[illegible]. Suppose not. Then, since the elementary i-characteristic passing through any point of J must exit at p, after replacing the original J by an appropriate subarc and changing C_1 and C_2 accordingly, we can assume that $\lambda(P \cap J) = \epsilon > 0$, $\lambda(N) < \frac{\epsilon}{8}$, and $\lambda(\theta(J) < \frac{1}{100K}$, where $N = J \backslash P$. Let C_k be parameterized by $z_k(s)$, $0 \le s \le \lambda_k$, with $z(0) = p$. Let $\{k, l\} = \{1, 2\}$. Let $J_k(s)$ denote the j-arc joining $z_k(s)$ to a point $w_k(s) \in C_l \cap G$. Note that we know only that $J_k(s)$ is defined for $s \le \lambda_k$ sufficiently near λ_k. It follows from length monotonicity (Proposition 2.7) that $\lambda(J_k(s)) \ge \lambda(P_k(s)) \ge \epsilon$, where $P_k(s)$ is the set of points of $J_k(s)$ joined to points of P by an i-arc. By the quasi-HP property $\lambda(\theta(J_k(s))) < \frac{1}{100}$, so that $J_k(s)$ is almost straight and in particular the distance between its endpoints is at least $\frac{1}{2}\lambda(J_k(s)) \ge \frac{1}{2}\lambda(P_k(s)) \ge \frac{\epsilon}{2}$. Let ξ_k be the infimum of all s for which $J_k(s)$ is defined. Since the distance between the endpoints of $J_k(s)$ is at least $\frac{\epsilon}{2}$, it is clear that at least one of ξ_1, ξ_2 must be positive, and for definiteness we assume that $\xi_1 > 0$. For $\sigma \in (\xi_1, \lambda_1]$ let $J_1(\sigma)$ be parameterized by $\zeta(s, \sigma)$, $0 \le s \le \lambda(J_1(\sigma))$, with $\zeta(0, \sigma) \in C_1$. It is clear that there are δ, $T > 0$ such that

$$\operatorname{dist}(\zeta(s, \sigma), C_1 \cup C_2) \ge Ts \quad \text{for} \quad s \in (0, \delta), \quad \sigma \in (\xi_1, \lambda_1]. \tag{3.2}$$

From the fact that a j-arc can intersect an i-arc at most once in G it easily follows that for each point $z \in C_1 \cap G$ there is a $\delta_1 = \delta_1(z)$ such that

$$|z - \zeta(s, \sigma)| \ge \delta_1 \quad \text{for} \quad s \in [\delta, \lambda(J_1(\sigma))], \quad \sigma \in (\xi_1, \lambda_1]. \tag{3.3}$$

From (3.2) and (3.3) together with the fact that for $\sigma \in (\xi_1, \lambda_1]$, $J_1(\sigma) = J_2(\sigma')$ for some $\sigma' \in (\xi_2, \lambda_2]$ it follows that as $\sigma \to \xi_1$, $J_1(\sigma)$ tends to an arc J_0 which contains p, which joins $z_1(\xi_1)$ to the point $z_2(\xi_2)$ of C_2, and the distance between whose endpoints is at least $\frac{\epsilon}{2}$. Furthermore, either J_0 consists of a j-arc joining $z_1(\xi_1)$ to p or (in the case that $\xi_2 > 0$) it consists of such an arc together with another j-arc joining p to $z_2(\xi_2)$. One of the endpoints of J_0, which we henceforth call q, is at a distance of at least $\frac{\epsilon}{4}$ from p. By renaming, if necessary, we can assume that $q = z_1(\xi_1) \in C_1$. Let J_0' be the subarc of J_0 which joins q to p. Let A denote the arc pq of C_1. Then J_0' and A form the two sides of a "characteristic bilateral" B. Let P_0' be the subset of points of J_0' which correspond to (i.e., are joined by i-arcs to) points of P (that is, P_0' is, apart from a set of linear measure 0, the set of points at which J_0 is nonconcave towards the inside of B), and let $N_0' \subset J_0'$ be the subset corresponding to N. Since, by length monotonicity, $\lambda(N_0') \le \lambda(N) \le \frac{\epsilon}{8}$, it follows that

$$\lambda(P_0') \ge \lambda(J_0') - \lambda(N_0') \ge \frac{\epsilon}{4} - \frac{\epsilon}{8} = \frac{\epsilon}{8}. \tag{3.4}$$

Let J_0' be parameterized by $z_0(s)$, $0 \le s \le \lambda(J_0')$, with $z_0(0) = p$, and for $s \in (0, \lambda(J_0'))$ let $A(s)$ be the part of the elementary i-characteristic through $z_0(s)$ in $\overline{B}$, so that $A(s)$ joins $z_0(s)$ to p (since its interior can cross neither A nor J_0'). It follows from Proposition 3.6 that $\operatorname{diam}(A(s)) \to 0$ as $s \to 0$. Let qp' be an arc of A for which $\lambda(\theta(qp')) < \frac{1}{100K}$. Since $\lambda(\theta(W)) < \frac{1}{100}$ for any translate W of either J_0' or qp' by the quasi-HP property, it follows that one can translate qp' in B all the way down $J_0' \backslash \{p\}$ from q without meeting the boundary of B, since for simple geometric reasons all these translates, being essentially perpendicular to the virtually straight arc J_0', must stay away from p. If $A'(s)$ denotes the translate of qp' with initial point $z_0(s)$, then $A'(s) \subset A(s)$, and therefore $\operatorname{diam}(A'(s)) \to 0$ as $s \to \lambda(J_0')$. This means that each point $z \in qp'$ is joined to p in B by a j-arc $J''(z)$ such that if $P''(z)$ is the set of points of $J''(z)$ joined to points of P by i arcs in T, then by (3.4) and length monotonicity $\lambda(P''(z)) \ge \frac{\epsilon}{8}$ and by the quasi-HP property $\lambda(\theta(J''(z))) < \frac{1}{100}$, so that

$$|z - p| \ge \frac{\epsilon}{16}. \tag{3.5}$$

We can now repeat this process starting with $J''(p')$ instead of $J_0' = J''(q)$ and continue doing so to obtain in the end $J''(z)$ for all $z \in A \backslash \{p\}$. However, by the argument we just gave we now have (3.5) for all $z \in A$, which is absurd since p is an endpoint of A. Therefore $\lambda(P) = 0$. □

PROPOSITION 3.8. [illegible] G [illegible]. This follows easily from Proposition 3.6. □

PROPOSITION 3.9. [illegible]. Assume to the contrary that points $p_1 \ne p_2$ of ∂G are joined by distinct elementary i-characteristics C_1 and C_2. It follows from Proposition 3.8 that the elementary i-characteristic through any point of the simply connected domain D bounded by $C_1 \cup C_2$ must also have endpoints p_1 and p_2. But then it follows easily from Proposition 3.7 that all j-characteristic arcs in D are straight line segments. But this contradicts Proposition 3.7. □

PROPOSITION 3.10. [illegible] G [illegible] G [illegible] $p \in G$ [illegible]. The proof is an easy consequence of Proposition 3.7 and the quasi-HP property. □

DEFINITION 3.11. [illegible] θ [illegible] G [illegible] C_0 [illegible] i [illegible] θ [illegible] $a, b \in \partial G$ [illegible] B [illegible] ∂G [illegible] a, b [illegible] D [illegible] G [illegible] $\partial D = C_0 \cup B$ [illegible] i-characteristic subdomain

When we wish to indicate the elementary i-characteristic involved, we will denote the i-characteristic subdomain by (D, C_0). The arc $B = \overline{\partial D - C_0} \subset \partial G$, called the [illegible] of (D, C_0) and denoted by $\operatorname{bot}(D)$, will be considered to have the order "$<$" corresponding to the positive orientation of ∂D. We shall freely use interval notation as well as the terms "to the right of," "to the left of," "between," etc., when dealing with $\operatorname{bot}(D)$. Furthermore, if ab is an elementary i-characteristic joining points a, b of $\operatorname{bot}(D)$, it will be understood that $a \le b$, unless otherwise indicated. When dealing with a characteristic subdomain (D, C_0), we shall work with the class $\mathcal{I}(D)$ of nontrivial elementary i-characteristics C which join points p, q of $\operatorname{bot}(D)$. Note that $C_0 \in \mathcal{I}(D)$. If $C = pq \in \mathcal{I}(D)$, then "above" C refers to the part of D not in the closed region bounded by $C \cup [p, q]$. If $F \subset \overline{D}$ is a compact set for which $F \cap \operatorname{bot}(D) \ne \emptyset$, we

say that an elementary i-characteristic $E = pq \in \mathcal{I}(D)$ [illegible] F, and write $F \preceq E$, if F is contained in the closed set bounded by the simple closed curve $[p, q] \cup pq$. We deal only with sets F for which each component of F has points in $\mathrm{bot}(D)$. For two such sets F_1, $F_2 \subset \overline{D}$ we say that F_1 [illegible] F_2 and write $F_1 \leq F_2$ if for all f_1, f_2 with $f_k \in F_k \cap \mathrm{bot}(D)$, $k = 1, 2$, there holds $f_1 \leq f_2$. It is clear that if C_1, $C_2 \in \mathcal{I}(D)$, then one of the following is true: $C_1 \preceq C_2$, $C_2 \preceq C_1$, $C_1 \leq C_2$, or $C_2 \leq C_1$. The first and second of these possibilities include the case $C_1 = C_2$.

In what follows, $L(G, p, d)$ will denote the segment $\overline{pq}$ of length d which is orthogonal to ∂G at p, which emanates from p into G and which is oriented from p to q.

PROPOSITION 3.12. [illegible] $\omega_0 = \omega_0 < 1$ [illegible] $\omega_1 = \omega_1(K, \rho)$ [illegible] $G \in \mathcal{G}(\rho)$, $p \in \partial G$, $\theta \in \mathrm{HP}(G, K)$ [illegible] C [illegible] $z(s)$, $0 \leq s \leq \lambda(C)$ [illegible] i [illegible] ρ [illegible]

$$C \cap L(G, p, \omega_0 \rho) = \{z(0)\}, \tag{3.6}$$

[illegible] $L(G, p, \omega_0\rho)$ [illegible] j [illegible] [illegible] C [illegible] ρ [illegible] ∂G [illegible] $w(s)$, $0 \leq s < \lambda(\partial G)$, [illegible] $w(0) = p$ [illegible] $|\arg\{z'(0)\} - \arg\{w'(0)\}| \leq \frac{\pi}{2}$ [illegible]

$$\arg\{z'(0)\} \geq \arg\{w'(0)\} - \omega_1 \sqrt{|z(0) - p|}$$

[illegible] C [illegible] $L(G, p, \xi_0)$ [illegible]

$$\arg\{z'(0)\} \geq \arg\{w'(0)\} + \omega_1 \sqrt{|z(0) - p|}$$

[illegible] C [illegible] $L(G, p, \omega_0)$ [illegible]. Clearly, it is enough to handle the case in which C emanates to the right of $L(G, p, \rho)$. Without loss of generality we can assume that $p = 0 = \arg\{w'(0)\}$, so that in particular $D = N(-\rho i, \rho) \subset \mathbb{C} \backslash G$ and $\partial N(-\rho i, \rho)$ is tangent to ∂G at 0. Let $d = |z(0) - p|$ and let $R_d = \{di + te^{-i\alpha} : t \geq 0\}$, $\alpha = \alpha(d) \in (0, \frac{\pi}{2})$ be the ray emanating to the right of $L(G, 0, \rho)$ from the point $di \in L(G, 0, \rho)$ which is tangent to ∂D, and let the point of tangency be z_d. Then $\alpha = \cos^{-1}(\frac{\rho}{\rho + d})$, so that α is bounded below and above by $\sqrt{1 - \frac{\rho}{\rho+d}}$ and $2\sqrt{1 - \frac{\rho}{\rho+d}}$, respectively. Thus

$$2\sqrt{d/\rho} \geq \alpha \geq \frac{\sqrt{d/\rho}}{2} \quad \text{for} \quad d \leq \rho. \tag{3.7}$$

Let T_d be the curvilinear triangle bounded by $L(G, 0, d)$, the line segment $[di, z_d]$ and the (shorter) arc of ∂D with endpoints 0, z_d. Then in light of (3.7) it is easy to see that

$$\mathrm{diam}(T_d) \leq \rho\alpha + d \leq 2\rho\sqrt{d/\rho} + d = 2\sqrt{\rho d} + d \quad \text{for} \quad d \leq \rho, \tag{3.8}$$

so that

$$\mathrm{diam}(T_d) < \rho \quad \text{for} \quad d \leq \frac{\rho}{16}. \tag{3.9}$$

Now assume that C is as in the hypothesis with $z(0) = di$, where $d \leq \frac{\rho}{16}$, and that

$$-\beta = \arg\{z'(0)\} \leq -N\alpha.$$

Here $N > 1$ is a number yet to be determined. Since, by (3.9), $\operatorname{diam}(C) \geq \rho > \operatorname{diam}(T_d)$, and since obvious angle considerations imply that C enters T_d at di, in light of assumption (3.6), C must exit T_d at a point of the segment $[di, z_d]$. Say s_0 is the smallest value of s for which $z(s) \in [di, z_d]$. Then obviously $\theta([0, s_0]) \supset [-\beta, -\alpha]$, so that $[0, s_0]$ has a subinterval $[s_1, s_2]$ for which $\theta([s_1, s_2]) = [-\beta, -\alpha]$. Since $\beta - \alpha \leq \frac{\pi}{2}$, and since the length of a curve given by $y = f(x)$, $x_1 \leq x \leq x_2$ for which $|f'(x)| \leq 1$ is at most $\sqrt{2}|x_2 - x_1|$, it follows that

$$s_2 - s_1 = \lambda(z([s_1, s_2]) \leq \sqrt{2}|z(s_2) - z(s_1)|$$

$$< 2\operatorname{diam}(T_d) \leq 2(2\sqrt{\rho d} + d),$$

by (3.8). Thus by the mean value theorem there must be some $s_0 \in [s_1, s_2]$ for which

$$D^+\theta(z(s_0)) \geq \frac{(N-1)\alpha}{2(2\sqrt{\rho d} + d)}. \tag{3.10}$$

But the curvature bound (Proposition 2.6) together with the hypothesis regarding the j-characteristics implies that $D^+\theta(z(s_0)) \leq \frac{K}{\rho}$, so that in light of (3.10) and the lower bound in (3.7) we have

$$\frac{\rho(N-1)\sqrt{d/\rho}}{8\sqrt{\rho d} + 4d} \leq K.$$

But the left-hand side of this inequality is $(N-1)/(8 + 4\sqrt{d/\rho})$, which is bounded below by $\frac{N-1}{9}$ for $d \leq \frac{\rho}{16}$, so that we have a contradiction for $N = 9K + 2$. Thus if $d \leq \frac{\rho}{16}$, we must have

$$\arg\{z'(0)\} \geq -2\frac{9K+2}{\sqrt{\rho}}\sqrt{d} \geq -\frac{22K\sqrt{d}}{\sqrt{\rho}},$$

in light of the upper bound in (3.7) and the fact that $K \geq 1$. Thus we have proved the proposition with $\omega_0 = \frac{1}{16}$ and $\omega_1 = \frac{22K}{\sqrt{\rho}}$. □

PROPOSITION 3.13. [illegible] $\xi_0 = \xi_0(K, \rho)$ [illegible] $\xi_1 = \xi_1(K, \rho)$ [illegible] $G \in \mathcal{G}(\rho)$, $\theta \in \mathrm{HP}(G, K)$ [illegible] $C = ab$ [illegible] i [illegible] (D, C) [illegible] C [illegible] $A = \operatorname{bot}(D)$ [illegible] $z(s)$, $0 \leq s \leq \lambda(C)$, [illegible] $w(s)$, $0 \leq s \leq \lambda(A)$, [illegible] $z(0) = w(0) = a$, a [illegible] $\operatorname{bot}(D)$ [illegible] $p = w(\sigma_0) \in A$, [illegible] $\operatorname{dist}(p, \partial G \backslash A) \geq \rho$, [illegible] $L(G, p, \xi_0)$ [illegible] C, [illegible] $z(s)$ [illegible]

$$|\arg\{z'(s)\} - \arg\{w'(\sigma_0)\}| \leq \xi_1\sqrt{|z(s) - p|}. \tag{3.11}$$

[illegible]. Without loss of generality we may assume that $p = 0 = \arg\{w'(\sigma_0)\}$. Let ω_0 and ω_1 be as in the preceding proposition. Let $L(\epsilon) = L(G, p, \epsilon)$. We assume for the moment that $z(s) \in L(\omega_0\frac{\rho}{2})$ is the only point of C on this segment. Since immediately to the left of C there are points in the complement of D and the interior of the segment $L(|z(s)|)$ lies in D, it is clear that if we write $\arg\{z'(s_0)\} = e^{i\tau}$, with $-\pi < \tau \leq \pi$, then $|\tau| \leq \frac{\pi}{2}$. Let E be either of the two subarcs of C, one of whose endpoints is $z(s)$ and the other of which is a point $q \in G$ for which $|z(s) - q| = \frac{\rho}{2}$. It follows from the preceding proposition that if $\omega_1(K, \frac{\rho}{2})\sqrt{|z(s)|} \leq \frac{\pi}{4}$, then C cannot

be tangent to $L(\omega_0\frac{\rho}{2})$. Thus, of the two arcs E, one moves to the right of $L(\omega_0\frac{\rho}{2})$ as we move along it away from $z(s)$ and the other moves to the left. But then by the preceding proposition we have (3.11) with

$$\xi_1 = \omega_1\left(K, \frac{\rho}{2}\right) \tag{3.12}$$

for any $z(s)$ for which

$$|z(s)| \leq \min\left\{\omega_0\frac{\rho}{2}, \left(\frac{\pi}{4\omega_1(K,\rho/2)}\right)^2\right\}.$$

Let

$$\xi_0 = \min\left\{\omega_0\frac{\rho}{10}, \left(\frac{\pi}{4\omega_1(K,\rho/2)}\right)^2, \frac{\pi\rho}{21K}\right\}. \tag{3.13}$$

Assume $\epsilon \leq \xi_0$ and that $L(\epsilon)$ contains at least two points of C. Then there are s', $s'' \in (0, \lambda(C))$, $s' < s''$, such that the interior of $L(\min\{|z(s')|, |z(s'')|\})$ contains no point of C (and is therefore contained in D) and $z(s')z(s'') \cap L(\epsilon) = \{z(s'), z(s'')\}$. By Proposition 3.6, $\operatorname{diam}(z(s')z(s'')) \leq 5\epsilon < \omega_0\frac{\rho}{2}$. There are the following two cases.

(i) $|z(s')| < |z(s'')|$. In this case, simple topological arguments show that $z(s')$ $z(s'')$ must lie to the right of $L(\epsilon)$. Also, by the foregoing and our definition of ξ_0, one easily has

$$|\arg\{z'(s')\} - \arg\{w'(\sigma_0)\}| \leq \frac{\pi}{4}.$$

But then since C crosses $L(\epsilon)$ again at $z(s'')$, we must have that for some $t' < t''$ in (s', s''), $\arg\{z'(t'')\} - \arg\{z'(t')\} \geq \frac{\pi}{2} - \frac{\pi}{4} = \frac{\pi}{4}$, so that by mean value considerations as in the proof of the preceding proposition together with the curvature bound we see that there must be a point $\sigma' \in (t', t'')$ at such that

$$\frac{K}{\rho/2} \geq \frac{d\arg\{z'(s)\}}{ds}|_{s=\sigma'} \geq \frac{\pi/4}{2\operatorname{diam}(z(s')z(s''))} \geq \frac{\pi}{10\epsilon} \geq \frac{\pi}{10\xi_0},$$

which implies that $\xi_0 \geq \frac{\pi\rho}{20K}$, a contradiction, since $\xi_0 \leq \frac{\pi\rho}{21K}$.

(ii) $|z(s')| > |z(s'')|$. In this case, simple topological arguments show that $z(s')$ $z(s'')$ must lie to the left of $L(\epsilon)$, and we proceed analogously to the way we did in case (i).

Thus, for $\epsilon \leq \xi_0$, $L(\epsilon)$ can contain at most one point of C. This completes the proof of the proposition with ξ_1 and ξ_0 as defined in (3.12) and (3.13), respectively. □

We now extend the notion of characteristic to include certain arcs whose interiors contain points of ∂G. Although what follows does not give the most exhaustive extension possible, it is sufficient for our present needs. Let (D_0, C_0) be an i-characteristic subdomain of G, and consider a monotone decreasing sequence $\{C_k = a_kb_k : k \geq 0\}$ in $\mathcal{I}(D_0)$. In other words, $a_k \leq a_{k+1} < b_{k+1} \leq b_k$, $k \geq 0$, so that the arcs $A_k = [a_k, b_k]$ of $\operatorname{bot}(D_0) = A_0$ are nested. Let $D_k \subset D_0$ be the i-characteristic subdomain bounded by $C_k \cup A_k$, so that $D_k \supset D_{k+1}$, $k \geq 0$. We regard C_k as being oriented from a_k to b_k. Let $a_k \to a$ and $b_k \to b$. We define C to be the set of limits of sequences $\{z_l\}$, where $z_l \in C_{k_l}$, $k_l \to \infty$. Any such C will be called an [illegible] a [illegible] b. An extended characteristic consisting of a single point $p \in \partial G$ will be called

[illegible]. The following proposition, in the statement and proof of which the notation is the same as that of the immediately preceding sentences, contains the basic properties of extended characteristics. Note that $M(G,K)$ is, as in Proposition 3.4, an upper bound on the length of elementary characteristics of K-quasi-HP functions on G.

PROPOSITION 3.14. [illegible] C [illegible] a [illegible] b [illegible] $a = b$, [illegible] $C = \{a\}$ [illegible] C [illegible] a [illegible] b [illegible] $\lambda(C) \leq M(G,K)$ [illegible] C [illegible] $z(s)$, $0 \leq s \leq \lambda(C)$, [illegible] $z(0) = a$, [illegible] $C \cap \partial G \subset [a,b]$ [illegible] $C \cap [a,b]$ [illegible] $A_0 = \mathrm{bot}(D_0)$ [illegible] s [illegible] z [illegible] $(0, \lambda(C))$, [illegible] $t \in (0, \lambda(C))$, $z(t)$ [illegible] $\partial G \backslash (a,b)$ [illegible] j [illegible] $J(t)$ [illegible] C [illegible]

$$D^+ \arg\{z'(t)\} \leq \frac{K}{\lambda(J(t))}. \tag{3.14}$$

[illegible]. We begin by observing that

$$A_0 \cap C \subset [a,b]. \tag{3.15}$$

To see this, note that for each $w \in A_0 \backslash [a,b]$ there is an n for which $w \notin A_n$. Since $C_n \cap A_0 = \{a_n, b_n\}$, w is not in C_n either, and therefore $w \notin \overline{D_n}$. But then, by the monotonicity of $\{\overline{D_k}\}$,

$$\mathrm{dist}(w, C_k) \geq \mathrm{dist}(w, \overline{D_k}) \geq \mathrm{dist}(w, \overline{D_n}) > 0 \text{ for } k \geq n,$$

from which the desired conclusion follows at once. From (3.15) it follows immediately that $C \cap \partial G \subset [a,b]$.

Next we note that if $a = b$, then Proposition 3.6 implies that $\mathrm{diam}(C_k) \to 0$, so that $C = \{a\}$. For the remainder of the proof we therefore assume that $a < b$.

By this assumption and Proposition 3.4 on the boundedness of the lengths of characteristics there exist l_1 and l_2 such that $0 < l_1 \leq \lambda(C_k) \leq l_2 < \infty$. Let C_k be parameterized by $z = z_k(s)$, $0 \leq s \leq \lambda(C_k)$. Let $0 < \epsilon < |b-a|/3$, and let n_0 be such that

$$|a_k - a|,\ |b_k - b| < \epsilon \quad \text{for} \quad k \geq n_0.$$

For $k \geq n_0$ let

$$\alpha_k = \sup\{s : z_k(s) \in \partial N(a,\epsilon)\}$$

and

$$\beta_k = \inf\{s : z_k(s) \in \partial N(b,\epsilon)\},$$

and let $E_k = E_k(\epsilon) = z_k([\alpha_k, \beta_k])$. Then

$$\delta = \inf\{\mathrm{dist}(E_k, \partial G \backslash A_k) : k \geq n_0\} > 0, \tag{3.16}$$

since otherwise there would be a point of C in $A_0 \backslash [a,b]$, in contradiction of (3.15). For $k \geq n_0$ and $s \in [\alpha_k, \beta_k]$, let $J_k(s)$ denote the j-half-characteristic emanating to the left of C_k and joining $z_k(s)$ to a point $w_k(s)$ of $\partial G \backslash A_k$. In light of (3.16),

$$\lambda(J_k(s)) \geq \delta > 0 \quad \text{for} \quad k \geq n_0, \quad s \in [\alpha_k, \beta_k]. \tag{3.17}$$

This means that for each $\epsilon > 0$ we have an upper bound on the curvature to the left of E_k. More precisely, the curvature bound implies that

$$D^+\theta(z_k(s)) \le \frac{K}{\lambda(J_k(s))} \le \frac{K}{\delta} \quad \text{for} \quad k \ge n_0, \quad s \in [\alpha_k, \beta_k]. \tag{3.18}$$

In addition, the curvature bound trivially implies that

$$D^-\theta(z_k(s)) \ge -\frac{K}{\operatorname{dist}(z_k(s), \partial G)}. \tag{3.19}$$

There is a neighborhood U of ∂G such that for each $z \in U$ there is a unique $p(z) \in \partial G$ for which $|z - p(z)| = \min\{\operatorname{dist}(z, \zeta) : \zeta \in \partial G\}$ and for which p is continuous. For q in ∂G, let $e^{i\phi(q)}$ be the positively oriented unit tangent to ∂G at q, so that, in U, $e^{i\phi(p(z))}$ is continuous. It follows from (3.18) and Proposition 3.13 that there is a $\Lambda = \Lambda(\epsilon)$ such that

$$|z_k'(s) - e^{i\phi(p(z_k(s)))}| \le \Lambda\sqrt{|z_k(s) - p(z_k(s))|} \quad \text{for} \quad k \ge n_0, \quad s \in [\alpha_k, \beta_k]. \tag{3.20}$$

Bounds (3.18), (3.19), and (3.20) imply that the family $\{z_k'(s)\}$ is uniformly bounded and equicontinuous (that is, there is a single modulus of continuity valid for all $z_k'(s)$, $k \ge n_0$, on the respective $[\alpha_k, \beta_k]$). From this it follows that there are α, β, and a sequence $\{k_l\}$ such that $\alpha_{k_l} \to \alpha$ and $\beta_{k_l} \to \beta$ and $z_{k_l}(s) \to z_\epsilon(s)$ uniformly (in the obvious sense), where z_ϵ is continuously differentiable and parameterizes an arc $C(\epsilon)$ which joins a point of $\partial N(a, \epsilon)$ to a point of $\partial N(b, \epsilon)$ in the part of $\overline{D_0}$ lying outside of both these circles. The arc $C(\epsilon)$ is simple, since otherwise there would be some $q \in (a, b)\backslash N(\{a, b\}, \epsilon)$ such that for arbitrarily small $\tau > 0$, $L(G, q, \tau)$ intersects some E_k more than once, which would contradict Proposition 3.13. Clearly, $\lambda(C(\epsilon)) \le M(G, K)$. The nested nature of the D_k then implies that (at least for sufficiently small ϵ) the entire sequence converges to $C(\epsilon)$. Also, it is clear that $C(\epsilon')$ is an extension of $C(\epsilon)$ for $\epsilon' < \epsilon$. We have that $C = \cup\{C(\epsilon) : \epsilon > 0\}$, since $\operatorname{diam}(z_k([0, \alpha_k]))$ and $\operatorname{diam}(z_k([\beta_k, \lambda(C_k)]))$ tend to 0 uniformly in k as $\epsilon \to 0$ by Proposition 3.6. It follows from $C = \cup\{C(\epsilon) : \epsilon > 0\}$ that $\lambda(C) \le M(G, K)$ and that C is a simple arc with endpoints a, b, and furthermore that C is parameterized by a function $z(s)$ which is continuously differentiable on $(0, \lambda(C))$. That the two possible orderings of the points of $C \cap [a, b]$ coincide follows from the fact that C is a simple arc and (3.15).

The existence and uniqueness of $J(t)$ is trivial when $z(t) \in G$. When $z(t) \in (a, b)$ the existence of $J(t)$ follows from a straightforward compactness argument. In light of (3.20), for such t, any corresponding $J(t)$ must be orthogonal to ∂G at $z(t)$, so that the uniqueness of $J(t)$ follows from Proposition 3.10. Bound (3.14) follows from (3.18). □

We will refer to an extended characteristic C joining a, $b \in \partial G$ as ab; points of $ab \cap \partial G$ will be called [illegible], and contact points other than a and b will be called [illegible]. It is clear that θ can be continuously extended to $G \cup (ab\backslash\{a, b\})$. For what is to follow it is important to understand that if (D_0, C_0) is an i-characteristic subdomain, then, in addition to the extended characteristics constructed above, D_0 might contain extended characteristics C' joining points $a' < b'$ arising from a sequence of i-characteristic subdomains $\{(D_k', C_k')\}$, where $C_k' = a_k'b_k'$ with $a_{k+1}' \le a_k' < b_k' \le b_{k+1}'$ (where the order is with respect to $A_0 = \operatorname{bot}(D_0)$, as above). Here the C_k' are contained in D_0, but the other part of the boundary of D_k' is $\partial G\backslash(a_k', b_k')$ (where here again the interval notation refers to the order on

$A_0 = \text{bot}(D_0)$). Note that if for such an extended characteristic C', $C' \cap \partial G$ has points other than a' and b' (that is, if C' is not simply an elementary characteristic), then the contact points will not occur monotonically with respect to the order on A_0 when C' is traversed from a' to b'. [illegible] D_0 the extended characteristics C constructed originally will be referred to as [illegible], and this other kind of extended characteristic C' with proper contact points will be said to be [illegible]. We consider that an extended characteristic ab exits G at all of its contact points, and we use the terms "exits regularly" and "exits singularly" at a or b in the obvious fashion. Clearly, ab exits regularly at its proper contact points.

PROPOSITION 3.15. [illegible] C [illegible] i [illegible] p [illegible] $z(s)$, $0 \le s \le L$, [illegible] $z(0) = p$ [illegible] $\phi(s) = \arg\{z'(s)\}$ [illegible] $\lim_{s\to 0} \phi(s)$ [illegible] $s \in (0, L)$, [illegible] $E(s)$ [illegible] j [illegible] $z(s)$ [illegible] $\epsilon, T > 0$, [illegible] $P(\epsilon, T) = \{s < \epsilon : \phi'(s) \ge T\}$ [illegible] $N(\epsilon, T) = \{s < \epsilon : \phi'(s) \le -T\}$ [illegible] $\epsilon, T > 0$, $P(\epsilon, T)$ [illegible] $N(\epsilon, T)$ [illegible] $\text{diam}(E(s)) \to 0$ [illegible] $s \to 0$ [illegible] $E(s)$ [illegible] p

[illegible]. Assume to the contrary that $\lambda(P(\epsilon, T)) > 0$ for some ϵ_0, $T_0 > 0$, $\lambda(P(\epsilon_0, T_0)) = 0$, so that $\phi'(s) \le T_0$ a.e. on $(0, \epsilon_0]$. Then $\phi = \phi^+ + \phi^-$ on $(0, \epsilon_0]$, where ϕ^+ is Lipschitz continuous and nondecreasing and ϕ^- is continuous and nonincreasing. From this in turn it follows that either ϕ^- has a finite limit as $s \to 0$ or it tends to ∞ as $s \to 0$, so that in fact the latter is the case since C exits singularly. But this means that C spirals around p, which is clearly impossible. Thus $P(\epsilon, T)$ must have positive measure for all $\epsilon, T > 0$. One sees similarly that $N(\epsilon, T)$ has positive measure. That $\text{diam}(E(s)) \to 0$ follows immediately from the characteristic length bound. To see that the last sentence of the statement is true, assume to the contrary that $E(\sigma)$ joins $z(\sigma)$ to p. Then, since distinct j-characteristics have no common point in G and can only cross C at one point in G, $E(s)$ exits at p for $0 < s \le \sigma$. But this is impossible in light of Proposition 3.7 and the fact that both $P(\epsilon, 1)$ and $N(\epsilon, 1)$ have positive measure. □

Let (D, C_0) be a characteristic subdomain of G, and let $F \subset D \cup \text{bot}(D)$ be a compact set for which $F \cap \text{bot}(D) \ne \emptyset$. The family $\mathcal{C}(F) = \{C \in \mathcal{I}(D) : F \preceq C\}$ is clearly linearly ordered with respect to the relation $\preceq$. From this it easily follows that there is a unique monotone extended i-characteristic $E_0 = ab$ for which $F \cap \text{bot}(D) \subset [a, b]$ and $E_0 \preceq C$ for all $C \in \mathcal{C}(F)$.

NOTATION 3.16. [illegible] i [illegible] E_0 [illegible] $\min_D(F)$

In the statement and proof of the following proposition all order relations are with respect to (D, C_0).

PROPOSITION 3.17 (structure of $\min_D(A \cup B)$). [illegible] (D, C_0) [illegible] i [illegible] G [illegible] $a_1 < a_2 < b_1 < b_2$ [illegible] $a_1a_2 = A$ [illegible] $b_1b_2 = B$ [illegible] $\mathcal{I}(D)$ [illegible] $U = \min_D(A \cup B) = ef$, $e < f$ [illegible]

(i) U [illegible] A [illegible] B [illegible] $ef \in \mathcal{C}(A \cup B)$ [illegible] i [illegible] ab [illegible] $e \le a \le b \le f$ [illegible]

(ii) ea [illegible] $L \in \mathcal{I}(D)$ [illegible] $A \preceq L \preceq U$, [illegible] $\preceq L$ [illegible]

(iii) bf [illegible] $L \in \mathcal{I}(D)$ [illegible] $B \preceq L \preceq U$, [illegible] $A \preceq L$ [illegible]

[illegible]. It follows from the hypotheses that $e < f$ (i.e., that $e \ne f$). We show that

if (i) does not hold, then at least one of (ii) or (iii) does. Let

$$e' = \sup\{z : z \in \text{bot}(D) \cap \min_D(A \cup B),\ z \le a_1\}$$

and

$$f' = \inf\{z : z \in \text{bot}(D) \cap \min_D(A \cup B),\ z \ge b_2\}.$$

Since (i) does not hold it is easy to see that the subarc $e'f'$ of ef is a member of $\mathcal{C}(A \cup B)$, so that in fact $e'f' = ef$. Obviously, $ef \cap (A \cup B) \subset \{e, f\}$, since otherwise ef would have to be A or B. Let w_0 be any point of ef other than e or f, and consider a small j-arc E whose initial point is w_0, which extends to the right of ef (that is, into the simply connected domain bounded by $ef \cup [e, f]$) and which is disjoint from $A \cup B$. Let E be parameterized by $z = w(s)$, $0 \le s \le \lambda_0$, with $w(\lambda_0) = w_0$, and let $C(s)$ denote the elementary i-characteristic through $w(s)$. Note that

$$C(s_1) \preceq C(s_2) \quad \text{for} \quad s_1 \le s_2. \tag{3.21}$$

Let the left and right endpoints of $C(s)$ be $l(s)$ and $r(s)$. By the minimality of ef it must be that for no $s \in (0, \lambda_0)$ can we have both $l(s) \le a_1$ and $r(s) \ge b_2$. From (3.21) it therefore follows that either for all $s \in (0, \lambda_0)$, $l(s) > a_1$, or for all $s \in (0, \lambda_0)$, $r(s) < b_2$. Assume the latter occurs. Then in fact $r(s) \le b_1$ for all $s \in (0, \lambda_0)$, since otherwise $C(s)$ would cross B in D, which is impossible since they are distinct elementary i-characteristics. Consider the i-characteristic subdomain $(D', C(0))$ bounded by $C(0)$ and $\partial G \backslash (l(0), r(0))$. If we take any sequence $\{s_k\}$ in $(0, \lambda_0)$ which tends monotonically to λ_0, and consider the corresponding sequence of elementary i-characteristics $C_k = C(s_k)$ in D', it is clear that they will give rise to an extended i-characteristic $C' = ab$ (with, as always, $a < b$ with respect to the order for $\text{bot}(D)$), which is nonmonotone with respect to the characteristic subdomain D, which contains ef as a subarc and for which $b \le b_1$. Clearly, $bf \cap ef = \{f\}$, so that $bf \preceq ef$. If we let

$$c' = \sup\{z : z \in \text{bot}(D) \cap bf,\ z \le b_1\}$$

and

$$c'' = \inf\{z : z \in \text{bot}(D) \cap bf,\ z \ge b_2\},$$

then $L = c'c'' \in \mathcal{I}(D)$, so that from the minimality of ef it follows that $c' \ge a_2$ and we have conclusion (iii). In exactly the same manner one obtains conclusion (ii) in the case that $s \in (0, \lambda_0)$, $l(s) > a_1$ for all $s \in (0, \lambda_0)$. □

COMMENT 3.18. (ii) ab $L' \in \mathcal{I}(D)$ $B \preceq L' \preceq U$ (ii) (iii) ab A (iii) (i) ef A B A B

DEFINITION 3.19. $p \in \partial G$ regular boundary point θ $\theta(z)$ $z \to p$ singular boundary point

PROPOSITION 3.20. [illegible] $p \in \partial G$ [illegible] p [illegible] $\phi \in (0, \pi)$ [illegible] ∂G [illegible] p

[illegible]. This follows immediately from the Peano existence theorem for (local) solutions of the initial value problem $y' = F(x, y)$, $y(x_0) = y_0$ when F is continuous in a neighborhood of (x_0, y_0). □

DEFINITION 3.21. [illegible] $p \in \partial G$ [illegible] θ [illegible] (θ, π) [illegible] p [illegible] θ [illegible] singularity of type 0 (singularity of type 1) [illegible] p [illegible] θ [illegible] [illegible] p [illegible] θ [illegible] singularity of type 2 [illegible] p

The following proposition is needed to make use of fans of characteristics in what is to follow.

PROPOSITION 3.22. [illegible] $C_1 = pq_1$ [illegible] $C_2 = pq_2$ [illegible] [illegible] i [illegible] [illegible] A [illegible] [illegible] ∂G [illegible] q_1 [illegible] q_2 [illegible] [illegible] p [illegible] T [illegible] [illegible] [illegible] $C_1 \cup C_2 \cup A$ [illegible] [illegible]

(i) [illegible] $d > 0$ [illegible] $z \in N(p, d) \cap T$ [illegible] [illegible] i [illegible] [illegible] z [illegible] p

(ii) p [illegible] [illegible] C

[illegible]. Let W be the set of all $z \in T$ for which the elementary i-characteristic $C(z)$ through z does not exit at p. For $z \in W$, $C(z)$ has no points in common with either $C_1 \backslash \{q_1\}$ or $C_2 \backslash \{q_2\}$, so that both endpoints of $C(z)$ lie on A. For each $z \in W$, let $D(z)$ denote the interior of the domain bounded by $C(z)$ and the arc of A whose endpoints are those of $C(z)$. For $w_1, w_2 \in T$, $C(w_1) \cap T$ and $C(w_2) \cap T$ are either identical or disjoint, so that for w_1, $w_2 \in W$, $D(w_1)$ and $D(w_2)$ are either nested or disjoint. Let $\xi = \frac{1}{2}\text{dist}(p, A) > 0$. If $z \in N(p, \frac{\xi}{2}) \cap W$, then it follows from Proposition 2.8(i) that $\mu(D(z)) \geq \eta\xi^2$ since $\lambda(C(z) \cap N(p, \xi)) \geq \xi$ and each of the j-arcs joining a point of $C(z) \cap N(p, \xi)$ to A in $D(z)$ has length at least ξ. Thus if $z_1, \ldots, z_n \in N(p, \frac{\xi}{2}) \cap W$ are such that the corresponding $D(z_k)$ are disjoint, then $n \leq \frac{\mu(G)}{\eta\xi^2}$. If (i) is not true, a pigeonhole (area exhaustion) argument then shows that there is a sequence $\{z_k : k \geq 1\}$ of points of W tending to p such that $\{D(z_k)\}$ is an increasing sequence. But our extended characteristic construction then gives us a monotone extended characteristic C (with respect to the characteristic subdomain bounded by $C(z_1)$ and the complement in ∂G of the subarc of A joining the endpoints of $C(z_1)$) for which $p \in C$. But the endpoints of C are in A since those of all the $D(z_k)$ are in A, so that p is a proper contact point of C. Thus C satisfies (ii). □

DEFINITION 3.23 (i-fan). [illegible] θ [illegible] i-fan [illegible] $p \in \partial G$ [illegible] p [illegible] [illegible] i [illegible] [illegible] θ [illegible] p [illegible] [illegible] [illegible] i [illegible] [illegible] p [illegible] $\mathcal{F}_i(p)$ [illegible] p [illegible] vertex [illegible]

Proposition 3.22 implies that if C_1 and C_2 are distinct elementary i-characteristics in $\mathcal{F}_i(p)$, then there is a $d > 0$ such that all points of $N(p, d)$ between them belong to members of $\mathcal{F}_i(p)$, so that the interior of $\cup\{C : C \in \mathcal{F}_i(p)\}$ is nonempty. Furthermore, it follows from Proposition 3.7 that the j-characteristic through any point in the interior of $\cup\{C : C \in \mathcal{F}_i(p)\}$ is strictly concave towards the side facing p. These two facts in turn imply that if there are i-fans at $p_1 \neq p_2$, then the interiors of $\cup\{C : C \in \mathcal{F}_i(p_k)\}$, $k = 1, 2$, must be disjoint. Since $\mu(\cup\{C : C \in \mathcal{F}_i(p)\}) > 0$, we have the following.

PROPOSITION 3.24.

PROPOSITION 3.25. $R = (R_1, R_2)$

. Let F be an extended i-characteristic which exits regularly at p. Without loss of generality we can assume that the positive direction along ∂G at p is that of the positive real axis. Let C be a nontrivial arc of F parameterized by $z = z(s)$, $0 \le s \le L$, with $z(0) = p$. Again, without loss of generality we can assume that $\gamma = \arg\{z'(s)\} = \theta(z(s))$. We consider the following three possibilities separately.

(i) $\gamma \in (0, \frac{\pi}{2}) \cup (\frac{\pi}{2}, \pi)$. In this case we can assume that C is an arc of an elementary i-characteristic exiting at p. To be specific, we assume that $\gamma \in (0, \frac{\pi}{2})$. Let q be an interior point of C. For any $\epsilon > 0$ there exist nontrivial j-characteristic arcs $E^+ = E^+(\epsilon)$ and $E^- = E^-(\epsilon)$ emanating from q to the right and left of C, respectively, such that $\lambda(\theta(E^+ \cup E^-)) < \epsilon$. Since there is no fan at p, none of the j-characteristics through any point of $E^+ \cup E^-$ other than q exits at p. Let $C(\epsilon)$ be an initial segment of C such that $\lambda(\theta(C \backslash \{p\})) < \epsilon$. Let $\alpha < \gamma$; we show that $\theta(z) \to \gamma$ as $z \to p$ between C and the ray $\arg\{z\} = \alpha$. It is easy to see that some initial segment of this ray (that is, the portion of the ray contained in $N(p, \xi)$ for some $\xi > 0$) is covered by a collection $\mathcal{Q}(\epsilon)$ of characteristic quadrilaterals Q, one of whose i-sides is a subarc of $C(\epsilon)$ and one of whose j-sides is a translate of an initial subarc of $E^+(\epsilon)$. The quasi-HP property then implies that there is a $\delta = \delta(\epsilon)$ such that if $|z - p| < \delta$ and z is between C and the ray $\arg\{z\} = \alpha$, then $|\theta(z) - \gamma| < 2K\epsilon$. Since ϵ is arbitrary, $\theta(z) \to \gamma$ as $z \to p$ between C and the ray. It is also clear that for sufficiently small ϵ the translate of E^- down to p is a nontrivial initial arc of a j-characteristic C' which exits regularly at p and which forms with ∂G an acute angle of size $\frac{\pi}{2} - \gamma$. What we have shown in regard to C now implies that if $\beta < \frac{\pi}{2} - \gamma$, then $\theta(z) + \frac{\pi}{2} \to \gamma + \frac{\pi}{2}$ as $z \to p$ between C' and the ray $\arg\{z\} = \pi - \beta$, so that $\theta(z) \to \gamma$ as $z \to p$ in that curvilinear sector. Finally, it is easy to see that $\theta(z) \to \gamma$ as $z \to p$ between C and C'. Since $\alpha < \gamma$ and $\beta < \frac{\pi}{2} - \gamma$ are arbitrary, we have the desired regularity at p. The case $\gamma \in (\frac{\pi}{2}, \pi)$ is handled in the same manner apart from minor changes of a notational nature. In the case that θ arises from the solution of a normal system it is clear from (ii) of Definition 1.1 that both $R_i(z)$ and $R_j(z)$ have limits as $z \to p$ in the sector $\alpha < \arg\{z\} < \beta$, so that the second conclusion is valid in this case.

(ii) $\gamma = \frac{\pi}{2}$. Here again we can take C to be an arc of an elementary i-characteristic exiting at p and proceed as in case (i). For any $\alpha < \frac{\pi}{2}$ it follows as in case (i) that $\theta(z) \to \gamma$ as $z \to p$ between C and the ray $\arg\{z\} = \alpha$. Again it is immediate that the same holds in the curvilinear sector between C and the ray $\arg\{z\} = \pi - \alpha$. The second conclusion is likewise immediate.

(iii) $\gamma \in \{0, \pi\}$. We deal with the case $\gamma = 0$, the case $\gamma = \pi$ being essentially the same. Here we can define $E^-(\epsilon)$ as in case (i), but because there is no fan at p the translate of $E^-(\epsilon)$ down to p is a nontrivial arc of a j-characteristic which is orthogonal to ∂G at p. This puts us in case (ii), so we are done. □

DEFINITION 3.26. $p \in \partial G$ i-singularity

The following is an immediate consequence of Proposition 3.15.

PROPOSITION 3.27. j C p

PROPOSITION 3.28. [illegible] 2-[illegible] i-[illegible] $i = 1$ [illegible] 2 [illegible]. Let C be any elementary i-characteristic, and let D be the characteristic subdomain bounded by C and the arc of ∂G containing p. Let $E = ef = \min_D(\{p\})$. If $E = p$, we are done, so that $E = ef$ is a nontrivial extended characteristic. If $p \in E$, Proposition 3.25 implies that (i) $p \in \{e, f\}$, since extended characteristics exit regularly at their proper contact points. If $p \notin E$, the minimality of E implies that (ii) E is an elementary i-characteristic. We deal with possibility (i) first. Let E be parameterized by $z(s)$, $0 \le s \le l$, with $z(0) = p$. Since p is a singularity of type 2, for no $\sigma > 0$ is it true that $z((0, \sigma)) \subset G$. On the other hand, it follows from the regularity of ∂G and Proposition 3.25 that for no $\sigma > 0$ is it true that $z((0, \sigma)) \subset \partial G$. It is then clear that E contains a sequence $\{C_k\}$ of subarcs which are elementary i-characteristics for which $\operatorname{diam}(C_k)$ and $\operatorname{dist}(C_k, p)$ tend to 0 as $k \to \infty$, so that p is indeed an i-singularity. We finish by showing that possibility (ii) cannot occur; to do so we proceed as in the proof of Proposition 3.17. Let w_0 be any point of E other than e or f, and consider a small j-arc $J \subset G$, which extends from w_0 to the right of E (i.e., into D). Let J be parameterized by $w(s)$, $0 \le s \le \lambda_0$, with $w(\lambda_0) = w_0$, and let $C(s) = l(s)r(s)$ be the elementary i-characteristic through $w(s)$. As in the the proof of Proposition 3.17, it follows from the minimality of E that either $l(s) > p$ for all $s \in (0, \lambda_0)$ or $r(s) < p$ for all $s \in (0, \lambda_0)$. Assume, for definiteness, that the latter occurs. By considering what happens as $s \to 0$ we obtain, as in that proof, a nonmonotone extended i-characteristic ab (with $a < b$ with respect to the order on $\operatorname{bot}(D)$) which contains ef as a proper subarc, for which $b < p$ and for which $bf \preceq ef$. But $p \notin bf$ by hypothesis, so that bf must have a subarc gh which is an elementary i-characteristic for which $g < p < h$, which contradicts the minimality of E. □

The following is an immediate consequence of Propositions 3.25, 3.27, and 3.28 and Definitions 3.21 and 3.26.

PROPOSITION 3.29. [illegible] $p \in \partial G$ [illegible]

(i) p [illegible] 0 [illegible]

(ii) p [illegible] 1 [illegible] k [illegible] $k = 1$ [illegible] 2

(iii) p [illegible] 2 [illegible] k [illegible] $k = 1$ [illegible] 2

COMMENT 3.30. [illegible] 2.2 [illegible] i [illegible] α [illegible] ff. [illegible] 0 [illegible] $\alpha < 1$

PROPOSITION 3.31 (type 1 singularities with fans). [illegible] C [illegible] i [illegible] $p \in \partial G$ [illegible] $q \in G$ [illegible] $z(s)$, $0 \le s \le l$, [illegible] $z(0) = p$ [illegible] $\eta < \frac{\pi}{2}$

$$\phi + \eta \le \arg\{z'(s)\} \le \phi + \pi - \eta \quad \text{[illegible]} \quad 0 < s \le l, \tag{3.22}$$

[illegible] ϕ [illegible] ∂G [illegible] p, $\lim_{s \to 0} \arg\{z'(s)\}$ [illegible] C [illegible] i [illegible] p [illegible]. For $0 < \xi < \pi$, let $R(p, \xi)$ denote the (open) ray

$$R(p, \xi) = \{z : \arg\{z - p\} = \xi\}.$$

Without loss of generality we can assume that $\phi = 0$. It follows immediately from hypothesis (3.22) that C lies in the sector $\{z : \eta \le \arg\{z - p\} \le \pi - \eta\}$. The hypothesis that $\lim_{s \to 0} \arg\{z'(s)\}$ does not exist implies that there is some δ, $0 < \delta \le \frac{\eta}{K+1}$, such

that for arbitrarily small $\sigma_1 > \sigma_2 > 0$

$$|\arg\{z'(\sigma_1)\} - \arg\{z'(\sigma_2)\}| \geq 2\delta. \tag{3.23}$$

For $0 < s \leq l$, let $F(s) = a(s)b(s)$ be the elementary j-characteristic through $z(s)$. It follows from the last sentence of Proposition 3.15 that $a(l) \neq p \neq b(l)$. Let D be the j-characteristic subdomain bounded by $F(l)$ and the arc of ∂G joining $a(l)$ to $b(l)$ and containing p. Clearly, $F(s) \cap C \cap G = \{z(s)\}$, and $a(s)$ is nonincreasing and $b(s)$ is nondecreasing with respect to the order on $\mathrm{bot}(D)$. Since, by Proposition 3.15, $\mathrm{diam}(F(s)) \to 0$ as $s \to 0$, by replacing C by a sufficiently short initial subarc we can assume that

$$R(p, \xi) \cap \partial D \subset F(l), \quad \frac{\delta}{2} \leq \xi \leq \pi - \frac{\delta}{2}. \tag{3.24}$$

Now consider any pair of numbers $\sigma_1 \neq \sigma_2$ in $(0, l)$ for which (3.23) holds. Obviously, for at least one of them, call it σ, there must hold $|\arg\{z'(\sigma)\} - \frac{\pi}{2}| \geq \delta$. Then $F(\sigma)$ must have a subarc $W = uv$ such that $\lambda(\theta(W)) = \delta$ and $z(\sigma) \in \{u, v\}$. To see this, say, for example, that $\arg\{z'(\sigma)\} \leq \frac{\pi}{2} - \delta$. If, along the arc of $F(\sigma)$ emanating to the left of C, the argument of the tangent were always within δ of its argument at $z(\sigma)$, then $F(\sigma)$ would never cross $R(p, \pi - \delta)$, and it would therefore not be able to exit D. An analogous argument may be used in the case that $\arg\{z'(\sigma)\} \geq \frac{\pi}{2} + \delta$.

From this it follows that there is a sequence $s_k \to 0$ of such numbers σ for all of which the corresponding j-arc $W_k = u_k v_k$ lies on one side of C or the other. To be specific, say $u_k = z(s_k)$ and W_k lies to the right of C. It follows from the quasi-HP property that if $W' = z(s)v$ is any translate of W_k along C in the direction of increasing s, then

$$\delta/K \leq \lambda(\theta(W')) \leq K\delta.$$

From this and the fact that $\delta \leq \frac{\eta}{K+1}$ it follows in turn that for $s > s_k$, along any i-characteristic arc whose initial point is in W_k and which is parallel to the subarc $z(s_k)z(s)$ of C, the inclination of the tangent is in the interval

$$[\eta - K\delta, \pi - \eta + K\delta] \subset [(K+1)\delta - K\delta, \pi - (K+1)\delta + K\delta] = [\delta, \pi - \delta].$$

For each k let

$$S_k = \{R(z, \xi) : z \in W_k \text{ and } \xi \in [\delta, \pi - \delta]\}.$$

Now $\mathrm{diam}(W_k) \leq \mathrm{diam}(F(s_k))$ and the latter tends to 0 as $k \to \infty$, so that in light of (3.24) by eliminating a finite number of elements of $\{s_k\}$ and renaming we can assume that all the $R(z, \xi)$ in each of the S_k meet ∂D a point of F before exiting G. From this it follows that the translates of $z(s_k)z(l)$ along W_k all lie in G. This means that for any $s \in [s_k, l]$ the complete translate of W_k along C from $z(s_k)$ up to $z(s)$ belongs to G. For the translate T_k of W_k up to $z(l)$ we have that $z(l) \in T_k \subset F(l)$, and by the quasi-HP property $\lambda(\theta(T_k)) \geq \delta/K$. This bound implies that there is a positive lower bound on the length of the T_k. Thus $\cap\{T_k : k \geq 1\} = T$ is a nontrivial arc of $F(l)$, one of whose endpoints is $z(l)$. However, the translate of T down to $z(s_k)$ is contained in $W_k \subset F(s_k)$. Since $\mathrm{dist}(F(s), \{p\}) \to 0$ as $s \to 0$, it follows that all i-characteristics through T exit at p, and this establishes the existence of the desired fan. □

We need the following elementary lemma.

LEMMA 3.32. [illegible] f [illegible] $[0,T]$ [illegible] $\int_0^T f(x)dx = A > 0$ [illegible] $\rho \in [0, \frac{1}{2})$

$$\lambda(\{\xi : f(\xi) \geq \rho\frac{A}{T} \quad \textit{and} \quad \int_0^\xi f(x)\,dx \geq \rho A\}) > 0.$$

[illegible]. Let $f(x) \leq M$ a.e. on $[0,T]$, and let $Q = \{\xi : f(\xi) \geq \rho\frac{A}{T}\}$. Obviously, $\lambda(Q) > 0$. Let Q^* be the set of density points of Q, so that $\lambda(Q^*) = \lambda(Q) > 0$. Let $\xi_0 = \sup\{\xi : \xi \in Q^*\}$. If the set $Q^* \cap \{\xi : \int_0^\xi f(x)\,dx \geq \rho A\}$ had measure 0, then for each $\delta > 0$ there would be a point $\xi \in (\xi_0 - \delta, \xi_0)$ for which $\int_0^\xi f(x)\,dx < \rho A$, so that

$$\begin{aligned} A &= \int_0^\xi f(x)dx + \int_\xi^{\xi_0} f(x)dx + \int_{\xi_0}^T f(x)dx < \rho A + \delta M + (T - \xi_0)\frac{\rho A}{T} \\ &< 2\rho A + \delta M < A, \end{aligned}$$

for δ sufficiently small, so that $\lambda(Q^* \cap \{\xi : \int_0^\xi f(x)\,dx \geq \rho A\})$ must be positive. ∎

The following proposition plays a fundamental role in the proof of Main Theorem 2.2.

PROPOSITION 3.33 (essentially singularity-free boundary arcs). [illegible] $\overline{\eta} = \overline{\eta}(K,\rho) < \rho$ [illegible] $G \in \mathcal{G}(\rho)$ [illegible] $\theta \in \mathrm{HP}(G,K)$ [illegible] C [illegible] i [illegible] θ [illegible] $p \in \partial G$ [illegible] $E = pp'$ [illegible] j [illegible] ∂G [illegible] p [illegible] D [illegible] j [illegible] G [illegible] E [illegible] A [illegible] ∂G [illegible] $b \in A \cap C$ [illegible] C [illegible] A [illegible] F [illegible] $[b,p']$ [illegible] A [illegible] $\mathrm{dist}(p,F) \geq \rho$ [illegible] $[p,p'']$ [illegible] A [illegible] $|p'' - p| = \overline{\eta}$ [illegible] θ

[illegible]. Without loss of generality we may assume that $p = 0$, that the positively oriented tangent to ∂G at p has the direction of the positive real axis, and that A extends to the right of p. Let C be parameterized by $z(s) = x(s)+iy(s)$, with $z(0) = p$. We shall introduce positive constants, which will depend only on K and ρ. In most cases these constants will be denoted by the same symbol B, but the use of a single symbol to denote different constants will not cause confusion or be misleading since any statement in which B plays a role will be valid if B is taken to be any suitably large number and since this convention is used only finitely many times. The symbol B_1, on the other hand, will refer to a specific constant, which again depends only on K and ρ and which will have the same value every time it is used.

If we give A in nonparametric form by $y = g(x)$, then

$$|g(x)| \leq \frac{x^2}{\rho} \quad \text{and} \quad |g'(x)| \leq \frac{2x}{\rho} \quad \text{for} \quad 0 \leq x \leq \frac{1}{10\rho}. \tag{3.25}$$

Clearly, Proposition 3.12 holds for extended characteristics with the obvious wording changes. Any j-arc emanating to the left of C from any point z of the subarc pb of C will exit G at a point of F, so that the length of any such j-arc is a least $\rho - |p - z|$. Since $\mathrm{dist}(z(s), \partial G) \leq |z(s)| \leq |s|$, it follows from Proposition 3.12 that $|\arg\{z'(s)\}| \leq \frac{1}{2}$ for $0 \leq s \leq \frac{1}{B}$, so that for these values of s we have

$$\frac{1}{B} \leq x'(s) \leq 1 \quad \text{and} \quad |y'(s)| \leq 1,$$

and we can represent C nonparametrically by $y = f(x)$, where $f(x(s)) = y(s)$. For $0 \le s \le \frac{1}{B}$ we have

$$|f'(x(s))| = |\tan(\arg\{z'(s)\})| \le 2|\arg\{z'(s)\}| \le B\sqrt{\operatorname{dist}(z(s), A)}$$
$$\le B\sqrt{|z(s) - x(s)| + \operatorname{dist}(x(s), A)} \le B\sqrt{f(x(s)) + x(s)^2},$$

where the second inequality follows from Proposition 3.12 and the fourth inequality follows from the first bound of (3.25) in the form $\operatorname{dist}(x(s), A)) \le \frac{(x(s))^2}{\rho}$. Thus there is a $B_1 \ge 1$ such that

$$|f'(x)| \le B_1\sqrt{|f(x)| + x^2} \quad \text{and} \quad |f(x)| \le B_1 x \quad \text{for } 0 \le x \le \frac{1}{B_1}. \tag{3.26}$$

For $0 \le x \le \frac{1}{B_1}$ we then have the following. In the first place,

$$|f'(x)| \le B_1\sqrt{B_1 x + x^2} \le 2^{1/2} B_1^{3/2} x^{1/2},$$

so that in fact $|f(x)| \le \frac{2}{3} 2^{1/2} B_1^{3/2} x^{\frac{3}{2}} < B_1^{3/2} x^{\frac{3}{2}}$. Repeating this argument we have that $|f'(x)| \le 2^{1/2} B_1^{7/4} x^{\frac{3}{4}}$, so that in fact $|f(x)| \le \frac{4}{7} 2^{1/2} B_1^{\frac{7}{4}} x^{\frac{7}{4}} < B_1^{\frac{7}{4}} x^{\frac{7}{4}}$, so that $|f'(x)| \le 2^{1/2} B_1^{\frac{15}{8}} x^{\frac{7}{8}}$, and so on. Thus, in fact,

$$|f(x)| \le B_1^2 x^2 \quad \text{for} \quad 0 \le x \le \frac{1}{B_1} \tag{3.27}$$

and

$$|f'(x)| \le \sqrt{2} B_1^2 x \quad \text{for} \quad 0 \le x \le \frac{1}{B_1}. \tag{3.28}$$

Before proceeding we remind the reader that each time the symbol B appears, it may have a value larger than it did at its previous appearance. For any $t \in [0, \frac{1}{2B}]$, let $J(t)$ be the j-half-characteristic emanating to the right of C (that is, downwards) from $t + if(t) = \alpha(t)$ and joining it to a point of A. Note that $J(t)$ will reduce to a single point if $\alpha(t) \in A$. Let $J(t)$ be given parametrically by $\zeta_t(s)$ with $\zeta_t(0) = \alpha(t)$. Let $t_0 = x_0^2$. Then, by (3.25) and (3.27), $|f(t_0) - g(t_0)| \le B x_0^4$ for $0 < x_0 \le \frac{1}{B}$. For notational convenience we can assume without loss of generality that $\arg\{z'(s)\} = \theta(z(s))$. We show that, with an appropriately large value of B, $0 < x_0 \le \frac{1}{B}$ implies that

$$|\theta(\zeta_{t_0}(s_1)) - \theta(\zeta_{t_0}(0))| \le x_0 = \sqrt{t_0} \tag{3.29}$$

for every $\zeta_{t_0}(s_1) \in J(t_0)$. If this were not true, there would be an $s_1 \in (0, \lambda(J(t_0)))$ such that $|\theta(\zeta_{t_0}(s_1)) - \theta(\zeta_{t_0}(0))| = x_0$. Let s_2 be the smallest number in $[0, s_1]$ for which $|\theta(\zeta_{t_0}(s_2)) - \theta(\zeta_{t_0}(0))| = x_0$, so that

$$\lambda(\theta(\zeta_{t_0}([0, s_2]))) \le 2x_0. \tag{3.30}$$

By increasing B if necessary, $t_0 = x_0^2 < \frac{1}{B^2}$ will be so small that

$$s_2 \le 2|f(t_0) - g(t_0)| \le B x_0^4. \tag{3.31}$$

By the preceding lemma (with $\rho = \frac{1}{3}$, $T = s_2$, $A = x_0$) it then follows that there is an $s_3 \in (0, s_2)$ for which

$$|D\theta(\zeta_{t_0}(s_3))| \ge \frac{x_0}{3s_2} \ge \frac{1}{Bx_0^3}$$

and

$$|\theta(\zeta_{t_0}(s_3)) - \theta(\zeta_{t_0}(0))| \geq \frac{x_0}{3}, \tag{3.32}$$

where the expressions inside the absolute values on the left-hand side of these last two bounds have the same sign. Let R be the i-half-characteristic through $\zeta_{t_0}(s_3)$ emanating from $J(t)$ towards its concave side (that is, to the left of $J(t_0)$ if $d\arg\{\zeta'_{t_0}(s)\}/ds$ is positive at s_3 and to the right if it is negative). It follows from the characteristic length bound (Proposition 2.5) that

$$\lambda(R) \leq Bx_0^3. \tag{3.33}$$

We concentrate on the case that R emanates to the left of $J(t_0)$; the opposite case is much easier to handle, as we indicate below. By (3.27), (3.31), and (3.33), R exits G at a point $g(\beta)$ with

$$\begin{aligned} \beta &\leq t_0 + |f(t_0)| + |\zeta_{t_0}(0) - \zeta_{t_0}(s_3)| + \lambda(R) \\ &\leq x_0^2 + O(x_0^3) \leq 2x_0^2 \quad \text{for} \quad x_0 \leq \frac{1}{B}. \end{aligned} \tag{3.34}$$

For $t \geq t_0$ let $\overline{J}(t)$ be the j-arc joining $\alpha(t) \in C$ to a point $r(t) \in R$, so that $\overline{J}(t_0) = \zeta_{t_0}([0, s_3])$. Obviously, $\overline{J}(t)$ is not defined for all $t \in [t_0, \frac{1}{2B_1}]$, but, for any t for which it is defined, $\overline{J}(t_0)$ and $\overline{J}(t)$ are the j-sides of a characteristic quadrilateral $Q(t)$, whose i-sides are the arc $\alpha(t_0)\alpha(t)$ of C and the arc $\zeta_{t_0}(s_3)r(t)$ of R. From the K-quasi-HP property and (3.30) it follows that

$$\lambda(\theta(\overline{J}(t))) \leq K\lambda(\theta(\overline{J}(t_0))) \leq K\lambda(\theta(\zeta_{t_0}([0, s_2]))) \leq 2Kx_0, \tag{3.35}$$

and by (3.28)

$$\lambda(\theta(\zeta_{t_0}(s_3)r(t))) \leq K\lambda(\theta(\alpha(t_0)\alpha(t))) \leq 2K\tan^{-1}(Bt) \leq Bt. \tag{3.36}$$

But for any $t \leq 10x_0^2$ for which $J(t)$ is defined, we have from (3.25) and (3.28) that

$$\begin{aligned} |\theta(\zeta_t(s))| &\leq \theta(\alpha(t)) + 2Kx_0 \leq \tan^{-1}(Bt) + 2Kx_0 \\ &\leq 20Bx_0^2 + 2Kx_0 \leq \frac{1}{100} \end{aligned}$$

for $x_0 \leq \frac{1}{B}$. From this together with (3.34) it is clear that $g(\beta)$ is the endpoint of $\overline{J}(t_1)$ for some $t_1 \in [x_0^2, 10x_0^2]$. It follows from the quasi-HP property that R, when oriented from $\zeta_{t_0}(s_3)$ to $r(t_1)$, has a well-defined (one-sided) tangent, whose argument we denote by ϕ_0. But then we have from (3.28), (3.32), (3.36), and the quasi-HP property that

$$\phi_0 \geq \frac{x_0}{3} - |\theta(\alpha(t_0))| - Bt_1 \geq \frac{x_0}{2} - \theta(\alpha(x_0^2)) - 10Bx_0^2 \geq \frac{x_0}{3} - Bx_0^2,$$

so that

$$\phi_0 \geq \frac{x_0}{4}, \tag{3.37}$$

for $x_0 \leq \frac{1}{B}$. By (3.25) and (3.24)

$$|\tan^{-1}(g'(\beta))| \leq |g'(\beta)| \leq \frac{2\beta}{\rho} \leq \frac{4}{\rho}x_0^2 \quad \text{for} \quad x_0 \leq \frac{1}{B}.$$

Taking into account the direction from which R crosses A at $g(\beta)$, one sees that $\phi_0 \le |\tan^{-1}(g'(\beta))|$, which is a contradiction for $x_0 < \min\{\frac{1}{B}, \frac{\rho}{17}\}$. If R emanates to the right of $J(t_0)$, we get the same contradiction more easily because in that case we move back along C towards p and there are smaller bounds throughout. This establishes (3.29) for $x_0 \le \frac{1}{B}$ (with, of course, an appropriately large B).

Thus, for $\sqrt{t} \le \frac{1}{B}$, $\lambda(\theta(J(t))) \le \sqrt{t}$. From this together with (3.27) it follows that

$$|\theta(z)| \le \sqrt{t} + Bt \le \frac{1}{100} \quad \text{for} \quad z \in J_t, \quad 0 < t < \frac{1}{B}. \tag{3.38}$$

Finally, after increasing B if necessary, we have $|\tan^{-1}(g'(t))| \le \frac{1}{100}$ for $|t| \le \frac{1}{B}$. Let $l_t = \lambda(J_t)$, and let $q(t) = \zeta_t(l_t) \in A$. We now show that $\{q(t) : 0 \le t \le \frac{1}{B}\}$ is an arc of A, for which we have to only show that $q(t)$ is continuous on $(0, \frac{1}{B})$. Clearly, we have from (3.38)

$$\left| \arg\left\{ \frac{\partial \zeta_t(s)}{\partial s} \right\} + \frac{\pi}{2} \right| \le \frac{1}{100} \quad \text{for} \quad t \le \frac{1}{B} \quad \text{and} \quad 0 \le s \le \lambda(t). \tag{3.39}$$

If $l_{t_0} = 0$, then what we have already shown implies that $l_t \to 0$ as $t \to t_0$, from which it immediately follows that $q(t) \to q(t_0)$ as $t \to t_0$. Thus consider a fixed t_0 for which $l_{t_0} > 0$. Let $\delta > 0$ be small, and let $s \in (l_{t_0} - \delta, l_{t_0})$. Let the elementary i-characteristic through $\zeta_{t_0}(s)$ be parameterized by $z = w_s(\sigma)$ with $w_s(0) = \zeta_{t_0}(s)$. It is clear that there is some $\delta' \in (0, \delta]$ such that for all $\sigma \in [-\delta', \delta']$, $w_s(\sigma) \in J(t(\sigma))$ (where $t(\sigma)$ is some continuous function of σ) and $|\theta(w_s(\sigma)) - \theta(w_s(0))| \le \frac{1}{100}$. Then it is clear from (3.39) that for $|\sigma| \le \delta'$, $J(t(\sigma))$ intersects A at a point within 2δ of $q(t_0)$. The desired continuity follows immediately since there is a positive δ'' such that for $|t - t_0| < \delta''$, $J(t)$ intersects $w_s((-\delta', \delta'))$.

From this and (3.38) it follows that, in fact, for $0 < t < \frac{1}{B}$, $|\theta(z)| \le 2\sqrt{t}$ for z in the domain bounded by J_t and the arcs of C and A with endpoints p and $q(t)$. The desired conclusion now follows immediately from Propositions 3.24, 3.25, and 3.31. □

We end this section with a technical proposition to be used in the proof of the main theorem given in section 4. The numbers $\eta = \eta(K)$ and $\eta' = \eta'(K)$ arising here are those of Proposition 2.8.

PROPOSITION 3.34 (trapped area bound). [illegible] $\eta_1 = \eta_1(K) \le \min\{1, \eta(K)\}$ [illegible] (D, V) [illegible] $U = u_1 u_2 \in \mathcal{I}(D)$ [illegible] $|p - q| \ge \xi$ [illegible] $p, q \in \mathrm{bot}(D)$ [illegible] $[u_1, u_2] \subset [p, q]$ [illegible] $\overline{D}$ [illegible] $u \in \{u_1, u_2\}$ [illegible] $U' \subset \overline{D}$ [illegible] U V [illegible] u u' [illegible] $u' < u_1$ $u' > u_2$ [illegible] $u = u_1$ $u = u_2$ [illegible] u' [illegible] U) [illegible] $|\Delta\theta(U')| \ge \frac{\pi}{4}$ [illegible] D' D [illegible] U V [illegible] $\eta_1 \xi^2$ [illegible]. For definiteness we assume that $u = u_1$, so that $u' < u_1$. Let $V = v_1 v_2$. Let U' be parameterized by $w = w(s)$, $0 \le s \le L$, with $w(0) = u_1$, and for $s \in [0, L)$ denote by $U(s) \preceq V$ the elementary i-characteristic containing $w(s)$, so that in particular $U(0) = U$. One of the endpoints $a(s)$ of $U(s)$ lies below U', and the other endpoint $b(s)$ is in $[v_1, v_2] \backslash (u_1, u_2)$. There are the following two possibilities.

A. The point $b(s) \ge u_2$ (i.e., lies to the right of u_2) for $0 \le s < L$. In this case $U \preceq U(s)$, and consequently $\lambda(U(s)) \ge \xi$, for all $s \in [0, L)$, so that by second

area bound (Proposition 2.8(ii)) the area of $\cup\{U(s) : 0 < s < L\} \subset D'$ is at least $\eta' \frac{\pi}{4}\xi^2$.

B. There is some $s \in (0, L)$ for which $b(s) \leq u_1$. Since $b(0) = u_2$, there is a decreasing sequence $\{s_k\}$ tending to some $\sigma \in [0, L)$ such that $b(\sigma) \geq u_2$, but $b(s_k) \leq u_1$ for $k \geq 1$. But then there is a nonmonotone (with respect to D) extended i-characteristic C joining $a_0 = \lim_{k\to\infty} a(s_k)$ to a point $b_0 = \lim_{k\to\infty} b(s_k) \leq a_0 \leq u_1$ for which $b(\sigma)$ is a proper contact point. Then C has subarcs $U(\sigma) = a(\sigma)b(\sigma)$ and $W = de$, which are elementary i-characteristics and for which $U(\sigma) \preceq W$ and $U(\sigma) \cap W \subset \{b(\sigma)\}$, and where $d \in [v_1, u']$, $e \in [b(\sigma), v_2]$. Since we therefore have $[u_1, u_2] \subset [d, e]$, we conclude that $\lambda(W) \geq |e - d| \geq \xi$. Regard W as oriented from e to d and consider the subarc W' of W of length $\frac{\xi}{2}$ which starts at e, and for each $p \in W'$ consider the j-arc $J(p)$ emanating to the left of W and which joins p to a point $q(p) \in \mathrm{bot}(D)$. Because $J(p)$ cannot intersect C at any interior point of C other than p, we have $d \leq q(p) \leq u_1$. Since the length of any curve joining e to a point to the left of u_1 must be at least ξ, it follows that $\lambda(J(p)) \geq \frac{\xi}{2}$. The first area bound (Proposition 2.8(i)) then implies that

$$\mu\Big(\bigcup\{J(p) : p \in W'\}\Big) \geq \eta\frac{\xi^2}{4}.$$

The conclusions of Cases A and B together imply that the area between U and V is at least $\min\{\eta\frac{\xi^2}{4}, \eta'\frac{\pi}{4}\xi^2\} = \eta_1\xi^2$, where $\eta_1 = \min\{\frac{\eta}{4}, \frac{\pi}{4}\eta'\}$. □

4. Proof of Main Theorem 2.2. The main ingredients in the proof are Proposition 3.33 about essentially singularity-free boundary arcs, Proposition 3.29, Proposition 3.17 regarding the structure of $\min_D(A \cup B)$, and the trapped area bound (Proposition 3.34). We also use the preservation of quasi-HP conditions under linear changes of variable, which allows one to normalize the arc one is working with to have any convenient length. In reference to a quasi-HP function θ on $G \in \mathcal{G}$, we will say that $E \subset \partial G$ is [illegible] (abbreviated ESF-i) if it has at most countably many i-singularities of θ. As is explained in detail in the final paragraph of the proof, it is enough to prove that there is a number $\tau = \tau(K) < 1$ such that on any suitably small boundary arc the set of all i-singularities has Hausdorff dimension at most τ. In the treatment of such arcs there is considerable freedom in the choice of the various explicitly given numerical constants that we use, and for the most part they are far bigger (or smaller) than necessary and have most often been chosen either for the sake of convenience or to avoid the necessity of going into careful geometric arguments. In the same vein, many of the bounds we give are far from being sharp, so that, if we state that the value of some expression is bounded below by 1, it may be clear that it is in fact bounded below by a considerably larger number. Furthermore, in some instances we use symbols to denote numerical constants which could without much effort be determined explicitly.

Let $G \in \mathcal{G}(\rho)$, so that the unsigned curvature of ∂G is everywhere at most $\frac{1}{\rho}$. For $p \in \partial G$ let $w(p) = e^{i\phi(p)}$ be the unit tangent to ∂G (with positive orientation) at p. Let δ be any positive for which

(1) $\delta \leq \frac{\rho}{10000}$.

This implies in addition that

(2) on any arc B of ∂G of length 100δ, $\lambda(w(B)) < \frac{1}{100}$, and that

(3) for any point $p \in \partial G$ and any $r \leq 20\delta$, $\partial N(p, r)$ meets ∂G in two points, so that for such r, $N(p, r) \cap G$ is essentially a semidisk.

The corners of $\partial N(p,9\delta)\cap G$ can be replaced by circular arcs of radius $\frac{\delta}{90}$ and then smoothed at the joins to form a C^2 curve which is the boundary of a subdomain

$$\Sigma = \Sigma(p,\delta) \subset N(p,10\delta)\cap G$$

of G with the following properties:

(1a) $\Sigma \in \mathcal{G}(\frac{\delta}{100})$.

(2a) The arc $N(p,4\delta)\cap\partial\Sigma$, to be referred to as the bottom of Σ, and which is an arc of ∂G, has unsigned curvature bounded above by $\frac{1}{10000\delta}$.

(3a) $\mu(\Sigma) \le 200\delta^2$.

Now consider the $X = X(p) = \frac{1}{\delta}(\Sigma(p,\delta) - p)$ which has the following properties:

(1b) $X \in \mathcal{G}(\frac{1}{100})$.

(2b) $B = N(p,4)\cap\partial X$, to be referred to as the bottom of X, is a C^2 arc on which the unsigned curvature is bounded above by $\frac{1}{10000}$.

(3b) $\mu(X) \le 200$.

Note that what we call the bottom B of X is very close to a straight line segment of length 8 centered at the "midpoint" p of what is close to being the straight portion of the boundary of a semidisk of radius 9. Note also that by Proposition 2.3, $\theta(p+\delta z)$ is a K-quasi-HP function on this $X(p)$. A domain X having these three properties will be called a [illegible].

Until the end of the proof of the main theorem we work exclusively with quasi-HP functions θ defined on a normalized domain X. It is clear from property (1b) that there is a universal constant $\gamma_0 \in (0,1)$ such that for any such X

$$|z_1 - z_2| \ge \gamma_0 \mathrm{dist}_{\mathrm{arc}}(z_1,z_2) \quad \text{for} \quad z_1, z_2 \in \partial X, \tag{4.1}$$

where $\mathrm{dist}_{\mathrm{arc}}(z_1,z_2)$ denotes the length of the shorter arc of ∂X with endpoints z_1, z_2. We shall prove the following proposition from which, as we will subsequently show, the main theorem follows almost immediately. We stress that for an arc F of the bottom of X, $\mathrm{diam}(F)$ is the distance between its endpoints.

PROPOSITION 4.1. [illegible] $\Delta_0 = \Delta_0(K) > 0$ [illegible] θ [illegible] K [illegible] X [illegible] X [illegible] i [illegible] Δ_0 [illegible]. It is clear from Proposition 2.3 that we can assume that $p = 0$ and that $w(p) = 1$. We establish the desired conclusion as follows (once again, the constants chosen are unnecessarily big or small). Let H_0 be an integer for which

$$H_0 \ge \max\left\{\frac{10^6}{\gamma_0^2\eta_1}, 10000\right\},$$

and let

$$\epsilon_0 = \overline{\eta}\left(K, \frac{\gamma_0}{10H_0}\right),$$

where $\eta_1 = \eta_1(K)$ is the constant of the trapped area bound (Proposition 3.34) and $\overline{\eta}$ is the constant of Proposition 3.33 about essentially singularity-free boundary arcs; H_0, η_1, and ϵ_0 depend solely on K. In particular we have

$$\epsilon_0 \le \frac{\gamma_0}{10H_0} < \frac{1}{10H_0} \le \frac{1}{10^5}.$$

Our strategy will be to show that there is some constant $\gamma_1 = \gamma_1(K)$ such that the assumption that

(4.2) the bottom B of X has no ESF-i arc of diameter ϵ_0

leads to the conclusion that the bottom of X has an ESF-i arc of diameter $\frac{\epsilon_0}{10^6}$ or one of diameter γ_1, so that B has an ESF-i arc of diameter $\Delta_0 = \min\{\frac{\epsilon_0}{10^6}, \gamma_1\}$. This underlying assumption (4.2) will be in force throughout and will be used many times.

The proof the existence of such a Δ_0 is divided into three steps.

1. There is an elementary i-characteristic $C_0 = \overline{a}\overline{b}$ which has the following properties:

(i) $|\overline{b} - \overline{a}| \geq 1$.

(ii) At least one of $\overline{a}$, $\overline{b}$ lies in B.

COMMENT 4.2.

We begin the proof of Step 1 by noting that by (4.2) there is an i-singularity on B within ϵ_0 of the left endpoint of B, so that there is an elementary i-characteristic C_0' which joins two points of B, both of which are within $2\epsilon_0$ of the left endpoint of B. We work with the right half B_R of B; the endpoints of B_R are 0 and a point d to the right of 0, with $|d| = 4$. In light of our assumption (4.2), it follows that there are two elementary i-arcs $F_1 = a_1a_2$ and $F_2 = b_1b_2$ joining points of B_R such that

$$|a_1 - a_2|, \quad |b_1 - b_2| < \frac{1}{H_0}$$

and

$$\frac{1}{H_0} < \text{dist}(F_1, 0), \quad \text{dist}(F_2, d) < \frac{2}{H_0}.$$

Consider the characteristic subdomain (D, C_0') for which $\text{bot}(D)$ contains the $\partial X \backslash B$, so that the only part of X not in D is the union of C_0' and the interior of the (small) subdomain bounded by C_0' and the arc of B which joins its endpoints. $\text{bot}(D)$. We apply Proposition 3.17 to $\min_D(F_1 \cup F_2)$ with $A = F_1$ and $B = F_2$ and examine in turn each of the three cases of its conclusion.

(i). If there were a contact point p of $\min_D(F_1 \cup F_2)$ between F_1 and F_2 for which

$$\text{dist}(F_1, p), \quad \text{dist}(F_2, p) > \frac{1}{H_0},$$

then Proposition 3.33 would imply that there is an ESF-i subarc of B_R of diameter ϵ_0, contrary to (4.2). Thus, for every contact point p of $\min_D(F_1 \cup F_2)$ between F_1 and F_2, one of

$$\text{dist}(F_1, p) \leq \frac{1}{H_0} \quad \text{or} \quad \text{dist}(F_2, p) \leq \frac{1}{H_0}$$

must hold. Say for definiteness that the former holds for some contact point p between F_1 and F_2, and let $\overline{a}$ be the rightmost such point. Then it is clear that $\min_D(F_1 \cup F_2)$ has an elementary subcharacteristic C_0 joining $\overline{a} \in B$ to a point $\overline{b} \in \text{bot}(D)$, where $\overline{b}$ is either between F_1 and F_2 but within $\frac{1}{H_0}$ of F_2 or to the right of F_2 (with respect to the order on $\text{bot}(D)$). In either event, $|\overline{b} - \overline{a}| \geq 1$. The case $\text{dist}(F_2, p) \leq \frac{1}{H_0}$ is handled similarly.

For the other two cases we let a, b, e, f, U, and L be as in the conclusion of Proposition 3.17. Furthermore, let the left and right endpoints of C_0' be l and r (with respect to the order on $\text{bot}(D)$, so that since $\text{bot}(D)$ is very close to a segment of $\mathbb{R}$, l lies to the right of r in the usual sense).

(ii). Let α and β be the left and right endpoints of L. If $|\beta - \alpha| \geq 1$, then we can take L for C_0 since α is to the left of F_1 and therefore is in B. Thus we may assume that $|\beta - \alpha| < 1$. Starting at a and traversing ∂X in the negative direction the indicated points occur in the following order: a, β, a_2, a_1, α, e, l, r, f, b (with some equalities possible). If $|e - f| < 1$, then the arc $e\alpha$ joins e, $\alpha \in B$ and $|e - \alpha| \geq 2$. It is then easy to see that either $e\alpha$ has a proper contact point g for which $|g - e|$, $|g - \alpha| > \frac{1}{H_0}$, which (in light of Proposition 3.33) would violate (4.2), or $e\alpha$ has a subarc C_0 which is an elementary i-characteristic with the desired properties. Thus we need only consider what happens if $|e - f| \geq 1$. But in this case $C_0 = ef$ has the desired properties since it is an elementary i-characteristic and $e \in B$.

(iii). Here we assume that we are not simultaneously in Case (ii), since were that so we would be done. The point b is obviously between F_1 and F_2, but, since we are not in Case (ii), a is between l and F_1. Let $L = pq$, with $p < q$. If $|b - p| \geq \frac{1}{H_0}$, then, again by Proposition 3.33, B would have an ESF-i arc of diameter ϵ_0 contradicting (4.2). Thus we can assume that $|b - p| < \frac{1}{H_0}$. If $|p - q| < 1$, then we will have $|b - a| > 1$ and we can take for C_0 any elementary i-characteristic closely approximating the extended characteristic ab (recall the construction of extended characteristics in section 3), since its endpoints can be made arbitrarily close to a and b, and consequently can be chosen to lie in B. On the other hand, if the distance between p and q is at least 1, then we can take C_0 to be the elementary i-characteristic pq, since $p \in B$. Thus we are done with Step 1.

Step 1 implies that there is a subarc P of ∂X and an elementary i-characteristic $C_0 = \overline{a}\overline{b}$ with $\overline{b} - \overline{a} \geq 1$ joining the two endpoints of P such that P contains a subarc I of B, the distance between whose endpoints is at least 1 and one of whose endpoints is an endpoint of C_0. To be specific we assume that the left endpoint of I is the one I has in common with C_0. We shall henceforth work with the characteristic subdomain (D_0, C_0) bounded by $P \cup C_0$, so that in particular all order related statements will refer to the order on $\text{bot}(D_0) = P$, unless otherwise indicated. We give P the usual arc length parameterization $z = z(s)$, $0 \leq s \leq L$, with increasing s corresponding to the positive orientation on ∂X and such that $z(0)$ is the left endpoint of I. Obviously, $z([0,1]) \subset I$. By the bound of $\frac{1}{10000}$ on the unsigned curvature of B it is clear that

$$|z(s_2) - z(s_1)| \geq \frac{9}{10}|s_2 - s_1| \quad \text{for} \quad z(s_1),\, z(s_2) \in I. \tag{4.3}$$

(Obviously, a constant considerably closer to 1 than $\frac{9}{10}$ would also work here.) We also observe that for α, $\beta \in \text{bot}(D_0)$

$$|\beta - \alpha| \geq \gamma_0 \min\{1, \lambda([\alpha', \beta'])\} \quad \text{for all } [\alpha', \beta'] \subset [\alpha, \beta]. \tag{4.4}$$

This follows from (4.1) and the fact that one of the arcs of ∂X joining α to β contains

$[\alpha', \beta']$ and the other contains the endpoints of C_0, the distance between which is at least 1. It is also easy to see that

$$\operatorname{dist}(z(0), P\backslash B) \geq 1. \tag{4.5}$$

2. There is a subarc $J = pq$ of I with $|q - p| \geq \frac{1}{40}$ such that p and q are joined by an elementary i-characteristic in D_0.

To establish this we again use an argument based on the case that results when Proposition 3.17 is applied. However, for this step this proposition must be applied, in conjunction with the trapped area bound (Propositions 3.34), in a sequential manner. By our underlying assumption (4.2) there are elementary i-characteristics $A_1, \ldots, A_{H_0} \in \mathcal{I}(D_0)$ for which the arc $I_k \subset I \subset \operatorname{bot}(D_0)$ joining the endpoints of A_k lies in the middle third of $z([\frac{k-1}{H_0}, \frac{k}{H_0}])$ (i.e., lies in $z([\frac{k-\frac{2}{3}}{H_0}, \frac{k-\frac{1}{3}}{H_0}])$), $1 \leq k \leq H_0$. Note that by (4.3)

$$\operatorname{dist}(I_{k_1}, I_{k_2}) \geq \frac{9}{10H_0}\left(|k_2 - k_1| - \frac{1}{3}\right). \tag{4.6}$$

Assume inductively that we have elementary i-characteristics C_k, $0 \leq k \leq t$, such that C_k envelopes only $A_{l(k)}, A_{l(k)+1}, \ldots, A_{r(k)}$, but none of the other A_n, such that

$$C_0 \succeq C_1 \succeq \cdots \succeq C_t,$$

$$1 = l(0) \leq l(1) \leq \cdots \leq l(t) < r(t) \leq r(t-1) \leq \cdots \leq r(0) = H_0$$

and such that $r(k) - l(k)$ is strictly decreasing and satisfies

$$r(k) - l(k) \geq \frac{H_0}{3}, \quad 0 \leq k \leq t. \tag{4.7}$$

We apply Proposition 3.17 with $A = A_{l(t)}$ and $B = A_{r(t)}$ to analyze $C = \min_{D_0}(A_{l(t)} \cup A_{r(t)})$ and consider separately each of the three cases in the conclusion of that proposition. More specifically, we will show three things: first, that if Case (iii) does not occur, either we will have obtained the desired J (and will therefore stop) or we will be able to produce C_{t+1} with

$$r(t+1) - l(t+1) = r(t) - l(t) - 1; \tag{4.8}$$

second, that when Case (iii) occurs we have the desired J; and third, that Case (iii) will have to occur long before (4.7) can be violated.

(i). There can be no contact points of C between $A_{l(t)+1}$ and $A_{r(t)-1}$, since, were there to be such a point p, the distance from p to each of the endpoints of C would, by (4.6), have to be at least $\frac{9}{10H_0}(\frac{2}{3}) > \frac{1}{10H_0}$, so that we can apply Proposition 3.33 to conclude that there is an ESF-i arc of diameter ϵ_0 on B, which contradicts (4.2). If there is a contact point of C between $A_{r(t)-1}$ and $A_{r(t)}$, we will have obtained the desired conclusion because in that case C would have to have a subarc E which is an elementary i-characteristic with left endpoint to the left of $A_{l(t)+1}$ and right endpoint between $A_{r(t)-1}$ and $A_{r(t)}$, so we stop the process here, Step 2 having been established with $J = E$ in light of (4.7). If there is no contact point of C between $A_{r(t)-1}$ and $A_{r(t)}$, then there is a contact point of C between $A_{l(t)}$ and $A_{l(t)+1}$ and C has a subarc C_{t+1} which is an elementary characteristic whose left endpoint is between $A_{l(t)}$ and $A_{l(t)+1}$ and whose right endpoint lies to the right of $A_{r(t)}$. We have $l(t+1) = l(t)+1$ and $r(t+1) = r(t)$, so that (4.8) holds.

For the other two cases we use the notation of Proposition 3.17, namely L, U, ef, and ab, where $ef = U = C = \min_{D_0}(A_{l(t)} \cup A_{r(t)})$.

(ii) (iii). Because we are not in Case (iii), b lies to the right of $A_{r(t)}$. We have that a is between $A_{l(t)}$ and $A_{l(t)+1}$, since otherwise $|e-a| \geq \frac{9}{10H_0}(\frac{2}{3}) > \frac{1}{10H_0}$, by (4.6), and then, since $[e,a] \subset [e,b]$,

$$|e-b| \geq \gamma_0 \min\{1, \lambda([e,a])\} \geq \gamma_0 \min\{1, |e-a|\} > \frac{\gamma_0}{10H_0}$$

by (4.4), so that by Proposition 3.33 applied to the contact point e there is an ESF-i arc of diameter ϵ_0 on B, which contradicts (4.2). From the definition of extended characteristics it follows that there are elementary i-characteristics $U' = a'b' \preceq U$ with a' and b' arbitrarily close to a and b, respectively. The point a' can therefore be taken to lie between $A_{l(t)}$ and $A_{l(t)+1}$, and b' can be taken to lie to the right of $A_{r(t)}$. In this case we let C_{t+1} be any such U' and set $l(t+1) = l(t)+1$ and $r(t+1) = r(t)$, so that we again have (4.8).

(iii). We will show that the first time this case occurs we will have obtained the desired conclusion of Step 2. Thus we assume that when we apply Proposition 3.17 to produce $C = \min_{D_0}(A_{l(t)} \cup A_{r(t)})$ we are in Case (iii). Now we can only say that a lies somewhere to the right of the left endpoint of C_t and that f lies somewhere to the right of $A_{r(t)}$, but, since we cannot use Proposition 3.33 to any effect (because f is not necessarily in B), we cannot conclude, in analogy with the preceding case, that b lies between $A_{r(t)-1}$ and $A_{r(t)}$. If $f \in B$, then by (4.3) and (4.7) it follows that $|f-e| \geq \frac{1}{6}$. On the other hand, if $f \notin B$, then since $f \in P$, (4.5) implies that $|f - z(0)| \geq 1$. Since by (4.7), $|e - z(0)| < \frac{7}{10}$, we have that $|f-e| \geq \frac{3}{10}$. Therefore, no matter what, $|f-e| \geq \frac{1}{6}$. Let D' be the subdomain of D_0 bounded by $ab \cup [a,b]$. It follows immediately from (4.3) that $\lambda([a,b]) \leq \frac{10}{9}|b-a|$. From the definition of extended characteristics it follows that for any $\epsilon > 0$ there are elementary i-characteristics E inside D', joining points of a', $b' \in [a,b]$ and containing points e' and f' which are within ϵ of a, b, e, f, respectively. But it follows from Proposition 3.6 that

$$\frac{1}{6} - 2\epsilon \leq |f'-e'| \leq \operatorname{diam}(e'f') \leq \operatorname{diam}(a'b') \leq 5\lambda([a',b']) \leq \frac{50}{9}|b'-a'|,$$

so that with ϵ appropriately small we see that $|b'-a'| > \frac{1}{40}$. But taking ϵ sufficiently small, the corresponding E will serve as the desired J.

Thus either we stop at t with the desired J or go on to $t+1$, the latter occurring only if we are in Case (i) or if we are in Case (ii) but not Case (iii). We now show that we must actually arrive at Case (iii) long before (4.7) can be violated. Say that we have arrived at $t = T < \frac{H_0}{3}$. Let $T' = [\frac{T}{2}]$. At least one of the following two things must have occurred:

(A) At least T' of the times that we passed from t to $t+1$ we will have done so because we are in Case (i) and there is a proper contact point p_t of $\min_{D_0}(A_{l(t)} \cup A_{r(t)})$ between $A_{l(t)}$ and $A_{l(t)+1}$ and p_t is the left endpoint of C_{t+1}.

(B) At least T' of the times that we passed from t to $t+1$ we will have done so because we are in Case (ii) but not Case (iii).

We deal with possibility (A) first. Say $k_1 < k_2$ are two values of t for which we are in Case (i). Let C' be the elementary j-characteristic, one of whose endpoints is p_{k_2}. Let its second endpoint be p'. If C' were to cross C_{k_1+1}, then, since a j-characteristic can have at most one point in common with an i-characteristic, the other endpoint of

C' would lie to the left of $A_{l(k_1)}$ or to the right of $A_{r(k_1)}$, and the distance between its endpoints would, by (4.6), have to be at least $\frac{9}{10H_0}(\frac{2}{3}) > \frac{1}{2H_0}$. However (as we have seen happen before), by (4.7) together with Proposition 3.33, B would then have an ESF-i arc of diameter ϵ_0, contradicting (4.2). Thus C' does not cross C_{k_1+1}, so that $p' \in \text{bot}(D_0)$. If α, β are points of $\text{bot}(D_0)$ with α lying to the left of C_{k_2+1} and β to its right, then $\lambda(\alpha\beta) \geq \frac{1}{4}$ since $T < \frac{H_0}{3}$, so that by (4.4)

$$|\beta - \alpha| \geq \frac{\gamma_0}{4}. \tag{4.9}$$

If p' lies to the right of C_{k_2+1}, then each point of $C_{k_2+1} \cap X$ is joined to a point in $\text{bot}(D_0)$ to the right of C_{k_2+1} by a j-half-characteristic lying between C_{k_2+1} and $C' \preceq C_{k_1+1}$. Then a simple argument (which was used in the proof of Proposition 3.34) based on Proposition 2.8(i) and the fact that for each point of the first half of C_{k_2+1}, which has length at least $\frac{\gamma_0}{8}$, the corresponding j-half-characteristic has length at least $\frac{\gamma_0}{8}$ shows that the area between C_{k_2+1} and C_{k_1+1} must be at least $\eta(\frac{\gamma_0}{8})^2 = \frac{\eta\gamma_0^2}{64} \geq \frac{\eta_1\gamma_0^2}{64}$. If, on the other hand, $p' < p_{k_2}$, then $|\Delta\theta(C')| \geq \frac{\pi}{4}$. Also, as we just saw, (4.9) holds for all α, $\beta \in \text{bot}(D_0)$ with α lying to the left of C_{k_2+1} and β to its right. Thus by the trapped area bound (Proposition 3.34) it follows that the area between C_{k_2+1} and C_{k_1+1} is at least $\frac{\eta_1\gamma_0^2}{16} > \frac{\eta_1\gamma_0^2}{64}$, so that this lower bound holds no matter which side of C_{k_2+1} the point p' lies on. But then $\frac{(T'-1)\eta_1\gamma_0^2}{64} \leq \mu(X) \leq 200$, so that $T' \leq \frac{12800}{\gamma_0^2\eta_1} + 1$. This in turn means that $T \leq \frac{30000}{\gamma_0^2\eta_1} < \frac{H_0}{10}$ (since γ_0 and η_1 are both in $(0,1)$).

Possibility (B) is handled in a similar manner. Say $k_1 < k_2$ are two values of t for which we are in Case (ii) but not in Case (iii) when passing from C_t to C_{t+1}. From the construction of C_{k_1+1} we have that $U = \min_{D_0}(A_{l(k_1)} \cup A_{r(k_1)}) = u_1u_2$ is a subarc of a nonmonotone extended i-characteristic W which has another subarc S which is also an elementary i-characteristic for which $S \preceq U$ and $A_{l(k_1)} \preceq S$. It follows in addition from that construction that S precedes $C_{k_1+1} \preceq U$, so that in particular S precedes A_k for all $k \geq l(k_1)+1$. There is an elementary j-characteristic S' which joins u_1 to a point $u' \in [u_1, u_2]$. It follows immediately from (4.7) and (4.4) that $|u_2 - u_1| \geq \frac{\gamma_0}{4}$. We claim that $S' \cap D_0 \cap C_{k_2+1} = \emptyset$. To see this, assume to the contrary that $z \in S' \cap D_0 \cap C_{k_2+1}$. It then follows from (4.4) and (4.6) that $|u' - u_1| \geq \frac{9\gamma_0}{10H_0}(\frac{2}{3}) > \frac{\gamma_0}{2H_0}$, so that by Proposition 3.33, B would have an ESF-i arc of diameter a least ϵ_0 in contradiction to our underlying assumption (4.2). Now we apply the trapped area bound to the i-characteristic subdomain (D_1, C_{k_2+1}), where D_1 is bounded by the curve made up of C_{k_2+1} together with $\partial X \backslash (\alpha_1, \alpha_2)$, where $\alpha_1 < \alpha_2$ are the endpoints of C_{k_2+1} (that is, D_1 is the part of X that remains when the part of D_0 on and below C_{k_2+1} is removed). In particular $S' \backslash \{u_1, u'\} \subset D_1$ and $U \in \mathcal{I}(D_1)$. It is also clear from (4.7) and (4.4) that (4.9) holds for α and β in $\text{bot}(D_1)$ on opposite sides of C_{k_1+1}. For the same reason that $S' \cap D_0 \cap C_{k_2+1} = \emptyset$, we have that u' must lie between u and α_1 with respect to the order on $\text{bot}(D_0)$. This means that both endpoints of S' are in B, so that we clearly have $\Delta\theta(S') \geq \frac{\pi}{4}$. It also means that with respect to the order on $\text{bot}(D_1)$, u_1 lies between u' and u_2. We can now apply the trapped area proposition (with (D_1, C_{k_2+1}) playing the role of (D, V)) to deduce that the area between U and C_{k_2+1} is bounded below by $\frac{\eta_1\gamma_0^2}{16}$, so that this same lower bound holds for the area between C_{k_1} and C_{k_2+1}. If the values of t in question are $t_1 < t_2 < \cdots < t_{T'}$, and if R_k is the region between C_{t_k} and $C_{t_{k+1}+1}$, then $R_1, R_3, \ldots$

are disjoint, so that

$$\left(\frac{T'-2}{2}\right)\frac{\eta_1\gamma_0^2}{16} \le \mu(X) \le 200,$$

and therefore $T' \le \frac{6400}{\gamma_0^2\eta_1} + 2$. Thus, as in the case that (A) holds, we again have $T < \frac{H_0}{10}$. This concludes the proof of Step 2.

Step 3. Now we work with the $J = pq \subset I$, with $|q-p| \ge \frac{1}{40}$, whose endpoints are joined by a $C = pq \in \mathcal{I}(D_0)$. Clearly, there are two points $a_1, a_2 \in J$ such that if we consider $X_k = \Sigma(a_k, \frac{1}{10^6})$, $k = 1, 2$, where the Σ (as defined in the third paragraph of this section) are with respect to the normalized domain X with which we are now working, then

$10^6(X_k - a_k)$ is a normalized domain, $k = 1, 2$,
$\operatorname{dist}(X_k, \{p, q\}\} \ge \frac{1}{500}$, $k = 1, 2$,
$\operatorname{dist}(X_1, X_2) \ge \frac{1}{500}$, and
the bottoms of X_1 and X_2 are in J.

