+\theta_j)} \\
&\quad + \sum_{1\le j\le l} A_{c'_j} e^{\lambda_1(c'_j)\left(-n+c'_j(t-k)+\theta'_j\right)} \quad \text{for any } t > 0.
\end{aligned}$$

By the arbitrariness of $k \in \mathbb{N}$, we have that (5.1) holds.

When $m = 0$, the inequality (5.1) reduces to the following:

$$\limsup_{t>-k, k\to+\infty} v_n^k\left(t\right) \le \chi K e^{\lambda_*(t+\theta_0)} + \sum_{1\le j\le l} A_{c'_j} e^{\lambda_1(c'_j)\left(-n+c'_j t+\theta'_j\right)},$$

which holds obviously. This completes the proof. □

Proof of Theorem 1.1. Define $v^k(t) = \{v_n^k(t)\}_{n\in\mathbb{Z}}$ with $v_n^k(t) := u_n(t+k;\psi^k)$ for any $(n,t) \in \mathbb{Z}\times[-\tau-k, +\infty)$, where

$$\begin{aligned}
\psi^k &= \left\{\psi_n^k\left(s\right)\right\}_{k\in\mathbb{Z}}, \\
\psi_n^k\left(s\right) &= \max\left\{ \max_{1\le i\le m} \phi_{c_i}\left(n + c_i\left(s-k\right) + \theta_i\right), \right. \\
&\qquad \left. \max_{1\le j\le l} \phi_{c'_j}\left(-n + c'_j\left(s-k\right) + \theta'_j\right), \chi\Gamma\left(\left(s-k\right)+\theta_0\right)\right\} < K
\end{aligned}$$

for any $(n,s) \in \mathbb{Z}\times[-\tau, 0]$. Note that

$$\begin{aligned}
&\max\left\{ \max_{1\le i\le m} \phi_{c_i}\left(n + c_i t + \theta_i\right), \max_{1\le j\le l} \phi_{c'_j}\left(-n + c'_j t + \theta'_j\right), \chi\Gamma\left(t+\theta_0\right)\right\} \\
&\quad \le v_n^k\left(t\right) \le v_n^{k+1}\left(t\right) \le \min\left\{K, \vartheta_m^+(n,t), \vartheta_l^-(n,t), \vartheta^0(n,t)\right\} \qquad (5.4)
\end{aligned}$$

for any $(n,t) \in \mathbb{Z}\times[-\tau-k, +\infty)$. From Lemma 5.1 and by a diagonal extraction process, there exists a subsequence $\{v^{k_i}(t) = \{v_n^{k_i}(t)\}_{n\in\mathbb{Z}} : i \in \mathbb{N}\}$ such that $v^{k_i}(t)$

converges to a function $\Phi(t)=\{\Phi_n(t)\}_{n\in\mathbb{Z}}$ in $\mathcal{T}$; that is, for any compact set $S\subset\mathbb{Z}\times\mathbb{R}$, $v_n^{k_i}(t)$ and $\frac{d}{dt}v_n^{k_i}(t)$ converge uniformly in $(n,t)\in S$ to $\Phi_n(t)$ and $\frac{d}{dt}\Phi_n(t)$, respectively. In view of $v_n^k(t)\le v_n^{k+1}(t)$ for any $t>-k$, we have $\lim_{k\to+\infty}v_n^k(t)=\Phi_n(t)$ for any $(n,t)\in\mathbb{Z}\times\mathbb{R}$. The limit function is unique, whence all of the functions $v^k(t)$ converge to the function $\Phi(t)$ in $\mathcal{T}$ as $k\to+\infty$. Since $u^{k_i}(t)=\{u_n^{k_i}(t)\}_{n\in\mathbb{Z}}$ satisfies (1.1), the limit function $\Phi(t)=\{\Phi_n(t)\}_{n\in\mathbb{Z}}$ is an entire solution of (1.1). In particular, it follows from (5.4) that (1.8) holds on $(n,t)\in\mathbb{Z}\times\mathbb{R}$.

Now we show (i); that is, $\frac{d}{dt}\Phi_n(t)>0$ on $\mathbb{R}$ for every $n\in\mathbb{Z}$. Since

$$\begin{aligned}\psi_n^k(s)&=\max\left\{\max_{1\le i\le m}\phi_{c_i}\left(n+c_i\left(s-k\right)+\theta_i\right),\right.\\&\qquad\left.\max_{1\le j\le l}\phi_{c_j'}\left(-n+c_j'\left(s-k\right)+\theta_j'\right),\chi\Gamma\left(\left(s-k\right)+\theta_0\right)\right\}\\&\le\max\left\{\max_{1\le i\le m}\phi_{c_i}\left(n+c_i\left(s+\varepsilon-k\right)+\theta_i\right),\right.\\&\qquad\left.\max_{1\le j\le l}\phi_{c_j'}\left(-n+c_j'\left(s+\varepsilon-k\right)+\theta_j'\right),\chi\Gamma\left(\left(s+\varepsilon-k\right)+\theta_0\right)\right\}\\&=\psi_n^k\left(s+\varepsilon\right)\end{aligned}$$

for any $\varepsilon>0$, $s\in[-\tau,0]$, and $n\in\mathbb{Z}$, we have $u_n^k(t;\psi^k(\cdot))\le u_n^k(t;\psi^k(\cdot+\varepsilon))$ for any $(n,t)\in\mathbb{Z}\times[-\tau,+\infty)$. On the other hand, $\psi_n^k(s+\varepsilon)\le u_n^k(s+\varepsilon;\psi^k(\cdot))$ for any $\varepsilon>0$, $s\in[-\tau,0]$, and $n\in\mathbb{Z}$, and, hence,

$$u_n^k\left(t;\psi^k\left(\cdot\right)\right)\le u_n^k\left(t;u_n^k\left(\cdot+\varepsilon;\psi^k\left(\cdot\right)\right)\right)=u_n^k\left(t+\varepsilon;\psi^k\left(\cdot\right)\right)$$

for any $(n,t)\in\mathbb{Z}\times[-\tau,+\infty)$. Thus, it follows from the arbitrariness of $\epsilon>0$; that $u_n^k(t)$ is increasing on t; that is, $v^k(t)$ is increasing on t. Therefore, $\Phi_n'(t)\ge0$ on $\mathbb{R}$ for every $n\in\mathbb{Z}$. Since $\Phi_n'(t)$ satisfies

$$\begin{aligned}\Phi_n''(t)&=D\sum_{i\in\mathbb{Z}\setminus\{0\}}I(i)\left[\Phi_{n-i}'(t)-\Phi_n'(t)\right]\\&\quad-d\Phi_n'(t)+\sum_{i\in\mathbb{Z}}J(i)\,b'\left(\Phi_{n-i}(t-\tau)\right)\Phi_{n-i}'(t-\tau),\end{aligned}\tag{5.5}$$

we have that $\Phi_n'(t)$ satisfies

$$\Phi_n'(t)=\Phi_n'(s)\,e^{-(D+d)(t-s)}+\int_s^t e^{-(D+d)(t-r)}R_n(\Phi)(r)\,dr\quad\text{for any } s<t,$$

where $R_n(\Phi)(t)=D\sum_{i\in\mathbb{Z}\setminus\{0\}}I(i)\Phi_{n-i}'(t)+\sum_{i\in\mathbb{Z}}J(i)b'(\Phi_{n-i}(t-\tau))\Phi_{n-i}'(t-\tau)\ge0$. Obviously, for each $n\in\mathbb{Z}$, if there exists $t_0\in\mathbb{R}$ such that $\Phi_n'(t_0)>0$, then $\Phi_n'(t)>0$ for any $t>t_0$. Therefore, there must be $\Phi_n'(t)>0$ for any $(n,t)\in\mathbb{Z}\times\mathbb{R}$. We argue by a contradiction. In fact, assume that, for some $n_1\in\mathbb{Z}$, there is t_1 such that $\Phi_{n_1}'(t_1)=0$ and, hence, then $\Phi_{n_1}'(t)=0$ for any $t\le t_1$, which implies that $\lim_{t\to-\infty}\Phi_{n_1}(t)=\Phi_{n_1}(t_1)>0$. But following from (1.8), we have $\lim_{t\to-\infty}\Phi_{n_1}(t)=0$, which yields a contradiction.

Now we prove (vii). For the sake of convenience, we denote

$$\Phi_{c_1,\dots,c_m;c_1',\dots,c_l';\theta_1,\dots,\theta_m;\theta_1',\dots,\theta_l';\theta_0}(t)$$

by $\Phi(t;\theta_0)$ and $\Phi_{c_1,\dots,c_m;c_1',\dots,c_l';\theta_1,\dots,\theta_m;\theta_1',\dots,\theta_l'}(t)$ by $\Phi(t;-\infty)$. For $\chi\in\{0,1\}$, let

$$\begin{aligned}
\psi^k(t)_\chi &= \left\{\psi_n^k(s)_\chi\right\}_{k\in\mathbb{Z}},\\
\psi_n^k(s)_\chi &= \max\left\{\max_{1\le i\le m}\phi_{c_i}\left(n+c_i(s-k)+\theta_i\right),\right.\\
&\qquad \left.\max_{1\le j\le l}\phi_{c_j'}\left(-n+c_j'(s-k)+\theta_j'\right),\chi\Gamma\left((s-k)+\theta_0\right)\right\},
\end{aligned}$$

and $v^k(t)_\chi=\{v_n^k(t)_\chi\}_{n\in\mathbb{Z}}$ with $v_n^k(t)_\chi := u_n(t+k;\psi^k(\cdot)_\chi)$ for any $(n,t)\in\mathbb{Z}\times[-\tau-k,+\infty)$. Set $\bar v^k(t)=v^k(t)_1-v^k(t)_0=\{v_n^k(t)_1-v_n^k(t)_0\}_{n\in\mathbb{Z}}$. Then $\bar v^k(t)$ satisfies $0\le\bar v^k(t)\le K$ for any $t\in[-\tau-k,+\infty)$ and

$$\frac{d}{dt}\bar v_n^k(t)\le D\sum_{i\in\mathbb{Z}\setminus\{0\}}I(i)\left[\bar v_{n-i}^k(t)-\bar v_n^k(t)\right]-d\bar v_n^k(t)+b'(0)\sum_{i\in\mathbb{Z}}J(i)\,\bar v_{n-i}^k(t-\tau).$$

Noting that $\bar v_n^k(s)\le Ke^{\lambda_*(s+\theta_0)}$ for any $s\in[-\tau-k,-k]$ and $w_n^k(t)=Ke^{\lambda_*(t+\theta_0)}$ satisfies

$$\frac{d}{dt}w_n^k(t)=D\sum_{i\in\mathbb{Z}\setminus\{0\}}I(i)\left[w_{n-i}^k(t)-w_n^k(t)\right]-dw_n^k(t)+b'(0)\sum_{i\in\mathbb{Z}}J(i)\,w_{n-i}^k(t-\tau)$$

for any $t\in[-\tau-k,+\infty)$, it follows from Theorem 3.4 that $0\le\bar v_n^k(t)\le Ke^{\lambda_*(t+\theta_0)}$ for any $(n,t)\in\mathbb{Z}\times[-\tau-k,+\infty)$ and $k\in\mathbb{N}$. Note that $\lim_{k\to+\infty}v_n^k(t)_0=\Phi_n(t;-\infty)$ and $\lim_{k\to+\infty}v_n^k(t)_1=\Phi_n(t;\theta_0)$ for any $(n,t)\in\mathbb{Z}\times\mathbb{R}$. Therefore, there must be $0<\Phi_n(t;\theta_0)-\Phi_n(t;-\infty)\le Ke^{\lambda_*(t+\theta_0)}$ for all $(n,t)\in\mathbb{Z}\times\mathbb{R}$, which implies that $\Phi(t;\theta_0)$ converges uniformly on $(n,t)\in\mathbb{Z}\times(-\infty,a]$ to $\Phi(t;-\infty)$ as $\theta_0\to-\infty$ for any $a\in\mathbb{R}$. For any sequence $\theta_0^k\to-\infty$ $(k\to+\infty)$, the functions $\Phi(t;\theta_0^k)$ converge to a solution of (1.1) in $\mathcal{T}$, which turns out to be $\Phi(t;-\infty)$. The limit does not depend on the sequence θ_0^k, whence all of the functions $\Phi(t;\theta_0)$ converge to $\Phi(t;-\infty)$ in $\mathcal{T}$ as $\theta_0\to-\infty$. The assertion as $\theta_0\to+\infty$ is obvious.

We next prove (viii). Assume $\chi=1$. Similarly to that in (vii), we denote

$$\Phi_{c_1,\dots,c_m;c_1',\dots,c_l';\theta_1,\dots,\theta_m;\theta_1',\dots,\theta_l';\theta_0}(t)$$

by $\Phi(t)_{\theta_i}$ and $\Phi_{c_1,\dots,c_{i-1},c_{i+1},\dots,c_m;c_1',\dots,c_l';\theta_1,\dots,\theta_{i-1},\theta_{i+1},\dots,\theta_m;\theta_1',\dots,\theta_l';\theta_0}(t)$ by $\Phi(t)_\infty$. Set

$$\begin{aligned}
\psi^k(t)_{\theta_i} &= \left\{\psi_n^k(s)_{\theta_i}\right\}_{k\in\mathbb{Z}},\\
\psi_n^k(s)_{\theta_i} &= \max\left\{\max_{1\le j\le m}\phi_{c_j}\left(n+c_j(s-k)+\theta_j\right),\right.\\
&\qquad \left.\max_{1\le j\le l}\phi_{c_j'}\left(-n+c_j'(s-k)+\theta_j'\right),\Gamma\left((s-k)+\theta_0\right)\right\},
\end{aligned}$$

and $v^k(t)_{\theta_i}=\{v_n^k(t)_{\theta_i}\}_{n\in\mathbb{Z}}$ with $v_n^k(t)_{\theta_i} := u_n(t+k;\psi^k(\cdot)_{\theta_i})$ for any $(n,t)\in\mathbb{Z}\times[-\tau-k,+\infty)$. Take

$$\begin{aligned}
\psi^k(t)_\infty &= \left\{\psi_n^k(s)_\infty\right\}_{k\in\mathbb{Z}},\\
\psi_n^k(s)_\infty &= \max\left\{\max_{j\in\{1,\dots,i-1,i+1,\dots,m\}}\phi_{c_j}\left(n+c_j(s-k)+\theta_j\right),\right.\\
&\qquad \left.\max_{1\le j\le l}\phi_{c_j'}\left(-n+c_j'(s-k)+\theta_j'\right),\Gamma\left((s-k)+\theta_0\right)\right\},
\end{aligned}$$

and $v^k(t)_\infty = \{v_n^k(t)_\infty\}_{n\in\mathbb{Z}}$ with $v_n^k(t)_\infty := u_n(t+k;\psi^k(\cdot)_\infty)$ for any $(n,t)\in\mathbb{Z}\times[-\tau-k,+\infty)$. Set $\hat{v}^k(t) = v^k(t)_{\theta_i} - v^k(t)_\infty = \{v_n^k(t)_{\theta_i} - v_n^k(t)_\infty\}_{n\in\mathbb{Z}}$. Then $\hat{v}^k(t)$ satisfies $0\le \hat{v}_n^k(t)\le K$ for any $(n,t)\in\mathbb{Z}\times[-\tau-k,+\infty)$ and

$$\frac{d}{dt}\hat{v}_n^k(t) \le D\sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)\left[\hat{v}_{n-i}^k(t) - \hat{v}_n^k(t)\right] - d\hat{v}_n^k(t) + b'(0)\sum_{i\in\mathbb{Z}} J(i)\,\hat{v}_{n-i}^k(t-\tau).$$

Noting that $\hat{v}_n^k(s)\le \phi_{c_i}(n+c_is+\theta_i)\le A_{c_i}e^{\lambda_1(c_i)(n+c_is+\theta_i)}$ for any $s\in[-\tau-k,-k]$ and that $\bar{w}_n^k(t) = A_{c_i}e^{\lambda_1(c_i)(n+c_it+\theta_i)}$ satisfies

$$\frac{d}{dt}\bar{w}_n^k(t) = D\sum_{i\in\mathbb{Z}\setminus\{0\}} I(i)\left[\bar{w}_{n-i}^k(t) - \bar{w}_n^k(t)\right] - d\bar{w}_n^k(t) + b'(0)\sum_{i\in\mathbb{Z}} J(i)\,\bar{w}_{n-i}^k(t-\tau)$$

for any $t\in[-\tau-k,+\infty)$, it follows from Theorem 3.4 that $0\le\hat{v}_n^k(t)\le A_{c_i}e^{\lambda_1(c_i)(n+c_it+\theta_i)}$ for any $(n,t)\in\mathbb{Z}\times[-\tau-k,+\infty)$ and $k\in\mathbb{N}$. Since $\lim_{k\to+\infty}v^k(t)_{\theta_i} = \Phi(t)_{\theta_i}$ and $\lim_{k\to+\infty}v^k(t)_\infty = \Phi(t)_\infty$, we have $0 < \Phi_n(t)_{\theta_i} - \Phi_n(t)_\infty \le A_{c_i}e^{\lambda_1(c_i)(n+c_it+\theta_i)}$ for all $(n,t)\in\mathbb{Z}\times\mathbb{R}$, which implies that $\Phi(t)_{\theta_i}$ converges uniformly on $(n,t)\in\{n: n\le N_0, n\in\mathbb{Z}\}\times(-\infty,a]$ to $\Phi(t)_\infty$ as $\theta_i\to-\infty$ for any $N_0\in\mathbb{Z}$ and $a\in\mathbb{R}$. For any sequence $\theta_i^k\to-\infty$ $(k\to+\infty)$, the functions $\Phi(t)_{\theta_i^k}$ converge to a solution of (1.1), which must be $\Phi(t)_\infty$. Since the limit is independent of the sequence θ_i^k, all of the functions $\Phi(t)_{\theta_i}$ converge to $\Phi(t)_\infty$ in $\mathcal{T}$ as $\theta_i\to-\infty$. The assertion as $\theta_j'\to-\infty$ and the case $\chi=0$ can be proved similarly.

Using the inequality (1.8), we can prove (ii)–(vi) and (ix) of Theorem 1.1. □

6. Proof of Theorem 1.2. In this section, we prove Theorem 1.2. We prove only the continuous dependence of the entire solution on the parameters c, c', θ, θ', and θ_0 and the uniqueness of the entire solutions satisfies (1.9). Other conclusions follow immediately from Theorem 1.1.

Consider (1.4) or

$$u_n'(t) = \frac{D}{2}\left[u_{n+1}+u_{n-1}-2u_n\right] + f\left(u_n(t)\right), \tag{6.1}$$

where f satisfies the conditions given after (1.4). Let $\phi_c(n+ct)$ be a traveling wave front of (6.1) with wave speed $c>c^*$. As done in section 1, we normalize $\phi_c(n+ct)$ so that $\phi(0)=\frac{1}{2}$. Then the functions $\phi_c(z)$ are continuous with respect to $c\in(c^*,+\infty)$ in the norms $C^1_{loc}(\mathbb{R})$ (see [20, p. 1267] for the definition of these norms). Indeed, if $c_l\to c\in(c^*,+\infty)$, then by the unique boundedness of $|\phi_{c_l}'(z)|$ and $|\phi_{c_l}''(z)|$ in $z\in\mathbb{R}$ on $l\in\mathbb{N}$ and by a diagonal extraction process, there exists a subsequence c_{l_i} such that $\phi_{c_{l_i}}\to\phi$ in $C^1_{loc}(\mathbb{R})$, where ϕ is a solution of

$$c\phi'(z) = \frac{D}{2}\left[\phi(z+1)+\phi(z-1)-2\phi(z)\right] + f\left(\phi(z)\right) \text{ in } z\in\mathbb{R}.$$

Obviously, ϕ is nondecreasing in $\mathbb{R}$ and is not a constant and $\phi(0)=\frac{1}{2}$. By the assumptions of f, we have $\phi(-\infty)=0$ and $\phi(+\infty)=1$. Thus, ϕ is a traveling wave front of (6.1) with wave speed c. Following Chen and Guo [5], we have $\phi\equiv\phi_c$. Finally, the whole sequence $\phi_{c_l}\to\phi_{c_0}$ in $C^1_{loc}(\mathbb{R})$ as $l\to+\infty$. In view of [4, 5], we know that α_c and A_c defined by (1.6) and (1.7), respectively, are still valid for (6.1). In addition, there exactly is $\lambda_* = f'(0)$ for (6.1).

LEMMA 6.1. *For* (6.1), $\alpha_c = \lim_{z\to-\infty}\phi_c(z)\,e^{-\lambda_1(c)z}$ *is continuous in* $c\in(c^*,+\infty)$.

Proof. Fix $c_0 \in (c^*, +\infty)$ and let $c_l \to c_0$ as $l \to +\infty$ with $c_l > c^*$ for each $l \in \mathbb{N}$. Then by Chen and Guo [4] (see also Ma, Weng, and Zou [25]), we know that, for each $c \in (c^*, +\infty)$, there exists a unique traveling wave front $\widetilde{\phi}_c$ such that $\widetilde{\phi}_c'(\cdot) > 0$, $\widetilde{\phi}_c(-\infty) = 0$, $\widetilde{\phi}_c(+\infty) = 1$, and

$$\lim_{z \to -\infty} \widetilde{\phi}_c(z)\, e^{-\lambda_1(c)z} = 1.$$

Then we have that $\widetilde{\phi}_{c_l} \to \widetilde{\phi}_{c_0}$ in $C^1_{loc}(\mathbb{R})$ as $l \to +\infty$. In fact, since $c_l \to c_0$ as $l \to +\infty$, then there exist a subsequence c_{l_i} and a function $\widetilde{\phi}$ such that $\widetilde{\phi}_{c_{l_i}} \to \widetilde{\phi}$ in $C^1_{loc}(\mathbb{R})$, where $\widetilde{\phi}$ is nondecreasing and satisfies

$$c\widetilde{\phi}'(z) = \frac{D}{2}\left[\widetilde{\phi}(z+1) + \widetilde{\phi}(z-1) - 2\widetilde{\phi}(z)\right] + f\left(\widetilde{\phi}(z)\right) \text{ in } z \in \mathbb{R}.$$

On the other hand, by Chen and Guo [4], there exist two constants $q > 1$ and $\beta > 1$, independent of c_l, such that

$$e^{\lambda_1(c_l)z} - qe^{\beta\lambda_1(c_l)z} \le \phi_{c_l}(z) \le e^{\lambda_1(c_l)z} + qe^{\beta\lambda_1(c_l)z} \text{ for any } z \in \mathbb{R}$$

and therefore, as $l \to \infty$,

$$e^{\lambda_1(c_0)z} - qe^{\beta\lambda_1(c_0)z} \le \widetilde{\phi}(z) \le e^{\lambda_1(c_0)z} + qe^{\beta\lambda_1(c_0)z} \text{ for any } z \in \mathbb{R},$$

which implies that $\widetilde{\phi}(z)$ is not a constant and satisfies $\widetilde{\phi}(z)e^{-\lambda_1(c_0)z} = 1$. Then it follows from Chen and Guo [5] (see also Ma, Weng, and Zou [25]) that $\widetilde{\phi} \equiv \widetilde{\phi}_{c_0}$. Consequently, the whole sequence $\widetilde{\phi}_{c_l} \to \widetilde{\phi}_{c_0}$ in $C^1_{loc}(\mathbb{R})$ as $l \to +\infty$.

Now let $\widetilde{\phi}_{c_0}(\varsigma_0) = \frac{1}{2}$ and $\widetilde{\phi}_{c_l}(\varsigma_l) = \frac{1}{2}$. Then we have that $\varsigma_l \to \varsigma_0$ as $l \to +\infty$. Assume that this assertion is not true. Take $\varsigma_l \to \overline{\varsigma} \ne \varsigma_0$ as $l \to +\infty$ (up to extraction of some subsequence). If $|\overline{\varsigma}| < \infty$, then, by $\widetilde{\phi}_{c_l} \to \widetilde{\phi}_{c_0}$ in $C^1_{loc}(\mathbb{R})$ as $l \to +\infty$, we have $\widetilde{\phi}_{c_0}(\overline{\varsigma}) = \frac{1}{2} = \widetilde{\phi}_{c_0}(\varsigma_0)$, which is impossible since $\frac{d}{dz}\widetilde{\phi}_{c_0}(z) > 0$ for any $z \in \mathbb{R}$ and $\overline{\varsigma} \ne \varsigma_0$. If $\overline{\varsigma} = +\infty$, then $\widetilde{\phi}_{c_l}(\varsigma_0 + 1) < \widetilde{\phi}_{c_l}(\varsigma_l) = \frac{1}{2}$ for sufficiently large l implies that $\widetilde{\phi}_{c_0}(\varsigma_0 + 1) \le \frac{1}{2} = \widetilde{\phi}_{c_0}(\varsigma_0)$, which is also impossible. Similarly, $\overline{\varsigma} = -\infty$ is impossible. Thus, we conclude that $\varsigma_l \to \varsigma_0$ as $l \to +\infty$.

Again applying Chen and Guo [5], we have that $\phi_{c_0}(\cdot) = \widetilde{\phi}_{c_0}(\varsigma_0 + \cdot)$ and $\phi_{c_l}(\cdot) = \widetilde{\phi}_{c_l}(\varsigma_l + \cdot)$. Since

$$\lim_{z \to -\infty} \phi_{c_0}(z)\, e^{-\lambda_1(c_0)(z+\varsigma_0)} = \lim_{z \to -\infty} \widetilde{\phi}_{c_0}(z + \varsigma_0)\, e^{-\lambda_1(c_0)(z+\varsigma_0)} = 1,$$

we have $\lim_{z \to -\infty} \phi_{c_0}(z)e^{-\lambda_1(c_0)z} = e^{\lambda_1(c_0)\varsigma_0} = \alpha_{c_0}$. Similarly, we have

$$\lim_{z \to -\infty} \phi_{c_l}(z)\, e^{-\lambda_1(c_l)z} = e^{\lambda_1(c_l)\varsigma_l} = \alpha_{c_l}.$$

Finally, there holds $\alpha_{c_l} \to \alpha_{c_0}$ as $l \to +\infty$. This completes the proof. ∎

Recall that

$$A_c = \inf\left\{A > 0 : Ae^{\lambda_1(c)z} \ge \phi_c(z) \text{ in } z \in \mathbb{R}\right\}.$$

LEMMA 6.2. *For* (6.1), A_c *is continuous on* $c \in (c^*, +\infty)$.

Proof. Fix $c_0 \in (c^*, +\infty)$ and let $c_l \to c_0$ as $l \to +\infty$ with $c_l > c^*$ for each $l \in \mathbb{N}$. We prove the theorem by way of contradiction. Assume $A_{c_l} \to A_0 \in \mathbb{R} \cup \{\infty\}$

as $l \to \infty$ (up to extraction of some subsequence) and $A_0 \neq A_{c_0}$. Since $A_{c_l} \geq e^{-\lambda_1(c_l)z}\phi_{c_l}(z)$ for any $z \in \mathbb{R}$, $A_0 \geq e^{-\lambda_1(c_0)z}\phi_{c_0}(z)$ and, hence, $A_0 > A_{c_0}$. Fix $b = \min\{\frac{A_0+A_{c_0}}{2}, A_{c_0}+1\}$. Then there exists $L \in \mathbb{N}$ such that for any $l > L$, $A_{c_l} > b$. On the other hand, since $\alpha_{c_l} \to \alpha_{c_0} \leq A_{c_0}$ and $\lambda_1(c_l) \to \lambda_1(c_0)$, there exists a constant $Z_0 > 0$, independent of c_l, such that $\phi_{c_l}(z)e^{-\lambda_1(c_l)z} \leq b$ for any $|z| > Z_0$. For $z \in [-Z_0, Z_0]$, by $\phi_{c_0}(z)e^{-\lambda_1(c_0)z} \leq A_{c_0}$, $\phi_{c_l}(z) \to \phi_{c_0}(z)$ in $C^1_{loc}(\mathbb{R})$, and the equicontinuity of $e^{-\lambda_1(c_l)z}$ on l, there exists $L' > L$ such that $\phi_{c_l}(z)e^{-\lambda_1(c_l)z} \leq b$ for any $l > L'$ and $z \in [-Z_0, Z_0]$. Therefore, $\phi_{c_l}(z)e^{-\lambda_1(c_l)z} \leq b$ for any $l > L'$ and $z \in \mathbb{R}$, which contradicts $A_{c_l} > b$ for any $l > L$. □

Before proving Theorem 1.2, we first consider the following linear Cauchy problem:

$$\begin{cases} \frac{d}{dt}u_n(t) = \frac{D}{2}\left[u_{n+1}(t) + u_{n-1}(t) - 2u_n(t)\right] + f'(0)\,u_n(t), & t > 0, \\ u_n(0) = u_n^0, \end{cases} \tag{6.2}$$

where $u^0 = \{u_n^0\}_{n\in\mathbb{Z}} \in l^\infty$. By Theorem 3.3, we know that (6.2) admits a unique solution $u(t) = u(t;u^0) = \{u_n(t)\}_{n\in\mathbb{Z}}$ on $t \in [0, +\infty)$. By using the discrete Fourier transformation, we can exactly solve the solution $u(t) = \{u_n(t)\}_{n\in\mathbb{Z}}$ of (6.2) as follows:

$$u_n(t) = \frac{1}{\pi}e^{f'(0)t}\sum_{i=-\infty}^{+\infty} u_i^0 \int_0^\pi \cos\left((i-n)\omega\right) e^{Dt(\cos\omega - 1)}d\omega. \tag{6.3}$$

This formulation is very crucial for the proof of Theorem 1.2.

Proof of Theorem 1.2. We prove only the case $\varrho = \varrho' = \chi = 1$. Consider a sequence

$$(c_k, c_k', \theta_k, \theta_k', \theta_{0,k}) \to (c, c', \theta, \theta', \theta_0) \in (c^*, +\infty)^2 \times \mathbb{R}^3 \quad \text{as} \quad k \to +\infty.$$

For given $(c_k, c_k', \theta_k, \theta_k', \theta_{0,k})$ and $(c, c', \theta, \theta', \theta_0)$, it follows from Theorem 1.1 that there exist entire solutions $\Phi_{c_k;c_k';\theta_k;\theta_k';\theta_{0,k}}(t)$ and $\Phi_{c;c';\theta;\theta';\theta_0}(t)$ of (1.4) satisfying (1.9). For the sake of convenience, set $\Phi^k(t) = \{\Phi_n^k(t)\}_{n\in\mathbb{Z}} = \Phi_{c_k;c_k';\theta_k;\theta_k';\theta_{0,k}}(t)$ and $\Phi(t) = \{\Phi_n(t)\}_{n\in\mathbb{Z}} = \Phi_{c;c';\theta;\theta';\theta_0}(t)$.

Using Lemma 5.1, there exists a function $\widetilde{\Phi}(t) = \{\widetilde{\Phi}_n(t)\}_{n\in\mathbb{Z}}$ such that $\Phi_n^k(t) \to \widetilde{\Phi}_n(t)$ as $k \to \infty$ (up to extraction of some subsequence) in $\mathcal{T}$. In particular, the function $\widetilde{\Phi}(t) = \{\widetilde{\Phi}_n(t)\}_{n\in\mathbb{Z}}$ is also an entire solution of (6.1) (or (1.4)). By passage to the limit $k \to +\infty$ in (1.9), the function $\widetilde{\Phi}(t) = \{\widetilde{\Phi}_n(t)\}_{n\in\mathbb{Z}}$ fulfills the estimates

$$\begin{aligned} &\max\left\{\phi_c(n+ct+\theta), \Gamma(t+\theta_0), \phi_{c'}(-n+c't+\theta')\right\} \\ &\leq \widetilde{\Phi}_n(t) \leq \min\Big\{1, \phi_c(n+ct+\theta) + e^{\lambda_*(t+\theta_0)} + A_{c'}e^{\lambda_1(c')(-n+c't+\theta')}, \\ &\qquad \Gamma(t+\theta_0) + A_c e^{\lambda_1(c)(n+ct+\theta)} + A_{c'}e^{\lambda_1(c')(-n+c't+\theta')}, \\ &\qquad \phi_{c'}(-n+c't+\theta') + e^{\lambda_*(t+\theta_0)} + A_c e^{\lambda_1(c)(n+ct+\theta)}\Big\} \end{aligned} \tag{6.4}$$

for any $(n,t) \in \mathbb{Z}\times\mathbb{R}$.

Let us now prove that $\widetilde{\Phi}_n(t) = \Phi_n(t)$ for any $(n,t) \in \mathbb{Z}\times\mathbb{R}$. Recall that the functions $v^k(t) = \{v_n^k(t)\}_{n\in\mathbb{N}}$, which are solutions of the Cauchy problems

$$\frac{d}{dt}v_n^k(t) = \frac{D}{2}\left[v_{n+1}^k(t) + v_{n-1}^k(t) - 2v_n^k(t)\right] + f\left(v_n^k(t)\right), \; t > -k, \; n \in \mathbb{N},$$

with the initial conditions

$$v_n^k(-k) = v_{n,0}^k = \max\left\{\phi_c(n-ck+\theta), \Gamma(-k+\theta_0), \phi_{c'}(-n-c'k+\theta')\right\},$$

converge to the function $\Phi(t) = \{\Phi_n(t)\}_{n\in\mathbb{N}}$ in $\mathcal{T}$; see the proof of Theorem 1.1. Let us now compare the functions $\widetilde{\Phi}(t)$ to the functions $v^k(t)$ for $t > -k$. Following (6.4), we get that

$$\begin{aligned}(6.5)\qquad &\left|\widetilde{\Phi}_n(-k) - v_n^k(-k)\right| \\ &\le \begin{cases} e^{f'(0)(-k+\theta_0)} + A_{c'}e^{\lambda_1(c')(-n-c'k+\theta')} & \text{if } n \ge n_k^+ + 2, \\ A_c e^{\lambda_1(c)(n-ck+\theta)} + A_{c'}e^{\lambda_1(c')(-n-c'k+\theta')} & \text{if } n_k^- + 1 \le n \le n_k^+ - 1, \\ e^{f'(0)(-k+\theta_0)} + A_c e^{\lambda_1(c)(n-ck+\theta)} & \text{if } n \le n_k^- - 2 \end{cases}\end{aligned}$$

for sufficiently large k, where n_k^- and n_k^+ are two integers defined as follows:

$$\begin{aligned} n_k^- &= \operatorname{int}\left[-c'k + \frac{f'(0)}{\lambda_1(c')}k + \theta' - \frac{1}{\lambda_1(c')}\ln\frac{1}{\alpha_{c'}} - \frac{f'(0)}{\lambda_1(c')}\theta_0\right], \\ n_k^+ &= \operatorname{int}\left[ck - \frac{f'(0)}{\lambda_1(c)}k - \theta + \frac{1}{\lambda_1(c)}\ln\frac{1}{\alpha_c} + \frac{f'(0)}{\lambda_1(c)}\theta_0\right]. \end{aligned}$$

n_k^- is obtained by comparing $\phi_{c'}(-n-c'k+\theta')$ and $\Gamma(-k+\theta_0)$ and using the asymptotic behaviors of $\phi_{c'}$ and Γ. Similarly, we obtain n_k^+.

For any $x \in \mathbb{R}$, define

$$\operatorname{int}[x] = \max\{m : m \in \mathbb{Z}, m \le x\}.$$

Fix $t_0 > -k$. For any $n \in \mathbb{Z}$ and $k \in \mathbb{N}$ with $k > -t_0$, define

$$a_n^k = \frac{1}{2\pi}e^{-D(t_0+k)}\int_0^\pi \cos(nw)\, e^{D(t_0+k)\cos w}dw.$$

By Weng, Huang, and Wu [40], we know that $a_n^k = a_{-n}^k > 0$ for any $n \in \mathbb{Z}$ and $\sum_{n=-\infty}^{+\infty} a_n^k = 1$. Furthermore, for $n > 1$ there is

$$\begin{aligned} a_n^k &= \frac{1}{2\pi}\int_0^\pi \cos(nw)\, e^{D(t_0+k)[\cos w-1]}dw = \frac{1}{2n\pi}\int_0^\pi e^{D(t_0+k)[\cos w-1]}d\sin(nw) \\ &= \frac{D(t_0+k)}{2n\pi}\int_0^\pi \sin(nw)\sin w e^{D(t_0+k)[\cos w-1]}dw \\ &= \frac{D(t_0+k)}{4n\pi}\int_0^\pi \left[\cos((n-1)w) - \cos((n+1)w)\right]e^{D(t_0+k)[\cos w-1]}dw \\ &= \frac{D(t_0+k)}{2n}\left(a_{n-1}^k - a_{n+1}^k\right), \end{aligned}$$

which implies that $a_{n-1}^k > a_{n+1}^k$ for any $n \in \mathbb{N}$. By the symmetry, $a_{-n-1}^k < a_{-n+1}^k$ for any $n \in \mathbb{N}$.

We claim that, for any given $\eta \in (0, +\infty)$, there hold

$$(6.6)\qquad a_{\operatorname{int}[\eta k]}^k \to 0 \quad \text{and} \quad a_{\operatorname{int}[\eta k]-1}^k \to 0 \quad \text{as} \quad k \to +\infty.$$

Consider $a^k_{\mathrm{int}[\eta k]} \to 0$ as $k \to +\infty$. If the assertion is false, then we can assume that $a^k_{\mathrm{int}[\eta k]} \to \delta > 0$ as $k \to +\infty$ (up to extraction of some subsequence). Taking k sufficiently large such that $\frac{\mathrm{int}[\eta k]}{2} > \frac{4}{\delta} + 1$ and $a^k_{\mathrm{int}[\eta k]} > \frac{\delta}{2}$, by $a^k_{n-1} > a^k_{n+1}$ for $n \in \mathbb{N}$, we have $\sum_{n=0}^{\mathrm{int}[\eta k]} a^k_n > 1$, which contradicts the fact $\sum_{n=-\infty}^{+\infty} a^k_n < 1$. Therefore, $\lim_{k\to+\infty} a^k_{\mathrm{int}[\eta k]} = 0$. Similarly, we have $\lim_{k\to+\infty} a^k_{\mathrm{int}[\eta k]-1} = 0$. For any $m > N$,

$$\begin{aligned}
\sum_{n=N\geq 1}^{m} a^k_n &= \frac{D(t_0+k)}{2N}\left(a^k_{N-1} - a^k_{N+1}\right) + \frac{D(t_0+k)}{2(N+1)}\left(a^k_N - a^k_{N+2}\right) \\
&\quad + \frac{D(t_0+k)}{2(N+2)}\left(a^k_{N+1} - a^k_{N+3}\right) \\
&\quad + \cdots + \frac{D(t_0+k)}{2(m-1)}\left(a^k_{m-2} - a^k_m\right) + \frac{D(t_0+k)}{2m}\left(a^k_{m-1} - a^k_{m+1}\right) \\
&= \frac{D(t_0+k)}{2N}a^k_{N-1} + \frac{D(t_0+k)}{2(N+1)}a^k_N - \frac{D(t_0+k)}{N(N+2)}a^k_{N+1} \\
&\quad - \frac{D(t_0+k)}{(N+1)(N+3)}a^k_{N+2} - \cdots - \frac{D(t_0+k)}{(m-3)(m-1)}a^k_{m-2} \\
&\quad - \frac{D(t_0+k)}{(m-2)m}a^k_{m-1} - \frac{D(t_0+k)}{2(m-1)}a^k_m - \frac{D(t_0+k)}{2m}a^k_{m+1} \\
&\leq \frac{D(t_0+k)}{2N}a^k_{N-1} + \frac{D(t_0+k)}{2(N+1)}a^k_N.
\end{aligned}$$

Therefore,

$$\sum_{n=N\geq 1}^{\infty} a^k_n \leq \frac{D(t_0+k)}{2N}a^k_{N-1} + \frac{D(t_0+k)}{2(N+1)}a^k_N.$$

Consequently, we obtain that for any given $\eta > 0$,

$$\sum_{n=\mathrm{int}[\eta k]}^{\infty} a^k_n \to 0 \quad \text{and} \quad \sum_{n=\mathrm{int}[\eta k]+1}^{\infty} a^k_n \to 0 \quad \text{as} \quad k \to +\infty \tag{6.7}$$

due to $\frac{D(t_0+k)}{[\eta k]} \to \frac{D}{\eta}$ as $k \to +\infty$.

Now fix $(n_0, t_0) \in \mathbb{Z} \times \mathbb{R}$; we estimate $\widetilde{\Phi}_{n_0}(t_0) - v^k_{n_0}(t_0)$ as $k \to +\infty$. We compare $\widetilde{\Phi}_n(t) - v^k_n(t)$ with a solution of the linear equation

$$\frac{d}{dt}u_n(t) = \frac{D}{2}\left[u_{n+1}(t) + u_{n-1}(t) - 2u_n(t)\right] + f'(0)\,u_n(t), \quad t > -k,$$

with the initial condition $u_n(-k) = |\widetilde{\Phi}_n(-k) - v^k_n(-k)|$. Using (6.3), we deduce that

$$
\begin{aligned}
&\left|\widetilde{\Phi}_{n_0}(t_0)-v^k_{n_0}(t_0)\right| \\
&\le \frac{1}{\pi}e^{f'(0)(t_0+k)}\sum_{n=-\infty}^{+\infty}\int_0^\pi \cos\left((n-n_0)w\right)e^{D(t_0+k)[\cos w-1]}\left|\widetilde{\Phi}_n(-k)-v^k_n(-k)\right|dw \\
&\le \frac{1}{\pi}e^{f'(0)(t_0+k)}\sum_{n=n_k^++2}^{+\infty}\int_0^\pi \cos\left((n-n_0)w\right)e^{D(t_0+k)[\cos w-1]}\left|\widetilde{\Phi}_n(-k)-v^k_n(-k)\right|dw \\
&\quad+\frac{1}{\pi}e^{f'(0)(t_0+k)}\int_0^\pi \cos\left(\left(n_k^++1-n_0\right)w\right)e^{D(t_0+k)[\cos w-1]}\left|\widetilde{\Phi}_n(-k)-v^k_n(-k)\right|dw \\
&\quad+\frac{1}{\pi}e^{f'(0)(t_0+k)}\int_0^\pi \cos\left(\left(n_k^+-n_0\right)w\right)e^{D(t_0+k)[\cos w-1]}\left|\widetilde{\Phi}_n(-k)-v^k_n(-k)\right|dw \\
&\quad+\frac{1}{\pi}e^{f'(0)(t_0+k)}\sum_{n=n_k^-+1}^{n_k^+-1}\int_0^\pi \cos\left((n-n_0)w\right)e^{D(t_0+k)[\cos w-1]}\left|\widetilde{\Phi}_n(-k)-v^k_n(-k)\right|dw \\
&\quad+\frac{1}{\pi}e^{f'(0)(t_0+k)}\int_0^\pi \cos\left(\left(n_k^--n_0\right)w\right)e^{D(t_0+k)[\cos w-1]}\left|\widetilde{\Phi}_n(-k)-v^k_n(-k)\right|dw \\
&\quad+\frac{1}{\pi}e^{f'(0)(t_0+k)}\int_0^\pi \cos\left(\left(n_k^--1-n_0\right)w\right)e^{D(t_0+k)[\cos w-1]}\left|\widetilde{\Phi}_n(-k)-v^k_n(-k)\right|dw \\
&\quad+\frac{1}{\pi}e^{f'(0)(t_0+k)}\sum_{n=-\infty}^{n_k^--2}\int_0^\pi \cos\left((n-n_0)w\right)e^{D(t_0+k)[\cos w-1]}\left|\widetilde{\Phi}_n(-k)-v^k_n(-k)\right|dw.
\end{aligned}
$$

Call I, II, III, IV, V, VI, and VII the seven terms on the right-hand side of this last inequality. We have

$$
\begin{aligned}
\mathrm{I} &= \frac{1}{\pi}e^{f'(0)(t_0+k)}\sum_{n=n_k^++2}^{+\infty}\int_0^\pi \cos\left((n-n_0)w\right)e^{D(t_0+k)[\cos w-1]}\left|\widetilde{\Phi}_n(-k)-v^k_n(-k)\right|dw \\
&\le \frac{1}{\pi}e^{f'(0)(t_0+k)}\sum_{n=n_k^++2}^{+\infty}\int_0^\pi \cos\left((n-n_0)w\right)e^{D(t_0+k)[\cos w-1]}e^{f'(0)(-k+\theta_0)}dw \\
&\quad+\frac{A_{c'}}{\pi}e^{f'(0)(t_0+k)}\sum_{n=n_k^++2}^{+\infty}\int_0^\pi \cos\left((n-n_0)w\right)e^{D(t_0+k)[\cos w-1]}e^{\lambda_1(c')\left(-n-c'k+\theta'\right)}dw \\
&= \mathrm{I}_1+\mathrm{I}_2.
\end{aligned}
$$

Obviously,

$$
\begin{aligned}
\mathrm{I}_1 &= \frac{1}{\pi}e^{f'(0)(t_0+k)}\sum_{n=n_k^++2}^{+\infty}\int_0^\pi \cos\left((n-n_0)w\right)e^{D(t_0+k)[\cos w-1]}e^{f'(0)(-k+\theta_0)}dw \\
&= 2e^{f'(0)(t_0+\theta_0)}\sum_{n=n_k^++2}^{+\infty}a^k_{n-n_0}\to 0 \text{ as } k\to+\infty
\end{aligned}
$$

due to the fact $\frac{n_k^++2-n_0}{k} > \frac{c\lambda_1(c)-f'(0)}{2\lambda_1(c)} > 0$ for sufficiently large k and (6.7). In

addition, we have

$$\begin{aligned}
\mathrm{I}_2 &= \frac{A_{c'}}{\pi} e^{f'(0)(t_0+k)} \sum_{n=n_k^++2}^{+\infty} \int_0^{\pi} \cos\left((n-n_0)\,w\right) e^{D(t_0+k)[\cos w-1]} e^{\lambda_1(c')\left(-n-c'k+\theta'\right)} dw \\
&= 2A_{c'} e^{\left(f'(0)-\lambda_1(c')c'\right)k} e^{f'(0)\left(t_0+\theta'\right)} \sum_{n=n_k^++2}^{+\infty} a_{n-n_0}^k e^{-\lambda_1(c')n} \\
&\le 2A_{c'} e^{f'(0)\left(t_0+\theta'\right)} \sum_{n=n_k^++2}^{+\infty} a_{n-n_0}^k \to 0 \text{ as } k \to \infty.
\end{aligned}$$

Consider II. In this case, let

$$0 \le \delta = \left(ck - \frac{f'(0)}{\lambda_1(c)}k - \theta + \frac{1}{\lambda_1(c)} \ln \frac{1}{\alpha_c} + \frac{f'(0)}{\lambda_1(c)}\theta_0\right) - n_k^+ < 1.$$

Then we have

$$\begin{aligned}
\mathrm{II} &= 2e^{f'(0)(t_0+k)} a_{n_k^++1-n_0}^k \left|\widetilde{\Phi}_{n_k^++1}(-k) - v_{n_k^++1}^k(-k)\right| \\
&\le 2e^{f'(0)(t_0+k)} a_{n_k^++1-n_0}^k \left[e^{f'(0)(-k+\theta_0)} + A_{c'} e^{\lambda_1(c')\left(-n_k^+-1-c'k+\theta'\right)}\right] \\
&\quad + 2e^{f'(0)(t_0+k)} a_{n_k^++1-n_0}^k \left[A_{c'} e^{\lambda_1(c')\left(-n_k^+-1-c'k+\theta'\right)} + A_c e^{\lambda_1(c)\left(n_k^++1-ck+\theta\right)}\right] \\
&= 2e^{f'(0)(t_0+k)} a_{n_k^++1-n_0}^k \left[e^{f'(0)(-k+\theta_0)} + 2A_{c'} e^{\lambda_1(c')\left(-n_k^+-1-c'k+\theta'\right)}\right] \\
&\quad + 2e^{f'(0)(t_0+k)} a_{n_k^++1-n_0}^k A_c e^{\lambda_1(c)\left\{\left(ck-\frac{f'(0)}{\lambda_1(c)}k-\theta+\frac{1}{\lambda_1(c)}\ln\frac{1}{\alpha_c}+\frac{f'(0)}{\lambda_1(c)}\theta_0\right)-\delta+1-ck+\theta\right\}} \\
&= 2e^{f'(0)(t_0+k)} a_{n_k^++1-n_0}^k \left[e^{f'(0)(-k+\theta_0)} + 2A_{c'} e^{\lambda_1(c')\left(-n_k^+-1-c'k+\theta'\right)}\right] \\
&\quad + \frac{2A_c}{\alpha_c} e^{\lambda_1(c)(1-\delta)+f'(0)(t_0+\theta_0)} a_{n_k^++1-n_0}^k \\
&\to 0 \qquad \text{as} \qquad k \to +\infty.
\end{aligned}$$

Similarly, we have that III$\to 0$ as $k \to +\infty$. For IV, we have

$$\begin{aligned}
\mathrm{IV} &= \frac{1}{\pi} e^{f'(0)(t_0+k)} \\
&\quad \times \sum_{n=n_k^-+1}^{n_k^+-1} \int_0^{\pi} \cos\left((n-n_0)\,w\right) e^{D(t_0+k)[\cos w-1]} \left|\widetilde{\Phi}_n(-k) - v_n^k(-k)\right| dw \\
&\le 2e^{f'(0)(t_0+k)} \sum_{n=n_k^-+1}^{n_k^+-1} a_{n-n_0}^k \left[A_c e^{\lambda_1(c)(n-ck+\theta)} + A_{c'} e^{\lambda_1(c')\left(-n-c'k+\theta'\right)}\right] \\
&= 2e^{f'(0)(t_0+k)} \sum_{n=0}^{n_k^+-1} a_{n-n_0}^k \left[A_c e^{\lambda_1(c)(n-ck+\theta)} + A_{c'} e^{\lambda_1(c')\left(-n-c'k+\theta'\right)}\right] \\
&\quad + 2e^{f'(0)(t_0+k)} \sum_{n=n_k^-+1}^{-1} a_{n-n_0}^k \left[A_c e^{\lambda_1(c)(n-ck+\theta)} + A_{c'} e^{\lambda_1(c')\left(-n-c'k+\theta'\right)}\right] \\
&= \mathrm{IV}_1 + \mathrm{IV}_2.
\end{aligned}$$

Consider IV_1. Then

$$\begin{aligned}
\mathrm{IV}_1 &= 2e^{f'(0)(t_0+k)} \sum_{n=0}^{n_k^+-1} a_{n-n_0}^k \left[A_c e^{\lambda_1(c)(n-ck+\theta)} + A_{c'} e^{\lambda_1(c')(-n-c'k+\theta')} \right] \\
&\le 2A_{c'} e^{-\left(\lambda_1(c')c'-f'(0)\right)k} e^{f'(0)t_0+\lambda_1(c')\theta'} \sum_{n=0}^{n_k^+} a_{n-n_0}^k \\
&\quad + 2A_c e^{f'(0)(t_0+k)} \sum_{n=\mathrm{int}\left[n_k^+/2\right]}^{n_k^+-1} a_{n-n_0}^k e^{\lambda_1(c)(n-ck+\theta)} \\
&\quad + 2A_c e^{f'(0)(t_0+k)} \sum_{n=0}^{\mathrm{int}\left[n_k^+/2\right]} a_{n-n_0}^k e^{\lambda_1(c)(n-ck+\theta)} \\
&\le 2A_{c'} e^{-\left(\lambda_1(c')c'-f'(0)\right)k} e^{f'(0)t_0+\lambda_1(c')\theta'} \\
&\quad + 2A_c e^{f'(0)(t_0+k)} e^{\lambda_1(c)\left(\left(n_k^+-1\right)-ck+\theta\right)} \sum_{n=\mathrm{int}\left[n_k^+/2\right]}^{\infty} a_{n-n_0}^k \\
&\quad + 2A_c e^{\lambda_1(c)\left(\mathrm{int}\left[n_k^+/2\right]-ck+\theta\right)} e^{f'(0)(t_0+k)} \\
&= \mathrm{IV}_1^1 + \mathrm{IV}_1^2 + \mathrm{IV}_1^3.
\end{aligned}$$

It is easy to see that $\mathrm{IV}_1^1 \le 2A_{c'} e^{-(\lambda_1(c')c'-f'(0))k} e^{f'(0)t_0+\lambda_1(c')\theta'} \to 0$ as $k \to +\infty$, because $\lambda_1(c')c' - f'(0) > 0$. By virtue of

$$\begin{aligned}
& e^{f'(0)(t_0+k)} e^{\lambda_1(c)\left(\left(n_k^+-1\right)-ck+\theta\right)} \\
&\quad \le A_c e^{f'(0)(t_0+k)} e^{\lambda_1(c)\left\{\left(ck-\frac{f'(0)}{\lambda_1(c)}k-\theta+\frac{1}{\lambda_1(c)}\ln\frac{1}{\alpha_c}+\frac{f'(0)}{\lambda_1(c)}\theta_0\right)-1-ck+\theta\right\}} \\
&\quad = \frac{1}{\alpha_c} e^{f'(0)(t_0+\theta_0)-\lambda_1(c)}
\end{aligned}$$

and $\frac{n_k^+}{2} - n_0 > \frac{c\lambda_1(c)-f'(0)}{4\lambda_1(c)}k$ for sufficiently large k, we have

$$\mathrm{IV}_1^2 = 2A_c e^{f'(0)(t_0+k)} e^{\lambda_1(c)\left(\left(n_k^+-1\right)-ck+\theta\right)} \sum_{n=\mathrm{int}\left[n_k^+/2\right]}^{\infty} a_{n-n_0}^k \to 0 \text{ as } k \to +\infty.$$

Moreover, we have

$$\begin{aligned}
\mathrm{IV}_1^3 &= 2A_c e^{\lambda_1(c)\left(\mathrm{int}\left[n_k^+/2\right]-ck+\theta\right)} e^{f'(0)(t_0+k)} \\
&\le 2A_c e^{\lambda_1(c)\left(\frac{1}{2}\left[ck-\frac{f'(0)}{\lambda_1(c)}k-\theta+\frac{1}{\lambda_1(c)}\ln\frac{1}{\alpha_c}+\frac{f'(0)}{\lambda_1(c)}\theta_0\right]-ck+\theta\right)} e^{f'(0)(t_0+k)} \\
&= 2A_c e^{f'(0)t_0+\frac{1}{2}\ln\frac{1}{\alpha_c}+\frac{1}{2}f'(0)\theta_0+\frac{1}{2}\lambda_1(c)\theta} e^{-\frac{1}{2}\left[\lambda_1(c)c-f'(0)\right]k} \\
&\to 0 \text{ as } k \to +\infty.
\end{aligned}$$

We can prove that IV_2, V, VI, and VII converge to zero as $k \to +\infty$ by arguments similar to those for IV_1, III, II, and I, respectively.

Eventually, $|\widetilde{\Phi}_{n_0}(t_0) - v_{n_0}^k(t_0)| \to 0$ as $k \to +\infty$. Since $v_{n_0}^k(t_0) \to \Phi_{n_0}(t_0)$ and $(n_0, t_0) \in \mathbb{Z} \times \mathbb{R}$ is arbitrary, we obtain that $\Phi_n(t) = \widetilde{\Phi}_n(t)$ for any $(n,t) \in \mathbb{Z} \times \mathbb{R}$. The limit function being unique, the whole sequence Φ^k converges to Φ as $k \to +\infty$.

Using the same estimates as above, we can prove that the entire solution of (1.4) satisfying (1.9) is unique. ∎

AN ELEMENTARY APPROACH TO A MODEL PROBLEM OF LAGERSTROM*

S. P. HASTINGS† AND J. B. MCLEOD‡

Abstract. The equation studied is $u'' + \frac{n-1}{r}u' + \varepsilon u\, u' + ku'^2 = 0$, with boundary conditions $u(1) = 0$, $u(\infty) = 1$. This model equation has been studied by many authors since it was introduced in the 1950s by P. A. Lagerstrom. We use an elementary approach to show that there is an infinite series solution which is uniformly convergent on $1 \le r < \infty$. The first few terms are easily derived, from which one quickly deduces the inner and outer asymptotic expansions, with no matching procedure or a priori assumptions about the nature of the expansion. We also give a short and elementary existence and uniqueness proof which covers all $\varepsilon > 0$, $k \ge 0$, and $n \ge 1$.

Key words. matched asymptotics, singular perturbation, boundary value problem

1. Introduction.

The main problem is to investigate the asymptotics as $\varepsilon \to 0$ of the boundary value problem

$$u'' + \frac{n-1}{r}u' + \varepsilon u u' + ku'^2 = 0, \tag{1}$$

with

$$u(1) = 0, u(\infty) = 1. \tag{2}$$

We consider the cases $k = 0$ and $k = 1$. Our interest in these problems, originally due to Lagerstrom in the 1950s [6], [7], was stimulated by two recent papers by Popovic and Szmolyan [10], [11], who adopt a geometric approach to the problem when $k = 0$, and there are many papers which use methods of matched asymptotics or multiple scales, with varying degrees of rigor. We will review some of this work below. The point of this paper is to give a completely rigorous and relatively short answer to the problem without making any appeal either to geometric methods or to matched asymptotics. We can express the solution as an infinite series, uniformly convergent for all values of the independent variable. From this series we obtain the inner and outer asymptotic expansions with no a priori assumption about the nature of these expansions. An important and, as far as we know, original feature is that there is no "matching."

Lagerstrom came up with these problems as models of viscous incompressible ($k = 0$) and compressible ($k = 1$) flow, so much of his work centered on $n = 2$ or 3, but he also discussed general $n \ge 1$ [8]. The infinite series we develop can be obtained for any real number n. What n controls is the rate of convergence of the series.

For $\varepsilon = k = 0$, there is an obvious distinction between $n > 2$ and $n \leq 2$. If $n > 2$, then the problem (1)–(2) has the unique solution

$$u = 1 - \frac{1}{r^{n-2}}, \tag{3}$$

so that the solution with ε small is presumably some sort of perturbation of this. If $n \leq 2$, then there is no such solution. A consequence is that the convergence as $\varepsilon \to 0$ is more subtle when $n \leq 2$ than when $n > 2$. Our analysis will show that there is little prospect of discussing the behavior for small ε if $n < 2$, but fortunately we can handle all $n \geq 2$. Although it has been thought that finding the asymptotics when $k = 1$ is considerably more difficult than when $k = 0$ [3], we will show that our technique covers each case with comparable effort.

Our methods are not restricted to Lagerstrom's problems (1)–(2). In subsequent work (in preparation), we will show that there is a general method which can yield similar results for a class of singularly perturbed boundary value problems.

We start in section 2 by showing that each of these problems has one and only one solution for any $n \geq 1$ and any $\varepsilon > 0$. This is based on a simple shooting argument plus a comparison principle. These results have been obtained before, but our proof is quite short. In the subsequent sections we develop the integral equation referred to above and show how it leads with relative ease to the inner and outer expansions. These expansions go back to Lagerstrom and Kaplun, with rigorous justification of some of the features to be found in [1] or [11], for example. We find the exposition in Hinch's book [3] particularly clear (though nonrigorous), and make that work our point of comparison in checking that we get the same expansions as were found previously.

2. Existence and uniqueness. As far as we know, the first existence proof was by Hsiao [4], who considered only $n = 1$ and sufficiently small $\varepsilon > 0$. Subsequently Tam gave what seems to be the first proof valid for all $\varepsilon > 0$ and $k \geq 0$ [14]. Subsequent proofs by MacGillivray [9], Cohen, Lagerstrom, and Fokas [1], Hunter, Tajdari, and Boyer [5], each of which covers all $\varepsilon > 0$, and by several other authors, e.g., [12], [10], for restricted ranges of ε, add to the variety of techniques which have been shown to work. Uniqueness is proved in [5] (for $k = 0$) by use of a contraction mapping theorem, and in [1] by essentially a comparison method. The goal of [10] is not to give a short proof, but to illustrate the application of geometric perturbation theory to a much studied problem in matched asymptotic expansions. The proofs we give of existence and uniqueness are considerably shorter than the others we have seen.

THEOREM 1. *There exists a unique solution to the problem* (1)–(2) *for any* $k \geq 0$, $\varepsilon > 0$, *and* $n \geq 1$.

Proof. Like some others, starting with [14], we prove existence using a shooting method by considering the initial value problem

$$u'' + \frac{n-1}{r}u' + \varepsilon u u' + k u'^2 = 0, \tag{4}$$

$$u(1) = 0,\ u'(1) = c, \tag{5}$$

for each $c > 0$. Since $u' = 0$ implies that $u'' = 0$ and u is constant, any solution to this problem is positive and increasing. As was observed in [14],

$$u'' + \varepsilon u u' \leq 0,$$

and so from (5),

$$u' + \frac{1}{2}\varepsilon u^2 \leq c.$$

In particular, since $u' \geq 0$,

$$u \leq \sqrt{\frac{2c}{\varepsilon}}, \tag{6}$$

so the solution exists, and satisfies this bound, on $[1, \infty)$. Therefore, $\lim_{r\to\infty} u(r)$ exists. Writing the equation in the form

$$\left(r^{n-1}u'\right)' + (\varepsilon u + ku')\left(r^{n-1}u'\right) = 0 \tag{7}$$

and integrating twice gives

$$r^{n-1}u'(r) = ce^{-ku(r)-\varepsilon\int_1^r u(s)ds}, \tag{8}$$

$$u(r) = \int_1^r \frac{c}{s^{n-1}} e^{-ku-\int_1^s \varepsilon u dt} ds. \tag{9}$$

If $u(2) < 1$, then since u is increasing, (9) implies that

$$u(2) > p(c) = \int_1^2 \frac{c}{s^{n-1}} e^{-\varepsilon-k} ds.$$

From this and (6), we see that there are c_1 and c_2, with $0 < c_1 < c_2$, such that if $c = c_1$, then $u(\infty) < 1$, while if $c = c_2$, then $u(\infty) > u(2) \geq 1$. Further, from (8) for any $r > R > 2$,

$$u(r) = u(R) + c\int_R^r \frac{1}{s^{n-1}} e^{-ku-\int_1^s \varepsilon u dt} ds.$$

If $n > 2$, the second term is bounded above by $\frac{c}{(n-2)R^{n-2}}$, while if $1 \leq n \leq 2$ and $R \geq 2$, it is bounded by $c\int_R^\infty e^{-\varepsilon(s-2)p(c)} ds$. Hence, this term tends to zero as $R \to \infty$, uniformly for $r \geq R$, $c_1 \leq c \leq c_2$. Since $u(R)$ is a continuous function of c, for any R, it follows that $u(\infty)$ is also continuous in c, and so there is a c with $u(\infty) = 1$, giving a solution to (1)–(2).

For uniqueness, suppose that there are two solutions of (1)–(2), say u_1 and u_2, with $u_1'(1) > u_2'(1) > 0$. Then $u_1 > u_2$ on some maximal interval, say $(1, X)$ where $X \leq \infty$. For the same initial conditions, if $\varepsilon = k = 0$, then direct integration shows that $u_1 > u_2$ on $(1, \infty)$, and, moreover, $u_1(\infty) > u_2(\infty)$. We then raise ε and k, looking for a pair (ε_1, k_1) such that $u_1(X) = u_2(X)$ for some $X \leq \infty$, and if $0 \leq \varepsilon < \varepsilon_1$ or $0 \leq k < k_1$, no such X exists. Hence, at (ε_1, k_1), $u_1 \geq u_2$ on $[0, \infty)$. If, at (ε_1, k_1), $X < \infty$, then u_1 and u_2 must be tangent at X, since $u_1 - u_2$ has a minimum there, contradicting the uniqueness of initial value problems for (1). Hence, $X = \infty$, and $u_1 > u_2$ on $(1, \infty)$.

Observe from (7) that if $u_1'(r) = u_2'(r)$ for some r, then $\left(r^{n-1}(u_1' - u_2')\right)' < 0$, since $u_1 > u_2$, so that there cannot be oscillations in $u_1' - u_2'$. Hence, $u_1(\infty) = u_2(\infty)$ implies that there is an R with $u_1'(R) = u_2'(R)$ and $u_1' < u_2'$ on (R, ∞). Integrating

(7), and recalling that $u_1(\infty) = u_2(\infty)$, gives

$$r^{n-1}(u_1' - u_2')|_R^\infty = \frac{1}{2}\varepsilon R^{n-1}\left(u_1^2 - u_2^2\right)|_R + \frac{1}{2}\varepsilon(n-1)\int_R^\infty s^{n-2}\left(u_1^2 - u_2^2\right)ds - k\int_R^\infty s^{n-1}\left(u_1'^2 - u_2'^2\right)ds.$$

The left-hand side is zero, and all the terms on the right are positive, giving the necessary contradiction. □

Remark 1. The existence theorem in [10] has one added part. It is shown there that as $\varepsilon \to 0$, the solution tends to a so-called singular solution obtained by taking a formal limit as $\varepsilon \to 0$. See [10] for details. This limit result follows from our rigorous asymptotic expansions given below.

Remark 2. There would seem to be no difficulty in extending the existence proof even to $n < 1$, but the uniqueness proof does use essentially the fact that $n \geq 1$.

3. The infinite series (with $k = 0$, $n \geq 2$). Starting again with (1), and $u(1) = 0$, we first consider the case $k = 0$ and obtain

$$r^{n-1}u' = Be^{-\varepsilon\int_1^r u(t)dt} \tag{10}$$

for some constant B. Since $u(\infty) = 1$, (10) implies that $u'(r)$ is exponentially small as $r \to \infty$. Hence we can rewrite (10) as

$$r^{n-1}u' = Ce^{-\varepsilon r - \varepsilon\int_\infty^r (u-1)dt},$$

so that

$$u - 1 = C\int_\infty^r \frac{1}{t^{n-1}}e^{-\varepsilon t - \varepsilon\int_\infty^t (u-1)ds}dt.$$

Setting $\varepsilon r = \rho$, $\varepsilon t = \tau$, and $\varepsilon s = \sigma$, we obtain

$$u(\rho) - 1 = C\varepsilon^{n-2}\int_\infty^\rho \frac{1}{\tau^{n-1}}e^{-\tau}e^{-\int_\infty^\tau (u(\sigma)-1)d\sigma}d\tau, \tag{11}$$

where we use the arguments ρ and σ to indicate that we mean the rescaled version of u. Here C is a constant satisfying

$$-1 = C\varepsilon^{n-2}\int_\infty^\varepsilon \frac{1}{\tau^{n-1}}e^{-\tau}e^{-\int_\infty^\tau (u-1)d\sigma}d\tau. \tag{12}$$

Since for each ε there is a unique solution, this determines a unique C, dependent on ε.

We now consider the integral

$$\int_\tau^\infty (1 - u(\sigma))\,d\sigma, \tag{13}$$

which appears in the exponent in (12). This integral has been seen to converge for each ε, but we need a bit more, namely, that it is bounded uniformly in $\varepsilon \leq \tau < \infty$ as $\varepsilon \to 0$. To see this, we note that as a function of σ, u satisfies

$$\frac{d^2u}{d\sigma^2} + \frac{n-1}{\sigma}\frac{du}{d\sigma} + u\frac{du}{d\sigma} = 0$$

$$u = 0 \text{ when } \sigma = \varepsilon,\ u(\infty) = 1.$$

Denoting the unique solution by $u_\varepsilon(\sigma)$, we claim that if $0 < \varepsilon_1 < \varepsilon_2$, then $u_{\varepsilon_1} > u_{\varepsilon_2}$ for $\varepsilon_2 \le \sigma < \infty$. If this is false, then ε_1 and ε_2 can be chosen so that $u_{\varepsilon_1}(\sigma_0) = u_{\varepsilon_2}(\sigma_0)$ for some $\sigma_0 \ge \varepsilon_2$. But then the problem

$$\frac{d^2u}{d\sigma^2} + \frac{n-1}{\sigma}\frac{du}{d\sigma} + u\frac{du}{d\sigma} = 0,$$

$$u(\sigma_0) = u_{\varepsilon_1}(\sigma_0),\ u(\infty) = 1,$$

has two solutions, contradicting our earlier uniqueness proof.

A consequence of this is that $\int_{\varepsilon_2}^{\infty}(1 - u_{\varepsilon_1}(\sigma))\,d\sigma < \int_{\varepsilon_2}^{\infty}(1 - u_{\varepsilon_2}(\sigma))\,d\sigma$, which implies that the integral in the exponent in (12), including the minus sign in front, is bounded below independently of $\tau \ge \varepsilon$ and of ε. We then see that the τ-integral in (12) approaches $-\infty$ as $\varepsilon \to 0$, and hence that

$$\lim_{\varepsilon \to 0^+} C\varepsilon^{n-2} = 0.$$

Since $\int_{\infty}^{\tau}(u-1)\,d\sigma > 0$, it follows from (11) that if

$$E_{n-1}(\rho) = \int_{\rho}^{\infty} \frac{1}{\tau^{n-1}} e^{-\tau} d\tau,$$

then

$$|u(\rho) - 1| < C\varepsilon^{n-2} E_{n-1}(\rho). \tag{14}$$

For purposes of future estimates, we make the obvious remark that

$$E_{n-1}(\rho) = \begin{cases} O\left(\rho^{2-n}\right) \text{ as } \rho \to 0 \text{ if } n > 2, \\ O(\log \rho) \text{ as } \rho \to 0 \text{ if } n = 2, \\ O\left(\rho^{1-n} e^{-\rho}\right) \text{ as } \rho \to \infty. \end{cases} \tag{15}$$

Hence if $n > 2$, there is a constant K such that

$$E_{n-1}(\rho) \le K \min\left(\rho^{2-n}, \rho^{1-n} e^{-\rho}\right). \tag{16}$$

The method now is to work from (11). As observed before, since $u'(r)$ is exponentially small as $r \to \infty$, the integral term $\int_{\rho}^{\infty}(u-1)\,d\sigma$ converges. Hence, for given $\varepsilon > 0$ and $\rho_0 > 0$, and any $\rho \ge \rho_0$,

(17)
$$u(\rho) - 1 = C\varepsilon^{n-2} \int_{\infty}^{\rho} \frac{1}{\tau^{n-1}} e^{-\tau} \left\{ 1 - \int_{\infty}^{\tau}(u-1)\,d\sigma + \frac{1}{2}\left(\int_{\infty}^{\tau}(u-1)\,d\sigma\right)^2 - \cdots \right\} d\tau,$$

where the series in the integrand converges uniformly for $\rho_0 \le \tau < \infty$.

In fact, we will need to use this series for all $\rho \ge \varepsilon$. Thus we need to check its convergence in this interval. This follows from (14) and (15), which imply that for any $\rho \ge \varepsilon$, if $n \ge 2$, then

$$\left| \int_{\rho}^{\infty} (u(s) - 1)\,ds \right| < C\varepsilon^{n-2} \int_{\varepsilon}^{\infty} E_{n-1}(s)\,ds \tag{18}$$

and

$$\varepsilon^{n-2}\int_{\varepsilon}^{\infty} E_{n-1}(s)\,ds = \begin{cases} o(1) \text{ as } \varepsilon \to 0 \text{ if } n > 2, \\ O(1) \text{ as } \varepsilon \to 0 \text{ if } n = 2. \end{cases}$$

Hence for $n > 2$ and any C, the series in the integrand of (17) converges uniformly on $[\varepsilon, \infty)$.

Now set

$$\Phi = C\varepsilon^{n-2}\int_{\varepsilon}^{\infty} E_{n-1}(s)\,ds.$$

We note that if $n > 2$, then $\Phi \to 0$ as $\varepsilon \to 0$, while if $n = 2$, then $\Phi \to 0$ as $C \to 0$.

We proceed to solve (17) by iteration. Thus, the first approximation is, from (16),

$$u(\rho) - 1 = C\varepsilon^{n-2}\int_{\infty}^{\rho} \frac{1}{\tau^{n-1}} e^{-\tau} d\tau + O\left(\Phi^2\right),$$

and we obtain the second approximation by substituting this back into (17). Repeating this, we reach

(19)
$$\begin{aligned} u - 1 = {} & -C\varepsilon^{n-2}E_{n-1} + \left(C\varepsilon^{n-2}\right)^2 \int_{\infty}^{\rho} \frac{1}{\tau^{n-1}} e^{-\tau} \left(\int_{\infty}^{\tau} E_{n-1}\,d\sigma\right) d\tau \\ & + \frac{1}{2}\left(C\varepsilon^{n-2}\right)^3 \int_{\infty}^{\rho} \frac{1}{\tau^{n-1}} e^{-\tau} \left(\int_{\infty}^{\tau} E_{n-1}\,d\sigma\right)^2 d\tau \\ & - \left(C\varepsilon^{n-2}\right)^3 \int_{\infty}^{\rho} \frac{1}{\tau^{n-1}} e^{-\tau} \int_{\infty}^{\tau} \left\{\int_{\infty}^{\sigma} \frac{1}{s^{n-1}} e^{-s} \left(\int_{\infty}^{s} E_{n-1}\,dt\right) ds\right\} d\sigma\,d\tau + O\left(\Phi^4\right), \end{aligned}$$

as $\Phi \to 0$.

To obtain C, we need to be able to evaluate each of these terms for small ρ (in particular, for $\rho = \varepsilon$), and this is a matter of integration by parts. Thus, for nonintegral n,

$$\begin{aligned} E_{n-1}(\rho) &= \int_{\rho}^{\infty} \frac{e^{-\tau}}{\tau^{n-1}} d\tau = -\frac{\rho^{2-n}}{2-n} e^{-\rho} + \frac{1}{2-n}\int_{\rho}^{\infty} \frac{e^{-\tau}}{\tau^{n-2}} d\tau \\ &= -\frac{\rho^{2-n}}{2-n} e^{-\rho} + \frac{1}{2-n} E_{n-2}, \end{aligned} \tag{20}$$

and this can be repeated to give E_{n-1} as a sum of terms of the form $c_k \rho^k e^{-\rho}$ and E_{n-p}, until $0 < n - p < 1$. Then

$$\begin{aligned} E_{n-p} &= \int_{0}^{\infty} \frac{e^{-\tau}}{\tau^{n-p}} d\tau - \int_{0}^{\rho} \frac{e^{-\tau}}{\tau^{n-p}} d\tau \\ &= \Gamma(p + 1 - n) - \int_{0}^{\rho} \frac{e^{-\tau}}{\tau^{n-p}} d\tau, \end{aligned}$$

and we can then continue to integrate by parts as far as we like. (If n is an integer, we will reach $\int_{\rho}^{\infty} \frac{e^{-\tau}}{\tau} d\tau$, which introduces a logarithm.)

Thus $E_{n-1}(\rho)$ can be expressed as a sum of terms of the form $c_k\rho^k e^{-\rho}$, and so obviously the same is true of E_{n-1}^2 , with $e^{-2\rho}$ in place of $e^{-\rho}$. Also,

$$\begin{aligned}\int_\infty^\rho E_{n-1}(\tau)\,d\tau &= \int_\infty^\rho \left(\int_\tau^\infty \frac{e^{-\sigma}}{\sigma^{n-1}}d\sigma\right)d\tau \\ &= \left[\tau\left(\int_\tau^\infty \frac{e^{-\sigma}}{\sigma^{n-1}}d\sigma\right)\right]\Big|_\infty^\rho + \int_\infty^\rho \frac{e^{-\tau}}{\tau^{n-2}}d\tau \\ &= \rho E_{n-1} - E_{n-2}, \qquad (21)\end{aligned}$$

so that $\int_\infty^\rho E_{n-1}d\tau$ can be expressed as the same type of sum. Hence the second term in (19) gives a sum of terms of the form $E_k(2\rho)$ and the third and fourth terms a sum involving $E_k(3\rho)$.

We now carry the process through in the most interesting cases, $n = 2, 3$.

4. The case $k = 0, n = 2$. When $n = 2$ we are interested in

$$\begin{aligned}E_1(\rho) &= \int_\rho^\infty \frac{1}{\tau}e^{-\tau}d\tau \\ &= -e^{-\rho}\log\rho + \int_\rho^\infty e^{-\tau}\log\tau d\tau \\ &= -e^{-\rho}\log\rho + \int_0^\infty e^{-\tau}\log\tau d\tau - \int_0^\rho e^{-\tau}\log\tau d\tau \\ &= -e^{-\rho}\log\rho - \gamma - \rho(\log\rho - 1)e^{-\rho} + O\left(\rho^2\log\rho\right), \text{ for small } \rho, \\ &= -\log\rho - \gamma + \rho + O\left(\rho^2\log\rho\right). \qquad (22)\end{aligned}$$

(See, for example, [2, Chapter 1].) Also, for future purposes, using (20) we obtain

$$E_2(\rho) = \frac{e^{-\rho}}{\rho} - E_1(\rho) \qquad (23)$$

$$= \frac{1}{\rho} + \log\rho + (\gamma - 1) - \frac{1}{2}\rho + O\left(\rho^2\log\rho\right) \text{ as } \rho \to 0. \qquad (24)$$

Looking now at (19), with $\rho = \varepsilon$, we see that as $\varepsilon \to 0$,

$$C\log\varepsilon \to -1$$

and

$$C = \frac{1}{\log\frac{1}{\varepsilon}} + O\left(\frac{1}{\left(\log\frac{1}{\varepsilon}\right)^2}\right).$$

Hence the series in (19) is in powers of $\frac{1}{\log\frac{1}{\varepsilon}}$.

Also, we will work our approximations (in order to compare the results with those of Hinch in [3]) to order $\frac{1}{\log^2\left(\frac{1}{\varepsilon}\right)}$, so that (for example)

$$u = \frac{a(r)}{\log\left(\frac{1}{\varepsilon}\right)} + \frac{b(r)}{\log^2\left(\frac{1}{\varepsilon}\right)} + O\left(\log^{-3}\frac{1}{\varepsilon}\right)$$

for any fixed value of r (ρ of order ε). This, as we shall see, necessitates finding

$$C = \frac{1}{\log\left(\frac{1}{\varepsilon}\right)}\left\{1 + \frac{A}{\log\left(\frac{1}{\varepsilon}\right)} + \frac{B}{\log^2\left(\frac{1}{\varepsilon}\right)} + O\left(\log^{-3}\left(\frac{1}{\varepsilon}\right)\right)\right\}$$

and requires use of all the terms in (19).

With this in mind, we look at the second term of (19). Thus from (21),

$$\int_\rho^\infty E_1 d\tau = -\rho E_1 + e^{-\rho}, \tag{25}$$

so that the second term is

$$\begin{aligned} C^2 \int_\infty^\rho \frac{1}{\tau} e^{-\tau}\left(\tau E_1 - e^{-\tau}\right) d\tau &= C^2\left\{\int_\infty^\rho e^{-\tau} E_1 d\tau - \int_\infty^\rho \frac{e^{-2\tau}}{\tau} d\tau\right\} \\ &= C^2\left\{\left[-e^{-\tau} E_1\right]|_\infty^\rho - 2\int_\infty^\rho \frac{e^{-2\tau}}{\tau} d\tau\right\} \\ &= C^2\left(-e^{-\rho} E_1(\rho) + 2E_1(2\rho)\right). \end{aligned} \tag{26}$$

From (22), the second term is therefore

$$\begin{aligned} &C^2\left(\log\rho + \gamma - 2\log 2\rho - 2\gamma + O(\rho)\right) \\ &= C^2\left(-\log\rho - \gamma - 2\log 2 + O(\rho)\right) \end{aligned} \tag{27}$$

as $\rho \to 0$.

In the third and fourth terms of (19) we need only the leading terms; i.e., we can ignore the equivalent of $\gamma + 2\log 2$ in (27). Using (25) the third term becomes

$$\frac{1}{2} C^3 \int_\infty^\rho \frac{e^{-\tau}}{\tau}\left(e^{-\tau} - \tau E_1\right)^2 d\tau = \frac{1}{2} C^3\left(\log\rho + O(1)\right) \text{ as } \rho \to 0. \tag{28}$$

Finally, in the fourth term, the integrand in the τ-integral is just the second term (as a function of σ), so that from (25), the fourth term is

$$M = -C^3 \int_\infty^\rho \frac{e^{-\tau}}{\tau}\left[\int_\infty^\tau \left\{-e^{-\sigma} E_1(\sigma) + 2E_1(2\sigma)\right\} d\sigma\right] d\tau. \tag{29}$$

It is seen from (25) that for any $\tau \leq \infty$, $\int_0^\tau E_1(\sigma)\, d\sigma$ converges. Hence we can write the inner integral above in the form $\int_\infty^0 + \int_0^\tau$, and it follows that

$$M = -C^3 \int_\infty^\rho \frac{e^{-\tau}}{\tau}\left\{K + r(\tau)\right\} d\tau,$$

where K is a constant, r is bounded, and $r(\tau) = O(\tau\log\tau)$ as $\tau \to 0$. It further follows that

$$M = C^3\left(K E_1(\rho) + O(1)\right) \text{ as } \rho \to 0.$$

We can evaluate K using (25) and (22):

$$\int_0^\infty E_1(2\sigma)\,d\sigma = \frac{1}{2}\int_0^\infty E_1(u)\,du = \frac{1}{2},$$

$$\int_0^\infty e^{-\sigma}E_1(\sigma)\,d\sigma = \left[-\left(e^{-\sigma}-1\right)E_1\right]_0^\infty - \int_0^\infty \left(e^{-\sigma}-1\right)\frac{e^{-\sigma}}{\sigma}d\sigma$$

$$= \lim_{\sigma\to 0}\left\{-E_1(2\sigma)+E_1(\sigma)\right\} = \lim_{\sigma\to 0}\left(\log 2\sigma - \log\sigma\right) = \log 2. \tag{30}$$

Hence, from (29), the fourth term of (19) is

$$C^3\left\{E_1(\rho)(\log 2-1)+O(1)\right\} = -C^3\left\{(\log 2-1)\log\rho + O(1)\right\} \text{ as } \rho\to 0. \tag{31}$$

Now setting $\rho=\varepsilon$ and using (27), (28), and (31), we obtain that

$$-1 = -C\left(-\log\varepsilon-\gamma+O(\varepsilon)\right) + C^2\left(-\log\varepsilon-\gamma-2\log 2+O(\varepsilon)\right)$$

$$+\frac{1}{2}C^3\left(\log\varepsilon+O(1)\right) - C^3\left\{(\log 2-1)\log\varepsilon+O(1)\right\}$$

as $\varepsilon\to 0$. Hence,

$$\frac{1}{\log\left(\frac{1}{\varepsilon}\right)} = C\left(1-\frac{\gamma}{\log\left(\frac{1}{\varepsilon}\right)}\right) - C^2\left(1-\frac{\gamma+2\log 2}{\log\left(\frac{1}{\varepsilon}\right)}\right)$$

$$+C^3\left(\frac{3}{2}-\log 2\right) + O\left(\log^{-4}\left(\frac{1}{\varepsilon}\right)\right), \tag{32}$$

and

$$C = \frac{1}{\log\left(\frac{1}{\varepsilon}\right)} + \frac{A}{\log^2\left(\frac{1}{\varepsilon}\right)} + \frac{B}{\log^3\left(\frac{1}{\varepsilon}\right)} + O\left(\frac{1}{\log^4\left(\frac{1}{\varepsilon}\right)}\right),$$

where

$$-\gamma + A - 1 = 0,$$

$$B - \gamma A - 2A + (\gamma + 2\log 2) + \frac{3}{2} - \log 2 = 0.$$

Hence,

$$A = \gamma + 1,$$

$$B = \gamma^2 + 2\gamma + \frac{1}{2} - \log 2.$$

Thus, for fixed r, ρ of order ε, we have, with $\lambda = \log\left(\frac{1}{\varepsilon}\right)$,

$$u-1 = \left(\frac{1}{\lambda} + \frac{\gamma+1}{\lambda^2} + \frac{(\gamma+1)^2 - \frac{1}{2} - \log 2}{\lambda^3}\right)(\log r + \log\varepsilon + \gamma)$$

$$+\frac{1}{\lambda^2}\left(1+\frac{2(\gamma+1)}{\lambda}\right)(-\log r - \log\varepsilon - \gamma - 2\log 2)$$

$$+\frac{1}{\lambda^3}\left(\frac{3}{2}-\log 2\right)(\log r + \log\varepsilon) + O\left(\lambda^{-4}\right),$$

so that, after cancellation,

$$u = \frac{\log r}{\lambda} + \frac{\gamma \log r}{\lambda^2} + O\left(\lambda^{-3}\right).$$

This is the "inner expansion." For the "outer expansion," i.e., fixed ρ, r of order $\frac{1}{\varepsilon}$, we use (19), truncated to second order, to get

$$u - 1 = -E_1(\rho)\left(\frac{1}{\lambda} + \frac{\gamma + 1}{\lambda^2}\right) + \frac{1}{\lambda^2}\left(2E_1(2\rho) - e^{-\rho}E_1(\rho)\right) + O\left(\lambda^{-3}\right).$$

These results are in accordance with those of Hinch and of others on this problem.

5. The case $k = 0, n = 3$. Here we are interested in (from (22) and (23))

$$E_2(\rho) = \frac{e^{-\rho}}{\rho} - E_1(\rho) = \frac{1}{\rho} + \log\rho + (\gamma - 1) - \frac{1}{2}\rho + O\left(\rho^2 \log\rho\right) \text{ as } \rho \to 0.$$

Thus, the first term on the right of (19) evaluated at $\rho = \varepsilon$ is

$$-C\left(1 + \varepsilon\log\varepsilon + (\gamma - 1) + O\left(\varepsilon^2\right)\right) \text{ as } \varepsilon \to 0.$$

The second term is

$$\begin{aligned}
&(C\varepsilon)^2 \int_\infty^\rho \frac{1}{\tau^2} e^{-\tau}\left(\int_\infty^\tau E_2 d\sigma\right) d\tau \\
&= (C\varepsilon)^2 \left\{\left[-E_2(\tau)\int_\infty^\tau E_2(\sigma)\, d\sigma\right]_\infty^\rho + \int_\infty^\rho E_2^2 d\tau\right\} \\
&= (C\varepsilon)^2 \left\{-E_2(\rho)\int_\infty^\rho E_2(\tau)\, d\tau + \int_\infty^\rho E_2^2 d\tau\right\}.
\end{aligned}$$

From (23) we see that

$$\int_\infty^\rho E_2^2 d\tau = -\frac{1}{\rho} + \log^2\rho + O(\log\rho) \text{ as } \rho \to 0,$$

while from (21),

$$\int_\infty^\rho E_2 d\tau = \rho E_2 - E_1 = 1 + \log\rho + \gamma + O(\rho\log\rho),$$

$$E_2 \int_\infty^\rho E_2 d\tau = \frac{1}{\rho}\log\rho + \frac{\gamma + 1}{\rho} + O\left(\log^2\rho\right).$$

In all, the second term is

$$(C\varepsilon)^2\left\{-\frac{1}{\rho}\log\rho - \frac{\gamma + 2}{\rho} + O\left(\log^2\rho\right)\right\}.$$

It is readily verified that the third and fourth terms in (19) give $O\{C^3\varepsilon^3(\frac{1}{\rho}\log^2\rho)\}$, which is negligible. Thus, evaluating (19) at $\rho = \varepsilon$, we have

$$-1 = -C\varepsilon\left(\frac{1}{\varepsilon} + \log\varepsilon + \gamma - 1\right) + (C\varepsilon)^2\left(-\frac{1}{\varepsilon}\log\varepsilon - \frac{\gamma + 2}{\varepsilon}\right) + O\left(C^3\varepsilon^2\log^2\varepsilon\right),$$

so that

$$C = 1 - 2\varepsilon \log \varepsilon - \varepsilon (2\gamma + 1) + O\left(\varepsilon^2 \log^2 \varepsilon\right).$$

Then, for fixed r, ρ of order ε, we have

$$u - 1 = -\varepsilon (1 - 2\varepsilon \log \varepsilon - \varepsilon (2\gamma + 1)) \left(\frac{1}{\varepsilon r} + \log \varepsilon + \log r + \gamma - 1\right)$$

$$+ \varepsilon^2 \left(-\frac{1}{\varepsilon r} (\log \varepsilon + \log r) - \frac{\gamma + 2}{\varepsilon r}\right) + O\left(\varepsilon^2 \log^2 \varepsilon\right),$$

$$u = 1 - \frac{1}{r} - \varepsilon \log \varepsilon \left(1 - \frac{1}{r}\right) - \varepsilon \left(\log r + \frac{\log r}{r}\right) + \varepsilon (1 - \gamma) \left(1 - \frac{1}{r}\right)$$

$$+ O\left(\varepsilon^2 \log^2 \varepsilon\right).$$

For fixed ρ, r of order ε^{-1}, we again use (19), to give

$$u - 1 = -\varepsilon (1 - 2\varepsilon \log \varepsilon - \varepsilon (2\gamma + 1)) E_2(\rho)$$

$$+ \varepsilon^2 \left\{E_1(\rho) E_2(\rho) - \rho E_2^2(\rho) - \int_\rho^\infty E_2^2 d\tau\right\} + O\left(\varepsilon^3\right). \tag{33}$$

Again, these results are in agreement with those of Hinch, and others, although (33) gives one term further.

Remark 3. It is of interest to consider what happens when $n < 2$, since, at least for $n \geq 1$, there still exists a unique solution. Equation (19) is still valid at $\rho = \varepsilon$, but since $E_{n-1}(\rho)$ is no longer singular at $\rho = 0$ for $n < 2$, (19) with $\rho = \varepsilon$ becomes merely an implicit equation for $C\varepsilon^{n-2}$. This tells us that $C \to 0$, since $\varepsilon^{n-2} \to \infty$, but we no longer get an asymptotic expansion. In particular, it is no longer obvious that C is unique. Of course, we know this from Theorem 1 if $n \geq 1$.

6. The case $k = 1$. We can in fact treat a generalization, which causes no further difficulties,

$$u'' + \frac{n-1}{r} u' + f(u) u'^2 + \varepsilon u\, u' = 0, \tag{34}$$

with the same boundary conditions. As before, we will compare our results with those of Hinch in [3].

As remarked in the proof of Theorem 1, the solution will necessarily have $u' > 0$ so that conditions on $f(u)$ are necessary only for $0 \leq u \leq 1$. We require only that f be continuous and positive in this interval.

Then (34) can be written as

$$\frac{\left(r^{n-1} u'\right)'}{r^{n-1} u'} + f(u) u' + \varepsilon u = 0,$$

so that

$$\log\left(r^{n-1} u'\right) = -F(u) - \varepsilon \int_1^r u dt + A$$

for some constant A, where

$$F(u) = \int_0^u f(s)\, ds.$$

This becomes

$$e^{F(u)} u' = \frac{C}{r^{n-1}} e^{-\varepsilon r - \varepsilon \int_\infty^r (u-1) ds},$$

or, on integration,

$$G(u) - G(1) = C \int_\infty^r \frac{1}{t^{n-1}} e^{-\varepsilon t - \varepsilon \int_\infty^t (u-1) ds} dt,$$

where

$$G(u) = \int_0^u e^{F(v)} dv.$$

In order to keep the manipulations simple and effect comparisons, we will consider from here the Lagerstrom model, where $f(u) = 1$, $F(u) = u$, $G(u) = e^u - 1$. Then, with $\varepsilon r = \rho$, $\varepsilon t = \tau$, we have

$$e^u - e = C\varepsilon^{n-2} \int_\infty^\rho \frac{1}{\tau^{n-1}} e^{-\tau} e^{-\int_\infty^\tau (u-1) d\sigma} d\tau, \tag{35}$$

and writing

$$u - 1 = \frac{u-1}{e^u - e} (e^u - e),$$

we get

$$e^u - e = C\varepsilon^{n-2} \int_\infty^\rho \frac{1}{\tau^{n-1}} e^{-\tau} e^{-\int_\infty^\tau \frac{u-1}{e^u-e}(e^u-e) d\sigma} d\tau. \tag{36}$$

As in section 3, we can integrate by parts, and since $0 \le \frac{u-1}{e^u-e} \le 1$ in $0 \le u < 1$, we will develop a convergent series as before. To get the first three terms (necessary to give Hinch's accuracy when $n = 2$), we have from (36) that

$$e^u - e = C\varepsilon^{n-2} \int_\infty^\rho \frac{1}{\tau^{n-1}} e^{-\tau} \left\{ 1 - \int_\infty^\tau \frac{u-1}{e^u-e} (e^u - e)\, d\sigma \right. \tag{37}$$

$$\left. + \frac{1}{2} \left(\int_\infty^\tau \frac{u-1}{e^u-e} (e^u - e)\, d\sigma \right)^2 + \cdots \right\} d\tau.$$

As before, since $e^u - e \to 0$ exponentially fast as $\rho \to \infty$, the series in the integrand converges uniformly for large τ, so that (37) is valid for large ρ. But again we need to extend it down to $\rho = \varepsilon$. From (35) we have

$$e^u - e \le C\varepsilon^{n-2} E_{n-1}(\rho),$$

and so the convergence proof is the same as that preceding (19).

Before proceeding further with $n = 2$, we make a couple of remarks about the simpler case $n > 2$. Then, as we saw in section 5, only two terms are necessary to give the required accuracy, and then (37) gives

$$e^u - u = C\varepsilon^{n-2} \int_\infty^\rho \frac{e^{-\tau}}{\tau^{n-1}} \left\{ 1 - \int_\infty^\tau \frac{u-1}{e^u - e} \left(e^u - e\right) d\sigma + \cdots \right\},$$

and since $\frac{u-1}{e^u-e}$ appears in what is already the highest order term, we can replace it by its limit as $u \to 1$, i.e., $\frac{1}{e}$. Thus we get, to the required order,

$$e^u - e = -C\varepsilon^{n-2} E_{n-1} - \left(\frac{C\varepsilon^{n-2}}{e} \right) \int_\infty^\rho \frac{e^{-\tau}}{\tau^{n-1}} \int_\infty^\tau \left(e^u - e\right) d\sigma d\tau.$$

(We will proceed more carefully for $n = 2$.) This, apart from the factor $\frac{1}{e}$, is the same equation dealt with in section 5 (with $e^u - e$ in place of $u - 1$), and the solution can be written down from there. If we had a general function f in place of 1, we would get

$$e^{F(u)} - e^{F(1)} = -C\varepsilon^{n-2} E_{n-1} - \frac{C\varepsilon^{n-2}}{e^{F(1)} f\left(1\right)} \int_\infty^\rho \frac{e^{-\tau}}{\tau^{n-1}} \left(\int_\infty^\tau \left(e^{F(u)} - e^{F(1)} \right) d\sigma \right) d\tau.$$

Turning now to the case $n = 2$ and $F\left(u\right) = u$, we need three terms on the right of (37). Thus,

$$\frac{u-1}{e^u - e} = \frac{1}{e} - \frac{1}{2e^2} \left(e^u - e\right) + O\left(e^u - e\right)^2 \text{ as } u \to 1. \tag{38}$$

We follow the method used just before (19) and obtain from (37) that

$$\begin{aligned}
&e^u - e \\
&= -C\varepsilon^{n-2} E_{n-1} + \frac{1}{e} \left(C\varepsilon^{n-2}\right)^2 \int_\infty^\rho \frac{1}{\tau^{n-1}} e^{-\tau} \left(\int_\infty^\tau E_{n-1} d\sigma \right) d\tau \\
&+ \frac{1}{2e^2} \left(C\varepsilon^{n-2}\right)^3 \int_\infty^\rho \frac{1}{\tau^{n-1}} e^{-\tau} \left(\int_\infty^\tau E_{n-1}^2 d\sigma \right) d\tau \\
&+ \frac{1}{2e^2} \left(C\varepsilon^{n-2}\right)^3 \int_\infty^\rho \frac{1}{\tau^{n-1}} e^{-\tau} \left(\int_\infty^\tau E_{n-1} d\sigma \right)^2 d\tau \\
&- \frac{1}{e^2} \left(C\varepsilon^{n-2}\right)^3 \int_\infty^\rho \frac{1}{\tau^{n-1}} e^{-\tau} \int_\infty^\tau \left\{ \int_\infty^\sigma \frac{1}{s^{n-1}} e^{-s} \left(\int_\infty^s E_{n-1} dt \right) ds \right\} d\sigma d\tau + O\left(\Phi^4\right) \\
&= -C\varepsilon^{n-2} E_{n-1} + F_1 + F_2 + F_3 + F_4 + O\left(\Phi^4\right),
\end{aligned}$$

say. As before, if $n > 2$, then this is valid for any C as $\varepsilon \to 0$, uniformly in $\rho \geq \varepsilon$, while if $n = 2$, it is valid as $C \to 0$.

For $n = 2$ we can continue to follow the argument in section 4. Thus, as $\rho \to 0$,

$$F_1 = \frac{1}{e} C^2 \left(-\log \rho - \gamma - 2\log 2 + O\left(\rho\right) \right),$$

$$F_3 = \frac{1}{2e^2} C^3 \left(\log \rho + O\left(1\right) \right),$$

$$F_4 = -\frac{1}{e^2} C^3 \left[\left(\log 2 - 1\right) \log \rho + O\left(1\right) \right].$$

The term F_2 did not appear before. Only the highest order term is needed for our expansion and this is

$$-\frac{1}{2e^2}C^3\left(\int_\infty^\rho \frac{1}{\tau}e^{-\tau}d\tau\right)\int_0^\infty E_1^2 d\sigma.$$

Now

$$\begin{aligned}\int_0^\infty E_1^2 d\sigma &= \left[\tau E_1^2\right]_0^\infty + 2\int_0^\infty \tau\frac{e^{-\tau}}{\tau}E_1 d\tau \\ &= 2\int_0^\infty e^{-\tau}E_1 d\tau = 2\log 2 \text{ from } (30).\end{aligned}$$

Thus,

$$F_2 = \frac{1}{e^2}C^3E_1\left(\log 2 + O\left(\rho\log^2\rho\right)\right) = -\frac{1}{e^2}C^3\left((\log 2)\log\rho + O(1)\right),$$

and, evaluating at $\rho = \varepsilon$, we have

$$\begin{aligned}1 - e &= C\left(\log\varepsilon + \gamma + O(\varepsilon)\right) \\ &\quad - \frac{1}{e}C^2\left(\log\varepsilon + \gamma + 2\log 2 + O(\varepsilon)\right) \\ &\quad + \frac{1}{2e^2}C^3\log\varepsilon\left(-2\log 2 + 1 - 2\log 2 + 2\right) + O\left(C^3\right), \\ \frac{e-1}{\log\frac{1}{\varepsilon}} &= C\left(1 - \frac{\gamma}{\log\left(\frac{1}{\varepsilon}\right)}\right) - \frac{1}{e}C^2\left(1 - \frac{\gamma + 2\log 2}{\log\left(\frac{1}{\varepsilon}\right)}\right) \\ &\quad + \frac{1}{2e^2}C^3\left(3 - 4\log 2 + O\left(\frac{C\varepsilon}{\log\varepsilon}\right) + O\left(\frac{C^2\varepsilon}{\log\varepsilon}\right) + O\left(\frac{C^3}{\log\varepsilon}\right)\right).\end{aligned}$$

Hence if

$$C = \frac{e-1}{\log\left(\frac{1}{\varepsilon}\right)} + \frac{A}{\log^2\left(\frac{1}{\varepsilon}\right)} + \frac{B}{\log^3\left(\frac{1}{\varepsilon}\right)} + O\left(\log^{-4}\left(\frac{1}{\varepsilon}\right)\right),$$

then

$$\begin{aligned}-\gamma(e-1) + A - \frac{(e-1)^2}{e} &= 0, \\ A &= \frac{e-1}{e}(\gamma e + e - 1),\end{aligned}$$

$$B - A\gamma + \frac{(e-1)^2}{e}(\gamma + 2\log 2) - \frac{2A(e-1)}{e} + \frac{1}{2e^2}(e-1)^3(3 - 4\log 2) = 0.$$

We can of course calculate B, but in fact its value will be irrelevant to the level of approximation that we take.

Then, for fixed r (ρ of order ε), we have, with $l = \log\left(\frac{1}{\varepsilon}\right)$,

$$\begin{aligned} e^u - e &= (e-1)\left\{\frac{1}{l} + \frac{\gamma + 1 - \frac{1}{e}}{l^2} + \frac{B/(e-1)}{l^3}\right\}(\log\varepsilon + \log r + \gamma) \\ &\quad + \frac{1}{e}(e-1)^2\left\{\frac{1}{l^2} + \frac{2\left(\gamma + 1 - \frac{1}{e}\right)}{l^3}\right\}(-\log\varepsilon - \log r - \gamma - 2\log 2) \\ &\quad + \frac{1}{2e^2}\frac{(e-1)^3}{l^3}(3 - 4\log 2)(\log\varepsilon + \log r) + O\left(l^{-3}\right) \\ &= 1 - e + \frac{(e-1)\log r}{l} + \frac{\gamma(e-1)\log r}{l^2} + O\left(l^{-3}\right). \end{aligned} \tag{39}$$

(Note that the definitions of A and B were such that $u = 0$ at $r = 1$ up to and including order l^{-2}, so that to that order there can be only terms in $\log r$, not constant terms. We do not need the explicit value of B.) To obtain u, we have to invert, so that

$$u = \log\left\{1 + \frac{e-1}{l}\log r + \frac{\gamma(e-1)}{l^2}\log r + O\left(l^{-3}\right)\right\}.$$

For fixed ρ, r of order ε^{-1}, we have

$$e^u - e = -\frac{e-1}{l}\left(1 + \frac{\gamma + 1 - \frac{1}{e}}{l}\right)E_1(\rho) + \frac{(e-1)^2}{el^2}\left(2E_1(2\rho) - e^{-\rho}E_1(\rho)\right) + O\left(l^{-3}\right).$$

Thus

$$\begin{aligned} u - 1 &= \frac{1}{e}(e^u - e) - \frac{1}{2e^2}(e^u - e)^2 + \cdots \\ &= -\frac{e-1}{e}\left(1 + \frac{\gamma + 1 - \frac{1}{e}}{l}\right)\frac{E_1(\rho)}{l} + \frac{(e-1)^2}{e^2}\frac{(2E_1(2\rho) - e^{-\rho}E_1(\rho))}{l^2} \\ &\quad - \frac{(e-1)^2}{2e^2}\frac{E_1^2(\rho)}{l^2} + O\left(l^{-3}\right). \end{aligned} \tag{40}$$

Again, these results are consistent with those of Hinch and others, except that Hinch has an algebraic mistake which in (40) replaces $\gamma + 1 - \frac{1}{e}$ by $\gamma - 1 + \frac{1}{e}$.

7. Final remarks. Starting with Lagerstrom, the terms involving $\log\varepsilon$ in the inner expansions have been considered difficult to explain. They are often called "switchback" terms, because there is nothing obvious in the equation which indicates the need for such terms, and because, starting with an expansion in powers of ε, one finds inconsistent results which are resolved only by adding terms of lower order, that is, powers of $\varepsilon\log\varepsilon$. The recent approach to the problem by geometric perturbation theory explains this by reference to a "resonance phenomenon," which is too complicated for us to describe here [10], [11].

In our work, the necessity for such terms is seen already from (11) and the resulting expansion (17):

$$u(\rho) - 1 = C\varepsilon^{n-2}\int_\infty^\rho \frac{1}{\tau^{n-1}}e^{-\tau}\left\{1 - \int_\infty^\tau (u-1)\,d\sigma + \frac{1}{2}\left(\int_\infty^\tau (u-1)\,d\sigma\right)^2 - \cdots\right\}d\tau.$$

In the existence proof it was seen in (9) that $C = O(1)$ as $\varepsilon \to 0$. On the right of (17) the first term is simply $-C\varepsilon^{n-2}E_{n-1}(\rho)$, and the simple expansions given for E_1 and E_2 show immediately the need for the logarithmic terms. There is no "switchback," because the procedure does not start with any assumption about the nature of the expansion, and there is no need for a "matching."

A number of authors have noted that the outer expansion is a uniformly valid asymptotic expansion on $[1, \infty)$, and therefore it "contains" the inner expansion [5], though this is more subtle when $k = 1$ [13]. Our twist on this is that both expansions are contained in the uniformly convergent series defined implicitly by (17). The simple derivation of this series via the integral equation (11) is new, as far as we know.

Acknowledgment. We thank the referees for some very helpful comments. In particular, they called our attention to earlier proofs of the existence and uniqueness results, in some cases by techniques similar to ours.

VECTOR FIELDS FOR MEAN VALUE COORDINATES*

S. L. LEE†

Abstract. We find vector fields $\mathbf{F}$ that provide the representation $\mathbf{v} = \int_{\partial D} \mathbf{r}\,\mathbf{F} \cdot d\mathbf{r} / \int_{\partial D} \mathbf{F} \cdot d\mathbf{r}$ for any compact 2-D manifold $D \subset \mathbb{R}^2$ with piecewise smooth boundary ∂D and $\mathbf{v} \in \mathbb{R}^2$, and the representation $\mathbf{v} = \iint_{\partial M} \mathbf{r}\,\mathbf{F} \cdot d\mathbf{S} / \iint_{\partial M} \mathbf{F} \cdot d\mathbf{S}$ for any compact 3-D manifold $M \subset \mathbb{R}^3$ and $\mathbf{v} \in \mathbb{R}^3$. Our method exploits properties of conservative fields in $\mathbb{R}^2$ and divergence free vector fields in $\mathbb{R}^3$. Discrete versions, which are more general than Floater's mean value coordinates, are derived from the above representations with a special choice of $\mathbf{F}$, either by taking points on the boundaries of $D \subset \mathbb{R}^2$ and $M \subset \mathbb{R}^3$ or by considering representations on boundaries of polygons in $\mathbb{R}^2$ or polyhedra in $\mathbb{R}^3$.

Key words. star-shaped region, mean value coordinates, conservative and divergence free vector fields, Stoke's theorem, divergence theorem, spherical harmonics

1. Introduction.

Representation of points and functionals on a set by its extreme points or boundary is an important problem in mathematics and its applications. Barycentric coordinates, the Krein–Millman theorem, and Choquet's theorem are examples of such a representation. Recently, in conjunction with the construction of one-one transformations and parametrizations of meshes in $\mathbb{R}^3$, Floater [2] has found an explicit formula for the representation of points that lie in the kernel of star-shaped polygons in $\mathbb{R}^2$ in terms of extreme points of the polygon. Because of its usefulness in computer graphics and its potential applications in functional approximation and interpolation, the idea has been quickly extended to star-shaped polyhedrons in $\mathbb{R}^3$ (see [3], [4], [5], [6], [7]). Floater's original idea was motivated by the mean value property of harmonic functions; i.e., if ϕ is harmonic in a region $\Omega \subset \mathbb{R}^2$, then for any disc $D(\mathbf{v}, r) \subset \Omega$ with center at $\mathbf{v}$ and radius r,

$$\phi(\mathbf{v}) = \frac{1}{2\pi r} \int_{\partial D} \phi(\mathbf{r}) ds, \tag{1.1}$$

where $ds = \left|\frac{d\mathbf{r}}{dt}\right| dt$ for a parametrization $\mathbf{r} = \mathbf{r}(t)$ of ∂D. He observed that a class of real-valued piecewise linear functions defined on a triangular mesh in $\mathbb{R}^2$, which he calls *convex combination functions*, shares discretely some properties of harmonic functions. Forcing the mean value property (1.1) on the convex combination functions produces the new coordinates, which he calls the *mean value coordinates.* The problem of computing these coordinates then reduces to integrating elementary trigonometric functions over the unit circle or the unit sphere (see [2], [3], [7]).

This paper explores the connection between mean value coordinates with conservative vector fields on compact 2-D manifolds in $\mathbb{R}^2$ and divergence free vector fields on compact 3-D manifolds in $\mathbb{R}^3$ that provide a mathematical foundation, and puts

mean value coordinates in a more general mathematical setting. In particular we find vector fields $\mathbf{F}$ that provide the representation

$$\mathbf{v} = \frac{\int_{\partial D} \mathbf{r}\ \mathbf{F}(\mathbf{r}-\mathbf{v}) \cdot d\mathbf{r}}{\int_{\partial D} \mathbf{F}(\mathbf{r}-\mathbf{v}) \cdot d\mathbf{r}}$$

for any compact 2-D manifold $D \subset \mathbb{R}^2$ with piecewise smooth boundary ∂D and for any vector $\mathbf{v} \in \mathbb{R}^2$, and

$$\mathbf{v} = \frac{\iint_{\partial M} \mathbf{r}\ \mathbf{F}(\mathbf{r}-\mathbf{v}) \cdot d\mathbf{S}}{\iint_{\partial M} \mathbf{F}(\mathbf{r}-\mathbf{v}) \cdot d\mathbf{S}}$$

for any compact 3-D manifold $M \subset \mathbb{R}^3$ and $\mathbf{v} \in \mathbb{R}^3$. We shall refer to these as *mean value representations.* Our method exploits properties of conservative and divergence free vector fields. With a special choice of $\mathbf{F}$ and restricting to points on the boundaries of the manifolds or by considering the representations on the boundaries of polygons in $\mathbb{R}^2$ and polyhedra in $\mathbb{R}^3$, discrete versions of mean value representation are obtained, which are more general than Floater's mean value coordinates.

In section 2 a search for vector fields that provide the mean value representation in $\mathbb{R}^2$ leads to a class of vector fields

$$\mathbf{F} = \left[\frac{1}{xy}\Phi\left(\frac{x}{r},\frac{y}{r}\right), \frac{-1}{y^2}\Phi\left(\frac{x}{r},\frac{y}{r}\right)\right]^T,$$

where Φ is an arbitrary real-valued differentiable function on the unit circle $\mathbb{S}^1$. For these $\mathbf{F}$, the vector fields $x\mathbf{F}$, $y\mathbf{F}$ are conservative on $\mathbb{R}^2 \setminus \{\mathbf{0}\}$. Further, if

$$\Phi(\cos\theta, \sin\theta) = -\cos\theta \sin^2\theta \left(1 + \sum_{k=2}^{\infty} a_k \cos k\theta + b_k \sin k\theta\right),$$

with $|\sum_{k=2}^{\infty} a_k \cos k\theta + b_k \sin k\theta| \le 1$, then the corresponding $\mathbf{F}$ provides a mean value representation. A more general form of Floater's mean value coordinates is derived from the particular choice of $\Phi(\cos\theta, \sin\theta) = -\cos\theta \sin^2\theta$, i.e., $\Phi(\frac{x}{r}, \frac{y}{r}) = -\frac{xy^2}{r^3}$, and hence $\mathbf{F}(x,y) := [-y/r^3, x/r^3]^T$. The derivation exploits properties of path independent integrals of conservative fields. A similar search in section 3 for vector fields that provide the mean value representations in $\mathbb{R}^3$ leads to a class

$$\mathbf{F}(\mathbf{r}) = \left[\frac{1}{xyz}\Phi\left(\frac{x}{\rho},\frac{y}{\rho},\frac{z}{\rho}\right), \frac{1}{x^2 z}\Phi\left(\frac{x}{\rho},\frac{y}{\rho},\frac{z}{\rho}\right), \frac{1}{x^2 y}\Phi\left(\frac{x}{\rho},\frac{y}{\rho},\frac{z}{\rho}\right)\right]^T,$$

where $\Phi : \mathbb{S}^2 \to \mathbb{R}$ is an arbitrary differentiable function and $\rho := (x^2+y^2+z^2)^{1/2}$. In this case $x\mathbf{F}$, $y\mathbf{F}$, and $z\mathbf{F}$ are divergence free on $\mathbb{R}^3 \setminus \{\mathbf{0}\}$. Further, if

$$\begin{aligned}\Phi\left(\frac{x}{\rho},\frac{x}{\rho},\frac{x}{\rho}\right) &= \frac{x^2 yz}{\rho^4}\left(1 + \Psi\left(\frac{x}{\rho},\frac{x}{\rho},\frac{x}{\rho}\right)\right) \\ &= \sin^3\phi \cos^2\theta \sin\theta \cos\phi\ (1 + \Psi(\sin\phi\cos\theta, \sin\phi\sin\theta, \cos\phi)),\end{aligned}$$

where Ψ is orthogonal to the first order spherical harmonics and $|\Psi| \le 1$, then $\mathbf{F}$ provides a mean value representation in $\mathbb{R}^3$. The derivation of Floater's type mean value coordinates in $\mathbb{R}^3$ is carried out in section 4. Here we take $\Psi = 0$, and hence

$\Phi(\frac{x}{\rho}, \frac{y}{\rho}, \frac{z}{\rho}) = \frac{x^2yz}{\rho^4}$ and $\mathbf{F} = \frac{\mathbf{r}}{\rho^4}$, and consider compact 3-D manifolds with polyhedral faces of any topology. The integral of $\iint_{\partial M} \mathbf{r}\mathbf{F} \cdot d\mathbf{S}$ over the boundary of such a manifold M is the sum of the integrals over its faces. The integral $\iint_S \mathbf{r}\mathbf{F} \cdot d\mathbf{S}$ over each face S is evaluated using Stoke's theorem. This is done by finding vector fields $\mathbf{A}$, $\mathbf{B}$, $\mathbf{C}$ such that $x\mathbf{F} = curl(\mathbf{A})$ $y\mathbf{F} = curl(\mathbf{B})$, $z\mathbf{F} = curl(\mathbf{C})$, which is possible since $\operatorname{div}(x\mathbf{F}) = \operatorname{div}(y\mathbf{F}) = \operatorname{div}(z\mathbf{F}) = 0$. This leads to a simple formula for the integrals over the faces of the boundary of M, from which discrete versions of the mean value representation or Floater's type mean value coordinates are obtained. If all the faces are triangular, the procedure leads to a unique solution. In all other cases the solutions are not unique.

2. Representation on boundaries of compact 2-D manifolds in $\mathbb{R}^2$. Let $D \subset \mathbb{R}^2$ be a compact 2-D manifold with piecewise smooth boundary ∂D, which is assumed to be oriented in the positive direction; i.e., if one travels along this direction, the region D lies on his left. We want to find a vector field $\mathbf{F} = [F_1(x, y), F_2(x, y)]^T$ such that for any $D \subset \mathbb{R}^2$ and $\mathbf{v} \in \mathbb{R}^2$,

$$\int_{\partial D} (\mathbf{r} - \mathbf{v})\mathbf{F}(\mathbf{r} - \mathbf{v}) \cdot d\mathbf{r} = 0 \tag{2.1}$$

and

$$\int_{\partial D} \mathbf{F}(\mathbf{r} - \mathbf{v}) \cdot d\mathbf{r} \neq 0, \tag{2.2}$$

so that

$$\mathbf{v} = \frac{\int_{\partial D} \mathbf{r}\ \mathbf{F}(\mathbf{r} - \mathbf{v}) \cdot d\mathbf{r}}{\int_{\partial D} \mathbf{F}(\mathbf{r} - \mathbf{v}) \cdot d\mathbf{r}}. \tag{2.3}$$

Without loss of generality, we may assume that $\mathbf{v} = \mathbf{0}$ so that the problem reduces to finding $\mathbf{F}$ such that for any D

(2.4)

$$\begin{aligned}\int_{\partial D} \mathbf{r}\ \mathbf{F} \cdot d\mathbf{r} &= \left[\int_{\partial D} xF_1(x, y)dx + xF_2(x, y)dy, \int_{\partial D} yF_1(x, y)dx + yF_2(x, y)dy\right]^T \\ &= \mathbf{0}\end{aligned}$$

and (2.2) holds, i.e., $\int_{\partial D} \mathbf{F}(\mathbf{r}) \cdot d\mathbf{r} \neq 0$.

First, suppose that $\mathbf{F}$ is continuously differentiable on a domain that contains D. By Green's theorem, (2.4) holds if

$$\frac{\partial(xF_1)}{\partial y} = \frac{\partial(xF_2)}{\partial x} \quad \text{and} \quad \frac{\partial(yF_1)}{\partial y} = \frac{\partial(yF_2)}{\partial x},$$

or, equivalently,

$$x\frac{\partial F_2}{\partial x} - x\frac{\partial F_1}{\partial y} = -F_2 \quad \text{and} \quad y\frac{\partial F_2}{\partial x} - y\frac{\partial F_1}{\partial y} = F_1. \tag{2.5}$$

The equations in (2.5) give $F_2 = \frac{-x}{y}F_1$, which together with the first equation of (2.5) lead to

$$x\frac{\partial F_1}{\partial x} + y\frac{\partial F_1}{\partial y} = -2F_1. \tag{2.6}$$

The general solution of (2.6) that vanishes at infinity is $F_1(x,y) = \frac{1}{xy}\Phi\left(\frac{x}{r},\frac{y}{r}\right)$, where Φ is an arbitrary real-valued differentiable function defined on the unit circle $\mathbb{S}^1$ and $r := ||\mathbf{r}|| = (x^2+y^2)^{1/2}$. Further, $\Phi\left(\frac{x}{r},\frac{y}{r}\right)$ is the general solution of the corresponding homogeneous equation.

PROPOSITION 2.1. *Let*

$$\mathbf{F} = [F_1, F_2]^T := \left[\frac{1}{xy}\Phi\left(\frac{x}{r},\frac{y}{r}\right), \frac{-1}{y^2}\Phi\left(\frac{x}{r},\frac{y}{r}\right)\right]^T, \tag{2.7}$$

where Φ is an arbitrary real-valued differentiable function on the unit circle $\mathbb{S}^1$. Then

$$x\mathbf{F} = \left[\frac{1}{y}\Phi\left(\frac{x}{r},\frac{y}{r}\right), \frac{-x}{y^2}\Phi\left(\frac{x}{r},\frac{y}{r}\right)\right]^T \quad \textit{and} \quad y\mathbf{F} = \left[\frac{1}{x}\Phi\left(\frac{x}{r},\frac{y}{r}\right), \frac{-1}{y}\Phi\left(\frac{x}{r},\frac{y}{r}\right)\right]^T \tag{2.8}$$

are conservative vector fields on any region not containing the origin with potential functions ϕ_1 and ϕ_2, respectively, where

$$\phi_1(x,y) = \int \frac{1}{y}\Phi\left(\frac{x}{r},\frac{y}{r}\right)\, dx = -\int \frac{x}{y^2}\Phi\left(\frac{x}{r},\frac{y}{r}\right)\, dy, \tag{2.9}$$

$$\phi_2(x,y) = \int \frac{1}{x}\Phi\left(\frac{x}{r},\frac{y}{r}\right)\, dx = -\int \frac{1}{y}\Phi\left(\frac{x}{r},\frac{y}{r}\right)\, dy. \tag{2.10}$$

Proof. Using the fact that $x\frac{\partial\Phi}{\partial x} + y\frac{\partial\Phi}{\partial y} = 0$, it is straightforward to verify that $x\mathbf{F} = \bigtriangledown\phi_1$ and $y\mathbf{F} = \bigtriangledown\phi_2$. □

It follows from Proposition 2.1 that the integrals of $x\mathbf{F}$ and $y\mathbf{F}$ over the boundary of any 2-D manifold in $\mathbb{R}^2$ that does not contain the origin are zero. We also require their integrals over any closed curve that encloses the origin to be zero, and it suffices to integrate over the unit circle $\mathbb{S}^1$. We have

$$\int_{\mathbb{S}^1} x\mathbf{F}\cdot d\mathbf{r} = -\int_0^{2\pi} \frac{1}{\sin^2\theta}\Phi(\cos\theta,\sin\theta)d\theta, \tag{2.11}$$

$$\int_{\mathbb{S}^1} y\mathbf{F}\cdot d\mathbf{r} = -\int_0^{2\pi} \frac{1}{\cos\theta\sin\theta}\Phi(\cos\theta,\sin\theta)d\theta. \tag{2.12}$$

If

$$\Phi(\cos\theta,\sin\theta) = -\cos\theta\sin^2\theta(1+\psi(\cos\theta,\sin\theta)), \tag{2.13}$$

where

$$\psi(\cos\theta,\sin\theta) := \sum_{k=2}^{\infty} a_k\cos k\theta + b_k\sin k\theta$$

is a differentiable function, then (2.11) and (2.12) give

$$\int_{\mathbb{S}^1} x\mathbf{F}\cdot d\mathbf{r} = \int_0^{2\pi} \cos\theta(1+\psi(\cos\theta,\sin\theta))d\theta = 0, \tag{2.14}$$

$$\int_{\mathbb{S}^1} y\mathbf{F}\cdot d\mathbf{r} = \int_0^{2\pi} \sin\theta(1+\psi(\cos\theta,\sin\theta))d\theta = 0, \tag{2.15}$$

since $1+\psi$ is orthogonal to $\cos\theta$ and $\sin\theta$.

We now state the results and complete the proof.

THEOREM 2.2. *Let* $\mathbf{F}$ *be as in Proposition* 2.1 *with* Φ *in* (2.13). *Then for any compact* 2*-D manifold* $D \subset \mathbb{R}^2$ *with piecewise smooth boundary* ∂D *and for* $\mathbf{v} \in \mathbb{R}^2 \setminus \partial D$,

$$\int_{\partial D} (\mathbf{r}-\mathbf{v})\ \mathbf{F}(\mathbf{r}-\mathbf{v}) \cdot d\mathbf{r} = \mathbf{0}. \tag{2.16}$$

Further, if $|\psi| \le 1$,

$$\mathbf{v} = \frac{\int_{\partial D} \mathbf{r}\ \mathbf{F}(\mathbf{r}-\mathbf{v}) \cdot d\mathbf{r}}{\int_{\partial D} \mathbf{F}(\mathbf{r}-\mathbf{v}) \cdot d\mathbf{r}} \tag{2.17}$$

for any $\mathbf{v} \in \mathbb{R}^2$.

We first prove a lemma, from which one can deduce that (2.2) holds if $|\psi| \le 1$.

LEMMA 2.3. *For any compact* 2*-D manifold* $D \subset \mathbb{R}^2$ *with piecewise smooth boundary,*

$$\int_{\partial D} \mathbf{F} \cdot d\mathbf{r} = \begin{cases} -\iint_D \frac{1}{r^3}\left(1+\psi\left(\frac{x}{r},\frac{y}{r}\right)\right)\ dxdy & \text{if } \mathbf{0} \notin D, \\ \iint_{\mathbb{R}^2\setminus D} \frac{1}{r^3}\left(1+\psi\left(\frac{x}{r},\frac{y}{r}\right)\right)\ dxdy & \text{if } \mathbf{0} \in D. \end{cases} \tag{2.18}$$

In particular, $\int_{\partial D} \mathbf{F} \cdot d\mathbf{r} \neq 0$ *if* $|\psi| \le 1$.

Proof. If $\mathbf{0} \notin D$, by Green's theorem

$$\begin{aligned} \int_{\partial D} \mathbf{F} \cdot d\mathbf{r} &= \iint_D \frac{\partial}{\partial x}\left(\frac{-1}{y^2}\Phi\right) - \frac{\partial}{\partial y}\left(\frac{1}{xy}\Phi\right)\ dxdy \\ &= \iint_D \frac{1}{xy^2}\Phi\left(\frac{x}{r},\frac{y}{r}\right) - \frac{1}{xy^2}\left\{x\frac{\partial\Phi}{\partial x} + y\frac{\partial\Phi}{\partial y}\right\}\ dxdy \\ &= \iint_D \frac{1}{xy^2}\Phi\left(\frac{x}{r},\frac{y}{r}\right)\ dxdy \\ &= -\iint_D \frac{1}{r^3}\left(1+\psi\left(\frac{x}{r},\frac{y}{r}\right)\right)\ dxdy. \end{aligned} \tag{2.19}$$

If $\mathbf{0} \in D$, take a disc D_R, with center at the origin and radius R, that contains D. By (2.19),

$$\int_{\partial D_R} \mathbf{F} \cdot d\mathbf{r} - \int_{\partial D} \mathbf{F} \cdot d\mathbf{r} = -\iint_{D_R\setminus D} \frac{1}{r^3}\left(1+\psi\left(\frac{x}{r},\frac{y}{r}\right)\right)\ dxdy$$

so that

$$\begin{aligned} \int_{\partial D} \mathbf{F} \cdot d\mathbf{r} &= \int_{\partial D_R} \mathbf{F} \cdot d\mathbf{r} + \iint_{D_R\setminus D} \frac{1}{r^3}\left(1+\psi\left(\frac{x}{r},\frac{y}{r}\right)\right)\ dxdy \\ &= -\frac{1}{R}\int_0^{2\pi} 1+\psi(\cos\theta,\sin\theta)d\theta + \iint_{D_R\setminus D} \frac{1}{r^3}\left(1+\psi\left(\frac{x}{r},\frac{y}{r}\right)\right)\ dxdy. \end{aligned}$$

Taking the limit as $R \to \infty$ gives the second formula in (2.18). ∎

Proof of Theorem 2.2. If $\mathbf{v} \notin \partial D$, (2.16) follows from Proposition 2.1 and (2.14) and (2.15). Equation (2.17) follows from (2.16) and Lemma 2.3.

If $\mathbf{v} \in \partial D$, for any $\epsilon > 0$, we replace an appropriate segment of ∂D that contains $\mathbf{v}$ by a circular arc with center at $\mathbf{v}$ and radius ϵ, so that $\mathbf{v}$ lies outside the resulting piecewise smooth curve, which we call ∂D_ϵ. Then (2.17) holds for ∂D_ϵ for all $\epsilon > 0$, and therefore holds in the limit as $\epsilon \to 0$. ∎

If we choose $\psi = 0$ in (2.13) so that

$$\Phi(\cos\theta, \sin\theta) = -\cos\theta \sin^2\theta, \tag{2.20}$$

a more general form of Floater's mean value coordinates [2] can be deduced as a corollary. The proof here, which is different from the existing methods (see [2], [3], [5] [6]), provides a better understanding why they work.

COROLLARY 2.4. *Let $D \subset \mathbb{R}^2$ be a compact 2-D manifold with piecewise smooth boundary ∂D, and let $\mathbf{v}_j \in \partial D$, $j = 1, 2, \ldots, k > 2$, be arranged in the positive orientation. Then for any $\mathbf{v} \in \mathbb{R}^2$,*

$$\mathbf{v} = \frac{\sum_{j=1}^k w_j \mathbf{v}_j}{\sum_{j=1}^k w_j}, \tag{2.21}$$

where

$$w_j := \frac{\tan(\alpha_{j-1}/2) + \tan(\alpha_j/2)}{||\mathbf{v}_j - \mathbf{v}||}, \quad j = 1, 2, \ldots, k-1, \tag{2.22}$$

and α_j is the angle at $\mathbf{v}$ of the oriented triangle $[\mathbf{v}, \mathbf{v}_j, \mathbf{v}_{j+1}]$ with $|\alpha_j| < \pi$ and takes a positive value if the vector $\frac{\mathbf{v}_j}{||\mathbf{v}_j||} - \frac{\mathbf{v}_{j+1}}{||\mathbf{v}_{j+1}||}$ is in the counterclockwise orientation and a negative value otherwise.

Proof. Take $\psi = 0$ in (2.13) so that $\Phi\left(\frac{x}{r}, \frac{y}{r}\right) = -\frac{xy^2}{r^3}$ and $\mathbf{F}(\mathbf{r}) \equiv \mathbf{F}(x, y) := [-y/r^3, x/r^3]^T$. By (2.9) and (2.10), $x\mathbf{F} = \bigtriangledown\phi_1$ and $y\mathbf{F} = \bigtriangledown\phi_2$, where

$$\phi_1(x, y) = -\frac{1}{y} \int \frac{xy^2}{r^3}\, dx = \frac{y}{r}, \tag{2.23}$$

$$\phi_2(x, y) = \int \frac{xy^2}{yr^3}\, dy = \frac{-x}{r}. \tag{2.24}$$

Hence the vector $[\phi_1(x, y), \phi_2(x, y)]^T = [y, -x]^T/r$ is the rotation of the $[x, y]^T/r$ along the unit circle in the clockwise direction through an angle of $\pi/2$. Let $\mathbf{v}_j = [x_j, y_j]$, $j = 1, 2, \ldots, k$, $\mathbf{v}_{k+1} := \mathbf{v}_1$. Then for $j = 1, 2, \ldots, k$,

$$\begin{aligned}\int_{\mathbf{v}_j}^{\mathbf{v}_{j+1}} \mathbf{r}\ \mathbf{F} \cdot d\mathbf{r} &= [\phi_1(\mathbf{v}_{j+1}), \phi_2(\mathbf{v}_{j+1})]^T - [\phi_1(\mathbf{v}_j), \phi_2(\mathbf{v}_j)]^T \\ &= [y_{j+1}, -x_{j+1}]^T/||\mathbf{v}_{j+1}|| - [y_j, -x_j]^T/||\mathbf{v}_j||.\end{aligned}$$

The vector $[y_{j+1}, -x_{j+1}]^T/||\mathbf{v}_{j+1}|| - [y_j, -x_j]^T/||\mathbf{v}_j||$ is parallel to $\mathbf{v}_{j+1}/||\mathbf{v}_{j+1}|| + \mathbf{v}_j/||\mathbf{v}_j||$ and

$$\begin{aligned}\left\| \frac{[y_{j+1}, -x_{j+1}]^T}{||\mathbf{v}_{j+1}||} - \frac{[y_j, -x_j]^T}{||\mathbf{v}_j||} \right\| &= \left\| \frac{\mathbf{v}_{j+1}}{||\mathbf{v}_{j+1}||} - \frac{\mathbf{v}_j}{||\mathbf{v}_j||} \right\| \\ &= \tan(\alpha_j/2) \left\| \frac{\mathbf{v}_{j+1}}{||\mathbf{v}_{j+1}||} + \frac{\mathbf{v}_j}{||\mathbf{v}_j||} \right\|,\end{aligned}$$

where α_j is the angle at the origin, $\mathbf{0}$, of the triangle $\left[\mathbf{0}, \frac{\mathbf{v}_j}{||\mathbf{v}_j||}, \frac{\mathbf{v}_{j+1}}{||\mathbf{v}_{j+1}||}\right]$. Hence

$$\int_{\mathbf{v}_j}^{\mathbf{v}_{j+1}} \mathbf{r}\ \mathbf{F}\cdot d\mathbf{r} = \tan(\alpha_j/2)\ \left\{\frac{\mathbf{v}_{j+1}}{||\mathbf{v}_{j+1}||} + \frac{\mathbf{v}_j}{||\mathbf{v}_j||}\right\}$$

with the convention that α_j takes the positive sign if $\frac{\mathbf{v}_{j+1}}{||\mathbf{v}_{j+1}||} - \frac{\mathbf{v}_j}{||\mathbf{v}_j||}$ is counterclockwise and the negative sign if it is clockwise. Hence for $\mathbf{v}\in\mathbb{R}^2$,

$$\int_{\mathbf{v}_j}^{\mathbf{v}_{j+1}} (\mathbf{r}-\mathbf{v})\ \mathbf{F}(\mathbf{r}-\mathbf{v})\cdot d\mathbf{r} = \tan(\alpha_j/2)\ \left\{\frac{\mathbf{v}_j-\mathbf{v}}{||\mathbf{v}_j-\mathbf{v}||} + \frac{\mathbf{v}_{j+1}-\mathbf{v}}{||\mathbf{v}_{j+1}-\mathbf{v}||}\right\},$$

where α_j is the angle at $\mathbf{v}$ of triangle $[\mathbf{v}, \mathbf{v}_j, \mathbf{v}_{j+1}]$. Substituting this into

$$\sum_{j=1}^{k}\int_{\mathbf{v}_j}^{\mathbf{v}_{j+1}} (\mathbf{r}-\mathbf{v})\ \mathbf{F}(\mathbf{r}-\mathbf{v})\cdot d\mathbf{r} = \int_{\partial D} (\mathbf{r}-\mathbf{v})\ \mathbf{F}(\mathbf{r}-\mathbf{v})\cdot d\mathbf{r} = \mathbf{0}$$

gives (2.21) with w_j given by (2.22). □

3. Representation on boundaries of compact 3-D manifolds in $\mathbb{R}^3$. As in the previous section, we want to find a differentiable vector field $\mathbf{F}(\mathbf{r}) = [F_1(x,y,z), F_2(x,y,z), F_3(x,y,z)]^T$, $\mathbf{r} = [x,y,z]^T \in \mathbb{R}^3\setminus\{\mathbf{0}\}$, that satisfies

$$\iint_{\partial M} \mathbf{r}\ \mathbf{F}(\mathbf{r})\cdot d\mathbf{S} = \mathbf{0} \tag{3.1}$$

and

$$\iint_{\partial M} \mathbf{F}(\mathbf{r})\cdot d\mathbf{S} \neq 0 \tag{3.2}$$

for any compact 3-D manifold $M\in\mathbb{R}^3$ with piecewise smooth boundary ∂M. We assume that the positive orientation of ∂M is one in which its normal points away from M. Then if (3.1) and (3.2) hold, then, for any $\mathbf{v}\in\mathbb{R}^3$,

$$\mathbf{v} = \frac{\iint_{\partial M} \mathbf{r}\ \mathbf{F}(\mathbf{r}-\mathbf{v})\cdot d\mathbf{S}}{\iint_{\partial M} \mathbf{F}(\mathbf{r}-\mathbf{v})\cdot d\mathbf{S}}. \tag{3.3}$$

A similar search as in the previous section requiring that $x\mathbf{F}$, $y\mathbf{F}$, and $z\mathbf{F}$ be divergence free, i.e., $\operatorname{div}(x\mathbf{F}) = \operatorname{div}(y\mathbf{F}) = \operatorname{div}(z\mathbf{F}) = 0$, shows that F_i, $i=1,2,3$, are solutions of the partial differential equation

$$x\frac{\partial U}{\partial x} + y\frac{\partial U}{\partial y} + z\frac{\partial U}{\partial z} = -3U. \tag{3.4}$$

The general solution of (3.4) that vanishes at infinity is

$$U(x,y,z) = \frac{1}{xyz}\Phi\left(\frac{x}{\rho}, \frac{y}{\rho}, \frac{z}{\rho}\right), \tag{3.5}$$

where $\Phi : \mathbb{S}^2 \to \mathbb{R}$ is an arbitrary differentiable function on the unit sphere $\mathbb{S}^2\subset\mathbb{R}^3$, $\rho := (x^2+y^2+z^2)^{1/2}$, and $\Phi\left(\frac{x}{\rho}, \frac{y}{\rho}, \frac{z}{\rho}\right)$ is the general solution of the corresponding homogeneous equation. To state the results, we define spherical harmonics

$$C_\ell^m(\phi,\theta) := N_\ell^m P_\ell^m(\cos\phi)\cos m\theta, \quad m = 0,1,\ldots,\ell,$$

$$S_\ell^m(\phi,\theta) := N_\ell^m P_\ell^m(\cos\phi)\sin m\theta, \quad m = 1,2,\ldots\ell,$$

where P_ℓ^m are the associated Legendre polynomials and N_ℓ^m are normalization constants (see [9]).

THEOREM 3.1. *Let*

(3.6)
$$\mathbf{F}(\mathbf{r}) \equiv \mathbf{F}(x,y,z) := \left[\frac{1}{xyz}\Phi\left(\frac{x}{\rho},\frac{y}{\rho},\frac{z}{\rho}\right), \frac{1}{x^2z}\Phi\left(\frac{x}{\rho},\frac{y}{\rho},\frac{z}{\rho}\right), \frac{1}{x^2y}\Phi\left(\frac{x}{\rho},\frac{y}{\rho},\frac{z}{\rho}\right)\right]^T,$$

where $\Phi : \mathbb{S}^2 \to \mathbb{R}$ is an arbitrary differentiable function. Then $x\mathbf{F}$, $y\mathbf{F}$, and $z\mathbf{F}$ are divergence free on $\mathbb{R}^3 \setminus \{\mathbf{0}\}$.

Further, if

$$\Phi\left(\frac{x}{\rho},\frac{x}{\rho},\frac{x}{\rho}\right) := \frac{x^2yz}{\rho^4}\left(1+\Psi\left(\frac{x}{\rho},\frac{x}{\rho},\frac{x}{\rho}\right)\right)$$

$$= \sin^3\phi\cos^2\theta\sin\theta\cos\phi\ (1+\Psi(\sin\phi\cos\theta,\sin\phi\sin\theta,\cos\phi)) \tag{3.7}$$

and

$$\Psi(\sin\phi\cos\theta,\sin\phi\sin\theta,\cos\phi) := \sum_{\ell=2}^{\infty}\left\{\sum_{m=0}^{\ell} a_\ell^m\ C_\ell^m(\phi,\theta) + \sum_{m=1}^{\ell} b_\ell^m\ S_\ell^m(\phi,\theta)\right\}, \tag{3.8}$$

then for any compact 3-D manifold M in $\mathbb{R}^3$ with piecewise smooth boundary and for $\mathbf{v} \in \mathbb{R}^3 \setminus \partial M$,

$$\iint_{\partial M} (\mathbf{r}-\mathbf{v})\ \mathbf{F}(\mathbf{r}-\mathbf{v}) \cdot d\mathbf{S} = \mathbf{0}. \tag{3.9}$$

In addition, if $|\Psi| \le 1$, then for any $\mathbf{v} \in \mathbb{R}^3$,

$$\mathbf{v} = \frac{\iint_{\partial M} \mathbf{r}\ \mathbf{F}(\mathbf{r}-\mathbf{v}) \cdot d\mathbf{S}}{\iint_{\partial M} \mathbf{F}(\mathbf{r}-\mathbf{v}) \cdot d\mathbf{S}}. \tag{3.10}$$

Proof. Suppose $\mathbf{F}$ is as in (3.6), where $\Phi : \mathbb{S}^2 \to \mathbb{R}$ is an arbitrary differentiable function on the unit sphere $\mathbb{S}^2$. Then

$$\operatorname{div}(x\mathbf{F}) = \frac{1}{xyz}\left(x\frac{\partial\Phi}{\partial x} + y\frac{\partial\Phi}{\partial y} + z\frac{\partial\Phi}{\partial z}\right) = 0, \quad (x,y,z) \in \mathbb{R}^3 \setminus \{\mathbf{0}\},$$

since $\Phi(\frac{x}{\rho},\frac{y}{\rho},\frac{z}{\rho})$ satisfies

$$x\frac{\partial\Phi}{\partial x} + y\frac{\partial\Phi}{\partial y} + z\frac{\partial\Phi}{\partial z} = 0.$$

Similarly, $\operatorname{div}(y\mathbf{F}) = \operatorname{div}(z\mathbf{F}) = 0$.

Suppose Φ is given by (3.7) and (3.8). To prove (3.9) we may assume $\mathbf{v} = \mathbf{0}$, so it reduces to proving (3.1). Since $x\mathbf{F}$, $y\mathbf{F}$, and $z\mathbf{F}$ are divergence free, (3.1) holds for any compact 3-D manifold M that does not contain the origin. To prove that (3.1) holds for any M that contains the origin, it suffices to prove that it holds for the unit

ball B with boundary $\partial B = \mathbb{S}^2$. In spherical polar coordinates,

$$\iint_{\mathbb{S}^2} x\mathbf{F}\cdot d\mathbf{S} = \int_0^{2\pi}\int_0^{\pi} \frac{\Phi(\sin\phi\cos\theta, \sin\phi\sin\theta, \cos\phi)}{\sin\phi\cos\phi\sin\theta\cos\theta} d\phi d\theta, \tag{3.11}$$

$$\iint_{\mathbb{S}^2} y\mathbf{F}\cdot d\mathbf{S} = \int_0^{2\pi}\int_0^{\pi} \frac{\Phi(\sin\phi\cos\theta, \sin\phi\sin\theta, \cos\phi)}{\sin\phi\cos\phi\cos^2\theta} d\phi d\theta, \tag{3.12}$$

$$\iint_{\mathbb{S}^2} z\mathbf{F}\cdot d\mathbf{S} = \int_0^{2\pi}\int_0^{\pi} \frac{\Phi(\sin\phi\cos\theta, \sin\phi\sin\theta, \cos\phi)}{\sin^2\phi\cos^2\theta\sin\theta} d\phi d\theta. \tag{3.13}$$

By (3.7) and (3.11)–(3.13),

$$\begin{aligned}\iint_{\mathbb{S}^2} \mathbf{r}\ \mathbf{F}\cdot d\mathbf{S} &\equiv \iint_{\mathbb{S}^2} [x,y,z]^T\mathbf{F}\cdot d\mathbf{S}\\ &= \int_0^{2\pi}\int_0^{\pi} (1+\Psi)\ [C_1^1(\phi,\theta), S_1^1(\phi,\theta), C_1^0(\phi,\theta)]^T\ \sin\phi d\phi d\theta,\end{aligned}$$

where

$$C_1^0(\phi,\theta) = \cos\phi, \quad C_1^1(\phi,\theta) = \sin\phi\cos\theta, \quad S_1^1(\phi,\theta) = \sin\phi\sin\theta$$

are the first order spherical harmonics. Since $1+\Psi$ is orthogonal to C_1^0, C_1^1, and S_1^1, it follows that $\iint_{\mathbb{S}^2} \mathbf{r}\ \mathbf{F}\cdot d\mathbf{S} = 0$.

To prove (3.10) we first show that (3.2) holds. The same argument as in the proof of Lemma 2.3 using the divergence theorem gives

$$\iint_{\partial M} \mathbf{F}\cdot d\mathbf{S} = \begin{cases} \iiint_M \frac{1}{\rho^4}\left(1+\Psi\left(\frac{x}{\rho},\frac{y}{\rho},\frac{z}{\rho}\right)\right)\ dxdydz & \text{if } \mathbf{0}\notin M,\\ -\iiint_{\mathbb{R}^3\setminus M} \frac{1}{\rho^4}\left(1+\Psi\left(\frac{x}{\rho},\frac{y}{\rho},\frac{z}{\rho}\right)\right)\ dxdydz & \text{if } \mathbf{0}\in M.\end{cases} \tag{3.14}$$

In particular, $\iint_{\partial M}\mathbf{F}\cdot d\mathbf{S} \neq 0$ if $|\Psi|\le 1$. Hence (3.10) follows from (3.9) for $\mathbf{v}\notin\partial M$. A limiting argument as in the proof of Theorem 2.2 shows that it also holds for $\mathbf{v}\in\partial M$. ∎

4. Mean value coordinates in $\mathbb{R}^3$. We now apply the results in Theorem 3.1 to compute mean value coordinates in $\mathbb{R}^3$. An explicit expression for mean value coordinates for points that lie in the kernel of a star-shaped polyhedron in $\mathbb{R}^3$ is given in [3]. An algorithm for computing these coordinates for all points in $\mathbb{R}^3$ can be found in [6], but no explicit expression is given there. In this section we derive a new formula for mean value coordinates for points in $\mathbb{R}^3$ with respect to the boundary of any compact 3-D manifold with polyhedral faces of any topology. In the case where all the faces of ∂M are triangular, the formula is equivalent to that in [3].

Consider $\mathbf{F} = [F_1, F_2, F_3]^T$ in (3.6), where Ψ is given by (3.7) as in Theorem 3.1. Throughout this section we shall assume that $\Psi \equiv 0$ so that Φ takes the simplest form:

$$\Phi\left(\frac{x}{\rho},\frac{y}{\rho},\frac{z}{\rho}\right) = \frac{x^2yz}{\rho^4}$$

and

$$\mathbf{F}\equiv\mathbf{F}(\mathbf{r}) = \frac{\mathbf{r}}{\rho^4}, \quad \rho\neq\mathbf{0}. \tag{4.1}$$

Now

$$curl(\mathbf{F}) = \bigtriangledown\left(\frac{1}{\rho^4}\right) \times \mathbf{r} + \frac{1}{\rho^4}\ curl(\mathbf{r})$$

$$= \frac{-4}{\rho^6}\mathbf{r} \times \mathbf{r} = \mathbf{0}$$

and

$$\text{div}(\mathbf{F}) = \bigtriangledown\left(\frac{1}{\rho^4}\right) \cdot \mathbf{r} + \frac{1}{\rho^4}\ \text{div}(\mathbf{r}) = -\frac{1}{\rho^4}, \quad \rho \neq 0.$$

Since

$$\text{div}(x\mathbf{F}) = \text{div}(y\mathbf{F}) = \text{div}(z\mathbf{F}) = 0,$$

we want to find vector fields $\mathbf{A}, \mathbf{B}, \mathbf{C}$ such that

$$x\mathbf{F} = curl(\mathbf{A}), \quad y\mathbf{F} = curl(\mathbf{B}), \quad z\mathbf{F} = curl(\mathbf{C}), \quad \rho \neq 0, \tag{4.2}$$

so that Stoke's theorem can be applied to evaluate the integrals of $x\mathbf{F}$, $y\mathbf{F}$, $z\mathbf{F}$ over the polyhedral faces of ∂M.

By (4.2)

$$curl(x\mathbf{F}) = \bigtriangledown(\text{div}(\mathbf{A})) - \bigtriangledown^2\mathbf{A},$$

so that if $\text{div}(\mathbf{A}) = 0$, the vector components of $\mathbf{A}$ satisfy Poisson's equations

$$\bigtriangledown^2\mathbf{A} = -curl(x\mathbf{F}), \quad \rho \neq 0. \tag{4.3}$$

Similarly, if $\text{div}(\mathbf{B}) = \text{div}(\mathbf{C}) = 0$,

$$\bigtriangledown^2\mathbf{B} = -curl(y\mathbf{F}), \tag{4.4}$$

$$\bigtriangledown^2\mathbf{C} = -curl(z\mathbf{F}), \quad \rho \neq 0. \tag{4.5}$$

Now

$$curl(x\mathbf{F}) = \bigtriangledown x \times \mathbf{F} + x\ curl(\mathbf{F}) = [0, -F_3, F_2]^T = \frac{1}{\rho^4}[0, -z, y]^T,$$

$$curl(y\mathbf{F}) = \bigtriangledown y \times \mathbf{F} + y\ curl(\mathbf{F}) = [F_3, 0, -F_1]^T = \frac{1}{\rho^4}[z, 0, -x]^T,$$

$$curl(z\mathbf{F}) = \bigtriangledown z \times \mathbf{F} + z\ curl(\mathbf{F}) = [-F_2, F_1, 0]^T = \frac{1}{\rho^4}[-y, x, 0]^T,$$

so that by (4.3)–(4.5),

$$\bigtriangledown^2\mathbf{A} = \frac{1}{\rho^4}[0, z, -y]^T, \tag{4.6}$$

$$\bigtriangledown^2\mathbf{B} = \frac{1}{\rho^4}[-z, 0, x]^T, \tag{4.7}$$

$$\bigtriangledown^2\mathbf{C} = \frac{1}{\rho^4}[y, -x, 0]^T, \quad \rho \neq 0. \tag{4.8}$$

We look for divergence free solutions, $\mathbf{A}, \mathbf{B}, \mathbf{C}$, of Poisson's equations (4.6), (4.7), (4.8), which satisfy (4.2) and vanish at infinity.

PROPOSITION 4.1. *The vector fields*

$$\mathbf{A} = \frac{1}{2\rho^2}[0, z, -y]^T, \quad \mathbf{B} = \frac{1}{2\rho^2}[-z, 0, x]^T, \quad \mathbf{C} = \frac{1}{2\rho^2}[y, -x, 0]^T \tag{4.9}$$

are divergence free and satisfy (4.2). *Further, they are unique divergence free solutions of* (4.6), (4.7), (4.8) *that satisfy* (4.2) *and vanish at infinity.*

Proof. It is straightforward to verify that $\mathbf{A}, \mathbf{B}, \mathbf{C}$ satisfy (4.2) and $\operatorname{div}(\mathbf{A}) = \operatorname{div}(\mathbf{B}) = \operatorname{div}(\mathbf{C}) = 0$. Hence they are particular solutions of (4.6), (4.7), (4.8), respectively. To prove uniqueness, we consider (4.6), in which the general solution is

$$\mathbf{A}_g = \left[U, U + \frac{z}{2\rho^2}, U - \frac{y}{2\rho^2}\right]^T,$$

where U is the general solution of the corresponding homogeneous equation, which is the Laplace equation. The conditions that $\operatorname{div}(\mathbf{A}_g) = 0$, $curl(\mathbf{A}_g) = x\mathbf{F}$, and $\mathbf{A}_g$ vanishes at infinity imply $U = 0$. Hence $\mathbf{A}_g = \mathbf{A}$. The proof of uniqueness of $\mathbf{B}$ and $\mathbf{C}$ is the same. □

Consider a 3-D manifold, $M \subset \mathbb{R}^3$, with polyhedral faces (not necessarily planar) of arbitrary topology, and each face has piecewise linear boundaries. Let $\mathcal{F}$ be the set of all its faces, which are oriented with their normals pointing away from M. The orientation of each face induces an orientation on the edges that form its boundary. Let $\mathcal{V}$ be the set of all vertices of ∂M.

PROPOSITION 4.2. *Let S be a face of ∂M whose boundary is the union of oriented line segments $[\mathbf{v}_j, \mathbf{v}_{j+1}]$, $j = 1, 2, \ldots, k = k(S)$, $\mathbf{v}_{k+1} = \mathbf{v}_1$. Then for any $\mathbf{v} \notin \partial S$,*

$$\iint_S (\mathbf{r} - \mathbf{v})\mathbf{F}(\mathbf{r} - \mathbf{v}) \cdot d\mathbf{S} = \frac{1}{2} \sum_{j=1}^{k} \alpha_j \, \mathbf{n}_j, \tag{4.10}$$

where $\alpha_j \in (0, \pi)$ is the angle at $\mathbf{v}$ of the triangle $[\mathbf{v}, \mathbf{v}_j, \mathbf{v}_{j+1}]$ and

$$\mathbf{n}_j = \frac{(\mathbf{v}_{j+1} - \mathbf{v}) \times (\mathbf{v}_j - \mathbf{v})}{||(\mathbf{v}_{j+1} - \mathbf{v}) \times (\mathbf{v}_j - \mathbf{v})||}. \tag{4.11}$$

Proof. We assume without loss of generality that $\mathbf{v} = \mathbf{0}$. By Stoke's theorem

$$\iint_S \mathbf{r}\ \mathbf{F} \cdot d\mathbf{S} = \left[\iint_S x\ \mathbf{F} \cdot d\mathbf{S}, \iint_S y\ \mathbf{F} \cdot d\mathbf{S}, \iint_S z\ \mathbf{F} \cdot d\mathbf{S}\right]^T$$

$$= \left[\int_{\partial S} \mathbf{A} \cdot d\mathbf{r}, \int_{\partial S} y\mathbf{B} \cdot d\mathbf{r}, \int_{\partial S} \mathbf{C} \cdot d\mathbf{r}\right]^T \tag{4.12}$$

$$= \sum_{j=1}^{k} \left[\int_{[\mathbf{v}_j, \mathbf{v}_{j+1}]} \mathbf{A} \cdot d\mathbf{r}, \int_{[\mathbf{v}_j, \mathbf{v}_{j+1}]} \mathbf{B} \cdot d\mathbf{r}, \int_{[\mathbf{v}_j, \mathbf{v}_{j+1}]} \mathbf{C} \cdot d\mathbf{r}\right]^T. \tag{4.13}$$

Let $\mathbf{v}_j = [x_j, y_j, z_j]^T$. A straightforward computation gives

$$\int_{[\mathbf{v}_j,\mathbf{v}_{j+1}]} \mathbf{A}\cdot d\mathbf{r} = -\begin{vmatrix} y_j & z_j \\ y_{j+1} & z_{j+1}\end{vmatrix}\left(\frac{\alpha_j}{2||\mathbf{v}_{j+1}\times\mathbf{v}_j||}\right),$$

$$\int_{[\mathbf{v}_j,\mathbf{v}_{j+1}]} \mathbf{B}\cdot d\mathbf{r} = \begin{vmatrix} x_j & z_j \\ x_{j+1} & z_{j+1}\end{vmatrix}\left(\frac{\alpha_j}{2||\mathbf{v}_{j+1}\times\mathbf{v}_j||}\right),$$

$$\int_{[\mathbf{v}_j,\mathbf{v}_{j+1}]} \mathbf{C}\cdot d\mathbf{r} = -\begin{vmatrix} x_j & y_j \\ x_{j+1} & y_{j+1}\end{vmatrix}\left(\frac{\alpha_j}{2||\mathbf{v}_{j+1}\times\mathbf{v}_j||}\right),$$

which, by (4.13), leads to (4.10) and (4.11). □

The next step in the computation of the mean value coordinates is to express the sum on the right of (4.10) in terms of $\mathbf{v}_j - \mathbf{v}$, $j = 1, 2, \ldots, k$:

$$\frac{1}{2}\sum_{j=1}^{k}\alpha_j\,\mathbf{n}_j = \sum_{j=1}^{k} a_j(S)(\mathbf{v}_j - \mathbf{v}), \tag{4.14}$$

where $a_j(S) \equiv a_{\mathbf{v}_j}(S)$ so that

$$\mathbf{0} = \sum_{S\in\mathcal{F}}\iint_S (\mathbf{r}-\mathbf{v})\mathbf{F}(\mathbf{r}-\mathbf{v})\cdot d\mathbf{S} = \sum_{S\in\mathcal{F}}\sum_{j=1}^{k(S)} a_j(S)(\mathbf{v}_j - \mathbf{v}),$$

which would lead to

$$\mathbf{v} = \frac{\sum_{S\in\mathcal{F}}\sum_{j=1}^{k(S)} a_j(S)\,\mathbf{v}_j}{\sum_{S\in\mathcal{F}}\sum_{j=1}^{k(S)} a_j(S)} = \frac{\sum_{\mathbf{p}\in\mathcal{V}}\lambda_{\mathbf{p}}\,\mathbf{p}}{\sum_{\mathbf{p}\in\mathcal{V}}\lambda_{\mathbf{p}}}, \tag{4.15}$$

where

$$\lambda_{\mathbf{p}} := \sum_{\substack{S\subset\mathcal{F}\\ \mathbf{p}\in S}} a_{\mathbf{p}}(S). \tag{4.16}$$

If $k = 3$, $a_j(S)$ can be obtained uniquely by taking the inner products of the expressions in (4.14) with $\mathbf{n}_\ell$ or $\mathbf{v}_\ell - \mathbf{v}$, $\ell = 1, 2, 3$. Taking the inner product with $\mathbf{n}_\ell$ gives

$$a_{\ell+2}(S) = \frac{1}{2\,\mathbf{n}_\ell\cdot(\mathbf{v}_{\ell+2}-\mathbf{v})}\sum_{j=1}^{3}\mathbf{n}_\ell\cdot\mathbf{n}_j\,\alpha_j, \quad \ell = 1, 2, 3,$$

where $a_j = a_{j+3}$ and $\mathbf{n}_j = \mathbf{n}_{j+3}$ for all j. These coordinates are the same as those obtained earlier in [3] for the representation of points in the kernel of 3-D star-shaped manifolds. We have shown that they are applicable to all points in $\mathbb{R}^3$ with respect to the boundaries of more general manifolds. If $k > 3$, the representation (4.14) exists, but is not unique. We shall derive a formula for $a_j(S)$ in (4.14) for the general case, which reduces to the above formula when $k = 3$. The idea is to express

$$\frac{1}{2}\sum_{j=1}^{k}\alpha_j\,\mathbf{n}_j = b_{\ell,0}(\mathbf{v}-\mathbf{v}_\ell) + b_{\ell,1}(\mathbf{v}-\mathbf{v}_{\ell+1}) + b_{\ell,2}(\mathbf{v}-\mathbf{v}_{\ell+2}) \tag{4.17}$$

for $\ell = 1, 2, \ldots, k$, where $b_{k+1,i} = b_{1,i}$, $i = 0, 1, 2$, and define

$$a_j(S) := \frac{1}{k}(b_{j,0} + b_{j-1,1} + b_{j-2,2}), \quad j = 1, 2, \ldots, k.$$

Then

$$\begin{aligned}\frac{1}{2}\sum_{j=1}^{k} \alpha_j \, \mathbf{n}_j &= \frac{1}{k}\sum_{\ell=1}^{k}\sum_{i=0}^{2} b_{\ell,i}(\mathbf{v} - \mathbf{v}_{\ell+i}) \\ &= \frac{1}{k}\sum_{j=1}^{k}\sum_{i=0}^{2} b_{j-i,i}(\mathbf{v} - \mathbf{v}_j) \\ &= \sum_{j=1}^{k} a_j(S)(\mathbf{v} - \mathbf{v}_j),\end{aligned}$$

as required by (4.14) so that (4.15) holds.

To compute the coefficients $b_{\ell,i}$, $i = 0, 1, 2$, taking the inner product of (4.17) with $\mathbf{n}_\ell$, $\mathbf{n}_{\ell+1}$, and $\mathbf{n}_{\ell+2}$ leads to

$$b_{\ell,2} = \frac{1}{2\ \mathbf{v}_{\ell+2} \cdot \mathbf{n}_\ell} \sum_{j=1}^{k} \mathbf{n}_\ell \cdot \mathbf{n}_j \ \alpha_j,$$

$$b_{\ell,0} = \frac{1}{2\ \mathbf{v}_\ell \cdot \mathbf{n}_{\ell+1}} \sum_{j=1}^{k} \mathbf{n}_{\ell+1} \cdot \mathbf{n}_j \ \alpha_j,$$

and

$$b_{\ell,1} = \frac{1}{2\ \mathbf{v}_{\ell+1} \cdot \mathbf{n}_{\ell+2}} \sum_{j=1}^{k} \mathbf{n}_{\ell+2} \cdot \mathbf{n}_j \ \alpha_j - \frac{\mathbf{v}_\ell \cdot \mathbf{n}_{\ell+2}}{2\ \mathbf{v}_\ell \cdot \mathbf{n}_{\ell+1}\ \mathbf{v}_{\ell+1} \cdot \mathbf{n}_{\ell+2}} \sum_{j=1}^{k} \mathbf{n}_{\ell+1} \cdot \mathbf{n}_j \ \alpha_j$$

for $\ell = 1, 2, \ldots, k$.

Remark. In general, the functions Φ and Ψ in (3.7) and (3.8), respectively, define the vector field

$$\mathbf{F}(\mathbf{r}) = \frac{g(\mathbf{r})}{\rho^4}\mathbf{r}, \quad \mathbf{r} = (x, y, z) \in \mathbb{R}^3 \setminus \{\mathbf{0}\},$$

where

$$g(\mathbf{r}) := 1 + \Psi\left(\frac{\mathbf{r}}{\rho}\right),$$

and $\mathbf{F}$ provides mean value representations. Since

$$\mathbf{F}(\mathbf{r}) = -g(\mathbf{r}) \bigtriangledown \left(\frac{1}{2\rho^2}\right) \tag{4.18}$$

and

$$\operatorname{div}(x\mathbf{F}(\mathbf{r})) = 0, \quad \operatorname{div}(y\mathbf{F}(\mathbf{r})) = 0, \quad \operatorname{div}(z\mathbf{F}(\mathbf{r})) = 0, \tag{4.19}$$

the system (4.18), (4.19) can be discretized by the mimetic finite difference schemes (see [1], [8], and the references therein) to give a large class of mean value type coordinates.

Acknowledgments. Thanks to an anonymous referee for pointing out the connection with mimetic finite difference schemes. Thanks also to Rick Beatson for useful discussions that generated my interest in the subject and to the Abdus Salam International Centre for Theoretical Physics, Trieste, for providing an excellent environment and financial support during my visit in March/April 2007.

COLLISIONS IN THREE-DIMENSIONAL FLUID STRUCTURE INTERACTION PROBLEMS*

MATTHIEU HILLAIRET† AND TAKÉO TAKAHASHI‡

Abstract. This paper deals with a system composed of a rigid ball moving into a viscous incompressible fluid over a fixed horizontal plane. The equations of motion for the fluid are the Navier–Stokes equations, and the equations for the motion of the rigid ball are obtained by applying Newton's laws. We show that for any weak solution of the corresponding system satisfying the energy inequality, the rigid ball never touches the plane. This result is the extension of that obtained in [M. Hillairet, *Comm. Partial Differential Equations*, 32 (2007), pp. 1345–1371] in the two-dimensional setting.

Key words. fluid structure interactions, Cauchy theory, qualitative properties, collisions

1. Introduction.

In the last decade, several studies showed that collisions between rigid bodies in a fluid would lead to great difficulties in the mathematical treatment of fluid-structure interaction models. For example, in [4, p. 287], Feireisl constructs a solution in which a sphere remains stuck to the ceiling of the cavity regardless of the intensity of the gravity. This example emphasizes that collisions would lead to unphysical solutions to standard mathematical systems. Indeed, Starovoitov proves also that several solutions exist when contact occurs [11, 12]. Therefore, at least one of these solutions does not represent a physical configuration.

Before handling the description of these collisions, several studies proved they do not occur in fluid structure systems. In [15], Vázquez and Zuazua prove no collision can occur between particles for a one-dimensional toy model. Then Starovoitov obtains a criterion for the velocity field of solutions [12] in the multidimensional setting. Namely, he proves no collision can occur if the gradient of the velocity field is sufficiently integrable. Finally, two parallel studies [8, 9] prove a no-collision result when there is only one body in a bounded (or partially bounded) two-dimensional cavity. In the first case, the author considers a rigid disk inside a bigger disk. In the second case, the author considers a rigid disk above a ramp. The aim of the present study is to extend these two-dimensional results to three-dimensional comparable configurations, i.e., for a rigid sphere above a ramp in $\mathbb{R}^3$.

1.1. Mathematical model.

We consider a homogeneous rigid sphere $\mathcal{B}$ with radius 1 and density $\rho_{\mathcal{B}}$. We denote by $\mathbf{G}$ its center (of mass), by $\mathbf{V}$ (resp., $\boldsymbol{\omega}$) its translation (resp., angular) velocity, and by m (resp., $\mathbb{J}$) its mass (resp., inertia). Notice that $\boldsymbol{\omega}$ is a vector in $\mathbb{R}^3$ and $\mathbb{J} = J\mathrm{I}_3$, where $J \in (0, \infty)$, and I_3 is the 3×3

identity matrix. The velocity field of $\mathcal{B}$ reads $\mathbf{V}+\boldsymbol{\omega}\times(\mathbf{x}-\mathbf{G})$ for all $\mathbf{x}\in\mathcal{B}$. The sphere evolves over a ramp $\mathcal{P}$. The remainder of the cavity $\mathbb{R}^3_+$ is denoted by $\mathcal{F}$. It contains an incompressible viscous and Newtonian fluid which does not slip on boundaries and has constant density $\rho_{\mathcal{F}}=1$ and viscosity μ. The whole system evolves only through the interactions between solid and fluid without any external force field.

The evolution of the fluid is described by $(\mathbf{u},p)$, a velocity/pressure field satisfying the incompressible Navier–Stokes equations:

$$\begin{cases}\partial_t\mathbf{u}+\mathbf{u}\cdot\nabla\mathbf{u}=\operatorname{div}\mathbb{T}(\mathbf{u},p)\\ \operatorname{div}\mathbf{u}=0\end{cases}\qquad\text{in }\mathcal{F},\tag{1.1}$$

where $\mathbb{T}(\mathbf{u},p)$ is the Newtonian stress tensor:

$$\mathbb{T}(\mathbf{u},p)=2\mu D(\mathbf{u})-p\mathrm{I}_3.$$

Here $D(\mathbf{u})$ stands for the symmetric part of the gradient of $\mathbf{u}$.

To describe the evolution of $\mathcal{B}$, we apply Newton's laws assuming continuity of the stress-tensor of the fluid on $\partial\mathcal{B}$. It yields

$$\begin{cases}-\displaystyle\int_{\partial\mathcal{B}}\mathbb{T}(\mathbf{u},p)\mathbf{n}\,\mathrm{d}\sigma=m\dot{\mathbf{V}},\\ -\displaystyle\int_{\partial\mathcal{B}}\mathbb{T}(\mathbf{u},p)\mathbf{n}\times(\mathbf{x}-\mathbf{G})\,\mathrm{d}\sigma=J\dot{\boldsymbol{\omega}}.\end{cases}\tag{1.2}$$

Here $\mathbf{n}$ stands for the normal to $\partial\mathcal{B}$ directed towards $\mathcal{B}$. As $\mathbb{J}$ is a scalar matrix, the inertial term $\mathbb{J}\boldsymbol{\omega}\times\boldsymbol{\omega}$ vanishes in the conservation of momentum.

This system is complemented with the boundary conditions

$$\mathbf{u}_{|\partial\mathcal{B}}=\mathbf{V}+\boldsymbol{\omega}\times(\mathbf{x}-\mathbf{G}),\quad \mathbf{u}_{|\mathcal{P}}=0,\quad \mathbf{u}_{|\infty}=0\tag{1.3}$$

and initial conditions

$$\mathbf{u}(0,\cdot)=\mathbf{u}^0,\quad \mathbf{V}(0)=\mathbf{V}^0,\quad \boldsymbol{\omega}(0)=\boldsymbol{\omega}^0,\quad \mathbf{G}(0)=\mathbf{G}^0.\tag{1.4}$$

For short, we shall refer to the whole system (1.1)–(1.3) as (FSIS) for fluid-solid interaction system. We emphasize that this system is strongly coupled. On the one hand, the position of the sphere $\mathcal{B}$ fixes the domain $\mathcal{F}$ where the incompressible Navier–Stokes equations (1.1) have to be solved and the movement of $\mathcal{B}$ fixes the boundary conditions for (1.1) on $\partial\mathcal{B}$. In particular, we lay stress upon these time-dependences, denoting by $\mathcal{F}(t)$ (resp., $\mathcal{B}(t)$) the domain occupied by the fluid (resp., the solid body) at time t in the following. We shall reserve the notation $\mathcal{B}$ (resp., $\mathcal{F}$) for the sphere (resp., the fluid) as "actors" in the scenarios provided by our solutions to (FSIS). On the other hand, the solution $(\mathbf{u},p)$ prescribes the displacement of $\mathcal{B}$ via the computation of the forces and torques applied to $\mathcal{B}$:

$$-\int_{\partial\mathcal{B}}\mathbb{T}(\mathbf{u},p)\mathbf{n}\,\mathrm{d}\sigma,\quad -\int_{\partial\mathcal{B}}\mathbb{T}(\mathbf{u},p)\mathbf{n}\times(\mathbf{x}-\mathbf{G})\,\mathrm{d}\sigma.$$

Our main result is that no collision can occur between $\mathcal{B}$ and $\mathcal{P}$ in finite time in solutions to (FSIS). This reads as follows.

THEOREM 1.1. *Given $T>0$, let $(\mathbf{u},\mathbf{G})$ be a weak solution to (FSIS) over $(0,T)$ with initial data $(\mathbf{u}^0,\mathbf{G}^0)$. Then there exists a decreasing function $h_{min}\in$*

$\mathcal{C}([0,T];(0,\infty))$ *depending only on initial data* $(\mathbf{u}^0,\mathbf{G}^0)$ *such that* $h(t):=\operatorname{dist}(\mathcal{B}(t),\mathcal{P})$ *satisfies*

$$h(t)\geqslant h_{min}(t)\quad\forall\, t\in(0,T).$$

This result has been expected ever since the computations of Cooley and O'Neill [1] in the slow motion regime. However, until now no rigorous mathematical result has been available in the full nonlinear case. We emphasize that this result still holds true when one adds a reasonable external force field $\mathbf{f}$, for example, the gravity or $\mathbf{f}\in L^2((0,T)\times\mathbb{R}^3_+)$. In section 3, we provide an interpretation for the weak formulation of (FSIS) explaining how the distance can be estimated from below with a suitable test function. Then we construct a test function explicitly. In section 4, the interpretation of the weak formulation is applied to the constructed test function. Technical details are postponed to the appendix.

As mentioned in Theorem 1.1, our result applies to any weak solution to (FSIS). However, the Cauchy theory of weak solutions has been developed only in bounded and in exterior domains (to our knowledge) so that we do not know whether one solution exists to (FSIS). For the sake of completeness, we extend classical results for the Cauchy theory of (FSIS) to a half-space in the next section. Eventually, we obtain that, for a sufficiently large class of initial data $(\mathbf{u}^0,\mathbf{G}^0)$, the system (FSIS) predicts that no collision can occur between $\mathcal{B}$ and $\mathcal{P}$.