By what we have shown it then follows that either the bottom one of X_1 or X_2 has an ESF-i of length $\frac{\epsilon_0}{10^6}$, in which case we have reached the desired conclusion, or for both $k = 1$ and $k = 2$ the bottom of X_k has a subarc p_kq_k, with

$$|q_k - p_k| \ge \frac{1}{4 \cdot 10^7} \tag{4.10}$$

whose endpoints are joined by an elementary i-characteristic C_k. In this latter case, since C joins the endpoints of J, $C_k \preceq C$, $k = 1, 2$, we can apply Proposition 3.17 to $\max_{D'}(C_1 \cup C_2)$, where D' is the characteristic subdomain bounded by $C \cup [p, q]$. But in light of the above conditions satisfied by the X_k and (4.10), and since all contact points of $\max_{D'}(C_1 \cup C_2)$ are in J, Proposition 3.33 immediately implies that there is a $\gamma_1 = \gamma_1(K)$ for which J has an ESF-i arc of J of diameter γ_1. Thus we have proved that the bottom of a normalized domain has an ESF-i arc of length $\Delta_0 = \min\{\frac{\epsilon_0}{10^6}, \gamma_1\}$. □

[illegible]. It follows from the opening discussion and the proposition we have just proved that there are $\delta_0 = \delta_0(G)$, $\alpha_0 = \alpha_0(K) \in (0, 1)$ such that any arc B of ∂G of diameter at most δ_0 has an ESF-i subarc B', for which $\operatorname{diam}(B') > \alpha_0 \operatorname{diam}(B)$. It is then clear that there are numbers $\xi_0 = \xi_0(K)$, $\tau_0 = \tau_0(K)$, both in $(0, 1)$, such that every arc B with $\operatorname{diam}(B) \le \delta_0$ has two disjoint subarcs B_1 and B_2 for which

$$(\operatorname{diam}(B_1))^{\tau_0} + (\operatorname{diam}(B_2))^{\tau_0} < \xi_0(\operatorname{diam}(B))^{\tau_0},$$

$$\operatorname{diam}(B_1), \operatorname{diam}(B_2) < (1 - \alpha_0)\operatorname{diam}(B),$$

$$B \backslash (B_1 \cup B_2) \text{ is ESF-}i.$$

Let $\operatorname{diam}(B) \le \delta_0$. We start with two such arcs B_1 and B_2 corresponding to B, then we apply the same fact to each of these to get four arcs of diameter $l_1, \ldots, l_4 < (1-\alpha_0)^2$ for which $\sum l_k^{\tau_0} < \xi_0^2\delta_0^{\tau_0}$, and such that the complement of their union is ESF-i, then we do so again to get eight arcs of length at most $(1-\alpha_0)^3$ for which the corresponding $\sum l_k^{\tau_0}$ is less than $\xi_0^3\delta_0^{\tau_0}$ and for which the complement of their union is ESF-i, and so on. At the nth stage we have 2^n arcs $B_k^{(n)}$ for which $\sum_k (\operatorname{diam}(B_k^{(n)}))^{\tau_0} < \xi_0^n\delta_0^{\tau_0}$, which tends to 0, and for which $B \backslash (\cup_k B_k^{(n)})$ is ESF-i. At this stage the diameter of

the largest of the 2^n arcs is at most $(1-\alpha_0)^n$. But then B is the union of a set of τ_0-dimensional Hausdorff measure 0 and a set that has at most countably many i-singularities. In light of Proposition 3.29 and the fact that there are at most countably many vertices of fans on ∂G (Proposition 3.24) it follows that the set of singularities on B, and therefore the set of singularities on all of ∂G, has Hausdorff dimension at most τ_0. This finishes the proof of the main theorem.

COROLLARY 4.3. [illegible] $\tau = \tau(\Theta) < 1$ [illegible] $G \subset \mathbb{C}$ [illegible] R, Θ [illegible] G [illegible] ∂G [illegible] R [illegible] ff [illegible] τ [illegible]. This is an immediate consequence of the main theorem and Propositions 3.20 and 3.25. □

5. Construction of solutions with singularity sets of positive Hausdorff dimension. Although we have chosen to carry out our construction in $\mathbb{H}$ to avoid cumbersome arguments, suitable, largely straightforward changes will allow an analogous procedure to be carried out in any smoothly bounded domain. Throughout this section Θ will denote any fixed normal system. We begin with a brief discussion of characteristic initial value problems for Θ since our construction largely proceeds by joining together solutions of appropriate instances of such problems in domains sharing a boundary characteristic.

Let C_k be C^∞ curves parameterized by $z_k(s)$, $0 \le s \le l_k$, $k = 1, 2$, for which $z_i(0) = z_j(0)$ and for which $z_i'(0)$ and $z_j'(0)$ are mutually orthogonal. (In fact l_k can be infinite, as is the case, for example, when C_k is a ray.) We want to construct a solution of the normal system Θ for which C_k is an k-characteristic arc, $k = 1, 2$. From the definition of normal system, for any ρ_1 there is a discrete set of values ρ_2 such that $e^{i\theta(\rho_1,\rho_2)}$ and $ie^{i\theta(\rho_1,\rho_2)}$ are tangent at $z_1(0)$ to C_1 and C_2, respectively. Given any such [illegible] $\rho = (\rho_1, \rho_2)$ there are unique continuous functions $R_k(s)$ such that $e^{i\theta(\rho_1,R_2(s))}$ and $ie^{i\theta(R_1(s),\rho_2)}$ are tangent to C_1 and C_2 at the points $z_1(s)$ and $z_2(s)$, respectively. For $t = (t_1, t_2)$ we define

$$\overline{R}(t) = (R_1(t_2), R_2(t_1)), \quad 0 \le t_k \le l_k, \quad k = 1, 2,$$

and

$$\overline{\theta}(t) = \theta(R_1(t_2), R_2(t_1)), \quad 0 \le t_k \le l_k, \quad k = 1, 2.$$

We seek $\zeta : [0, l_1] \times [0, l_2] \to \mathbb{C}$, where $\zeta(t) = \xi(t) + i\eta(t)$, for which $e^{i\overline{\theta}(t)}$ and $ie^{i\overline{\theta}(t)}$ are tangent to the curves $\zeta([0, l_1], t_2)$ and $\zeta(t_1, [0, l_2])$, respectively, at the point $\zeta(t)$ and which satisfies the initial conditions

$$\zeta(t_1, 0) = z_1(t_1) \quad \text{and} \quad \zeta(t_2, 0) = z_2(t_2). \tag{5.1}$$

The tangency condition can be written as the linear hyperbolic system

$$\cos\overline{\theta}\frac{\partial\eta}{\partial t_1} - \sin\overline{\theta}\frac{\partial\xi}{\partial t_1} = 0, \quad \sin\overline{\theta}\frac{\partial\eta}{\partial t_2} + \cos\overline{\theta}\frac{\partial\xi}{\partial t_2} = 0. \tag{5.2}$$

The problem (5.2) with initial conditions (5.1) is well posed and has a C^∞ solution $\overline{\theta}$ for any C^∞ initial curves C_1 and C_2. First consider the case in which the $\zeta(t) = \zeta(C_1, C_2, \rho, t)$ determined in this manner has an everywhere nonzero Jacobian

determinant and is globally one-to-one. We then have a solution to the system Θ in $\zeta([0,l_1]\times[0,l_2])$, which is a characteristic quadrilateral, given by

$$R(\zeta(t)) = \overline{R}(t). \tag{5.3}$$

We refer to this solution as $R(C_1, C_2, \rho, z)$ and to the characteristic quadrilateral in which it is defined as $Q(C_1, C_2, \rho)$. Even if ζ is not one-to-one on $[0,l_1]\times[0,l_2]$, then (5.3) gives a multivalued solution of Θ on any domain $\zeta(E)$, provided that ζ is a local diffeomorphism on E. Let i and j be such that $\arg\{z_j'(0)\} = \arg\{z_i'(0)\} + \frac{\pi}{2}$. It is a well-known property of the characteristic initial value problem for genuinely nonlinear systems that if $\frac{d\arg\{z_i'(t)\}}{dt} \le 0$ on $[0,l_i]$ and $\frac{d\arg\{z_j'(s)\}}{ds} \ge 0$ on $[0,l_j]$, then ζ will be locally diffeomorphic on $[0,l_1]\times[0,l_2]$. This is simply a reflection of the fact that, in light of the quasi-HP nature of the the associated inclination function and the length monotonicity property (Proposition 2.7), under these hypotheses the curvature of j-characteristics will not blow up as one moves along i-characteristics away from the convex side of a j-characteristic C, and analogously when the roles of i and j are interchanged. We note that this property holds in the particular case in which one of the initial characteristics is a line segment or ray. We also note that it holds even if one or both of the initial curves is not a simple arc, so that ζ will be a local homeomorphism if, for example, one of these curves is a circle covered several times.

We next need to discuss briefly the smooth adjunction of line segments and circles to C^∞ curves in a specific, constructive fashion; this is another essential element of the construction process. Let C be a C^∞ curve parameterized by $Z(s)$, $0 \le s \le l+\delta$. We want to perform the adjunction with no change in Z on $[0,l]$. Let κ_0 be any number. It is clear that there is an operator $F(Z,l,\delta,\kappa_0,\tau)$ such that $w = F(Z,l,\delta,\kappa_0,\tau) \in C^\infty([0,\infty))$ has the following properties:

(i) $w(s) = Z(s)$, $0 \le s \le l$.

(ii) If $w'(s) = e^{i\phi(s)}$, then $\phi(s) = (s-l-\delta)\kappa_0 + \tau$, $s \ge l+\delta$.

It is clear how this can be done. Indeed, if $Z'(s) = e^{i\alpha(s)}$ on $[0,l+\delta]$, we let $\beta(s)$ be the continuous function which coincides with $\alpha(s)$ on $[0,l+\delta/3]$, which is given by $(s-l-\delta)\kappa_0 + \tau$ for $s \ge l + 2\delta/3$ and is linear on $[l+\delta/3, l+2\delta/3]$. We let σ be a specific nonnegative C^∞ function on $\mathbb{R}$ with support in $(-1,1)$ and $\int_{-\infty}^{\infty}\sigma(s)ds = 1$ and then convolve $\beta(s)$ with $\frac{10}{\delta}\sigma(\frac{10s}{\delta})$. The desired $w = F(Z,l,\delta,\kappa_0,\tau)$ is defined by with $w'(s) = e^{i\beta(s)}$, $w(0) = Z(0)$. We note that if C is convex to the right (left) and κ_0, $\tau - \kappa_0\delta/3 - \alpha(l+\delta/3) \ge 0$ (≤ 0), then the curve given by $F(Z,l,\delta,\kappa_0,\tau)$ is concave towards the same side as C.

We now introduce notation and terminology to be used in our construction. We denote by $\mathcal{CL}$ the family of C^∞ arcs with initial and terminal straight subarcs. Let $\mathcal{S}(\epsilon)$ denote the class of C^∞ curves parameterized by $z = z(s)$, $0 \le s \le L$, with the following properties:

(i) $\Im\{z(0)\} = \Im\{z(L)\} = -\epsilon$.

(ii) $\arg\{z'(0)\} = \frac{\pi}{2} + \epsilon$ and $\arg\{z'(L)\} = -(\frac{\pi}{2} + \epsilon)$.

(iii) $\frac{d\arg\{z'(s)\}}{ds} \le 0$, $0 \le s \le L$.

(iv) $C \subset N(\partial N(0,1)\cap\mathbb{H}, 2\epsilon)$.

(v) $C \in \mathcal{CL}$.

For $t > 0$ and $\alpha \in \mathbb{R}$ we denote $\{tS + \alpha : S \in \mathcal{S}(\epsilon)\}$ by $\mathcal{S}(\epsilon, t, \alpha)$. If C is any arc joining $a < b$ in $\overline{\mathbb{H}}$, $B(C)$ will denote the set whose boundary is $C \cup [a,b]$. For two such arcs C_1, C_2 with $C_1 \subset B(C_2)$ we denote the closure of $B(C_2)\backslash B(C_1)$ by

$E(C_1, C_2)$. In what follows we will often deal with a C^∞ solution R defined only in a neighborhood in $B(C)$ of C, where C is an i-arc of R (by which we mean that R can be extended to a C^∞ solution in a two-sided neighborhood of C and that C is an i-arc of this extension). In this case we shall call C a [illegible] of R. An i-characteristic C of a solution R will be said to satisfy the [illegible] (OSC) if the j-characteristics passing through each point $c \in C$ all contain a straight line subarc containing c in its interior; obviously, it is enough for a single point $c \in C$ to have this property for the OSC to hold. We extend the use of the term OSC in the obvious manner to apply to one-sided characteristics. If D is a domain separated into two subdomains D_1 and D_2 by an arc C, and $R^{(1)}$ and $R^{(2)}$ are C^∞ solutions in these domains, respectively, for which C is a one-sided i-characteristic satisfying the OSC, then together $R^{(1)}$ and $R^{(2)}$ give a C^∞ solution in all of D. Our construction uses this simple fact, which allows for the smooth pasting together of solutions of characteristic initial value problems in contiguous domains.

Next we discuss a specific class of characteristic initial value problems in which one of the initial characteristics is a ray. Let C be parameterized by $z(s)$ satisfying

$$D \arg\{z'(s)\} \leq 0, \quad 0 \leq s \leq L, \quad \text{with } \Im\{z(0)\}, \quad \Im\{z(L)\} < 0, \tag{5.4}$$

and

$$\arg\{z'(0)\} \geq \frac{\pi}{2} + \epsilon \quad \text{and} \quad \arg\{z'(L)\} \leq -\left(\frac{\pi}{2} + \epsilon\right), \tag{5.5}$$

and consider the solution of the initial characteristic value problem where $C_i = C$ and C_j is a ray orthogonal to C at $z(0)$ and emanating to the left of C. Then the j-characteristics of any corresponding solution are all rays orthogonal to C_i and the i-characteristics are the orthogonal trajectories of this family of rays, and in fact are the curves $C(r)$, $r > 0$, parameterized by $z(t)+rz'(t)i$, $0 \leq t \leq L$. As r tends to ∞ the $C(r)$ tend to arcs of a circle of radius r and radian measure $\arg\{z'(0)\} - \arg\{z'(L)\}$.

We next construct two special C^∞ arcs U_i, where it is understood that the ϵ referred to below is some sufficiently small positive number. The arc U_1, parameterized by $u_1(s)$, $0 \leq s \leq \lambda_1$ will have the following properties:

(i) $D \arg\{u_1'(s)\} \leq 0$, $0 \leq s \leq \lambda_1$.
(ii) $\Im\{u_1(0)\} = -\epsilon$ and $u_1(\lambda_1) \in \mathbb{R}$.
(iii) $U_1 \in \mathcal{CL}$.
(iv) $u_1'(0) = e^{i(\frac{\pi}{2}+\epsilon)}$.
(v) $u_1'(s) = e^{-i\pi/4}$, $\lambda_1 - d \leq s \leq \lambda_1$ for some $d > 0$.
(vi) $U_1 \cap N(0, 2) = \emptyset$.

(vii) Let any C' be any curve in $\mathcal{S}(\epsilon)$, and let $\alpha = \alpha(C)$ be such that the initial point of $C = C' + \alpha \in \mathcal{S}(\epsilon, 1, \alpha)$ is $p = -1 - \epsilon i$. Let $\rho \in \mathbb{R}^2$ be such that $ie^{i\theta(\rho)}$ is tangent to C at its left endpoint p. Then there is a solution to the system Θ in $E(C) = E(C \cap \mathbb{H}, U_1 \cap \mathbb{H})$ for which $R(p) = \rho$, for which C is a 2-characteristic and U_1 is an 1-characteristic, and for which both C and U_1 satisfy the OSC.

We stress that the idea is that for the appropriate translate C of [illegible] $C' \in \mathcal{S}(\epsilon)$ and any admissible value ρ of R at the initial point (i.e., left endpoint) c_l of C we have a solution in the domain $E(C \cap \mathbb{H}, U_1 \cap \mathbb{H})$. If we can construct such a curve, it is obvious that it will have a right-hand counterpart U_2, having properties corresponding to (i)–(vii). In regard to ( ), U_2 will terminate in a line segment of slope $\frac{\pi}{4}$ at its left end. In regard to (vii), U_2 and C will be 2- and 1-characteristics, respectively, and the initial value ρ will be the value of R at the [illegible] endpoint of C, which in any

case determines its value at the right endpoint of C since the total curvature of C is exactly $\pi + 2\epsilon$. For lack of a better term we shall refer to U_1 and U_2 as [illegible] for the system Θ. It is clear that translates $U_i + \alpha$, $\alpha \in \mathbb{R}$ of U_i have an analogous universal property.

We show that such a U_1 exists, the existence of U_2 being identical apart from trivial details. Let $A \leq |\frac{\partial\theta}{\partial R_k}| \leq B$ on $\mathbb{R}^2$ (as in the definition of normal system), so that the net of characteristics of any solution of the system Θ in a domain G is a K-quasi-HP net on G with $K = \frac{B}{A}$. Let W be any C^∞ arc parameterized by $w(s)$, $0 \leq s \leq L$, for which $D\arg\{w'(s)\} \leq 0$ and which has total curvature $-\Delta < 0$. Let $V \in \mathcal{CL}$ be parameterized by $v(s)$, $0 \leq s \leq 1$, with $v(0) = w(0)$, $v'(0) = iw'(0)$, for which $0 \geq D\arg\{v'(s)\} \geq -\delta$. One easily show that for any admissible corner value ρ the characteristic coordinate mapping $\zeta(V, W, \rho, t)$ is a local diffeomorphism on all of the corresponding characteristic coordinate rectangles $S = [0,1] \times [0, L]$ for all such W, provided that $\delta K(L + K\Delta) < 1$. To do so, one simply subdivides S into small subrectangles and solves the corresponding initial value problem piece by piece, the key point being that the length change estimate (Proposition 2.5) implies that no blow-up will occur (that is, the Jacobian determinant will never vanish). Indeed, in light of the convexity of W the lengths of its translates increase, while in light of the concavity of V the lengths of its translates decrease. The characteristic length bound as applied to the translates of W shows that they all have length at most $L + K\Delta$, so that by the characteristic length bound the lengths of the translates of V will remain bounded away from 0 if $\delta K(L + K\Delta) < 1$. We start with $W = W_0$, $V = V_0$ and inductively define ρ_{k+1} to be the value of $R(V_k, W_k, \rho_k, \zeta(V_k, W_k, \rho_k, (1, 0)))$, that is, the value of $R(V_k, W_k, \rho_k, p)$, where p is the the final endpoint of V_k, and we define W_{k+1} to be the final translate of W_k along V_k to the end of V_k, that is, $W_{k+1} = \zeta(V_k, W_k, \rho_k, (1, [0, L_k]))$, where $L_k = \lambda(W_k)$. By the foregoing $L_{k+1} \leq L_k + K\Delta$, and the total curvature of V_k can be any $-\delta_k$, for which $0 \leq \delta_k \leq \frac{1}{2K(L_k + K\Delta)}$. We obviously have $L_k \leq L_0 + kK\Delta$, so that the only restriction on δ_k is $0 \leq \delta_k \leq \frac{1}{2K(L_0 + (k+1)K\Delta)}$, this upper bound obviously being the general term of a divergent series for $\Delta > 0$. Let $\epsilon = \frac{1}{100}$, so that if $W_0 = C$, where C is the appropriate translate of any element of $\mathcal{S}(\epsilon)$ as indicated in (vii), then $\pi - \frac{1}{10} \leq \lambda(W_0) \leq \pi + \frac{1}{10}$ and $\Delta = \pi + \epsilon$. Clearly, there is some positive integer M such that for some sufficiently small $\eta \in (0, \frac{\pi}{4})$ there is a curve V, the union of $V_0, \ldots, V_M$, parameterized by $v(s)$, $0 \leq s \leq M$, such that V terminates in a straight line segment whose initial point is in $\mathbb{H}$ and whose slope is $-\tan\eta$. We note that by reducing the size of ϵ if necessary, we can assume that the first subarc V_0 of $V \subset V^1$ intersects $\mathbb{R}$ at a point $v_0(s)$ for which $\arg\{v_1'(s)\} \in (-\pi, -\pi + \delta_0) \subset (-\pi, -\frac{3\pi}{4})$. In addition, we can allow the length of the final straight segment of V to be as large as we want, so that we can take the imaginary part of the terminal point of V to be $-\epsilon$. We emphasize that V is independent of W_0. We next extend V at its right end by smoothly adjoining a ray with slope exactly $-\frac{\pi}{4}$ (by means of $F(v, \lambda(V) - \frac{\epsilon}{2}, \frac{\epsilon}{2}, 0, -\frac{\pi}{4})$, as described above, where $v(s)$ parameterizes V); this extended curve will be called V^1. We now consider the characteristic initial value problem with V^1 as the 1-arc and, as the 2-arc, a segment A of length r orthogonal to it at its initial point and emanating to the left of V^1. Because V^1 satisfies the OSC, the solution so generated will be C^∞ in the domain made up of $E(C \cap \mathbb{H}, V^1 \cap \mathbb{H})$ together with translates of A around V^1. Note that the corresponding solution is constant in the quarter-plane made up of all the translates of A emanating from points on the ray in which V^1 ends. From this it is clear that for $r = \lambda(A)$ sufficiently large, an appropriate subarc of the translate $V^1(r)$

of V^1 to the outer endpoint of A has properties (i), (v), (vi), and (vii). Properties (ii), (iii), and (iv) can be achieved in the following manner. First, we take r so large that at the left intersection point of $V^1(r)$ with $\mathbb{R}$ the angle formed by $V^1(r)$ is within $\frac{\epsilon}{4}$ of $\frac{\pi}{2}$. Then we remove the arc of $V^1(r)$ joining its initial point to a point with imaginary part between $-\frac{\epsilon}{2}$ and 0 and at which the direction of the tangent vector is within $\frac{\epsilon}{2}$ of $\frac{\pi}{2}$. Finally, we can use the operator F to smoothly adjoin an arc to the remaining part of $V^1(r)$ in such a way that (ii), (iii), and (iv) hold. The resulting curve is our U_1. Note that in (vii) we do not require the solution to bear any particular relation to the part of U_1 that lies in the lower half-plane.

The left and right endpoints of U_1 will be called e_1 and m_1; the left and right endpoints of U_2 will be called m_2 and e_2 (m for middle and e for end, for reasons to be made clear momentarily). It is clear that U_1 depends solely on Θ and the parameter ϵ and that once these have been fixed, the solution R generated in $E(C)$ depends on C but that its values on U_1 depend only on $\rho = R(c_l)$, c_l being the left endpoint of C; analogous statements hold for U_2. For $\rho \in \mathbb{R}^2$ we denote by $f_k(\rho)$ the value of this solution R at m_k. We also observe that in the case of U_1 we always have

$$\theta(f_1(\rho)) - \theta(\rho) = \theta(m_1) - \theta(c_l) = -\left(\frac{5\pi}{4} + \epsilon\right). \tag{5.6}$$

As indicated above, in the case of U_2 we still take as ρ the value of R at the left endpoint c_l of the initial curve C used in the above construction which, as we have pointed out, uniquely determines the value of R at the right endpoint of C since the total curvature of all arcs in the family $\mathcal{S}(\epsilon)$ is $\pi + 2\epsilon$. Here we have that

$$\theta(f_2(\rho)) - \theta(\rho) = \theta(m_2) - \theta(c_l) = -(\pi + 2\epsilon) + \left(\frac{5\pi}{4} + \epsilon\right) = \frac{\pi}{4} - \epsilon. \tag{5.7}$$

The f_k are continuous functions of ρ and there is a number B_0 (that depends only on the bounds on the $\frac{\partial\theta}{\partial R_k}$ associated with Θ) such that

$$\|f_k(\rho) - \rho\| \le B_0, \quad \rho \in \mathbb{R}^2, \quad k = 1, 2, \tag{5.8}$$

where the norm is just the Euclidean norm in $\mathbb{R}^2$ (actually, any norm will do). Both the continuity and the bound come from the simple observation that on any i-characteristic, R_i is constant and R_j is a Lipschitz continuous function of the tangent inclination (with the Lipschitz constant depending solely on the system Θ).

For our next step we consider translates $U_1' = U_1 - m_1$ and $U_2' = U_2 - m_2$ which have the common point 0. Note that U_1' and U_2' are orthogonal to each other at 0 and so can be used as initial curves for a characteristic initial value problem, U_k' being a k-arc. For ϵ sufficiently small (so that U_1 and U_2 are virtually orthogonal to the horizontal line $\Im\{z\} = -\epsilon$ at e_1 and e_2, respectively) convexity considerations easily show that for any admissible corner value $\rho = R(0)$ the mapping $\zeta(U_1', U_2', \rho, t)$ is one-to-one on the corresponding characteristic coordinate rectangle. To see that this is indeed the case, note that since the change in θ from the left end of U_1' to the right end of U_2' is $-(\frac{3\pi}{2} + 2\epsilon)$ (that is, the change in θ along U_1' + the change in θ along U_2', both from left to right, is $-(\frac{3\pi}{2} + 2\epsilon)$), the total change along the top two sides of the characteristic quadrilateral is also $-(\frac{3\pi}{2} + 2\epsilon)$. The resulting solution $R_\rho(z) = R(U_1', U_2', \rho, z)$ and the quadrilateral $Q_\rho = Q(U_1', U_2', \rho)$ itself depend solely on $\rho = R(0)$. Note also that because U_1', $U_2' \in \mathcal{CL}$, the other two sides of Q_ρ also belong to $\mathcal{CL}$.

Next we next show how we can produce curves $X_k \in \mathcal{S}(\epsilon, t_k, \alpha_k)$, such that $B(X_k \cap \overline{\mathbb{H}}) \supset Q_\rho \cap \mathbb{H}$, and a solution in $B(X_k \cap \overline{\mathbb{H}}) \backslash (Q_\rho \cap \mathbb{H})$ which gives a C^∞ extension of R_ρ for which X_k is a one-sided k-arc which satisfies the OSC. We show how to get X_2, the case of X_1 being identical apart from obvious details.

First, we extend U_2' on the right by continuously adjoining a circle of radius $\frac{\epsilon}{10}$ lying in the open lower half-plane by using $F(\overline{u}_2 - m_2, \lambda(U_2) - \delta, \delta, \frac{10}{\epsilon}, -(\frac{\pi}{2} + \epsilon))$, where $\overline{u}_2$ parameterizes U_2 from left to right (i.e., with $\overline{u}_2(0) = m_2$) and where δ is so small that $\overline{u}_2([\lambda(U_2) - \delta, \lambda(U_2)])$ is a line segment. This in turn allows us to extend the other 2-side of Q_ρ rightwards and eventually downwards (in light of the quasi-HP property) until it gets to a point p for which $\Im\{p\} = -\frac{\epsilon}{2}$; call this extended 2-side T. The corresponding solution is defined in the simply covered domain $E = E(U_1' \cup U_2', T')$, where T' is the subarc of T which joins a point of $\mathbb{R}$ to the left of U_1' to a point of $\mathbb{R}$ to the right of U_2'. This means that if we change T below $\mathbb{R}$ to form a new curve T_2, which we subsequently use as the 2-arc for a characteristic initial value problem with a straight initial 1-arc outside of E, then the solution is compatible with the restriction to E of the solution we have so far. Using an appropriate instance of the operator F, we obtain an extension T_2 of T by smoothly adjoining to T at its right end a segment in such a way that the argument of the tangent at the right endpoint of T_2 is less than or equal to $-(\pi/2 + \epsilon)$. Obviously, $T_2 \in \mathcal{CL}$. It is also clear from the construction that T_2 depends solely on $\rho = R(0)$ and that all derivatives of its arc length parameterization depend continuously on ρ. This outside curve T_2 clearly satisfies the hypotheses (5.4) and (5.5) of the straight line characteristic initial value construction. Using a straight 1-arc of length r_0 we therefore obtain an "almost circular" 2-arc S parallel T_2 which is contained in $N(0, (1 + \epsilon/2)r_0) \backslash (0, (1 - \epsilon/2)r_0)$. Let $q_1 < q_2$ be the points of $S \cap \mathbb{R}$. By choosing r_0 sufficiently large we can be certain that the interior angles of this S at q_1 and q_2 are within $\frac{\epsilon}{2}$ of $\frac{\pi}{2}$. Simple curvature considerations show that there is a single, sufficiently large value of r_0 that works for all admissible corner values $\rho = R(0)$. Let p_1, $p_2 \in T_2$ lie on the straight 1-characteristics which terminate at q_1 and q_2, respectively. It is clear that for the solution our process has generated, $R(p_1)$ and $R(p_2)$ are continuous functions of ρ which, moreover, satisfy bounds of the form (5.8) (with $f_k(\rho)$ replaced by $R(p_k)$ and with an appropriate B_0). The solution is defined and C^∞ in the part of $\mathbb{H}$ between $U_1' \cup U_2'$ and S, and S is a 2-characteristic arc satisfying the OSC. Finally, we smoothly alter S below $\mathbb{R}$ to obtain an S' such that for appropriate $\xi = \xi(\rho)$, the arc $X_2 = \xi S'$ belongs to $\mathcal{S}(\epsilon)$. If x_l is the left endpoint of X_2, then $g_2(\rho) = R(x_l)$ is a continuous function of ρ, and similarly for the value $g_1(\rho)$ of R at the left endpoint of the analogously constructed X_1. Here again one easily sees that in the case of X_2

$$\theta(g_2(\rho)) - \theta(\rho) = \frac{3\pi}{4} + \epsilon - \frac{\pi}{2} = \frac{\pi}{4} + \epsilon \tag{5.9}$$

and in the case of X_1 that

$$\theta(g_1(\rho)) - \theta(\rho) = \frac{3\pi}{4} + \epsilon. \tag{5.10}$$

Let $U = U_1' \cup U_2'$. By the universal property of U_1', for appropriate $t^{(2)}$ and $\alpha^{(2)}$ we can use $t^{(2)}X_2 + \alpha^{(2)}$ as the 2-arc under U_1' (see property (vii) in the discussion of the universal arcs given above), and similarly we can use some $t^{(1)}X_1 + \alpha^{(1)}$ as the 1-arc under U_2. These $t^{(k)}X_k + \alpha^{(k)}$ in turn come from $t^{(k)}U + \alpha^{(k)}$. If we perform the construction of X_k using the value $\rho^{(k)}$ of R at the center $\alpha^{(k)}$ of $t^{(k)}U + \alpha^{(k)}$,

then the value of R at the left endpoint of X_k is $g_k(\rho^{(k)})$, so that the value of the solution R (corresponding to property (vii) of universal arcs) in the part of the $B(U_j')$ between $t^{(i)}U + \alpha^{(i)}$ and U_j' at 0 is $f_j(g_i(\rho^{(i)}))$. We claim that there is a $\rho^{(i)}$ for which $f_j(g_i(\rho^{(i)}))$ is any given admissible corner value ρ_0 for the characteristic initial value problem with 1- and 2-arcs U_1 and U_2. To see that such a $\rho^{(i)}$ exists in the case that $i = 2$, $j = 1$, for example, note that from (5.6) and (5.9) we have that

$$\theta(f_1(g_2(\rho^{(2)}))) - \theta(\rho^{(2)}) = \theta(f_1(g_2(\rho^{(2)}))) - \theta(g_2(\rho^{(2)})) + \theta(g_2(\rho^{(2)})) - \theta(\rho^{(2)})$$

$$= -\left(\frac{5\pi}{4} + \epsilon\right) + \frac{\pi}{4} + \epsilon = -\pi.$$

Thus, given ρ_0, the point $\rho^{(2)}$ must lie on the curve

$$\theta(R) = \theta(\rho_0) + \pi \tag{5.11}$$

in the R-plane. The level curves $\theta(R) = \theta_0$ in the R-plane are the graphs $R_i = h_{i,\theta_0}(R_j)$ of monotone functions, for which h_{i,θ_0}' are uniformly bounded and uniformly bounded away from 0. Thus as $\rho^{(2)}$ moves along the curve (5.11) it follows from the continuity of f_1 and g_2 and the bound (5.8) and the corresponding bound for the g_k that $f_1(g_2(\rho^{(2)}))$ traces out the entire curve $\theta(R) = \theta(\rho_0)$, so that there is indeed a (unique) $\rho^{(1,2)}$ for which $f_1(g_2(\rho^{(2)})) = \rho_0$. The case of $f_2(g_1(\rho^{(1)})) = \rho_0$ is handled in the same manner, using (5.7) and (5.10) instead of (5.6) and (5.9).

It is now clear that we can iterate this construction to produce a solution $R^* = (R_1^*, R_2^*)$ in $B(U_1' \cap \overline{\mathbb{H}}) \cup B(U_2' \cap \overline{\mathbb{H}})$, and, in fact, a solution in all of $\mathbb{H}$, by appropriately extending the solution we have in X_1 (or in X_2, for that matter). More specifically, the solution in $B(U_1' \cap \overline{\mathbb{H}}) \cup B(U_2' \cap \overline{\mathbb{H}})$ is obtained by placing a suitable similar copy of the form $tU + \alpha$ under each of U_k' in the way described and then under each of the corresponding $tU_k' + \alpha$ smaller similar copies of the form $tU + \alpha$ (with a smaller value of t, of course). At the nth stage (where we regard the initial U as corresponding to the 0th stage) we have 2^n disjoint similar copies $U_l^{(n)}$, $1 \le l \le 2^n$, of U. Let $I_l^{(n)}$ be the interval of $\mathbb{R}$ joining the left and right endpoints of $U_l^{(n)} \cap \overline{\mathbb{H}}$. It is an immediate consequence of the shape of the U_k' that (once ϵ has been fixed) there is a constant $\delta_1 = \delta_1(\Theta) > 0$ such that for all points $p \in I_l^{(n)}$

$$\lambda(\theta(R^*(\{z : \delta_1 < \arg\{z - p\} < \pi - \delta_1,\ z \in U_l^{(n)} \cap \mathbb{H}\}))) \ge \delta_1.$$

Since, on U_i', θ and R_j are bi-Lipschitz functions of each other, it follows that there are $r_1 = r_1(\Theta)$, $\delta_2 = \delta_2(\Theta) > 0$ such that for all $p \in I_l^{(n)}$ the range of R_k^* in

$$N(r_1^n, p) \cap \{z : \delta_1 < \arg\{z - p\} < \pi - \delta_1\}$$

is an interval of length at least δ_2, $k = 1, 2$. Let $M^{(n)} = \cup\{I_l^{(n)} : 1 \le l \le 2^n\}$. Then $M = \cap\{M^{(n)} : n \ge 1\}$ consists entirely of boundary singularities of the solution R^* that we have constructed. To those who have read about Cantor sets it is probably obvious that M has positive Hausdorff dimension, but for completeness we include an appropriately modified version of the argument given by Falconer [F] for the classical excluded middle third case.

First of all, it is clear from the self-similar nature of the construction that there is a number $\gamma \in (0, 1)$ such that the minimum distance between the 2^n intervals

making up the set $M^{(n)}$ is bounded below by γ^n. We show that the τ-dimensional Hausdorff measure of M is positive, where τ is defined by

$$\gamma^\tau = \frac{1}{2}.$$

Let $\{G_k\}$ be an open cover of M, which we can assume to be finite since M is compact. Let $\max\{\text{diam}(G_k)\} < 1$. For each k there is a nonnegative integer $l = l(k)$ such that

$$\gamma^{l+1} \le \text{diam}(G_k) < \gamma^l.$$

From the definition of γ it follows that such a G_k can have a nonempty intersection with at most one of the intervals that make up $M^{(l)}$. Consequently, for $p \ge l(k)$ at most $2^{p-l(k)}$ of the intervals making up $M^{(p)}$ can have a nonempty intersection with such a G_k. For each $p \ge l = l(k)$ we therefore have

$$2^{p-l} = \frac{2^p}{2^l} = \frac{2^p(\gamma^{l+1})^\tau}{2^l\gamma^\tau l\gamma^\tau} \le \frac{2^p(\text{diam}(G_k))^\tau}{(2\gamma^\tau)^l\gamma^\tau}.$$

Let p be so large that $\min\{\text{diam}(G_k)\} \ge \gamma^{p+1}$, so that $p \ge l(k)$ for all k. Since there are 2^p intervals in $M^{(p)}$, if we denote by N_k the number of intervals touched by G_k, then

$$2^p \le \sum_k N_k \le \sum_k \frac{2^p(\text{diam}(G_k))^\tau}{(2\gamma^\tau)^{l(k)}\gamma^\tau} = \sum_k \frac{2^p(\text{diam}(G_k))^\tau}{\gamma^\tau},$$

so that

$$\sum_k (\text{diam}(G_k))^\tau \ge \gamma^\tau = \frac{1}{2}.$$

This means that the τ-dimensional Hausdorff measure of M is at least $\frac{1}{2}$, so that M has Hausdorff dimension at least τ.

6. A few concluding remarks. We briefly discuss some of the issues and problems suggested by the foregoing. In the first place, it would be interesting to determine whether Corollary 4.3 is true for genuinely nonlinear systems (see the definitions of the terms "system" and "genuinely nonlinear" between relations (1.4) and (1.5)) which are not necessarily normal. Probably, though, some hypothesis in the spirit of (ii) of Definition 1.1 as well as some bound like

$$\epsilon < |\theta_1(R) - \theta_2(R)| < \pi - \epsilon \quad \text{for all } R \in \mathbb{R}^2$$

is necessary, so that, using the approach of section 5, or otherwise, one might try to construct a solution of a 2×2 genuinely nonlinear hyperbolic system not satisfying one or the other or both of these conditions and which has a set of boundary singularities of Hausdorff dimension 1. In a wider context one can ask if Corollary 4.3 has any counterparts for an appropriate class of sufficiently nonlinear $n \times n$ planar hyperbolic systems. In reference to normal systems, our analysis leaves open the question of whether in a half-plane $\mathbb{H}$, for example, there can be a solution for which the set of boundary singularities of type 1 has positive Hausdorff dimension. Corresponding to such a solution there would have to be set $A \subset \partial G$ of positive Hausdorff dimension such that for each $a \in A$ there is a characteristic C_a exiting at a but for which

hypothesis (3.22) of Proposition 3.31 does not hold. Also open is the question of whether the word "nontangential" is necessary in the conclusion of Main Theorem 2.2.

As we shall show elsewhere, the ideas of section 5 can be used to construct in an arbitrary Jordan domain cps-mappings with arbitrary (distinct) principal stretch factors which have infinitely many isolated singularities, and in fact these singularities can be of spiral type (see [G3] for the classification of isolated singularities of cps-mappings). This raises the question of how such singularities can be distributed, and in this regard we conjecture that there is some absolute constant $\gamma > 1$ such that if $\{a_n\}$ is the sequence of isolated singularities of any cps-mapping in any smoothly bounded Jordan domain for which $\{\text{dist}(a_n, \partial G)\}$ is nonincreasing, then

$$\sum_n \text{dist}(a_n, \partial D)\gamma^n < \infty. \tag{6.1}$$

Note that this was shown with $\gamma = 1$ in [G3, Corollary 4.1]. More generally, there are other 2×2 genuinely nonlinear systems for which there exist corresponding unambiguously defined nets of characteristics which have isolated singularities, and for any such system one could attempt to obtain a classification of such singularities along the lines of [G3] and seek a bound of type (6.1) on their density.

ASYMPTOTIC STABILITY OF ASCENDING SOLITARY MAGMA WAVES*

GIDEON SIMPSON† AND MICHAEL I. WEINSTEIN†

Abstract. Coherent structures, such as solitary waves, appear in many physical problems, including fluid mechanics, optics, quantum physics, and plasma physics. A less studied setting is found in geophysics, where highly viscous fluids couple to evolving material parameters, modeling partially molten rock, magma, in the Earth's interior. Solitary waves are also found here, but the equations lack useful mathematical structures such as an inverse scattering transform or even a variational formulation. A common question in all of these applications is whether or not these structures are stable to perturbation. We prove that the solitary waves in this earth science setting are asymptotically stable and accomplish this without any preexisting Lyapunov stability. This holds true for a family of equations, extending beyond the physical parameter space. Furthermore, this extends existing results on well-posedness to data in a neighborhood of the solitary waves.

Key words. solitary waves, stability, viscously deformable porous media, magma

1. Introduction.

Coherent structures, such as solitary waves, appear in many physical problems, including fluid mechanics, optics, quantum physics, and plasma physics. A less studied setting is found in geophysics, where highly viscous fluids couple to evolving material parameters, modeling partially molten rock, magma, in the Earth's interior. Solitary waves are also found here, but the equations lack the useful structures such as an inverse scattering transform or even a variational formulation.

A important question in all of these applications is whether or not the coherent structures are stable to perturbation. We prove that the solitary waves in this earth science setting are asymptotically stable and accomplish this without any preexisting Lyapunov stability.

1.1. Magma: Porous flow in a viscously deformable media.

Models of magma in the Earth's interior couple Stokes flow of the viscous melt to the slow, creeping deformation of the porous rock. These force-balance equations couple to transport equations for the volume fraction of melt, the *porosity*. Formulations may be found in [5, 20, 35, 36, 41]. Nonlinearity appears in fluxes and through the material properties, the *permeability* and *viscosity* of the porous, deformable rock, which depend nonlinearly on the porosity. Consequently, such models are known, from computations, to feature localization and generate coherent structures; see [1, 2, 3, 15, 35, 36, 41, 42, 43, 44, 51]. The physical assumptions and their implications will be discussed in a forthcoming review article [39].

Under certain assumptions (small fluid fraction, absence of large-scale shear, no melting, etc.), such a system reduces to a single scalar equation for the porosity's

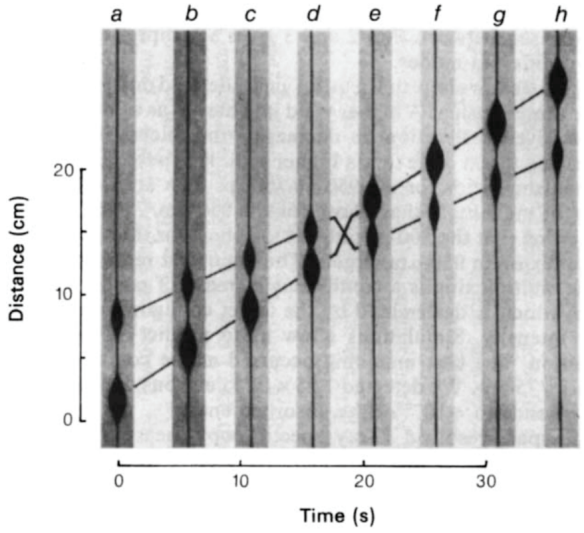

FIG. 1. *Solitary waves colliding and propagating in an experiment with honey. From Figure* 1 *of* [37]. *Reprinted by permission from Macmillan Publishers Ltd.*

evolution [2, 3, 41, 42]. The d-dimensional equation is

$$\partial_t \phi + \partial_z \left(\phi^n\right) - \nabla \cdot \left[\phi^n \nabla \left(\phi^{-m} \partial_t \phi\right)\right] = 0, \quad \mathbf{x} \in \mathbb{R}^d, t > 0, \tag{1.1}$$

with the boundary conditions that $\phi(\mathbf{x}, t) \to 1$ as $|\mathbf{x}| \to \infty$. $\nabla = (\partial_x, \partial_y, \partial_z)$ for $d = 3$ and $\nabla = (\partial_x, \partial_z)$ for $d = 2$. The nonlinearity n comes from the relationship between the permeability, K, and the porosity of the rock, $K \propto \phi^n$. m relates to the bulk viscosity, ζ, to the porosity of the rock, $\zeta \propto \phi^{-m}$. In the physical regime, these exponents have values $2 \leq n \leq 3$ and $0 \leq m \leq 1$ [12, 13, 20, 31, 35, 36, 45, 46, 52].

Equation (1.1) appears elsewhere in earth science as a model for convective mantle plumes. Manifesting themselves as *hot spots* at the surface, these plumes transport warm buoyant material. Examples include the Hawaiian Island chain and Iceland. Modeled as the flow of a viscous fluid up a conduit embedded in a higher viscosity medium, an equation of the form (1.1) was derived in [24]. There, the equation is one-dimensional ($d = 1$), the exponents are $(n, m) = (2, 1)$, and the dependent variable ϕ is the cross-sectional area of the pipe.

Numerical simulations of (1.1) in one, two, and three dimensions were performed in [2, 3, 35, 36, 51], where stable, radially symmetric, *solitary traveling waves* were observed. In [23], it was shown that in one dimension, solitary waves, $U_c(x - ct)$, in excess of the reference state, $\phi \equiv 1$, exist for $n > 1$. In the context of conduit flow, discussed in the preceding paragraph, analogue experiments using viscous syrups appear in [24, 37, 49]; robust solitary waves appeared as predicted; see Figure 1.

1.2. Stability of solitary waves. We consider (1.1) in one dimension,

$$\partial_t \phi + \partial_x \left(\phi^n\right) - \partial_x \left[\phi^n \partial_x \left(\phi^{-m} \partial_t \phi\right)\right] = 0, \quad \lim_{|x| \to \infty} \phi(x, t) = 1, \tag{1.2}$$

where the z coordinate has been relabeled x. A cursory explanation for the solitary waves' stability may be found in [50]. Under a small amplitude scaling, (1.2) is, to leading order, governed by the Korteweg–de Vries (KdV) equation. Since KdV solitons

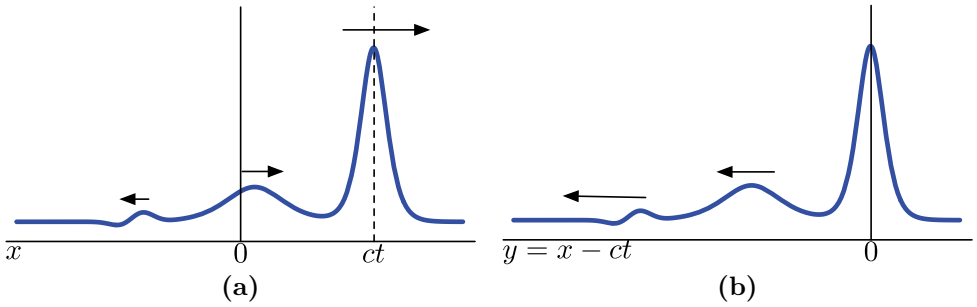

FIG. 2. *The largest solitary wave in* (a) *travels faster than smaller solitary waves and dispersive waves behind it. In the frame of this wave, the rest of the solution appears to move leftward, as in* (b).

are stable, on a timescale for which KdV approximates (1.2) its solitary waves should also be stable.

Based on observations of numerical experiments, we expect a slightly perturbed solitary wave to evolve into another wave with similar amplitude and phase. It will be accompanied by some small amplitude dispersive waves and, perhaps, another solitary wave of smaller amplitude. The leading wave will *outrun* these other disturbances, cease interacting with them, and stabilize.

Some intuition for this stability may be found in two properties. First, taller solitary waves travel with greater speed, c, than smaller ones. In the frame of the largest solitary wave, $y = x - ct$, the other waves travel leftward. Second, in the frame of the leading solitary wave, small perturbations of the reference state, $\phi(x,t) = 1 + \psi(x - ct, t)$ and $|\psi| \ll 1$, evolve under the linear flow

$$\partial_t \psi - c\partial_y \psi + n\partial_y \psi - \partial_y^2 \partial_t \psi + c\partial_y^3 \psi = 0.$$

The dispersion relation and group velocity are

$$\omega(k) = \frac{nk}{1+k^2} - ck, \quad \omega'(k) = n\frac{1-k^2}{(1+k^2)^2} - c.$$

Since the solitary waves of (1.2) that we study travel with speed $c > n > 1$, both phase and group velocities are negative for all k. Therefore, small dispersive waves also travel leftward. These two mechanisms are diagrammed in Figure 2, and we will exploit them to prove the main theorems.

As the system is conservative, perturbations, such as a small solitary wave, will not vanish in a translation invariant norm. A suitable norm will register leftward motion as decay. We will use exponentially weighted norms, in the frame of the leading solitary wave. These norms are defined in section 1.4.

Several paths to proving stability are available. One method is to seek constants of motion that can be combined into a metric centered at the solitary wave. Since the metric is time independent, if the perturbation is initially small, it will remain so. This elegant method relies on the calculus of variations, and for equations such as KdV and nonlinear Schrödinger (NLS) it may be used to prove *orbital stability* [4, 8, 47, 48]. A solitary wave, U_c, is said to be orbitally stable if for data sufficiently close to it

$$\inf_{y\in\mathbb{R}} \|u(t) - U_c(\cdot + y)\|_X < \delta \quad \text{for all } t$$

for some $\delta > 0$ and an appropriate norm $\|\cdot\|_X$. Typically, the norm is equivalent to $L^2(\mathbb{R})$ or $H^1(\mathbb{R})$.

However, in general, (1.2) lacks a sufficient number of conservation laws for this approach. Indeed, in [3], the authors searched for an additional conservation law, in hopes of proving orbital stability [7]. There are many such equations, including some of the Boussinesq systems [29] and many of the "compacton" equations [32], which also lack such structure, yet appear, in numerical experiments, to possess stable solitary waves. Note that when $n + m = 0$, (1.2) is Hamiltonian, and we have investigated this, proving orbital stability in [40]. We wish to consider the general case, which includes the physically interesting cases $(n, m) = (2, 1)$ and $(3, 0)$.

Another approach to stability is to linearize the problem $u_t = N(u, u_x, u_{xx}, \dots)$ about a solitary wave and establish linear stability. Then one seeks a way to perturbatively "boost" this to prove stability for the nonlinear flow. This may rely on direct spectral analysis of the linearized evolution operator. We employ this method, following the work of Pego and Weinstein [28, 29] and Miller and Weinstein [21]. Through this, we prove that the solitary waves are *asymptotically stable*, our main result. By this we mean that in an appropriate norm, $\|\cdot\|_Y$,

$$\|u(t) - U_c\|_Y \to 0 \quad \text{as } t \to +\infty$$

for data sufficiently close to U_c.

We note that another method recently appeared in the work of Martel and Merle [19]. Without linearizing, the authors employ a virial inequality to directly prove asymptotic stability of generalized KdV solitary waves in $H^1_{\text{loc}}(\mathbb{R})$.

Our problem is an example of an equation for which one can prove asymptotic stability in the absence of orbital stability. Upon reflection, it is clear that the asymptotic stability of generalized KdV and Benjamin–Bona–Mahony (BBM) solitary waves could have been proven without using the orbital stability results.

1.3. Main results and outline. The main results are as follows.

THEOREM 1.1. *There exists $c_\star > n$ such that for all $c_0 \in (n, c_\star]$, if $\phi_{c_0}(x - \theta_0)$ is a solitary wave solution of (1.2), then there exist constants $K_* > 0$, $\epsilon_* > 0$, and $a > 0$, such that for $\epsilon \le \epsilon_*$, if*

$$\|v_0\|_{H^1} + \|e^{ax} v_0\|_{H^1} \le \epsilon,$$

then

(a) (1.2) *has a solution with data $\phi_0(x) = \phi_{c_0}(x + \theta_0) + v_0(x)$ for all time;*
(b) *there exist c_∞, θ_∞, K_*, and $\kappa > 0$ such that*

$$\|\phi(\cdot, t) - \phi_{c_\infty}(\cdot - c_\infty t + \theta_\infty)\|_{H^1} \le K_* \epsilon, \tag{1.3}$$

$$\|e^{ax}\left[\phi(\cdot + c_\infty t - \theta_\infty, t) - \phi_{c_\infty}(\cdot)\right]\|_{H^1} \le K_* \epsilon e^{-\kappa t}, \tag{1.4}$$

$$|c_\infty - c_0| + |\theta_\infty - \theta_0| \le K_* \epsilon. \tag{1.5}$$

COROLLARY 1.2. *Let $n + m = 0$. If $\partial_c \mathcal{N}[\phi_c] > 0$, $\mathcal{N}$ defined in (2.8), then Theorem 1.1 holds for all $c > c_\star$, except for a discrete set with no accumulation point.*

Remark 1.3. For general $n > 1$, Theorem 1.1 is limited to $c \le c_\star$ because we are only able to rigorously treat the spectrum of a linear operator perturbatively. This can be extended by a numerical computation of the spectrum. See sections 3.3–3.4.

The feature of (1.2) that allows us to prove nonlinear stability from the linear stability is a nonnegative invariant, denoted $\mathcal{N}[\phi]$, and defined in (2.8). The Taylor expansion of $\mathcal{N}$ about a solitary wave is

$$\mathcal{N}[\phi_c + v] = \mathcal{N}[\phi_c] + \langle \delta\mathcal{N}[\phi_c], v\rangle + \left\langle \delta^2\mathcal{N}[\phi_c]v, v\right\rangle + O\left(\|v\|_{H^1}^3\right).$$

The first variation does not vanish and the second variation is not a positive definite quadratic form. However, in the frame of the solitary wave, the perturbation v is migrating to $-\infty$. Therefore

$$\langle \delta\mathcal{N}[\phi_c], v\rangle \to 0 \quad \text{as } t \to +\infty.$$

The second variation may be decomposed as $\delta^2\mathcal{N}[\phi_c] = P + Q$, P a positive quadratic form and $Q = Q(x)$ a localized function. Then since the perturbation moves leftward

$$\begin{aligned} &\langle Pv, v\rangle \geq \kappa^2 \langle v, v\rangle, \\ &\langle Qv, v\rangle \to 0 \quad \text{as } t \to +\infty. \end{aligned}$$

Asymptotically,

$$\|v\|_{H^1} \leq K\Delta\mathcal{N}, \quad \Delta\mathcal{N} = |\mathcal{N}[\phi_c + v] - \mathcal{N}[\phi_c]|,$$

giving a Lyapunov-type bound on the perturbation. Control of $\Delta\mathcal{N}$ is essential in using this estimate to prove nonlinear stability. Though we rely on the invariance of $\mathcal{N}$, if $\Delta\mathcal{N}$ were merely bounded in terms of the data, it would be sufficient.

However, more is needed to formalize this into a proof, notably a sense in which the perturbation recedes from the solitary wave. This is accomplished by analyzing the spectrum of the linearized evolution operator in a weighted space, in which the perturbation will decay.

The plan of the proof is as follows:

(I) In section 2 we review properties of (1.2) and establish regularity properties of the solitary waves.

(II) In section 3, we prove that the linearized operator, A_a, has the property that there exists $\varepsilon > 0$ such that

$$\sigma(A_a) \cap \{\Re\lambda \geq -\varepsilon\} = \{0\}$$

and zero is an eigenvalue of algebraic multiplicity two.

(III) In section 4, we prove

$$\|w(t)\|_{H^1} = \|e^{A_a t}w_0\|_{H^1} \leq Ke^{-bt}\|w_0\|_{H^1}$$

for appropriate w_0, K, and b positive constants.

(IV) In section 5, we make several estimates, including a formalization of the Lyapunov bound. We also formulate equations for the speed and phase parameters of the solitary wave $(c(t), \theta(t))$, coupling them to the infinite-dimensional system for the perturbation.

(V) In section 6, we prove the main results, asymptotic stability and global existence of data near a solitary wave solution.

Some remarks are made in section 7, and additional details are located in the appendices.

1.4. Notation. Generic constants will typically be denoted by the capital letters K, M, and N, sometimes with tildes, overlines, or primes. Subscripts, such as M_γ, may appear in order to indicate that M depends on γ. We avoid using C as a generic constant, as c appears throughout the paper as the speed parameter, and an operator $C(\lambda)$ appears in section 3.

Functions will typically live in spaces $H^k(\mathbb{R}) = W^{1,k}(\mathbb{R})$, k a nonnegative integer, the spaces of square integrable functions with square integrable (weak) derivatives up to order k. We will frequently omit writing $\mathbb{R}$. The $L^p(\mathbb{R})$ spaces will also appear, in particular L^2 and L^∞. While we write $\|f\|_{H^k}$ for the norm of a function in H^k, we only write $\|f\|_p$ for the norm of a function in L^p.

We will be interested in functions in the exponentially weighted space,

$$H^k_a = \left\{u : e^{ax}u(x) \in H^k\right\}$$

for $k = 0, 1, 2, \ldots$, and $a > 0$ with associated norm

$$\|u\|_{H^k_a} = \|e^{ax}u\|_{H^k}.$$

We also define the norm

$$\|f\|_{H^1 \cap H^1_a} \equiv \|f\|_{H^1} + \|f\|_{H^1_a}.$$

The exponential weight will *always* be a positive number; we will often omit the assumption $a > 0$ in statements.

Frequently, we will have an operator T defined on a weighted space, H^k_a, but wish to make computations in the unweighted space. To T we associate $T_a = e^{ax}Te^{-ax}$, an operator on H^k. For the differentiation operator, $\partial_x \mapsto D_a = \partial_x - a$.

2. Preliminaries.

2.1. Properties of the equation in a weighted space. Much of the analysis involves studying (1.2) in an exponentially weighted space. We therefore state the following extension of the well-posedness results obtained in [38] for H^k spaces.

THEOREM 2.1 (local existence in time and continuous dependence upon data). *Given $0 < a < 1$, let $\phi_0(x)$ satisfy*

$$\|\phi_0 - 1\|_{H^1 \cap H^1_a} \leq R < \infty, \tag{2.1}$$

$$\inf_x \phi_0(x) \geq \alpha_0 > 0, \tag{2.2}$$

$$\inf_x \phi_0(x)^m - a^2\phi_0(x)^n \geq \beta_0 > 0. \tag{2.3}$$

Then there exist $T_{\text{local}} > 0$ and $\phi(x,t) - 1 \in C^1([0, T_{\text{local}}), H^1 \cap H^1_a)$, a solution of (1.2) with data ϕ_0, satisfying

$$\|\phi(\cdot,t) - 1\|_{H^1 \cap H^1_a} \leq 2R, \tag{2.4}$$

$$\inf_x \phi(x,t) \geq \frac{1}{2}\alpha_0, \tag{2.5}$$

$$\inf_x \phi(x,t)^m - a^2\phi(x,t)^n \geq \frac{1}{2}\beta_0 \tag{2.6}$$

for $t < T_{\text{local}}$.

Moreover, there is a maximal time of existence $T_{\max}$*, such that if* $T_{\max} < \infty$*, then*

$$\lim_{t \to T_{\max}} \|\phi(\cdot,t) - 1\|_{H^1 \cap H^1_a} + \left\| \frac{1}{\phi(\cdot,t)} \right\|_\infty + \left\| \frac{1}{\phi(\cdot,t)^m - a^2 \phi(\cdot,t)^n} \right\|_\infty = \infty. \tag{2.7}$$

Remark 2.2. When $a = 0$, (2.3) is unnecessary; this case was treated in [38]. The importance of this condition for $a > 0$ will be discussed in section 2.3.

THEOREM 2.3. *Given* $0 < a < 1$*, let* $\phi^{(j)} - 1 \in C^1([0,T]; H^1 \cap H^1_a)$*,* $j = 1, 2$*, be two solutions of* (1.2) *such that*

$$\|\phi^{(j)}(\cdot,t) - 1\|_{H^1 \cap H^1_a} \le R < \infty,$$
$$\inf_x \phi^{(j)}(x,t) \ge \alpha_0 > 0,$$
$$\inf_x (\phi(x,t)^{(j)})^m - a^2 (\phi(x,t)^{(j)})^n \ge \beta_0 > 0.$$

There exists a constant $K = K(R, \alpha_0, \beta_0, a)$*, such that*

$$\|\phi^{(1)}(\cdot,t) - \phi^{(2)}(\cdot,t)\|_{H^1 \cap H^1_a} \le e^{Kt} \|\phi_0^{(1)} - \phi_0^{(2)}\|_{H^1 \cap H^1_a} \quad \text{for } t \le T.$$

Additionally, (1.2) possesses the conservation law

$$\mathcal{N}[\phi] = \begin{cases} \int \left(\frac{1}{2} \phi^{-2m} \phi_x^2 + \phi \log(\phi) - \phi + 1 \right) dx & \text{if } n + m = 1, \\ \int \left(\frac{1}{2} \phi^{-2m} \phi_x^2 + \phi - 1 - \log(\phi) \right) dx & \text{if } n + m = 2, \\ \int \left(\frac{1}{2} \phi^{-2m} \phi_x^2 + \frac{\phi^{2-n-m} - 1 + (n+m-2)(\phi - 1)}{(n+m-1)(n+m-2)} \right) dx & \text{for all other } n \text{ and } m. \end{cases} \tag{2.8}$$

$\mathcal{N}$ is well defined for ϕ bounded from below away from zero and $\|\phi - 1\|_{H^1} < \infty$. It is also locally convex about $\phi \equiv 1$. See section 3 of [38] for details.

Remark 2.4. The physical significance of $\mathcal{N}$ remains elusive. In the Hamiltonian case, $n + m = 0$, $\mathcal{N}$ revealed itself to be the generalized momentum of the equation [40].

2.2. Solitary waves and their analytic properties. Let us review the properties of the solitary waves associated with (1.2). In particular, we identify their decay and regularity properties and introduce the KdV scaling for later use.

Substituting the traveling wave ansatz, $\phi_c(x,t) = \phi_c(x - ct)$, into (1.2) with boundary conditions

$$\lim_{y \to \pm\infty} \phi_c(y) = 1, \quad \lim_{y \to \pm\infty} \partial_y^j \phi_c(y) = 0 \quad \text{for } j = 1, 2, \ldots \tag{2.9}$$

we have, after one integration,

$$-c(\phi_c - 1) + \phi_c^n - 1 + c\phi_c^n \partial_y \left(\phi_c^{-m} \partial_y \phi_c \right) = 0. \tag{2.10}$$

Letting $u_c = 1 - \phi_c$, u_c satisfies

$$-cu_c + (u_c + 1)^n - 1 + c(u_c + 1)^n \partial_y \left((u_c + 1)^{-m} \partial_y u_c \right) = 0. \tag{2.11}$$

Equation (2.10) may also be integrated up to a first order equation,

$$\frac{1}{2} \phi_c^{-2m} (\partial_x \phi_c)^2 - F_1(\phi_c; c) = 0, \tag{2.12}$$

after applying the boundary condition $\phi_c \to 1$ at $\pm\infty$. F_1 depends on the particular exponents:

$$F_1(x;c) = \begin{cases} \frac{x^{1-n}-1}{1-n} + \left(1-\frac{1}{c}\right)\frac{x^{-n}-1}{n} - \frac{1}{c}\log(x) & \text{if } m=1, \\ x-1-\left(1-\frac{1}{c}\right)\log(x) - \frac{1}{c}\frac{x^n-1}{c} & \text{if } n+m=1, \\ \log(x) + \left(1-\frac{1}{c}\right)\left(\frac{1}{x}-1\right) - \frac{1}{c}\frac{x^{n-1}-1}{n-1} & \text{if } n+m=2, \\ \frac{x^{2-n-m}-1}{2-n-m} - \left(1-\frac{1}{c}\right)\frac{x^{1-n-m}-1}{1-n-m} - \frac{1}{c}\frac{x^{1-m}-1}{1-m} & \text{otherwise.} \end{cases} \tag{2.13}$$

Using (2.12), an equivalent second order, self-adjoint equation for the solitary waves is

$$F_2(\phi_c;c) = -\partial_x^2\phi_c, \tag{2.14}$$

$$F_2(x;c) = x^{m-n}\left[-(x-1) + c^{-1}(x^n-1) - 2mx^{n-m-1}F_1(x;c)\right]. \tag{2.15}$$

Let us introduce the KdV scaling. Define

$$\boxed{\gamma = \sqrt{\frac{c-n}{c}}.} \tag{2.16}$$

Applying the scalings,

$$\xi = \gamma(x-ct), \quad u_c(y) = \frac{\gamma^2}{n-1}U(\xi(y);\gamma), \tag{2.17}$$

(2.11) becomes

$$-U + \frac{1}{2}U^2 + \partial_\xi^2 U = O(\gamma^2). \tag{2.18}$$

Remark 2.5. The parameter γ, (2.16), will be used throughout the paper. Because it uniquely maps $c \in (n,\infty)$ onto $(0,1)$, we will use c and γ interchangeably.

We summarize what is known about (2.11) and (2.18) in the following two results.

THEOREM 2.6. *For any $c > n > 1$, (2.11) has a unique positive, even solution u_c, going to zero at $\pm\infty$. In the KdV scaling, (2.18), U is real analytic in the arguments $(\xi,\gamma) \in \mathbb{R}\times[0,1)$. When $\gamma = 0$*

$$U(\xi;0) = U_\star(\xi) = 3\mathrm{sech}^2\left(\frac{1}{2}\xi\right).$$

Furthermore, for γ in any compact subset of $[0,1)$

$$\partial_\xi^j U(\xi;\gamma)e^{\pm\xi}(\mathrm{sign}(\xi))^j \to K_j(\gamma) \quad \text{as } \xi \to \pm\infty \text{ for } j = 0,1,2.$$

COROLLARY 2.7. *Given a compact interval $[0,\gamma_0] \subset [0,1)$, there exists a constant K such that for all $\gamma \in [0,\gamma_0]$,*

$$|\partial_\xi^j U(\xi;\gamma)| \le Ke^{-|\xi|} \quad \text{for } j = 0,1,2,\ -\infty < \xi < \infty, \tag{2.19}$$

$$|\partial_y^j u_c(y)| \le K\frac{\gamma^{2+j}}{n-1}e^{-\gamma|y|} \quad \text{for } j = 0,1,2,\ -\infty < y < \infty. \tag{2.20}$$

Proof. From [23], solitary waves exist, provided $c > n > 1$ and $m \in \mathbb{R}$. Writing the problem as a two-dimensional dynamical system, we may apply the stable manifold theorem about the hyperbolic point $(0,0)$ to deduce the exponential decay, as in [29, Theorem 2.1, Corollary 2.2]. ∎

Remark 2.8. When the parameter γ is small, ϕ_c is in the regime of small amplitude, long waves, where KdV appears as the leading order equation in a perturbation expansion of (1.2), as in [50].

COROLLARY 2.9. *For each $c > n > 1$, the solitary wave solution, $\phi_c - 1$, lies in $H^\infty(\mathbb{R})$. Furthermore, there exists $\sigma_0 > 0$ such that the solitary wave ϕ_c may be analytically continued off the real axis into the strip $\{z : |\Im z| < \sigma_0\}$.*

Proof. This is a consequence of Corollary 2.7 and [9, Corollary 4.1.6]; see Appendix A.1. ∎

COROLLARY 2.10. *Given a solitary wave ϕ_c, $c > n$, assume $0 < a < \gamma$. Then $\phi_c - 1 \in H^\infty_a$.*

COROLLARY 2.11. *Let $n > 1$.*

(a) *The mapping $c \mapsto \phi_c - 1$ is $C^1\left((n,\infty); H^2\right)$. In fact the mapping is analytic.*
(b) *The mapping $c \mapsto \phi_c - 1$ is analytic, and, for fixed x, $c \mapsto \phi_c(x)$ is an analytic function of c.*
(c) *Given $a < \frac{1}{2}$, the mapping is also $C^1\left(\left(n/(1-4a^2),\infty\right); H^2 \cap H^2_a\right)$.*

Proof. All parts are proved using the implicit function theorem, applied to the functional

$$\mathcal{F}[c,u] = \partial_x^2 u + F_2(1+u;c).$$

See Appendix A.2 for details and [6] for a statement and proof of the implicit function theorem for analytic mappings. ∎

2.3. Remarks and assumptions on the exponential weight. We see in Theorem 2.1 and Corollary 2.11 that the particular exponential weight restricts what data and which solitary waves will be permissible. For the solitary wave result, this restriction comes from the decay rate associated with the speed; see Corollary 2.7.

In the case of the existence theorem, (1.2) may be written as

$$\begin{aligned}\partial_t \phi &= -\left\{I - \partial_x\left[\phi^n \partial_x\left(\phi^{-m}\cdot\right)\right]\right\}^{-1} \partial_x\left(\phi^n\right)\\ &= -\phi^m\left\{\phi^{-m}\left[I - \partial_x\left(\phi^n\partial_x\left(\phi^{-m}\cdot\right)\right)\right]^{-1}\right\}\partial_x\left(\phi^n\right)\\ &= -\phi^m H_\phi^{-1}\partial_x(\phi^n).\end{aligned} \tag{2.21}$$

The operator H_ϕ is

$$H_\phi = \phi(x)^m - \partial_x\left(\phi(x)^n\partial_x\cdot\right). \tag{2.22}$$

This is a bounded operator on $L^2 \to H^1$, provided ϕ is continuous and bounded from below away from zero. However, the exponential weight introduces a second constraint. Consider solving $H_\phi u = f$, $f \in L^2_a$, for $u \in H^1_a$. Letting $g = e^{ax}f$ and $v = e^{ax}u$, this is equivalent to solving

$$\left[\phi^m - D_a\left(\phi^n D_a\right)\right] v = g, \quad v \in H^1.$$

Multiplying by v and integrating by parts,

$$\int \left(\phi^m - a^2\phi^n\right) v^2 + \phi^n\left(\partial_x v\right)^2 dx = \int gv dx.$$

A unique solution exists, provided a and ϕ satisfy $\inf_x \phi(x)^m - a^2\phi(x)^n > 0$; this is condition (2.3).

We invert these restrictions; given a solitary wave of speed c, we will assume that a is sufficiently small so that these, and other, properties hold. There are three restrictions in what follows.

Let

$$a_1 = \frac{1}{3}\gamma(c). \tag{2.23}$$

$\phi_c - 1$ will then be in $H^2_{a_1}$ and $H^2_{2a_1}$, as will all solitary waves of nearby speed. Let

$$a_2 = \frac{1}{2}\inf_x \phi_c(x)^{(m-n)/2}. \tag{2.24}$$

Then for an $a \leq \min\{a_1, a_2\}$, ϕ_c will satisfy (2.3), with

$$\inf_x \phi_c(x)^m - a^2\phi_c(x)^n \geq \frac{3}{4}\inf_x \phi_c(x)^m > 0.$$

Hence, the solitary waves will live in a set on which the existence theorem applies. Moreover, for all data ϕ_0 sufficiently close to ϕ_c in the H^1 norm, an analogous lower bound will exist.

Remark 2.12. $\inf_x \phi_c(x)^{(m-n)/2}$ is related to a physical length scale known as the *compaction length* [20]. This length, $\delta_{\text{comp.}}$, is given by

$$\delta_{\text{comp.}}(x) = \sqrt{\phi(x)^{n-m}}.$$

It measures the distances over which there will be geometrical rearrangement of the material, appearing macroscopically as changes in ϕ, in response to viscous stresses.

The stipulation $a < \inf_x \phi(x)^{(m-n)/2}$ may be interpreted as requiring the length scale associated with the exponential weight, a^{-1}, to never be smaller than this intrinsic, spatially varying length. However, we draw no physical conclusions from this observation.

Finally, there is a constraints related to the *essential spectrum* of a linear operator, discussed in section 3. Let

$$a_3 = \sqrt{\frac{2c}{n + 2c + \sqrt{n\,(n+8c)}}}\sqrt{\frac{c-n}{c}}. \tag{2.25}$$

This will ensure that for any $a \leq a_3$, the essential spectrum is located in a specific part of the complex plane. Let

$$a_\star(c) = \min\left\{a_1(c), a_2(c), \frac{1}{2}a_3(c)\right\}. \tag{2.26}$$

Then for any $a \leq a_\star(c)$, all of these properties will be satisfied for ϕ sufficiently close in H^1 to ϕ_c.

2.4. Ansatz and linearization. Given a perturbed solitary wave solution, ϕ, of (1.2), assume that there exists decomposition of ϕ into a (time-dependent) solitary wave of some speed $c(t)$ and phase $\theta(t)$ and a perturbation, v; this decomposition's

existence will be proved in section 5.1. Transforming our coordinate system into the frame of this modulating solitary wave,

$$y(x,t) = x - \int_0^t c(s)ds + \theta(t), \tag{2.27}$$

$$\phi(x,t) = \phi_{c(t)}(y(x,t)) + v(y(x,t),t) = \phi_c(y,t) + v(y,t). \tag{2.28}$$

The perturbation, v, is governed by

$$\partial_t v = A_c v - \dot\theta \partial_y v - \dot c \partial_c \phi_c - \dot\theta \partial_y \phi_c + \mathcal{F}_1[v;\phi_c], \tag{2.29}$$

where

$$A_c v = \phi_c^m H_{\phi_c}^{-1} \partial_y L_c v, \tag{2.30}$$

$$L_c v = -c\phi_c^n \partial_y^2 \left(\phi_c^{-m} v\right) + \left[c - n\phi_c^{-1} + cn(\phi_c^{-1} - 1)\right] v, \tag{2.31}$$

and (B.6) gives the definition of $\mathcal{F}_1[v;\phi_c]$, composed of terms nonlinear in v. We make two remarks about (2.29). First, the linear operator A_c is time dependent; $c = c(t)$, and we would prefer to work with a time-*independent* linear operator. Second, the appearance of the term $\dot\theta \partial_y v$ will prove problematic for studying the equation in H^1.

The first problem is addressed by adding and subtracting A_{c_0}, and considering the difference $A_c - A_{c_0}$ as another perturbation of the linear flow. To remove the $\partial_y v$ term, we introduce a renormalized time,

$$\tau = {c_0}^{-1} \left[\int_0^t c(s)ds - \theta(t)\right]. \tag{2.32}$$

The asymptotic stability proof of BBM required a similar transformation [21]. In addition, the problem will be considered in the weighted space H^1_a, with $w(y,t) = e^{ay}v(y,t)$. All together, we have the following.

PROPOSITION 2.13 (perturbation equation). *The perturbation to a solitary wave of speed c_0 associated with the ansatz in* (2.28)*, v, and its weighted perturbation $w = e^{ay}v$ evolves according to the equations in t- and τ-time, respectively.*

$$\partial_t v = A_c v - \dot\theta \partial_y v - \dot c \partial_c \phi_c - \dot\theta \partial_y \phi_c + \mathcal{F}_1[v;\phi_c], \tag{2.33}$$

$$\partial_t w = A_{c,a} w - \dot\theta \left(\partial_y - a\right) w - e^{ay}\left(\dot c \partial_c \phi_c + \dot\theta \partial_y \phi_c\right) + \mathcal{G}_1[w,v;\phi_c], \tag{2.34}$$

$$\partial_\tau v = A_{c_0} - \frac{c_0}{c - \dot\theta}\left(c\partial_c\phi_c + \dot\theta\partial_y\phi_c\right) + S[c_0, c, \dot\theta]v + \frac{c_0}{c-\dot\theta}\mathcal{F}_1[v;\phi_c], \tag{2.35}$$

$$\begin{aligned} \partial_\tau w &= A_{c_0,a} w - \frac{c_0}{c-\dot\theta} e^{ay}\left(\dot c\partial_c\phi_c + \dot\theta\partial_y\phi_c\right) + S_a[c_0,c,\dot\theta]w + \frac{c_0}{c-\dot\theta}\mathcal{G}_1[w,v;\phi_c] \\ &= A_{c_0,a} w + \mathcal{G}\left[w, v; c_0, c, \dot\theta\right]. \end{aligned} \tag{2.36}$$

The operator S and the terms $\mathcal{F}_1$ and $\mathcal{G}_1$ are given explicitly in Appendix B.

Proof. $\mathcal{G}_1$ is obtained from $\mathcal{F}_1$ by substituting $e^{-ay}w$ for one of the v's; $e^{ay}\mathcal{F}_1[v;\phi_c] = \mathcal{G}_1[e^{ay}v, v;\phi_c]$. The details appear in Appendix B. ∎

Note: From here on, we assume c_0 to be fixed and will suppress its appearance in the linear operators A_{c_0} and $A_{c_0,a}$.

3. Spectral properties of the linearized operator. In this section we analyze the spectrum of A and A_a. We will use c in place of c_0 and x in place of y as the independent variable.

$$AY = \lambda Y, \tag{3.1}$$

$$A = \left\{ I - \partial_x \left[\phi_c^n \partial_x \left(\phi_c^{-m} \cdot \right) \right] \right\}^{-1} \partial_x L_c, \tag{3.2}$$

$$L_c = -c\phi_c^n \partial_x^2 \left(\phi_c^{-m} \cdot \right) + \left[c - n\phi_c^{-1} + cn \left(\phi_c^{-1} - 1 \right) \right], \tag{3.3}$$

$$A_a = e^{ax} A e^{-ax}. \tag{3.4}$$

Our goal is to prove that the linearized problem is asymptotically stable: $\| e^{A_a t} w_0 \|_{H^1} \to 0$ as $t \to +\infty$. We will actually show something much stronger, that this convergence to zero happens exponentially fast. Our strategy is that of Pego and Weinstein [28, 29] and Miller and Weinstein [21]. We will

1. identify the essential spectrum of A_a by showing it to be a relatively compact perturbation of a constant coefficient operator;
2. rule out the point spectrum (eigenvalues of finite multiplicity) of A_a for $|\lambda|$ sufficiently large via an operator estimate;
3. use the *Evans function*, an infinite-dimensional analogue of the characteristic polynomial, to rule out nonzero point spectra of A_a in the set of "small" λ, which will be compact;
4. show decay in time of the C_0-semigroup $e^{A_a t}$ associated with A_a.

The spectral analysis is handled in this section, and the semigroup theory in the following section.

The principle result of this section is as follows.

THEOREM 3.1 (spectrum of linearized operator).

(a) *Let $a \in (0, a_\star(\gamma)]$. The essential spectrum of A_a denoted by $\sigma_{\text{ess}}(A_a)$ is a curve lying in the open left half-plane, with rightmost point $-\omega$,*

$$-\omega = \max\{ \Re z | z \in \sigma_{\text{ess}}(A_a) \} < 0. \tag{3.5}$$

(b) *There exist $\gamma_\star \in (0,1)$ and $\hat{\vartheta} > 0$ such that for each $\gamma \in (0, \gamma_\star]$ and $a \in (\gamma\hat{\vartheta}, a_\star(\gamma)]$, there exists $\varepsilon(\gamma, a) > 0$ such that the only eigenvalue of A_a with $\Re\lambda \geq -\varepsilon$ is $\lambda = 0$, and this is an eigenvalue of algebraic multiplicity two.*

(c) *In the Hamiltonian case, $n + m = 0$, part* (b) *may be extended for $\gamma \in (\gamma_\star, 1)$ to all but a discrete set with no accumulation point.*

The spectrum is pictured in Figure 3.

3.1. Essential spectrum. We make use of the definition of the essential spectrum of an operator from [33, 34], which states that for a closed, densely defined operator A on a Banach space X,

$$\sigma_{\text{ess}}(A) = \bigcap_{C \in \mathcal{K}(X)} \sigma(A + C), \tag{3.6}$$

where $\mathcal{K}(X)$ denotes the set of compact operators on X. Other definitions are possible and well known; see Chapter IX of [10] for a discussion of how these definitions relate to one another.

$\sigma(A) \setminus \sigma_{\text{ess}}(A)$ then consists of point spectra. This is so because, by Theorem 7.27 of [34], if λ is not in the essential spectrum, then $\lambda I - A$ is Fredholm with index zero.

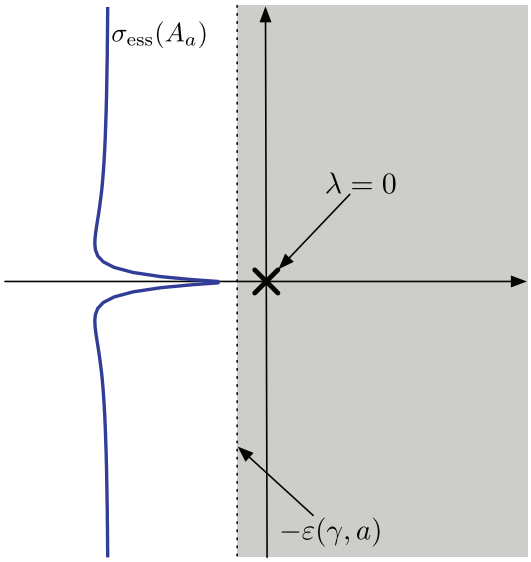

FIG. 3. *The spectrum of the operator A_a. The only eigenvalue with $\Re\lambda \geq -\varepsilon$ is $\lambda = 0$.*

Hence, it has a closed range and a finite kernel. Therefore, it must be an eigenvalue of finite multiplicity.

To prove Theorem 3.1 (a), we express A_a as a perturbation of a constant coefficient operator, A_a^∞, obtained by setting $\phi_c(x)$ equal to its asymptotic state, 1:

$$A_a^\infty = (I - D_a^2)^{-1} D_a(-cD_a^2 + c - n). \tag{3.7}$$

The difference between A_a and A_a^∞, given explicitly in (B.16), may be shown to be an A_a^∞-compact operator. Hence, A_a is a relatively compact perturbation of A_a^∞ and

$$\sigma_{\text{ess}}(A_a) = \sigma_{\text{ess}}(A_a^\infty).$$

Upon examination of the Fourier symbol of A_a^∞, the essential spectrum of A_a is

$$\boxed{\sigma_{\text{ess}}(A_a) = \left\{ \frac{(i\ell - a)(-c(i\ell - a)^2 + c - n)}{1 - (i\ell - a)^2}, \quad \ell \in \mathbb{R} \right\}} \tag{3.8}$$

and

$$-\omega = \max\{\Re z | z \in \sigma_{\text{ess}}(A_a)\} = -ac + \frac{an}{1 - a^2} < 0.$$

$\sigma_{\text{ess}}(A_a)$ lies in the open left half-plane if $0 < a < \gamma$. This set is pictured in Figure 3.

In addition, for $0 < a \leq a_\star < a_3$, a_3 defined by (2.25), the spectrum moves rightward as $a \to 0$. This is because a_3 is the value for which $-\omega$ is leftmost in $\mathbb{C}$, maximizing the rate of decay of e^{ay} as $y \to -\infty$.

3.2. Large eigenvalues. As in [21], we will study the eigenvalues of A_a by considering separately a large $|\lambda|$ regime and a small $|\lambda|$ regime.

Rewriting the linear operator A_a as

$$A_a = c\phi_c^m D_a\left(\phi_c^{-m}\cdot\right) - n\phi_c^m H_{\phi_c,a}^{-1} D_a\left(\phi_c^{-1}\cdot\right) + cm\phi_c^m H_{\phi_c,a}^{-1}\left(\phi_c^{-1}\partial_y\phi_c\cdot\right) + cn\phi_c^m H_{\phi_c,a}^{-1} D_a\left[\left(\phi_c^{-1}-1\right)\cdot\right], \tag{3.9}$$

we note that λ is an L^2 eigenvalue of A_a if and only if it is also an L^2 eigenvalue of $\tilde{A}_a = \phi_c^{-m} A_a \phi_c^m$, given by

$$\tilde{A}_a = cD_a - nH_{\phi_c,a}^{-1} D_a\left(\phi_c^{m-1}\cdot\right) + cmH_{\phi_c,a}^{-1}\left(\phi_c^{m-1}\partial_y\phi_c\cdot\right) + cnH_{\phi_c,a}^{-1} D_a\left[\phi_c^m\left(\phi_c^{-1}-1\right)\cdot\right]. \tag{3.10}$$

We will rule out eigenvalues of $\tilde{A}_a$, thus ruling them out for A_a. This is equivalent to studying A_a in a space weighted by $\phi_c^{-m}(x)$, a strictly positive, smooth, and bounded function. $\tilde{A}_a$ is also a relatively compact perturbation of $\tilde{A}_a^\infty = A_a^\infty$; they share the same essential spectrum.

Let the operator $C(\lambda)$ satisfy

$$C(\lambda) = \left(\lambda I - \tilde{A}_a^\infty\right)^{-1}\left(\tilde{A}_a - \tilde{A}_a^\infty\right).$$

PROPOSITION 3.2.

(a) *The operator $C(\lambda)$ is compact for λ not in σ_{ess}. In particular, $C(\lambda)$ is compact for all λ with $\Re\lambda > -\omega$.*

(b) *For any $\lambda \in \mathbb{C}\setminus\sigma_{\text{ess}}(A_a)$, we have that λ is an eigenvalue of A_a if and only if $1 \in \sigma(C(\lambda))$.*

(c) *Let $\lambda \in \mathbb{C}\setminus\sigma_{\text{ess}}(A_a)$. A sufficient condition for λ not to be an eigenvalue of A_a is that $\|C(\lambda)\| < 1$, with norm either L^2 or H^1, depending on which space is under consideration.*

Proof. Using the equivalence of eigenvalues of A_a and $\tilde{A}_a$, parts (b) and (c) will follow once (a) is established; see [21]. The Fourier symbol of $(\lambda I - \tilde{A}_a^\infty)^{-1}$ is

$$\frac{1-(\imath\ell-a)^2}{\lambda(1-(\imath\ell-a)^2) - (\imath\ell-a)(-c(\imath\ell-a)^2 + c - n)}.$$

This operator is bounded for λ not in the essential spectrum. The difference, given explicitly in (B.17), is a sum of Hilbert–Schmidt compact operators composed with bounded operators on $L^2 \to L^2$; hence $C(\lambda)$ is compact on this space.

For $C(\lambda)$ to be a compact operator on $H^1 \to H^1$, it will be sufficient to prove that

$$(I-\partial_x^2)^{1/2} C(\lambda)(I-\partial_x^2)^{-1/2} = (\lambda I - \tilde{A}_a^\infty)^{-1}(I-\partial_x^2)^{1/2}(\tilde{A}_a - \tilde{A}_a^\infty)(I-\partial_x^2)^{-1/2}$$

is compact on $L^2 \to L^2$. $(\lambda I - A_a^\infty)^{-1}$ is still bounded, and by commuting operators, it may be proven that $(I-\partial_x^2)^{1/2}(\tilde{A}_a - \tilde{A}_a^\infty)(I-\partial_x^2)^{-1/2}$ is compact. ∎

PROPOSITION 3.3. *Let $\delta \in (0,1)$ be fixed.*

(a) *Let $c_\star > n$ and*

$$\hat{\vartheta} \in \left(0, \sup_{c\in(n,c_\star]} a_\star(c)/\gamma(c)\right). \tag{3.11}$$

Then there exists $M = M(c_\star, \hat{\vartheta}) > 0$ *such that for* $c \in (n, c_\star]$ *and* $a \in (\gamma(c)\hat{\vartheta}, a_\star(c)]$, *if*

$$\Re\lambda \geq -\frac{1}{2}ac\gamma^2$$

and at least one of

$$|\Im\lambda| > cM\gamma^3,$$
$$\Re\lambda > cM\gamma^3$$

holds, then $\|C(\lambda)\|_{L^2\to L^2} < 1-\delta$.

(b) *This result also holds for* $\|C(\lambda)\|_{H^1\to H^1}$.

Proof. If $M \geq 1$, then by the assumptions on $\Re\lambda$ and $\Im\lambda$, λ is not in $\sigma_{\mathrm{ess}}(A_a)$; hence we may apply Proposition 3.2 (a) to conclude that $C(\lambda)$ is a compact operator. If the norm of $C(\lambda)$ is less than one, part (c) of that proposition will imply it is not an eigenvalue; we seek an $M \geq 1$ for which $\|C(\lambda)\|$ can be made sufficiently small.

Let $\gamma_0 = \gamma(c_\star)$. For all (γ, a) in $\{(\gamma, a) \mid \gamma \in [0, \gamma_0], a \leq a_\star(\gamma)\}$, there exist K_1 and K_2 such that

$$\begin{aligned}\|C(\lambda)\|_{L^2\to L^2} \leq{}& \|(\lambda I - A_a^\infty)^{-1} H_{1,a}^{-1} D_a\|_{L^2\to L^2}\left(cK_1\gamma^2\right)\\ &+ \|(\lambda I - A_a^\infty)^{-1} H_{1,a}^{-1}\|_{L^2\to L^2}\left(cK_2\gamma^3\right).\end{aligned}$$

This comes from expanding the difference $\tilde{A}_a - \tilde{A}_a^\infty$ and commutating operators; see (B.17). $(\lambda I - A_a^\infty)^{-1} H_{1,a}^{-1} D_a$ and $(\lambda I - A_a^\infty)^{-1} H_{1,a}^{-1}$ are constant coefficient operators and we will treat them in Fourier space.

Thus, if we can prove that, for λ satisfying the hypotheses,

$$\sup_{\ell\in\mathbb{R}}\left|\frac{(\imath\ell - a)\, cK_1\gamma^2}{\lambda\left[1-(\imath\ell-a)^2\right] - (\imath\ell - a)\left[-c(\imath\ell-a)^2 + c\gamma^2\right]}\right| < \frac{1-\delta}{2},$$

$$\sup_{\ell\in\mathbb{R}}\left|\frac{cK_2\gamma^3}{\lambda\left[1-(\imath\ell-a)^2\right] - (\imath\ell - a)\left[-c(\imath\ell-a)^2 + c\gamma^2\right]}\right| < \frac{1-\delta}{2},$$

we will be done.

Introducing the scalings $\lambda = c\Lambda\gamma^3$, $\ell = \gamma\xi$, and $a = \gamma\vartheta$, this is equivalent to identifying $M \geq 1$ such that when $\Re\Lambda \geq -\frac{1}{2}\vartheta$ and $\Re\Lambda > M$ or $|\Im\Lambda| > M$ then both

$$\sup_{\xi\in\mathbb{R}}\left|\frac{(\imath\xi - \vartheta)\, K_1}{\Lambda\left[1-\gamma^2(\imath\xi-\vartheta)^2\right] - (\imath\xi - \vartheta)\left[-(\imath\xi-\vartheta)^2 + 1\right]}\right| < \frac{1-\delta}{2}, \tag{3.12}$$

$$\sup_{\xi\in\mathbb{R}}\left|\frac{K_2}{\Lambda\left[1-\gamma^2(\imath\xi-\vartheta)^2\right] - (\imath\xi - \vartheta)\left[-(\imath\xi-\vartheta)^2 + 1\right]}\right| < \frac{1-\delta}{2} \tag{3.13}$$

are satisfied. By our assumption on a, $\vartheta \in (\hat{\vartheta}, 1)$.

Squaring both sides, (3.12) and (3.13) may be rewritten as two polynomial inequalities, $P_1(\Im\Lambda, \Re\Lambda, \xi) > 0$ and $P_2(\Im\Lambda, \Re\Lambda, \xi) > 0$, respectively. We will show that

for appropriately chosen Λ, the inequalities hold for all ξ. P_1 and P_2 are treated similarly. We study P_2:

$$\begin{aligned}
P_2(\Im\Lambda, \Re\Lambda, \xi) &= \alpha(\Im\Lambda)^2 + \beta\Im\Lambda + \eta_1(\Re\Lambda)^2 + \eta_2\Re\Lambda + \eta_3,\\
\alpha &= \gamma^2\xi^4 + 2\xi^2\gamma^2(1+\gamma^2\vartheta^4) + (1-\gamma^2\vartheta^2)^2,\\
\beta &= -2\xi^5\gamma^2 - 2\xi^3(1+\gamma^2(1+2\vartheta^2)) - 2\xi(1+(-3+\gamma^2)\vartheta^2+\gamma^2\vartheta^4),\\
\eta_1 &= \alpha,\\
\eta_2 &= 2\vartheta\xi^4\gamma^2 + 2\vartheta\xi^2(3+\gamma^2(-1+2\vartheta^2)) + 2\vartheta(1-\vartheta^2)(1-\gamma^2\vartheta^2),\\
\eta_3 &= \xi^6 + \vartheta^2(1-\vartheta^2)^2 + \xi^4(2+3\vartheta^2) + \xi^2(1+3\vartheta^4) - \varpi^2,\\
\varpi &= 2K_2/(1-\delta).
\end{aligned}$$

Using analysis similar to that for P_1 in [21], we first consider P_2 as quadratic in $\Im\Lambda$.[1] Examining its discriminant,

$$\begin{aligned}
\text{discriminant} = \gamma^4 &\left[-4\xi^8\left(\vartheta+\gamma^2\Re\Lambda\right)^2 + O(\xi^6)\right]\\
&+ \gamma^2\left[-24\vartheta^2\xi^6 + O(\xi^4)\right]\\
&- 36\xi^4\vartheta^3 + O(\xi^2).
\end{aligned}$$

If $0 \geq \Re\Lambda \geq -\vartheta/2$, then there exists $M_0 > 0$ such that for all $\Im\Lambda$, $\gamma \in [0,\gamma_0]$, $\vartheta \in (\hat{\vartheta}, 1)$, and $|\xi| > M_0$ the discriminant is negative and $P_2 > 0$. Furthermore, since the coefficient α is always positive, there exists $R_1 > 0$ such that $P_2 > 0$ when $\gamma \in [0,\gamma_0]$, $|\Im\Lambda| > R_1$, $0 \geq \Re\Lambda \geq -\vartheta/2$, and $|\xi| \leq M_0$.

For $\gamma \in [0,\gamma_0]$ and $\vartheta \in (\hat{\vartheta}, 1)$, both η_1 and η_2 are positive; if $P_2(\Im\Lambda, \Re\Lambda, \xi) > 0$, then $P_2(\Im\Lambda, \Re\Lambda + K, \xi) > 0$ for any $K > 0$. Therefore, $P_2 > 0$ for all ξ if $\gamma \in [0,\gamma_0]$, $|\Im\Lambda| > R_1$, and $\Re\Lambda \geq -\vartheta/2$. Also, $P_2 > 0$ for $|\xi| > M_0$ and all $\Im\Lambda$ if $\Re\Lambda \geq -\vartheta/2$.

We must still treat the case of $|\Im\Lambda| \leq R_1$ and $|\xi| \leq M_0$ simultaneously. Consider P_2 as quadratic in $\Re\Lambda$. η_1 and η_2 are positive for all ξ, and η_3 is bounded from below. Therefore there is some $R_2 > 0$ such that $P_2 > 0$ for all ξ if $\gamma \in [0,\gamma_0]$, $|\Im\Lambda| \leq R_1$, and $\Re\Lambda > R_2$. Thus, for any $\vartheta \in (\hat{\vartheta}, 1)$, $\gamma_0 \in [0,\gamma_0]$, there exist $R_1 > 0$ and $R_2 > 0$ such that $P_2 > 0$ for all ξ if

$$\begin{gathered}
\gamma \in [0,\gamma_0],\\
\Re\Lambda \geq -\vartheta/2,\\
|\Im\Lambda| \leq R_1 \quad \text{or} \quad \Re\Lambda > R_2.
\end{gathered}$$

For $C(\lambda) : H^1 \to H^1$, the proof is similar, with constants $\tilde{K}_1$ and $\tilde{K}_2$ in place of K_1 and K_2. □

[1] Though this proof largely follows that for the analogous proposition in [21], we have made two modifications. The first is to introduce $\hat{\vartheta} > 0$ in (3.11). Though this restriction may not be needed, by placing a lower bound on ϑ, estimates are more obviously uniform in γ and ϑ. A second change is to take $\Re\lambda \geq -\vartheta/2$ instead of $\Re\Lambda \geq -\vartheta/(4\gamma^2)$. Our condition is less sharp but, again, makes the intermediary bounds clearly uniform in γ and ϑ.

3.3. Small eigenvalues: The Evans function. In this section we rule out eigenvalues of A_a in the set $|\lambda| \leq M\gamma^3$. This is done using the *Evans function*, an analytic function that vanishes at eigenvalues of A_a. The Evans function, $D = D(\lambda;\gamma)$, is constructed for the eigenvalue problem using particular solutions of an associated dynamical system,

$$\dot{\mathbf{y}} = B(x,\lambda,\gamma)\mathbf{y}, \tag{3.14}$$

$$\mathbf{y} = O(e^{\mu_1 x}) \quad \text{as } x \to +\infty, \tag{3.15}$$

and the adjoint system,

$$\dot{\mathbf{z}} = -\mathbf{z}B(x,\lambda,\gamma), \tag{3.16}$$

$$\mathbf{z} = O(e^{\mu_1 x}) \quad \text{as } x \to -\infty. \tag{3.17}$$

μ_1 will be the eigenvalue of smallest real part of B^∞, the limit as $x \to \pm\infty$ of B. When certain conditions, described in Theorem 3.4, are met, the Evans function exists and may be explicitly defined as

$$D(\lambda;\gamma) = \mathbf{z}(x;\lambda,\gamma)\cdot\mathbf{y}(x;\lambda,\gamma). \tag{3.18}$$

The idea is to measure the angle between the subspace of solutions decaying at $+\infty$ with the subspace decaying at $-\infty$; hence the appearance of the dot product. The Evans function has an equivalent formulation in terms of the determinant of the fundamental solution of (3.14). For a more complete discussion of the Evans function, see [27].

THEOREM 3.4 (see [27, 29]). *Let Ω be a simply connected subset of $\mathbb{C}^2$. Suppose that the system* (3.14) *satisfies the following hypotheses:*

(i) *$B : \mathbb{R}\times\Omega \to \mathbb{C}^{n\times n}$ is continuous in (x,λ,γ) and analytic in (λ,γ) for fixed x.*

(ii) *$B^\infty(\lambda,\gamma) = \lim_{x\to\pm\infty} B(x,\lambda,\gamma)$ exists for all $(\lambda,\gamma)\in\Omega$. The limit is attained uniformly on compact subsets of Ω.*

(iii) *The integral*

$$\int_{-\infty}^{\infty} \|B(x,\lambda,\gamma) - B^\infty(\lambda,\gamma)\|dx$$

converges for all $(\lambda,\gamma)\in\Omega$ and the convergence is uniform on compact subsets of Ω.

(iv) *For every $(\lambda,\gamma)\in\Omega$, the matrix $B^\infty(\lambda,\gamma)$ has a unique eigenvalue of smallest real part, which is simple, denoted μ_1.*

Then $D(\lambda;\gamma)$ is well defined and analytic on Ω, such that $D(\lambda;\gamma) = 0$ if and only if 3.14 *has a solution $\mathbf{y}(x)$ satisfying* (3.15) *and*

$$\mathbf{y}(x) = o(e^{\mu_1 x}) \quad \text{as } x \to -\infty. \tag{3.19}$$

3.3.1. The KdV Evans function. In the case of the KdV equation, the eigenvalue problem may be scaled to

$$\partial_x L_{\mathrm{KdV}} Y = \partial_x\left(-\partial_x^2 Y + Y - 3\mathrm{sech}^2\left(\frac{1}{2}x\right)Y\right) = \Lambda Y. \tag{3.20}$$

Because the speed parameter has been scaled out, there is only one eigenvalue parameter, Λ.

Making the identification

$$\mathbf{y} = \left(Y, \quad \partial_x Y, \quad L_{\mathrm{KdV}} Y\right)^T, \tag{3.21}$$

we see that $\mathbf{y}$ satisfies the dynamical system

$$\dot{\mathbf{y}} = B_{\mathrm{KdV}}(x,\Lambda)\mathbf{y}, \tag{3.22}$$

$$B_{\mathrm{KdV}}(x,\Lambda) = \begin{pmatrix} 0 & 1 & 0 \\ 1 - 3\mathrm{sech}\left(\frac{1}{2}x\right)^2 & 0 & -1 \\ \Lambda & 0 & 0 \end{pmatrix}. \tag{3.23}$$

A complete description of the associated Evans may be found in [28]. We summarize as follows.

THEOREM 3.5 (the KdV Evans function).

(a) *The Evans function* $D_{\mathrm{KdV}}(\Lambda)$ *associated with* (3.20) *is given by*

$$D_{\mathrm{KdV}}(\Lambda) = \left(\frac{\mu_1(\Lambda)+1}{\mu_1(\Lambda)-1}\right)^2,$$

where $\mu_1(\Lambda)$ *denotes the root of* $\mu^3 - \mu + \Lambda = 0$ *of minimal real part.*

(b) *The domain of* $D_{\mathrm{KdV}}(\Lambda)$ *is the slit complex plane*

$$\Delta_{\mathrm{KdV}} = \mathbb{C} \setminus \left(-\infty, -\sqrt{\frac{4}{27}}\right].$$

(c) *The essential spectrum of* $A_{\mathrm{KdV}} : L^2_a \to L^2_a$ *is a curve contained entirely in the domain* $\{\lambda : \Re\lambda < -\epsilon\}$ *for some* $\epsilon > 0$. *Furthermore, if* $\Delta^+_{\mathrm{KdV}}(a)$ *denotes the component of* $\mathbb{C}\setminus\sigma_{\mathrm{ess}}(A_{\mathrm{KdV}})$ *that contains the right half-plane, then* $D_{\mathrm{KdV}}(\Lambda)$ *has no zeros in* $\Delta^+_{\mathrm{KdV}}(a)$ *except for a zero of multiplicity two at* $\Lambda = 0$.

3.3.2. The Evans function applied. The eigenvalue problem $AY = \lambda Y$,

$$\{I - \partial_x[\phi_c^n \partial_x(\phi_c^{-m}\cdot)]\}^{-1}\partial_x\{-c\phi_c^n\partial_x^2(\phi_c^{-m}\cdot) + [c - n\phi_c^{-1} + cn(\phi_c^{-1}-1)]\}Y = \lambda Y,$$

is equivalent to

$$\boxed{\partial_x L_c Y - \lambda\left[I - \partial_x\left(\phi_c^n\partial_x\left(\phi_c^{-m}\cdot\right)\right)\right]Y = 0.} \tag{3.24}$$

Defining

$$\mathbf{y} = \left(\phi_c^{-m}Y, \quad \partial_x\left(\phi_c^{-m}Y\right), \quad L_cY + \lambda\phi_c^n\partial_x\left(\phi_c^{-m}Y\right)\right)^T, \tag{3.25}$$

$\mathbf{y}$ solves the dynamical system

$$\dot{\mathbf{y}} = B(x,\lambda,c)\mathbf{y}, \tag{3.26}$$

$$B(x,\lambda,c) = \begin{pmatrix} 0 & 1 & 0 \\ c^{-1}\phi_c^{m-n}\left[c - n\phi_c^{-1} + cn\left(\phi_c^{-1}-1\right)\right] & \lambda/c & -c^{-1}\phi_c^{-n} \\ \lambda\phi_c^m & 0 & 0 \end{pmatrix}. \tag{3.27}$$

The matrix B may be decomposed as $B = B^\infty(\lambda, c) + R(x, \lambda, c)$.