1.2. Notation. Throughout, bold symbols stand for vectors. Given $\mathbf{a}\in\mathbb{R}^3$ we denote by $\mathbf{a}\otimes\mathbf{a}$ the symmetric matrix with entries a_ia_j. Coordinates $\mathbf{x}=(x_1,x_2,x_3)$ are centered on $\mathcal{P}$. For example, we have $\mathcal{P}:=\{(x_1,x_2,0),\ (x_1,x_2)\in\mathbb{R}^2\}$. The half-space above $\mathcal{P}$ is $\mathbb{R}^3_+$ and $\mathbb{R}^3_{++}$ stands for $\{(x_1,x_2,x_3)$ with $x_3>1\}$. This is the domain where the center of mass $\mathbf{G}$ can evolve as long as no collision between $\mathcal{B}$ and $\mathcal{P}$ occurs.

Given $\mathbf{G}\in\mathbb{R}^3$ and $\delta>0$, we denote by $\mathcal{B}(\mathbf{G},\delta)$ the sphere with center $\mathbf{G}$ and radius δ. For short, we also set $\mathcal{B}_{\mathbf{G}}=\mathcal{B}(\mathbf{G},1)$. This is the domain occupied by $\mathcal{B}$ when its center of mass meets $\mathbf{G}$. In this case, the fluid domain $\mathcal{F}_{\mathbf{G}}$ is the complementary of $\mathcal{B}_{\mathbf{G}}$ in $\mathbb{R}^3_+$. If the orthogonal projection of $\mathbf{G}$ on $\mathcal{P}$ is the center of coordinates, we have $\mathbf{G}=\mathbf{G}_h=(0,0,1+h)$ with $h=\operatorname{dist}(\mathcal{B}_{\mathbf{G}},\mathcal{P})$. In this case the suitable parameter is h and not $\mathbf{G}$. Thus, when using notation with h as subscript instead of $\mathbf{G}$, we implicitly mean that the subscript should be $\mathbf{G}_h$. For example, $\mathcal{B}_h:=\mathcal{B}_{\mathbf{G}_h}$.

In the whole paper, we denote by $\eta:[0,\infty)\to[0,1]$ a smooth function such that

$$\eta(s)=\begin{cases}1 & \text{if } s<\frac{1}{2},\\ 0 & \text{if } s>1,\end{cases}$$

and we set $\eta_\alpha=\eta(\cdot/\alpha)$ for all parameters $\alpha>0$.

We use the classical Lebesgue and Sobolev spaces $L^\alpha(A)$, $W^{\beta,\alpha}(A)$, $H^\beta(A)$ with A an open set, $\alpha\geqslant 1$, and $\beta\geqslant 0$. We define

$$\mathcal{H}=\{\boldsymbol{\phi}\in L^2(\mathbb{R}^3_+)\ ;\ \operatorname{div}\boldsymbol{\phi}=0,\ \boldsymbol{\phi}\cdot\mathbf{n}=0 \text{ on } \mathcal{P}\},$$

$$\mathcal{V}=\{\boldsymbol{\phi}\in H^1(\mathbb{R}^3_+)\ ;\ \operatorname{div}\boldsymbol{\phi}=0,\ \boldsymbol{\phi}=0 \text{ on } \mathcal{P}\}.$$

We recall that $\mathcal{H}$ and $\mathcal{V}$ are closed subspaces of $L^2(\mathbb{R}^3_+)$ and $H^1_0(\mathbb{R}^3_+)$, respectively. Thus, they form Hilbert spaces with respect to the induced inner products. For an open subset $A\subset\mathbb{R}^3_+$, we also consider the following Hilbert spaces:

$$\mathbb{H}(A)=\{\boldsymbol{\phi}\in\mathcal{H}\ ;\ D(\boldsymbol{\phi})=0 \text{ in } A\},$$

$$\mathbb{V}(A)=\{\boldsymbol{\phi}\in\mathcal{V}\ ;\ D(\boldsymbol{\phi})=0 \text{ in } A\}.$$

To simplify, if $\mathbf{G} \in \mathbb{R}^3_{++}$, we set

$$\mathbb{H}(\mathbf{G}) = \mathbb{H}(\mathcal{B}_{\mathbf{G}}), \quad \mathbb{V}(\mathbf{G}) = \mathbb{V}(\mathcal{B}_{\mathbf{G}}).$$

For all $\mathbf{G} \in \mathbb{R}^3_{++}$, we also denote by $\rho_{\mathbf{G}}$ the function

$$\rho_{\mathbf{G}}(\mathbf{x}) = \begin{cases} \rho_{\mathcal{B}} & \text{if } \mathbf{x} \in \mathcal{B}_{\mathbf{G}}, \\ 1 & \text{if } \mathbf{x} \in \mathcal{F}_{\mathbf{G}}. \end{cases}$$

If $\mathbf{v} \in \mathbb{H}(\mathbf{G})$, from [14, p. 18], there exists a unique pair $(\mathbf{V}[\mathbf{v}], \boldsymbol{\omega}[\mathbf{v}]) \in \mathbb{R}^3 \times \mathbb{R}^3$ such that

$$\mathbf{v}|_{\mathcal{B}_{\mathbf{G}}} = \mathbf{V}[\mathbf{v}] + \boldsymbol{\omega}[\mathbf{v}] \times (\mathbf{x} - \mathbf{G}).$$

In particular, if $(\mathbf{u}, \mathbf{v}) \in \mathbb{H}(\mathbf{G})^2$,

$$\int_{\mathbb{R}^3_+} \rho_{\mathbf{G}} \mathbf{u} \cdot \mathbf{v} \, \mathrm{d}\mathbf{x} = \int_{\mathbb{R}^3_+ \setminus \mathcal{B}_{\mathbf{G}}} \mathbf{u} \cdot \mathbf{v} \, \mathrm{d}\mathbf{x} + m\mathbf{V}[\mathbf{u}] \cdot \mathbf{V}[\mathbf{v}] + J\boldsymbol{\omega}[\mathbf{u}] \cdot \boldsymbol{\omega}[\mathbf{v}].$$

2. Cauchy theory. First, we give the definition of weak solution to (FSIS).

DEFINITION 2.1. *Given $\mathbf{G}^0 \in \mathbb{R}^3_{++}$ and $\mathbf{u}^0 \in \mathbb{H}(\mathbf{G}^0)$, a pair $(\mathbf{u}, \mathbf{G})$ is called a weak solution to (FSIS) on $(0,T)$ with initial data $(\mathbf{u}^0, \mathbf{G}^0)$ if*

$$\mathbf{G} \in W^{1,\infty}(0,T;\mathbb{R}^3_{++}), \quad \text{with} \quad \mathbf{G}(0) = \mathbf{G}^0, \tag{2.1}$$

$$\mathbf{u} \in L^\infty(0,T;\mathcal{H}) \cap L^2(0,T;\mathcal{V}), \tag{2.2}$$

$$\mathbf{u} = \mathbf{V} + \boldsymbol{\omega} \times (\mathbf{x} - \mathbf{G}) \quad \text{in } \mathcal{B}_{\mathbf{G}}, \quad \text{with} \quad \mathbf{V} = \dot{\mathbf{G}}; \tag{2.3}$$

if for all $\mathbf{v} \in \mathcal{C}([0,T];H^1_0(\mathbb{R}^3_+)) \cap H^1(0,T;L^2(\mathbb{R}^3_+))$ with compact support in $(0,T)\times\mathbb{R}^3_+$ and such that $\mathbf{v} \in \mathbb{V}(\mathbf{G}(t))$ for all $t \in [0,T]$,

$$-\int_0^T \int_{\mathbb{R}^3_+} \rho_{\mathbf{G}} \mathbf{u} \cdot \partial_t \mathbf{v} \, \mathrm{d}\mathbf{y} \, \mathrm{d}t + 2\mu \int_0^T \int_{\mathbb{R}^3_+} D(\mathbf{u}) : D(\mathbf{v}) \, \mathrm{d}\mathbf{y} \, \mathrm{d}t - \int_0^T \int_{\mathbb{R}^3_+} \mathbf{u} \otimes \mathbf{u} : D(\mathbf{v}) \, \mathrm{d}\mathbf{y} \, \mathrm{d}t = 0; \tag{2.4}$$

if for all $\mathbf{v} \in \mathcal{C}([0,T];L^2(\mathbb{R}^3_+))$ with compact support in $[0,T) \times \mathbb{R}^3_+$ and such that $\mathbf{v} \in \mathbb{H}(\mathbf{G}(t))$ for all $t \in [0,T]$ we have

$$W : t \mapsto \int_{\mathbb{R}^3_+} \rho_{\mathbf{G}} \mathbf{u} \cdot \mathbf{v} \, \mathrm{d}\mathbf{x} \in \mathcal{C}([0,T]) \quad \text{with} \quad W(0) = \int_{\mathbb{R}^3_+} \rho_{\mathbf{G}^0} \mathbf{u}^0 \cdot \mathbf{v} \, \mathrm{d}\mathbf{x}; \tag{2.5}$$

if the energy estimate holds true:

$$\frac{1}{2} \int_{\mathbb{R}^3_+} \rho_{\mathbf{G}} |\mathbf{u}|^2 \, \mathrm{d}\mathbf{x} + 2\mu \int_0^t \int_{\mathbb{R}^3_+} |D(\mathbf{u})|^2 \, \mathrm{d}\mathbf{x} \, \mathrm{d}s \leqslant \frac{1}{2} \int_{\mathbb{R}^3_+} \rho_{\mathbf{G}^0} |\mathbf{u}^0|^2 \, \mathrm{d}\mathbf{x} \quad \text{for a.a. } t \in (0,T).$$

Before going to our existence result for such weak solutions, let us recall some of their straightforward properties. First, combining (2.2) and (2.3) yields that $\mathbf{u}(t,\cdot) \in$

$\mathbb{V}(\mathbf{G}(t))$ for almost all $t \in (0,T)$. Moreover, it follows from standard arguments that the pair $(\mathbf{V},\boldsymbol{\omega})$ such that (2.3) holds satisfies

$$|\mathbf{V}|^2 + |\boldsymbol{\omega}|^2 \leqslant C \int_{\mathbb{R}^3_+} \rho_{\mathbf{G}} |\mathbf{u}|^2 \, \mathrm{d}\mathbf{x}, \tag{2.6}$$

where C depends only on ρ_B. In particular, the pair $(\mathbf{V},\boldsymbol{\omega})$ associated to a weak solution $(\mathbf{u},\mathbf{G})$ belongs to $L^\infty(0,T)$.

The result of well-posedness we obtain for (FSIS) can be stated as follows.

THEOREM 2.2. *Assuming $\mathbf{G}^0 \in \mathbb{R}^3_{++}$ and $\mathbf{u}^0 \in \mathbb{H}(\mathbf{G}^0)$, there exists at least one maximal weak solution $(T_0,(\mathbf{U},\mathbf{G}))$ to (FSIS) with initial data $(\mathbf{U}^0,\mathbf{G}^0)$. Moreover, we have the alternative:*

- $T_0 = \infty$,
- $T_0 < \infty$ *and* $G_3(t) \to 1$ *as* $t \to T_0$.

The proof of Theorem 2.2 given in what follows is inspired by methods developed in other papers, and since we use many similar arguments, we choose to present here only the main ideas and refer to the appropriate references to avoid repeating technical calculations which are not the main interest of this paper. From now on $(\mathbf{G}^0,\mathbf{u}^0) \in \mathbb{R}^3_{++} \times \mathbb{H}(\mathbf{G}^0)$ is a fixed initial condition. We denote $(\mathbf{V}^0,\boldsymbol{\omega}^0) = (\mathbf{V}[\mathbf{u}^0],\boldsymbol{\omega}[\mathbf{u}^0])$ and $d^0 := \operatorname{dist}(\mathcal{B}_{\mathbf{G}^0},\mathcal{P})$. Due to our assumption, there holds $d^0 > 0$. The remainder of the section is devoted to the proof of Theorem 2.2.

2.1. Strong solutions for an approximate system. As in [7], we prove the existence of weak solutions by first obtaining strong solutions for an approximate problem of (FSIS). More precisely, we consider an even nonnegative function $\kappa \in C_0^\infty(\mathbb{R})$ such that $\kappa(s) = 0$ if $|s| \geqslant 1$. We define for all $\varepsilon > 0$

$$K_\varepsilon(\mathbf{x}) = \frac{c}{\varepsilon^3}\kappa\left(\left|\frac{\mathbf{x}}{\varepsilon}\right|^2\right) \quad (\mathbf{x} \in \mathbb{R}^3). \tag{2.7}$$

The constant c is chosen so that

$$\int_{\mathbb{R}^3} K_\varepsilon(\mathbf{x}) \, \mathrm{d}\mathbf{x} = 1 \quad \forall\, \varepsilon > 0.$$

Then, for all $\mathbf{u} \in L^2((0,T)\times\mathbb{R}^3_+)$ and for all $\varepsilon > 0$, we set

$$\mathbf{u}_\varepsilon(t,\mathbf{x}) = \int_{\mathbb{R}^3_+} K_\varepsilon(\mathbf{x}-\mathbf{y})\mathbf{u}(t,\mathbf{y}) \, \mathrm{d}\mathbf{y}.$$

Let us consider the following problem, which approximates (FSIS):

$$\partial_t \mathbf{u} - \mu\Delta\mathbf{u} + (\mathbf{u}_\varepsilon \cdot \nabla)\mathbf{u} + \nabla p = 0 \quad \text{in } \mathcal{F}_{\mathbf{G}(t)},\ t \in (0,T), \tag{2.8}$$

$$\operatorname{div}\mathbf{u} = 0 \quad \text{in } \mathcal{F}_{\mathbf{G}(t)},\ t \in (0,T), \tag{2.9}$$

$$\mathbf{u} = 0 \quad \text{on } \mathcal{P},\ t \in (0,T), \tag{2.10}$$

$$\mathbf{u}_{|_\infty} = 0, \quad t \in (0,T), \tag{2.11}$$

$$\mathbf{u} = \dot{\mathbf{G}} + \boldsymbol{\omega} \times (\mathbf{x} - \mathbf{G}) \quad \text{on } \partial\mathcal{B}_{\mathbf{G}},\ t \in (0,T), \tag{2.12}$$

$$m\ddot{\mathbf{G}} = -\int_{\partial\mathcal{B}_{\mathbf{G}}} \mathbb{T}(\mathbf{u},p)\mathbf{n}\,\mathrm{d}\sigma + \frac{1}{2}\int_{\partial\mathcal{B}_{\mathbf{G}}} ((\mathbf{u}_\varepsilon - \mathbf{u})\cdot\mathbf{n})\mathbf{u}\,\mathrm{d}\sigma \quad \text{in } (0,T), \tag{2.13}$$

$$\begin{aligned} J\dot{\boldsymbol{\omega}} = &-\int_{\partial\mathcal{B}_{\mathbf{G}}} (\mathbf{x}-\mathbf{G})\times\mathbb{T}(\mathbf{u},p)\mathbf{n}\,\mathrm{d}\sigma \\ &+\frac{1}{2}\int_{\partial\mathcal{B}_{\mathbf{G}}} ((\mathbf{u}_\varepsilon-\mathbf{u})\cdot\mathbf{n})(\mathbf{x}-\mathbf{G})\times\mathbf{u}\,\mathrm{d}\sigma \quad \text{in } (0,T). \end{aligned} \tag{2.14}$$

We complete the system with the initial conditions

$$\mathbf{u}(0,\cdot) = \mathbf{u}^0, \quad \dot{\mathbf{G}}(0) = \mathbf{V}^0, \quad \boldsymbol{\omega}(0) = \boldsymbol{\omega}^0, \quad \mathbf{G}(0) = \mathbf{G}^0. \tag{2.15}$$

We define the space $\widehat{H^1}(A)$ by

$$\widehat{H^1}(A) = \{q \in L^2_{loc}(\overline{A})\ ;\ \nabla q \in L^2(A)\}.$$

We denote

$$\mathcal{F}_T = \{(t,\mathbf{x}) \in [0,T]\times\mathbb{R}^3\ ;\ \mathbf{x} \in \mathcal{F}_{\mathbf{G}(t)}\}.$$

Consider a smooth mapping $\mathbf{X} : \mathbb{R}^3_{++}\times\mathcal{F}_{\mathbf{G}^0} \to \mathbb{R}^3$ such that for all $\mathbf{G}\in\mathbb{R}^3_{++}$, $\mathbf{X}(\mathbf{G},\cdot)$ is a C^∞-diffeomorphism from $\mathcal{F}_{\mathbf{G}^0}$ onto $\mathcal{F}_{\mathbf{G}}$. Moreover, suppose that the mappings

$$(\mathbf{G},\mathbf{y}) \mapsto D_{\mathbf{G}} D_y^\alpha \mathbf{X}(\mathbf{G},\mathbf{y}), \quad \alpha\in\mathbb{N}^3,$$

exist and are continuous and compactly supported in $\mathcal{F}_{\mathbf{G}^0}$. For any $\mathbf{g} : \mathcal{F}_T \to \mathbb{R}^3$, we denote by $\mathbf{g}_\mathbf{X} : [0,T]\times\mathcal{F}_{\mathbf{G}^0} \to \mathbb{R}^3$ the mapping $\mathbf{g}_\mathbf{X}(t,\mathbf{y}) = \mathbf{g}(t,\mathbf{X}(\mathbf{G}(t),\mathbf{y}))$ for all $t \geqslant 0$ for all $\mathbf{y}\in\mathcal{F}_{\mathbf{G}^0}$. We use similar notation for $g : \mathcal{F}_T \to \mathbb{R}$.

We introduce the following function spaces in a variable domain:

$$\begin{aligned} L^2(0,T;H^2(\mathcal{F}(t))) &= \{\mathbf{u}\ ;\ \mathbf{u}_\mathbf{X} \in L^2(0,T;H^2(\mathcal{F}_{\mathbf{G}^0}))\},\\ H^1(0,T;L^2(\mathcal{F}(t))) &= \{\mathbf{u}\ ;\ \mathbf{u}_\mathbf{X} \in H^1(0,T;L^2(\mathcal{F}_{\mathbf{G}^0}))\},\\ C([0,T],H^1(\mathcal{F}(t))) &= \{\mathbf{u}\ ;\ \mathbf{u}_\mathbf{X} \in C([0,T],H^1(\mathcal{F}_{\mathbf{G}^0}))\},\\ L^2(0,T;\widehat{H}^1(\mathcal{F}(t))) &= \{p\ ;\ p_\mathbf{X} \in L^2(0,T;\widehat{H}^1(\mathcal{F}_{\mathbf{G}^0}))\}. \end{aligned}$$

THEOREM 2.3. *Assume the initial conditions satisfy*

$$\operatorname{dist}(\mathcal{B}_{\mathbf{G}^0},\mathcal{P}) = d^0 > 0, \quad \mathbf{u}^0 \in \mathbb{V}(\mathbf{G}^0).$$

Then, given $\varepsilon > 0$, there exist a time $T > 0$ depending only on $\|\mathbf{u}^0\|_{L^2(\mathbb{R}^3_+)}$ and a 4-uplet $(\mathbf{u},\mathbf{G},\omega,p)$ satisfying

$$\mathbf{G} \in H^2(0,T), \quad \operatorname{dist}(\mathcal{B}_{\mathbf{G}(t)},\mathcal{P}) \geqslant \frac{d^0}{2} > 0 \quad \forall\, t\in[0,T], \tag{2.16}$$

$$\mathbf{u} \in L^2(0,T;H^2(\mathcal{F}(t))) \cap C([0,T];H^1(\mathcal{F}(t))) \cap H^1(0,T;L^2(\mathcal{F}(t))), \tag{2.17}$$

$$p \in L^2(0,T;\widehat{H^1}(\mathcal{F}(t))), \quad \boldsymbol{\omega} \in H^1(0,T), \tag{2.18}$$

and satisfying (2.8)–(2.14) *almost everywhere on* $[0,T]$ *or in the trace sense.*

Proof. One can obtain local existence of strong solutions to (2.8)–(2.14) via arguments similar to those in the proof of Theorem 1.1 in [2] (see also [3, 13, 10] for

results obtained applying similar techniques). For the sake of brevity, we compute only energy estimates here in order to prove that these local strong solutions can be continued up to collision between $\mathcal{B}$ and $\mathcal{P}$. We refer the reader to the mentioned articles for technical details.

First, we multiply (2.8) by $\mathbf{u}$, (2.13) by $\dot{\mathbf{G}}$, and (2.14) by $\boldsymbol{\omega}$. We deduce the energy estimate

$$\frac{1}{2}\int_{\mathbb{R}^3_+}\rho_{\mathbf{G}(t)}|\mathbf{u}|^2(t)\,\mathrm{d}\mathbf{x}+2\mu\int_0^t\int_{\mathbb{R}^3_+}|D(\mathbf{u})|^2\,\mathrm{d}\mathbf{x}\,\mathrm{d}s=\frac{1}{2}\int_{\mathbb{R}^3_+}\rho_{\mathbf{G}^0}|\mathbf{u}^0|^2\,\mathrm{d}\mathbf{x}. \tag{2.19}$$

From the above estimate and (2.6) we obtain a time $T>0$ depending on $\int_{\mathbb{R}^3_+}\rho_{\mathbf{G}^0}|\mathbf{u}^0|^2\,\mathrm{d}\mathbf{x}$ such that (2.16) holds for all ε.

Then we introduce a smooth function Υ with compact support in $\mathcal{B}(\mathbf{G}^0,1+d_0/4)$ and such that $\Upsilon=1$ on $\mathcal{B}_{\mathbf{G}^0}$. We also set

$$\mathbf{w}_R=\frac{1}{2}\left(\dot{\mathbf{G}}\times(\mathbf{x}-\mathbf{G})+|\mathbf{x}-\mathbf{G}|^2\boldsymbol{\omega}\right),$$
$$\mathbf{u}_R(t,\mathbf{x})=\operatorname{curl}\left[\Upsilon\left(\mathbf{x}-\mathbf{G}(t)+\mathbf{G}^0\right)\mathbf{w}_R(t,\mathbf{x})\right].$$

The function $\mathbf{u}_R$ has a compact support in $\mathcal{B}(\mathbf{G}^0,1+d_0/4)$ and satisfies

$$\operatorname{div}\mathbf{u}_R=0,\quad \mathbf{u}_R=\dot{\mathbf{G}}+\boldsymbol{\omega}\times(\mathbf{x}-\mathbf{G})\text{ on }\mathcal{B}(t).$$

We multiply (2.8) by

$$\boldsymbol{\varphi}=\partial_t\mathbf{u}+(\mathbf{u}_R\cdot\nabla)\mathbf{u}-(\mathbf{u}\cdot\nabla)\mathbf{u}_R,$$

which yields

$$\int_{\mathcal{F}(t)}(\partial_t\mathbf{u}+\mathbf{u}_\varepsilon\cdot\nabla\mathbf{u})\cdot\boldsymbol{\varphi}\,\mathrm{d}\mathbf{x}=\int_{\mathcal{F}(t)}\operatorname{div}\mathbb{T}(\mathbf{u},p)\cdot\boldsymbol{\varphi}\,\mathrm{d}\mathbf{x}. \tag{2.20}$$

Using the regularization of the nonlinear term, we obtain the existence of a constant C_0 depending only on $\|\mathbf{u}_0\|_{L^2(\mathbb{R}^3_+)}$ such that the left-hand side of (2.20) can be written as

$$LHS=\int_{\mathcal{F}(t)}|\partial_t\mathbf{u}|^2\,\mathrm{d}\mathbf{x}+R_l\quad\text{with}\quad|R_l|\leqslant C_0\int_{\mathcal{F}(t)}|\nabla\mathbf{u}|^2\,\mathrm{d}\mathbf{x}+\frac{1}{2}\int_{\mathcal{F}(t)}|\partial_t\mathbf{u}|^2\,\mathrm{d}\mathbf{x}.$$

Concerning the right-hand side of (2.20), we apply the same arguments as in the proof of Lemma 4.3 in [3] and obtain (see [3, (4.24)])

$$RHS=-\mu\frac{\mathrm{d}}{\mathrm{dt}}\int_{\mathcal{F}(t)}|D(\mathbf{u})|^2\,\mathrm{d}\mathbf{x}+I_r+R_r,$$

where

$$I_r=\int_{\partial\mathcal{B}(t)}\mathbb{T}(\mathbf{u},p)\mathbf{n}\cdot\left[\ddot{\mathbf{G}}+\dot{\boldsymbol{\omega}}\times(\mathbf{x}-\mathbf{G})-\boldsymbol{\omega}\times\dot{\mathbf{G}}\right]\,\mathrm{d}\sigma,$$

and, with the same convention as previously for C_0, we obtain

$$|R_r|\leqslant C_0\left[1+\int_{\mathcal{F}(t)}|\nabla\mathbf{u}|^2\,\mathrm{d}\mathbf{x}\right].$$

Finally, using (2.13)–(2.14), we deduce

$$I_r = -\left[m|\ddot{\mathbf{G}}|^2 + J|\dot{\boldsymbol{\omega}}|^2 - m\ddot{\mathbf{G}}\cdot(\boldsymbol{\omega}\times\dot{\mathbf{G}})\right] + \tilde{R}_r,$$

with

$$\tilde{R}_r = \frac{1}{2}\int_{\partial\mathcal{B}(t)} (\mathbf{u}-\mathbf{u}_\varepsilon)\cdot\mathbf{n}\left(\dot{\mathbf{G}}+\boldsymbol{\omega}\times(\mathbf{x}-\mathbf{G})\right)\cdot\left(\ddot{\mathbf{G}}-\boldsymbol{\omega}\times\dot{\mathbf{G}}+\dot{\boldsymbol{\omega}}\times(\mathbf{x}-\mathbf{G})\right)\,\mathrm{d}\sigma.$$

In this last integral, extending the rigid velocity fields to $\mathcal{B}(\mathbf{G}, 1+d_0/4)$ in a similar fashion to that in $\mathbf{u}_R$, we obtain, after integration by parts,

$$|\tilde{R}_r| \leqslant C_0 + \frac{m}{2}|\ddot{\mathbf{G}}|^2 + \frac{J}{2}|\dot{\boldsymbol{\omega}}|^2.$$

Combining all these estimates, we finally deduce

$$\begin{aligned}\mu\frac{\mathrm{d}}{\mathrm{dt}}\left[\int_{\mathcal{F}(t)}|\nabla\mathbf{u}|^2\,\mathrm{d}\mathbf{x}\right] + \frac{1}{2}\left[m|\ddot{\mathbf{G}}|^2 + J|\dot{\boldsymbol{\omega}}|^2 + \int_{\mathcal{F}(t)}|\partial_t\mathbf{u}|^2\,\mathrm{d}\mathbf{x}\right]\\ \leqslant C_0\left[1+\int_{\mathbb{R}^3_+}|\nabla\mathbf{u}|^2\,\mathrm{d}\mathbf{x}\right].\end{aligned}$$

As a consequence, we have obtained that the mapping $t\mapsto\|\mathbf{u}\|_{H^1(\mathcal{F}(t))}$ is bounded on $[0,T]$. □

2.2. Convergences. As in the assumptions of our theorem, we assume that the initial condition $\mathbf{u}^0$ belongs to $\mathbb{H}(\mathbf{G}^0)$; we introduce a sequence $\mathbf{u}^{0k}\in\mathbb{V}(\mathbf{G}^0)$ such that

$$\mathbf{u}^{0k}\to\mathbf{u}^0 \quad \text{in } \mathbb{H}(\mathbf{G}^0).$$

We also take a sequence $\varepsilon^k\to 0$. Then, applying Theorem 2.3, we can consider a (uniform) time T such that, for all k, the corresponding solutions $(\mathbf{u}^k,\mathbf{G}^k,\omega^k,p^k)$ exist on $[0,T]$ and satisfy

$$\operatorname{dist}(\mathcal{B}_{\mathbf{G}^k(t)},\mathcal{P}) > \frac{d^0}{2} \quad \forall\, t\in[0,T],\ \forall\, k.$$

In the following, we extend $\mathbf{u}^k$ with the value of the rigid velocity field $\mathbf{V}^k+\boldsymbol{\omega}^k\times(\mathbf{x}-\mathbf{G}^k)$ on the solid domain. From (2.19), the following holds:

$$\mathbf{u}^k \text{ is bounded in } L^\infty(0,T;L^2(\mathbb{R}^3_+))\cap L^2(0,T;H^1_0(\mathbb{R}^3_+)),$$

so that, up to a subsequence (which we do not relabel), we can assume

$$\mathbf{u}^k \rightharpoonup \mathbf{u} \quad \text{in } L^2(0,T;H^1(\mathbb{R}^3_+))\text{-weak and } L^\infty(0,T;L^2(\mathbb{R}^3_+))\text{-weak}^*, \tag{2.21}$$

$$\mathbf{G}^k\to\mathbf{G} \quad \text{in } C([0,T];\mathbb{R}^3_{++}). \tag{2.22}$$

Taking any $\mathbf{U}\in\mathcal{D}((0,T)\times\mathbb{R}^3_+)$ such that $D(\mathbf{U})=0$ in a neighborhood of $\mathcal{B}_{\mathbf{G}(t)}$ for all $t\in(0,T)$, we can multiply (2.8) by $\mathbf{U}$ for k sufficiently large. Integrating by

parts and using Reynolds' transport theorem yields

$$
\begin{aligned}
(2.23)\quad & -\int_0^T \int_{\mathbb{R}^3_+} \rho_{\mathbf{G}^k} \mathbf{u}^k \cdot \partial_t \mathbf{U} \, \mathrm{d}\mathbf{x} \, \mathrm{d}s \\
& \quad + \int_0^T \int_{\mathbb{R}^3_+} (\mathbf{u}^k \otimes \mathbf{u}^k) : D(\mathbf{U}) \, \mathrm{d}\mathbf{x} \, \mathrm{d}s + 2\mu \int_0^T \int_{\mathbb{R}^3_+} D(\mathbf{u}^k) : D(\mathbf{U}) \, \mathrm{d}\mathbf{x} \, \mathrm{d}s \\
& = \int_0^T \int_{\mathcal{F}_{\mathbf{G}^k(t)}} \left[((\mathbf{u}^k_{\varepsilon^k} - \mathbf{u}^k) \cdot \nabla) \mathbf{U} \right] \cdot \mathbf{u}^k \, \mathrm{d}\mathbf{x} - \frac{1}{2} \int_0^T \int_{\partial \mathcal{B}_{\mathbf{G}^k(t)}} (\mathbf{U} \cdot \mathbf{u}^k)((\mathbf{u}^k_{\varepsilon^k} - \mathbf{u}^k) \cdot \mathbf{n}) \, \mathrm{d}\sigma.
\end{aligned}
$$

In order to pass to the limit in this weak formulation, we need to prove L^2-compactness of the $\mathbf{u}^k$. As usual, this is the main difficulty of the proof. The procedure to prove this compactness property follows closely the method developed in [7]. The main difference here is that our cavity is unbounded. Therefore, we do not look for a compactness property of the sequence $\mathbf{u}^k$ on the whole domain but only locally in space. Indeed, with the help of Friedrichs' lemma (see [6, Lemma II.4.2]) we have the following: for all relatively compact $\mathcal{O} \subset \mathbb{R}^3_+$, for any $\gamma > 0$ there exist $I = I(\gamma, \mathcal{O}) \in \mathbb{N}$ and functions $\boldsymbol{\psi}_j \in L^\infty(\mathcal{O})$, $j = 1, \ldots, I$, such that

$$
\begin{aligned}
(2.24)\quad & \left\| \mathbf{u}^k - \mathbf{u} \right\|^2_{L^2(0,T;L^2(\mathcal{O}))} \\
& \leqslant \sum_{j=1}^{I} \int_0^T \left(\int_{\mathcal{O}} \rho_{\mathbf{G}} \left(\mathbf{u}^k(t) - \mathbf{u}(t) \right) \cdot \boldsymbol{\psi}_j \, \mathrm{d}\mathbf{y} \right)^2 \mathrm{d}t + \gamma \left\| \nabla \mathbf{u}^k - \nabla \mathbf{u} \right\|^2_{L^2(0,T;L^2(\mathcal{O}))}.
\end{aligned}
$$

Due to the uniform bound on $\mathbf{u}^k$ in $L^2(0,T;H^1_0(\mathbb{R}^3_+))$, our remaining task is to prove that, for any $\boldsymbol{\psi} \in L^\infty(\mathcal{O})$, there exists a subsequence (which we do not relabel) for which there holds

$$
(2.25)\qquad \lim_{k \to \infty} \int_0^T \left(\int_{\mathcal{O}} \rho_{\mathbf{G}} \left(\mathbf{u}^k(t) - \mathbf{u}(t) \right) \cdot \boldsymbol{\psi} \, \mathrm{d}\mathbf{y} \right)^2 \mathrm{d}t = 0.
$$

As a first step, we obtain results similar to those of (2.25) for another family of test functions (not included in $L^\infty(\mathcal{O})$. To this end, we divide the segment $[0,T]$ into N segments $[t_{i-1}, t_i]$, with $\Delta t = t_i - t_{i-1} = T/N$, $i = 1, \ldots, N$. For all i and for $\delta < \frac{d^0}{2}$, we consider an orthonormal basis $(\mathbf{e}^{i,\delta}_j)$ of $\mathbb{V}(\mathcal{B}(\mathbf{G}(t_i), 1+\delta))$. Without further restrictions, we assume all the $\mathbf{e}^{i,\delta}_j$ with compact support. We also consider the set of piecewise linear functions in t:

$$
(2.26)\qquad \mathbf{U}^\delta(t, \mathbf{x}) = \mathbf{e}^{i-1,\delta}_j(\mathbf{x}) + \frac{t - t_i}{\Delta t} \left(\mathbf{e}^{i,\delta}_l(\mathbf{x}) - \mathbf{e}^{i-1,\delta}_j(\mathbf{x}) \right)
$$

for $t \in [t_{i-1}, t_i]$, $j, l \in \mathbb{N}$, $i \in \{1, \ldots, N\}$. There exists a countable set of functions satisfying (2.26).

It is worth noting that, since $\mathbf{G}$ is uniformly continuous, for N big enough, the functions $\mathbf{U}^\delta$ of the above form satisfy $D(\mathbf{U}^\delta(t)) = 0$ in $\mathcal{B}(\mathbf{G}(t), 1 + \delta/2)$ for all t. In particular, these functions are in $C([0,T]; \mathbb{V}(\mathbf{G}(t)))$. These functions are important to approximate continuous functions in time with value in $\mathbb{H}(\mathbf{G}(t))$ and thus functions in $L^2(0,T;\mathbb{H}(\mathbf{G}(t)))$ (see Lemmas 4.1 and 4.2 in [7]). From (2.22), there exists $k_0 = k_0(\delta)$ such that for $k \geqslant k_0$,

$$
D(\mathbf{U}^\delta) = 0 \quad \text{in } \mathcal{B}_{\mathbf{G}^k(t)} \quad \forall\, t \in [0,T]
$$

for all functions satisfying (2.26).

We multiply (2.8) by $\mathbf{U}^\delta$ satisfying (2.26). After similar computations to those leading to (2.23), we obtain

$$\frac{d}{dt}\int_{\mathbb{R}^3_+}\rho_{\mathbf{G}^k}\mathbf{u}^k\cdot\mathbf{U}^\delta\,\mathrm{d}\mathbf{x} = -2\mu\int_{\mathcal{F}^k(t)}D(\mathbf{u}^k):D(\mathbf{U}^\delta)\,\mathrm{d}\mathbf{x} + \int_{\mathcal{F}^k(t)}\left(\partial_t\mathbf{U}^\delta+(\mathbf{u}^k_\varepsilon\cdot\nabla)\mathbf{U}^\delta\right)\cdot\mathbf{u}^k\,\mathrm{d}\mathbf{x} - \frac{1}{2}\int_{\partial\mathcal{B}_{\mathbf{G}^k(t)}}(\mathbf{U}^\delta\cdot\mathbf{u}^k)((\mathbf{u}^k_\varepsilon-\mathbf{u}^k)\cdot\mathbf{n})\,\mathrm{d}\sigma. \tag{2.27}$$

Following the estimates of [7], using Arzelà and Ascoli and the diagonal Cantor procedure, we obtain that for all $\mathbf{U}^\delta$ satisfying (2.26), we have

$$\int_{\mathbb{R}^3_+}\rho_{\mathbf{G}^k}\mathbf{u}^k\cdot\mathbf{U}^\delta\,\mathrm{d}\mathbf{x}\to\int_{\mathbb{R}^3_+}\rho_{\mathbf{G}}\mathbf{u}\cdot\mathbf{U}^\delta\,\mathrm{d}\mathbf{x}\quad\text{in } C([0,T]). \tag{2.28}$$

However, as $\mathbf{G}^k\to\mathbf{G}$ in $\mathcal{C}([0,T])$, and $\mathbf{u}^k$ is bounded in $L^\infty(0,T;L^2(\mathbb{R}^3_+))\cap L^2(0,T;H^1_0(\mathbb{R}^3_+))$, this also leads to

$$\int_{\mathbb{R}^3_+}\rho_{\mathbf{G}}\mathbf{u}^k\cdot\mathbf{U}^\delta\,\mathrm{d}\mathbf{x}\to\int_{\mathbb{R}^3_+}\rho_{\mathbf{G}}\mathbf{u}\cdot\mathbf{U}^\delta\,\mathrm{d}\mathbf{x}\quad\text{in } C([0,T]). \tag{2.29}$$

Via a density argument (see Lemmas 4.1 and 4.2 in [7] for details), we might extend this convergence result to all $\mathbf{U}\in C([0,T];L^2(\mathbb{R}^3_+))$, $\operatorname{div}\mathbf{U}=0$, $D(\mathbf{U})=0$ in $\mathcal{B}(\mathbf{G}(t),1)$,

$$\int_{\mathbb{R}^3_+}\rho_{\mathbf{G}}\mathbf{u}^k\cdot\mathbf{U}\,\mathrm{d}\mathbf{x}\to\int_{\mathbb{R}^3_+}\rho_{\mathbf{G}}\mathbf{u}\cdot\mathbf{U}\,\mathrm{d}\mathbf{x}\quad\text{in } C([0,T]), \tag{2.30}$$

and to all $\mathbf{U}\in L^2(0,T;L^2(\mathbb{R}^3_+))$, $\operatorname{div}\mathbf{U}=0$, $D(\mathbf{U})=0$ in $\mathcal{B}(\mathbf{G}(t),1)$,

$$\int_{\mathbb{R}^3_+}\rho_{\mathbf{G}}\mathbf{u}^k\cdot\mathbf{U}\,\mathrm{d}\mathbf{x}\to\int_{\mathbb{R}^3_+}\rho_{\mathbf{G}}\mathbf{u}\cdot\mathbf{U}\,\mathrm{d}\mathbf{x}\quad\text{in } L^2(0,T). \tag{2.31}$$

Relation (2.30) implies in particular that $\mathbf{u}$ satisfies the initial conditions.

However, in (2.25), no assumption is made on the velocity field ψ over $\mathcal{B}_{\mathbf{G}}$. In order to reduce (2.25) to the above convergence result, we need to project such $\psi\in L^\infty(\mathcal{O})$ on velocity fields which are rigid over $\mathcal{B}_{\mathbf{G}}$. Similarly, $\mathbf{u}^k$ is rigid on $\mathcal{B}_{\mathbf{G}^k}$, so we also modify $\mathbf{u}^k$ slightly to obtain a function with the same properties but which is rigid in $\mathcal{B}_{\mathbf{G}}$. To this end, we extend $\mathbf{u}^k$ by 0 in $\mathbb{R}^3\setminus\mathbb{R}^3_+$, and since $\mathbf{u}^k=0$ on $\mathcal{P}$, we have $\mathbf{u}^k\in L^2(0,T;H^1(\mathbb{R}^3))$. We set

$$\widehat{\mathbf{u}}^k(t,\mathbf{y})=\mathbf{u}^k(t,\mathbf{y}+\mathbf{G}^k(t)-\mathbf{G}(t)).$$

We have

$$\operatorname{div}\widehat{\mathbf{u}}^k=0,\quad \widehat{\mathbf{u}}^k=0\quad\text{on }\{\mathbf{y}\in\mathbb{R}^3\ ;\ y_3=G_3-G_3^k\},\quad D(\mathbf{u}^k)=0\quad\text{in }\mathcal{B}_{\mathbf{G}}$$

and

$$\|\widehat{\mathbf{u}}^k-\mathbf{u}^k\|_{L^2((0,T)\times\mathbb{R}^3)}\leqslant\|\mathbf{G}^k-\mathbf{G}\|_{L^\infty(0,T)}\|\nabla\mathbf{u}^k\|_{L^2((0,T)\times\mathbb{R}^3)}\to 0. \tag{2.32}$$

We define

$$\mathcal{L}^2(\mathbb{R}^3)=\left\{\mathbf{v}\in L^2(\mathbb{R}^3)\ ;\ \operatorname{div}\mathbf{v}=0\quad\text{in }\mathbb{R}^3\right\}.$$

Following [7] (see (4.37) in [7]), there exists a function $\Lambda : \mathcal{L}^2(\mathbb{R}^3) \to \mathcal{L}^2(\mathbb{R}^3)$ such that for all $\mathbf{v} \in \mathcal{L}^2(\mathbb{R}^3)$, $\mathbf{u} = \Lambda(\mathbf{v})$ satisfies

$$\mathbf{u} = \mathbf{v} \quad \text{in } \mathcal{B}_{\mathbf{G}^0}, \quad \mathbf{u} = 0 \quad \text{in } \mathbb{R}^3 \setminus \overline{\mathcal{B}\left(\mathbf{G}^0, 1 + \frac{d^0}{4}\right)},$$

$$\|\mathbf{u}\|_{L^2(\mathbb{R}^3)} \leqslant c\|\mathbf{v}\|_{L^2(\mathbb{R}^3)}.$$

Moreover,

$$\text{if} \quad \mathbf{v} \in C([0,T]; L^2(\mathbb{R}^3)), \quad \text{then} \quad \Lambda\mathbf{v} \in C([0,T]; L^2(\mathbb{R}^3)),$$

and

$$\text{if} \quad \mathbf{v} \in L^2(0,T; L^2(\mathbb{R}^3)), \quad \text{then} \quad \Lambda\mathbf{v} \in L^2(0,T; L^2(\mathbb{R}^3)).$$

We also define $\check{\Lambda}^t : \mathcal{L}^2(\mathbb{R}^3) \to \mathcal{L}^2(\mathbb{R}^3)$ as follows:

$$\check{\Lambda}^t \check{\mathbf{v}}(\mathbf{y}) = [\Lambda\check{\mathbf{v}}]\,(\mathbf{y} + \mathbf{G}^0 - \mathbf{G}(t)),$$

where

$$\check{\mathbf{v}}(\mathbf{x}) = \mathbf{v}(\mathbf{x} + \mathbf{G}(t) - \mathbf{G}^0).$$

Then, as in [7], we consider

$$\overline{\mathbf{u}}^k(\mathbf{x}, t) = \mathbf{u}^k + \check{\Lambda}^t(\widehat{\mathbf{u}}^k - \mathbf{u}^k).$$

This function is rigid in $\mathcal{B}_{\mathbf{G}(t)}$ and

$$\|\overline{\mathbf{u}}^k - \mathbf{u}^k\|_{L^2((0,T)\times\mathbb{R}^3)} \to 0. \tag{2.33}$$

We are now in a position to prove (2.25) by using (2.31). Assume that $\boldsymbol{\psi} \in L^\infty(\mathcal{O})$. We set

$$I_k := \int_0^T \left(\int_{\mathcal{O}} \rho_{\mathbf{G}} \left(\mathbf{u}^k(t) - \mathbf{u}(t)\right) \cdot \boldsymbol{\psi} \, \mathrm{d}\mathbf{y} \right)^2 \mathrm{d}t$$

and

$$\overline{I}_k = \int_0^T \left(\int_{\mathcal{O}} \rho_{\mathbf{G}} \left(\overline{\mathbf{u}}^k(t) - \mathbf{u}(t)\right) \cdot \boldsymbol{\psi} \, \mathrm{d}\mathbf{y} \right)^2 \mathrm{d}t.$$

From (2.33), to prove that I_k goes to 0, it is sufficient to prove that $\overline{I}_k$ goes to 0. Then, given $\mathbf{G} \in \mathbb{R}^3_+$ such that $\operatorname{dist}(\mathcal{B}_{\mathbf{G}}, \mathcal{P}) > 0$, we denote by $P(\mathbf{G})$ the orthogonal projection from $L^2(\mathbb{R}^3_+, \rho_{\mathbf{G}}\mathrm{d}\mathbf{x})$ onto $\mathbb{H}(\mathbf{G})$ and introduce

$$\widetilde{\boldsymbol{\psi}}(t, \mathbf{x}) = P(\mathbf{G}(t))\boldsymbol{\psi}(\mathbf{x}).$$

We notice that $\widetilde{\boldsymbol{\psi}} \in L^\infty(0,T; L^2(\mathbb{R}^3_+))$, $\operatorname{div}\widetilde{\boldsymbol{\psi}} = 0$, $D(\widetilde{\boldsymbol{\psi}}) = 0$ in $\mathcal{B}(\mathbf{G}(t), 1)$ and

$$\overline{I}_k := \int_0^T \left(\int_{\mathcal{O}} \rho_{\mathbf{G}} \left(\overline{\mathbf{u}}^k(t) - \mathbf{u}(t)\right) \cdot \widetilde{\boldsymbol{\psi}} \, \mathrm{d}\mathbf{y} \right)^2 \mathrm{d}t.$$

We set

$$\widetilde{I}_k := \int_0^T \left(\int_{\mathcal{O}} \rho_{\mathbf{G}} \left(\mathbf{u}^k(t) - \mathbf{u}(t) \right) \cdot \widetilde{\boldsymbol{\psi}} \, \mathrm{d}\mathbf{y} \right)^2 \, \mathrm{d}t$$

and notice that, as before, if $\widetilde{I}_k$ goes to 0, then $\overline{I}_k$ goes to 0. However, since $\widetilde{\boldsymbol{\psi}} \in L^\infty(0,T;L^2(\mathbb{R}^3_+))$ we can take $\mathbf{U} = \widetilde{\boldsymbol{\psi}}$ in (2.31). Consequently, we obtain that there exists a subsequence we do not relabel such that $\overline{I}_k \to 0$. This ends the proof of L^2-compactness of the sequence $\mathbf{u}^k$. In particular we conclude from (2.24) that

$$\left\| \mathbf{u}^k - \mathbf{u} \right\|_{L^2(0,T;L^2(\mathcal{O}))} \to 0.$$

Combining (2.33) and the above relation, we obtain that

$$\left\| \overline{\mathbf{u}}^k - \mathbf{u} \right\|_{L^2(0,T;L^2(\mathcal{B}_{\mathbf{G}}))} \to 0.$$

This implies that

$$\dot{\mathbf{G}}^k \to \dot{\mathbf{G}} \quad \text{and} \quad \boldsymbol{\omega}^k \to \boldsymbol{\omega} \quad \text{in } L^2(0,T).$$

Using the above compactness, we can pass to the limit in (2.23) in the first three terms. For the two terms of the last line of (2.23), we proceed as follows. First, we can notice that

$$\int_{\mathcal{F}_{\mathbf{G}^k(t)}} \left| \mathbf{u}^k_{\varepsilon^k} - \mathbf{u}^k \right|^2 \, \mathrm{d}\mathbf{x} \leqslant C\varepsilon^k \|\mathbf{u}^k\|^2_{H^1(\mathcal{F}_{\mathbf{G}^k(t)})}$$

and thus

$$\int_0^T \int_{\mathcal{F}_{\mathbf{G}^k(t)}} \left[((\mathbf{u}^k_{\varepsilon^k} - \mathbf{u}^k) \cdot \nabla) \mathbf{U} \right] \cdot \mathbf{u}^k \, \mathrm{d}\mathbf{x} \to 0,$$

as $k \to \infty$.

Second, from the choice of κ and K_ε (see (2.7)), we can easily check that

$$\mathbf{u}^k_{\varepsilon^k} = \dot{\mathbf{G}}^k + \boldsymbol{\omega}^k \times (\mathbf{x} - \mathbf{G}^k) \quad \text{in } \mathcal{B}(\mathbf{G}^k(t), 1 - \varepsilon^k).$$

As a consequence, using Lemma 4.10 in [5], we conclude that

$$\int_{\partial\mathcal{B}_{\mathbf{G}^k(t)}} \left| \mathbf{u}^k_{\varepsilon^k} - \mathbf{u}^k \right|^2 \, \mathrm{d}\sigma \leqslant C\varepsilon^k \int_{\mathcal{B}_{\mathbf{G}^k(t)}} \left| \nabla \mathbf{u}^k_{\varepsilon^k} - \nabla \mathbf{u}^k \right|^2 \, \mathrm{d}\mathbf{x}.$$

The above inequality implies that

$$-\frac{1}{2} \int_0^T \int_{\partial\mathcal{B}_{\mathbf{G}^k(t)}} (\mathbf{U} \cdot \mathbf{u}^k)((\mathbf{u}^k_{\varepsilon^k} - \mathbf{u}^k) \cdot \mathbf{n}) \, \mathrm{d}\sigma \to 0,$$

as $k \to \infty$.

Finally, we can pass to the limit in (2.23) and obtain the weak formulation (2.4) for smooth test functions. We can pass from smooth test functions to the required regularity for $\mathbf{v}$ by applying the same approximation technique as when we obtained (2.29).

3. Constructing test functions. Let us begin with some notation. We introduce (r, θ, z), the cylindrical coordinates associated to (x_1, x_2, x_3):

$$x_1 = r\cos(\theta), \quad x_2 = r\sin(\theta), \quad x_3 = z.$$

Given $h > 0$ and $l > 0$, we denote by $\Omega_{h,l}$ the cylindric domain under $\mathcal{B}_h$ with radius l:

$$\Omega_{h,l} := \{(r, \theta, z) \in \mathcal{F}_h \text{ such that } r \in [0, l), z \in (0, 1 + h)\}. \tag{3.1}$$

We notice that whenever $l < 1$, the upper boundary of $\Omega_{h,\delta}$ is parametrized by (r, θ):

$$(r, \theta, z) \in \partial\Omega_{h,l} \cap \partial\mathcal{B}_h \Leftrightarrow \{r \in [0, \delta) \text{ and } z = \delta_h(r)\},$$

where, for arbitrary nonnegative h,

$$\delta_h(s) := 1 + h - \sqrt{1 - s^2} \quad \forall\, s \in [0, 1). \tag{3.2}$$

As in [9], we estimate the distance between $\mathcal{B}$ and $\mathcal{P}$ from below with a suitable choice of test function in the weak formulation. To this end, we introduce an approximation of the Stokes solution for a given position of $\mathcal{B}$ in $\mathbb{R}^3_+$ (namely, $\mathcal{B}_h$). We call these approximations "static functions" and denote them by $(\mathbf{w}_h)_{h>0}$. Given a weak solution $(\mathbf{u}, \mathbf{G})$ to (FSIS) in $(0, T)$, we construct admissible test functions by setting

$$\begin{array}{rccl} \widetilde{\mathbf{w}}: & (0,T)\times\mathbb{R}^3_+ & \longrightarrow & \mathbb{R}^3, \\ & (t, \mathbf{x}) & \longmapsto & \zeta(t)\mathbf{w}_{h(t)}(x_1 - G_1(t), x_2 - G_2(t), x_3) \end{array} \tag{3.3}$$

for arbitrary $\zeta \in \mathcal{D}(0, T)$. In this definition $h(t)$ stands for the distance between the sphere and the ramp at time t.

Applying the weak formulation, we obtain

$$\int_0^T \int_{\mathbb{R}^3_+} [\rho_{\mathbf{G}}\mathbf{u} \cdot \widetilde{\mathbf{w}}_t + (\mathbf{u} \otimes \mathbf{u} - 2\mu \mathrm{D}(\mathbf{u})) : \mathrm{D}(\widetilde{\mathbf{w}})] \ \mathrm{d}\mathbf{x}\ \mathrm{d}t = 0.$$

In this equation, the key ingredient is

$$\int_{\mathbb{R}^3_+} \mathrm{D}(\mathbf{u}) : \mathrm{D}(\mathbf{w}_h)\ \mathrm{d}\mathbf{x}.$$

It shall behave like $\dot{h}/h^\alpha$ with an exponent α to be made precise. The other terms appear as remainders. We shall bound them by an integrable (in time) function. This relies on the following lemma.

LEMMA 3.1. *Given $h > 0$, $r_0 > 0$, and $(\mathbf{u}, \mathbf{w}) \in H^1_0(\mathbb{R}^3_+) \times (\mathbb{H}(\mathbf{G}_h) \cap \mathcal{C}^\infty(\mathcal{F}_h))$, we assume $\mathbf{w}$ is with compact support. Then there exists C depending only on the size of the support of $\mathbf{w}$ such that*

$$\left| \int_{\mathbb{R}^3_+} \mathbf{u} \cdot \mathbf{w} \ \ \mathrm{d}\mathbf{x} \right| \leqslant C \|\nabla \mathbf{u}\|_{L^2(\mathbb{R}^3_+)} \left[\|\mathbf{w}\|_{2,2} + \|\mathbf{w}\|_{L^2\left(\mathbb{R}^3_+ \setminus \Omega_{h,r_0}\right)} \right], \tag{3.4}$$

where

$$\|\mathbf{w}\|^2_{2,2} = \int_0^{r_0} \left(\delta_h(r)^2 \left[\int_0^{\delta_h(r)} \sup_{\theta \in (0, 2\pi)} \{|\mathbf{w}(r, \theta, z)|^2)\}\ \mathrm{d}z \right] \right) r\ \mathrm{d}r.$$

If, moreover, $\mathbf{w} \in \mathbb{V}(\mathbf{G}_h)$*, we have*

$$\left| \int_{\mathbb{R}^3_+} \mathbf{u} \otimes \mathbf{u} : D(\mathbf{w}) \ \mathrm{d}\mathbf{x} \right| \leqslant C \|\nabla \mathbf{u}\|^2_{L^2(\mathbb{R}^3_+)} \left[\|\mathbf{w}\|_{\infty,2} + \|D(\mathbf{w})\|_{L^\infty\left(\mathcal{F}_h \setminus \Omega_{h,r_0}\right)} \right], \tag{3.5}$$

where

$$\|\mathbf{w}\|_{\infty,2} = \sup_{r \in (0,r_0)} \left\{ \delta_h(r)^{\frac{3}{2}} \left[\int_0^{\delta_h(r)} \sup_{\theta \in (0,2\pi)} \{ |\nabla \mathbf{w}(r,\theta,z)|^2 \} \ \mathrm{d}z \right]^{\frac{1}{2}} \right\}.$$

Proof. We denote by I_1 and I_2 the two integrals we want to estimate in (3.5) and (3.4).

We first deal with I_1. As $D(\mathbf{w}) = 0$ in $\mathcal{B}_h$, we might restrict the integration domain to $\mathcal{F}_h$. We split the integral into an integral in $\mathcal{F}_h \setminus \Omega_{h,r_0}$ and an integral in Ω_{h,r_0}: $I_1 = I_1^{in} + I_1^{out}$ with

$$|I_1^{out}| = \left| \int_{\mathcal{F}_h \setminus \Omega_{h,r_0}} \mathbf{u} \otimes \mathbf{u} : D(\mathbf{w}) \ \mathrm{d}\mathbf{x} \right| \leqslant \|\mathbf{u}\|^2_{L^2(\mathrm{Supp}(\mathbf{w}))} \|D(\mathbf{w})\|_{L^\infty\left(\mathcal{F}_h \setminus \Omega_{h,r_0}\right)}.$$

Because $\mathrm{Supp}(\mathbf{w})$ is bounded and $\mathbf{u} \in H^1_0(\mathbb{R}^3_+)$, we can use the Poincaré inequality. Concerning the integral in Ω_{h,r_0}, we have

$$I_1^{in} = \int_0^{2\pi} \int_0^{r_0} \int_0^{\delta_h(r)} [\mathbf{u}(r,\theta,z) \otimes \mathbf{u}(r,\theta,z) : D(\mathbf{w})(r,\theta,z)] \, r \ \mathrm{d}z \ \mathrm{d}r \ \mathrm{d}\theta.$$

Using a Hölder inequality with respect to the z-variable, we deduce

$$|I_1^{in}| \leqslant C \int_0^{2\pi} \int_0^{r_0} \left[\int_0^{\delta_h(r)} |\mathbf{u}(r,\theta,z)|^4 \mathrm{d}z \right]^{\frac{1}{2}} \left[\int_0^{\delta_h(r)} |D(\mathbf{w})|^2 \ \mathrm{d}z \right]^{\frac{1}{2}} r \ \mathrm{d}r \ \mathrm{d}\theta.$$

Then a direct generalization of the Poincaré inequality (see Lemma 12 in [9]) implies

$$\left[\int_0^{\delta_h(r)} |\mathbf{u}(r,\theta,z)|^4 \ \mathrm{d}z \right]^{\frac{1}{2}} \leqslant C \delta_h(r)^{\frac{3}{2}} \left[\int_0^{\delta_h(r)} |\nabla \mathbf{u}(r,\theta,z)|^2 \ \mathrm{d}z \right].$$

Substituting this in I_1^{in} and using again a Hölder inequality, we then obtain (3.5).

To estimate I_2, we decompose it in the same manner as I_1, and with the same proof, we deduce that there exists $C = C(\mathrm{Supp}(\mathbf{w}))$ such that

$$|I_2^{out}| \leqslant C \|\nabla \mathbf{u}\|_{L^2(\mathbb{R}^3_+)} \|\mathbf{w}\|_{L^2\left(\mathbb{R}^3_+ \setminus \Omega_{h,r_0}\right)}.$$

It remains to estimate the integral in Ω_{h,r_0}:

$$I_2^{in} = \int_0^{2\pi} \int_0^{r_0} \int_0^{\delta_h(r)} [\mathbf{u}(r,\theta,z) \cdot \mathbf{w}(r,\theta,z)] \, r \ \mathrm{d}z \ \mathrm{d}r \ \mathrm{d}\theta.$$

As above, a Hölder inequality in the z-variable associated to the Poincaré inequality implies

$$|I_2^{in}| \leqslant C \int_0^{2\pi} \int_0^{r_0} \left[\int_0^{\delta_h(r)} |\nabla \mathbf{u}(r,\theta,z)|^2 \ \mathrm{d}z \right]^{\frac{1}{2}} \delta_h(r) \left[\int_0^{\delta_h(r)} |\mathbf{w}|^2 \ \mathrm{d}z \right]^{\frac{1}{2}} r \ \mathrm{d}r \ \mathrm{d}\theta.$$

We conclude by using a Cauchy–Schwarz inequality. ∎

3.1. Explicit formula. From now on h is a fixed positive parameter. As in [9], we introduce a velocity field which is a good approximation (in a sense to be made precise) to the solution to the Stokes problem

$$\left\{\begin{array}{rl} \operatorname{div}\mathbb{T}(\mathbf{w},q)=0 & \\ \operatorname{div}\mathbf{w}=0 & \text{in } \mathcal{F}_h,\\ \mathbf{w}_{|\mathcal{P}}=0, & \\ \mathbf{w}_{|\partial\mathcal{B}_h}=\mathbf{e}_3. & \end{array}\right. \tag{3.6}$$

At first, we focus on the divergence-free and boundary conditions. So we introduce a potential vector field $\mathbf{a}_h$ and set $\mathbf{w}_h=\operatorname{curl}\mathbf{a}_h$. One choice for $\mathbf{a}_h$ could be

$$\mathbf{a}_h^s(\mathbf{x}):=\frac{\eta_{h_0}(|\mathbf{x}-\mathbf{G}_h|-1)}{2}(\mathbf{e}_3\times(\mathbf{x}-\mathbf{G}_h))\quad\forall\,\mathbf{x}\in\mathcal{F}_h,\quad\text{with } h_0>0.$$

The field $\mathbf{w}_h^s:=\operatorname{curl}\mathbf{a}_h^s$ satisfies the divergence-free and boundary conditions regardless of the value of $h_0<h$. However, when h goes to 0, this particular velocity field does not take advantage of the particular shape of the aperture between $\mathcal{B}$ and $\mathcal{P}$. Thus, we need to find another velocity field, especially in this aperture, in $\Omega_{h,1/2}$.

As we want to obtain an approximation of the Stokes problem, we construct a velocity field in which the fluid escapes from under the sphere with the most efficiency. Consequently, we want the velocity field to be planar and radial in each plane. Thus, our potential vector field reads, in cylindrical coordinates,

$$\mathbf{a}_h^d(r,\theta,z)=\big(-\phi_h^d(r,z)\sin(\theta),\phi_h^d(r,z)\cos(\theta),0\big)^\top\quad\forall\,(r,\theta,z)\in\Omega_{h,1/2},$$

so that, for all $(r,\theta,z)\in\Omega_{h,1/2}$,

$$\mathbf{w}_h^d(r,\theta,z)=\left(-\partial_z\phi_h^d(r,z)\cos(\theta),-\partial_z\phi_h^d(r,z)\sin(\theta),\partial_r\phi_h^d(r,z)+\frac{\phi_h^d(r,z)}{r}\right)^\top.$$

We set, in order to fit boundary conditions (this shall be critical in Lemma 3.2),

$$\phi_h^d(r,z)=r\chi_o\left(\frac{z}{\delta_h(r)}\right),\ \text{with } \chi_o(s)=\frac{s^2(3-2s)}{2}\quad\forall\,s\in(0,1).$$

From now on, we set $h_0=(\sqrt{17/16}-1)/2$. It remains to interpolate $\mathbf{w}_h^s$ and $\mathbf{w}_h^d$ so that we obtain

$$\mathbf{a}_h(\mathbf{x})=\left\{\begin{array}{rl} \eta_{1/2}(r)\mathbf{a}_h^d(r,\theta,z)+(1-\eta_{1/2}(r))\mathbf{a}_h^s(\mathbf{x}) & \text{in } \Omega_{h,1/2},\\ \mathbf{a}_h^s(\mathbf{x}) & \text{in } \mathbb{R}^3_+\setminus\Omega_{h,1/2}\end{array}\right.$$

and $\mathbf{w}_h=\operatorname{curl}\mathbf{a}_h$. Explicitly, in $\Omega_{h,1/2}$, we have

$$\mathbf{w}_h(r,\theta,z)=\eta_{1/2}(r)\mathbf{w}_h^d(r,\theta,z)+(1-\eta_{1/2}(r))\mathbf{w}_h^s(\mathbf{x})+\mathbf{rem}_0(\mathbf{x}),\tag{3.7}$$

where, denoting by $\boldsymbol{n\pi}_3(\mathbf{x})=(x_1,x_2,0)^\top/\sqrt{x_1^2+x_2^2}$, we have

$$\mathbf{rem}_0(\mathbf{x})=\eta'_{1/2}(r)\boldsymbol{n\pi}_3(\mathbf{x})\times\big(\mathbf{a}_h^d(r,\theta,z)-\mathbf{a}_h^s(\mathbf{x})\big)\quad\text{in } \Omega_{h,1/2}.$$

3.2. From static to moving test function. The main point in this subsection is to prove that, given a weak solution to (FSIS) $(\mathbf{u}, \mathbf{G})$ and $\zeta \in \mathcal{D}(0,T)$, the function $\widetilde{\mathbf{w}}$ constructed in (3.3) is a suitable test function. To this end, we need to extend $\mathbf{w}_h$ on $\mathbb{R}^3_+$ first. This is possible thanks to the following technical result.

LEMMA 3.2. *Given $h > 0$, we have*

$$\begin{aligned} &\mathbf{w}_h(\mathbf{x}) = \mathbf{e}_3, \quad &&\mathbf{a}_h(\mathbf{x}) = (\mathbf{e}_3 \times \mathbf{x})/2 \quad &&\forall\, \mathbf{x} \in \partial\mathcal{B}_h, \\ &\mathbf{w}_h(\mathbf{x}) = 0, \quad &&\mathbf{a}_h(\mathbf{x}) = 0 \quad &&\forall\, \mathbf{x} \in \mathcal{P}. \end{aligned}$$

Proof. We set $\lambda = z/\delta_h(r)$ and differentiations of λ by subscripts. We have

$$\partial_z \phi_h^d(r,z) = r\lambda_z \chi_o'(\lambda), \quad \partial_r \phi_h^d(r,z) = \chi_o(\lambda) + r\lambda_r \chi_o'(\lambda). \tag{3.8}$$

Computing with the value of λ yields

$$\lambda_z = \frac{1}{\delta_h(r)}, \quad \lambda_r = -\frac{z\delta_h'(r)}{(\delta_h(r))^2}.$$

Our choice for χ_o implies that

$$\chi_o(0) = \chi_o'(0) = 0, \quad \chi_o(1) = \frac{1}{2}, \quad \chi_o'(1) = 0.$$

Replacing λ by 0 in (3.8) yields

$$\phi_h^d(r,z) = \partial_z \phi_h^d(r,z) = \partial_r \phi_h^d(r,z) = 0 \quad \text{ on } \mathcal{P}.$$

Consequently, $\mathbf{a}_h^d = \mathbf{w}_h^d = 0$ on $\mathcal{P}$. Replacing λ by 1,

$$\partial_z \phi_h^d(r,z) = 0, \quad \phi_h^d(r,z) = \frac{r}{2}, \quad \partial_r \phi_h^d(r,z) = \frac{1}{2} \quad \text{ on } \partial\mathcal{B}_h.$$

Consequently, $\mathbf{a}_h^d(\mathbf{x}) = (\mathbf{e}_3 \times \mathbf{x})/2$ and $\mathbf{w}_h^d = \mathbf{e}_3$ on $\mathcal{B}_h$.

Concerning the smooth part, a straightforward computation leads to

$$\mathbf{w}_h^s(\mathbf{x}) = \eta_{h_0}(|\mathbf{x} - \mathbf{G}_h| - 1)\mathbf{e}_3 + \eta_{h_0}'(|\mathbf{x} - \mathbf{G}_h| - 1)\frac{\mathbf{x} - \mathbf{G}_h}{|\mathbf{x} - \mathbf{G}_h|} \times \frac{(\mathbf{e}_3 \times (\mathbf{x} - \mathbf{G}_h))}{2}.$$

Due to our choice, we have

$$\eta_{h_0}(|\mathbf{x} - \mathbf{G}_h| - 1) = 1, \quad \eta_{h_0}'(|\mathbf{x} - \mathbf{G}_h| - 1) = 0 \quad \text{ on } \partial\mathcal{B}_h.$$

Consequently $\mathbf{a}_h^s(\mathbf{x}) = (\mathbf{e}_3 \times \mathbf{x})/2$ and $\mathbf{w}_h^s = \mathbf{e}_3$ on $\partial\mathcal{B}_h$. Then

$$\eta_{h_0}(|\mathbf{x} - \mathbf{G}_h| - 1) = 0, \quad \eta_{h_0}'(|\mathbf{x} - \mathbf{G}_h| - 1) = 0 \quad \text{ if } |\mathbf{x} - \mathbf{G}_h| \geqslant 1 + 2h_0 = \sqrt{17/16}.$$

Moreover, if $\mathbf{x} \in \mathcal{P} \setminus \overline{\Omega_{h,1/4}}$, we have $r > 1/4$ and, as $\mathbf{G}_h = (0,0,1+h)$,

$$|\mathbf{x} - \mathbf{G}_h|^2 > (1+h)^2 + (1/4)^2 > 17/16.$$

Consequently, $\mathbf{a}_h^s(\mathbf{x}) = \mathbf{w}_h^s(\mathbf{x}) = 0$ for $\mathbf{x} \in \mathcal{P} \setminus \overline{\Omega_{h,1/4}}$.

It remains to check that boundary conditions are satisfied in the transition region, i.e., when $\mathbf{x} \in \overline{\Omega_{h,1/2}} \setminus \Omega_{h,1/4}$. On $\mathcal{P}$, we remark that $\mathbf{w}_h^d(\mathbf{x}) = \mathbf{w}_h^s(\mathbf{x}) = 0 = \mathbf{a}_h^s(\mathbf{x}) =$

$\mathbf{a}_h^d(\mathbf{x}) = 0$. Interpolating the potential vector fields, we obtain $\mathbf{w}_h = 0$ on $\mathcal{P}$. Finally, on $\overline{\mathcal{B}_h \cap \overline{\Omega_{h,1/4}}}$ we have already computed

$$\mathbf{w}_h^d(\mathbf{x}) = \mathbf{w}_h^s(\mathbf{x}) = \mathbf{e}_3 \quad \text{and} \quad \mathbf{a}_h^s(\mathbf{x}) = \mathbf{a}_h^d(\mathbf{x}) = (\mathbf{e}_3 \times \mathbf{x})/2.$$

Interpolating the potential vector fields, we deduce $\mathbf{w}_h(\mathbf{x}) = \mathbf{e}_3$. This concludes the proof. ∎

Remark 3.1. According to this lemma, we extend $\mathbf{a}_h$ (resp., $\mathbf{w}_h$) to $\mathbb{R}^3_+$ with the value $(\mathbf{e}_3 \times \mathbf{x})/2$ (resp., $\mathbf{e}_3$) in $\mathcal{B}_h$. In what follows, we consider the functions $\mathbf{a} : (h, \mathbf{x}) \to \mathbf{a}_h(\mathbf{x})$ and $\mathbf{w} : (h, \mathbf{x}) \to \mathbf{w}_h(\mathbf{x})$. Denoting by $\mathcal{Q}_c = \{(h, \mathbf{x}) \in (0, 1) \times \mathbb{R}^3 \ ; \ \mathbf{x} \in \mathcal{B}_h\}$, standard analytic arguments imply $\mathbf{a} \in \mathcal{C}^\infty(\mathcal{Q}_c) \cap \mathcal{C}^\infty(((0, 1) \times \mathbb{R}^3_+) \setminus \overline{\mathcal{Q}_c})$. We note that $\mathbf{w}_h$ vanishes as soon as $|\mathbf{x} - \mathbf{G}_h| > (\sqrt{17/16} - 1)/2$ and $|\mathbf{x}| > 1/2$. Consequently, the above lemma implies $\mathbf{w} \in H^1((\bar{h}, 1) \times \mathbb{R}^3_+)$ for any $\bar{h} > 0$ and, after standard composition arguments, this yields

$$\widetilde{\mathbf{w}} \in \mathcal{C}([0, T]; \mathrm{H}^1(\mathbb{R}^3_+)) \cap H^1(0, T; \mathrm{L}^2(\mathbb{R}^3_+))$$

as long as $h(t) \in (\bar{h}, 1]$ for all $t \in (0, T)$. So, $\widetilde{\mathbf{w}}$ is a suitable test function for the weak formulation as long as $h(0, T) \subset (\bar{h}, 1)$.

3.3. Estimate of remainder terms. In order to exploit the weak formulation with our test function, we need to dominate remainder terms according to Lemma 3.1. We begin with estimates on Sobolev norms of $\mathbf{w}_h$.

By construction, our test functions behave differently under the sphere (in $\Omega_{h,\delta}$) and above the sphere (in $\mathcal{F}_h \setminus \Omega_{h,\delta}$ for arbitrary fixed $\delta > 0$). Above the sphere we have the following.

LEMMA 3.3. *Given $\alpha \geqslant 0$ and $\delta > 0$ there exists $C(\alpha, \delta) < \infty$ such that*

$$\|\mathbf{a}_h\|_{H^\alpha(\mathcal{F}_h \setminus \Omega_{h,\delta})} \leqslant C(\alpha, \delta) \quad \forall\, h \in (0, 1).$$

Proof. By construction the restriction $\mathbf{a} : \mathcal{Q}_{c,\delta} \to \mathbb{R}^3$, with

$$\mathcal{Q}_{c,\delta} := \{(h, \mathbf{x}) \in [0, 1] \times \overline{\mathbb{R}^3_+} \quad \text{with } \mathbf{x} \notin \Omega_{h,\delta}\},$$

is smooth and with compact support. ∎

Inside $\Omega_{h,1/4}$, estimates rely essentially on dominations of integrals:

$$\int_0^{\frac{1}{4}} \frac{r^\alpha \, \mathrm{d}r}{[\delta_h(r)]^\beta}.$$

We refer the reader to the appendix for such computations.

LEMMA 3.4. *The family $(\mathbf{w}_h)_{0<h<1}$ is uniformly bounded in $L^2(\mathbb{R}^3_+)$.*

Proof. Because of the previous lemma, we focus on $\mathbf{w}_h^d$ inside $\Omega_{h,1/4}$.

In this region, we have

$$(\mathbf{w}_h^d(r, \theta, z))_1 = -\partial_z \phi_h^d(r, z) \cos(\theta), \quad (\mathbf{w}_h^d(r, \theta, z))_2 = -\partial_z \phi_h^d(r, z) \sin(\theta),$$

and

$$(\mathbf{w}_h^d(r, \theta, z))_3 = \partial_r \phi_h^d(r, z) + \frac{\phi_h^d(r, z)}{r}.$$

Thus

$$|\mathbf{w}_h^d(r, \theta, z)| \leqslant |\partial_z \phi_h^d(r, z)| + |\partial_r \phi_h^d(r, z)| + \frac{|\phi_h^d(r, z)|}{r}.$$

Applying Lemma A.3, this leads to

$$|\mathbf{w}_h^d(r,\theta,z)| \leqslant C\left(1+\frac{r}{\delta_h(r)}\right) \quad \forall\,(r,\theta,z)\in\Omega_{h,1/4}, \quad \forall\, h\in(0,1).$$

The result then follows from Lemma A.1 with $(\alpha,\beta)=(3,1)$. ∎

As a technical device for applying Lemma 3.1, we have the following.

LEMMA 3.5. *Let us define*

$$w_h(r,\theta,z)=|\partial_r \mathbf{w}_h^d(r,\theta,z)|+\frac{|\partial_\theta \mathbf{w}_h^d(r,\theta,z)|}{r}+|\partial_h \mathbf{w}_h^d(r,\theta,z)| \quad \forall\,(r,\theta,z)\in\Omega_{h,1/4}.$$

Then

$$\int_0^{\frac{1}{4}}\left(\delta_h(r)^2\left[\int_0^{\delta_h(r)}\sup_{\theta\in(0,2\pi)}|w_h(r,\theta,z)|^2\ \mathrm{d}z\right]\right) r\ \mathrm{d}r \tag{3.9}$$

is uniformly bounded for $h\in(0,1)$.

Proof. A straightforward computation yields, for all $(r,\theta,z)\in\Omega_{h,1/4}$,

$$|\partial_r \mathbf{w}_h^d(r,\theta,z)| \leqslant C\left(|\partial_{rz}\phi_h^d(r,z)|+|\partial_{rr}\phi_h^d(r,z)|+\left|\frac{\partial_r\phi_h^d(r,z)}{r}-\frac{\phi_h^d(r,z)}{r^2}\right|\right)$$

and

$$\begin{aligned}\frac{|\partial_\theta \mathbf{w}_h^d(r,\theta,z)|}{r} &\leqslant \frac{|\partial_z\phi_h^d(r,z)|}{r},\\ |\partial_h \mathbf{w}_h^d(r,\theta,z)| &\leqslant \frac{|\partial_h\phi_h^d(r,z)|}{r}+|\partial_{hr}\phi_h^d(r,z)|+|\partial_{hz}\phi_h^d(r,z)|.\end{aligned}$$

Combining the above inequalities with Lemma A.3, we deduce there exists a constant C independent of h such that

$$|w_h(r,\theta,z)| \leqslant C\left(\frac{1}{\delta_h(r)}+\frac{r}{\delta_h(r)^2}\right)$$

for all $(r,\theta,z)\in\Omega_{h,1/4}$. Consequently,

$$\int_0^{1/4}\left(\delta_h(r)^2\left[\int_0^{\delta_h(r)}\sup_{\theta\in(0,2\pi)}|w_h(r,\theta,z)|^2\ \mathrm{d}z\right]\right) r\ \mathrm{d}r \leqslant C\int_0^{1/4}(\delta_h(r)+1)r\ \mathrm{d}r.$$

As the last integral remains bounded when h goes to 0, the same holds for the integral of w_h. ∎

Then, to dominate the trilinear form, we need the following result.

LEMMA 3.6. *We set*

$$dw_h(r,\theta,z)=|\partial_r \mathbf{w}_h^d(r,\theta,z)|+\frac{|\partial_\theta \mathbf{w}_h^d(r,\theta,z)|}{r}+|\partial_z \mathbf{w}_h^d(r,\theta,z)| \quad \forall\,(r,\theta,z)\in\Omega_{h,1/4}.$$

Then the quantity

$$\sup_{r\in(0,1/4)}\left\{\delta_h(r)^{\frac{3}{2}}\left[\int_0^{\delta_h(r)}\sup_{\theta\in(0,2\pi)}\{|dw_h(r,\theta,z)|^2\}\ \mathrm{d}z\right]^{\frac{1}{2}}\right\} \tag{3.10}$$

is uniformly bounded for $h\in(0,1)$.

Proof. As in the previous proof, there exists a constant C independent of h such that

$$|dw_h(r,\theta,z)| \leqslant C\left(\frac{1}{\delta_h(r)} + \frac{r}{\delta_h(r)^2}\right)$$

for all $(r,\theta,z) \in \Omega_{h,1/4}$. Therefore

$$\int_0^{\delta_h(r)} |dw_h(r,z)|^2 \,\mathrm{d}z \leqslant C\left(\frac{1}{\delta_h(r)} + \frac{r^2}{\delta_h(r)^3}\right)$$

and

$$\sup_{r\in(0,1/4)}\left\{\delta_h(r)^{\frac{3}{2}}\left[\int_0^{\delta_h(r)} \sup_{\theta\in(0,2\pi)}\{|dw_h(r,\theta,z)|^2\}\,\mathrm{d}z\right]^{\frac{1}{2}}\right\} \leqslant C \sup_{r\in(0,1/4)}(\delta_h(r)+r),$$

which is uniformly bounded when $h \in (0,1)$. ∎

Finally, there holds the following lemma, which is reminiscent of works by Starovoitov.

LEMMA 3.7. *There exists a constant $C > 0$ such that*

$$|\nabla \mathbf{w}_h|_2^2 \geqslant \frac{C}{h} \quad \forall\, h \in (0,1).$$

Proof. Given $h > 0$ we already noticed that

$$\mathbf{w}_h(\mathbf{x}) = \mathbf{w}_h^d(\mathbf{x}) \quad \forall\, \mathbf{x} \in \Omega_{h,1/4}.$$

Consequently,

$$|\nabla \mathbf{w}_h(\mathbf{x})| \geqslant |\partial_z \mathbf{w}_h^d(\mathbf{x})| \quad \forall\, \mathbf{x} \in \Omega_{h,1/4}.$$

With the explicit formula for $\mathbf{w}_h^d$, we have $|\partial_z \mathbf{w}_h^d| \geqslant |\partial_{zz}\phi_h^d|$, where $|\partial_{zz}\phi_h^d(r,z)| = \dfrac{r}{\delta_h^2(r)}\chi_o''(\lambda)$. Consequently,

$$|\nabla \mathbf{w}_h|_2^2 \geqslant 2\pi \int_0^{\frac{1}{4}} \frac{r^3\,\mathrm{d}r}{\delta_h(r)^3} \int_0^1 |\chi_o''(s)|^2 \,\mathrm{d}s.$$

As χ is a polynomial with degree 3, its second derivative does not vanish, and neither does the s-integral. Then we obtain the result by applying Lemma A.1 with $\alpha = \beta = 3$. ∎

3.4. Our test function and the Stokes problem. First, we prove that our choice is a good one because it is a good approximation of the solution to the Stokes problem.

LEMMA 3.8. *There exist $q_h \in \mathcal{C}^\infty(\overline{\mathcal{F}_h})$ and $\mathbf{f}_h \in \mathcal{C}_c^\infty(\overline{\mathcal{F}_h})$ such that*

$$\left\{\begin{array}{ll} \mu\Delta \mathbf{w}_h - \nabla q_h = \mathbf{f}_h & \\ \operatorname{div} \mathbf{w}_h = 0 & \end{array}\right. \quad \text{in } \mathcal{F}_h, \tag{3.11}$$

where there exists an absolute constant C for which

$$\int_0^{2\pi}\int_0^{\frac{1}{4}}\left(\delta_h(r)^2\left[\int_0^{\delta_h(r)}|\mathbf{f}_h|^2\,\mathrm{d}z\right]\right) r\,\mathrm{d}r\,\mathrm{d}\theta + \|\mathbf{f}_h\|^2_{L^2(\mathcal{F}_h\setminus\Omega_{h,1/4})} \leqslant C.$$

Proof. By construction, we have $\mathbf{w}_h = \operatorname{curl} \widetilde{\mathbf{a}}_h^d + \operatorname{curl} \widetilde{\mathbf{a}}_h^s$, where

$$\widetilde{\mathbf{a}}_h^d(\mathbf{x}) = \begin{cases} \eta_{1/2}(r)\mathbf{a}_h^d(\mathbf{x}), & \mathbf{x} \in \Omega_{h,1/2}, \\ 0 \quad \text{else}, \end{cases} \quad \widetilde{\mathbf{a}}_h^s(\mathbf{x}) = \begin{cases} (1-\eta_{1/2}(r))\mathbf{a}_h^s(\mathbf{x}), & \mathbf{x} \in \Omega_{h,1/2}, \\ \mathbf{a}_h^s(\mathbf{x}) \quad \text{else}. \end{cases}$$

Then, according to Lemma 3.3, the smooth part $\widetilde{\mathbf{a}}_h^s$ is bounded in any Sobolev space uniformly in h. Consequently, $\widetilde{\mathbf{f}}_h = \mu\Delta \operatorname{curl} \widetilde{\mathbf{a}}_h^s$ is bounded in all Sobolev spaces. We have

$$\mu\Delta\mathbf{w}_h = \mu\Delta \operatorname{curl} \widetilde{\mathbf{a}}_h^d + \widetilde{\mathbf{f}}_h.$$

In the following we write $\widetilde{\phi}_h^d(r,z) = \eta_{1/2}(r)\phi_h^d(r,z)$ for all $(r,\theta,z) \in \Omega_{h,1/2}$. Let us recall that in cylindrical coordinates we have

$$\Delta = \frac{\partial_r[r\partial_r]}{r} + \frac{\partial_{\theta\theta}}{r^2} + \partial_{zz}.$$

Consequently,

$$\left[\Delta \operatorname{curl} \widetilde{\mathbf{a}}_h^d\right]_1 = -\left[\partial_{rrz}\widetilde{\phi}_h^d + \frac{\partial_{rz}\widetilde{\phi}_h^d}{r} - \frac{\partial_z\widetilde{\phi}_h^d}{r^2} + \partial_{zzz}\widetilde{\phi}_h^d\right]\cos(\theta)$$

and

$$\left[\Delta \operatorname{curl} \widetilde{\mathbf{a}}_h^d\right]_2 = -\left[\partial_{rrz}\widetilde{\phi}_h^d + \frac{\partial_{rz}\widetilde{\phi}_h^d}{r} - \frac{\partial_z\widetilde{\phi}_h^d}{r^2} + \partial_{zzz}\widetilde{\phi}_h^d\right]\sin(\theta),$$

$$\left[\Delta \operatorname{curl} \widetilde{\mathbf{a}}_h^d\right]_3 = \partial_{rrr}\widetilde{\phi}_h^d + 2\frac{\partial_{rr}\widetilde{\phi}_h^d}{r} - \frac{\partial_r\widetilde{\phi}_h^d}{r^2} + \frac{\widetilde{\phi}_h^d}{r^3} + \partial_{zz}\left[\partial_r\widetilde{\phi}_h^d + \frac{\widetilde{\phi}_h^d}{r}\right].$$

We remark here that

$$\partial_{zzz}\widetilde{\phi}_h^d(r,z) = -6\frac{r\,\eta_{1/2}(r)}{\delta_h^3(r)}.$$

Consequently, denoting by Φ a primitive of $s \mapsto -6s\eta_{1/2}(s)/(\delta_h(s))^3$, we have

$$\nabla\Phi(r) = (\partial_{zzz}\phi_h^d\cos(\theta), \partial_{zzz}\phi_h^d\sin(\theta), 0)^\top.$$

We set

$$q_h(\mathbf{x}) = \mu\Phi(r) + \mu\partial_z\left[\partial_r\widetilde{\phi}_h^d + \frac{\widetilde{\phi}_h^d}{r}\right], \quad \check{\mathbf{f}}_h = \mu\Delta \operatorname{curl} \widetilde{\mathbf{a}}_h^d - \nabla q_h.$$

In particular $\mu\Delta\mathbf{w}_h - \nabla q_h = \widetilde{\mathbf{f}}_h + \check{\mathbf{f}}_h$, so that our result follows from the same result for $\check{\mathbf{f}}_h$. Denoting by $\check{f}_1, \check{f}_2, \check{f}_3$ the Cartesian components of $\check{\mathbf{f}}_h$, straightforward computations show that

$$|\check{f}_1|^2 + |\check{f}_2|^2 \leqslant 4\left[\partial_{rrz}\widetilde{\phi}_h^d + \frac{\partial_{rz}\widetilde{\phi}_h^d}{r} - \frac{\partial_z\widetilde{\phi}_h^d}{r^2}\right]^2.$$

As $\eta'_{1/2}$ vanishes uniformly in $\Omega_{h,1/4}$, Lemma 3.3 implies there exists a universal constant C such that

$$|\check{f}_1|^2 + |\check{f}_2|^2 \leqslant C\left[1 + \left|\partial_{rrz}\phi_h^d + \frac{\partial_{rz}\phi_h^d}{r} - \frac{\partial_z\phi_h^d}{r^2}\right|\right]^2.$$

Then, for the same reasons, we have

$$|\check{f}_3|^2 \leqslant C\left[1 + \left|\partial_{rrr}\phi_h^d\right| + \left|\frac{2\partial_{rr}\phi_h^d}{r}\right| + \left|\frac{\phi_h^d}{r^3} - \frac{\partial_r\phi_h^d}{r^2}\right|\right]^2.$$

Replacing with the size computed in Lemma A.3, we obtain

$$|\check{\mathbf{f}}_h(\mathbf{x})|^2 \leqslant C\left(\frac{r}{\delta_h^2(r)} + \frac{1}{\delta_h(r)}\right)^2.$$

Consequently, for arbitrary $r \in (0, 1/2)$

$$\int_0^{\delta_h(r)} |\check{\mathbf{f}}_h|^2 \,\mathrm{d}z \leqslant C\left(\frac{r^2}{\delta_h(r)^3} + \frac{1}{\delta_h(r)}\right)$$

and

$$\int_0^{2\pi}\int_0^{1/2} \delta_h(r)^2 \int_0^{\delta_h(r)} |\check{\mathbf{f}}_h|^2 \,\mathrm{d}z r \,\mathrm{d}r \,\mathrm{d}\theta \leqslant C\int_0^{1/2}\left(\frac{r^3}{\delta_h(r)} + r\delta_h(r)\right)\,\mathrm{d}r,$$

which is uniformly bounded for $h \in (0,1)$. This concludes the proof. ∎

As a direct corollary, we get the following lemma.

LEMMA 3.9. *There exist $K_m < \infty$ and a function $\widetilde{n}_3 : [0,1] \to \mathbb{R}_+$ such that, for any $h < 1$ and $\mathbf{w} \in \mathbb{V}(\mathbf{G}_h)$ such that $\mathbf{w} = \mathbf{V}_\mathbf{w} + \mathbf{R}_\mathbf{w} \times (\mathbf{x} - \mathbf{G}_h)$ in $\mathcal{B}_h$, we have*

$$\left|2\mu\int_{\mathbb{R}^3_+} D(\mathbf{w}_h) : D(\mathbf{w}) \;\,\mathrm{d}\mathbf{x} - \widetilde{n}_3(h)\mathbf{V}_\mathbf{w}\cdot\mathbf{e}_3\right| \leqslant K_m\|\nabla\mathbf{w}\|_{L^2(\mathbb{R}^3_+)}. \tag{3.12}$$

Moreover, there exist $h_m > 0$ and a constant $c > 0$ such that $\widetilde{n}_3(h) \geqslant c/h$ for all $h < h_m$.

Proof. Given $h > 0$ and $\mathbf{w} \in \mathbb{V}(\mathbf{G}_h)$, we apply the Stokes identity with (3.11) and obtain

$$2\mu\int_{\mathbb{R}^3_+} \mathrm{D}(\mathbf{w}_h) : \mathrm{D}(\mathbf{w}) \,\mathrm{d}\mathbf{x} = \int_{\partial\mathcal{B}_h} \mathbb{T}(\mathbf{w}_h, p_h)\mathbf{n}\cdot\mathbf{w} \,\mathrm{d}\sigma - \int_{\mathcal{F}_h} \mathbf{f}_h\cdot\mathbf{w} \,\mathrm{d}\mathbf{x}. \tag{3.13}$$

For symmetry reasons, there exists $\widetilde{n}_3 : (0,1) \to \mathbb{R}$ such that

$$\int_{\partial\mathcal{B}_h} \mathbb{T}(\mathbf{w}_h, p_h)\mathbf{n} \,\mathrm{d}\sigma = \widetilde{n}_3(h)\mathbf{e}_3$$

and

$$\int_{\partial\mathcal{B}_h} (\mathbf{x} - \mathbf{G}_h) \times \mathbb{T}(\mathbf{w}_h, p_h)\mathbf{n} \,\mathrm{d}\sigma = 0.$$

On the other hand, applying (3.4) and Lemma 3.8, we also deduce

$$\left|\int_{\mathcal{F}_h} \mathbf{f}_h\cdot\mathbf{w} \,\mathrm{d}\mathbf{x}\right| \leqslant C\|\nabla\mathbf{w}\|_{L^2(\mathbb{R}^3_+)} \quad \forall\, h \in (0,1),$$

where C is a positive constant. Finally, we have obtained the existence of a constant K such that, for arbitrary $h \in (0,1)$ and $\mathbf{w} \in \mathbb{V}(\mathbf{G})$,

$$\left| 2\mu \int_{\mathbb{R}^3_+} \mathrm{D}(\mathbf{w}_h) : \mathrm{D}(\mathbf{w}) \, \mathrm{d}\mathbf{x} - \widetilde{n}_3(h) \mathbf{V}_{\mathbf{w}} \cdot \mathbf{e}_3 \right| \leqslant K \|\nabla \mathbf{w}\|_{L^2(\mathbb{R}^3_+)}.$$

In order to estimate $\widetilde{n}_3$, we take $\mathbf{w} = \mathbf{w}_h$ in (3.13) and obtain

$$\widetilde{n}_3 = \int_{\partial \mathcal{B}_h} \mathbb{T}(\mathbf{w}_h, p_h)\mathbf{n} \cdot \mathbf{e}_3 \, \mathrm{d}\sigma = 2\mu \int_{\mathbb{R}^3_+} |D(\mathbf{w}_h)|^2 \, \mathrm{d}\mathbf{x} + \int_{\mathcal{F}_h} \mathbf{f}_h \cdot \mathbf{w}_h \, \mathrm{d}\mathbf{x}. \tag{3.14}$$

Dealing as previously with the last integral, we deduce that

$$\left| \int_{\mathcal{F}_h} \mathbf{f}_h \cdot \mathbf{w}_h \, \mathrm{d}\mathbf{x} \right| \leqslant K \|\nabla \mathbf{w}_h\|_{L^2(\mathbb{R}^3_+)} \quad \forall\, h \in (0,1).$$

But, applying Lemma 3.7, we have that

$$2\mu \int_{\mathbb{R}^3_+} |D(\mathbf{w}_h)|^2 \, \mathrm{d}\mathbf{x} = \mu \int_{\mathbb{R}^3_+} |\nabla \mathbf{w}_h|^2 \, \mathrm{d}\mathbf{x} \geqslant \frac{C}{h} \quad \forall\, h \in (0,1).$$

Consequently, the asymptotic behavior of the right-hand side in (3.14) when h goes to 0 is prescribed by the first integral. Hence, there exist $h_m > 0$ and constants $\widetilde{c}, c > 0$ such that

$$\widetilde{n}_3(h) \geqslant \widetilde{c} \int_{\mathbb{R}^3_+} |D(\mathbf{w}_h)|^2 \, \mathrm{d}\mathbf{x} \geqslant \frac{c}{h} \quad \forall\, h \in (0, h_m). \qquad \square$$

4. Proof of Theorem 1.1. We let the reader convince himself that Theorem 1.1 is a direct consequence of the following theorem.

THEOREM 4.1. *Given $(\mathbf{u}, \mathbf{G})$ a weak solution to (FSIS) on $(0,T)$ with initial data $(\mathbf{u}^0, \mathbf{G}^0)$, we assume there exists $0 \leqslant \tau_0 < \tau_1 \leqslant T$ for which*

$$h(t) := \mathrm{dist}(\mathcal{B}(t), \mathcal{P}) \leqslant 1 \quad \forall\, t \in [\tau_0, \tau_1].$$

Then there exists $C(\|\mathbf{u}^0\|_{L^2(\mathbb{R}^3_+)}) < \infty$ depending only on the L^2-norm of initial data such that

$$h(t) \geqslant h(\tau_0) \exp\left[-C(\|\mathbf{u}^0\|_{L^2(\mathbb{R}^3_+)})(1 + \sqrt{T}) \right] \quad \forall\, t \in (\tau_0, \tau_1).$$

The remainder of this paper is devoted to the proof of this result. From now on $(\mathbf{u}, \mathbf{G})$ is a given weak solution to (FSIS) with initial data $(\mathbf{u}^0, \mathbf{G}^0)$. For simplicity, we assume that $h(t) \leqslant 1$ for all $t \in (0,T)$. This means that $\tau_0 = 0$ and $\tau_1 = T$ in the assumptions of our theorem.

As mentioned before, we estimate the distance h from below with our approximation of the Stokes problem. So, from now on, $(\mathbf{w}_h)_{h \in (0,1)}$ are the approximations constructed in section 3.1. Given $0 < t_0 < t_1 < 1$, we set

$$\zeta_\varepsilon(t) = \eta_\varepsilon(\mathrm{dist}(t, [t_0, t_1])).$$

Then $\zeta_\varepsilon \in \mathcal{D}(0,T)$ whenever ε is sufficiently small. Consequently, according to Remark 3.1, for ε sufficiently small

$$\begin{array}{rccl} \widetilde{\mathbf{w}}_\varepsilon : & (0,T) \times \mathbb{R}^3_+ & \longrightarrow & \mathbb{R}^3, \\ & (t, \mathbf{x}) & \longmapsto & \zeta_\varepsilon(t) \mathbf{w}_{h(t)}(x_1 - G_1(t), x_2 - G_2(t), x_3) \end{array}$$

can be taken as a test function in (2.4):

$$\int_{(0,T)\times\mathbb{R}^3_+} [\rho_{\mathbf{G}}\mathbf{u}\cdot\partial_t\widetilde{\mathbf{w}}_\varepsilon + (\mathbf{u}\otimes\mathbf{u} - 2\mu\mathrm{D}(\mathbf{u})) : \mathrm{D}(\widetilde{\mathbf{w}}_\varepsilon)] \ \ \mathrm{d}\mathbf{x} \ \ \mathrm{d}t = 0. \tag{4.1}$$

In the following, we set

$$\begin{aligned} I_1 &:= \int_{(0,T)\times\mathbb{R}^3_+} \rho_{\mathbf{G}}\mathbf{u}\cdot\partial_t\widetilde{\mathbf{w}}_\varepsilon \ \mathrm{d}t \ \mathrm{d}\mathbf{x}, \\ I_2 &:= \int_{(0,T)\times\mathbb{R}^3_+} \mathbf{u}\otimes\mathbf{u} : D(\widetilde{\mathbf{w}}_\varepsilon) \ \mathrm{d}t \ \mathrm{d}\mathbf{x}, \\ I_3 &:= \int_{(0,T)\times\mathbb{R}^3_+} D(\mathbf{u}) : D(\widetilde{\mathbf{w}}_\varepsilon) \ \mathrm{d}t \ \mathrm{d}\mathbf{x}. \end{aligned}$$

After a change of variables, we have for almost all $t \in (0,T)$

$$\int_{\mathbb{R}^3_+} D(\mathbf{u})(t,\cdot) : D(\widetilde{\mathbf{w}}_\varepsilon)(t,\cdot) \ \mathrm{d}\mathbf{x} = \zeta_\varepsilon(t) \int_{\mathbb{R}^3_+} D(\mathbf{u})(t, x_1+G_1, x_2+G_2, x_3) : D(\mathbf{w}_{h(t)}) \ \mathrm{d}\mathbf{x}.$$

Thus, applying Lemma 3.9,

$$\int_{\mathbb{R}^3_+} D(\mathbf{u})(t, x_1+G_1, x_2+G_2, x_3) : D(\mathbf{w}_{h(t)}) \ \mathrm{d}\mathbf{x} = \dot{h}\widetilde{n}_3(h) + E(t),$$

where $|E(t)| = K_M|\nabla\mathbf{u}(t,\cdot)|_2$. Consequently,

$$I_3 = \int_0^T \zeta_\varepsilon(t)\dot{h}(t)\widetilde{n}_3(h(t)) \ \mathrm{d}t + \widetilde{E}, \tag{4.2}$$

where

$$|\widetilde{E}| \leqslant K_M\sqrt{T}\|\mathbf{u}_0\|_2. \tag{4.3}$$

Similarly, for almost all $t \in (0,T)$,

$$\begin{aligned} &\int_{\mathbb{R}^3_+} [\mathbf{u}\otimes\mathbf{u}](t,\cdot) : D(\widetilde{\mathbf{w}}_\varepsilon)(t,\cdot) \ \mathrm{d}\mathbf{x} \\ &\qquad = \zeta_\varepsilon(t) \int_{\mathbb{R}^3_+} [\rho_{\mathbf{G}_h}\mathbf{u}\otimes\mathbf{u}](t, x_1+G_1, x_2+G_2, x_3) : D(\mathbf{w}_{h(t)})(\mathbf{x}) \ \mathrm{d}\mathbf{x}. \end{aligned}$$

Consequently, applying Lemma 3.1 together with Lemmas 3.6 and 3.3, we obtain

$$\left| \int_{\mathbb{R}^3_+} [\mathbf{u}\otimes\mathbf{u}](t,\cdot) : D(\widetilde{\mathbf{w}}_\varepsilon)(t,\cdot) \ \mathrm{d}\mathbf{x} \right| \leqslant K_m\|\nabla\mathbf{u}\|^2_{L^2(\mathbb{R}^3_+)}.$$

Thus,

$$|I_2| \leqslant K_m\|\mathbf{u}_0\|^2_{L^2(\mathbb{R}^3_+)}. \tag{4.4}$$

Finally, computing $\partial_t\widetilde{\mathbf{w}}_\varepsilon$ we have, after our change of variable,

$$I_1 = I_1^\chi + I_1^w,$$

where

$$I_1^\chi := \int_0^T \int_{\mathbb{R}^3_+} [\rho_{\mathbf{G}_h}\mathbf{u}](t, x_1 + G_1, x_2 + G_2, x_3)] \cdot \zeta_\varepsilon'(t)\mathbf{w}_{h(t)}(\mathbf{x}) \, \mathrm{d}\mathbf{x} \, \mathrm{d}t$$

and

$$I_1^w := \int_0^T \zeta_\varepsilon(t) \int_{\mathbb{R}^3_+} [\rho_{\mathbf{G}_h}\mathbf{u}](x_1 + G_1, x_2 + G_2, x_3) \cdot \left[\dot{h}\partial_h \mathbf{w}_h - V_1 \partial_{x_1}\mathbf{w}_h - V_2\partial_{x_2}\mathbf{w}_h\right](\mathbf{x}) \, \mathrm{d}\mathbf{x} \, \mathrm{d}t.$$

Applying the Cauchy–Schwarz inequality and Lemma 3.4 on $\mathbf{w}_h$, we deduce that

$$|I_1^\chi| \leqslant C \left[\int_{t_0-\varepsilon}^{t_0} |\zeta_\varepsilon'(t)| \ \|\mathbf{u}(t,\cdot)\|_{L^2(\mathbb{R}^3_+)} \, \mathrm{d}t + \int_{t_1}^{t_1+\varepsilon} |\zeta_\varepsilon'(t)| \ \|\mathbf{u}(t,\cdot)\|_{L^2(\mathbb{R}^3_+)} \, \mathrm{d}t\right],$$

and therefore, using the uniform L^2-bound on $\mathbf{u}$, we obtain

$$|I_1^\chi| \leqslant K\|\mathbf{u}^0\|_{L^2(\mathbb{R}^3_+)}. \tag{4.5}$$

Finally, applying (3.4) in Lemma 3.1 together with (3.9) in Lemma 3.5, we conclude that

$$|I_1^w| \leqslant K_m \int_0^T [|\dot{h}|^2 + |\mathbf{V}_1|^2 + |\mathbf{V}_2|^2]^{\frac{1}{2}} \|\nabla \mathbf{u}\|_{L^2(\mathbb{R}^3_+)} \ \mathrm{d}t,$$

so that, with standard energy estimate,

$$|I_1^w| \leqslant K_m\sqrt{T}\|\mathbf{u}_0\|^2_{L^2(\mathbb{R}^3_+)}. \tag{4.6}$$

Gathering (4.2), (4.4), (4.5), (4.6) with (4.1) yields

$$\left|\int_0^T \zeta_\varepsilon(t)\dot{h}(t)\widetilde{n}_3(h(t)) \ \mathrm{d}t\right| \leqslant K_m(1+\sqrt{T})\left\{\|\mathbf{u}_0\|_{L^2(\mathbb{R}^3_+)} + \|\mathbf{u}_0\|^2_{L^2(\mathbb{R}^3_+)}\right\},$$

where we emphasize that K_m depend only on our choice for the approximation of the solution to the Stokes problem, but not on ε. Thus, letting ε go to 0, as h and $\widetilde{n}_3$ are continuous functions, we obtain

$$|N_3(h(t_1)) - N_3(h(t_0))| \leqslant K_m(1+\sqrt{T})\left\{\|\mathbf{u}_0\|_{L^2(\mathbb{R}^3_+)} + \|\mathbf{u}_0\|^2_{L^2(\mathbb{R}^3_+)}\right\},$$

where N_3 is a primitive of $\widetilde{n}_3$ which vanishes in $h = 1$, for example. Applying Lemma 3.9, we have $\widetilde{n}_3(h) \geqslant c/h$ when $0 < h < h_m$ for some $c > 0$ and $h_m > 0$, and we finally deduce

$$|\ln(h(t)/h(t_0))| \leqslant K_m(1+\sqrt{T})\left\{\|\mathbf{u}_0\|_{L^2(\mathbb{R}^3_+)} + \|\mathbf{u}_0\|^2_{L^2(\mathbb{R}^3_+)}\right\}.$$

Because h is continuous, letting t_0 tend to 0, we finally obtain

$$h(t) \geqslant h(0)\exp\left[-K_m(1+\sqrt{T})\left\{\|\mathbf{u}_0\|_{L^2(\mathbb{R}^3_+)} + \|\mathbf{u}_0\|^2_{L^2(\mathbb{R}^3_+)}\right\}\right].$$

This is the expected result.

Appendix. Detailed description of ϕ_h^d. In this section we estimate the size of ϕ_h^d and its derivatives. We recall that

$$\phi_h^d(r,\theta,z) = r\chi_o(z/\delta_h(r)), \quad \text{with} \quad \chi_o(s) = \frac{s^2(3-2s)}{2}.$$

In order to compare functions in the following, we introduce the following conventions. Given families $(f_h : \Omega_{h,1/4} \to \mathbb{R})_{h\in(0,1)}$ and $(g_h : \Omega_{h,1/4} \to \mathbb{R})_{h\in(0,1)}$ we denote $f_h \prec g_h$ if there exists an absolute constant such that

$$|f_h(\mathbf{x})| \leqslant Cg_h(\mathbf{x}) \quad \forall\, \mathbf{x} \in \Omega_{h,1/4} \text{ and } h < 1.$$

Given nonnegative functions $f : (0,1) \to \mathbb{R}^+$ and $g : (0,1) \to \mathbb{R}^+$, we also denote

$$f(s) \sim g(s) \quad \forall s \in (0,1)$$

if there exist two positive constants c and C such that

$$cf(s) \leqslant g(s) \leqslant Cf(s) \quad \forall s \in (0,1).$$

First, we compute typical $L^1(0,1/4)$-sizes of functions $r \mapsto r^\alpha/(\delta_h(r))^\beta$.

LEMMA A.1. *Given $(\alpha,\beta) \in (\mathbb{R}_+)^2$, we have the following estimations for all $h \in (0,1)$:*

$$\int_0^{\frac14} \frac{r^\alpha}{\delta_h(r)^\beta}\,\mathrm{d}r \sim \begin{cases} 1 & \text{if } \alpha > 2\beta - 1, \\ h^{\frac{(\alpha+1)-2\beta}{2}} & \text{if } \alpha < 2\beta - 1. \end{cases}$$

Proof. As in [9], we remark that, for all $h \in (0,1)$, we have

$$h + \frac{s^2}{2} \leqslant \delta_h(s) \leqslant h + s^2 \quad \forall s \in (0,1/4).$$

Consequently, we can replace $\delta_h(r)$ by $h + \gamma r^2$ with some generic parameter $\gamma > 0$, and we are bound to calculate

$$I_{\alpha,\beta} := \int_0^{1/4} \frac{r^\alpha}{(h+\gamma r^2)^\beta}\,\mathrm{d}r,$$

in which we set $r = \sqrt{h}s$. This yields

$$I_{\alpha,\beta} := h^{\frac{(\alpha+1)-2\beta}{2}} \int_0^{\frac{1}{4\sqrt{h}}} \frac{s^\alpha}{(1+\gamma s^2)^\beta}\,\mathrm{d}s.$$

Consequently, if $\alpha > 2\beta - 1$, the integral behaves like $Ch^{-\frac{(\alpha+1)-2\beta}{2}}$, and we obtain the first case, while if $\alpha < 2\beta - 1$, the integral goes to a finite positive value as $h \to \infty$, and we obtain the second case. ∎

We now compare $\lambda(r,z,h) = z/\delta_h(r)$ to member functions $(r,\theta,z) \mapsto r^\alpha/(\delta_h(r))^\beta$ in $\Omega_{h,1/4}$.

LEMMA A.2. *We have the following sizes:*

$$\begin{array}{llll} \lambda \prec 1, & \lambda_r \prec r/\delta_h, & \lambda_z \prec 1/\delta_h, & \lambda_h \prec 1/\delta_h, \\ \lambda_{rh} \prec r/\delta_h^2, & \lambda_{zh} \prec 1/\delta_h^2, & \lambda_{rr} \prec 1/\delta_h, & \lambda_{rz} \prec r/\delta_h^2, \\ \lambda_{rrz} \prec 1/\delta_h^2, & & \lambda_{rrr} \prec r/\delta_h^2. & \end{array}$$

Proof. The reader may rapidly check that all the derivatives of δ_h are independent of h and that all the odd ones are bounded by r over $(0, 1/4)$. Then in $\Omega_{h,1/4}$ we have $z \in (0, \delta_h(r))$, and consequently $\lambda \prec 1$. Then

$$\lambda_r = -\frac{\lambda \delta_h'}{\delta_h}, \quad \lambda_z = \frac{1}{\delta_h}, \quad \lambda_h = -\frac{\lambda}{\delta_h}.$$

As δ' is bounded by r necessarily independent of h, we get $\lambda_r \prec r/\delta_h$ and $\lambda_z \prec 1/\delta_h$, $\lambda_h \prec 1/\delta_h$. To the next order, we get

$$\lambda_{rz} = -\frac{\delta_h'}{\delta_h^2}, \quad \lambda_{rr} = \lambda \left(2\frac{(\delta_h')^2}{\delta_h^2} - \frac{\delta_h''}{\delta_h} \right), \quad \lambda_{rh} = -2\frac{\lambda \delta_h'}{\delta_h^2}, \quad \lambda_{zh} = -\frac{1}{\delta_h^2}.$$

As δ'' is bounded independently of h and $r^2 \leqslant h + r^2$, we obtain

$$\lambda_{rz} \prec \frac{r}{\delta_h^2}, \quad \lambda_{rr} \prec \frac{1}{\delta_h}, \quad \lambda_{rh} \prec \frac{r}{\delta_h}, \quad \lambda_{zh} \prec \frac{1}{\delta_h^2}.$$

Finally,

$$\lambda_{rrz} = \frac{1}{\delta_h} \left(2\frac{(\delta_h')^2}{\delta_h^2} - \frac{\delta_h''}{\delta_h} \right), \quad \lambda_{rrr} = \lambda \left(6\frac{\delta_h'' \delta_h'}{\delta_h^2} - 6\frac{(\delta_h')^3}{\delta_h^3} - \frac{\delta_h^{(3)}}{\delta_h} \right).$$

And, as $\delta_h^{(3)}$ is bounded by r and $r^2 \leqslant \delta_h$,

$$\lambda_{rrz} \prec \frac{1}{\delta_h^2}, \quad \lambda_{rrr} \prec \frac{r}{\delta_h^2}. \qquad \square$$

Then we obtain the following lemma.

LEMMA A.3. *We have the following sizes:*

$$\begin{array}{llll}
\phi_h^d \prec r, & \partial_r \phi_h^d \prec 1, & \partial_z \phi_h^d \prec r/\delta_h, & \partial_r \phi_h^d / r - \phi_h^d / r^2 \prec r/\delta_h, \\
\partial_h \phi_h^d \prec r/\delta_h, & \partial_{rh} \phi_h^d \prec 1/\delta_h, & \partial_{zh} \phi_h^d \prec r/\delta_h^2, & \partial_{rz} \phi_h^d / r - \partial_z \phi_h^d / r^2 \prec r/\delta_h^2, \\
\partial_{rr} \phi_h^d \prec r/\delta_h, & \partial_{rz} \phi_h^d \prec 1/\delta_h, & \partial_{zz} \phi_h^d \prec r/\delta_h^2, & \\
\partial_{rrr} \phi_h^d \prec 1/\delta_h, & \partial_{rzz} \phi_h^d \prec 1/\delta_h^2, & \partial_{rrz} \phi_h^d \prec r/\delta_h^2, & \partial_{zzz} \phi_h^d \prec r/\delta_h^3.
\end{array}$$

Proof. By definition, we have $\phi_h^d(r, z) = r\chi_o(\lambda)$, where χ_o is a fixed polynomial and, according to the previous lemma, λ is bounded. Consequently, we obtain $\phi_h^d \prec r$.

In the following, we shall drop all dependencies of χ_o in λ. Due to the same argument as for χ_o, all those quantities depending only on χ_o are bounded independently of (h, r, z) in $\Omega_{h,1/4}$.

So, we compute

$$\partial_r \phi_h^d = \chi_o + r\lambda_r \chi_o', \quad \partial_z \phi_h^d = r\lambda_z \chi_o', \quad \partial_h \phi_h^d = r\lambda_h \chi_o'.$$

Applying the previous lemma and $r^2 \leqslant \delta_h(r)$, we get

$$\partial_r \phi_h^d \prec 1, \quad \partial_z \phi_h^d \prec r/\delta_h, \quad \partial_h \phi_h^d \prec r/\delta_h, \quad \partial_r \phi_h^d / r - \phi_h^d / r^2 = \lambda_r \chi_o' \prec r/\delta_h.$$

To the next order, we obtain, as λ_z is independent of z,

$$\partial_{rr} \phi_h^d = (2\lambda_r + r\lambda_{rr})\chi_o' + r(\lambda_r)^2 \chi_o'',$$

$$\partial_{rz} \phi_h^d = (\lambda_z + r\lambda_{rz})\chi_o' + r\lambda_r \lambda_z \chi_o'' \quad \partial_{zz} \phi_h^d = r(\lambda_z)^2 \chi_o'',$$

$$\partial_{zh} \phi_h^d = r\lambda_z \lambda_h \chi_o'' + r\lambda_{hz} \chi_o', \quad \text{and} \quad \partial_{rh} \phi_h^d = \lambda_h \chi_o' + r\lambda_{rh} \chi_o' + r\lambda_r \lambda_h \chi_o''.$$

As above,

$$\partial_{rr}\phi_h^d \prec r/\delta_h, \quad \partial_{rz}\phi_h^d \prec 1/\delta_h, \quad \partial_{zz}\phi_h^d \prec r/\delta_h^2, \quad \partial_{rh}\phi_h^d \prec 1/\delta_h, \quad \partial_{zh}\phi_h^d \prec r/\delta_h^2$$

and

$$\frac{\partial_{rz}\phi_h^d}{r} - \frac{\partial_z\phi_h^d}{r^2} = \lambda_{rz}\chi_o' + \lambda_r\lambda_z\chi_o'' \prec r/\delta_h^2.$$

To the next order, we obtain

$$\partial_{rrr}\phi_h^d = (3\lambda_{rr} + r\lambda_{rrr})\chi_o' + (3\lambda_r^2 + 3r\lambda_{rr}\lambda_r))\chi_o'' + r(\lambda_r)^3\chi_o^{(3)},$$

and thus $\partial_{rrr}\phi_h^d \prec 1/\delta_h$; and

$$\partial_{rzz}\phi_h^d = (\lambda_z^2 + 2r\lambda_{rz}\lambda_z)\chi_o'' + r(\lambda_z)^2\lambda_r\chi_o^{(3)},$$

so $\partial_{rzz}\phi_h^d \prec 1/\delta_h^2$; and

$$\partial_{rrz}\phi_h^d = (2\lambda_{rz} + r\lambda_{rrz})\chi_o' + (2\lambda_r\lambda_z + r(\lambda_{rr}\lambda_z + 2\lambda_{rz}\lambda_r)\chi_o'' + r(\lambda_r)^2\lambda_z\chi_o^{(3)},$$

so $\partial_{rrz}\phi_h^d \prec r/\delta_h^2$. Finally, $\partial_{zzz}\phi_h^d = r(\lambda_z)^3\chi_o^{(3)}$, so that $\partial_{zzz}\phi_h^d \prec r/{\delta_h}^3$. □

ASYMPTOTIC STABILITY OF PERIODIC SOLUTIONS FOR NONSMOOTH DIFFERENTIAL EQUATIONS WITH APPLICATION TO THE NONSMOOTH VAN DER POL OSCILLATOR*

ADRIANA BUICĂ†, JAUME LLIBRE‡, AND OLEG MAKARENKOV§

Abstract. In this paper we study the existence, uniqueness, and asymptotic stability of the periodic solutions of the Lipschitz system $\dot{x} = \varepsilon g(t, x, \varepsilon)$, where $\varepsilon > 0$ is small. Our results extend the classical second Bogoliubov theorem for the existence of stable periodic solutions to nonsmooth differential systems. As an application we prove the existence of asymptotically stable 2π-periodic solutions of the nonsmooth van der Pol oscillator $\ddot{u} + \varepsilon\,(|u| - 1)\,\dot{u} + (1 + a\varepsilon)u = \varepsilon\lambda \sin t$. Moreover, we construct the so-called resonance curves that describe the dependence of the amplitude of these solutions as a function of the parameters a and λ. Finally we compare such curves with the resonance curves of the classical van der Pol oscillator $\ddot{u} + \varepsilon\left(u^2 - 1\right)\dot{u} + (1 + a\varepsilon)u = \varepsilon\lambda \sin t$.

1. Introduction.

In this paper we study the existence, uniqueness, and asymptotic stability of the T-periodic solutions of the system

$$\dot{x} = \varepsilon g(t, x, \varepsilon), \tag{1.1}$$

where $\varepsilon > 0$ is a small parameter, and the function $g \in C^0(\mathbb{R} \times \mathbb{R}^k \times [0, 1], \mathbb{R}^k)$ is T-periodic in the first variable and locally Lipschitz with respect to the second. For this class of differential systems, the study of the T-periodic solutions can be made using the averaging function

$$g_0(v) = \int_0^T g(\tau, v, 0)d\tau \tag{1.2}$$

and looking for the periodic solutions that starts near some $v_0 \in g_0^{-1}(0)$.

In the case that g is of class C^1, we recall the stable periodic case of the second Bogoliubov's theorem [6, Chap. 1, section 5, Theorem II] which states *If* $\det (g_0)'(v_0) \neq 0$ *and* $\varepsilon > 0$ *is sufficiently small, then system* (1.1) *has a unique* T*-periodic solution in a neighborhood of* v_0*. Moreover, if all the eigenvalues of the Jacobian matrix*

$(g_0)'(v_0)$ *have negative real part, then this periodic solution is asymptotically stable.* This theorem has a long history and includes results by Fatou [15], Mandelstam and Papaleksi [31], and Krylov and Bogoliubov [25, section 2].

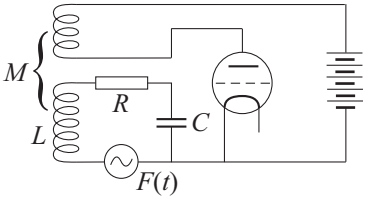

FIG. 1.1. *Circuit scheme for the classical triode oscillator (see* [3, *Chap.* VIII, section 2, *Figure* 348], [30, *Chap.* I, section 5, *Figure* 1], *and* [36, section 3.1.7, *Figures* 3–5]*).*

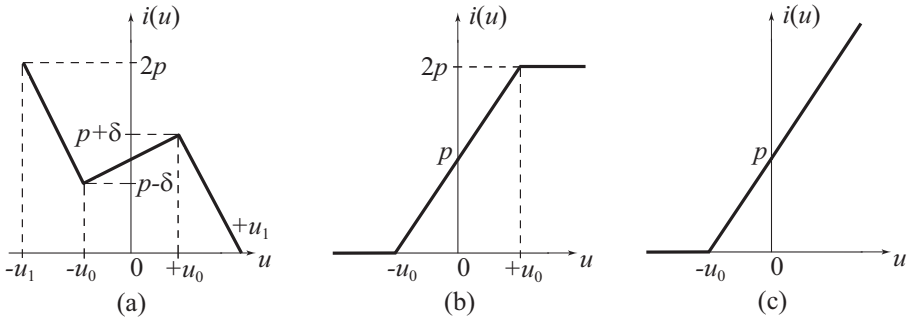

FIG. 1.2. *Characteristics of the triode of the circuit of Figure* 1.1. (a) *Triode in a harsh regime (see* [3, *Chap.* IV, section 7, *Figure* 212b], [30, *Chap.* I, section 5, *comments for eqs.* 5.3–5.4]*);* (b) *triode with saturation (see* [3, *Chap.* VIII, section 3, *Figure* 364]*);* (c) *triode without saturation (see* [3, *Chap.* IX, section 7, *Figure* 482]*).*

The Bogoliubov result provided a theoretical justification for some resonance phenomena which appear in many real physical systems. One of the most significant examples is the classical triode oscillator whose scheme is drawn in Figure 1.1 and whose current u is described by the second order differential equation

$$\ddot{u} + \frac{1}{LC}\left(RC - Mi'(u)\right)\dot{u} + \omega^2 u = \frac{1}{LC}F(t), \tag{1.3}$$

where $R = \varepsilon R_0$, $M = \varepsilon M_0$, $\omega^2 = 1 + \varepsilon b$, $F(t) = \varepsilon\lambda \sin t$, $\varepsilon > 0$, is assumed to be small and the triode characteristic $i(u)$ is drawn in Figure 1.2(a). The analysis of the diagram of bifurcation of the periodic solutions in this system is performed in almost every book on nonlinear oscillations (see Andronov, Witt, and Khaikin [3, Chap. VIII, section 2], Malkin [30, Chap. I, section 5], and Nayfeh and Mook [36, section 3.1.7]) but with the smooth approximation $i(u) = i_{(a)}(u) = S_0 + S_1 u - \frac{1}{3}S_3 u^3$ (leading to the classical van der Pol equation). Therefore it is natural to look for a technique that permits one to avoid this smooth approximation and allows one to work with the original shape of the triode characteristic drawn in Figure 1.2(a).

Though the unforced equation (1.3) (i.e., for $F = 0$) with i described by Figure 1.2(b) and Figure 1.2(c) is well studied (see [3, Chap. VIII, section 3 and Chap. IX, section 7]), the question about resonances in these equations when $F \neq 0$ (e.g., $F(t) = \varepsilon\lambda \sin t$) is still partially open. In this direction Levinson [29] uncovered a

family of solutions of (1.3) of remarkable singular structure and Levi [28] completed the study of the limit behavior of all solutions. The present paper complements these results by describing the location of asymptotically stable periodic solutions of (1.3).

Studying (1.3) with the triode characteristic given by Figure 1.2(a), 1.2(b), or 1.2(c) we finally note that there exists a change of variables (see, for example, how Levinson changed equation 2.0 in [29]) that allows one to rewrite (1.3) into the form (1.1) with some function g that is not C^1 but is Lipschitz with respect to the second variable. Therefore the goal of this work is to generalize the results on the existence of a stable periodic solution of the second Bogoliubov theorem to the case that the function g of (1.1) is only Lipschitz.

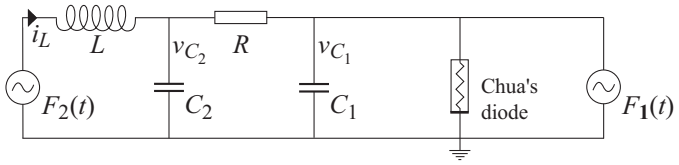

FIG. 1.3. *Forced Chua's circuit (see* [5, 11, 20, 35, 40]*).*

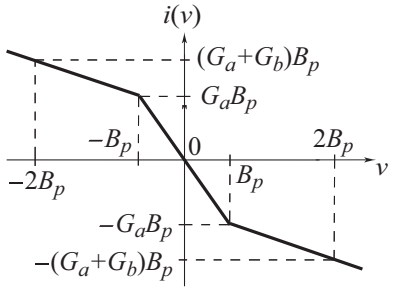

FIG. 1.4. *Nonlinear characteristic of the Chua's diode of the circuit drawn at Figure* 1.3 *given by* $i(v) = G_b v + (1/2)(G_a - G_b)\,(|v + B_p| - |v - B_p|)$, *where* $G_a, G_b, B_p \in \mathbb{R}$ *are some constants depending on the properties of the Chua's diode (see* [10]*).*

Another motivation of this paper comes from the forced Chua's circuit (see Figure 1.3) studied in a large number of papers in the modern electrical engineering. This circuit is described by the three-dimensional system

$$
\begin{aligned}
C_1 \frac{dv_{C_1}}{dt} &= \frac{v_{C_2} - v_{C_1}}{R} - i(v_{C_1}) + F_1(t),\\
C_2 \frac{dv_{C_2}}{dt} &= \frac{v_{C_1} - v_{C_2}}{R} + i_L,\\
L \frac{di_L}{dt} &= -v_{C_2} + F_2(t, v_{C_2}),
\end{aligned}
\tag{1.4}
$$

where $i(v)$ (the characteristic of the Chua's diode) is a piecewise linear function, as it is represented in Figure 1.4. The recent literature provides insight into the numerical simulations of (1.4) (see [40, 20], where $F_1 \neq 0$ and $F_2 \neq 0$, [5, 35], where $F_1 = 0$ and F_2 is periodic, or [11] where both F_1 and F_2 are periodic). Generalization of the Bogoliubov result for (1.1) with Lipschitz right-hand part will allow for the first

time the theoretical detection of asymptotically stable periodic solutions of (1.4) in the case that C_1 is large enough. Eventually this theoretical analysis may provide new interesting parameters of the forced Chua's circuit for doing additional numerical experiments.

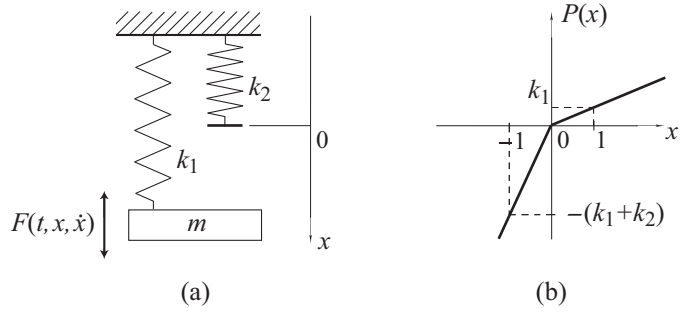

FIG. 1.5. *A prototypic device presented in* (a) *where a driven mass is attached to a immovable beam via a spring with piecewise linear stiffness like in* (b)*; see, e.g.,* [7], [24, *Chap.* I, *p.* 16 *and Chap.* IV, *p.* 100]*, and* [38].

On the other hand, part of the interest in generalizing the Bogoliubov result comes from mechanics, where differential systems with piecewise linear stiffness describe various oscillating processes. One of these systems is exhibited by the device drawn in Figure 1.5(a), where a forced mass is attached to a spring whose stiffness changes from k_1 to $k_1 + k_2$ when the mass coordinate crosses 0 in the negative direction. This device is governed by the second order differential equation

$$m\ddot{x} + P(x) = F(t, x, \dot{x}), \tag{1.5}$$

where the piecewise linear stiffness P is drawn in Figure 1.5(b). Depending on the particular configuration of the device of Figure 1.5(a), different expressions for F in (1.5) must be considered. Thus we have that $F(t, x, \dot{x}) = -f(x)\dot{x} + M\cos\omega t$ with piecewise constant f for a shock-absorber and jigging conveyor (see [24, Chap. I, p. 16 and Chap. IV, p. 100]), where the original Bogoliubov result is employed without justification). The function F takes the simpler form $F(t, x, \dot{x}) = -c\dot{x} + MQ(t)$ for an impact resonator, and $F(t, x, \dot{x}) = -c\dot{x} + M\sin\omega t$ for a cracked-body model (see [38, 7], where only numerical experiments are performed). In each of these situations (1.5) can be rewritten in the form (1.1) with g Lipschitz, provided that the constant k_2 and the amplitude of the force F are sufficiently small. Therefore the extension of the Bogoliubov result to the nonsmooth case that we shall do will allow one to justify the resonances that appeared in all these results. We note that the recent report by Los Alamos National Laboratory [13] describes the increasing interest in a specific form of the model of Figure 1.5(a) called the cracked-body model and, particularly, in the suspension bridge models. Consequently the results of this paper can be applied to such models.

A first model of a one-dimensional suspended bridge is drawn in Figure 1.6(a). It is represented (see [16, 27]) by the beam bending under its own weight and being supported by cables whose restoring force due to elasticity is proportional to u^+ (see Figure 1.6(b)), where $u = u(t, x)$ is the displacement of a point at a distance x from one end of the bridge at time t and u is measured in the downward direction. Looking for u of the form $u(t, x) = z(t)\sin(\pi x/L)$ and considering $F(x, t) = h(t)\sin(\pi x/L)$,

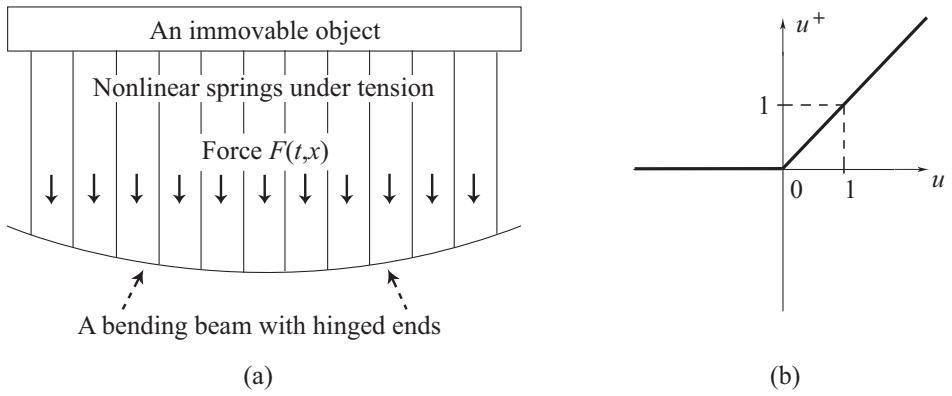

FIG. 1.6. (a) *The first idealization of the suspension bridge: the beam bending under its own weight is supported by the nonlinear cables (see* [27, *Figure* 2]*);* (b) *characteristic of stiffness of nonlinear springs.*

we arrive (see [16]) at the following particular case of differential equation (1.5):

$$m\ddot{z} + \delta\dot{z} + c(\pi/L)^4 z + dz^+ = mg + h(t), \tag{1.6}$$

where the constant $m > 0$ is the mass per unit of length, $\delta > 0$ is a small viscous damping coefficient, $c > 0$ measures the flexibility or stiffness of the bridge, $L > 0$ is the length of the bridge, $d > 0$ represents the stiffness of nonlinear springs, and h is a continuous T-periodic force modelling wind, marching troops, or cattle (see [19] for details). Considering $c > 0$ and $d > 0$ fixed and assuming that either $c > 0$ and $h(t)$ are sufficiently small, or that $c > 0$ is fixed and $h(t)$ is sufficiently large, or that $c > 0$ is sufficiently small and $h(t)$ fixed, Glover, Lazer, and McKenna [16], Lazer and McKenna [27], and Fabry [14] proved various theorems on the location of asymptotically stable T-periodic solutions in (1.6). The question *What happens with these solutions when* $d > 0$*,* $\delta > 0$*, and* $h(t)$ *are all sufficiently small?* was open and can be solved using the generalization of the Bogoliubov result that we provide. Lazer and McKenna proved in [26] that the Poincaré map for (1.6) is differentiable, but we note that this is not sufficient for applying the original Bogoliubov result.

We end the list of possible applications noting that system (1.4) describing the Chua's circuit (Figure 1.3) appeared recently for studying the so-called negative slope mechanical systems (see Awrejcewicz [4, section 8.2.2]). So our results can also be applied to these mechanical systems.

These applications require generalizations of the second Bogoliubov theorem for Lipschitz right-hand parts. To the best of our knowledge Mitropol'skii was the first to consider such a kind of generalization. Assuming that g is Lipschitz, $g_0 \in C^3(\mathbb{R}^k, \mathbb{R}^k)$, and all the eigenvalues of the matrix $(g_0)'(v_0)$ have negative real part, Mitropol'skii [34] developed the Bogoliubov result proving the existence and uniqueness of a T-periodic solution of system (1.1) in a neighborhood of v_0. There was great progress weakening the assumptions of the existence result (see Samoilenko [39] and Mawhin [32]), but this progress did not take place in the case of the uniqueness. Moreover, the asymptotic stability of the T-periodic solution remained unstudied in the case of Lipschitz systems for a long time. It has been done recently by Buică and Daniilidis in [8] for Lipschitz systems (1.1) assuming that the function $v \mapsto g(t, v, 0)$ is differentiable at v_0 for almost any $t \in [0, T]$ and that the eigenvectors of the matrix $(g_0)'(v_0)$ are orthogonal.

In section 2, assuming that g is piecewise differentiable in the second variable, we prove in Theorem 2.5 that the stable periodic solution of the Bogoliubov theorem persists when g is not necessary C^1. Theorem 2.5 follows from this more general Theorem 2.1 whose hypotheses do not use any differentiability—neither of g, nor of g_0. Assuming only continuity for g, we show in Theorem 2.9 the existence of a nonasymptotically stable T-periodic solution of system (1.1) if the Brouwer topological degree of $-g_0$ is negative. In section 3 we illustrate our results constructing the resonance curves of the nonsmooth van der Pol oscillator, also studied in [18], and compare these curves with the resonance curves of the classical van der Pol oscillator, which were constructed by Andronov and Witt [1, 2].[1]

2. Main results. Throughout the paper $\Omega \subset \mathbb{R}^k$ will be an open set. For any $\delta > 0$ we denote $B_\delta(v_0) = \left\{v \in \mathbb{R}^k \ : \ \|v - v_0\| \leq \delta\right\}$. We have the following main result on the existence, uniqueness, and asymptotic stability of T-periodic solutions for system (1.1).

THEOREM 2.1. *Let $g \in C^0(\mathbb{R} \times \Omega \times [0,1], \mathbb{R}^k)$ and $v_0 \in \Omega$. Assume the following four conditions.*

(i) *For some $L > 0$ we have that $\|g(t, v_1, \varepsilon) - g(t, v_2, \varepsilon)\| \leq L \|v_1 - v_2\|$ for any $t \in [0, T]$, $v_1, v_2 \in \Omega$, $\varepsilon \in [0, 1]$.*

(ii) *For any $\gamma > 0$ there exists $\delta > 0$ such that*

$$\left\| \int_0^T g(\tau, v_1 + u(\tau), \varepsilon) d\tau - \int_0^T g(\tau, v_2 + u(\tau), \varepsilon) d\tau \right.$$
$$\left. - \int_0^T g(\tau, v_1, 0) d\tau + \int_0^T g(\tau, v_2, 0) d\tau \right\| \leq \gamma \|v_1 - v_2\|$$

for any $u \in C^0([0,T], \mathbb{R}^k)$, $\|u\| \leq \delta$, $v_1, v_2 \in B_\delta(v_0)$, and $\varepsilon \in [0, \delta]$.

(iii) *Let g_0 be the averaged function given by (1.2) and consider that $g_0(v_0) = 0$.*

(iv) *There exist $q \in [0,1)$, $\alpha, \delta_0 > 0$, and a norm $\|\cdot\|_0$ on $\mathbb{R}^k$ such that $\|v_1 + \alpha g_0(v_1) - v_2 - \alpha g_0(v_2)\|_0 \leq q \|v_1 - v_2\|_0$ for any $v_1, v_2 \in B_{\delta_0}(v_0)$.*

Then there exists $\delta_1 > 0$ such that for every $\varepsilon \in (0, \delta_1]$, system (1.1) has exactly one T-periodic solution x_ε with $x_\varepsilon(0) \in B_{\delta_1}(v_0)$. Moreover, the solution x_ε is asymptotically stable and $x_\varepsilon(0) \to v_0$ as $\varepsilon \to 0$.

When the solution $x(\cdot, v, \varepsilon)$ of system (1.1) with the initial condition $x(0, v, \varepsilon) = v$ is well defined on $[0, T]$ for any $v \in B_{\delta_0}(v_0)$, the map $v \mapsto x(T, v, \varepsilon)$ is also well defined and is called the *Poincaré map* at time T of system (1.1). In order to prove the existence, uniqueness, and stability of the T-periodic solutions of system (1.1) stated in Theorem 2.1, it is sufficient to study the same properties for the fixed points of this Poincaré map.

Before proving Theorem 2.1 we state and prove two lemmas. In order to state the first lemma, we need to introduce the function

$$g_\varepsilon(v) = \int_0^T g(\tau, x(\tau, v, \varepsilon), \varepsilon) d\tau$$

[1] At the final stage of publishing of this paper, we have been informed by Prof. Michael Guevara that the resonance curves mentioned appeared for the first time in [Balth. van der Pol, *Tijdschr. Ned Rad Gen.*, (1924) (in Dutch)], an English translation appeared in [*Phil. Mag.*, vol. 3, 1927, p. 65]. We thank Prof. Guevara for calling our attention to those papers and some other historical background on resonance curves.

and to note that by writing the equivalent integral equation of system (1.1) we have

$$x(T, v, \varepsilon) = v + \varepsilon g_\varepsilon(v).$$

LEMMA 2.2. *Let $g \in C^0(\mathbb{R} \times \Omega \times [0,1], \mathbb{R}^k)$ and $\delta_0 > 0$ be such that $B_{\delta_0}(v_0) \subset \Omega$. If* (i) *is satisfied, then there exist $\delta \in [0, \delta_0]$ and $L_1 > 0$ such that the map $(v, \varepsilon) \mapsto g_\varepsilon(v)$ is well defined and continuous on $B_{\delta_0}(v_0) \times [0, \delta]$ and*

$$\|g_\varepsilon(v_1) - g_\varepsilon(v_2)\| \le L_1 \|v_1 - v_2\| \quad \textit{for any } \varepsilon \in [0, \delta],\ v_1, v_2 \in B_{\delta_0}(v_0).$$

If both (i) *and* (ii) *are satisfied, then for any $\gamma > 0$ there exists $\delta \in [0, \delta_0]$ such that*

$$\|g_\varepsilon(v_1) - g_0(v_1) - g_\varepsilon(v_2) + g_0(v_2)\| \le \gamma \|v_1 - v_2\|$$

for any $v_1, v_2 \in B_\delta(v_0)$ and $\varepsilon \in [0, \delta]$.

Proof. Using the continuity of the solution of a differential system with respect to the initial data and the parameter (see [37, Chap. 4, section 23, statements G and D]), we obtain the existence of $\varepsilon_0 > 0$ such that $x(t, v, \varepsilon) \in \Omega$ for any $t \in [0, T]$, $v \in B_{\delta_0}(v_0)$, and $\varepsilon \in [0, \varepsilon_0]$. Using the Grönwall–Bellman lemma (see [17, Lemma 6.2] or [12, Chap. II, section 11]) from the representation $x(t, v, \varepsilon) = v + \varepsilon \int_0^t g(\tau, x(\tau, v, \varepsilon), \varepsilon) d\tau$ and the property (i), we obtain $\|x(t, v_1, \varepsilon) - x(t, v_2, \varepsilon)\| \le e^{\varepsilon L T} \|v_1 - v_2\|$ for all $t \in [0, T]$, v_1, $v_2 \in B_{\delta_0}(v_0)$, and $\varepsilon \in [0, \varepsilon_0]$. Therefore $y(t, v, \varepsilon) = \int_0^t g(\tau, x(\tau, v, \varepsilon), \varepsilon) d\tau$ satisfies the property

$$\|y(t, v_1, \varepsilon) - y(t, v_2, \varepsilon)\| \le L_1 \|v_1 - v_2\| \tag{2.1}$$

for all $t \in [0, T]$, v_1, $v_2 \in B_{\delta_0}(v_0)$, $\varepsilon \in [0, \varepsilon_0]$, and $L_1 = L T e^{\varepsilon_0 L T}$. Since $g_\varepsilon(v) = y(T, v, \varepsilon)$ the first part of the lemma has been proven.

Taking into account that $x(t, v, \varepsilon) = v + \varepsilon y(t, v, \varepsilon)$, we have

$$y(T, v_1, \varepsilon) - y(T, v_1, 0) - y(T, v_2, \varepsilon) + y(T, v_2, 0) = I_1(v_1, v_2, \varepsilon) + I_2(v_1, v_2, \varepsilon), \tag{2.2}$$

where

$$I_1(v_1, v_2, \varepsilon) = \int_0^T [g(\tau, v_2 + \varepsilon y(\tau, v_1, \varepsilon), \varepsilon) - g(\tau, v_2 + \varepsilon y(\tau, v_2, \varepsilon), \varepsilon)] d\tau,$$

$$I_2(v_1, v_2, \varepsilon) = \int_0^T [(g(\tau, v_1 + \varepsilon y(\tau, v_1, \varepsilon), \varepsilon) - g(\tau, v_2 + \varepsilon y(\tau, v_1, \varepsilon), \varepsilon))] d\tau$$

$$- \int_0^T (g(\tau, v_1, 0) - g(\tau, v_2, 0)) d\tau.$$

Since $(t, v, \varepsilon) \mapsto y(t, v, \varepsilon)$ is bounded on $[0, T] \times B_{\delta_0}(v_0) \times [0, \varepsilon_0]$, we have that $\varepsilon y(t, v, \varepsilon) \to 0$ as $\varepsilon \to 0$ uniformly with respect to $t \in [0, T]$ and $v \in B_{\delta_0}(v_0)$. Decreasing $\varepsilon_0 > 0$, if necessary, we get that $v_2 + \varepsilon y(t, v_1, \varepsilon) \in \Omega$ for any $t \in [0, T]$, $v_1, v_2 \in B_{\delta_0}(v_0)$, $\varepsilon \in [0, \varepsilon_0]$. By assumption (i) and relation (2.1) we obtain that $\|I_1(v_1, v_2, \varepsilon)\| \le T \cdot \varepsilon L L_1 \|v_1 - v_2\|$ for all $\varepsilon \in [0, \varepsilon_0]$, $v_1, v_2 \in B_{\delta_0}(v_0)$.

We fix $\gamma > 0$ and take $\delta > 0$ given by (ii). Without loss of generality we can consider that $\delta \le \min\{\delta_0, \varepsilon_0, \gamma/(2TLL_1)\}$. Therefore assumption (ii) implies that $\|I_2(v_1, v_2, \varepsilon)\| \le (\gamma/2)\|v_1 - v_2\|$ for any $\varepsilon \in [0, \delta]$, $v_1, v_2 \in B_\delta(v_0)$. Substituting the obtained estimations for I_1 and I_2 into (2.2) we have $\|y(T, v_1, \varepsilon) - y(T, v_1, 0) - y(T, v_2, \varepsilon) +$

$y(T, v_2, 0)\| \le (\varepsilon TLL_1 + \gamma/2)\|v_1 - v_2\| \le \gamma\|v_1 - v_2\|$ for any $\varepsilon \in [0, \delta]$, $v_1, v_2 \in B_\delta(v_0)$. Hence the proof is complete. □

LEMMA 2.3. *Let $g_0 : \Omega \to \mathbb{R}^k$, satisfying assumption* (iv) *for some $q \in (0,1)$, $\alpha, \delta_0 > 0$, and a norm $\|\cdot\|_0$ on $\mathbb{R}^k$. Then $\|v_1 + \varepsilon g_0(v_1) - v_2 - \varepsilon g_0(v_2)\|_0 \le (1 - \varepsilon(1-q)/\alpha)\,\|v_1 - v_2\|_0$ for any $v_1, v_2 \in B_{\delta_0}(v_0)$ and any $\varepsilon \in [0, \alpha]$.*

Proof. Indeed, the equality $v + \varepsilon g_0(v) = (1 - \varepsilon/\alpha)v + \varepsilon/\alpha\,(v + \alpha g_0(v))$ implies that the Lipschitz constant of the function $I + \varepsilon g_0$ with respect to the norm $\|\cdot\|_0$ is $(1 - \varepsilon/\alpha) + \varepsilon/\alpha\, q = 1 - \varepsilon(1-q)/\alpha$. □

Proof of Theorem 2.1. By Lemma 2.2 we have that there exists $\delta_1 \in [0, \delta_0]$ such that

$$\|g_\varepsilon(v_1) - g_0(v_1) - g_\varepsilon(v_2) + g_0(v_2)\|_0 \le ((1-q)/(2\alpha))\|v_1 - v_2\|_0 \tag{2.3}$$

for any $\varepsilon \in [0, \delta_1]$, $v_1, v_2 \in B_{\delta_1}(v_0)$. First we prove that there exists $\varepsilon_1 \in [0, \delta_1]$ such that for every $\varepsilon \in [0, \varepsilon_1]$ there exists $v_\varepsilon \in B_{\delta_1}(v_0)$ such that $x(\cdot, v_\varepsilon, \varepsilon)$ is a T-periodic solution of (1.1) by showing that there exists v_ε such that $x(T, v_\varepsilon, \varepsilon) = v_\varepsilon$. Using (iii) and (iv) we have

$$\|v + \alpha g_0(v) - v_0\|_0 \le q\|v - v_0\|_0 \quad \text{for any } v \in B_{\delta_1}(v_0).$$

Therefore we have that the map $I + \alpha g_0$ maps $B_{\delta_1}(v_0)$ into itself. From Lemma 2.2 we have that there exists $\varepsilon_0 > 0$ such that the map $(v, \varepsilon) \mapsto g_\varepsilon(v)$ is well defined and continuous on $B_{\delta_1}(v_0) \times [0, \varepsilon_0]$. We deduce that there exists $\varepsilon_1 > 0$ sufficiently small such that, for every $\varepsilon \in [0, \varepsilon_1]$, the map $I + \alpha g_\varepsilon$ maps $B_{\delta_1}(v_0)$ into itself as well. Therefore, by the Brouwer theorem (see, for example, [23, Theorem 3.1]) we have that $B_{\delta_1}(v_0)$ contains at least one fixed point of the map $I + \alpha g_\varepsilon$ for any $\varepsilon \in [0, \varepsilon_1]$. Denote this fixed point by v_ε. Then we have $g_\varepsilon(v_\varepsilon) = 0$ and $x(T, v_\varepsilon, \varepsilon) = v_\varepsilon$ for any $\varepsilon \in [0, \varepsilon_1]$.

Now we prove that $x(\cdot, v_\varepsilon, \varepsilon)$ is the only T-periodic solution of (1.1) starting near v_0 and that, moreover, it is asymptotically stable. Knowing that $x(T, v, \varepsilon) = v + \varepsilon g_\varepsilon(v)$ we write the following identity:

$$x(T, v, \varepsilon) = v + \varepsilon g_0(v) + \varepsilon\,(g_\varepsilon(v) - g_0(v))\,. \tag{2.4}$$

Using Lemma 2.3 we have from (2.3) and (2.4) that

$$\begin{aligned} \|x(T, v_1, \varepsilon) - x(T, v_2, \varepsilon)\|_0 \le &\quad (1 - \varepsilon(1-q)/\alpha + \varepsilon(1-q)/(2\alpha))\|v_1 - v_2\|_0 \\ = &\quad (1 - \varepsilon(1-q)/(2\alpha))\|v_1 - v_2\|_0 \end{aligned}$$

for all $v_1, v_2 \in B_{\delta_1}(v_0)$ and $\varepsilon \in [0, \delta_1]$. We proved before that there exists $\varepsilon_1 > 0$ such that for every $\varepsilon \in [0, \varepsilon_1]$ there exists $v_\varepsilon \in B_{\delta_1}(v_0)$ with $x(\cdot, v_\varepsilon, \varepsilon)$ a T-periodic solution of (1.1). Since $\varepsilon(1-q)/(2\alpha) > 0$ and $\varepsilon_1 \le \delta_1$, the last inequality implies that for each $\varepsilon \in [0, \delta_1]$, the T-periodic solution $x(\cdot, v_\varepsilon, \varepsilon)$ is the only T-periodic solution of (1.1) in $B_{\delta_1}(v_0)$ and, moreover (see [23, Lemma 9.2]), it is asymptotically stable. □

Remark 2.4. We note that a similar result close to Theorem 2.1 is contained in [8, Theorem 3.5]. But instead of the assumption (iv) with a fixed $\alpha > 0$, it is assumed in [8] with any $\alpha > 0$ sufficiently small. Anyway, notice that Lemma 2.3 implies that it is the same to assume (iv) for only one $\alpha > 0$ or for all $\alpha > 0$ sufficiently small. The advantage of our Theorem 2.1 is that it does not require differentiability of $g(t, \cdot, \varepsilon)$ at any point, while [8] needs it at v_0. See also Remark 2.8.

In general it is not easy to check assumptions (ii) and (iv) in the applications of Theorem 2.1. Thus we also give the following theorem based on Theorem 2.1 which assumes certain type of piecewise differentiability instead of (ii) and deals with properties of the matrix $(g_0)'(v_0)$ instead of the Lipschitz constant of g_0.

For any set $M \subset [0,T]$ measurable in the sense of Lebesgue we denote by $\mathrm{mes}(M)$ the Lebesgue measure of M (see [21, Chap. V, section 3]).

THEOREM 2.5. *Let $g \in C^0(\mathbb{R}\times\Omega\times[0,1],\mathbb{R}^k)$ satisfying* (i). *Let g_0 be the averaged function given by* (1.2) *and consider $v_0 \in \Omega$ such that $g_0(v_0)=0$. Assume that*

(v) *given any $\widetilde{\gamma}>0$ there exist $\widetilde{\delta}>0$ and $M\subset[0,T]$ with $\mathrm{mes}(M)<\widetilde{\gamma}$ such that for every $v\in B_{\widetilde{\delta}}(v_0)$, $t\in[0,T]\setminus M$, and $\varepsilon\in[0,\widetilde{\delta}]$ we have that $g(t,\cdot,\varepsilon)$ is differentiable at v and $\|g'_v(t,v,\varepsilon)-g'_v(t,v_0,0)\|\le\widetilde{\gamma}$.*

Finally assume that

(vi) *g_0 is continuously differentiable in a neighborhood of v_0 and the real parts of all the eigenvalues of $(g_0)'(v_0)$ are negative.*

Then there exists $\delta_1>0$ such that for every $\varepsilon\in(0,\delta_1]$, system (1.1) *has exactly one T-periodic solution x_ε with $x_\varepsilon(0)\in B_{\delta_1}(v_0)$. Moreover, the solution x_ε is asymptotically stable and $x_\varepsilon(0)\to v_0$ as $\varepsilon\to 0$.*

For proving Theorem 2.5 we need two preliminary lemmas.

LEMMA 2.6. *Let $g\in C^0(\mathbb{R}\times\Omega\times[0,1],\mathbb{R}^k)$ satisfying* (i). *If* (v) *holds, then* (ii) *is satisfied.*

Proof. Let $\gamma>0$ be an arbitrary number. We show that (ii) holds with $\delta=\widetilde{\delta}/2$, where $\widetilde{\delta}$ is given by (v) applied with $\widetilde{\gamma}=\min\{\gamma/(4L),\gamma/(4T)\}$. We consider also $M\subset[0,T]$ given by (v) applied with the same value of $\widetilde{\gamma}$.

Let $u\in C^0([0,T],\mathbb{R}^k)$, $\|u\|\le\delta$, and $F(v)=\int_0^T g(\tau,v+u(\tau),\varepsilon)d\tau-\int_0^T g(\tau,v,0)d\tau$. Let $v_1,v_2\in B_\delta(v_0)$ and $\varepsilon\in[0,\delta]$. We have $F(v)=F_1(v)+F_2(v)$, where $F_1(v)=\int_M(g(\tau,v+u(\tau),\varepsilon)-g(\tau,v,0))d\tau$ and $F_2(v)=\int_{[0,T]\setminus M}(g(\tau,v+u(\tau),\varepsilon)-g(\tau,v,0))d\tau$. By (i) we have that $\|F_1(v_1)-F_1(v_2)\|\le 2L\cdot\mathrm{mes}(M)\|v_1-v_2\|<2L\widetilde{\gamma}\|v_1-v_2\|\le(\gamma/2)\|v_1-v_2\|$. On the other hand, using (v), we will prove that a similar relation holds for F_2. In order to do this, we denote $h(\tau,v)=g(\tau,v+u(\tau),\varepsilon)-g(\tau,v,0)$. Notice that for each $\tau\in[0,T]\setminus M$ we can write $h'_v(\tau,v)=(g'_v(\tau,v+u(\tau),\varepsilon)-g'_v(\tau,v_0,0))-(g'_v(\tau,v,0)-g'_v(\tau,v_0,0))$. As a direct consequence of (v) we deduce that $\|h'_v(\tau,v)\|\le 2\widetilde{\gamma}$ for all $v\in B_\delta(v_0)$ and $\tau\in[0,T]\setminus M$. Now applying the mean value theorem for the function $h(\tau,\cdot)$, we have $\|h(\tau,v_1)-h(\tau,v_2)\|\le 2\widetilde{\gamma}\|v_1-v_2\|$ for all $\tau\in[0,T]\setminus M$ and all $v_1,v_2\in B_\delta(v_0)$. Then $\|F_2(v_1)-F_2(v_2)\|\le\int_{[0,T]\setminus M}\|h(\tau,v_1)-h(\tau,v_2)\|d\tau\le 2T\widetilde{\gamma}\|v_1-v_2\|\le(\gamma/2)\|v_1-v_2\|$. Therefore we have proved that $\|F(v_1)-F(v_2)\|\le\gamma\|v_1-v_2\|$, which coincides with (ii). ∎

LEMMA 2.7. *Let $g_0:\Omega\to\mathbb{R}^k$ satisfying assumption* (vi) *for some $v_0\in\Omega$. Then there exist $q\in[0,1)$, α, $\delta_0>0$ and a norm $\|\cdot\|_0$ on $\mathbb{R}^k$ such that* (iv) *is satisfied.*

Proof. If λ is an eigenvalue of $\alpha(g_0)'(v_0)$, then $\lambda+1$ is an eigenvalue of $I+(\alpha g_0)'(v_0)$. Since the eigenvalues of $\alpha(g_0)'(v_0)$ tend to 0 as $\alpha\to 0$ and have negative real parts, then there exists $\alpha\in[0,1)$ such that the absolute values of all the eigenvalues of $I+\alpha(g_0)'(v_0)$ are less than one. Therefore (see [22, p. 90, Lemma 2.2]) there exist $\widetilde{q}\in[0,1)$ and a norm $\|\cdot\|_0$ on $\mathbb{R}^k$ such that $\sup_{\|\xi\|_0\le 1}\|\xi+\alpha(g_0)'(v_0)\xi\|_0\le\widetilde{q}$.

By continuous differentiability of g_0 in a neighborhood of v_0 we have that $\|g_0(v_1)-g_0(v_2)-(g_0)'(v_0)(v_1-v_2)\|/\|v_1-v_2\|\le\|g_0(v_1)-g_0(v_2)-(g_0)'(v_2)(v_1-v_2)\|+\|(g_0)'(v_2)(v_1-v_2)-(g_0)'(v_0)(v_1-v_2)\|/\|v_1-v_2\|\to 0$ as $\max\{\|v_1-v_0\|,\|v_2-v_0\|\}\to 0$. Therefore taking into account that all norms on $\mathbb{R}^k$ are equivalent, there exists $\delta_0>0$ such that $\|g_0(v_1)-g_0(v_2)-(g_0)'(v_0)(v_1-v_2)\|_0\le(1-\widetilde{q})/(2\alpha)\|v_1-v_2\|_0$ for all

$v_1, v_2 \in B_{\delta_0}(v_0)$. Then

$$\begin{aligned}
&\|v_1+\alpha g_0(v_1) - v_2 - \alpha g_0(v_2)\|_0 \\
&\quad\le \alpha\|g_0(v_1) - g_0(v_2) - (g_0)'(v_0)(v_1 - v_2)\|_0 + \|v_1 - v_2 + \alpha(g_0)'(v_0)(v_1 - v_2)\|_0 \\
&\quad\le (1 + \widetilde{q})/2\,\|v_1 - v_2\|_0
\end{aligned}$$

for all $v_1, v_2 \in B_{\delta_0}(v_0)$. □

Proof of Theorem 2.5. Lemmas 2.6 and 2.7 imply that assumptions (ii) and (iv) of Theorem 2.1 are satisfied. Therefore the conclusion of the theorem follows by applying Theorem 2.1. □

It was observed by Mitropol'skii in [34] that in spite of the fact that $g(t, \cdot, \varepsilon)$ in (1.1) is only Lipschitz, sometimes the function g_0 turns out to be differentiable in applications. In particular we will see in section 3 that this is the case for the nonsmooth van der Pol oscillator.

Clearly if $g \in C^1(\mathbb{R} \times \mathbb{R}^k \times [0,1], \mathbb{R}^k)$, then (i) and (v) hold in any open bounded set $\Omega \subset \mathbb{R}^k$. Therefore Theorem 2.5 is a generalization of the stable periodic case of the second Bogoliubov theorem formulated in the introduction.

Remark 2.8. Theorem 2.5 does not require the eigenvectors of $(g_0)'(v_0)$ to be orthogonal as in [8, Theorem 3.6]. Moreover, assumption (H_2) of [8] is more restrictive than (v).

For completeness we also give the following theorem on the existence of nonasymptotically stable T-periodic solutions for (1.1). In the theorem below, $d(F, V)$ denotes the Brouwer topological degree of the vector field $F \in C^0(\mathbb{R}^k, \mathbb{R}^k)$ on the open and bounded set $V \subset \mathbb{R}^k$ (see [23, Chap. 2, section 5.2]).

THEOREM 2.9. *Let $g \in C^0(\mathbb{R} \times \mathbb{R}^k \times [0,1], \mathbb{R}^k)$. Assume that there exists an open bounded set $V \subset \mathbb{R}^k$ such that $g_0(v) \neq 0$ for any $v \in \partial V$ and*

(vii) $d(-g_0, V) < 0$.

Then there exists $\varepsilon_0 > 0$ such that for any $\varepsilon \in (0, \varepsilon_0]$ system (1.1) *has at least one nonasymptotically stable T-periodic solutions x_ε with $x_\varepsilon(0) \in V$.*

Proof. Since $g_0(v) \neq 0$ for any $v \in \partial V$, then from Mawhin's theorem [32] (or [33, section 5]) we have that there exists $\varepsilon_0 > 0$ such that

$$d(-g_0, V) = d(I - x(T, \cdot, \varepsilon), V) \quad \text{for any } \varepsilon \in (0, \varepsilon_0]. \tag{2.5}$$

By [23, Theorem 9.6] for any asymptotically stable T-periodic solution x_ε of (1.1) we have that $d(I - x(T, \cdot, \varepsilon), B_\delta(x_\varepsilon(0))) = 1$ for $\delta > 0$ sufficiently small. Therefore if all the possible T-periodic solutions of (1.1) with $\varepsilon \in (0, \varepsilon_0]$ had been asymptotically stable, then the degree $d(I - x(T, \cdot, \varepsilon), V)$ would have been nonnegative, contradicting (vii) and (2.5). □

Remark 2.10. Assumptions (iii) and (iv) imply that $d(-g_0, V) = 1$ (see [23, Theorem 5.16]).

Finally thinking in terms of the application to the nonsmooth van der Pol oscillator, we formulate the following theorem which combines Mawhin's theorem (see [32] or [33, Theorem 3]) and Theorems 2.5 and 2.9. In this theorem $([g_0]_i)'_{(j)}$ stays for the derivative of the ith component of the function g_0 with respect to the jth variable.

THEOREM 2.11. *Let $g \in C^0(\mathbb{R} \times \Omega \times [0,1], \mathbb{R}^2)$. Let $v_0 \in \Omega$ be such a point that $g_0(v_0) = 0$ and g_0 is continuously differentiable in a neighborhood of v_0.*

(a) *If $\det (g_0)'(v_0) \neq 0$, then there exists $\varepsilon_0 > 0$ such that for any $\varepsilon \in (0, \varepsilon_0]$ system* (1.1) *has at least one T-periodic solution x_ε satisfying $x_\varepsilon(0) \to v_0$ as $\varepsilon \to 0$.*

(b) *If* (i) *and* (v) *hold and*

$$\det (g_0)'(v_0) > 0 \quad \textit{and} \quad ([g_0]_1)'_{(1)}(v_0) + ([g_0]_2)'_{(2)}(v_0) < 0, \tag{2.6}$$

then there exists $\varepsilon_0 > 0$ *such that for any* $\varepsilon \in (0, \varepsilon_0]$ *system* (1.1) *has exactly one* T*-periodic solution* x_ε *such that* $x_\varepsilon(0) \to v_0$ *as* $\varepsilon \to 0$. *Moreover, the solution* x_ε *is asymptotically stable.*

(c) *If* $\det (g_0)'(v_0) < 0$, *then there exists* $\varepsilon_0 > 0$ *such that for any* $\varepsilon \in (0, \varepsilon_0]$ *system* (1.1) *has at least one nonasymptotically stable* T*-periodic solution* x_ε *such that* $x_\varepsilon(0) \to v_0$ *as* $\varepsilon \to 0$.

Proof. Statement (a) is added for the completeness of the formulation of Theorem 2.11 and it follows from Mawhin's theorem (see [32] or [33, Theorem 3]).

On the other hand, it is a simple calculation to show that (2.6) implies that all the eigenvalues of $(g_0)'(v_0)$ have negative real part. Therefore assumption (vi) of Theorem 2.5 is also satisfied and statement (b) follows from this theorem.

Statement (c) follows from Theorem 2.9. Indeed, since $\det (g_0)'(v_0) < 0$, it implies (see [23, Theorem 5.9]) that $d(g_0, B_\rho(v_0))$ is defined for any $\rho > 0$ sufficiently small and that $d(g_0, B_\rho(v_0)) = \det(g_0)'(v_0) < 0$. ∎

3. Application to the nonsmooth van der Pol oscillator. In [18] Hogan first demonstrated the existence of a limit cycle for the nonsmooth van der Pol equation $\ddot{u}+\varepsilon(|u|-1)\dot{u}+u = 0$. This equation governs the circuit drawn at Figure 1.1 with the triode characteristic $i(u) = S_0 + S_1 u - S_2 u|u|$ whose derivative $i'(u) = S_1 - 2S_2|u|$ is nondifferentiable (see Nayfeh and Mook [36, section 3.3.4], where the same stiffness characteristic appears in mechanics). In this paper we extend this study by considering the van der Pol problem on the location of stable and unstable periodic solutions of the perturbed equation

$$\ddot{u} + \varepsilon \left(|u| - 1\right) \dot{u} + (1 + a\varepsilon)u = \varepsilon\lambda \sin t, \tag{3.1}$$

where a is a detuning parameter and $\varepsilon\lambda \sin t$ is an external force. We assume that $\varepsilon > 0$ is sufficiently small, and we consider that the parameters a and λ vary in $\mathbb{R}$.

We finally note that standard change of variables (see example in section 3) brings (1.3) into the form (1.1), with g sufficiently smooth to satisfy the hypotheses of the second Bogoliubov theorem. But we remind the reader that our aim is to apply directly Theorem 2.5, in the same way that Andronov and Witt applied Bogoliubov theorem to the classical van der Pol oscillator

$$\ddot{u} + \varepsilon \left(u^2 - 1\right) \dot{u} + (1 + a\varepsilon)u = \varepsilon\lambda \sin t, \tag{3.2}$$

which can be found in [1, Figure 4] or in [30, Chap. I, section 16, Figure 15].

A function u is a solution of (3.1) if and only if $(z_1, z_2) = (u, \dot{u})$ is a solution of the system

$$\begin{aligned} \dot{z}_1 &= \dot{z}_2, \\ \dot{z}_2 &= -z_1 + \varepsilon[-az_1 - (|z_1| - 1)z_2 + \lambda \sin t]. \end{aligned} \tag{3.3}$$

After the change of variables

$$\begin{pmatrix} z_1(t) \\ z_2(t) \end{pmatrix} = \begin{pmatrix} \cos t & \sin t \\ -\sin t & \cos t \end{pmatrix} \begin{pmatrix} x_1(t) \\ x_2(t) \end{pmatrix},$$

system (3.3) takes the form

$$
\begin{aligned}
\dot{x}_1 &= \varepsilon \sin(-t)\left[-a(x_1\cos t + x_2 \sin t)\right. \\
&\quad \left. -\left(|x_1\cos t + x_2 \sin t| - 1\right)(-x_1 \sin t + x_2 \cos t) + \lambda \sin t\right], \\
\dot{x}_2 &= \varepsilon \cos(-t)\left[-a(x_1\cos t + x_2 \sin t)\right. \\
&\quad \left. -\left(|x_1\cos t + x_2 \sin t| - 1\right)(-x_1 \sin t + x_2 \cos t) + \lambda \sin t\right].
\end{aligned} \tag{3.4}
$$

The corresponding averaged function g_0, calculated using (1.2), is given by

$$
\begin{aligned}
[g_0]_1(M,N) &= \pi a N - \pi\lambda + \pi M - \tfrac{4}{3}M\sqrt{M^2+N^2}, \\
[g_0]_2(M,N) &= -\pi a M + \pi N - \tfrac{4}{3}N\sqrt{M^2+N^2},
\end{aligned} \tag{3.5}
$$

and it is continuously differentiable in $\mathbb{R}^2\backslash\{0\}$.

In short, by statement (a) of Theorem 2.11, the zeros $(M,N) \in \mathbb{R}^2$ of this function with the property that $\det (g_0)'(M,N) \neq 0$ determine the 2π-periodic solutions of (3.3) emanating from the solution of the unperturbed system

$$
\begin{aligned}
u_1(t) &= M\cos t + N \sin t, \\
u_2(t) &= -M \sin t + N \cos t.
\end{aligned} \tag{3.6}
$$

We have the following expression for the determinant:

$$
\det (g_0)'(M,N) = \pi^2(1+a^2) + \frac{32}{9}(M^2+N^2) - 4\pi\sqrt{M^2+N^2}. \tag{3.7}
$$

Following Andronov and Witt [1] we are concerned with the dependence of the amplitude of the solution (3.6) with respect to a and λ. Thus we decompose this solution as follows:

$$
u_1(t) = A\sin(t+\phi), \quad u_2(t) = A\cos(t+\phi), \tag{3.8}
$$

where (M,N) is related to (A,ϕ) by

$$
M = A\sin\phi, \quad N = A\cos\phi. \tag{3.9}
$$

Substituting (3.9) into (3.5) and (3.7) we obtain

$$
\begin{aligned}
[g_0((A\sin\phi, A\cos\phi))]_1 &= -(4/3)\cdot A|A|\sin\phi + \pi a A\cos\phi + \pi A\sin\phi - \pi\lambda, \\
[g_0((A\sin\phi, A\cos\phi))]_2 &= -(4/3)\cdot A|A|\cos\phi - \pi a A\sin\phi + \pi A\cos\phi,
\end{aligned} \tag{3.10}
$$

and, respectively,

$$
\det (g_0)'((A\sin\phi, A\cos\phi)) = \pi^2(1+a^2) + \frac{32}{9}A^2 - 2\pi|A|. \tag{3.11}
$$

Looking for the zeros (A,ϕ) of (3.10), we find the implicit formula

$$
A^2\left(a^2 + \left(1 - \frac{4}{3\pi}|A|\right)^2\right) = \lambda^2 \tag{3.12}
$$

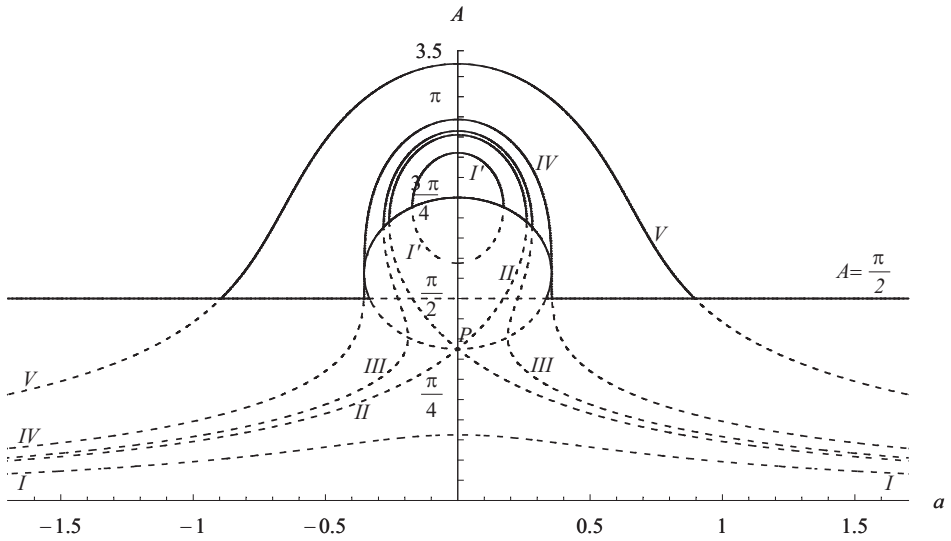

FIG. 3.1. *Dependence of the amplitude of stable (solid curves) and unstable (dash curves)* 2π*-periodic solutions of the nonsmooth periodically perturbed van der Pol equation* (3.1) *on the detuning parameter* a *obtained over formulas* (3.12), (3.16), *and* (3.17) *for different values of* λ. *The curve* I *is plotted with* $\lambda = 0.4$, II *with* $\lambda = 3\pi/16$, III *with some* $\lambda = \sqrt{0.4} \in (3\pi/16, 9\sqrt{3}\pi/64)$, IV *with* $\lambda = 9\sqrt{3}\pi/64$, *and* V *with* $\lambda = 1.5$. *Point* P *is* $2/\sqrt{3}$.

for determining A. Observe that the number of positive zeros of (3.12) coincide with the number of zeros of the equation $A^2\left(a^2 + \left(1 - \frac{4}{3\pi}A\right)^2\right) = \lambda^2$. To estimate this number we define

$$f(A) = A^2\left(a^2 + \left(1 - \frac{4}{3\pi}A\right)^2\right) - \lambda^2,$$

and we have

$$f'(A) = 2A\left(a^2 + \left(1 - \frac{4}{3\pi}A\right)^2\right) - \frac{8}{3\pi}A^2\left(1 - \frac{4}{3\pi}A\right).$$

Since f' has one or two zeros, then (3.12) has one, two, or three positive solutions A for any fixed a and λ. In order to understand the different situations that can appear, we follow Andronov and Witt, who suggested in [1] (see also [2]) to construct the so-called *resonance curves*, namely, the curves A in function of a, for λ fixed. The equation of this curve is given by formula (3.12). Some curves (3.12) corresponding to different values of λ are drawn in Figure 3.1. The way for describing these resonance curves (3.12) is borrowed from [30, Ch. 1, section 5], where the classical van der Pol equation is considered.