(3.28)
$$B^\infty(\lambda, c) = \begin{pmatrix} 0 & 1 & 0 \\ \gamma^2 & \lambda/c & -c^{-1} \\ \lambda & 0 & 0 \end{pmatrix},$$

(3.29)
$$R(x, \lambda, \gamma) = \begin{pmatrix} 0 & 0 & 0 \\ c^{-1}\phi_c^{m-n}\left[c - n\phi_c^{-1} + cn\left(\phi_c^{-1} - 1\right)\right] - \gamma^2 & 0 & -c^{-1}\left(\phi_c^{-n} - 1\right) \\ \lambda\left(\phi_c^m - 1\right) & 0 & 0 \end{pmatrix}.$$

Also note that for the corresponding adjoint eigenvalue problem

(3.30)
$$\boxed{-L_c^\star \partial_x W - \lambda\left[I - \phi_c^{-m}\partial_x\left(\phi_c^n \partial_x \cdot\right)\right] W = 0}$$

under the identifications

(3.31)
$$\mathbf{z} = \left(-c\partial_x\left(\phi_c^n \partial_x W\right) - \lambda\phi_c^n \partial_x W, \quad c\phi_c^n \partial_x W, \quad W\right)$$

$\mathbf{z}$ solves

(3.32)
$$\dot{\mathbf{z}} = -\mathbf{z}B(x, \lambda, \gamma).$$

THEOREM 3.6 (properties of the Evans function).

(a) *The Evans function is defined and analytic on the set* $\Omega \subset \mathbb{C}^2$,

(3.33)
$$\boxed{\Omega = \{(\lambda, \gamma) \mid \gamma \in (0,1) \text{ and } \lambda \in \Omega_\gamma\}}$$

with

(3.34)
$$\boxed{\Omega_\gamma = \{\lambda \mid \Re\lambda > -\lambda_0\} \setminus \left(-\lambda_0, -\lambda_{\text{cut}}(\gamma)\right],}$$

where

$$\lambda_{\text{cut}} = \sqrt{\frac{1}{8}}\sqrt{8c^2 + 20cn - n^2 - 8c\sqrt{n^2 + 8cn} - n\sqrt{n^2 + 8cn}}$$

(3.35)
$$= \frac{2}{3\sqrt{3}} n\gamma^3 + \frac{8}{9\sqrt{3}} n\gamma^5 + O(\gamma^7)$$

and $\lambda_0 = n\sqrt{27/16}$.

(b) *Given* $(\lambda, \gamma) \in \Omega$ *and* $a \le a_\star(\gamma)$, *if* λ *is to the right of* $\sigma_{\text{ess}}(A_a)$, *then the following are equivalent:*
- $D(\lambda; \gamma) = 0$.
- λ *is an* L^2 *eigenvalue of* A_a.

(c) *For such zeros of* D, *the algebraic multiplicity of* λ *as an eigenvalue of* A_a *is equal to the order of* λ *as a zero of* $D(\lambda; \gamma)$.

(d) $D(0; \gamma) = \partial_\lambda D(0; \gamma) = 0$, *and hence it is an eigenvalue of algebraic multiplicity* at least *two.*

Remark 3.7. With this construction, for $\Re\lambda < 0$, $\lambda \in \Omega_\gamma$, the characteristic polynomial, (3.36), not only has a unique root of minimal real part, but all roots have distinct real part as well. This is stronger than is needed.

Remark 3.8. λ_{cut} is labeled as such because there is a branch cut in the Evans function there.

Remark 3.9. The eigenvalue at the origin is related to the solitary waves being a two-parameter (speed and phase) family of solutions of (1.2). The presence of the corresponding bound states, explicitly given in Proposition 3.23, could lead to a weak instability of algebraic growth in t. However, we will project out these modes by allowing our leading order solitary wave to modulate its speed and phase.

Proof of Theorem 3.6. Part (a) requires the verification of the hypotheses of Theorem 3.4 for this system. Applying the properties of the ϕ_c and Corollaries 2.9 and 2.11, and through examination of (3.27), B is clearly continuous in its three arguments for $\lambda \in \mathbb{C}$ and $c \geq n$. In addition, for fixed x, it will be analytic in (λ, c), or, equivalently, (λ, γ). Thus property (i) of Theorem 3.4 holds.

By Corollary 2.7, the limiting matrix B^∞ exists and $B - B^\infty$ is in L^1. This will be uniform on compact subsets of $\mathbb{C} \times [0, 1)$, establishing properties (ii) and (iii) of Theorem 3.4.

Lastly, we must verify the existence of μ_1, the unique eigenvalue of minimal real part. We divide this into two parts, $\Re\lambda \geq 0$ and $\Re\lambda < 0$. The characteristic polynomial, $\mathcal{P}(\mu)$, of B^∞ is

$$\boxed{c\mathcal{P}(\mu) = (\lambda - c\mu)(1 - \mu^2) + n\mu.} \tag{3.36}$$

Following the analysis in section 2(c) of [27] for a similar polynomial in the case of generalized BBM, one confirms that property (iv) holds for $\Re\lambda \geq 0$ and all γ, and hence the Evans function exists in $\{\Re\lambda \geq 0\} \times [0, 1)$.

Using the analysis in [21] for Theorem 2.7 of the polynomial, one can conclude the existence of some $\lambda_1 > 0$ and identify $\widetilde{\Omega}(\gamma)$, such that for all $\gamma \in (0, 1)$, a unique root of minimal real part exists for λ in the set

$$\{\lambda : \quad \Re\lambda < -\lambda_1\} \setminus (-\lambda_1, -\widetilde{\Omega}(\gamma)].$$

Alternatively, we give a more precise analysis of (3.36) in Appendix C that yields values of λ_0 and $\widetilde{\Omega}$ given in the proposition. This concludes the proof of part (a).

To prove part (b), we need a lemma regarding the location of $\sigma_{\text{ess}}(A_a)$.

LEMMA 3.10. *Let $\gamma \in (0, 1)$ and $a \leq a_\star(\gamma)$. Let $\Omega_+ = \Omega_+(\gamma, a)$ denote the component of $\mathbb{C} \setminus \sigma_{\text{ess}}(A_a)$ containing the origin. Then for $\lambda \in \Omega_+ \cap \Omega_\gamma$, the roots of the characteristic polynomial satisfy the relation*

$$\Re\mu_1 < -a < \Re\mu_{j\neq 1}. \tag{3.37}$$

Proof. By inspection, if $\lambda \in \sigma_{\text{ess}}(A_a)$, there is a root μ_j of (3.36) with $\Re\mu_j = -a$. Conversely, if there is a root with real part $-a$, then λ is in the essential spectrum. Hence the characteristic polynomial has a root with real part $-a$ if and only if $\lambda \in \sigma_{\text{ess}}(A_a)$

As noted in [27, section 2 (c)], for large $|\lambda|$, the roots of the characteristic polynomial (3.36) are

$$-1 + O\left(|\lambda|^{-1}\right), \quad 1 + O\left(|\lambda|^{-1}\right), \quad \lambda/c + O\left(|\lambda|^{-1}\right).$$

So for large λ in the right half-plane, (3.37) holds because $a < 1$. Now suppose for some $\lambda \in \Omega_+ \cap \Omega_\gamma$ the inequality were false. Because the $\Re\mu_j$ depend continuously on λ, equality would have to hold for some λ, but then it must be that $\lambda \in \sigma_{\rm ess}(A_a)$, which we have assumed is not the case. □

We now prove part (b) of Theorem 3.6. If $D(\lambda;\gamma) = 0$, then there is a solution to the ODE, $\dot{\mathbf{y}} = B\mathbf{y}$, such that

$$\mathbf{y}(x) = O(e^{\mu_1 x}) \quad \text{as } x \to +\infty \quad \text{and} \quad \mathbf{y}(x) = o(e^{\mu_1 x}) \quad \text{as } x \to -\infty.$$

Hence, by Part 1(d) of Proposition 1.6 of [27], for sufficiently small ϵ,

$$\mathbf{y}(x) = O(e^{\mu_\star x + \epsilon|x|}) \quad \text{as } x \to -\infty.$$

Letting $W(x) = e^{ax}\phi_c(x)^m y_1(x)$,

$$W(x) = O(e^{(\mu_\star + a)x + \epsilon|x|}) \quad \text{as } x \to -\infty \quad \text{and} \quad W(x) = O(e^{(\mu_1+a)x}) \quad \text{as } x \to +\infty.$$

From (3.37), $\mu_1 + a < 0 < \mu_\star + a$, so W will decay exponentially fast at $\pm\infty$. Hence it is an L^2 solution to the eigenvalue problem $A_a W = \lambda W$.

Conversely, if we have an L^2 eigenfunction, then it must satisfy

$$W(x) = O(e^{(\mu_1+a)x}) \quad \text{as } x \to +\infty \quad \text{and} \quad W(x) = o(e^{(\mu_1+a)x}) \quad \text{as } x \to -\infty.$$

$Y(x) = e^{-ax}W(x)$ will then satisfy (3.24) in a classical sense, although it may not be in L^2. However it will satisfy the necessary decay estimates on $\mathbf{y}$, constructed from Y as in (3.25), such that $D(\lambda;\gamma) = 0$. This concludes the proof of part (b).

The proof of part (c) follows that of Lemma 2.9 from [28]. First, it is proved that if, for a given γ, λ is a zero of order k of $D(\lambda;\gamma)$, then λ is an L^2 eigenvalue of A_a of algebraic multiplicity at least k. It is then shown that it cannot have algebraic multiplicity greater than k. We omit repeating these details. Part (d) is then a consequence of (c) and the calculations in Appendix D that $D(0;\gamma) = \partial_\lambda D(0;\gamma) = 0$ for all γ. □

Remark 3.11. For $\Re\lambda \le 0$ with $D(\lambda;\gamma) = 0$, it is likely, but not proved, that λ is not an L^2 eigenvalue of A.

3.3.3. The Evans function in the KdV scaling. We now introduce $D_\star(\Lambda;\gamma)$, the Evans function for (3.24) under the KdV scalings introduced in section 2.2:

$$\xi = \gamma x, \quad \lambda = c\Lambda\gamma^3, \quad \phi_c(x) = 1 + \frac{\gamma^2}{n-1}U(\xi(x);\gamma). \tag{3.38}$$

The eigenvalue problem is now

$$\begin{aligned}\partial_\xi L_\gamma Y = {}& \partial_\xi\left[-\left(1+\frac{\gamma^2}{n-1}U\right)^n \partial_\xi^2\left(\left(1+\frac{\gamma^2}{n-1}U\right)^{-m}\cdot\right)\right]Y \\ & + \partial_\xi\left[\left(1+\frac{\gamma^2}{n-1}U\right)^{-1}(1-U)\right]Y \\ & = \Lambda\left[I - \gamma^2\partial_\xi\left(\left(1+\frac{\gamma^2}{n-1}U\right)^n \partial_\xi\left(\left(1+\frac{\gamma^2}{n-1}U\right)^{-m}\cdot\right)\right)\right]Y.\end{aligned} \tag{3.39}$$

Recall that $U = U(\xi;\gamma)$ is the solution of (2.18), and for $\gamma = 0$, $U = U_\star$, the KdV soliton.

We can construct a dynamical system formulation of (3.39), defining the vector $\mathbf{Y}$ as

$$\mathbf{Y} = \begin{pmatrix} \left(1+\frac{\gamma^2}{n-1}U\right)^{-m} Y \\ \partial_\xi\left[\left(1+\frac{\gamma^2}{n-1}U\right)^{-m} Y\right] \\ L_\gamma Y + \gamma^2\Lambda\left(1+\frac{\gamma^2}{n-1}U\right)^{n}\partial_\xi\left[\left(1+\frac{\gamma^2}{n-1}U\right)^{-m} Y\right] \end{pmatrix}, \tag{3.40}$$

which satisfies

$$\dot{\mathbf{Y}} = B_\star(\xi,\Lambda,\gamma)\mathbf{Y}, \tag{3.41}$$

(3.42)

$$B_\star(\xi,\Lambda,\gamma) = \begin{pmatrix} 0 & 1 & 0 \\ \left(1+\frac{\gamma^2}{n-1}U(\xi;\gamma)\right)^{m-n-1}(1-U(\xi;\gamma)) & \gamma^2\Lambda & -\left(1+\frac{\gamma^2}{n-1}U(\xi;\gamma)\right)^{-n} \\ \Lambda\left(1+\frac{\gamma^2}{n-1}U(\xi;\gamma)\right)^{m} & 0 & 0 \end{pmatrix}.$$

As $\xi\to\infty$, the matrix is

$$B_\star^\infty(\Lambda,\gamma) = \begin{pmatrix} 0 & 1 & 0 \\ 1 & \gamma^2\Lambda & -1 \\ \Lambda & 0 & 0 \end{pmatrix}, \tag{3.43}$$

which has the characteristic polynomial

$$P_\star(\nu;\Lambda,\gamma) = \nu^3 - \gamma^2\Lambda\nu^2 - \nu + \Lambda. \tag{3.44}$$

A few remarks about the scaled problem. The assumptions stated in Theorem 3.4 remain the same, except now the matrix under inspection is $B_\star$, with eigenvalue parameters (Λ,γ). $\mathbf{Y}$ and $\mathbf{y}$ are related:

$$\mathbf{y}(x) = \begin{pmatrix} Y_1(\xi(x)) \\ \gamma Y_2(\xi(x)) \\ c\gamma^2 Y_3(\xi(x)) \end{pmatrix}.$$

At $\gamma = 0$, (3.39) is

$$\partial_\xi L_0 Y = \partial_\xi\left[-\partial_\xi^2 Y + (1-U_\star(\xi;0)Y\right] = \Lambda Y,$$

the KdV eigenvalue problem, (3.20), and

$$B_\star(\xi,\Lambda,0) = \begin{pmatrix} 0 & 1 & 0 \\ 1-U_\star(\xi) & 0 & -1 \\ \Lambda & 0 & 0 \end{pmatrix}$$

is the matrix for the KdV dynamical system.

PROPOSITION 3.12 (scaled Evans function).
(a) *$D_\star(\Lambda;\gamma)$ is defined and analytic on the set $\Delta \subset \mathbb{C}^2$,*

$$\Delta = \{(\Lambda,\gamma) \mid \gamma \in [0,1) \text{ and } \lambda \in \Delta_\gamma\}, \tag{3.45}$$

where, for $\gamma > 0$,

$$\begin{aligned}\Delta_\gamma &= \left\{\Lambda \mid \Re\Lambda > -\frac{\lambda_0}{c\gamma^3}\right\} \setminus \left(-\frac{\lambda_0}{c\gamma^3}, -\frac{\lambda_{\text{cut}}(\gamma)}{c\gamma^3}\right] \\ &= \left\{\Lambda \mid \Re\Lambda > -\gamma^{-3}\sqrt{\frac{27}{16}} + O(\gamma^{-1})\right\} \\ &\qquad \setminus \left(-\gamma^{-3}\sqrt{\frac{27}{16}} + O(\gamma^{-1}), -\sqrt{\frac{4}{27}} + O(\gamma^2)\right].\end{aligned}$$

λ_0 and $\widetilde{\Omega}$ are as defined by Theorem 3.6. When $\gamma = 0$,

$$\Delta_0 = \Delta_{\text{KdV}} = \mathbb{C} \setminus \left(-\infty, -\sqrt{4/27}\right].$$

(b) *For fixed $\gamma \in (0,1)$ and $\Lambda \in \Delta_\gamma$,*

$$D_\star(\Lambda;\gamma) = D(c\Lambda\gamma^3;\gamma).$$

(c) *For $\Lambda \in \Delta_0$,*

$$D_\star(\Lambda;0) = D_{\text{KdV}}(\Lambda).$$

Proof. The proof of these statements follows that of Proposition 2.8 in [21] and Theorems 4.9–4.11 of [29].

Proof of part (a). For $\gamma > 0$, as in Theorem 3.6, we must identify a set in $\mathbb{C}^2$ in which the hypotheses of Theorem 3.4 are valid. Parts (i)–(iii) are obvious as the solitary wave $U(\xi;\gamma)$ decays exponentially in ξ and, for fixed ξ, will be analytic in γ. We are left to verify part (iv). The characteristic polynomial of $B_\star^\infty$ is (3.44). As noted in [21], the roots of $P_\star$ are related to those of P, (3.36), by

$$\mu(\lambda,\gamma) = \gamma\nu(\Lambda,\gamma).$$

So $P_\star$ will have a unique root of minimal real part for a given Λ and γ when P has such a unique root for $\lambda = c\Lambda\gamma^3$. Therefore, for $\gamma \in (0,1)$, if Λ is in the set

$$\Delta_\gamma = \frac{1}{c\gamma^3}\Omega_\gamma,$$

(iv) will be satisfied. If $\gamma = 0$, (3.41) and (3.42) coincide with the KdV system, for which $\Delta_0 = \mathbb{C} \setminus (-\infty, -\sqrt{4/27}]$. Clearly, as $\gamma \to 0$, Δ_γ limits to Δ_0.

Proof of part (b). From part (a), $\lambda = c\Lambda\gamma^3 \in \Omega_\gamma$ and, by construction,

$$\begin{aligned} y_1(x,\lambda,\gamma) &\sim e^{\mu_1 x} \quad \text{as } x \to +\infty, \\ Y_1(\xi,\Lambda,\gamma) &\sim e^{\nu_1 \xi} \quad \text{as } \xi \to +\infty. \end{aligned}$$

At $\xi = \gamma x$, $\mu_1 = \gamma\nu_1$, $\lambda = c\Lambda\gamma^3$, $y_1(x,\lambda,\gamma) = Y_1(\xi,\Lambda,\gamma)$. Using the *transmission coefficient* interpretation of the Evans function, we then have

$$\mathbf{y}(x,\lambda,\gamma) \sim D(\lambda;\gamma)e^{\mu_1 x}\,(1, \quad \mu_1, \quad \lambda/\mu_1)^T \quad \text{as } x \to -\infty,$$
$$\mathbf{Y}(\xi,\Lambda,\gamma) \sim D_\star(\Lambda;\gamma)e^{\nu_1 \xi}\,(1, \quad \nu_1, \quad \Lambda/\nu_1)^T \quad \text{as } \xi \to -\infty,$$

implying

$$D(c\Lambda\gamma^3;\gamma) = D_\star(\Lambda;\gamma).$$

Proof of part (c). Trivially, when $\gamma = 0$, this is the KdV Evans function problem exactly. ∎

PROPOSITION 3.13. *Let* $\varepsilon_2 \in (0, \sqrt{4/27})$ *and* $M > 0$. *Set*

$$\mathcal{O} = \{\Re\Lambda \geq -\varepsilon_2, \quad |\Lambda| < M\}.$$

Then for all γ *sufficiently small,* $\mathcal{O} \subset \Delta_\gamma$ *and*

$$\lim_{\gamma\to 0} D_\star(\Lambda;\gamma) = D_\star(\Lambda;0) = D_{\mathrm{KdV}}(\Lambda)$$

with uniform convergence for $\Lambda \in \mathcal{O}$.

Proof. Clearly, for γ sufficiently close to zero, $\mathcal{O} \subset \Delta_\gamma$. Since $\mathcal{O}$ is compact and $D_\star$ is analytic in both arguments,

$$\sup_{\Lambda\in\mathcal{O}} |D_\star(\Lambda;\gamma) - D_\star(\Lambda;0)|$$

may be made arbitrary small by taking γ sufficiently close to zero. ∎

THEOREM 3.14. *There exist* $\gamma_\star \in (0,1)$ *and* $\hat{\vartheta} > 0$ *such that for all* $\gamma \in (0,\gamma_\star]$ *and* $a \in (\gamma\hat{\vartheta}, a_\star(\gamma)]$, *there exists* $\varepsilon = \varepsilon(\gamma,a) > 0$, *such that*

- *the only eigenvalue of* A_a *with* $\Re\lambda \geq -\varepsilon$ *is* $\lambda = 0$, *with algebraic multiplicity two;*
- *the only zero of* $D(\lambda;\gamma)$ *with* $\Re\lambda \geq -\varepsilon$ *is* $\lambda = 0$, *a root of order two.*

Proof. Adapting the proof of Theorem 2.1 in [21] we break a half-plane into two parts: a bounded set about the origin and its unbounded complement. The operator estimates from Proposition 3.3 will rule out eigenvalues in the unbounded part, and the Evans function in the KdV scaling will control eigenvalues in the bounded part.

Let us apply Proposition 3.3 (a) with $\delta = 1/4$, $c_\star = 4n$, and

$$\hat{\vartheta} = \frac{1}{4}\sup_{c\in(n,c_\star]} \frac{a_\star(c)}{\gamma(c)}.$$

Then there exists $M > 0$, such that for any $c \in (n,4n]$, $a \in (\gamma\hat{\vartheta}, a_\star(\gamma)]$, and $\lambda \in \Omega_{\mathrm{U}}$,

$$\Omega_{\mathrm{U}} = \left\{\lambda : \Re\lambda \geq -\frac{1}{2}ac\gamma^2, \quad |\lambda| > cM\gamma^3\right\},$$

$\|C(\lambda)\|_{L^2\to L^2} < 1$. By Proposition 3.2 (c), such λ cannot be L^2 eigenvalues of A_a.

Using this M, let $\varepsilon_2 = \frac{1}{4}$ and set

$$\mathcal{O} = \{\Lambda : \Re\Lambda \geq -\varepsilon_2, \quad |\Lambda| \leq M\}.$$

Define

$$m = \min\{|D_{\mathrm{KdV}}(\Lambda)| \min \Lambda \in \partial\mathcal{O}\}.$$

By Proposition 3.13, there exists a $\gamma_\star \leq 1/2$ such that for all $\gamma \in [0, \gamma_\star]$,

$$|D_\star(\Lambda;\gamma) - D_\star(\Lambda;0)| = |D_\star(\Lambda;\gamma) - D_{\mathrm{KdV}}(\Lambda)| < m \quad \text{for all } \Lambda \in \partial\mathcal{O}.$$

By Theorem 3.5, the only root of D_{KdV} in $\mathcal{O}$ is at $\Lambda = 0$, with multiplicity two. Applying Rouché's theorem (see, for example, [16, 17]), for all $\gamma \in [0, \gamma_\star]$, $D_\star(\cdot,\gamma)$ and D_{KdV} have the same number of roots in $\mathcal{O}$. By Proposition 3.12 (b), if $\gamma \in (0, \gamma_\star]$ and $\Lambda \in \mathcal{O}$, $D_\star(\Lambda;\gamma) = D(c\Lambda\gamma^3;\gamma)$; therefore on the set Ω_{B},

$$\Omega_{\mathrm{B}} = c\gamma^3\mathcal{O} = \left\{\lambda : \Re\Lambda \geq -\varepsilon_2 c\gamma^3, \quad |\lambda| \leq cM\gamma^3\right\}.$$

$D(\lambda;\gamma)$ also has only two zeros. Theorem 3.6 (d) asserts that these two roots are at the origin, corresponding to an eigenvalue of algebraic multiplicity two. By Theorem 3.6 (b), A_a then has no *nonzero* L^2 eigenvalues in Ω_{B}.

Combining Ω_{U} and Ω_{B}, if we set

$$\varepsilon(\gamma, a) = \min\left\{\frac{1}{2}ac\gamma^2, \quad \varepsilon_2 c\gamma^3, \quad \frac{1}{2}\omega, \quad \frac{1}{2}\lambda_{\mathrm{cut}}(\gamma), \quad \frac{1}{2}\lambda_0\right\}, \tag{3.46}$$

then by Theorem 3.6 (b), $\lambda = 0$ is both the only eigenvalue of A_a and the only root of $D(\lambda;\gamma)$ with $\Re\lambda \geq -\varepsilon$. □

COROLLARY 3.15. *For $\gamma \in (0, \gamma_\star]$, $\partial_c\mathcal{N}[\phi_c] \neq 0$.*

Proof. This is a consequence the preceding theorem and the relation $\partial_\lambda^2 D(0;\gamma) \propto \partial_c\mathcal{N}[\phi_c]$; see Appendix D. □

3.4. The Evans function beyond the KdV scaling. For $\gamma > \gamma_\star$, one may compute the Evans function numerically to assert that a given λ is not an eigenvalue. Moreover, the winding number of the image of the Evans function evaluated on the line $\Re\lambda = -\lambda_1 < 0$ equals the number of zeros in the set $\Re\lambda > -\lambda_1$. Therefore, one might evaluate the Evans function on such a line and exam the plot, as we do in Figures 4 and 5.

These plots indicate that $\lambda = 0$ is the only zero in the closed right half-plane for the values of c, n, and m under consideration. Up to the acceptance of these numerics, this extends Theorem 3.14. Note that we do not evaluate out to $-\lambda_1 + \imath\infty$, but merely compute at sufficiently large values of λ such that we are near the asymptotic value of the Evans function. It may be proven that there exists $D_\infty(\gamma)$ such that

$$\lim_{|\lambda|\to\infty, \lambda\in\Omega} D(\lambda;\gamma) = D_\infty(\gamma).$$

A further numerical computation will reveal that this value is nonzero.

In the Hamiltonian case, $n + m = 0$, an analytical result is possible for $\gamma > \gamma_\star$. The linearized operator, A, may be written as $A = J_c L_c$,

$$J_c = \left[I - \partial_x\left(\phi_c^n \partial_x\left(\phi_c^n \cdot\right)\right)\right]^{-1}\partial_x, \qquad J_c^\star = -J_c, \tag{3.47}$$

$$L_c = -c\phi_c^n\partial_x^2\left(\phi_c^n\right) + \left(c - n\phi_c^{-1} + cn\left(\phi_c^{-1} - 1\right)\right), \qquad L_c^\star = L_c. \tag{3.48}$$

This structure permits an extension of Theorem 3.14 beyond the KdV regime, given below in Theorem 3.21. However, this is absent for general n and m.

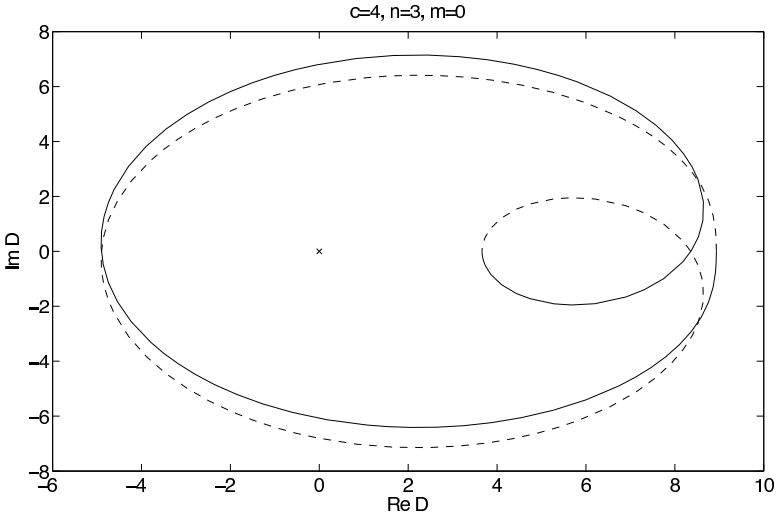

FIG. 4. $D(\cdot; c = 4)$ *evaluated on a portion of the strip* $\Re\lambda = -1/5$. *Since* $D(\overline{\lambda}) = \overline{D(\lambda)}$ *we only compute* $\Im\lambda > 0$, *and then reflect; this is the dashed curve. The curve wraps around the origin, marked by x, twice. In this case,* $n = 3$ *and* $m = 0$.

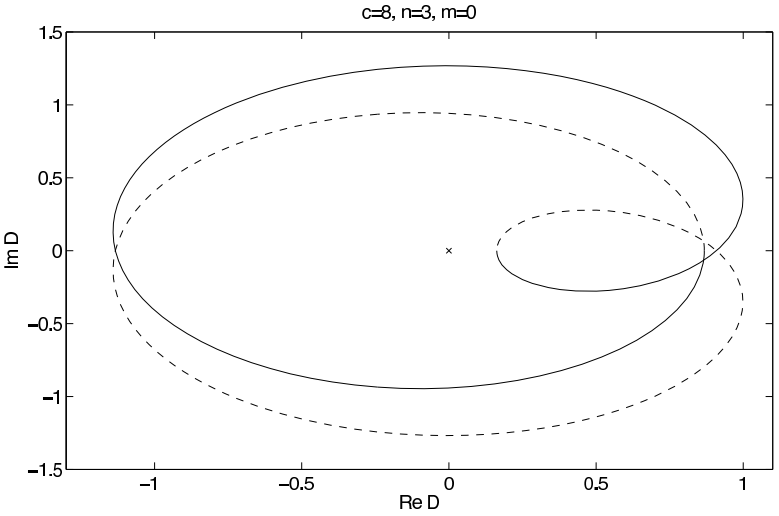

FIG. 5. $D(\cdot; c = 8)$ *evaluated on a portion of the strip* $\Re\lambda = -1$. *Since* $D(\overline{\lambda}) = \overline{D(\lambda)}$ *we only compute* $\Im\lambda > 0$, *and then reflect; this is the dashed curve. The curve wraps around the origin, marked by x, twice. In this case,* $n = 3$ *and* $m = 0$.

Remark 3.16. This section is the only place where the analyticity of the Evans function in the γ argument is used. In turn, this is the only place requiring analyticity of ϕ_c in c from Corollary 2.11 (b). For the results in the preceding section, *joint continuity* of $D(\lambda; \gamma)$ in its two arguments is sufficient.

LEMMA 3.17. *In the Hamiltonian case, the following are equivalent for* $\Re\lambda \geq 0$, $a \leq a_\star(\gamma)$*:*

- λ *is an* L^2 *eigenvalue of* A.
- $D(\lambda; \gamma) = 0$.

Proof. For $\Re\lambda > 0$, we know that $\mu_\star = \min\{\Re\mu_2, \Re\mu_3\} > 0$, so an eigenfunction, having submaximal growth at $-\infty$, must decay exponentially fast. This is very similar to the relation in the case of the weighted operator from Theorem 3.6 (b).

For $\Re\lambda = 0$, the proof relies on the JL structure of the operator A. See the proof of [27, Theorem 3.6]. ∎

LEMMA 3.18. *If λ is a nonzero purely imaginary eigenvalue, then $\partial_\lambda D(\lambda;\gamma) \neq 0$.*

Proof. The proof is by contradiction. Let $Y+$ be the corresponding eigenfunction, $AY^+ = \lambda Y^+$. It may be proven that the subspace $\mathcal{Y} = \operatorname{span}\{Y^+, \overline{Y^+}\}$ satisfies

$$\langle L_c u, v\rangle = 0 \quad \text{for all } u, v \in \mathcal{Y}.$$

As $\mathcal{Y} \cap \ker(L_c) = \{0\}$, we may apply Lemma 3.3 of [27] to conclude $\dim \mathcal{Y} \leq 1$, a contradiction. See Lemma 3.3 from [28] for details. ∎

LEMMA 3.19 (monotonicity of functional analytically confirmed for $n = 2$). *In the Hamiltonian case, assuming $\partial_c \mathcal{N}[\phi_c] \neq 0$ for all c, then for all c, there are no eigenvalues with $\Re\lambda > 0$.*

Proof. By Theorem 3.14, the result holds for $c \leq c_\star$. We argue by contradiction to extend it beyond $c_\star$. Assume for some $\gamma_0 > \gamma_\star$ that there exists λ_0, $\Re\lambda_0 > 0$, such that $D(\lambda_0;\gamma_0) = 0$. If $\Im\lambda_0 \neq 0$, then $D(\overline{\lambda_0};\gamma_0) = 0$ and there would be two eigenvalues in the right half-plane. But by Theorem 3.1 of [27], $A = J_c L_c$ has no more eigenvalues (counting multiplicity) with $\Re\lambda > 0$ than L_c does with $\Re\lambda < 0$. As is discussed in [40], L_c has exactly one negative eigenvalue; this is a contradiction, so λ_0 is real.

Because the number of zeros in the right half-plane is at most one, counting multiplicity, we know $\partial_\lambda D(\lambda_0;\gamma_0) \neq 0$. Applying the implicit function theorem, we get an analytic function, $\lambda(\gamma)$, defined in a neighborhood of γ_0, such that $\lambda(\gamma_0) = \lambda_0$ and $D(\lambda(\gamma);\gamma) = 0$.

Let $\mathcal{O}$ be the maximal domain of analyticity of $\lambda(\gamma)$. In a sufficiently small neighborhood of γ_0, $\Re\lambda(\gamma) > 0$. For real-valued γ in this neighborhood, we must have, by the above argument about complex-conjugates, that $\Im\lambda(\gamma) = 0$. Considering the power series expansion of $\lambda(\gamma)$, about γ_0, $\lambda(\gamma)$ will be real-valued for real-valued $\gamma \in \mathcal{O}$.

Let

$$\gamma_1 = \inf\{\gamma \in (\gamma_\star/2, \gamma_0) \cap \mathcal{O} \mid D(\lambda(\gamma);\gamma) = 0\}.$$

For all $\gamma \in [\gamma_1, \gamma_0]$, we must have $\lambda(\gamma) > 0$. Suppose this is not the case. Then, by continuity, for some γ, we must have $\lambda(\gamma) = 0$. But this would imply that $\lambda = 0$ was a root of multiplicity three, contradicting the assumption on $\mathcal{N}$, which ensures it is a root of multiplicity two.

$\lambda(\gamma)$ may be analytically continued down till at least $\gamma_\star/2$. If not, then $\gamma_1 > \gamma_\star/2$ and $\partial_\lambda D(\lambda(\gamma_1);\gamma_1) \neq 0$ since this root must be simple. Therefore we could apply the implicit function theorem again and extend $\lambda(\gamma)$ below γ_1, contradicting its minimality.

But then $D(\lambda(\gamma_\star);\gamma_\star) = 0$, and $\lambda(\gamma_\star) > 0$, contradicting Theorem 3.14. ∎

Remark 3.20. An analogous result may be found in Theorem 3.4 [27] for generalized KdV and generalized BBM. However, the argument there is very different because it may be proven that $D(\lambda) \to 1$ as $|\lambda| \to \infty$. This does not hold for the Evans function associated with (1.2), due to the appearance of a nonlinearity in the dispersive term.

THEOREM 3.21 (monotonicity of functional analytically confirmed for $n = 2$). *In the Hamiltonian case, assuming $\partial_c \mathcal{N}[\phi_c] \neq 0$ for all c, Theorem* 3.14 *may be extended to all $\gamma \in (\gamma_\star, 1)$, except for a discrete set whose only possible accumulation point is $\gamma = 1$.*

Proof. By Lemma 3.19, if Theorem 3.4 were false for some $\gamma > \gamma_\star$, it would be due to a zero appearing on the imaginary axis. We will prove by contradiction that the set

$$E = \{\gamma \in [0,1) \mid \text{there exists } \beta > 0 \text{ such that } D_\star(\imath\beta;\gamma) = 0\} \tag{3.49}$$

has no accumulation points. We consider only positive β's because if $\imath\beta$ is a root, then so is $-\imath\beta$. This follows the proofs of Theorem 3.6 of [28] and Theorem 2.1 of [21].

Assuming E has a limit point, there exists a sequence, $\gamma_j \in E$, $\gamma_j \to \gamma_0 \in E$ as $j \to \infty$. Taking a subsequence if necessary, γ_j and γ_0 are bounded away from $\gamma = 1$. We will now rule out large eigenvalues, and then argue by contradiction to rule out small eigenvalues.

Applying Proposition 3.3 to this range of γ values, there will exist $M > 0$, such that the corresponding $\beta_j > 0$ must satisfy $\beta_j \leq M$. Taking a subsequence if necessary, $\beta_j \to \beta_0$, $\beta_0 \leq M$, $D_\star(\imath\beta_j;\gamma_j) = 0$, and, by continuity, $D_\star(\imath\beta_0;\gamma_0) = 0$.

Note that $\beta_0 \neq 0$. $\Lambda = 0$ is always a root of order at least two. The assumption $\partial_c \mathcal{N}[\phi_c] \propto \partial_\lambda^2 D(0;\gamma) = (c^2\gamma^6)^{-1}\partial_\Lambda^2 D_\star(0;\gamma) \neq 0$ forces it to be a root of order exactly two. But $\beta_0 = 0$ would imply that it was a zero of at least four, a contradiction.

Applying Lemma 3.18, $\partial_\Lambda D_\star(\imath\beta_j;\gamma_j) \neq 0$ and $\partial_\Lambda D_\star(\imath\beta_0;\gamma_0) \neq 0$. By the implicit function theorem, there is an analytic function $\Lambda_0(\gamma)$ defined in a neighborhood of γ_0, such that $\Lambda_0(\gamma_0) = \imath\beta_0$ and $D_\star(\Lambda_0(\gamma);\gamma) = 0$. By considering the power series expansion of $\Lambda_0(\gamma)$ about γ_0, we see, by taking γ_j sufficiently close to γ_0, that $\Lambda_0(\gamma)$ is purely imaginary for real γ in its maximal domain of analyticity, $\mathcal{O}$.

Let

$$\gamma_1 = \inf\{\gamma \in [0,\gamma_0) \cap \mathcal{O} \mid D_\star(\Lambda_0(\gamma);\gamma) = 0\}.$$

For all $\gamma \in [\gamma_1, \gamma_0]$, we must have $\Im\Lambda_0(\gamma) > 0$. If not, then by continuity there would exist $\gamma \in (\gamma_1, \gamma_0)$, for which $\Lambda_0(\gamma) = 0$, yielding a contradiction as before.

Suppose $\gamma_1 > 0$. $\Im\Lambda_0(\gamma_1) > 0$ because, if not, then by continuity there would exist $\gamma \in (\gamma_1, \gamma_0)$, for which $\Lambda_0(\gamma) = 0$, leading to a contradiction again. Therefore, we may be sure that $\partial_\Lambda D_\star(\Lambda_0(\gamma_1);\gamma_1) \neq 0$. We may then apply the implicit function theorem, allowing us to continue Λ_0 below γ_1, another contradiction. Therefore $\gamma_1 = 0$. But then $\Im\Lambda_0(0) > 0$ and $0 = D_\star(\Lambda_0(0);0) = D_{\mathrm{KdV}}(\Lambda_0(0))$, a contradiction. ∎

Remark 3.22. This result is limited by our inability to analytically evaluate the functional $\mathcal{N}[\phi_c]$. The authors were similarly stymied in [40], where the orbital stability of the solitary waves relies on proving $\partial_c \mathcal{N}[\phi_c] > 0$. Here, as there, one may numerically evaluate the functional and observe its monotonicity in the speed argument. See [40] for the case $n = 2$.

This result, along with (3.8) and Theorem 3.14, completes the proof of Theorem 3.1.

3.5. The generalized kernel.

PROPOSITION 3.23. *Let $c > n$, $a \le a_\star(c)$ and assume $\partial_c \mathcal{N}[\phi_c] \neq 0$. Define*

$$\tilde{\xi}_1 = \partial_x \phi_c,$$

$$\tilde{\xi}_2 = \partial_c \phi_c,$$

$$\tilde{\eta}_1 = \Theta \left[I - \phi_c^{-m} \partial_x \left(\phi_c^n \partial_x \cdot \right) \right] \int_{-\infty}^{x} \left(L_c^\star \right)^{-1} \left[I - \phi_c^{-m} \partial_x \left(\phi_c^n \partial_x \cdot \right) \right] \int_{-\infty}^{x} \frac{\partial_x \phi_c}{\phi_c^{n+m}} dx,$$

$$\tilde{\eta}_2 = \Theta \left[I - \phi_c^{-m} \partial_x \left(\phi_c^n \partial_x \cdot \right) \right] \int_{-\infty}^{x} \frac{\partial_x \phi_c}{\phi_c^{n+m}} dx,$$

$$\Theta = \left(\partial_c \mathcal{N}[\phi_c] \right)^{-1}.$$

For $j = 1, 2$, set

$$\xi_j = e^{ay} \tilde{\xi}_j \quad \textit{and} \quad \eta_j = e^{-ay} \tilde{\eta}_j.$$

Then $\{\xi_1, \xi_2\}$ and $\{\eta_1, \eta_2\}$ are biorthogonal bases for $\ker_g(A_a)$ and $\ker_g(A_a^\star)$, $\langle \xi_i, \eta_j \rangle = \delta_{ij}$. They satisfy the relations

$$A_a \xi_1 = 0, \qquad A_a^\star \eta_2 = 0,$$

$$A_a \xi_2 = -\xi_1, \qquad A_a^\star \eta_1 = -\eta_2.$$

Proof. It is easy to verify $A\tilde{\xi}_1 = 0$, $A\tilde{\xi}_2 = -\xi_1$, and $A^\star \tilde{\eta}_2 = 0$.

$$\ker(L_c^\star) = \operatorname{span} \left\{ \phi_c^{-n-m} \partial_x \phi_c \right\}.$$

The kernel is orthogonal to $\tilde{\eta}_2$ because $\tilde{\eta}_2$ is an even function, while the kernel is odd. Therefore, $\tilde{\eta}_1$ is well defined and $A^\star \tilde{\eta}_1 = -\tilde{\eta}_2$. □

4. Semigroup decay. The following result proves the convective stability of solitary waves under the *linearized* flow. As we will do in section 6, this may be employed to prove full nonlinear stability.

THEOREM 4.1 (linearized stability). *Assume $\gamma \in (0, 1)$, $a \le a_\star(\gamma)$, and there exists $\varepsilon > 0$ such that $\lambda = 0$ is the only eigenvalue of A_a with $\Re\lambda \ge -\varepsilon$. Then the initial-value problem*

$$w_t = A_a w,$$

$$w(0) = w_0 \in H^1 \cap \ker{}_g(A_a^\star)^\perp$$

has a unique solution $w(t) = e^{A_a t} w_0 \in C_0([0, \infty); H^1)$ with

$$\|w(t)\|_{H^1} \le C e^{-bt} \|w_0\|_{H^1} \tag{4.1}$$

for some $C > 0$ and $b > 0$.

Remark 4.2. There exists a $b_{\max} > 0$ such that (4.1) will hold for all $b \in (0, b_{\max})$. In particular, for $\gamma \in (0, \gamma_\star]$ and $a \in (\gamma \hat{\vartheta}, a_\star(\gamma)]$, $b_{\max} \ge \varepsilon$; see Theorem 3.1.

Proof of Theorem 4.1. This is based on a result due to Prüss [30].

THEOREM 4.3. *Let B be the infinitesimal generator of a C_0-semigroup on a Hilbert space Z. Let $b > 0$. If there exists $M > 0$ such that*

$$\|(\lambda I - B)^{-1}\|_{Z \to Z} \le M \quad \textit{for all } \Re\lambda > -b,$$

then $\|e^{Bt}\|_{Z \to Z} \le e^{-bt}$.

Following the approach in [21] for Proposition 3.1, we first show that A_a is the infinitesimal generator of a C_0-semigroup on H^1. Examining the Fourier symbol of A_a^∞, A_a^∞ is such a semigroup. As (B.16) shows, $A_a - A_a^\infty$ is a bounded operator, so we may apply Theorem 3.1.1 of [25], which states that bounded perturbations of infinitesimal generators are also infinitesimal generators.

Consider the Hilbert space

$$Z = H^1 \cap \ker_{\mathrm{g}}(A_a^\star)^\perp$$

equipped with the H^1 norm and the operator

$$B = A_a|_Z$$

the restriction of A_a to Z. B inherits from A_a that it is the infinitesimal generator of a C_0-semigroup on Z. Also note that $\sigma(B) = \sigma(A_a) \setminus \{0\}$ by Theorem III-6.17 of [14].

Recall from Theorem 3.1 that $\sigma_{\mathrm{ess}}(A_a)$ is contained in left half-plane, and all points in $\sigma(A_a) \setminus \sigma_{\mathrm{ess}}(A_a)$ are eigenvalues of finite multiplicity. By the assumption on the spectrum of A_a, the spectrum of B is contained in the open left half-plane.

We will now prove there exists a uniform bound on resolvent of B for $\Re\lambda > -b$ for some $b > 0$. For $\lambda \in \rho(B)$,

$$(\lambda I - B)^{-1} = (\lambda I - A_a)^{-1}|_Z,$$

so

$$\|(\lambda I - B)^{-1}\|_{Z\to Z} \le \|(\lambda I - A_a)^{-1}\|_{H^1\to H^1}.$$

The resolvent of A_a may be written as

$$(\lambda I - A_a)^{-1} = (I - C(\lambda))^{-1}(\lambda I - A_a^\infty)^{-1},$$

with $C(\lambda)$ as defined in Proposition 3.2. Since $\Re\sigma_{\mathrm{ess}}(A_a) \le -\omega < 0$, we must have $b < \omega$. Then, for $\Re\lambda \ge -b$, the Fourier symbol of $(\lambda I - A_a^\infty)^{-1}$ is uniformly bounded, so

$$\|(\lambda I - A_a^\infty)^{-1}\|_{H^1\to H^1} \le M' \quad \text{for some } M' > 0.$$

By Proposition 3.3, for $\Re\lambda \ge -b \ge -\frac{1}{2}ac\gamma^2$, there exists $R' > 0$ such that

$$\|(I - C(\lambda))^{-1}\|_{H^1\to H^1} \le 2 \quad \text{for } |\lambda| > R'.$$

Therefore,

$$\|(\lambda I - B)^{-1}\|_{Z\to Z} \le \|(\lambda - A_a)^{-1}\|_{H^1\to H^1} \le 2M' \quad \text{for } \Re\lambda \ge -b \text{ and } |\lambda| > R'.$$

For $|\lambda| \le R'$ and $\Re\lambda \ge -\varepsilon$, B has no eigenvalues. B is a closed operator, and therefore $(\lambda I - B)^{-1}$ is holomorphic on this compact set (see Theorem III-6.7 of [14]) giving the bound

$$\|(\lambda I - B)^{-1}\|_{Z\to Z} \le M'' \quad \text{for some } M'' > 0.$$

Hence for all $\Re\lambda \ge -\min\{b, \varepsilon\}$,

$$\|(\lambda - B)^{-1}\|_{Z\to Z} \le \max\{2M', M''\},$$

and we may apply Theorem 4.3. ∎

5. Prelude to nonlinear stability. We need three results about our system before we can prove Theorem 1.1. First, we establish a criterion for when a decomposition of ϕ into a modulating solitary wave and a perturbation is possible. Then we derive equations for the evolution of the parameters associated with this modulating solitary wave. Finally, we relate the H^1 norm to the H^1_a norm of the perturbation.

5.1. Local existence of decomposition and continuation principles. In analyzing the weighted perturbation w, we wish to treat the nonlinear terms perturbatively, with the leading order behavior governed by the linear operator A_a. As noted in Proposition 3.23, the operator has a two-dimensional kernel. To prevent the appearance of secular terms, the perturbation must be orthogonal to $\ker_g(A_a^\star)$; this reveals how the decomposition of ϕ into a perturbation and a modulated solitary wave, (2.28), occurs. This follows the strategy of [26] and [21].

PROPOSITION 5.1. *Let $c_0 > n$, $a \le a_\star(c_0)$, and $t_1 > 0$. Given $\delta_1 > 0$, there exists $\delta_0 > 0$ such that for any $\phi - 1 \in C^1([0,t_1]; H^1 \cap H^1_a)$ satisfying*

$$\sup_{t\le t_1} \|e^{a(\cdot+\theta_0)}(\phi(\cdot,t) - \phi_{c_0}(\cdot - c_0 t + \theta_0))\|_{H^1} \le \delta_0 \quad \text{for some } \theta_0 \in \mathbb{R} \tag{5.1}$$

there exists a unique mapping $t \mapsto (\theta(t), c(t))$ in $C^1([0,t_1];\mathbb{R}^2)$ such that

$$\sup|\theta(t) - \theta_0| + \sup|\dot\theta(t)| + \sup|c(t) - c_0| + \sup|\dot c(t)| \le \delta_1, \quad t \le t_1, \tag{5.2}$$

$$\mathcal{T}_k[\phi - 1, \theta, c] = \left\langle \phi(x,t) - \phi_{c(t)}(y), \tilde\eta_j(y)\right\rangle = 0 \quad \text{for } j = 1,2 \text{ and } t \in [0,t_1], \tag{5.3}$$

where $y = x - \int_0^t c(s)ds + \theta(t)$.

The number δ_0 may be chosen as a decreasing function of t_1.

Proof. The proof is via the implicit function theorem. In this context, the Banach spaces are $C^1([0,t_1]; H^1_a)$ and $C^1([0,t_1];\mathbb{R}^2)$, the latter space equipped with the norm

$$\sup_{t\le t_1}|\theta(t)| + \sup_{t\le t_1}|\dot\theta(t)| + \sup_{t\le t_1}|c(t)| + \sup_{t\le t_1}|\dot c(t)|.$$

The functional is

$$\mathcal{T} = (\mathcal{T}_1, \mathcal{T}_2)^T : C^1([0,t_1]; H^1_a) \times C^1([0,t_1];\mathbb{R}^2) \to C^1([0,t_1];\mathbb{R}^2),$$

and it is C^1 in its arguments, permitting the use of the implicit function theorem.

Setting

$$\mathbf{U}_0 = (\phi_{c_0}(x - c_0 t) - 1, \quad 0, \quad c_0)$$

we see $\mathcal{T}[\mathbf{U}_0] = 0$. The Fréchet derivative at $\mathbf{U}_0$ is

$$\begin{aligned} &D\mathcal{T}[\mathbf{U}_0]\,(\delta\phi, \quad \delta\theta, \quad \delta c) \\ &\quad = \begin{pmatrix} \left\langle e^{a(x-c_0t)}\delta\phi(x,t), \eta_1(x-c_0t)\right\rangle - \int_0^1 \delta c(s)ds + \delta\theta(t) \\ \left\langle e^{a(x-c_0t)}\delta\phi(x,t), \eta_2(x-c_0t)\right\rangle + \delta c(t) \end{pmatrix}. \end{aligned} \tag{5.4}$$

The derivative acting on the (θ, c) is $\left(\begin{smallmatrix} I & -B \\ 0 & I \end{smallmatrix}\right)$, $(Bf)(t) = \int_0^t f(s)ds$. This block operator has a bounded inverse on $C^1([0,t_1];\mathbb{R}^2) \to C^1([0,t_1];\mathbb{R}^2)$. By the implicit function theorem, there exists $\delta_0 > 0$, such that if

$$\sup_{t\le t_1}\|\phi(\cdot - \theta_0, t) - \phi_{c_0}(\cdot - c_0 t)\|_{H^1_a} < \delta_0 \quad \text{for some } \theta_0 \in \mathbb{R},$$

then there exists a mapping in $C^1([0,t_1];\mathbb{R}^2)$, $t \mapsto (\tilde{\theta}(t), c(t))$, satisfying

$$\sup|\tilde{\theta}(t)| + \sup|\dot{\tilde{\theta}}(t)| + \sup|c(t)-c_0| + \sup|\dot{c}(t)| < \delta_1 \quad \text{for } t \le t_1,$$
$$\mathcal{T}[\phi(\cdot - \theta_0, t)) - 1, \tilde{\theta}(t), c(t)] = 0 \quad \text{for } t \le t_1.$$

Defining $\theta(t) = \tilde{\theta}(t) + \theta_0$, and applying the change of variables $x \mapsto \tilde{x} + \theta_0$, we obtain the form given in (5.1), (5.2), and (5.3).

Finally, because our norms are taken as the supremum over $t \le t_1$, if δ_0 works for t_1, then it will also work for any $t_2 \le t_1$. This allows δ_0 to be constructed as a decreasing function of t_1. ∎

PROPOSITION 5.2. *Let $c_0 > n$, $a \le a_\star(c_0)$ and assume $\phi - 1 \in C^1([0,T_{\max}]; H^1 \cap H^1_a)$, $T_{\max} > 0$ solves* (1.2).

Given $\delta_1 > 0$, there exist $\delta_0 > 0$ and $\delta_0' > 0$, such that for any $t_0 \in [0, T_{\max})$, if the decomposition of ϕ, $v(y,t) = \phi(x,t) - \phi_{c(t)}(y)$, $y = x - \int_0^t c(s)ds + \theta(t)$, and $(\theta, c) \in C^1([0,t_0];\mathbb{R}^2)$ satisfies

$$\sup_{t \le t_0} \|v(t)\|_{H^1_a} \le \delta_0/3, \tag{5.5}$$

$$\sup_{t \le t_0} |c(t) - c_0| \le \delta_0', \tag{5.6}$$

$$\mathcal{T}[\phi - 1, \theta, c](t) = 0 \quad \textit{for } t \in [0, t_0], \tag{5.7}$$

then there is a unique extension of (θ, c) in $C^1([0, t_0 + t_\star];\mathbb{R}^2)$ for some $t_\star > 0$ such that

$$\mathcal{T}[\phi - 1, \theta, c](t) = 0 \quad \textit{for } t \le t_0 + t_\star \le T_{\max}, \tag{5.8}$$

$$\begin{aligned} &\sup|\theta(t) - \theta(t_0)| + \sup|\dot{\theta}(t)| \\ &\quad + \sup|c(t) - c(t_0)| + \sup|\dot{c}(t)| \le \delta_1, \quad t \in [t_0, t_0 + t_\star]. \end{aligned} \tag{5.9}$$

Proof. This follows the proof of Proposition 5.2 in [28], although we are forced to modify it as we do not know a priori that a solution exists for all time.

Given δ_1, let $\delta_0 > 0$ be the value from Proposition 5.1 with $t_1 = \frac{1}{2}(T_{\max} - t_0)$. Set $\tilde{\phi}(x,t) = \phi(x, t + t_0)$, $\theta_1 = -\int_0^{t_0} c(s)ds + \theta(t_0)$. Let δ_0' be sufficiently small such that

$$\|\phi_{c'} - \phi_{c_0}\|_{H^1 \cap H^1_a} \le \delta_0/3 \quad \text{for all } c' \text{ such that} \quad |c' - c_0| \le \delta_0'. \tag{5.10}$$

Then, since

$$\begin{aligned} \left\| e^{a(\cdot+\theta_1)} \left(\tilde{\phi}(0) - \phi_{c_0}(\cdot + \theta_1) \right) \right\|_{H^1} &\le \left\| e^{a(\cdot+\theta_1)} \left(\tilde{\phi}(0) - \phi_{c_1}(\cdot + \theta_1) \right) \right\|_{H^1} \\ &\quad + \| e^{a(\cdot+\theta_1)} \left(\phi_{c_1}(\cdot + \theta_1) - \phi_{c_0}(\cdot + \theta_1) \right) \|_{H^1} \\ &= \|v(t_0)\|_{H^1_a} + \|\phi_{c_1} - \phi_{c_0}\|_{H^1_a} \le \frac{2}{3}\delta_0, \end{aligned}$$

we have

$$\begin{aligned} \left\| e^{a(\cdot+\theta_1)} \left(\tilde{\phi}(t) - \phi_{c_0}(\cdot - c_0 t + \theta_1) \right) \right\|_{H^1} &\le \left\| e^{a(\cdot+\theta_1)} \left(\tilde{\phi}(t) - \tilde{\phi}(0) \right) \right\|_{H^1} + \frac{2}{3}\delta_0 \\ &= e^{a\theta_1} \|\phi(t + t_0) - \phi(t_0)\|_{H^1 \cap H^1_a} + \frac{2}{3}\delta_0. \end{aligned}$$

As ϕ is continuous in time, there exists a $t_\star \le t_1$, such that

$$\sup_{t\le t_\star} \|e^{a(\cdot+\theta_1)}\left(\tilde\phi(t) - \phi_{c_0}(\cdot - c_0 t + \theta_1)\right)\|_{H^1} \le \delta_0.$$

Therefore, $\tilde\phi$ satisfies the hypotheses of Proposition 5.1. We have a unique $(\tilde\theta(t), \tilde c(t))$ with $(\tilde\theta(0), \tilde c(0)) = (\theta(t_0), c(t_0))$. This gives us the extension $(\theta(t), c(t)) = (\tilde\theta(t - t_0) - \theta_0 + \theta(t_0), \tilde c(t - t_0))$ for $t \in [t_0, t_0 + t_\star]$ and (5.9) will hold. ∎

5.2. Modulation equations. Given that the perturbation must be orthogonal to $\ker_{\mathrm{g}}(A_a^\star)$, the associated constraints give a pair of ODEs, coupled to the perturbation, giving a complete system of three equations for the three dependent variables.

Let P denote the projection onto $\ker_{\mathrm{g}}(A_a^\star)$. Assuming this space is two-dimensional, we use the biorthogonal bases given in Proposition 3.23 to define projection onto this space and its complement,

$$P = \langle \eta_1, \cdot\rangle\, \xi_1 + \langle \eta_2, \cdot\rangle\, \xi_2, \tag{5.11}$$

$$Q = I - P. \tag{5.12}$$

The secular terms are excised from the perturbation equation, (2.36), by requiring that

$$w_\tau = A_a w + Q\mathcal{G}, \tag{5.13}$$

$$P\mathcal{G} = 0, \tag{5.14}$$

$$Pw(\tau = 0) = 0. \tag{5.15}$$

Constraint (5.14) corresponds to

$$\langle \eta_j, \mathcal{G}\rangle = 0 \quad \text{for } j = 1, 2. \tag{5.16}$$

These two equations govern $c(t)$ and $\theta(t)$, completing our system.

Defining $p_1(y,t) = \partial_y \phi_{c(t)}(y) - \partial_y \phi_{c_0}(y)$ and $p_2(y,t) = \partial_c \phi_{c(t)}(y) - \partial_c \phi_{c_0}(y)$, the derived system is

(5.17)

$$\begin{pmatrix} 1 + \langle \tilde\eta_1, p_1\rangle & \langle \tilde\eta_1, p_2\rangle \\ \langle \tilde\eta_2, p_1\rangle & 1 + \langle \tilde\eta_2, p_2\rangle \end{pmatrix} \begin{pmatrix} \dot\theta \\ \dot c \end{pmatrix} = \frac{c - \dot\theta}{c_0} \begin{pmatrix} \left\langle \eta_1, S_a[c_0, c, \dot\theta] w \right\rangle \\ \left\langle \eta_2, S_a[c_0, c, \dot\theta] w \right\rangle \end{pmatrix} + \begin{pmatrix} \langle \eta_1, \mathcal{G}_1\rangle \\ \langle \eta_2, \mathcal{G}_1\rangle \end{pmatrix}.$$

However, the right-hand side still has $\dot\theta$ dependence. Observe that

(5.18)

$$\begin{aligned} \frac{c - \dot\theta}{c_0} S_a[c_0, c, \dot\theta] w = {} & cm \left[\partial_y \log\left(\frac{\phi_{c_0}}{\phi_c}\right)\right] w - \dot\theta m \partial_y \log(\phi_{c_0})\, w \\ & + \Big[\frac{c}{c_0} n \phi_{c_0}^m H_{\phi_{c_0},a}^{-1} D_a \left[\left(\phi_{c_0}^{-1} - c_0(\phi_{c_0}^{-1} - 1)\right)\cdot\right] \\ & \quad - n\phi_c^m H_{\phi_c,a}^{-1} D_a \left[\left(\phi_c^{-1} - c(\phi_c^{-1} - 1)\right)\cdot\right]\Big] w \\ & - \frac{\dot\theta}{c_0} \phi_{c_0}^m H_{\phi_{c_0},a}^{-1} D_a \left[\left(\phi_{c_0}^{-1} - c_0(\phi_{c_0}^{-1} - 1)\right)\cdot\right] w \\ & - cm \left[\phi_{c_0}^m H_{\phi_{c_0},a}^{-1} \left[\partial_y (\log \phi_{c_0})\,\cdot\right] - \phi_c^m \mathcal{H}_{\phi_c,a}^{-1} \left[\partial_y (\log \phi_c)\,\cdot\right]\right] w \\ & + \dot\theta m \phi_{c_0}^m H_{\phi_{c_0},a}^{-1} \left[\partial_y (\log \phi_{c_0})\,\cdot\right] w. \end{aligned}$$

Defining

$$\widetilde{S}_a = \widetilde{S}_a^1 + \widetilde{S}_a^2 + \widetilde{S}_a^3, \tag{5.19}$$

$$\widetilde{S}_a^1 = cm\left(\phi_{c_0}^{-1}\partial_y\phi_{c_0} - \phi_c^{-1}\partial_y\phi_c\right), \tag{5.20}$$

$$\begin{aligned}\widetilde{S}_a^2 = n\Big\{ &\frac{c}{c_0}\phi_{c_0}^m H_{\phi_{c_0},a}^{-1} D_a\left[\left(\phi_{c_0}^{-1} - c_0(\phi_{c_0}^{-1}-1)\right)\cdot\right] \\ &- \phi_c^m H_{\phi_c,a}^{-1} D_a\left[\left(\phi_c^{-1} - c(\phi_c^{-1}-1)\right)\cdot\right]\Big\},\end{aligned} \tag{5.21}$$

$$\widetilde{S}_a^3 = -cm\left[\phi_{c_0}^m H_{\phi_{c_0},a}^{-1}\left(\phi_{c_0}^{-1}\partial_y\phi_{c_0}\cdot\right) - \phi_c^m H_{\phi_c,a}^{-1}\left(\phi_c^{-1}\partial_y\phi_c\cdot\right)\right], \tag{5.22}$$

and

$$\begin{aligned}T_a = &-m\phi_{c_0}^{-1}\partial_y\phi_{c_0} - {c_0}^{-1}\phi_{c_0}^m H_{\phi_{c_0},a}^{-1} D_a\left[\left(\phi_{c_0}^{-1} - c_0(\phi_{c_0}^{-1}-1)\right)\cdot\right] \\ &+ m\phi_{c_0}^m H_{\phi_{c_0},a}^{-1}\left(\phi_{c_0}^{-1}\partial_y\phi_{c_0}\cdot\right),\end{aligned} \tag{5.23}$$

the right-hand side of (5.17) may be written as

$$\begin{pmatrix}\left\langle \eta_1, \widetilde{S}_a w\right\rangle \\ \left\langle \eta_2, \widetilde{S}_a w\right\rangle\end{pmatrix} + \dot\theta\begin{pmatrix}\langle \eta_1, T_a w\rangle \\ \langle \eta_2, T_a w\rangle\end{pmatrix} + \begin{pmatrix}\langle \eta_1, \mathcal{G}_1\rangle \\ \langle \eta_2, \mathcal{G}_1\rangle\end{pmatrix}.$$

Equation(5.17) may be solved algebraically so that $\dot\theta$ appears only on the left-hand side,

$$\begin{aligned}\mathcal{B}(t)\begin{pmatrix}\dot\theta \\ \dot c\end{pmatrix} &= \begin{pmatrix}1 + \langle\tilde\eta_1, p_1\rangle - \langle \eta_1, T_a w\rangle & \langle\tilde\eta_1, p_2\rangle \\ \langle\tilde\eta_2, p_1\rangle - \langle \eta_2, T_a w\rangle & 1 + \langle\tilde\eta_2, p_2\rangle\end{pmatrix}\begin{pmatrix}\dot\theta \\ \dot c\end{pmatrix} \\ &= \begin{pmatrix}\left\langle \eta_1, \widetilde{S}_a w\right\rangle \\ \left\langle \eta_2, \widetilde{S}_a w\right\rangle\end{pmatrix} + \begin{pmatrix}\langle \eta_1, \mathcal{G}_1\rangle \\ \langle \eta_2, \mathcal{G}_1\rangle\end{pmatrix},\end{aligned} \tag{5.24}$$

where $\mathcal{B}(t) = I + O(|c(t)-c_0|) + O(\|w\|_{L^2})$; for sufficiently small $|c(t)-c_0| + \|w\|_{L^2}$, $\mathcal{B}$ is invertible. Thus we have equations for $\dot\theta$ and $\dot c$, closing the system for (v, c, θ).

Remark 5.3. In (5.24), we see that when $\mathcal{B}(t)$ is inverted, the right-hand side of the system is continuous in t. Therefore, provided $c(t)$, $\theta(t)$, and $w(t)$ are continuous in t, $c(t)$ and $\theta(t)$ will actually be C^1.

5.3. Lyapunov bound. Using the functional $\mathcal{N}[\phi]$, defined in (2.8), we have the following.

PROPOSITION 5.4. *Let $c_0 > n$, $a \le a_\star(c_0)$, and let $\phi(x,t)$ be a solution to* (1.2) *in $C^1([0,T]; H^1 \cap H_a^1)$ with data*

$$\phi_0 = \phi_{c_0}(x+\theta_0) + v_0(x), \quad \theta_0 \in \mathbb{R}.$$

Assume the decomposition $\phi(x,t) \to (v(y,t), \theta(t), c(t))$ exists for $t \le T$ and

$$|c(t)-c_0| + \|v(\cdot,t)\|_{H^1} \le \delta_1 < 1 \quad \text{for } t \le T,$$

$$\partial_c \mathcal{N}[\phi_c]\Big|_{c=c_0} \neq 0.$$

Then there exist constants K and K' such that

$$\begin{aligned}\|v\|_{H^1}^2\left(1-K'\|v\|_{H^1}\right) \le K\Big(&|\Delta\mathcal{N}| + \|w\|_{L^2} + \|w\|_{L^2}^2 \\ &+ |c(t)-c_0| + |c(t)-c_0|^2 + |c(t)-c_0|^3\Big),\end{aligned} \tag{5.25}$$

$$\Delta\mathcal{N} = \mathcal{N}[\phi_{c(t)}+v] - \mathcal{N}[\phi_{c_0}].$$

Remark 5.5. This proposition, which relates the unweighted norm of the perturbation to the weighted norm, is where the invariance of $\mathcal{N}$ is particularly useful. In [29], the Boussinesq equations lacked such an invariant; thus, only linear stability was proven. Strictly speaking, it would be sufficient for $\Delta\mathcal{N}$ to be bounded in terms of the data; the conservation of $\mathcal{N}$ is not essential, though it is helpful.

Proof. Taylor expanding $\mathcal{N}$ about a solitary wave with perturbation z, we obtain

$$\mathcal{N}[\phi_{c_0}+z] = \mathcal{N}[\phi_{c_0}] + \langle \delta\mathcal{N}[\phi_{c_0}], z\rangle + \frac{1}{2}\left\langle \delta^2\mathcal{N}[\phi_{c_0}]z, z\right\rangle + O(\|z\|_{H^1}^3).$$

From [38], the first and second variations are

$$\begin{aligned}\langle \delta\mathcal{N}[\phi_{c_0}], z\rangle &= \int\left(\frac{1-\phi_{c_0}^{1-n-m}}{n+m-1} + m\phi_{c_0}^{-2m-1}\left(\partial_x\phi_{c_0}\right)^2 - \partial_x^2\phi_{c_0}^{-2m}\phi_{c_0}\right) z\,dx \\ &= \Theta^{-1}\left\langle\tilde{\eta}_2, z\right\rangle,\end{aligned} \tag{5.26}$$

$$\begin{aligned}\left\langle \delta^2\mathcal{N}[\phi_{c_0}]z, z\right\rangle = &\int\left(\phi_{c_0}^{-n-m} - m(1+2m)\phi_{c_0}^{-2m-2}\left(\partial_x\phi_{c_0}\right)^2\right) z^2\,dx \\ &+ \int\left(2m\phi_{c_0}^{-2m-1}\partial_x^2\phi_{c_0}\right) z^2\,dx + \int\phi_{c_0}^{-2m}\left(\partial_x z\right)^2 dx,\end{aligned} \tag{5.27}$$

where $\tilde{\eta}_2$ and Θ are as defined in Proposition 3.23.

Take $z(y,t) = \phi_{c(t)}(y) - \phi_{c_0}(y) + v(y,t) = \phi(x,t) - \phi_{c_0}(y)$. Then

$$\begin{aligned}\langle \delta\mathcal{N}[\phi_{c_0}], z\rangle &= \left\langle \Theta^{-1}\tilde{\eta}_2, z(y,t)\right\rangle \\ &= \Theta^{-1}\left\langle\tilde{\eta}_2, \phi_{c(t)}(y) - \phi_{c_0}(y)\right\rangle + \Theta^{-1}\left\langle\tilde{\eta}_2, v(y,t)\right\rangle.\end{aligned} \tag{5.28}$$

Using the continuity of $c \mapsto \phi_c - 1$,

$$\Theta^{-1}\left\langle\tilde{\eta}_2, \phi_{c(t)}(y) - \phi_{c_0}(y)\right\rangle \le K|c(t)-c_0|. \tag{5.29}$$

The term with the perturbation, v, may be bounded by

$$\Theta^{-1}\left\langle\tilde{\eta}_2, v(y,t)\right\rangle = \Theta^{-1}\left\langle\eta_2, w(y,t)\right\rangle \le \Theta^{-1}\|\eta_2\|_{L^2}\|w\|_{L^2} \le K\|w\|_{L^2}. \tag{5.30}$$

Now we bound the second variation. For brevity, let

$$\Phi_{c_0} = -m(1+2m)\phi_{c_0}^{-2m-2}\left(\partial_x\phi_{c_0}\right)^2 + 2m\phi_{c_0}^{-2m-1}\partial_x^2\phi_{c_0}.$$

Then

$$\begin{aligned}\left\langle \delta^2\mathcal{N}[\phi_{c_0}]z, z\right\rangle &= \int\phi_{c_0}^{-2m}\left(\partial_x z\right)^2 + \phi_{c_0}^{-n-m}z^2 + \int\Phi_{c_0}z^2 \\ &\ge K\|z\|_{H^1}^2 + \left\langle\Phi_{c_0}, \left(\phi_{c(t)}-\phi_{c_0}\right)^2\right\rangle \\ &\quad + 2\left\langle\Phi_{c_0}, \left(\phi_{c(t)}-\phi_{c_0}\right)v\right\rangle + \left\langle\Phi_{c_0}, v^2\right\rangle \\ &\ge K_1\|v\|_{H^1}^2 - K_2|c(t)-c_0|^2 \\ &\quad - K_3|c(t)-c_0| - K_4\left\langle\Phi_{c_0}e^{-ay}, w^2\right\rangle.\end{aligned} \tag{5.31}$$

We would like $\Phi_{c_0} e^{-2ay} \in L^\infty$, so that the last term may be estimated by $\|w\|_{L^2}^2$. Since $a \leq a_\star(\gamma) < \frac{1}{2}\gamma$, we may do this.

Lastly, we have the remainder term $\mathcal{R}[\phi_{c_0}, z]$. Because of the a priori bound on $\|v\|_{H^1}$, this may be estimated as

$$|\mathcal{R}[\phi_{c_0}, z]| \leq K\|z\|_{H^1}^3 \leq K\left(|c(t)-c_0|^3 + \|v\|_{H^1}^3\right). \tag{5.32}$$

Combining these estimates, (5.29), (5.30), (5.31), and (5.32), gives us

$$\begin{aligned}\|v\|_{H^1}^2(1 - D\|v\|_{H^1}) \leq K&\left(|\Delta\mathcal{N}| + |c(t)-c_0| + |c(t)-c_0|^2 + |c(t)-c_0|^3\right)\\ &+ K\left(\|w\|_{L^2} + \|w\|_{L^2}^2\right). \qquad \square\end{aligned}$$

6. Proof of main results. Before proving Theorem 1.1, we make an a priori estimate.

6.1. A priori estimates.

PROPOSITION 6.1. *Let $c_0 > n$, $a \leq a_\star(c_0)$, and assume there exists $\varepsilon > 0$ such that*

$$\sigma(A_a) \cap \{\Re\lambda \geq -\varepsilon\} = \{0\}, \quad \lambda = 0 \text{ is an eigenvalue of algebraic multiplicity two.}$$

Let $T > 0$. There exist $\delta_\star \in (0,1)$ and $K_\star \geq 1$ such that if the $\phi(x,t) - 1 \in C^1\left([0,T]; H^1 \cap H^1_a\right)$ solves (1.2) and satisfies, for $t \leq T$,

$$\inf_x \phi(x,t) \geq \alpha_0 > 0, \tag{6.1}$$

$$\inf_x \phi(x,t)^m - a^2\phi(x,t)^n \geq \beta_0 > 0, \tag{6.2}$$

and furthermore

(i) *the decomposition $\phi(x,t) \mapsto (v(y,t), c(t), \theta(t))$ exists for $t \leq T$;*

(ii) *for $t \leq T$*

$$\begin{aligned}&\sqrt{|\Delta\mathcal{N}|} + \sqrt{\|w(t)\|_{H^1}} + \sqrt{|c(t)-c_0|}\\ &\quad + |\theta(t)-\theta_0| + \left|1 - \frac{c_0}{c(t)-\dot\theta(t)}\right| + \|v(t)\|_{H^1} \leq \delta_\star;\end{aligned} \tag{6.3}$$

(iii) *the data satisfies*

$$\sqrt{|c(0)-c_0|} + |\theta(0)-\theta_0| + \sqrt{|\Delta\mathcal{N}|} + \sqrt{\|w(0)\|_{H^1}} \leq \epsilon < \delta_\star; \tag{6.4}$$

then for $t \in [0,T]$,

$$\sqrt{e^{\kappa t}\|w(t)\|_{H^1}} + \sqrt{|c(t)-c_0|} + |\theta(t)-\theta_0| + \left|1 - \frac{c_0}{c(t)-\dot\theta(t)}\right| + \|v(t)\|_{H^1} \leq K_\star\epsilon, \tag{6.5}$$

with $\kappa = \kappa(\alpha_0, \beta_0, \delta_\star) \in (0, b_{\max})$.

Proof. The strategy for proving this proposition is to show that the left-hand side of (6.5) may be estimated in terms of their data, (6.4), using (6.3). This largely follows the proof in [21], with a few changes. The need to estimate $|1 - c_0/(c-\dot\theta)|$ in terms of the data will require use of the modulation equations, (5.24), to control $\dot\theta$, and to control $\|w\|_{H^1}$, we will need to work in τ-time. Thus we make the following estimates.

Temporal change of variables. First, let us assume that $\delta_\star \leq \frac{1}{2}$. Then, since $c_0 > n > 1$, $\frac{1}{2}c_0 \leq c(t) \leq \frac{3}{2}c_0$. Furthermore, this initial choice of $\delta_\star$ ensures

$$\frac{1}{2} \leq \frac{c_0}{c(t) - \dot{\theta}(t)} = \frac{d\tau}{dt} \leq \frac{3}{2},$$

so the change of variables $\tau = \tau(t)$ is well defined.

Time derivatives of modulation parameters. Examining (5.24), $\mathcal{B}(t) = I + O(|c(t) - c_0|) + O(\|w\|_{L^2})$; so there exists $\delta_{\mathcal{B}} > 0$ such that for $\delta_\star \leq \delta_{\mathcal{B}}$, $\mathcal{B}(t)$ will be invertible. Therefore

(6.6)
$$|\dot{\theta}(t)| + |\dot{c}(t)| \leq |\mathcal{B}(t)^{-1}| \left(\|\widetilde{S}_a w\|_{L^2} + \|\mathcal{G}_1\|_{L^2} \right)_{L^2} \leq K_1 \left(|c - c_0| + \|v\|_{H^1} \right) \|w\|_{L^2},$$

permitting the estimate

$$|\dot{\theta}(t)| + |\dot{c}(t)| \leq K_1 \delta_\star^3. \tag{6.7}$$

As terms of the form $1/(c - \dot{\theta})$ will appear, we will assume that

$$\delta_\star \leq \left(\frac{1}{2K_1} \right)^{1/3} = \delta_\theta,$$

so $|\dot{\theta}| \leq \frac{1}{2}$, and this quotient will be well defined and bounded.

Weighted perturbation. In τ-time, $\|w(\tau)\|_{H^1}$ is

$$w(\tau) = e^{A_a \tau} w(\tau(t = 0)) + \int_{\tau(0)}^{\tau} e^{A_a(\tau - s)} Q\mathcal{G}(s) ds.$$

By the semigroup decay estimate of Theorem 4.1, there exist $K_2 > 0$ and $b_{\max} > 0$ such that

$$\|w(\tau)\|_{H^1} \leq K_2 e^{-b\tau} \|w(\tau(0))\|_{H^1} + K_2 \int_{\tau(0)}^{\tau} e^{-b(\tau - s)} \|Q\mathcal{G}(s)\|_{H^1} ds$$

for any $b \in (0, b_{\max})$. Estimating $\mathcal{G}$, we obtain

$$\begin{aligned} \|\mathcal{G}\|_{H^1} &\leq K \left[\left| \frac{c_0}{c - \dot{\theta}} \right| \left(|\dot{\theta}| + |\dot{c}| \right) + \left(|c - c_0| + \left| 1 - \frac{c_0}{c - \dot{\theta}} \right| \right) \|w\|_{H^1} \right] \\ &\quad + K \left[\left| \frac{c_0}{c - \dot{\theta}} \right| \|v\|_{H^1} \|w\|_{H^1} \right] \\ &\leq K_3 \delta_\star \|w\|_{H^1}. \end{aligned} \tag{6.8}$$

We have made use of (6.6) to control $\dot{\theta}$ and $\dot{c}$ in terms of $\|w\|_{H^1}$.

Therefore,

$$\|w(\tau)\|_{H^1} \leq K_2 e^{-b\tau} \|w(\tau(0))\|_{H^1} + K_2 K_3 \delta_\star \int_{\tau(0)}^{\tau} e^{-b(\tau - s)} \|w(s)\|_{H^1} ds. \tag{6.9}$$

Defining $\psi(s) = e^{bs} \|w(s)\|_{H^1}$, (6.9) becomes

$$\psi(\tau) \leq K_2 \|w(0)\|_{H^1} + K_2 K_3 \delta_\star \int_{\tau(0)}^{\tau} \psi(s) ds,$$

for which we may apply Gronwall's inequality to get

$$\|w(\tau)\|_{H^1} \leq K_2 \|w(\tau(0))\|_{H^1} e^{-(b-K_2K_3\delta_\star)(\tau-\tau(0))}. \tag{6.10}$$

So for $\delta_\star$ small enough, $b - K_2K_3\delta_\star > 0$ and we induce decay in the H^1 norm of w. In particular, suppose that $\delta_\star \leq \delta_b = \frac{1}{2}b/(K_2K_3)$ and let

$$b' = b - K_2K_3\delta_\star.$$

We then return to t-time,

$$\tau - \tau(0) = \frac{1}{c_0}\int_0^t c(s)ds + \frac{1}{c_0}\left(\theta(0) - \theta(t)\right) \geq \frac{1}{c_0}\left(c_0 - \delta_\star\right)t - 2\frac{\delta_\star}{c_0}.$$

Therefore,

$$\|w(t)\|_{H^1} \leq \tilde{K}_2 \|w(t=0)\|_{H^1} e^{-\kappa t} \tag{6.11}$$

with $\kappa = \frac{1}{2}b'$. We now have $e^{\kappa t}\|w\|_{H^1}$ estimated in terms of the data.

Unweighted perturbation. Applying this to Proposition 5.4, we have the estimate

$$\begin{aligned}
\|v(t)\|_{H^1} &\leq K\left(\sqrt{|\Delta\mathcal{N}|} + \sqrt{|c(t)-c_0|} + |c(t)-c_0| + |c(t)-c_0|^{3/2}\right) \\
&\quad + K\left(\sqrt{\|w(t)\|_{L^2}} + \|w(t)\|_{H^1}\right) \\
&\leq K\left(\sqrt{|\Delta\mathcal{N}|} + \sqrt{|c(t)-c_0|}(1+\delta_\star+\delta_\star^2) + \sqrt{\|w(t)\|_{L^2}}(1+\delta_\star)\right) \\
&\leq K\left(\sqrt{|\Delta\mathcal{N}|} + \sqrt{|c(t)-c_0|} + \sqrt{\|w(0)\|_{L^2}}\right).
\end{aligned} \tag{6.12}$$

If we had control of $\sqrt{|c(t)-c_0|}$, then we would also control $\|v(t)\|_{H^1}$ in terms of the data.

Deviation in c from c_0. Estimating $|c(t)-c_0|$ using (6.6) and (6.11), we get

$$\begin{aligned}
|c(t)-c_0| &\leq |c(0)-c_0| + \int_0^t |\dot{c}(s)|ds \leq |c(0)-c_0| \\
&\quad + \int_0^t K_1\left(|c(s)-c_0| + \|v(s)\|_{H^1}\right)\|w(s)\|_{L^2}ds \\
&\leq |c(0)-c_0| + K_1\delta_\star\int_0^t \|w(s)\|_{H^1}ds \leq |c(0)-c_0| \\
&\quad + K_1\delta_\star\int_0^t K_2\|w(t0)\|_{H^1}e^{-\kappa s}ds \\
&\leq |c(0)-c_0| + K_1K_2\delta_\star\|w(0)\|_{H^1}/\kappa.
\end{aligned}$$

So we now have $|c(t)-c_0|$ in terms of data, which we rewrite as

$$\sqrt{|c(t)-c_0|} \leq K_4\left(\sqrt{|c(0)-c_0|} + \sqrt{\|w(0\|_{H^1}}\right), \tag{6.13}$$

which in turn gives

$$\|v(t)\|_{H^1} \leq K_5\left(\sqrt{|\Delta\mathcal{N}|} + \sqrt{|c(0)-c_0|} + \sqrt{\|w(0)\|_{H^1}}\right). \tag{6.14}$$

Deviation in θ from θ_0. As with the speed parameter,

$$\begin{aligned}|\theta(t)-\theta_0| &\le |\theta(0)-\theta_0| + \int_0^t |\dot\theta(s)|ds \le |\theta(0)-\theta_0| \\ &\quad + \int_0^t K_1\left(|c(s)-c_0| + \|v(s)\|_{H^1}\right)\|w(s)\|_{L^2}ds \\ &\le |\theta(0)-\theta_0| + K_1\delta_\star\int_0^t \|w(s)\|_{H^1}ds \le |c(0)-c_0| \\ &\quad + K_1\delta_\star\int_0^t K_2\|w(t0)\|_{H^1}e^{-\kappa s}ds \\ &\le |\theta(0)-\theta_0| + K_1K_2\delta_\star\|w(0)\|_{H^1}/\kappa.\end{aligned}$$

This is rewritten as

$$|\theta(t)-\theta_0| \le K_7\left(|\theta(0)-\theta_0| + \sqrt{\|w(0\|_{H^1}}\right). \tag{6.15}$$

Another estimate on the temporal change of variables.

$$\left|1-\frac{c_0}{c-\dot\theta}\right| \le \frac{|c-c_0|+|\dot\theta|}{|c-\dot\theta|} \le 2\left(|c-c_0|+|\dot\theta|\right).$$

Then using (6.6) and (6.13)

$$\begin{aligned}\left|1-\frac{c_0}{c-\dot\theta}\right| &\le K\left(\sqrt{|c(0)-c_0|}+\|w(t)\|_{H^1}\right)K \le \left(|c(0)-c_0| + K_2\|w(0)\|_{H^1}\right) \\ &\le K_6\left(\sqrt{|c(0)-c_0|}+\sqrt{\|w(0)\|_{H^1}}\right).\end{aligned} \tag{6.16}$$

Combining (6.11), (6.13), (6.14), (6.15), and (6.16), we have (6.5) with $\delta_\star = \min\{\frac{1}{2}, \delta_{\mathcal{A}}, \delta_b, \delta_\tau, \delta_\theta\}$, $K_\star = \max\{\tilde K_2, K_4, K_5, K_6, K_7\}$. ∎

6.2. Main result. We now prove Theorem 1.1. Let $c_\star$ and $\hat\vartheta$ be as in Theorem 3.1 (b). Take $c_0 \in (n, c_\star]$ and $a \in (\gamma\hat\vartheta, a_\star(c_0)]$. By Theorem 3.1 (b), there exists $\varepsilon > 0$ such that the only eigenvalue of $A_{c_0,a}$ with $\Re\lambda \ge -\varepsilon$ is at the origin. Thus we satisfy the first assumption of Proposition 6.1.

Define $\mathcal{T}$ to be the set of nonnegative numbers, T, such that, given c_0, a, and $v_0 \in H^1 \cap H^1_a$,

- a solution exists, $\phi - 1 \in C([0,T), H^1 \cap H^1_a)$, satisfying

$$\inf_x \phi(x,t) \ge \frac{1}{4} = \alpha_0 > 0, \tag{6.17}$$

$$\inf_x\left(\phi(x,t)^m - a^2\phi(x,t)^n\right) \ge \frac{1}{4}\inf_x\left(\phi_{c_0}(x)^m - a^2\phi_{c_0}(x)^n\right) = \beta_0 > 0; \tag{6.18}$$

- a decomposition of ϕ into $(v(y(x,t),t), \theta(t), c(t))$ exists for $t \in [0,T)$;
- (6.3) holds for $t \in [0,T)$.

Set $T_* = \sup\mathcal{T}$. We will first show that there exists $\epsilon_* > 0$, such that for $\epsilon \le \epsilon_*$, if

$$\|v_0\|_{H^1} + \|v_0\|_{H^1_a} \le \epsilon,$$

then $T_* > 0$. This will be proved using the continuous dependence upon the data. Using Proposition 6.1, we will then prove $T_* = \infty$.

Let $\delta_\star$ and $K_\star$ be as in Proposition 6.1.

The most difficult part of the proof will be ensuring the persistence of (6.3). Consider that, at $t = 0$, the left-hand side of that equation may be estimated with

$$\begin{aligned}\mathrm{LHS}(t=0) \leq\ & |\Delta\mathcal{N}| + \|v_0\|_{H^1} + \|\partial_y \phi_{c_0}\|_{H^1}|\theta_0 - \theta(0)| \\ & + \sqrt{|c(0) - c_0|} + |\theta(0) - \theta_0| + \|\phi_{c_0} - \phi_{c(0)}\|_{H^1} \\ & + \left|1 - \frac{c_0}{c(0) - \dot\theta(0)}\right| + \sqrt{e^{a\theta(0)}\|v_0\|_{H^1_a}} \\ & + \sqrt{\|\partial_y \phi_{c_0}\|_{H^1_a}|\theta_0 - \theta(0)|} + \sqrt{\|\phi_{c_0} - \phi_{c(0)}\|_{H^1_a}}.\end{aligned} \tag{6.19}$$

There exists a choice of δ' and ϵ' such that if

$$|c(0) - c_0| + |\dot c(0)| + |\theta(0) - \theta_0| + |\dot\theta(0)| \leq \delta' \tag{6.20}$$

$$\|v_0\|_{H^1 \cap H^1_a} \leq \epsilon', \tag{6.21}$$

then the right-hand side of (6.19) will be bounded by $\frac{1}{2}\delta_\star$. Set $\delta_1 = \min\left\{\frac{1}{4}, \delta'\right\}$. From Propositions 5.1 and 5.2, let δ_0, δ_0' be the corresponding values for δ_1.

There exists $\epsilon_{\text{exist}} \in (0,1)$ such that if $\|v_0\|_{H^1 \cap H^1_a} \leq \epsilon_{\text{exist}}$, then

$$\begin{aligned}&\inf_x \left[\phi_{c_0}(x + \theta_0) + v_0(x)\right] \geq 2\alpha_0, \\ &\inf_x \left[\left(\phi_{c_0}(x + \theta_0) + v_0(x)\right)^m - a^2\left(\phi_{c_0}(x + \theta_0) + v_0(x)\right)^n\right] \geq 2\beta_0.\end{aligned}$$

By Theorem 2.1, there exist $t_1 > 0$ and a solution in $C^1([0, t_1], H^1 \cap H^1_a)$ satisfying (6.17) and (6.18). Furthermore, we will have the a priori $H^1 \cap H^1_a$ bound that

$$\sup_{t \leq t_1} \|\phi(t) - 1\|_{H^1 \cap H^1_a} \leq 2\|\phi_{c_0}(\cdot + \theta_0) + v_0 - 1\|_{H^1 \cap H^1_a} \leq 2(\|\phi_{c_0} - 1\| + 1).$$

Set

$$\epsilon_1 = \min\left\{\epsilon_{\text{exist}}, \epsilon', \frac{1}{2}e^{-a\theta_0}\delta_0\right\} \tag{6.22}$$

and let $\|v_0\| \leq \epsilon_1$. As noted, the solution exists, satisfying (6.17) and (6.18), until at least $t_1 > 0$. At $t = 0$,

$$\|e^{a(\cdot + \theta_0)}\left(\phi_0 - \phi_{c_0}(\cdot + \theta_0)\right\|_{H^1} \leq e^{a\theta_0}\|v_0\|_{H^1} \leq \frac{1}{2}\delta_0,$$

so by the continuity of ϕ in time, we have

$$\|e^{a(\cdot + \theta_0)}\left(\phi(t) - \phi_{c_0}(\cdot - c_0 t + \theta_0)\right\|_{H^1} \leq \delta_0 \quad \text{for some } t_2 \in (0, t_1).$$

Therefore the decomposition exists, with the δ_1 bound on the modulation parameters, up till $t_2 > 0$.

Also at $t = 0$, using the δ_1 bound on the parameters,

$$\sqrt{|\Delta\mathcal{N}|} + \sqrt{\|w(0)\|_{H^1}} + \sqrt{|c(0) - c_0|} + \left|1 - \frac{c_0}{c(0) - \dot\theta(0)}\right| + \|v(0)\|_{H^1} \leq \frac{1}{2}\delta_\star. \tag{6.23}$$

All of these terms are continuous in time, and there exists some $t_3 \in (0, t_2)2$, for which this remains smaller than $\delta_\star$. Therefore, for $\epsilon_* \le \epsilon_1$, $t_3 \in \mathcal{T}$ and $T_* > 0$.

Continuing to infinity. A few more constraints on ϵ_* are needed to continue out to $t = \infty$. There exists $\epsilon_{\alpha\beta}$ such that for $\epsilon \le \epsilon_{\alpha\beta}$, if

$$\sqrt{|c - c_0|} + \|v\|_{H^1} \le \epsilon,$$

then

$$\inf_y \left[\phi_c(y) + v(y)\right] \ge \alpha_0,$$
$$\inf_y \left[(\phi_c(y) + v_0(y))^m - a^2 (\phi_c(y) + v_0(y))^n\right] \ge \beta_0.$$

Let $\epsilon_2 > 0$ be so small that

$$K_\star \epsilon_2 = \min\left\{\frac{\delta_\star}{3}, \sqrt{\delta_0/3}, \sqrt{\delta_0'}, \frac{1}{2}\epsilon_{\alpha\beta}\right\} \tag{6.24}$$

and set

$$\epsilon_* = \min\left\{\epsilon_1, \epsilon_2\right\}. \tag{6.25}$$

Now, assume $\|v_0\|_{H^1 \cap H^1_a} \le \epsilon \le \epsilon_*$. As above, for this data we will have $T_* > 0$. Assume $T_* < \infty$. For any $T < T_*$, on the interval $[0, T]$, the solution exists with (6.17) and (6.18), as does the decomposition, and (6.3) holds.

Then

$$\begin{aligned}\|\phi(t) - 1\|_{H^1 \cap H^1_a} &\le \max\left\{1, e^{a\left(\int_0^t c(s)ds - \theta(t)\right)}\right\}\left(\|\phi_{c(t)} - 1\|_{H^1 \cap H^1_a} + \|v(t)\|_{H^1 \cap H^1_a}\right) \\ &\le e^{a((c_0+\delta_\star)T_* + |\theta_0| + \delta_\star)}\left(\sup_{|c-c_0|\le\delta_\star} \|\phi_c - 1\|_{H^1 \cap H^1_a} + \delta_\star + \delta_\star^2\right) < \infty,\end{aligned}$$

and this bound is uniform in $T < T_*$. By assumption, (6.17) and (6.18) hold for $t \in [0, T]$, uniformly in $T < T_*$, which may written as

$$\left\|\frac{1}{\phi(\cdot, t)}\right\|_{L^\infty} \le \frac{1}{\alpha_0} < \infty \quad \text{and} \quad \left\|\frac{1}{\phi(\cdot, t)^m - a^2\phi(\cdot, t)^n}\right\|_{L^\infty} \le \frac{1}{\beta_0} < \infty.$$

Therefore, according to (2.7), $\phi(x, t)$ may be extended beyond T_* by some amount $t_2 > 0$. Hence, if $T_* \ne \infty$, it must be a failure for either the decomposition to continue to exist or for (6.3) to hold.

Again using the Proposition 6.1 and our choice of ϵ_*,

$$\|w(\cdot, t)\|_{H^1_a} \le \delta_0/3 \quad \text{and} \quad |c(t) - c_0| \le \delta_0' \quad \text{for all } t \le T, \text{ uniformly in } T < T_*.$$

Since ϕ exists until at least $T_* + t_2$, we may apply Proposition 5.2 to extend the decomposition for some amount $t_\star \le t_2$ also beyond T_*.

By assumption,

$$\sqrt{|c(t) - c_0|} + \|v(t)\|_{H^1} \le K_\star \epsilon_* \le \frac{1}{2}\epsilon_{\alpha\beta} \quad \text{for } t < T_*.$$

Again, by continuity, these remain bounded by $\epsilon_{\alpha\beta}$ until some time $t_3 \in (0, t_\star)$ beyond T_*, so (6.17) and (6.18) also persist beyond T_*.

We may now apply Proposition 6.1 past T_*. This gives

$$\sqrt{\|w(\cdot,t)\|_{H^1}}+\sqrt{|c(t)-c_0|}+|\theta(t)-\theta_0|+\left|1-\frac{c_0}{c(t)-\dot\theta(t)}\right|+\|v(\cdot,t)\|_{H^1}\leq K_\star\epsilon_*\leq\frac{1}{3}\delta_\star$$

for $t\leq T<T_*$. As $\sqrt{|\Delta\mathcal{N}|}$ is time invariant and smaller than $\frac{1}{2}\delta_\star$,

$$\begin{aligned}\sqrt{|\Delta\mathcal{N}|}+\sqrt{\|w(\cdot,t)\|_{H^1}}+\sqrt{|c(t)-c_0|}+|\theta(t)-\theta_0|\\ +\left|1-\frac{c_0}{c(t)-\dot\theta(t)}\right|+\|v(\cdot,t)\|_{H^1}\leq K_\star\epsilon_*\leq\frac{5}{6}\delta_\star\end{aligned}$$

for $t\leq T$, uniformly in $T<T_*$. But all of these functions are continuous for $t\in[0,T_*+t_3]$; so for some $t_4>0$, this expression remains bounded by $\delta_\star$. This contradicts $T_*<\infty$. So a solution exists for all time satisfying (6.17), (6.18), along with a decomposition and (6.3).

Since we may then apply Proposition 6.1 for all time, we will always have (6.5). By virtue of $K_\star\epsilon_*<\delta_\star\leq\delta_{\mathcal{B}}$, we will be able to invert the matrix $\mathcal{B}(t)$ for the modulation equations, (5.24). Therefore $|\dot c(t)|+|\dot\theta(t)|\leq K\epsilon e^{-\kappa t}$ and

$$\lim_{t\to\infty}c(t)=c_\infty$$

exists, and if we define

$$\lim_{t\to\infty}\left(\theta(t)+\int_0^t(c(s)-c_\infty)\,ds\right)=\theta_\infty,$$

then

$$\begin{aligned}&\|\phi(\cdot,t)-\phi_{c_\infty}(\cdot-c_\infty t+\theta_\infty)\|_{H^1}\\ &\quad\leq K_\star\epsilon+\|\phi_{c_\infty}(\cdot-c_\infty t+\theta_\infty)-\phi_{c(t)}\left(\cdot-\textstyle\int_0^t c(s)ds+\theta(t)\right)\|_{H^1}\\ &\quad\leq K_\star\epsilon+K|c(t)-c_\infty|+\|\partial_y\phi_{c_\infty}\|_{H^1}\left|\theta(t)+\int_0^t(c(s)-c_\infty)\,ds-\theta_\infty\right|\\ &\quad\leq K_*\epsilon.\end{aligned}$$

Similarly

$$\|\phi(\cdot+c_\infty t-\theta_\infty,t)-\phi_{c_\infty}\|_{H^1_a}\leq K_*\epsilon e^{-\kappa t}.\qquad\square$$

6.3. Remarks. This proof is equally applicable in the Hamiltonian case, $n+m=0$, for values of c not in the discrete set, E, of points for which A_a has an imaginary eigenvalue.

7. Summary and discussion. We have thus shown that in the space $H^1\cap H^1_a$, the solitary waves are asymptotically stable. This dovetails with an extension of global existence to data in a neighborhood of the solitary waves. In the Hamiltonian case, we can extend it beyond $c_\star$ via analytic continuation, as was done in [21], and this is analytically verified for $n=2$, with computations in [40] suggesting it is true for all $n>1$. Furthermore, to the extent that we will accept a computation of the Evans function as proof, our result generalizes to large amplitude solitary waves with $c>c_\star$.

To our knowledge, this is the first result for which asymptotic stability is established for a conservative PDE in the absence of a variational principle.

Open problems include a weakening of the assumption of exponential decay on the perturbation. This might be accomplished through the use of an algebraic spatial weight, which would require the perturbation to decay algebraically rapidly. Yet less restrictive would be to use the approach of Merle and his colleagues [11, 18, 19, 22]. However, there is a tradeoff in both of these approaches: weakening the assumption on the spatial decay rate of the perturbation also weakens what can be proved about the rate at which the perturbation decays in time.

Finally we remark that the multidimensional case of (1.1) is wide open. While there is no existence theory for the two- and three-dimensional problems, perhaps a similar approach, of working in a neighborhood of a solitary wave, could be applied proving both existence and stability.

Appendix A. Properties of solitary waves.

A.1. Analyticity. Here we provide a proof of Corollary 2.9. Let us restate the crucial theorem.

THEOREM A.1 (Corollary 4.1.6 of [9]). *Suppose that f is a solution of the convolution equation $f = K * G(f)$ such that $f \in L^2 \cap L^\infty$ and $\lim_{|x|\to\infty} f(x) = 0$. If the Fourier transform $\hat{K}$ of the integral kernel K satisfies the decay condition $|\hat{K}(\xi)| \le A_1(1 + A_2|\xi|^m)$ for some constants $A_1, A_2 > 0$ and $m \ge 1$, and G is an infinitely differentiable function whose domain contains the range $R(f)$ of f, having all its derivatives bounded on $R(f)$ and satisfying the condition $G(0) = 0$, then $f, G(f) \in H^\infty$. In addition, if G is an analytic function on an open set U containing $R(f)$, G is continuous up to the boundary of ∂U of U, and*

$$\mathrm{d}\left(\partial U, R(f)\right) > \|K\|_{L^2}, \tag{A.1}$$

then there exists a constant $\sigma_0 > 0$ such that f and $G(f)$ both have analytic extensions to the strip $\{z \in \mathbb{C} : |\Im z| < \sigma_0\}$.

Let $u_c = \phi_c - 1$. By Theorem 2.6 and Corollary 2.7, u_c is positive, in $L^\infty \cap L^2$, and decays exponentially fast at $\pm\infty$. Using (2.14) and (2.15), the equation may be written as

$$-\gamma^2 u_c + \partial_x^2 u_c + \int_0^{u_c} \partial_\tau^3 F_2(1+\tau; c)\frac{(u_c + 1 - \tau)^2}{2} d\tau = 0. \tag{A.2}$$

Define

$$G(z) = \int_0^{z} \partial_\tau^3 F_2(1+\tau; c)\frac{(z + 1 - \tau)^2}{2} d\tau. \tag{A.3}$$

Taking a Fourier transform of (A.2), the equation is

$$-\gamma^2 \widehat{u_c}(\xi) - \xi^2 \widehat{u_c}(\xi) + \widehat{G(u_c)}(\xi) = 0.$$

This becomes the nonlinear convolution equation

$$u_c(x) = K * G(u_c)(x), \tag{A.4}$$

$$\hat{K}(\xi) = \frac{1}{\gamma^2 + \xi^2}. \tag{A.5}$$

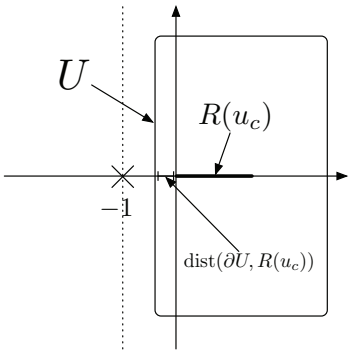

FIG. 6. *A plot of a possible domain U and the range of u_c, $R(u_c)$. Note that the distance between these sets as drawn is the distance into the left-hand side of the complex plane that U extends, and that any such ovoid will be acceptable as long as it stays to the right of $\Re z = -1$.*

For purposes of satisfying (A.1), let us take $\tilde{K}(x) = \alpha K(x)$ and $\tilde{G}(z) = \alpha^{-1} G(z)$ for $\alpha > 0$, where α is to be determined. Under this trivial scaling, $u_c = \tilde{K} * \tilde{G}(u_c)$.