When $\lambda = 0$ the curve (3.12) is formed by the axis $A = 0$ and the isolated point $(0, 3\pi/4)$. When $\lambda > 0$ but sufficiently small, the resonance curve consists of two branches: instead of $A = 0$ we have the curve of the type $I - I$, and instead of the point $(0, 3\pi/4)$ we obtain an oval $I' - I'$ surrounding this point. When $\lambda > 0$ increases, the oval $I' - I'$ and the branch $I - I$ tend to each other, and, for a certain λ, there exists only one branch $II - II$ with a double point P. The value of this λ can be obtained assuming that (3.12) has for $a = 0$ a double root and, therefore, (3.11)

should be zero. Solving jointly (3.12) and (3.11) with $a = 0$ we obtain $\lambda = 3\pi/16$ and $P = 2\pi/8$. If $\lambda > 3\pi/16$, then we have curves of the type III which take form V when $\lambda > 0$ crosses the value $\lambda = 9\sqrt{3}\pi/64$. From here, if $\lambda < 3\pi/16$, then (3.12) has three real roots when $|a|$ is sufficiently small, and only one root when $|a|$ is greater than a certain number which depends on λ. When $3\pi/16 < \lambda < 9\sqrt{3}\pi/64$ (3.12) has one, three, and again one solution according to whether $a < a_1$, $a_1 < a < a_2$, and $a > a_2$, respectively, where a_1, a_2 depend on λ. The amplitude curves of type V provide exactly one solution of (3.12) for any value of a. The value $\lambda = 9\sqrt{3}\pi/64$, which separates the curves where (3.12) has three solutions from the curves where (3.12) has one solution, is obtained from the property that (3.12) with this λ has a double root for some a and thus this value of a vanishes (3.11). Therefore $\lambda = 9\sqrt{3}\pi/64$ is the point separating the interval $(0, \lambda)$ where the system formed by (3.12) and

$$\pi^2(1 + a^2) + \frac{32}{9}A^2 - 2\pi|A| = 0 \tag{3.13}$$

has at least one solution from the interval (λ, ∞) where (3.12)–(3.13) has no solutions.

In short, we have studied the amplitudes of the 2π-periodic solutions of system (3.3) depending on a and λ, when a physical system described by (3.3) possesses 2π-periodic oscillations and when some of them are asymptotically stable. To find the answer we have used statement (b) of Theorem 2.11. Assumption (i) is obviously satisfied with $\Omega = \mathbb{R}^2$. The next statement shows that the right-hand side of system (3.4) satisfies (v).

PROPOSITION 3.1. *Let $v_0 \in \mathbb{R}^2$, $v_0 \neq 0$. Then the right-hand side of* (3.4) *satisfies* (v) *for any $a, \lambda \in \mathbb{R}$.*

The proof of Proposition 3.1 is given in section 4.

Thus we have to study the signs of (3.11) and $([g_0]_1)'_M(A\sin\phi, A\cos\phi) + ([g_0]_2)'_N(A\sin\phi, A\cos\phi)$. We have

$$([g_0]_1)'_M(M, N) + ([g_0]_2)'_N(M, N) = 2\left(\pi - 2\sqrt{M^2 + N^2}\right),$$

and therefore the conditions for the asymptotic stability of the 2π-periodic solutions of (3.3) near (3.6) are

$$\pi^2(1 + a^2) + \frac{32}{9}(M^2 + N^2) - 4\pi\sqrt{M^2 + N^2} > 0 \tag{3.14}$$

and

$$2\left(\pi - 2\sqrt{M^2 + N^2}\right) < 0. \tag{3.15}$$

Substituting (3.9) into the inequalities (3.14) and (3.15), we obtain the following equivalent inequalities in terms of the amplitude A:

$$\pi^2(1 + a^2) + \frac{32}{9}A^2 - 2\pi|A| > 0 \tag{3.16}$$

and

$$2\pi - 4|A| < 0. \tag{3.17}$$

Conditions (3.16) and (3.17) mean that the asymptotically stable 2π-periodic solutions of (3.3) correspond to those parts of resonance curves under consideration which are

outside the ellipse (3.13) and above the line $A = \pi/2$. All the results are collected in Figure 3.1, where it is easy to see that for any detuning parameter a and any amplitude $\lambda > 0$, (3.1) possesses at least one asymptotically stable 2π-periodic solution with amplitude close to A obtained from (3.12). Among all the asymptotically stable 2π-periodic solutions of (3.1), there exists exactly one whose fixed neighborhood does not contain any nonasymptotically stable 2π-periodic solution of (3.1) for sufficiently small $\varepsilon > 0$. The amplitude of this asymptotically stable 2π-periodic solution is obtained from (3.16)–(3.17).

To compare the changes due to nonsmoothness in the behavior of the resonance curves, we give in Figure 3.2 the resonance curves of the classical van der Pol oscillator (3.2).

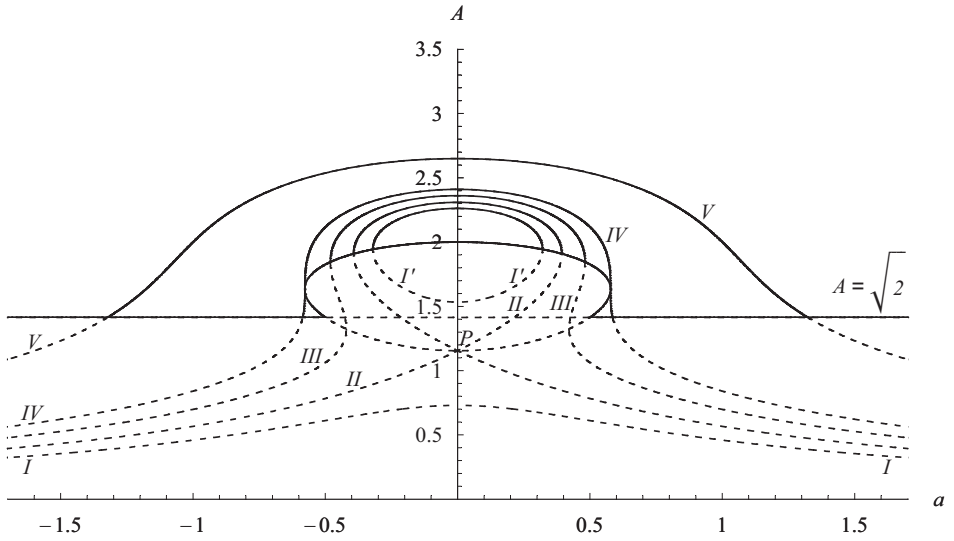

FIG. 3.2. *Dependence of the amplitude of stable (solid curves) and unstable (dash curves) 2π-periodic solutions of the classical periodically perturbed van der Pol equation* (3.2) *on the detuning parameter a for different values of λ. Following Andronov and Witt (see* [1, *Figure* 4]*), curve I is plotted with $\lambda = \sqrt{0.4}$, II with $\lambda = 4\sqrt{3}/9$, III with some $4\sqrt{3}/9 < \lambda < \sqrt{32/27}$, IV with $\lambda = \sqrt{32/27}$, and V with $\lambda = 2$. Point P is $2/\sqrt{3}$.*

The formulas of Figure 3.1 can be compared with the formulas for Figure 3.2. In fact, the corresponding expressions (3.12)–(3.13) and (3.14)–(3.15) are (see the formulas (5.21)–(5.22) and (16.6)–(16.7) of [30])

$$A^2\left(a^2 + \left(1 - \frac{A^2}{4}\right)^2\right) = \lambda^2,$$

$$1 - a^2 - A^2 + \frac{3}{16}A^4 = 0,$$

and

$$1 + a^2 - (M^2 + N^2) + \frac{3}{16}(M^2 + N^2)^2 > 0,$$

$$2 - (M^2 + N^2) < 0,$$

respectively, when we consider the classical van der Pol equation (3.2).

It can be checked that the eigenvectors of the matrix $(g_0)'((A\sin\phi, A\cos\phi))$ are orthogonal only for $A = 0$, so Theorem 3.6 from [8] cannot be applied. At the same time assumption (H2) from [8] is not satisfied for our problem (see Remark 2.8).

4. Appendix.

Proof of Proposition 3.1. As before, $[v]_i$ is the ith component of the vector $v \in \mathbb{R}^2$. Let $g(t,v) = |[v]_1\cos t + [v]_2\sin t|$, and notice that it is enough to prove that $g : [0,2\pi]\times\mathbb{R}^2 \to \mathbb{R}$ satisfies (v). In the case that $[v_0]_2 \neq 0$, denote $\theta(v) = \arctan(-[v]_1/[v]_2)$ if $[v_0]_2 = 0$, denote $\theta(v) = \arctan(-[v]_1/[v]_2)$ if $[v_0]_1[v]_2 < 0$, $\theta(v_0) = \pi/2$, and, respectively, $\theta(v) = \arctan(-[v]_1/[v]_2) + \pi$ if $[v_0]_1[v]_2 > 0$. In any case notice that the function $v \mapsto \theta(v)$ is continuous in every sufficiently small neighborhood of v_0. Fix $\widetilde{\gamma} > 0$. Let M be the union of two intervals centered in $\theta(v_0)$ (respectively, $\theta(v_0) + 2\pi$ if $\theta(v_0) < 0$) and in $\theta(v_0) + \pi$, each of length $\widetilde{\gamma}/2$. Denote them M_1 and M_2. Take $\widetilde{\delta} > 0$ such that $\theta(v) \in M_1$ for all $v \in B_{\widetilde{\delta}}(v_0)$. Of course, also $\theta(v) + \pi \in M_2$ for all $\|v - v_0\| \leq \widetilde{\delta}$. This implies that for fixed $t \in [0,2\pi]\setminus M$, $[v]_1\cos t + [v]_2\sin t$ has constant sign for all $v \in B_{\widetilde{\delta}}(v_0)$, which further gives that $g(t,\cdot)$ is differentiable and $g'_v(t,v) = g'_v(t,v_0)$ for all $v \in B_{\widetilde{\delta}}(v_0)$. Hence (v) is fulfilled. ∎

Acknowledgments. The authors are grateful to the anonymous referee who motivated us to include a list of several applications of Theorem 2.5 in the introduction—that definitely improved the paper. The authors also thank Aris Daniilidis for helpful discussions and Rafael Ortega who called our attention to the change of variables used in the Levinson paper [29]. Part of this work was done during a visit of the first and the third author to the Centre de Recerca Matemàtica, Barcelona (CRM). They express their gratitude to the CRM for providing very nice working conditions.

Finally we thank Martin Golubitsky and Andre Vanderbauwhede, who invited us to present the paper at their minisimposia "Recent developments in bifurcation theory" of Equadiff 2007 (see [9]), giving a significant impact to its recognition.

SPATIAL DYNAMICS OF A NONLOCAL PERIODIC REACTION-DIFFUSION MODEL WITH STAGE STRUCTURE*

YU JIN† AND XIAO-QIANG ZHAO†

Abstract. In this paper, we investigate a nonlocal periodic reaction-diffusion population model with stage structure. In the case of unbounded spatial domain, we establish the existence of the asymptotic speed of spread and show that it coincides with the minimal wave speed for monotone periodic traveling waves. In the case of bounded spatial domain, we obtain a threshold result on the global attractivity of either zero or a positive periodic solution.

Key words. nonlocal periodic model, spreading speed, traveling waves, positive periodic solution, global attractivity

1. Introduction.

Age structure has been an interesting topic in population dynamics (see, e.g., [1, 2, 3, 5, 6, 7, 9, 14, 17, 18, 20] and the references therein), since we can investigate the separate quantities of immature and mature populations in an age-structured population model. To derive a model for a single species of population with age structure and diffusion, we usually assume that individuals move around not only after maturity, but also while immature. For a standard argument, Metz and Diekmann [14] give

$$\frac{\partial u}{\partial t}+\frac{\partial u}{\partial a}=D(a)\frac{\partial^2 u}{\partial x^2}-\mu(a)u,$$

where $u(t,a,x)$ is the density of the population of the species at time $t\geq 0$, age $a\geq 0$, and location x in a spatial domain Ω; $D(a)\geq 0$ and $\mu(a)\geq 0$ are the diffusion rate and the death rate of the population at age a, respectively.

To study the behaviors of immature individuals and mature individuals, we can also divide the population of a species into two groups: immature population and mature population. For simplicity, we assume that the maturation time (or the length of the juvenile period) is the same for all juvenile individuals, denoted by $\tau\geq 0$. For distributed maturation delay, see, e.g., [2, 3] and the references therein. Assume that the diffusion rate and death rate are age-dependent for immature individuals, but age-independent for mature individuals. As a result, we have the following system for a single species of population with age structure and diffusion (see also [5, 17, 18, 20]):

(1.1)
$$\begin{cases}\partial_t u(t,a,x)+\partial_a u(t,a,x)=d_j(a)\Delta u-\mu_j(a)u(t,a,x), & t>0, 0<a<\tau, x\in\Omega,\\ u(t,0,x)=f(u_m(t,x)), & t\geq -\tau, x\in\Omega,\\ \partial_t u_m(t,x)=d_m\Delta u_m-g(u_m(t,x))+u(t,\tau,x), & t>0, x\in\Omega,\end{cases}$$

where $u(t,a,x)$ is the density of the population at time $t \geq -\tau$, age $a \geq 0$, location $x \in \Omega$, $u_m(t,x)$ is the density of the mature population, $f(u_m)$ and $g(u_m)$ are the birth rate and the mortality rate of mature individuals, respectively, $d_j(a) \geq 0$ is the diffusion rate of the immature individuals at age $a \in (0,\tau)$, $d_m \geq 0$ is the diffusion rate of the mature individuals, $\mu_j(a) > 0$ denotes the per capita mortality rate of juveniles at age a, $u(t,\tau,x)$ is the adults recruitment term for those of maturation age τ, Δ is the Laplacian operator.

In fact, the dynamics of many populations is influenced greatly by the time varying environments (e.g., due to seasonal variation). For example, in a one year period, the birth rate may be high in spring and summer and low in winter, while in winter more individuals might be at risk of death because of low temperature, lack of food, or some other reasons. Moreover, populations usually like to move in warm weather during the spring and summer time. Therefore, it is more realistic to consider a nonautonomous version of (1.1) for population dynamics. In particular, a periodic model, in which the birth rate, mortality rates, and diffusion rates are assumed to be periodic in time, is probably the simplest but nonetheless interesting and realistic case. In this paper, we consider the following model:

(1.2)
$$\begin{cases} \partial_t u(t,a,x) + \partial_a u(t,a,x) = d_j(t,a)\Delta u - \mu_j(t,a)u(t,a,x), & t > 0, a \in (0,\tau),\ x \in \Omega, \\ u(t,0,x) = f(t,u_m(t,x)), & t \geq -\tau,\ x \in \Omega, \\ \partial_t u_m(t,x) = d_m(t)\Delta u_m - g(t,u_m(t,x)) + u(t,\tau,x), & t > 0,\ x \in \Omega, \end{cases}$$

where $d_j(t,a) \geq 0$ and $\mu_j(t,a) \geq 0$ denote the diffusion rate and the per capita mortality rate of juveniles at age a at time t, respectively; $d_m(t) \geq 0$ denotes the diffusion rate of mature individuals at time t; $f(t,u_m)$ and $g(t,u_m)$ are the birth and mortality rates of mature individuals at time t, respectively.

Similarly as in [18] (see also [16]), we integrate along characteristics to reduce the system (1.2) to one equation with nonlocal terms. Let $v(r,a,x) = u(a+r,a,x)$, where r is regarded as a parameter. It follows that

$$\begin{cases} \partial_a v(r,a,x) = \big[\partial_t u(t,a,x) + \partial_a u(t,a,x)\big]_{t=r+a} \\ \qquad\qquad = d_j(a+r,a)\Delta v(r,a,x) - \mu_j(a+r,a)v(r,a,x), \\ v(r,0,x) = f(r,u_m(r,x)). \end{cases}$$

Integrating the last equation, we obtain

$$v(r,a,x) = \int_\Omega \Gamma(\zeta(r,a),x-y)F(r,a)f(r,u_m(r,y))dy,$$

where Γ is the fundamental solution associated with the partial differential operator $\partial_t - \Delta$ and

$$\zeta(r,a) = \int_0^a d_j(s+r,s)ds, \qquad F(r,a) = \exp\left(-\int_0^a \mu_j(s+r,s)ds\right). \tag{1.3}$$

Since $u(t,a,x) = v(t-a,a,x)$, it follows that

$$u(t,a,x) = \int_\Omega \Gamma(\zeta(t-a,a),x-y)F(t-a,a)f(t-a,u_m(t-a,y))dy. \tag{1.4}$$

Set

$$a(t) := \zeta(t-\tau,\tau), \quad b(t) := F(t-\tau,\tau), \quad f_{-\tau}(t,u) := f(t-\tau,u).$$

Substituting (1.4) into the equation for u_m in (1.2), we finally reduce the age-structured population model (1.2) to the following time-delayed reaction-diffusion equation for mature individuals:

(1.5)
$$\begin{cases} \partial_t u_m(t,x) \\ = d_m(t)\Delta u_m - g(t,u_m(t,x)) + b(t)\int_\Omega \Gamma(a(t),x-y) f_{-\tau}(t,u_m(t-\tau,y))dy, \\ u_m(s,x) = \phi(s,x), \quad s\in[-\tau,0],\ x\in\Omega, \end{cases}$$

where $\phi(t,x)$ is an initial function to be specified later. For simplicity, dropping all m's and writing $u_m(t,x)$ as $u(t,x)$, we investigate the following system:

(1.6)
$$\begin{cases} \partial_t u(t,x) = d(t)\Delta u - g(t,u(t,x)) + b(t)\displaystyle\int_\Omega \Gamma(a(t),x-y) f_{-\tau}(t,u(t-\tau,y))dy, \\ u(s,x) = \phi(s,x), \quad s\in[-\tau,0],\ x\in\Omega. \end{cases}$$

Basically we assume that $d_j(t,a)$ and $\mu_j(t,a)$ are periodic in $t\ge 0$ with the period $\omega>0$ for $a\in(0,\tau)$, and that $d(t)$, $g(t,u)$, and $f(t,u)$ are periodic in t with the period $\omega>0$ for $u\in\mathbb{R}_+$. This implies that $a(t)=a(t+\omega)$, $d(t)=d(t+\omega)$, $b(t)=b(t+\omega)$, $g(t,u)=g(t+\omega,u)$, and $f(t,u)=f(t+\omega,u)$ for all $t\ge 0$, $u\in\mathbb{R}_+$. Moreover, we assume $d(t)\ge d>0$ for all $t\ge 0$, and

(H1) $f\in C^1([-\tau,+\infty)\times\mathbb{R}_+,\mathbb{R}_+)$, $g\in C^1(\mathbb{R}^2_+,\mathbb{R}_+)$, $f(t,0)=0$ for $t\ge-\tau$, $f_u(t,u)>0$ for all $t\ge-\tau$ and $u\ge 0$, $g(t,0)=0$ for $t\ge 0$, and there exists $l_1>0$ such that $|g(t,u)-g(t,v)|\le l_1|u-v|$ for all $t\ge 0$ and $u,v\in\mathbb{R}_+$;

(H2) $G(t,u,v) := -g(t,u)+b(t)f_{-\tau}(t,v)$ is strictly subhomogeneous in (u,v) in the sense that for any $\alpha\in(0,1)$, $G(t,\alpha u,\alpha v)>\alpha G(t,u,v)$ for all $u,v\ge 0$;

(H3) there exists positive number $L>0$ such that $G(t,\bar L,\bar L)\le 0$ for all $t\ge 0$, $\bar L\ge L$.

The purpose of this paper is to study the asymptotic speed of spread and periodic traveling waves of (1.6) in the infinite spatial domain, and the global attractivity of zero or a positive periodic solution of (1.6) in a bounded spatial domain. The asymptotic speed of spread (in short, spreading speed) was first introduced by Aronson and Weinberger [4] for reaction-diffusion equations and has been an important ecological metric in a wide range of ecological applications; see, e.g., [10, 11, 18] and the references therein. Intuitively, the spreading speed c^* in a spatial epidemic model can be interpreted as: if one runs at a speed $c>c^*$, then one will leave the epidemic behind; whereas if one runs at a speed $c<c^*$, then one will eventually be surrounded by the epidemic. Traveling wave solutions have also been investigated extensively for a variety of evolution systems; see, e.g., [5, 10, 11, 17, 18] and the references therein. For the autonomous case of (1.6), the dynamics, including spreading speed and traveling waves, have been studied extensively. So, Wu and Zou [17] investigated traveling wave fronts in the case where $\Omega=\mathbb{R}$, $g(u)=\beta u$. Gourley and Kuang [5] established the linear stabilities of two spatially homogeneous equilibrium solutions, studied traveling

wave fronts in the case where $\Omega = \mathbb{R}$, $f(u) = \alpha u$, and $g(u) = \beta u^2$, and obtained a global convergence theorem in the case of bounded intervals. Thieme and Zhao [18] studied the traveling wave solutions, minimal wave speed, and asymptotic speed of spread in the case of $\Omega = \mathbb{R}^n$. Xu and Zhao [20] established a threshold dynamic and global attractivity of the positive steady state when Ω is a bounded domain in $\mathbb{R}^n$.

This paper is organized as follows. In section 2, we first establish the well-posedness and the comparison principle for (1.6) with $\Omega = \mathbb{R}$, then prove the existence of the spreading speed c^* for solutions of (1.6) with initial data having compact supports, and show that it coincides with the minimal wave speed for monotone periodic traveling waves, by appealing to the theory of the spreading speed and traveling waves for monotone periodic semiflows developed in [10, 11]. In section 3, we use the theory of monotone and subhomogeneous dynamical systems to investigate the global dynamics of (1.6) in a bounded domain $\Omega \subseteq \mathbb{R}^n$, and obtain a threshold result for global attractivity of either zero or a positive periodic solution.

2. Spreading speed and traveling waves. In this section, we consider that the population diffuses in an unbounded spatial domain and study (1.6) with $\Omega = \mathbb{R}$:

(2.1)
$$\begin{cases} \partial_t u(t,x) = d(t)\Delta u - g(t,u(t,x)) + b(t)\displaystyle\int_{\mathbb{R}} \Gamma(a(t), x-y) f_{-\tau}(t, u(t-\tau, y))dy, \\ \\ u(t,x) = \phi(t,x), \quad t \in [-\tau, 0],\ x \in \mathbb{R}. \end{cases}$$

In the following, we first apply the threshold dynamics in a scalar periodic and time-delayed equation, developed by Xu and Zhao [21], to the spatially homogeneous system associated with (2.1) to find a periodic solution of (2.1). Then we use the theory of abstract functional differential equations and reaction-diffusion systems to establish the existence of solutions to (2.1) and a comparison principle. Finally, we prove that the solution periodic semiflow of (2.1) satisfies all the assumptions on monotone periodic semiflows in [10], and hence, we obtain the existence of the spreading speed and traveling wave solutions for (2.1).

Let $\mathbb{Y}$ be the space of all continuous functions from $[-\tau, 0]$ to $\mathbb{R}$ with the usual supreme norm $\|\cdot\|_{\mathbb{Y}}$ (i.e., $\mathbb{Y} = C([-\tau, 0], \mathbb{R})$), and let $\mathbb{Y}_+ = C([-\tau, 0], \mathbb{R}_+)$. Then $(\mathbb{Y}, \mathbb{Y}_+)$ is an ordered Banach space. For $\varphi, \psi \in \mathbb{Y}$, we write $\varphi \le \psi$ if $\psi - \varphi \in \mathbb{Y}_+$, $\varphi < \psi$ if $\psi - \varphi \in \mathbb{Y}_+ \setminus \{0\}$, $\varphi \ll \psi$ if $\psi - \varphi \in \mathrm{int}(\mathbb{Y}_+)$. Moreover, we define $\mathbb{Y}_r = \{\varphi \in \mathbb{Y} : 0 \le \varphi \le r\}$ for any $r \in \mathbb{Y}$ with $r \gg 0$.

Let $\mathbb{X}$ be the set of all bounded and continuous functions from $\mathbb{R}$ into $\mathbb{R}$ and $\mathbb{X}_+ = \{\varphi \in \mathbb{X}; \varphi(x) \ge 0 \text{ for all } x \in \mathbb{R}\}$. For $\varphi, \psi \in \mathbb{X}$, we write $\varphi \le \psi (\varphi \ll \psi)$ if $\varphi(x) \le \psi(x)$ $(\varphi(x) < \psi(x))$ for all $x \in \mathbb{R}$, $\varphi < \psi$ if $\varphi \le \psi$ but $\varphi \ne \psi$. It is easy to see that $\mathbb{X}_+$ is a positive cone of $\mathbb{X}$. Define $\mathbb{X}_r = \{\varphi \in \mathbb{X} : 0 \le \varphi \le r\}$ for any $r \in \mathbb{X}$ with $r \gg 0$. We equip $\mathbb{X}$ with the compact open topology, i.e., $u^m \to u$ in $\mathbb{X}$ means that the sequence of $u^m(x)$ converges to $u(x)$ as $m \to \infty$ uniformly for x in any compact set on $\mathbb{R}$. Define

$$\| u \|_{\mathbb{X}} = \sum_{k=1}^{\infty} \frac{\max_{|x| \le k} |u(x)|}{2^k} \qquad \forall u \in \mathbb{X},$$

where $|\cdot|$ denotes the usual norm in $\mathbb{R}$. Then $(\mathbb{X}, \|\cdot\|_{\mathbb{X}})$ is a normed space. Let $d_{\mathbb{X}}(\cdot,\cdot)$ be the distance induced by the norm $\|\cdot\|_{\mathbb{X}}$. It follows that the topology in the metric space $(\mathbb{X}, d_{\mathbb{X}})$ is the same as the compact open topology in $\mathbb{X}$. Moreover, $(\mathbb{X}_r, d_{\mathbb{X}})$ is a complete metric space.

Let C be the set of continuous functions from $[-\tau, 0]$ into $\mathbb{X}$, $C_+ = \{\varphi \in C, \varphi(s) \in \mathbb{X}_+, s \in [-\tau, 0]\}$ and $C_r = \{\varphi \in C : 0 \le \varphi \le r\}$ for any $r \in \mathbb{Y}$ with $r \gg 0$. Then C_+ is a positive cone of C. For convenience, we also identify an element $\varphi \in C$ as a function from $[-\tau, 0] \times \mathbb{R}$ into $\mathbb{R}$ defined by $\varphi(s, x) = \varphi(s)(x)$ for any $s \in [-\tau, 0]$ and $x \in \mathbb{R}$. For $\varphi, \psi \in C$, we write $\varphi \le \psi (\varphi \ll \psi)$ if $\varphi(s, x) \le \psi(s, x)$ $(\varphi(s, x) < \psi(s, x))$ for all $s \in [-\tau, 0], x \in \mathbb{R}$, $\varphi < \psi$ if $\varphi \le \psi$ but $\varphi \ne \psi$. For any continuous function $w(\cdot) : [-\tau, b) \to \mathbb{X}$, $b > 0$, we define $w_t \in C$ by $w_t(s) = w(t + s)$ for all $t \in [0, b)$, $s \in [-\tau, 0]$. It is then easy to see that $t \to w_t$ is a continuous function from $[0, b)$ to C. Moreover, we also equip C with the compact open topology and define the norm on C:

$$\| u \|_C = \sum_{k=1}^{\infty} \frac{\max_{|x| \le k, s \in [-\tau, 0]} |u(s, x)|}{2^k} \qquad \forall u \in C,$$

where $|\cdot|$ denotes the usual norm in $\mathbb{R}$.

For any constant $N > 0$, $\widehat{N}$ denotes the constant function with value N in $\mathbb{Y}$, $\mathbb{X}$, or C.

Now we consider the spatially homogeneous system associated with (2.1). Letting $u(t, x) = w(t)$, we have

$$\begin{cases} \dfrac{dw(t)}{dt} = -g(t, w(t)) + b(t) f_{-\tau}(t, w(t - \tau)), \\ w(t) = \varphi(t), \quad t \in [-\tau, 0], \quad \varphi \in \mathbb{Y}_+. \end{cases} \tag{2.2}$$

The linearized equation associated with (2.2) at $w = 0$ is

$$\begin{cases} \dfrac{dw(t)}{dt} = -g_u(t, 0) w(t) + b(t) \partial_u f_{-\tau}(t, 0) w(t - \tau), \\ w(t) = \varphi(t), \quad t \in [-\tau, 0], \quad \varphi \in \mathbb{Y}_+. \end{cases} \tag{2.3}$$

Since g, b, and $f_{-\tau}$ are periodic functions in $t \ge 0$, we can easily see that for any $\varphi \in \mathbb{Y}_+$, (2.3) admits a unique solution $w(t, \varphi)$ existing for all $t \ge -\tau$ with $w(s, \varphi) = \varphi(s)$ for $s \in [-\tau, 0]$, and $w_t(\varphi) \in \mathbb{Y}_+$ for all $t \ge 0$, where $\{w_t\}_{t \ge 0}$ is the solution semiflow for (2.3) defined by $w_t(\varphi)(s) = w(t + s, \varphi)$ for all $s \in [-\tau, 0]$, $t > 0$.

Define the Poincaré map of (2.3) $P : \mathbb{Y}_+ \to \mathbb{Y}_+$ by $P(\varphi) = w_\omega(\varphi)$ for all $\varphi \in \mathbb{Y}_+$, and let $r = r(P)$ be the spectral radius of P. The following two results come from [21].

PROPOSITION 2.1 (see [21, Proposition 2.1]). *$r = r(P)$ is positive and is an eigenvalue of P with a positive eigenfunction φ^*. Moreover, if $\tau = k\omega$ for some integer $k \ge 0$, then $r - 1$ has the same sign as $\int_0^\omega [-g_u(t, 0) + b(t) \partial_u f_{-\tau}(t, 0)] dt$.*

THEOREM 2.2 (see [21, Theorem 2.1]). *Let* (H1)–(H3) *hold. The following statements are valid.*

(i) *If $r \le 1$, then zero solution is globally asymptotically stable for* (2.2) *with respect to $\mathbb{Y}_+$.*

(ii) *If $r > 1$, then* (2.2) *has a unique positive ω-periodic solution $\beta^*(t)$, and $\beta^*(t)$ is globally asymptotically stable with respect to $\mathbb{Y}_+ \setminus \{0\}$.*

In the remainder of this section, we further assume that

(H4) $r = r(P) > 1$.

By the proof of [21, Theorem 2.1] and (H3), it is easy to see that $\beta^*(t) \in [0, L]$ for all $t \ge -\tau$ and $[\hat{0}, \hat{L}]$ is positively invariant for (2.1). Define $\beta_0^* \in \mathbb{Y}_{\hat{L}}$ as $\beta_0^*(s) = \beta^*(s)$ for all $s \in [-\tau, 0]$.

Consider

$$\begin{cases} \partial_t u(t,x) = d(t)\Delta u, \quad t > 0, \\ u(0,x) = \phi(x), \quad x \in \mathbb{R}, \phi \in \mathbb{X}. \end{cases} \tag{2.4}$$

The solution of (2.4) can be expressed as

$$u(t,x,\phi) = \int_{\mathbb{R}} \Gamma(\eta(t), x-y)\phi(y)dy, \quad t \geq 0, \tag{2.5}$$

where $\eta(t) = \int_0^t d(s)ds$. According to [8, Chapter II], (2.4) admits an evolution operator $U(t,s) : \mathbb{X} \to \mathbb{X}$, $0 \leq s \leq t$, which satisfies $U(t,t) = I$, $U(t,s)U(s,\rho) = U(t,\rho)$ for all $0 \leq \rho \leq s \leq t$, and $U(t,0)(\phi)(x) = u(t,x,\phi)$ for $t \geq 0$, $x \in \mathbb{R}$, and $\phi \in \mathbb{X}$, where $u(t,x,\phi)$ is the solution of (2.4). Moreover, for any $0 \leq s < t$, $U(t,s)$ is a compact and positive operator on $\mathbb{X}$, and $U(t,s)(\phi)(x) > 0$ for all $0 \leq s < t$, $x \in \mathbb{R}$, and $\phi \in \mathbb{X}$ provided that $\phi(x) \geq 0$ and $\phi \not\equiv 0$.

Define $B : [0,\infty) \times C \to \mathbb{X}$ by $B(t,\phi) := -g(t,\phi(0,\cdot)) + b(t)\int_{\mathbb{R}} \Gamma(a(t),\cdot - y)f_{-\tau}(t,\phi(-\tau,y))dy$ for any $t \in [0,\infty)$, $\phi \in C$. Then (2.1) becomes

$$\begin{cases} \partial_t u(t,x) = d(t)\Delta u + B(t,u_t), \quad t > 0, \\ u(t,x) = \phi(t,x), \quad t \in [-\tau,0], \ x \in \mathbb{R}, \end{cases} \tag{2.6}$$

which can be written as an integral equation

$$u(t,\cdot,\phi) = U(t,0)\phi(0,\cdot) + \int_0^t U(t,s)B(s,u_s)ds, \quad t \geq 0, \quad \phi \in C, \tag{2.7}$$

whose solutions are called mild solutions to (2.6).

THEOREM 2.3. *Let* (H1)–(H4) *hold. For any* $\phi \in C_{\hat{L}}$, *system* (2.1) *has a unique mild solution* $u(t,x,\phi)$ *with* $u_0(\cdot,\cdot,\phi) = \phi$ *and* $u_t(\cdot,\cdot,\phi) \in C_{\hat{L}}$ *for all* $t \geq 0$, *and* $u(t,x,\phi)$ *is a classic solution when* $t > \tau$. *Moreover, if* $\hat{u}(t,x)$ *and* $\bar{u}(t,x)$ *are a pair of lower and upper solutions of* (2.1), *respectively, with* $\hat{u}_0(\cdot,\cdot) \leq \bar{u}_0(\cdot,\cdot)$, *then* $\hat{u}_t(\cdot,\cdot) \leq \bar{u}_t(\cdot,\cdot)$ *for all* $t \geq 0$.

Proof. We first show that B is quasi-monotone on $[0,\infty) \times C_{\hat{L}}$ in the sense that

$$\lim_{h \to 0^+} d(\psi(0,\cdot) - \phi(0,\cdot) + h[B(t,\psi) - B(t,\phi)], \mathbb{X}_+) = 0 \tag{2.8}$$

for all $\phi, \psi \in C_{\hat{L}}$ with $\phi(s,x) \leq \psi(s,x)$ for all $s \in [-\tau,0]$, $x \in \mathbb{R}$. In fact, for any $\phi, \psi \in C_{\hat{L}}$ with $\phi(s,x) \leq \psi(s,x)$ for all $(s,x) \in [-\tau,0] \times \mathbb{R}$, we have

$$\begin{aligned} &\psi(0,\cdot) - \phi(0,\cdot) + h[B(t,\psi) - B(t,\phi)] \\ &= \psi(0,\cdot) - \phi(0,\cdot) + h[-(g(t,\psi(0,\cdot)) - g(t,\phi(0,\cdot)))] \\ &+ h\left[\int_{\mathbb{R}} \Gamma(a(t),\cdot - y)b(t)(f_{-\tau}(t,\psi(-\tau,y)) - f_{-\tau}(t,\phi(-\tau,y)))dy\right] \\ &\geq \psi(0,\cdot) - \phi(0,\cdot) - h(g(t,\psi(0,\cdot)) - g(t,\phi(0,\cdot))) \\ &\geq (1 - hl_1)(\psi(0,\cdot) - \phi(0,\cdot)). \end{aligned}$$

Thus, for $1 - hl_1 > 0$, $\psi(0,\cdot) - \phi(0,\cdot) + h[B(t,\psi) - B(t,\phi)] \in \mathbb{X}_+$, and hence, (2.8) holds. Then by [13, Corollary 5] (for $v^- = \hat{0}$, $v^+ = \hat{L}$, $S^+ = S^- = S = T \equiv U$,

$B^+ = B^- = B$), (2.1) admits a unique mild solution $u(t,\cdot,\phi)$ on $[-\tau,\infty)$ for any $\phi \in C_{\widehat{L}}$ and $u_t(\cdot,\cdot,\phi) \in C_{\widehat{L}}$ for all $t \geq 0$. Moreover, the comparison principle holds for lower and upper solutions. □

In order to study the spreading speed and traveling waves, we introduce the assumptions in [10, 11]. Let $u \in C$. Define the reflection operator $\mathcal{R}$ by $\mathcal{R}[u](\theta,x) := u(\theta,-x)$ for all $\theta \in [-\tau,0], x \in \mathbb{R}$. Given $y \in \mathbb{R}$, define the translation operator T_y by $T_y[u](\theta,x) := u(\theta,x-y)$ for all $\theta \in [-\tau,0], x \in \mathbb{R}$. Let $Q : C_{b^*} \to C_{b^*}$ be a map, where $b^* \in \mathbb{Y}$ with $b^* \gg 0$. Assume the following:

(A1) $Q[\mathcal{R}[u]] = \mathcal{R}[Q[u]]$, $T_y[Q[u]] = Q[T_y[u]]$ $\forall y \in \mathbb{R}$.

(A2) $Q : C_{b^*} \to C_{b^*}$ is continuous with respect to the compact open topology.

(A4) $Q : C_{b^*} \to C_{b^*}$ is monotone in the sense that $Q[u] \geq Q[v]$ whenever $u \geq v$ in C_{b^*}.

(A5) $Q : \mathbb{Y}_{b^*} \to \mathbb{Y}_{b^*}$ admits exactly two fixed points 0 and b^*, and for any positive number ε, there is an $\alpha \in \mathbb{Y}_{b^*}$ with $\| \alpha \|_{\mathbb{Y}} < \varepsilon$ such that $Q[\alpha] \gg \alpha$.

(A6) One of the following two conditions holds:

(a) $Q[C_{b^*}]$ is precompact in C_{b^*}.

(b′) The set $Q[C_{b^*}](0,\cdot)$ is precompact in $\mathbb{X}$, and there is a positive number $\varsigma \leq \tau$ such that $Q[u](\theta,x) = u(\theta+\varsigma,x)$ for $-\tau \leq \theta \leq -\varsigma$, the operator

$$S[u](\theta,x) := \begin{cases} u(0,x), & -\tau \leq \theta < -\varsigma, \\ Q[u](\theta,x), & -\varsigma \leq \theta \leq 0 \end{cases}$$

is continuous on C_{b^*}, and $S[D](\cdot,0)$ is precompact in $\mathbb{Y}$ for any T-invariant set $D \subseteq C_{b^*}$ with $D(0,\cdot)$ being precompact in $\mathbb{X}$. A set $W \subseteq C_{b^*}$ is said to be T-invariant if $T_y W = W$ for all $y \in \mathbb{R}$.

Recall that a family of operators $\{\Phi_t\}_{t\geq 0}$ is an ω-periodic semiflow on a metric space (X,ρ) with the metric ρ, provided that $\{\Phi_t\}$ satisfies

(i) $\Phi_0(v) = v$ $\forall v \in X$;

(ii) $\Phi_t(\Phi_\omega(v)) = \Phi_{t+\omega}(v)$ $\forall t \geq 0, v \in X$;

(iii) $\Phi(t,v) = \Phi_t(v)$ is continuous in (t,v) on $[0,+\infty) \times X$.

Define a family of operators $\{Q_t\}_{t\geq 0}$ on $C_{\widehat{L}}$ by

$$Q_t(\phi)(s,x) = u(t+s,x,\phi) \quad \forall t \geq 0, \quad s \in [-\tau,0], \quad x \in \mathbb{R}, \quad \phi \in C_{\widehat{L}},$$

where $u(t,x,\phi)$ is the mild solution of (2.1) with $u(s,x) = \phi(s,x)$ for $s \in [-\tau,0]$, $x \in \mathbb{R}$. Note that for any $(t_0,\phi_0) \in \mathbb{R}_+ \times C_{\widehat{L}}$, we have

$$\| Q_t(\phi) - Q_{t_0}(\phi_0) \|_C \leq \| Q_t(\phi) - Q_t(\phi_0) \|_C + \| Q_t(\phi_0) - Q_{t_0}(\phi_0) \|_C.$$

Note that $U(t,0)\varphi$ is continuous in $(t,\varphi) \in [0,\infty) \times \mathbb{X}$ with respect to the compact open topology. By a similar argument as in [12, Theorem 8.5.2], it follows that $Q_t(\phi)$ is continuous at (t_0,ϕ_0) with respect to the compact open topology. Thus, $\{Q_t\}_{t\geq 0}$ is an ω-periodic semiflow on $C_{\widehat{L}}$.

LEMMA 2.4. *For each $t > 0$, Q_t is strictly subhomogeneous.*

Proof. For any $\phi \in C_{\widehat{L}}$ with $\phi \not\equiv 0$, let $u(t,x,\phi)$ be the solution of (2.1) with $u(s,x) = \phi(s,x)$ for $s \in [-\tau,0]$, $x \in \mathbb{R}$. Fix $k \in (0,1)$. Since $G(t,u,v)$ is strictly subhomogeneous in (u,v), we have

$$\begin{aligned} &\partial_t(ku(t,x)) \\ &= d(t)\Delta(ku) - kg(t,u(t,x)) + kb(t)\int_{\mathbb{R}} \Gamma(a(t),x-y) f_{-\tau}(t,u(t-\tau,y))dy \\ &\leq d(t)\Delta(ku) - g(t,ku(t,x)) + b(t)\int_{\mathbb{R}} \Gamma(a(t),x-y) f_{-\tau}(t,ku(t-\tau,y))dy. \end{aligned}$$

Thus, $ku(t,x,\phi)$ is a lower solution of (2.1) with $ku(s,x,\phi) = k\phi(s,x)$ for $s \in [-\tau,0], x \in \mathbb{R}$. Then, $ku(t,x,\phi) \le u(t,x,k\phi)$ for $t \ge 0$, where $u(t,x,k\phi)$ is the solution of (2.1) with $u(s,x,k\phi) = k\phi(s,x)$ for $(s,x) \in [-\tau,0] \times \mathbb{R}$.

Let $w(t,x) = u(t,x,k\phi) - ku(t,x,\phi)$. Then $w(s,x) = 0$ for $(s,x) \in [-\tau,0] \times \mathbb{R}$ and $w(s,x) \ge 0$ for $(s,x) \in [-\tau,\infty) \times \mathbb{R}$. We further show that $w(t,x) > 0$ for all $t > 0, x \in \mathbb{R}$. For simplicity, we write $\widetilde{F}(t,u(t,x),v(t,x)) = -g(t,u(t,x)) + b(t)\int_{\mathbb{R}} \Gamma(a(t),x-y) f_{-\tau}(t,v(t,y))dy$. It follows that

(2.9)

$$
\begin{aligned}
&\frac{\partial w(t,x)}{\partial t} \\
&= \frac{\partial u(t,x,k\phi)}{\partial t} - k\frac{\partial u(t,x,\phi)}{\partial t} \\
&= d(t)\Delta u(t,x,k\phi) + \widetilde{F}(t,u(t,x,k\phi),u(t-\tau,x,k\phi)) \\
&-k[d(t)\Delta u(t,x,\phi) + \widetilde{F}(t,u(t,x,\phi),u(t-\tau,x,\phi))] \\
&= d(t)\Delta w(t,x) + [\widetilde{F}(t,u(t,x,k\phi),u(t-\tau,x,k\phi)) - \widetilde{F}(t,ku(t,x,\phi),ku(t-\tau,x,\phi))] \\
&+[\widetilde{F}(t,ku(t,x,\phi),ku(t-\tau,x,\phi)) - k\widetilde{F}(t,u(t,x,\phi),u(t-\tau,x,\phi))] \\
&= d(t)\Delta w(t,x) - g(t,u(t,x,k\phi)) + g(t,ku(t,x,\phi)) + h(t,x) \\
&+b(t)\int_{\mathbb{R}} \Gamma(a(t),x-y)[f_{-\tau}(t,u(t-\tau,y,k\phi)) - f_{-\tau}(t,ku(t-\tau,y,\phi))]dy \\
&\ge d(t)\Delta w(t,x) - g(t,u(t,x,k\phi)) + g(t,ku(t,x,\phi)) + h(t,x) \\
&\ge d(t)\Delta w(t,x) - l_1 w(t,x) + h(t,x),
\end{aligned}
$$

where $h(t,x) = \widetilde{F}(t,ku(t,x,\phi),ku(t-\tau,x,\phi)) - k\widetilde{F}(t,u(t,x,\phi),u(t-\tau,x,\phi))$. Let $\widetilde{U}(t,s) : \mathbb{X} \to \mathbb{X}$, $0 \le s \le t$, be the evolution operator of

$$
\begin{cases}
\partial_t u(t,x) = d(t)\Delta u - l_1 u(t,x), & t > 0, \\
u(0,x) = \psi(x), & x \in \mathbb{R}, \psi \in \mathbb{X}.
\end{cases}
$$

Then $\widetilde{U}(t,s)(\psi)(x) = e^{-l_1(t-s)}U(t,s)(\psi)(x)$ for all $t \ge s \ge 0$, $x \in \Omega$, $\psi \in C$, where $U(t,s)$ is the evolution operator of (2.4). Thus, the equation

$$
\begin{cases}
\partial_t u(t,x) = d(t)\Delta u - l_1 u(t,x) + h(t,x), \\
u(0,x) = \psi(x), \quad x \in \mathbb{R}, \psi \in \mathbb{X}
\end{cases} \tag{2.10}
$$

can be written as

$$
u(t,x,\psi) = \widetilde{U}(t,0)(\psi)(x) + \int_0^t \widetilde{U}(t,s)h(s,x)ds, \quad t \ge 0, x \in \mathbb{R}, \psi \in C. \tag{2.11}
$$

By (H2), we have $h(t,x) > 0$ for all $t > 0, x \in \mathbb{R}$. It then follows from (2.11) and the property of $\widetilde{U}(t,s)$ that for any $\psi \ge 0$ with $\psi \not\equiv 0$, the solution of (2.10) satisfies $u(t,x,\psi) > 0$ for all $t > 0, x \in \mathbb{R}$. Then by (2.9) and the comparison principle, we have $w(t,x) > 0$ for all $t > 0, x \in \mathbb{R}$. Therefore, $u(t,x,k\phi) > ku(t,x,\phi)$ for all $t > 0, x \in \mathbb{R}$, and hence, $Q_t(k\phi) > kQ_t(\phi)$ for all $t > 0$, which indicates that for each $t > 0$, Q_t is strictly subhomogeneous. ∎

LEMMA 2.5. *For any $\varphi \in C_{\widehat{L}}$ with $\varphi \not\equiv 0$, $u(t,x,\varphi) > 0$ for all $t \geq \tau$, $x \in \mathbb{R}$.*

Proof. Let $\varphi \in C_{\widehat{L}}$ with $\varphi \not\equiv 0$. By Theorem 2.3, $u(t,x,\varphi) \geq 0$ for all $t \geq 0$ and $x \in \mathbb{R}$. It follows from (H1) that for any $t > 0$, $u(t,x,\varphi)$ satisfies

$$\begin{aligned}\partial_t u(t,x) &= d(t)\Delta u - g(t,u(t,x,\varphi)) + b(t)\int_{\mathbb{R}} \Gamma(a(t),x-y) f_{-\tau}(t,u(t-\tau,y,\varphi))\\ &\geq d(t)\Delta u - g(t,u(t,x,\varphi))\\ &\geq d(t)\Delta u - l_1 u(t,x,\varphi).\end{aligned}$$

By [19, Theorem 5.5.4], $u(t,x,\varphi) > 0$ for all $t > 0$, $x \in \mathbb{R}$, provided that $\varphi(0,\cdot) > 0$.

Now we show that for any $\varphi \in C_{\widehat{L}}$ with $\varphi \not\equiv 0$ and $\varphi(0,\cdot) = 0$, there exists $t_0 = t_0(\varphi) \in [0,\tau]$ such that $u(t_0,\cdot,\varphi) > 0$. Assume, by contradiction, that for some $\varphi \in C_{\widehat{L}}$ with $\varphi \not\equiv 0$ and $\varphi(0,\cdot) = 0$ we have $u(t,\cdot,\varphi) \equiv 0$ for all $t \in [0,\tau]$. It follows from (2.7) that

$$0 = \int_0^t U(t,s)b(s)\int_{\mathbb{R}} \Gamma(a(s),x-y) f_{-\tau}(s,u_s(-\tau,y))dyds, \quad t \in [0,\tau],$$

which implies that $\int_{\mathbb{R}} \Gamma(a(s),x-y) f_{-\tau}(s,u_s(-\tau,y))dy = 0$ for any $s \in [0,\tau]$, and hence, $f_{-\tau}(s,u_s(-\tau,y)) = 0$ for any $s \in [0,\tau]$, $y \in \mathbb{R}$. Then by (H1), $u_s(-\tau,y) = 0$ for any $s \in [0,\tau]$, $y \in \mathbb{R}$. That is, $\varphi \equiv 0$, a contradiction. Thus, we have $u(t_0,\cdot,\varphi) > 0$ for some $t_0 = t_0(\varphi) \in [0,\tau]$. Then for any $t > t_0$, $\widetilde{U}(t,t_0)[u(t_0,\cdot,\varphi)](x) = e^{-l_1(t-t_0)}U(t,t_0)[u(t_0,\cdot,\varphi)](x) > 0$, and hence, by the comparison principle, we have $u(t,x,\varphi) > 0$ for all $t > t_0$, $x \in \mathbb{R}$.

Therefore, for any $\varphi \in C_{\widehat{L}}$ with $\varphi \not\equiv 0$, $u(t,x,\varphi) > 0$ for all $t > \tau, x \in \mathbb{R}$. ∎

LEMMA 2.6. *For any $t > 0$, Q_t satisfies* (A1), (A2), (A4), *and* (A6) *with $b^* = \widehat{L}$, and Q_ω satisfies* (A5) *with $b^* = \beta_0^*$, where $\beta_0^* \in \mathbb{Y}_{\widehat{L}}$ with $\beta_0^*(s) = \beta^*(s)$ for all $s \in [-\tau,0]$.*

Proof. It is easy to see that Q_t satisfies (A1), (A2), and (A4) with $b^* = \widehat{L}$ for any $t > 0$.

Let $\hat{Q}_t = Q_t|_{\mathbb{Y}_{\widehat{L}}}$. Then $\hat{Q}_t : \mathbb{Y}_{\widehat{L}} \to \mathbb{Y}_{\widehat{L}}$ is the ω-periodic semiflow generated by (2.2). Moreover, it is not difficult to see that $\hat{Q}_t$ is strictly monotone for any $t \geq \tau$ and strongly monotone for any $t \geq 2\tau$ on $\mathbb{Y}_{\widehat{L}}$. Note that (2.2) has a positive ω-periodic solution $\beta^*(t)$ which is globally asymptotically stable in $\mathbb{Y}_{\widehat{L}} \setminus \{0\}$. We see that $\hat{Q}_\omega$ has only two fixed points 0 and β_0^* in $\mathbb{Y}_{\widehat{L}}$, where $\beta_0^*(s) = \beta^*(s)$ for all $s \in [-\tau,0]$. Thus, by the Dancer–Hess connecting orbit lemma (see, e.g., [23]), the map $\hat{Q}_\omega$ admits a strictly monotone full orbit $\{\varphi_n\}_{-\infty}^{\infty} \subseteq \mathbb{Y}_{\beta_0^*}$ connecting 0 to β_0^* and $\varphi_n < \varphi_{n+1}$ for any $n = 0, \pm 1, \pm 2, \ldots$. For any $\bar{n} \in \mathbb{N}$ such that $\bar{n}\omega \geq 2\tau$, since $\hat{Q}_{\bar{n}\omega}$ is strongly monotone, we have $\hat{Q}_{\bar{n}\omega}(\varphi_n) = \hat{Q}_\omega^{\bar{n}}(\varphi_n) \ll \hat{Q}_\omega^{\bar{n}}(\varphi_{n+1}) = \hat{Q}_{\bar{n}\omega}(\varphi_{n+1})$ for any $n = 0, \pm 1, \pm 2, \ldots$. That is, $\varphi_{n+\bar{n}\omega} \ll \varphi_{n+1+\bar{n}\omega}$ for any $n = 0, \pm 1, \pm 2, \ldots$. Therefore, $\varphi_n \ll \varphi_{n+1}$ for any $n = 0, \pm 1, \pm 2, \ldots$, and hence, Q_ω satisfies (A5) with $b^* = \beta_0^*$.

Now we show that Q_t satisfies (A6)(a) with $b^* = \widehat{L}$ for $t > \tau$. Fix $t_0 > \tau$ and set $a = t_0 - \tau$, $b = t_0$. Let $u(t,\varphi)$ be the solution of (2.1) with $u_0(\varphi) = \varphi \in C_{\widehat{L}}$ and define the Kuratowski measure of noncompactness of a subset A of $\mathbb{X}$ as

$$\alpha(A) = \inf\{r > 0 : A \text{ has a finite cover of diameter } \leq r\}.$$

First we prove that $\overline{\{u(t,\varphi): a\le t\le b, \varphi\in C_{\widehat{L}}\}}$ is compact in $\mathbb{X}$. By (2.7), for any $\epsilon\in(0,a), t\in[a,b]$, and $\varphi\in C_{\widehat{L}}$, we have

$$\begin{aligned}
&u(t,\varphi)\\
&= U(t,0)\varphi(0,\cdot)+\int_0^{t-\epsilon} U(t,s)B(s,u_s)ds+\int_{t-\epsilon}^{t} U(t,s)B(s,u_s)ds\\
&= U(t,t-\epsilon)\left[U(t-\epsilon,0)\varphi(0,\cdot)+\int_0^{t-\epsilon} U(t-\epsilon,s)B(s,u_s)ds\right]+\int_{t-\epsilon}^{t} U(t,s)B(s,u_s)ds\\
&= U(t,t-\epsilon)u(t-\epsilon,\varphi)+\int_{t-\epsilon}^{t} U(t,s)B(s,u_s)ds.
\end{aligned}$$

Since $\{u(t-\epsilon,\varphi), t\in[a,b], \varphi\in C_{\widehat{L}}\}$ is bounded in $\mathbb{X}_+$ and $U(t,t-\epsilon)$ is compact, we have

$$\alpha(\{U(t,t-\epsilon)u(t-\epsilon,\varphi), t\in[a,b], \varphi\in C_{\widehat{L}}\})=0.$$

It is easy to see $\{U(t,s)B(s,u_s): t\in[a,b], s\in[0,t], \varphi\in C_{\widehat{L}}\}$ is bounded in $\mathbb{X}_+$. Let $N>0$ such that $\|\ U(t,s)B(s,u_s)\ \|_{\mathbb{X}}\le N$ for all $t\in[a,b], s\in[0,t], \varphi\in C_{\widehat{L}}$. By the fact of $\alpha(A)\le\delta(A)$, where $\delta(A)$ is the diameter of $A\subseteq\mathbb{X}$, we have

$$\alpha\left(\left\{\int_{t-\epsilon}^{t} U(t,s)B(s,u_s)ds: t\in[a,b], s\in[t-\epsilon,t], \varphi\in C_{\widehat{L}}\right\}\right)\le 2\epsilon N.$$

Thus,

$$\begin{aligned}
&\alpha(\{u(t,\varphi): t\in[a,b], \varphi\in C_{\widehat{L}}\})\\
&\le \alpha(\{U(t,t-\epsilon)u(t-\epsilon,\varphi), t\in[a,b], \varphi\in C_{\widehat{L}}\})\\
&\quad+\alpha\left(\left\{\int_{t-\epsilon}^{t} U(t,s)B(s,u_s)ds: t\in[a,b], s\in[t-\epsilon,t], \varphi\in C_{\widehat{L}}\right\}\right)\\
&\le 2\epsilon N.
\end{aligned}$$

Letting $\epsilon\to 0$, we have $\alpha(\{u(t,\varphi): t\in[a,b], \varphi\in C_{\widehat{L}}\})=0$, and hence, $\{u(t,\varphi): t\in[a,b], \varphi\in C_{\widehat{L}}\}$ is precompact in $\mathbb{X}$.

Given a compact interval $I\subseteq\mathbb{R}$, let $K=\min\{K_1>0: I\subseteq[-K_1,K_1]\}$. Since $\{u(t,\varphi): t\in[a,b], \varphi\in C_{\widehat{L}}\}$ is precompact in $\mathbb{X}$, $\{u(t,\varphi)|_I: t\in[a,b],\ \varphi\in C_{\widehat{L}}\}$ is equicontinuous in $\mathbb{X}$, and hence, for any $\epsilon>0$, there exists $\delta>0$ such that

$$|u(t,x_1,\varphi)-u(t,x_2,\varphi)|<\epsilon \tag{2.12}$$

for all $t\in[a,b]$ and $\varphi\in C_{\widehat{L}}$, provided that $x_1,x_2\in I$ and $|x_1-x_2|<\delta$.

Let $[a_1,b_1]$ be any bounded interval on $\mathbb{R}$ with $a_1>0$ and let $U_0(t)$ be the semigroup generated by $u_t=\Delta u$. Then $U_0(t)\varphi(x)=\int_{-\infty}^{+\infty}\Gamma(t,x-y)\varphi(y)dy$ for all $t>0$, $x\in\mathbb{R}$, $\varphi\in\mathbb{X}$.

By the properties of Γ, we can find an $N_0>0$ such that $\int_{|y|\ge N_0}\Gamma(b_1,y)dy\le\epsilon$. Since $\frac{\partial\Gamma(t,y)}{\partial t}>0$ for all $t>0$ and $y^2>2t$, we have $\int_{|y|\ge N_1}\Gamma(t,y)dy\le\epsilon$ for all $t\in[a_1,b_1]$, where $N_1=\max\{N_0,\sqrt{2b_1}\}$. Moreover, since $\int_{-N_1}^{N_1}\Gamma(t,y)dy$ is continuous in $t\in[a_1,b_1]$, there is a $\delta_1>0$ such that $|\int_{-N_1}^{N_1}(\Gamma(t_1,y)-\Gamma(t_2,y))dy|<\epsilon$ provided that

$t_1, t_2 \in [a_1, b_1]$ and $|t_1 - t_2| < \delta_1$. Therefore, for any $t_1, t_2 \in [a_1, b_1]$ and $|t_1 - t_2| < \delta_1$, $\psi \in \mathbb{X}_{\widehat{L}}, x \in I$,

$$\begin{aligned}
&|(U_0(t_1)\psi)(x) - (U_0(t_2)\psi)(x)| \\
&= \left| \int_{\mathbb{R}} \Gamma(t_1, x-y)\psi(y)dy - \int_{\mathbb{R}} \Gamma(t_2, x-y)\psi(y)dy \right| \\
&= \left| \int_{\mathbb{R}} (\Gamma(t_1, y) - \Gamma(t_2, y))\psi(x-y)dy \right| \\
&\le \left| \int_{|y|\le N_1} (\Gamma(t_1, y) - \Gamma(t_2, y))\psi(x-y)dy \right| + \left| \int_{|y|\ge N_1} (\Gamma(t_1, y) - \Gamma(t_2, y))\psi(x-y)dy \right| \\
&< 2\epsilon L.
\end{aligned}$$

It follows from the continuity of $\eta(t)$ in $t \in \mathbb{R}_+$ and definitions of $U_0(t)$ and $U(t,s)$ that there exists $\delta_2 > 0$ such that

$$|(U(t_1, 0)\varphi(0, \cdot))(x) - (U(t_2, 0)\varphi(0, \cdot))(x)| < 2\epsilon L$$

for all $x \in I$, $\varphi \in C_{\widehat{L}}$, provided that $t_1, t_2 \in [a, b]$ and $|t_1 - t_2| < \delta_2$. Let $\bar{\delta} \in (0, \min\{\epsilon, \delta_2\})$. Then for $x \in I$, $\varphi \in C_{\widehat{L}}$, $t_1, t_2 \in [a, b]$, and $|t_1 - t_2| < \bar{\delta}$, we have

$$\begin{aligned}
&|u(t_1, x, \varphi) - u(t_2, x, \varphi)| \\
&\le |(U(t_1, 0)\varphi(0, \cdot))(x) - (U(t_2, 0)\varphi(0, \cdot))(x)| \\
&\quad + \left| \int_0^{t_1} (U(t_1, s)B(s, u_s))(x)ds - \int_0^{t_2} (U(t_2, s)B(s, u_s))(x)ds \right| \\
&\le 2L\epsilon + 2N \cdot 2^K \bar{\delta} \\
&\le 2(L + 2^K N)\epsilon,
\end{aligned} \tag{2.13}$$

where N was defined in the former paragraph of this proof. This implies that $u(t, x, \varphi)$ is equicontinuous in $t \in [a, b]$ for $x \in I$ and $\varphi \in C_{\widehat{L}}$.

Consequently, by (2.12) and (2.13), for any $\varphi \in C_{\widehat{L}}$, $\theta_1, \theta_2 \in [-\tau, 0]$, $x_1, x_2 \in I$ with $|\theta_1 - \theta_2| < \bar{\delta}$ and $|x_1 - x_2| < \delta$, we have

$$\begin{aligned}
&|u_{t_0}(\varphi)(\theta_1, x_1) - u_{t_0}(\varphi)(\theta_2, x_2)| \\
&= |u(t_0 + \theta_1, x_1, \varphi) - u(t_0 + \theta_2, x_2, \varphi)| \\
&\le |u(t_0 + \theta_1, x_1, \varphi) - u(t_0 + \theta_1, x_2, \varphi)| + |u(t_0 + \theta_1, x_2, \varphi) - u(t_0 + \theta_2, x_2, \varphi)| \\
&\le (2L + 2^{K+1}N + 1)\epsilon,
\end{aligned}$$

which indicates that $\{u_{t_0}(\varphi) : \varphi \in C_{\widehat{L}}\}$ is equicontinuous for $(\theta, x) \in [-\tau, 0] \times I$. Therefore, $\{u_{t_0}(\varphi) : \varphi \in C_{\widehat{L}}\}$ is precompact in $C_{\widehat{L}}$ and (A6)(a) follows from $Q_{t_0}(C_{\widehat{L}}) = \{u_{t_0}(\varphi) : \varphi \in C_{\widehat{L}}\}$ for $t_0 > \tau$.

Finally, we show that Q_t satisfies (A6)(b′) with $b^* = \widehat{L}$ for $0 < t \le \tau$. Fix $t_1 \in (0, \tau]$ and define

$$S[\varphi](\theta, x) := \begin{cases} \varphi(0, x), & -\tau \le \theta < -t_1, \\ Q_{t_1}(\varphi)(\theta, x), & -t_1 \le \theta \le 0 \end{cases}$$

for any $\varphi \in C_{\widehat{L}}$. By the above analysis, we know that $\{u(t,\varphi) : a \le t \le b, \varphi \in C_{\widehat{L}}\}$ is precompact in $\mathbb{X}$ for any $0 < a \le b$. In particular, fixing $a = b = t_1$, we can easily see that $\{u_{t_1}(\varphi)(0,\cdot), \varphi \in C_{\widehat{L}}\} = \{u(t_1,\cdot,\varphi), \varphi \in C_{\widehat{L}}\}$ is precompact in $\mathbb{X}$, that is, $Q_{t_1}[C_{\widehat{L}}](0,\cdot)$ is precompact in $\mathbb{X}$.

Since Q_t is an ω-periodic semiflow, it is easy to see that $S[\varphi]$ is continuous on $C_{\widehat{L}}$. Let D be a T-invariant subset of $C_{\widehat{L}}$ (i.e., $T_y D = D$ for all $y \in \mathbb{R}$) with $D(0,\cdot)$ being precompact in $\mathbb{X}$. Now we show that for any given compact interval $I \subseteq \mathbb{R}$, $S[D]$ is equicontinuous on $[-\tau, 0] \times I$, that is, for any $\epsilon > 0$, there exist $\delta_1, \delta_2 > 0$ such that $|S[\varphi](\theta_1, x_1) - S[\varphi](\theta_2, x_2)| < \epsilon$ for any $\varphi \in D$ if $\theta_1, \theta_2 \in [-\tau, 0], x_1, x_2 \in I$, and $|\theta_1 - \theta_2| < \delta_1, |x_1 - x_2| < \delta_2$.

Since $S[\varphi](\theta, x) = \varphi(0, x)$ for all $\varphi \in D$, $\theta \in [-\tau, -t_1]$, $x \in I$, and $D(0,\cdot)$ is precompact in $\mathbb{X}$, it is obvious that $S[D]$ is equicontinuous on $[-\tau, -t_1] \times I$.

Note that there exists $N > 0$ such that $\| U(t,s)B(s,u_s) \|_{\mathbb{X}} \le N$ for all $t \in [0, t_1], s \in [0,t], \varphi \in C_{\widehat{L}}$. Let $\delta_0 = \min\{\epsilon/(2^K N), t_1\}$. Then for any $t < \delta_0$, $x \in I$, and $\varphi \in D$, we have

$$\left| \int_0^t U(t,s)B(s,u_s)(x)ds \right| < 2^K N \delta_0 = \epsilon. \tag{2.14}$$

Let $\mathcal{F}(t,\psi) := U(t,0)\psi$ for $(t,\psi) \in [0,\delta_0] \times D(0,\cdot)$. Then $\mathcal{F}$ is continuous on $[0,\delta_0] \times D(0,\cdot)$ and $\mathcal{F}([0,\delta_0] \times D(0,\cdot))$ is precompact in $\mathbb{X}$. Thus, for the above I, there exists $\delta_2 > 0$ such that for $x_1, x_2 \in I$ and $|x_1 - x_2| < \delta_2$, we have

$$|U(t,0)\psi(x_1) - U(t,0)\psi(x_2)| < \epsilon \quad \forall t \in [0,\delta_0], \psi \in D(0,\cdot). \tag{2.15}$$

Moreover, since $\mathcal{F}$ is uniformly continuous on $[0,\delta_0] \times D(0,\cdot)$, there exists $\delta_1 > 0$, $\delta_3 > 0$ such that $\| \mathcal{F}(\bar{t}_1, \psi_1) - \mathcal{F}(\bar{t}_2, \psi_2) \|_{\mathbb{X}} < \epsilon/2^K$ if $\bar{t}_1, \bar{t}_2 \in [0,\delta_0]$, $\psi_1, \psi_2 \in D(0,\cdot)$, and $|\bar{t}_1 - \bar{t}_2| < \delta_1, ||\psi_1 - \psi_2||_{\mathbb{X}} < \delta_3$. In particular, we have $\| U(\bar{t}_1, 0)\psi - U(\bar{t}_2, 0)\psi \|_{\mathbb{X}} < \epsilon/2^K$ if $\bar{t}_1, \bar{t}_2 \in [0,\delta_0]$, $\psi \in D(0,\cdot)$, and $|\bar{t}_1 - \bar{t}_2| < \delta_1$. Then

$$|U(\bar{t}_1, 0)\psi(x) - U(\bar{t}_2, 0)\psi(x)| < \epsilon \quad \forall \psi \in D(0,\cdot), x \in I, \bar{t}_1, \bar{t}_2 \in [0,\delta_0], \text{ and } |\bar{t}_1 - \bar{t}_2| < \delta_1. \tag{2.16}$$

By (2.14)–(2.16), we can easily obtain that if $\theta_1, \theta_2 \in [-t_1, \delta_0 - t_1], x_1, x_2 \in I$ and $|\theta_1 - \theta_2| < \delta_1, |x_1 - x_2| < \delta_2$, then for any $\varphi \in D$,

$$\begin{aligned}
&|S[\varphi](\theta_1, x_1) - S[\varphi](\theta_2, x_2)| \\
&= |Q_{t_1}[\varphi](\theta_1, x_1) - Q_{t_1}[\varphi](\theta_2, x_2)| \\
&= |u(t_1 + \theta_1, x_1, \varphi) - u(t_1 + \theta_2, x_2, \varphi)| \\
&\le |(U(t_1 + \theta_1, 0)\varphi(0,\cdot))(x_1) - (U(t_1 + \theta_2, 0)\varphi(0,\cdot))(x_2)| \\
&\quad + \left| \int_0^{t_1+\theta_1} U(t_1 + \theta_1, s)B(s,u_s)(x_1)ds - \int_0^{t_1+\theta_2} U(t_1 + \theta_2, s)B(s,u_s)(x_2)ds \right| \\
&\le |(U(t_1 + \theta_1, 0)\varphi(0,\cdot))(x_1) - (U(t_1 + \theta_1, 0)\varphi(0,\cdot))(x_2)| \\
&\quad + |(U(t_1 + \theta_1, 0)\varphi(0,\cdot))(x_2) - (U(t_1 + \theta_2, 0)\varphi(0,\cdot))(x_2)| + 2\epsilon \\
&< 4\epsilon,
\end{aligned}$$

which implies that $S[D]$ is equicontinuous on $[-t_1, \delta_0 - t_1] \times I$.

By a similar argument as for (A6)(a), it is easy to see that S[D] is equicontinuous on $[\delta_0 - t_1, 0] \times I$.

Therefore, $S[D]$ is equicontinuous on $[-\tau, 0] \times I$, and hence, $S[D]$ is precompact in $C_{\widehat{L}}$. Thus, (A6)(b′) is valid for Q_t, $t \in (0, \tau]$. □

It then follows from Lemma 2.6 and [11, Theorems 2.11 and 2.15] that Q_ω has an asymptotic speed of spread $c^*_\omega > 0$.

Consider the linearized system of (2.1) at the zero solution:

(2.17)
$$\begin{cases} \partial_t u(t,x) = d(t)\Delta u - g_u(t,0)u(t,x) + b(t)\partial_u f_{-\tau}(t,0)\displaystyle\int_{\mathbb{R}} \Gamma(a(t), x-y)u(t-\tau,y)dy, \\ u(t,x) = \phi(t,x), \quad t \in [-\tau, 0],\ x \in \mathbb{R}. \end{cases}$$

For $\alpha > 0$, let $u(t,x) = e^{-\alpha x}v(t)$. Substituting $u(t,x)$ into (2.17) yields

$$\begin{aligned} &e^{-\alpha x}v'(t) \\ &= \dot{d}(t)\alpha^2 e^{-\alpha x}v(t) - g_u(t,0)v(t)e^{-\alpha x} + b(t)\partial_u f_{-\tau}(t,0)v(t-\tau)\textstyle\int_{\mathbb{R}} \Gamma(a(t),y)e^{-\alpha(x-y)}dy. \end{aligned}$$

Since $\Gamma(t,x)$ is even in x and by [18, Proposition 4.2], we obtain

(2.18)
$$\begin{aligned} v'(t) &= d(t)\alpha^2 v(t) - g_u(t,0)v(t) + b(t)\partial_u f_{-\tau}(t,0)v(t-\tau)\int_{\mathbb{R}} \Gamma(a(t),y)e^{\alpha y}dy, \\ &= d(t)\alpha^2 v(t) - g_u(t,0)v(t) + b(t)\partial_u f_{-\tau}(t,0)v(t-\tau)\int_{\mathbb{R}} \Gamma(a(t),y)e^{-\alpha y}dy, \\ &= d(t)\alpha^2 v(t) - g_u(t,0)v(t) + b(t)\partial_u f_{-\tau}(t,0)v(t-\tau)e^{\alpha^2 a(t)}. \end{aligned}$$

Then $u(t,x) = e^{-\alpha x}v(t)$ satisfies (2.17) with $\phi(s,x) = e^{-\alpha x}v(s)$ for $s \in [-\tau, 0]$ and $x \in \mathbb{R}$ if $v(t)$ satisfies (2.18) for $t \geq 0$.

Let M_t be the linear solution map defined by (2.17) and let $v(t, v_0)$ be the solution of (2.18) with $v(s, v_0) = v_0(s)$ for $s \in [-\tau, 0]$, $v_0 \in \mathbb{Y}$. Define $B^t_\alpha(v_0) := M_t(v_0 e^{-\alpha x})(0)$. It is not difficult to see that $B^t_\alpha(v_0) = v(t, v_0)$, and hence, B^t_α is the solution map associated with (2.18) on $\mathbb{Y}$.

Let $\gamma(\alpha)$ be the spectral radius of the Poincaré map associated with (2.18), and [21, Proposition 2.1] implies that $\gamma(\alpha) > 0$. It follows from the proof of [21, Proposition 2.1] that there exists a positive ω-periodic function $w(t)$ such that $v(t) = e^{\lambda(\alpha)t}w(t)$ is a solution of (2.18), where $\lambda(\alpha) = \frac{\ln \gamma(\alpha)}{\omega}$. Define $\psi \in \mathbb{Y}$ by $\psi(\theta) = e^{\lambda(\alpha)\theta}w(\theta)$ for all $\theta \in [-\tau, 0]$. Clearly, $v(t, \psi) = e^{\lambda(\alpha)t}w(t)$ for all $t \geq 0$. Then we have

$$B^t_\alpha(\psi)(\theta) = v(t+\theta, \psi) = e^{\lambda(\alpha)t}e^{\lambda(\alpha)\theta}w(t+\theta)\ \forall \theta \in [-\tau, 0], t \geq 0.$$

By the ω-periodicity of $w(t)$, it follows that

$$B^\omega_\alpha(\psi)(\theta) = e^{\lambda(\alpha)\omega}e^{\lambda(\alpha)\theta}w(\theta) = e^{\lambda(\alpha)\omega}\psi(\theta)\ \forall \theta \in [-\tau, 0],$$

that is, $B^\omega_\alpha(\psi) = e^{\lambda(\alpha)\omega}\psi$. This implies that $e^{\lambda(\alpha)\omega}$ is the principle eigenvalue of B^ω_α with positive eigenfunction ψ.

Let $\Phi(\alpha) := \frac{1}{\alpha}\ln e^{\lambda(\alpha)\omega} = \frac{\lambda(\alpha)\omega}{\alpha} = \frac{\ln \gamma(\alpha)}{\alpha}$. Then we have the following result.

PROPOSITION 2.7. *Assume that* (H1)–(H4) *hold. Let* c^*_ω *be the asymptotic speed of spread of* Q_ω. *Then* $c^*_\omega = \inf_{\alpha>0}\Phi(\alpha) = \inf_{\alpha>0}\frac{\ln\gamma(\alpha)}{\alpha}$.

Proof. When $\alpha = 0$, (2.18) becomes (2.3). It follows from (H4) that $\gamma(0) > 1$, and hence (C7) in [11] is satisfied. Now we prove that $\Phi(\infty) = \infty$. By (2.18), we have

$$v'(t) \geq [\alpha^2 d(t) - g_u(t,0)]v(t) \ \forall t \geq 0,$$

and hence,

$$\frac{w'(t)}{w(t)} \geq \alpha^2 d(t) - g_u(t,0) - \lambda(\alpha).$$

Then

$$0 = \int_0^\omega \frac{w'(t)}{w(t)}dt \geq \int_0^\omega (\alpha^2 d(t) - g_u(t,0))dt - \lambda(\alpha)\omega,$$

which implies that

$$\lambda(\alpha)\omega \geq \alpha^2 \int_0^\omega d(t)dt - \int_0^\omega g_u(t,0)dt.$$

Therefore,

$$\Phi(\alpha) = \frac{\lambda(\alpha)\omega}{\alpha} \geq \alpha \int_0^\omega d(t)dt - \frac{\int_0^\omega g_u(t,0)dt}{\alpha}.$$

Letting $\alpha \to \infty$, we can easily obtain $\Phi(\infty) = \infty$.

Since $G(t,\cdot,\cdot)$ is subhomogeneous in (u,v), it follows from [23, Lemma 2.3.2] that $G(t,u,v) \leq G_u(t,0,0)u + G_v(t,0,0)v$, that is,

$$-g(t,u) + b(t)f_{-\tau}(t,v) \leq -g_u(t,0)u + b(t)\partial_u f_{-\tau}(t,0)v,$$

and hence, we have

$$\begin{aligned}&-g(t,u(t,x)) + b(t)\int_{\mathbb{R}} \Gamma(a(t),x-y)f_{-\tau}(t,u(t-\tau,y))dy\\ &\leq -g_u(t,0)u(t,x) + b(t)\partial_u f_{-\tau}(t,0)\int_{\mathbb{R}} \Gamma(a(t),x-y)u(t-\tau,y)dy.\end{aligned}$$

By the comparison principle, we have $Q_\omega(\varphi) \leq M_\omega(\varphi)$ for any $\varphi \in C_{\beta^*_0}$. Thus, [11, Theorem 3.10] implies that $c^*_\omega \leq \inf_{\alpha>0}\Phi(\alpha)$.

Let $K > 0$ such that $K - g_u(t,0) > 0$ for all $t \in [0,\omega]$. Set $\bar{G}(t,u,v) = Ku + G(t,u,v)$. Then $\bar{G}_u(t,0,0) > 0$, $\bar{G}_v(t,0,0) > 0$ for all $t \in [0,\omega]$. It is easy to see that for any $\epsilon \in (0,1)$, there exists $\delta = \delta(\epsilon) \in (0,L)$ such that

$$\bar{G}(t,u,v) \geq (1-\epsilon)\bar{G}_u(t,0,0)u + (1-\epsilon)\bar{G}_v(t,0,0)v \ \forall (u,v) \in [0,\delta]^2,$$

and hence, for any $(u,v) \in [0,\delta]^2$,

$$G(t,u,v) = -Ku + \bar{G}(t,u,v) \geq [(1-\epsilon)G_u(t,0,0) - \epsilon K]u + (1-\epsilon)G_v(t,0,0)v.$$

Moreover, there exists $\xi = \xi(\delta) > 0$ such that for any $\varphi \in C_{\hat{\xi}}$, we have

$$0 \le u(t,x,\varphi) \le u(t,x,\hat{\xi}) < \delta \quad \forall x \in \mathbb{R}, t \in [0,\omega].$$

Thus, for any $\varphi \in C_{\hat{\xi}}$, $u(t,x,\varphi)$ satisfies

$$\begin{aligned}\partial_t u(t,x) \ge & d(t)\Delta u(t,x) + [(1-\epsilon)g_u(t,0) - \epsilon K]u(t,x) \\ & + (1-\epsilon)b(t)\partial_u f_{-\tau}(t,0)\int_{\mathbb{R}} \Gamma(a(t),x-y)u(t-\tau,y)dy \quad \forall t \in [0,\omega].\end{aligned}$$

Let $M_t^\epsilon, t \ge 0$, be the solution maps associated with the linear system

$$\begin{aligned}\partial_t u(t,x) = & d(t)\Delta u(t,x) + [(1-\epsilon)g_u(t,0) - \epsilon K]u(t,x) \\ & + (1-\epsilon)b(t)\partial_u f_{-\tau}(t,0)\int_{\mathbb{R}} \Gamma(a(t),x-y)u(t-\tau,y)dy \quad \forall t \in [0,\omega].\end{aligned}$$

The comparison principle implies that $M_t^\epsilon(\varphi) \le Q_t(\varphi)$ for all $\varphi \in C_{\hat{\xi}}, t \in [0,\omega]$. In particular, $M_\omega^\epsilon(\varphi) \le Q_\omega(\varphi)$ for all $\varphi \in C_{\hat{\xi}}$. By a similar analysis for M_t^ϵ as for M_t, it follows from [11, Theorem 3.10] that $\inf_{\alpha>0}\Phi_\epsilon(\alpha) \le c_\omega^*$.

Therefore, $\inf_{\alpha>0}\Phi_\epsilon(\alpha) \le c_\omega^* \le \inf_{\alpha>0}\Phi(\alpha)$ for all $\epsilon \in (0,1)$. Letting $\epsilon \to 0$, we have $c_\omega^* = \inf_{\alpha>0}\Phi(\alpha)$. □

Let $c^* = \frac{c_\omega^*}{\omega} = \frac{1}{\omega}\inf_{\alpha>0}\Phi(\alpha) = \frac{1}{\omega}\inf_{\alpha>0}\frac{\ln\gamma(\alpha)}{\alpha}$. The following result shows that c^* is the spreading speed of solutions of (2.1) with initial functions having compact support.

THEOREM 2.8. *Assume that* (H1)–(H4) *hold and let* $c^* = c_\omega^*/\omega$. *Then the following statements are valid.*

(1) *For any* $c > c^*$, *if* $\varphi \in C_{\beta_0^*}$ *with* $0 \le \varphi \ll \beta_0^*$ *and* $\varphi(\cdot,x) = 0$ *for* x *outside a bounded interval, then*

$$\lim_{t\to\infty, |x|\ge ct} u(t,x,\varphi) = 0.$$

(2) *For any* $c < c^*$, *if* $\varphi \in C_{\beta_0^*}$ *with* $\varphi \not\equiv 0$, *then*

$$\lim_{t\to\infty, |x|\le ct} (u(t,x,\varphi) - \beta^*(t)) = 0.$$

Proof. Conclusion (1) follows from [10, Theorem 2.1]. By Lemma 2.4 and [10, Theorem 2.1], for any $c < c^*$, there is a positive number σ such that, if $\varphi \in C_{\beta_0^*}$ with $\varphi(\cdot,x) > 0$ for x on an interval of length 2σ, then $\lim_{t\to\infty,|x|\le ct}(u(t,x,\varphi) - \beta^*(t)) = 0$. It follows from Lemma 2.5 that for any $\varphi \in C_{\beta_0^*}$ with $\varphi \not\equiv 0$, $Q_t(\varphi) \gg 0$ for all $t > 2\tau$. We can fix $t_0 > 2\tau$ and take $Q_{t_0}(\varphi)$ as a new initial value for $u(t,x,\varphi)$. Then by the above analysis, conclusion (2) is valid. □

We say $u(t,x) = \mathcal{U}(t,x-ct)$ is an ω-periodic traveling wave of (2.1) connecting $\beta^*(t)$ to 0 if it is a solution of (2.1), $\mathcal{U}(t,\xi)$ is ω-periodic in t, and $\mathcal{U}(t,-\infty) = \beta^*(t)$ and $\mathcal{U}(t,\infty) = 0$ uniformly for $t \in [0,\omega]$. By [10, Theorems 2.2 and 2.3], we have the following result about traveling waves of (2.1).

THEOREM 2.9. *Assume that* (H1)–(H4) *hold. Let* c^* *be defined as* $c^* = c_\omega^*/\omega$. *Then for any* $c \ge c^*$, (2.1) *has an* ω*-periodic traveling wave solution* $\mathcal{U}(t,x-ct)$ *connecting*

$\beta^*(t)$ to 0 such that $\mathcal{U}(t,s)$ is continuous and nonincreasing in s. Moreover, for any $c < c^*$, (2.1) has no ω-periodic traveling wave $\mathcal{U}(t, x-ct)$ connecting $\beta^*(t)$ to 0.

3. Dynamics in a bounded domain. In this section, we consider (1.6) in a bounded spatial domain

$$
(3.1)\quad \begin{cases} \partial_t u(t,x) = d(t)\Delta u - g(t,u) + b(t)\displaystyle\int_\Omega \Gamma(a(t), x-y) f_{-\tau}(t, u(t-\tau, y))dy, \\ \qquad\qquad (t,x) \in (0,\infty)\times\Omega, \\ Bu(t,x) = 0 \text{ on } (0,\infty)\times\partial\Omega, \\ u(t,x) = \phi(t,x), \quad t \in [-\tau, 0],\ x \in \Omega, \end{cases}
$$

where $\Omega \subseteq \mathbb{R}^n$ is a bounded domain with boundary $\partial\Omega$ of class $C^{1+\theta}(0 < \theta \le 1)$, the boundary condition is either $Bu = u$ (Dirichlet boundary condition) or $Bu = (\partial u/\partial\nu) + \alpha(x)u$ (Robin type boundary condition) for some nonnegative function $\alpha \in C^{1+\theta}(\partial\Omega, \mathbb{R})$, and $\partial u/\partial\nu$ denotes the differentiation in the direction of outward normal ν to $\partial\Omega$.