$\widehat{\tilde{K}}$ satisfies the decay estimate for Theorem A.1. $\tilde{G}(z)$ will have a singularity at $z = -1$ but is otherwise analytic. The range of u_c is the finite segment

$$R(u_c) = [0, u_{\max}],$$

and $\tilde{G}$ is infinitely differential there, with all derivatives bounded. $G(0) = 0$. Hence, the first part of Theorem A.1 applies: u_c and $\tilde{G}(u_c)$ are in H^∞.

Now, consider the set U in Figure 6. In this figure, $\mathrm{d}(\partial U, R(u_c))$ is the distance U stretches into the left half-plane:

$$\|\tilde{K}\|_2 = \alpha \sqrt{\frac{\pi}{2}} \gamma^{-3/2}.$$

Picking α so small that the norm is less than 1, we can find a U such that the distance between ∂U and $R(u_c)$ exceeds $\|\tilde{K}\|_2$, satisfying (A.1) and proving analyticity in a strip. □

A.2. Continuity as a function of speed. Consider the functional

$$\mathcal{F}[c, u] = \partial_x^2 u + F_2(1 + u; c) \tag{A.6}$$

as a mapping from $H^2 \times \mathbb{R} \to L^2$. The solitary wave $u_c = \phi_c - 1$ satisfies $\mathcal{F}[c, u_c] = 0$. Using this functional, we prove Corollary 2.11 via the implicit function theorem. Given a particular $\hat{c} > n$, set $\hat{u} = u_{\hat{c}}$.

Let H^2_{even} and L^2_{even} be the subspaces of H^2 and L^2, respectively, of only even functions. Define the sets

$$M_0 = \left(\hat{c} - \frac{\hat{c} - n}{2}, \hat{c} + \frac{\hat{c} - n}{2} \right) \subset \mathbb{R},$$

$$N_0 = \left\{ u \in H^2_{\mathrm{even}} : \quad \|u - \hat{u}\|_{H^2} \leq \frac{1}{2} \right\} \subset H^2_{\mathrm{even}},$$

$$Z = L^2_{\mathrm{even}}.$$

Note that set M_0 is bounded away from zero and all of the functions in N_0 are uniformly bounded from below by $\frac{1}{2}$. Therefore $\mathcal{F}$ is well defined on $M_0 \times N_0$ and will be a C^1 mapping on this set into Z.

Set

$$T = \frac{\delta \mathcal{F}}{\delta c}[\hat{c}, \hat{u}] = \partial_c F_2(1+\hat{u}; \hat{c}),$$
$$S = \frac{\delta \mathcal{F}}{\delta u}[\hat{c}, \hat{u}] = \partial_x^2 + \partial_u F_2(1+\hat{u}; \hat{c}).$$

T and S are bounded operators on $\mathbb{R} \to L^2_{\text{even}}$ and $H^2_{\text{even}} \to L^2_{\text{even}}$, respectively.

Let $f \in L^2_{\text{even}}$ and consider the problem $Su = f$. As an elliptic problem, this has a solution, provided $f \perp \ker\left(S^\dagger\right)$. Note that $S\partial_x \hat{u} = 0$. S is self-adjoint, has smooth coefficients, and is in one spatial dimension; this is the unique element of the kernel. But $\partial_x \hat{u}$ is an odd function, hence f is orthogonal to it and the equation has a solution u satisfying a bound

$$\|u\|_{H^2} \leq K \|u\|_{L^2}.$$

Because the coefficients in S and the right-hand side, f, are all even functions, $\tilde{u}(x) = u(-x)$ also solves $Su = f$. By the uniqueness of the solution, $u = \tilde{u}$, so u is an even function. Therefore $u \in H^2_{\text{even}}$ and the map $S : H^2_{\text{even}} \to L^2_{\text{even}}$ is onto with bounded inverse.

The kernel of S, restricted to $u \in H^2_{\text{even}}$, is trivial, so the implicit function theorem may be applied to conclude the existence of a function $\mathcal{G} : M_1 \to H^2_{\text{even}}$, $\hat{c} \in M_1 \subset M_0$, such that

$$\mathcal{F}[c, \mathcal{G}(c)] = 0$$

for all $c \in M_1$. The mapping $\mathcal{G}$ is C^1. For any such c,

$$\partial_x^2 \mathcal{G}(c) + F_2(\mathcal{G}(c) + 1; c) = 0.$$

This is just the solitary wave equation. Therefore $\mathcal{G}(c) = u_c = \phi_c - 1$, and the mapping $c \mapsto \phi_c - 1$ is $C^1(\mathbb{R}; H^2)$. The analyticity of the mapping may be proven by checking the analyticity of $\mathcal{F}$ in a neighborhood of $(\hat{c}, \hat{u})$.

To prove continuity in $H^2 \cap H^2_a$, the proof is similar. Fixing $a < \frac{1}{2}$, and taking $\hat{c} \in (n/(1-4a^2), \infty)$, we let $M_a = M_0 \cap (n/(1-4a^2), \infty)$, $N_a = N_0 \cap H^2_a$, and $Z_a = Z \cap L^2_a$. We must check that $S : H^2_{\text{even}} \cap H^2_a \to L^2_{\text{even}} \cap L^2_a$ is onto with bounded inverse. This is accomplished using the previous result and studying $S_a = D_a^2 + \partial_u F_2(1+\hat{u}; \hat{c})$ on $H^2_{\text{even}} \to L^2_{\text{even}}$.

Appendix B. Perturbation expansions. Here we provide some explicit calculations, including those for Proposition 2.13.

Note the expansions

$$\phi^n = \phi_c^n + n\phi_c^{n-1} v + f_n[\phi_c, v]v,$$
$$\phi^m = \phi_c^m + m\phi_c^{m-1} v + f_m[\phi_c, v]v,$$
$$f_p[a,b] = \int_0^1 \left[p\,(a+\tau b)^{p-1} - pa^{p-1}\right] d\tau,$$

and

$$\begin{aligned} H_\phi^{-1} = H_{\phi_c}^{-1} - H_{\phi_c}^{-1} B\left[n\phi_c^{n-1}v + f_n[\phi_c,v]v, m\phi_c^{m-1}v + f_m[\phi_c,v]v\right] H_{\phi_c}^{-1} \\ + H_{\phi_c}^{-1} B[\phi^n - \phi_c^n, \phi^m - \phi_c^m]\left(H_\phi^{-1} - H_{\phi_c}^{-1}\right), \end{aligned} \tag{B.1}$$

$$B[a,b]u = -\partial_x\left(a\partial_x u\right) + bu. \tag{B.2}$$

Recall (1.2),

$$\partial_t\phi = \dot{c}\partial_c\phi_c + \left(\dot{\theta} - c\right)\partial_y\phi_c + \left(\dot{\theta} - c\right)\partial_y v + v_t = -\left(\phi_c + v\right)^n H_{\phi_c+v}^{-1}\partial_y\left(\phi_c + v\right)^n.$$

Using the above expansions and the solitary wave equation, $c\partial_y\phi_c = \phi_c^m H_{\phi_c}^{-1}\partial_y\left(\phi_c^n\right)$, this may be expanded into

$$v_t = \phi_c^m H_{\phi_c}^{-1}\partial_y\left[-c\phi_c^n\partial_y^2\left(\phi_c^{-m}v\right) + cv - n\phi_c^{n-1}v - cn\phi_c^{n-1}\partial_y\left(\phi_c^{-m}\partial_y\phi_c\right)v\right] \tag{B.3}$$

$$\begin{aligned} &- \dot{\theta}\partial_y v - \dot{c}\partial_c\phi_c - \dot{\theta}\partial_y\phi_c \\ &- f_m[\phi_c,v]vH_{\phi_c}^{-1}\partial_y(\phi^n) + m\phi_c^{m-1}vH_{\phi_c}^{-1}\left(H_\phi - H_{\phi_c}\right)H_\phi^{-1}\partial_y(\phi^n) \\ &- m\phi_c^{m-1}vH_{\phi_c}^{-1}\partial_y\left(\phi^n - \phi_c^n\right) - \phi_c^m H_{\phi_c}^{-1}\partial_y\left(f_n[\phi_c,v]v\right) \end{aligned} \tag{B.4}$$

$$\begin{aligned} &+ \phi_c^m H_{\phi_c}^{-1} B[f_n[\phi_c,v]v, f_m[\phi_c,v]v]H_\phi^{-1}\partial_y\left(\phi^n\right) \\ &- \phi_c^m H_{\phi_c}^{-1} B[n\phi_c^{n-1}v, m\phi_c^{m-1}v]H_{\phi_c}^{-1}\left(H_\phi - H_{\phi_c}\right)H_\phi^{-1}\partial_y\left(\phi^n\right) \\ &+ \phi_c^m H_{\phi_c}^{-1} B[n\phi_c^{n-1}v, m\phi_c^{m-1}v]H_{\phi_c}^{-1}\partial_y\left(\phi^n - \phi_c^n\right). \end{aligned} \tag{B.5}$$

(B.3) is a linear term. (B.4) will decay to zero as $\theta(t)$ and $c(t)$, the modulating parameters, approach their asymptotic limits. (B.5) is purely nonlinear in v.

We define $\mathcal{F}_1[v;\phi_c]$, the term nonlinear in v, as

$$\begin{aligned} \mathcal{F}_1[v;\phi_c] = &- f_m[\phi_c,v]vH_{\phi_c}^{-1}\partial_y(\phi^n) + m\phi_c^{m-1}vH_{\phi_c}^{-1}\left(H_\phi - H_{\phi_c}\right)H_\phi^{-1}\partial_y(\phi^n) \\ &- m\phi_c^{m-1}vH_{\phi_c}^{-1}\partial_y\left(\phi^n - \phi_c^n\right) - \phi_c^m H_{\phi_c}^{-1}\partial_y\left(f_n[\phi_c,v]v\right) \\ &+ \phi_c^m H_{\phi_c}^{-1} B[f_n[\phi_c,v]v, f_m[\phi_c,v]v]H_\phi^{-1}\partial_y\left(\phi^n\right) \\ &- \phi_c^m H_{\phi_c}^{-1} B[n\phi_c^{n-1}v, m\phi_c^{m-1}v]H_{\phi_c}^{-1}\left(H_\phi - H_{\phi_c}\right)H_\phi^{-1}\partial_y\left(\phi^n\right) \\ &+ \phi_c^m H_{\phi_c}^{-1} B[n\phi_c^{n-1}v, m\phi_c^{m-1}v]H_{\phi_c}^{-1}\partial_y\left(\phi^n - \phi_c^n\right). \end{aligned} \tag{B.6}$$

The operator S is given by

$$\begin{aligned} S[c_0,c,\dot{\theta}] = &\, mc_0\left(\phi_{c_0}^{-1}\partial_y\phi_{c_0} - \frac{c}{c-\dot{\theta}}\phi_c^{-1}\partial_y\phi_c\right) \\ &+ n\phi_{c_0}^m H_{c_0}^{-1}\partial_y\left[\left(\phi_{c_0}^{-1} - c_0(\phi_{c_0}^{-1} - 1)\right)\cdot\right] \\ &- \frac{nc_0}{c-\dot{\theta}}\phi_c^m H_{\phi_c}^{-1}\partial_y\left[\left(\phi_c^{-1} - c(\phi_c^{-1} - 1)\right)\cdot\right] \\ &- c_0 m\left\{\phi_{c_0}^m H_{\phi_{c_0}}^{-1}\left[\phi_{c_0}^{-1}\partial_y\phi_{c_0}\cdot\right] - \frac{c}{c-\dot{\theta}}\phi_c^m H_{\phi_c}^{-1}\left[\phi_c^{-1}\partial_y\phi_c\cdot\right]\right\}. \end{aligned} \tag{B.7}$$

Finally, the terms making up $\mathcal{G}_1$ from (2.36):

$$\mathcal{G}_1 = \tilde{\mathcal{G}}_1 + \tilde{\mathcal{G}}_2 + \tilde{\mathcal{G}}_3 + \tilde{\mathcal{G}}_4 + \tilde{\mathcal{G}}_5 + \tilde{\mathcal{G}}_6 + \tilde{\mathcal{G}}_7, \tag{B.8}$$

$$\tilde{\mathcal{G}}_1 = -f_m[\phi_c, v] w H_{\phi_c}^{-1} \partial_y(\phi^n), \tag{B.9}$$

$$\tilde{\mathcal{G}}_2 = m\phi_c^{m-1} w H_{\phi_c}^{-1} \left(H_\phi - H_{\phi_c}\right) H_\phi^{-1} \partial_y \left(\phi^n\right), \tag{B.10}$$

$$\tilde{\mathcal{G}}_3 = -m\phi_c^{m-1} w H_{\phi_c}^{-1} \partial_y \left(n\phi_c^{n-1} v + f_n[\phi_c, v] v\right), \tag{B.11}$$

$$\tilde{\mathcal{G}}_4 = -\phi_c^m H_{\phi_c,a}^{-1} D_a \left(f_n[\phi_c, v] w\right), \tag{B.12}$$

$$\tilde{\mathcal{G}}_5 = \phi_c^m H_{\phi_c,a}^{-1} B_a \left[f_n[\phi_c, v] w, f_m[\phi_c, v] w\right] H_\phi^{-1} \partial_y \left(\phi^n\right), \tag{B.13}$$

$$\tilde{\mathcal{G}}_6 = -\phi_c^m H_{\phi_c,a}^{-1} B_a \left[n\phi_c^{n-1} w, m\phi_c^{m-1} w\right] H_{\phi_c}^{-1} \left(H_\phi - H_{\phi_c}\right) H_\phi^{-1} \partial_y \left(\phi^n\right), \tag{B.14}$$

$$\tilde{\mathcal{G}}_7 = \phi_c^m H_{\phi_c,a}^{-1} B_a \left[n\phi_c^{n-1} w, m\phi_c^{m-1} w\right] H_{\phi_c}^{-1} \partial_y \left(\phi^n - \phi_c^n\right). \tag{B.15}$$

The difference between A_a and A_a^∞ may be written as

$$\begin{aligned} A_a - A_a^\infty = & -cm\phi_c^{-1}\partial_y\phi_c - (\phi_c^m - 1) H_{\phi_c,a}^{-1} D_a \left(n\phi_c^{n-1}\cdot\right) \\ & + cm\phi_c^m H_{\phi_c,a}^{-1} \left(\phi_c^{-1}\partial_y\phi_c\cdot\right) - cn\phi_c^m H_{\phi_c,a}^{-1} D_a \left[(1-\phi_c^{-1})\cdot\right] \\ & + H_{1,a}^{-1} D_a \left[n(1-\phi_c^{n-1})\cdot\right] + H_{1,a}^{-1} \left(\phi_c^m - 1\right) H_{\phi_c,a}^{-1} D_a \left(n\phi_c^{n-1}\cdot\right) \\ & + H_{1,a}^{-1} D_a \left(1-\phi_c^n\right) D_a H_{\phi_c,a}^{-1} D_a \left(n\phi_c^{n-1}\cdot\right). \end{aligned} \tag{B.16}$$

In the space weighted by $\phi_c(x)^{-m}$, this difference is

$$\begin{aligned} \tilde{A}_a - \tilde{A}_a^\infty = & nH_{1,a}^{-1} D_a \left[\left(1-\phi_c^{m-1}\right)\cdot\right] + nH_{1,a}^{-1} D_a \left(\phi_c^m - 1\right) H_{1,a}^{-1} \left(\phi_c^{m-1}\cdot\right) \\ & - nH_{1,a}^{-1} \left[D_a \left(\phi_c^m - 1\right)\right] H_{1,a}^{-1} \left(\phi_c^{m-1}\cdot\right) \\ & - nH_{1,a}^{-1} \left(\phi_c^m - 1\right) H_{1,a}^{-1} \left(\phi_c^m - 1\right) H_{\phi_c,a}^{-1} D_a \left(\phi_c^{m-1}\cdot\right) \\ & + nH_{1,a}^{-1} \left(\phi_c^m - 1\right) H_{1,a}^{-1} D_a \left(\phi_c^n - 1\right) D_a H_{\phi_c,a}^{-1} D_a \left(\phi_c^{m-1}\cdot\right) \\ & - nH_{1,a}^{-1} D_a \left(\phi_c^n - 1\right) D_a H_{\phi_c,a}^{-1} D_a \left(\phi_c^{m-1}\cdot\right) + cmH_{1,a}^{-1} \left(\phi_c^{m-1}\partial_y\phi_c\cdot\right) \\ & + cmH_{1,a}^{-1} \left(\phi_c^m - 1\right) H_{\phi_c,a}^{-1} \left(\phi_c^{m-1}\partial_y\phi_c\cdot\right) \\ & - cmH_{1,a}^{-1} D_a \left(\phi_c^n - 1\right) D_a H_{\phi_c,a}^{-1} \left(\phi_c^{m-1}\partial_y\phi_c\cdot\right) \\ & + cnH_{1,a}^{-1} D_a \left[\phi_c^m \left(\phi_c^{-1} - 1\right)\cdot\right] \\ & + cnH_{1,a}^{-1} \left(\phi_c^m - 1\right) H_{\phi_c,a}^{-1} D_a \left[\phi_c^m \left(\phi_c^{-1} - 1\right)\cdot\right] \\ & - cnH_{1,a}^{-1} D_a \left(\phi_c^n - 1\right) D_a H_{\phi_c,a}^{-1} D_a \left[\phi_c^m \left(\phi_c^{-1} - 1\right)\cdot\right]. \end{aligned} \tag{B.17}$$

Appendix C. Analysis of the characteristic polynomial. In this section we prove that (3.36), $(\lambda - c\mu)(1-\mu^2) + n\mu = 0$, has a unique root of minimal real part on a slit half-plane

$$\{\lambda : \Re\lambda > -\lambda_0\} \backslash (-\lambda_0, -\tilde{\Omega}(\gamma)].$$

There are two ways that this could be false: there could be either a multiple root or two roots with the same real part, but differing imaginary parts. As previously

noted, we will have a unique root of minimal real part for λ in the closed right half-plane, so we need only concern ourselves with $\Re\lambda < 0$.

We will identify a portion of the domain $\Re\lambda < 0$ for which there are neither multiple roots nor complex roots with the same real part. Note that this is a stricter condition than is needed, as the polynomial could have a double root for some λ, where the third root of $P(\mu)$ has a smaller real part than the multiple root.

Note that $P(\pm 1)$ never vanishes, and hence $P(\mu) = 0$ is equivalent to $R(\mu) = \lambda$, where

$$R(\mu) = c\mu + \frac{n\mu}{\mu^2 - 1}. \tag{C.1}$$

C.1. Roots of order greater than one. We start with the possibility of a double or triple root, as this is very easy to rule out. If μ is a multiple root, then in addition to $R(\mu) = \lambda$, we will also have

$$\frac{dR}{d\mu} = c - n\frac{1+\mu^2}{(1-\mu^2)^2} = 0,$$

which has solutions

$$\mu = -\sqrt{\frac{2c + n \pm \sqrt{8cn + n^2}}{2c}}.$$

We have ignored the roots with a + sign in front, as these will correspond to positive λ. Note that they are all real, and hence λ will also be real.

The λ one gets from the root

$$\mu_+ = -\sqrt{\frac{2c + n + \sqrt{8cn + n^2}}{2c}} \leq -\frac{3\sqrt{3}}{2}n$$

is decreasing in c. The other root,

$$\mu_- = -\sqrt{\frac{2c + n - \sqrt{8cn + n^2}}{2c}},$$

will map to λ values

$$\lambda(\mu_-) = -\sqrt{\frac{1}{8}}\sqrt{8c^2 + 20cn - n^2 - 8c\sqrt{n^2 + 8cn} - n\sqrt{n^2 + 8cn}}. \tag{C.2}$$

It can be checked that for $c > n > 1$, $R(\mu_+) < R(\mu_-)$. Therefore, for $\lambda > -\widetilde{\Omega}(c)$, with

$$\widetilde{\Omega}(c) = \sqrt{\frac{1}{8}}\sqrt{8c^2 + 20cn - n^2 - 8c\sqrt{n^2 + 8cn} - n\sqrt{n^2 + 8cn}}, \tag{C.3}$$

$P(\mu)$ cannot have a multiple root.

C.2. Roots of differing imaginary part. If $\mu_1 = \alpha + \imath\beta_1$ and $\mu_2 = \alpha + \imath\beta_2$ are two roots of P, then

$$R(\alpha + \imath\beta_1) = R(\alpha + \imath\beta_2).$$

After matching real and imaginary parts in this expression, the three unknowns, α, β_1, β_2, must satisfy the two equations

$$\begin{aligned}\Re\lambda &= c\alpha + \frac{n\alpha(-1+\alpha^2+\beta_1^2)}{(-1+\alpha^2)^2+2(1+\alpha^2)\beta_1^2+\beta_1^4} \\ &= c\alpha + \frac{n\alpha(-1+\alpha^2+\beta_2^2)}{(-1+\alpha^2)^2+2(1+\alpha^2)\beta_2^2+\beta_2^4},\end{aligned} \tag{C.4}$$

$$\begin{aligned}\Im\lambda &= c\beta_1 - \frac{n\beta_1(1+\alpha^2+\beta_1^2)}{(-1+\alpha^2)^2+2(1+\alpha^2)\beta_1^2+\beta_1^4} \\ &= c\beta_2 - \frac{n\beta_2(1+\alpha^2+\beta_2^2)}{(-1+\alpha^2)^2+2(1+\alpha^2)\beta_2^2+\beta_2^4}.\end{aligned} \tag{C.5}$$

Solving the (C.4) for β_2^2 in terms of α and β_1, there are two families of solutions:

$$\beta_2^2 = \beta_1^2, \tag{C.6}$$

$$\beta_2^2 = \frac{\left(1-\alpha^2\right)\left(3+\beta_1^2+\alpha^2\right)}{\alpha^2+\beta_1^2-1}. \tag{C.7}$$

Without loss of generality, we assume $\beta_1 \neq 0$.

Recall that λ is imaginary if and only if $P(\mu)$ has a purely imaginary root; hence the condition $\Re\lambda < 0$ ensures $\alpha \neq 0$. Then (C.7) implies $0 < |\alpha| \leq 1$. Furthermore, if $|\alpha| = 1$, then either the roots are conjugate or $\beta_2 = 0$. But if $\beta_2 = 0$, then $\mu_2 = 1$, which we know is not a root of $P(\mu)$.

C.2.1. Complex conjugates. When $\beta_1 = -\beta_2 = \beta$, (C.5) implies that λ is real and

$$c - \frac{n(1+\alpha^2+\beta^2)}{(-1+\alpha^2)^2+2(1+\alpha^2)\beta^2+\beta^4} = 0, \tag{C.8}$$

which has roots β^2,

$$\beta^2 = -1-\alpha^2+\frac{n}{2c} \pm \frac{\sqrt{n^2+16c^2\alpha^2}}{2c}. \tag{C.9}$$

We may immediately rule out the negative root for β^2. For $\beta^2 > 0$, α^2 must satisfy

$$1+\frac{n}{2c}-\frac{\sqrt{n^2+24c}}{2c} < \alpha^2 < 1+\frac{n}{2c}+\frac{\sqrt{n^2+24c}}{2c}. \tag{C.10}$$

Using (C.4),

$$\lambda(\alpha) = \frac{n+8c\alpha^2-\sqrt{n^2+16c^2\alpha^2}}{4\alpha}.$$

Since we are concerned only with $\lambda < 0$ here, α must, in addition to (C.10), satisfy

$$\frac{n+8c\alpha^2-\sqrt{n^2+16c^2\alpha^2}}{4\alpha} < 0. \tag{C.11}$$

When $\alpha > 0$, (C.11) requires

$$0 < \alpha^2 < \frac{c-n}{4c}.$$

But $\frac{1}{4}(c-n)/c < 1 + n/(2c) - \sqrt{n^2+24c}/(2c)$, so complex conjugate roots with $\alpha > 0$ are not possible with λ in the left half-plane.

When $\alpha < 0$, (C.11) requires

$$\alpha < -\frac{1}{2}\sqrt{\frac{c-n}{c}}$$

to satisfy (C.11). Consider α in the interval

$$\left[-\sqrt{1+\frac{n}{2c}-\frac{\sqrt{n^2+8cn}}{2c}}, -\frac{1}{2}\sqrt{\frac{c-n}{c}}\right).$$

In this interval, there will not be complex conjugate roots, as it violates (C.10).

λ, as a function of α, is negative and increasing on this interval. For λ in the image of this interval, we may completely rule out complex conjugate roots. The image of this interval is

$$\lambda\left(\left[-\sqrt{1+\frac{n}{2c}-\frac{\sqrt{n^2+8cn}}{2c}}, -\frac{1}{2}\sqrt{\frac{c-n}{c}}\right)\right) = \left[-\widetilde{\Omega}(c), 0\right).$$

Hence, for $0 > \lambda > -\tilde{\Omega}$, one may rule out both multiple roots and complex conjugates.

C.2.2. Nonconjugate complex roots. Consider the case of complex roots with the same real part, but imaginary parts such that $|\beta_1| \neq |\beta_2|$. Squaring both sides of (C.5) and plugging in (C.7) for β_2^2, we get a sixth order polynomial in β_1^2. The roots, as functions of α, are

$$\beta_1^2 = -1 - 2\alpha - \alpha^2, \tag{C.12}$$

$$\beta_1^2 = -1 + 2\alpha - \alpha^2, \tag{C.13}$$

$$\beta_1^2 = 1 - \alpha^2 - 2\sqrt{1-\alpha^2}, \tag{C.14}$$

$$\beta_1^2 = 1 - \alpha^2 + 2\sqrt{1-\alpha^2}, \tag{C.15}$$

$$\beta_1^2 = \frac{(n/c)^2 + 4(n/c)(1-\alpha^2) - 8(1-\alpha^4)}{8(1-\alpha^2)} - \frac{\sqrt{((n/c)^2 - 16(1-\alpha^2))((n/c)^2 - 8(1-\alpha^2)(2\alpha^2 - (n/c)))}}{8(1-\alpha^2)}, \tag{C.16}$$

$$\beta_1^2 = \frac{(n/c)^2 + 4(n/c)(1-\alpha^2) - 8(1-\alpha^4)}{8(1-\alpha^2)} + \frac{\sqrt{((n/c)^2 - 16(1-\alpha^2))((n/c)^2 - 8(1-\alpha^2)(2\alpha^2 - (n/c)))}}{8(1-\alpha^2)}. \tag{C.17}$$

(C.12) and (C.13) force β_1 to be imaginary, and hence they can be ruled out. Using (C.7), if β_1 is either (C.14) or (C.15), then $\beta_2 = \pm\beta_1$, conjugate roots.

In the last two cases, if β_1^2 is to be real, then

$$((n/c)^2 - 16(1-\alpha^2))((n/c)^2 - 8(1-\alpha^2)(2\alpha^2 - (n/c))) \geq 0. \tag{C.18}$$

If we can find for λ in the left half-plane sufficiently close enough to the imaginary axis that it is negative, we will be done. (C.18) is negative at $\alpha = 0$, so there exists a neighborhood of the imaginary axis, such that complex nonconjugate roots may be ruled out.

The roots on the left-hand side of (C.18) are

$$\alpha^2 = 1 - \frac{1}{16}\left(\frac{n}{c}\right)^2 = \frac{1}{16}(5-\gamma^2)(3+\gamma^2), \tag{C.19}$$

$$\alpha^2 = \frac{1}{2} + \frac{1}{4}\frac{n}{c} + \frac{1}{2}\sqrt{1-\frac{n}{c}} = \frac{1}{4}(3-\gamma)(1+\gamma), \tag{C.20}$$

$$\alpha^2 = \frac{1}{2} + \frac{1}{4}\frac{n}{c} - \frac{1}{2}\sqrt{1-\frac{n}{c}} = \frac{1}{4}(1-\gamma)(3+\gamma). \tag{C.21}$$

These are positive for $\gamma \in [0,1]$. It may be checked that (C.21) is the smallest for all γ. Hence the root of (C.18) such that μ will be closest to the imaginary axis is

$$\alpha = -\frac{1}{2}\sqrt{(1-\gamma)(3+\gamma)}. \tag{C.22}$$

α larger than (C.22) and less than zero will yield a λ that does not have nonconjugate complex roots.

Given λ, if $\mathcal{P}(\mu;\lambda)$ is to have two roots of same real part, α, but differing imaginary part, then, by trying any of the last four roots for β_1 (both positive and negative square roots of (C.16) and (C.17)), in (C.4) the real part of λ and α are related by

$$\Re\lambda = c\alpha\left(2 - \frac{(n/c)}{4(1-\alpha^2)+(n/c)}\right). \tag{C.23}$$

Note that

$$\frac{d\Re\lambda}{d\alpha} = c\left(\frac{32(1-\alpha^2)^2 + 12(n/c) - 20\alpha^2(n/c) + (n/c)^2}{\left(4(1-\alpha^2)+(c/n)\right)^2}\right) \tag{C.24}$$

and the derivative has one negative root with $|\alpha| < 1$ at

$$\alpha = -\sqrt{1 + \frac{5}{16}\frac{n}{c} - \frac{1}{16}\sqrt{64\frac{n}{c} + 17\left(\frac{n}{c}\right)^2}}. \tag{C.25}$$

Comparing (C.22) with (C.25), at $\gamma = 1$

$$\text{(C.25)} = -1 < 0 = \text{(C.22)},$$

and at $\gamma = 0$

$$\text{(C.25)} = -\sqrt{\frac{3}{4}} = \text{(C.22)}.$$

In addition, one may check that (C.25) is increasing in $\gamma \in [0,1]$, while (C.22) is decreasing on the same interval. Therefore

$$-\sqrt{1 + \frac{5}{16}\frac{n}{c} - \frac{1}{16}\sqrt{64\frac{n}{c} + 17\left(\frac{n}{c}\right)^2}} \le -\frac{1}{2}\sqrt{(1-\gamma)(3+\gamma)}$$

for all $\gamma \in [0,1]$.

For $\Re\mu = \alpha$ in

$$\left(-\frac{1}{2}\sqrt{(1-\gamma)(3+\gamma)}, 0\right) \tag{C.26}$$

(C.23) will be an increasing function in α, and (C.24) is positive at $\alpha = 0$. On the interval (C.26), the mapping is invertible and its image is

$$\left(-\frac{1}{4}c\sqrt{1-\gamma}\,(\gamma+3)^{3/2}, 0\right). \tag{C.27}$$

Therefore if λ has real part in the interval (C.27), and $\mathcal{P}(\mu;\lambda)$ is to have nonconjugate complex roots, α must lie in (C.26). But such an α violates (C.18), and we may conclude that there are no such roots. Letting $-\lambda_0$ denote the $\Re\lambda$ value at the left end point of (C.27),

$$\lambda_0 = \frac{c}{4}\sqrt{1-\gamma}\,(\gamma+3)^{3/2} = \frac{n}{4(1-\gamma^2)}\sqrt{1-\gamma}\,(\gamma+3)^{3/2}. \tag{C.28}$$

Hence for $\Re\lambda > -\lambda_0$, nonconjugate complex roots are not possible for $P(\mu)$.

Appendix D. The zero eigenvalue. In section 3.5, $\lambda = 0$ was identified as an eigenvalue of multiplicity at least two. Using the Evans function, the order of this eigenvalue may be related to the slope with respect to c of the invariant functional $\mathcal{N}[\phi_c]$.

Using the framework from section 3.3.2, set

$$\mathbf{y}^+ = \begin{pmatrix} \phi_c^{-m}\partial_x\phi_c \\ \partial_x\left(\phi_c^{-m}\partial_x\phi_c\right) \\ 0 \end{pmatrix}, \tag{D.1}$$

$$\mathbf{z}^- = \left(c\partial_x\left(\phi_c^{-m}\partial_x\phi_c\right), \quad -c\phi_c^{-m}\partial_x\phi_c, \quad -\int_{-\infty}^{x}\phi_c^{-n-m}\partial_x\phi_c\right). \tag{D.2}$$

These are solutions to the dynamical systems

$$\dot{\mathbf{y}} = B(x,\lambda=0,\gamma)\mathbf{y} \quad \text{and} \quad \dot{\mathbf{z}} = -\mathbf{z}B(x,\lambda=0,\gamma).$$

Here, $\mu_1 = -\gamma$. Employing the notation and formulation of the Evans function of [27], by [27, Proposition 1.6, parts 2 and 3], since

$$\mathbf{y}^+ = O(e^{-\gamma x}) \quad \text{as } x \to +\infty \quad \text{and} \quad \mathbf{z}^- = O(e^{\gamma x}) \quad \text{as } x \to -\infty,$$

$\mathbf{y}^+$ and $\mathbf{z}^-$ are scalar multiples of ζ^+ and η^-, respectively. ζ^+ and η^- are the solutions of the dynamical systems satisfying

$$\zeta^+ e^{\gamma x} \to \mathbf{v}^+ \quad \text{as } x \to +\infty \quad \text{and} \quad \eta^- e^{-\gamma x} \to \mathbf{w}^- \quad \text{as } x \to -\infty,$$

with

$$B^\infty\mathbf{v}^+ = -\gamma\mathbf{v}^+, \qquad \mathbf{w}^-B^\infty = -\gamma\mathbf{w}^-,$$

$$\mathbf{v}^+ = (1, \quad -\gamma, \quad 0)^T, \qquad \mathbf{w}^- = \left(2c\gamma^2\right)^{-1}\left(c\gamma^2, \quad -c\gamma, \quad -1\right),$$

allowing us to define the Evans function as

$$D(\lambda = 0) = \eta^-(x, \lambda = 0) \cdot \zeta^+(x, \lambda = 0).$$

From the properties of the solitary waves, discussed in section 2.2, there exists $\beta > 0$ such that

$$\phi_c^{-m} \partial_x \phi_c e^{\gamma x} \to -\beta \text{ as } x \to +\infty,$$

and hence

$$\zeta^+ = \frac{1}{-\beta} \mathbf{y}^+ \quad \text{and} \quad \eta^- = \frac{1}{-2\gamma c \beta} \mathbf{z}^-.$$

$D(0) = 0$ by inspection. From [27], the derivative of the Evans function for a system akin to ours is[2]

$$\partial_\lambda D(\lambda) = -\int_{-\infty}^{\infty} \eta^-(x, \lambda) \partial_\lambda \left[B(x, \lambda) - \mu_1(\lambda) I \right] \zeta^+(x, \lambda) dx. \tag{D.3}$$

It is then trivial to compute that $\partial_\lambda D(0) = 0$, since the integrand is an odd function.

Taking the derivative of (D.3) at $\lambda = 0$ gives an equation for $\partial_\lambda^2 D(0)$,

$$\partial_\lambda^2 D(0) = -\int_{-\infty}^{\infty} \eta_\lambda^- B_\lambda \zeta^+ dx - \int_{-\infty}^{\infty} \eta^- B_\lambda \zeta_\lambda^+ dx. \tag{D.4}$$

ζ_λ^+ and η_λ^- satisfy the ODEs

$$\dot{\mathbf{y}}_\lambda = B \mathbf{y}_\lambda + B_\lambda \mathbf{y} \quad \text{and} \quad \dot{\mathbf{z}}_\lambda = -\mathbf{z}_\lambda B - \mathbf{z} B_\lambda.$$

These problems are associated with the derivatives with respect to λ of (3.24) and (3.30) at $\lambda = 0$,

$$\partial_x L_c Y_\lambda = \left[I - \partial_x \left(\phi_c^n \partial_x \left(\phi_c^{-m} \cdot \right) \right) \right] Y, \tag{D.5}$$

$$-L_c^\star \partial_x Z_\lambda = \left[I - \phi_c^{-m} \partial_x \left(\phi_c^n \partial_x \cdot \right) \right] Z, \tag{D.6}$$

through the identifications

$$\begin{aligned} y_\lambda^{(1)} &= \phi_c^{-m} Y_\lambda, & z_\lambda^{(1)} &= c \partial_x \left(\phi_c^n \partial_x Z_\lambda \right), \\ y_\lambda^{(2)} &= \partial_x \left(\phi_c^{-m} Y_\lambda \right), & z_\lambda^{(2)} &= -c \phi_c^n \partial_x Z_\lambda, \\ y_\lambda^{(3)} &= L_c Y_\lambda + \phi_c^n \partial_x \left(\phi_c^{-m} Y \right), & z_\lambda^{(3)} &= -Z_\lambda. \end{aligned}$$

For $\lambda = 0$, (3.24), (3.30), (D.5), and (D.6) are related to the generalized kernels of A and $A^\star$:

$$\begin{aligned} Y &= \partial_x \phi_c, & Y_\lambda &= -\partial_c \phi_c, \\ Z &= \int_{-\infty}^{x} \frac{\partial_x \phi_c}{\phi_c^{n+m}} dx, & Z_\lambda &= -\int_{-\infty}^{x} \left(L_c^\star \right)^{-1} \left[I - \phi_c^{-m} \partial_x \left(\phi_c^n \partial_x \cdot \right) \right] \int_{-\infty}^{x} \frac{\partial_x \phi_c}{\phi_c^{n+m}} dx. \end{aligned}$$

[2] In particular, a system for which the matrix B has the same limit at $\pm\infty$.

Then

$$\zeta_\lambda^+ = \frac{1}{-\beta}\left(-\phi_c^{-m}\partial_c\phi_c, \quad -\partial_x\left(\phi_c^{-m}\partial_c\phi_c\right), \quad -L_c\partial_c\phi_c + \phi_c^n\partial_x\left(\phi_c^{-m}\partial_x\phi_c\right)\right)^T,$$

$$\eta_\lambda^- = \frac{1}{2\gamma c\beta}\left(c\partial_x\left(\phi_c^n\partial_x Z_\lambda\right), \quad -c\phi_c^n\partial_x Z_\lambda, \quad -Z_\lambda\right).$$

Finally, we compute

$$\partial_\lambda^2 D(0) = \frac{1}{c\gamma\beta^2}\partial_c\mathcal{N}[\phi_c]. \tag{D.7}$$

ENERGY TRANSPORT BY ACOUSTIC MODES OF HARMONIC LATTICES*

LISA HARRIS†, JANI LUKKARINEN‡, STEFAN TEUFEL§, AND FLORIAN THEIL†

Abstract. We study the large scale evolution of a scalar lattice excitation u which satisfies a discrete wave equation in three dimensions, $\ddot{u}_t(\gamma) = -\sum_{\gamma'} \alpha(\gamma-\gamma')u_t(\gamma')$, where $\gamma, \gamma' \in \mathbb{Z}^3$ are lattice sites. We assume that the dispersion relation ω associated to the elastic coupling constants $\alpha(\gamma-\gamma')$ is acoustic; i.e., it has a singularity of the type $|k|$ near the vanishing wave vector, $k=0$. To derive equations describing the macroscopic energy transport, we employ a related multiscale Wigner transform and a scale parameter $\varepsilon > 0$. The spatial and temporal scales of the Wigner transform are related to the corresponding lattice parameters via a scaling by ε. In the continuum limit, which is achieved by sending the parameter ε to 0, the Wigner transform disintegrates into three different limit objects: the Wigner transform of a rescaled weak-L^2 limit, an H-measure, and a Wigner measure. The first two provide the finer resolution of the energy concentrating at $k=0$ so that a set of closed evolution equations may arise. We demonstrate that these three limit objects satisfy a set of decoupled transport equations: a wave equation for the weak limit, a geometric optics transport equation for the H-measure limit, and a dispersive transport equation for the standard limiting Wigner measure. This yields a complete characterization of macroscopic energy transport in harmonic lattices with regular acoustic dispersion relations.

1. Introduction.

The energy transport by atomic oscillations in crystalline solids is a central problem in solid state physics. To the first order approximation, the oscillations can be described by a discrete wave equation

$$\ddot{u}_t(\gamma) = -\sum_{\gamma'} \alpha(\gamma-\gamma')u_t(\gamma') \tag{1.1}$$

where $u(\gamma) \in \mathbb{R}$ is composed of the displacements of the crystal atoms from their equilibrium position, as will be discussed in section 1.1. To analyze physically relevant properties of the crystal, such as its thermal conductivity, we first need to understand how energy is transported within the crystal via purely harmonic vibrations. Such transport properties are determined by the dispersion relation ω of the crystal, here $\omega(k) = \sqrt{\hat{\alpha}(k)}$, the "hat" denoting a discrete Fourier transform. If ω is not smooth, then depending on the wavelength different types of continuum energy transport equations can arise. The different contributions to the continuum energy are described by different limit objects, so-called Wigner measures, or microlocal defect measures.

These concepts were introduced by Tartar [23] and Gérard [10] to analyze the weak limits of certain nonlinear quantities, the energy density being one of them. Two-scale Wigner measures of the type we use here were first introduced independently by Fermanian Kammerer [5, 6] and by Nier [18].

Our main interest is to characterize the macroscopic evolution of the energy density. The starting point of our mathematical analysis is the *Wigner transform*, which can be interpreted as a "wavenumber resolved" energy density. Let us leave the details for section 2.1, and only summarize the main findings here. Let $v_t = \dot{u}_t$. We can then construct a complex field $\psi_t \in \ell_2(\mathbb{Z}^3)$, corresponding to a normal mode of the oscillations, out of the fields u_t and v_t. On the other hand, for any given $\psi \in \ell_2(\mathbb{Z}^3)$ and $\varepsilon > 0$, the lattice Wigner transform $W^\varepsilon = W^\varepsilon[\psi]$ allows defining a corresponding "energy" density, $e^\varepsilon = e^\varepsilon[\psi]$, by the formula

$$e^\varepsilon(x) = \int_{\mathbb{T}^3} \mathrm{d}k\, W^\varepsilon(x,k), \tag{1.2}$$

where $\varepsilon > 0$ denotes the "lattice spacing" and $x \in \mathbb{R}^3$ is a variable which interpolates between the points of the scaled lattice $\varepsilon\mathbb{Z}^3$. Here $\mathbb{T}^3$ denotes the 3-torus, and we identify $\mathbb{T}^3 = \mathbb{R}^3/\mathbb{Z}^3$. Then $e^\varepsilon(x,t) = e^\varepsilon[\psi_{t/\varepsilon}](x)$ can be considered to be a proper energy density at a macroscopic time t, as it satisfies $\int_{\mathbb{R}^3} \mathrm{d}x\, e^\varepsilon(x,t) = H(u_{t/\varepsilon}, v_{t/\varepsilon})$, where H denotes the Hamiltonian related to (1.1).

In general, a limit of a sequence of scaled Wigner transforms, $(W^\varepsilon[\psi^\varepsilon])$ with ε tending to 0, is given by a nonnegative Radon measure $\mu \in M_+(\mathbb{R}^3 \times \mathbb{T}^3)$. In the setup considered here, we have for a given time t a sequence of normal mode fields $\psi_{t/\varepsilon}$ which would then yield a family of nonnegative Radon measures μ_t as limit points of the corresponding Wigner transforms. However, for these limit measures to form a useful approximation of the original dynamical system, μ_t should also satisfy an autonomous evolution equation. This is typically not possible if the initial measure concentrates on the singular set of ω, i.e., to the points where ω is not smooth.

Here we will augment the standard Wigner transform scheme to encompass the most common type of singularity encountered in solid state physics: acoustic singularities, with $\omega(k)$ behaving like $|k|$ near $k = 0$. Such modes occur in general within crystal models with short range interactions, and they are particularly important as they are responsible for sound propagation in the crystal. With some effort, in the spirit of the results proven in [6], it is likely that these results could be extended to cover more complicated singular sets of ω, but we do not consider such generalizations here. Our result can also be seen as a generalization of the analysis in [17]. There it is shown that μ_t can be computed from μ_0 by solving a dispersive linear transport equation, provided that μ_0 does not concentrate on wavenumbers k where the dispersion relation ω is not $C^{(1)}$.

For acoustic modes, the dispersion relation fails to be $C^{(1)}$ at $k = 0$, and it is necessary to resolve finer details of the solutions near the singular point, whenever a concentration at $k = 0$ is possible. This will be accomplished here by introducing a second scale to the lattice Wigner transform. The multiscale Wigner transform, defined in section 2.1, maps a field ψ into a distribution $W^\varepsilon[\psi](x,k,q)$ where the new parameter $q \in \mathbb{R}^3$ resolves the energy density for wavenumbers of the order of ε. We consider a sequence of initial conditions such that the corresponding initial fields ψ_0^ε are bounded and tight in $\ell_2(\varepsilon\mathbb{Z}^3)$. We prove in Theorem 3.2 that then for all $t \in \mathbb{R}$ there are two measures, a Wigner measure μ_t on $\mathbb{R}^3 \times \mathbb{T}^3_*$, $\mathbb{T}^3_* = \mathbb{T}^3 \setminus \{0\}$, and an H-measure μ_t^{H} on $\mathbb{R}^3 \times S^2$, as well as an L^2-function ϕ_t such that $W^\varepsilon[\psi^\varepsilon_{t/\varepsilon}]$ converges

along a subsequence to a limit determined by $(\mu_t, \mu_t^{\mathrm{H}}, \phi_t)$. The subsequence can be chosen independently of t, and it will only be relevant for determining the limit of the initial data, that is, $(\mu_0, \mu_0^{\mathrm{H}}, \phi_0)$. For all other times $t \in \mathbb{R}$, the measures $\mu_t, \mu_t^{\mathrm{H}}$ and the L^2-function ϕ_t can be determined using the transport equations

$$\partial_t \mu_t(x,k) + \tfrac{1}{2\pi} \nabla\omega(k) \cdot \nabla_x \mu_t(x,k) = 0, \qquad k \in \mathbb{T}^3_*\,, \tag{1.3}$$

$$\partial_t \mu_t^{\mathrm{H}}(x,q) + \tfrac{1}{2\pi} \nabla\omega_0(q) \cdot \nabla_x \mu_t^{\mathrm{H}}(x,q) = 0, \quad q \in S^2\,, \tag{1.4}$$

$$\partial_t^2 \phi_t(x) = \mathrm{div}(\tfrac{1}{(2\pi)^2} A_0 \nabla \phi_t(x)), \tag{1.5}$$

where $x \in \mathbb{R}^3$, together with the initial conditions

$$\mu_t|_{t=0} = \mu_0, \quad \mu_t^{\mathrm{H}}\big|_{t=0} = \mu_0^{\mathrm{H}}, \quad \phi_t|_{t=0} = \phi_0, \quad \partial_t \hat{\phi}_t(p)|_{t=0} = -i\omega_0(p)\hat{\phi}_0(p), \quad p \in \mathbb{R}^3\,, \tag{1.6}$$

given by the limit objects $(\mu_0, \mu_0^{\mathrm{H}}, \phi_0)$ at $t = 0$. Here the constant matrix A_0 and the function ω_0 are determined by the Hessian of the square of the dispersion relation ω (defined in (2.6)) at $k = 0$, explicitly

$$A_0 = \frac{1}{2} D^2 \omega^2(0), \qquad \omega_0(p) = \sqrt{p \cdot A_0 p}\,. \tag{1.7}$$

It also follows from our analysis that the sum of the energies related to μ_t, μ_t^{H}, and ϕ_t is a constant of motion and equals the limiting value of the total energy of the initial excitations. This shows that no energy is lost in the taking of the continuum limit.

Equation (1.3) describes the propagation of energy along the harmonic lattice with the group velocity $\nabla\omega(k)/(2\pi)$. Equation (1.5) is a wave equation describing the evolution of macroscopic fluctuations. Equation (1.4) is usually known under the name "geometric optics" and describes the evolution of macroscopic fluctuations whose wavelength is much longer than the lattice spacing ε and much smaller than 1, the wavelength of the fluctuations resolved by ϕ_t. The surprising feature about acoustic modes is the separate evolution equation for the macroscopic perturbations ϕ_t. As will be apparent in Theorem 3.2, but as also indicated by the fact that the evolution equation for ϕ_t involves only the Hessian of ω^2 at $k = 0$, its evolution is determined by the second, fine-resolution scale introduced to the Wigner transform. This is in contradistinction to the case of ω which is smooth, as then the evolution of the energy density would not depend on the second scaling parameter.

The Wigner transform, or the Wigner function, was originally introduced to study semiclassical behavior in quantum mechanics, but it has been proven to be a useful tool in studying large scale behavior of wave equations as well [12, 19]. In particular, the method of calculating continuous, macroscopic energy by finding the limit object of a sequence of energies e^{ε} on rescaled lattice models is one that has been widely used and justified, for example, in [9, 14, 17]. In [17], the Wigner transform of the normal modes is employed in solving the macroscopic transport of energy in the above harmonic systems for deterministic initial data. The same system is considered in [3] with random initial data and in a larger function space, excluding, however, the type of concentration effects we study here. In [6] two-scale Wigner measures of the same type we use here were introduced for the study of concentration effects near shock hypersurfaces for the heat equation. The precise connection to the results in [5, 6] will be explained in Remark 3.6 in section 3.

In [8] spatially homogeneous Wigner measures are employed to study energy asymptotics in static systems. Both the method (which was developed before the

theory of 2-microlocal measures became available) and the results are in spirit very similar to ours. Using specific profile functions, three limit objects are constructed which capture the asymptotic behavior of the energy along bounded sequences. Only Fourier methods are used in [8] and therefore the spatial distribution of the energy cannot be characterized.

The main use of the Wigner transform is that, unlike the energy density e^ε itself, it contains enough information to satisfy a closed evolution equation in the limit $\varepsilon \to 0$. Indeed, it was shown in [17] that as long as there is no concentration on the singular set of the dispersion relation faster than $\varepsilon^{1/2}$, the Wigner transform of the time-evolved state vector $\psi_{t/\varepsilon}$ converges to a limit measure $\tilde{\mu}_t$ on $\mathbb{R} \times \mathbb{K}$. Here $\mathbb{K}$ is a suitable compactification of $\mathbb{T}^3 \setminus \mathbb{S}$, $\mathbb{S}$ being the singular set, which allows a continuous extension of the group velocity $\nabla\omega$. The measure $\tilde{\mu}_t$ is then proven to satisfy the transport equation

$$\partial_t \tilde{\mu}_t(x,k) + \tfrac{1}{2\pi} \nabla\omega(k) \cdot \nabla_x \tilde{\mu}_t(x,k) = 0. \tag{1.8}$$

However, the above assumption about the rate of convergence excludes macroscopic variations of the initial data in the case of acoustic singularities, and enforces $\phi_t = 0$ in the present terminology. Separately, it was also shown in [17] that if the weak limit of the rescaled initial data exists, then the limit satisfies a continuum wave equation. However, a combination of these results was not possible, leaving open the exact effect the continuum wave equation will have on the energy density. In [15] it is shown that the Wigner measures generated by sequences of solutions of discrete wave equations satisfy transport equations; energy conservation along the sequence is not discussed.

In this paper we will show how to overcome the above difficulties in a physically relevant class of models with a singular dispersion relation. Our main additional contribution to the results of the above-mentioned references is to introduce a lattice version of the multiscale Wigner transform and to employ this in solving the macroscopic evolution of the energy density in the presence of an acoustic singularity. In section 2 we will first present the microscopic dynamical model in detail. In section 2.1 we will define the Wigner transform, and discuss its relation to the energy of the microscopic lattice model. The main results will be presented in section 3.

1.1. Relation with solid state physics. A crystal in solid state physics is a state of matter in which the atoms retain a nearly perfect periodic structure over macroscopic times. The Hamiltonian model used for the time evolution in such a crystal is, to the first order accuracy, harmonic. If we assume that each periodic cell of the idealized perfectly periodic crystal structure contains n atoms, then we can form a vector $q(\gamma) \in \mathbb{R}^{3n}$ out of the displacements of the atoms in the periodic cell labeled by $\gamma \in \mathbb{Z}^3$. The (classical) Hamiltonian equations of motion of this harmonic model are then

$$\dot{q}_i(\gamma,t) = \frac{1}{m_i} p_i(\gamma,t), \qquad \dot{p}_i(\gamma,t) = -\sum_{\gamma',i'} \mathbb{A}(\gamma-\gamma')_{i,i'} q_{i'}(\gamma',t), \tag{1.9}$$

where $\gamma \in \mathbb{Z}^3$, $i = 1,\dots,3n$, and m_i denotes the mass of the atom whose displacement q_i measures.

By the change of variables to $\tilde{q}_i(\gamma) = m_i^{\frac{1}{2}} q_i(\gamma)$, $\tilde{p}_i(\gamma) = m_i^{-\frac{1}{2}} p_i(\gamma)$, these equations can be transformed into a standard form whose force matrix is given by $\tilde{\mathbb{A}}(\gamma)_{i,i'} = m_i^{-1/2} \mathbb{A}(\gamma)_{i,i'} m_{i'}^{-1/2}$. The standard form equations can then be solved by Fourier transform, and a diagonalization of the remaining multiplicative evolution equations

decomposes the $3n$ vector degrees of freedom into independent *normal modes*, called *phonons* in solid state physics. Each normal mode is a complex scalar field on the crystal lattice, and its time evolution is unitary and uniquely determined by the corresponding dispersion relation $\omega_i(k)$ on $\mathbb{T}^3$. More details on the related mathematical issues can be found in [3, 17].

The complete decoupling of the evolution equations of the normal modes allows us to study a scalar, single-mode model and still retain a straightforward applicability of the results in the above, physically more relevant, vector models. As the above procedure is fairly standard and well covered in the references, we will not present the decomposition in any more detail here. However, to illustrate the matter, we have performed the equivalent steps for the scalar model (1.1) in the beginning of section 2.

In solid state physics, the normal modes are divided into *optical* and *acoustic* depending on their regularity at $k = 0$: if the dispersion relation is regular at $k = 0$, then the mode is called optical, and if it behaves as $|k|$ at $k = 0$, the mode is called acoustic. The latter name arises as these modes are believed to be responsible for the propagation of sound waves in the crystal. Acoustic dispersion relations arise generally from atomistic Hamiltonians with short range interactions, and crystal models are typically expected to have three of them, related to the translation invariance of the microscopic forces.

Finally, let us remark that the discrete *linear* wave equation alone does not suffice to determine the physically relevant properties of the crystal, such as its thermal conductivity. However, it forms the basis for perturbative treatments which can address such questions. We refer to [1, 20, 21, 22, 25] for further details on the physical aspects of the topic, and to [2] for a review about related open problems.

2. The microscopic model. There are two mathematically equivalent descriptions of harmonic crystals. On the one hand, one can work with the Hamiltonian equations of motion and analyze the properties of the solutions. Anharmonic crystals can then be discussed in the same manner. On the other hand, one can employ the Fourier transform and the linearity to condense the Hamiltonian into the dispersion relation. Although the second approach leads to an immediate solution of the harmonic system, it cannot be used directly to analyze nonlinear models.

We will show in this chapter how the first approach reduces to the second one for harmonic lattices. Then we demonstrate how the Wigner transform can be employed in the analysis of the time evolution of the energy density of the Hamiltonian description.

We assume that the scalar excitation $u_t(\gamma)$, $\gamma \in \mathbb{Z}^3$, satisfies the discrete wave equation

$$\frac{\partial^2}{\partial t^2} u_t(\gamma) = -\sum_{\gamma' \in \mathbb{Z}^3} \alpha(\gamma - \gamma') u_t(\gamma') \tag{2.1}$$

with initial data $(u_t|_{t=0}, v_t|_{t=0}) \in X = \ell_2 \times \ell_2$, where v_t denotes the velocity field, $v_t = \partial_t u_t$. The numbers $\alpha(\gamma - \gamma')$ are the elastic coupling constants between the sites γ and γ'. We assume that α is real and symmetric ($\alpha(-\gamma) = \alpha(\gamma)$). Clearly, system (2.1) can be written in a Hamiltonian form and the energy

$$H(u, v) = \frac{1}{2}\Big(\sum_{\gamma \in \mathbb{Z}^3} |v(\gamma)|^2 + \sum_{\gamma \in \mathbb{Z}^3} \Big[\sum_{\gamma' \in \mathbb{Z}^3} u(\gamma)\alpha(\gamma - \gamma')u(\gamma') \Big] \Big) \tag{2.2}$$

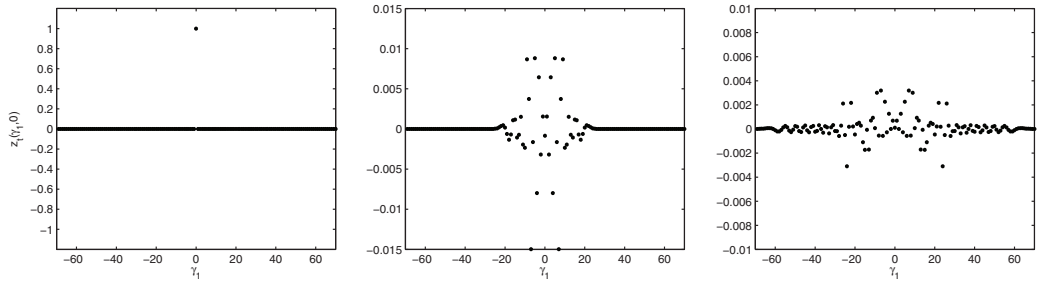

FIG. 2.1. *Values of $u_t(\gamma)$ along the axis $\gamma_2 = \gamma_3 = 0$ for $t = 0$, $t = 0.1/\varepsilon$, $t = 0.9/\varepsilon$ with $\varepsilon = \frac{1}{7} * 10^{-1}$. The evolution is given by* (2.1) *with the nearest neighbor elastic couplings* (2.13)*, and the initial conditions are $u_{t=0}(0) = 1$, $u_{t=0}(\gamma) = 0$ for all $\gamma \neq 0$, and $\dot{u}_{t=0} \equiv 0$.*

is constant along solutions. Depending on the initial conditions, the solutions of system (2.1) may develop large scale oscillations which carry a finite amount of energy; cf. Figure 2.1, where snapshots of u at several times are plotted.

Since system (2.1) is linear and invariant under discrete translations, we can write the solutions in a closed form using the Fourier transform.

DEFINITION 2.1. *We define the Fourier transform $\ell_2(\mathbb{Z}^3) \to L^2(\mathbb{T}^3)$ by extending*

$$(\mathcal{F}_{\gamma\to k}\psi)(k) = \hat{\psi}(k) = \sum_{\gamma\in\mathbb{Z}^3} \mathrm{e}^{-2\pi \mathrm{i} k\cdot\gamma}\psi(\gamma) \tag{2.3}$$

from ψ with finite support to all of $\ell_2(\mathbb{Z}^3)$. Here $\mathbb{T}^3 = \mathbb{R}^3/\mathbb{Z}^3$ denotes the unit 3-torus. The inverse transform is pointwise convergently defined by the integral

$$(\mathcal{F}_{k\to\gamma}\hat{\psi})(\gamma) = \int_{\mathbb{T}^3} \mathrm{d}k\, \mathrm{e}^{2\pi \mathrm{i} k\cdot\gamma}\hat{\psi}(k) = \psi(\gamma), \tag{2.4}$$

where the measure $\mathrm{d}k$ is induced by the Lebesgue measure on the parameterization T^3 of $\mathbb{T}^3$, where $T = (-\frac{1}{2}, \frac{1}{2}]$. In particular, $\int_{\mathbb{T}^3} \mathrm{d}k = 1$.

From now on the notation T^3 will refer to the above explicit parameterization of the torus $\mathbb{T}^3$. Occasionally, integration over $k \in \mathbb{T}^3$ will be applied to functions $f(k)$ which are not periodic in k. In these cases, using the parameterization $k \in T^3$ is implicitly understood. The parameterization mapping $\mathbb{T}^3 \to T^3$ will be denoted by $k \mapsto (k \bmod T^3)$ whenever the use of the parameterization needs to be explicitly stressed.

If one applies the Fourier transform to the Hamiltonian equations of motion determined by $H(u, v)$, one obtains a simpler system equivalent to (2.1):

$$\frac{\partial}{\partial t}\begin{pmatrix}\hat{u}_t(k)\\ \hat{v}_t(k)\end{pmatrix} = \begin{pmatrix}0 & 1\\ -\omega^2(k) & 0\end{pmatrix}\begin{pmatrix}\hat{u}_t(k)\\ \hat{v}_t(k)\end{pmatrix}, \quad k \in \mathbb{T}^3\,. \tag{2.5}$$

The function $\omega : \mathbb{T}^3 \to \mathbb{R}$ is the dispersion relation and it is related to the Hamiltonian via the following formula:

$$\omega(k) = \sqrt{\hat{\alpha}(k)} = \sqrt{\sum_{\gamma\in\mathbb{Z}^3} \alpha(\gamma)\cos(2\pi\gamma\cdot k)}, \tag{2.6}$$

where we have employed the assumption $\alpha(\gamma) = \alpha(-\gamma)$. Since α is real and satisfies the above symmetry property, we find that ω is also real and symmetric, i.e., $\omega(k) = \omega(-k)$.

A diagonalization of the matrix on the right-hand side of (2.5) motivates combining the real scalar fields u and v into the two complex fields $\psi_\pm = \psi_\pm[u,v] \in \ell_2(\mathbb{Z}^3,\mathbb{C})$ defined by the formula

$$\hat{\psi}_\sigma(k) = \frac{1}{\sqrt{2}}\left(\omega(k)\hat{u}(k) + \mathrm{i}\sigma\hat{v}(k)\right), \quad \sigma \in \{\pm 1\},\ k \in \mathbb{T}^3\,. \tag{2.7}$$

For all $(u,v) \in X$, we clearly have $\hat{\psi}_\sigma \in L^2(\mathbb{T}^3)$, and thus $\psi_\sigma \in \ell_2(\mathbb{Z}^3)$. In addition, since $\omega(-k) = \omega(k)$, we also have $\psi_-(\gamma) = \overline{\psi_+(\gamma)}$ for all γ. The transformation can always be inverted by applying

$$\hat{u} = \frac{1}{\omega\sqrt{2}}(\hat{\psi}_+ + \hat{\psi}_-)\,, \quad \hat{v} = -\frac{\mathrm{i}}{\sqrt{2}}(\hat{\psi}_+ - \hat{\psi}_-)\,. \tag{2.8}$$

Given a solution u_t, $v_t = \dot{u}_t$ to (2.1), we then define the complex normal mode fields by the formula

$$\psi_\sigma(\gamma,t) = \psi_\sigma[u_t,v_t](\gamma), \quad \sigma \in \{\pm 1\},\ \gamma \in \mathbb{Z}^3,\ t \in \mathbb{R}\,. \tag{2.9}$$

To see that these fields are indeed normal modes of the harmonic system, we apply (2.5) and find the evolution equations

$$\frac{\partial}{\partial t}\begin{pmatrix}\hat{\psi}_+(k,t)\\ \hat{\psi}_-(k,t)\end{pmatrix} = -\mathrm{i}\begin{pmatrix}\omega(k) & 0\\ 0 & -\omega(k)\end{pmatrix}\begin{pmatrix}\hat{\psi}_+(k,t)\\ \hat{\psi}_-(k,t)\end{pmatrix}, \tag{2.10}$$

which are readily solved to yield for all $t \in \mathbb{R}$, $k \in \mathbb{R}^3$

$$\hat{\psi}_\pm(k,t) = \mathrm{e}^{\mp\mathrm{i}\omega(k)t}\hat{\psi}_\pm(k,0)\,. \tag{2.11}$$

These are exactly the two evolution equations corresponding to a "phonon" mode with a dispersion relation ω. The fields ψ_t mentioned in the introduction can now be identified with $\psi_+(\cdot,t)$ in the present notation.

After these reduction steps it is obvious that the dispersion relation ω fully determines the properties of the solutions. We will assume throughout this paper that ω is of the acoustic type in the following precise sense.

DEFINITION 2.2. *We call $\omega \in C(\mathbb{T}^3,[0,\infty))$ an* acoustic dispersion relation *if $\lambda = \omega^2$ satisfies the following:*

1. *$\lambda \in C^{(3)}(\mathbb{T}^3,[0,\infty))$.*
2. *$\lambda(0) = 0$, and the Hessian of λ is invertible at 0.*

A dispersion relation is called regular acoustic *if it is acoustic and $\lambda(k) > 0$ for $k \neq 0$. The 3×3-matrix A_0 is the Hessian of $\frac{1}{2}\lambda$ at $k = 0$ and $\omega_0(q) = \sqrt{q\cdot A_0 q}$.*

Let us briefly motivate why these assumptions should be satisfied quite generally. For instance, if α is exponentially decaying, $\lambda = \hat{\alpha}$ will be analytic and thus satisfies the first requirement. The stability condition $\lambda \geq 0$ also needs to be satisfied everywhere; otherwise, the harmonic system has exponentially increasing solutions and is a poor model for oscillations in a crystal. If $\lambda(0) \neq 0$, the dispersion relation is not singular at $k = 0$. Thus in order to have a singular dispersion relation, the only real restriction for exponentially decaying stable interactions is the assumption about invertibility of the Hessian. Our analysis could likely be extended to cover also more degenerate instances of λ, although this would require some additional effort. By analogous reasoning, acoustic normal modes—in the above sense—are seen to appear commonly also in the vector models discussed in section 1.1, at least for exponentially

decaying interactions. However, in the vector models level crossings can lead to additional singularities in the dispersion relations, which would require a separate study. Finally, let us remark that exponential decay is not essential, since only sufficient regularity of the Hessian of λ will be required in the proof. For instance, if there are $C, \delta > 0$ such that $|\alpha(\gamma)| \leq C|\gamma|^{-6-\delta}$, then $\lambda = \hat{\alpha}$ satisfies item 1 in Definition 2.2. This permits us to deal also with situations where α is obtained via linearization around an equilibrium of a nonlinear system with potentials decaying slightly faster than a Lennard–Jones potential.

A prototype for the kind of dispersion relations considered here is the dispersion relation of the nearest neighbor square lattice,

$$\omega_{\mathrm{nn}}(k) = \Big[\sum_{\nu=1}^{3} 2(1-\cos(2\pi k^{\nu}))\Big]^{\frac{1}{2}}. \tag{2.12}$$

This is clearly a regular acoustic dispersion relation, in the sense of Definition 2.2, and for it A_0 is proportional to a unit matrix and $\omega_0(q) = 2\pi|q|$. The corresponding elastic couplings are given by $\alpha_{\mathrm{nn}}(\gamma' - \gamma) = -\Delta_{\gamma'\gamma}$, where Δ is the discrete Laplacian of the square lattice. Explicitly,

$$\alpha_{\mathrm{nn}}(\gamma) = \begin{cases} 6 & \text{if } \gamma = 0, \\ -1 & \text{if } |\gamma| = 1, \\ 0, & \text{otherwise.} \end{cases} \tag{2.13}$$

To allow the creation of macroscopic oscillations we work with sequences of initial conditions that depend on the scaling parameter $\varepsilon > 0$ and consider the asymptotic behavior of the solutions as ε tends to 0.

2.1. Energy density and the lattice Wigner transform. From now on we will focus on analyzing asymptotic behavior of the fields $\psi_{\pm}$ as ε tends to 0. As is carefully discussed in [17], generalizing the definitions of the energy density and of the Wigner transform to the discrete setting is not completely obvious. In an attempt to minimize unnecessary repetition of certain basic results related to Wigner transforms, we will resort here to the definitions used in [14], which will allow us to rely on the properties proven in Appendix B of that reference. However, we wish to keep in mind that this choice might not be optimal for all purposes, and we refer the interested reader to the discussion and references found in [16, 17, 24] for further possibilities.

We employ here the definition that for any state $(u, v) \in X$, its energy density, $e^{\varepsilon} = e^{\varepsilon}[u, v]$, scaled to a lattice spacing $\varepsilon > 0$, is the following tempered distribution defined via the complex fields $\psi_{\sigma} = \psi_{\sigma}[u, v]$ in (2.7):

$$e^{\varepsilon}(x) = \sum_{\gamma \in \mathbb{Z}^3} \delta(x - \varepsilon\gamma) \frac{1}{2} \sum_{\sigma=\pm 1} |\psi_{\sigma}(\gamma)|^2, \tag{2.14}$$

where δ denotes the Dirac delta-distribution. This is a manifestly positive distribution which is identifiable with a measure whose total mass equals the total energy,

$$\begin{aligned} \int \mathrm{d}x\, e^{\varepsilon}[u, v](x) &= \sum_{\gamma \in \mathbb{Z}^3} \frac{1}{2} \sum_{\sigma=\pm 1} |\psi_{\sigma}(\gamma)|^2 = \frac{1}{2} \sum_{\sigma=\pm 1} \|\psi_{\sigma}\|^2 \\ &= \frac{1}{4} \sum_{\sigma=\pm 1} \int \mathrm{d}k\, |\omega(k)\hat{u}(k) + \mathrm{i}\sigma\hat{v}(k)|^2 = H(u, v) < \infty. \end{aligned} \tag{2.15}$$

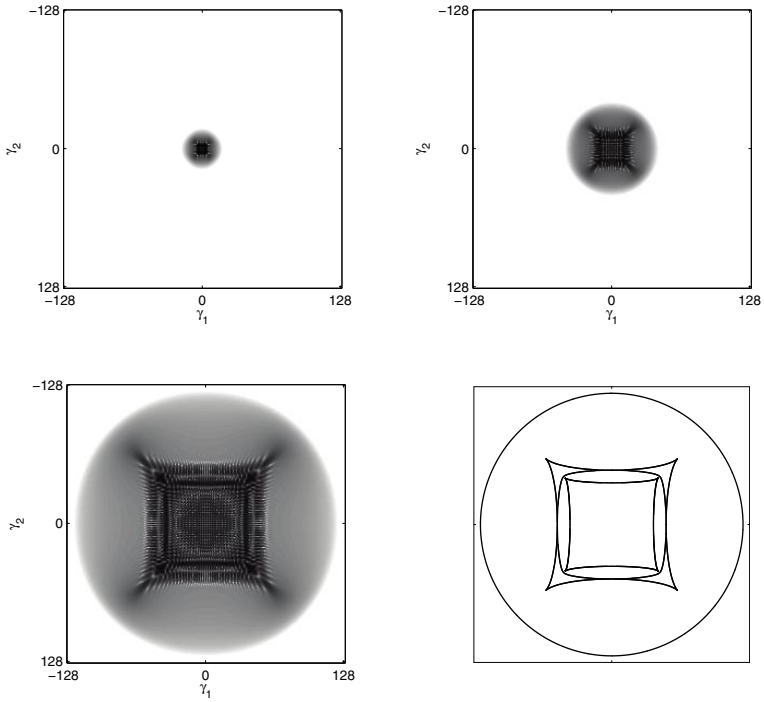

FIG. 2.2. *First three panels: Snapshots of the energy density* $|\psi_+(\gamma,t)|^2$ *in the plane* $\gamma_3 = 0$ *at* $t = 0.1/\varepsilon$, $t = 0.3/\varepsilon$, *and* $t = 0.95/\varepsilon$, $\varepsilon = \frac{1}{128}$, *with initial data and elastic constants as in Figure* 2.1. *The plot is of the logarithm of the density, with all values less than a fixed cutoff shown white. Last panel: Plot of the restriction to the plane* $x_3 = 0$ *of the singular set of the energy of the solution to the transport equation* (1.3), *using a corresponding choice of macroscopic initial data. As the solution is scale-invariant, no explicit length scale has been denoted.*

This justifies calling $e^\varepsilon[u,v]$ an energy density: it defines a distribution of the positive total energy between the lattice sites. The symmetry of ω implies that $|\psi_-(\gamma)| = |\psi_+(\gamma)|$, and thus we can also identify the energy density directly with the norm-density of $\psi_+[u,v]$,

$$e^\varepsilon(x) = \sum_{\gamma\in\mathbb{Z}^3} \delta(x-\varepsilon\gamma)|\psi_+(\gamma)|^2. \tag{2.16}$$

Then also for all $\varepsilon > 0$,

$$H(u,v) = \int \mathrm{d}x\, e^\varepsilon[u,v](x) = \|\psi_+\|^2_{\ell_2(\mathbb{Z}^3)} = \|\hat\psi_+\|^2_{L^2(\mathbb{T}^3)} = \|\hat\psi_-\|^2_{L^2(\mathbb{T}^3)}, \tag{2.17}$$

which is independent of t for any $(u,v) = (u_t, v_t)$.

Let us now concentrate on the case when a solution u_t to (2.1) has been given, and define for any t the distribution $e^\varepsilon(x,t)$ by setting

$$e^\varepsilon(x,t) = e^\varepsilon[u_{t/\varepsilon}, v_{t/\varepsilon}](x), \qquad x\in\mathbb{R}^3,\ t\in\mathbb{R}\,. \tag{2.18}$$

We have given an example of the time evolution of the energy density in Figure 2.2. The last panel in the figure contains the most obvious features which are implied

by the corresponding macroscopic evolution equation: the points of discontinuity of the solution. The macroscopic initial data is given by $\mathrm{d}\mu_0(x,k) = \delta(x)\frac{1}{2}|\omega(k)|^2\mathrm{d}x\mathrm{d}k$, which has no concentration at $k=0$. Thus only (1.3) is relevant. It is readily solved to yield as the energy density (defined in this case simply by integrating μ_t over the k-variable)

$$e(x,t) = \int_{\mathbb{T}^3} \mathrm{d}k\, \delta(x - t\tfrac{1}{2\pi}\nabla\omega(k)) = t^{-3}\int_{\mathbb{T}^3} \mathrm{d}k\, \delta(\tfrac{x}{t} - \tfrac{1}{2\pi}\nabla\omega(k))\,. \tag{2.19}$$

Evaluation of such integrals has been considered, for instance, in section 6.4 of [17]. $|\nabla\omega(k)|$ has its maximum near the point of discontinuity of the gradient, at $k=0$. This defines the outer circle outside which the solution must be zero. Inside the circle, the solution has a finite density, apart from points which correspond to values of k for which the Hessian of ω is not invertible. We have computed the positions of such points using *Mathematica* and plotted the result in the last panel in Figure 2.2. For a reader interested in the details of the computation, we point out that considering the case $x_3 = 0$ simplifies the problem, as it implies that either $k_3 = 0$ or $k_3 = \frac{1}{2}$.

We are interested in the limiting behavior of $e^\varepsilon(x,t)$ as ε tends to 0. Since the velocity of the waves with wave vector k depends on k, it is necessary to work with an object that encodes the density of waves with wave vector $k \in \mathbb{T}^3$ at $x \in \mathbb{R}^3$. This job is conveniently done by the Wigner transform. In order to avoid certain technical difficulties, we are going to define our Wigner transform only in the sense of distributions, i.e., via a duality principle.

First we introduce the space of Schwartz functions.

DEFINITION 2.3. *Let $\mathcal{S}_d = \mathcal{S}(\mathbb{R}^d)$ denote the Schwartz space and $\|\cdot\|_{\mathcal{S}_d,N}$ the corresponding Nth Schwartz norm. Explicitly, with α denoting an arbitrary multi-index and with $\langle x\rangle = \sqrt{1+x^2}$, then*

$$\|f\|_{\mathcal{S}_d,N} = \sup_{x\in\mathbb{R}^d}\max_{|\alpha|\le N} |\langle x\rangle^N \partial^\alpha f(x)|. \tag{2.20}$$

We also employ the shorthand notation $\mathcal{S} = \mathcal{S}_3$.

To extract the relevant weak limits as ε tends to 0, we have to specify a space of suitable test functions. We need to track the evolution of three different kinds of lattice vibrations (short, medium, and long wavelength), all done compatibly with the periodicity in the Fourier variable. This leads to the following, somewhat involved notion of multiscale test functions.

DEFINITION 2.4. *We call a test function $a \in C^\infty(\mathbb{R}^3\times\mathbb{T}^3\times\mathbb{R}^3)$* admissible *if it satisfies the following properties:*

1. $\sup_{k,q,|\alpha|\le N} \|\partial^\alpha_{k,q} a(\cdot,k,q)\|_{\mathcal{S},N} < \infty$ *for all* $N \ge 0$.
2. $q \mapsto a(x,k,q)$ *is constant for all* $x \in \mathbb{R}^3$ *and* k *such that* $\max_i |k_i \bmod T| \ge \frac{1}{4}$.
3. *There is a function* $b \in C^\infty(\mathbb{R}^3\times\mathbb{T}^3\times S^2)$ *such that for any* $N \ge 0$

$$\sup_{|q|\ge R, k\in\mathbb{T}^3} \|a(\cdot,k,q) - b(\cdot,k,\tfrac{q}{|q|})\|_{\mathcal{S},N} \to 0, \quad \text{when } R\to\infty. \tag{2.21}$$

The first and third conditions are the most important and can be summarized as follows: we assume the test functions to be Schwartz in x and smooth with bounded derivatives in k and q and to have a radial limit b in q which is approached uniformly in any of the Schwartz norms. The above requirements are not minimal. The second condition is only needed in order to guarantee that $k \mapsto a(x,k,(k \bmod T^3)/\varepsilon)$ is always

smooth on $\mathbb{T}^3$. Also, taking arbitrarily large N in the last step is not necessary; most likely $N = d + 3 = 6$ would suffice.

Having the notion of admissible test functions at our disposal we can define the central object of this paper: the multiscale Wigner transform.

DEFINITION 2.5. *Let $\psi \in \ell_2(\mathbb{Z}^3)$. We define the multiscale lattice Wigner transform $W^\varepsilon[\psi]$ at scale $\varepsilon > 0$ by*

$$\langle a, W^\varepsilon[\psi]\rangle = \int_{\mathbb{R}^3} \mathrm{d}p \int_{T^3} \mathrm{d}k\, \overline{\hat{a}(p, k, \tfrac{k}{\varepsilon})}\, \overline{\hat{\psi}(k - \varepsilon\tfrac{p}{2})}\hat{\psi}(k + \varepsilon\tfrac{p}{2}), \tag{2.22}$$

where a is an admissible test function and $\hat{a} = \mathcal{F}_{x\to p}a$, i.e.,

$$\hat{a}(p, k, q) = \int_{\mathbb{R}^3} \mathrm{d}x\, \mathrm{e}^{-2\pi \mathrm{i} p\cdot x} a(x, k, q). \tag{2.23}$$

The L^2-Wigner transform $W^{(\varepsilon)}_{cont}[\phi]$ of a function $\phi \in L^2(\mathbb{R}^3)$ at the scale $\varepsilon > 0$ is given by the distribution

$$b \mapsto \langle b, W^{(\varepsilon)}_{cont}[\phi]\rangle = \int_{\mathbb{R}^3\times\mathbb{R}^3} \mathrm{d}p\, \mathrm{d}q\, \overline{\hat{b}(p, q)}\, \overline{\hat{\phi}(q - \varepsilon\tfrac{p}{2})}\hat{\phi}(q + \varepsilon\tfrac{p}{2}) \tag{2.24}$$

for all $b \in \mathcal{S}(\mathbb{R}^3, C^\infty(\mathbb{R}^3))$, and with $\hat{b} = \mathcal{F}_{x\to p}b$.

The Wigner transform $W^{(\varepsilon)}_{\mathrm{cont}}$ is a rescaled version of the standard Wigner transform in L^2. The test-function space $\mathcal{S}(\mathbb{R}^3, C^\infty(\mathbb{R}^3))$ used above in its definition is obtained via the family of seminorms $p_N(b) = \sup_{|\alpha|,|x|,|q|\le N} |\langle x\rangle^N \partial^\alpha_{x,q} b(x, q)|$ with $b \in C^\infty(\mathbb{R}^3 \times \mathbb{R}^3)$. This is a Fréchet space, and $W^{(\varepsilon)}_{\mathrm{cont}}[\phi]$ is a continuous functional on it for any $\phi \in L^2(\mathbb{R}^3)$, as the following estimate reveals:

$$|\langle b, W^{(\varepsilon)}_{\mathrm{cont}}[\phi]\rangle| \le \sup_{p,q} |\langle p\rangle^4 \hat{b}(p, q)|\, \|\phi\|^2 \int_{\mathbb{R}^3} \mathrm{d}p\, \langle p\rangle^{-4}. \tag{2.25}$$

Although $\mathcal{S}_6$ is not dense in this test-function space, it is nevertheless enough to know how $W^{(\varepsilon)}_{\mathrm{cont}}$ acts on it. More precisely, if $W_i = W^{(\varepsilon)}_{\mathrm{cont}}[\phi_i]$, $i = 1, 2$, and $\langle b, W_1\rangle = \langle b, W_2\rangle$ for all $b \in \mathcal{S}_6$, then $W_1 = W_2$. This follows straightforwardly from an estimate similar to (2.25) using smooth cutoff functions to cut out the infinity of the q-variable. In addition, we will also need the property that if $b(x, q) = f(x)$, with $f \in \mathcal{S}_3$, then

$$\langle b, W^{(\varepsilon)}_{\mathrm{cont}}[\phi]\rangle = \int_{\mathbb{R}^3} \mathrm{d}x \overline{f(x)} |\phi(x)|^2. \tag{2.26}$$

That is, $\int_{\mathbb{R}^3} \mathrm{d}q\, W^{(\varepsilon)}_{\mathrm{cont}}[\phi](x, q) = |\phi(x)|^2$. For a more careful analysis of the properties of the standard Wigner transform, see [12].

In [14] the Wigner transform of a lattice state was defined as a distribution $W^\varepsilon_{\mathrm{latt}} \in \mathcal{S}'(\mathbb{R}^3 \times \mathbb{T}^3)$. The above definition is simply a refinement of this definition: formally for any ψ

$$W^\varepsilon(x, k, q) = \delta\big(q - \tfrac{k}{\varepsilon}\big) W^\varepsilon_{\mathrm{latt}}(x, k), \qquad x \in \mathbb{R}^3,\ k \in T^3,\ q \in \mathbb{R}^3\,. \tag{2.27}$$

This follows immediately from equation (B.6) of [14], after one realizes that if a is an admissible test function, then $(x, k) \mapsto a(x, k, (k \bmod T^3)/\varepsilon)$ belongs to $\mathcal{S}(\mathbb{R}^3 \times \mathbb{T}^3)$ for any $\varepsilon > 0$. This identification immediately allows us to use the results in [14] and

to prove that many of the basic properties of the usual Wigner transform carry over to the multiscale Wigner transform. Particularly important for us is the following relation.

PROPOSITION 2.6. *For any $f \in \mathcal{S}(\mathbb{R}^3)$, the test function $a_f(x,k,q) = f(x)$ is admissible, and for all $\varepsilon > 0$ and for all $(u,v) \in X$,*

$$\langle f, e^\varepsilon \rangle = \langle a_f, W^\varepsilon[\psi] \rangle, \tag{2.28}$$

where $e^\varepsilon = e^\varepsilon[u,v]$ and $\psi = \psi_+[u,v]$.

Proof. By inspection, we find that a is a well-defined test function and $\psi \in \ell_2$. Then, by the above-mentioned relation, $\langle a_f, W^\varepsilon[\psi] \rangle = \langle J_f, W^\varepsilon_{\mathrm{latt}}[\psi] \rangle$ with $J_f(x,k) = f(x)$. On the other hand, it follows directly from the definition of $W^\varepsilon_{\mathrm{latt}}$ (equation (B.2) in [14]) that

$$\begin{aligned} \langle J_f, W^\varepsilon_{\mathrm{latt}}[\psi] \rangle &= \sum_{\gamma,\gamma' \in \mathbb{Z}^3} \psi(\gamma)\overline{\psi(\gamma')} \int_{\mathbb{T}^3} \mathrm{d}k\, \mathrm{e}^{2\pi \mathrm{i} k \cdot (\gamma' - \gamma)} \overline{f(\varepsilon(\gamma' + \gamma)/2)} \\ &= \sum_{\gamma \in \mathbb{Z}^3} \overline{f(\varepsilon\gamma)} |\psi(\gamma)|^2 = \langle f, e^\varepsilon \rangle. \end{aligned} \tag{2.29}$$

This proves (2.28). ∎

The above proposition can be formally summarized by the formula

$$e^\varepsilon(x) = \int_{\mathbb{T}^3} \mathrm{d}k \int_{\mathbb{R}^3} \mathrm{d}q\, W^\varepsilon[\psi](x,k,q), \tag{2.30}$$

which implies also (in the sense of choosing any suitable test-function sequence approaching 1)

$$\int_{\mathbb{R}^3 \times \mathbb{T}^3 \times \mathbb{R}^3} \mathrm{d}x\, \mathrm{d}k\, \mathrm{d}q\, W^\varepsilon[\psi](x,k,q) = \|\psi\|^2_{\ell_2(\mathbb{Z}^3)}. \tag{2.31}$$

As noted earlier, analogous results hold for the L^2-Wigner transform.

Several definitions have been used in the literature to study homogenization limits of lattice systems. We follow [14] mainly for convenience. The definition in [14] is based on the "Weyl quantization rule" of symbols, and a similar definition of the Wigner transform as distributions with a "classical quantization rule" was proposed earlier in [16]. Other choices include using Husimi transforms or considering $L^2(\mathbb{T}^3) = L^2(T^3)$ as a subspace of $L^2(\mathbb{R}^3)$ and then relying on the standard Wigner transform [17]. Finally, one can consider also interpolations of the fields between lattice sites and then using the Wigner series defined in [12]. The relations between the various definitions are discussed in [11, 16, 17, 24]. As is apparent from the results presented in these references, the various 1-microlocal definitions tend to lead to the same limit Wigner measures. This is not the case for the above 2-microlocal measures, since at least the information about the quantization rule will be carried over to the homogenization limits. However, a more systematic study would be required to settle the issue.

3. Main results. The macroscopic evolution is obtained by sending ε to 0. Our objective is to characterize the asymptotic behavior of the Wigner transform $W^\varepsilon[\psi^\varepsilon_{t/\varepsilon}]$ of the solution $\psi^\varepsilon_{t/\varepsilon}$ of (2.10). The limit strongly depends on the dispersion relation ω. We will consider here regular acoustic dispersion relations, keeping in

mind that, for instance, in the case of a scalar field and nearest neighbor interactions in $\mathbb{Z}^3$ the dispersion relation ω is given by (2.12), which is regular acoustic with $\omega_0(q) = 2\pi|q|$. The main achievement of this paper as compared to [17] is that complicated assumptions concerning the concentrations of the Wigner transform W^ε in wavenumber space as ε tends to 0 are no longer needed. The only remaining requirements are boundedness and tightness of the sequence of initial excitations.

ASSUMPTION 3.1. *We consider a sequence of values $\varepsilon > 0$ such that $\varepsilon \to 0$. For each ε in the sequence we assume that there is given an initial data vector $\psi_0^\varepsilon \in \ell_2(\mathbb{Z}^3)$ such that*

1. $\sup_\varepsilon \|\psi_0^\varepsilon\| < \infty$;
2. *the sequence ψ_0^ε is tight on the scale ε^{-1}:*

$$\lim_{R\to\infty} \limsup_{\varepsilon\to 0} \sum_{|\gamma|>R/\varepsilon} |\psi_0^\varepsilon(\gamma)|^2 = 0. \tag{3.1}$$

After these preparations we are in a position to state our result. The main point is that if ω is a regular acoustic dispersion relation, the asymptotic behavior of the energy density is characterized by precisely three different objects: a Wigner transform of a weak limit (macroscopic waves), an H-measure (short macroscopic waves), and a Wigner measure (microscopic waves). No assumptions concerning energy concentrations except those stated in Assumption 3.1 are required.

THEOREM 3.2. *Let $\psi_0^\varepsilon \in \ell_2(\mathbb{Z}^3)$ be a sequence which satisfies Assumption* 3.1. *Let ω be a regular acoustic dispersion relation and define $\psi_t^\varepsilon \in \ell_2(\mathbb{Z}^3)$ for all $t \in \mathbb{R}$ by the formula*

$$\hat{\psi}_t^\varepsilon(k) = \mathrm{e}^{-\mathrm{i}t\omega(k)} \hat{\psi}_0^\varepsilon(k). \tag{3.2}$$

Let also $\mathbb{T}^3_* = \mathbb{T}^3 \setminus \{0\}$. Then there are positive, bounded Radon measures $\mu_0, \mu_0^{\mathrm{H}}$ on $\mathbb{R}^3 \times \mathbb{T}^3_*$ and $\mathbb{R}^3 \times S^2$, respectively, a function $\phi_0 \in L^2(\mathbb{R}^3)$, and a subsequence (not relabeled) such that for all admissible test functions a and $t \in \mathbb{R}$,

$$\begin{aligned} \lim_{\varepsilon\to 0} \langle a, W^\varepsilon[\psi^\varepsilon_{t/\varepsilon}]\rangle &= \int_{\mathbb{R}^3\times\mathbb{T}^3_*} \mathrm{d}\mu_t(x,k)\, \overline{b(x,k,\tfrac{k}{|k|})} \\ &\quad + \int_{\mathbb{R}^3\times S^2} \mathrm{d}\mu_t^{\mathrm{H}}(x,q)\, \overline{b(x,0,q)} + \langle a_0, W^{(1)}_{cont}[\phi_t]\rangle\,, \end{aligned} \tag{3.3}$$

where $b(x,k,q) = \lim_{R\to\infty} a(x,k,Rq)$ for $|q| = 1$, $a_0(x,q) = a(x,0,q)$, and ϕ_t, μ_t and μ_t^{H} are determined for any $f \in C(\mathbb{R}^3 \times \mathbb{T}^3_*)$ and $g \in C(\mathbb{R}^3 \times S^2)$ by

$$\hat{\phi}_t(q) := \mathrm{e}^{-\mathrm{i}t\omega_0(q)} \hat{\phi}_0(q), \tag{3.4}$$

$$\int_{\mathbb{R}^3\times\mathbb{T}^3_*} f(x,k)\,\mathrm{d}\mu_t(x,k) := \int_{\mathbb{R}^3\times\mathbb{T}^3_*} f(x + t\tfrac{1}{2\pi}\nabla\omega(k), k)\,\mathrm{d}\mu_0(x,k), \tag{3.5}$$

$$\int_{\mathbb{R}^3\times S^2} g(x,q)\,\mathrm{d}\mu_t^{\mathrm{H}}(x,q) := \int_{\mathbb{R}^3\times S^2} g(x + t\tfrac{1}{2\pi}\nabla\omega_0(q), q)\,\mathrm{d}\mu_0^{\mathrm{H}}(x,q)\,. \tag{3.6}$$

Moreover, for all t the energy equality holds:

$$\lim_{\varepsilon\to 0} \|\psi_0^\varepsilon\|^2 = \mu_t(\mathbb{R}^3\times\mathbb{T}^3_*) + \mu_t^{\mathrm{H}}(\mathbb{R}^3\times S^2) + \|\phi_t\|^2_{L^2(\mathbb{R}^3)}\,. \tag{3.7}$$

Remark 3.3. It is immediate from the definition that ϕ, μ, and μ^{H} are weak solutions of the set of decoupled linear transport equations (1.3)–(1.5).

The proof of Theorem 3.2 also shows that the subsequences which are extracted in the statement of the theorem can be characterized by a simple condition. In particular, the initial state of the wave equation, ϕ_0, is determined as the weak-$L^2(\mathbb{R}^3)$ limit of the sequence of the functions (ϕ_0^ε) with Fourier transforms

$$\hat{\phi}_0^\varepsilon(q) = \begin{cases} \varepsilon^{\frac{3}{2}} \hat{\psi}_0^\varepsilon(\varepsilon q) & \text{if } \|q\|_\infty \leq \frac{1}{2\varepsilon}, \\ 0, & \text{otherwise.} \end{cases} \tag{3.8}$$

The exact characterization is contained in the following corollary, whose proof will be given in section 5.

COROLLARY 3.4. *Let (ψ_0^ε) be a sequence which satisfies Assumption* 3.1. *Suppose that ϕ_0^ε converges weakly to ϕ_0, and that $\lim_{\varepsilon\to 0}\langle a, W^\varepsilon[\psi_0^\varepsilon]\rangle$ exists for every admissible test function a. Then there are unique positive, bounded Radon measures $\mu_0, \mu_0^{\mathrm{H}}$ on $\mathbb{R}^3 \times \mathbb{T}^3_*$ and $\mathbb{R}^3 \times S^2$, respectively, such that for every admissible test function a*

$$\begin{aligned} \lim_{\varepsilon\to 0}\langle a, W^\varepsilon[\psi_0^\varepsilon]\rangle = &\int_{\mathbb{R}^3\times\mathbb{T}^3_*} \mathrm{d}\mu_0(x,k)\, \overline{b(x,k,\tfrac{k}{|k|})} \\ &+ \int_{\mathbb{R}^3\times S^2} \mathrm{d}\mu_0^{\mathrm{H}}(x,q)\, \overline{b(x,0,q)} + \langle a_0, W^{(1)}_{cont}[\phi_0]\rangle\,, \end{aligned} \tag{3.9}$$

where a_0 and b are defined as in Theorem 3.2. *In addition, then* (3.3) *holds for all $t \in \mathbb{R}$ along the original sequence ε with the initial macroscopic data determined by the triplet $(\mu_0, \mu_0^{\mathrm{H}}, \phi_0)$.*

Remark 3.5. According to (2.27) for $a \in \mathcal{S}(\mathbb{R}^3 \times \mathbb{T}^3)$ the lattice Wigner transform $W^\varepsilon_{\mathrm{latt}}[\psi_0^\varepsilon]$ satisfies

$$\langle a, W^\varepsilon_{\mathrm{latt}}[\psi_0^\varepsilon]\rangle = \langle a, W^\varepsilon[\psi_0^\varepsilon]\rangle\,. \tag{3.10}$$

It is well known (see, e.g., [14]) that $W^\varepsilon_{\mathrm{latt}}[\psi_0^\varepsilon]$ has a limit μ_{latt},

$$\lim_{\varepsilon\to 0}\langle a, W^\varepsilon_{\mathrm{latt}}[\psi_0^\varepsilon]\rangle = \int_{\mathbb{R}^3\times\mathbb{T}^3} \mathrm{d}\mu_{\mathrm{latt}}(x,k)\, \overline{a(x,k)}\,, \tag{3.11}$$

which is a positive Radon measure on $\mathbb{R}^3 \times \mathbb{T}^3$. Evaluating (3.9) for $a \in \mathcal{S}(\mathbb{R}^3 \times \mathbb{T}^3)$ shows that the "standard Wigner measure" μ_{latt} can be expressed in terms of the two-scale Wigner measure according to

$$\mathrm{d}\mu_{\mathrm{latt}}(x,k) = \mathrm{d}\mu_{\mathrm{latt}}(x,k)\, \mathbb{1}(k \neq 0) + \int_{q\in S^2} \mathrm{d}\mu_0^{\mathrm{H}}(x,q) \otimes \delta(k)\mathrm{d}k + |\phi_0(x)|^2 \mathrm{d}x \otimes \delta(k)\mathrm{d}k\,, \tag{3.12}$$

where $\mathrm{d}x$ denotes Lebesgue measure on $\mathbb{R}^3$, δ the Dirac δ-function, and $\mathbb{1}$ the characteristic function.

Remark 3.6. Our proof of the existence of two-scale Wigner measures is similar to the strategy proposed by Fermanian Kammerer in [4, 5]. For a general result on existence of two-scale Wigner measures concentrating on hypersurfaces, see [6]. (See [6, Theorem 1.4] for a simple formulation in one dimension and [6, Theorem 1.6] for the general case.) Concerning the existence part the only novelty in our result is thus the use of the lattice Wigner transform.

However, in our approach we obtain the existence of the measures together with their time evolution. While the strategy for obtaining transport equations for two-scale Wigner measures outlined in section 6 of [7] is not directly applicable in our

case due to the singular nature of the dispersion relation ω, it could certainly be adapted. The existence part and the transport part of the result could thus be separated. However, our proof is technically simpler and we do not rely on any advanced pseudodifferential calculus.

4. Proof of Theorem 3.2. Let a be an admissible test function and consider a fixed $t \in \mathbb{R}$ when we need to inspect the $\varepsilon \to 0$ limit of

$$\langle a, W^\varepsilon[\psi^\varepsilon_{t/\varepsilon}]\rangle = \int_{\mathbb{R}^3} \mathrm{d}p \int_{\mathbb{T}^3} \mathrm{d}k\, \overline{\hat{a}(p,k,\tfrac{k}{\varepsilon})}\, \mathrm{e}^{-\mathrm{i}\frac{t}{\varepsilon}\left(\omega(k+\varepsilon\frac{p}{2})-\omega(k-\varepsilon\frac{p}{2})\right)}\, \overline{\hat{\psi}^\varepsilon_0(k-\varepsilon\tfrac{p}{2})}\, \hat{\psi}^\varepsilon_0(k+\varepsilon\tfrac{p}{2})\,. \tag{4.1}$$

First we identify the function ϕ_0 which contains the contributions of the long-wave excitations. Let $\hat{\phi}^\varepsilon_0$ be defined by (3.8). Since $\limsup_{\varepsilon\to 0}\|\hat{\phi}^\varepsilon_0\|_{L^2} = \limsup_{\varepsilon\to 0}\|\psi^\varepsilon_0\|_{\ell_2}$ is bounded by Assumption 3.1 there exist a subsequence and a function $\phi_0 \in L^2(\mathbb{R}^3)$ such that ϕ^ε_0 converges weakly to ϕ_0 in $L^2(\mathbb{R}^3)$. We then define ϕ_t by (3.4).

Using a localization function χ, which will be specified later, we now split the integral I on the right-hand side of (4.1) into three parts and an error term so that the contributions of short-, medium-, and long-wave excitation can be analyzed separately. We define

$$\begin{aligned}
I_> &= \int_{\mathbb{R}^3} \mathrm{d}p \int_{\mathbb{T}^3} \mathrm{d}k\, \overline{\hat{a}(p,k,\tfrac{k}{\varepsilon})}\, \mathrm{e}^{-\mathrm{i}\frac{t}{\varepsilon}\left(\omega(k+\varepsilon\frac{p}{2})-\omega(k-\varepsilon\frac{p}{2})\right)}\, \overline{\hat{\psi}^\varepsilon_0(k-\varepsilon\tfrac{p}{2})}\, \hat{\psi}^\varepsilon_0(k+\varepsilon\tfrac{p}{2})(1-\chi),\\
I^{\mathrm{H}}_< &= \int_{\mathbb{R}^3} \mathrm{d}p \int_{\mathbb{T}^3} \mathrm{d}k\, \overline{\hat{a}(p,k,\tfrac{k}{\varepsilon})}\, \mathrm{e}^{-\mathrm{i}\frac{t}{\varepsilon}\left(\omega(k+\varepsilon\frac{p}{2})-\omega(k-\varepsilon\frac{p}{2})\right)}\, \overline{(\hat{\psi}^\varepsilon_0(k-\varepsilon\tfrac{p}{2}) - \varepsilon^{-\frac{3}{2}}\hat{\phi}_0(\tfrac{k}{\varepsilon}-\tfrac{p}{2}))}\\
&\qquad \times (\hat{\psi}^\varepsilon_0(k+\varepsilon\tfrac{p}{2}) - \varepsilon^{-\frac{3}{2}}\hat{\phi}_0(\tfrac{k}{\varepsilon}+\tfrac{p}{2}))\chi,\\
I^{\mathrm{wv}}_< &= \varepsilon^{-3}\int_{\mathbb{R}^3} \mathrm{d}p \int_{\mathbb{T}^3} \mathrm{d}k\, \overline{\hat{a}(p,k,\tfrac{k}{\varepsilon})}\, \mathrm{e}^{-\mathrm{i}\frac{t}{\varepsilon}\left(\omega(k+\varepsilon\frac{p}{2})-\omega(k-\varepsilon\frac{p}{2})\right)}\, \overline{\hat{\phi}_0(\tfrac{k}{\varepsilon}-\tfrac{p}{2})}\, \hat{\phi}_0(\tfrac{k}{\varepsilon}+\tfrac{p}{2})\chi,\\
R &= I - I_> - I^{\mathrm{H}}_< - I^{\mathrm{wv}}_<.
\end{aligned}$$

The definition of R implies that

$$\langle a, W^\varepsilon[\psi^\varepsilon_{t/\varepsilon}]\rangle = I_> + I^{\mathrm{H}}_< + I^{\mathrm{wv}}_< + R. \tag{4.2}$$

To localize the oscillations in Fourier space we need smooth cutoff functions.

DEFINITION 4.1. *Let $f \in C^\infty(\mathbb{R},[0,1])$ denote a fixed function which is symmetric, $f(-x) = f(x)$, strictly monotonically decreasing on $[1,2]$, and*

$$f(x) = \begin{cases} 1 & \text{if } |x| \le 1,\\ 0 & \text{if } |x| \ge 2. \end{cases} \tag{4.3}$$

We further define $\varphi \in C^\infty(\mathbb{R}^3,[0,1])$ by $\varphi(k) = f(|k|)$.

Let $0 < \rho \le \frac{1}{4}$ be arbitrary and set $\chi = \chi(k,p;\varepsilon,\rho) = \varphi(\frac{k_+}{\rho})\varphi(\frac{k_-}{\rho})$, where $k_\pm = k \pm \varepsilon\frac{p}{2}$. We will continue to use this shorthand notation in the following under the tacit assumption that $k_\pm$ is always really a function of both k and εp. Let us now also point out that all four terms in the decomposition (4.2) depend on ε and ρ, via χ, even though we have not denoted this dependence explicitly.