Let $p \in (1,\infty)$ be fixed. For each $\beta \in (\frac{1}{2} + \frac{1}{2p}, 1)$, let $\mathbb{X}_\beta$ be the fractional power space of $L^p(\Omega)$ with respect to $-\Delta$ and the boundary condition $Bu = 0$ (see, e.g., [8]). Then $\mathbb{X}_\beta$ is an ordered Banach space with the positive cone $\mathbb{X}_\beta^+$ consisting of all nonnegative functions in $\mathbb{X}_\beta$, and $\mathbb{X}_\beta^+$ has nonempty interior $\mathrm{int}(\mathbb{X}_\beta^+)$. Moreover, $\mathbb{X}_\beta \subseteq C^{1+\nu}(\bar\Omega)$ with continuous inclusion for $\nu \in [0, 2\beta - 1 - \frac{1}{p})$. Denote the norm on $\mathbb{X}_\beta$ by $\|\cdot\|_\beta$. Then there exists a constant $k_\beta > 0$ such that $\|\phi\|_\infty := \max_{x\in\bar\Omega}|\phi(x)| \le k_\beta \|\phi\|_\beta$ for all $\phi \in \mathbb{X}_\beta$.

Let $\bar C = C([-\tau, 0], \mathbb{X}_\beta)$ and $\bar C^+ = C([-\tau, 0], \mathbb{X}_\beta^+)$. For convenience, we identify an element $\phi \in \bar C$ as a function from $[-\tau, 0]\times\bar\Omega$ to $\mathbb{R}$ defined by $\phi(s,x) = \phi(s)(x)$. For any $N \ge L$, let $\bar C_{\widehat N} = \{\phi \in \bar C : 0 \le \phi(s,x) \le N, (s,x) \in [-\tau, 0]\times\bar\Omega\}$. For any function $y(\cdot) : [-\tau, b) \to \mathbb{X}_\beta$, where $b > 0$, define $y_t \in \bar C$, by $y_t(s) = y(t+s)$ for all $s \in [-\tau, 0]$, $t \in [0, b)$.

Note that the differential operator Δ generates an analytic semigroup $\bar U_0(t)$ on $L^p(\Omega)$ and that the standard parabolic maximum principle (see, e.g., [15, Corollary 7.2.3]) implies that the semigroup $\bar U_0(t) : \mathbb{X}_\beta \to \mathbb{X}_\beta$ is strongly positive in the sense that $\bar U_0(t)(\mathbb{X}_\beta^+ \setminus \{0\}) \subseteq \mathrm{int}(\mathbb{X}_\beta^+)$ for all $t > 0$. By a similar analysis as in section 2, we can write (3.1) as an integral equation (2.7) with $u_0 = \phi \in \bar C^+$. It then follows from [13, Corollary 5] that, for any $\phi \in \bar C_{\widehat L}$, (3.1) has a unique mild solution $u(t,x,\phi)$ with $u_0(\cdot,\cdot,\phi) = \phi$ and $u_t(\cdot,\cdot,\phi) \in \bar C_{\widehat L}$ for all $t \ge 0$. Moreover, $u(t,x,\phi)$ is a classic solution when $t > \tau$ and the comparison theorem holds for (3.1).

Define a family of operators $\{Q_t\}_{t\ge0}$ on $\bar C^+$ by

$$
Q_t(\phi)(s,x) = u(t+s,x,\phi) \quad \forall \phi \in \bar C^+, x \in \bar\Omega, \quad t \ge 0, \quad s \in [-\tau, 0].
$$

Similarly as in section 2, we can show that $\{Q_t\}_{t\ge0}$ is a monotone ω-periodic semiflow on $\bar C^+$; $u(t,x,\phi) > 0$ for $t > \tau$, $x \in \bar\Omega$, $\phi \in \bar C^+$ with $\phi \not\equiv 0$, and hence, Q_t is strongly positive for $t > 2\tau$; moreover, Q_t is compact on $\bar C^+$ for all $t > \tau$. Let $n_1 = \min\{n \in \mathbb{N}, n\omega > 2\tau\}$. Then $Q_{n_1\omega}$ is compact and strongly positive on $\bar C^+$. We

can further show that the periodic semiflow $\{Q_t\}_{t\geq 0}$ is point dissipative on $\bar{C}^+$. By [23, Theorem 1.1.3], we have the following result.

LEMMA 3.1. *Let* (H1)–(H3) *hold. Then* $Q_{n_1\omega}$ *admits a global attractor on* $\bar{C}^+$.

Consider the linearized system of (3.1) at the zero solution

(3.2)
$$\begin{cases} \partial_t \tilde{u}(t,x) = d(t)\Delta\tilde{u} - g_u(t,0)\tilde{u}(t,x) + b(t)\partial_u f_{-\tau}(t,0)\displaystyle\int_\Omega \Gamma(a(t),x-y)\tilde{u}(t-\tau,y)dy, \\ \qquad\qquad t>0, x\in\Omega, \\ B\tilde{u}(t,x) = 0, \quad t>0, x\in\partial\Omega, \\ \tilde{u}(s,x) = \phi(s,x), \quad s\in[-\tau,0],\ x\in\Omega, \phi\in\bar{C}. \end{cases}$$

Similarly as in Theorem 2.3, we can show that the comparison principle holds for (3.2), and hence, the solution map $\tilde{u}_t$ of (3.2) is monotone increasing for all $t\geq 0$.

Now we consider (3.1) and (3.2) as $n_1\omega$-periodic systems. Define the Poincaré map of (3.2) $P_1 : \bar{C}\to\bar{C}$ by $P_1(\phi) = \tilde{u}_{n_1\omega}(\phi)$ for all $\phi\in\bar{C}$, where $\tilde{u}_{n_1\omega}(\phi)(s,x) = \tilde{u}(n_1\omega+s,x,\phi)$ for all $(s,x)\in[-\tau,0]\times\bar{\Omega}$, and $\tilde{u}(t,x,\phi)$ is the solution of (3.2) with $\tilde{u}(s,x)=\phi(s,x)$ for all $(s,x)\in[-\tau,0]\times\bar{\Omega}$. Similarly as in section 2, we can obtain that P_1 is also compact and strongly positive. Let $r_1 = r(P_1)$ be the spectral radius of P_1. By the Krein–Rutman theorem (see, e.g., [8, Theorem 7.2]), $r_1>0$ and P_1 has a positive eigenfunction $\bar{\phi}\in\mathrm{int}(\bar{C}^+)$ corresponding to r_1.

LEMMA 3.2. *Let* $\mu = -\frac{1}{n_1\omega}\ln r_1$. *Then there exists a positive* $n_1\omega$*-periodic function* $v(t,x)$ *such that* $e^{-\mu t}v(t,x)$ *is a solution of* (3.2).

Proof. By the definitions of r_1 and $\bar{\phi}$, we have $P_1\bar{\phi} = r_1\bar{\phi}$. Let $\tilde{u}(t,x,\bar{\phi})$ be the solution of (3.2) with $\tilde{u}(s,x)=\bar{\phi}(s,x)$ for all $s\in[-\tau,0], x\in\Omega$. Since $\bar{\phi}\gg 0$, it is not difficult to see that $\tilde{u}(\cdot,\cdot,\bar{\phi})\gg 0$. Let $\mu = -\frac{1}{n_1\omega}\ln r_1$ and $v(t,x) = e^{\mu t}\tilde{u}(t,x,\bar{\phi})$ for all $t\geq -\tau, x\in\Omega$. Then $r_1 = e^{-n_1\omega\mu}$ and $v(t,x)>0$ for all $t\in[-\tau,\infty), x\in\Omega$. Moreover,

(3.3)
$$\begin{aligned} &v_t(t,x) \\ &= e^{\mu t}\tilde{u}_t(t,x,\bar{\phi}) + \mu e^{\mu t}\tilde{u}(t,x,\bar{\phi}) \\ &= e^{\mu t}[d(t)\Delta\tilde{u} - g_u(t,0)\tilde{u}(t,x,\bar{\phi}) \\ &+ b(t)\partial_u f_{-\tau}(t,0)\int_\Omega \Gamma(a(t),x-y)\tilde{u}(t-\tau,y,\bar{\phi})dy] + \mu v \\ &= d(t)\Delta v - g_u(t,0)v(t,x) + e^{\mu\tau}b(t)\partial_u f_{-\tau}(t,0)\int_\Omega \Gamma(a(t),x-y)v(t-\tau,y)dy + \mu v \end{aligned}$$

for all $(t,x)\in(0,\infty)\times\Omega$. Thus, $v(t,x)$ is a solution of $n_1\omega$-periodic equation (3.3) with $Bv=0$ on $(0,\infty)\times\partial\Omega$ and $v(s,x) = e^{\mu s}\bar{\phi}(s,x)$ for all $s\in[-\tau,0], x\in\Omega$.

For any $\theta\in[-\tau,0]$, $x\in\Omega$, we have

$$v(n_1\omega+\theta,x) = e^{\mu(n_1\omega+\theta)}\cdot P_1(\bar{\phi})(\theta,x) = e^{\mu(n_1\omega+\theta)}\cdot r_1\bar{\phi}(\theta,x) = e^{\mu\theta}\cdot\tilde{u}(\theta,x,\bar{\phi}) = v(\theta,x).$$

Therefore, $v_0(\theta,\cdot) = v_{n_1\omega}(\theta,\cdot)$ for all $\theta\in[-\tau,0]$, and hence, the existence and uniqueness of solutions of (3.3) imply that

$$v(t,x) = v(t+n_1\omega,x) \quad \forall t\geq -\tau, x\in\Omega,$$

that is, $v(t,x)$ is an $n_1\omega$-periodic solution of (3.3). Clearly, $e^{-\mu t}v(t,x)$ is a solution of (3.2). □

Define $P_0 : \bar{C} \to \bar{C}$ by $P_0(\phi) = \tilde{u}_\omega(\phi)$ for all $\phi \in \bar{C}$, where $\tilde{u}(t,x,\phi)$ is the solution of (3.2) with $\tilde{u}(s,x) = \phi(s,x)$ for all $s \in [-\tau, 0]$, $x \in \Omega$. Let $r_0 = r(P_0)$ be the spectral radius of P_0.

THEOREM 3.3. *Let* (H1)–(H3) *hold. For any* $\phi \in \bar{C}^+$, *denote by* $u(t,x,\phi)$ *the solution of* (3.1) *with* $u(s,x) = \phi(s,x)$ *for all* $(t,x) \in [-\tau, 0] \times \Omega$. *Then the following two statements are valid.*

(i) *If* $r_0 < 1$, *then* $\lim_{t\to\infty} \| u(t,\cdot,\phi) \|_\beta = 0$ *for every* $\phi \in \bar{C}^+$.

(ii) *If* $r_0 > 1$, *then* (3.1) *admits a unique positive* ω*-periodic solution* $u^*(t,x)$ *and* $\lim_{t\to\infty} \| u(t,\cdot,\phi) - u^*(t,\cdot) \|_\beta = 0$ *for all* $\phi \in \bar{C}^+ \setminus \{0\}$.

Proof. Since $P_1 = \tilde{u}_{n_1\omega}$, $P_0 = \tilde{u}_\omega$, and $\tilde{u}_{n_1\omega} = \tilde{u}_\omega^{n_1}$, where $\tilde{u}_t$ is the solution map of (3.2), by the properties of spectral radius of linear operators, we know that $r(P_1) = (r(P_0))^{n_1}$, i.e., $r_1 = (r_0)^{n_1}$. Note that the qualitative solutions of (3.1) and (3.2) do not change whether we consider them as $n_1\omega$-periodic systems or ω-periodic systems. The conditions in Theorem 3.3 can be replaced by $r_1 < 1$ and $r_1 > 1$, respectively. In the following, we will consider (3.1) and (3.2) as $n_1\omega$-periodic systems and prove the theorem under the conditions of $r_1 < 1$ and $r_1 > 1$.

In the case where $r_1 < 1$, we have $\mu = -\frac{1}{n_1\omega} \ln r_1 > 0$. By Lemma 3.2, (3.2) has a solution $\tilde{u}(t,x) := \tilde{u}(t,x,\bar{\phi}) = e^{-\mu t}v(t,x)$ with $\tilde{u}(s,x) = \bar{\phi}(s,x)$ for all $(s,x) \in [-\tau, 0] \times \Omega$, where $\bar{\phi} \in \text{int}(\bar{C}^+)$ is the positive eigenfunction of P_1 corresponding to r_1 and $v(t,x)$ is $n_1\omega$-periodic in $t \geq -\tau$. Then v is bounded on $[-\tau, \infty) \times \bar{\Omega}$, and hence, there exists $\rho > 0$ such that $\| v(t,\cdot) \|_\infty \leq \rho$ for all $t \geq -\tau$. Thus, $\lim_{t\to\infty} \| \tilde{u}(t,\cdot) \|_\infty = 0$. By the basic analysis of solutions of (3.2), it follows that $\lim_{t\to\infty} \| \tilde{u}(t,\cdot) \|_\beta = 0$.

Given $\phi \in \bar{C}^+$, since $\lim_{\delta\to 0^+}(\bar{\phi} - \delta\phi) = \bar{\phi} \in \text{int}(\bar{C}^+)$ for any $\epsilon > 0$, there exists $\delta_\phi > 0$, such that $\bar{\phi} - \delta\phi \in B_\epsilon(\bar{\phi}) \subseteq \bar{C}^+$ for $0 < \delta \leq \delta_\phi$, where $B_\epsilon(\bar{\phi})$ is an open ball in $\bar{C}^+$ centered at $\bar{\phi}$ with radius ϵ. Therefore, $\bar{\phi} \geq \delta_\phi\phi$ in $\bar{C}^+$. It then follows from the comparison principle that $\tilde{u}(t,x) \geq \delta_\phi \tilde{u}(t,x,\phi)$ for all $t \geq -\tau, x \in \bar{\Omega}$, where $\tilde{u}(t,\cdot,\phi)$ is the solution of (3.2) with $\tilde{u}(s,x) = \phi(s,x)$ for all $(s,x) \in [-\tau, 0] \times \Omega$. Thus, $\lim_{t\to\infty} \| \tilde{u}(t,\cdot,\phi) \|_\infty = 0$, and hence, $\lim_{t\to\infty} \| \tilde{u}(t,\cdot,\phi) \|_\beta = 0$ for any $\phi \in \bar{C}^+$.

Note that a solution of (3.1) satisfies

$$\partial_t u(t,x) \leq d(t)\Delta u - g_u(t,0)u(t,x) + b(t)\partial_u f_{-\tau}(t,0) \int_\Omega \Gamma(a(t), x-y)u(t-\tau,y)dy$$

for any $t > 0$, $x \in \Omega$. Similarly to the proof of Theorem 2.3, we can show that the comparison theorem for abstract functional differential equations [13, Proposition 3] can be applied to (3.1) and (3.2). Therefore, for any $\phi \in \bar{C}^+$, $u(t,\cdot,\phi) \leq \tilde{u}(t,\cdot,\phi)$ for all $t \geq -\tau$, where $u(t,\cdot,\phi)$ and $\tilde{u}(t,\cdot,\phi)$ are solutions of (3.1) and (3.2), respectively. It then follows that solutions of (3.1) satisfy $\lim_{t\to\infty} \| u(t,\cdot,\phi) \|_\beta = 0$ for all $\phi \in \bar{C}^+$.

In the case where $r_1 > 1$, we have $\mu < 0$. Let $\bar{C}_0 = \{\phi \in \bar{C}^+ : \phi \not\equiv 0\}$, $\partial\bar{C}_0 = \bar{C}^+ \setminus \bar{C}_0 = \{0\}$. Similarly to the proof of Lemma 2.5, we can show that for any $\phi \in \bar{C}_0$, the solution $u(t,x,\phi)$ of (3.1) satisfies $u(t,x,\phi) > 0$ for all $t > \tau$, $x \in \Omega$. It follows that $Q_t(\bar{C}_0) \subseteq int(\bar{C}^+)$ for all $t > 2\tau$. Clearly, $Q_t(0) = 0$ for all $t \geq 0$. We now have the following claim.

Claim. Zero is a uniform weak repeller for $\bar{C}_0$ in the sense that there exists $\delta_0 > 0$ such that $\lim_{t\to\infty} \sup \| Q_t(\phi) \|_\beta \geq \delta_0$ for all $\phi \in \bar{C}_0$.

Indeed, we consider the following system:

$$
\begin{cases}
\partial_t u^\varepsilon(t,x) = d(t)\Delta u^\varepsilon - (g_u(t,0)+\varepsilon)u^\varepsilon(t,x) \\
\qquad\qquad + b(t)(\partial_u f_{-\tau}(t,0)-\varepsilon)\displaystyle\int_\Omega \Gamma(a(t),x-y)u^\varepsilon(t-\tau,y)dy, \\
Bu^\varepsilon(t,x) = 0, \quad t>0, x\in\partial\Omega, \\
u^\varepsilon(s,x) = \phi(s,x), \quad s\in[-\tau,0],\ x\in\Omega, \phi\in\bar{C}.
\end{cases} \tag{3.4}
$$

Define the Poincaré map of (3.4) $P_\varepsilon : \bar{C}\to\bar{C}$ by

$$P_\varepsilon(\phi) = u^\varepsilon_{n_1\omega}(\phi) \quad \forall\phi\in\bar{C},$$

where

$$u^\varepsilon_{n_1\omega}(\phi)(s,x) = u^\varepsilon(n_1\omega+s,x,\phi) \quad \forall(s,x)\in[-\tau,0]\times\bar{\Omega}$$

and $u^\varepsilon(t,x,\phi)$ is the solution of (3.4) with $u^\varepsilon(s,x)=\phi(s,x)$ for all $s\in[-\tau,0], x\in\Omega$. Let $r_\varepsilon = r(P_\varepsilon)$ be the spectral radius of P_ε. Since $r_1 = r(P_1) > 1$, there exists a sufficiently small positive number ε_1 such that $r_\varepsilon > 1$ for all $\varepsilon\in[0,\varepsilon_1)$. We fix an $\varepsilon\in(0,\varepsilon_1)$. Since $\lim_{u\to0^+}\frac{g(t,u)}{u} = g_u(t,0)$ and $\lim_{u\to0^+}\frac{f_{-\tau}(t,u)}{u} = \partial_u f_{-\tau}(t,0)$ uniformly for $t\in[0,n_1\omega]$, there exists $\delta_\varepsilon>0$ such that $g(t,u) < (g_u(t,0)+\varepsilon)u$ and $f_{-\tau}(t,u) > (\partial_u f_{-\tau}(t,0)-\varepsilon)u$ for $u\in(0,\delta_\varepsilon)$, $t\in[0,n_1\omega]$. Let $\delta_0 = \delta_\varepsilon/k_\beta$. Suppose, by contradiction, that there exists $\phi_0\in\bar{C}_0$ such that $\lim_{t\to\infty}\sup\parallel Q_t(\phi)\parallel_\beta < \delta_0$. Then there exists $t_0>\tau$ such that $\parallel u(t,\cdot,\phi_0)\parallel_\infty \le k_\beta\parallel u(t,\cdot,\phi_0)\parallel_\beta < \delta_\varepsilon$ for all $t\ge t_0$. Therefore, $u(t,x,\phi_0)$ satisfies

$$
\begin{aligned}
&\partial_t u(t,x) \\
&> d(t)\Delta u - (g_u(t,0)+\varepsilon)u(t,x) + b(t)(\partial_u f_{-\tau}(t,0)-\varepsilon)\textstyle\int_\Omega \Gamma(a(t),x-y)u(t-\tau,y)dy
\end{aligned} \tag{3.5}
$$

for $t\ge t_0, x\in\Omega$. Let $\bar{\phi}_\varepsilon$ be the positive eigenfunction of P_ε associated with r_ε and $\mu_\varepsilon = -\frac{1}{n_1\omega}\ln r_\varepsilon$. Then by Lemma 3.2, the solution $u^\varepsilon(t,x,\bar{\phi}_\varepsilon)$ of (3.4) with $u^\varepsilon(s,x) = \bar{\phi}_\varepsilon(s,x)$ for all $s\in[-\tau,0]$, $x\in\Omega$, satisfies $u^\varepsilon(t,x,\bar{\phi}_\varepsilon) = e^{-\mu_\varepsilon t}v_\varepsilon(t,x)$, where $v_\varepsilon(t,x)$ is a positive $n_1\omega$-periodic function in $t\ge-\tau$. Since $u(t,x,\phi_0)>0$ for all $t\ge\tau$, $x\in\Omega$, there exists $\zeta>0$ such that

$$u(t_0+s,x,\phi_0)\ge\zeta u^\varepsilon(s,x,\bar{\phi}_\varepsilon) = \zeta\bar{\phi}_\varepsilon(s,x) \quad \forall s\in[-\tau,0], x\in\bar{\Omega}.$$

By (3.5) and the comparison theorem, we have

$$u(t,x,\phi_0)\ge\zeta u^\varepsilon(t-t_0,x,\bar{\phi}_\varepsilon) = \zeta e^{-\mu_\varepsilon(t-t_0)}v_\varepsilon(t,x) \quad \forall t\ge t_0, x\in\bar{\Omega}.$$

Since $\mu_\varepsilon<0$, it follows that $u(t,x,\phi_0)$ is unbounded, a contradiction. Thus, the claim is true.

By the claim above, $Q_{n_1\omega}$ is weakly uniformly persistent with respect to $(\bar{C}_0,\partial\bar{C}_0)$. Since $Q_{n_1\omega}$ admits a global attractor on $\bar{C}^+$, it follows from [23, Theorem 1.3.3] that $Q_{n_1\omega}$ is uniformly persistent with respect to $(\bar{C}_0,\partial\bar{C}_0)$ in the sense that there exists $\delta_1>0$ such that $\lim_{n\to\infty}\inf\parallel Q^n_{n_1\omega}(\phi)\parallel_\beta\ge\delta_1$ for all $\phi\in\bar{C}_0$.

Note that $Q_{n_1\omega}$ is compact, point dissipative, and uniformly persistent. It follows from [23, Theorem 1.3.6] that $Q_{n_1\omega}:\bar{C}_0\to\bar{C}_0$ admits a global attractor A_0 and

has a fixed point $\hat{\phi}$ in A_0. Similarly as in the proof of Lemma 2.4, we can show that $Q_{n_1\omega}$ is strictly subhomogeneous. Then [22, Lemma 1] implies that $Q_{n_1\omega}$ has at most one fixed point. Thus, $Q_{n_1\omega}$ has a unique equilibrium $\hat{\phi}$ in $\bar{C}_0$. Clearly, by the strong monotonicity of $Q_{n_1\omega}$, we have $\hat{\phi} \in \text{int}(\bar{C}^+)$. Moreover, it follows from [23, Theorem 2.3.2] that $A_0 = \{\hat{\phi}\}$ since $Q_{n_1\omega}$ is strongly monotone and strictly subhomogeneous. Thus, $\hat{\phi}$ is globally attractive in $\bar{C}_0$ for $Q_{n_1\omega}$.

Let $u(t, x, \hat{\phi})$ be the solution of (3.1) with $u(s, x) = \hat{\phi}(s, x)$ for all $(s, x) \in [-\tau, 0] \times \Omega$. Since $\hat{\phi}$ is a fixed point of $Q_{n_1\omega}$ and is globally attractive in $\bar{C}_0$, $u(t, x, \hat{\phi})$ is an $n_1\omega$-periodic solution of (3.1) which attracts all solutions of (3.1) in $\bar{C}^+ \setminus \{0\}$. That is,

$$\lim_{t\to\infty} \| u(t, \cdot, \phi) - u(t, \cdot, \hat{\phi}) \|_\beta = 0 \ \forall \ \phi \in \bar{C}_0.$$

Now we show that $u(t, x, \hat{\phi})$ is also ω-periodic. Since $Q_{n_1\omega}(\hat{\phi}) = \hat{\phi}$, we have $Q_\omega(Q_{n_1\omega}(\hat{\phi})) = Q_\omega(\hat{\phi})$, i.e., $Q_{n_1\omega}(Q_\omega(\hat{\phi})) = Q_\omega(\hat{\phi})$, which implies that $Q_\omega(\hat{\phi})$ is also a fixed point of $Q_{n_1\omega}$. By the fact that $\hat{\phi} \gg 0$ and the fact that Q_ω is monotone, it follows that $Q_\omega(\hat{\phi}) \gg 0$. Note that $Q_{n_1\omega}$ has a unique fixed point in $\text{int}(\bar{C}^+)$. Then $Q_\omega(\hat{\phi}) = \hat{\phi}$, that is, $\hat{\phi}$ is a fixed point of Q_ω, and hence, $u(t, x, \hat{\phi})$ is an ω-periodic solution of (3.1). Thus, $u^*(t, x) := u(t, x, \hat{\phi})$ for all $(t, x) \in [-\tau, \infty) \times \bar{\Omega}$, is the desired ω-periodic solution. □

EXISTENCE OF SOLUTIONS FOR A MODEL DESCRIBING THE DYNAMICS OF JUNCTIONS BETWEEN DISLOCATIONS*

NICOLAS FORCADEL† AND RÉGIS MONNEAU‡

Abstract. We study a dynamical version of a multiphase field model of Koslowski and Ortiz for planar dislocation networks. We consider a two-dimensional vector field which describes phase transitions between constant phases. Each phase transition corresponds to a dislocation line, and the vectorial field description allows the formation of junctions between dislocations. This vector field is assumed to satisfy a nonlocal vectorial Hamilton–Jacobi equation with nonzero viscosity. For this model, we prove the existence for all time of a weak solution.

Key words. dislocation dynamics, nonlocal equations, junctions, parabolic system of equations

1. Introduction.

1.1. Physical motivation. Dislocations are line defects in crystal, and their motion is at the origin of plastic properties of metals (see, for instance, the book of Hirth and Lothe [13]). The typical length of these dislocation lines is of the order of the micrometer, and their typical thickness is of the order of the nanometer. Dislocation lines exist in almost all metals. At low temperatures, these lines are contained in their crystallographic plane, called the slip plane. When an elastic stress field is applied, these lines can move in their slip plane. The normal velocity of these lines is then proportional to the effective stress in the material.

Another important property of dislocations is that each dislocation line is characterized by a vector quantity, called the Burgers vector (see [13] for more details). To explain this briefly, let us say that this Burgers vector reflects the microscopic nature of the dislocation defect in a crystal lattice. To fix the ideas, let us consider three unit vectors b^1, b^2, and b^3 in the plane such that

$$b^1 + b^2 + b^3 = 0. \tag{1.1}$$

Then each dislocation line can be of three different natures: with Burgers vector b^1, with Burgers vector b^2, or with Burgers vector b^3. The Burgers vector is an invariant of the dislocation line and then does not change during the evolution of the dislocation.

A consequence of the existence of this Burgers vector is the possibility for the dislocation lines to create some triple junctions, with three dislocation lines, respectively, of Burgers vector b^1, b^2, and b^3, satisfying (1.1). Indeed, in real crystals, we can observe such junctions. We can even observe networks of dislocations related by junctions. Those self-organized structures are called Frank networks (see Figure 1.1). See, also, for instance, p. 190 in Hull and Bacon [14] for such networks in body-

centered cubic (BCC) iron or p. 188 for hexagonal networks in face-centered cubic (FCC) crystals.

In the present paper, we consider a special case of a set of dislocations contained in a single slip plane, where the dislocations can move. We are interested, in particular, in the motion of the junctions between dislocations, which has not been studied a lot, both from the modeling point of view and from the mathematical analysis point of view (see, for instance, the work of Rodney, Le Bouar, and Finel [20]). Let us mention, for the stationary case, the work of Cacace and Garroni [9]. The goal of the present paper is to propose and to study a model for the dynamics of junctions of dislocations.

Nevertheless, the question of junctions has several other physical applications, and there is a lot of literature on this subject. Let us mention, for instance, the problem of crystal growth or grain growth (see Taylor [23, 24] and Bronsard and Reitich [8]). We also refer to Bonnet [7] for problems concerning the minimization of the Mumford–Shah functional.

1.2. A phase field model for the dynamics of junctions. In a phase field model, the dislocation can be represented as the phase transition of a phase parameter $\rho(x) = \rho_1(x)e^1 + \rho_2(x)e^2 \in \mathbb{R}^2$ defined for $x = x_1e^1 + x_2e^2$ in the plane $\mathbb{R}^2$ with (e^1, e^2) an orthonormal basis. As in the work of Koslowski and Ortiz [15], we consider only the case of a periodic distribution of dislocations, reducing the problem on the torus, for $x \in \mathbb{T}^2 = \mathbb{R}^2/\mathbb{Z}^2$. Then the energy of the dislocations, in the presence of a constant exterior applied resolved stress $\sigma^0 \in \mathbb{R}^2$, is then given (see [15]) by

$$\mathcal{E}(\rho) = \int_{\mathbb{T}^2} -\frac{1}{2}\left(C^0 \star \rho\right) \cdot \rho - \sigma^0 \cdot \rho + W(\rho). \tag{1.2}$$

In (1.2) and throughout the paper, we denote by $A \cdot B$ the scalar product between two vectors $A, B \in \mathbb{R}^2$. The precise meaning of the whole expression (1.2) will be explained later.

For any phase transition between two states $\rho = A$ and $\rho = B$, the difference $B - A$ needs physically to be the Burgers vector of the dislocation, i.e., a vector of the lattice $\Lambda = \mathbb{Z}a^1 + \mathbb{Z}a^2$ of the crystal we are considering, with a general given basis (a^1, a^2). This information is encoded in the potential $W : \mathbb{R}^2 \longrightarrow \mathbb{R}_+$, which is assumed to be minimal on Λ and to have the periodicity of the lattice Λ:

$$W(\rho + a) = W(\rho) \quad \text{for any} \quad a \in \Lambda. \tag{1.3}$$

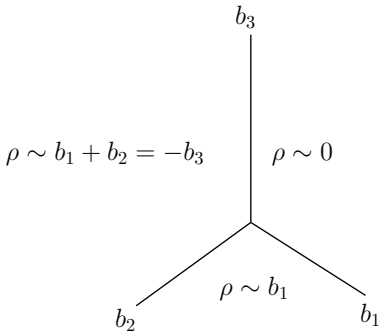

FIG. 1.2. *The junction of three dislocations as phase transitions of ρ.*

In other words, because ρ can be defined up to addition of any vector of the lattice Λ, only the transitions of ρ between two phases, i.e., two constant vectors of the lattice Λ, are physically meaningful. In particular, in this model, junctions of three dislocations of Burgers vectors $b^1, b^2, b^3 \in \Lambda$ with $b^1 + b^2 + b^3 = 0$ are expected, like, for instance, as the phase transitions between the states $0, b^1, -b^3$ (see Figure 1.2).

In the expression giving the energy (1.2), the kernel $C^0(x)$ is a 2×2 symmetric matrix which takes into account the long range elastic interactions between dislocations and

$$\left(C^0 \star \rho\right)_i = \sum_{j=1,2} C^0_{ij} \star \rho_j \quad \text{for} \quad i = 1, 2,$$

where $\star$ denotes the usual convolution on the torus $\mathbb{T}^2$. For instance, in the particular case of isotropic elasticity, for $k = (k_1, k_2) \in \mathbb{Z}^2$, the k-Fourier coefficient of the matrix C^0 is given (see [15] and also a limit case of the Peierls–Nabarro model in Alvarez et al. [3]) by

$$\widehat{C}^0(k) = -\frac{\mu}{2|k|}\left(\frac{1}{(1-\nu)} k \otimes k + k^\perp \otimes k^\perp\right), \tag{1.4}$$

where $k^\perp = (-k_2, k_1)$ is the vector obtained by a rotation of k of angle $\pi/2$. Here, $\mu > 0$ is a Lamé coefficient and $\nu \in (-1, 1/2)$ is the Poisson ratio of the material.

The fact that the matrix $-\widehat{C}^0(k)$ is nonnegative is related to the fact that the elastic energy is nonnegative. This insures that the elastic part of the energy $\int_{\mathbb{T}^2} -\frac{1}{2}(C^0 \star \rho) \cdot \rho$ created by the dislocations is nonnegative. The fact that the matrix $\widehat{C}^0(k)$ is not proportional to the identity reflects the fact that the existence of a Burgers vector associated to the dislocation line (that can be seen in the phase transition of ρ) creates some anisotropic elastic stress, even if we work in the framework of isotropic elasticity. The stress created by a dislocation line has somehow a preferred direction which is given by its Burgers vector.

When the material is submitted to an exterior shear stress, it makes the dislocations move. The dynamics of a given dislocation line is physically given by its normal velocity, which is called the resolved Peach–Koehler force. This force is the sum of the resolved exterior shear stress and the stress created by all of the dislocation lines, including the line itself. The total resolved stress $\sigma[\rho]$ is then formally given by the opposite of the gradient of the energy, i.e., $-\mathcal{E}'(\rho)$, and can be expressed as the

following nonlocal quantity:

$$\sigma[\rho] = \sigma^0 + C^0 \star \rho - W'_\rho(\rho). \tag{1.5}$$

Let us remark that one mathematical difficulty in the computation of this stress comes from the term $C^0 \star \rho$, which, from the point of view of the regularity, behaves like $\nabla\rho$, because of the linear growth of $\widehat{C^0}(k)$ in k. We have now to write an evolution equation for ρ, keeping in mind that the normal velocity has to be proportional to the stress, which means roughly speaking that

$$\rho = \bar\rho b^1 \quad \text{with} \quad \bar\rho(t,x) \in \mathbb{R}$$

has to satisfy

$$\frac{\bar\rho_t}{|\nabla\bar\rho|} = \bar\sigma[\bar\rho] \quad \text{with} \quad \bar\sigma[\bar\rho] = b^1 \cdot \sigma[\bar\rho b^1]. \tag{1.6}$$

Indeed, (1.6) is an equation very difficult to study mathematically, because $\bar\sigma[\bar\rho]$ behaves like $\nabla\bar\rho$. Up to our knowledge no results exist for (1.6), even in a framework of viscosity solutions for nonlocal equations. Indeed, one of the mathematical difficulties is due to the fact that, even putting the matrix C^0 to zero, (1.6) would become an equation like the Burgers equation, because of the presence of the derivative of the potential W in $\bar\sigma[\bar\rho]$, and could then create shocks in finite time. The presence of C^0 in the stress, even if this corresponds to a kind of degenerate diffusion (when $\nabla\bar\rho = 0$) in the equation, does not help sufficiently to get a good framework for a suitable notion of the solution to (1.6).

Because of these high mathematical difficulties and because our goal is really to deal with the dynamics of junctions of dislocations, we simplify mathematically the equation adding an artificial small viscosity $\varepsilon \in (0,1)$ and considering, instead of (1.6), the following equation:

$$\bar\rho_t = \bar\sigma[\bar\rho]|\nabla\bar\rho| + \varepsilon\Delta\bar\rho. \tag{1.7}$$

If the solution for the limit case $\varepsilon = 0$ is smooth enough, it seems reasonable to think that the solution to (1.7) is a good approximation. Moreover, any reasonable solution of the limit equation for $\varepsilon = 0$ should probably be seen as a limit of the solution to the ε-equation when ε goes to zero. Even numerically, if we would like to compute the solution in the limit case $\varepsilon = 0$, every classical numerical method introduces a numerical diffusion, which can be more or less interpreted as the additional viscosity $\varepsilon > 0$ in (1.7). For all of these reasons, (1.7) seems a good candidate for the evolution equation. As we will see in this paper, it is then mathematically possible to deal with this equation and to prove the existence of a global solution to (1.7). Nevertheless, even the study of this equation with ε-viscosity is not so simple, because, for instance, the uniqueness of the solution to (1.7) remains an open (and probably very difficult) problem in general.

As explained above, our goal is really to generalize (1.7) to take into account the evolution of junctions. To this end, we assume that the phase parameter $\rho(t,x) \in \mathbb{R}^2$ satisfies the following evolution equation:

$$\begin{cases} (\rho_k)_t = |\nabla\rho|^{-1} \displaystyle\sum_{i=1,2}\sum_{j=1,2} (\sigma[\rho])_i \nabla_j\rho_i \nabla_j\rho_k + \varepsilon\Delta\rho_k & \text{for} \quad k = 1,2 \\ & \text{in} \quad (0,T)\times\mathbb{T}^2, \\ \rho(0,x) = \rho^0(x) & \text{on} \quad \mathbb{T}^2, \end{cases} \tag{1.8}$$

where σ is given in (1.5), $\rho_t = \frac{\partial \rho}{\partial t}$ and $\nabla_j \rho_i = \frac{\partial \rho_i}{\partial x_j}$ for $i, j = 1, 2$, and

$$|\nabla \rho|^2 = \sum_{i=1,2} \sum_{j=1,2} |\nabla_j \rho_i|^2.$$

Here, we can check easily that (1.8) reduces to (1.7) when $\rho = \bar{\rho} b^1$ for any Burgers vector b^1 satisfying $|b^1| = 1$. For this reason, (1.8) seems to be a nice model to describe the general dynamics of junctions of dislocations.

Finally, let us mention that our model (1.8) has some similarities with the model of Allen and Cahn [2] on the motion of curved boundaries in which they consider gradient flow associated with a free-energy functional. This led to the study of scalar Ginzburg–Landau-type diffusion equations like

$$u_t = \Delta u - W'(u).$$

1.3. Main result. We need to introduce some assumptions that we will comment on below.

We make the following assumption on the kernel $C^0 : \mathbb{T}^2 \longrightarrow \mathbb{R}^{2\times 2}_{sym}$.

(A) We assume that there exists a constant $m > 0$ such that, for any $k \in \mathbb{Z}^2$, the Fourier coefficients of the kernel $\widehat{C}^0(k) = \int_{\mathbb{T}^2} dx\ e^{-2i\pi k\cdot x} C^0(x)$ satisfy $\widehat{C}^0(k) = M(k)$, where for any $\xi = (\xi_1, \xi_2) \in \mathbb{R}^2$ and any $p = (p_1, p_2) \in \mathbb{R}^2$

$$\text{(1.9)} \quad \begin{cases} M \in C^\infty\left(\mathbb{R}^2 \setminus \{0\}; \mathbb{R}^{2\times 2}_{sym}\right), \quad M(-\xi) = M(\xi), \quad M(\xi) = |\xi| M\left(\dfrac{\xi}{|\xi|}\right), \\ \dfrac{|\xi|\ |p|^2}{m} \geq -\displaystyle\sum_{i=1,2} \sum_{j=1,2} p_i \cdot M_{ij}(\xi) \cdot p_j \geq m|\xi|\ |p|^2 \quad \text{with} \quad |p|^2 = \displaystyle\sum_{i=1,2} (p_i)^2. \end{cases}$$

We also make the following assumption on the potential $W : \mathbb{T}^2 \longrightarrow \mathbb{R}_+$.

(B) We assume that $W \in C^2$ and W satisfies (1.3).

Condition (1.3) of assumption (B) is natural for the potential W, as explained in subsection 1.2. In assumption (B), we assume moreover that W is smooth enough (here C^2).

Assumption (A) requires more comments. First of all, remark that assumption (A) is satisfied by the matrix C^0 given by Koslowski and Ortiz [15] for isotropic elasticity (see (1.4)). Moreover, for general elasticity, the matrix $-\widehat{C}^0(k)$ has to be symmetric and nonnegative, because it corresponds physically to the nonnegative elastic energy of the dislocations. The last point concerns the 1-homogeneity in k of the matrix $\widehat{C}^0(k)$. Indeed, this is a general fact, when we compute $\widehat{C}^0(k)$ for general linear elasticity (see, for instance, the computation in the case of cubic elasticity done in Alvarez et al. [3]). Indeed, we start with a three-dimensional (3D) elastic energy, which behaves like the square of the H^1-norm of the displacement. When we consider dislocations in a single plane, as in the present model, this naturally reduces the problem from a 3D to a 2D problem and creates an energy as the square of the $H^{\frac{1}{2}}$-norm of the phase parameter, i.e., an energy like $\sum_{k\in\mathbb{Z}^2} |k||\widehat{\rho}|^2$, which is directly reflected into the 1-homogeneity in k of the matrix $\widehat{C}^0(k)$.

Then we have the following result for the model of dynamics of junctions between dislocations.

THEOREM 1.1 (existence of a solution). *Under assumptions* (A) *and* (B), *if* $\rho^0 \in (H^1(\mathbb{T}^2))^2$, *then, for any constant applied stress* $\sigma^0 \in \mathbb{R}^2$ *and for any time* $T > 0$, *there exists a solution* ρ *of* (1.8) *with* $\rho \in C^0([0, T); (L^{\frac{4}{3}}(\mathbb{T}^2))^2)$.

As mentioned above, the uniqueness of the solution is not known. Let us also mention that (1.8) is a nonlocal system of scalar equations and can be sketched as the following equation:

$$v_t = |\nabla v|^2 + \Delta v. \tag{1.10}$$

Indeed, this comes from our assumption (A) that the convolution with the kernel behaves like a first order operator. A lot of work has been done on equations (or systems) like (1.10). Let us mention, for instance, the works of Boccardo, Murat, and Puel [4, 5, 6] in which they study general equations including (1.10) and prove the existence result.

Equation (1.10) is also similar to the Navier–Stokes equations written for the potential A such that the velocity of the fluid is given by $u = \operatorname{curl} A$ (see, for instance, Leray [17]).

1.4. Organization of the paper. In section 2, we study an approximate problem of (1.8) where the right-hand side is approached by some term at most linear in the solution. The main result is proved in section 3. In a first subsection, we give some a priori estimates for the solution of the approximate problem, and then, in a second subsection, we pass to the limit in the approximate problem.

1.5. Notation. In what follows, we will denote by C a generic constant, which will then satisfy $C + C = C$, $C \cdot C = C$, and so on. We also use the following set:

$$W^{2,1;p}(Q_T) = \left\{ u \in L^p(Q_T);\ u_t \in L^p(Q_T) \text{ and } \frac{\partial^2 u}{\partial x_i, \partial x_j} \in L^p(Q_T) \text{ for } i,j = 1,2 \right\},$$

where $Q_T = (0,T) \times \mathbb{T}^2$.

2. An approximate problem. We first start to approximate the right-hand side of (1.8) by some term at most linear in the solution. To this end, we introduce a function h^n defined by

$$h^n(r) = h^0(r - n)$$

with

$$h^0(r) = \begin{cases} 1 & \text{if} \quad r \le 0, \\ 1 - r & \text{if} \quad 0 \le r \le 1, \\ 0 & \text{if} \quad r \ge 1. \end{cases}$$

We then look at the following approximate problem:

$$\begin{cases} \rho_t - \epsilon \Delta \rho = f^n[\rho] & \text{on} \quad Q_T := (0,T) \times \mathbb{T}^2, \\ \rho(0,\cdot) = \rho^0 & \text{on} \quad \mathbb{T}^2, \end{cases} \tag{2.1}$$

where

$$f^n[\rho] = h^n(|\nabla \rho|)\ |\nabla \rho|^{-1}\ (\nabla \rho)^T \cdot \nabla \rho \cdot \sigma[\rho]$$

and $\sigma[\rho]$ is given in (1.5) and is at most linear in ρ.

The natural idea to find a solution to (2.1) is to define the map Φ which associates to any function u, the solution $\rho = \Phi(u)$ of

$$\begin{cases} \rho_t - \epsilon\Delta\rho = f^n[u] & \text{on} \quad Q_T := (0,T)\times\mathbb{T}^2, \\ \rho(0,\cdot) = \rho^0 & \text{on} \quad \mathbb{T}^2, \end{cases} \tag{2.2}$$

and to prove that Φ has a fixed point in a suitable space. This way, we will prove the following result.

THEOREM 2.1 (existence of a solution for the approximate problem). *If $\rho^0 \in (H^1(\mathbb{T}^2))^2$, then, for any $n \geq 1$ and any $T > 0$, there exists a solution ρ^n of (2.1) with $\rho^n \in L^2((0,T);(H^2(\mathbb{T}^2))^2) \cap C^0([0,T);(L^2(\mathbb{T}^2))^2)$.*

In this section, we will give the proof of this theorem. In a first subsection, we will collect some preliminary results, and, in a second subsection, we will prove that Φ has a fixed point.

2.1. Preliminary results. The following lemma will be important.

LEMMA 2.2 (estimate on $C^0 \star \rho$). *For any $p \in (1,+\infty)$, there exists a constant C (depending on p and on the constant m defined in assumption* (A)*) such that, for any $\rho \in \left(W^{1,p}(\mathbb{T}^2)\right)^2$, we have*

$$\left\|C^0 \star \rho\right\|_{(L^p(\mathbb{T}^2))^2} \leq C\|\nabla\rho\|_{(L^p(\mathbb{T}^2))^{2\times 2}}. \tag{2.3}$$

Partial proof of Lemma 2.2. Let us make the proof for $p = 2$. We have, with $\sigma = \sigma[\rho]$,

$$\begin{aligned} |C^0 \star \rho|^2_{(L^2(\mathbb{T}^2))^2} &= \sum_{k\in\mathbb{Z}^2} \left|\widehat{(C^0 \star \rho)}(k)\right|^2 \\ &= \sum_{k\in\mathbb{Z}^2} \left|\widehat{C}^0(k)\cdot\widehat{\rho}(k)\right|^2 \\ &\leq \frac{1}{m^2}\sum_{k\in\mathbb{Z}^2} |k|^2|\widehat{\rho}(k)|^2 \\ &\leq \frac{1}{(2\pi m)^2}\sum_{k\in\mathbb{Z}^2} \left|\widehat{\nabla\rho}(k)\right|^2 \\ &= \frac{1}{(2\pi m)^2}|\nabla\rho|^2_{(L^2(\mathbb{T}^2))^{2\times 2}} \end{aligned}$$

which provides the result in the case $p = 2$.
The proof for the general case $p \in (1,+\infty)$ is given in Appendix A. ∎

An immediate corollary is the following estimate on the stress.

COROLLARY 2.3 (estimate on $\sigma[\rho]$). *For any $p \in (1,+\infty)$, there exists a constant C (depending on p, on the constant σ^0, on the potential W, and on the constant m defined in assumption* (A)*) such that, for any $\rho \in (W^{1,p}(\mathbb{T}^2))^2$, we have*

$$\|\sigma[\rho]\|_{(L^p(\mathbb{T}^2))^2} \leq C\left(1 + \|\nabla\rho\|_{(L^p(\mathbb{T}^2))^{2\times 2}}\right). \tag{2.4}$$

We will also need the following result.

LEMMA 2.4 (estimate on $f^n[u]$). *If $u \in (H^1(\mathbb{T}^2))^2$, then $f^n[u] \in (L^2(\mathbb{T}^2))^2$ with the following estimate:*

$$\|f^n[u]\|_{(L^2(\mathbb{T}^2))^2} \leq C(n+1)\left(1 + \|\nabla u\|_{L^2(\mathbb{T}^2)^{2\times 2}}\right),$$

where the constant C depends on σ^0, on the potential W, and on the constant m defined in assumption (A).

Proof of Lemma 2.4. Since $\mathrm{supp}(h^n) \subset [0, n+1]$, the following holds:

$$|f^n[u]| \leq (n+1)|\sigma[u]|, \tag{2.5}$$

where we have used the fact that $|B^T \cdot B \cdot p| \leq |B|^2|p|$ for $B \in \mathbb{R}^{2\times 2}$ and $p \in \mathbb{R}^2$. Then

$$\begin{aligned}\|f^n[u]\|_{(L^2(\mathbb{T}^2))^2} \leq & (n+1)\|\sigma[u]\|_{(L^2(\mathbb{T}^2))^2} \\ \leq & C(n+1)\left(1 + \|\nabla u\|_{L^2(\mathbb{T}^2)^{2\times 2}}\right),\end{aligned}$$

where we have used Corollary 2.3. □

We now recall some classical results. We start with the following parabolic estimates for the following equation:

$$\begin{cases} g_t - \epsilon\Delta g = f & \text{on} \quad Q_T := (0,T)\times\mathbb{T}^2, \\ g(0,\cdot) = g^0 & \text{on} \quad \mathbb{T}^2. \end{cases} \tag{2.6}$$

Proposition 2.5 (parabolic estimates for the heat equation). *Let $g^0 \in H^1(\mathbb{T}^2)$ and $f \in L^2(Q_T)$. Then there exists a unique solution g to* (2.6) *with*

$$g \in L^2\left((0,T); H^2\left(\mathbb{T}^2\right)\right) \cap L^\infty\left((0,T); H^1\left(\mathbb{T}^2\right)\right), \quad g_t \in L^2(Q_T). \tag{2.7}$$

We have the following estimate:

$$\begin{aligned}&\sup_{0\leq t\leq T} \|g(t)\|_{H^1(\mathbb{T}^2)} + \|g\|_{L^2((0,T);H^2(\mathbb{T}^2))} + \|g_t\|_{L^2((0,T);L^2(\mathbb{T}^2))} \\ &\leq C_T\left(\|f\|_{L^2(Q_T)} + \|g^0\|_{H^1(\mathbb{T}^2)}\right),\end{aligned} \tag{2.8}$$

where the constant C_T depends only on T and ε.

Moreover, we have

$$\sup_{0\leq t\leq T}\int_{\mathbb{T}^2} g^2(t) + 4\varepsilon\int_0^T\int_{\mathbb{T}^2}|\nabla g|^2 \leq 4\int_{\mathbb{T}^2}\left(g^0\right)^2 + 16T\int_0^T\int_{\mathbb{T}^2} f^2. \tag{2.9}$$

Proof of Proposition 2.5. For the proof of (2.7)–(2.8), we refer to Evans [11, Theorem 5, p. 360].

To prove (2.9), we simply multiply (2.6) by g and integrate over $\mathbb{T}^2$ and $(0,t)$, taking the supremum for $0 \leq t \leq T$. We get

$$\sup_{0\leq t\leq T}\int_{\mathbb{T}^2}\frac{g^2(t)}{2} \leq \sup_{0\leq t\leq T}\left(\int_{\mathbb{T}^2}\frac{g^2(t)}{2} + \varepsilon\int_0^t\int_{\mathbb{T}^2}|\nabla g|^2\right) \leq \int_{\mathbb{T}^2}\frac{\left(g^0\right)^2}{2} + \int_0^T\int_{\mathbb{T}^2}|g\ f| \tag{2.10}$$

and

$$\varepsilon\int_0^T\int_{\mathbb{T}^2}|\nabla g|^2 \leq \int_{\mathbb{T}^2}\frac{g^2(T)}{2} + \varepsilon\int_0^T\int_{\mathbb{T}^2}|\nabla g|^2 \leq \int_{\mathbb{T}^2}\frac{\left(g^0\right)^2}{2} + \int_0^T\int_{\mathbb{T}^2}|g\ f|. \tag{2.11}$$

Summing (2.10) and (2.11), we finally get

$$\sup_{0\leq t\leq T}\int_{\mathbb{T}^2}\frac{g^2(t)}{2} + \varepsilon\int_0^T\int_{\mathbb{T}^2}|\nabla g|^2 \leq \int_{\mathbb{T}^2}\left(g^0\right)^2 + 2\int_0^T\int_{\mathbb{T}^2}|g\ f|.$$

We now use the fact that

$$2\int_0^T\int_{\mathbb{T}^2}|g\ f| \le 2\left(\int_0^T\int_{\mathbb{T}^2} g^2\right)^{\frac{1}{2}}\cdot\left(\int_0^T\int_{\mathbb{T}^2} f^2\right)^{\frac{1}{2}}$$

$$\le 2\left(T\sup_{0\le t\le T}\int_{\mathbb{T}^2} g^2(t)\right)^{\frac{1}{2}}\cdot\left(\int_0^T\int_{\mathbb{T}^2} f^2\right)^{\frac{1}{2}}$$

$$\le \quad \frac{1}{4}\sup_{0\le t\le T}\int_{\mathbb{T}^2} g^2(t) + 4T\int_0^T\int_{\mathbb{T}^2} f^2,$$

which implies the result. □

We also recall the following theorem.

THEOREM 2.6 (Schaefer's fixed point theorem). *Let X be a real Banach space. Suppose that*

$$\Phi : X \to X$$

is a continuous and compact mapping. Assume further that the set

$$\{u \in X, \quad u = \lambda\Phi(u) \quad \text{for some} \quad \lambda \in [0,1]\}$$

is bounded. Then Φ has a fixed point.

For the proof of this theorem, we refer to Evans [11, Theorem 4, p. 504].

Finally, we will need some compactness argument and a weak continuity property contained in the following two classical results.

PROPOSITION 2.7 (compactness). *We recall that*

$$W^{2,1;2}(Q_T) = \left\{g \in L^2\left((0,T);H^2\left(\mathbb{T}^2\right)\right), \quad g_t \in L^2(Q_T)\right\}.$$

Then the injection

$$W^{2,1;2}(Q_T) \longrightarrow L^2\left((0,T);H^1\left(\mathbb{T}^2\right)\right) \quad \text{is compact.}$$

For the proof of this result, we refer to Lions [18, Theorem 5.1, p. 58].

PROPOSITION 2.8 (continuity). *With the notation of Proposition* 2.7, *let us consider a sequence $(g^m)_m$ such that*

$$g^m \rightharpoonup g \quad \text{weakly in} \quad W^{2,1;2}(Q_T).$$

We assume, also, that $g^m_{|t=0} = \rho^0$. Then

$$g_{|t=0} = \rho^0.$$

This result is classical, but for the reader's convenience we give the proof in Appendix A.

2.2. Proof of Theorem 2.1. We are now ready to make the proof of Theorem 2.1. To this end, for any $T > 0$, we set

$$X_T = L^2\left((0,T);H^1\left(\mathbb{T}^2\right)\right).$$

In all that follows, the index n is assumed fixed. We first remark that if $u \in X_T^2$, then $f^n[u] \in (L^2(Q_T))^2$, and then we can consider the solution ρ of

$$\begin{cases} \rho_t - \epsilon\Delta\rho = f^n[u] & \text{on} \quad Q_T := (0,T)\times\mathbb{T}^2, \\ \rho(0,\cdot) = \rho^0 & \text{on} \quad \mathbb{T}^2, \end{cases} \tag{2.12}$$

which satisfies $\rho \in X_T^2$ because of the parabolic estimates of Proposition 2.5. Then we set $\Phi(u) = \rho$ and see that Φ maps X_T^2 into X_T^2. We will prove that Φ admits a fixed point using Schaefer's fixed point theorem. We do the proof in four steps.

Step 1 (weak continuity of Φ). Let us consider sequences $(u^m)_m, (\rho^m)_m$ such that

$$\begin{cases} u^m \in X_T^2, \quad \rho^m = \Phi(u^m), \\ u^m \longrightarrow u \quad \text{in} \quad X_T^2. \end{cases}$$

From Lemma 2.4, we deduce that

$$||f^n[u^m]||_{(L^2(Q_T))^2} \leq C(n+1)\left(1 + ||u^m||_{X_T^2}\right). \tag{2.13}$$

From the parabolic estimates (Proposition 2.5), we deduce that ρ^m is bounded in $(W^{2,1;2}(Q_T))^2$; i.e., there exists a constant $C > 0$ such that

$$||\rho^m||_{(W^{2,1;2}(Q_T))^2} \leq C. \tag{2.14}$$

Therefore, up to a subsequence, we have

$$\rho^m \rightharpoonup \rho \quad \text{in} \quad \left(W^{2,1;2}(Q_T)\right)^2,$$

and, from Proposition 2.8, we deduce that

$$\rho_{|t=0} = \rho^0 \quad \text{on} \quad \mathbb{T}^2.$$

We now claim that

$$f^n[u^m] \longrightarrow f^n[u] \quad \text{in} \quad L^1(Q_T). \tag{2.15}$$

Indeed, we can write

$$f^n[u] = g^n(\nabla u)\cdot\sigma[u] \quad \text{with} \quad g^n(\nabla u) := h^n(|\nabla u|)\ |\nabla u|^{-1}\ (\nabla u)^T \cdot \nabla u.$$

From Lemma 2.2, for $p = 2$, and the continuity of W', we already deduce that

$$\sigma[u^m] \longrightarrow \sigma[u] \quad \text{in} \quad L^2(Q_T). \tag{2.16}$$

From the convergence of u^m to u in X_T^2, we deduce that, up to a subsequence, we have $\nabla u^m \longrightarrow \nabla u$ a.e. in Q_T. Now, from the fact that g^n is continuous and bounded, we deduce, in particular, that

$$g^n(\nabla u^m) \longrightarrow g^n(\nabla u) \quad \text{in} \quad L^2(Q_T). \tag{2.17}$$

Then the convergence (2.15) follows from (2.16) and (2.17).

Therefore, we conclude that ρ solves (2.12). Finally, by uniqueness of the solutions of (2.12), we deduce that the limit ρ does not depend on the choice of the subsequence and then that the full sequence converges:

$$\rho^m \rightharpoonup \rho \quad \text{weakly in} \quad \left(W^{2,1;2}(Q_T)\right)^2, \quad \text{with} \quad \rho = \Phi(u).$$

Step 2 (compactness of Φ). The compactness (and the usual strong continuity) of Φ follows from the compactness of the injection $(W^{2,1;2}(Q_T))^2 \longrightarrow X_T^2$ (see Proposition 2.7).

Step 3 (a priori bounds on the solutions of $u = \lambda\Phi(u)$ for T small). Let us consider a solution u of

$$u = \lambda\Phi(u) \quad \text{for some} \quad \lambda \in [0,1]. \tag{2.18}$$

Then, from the parabolic estimates (2.9), we have

$$\begin{aligned}
&\sup_{0\le t\le T}\int_{\mathbb{T}^2}|u(t)|^2 + 4\varepsilon\int_0^T\int_{\mathbb{T}^2}|\nabla u|^2\\
&\le 4\int_{\mathbb{T}^2}\left|\rho^0\right|^2 + 16T\int_0^T\int_{\mathbb{T}^2}|\lambda f^n[u]|^2\\
&\le 4\int_{\mathbb{T}^2}\left|\rho^0\right|^2 + 32TC^2(n+1)^2\left(T + \int_0^T\int_{\mathbb{T}^2}|\nabla u|^2\right),
\end{aligned}$$

where, in the third line, we have used Lemma 2.4 and the fact that $|\lambda| \le 1$. Therefore, for

$$T \le T^* := \left(16C^2(n+1)^2\right)^{-1}\varepsilon \tag{2.19}$$

we have

$$\sup_{0\le t\le T}\int_{\mathbb{T}^2}|u(t)|^2 + 2\varepsilon\int_0^T\int_{\mathbb{T}^2}|\nabla u|^2 \le 4\int_{\mathbb{T}^2}\left|\rho^0\right|^2 + 2\varepsilon T,$$

which proves that there exists a constant $C > 0$ such that any solution of (2.18) satisfies

$$||u||_{X_T^2} \le C.$$

We can then apply Schaefer's fixed point theorem (Theorem 2.6) to deduce that Φ has a fixed point on X_T^2, and, therefore, there is a solution ρ of (2.1) on the time interval $(0,T)$ if T satisfies (2.19), i.e., if T is small enough independently on the initial data ρ^0.

Step 4 (solution for any time). Let us call $\rho(\rho^0,t)$ the function $\rho(t,\cdot)$ obtained at Step 3 as a solution of (2.1) on the time interval $[0,T^*)$ with initial data ρ^0. From the parabolic estimates (Proposition 2.5), we also know that $\rho(t,\cdot) \in (H^1(\mathbb{T}^2))^2$ for any $t \in [0,T^*)$. Then we can define with $\tau = T^*/2$

$$u(0) = \rho^0 \quad \text{and} \quad u(t) = \rho\left(u(k\tau),t\right) \quad \text{if} \quad k\tau \le t < (k+1)\tau \quad \text{with} \quad k \in \mathbb{N}.$$

Using the fact that $u_t \in L^2_{loc}((0,+\infty);(L^2(\mathbb{T}^2))^2)$ and the fact that the problem is invariant by translation in time, we can easily check that u solves (2.1) for any $T > 0$ and provides the desired solution $\rho^n = u$ of Theorem 2.1.

This ends the proof of Theorem 2.1. □

3. A priori estimates and proof of Theorem 1.1.

3.1. A priori estimates. We have the following a priori estimates.

LEMMA 3.1 (a priori estimates). *There exists a constant $C > 0$ such that, for all $T > 0, n \geq 1$, and $0 < \varepsilon < 1$, any solution ρ^n of (2.1) given by Theorem 2.1 satisfies*

$$\|\rho^n\|^2_{L^\infty\left((0,T);\left(H^{\frac{1}{2}}(\mathbb{T}^2)\right)^2\right)} \leq Ce^{\frac{CT}{\varepsilon}}, \tag{3.1}$$

$$\|\rho^n\|^2_{L^2\left((0,T);\left(H^{\frac{3}{2}}(\mathbb{T})\right)^2\right)} \leq \frac{C}{\varepsilon}e^{\frac{CT}{\varepsilon}}, \tag{3.2}$$

and

$$\left\|h^n(|\nabla\rho^n|)|\nabla\rho^n|^{-\frac{1}{2}}\nabla\rho^n \cdot \sigma[\rho^n]\right\|^2_{(L^2(Q_T))^2} \leq Ce^{\frac{CT}{\varepsilon}}. \tag{3.3}$$

Proof of Lemma 3.1.

Step 1 (preliminaries on the energy). We first recall the expression of the energy for a general $\mathbb{Z}^2$-periodic smooth function $\rho(x) = (\rho_1(x), \rho_2(x))$:

$$\mathcal{E}(\rho) = \int_{\mathbb{T}^2} -\frac{1}{2}\left(C^0 \star \rho\right) \cdot \rho - \sigma^0 \cdot \rho + W(\rho).$$

For future use, we start to evaluate from below the first term in the energy, using Fourier series

$$\begin{aligned}\int_{\mathbb{T}^2} -\left(C^0 \star \rho\right) \cdot \rho &= \sum_{k\in\mathbb{Z}^2} -\widehat{(C^0 \star \rho)}(k) \cdot \widehat{\rho}^*(k) \\ &= \sum_{k\in\mathbb{Z}^2} -\left(\widehat{C}^0(k) \cdot \widehat{\rho}(k)\right) \cdot \widehat{\rho}^*(k) \\ &\geq m \sum_{k\in\mathbb{Z}^2} |k|\ |\widehat{\rho}(k)|^2,\end{aligned}$$

where we have used, in the first line, the fact that ρ and C^0 are real, and, in the last line, we have used assumption (A). Then we define

$$||\rho||^2_{\left(\dot{H}^{\frac{1}{2}}(\mathbb{T}^2)\right)^2} := \sum_{k\in\mathbb{Z}^2} |k|\ |\widehat{\rho}(k)|^2.$$

Similarly, we compute

$$\begin{aligned}&\int_{\mathbb{T}^2} -\left(C^0 \star (\nabla\rho)^T\right) : \nabla\rho \\ &= (2\pi)^2 \sum_{k\in\mathbb{Z}^2} -\left(\widehat{C}^0(k) \cdot \widehat{\rho}(k) \otimes (ik)\right) : (ik)^* \otimes \widehat{\rho}^*(k) \\ &= (2\pi)^2 \sum_{k\in\mathbb{Z}^2} -|k|^2\left(\widehat{C}^0(k) \cdot \widehat{\rho}(k)\right) : \widehat{\rho}^*(k) \\ &\geq (2\pi)^2 m \sum_{k\in\mathbb{Z}^2} |k|^3\ |\widehat{\rho}(k)|^2,\end{aligned}$$

where we have used assumption (A) in the last line. Then we define

$$||\rho||^2_{\left(\dot{H}^{\frac{3}{2}}(\mathbb{T}^2)\right)^2} := \sum_{k\in\mathbb{Z}^2} |k|^3\ |\widehat{\rho}(k)|^2.$$

Step 2 (estimate on the time derivative of the energy). Let us fix $T > 0$. We know that any solution ρ^n given by Theorem 2.1 belongs to the space $W^{2,1;2}(Q_T)$. In particular, using the following general fact (because of assumption (A))

$$\int_{\mathbb{T}^2} -\left(C^0 \star \rho\right)\cdot\rho = \mathrm{Re}\left(\sum_{k\in\mathbb{Z}^2} -|k|\left(\hat{C}^0\left(\frac{k}{|k|}\right)\cdot\widehat{\rho}(k)\right)\cdot\widehat{\rho}^*(k)\right)$$

we deduce that the energy $\mathcal{E}(\rho^n(t))$ is well-defined for almost every $t \in [0,T)$ and that, for almost every time $t \in [0,T)$, we have

$$\begin{aligned}
\frac{d}{dt}\mathcal{E}(\rho^n(t)) &= \int_{\mathbb{T}^2} -\sigma[\rho^n]\cdot\rho^n_t \\
&= \int_{\mathbb{T}^2} -h^n(|\nabla\rho^n|)|\nabla\rho^n|^{-1}\ |\nabla\rho^n\cdot\sigma[\rho^n]|^2 - \varepsilon\sigma[\rho^n]\cdot\Delta\rho^n \\
&= \int_{\mathbb{T}^2} -h^n(|\nabla\rho^n|)|\nabla\rho^n|^{-1}\ |\nabla\rho^n\cdot\sigma[\rho^n]|^2 \\
&\quad - \int_{\mathbb{T}^2} \varepsilon\left\{W''(\rho^n) : ((\nabla\rho^n)^T\cdot\nabla\rho^n) - \left(C^0\star(\nabla\rho^n)^T\right) : \nabla\rho^n\right\}.
\end{aligned}$$

Therefore,

$$\begin{aligned}
&\frac{d}{dt}\mathcal{E}(\rho^n(t)) + \int_{\mathbb{T}^2} h^n(|\nabla\rho^n|)|\nabla\rho^n|^{-1}\ |\nabla\rho^n\cdot\sigma[\rho^n]|^2 \\
&\leq C\varepsilon\left\{\int_{\mathbb{T}^2}|\nabla\rho^n|^2 + \left(C^0\star(\nabla\rho^n)^T\right) : \nabla\rho^n\right\}. \qquad (3.4)
\end{aligned}$$

But now (with a generic constant C)

$$\begin{aligned}
\|\nabla\rho^n\|^2_{(L^2(\mathbb{T}^2))^{2\times 2}} &\leq C\sum_{k\in\mathbb{Z}^2}|k|^2|\widehat{\rho}^n(k)|^2 \\
&\leq C\sum_{k\in\mathbb{Z}^2}|k|^{\frac{3}{2}}|\widehat{\rho}^n(k)|\cdot|k|^{\frac{1}{2}}|\widehat{\rho}^n(k)| \\
&\leq C\left(\sum_{k\in\mathbb{Z}^2}\frac{1}{2\alpha}|k|^3|\widehat{\rho}^n(k)|^2 + \frac{\alpha}{2}|k||\widehat{\rho}^n(k)|^2\right) \\
&\leq C\left(\int_{\mathbb{T}^2} -\frac{1}{\alpha}\left(C^0\star(\nabla\rho^n)^T\right) : \nabla\rho^n + \int_{\mathbb{T}^2} -\alpha\left(C^0\star\rho^n\right)\cdot\rho^n\right),
\end{aligned}$$

where $\widehat{\rho}^n(k)$ are the Fourier coefficients of ρ^n and α is a constant which will be precised later. We then deduce finally that

$$\begin{aligned}
&\frac{d}{dt}\mathcal{E}(\rho^n(t)) + \int_{\mathbb{T}^2} h^n(|\nabla\rho^n|)|\nabla\rho^n|^{-1}\ |\nabla\rho^n\cdot\sigma[\rho^n]|^2 \\
&\leq -C\varepsilon\left(1-\frac{1}{\alpha}\right)\int_{\mathbb{T}^2} -\left(C^0\star(\nabla\rho^n)^T\right) : \nabla\rho^n + C\varepsilon\alpha\int_{\mathbb{T}^2} -\left(C^0\star\rho^n\right)\cdot\rho^n \qquad (3.5) \\
&\leq -C\varepsilon\|\rho^n(t)\|^2_{\left(\dot{H}^{\frac{3}{2}}(\mathbb{T}^2)\right)^2} + C\varepsilon\left(1+\mathcal{E}(\rho^n(t)) + \left|\sigma^0\right|\left|\int_{\mathbb{T}^2}\rho^n(t)\right|\right)
\end{aligned}$$

for α chosen large enough, with C a suitable positive constant.

Step 3 (estimate on the time derivative of the mean value of the solution). Integrating in space equation (2.1), we get

$$\frac{d}{dt}\int_{\mathbb{T}^2}\rho^n(t) \quad = \int_{\mathbb{T}^2} h^n(|\nabla\rho^n|)|\nabla\rho^n|^{-1}\ (\nabla\rho^n)^T\cdot\nabla\rho^n\cdot\sigma[\rho^n]$$

and then

(3.6)
$$\begin{aligned}\frac{d}{dt}\left|\int_{\mathbb{T}^2}\rho^n(t)\right| &\le \int_{\mathbb{T}^2}(h^n(|\nabla\rho^n|)|\nabla\rho^n|)^{\frac12}\cdot\left(\left(h^n(|\nabla\rho^n|)|\nabla\rho^n|^{-1}\right)^{\frac12}|\nabla\rho^n\cdot\sigma[\rho^n]|\right)\\ &\le \int_{\mathbb{T}^2}\left(1+|\sigma^0|\right)h^n(|\nabla\rho^n|)|\nabla\rho^n|\\ &\quad+\frac{1}{4(1+|\sigma^0|)}h^n(|\nabla\rho^n|)|\nabla\rho^n|^{-1}|\nabla\rho^n\cdot\sigma[\rho^n]|^2.\end{aligned}$$

Step 4 (estimate on the energy). Setting

$$F^n(t)=1+\mathcal{E}(\rho^n(t))+\left(1+|\sigma^0|\right)\left|\int_{\mathbb{T}^2}\rho^n(t)\right|+\left(1+|\sigma^0|\right)^4, \tag{3.7}$$

we deduce from (3.5) and (3.6) that

$$\begin{aligned}&\frac{d}{dt}F^n(t)+\frac34\int h^n(|\nabla\rho^n|)|\nabla\rho^n|^{-1}|\nabla\rho^n\cdot\sigma[\rho^n]|^2\\ &\le -C\varepsilon\|\rho^n(t)\|^2_{\left(\dot H^{\frac32}(\mathbb{T}^2)\right)^2}+C\varepsilon\left(1+\mathcal{E}(\rho^n(t))+|\sigma^0|\left|\int_{\mathbb{T}^2}\rho^n(t)\right|\right)\\ &\quad+\left(1+|\sigma^0|\right)^2\int_{\mathbb{T}^2}h^n(|\nabla\rho^n|)|\nabla\rho^n|.\end{aligned}$$

Now we remark that

$$\begin{aligned}\left(1+|\sigma^0|\right)^2\int_{\mathbb{T}^2}h^n(|\nabla\rho^n|)|\nabla\rho^n| &\le \left(1+|\sigma^0|\right)^2\int_{\mathbb{T}^2}|\nabla\rho^n|\\ &\le \frac{C\varepsilon}{2}\int_{\mathbb{T}^2}|\nabla\rho^n|^2+\frac{\left(1+|\sigma^0|\right)^4}{2C\varepsilon}.\end{aligned}$$

Using the fact that (since the domain is bounded)

$$\int_{\mathbb{T}^2}|\nabla\rho^n|^2\le\|\rho^n(t)\|^2_{\left(\dot H^{\frac32}(\mathbb{T}^2)\right)^2},$$

we get

$$\begin{aligned}&\frac{d}{dt}F^n(t)+\frac34\int_{\mathbb{T}^2}h^n(|\nabla\rho^n|)|\nabla\rho^n|^{-1}|\nabla\rho^n\cdot\sigma[\rho^n]|^2+\frac{C\varepsilon}{2}\|\rho^n(t)\|^2_{\left(\dot H^{\frac32}(\mathbb{T}^2)\right)^2}\\ &\le C\varepsilon\left(1+\mathcal{E}(\rho^n(t))+\left|\sigma^0\right|\left|\int_{\mathbb{T}^2}\rho^n(t)\right|\right)+\frac{\left(1+|\sigma^0|\right)^4}{2C\varepsilon}\\ &\le\frac{C}{\varepsilon}F^n(t).\end{aligned} \tag{3.8}$$

This implies, using the Gronwall lemma,

$$F^n(t) \le F^n(0) e^{\frac{C}{\varepsilon}t}. \tag{3.9}$$

Step 5 (estimate on ρ^n). Let us first remark that

$$\mathcal{E}(\rho^n(t)) \ge \int -\frac{1}{2}\left(C^0 \star \rho^n\right)\cdot \rho^n - \left|\sigma^0\right| \left| \int_{\mathbb{T}^2} \rho^n(t) \right|. \tag{3.10}$$

Using (3.9), (3.10), and the definition of $F^n(t)$ yields

$$\int_{\mathbb{T}^2} -\frac{1}{2}\left(C^0 \star \rho^n\right)\cdot \rho^n + \left| \int_{\mathbb{T}^2} \rho^n(t) \right| \le C e^{\frac{C}{\varepsilon}t}.$$

Using Step 1, we then get

$$\|\rho^n\|^2_{L^\infty\left((0,T);\left(\dot{H}^{\frac{1}{2}}(\mathbb{T}^2)\right)^2\right)} \le C e^{\frac{C}{\varepsilon}T} \quad \text{and} \quad \left| \int_{\mathbb{T}^2} \rho^n(t) \right| \le C e^{\frac{C}{\varepsilon}T}.$$

This implies (3.1). Taking the integral $\int_0^T$ in (3.8) and using the fact that $\forall t \le T$, $F^n(t) \ge 0$, we get

$$\|h_n(|\nabla\rho^n|)|\nabla\rho^n|^{-\frac{1}{2}}\nabla\rho^n \cdot \sigma[\rho^n]\|^2_{(L^2(Q_T))^2} + \varepsilon C \|\rho^n\|^2_{L^2\left((0,T);\left(\dot{H}^{\frac{3}{2}}(\mathbb{T}^2)\right)\right)} \le C e^{\frac{C}{\varepsilon}T},$$

which implies (3.2) and (3.3). ∎

3.2. Proof of Theorem 1.1. We are now able to prove Theorem 1.1. In this section, we denote by C a generic constant which can depend on ρ^0, ε, and T but which does not depend on n.

Proof of Theorem 1.1. Let $T > 0$. The idea of the proof is to pass to the limit in (2.1). The only difficulty is to prove that the nonlinear term $f^n[\rho^n]$ converges in a certain sense to $|\nabla\rho|^{-1}(\nabla\rho)^T \cdot \nabla\rho \cdot \sigma[\rho]$, where ρ is the limit of ρ^n in an appropriate norm. The proof is decomposed into five steps.

Step 1 (a priori bound on $f^n[\rho^n]$). We have the following estimate on $f^n[\rho^n]$:

$$\|f^n[\rho^n]\|_{\left(L^{\frac{4}{3}}(Q_T)\right)^2} \le C. \tag{3.11}$$

To prove this, let us write

$$f^n[\rho^n] = \left(|\nabla\rho^n|^{-1}(\nabla\rho^n)^T\right)\cdot\left(|\nabla\rho^n|^{\frac{1}{2}}\right)\left(h_n(|\nabla\rho^n|)|\nabla\rho^n|^{-\frac{1}{2}}\nabla\rho^n\cdot\sigma[\rho^n]\right).$$

Using (3.3), we have that the last term is bounded in $(L^2(Q_T))^2$ by C. Moreover, the first term is bounded by 1 in $(L^\infty(Q_T))^{2\times 2}$, and then we just have to bound the term $|\nabla\rho^n|^{\frac{1}{2}}$ in $L^4(Q_T)$. Using (3.2), we have

$$\||\nabla\rho^n|^{\frac{1}{2}}\|_{L^4(Q_T)} = \left(\int_{Q_T} |\nabla\rho^n|^2\right)^{\frac{1}{4}} \le \|\rho^n\|^{\frac{1}{2}}_{L^2\left((0,T);\left(H^{\frac{3}{2}}(\mathbb{T})\right)^2\right)} \le C. \tag{3.12}$$

This implies (3.11).

Step 2 (strong convergence of $\nabla\rho^n$ in $L^2((0,T);(L^{\frac{4}{3}}(\mathbb{T}^2))^{2\times 2})$). Using the parabolic estimates for the heat equation (see [16, Chapter 4.3, p. 80 and Chapter 4.9, p. 341]) and Step 1, we get

$$\|\nabla\rho^n\|_{W^{\frac{1}{2};\frac{4}{3}}\left((0,T);\left(L^{\frac{4}{3}}(\mathbb{T}^2)\right)^{2\times 2}\right)} \leq C \tag{3.13}$$

where, for a Banach space B,

$$W^{\frac{1}{2};p}((0,T);B) = \left\{ g \in L^p((0,T);B),\ \int_0^T \int_0^T \frac{\|g(t)-g(s)\|_B^p}{|t-s|^{\frac{1}{2}p+1}}\, dt\, ds < \infty \right\}$$

is equipped with the following norm:

$$\|g\|_{W^{\frac{1}{2};p}((0,T);B)} := \left(\int_0^T \int_0^T \frac{\|g(t)-g(s)\|_B^p}{|t-s|^{\frac{1}{2}p+1}}\, dt\, ds \right)^{\frac{1}{p}}.$$

Moreover, using (3.2) we get

$$\|\nabla\rho^n\|_{L^2\left((0,T);\left(H^{\frac{1}{2}}(\mathbb{T}^2)\right)^{2\times 2}\right)} \leq C. \tag{3.14}$$

We then use the following lemma.

LEMMA 3.2 (compactness result). *Let $(g_n)_n$ be a sequence uniformly bounded in*

$$L^2\left((0,T);H^{\frac{1}{2}}\left(\mathbb{T}^2\right)\right) \cap W^{\frac{1}{2};\frac{4}{3}}\left((0,T);L^{\frac{4}{3}}\left(\mathbb{T}^2\right)\right);$$

then, for a subsequence,

$$g_n \to g \text{ strongly in } L^2\left((0,T);L^{\frac{4}{3}}\left(\mathbb{T}^2\right)\right).$$

Formally, the proof uses the fact that $H^{\frac{1}{2}} \subset L^{\frac{4}{3}}$ with compact injection in space, while the compactness in time comes from (3.13). We refer to Simon [21, Corollary 5, p. 86] for a more general result and for the proof of this lemma.

Using (3.13), (3.14), and Lemma 3.2, we then deduce that, for a subsequence, $\nabla\rho^n \to \nabla\rho$ strongly in $L^2((0,T);(L^{\frac{4}{3}}(\mathbb{T}^2))^2)$ and almost everywhere.

Step 3. (weak convergence of $\sigma[\rho^n]$ in $L^2((0,T);(L^4(\mathbb{T}^2))^2)$). We have $H^{\frac{1}{2}}(\mathbb{T}^2) \subset L^4(\mathbb{T}^2)$ with continuous injection (see Adams [1, Theorem 7.57, p. 217]). So $L^2((0,T);H^{\frac{1}{2}}(\mathbb{T}^2)) \subset L^2((0,T);L^4(\mathbb{T}^2))$ with continuous injection. We then deduce from (3.2) that

$$\|\nabla\rho^n\|_{L^2\left((0,T);(L^4(\mathbb{T}^2))^{2\times 2}\right)} \leq C. \tag{3.15}$$

Using Lemma 2.2, we then get

$$\left\|C^0 \star \rho^n\right\|_{L^2\left((0,T);(L^4(\mathbb{T}^2))^2\right)} \leq C. \tag{3.16}$$

Using the fact that the application $W^{2,1,\frac{4}{3}}_{x,t}(Q_T) \mapsto L^{\frac{4}{3}}(Q_T)$ is compact and the converse of the Lebesgue theorem, we deduce that $W'(\rho^n) \to W'(\rho)$ almost everywhere. This implies that $\sigma[\rho^n] \rightharpoonup \sigma[\rho]$ in $L^2((0,T);(L^4(\mathbb{T}^2))^2)$.

Step 4. (passing to the limit). Using Steps 2 and 3 and the fact that $|\nabla\rho^n|^{-1}\nabla\rho^n$ is bounded by 1, we deduce that

$$f_n[\rho^n] \to |\nabla\rho|^{-1}(\nabla\rho)^T \cdot \nabla\rho \cdot \sigma[\rho] \quad \text{in the distributions sense.}$$

By passing to the limit in (2.1), we obtain

$$\rho_t - \epsilon\Delta\rho = |\nabla\rho|^{-1}(\nabla\rho)^T \cdot \nabla\rho \cdot \sigma[\rho] \text{ in } \mathcal{D}'\left((0,T)\times\mathbb{T}^2\right). \tag{3.17}$$

Step 5 (initial condition). Using the fact that ρ_t^n are bounded uniformly in $L^{\frac{4}{3}}(Q_T)$ (by parabolic estimates for the heat equation and Step 1), we deduce that (uniformly in n)

$$\|\rho^n(t+h) - \rho^n(t)\|_{\left(L^{\frac{4}{3}}(\mathbb{T}^2)\right)^2} \le Ch^{\frac{1}{4}}\|\rho_t^n\|_{L^{\frac{4}{3}}\left((0,T);\left(L^{\frac{4}{3}}(\mathbb{T}^2)\right)^2\right)}$$

and then $\rho \in C^0((0,T);(L^{\frac{4}{3}}(\mathbb{T}^2))^2)$ and $\rho_{|t=0} = \rho^0$.

This achieves the proof of Theorem 1.1. □

Appendix A.

Full proof of Lemma 2.2. Here we do the proof for any $p \in (1,+\infty)$. Under assumption (A), there exists a constant $C > 0$ depending only on p such that the following result holds for any $\tilde\rho \in W^{1,p}(\mathbb{R}^2)$:

$$\left|\tilde C^0 \star_{\mathbb{R}^2} \tilde\rho\right|_{(L^p(\mathbb{R}^2))^2} \le \frac{C}{m}|\nabla\tilde\rho|_{(L^p(\mathbb{R}^2))^{2\times 2}},$$

where the Fourier transform of $\tilde C^0$ satisfies $\hat{\tilde C}^0 = M$ with M as in (1.9).

This result can be found in the scalar case on $\mathbb{R}^n$ in Stein [22, Proposition 5, p. 251] or Coifman, Meyer [10, Theorem 9, p. 39 and Proposition 2, p. 41]. See, also, Calderon–Zygmund inequalities Theorem 2.7.2 in Morrey [19]. Here the convolution by $\tilde C^0$ is a multiplier operator in the class S^1 of pseudodifferential operators. We then get the result in the vectorial case, summing the scalar components. See, also, the book of Garroni and Menaldi [12] for complements on integro-differential operators.

The fact that the result holds on the torus $\mathbb{T}^2$ is then classical. We prove it for the convenience of the reader. To this end, we consider a smooth function φ such that

$$\varphi(x) = 1 \quad \text{on} \quad [-1/3,1/3]^2, \qquad \text{supp } \varphi \subset [-2/3,2/3]^2, \quad \text{and} \quad 0 \le \varphi \le 1$$

such that

$$\sum_{k\in\mathbb{Z}^2} \varphi(x-k) = 1.$$

For any smooth function $\rho : \mathbb{R}^2 \longrightarrow \mathbb{R}^2$, which is $\mathbb{Z}^2$-periodic, we then set for $K > 0$

$$(S_{2K}\rho)(x) = \sum_{|k|\le 2K,\ k\in\mathbb{Z}^2} \varphi(x-k)\rho(x).$$

Therefore, we get for $K > 0$ large enough

$$\begin{aligned}
&|B_K| \left\{ \left| \tilde{C}^0 \star_{\mathbb{R}^2} \rho \right|_{L^p((-1/2,1/2)^2)} + 0(1/K) \right\} \\
&\leq \left| \tilde{C}^0 \star_{\mathbb{R}^2} \rho \right|_{L^p(B_K)} \\
&\leq \left| \tilde{C}^0 \star_{\mathbb{R}^2} (S_{2K}\rho) \right|_{L^p(\mathbb{R}^2)} + \left| \tilde{C}^0 \star_{\mathbb{R}^2} (\rho - (S_{2K}\rho)) \right|_{L^p(B_K)} \\
&\leq \frac{C}{m} |\nabla(S_{2K}\rho)|_{L^p(\mathbb{R}^2)} + \left| \tilde{C}^0 \star_{\mathbb{R}^2} (\rho - (S_{2K}\rho)) \right|_{L^p(B_K)} \\
&\leq \frac{C}{m} |B_{2K}| \left\{ |\nabla\rho|_{(L^p(-1/2,1/2))^{2\times 2}} + 0(1/K) \right\} + |\rho|_{(L^\infty(\mathbb{R}^2))^2} |B_K| \int_{|z|\geq K-1} \left| \tilde{C}^0(z) \right|.
\end{aligned}$$

Using the fact that $\int_{|z|\geq K-1} |\tilde{C}^0(z)| = O(1/K)$, dividing by $|B_K|$, and taking the limit as $K \longrightarrow +\infty$, we get

$$\left| \tilde{C}^0 \star_{\mathbb{R}^2} \rho \right|_{(L^p(\mathbb{T}^2))^2} \leq \frac{C}{m} \frac{|B_2|}{|B_1|} |\nabla\rho|_{(L^p(\mathbb{T}^2))^{2\times 2}},$$

i.e.,

$$\left| C^0 \star_{\mathbb{T}^2} \rho \right|_{(L^p(\mathbb{T}^2))^2} \leq \frac{4C}{m} |\nabla\rho|_{(L^p(\mathbb{T}^2))^{2\times 2}}$$

with

$$C^0(x) = \sum_{k\in\mathbb{Z}^2} \tilde{C}^0(x-k).$$

We then get the final result by density of smooth functions in $(W^{1,p}(\mathbb{T}^2))^2$. □

Proof of Proposition 2.8. For simplicity of notation, we denote by $g(t)$ the function $x \mapsto g(t,x)$. We have

$$\begin{aligned}
\left\| g^m(t) - \rho^0 \right\|_{(L^2(\mathbb{T}^2))^2} &\leq \int_0^t ds \, \|g_t^m(s)\|_{(L^2(\mathbb{T}^2))^2} \\
&\leq \sqrt{t} \, \|g_t^m\|_{(L^2(Q_T))^2}.
\end{aligned}$$

Using the fact that g^m is bounded uniformly in $W^{2,1;2}(Q_T)$ (this is a consequence of the fact that $g^m \rightharpoonup g$ in $W^{2,1;2}(Q_T)$), we get

$$\left\| g^m(t) - \rho^0 \right\|_{(L^2(\mathbb{T}^2))^2} \leq C\sqrt{t}. \tag{A.1}$$

Now let $\varphi \in C_c^\infty([0,+\infty),\mathbb{R})$ be such that $\varphi \geq 0$. Using (A.1), we get that

$$\int_0^t ds \, \left\| g^m(s) - \rho^0 \right\|^2_{(L^2(\mathbb{T}^2))^2} \varphi(s) \leq C \int_0^t ds \, s \, \varphi(s).$$

Using Fatou's lemma, we deduce that

$$\int_0^t \left(\left\| g(s) - \rho^0 \right\|^2_{(L^2(\mathbb{T}^2))^2} - Cs \right) \varphi(s) \leq 0.$$

Using that $\varphi \geq 0$ is arbitrary, we deduce that, for almost every t, we have

$$\left\| g(t) - \rho^0 \right\|^2_{(L^2(\mathbb{T}^2))^2} \leq \sqrt{Ct}.$$

This implies the result. □

Acknowledgments. The authors thank A. El Hajj for fruitful discussion in the preparation of this paper. They also thank the referees for their comments and questions that helped to improve the manuscript.

MINIMIZATION OF ELECTROSTATIC FREE ENERGY AND THE POISSON–BOLTZMANN EQUATION FOR MOLECULAR SOLVATION WITH IMPLICIT SOLVENT*

BO LI†

Abstract. In an implicit-solvent description of the solvation of charged molecules (solutes), the electrostatic free energy is a functional of concentrations of ions in the solvent. The charge density is determined by such concentrations together with the point charges of the solute atoms, and the electrostatic potential is determined by the Poisson equation with a variable dielectric coefficient. Such a free-energy functional is considered in this work for both the case of point ions and that of ions with a uniform finite size. It is proved for each case that there exists a unique set of equilibrium concentrations that minimize the free energy and that are given by the corresponding Boltzmann distributions through the equilibrium electrostatic potential. Such distributions are found to depend on the boundary data for the Poisson equation. Pointwise upper and lower bounds are obtained for the free-energy minimizing concentrations. Proofs are also given for the existence and uniqueness of the boundary-value problem of the resulting Poisson–Boltzmann equation that determines the equilibrium electrostatic potential. Finally, the equivalence of two different forms of such a boundary-value problem is proved.

Key words. implicit solvent, electrostatic free energy, ionic concentrations, electrostatic potentials, the Poisson–Boltzmann equation, variational methods, nonlinear elliptic interface problems

1. Introduction.

It has long been realized that the electrostatic potential of a charged molecular system extremizes an electrostatic free-energy functional [3, 6, 12, 13, 15, 18, 20, 26, 28, 29]. In a simple setting, this functional is given by

$$F[c_1,\dots,c_M;\psi]=\int\left\{-\frac{\varepsilon}{8\pi}|\nabla\psi|^2+\rho\psi+\beta^{-1}\sum_{j=1}^{M}c_j\left[\ln\left(\Lambda^3c_j\right)-1\right]-\sum_{j=1}^{M}\mu_jc_j\right\}dx,$$

where $c_1,\dots,c_M$ are ionic concentrations, ψ is an electrostatic potential, ε is the dielectric constant, ρ is the charge density defined to be a linear combination of the ionic concentrations, β is the inverse thermal energy, Λ is the thermal de Broglie wavelength, and μ_j is the chemical potential of the jth ionic species. Throughout, we use the electrostatics CGS units. We also use $\log x$ to denote the natural logarithm of $x>0$. Extremizing this functional with respect to the concentrations and the potential lead to the Boltzmann distribution of concentrations and the Poisson equation for the equilibrium potential, respectively [3, 6, 12, 13, 15, 26, 28]. Notice, however, that this free-energy functional is concave with respect to the electrostatic potential. Therefore, the extremizing concentrations and potential do not minimize this free-energy functional, rather they form an unstable saddle point of the system [1, 6, 12, 13]. This flaw of theory is removed in the free-energy minimization approach that was proposed

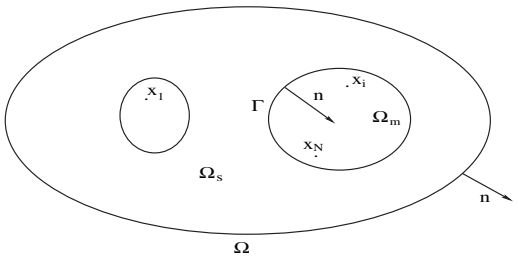

FIG. 1. *The geometry of a solvation system with an implicit solvent.*

in [12, 20]. The key point in this new approach is that the electrostatic free-energy functional depends solely on the ionic concentrations and the electrostatic potential is determined by such concentrations through the Poisson equation. In the recent article [5], this free-energy minimization approach was revisited and applied to the implicit-solvent (or continuum-solvent) description of solvation.

The present work is a mathematical study of the free-energy minimization approach to the electrostatics applied to the solvation of molecules with an implicit-solvent. Such application introduces additional mathematical complications due to the presence of point charges in solutes and the dielectric boundaries. We consider both the case of point ions—ions modeled as points without volumes—and that of ions with a uniform finite size. The finite-size effect of ions is known to be important in continuum modeling of electrostatics in molecular systems. Our analysis shows particularly that the free-energy minimizing ionic concentrations are uniformly bounded from above and away from zero at each spatial point. This uniform boundedness, which is proved by somewhat tedious constructions, is a consequence of the property that the free-energy minimizing concentrations have a large entropy. We do not consider the more general case of ions with different sizes for which there seems no explicit Boltzmann distributions.

Consider now the solvation of charged molecules with an implicit solvent [27]. We divide the entire region Ω of the solvation system into the region of solute molecules $\Omega_m \subset \mathbb{R}^3$ that is possibly multiply connected, the region of solvent (such as salted water) $\Omega_s \subset \mathbb{R}^3$, and the solute-solvent interface $\Gamma = \partial\Omega_m \cap \partial\Omega_s$; cf. Figure 1. This interface Γ serves as the dielectric boundary. Assume the solutes consist of N atoms with the ith one located at x_i and carrying a charge Q_i. Assume also there are M ionic species in the solvent with $q_j = ez_j$ the buck charge of the jth ionic species, where e is the elementary charge and z_j the valence of jth ionic species. Denote by $c_j = c_j(x)$ the local concentration at $x \in \Omega_s$ of the jth ionic species. Following the common assumption that the mobile ions in the solvent cannot penetrate the dielectric boundary Γ, we define $c_j(x) = 0$ for all $x \in \Omega_m$ and $1 \le j \le M$.

We consider two mean-field approximations of the electrostatic free energy of the solvation system as functionals of the local ionic concentrations $c = (c_1, \ldots, c_M)$ in the solvent region. In the first one, point ions are assumed, and the related electrostatic free-energy functional is given by [5, 12, 19, 20, 26]

$$F_0[c] = \frac{1}{2}\sum_{i=1}^{N} Q_i(\psi - \psi_{vac})(x_i) + \frac{1}{2}\int_{\Omega_s}\left(\sum_{j=1}^{M} q_j c_j\right)\psi dx$$
$$+ \beta^{-1}\sum_{j=1}^{M}\int_{\Omega_s} c_j\left[\log\left(a^3 c_j\right) - 1\right]dx - \sum_{j=1}^{M}\int_{\Omega_s}\mu_j c_j dx. \tag{1.1}$$

In the second approximation, all ions are assumed to have a uniform linear size, and the related free-energy functional is given by [3, 20]

$$F_a[c] = \frac{1}{2}\sum_{i=1}^{N} Q_i(\psi - \psi_{vac})(x_i) + \frac{1}{2}\int_{\Omega_s}\left(\sum_{j=1}^{M} q_j c_j\right)\psi dx$$
$$+ \beta^{-1}\sum_{j=0}^{M}\int_{\Omega_s} c_j\left[\log\left(a^3 c_j\right) - 1\right]dx - \sum_{j=1}^{M}\int_{\Omega_s}\mu_j c_j\,dx, \tag{1.2}$$

where the summation in the β^{-1} term starts from $j = 0$ and

$$c_0(x) = a^{-3}\left[1 - \sum_{j=1}^{M} a^3 c_j(x)\right] \qquad \forall x \in \Omega_s. \tag{1.3}$$

In (1.1) and (1.2), ψ is the electrostatic potential of the solvation system,

$$\psi_{vac}(x) = \sum_{i=1}^{N}\frac{Q_i}{\varepsilon_m|x - x_i|} \tag{1.4}$$

defines the electrostatic potential generated by all the point charges Q_i at x_i in a medium with the dielectric constant ε_m (usually taken as that in the vacuum), $a > 0$ is a constant, and μ_j is the constant chemical potential of the jth ionic species. The constant $a > 0$ represents in (1.1) a nonphysical cut-off which is often chosen to be the thermal de Broglie wavelength and in (1.2) the uniform linear size of ions.

The electrostatic potential ψ is determined by the Poisson equation

$$\nabla \cdot \varepsilon_\Gamma \nabla\psi = -4\pi\rho \qquad \text{in } \Omega, \tag{1.5}$$

where ε_Γ is the dielectric coefficient and ρ is the charge density, together with a boundary condition which is usually taken to be

$$\psi = \psi_0 \qquad \text{on } \partial\Omega, \tag{1.6}$$

where ψ_0 is a given function. The dielectric coefficient is defined to be

$$\varepsilon_\Gamma(x) = \begin{cases} \varepsilon_m & \text{if } x \in \Omega_m, \\ \varepsilon_s & \text{if } x \in \Omega_s, \end{cases} \tag{1.7}$$

where ε_m and ε_s are the dielectric constants of the solutes and the solvent, respectively. The charge density is given by

$$\rho = \sum_{i=1}^{N} Q_i\delta_{x_i} + \sum_{j=1}^{M} q_j c_j \qquad \text{in } \Omega, \tag{1.8}$$

where δ_{x_i} denotes the Dirac delta function centered at x_i.

The first two terms in (1.1) or (1.2) represent the internal electrostatic energy, which are often written formally as the integral of $\rho\psi/2$ over the entire region Ω. Based on Born's definition [2], the contribution to the electrostatic free energy due to the solute point charges is given as the first term in (1.1) or (1.2) though the reaction

field $\psi-\psi_{vac}$. The β^{-1} term represents the ideal gas entropy. The term $1-\sum_{j=1}^{M} a^3 c_j$ in (1.2) is the concentration of solvent molecules. It describes the effect of finite size of ions. The last term in (1.1) or (1.2) accounts for a constant chemical potential in the system. The osmotic pressure from the mobile ions is dropped, since it is only an additive constant to the free-energy functional in the present setting. We remark that the use of notations F_0 and F_a does not indicate that we can obtain the functional F_0 by simply setting $a = 0$ in F_a.

In this work, we prove the following results:

(1) For each of the free-energy functionals (1.1) and (1.2), there admits a unique minimizer $c_1, \ldots, c_M$, which is also the unique equilibrium, in an admissible set of concentrations. Moreover, such concentrations and the corresponding equilibrium electrostatic potential ψ are related by the boundary-data dependent Boltzmann distributions

$$c_j(x) = \begin{cases} c_j^{\infty} e^{-\beta q_j \left[\psi(x) - \hat{\psi}_0(x)/2\right]} & \text{for point ions,} \\ \dfrac{c_j^{\infty} e^{-\beta q_j [\psi(x) - \hat{\psi}_0(x)/2]}}{1 + a^3 \sum_{i=1}^{M} c_i^{\infty} e^{-\beta q_i [\psi(x) - \hat{\psi}_0(x)/2]}} & \text{for finite-size ions,} \end{cases} \tag{1.9}$$

for a.e. $x \in \Omega_s$ and $1 \le j \le M$, where $c_j^{\infty} = a^{-3} e^{\beta \mu_j}$ and $\hat{\psi}_0 \in H^1(\Omega)$ is determined by

$$\begin{cases} \displaystyle\int_{\Omega} \varepsilon_{\Gamma} \nabla \hat{\psi}_0 \cdot \nabla \eta dx = 0 & \forall \eta \in H_0^1(\Omega), \\ \hat{\psi}_0 = \psi_0 & \text{on } \partial\Omega. \end{cases} \tag{1.10}$$

The free-energy minimizing concentrations are shown to be uniformly bounded above and below away from zero. These results are summarized in Theorems 2.3–2.5 and Lemmas 3.4 and 3.5.

(2) The equilibrium electrostatic potential ψ is the unique solution to the boundary-data dependent Poisson–Boltzmann equation (PBE) [3, 4, 10, 11, 16, 17, 20, 31], together with the boundary condition (1.6),

$$\nabla \cdot \varepsilon_{\Gamma} \nabla \psi + 4\pi \chi_{\Omega_s} \sum_{j=1}^{M} q_j c_j^{\infty} e^{-\beta q_j \left(\psi - \hat{\psi}_0/2\right)} = -4\pi \sum_{i=1}^{N} Q_i \delta_{x_i} \qquad \text{in } \Omega \tag{1.11}$$

for the case of point ions, and

$$\nabla \cdot \varepsilon_{\Gamma} \nabla \psi + 4\pi \chi_{\Omega_s} \sum_{j=1}^{M} \frac{q_j c_j^{\infty} e^{-\beta q_j \left(\psi - \hat{\psi}_0/2\right)}}{1 + a^3 \sum_{i=1}^{M} c_i^{\infty} e^{-\beta q_i \left(\psi - \hat{\psi}_0/2\right)}} = -4\pi \sum_{i=1}^{N} Q_i \delta_{x_i} \qquad \text{in } \Omega \tag{1.12}$$

for the case of finite-size ions, where χ_{Ω_s} is the characteristic function of Ω_s. These equations can be written together as

$$\nabla \cdot \varepsilon_{\Gamma} \nabla \psi - 4\pi \chi_{\Omega_s} B' \left(\psi - \frac{\hat{\psi}_0}{2} \right) = -4\pi \sum_{i=1}^{N} Q_i \delta_{x_i} \qquad \text{in } \Omega, \tag{1.13}$$

where B' is the derivative of the function $B : \mathbb{R} \to \mathbb{R}$ defined by

(1.14)
$$B(\psi) = \begin{cases} \displaystyle\sum_{j=1}^{M} \beta^{-1} c_j^\infty e^{-\beta q_j \psi} & \text{for point ions,} \\ \beta^{-1} a^{-3} \log\left(1 + a^3 \displaystyle\sum_{j=1}^{M} c_j^\infty e^{-\beta q_j \psi}\right) & \text{for finite-size ions.} \end{cases}$$

See Theorem 2.1.

(3) The boundary-value problem of the PBE (1.13) and (1.6) is equivalent to the elliptic interface problem

(1.15)
$$\begin{cases} \nabla \cdot \varepsilon_m \nabla \psi = -4\pi \displaystyle\sum_{i=1}^{N} Q_i \delta_{x_i} & \text{in } \Omega_m, \\ \nabla \cdot \varepsilon_s \nabla \psi - 4\pi B'\left(\psi - \dfrac{\hat{\psi}_0}{2}\right) = 0 & \text{in } \Omega_s, \\ [\![\psi]\!] = [\![\varepsilon_\Gamma \nabla \psi \cdot n]\!] = 0 & \text{on } \Gamma, \\ \psi = \psi_0 & \text{on } \Omega. \end{cases}$$

Here and below, we denote for any function u on Ω, $u_m = u|_{\Omega_m}$, $u_s = u|_{\Omega_s}$,, and $[\![u]\!] = u_s - u_m$ on Γ. See Theorem 2.2.

Two variations of the PBE (1.11) with $\psi_0 = 0$ are commonly used [8, 15, 29]. First, we have by the Taylor expansion and the electrostatic neutrality $\sum_{j=1}^{M} c_j^\infty = 0$ that

$$\sum_{j=1}^{M} q_j c_j^\infty e^{-\beta q_j \psi} \approx -\left(\sum_{j=1}^{M} \beta q_j^2 c_j^\infty\right) \psi,$$

if $|\psi|$ is small, leading to the linearized PBE [9]

$$\nabla \cdot \varepsilon_\Gamma \nabla \psi - \varepsilon_s \kappa^2 \chi_{\Omega_s} \psi = -4\pi \sum_{i=1}^{N} Q_i \delta_{x_i} \qquad \text{in } \Omega,$$

where $\kappa = \sqrt{4\pi\beta \sum_{i=1}^{M} q_j^2 c_j^\infty / \varepsilon_s^2}$ is the ionic strength or the inverse Debye–Hückel screening length. Clearly, all of our results for the nonlinear PBE (1.11) hold true for the linearized PBE. Second, for the common $z : -z$ type of salt such as NaCl in the solution, we have $M = 2$, $c_1^\infty = c_2^\infty$, and $q_1 = -q_2 = ze$. The PBE (1.11) reduces to the following sinh PBE:

$$\nabla \cdot \varepsilon_\Gamma \nabla \psi - 8\pi z e c_1^\infty \chi_{\Omega_s} \sinh(\beta z e \psi) = -4\pi \sum_{i=1}^{N} Q_i \delta_{x_i} \qquad \text{in } \Omega.$$

In proving the existence of minimizers of the functionals F_0 and F_a, we use de la Vallée Poussin's criterion [25] of the sequential compactness in $L^1(\Omega)$. The uniqueness of such minimizers follows basically from the convexity of these functionals. A crucial step in defining and deriving equilibriums of F_0 and F_a is the construction of

L^∞-concentrations that are bounded below in Ω_s by a positive constant and that have low free energies. Such constructions are made by increasing the entropy of ionic concentrations through their small perturbations. The effect of inhomogeneous Dirichlet boundary data to the Boltzmann distributions and, hence, to the PBE can be useful to guide practical numerical computations. The equivalence of the two formulations is a common property for many physical problems. The interface formulation of the boundary-value problem of the PBE has been used for numerical computations using boundary integral method [22–24]. The finite-size effect is important in modeling electrostatics [3, 20].

The rest of the paper is organized as follows: In section 2, we state our main results; in section 3, we provide some lemmas; in section 4, we prove our theorems on the boundary-value problem of PBE; in section 5, we prove our theorems on the free-energy minimization. Finally, in Appendix, we give the proof of two lemmas.

2. Main results. Throughout the rest of the paper, we make the following assumptions:

A1. The set $\Omega \subset \mathbb{R}^3$ is nonempty, bounded, open, and connected. The sets $\Omega_m \subset \mathbb{R}^3$ and $\Omega_s \subset \mathbb{R}^3$ are nonempty, bounded, and open, and satisfy that $\overline{\Omega_m} \subset \Omega$ and $\Omega_s = \Omega \setminus \overline{\Omega_m}$. The N points $x_1, \ldots, x_N$ for some integer $N \geq 1$ belong to Ω_m. Both $\partial\Omega$ and Γ are of C^2. The unit exterior normal at the boundary of Ω_s is denoted by n; cf. Figure 1.

A2. $M \geq 2$ is an integer. All $a > 0$, $\beta > 0$, $Q_i \in \mathbb{R}$ $(1 \leq i \leq N)$, $q_j \in \mathbb{R}$ and $\mu_j \in \mathbb{R}$ $(1 \leq j \leq M)$, $\varepsilon_m > 0$, and $\varepsilon_s > 0$ are constants;

A3. The functions ψ_{vac} and ε_Γ are defined in (1.4) and (1.7), respectively. The boundary data ψ_0 is the trace of a given function, also denoted by ψ_0, in $W^{2,\infty}(\Omega)$.

Boundary values are understood as traces. When no confusion arises, the capital letter C, with or without a subscript, denotes a positive constant that can depend on all Ω_m, Ω_s, Ω, Γ, ε_m, ε_s, a, β, N, M, x_i, and Q_i $(1 \leq i \leq N)$, q_j and μ_j $(1 \leq j \leq M)$, and ψ_0.

For any open set $U \subseteq \mathbb{R}^3$ that contains all $x_1, \ldots, x_N$, we denote

$$H^1_*(U) = \left\{ u \in W^{1,1}(U) : u|_{U_\alpha} \in H^1(U_\alpha) \, \forall \alpha > 0 \right\},$$

where $U_\alpha = U \setminus (\cup_{i=1}^N \overline{B(x_i, \alpha)})$ and $B(x_i, \alpha)$ denotes the ball centered at x_i with radius α.

DEFINITION 2.1. *A function $\psi \in H^1_*(\Omega)$ is a weak solution to the boundary-value problem of the PBE* (1.13) *and* (1.6)*, if $\psi = \psi_0$ on $\partial\Omega$, $\chi_{\Omega_s} B(\psi) \in L^2(\Omega_s)$, and*

(2.1)
$$\int_\Omega \left[\varepsilon_\Gamma \nabla\psi \cdot \nabla\eta + 4\pi\chi_{\Omega_s} B'\left(\psi - \frac{\hat{\psi}_0}{2}\right)\eta \right] dx = 4\pi \sum_{i=1}^N Q_i \eta(x_i) \qquad \forall \eta \in C_c^\infty(\Omega).$$

We remark that if $\phi \in H^1(U)$ for some bounded and smooth domain $U \subset \mathbb{R}^3$, then e^ϕ and, hence, $B(\phi)$ may not be in $L^1(U)$. For example, let $U = B(0,1)$ be the unit ball of $\mathbb{R}^3$ and $\alpha \in (0, 1/2)$. Define $\phi(x) = |x|^{-\alpha}$ for any $x \in U$. Then $\phi \in H^1(U)$ and that $e^\phi \notin L^1(U)$. Notice by (1.14) that $\chi_{\Omega_s} B(\psi) \in L^2(\Omega_s)$ is equivalent to $\chi_{\Omega_s} e^{-\beta q_j \psi} \in L^2(\Omega_s)$ or $\chi_{\Omega_s} e^{-\beta q_j(\psi - \hat{\psi}_0/2)} \in L^2(\Omega_s)$ $(j = 1, \ldots, M)$, which in turn are equivalent to $\chi_{\Omega_s} B(\psi - \hat{\psi}_0/2) \in L^2(\Omega_s)$.

THEOREM 2.1. *There exists a unique weak solution $\psi \in H^1_*(\Omega)$ to the boundary-value problem of the PBE* (1.13) *and* (1.6)*. Moreover, $\psi \in C(\overline{\Omega} \setminus (\cup_{i=1}^N \overline{B(x_i, \alpha)}))$*

for any $\alpha > 0$ such that the closure of $\cup_{i=1}^N B(x_i, \alpha)$ is contained in Ω_m, and $\psi \in C^\infty((\Omega_m \setminus \{x_1, \dots, x_N\}) \cup \Omega_s)$.

DEFINITION 2.2. *A function $\psi : \Omega \to \mathbb{R}$ is a weak solution of the interface problem* (1.15)*, if the following are satisfied: $\psi_m \in H^1_*(\Omega_m)$ and*

$$\int_{\Omega_m} \varepsilon_m \nabla\psi \cdot \nabla\eta dx = 4\pi \sum_{i=1}^N Q_i \eta(x_i) \qquad \forall \eta \in C_c^\infty(\Omega_m); \tag{2.2}$$

$\psi_s \in H^1(\Omega_s)$, $\chi_{\Omega_s} B(\psi) \in L^2(\Omega_s)$, and

$$\int_{\Omega_s} \left[\varepsilon_s \nabla\psi \cdot \nabla\eta + 4\pi\chi_{\Omega_s} B'\left(\psi - \frac{\hat{\psi}_0}{2}\right)\eta \right] dx = 0 \qquad \forall \eta \in C_c^\infty(\Omega_s); \tag{2.3}$$

and the third and fourth equations in (1.15) *hold true.*

THEOREM 2.2. *A function $\psi : \Omega \to \mathbb{R}$ is a weak solution to the boundary-value problems* (1.13) *and* (1.6)*, if and only if it is a weak solution to the boundary-value problem* (1.15)*.*

Let $U \subset \mathbb{R}^3$ be a nonempty, bounded, and open set. Let $f \in L^1(U)$. Assume

$$\sup_{0 \neq \xi \in L^\infty(U) \cap H_0^1(U)} \frac{\int_U f\xi \, dx}{\|\xi\|_{H^1(U)}} < \infty. \tag{2.4}$$

Since $L^\infty(U) \cap H_0^1(U)$ is dense in $H_0^1(U)$, we can identify f as an element in $H^{-1}(U)$, the dual of $H_0^1(U)$, with

$$\langle f, \xi \rangle = \int_U f\xi dx \qquad \forall \xi \in L^\infty(U) \cap H_0^1(U),$$

and we write $f \in L^1(U) \cap H^{-1}(U)$. The $H^{-1}(U)$ norm of f is given by (2.4). We define

$$X = \left\{ c = (c_1, \dots, c_M) \in L^1\left(\Omega, \mathbb{R}^M\right) : c = 0 \text{ a.e. } \Omega_m \text{ and } \sum_{j=1}^M q_j c_j \in H^{-1}(\Omega) \right\},$$

$$\|c\|_X = \sum_{j=1}^M \|c_j\|_{L^1(\Omega_s)} + \left\| \sum_{j=1}^M q_j c_j \right\|_{H^{-1}(\Omega)} \qquad \forall c = (c_1, \dots, c_M) \in X.$$

Clearly, $(X, \|\cdot\|_X)$ is a Banach space.

Let $\alpha \in \mathbb{R}$ and define $S_\alpha : [0, \infty) \to \mathbb{R}$ by $S_\alpha(0) = 0$ and $S_\alpha(u) = u(\alpha + \log u)$ if $u > 0$. It is easy to see that S_α is bounded below on $[0, \infty)$ and strictly convex on $(0, \infty)$. Define

$$V_0 = \left\{ (c_1, \dots, c_M) \in X : \ c_j \geq 0 \text{ a.e. } \Omega_s \text{ and } \int_\Omega S_0(c_j)\, dx < \infty, \ j = 1, \dots, M \right\},$$

$$W_0 = \left\{ (c_1, \dots, c_M) \in V_0 : \text{ there exists } p > \frac{3}{2} \text{ such that } c_j \in L^p(\Omega), j = 1, \dots, M \right\},$$

$$V_a = \left\{ (c_1, \dots, c_M) \in V_0 : \ c_0 = a^{-3}\left(1 - \sum_{j=1}^M a^3 c_j\right) \geq 0 \text{ a.e. } \Omega_s \right\}.$$

Clearly, all V_0, W_0, and V_a are nonempty and convex. For any $c = (c_1, \ldots, c_M) \in V_0$, there exists a unique weak solution $\psi = \psi(c)$ of the boundary-value problem (1.5) and (1.6) with the charge density ρ given by (1.8); in particular, $\psi - \psi_{vac}$ is harmonic in Ω_m, cf. Lemma 3.2. We shall call $\psi = \psi(c)$ the electrostatic potential corresponding to c. Therefore, $F_0 : V_0 \to \mathbb{R}$ and $F_a : V_a \to \mathbb{R}$ are well defined. We use V, F to denote V_0, F_0 or W_0, F_0 or V_a, F_a.

DEFINITION 2.3. *An element $c = (c_1, \ldots, c_M) \in V$ is an equilibrium of $F : V \to \mathbb{R}$, if*

(2.5)

there exist $\gamma_1 > 0$ and $\gamma_2 > 0$ such that $\gamma_1 \le c_j(x) \le \gamma_2$ a.e. $x \in \Omega_s$, $j = 1, \ldots, M$,

for the case of point ions, or

(2.6) *there exists $\theta_0 \in (0, 1)$ such that $a^3 c_j(x) \ge \theta_0$ a.e. $x \in \Omega_s$, $j = 0, 1, \ldots, M$,*

for the case of finite-size ions; and

$$\delta F[c]e := \lim_{t \to 0} \frac{F[c + te] - F[c]}{t} = 0 \qquad \forall e \in X \cap L^\infty\left(\Omega, \mathbb{R}^M\right).$$

DEFINITION 2.4. *An element $c \in V$ is a local minimizer of $F : V \to \mathbb{R}$, if there exists $\varepsilon > 0$ such that $F[d] \ge F[c]$ for any $d \in V$ with $\|d - c\|_X < \varepsilon$.*

THEOREM 2.3. *There exists a unique minimizer of $F_0 : V_0 \to \mathbb{R}$. It is also the unique local minimizer of $F_0 : V_0 \to \mathbb{R}$.*

It is an open question if the unique minimizer of $F_0 : V_0 \to \mathbb{R}$ is an equilibrium of $F_0 : V_0 \to \mathbb{R}$ as defined in Definition 2.3. The answer to this question would be yes if this minimizer were in W_0 or if $\min_{d \in V_0} F_0[d] = \min_{d \in W_0} F_0[d]$, neither of which is clearly true. This is the reason we introduce the class of concentrations W_0. See the proof of Lemma 3.4 in Appendix.

THEOREM 2.4.

(1) *There exists a unique equilibrium $c = (c_1, \ldots, c_M)$ of $F_0 : W_0 \to \mathbb{R}$. It is also the unique global minimizer and the unique local minimizer of $F_0 : W_0 \to \mathbb{R}$.*
(2) *If $\psi = \psi(c)$ is the corresponding electrostatic potential, then the Boltzmann distributions* (1.9) *for point ions holds true and ψ is the unique weak solution to the corresponding boundary-value problem of PBE* (1.11) *and* (1.6). *Moreover,*

$$\min_{d \in W_0} F_0[d] = \frac{1}{2} \sum_{i=1}^{N} Q_i(\psi - \psi_{vac})(x_i) + \int_\Gamma \frac{1}{8\pi} \left(\psi - \hat{\phi}_0\right) \varepsilon_\Gamma \partial_n \left(\psi - \hat{\psi}_0\right) dS$$

$$- \int_{\Omega_s} \frac{\varepsilon_s}{8\pi} \left|\nabla \left(\psi - \hat{\psi}_0\right)\right|^2 dx - \beta^{-1} \sum_{j=1}^{M} \int_{\Omega_s} c_j^\infty e^{-\beta q_j \left(\psi - \hat{\psi}_0/2\right)} dx. \tag{2.7}$$

THEOREM 2.5.

(1) *There exists a unique equilibrium $c = (c_1, \ldots, c_M)$ of $F_a : V_a \to \mathbb{R}$. It is also the unique global minimizer and the unique local minimizer of $F_a : V_a \to \mathbb{R}$.*
(2) *If $\psi = \psi(c)$ is the corresponding electrostatic potential, then the Boltzmann distributions* (1.9) *for finite-size ions holds true and ψ is the unique weak solution to the corresponding boundary-value problem of PBE* (1.12) *and* (1.6).

Moreover,

$$\min_{d\in V_a} F_a[d] = \frac{1}{2}\sum_{i=1}^{N} Q_i(\psi-\psi_{vac})(x_i) + \int_\Gamma \frac{1}{8\pi}\left(\psi-\hat{\phi}_0\right)\varepsilon_\Gamma \partial_n\left(\psi-\hat{\psi}_0\right) dS$$
$$- \int_{\Omega_s} \frac{\varepsilon_\Gamma}{8\pi}\left|\nabla\left(\psi-\hat{\psi}_0\right)\right|^2 dx - \beta^{-1}a^{-3}\int_{\Omega_s} \left[1+\log\left(1+a^3\sum_{j=1}^{M} c_j^\infty e^{-\beta q_j\left(\psi-\hat{\psi}_0/2\right)}\right)\right] dx. \tag{2.8}$$

3. Some lemmas. The key point of our first lemma below is the existence and continuity across the interface Γ of the normal flux for a solution of an elliptic interface problem. In terms of electrostatics, this means that the electrostatic potential and the normal component of electrostatic displacement are continuous across dielectric boundaries. These seem to be known results. For completeness, we give a proof here.

LEMMA 3.1. *Let $U \subset \mathbb{R}^3$ be an open set such that $\Gamma \subset U \subseteq \Omega$. Let $g \in L^1(U)\cap H^{-1}(U)$. Suppose $u \in H^1(U)$ satisfies*

$$\int_U \varepsilon_\Gamma \nabla u\cdot\nabla\eta dx = \int_U g\eta dx \qquad \forall \eta \in C_c^\infty(U). \tag{3.1}$$

Then $[\![u]\!] = 0$ on Γ. If in addition $g \in L^2(U)$, then $[\![\varepsilon_\Gamma \partial_n u]\!] = 0$ on Γ.

Proof. Fix an open ball $B \subset U$ such that $\Gamma\cap B \neq \emptyset$. Let $\eta \in C_c^\infty(U)$ with $\operatorname{supp}\eta \subset B$. Let n_j with $1 \le j \le 3$ be the jth component of n, the unit normal at the Γ, pointing from Ω_s to Ω_m. It follows from the fact that $u \in H^1(\Omega)$ and integration by parts that

$$\begin{aligned}
-\int_B u\partial_j\eta\, dx &= \int_B (\partial_j u)\eta\, dx \\
&= \int_{B\cap\Omega_m} (\partial_j u)\eta\, dx + \int_{B\cap\Omega_s} (\partial_j u)\eta\, dx \\
&= -\int_{B\cap\Omega_m} u\partial_j\eta\, dx - \int_{\Gamma\cap B} u_m\eta n_j\, dS - \int_{B\cap\Omega_s} u\partial_j\eta\, dx + \int_{\Gamma\cap B} u_s\eta n_j\, dS \\
&= -\int_B u\partial_j\eta\, dx + \int_{\Gamma\cap B}(u_s-u_m)\eta n_j\, dS, \qquad j=1,2,3.
\end{aligned}$$

This and the arbitrariness of η imply $[\![u]\!] = 0$ on Γ.

To show the continuity of $\varepsilon_\Gamma\nabla u\cdot n$ across Γ, we fix an open set $U_0 \subset \mathbb{R}^3$ such that $\Gamma \subset U_0 \subset \overline{U_0} \subset U$ and that the boundary ∂U_0 is C^2. By the fact that $u \in H^1(U)$ and $g \in L^2(U)$, and by (3.1), we have

$$(\varepsilon_t\nabla u_t)|_{U_0\cap\Omega_t} \in L^2\left(U_0\cap\Omega_t, \mathbb{R}^3\right) \quad \text{and}$$
$$(\nabla\cdot\varepsilon_t\nabla u_t)|_{U_0\cap\Omega_t} = -g \in L^2(U_0\cap\Omega_t), \quad t = m, s.$$

Therefore, by Theorem 1.2 in [30], the trace of $(\varepsilon_t\nabla u_t)|_{U_0\cap\Omega_t}\cdot\nu \in H^{-1/2}(\partial(U_0\cap\Omega_t))$ exists, and also by (3.1),

$$\int_{U_0\cap\Omega_t} \varepsilon_t\nabla u_t\cdot\nabla\eta dx = \int_{U_0\cap\Omega_t} g\eta dx + \int_{\partial(U_0\cap\Omega_t)} (\varepsilon_t\nabla u_t\cdot\nu)\eta dS \quad \forall\eta\in C_c^\infty(U_0\cap\Omega_t), \tag{3.2}$$

where ν denotes the unit exterior normal of the boundary $\partial(U_0 \cap \Omega_t)$ which contains Γ and $t = m, s$. Notice that the normals ν at Γ from both sides $U_0 \cap \Omega_m$ and $U_0 \cap \Omega_s$ are in opposite directions.

These traces are determined independent of the choice of U_0. In fact, if $Q_0 \subset \mathbb{R}^3$ is another open set such that $\Gamma \subset Q_0 \subset \overline{Q_0} \subset U$ and the boundary ∂Q_0 is C^2, then the traces $(\varepsilon_m \nabla u_m)|_{Q_0 \cap \Omega_m} \cdot \nu \in H^{-1/2}(\partial(Q_0 \cap \Omega_m))$ and $(\varepsilon_s \nabla u_s)|_{Q_0 \cap \Omega_s} \cdot \nu \in H^{-1/2}(\partial(Q_0 \cap \Omega_m))$ exist, and (3.2) holds true for $t = m, s$ when U_0 is replaced by Q_0. Consider now (3.2) with $t = m$. Choose any $\eta \in C_c^1(U_0 \cap Q_0)$ such that $\eta = 0$ on $\partial(U_0 \cap \Omega_m) \setminus \Gamma$ and on $\partial(Q_0 \cap \Omega_m) \setminus \Gamma$. Extend η by $\eta = 0$ to outside $U_0 \cap Q_0$. By (3.2) with $t = m$ and the corresponding equation with U_0 replaced by Q_0, we obtain that

$$\int_{\partial(U_0 \cap \Omega_m)} (\varepsilon_m \nabla u_m \cdot \nu) \eta dS = \int_{\partial(Q_0 \cap \Omega_m)} (\varepsilon_m \nabla u_m \cdot \nu) \eta dS.$$

The arbitrariness of η then implies that the trace of $(\varepsilon_m \nabla u_m \cdot \nu)|_{U_0 \cap \Omega_m}$ on Γ determined by U_0 is the same as that determined by Q_0. By the same argument, we see that the trace of $(\varepsilon_s \nabla u_s \cdot n)|_{U_0 \cap \Omega_s}$ on Γ determined by U_0 is the same as that determined by Q_0.

Now, by the fact that $U_0 = (U_0 \cap \Omega_m) \cup (U_0 \cap \Omega_s)$ and $(U_0 \cap \Omega_m) \cap (U_0 \cap \Omega_s) = \emptyset$, and by our convention for the direction of the unit normal n along Γ, we obtain from (3.1) and (3.2) that for any $\eta \in C_c^\infty(U)$ with $\operatorname{supp} \eta \subset U_0$

$$\int_\Gamma \left(\varepsilon_m \frac{\partial u_m}{\partial n} - \varepsilon_s \frac{\partial u_s}{\partial n} \right) \eta dS = 0.$$

The arbitrariness of η implies $[\![\varepsilon_\Gamma \partial_n u]\!] = 0$ on Γ. □

Let $L : H^{-1}(\Omega) \to H^1(\Omega)$ be the linear operator defined as follows: for any $\xi \in H^{-1}(\Omega)$, $L\xi \in H_0^1(\Omega)$ is the unique function in $H_0^1(\Omega)$ that satisfies

$$\frac{1}{4\pi} \int_\Omega \varepsilon_\Gamma \nabla (L\xi) \cdot \nabla v \, dx = \xi(v) \qquad \forall v \in H_0^1(\Omega). \tag{3.3}$$

It is easy to see that $\langle \xi, \eta \rangle = \xi(L\eta)$ defines an inner product of $H^{-1}(\Omega)$. Denote by $|\!|\!| \cdot |\!|\!|$ the corresponding norm of $H^{-1}(\Omega)$, i.e., $|\!|\!| \xi |\!|\!| = \sqrt{\langle \xi, \xi \rangle} = \sqrt{\xi(L\xi)}$ for any $\xi \in H^{-1}(\Omega)$. One can verify that there exist $C_1 = C_1(\Omega, \varepsilon_m, \varepsilon_s) > 0$ and $C_2 = C_2(\varepsilon_m, \varepsilon_s) > 0$ such that

$$C_1 |\!|\!| \xi |\!|\!| \le \|\xi\|_{H^{-1}(\Omega)} \le C_2 |\!|\!| \xi |\!|\!| \qquad \forall \xi \in H^{-1}(\Omega). \tag{3.4}$$

It follows from [21] (with minor modifications) that there exists a unique $G \in H_*^1(\Omega)$ such that $G = 0$ on $\partial\Omega$ and

$$\int_\Omega \varepsilon_\Gamma \nabla G \cdot \nabla \eta dx = 4\pi \sum_{i=1}^N Q_i \eta(x_i) \qquad \forall \eta \in C_c^\infty(\Omega). \tag{3.5}$$

Clearly, $G - \psi_{vac}$ is harmonic in Ω_m and $G \in W^{1,p}(\Omega)$ for any $p \in [1, 3/2)$. Notice that the function $\hat{\psi}_0 \in H^1(\Omega)$ defined in (1.10) is harmonic in $\Omega_m \cup \Omega_s$.

The next lemma gives a solution decomposition of the Poisson equation (1.5) with its right-hand side consisting of Dirac masses and a function in $H^{-1}(\Omega)$ that represents the density of ionic charges. This decomposition is a mathematical formulation of the Born cycle [2].

LEMMA 3.2. *Let $f \in L^1(\Omega) \cap H^{-1}(\Omega)$ be such that $f = 0$ in Ω_m. Then $\psi := G + \hat{\psi}_0 + Lf$ is the unique function in $H^1_*(\Omega)$ that satisfies $\psi = \psi_0$ on $\partial\Omega$ and*

$$\int_\Omega \varepsilon_\Gamma \nabla\psi \cdot \nabla\eta dx = 4\pi \sum_{i=1}^N Q_i \eta(x_i) + 4\pi \int_{\Omega_s} f\eta dx \qquad \forall \eta \in C_c^\infty(\Omega). \tag{3.6}$$

Moreover, Lf and $\psi - \psi_{vac}$ are harmonic in Ω_m, and

$$\sum_{i=1}^N Q_i \left(Lf\right)(x_i) = \int_{\Omega_s} Gf dx. \tag{3.7}$$

Proof. From the definition of G, $\hat{\psi}_0$, and L (cf. (3.5), (1.10), and (3.3)), we easily verify that the function ψ is in $H^1_*(\Omega)$, $\psi = \psi_0$ on $\partial\Omega$, and (3.6) holds true. If $\bar{\psi} \in H^1_*(\Omega)$ satisfies $\bar{\psi} = 0$ on $\partial\Omega$ and $\int_\Omega \varepsilon_\Gamma \nabla\bar{\psi} \cdot \nabla\eta \, dx = 0$ for all $\eta \in C_c^\infty(\Omega)$, then clearly $\bar{\psi} \in H^1_0(\Omega)$ and in fact $\bar{\psi} = 0$ a.e. Ω. This proves the needed uniqueness.

By the fact that $f = 0$ in Ω_m and the definition of L (cf. (3.3)), Lf is harmonic in Ω_m. The fact that $\psi - \psi_{vac}$ is harmonic in Ω_m follows from (3.6) with $\eta \in C_c^\infty(\Omega)$ so chosen that $\operatorname{supp}\eta \subset \Omega_m$ and

$$\int_{\Omega_m} \varepsilon_m \nabla\psi_{vac} \cdot \nabla\eta dx = 4\pi \sum_{i=1}^N Q_i \eta(x_i) \qquad \forall \eta \in C_c^\infty(\Omega_m).$$

It remains to prove (3.7). Denote $\psi_c = Lf \in H^1_0(\Omega)$. Let $\alpha > 0$ be sufficiently small and let $B_\alpha = \cup_{i=1}^N B(x_i, \alpha)$. By the fact that G is harmonic in $\Omega_m \setminus B_\alpha$ and $G - \psi_{vac}$ is harmonic in Ω_m, we obtain by a series of routine calculations that

$$\begin{aligned}
\int_{\Omega_m} \varepsilon_m \nabla G \cdot \nabla\psi_c dx &= \int_{\Omega_m \setminus B_\alpha} \varepsilon_m \nabla G \cdot \nabla\psi_c dx + \int_{B_\alpha} \varepsilon_m \nabla G \cdot \nabla\psi_c dx \\
&= -\int_{\Omega_m \setminus B_\alpha} \varepsilon_m (\Delta G)\psi_c dx + \int_{\partial(\Omega_m \setminus B_\alpha)} \varepsilon_m \psi_c \frac{\partial G}{\partial\nu} dS + O(\alpha) \\
&= -\int_\Gamma \varepsilon_m \psi_c|_m \frac{\partial G|_m}{\partial n} dS + \int_{\partial B_\alpha} \varepsilon_m \psi_c \frac{\partial G}{\partial\nu} dS + O(\alpha) \\
&= -\int_\Gamma \varepsilon_m \psi_c|_m \frac{\partial G|_m}{\partial n} dS + \int_{\partial B_\alpha} \varepsilon_m \psi_c \frac{\partial \left(G - \psi_{vac}\right)}{\partial\nu} dS \\
&\quad + \sum_{i=1}^N \int_{\partial B(x_i,\alpha)} \varepsilon_m \psi_c \frac{\partial\psi_{vac}}{\partial\nu} dS + O(\alpha) \\
&\to -\int_\Gamma \varepsilon_m \psi_c|_m \frac{\partial G|_m}{\partial n} dS + 4\pi \sum_{i=1}^N Q_i \psi_c(x_i) \qquad \text{as } \alpha \to 0,
\end{aligned}$$

where ν is the exterior unit normal of $\partial(\Omega_m \setminus B_\alpha)$ and $\nu = -n$ on Γ by our convention for the direction of n. Consequently, by the continuity of $\varepsilon_\Gamma \nabla G \cdot n$ across Γ (cf.

Lemma 3.1), the fact that G is harmonic in Ω_s, and $G = \psi_c = 0$ on $\partial\Omega$, we obtain

$$\begin{aligned} 4\pi \sum_{i=1}^{N} Q_i \psi_c(x_i) &= \int_\Gamma \varepsilon_s \psi_c|_s \frac{\partial G|_s}{\partial n} dS + \int_{\Omega_m} \varepsilon_m \nabla G \cdot \nabla \psi_c dx \\ &= \int_{\Omega_s} \varepsilon_s (\Delta G) \psi_c dx + \int_{\Omega_s} \varepsilon_s \nabla G \cdot \nabla \psi_c dx + \int_{\Omega_m} \varepsilon_m \nabla G \cdot \nabla \psi_c dx \\ &= \int_\Omega \varepsilon_\Gamma \nabla G \cdot \nabla \psi_c dx. \end{aligned} \tag{3.8}$$

Since $\psi_c = Lf \in H_0^1(\Omega)$ is harmonic in Ω_m, we also have by the properties of G (cf. [21]) and integration by parts that

$$\begin{aligned} \int_{\Omega_m} \varepsilon_m \nabla G \cdot \nabla \psi_c dx &= \int_{\Omega_m \setminus B_\alpha} \varepsilon_m \nabla G \cdot \nabla \psi_c dx + \int_{B_\alpha} \varepsilon_m \nabla G \cdot \nabla \psi_c dx \\ &= -\int_{\Omega_m \setminus B_\alpha} \varepsilon_m G \Delta \psi_c dx + \int_{\partial(\Omega_m \setminus B_\alpha)} \varepsilon_m G \frac{\partial \psi_c}{\partial \nu} dS + O(\alpha) \\ &= -\int_\Gamma \varepsilon_m G|_m \frac{\partial \psi_c|_m}{\partial n} dS + \int_{\partial B_\alpha} \varepsilon_m G \frac{\partial \psi_c}{\partial \nu} dS + O(\alpha) \\ &\to -\int_\Gamma \varepsilon_m G|_m \frac{\partial \psi_c|_m}{\partial n} dS \qquad \text{as } \alpha \to 0. \end{aligned} \tag{3.9}$$

Let $\hat{G} \in H^1(\Omega_m)$ be such that $\hat{G} = G$ on $\Gamma = \partial\Omega_m$. Replacing G in (3.9) by $\hat{G}$ and repeating the same calculations, we obtain

$$\int_{\Omega_m} \varepsilon_m \nabla G \cdot \nabla \psi_c dx = \int_{\Omega_m} \varepsilon_m \nabla \hat{G} \cdot \nabla \psi_c dx. \tag{3.10}$$

Define $\overline{G} : \Omega \to \mathbb{R}$ by $\overline{G}(x) = \hat{G}(x)$ if $x \in \overline{\Omega_m}$ and by $\overline{G}(x) = G(x)$ if $x \in \Omega_s$. Clearly, $\overline{G} \in H_0^1(\Omega)$. Since $\psi_c = Lf$ and $f = 0$ in Ω_m, we, thus, have by (3.8) and (3.10) that

$$\begin{aligned} 4\pi \sum_{i=1}^{N} Q_i \psi_c(x_i) &= \int_{\Omega_m} \varepsilon_m \nabla \hat{G} \cdot \nabla \psi_c dx + \int_{\Omega_s} \varepsilon_s \nabla G \cdot \nabla \psi_c dx \\ &= \int_\Omega \varepsilon_\Gamma \nabla \overline{G} \cdot \nabla \psi_c dx = 4\pi \int_\Omega \overline{G} f dx = 4\pi \int_{\Omega_s} G f dx. \end{aligned}$$

This implies (3.7). □

By Lemma 3.2, the potential $\psi = \psi(c_1, \ldots, c_M)$ corresponding to a set of concentrations $(c_1, \ldots, c_M)$ is well defined with $f = \sum_{j=1}^{M} q_j c_j$ and is given by

$$\psi(c_1, \ldots, c_M) = G + \hat{\psi}_0 + L\left(\sum_{j=1}^{M} q_j c_j\right). \tag{3.11}$$

Moreover, the functional $F_0 : V_0 \to \mathbb{R}$ and $F_a : V_a \to \mathbb{R}$ can be rewritten as

$$\begin{aligned} F_0[c] &= \frac{1}{2}\int_{\Omega_s}\left(\sum_{j=1}^{M} q_j c_j\right) L\left(\sum_{j=1}^{M} q_j c_j\right) dx + \sum_{j=1}^{M}\int_{\Omega_s} \mu_{0j} c_j dx \\ &\quad + \beta^{-1}\sum_{j=1}^{M}\int_{\Omega_s} S_{-1}(c_j)dx + E_0, \qquad \forall c = (c_1, \ldots, c_M) \in V_0, \end{aligned} \tag{3.12}$$

$$\begin{aligned} F_a[c] &= \frac{1}{2}\int_{\Omega_s}\left(\sum_{j=1}^{M} q_j c_j\right) L\left(\sum_{j=1}^{M} q_j c_j\right) dx + \sum_{j=1}^{M}\int_{\Omega_s} \mu_{aj} c_j dx \\ &\quad + \beta^{-1}\sum_{j=0}^{M}\int_{\Omega_s} S_{-1}(c_j)dx + E_a \qquad \forall c = (c_1, \ldots, c_M) \in V_a, \end{aligned} \tag{3.13}$$

respectively, where

$$\mu_{0j}(x) = q_j G(x) + \frac{1}{2} q_j \hat{\psi}_0(x) + 3\beta^{-1}\log a - \mu_j \qquad \forall x \in \Omega_s,\ j = 1, \ldots, M, \tag{3.14}$$

$$E_0 = \frac{1}{2}\sum_{i=1}^{N} Q_i \left(G + \hat{\psi}_0 - \psi_{vac}\right)(x_i), \tag{3.15}$$

$$\mu_{aj}(x) = q_j G(x) + \frac{1}{2} q_j \hat{\psi}_0(x) - \mu_j \qquad \forall x \in \Omega_s,\ j = 1, \ldots, M, \tag{3.16}$$

$$E_a = \frac{1}{2}\sum_{i=1}^{N} Q_i \left(G + \hat{\psi}_0 - \psi_{vac}\right)(x_i) + 3\beta^{-1}a^{-3}(\log a)|\Omega_s|, \tag{3.17}$$

where $|E|$ denotes the Lebesgue measure of a Lebesgue measurable set $E \subset \mathbb{R}^3$.

LEMMA 3.3. *Let $D \subset \mathbb{R}^3$ be a bounded and open set. Let $\alpha \in \mathbb{R}$. Let $\{u^{(k)}\}$ be a sequence of functions in $L^1(D)$ such that $u^{(k)} \geq 0$ a.e. D for each $k \geq 1$ and that*

$$\sup_{k\geq 1}\int_D S_\alpha\left(u^{(k)}\right) dx < \infty.$$

Then there exists a subsequence $\{u^{(k_j)}\}$ of $\{u^{(k)}\}$ such that $\{u^{(k_j)}\}$ converges weakly in $L^1(D)$ to some $u \in L^1(D)$ with $u \geq 0$ a.e. D and

$$\int_D S_\alpha(u)\, dx \leq \liminf_{k\to\infty}\int_D S_\alpha\left(u^{(k)}\right) dx.$$

Proof. Since $S_\alpha : [0, \infty) \to \mathbb{R}$ is bounded below, by passing to a subsequence if necessary, we may assume that the limit

$$A := \lim_{k\to\infty}\int_D S_\alpha\left(u^{(k)}\right) dx = \liminf_{k\to\infty}\int_D S_\alpha\left(u^{(k)}\right) dx \tag{3.18}$$

exists and is finite. Since $S_\alpha(\lambda)/\lambda \to +\infty$ as $\lambda \to +\infty$, $\{u^{(k)}\}$ is weakly sequentially compact in $L^1(D)$ by de la Vallée Poussin's criterion [25]. Therefore, this sequence has a subsequence, not relabeled, that converges weakly in $L^1(D)$ to some $u \in L^1(D)$. Clearly, $u \geq 0$ a.e. D.

Let $\varepsilon > 0$. By (3.18), there exists an integer $K > 0$ such that

$$\int_D S_\alpha\left(u^{(k)}\right) dx \leq A + \varepsilon \qquad \forall k > K. \tag{3.19}$$

By Mazur's theorem [7, 32], there exist convex combinations $v^{(k)}$ of $u^{(K+1)}, \dots, u^{(K+k)}$ for all $k \geq 1$ such that $v^{(k)} \to u$ in $L^1(D)$. Let $v^{(k)} = \sum_{j=1}^k \lambda_{k,j} u^{(K+j)}$ with $\lambda_{k,j} \geq 0$ for all j and k, and $\sum_{j=1}^k \lambda_{k,j} = 1$ for all k. Since $S_\alpha : [0,\infty) \to \mathbb{R}$ is convex, we have by Jensen's inequality and (3.19) that

$$S_\alpha\left(v^{(k)}\right) \leq \sum_{j=1}^k \lambda_{k,j} S_\alpha\left(u^{(K+j)}\right) \leq \sum_{j=1}^k \lambda_{k,j}(A+\varepsilon) = A + \varepsilon \qquad \forall k \geq 1. \tag{3.20}$$

Since $v^{(k)} \to u$ in $L^1(D)$, there exists a subsequence $\{v^{(k_j)}\}$ of $\{v^{(k)}\}$ such that $v^{k_j}(x) \to u(x)$ a.e. $x \in D$. Consequently, since $S_\alpha : [0,\infty) \to \mathbb{R}$ is continuous and bounded below, we have by Fatou's lemma and (3.20) that

$$\int_D S_\alpha(u(x))\, dx = \int_D \lim_{j\to\infty} S_\alpha\left(v^{k_j}(x)\right)\, dx \leq \liminf_{j\to\infty} \int_D S_\alpha\left(v^{k_j}(x)\right)\, dx \leq A + \varepsilon,$$

concluding the proof by the arbitrariness of $\varepsilon > 0$. ∎

The next two lemmas state some boundedness of concentrations that have low free energies. Their proofs are somewhat tedious, and are given in Appendix A.

LEMMA 3.4. *Let $c = (c_1, \dots, c_M) \in W_0$ satisfy that $c \notin L^\infty(\Omega, \mathbb{R}^M)$ or there exists $j \in \{1, \dots, M\}$ with $|\{x \in \Omega_s : c_j(x) < \alpha\}| > 0$ for all $\alpha > 0$. Then for any $\varepsilon > 0$ there exist $\hat{c} = (\hat{c}_1, \dots, \hat{c}_M) \in W_0$ that satisfies (2.5) with c replaced by $\hat{c}$, $\|\hat{c} - c\|_X < \varepsilon$, and $F_0[\hat{c}] < F_0[c]$.*

LEMMA 3.5. *Let $c = (c_1, \dots, c_M) \in V_a$ and c_0 be defined by (1.3). Assume there exists $j \in \{0, 1, \dots, M\}$ such that $|\{x \in \Omega_s : a^3 c_j(x) < \alpha\}| > 0$ for all $\alpha > 0$. Let $\varepsilon > 0$. Then there exists $\hat{c} = (\hat{c}_1, \dots, \hat{c}_M) \in V_a$ that satisfies (2.6) with c replaced by $\hat{c}$, $\|\hat{c} - c\|_X < \varepsilon$, and $F_a[\hat{c}] < F_a[c]$.*

4. The Poisson–Boltzmann equation: Proof of Theorems 2.1 and 2.2. *Proof of Theorem* 2.1. It is easy to verify that the function $B : \mathbb{R} \to \mathbb{R}$ defined in (1.14) is convex for both the case of point ions and that of finite-size ions. Let

$$\mathcal{K} := \left\{u \in H^1(\Omega) : u = \psi_0 \text{ on } \partial\Omega \text{ and } \chi_{\Omega_s} B(u) \in L^2(\Omega)\right\}.$$

Clearly, $\mathcal{K} \neq \emptyset$ since $\psi_0 \in \mathcal{K}$ and $\mathcal{K}$ is convex since $B : \mathbb{R} \to \mathbb{R}$ is convex. We show now that $\mathcal{K}$ is closed in $H^1(\Omega)$. Let $u_k \in \mathcal{K}$ $(k = 1, 2, \dots)$ and $u_k \to u$ in $H^1(\Omega)$

for some $u \in H^1(\Omega)$. Clearly, $u = \psi_0$ on $\partial\Omega$. Up to a subsequence, not relabeled, $u_k(x) \to u(x)$ a.e. $x \in \Omega$. Since $B : \mathbb{R} \to \mathbb{R}$ is convex and positive, we have

$$\frac{d^2}{dv^2}\left([B(v)]^2\right) = 2[B'(v)]^2 + 2B(v)B''(v) > 0 \qquad \forall v \in \mathbb{R}.$$

Thus, $v \mapsto [B(v)]^2$ is convex. It then follows from Fatou's lemma, Jensen's inequality, and the $H^1(\Omega)$-boundedness of $\{u_k\}$ that

$$\begin{aligned}\frac{1}{|\Omega_s|}\int_{\Omega_s}[B(u)]^2\,dx &\le \liminf_{k\to\infty}\frac{1}{|\Omega_s|}\int_{\Omega_s}[B(u_k)]^2\,dx\\ &\le \liminf_{k\to\infty}\left[B\left(\frac{1}{|\Omega_s|}\int_{\Omega_s}u_k dx\right)\right]^2 < \infty.\end{aligned}$$

This implies that $u \in \mathcal{K}$. Therefore, $\mathcal{K}$ is closed in $H^1(\Omega)$. Since $\mathcal{K}$ is convex, it is also weakly closed in $H^1(\Omega)$.

Define now $J : \mathcal{K} \to \mathbb{R}$ by

$$J[u] = \int_\Omega \left[\frac{\varepsilon_\Gamma}{2}|\nabla u|^2 + 4\pi\chi_{\Omega_s}B\left(u + G - \frac{\hat{\psi}_0}{2}\right)\right]dx \qquad \forall u \in \mathcal{K},$$

where G and $\hat{\psi}_0$ are defined in (3.5) and (1.10), respectively. Note that $\psi_0 \in \mathcal{K}$ and that $J[\psi_0] < \infty$. By the Poincaré inequality, there exist constants $C_3 > 0$ and $C_4 \ge 0$ such that $J[u] \ge C_3\|u\|^2_{H^1(\Omega)} - C_4$ for all $u \in \mathcal{K}$. Thus, $\alpha := \inf_{u\in\mathcal{K}} J[u]$ is finite. Let $v_k \in \mathcal{K}$ $(k = 1, 2\dots)$ be such that $\lim_{k\to\infty} J[v_k] = \alpha$. Then, $\{v_k\}$ is bounded in $H^1(\Omega)$ and, hence, it has a subsequence, not relabeled, that weakly converges to some $v \in H^1(\Omega)$. Since $\mathcal{K}$ is weakly closed, $v \in \mathcal{K}$. Since the embedding $H^1(\Omega) \hookrightarrow L^2(\Omega)$ is compact, up to a further subsequence, again not relabeled, $v_k \to v$ a.e. in Ω. Therefore, since $B : \mathbb{R} \to \mathbb{R}$ is continuous and nonnegative, Fatou's lemma implies

$$\liminf_{k\to\infty}\int_\Omega \chi_{\Omega_s}B\left(v_k + G - \frac{\hat{\psi}_0}{2}\right)dx \ge \int_\Omega \chi_{\Omega_s}B\left(v + G - \frac{\hat{\psi}_0}{2}\right)dx.$$

Since $u \mapsto \int_\Omega \varepsilon_\Gamma|\nabla u|^2 dx$ is convex and $H^1(\Omega)$ continuous, it is sequentially weakly lower semicontinuous. Consequently, $\liminf_{k\to\infty} J[v_k] \ge J[v]$. Thus, v is a minimizer of $J : \mathcal{K} \to \mathbb{R}$.

Notice that $\chi_{\Omega_s}B'(v + G - \hat{\psi}_0/2) \in L^2(\Omega_s)$. Simple calculations of the first variation of $J : \mathcal{K} \to \mathbb{R}$ at any $\eta \in C_c^\infty(\Omega)$ leads to

$$\int_\Omega \left[\varepsilon_\Gamma\nabla v\cdot\nabla\eta + 4\pi\chi_{\Omega_s}B'\left(v + G - \frac{\hat{\psi}_0}{2}\right)\eta\right]dx = 0 \qquad \forall \eta \in C_c^\infty(\Omega).$$

The function $\psi = v + G$ is, thus, a needed solution.

We now prove the uniqueness. Let ϕ be another weak solution. Let $\xi = \psi - \phi$. Then, $\xi \in H^1_*(\Omega)$, $\xi = 0$ on $\partial\Omega$, and

$$\int_\Omega \left\{\varepsilon_\Gamma\nabla\xi\cdot\nabla\eta + 4\pi\chi_{\Omega_s}\left[B'\left(\psi - \frac{\hat{\psi}_0}{2}\right) - B'\left(\phi - \frac{\hat{\psi}_0}{2}\right)\right]\eta\right\}dx = 0 \qquad \forall \eta \in C_c^\infty(\Omega).$$

Choosing the test functions $\eta \in C_c^\infty(\Omega)$ so that $\operatorname{supp}\eta \subset \Omega_m$, we find that ξ is harmonic in Ω_m. This and the fact that $\xi \in H^1_*(\Omega)$ imply that $\xi \in H^1_0(\Omega)$. Thus, the above test functions η can be chosen from $H^1_0(\Omega)$. In particular, setting $\eta = \xi$ and using the convexity of $B : \mathbb{R} \to \mathbb{R}$, we obtain that $\xi = 0$ and, hence, $\psi = \phi$ in $H^1(\Omega)$.

Let $\sigma > 0$ be such that the closure of $B_\sigma := \cup_{i=1}^N B(x_i, \sigma)$ is contained in Ω_m. Clearly, the unique weak solution $\psi \in H^1_*(\Omega)$ satisfies

$$\int_{\Omega\setminus\overline{B_\sigma}} \varepsilon_\Gamma \nabla\psi\cdot\nabla\eta dx = \int_{\Omega\setminus\overline{B_\sigma}} g\eta dx \qquad \forall \eta \in C_c^\infty\left(\Omega\setminus\overline{B_\sigma}\right), \tag{4.1}$$

where $g = -4\pi\chi_{\Omega_s}B'(\psi - \hat{\psi}_0/2) \in L^2(\Omega\setminus\overline{B_\sigma})$. Therefore, $\psi \in C(\overline{\Omega}\setminus B_\sigma)$ by the standard regularity theory [14]. Since $\varepsilon_\Gamma = \varepsilon_m$ in Ω_m and $\varepsilon_\Gamma = \varepsilon_s$ in Ω_s, ψ is harmonic in $\Omega_m\setminus\overline{B_\sigma}$. Hence, $\psi \in C^\infty(\Omega_m\setminus\overline{B_\sigma})$. Notice that $B \in C^\infty(\mathbb{R})$; thus, we have $\psi \in C^\infty(\Omega_s)$ by a standard bootstrapping argument. □

Proof of Theorem 2.2. Let $\psi \in H^1_*(\Omega)$ be a weak solution to the boundary-value problem (1.13) and (1.6). Clearly, $\psi_m \in H^1_*(\Omega_m)$. For any $\eta \in C_c^\infty(\Omega_m)$, we extend η to the entire Ω by defining $\eta = 0$ outside Ω_m. Then, we obtain (2.2) from (2.1). Since all $x_i \in \Omega_m$ $(i = 1, \dots, N)$, we have $\psi_s \in H^1(\Omega_s)$. Since $\chi_{\Omega_s}B(\psi) \in L^2(\Omega_s)$, it follows from (1.14) that $\chi_{\Omega_s}B'(\psi) \in L^2(\Omega_s)$. For any $\eta \in C_c^\infty(\Omega_s)$, we, again, extend η to Ω by defining $\eta = 0$ outside Ω_s. Then, we obtain (2.3) from (2.1). Finally, by Lemma 3.1, (4.1), and (1.6), the last two equations in (1.15) hold true. Hence, ψ is a weak solution to (1.15).

Now let $\psi : \Omega \to \mathbb{R}$ be a solution to the boundary-value problem (1.15). We first show that $\psi \in H^1_*(\Omega)$. Let $\sigma > 0$ be small enough so that the closure of $B_\sigma := \cup_{i=1}^N B(x_i, \sigma)$ is contained in Ω_m. Since $\psi_m \in H^1_*(\Omega_m)$, $\psi_m \in H^1(\Omega_m\setminus\overline{B_\sigma})$. Thus, the trace $\psi_m|_\Gamma \in L^2(\Gamma)$, and is independent on the choice of σ. Similarly, $\psi_s \in H^1(\Omega_s)$, and, hence, $\psi_s|_\Gamma \in L^2(\Gamma)$. Fix $j \in \{1, 2, 3\}$. Define $\xi_j : \Omega\setminus\overline{B_\sigma} \to \mathbb{R}$ by $\xi_j = \partial_j\psi_m$ in $\Omega_m\setminus\overline{B_\sigma}$ and $\xi_j = \partial_j\psi_s$ in Ω_s. Clearly, $\xi_j \in L^2(\Omega\setminus\overline{B_\sigma})$. Let n_j be the jth component of the unit exterior normal n at Γ, pointing from Ω_s to Ω_m. Then, for any $\eta \in C_c^\infty(\Omega\setminus\overline{B_\sigma})$, we have

$$\begin{aligned}
\int_{\Omega\setminus\overline{B_\sigma}} \xi_j\eta\, dx &= \int_{\Omega_m\setminus\overline{B_\sigma}} (\partial_j\psi_m)\eta\, dx + \int_{\Omega_s} (\partial_j\psi_s)\eta\, dx \\
&= -\int_{\Omega_m\setminus\overline{B_\sigma}} \psi\partial_j\eta\, dx - \int_\Gamma \psi_m\eta n_j\, dS - \int_{\Omega_s} \psi\partial_j\eta\, dx + \int_\Gamma \psi_s\eta n_j\, dS \\
&= -\int_{\Omega\setminus\overline{B_\sigma}} \psi\partial_j\eta\, dx + \int_\Gamma [\![\psi]\!] n_j\eta\, dS \\
&= -\int_{\Omega\setminus\overline{B_\sigma}} \psi\partial_j\eta\, dx,
\end{aligned}$$

where in the last step we used the fact that $[\![\psi]\!] = 0$ on Γ. Thus, $\xi_j = \partial_j\psi \in L^2(\Omega\setminus\overline{B_\sigma})$, and, hence, $\psi \in H^1_*(\Omega)$ by the arbitrariness of $\sigma > 0$.

Clearly, $\chi_{\Omega_s}B'(\psi) \in L^2(\Omega_s)$ and $\psi = \psi_0$ on $\partial\Omega$. It remains to show that (2.1) holds true. Let $\eta \in C_c^\infty(\Omega)$. Let V_1 and V_2 be two open sets in $\mathbb{R}^3$ such that ∂V_1 and ∂V_2 are of C^2, $x_i \notin V_2$ for $i = 1, \dots, N$, and $\Gamma \subset V_1 \subset \overline{V}_1 \subset V_2 \subset \overline{V}_2 \subset \Omega$. Let

$\zeta \in C_c^\infty(\Omega)$ be such that $\operatorname{supp}\zeta \subset V_2$ and $\zeta = 1$ on V_1. Then, $(1-\zeta)\eta|_{\Omega_m} \in C_c^\infty(\Omega_m)$, $(1-\zeta)\eta|_{\Omega_s} \in C_c^\infty(\Omega_s)$, and $(1-\zeta(x_i))\eta(x_i) = \eta(x_i),\ i = 1, \ldots, N$. We, thus, have by (2.2) and (2.3) that

$$
\begin{aligned}
&\int_\Omega \left[\varepsilon_\Gamma \nabla\psi\cdot\nabla\eta + 4\pi\chi_{\Omega_s} B'\left(\psi - \frac{\hat\psi_0}{2}\right)\eta\right] dx \\
&\quad = \int_\Omega \left[\varepsilon_\Gamma \nabla\psi\cdot\nabla((1-\zeta)\eta) + 4\pi\chi_{\Omega_s} B'\left(\psi - \frac{\hat\psi_0}{2}\right)(1-\zeta)\eta\right] dx \\
&\qquad + \int_\Omega \left[\varepsilon_\Gamma \nabla\psi\cdot\nabla(\zeta\eta) + 4\pi\chi_{\Omega_s} B'\left(\psi - \frac{\hat\psi_0}{2}\right)\zeta\eta\right] dx \\
&\quad = \int_{\Omega_m} \varepsilon_\Gamma \nabla\psi\cdot\nabla((1-\zeta)\eta) dx \\
&\qquad + \int_{\Omega_s} \left[\varepsilon_\Gamma \nabla\psi\cdot\nabla((1-\zeta)\eta) + 4\pi\chi_{\Omega_s} B'\left(\psi - \frac{\hat\psi_0}{2}\right)(1-\zeta)\eta\right] dx \\
&\qquad + \int_{V_2} \left[\varepsilon_\Gamma \nabla\psi\cdot\nabla(\zeta\eta) + 4\pi\chi_{\Omega_s} B'\left(\psi - \frac{\hat\psi_0}{2}\right)\zeta\eta\right] dx \\
&\quad = 4\pi\sum_{i=1}^N Q_i\eta(x_i) + \int_{V_2} \left[\varepsilon_\Gamma \nabla\psi\cdot\nabla(\zeta\eta) + 4\pi\chi_{\Omega_s} B'\left(\psi - \frac{\hat\psi_0}{2}\right)\zeta\eta\right] dx. \qquad (4.2)
\end{aligned}
$$

We now show that the second term in (4.2) is zero. Notice that $\psi|_{V_2} \in H^1(V_2)$ and $x_i \notin V_2$ $(1 \le i \le N)$. Denoting $V_m = V_2 \cap \Omega_m$ and $V_s = V_2 \cap \Omega_s$, we have by (2.2) and (2.3) that

$$
\begin{aligned}
&\int_{V_m} \varepsilon_m \nabla\psi\cdot\nabla\xi\, dx = 0 \qquad \forall \xi \in C_c^\infty(V_m), \\
&\int_{V_s} \varepsilon_s \nabla\phi\cdot\nabla\xi\, dx = -4\pi\int_{V_s} B'\left(\psi - \frac{\hat\psi_0}{2}\right)\xi\, dx \qquad \forall \xi \in C_c^\infty(V_s).
\end{aligned}
$$

Consequently, since $\chi_{\Omega_s} B'(\psi - \hat\psi_0/2) \in L^2(\Omega_s)$, we infer from the regularity theory of elliptic boundary-value problems [14] that $\psi|_{V_m} \in H^2(V_m)$ and $\psi|_{V_s} \in H^2(V_s)$, and that

$$
\begin{aligned}
\nabla\cdot\varepsilon_m\nabla\psi &= 0 \qquad \text{a.e. } V_m, \\
\nabla\cdot\varepsilon_s\nabla\psi - 4\pi B'\left(\psi - \frac{\hat\psi_0}{2}\right) &= 0 \qquad \text{a.e. } V_s.
\end{aligned}
$$

Therefore, the trace of $\varepsilon_m \nabla\psi \cdot n$ and that of $\varepsilon_s \nabla\psi \cdot n$ on Γ both exist. Moreover,

$$\begin{aligned}
&\int_{V_2} \left[\varepsilon_\Gamma \nabla\psi \cdot \nabla(\zeta\eta) + 4\pi\chi_{\Omega_s} B'\left(\psi - \frac{\hat{\psi}_0}{2}\right)\zeta\eta \right] dx \\
&= \int_{V_m} \varepsilon_m \nabla\psi \cdot \nabla(\zeta\eta) dx + \int_{V_s} \left[\varepsilon_s \nabla\psi \cdot \nabla(\zeta\eta) + 4\pi\chi_{\Omega_s} B'\left(\psi - \frac{\hat{\psi}_0}{2}\right)\zeta\eta \right] dx \\
&= -\int_{V_m} (\nabla \cdot \varepsilon_m \nabla\psi)\zeta\eta \, dx - \int_\Gamma (\varepsilon_m \nabla\psi \cdot n)\zeta\eta \, dS \\
&\quad + \int_{V_s} \left[-(\nabla \cdot \varepsilon_s \nabla\psi)(\zeta\eta) + 4\pi\chi_{\Omega_s} B'\left(\psi - \frac{\hat{\psi}_0}{2}\right)\zeta\eta \right] dx + \int_\Gamma (\varepsilon_s \nabla\psi \cdot n)\zeta\eta \, dS \\
&= \int_\Gamma [\![\varepsilon \nabla\psi \cdot n]\!] \zeta\eta \, dS \\
&= 0,
\end{aligned} \tag{4.3}$$

where in the last step, we used the third equation of (1.15). Now, since $\eta \in C_c^\infty(\Omega)$ is arbitrary, we obtain (2.1) from (4.2) and (4.3). ∎

5. Minimization of the electrostatic free energy: Proof of Theorems 2.3, 2.4, and 2.5.

Proof of Theorem 2.3. Let $t = 1 + \beta \max_{1\le j\le M} \|\mu_{0j}\|_{L^\infty(\Omega_s)}$, where μ_{0j} $(j = 1, \dots, M)$ are defined in (3.14). It follows from (3.12) and (3.4) that there exists $C_5 > 0$ such that

$$F_0[c] \ge C_5 \left\| \sum_{j=1}^M q_j c_j \right\|^2_{H^{-1}(\Omega)} + \beta^{-1} \sum_{j=1}^M \int_{\Omega_s} S_{-t}(c_j) dx + E_0 \qquad \forall c = (c_1, \dots, c_M) \in V_0, \tag{5.1}$$

where E_0 is defined in (3.15). Let $z = \inf_{c\in V_0} F_0[c]$. Since $S_{-t} : [0,\infty) \to \mathbb{R}$ is bounded below, z is finite.

Let $c^{(k)} = (c_1^{(k)}, \dots, c_M^{(k)}) \in V_0$ $(k = 1, 2, \dots)$ be such that $\lim_{k\to\infty} F_0[c^{(k)}] = z$. It follows from (5.1) that $\{\int_{\Omega_s} S_{-t}(c_j^{(k)})dx\}$ is bounded for each $j = 1, \dots, M$. Therefore, by Lemma 3.3, up to a subsequence that is not relabeled, $\{c_j^{(k)}\}$ converges weakly in $L^1(\Omega_s)$ to some $c_j \in L^1(\Omega_s)$, and

$$\int_{\Omega_s} S_{-t}(c_j)\, dx \le \liminf_{k\to\infty} \int_{\Omega_s} S_{-t}\left(c_j^{(k)}\right) dx < \infty \qquad j = 1, \dots, M. \tag{5.2}$$

Define $c_j = 0$ on Ω_m for all $j = 1, \dots, M$. By (5.1), $\{\sum_{j=1}^M q_j c_j^{(k)}\}$ is bounded in $H^{-1}(\Omega)$. Since $H^{-1}(\Omega)$ is a Hilbert space, $\{\sum_{j=1}^M q_j c_j^{(k)}\}$ has a subsequence, again not relabeled, that weakly converges to some $F \in H^{-1}(\Omega)$. Let $\xi \in L^\infty(\Omega) \cap H_0^1(\Omega)$. We have

$$F(\xi) = \lim_{k\to\infty} \int_\Omega \left(\sum_{j=1}^M q_j c_j^{(k)} \right) \xi dx = \int_\Omega \left(\sum_{j=1}^M q_j c_j \right) \xi dx.$$

Therefore, $\sum_{j=1}^M q_j c_j \in H^{-1}(\Omega)$ and, hence, $c = (c_1, \dots, c_M) \in V_0$.

By (5.2) and the fact that the norm of a Banach space is sequentially weakly lower semicontinuous, we have $z = \liminf_{k\to\infty} F_0[c^{(k)}] \geq F_0[c] \geq z$. This implies that $c \in V_0$ is a global minimizer of $F_0 : V_0 \to \mathbb{R}$.

Let $d = (d_1, \ldots, d_M) \in V_0$ be a local minimizer of $F_0 : V_0 \to \mathbb{R}$. Then for $\lambda \in (0, 1)$ close to 0, we have by the convexity of $F_0 : V_0 \to \mathbb{R}$ that

$$F_0[d] \leq F_0[\lambda c + (1-\lambda)d] \leq \lambda F_0[c] + (1-\lambda)F_0[d],$$

leading to $F_0[d] \leq F_0[c]$. Thus, d is also a global minimizer of $F_0 : V_0 \to \mathbb{R}$. Clearly, $(c+d)/2 \in V_0$. Consequently, it follows from the definition of the norm $|||\cdot|||$ and the Cauchy–Schwarz inequality with respect to the inner product $\langle \xi, \eta \rangle = \xi(L\eta)$ $(\xi, \eta \in H^{-1}(\Omega))$ that

$$\begin{aligned}
0 &\leq F_0\left[\frac{c+d}{2}\right] - \min_{e\in V_0} F_0[e] \\
&= F_0\left[\frac{c+d}{2}\right] - \frac{1}{2}F_0[c] - \frac{1}{2}F_0[d] \\
&= \frac{1}{8}\left|\left|\left|\sum_{j=1}^{M} q_j(c_j + d_j)\right|\right|\right|^2 - \frac{1}{4}\left|\left|\left|\sum_{j=1}^{M} q_j c_j\right|\right|\right|^2 - \frac{1}{4}\left|\left|\left|\sum_{j=1}^{M} q_j d_j\right|\right|\right|^2 \\
&\quad + \beta^{-1}\sum_{j=1}^{M}\int_{\Omega_s}\left[S_{-1}\left(\frac{c_j+d_j}{2}\right) - \frac{1}{2}S_{-1}(c_j) - \frac{1}{2}S_{-1}(d_j)\right]dx \\
&\leq \beta^{-1}\sum_{j=1}^{M}\int_{\Omega_s}\left[S_{-1}\left(\frac{c_j+d_j}{2}\right) - \frac{1}{2}S_{-1}(c_j) - \frac{1}{2}S_{-1}(d_j)\right]dx.
\end{aligned}$$

This, together with the convexity of S_{-1} on $[0, \infty)$, implies that

$$S_{-1}\left(\frac{c_j(x)+d_j(x)}{2}\right) = \frac{1}{2}S_{-1}(c_j(x)) + \frac{1}{2}S_{-1}(d_j(x)) \qquad \forall j = 1, \ldots, M,\ \forall x \in \Omega_s \backslash \omega_s,$$

for some $\omega_s \subset \Omega_s$ with $|\omega_s| = 0$. Let $x \in \Omega_s \setminus \omega_s$. Then it follows from the definition of $S_{-1} : [0, \infty) \to \mathbb{R}$ that $c_j(x) = 0$ if and only if $d_j(x) = 0$ for all $j = 1, \ldots, M$. The strict convexity of S_0 on $(0, \infty)$ then implies that $c = d$ a.e. Ω_s. Hence, $c = d$ in V_0. □

Proof of Theorem 2.4. (1) Let $c = (c_1, \ldots, c_M) \in W_0$. We show that the following four statements are equivalent:

(i) c is an equilibrium of $F_0 : W_0 \to \mathbb{R}$;

(ii) The property (2.5) holds true, and

$$q_j L\left(\sum_{j=1}^{M} q_j c_j\right) + \mu_{0j} + \beta^{-1}\log c_j = 0 \qquad \text{a.e. } \Omega_s, \quad j = 1, \ldots, M; \tag{5.3}$$

(iii) c is a global minimizer of $F_0 : W_0 \to \mathbb{R}$;

(iv) c is a local minimizer of $F_0 : W_0 \to \mathbb{R}$.

Assume (i) is true. Then (2.5) holds true by Definition 2.3. Let $e = (e_1, \ldots, e_M) \in X \cap L^\infty(\Omega, \mathbb{R}^M)$. Notice that $S'_{-1}(u) = \log u$ for any $u > 0$. Thus, for each $j \in \{1, \ldots, M\}$ and each $x \in \Omega_s$, the mean-value theorem implies the existence of $\theta_j(x) \in [0, 1]$ such that

$$S_{-1}(c_j(x) + te_j(x)) - S_{-1}(c_j(x)) = te_j(x)\log(c_j(x) + t\theta_j(x)e_j(x)).$$

Hence, by the Lebesgue dominated convergence theorem,

$$\lim_{t\to 0}\int_{\Omega_s}\frac{S_{-1}(c_j+te_j)-S_{-1}(c_j)}{t}dx=\int_{\Omega_s}e_j\log c_j\,dx,\qquad j=1,\dots,M.$$

Therefore, it follows from Definition 2.3, the definition of the norm $\|\!|\cdot|\!\|$, (3.12), and (3.4) that

$$\begin{aligned}
0&=\delta F_0[c]e\\
&=\lim_{t\to 0}\frac{F_0[c+te]-F_0[c]}{t}\\
&=\lim_{t\to 0}\left\{\frac{1}{2}t\left|\!\left|\!\left|\sum_{j=1}^M q_je_j\right|\!\right|\!\right|^2+\int_{\Omega_s}\left(\sum_{j=1}^M q_je_j\right)L\left(\sum_{j=1}^M q_jc_j\right)dx\right.\\
&\qquad\left.+\sum_{j=1}^M\int_{\Omega_s}\mu_{0j}e_j dx+\beta^{-1}\sum_{j=1}^M\int_{\Omega_s}\frac{1}{t}\left[S_{-1}(c_j+te_j)-S_{-1}(c_j)\right]dx\right\}\\
&=\sum_{j=1}^M\int_{\Omega_s}\left[q_jL\left(\sum_{j=1}^M q_jc_j\right)+\mu_{0j}+\beta^{-1}\log c_j\right]e_j dx\qquad\forall e\in X\cap L^\infty\left(\Omega,\mathbb{R}^M\right).
\end{aligned}\tag{5.4}$$

This implies (5.3). Hence, (ii) is true.