The first term containing $1-\chi$ in (4.2) is zero if $|k_\pm| \le \rho$, while the remainder is zero if $|k_+|$ or $|k_-| \ge 2\rho$. Thus the chosen decomposition splits the integration over k and p into "large," "intermediate," and "small" wavenumbers. We will demonstrate

that the following convergences hold: there is a sequence of ρ, a subsequence of ε, and measures $\mu_t, \mu_t^{\mathrm{H}}$ satisfying the statements made in the theorem, such that

$$\lim_{\rho\to 0}\lim_{\varepsilon\to 0} I_> = \int_{\mathbb{R}^3\times\mathbb{T}^3_*} \mathrm{d}\mu_t(x,k)\,\overline{b(x,k,\tfrac{k}{|k|})}, \tag{4.4}$$

$$\lim_{\rho\to 0}\lim_{\varepsilon\to 0} I_<^{\mathrm{H}} = \int_{\mathbb{R}^3\times S^2} \mathrm{d}\mu_t^{\mathrm{H}}(x,q)\,\overline{b(x,0,q)}, \tag{4.5}$$

$$\lim_{\rho\to 0}\limsup_{\varepsilon\to 0}\left| I_<^{\mathrm{wv}} - \langle a_0, W^{(1)}_{\mathrm{cont}}[\phi_t]\rangle\right| = 0, \tag{4.6}$$

$$\lim_{\rho\to 0}\limsup_{\varepsilon\to 0}|R| = 0. \tag{4.7}$$

Clearly, (4.4)–(4.7) then imply (3.3).

Large wavenumbers. We split $I_>$ further into two parts using

$$\begin{aligned} 1-\varphi\left(\tfrac{k_-}{\rho}\right)\varphi\left(\tfrac{k_+}{\rho}\right) &= 1-\varphi\left(\tfrac{k}{\rho}\right)^2 + \left(\varphi\left(\tfrac{k}{\rho}\right)-\varphi\left(\tfrac{k_+}{\rho}\right)\right)\varphi\left(\tfrac{k}{\rho}\right) \\ &\quad + \left(\varphi\left(\tfrac{k}{\rho}\right)-\varphi\left(\tfrac{k_-}{\rho}\right)\right)\varphi\left(\tfrac{k_+}{\rho}\right). \end{aligned} \tag{4.8}$$

Let $h_\rho(k) = 1-\varphi(\frac{k}{\rho})^2$, which is a smooth function. The integral then becomes $I_> = I_>^1 + R_1$, where

$$I_>^1 = \int_{\mathbb{R}^3}\mathrm{d}p\int_{\mathbb{T}^3}\mathrm{d}k\,\overline{\hat a(p,k,\tfrac{k}{\varepsilon})}h_\rho(k)\,\mathrm{e}^{-\mathrm{i}\frac{t}{\varepsilon}\left(\omega(k+\varepsilon\frac{p}{2})-\omega(k-\varepsilon\frac{p}{2})\right)}\,\overline{\hat\psi_0^\varepsilon(k-\varepsilon\tfrac{p}{2})}\,\hat\psi_0^\varepsilon(k+\varepsilon\tfrac{p}{2}). \tag{4.9}$$

The remainder R_1 can be estimated using $|\varphi|\le 1$ and

$$\varphi\left(\tfrac{k_\pm}{\rho}\right)-\varphi\left(\tfrac{k}{\rho}\right) = \pm\tfrac{\varepsilon}{2\rho}\int_0^1 \mathrm{d}s\, p\cdot\nabla\varphi\Big(\tfrac{1}{\rho}(k\pm s\tfrac{\varepsilon}{2}p)\Big), \tag{4.10}$$

which yield the bound, with a universal constant C,

$$|R_1| \le C\tfrac{\varepsilon}{\rho}\sup_{k,q}\|a(\cdot,k,q)\|_{\mathcal{S},d+2}\|\hat\psi_0^\varepsilon\|^2\|\nabla\varphi\|_\infty. \tag{4.11}$$

Therefore, there is a constant c' such that $|R_1|\le c'\varepsilon/\rho$ and thus $R_1\to 0$ when $\varepsilon\to 0$ for all ρ.

We then consider $I_>^1$. The presence of h_ρ guarantees that the integrand is zero unless $|k|\ge\rho$. Thus we can change $\hat a(p,k,k/\varepsilon)$ to $\hat b(p,k,k/|k|)$ in the integrand with an error R_2 bounded by

$$|R_2| \le C\sup_{k,|q|\ge\rho/\varepsilon}\|a(\cdot,k,q)-b(\cdot,k,\tfrac{q}{|q|})\|_{\mathcal{S},d+1}\|\hat\psi_0^\varepsilon\|^2, \tag{4.12}$$

where C is a universal constant. Therefore, the assumptions imply that $R_2\to 0$ when $\varepsilon\to 0$ for all ρ. On the other hand, for $|k|\ge\rho$ and $|p|<\rho/\varepsilon$, inequality (A.2) derived in the appendix implies

$$\left|\tfrac{1}{\varepsilon}\left(\omega(k+\varepsilon\tfrac{p}{2})-\omega(k-\varepsilon\tfrac{p}{2})\right)-p\cdot\nabla\omega(k)\right| \le C_3\varepsilon\tfrac{|p|^2}{|k|}\le C_3\tfrac{\varepsilon}{\rho}|p|^2. \tag{4.13}$$

Therefore, using the estimate $|\mathrm{e}^{\mathrm{i}x} - \mathrm{e}^{\mathrm{i}y}| \leq \min(|x-y|, 2)$, valid for all $x, y \in \mathbb{R}$, we find that we can further change the t-dependent exponential in the integrand to $\mathrm{e}^{-\mathrm{i}tp\cdot\nabla\omega(k)}$ with an error R_3 satisfying

$$|R_3| \leq C \sup_{k,q} \|b(\cdot,k,q)\|_{\mathcal{S},d+3} \Big(\tfrac{\varepsilon}{\rho}|t| + \int_{|p|\geq\rho/\varepsilon} \mathrm{d}p \langle p\rangle^{-d-3} \Big) \tag{4.14}$$

for some constant C. Therefore, also $\lim_{\varepsilon\to 0} R_3 = 0$ for all ρ. In summary, $I^1_> = I^2_> + R_2 + R_3$, where R_2, R_3 are negligible, and

$$I^2_> = I^2_>(\varepsilon,\rho) = \int_{\mathbb{R}^3} \mathrm{d}p \int_{\mathbb{T}^3} \mathrm{d}k\, \overline{\hat{b}(p,k,\tfrac{k}{|k|})} h_\rho(k) \mathrm{e}^{-\mathrm{i}tp\cdot\nabla\omega(k)}\, \overline{\hat{\psi}^\varepsilon_0(k-\varepsilon\tfrac{p}{2})}\, \hat{\psi}^\varepsilon_0(k+\varepsilon\tfrac{p}{2})\,. \tag{4.15}$$

Let us for a moment consider the lattice Wigner transform $W^\varepsilon_{\mathrm{latt}}$ of ψ^ε_0 as defined in [14]. As pointed out after Definition 2.5, then for any test function $f \in \mathcal{S}(\mathbb{R}^3\times\mathbb{T}^3)$, we get an admissible test function by the formula $a_f(x,k,q) = f(x,k)$ and $\langle f, W^\varepsilon_{\mathrm{latt}}\rangle = \langle a_f, W^\varepsilon[\psi^\varepsilon_0]\rangle$. Since ψ^ε_0 is a norm-bounded sequence, the sequence $W^\varepsilon_{\mathrm{latt}}$ is weak-$*$ bounded, and thus there are $W^0_{\mathrm{latt}} \in \mathcal{S}'(\mathbb{R}^3\times\mathbb{T}^3)$ and a subsequence along which $W^\varepsilon_{\mathrm{latt}} \overset{*}{\rightharpoonup} W^0_{\mathrm{latt}}$.

Since the sequence ψ^ε_0 is by assumption also tight on the scale ε^{-1}, we can then apply Theorems B.4 and B.5 of [14] and conclude that W^0_{latt} is given by a positive, bounded Radon measure μ on $\mathbb{R}^3\times\mathbb{T}^3$ such that for all *continuous* functions $f \in C(\mathbb{T}^3)$ and $p \in \mathbb{R}^3$,

$$\lim_{\varepsilon\to 0} \int_{\mathbb{T}^3} \mathrm{d}k\, f(k) \overline{\hat{\psi}^\varepsilon_0(k-\varepsilon\tfrac{p}{2})}\, \hat{\psi}^\varepsilon_0(k+\varepsilon\tfrac{p}{2}) = \int_{\mathbb{R}^3\times\mathbb{T}^3} \mathrm{d}\mu(x,k)\, f(k) \mathrm{e}^{-2\pi\mathrm{i}p\cdot x}. \tag{4.16}$$

Because $\nabla\omega(k)$ and $\frac{k}{|k|}$ are continuous apart from $k=0$, the function $k \mapsto h_\rho(k)\overline{\hat{b}(p,k,\frac{k}{|k|})}\mathrm{e}^{-\mathrm{i}tp\cdot\nabla\omega(k)}$ is everywhere continuous for all $\rho > 0$ and $p \in \mathbb{R}^3$. Therefore, by the dominated convergence theorem, for all ρ we find

$$\begin{aligned} \lim_{\varepsilon\to 0} I^2_> &= \int_{\mathbb{R}^3} \mathrm{d}p \int_{\mathbb{R}^3\times\mathbb{T}^3} \mathrm{d}\mu(x,k)\, \overline{\hat{b}(p,k,\tfrac{k}{|k|})} h_\rho(k) \mathrm{e}^{-2\pi\mathrm{i}p\cdot(x+t\nabla\omega(k)(2\pi)^{-1})} \\ &= \int_{\mathbb{R}^3\times\mathbb{T}^3} \mathrm{d}\mu(x,k)\, h_\rho(k) \overline{b(x+t\tfrac{1}{2\pi}\nabla\omega(k),k,\tfrac{k}{|k|})}\,. \end{aligned} \tag{4.17}$$

When $\rho\to 0$, the integrand approaches pointwise $\overline{b(x+t\frac{1}{2\pi}\nabla\omega(k),k,\frac{k}{|k|})}$ apart from $k=0$ when the limit is 0. Therefore, by the dominated convergence theorem

$$\begin{aligned} &\lim_{\rho\to 0} \int_{\mathbb{R}^3\times\mathbb{T}^3} \mathrm{d}\mu(x,k)\, h_\rho(k) \overline{b(x+t\tfrac{1}{2\pi}\nabla\omega(k),k,\tfrac{k}{|k|})} \\ &= \int_{\mathbb{R}^3\times\mathbb{T}^3_*} \mathrm{d}\mu(x,k)\, \overline{b(x+t\tfrac{1}{2\pi}\nabla\omega(k),k,\tfrac{k}{|k|})} = \int_{\mathbb{R}^3\times\mathbb{T}^3_*} \mathrm{d}\mu_t(x,k)\, \overline{b(x,k,\tfrac{k}{|k|})}, \end{aligned} \tag{4.18}$$

where we have defined the bounded, positive Radon measure μ_t using $\mu_0 = \mu|_{\mathbb{R}^3\times\mathbb{T}^3_*}$ in the formula (3.5). We have shown that (4.4) holds.

Small wavenumbers and the remainder. After a change of variables $q = \frac{k}{\varepsilon}$, one obtains that

$$I^{\mathrm{wv}}_< = \int_{\mathbb{R}^3} \mathrm{d}p \int_{T^3/\varepsilon} \mathrm{d}q\, \overline{\hat{a}(p,\varepsilon q,q)}\, \mathrm{e}^{-\mathrm{i}\frac{t}{\varepsilon}(\omega(\varepsilon q_+)-\omega(\varepsilon q_-))}\, \overline{\hat{\phi}_0(q_-)}\, \hat{\phi}_0(q_+)\, \varphi(\tfrac{\varepsilon q_+}{\rho})\, \varphi(\tfrac{\varepsilon q_-}{\rho})\,, \tag{4.19}$$

where $q_\pm = q \pm \frac{p}{2}$. We can immediately replace the integration region for the q-integral by $\mathbb{R}^3$. To see this, note that the integrand is zero, unless $|q \pm \frac{p}{2}| \leq \frac{2\rho}{\varepsilon}$ for both signs. Since $2q = q_+ + q_-$, this can happen only if also $|q| \leq \frac{2\rho}{\varepsilon} \leq \frac{1}{2\varepsilon}$, which implies that the integrand is zero if $\|q\|_\infty > \frac{1}{2\varepsilon}$.

However, if $|\varepsilon q| \leq 2\rho$, then

$$|\hat{a}(p, \varepsilon q, q) - \hat{a}(p, 0, q)| \leq \sup_k |\nabla_k \hat{a}(p, k, q)|\, 2\rho, \tag{4.20}$$

and thus we can replace in the integrand the function $\hat{a}(p, \varepsilon q, q)$ by $\hat{a}(p, 0, q)$, with an error R_1' which is bounded by $C\rho$ with a constant C independent of ε and ρ. Thus we only need to consider the integral

$$I_<^1 = \int_{\mathbb{R}^3} \mathrm{d}p \int_{\mathbb{R}^3} \mathrm{d}q\, \overline{\hat{a}(p, 0, q)}\, \mathrm{e}^{-\mathrm{i}\frac{t}{\varepsilon}(\omega(\varepsilon q_+) - \omega(\varepsilon q_-))}\, \overline{F^{\varepsilon,\rho}(q_-)} F^{\varepsilon,\rho}(q_+), \tag{4.21}$$

where $F^{\varepsilon,\rho}(q) = \hat{\phi}_0(q)\varphi(\frac{\varepsilon q}{\rho})$. Next we apply the estimate (A.3) derived in the appendix, proving that if now $|p| \leq \frac{1}{2\varepsilon}$, then

$$\left|\tfrac{1}{\varepsilon}(\omega(\varepsilon q_+) - \omega(\varepsilon q_-)) - \omega_0(q_+) + \omega_0(q_-)\right| \leq C_4 \varepsilon |p|\, |q|\,. \tag{4.22}$$

Following the same argument as earlier, we can then conclude that the t-dependent exponential can be changed to $\mathrm{e}^{-\mathrm{i}t(\omega_0(q_+) - \omega_0(q_-))}$, with an error R_2' which satisfies the estimate

$$|R_2'| \leq C \sup_q \|a(\cdot, 0, q)\|_{\mathcal{S}, d+2} \Big(|t|\rho + \int_{|p| \geq (2\varepsilon)^{-1}} \mathrm{d}p\, \langle p \rangle^{-d-2} \Big). \tag{4.23}$$

Thus $\lim_{\rho \to 0} \limsup_{\varepsilon \to 0} |R_2'| = 0$ for all t. Finally, we need to change $F^{\varepsilon,\rho}$ to $\hat{\phi}_0$, with an error R_3' which can be bounded by $C\|F^{\varepsilon,\rho} - \hat{\phi}_0\|$. Since the bound goes to zero when $\varepsilon \to 0$ and

$$I_<^{\mathrm{wv}} = \int_{\mathbb{R}^3} \mathrm{d}p \int_{\mathbb{R}^3} \mathrm{d}q\, \overline{\hat{a}(p, 0, q)}\, \mathrm{e}^{-\mathrm{i}t(\omega_0(q_+) - \omega_0(q_-))}\, \overline{\hat{\phi}_0(q_-)} \hat{\phi}_0(q_+) + R_1' + R_2' + R_3', \tag{4.24}$$

equation (4.6) has been established.

Similar estimates can be employed to demonstrate the vanishing of the remainder, (4.7). From the definition of R we get

$$\begin{aligned} R = &\int_{\mathbb{R}^3} \mathrm{d}p \int_{T^3/\varepsilon} \mathrm{d}q\, \overline{\hat{a}(p, \varepsilon q, q)}\, \mathrm{e}^{-\mathrm{i}\frac{t}{\varepsilon}(\omega(\varepsilon q_+) - \omega(\varepsilon q_-))}\, \overline{\Big(\hat{\phi}_0^\varepsilon(q_-) - \hat{\phi}_0(q_-)\Big)}\, \hat{\phi}_0(q_+) \varphi(\tfrac{\varepsilon q_+}{\rho})\, \varphi(\tfrac{\varepsilon q_-}{\rho}) \\ &+ \int_{\mathbb{R}^3} \mathrm{d}p \int_{T^3/\varepsilon} \mathrm{d}q \overline{\hat{a}(p, \varepsilon q, q)}\, \mathrm{e}^{-\mathrm{i}\frac{t}{\varepsilon}(\omega(\varepsilon q_+) - \omega(\varepsilon q_-))}\, \overline{\hat{\phi}_0(q_-)} \Big(\hat{\phi}_0^\varepsilon(q_+) - \hat{\phi}_0(q_+)\Big) \varphi(\tfrac{\varepsilon q_+}{\rho}) \varphi(\tfrac{\varepsilon q_-}{\rho}). \end{aligned} \tag{4.25}$$

We then apply the above estimates to remove the ε-dependence from all other terms in the integrands, apart from the differences $\hat{\phi}_0^\varepsilon - \hat{\phi}_0$. The error has a bound which vanishes when $\rho \to 0$. We are then left with

$$\begin{aligned} &\int_{\mathbb{R}^3} \mathrm{d}\eta \int_{\mathbb{R}^3} \mathrm{d}\xi\, \overline{\hat{a}(\eta - \xi, 0, \tfrac{1}{2}(\eta + \xi))}\, \mathrm{e}^{-\mathrm{i}t(\omega_0(\eta) - \omega_0(\xi))}\, \overline{\Big(\hat{\phi}_0^\varepsilon(\xi) - \hat{\phi}_0(\xi)\Big)}\, \hat{\phi}_0(\eta) \\ &+ \int_{\mathbb{R}^3} \mathrm{d}\eta \int_{\mathbb{R}^3} \mathrm{d}\xi\, \overline{\hat{a}(\eta - \xi, 0, \tfrac{1}{2}(\eta + \xi))}\, \mathrm{e}^{-\mathrm{i}t(\omega_0(\eta) - \omega_0(\xi))}\, \overline{\hat{\phi}_0(\xi)} \Big(\hat{\phi}_0^\varepsilon(\eta) - \hat{\phi}_0(\eta)\Big), \end{aligned} \tag{4.26}$$

which vanishes as $\varepsilon \to 0$, since ϕ_0^ε converges weakly to ϕ_0. This establishes (4.7).

Intermediate wavenumbers. Changing coordinates to $q = \frac{k}{\varepsilon}$ yields

$$I^{\mathrm{H}}_{<} = \int_{\mathbb{R}^3} \mathrm{d}p \int_{T^3/\varepsilon} \mathrm{d}q\, \overline{\hat{a}(p, \varepsilon q, q)}\, \mathrm{e}^{-\mathrm{i}\frac{t}{\varepsilon}(\omega(\varepsilon q_+)-\omega(\varepsilon q_-))}\, \overline{\hat{f}^{\varepsilon,\rho}(q_-)} \hat{f}^{\varepsilon,\rho}(q_+)\,,$$

where $\hat{f}^{\varepsilon,\rho}(q) = \varphi(\frac{\varepsilon q}{\rho})(\hat{\phi}^{\varepsilon}_0(q) - \hat{\phi}_0(q))$. Let $M > 0$ be arbitrary. We split off the values $|p| > M$ from the integral defining $I^3_<$. The difference $R'_4 = R'_4(\varepsilon, \rho, M)$ can be bounded by $C \int_{|p|>M} \mathrm{d}p\, \langle p\rangle^{-d-1}$ and thus $\lim_{M\to\infty} \sup_{\rho,\varepsilon} |R'_4| = 0$. We divide the remaining integral over $|p| \le M$ further into two parts using the identity

$$1 = \tilde{\varphi}\left(\tfrac{q_-}{2M}\right) \tilde{\varphi}\left(\tfrac{q_+}{2M}\right) + 1 - \tilde{\varphi}\left(\tfrac{q_-}{2M}\right) \tilde{\varphi}\left(\tfrac{q_+}{2M}\right), \tag{4.27}$$

where $\tilde{\varphi} = 1 - \varphi$. If $|q| \ge 5M$, then $|q_\pm| \ge 4M$ and the second part is zero. It can be checked by inspection that the sequence $(f^{\varepsilon,\rho})_\varepsilon$ is bounded and tight, and it has a weak limit zero. Of these properties only the tightness is nonobvious, but this can also be easily deduced from the formula

$$f^{\varepsilon,\rho}(x) = \rho^3 \varepsilon^{-3/2} \sum_{\gamma\in\mathbb{Z}^3} \psi^{\varepsilon}_0(\gamma) \hat{\varphi}(\rho(\gamma - \tfrac{1}{\varepsilon}x)) - \int_{\mathbb{R}^3} \mathrm{d}y\, \phi_0(x + \tfrac{\varepsilon}{\rho}y)\hat{\varphi}(y). \tag{4.28}$$

Therefore, by Lemma A.2, $\lim_{\varepsilon\to 0} \|\hat{f}^{\varepsilon,\rho}\|_{L^2(B_{6M})} = 0$ for all M, ρ. This implies that the contribution of the second term, denoted by R'_5, satisfies $\lim_{\varepsilon\to 0} |R'_5| = 0$ for all M, ρ.

We are thus left with

$$I^4_{<} = \int_{|p|\le M} \mathrm{d}p \int_{\mathbb{R}^3} \mathrm{d}q\, \overline{\hat{a}(p, 0, q)}\, \mathrm{e}^{-\mathrm{i}t(\omega_0(q_+)-\omega_0(q_-))}\, \overline{\hat{g}^{\varepsilon,\rho,M}(q_-)} \hat{g}^{\varepsilon,\rho,M}(q_+), \tag{4.29}$$

where $\hat{g}^{\varepsilon,\rho,M}(q) = \tilde{\varphi}\left(\frac{q}{2M}\right) \hat{f}^{\varepsilon,\rho}(q)$ and the integrand can be nonzero only for $|q| \ge M$. We thus only need to consider $|q| \ge M$ and $|p| \le M$. First we replace in the integrand $\hat{a}(p, 0, q)$ by $\hat{b}(p, 0, \hat{q})$, $\hat{q} = \frac{q}{|q|}$, with an error R'_6 which is bounded by

$$|R'_6| \le C \sup_{k,|q|\ge M} \|a(\cdot, k, q) - b(\cdot, k, \tfrac{q}{|q|})\|_{\mathcal{S},d+1} \tag{4.30}$$

for some constant C. Then we change $\mathrm{e}^{-\mathrm{i}t(\omega_0(q_+)-\omega_0(q_-))}$ to $\mathrm{e}^{-\mathrm{i}tp\cdot\nabla\omega_0(\hat{q})}$ with an error R'_7 which can be estimated using the inequality (A.4) of the appendix. This proves that there is a constant C such that

$$|R'_7| \le C\tfrac{|t|}{M} \sup_{k,q} \|b(\cdot, k, q)\|_{\mathcal{S},d+3}. \tag{4.31}$$

Therefore, $I^4_< = I^5_< + R'_6 + R'_7$, where

$$I^5_{<} = \int_{|p|\le M} \mathrm{d}p \int_{\mathbb{R}^3} \mathrm{d}q\, \overline{\hat{b}(p, 0, \hat{q})}\, \mathrm{e}^{-\mathrm{i}tp\cdot\nabla\omega_0(\hat{q})}\, \overline{\hat{g}^{\varepsilon,\rho,M}(q_-)} \hat{g}^{\varepsilon,\rho,M}(q_+) \tag{4.32}$$

and $\lim_{M\to\infty} \sup_{\rho,\varepsilon} |R'_6 + R'_7| = 0$ for all t.

Let

$$b_t(x, \hat{q}) = b(x + t\tfrac{1}{2\pi}\nabla\omega_0(\hat{q}), 0, \hat{q}). \tag{4.33}$$

Then $b_t \in \mathcal{S}(\mathbb{R}^3 \times S^2)$, and it has an extension to a function $J_t \in \mathcal{S}_6$; i.e., there is J_t such that $J_t(x,q) = b_t(x,q)$ for all $|q| = 1$. On the other hand, then

$$I^5_< = \int_{|p|\le M} \mathrm{d}p \int_{\mathbb{R}^3} \mathrm{d}q\, \overline{\hat{b}_t(p,\hat{q})}\, \overline{\hat{g}^{\varepsilon,\rho,M}(q_-)} \hat{g}^{\varepsilon,\rho,M}(q_+) = \langle J_t, \Lambda^{\varepsilon,\rho,M}\rangle, \tag{4.34}$$

where $\Lambda^{\varepsilon,\rho,M} \in \mathcal{S}_6'$ denotes the distribution

$$J \mapsto \langle J, \Lambda^{\varepsilon,\rho,M}\rangle = \int_{|p|\le M} \mathrm{d}p \int_{\mathbb{R}^3} \mathrm{d}q\, \overline{\hat{J}(p,\hat{q})}\, \overline{\hat{g}^{\varepsilon,\rho,M}(q_-)} \hat{g}^{\varepsilon,\rho,M}(q_+). \tag{4.35}$$

Clearly, each $\Lambda^{\varepsilon,\rho,M}$ has support in $\mathbb{R}^3 \times S^2$, and there is a constant C such that for all J, ε, ρ, M

$$|\langle J, \Lambda^{\varepsilon,\rho,M}\rangle| \le C \|\hat{g}^{\varepsilon,\rho,M}\|^2 \|J\|_{\mathcal{S},d+1}, \tag{4.36}$$

with $\|\hat{g}^{\varepsilon,\rho,M}\|$ denoting the $L^2(\mathbb{R}^3)$-norm. However, since we have $\|\hat{g}^{\varepsilon,\rho,M}\| \le \|\hat{f}^{\varepsilon,\rho}\|$, where $\|\hat{f}^{\varepsilon,\rho}\|$ is bounded in ε, the Banach–Alaoglu theorem implies that the family $(\Lambda^{\varepsilon,\rho,M})_{\varepsilon,\rho,M}$ belongs to a weak-$*$ sequentially compact set. Therefore, for every ρ, M there is a subsequence of (ε) and $\Lambda^{\rho,M}$ such that $\Lambda^{\varepsilon,\rho,M} \overset{*}{\rightharpoonup} \Lambda^{\rho,M}$ along this subsequence. In addition, for every ρ there is Λ^ρ and a sequence of integers M such that $\Lambda^{\rho,M} \overset{*}{\rightharpoonup} \Lambda^\rho$ along this sequence. Finally, there are $\Lambda \in \mathcal{S}_6'$ and a sequence of integers $N \ge 4$ such that for $\rho = \frac{1}{N}$, $\Lambda^\rho \overset{*}{\rightharpoonup} \Lambda$.

All of the above distributions clearly must have support on $\mathbb{R}^3 \times S^2$. We will soon prove that, in addition, for all $f \in \mathcal{S}_6$ and ρ

$$\langle |f|^2, \Lambda^\rho\rangle \ge 0. \tag{4.37}$$

This implies that then also $\langle |f|^2, \Lambda\rangle \ge 0$. Therefore, by the Bochner–Schwartz theorem, there is a positive Radon measure μ^{H} on $\mathbb{R}^6$ such that for all test functions J, $\langle J, \Lambda\rangle = \int \mu^{\mathrm{H}}(\mathrm{d}x, \mathrm{d}k)\, J(x,k)$. Since also μ^{H} must have support on $\mathbb{R}^3 \times S^2$, we can thus identify it with a positive Radon measure μ^{H}_0 on $\mathbb{R}^3 \times S^2$. By considering test functions $J(x,k) = \mathrm{e}^{-\delta^2 x^2}$ in the limit $\delta \to 0$, it is also clear that μ^{H}_0 must be bounded. We then define the positive, bounded Radon measures μ^{H}_t, $t \in \mathbb{R}$, by the formula (3.6). It follows from the construction of μ^{H}_t that (4.5) holds along the above sequences ρ, ε.

The main missing ingredient is provided by the following lemma.

LEMMA 4.1. *For $p, q \in \mathbb{R}^3$, let us denote $q_\pm = q \pm \frac{p}{2}$, $\hat{q}_\pm = q_\pm/|q_\pm|$, and $\hat{q} = q/|q|$. There is a constant C such that for all $q, q' \in \mathbb{R}^3$ and $f \in \mathcal{S}_6$*

$$\left| \int_{\mathbb{R}^3} \mathrm{d}x\, \mathrm{e}^{-2\pi \mathrm{i} p\cdot x} \overline{f(x,q')} f(x,q) \right| \le C \langle p\rangle^{-d-1} \|f\|^2_{\mathcal{S},d+1}. \tag{4.38}$$

If, in addition, $|q| \ge M$ and $|p| \le M$, then also

$$\left| \mathcal{F}_{x\to p}(|f|^2)(p,\hat{q}) - \int_{\mathbb{R}^3} \mathrm{d}x\, \mathrm{e}^{-2\pi \mathrm{i} p\cdot x} \overline{f(x,\hat{q}_+)} f(x,\hat{q}_-) \right| \le \tfrac{1}{M} C \langle p\rangle^{-d-1} \|f\|^2_{\mathcal{S},d+2}. \tag{4.39}$$

Before proving the lemma we demonstrate that it implies the inequality (4.37). Let $f \in \mathcal{S}_6$ be arbitrary. Define $q_\pm, \hat{q}_\pm$ as in Lemma 4.1, except that here also let $\hat{0} = 0$, and let

$$I^{\varepsilon,\rho,M,f} = \int_{\mathbb{R}^3} \mathrm{d}p \int_{\mathbb{R}^3} \mathrm{d}q \left[\int_{\mathbb{R}^3} \mathrm{d}x\, \mathrm{e}^{2\pi \mathrm{i} p\cdot x} f(x,\hat{q}_+) \overline{f(x,\hat{q}_-)} \right] \overline{\hat{g}^{\varepsilon,\rho,M}(q_-)} \hat{g}^{\varepsilon,\rho,M}(q_+). \tag{4.40}$$

Note that this integral is well-defined by (4.38). Then, by the estimate (4.39) and uniform boundedness of $g^{\varepsilon,\rho,M}$, there is a constant c such that

$$\big|\langle |f|^2, \Lambda^{\varepsilon,\rho,M}\rangle - I^{\varepsilon,\rho,M,f}\big| \leq c\|f\|^2_{\mathcal{S},d+2}\Big(\int_{|p|\geq M} \mathrm{d}p\, \langle p\rangle^{-d-1} + \tfrac{1}{M}\Big). \tag{4.41}$$

On the other hand, $I^{\varepsilon,\rho,M,f} \geq 0$ always. To see this, consider first the case when $g^{\varepsilon,\rho,R} \in \mathcal{S}$. Then $\hat{g}^{\varepsilon,\rho,R} \in \mathcal{S}$, and by changing variables from (q,p) to (q_+,q_-) in (4.40) and then using Fubini's theorem to reorder the integrals, we find that

$$I^{\varepsilon,\rho,M,f} = \int_{\mathbb{R}^3} \mathrm{d}x |G(x)|^2, \qquad \text{with } G(x) = \int_{\mathbb{R}^3} \mathrm{d}q\, \mathrm{e}^{2\pi \mathrm{i} q\cdot x} f(x,\hat{q})\hat{g}^{\varepsilon,\rho,R}(q) \in L^2. \tag{4.42}$$

Since $I^{\varepsilon,\rho,M,f}$ depends L^2-continuously on $g^{\varepsilon,\rho,R}$ this implies that also for general $g^{\varepsilon,\rho,R} \in L^2$ we have $I^{\varepsilon,\rho,M,f} \geq 0$. Since the right-hand side of (4.41) vanishes if first $\varepsilon \to 0$ and then $M \to \infty$, we must thus also have $\langle |f|^2, \Lambda^\rho\rangle \geq 0$. This proves (4.37).

The only remaining task is to prove Lemma 4.1. Consider first (4.38). If $|p| \leq 1$, we have trivially a bound

$$\int_{\mathbb{R}^3} \mathrm{d}x\, |f(x,q')|\, |f(x,q)| \leq \|f\|^2_{\mathcal{S},d+1} \int_{\mathbb{R}^3} \mathrm{d}x\, \langle x\rangle^{-2d-2} \leq c\|f\|^2_{\mathcal{S},d+1}. \tag{4.43}$$

If $|p| \geq 1$, we perform N partial integrations in the direction of p, i.e., in the direction $\hat{p} = \frac{p}{|p|}$, yielding

$$\int_{\mathbb{R}^3} \mathrm{d}x\, \mathrm{e}^{-2\pi\mathrm{i}p\cdot x}\overline{f(x,q')}f(x,q) = \tfrac{1}{(2\pi\mathrm{i}|p|)^N} \int_{\mathbb{R}^3} \mathrm{d}x\, \mathrm{e}^{-2\pi\mathrm{i}p\cdot x}(\hat{p}\cdot\nabla)^N\big(\overline{f(x,q')}f(x,q)\big). \tag{4.44}$$

By the Leibniz rule,

$$(\hat{p}\cdot\nabla)^N\left(\overline{f(x,q')}f(x,q)\right) = \sum_{n=0}^N \binom{N}{n} (\hat{p}\cdot\nabla)^n \overline{f(x,q')}(\hat{p}\cdot\nabla)^{N-n} f(x,q), \tag{4.45}$$

which is bounded by $c'_N\langle x\rangle^{-N}\|f\|^2_{\mathcal{S},N}$. Choosing $N = d+1$ then yields (4.38) for some constant. Adjusting the constant C so that the bound is true also for $|p| \leq 1$ proves that (4.38) is valid.

To prove (4.39), consider q,p as required in the second part of the lemma. Also let $q(s) = q + \frac{s}{2}p$. Then $|q(s)| \geq |q|/2 > 0$ for all $|s| \leq 1$, and $\hat{q}(s)$ is thus well-defined and smooth. Therefore, for any $g \in \mathcal{S}_6$ and $s_0 \in [-1,1]$,

$$\begin{aligned} g(x,\hat{q}(s_0)) - g(x,\hat{q}) &= \int_0^{s_0} \mathrm{d}s\, \tfrac{\mathrm{d}}{\mathrm{d}s} g(x,\hat{q}(s)) \\ &= \int_0^{s_0} \mathrm{d}s\, \Big(\tfrac{1}{2|q(s)|}p - \tfrac{p\cdot\hat{q}(s)}{2|q(s)|}\hat{q}(s)\Big)\cdot \nabla_q g(x,q)|_{q=\hat{q}(s)}, \end{aligned} \tag{4.46}$$

implying

$$|g(x,\hat{q}_\pm) - g(x,\hat{q})| \leq 2\tfrac{|p|}{|q|} \sup_{|q|=1} |\nabla_q g(x,q)|. \tag{4.47}$$

Also for all $g_1, g_2 \in \mathcal{S}_6$,

$$\begin{aligned}&\overline{g_1(x,\hat{q})}g_2(x,\hat{q}) - \overline{g_1(x,\hat{q}_-)}g_2(x,\hat{q}_+)\\ &\quad= \overline{(g_1(x,\hat{q}) - g_1(x,\hat{q}_-))}g_2(x,\hat{q}) + \overline{g_1(x,\hat{q}_-)}\,(g_2(x,\hat{q}) - g_2(x,\hat{q}_+))\,.\end{aligned} \tag{4.48}$$

Following the steps made in the first part of the proof, and replacing the earlier estimates with the above more accurate ones when necessary, we can conclude that the constant C can be adjusted so that for these values of q, p (4.39) also holds. This completes the proof of (4.5).

Energy equality. The energy equality (3.7) follows by considering a sequence of test functions $a^\delta = \mathrm{e}^{-\delta^2 x^2}$ and taking $\delta \to 0$. To see this, first note that the right-hand side of (3.7) is clearly independent of t, and thus it is enough to consider $t = 0$. Thanks to (2.28) and to the tightness of the sequence ψ_0^ε, we obtain for this particular test function that

$$\lim_{\delta\to 0}\lim_{\varepsilon\to 0}\langle a^\delta, W^\varepsilon[\psi_0^\varepsilon]\rangle = \lim_{\delta\to 0}\lim_{\varepsilon\to 0}\langle a^\delta, e^\varepsilon\rangle = \lim_{\varepsilon\to 0}\|\psi_0^\varepsilon\|^2.$$

Equation (3.3) implies that

$$\begin{aligned}\lim_{\varepsilon\to 0}\langle a^\delta, W^\varepsilon[\psi_0^\varepsilon]\rangle = \int_{\mathbb{R}^3}\mathrm{d}x\, a^\delta(x)|\phi_0(x)|^2 + \int_{\mathbb{R}^3}\int_{\mathbb{T}^3} a^\delta(x)\,\mathrm{d}\mu_0(x,k)\\ + \int_{\mathbb{R}^3}\int_{S^2} a^\delta(x)\,\mathrm{d}\mu_0^{\mathrm{H}}(x,k).\end{aligned}$$

Sending δ to 0 yields that

$$\lim_{\varepsilon\to 0}\|\hat{\psi}_0^\varepsilon\|^2 = \|\phi_0\|^2_{L^2(\mathbb{R}^3)} + \mu_0(\mathbb{R}^3\times\mathbb{T}^3) + \mu_0^{\mathrm{H}}(\mathbb{R}^3\times S^2),$$

and the energy equality has been established. This finishes the proof of Theorem 3.2.

5. Proof of Corollary 3.4. Let I_0 denote the original sequence of ε, and consider an arbitrary subsequence I of I_0. Since $(\psi_0^\varepsilon)_{\varepsilon\in I}$ then also satisfies Assumption 3.1, we can conclude from Theorem 3.2 that for every I there is a subsequence I' such that (3.3) holds for all t with the initial conditions given by some triplet $(\mu_I, \mu_I^{\mathrm{H}}, \phi_I)$. From the construction of the subsequence in the proof of Theorem 3.2, we know that ϕ_I can be chosen as the weak limit of ϕ_0^ε along the subsequence I'. The first assumption thus implies that we can always choose $\phi_I = \phi_0$. Let us also denote $\mu_0 = \mu_{I_0}$ and $\mu_0^{\mathrm{H}} = \mu_{I_0}^{\mathrm{H}}$, and to prove the stated uniqueness, we will prove that $\mu_I = \mu_0$ and $\mu_I^{\mathrm{H}} = \mu_0^{\mathrm{H}}$ for all I.

Consider first an arbitrary $\tilde{a} \in C_c^\infty(\mathbb{R}^3\times\mathbb{T}^3_*)$. Let $a(x,k,q) = \tilde{a}(x,k)$ for $k \neq 0$ and define $a(x,0,q) = 0$. Then a is an admissible test function with $a_0 = 0 = b(k,0,q)$, and for any subsequence I we thus obtain, using the second assumption,

$$\int_{\mathbb{R}^3\times\mathbb{T}^3_*}\mathrm{d}\mu_I(x,k)\,\overline{\tilde{a}(x,k)} = \lim_{\varepsilon\in I}\langle a, W^\varepsilon[\psi_0^\varepsilon]\rangle = \int_{\mathbb{R}^3\times\mathbb{T}^3_*}\mathrm{d}\mu_0(x,k)\,\overline{\tilde{a}(x,k)}. \tag{5.1}$$

Such $\tilde{a}$ are dense in $C_c(\mathbb{R}^3\times\mathbb{T}^3_*)$, and thus $\mu_I = \mu_0$ on $\mathbb{R}^3\times\mathbb{T}^3_*$.

Consider then an arbitrary $b \in C_c^\infty(\mathbb{R}\times S^2)$. Let φ be a smooth cutoff function as in Definition 4.1, and define $a(x,k,q) = b(x, q/|q|)\,(1-\varphi(2q))$. Then a is an admissible

test function and indeed $\lim_{R\to\infty} a(x,k,Rq) = b(x,q)$ for all $|q|=1$. By the already proven results we then find that for any subsequence I

$$\int_{\mathbb{R}^3\times S^2} \mathrm{d}\mu_I^{\mathrm{H}}(x,q)\,\overline{b(x,q)} = \lim_{\varepsilon\to 0}\langle a, W^\varepsilon[\psi_0^\varepsilon]\rangle - \int_{\mathbb{R}^3\times\mathbb{T}^3_*} \mathrm{d}\mu_0(x,k)\,\overline{b(x,\tfrac{k}{|k|})} - \langle a_0, W^{(1)}_{\mathrm{cont}}[\phi_0]\rangle$$

$$= \int_{\mathbb{R}^3\times S^2} \mathrm{d}\mu_0^{\mathrm{H}}(x,q)\,\overline{b(x,q)}\,. \tag{5.2}$$

Therefore, also $\mu_I^{\mathrm{H}} = \mu_0^{\mathrm{H}}$, which concludes the uniqueness part of the proof of the corollary.

Finally, define for $t\neq 0$ the triplet $(\mu_t, \mu_t^{\mathrm{H}}, \phi_t)$ using $(\mu_0, \mu_0^{\mathrm{H}}, \phi_0)$ as the initial data. By the uniqueness proved above, for any subsequence I, (3.3) holds along the subsubsequence I'. As the right-hand side is thus independent of I, this proves that the limit also holds along the original sequence I_0. This completes the proof of the corollary. ∎

Appendix. The proof of Theorem 3.2 uses two simple lemmas, which are provided here. The first lemma summarizes several properties of regular acoustic dispersion relations.

LEMMA A.1. *Let ω be a regular acoustic dispersion relation, as in Definition 2.2, and let λ, A_0, and ω_0 be related to ω as in the definition. Then the following assertions are true.*

1. $\omega \in C^{(3)}(\mathbb{T}^3\setminus\{0\},\mathbb{R})$.
2. $\nabla\lambda(0) = 0$ *and* $A_0 > 0$.
3. *There are constants $C_1, C_2 > 0$ such that for all $\|k\|_\infty \le \frac{3}{4}$,*

$$\omega(k) \ge C_1|k|, \qquad |\nabla\lambda(k)| \le C_2|k|\,. \tag{A.1}$$

   In addition, $\|\nabla\omega\|_\infty < \infty$.
4. *There is C_3 such that if $\varepsilon > 0$, $p\in\mathbb{R}^3$, and $\|k\|_\infty \le \frac{1}{2}$, with $|k| > \varepsilon|p|$, then*

$$|\omega(k+\tfrac{1}{2}\varepsilon p) - \omega(k-\tfrac{1}{2}\varepsilon p) - \varepsilon p\cdot\nabla\omega(k)| \le C_3\varepsilon^2\tfrac{|p|^2}{|k|}. \tag{A.2}$$

5. *There is C_4 such that if $\varepsilon > 0$ and $p,q\in\mathbb{R}^3$ with $|p|, \|q\|_\infty \le \frac{1}{2}\varepsilon^{-1}$, then for $q_\pm = q \pm \frac{1}{2}p$,*

$$|\omega(\varepsilon q_+) - \omega(\varepsilon q_-) - \omega_0(\varepsilon q_+) + \omega_0(\varepsilon q_-)| \le C_4\varepsilon^2|p|\,|q|\,. \tag{A.3}$$

6. *There is C_5 such that if $p,q\in\mathbb{R}^3$ with $q\neq 0$ and $|p|\le|q|$, then for $q_\pm = q\pm\frac{1}{2}p$,*

$$|\omega_0(q_+) - \omega_0(q_-) - p\cdot\nabla\omega_0(\tfrac{q}{|q|})| \le C_5\tfrac{|p|^2}{|q|}. \tag{A.4}$$

Proof. From now on, we consider ω, λ, A_0, and ω_0 satisfying Definition 2.2. The first item is then obvious, and the second one follows from the assumptions, since 0 is a minimum. The second inequality in (A.1) follows by using item 2 and $\|D^2\lambda\|_\infty < \infty$, when by Taylor expansion $|\nabla\lambda(k)| \le C_2|k|$ for all $k\in\mathbb{R}$. To prove the first inequality, we first note that, by continuity, also $\|D^3\lambda\|_\infty < \infty$. Thus there is c' such that for all $k\in\mathbb{R}^3$

$$|\lambda(k) - \lambda_0(k)| \le c'|k|^3, \tag{A.5}$$

where $\lambda_0(k) = \frac{1}{2}k \cdot A_0 k$. Since $A_0 > 0$, there is $c > 0$ such that $\lambda_0(k) \geq c^2 k^2$ for all k. Thus there is $\delta' > 0$ such that for all $|k| < \delta'$, we have $|1 - \lambda(k)/\lambda_0(k)| \leq \frac{3}{4}$, and for these k therefore also $\omega(k) = \sqrt{\lambda(k) - \lambda_0(k) + \lambda_0(k)} \geq \frac{1}{2}\sqrt{\lambda_0(k)} \geq \frac{c}{2}|k|$. Since λ has no zeroes in the complement set, the constant can then be adjusted so that (A.1) holds for all k with $\|k\|_\infty \leq \frac{3}{4}$.

We still need to prove the third property, boundedness of $\nabla\omega$. For later use, let us, more generally, consider a nonnegative $f \in C^{(2)}(\mathbb{R}^3)$, $q \in \mathbb{R}^3$, and k such that $f(k) \neq 0$. Then we have

$$(q \cdot \nabla)\sqrt{f(k)} = \frac{1}{2\sqrt{f(k)}} q \cdot \nabla f(k), \tag{A.6}$$

$$(q \cdot \nabla)^2\sqrt{f(k)} = -\frac{1}{4f(k)^{3/2}}(q \cdot \nabla f(k))^2 + \frac{1}{2\sqrt{f(k)}}(q \cdot \nabla)^2 f(k). \tag{A.7}$$

This implies that there is a constant C such that for all $q \in \mathbb{R}^3$ and $k \neq 0$, with $\|k\|_\infty \leq \frac{3}{4}$,

$$|q \cdot \nabla\omega(k)|, |q \cdot \nabla\omega_0(k)| \leq C|q|\,, \tag{A.8}$$

$$|(q \cdot \nabla)^2\omega(k)|, |(q \cdot \nabla)^2\omega_0(k)| \leq C\frac{|q|^2}{|k|}\,. \tag{A.9}$$

In particular, by periodicity therefore $\|\nabla\omega\|_\infty < \infty$.

To prove item 4, consider k, p, ε as in the claim, and define a function $f(s) = \omega(k_+) - \omega(k_-)$ with $k_\pm = k \pm s\frac{1}{2}p$ and $s \in [-\varepsilon, \varepsilon]$. Then $\|k_\pm\|_\infty \leq \frac{3}{2}\|k\|_\infty$ and $|k_\pm| \geq |k| - \varepsilon\frac{1}{2}p \geq \frac{1}{2}|k| > 0$, and thus f belongs to $C^{(3)}$. In particular, $f(0) = 0$, $f'(0) = p \cdot \nabla\omega(k)$, and

$$\begin{aligned} f''(s) = \frac{1}{2}\Big[&\frac{1}{\omega(k_+)}\Big(\frac{p}{2} \cdot \nabla\Big)^2\lambda(k_+) - \frac{1}{\omega(k_-)}\Big(\frac{p}{2} \cdot \nabla\Big)^2\lambda(k_-) \\ &- \frac{1}{2\omega(k_+)^3}\Big(\frac{p}{2} \cdot \nabla\lambda(k_+)\Big)^2 + \frac{1}{2\omega(k_-)^3}\Big(\frac{p}{2} \cdot \nabla\lambda(k_-)\Big)^2\Big]. \end{aligned} \tag{A.10}$$

Using item 3, we find that there is C such that this is uniformly bounded by $C|p|^2/|k|$. Then a Taylor expansion at the origin proves item 4.

Since for all $k \neq 0$

$$\omega(k) - \omega_0(k) = \sqrt{\lambda(k)} - \sqrt{\lambda_0(k)} = \frac{\lambda(k) - \lambda_0(k)}{\sqrt{\lambda(k)} + \sqrt{\lambda_0(k)}}\,, \tag{A.11}$$

we then also have

$$q \cdot \nabla(\omega(k) - \omega_0(k)) = \frac{q \cdot \nabla\lambda(k) - q \cdot \nabla\lambda_0(k)}{\omega(k) + \omega_0(k)} - (\lambda(k) - \lambda_0(k))\frac{q \cdot \nabla\omega(k) + q \cdot \nabla\omega_0(k)}{(\omega(k) + \omega_0(k))^2}\,. \tag{A.12}$$

By Taylor expansion at the origin, we find that there is C' such that for all $q \in \mathbb{R}^3$,

$$|\lambda(k) - \lambda_0(k)| \leq C'|k|^3, \qquad |q \cdot \nabla\lambda(k) - q \cdot \nabla\lambda_0(k)| \leq C'|k|^2|q|, \tag{A.13}$$

$$|(q \cdot \nabla)^2\lambda(k) - (q \cdot \nabla)^2\lambda_0(k)| \leq C'|k|\,|q|^2\,. \tag{A.14}$$

Thus there is also C such that for all $q \in \mathbb{R}^3$, and for $\|k\|_\infty \leq \frac{3}{4}$ with $k \neq 0$,

$$|q \cdot \nabla(\omega(k) - \omega_0(k))| \leq C|k|\,|q|\,, \qquad |(q \cdot \nabla)^2(\omega(k) - \omega_0(k))| \leq C|q|^2. \tag{A.15}$$

Let us then consider q, p, ε satisfying the assumptions made in the final item. Since then $\|\varepsilon q_\pm\|_\infty \leq \frac{3}{4}$, we can apply the previous estimates. If $p = 0$, then $q_- = q_+$ and the bound in (A.3) is trivially valid for any C_4. Consider thus $p \neq 0$, and assume first that p is not proportional to q. Since then the line segment $[0,1] \ni s \mapsto \varepsilon q + s\varepsilon p/2$ does not pass through the origin, the function $s \mapsto \omega(\varepsilon q + s\varepsilon p/2) - \omega_0(\varepsilon q + s\varepsilon p/2)$ is in $C^{(3)}([0,1])$. We make a Taylor expansion of this function at $s = 0$, yielding

$$\omega(\varepsilon q + \varepsilon\tfrac{p}{2}) - \omega_0(\varepsilon q + \varepsilon\tfrac{p}{2}) = \omega(\varepsilon q) - \omega_0(\varepsilon q) + \varepsilon\tfrac{p}{2} \cdot (\nabla\omega(\varepsilon q) - \nabla\omega_0(\varepsilon q)) + R\,. \tag{A.16}$$

Here (A.15) implies $|R| \leq C\varepsilon^2|p|^2$, since

$$R = \int_0^1 \mathrm{d}s\,(1-s)\Big(\varepsilon\tfrac{p}{2} \cdot \nabla\Big)^2 (\omega(\varepsilon q + s\varepsilon\tfrac{p}{2}) - \omega_0(\varepsilon q + s\varepsilon\tfrac{p}{2}))\,. \tag{A.17}$$

This proves that (A.3) holds in this case for some constant C_4. In the final case $p \propto q$, we choose a direction u orthogonal to q, and use the previous estimate with $p + \delta u$ instead of p for an arbitrary $0 < \delta \leq 1$. Since the left-hand side of (A.3) is continuous in δ, the bound must then hold also for $\delta = 0$, proving the validity of the estimate also in this case.

To prove (A.4), we use the fact that by assumption $|q_\pm| \geq \frac{1}{2}|q| > 0$, and thus denoting $\hat{q} = q/|q|$, we get

$$\omega_0(q_+) - \omega_0(q_-) = |q|\big(\omega_0\big(\hat{q} + \tfrac{p}{2|q|}\big) - \omega_0\big(\hat{q} - \tfrac{p}{2|q|}\big)\big) = p \cdot \nabla\omega_0(\hat{q}) + R, \tag{A.18}$$

where $|R| \leq C|p|^2/|q|$. We have thus completed the proof of the lemma. ∎

The second lemma recalls a well-known fact in Fourier analysis: the Fourier transform of a bounded and tight sequence of L^2 functions converges strongly on compact sets. For the convenience of the reader we give a proof.

LEMMA A.2. *Let $f^\varepsilon \in L^2(\mathbb{R}^d)$ be a bounded and tight sequence of functions such that $f^\varepsilon \rightharpoonup 0$ as $\varepsilon \to 0$. Then for every $\Omega \subset \mathbb{R}^d$ with a finite measure*

$$\lim_{\varepsilon\to 0} \|\hat{f}^\varepsilon\|_{L^2(\Omega)} = 0. \tag{A.19}$$

Proof. Let $\beta > 0$ be arbitrary. By tightness of f^ε there is $R_\beta > 0$ such that

$$\limsup_{\varepsilon\to 0} \int_{|x|\geq R_\beta} \mathrm{d}x\,|f^\varepsilon(x)|^2 \leq \beta^2. \tag{A.20}$$

Define now

$$f^{\varepsilon,\beta}(x) = \begin{cases} f^\varepsilon(x) & \text{if } |x| \leq R_\beta, \\ 0, & \text{otherwise.} \end{cases} \tag{A.21}$$

By the boundedness of $f^{\varepsilon,\beta}$ in $L^2(\mathbb{R}^d)$ there exist g^β and a subsequence (ε') such that $f^{\varepsilon',\beta} \rightharpoonup g^\beta$ in $L^2(\mathbb{R}^d)$ as $\varepsilon' \to 0$. Estimate (A.20) implies that $\limsup_{\varepsilon\to 0} \|f^\varepsilon - f^{\varepsilon,\beta}\|^2_{L^2(\mathbb{R}^3)} \leq \beta^2$. Since also $f^\varepsilon \rightharpoonup 0$, we have

$$\|g^\beta\|^2 = \lim_{\varepsilon'} |\langle g^\beta, f^{\varepsilon',\beta}\rangle| \leq \|g^\beta\| \limsup_{\varepsilon\to 0} \|f^\varepsilon - f^{\varepsilon,\beta}\| \tag{A.22}$$

and, therefore, $\|g^\beta\|_{L^2(\mathbb{R}^d)} \leq \beta$.

Since g^β has support in a ball of radius R_β, also $g_1^\beta(x) = -2\pi i x g^\beta(x) \in L^2(\mathbb{R}^d)$. Therefore, $\hat{g}^\beta \in H^1(\mathbb{R}^d)$ and $\nabla \hat{g}^\beta = \hat{g}_1^\beta$. Similarly, also $\hat{f}^{\varepsilon,\beta} \in H^1(\mathbb{R}^d)$ and it is straightforward to check that $\nabla \hat{f}^{\varepsilon',\beta} \rightharpoonup \nabla \hat{g}^\beta$ in L^2. Since Ω is assumed to be a set of finite measure, we then have $\lim_{\varepsilon'\to 0} \|\hat{f}^{\varepsilon',\beta} - \hat{g}^\beta\|_{L^2(\Omega)} = 0$ (for a proof, see, for instance, Theorem 8.6. in [13]). Collecting all the above estimates together proves that

$$\begin{aligned}&\limsup_{\varepsilon'\to 0} \|\hat{f}^{\varepsilon'}\|_{L^2(\Omega)} \\ &\quad \le \limsup_{\varepsilon'\to 0} \|\hat{f}^{\varepsilon'} - \hat{f}^{\varepsilon',\beta}\|_{L^2(\Omega)} + \limsup_{\varepsilon'\to 0} \|\hat{f}^{\varepsilon',\beta} - \hat{g}^\beta\|_{L^2(\Omega)} + \|\hat{g}^\beta\|_{L^2(\Omega)} \le 2\beta.\end{aligned}$$

Since β can be arbitrarily small, there must be a subsequence (ε'') such that $\lim_{\varepsilon''\to 0} \|\hat{f}^{\varepsilon''}\|_{L^2(\Omega)} = 0$.

Since the assumptions on the sequence f^ε are preserved for subsequences, we can consider an arbitrary subsequence and apply the above result to it. Then we can conclude that for every subsequence there is a subsubsequence along which (A.19) holds. This implies that the limit (A.19) actually holds also along the original sequence. ∎

Acknowledgments. The authors would like to thank Clotilde Fermanian Kammerer, Alexander Mielke, and Herbert Spohn for several instructive discussions. We are also grateful to the anonymous referees for a careful reading of the manuscript and for suggesting several useful references.

CONCENTRATION PHENOMENA IN A NONLOCAL QUASI-LINEAR PROBLEM MODELLING PHYTOPLANKTON I: EXISTENCE*

YIHONG DU† AND SZE-BI HSU‡

Abstract. We study the positive steady state of a quasi-linear reaction-diffusion system in one space dimension introduced by Klausmeier and Litchman for the modelling of the distributions of phytoplankton biomass and its nutrient. The system has nonlocal dependence on the biomass function, and it has a biomass-dependent drifting term describing the active movement of the biomass towards the location of the optimal growth condition. We obtain complete descriptions of the profile of the solutions when the coefficient of the drifting term is large, rigorously proving the numerically observed phenomenon of concentration of biomass for this model. Our theoretical results reveal four critical numbers for the model not observed before and offer several further insights into the problem being modelled. This is Part I of a two-part series, where we obtain nearly optimal existence and nonexistence results. The asymptotic profile of the solutions is studied in the separate Part II.

Key words. quasi-linear, nonlocal dependence, phytoplankton, concentration phenomenon, reaction-diffusion equation

1. Introduction.

In this paper, we study the problem

$$\begin{cases} -[d_1 u_x + \sigma c(x)u]_x = [g(x) - m]u, & 0 < x < 1, \\ -d_2 v_{xx} = -g(x)u, & 0 < x < 1, \\ d_1 u_x + \sigma c(x)u = 0, & x = 0, 1, \\ v_x(0) = 0, \quad v_x(1) = \beta[v_0 - v(1)], \end{cases} \tag{1.1}$$

where d_1, d_2, σ, m, v_0, and β are positive constants,

$$g(x) = f(\min\{\alpha v(x), w(x)\}), \quad f(s) = \frac{rs}{K_I + s},$$

and

$$w(x) = w_0 \exp\left[- A_0 x - A \int_0^x u(s)ds \right],$$

with α, r, K_I, w_0, A, and A_0 positive constants. We note that the right-hand sides of the differential equations in (1.1) depend on the unknown functions u and v in a nonlocal manner. Moreover, the positive function $c(x)$ is determined by u and v in a rather unconventional way to be explained below. We are interested in positive

solutions of (1.1), namely $u > 0$ and $v > 0$ in $[0, 1]$. From (1.1) it is easy to see that for any such solution, v is an increasing function. Clearly w is a decreasing function. The function $c(x)$ is defined by

$$c(x) = \frac{x - x_0}{\delta + |x - x_0|},$$

where $\delta > 0$ is a small constant and $x_0 \in [0, 1]$ is the intersection point of the functions $\alpha u(x)$ and $w(x)$ whenever such an intersection occurs in $[0, 1]$; if $\alpha u(x)$ and $v(x)$ do not intersect, then $x_0 = 0$ if $\alpha v > w$ on $[0, 1]$, and $x_0 = 1$ if $\alpha v < w$ on [0,1]. In other words, x_0 is given by the following description:

$$\min\{\alpha v(x), w(x)\} = \alpha v(x)\ \forall x \in [0, x_0); \quad \min\{\alpha v(x), w(x)\} = w(x)\ \forall x \in (x_0, 1].$$

This unconventional dependence of c on the unknown solution (u, v) makes (1.1) a very special quasi-linear problem.

Such a system arises in the mathematical modelling of phytoplankton in a one-dimensional water column, where $u(x)$ represents the distribution of phytoplankton biomass, $v(x)$ stands for the distribution of nutrient, and x denotes the depth in the water column, with $x = 0$ at the surface and $x = 1$ at the bottom. The term $\sigma c(x)$ is used to describe the active movement of the biomass towards the spatial location with the optimal growth condition. Klausmeier and Litchman [KL] propose using this model to study the concentration phenomenon widely observed for phytoplankton in lakes and oceans. Their numerical analysis in [KL] demonstrates that for large σ, the biomass function $u(x)$ concentrates at a certain level $x = x_*$ while the nutrient function $v(x)$ is close to a piecewise linear function. They then treat u as a constant multiple of the δ-function concentrating at x_* and propose a game theoretical model to determine the location of x_*.

In this paper, we rigorously prove the existence of such a concentration phenomenon and obtain accurate formulas for the determination of x_* and the total biomass. Our theoretical results offer several further insights into the model besides those obtained through numerical analysis in [KL]; for example, we show the existence of four critical values $v_{**} < v_* < v^* < v^{**}$ for v_0 (the nutrient level at the sediment), such that

(i) $x_* = 0$ when $v_0 \geq v^*$, $x_* \in (0, 1)$ when $v_0 \in (v_*, v^*)$, and $x_* = 1$ when $v_0 \leq v_*$;

(ii) the total biomass increases with v_0 in the range $v_{**} < v_0 < v^{**}$, but it stays constant for $v_0 \geq v^{**}$ or $v_0 \leq v_{**}$ (and with v_0 above a certain level so that the biomass can survive).

It turns out that the game theoretical model of [KL] is a simplified version of our equations governing x_* and the total phytoplankton biomass for the case $v_* \leq v_0 \leq v^*$. A more detailed description of these results is given in the introduction of Part II, with their biological interpretations given in section 4 there.

To explain this model more precisely, we start by a brief description of the background and motivation of this research. Phytoplankton, the generic name of microorganisms living in lakes and oceans, is the basis of the aquatic food chain. Its importance for the proper functioning of the aquatic ecosystem has long been recognized, and its behavior has been widely studied. The distribution of phytoplankton in lakes and oceans is highly heterogeneous. To better understand this property of the phytoplankton, various mathematical models have been proposed and numerically analyzed; see, for example, [EATSH, KL, PT, PTHS, HTKS]. However, little

rigorous mathematical analysis is available. In [YN], an ordinary differential equation model for the vertical distributions of phytoplankton is theoretically analyzed; see also [IT, BFH, BFHK] for earlier related research. It is our hope that the current paper may induce further rigorous mathematical research in this direction and that the techniques developed here may find more applications.

We now describe the model in more detail. In poorly mixed water columns, it has been observed that algae can be heterogeneously distributed, with thin layers of biomass on the surface, at depth, or on the sediment surface; examples for each of these cases can be found in [KL]. To model these phenomena, [KL] proposes a reaction-diffusion-taxis model of phytoplankton, nutrients, and light, based on the principle of light and nutrient competition. They use the following system to describe the distribution of phytoplankton in a one-dimensional water column, with depth represented by $0 \le z \le z_b$; $z = 0$ at the surface and $z = z_b$ at the bottom:

$$\text{(1.2)}\qquad \begin{cases} b_t = D_b b_{zz} + [\nu(g^0_z)b]_z + [g^0 - m]b, & 0 < z < z_b, t > 0, \\ R_t = D_R R_{zz} - bg^0/Y + \epsilon mb/Y, & 0 < z < z_b, t > 0, \\ D_b b_z + \nu(g^0_z)b = 0, & z = 0, z_b, t > 0, \\ R_z(t,0) = 0, R_z(t,z_b) = h[R_{in} - R(t,z_b)], & t > 0, \\ I(t,z) = I_{in} \exp\Big(- \displaystyle\int_0^z [ab(t,s) + a_{bg}]ds\Big), & 0 < z < z_b, t > 0, \end{cases}$$

where a, a_{bg}, h, D_b, D_R, m, I_{in}, R_{in}, and Y are positive constants, $\epsilon \in [0,1)$, $\nu(s)$ is an odd decreasing function that approaches $\nu_{max} > 0$ as $s \to -\infty$, and

$$g^0(t,z) = \min\{f_I(I(t,z)), f_R(R(t,z))\},$$

with

$$f_I(s) = r\frac{s}{s+K_I}, \quad f_R(s) = r\frac{s}{s+K_R}, \quad r, K_I, K_R > 0.$$

In (1.2), $b(t,z)$ denotes the distribution of the phytoplankton biomass, $R(t,z)$ represents the nutrient distribution, and $I(t,z)$ stands for the distribution of light. The constant I_{in} is the light distribution at the surface, and, by the Lambert–Beer law, light at depth z is given by

$$I(t,z) = I_{in} \exp\Big(- \int_0^z [ab(t,s) + a_{bg}]ds\Big),$$

where a and a_{bg} are, respectively, the phytoplankton and background attenuation coefficients. In this model, it is assumed that the change in phytoplankton biomass at depth z results from three processes: growth, loss, and movement. The functions $f_I(I)$ and $f_R(R)$ are the phytoplankton growth rate when only one of the resources I and R is limited (the other being regarded as sufficient). By Liebig's law of the minimum for essential resources, the gross phytoplankton growth rate is given by $g^0(t,z) = \min\{f_I(I(t,z)), f_R(R(t,z))\}$. Biomass is lost at density-dependent rate m, representing respiration, death, and grazing. D_b is the passive diffusion rate of the biomass, while $[\nu(g^0_z)b]_z$ describes active movement of the biomass towards a spatial location (i.e., depth) with a better growth condition. The no-flux boundary condition for b means that no phytoplankton enters or leaves the water column at $z = 0$ and $z = z_b$. The equation for R is based on the assumption that nutrients in

the water column are mixed with eddy diffusion with diffusion coefficient D_R and are consumed by phytoplankton at the rate $-bg^0/Y$, and the term $\epsilon mb/Y$ means that ϵ proportion of the nutrients in dead phytoplankton is immediately recycled. Here Y describes the yield of phytoplankton biomass per unit nutrient consumed. The boundary condition for R means that nutrients do not leave or enter the top of the water column but are supplied at the bottom, with nutrients in the sediments fixed at constant concentration R_{in}, which diffuse across the sediment-water interface at a rate proportional to the concentration difference across the interface; the parameter h describes the permeability of the interface.

In [KL], taking $\epsilon = 0$ and $\nu(s) = \nu_0(s) := -\nu_{max}\mathrm{sgn}(s)$ (where $\mathrm{sgn}(s)$ is the sign function, which equals 1, -1, or 0 according to whether $s > 0$, $s < 0$, or $s = 0$), the equilibrium distributions of b, R, and I are calculated numerically for various parameter values (see Table 1 and Figure 1 in [KL]). The numerical simulation in [KL] shows that as ν_{max} increases, the biomass distribution concentrates at a certain depth $z = z^*$. Further, based on intuition and formal analysis, a game theoretical approach is proposed in [KL], which can be used to calculate z^*. Though the connection between (1.2) and the simplified game theoretical approach is not rigorously established, the predictions deduced from the game theoretical model agree well with the numerical results based on (1.2); see details in [KL].

In this paper, we theoretically analyze the equilibrium solutions of (1.2). So $b = b(z)$, $R = R(z)$, and $I = I(z)$. Naturally, only positive solutions are of interest to us.

As in [KL], we assume that $\epsilon = 0$. We denote $f(s) = rs/(s+K_I)$ and $\alpha = K_I/K_R$. Then

$$f_I(s) = f(s), \quad f_R(s) = f(\alpha s).$$

Since $f'(s) > 0$ we find that

$$g^0(z) = \min\{f(I(z)), \quad f(\alpha R(z))\} = f(\min\{I(z), \alpha R(z)\}).$$

Clearly $I(z)$ is a decreasing function. Since $D_R R'' = bg^0/Y > 0$ and $R'(0) = 0$, we find that $R'(z) > 0$ for $z \in (0, z_b]$. Therefore $R(z)$ is increasing, and we can always find a unique $z_0 \in [0, z_b]$ such that

$$g^0(z) = f(\alpha R(z)) \ \forall z \in [0, z_0), \quad g^0(z) = f(I(z)) \ \forall z \in (z_0, z_b].$$

Evidently z_0 depends on I and R, and $z_0 = 0$ if $\alpha R(z) \geq I(z)$ on $[0, z_b]$, and $z_0 = z_b$ when $\alpha R(z) \leq I(z)$ on $[0, z_b]$.

In view of the above discussions for $g^0(z)$, we see that

$$\nu_0(g^0_z(z)) = -\nu_{max}\mathrm{sgn}(g^0_z(z)) = -\nu_{max} \ \forall z \in [0, z_0),$$
$$\nu_0(g^0_z(z)) = -\nu_{max}\mathrm{sgn}(g^0_z(z)) = \nu_{max} \ \forall z \in (z_0, z_b].$$

In this paper, we use a continuous approximation of the above step function used in [KL]; namely, we take

$$\nu(g^0_z(z)) = \nu_{\delta'}(z) := \nu_{max}\frac{z - z_0}{\delta' + |z - z_0|}.$$

It is easily seen that $\nu_{\delta'}(z) \to \nu_0(g^0_z(z))$ as $\delta' \to 0$. We stress again that $\nu_{\delta'}$ depends on I and R through the definition of z_0.

Next we normalize the functions in (1.2) by

$$u(x) = b(z_b x)/Y, \quad v(x) = R(z_b x), \quad w(x) = I(z_b x), \quad 0 \le x \le 1,$$

and define

$$d_1 = z_b^2 D_b, \quad d_2 = z_b^2 D_R, \quad \sigma = \nu_{max} z_b, \quad \delta = \delta'/z_b,$$

$$A = a z_b Y, \quad A_0 = a_{bg} z_b, \quad \beta = h z_b, v_0 = R_{in}, \quad w_0 = I_{in}.$$

We denote

$$c(x) = c_{v,w}(x) = \frac{x - x_0}{\delta + |x - x_0|}, \quad x_0 = \frac{z_0}{z_b}.$$

Then after some simple calculations we find that the steady-state version of (1.2) becomes (1.1), or, written in a more comprehensive form,

$$\text{(1.3)} \qquad \begin{cases} -[d_1 u_x + \sigma c(x) u]_x = [f(\min\{\alpha v, w\}) - m]u, & 0 < x < 1, \\ -d_2 v_{xx} = -f(\min\{\alpha v, w\})u, & 0 < x < 1, \\ d_1 u_x(0) + \sigma c(0)u(0) = d_1 u_x(1) + \sigma c(1)u(1) = 0, & \\ v_x(0) = 0, \quad v_x(1) = \beta[v_0 - v(1)], & \\ w(x) = w_0 \exp\left[- A_0 x - A \displaystyle\int_0^x u(s)ds \right], & 0 \le x \le 1. \end{cases}$$

Let us note that from the equation for u and the strong maximum principle, if u is nonnegative on $[0, 1]$, then it is either identically 0 or positive everywhere in $[0, 1]$. It is also easy to see that whenever u is positive, $0 < v < v_0$ in $[0, 1]$.

Since this paper is very long, and the techniques used in the first half of the paper are rather different from those in the second half, we divide it into two separate parts. Part I here is mainly concerned with the existence and nonexistence problem, and Part II studies the asymptotic behavior of the positive solutions as $\sigma \to \infty$.

In section 2, treating m as a parameter, we make use of a bifurcation argument to obtain two critical numbers $0 < m_* \le m^*$ such that (1.3) has no positive solution when $m \ge m^*$ and it has at least one positive solution when $0 < m < m_*$. We also show that as m (the death rate of the biomass) decreases to 0, the biomass blows up everywhere; the exact limiting profiles of the biomass function and the nutrient function as $m \to 0$ are also obtained. In section 3, we show that as $\sigma \to \infty$, m_* and m^* converge to the same limit $f(\min\{\alpha v_0, w_0\})$. This demonstrates that our existence and nonexistence results are sharp for large σ.

The asymptotic behavior of the positive solutions when $\sigma \to \infty$ is investigated separately in Part II (see [DH]), where we fix $0 < m < f(\min\{\alpha v_0, w_0\})$ and study the asymptotic behavior of a positive solution (u_n, v_n) of (1.3) with $\sigma = \sigma_n \to \infty$.

2. Existence and nonexistence results. The function $c(x)$ appearing in (1.3) plays a very important role in our analysis. From the definition of $c(x) = c_{v,w}(x)$ we find that it is well defined if $v(x)$ is increasing in $[0, 1]$ and $w(x)$ is decreasing in $[0, 1]$, and

$$c(x) = \frac{x - x_0}{\delta + |x - x_0|},$$

where $x_0 \in [0,1]$ is uniquely determined by the following:

$$\min\{\alpha v(x), w(x)\} = \alpha v(x)\ \forall x \in [0, x_0); \quad \min\{\alpha v(x), w(x)\} = w(x)\ \forall x \in (x_0, 1].$$

It is easily seen that for the definition of $c_{v,w}(x)$, the requirement that v is increasing and w is decreasing can be relaxed; we can allow one (but not both) of the following:

$$\text{(i) } v \text{ is nondecreasing, (ii) } w \text{ is nonincreasing.}$$

Let us also observe that $c(x)$ is a C^1 function, with $c'(x) = \delta(\delta + |x - x_0|)^{-2}$.

With this in mind, we find that $(u, v, w) = (0, v_0, w_*)$ solves (1.3), where $w_*(x) = w_0 e^{-A_0 x}$. We will call this the trivial solution. To find nontrivial solutions, we now treat m as a parameter and look for special values of m so that positive solutions of (1.3) may bifurcate from this trivial solution. If $m_* \geq 0$ is such a value, then there exist $m_n \to m_*$ and (u_n, v_n, w_n) solving (1.3) with $m = m_n$ such that $u_n > 0$, $v_n > 0$, and $u_n \to 0$, $v_n \to v_0$, and $w_n \to w_*$ and in $C^1[0,1]$ as $n \to \infty$. Now $v_n(x)$ is increasing and $w_n(x)$ is decreasing for $x \in [0,1]$; therefore $c_{v_n,w_n}(x)$ is well defined. Moreover, it is easily checked that $c_{v_n,w_n} \to c_{v_0,w_*}$ in $C([0,1])$ as $n \to \infty$. To simplify the notation, we write $c^n(x) = c_{v_n,w_n}(x)$ and $c^0(x) = c_{v_0,w_*}(x)$. Therefore u_n satisfies

$$\begin{cases} -[d_1 u_n' + \sigma c^n(x) u_n]' = [f(\min\{\alpha v_n, w_n\}) - m_n] u_n & \text{in } (0,1), \\ d_1 u_n' + \sigma c^n(x) u_n = 0 & \text{for } x = 0, 1. \end{cases}$$

Here and in what follows, we use the notation $u' = u_x$, etc. To determine the value of m_*, we first deduce a useful equation from the equation for u_n. So we define $\hat{u}_n = u_n / \|u_n\|_\infty$. Then we have

$$\text{(2.1)} \qquad \begin{cases} -(d_1 \hat{u}_n' + \sigma c^n \hat{u}_n)' + m_n \hat{u}_n = f(\min\{\alpha v_n, w_n\}) \hat{u}_n & \text{in } (0,1), \\ d_1 \hat{u}_n' + \sigma c^n \hat{u}_n = 0 & \text{for } x = 0, 1. \end{cases}$$

Since the right-hand side of the first equation in (2.1) and $\{\hat{u}_n\}$ are both bounded in $L^\infty([0,1])$, and since m_n, c^n, $(c^n)'$ are bounded in $L^\infty([0,1])$, we can use standard L^p theory for elliptic operators (see [GT]) to conclude that $\{\hat{u}_n\}$ is a bounded sequence in $W^{2,p}([0,1])$ for any $p > 1$. By the Sobolev embedding theorem, we see that $\{\hat{u}_n\}$ is compact in $C^1([0,1])$. By passing to a subsequence, we may assume that $\hat{u}_n \to \hat{u}$ in $C^1([0,1])$, and then we easily see that $\hat{u}$ satisfies (in the weak sense)

$$\text{(2.2)} \qquad \begin{cases} -(d_1 \hat{u}' + \sigma c^0 \hat{u})' + m_* \hat{u} = f(\min\{\alpha v_0, w_*\}) \hat{u} & \text{in } (0,1), \\ d_1 \hat{u}' + \sigma c^0 \hat{u} = 0 & \text{for } x = 0, 1. \end{cases}$$

Since $\hat{u} \geq 0$ and $\|\hat{u}\|_\infty = 1$, we necessarily have, by applying the strong maximum principle to (2.2), that $\hat{u} > 0$. This implies that $-m_*$ is the principal eigenvalue of the problem

$$\text{(2.3)} \qquad \begin{cases} -(d_1 u' + \sigma c^0 u)' - f(\min\{\alpha v_0, w_*\}) u = \lambda u & \text{in } (0,1), \\ d_1 u' + \sigma c^0 u = 0 & \text{for } x = 0, 1. \end{cases}$$

One easily checks that 0 is the first eigenvalue of the problem

$$\begin{cases} -(d_1 u' + \sigma c^0 u)' = \lambda u & \text{in } (0,1), \\ d_1 u' + \sigma c^0 u = 0 & \text{for } x = 0, 1. \end{cases}$$

Since $-f(\min\{\alpha v_0, w_*\}) < 0$, by the characterization of the first eigenvalues (see, for example, Theorems 2.4 and 2.8 of [D]), the first eigenvalue of (2.3) is less than 0, and hence $m_* > 0$. On the other hand, if (u, v, w) is a positive solution to (1.3), then rewriting the equation for u in the form

$$\begin{cases} -(d_1 u' + \sigma c u)' - f(\min\{\alpha v, w\})u = -mu & \text{in } (0,1), \\ d_1 u' + \sigma c u = 0 & \text{for } x = 0, 1, \end{cases}$$

we find that $-m$ is the first eigenvalue of the problem

$$\begin{cases} -(d_1 u' + \sigma c u)' - f(\min\{\alpha v, w\})u = \lambda u & \text{in } (0,1), \\ d_1 u' + \sigma c u = 0 & \text{for } x = 0, 1, \end{cases}$$

which we denote by $\lambda_1(c, v, w)$. Clearly $v < v_0$ and $w < w_*$ in $(0,1)$. It follows that $-f(\min\{\alpha v, w\}) > -f(\min\{\alpha v_0, w_*\})$ in $(0,1)$ and hence

$$\lambda_1(c, v, w) > \lambda_1(c, v_0, w_*). \tag{2.4}$$

In this notation, clearly $-m_* = \lambda_1(c^0, v_0, w_*)$. Since $c(x) = (x - x_0)/(\delta + |x - x_0|)$ is determined completely by x_0, it is convenient to introduce the notation

$$C_{x_0} = \frac{x - x_0}{\delta + |x - x_0|}$$

and

$$m^* = -\inf_{x_0 \in [0,1]} \lambda_1(C_{x_0}, v_0, w_*).$$

It is easy to show that m^* is achieved by some $x_0 \in [0,1]$, and $m^* \geq m_*$. Moreover, from the above discussion, we have the following result.

PROPOSITION 2.1. *If* (1.3) *has a positive solution, then necessarily* $m < m^*$.

We will show that (1.3) has a positive solution for every $0 < m < m_*$. Before that we briefly discuss some further simple estimates for the values of m so that (1.3) has a positive solution. So suppose that (1.3) has a positive solution (u, v, w). Integrating the equation for u over $[0,1]$, we obtain

$$\int_0^1 \Big[f(\min\{\alpha v, w\}) - m \Big] u dx = 0.$$

Since $u > 0$, $[f(\min\{\alpha v, w\}) - m]$ must change sign over $(0,1)$, and therefore

$$\min_{[0,1]} f(\min\{\alpha v(x), w(x)\}) < m < \max_{[0,1]} f(\min\{\alpha v(x), w(x)\}).$$

It follows that

$$f(\min\{\alpha v(0), w(1)\}) < m < f(\min\{\alpha v_0, w_0\}). \tag{2.5}$$

From a similar consideration, we have

$$m^*, m_* \in \big(f(\min\{\alpha v_0, w_*(1)\}), f(\min\{\alpha v_0, w_0\}) \big). \tag{2.6}$$

We now use a global bifurcation argument to show that (1.3) has a positive solution for every $m \in (0, m_*)$. First, we transform (1.3) into an abstract nonlinear

equation. Due to its unconventional nature, we cannot use a simple inverse operator trick to do this. In fact, to cope with the rather implicit dependence of $c_{v,w}$ on (v,w), in the following, we have to choose the function spaces for the abstract setting very carefully and then analyze the properties of the abstract operator mostly by definitions.

Fix $\gamma \in (0,1)$ and set

$$K := \{\phi \in C^{1,\gamma}([0,1]) : \phi \text{ is nondecreasing in } [0,1]\},$$
$$P := \{\phi \in C^{1,\gamma}([0,1]) : \phi \text{ is nonnegative in } [0,1]\}.$$

Clearly they are closed convex sets in $C^{1,\gamma}([0,1])$, and, moreover, P is a positive cone.

For given $(u,v) \in P \times K$ and $m \geq 0$, we define

$$w = w_0 \exp\Big[- A_0 x - A \int_0^x u(s)ds\Big],$$
$$c(x) = c_{v,w}(x), \quad v_+ = \max\{v, 0\}$$

and will use the solutions of the following problems to define an abstract operator $T(m,u,v)$ such that $T(m,u,v) = (u,v)$ for $(u,v) \in P \times K$ if and only if (u,v) is a nonnegative solution of (1.3). So we consider the problems

$$\text{(2.7)} \quad \begin{cases} -(d_1\phi' + \sigma c\phi)' + (m+1)\phi = f(\min\{\alpha v_+, w\})u + u, & 0 < x < 1, \\ d_1\phi' + \sigma c\phi = 0, & x = 0, 1, \end{cases}$$

and

$$\text{(2.8)} \quad \begin{cases} -d_2\psi'' = -f(\min\{\alpha v_+, w\})u, & 0 < x < 1, \\ \psi'(0) = 0, \quad \psi'(1) = \beta[v_0 - \psi(1)]. \end{cases}$$

Clearly (2.7) has a unique solution ϕ, and it is nonnegative. Let $\zeta(x) = v_0 - \psi(x)$. Then (2.8) becomes

$$\text{(2.9)} \quad \begin{cases} -d_2\zeta'' = f(\min\{\alpha v_+, w\})u, & 0 < x < 1, \\ \zeta'(0) = 0, \quad \zeta'(1) + \beta\zeta(1) = 0. \end{cases}$$

It is easily seen that (2.9) has a unique solution ζ, and it is nonnegative. Moreover, from $\zeta'' \leq 0$, and $\zeta'(0) = 0$ we deduce that ζ is nonincreasing. Hence ψ is nondecreasing and $\psi(x) \leq v_0$ in $[0,1]$. Thus the solution operator $(\phi,\psi) = T(m,u,v)$ is well defined for $(u,v) \in P \times K$ and $m \geq 0$, and $T(m,\cdot,\cdot)$ maps $P \times K$ into itself.

We show next that T is continuous. Suppose that $(m_n, u_n, v_n) \in [0,\infty) \times P \times K$, $m_n \to m$, and $(u_n, v_n) \to (u,v)$ in $C^{1,\gamma}([0,1]) \times C^{1,\gamma}([0,1])$. Then it is easily checked that $c^n := c_{v_n,w_n} \to c := c_{v,w}$ in $C^1([0,1])$. Denote $(\phi_n, \psi_n) = T(m_n, u_n, v_n)$ and $\zeta_n = v_0 - \psi_n$. We have

(2.10)

$$\begin{cases} -(d_1\phi_n' + \sigma c^n\phi_n)' + (m_n+1)\phi_n = f(\min\{\alpha(v_n)_+, w_n\})u_n + u_n, & 0 < x < 1, \\ d_1\phi_n' + \sigma c^n\phi_n = 0, & x = 0, 1, \end{cases}$$

and

$$\begin{cases} -d_2\zeta_n'' = f(\min\{\alpha(v_n)_+, w_n\})u_n, & 0 < x < 1, \\ \zeta_n'(0) = 0, \quad \zeta_n'(1) + \beta\zeta_n(1) = 0. \end{cases} \tag{2.11}$$

Applying standard L^p theory to both (2.10) and (2.11), we find that $\{\phi_n\}$ and $\{\zeta_n\}$ are bounded in $W^{2,p}([0,1])$ for all $p > 1$. Hence they are precompact in $C^{1,\gamma}([0,1])$. This implies that by passing to a subsequence, $\phi_n \to \phi$ and $\psi_n \to \psi$ in $C^{1,\gamma}([0,1])$. Moreover, letting $n \to \infty$ in (2.10) and (2.11) we find that necessarily $(\phi, \psi) = T(m, u, v)$. Therefore the entire original sequence converges with limit (ϕ, ψ). This proves the continuity of T.

We further show that T is compact. Suppose that $\{(m_n, u_n, v_n)\} \subset [0,\infty) \times P \times K$ is bounded. Then along some subsequence n_k, (u_n, v_n) converges in the $C^1([0,1]) \times C^1([0,1])$ norm to some (u, v), and, by passing to a further subsequence, we may assume that $m_{n_k} \to m$. We may now repeat the arguments in the above continuity proof to conclude that $T(m_{n_k}, u_{n_k}, v_{n_k}) \to T(m, u, v)$ in $C^{1,\gamma}([0,1])$. Therefore T is a compact operator on $[0,\infty) \times P \times K$.

Suppose that $m \geq 0$ and $(u, v) \in P \times K$ satisfies $(u, v) = T(m, u, v)$. We claim that $v \geq 0$ in $[0,1]$. Otherwise, due to the monotonicity of v there exists $x_0 \in (0,1]$ such that $v < 0$ in $[0, x_0)$ and $v \geq 0$ in $(x_0, 1]$. Therefore, by (2.8),

$$-v'' = 0 \text{ in } (0, x_0).$$

Since $v'(0) = 0$, we deduce that $v'(x) = 0$ in $(0, x_0)$, and hence v is a negative constant in $(0, x_0)$, say $v = -c$. This is possible only if $x_0 = 1$ (otherwise, v is discontinuous at $x = x_0$ since $v \geq 0$ in $(x_0, 1]$), but then from $v'(1) = \beta[v_0 - v(1)]$ we deduce that $-c = v_0 > 0$, a contradiction. Therefore we must have $v \geq 0$ in $[0,1]$, as claimed. Thus (u, v) is a nonnegative solution of (1.3) if and only if $(u, v) \in P \times K$ and $T(m, u, v) = (u, v)$.

In order to apply the global bifurcation theory to the operator equation

$$(u, v) - T(m, u, v) = 0,$$

we now calculate the Fréchet derivative of T with respect to (u, v) at $(m, 0, v_0)$, in the convex set $P \times K$ of $C^{1,\gamma}([0,1]) \times C^{1,\gamma}([0,1])$, where $m \geq 0$. From (2.7) and (2.8) we easily see that $T(m, 0, v_0) = (0, v_0)$. For $(u, v) \in C([0,1]) \times C([0,1])$, we define $(\xi, \eta) = L_m(u, v)$ to be the unique solution of the following linear problems:

$$\begin{cases} -(d_1\xi' + \sigma c^0\xi)' + (m+1)\xi = f(\min\{\alpha v_0, w_*\})u + u, & 0 < x < 1, \\ d_1\xi' + \sigma c^0\xi = 0, & x = 0, 1, \end{cases} \tag{2.12}$$

$$\begin{cases} -d_2\eta'' = -f(\min\{\alpha v_0, w_*\})u, & 0 < x < 1, \\ \eta'(0) = 0, \quad \eta'(1) + \beta\eta(1) = 0, \end{cases} \tag{2.13}$$

where c^0 and w_* are defined as at the beginning of this section.

Suppose $(u_n, v_n) \to (0, v_0)$ in $P \times K$. Denote

$$(\phi_n, \psi_n) = T(m, u_n, v_n) \text{ and } (\tau_n, \theta_n) = L_m(u_n, v_n - v_0).$$

We want to show that

$$\|(\phi_n, \psi_n) - (0, v_0) - (\tau_n, \theta_n)\| = o(\|(u_n, v_n - v_0)\|), \tag{2.14}$$

where $\|(u,v)\| = \max\{\|u\|, \|v\|\}$, and $\|u\| = \|u\|_{C^{1,\gamma}([0,1])}$. This would imply that the Fréchet derivative of T with respect to (u,v) at $(m,0,v_0)$, in the convex set $P \times K$, is the linear operator L_m.

Suppose $(u_n, v_n) \to (0, v_0)$ in $P \times K$. Without loss of generality we assume that $u_n \not\equiv 0$. We define w_n and $c^n = c_{v_n,w_n}$ as before, and let $\hat{\phi}_n = \phi_n/\|u_n\|$, $\hat{u}_n = u_n/\|u_n\|$. Then

(2.15)
$$\begin{cases} -(d_1\hat{\phi}_n' + \sigma c^n \hat{\phi}_n)' + (m+1)\hat{\phi}_n = f(\min\{\alpha(v_n)_+, w_n\})\hat{u}_n + \hat{u}_n, & 0 < x < 1, \\ d_1\hat{\phi}_n' + \sigma c^n \hat{\phi}_n = 0, & x = 0, 1. \end{cases}$$

Since the right-hand side of the first equation in (2.15) is bounded in $L^\infty([0,1])$, much as before we deduce from the L^p theory and the Sobolev imbedding theorem that there exists some positive constant C independent of n such that

$$\|\hat{\phi}_n\| \le C \ \forall n \ge 1.$$

We now define $\Phi_n = (\phi_n - \tau_n)/\|u_n\|$, and from the equations for ϕ_n and τ_n we obtain

$$\begin{cases} -(d_1\Phi_n' + \sigma c^0 \Phi_n)' + (m+1)\Phi_n = f_n, & 0 < x < 1, \\ d_1\Phi_n' + \sigma c^0 \hat{\Phi}_n = g_n, & x = 0, 1, \end{cases} \tag{2.16}$$

where

$$f_n := [f(\min\{\alpha(v_n)_+, w_n\}) - f(\min\{\alpha v_0, w_*\})]\hat{u}_n + [\sigma(c^n - c^0)\hat{\phi}_n]'$$

and

$$g_n = \sigma(c^0 - c^n)\hat{\phi}_n.$$

It is easy to check that f_n converges to 0 in $L^\infty([0,1])$, and g_n converges to 0 in $C^1([0,1])$. Since $(m+1) \ge 1$, we may apply the L^p estimate to (2.16) to conclude that $\|\Phi_n\| \to 0$ as $n \to \infty$. Hence

$$\|\phi_n - \tau_n\| = o(\|u_n\|).$$

Define $\Psi_n = [(v_0 - \psi_n) + \theta_n]/\|u_n\|$. Then from the equations for ψ_n and θ_n we deduce that

$$\begin{cases} -d_2\Psi_n'' = [f(\min\{\alpha(v_n)_+, w_n\}) - f(\min\{\alpha v_0, w_*\})]\hat{u}_n, & 0 < x < 1, \\ \Psi_n'(0) = 0, \quad \Psi_n'(1) + \beta\Psi_n(1) = 0. \end{cases} \tag{2.17}$$

Since the right-hand side of the first equation in (2.17) converges to 0 in $L^\infty([0,1])$, we can apply the L^p theory to (2.17) to conclude that $\|\Psi_n\| \to 0$ as $n \to \infty$. Therefore

$$\|\psi_n - v_0 - \theta_n\| = o(\|u_n\|).$$

Thus we have

$$\|(\phi_n, \psi_n) - (0, v_0) - (\tau_n, \theta_n)\| = o(\|(u_n, v_n - v_0)\|).$$

Summarizing the above discussions, we have the following result.

PROPOSITION 2.2. *The operator $T : [0,\infty) \times P \times K \to P \times K$ is completely continuous, and it is Fréchet differentiable at $(m, 0, v_0)$ with respect to (u, v) in the convex set $P \times K$, with derivative operator L_m. Moreover, $(u, v) = T(m, u, v)$ implies that $v \in P$; (u, v) is a nonnegative solution of (1.3) if and only if $(u, v) = T(m, u, v)$.*

We are now ready to prove the main result of this section.

THEOREM 2.3. *For every $m \in (0, m_*)$, problem (1.3) has at least one positive solution. Moreover, if m_n decreases to 0 and (u_n, v_n) is a positive solution of (1.3) with $m = m_n$, then $u_n \to \infty$ uniformly in $[0, 1]$ and there exists a unique $\tau \in \big(0, \frac{v_0}{1+\beta^{-1}}\big)$ (determined by (2.27) below) such that*

$$\frac{u_n(x)}{\|u_n\|_\infty} \to \Big(1 + \frac{x}{\delta}\Big)^{\frac{\sigma}{d_1}\delta} e^{-\frac{\sigma}{d_1}x}, \quad v_n(x) \to \tau x + v_0 - \tau(1 + \beta^{-1})$$

uniformly in $[0, 1]$. Furthermore, for each $m \in (0, m_*)$, there is a positive solution (m, u, v) lying on the global bifurcation branch, $\Gamma = \{(m, u, v)\} \subset (0,\infty) \times C^{1,\gamma}([0, 1]) \times C^{1,\gamma}([0, 1])$, bifurcating from the trivial solution branch $\Gamma_0 := \{(m, 0, v_0) : m \in (-\infty,\infty)\}$ at $m = m_*$.

Proof. Since the proof is rather long, we divide it into several steps.

Step 1: *Existence of an unbounded global solution branch.*

We observe that 1 is an eigenvalue of L_{m_*} with eigenvector (ϕ_1, ψ_1) satisfying $\phi_1 > 0$ and $\psi_1 < 0$. Indeed, $\phi_1 > 0$ is a principal eigenfunction of (2.3) with $\lambda = -m_*$, and ψ_1 is the unique solution of (2.13) with $u = \phi_1$, and hence $\psi_1 < 0$. In order to apply the abstract global bifurcation theory in positive cones, we define $S : [0,\infty) \times P \times (-K) \to P \times (-K)$ by

$$S(m, u, \xi) = (\phi, \zeta) \text{ if and only if } T(m, u, v_0 - \xi) = (\phi, v_0 - \zeta).$$

Then from the properties of T we find that S is completely continuous. Moreover, if we denote by $DS(m, 0, 0)$ the Fréchet derivative of S with respect to (u, ξ) in $P \times (-K)$ at $(u, \xi) = (0, 0)$, then 1 is an eigenvalue of $DS(m_*, 0, 0)$ with eigenvector $(\phi_1, -\psi_1)$, where ϕ_1 and ψ_1 are as given above. Let us denote by P_0 the nonnegative functions in $(-K)$. Clearly P_0 is a cone in $C^{1,\gamma}([0, 1])$, and hence $P \times P_0$ is a cone in $C^{1,\gamma}([0, 1]) \times C^{1,\gamma}([0, 1])$. Moreover, it is easy to check through the definition of T that $S(m, \cdot, \cdot)$ maps $P \times P_0$ into itself, and 1 is the only eigenvalue of $DS(m_*, 0, 0)$ with an eigenvector in $P \times P_0$, and for any $m \geq 0$, $m \neq m_*$, 1 is not an eigenvalue of $DS(m, 0, 0)$ corresponding to an eigenvector in $P \times P_0$. These properties allow us to apply Corollary 18.4 of [A] to conclude that there exists a global unbounded branch of solutions of $(u, \zeta) = S(m, u, \zeta)$ in $R^1 \times \big(P \times P_0 \setminus \{(0, 0)\}\big)$. We denote this global branch by $\tilde{\Gamma} = \{(m, u, \zeta)\}$ and define

$$\Gamma := \{(m, u, v_0 - \zeta) : (m, u, \zeta) \in \tilde{\Gamma}\}.$$

Clearly Γ is a global branch of solutions to $(u, v) = T(m, u, v)$ with $u \geq 0$ and $v = v_0 - \zeta \leq v_0$. We claim that $u \neq 0$. Otherwise, $u = 0$ and we deduce that $v = v_0 - \zeta = v_0$. Hence $\zeta = 0$, contradicting the fact that $(m, u, \zeta) \in R^1 \times \big(P \times P_0 \setminus \{(0, 0)\}\big)$. Hence $u \geq 0$ and $u \neq 0$. It then follows from Proposition 2.2 that $v_0 - \zeta \geq 0$. But $u \neq 0$ implies that $v_0 - \zeta \neq 0$, and hence $(u, v_0 - \zeta)$ is a positive solution of (1.3). Thus we have proved that Γ is an unbounded branch of positive solutions of (1.3).

Step 2: *We show that the m-range of Γ covers $(0, m_*)$.*

If $(m,u,v)\in\Gamma$, then from Proposition 2.1 and (2.5) we deduce that $0<m<m^*$. Therefore we can find a sequence $(m_n,u_n,v_n)\in\Gamma$ such that $m_n\to m_0\in[0,m^*]$ and $\|(u_n,v_n)\|\to\infty$. Note that $c_{v_n,w_n}=C_{x_n}$ for some $x_n\in[0,1]$ uniquely determined by v_n and w_n. By passing to a subsequence we may assume that $x_n\to x_0\in[0,1]$. Then it is easily seen that $C_{x_n}\to C_{x_0}$ in $C^1([0,1])$. We necessarily have, by passing to a subsequence, that $\|u_n\|_\infty\to\infty$, for otherwise from the equation for u_n we can deduce that $\|u_n\|$ is bounded, which in turn implies that $\|v_n\|$ is bounded, contradicting our assumption that $\|(u_n,v_n)\|\to\infty$. Therefore we may assume that $\|u_n\|_\infty\to\infty$. Denote $\hat{u}_n=u_n/\|u_n\|_\infty$. Then we can use the L^p estimate to the equation for $\hat{u}_n$ to deduce that $\{\hat{u}_n\}$ is precompact in $C^{1,\gamma}([0,1])$. Hence we may assume that $\hat{u}_n\to\hat{u}$ in $C^{1,\gamma}([0,1])$. Since $0\le f(\min\{\alpha v_n,w_n\})\le f(w_*)$, we may assume that $f(\min\{\alpha v_n,w_n\})$ converges to f_0 weakly in $L^2([0,1])$. Clearly we also have $0\le f_0\le f(w_*)$. Passing to the weak limit in the equation for $\hat{u}_n$ we deduce that $\hat{u}$ is a weak solution of

$$\begin{cases} -(d_1\hat{u}'+\sigma C_{x_0}\hat{u})'=(f_0-m_0)\hat{u}, & 0<x<1,\\ d_1\hat{u}'+\sigma C_{x_0}\hat{u}=0, & x=0,1. \end{cases} \tag{2.18}$$

Since $\hat{u}\ge 0$ and $\|\hat{u}\|_\infty=1$, we can apply the Harnack inequality and the strong maximum principle to (2.18) to conclude that $\hat{u}>0$ in $[0,1]$. This implies that $u_n=\|u_n\|_\infty\hat{u}_n\to\infty$ uniformly in $[0,1]$. Therefore $w_n\to 0$ uniformly on any compact subset of $(0,1]$. This implies that $f_0=0$, and hence we deduce from (2.18) that $-m_0$ is the first eigenvalue of

$$\begin{cases} -(d_1u'+\sigma C_{x_0}u)'=\lambda u, & 0<x<1,\\ d_1u'+\sigma C_{x_0}u=0, & x=0,1. \end{cases} \tag{2.19}$$

Hence $m_0=0$ and

$$\hat{u}=\exp\Big[-\frac{\sigma}{d_1}\int_0^x C_{x_0}(s)ds\Big].$$

This implies that the entire original sequence $\{m_n\}$ converges to 0. By the connectedness of Γ, we can conclude that for every $m\in(0,m_*)$, (1.3) has at least one positive solution lying on Γ. Moreover, when $x_n\to x_0$, we have

$$\frac{u_n}{\|u_n\|_\infty}\to\exp\Big[-\frac{\sigma}{d_1}\int_0^x C_{x_0}(s)ds\Big].$$

Step 3: *The limiting profile of* u_n.

We will show in a moment that $x_0=0$ and hence the entire original sequence $u_n/\|u_n\|_\infty$ converges in $C^{1,\gamma}([0,1])$ to $\exp\big[-\frac{\sigma}{d_1}\int_0^x C_0(s)ds\big]$.

Let $\zeta_n=v_0-v_n$. Then

$$\begin{cases} -d_2\zeta_n''=f(\min\{\alpha v_n,w_n\})u_n, & 0<x<1,\\ \zeta_n'(0)=0, \quad \zeta_n'(1)+\beta\zeta_n(1)=0. \end{cases} \tag{2.20}$$

We have

$$0\le f(\min\{\alpha v_n,w_n\})u_n\le f(w_n(x))u_n(x).$$

Moreover,

$$\begin{aligned} f(w_n(x))u_n(x) &\leq (r/K_I)w_n(x)u_n(x) \\ &= (r/K_I)e^{-A_0x}e^{-A\int_0^x u_n(s)ds}u_n(x) \\ &\leq Ce^{-A\|u_n\|_\infty \int_0^x \hat{u}_n(s)ds}\|u_n\|_\infty \hat{u}_n(x). \end{aligned}$$

Since $\hat{u}_n \to \hat{u} > 0$ uniformly in $[0,1]$, there exist $c_1, c_2 > 0$ such that $c_1 \leq \hat{u}_n \leq c_2$ and hence

$$\begin{aligned} g_n &:= Ce^{-A\|u_n\|_\infty \int_0^x \hat{u}_n(s)ds}\|u_n\|_\infty \hat{u}_n(x) \\ &\leq Cc_2e^{-Ac_1\|u_n\|_\infty x}\|u_n\|_\infty. \end{aligned}$$

One easily sees from the above inequality that $g_n \to 0$ uniformly in compact subsets of $(0,1]$. It follows that

$$f_n := f(\min\{\alpha v_n, w_n\})u_n \to 0$$

uniformly in compact subsets of $(0,1]$.

We can now prove that $x_0 = 0$. Otherwise, $x_0 \in (0,1]$ and thus $x_n > x_0/2$ for all large n. Since $v_n(x)$ is increasing in x, and $\alpha v_n(x) < w_n(x)$ in $[0, x_n)$, it follows that

$$f(\min\{\alpha v_n, w_n\})u_n \leq f(\alpha v_n(x_0/2))u_n \leq f(w_n(x_0/2))u_n \text{ in } [0, x_0/2].$$

By our earlier estimates for g_n, we find that

$$f(w_n(x_0/2))u_n \leq Cc_2e^{-Ac_1\|u_n\|_\infty (x_0/2)}\|u_n\|_\infty \to 0.$$

Hence $f_n \to 0$ uniformly in $[0,1]$, which implies, by (2.20), that $\zeta_n \to 0$ in $C^{1,\gamma}([0,1])$. In particular, $\zeta_n \to 0$ uniformly in $[0,1]$; but this leads to a contradiction:

$$v_0 - \zeta_n = v_n \leq w_n/\alpha \leq w_n(x_0/2)/\alpha \to 0 \text{ uniformly in } [x_0/2, x_n].$$

Hence $x_0 = 0$. Therefore we have

$$x_n \to 0 \text{ and } u_n/\|u_n\|_\infty \to \phi_0, \tag{2.21}$$

where

$$\phi_0(x) = \exp\left[-\frac{\sigma}{d_1}\int_0^x C_0(s)ds\right] = e^{-\frac{\sigma}{d_1}x}\Big(1+\frac{x}{\delta}\Big)^{\frac{\sigma}{d_1}\delta}.$$

Step 4: *The limiting profile of* v_n.