Assume (ii) is true. We show that (iii) is true. By Lemma 3.4, we need only to show that $F_0[c]\le F_0[d]$ for any fixed $d=(d_1,\dots,d_M)\in W_0$ that satisfies (2.5) with c replaced by d. In fact, setting $e=(e_1,\dots,e_M)=d-c\in X\cap L^\infty(\Omega,\mathbb{R}^M)$, we have by the convexity of $S_{-1}:[0,\infty)\to\mathbb{R}$ that

$$S_{-1}(d_j)-S_{-1}(c_j)\ge(d_j-c_j)S'_{-1}(c_j)=e_j\log c_j\qquad\text{a.e. }\Omega_s.$$

Therefore, it follows from (3.12) and (5.3) that

$$\begin{aligned}
F_0[d]-F_0[c]&=\frac{1}{2}\int_{\Omega_s}\left(\sum_{j=1}^M q_je_j\right)L\left(\sum_{j=1}^M q_je_j\right)dx+\int_{\Omega_s}\left(\sum_{j=1}^M q_je_j\right)L\left(\sum_{j=1}^M q_jc_j\right)dx\\
&\quad+\sum_{j=1}^M\int_{\Omega_s}\mu_{0j}e_j dx+\beta^{-1}\sum_{j=1}^M\int_{\Omega_s}\left[S_{-1}(d_j)-S_{-1}(c_j)\right]dx\\
&\ge\sum_{j=1}^M\int_{\Omega_s}\left[q_jL\left(\sum_{i=1}^M q_ic_i\right)+\mu_{0j}+\beta^{-1}\log c_j\right]e_j dx\\
&=0.
\end{aligned}$$

Hence, $F_0[c]\le F_0[d]$, and (iii) is true.

Clearly, (iii) implies (iv).

Finally, assume (iv) is true. By Lemma 3.4, (2.5) holds true. For any $e\in X\cap L^\infty(\Omega,\mathbb{R}^M)$, it is easy to see that $\delta F_0[c]e$ exists, cf. (5.4). Since $F_0[c+te]\ge F_0[c]$ for $|t|$ small enough, we have $\delta F_0[c]e=0$. Therefore, c is an equilibrium of $F_0:W_0\to\mathbb{R}$, and (i) is true.

Let now $\psi \in H^1_*(\Omega)$ be the unique weak solution to the boundary-value problem of the PBE (1.11) and (1.6), cf. Theorem 2.1. Define $c = (c_1, \dots, c_M) : \Omega \to \mathbb{R}$ by (1.9) for point ions and $c_j(x) = 0$ for all $x \in \Omega_m$ and all $j = 1, \dots, M$. Clearly, $c \in W_0$. Moreover, by Theorem 2.1, $\psi|_{\Omega_s} \in C(\overline{\Omega_s})$. This implies (2.5). It follows from (1.11), (1.6), (1.9) for point ions, and Lemma 3.2 with $f = \sum_{j=1}^M q_j c_j$ that ψ is the electrostatic potential corresponding to c; i.e., $\psi = G + \hat{\psi}_0 + L(\sum_{j=1}^M q_j c_j)$. This, together with the Boltzmann relations (1.9) for point ions and (3.14), implies (5.3). Hence, c is an equilibrium, and, thus, a local and global minimizer, of $F_0 : W_0 \to \mathbb{R}$. The uniqueness of equilibria or local minimizers is equivalent to that of global minimizers, and can be proved by the same argument used in the proof of Theorem 2.3.

(2) It is clear that from our definition of c and ψ that we need only to prove (2.7). Since c is the unique minimizer of $F_0 : W_0 \to \mathbb{R}$ and ψ is the corresponding electrostatic potential determined by (3.11), we have by (1.1) and (1.9) for point ions that

$$\begin{aligned}
\min_{d \in W_0} F_0[d] &= F_0[c] \\
&= \frac{1}{2}\sum_{i=1}^N Q_i(\psi - \psi_{vac})(x_i) + \frac{1}{2}\int_{\Omega_s}\left(\sum_{j=1}^M q_j c_j\right)\psi dx \\
&\quad + \beta^{-1}\sum_{j=1}^M \int_{\Omega_s} c_j\left[\log\left(a^3 c_j\right) - 1\right]dx - \sum_{j=1}^M \int_{\Omega_s} \mu_j c_j dx \\
&= \frac{1}{2}\sum_{i=1}^N Q_i(\psi - \psi_{vac})(x_i) - \frac{1}{2}\sum_{j=1}^M \int_{\Omega_s} q_j c_j^\infty e^{-\beta q_j\left(\psi - \hat{\psi}_0/2\right)}\left(\psi - \hat{\psi}_0\right)dx \\
&\quad - \beta^{-1}\sum_{j=1}^M \int_{\Omega_s} c_j^\infty e^{-\beta q_j\left(\psi - \hat{\psi}_0/2\right)} dx. \qquad (5.5)
\end{aligned}$$

Since ψ is the unique solution to the boundary-value problem of PBE (1.11) and (1.6), and since $\hat{\psi}_0$ is harmonic in Ω_s by (1.10), we have

$$\varepsilon_s \Delta\left(\psi - \hat{\psi}_0\right) + 4\pi\sum_{j=1}^M q_j c_j^\infty e^{-\beta q_j\left(\psi - \hat{\psi}_0/2\right)} = 0 \qquad \text{a.e. } \Omega_s.$$

Multiplying both sides of this equation by $\psi - \hat{\psi}_0$ and integrate the resulting terms over Ω_s, we obtain by integration by parts and the fact that by Lemma 3.1 both $\psi - \hat{\psi}_0$ and $\varepsilon_\Gamma \partial_n(\psi - \hat{\psi}_0)$ are continuous across Γ,

$$\begin{aligned}
&-\int_{\Omega_s} \varepsilon_s \left|\nabla\left(\psi - \hat{\psi}_0\right)\right|^2 dx + \int_\Gamma \varepsilon_\Gamma\left(\psi - \hat{\psi}_0\right)\partial_n\left(\psi - \hat{\psi}_0\right)dS \\
&\quad + 4\pi\sum_{j=1}^M \int_{\Omega_s} q_j c_j^\infty e^{-\beta q_j\left(\psi - \hat{\psi}_0/2\right)}\left(\psi - \hat{\psi}_0\right)dx = 0.
\end{aligned}$$

This and (5.5) imply (2.7). ∎

Proof of Theorem 2.5. (1) We first show that $F_a : V_a \to \mathbb{R}$ is a convex functional. Define $T_M = \{(u_1, \dots, u_M) \in \mathbb{R}^M : u_j > 0 \text{ for } j = 1, \dots, M, \text{ and } \sum_{j=1}^M u_j < 1\}$ and

$$h(u) = \left(1 - \sum_{j=1}^M u_j\right)\left[\log\left(1 - \sum_{j=1}^M u_j\right) - 1\right] \qquad \forall u = (u_1, \dots, u_M) \in T_M.$$

Clearly, T_M is convex. We have $\partial_{u_i u_j} h(u) = (1 - \sum_{k=1}^M u_k)^{-1}$ for all $1 \le i, j \le M$. Let $H(u) = (\partial_{u_i u_j} h)$ be the Hessian of $h : T_M \to \mathbb{R}$. Then, for any $y = (y_1, \dots, y_M) \in R^M$, we have $y \cdot H(u)y = (\sum_{k=1}^M y_k)^2/(1 - \sum_{k=1} u_k) \ge 0$. Therefore, $H(u)$ is symmetric, semidefinite for any $u \in T_M$. Hence, $h : T_M \to \mathbb{R}$ is convex. Consequently, since V_a is a convex subset of X and $S_{-1} : [0, \infty) \to \mathbb{R}$ is convex, we conclude by (3.13) that $F_a : V_a \to \mathbb{R}$ is convex.

Let now $c = (c_1, \dots, c_M) \in V_a$. By the same argument used in the proof of Theorem 2.4, we obtain the equivalence of the following four statements:

(i) c is an equilibrium of $F_a : V_a \to \mathbb{R}$;

(ii) The property (2.6) holds true, and

$$q_j L\left(\sum_{i=1}^M q_i c_i\right) + \mu_{aj} + \beta^{-1} \log\left(\frac{a^3 c_j}{1 - a^3 \sum_{i=1}^M c_i}\right) = 0 \quad \text{a.e. } \Omega_s, \quad j = 1, \dots, M; \tag{5.6}$$

(iii) c is a global minimizer of $F_a : V_a \to \mathbb{R}$;

(iv) c is a local minimizer of $F_a : V_a \to \mathbb{R}$.

Let $\psi \in H^1_*(\Omega)$ be the unique weak solution to the boundary-value problem of the PBE (1.12) and (1.6), cf. Theorem 2.1. Define $c = (c_1, \dots, c_M) : \Omega \to \mathbb{R}$ by (1.9) for finite-size ions and $c_j(x) = 0$ for all $x \in \Omega_m$ and all $j = 1, \dots, M$. Clearly, $c \in V_a$. Moreover, by Theorem 2.1, $\psi|_{\Omega_s} \in C(\overline{\Omega_s})$. This implies (2.6). By (1.9) for finite-size ions, we have

$$a^3 \sum_{j=1}^M c_j(x) = 1 - \frac{1}{1 + a^3 \sum_{i=1}^M c_i^\infty e^{-\beta q_i\left(\psi - \hat{\psi}_0/2\right)}}.$$

This together with (1.9) for finite-size ions imply that

$$\frac{c_j}{1 - a^3 \sum_{i=1}^M c_i} = c_j^\infty e^{-\beta q_j\left(\psi - \hat{\psi}_0/2\right)}, \qquad j = 1, \dots, M. \tag{5.7}$$

It follows from (1.12), (1.6), (1.9) for finite-size ions, and Lemma 3.2 with $f = \sum_{j=1}^M q_j c_j$ that ψ is the electrostatic potential corresponding to c, i.e., $\psi = G + \hat{\psi}_0 + L(\sum_{j=1}^M q_j c_j)$. This, together with (5.7) and (3.16), implies (5.6). Hence, c is an equilibrium, and, thus, a local and global minimizer, of $F_a : V_a \to \mathbb{R}$. The uniqueness of equilibria or local minimizers is equivalent to that of global minimizers, and can be proved by the same argument used in the proof of Theorem 2.3.

(2) We need only to prove (2.8). Since c is the unique minimizer of $F_a : V_a \to \mathbb{R}$ and ψ is the corresponding electrostatic potential determined by (3.11), we have by

(1.2), (1.3), and (1.9) for finite-size ions that

$$\begin{aligned}
&\min_{d\in V_a} F_a[d] = F_a[c] \\
&\quad = \frac{1}{2}\sum_{i=1}^{N} Q_i(\psi-\psi_{vac})(x_i) + \frac{1}{2}\int_{\Omega_s}\left(\sum_{j=1}^{M} q_j c_j\right)\psi dx \\
&\qquad + \beta^{-1}\sum_{j=0}^{M}\int_{\Omega_s} c_j\left[\log\left(a^3 c_j\right)-1\right]dx - \sum_{j=1}^{M}\int_{\Omega_s}\mu_j c_j dx \\
&\quad = \frac{1}{2}\sum_{i=1}^{N} Q_i(\psi-\psi_{vac})(x_i) - \frac{1}{2}\sum_{j=1}^{M}\int_{\Omega_s}\frac{q_j c_j^{\infty} e^{-\beta q_j\left(\psi-\hat{\psi}_0/2\right)}\left(\psi-\hat{\psi}_0\right)}{1+a^3\sum_{i=1}^{M} c_i^{\infty} e^{-\beta q_i\left(\psi-\hat{\psi}_0/2\right)}}dx \\
&\qquad - \beta^{-1}a^{-3}\int_{\Omega_s}\left[1+\log\left(1+a^3\sum_{i=1}^{M} c_i^{\infty} e^{-\beta q_i\left(\psi-\hat{\psi}_0/2\right)}\right)\right]dx. \qquad (5.8)
\end{aligned}$$

Since ψ is the unique solution to the boundary-value problem of PBE (1.12) and (1.6), and since $\hat{\psi}_0$ is harmonic in Ω_s by (1.10), we have

$$\varepsilon_s\Delta\left(\psi-\hat{\psi}_0\right) + 4\pi\sum_{j=1}^{M}\frac{q_j c_j^{\infty} e^{-\beta q_j\left(\psi-\hat{\psi}_0/2\right)}}{1+a^3\sum_{i=1}^{M} c_i^{\infty} e^{-\beta q_i\left(\psi-\hat{\psi}_0/2\right)}} = 0 \qquad \text{a.e. } \Omega_s.$$

Multiplying both sides of this equation by $\psi-\hat{\psi}_0$ and integrating the resulting terms over Ω_s, we obtain by integration by parts and the fact that by Lemma 3.1 both $\psi-\hat{\psi}_0$ and $\varepsilon_\Gamma\partial_n(\psi-\hat{\psi}_0)$ are continuous across Γ,

$$\begin{aligned}
&-\int_{\Omega_s}\varepsilon_s\left|\nabla\left(\psi-\hat{\psi}_0\right)\right|^2 dx + \int_{\Gamma}\varepsilon_\Gamma\left(\psi-\hat{\psi}_0\right)\partial_n\left(\psi-\hat{\psi}_0\right)dS \\
&\qquad + 4\pi\sum_{j=1}^{M}\int_{\Omega_s}\frac{q_j c_j^{\infty} e^{-\beta q_j\left(\psi-\hat{\psi}_0/2\right)}\left(\psi-\hat{\psi}_0\right)}{1+a^3\sum_{i=1}^{M} c_i^{\infty} e^{-\beta q_i\left(\psi-\hat{\psi}_0/2\right)}}dx = 0.
\end{aligned}$$

This and (5.8) imply (2.8). ∎

Appendix A.

We now prove Lemma 3.4 and Lemma 3.5 by constructing ionic concentrations that satisfy required conditions and that have lower free energies. The key idea here is based on the following observation: the function $S_\alpha : [0,\infty)\to\mathbb{R}$, defined for any $\alpha\in\mathbb{R}$ by $S_\alpha(0)=0$ and $S_\alpha(u)=u(\alpha+\log u)$ if $u>0$, has a unique minimizer which is a positive number. Moreover, the magnitude $|S'_\alpha(u)|$ is very large if u is close to 0 or ∞. Notice that $-S_\alpha$ represents the entropy of the system. Therefore, small changes of concentrations near zero or infinity can largely increase the corresponding entropy and, hence, decrease the free energy.

Proof of Lemma 3.4. We first construct $\bar{c}\in W_0$ that satisfies

$$\bar{c}_j(x)\le\gamma_2' \qquad \text{a.e. } x\in\Omega_s,\ j=1,\dots,M, \qquad (A.1)$$

for some constant $\gamma_2'>0$, $\|\bar{c}-c\|_X<\varepsilon/2$, and $F_0[\bar{c}]\le F_0[c]$ with a strict inequality if $c\notin L^\infty(\Omega,\mathbb{R}^M)$. Let $A>0$. Define $\bar{c}=(\bar{c}_1,\dots,\bar{c}_M):\Omega\to\mathbb{R}$ by

$$\bar{c}_j(x) = \begin{cases} c_j(x) & \text{if } c_j(x)\le A \\ 0 & \text{if } c_j(x)>A \end{cases} \qquad \forall x\in\Omega,\ j=1,\dots,M. \qquad (A.2)$$

Clearly, $\bar{c} \in W_0$ and (A.1) holds true with $\gamma_2' = A$. Moreover, $\sum_{j=1}^M \|\bar{c}_j - c_j\|_{L^1(\Omega)} < \varepsilon/4$ for $A > 0$ large enough.

Denote

$$\tau_j(A) = \{x \in \Omega_s : c_j(x) > A\}, \qquad j = 1, \dots, M.$$

Since $c \in W_0$, there exists $p > 3/2$ such that each $c_j \in L^p(\Omega)$ $(1 \le j \le M)$. Thus,

$$\sum_{j=1}^M q_j \bar{c}_j - \sum_{j=1}^M q_j c_j = -\sum_{j=1}^M q_j \chi_{\tau_j(A)} c_j \to 0 \qquad \text{in } L^p(\Omega) \quad \text{as } A \to \infty.$$

By the definition of $L : H^{-1}(\Omega) \to H_0^1(\Omega)$ and the regularity theory for elliptic problems [14], we have $L(\sum_{j=1}^M q_j \chi_{\tau_j(A)} c_j)|_{\Omega_s} \in W^{2,p}(\Omega_s)$ and

$$\left\| L\left(\sum_{j=1}^M q_j \chi_{\tau_j(A)} c_j \right) \right\|_{W^{2,p}(\Omega_s)} \le C \left\| \sum_{j=1}^M q_j \chi_{\tau_j(A)} c_j \right\|_{L^p(\Omega_s)} \to 0 \qquad \text{as } A \to \infty.$$

Hence, by (3.4) and the embedding $W^{2,p}(\Omega_s) \hookrightarrow L^\infty(\Omega_s)$ that

$$\begin{aligned}
\left\| \sum_{j=1}^M q_j \bar{c}_j - \sum_{j=1}^M q_j c_j \right\|_{H^{-1}(\Omega)}^2 &\le C \int_{\Omega_s} \left(\sum_{j=1}^M q_j \chi_{\tau_j(A)} c_j \right) L\left(\sum_{j=1}^M q_j \chi_{\tau_j(A)} c_j \right) dx \\
&\le C \left\| \sum_{j=1}^M q_j \chi_{\tau_j(A)} c_j \right\|_{L^1(\Omega_s)} \left\| L\left(\sum_{j=1}^M q_j \chi_{\tau_j(A)} c_j \right) \right\|_{L^\infty(\Omega_s)} \\
&\le C \left\| \sum_{j=1}^M q_j \chi_{\tau_j(A)} c_j \right\|_{L^p(\Omega_s)} \left\| L\left(\sum_{j=1}^M q_j \chi_{\tau_j(A)} c_j \right) \right\|_{W^{2,p}(\Omega_s)} \\
&\le C \left\| \sum_{j=1}^M q_j \chi_{\tau_j(A)} c_j \right\|_{L^p(\Omega_s)}^2 \\
&\to 0 \qquad \text{as } A \to \infty.
\end{aligned}$$

Therefore, $\|\bar{c} - c\|_X < \varepsilon$ if $A > 0$ is large enough.

Notice that $\bar{c}_j = c_j - \chi_{\tau_j(A)} c_j$ for all $j = 1, \dots, M$. Thus,

$$\begin{aligned}
&\frac{1}{2} \int_{\Omega_s} \left(\sum_{j=1}^M q_j \bar{c}_j \right) L\left(\sum_{j=1}^M q_j \bar{c}_j \right) dx - \frac{1}{2} \int_{\Omega_s} \left(\sum_{j=1}^M q_j c_j \right) L\left(\sum_{j=1}^M q_j c_j \right) dx \\
&\quad = -\frac{1}{2} \int_{\Omega_s} \left(\sum_{j=1}^M q_j \chi_{\tau_j(A)} c_j \right) L\left(\sum_{j=1}^M q_j c_j + \sum_{j=1}^M q_j \bar{c}_j \right) dx \\
&\quad \le \frac{1}{2} \sum_{j=1}^M |q_j| d_j(A) \int_{\tau_j(A)} c_j dx, \qquad \text{(A.3)}
\end{aligned}$$

where

$$d_j(A) = \left\| L\left(\sum_{j=1}^M q_j c_j\right)\right\|_{L^\infty(\Omega_s)} + \left\| L\left(\sum_{j=1}^M q_j \bar{c}_j\right)\right\|_{L^\infty(\Omega_s)}.$$

Since

$$\begin{aligned}\left\| L\left(\sum_{j=1}^M q_j \bar{c}_j\right)\right\|_{L^\infty(\Omega_s)} &\le C\left\| L\left(\sum_{j=1}^M q_j \bar{c}_j\right)\right\|_{W^{2,p}(\Omega_s)}\\ &\le C\left\|\sum_{j=1}^M q_j \bar{c}_j\right\|_{L^p(\Omega_s)} \to \left\|\sum_{j=1}^M q_j c_j\right\|_{L^p(\Omega_s)}\end{aligned}$$

as $A \to \infty$, we have $\max_{1\le j\le M} d_j(A) \le C$ as $A > 0$ large enough. For each fixed $j \in \{1,\dots,M\}$ and $x \in \tau_j(A)$, we also have

$$S_{-1}(\bar{c}_j(x)) - S_{-1}(c_j(x)) = -S_{-1}(c_j(x)) = -c_j(x)\log c_j(x) \le -c_j(x)\log A. \tag{A.4}$$

Therefore, it follows from (3.12), (A.3), and (A.4) that

$$F_0[\bar{c}] - F_0[c] \le \sum_{j=1}^M \left(\frac{1}{2}|q_j| d_j(A) + \|\mu_{0j}\|_{L^\infty(\Omega_s)} - \beta^{-1}\log A\right)\int_{\tau_j(A)} c_j dx.$$

If $A > 0$ is large enough, this is nonpositive. If $c \notin L^\infty(\Omega,\mathbb{R}^M)$, then there exists $j \in \{1,\dots,M\}$ such that $|\tau_j(A)| > 0$ for all $A > 0$. In this case, we have the strict inequality $F_0[\bar{c}] < F_0[c]$.

We now construct $\hat{c} \in W_0$ that satisfies (2.5) with c replaced by $\hat{c}$, $\|\hat{c}-\bar{c}\|_X < \varepsilon/2$, and $F_0[\hat{c}] \le F_0[\bar{c}]$ with a strict inequality if there exists $j \in \{1,\dots,M\}$ such that $|\{x \in \Omega_s : c_j(x) < \alpha\}| > 0$ for all $\alpha > 0$, all these implying that $\hat{c}$ satisfies all the desired properties. If there exists $\gamma_1' > 0$ such that $c_j(x) \ge \gamma_1'$ for a.e. $x \in \Omega_s$ and $j = 1,\dots,M$, then $\hat{c} = \bar{c}$ with $A \ge \gamma_1'$ (cf. (A.2)) satisfies all the desired properties with $\gamma_1 = \gamma_1'$ and $\gamma_2 = \gamma_2'$. Assume otherwise there exists $j_0 \in \{1,\dots,M\}$ such that $|\{x \in \Omega_s : c_{j_0}(x) < \alpha\}| > 0$ for all $\alpha > 0$. This means that $|\{x \in \Omega_s : \bar{c}_{j_0}(x) < \alpha\}| > 0$ for all $\alpha > 0$.

Define

$$\begin{aligned}&\rho_j(\alpha) = \{x \in \Omega_s : \bar{c}_j(x) < \alpha\} \qquad \forall \alpha > 0, \quad j = 1,\dots,M,\\ &I_0 = \{j \in \{1,\dots,M\} : |\rho_j(\alpha)| > 0\ \forall \alpha > 0\},\\ &I_1 = \{1,\dots,M\} \setminus I_0.\end{aligned}$$

Clearly, $I_0 \ne \emptyset$. If $I_1 \ne \emptyset$, then there exists $\alpha_1 > 0$ such that

$$\bar{c}_j(x) \ge \alpha_1 \qquad \text{a.e. } x \in \Omega_s, \quad \forall j \in I_1.$$

Define for $0 < \alpha < \alpha_1$ and $1 \le j \le M$

$$\hat{c}_j(x) = \begin{cases} \bar{c}_j(x) + \alpha\chi_{\rho_j(\alpha)}(x) & \text{if } j \in I_0\\ \bar{c}_j(x) & \text{if } j \in I_1\end{cases} \qquad \forall x \in \Omega.$$

Clearly, $\hat{c} = (\hat{c}_1,\dots,\hat{c}_M) \in W_0$ and (2.5) holds true with c replaced by $\hat{c}$, $\gamma_1 = \alpha$, and $\gamma_2 = \gamma_2' + \alpha$. Moreover, $\sum_{j=1}^M \|\hat{c}_j - \bar{c}_j\|_{L^1(\Omega)} < \varepsilon/4$ if $\alpha > 0$ is small enough.

Furthermore,

$$\left\|\sum_{j=1}^{M} q_j\hat{c}_j - \sum_{j=1}^{M} q_j\bar{c}_j\right\|_{H^{-1}(\Omega)} = \alpha\left\|\sum_{j\in I_0} q_j\chi_{\rho_j(\alpha)}\right\|_{H^{-1}(\Omega)} \le \alpha\left\|\sum_{j\in I_0} q_j\chi_{\rho_j(\alpha)}\right\|_{L^2(\Omega)}$$

$$\le \alpha\sum_{j\in I_0}|q_j|\sqrt{|\rho_j(\alpha)|} \to 0 \qquad \text{as } \alpha\to 0. \tag{A.5}$$

Hence, $\|\hat{c}-\bar{c}\|_X < \varepsilon/2$ if $\alpha>0$ is small enough.

By the mean-value theorem and the fact that $S'_{-1}(u)=\log u$ for any $u>0$,

$$\sum_{j=1}^{M}\int_{\Omega_s}[S_{-1}(\hat{c}_j)-S_{-1}(\bar{c}_j)]\,dx = \sum_{j\in I_0}\int_{\rho_j(\alpha)}[S_{-1}(\hat{c}_j)-S_{-1}(\bar{c}_j)]\,dx$$
$$\le \alpha\log(2\alpha)\sum_{j\in I_0}|\rho_j(\alpha)|.$$

Consequently, it follows from (3.13), (3.4), (A.5) that

$$\begin{aligned}
F_0[\hat{c}]-F_0[\bar{c}] &= \frac{1}{2}\int_{\Omega_s}\left(\sum_{j=1}^{M} q_j\bar{c}_j+\alpha\sum_{j\in I_0} q_j\chi_{\rho_j(\alpha)}\right)L\left(\sum_{j=1}^{M} q_j\bar{c}_j+\alpha\sum_{j\in I_0} q_j\chi_{\rho_j(\alpha)}\right)dx\\
&\quad-\frac{1}{2}\int_{\Omega_s}\left(\sum_{j=1}^{M} q_j\bar{c}_j\right)L\left(\sum_{j=1}^{M} q_j\bar{c}_j\right)dx+\alpha\sum_{j\in I_0}\int_{\rho_j(\alpha)}\mu_{0j}dx\\
&\quad+\beta^{-1}\sum_{j\in I_0}\int_{\rho_j(\alpha)}[S_{-1}(\hat{c}_j)-S_{-1}(\bar{c}_j)]\,dx\\
&\le \frac{\alpha^2}{2}\int_{\Omega_s}\left(\sum_{j\in I_0} q_j\chi_{\rho_j(\alpha)}\right)L\left(\sum_{j\in I_0} q_j\chi_{\rho_j(\alpha)}\right)dx\\
&\quad+\alpha\int_{\Omega_s}\left(\sum_{j\in I_0} q_j\chi_{\rho_j(\alpha)}\right)L\left(\sum_{j=1}^{M} q_j\bar{c}_j\right)dx\\
&\quad+\alpha\sum_{j\in I_0}\|\mu_{0j}\|_{L^\infty(\Omega_s)}|\rho_j(\alpha)|+\alpha\sum_{j\in I_0}\beta^{-1}\log(2\alpha)|\rho_j(\alpha)|\\
&\le \frac{\alpha^2}{2}\left(\sum_{i\in I_0} q_i^2\right)\sum_{j\in I_0}|\rho_j(\alpha)|+\alpha\left\|L\left(\sum_{j=1}^{M} q_j\bar{c}_j\right)\right\|_{L^\infty(\Omega_s)}\sum_{j\in I_0}|q_j||\rho_j(\alpha)|\\
&\quad+\alpha\sum_{j\in I_0}\|\mu_{0j}\|_{L^\infty(\Omega_s)}|\rho_j(\alpha)|+\alpha\sum_{j\in I_0}\beta^{-1}\log(2\alpha)|\rho_j(\alpha)|\\
&= \alpha\sum_{j\in J_0}\left[\frac{\alpha}{2}\left(\sum_{j\in I_0} q_j^2\right)+|q_j|\left\|L\left(\sum_{j=1}^{M} q_j\bar{c}_j\right)\right\|_{L^\infty(\Omega_s)}\right.\\
&\qquad\left.+\|\mu_{0j}\|_{L^\infty(\Omega_s)}+\beta^{-1}\log(2\alpha)\right|\rho_j(\alpha)|.
\end{aligned}$$

Since $I_0\neq\emptyset$, this is strictly negative if $\alpha>0$ is small enough.

Proof of Lemma 3.5. We first construct $\bar{c} = (\bar{c}_1, \dots, \bar{c}_M) \in V_a$ such that

$$a^3 \bar{c}_0(x) = 1 - a^3 \sum_{j=1}^{M} \bar{c}_j(x) \geq \theta_1 \qquad \text{a.e. } x \in \Omega_s \tag{A.6}$$

for some constant $\theta_1 \in (0,1)$, $\|\bar{c} - c\|_X < \varepsilon/2$, and $F_a[\bar{c}] \leq F_a[c]$ with a strict inequality if $|\{x \in \Omega_s : a^3 c_0(x) < \alpha\}| > 0$ for all $\alpha > 0$.

Denote for any $\alpha > 0$

$$\omega_0(\alpha) = \left\{ x \in \Omega_s : a^3 c_0(x) < \alpha \right\}.$$

If there exists a constant $\alpha_1 > 0$ such that $|\omega_0(\alpha_1)| = 0$, i.e., $a^3 c_0(x) \geq \alpha_1$ a.e. Ω_s, then $(\bar{c}_1, \dots, \bar{c}_M) = (c_1, \dots, c_M) \in V_a$ satisfies all the desired properties with $\theta_1 = \alpha_1/(1+\alpha_1) \in (0,1)$. Suppose $|\omega_0(\alpha)| > 0$ for any $\alpha > 0$. Let $0 < \alpha < 1/(4M)$. Let $x \in \omega_0(\alpha)$. Then there exists some $j = j(x) \in \{1, \dots, M\}$ such that $a^3 c_j(x) \geq 1/(2M)$. In fact, if this were not true, then $a^3 c_i(x) < 1/(2M)$ for all $i = 1, \dots, M$. Hence, $a^3 c_0(x) = 1 - a^3 \sum_{i=1}^{M} c_i(x) > 1/2 > \alpha$. This would mean that $x \notin \omega_0(\alpha)$, a contradiction. Denoting

$$H_j(\alpha) = \left\{ x \in \omega_0(\alpha) : a^3 c_j(x) \geq \frac{1}{2M} \right\}, \qquad j = 1, \dots, M,$$

we, thus, have $\omega_0(\alpha) = \cup_{j=1}^{M} H_j(\alpha)$. Since $|\omega_0(\alpha)| > 0$, we have $|H_{j_1}(\alpha)| > 0$ for some j_1 $(1 \leq j_1 \leq M)$. If $|H_j(\alpha) \setminus H_{j_1}(\alpha)| = 0$ for all $j \neq j_1$, then we have $\omega_0(\alpha) = \tilde{K}_1(\alpha) \cup H_{j_1}(\alpha)$ for some $\tilde{K}_1(\alpha) \subset \omega_0(\alpha)$ with $|\tilde{K}_1(\alpha)| = 0$. Otherwise, $|H_{j_2}(\alpha) \setminus H_{j_1}(\alpha)| > 0$ for some $j_2 \neq j_1$. In case $|\omega_0(\alpha) \setminus [H_{j_1}(\alpha) \cup H_{j_2}(\alpha)]| = 0$, we have $\omega_0(\alpha) = \tilde{K}_2(\alpha) \cup H_{j_1}(\alpha) \cup [H_{j_2}(\alpha) \setminus H_{j_1}(\alpha)]$ for some $\tilde{K}_2(\alpha) \subset \omega_0(\alpha)$ with $|\tilde{K}_2(\alpha)| = 0$. By induction, we see that there exist $m \in \{1, \dots, M\}$, $\tilde{K}_m(\alpha) \subset \omega_0(\alpha)$ with $|\tilde{K}_m(\alpha)| = 0$, and mutually disjoint sets $K_{j_1}(\alpha), \dots, K_{j_m}(\alpha) \subseteq \omega_0(\alpha)$ such that $K_{j_i}(\alpha) \subseteq H_{j_i}(\alpha)$ and $|K_{j_i}(\alpha)| > 0$ for $i = 1, \dots, m$, and $\omega_0(\alpha) = \tilde{K}_m(\alpha) \cup [\cup_{i=1}^{m} K_{j_i}(\alpha)]$. By relabeling, we may assume that $j_i = i$ for $i = 1, \dots, m$.

Define now

$$\bar{c}_j(x) = \begin{cases} c_j(x) - \alpha a^{-3} \chi_{K_j(\alpha)}(x) & \forall x \in \Omega,\ j = 1, \dots, m, \\ c_j(x) & \forall x \in \Omega,\ j = m+1, \dots, M, \end{cases} \tag{A.7}$$

$$\bar{c}_0(x) = a^{-3} \left[1 - a^3 \sum_{j=1}^{M} \bar{c}_j(x) \right] \qquad \forall x \in \Omega_s.$$

It is easy to see that $(\bar{c}_1, \dots, \bar{c}_M) \in V_a$. Moreover,

$$a^3 \bar{c}_0(x) = a^3 c_0(x) + \alpha \chi_{\omega_0(\alpha)}(x) \geq \alpha \qquad \text{a.e. } x \in \Omega_s, \tag{A.8}$$

implying (A.6) with $\theta_1 = \alpha$. Clearly, $\sum_{j=1}^{M} \|\bar{c}_j - c_j\|_{L^1(\Omega)} \leq \alpha a^{-3} \sum_{j=1}^{m} |K_j(\alpha)|$. Moreover,

$$\left\| \sum_{j=1}^{M} q_j \bar{c}_j - \sum_{j=1}^{M} q_j c_j \right\|_{H^{-1}(\Omega)} \leq \alpha a^{-3} \left\| \sum_{j=1}^{m} q_j \chi_{K_j(\alpha)} \right\|_{L^2(\Omega)} \leq \alpha a^{-3} \sqrt{\sum_{j=1}^{m} q_j^2 |K_j(\alpha)|}.$$

Therefore, $\|\bar{c} - c\|_X < \varepsilon/2$, provided that $\alpha > 0$ is small enough.

If $x \in K_j(\alpha)$ for some j with $1 \le j \le m$, then $c_j(x) \ge 1/(2Ma^3)$, and $\bar{c}_j(x) \ge 1/(4Ma^3)$ since $0 < \alpha < 1/(4M)$. By the mean-value theorem and the fact that $S'_{-1}(u) = \log u$ for any $u > 0$, there exists $\eta_j(x)$ with $\bar{c}_j(x) \le \eta_j(x) \le c_j(x)$ such that

$$\begin{aligned} S_{-1}\left[\bar{c}_j(x)\right] - S_{-1}\left[c_j(x)\right] &= \left[\bar{c}_j(x) - c_j(x)\right] \log \eta_j(x) \\ &\le -\alpha a^{-3} \log \bar{c}_j(x) \le \alpha a^{-3} \log\left(4Ma^3\right). \end{aligned}$$

By the same argument using (A.8) and the definition of $\omega_0(\alpha)$, we obtain

$$S_{-1}\left(\bar{c}_0(x)\right) - S_{-1}\left(c_0(x)\right) \le \alpha a^{-3} \log\left(a^{-3}\alpha\right) \qquad \text{a.e. } x \in \omega_0(\alpha).$$

Consequently, we have by (3.13), (3.4), and the embedding $L^2(\Omega_s) \hookrightarrow H^{-1}(\Omega_s)$ that

$$\begin{aligned} F_a[\bar{c}] - F_a[c] = \frac{1}{2}\int_{\Omega_s} &\left(\sum_{j=1}^M q_j c_j - \alpha a^{-3} \sum_{j=1}^m q_j \chi_{K_j(\alpha)}\right) \\ &L\left(\sum_{j=1}^M q_j c_j - \alpha a^{-3} \sum_{j=1}^m q_j \chi_{K_j(\alpha)}\right) dx \\ &- \frac{1}{2}\int_{\Omega_s} \left(\sum_{j=1}^M q_j c_j\right) L\left(\sum_{j=1}^M q_j c_j\right) dx - \alpha a^{-3} \sum_{j=1}^m \int_{K_j(\alpha)} \mu_{aj} dx \\ &+ \beta^{-1} \sum_{j=0}^m \int_{\omega_0(\alpha)} \left[S_{-1}(\bar{c}_j) - S_{-1}(c_j)\right] dx \\ \le \frac{1}{2}\alpha^2 a^{-6} &\int_{\Omega_s} \left(\sum_{j=1}^m q_j \chi_{K_j(\alpha)}\right) L\left(\sum_{j=1}^m q_j \chi_{K_j(\alpha)}\right) dx \\ &- \alpha a^{-3} \int_{\Omega_s} \left(\sum_{j=1}^m q_j \chi_{K_j(\alpha)}\right) L\left(\sum_{j=1}^m q_j c_j\right) dx \\ &+ \alpha a^{-3} \sum_{j=1}^m \|\mu_{aj}\|_{L^\infty(\Omega_s)} |K_j(\alpha)| \\ &+ \beta^{-1} \alpha a^{-3} \log\left(a^{-3}\alpha\right) |\omega_0(\alpha)| + \beta^{-1} \alpha a^{-3} \log\left(4Ma^3\right) |\omega_0(\alpha)| \\ \le C\alpha^2 a^{-6} &\left\| \sum_{j=1}^m q_j \chi_{K_j(\alpha)} \right\|^2_{L^2(\Omega_s)} \\ &+ \alpha a^{-3} \left\| L\left(\sum_{j=1}^M q_j c_j\right) \right\|_{L^\infty(\Omega)} \sum_{j=1}^m |q_j| |K_j(\alpha)| \\ &+ \alpha a^{-3} \sum_{j=1}^m \|\mu_{aj}\|_{L^\infty(\Omega_s)} |K_j(\alpha)| + \beta^{-1} \alpha a^{-3} \log\left(8Ma^3\alpha\right) \sum_{j=1}^m |K_j(\alpha)| \\ = \alpha \sum_{j=1}^M &\left[C\alpha a^{-6} q_j^2 + a^{-3}|q_j| \left\| L\left(\sum_{j=1}^M q_j c_j\right) \right\|_{L^\infty(\Omega)} + a^{-3} \|\mu_{aj}\|_{L^\infty(\Omega_s)} \right. \\ &\left. + \beta^{-1} a^{-3} \log\left(8Ma^3\alpha\right) \right] |K_j(\alpha)|, \end{aligned}$$

where $C > 0$ is a constant independent of α. Thus, $F_a[\bar{c}] - F_a[c]$ is nonpositive for $\alpha > 0$ sufficiently small. It is strictly negative, if $|\omega_0(\alpha)| = \sum_{j=1}^m |K_j(\alpha)| > 0$ for all $\alpha > 0$, i.e., if $|\{x \in \Omega_s : a^3 c_0(x) < \alpha\}| > 0$ for all $\alpha > 0$.

We now construct $\hat{c} \in V_a$ that satisfies (2.6) with c replaced by $\hat{c}$, $\|\hat{c} - \bar{c}\|_X < \varepsilon/2$, and $F_a[\hat{c}] \leq F_a[\bar{c}]$ with a strict inequality if there exists $j \in \{1, \ldots, M\}$ such that $|\{x \in \Omega_s : a^3 c_j(x) < \alpha\}| > 0$ for all $\alpha > 0$, all these implying that $\hat{c}$ satisfies all the desired properties. If there exists $\theta_2 \in (0, 1)$ such that $c_j(x) \geq \theta_2$ for a.e. $x \in \Omega_s$ and all $j = 1, \ldots, M$, then $\hat{c} = \bar{c}$ with $0 < \alpha < \theta_2/2$ (cf. (A.7)) satisfies all the desired properties with $\theta_0 = \min(\theta_1, \theta_2/2)$. Assume otherwise there exists $j_0 \in \{1, \ldots, M\}$ such that $|\{x \in \Omega_s : c_{j_0}(x) < \alpha\}| > 0$ for all $\alpha > 0$. This means that $|\{x \in \Omega_s : \bar{c}_{j_0}(x) < \alpha\}| > 0$ for all $\alpha > 0$.

Define

$$\begin{aligned} \sigma_j(\alpha) &= \{x \in \Omega_s : a^3 \bar{c}_j(x) < \alpha\} \qquad \forall \alpha > 0, \quad j = 1, \ldots, M, \\ J_0 &= \{j \in \{1, \ldots, M\} : |\sigma_j(\alpha)| > 0 \ \forall \alpha > 0\}, \\ J_1 &= \{1, \ldots, M\} \setminus J_0. \end{aligned}$$

Clearly, $J_0 \neq \emptyset$. If $J_1 \neq \emptyset$, then there exists $\alpha_2 > 0$ such that

$$a^3 \bar{c}_j(x) \geq \alpha_2 \qquad \text{a.e. } x \in \Omega_s, \quad \forall j \in J_1.$$

Define for $0 < \alpha < \min\{\alpha_2, \theta_1/M\}$ and $1 \leq j \leq M$

$$\hat{c}_j(x) = \begin{cases} \bar{c}_j(x) + \alpha a^{-3} \chi_{\sigma_j(\alpha)}(x) & \text{if } j \in J_0 \\ \bar{c}_j(x) & \text{if } j \in J_1 \end{cases} \qquad \forall x \in \Omega.$$

$$\hat{c}_0(x) = a^{-3} \left[1 - \sum_{j=1}^M a^3 \hat{c}_j(x) \right] \qquad \forall x \in \Omega_s.$$

Notice by (A.6) that

$$\begin{aligned} a^3 \hat{c}_0(x) &= 1 - \sum_{j=1}^M a^3 \hat{c}_j(x) = 1 - \sum_{j=1}^M a^3 \bar{c}_j(x) - \alpha \sum_{j \in J_0} \chi_{\sigma_j(\alpha)} \\ &\geq \theta_1 - \alpha M > 0 \qquad \text{a.e. } x \in \Omega_s. \end{aligned}$$

Thus, $\hat{c} = (\hat{c}_1, \ldots, \hat{c}_M) \in V_a$. Clearly, (2.6) holds true for $\theta_0 = \min\{\alpha, \alpha_2, \theta_1 - \alpha M\}$. Applying the same argument used above, we obtain that $\|\hat{c} - \bar{c}\|_X < \varepsilon/2$ for $\alpha > 0$ small enough.

We have now by the mean-value theorem that

$$\begin{aligned} \sum_{j=1}^M \int_{\Omega_s} [S_{-1}(\hat{c}_j) - S_{-1}(\bar{c}_j)] \, dx &= \sum_{j \in J_0} \int_{\sigma_j(\alpha)} [S_{-1}(\hat{c}_j) - S_{-1}(\bar{c}_j)] \, dx \\ &\leq \alpha a^{-3} \log\left(2\alpha a^{-3}\right) \sum_{j \in J_0} |\sigma_j(\alpha)|. \end{aligned}$$

Similarly, we have by (2.6) that

$$\int_{\Omega_s} [S_{-1}(\hat{c}_0) - S_{-1}(\bar{c}_0)] \, dx \leq -\alpha a^{-3} \log\left(a^{-3}\theta_0\right) \sum_{j \in J_0} |\sigma_j(\alpha)|.$$

Consequently, we have by (3.13) and a similar argument that

$$
\begin{aligned}
F_a[\hat{c}] - F_a[\bar{c}] = {} & \frac{1}{2}\int_{\Omega_s}\left(\sum_{j=1}^{M} q_j\bar{c}_j + \alpha a^{-3}\sum_{j\in J_0} q_j\chi_{\sigma_j(\alpha)}\right) \\
& L\left(\sum_{j=1}^{M} q_j\bar{c}_j + \alpha a^{-3}\sum_{j\in J_0} q_j\chi_{\sigma_j(\alpha)}\right)dx \\
& - \frac{1}{2}\int_{\Omega_s}\left(\sum_{j=1}^{M} q_j\bar{c}_j\right) L\left(\sum_{j=1}^{M} q_j\bar{c}_j\right)dx + \alpha a^{-3}\sum_{j\in J_0}\int_{\sigma_j(\alpha)}\mu_{aj}dx \\
& + \beta^{-1}\sum_{j\in J_0}\int_{\sigma_j(\alpha)}\left[S_{-1}(\hat{c}_j) - S_{-1}(\bar{c}_j)\right]dx \\
& + \beta^{-1}\int_{\Omega_s}\left[S_{-1}(\hat{c}_0) - S_{-1}(\bar{c}_0)\right]dx \\
\le {} & C\alpha^2 a^{-6}\left\|\sum_{j\in J_0} q_j\chi_{\sigma_j(\alpha)}\right\|^2_{L^2(\Omega_s)} + \alpha a^{-3}\left\|\sum_{j=1}^{M} q_j\bar{c}_j\right\|_{L^\infty(\Omega_s)}\sum_{j\in J_0}|q_j||\sigma_j(\alpha)| \\
& + \alpha a^{-3}\sum_{j\in J_0}\|\mu_{aj}\|_{L^\infty(\Omega_s)}|\sigma_j(\alpha)| + \beta^{-1}\alpha a^{-3}\log(2\alpha/\theta_0)\sum_{j\in J_0}|\sigma_j(\alpha)| \\
\le {} & \alpha\sum_{j\in J_0}\left[C\alpha a^{-6}q_j^2 + a^{-3}|q_j|\left\|\sum_{j=1}^{M} q_j\bar{c}_j\right\|_{L^\infty(\Omega_s)} + a^{-3}\|\mu_{aj}\|_{L^\infty(\Omega_s)}\right. \\
& \left. + \beta^{-1}a^{-3}\log(2\alpha/\theta_0)\right]|\sigma_j(\alpha)|.
\end{aligned}
$$

Since $J_0 \neq \emptyset$, this is strictly negative if $\alpha > 0$ is sufficiently small. The case that $J_1 = \emptyset$ can be treated similarly. ∎

Acknowledgments. The author thanks Dr. Jianwei Che, Dr. Joachim Dzubiella, and Dr. Benzhuo Lu for helpful discussions on the background of the underlying problem.

WAVE BREAKING AND PERSISTENCE PROPERTIES FOR THE DISPERSIVE ROD EQUATION*

ZHENGGUANG GUO† AND YONG ZHOU‡

Abstract. This paper is concerned with some aspects of blow up of solutions and persistence properties. Firstly, we will try to give sufficient conditions on the initial data, which guarantee finite time singularity formation for the corresponding solutions. Then a particular class of initial data for the periodic case is also considered in this paper. Finally, we investigate the persistence properties of the strong solutions.

Key words. rod equation, convolution problem, blow up, persistence property

1. Introduction.

Although a rod is always three-dimensional, if its diameter is much less than the axial length scale, one-dimensional equations can give a good description of the motion of the rod. Recently Dai [18] derived a new (one-dimensional) nonlinear dispersive equation including extra nonlinear terms involving second-order and third-order derivatives for a compressible hyperelastic material. The equation reads

$$v_\tau + \sigma_1 v v_\xi + \sigma_2 v_{\xi\xi\tau} + \sigma_3(2v_\xi v_{\xi\xi} + v v_{\xi\xi\xi}) = 0,$$

where $v(\xi,\tau)$ represents the radial stretch relative to a prestressed state, $\sigma_1 \neq 0$, $\sigma_2 < 0$, and $\sigma_3 \leq 0$ are constants determined by the prestress and the material parameters. If one introduces the following transformations

$$\tau = \frac{3\sqrt{-\sigma_2}}{\sigma_1}t, \quad \xi = \sqrt{-\sigma_2}x,$$

then the above equation turns into

$$u_t - u_{xxt} + 3uu_x = \gamma(2u_x u_{xx} + uu_{xxx}), \tag{1.1}$$

where $\gamma = 3\sigma_3/(\sigma_1\sigma_2)$. In [19], the authors derived that the value range of γ is from -29.4760 to 3.4174 for some special compressible materials. In this paper, from the mathematical viewpoint, we regard γ as a real number.

When $\gamma = 1$ in (1.1), we recover the shallow water (Camassa–Holm) equation derived physically by Camassa and Holm in [4] by approximating directly the Hamiltonian for Euler's equations in the shallow water regime, where $u(x,t)$ represents the free surface above a flat bottom. Recently, the alternative derivations of the

Camassa–Holm equation were presented in [5, 25, 13]. Some satisfactory results have been obtained for this shallow water equation recently. Local well-posedness for the initial datum $u_0(x) \in H^s$, with $s > 3/2$ was proved by several authors [10, 26, 32, 34]. For the initial data with lower regularity, we refer to Molinet's paper [30] and also the recent paper [3]. Moreover, wave breaking for a large class of initial data has been established in [8, 9, 10, 11, 26, 29, 36, 40, 41]. Later, in [20], the first author considered the Camassa–Holm equation with weakly dissipative term and established blow-up criteria and sufficient conditions on global existence of the solutions. Recently, in [24], among others, Himonas et al. showed the infinite propagation speed for the Camassa–Holm equation in the sense that a strong solution of the Cauchy problem with compact initial profile cannot be compactly supported at any later time unless it is the zero solution, which is an improvement of previous results in this direction obtained in [6, 21, 22]. These results were recently extended in [23] for a large range of physically important equations. However, in [38], global existence of weak solutions is proved, but uniqueness is obtained only under an a priori assumption that is known to hold only for initial data $u_0(x) \in H^1$ such that $u_0 - u_{0xx}$ is a sign-definite Radon measure (under this condition, global existence and uniqueness was also shown in [14], in which case a stronger concept of weak solutions can be introduced). Actually, there are approaches towards unique global weak solutions for initial data in H^1, the important distinction being between conservative solutions [3] and dissipative solutions [2]. The solitary waves of the Camassa–Holm equation are peaked solitons [4] with $u(x,t) = e^{-|x-ct|}$, where $c \in \mathbb{R}$ is the wave speed. The orbital stability of the peakons was shown by Constantin and Strauss [16]. An alternative approach is proposed in the paper [15]. Here it is worth it to point out that the peakons replicate a feature that is characteristic for the waves of great height-waves of largest amplitude that are exact solutions of the governing equations for water waves; cf. [7, 35, 12].

If $\gamma = 0$, (1.1) is the Benjamin–Bona–Mahony (BBM) equation, a well-known model for surface waves in a canal [1], and its solutions are global.

For general $\gamma \in \mathbb{R}$, much of the early results were proven by Constantin and Strauss in [17] first. Local well-posedness of strong solutions to (1.1) was established by applying Kato's theory, and some sufficient conditions on the initial data were found to guarantee the finite blow up of the corresponding solutions for the spatially nonperiodic case. Later, Zhou [43] proved the well-posedness result in detail, and various refined sufficient conditions on the initial data were found to guarantee the finite time blow up of the corresponding solutions for both the spatially periodic and nonperiodic case; he also applied the best constant of a convolution problem to establish the corresponding blow-up criteria [44]. Recently, blow-up criteria were presented in [37, 39, 42]. It should be mentioned that Liu and Zhou improved their previous results by applying the optimal constant on a kind of Sobolev inequality in [27] (see also a recent paper [28]). Mustafa [31] established a solution with constant H^1 energy. For $\gamma < 1$, the stability of solitary waves was established in [17, 45].

We now finish this introduction by outlining the rest of the paper. In section 2, we recall the local well-posedness for (1.1) with initial datum $u_0 \in H^s$, $s > 3/2$, and the lifespan of the corresponding solution is finite if and only if its first-order derivative blows up. In section 3, we investigate various sufficient conditions of the initial datum to guarantee the finite time blow up. Persistence properties are established for (1.1) in section 4.

2. Preliminaries. In this section, we would like to list some useful theorems for later use.

THEOREM 2.1 (see [39]). *Let the initial datum $u_0(x) \in H^s(\Omega)$, $s > 3/2$. Then there exist $T = T(\| u_0 \|) > 0$ and a unique solution $u(x,t)$, which depends continuously on the initial datum u_0 to* (1.1) *such that*

$$u \in C([0,T); H^s(\Omega)) \cap C^1\left([0,T); H^{s-1}(\Omega)\right).$$

Moreover, the following two quantities $E_1(u)$ and $E_2(u)$ are invariants with respect to time t for (1.1):

$$E_1(u) = \int_\Omega \left(u^2 + u_x^2\right) dx, \quad E_2(u) = \int_\Omega \left(u^3 + \gamma u u_x^2\right) dx.$$

Actually, the local well-posedness was proved for both the periodic and nonperiodic case in the above paper; these two invariants play an important role in considering blow-up phenomenon.

The maximum value of T in Theorem 2.1 is called the lifespan of the solution, in general. If $T < \infty$, that is, $\limsup_{t \uparrow T} \| u(.,t) \|_{H^s} = \infty$, we say that the solution blows up in finite time. The following theorem tells us that the solution blows up if and only if the first-order derivative blows up. This phenomenon coincides physically with the rod breaking.

THEOREM 2.2 (see [17]). *Let $u_0(x) \in H^s(\Omega)$, $s > 3/2$, and $u(x,t)$ be the corresponding solution to problem* (1.1)*, with lifespan T. Then*

$$\sup_{x \in \Omega, 0 \le t < T} |u(x,t)| \le C(\| u_0 \|_{H^1}). \tag{2.1}$$

T is bounded if and only if

$$\lim_{t \uparrow T} \inf \inf_{x \in \Omega} \{\gamma u_x(x,t)\} = -\infty. \tag{2.2}$$

For $\gamma \neq 0$, we set

$$m(t) := \inf_{x \in \Omega} (u_x(x,t) sign\{\gamma\}), \quad t > 0, \tag{2.3}$$

where $sign\{a\}$ in the sign function of $a \in \mathbb{R}$ and we set $m_0 := m(0)$. Then for every $t \in [0,T)$, there exists at least one point $\xi(t) \in \Omega$, with $m(t) = u_x(\xi(t), t)$. Just as the proof given in [11], one can show the following property of m(t).

THEOREM 2.3 (see [11]). *Let $u(t)$ be the solution to* (1.1) *on $[0,T)$, with initial data $u_0 \in H^s(\Omega)$, $s > 3/2$, as given by Theorem* 2.1*. Then the function $m(t)$ is almost everywhere differentiable on $[0,T)$, with*

$$\frac{dm(t)}{dt} = u_{xt}(\xi(t), t), \quad a.e. \quad on(0,T).$$

To consider the quantity $m(t)$ for wave breaking comes from an idea of Seliger [33] originally, the rigorous regularity proof is given in [11] for the Camassa–Holm equation. As we know, the operator $(I - \partial_x^2)^{-1}$ can be expressed by

$$\left(I - \partial_x^2\right)^{-1} f = G * f = \int_\Omega G(x-y) f(y)\, dy$$

for all $f \in L^2(\Omega)$, where $G(x)$ is the associated Green's function. For the periodic case and the whole line case $G(x) = \frac{\cosh(x - [x] - \frac{1}{2})}{2 \sinh(\frac{1}{2})}$ and $G(x) = \frac{1}{2} e^{-|x|}$, respectively, where $[x]$ denotes the integer part of x.

In this paper, $\mathbb{S} := \mathbb{R}/\mathbb{Z}$ stands for the unit circle and $\Omega = \mathbb{R}$ or $\mathbb{S}$. Then (1.1) can be rewritten as

$$u_t + \gamma u u_x + \partial_x G * \left(\frac{3-\gamma}{2} u^2 + \frac{\gamma}{2} u_x^2 \right) = 0. \tag{2.4}$$

In what follows, just for simplicity, we assume that $0 < \gamma < 3$ and introduce the following notation:

$$F(u) = \frac{3-\gamma}{2} u^2 + \frac{\gamma}{2} u_x^2.$$

3. Blow-up phenomena. In this section, we investigate sufficient conditions on the initial data which guarantee the finite time blow up of the corresponding solutions to (1.1). Firstly, we consider the following convolution problem. We can compute

$$\begin{aligned} G * \left(\frac{\gamma\alpha^2}{2} u^2 + \frac{\gamma}{2} u_x^2 \right)(x) &= \frac{1}{2} e^{-x} \int_{-\infty}^{x} e^y \left(\frac{\gamma\alpha^2}{2} u^2 + \frac{\gamma}{2} u_x^2 \right) dy \\ &\quad + \frac{1}{2} e^{x} \int_{x}^{\infty} e^{-y} \left(\frac{\gamma\alpha^2}{2} u^2 + \frac{\gamma}{2} u_x^2 \right) dy \\ &\geq \frac{1}{2} e^{-x} \int_{-\infty}^{x} \gamma\alpha e^y u u_x dy - \frac{1}{2} e^{x} \int_{x}^{\infty} \gamma\alpha e^{-y} u u_x dy \\ &= \frac{\gamma\alpha}{2} u^2 - \frac{\gamma\alpha}{4} \int_{-\infty}^{x} e^y u^2 dy - \frac{\gamma\alpha}{4} \int_{x}^{\infty} e^{-y} u^2 dy, \end{aligned}$$

where α is a positive number. So we obtain

$$G * \left(\frac{\gamma\alpha^2 + \gamma\alpha}{2} u^2 + \frac{\gamma}{2} u_x^2 \right)(x) \geq \frac{\gamma\alpha}{2} u^2(x).$$

Now we let

$$\alpha^2 + \alpha = \frac{3-\gamma}{\gamma}. \tag{3.1}$$

Therefore,

$$G * \left(\frac{3-\gamma}{2} u^2 + \frac{\gamma}{2} u_x^2 \right)(x) \geq \frac{\gamma\alpha}{2} u^2(x). \tag{3.2}$$

Moreover, $\frac{\gamma\alpha}{2}$ is the best constant if and only if

$$\alpha u = u_x \quad \text{in } (-\infty, x) \quad \text{and} \quad -\alpha u = u_x \quad \text{in } (x, \infty),$$

which can be solved as $u = \lambda e^{-\alpha|x-y|}$ for some $\lambda, y \in \mathbb{R}$, α is a positive root determined by (3.1).

The following theorem refines the result first obtained in [17] by admitting a larger class of initial data.

THEOREM 3.1. *Assume $u_0(x) \in H^3(\mathbb{R})$ is odd, and $u_0'(0) < 0$. Then the corresponding solution of* (1.1) *blows up in finite time.*

Proof. Let $T > 0$ is the maximal time of existence of the solution $u(x,t)$ to (1.1), with initial data u_0. As one can check, the function $-u(-x,t)$ is also a solution to

(1.1), with initial data $-u_0(-x)$. By this fact, $-u_0(-x) = u_0(x)$ and the uniqueness of solution to (1.1), we get

$$u(x,t) = -u(-x,t) \quad \text{for all } t \in [0,T), \quad x \in \mathbb{R}.$$

Differentiating both sides of (2.4) with respect to variable x, we obtain

$$u_{xt} = -\frac{\gamma}{2}u_x^2 + \frac{3-\gamma}{2}u^2 - \gamma u u_{xx} - \left[G * \left(\frac{3-\gamma}{2}u^2 + \frac{\gamma}{2}u_x^2\right)\right](x,t). \tag{3.3}$$

In view of the above analysis, we have

$$u(0,t) = u_{xx}(0,t) = 0, \quad t \in [0,T).$$

Therefore,

$$\frac{du_x(0,t)}{dt} \le -\frac{\gamma}{2}u_x^2(0,t).$$

From the hypothesis, we have $u_0'(0) < 0$. Therefore, $u_x(0,t) < 0$ for all $t \in [0,T)$. Solving the above inequality, we get

$$-\frac{1}{u_x(0,t)} + \frac{1}{u_0'(0)} \le -\frac{\gamma}{2}t.$$

We conclude that there exists T and

$$T \le -\frac{2}{\gamma u_0'(0)}$$

such that $\lim_{t\uparrow T} u_x(0,t) = -\infty$. Thus, we finish the proof by Theorem 2.2. □

The following theorem gives the blow-up phenomenon via initial potential data y_0, which reads as follows.

COROLLARY 3.1. *Suppose $y_0 \in H^1(\mathbb{R})$ is an odd function, satisfies $\int_0^\infty e^{-\xi}y_0(\xi)\,d\xi < 0$. Then the maximum time of existence of the corresponding solution $u(x,t)$ to (1.1) is finite.*

In fact, y_0 is an odd function; we can easily check that u_0 is also odd. At this time, $u_0'(0) = \int_0^\infty e^{-\xi}y_0(\xi)d\xi$. By the hypothesis and theorem above, we get the desired result. We omit the detailed proof for conciseness.

THEOREM 3.2. *Assume $u_0 \in H^3(\mathbb{S})$, $u_0 \not\equiv 0$, $\int_{\mathbb{S}}(u_0^3 + \gamma u_0 u_{0x}^2)dx = 0$, and one of the following conditions is satisfied:*

$$\text{(i)} \quad \gamma \in \left(\frac{3\sinh\left(\frac{1}{2}\right)}{2+\sinh\left(\frac{1}{2}\right)}, 3\right),$$

$$\text{(ii)} \quad \gamma \in \left(0, \frac{3\sinh\left(\frac{1}{2}\right)}{2+\sinh\left(\frac{1}{2}\right)}\right],$$

$$m(0) < -\frac{\sqrt{2}}{2}\alpha \parallel u_0 \parallel_{H^1(\mathbb{S})}.$$

Then the corresponding solution to (1.1) blows up in finite time.

Proof. By assumption and the invariance property of $E_2(u)$, we have

$$\int_{\mathbb{S}} u^3 + \gamma u u_x^2 dx = \int_{\mathbb{S}} u_0^3 + \gamma u_0 u_{0x}^2 dx = 0.$$

Therefore, $u(x,t)$ must change sign, so there exists at least one zero point on $\mathbb{S}$. Then for each $t \in [0,T)$, suppose there is a $\xi_t \in [0,1]$ such that $u(\xi_t,t)=0$, for $x \in \mathbb{S}$ we have

$$u^2(x,t)=\left(\int_{\xi_t}^{x} u_x dx\right)^2 \le (x-\xi_t)\int_{\xi_t}^{x} u_x^2 dx, \quad x \in \left[\xi_t, \xi_t+\frac{1}{2}\right]. \tag{3.4}$$

Thus, the relation above and an integration by parts yield

$$\begin{aligned}\int_{\xi_t}^{\xi_t+\frac{1}{2}} u^2 u_x^2 dx &\le \int_{\xi_t}^{\xi_t+\frac{1}{2}} (x-\xi_t)u_x^2\left(\int_{\xi_t}^{x} u_x^2\right)dx \\ &= \int_{\xi_t}^{\xi_t+\frac{1}{2}} (x-\xi_t)\left(\int_{\xi_t}^{x} u_x^2\right) d\left(\int_{\xi_t}^{x} u_x^2\right) \\ &\le \frac{1}{4}\left(\int_{\xi_t}^{\xi_t+\frac{1}{2}} u_x^2 dx\right)^2. \end{aligned} \tag{3.5}$$

Doing a similar estimate on $[\xi_t+\frac{1}{2}, \xi_t+1]$, we obtain

$$\int_{\mathbb{S}} u^2 u_x^2 dx \le \frac{1}{4}\left(\int_{\mathbb{S}} u_x^2 dx\right)^2. \tag{3.6}$$

In view of (3.4), we also have

$$\| u(x,t) \|_{L^\infty}^2 \le \frac{1}{2}\int_{\mathbb{S}} u_x^2 dx. \tag{3.7}$$

Let

$$q(t)=\int_{\mathbb{S}} u_x^3 dx, \quad t \ge 0.$$

Multiplying both sides of (3.3) with u_x^2, then integrating by parts, we obtain the equation for $q(t)$ as

$$\begin{aligned}\frac{dq(t)}{dt} &= -\frac{\gamma}{2}\int_{\mathbb{S}} u_x^4 dx + \frac{3(3-\gamma)}{2}\int_{\mathbb{S}} u^2 u_x^2 dx - 3\int_{\mathbb{S}} u_x^2 G*F(u) dx \\ &\le -\frac{\gamma}{2}\int_{\mathbb{S}} u_x^4 dx - \left(\frac{3\gamma}{4\sinh\left(\frac{1}{2}\right)} - \frac{3(3-\gamma)}{8}\right)\left(\int_{\mathbb{S}} u_x^2\right)^2, \end{aligned} \tag{3.8}$$

where we use the fact $\frac{1}{2\sinh(\frac{1}{2})} \le G(x) \le \frac{\cosh(\frac{1}{2})}{2\sinh(\frac{1}{2})}$.

If $\gamma \in (\frac{3\sinh(\frac{1}{2})}{2+\sinh(\frac{1}{2})}, 3)$, then $\frac{3\gamma}{4\sinh(\frac{1}{2})} - \frac{3(3-\gamma)}{8} \ge 0$. On the other hand, we have $\int_{\mathbb{S}} u_x^2 dx \ge \frac{2}{3}\| u_0 \|_{H^1}^2$. Therefore, the above inequality yields

$$\begin{aligned}\frac{dq(t)}{dt}dx &= -\frac{\gamma}{2}\int_{\mathbb{S}} u_x^4 dx + \frac{3(3-\gamma)}{2}\int_{\mathbb{S}} u^2 u_x^2 dx - 3\int_{\mathbb{S}} u_x^2 G*F(u) dx \\ &\le -\frac{\gamma}{2}\int_{\mathbb{S}} u_x^4 dx - \frac{4}{9}\left(\frac{3\gamma}{4\sinh\left(\frac{1}{2}\right)} - \frac{3(3-\gamma)}{8}\right)\| u_0 \|_{H^1}^4. \end{aligned} \tag{3.9}$$

For simplicity, we set $\mu = \frac{4}{9}(\frac{3\gamma}{4\sinh(\frac{1}{2})} - \frac{3(3-\gamma)}{8})$ and in view of Holder's inequality, we get

$$\begin{aligned}\frac{dq(t)}{dt} &= -\frac{\gamma}{2}\int_{\mathbb{S}} u_x^4 dx + \frac{3(3-\gamma)}{2}\int_{\mathbb{S}} u^2 u_x^2 dx - 3\int_{\mathbb{S}} u_x^2 G * F(u) dx \\ &\le -\frac{\gamma}{2} q^{\frac{4}{3}}(t) - \mu \parallel u_0 \parallel_{H^1}^4 . \end{aligned} \tag{3.10}$$

First, since $q(t) \le q_0 - \mu \parallel u_0 \parallel_{H^1}^4 t$, it is easy to find that there exist a time $t_0 \ge 0$ such that $q(t_0) < 0$. Then for $t > t_0$, we have

$$\frac{dq(t)}{dt} \le -\frac{\gamma}{2} q^{\frac{4}{3}}(t), \quad \text{with } q(t_0) < 0.$$

So the solution to (3.10) satisfies

$$q(t) \le \left(q^{-\frac{1}{3}}(t_0) + \frac{\gamma}{6}(t - t_0)\right)^{-3},$$

which reaches to $-\infty$ before t arrives at $T_0 = -6q^{-\frac{1}{3}}(t_0)/\gamma + t_0$.

On the other hand, since

$$\left|\int_{\mathbb{S}} u_x^3 dx\right| \le C(s) \parallel u_0 \parallel_{H^1}^2 \parallel u \parallel_{H^s} \quad \text{for} \quad s \in \left(\frac{3}{2}, 3\right],$$

then

$$\int_{\mathbb{S}} u_x^3 dx \ge \inf u_x(x,t) \parallel u_0 \parallel_{H^1}^2$$

shows that $\lim_{t\to T_0} \inf_{x\in\mathbb{S}} u_x(x,t) = -\infty$.

If $\gamma \in (0, \frac{3\sinh(\frac{1}{2})}{2+\sinh(\frac{1}{2})}]$, we can derive an equation for $m(t)$ as

$$\frac{dm}{dt} = -\frac{\gamma}{2}m^2 + \frac{3-\gamma}{2}u^2(\xi(t),t) - [G * F(u)](\xi(t),t) = 0.$$

Now combining the above equation and (3.2) together, we have

$$\frac{dm(t)}{dt} \le -\frac{\gamma}{2}m^2(t) + \frac{3-\gamma-\gamma\alpha}{4} \parallel u_0 \parallel_{H^1}^2 . \tag{3.11}$$

If

$$m(0) < -\left(\frac{3-\gamma-\gamma\alpha}{2\gamma}\right)^{\frac{1}{2}} \parallel u_0 \parallel_{H^1} = -\frac{\sqrt{2}}{2}\alpha \parallel u_0 \parallel_{H^1},$$

then we can conclude the solution to (3.11) goes to $-\infty$ in finite time. This completes the proof. □

Remark 3.1. $\int_{\mathbb{S}} u_0 dx = 0$ or $\int_{\mathbb{S}} y_0 dx = 0$ can be a substitute of the condition $\int_{\mathbb{S}}(u_0^3 + \gamma u_0 u_{0x}^2)dx = 0$; the theorem still holds. If $\gamma = 1$, we recover the case for the Camassa–Holm equation [10]. Moreover, one may find Theorem 3.2 is different from Theorem 3.4 in [42]. However, in [39], Yin didn't consider the case (ii) of this theorem for (1.1).

4. Persistence properties and unique continuation. In this section, we shall investigate persistence properties of the solution to (1.1) in L^∞-space. The main idea comes from a recent work of Himonas et al. [24].

THEOREM 4.1. *Assume that $u_0(x) \in H^s(\mathbb{R})$ and $s > \frac{3}{2}$, if for some $\theta \in (0,1)$,*

$$|u_0(x)|, \quad |u_{0x}(x)| \sim O\left(e^{-\theta x}\right) \quad as \quad x \uparrow \infty.$$

Then the corresponding strong solution $u(x,t) \in C([0,T]; H^s(\mathbb{R}))$ to (1.1) satisfies that

$$|u(x,t)|, \quad |u_x(x,t)| \sim O\left(e^{-\theta x}\right) \quad as \quad x \uparrow \infty$$

uniformly in the time interval $[0,T]$ before blow up.

Notation.

$$|u(x)| \sim O\left(e^{-\theta x}\right) \qquad as \quad x \uparrow \infty \qquad if \quad \lim_{x\to\infty} \frac{|u(x)|}{e^{-\theta x}} = L,$$

and

$$|u(x)| \sim o\left(e^{-\beta x}\right) \qquad as \quad x \uparrow \infty \qquad if \quad \lim_{x\to\infty} \frac{|u(x)|}{e^{-\beta x}} = 0.$$

Proof. The proof is organized as follows. Firstly, we will give estimates on $\| u(x,t) \|_\infty$ and $\| u_x(x,t) \|_\infty$. Here $\| \cdot \|_p$ means the L^p norm. Secondly, we use the weight function to obtain the desired result.

Multiplying (1.1) by u^{2n-1}, with $n \in \mathbb{Z}^+$, then integrating both sides with respect to x variable, we can get

$$\int_{\mathbb{R}} u^{2n-1} u_t dx + \gamma \int_{\mathbb{R}} u^{2n-1} u u_x dx + \int_{\mathbb{R}} u^{2n-1} \partial_x G * F(u) dx = 0. \tag{4.1}$$

The first term of the above identity is

$$\int_{\mathbb{R}} u^{2n-1} u_t dx = \frac{1}{2n} \frac{d}{dt} \| u(t) \|_{2n}^{2n} = \| u(t) \|_{2n}^{2n-1} \frac{d}{dt} \| u(t) \|_{2n} \tag{4.2}$$

and

$$\left| \int_{\mathbb{R}} u^{2n-1} u u_x dx \right| \leq \| u_x(t) \|_\infty \| u(t) \|_{2n}^{2n}. \tag{4.3}$$

In view of Holder's inequality

$$\int_{\mathbb{R}} u^{2n-1} \partial_x G * F(u) dx \leq \| u(t) \|_{2n}^{2n-1} \| \partial_x G * F(u) \|_{2n}, \tag{4.4}$$

so

$$\frac{d}{dt} \| u(t) \|_{2n} \leq \gamma \| u_x(t) \|_\infty \| u(t) \|_{2n} + \| \partial_x G * F(u) \|_{2n}. \tag{4.5}$$

In view of the Soblev embedding theorem, then there exists a constant $M > 0$ such that applying Gronwall's gives us

$$\| u(t) \|_{2n} \leq e^{Mt} \left(\| u(0) \|_{2n} + \int_0^t \| \partial_x G * F(u) \|_{2n} \, d\tau \right). \tag{4.6}$$

Note that

$$\lim_{p\to\infty} \| f \|_p = \| f \|_\infty \qquad \text{when} \qquad f \in L^1(\mathbb{R}) \cap L^\infty(\mathbb{R}). \tag{4.7}$$

Taking limits in (4.6) we obtain

$$\| u(t) \|_\infty \leq e^{Mt} \left(\| u(0) \|_\infty + \int_0^t \| \partial_x G * F(u) \|_\infty \, d\tau \right). \tag{4.8}$$

Next, we will establish an estimate on $\| u_x(t) \|_\infty$ using the same method as above. Differentiating (1.1) with respect to x variable produces the following equation:

$$u_{xt} + \gamma u u_{xx} + \gamma u_x^2 + \partial_x^2 G * F(u) = 0. \tag{4.9}$$

Multiplying the above identity by u_x^{2n-1}, considering the second term with integration by parts,

$$\int_{\mathbb{R}} u u_{xx} u_x^{2n-1} dx = -\frac{1}{2n} \int_{\mathbb{R}} u_x^{2n} u_x dx, \tag{4.10}$$

so we get

$$\int_{\mathbb{R}} u_x^{2n-1} u_{xt} dx + \gamma \int_{\mathbb{R}} u_x^{2n+1} dx - \frac{\gamma}{2n} \int_{\mathbb{R}} u_x^{2n} u_x dx + \int_{\mathbb{R}} u_x^{2n-1} \partial_x^2 G * F(u) dx = 0. \tag{4.11}$$

Similarly, one can get the inequality

$$\frac{d}{dt} \| u_x(t) \|_{2n} \leq 2\gamma \| u_x(t) \|_\infty \| u_x(t) \|_{2n} + \| \partial_x^2 G * F(u) \|_{2n}, \tag{4.12}$$

and therefore, as before, we obtain

$$\| u_x(t) \|_{2n} \leq e^{2Mt} \left(\| u_x(0) \|_{2n} + \int_0^t \| \partial_x^2 G * F(u) \|_{2n} \, d\tau \right). \tag{4.13}$$

Taking limits in (4.13) to obtain

$$\| u_x(t) \|_\infty \leq e^{2Mt} \left(\| u_x(0) \|_\infty + \int_0^t \| \partial_x^2 G * F(u) \|_\infty \, d\tau \right). \tag{4.14}$$

In order to get the desired result, we introduce the function $\psi_N(x)$, which is independent on t as follows:

$$\psi_N(x) = \begin{cases} 1, & x \leq 0, \\ e^{\theta x}, & x \in (0, N), \\ e^{\theta N}, & x \geq N, \end{cases} \tag{4.15}$$

where $N \in \mathbb{Z}^+$. From (1.1) we obtain

$$\psi_N u_t + \psi_N \gamma u u_x + \psi_N \partial_x G * F(u) = 0, \tag{4.16}$$

while for (4.9), we get

$$u_{xt} \psi_N + \psi_N \gamma u u_{xx} + \psi_N \gamma u_x^2 + \psi_N \partial_x^2 G * F(u) = 0. \tag{4.17}$$

In order to get the estimate on $u_x\psi_N$, we need to remove the second derivatives, by using integration by parts, we obtain

$$\begin{aligned}\left|\int_{\mathbb{R}}\psi_N u u_{xx}(u_x\psi_N)^{2n-1}dx\right| &= \left|\int_{\mathbb{R}} u(\psi_N u_x)^{2n-1}((u_x\psi_N)_x - u_x\psi_N')dx\right| \\ &= \left|\int_{\mathbb{R}} u\left(\frac{(u_x\psi_N)^{2n}}{2n}\right)_x dx - \int_{\mathbb{R}} u u_x\psi_N'(u_x\psi_N)^{2n-1}dx\right| \\ &\le 2(\| u \|_\infty + \| u_x(t) \|_\infty) \| u_x\psi_N \|_{2n}^{2n}, \end{aligned} \tag{4.18}$$

where we use the fact $0 \le \psi_N'(x) \le \psi_N(x)$ a.e. $x \in \mathbb{R}$. Next, we will do estimates on $\| u\psi_N \|_\infty$ and $\| u_x\psi_N \|_\infty$ step-by-step as before what were done on $\| u \|_\infty$ and $\| u_x \|_\infty$, we may get

$$\begin{aligned}\| u(t)\psi_N \|_\infty + \| u_x\psi_N \|_\infty &\le e^{2Mt}(\| u(0)\psi_N \|_\infty + \| u_x(0)\psi_N \|_\infty) \\ &\quad + e^{2Mt}\int_0^t (\| \psi_N\partial_x G * F(u) \|_\infty \\ &\quad + \| \psi_N\partial_x^2 G * F(u) \|_\infty)d\tau. \end{aligned} \tag{4.19}$$

On the other hand, computing the integral we see there exists a $c_1 > 0$, depending only on $\theta \in (0,1)$ such that

$$\psi_N(x)\int_{\mathbb{R}} e^{-|x-y|}\frac{1}{\psi_N(y)}dy \le c_1. \tag{4.20}$$

Therefore, one gets

$$\begin{aligned}|\psi_N\partial_x G * g^2(x)| &\le \frac{1}{2}\psi_N(x)\int_{\mathbb{R}} e^{-|x-y|}\frac{1}{\psi_N(y)}\psi_N(y)g(y)g(y)dy \\ &\le \frac{1}{2}\| \psi_N g \|_\infty \| g \|_\infty \left(\psi_N(x)\int_{\mathbb{R}} e^{-|x-y|}\frac{1}{\psi_N(y)}dy\right) \\ &\le c_1 \| \psi_N g \|_\infty \| g \|_\infty . \end{aligned} \tag{4.21}$$

Similarly,

$$|\psi_N\partial_x^2 G * g^2(x)| \le c_1 \| \psi_N g \|_\infty \| g \|_\infty . \tag{4.22}$$

Thus, combining (4.21) and (4.22) with (4.19), it follows that there exists a constant $C_1 = C_1(M,T) > 0$ such that

$$\begin{aligned}\| u(t)\psi_N \|_\infty + \| u_x\psi_N \|_\infty &\le C_1(\| u(0)\psi_N \|_\infty + \| u_x(0)\psi_N \|_\infty) \\ &\quad + C_1\int_0^t (\| u(\tau) \|_\infty + \| u_x(\tau) \|_\infty) \\ &\quad (\| u(\tau)\psi_N \|_\infty + \| u_x(\tau)\psi_N \|_\infty)d\tau \\ &\le C_1\Big(\| u(0)\psi_N \|_\infty + \| u_x(0)\psi_N \|_\infty \\ &\quad + \int_0^t (\| u(\tau)\psi_N \|_\infty + \| u_x(\tau)\psi_N \|_\infty)d\tau\Big). \end{aligned} \tag{4.23}$$

Then for any $N \in \mathbb{Z}^+$ and any $t \in [0,T]$, $x > 0$, we have

$$\begin{aligned}\| u(t)\psi_N \|_\infty + \| u_x\psi_N \|_\infty &\le C_1(\| u(0)\psi_N \|_\infty + \| u_x(0)\psi_N \|_\infty) \\ &\le C_1(\| u(0)e^{\theta x} \|_\infty + \| u_x(0)e^{\theta x} \|_\infty). \end{aligned} \tag{4.24}$$

Taking the limit as N goes to infinity in (4.24), we obtain

$$\left(\left|u(x,t)e^{\theta x}\right| + \left|u_x(x,t)e^{\theta x}\right|\right) \leq C_1 \left(\| u(0)e^{\theta x} \|_\infty + \| u_x(0)e^{\theta x} \|_\infty\right). \tag{4.25}$$

This completes the proof. □

The following result ensures that the only solution which can decay at a determined rate, at any two distinct times, is the trivial solution $u \equiv 0$.

THEOREM 4.2. *Assume that $u_0(x) \in H^s(\mathbb{R})$ and $s > \frac{3}{2}$, satisfies that for some $\delta \in (\frac{1}{2}, 1)$,*

$$|u_0(x)| \sim o(e^{-x}) \quad \text{and} \quad |u_{0x}(x)| \sim O\left(e^{-\delta x}\right) \qquad \text{as } x \uparrow \infty,$$

$u(x,t) \in C([0,T]; H^s(\mathbb{R}))$ is the corresponding strong solution to (1.1), *and there exists $t_1 \in (0,T]$ for some $T > 0$ such that*

$$|u(x,t_1)| \sim o\left(e^{-x}\right) \qquad \text{as } x \uparrow \infty, \tag{4.26}$$

then $u \equiv 0$.

Proof. Integrating (1.1) from 0 to t_1, we get

$$u(x,t_1) - u(x,0) + \gamma \int_0^{t_1} u u_x d\tau + \int_0^{t_1} \partial_x G * F(u) d\tau = 0. \tag{4.27}$$

According to the hypothesis, we easily have

$$u(x,t_1) - u(x,0) \sim o\left(e^{-x}\right) \quad \text{as } x \uparrow \infty. \tag{4.28}$$

At the same time, in view of Theorem 4.1 it follows that

$$\int_0^{t_1} u u_x d\tau \sim O\left(e^{-2\delta x}\right) \quad \text{as } x \uparrow \infty, \tag{4.29}$$

and so

$$\int_0^{t_1} u u_x d\tau \sim o\left(e^{-x}\right) \quad \text{as } x \uparrow \infty. \tag{4.30}$$

If $u(x,t) \neq 0$, the following deduction tells us the last term of (4.27) is infinitesimal with the same order not higher order of e^{-x}. Thus, a contradiction occurs.

$$\begin{aligned} \int_0^{t_1} \partial_x G * F(u) d\tau &= \partial_x G * \int_0^{t_1} F(u) d\tau \\ &= \partial_x G * f(x). \end{aligned} \tag{4.31}$$

However,

$$0 \leq f(x) \sim O\left(e^{-2\delta x}\right) \quad \text{so that} \quad f(x) \sim o\left(e^{-x}\right) \quad \text{as } x \uparrow \infty. \tag{4.32}$$

Therefore,

$$\partial_x G * f(x) = -\frac{1}{2} e^{-x} \int_{-\infty}^{x} e^y f(y) dy + \frac{1}{2} e^x \int_x^{\infty} e^{-y} f(y) dy. \tag{4.33}$$

From (4.32) it follows that

$$e^x \int_x^\infty e^{-y} f(y)dy = e^x \int_x^\infty e^{-y} o(e^{-y})dy = o(1)e^x \int_x^\infty e^{-2y}dy \sim o(1)e^{-x} \sim o(e^{-x}).$$

If $f(x) \neq 0$, one has that

$$\int_{-\infty}^x e^y f(y)dy \geq C_0 \quad \text{for } x \text{ large enough.} \tag{4.34}$$

Hence,

$$\begin{aligned} -\partial_x G * f(x) &= \frac{1}{2}e^{-x} \int_{-\infty}^x e^y f(y)dy - \frac{1}{2}e^x \int_x^\infty e^{-y} f(y)dy \\ &\geq \frac{C_0}{2}e^{-x} \quad \text{for } x \text{ large enough.} \end{aligned} \tag{4.35}$$

So a contradiction occurs by combination with (4.27)–(4.30) and (4.35). Thus, $f(x) \equiv 0$ and consequently, $u(x,t) \equiv 0$. The theorem is proved. □

At the end of this paper, we would like to make a simple comparison between the rod equation and the Camassa–Holm equation. In the whole paper, we do not discuss sufficient conditions to guarantee the global existence of smooth solutions to (1.1) for general γ, which was discussed in [17].

We know for (1.1), $y = u - u_{xx}$ satisfies

$$y_t + \gamma y_x u + 2\gamma y u_x + \frac{3(\gamma-1)}{2}\left(u^2\right)_x = 0.$$

It is a pity that we couldn't obtain the proper particle trajectory line equation to consider this problem just as it was done for the Camassa–Holm equation. Moreover, for $\gamma \neq 1$, few beautiful identities that appeared in the Camassa–Holm equation are obtained for (1.1).

Acknowledgments. The first author is greatly indebted to Prof. Zhou for his constructive suggestions and constant encouragement throughout this work. The authors thank the referees for their constructive and helpful suggestions and comments.