Since $v_n \geq 0$ we have $0 \leq \zeta_n \leq v_0$. Moreover, due to (2.20) and the fact that $f_n \to 0$ uniformly in compact subsets of $(0,1]$, we can use standard elliptic regularity theory and a diagonal process to find a subsequence of $\{\zeta_n\}$, still denoted by ζ_n, such that $\zeta_n \to \zeta$ in $C^1([\epsilon,1])$ for every $\epsilon \in (0,1)$, and ζ satisfies

$$-d_2\zeta'' = 0 \text{ in } (0,1], \quad \zeta'(1) + \beta\zeta(1) = 0, \quad 0 \leq \zeta \leq v_0.$$

It follows that

$\zeta(x) = \tau(1 + \beta^{-1} - x)$ for some $\tau \geq 0$ to be determined below.

On the other hand, ζ_n can be explicitly expressed as

$$\zeta_n(x) = d_2^{-1}(1 + \beta^{-1} - x) \int_0^1 f_n(s)ds + d_2^{-1} \int_x^1 (x - s) f_n(s)ds.$$

Since

$$\int_0^1 f_n(s)ds = d_2\beta\zeta_n(1) \in (0, d_2\beta v_0(1)],$$

and $f_n \to 0$ uniformly on any compact subset of $(0, 1]$, one easily sees that

$$\int_x^1 (x - s) f_n(s)ds \to 0$$

uniformly for $x \in [0, 1]$. Thus

$$\tau = \beta\zeta(1) = \lim_{n\to\infty} \beta\zeta_n(1) = d_2^{-1} \lim_{n\to\infty} \int_0^1 f_n(s)ds = d_2^{-1} \lim_{n\to\infty} \int_0^\epsilon f_n(s)ds \tag{2.22}$$

for any $\epsilon \in (0, 1)$.

Since $v_n(x)$ is monotone increasing in x and $v_n''(x) \geq 0$, by an elementary argument we see that the fact that $v_n \to v_0 - \zeta$ in $C^1([\epsilon, 1])$ for every $\epsilon \in (0, 1)$ implies that $v_n \to v_0 - \zeta$ uniformly in $[0, 1]$.

We now show that $\tau > 0$. Suppose $\tau = 0$. Then $\zeta_n \to 0$ and hence $v_n \to v_0$ in $C^1([0, 1])$. Therefore, due to

$$w_n(0) = w_0 \text{ and } w_n \to 0 \text{ uniformly in } [\epsilon, 1] \ \forall \text{ small } \epsilon > 0,$$

when $w_0 > \alpha v_0$, we have $0 < x_n < 1$ for all large n, and

$$w_n(x_n) = \alpha v_n(x_n) \to \alpha v_0 \text{ as } n \to \infty;$$

if $w_0 < \alpha v_0$, then $x_n = 0$ and $w_n(x_n) = w_0$ for all large n; if $w_0 = \alpha v_0$, then either $0 < x_n < 1$ and $w_n(x_n) = \alpha v_n(x_n)$, or $x_n = 0$ and $w_n(x_n) = w_0$; in either case we can conclude that $w_n(x_n) \to w_0$ as $n \to \infty$.

Summarizing, we find that we always have

$$w_0 e^{-A_0 x_n} e^{-A\int_0^{x_n} u_n(s)ds} = w_n(x_n) \to \sigma_0 := \min\{w_0, \alpha v_0\}.$$

Since $x_n \to 0$ and $\hat{u}_n \to \phi_0$, we have $e^{-A_0 x_n} = 1 + o(1)$, and

$$\int_0^{x_n} u_n(s)ds = \|u_n\|_\infty \int_0^{x_n} \hat{u}_n(s)ds = \|u_n\|_\infty x_n \phi_0(0)[1 + o(1)] = \|u_n\|_\infty x_n[1 + o(1)].$$

Here $o(1)$ denotes a generic sequence converging to 0 as $n \to \infty$. This implies that

$$w_0 e^{-A\|u_n\|_\infty x_n} \to \sigma_0.$$

Hence

$$\|u_n\|_\infty x_n \to \tau_0 := A^{-1} \ln\Big(\frac{w_0}{\sigma_0}\Big). \tag{2.23}$$

Since we now assume that $\tau = 0$, by (2.22) we must have $\lim_{n\to\infty} \int_0^\epsilon f_n(x)dx = 0$. On the other hand, making use of $x_n \to 0$, $\|u_n\|_\infty x_n \to \tau_0$, $\hat{u}_n \to \phi_0$, and $\phi_0(0) = 1$, we have, for all large n and small ϵ,

$$\begin{aligned}
\int_0^\epsilon f_n(x)dx &\geq \int_{x_n}^\epsilon f(w_n(x))u_n(x)dx \\
&\geq \int_{x_n}^\epsilon f\Big(w_0 e^{-A\epsilon} \exp[-A\|u_n\|_\infty 2\phi_0(0)x]\Big)\frac{\phi_0(0)}{2}\|u_n\|_\infty dx \\
&= \int_{\|u_n\|_\infty x_n}^{\|u_n\|_\infty \epsilon} f\Big(w_0 e^{-A\epsilon} e^{-2Ay}\Big)\Big(\frac{1}{2}\Big)dy \\
&\to \Big(\frac{1}{2}\Big)\int_{\tau_0}^\infty f\Big(w_0 e^{-A\epsilon} e^{-2Ay}\Big)dy > 0.
\end{aligned}$$

This contradiction shows that we must have $\tau > 0$.

In order to find the asymptotic limit of the entire sequence $\{v_n\}$, we need to determine the value of τ. Recall that by passing to a subsequence, $v_n \to v_0 - \zeta$ uniformly in $[0, 1]$. Since $x_n \to 0$, we have either

$$w_n(x_n) = \alpha v_n(x_n) \to \alpha[v_0 - \zeta(0)] = \alpha[v_0 - \tau(1 + \beta^{-1})] := \xi_\tau,$$

which is the case when $\xi_\tau < w_0$, or $w_n(x_n) \to w_0$ when $\xi_\tau \geq w_0$. By the expression of $w_n(x_n)$, as before, we deduce that

$$w_0 e^{-A\|u_n\|_\infty x_n} \to \tilde{\xi}_\tau := \min\{w_0, \xi_\tau\}, \quad \|u_n\|_\infty x_n \to \sigma_\tau := A^{-1} \ln\big(w_0/\tilde{\xi}_\tau\big). \tag{2.24}$$

For fixed $\epsilon \in (0, 1)$, we have

$$\int_0^\epsilon f_n(x)dx = \int_0^{x_n} f_n(x)dx + \int_{x_n}^\epsilon f(w_n(x))u_n(x)dx.$$

It is easy to check that, in every possible case, we have

$$\int_0^{x_n} f_n(x)dx = f(\tilde{\xi}_\tau)\phi_0(0)[1 + o(1)]\|u_n\|_\infty x_n = f(\tilde{\xi}_\tau)\sigma_\tau[1 + o(1)].$$

Since we already know that $f(w_n(x))u_n(x) \to 0$ uniformly on any compact subset of $(0, 1]$, we find that, for any fixed $\epsilon_1 \in (0, \epsilon)$ and all large n,

(2.25)

$$
\begin{aligned}
&\int_{x_n}^{\epsilon} f\big(w_n(x)\big)u_n(x)dx\\
&= \int_{x_n}^{\epsilon_1} f\big(w_n(x)\big)u_n(x)dx + o_n(1)\\
&= \int_{x_n}^{\epsilon_1} f\big(w_0 e^{-A_0 x} e^{-A\int_0^x u_n(s)ds}\big)u_n(x)dx + o_n(1)\\
&= \int_{x_n}^{\epsilon_1} f\big(w_0[1+o_{\epsilon_1}(1)]e^{-A\|u_n\|_\infty \hat{u}_n(0)x[1+o_{\epsilon_1}(1)]}\big)\|u_n\|_\infty \hat{u}_n(0)[1+o_{\epsilon_1}(1)]dx + o_n(1)\\
&= [1+o_{\epsilon_1}(1)]\int_{x_n}^{\epsilon_1} f\big(w_0 e^{-A\|u_n\|_\infty \hat{u}_n(0)x}\big)\|u_n\|_\infty \hat{u}_n(0)dx + o_n(1)\\
&= [1+o_{\epsilon_1}(1)]\int_{\|u_n\|_\infty \hat{u}_n(0)x_n}^{\epsilon_1\|u_n\|_\infty \hat{u}_n(0)} f\big(w_0 e^{-Ay}\big)dy + o_n(1)\\
&= [1+o_{\epsilon_1}(1)]\bigg[\int_{\sigma_\tau}^{\infty} f\big(w_0 e^{-Ay}\big)dy + o_n(1)\bigg] + o_n(1),
\end{aligned}
$$

where $o_n(1) \to 0$ as $n \to \infty$ for fixed ϵ_1, and $o_{\epsilon_1}(1) \to 0$ as $\epsilon_1 \to 0$ uniformly in n. For arbitrary $\epsilon_1 \in (0, \epsilon)$, we first let $n \to \infty$ and then let $\epsilon_1 \to 0$, and we obtain from (2.25) that

$$
\lim_{n\to\infty}\int_{x_n}^{\epsilon} f\big(w_n(x)\big)u_n(x)dx = \int_{\sigma_\tau}^{\infty} f\big(w_0 e^{-Ay}\big)dy.
$$

Therefore

$$
\lim_{n\to\infty}\int_{0}^{\epsilon} f_n(x)dx = f(\tilde{\xi}_\tau)\sigma_\tau + \int_{\sigma_\tau}^{\infty} f\big(w_0 e^{-Ay}\big)dy. \tag{2.26}
$$

Making use of (2.24) and (2.26), we can rewrite (2.22) as

$$
d_2\tau = f(w_0 e^{-A\sigma_\tau})\sigma_\tau + \int_{\sigma_\tau}^{\infty} f\big(w_0 e^{-Ay}\big)dy. \tag{2.27}
$$

It can be easily checked that the function

$$
F(\theta) := f(w_0 e^{-A\theta})\theta + \int_{\theta}^{\infty} f\big(w_0 e^{-Ay}\big)dy
$$

satisfies $F'(\theta) < 0$ and hence it is decreasing in $[0, \infty)$, with

$$
F(0) = \int_0^{\infty} f\big(w_0 e^{-Ay}\big)dy = \frac{r}{A}\ln\bigg(\frac{w_0 + K_I}{K_I}\bigg), \quad F(\infty) = 0.
$$

From the definition of σ_τ, we find that $\tau \to \sigma_\tau$ is nondecreasing, with

$$
\sigma_0 = A^{-1}\ln\bigg(\frac{w_0}{\min\{w_0, \alpha v_0\}}\bigg), \quad \sigma_{v_0/(1+\beta^{-1})} = \infty.
$$

Therefore

$\tau \to F(\sigma_\tau)$ is nonincreasing in $[0, v_0/(1+\beta^{-1}))$ with $F(\sigma_0) > 0, F(\sigma_{v_0/(1+\beta^{-1})}) = 0$.

This implies that (2.27) has a unique solution $\tau \in \big(0, v_0/(1+\beta^{-1}\big)$. Thus,

$$v_n \to v_0 - \tau(1+\beta^{-1}-x) \text{ uniformly in } [0,1],$$

with τ uniquely determined by (2.27). Since $\tau > 0$ is uniquely determined, the above convergence is true for the entire original sequence $\{v_n\}$.

The proof is complete. □

3. The limit of m_* and m^* as $\sigma \to \infty$. In order to investigate the asymptotic behavior of the positive solutions of (1.3) as $\sigma \to \infty$, we need to first understand the limits of m_* and m^* as $\sigma \to \infty$. To stress their dependence on σ, we write $m_* = m_*(\sigma)$ and $m^* = m^*(\sigma)$. Let us recall that (2.6) holds; that is, $m_*(\sigma)$ and $m^*(\sigma)$ are always between the positive numbers $f(\min\{\alpha v_0, w_*(1)\})$ and $f(\min\{\alpha v_0, w_0\})$. We now prove the following result.

THEOREM 3.1.

$$\lim_{\sigma\to\infty} m_*(\sigma) = \lim_{\sigma\to\infty} m^*(\sigma) = f(\min\{\alpha v_0, w_0\}). \tag{3.1}$$

Proof. Since

$$m_*(\sigma) \le m^*(\sigma) \le f(\min\{\alpha v_0, w_0\}),$$

we need only show that

$$\lim_{\sigma\to\infty} m_*(\sigma) = f(\min\{\alpha v_0, w_0\}).$$

Moreover, it suffices to prove this along an arbitrary sequence of positive numbers increasing to ∞. Let $\{\sigma_n\}$ be such a sequence, and denote $m_n = m_*(\sigma_n)$. By definition, there exists $u_n > 0$ in $[0,1]$ such that

$$\begin{cases} -[d_1 u_n' + \sigma_n c^0(x) u_n]' = [f(\min\{\alpha v_0, w_*\}) - m_n] u_n & \text{in } (0,1), \\ d_1 u_n' + \sigma_n c^0(x) u_n = 0 & \text{for } x = 0, 1. \end{cases} \tag{3.2}$$

To simplify the notation, we will write

$$f_0(x) = f(\min\{\alpha v_0, w_*(x)\}).$$

Moreover, we define x_0^* by

$$c^0(x) = C_{x_0^*}(x) = \frac{x - x_0^*}{\delta + |x - x_0^*|}.$$

If $x_0^* = 1$, i.e., $\alpha v_0 \le w_*(x)$ in $[0,1]$ and hence $f_0(x) \equiv f(\alpha v_0)$, then clearly

$$m_n \equiv f(\alpha v_0) = f(\min\{\alpha v_0, w_0\}).$$

So (3.1) holds trivially in this case.

Suppose from now on that $x_0^* \in [0,1)$. Therefore $f_0(x)$ is a constant in $[0, x_0^*)$ and is decreasing in $[x_0^*, 1]$. As before, integrating the first equation of (3.2) we find that $(f_0(x) - m_n)$ must change sign in $(0,1)$, and therefore there exists a unique $x_n \in (0,1)$ such that $f_0(x) > m_n$ in $[0, x_n)$, and $f_0(x) < m_n$ in $(x_n, 1]$.

By (2.6), $\{m_n\}$ is a bounded sequence, and, by passing to a subsequence, we may assume that

$$m_n \to m_0 \le f(\min\{(\alpha v_0, w_0\}) = f_0(x_0^*).$$

To determine the value of m_0, we use several steps.

Step 1: *Change of variables.*

Let

$$\phi_n(x) := \exp\left[-\frac{\sigma_n}{d_1}\int_{x_0^*}^{x} c^0(x)dx\right].$$

Clearly

$$d_1\phi_n' + \sigma_n c^0\phi_n = 0, \quad \phi_n(x_0^*) = 1, \quad 0 < \phi_n(x) \le 1 \text{ in } [0,1],$$

and $\phi_n \to 0$ uniformly on compact subsets of $[0,1]\setminus\{x_0^*\}$.

Define

$$\psi_n(x) = u_n(x)/\phi_n(x).$$

Then (3.2) becomes

$$\begin{cases} -(d_1\phi_n\psi_n')' = [f_0(x) - m_n]\phi_n\psi_n & \text{in } (0,1), \\ \psi_n' = 0 & \text{for } x = 0, 1. \end{cases} \tag{3.3}$$

Define

$$\xi_n(x) = \sigma_n^{-1/2}\int_0^x \frac{1}{\phi_n(s)}ds.$$

Then ξ_n is an increasing function in $[0,1]$, with $\xi_n(0) = 0$ and

$$\xi_n(1) = y_n := \sigma_n^{-1/2}\int_0^1 \frac{1}{\phi_n(x)}dx \to \infty \text{ as } n \to \infty.$$

Let $\eta_n : [0, y_n] \to [0,1]$ be the inverse function of $\xi_n(x)$, and define

$$U_n(y) = \psi_n(\eta_n(y)) = \psi_n(x).$$

From (3.3) a simple calculation shows that

$$\begin{cases} -U_n'' = d_1^{-1}\sigma_n\phi_n^2(\eta_n(y))[f_0(\eta_n(y)) - m_n]U_n & \text{in } (0, y_n), \\ U_n'(0) = U_n'(y_n) = 0. \end{cases} \tag{3.4}$$

Step 2: *Estimates of* $\sigma_n\phi_n^2(\eta_n(y))$.

For our later estimates, we need to analyze the function $\tilde{\phi}_n(y) := \sigma_n\phi_n^2(\eta_n(y))$. To this end, for some $\tau > 0$ small to be determined later, we define $\hat{y}_n$ and Δ_n by

$$\hat{y}_n := \xi_n(x_0^*), \quad \sigma_n^{-\tau} := \sigma_n^{-1/2}\int_{x_0^*}^{x_0^*+\Delta_n} \frac{1}{\phi_n(x)}dx,$$

so that

$$\hat{y}_n \pm \sigma_n^{-\tau} = \xi_n(x_0^* \pm \Delta_n), \quad x_0^* \pm \Delta_n = \eta_n(\hat{y}_n \pm \sigma_n^{-\tau}).$$

We will show that $\tilde{\phi}_n(y)$ behaves like a δ-function concentrating at $y = \hat{y}_n$. For definiteness, we assume that $x_0^* > 0$; the case $x_0^* = 0$ can be treated by a simple modification of the arguments below. Then it is easily seen that as $n \to \infty$,

$$\hat{y}_n \to \infty, \quad y_n - \hat{y}_n \to \infty, \quad \Delta_n \to 0.$$

Using $c^0(x) = \frac{x-x_0^*}{\delta+|x-x_0^*|}$, we can easily check that, for any given small $\epsilon > 0$, there exists $\delta_0 = \delta_0(\epsilon) > 0$ small so that, when $|x - x_0^*| \le \delta_0$,

$$\exp\left[-\frac{\sigma_n}{2\delta d_1}(x-x_0^*)^2\right] \le \phi_n(x) \le \exp\left[-\frac{\sigma_n(1-\epsilon)}{2\delta d_1}(x-x_0^*)^2\right]. \tag{3.5}$$

Therefore, for all large n,

$$\begin{aligned}
\sigma_n^{1/2-\tau} &= \int_{x_0^*}^{x_0^*+\Delta_n} \frac{1}{\phi_n(x)}dx \\
&\le \int_{x_0^*}^{x_0^*+\Delta_n} \exp\left[\frac{\sigma_n}{2\delta d_1}(x-x_0^*)^2\right]dx \\
&= \int_0^{\Delta_n} \exp\left(\frac{\sigma_n}{2\delta d_1}x^2\right)dx \\
&\le \Delta_n \exp\left(\frac{\sigma_n\Delta_n^2}{2\delta d_1}\right),
\end{aligned}$$

$$\begin{aligned}
\sigma_n^{1/2-\tau} &= \int_{x_0^*}^{x_0^*+\Delta_n} \frac{1}{\phi_n(x)}dx \\
&\ge \int_{x_0^*}^{x_0^*+\Delta_n} \exp\left[\frac{\sigma_n(1-\epsilon)}{2\delta d_1}(x-x_0^*)^2\right]dx \\
&= \int_0^{\Delta_n} \exp\left[\frac{\sigma_n(1-\epsilon)}{2\delta d_1}x^2\right]dx \\
&\ge \int_{(1-\epsilon)\Delta_n}^{\Delta_n} \exp\left[\frac{\sigma_n(1-\epsilon)}{2\delta d_1}x^2\right]dx \\
&\ge \epsilon\Delta_n \exp\left[\frac{\sigma_n\Delta_n^2(1-\epsilon)^3}{2\delta d_1}\right].
\end{aligned}$$

It follows that $\sigma_n\Delta_n^2 \to \infty$, and

$$\exp\left(-\frac{\sigma_n\Delta_n^2}{2\delta d_1}\right) \le \Delta_n\sigma_n^{\tau-1/2}, \tag{3.6}$$

and

$$\sigma_n^{1/2}\Delta_n \exp\left[\frac{\sigma_n\Delta_n^2(1-\epsilon)^3}{2\delta d_1}\right] \le \epsilon^{-1}\sigma_n^{1-\tau},$$

which gives

$$\left(\frac{1}{2}\right)\ln(\sigma_n\Delta_n^2) + \frac{(1-\epsilon)^3}{2\delta d_1}\sigma_n\Delta_n^2 \le \ln\left(\epsilon^{-1}\sigma_n^{1-\tau}\right).$$

Since $\ln(\sigma_n\Delta_n^2) = o(\sigma_n\Delta_n^2)$, and

$$\ln(\epsilon^{-1}\sigma_n^{1-\tau}) = (1-\tau)\ln\sigma_n + o(\ln\sigma_n),$$

the last inequality above implies that

$$\sigma_n\Delta_n^2 \le C_\epsilon \ln\sigma_n \tag{3.7}$$

for some $C_\epsilon > 0$ and all large n.

As a consequence of (3.5), (3.6), and (3.7) we have

$$\begin{aligned}
\tilde{\phi}_n(\hat{y}_n \pm \sigma_n^{-\tau}) &= \sigma_n\phi_n^2(x_0^* \pm \Delta_n)\\
&\le \sigma_n \exp\Big[-\frac{\sigma_n(1-\epsilon)}{\delta d_1}\Delta_n^2\Big]\\
&\le \sigma_n\big[\Delta_n^2\sigma_n^{2\tau-1}\big]^{(1-\epsilon)}\\
&\le \big[C_\epsilon\ln\sigma_n\big]^{(1-\epsilon)}\sigma_n^{1+2(\tau-1)(1-\epsilon)}\\
&\to 0 \text{ as } n\to\infty,
\end{aligned}$$

provided that τ is chosen in the interval $(0,1/2)$ and $\epsilon > 0$ is small enough.

From the property of $\phi_n(x)$, we see that the above estimates imply that

$$\tilde{\phi}_n(y) \to 0 \text{ uniformly in } [0,y_n]\setminus[\hat{y}_n - \sigma_n^{-\tau}, \hat{y}_n + \sigma_n^{-\tau}], \tag{3.8}$$

and for any $M > 0$,

$$\begin{aligned}
\int_{\hat{y}_n - M}^{\hat{y}_n + M} \tilde{\phi}_n(y)dy &= \int_{\hat{y}_n-\sigma_n^{-\tau}}^{\hat{y}_n+\sigma_n^{-\tau}} \tilde{\phi}_n(y)dy + o(1)\\
&= \int_{\eta_n(\hat{y}_n-\sigma_n^{-\tau})}^{\eta_n(\hat{y}_n+\sigma_n^{-\tau})} \sigma_n\phi_n^2(x)\xi_n'(x)dx + o(1)\\
&= \int_{x_0^*-\Delta_n}^{x_0^*+\Delta_n} \sigma_n^{1/2}\phi_n(x)dx + o(1)\\
&= 2\sigma_n^{1/2}\int_0^{\Delta_n} \exp\Big(-\frac{\sigma_n x^2}{2\delta d_1}[1+o(1)]\Big)dx + o(1)\\
&= [2+o(1)]\int_0^{\sigma_n^{1/2}\Delta_n} \exp\Big(-\frac{x^2}{2\delta d_1}\Big)dx + o(1)\\
&= 2\int_0^{\infty} \exp\Big(-\frac{x^2}{2\delta d_1}\Big)dx + o(1).
\end{aligned}$$

In other words, for any $M > 0$,

$$\lim_{n\to\infty}\int_{\hat{y}_n-M}^{\hat{y}_n+M} \tilde{\phi}_n(y)dy = c_0 := 2\int_0^{\infty}\exp\Big(-\frac{x^2}{2\delta d_1}\Big)dx. \tag{3.9}$$

Step 3: *The limiting profile of* $U_n(y)$.

We now define

$$\begin{aligned}
\hat{U}_n(y) &= U_n(y+\hat{y}_n-1)/U_n(\hat{y}_n-1),\\
\hat{f}_n &= d_1^{-1}\tilde{\phi}_n(y+\hat{y}_n-1)\big[f_0\big(\eta_n(y+\hat{y}_n-1)\big) - m_n\big].
\end{aligned}$$

Clearly $\hat{U}_n(0) = 1$, and by (3.4) we have

$$\begin{cases} -\hat{U}_n'' = \hat{f}_n \hat{U}_n \text{ in } (1-\hat{y}_n, y_n + 1 - \hat{y}_n), \\ \hat{U}_n'(1-\hat{y}_n) = \hat{U}_n'(y_n + 1 - \hat{y}_n) = 0. \end{cases} \tag{3.10}$$

From (3.8) we see that

$$\hat{f}_n(y) \to 0 \text{ uniformly in } [1-\hat{y}_n, 1-\sigma_n^{-\tau}] \cup [1+\sigma_n^{-\tau}, y_n + 1 - \hat{y}_n].$$

Since $\hat{U}_n(0) = 1$, the boundedness of $\hat{f}_n$ over $[1-\hat{y}_n, 1-\sigma_n^{-\tau}]$ allows us to apply the Harnack inequality to conclude that $\hat{U}_n$ has a bound C_J independent of n over any bounded interval $J \subset [1-\hat{y}_n, 1-\sigma_n^{-\tau}]$ with $0 \in J$. We can now apply to (3.10) the L^p theory, the Sobolev imbedding theorem, and a standard diagonal argument, to obtain a subsequence of $\{\hat{U}_n\}$, still denoted by $\hat{U}_n$, such that $\hat{U}_n \to \hat{U}$ in $C^1(J)$ for any bounded interval $J \subset (-\infty, 1)$, and $\hat{U}$ satisfies

$$\hat{U}'' = 0 \text{ in } (-\infty, 1), \quad \hat{U}(0) = 1. \tag{3.11}$$

Since $\hat{U}$ is nonnegative in $(-\infty, 1)$, we deduce from (3.11) that

$$\hat{U}(y) = 1 + ay, \quad a \in [-1, 0].$$

Now consider the sequence $\{\hat{U}_n(2)\}$. We claim that this is a bounded sequence. Indeed, from our earlier observation for the sign of $[f_0(x) - m_n]$, we know that the right-hand side of the first equation in (3.4) changes sign from positive to negative when y increases across $\tilde{y}_n := \xi_n(x_n)$. It follows that $U_n''(y)$ changes sign from negative to positive as y increases across $\tilde{y}_n$. Since $U_n'(0) = U_n'(y_n) = 0$, we find that $U_n' \le 0$ in $[0, y_n]$ and hence $U_n(y)$ is nonincreasing in y, which implies that $\hat{U}_n(y)$ is nonincreasing in y and hence $0 \le \hat{U}_n(2) \le \hat{U}_n(0) = 1$. We can now use the fact that $\hat{f}_n \to 0$ uniformly in $[1+\sigma_n^{-\tau}, y_n+1-\hat{y}_n]$, as above, to conclude that, subject to passing to a further subsequence, $\hat{U}_n \to \hat{U}_*$ in $C^1(J)$ for any bounded interval $J \subset (1, \infty)$, and $\hat{U}_*$ satisfies

$$\hat{U}_*'' = 0, \quad 0 \le \hat{U}_* \le 1 \text{ in } (1, \infty).$$

Therefore $\hat{U}_*$ must be a constant, say $\hat{U}_* \equiv b$.

Using (3.9) we find that $\hat{f}_n$ is a bounded sequence in $L^1([0,2])$. By (3.10), we have

$$\hat{U}_n'(y) = \hat{U}_n'(0) - \int_0^y \hat{f}_n(y)\hat{U}_n(y)dy \quad \forall y \in [0,2].$$

Since $\hat{U}_n'(0) \to \hat{U}'(0) = a$ and $0 \le \hat{U}_n(y) \le \hat{U}_n(0) = 1$, the above identity implies that $|\hat{U}_n'(y)| \le C$ for some $C > 0$ and all $n \ge 1$ and $y \in [0,2]$. Therefore $\{\hat{U}_n(y)\}$ is equicontinuous in $[0,2]$. It follows that $\hat{U}_*$ must be a continuous extension of $\hat{U}$. Therefore $b = 1 + a$.

Step 4: *We show that* $m_0 = f(x_0^*)$.

We are now ready to determine the value of m_0 by using our estimates for $\tilde{\phi}_n$ and $\hat{U}_n$. We note that (3.8) and (3.9) imply that, for large n, $\tilde{\phi}_n(y + \hat{y}_n - 1)$ behaves like the δ-function concentrating at $y = 1$. We now use these properties of $\tilde{\phi}_n$ and (3.10) to obtain

$$\hat{U}_n'(2) = \hat{U}_n'(0) - \int_0^2 \hat{f}_n(y)\hat{U}_n(y)dy \to a - [f_0(x_0^*) - m_0](1+a)c_0.$$

But since $\hat{U}_*$ is a constant function over $(1,\infty)$, we have $\hat{U}_n'(2) \to \hat{U}_*'(2) = 0$. Therefore

$$a = [f_0(x_0^*) - m_0](1+a)c_0.$$

The right-hand side of the above identity is nonnegative, but $a \le 0$. Therefore we must have $a = 0$ and $m_0 = f_0(x_0^*)$. This implies that the entire original sequence $\{m_n\}$ converges to $f_0(x_0^*)$. Hence (3.1) holds, and the proof is complete. □

If we fix m such that $0 < m < f(\min\{\alpha v_0, w_0\})$ and let σ_n be an increasing sequence of positive numbers converging to ∞, then by Theorems 2.3 and 3.1, for all large n, (1.3) with $\sigma = \sigma_n$ has at least one positive solution. Suppose that (u_n, v_n) is such a solution. We will analyze the behavior of (u_n, v_n) as $n \to \infty$. This will be done in Part II; see [DH].

Acknowledgments. We thank the referees for their useful suggestions and comments. One referee pointed us to extra references ([IT] and [HTKS]) and provided detailed suggestions on improving the exposition of the paper (for both Part I and Part II); these have been very helpful. Y. Du thanks NCTS for the hospitality during his visit, when a major part of this paper was being written.

CONCENTRATION PHENOMENA IN A NONLOCAL QUASI-LINEAR PROBLEM MODELLING PHYTOPLANKTON II: LIMITING PROFILE*

YIHONG DU† AND SZE-BI HSU‡

Abstract. This is Part II of our study on the positive steady state of a quasi-linear reaction-diffusion system in one space dimension introduced by Klausmeier and Litchman for the modelling of the distributions of phytoplankton biomass and its nutrient. In Part I, we proved nearly optimal existence and nonexistence results. In Part II, we obtain complete descriptions of the profile of the solutions when the coefficient of the drifting term is large, rigorously proving the numerically observed phenomenon of concentration of biomass for this model. Moreover, we reveal four critical numbers for the model and provide further insights to the problem being modelled.

Key words. quasi-linear, nonlocal dependence, phytoplankton, concentration phenomenon, reaction-diffusion equation

1. Introduction.

We continue our investigation in [DH] on the problem

$$\begin{cases} -[d_1 u_x + \sigma c(x) u]_x = [g(x) - m]u, & 0 < x < 1, \\ -d_2 v_{xx} = -g(x)u, & 0 < x < 1, \\ d_1 u_x + \sigma c(x) u = 0, & x = 0,\ 1, \\ v_x(0) = 0,\ v_x(1) = \beta[v_0 - v(1)], \end{cases} \tag{1.1}$$

where d_1, d_2, σ, m, v_0, and β are positive constants,

$$g(x) = f(\min\{\alpha v(x), w(x)\}), \qquad f(s) = \frac{rs}{K_I + s},$$

and

$$w(x) = w_0 \exp\left[-A_0 x - A \int_0^x u(s)ds\right],$$

with α, r, K_I, w_0, A, and A_0 positive constants. We are interested in positive solutions of (1.1), namely, $u > 0$ and $v > 0$ in $[0, 1]$. From (1.1) it is easy to see that for any such solution v is an increasing function. Clearly w is a decreasing function. The function $c(x)$ is defined by

$$c(x) = \frac{x - x_0}{\delta + |x - x_0|},$$

where $\delta > 0$ is a small constant and $x_0 \in [0,1]$ is uniquely determined by the following description:

$$\min\{\alpha v(x), w(x)\} = \alpha v(x) \quad \forall x \in [0, x_0); \quad \min\{\alpha v(x), w(x)\} = w(x) \quad \forall x \in (x_0, 1].$$

(Due to the monotonicity of $v(x)$ and $w(x)$, such x_0 always exists.)

Problem (1.1) is a rescaled version of a model proposed by Klausmeier and Litchman in [KL] for the study of phytoplankton in a one-dimensional water column, where $u(x)$ represents the distribution of phytoplankton biomass, $v(x)$ stands for the distribution of nutrient, and x denotes the depth in the water column, with $x = 0$ at the surface and $x = 1$ at the bottom. The term $\sigma c(x)$ is used to describe the active movement of the biomass towards spatial location with optimal growth condition. Klausmeier and Litchman [KL] use this system to model the concentration phenomenon of phytoplankton in lakes and oceans, and the numerical analysis in [KL] demonstrates that, for large σ, the biomass function $u(x)$ concentrates at a certain level $x = x_*$, while the nutrient function $v(x)$ is close to a piecewise linear function. They then treat u as a constant multiple of the δ-function concentrating at x_* and propose a game theoretical model to determine the location of x_*. We refer the reader to Part I [DH] for further details regarding the background of (1.1).

Here we rigorously prove the existence of such a concentration phenomenon and obtain exact formulas for the determination of x_* and the total biomass. In doing so, we reveal the existence of four critical values $v_{**} < v_* < v^* < v^{**}$ for v_0 (the nutrient level at the sediment) such that

(i) $x_* = 0$ when $v_0 \geq v^*$, $x_* \in (0,1)$ when $v_0 \in (v_*, v^*)$, and $x_* = 1$ when $v_0 \leq v_*$;

(ii) the total biomass increases with v_0 in the range $v_{**} < v_0 < v^{**}$, but stays constant for $v_0 \geq v^{**}$ or $v_0 \leq v_{**}$ (but with v_0 above a certain level so that the biomass can survive).

In order to give a more detailed description of these results, we first recall the main results of Part I [DH], where we proved the following two theorems.

THEOREM 1.1. *There exist* $0 < m_* \leq m^* < \infty$ *such that* (1.1) *has a positive solution for* $m \in (0, m_*)$ *and has no positive solution for* $m > m^*$.

The values of m_* and m^* depend on the parameters in (1.1). To stress their dependence on σ, we write $m_* = m_*(\sigma)$, $m^* = m^*(\sigma)$.

THEOREM 1.2.

$$\lim_{\sigma\to\infty} m_*(\sigma) = \lim_{\sigma\to\infty} m^*(\sigma) = f(\min\{\alpha v_0, w_0\}).$$

To investigate the limiting profile of the positive solutions of (1.1) as $\sigma \to \infty$, we will fix m such that $0 < m < f(\min\{\alpha v_0, w_0\})$ and let σ_n be an increasing sequence of positive numbers converging to ∞. By Theorems 1.1 and 1.2, for all large n, (1.1) with $\sigma = \sigma_n$ has at least one positive solution. Suppose that (u_n, v_n) is such a solution. We will analyze the behavior of (u_n, v_n) as $n \to \infty$. This will be done in the following two sections.

In section 2, we find all the possible limiting profiles that a subsequence of $\{(u_n, v_n)\}$ can have; in particular, we find the limiting equations governing these possible limiting profiles. More precisely, let $x_n \in [0,1]$ be uniquely determined by

$$\begin{cases} \min\{\alpha v_n(x), w_n(x)\} = \alpha v_n(x) & \text{for } x \in [0, x_n), \\ \min\{\alpha v_n(x), w_n(x)\} = w_n(x) & \text{for } x \in (x_n, 1], \end{cases}$$

where

$$w_n(x) = w_0 \exp\Big[-A_0 x - A\int_0^x u_n(s)ds\Big].$$

We consider the following possibilities:

$$\text{(i) } x_n \to x_* \in (0,1), \qquad \text{(ii) } x_n \to 0, \qquad \text{(iii) } x_n \to 1.$$

The cases (ii) and (iii) are each further divided into two subcases, namely, for case (ii),

$$\text{(a1) } \sigma_n^{1/2} x_n \to \infty, \qquad \text{(a2) } \sigma_n^{1/2} x_n \to a_* \in [0,\infty);$$

for case (iii),

$$\text{(b1) } \sigma_n^{1/2}(1-x_n) \to \infty, \qquad \text{(b2) } \sigma_n^{1/2}(1-x_n) \to b_* \in [0,\infty).$$

One easily sees that, subject to a subsequence, the above are all the possible behaviors of the sequence $\{x_n\}$. Eventually we will show in section 3 that the limit of the entire sequence $\{x_n\}$ always exists and that this limit is completely determined by the value of v_0, which in turn allows us to completely determine the profiles of u_n and v_n for large n. But in order to prove these facts, we need to first find all the possible limiting profiles of $\{(u_n, v_n)\}$ and the limiting equations that govern these profiles for each of the above listed cases. The main results of section 2 are summarized below.

If case (i) occurs, we show (see Lemma 2.3) that as $n \to \infty$, subject to a subsequence, $u_n \to 0$ uniformly in $[0, x_* - \epsilon] \cup [x_* + \epsilon, 1]$ for any small $\epsilon > 0$ and

$$\int_0^1 u_n(x)dx \to \tau_* C_0, \qquad C_0 := \int_{-\infty}^{\infty} e^{-x^2/(2\delta d_1)}dx = \sqrt{2\delta d_1 \pi},$$

$$v_n \to v_0 - \frac{\tau_*}{d_2} m C_0 (1 + \beta^{-1} - \max\{x, x_*\})$$

uniformly in $[0,1]$, where $x_* \in (0,1)$ and $\tau_* > 0$ are determined by

$$\text{(1.2)} \qquad \begin{cases} w_0 e^{-A_0 x_* - A\tau_*(C_0/2)} = \alpha\Big[v_0 - \dfrac{\tau_*}{d_2} m C_0 (1 + \beta^{-1} - x_*)\Big], \\ m = \displaystyle\int_0^1 f\big(w_0 e^{-A_0 x_* - A\tau_* \max\{C_0/2, C_0 y\}}\big)dy. \end{cases}$$

If case (ii)(a1) occurs, we show (see Lemma 2.4) that the above conclusions hold with $x_* = 0$; in particular,

$$\text{(1.3)} \qquad w_0 e^{-A\tau_*(C_0/2)} = \alpha\Big[v_0 - \frac{\tau_*}{d_2} m C_0 (1 + \beta^{-1})\Big],$$

and

$$\text{(1.4)} \qquad m = \int_0^1 f\big(w_0 e^{-A\tau_* \max\{C_0/2, C_0 y\}}\big)dy.$$

Since (1.4) uniquely determines $\tau_* > 0$, we can substitute this τ_* into (1.3) to obtain a special value for v_0, say $v_0 = v_*$.

Similarly, if case (iii)(b1) occurs, we can show (Lemma 2.5) that the conclusions of case (i) hold except that $x_* = 1$; in particular,

$$w_0 e^{-A_0 - A\tau_*(C_0/2)} = \alpha\left[v_0 - \frac{\tau_*}{d_2} mC_0(1+\beta^{-1}-1)\right], \tag{1.5}$$

and

$$m = \int_0^1 f\big(w_0 e^{-A_0 - A\tau_* \max\{C_0/2, C_0 y\}}\big)dy. \tag{1.6}$$

Analogously, $\tau_* > 0$ is uniquely determined by (1.6), and one can then use (1.5) to obtain a special value for v_0, say $v_0 = v^*$.

If case (ii)(a2) occurs, we show (Lemma 2.4) that as $n \to \infty$, subject to a subsequence, $u_n \to 0$ uniformly in $[\epsilon, 1]$ for any small $\epsilon > 0$,

$$\int_0^1 u_n(x)dx \to \tau_* C(a_*), \qquad C(a_*) = \int_{-a_*}^{\infty} e^{-x^2/(2\delta d_1)}dx,$$

$$v_n \to v_0 - \frac{\tau_*}{d_2} mC(a_*)(1+\beta^{-1}-x)$$

uniformly in $[0,1]$, where $a_* \in [0,\infty)$ and $\tau_* > 0$ are determined by

$$m = \int_0^1 f\big(w_0 e^{-A\tau_* \max\{C(a_*) - C_0/2, C(a_*)y\}}\big)dy, \tag{1.7}$$

and

$$\alpha\Big(v_0 - \frac{\tau_*}{d_2} mC(a_*)(1+\beta^{-1})\Big) = w_0 e^{-A\tau_*[C(a_*) - C_0/2]} \quad \text{if } a_* > 0, \tag{1.8}$$

$$\alpha\left(v_0 - \frac{\tau_*}{d_2} m\left(\frac{C_0}{2}\right)(1+\beta^{-1})\right) \geq w_0 \quad \text{if } a_* = 0. \tag{1.9}$$

If case (iii)(b2) occurs, we show (Lemma 2.5) that as $n \to \infty$, subject to a subsequence, $u_n \to 0$ uniformly in $[0, 1-\epsilon]$ for any small $\epsilon > 0$,

$$\int_0^1 u_n(x)dx \to \tau_* \tilde{C}(b_*), \qquad \tilde{C}(b_*) = \int_{-\infty}^{b_*} e^{-x^2/(2\delta d_1)}dx = C(-b_*),$$

and

$$v_n \to v_0 - \frac{\tau_*}{d_2}\beta^{-1}\tilde{C}(b_*),$$

where $b_* \in [0,\infty)$ and $\tau_* > 0$ are determined by

$$m = \int_0^1 f\big(w_0 e^{-A_0 - A\tau_* \max\{C_0/2, \tilde{C}(b_*)y\}}\big)dy \tag{1.10}$$

and

$$\alpha\Big(v_0 - \frac{\tau_*}{d_2\beta} C(b_*)\Big) = w_0 e^{-A_0 - A\tau_* C_0/2} \quad \text{if } b_* > 0, \tag{1.11}$$

$$\alpha\left(v_0 - \frac{\tau_*}{d_2\beta}\left(\frac{C_0}{2}\right)\right) \leq w_0 e^{-A_0 - A\tau_* C_0/2} \quad \text{if } b_* = 0. \tag{1.12}$$

In section 3, through careful analysis of the limiting equations (1.2)–(1.12), we show that the entire sequence $\{x_n\}$ always converges to a point $x_* \in [0,1]$, that exactly one of the cases considered in section 2 occurs, and that in each case the limit of the entire sequence in the conclusion exists. More precisely, if $v_* < v_0 < v^*$ (recall that v_* and v^* are defined above in cases (ii)(a1) and (iii)(b1), respectively), then case (i) must occur, and (1.2) uniquely determines x_* and τ_*. If $v_0 = v_*$, then case (ii)(a1) occurs; if $v_0 = v^*$, then case (iii)(b1) occurs. If $v_0 > v^*$, then case (ii)(a2) must happen, and if $v_0 < v_*$, then case (iii)(b2) must happen. Moreover, our analysis on the limiting total biomass $\lim_{n\to\infty} \int_0^1 u_n(x)dx$ reveals two further critical values of v_0, $v_{**} < v_*$ and $v^{**} > v^*$ such that this limiting total biomass is strictly increasing with v_0 for v_0 in the range $v_{**} \le v_0 \le v^{**}$ but remains constant (i.e., no longer changes with v_0) when $v_0 \ge v^{**}$ or when $v_0 \le v_{**}$. See Theorems 3.1–3.3 for more accurate descriptions of these results.

In section 4 we give biological interpretations of our main results and compare our rigorous limiting equations with the game theoretical model of [KL].

Though the proofs are rather involved, they consist mainly of elementary mathematical analysis; most of the proofs in section 2 and all of the arguments in section 3 can be understood with sound knowledge of calculus and real analysis.

2. The limiting equations. We will keep using the notation of Part I [DH]. It turns out that the techniques used in the proof of Theorem 3.1 in Part I are not quite suitable for our purpose here. We will introduce some different techniques.

Suppose that $0 < m < f(\min\{\alpha v_0, w_0\})$ and σ_n, (u_n, v_n) are as given in the introduction above. Suppose $c_{v_n,w_n}(x) = C_{x_n}(x)$, $x_n \in [0,1]$. By passing to a subsequence we may assume that $x_n \to x_* \in [0,1]$. Then

$$C_{x_n} = \frac{x - x_n}{\delta + |x - x_n|} \to C_{x_*}$$

in $C^1([0,1])$.

In order to obtain useful equations to determine the profiles of u_n and v_n, we need to stretch the variable x appropriately. We define

$$\Phi_n(x) = \exp\left[-\frac{\sigma_n}{2d_1}\int_{x_n}^{x} C_{x_n}(s)ds\right]$$

and

$$\Psi_n(x) = u_n(x)/\Phi_n(x).$$

By a direct computation we obtain

$$\begin{cases} -d_1\Psi_n'' + \sigma_n\Gamma_n(x)\Psi_n = \big[f(\min\{\alpha v_n, w_n\}) - m\big]\Psi_n, & x \in (0,1), \\ d_1\Psi_n' + (\sigma_n/2)C_{x_n}\Psi_n = 0, & x = 0,1, \end{cases}$$

where

$$\Gamma_n(x) := \frac{\sigma_n(x - x_n)^2 - 2d_1\delta}{4d_1(\delta + |x - x_n|)^2}.$$

Let us introduce the stretched variable $y = \sigma^{1/2}(x - x_n)$ and define

$$V_n(y) := \Psi_n\big(\sigma_n^{-1/2}y + x_n\big), \qquad C_n(y) := \sigma_n^{1/2}C_{x_n}\big(\sigma_n^{-1/2}y + x_n\big) = \frac{y}{\delta + \sigma_n^{-1/2}|y|},$$

$$a_n := -\sigma_n^{1/2}x_n, \qquad b_n := \sigma_n^{1/2}(1 - x_n),$$

and

$$F_n(y) := f\big(\min\{\alpha v_n(\sigma_n^{-1/2}y + x_n), w_n(\sigma_n^{-1/2}y + x_n)\}\big).$$

Then

$$\text{(2.1)}\quad \begin{cases} -d_1 V_n'' + \dfrac{y^2 - 2d_1\delta}{4d_1(\delta + \sigma_n^{-1/2}|y|)^2} V_n = \sigma_n^{-1}\big[F_n(y) - m\big]V_n, & y \in (a_n, b_n), \\ d_1 V_n' + (1/2)C_n V_n = 0, & y = a_n, b_n. \end{cases}$$

In the discussions below, we will consider the cases $x_* \in (0,1)$, $x_* = 0$, and $x_* = 1$ separately.

LEMMA 2.1. *Suppose $x_n \to x_* \in (0,1)$, and set $\tilde{V}_n(y) = V_n(y)/\|V_n\|_{L^\infty([a_n,b_n])}$. Then*

$$\tilde{V}_n \to V_0 \quad \text{in } C^1(J) \text{ for any finite interval } J \subset (-\infty, \infty),$$

where $V_0(y) = \exp[-\frac{y^2}{4d_1\delta}]$ is the unique solution of

$$-d_1 V'' = \frac{2d_1\delta - y^2}{4d_1\delta^2} V, \quad 0 < V \le 1,\ V(0) = 1,\ V'(0) = 0.$$

Proof. Since $x_* \in (0,1)$, we have $a_n \to -\infty$ and $b_n \to \infty$ as $n \to \infty$. Let us note that, for $y \in [a_n, -(2d_1\delta)^{1/2} - \epsilon]$ with $\epsilon > 0$ sufficiently small and all large n, the first equation in (2.1) implies that $V_n''(y) > 0$. Since $d_1 V_n'(a_n) = -(1/2)C_n(a_n)V_n(a_n) \ge 0$, we deduce that $V_n'(y) > 0$ in $(a_n, -(2d_1\delta)^{1/2} - \epsilon]$ for all large n. Hence V_n is increasing in this range. Similarly, we can see that $V_n(y)$ is decreasing in the range $y \in [(2d_1\delta)^{1/2} + \epsilon, b_n]$ for all large n. Therefore $\max V_n = V_n(y_n)$ for some $y_n \in [-(2d_1\delta)^{1/2} - \epsilon, (2d_1\delta)^{1/2} + \epsilon]$, and $\tilde{V}_n(y) = V_n(y)/V_n(y_n)$. We may assume that $y_n \to y^*$ as $n \to \infty$. We now define

$$\tilde{F}_n(y) := \frac{2d_1\delta - y^2}{4d_1(\delta + \sigma_n^{-1/2}|y|)^2} + \sigma_n^{-1}\big[F_n(y) - m\big].$$

Then $\tilde{V}_n(y_n) = 1$, and

$$\text{(2.2)}\quad \begin{cases} -d_1 \tilde{V}_n'' = \tilde{F}_n \tilde{V}_n, \quad 0 < \tilde{V}_n \le 1, & y \in (a_n, b_n), \\ d_1 \tilde{V}_n' + (1/2)C_n \tilde{V}_n = 0, & y = a_n,\ b_n. \end{cases}$$

Since $\{\tilde{F}_n\}$ is uniformly bounded over any bounded interval and $0 \le \tilde{V}_n \le 1$, we may apply the interior L^p theory (see [GT]) to (2.2) and use the Sobolev imbedding theorem and a standard diagonal argument to conclude that, by passing to a subsequence, $\tilde{V}_n \to \tilde{V}$ in $C^1(J)$ for any bounded interval J, and $\tilde{V}$ satisfies

$$\text{(2.3)}\quad -d_1 \tilde{V}'' = \frac{2d_1\delta - y^2}{4d_1\delta^2}\tilde{V}, \quad 0 < \tilde{V} \le 1 \text{ in } (-\infty, \infty),\ \tilde{V}(y^*) = 1,\ \tilde{V}'(y^*) = 0.$$

By the monotonicity property of $V_n(y)$ observed earlier, we know that $\tilde{V}(y)$ is nondecreasing in $(-\infty, -(2d_1\delta)^{1/2})$ and is nonincreasing in $((2d_1\delta)^{1/2}, \infty)$. We can now use (2.3) to conclude that $\tilde{V}'(y)$ is positive and increasing in $(-\infty, -(2d_1\delta)^{1/2})$, reaching a positive maximum at $y = -(2d_1\delta)^{1/2}$; then is decreasing in $(-(2d_1\delta)^{1/2},$

$(2d_1\delta)^{1/2}$), reaching a negative minimum at $y = (2d_1\delta)^{1/2}$; and for $y > (2d_1\delta)^{1/2}$, is increasing and stays negative. Therefore $V'(y)$ has a unique zero at some $y_0 \in \big(-(2d_1\delta)^{1/2}, (2d_1\delta)^{1/2}\big)$, which is the unique maximum point of $\tilde{V}$. Thus $y_0 = y^*$. In other words, $\tilde{V}(y)$ is increasing in $(-\infty, y^*)$ and is decreasing in $(y^*, 0)$. It then follows from an elementary analysis that $\tilde{V}$ decays to 0 as $|y| \to \infty$, and there exists $C_1, C_2 > 0$ such that

$$\tilde{V}(y),\ |\tilde{V}'(y)| \le C_1 e^{-C_2|y|} \quad \forall y \in (-\infty, \infty).$$

We now multiply $\tilde{V}(-y)$ to (2.3), integrate over $[y^*, \infty)$, and then apply integration by parts. Since $\tilde{V}(-y)$ satisfies the differential equation in (2.3), we deduce

$$\tilde{V}'(-y^*)\tilde{V}(y^*) + \tilde{V}'(y^*)\tilde{V}(-y^*) = 0.$$

It follows that $\tilde{V}'(-y^*) = 0$. Since y^* is the only zero of $\tilde{V}'$, we must have $y^* = -y^*$, that is, $y^* = 0$. By the uniqueness theorem of initial value problems of ordinary differential equations, we must have $\tilde{V} = V_0$, the unique solution of (2.3) with $y^* = 0$. A simple calculation confirms that the function $\exp[-\frac{y^2}{4d_1\delta}]$ solves the equation for V_0. Hence, by uniqueness,

$$V_0(y) = \exp\left[-\frac{y^2}{4d_1\delta}\right].$$

Since V_0 is uniquely determined, it follows that the entire original sequence $\{\tilde{V}_n\}$ converges to V_0. □

Using the monotonicity of $\tilde{V}_n$ and the fact that $V_0(y) \to 0$ as $|y| \to \infty$, we see that Lemma 2.1 implies

$$\big\|\Psi_n(\cdot)/\|\Psi_n\|_\infty - V_0\big(\sigma_n^{1/2}(\cdot - x_n)\big)\big\|_{L^\infty([0,1])} \to 0 \quad \text{as } n \to \infty, \tag{2.4}$$

since for large n the function

$$\Psi_n(x)/\|\Psi_n\|_\infty - V_0\big(\sigma_n^{1/2}(x - x_n)\big)$$

is uniformly small at those values of $x \in [0,1]$ such that $\sigma_n^{1/2}(x - x_n)$ stays bounded (by Lemma 2.1), and, by the properties of $\tilde{V}_n$ and V_0, the values of the function at the remaining $x \in [0,1]$ are also small.

We now denote $\tilde{\Psi}_n(x) = \Psi_n(x)/\|\Psi_n\|_\infty$ and consider the function

$$\tilde{u}_n(x) := \sigma_n^{1/2}\Phi_n(x)\tilde{\Psi}_n(x) = \left(\frac{\sigma_n^{1/2}}{\|\Psi_n\|_\infty}\right)u_n.$$

We will show that, for large n, $\tilde{u}_n$ behaves like the δ-function concentrating at x_*. Indeed, we have the following result.

LEMMA 2.2. *For any given small $\epsilon > 0$, $|x - x_n| \ge \epsilon$ implies*

$$0 < \tilde{u}_n(x) \le \sigma_n^{1/2} \exp\left[-\frac{\sigma_n}{4(\delta+1)d_1}\epsilon^2\right] \to 0. \tag{2.5}$$

Moreover, when $x_n \to x_* \in (0,1)$,

$$\lim_{n\to\infty} \int_0^1 \tilde{u}_n(x)dx = C_0 := \int_{-\infty}^{\infty} e^{-x^2/(2\delta d_1)}dx = \sqrt{2\delta d_1 \pi}. \tag{2.6}$$

Proof. For any given small $\epsilon > 0$, there exists $\delta_0 = \delta_0(\epsilon) > 0$ small so that, when $|x - x_n| \le \delta_0$,

$$\exp\Big[-\frac{\sigma_n}{4\delta d_1}(x-x_n)^2\Big] \le \Phi_n(x) \le \exp\Big[-\frac{\sigma_n(1-\epsilon)}{4\delta d_1}(x-x_n)^2\Big].$$

For any $x \in [0,1]$, we have

$$\exp\Big[-\frac{\sigma_n}{4\delta d_1}(x-x_n)^2\Big] \le \Phi_n(x) \le \exp\Big[-\frac{\sigma_n}{4(\delta+1) d_1}(x-x_n)^2\Big].$$

Since $\tilde{\Psi}_n \le 1$, for $|x - x_n| \ge \epsilon$, we have

$$\tilde{u}_n(x) \le \sigma_n^{1/2} \exp\Big[-\frac{\sigma_n}{4(\delta+1)d_1}\epsilon^2\Big] \to 0.$$

This proves (2.5). Moreover, we have

$$\begin{aligned}
\int_0^1 \tilde{u}_n(x)dx &= \int_{x_n-\epsilon}^{x_n+\epsilon} \sigma_n^{1/2}\Phi_n(x)\tilde{\Psi}_n(x)dx + o(1)\\
&= \int_{-\epsilon\sigma_n^{1/2}}^{\epsilon\sigma_n^{1/2}} \Phi_n(x_n+\sigma_n^{-1/2}y)\tilde{V}_n(y)dy + o(1)\\
&= \int_{-\infty}^{\infty} \exp\Big[-\frac{y^2}{4d_1\delta}\Big]V_0(y)dy + o(1)\\
&= \int_{-\infty}^{\infty} \exp\Big[-\frac{y^2}{2d_1\delta}\Big]dy + o(1).
\end{aligned}$$

Hence (2.6) holds. For later application, let us also note from the above argument that

$$\lim_{n\to\infty}\int_{x_n}^1 \tilde{u}_n(x)dx = \lim_{n\to\infty}\int_0^{x_n} \tilde{u}_n(x)dx = C_0/2. \qquad \square \tag{2.7}$$

Denote $\tau_n := \|\Psi_n\|_\infty \sigma_n^{-1/2}$. We find that

$$u_n(x) = \tau_n \tilde{u}_n(x).$$

LEMMA 2.3. *Suppose that $x_n \to x_* \in (0,1)$. Then $\{\tau_n\}$ has a subsequence, still denoted by itself, such that $\tau_n \to \tau_* > 0$. Moreover, τ_* and x_* must satisfy*

$$w_0 e^{-A_0 x_* - A\tau_*(C_0/2)} = \alpha\Big[v_0 - \frac{\tau_*}{d_2} m C_0(1+\beta^{-1}-x_*)\Big] \tag{2.8}$$

and

$$m = \int_0^1 f\big(w_0 e^{-A_0 x_* - A\tau_* \max\{C_0/2, C_0 y\}}\big)dy. \tag{2.9}$$

Furthermore, by possibly passing to a further subsequence, $u_n \to 0$ in $C([0,1]\setminus[x_*-\epsilon, x_*+\epsilon])$, for all $\epsilon > 0$, and

$$v_n(x) \to v_0 - \frac{\tau_*}{d_2} m C_0(1+\beta^{-1} - \max\{x, x_*\}) \tag{2.10}$$

uniformly in $[0,1]$.

Proof. By passing to a subsequence, we have two possible cases:

$$\text{(i)}\ \ \tau_n \to \infty, \quad \text{(ii)}\ \ \tau_n \to \tau_* \in [0,\infty).$$

Step 1. Case (i) cannot happen.

Suppose $\tau_n \to \infty$; we are going to derive a contradiction. Denote

$$f_n = f(\min\{\alpha v_n, w_n\}).$$

Since

$$w_n(x_n) \le w_0 e^{-A\tau_n \int_0^{x_n} \tilde{u}_n(s)ds},$$

and by (2.7)

$$\int_0^{x_n} \tilde{u}_n(s)ds \to C_0/2 > 0,$$

we easily see that $w_n(x_n) \to 0$. It follows that

$$\|f_n\|_\infty = f_n(x_n) = f(w_n(x_n)) \to 0.$$

This implies that

$$\int_0^1 f_n \tilde{u}_n dx \to 0.$$

On the other hand, we may integrate the equation for u_n to obtain

$$\int_0^1 [f_n(x) - m]u_n dx = 0,$$

which implies that

$$\int_0^1 [f_n(x) - m]\tilde{u}_n dx = 0.$$

Letting $n \to \infty$ and using (2.6), we obtain

$$mC_0 = \lim_{n\to\infty} \int_0^1 f_n \tilde{u}_n dx = 0,$$

which contradicts our assumption that $m > 0$. Therefore case (i) cannot happen.

Step 2. The limiting profile of u_n and v_n.

We next consider case (ii), namely, $\tau_n \to \tau_* \in [0,\infty)$. In this case, due to (2.5), $u_n = \tau_n \tilde{u}_n \to 0$ in $C([0,1] \setminus [x_* - \epsilon, x_* + \epsilon])$, for all $\epsilon > 0$, and hence

$$\tau_n f_n \tilde{u}_n \to 0 \quad \text{uniformly in } [0, x_* - \epsilon] \cup [x_* + \epsilon, 1] \quad \forall \epsilon > 0. \tag{2.11}$$

Let $\zeta_n = v_0 - v_n$. Then

$$-d_2 \zeta_n'' = \tau_n f_n \tilde{u}_n \text{ in } (0,1), \quad \zeta_n'(0) = 0, \quad \zeta_n'(1) + \beta \zeta_n(1) = 0. \tag{2.12}$$

Since $v_n \geq 0$, we have $\zeta_n \leq v_0$. Since $\tau_n f_n \tilde{u}_n > 0$, from (2.12) and the maximum principle, we deduce that $\zeta_n > 0$. Hence we always have $0 < \zeta_n \leq v_0$. Therefore we can integrate (2.12) to obtain

$$\eta_n := \tau_n \int_0^1 f_n \tilde{u}_n dx = d_2[\zeta_n'(0) - \zeta_n'(1)] = d_2\beta\zeta_n(1) \in [0, d_2\beta v_0].$$

This implies that, by passing to a subsequence, we may assume that $\eta_n \to \eta_* \in [0, d_2\beta v_0]$.

Moreover, using (2.11), (2.12), and $\eta_n \to \eta_*$, we find that

$$\begin{aligned}
&\{\zeta_n'\} \text{ is a bounded sequence in } L^\infty([0,1]),\\
&\zeta_n'(x) \to 0 \text{ uniformly in } [0, x_* - \epsilon] \quad \forall \epsilon > 0,\\
&\zeta_n'(x) \to -\eta_*/d_2 \text{ uniformly in } [x_* + \epsilon, 1] \quad \forall \epsilon > 0.
\end{aligned}$$

Since, moreover, $0 \leq \zeta_n \leq v_0$, we conclude that $\{\zeta_n\}$ is precompact in $C([0,1])$. Hence, by passing to a subsequence, we may assume that $\zeta_n \to \zeta$ in $C([0,1])$.

On the other hand, we may apply the L^p theory to (2.12) and the Sobolev imbedding theorem to find a further subsequence, still denoted by ζ_n, such that $\zeta_n \to \tilde{\zeta}$ in $C^1(J)$ for any compact interval $J \subset [0, x_*) \cup (x_*, 1]$, and $\tilde{\zeta}$ satisfies (in the weak sense)

$$-d_2\tilde{\zeta}'' = 0 \text{ in } [0, x_*) \cup (x_*, 1], \qquad \tilde{\zeta}'(0) = 0, \qquad \tilde{\zeta}'(1) + \beta\tilde{\zeta}(1) = 0.$$

Clearly we must have $\tilde{\zeta} = \zeta$. Moreover, our earlier analysis on ζ_n implies that $\zeta'(x) = 0$ in $[0, x_*)$ and $\zeta'(x) = -\eta_*/d_2$ in $(x_*, 1]$. These properties uniquely determine ζ:

$$\zeta(x) = (\eta_*/d_2)(1 + \beta^{-1} - \max\{x_*, x\}). \tag{2.13}$$

Step 3. $\tau_* > 0$.

Otherwise, $\tau_* = 0$ and hence $\eta_* = 0$. It follows that $\zeta = 0$ and $v_n \to v_0$ uniformly in $[0,1]$, and that

$$w_n(x) = w_0 e^{-A_0 x} e^{-A\tau_n \int_0^x \tilde{u}_n(s)ds} \to w_0 e^{-A_0 x} = w_*(x)$$

uniformly in $[0,1]$. This implies that

$$x_* = x_0^* \quad \text{and} \quad f_n(x) \to f_0(x) := f(\min\{\alpha v_0, w_*\}) \text{ uniformly in } [0,1].$$

We may now integrate the equation for u_n to obtain, as before,

$$\int_0^1 [f_n(x) - m]\tilde{u}_n dx = 0.$$

Letting $n \to \infty$, we deduce

$$[f_0(x_0^*) - m]C_0 = 0,$$

which contradicts our assumption that $m < f(\min\{\alpha v_0, w_0\}) = f_0(x_0^*)$. Hence $\tau_* > 0$.

Step 4. The equations for x_* and τ_*.

We now set out to find the equations that determine x_* and τ_*. By (2.7),

$$w_n(x_n) = w_0 e^{-A_0 x_n} e^{-A\tau_n \int_0^{x_n} \tilde{u}_n(s)ds} \to w_0 e^{-A_0 x_*} e^{-A\tau_*(C_0/2)}.$$

On the other hand,

$$w_n(x_n) = \alpha v_n(x_n) \to \alpha\big[v_0 - \zeta(x_*)\big].$$

Thus we necessarily have

$$w_0 e^{-A_0 x_* - A\tau_*(C_0/2)} = \alpha\big[v_0 - \zeta(x_*)\big] = \alpha\big[v_0 - (\eta_*/d_2)(1+\beta^{-1} - x_*)\big]. \tag{2.14}$$

Moreover, using (2.5), (2.7), and the fact that $\alpha v_n \to \alpha(v_0 - \zeta)$ uniformly in $[0,1]$, we deduce

$$\int_0^{x_n} f(\alpha v_n)\tilde{u}_n dx \to (C_0/2) f\big(\alpha v_0 - \alpha\zeta(x_*)\big). \tag{2.15}$$

Using

$$w_n(x) = w_0 e^{-A_0 x} e^{-A\tau_n \int_0^x \tilde{u}_n(s)ds}$$

and the property of $\tilde{u}_n$, we obtain, for any small $\epsilon > 0$,

$$\begin{aligned}
&\int_{x_n}^1 f(w_n)\tilde{u}_n dx \\
&\quad = \int_{x_n}^1 f\big(w_0 e^{-A_0 x - A\tau_n \int_0^{x_n} \tilde{u}_n(s)ds - A\tau_n \int_{x_n}^x \tilde{u}_n(s)ds}\big)\tilde{u}_n dx \\
&\quad = \int_{x_n}^{x_*+\epsilon} f\big(w_0 e^{-A_0 x - A\tau_n(C_0/2) e^{-A\tau_n \int_{x_n}^x \tilde{u}_n(s)ds}}\big)\tilde{u}_n dx + o(1) \\
&\quad = [1+o_\epsilon(1)] \int_{x_n}^{x_*+\epsilon} f\big(w_0 e^{-A_0 x_* - A\tau_*(C_0/2) e^{-A\tau_n \int_{x_n}^x \tilde{u}_n(s)ds}}\big)\tilde{u}_n dx + o(1) \\
&\quad = [1+o_\epsilon(1)] \int_0^{[\int_{x_n}^1 \tilde{u}_n(s)ds]} f\big(w_0 e^{-A_0 x_* - A\tau_*(C_0/2) e^{-A\tau_n y}}\big)dy + o(1) \\
&\quad = [1+o_\epsilon(1)] \int_0^{C_0/2} f\big(w_0 e^{-A_0 x_* - A\tau_*(C_0/2) e^{-A\tau_* y}}\big)dy + o(1),
\end{aligned}$$

where $o_\epsilon(1)$ represents a quantity that converges to 0 as $\epsilon \to 0$.

Thus

$$\int_{x_n}^1 f(w_n)\tilde{u}_n(x)dx \to \int_0^{C_0/2} f\big(w_0 e^{-A_0 x_* - A\tau_*(C_0/2) e^{-A\tau_* y}}\big)dy \tag{2.16}$$

as $n \to \infty$.

Combining (2.15) and (2.16), we obtain

$$\begin{aligned}
\eta_* &= \lim_{n\to\infty} \tau_n \int_0^1 f_n \tilde{u}_n dx \\
&= \tau_* \left[(C_0/2) f\big(\alpha v_0 - \alpha\zeta(x_*)\big) + \int_0^{C_0/2} f\big(w_0 e^{-A_0 x_* - A\tau_*(C_0/2) e^{-A\tau_* y}}\big)dy \right].
\end{aligned} \tag{2.17}$$

Moreover, we may integrate the equation for u_n to obtain

$$\int_0^1 [f_n(x) - m]\tilde{u}_n dx = 0.$$

Letting $n \to \infty$ and using (2.15), (2.16), we obtain

$$mC_0 = (C_0/2)f(\alpha v_0 - \alpha\zeta(x_*)) + \int_0^{C_0/2} f\big(w_0 e^{-A_0 x_* - A\tau_*(C_0/2)} e^{-A\tau_* y}\big)dy.$$

This combined with (2.17) yields

$$\eta_* = \tau_* mC_0 \tag{2.18}$$

and combined with (2.14) gives

$$\begin{aligned} m &= (1/2)f(w_0 e^{-A_0 x_* - A\tau_*(C_0/2)}) + C_0^{-1}\int_0^{C_0/2} f\big(w_0 e^{-A_0 x_* - A\tau_*(C_0/2)} e^{-A\tau_* y}\big)dy \\ &= C_0^{-1}\int_0^{C_0} f\big(w_0 e^{-A_0 x_* - A\tau_* \max\{C_0/2, y\}}\big)dy \\ &= \int_0^1 f\big(w_0 e^{-A_0 x_* - A\tau_* \max\{C_0/2, C_0 y\}}\big)dy; \end{aligned}$$

thus (2.9) is proved. Equation (2.8) and (2.10) clearly follow from (2.13), (2.14), and (2.18). □

We now consider the case $x_* = 0$. By passing to a subsequence, we have two subcases:

$$\text{(a1) } a_n := \sigma_n^{1/2} x_n \to \infty, \qquad \text{(a2) } a_n \to a_* \in [0, \infty).$$

LEMMA 2.4. *In subcase* (a1)*, all of the conclusions in Lemmas* 2.2 *and* 2.3 *hold. In subcase* (a2)*, $\{\tau_n\}$ has a subsequence, still denoted by itself, such that $\tau_n \to \tau_* > 0$. Moreover, τ_* and a_* must satisfy*

$$m = \int_0^1 f\big(w_0 e^{-A\tau_* \max\{C(a_*) - C_0/2, C(a_*)y\}}\big)dy \tag{2.19}$$

and

$$\alpha\Big(v_0 - \frac{\tau_*}{d_2} mC(a_*)(1+\beta^{-1})\Big) = w_0 e^{-A\tau_*[C(a_*) - C_0/2]} \qquad \text{if } a_* > 0, \tag{2.20}$$

$$\alpha\left(v_0 - \frac{\tau_*}{d_2} m\left(\frac{C_0}{2}\right)(1+\beta^{-1})\right) \geq w_0 \qquad \text{if } a_* = 0, \tag{2.21}$$

where

$$C(a_*) := \int_{-a_*}^{\infty} \exp\left[-\frac{y^2}{2d_1\delta}\right]dy.$$

Furthermore, by possibly passing to a further subsequence, $u_n \to 0$ in $C([\epsilon, 1])$, for all $\epsilon \in (0,1)$,

$$\lim_{n\to\infty}\int_0^{x_n} \tilde{u}_n(x)dx = C(a_*) - C_0/2, \qquad \lim_{n\to\infty}\int_0^1 \tilde{u}_n(x)dx = C(a_*), \tag{2.22}$$

and

$$v_n(x) \to v_0 - \frac{\tau_*}{d_2} mC(a_*)(1 + \beta^{-1} - x) \tag{2.23}$$

uniformly in $[0,1]$.

Proof. In subcase (a1), we may repeat the arguments used for the case $x_* \in (0,1)$ above to see that all the conclusions there (with x_* replaced by 0) remain valid; the proofs carry over with minor modifications.

Consider now subcase (a2). In this case, we may use interior and boundary L^p estimates and the Sobolev imbedding theorem to conclude that, by passing to a subsequence, $\|\tilde{V}_n - \tilde{V}\|_{C^1([a_n,M])} \to 0$ for all $M > 0$, where $\tilde{V}$ satisfies, instead of (2.3),

$$\begin{cases} -d_1\tilde{V}'' = \dfrac{2d_1\delta - y^2}{4d_1\delta^2}\tilde{V}, \quad 0 < \tilde{V} \le 1 \text{ in } (-a_*, \infty), \\ d_1\tilde{V}'(-a_*) - \dfrac{a_*}{2\delta}\tilde{V}(-a_*) = 0, \quad \tilde{V}(y^*) = 1,\ \tilde{V}'(y^*) = 0. \end{cases} \tag{2.24}$$

Note that as before $\tilde{V}$ is decreasing in $[(2d_1\delta)^{1/2}, \infty)$. This and (2.24) imply that $\tilde{V}$ converges to 0 as $y \to \infty$. Moreover, an elementary consideration shows that

$$|\tilde{V}'(y)|, \tilde{V}(y) \le C_1 e^{-C_2 y}$$

for some C_1, $C_2 > 0$, and all $y > 0$.

We will show that $y^* = 0$ and $\tilde{V}$ is again the unique solution of (2.3) with $y^* = 0$, namely V_0. Since V_0 and $|V_0'|$ are bounded from above by a function of the form $C_1 e^{-C_2|y|}$, we can multiply the first equation in (2.24) by V_0, integrate over $[y^*, \infty)$, and use integration by parts to deduce

$$d_1[\tilde{V}V_0' - \tilde{V}'V_0]\big|_{y^*}^{\infty} = 0.$$

It follows that $V_0'(y^*) = 0$, which implies that $y^* = 0$. Therefore, by the uniqueness of initial value problems of the ordinary differential equations, we deduce $\tilde{V} \equiv V_0$. Let us note that a direct calculation shows

$$d_1 V_0'(y) + \frac{y}{2\delta}V_0(y) = 0 \quad \text{for every } y \in (-\infty, \infty).$$

Therefore (2.24) does not introduce any restriction for a_*.

Since now $\sigma_n^{1/2} x_n \to a_*$, instead of (2.6), we have

$$\lim_{n\to\infty} \int_0^{x_n} \tilde{u}_n(x)dx = C(a_*) - C_0/2, \qquad \lim_{n\to\infty} \int_0^{1} \tilde{u}_n(x)dx = C(a_*), \tag{2.25}$$

where

$$C(a_*) := \int_{-a_*}^{\infty} \exp\left[-\frac{y^2}{4d_1\delta}\right] V_0(y)dy = \int_{-a_*}^{\infty} \exp\left[-\frac{y^2}{2d_1\delta}\right] dy.$$

We proceed as in the case $x_* \in (0,1)$ and have two possibilities for τ_n as before. We show that, in the current case, we still cannot have $\tau_n \to \infty$. Arguing indirectly, we assume that $\tau_n \to \infty$.

Then in the case $a_* > 0$, we have $C(a_*) - C_0/2 > 0$, and hence

$$w_n(x_n) \le w_0 e^{-A\tau_n \int_0^{x_n} \tilde{u}_n(s)ds} \to 0.$$

It follows that

$$\|f_n\|_\infty = f_n(x_n) = f(w_n(x_n)) \to 0$$

and

$$\int_0^1 f_n \tilde{u}_n dx \to 0.$$

If $a_* = 0$, then $C(a_*) - C_0/2 = 0$ and

$$\begin{aligned}
\int_0^1 f_n(x)\tilde{u}_n(x)dx &= \int_{x_n}^1 f(w_n(x))\tilde{u}_n(x)dx + o(1)\\
&\le \int_{x_n}^1 f\big(w_0 e^{-A\tau_n \int_{x_n}^x \tilde{u}_n(s)ds}\big)\tilde{u}_n dx + o(1)\\
&= \int_0^{[\int_{x_n}^1 \tilde{u}_n(s)ds]} f\big(w_0 e^{-A\tau_n y}\big)dy + o(1)\\
&\le \epsilon f(w_0) + \int_\epsilon^{C_0/2} f\big(w_0 e^{-A\tau_n y}\big)dy + o(1)\\
&= \epsilon f(w_0) + o(1) \quad \forall \epsilon \in (0, C_0/2).
\end{aligned}$$

Therefore we always have

$$\int_0^1 f_n \tilde{u}_n dx \to 0 \text{ as } n \to \infty.$$

As before, we may integrate the equation for u_n to obtain

$$\int_0^1 [f_n(x) - m]\tilde{u}_n dx = 0.$$

Letting $n \to \infty$ and using the above estimate, we deduce

$$-mC(a_*) = 0,$$

a contradiction to our assumption that $m > 0$. Therefore we cannot have $\tau_n \to \infty$.

Thus we can only have the case $\tau_n \to \tau_*$. Then much as before we deduce $u_n \to 0$ in $C([\epsilon, 1])$ for all $\epsilon \in (0, 1)$, and

$$\zeta_n \to \zeta := (\eta_*/d_2)(1 + \beta^{-1} - x)$$

in $C([0,1]) \cap C^1([\epsilon, 1])$ for all $\epsilon \in (0,1)$. If $\tau_* = 0$, we can deduce as before that $m = f_0(x_0^*)$, a contradiction to our initial assumption on m. Therefore $\tau_* > 0$.

If $a_* = 0$, we first choose $y_n \in (x_n, 1)$ such that $y_n \to 0$ and $\int_{y_n}^1 \tilde{u}_n(x)dx \to 0$, and then we have

$$\begin{aligned}
\int_0^1 f_n(x)\tilde{u}_n(x)dx &= \int_{x_n}^{y_n} f(w_n(x))\tilde{u}_n(x)dx + o(1)\\
&= \int_{x_n}^{y_n} f\big(w_0 e^{-A_0 x - A\tau_n \int_0^{x_n} \tilde{u}_n(s)ds - A\tau_n \int_{x_n}^x \tilde{u}_n(s)ds}\big)\tilde{u}_n dx + o(1)\\
&= \int_{x_n}^{y_n} f\big(w_0 e^{-A\tau_n \int_{x_n}^x \tilde{u}_n(s)ds}\big)\tilde{u}_n dx + o(1)\\
&= \int_{x_n}^1 f\big(w_0 e^{-A\tau_n \int_{x_n}^x \tilde{u}_n(s)ds}\big)\tilde{u}_n dx + o(1)\\
&= \int_0^{C_0/2} f\big(w_0 e^{-A\tau_* y}\big)dy + o(1).
\end{aligned}$$

If $a_* > 0$, then $x_n > 0$ and $w_n(x_n) = \alpha v_n(x_n)$. From

$$v_n(x_n) \to v_0 - \zeta(0)$$

and

$$w_n(x_n) = w_0 e^{-A_0 x_n - A\tau_n \int_0^{x_n} \tilde{u}_n dx} \to w_0 e^{-A\tau_*[C(a_*) - C_0/2]}$$

we obtain

$$\alpha[v_0 - \zeta(0)] = w_0 e^{-A\tau_*[C(a_*) - C_0/2]}.$$

Moreover, similar to the above,

$$\begin{aligned}\int_{x_n}^1 f_n(x)\tilde{u}_n(x) &= \int_{x_n}^{y_n} f(w_n(x))\tilde{u}_n(x)dx + o(1)\\ &= \int_{x_n}^{y_n} f\big(w_0 e^{-A\tau_n \int_0^{x_n} \tilde{u}_n(s)ds - A\tau_n \int_{x_n}^{x} \tilde{u}_n(s)ds}\big)\tilde{u}_n dx + o(1)\\ &= \int_0^{C_0/2} f\big(w_0 e^{-A\tau_*[C(a_*) - C_0/2] - A\tau_* y}\big)dy + o(1),\end{aligned}$$

and

$$\begin{aligned}\int_0^{x_n} f_n(x)\tilde{u}_n(x)dx &= \int_0^{x_n} f(\alpha v_n(x))\tilde{u}_n(x)dx\\ &= f\big(\alpha[v_0 - \zeta(0)]\big)[C(a_*) - C_0/2] + o(1)\\ &= [C(a_*) - C_0/2] f\big(w_0 e^{-A\tau_*[C(a_*) - C_0/2]}\big) + o(1).\end{aligned}$$

Therefore we always have

$$\int_0^1 f_n \tilde{u}_n dx \to \int_0^{C(a_*)} f\big(w_0 e^{-A\tau_* \max\{[C(a_*) - C_0/2], y\}}\big)dy. \tag{2.26}$$

We may now use

$$\int_0^1 [f_n(x) - m]\tilde{u}_n dx = 0$$

to obtain

$$mC(a_*) = \int_0^{C(a_*)} f\big(w_0 e^{-A\tau_* \max\{C(a_*) - C_0/2, y\}}\big)dy.$$

Therefore

$$m = \int_0^1 f\big(w_0 e^{-A\tau_* \max\{C(a_*) - C_0/2, C(a_*)y\}}\big)dy,$$

and (2.19) is proved.

We thus obtain

$$\eta_* = \tau_* \lim_{n\to\infty} \int_0^1 f_n \tilde{u}_n dx = \tau_* m C(a_*).$$

Therefore,

$$v_n(x) \to v_0 - \zeta = v_0 - \frac{\tau_*}{d_2} mC(a_*)(1+\beta^{-1}-x)$$

uniformly in $[0,1]$; that is, (2.23) holds.

Let us note that (2.22) was already proved in (2.25). So it remains to prove (2.20) and (2.21). If $a_* > 0$, then $x_n > 0$, and we necessarily have $\alpha v_n(x_n) = w_n(x_n)$. Recall that

$$w_n(x_n) \to w_0 e^{-A\tau_*[C(a_*)-C_0/2]}, \qquad v_n(x_n) \to v_0 - \zeta(0).$$

Hence

$$\alpha\Big(v_0 - \frac{\tau_*}{d_2} mC(a_*)(1+\beta^{-1})\Big) = w_0 e^{-A\tau_*[C(a_*)-C_0/2]}.$$

If $a_* = 0$, then $x_n = 0$ is possible, and so we have $\alpha v_n(x_n) \ge w_n(x_n)$ in general, and instead of the above identity we should have

$$\alpha\left(v_0 - \frac{\tau_*}{d_2} m\left(\frac{C_0}{2}\right)(1+\beta^{-1})\right) \ge w_0.$$

Thus (2.20) and (2.21) are established. The proof is now complete. □

Finally we consider the case $x_* = 1$. By passing to a subsequence, we have two subcases:

$$\text{(b1) } b_n := \sigma_n^{1/2}(1-x_n) \to \infty, \qquad \text{(b2) } b_n \to b_* \in [0,\infty).$$

LEMMA 2.5. *In subcase* (b1)*, all of the conclusions in Lemmas* 2.2 *and* 2.3 *hold. In subcase* (b2)*, $\{\tau_n\}$ has a subsequence, still denoted by itself, such that $\tau_n \to \tau_* > 0$. Moreover, τ_* and b_* must satisfy*

$$m = \int_0^1 f\big(w_0 e^{-A_0 - A\tau_* \max\{C_0/2, \tilde{C}(b_*)y\}}\big)dy \tag{2.27}$$

and

$$\alpha\Big(v_0 - \frac{\tau_*}{d_2\beta}\tilde{C}(b_*)\Big) = w_0 e^{-A_0 - A\tau_* C_0/2} \quad \text{if } b_* > 0, \tag{2.28}$$

$$\alpha\left(v_0 - \frac{\tau_*}{d_2\beta}\left(\frac{C_0}{2}\right)\right) \le w_0 e^{-A_0 - A\tau_* C_0/2} \quad \text{if } b_* = 0, \tag{2.29}$$

where

$$\tilde{C}(b_*) := \int_{-\infty}^{b_*} \exp\Big[-\frac{y^2}{2d_1\delta}\Big]dy = C(-b_*).$$

Furthermore, by possibly passing to a further subsequence, $u_n \to 0$ in $C([0,1-\epsilon])$ for every $\epsilon \in (0,1)$,

$$\lim_{n\to\infty}\int_{x_n}^1 \tilde{u}_n(x)dx = \tilde{C}(b_*) - C_0/2, \qquad \lim_{n\to\infty}\int_0^1 \tilde{u}_n(x)dx = \tilde{C}(b_*), \tag{2.30}$$

$$v_n(x) \to v_0 - \zeta = v_0 - \frac{\tau_*}{d_2\beta}\tilde{C}(b_*) \tag{2.31}$$

uniformly in $[0,1]$.

Proof. In subcase (b1), we may repeat the arguments used in Lemmas 2.2 and 2.3 for the case $x_* \in (0,1)$ to see that all the conclusions there (with x_* replaced by 1) remain valid; the proofs need only minor modifications.

We now consider subcase (b2). Then instead of (2.3) we have

$$\begin{cases} -d_1\tilde{V}'' = \dfrac{2d_1\delta - y^2}{4d_1\delta}\tilde{V}, \quad 0 < \tilde{V} \le 1 \text{ in } (-\infty, b_*), \\ \tilde{V}'(b_*) + \dfrac{b_*}{2\delta}\tilde{V}(b_*) = 0, \quad \tilde{V}(y^*) = 1,\ \tilde{V}'(y^*) = 0. \end{cases} \tag{2.32}$$

Note that as before $\tilde{V}$ is increasing in $(-\infty, -(2d_1\delta)^{1/2}]$. This and (2.32) imply that $\tilde{V}$ converges to 0 as $y \to -\infty$. Moreover, an elementary consideration shows that

$$|\tilde{V}'(y)|, \tilde{V}(y) \le C_1 e^{-C_2|y|}$$

for some C_1, $C_2 > 0$, and all $y < 0$.

As in the case for (2.24), we can similarly show that $y^* = 0$ and $\tilde{V} \equiv V_0$, the unique solution of (2.3) with $y^* = 0$. Moreover, (2.32) introduces no restriction for b_*.

Since $\sigma_n^{1/2}(1 - x_n) \to b_*$, instead of (2.6), we have

$$\lim_{n\to\infty} \int_{x_n}^1 \tilde{u}_n(x)dx = \tilde{C}(b_*) - C_0/2, \qquad \lim_{n\to\infty} \int_0^1 \tilde{u}_n(x)dx = \tilde{C}(b_*),$$

where

$$\tilde{C}(b_*) := \int_{-\infty}^{b_*} \exp\left[-\frac{y^2}{4d_1\delta}\right] V_0(y)dy = C(-b_*).$$

This establishes (2.30).

We proceed as in the case $x_* \in (0,1)$ and have two possibilities for τ_n as before. We show that in the current case, we still cannot have $\tau_n \to \infty$. Arguing indirectly, we assume that $\tau_n \to \infty$.

Since $\int_0^{x_n} \tilde{u}_n dx \to C_0/2$, we have

$$w_n(x_n) \le w_0 e^{-A\tau_n \int_0^{x_n} \tilde{u}_n(s)ds} \to 0.$$

It follows that

$$\|f_n\|_\infty = f_n(x_n) \le f(w_n(x_n)) \to 0,$$

and

$$\int_0^1 f_n \tilde{u}_n dx \to 0.$$

As before, we may integrate the equation for u_n to obtain

$$\int_0^1 [f_n(x) - m]\tilde{u}_n dx = 0.$$

Letting $n \to \infty$ and using the above estimate, we deduce

$$-m\tilde{C}(b_*) = 0,$$

a contradiction to our assumption that $m > 0$. Therefore we cannot have $\tau_n \to \infty$.

Thus we can have only the case $\tau_n \to \tau_*$. Then much as before we deduce $u_n \to 0$ in $C([0, 1-\epsilon])$ for each $\epsilon \in (0,1)$ and $\zeta_n \to \zeta$ in $C([0,1]) \cap C^1([0,1-\epsilon])$, for all $\epsilon \in (0,1)$, with ζ satisfying

$$\zeta'' = 0 \text{ in } [0,1), \qquad \zeta' = 0 \text{ in } [0,1).$$

Hence ζ is a constant. To determine its value, we use

$$-d_2\zeta_n'(1) = \int_0^1 \tau_n f_n \tilde{u}_n dx \to \tau_* \tilde{C}(b_*)$$

and

$$\zeta_n'(1) + \beta\zeta_n(1) = 0$$

to deduce

$$-\frac{\tau_*}{d_2}\tilde{C}(b_*) + \beta\zeta = 0,$$

and hence

$$\zeta = \frac{\tau_*}{d_2\beta}\tilde{C}(b_*). \tag{2.33}$$

If $\tau_* = 0$, then $\zeta \equiv 0$, and hence $v_n \to v_0$ uniformly in $[0,1]$ and

$$w_n(x) = w_0 e^{-A_0 x - A\tau_n \int_0^x \tilde{u}_n dx} \to w_0 e^{-A_0 x}$$

uniformly in $[0,1]$. Then we can deduce as before that $m = f_0(x_0^*)$, a contradiction to our initial assumption on m. Therefore $\tau_* > 0$.

We have

$$\begin{aligned}\int_0^{x_n} f_n(x)\tilde{u}_n(x)dx &= \int_0^{x_n} f(\alpha v_n(x))\tilde{u}_n(x)dx \\ &= (C_0/2) f\big(\alpha(v_0 - \zeta)\big) + o(1).\end{aligned}$$

If $b_* = 0$, then

$$\int_{x_n}^1 f_n(x)\tilde{u}_n(x)dx = o(1).$$

If $b_* > 0$, then $x_n > 0$ and $w_n(x_n) = \alpha v_n(x_n)$. From

$$v_n(x_n) \to v_0 - \zeta = v_0 - \frac{\tau_*}{d_2\beta}\tilde{C}(b_*)$$

and

$$w_n(x_n) = w_0 e^{-A_0 x_n - A\tau_n \int_0^{x_n} \tilde{u}_n dx} \to w_0 e^{-A_0 - A\tau_* C_0/2},$$

we obtain

$$\alpha\Big(v_0 - \frac{\tau_*}{d_2\beta}\tilde{C}(b_*)\Big) = w_0 e^{-A_0 - A\tau_* C_0/2}. \tag{2.34}$$

Moreover,

$$\begin{aligned}\int_{x_n}^1 f_n(x)\tilde{u}_n(x)dx &= \int_{x_n}^1 f(w_n(x))\tilde{u}_n(x)dx\\ &= \int_{x_n}^1 f\big(w_0 e^{-A_0 x - A\tau_n\int_0^{x_n}\tilde{u}_n(s)ds - A\tau_n\int_{x_n}^x \tilde{u}_n(s)ds}\big)\tilde{u}_n dx\\ &= \int_0^{\tilde{C}(b_*)-C_0/2} f\big(w_0 e^{-A_0 - A\tau_* C_0/2 - A\tau_* y}\big)dy + o(1).\end{aligned}$$

Therefore, whether $b_* = 0$ or $b_* > 0$, we always have

$$\int_0^1 f_n(x)\tilde{u}_n(x)dx \to \int_0^{\tilde{C}(b_*)} f\big(w_0 e^{-A_0 - A\tau_* \max\{C_0/2, y\}}\big)dy. \tag{2.35}$$

We may now use

$$\int_0^1 [f_n(x) - m]\tilde{u}_n dx = 0$$

to obtain

$$m\tilde{C}(b_*) = \int_0^{\tilde{C}(b_*)} f\big(w_0 e^{-A_0 - A\tau_* \max\{C_0/2, y\}}\big)dy,$$

which gives (2.27).

Note that if $b_* = 0$, then $x_n = 1$ is possible, and we have only $w_n(x_n) \geq \alpha v(x_n)$, so instead of (2.27), we should have

$$\alpha\Big(v_0 - \frac{\tau_*}{d_2\beta}\tilde{C}(b_*)\Big) \leq w_0 e^{-A_0 - A\tau_* C_0/2}.$$

Thus we have established (2.28) and (2.29). Clearly (2.31) follows from (2.33) and the fact that $v_n \to v_0 - \zeta$ uniformly in $[0,1]$. The proof is complete. □

3. Limiting profile of the positive solutions. We are now ready to state and prove our main results. We will show that the limiting equations obtained in the previous section uniquely determine x_* and τ_*, and the value of v_0 determines which set of limiting equations should be used for calculating x_* and τ_*. In this way, the asymptotic behavior of the positive solutions is completely determined.

Let us recall that m is fixed such that

$$0 < m < f(\min\{\alpha v_0, w_0\}), \tag{3.1}$$

and $\sigma_n \to \infty$ is a sequence of positive numbers. Therefore by Theorems 1.1 and 1.2, problem (1.1) with $\sigma = \sigma_n$ has a positive solution (u_n, v_n) for all large n. Recall that $C_0 > 0$ is given in (2.6), which is completely determined by δ and d_1. Due to (3.1) there exists a unique $\tau_0^* > 0$ such that

$$m = \int_0^1 f\big(w_0 e^{-A\tau_0^* \max\{C_0/2, C_0 y\}}\big)dy. \tag{3.2}$$

Let us then define

$$v^* = v^*(m) := \frac{w_0}{\alpha}e^{-A\tau_0^* C_0/2} + \frac{\tau_0^*}{d_2}mC_0(1+\beta^{-1}). \tag{3.3}$$

Let $\underline{v}(m) > 0$ be uniquely determined by

$$m = f(\alpha \underline{v}(m)).$$

By (3.1), we always have $v_0 > \underline{v}(m)$.

When $m < f(w_0 e^{-A_0})$, we can find a unique $\tau_1^* > 0$ such that

$$m = \int_0^1 f\big(w_0 e^{-A_0 - A\tau_1^* \max\{C_0/2, C_0 y\}}\big) dy. \tag{3.4}$$

We now define

$$v_* = v_*(m) := \begin{cases} \dfrac{w_0}{\alpha} e^{-A_0 - A\tau_1^* C_0/2} + \dfrac{\tau_1^*}{d_2} m C_0 \beta^{-1} & \text{if } m < f(w_0 e^{-A_0}), \\ \underline{v}(m) & \text{if } f(w_0 e^{-A_0}) \le m < f(w_0). \end{cases} \tag{3.5}$$

It is easily seen that $v_*(m)$ is continuous in m.

As we will see below, to completely determine the asymptotic profile of (u_n, v_n), it is necessary to distinguish the cases $v_0 \in [v_*(m), v^*(m)]$, $v_0 > v^*(m)$, and $v_0 < v_*(m)$.

THEOREM 3.1. *Suppose that* $v_0 > \underline{v}(m)$ *and*

$$v_*(m) \le v_0 \le v^*(m). \tag{3.6}$$

Then the system (2.8) *and* (2.9), *namely,*

$$\begin{cases} w_0 e^{-A_0 x_* - A\tau_*(C_0/2)} = \alpha \left[v_0 - \dfrac{\tau_*}{d_2} m C_0 (1 + \beta^{-1} - x_*) \right], \\ m = \displaystyle\int_0^1 f\big(w_0 e^{-A_0 x_* - A\tau_* \max\{C_0/2, C_0 y\}}\big) dy, \end{cases}$$

has a unique solution pair (x_*, τ_*) *satisfying* $x_* \in [0,1]$ *and* $\tau_* > 0$. *Moreover,*

$$u_n \to 0 \text{ in } C([0,1] \setminus [x_* - \epsilon, x_* + \epsilon]) \quad \forall\, \epsilon > 0, \qquad \int_0^1 u_n dx \to \tau_* C_0,$$

$$v_n(x) \to v_0 - \frac{\tau_*}{d_2} m C_0 (1 + \beta^{-1} - \max\{x, x_*\}) \quad \text{uniformly in } [0,1].$$

Furthermore, $x_* = 0$ *if* $v_0 = v^*(m)$, $x_* \in (0,1)$ *if* $v_*(m) < v_0 < v^*(m)$, *and* $x_* = 1$ *if* $v_0 = v_*(m)$.

Proof. Using the notation of the previous section, by passing to a subsequence, $x_n \to x_* \in [0,1]$. By possibly passing to a further subsequence, the behavior of (u_n, v_n) as $n \to \infty$ is then determined by Lemmas 2.2, 2.3 (if $x_* \in (0,1)$), Lemma 2.4 (if $x_* = 0$ and subcases (a1) and (a2) occur), and Lemma 2.5 (if $x_* = 1$ and subcases (b1) and (b2) happen).

If we can show that x_* and τ_* are uniquely determined by the value of v_0, then the corresponding results in the previous section would hold not only for a subsequence, but for the entire original sequence, and hence the behavior of (u_n, v_n) as $n \to \infty$ would be completely determined.

The rather long proof below is broken into several steps.

Step 1. Subcases (a2) and (b2) do not happen

First we observe that subcase (a2) does not happen. Indeed, if this case occurs, then since $C(a_*) < C_0/2$, we see (as explained below) from a careful comparison of (2.19) and (3.2) that

$$\tau_* > \tau_0^*, \quad \tau_* C(a_*) < \tau_0^* C_0/2, \quad \tau_*[C_0/2 + C(a_*)] > \tau_0^* C_0.$$

In the comparison, we can deduce these inequalities one at a time, in the above order, and the previous inequalities are used for obtaining the next inequality. For example, to deduce $\tau_* C(a_*) < \tau_0^* C_0/2$ from $\tau_* > \tau_0^*$, we observe that $\tau_* C(a_*) \geq \tau_0^* C_0/2$ and $\tau_* > \tau_0^*$ would imply

$$\begin{aligned}\tau_* \max\{C(a_*), [C_0/2 + C(a_*)]y\} &\geq \max\{\tau_0^* C_0/2, [\tau_* C_0/2 + \tau_0^* C_0/2]y\} \\ &\geq \tau_0^* \max\{C_0/2, C_0 y\}\end{aligned}$$

with strict inequality holding in the last step for $y \in [1/2, 1]$, which is impossible when one compares (2.19) with (3.2).

It then follows from (2.20) and (2.21) that $v_0 > v^*(m)$, contradicting (3.6).

Similarly, if subcase (b2) happens, then from (2.27) we deduce

$$\tau_* > \tau_1^* \quad \text{and} \quad \tau_*[C_0/2 + \tilde{C}(b_*)] < \tau_1^* C_0,$$

which imply, by (2.28) and (2.29), that $v_0 < v_*(m)$, again contradicting (3.6). Therefore subcase (b2) cannot happen.

Thus, by our discussion in the previous section, we have the cases where (2.8) and (2.9) hold. To show that (2.8) and (2.9) have a unique solution (x_*, τ_*) satisfying $x_* \in [0, 1]$ and $\tau_* > 0$, we establish a procedure to uniquely find x_* and τ_*. In the discussion below, we will treat $v_0 > 0$ as a varying parameter.

Step 2. A procedure to solve (2.8) and (2.9).

It is useful to use the new variable

$$\lambda = A_0 x_* + A\tau_* C_0/2.$$

Then

$$x_* = (\lambda - A\tau_* C_0/2)/A_0,$$

and (2.8) can be rewritten as

$$\frac{w_0}{\alpha} e^{-\lambda} = v_0 - \frac{\tau_*}{d_2} m C_0 \left(1 + \beta^{-1} - \frac{\lambda - A\tau_* C_0/2}{A_0}\right)$$

or

$$\frac{mC_0}{d_2 A_0} \tau_* \big[(1 + \beta^{-1})A_0 - \lambda + A(C_0/2)\tau_*\big] = v_0 - \frac{w_0}{\alpha} e^{-\lambda}.$$

We now consider the quadratic equation of τ:

$$\frac{mC_0}{d_2 A_0} \tau \big[(1 + \beta^{-1})A_0 - \lambda + A(C_0/2)\tau\big] = v_0 - \frac{w_0}{\alpha} e^{-\lambda}. \tag{3.7}$$

For each $v_0 > 0$, let $\lambda_0(v_0)$ denote the minimal nonnegative λ such that $v_0 - \frac{w_0}{\alpha} e^{-\lambda} \geq 0$. Clearly

$$\lambda_0(v_0) = 0 \text{ if } v_0 \geq w_0/\alpha, \ \lambda_0(v_0) \text{ is decreasing in } (0, w_0/\alpha], \ \lim_{v_0 \to 0} \lambda_0(v_0) = \infty. \tag{3.8}$$

For each $v_0 > 0$ and $\lambda \geq \lambda_0(v_0)$, the quadratic equation (3.7) has a maximal zero, which we denote by $\tau(\lambda, v_0)$. It is easily seen that $\tau(\lambda, v_0) \geq 0$ and

$$\text{when } v_0 \leq w_0/\alpha,\ \tau(\lambda_0(v_0), v_0) = \max\left\{0, \frac{\lambda_0(v_0) - A_0(1+\beta^{-1})}{AC_0/2}\right\}, \tag{3.9}$$

$$\tau(\lambda, v_0) \text{ is increasing in } \lambda \text{ and in } v_0, \quad \lim_{v_0\to\infty} \tau(\lambda, v_0) = \infty \text{ for fixed } \lambda \geq 0. \tag{3.10}$$

Since $\lambda_0(w_0/\alpha) = 0$, by (3.9), $\tau(\lambda_0(w_0/\alpha), w_0/\alpha) = 0$. Let us consider the continuous function

$$M(v_0) = \int_0^1 f\big(w_0 e^{-\lambda_0(v_0) - A\tau(\lambda_0(v_0), v_0)\max\{0, C_0 y - C_0/2\}}\big)dy.$$

The above observation shows that $M(w_0/\alpha) = f(w_0) > m$. By (3.8), we have $M(v_0) \to 0$ as $v_0 \to 0$. By (3.10), we deduce $M(v_0) \to 0$ as $v_0 \to \infty$. Hence from the continuity of $M(v_0)$ we can find v_{min} and v_{max} such that

$$0 < v_{min} < w_0/\alpha < v_{max} < \infty,$$

$$M(v_0) > m \quad \forall v_0 \in (v_{\min}, v_{max}), \qquad M(v_{min}) = M(v_{max}) = m.$$

Now for each $v_0 \in (v_{min}, v_{max})$,

$$m < \int_0^1 f\big(w_0 e^{-\lambda_0(v_0) - A\tau(\lambda_0(v_0), v_0)\max\{0, C_0 y - C_0/2\}}\big)dy.$$

This and the monotonicity of $\tau(\lambda, v_0)$ in λ imply that for such v_0 we can find a unique $\lambda_* = \lambda_*(v_0) > \lambda_0(v_0)$ such that

$$m = \int_0^1 f\big(w_0 e^{-\lambda_* - A\tau(\lambda_*, v_0)\max\{0, C_0 y - C_0/2\}}\big)dy.$$

Clearly $v_0 \to \lambda_*(v_0)$ is continuous and

$$\lambda_*(v_{min} + 0) = \lambda_0(v_{min}), \qquad \lambda_*(v_{max} - 0) = \lambda_0(v_{max}).$$

So we may define

$$\lambda_*(v_{min}) = \lambda_0(v_{min}), \qquad \lambda_*(v_{max}) = \lambda_0(v_{max}).$$

We claim that the function $T(v_0) := \tau(\lambda_*(v_0), v_0)$ is increasing in $[v_{min}, v_{max}]$. Otherwise, we can find $v_{min} \leq s_1 < s_2 \leq v_{max}$ such that $T(s_1) \geq T(s_2)$. Since

$$\int_0^1 f\big(w_0 e^{-\lambda_*(s_1) - AT(s_1)\max\{0, C_0 y - C_0/2\}}\big) = \int_0^1 f\big(w_0 e^{-\lambda_*(s_2) - AT(s_2)\max\{0, C_0 y - C_0/2\}}\big),$$

$T(s_1) \geq T(s_2)$ implies that $\lambda_*(s_1) \leq \lambda_*(s_2)$, which implies, by the monotonicity of $\tau(\lambda, v_0)$,

$$T(s_1) = \tau(\lambda_*(s_1), s_1) < \tau(\lambda_*(s_2), s_2) = T(s_2).$$

This contradiction proves the claimed monotonicity of $T(v_0)$.

We show next that $T(v_{max}) > \tau_0^*$. Since $v_{max} > w_0/\alpha$, we have $\lambda_0(v_{max}) = 0$ and hence

$$m = M(v_{max}) = \int_0^1 f\big(w_0 e^{-A\tau(0,v_{max})\max\{0,C_0y-C_0/2\}}\big)dy.$$

By (3.2),

$$m = \int_0^1 f\big(w_0 e^{-A\tau_0^* C_0/2 - A\tau_0^*\max\{0,C_0y-C_0/2\}}\big)dy.$$

Comparing the above two expressions, we obtain $\tau(0, v_{max}) > \tau_0^*$. Hence

$$T(v_{max}) = \tau(\lambda_*(v_{max}), v_{max}) = \tau(\lambda_0(v_{max}), v_{max}) = \tau(0, v_{max}) > \tau_0^*,$$

as we wanted.

We now consider $T(v_{min})$. We have two different cases: $m < f(w_0e^{-A_0})$ and $m \geq f(w_0e^{-A_0})$. First consider the case $m < f(w_0e^{-A_0})$. We show that $T(v_{min}) < \tau_1^*$ in this case. Since $\lambda_*(v_{min}) = \lambda_0(v_{min})$ we have

$$T(v_{min}) = \tau(\lambda_0(v_{min}), v_{min}).$$

Hence, by (3.9),

$$T(v_{min}) = \max\left\{0, \frac{\lambda_0(v_{min}) - A_0(1+\beta^{-1})}{AC_0/2}\right\}.$$

If $\frac{\lambda_0(v_{min})-A_0(1+\beta^{-1})}{AC_0/2} \leq 0$, then $T(v_{min}) = 0 < \tau_1^*$. If $\frac{\lambda_0(v_{min})-A_0(1+\beta^{-1})}{AC_0/2} > 0$, then

$$T(v_{min}) = \frac{\lambda_0(v_{min}) - A_0(1+\beta^{-1})}{AC_0/2},$$

and hence

$$\begin{aligned} m &= \int_0^1 f\big(w_0 e^{-\lambda_0(v_{min})-AT(v_{min})\max\{0,C_0y-C_0/2\}}\big)dy \\ &= \int_0^1 f\big(w_0 e^{-A_0(1+\beta^{-1})-AT(v_{min})C_0/2-AT(v_{min})\max\{0,C_0y-C_0/2\}}\big)dy \\ &= \int_0^1 f\big(w_0 e^{-A_0(1+\beta^{-1})-AT(v_{min})\max\{C_0/2,C_0y\}}\big)dy. \end{aligned}$$

Comparing this with (3.4), we find that $T(v_{min}) < \tau_1^*$.

With the above properties of $T(v_0)$, we can uniquely determine v_* and v^* with $v_{min} < v_* < v^* < v_{max}$ such that

$$T(v^*) = \tau_0^*, \qquad T(v_*) = \tau_1^*.$$

We claim that $v^* = v^*(m)$ and $v_* = v_*(m)$. Indeed, from

$$m = \int_0^1 f\big(w_0 e^{-\lambda_*(v^*)-AT(v^*)\max\{0,C_0y-C_0/2\}}\big)dy$$

and $T(v^*) = \tau_0^*$, we easily see by comparing with (3.2) that $\lambda_*(v^*) = \tau_0^* AC_0/2$. Hence

$$\tau_0^* = T(v^*) = \tau(\lambda_*(v^*), v^*) = \tau(\tau_0^* AC_0/2, v^*).$$

By the definition of $\tau(\lambda, v_0)$, the above identity means that $\tau = \tau_0^*$ solves (3.7) with $\lambda = \tau_0^* AC_0/2$ and $v_0 = v^*$. Therefore we may compare with (3.3) to deduce $v^* = v^*(m)$. Similarly, we can show that $v_* = v_*(m)$.

Since T is monotone, for each $v_0 \in [v_*(m), v^*(m)]$, $T(v_0) \in [\tau_1^*, \tau_0^*]$. Hence we can compare (3.2) and (3.4) with

$$m = \int_0^1 f\big(w_0 e^{-\lambda_*(v_0) - AT(v_0)\max\{0, C_0 y - C_0/2\}}\big) dy$$

to find that, for such v_0, we necessarily have

$$AT(v_0)C_0/2 \le \lambda_*(v_0) \le A_0 + AT(v_0)C_0/2;$$

otherwise we would arrive at contradictions to $T(v_0) \in [\tau_1^*, \tau_0^*]$. This implies that there exists a unique $x_* \in [0, 1]$ such that

$$\lambda_*(v_0) = A_0 x_* + AT(v_0)C_0/2.$$

Let $\tau_* = T(v_0)$; we find that (x_*, τ_*) solves (2.8) and (2.9).

We next consider the case $m \ge f(w_0 e^{-A_0})$. In this case, $v_*(m) = \underline{v}(m)$; moreover, we show that

$$T(v_{min}) = 0, \quad v_{min} = \underline{v}(m).$$

Indeed, from

$$T(v_{min}) = \tau(\lambda_*(v_{min}), v_{min}) = \tau(\lambda_0(v_{min}), v_{min}),$$

we obtain

$$\begin{aligned} m &= \int_0^1 f\big(w_0 e^{-\lambda_0(v_{min}) - A\tau(\lambda_0(v_{min}), v_{min})\max\{0, C_0 y - C_0/2\}}\big) dy \\ &\le f(w_0 e^{-\lambda_0(v_{min})}). \end{aligned}$$

It follows that $\lambda_0(v_{min}) \le A_0 < A_0(1+\beta^{-1})$. By (3.9), we deduce $\tau(\lambda_0(v_{min}), v_{min}) = 0$, that is, $T(v_{min}) = 0$. This gives

$$m = \int_0^1 f(w_0 e^{-\lambda_0(v_{min})}) dy = f(w_0 e^{\lambda_0(v_{min})}).$$

Hence

$$\alpha \underline{v}(m) = w_0 e^{-\lambda_0(v_{min})}.$$

On the other hand, since $v_{min} < w_0/\alpha$, by the definition of the function λ_0,

$$v_{min} - \frac{w_0}{\alpha} e^{-\lambda_0(v_{min})} = 0.$$

Therefore we have $v_{min} = \underline{v}(m)$.

We can now conclude that there exists a unique $v^* \in (v_{min}, v_{max})$ such that $T(v^*) = \tau_0^*$. We may then prove $v^* = v^*(m)$ as before. Since T is monotone, for each $v_0 \in (v_*(m), v^*(m)] = (\underline{v}(m), v^*(m)]$, $T(v_0) \in (0, \tau_0^*]$. Hence we can compare (3.2) and $m \geq f(w_0 e^{-A_0})$ with (3.1) to deduce

$$AT(v_0)C_0/2 \leq \lambda_*(v_0) < A_0 + AT(v_0)C_0/2,$$

and there exists a unique $x_* \in [0, 1)$ such that

$$\lambda_*(v_0) = A_0 x_* + AT(v_0)C_0/2.$$

Let $\tau_* = T(v_0)$; we find that (x_*, τ_*) solves (2.8) and (2.9).

The above discussion shows that when (3.6) holds, (2.8) and (2.9) have at least one solution (x_*, τ_*) satisfying $x_* \in [0, 1]$ and $\tau_* > 0$, and such a solution can be found by following the above procedure.

Step 3. Uniqueness of (x_*, τ_*) and completion of the proof.

We next show that when (3.6) holds, (2.8) and (2.9) have a unique solution (x_*, τ_*) satisfying $x_* \in [0, 1]$ and $\tau_* > 0$. So let (x_*, τ_*) be an arbitrary solution of (2.8) and (2.9) with $v_0 \in [v_*(m), v^*(m)] \cap (\underline{v}(m), v^*(m)]$ and $x_* \in [0, 1]$, $\tau_* > 0$. Then τ_* must be the maximal zero of (3.7) with $\lambda = A_0 x_* + A\tau_* C_0/2 > 0$; this is the case because $v_0 - \frac{w_0}{\alpha} e^{-\lambda} > 0$, and thus the two zeros of (3.7) are of opposite sign. Therefore, using our earlier notation,

$$\tau_* = \tau(\lambda, v_0), \quad \lambda > \lambda_0(v_0).$$

Then (2.9) yields

$$\begin{aligned} m &= \int_0^1 f(w_0 e^{-A_0 x_* - A\tau_* \max\{C_0/2, C_0 y\}}) dy \\ &= \int_0^1 f(w_0 e^{-\lambda - A\tau(\lambda, v_0) \max\{0, C_0 y - C_0/2\}}) dy. \end{aligned}$$

Since $v_0 \in [v_*(m), v^*(m)] \cap (\underline{v}(m), v^*(m)] \subset (v_{min}, v_{max})$, in view of the above identity, our definition of $\lambda_*(v_0)$ implies that $\lambda = \lambda_*(v_0)$ and hence $\tau(\lambda, v_0) = T(v_0)$; that is, $\tau_* = \tau(\lambda, v_0) = T(v_0)$. This implies that the solution pair (x_*, τ_*) is the same as the one obtained through our procedure introduced above for solving (2.8) and (2.9). Hence there is a unique solution.

With τ_* and x_* uniquely determined now, it is easily seen that our conclusions for u_n and v_n follow from Lemmas 2.2, 2.3, 2.4, and 2.5.

Moreover, from the above procedure for finding (x_*, τ_*), we easily see that $x_* = 0$ if $v_0 = v^*(m)$, $x_* \in (0, 1)$ if $v_*(m) < v_0 < v^*(m)$, and $x_* = 1$ if $v_0 = v_*(m)$.

The proof of the theorem is now complete. □

Next we consider the case that $v_0 > v^*(m)$. Let $0 < \lambda_0 < \lambda^0$ be uniquely determined by

$$m = f(w_0 e^{-A\lambda_0}) = \int_0^1 f\big(w_0 e^{-A\lambda^0 y}\big) dy. \tag{3.11}$$

For each $\lambda \in [0, \lambda_0]$, we can find a unique $\Gamma = \Gamma(\lambda)$ such that

$$m = \int_0^1 f\big(w_0 e^{-A \max\{\lambda, \Gamma y\}}\big) dy. \tag{3.12}$$

Moreover, it is easily seen that $\lambda \mapsto \Gamma(\lambda)$ is a continuous decreasing function with

$$\Gamma(\lambda_0) = \lambda_0, \qquad \Gamma(0) = \lambda^0.$$

Therefore we can find a unique $\lambda_*^0 \in (0, \lambda_0)$ such that

$$\Gamma(\lambda_*^0) = 2\lambda_*^0.$$

Comparing with (3.2), we find that actually

$$\lambda_*^0 = \tau_0^* C_0/2. \tag{3.13}$$

We define

$$\Lambda(\lambda) := \frac{w_0}{\alpha} e^{-A\lambda} + \frac{\Gamma(\lambda)}{d_2} m(1+\beta^{-1}).$$

Clearly $\Lambda(\lambda)$ is a decreasing function on $[0, \lambda_0]$ with

$$\Lambda(0) = \frac{w_0}{\alpha} + \frac{\lambda^0}{d_2} m(1+\beta^{-1}), \qquad \Lambda(\lambda_*^0) = \frac{w_0}{\alpha} e^{-A\lambda_*^0} + \frac{2\lambda_*^0}{d_2} m(1+\beta^{-1}).$$

Due to (3.13), we find that

$$\Lambda(\lambda_*^0) = v^*(m).$$

THEOREM 3.2. *Suppose that*

$$v_0 > v^*(m) = \Lambda(\lambda_*^0). \tag{3.14}$$

If $v_0 < \Lambda(0)$ *and* $\lambda^* \in (0, \lambda_*^0)$ *is uniquely determined by* $v_0 = \Lambda(\lambda^*)$*, then*

$$u_n \to 0 \text{ in } C([\epsilon, 1]) \quad \forall \epsilon \in (0,1), \qquad \int_0^1 u_n dx \to \Gamma(\lambda^*),$$

$$v_n(x) \to v_0 - \frac{\Gamma(\lambda^*)}{d_2} m(1+\beta^{-1}-x) \text{ uniformly in } [0,1].$$

If $v_0 \geq \Lambda(0)$*, then the above conclusions hold with* $\lambda^* = 0$.

Proof. We first show that case (a2) happens. Let us start by observing that the cases leading to (2.8) and (2.9) (namely, cases (i), (ii)(a1), and (iii)(b1)) cannot happen. Indeed, in these cases, (x_*, τ_*) solves (2.8) and (2.9) with $x_* \in [0,1]$ and $\tau_* > 0$. As in Step 3 of the proof of Theorem 3.1, denoting $\lambda = A_0 x_* + A\tau_* C_0/2$, we must have $\tau_* = \tau(\lambda, v_0)$ and $\lambda > \lambda_0(v_0)$. Then (2.9) gives

$$m = \int_0^1 f(w_0 e^{-\lambda - A\tau(\lambda, v_0)\max\{0, C_0 y - C_0/2\}}) dy.$$

Since $v_0 > v^*(m)$, we have either

$$v_0 > v_{max} \quad \text{or} \quad v_0 \in (v^*(m), v_{max}].$$

If $v_0 \in (v^*(m), v_{max}] \subset (v_{min}, v_{max})$, then the above identity implies that $\lambda = \lambda_*(v_0)$ and hence $\tau(\lambda, v_0) = T(v_0)$. From $v_0 > v^*(m)$ we now deduce $\tau_* = T(v_0) > \tau_0^*$, and hence we can compare (2.9) with (3.2) to deduce $x_* < 0$, a contradiction.

If $v_0 > v_{max}$, then by the monotonicity of $\tau(\cdot,\cdot)$, we deduce

$$\tau(\lambda, v_0) > \tau(\lambda, v_{max}) > \tau(0, v_{max}).$$

Therefore, recalling $\lambda_*(v_{max}) = \lambda_0(v_{\max}) = 0$, we obtain

$$\begin{aligned} m &= \int_0^1 f(w_0 e^{-\lambda - A\tau(\lambda,v_0)\max\{0, C_0 y - C_0/2\}})dy \\ &< \int_0^1 f(w_0 e^{-A\tau(0,v_{max})\max\{0, C_0 y - C_0/2\}})dy \\ &= m, \end{aligned}$$

again a contradiction. Therefore none of the cases that lead to (2.8) and (2.9) can happen. This implies that either (a2) or (b2) happens.

Next we show that case (b2) cannot happen. Otherwise, by (2.27) we obtain

$$m < f(w_0 e^{-A_0}).$$

Hence $\tau_1^* > 0$ is defined. Moreover, comparing (2.27) with (3.4), we obtain

$$\tau_* > \tau_1^*, \qquad \tau_* \tilde{C}(b_*) < \tau_1^* C_0,$$

which imply, by (2.28) and (2.29), that $v_0 < v_*(m) < v^*(m)$, contradicting (3.14).

Therefore we necessarily have case (a2). We now introduce the notation

$$\lambda = \tau_*[C(a_*) - C_0/2], \quad \Gamma = \tau_* C(a_*).$$

From (2.19), (2.20), and (2.21) we find that

$$m = \int_0^1 f\big(w_0 e^{-A\max\{\lambda, \Gamma y\}}\big)dy, \tag{3.15}$$

$$v_0 \geq \frac{w_0}{\alpha} e^{-A\lambda} + \frac{\Gamma}{d_2} m(1 + \beta^{-1}), \tag{3.16}$$

with equality holding if $a_* > 0$.

Suppose now that $v_0 \geq \Lambda(0)$. We claim that in this case we have $\lambda = 0$ and hence, by (3.15), $\Gamma = \Gamma(0) = \lambda^0$. Suppose for the sake of contradiction that $\lambda > 0$. From (3.15) and (3.11) we easily see that $\lambda \leq \lambda_0$. Now $C(a_*) - C_0/2 > 0$, and hence $a_* > 0$. Thus equality in (3.16) holds. By (3.15) we deduce $\Gamma = \Gamma(\lambda)$, and hence it follows from (3.16) that $v_0 = \Lambda(\lambda) < \Lambda(0)$, contradicting our assumption on v_0 above. Hence in this case, we have $\lambda = 0$ and thus

$$C(a_*) - C_0/2 = 0, \qquad \tau_* = \Gamma(0)/(C_0/2).$$

Next we suppose that $v^*(m) < v_0 < \Lambda(0)$. From (3.15) we deduce $\Gamma = \Gamma(\lambda)$ for some $\lambda \in [0, \lambda_0]$. We must have $\lambda > 0$ for otherwise, from (3.15) and (3.16), we deduce $\Gamma = \Gamma(0)$ and $v_0 \geq \Lambda(0)$, contradicting our current assumption on v_0. Therefore $\lambda > 0$ and hence $a_* > 0$, implying that equality in (3.16) holds. Recalling $\Gamma = \Gamma(\lambda)$, we thus obtain $v_0 = \Lambda(\lambda)$ and $\lambda = \lambda^*$. It follows that τ_* and a_* in Lemma 2.4 are uniquely determined by

$$\tau_*[C(a_*) - C_0/2] = \lambda^*, \qquad \tau_* C(a_*) = \Gamma(\lambda^*),$$

namely,

$$\tau_* = \frac{\Gamma(\lambda^*) - \lambda^*}{C_0/2}, \qquad a_* = C^{-1}(\lambda^*/\tau_* + C_0/2).$$

The rest of the proof now follows from Lemma 2.4. ∎

We now consider the remaining case that $\underline{v}(m) < v_0 < v_*(m)$, which can happen only if $m < f(w_0 e^{-A_0})$. Suppose that λ_0, λ^0, λ^0_*, and $\Gamma(\lambda)$ are as in Theorem 3.2 but with w_0 there replaced by $w_0 e^{-A_0}$, and we denote them by $\tilde{\lambda}_0$, $\tilde{\lambda}^0$, $\tilde{\lambda}^0_*$, and $\tilde{\Gamma}(\lambda)$, respectively. Define

$$\Delta(\lambda) := \frac{w_0}{\alpha} e^{-A_0 - A\lambda} + \frac{\tilde{\Gamma}(\lambda)}{d_2} m\beta^{-1}.$$

Then $\Delta(\lambda)$ is a decreasing function over $[0, \tilde{\lambda}_0]$ with

$$\Delta(0) = \frac{w_0}{\alpha} e^{-A_0} + \frac{\tilde{\lambda}^0}{d_2} m\beta^{-1}, \qquad \Delta(\tilde{\lambda}^0_*) = \frac{w_0}{\alpha} e^{-A_0 - A\tilde{\lambda}^0_*} + \frac{\tilde{\lambda}^0_*}{d_2} m\beta^{-1} = v_*(m).$$

THEOREM 3.3. *Suppose that* $m < f(w_0 e^{-A_0})$ *and*

$$\underline{v}(m) < v_0 < v_*(m) = \Delta(\tilde{\lambda}^0_*). \tag{3.17}$$

If $v_0 > \Delta(0)$ *and* $\lambda_* \in (0, \tilde{\lambda}^0_*)$ *is uniquely determined by* $v_0 = \Delta(\lambda_*)$, *then*

$$u_n \to 0 \text{ in } C([0, 1-\epsilon])\ \forall \epsilon \in (0,1), \quad \int_0^1 u_n dx \to \tilde{\Gamma}(\lambda_*),$$

$$v_n(x) \to v_0 - \frac{\tilde{\Gamma}(\lambda_*)}{d_2} m\beta^{-1} \text{ uniformly in } [0,1].$$

If $\underline{v}(m) < v_0 \le \Delta(0)$, *then the above conclusions hold with* $\lambda_* = 0$.

Proof. This is similar to the proof of Theorem 3.2. Here we can show that case (b2) must happen, and then we use Lemma 2.5. We omit the details. ∎

Remark 3.4. Our results in this section reveal an interesting property for the limiting total biomass $\lim_{n\to\infty} \int_0^1 u_n(x)dx$. First consider the case $v_*(m) \le v_0 \le v^*(m)$. By Theorem 3.1, in this case the above limit has value $\tau_* C_0$. By the proof of Theorem 3.1, we know that $\tau_* = T(v_0)$ with $T(v_0)$ a strictly increasing function of v_0. Therefore the limit is strictly increasing with v_0 for $v_0 \in [v_*(m), v^*(m)]$.

If $v_0 \in (v^*(m), \Lambda(0))$, then by Theorem 3.2, $\lim_{n\to\infty} \int_0^1 u_n(x)dx = \Gamma(\lambda^*) = \Gamma \circ \Lambda^{-1}(v_0)$. Since $\Gamma(\cdot)$ and $\Lambda(\cdot)$ are both strictly decreasing functions, $\Gamma \circ \Lambda^{-1}(\cdot)$ is strictly increasing, and hence the limit is strictly increasing with v_0 for $v_0 \in (v^*(m), \Lambda(0))$. However, by Theorem 3.2, this limit takes the same value $\Gamma(0)$ for all $v_0 \ge \Lambda(0)$.

If $v_0 \in (\Delta(0), v_*(m))$, then by Theorem 3.3, the limit takes value $\tilde{\Gamma}(\lambda_*) = \tilde{\Gamma} \circ \Delta^{-1}(v_0)$, which is strictly increasing in v_0, but it takes the same value $\tilde{\Gamma}(0)$ for all $v_0 \in (\underline{v}(m), \Delta(0)]$.

Therefore if we denote

$$v_{**} = v_{**}(m) := \Delta(0), \qquad v^{**} = v^{**}(m) := \Lambda(0),$$

then $\lim_{n\to\infty} \int_0^1 u_n(x)dx$ is strictly increasing with v_0 as v_0 varies in the range $v_{**} \le v_0 \le v^{**}$, but is constant for $v_0 \ge v^{**}$ or for $v_0 \in (\underline{v}(m), v_{**}]$.

4. Biological interpretations. In this section we compare our results with the game theoretical model in [KL] and explain the predictions that our theoretical results offer for the phytoplankton problem being modelled.

Since $u(x)$ and $v(x)$ are, respectively, rescaled versions of the biomass function $b(x)$ and the nutrient function $R(x)$ used in the original model of [KL] (see Part I for details), we will interpret $u(x)$ and $v(x)$ as representing the (steady) distributions of the biomass and nutrient at depth x of a water column with surface at $x = 0$ and bottom at $x = 1$.

(i) First we note that, if we replace $\max\{C_0/2, C_0 y\}$ in (2.9) by C_0, then the system of equations for (x_*, τ_*) in Theorem 3.1 reduces to the game theoretical model of [KL], namely, equations (4) and (5) in [KL] with $\hat{B} = \tau_* C_0$. Thus the game theoretical model of [KL] is a simplified version of the rigorous limiting equations here. It captures the main properties of the limiting equations but only in the case that $v_* \le v_0 \le v^*$.

(ii) When $v_0 > v^* = v^*(m)$, from Theorem 3.2 and Step 1 of the proof of Theorem 3.1, we see that as $\sigma \to \infty$ the total biomass has limit

$$\Gamma(\lambda^*) = \tau_* C(a_*) > \tau_0^* C_0.$$

If we have simply used (2.8) and (2.9) with $x_* = 0$ to calculate the total biomass, we would have obtained the incorrect limit $\tau_0^* C_0$. Similarly, the limit of the total biomass in the case of Theorem 3.3 is less than the value one would have obtained by simply using (2.8) and (2.9) with $x_* = 1$.

(iii) Remark 3.4 shows that as $\sigma \to \infty$, the limit of the total biomass is strictly increasing with v_0 in the range $v_{**} \le v_0 \le v^{**}$. It is interesting to notice that the layer position of the biomass (in the limit) already reaches the surface at $v_0 = v^*$ (i.e., $x_* = 0$ when $v_0 = v_*$), but as the nutrient level at the sediment v_0 increases past the critical value v^*, though the layer remains at the surface, the total biomass keeps increasing until v_0 reaches a second critical value v^{**}, where the total biomass reaches a maximum, and then remains at this value even if v_0 is further increased. On the other hand, if v_0 is decreased to v_*, the layer of the biomass lowers to the bottom ($x_* = 1$), but as v_0 decreases past v_*, though the layer remains at the bottom, the total biomass keeps decreasing until v_0 reaches the critical value v_{**}, where the total biomass reaches its minimal value, and then remains at this minimal value until v_0 is so low ($v_0 \le \underline{v}(m)$) that the phytoplankton can no longer survive.

(iv) Our results support the important predictions in [KL] that depth-regulating phytoplankton can form a thin layer in a poorly mixed water column and that the concentration of the limiting nutrient should be low and constant above the phytoplankton layer and linearly increasing with depth below the layer. The predictions in item (iii) above seem to provide new insights to this problem.

(v) We could fix v_0 and use a different parameter in the model, say the surface light level w_0, as a varying parameter to interpret the phenomena represented in items (i)–(iii) above.

ON p-HARMONIC MAP HEAT FLOWS FOR $1 \le p < \infty$ AND THEIR FINITE ELEMENT APPROXIMATIONS*

JOHN W. BARRETT†, XIAOBING FENG‡, AND ANDREAS PROHL§

Abstract. Motivated by emerging applications from imaging processing, this paper studies the heat flow of a generalized p-harmonic map into spheres for the whole spectrum, $1 \le p < \infty$, in a unified framework. The existence of global weak solutions is established for the flow using the energy method together with a regularization and a penalization technique. In particular, a BV-solution concept is introduced and the existence of such a solution is proved for the 1-harmonic map heat flow. The main idea used to develop such a theory is to exploit the properties of measures of the forms $\mathcal{A} \cdot \nabla \mathbf{v}$ and $\mathcal{A} \wedge \nabla \mathbf{v}$, which pair a divergence-L^1, or a divergence-measure, tensor field $\mathcal{A}$ and a BV-vector field $\mathbf{v}$. Based on these analytical results, a practical fully discrete finite element method is then proposed for approximating weak solutions of the p-harmonic map heat flow, and the convergence of the proposed numerical method is also established.

Key words. p-harmonic maps, heat flow, penalization, energy method, color image denoising, finite element method

1. Introduction.

Let $\Omega \subset \mathbf{R}^m$ be a bounded domain with smooth boundary $\partial\Omega$, and let S^{n-1} denote the unit sphere in $\mathbf{R}^n$. A map $\mathbf{u} \in C^1(\Omega, S^{n-1})$ is called a *p-harmonic map* if it is a critical point of the following p-energy:

$$E_p(\mathbf{v}) := \frac{1}{p} \int_\Omega |\nabla \mathbf{v}|^p \, \mathrm{d}x, \qquad 1 \le p < \infty. \tag{1.1}$$

It is well known [12, 21, 40] that the Euler–Lagrange equation of the p-energy is

$$-\Delta_p \mathbf{u} = |\nabla \mathbf{u}|^p \mathbf{u}, \tag{1.2}$$

where

$$\Delta_p \mathbf{u} := \mathrm{div}(|\nabla \mathbf{u}|^{p-2} \nabla \mathbf{u}). \tag{1.3}$$

Note that Δ_p is often called the p-Laplacian. It is easy to see that (1.2) is a *degenerate elliptic* equation for $p > 2$ and a *singular elliptic* equation for $1 \le p < 2$. These degeneracy and singular characteristics both disappear when $p = 2$.

We call a map $\mathbf{u} \in W^{1,p}(\Omega, S^{n-1})$ a *weakly p-harmonic map* if $\mathbf{u}$ satisfies (1.2) in the distributional sense. Here $W^{1,p}(\Omega, S^{n-1})$ denotes the Sobolev space

$$W^{1,p}(\Omega, S^{n-1}) := \left\{ \mathbf{u} \in W^{1,p}(\Omega, \mathbf{R}^n);\ \mathbf{u}(x) \in S^{n-1} \text{ for a.e. } x \in \Omega \right\}.$$

One well-known method for looking for a weakly p-harmonic map is the homotopy method (or the gradient descent method), which then leads to considering the following gradient flow (or heat flow) for the p-energy functional E_p complemented with some given boundary and initial conditions:

$$\mathbf{u}_t - \Delta_p \mathbf{u} = |\nabla \mathbf{u}|^p \mathbf{u} \qquad \text{in } \Omega_T := \Omega \times (0,T), \tag{1.4}$$

$$|\mathbf{u}| = 1 \qquad \text{in } \Omega_T. \tag{1.5}$$

Clearly, (1.4) is a *degenerate parabolic* equation for $p > 2$ and a *singular parabolic* equation for $1 \le p < 2$. Again, these degeneracy and singular characteristics both disappear when $p = 2$.

We remark that p-harmonic maps and weakly p-harmonic maps between two Riemannian manifolds (M, g) and (N, h) and their heat flows can be defined in the same fashion (cf. [21, 43, 44, 46, 47]). In this paper, we shall only consider the case $M = \Omega$ and $N = S^{n-1}$, which is sufficient for the applications that we are interested in.

The p-harmonic map and its heat flow, in particular, the harmonic map and the harmonic map heat flow ($p = 2$), have been extensively studied in the past twenty years for $1 < p < \infty$ (cf. [9, 11, 12, 13, 16, 17, 18, 21, 22, 25, 30, 31, 32, 34, 38, 39, 40, 41, 46, 48] for $1 < p < \infty$; [26, 27] for $p = 1$). In the case when the target manifold is a sphere, the existence of a global weak solution for the harmonic flow was first proved by Chen in [11] using a penalization technique. The result and the penalization technique were extended to the p-harmonic flow for $p > 2$ by Chen, Hong, and Hungerbühler in [12]. The p-harmonic flow for $1 < p < 2$ was solved by Misawa in [41] using a time discretization technique (the method of Rothe) proposed in [31], and by Liu in [39] using a penalization technique similar to that of [12]. The p-harmonic flow ($1 < p < \infty$) from a unit ball in $\mathbf{R}^m$ into $S^1 \subset \mathbf{R}^2$ was studied by Courilleau and Demengel in [16]. In the case of general target manifolds the p-harmonic flow ($1 < p < \infty$) with small initial data was treated by Fardoun and Regbaoui in [22], and the conformal case of the p-harmonic flow was considered by Hungerbühler in [33]. Nonuniqueness of the p-harmonic flow was addressed in [15, 32]. Recently, Giga, Kashima, and Yamazaki [28] proved existence of strong local solutions for 1-harmonic map heat flow using nonlinear semigroup theory. Besides the great amount of mathematical interests in the p-harmonic map and the p-harmonic flow, research on these problems has been strongly motivated by applications of the harmonic map and its heat flow in liquid crystals and micromagnetism; we refer to [2, 5, 7, 8, 19, 29, 36, 37, 51] and the references therein for detailed exposition in this direction.

Another reason, which is the main motivation of this paper, for studying the p-harmonic map and its heat flow, in particular, for $1 \le p < 2$, arises from their emerging and intriguing applications to image processing for denoising color images (cf. [49, 50]). We recall that a color image is often expressed by the RGB color system, in which a vector $\mathbf{I}(x) = (r(x), g(x), b(x))$ for each pixel $x = (x_1, x_2)$ is used to represent the intensity of the three primary colors (red, green, and blue). The chromaticity and brightness of a color image are deduced from the RGB system by decomposing $\mathbf{I}(x)$ into two components,

$$\eta(x) := |\,\mathbf{I}(x)\,| \qquad \text{(brightness)},$$

$$\mathbf{g} := \frac{\mathbf{I}(x)}{|\,\mathbf{I}(x)\,|} \qquad \text{(chromaticity)},$$

where $|\mathbf{I}(x)|$ stands for the Euclidean norm of $\mathbf{I}(x)$. By definition, the chromaticity must lie on the unit sphere S^2. One of the main benefits of the chromaticity and brightness decomposition is that it allows one to denoise η and $\mathbf{g}$ separately using different methods. For example, one may denoise η by the well-known total variation (TV) model of Rudin, Osher, and Fatemi [42] (also see [24]), but denoise $\mathbf{g}$ by another model. One such model is to define the recovered chromaticity $\mathbf{u}$ as a (generalized) p-harmonic map [49, 50]

$$\mathbf{u} = \operatorname*{argmin}_{\mathbf{v}\in W^{1,p}(\Omega;S^2)} J_{p,\lambda}(\mathbf{v}) \qquad \text{for } p \geq 1, \tag{1.6}$$

where

$$J_{p,\lambda}(\mathbf{v}) := E_p(\mathbf{v}) + \frac{\lambda}{2}\int_\Omega |\mathbf{v}-\mathbf{g}|^2\,dx \qquad \text{for } \lambda > 0. \tag{1.7}$$

In particular, the cases $1 \leq p < 2$ are the most important and interesting since the recovered images keep geometric information such as edges and corners of the noisy color images. We shall call (1.6) the *p-harmonic model* for color image denoising. We also remark that the second term on the right-hand side of (1.7) is often called a fidelity term. As in the TV model [42, 24], the parameter λ controls the trade-off between goodness of fit-to-the-data and variability in $\mathbf{u}$.

Again, to find a solution for the p-harmonic map model (1.6), we consider the gradient flow (heat flow) for the energy functional $J_{p,\lambda}$, which is given by

$$\mathbf{u}_t - \Delta_p\mathbf{u} + \lambda(\mathbf{u}-\mathbf{g}) = \mu_{p,\lambda}\mathbf{u} \qquad \text{in } \Omega_T, \tag{1.8}$$

$$|\mathbf{u}| = 1 \qquad \text{in } \Omega_T, \tag{1.9}$$

$$\mathcal{B}_p\mathbf{n} = 0 \qquad \text{on } \partial\Omega_T := \partial\Omega\times(0,T), \tag{1.10}$$

$$\mathbf{u} = \mathbf{u}_0 \qquad \text{on } \Omega\times\{t=0\}, \tag{1.11}$$

where

$$\mathcal{B}_p := |\nabla\mathbf{u}|^{p-2}\nabla\mathbf{u}, \qquad \mu_{p,\lambda} := |\nabla\mathbf{u}|^p + \lambda\,(1-\mathbf{u}\cdot\mathbf{g}). \tag{1.12}$$

The goals of this paper are twofold. First, we shall present a general theory of weak solutions for the parabolic system (1.8)–(1.11) for the whole spectrum $1 \leq p < \infty$. To the best of our knowledge, there is no theory known in the literature for the 1-harmonic map and its heat flow, which on the other hand is the most important (and most difficult) case for the color image denoising application. So our theory and results fill this void. Furthermore, our theory handles the p-harmonic map heat flow (1.8)–(1.11) for all $1 \leq p < \infty$ in a unified fashion, rather than treating the system separately for different values of p and using different methods (cf. [11, 12, 13, 16, 18, 21, 22, 30, 31, 34, 41, 46, 48]). Second, based on the above theoretical work, we also develop and analyze a practical fully discrete finite element method for approximating the solutions of the p-harmonic map heat flow (1.8)–(1.11).

We now highlight the main ideas and key steps of our approach. Notice that there are two nonlinear terms in the p-harmonic flow: the p-Laplace term and the right-hand side due to the nonconvex constraint $|\mathbf{u}| = 1$, so the main difficulties are how to handle these two terms and how to pass to the limit in these two terms when a

compactness argument is employed. To handle the degeneracy of the p-Laplace term, we approximate the p-energy $E_p(\mathbf{v})$ by the following regularized energy

$$E_p^\varepsilon(\mathbf{v}) := \frac{b_p(\varepsilon)}{2}\int_\Omega |\nabla \mathbf{v}|^2\,dx + \frac{1}{p}\int_\Omega |\nabla \mathbf{v}|_\varepsilon^p\,dx \tag{1.13}$$

$$= \int_\Omega \Big\{ \frac{b_p(\varepsilon)}{2}|\nabla \mathbf{v}|^2 + \frac{1}{p}\big[\,|\nabla \mathbf{v}|^2 + a_p(\varepsilon)^2\,\big]^{\frac{p}{2}}\Big\} dx,$$

where $\varepsilon > 0$ and

$$a_p(\varepsilon) := \begin{cases} 0 & \text{if } 2 \le p < \infty, \\ \varepsilon & \text{if } 1 \le p < 2, \end{cases} \qquad b_p(\varepsilon) := \varepsilon^\alpha \quad \text{for } 1 \le p < \infty \tag{1.14}$$

for some $\alpha > 0$. Here and in the rest of this paper we adopt the shorthand notation

$$|\nabla \mathbf{v}|_\varepsilon := \sqrt{|\nabla \mathbf{v}|^2 + a_p(\varepsilon)^2}. \tag{1.15}$$

To handle the nonconvex constraint $|\mathbf{u}| = 1$, we approximate it by the well-known Ginzburg–Landau penalization [7], that is, we abandon the exact constraint, but enforce it approximately by adding a penalization term to the regularized p-energy E_p^ε. To this end, we replace the energy E_p^ε by

$$E_p^{\varepsilon,\delta}(\mathbf{v}) := E_p^\varepsilon(\mathbf{v}) + L^\delta(\mathbf{v}) \qquad \text{for } \varepsilon, \delta > 0, \tag{1.16}$$

where

$$L^\delta(\mathbf{v}) := \frac{1}{\delta}\int_\Omega F(\mathbf{v})\,dx, \qquad F(\mathbf{v}) := \frac{1}{4}\big(|\mathbf{v}|^2 - 1\big)^2 \qquad \forall \delta > 0,\ \mathbf{v} \in \mathbf{R}^n. \tag{1.17}$$

So the idea is, as δ gets smaller and smaller, the energy functional $E_p^{\varepsilon,\delta}$ becomes more and more favorable for maps $\mathbf{u}$ which take values close to the unit sphere S^{n-1}.

Consequently, the regularized model for the p-harmonic model (1.6) (with general m and n) reads

$$\mathbf{u}^{\varepsilon,\delta} = \operatorname*{argmin}_{\mathbf{v} \in W^{1,p}(\Omega;\mathbf{R}^n)} J_{p,\lambda}^{\varepsilon,\delta}(\mathbf{v}) \qquad \text{for } p \ge 1, \tag{1.18}$$

where

$$J_{p,\lambda}^{\varepsilon,\delta}(\mathbf{v}) := E_p^{\varepsilon,\delta}(\mathbf{v}) + \frac{\lambda}{2}\int_\Omega |\mathbf{v} - \mathbf{g}|^2\,dx. \tag{1.19}$$

In addition, the gradient flow for the regularized energy functional $J_{p,\lambda}^{\varepsilon,\delta}$ is given by

$$\mathbf{u}_t^{\varepsilon,\delta} - \Delta_p^\varepsilon \mathbf{u}^{\varepsilon,\delta} + \frac{1}{\delta}\big(|\mathbf{u}^{\varepsilon,\delta}|^2 - 1\big)\mathbf{u}^{\varepsilon,\delta} + \lambda(\mathbf{u}^{\varepsilon,\delta} - \mathbf{g}) = 0 \qquad \text{in } \Omega_T, \tag{1.20}$$

$$\mathcal{B}_p^{\varepsilon,\delta}\mathbf{n} = 0 \qquad \text{on } \partial\Omega_T, \tag{1.21}$$

$$\mathbf{u}^{\varepsilon,\delta} = \mathbf{u}_0 \qquad \text{on } \Omega \times \{t = 0\}, \tag{1.22}$$

which is an approximation to the original flow (1.8)–(1.11), where

$$\mathcal{B}_p^{\varepsilon,\delta} := b_p(\varepsilon)\nabla \mathbf{u}^{\varepsilon,\delta} + |\nabla \mathbf{u}^{\varepsilon,\delta}|_\varepsilon^{p-2}\nabla \mathbf{u}^{\varepsilon,\delta}, \qquad \Delta_p^\varepsilon \mathbf{u}^{\varepsilon,\delta} := \operatorname{div} \mathcal{B}_p^{\varepsilon,\delta}. \tag{1.23}$$

After having introduced the regularized flow (1.20)–(1.22), the next step is to analyze this regularized flow, in particular, to derive uniform (in ε and δ) a priori estimates. Finally, we pass to the limit in (1.20)–(1.22), first letting $\delta \to 0$ and then setting $\varepsilon \to 0$. As pointed out earlier, the main difficulty here is passing to the limit in two nonlinear terms on the left-hand side of (1.20). For $1 < p < \infty$, this will be done using a compactness technique and exploiting the symmetries of the unit sphere S^{n-1}, as done in [11, 12, 13, 21, 32, 41, 46]. However, for $p = 1$, since $L^1(\Omega)$ is not a reflexive Banach space, instead of working in the Sobolev space $W^{1,1}(\Omega)$, we are forced to work in $BV(\Omega)$, the space of functions of bounded variation, since solutions of the original 1-harmonic map heat flow (1.8)–(1.11) belong only to $L^\infty((0,T);[BV(\Omega)]^n)$ in general. This lack of regularity makes the analysis for $p = 1$ much more delicate than that for $1 < p < \infty$.

We note also that the regularized flow (1.20)–(1.22) not only plays an important role for proving existence of weak solutions for the flow (1.8)–(1.11), but also provides a practical and convenient formulation for approximating the solutions. The second goal of this paper is to develop a practical fully discrete finite element method for approximating solutions of the regularized flow (1.20)–(1.22); and hence, approximating solutions of the original p-harmonic flow (1.8)–(1.11) via the regularized flow. It is well known that explicitly enforcing the nonconvex constraint $|\mathbf{u}| = 1$ at the discrete level is hard to achieve. The penalization used in (1.20) allows one to get around this numerical difficulty at the expense of introducing an additional scale, δ. As expected, the numerical difficulty now is to control the dependence of the regularized solutions on δ and to establish scaling laws which relate the numerical scales (spatial and temporal mesh sizes) to the penalization scale δ for both stability and accuracy concerns. We refer to [6] and the references therein for more discussions in this direction and discussions on a related problem arising from liquid crystal applications. Borrowing a terminology from the phase transition of materials science, the regularized flow (1.20)–(1.22) may be regarded as a "diffuse interface" model for the original "sharp interface" model (1.8)–(1.11), and the "diffuse interface" is represented by the region $\{|\mathbf{u}^{\varepsilon,\delta}| < 1 - \delta\}$.

The remaining part of the paper is organized as follows. In section 2 we collect some known results and facts, which will be used in the later sections. In section 3 we present a complete analysis for the regularized flow (1.20)–(1.22), which includes proving its well-posedness, an energy law, a maximum principle, and uniform (in ε and δ) a priori estimates. As expected, these uniform a priori estimates serve as the basis for carrying out the energy method and the compactness arguments in the later sections. In section 4 we pass to the limit in (1.20)–(1.22) as $\delta \to 0$ for each *fixed* $\varepsilon > 0$. As in [13, 12, 32, 41], the main idea is to exploit the monotonicity of the operator Δ_p^ε and the symmetries of the unit sphere S^{n-1}. Sections 5 and 6 are devoted to passing to the limit as $\varepsilon \to 0$ in the ε-dependent limiting system obtained in section 4. For $1 < p < \infty$, this will be done by following the idea of section 4. However, for $p = 1$ the analysis becomes much more delicate because the nonreflexivity of $W^{1,1}(\Omega)$ forces us to work in the $BV(\Omega)$ space. The main idea used to develop a BV-solution concept is to exploit the properties of measures of the forms $\mathcal{A} \cdot \nabla \mathbf{v}$ and $\mathcal{A} \wedge \nabla \mathbf{v}$, which pair a divergence-L^1, or a divergence-measure, tensor field $\mathcal{A}$ and a BV-vector field $\mathbf{v}$. Finally, based on the theoretical results of sections 3–6, in section 7 we propose and analyze a practical fully discrete finite element method for approximating solutions of the p-harmonic flow (1.8)–(1.11) via the regularized flow (1.20)–(1.22). It is proved that the proposed numerical scheme

satisfies a discrete energy inequality, which mimics the differential energy inequality, and this leads to uniform (in ε and δ) a priori estimates and the convergence of the numerical approximations to the solutions of the flow (1.8)–(1.11) as the spatial and temporal mesh sizes, and the parameters ε and δ, all tend to zero.

2. Preliminaries. The standard notation for spaces is adopted in this paper (cf. [1, 3]). For example, $W^{k,p}(\Omega)$, $k \geq 0$ integer and $1 \leq p < \infty$, denotes the Sobolev spaces over the domain Ω and $\|\cdot\|_{W^{k,p}}$ denotes its norm. $W^{0,p}(\Omega) = L^p(\Omega)$ and $W^{k,2}(\Omega) = H^k(\Omega)$ are also used. $L^q((0,T); W^{k,p}(\Omega, \mathbf{R}^n))$ denotes the space of vector-valued functions (or maps), whose $W^{k,p}(\Omega)$-norm is L^q-integrable as a function of t over the interval $(0,T)$, and $\|\cdot\|_{L^q(W^{k,p})} := (\int_0^T \|\cdot\|^q_{W^{k,p}} dt)^{\frac{1}{q}}$ for $q \in [1,\infty)$ denotes its norm, with the standard modification for $q = \infty$. We use $\langle \cdot, \cdot \rangle$ to denote a generic dual product between elements of a Banach space X and its dual space X'.

In addition, $\mathcal{M}(\Omega)$ (resp., $[\mathcal{M}(\Omega)]^n$) denotes the space of real-valued (resp., $\mathbf{R}^n$-valued) finite Radon measures on Ω. Recall that $\mathcal{M}(\Omega)$ is the dual space of $C_0(\Omega)$ (cf. [3]). For a positive non-Lebesgue measure $\mu \in \mathcal{M}(\Omega)$, $L^p(\Omega, \mu)$ is used to denote the space of L^p-integrable functions with respect to the measure μ, and for $f \in L^1(\Omega, \mu)$, the measure $f\mu$ is defined by

$$f\mu(A) := \int_A f \, d\mu \qquad \text{for any Borel set } A \subset \Omega.$$

For any $\mu \in \mathcal{M}(\Omega)$, $\mu = \mu^a + \mu^s$ denotes its Radon–Nikodým decomposition, where μ^a and μ^s, respectively, denotes the absolute continuous part and the singular part of μ with respect to the Lebesgue measure $\mathcal{L}^n$.

Furthermore, $BV(\Omega)$ is used to denote the space of functions of bounded variation. Recall that a function $u \in L^1(\Omega)$ is called a function of *bounded variation* if all of its first order partial derivatives (in the distributional sense) are measures with finite total variations in Ω. Hence, the gradient of such a function u, denoted by Du, is a bounded vector-valued measure, with the finite total variation

$$|Du| \equiv |Du|(\Omega) := \sup\Big\{ \int_\Omega -u \operatorname{div} \mathbf{v} \, dx \,;\ \mathbf{v} \in [C_0^1(\Omega)]^n,\ \|\mathbf{v}\|_{L^\infty} \leq 1 \Big\}. \tag{2.1}$$

$BV(\Omega)$ is known to be a Banach space endowed with the norm

$$\|u\|_{BV} := \|u\|_{L^1} + |Du|. \tag{2.2}$$

For any $u \in BV(\Omega)$, $(Du)^a$ and $|Du|^a$ are used to denote, respectively, the absolute continuous part of Du and $|Du|$ with respect to the Lebesgue measure $\mathcal{L}^n$. We refer to [3] for detailed discussions about the space $BV(\Omega)$ and properties of BV functions.

For any vector $\mathbf{a} \in \mathbf{R}^n$ and any matrices $\mathcal{A}$, $\mathcal{B} \in \mathbf{R}^{n \times m}$ with jth column vectors $\mathcal{A}^{(j)}$ and $\mathcal{B}^{(j)}$, respectively, we define the following wedge products:

$$\mathcal{A} \wedge \mathbf{a} := [\mathcal{A}^{(1)} \wedge \mathbf{a}, \ldots, \mathcal{A}^{(m)} \wedge \mathbf{a}], \qquad \mathbf{a} \wedge \mathcal{A} := [\mathbf{a} \wedge \mathcal{A}^{(1)}, \ldots, \mathbf{a} \wedge \mathcal{A}^{(m)}], \tag{2.3}$$

$$\mathcal{A} \wedge \mathcal{B} := \mathcal{A}^{(1)} \wedge \mathcal{B}^{(1)} + \cdots + \mathcal{A}^{(m)} \wedge \mathcal{B}^{(m)}. \tag{2.4}$$

We point out that (2.4) defines $\mathcal{A} \wedge \mathcal{B}$ to be a vector instead of a matrix, which seems not to be natural. However, we shall see in section 6 that it turns out that this is a convenient and useful notation.

We conclude this section by citing some known results which will be used in the later sections. The first result is known as "the decisive monotonicity trick," and its proof can be found in [52].

LEMMA 2.1. *Let X be a reflexive Banach space, and X' denote the dual space of X. Suppose that an operator $\mathcal{F} : X \longrightarrow X'$ satisfies*

(i) *$\mathcal{F}$ is monotone on X, that is, $\langle \mathcal{F}u - \mathcal{F}v, u - v\rangle \geq 0$ for all $u, v \in X$;*

(ii) *$\mathcal{F}$ is hemicontinuous, that is, the function $t \mapsto \langle \mathcal{F}(u + tv), w\rangle$ is continuous on $[0, 1]$ for all $u, v, w \in X$.*

In addition, suppose that $u_k \to u$ and $\mathcal{F}u_k \to f$ weakly in X and X', respectively, as $n \to \infty$, and

$$\overline{\lim_{k\to\infty}} \langle \mathcal{F}u_k, u_k\rangle \leq \langle f, u\rangle.$$

Then

$$\mathcal{F}u = f.$$

The second lemma is a compactness result, it can be proved following the proof of Theorem 2.1 of [12] (also see Theorem 3 of Chapter 4 of [20]) using the fact that the operator Δ_p^ε is uniformly elliptic.

LEMMA 2.2. *For $1 \leq p < \infty$, let $p^* = \max\{2, p\}$. For a fixed $\varepsilon > 0$, let $\{\mathbf{w}^{\varepsilon,\delta}\}_{\delta>0}$ be bounded in $L^\infty((0,T); W^{1,p^*}(\Omega, \mathbf{R}^n))$, and let $\{\mathbf{f}^{\varepsilon,\delta}\}_{\delta>0}$ be bounded in $L^1((0,T); L^1(\Omega,\ \mathbf{R}^n))$, both uniformly in δ. Moreover, suppose that $\{\frac{\partial \mathbf{w}^{\varepsilon,\delta}}{\partial t}\}_{\delta>0}$ is bounded in $L^2((0,T);\ L^2(\Omega, \mathbf{R}^n))$ uniformly in δ and $\mathbf{w}^{\varepsilon,\delta}$ satisfies the equation*

$$\frac{\partial \mathbf{w}^{\varepsilon,\delta}}{\partial t} - \Delta_p^\varepsilon \mathbf{w}^{\varepsilon,\delta} = \mathbf{f}^{\varepsilon,\delta} \qquad \text{in } \Omega_T, \quad \delta > 0,$$

in the distributional sense. Then $\{\mathbf{w}^{\varepsilon,\delta}\}_{\delta>0}$ is precompact in $L^q((0,T); W^{1,q}(\Omega, \mathbf{R}^n))$ for all $1 \leq q < p^*$.

The last lemma is a variation of Lemma 2.2, and its proof can be found in [38] (also see Lemma 9 of [40]).

LEMMA 2.3. *For $1 < p < \infty$, let $\{\mathbf{w}^\varepsilon\}_{\varepsilon>0}$ be bounded in $L^\infty((0,T); W^{1,p}(\Omega, \mathbf{R}^n))$, and $\{\mathbf{f}^\varepsilon\}$ be bounded in $L^1((0,T);\ L^1(\Omega, \mathbf{R}^n))$, both uniformly in ε. Moreover, suppose that $\{\frac{\partial \mathbf{w}^\varepsilon}{\partial t}\}$ is bounded uniformly in ε in $L^2((0,T); L^2(\Omega, \mathbf{R}^n))$ and $\mathbf{w}^\varepsilon$ satisfies the equation*

$$\frac{\partial \mathbf{w}^\varepsilon}{\partial t} - \Delta_p^\varepsilon \mathbf{w}^\varepsilon = \mathbf{f}^\varepsilon \qquad \text{in } \Omega_T, \quad \varepsilon > 0,$$

in the distributional sense. Then $\{\mathbf{w}^\varepsilon\}_{\varepsilon>0}$ is precompact in $L^q((0,T); W^{1,q}(\Omega, \mathbf{R}^n))$ for all $1 \leq q < p$.

Remark 2.1. In Lemma 2.2, $\varepsilon > 0$ is a fixed parameter and the differential operator Δ_p^ε does not depend on the variable index δ. It can be shown that (cf. Theorem 2.1 of [12]) that the lemma still holds for $\varepsilon = 0$ when $p \geq 2$. On the other hand, ε is a variable index in Lemma 2.3, and the operator Δ_p^ε also depends on the variable index ε.

3. Well-posedness of the regularized flow (1.20)–(1.22). In this section we shall analyze the regularized flow (1.20)–(1.22) for each fixed pair of positive numbers (ε, δ). We establish an energy law, a maximum principle, uniform (in both ε and δ) a priori estimates, and existence and uniqueness of weak and classical solutions. We begin with a couple of definitions for solutions to (1.20)–(1.22).

DEFINITION 3.1. *For $1 \le p < \infty$, a map $\mathbf{u}^{\varepsilon,\delta} : \Omega_T \to \mathbf{R}^n$ is called a global* weak *solution to* (1.20)–(1.22) *if*

(i) $\mathbf{u}^{\varepsilon,\delta} \in L^\infty((0,T); W^{1,p^*}(\Omega,\mathbf{R}^n)) \cap H^1((0,T); L^2(\Omega,\mathbf{R}^n))$, *for* $p^* = \max\{2,p\}$;

(ii) $|\mathbf{u}^{\varepsilon,\delta}| \le 1$ *a.e. in* Ω_T;

(iii) $\mathbf{u}^{\varepsilon,\delta}$ *satisfies* (1.20)–(1.22) *in the distributional sense.*

DEFINITION 3.2. *A weak solution $\mathbf{u}^{\varepsilon,\delta}$ to* (1.20)–(1.22) *is called a* strong *solution if $\mathbf{u}^{\varepsilon,\delta} \in L^p((0,T);\, W^{2,p^*}(\Omega,\mathbf{R}^n)) \cap H^1((0,T); L^{p^*}(\Omega,\mathbf{R}^n))$. It is called a* regular *solution if in addition $\mathbf{u}^{\varepsilon,\delta} \in H^1((0,T);\, W^{1,p^*}(\Omega,\mathbf{R}^n))$.*

3.1. Energy law and a priori estimates. Since (1.20)–(1.22) is the gradient flow for the functional $J^{\varepsilon,\delta}_{p,\lambda}$, its regular solutions must satisfy a dissipative energy law. Indeed, we have the following lemma.

LEMMA 3.3. *Let $\mathbf{u}_0$ and $\mathbf{g}$ be sufficiently smooth, and suppose that $\mathbf{u}^{\varepsilon,\delta}$ is a regular solution to* (1.20)–(1.22). *Then $\mathbf{u}^{\varepsilon,\delta}$ satisfies the following energy law:*

$$J^{\varepsilon,\delta}_{p,\lambda}(\mathbf{u}^{\varepsilon,\delta}(s)) + \int_0^s \| \mathbf{u}^{\varepsilon,\delta}_t(t) \|^2_{L^2}\, dt = J^{\varepsilon,\delta}_{p,\lambda}(\mathbf{u}_0) \qquad \text{for a.e. } s \in [0,T]. \tag{3.1}$$

Proof. Testing (1.20) with $\mathbf{u}^{\varepsilon,\delta}_t$ we get

$$\| \mathbf{u}^{\varepsilon,\delta}_t(t) \|^2_{L^2} + \frac{d}{dt} \int_\Omega \Big\{ \frac{b_p(\varepsilon)}{2} |\nabla \mathbf{u}^{\varepsilon,\delta}(t)|^2 + \frac{1}{p} |\nabla \mathbf{u}^{\varepsilon,\delta}(t)|^p_\varepsilon + \frac{1}{\delta} F(\mathbf{u}^{\varepsilon,\delta}(t)) + \frac{\lambda}{2} |\mathbf{u}^{\varepsilon,\delta}(t) - \mathbf{g}|^2 \Big\} dx = 0.$$

The desired identity (3.1) then follows from integrating the above equation in t over the interval $[0,s]$ and using the definition of $J^{\varepsilon,\delta}_{p,\lambda}$. ∎

The above energy law immediately implies the following uniform (in ε and δ) a priori estimates.

COROLLARY 3.4. *Suppose that $\mathbf{u}_0$ and $\mathbf{g}$ satisfy*

$$J^{\varepsilon,\delta}_{p,\lambda}(\mathbf{u}_0) \le c_0 \tag{3.2}$$

for some positive constant c_0 independent of ε and δ. Then there exists another positive constant $C := C(p,\lambda,c_0)$ which is also independent of ε and δ such that

$$\| \mathbf{u}^{\varepsilon,\delta} \|_{L^\infty(W^{1,p})} + \| \mathbf{u}^{\varepsilon,\delta} \|_{H^1(L^2)} \le C \qquad \text{for } 1 \le p < \infty, \tag{3.3}$$

$$\delta^{-\frac{1}{2}} \| \, |\mathbf{u}^{\varepsilon,\delta}|^2 - 1 \, \|_{L^\infty(L^2)} \le C \qquad \text{for } 1 \le p < \infty, \tag{3.4}$$

$$\| \, |\nabla \mathbf{u}^{\varepsilon,\delta}|^{p-2}_\varepsilon \nabla \mathbf{u}^{\varepsilon,\delta} \, \|_{L^\infty(L^{p'})} \le C \qquad \text{for } p' = \frac{p}{p-1}, \quad 1 \le p < \infty, \tag{3.5}$$

$$\sqrt{b_p(\varepsilon)} \, \| \nabla \mathbf{u}^{\varepsilon,\delta} \|_{L^\infty(L^2)} \le C \qquad \text{for } 1 \le p < \infty. \tag{3.6}$$

Next, using a test function technique of [12], we show that the modulus $|\mathbf{u}^{\varepsilon,\delta}|$ of every weak solution $\mathbf{u}^{\varepsilon,\delta}$ to (1.20)–(1.22) satisfies a maximum principle.

LEMMA 3.5. *Suppose that $|\mathbf{g}| \le 1$ and $|\mathbf{u}_0| \le 1$ a.e. in Ω. Then weak solutions to* (1.20)–(1.22) *satisfy $|\mathbf{u}^{\varepsilon,\delta}| \le 1$ a.e. in Ω_T.*

Proof. Define the function

$$\chi(z) := \frac{(z-1)_+}{z} = \begin{cases} 0 & \text{for } 0 \le z \le 1, \\ \dfrac{z-1}{z} & \text{for } z > 1. \end{cases} \tag{3.7}$$

It is easy to check that χ is a nonnegative monotone increasing function on the interval $[0,\infty)$.

Now testing (1.20) with $\mathbf{v} := \mathbf{u}^{\varepsilon,\delta}\chi(|\mathbf{u}^{\varepsilon,\delta}|)$ we get

$$\frac{1}{2}\frac{d}{dt}\int_{\{|\mathbf{u}^{\varepsilon,\delta}|>1\}}\big(|\mathbf{u}^{\varepsilon,\delta}|-1\big)^2\,dx+\int_{\{|\mathbf{u}^{\varepsilon,\delta}|>1\}}\Big\{\,b_p(\varepsilon)|\nabla\mathbf{u}^{\varepsilon,\delta}|^2+|\nabla\mathbf{u}^{\varepsilon,\delta}|_\varepsilon^{p-2}\,|\nabla\mathbf{u}^{\varepsilon,\delta}|^2$$
$$+\frac{1}{\delta}\big(|\mathbf{u}^{\varepsilon,\delta}|^2-1\big)|\mathbf{u}^{\varepsilon,\delta}|^2+\lambda\big(|\mathbf{u}^{\varepsilon,\delta}|^2-\mathbf{u}^{\varepsilon,\delta}\cdot\mathbf{g}\big)\,\Big\}\,\chi(|\mathbf{u}^{\varepsilon,\delta}|)\,dx$$
$$+\frac{1}{4}\int_{\{|\mathbf{u}^{\varepsilon,\delta}|>1\}}\frac{[b_p(\varepsilon)+|\nabla\mathbf{u}^{\varepsilon,\delta}|_\varepsilon^{p-2}]\,|\nabla|\mathbf{u}^{\varepsilon,\delta}|^2|^2}{|\mathbf{u}^{\varepsilon,\delta}|^3}\,dx=0.$$

Since $\mathbf{u}^{\varepsilon,\delta}\cdot\mathbf{g}\le|\mathbf{u}^{\varepsilon,\delta}|\cdot|\mathbf{g}|\le|\mathbf{u}^{\varepsilon,\delta}|$, the second integral is nonnegative. The assertion then follows from integrating the above inequality and using the assumption $|\mathbf{u}_0|\le 1$ a.e. in Ω. ∎

3.2. Existence of global weak and classical solutions. We now state and prove the existence of global weak and classical solutions to the regularized flow (1.20)–(1.22) for each fixed pair of positive numbers (ε,δ). Since $-\Delta_p^\varepsilon$ is uniformly elliptic for all $1\le p<\infty$, the existence of classical solutions follows immediately from the classical theory of parabolic partial differential equations (cf. [35]).

THEOREM 3.6. *Let $\Omega\subset\mathbf{R}^m$ be a bounded domain with a smooth boundary. Suppose that $\mathbf{u}_0$ and $\mathbf{g}$ are sufficiently smooth functions (say, $\mathbf{u}_0,\mathbf{g}\in[C^3(\overline{\Omega})]^n$) and satisfy* (3.2). *Then for each fixed pair of positive numbers (ε,δ), the regularized flow* (1.20)–(1.22) *possesses a unique global classical solution $\mathbf{u}^{\varepsilon,\delta}$. Moreover, $\mathbf{u}^{\varepsilon,\delta}$ satisfies the following energy law:*

$$J_{p,\lambda}^{\varepsilon,\delta}(\mathbf{u}^{\varepsilon,\delta}(s))+\int_0^s\|\,\mathbf{u}_t^{\varepsilon,\delta}(t)\,\|_{L^2}^2\,dt=J_{p,\lambda}^{\varepsilon,\delta}(\mathbf{u}_0)\qquad\text{for a.e. } s\in[0,T]. \tag{3.8}$$

Proof. The existence and uniqueness follow from an application of the standard results for parabolic systems; see Chapter 5 of [35]. Equation (3.8) follows from Lemma 3.3. ∎

For less regular functions $\mathbf{u}_0$ and $\mathbf{g}$, we have the following weaker result.

THEOREM 3.7. *Let $\Omega\subset\mathbf{R}^m$ be a bounded domain with smooth boundary. Suppose that $|\mathbf{u}_0|\le 1$ and $|\mathbf{g}|\le 1$ a.e. in Ω and $J_{p,\lambda}^{\varepsilon,\delta}(\mathbf{u}_0)<\infty$. Then the regularized flow* (1.20)–(1.22) *has a unique global weak solution $\mathbf{u}^{\varepsilon,\delta}$ in the sense of Definition* 3.1. *Moreover, $\mathbf{u}^{\varepsilon,\delta}$ satisfies the following energy inequality:*

$$J_{p,\lambda}^{\varepsilon,\delta}(\mathbf{u}^{\varepsilon,\delta}(s))+\int_0^s\|\,\mathbf{u}_t^{\varepsilon,\delta}(t)\,\|_{L^2}^2\,dt\le J_{p,\lambda}^{\varepsilon,\delta}(\mathbf{u}_0)\qquad\forall s\in[0,T]. \tag{3.9}$$

Proof. Let η_ρ denote any well-known mollifier (cf. [35]), and let $\mathbf{u}_{0,\rho}:=\eta_\rho*\mathbf{u}_0$ and $\mathbf{g}_\rho:=\eta_\rho*\mathbf{g}$ denote the mollifications of $\mathbf{u}_0$ and $\mathbf{g}$, respectively. Let $\mathbf{u}_\rho^{\varepsilon,\delta}$ denote the classical solution to (1.20)–(1.22) corresponding to the smoothed datum functions $\mathbf{u}_{0,\rho}$ and $\mathbf{g}_\rho$. Hence, $\mathbf{u}_\rho^{\varepsilon,\delta}$ satisfies the energy law (3.8) with $\mathbf{u}_{0,\rho}$ and $\mathbf{g}_\rho$ in the place of $\mathbf{u}_0$ and $\mathbf{g}$.

From Lemma 3.5 we know that $|\mathbf{u}_\rho^{\varepsilon,\delta}|$ satisfies the maximum principle, thus,

$$\max_{(x,t)\in\overline{\Omega}_T}|\mathbf{u}_\rho^{\varepsilon,\delta}(x,t)|\le 1.$$

Next, since

$$\lim_{\rho\to 0} J^{\varepsilon,\delta}_{p,\lambda}(\mathbf{u}^{\varepsilon}_{0,\rho}) = J^{\varepsilon,\delta}_{p,\lambda}(\mathbf{u}_0) < \infty,$$

the energy law for $\mathbf{u}^{\varepsilon,\delta}_{\rho}$ immediately implies that $\mathbf{u}^{\varepsilon,\delta}_{\rho}$ satisfies estimates (3.3)–(3.6), *uniformly* in ρ and δ.

The remainder of the proof is to extract a convergent subsequence of $\{\mathbf{u}^{\varepsilon,\delta}_{\rho}\}_{\rho>0}$ and to pass to the limit as $\rho \to 0$ in the weak formulation of (1.20). This can be done easily in all terms of (1.20) except the nonlinear term in Δ^{ε}_{p} (see (1.23)). To overcome the difficulty, we appeal to Minty's trick or the "decisive monotonicity trick" as described in Lemma 2.1. Since this part of proof is the same as that of Theorem 1.5 of [12], we omit it and refer to [12] for the details.

The uniqueness of weak solutions follows from a standard perturbation argument and using the fact that Δ^{ε}_{p} is a monotone operator. Finally, (3.9) follows from setting $\rho \to 0$ in the energy law (3.8) for $\mathbf{u}^{\varepsilon,\delta}_{\rho}$ and from using the lower semicontinuity of $J^{\varepsilon,\delta}_{p,\lambda}$ and the L^2-norm with respect to L^2 weak convergence. ∎

We conclude this section with some remarks.

Remark 3.1. (a) Since $W^{1,1}(\Omega)$ is not a *reflexive* Banach space, Minty's trick would not apply in the case $p = 1$ without the help of the $b_p(\varepsilon)\Delta$ term in the operator Δ^{ε}_{p} (see (1.23)). On the other hand, in the presence of this term, Minty's trick does apply since we now deal with the Sobolev space $H^1(\Omega)$ instead of $W^{1,1}(\Omega)$. In fact, if $b_p(\varepsilon) = 0$ in (1.20), BV solutions are what one can only expect in general for the regularized flow (1.20)–(1.22) in the case $p = 1$ (cf. [24]).

(b) We also point out that using nonzero parameter $b_p(\varepsilon)$ is not necessary in the case $1 < p < \infty$. For example, the conclusion of Theorem 3.7 still holds if we replace the above $b_p(\varepsilon)$ and p^* by

$$\widehat{b}_p(\varepsilon) = \begin{cases} 0 & \text{if } 1 < p < \infty, \\ \varepsilon^{\alpha} & \text{if } p = 1 \quad (\alpha > 0) \end{cases} \qquad \text{and} \quad \widehat{p^*} = \begin{cases} p & \text{if } 1 < p < \infty, \\ 2 & \text{if } p = 1. \end{cases}$$

On the other hand, the conclusion of Theorem 3.6 may no longer be true after this modification.

(c) Theorem 3.7 also holds when Ω is a bounded Lipschitz domain. One way to prove this assertion is to use the Galerkin method as done in [12], or to use the finite element method to be introduced in section 7.

4. Passing to the limit as $\delta \to 0$. The goal of this section is to derive the limiting flow of (1.20)–(1.22) as $\delta \to 0$ for each *fixed* $\varepsilon > 0$. As in [11, 12, 13, 31, 41, 46], the key ideas for passing to the limit are to use the compactness result of Lemma 2.2 and to exploit the symmetries of the unit sphere S^{n-1}. Our main result of this section is the following existence theorem.

THEOREM 4.1. *Let $p^* := \max\{2, p\}$ and let $\Omega \subset \mathbf{R}^m$ be a bounded Lipschitz domain. For $1 \le p < \infty$, suppose that $\mathbf{u}_0 \in W^{1,p^*}(\Omega, \mathbf{R}^n)$, $|\mathbf{u}_0| = 1$ and $|\mathbf{g}| \le 1$ in Ω. Then there exists a map $\mathbf{u}^{\varepsilon} \in L^{\infty}((0,T); W^{1,p^*}(\Omega, \mathbf{R}^n)) \cap H^1((0,T); L^2(\Omega, \mathbf{R}^n))$ such that*

$$|\mathbf{u}^{\varepsilon}| = 1 \qquad \text{a.e. in } \Omega_T, \tag{4.1}$$

and $\mathbf{u}^\varepsilon$ *is a weak solution (in the distributional sense; see* (4.29)*) to the problem*

$$\mathbf{u}_t^\varepsilon - \Delta_p^\varepsilon \mathbf{u}^\varepsilon + \lambda(\mathbf{u}^\varepsilon - \mathbf{g}) = \mu_{p,\lambda}^\varepsilon \mathbf{u}^\varepsilon \qquad \text{in } \Omega_T, \tag{4.2}$$

$$\mathcal{B}_p^\varepsilon \mathbf{n} = 0 \qquad \text{on } \partial\Omega_T, \tag{4.3}$$

$$\mathbf{u}^\varepsilon = \mathbf{u}_0 \qquad \text{on } \Omega \times \{t = 0\}, \tag{4.4}$$

where

$$\mu_{p,\lambda}^\varepsilon := b_p(\varepsilon)|\nabla \mathbf{u}^\varepsilon|^2 + |\nabla \mathbf{u}^\varepsilon|_\varepsilon^{p-2}\,|\nabla \mathbf{u}^\varepsilon|^2 + \lambda(1 - \mathbf{u}^\varepsilon \cdot \mathbf{g}). \tag{4.5}$$

Moreover, $\mathbf{u}^\varepsilon$ *satisfies the energy inequality*

$$J_{p,\lambda}^\varepsilon(\mathbf{u}^\varepsilon(s)) + \int_0^s \| \mathbf{u}_t^\varepsilon(t) \|_{L^2}^2 \, dt \le J_{p,\lambda}^\varepsilon(\mathbf{u}_0) \le J_{p,\lambda}^1(\mathbf{u}_0) \qquad \text{for a.e. } s \in [0,T] \tag{4.6}$$

and the additional estimates

$$\| \, |\nabla \mathbf{u}^\varepsilon|_\varepsilon^{p-2} \nabla \mathbf{u}^\varepsilon \, \|_{L^\infty(L^{p'})} \le C \qquad \text{for } p' = \frac{p}{p-1}, \quad 1 \le p < \infty, \tag{4.7}$$

$$\| \operatorname{div} \mathcal{B}_p^\varepsilon \|_{L^2(L^1)} \le C \qquad \text{for } 1 \le p < \infty, \tag{4.8}$$

$$\| \operatorname{div} (\mathcal{B}_p^\varepsilon \wedge \mathbf{u}^\varepsilon) \|_{L^2(L^2)} \le C \qquad \text{for } 1 \le p < \infty, \tag{4.9}$$

$$\sqrt{b_p(\varepsilon)} \| \nabla \mathbf{u}^\varepsilon \|_{L^\infty(L^2)} \le C \tag{4.10}$$

for some positive ε*-independent constant* C*. Here* $\mathcal{B}_p^\varepsilon$ *is the* $n \times m$ *matrix*

$$\mathcal{B}_p^\varepsilon := b_p(\varepsilon)\nabla \mathbf{u}^\varepsilon + |\nabla \mathbf{u}^\varepsilon|_\varepsilon^{p-2} \nabla \mathbf{u}^\varepsilon \tag{4.11}$$

and

$$J_{p,\lambda}^\varepsilon(\mathbf{v}) := E_p^\varepsilon(\mathbf{v}) + \frac{\lambda}{2} \int_\Omega |\mathbf{v} - \mathbf{g}|^2 \, dx. \tag{4.12}$$

Proof. In light of Remark 3.1(c) and the density argument, without loss of the generality we assume that Ω is a bounded smooth domain, and $\mathbf{u}_0$ and $\mathbf{g}$ are smooth functions. On noting that $|\mathbf{u}_0| = 1$ implies that $L^\delta(\mathbf{u}_0) = 0$, then $E_p^{\varepsilon,\delta}(\mathbf{u}_0) = E_p^\varepsilon(\mathbf{u}_0)$ in (1.16). Since $E_p^\varepsilon(\mathbf{u}_0) \le E_p^1(\mathbf{u}_0)$, hence the assumptions on $\mathbf{u}_0$ and $\mathbf{g}$ ensure (3.2) holds. Since the proof is long, we divide it into three steps.

Step 1: *Extracting a convergent subsequence.* Let $\mathbf{u}^{\varepsilon,\delta}$ be the weak solution solution to (1.20)–(1.22) whose existence is established in Theorem 3.7. Since $E_p^{\varepsilon,\delta}(\mathbf{u}_0) \le E_p^1(\mathbf{u}_0)$, then $J_{p,\lambda}^{\varepsilon,\delta}(\mathbf{u}_0)$ is uniformly bounded with respect to ε and δ. Hence, (3.9) implies that $\mathbf{u}^{\varepsilon,\delta}$ satisfies the uniform (in both ε and δ) estimates (3.3)–(3.6) and the maximum principle $|\mathbf{u}^{\varepsilon,\delta}| \le 1$ on $\overline{\Omega}_T$.

By the weak compactness of $W^{1,p}(\Omega)$ and Sobolev embedding (cf. [1, 45]), there exists a subsequence of $\{\mathbf{u}^{\varepsilon,\delta}\}_{\delta>0}$ (still denoted by the same notation) and a map

$\mathbf{u}^{\varepsilon} \in L^{\infty}((0,T);W^{1,p^*}(\Omega,\mathbf{R}^n)) \cap H^1((0,T);L^2(\Omega,\mathbf{R}^n))$ such that as $\delta \to 0$

$$\mathbf{u}^{\varepsilon,\delta} \longrightarrow \mathbf{u}^{\varepsilon} \qquad \text{weakly* in } L^{\infty}((0,T);W^{1,p^*}(\Omega,\mathbf{R}^n)), \tag{4.13}$$

$$\text{strongly in } L^2((0,T);L^2(\Omega,\mathbf{R}^n)), \tag{4.14}$$

$$\text{a.e. in } \Omega_T, \tag{4.15}$$

$$\mathbf{u}_t^{\varepsilon,\delta} \longrightarrow \mathbf{u}_t^{\varepsilon} \qquad \text{weakly in } L^2((0,T);L^2(\Omega,\mathbf{R}^n)), \tag{4.16}$$

$$|\mathbf{u}^{\varepsilon,\delta}| \longrightarrow 1 \qquad \text{strongly in } L^2((0,T);L^2(\Omega)). \tag{4.17}$$

It follows immediately from (4.15) and (4.17) that

$$|\mathbf{u}^{\varepsilon}| = 1 \qquad \text{a.e. in } \Omega_T. \tag{4.18}$$

Step 2: *Wedge product technique and passing to the limit.* Since $|\mathbf{u}^{\varepsilon,\delta}| \leq 1$ in $\overline{\Omega}_T$, an application of the Lebesgue-dominated convergence theorem yields, on noting (4.15), that

$$\mathbf{u}^{\varepsilon,\delta} \overset{\delta \searrow 0}{\longrightarrow} \mathbf{u}^{\varepsilon} \qquad \text{strongly in } L^r((0,T);L^r(\Omega,\mathbf{R}^n)) \quad \forall r \in [1,\infty). \tag{4.19}$$

Let

$$\mathbf{f}^{\varepsilon,\delta} := \frac{1}{\delta}\big(1 - |\mathbf{u}^{\varepsilon,\delta}|^2\big)\mathbf{u}^{\varepsilon,\delta} - \lambda\big(\mathbf{u}^{\varepsilon,\delta} - \mathbf{g}\big).$$

It follows from the estimate $|\mathbf{u}^{\varepsilon,\delta}| \leq 1$ and the inequality $|\mathbf{u}^{\varepsilon,\delta}| \leq \frac{1}{2}\big(1 + |\mathbf{u}^{\varepsilon,\delta}|^2\big)$ that

$$\frac{1}{\delta}\int_0^T \int_\Omega \big(1 - |\mathbf{u}^{\varepsilon,\delta}|^2\big)\,|\mathbf{u}^{\varepsilon,\delta}|\,dxdt \leq \frac{1}{\delta}\int_0^T \int_\Omega \big(1 - |\mathbf{u}^{\varepsilon,\delta}|^2\big)^2\,dxdt + \frac{1}{\delta}\int_0^T \int_\Omega \big(1 - |\mathbf{u}^{\varepsilon,\delta}|^2\big)\,|\mathbf{u}^{\varepsilon,\delta}|^2\,dxdt.$$

Inequality (3.4) immediately implies that the first term on the right-hand side is uniformly bounded in δ. Testing (1.20) by $\mathbf{u}^{\varepsilon,\delta}$ and using estimates (3.3), (3.5), and (3.6), we conclude that the second term on the right-hand side is also uniformly bounded in δ. Hence, $\mathbf{f}^{\varepsilon,\delta}$ is uniformly bounded with respect to δ in $L^1((0,T);L^1(\Omega,\mathbf{R}^n))$. By Lemma 2.2 we have that

$$\nabla\mathbf{u}^{\varepsilon,\delta} \overset{\delta \searrow 0}{\longrightarrow} \nabla\mathbf{u}^{\varepsilon} \qquad \text{strongly in } L^q((0,T);L^q(\Omega,\mathbf{R}^{n\times m})) \quad \forall q \in [1,p^*). \tag{4.20}$$

This and (3.5) imply that

$$|\nabla\mathbf{u}^{\varepsilon,\delta}|_{\varepsilon}^{p-2}\nabla\mathbf{u}^{\varepsilon,\delta} \overset{\delta \searrow 0}{\longrightarrow} |\nabla\mathbf{u}^{\varepsilon}|_{\varepsilon}^{p-2}\nabla\mathbf{u}^{\varepsilon} \tag{4.21}$$

weakly* in $L^{\infty}((0,T);L^{p'}(\Omega,\mathbf{R}^{n\times m}))$ with $p' = \frac{p}{p-1}$ if $p \neq 1$ and weakly* in $L^{\infty}((0,T);L^{\infty}(\Omega,\mathbf{R}^{n\times m}))$ if $p = 1$.

Next, taking the wedge product of (1.20) with $\mathbf{u}^{\varepsilon,\delta}$ yields

$$\mathbf{u}_t^{\varepsilon,\delta} \wedge \mathbf{u}^{\varepsilon,\delta} - \operatorname{div}\big(\mathcal{B}_p^{\varepsilon,\delta} \wedge \mathbf{u}^{\varepsilon,\delta}\big) - \lambda\,\mathbf{g} \wedge \mathbf{u}^{\varepsilon,\delta} = 0, \tag{4.22}$$

where $\mathcal{B}_p^{\varepsilon,\delta}$ is defined in (1.23).

Testing (4.22) with any $\mathbf{w} \in L^\infty((0,T);W^{1,p^*}(\Omega,\mathbf{R}^n))$ we get

$$\int_0^T \int_\Omega \Big\{ \big(\mathbf{u}_t^{\varepsilon,\delta} \wedge \mathbf{u}^{\varepsilon,\delta}\big) \cdot \mathbf{w} + \big(\mathcal{B}_p^{\varepsilon,\delta} \wedge \mathbf{u}^{\varepsilon,\delta}\big) \cdot \nabla \mathbf{w} - \lambda \big(\mathbf{g} \wedge \mathbf{u}^{\varepsilon,\delta}\big) \cdot \mathbf{w} \Big\}\, dxdt = 0. \tag{4.23}$$

It follows from setting $\delta \to 0$ in (4.23) and using (4.16), (4.19), and (4.21) that

$$\int_0^T \int_\Omega \Big\{ \big(\mathbf{u}_t^{\varepsilon} \wedge \mathbf{u}^{\varepsilon}\big) \cdot \mathbf{w} + \big(\mathcal{B}_p^{\varepsilon} \wedge \mathbf{u}^{\varepsilon}\big) \cdot \nabla \mathbf{w} - \lambda \big(\mathbf{g} \wedge \mathbf{u}^{\varepsilon}\big) \cdot \mathbf{w} \Big\}\, dxdt = 0, \tag{4.24}$$

where $\mathcal{B}_p^{\varepsilon}$ is given by (4.11).

Note that (4.18) implies

$$\mathbf{u}_t^{\varepsilon} \cdot \mathbf{u}^{\varepsilon} = 0, \qquad \big(\mathcal{B}_p^{\varepsilon}\big)^T \mathbf{u}^{\varepsilon} = 0 \qquad \text{a.e. in } \Omega_T. \tag{4.25}$$

This in turn yields the following identity

$$\int_0^T \int_\Omega \Big\{ \mathbf{u}_t^{\varepsilon} \cdot \mathbf{u}^{\varepsilon} \varphi + \mathcal{B}_p^{\varepsilon} \cdot \nabla (\mathbf{u}^{\varepsilon} \varphi) + \lambda \big(\mathbf{u}^{\varepsilon} - \mathbf{g}\big) \cdot \mathbf{u}^{\varepsilon} \varphi \Big\} dxdt = \int_0^T \int_\Omega \mu_{p,\lambda}^{\varepsilon}\, \varphi\, dxdt \tag{4.26}$$

for any $\varphi \in L^\infty(\Omega_T) \cap L^\infty((0,T);W^{1,p^*}(\Omega))$, where $\mu_{p,\lambda}^{\varepsilon}$ is defined by (4.5).

Finally, for any $\mathbf{v} \in [C^1(\overline{\Omega}_T)]^n$, taking $\mathbf{w} = \mathbf{u}^{\varepsilon} \wedge \mathbf{v}$ in (4.24), $\varphi = \mathbf{u}^{\varepsilon} \cdot \mathbf{v}$ in (4.26), and using the formula $\mathbf{a} \cdot (\mathbf{b} \wedge \mathbf{c}) = (\mathbf{a} \wedge \mathbf{b}) \cdot \mathbf{c}$ yield

$$\begin{aligned} \int_0^T \int_\Omega \Big\{ & \mathbf{u}_t^{\varepsilon} \cdot \big(\mathbf{u}^{\varepsilon} \wedge (\mathbf{u}^{\varepsilon} \wedge \mathbf{v})\big) + \mathcal{B}_p^{\varepsilon} \cdot \nabla (\mathbf{u}^{\varepsilon} \wedge (\mathbf{u}^{\varepsilon} \wedge \mathbf{v})) \\ & - \lambda\, \mathbf{g} \cdot \big(\mathbf{u}^{\varepsilon} \wedge (\mathbf{u}^{\varepsilon} \wedge \mathbf{v})\big) \Big\} dxdt = 0, \end{aligned} \tag{4.27}$$

$$\begin{aligned} \int_0^T \int_\Omega \Big\{ & \mathbf{u}_t^{\varepsilon} \cdot \mathbf{u}^{\varepsilon} (\mathbf{u}^{\varepsilon} \cdot \mathbf{v}) + \mathcal{B}_p^{\varepsilon} \cdot \nabla (\mathbf{u}^{\varepsilon} (\mathbf{u}^{\varepsilon} \cdot \mathbf{v})) \\ & + \lambda \big(\mathbf{u}^{\varepsilon} - \mathbf{g}\big) \cdot \mathbf{u}^{\varepsilon} (\mathbf{u}^{\varepsilon} \cdot \mathbf{v}) \Big\}\, dxdt = \int_0^T \int_\Omega \mu_{p,\lambda}^{\varepsilon} \mathbf{u}^{\varepsilon} \cdot \mathbf{v}\, dxdt. \end{aligned} \tag{4.28}$$

Subtracting (4.27) from (4.28) and using the identity

$$\mathbf{v} = (\mathbf{u}^{\varepsilon} \cdot \mathbf{v})\, \mathbf{u}^{\varepsilon} - \mathbf{u}^{\varepsilon} \wedge (\mathbf{u}^{\varepsilon} \wedge \mathbf{v}),$$

we obtain that

$$\int_0^T \int_\Omega \Big\{ \mathbf{u}_t^{\varepsilon} \cdot \mathbf{v} + \mathcal{B}_p^{\varepsilon} \cdot \nabla \mathbf{v} + \lambda \big(\mathbf{u}^{\varepsilon} - \mathbf{g}\big) \cdot \mathbf{v} \Big\}\, dxdt = \int_0^T \int_\Omega \mu_{p,\lambda}^{\varepsilon} \mathbf{u}^{\varepsilon} \cdot \mathbf{v}\, dxdt \tag{4.29}$$

for any $\mathbf{v} \in [C^1(\overline{\Omega}_T)]^n$. This is equivalent to saying that $\mathbf{u}^{\varepsilon}$ is a weak solution (in the distributional sense) to (4.2)–(4.4).

Step 3: *Wrapping up.* We conclude the proof by showing the estimates (4.6)–(4.10). First, (4.6) follows immediately from letting $\delta \to 0$ in (3.9), appealing to

Fatou's lemma and the lower semicontinuity of L^2- and L^{p^*}-norms with respect to L^2- and L^{p^*}-weak convergence. We emphasize again that this is possible in the case $p = 1$, because the uniform (in δ) estimate (3.6) implies that $u^\varepsilon \in L^\infty((0,T);H^1(\Omega,\mathbf{R}^n))$. Inequalities (4.7) and (4.10) are direct consequences of (4.6). Finally, the bounds (4.8) and (4.9) follow immediately from (4.29) and (4.24), respectively. Hence the proof is complete. □

Remark 4.1. If $b_p(\varepsilon) = 0$ is used in the regularization, the solutions to (4.1)–(4.4) are only expected to belong to $L^\infty((0,T);[BV(\Omega)]^n)$ in general when $p = 1$.

5. Passing to the limit as $\varepsilon \to 0$: The case $1 < p < \infty$. In this section, we shall pass to the limit as $\varepsilon \to 0$ in (4.1)–(4.4) and show that the limit map is a weak solution to (1.8)–(1.11). Since the analysis and techniques for passing the limit for $1 < p < \infty$ and $p = 1$ are quite different, we shall first consider the case $1 < p < \infty$ in this section and leave the case $p = 1$ to the next section. We begin with a definition of weak solutions to (1.8)–(1.11) in the case $1 < p < \infty$.

DEFINITION 5.1. *For $1 < p < \infty$, a map $\mathbf{u} : \Omega_T \to \mathbf{R}^n$ is called a global* weak *solution to* (1.8)–(1.11) *if*

(i) $\mathbf{u} \in L^\infty((0,T);W^{1,p}(\Omega,\mathbf{R}^n)) \cap H^1((0,T);L^2(\Omega,\mathbf{R}^n))$;

(ii) $|\,bu| = 1$ *a.e. on* Ω_T;

(iii) $\mathbf{u}$ *satisfies* (1.8)–(1.11) *in the distributional sense.*

Our main result of this section is the following existence theorem.

THEOREM 5.2. *Let $1 < p < \infty$, and suppose that the assumptions on $\mathbf{u}_0$ and $\mathbf{g}$ in Theorem* 4.1 *still hold. Then problem* (1.8)–(1.11) *has a weak solution $\mathbf{u}$ in the sense of Definition* 5.1. *Moreover, $\mathbf{u}$ satisfies the energy inequality*

$$J_{p,\lambda}(\mathbf{u}(s)) + \int_0^s \|\,\mathbf{u}_t(t)\,\|_{L^2}^2\,dt \le J_{p,\lambda}(\mathbf{u}_0) \qquad \text{for a.e. } s \in [0,T], \tag{5.1}$$

where $J_{p,\lambda}$ is defined by (1.7).

Proof. We divide the proof into three steps.

Step 1: *Extracting a convergent subsequence.* Let $\mathbf{u}^\varepsilon$ denote the solution of (4.1)–(4.4) constructed in Theorem 4.1. From (4.1), (4.6)–(4.10), the weak compactness of $W^{1,p}(\Omega)$, and Sobolev embedding (cf. [1, 45]), there exists a subsequence of $\{\mathbf{u}^\varepsilon\}_{\varepsilon>0}$ (still denoted by the same notation) and a map $\mathbf{u} \in L^\infty((0,T);W^{1,p}(\Omega,\mathbf{R}^n)) \cap H^1((0,T);L^2(\Omega,\mathbf{R}^n))$ such that as $\varepsilon \to 0$

$$\mathbf{u}^\varepsilon \longrightarrow \mathbf{u} \qquad \text{weakly* in } L^\infty((0,T);W^{1,p}(\Omega,\mathbf{R}^n)), \tag{5.2}$$

$$\text{strongly in } L^2((0,T);L^p(\Omega,\mathbf{R}^n)), \tag{5.3}$$

$$\text{a.e. in } \Omega_T, \tag{5.4}$$

$$b_p(\varepsilon)\nabla\mathbf{u}^\varepsilon \longrightarrow 0 \qquad \text{weakly in } L^2((0,T);L^2(\Omega,\mathbf{R}^{n\times m})), \tag{5.5}$$

$$\mathbf{u}_t^\varepsilon \longrightarrow \mathbf{u}_t \qquad \text{weakly in } L^2((0,T);L^2(\Omega,\mathbf{R}^n)). \tag{5.6}$$

It follows immediately from (5.4) and (4.18) that

$$|\mathbf{u}| = 1 \qquad \text{a.e. in } \Omega_T. \tag{5.7}$$

Step 2: *Passing to the limit.* First, by (5.4) and the Lebesgue-dominated convergence theorem we have that

$$\mathbf{u}^\varepsilon \overset{\varepsilon\searrow 0}{\longrightarrow} \mathbf{u} \qquad \text{strongly in } L^r((0,T);L^r(\Omega,\mathbf{R}^n)) \quad \forall r \in [1,\infty). \tag{5.8}$$

Next, let $\mathbf{f}^\varepsilon := \mu_{p,\lambda}^\varepsilon \mathbf{u}^\varepsilon - \lambda(\mathbf{u}^\varepsilon - \mathbf{g})$. Clearly, $\mathbf{f}^\varepsilon \in L^1((0,T);L^1(\Omega;\mathbf{R}^n))$ and is uniformly bounded, on noting (4.5)–(4.6). By Lemma 2.3 we get

$$\nabla \mathbf{u}^\varepsilon \overset{\varepsilon\searrow 0}{\longrightarrow} \nabla \mathbf{u} \qquad \text{strongly in } L^q((0,T);L^q(\Omega,\mathbf{R}^{n\times m})) \quad \forall q\in[1,p), \tag{5.9}$$

which, using (4.7) and (5.5), implies that

$$|\nabla \mathbf{u}^\varepsilon|_\varepsilon^{p-2}\nabla \mathbf{u}^\varepsilon \overset{\varepsilon\searrow 0}{\longrightarrow} |\nabla \mathbf{u}|^{p-2}\nabla \mathbf{u} \quad \text{weakly* in } L^\infty((0,T);L^{p'}(\Omega,\mathbf{R}^{n\times m})), \tag{5.10}$$

$$\mathcal{B}_p^\varepsilon \overset{\varepsilon\searrow 0}{\longrightarrow} \mathcal{B}_p := |\nabla \mathbf{u}|^{p-2}\nabla \mathbf{u} \quad \text{weakly in } L^2((0,T);L^{p'_*}(\Omega,\mathbf{R}^{n\times m})), \tag{5.11}$$

where $p' = \frac{p}{p-1}$ and $p'_* := \min\{2,p'\}$.

It then follows from taking $\varepsilon\to 0$ in (4.24) and using (5.6), (5.8), and (5.11) that

$$\int_0^T\int_\Omega \Big\{ \big(\mathbf{u}_t \wedge \mathbf{u}\big)\cdot \mathbf{w} + \big(\mathcal{B}_p \wedge \mathbf{u}\big)\cdot \nabla \mathbf{w} - \lambda\big(\mathbf{g}\wedge \mathbf{u}\big)\cdot \mathbf{w}\Big\}\, dxdt = 0 \tag{5.12}$$

for any $\mathbf{w}\in C^1(\overline{\Omega}_T)$. Since $\mathcal{B}_p \in L^\infty((0,T);L^{p'}(\Omega,\mathbf{R}^{n\times m}))$, by the standard density argument one can show that (5.12) also holds for all $\mathbf{w}\in L^\infty((0,T);W^{1,p}(\Omega,\mathbf{R}^n))\cap L^\infty(\Omega_T)$.

Since $|\mathbf{u}| = 1$ a.e. in Ω_T, there holds the following identity, which is analogous to (4.26):

$$\int_0^T\int_\Omega \Big\{ \mathbf{u}_t\cdot \mathbf{u}\varphi + \mathcal{B}_p\cdot\nabla(\mathbf{u}\varphi) + \lambda\big(\mathbf{u}-\mathbf{g}\big)\cdot \mathbf{u}\varphi\Big\}\, dxdt = \int_0^T\int_\Omega \mu_{p,\lambda}\varphi\, dxdt \tag{5.13}$$

for any $\varphi\in L^\infty(\Omega_T)\cap L^\infty((0,T);W^{1,p}(\Omega,\mathbf{R}^n))$, where $\mu_{p,\lambda}$ is defined by (1.12).

Finally, for any $\mathbf{v}\in [C^1(\overline{\Omega}_T)]^n$, on choosing $\mathbf{w} = \mathbf{u}\wedge\mathbf{v}$ in (5.12) and $\varphi = \mathbf{u}\cdot\mathbf{v}$ in (5.13), subtracting the resulting equations, and using the identity

$$\mathbf{v} = (\mathbf{u}\cdot\mathbf{v})\,\mathbf{u} - \mathbf{u}\wedge(\mathbf{u}\wedge\mathbf{v}),$$

we obtain that

$$\int_0^T\int_\Omega \Big\{ \mathbf{u}_t\cdot\mathbf{v} + \mathcal{B}_p\cdot\nabla\mathbf{v} + \lambda\big(\mathbf{u}-\mathbf{g}\big)\cdot\mathbf{v}\Big\}\, dxdt = \int_0^T\int_\Omega \mu_{p,\lambda}\mathbf{u}\cdot\mathbf{v}\, dxdt \tag{5.14}$$

for any $\mathbf{v}\in[C^1(\overline{\Omega}_T)]^n$. Hence, $\mathbf{u}$ is a weak solution to (1.8)–(1.11).

Step 3: *Wrapping up.* We conclude the proof by showing the energy inequality (5.1). First, notice that (4.6) implies that

$$\int_\Omega \Big\{\frac{1}{p}|\nabla \mathbf{u}^\varepsilon(s)|^p + \frac{\lambda}{2}|\mathbf{u}^\varepsilon(s)-\mathbf{g}|^2\Big\}dx + \int_0^s \|\,\mathbf{u}_t^\varepsilon(t)\,\|_{L^2}^2\, dt \le J_{p,\lambda}^\varepsilon(\mathbf{u}_0) \quad \forall s\in[0,T]. \tag{5.15}$$

Then (5.1) follows from taking $\varepsilon\to 0$ in (5.15) and using Fatou's lemma and the lower semicontinuity of the L^p-norm with respect to L^p-weak convergence. The proof is complete. □

Remark 5.1. (a) We remark that it was proved in [15, 32, 41] that weak solutions to (1.8)–(1.11) are not unique in general.

(b) Although the above proof is carried out for any $\alpha>0$ in the definition of $b_p(\varepsilon)$ (cf. (1.15)), α should be chosen large enough so that the error due to the perturbation

term $b_p(\varepsilon)\Delta$ is much smaller than the error due to other regularization terms in numerical simulations.

(c) The existence result of Theorem 5.2 is established under the assumption $\mathbf{u}_0 \in W^{1,p*}(\Omega,\mathbf{R}^n)$ with $p* = \max\{p,2\}$. This condition can be weakened to $\mathbf{u}_0 \in W^{1,p}(\Omega,\mathbf{R}^n)$ in the case $1 < p < 2$ by a smoothing technique.

6. Passing to the limit as $\varepsilon \to 0$: The case $p = 1$. In this section, we consider the case $p = 1$ and establish the existence of global weak solutions for the 1-harmonic map heat flow (1.8)–(1.11) by passing to the limit as $\varepsilon \to 0$ in (4.2)–(4.4). There are two main difficulties which prevent one from repeating the analysis and techniques of the previous section. First, the compactness result of Lemma 2.3 no longer holds when $p = 1$. Second, since the sequence $\{\mathbf{u}^\varepsilon\}_{\varepsilon>0}$ is uniformly bounded only in $L^\infty((0,T);[W^{1,1}(\Omega)\cap L^\infty(\Omega)]^n)$, and $W^{1,1}(\Omega,\mathbf{R}^n)$ is not a reflexive Banach space, hence the limiting map $\mathbf{u}$ now belongs to $L^\infty((0,T);[BV(\Omega)\cap L^\infty(\Omega)]^n)$; i.e., $\mathbf{u}(t)$ is only a map of bounded variation. As expected, these two difficulties make the passage to the limit as $\varepsilon \to 0$ more difficult and delicate.

6.1. Technical tools and lemmas. In this subsection, we shall cite some technical tools and lemmas in order to develop a weak solution concept to be given in the next subsection for the 1-harmonic map heat flow. Specifically, we need the pairings $\mathcal{A}\cdot D\mathbf{v}$ and $\mathcal{A}\wedge D\mathbf{v}$ between a tensor field $\mathcal{A}$ and a BV-vector field $\mathbf{v}$ as a generalization of the pairing $\mathbf{b}\cdot Dv$ between a vector field $\mathbf{b}$ and a BV-function v developed in [4, 10]. The proofs of the key results in achieving this can be found in [23], where an extension of the theory for the 1-harmonic case studied in this section is developed for a general linear growth functional on the gradient.

We recall from [23] the space of *divergence-L^q tensors*

$$\mathcal{Y}(\Omega)_q := \{\mathcal{A}\in L^\infty(\Omega;\mathbf{R}^{n\times m});\ \mathrm{div}\mathcal{A}\in L^q(\Omega;\mathbf{R}^n)\}\qquad \text{for } 1\le q<\infty, \tag{6.1}$$

and that $\mathcal{A}\cdot D\mathbf{v}$ and $\mathcal{A}\wedge D\mathbf{v}$ are defined as follows.

Definition 6.1. *For any $\mathcal{A}\in\mathcal{Y}(\Omega)_1$ and $\mathbf{v}\in[BV(\Omega)\cap L^\infty(\Omega)]^n$, we define $\mathcal{A}\cdot D\mathbf{v}$ and $\mathcal{A}\wedge D\mathbf{v}$ to be the functionals on $C_0^\infty(\Omega)$ and $[C_0^\infty(\Omega)]^n$, respectively, by*

$$\langle \mathcal{A}\cdot D\mathbf{v},\psi\rangle := -\int_\Omega (\mathcal{A}^T\mathbf{v})\cdot\nabla\psi\,dx - \int_\Omega (\mathrm{div}\mathcal{A}\cdot\mathbf{v})\psi\,dx \quad \forall\psi\in C_0^\infty(\Omega), \tag{6.2}$$

$$\langle \mathcal{A}\wedge D\mathbf{v},\mathbf{w}\rangle := -\int_\Omega (\mathcal{A}\wedge\mathbf{v})\cdot\nabla\mathbf{w}\,dx - \int_\Omega (\mathrm{div}\mathcal{A}\wedge\mathbf{v})\cdot\mathbf{w}\,dx \quad \forall\mathbf{w}\in[C_0^\infty(\Omega)]^n, \tag{6.3}$$

where $\mathcal{A}^T$ stands for the matrix transpose of $\mathcal{A}$ and the notation (2.4) *is used in* (6.3).

We now list some properties of the pairings $\mathcal{A}\cdot D\mathbf{v}$ and $\mathcal{A}\wedge D\mathbf{v}$ and refer to section 2 of [23] for their proofs. The first lemma declares that $\mathcal{A}\cdot D\mathbf{v}$ and $\mathcal{A}\wedge D\mathbf{v}$ are Radon measures in Ω.

Lemma 6.2. *For any Borel set $E\subset\Omega$, there hold*

$$\big|\langle\mathcal{A}\cdot D\mathbf{v},\psi\rangle\big| \le \max_{x\in E}|\psi(x)|\cdot\|\,\mathcal{A}\,\|_{L^\infty(E,\mathbf{R}^{n\times m})}\cdot|D\mathbf{v}|(E)\quad\forall\psi\in C_0(E),$$

$$\big|\langle\mathcal{A}\wedge D\mathbf{v},\mathbf{w}\rangle\big| \le \max_{x\in E}|\mathbf{w}(x)|\cdot\|\,\mathcal{A}\,\|_{L^\infty(E,\mathbf{R}^{n\times m})}\cdot|D\mathbf{v}|(E)\quad\forall\mathbf{w}\in[C_0(E)]^n.$$

Hence, it follows from the Riesz theorem (cf. Theorem 1.54 *of* [3]*) that both functionals $\mathcal{A}\cdot D\mathbf{v}$ and $\mathcal{A}\wedge D\mathbf{v}$ are Radon measures in Ω.*

COROLLARY 6.3. *The measures $\mathcal{A}\cdot D\mathbf{v}$, $|\mathcal{A}\cdot D\mathbf{v}|$, $\mathcal{A}\wedge D\mathbf{v}$, and $|\mathcal{A}\wedge D\mathbf{v}|$ all are absolutely continuous with respect to the measure $|D\mathbf{v}|$ in Ω. Moreover, there hold inequalities*

$$\big|(\mathcal{A}\cdot D\mathbf{v})(E)\big| \le \big|\mathcal{A}\cdot D\mathbf{v}\big|(E) \le \|\,\mathcal{A}\,\|_{L^\infty(E',\mathbf{R}^{n\times m})}\cdot|D\mathbf{v}|(E), \tag{6.4}$$

$$\big|(\mathcal{A}\wedge D\mathbf{v})(E)\big| \le \big|\mathcal{A}\wedge D\mathbf{v}\big|(E) \le \|\,\mathcal{A}\,\|_{L^\infty(E',\mathbf{R}^{n\times m})}\cdot|D\mathbf{v}|(E) \tag{6.5}$$

for all Borel sets E and for all open sets E' such that $E\subset E'\subset\Omega$.

Hence, by the Radon–Nikodým theorem (cf. Theorem 1.28 *of* [3]*), there exist $|D\mathbf{v}|$-measurable functions $\Theta:=\Theta(\mathcal{A},D\mathbf{v},x):\Omega\to\mathbf{R}$ and $\Lambda:=\Lambda(\mathcal{A},D\mathbf{v},x):\Omega\to\mathbf{R}^n$ such that*

$$(\mathcal{A}\cdot D\mathbf{v})(E)=\int_E\Theta\,d|D\mathbf{v}| \quad \textit{and} \quad \|\,\Theta\,\|_{L^\infty(\Omega,|D\mathbf{v}|)}\le\|\,\mathcal{A}\,\|_{L^\infty(\Omega,\mathbf{R}^{n\times m})}, \tag{6.6}$$

$$(\mathcal{A}\wedge D\mathbf{v})(E)=\int_E\Lambda\,d|D\mathbf{v}| \quad \textit{and} \quad \|\,\Lambda\,\|_{L^\infty(\Omega,|D\mathbf{v}|)}\le\|\,\mathcal{A}\,\|_{L^\infty(\Omega,\mathbf{R}^{n\times m})} \tag{6.7}$$

for all Borel sets $E\subset\Omega$.

The second lemma declares that every $\mathcal{A}\in\mathcal{Y}(\Omega)_1$ has a well-behaved *traction* $\mathcal{A}\mathbf{n}$ on the boundary of a Lipschitz domain Ω.

LEMMA 6.4. *Let Ω be a bounded domain with a Lipschitz continuous boundary $\partial\Omega$ in $\mathbf{R}^m$. Then there exists a linear operator $\beta:\mathcal{Y}(\Omega)_1\to L^\infty(\partial\Omega;\mathbf{R}^n)$ such that*

$$\|\,\beta(\mathcal{A})\,\|_{L^\infty(\partial\Omega,\mathbf{R}^n)}\le\|\,\mathcal{A}\,\|_{L^\infty(\Omega,\mathbf{R}^{n\times m})}, \tag{6.8}$$

$$\langle\mathcal{A},\mathbf{v}\rangle_{\partial\Omega}=\int_{\partial\Omega}\beta(\mathcal{A})(x)\,\mathbf{v}(x)\,d\mathcal{H}^{m-1} \quad \forall\mathbf{v}\in[BV(\Omega)\cap L^\infty(\Omega)]^n, \tag{6.9}$$

$$\beta(\mathcal{A})(x)=\mathcal{A}(x)\mathbf{n}(x) \qquad \forall x\in\partial\Omega,\ \mathcal{A}\in C^1(\overline{\Omega},\mathbf{R}^{n\times m}). \tag{6.10}$$

Remark 6.1. Since $\beta(\mathcal{A})$ is a weakly defined traction of $\mathcal{A}$ on $\partial\Omega$, hence we shall use $\mathcal{A}\mathbf{n}$ to denote $\beta(\mathcal{A})$ in the rest of this section.

The third lemma declares that the following hold.

LEMMA 6.5. *Let Ω be a bounded domain with a Lipschitz continuous boundary $\partial\Omega$ in $\mathbf{R}^m$. Then for any $\mathcal{A}\in\mathcal{Y}(\Omega)_1$ and $\mathbf{v}\in[BV(\Omega)\cap L^\infty(\Omega)]^n$ there hold the identities*

$$\int_\Omega \mathrm{div}\mathcal{A}\cdot\mathbf{v}\,dx+(\mathcal{A}\cdot D\mathbf{v})(\Omega)=\int_{\partial\Omega}\mathcal{A}\mathbf{n}\cdot\mathbf{v}\,d\mathcal{H}^{m-1}, \tag{6.11}$$

$$\int_\Omega \mathrm{div}\mathcal{A}\wedge\mathbf{v}\,dx+(\mathcal{A}\wedge D\mathbf{v})(\Omega)=\int_{\partial\Omega}\mathcal{A}\mathbf{n}\wedge\mathbf{v}\,d\mathcal{H}^{m-1}. \tag{6.12}$$

Lemmas 6.6 and 6.7 state continuity results for the measure $\mathcal{A}\cdot D\mathbf{v}$ and $\mathcal{A}\wedge D\mathbf{v}$ with respect to $\mathcal{A}$ and $\mathbf{v}$, respectively.

LEMMA 6.6. *Let $\mathcal{A}_j,\mathcal{A}\in\mathcal{Y}(\Omega)_1$ and suppose that*

$$\mathcal{A}_j\longrightarrow\mathcal{A} \quad \textit{weakly}* \textit{ in } L^\infty(E),$$

$$\mathrm{div}\mathcal{A}_j\longrightarrow\mathrm{div}\mathcal{A} \quad \textit{weakly in } L^1(E)$$

for all open sets $E \subset\subset \Omega$. Then for all $\mathbf{v} \in [BV(\Omega) \cap L^\infty(\Omega)]^n$ the following hold:

$$\mathcal{A}_j \cdot D\mathbf{v} \longrightarrow \mathcal{A} \cdot D\mathbf{v} \quad \textit{weakly}* \textit{ in } \mathcal{M}(\Omega), \tag{6.13}$$

$$\mathcal{A}_j \wedge D\mathbf{v} \longrightarrow \mathcal{A} \wedge D\mathbf{v} \quad \textit{weakly}* \textit{ in } [\mathcal{M}(\Omega)]^n \tag{6.14}$$

and

$$\Theta(\mathcal{A}_j, D\mathbf{v}, \cdot) \longrightarrow \Theta(\mathcal{A}, D\mathbf{v}, \cdot) \quad \textit{weakly}* \textit{ in } L^\infty(E)\, \forall E \subset\subset \Omega, \tag{6.15}$$

$$\Lambda(\mathcal{A}_j, D\mathbf{v}, \cdot) \longrightarrow \Lambda(\mathcal{A}, D\mathbf{v}, \cdot) \quad \textit{weakly}* \textit{ in } [L^\infty(E)]^n\, \forall E \subset\subset \Omega. \tag{6.16}$$

Here "$E \subset\subset \Omega$" means that E is compactly contained in Ω; that is, $E \subset \overline{E} \subset \Omega$ and $\overline{E}$ is compact.

LEMMA 6.7. *Let $\mathcal{A} \in \mathcal{Y}(\Omega)_1$ and $\mathbf{v} \in [BV(\Omega) \cap L^\infty(\Omega)]^n$. Suppose that $\{\mathbf{v}_j\} \subset [C^\infty(\Omega) \cap BV(\Omega)]^n$ strictly converges to $\mathbf{v}$ (cf. Definition* 3.14 *of* [3]*). Then*

$$\mathcal{A} \cdot D\mathbf{v}_j \longrightarrow \mathcal{A} \cdot D\mathbf{v} \quad \textit{weakly}* \textit{ in } \mathcal{M}(\Omega), \tag{6.17}$$

$$\mathcal{A} \wedge D\mathbf{v}_j \longrightarrow \mathcal{A} \wedge D\mathbf{v} \quad \textit{weakly}* \textit{ in } [\mathcal{M}(\Omega)]^n. \tag{6.18}$$

Moreover,

$$\int_\Omega \mathcal{A} \cdot D\mathbf{v}_j \, dx \longrightarrow \int_\Omega \mathcal{A} \cdot D\mathbf{v}, \tag{6.19}$$

$$\int_\Omega \mathcal{A} \wedge D\mathbf{v}_j \, dx \longrightarrow \int_\Omega \mathcal{A} \wedge D\mathbf{v}. \tag{6.20}$$

Lemma 6.8 gives the precise representations for the density functions Θ and Λ defined in Corollary 6.3.

LEMMA 6.8. (i) *If $\mathcal{A} \in \mathcal{Y}(\Omega)_1 \cap C(\Omega, \mathbf{R}^{n\times m})$ and $\mathbf{v} \in [BV(\Omega) \cap L^\infty(\Omega)]^n$, then there hold*

$$\Theta(\mathcal{A}, D\mathbf{v}, x) = \mathcal{A}(x) \cdot \frac{D\mathbf{v}}{|D\mathbf{v}|}(x), \qquad \Lambda(\mathcal{A}, D\mathbf{v}, x) = \mathcal{A}(x) \wedge \frac{D\mathbf{v}}{|D\mathbf{v}|}(x) \tag{6.21}$$

for $|D\mathbf{v}|$ a.e. in Ω.

(ii) *If $\mathcal{A} \in \mathcal{Y}(\Omega)_1$ and $\mathbf{v} \in [BV(\Omega) \cap L^\infty(\Omega)]^n$, then there hold*

$$\Theta(\mathcal{A}, D\mathbf{v}, x) = \mathcal{A}(x) \cdot \frac{D\mathbf{v}}{|D\mathbf{v}|}(x), \qquad \Lambda(\mathcal{A}, D\mathbf{v}, x) = \mathcal{A}(x) \wedge \frac{D\mathbf{v}}{|D\mathbf{v}|}(x) \tag{6.22}$$

for $|D\mathbf{v}|^a$ a.e. in Ω, where $\frac{D\mathbf{v}}{|D\mathbf{v}|}$ denotes the density function of the measure $D\mathbf{v}$ with respect to the measure $|D\mathbf{v}|$, and $|D\mathbf{v}|^a$ denotes the absolute continuous part of the measure $|D\mathbf{v}|$ with respect to the Lebesgue measure $\mathcal{L}^n$.

Next, we recall from [23] the space of *divergence-measure tensors*

$$\mathcal{DT}(\Omega) := \left\{ \mathcal{A} \in L^\infty(\Omega, \mathbf{R}^{n\times m}); \operatorname{div}\mathcal{A} \in [\mathcal{M}(\Omega)]^n \right\} \tag{6.23}$$

and briefly discuss two of its important properties. First, as in the case of the space of the divergence-L^1 tensors $\mathcal{Y}(\Omega)_1$, Definition 6.1 is still valid for $\mathcal{A} \in \mathcal{DT}(\Omega)$ and $\mathbf{v} \in [BV(\Omega) \cap L^\infty(\Omega) \cap C(\Omega)]^n$ (cf. [4]). Second, there is a well-behaved traction $\mathcal{A}\mathbf{n}$ for every $\mathcal{A} \in \mathcal{DT}(\Omega)$.

LEMMA 6.9. *Let Ω be a bounded domain with Lipschitz continuous boundary $\partial\Omega$ in $\mathbf{R}^m$. Then there exists a linear operator $\alpha : \mathcal{DT}(\Omega) \to L^\infty(\partial\Omega; \mathbf{R}^n)$ such that*

$$\| \alpha(\mathcal{A}) \|_{L^\infty(\partial\Omega, \mathbf{R}^n)} \le \| \mathcal{A} \|_{L^\infty(\Omega, \mathbf{R}^{n\times m})}, \tag{6.24}$$

$$\langle \mathcal{A}, \mathbf{v} \rangle_{\partial\Omega} = \int_{\partial\Omega} \alpha(\mathcal{A})(x)\, \mathbf{v}(x)\, d\mathcal{H}^{m-1} \qquad \forall \mathbf{v} \in [BV(\Omega) \cap L^\infty(\Omega) \cap C(\Omega)]^n, \tag{6.25}$$

$$\alpha(\mathcal{A})(x) = \mathcal{A}(x)\mathbf{n}(x) \qquad \forall x \in \partial\Omega,\ \mathcal{A} \in C^1(\overline{\Omega}, \mathbf{R}^{n\times m}). \tag{6.26}$$

Moreover, for any $\mathcal{A} \in \mathcal{DT}(\Omega)$ and $\mathbf{v} \in [BV(\Omega) \cap L^\infty(\Omega) \cap C(\Omega)]^n$, let $\mathcal{A}\mathbf{n} := \alpha(\mathcal{A})$ on $\partial\Omega$. Then there hold the following Green's formulas:

$$(\mathrm{div}\mathcal{A} \cdot \mathbf{v})(\Omega) + (\mathcal{A} \cdot D\mathbf{v})(\Omega) = \int_{\partial\Omega} \mathcal{A}\mathbf{n} \cdot \mathbf{v}\, d\mathcal{H}^{m-1}, \tag{6.27}$$

$$(\mathrm{div}\mathcal{A} \wedge \mathbf{v})(\Omega) + (\mathcal{A} \wedge D\mathbf{v})(\Omega) = \int_{\partial\Omega} \mathcal{A}\mathbf{n} \wedge \mathbf{v}\, d\mathcal{H}^{m-1}. \tag{6.28}$$

Third, the following product rule holds.

LEMMA 6.10. *For any $\mathcal{A} \in \mathcal{DT}(\Omega)$ and $\mathbf{v} \in [BV(\Omega) \cap L^\infty(\Omega)]^n$, the identities*

$$\mathrm{div}(\mathcal{A}^T\mathbf{v}) = (\mathrm{div}\mathcal{A}) \cdot \overline{\mathbf{v}} + \overline{\mathcal{A} \cdot D\mathbf{v}}, \tag{6.29}$$

$$\mathrm{div}(\mathcal{A} \wedge \mathbf{v}) = (\mathrm{div}\mathcal{A}) \wedge \overline{\mathbf{v}} + \overline{\mathcal{A} \wedge D\mathbf{v}} \tag{6.30}$$

hold in the sense of Radon measures in Ω, where $\overline{\mathbf{v}}$ denotes the limit of a mollified sequence for $\mathbf{v}$ through a positive symmetric mollifier, and $\overline{\mathcal{A} \cdot D\mathbf{v}}$ (resp., $\overline{\mathcal{A} \wedge D\mathbf{v}}$) is a Radon measure which is absolutely continuous with respect to the measure $|D\mathbf{v}|$, and whose absolutely continuous part $(\overline{\mathcal{A} \cdot D\mathbf{v}})^a$ (resp., $(\overline{\mathcal{A} \wedge D\mathbf{v}})^a$) with respect to the Lebesgue measure $\mathcal{L}^m$ in Ω coincides with $\mathcal{A} \cdot (\nabla\mathbf{v})^a$ (resp., $\mathcal{A} \wedge (\nabla\mathbf{v})^a$) a.e. in Ω, that is, $(\overline{\mathcal{A} \cdot D\mathbf{v}})^a = \mathcal{A} \cdot (\nabla\mathbf{v})^a$ (resp., $(\overline{\mathcal{A} \wedge D\mathbf{v}})^a = \mathcal{A} \wedge (\nabla\mathbf{v})^a$) for $\mathcal{L}^m$ a.e. in Ω.

Remark 6.2. Equations (6.29) and (6.30) hold without all the overbars if either $\mathbf{v} \in [BV(\Omega) \cap L^\infty(\Omega) \cap C(\Omega)]^n$ or $\mathcal{A} \in \mathcal{Y}(\Omega)_1$.

Remark 6.3. It should be noted that the results of Lemmas 6.6–6.8 also hold for the tensor fields in $\mathcal{DT}(\Omega)$ and the vector fields in $[BV(\Omega) \cap L^\infty(\Omega) \cap C(\Omega)]^n$.

6.2. Existence of weak solutions of 1-harmonic map heat flow. Throughout the rest of this paper we let $B_1(\mathbf{R}^{n\times m})$ denote the unit ball in the Euclidean space $\mathbf{R}^{n\times m}$; that is,

$$B_1(\mathbf{R}^{n\times m}) = \Big\{ \mathcal{A} \in \mathbf{R}^{n\times m};\ |\mathcal{A}| := \Big(\sum_{j=1}^{m} \sum_{i=1}^{n} \mathcal{A}_{ij}^2 \Big)^{\frac{1}{2}} \le 1 \Big\}.$$

In addition, let

$$\sigma_\lambda^\varepsilon := \mu_{1,\lambda}^\varepsilon \mathbf{u}^\varepsilon, \qquad \mathcal{B}^\varepsilon := \frac{\nabla\mathbf{u}^\varepsilon}{|\nabla\mathbf{u}^\varepsilon|_\varepsilon}.$$

Hence $\mathcal{B}_1^\varepsilon = b_1(\varepsilon)\nabla\mathbf{u}^\varepsilon + \mathcal{B}^\varepsilon$ (cf. (4.11)).

We now give a definition of weak solutions to (1.8)–(1.11) in the case $p = 1$.

DEFINITION 6.11. *For $p = 1$, a map $\mathbf{u} : \Omega_T \to \mathbf{R}^n$ is called a global* weak *solution to* (1.8)–(1.11) *if there exists a tensor (or matrix-valued function) $\mathcal{B}$ such that*

(i) $\mathbf{u} \in L^\infty((0,T);[BV(\Omega)\cap L^\infty(\Omega)]^n)\cap H^1((0,T);L^2(\Omega,\mathbf{R}^n))$;
(ii) $|\mathbf{u}| = 1$ *for* $\mathcal{L}^{m+1}$ *a.e. in* Ω_T;
(iii) $\mathcal{B} \in L^\infty((0,T);L^\infty(\Omega,B_1(\mathbf{R}^{n\times m})))\cap L^2((0,T);\mathcal{DT}(\Omega))$;
(iv) $\mathbf{u}$ *and* $\mathcal{B}$ *satisfy* $\mathcal{B}\wedge\mathbf{u}\in L^2((0,T);\mathcal{Y}(\Omega)_2)$, $\mathcal{B}^T\mathbf{u}=0$, *and* $\mathcal{B}\cdot(D\mathbf{u})^a = |D\mathbf{u}|^a$ *for* $\mathcal{L}^{m+1}$ *a.e. in* Ω_T;
(v) $\mathcal{B}\mathbf{n} = 0$ *on* $\partial\Omega_T$ *in the sense of Lemma* 6.9;
(vi) *there holds the identity*

$$\int_0^T\int_\Omega \Big\{\mathbf{u}_t\cdot\mathbf{v} + \mathcal{B}\cdot\nabla\mathbf{v} + \lambda(\mathbf{u}-\mathbf{g})\cdot\mathbf{v}\Big\}\,dxdt = \int_0^T\Big(\int_\Omega \mathbf{v}\,d\sigma_\lambda\Big)\,dt$$

for any $\mathbf{v}\in[C^1(\overline{\Omega}_T)]^n$, *where* σ_λ *denotes the vector-valued Radon measure*

$$\sigma_\lambda = (\mathcal{B}\wedge\mathbf{u})\wedge D\mathbf{u} + \lambda\,(1-\mathbf{g}\cdot\mathbf{u})\,\mathbf{u}. \tag{6.31}$$

Moreover, the Radon measure $(\mathcal{B}\wedge\mathbf{u})\wedge D\mathbf{u}$ *is absolutely continuous with respect to the measure* $|D\mathbf{u}|$, *and for* $\mathcal{L}^1$ *a.e.* $t\in(0,T)$ *there exists a function* $\Phi(\mathcal{B},D\mathbf{u},x,t):\Omega\to\mathbf{R}$ *such that*

$$((\mathcal{B}\wedge\mathbf{u})\wedge D\mathbf{u})(E) = \int_E \Phi(\mathcal{B}\wedge\mathbf{u},D\mathbf{u},x,t)\,d|D\mathbf{u}| \quad \textit{for all Borel sets } E\subset\Omega,$$

$$\|\,\Phi(t)\,\|_{L^\infty(\Omega,|D\mathbf{u}|)} \le \|\,\mathcal{B}(t)\,\|_{L^\infty(\Omega,\mathbf{R}^{n\times m})} \quad \textit{for } \mathcal{L}^1 \textit{ a.e. } t\in(0,T),$$

$$\Phi(\mathcal{B}\wedge\mathbf{u},D\mathbf{u},x,t) = (\mathcal{B}(t)\wedge\mathbf{u})\wedge\frac{D\mathbf{u}}{|D\mathbf{u}|} \quad \textit{for } |D\mathbf{u}|^a \textit{ a.e. in } \Omega,\ \mathcal{L}^1 \textit{ a.e. } t\in(0,T),$$

$$((\mathcal{B}\wedge\mathbf{u})\wedge D\mathbf{u})^a = (\mathcal{B}\wedge\mathbf{u})\wedge(D\mathbf{u})^a = |D\mathbf{u}|^a\mathbf{u} \quad \textit{for } \mathcal{L}^{m+1} \textit{ a.e. in } \Omega_T.$$

Remark 6.4. (a) The tensor field $\mathcal{B}$ extends $\frac{D\mathbf{u}}{|D\mathbf{u}|}$ as a calibration across the gulfs.

(b) If $\mathbf{u}(t)\in W^{1,1}_{\rm loc}(\Omega)$ and $\mathcal{B}(t)\in\mathcal{Y}(\Omega)_1$, using (ii) and (iv) and the identity $(\mathbf{a}\wedge\mathbf{b})\wedge\mathbf{c} = (\mathbf{a}\cdot\mathbf{c})\mathbf{b} - (\mathbf{b}\cdot\mathbf{c})\mathbf{a}$ we get that $(\mathcal{B}\wedge\mathbf{u})\wedge D\mathbf{u} = |\nabla\mathbf{u}|\,\mathbf{u}$. Hence, (6.31) can be rewritten as

$$\sigma_\lambda = |\nabla\mathbf{u}|\,\mathbf{u} + \lambda\,(1-\mathbf{g}\cdot\mathbf{u})\,\mathbf{u}. \tag{6.32}$$

Thus, (6.31) is a weak form of (6.32) since $|D\mathbf{u}|\,\mathbf{u}$ may not be defined for $\mathbf{u}(t)\in[BV(\Omega)\cap L^\infty(\Omega)]^n$ and $\mathcal{B}(t)\in\mathcal{DT}(\Omega)$.

Our main result of this section is the following existence theorem.

THEOREM 6.12. *Let* $p=1$, *and suppose that* $\mathbf{u}_0\in H^1(\Omega,\mathbf{R}^n)$ *and* $\mathbf{g}\in L^2(\Omega,\mathbf{R}^n)$ *with* $|\mathbf{u}_0| = 1$ *and* $|\mathbf{g}|\le 1$ *a.e. in* Ω. *Then problem* (1.8)–(1.11) *has a global weak solution* $\mathbf{u}$ *in the sense of Definition* 6.11. *Moreover,* $\mathbf{u}$ *satisfies the energy inequality*

$$I_\lambda(\mathbf{u}(s)) + \int_0^s \|\,\mathbf{u}_t(t)\,\|_{L^2}^2\,dt \le I_\lambda(\mathbf{u}_0) \qquad \textit{for a.e. } s\in[0,T], \tag{6.33}$$

where

$$I_\lambda(\mathbf{u}) := |D\mathbf{u}|(\Omega) + \frac{\lambda}{2}\int_\Omega |\mathbf{u}-\mathbf{g}|^2\,dx. \tag{6.34}$$

Proof. The proof is divided into four steps.

Step 1: *Extracting a convergent subsequence and passing to the limit.* Let $\mathbf{u}^\varepsilon$ denote the solution of (4.1)–(4.4) constructed in Theorem 4.1. It follows from (4.1), (4.6), (4.7), and (4.8) that $\{\mathbf{u}^\varepsilon\}_{\varepsilon>0}$ is uniformly bounded in $L^\infty((0,T);[W^{1,1}(\Omega)\cap L^\infty(\Omega)]^n)\cap H^1((0,T);L^2(\Omega,\mathbf{R}^n))$, $\{\mathcal{B}^\varepsilon\}_{\varepsilon>0}$ in $L^\infty((0,T);L^\infty(\Omega,B_1(\mathbf{R}^{n\times m})))$, and $\{\mathrm{div}\mathcal{B}_1^\varepsilon\}_{\varepsilon>0}$ in $L^2((0,T);L^1(\Omega;\mathbf{R}^n))$, and $\{\sigma_\lambda^\varepsilon\}_{\varepsilon>0}$ is uniformly bounded in $L^\infty((0,T);L^1(\Omega,\mathbf{R}^n))$. Since $L^1(\Omega)\subset\mathcal{M}(\Omega)$ and $W^{1,1}(\Omega)\subset BV(\Omega)$, by the weak compactness of $\mathcal{M}(\Omega)$ and $BV(\Omega)$ (cf. [3]) we have that there exist subsequences of $\{\mathbf{u}^\varepsilon\}_{\varepsilon>0}$, $\{\mathcal{B}^\varepsilon\}_{\varepsilon>0}$, $\{\mathcal{B}_1^\varepsilon\}_{\varepsilon>0}$, and $\{\sigma_\lambda^\varepsilon\}_{\varepsilon>0}$ (still denoted by the same notation), respectively, and maps $\mathbf{u}\in L^\infty((0,T);[BV(\Omega)\cap L^\infty(\Omega)]^n)\cap H^1((0,T);L^2(\Omega,\mathbf{R}^n))$, $\mathcal{B}\in L^\infty((0,T);L^\infty(\Omega,B_1(\mathbf{R}^{n\times m})))$, $\nu\in L^2((0,T);[\mathcal{M}(\Omega)]^n)$, and $\sigma_\lambda\in L^\infty((0,T);[\mathcal{M}(\Omega)]^n)$, respectively, such that as $\varepsilon\to 0$

$$\mathbf{u}^\varepsilon \longrightarrow \mathbf{u} \qquad \text{weakly* in } L^\infty((0,T);[BV(\Omega)\cap L^\infty(\Omega)]^n), \tag{6.35}$$

$$\text{strongly in } L^2((0,T);L^1(\Omega,\mathbf{R}^n)) \tag{6.36}$$

$$\text{a.e. in } \Omega_T, \tag{6.37}$$

$$b_1(\varepsilon)\nabla\mathbf{u}^\varepsilon \longrightarrow 0 \qquad \text{weakly in } L^2((0,T);L^2(\Omega,\mathbf{R}^{n\times m})), \tag{6.38}$$

$$\mathbf{u}_t^\varepsilon \longrightarrow \mathbf{u}_t \qquad \text{weakly in } L^2((0,T);L^2(\Omega,\mathbf{R}^n)), \tag{6.39}$$

$$\mathrm{div}\mathcal{B}_1^\varepsilon \longrightarrow \nu \qquad \text{weakly* in } L^2((0,T);[\mathcal{M}(\Omega)]^n), \tag{6.40}$$

$$\mathcal{B}^\varepsilon \longrightarrow \mathcal{B} \qquad \text{weakly* in } L^\infty((0,T);L^\infty(\Omega,B_1(\mathbf{R}^{n\times m}))), \tag{6.41}$$

$$\sigma_\lambda^\varepsilon \longrightarrow \sigma_\lambda \qquad \text{weakly* in } L^\infty((0,T);[\mathcal{M}(\Omega)]^n). \tag{6.42}$$

It follows immediately from (6.37) and (4.18) that

$$|\mathbf{u}| = 1 \qquad \text{a.e. in } \Omega_T, \tag{6.43}$$

and an application of the Lebesgue-dominated convergence theorem yields that

$$\mathbf{u}^\varepsilon \overset{\varepsilon\searrow 0}{\longrightarrow} \mathbf{u} \qquad \text{strongly in } L^r((0,T);L^r(\Omega,\mathbf{R}^n)) \quad \forall r\in[1,\infty). \tag{6.44}$$

Now, taking $\varepsilon\to 0$ in (4.24), and (4.29) (with $p=1$) we have for any $\mathbf{v}\in[C^1(\overline{\Omega}_T)]^n$ and $\mathbf{w}\in L^\infty((0,T);H^1(\Omega;\mathbf{R}^n))$

$$\int_0^T\int_\Omega \Big\{\big(\mathbf{u}_t\wedge\mathbf{u}\big)\cdot\mathbf{w}+\big(\mathcal{B}\wedge\mathbf{u}\big)\cdot\nabla\mathbf{w}-\lambda\big(\mathbf{g}\wedge\mathbf{u}\big)\cdot\mathbf{w}\Big\}\,dxdt=0, \tag{6.45}$$

$$\int_0^T\int_\Omega \Big\{\mathbf{u}_t\cdot\mathbf{v}+\mathcal{B}\cdot\nabla\mathbf{v}+\lambda\big(\mathbf{u}-\mathbf{g}\big)\cdot\mathbf{v}\Big\}\,dxdt=\int_0^T\Big(\int_\Omega \mathbf{v}\,d\sigma_\lambda\Big)\,dt. \tag{6.46}$$

Step 2: *Identifying ν and σ_λ.* First, it follows from the identity $(\mathcal{B}^\varepsilon)^T\mathbf{u}^\varepsilon=0$ (cf. (4.25)), (6.41), and (6.44) that

$$\mathcal{B}^T\mathbf{u}=0 \qquad \text{a.e. in } \Omega_T. \tag{6.47}$$

Second, for any $\mathbf{v}\in[C^1(\overline{\Omega}_T)]^n$, it follows from (6.38), (6.40), and (6.41) that

$$\int_{\Omega_T}\mathbf{v}\cdot d\nu=\lim_{\varepsilon\to0}\int_{\Omega_T}\mathbf{v}\cdot\mathrm{div}\,\mathcal{B}_1^\varepsilon\,dxdt=-\lim_{\varepsilon\to0}\int_{\Omega_T}\nabla\mathbf{v}\cdot\mathcal{B}_1^\varepsilon\,dxdt=-\int_{\Omega_T}\nabla\mathbf{v}\cdot\mathcal{B}\,dxdt.$$

Hence, div$\mathcal{B}$ exists and

$$\operatorname{div}\mathcal{B} = \nu, \qquad \text{and therefore} \quad \mathcal{B} \in L^2((0,T);\mathcal{DT}(\Omega)). \tag{6.48}$$

It then follows from (6.11) that

$$\mathcal{B}\mathbf{n} = 0 \qquad \text{on } \partial\Omega_T.$$

Third, notice that (6.45) immediately implies that

$$\operatorname{div}(\mathcal{B}\wedge\mathbf{u}) \in L^2(\Omega_T,\mathbf{R}^n), \qquad \text{and hence} \quad \mathcal{B}\wedge\mathbf{u} \in L^2((0,T);\mathcal{Y}(\Omega)_2). \tag{6.49}$$

Let $\{\mathbf{u}_\rho\}$ denote the smooth approximation sequence of $\mathbf{u}$ as constructed in Theorem 3.9 of [3]. For any $\mathbf{v} \in [C_0^1(\Omega_T)]^n$, setting $\mathbf{w} = \mathbf{u}_\rho \wedge \mathbf{v}$ in (6.45) we get

$$\int_0^T \int_\Omega \Big\{ \mathbf{u}_t \cdot \big(\mathbf{u}\wedge(\mathbf{u}_\rho\wedge\mathbf{v})\big) + \big(\mathcal{B}\wedge\mathbf{u}\big)\cdot\nabla(\mathbf{u}_\rho\wedge\mathbf{v}) - \lambda\,\mathbf{g}\cdot\big(\mathbf{u}\wedge(\mathbf{u}_\rho\wedge\mathbf{v})\big)\Big\}\,dxdt = 0. \tag{6.50}$$

It follows from (6.43), the convergence property of $\mathbf{u}_\rho$ (cf. [3]), and the identity $\mathbf{u}\wedge(\mathbf{u}\wedge\mathbf{v}) = \mathbf{u}(\mathbf{u}\cdot\mathbf{v}) - \mathbf{v}$ that

$$\begin{aligned}
\lim_{\rho\to 0}\int_\Omega \mathbf{u}_t\cdot\big(\mathbf{u}\wedge(\mathbf{u}_\rho\wedge\mathbf{v})\big)\,dx &= \int_\Omega \mathbf{u}_t\cdot\big(\mathbf{u}\wedge(\mathbf{u}\wedge\mathbf{v})\big)\,dx = \int_\Omega \mathbf{u}_t\cdot\big(\mathbf{u}(\mathbf{u}\cdot\mathbf{v})-\mathbf{v}\big)\,dx \\
&= -\int_\Omega \mathbf{u}_t\cdot\mathbf{v}\,dx, \\
\lim_{\rho\to 0}\int_\Omega \mathbf{g}\cdot\big(\mathbf{u}\wedge(\mathbf{u}_\rho\wedge\mathbf{v})\big)\,dx &= \int_\Omega \mathbf{g}\cdot\big(\mathbf{u}\wedge(\mathbf{u}\wedge\mathbf{v})\big)\,dx \\
&= \int_\Omega \Big\{\big(\mathbf{u}-\mathbf{g}\big)\cdot\mathbf{v} - (1-\mathbf{g}\cdot\mathbf{u})\mathbf{u}\cdot\mathbf{v}\Big\}dx.
\end{aligned}$$

It follows from Theorem 3.9 of [3], Lemma 6.7, and the identity

$$\int_\Omega \big(\mathcal{B}\wedge\mathbf{u}\big)\cdot\nabla(\mathbf{u}_\rho\wedge\mathbf{v})\,dx = \int_\Omega \Big\{\big((\mathcal{B}\wedge\mathbf{u})\wedge\mathbf{u}_\rho\big)\cdot\nabla\mathbf{v} + \big((\mathcal{B}\wedge\mathbf{u})\wedge\nabla\mathbf{u}_\rho\big)\cdot\mathbf{v}\Big\}dx$$

that

$$\begin{aligned}
\lim_{\rho\to 0}\int_\Omega \big(\mathcal{B}\wedge\mathbf{u}\big)\cdot\nabla(\mathbf{u}_\rho\wedge\mathbf{v})\,dx &= \int_\Omega \big((\mathcal{B}\wedge\mathbf{u})\wedge\mathbf{u}\big)\cdot\nabla\mathbf{v}\,dx + \langle(\mathcal{B}\wedge\mathbf{u})\wedge D\mathbf{u},\mathbf{v}\rangle \\
&= -\int_\Omega \mathcal{B}\cdot\nabla\mathbf{v}\,dx + \langle(\mathcal{B}\wedge\mathbf{u})\wedge D\mathbf{u},\mathbf{v}\rangle.
\end{aligned}$$

Here we have used the fact that $(\mathcal{B}\wedge\mathbf{u})\wedge\mathbf{u} = -\mathcal{B}$ in light of (6.43) and (6.47), and the measure $(\mathcal{B}\wedge\mathbf{u})\wedge D\mathbf{u}$ is defined by (6.3) with $\mathcal{A} = \mathcal{B}\wedge\mathbf{u}$ and $\mathbf{v} = \mathbf{u}$.

Finally, substituting the above three equations into (6.50) and multiplying the equation by (-1) we get

$$\begin{aligned}
&\int_0^T\int_\Omega \Big\{\mathbf{u}_t\cdot\mathbf{v} + \mathcal{B}\cdot\nabla\mathbf{v} + \lambda\,\big(\mathbf{u}-\mathbf{g}\big)\cdot\mathbf{v}\Big\}\,dxdt \\
&\qquad = \int_0^T \big\langle(\mathcal{B}\wedge\mathbf{u})\wedge D\mathbf{u} + \lambda(1-\mathbf{g}\cdot\mathbf{u})\mathbf{u},\mathbf{v}\big\rangle\,dt
\end{aligned} \tag{6.51}$$

for any $\mathbf{v} \in [C_0^1(\Omega_T)]^n$. This and (6.46) imply that

$$\sigma_\lambda = (\mathcal{B} \wedge \mathbf{u}) \wedge D\mathbf{u} + \lambda(1 - \mathbf{g} \cdot \mathbf{u})\mathbf{u}.$$

Step 3: *Identifying* $\mathcal{B}$. First, since $\{\mathcal{B}^\varepsilon \cdot \nabla \mathbf{u}^\varepsilon\}$ is uniformly bounded in $L^2((0,T); L^1(\Omega))$, then there exists a subsequence (still denoted by the same notation) and $\mu \in L^2((0,T); \mathcal{M}(\Omega))$ such that

$$\mathcal{B}^\varepsilon \cdot \nabla \mathbf{u}^\varepsilon \longrightarrow \mu \quad \text{weakly* in } L^2((0,T); \mathcal{M}(\Omega)). \tag{6.52}$$

Let $\mathbf{u}_\rho^\varepsilon$ and $\mathbf{u}_\rho$ denote mollified sequences for $\mathbf{u}^\varepsilon$ and $\mathbf{u}$, respectively, through a positive symmetric mollifier. For any open set $E \subset \Omega$ we have

$$\begin{aligned}
\lim_{\varepsilon\to 0} \int_0^T \int_E \mathcal{B}^\varepsilon \cdot \nabla \mathbf{u}^\varepsilon \, dxdt &= \lim_{\varepsilon\to 0} \lim_{\rho\to 0} \int_0^T \int_E \mathcal{B}^\varepsilon \cdot D\mathbf{u}_\rho^\varepsilon \, dxdt \\
&= \lim_{\rho\to 0} \lim_{\varepsilon\to 0} \int_0^T \int_E \mathcal{B}^\varepsilon \cdot D\mathbf{u}_\rho^\varepsilon \, dxdt \\
&= \lim_{\rho\to 0} \int_0^T (\mathcal{B} \cdot D\mathbf{u}_\rho)(E)\, dt \quad \text{(by (6.41), (6.44))} \\
&= \int_0^T \overline{\mathcal{B} \cdot D\mathbf{u}}\,(E)\, dt \quad \text{(by (6.29))},
\end{aligned} \tag{6.53}$$

where $\overline{\mathcal{B} \cdot D\mathbf{u}}$ is defined in Lemma 6.10.

Hence, it follows from (6.52), (6.53), and Lemma 6.10 that

$$\mu = \overline{\mathcal{B} \cdot D\mathbf{u}} << |D\mathbf{u}|. \tag{6.54}$$

We refer the reader to Definition 1.24 of [3] for the notation "<<."

On the other hand, a direct calculation yields that

$$\mathcal{B}^\varepsilon \cdot \nabla \mathbf{u}^\varepsilon = \frac{|\nabla \mathbf{u}^\varepsilon|^2}{|\nabla \mathbf{u}^\varepsilon|_\varepsilon} \geq |\nabla \mathbf{u}^\varepsilon|_\varepsilon - \varepsilon.$$

Setting $\varepsilon \to 0$ and by the lower semicontinuity of the BV-norm (cf. [3]) we obtain

$$\mu >> |D\mathbf{u}|,$$

which together with (6.54) and Lemma 6.10 yield that

$$|D\mathbf{u}| = \mu = \overline{\mathcal{B} \cdot D\mathbf{u}}, \tag{6.55}$$

and hence

$$|D\mathbf{u}|^a = (\overline{\mathcal{B} \cdot D\mathbf{u}})^a = \mathcal{B} \cdot (D\mathbf{u})^a. \tag{6.56}$$

Finally, we note that all other properties of $\mathcal{B}$ and the measure $(\mathcal{B} \wedge \mathbf{u}) \wedge D\mathbf{u}$ listed in (vi) of Definition 6.11 are immediate consequences of (6.55) and Lemmas 6.2, 6.4–6.10, and Corollary 6.3.

Step 4: *Finishing up.* We now conclude the proof of the theorem by showing the energy inequality (6.33). First, notice that (4.6) implies that for a.e. $s \in [0,T]$

$$I_\lambda(\mathbf{u}^\varepsilon(s)) + \int_0^s \| \mathbf{u}_t^\varepsilon(t) \|_{L^2}^2 \, dt \le J_{1,\lambda}^\varepsilon(\mathbf{u}_0) \tag{6.57}$$

$$\le \frac{b_1(\varepsilon)}{2} \| \nabla \mathbf{u}_0 \|_{L^2}^2 + a_1(\varepsilon)|\Omega| + I_\lambda(\mathbf{u}_0).$$

Then (6.33) follows from taking $\varepsilon \to 0$ in (6.57), using the lower semicontinuity of the BV-seminorm and the L^2-norm with respect to L^2-weak convergence. The proof is complete. ∎

Remark 6.5. (a) Since weak solutions to (1.8)–(1.11) are not unique in general for $1 < p < \infty$ (cf. [15, 32, 41]), we expect that this nonuniqueness also holds for the case $p = 1$.

(b) The existence result in Theorem 6.12 is proved under the assumption $\mathbf{u}_0 \in H^1(\Omega, \mathbf{R}^n)$. This assumption can be weakened to $\mathbf{u}_0 \in [BV(\Omega) \cap L^\infty(\Omega)]^n$ using a smoothing technique.

7. Fully discrete finite element approximations.

7.1. Formulation of fully discrete finite element methods. For ease of exposition, we assume Ω is a polytope in this section. Let $\mathcal{T}_h$ be a quasi-uniform "triangulation" of the domain Ω of mesh size $0 < h < 1$ and $\overline{\Omega} = \bigcup_{K \in \mathcal{T}_h} \overline{K}$ ($K \in \mathcal{T}_h$ are tetrahedrons in the case $m = 3$). Let $J_\tau := \{t_k\}_{k=0}^L$ be a uniform partition of $[0,T]$ with mesh size $\tau := \frac{T}{L}$, and $\partial_t \mathbf{v}^k := (\mathbf{v}^k - \mathbf{v}^{k-1})/\tau$. For an integer $r \ge 1$, let $P_r(K)$ denote the space of polynomials of degree less than or equal to r on K. We introduce the finite element space

$$\mathbf{V}^h = \big\{ \mathbf{v}_h \in C(\overline{\Omega}, \mathbf{R}^n) \cap H^1(\Omega, \mathbf{R}^n);\ \mathbf{v}_h|_K \in [P_r(K)]^n \, \forall K \in \mathcal{T}_h \big\}.$$

Notice that the density function F defined in (1.17) is not a convex function. On the other hand, there exist two convex functions W_+ and W_- such that

$$F(\mathbf{v}) = W_+(\mathbf{v}) - W_-(\mathbf{v}). \tag{7.1}$$

One such an example is $W_+(\mathbf{v}) = \frac{|\mathbf{v}|^4}{4}$ and $W_-(\mathbf{v}) = \frac{|\mathbf{v}|^2}{2} - \frac{1}{4}$. Clearly, the above decomposition is not unique.

We are now ready to introduce our fully discrete finite element discretizations for the initial boundary value problem (1.20)–(1.22). Find $\mathbf{u}_h^k \in \mathbf{V}^h$ for $k = 1, 2, \ldots, L$ such that

$$\int_\Omega \Big\{ \partial_t \mathbf{u}_h^k \cdot \mathbf{v}_h + \mathcal{B}_h^k \cdot \nabla \mathbf{v}_h + \lambda \left(\mathbf{u}_h^k - \mathbf{g} \right) \cdot \mathbf{v}_h + \frac{1}{\delta} W_+'(\mathbf{u}_h^k) \cdot \mathbf{v}_h \Big\} \, dx \tag{7.2}$$

$$= \frac{1}{\delta} \int_\Omega W_-'(\mathbf{u}_h^{k-1}) \cdot \mathbf{v}_h \, dx \qquad \forall \mathbf{v} \in \mathbf{V}^h,$$

where

$$\mathcal{B}_h^k = \big[\, b_p(\varepsilon) + |\nabla \mathbf{u}_h^k|_\varepsilon^{p-2} \, \big] \nabla \mathbf{u}_h^k, \tag{7.3}$$

with some starting value $\mathbf{u}_h^0 \in \mathbf{V}^h$ to be specified later. Note that for notational brevity we have omitted the indices ε, δ, and p on $\mathbf{u}_h^k$ and $\mathcal{B}_h^k$

For each k, (7.2) is a nonlinear equation in $\mathbf{u}_h^k$. Hence, the above numerical method is an implicit scheme, and its well-posedness is ensured by the following theorem.

THEOREM 7.1. *For each fixed $k \geq 1$, suppose that $\mathbf{u}_h^{k-1} \in \mathbf{V}^h$ is known. Then there exists a unique solution $\mathbf{u}_h^k \in \mathbf{V}^h$ to* (7.2)–(7.3). *Moreover, $\{\mathbf{u}_h^k\}_{k=0}^L$ satisfies the following energy estimate:*

$$\frac{\tau}{2}\sum_{k=1}^{\ell} \| \partial_t \mathbf{u}_h^k \|_{L^2}^2 + J_{p,\lambda}^{\varepsilon,\delta}(\mathbf{u}_h^k) \leq J_{p,\lambda}^{\varepsilon,\delta}(\mathbf{u}_h^0) \qquad \text{for } 1 \leq \ell \leq L. \tag{7.4}$$

Here $J_{p,\lambda}^{\varepsilon,\delta}$ is defined by (1.19).

Proof. For each fixed $k \geq 1$, it is easy to check that (7.2)–(7.3) is the Euler–Lagrange equation of the following functional over $\mathbf{V}^h$:

$$G_k(\mathbf{v}) := \int_\Omega \Big\{ \frac{1}{2\tau}|\mathbf{v} - \mathbf{u}_h^{k-1}|^2 + \frac{b_p(\varepsilon)}{2}\,|\nabla \mathbf{v}|^2 + \frac{1}{p}\,|\nabla \mathbf{v}|_\varepsilon^p + \frac{\lambda}{2}|\mathbf{v} - \mathbf{g}|^2 + \frac{1}{\delta} W_+(\mathbf{v}) \Big\}\, dx - \frac{1}{\delta}\int_\Omega W_-'(\mathbf{u}_h^{k-1}) \cdot \mathbf{v}\, dx. \tag{7.5}$$

Since G_k is a convex, coercive, and differentiable functional, then it has a unique minimizer $\mathbf{u}_h^k \in \mathbf{V}^h$ (cf. [47]), and hence (7.2)–(7.3) has a unique solution.

Since $\mathbf{u}_h^k$ is the minimizer of G_k over $\mathbf{V}^h$, we have that

$$G_k(\mathbf{u}_h^k) \leq G_k(\mathbf{u}_h^{k-1}). \tag{7.6}$$

It follows from the convexity of W_- that

$$W_-'(\mathbf{u}_h^{k-1})\big(\mathbf{u}_h^k - \mathbf{u}_h^{k-1}\big) \leq W_-(\mathbf{u}_h^k) - W_-(\mathbf{u}_h^{k-1}).$$

This and (7.6) imply that

$$\frac{1}{2}\| \partial_t \mathbf{u}_h^k \|_{L^2}^2 + \frac{J_{p,\lambda}^{\varepsilon,\delta}(\mathbf{u}_h^k) - J_{p,\lambda}^{\varepsilon,\delta}(\mathbf{u}_h^{k-1})}{\tau} \leq 0.$$

The bound (7.4) then follows from applying the summation operator $\tau \sum_{k=1}^{\ell}$ ($1 \leq \ell \leq L$) to the last inequality. Hence the proof is complete. ∎

7.2. Convergence analysis. The goal of this subsection is to show that the numerical solution of (7.2)–(7.3) converges to the unique weak solution of (1.20)–(1.22) as $h, \tau \to 0$. There are two approaches to reach this goal. The first approach assumes the existence of the solution of (1.20)–(1.22), which in fact has been proved in Theorem 3.7, and then proves that $\mathbf{u}_h^k$ converges to that solution. The other approach shows the convergence *without* assuming the existence of the solution of (1.20)–(1.22). This can be done by applying the energy method and compactness argument used in the proof of Theorem 3.7 to the finite element solution $\{\mathbf{u}_h^k\}$. In the following, we shall go with the latter approach since this will also provide an alternative proof for Theorem 3.7 as alluded to in Remark 3.1(c).

For the fully discrete finite element solution $\{\mathbf{u}_h^k\}$, we define its linear interpolation in t as follows:

$$\mathbf{U}^{\varepsilon,\delta,h,\tau}(\cdot,t) := \frac{t - t_{k-1}}{\tau}\mathbf{u}_h^k(\cdot) + \frac{t_k - t}{\tau}\mathbf{u}_h^{k-1}(\cdot) \quad \forall\, t \in [t_{k-1}, t_k], \quad 1 \leq k \leq L. \tag{7.7}$$

Clearly, $\mathbf{U}^{\varepsilon,\delta,h,\tau}$ is continuous in both x and t.

The main result of this section is the following convergence theorem.

THEOREM 7.2. *For $1 \le p < \infty$, suppose that $\mathbf{u}_0 \in W^{1,p^*}(\Omega,\mathbf{R}^n)$ with $p^* = \max\{2,p\}$, $|\mathbf{u}_0| = 1$, and $|\mathbf{g}| \le 1$ in Ω. For each pair of positive numbers (ε,δ), let $\mathbf{U}^{\varepsilon,\delta,h,\tau}$ be defined by* (7.7)*. Then there exists $\mathbf{u}^{\varepsilon,\delta} \in L^\infty(\Omega_T)$ such that*

$$\lim_{h,\tau\to 0} \| \mathbf{u}^{\varepsilon,\delta} - \mathbf{U}^{\varepsilon,\delta,h,\tau} \|_{L^q(\Omega_T)} = 0 \qquad \forall q \in [1,\infty), \tag{7.8}$$

provided that

$$\lim_{h\to 0} \| \mathbf{u}_0 - \mathbf{u}_h^0 \|_{W^{1,p^*}(\Omega)} = 0.$$

Moreover, $\mathbf{u}^{\varepsilon,\delta}$ solves (1.20)–(1.22) *in the sense of Definition* 3.1.

Proof. The proof follows along the same lines as that of Theorem 1.5 of [12], where the convergence of a general Galerkin approximation was proved for the case $p \ge 2$. Since the finite element approximation is a special Galerkin approximation, the proof of Theorem 1.5 of [12] can easily be adapted to the finite element approximation $\mathbf{U}^{\varepsilon,\delta,h,\tau}$ for $p \ge 2$ thanks to the discrete energy estimate (7.4) and the facts that $\partial_t \mathbf{u}_h^k = \mathbf{U}_t^{\varepsilon,\delta,h,\tau}$ and $\tau \sum_{k=1}^L \| \partial_t \mathbf{u}_h^k \|_{L^2}^2 = \| \mathbf{U}_t^{\varepsilon,\delta,h,\tau} \|_{L^2(L^2)}$.

Since the operator $-\Delta_p^\varepsilon$ is *uniformly* elliptic, as a result, the compactness of Lemma 2.2 holds not only for $p \ge 2$ but also for $1 \le p < 2$. In addition, note that $\mathbf{U}^{\varepsilon,\delta,h,\tau}$ is uniformly (in h and τ) bounded in $L^\infty((0,T);H^1(\Omega,\mathbf{R}^n))$ for $1 \le p < 2$. Hence, the proof of Theorem 1.5 of [12] can be adapted with slight modifications to prove (7.8) for the case $1 \le p < 2$. ∎

Remark 7.1. Several practical choices of $\mathbf{u}_h^0$ are possible. For instance, both the L^2-projection of $\mathbf{u}_0$ and the Clemént finite element interpolation of $\mathbf{u}_0$ into $\mathbf{V}^h$ (cf. [14]) are qualified candidates for $\mathbf{u}_h^0$.

An immediate consequence of Theorems 4.1, 5.2, 6.12, 7.1, and 7.2 is the following convergence theorem.

THEOREM 7.3. *Let $1 \le p < \infty$, let $\mathbf{U}^{\varepsilon,\delta,h,\tau}$ be defined by* (7.7)*, and assume that the assumptions of Theorems* 7.1, 7.2, 4.1, 5.2, *and* 6.12 *hold. Then there exists a subsequence of $\{\mathbf{U}^{\varepsilon,\delta,h,\tau}\}$ (still denoted by the same notation) and a weak solution $\mathbf{u}$ of* (1.8)–(1.11) *such that*

$$\lim_{\varepsilon,\delta\to 0,\ h,\tau\to 0,} \| \mathbf{u} - \mathbf{U}^{\varepsilon,\delta,h,\tau} \|_{L^q(\Omega_T)} = 0 \qquad \forall q \in [1,\infty). \tag{7.9}$$

GLOBAL EXISTENCE OF SOME INFINITE ENERGY SOLUTIONS FOR A PERFECT INCOMPRESSIBLE FLUID*

RALPH SAXTON† AND FERIDE TIĞLAY†

Abstract. This paper provides results on local and global existence for a class of solutions to the Euler equations for an incompressible, inviscid fluid. By considering a class of solutions which exhibits a characteristic growth at infinity we obtain an initial value problem for a nonlocal equation. We establish local well-posedness in all dimensions and persistence in time of these solutions for three and higher dimensions. We also examine a weaker class of global solutions.

Key words. incompressible fluid, three dimensions, stagnation point, global existence, Cauchy problem for periodic initial data, infinite energy

1. Introduction. A fundamental question in the study of fluids concerns the possibility of finite time blow up of solutions to the Euler equations for a perfect, incompressible fluid. It is well known that blow up cannot take place in the two-dimensional case for solutions defined over a bounded domain subject to Dirichlet boundary conditions (see, for example, the work of Wolibner [17] and Ebin [7]), since smooth data in this case lead to solutions remaining smooth for all time. However, the question remains open in higher dimensions.

A separate class of solutions consists of those having "stagnation-point" form, which attracted early attention by Weyl [16] and Lin [13], and provides a set of equations which depend on only a single spatial variable and time. The resulting equations, once solved, provide exact solutions to the full Euler equations. However, the associated growth of the full solutions in certain directions means that the flows possess, at best, only locally finite kinetic energy. Nevertheless, one may discuss such questions as finite time blow up for this class, and it has been shown by Stuart in [15] that this can take place when the reduced equations are defined over the real line and those solutions decay at infinity. In this case the corresponding spatial domain for the full equations is $\mathbb{R}^n$ for $n = 2$ and $n = 3$, with the full set of solutions growing linearly in the other direction(s).

The evolution of two-dimensional solutions, which can blow up on the unbounded domain $\mathbb{R}^2$, therefore differs significantly from the class of globally defined solutions which exists for bounded subdomains of $\mathbb{R}^2$. So the consequences of higher-dimensional stagnation-point solutions blowing up might be thought to result simply from their behavior at infinity rather than bearing on the question of singularity formation. This view is in some sense strengthened by the results of Childress et al. in [3] (see also a related result by Cox in [5]), where solutions defined over a two-dimensional, infinite strip were examined. Since blow up was still found over this, smaller, semi-infinite domain, stagnation-point solutions defined over such domains

would give the appearance of behaving, generally, much as those defined on the full space.

A similar approach is implemented by Constantin in [4] to reduce the three-dimensional Euler equations, periodic in two directions, to a nonlocal Riccati equation and prove the blow up in finite time by solving these equations on characteristics.

In this paper we consider a stagnation-point class of solutions defined over $\mathbb{R}^n$ which is spatially periodic in one coordinate direction. In two dimensions, the equations reduce to those of [3] and, although we examine slightly different boundary conditions, the same blow up results essentially apply. In three and higher dimensions, however, we find a "regularizing" effect not present in solutions which decay to zero at infinity in the same coordinate direction, and this leads to the existence for all time of all such solutions, stemming from sufficiently smooth initial data.

Section 2 sets out the fundamental field equations, which in a basic sense date back to [13], [16]. Section 3 is devoted to local well-posedness (existence, uniqueness, and continuous dependence on initial data) of classical solutions to the initial value problem for the pseudodifferential equation derived in section 2. We establish this result by rewriting the problem on the topological group $\mathcal{D}$ of C^1 class diffeomorphisms as an initial value problem for an ordinary differential equation. Section 4 provides a priori estimates for more regular classes of solutions, leading to global existence of such solutions in three and higher dimensions.

In section 5, we reconsider a class of piecewise affine solutions previously mentioned in [3]. These solutions are less regular than those arising in our existence results. It is found that they exist globally, independently of the underlying dimension.

2. The *n*-dimensional equation. Consider the n-dimensional Euler equations for an ideal, inviscid and incompressible fluid

$$\partial_t \mathbf{u} + \mathbf{u}.\nabla \mathbf{u} + \nabla p = 0, \tag{2.1a}$$

$$\nabla.\mathbf{u} = 0, \tag{2.1b}$$

where $\mathbf{x} = (x_1, \dots x_n) \equiv (x_1, \mathbf{x}')$. Denoting x_1 by x, $\mathbf{u}(x, \mathbf{x}', t)$ represents the spatial velocity field of the fluid and $p(x, \mathbf{x}', t)$ its pressure. We impose the ansatz

$$\mathbf{u}(x, \mathbf{x}', t) = (u(x,t), -\partial_x u(x,t)\mathbf{v}(\mathbf{x}', t)), \tag{2.2}$$

where the $(n-1)$-dimensional vector field, $\mathbf{v}$, will be chosen below. As a consequence of (2.2), (2.1a) may be written as

$$\partial_t u + u\partial_x u + \partial_x p = 0, \tag{2.3}$$

together with

$$\partial_t \partial_x u\, \mathbf{v} + \partial_x u\, \partial_t \mathbf{v} + u\partial_x^2 u\, \mathbf{v} - (\partial_x u)^2 \mathbf{v} \cdot \nabla' \mathbf{v} - \nabla' p = \mathbf{0}, \tag{2.4}$$

where the primed operators refer to the variable $\mathbf{x}'$. Using (2.2) and (2.3), one sees that $\nabla' \partial_x p = 0$. Hence, differentiating (2.4) in x eliminates the pressure term to give

$$\partial_x(\partial_t \partial_x u + u\partial_x^2 u)\, \mathbf{v} + \partial_x^2 u\, \partial_t \mathbf{v} - \partial_x((\partial_x u)^2)\mathbf{v} \cdot \nabla' \mathbf{v} = \mathbf{0}. \tag{2.5}$$

Applying the $\nabla' \cdot$ operator to (2.5) and using (2.1b) with (2.2) to find that $\nabla' \cdot \mathbf{v} = 1$ shows

$$\partial_x(\partial_t \partial_x u + u\partial_x^2 u) - \partial_x((\partial_x u)^2)\ \nabla' \mathbf{v} : \nabla' \mathbf{v} = 0, \tag{2.6}$$

where $\nabla' \mathbf{v} : \nabla' \mathbf{v} = \mathrm{tr}(\nabla' \mathbf{v})^2 = \partial_j v_k \, \partial_k v_j$ (summing over j, k from 2 to n). For compatibility, we must choose $\mathbf{v}$ such that $\nabla' \mathbf{v} : \nabla' \mathbf{v}$ is independent of $\mathbf{x}'$. This can be done, for instance, by choosing $\mathbf{v} = \frac{1}{n-1} \mathbf{x}'$, in which case $\nabla' \mathbf{v} : \nabla' \mathbf{v} = \frac{1}{n-1}$ and (2.4) takes the form

$$\left(\partial_t \partial_x u + u \partial_x^2 u - \frac{1}{n-1} (\partial_x u)^2 \right) \mathbf{v} - \nabla' p = \mathbf{0}. \tag{2.7}$$

We note that this particular choice of $\mathbf{v}$ corresponds to the stagnation-point form solution referred to in the introduction. As a result, the solution becomes unbounded in the $\mathbf{x}'$ direction, and hence has infinite energy when considered over the entire n-dimensional domain. We next examine the periodic, initial-boundary value problem, with boundary conditions for $x \in \mathbb{T} \simeq \mathbb{R}/\mathbb{Z}, t \geq 0$, given by

$$\mathbf{u}(0, \mathbf{x}', t) = \mathbf{u}(1, \mathbf{x}', t) \tag{2.8}$$

and

$$p(0, \mathbf{x}', t) = p(1, \mathbf{x}', t). \tag{2.9}$$

Since (2.6) now becomes

$$\partial_x (\partial_t \partial_x u + u \partial_x^2 u) - \frac{1}{n-1} \partial_x ((\partial_x u)^2)) = 0, \tag{2.10}$$

which we remark happens to be the x-derivative of a Calogero-class equation (see [2])

$$\partial_x \partial_t u + u \partial_x^2 u - \Phi(\partial_x u) = 0,$$

we obtain the equation

$$\partial_t \partial_x u + u \partial_x^2 u - \frac{1}{n-1} (\partial_x u)^2 = f \tag{2.11}$$

with f purely a function of time. This implies, by (2.7), that

$$\nabla' p = \frac{f}{n-1} \ \mathbf{x}', \tag{2.12}$$

while by (2.3), $-\partial_x^2 p = \frac{n}{n-1} (\partial_x u)^2 + f$ and so $\Delta p = -\frac{n}{n-1} (\partial_x u)^2$. Finally, for sufficiently smooth functions $u(x, t)$, using (2.8) and integrating (2.11) we have

$$f = -\frac{n}{n-1} \int_{\mathbb{T}} (\partial_x u)^2 dx, \tag{2.13}$$

while (2.3), (2.8), and (2.9) imply that

$$\frac{d}{dt} \int_{\mathbb{T}} u \, dx = 0. \tag{2.14}$$

Let us introduce the operator ∂_x^{-1} defined by

$$\partial_x^{-1} \phi(x, t) = \int_{x_0}^{x} \phi(y, t) dy - \int_{\mathbb{T}} \int_{x_0}^{x} \phi(y, t) \, dy dx.$$

We make the observation that ∂_x and ∂_x^{-1} generally do not commute since $[\partial_x, \partial_x^{-1}]\phi = \int_{\mathbb{T}} \phi \, dx$, where $[P, Q] = PQ - QP$. Consider (2.11), written in the form

$$\partial_x(\partial_t u + u\partial_x u) = \frac{n}{n-1}(\partial_x u)^2 + f(t) \tag{2.15}$$

with $n > 1$. As a result of (2.13) and the fact that $\partial_x^{-1}\partial_x\phi = \phi - \int_{\mathbb{T}} \phi \, dx$, we may write (2.15) in a nonlocal form as

$$\partial_x(\partial_t u + u\partial_x u) = \frac{n}{n-1}\,\partial_x^{-1}\partial_x((\partial_x u)^2) \tag{2.16}$$

and then, using the periodicity of u, we obtain

$$\partial_t u + u\partial_x u = \frac{n}{n-1}\,\partial_x^{-2}\partial_x((\partial_x u)^2). \tag{2.17}$$

Okamoto and Zhu [14] previously established local existence for (2.10) with $u \in H^2$, using a method introduced by Kato and Lai. Their approach requires showing uniqueness separately and then using uniqueness to prove continuous dependence on initial data. Here we instead derive a local well-posedness result in C^1 which follows from Picard iteration after rewriting the equation as an ordinary differential equation on an infinite-dimensional Banach space. This method can also be used to prove well-posedness in Sobolev spaces $H^s(\mathbb{T})$ for $s > 3/2$ (see [10] and [12], for example, for a similar result for the Camassa–Holm equation).

3. Local existence of classical solutions. In [1], Arnold observed that the initial value problem for the classical Euler equations of a perfect fluid can be stated as a geometric problem of finding geodesics on the group of volume preserving diffeomorphisms. Following this observation, Ebin and Marsden [8] developed the functional analytic tools to establish sharp local well-posedness results for the Euler equations. This method has since been used for other equations with similar geometric interpretations; for example, Misiołek [12] obtained local well-posedness in $C^1(\mathbb{T})$ for the Camassa–Holm equation, which is the equation for geodesics of the H^1 metric on the Virasoro group.

In this section we develop an appropriate analytic framework for (2.17), using a similar approach to prove the following theorem.

THEOREM 3.1. *Suppose that $n > 1$. Then there exists a unique solution*

$$u \in C^0([0,T), C^1(\mathbb{T})) \cap C^1([0,T), C^0(\mathbb{T}))$$

to the Cauchy problem for (2.17) *with initial data $u_0 \in C^1(\mathbb{T})$ for some $T > 0$, and the solution depends continuously on the initial data.*

Let γ be the flow generated by u, that is,

$$\frac{d\gamma}{dt}(x,t) = u(\gamma(x,t),t),$$

or $u = \dot{\gamma} \circ \gamma^{-1}$. Then we obtain the equation

$$\ddot{\gamma} = \frac{n}{n-1}\,\partial_x^{-2}\partial_x\left((\partial_x(\dot{\gamma}\circ\gamma^{-1}))^2\right)\circ\gamma \tag{3.1}$$

from (2.17). Therefore it is sufficient to prove that

$$F(X,\gamma) = \frac{n}{n-1}\,\left(\partial_x^{-2}\partial_x\left((\partial_x(X\circ\gamma^{-1}))^2\right)\right)\circ\gamma$$

defines a continuously differentiable vector field in a neighborhood of the identity on the topological group $\mathcal{D}$ of C^1 class diffeomorphisms. Then Theorem 3.1 follows by Picard iteration over Banach spaces.

We remark that the smooth dependence on initial data for (3.1) implies only continuous dependence on initial data for (2.17). The map $\gamma \to \gamma^{-1}$ is continuous but not locally Lipschitz [8], and this prevents obtaining more regularity for the initial data to solution map by this method. The question of whether the regularity of the solution map $u_0 \to u(t)$ can be improved, or not, is open. It is known, for instance, that it is not possible to improve the regularity of this map for the Camassa–Holm equation in Sobolev spaces [11].

In the remainder of this section, C_γ will represent a generic constant depending only on the C^1 norms of γ and γ^{-1}.

Proof of Theorem 3.1. Let us denote by P_γ the operator given by conjugation

$$P_\gamma(\phi) := P(\phi \circ \gamma^{-1}) \circ \gamma$$

for any $\gamma \in \mathcal{D}$ and pseudodifferential operator P. Using this notation we write

$$F(X,\gamma) = \frac{n}{n-1}\,(\partial_x^{-2}\partial_x)_\gamma((\partial_x)_\gamma X)^2.$$

Next we compute the directional derivative $\partial_\gamma F_{(X,\gamma)}$ and prove that it is a bounded linear map.

Note that $(\partial_x^{-2}\partial_x)f = \partial_x^{-1}\{f - \int_0^1 f\,dx\}$ is a bounded operator from $C^0(\mathbb{T})$ into $C^1(\mathbb{T})$. Furthermore we abuse the notation slightly and denote by $\mathcal{D}$ the connected component of orientation preserving C^1 diffeomorphisms of $\mathbb{T}$.

Let $s \to \gamma_s$ be a smooth curve in $\mathcal{D}$ such that $\gamma_0 = id$ and $\partial_s\gamma_s|_{s=0} = W$ for $W \in C^1(\mathbb{T})$. Then we have

$$\partial_\gamma F_{(X,\gamma)}(W) = \frac{n}{n-1}\{(\partial_\varepsilon G_\varepsilon)|_{\varepsilon=0} \circ \gamma + W(\partial_x G_\varepsilon)_{\varepsilon=0} \circ \gamma\}, \tag{3.2}$$

where $G_\varepsilon = \partial_x^{-2}\partial_x\{(\partial_x(X \circ \gamma_\varepsilon^{-1}))^2\}$. We know that $\partial_x\partial_x^{-1}$ gives the identity; hence the second summand on the right in (3.2) can be written as

$$W\partial_x G_\varepsilon|_{\varepsilon=0} \circ \gamma = \left\{((\partial_x)_\gamma X)^2 - \int_0^1 (\partial_x(X \circ \gamma^{-1}))^2 dx\right\} W. \tag{3.3}$$

Moreover, the computation of the first summand on the right in (3.2) is reduced by

$$(\partial_\varepsilon G_\varepsilon)|_{\varepsilon=0} = \partial_x^{-2}\partial_x(\partial_\varepsilon H_\varepsilon|_{\varepsilon=0}) \tag{3.4}$$

to determine $\partial_\varepsilon H_\varepsilon|_{\varepsilon=0}$, where $H_\varepsilon = (\partial_x(X \circ \gamma_\varepsilon^{-1}))^2$. Here a straightforward computation leads to

$$\partial_\varepsilon H_\varepsilon|_{\varepsilon=0} = -\left(\partial_x(X \circ \gamma^{-1})\right)^2 \partial_x(W \circ \gamma^{-1}) - \partial_x\{(W \circ \gamma^{-1})\left(\partial_x(X \circ \gamma^{-1})\right)^2\}. \tag{3.5}$$

Then, after an integration by parts, we obtain

$$\begin{aligned}\partial_\varepsilon G_\varepsilon|_{\varepsilon=0} = &-\left(\partial_x(X \circ \gamma^{-1})\right)^2 (W \circ \gamma^{-1}) + \textstyle\int_0^1 \left(\partial_x(X \circ \gamma^{-1})\right)^2 (W \circ \gamma^{-1})dx \\ &- \partial_x^{-2}\partial_x\{(\partial_x(X \circ \gamma^{-1}))^2\partial_x(W \circ \gamma^{-1})\} \\ &+ \left(x - \frac{1}{2}\right)\{\left(\partial_x(X \circ \gamma^{-1})\right)^2 (W \circ \gamma^{-1})\}|_0^1.\end{aligned}$$

The last term on the left-hand side of the above inequality vanishes since X and W are periodic functions and γ is an orientation preserving diffeomorphism. Therefore we have

$$\begin{aligned}\partial_\gamma F_{(X,\gamma)}(W) = \frac{n}{n-1}\Big\{ &- \partial_x^{-2}\partial_x\{(\partial_x(X\circ\gamma^{-1}))^2\partial_x(W\circ\gamma^{-1})\}\circ\gamma \\ &+ \int_0^1 (\partial_x(X\circ\gamma^{-1}))^2 W\circ\gamma^{-1}dx \\ &- W\int_0^1 (\partial_x(X\circ\gamma^{-1}))^2 dx\Big\}. \end{aligned} \tag{3.6}$$

The linearity of the map $W \to \partial_\gamma F_{(X,\gamma)}(W)$ is clear. Thus we proceed to show that it is bounded. It is sufficient to estimate the C^1 norms of all three summands on the right in (3.6). The second and third terms are both bounded by $C_\gamma\|W\|_{C^0}\|X\|_{C^1}^2$. For the first term on the right in (3.6), we have

$$\begin{aligned}\|(\partial_x^{-2}\partial_x)_\gamma\{((\partial_x)_\gamma X)^2(\partial_x)_\gamma W\}\|_{C^1} \le &\|(\partial_x^{-2}\partial_x)_\gamma\{((\partial_x)_\gamma X)^2(\partial_x)_\gamma W\}\|_{C^0} \\ &+ \|((\partial_x)_\gamma X)^2(\partial_x)_\gamma W\|_{C^0}\|\gamma\|_{C^1},\end{aligned} \tag{3.7}$$

which is bounded by $C_\gamma\|X\|_{C^1}^2\|W\|_{C^1}$.

In the direction of X, the Gâteaux derivative of F is given by

$$\partial_X F_{(X,\gamma)}(W) = \frac{2n}{n-1}(\partial_x^{-2}\partial_x)_\gamma\left((\partial_x)_\gamma X(\partial_x)_\gamma W\right),$$

and this is a bounded map since

$$\begin{aligned}\|\partial_X F_{(X,\gamma)}(W)\|_{C^1} &\le C_n\|(\partial_x^{-2}\partial_x)_\gamma\left((\partial_x)_\gamma X(\partial_x)_\gamma W\right)\|_{C^0} \\ &\quad + \left\|(\partial_x)_\gamma X(\partial_x)_\gamma W - \int_{\mathbb{T}}(\partial_x)_\gamma X(\partial_x)_\gamma W\, dx\right\|_{C^0}\|\gamma\|_{C^1} \\ &\le C_{n,\gamma}\|X\|_{C^1}\|W\|_{C^1},\end{aligned}$$

where $C_{n,\gamma}$ depends only on n and C^1 norms of γ and γ^{-1}.

In order to complete the proof of Theorem 3.1 it is sufficient to show that F is Fréchet differentiable; i.e., both directional derivatives $\partial_\gamma F$ and $\partial_X F$ are continuous maps.

Continuity of $(X,\gamma) \to \partial_\gamma F_{(X,\gamma)}(W)$. The following inequality reduces the proof of continuity of $\partial_\gamma F_{(X,\gamma)}(W)$ to estimating the two summands on the right-hand side:

$$\begin{aligned}\|\partial_\gamma F_{(X_1,\gamma_1)}(W) - \partial_\gamma F_{(X_2,\gamma_2)}(W)\|_{C^1} \le\ &\|\partial_\gamma F_{(X_1,\gamma_1)}(W) - \partial_\gamma F_{(X_2,\gamma_1)}(W)\|_{C^1} \\ &+ \|\partial_\gamma F_{(X_2,\gamma_1)}(W) - \partial_\gamma F_{(X_2,\gamma_2)}(W)\|_{C^1}\end{aligned}$$

where the inequality holds up to a constant depending on n. We rewrite the C^1 norm that we wish to estimate to show continuity in X as

$$\begin{aligned}\|\partial_\gamma F_{(X_1,\gamma)} - \partial_\gamma F_{(X_2,\gamma)}\|_{C^1} \leq & \|(\partial_x^{-2}\partial_x)_\gamma \left\{(((\partial_x)_\gamma X_1)^2 - ((\partial_x)_\gamma X_2)^2)(\partial_x)_\gamma W\right\}\|_{C^1} \\ & + \left|\int_0^1 \left(\partial_x(X_1\circ\gamma - X_2\circ\gamma)\right)^2 W\circ\gamma^{-1}dx\right| \\ & + |W|\left|\int_0^1 \left(\partial_x(X_1\circ\gamma - X_2\circ\gamma)\right)^2 dx\right|. \end{aligned} \tag{3.8}$$

The last two summands in (3.8) are bounded by $C_\gamma\|X_1 - X_2\|_{C^1}^2\|W\|_{C^0}$. For the remaining term, we have

$$\begin{aligned}&\|(\partial_x^{-2}\partial_x)_\gamma \left\{(((\partial_x)_\gamma X_1)^2 - ((\partial_x)_\gamma X_2)^2)(\partial_x)_\gamma W\right\}\|_{C^1} \\ &\quad \leq \|(\partial_x^{-2}\partial_x)_\gamma \left\{(((\partial_x)_\gamma X_1)^2 - ((\partial_x)_\gamma X_2)^2)(\partial_x)_\gamma W\right\}\|_{C^0} \\ &\qquad + \|\left((\partial_x(X_1\circ\gamma^{-1}))^2 - (\partial_x(X_2\circ\gamma^{-1}))^2\right)\partial_x(W\circ\gamma^{-1})\|_{C^0}\|\partial_x\gamma\|_{C^0},\end{aligned}$$

which is bounded by $C_\gamma\|X_1 - X_2\|_{C^1}\|X_1 + X_2\|_{C^1}\|W\|_{C^1}$.

Our next estimate establishes continuity of $\gamma \to \partial_\gamma F_{(X,\gamma)}(W)$. Note that it is sufficient to consider

$$\begin{aligned}&\|\partial_\gamma F_{(X,\gamma)}(W) - \partial_\gamma F_{(X,id)}(W)\|_{C^1} \\ &\quad \leq \|(\partial_x^{-2}\partial_x)_\gamma \left\{((\partial_x)_\gamma X)^2(\partial_x)_\gamma W\right\} - \partial_x^{-2}\partial_x((\partial_x X)^2\partial_x W)\|_{C^1} \qquad (3.9)\\ &\qquad + \left|\int_0^1 \left\{(\partial_x(X\circ\gamma^{-1}))^2(W\circ\gamma^{-1}) - (\partial_x X)^2 W\right\}dx\right| \qquad (3.10)\\ &\qquad + \|W\|_{C^0}\left|\int_0^1 \left\{(\partial_x(X\circ\gamma^{-1}))^2 - (\partial_x X)^2\right\}dx\right|, \qquad (3.11)\end{aligned}$$

where the inequality is up to a constant depending on n. After adding and subtracting the appropriate terms, (3.10) is bounded by

$$\|W\|_{C^0}\|\partial_x X\|_{C^0}\|(\partial_x X\circ\gamma^{-1})\partial_x\gamma^{-1} - \partial_x X\|_{C^0} + \|\partial_x X\|_{C^0}^2\|W\|_{C^1}\|\gamma - id\|_{C^0}, \tag{3.12}$$

which is bounded (up to a constant C_γ) by $\|X\|_{C^1}^2\|W\|_{C^1}\|\gamma - id\|_{C^1}$. The term in (3.11) is estimated similarly. Hence in order to establish continuity in γ it is sufficient to bound

$$\begin{aligned}&\|(\partial_x^{-2}\partial_x)_\gamma \left\{((\partial_x)_\gamma X)^2(\partial_x)_\gamma W\right\} - \partial_x^{-2}\partial_x((\partial_x X)^2\partial_x W)\|_{C^1} \\ &\quad \leq \|(\partial_x^{-2}\partial_x)_\gamma \left\{((\partial_x)_\gamma X)^2(\partial_x)_\gamma W\right\} - \partial_x^{-2}\partial_x((\partial_x X)^2\partial_x W)\|_{C^0} \qquad (3.13)\\ &\qquad + \|\left\{(\partial_x(X\circ\gamma^{-1})^2\partial_x(W\circ\gamma^{-1})\right\}\circ\gamma\partial_x\gamma - (\partial_x X)^2\partial_x W\|_{C^0}. \qquad (3.14)\end{aligned}$$

The norm in (3.14) is equal to

$$\|\partial_x W(\partial_x X)^2\left\{(\partial_x\gamma^{-1})^2\circ\gamma - 1\right\}\|_{C_0}, \tag{3.15}$$

which is bounded by $C_\gamma\|\partial_x X\|_{C^0}^2\|\partial_x W\|_{C^0}\|\gamma - id\|_{C^1}$. For (3.13) it is sufficient to estimate

$$\|(\partial_x^{-2}\partial_x)_\gamma S - \partial_x^{-2}\partial_x S\|_{C^0} + \|\partial_x^{-2}\partial_x S - \partial_x^{-2}\partial_x((\partial_x X)^2\partial_x W)\|_{C^0}, \tag{3.16}$$

where

$$S = S(X, \gamma, W) = (\partial_x(X \circ \gamma^{-1}))^2 \circ \gamma \partial_x(W \circ \gamma^{-1}) \circ \gamma.$$

After a change of variables we regroup the terms in the first summand of (3.16) to obtain

(3.17)
$$(\partial_x^{-2}\partial_x)_\gamma S - \partial_x^{-2}\partial_x S = \int_0^1 \int_{\gamma^{-1}(x)}^x S(y)\partial_x\gamma(y)dydx + \int_{x_0}^x S(y)(\partial_x\gamma(y) - 1)dy$$

(3.18)
$$- \int_0^1 \int_{x_0}^x S(y)(\partial_x\gamma(y) - 1)dydx$$

(3.19)
$$- \left(\gamma(x) - \frac{1}{2}\right) \int_0^1 S \circ \gamma^{-1}(y)dy + \left(x - \frac{1}{2}\right) \int_0^1 S(y)dy.$$

The right-hand side of this equality can be simplified further as

(3.20)
$$(\partial_x^{-2}\partial_x)_\gamma S - \partial_x^{-2}\partial_x S = \int_0^1 \int_{\gamma^{-1}(x)}^x S(y)\partial_x\gamma(y)dydx$$

(3.21)
$$+ \partial_x^{-2}\partial_x(S(\partial_x\gamma - 1)) - (\gamma(x) - x) \int_0^1 S \circ \gamma^{-1}(y)dy.$$

Clearly the sup norms of all three summands in (3.20)–(3.21) vanish in the limit as γ goes to id in C^1. The second summand in (3.16) is equal to the C^0 norm of

(3.22)
$$\partial_x^{-2}\partial_x \left(\partial_x W(\partial_x X)^2 \left\{(\partial_x\gamma^{-1})^3 \circ \gamma - 1\right\}\right),$$

which is bounded by $C_\gamma \|W\|_{C^1} \|X\|_{C^1}^2 \|\gamma - id\|_{C^1}$. Hence the continuity of $\gamma \to \partial F_{(X,\gamma)}$ follows.

The continuity of $(X, \gamma) \to \partial_X F_{(X,\gamma)}$ can be shown analogously. Therefore $F(X, \gamma)$ defines a continuously differentiable map in a neighborhood of (id, u_0). This completes the proof of Theorem 3.1. □

4. Global existence for $n \geq 3$. In this section we investigate the persistence of solutions of the initial value problem for (2.17) and show that, unlike the two-dimensional case where solutions may blow up in finite time (see [3], [5]), they persist for $n \geq 3$ in the appropriate function spaces.

For the theorem below let us use the following notation:

$$X_n(\mathbb{T}) = \begin{cases} W^{2,\infty}(\mathbb{T}), & n = 3, \\ W^{2,\frac{n-1}{n-3}}(\mathbb{T}), & n > 3, \end{cases}$$

and

$$Y_n(\mathbb{T}) = \begin{cases} W^{1,\infty}(\mathbb{T}), & n = 3, \\ W^{1,\frac{n-1}{n-3}}(\mathbb{T}), & n > 3. \end{cases}$$

THEOREM 4.1. *Let $n \geq 3$ and assume that $u_0(x) \in X_n(\mathbb{T})$. Then the solution $u(x,t)$ from Theorem 3.1 has a unique extension to all $T < \infty$ such that $u(x,t) \in C^0([0,T], X_n(\mathbb{T})) \cap C^1([0,T], Y_n(\mathbb{T}))$.*

Proof. Consider (2.10), expressed in the form

$$\partial_t \partial_x^2 u + u\partial_x^3 u + \frac{n-3}{n-1}\,\partial_x u \partial_x^2 u = 0. \tag{4.1}$$

Using the flow γ of u ($\dot\gamma = u \circ \gamma$) in (4.1), we first solve for $\partial_x^2 u$:

$$\partial_x^2 u \circ \gamma(t) = u_0'' \exp\left(-\frac{n-3}{n-1}\int_0^t \partial_x u \circ \gamma(s) ds\right). \tag{4.2}$$

By the identity $\partial_x \dot\gamma = \partial_x u \circ \gamma\, \partial_x \gamma$, we also have

$$\partial_x \gamma(t) = \exp\left(\int_0^t \partial_x u \circ \gamma(s) ds\right). \tag{4.3}$$

Therefore

$$\partial_x^2 u \circ \gamma(t) (\partial_x \gamma(t))^{\frac{n-3}{n-1}} = u_0''. \tag{4.4}$$

Note that Theorem 3.1 implies that $\gamma \in C^1$ locally in time and it follows, given $\partial_x \gamma(0) = 1$, that there exists an interval, $t \in [0, \tau(\varepsilon))$, over which $0 < \varepsilon \leq \inf_{x\in\mathbb{T}} \partial_x\gamma(t) \leq \sup_{x\in\mathbb{T}} \partial_x\gamma(t) \leq \varepsilon^{-1}$. Equation (4.4) then implies that, locally, $u \in X_n(\mathbb{T})$, since γ maps $\mathbb{T}$ diffeomorphically to itself. In turn, (2.16) shows that $\partial_t u \in Y_n(\mathbb{T})$ over the same time interval. (With additional assumptions on the data, further regularity can also be bootstrapped to higher derivatives.)

Assuming then that sufficient smoothness holds locally in time, we find on multiplying (4.1) by $|\partial_x^2 u|^{p-2}\,\partial_x^2 u$ that

$$\partial_t |\partial_x^2 u|^p + u\partial_x |\partial_x^2 u|^p + p\,\frac{n-3}{n-1}\,\partial_x u |\partial_x^2 u|^p = 0. \tag{4.5}$$

Since (2.2) and (2.8) imply that both u and $\partial_x u$ are periodic functions of x, the same is true of $\partial_x^2 u$, by (2.11). One therefore obtains, on integrating (4.5) over $\mathbb{T}$,

$$\frac{d}{dt}\int_{\mathbb{T}} |\partial_x^2 u|^p dx + \left(p\,\frac{n-3}{n-1} - 1\right)\int_{\mathbb{T}} \partial_x u |\partial_x^2 u|^p dx = 0, \tag{4.6}$$

from which it follows that the $L^{\frac{n-1}{n-3}}(\mathbb{T})$ norm of $\partial_x^2 u$ is uniformly conserved in time for $n > 3$. The case $n = 3$ can either be considered as the limit $n \to 3$ with $p \to \infty$ in (4.6), or directly using (4.1) which shows that $\partial_x^2 u$ is constant along characteristics and hence its $L^\infty(\mathbb{T})$ norm is uniformly conserved.

Periodicity of $u(x,t)$ in x implies there exists a zero for $\partial_x u$, say at $x = x_0(t)$, and so for $x, x_0 \in \mathbb{T}$,

$$\partial_x u(x,t) = \int_{x_0}^x \partial_y^2 u(y,t) dy.$$

For $n > 3$, we therefore have the estimate

$$|\partial_x u(x,t)| \leq |x - x_0|^{\frac{2}{n-1}} ||u_0''||_{\frac{n-1}{n-3}} \leq ||u_0''||_{\frac{n-1}{n-3}}$$

using Hölder's inequality, and so

$$||\partial_x u||_\infty \leq ||u_0''||_{\frac{n-1}{n-3}}.$$

If $n = 3$, then

$$||\partial_x^2 u||_\infty = ||u_0''||_\infty,$$

which means

$$|\partial_x u(x,t)| \leq |x - x_0|||u_0''||_\infty \leq ||u_0''||_\infty$$

for all $x \in \mathbb{T}$, and so

$$||\partial_x u||_\infty \leq ||u_0''||_\infty$$

for all $t > 0$.

Further, since $u(x,t) - u_0(x)$ has mean zero by (2.14), there exists $x = x_1(t)$, where $u(x_1,t) = u_0(x_1)$ and, for $x, x_1 \in \mathbb{T}$, we have

$$u(x,t) = u_0(x) + \int_{x_1}^{x} (\partial_y u(y,t) - u_0'(y))dy.$$

It follows that

$$|u(x,t)| \leq ||u_0||_\infty + |x - x_1|(||\partial_x u||_\infty + ||u_0'||_\infty)$$

for all $x \in \mathbb{T}$, which gives the inequality

$$||u||_\infty \leq ||\partial_x u||_\infty + ||u_0||_{C^1}.$$

Combining the results of the previous two paragraphs shows that

$$||u||_{C^1} \leq ||u_0||_{C^2} \quad \text{for} \quad n = 3, \tag{4.7}$$

and

$$||u||_{C^1} \leq ||u_0||_{C^1} + ||u_0''||_{\frac{n-1}{n-3}} \quad \text{for} \quad n > 3. \tag{4.8}$$

Finally, on using the properties of the operators $\partial_x^{-1}\partial_x$ and $\partial_x^{-2}\partial_x$ in (2.16) and (2.17) together with the above estimates, it is seen that $||\partial_t u||_\infty$ and $||\partial_t \partial_x u||_\infty$ are majorized by a function of $||u_0||_{C^2}$ for $n = 3$, while $||\partial_t u||_\infty$ and $||\partial_t \partial_x u||_{\frac{n-1}{n-3}}$ are majorized by a function of $||u_0||_{W^{2,\frac{n-1}{n-3}}}$ for $n > 3$.

In both of these cases it follows that the $C^1(\mathbb{T})$ norm of u and the $C^0(\mathbb{T})$ norm of $\partial_t u$ remain uniformly bounded in time over any interval of local existence and, by bootstrapping the arguments of Theorem 3.1, the solution can be continued, globally, in time. □

As a remark, we note here how a blow up argument made in [3], which involves a nontrivial class of separable solutions to (2.10) for $n = 2$, fails to apply in the case $n > 3$. In particular, the possible appearance of a $(\tau - t)^{-1}$ factor, $\tau > 0$, in the two-dimensional case no longer exists in higher dimensions.

Given the solution form $u(x,t) = X(x)T(t)$, (2.10) reduces to

$$\lambda X''(x) + \frac{n-3}{n-1} X'(x)X''(x) + X(x)X'''(x) = 0, \ x \in \mathbb{T}, \tag{4.9}$$

where

$$\dot{T}(t) - \lambda T(t)^2 = 0,\ t \geq 0, \tag{4.10}$$

and λ is a constant. Multiplying (4.9) by $|X''(x)|^{\frac{5-n}{n-3}}X''(x)$ now gives

$$\lambda|X''(x)|^{\frac{n-1}{n-3}} + \frac{n-3}{n-1}(X'(x)|X''(x)|^{\frac{n-1}{n-3}} + X(x)(|X''(x)|^{\frac{n-1}{n-3}})') = 0. \tag{4.11}$$

By using periodicity, an integration of (4.11) over $\mathbb{T}$ for $n > 3$ therefore shows

$$\lambda \int_{\mathbb{T}} |X''(x)|^{\frac{n-1}{n-3}} dx = 0 \tag{4.12}$$

and the result then follows. We note that there are in general one or more points of inflection in nontrivial, periodic solutions, which prevents this argument from holding in two dimensions.

5. Weak solutions. In this section, we construct a basic, piecewise differentiable class of weak solutions $u(x,t) \in C^0([0,T), PC^1(\mathbb{T})) \cap C^1([0,T), PC^0(\mathbb{T}))$ to (2.11), which are found to exist for all $T > 0$, regardless of the underlying dimension.

For every vector field $\Phi(\mathbf{x},t) \in C_0^\infty([0,T) \times \mathbb{T} \times \mathbb{R}^{n-1}; \mathbb{R}^n)$ such that $\nabla \cdot \Phi = 0$, and for every scalar function $\theta(\mathbf{x},t) \in C_0^\infty([0,T) \times \mathbb{T} \times \mathbb{R}^{n-1}; \mathbb{R})$, the velocity field $\mathbf{u}(\mathbf{x},t)$ in (2.1b) satisfies

$$\int_Q \partial_t \Phi \cdot \mathbf{u} + (\nabla \Phi\, \mathbf{u}) \cdot \mathbf{u}\, d\mathbf{x}\, dt + \int_{\mathbb{T}\times\mathbb{R}^{n-1}} \Phi(\mathbf{x},0) \cdot \mathbf{u}(\mathbf{x},0)\, d\mathbf{x} = 0, \tag{5.1}$$

$$\int_{\mathbb{R}^n} \nabla\theta \cdot \mathbf{u}\, d\mathbf{x} = 0, \tag{5.2}$$

where $Q = [0,T) \times \mathbb{T} \times \mathbb{R}^{n-1}$.

In terms of (2.2), (5.1) and (5.2) reduce to

$$\begin{aligned} &\int_Q \partial_t\phi\, u - \partial_t\Phi' \cdot \mathbf{v}\, \partial_x u\, d\mathbf{x}\, dt \\ &+ \int_Q \partial_x\phi\, u^2 - (\partial_x\Phi' + \nabla'\phi) \cdot \mathbf{v}\, u\partial_x u + (\nabla'\Phi'\, \mathbf{v}) \cdot \mathbf{v}\, (\partial_x u)^2\, d\mathbf{x}\, dt \\ &+ \int_{\mathbb{T}\times\mathbb{R}^{n-1}} \phi(\mathbf{x},0)u(x,0) - \Phi'(\mathbf{x},0) \cdot \mathbf{v}(\mathbf{x},0)\partial_x u(x,0)\, d\mathbf{x} = 0, \end{aligned} \tag{5.3}$$

$$\int_{\mathbb{T}\times\mathbb{R}^{n-1}} \partial_x\theta\, u - \nabla'\theta \cdot \mathbf{v}\, \partial_x u\, d\mathbf{x} = 0, \tag{5.4}$$

in which we have used the notation $\Phi = (\phi, \Phi')$ to distinguish the first component from the remaining $n-1$ components of Φ. Denoting by $[\mathbf{u}] = \mathbf{u}_+ - \mathbf{u}_-$ the jump in $\mathbf{u}$ across any smooth surface of discontinuity, S, and considering test functions whose support crosses S, (5.2) shows that

$$[\mathbf{u}] \cdot \mathbf{n} = 0, \tag{5.5}$$

where $\mathbf{n} = (\mathfrak{n}, \mathbf{n}')$ is normal to S. Then, by (5.4), we have

$$[u]\mathfrak{n} - [\partial_x u]\mathbf{v}\cdot\mathbf{n}' = 0, \text{ where } \mathbf{v} = \frac{1}{n-1}\mathbf{x}'. \tag{5.6}$$

In examining weak, frontlike, piecewise continuous solutions for which $[u] = 0$ and $[\partial_x u] \neq 0$ (see [6]), it follows that these discontinuities propagate so that $\mathbf{n}' \cdot \mathbf{x}' = 0$. A weak formulation specific to such discontinuities may be derived by means of appropriate choice of test functions from (5.3), or by observing that (2.11) may be written in conservation form as

$$\partial_t((\partial_x u)^{1-n}) + \partial_x(u(\partial_x u)^{1-n}) + (n-1)(\partial_x u)^{-n} f = 0, \ x \in \mathbb{T}. \tag{5.7}$$

We will admit weak solutions, $u(x,t)$, which satisfy the relation

$$\int_{\mathfrak{Q}} \partial_t\varphi\,(\partial_x u)^{1-n} + \partial_x\varphi\, u(\partial_x u)^{1-n} - (n-1)f\varphi(\partial_x u)^{-n}\,dx\,dt \tag{5.8}$$

$$+ \int_{\mathbb{T}} \varphi(x,0)(\partial_x u)^{1-n}(x,0)\,dx = 0 \tag{5.9}$$

for all $\varphi(x,t) \in C_0^\infty(\mathfrak{Q})$, where $\mathfrak{Q} = [0,T) \times \mathbb{T}$. Using standard Rankine–Hugoniot-type arguments [6], discontinuities in $\partial_x u$ that jump across a curve $x = \psi(t)$ are seen to satisfy

$$(-\dot{\psi} + u(\psi,t))[(\partial_x u)^{1-n}] = 0, \tag{5.10}$$

and such discontinuities therefore propagate with the flow of (2.11); i.e., $\psi(t)$ is a member of the characteristic family $\dot{\gamma} = u \circ \gamma$.

5.1. Piecewise affine solutions. We begin by commenting on the general case of periodic, N-phase, piecewise affine solutions. Given that both $\partial_x u$ and $\partial_t u$ may be discontinuous across the curves $x = \psi_i(t), 1 \leq i \leq N-1$, in order for u to remain continuous there we must have $[u](\gamma(t),t) = 0$, and so $\frac{d}{dt}[u](\gamma(t),t) = 0$. As a result, $\partial_t[u] + u\partial_x[u] = 0$, and first derivative jumps are seen to satisfy the relations

$$[\partial_t u] + u[\partial_x u] = 0 \text{ and } [\partial_x p] = 0 \tag{5.11}$$

from (2.3). Under these conditions on u, the expression for $f(t)$, which was obtained in (2.13) by integrating (2.11) for $u \in C^1(\mathbb{T})$, remains unchanged:

$$f = -\frac{n}{n-1}\int_{\mathbb{T}} (\partial_x u)^2 dx. \tag{5.12}$$

In the special case, $N = 2$, which we consider here, our form of solution is given by the periodic extension of the function

$$u(x,t) = \alpha + \begin{cases} x\,p, & x \in (0,\tilde{\phi}), \\ \tilde{\phi}p + (x-\tilde{\phi})\,q, & x \in (\tilde{\phi},\tilde{\psi}), \\ \tilde{\phi}p + (\tilde{\psi}-\tilde{\phi})\,q + (x-\tilde{\psi})\,p, & x \in (\tilde{\psi},1), \end{cases} \tag{5.13}$$

where $\tilde{\phi} = \phi - [[\phi]], \tilde{\psi} = \psi - [[\psi]]$, with $[[.]]$ denoting the "integer part" of the argument. The functions $\tilde{\phi}(t)$ and $\tilde{\psi}(t)$ are the representatives in $[0,1]$ of the phase

curves $\phi(t), \psi(t) \in (-\infty, \infty)$, which start out from $\phi(0), \psi(0) \in [0,1]$ and separate those regions where $\partial_x u(x,t)$ periodically takes on values of $p(t)$ or $q(t)$.

Proceeding heuristically for the moment, periodicity of $u(x,t)$ requires that

$$\mathcal{N}(t) = \phi(t)p(t) + (\psi(t) - \phi(t))q(t) + (1 - \psi(t))p(t) = 0. \tag{5.14}$$

Given the spatial periodicity in pressure (see (2.9)), we recall that integration of (2.3) over one period showed the integral $\int_0^1 u(x,t)dx$ to be independent of time. This allows (5.13) to be used to give an expression for $\alpha(t)$. The result may be written, for instance, in terms of $p, \tilde{\phi}$, and $\tilde{\psi}$, as

$$\alpha + \frac{p}{2}(\tilde{\phi} + \tilde{\psi} - 1) = c, \tag{5.15}$$

where we have set $c = \int_0^1 u(x,0)\,dx = \alpha(0) + \frac{p(0)-q(0)}{2}(\psi(0) - \phi(0))(\phi(0) + \psi(0) - 1)$. We will assume that $0 < \phi(0) < \psi(0) < 1$. Choosing, for convenience, $c = 0$, the "average characteristic" must propagate with speed zero and we will see, consequently, that both $\phi(t)$ and $\psi(t)$ remain in $[0,1]$ for all time. The distinctions between $\tilde{\phi}$ and ϕ, $\tilde{\psi}$, and ψ will therefore not be made further here.

Combining (2.11), (5.12), and (5.13) now gives

$$\dot{p} = \frac{1}{n-1}p^2 + f, \quad \dot{q} = \frac{1}{n-1}q^2 + f, \tag{5.16}$$

where

$$f = -\frac{n}{n-1}(\phi p^2 + (\psi - \phi)q^2 + (1 - \psi)p^2). \tag{5.17}$$

Also, by (5.10),

$$\dot{\phi} = \alpha + \phi p \tag{5.18}$$

and

$$\dot{\psi} = \alpha + \phi p + (\psi - \phi)q. \tag{5.19}$$

We next verify that (5.14) follows from the system of equations (5.16)–(5.19). Differentiation and some simplification gives

$$\begin{aligned}\dot{\mathcal{N}} &= -(\psi - \phi)(p - q)q + (\psi - \phi)q^2 + (\phi + (1 - \psi))\left(\frac{p^2}{n-1} + f\right) + (\psi - \phi)\left(\frac{q^2}{n-1} + f\right) \\ &= -(\psi - \phi)(p - q)q - ((\phi + (1 - \psi))p^2 + (\psi - \phi)q^2) \\ &= -p(q(\psi - \phi) + p(\phi + (1 - \psi))) \\ &= -p\mathcal{N},\end{aligned}$$

and so $\mathcal{N}(t) = \mathcal{N}(0)e^{-\int_0^t p(s)ds}$. In particular, taking periodic data, $\mathcal{N}(0) = 0$, means that $\mathcal{N}(t) = 0$, $t > 0$. We may therefore use (5.14) to write (5.19) as

$$(1 - \psi)^{\cdot} = -\alpha + (1 - \psi)p, \tag{5.20}$$

and again employ (5.14) to express the following phase fractions as functions of p and q:

$$\psi - \phi = \frac{p}{p-q}, \quad \phi + (1-\psi) = \frac{-q}{p-q}\,. \tag{5.21}$$

Using these relations in (5.17) leads to

$$f = \frac{n}{n-1} pq \tag{5.22}$$

from which (5.16) reduces to the autonomous system

$$\dot{p} = \frac{1}{n-1}(p^2 + n\,pq), \tag{5.23}$$

$$\dot{q} = \frac{1}{n-1}(q^2 + n\,pq). \tag{5.24}$$

Subtracting (5.18) from (5.19) implies

$$\psi(t) - \phi(t) = (\psi(0) - \phi(0)) \exp\left(\int_0^t q(s)ds\right), \tag{5.25}$$

which means that the center phase fraction does not collapse as long as $\int_0^t q(s)ds$ remains bounded away from $-\infty$. Similarly, adding (5.18) and (5.20) gives

$$\phi(t) + (1-\psi(t)) = (\phi(0) + (1-\psi(0)) \exp\left(\int_0^t p(s)ds\right), \tag{5.26}$$

and the outer phase fraction exists as long as $\int_0^t p(s)ds > -\infty$. Comparing (5.25) and (5.26) shows also that periodicity imposes the following requirement on $p(t)$ and $q(t)$ in terms of their initial phase fractions:

$$(\phi(0) + (1-\psi(0)) \exp\left(\int_0^t p(s)ds\right) + (\psi(0) - \phi(0)) \exp\left(\int_0^t q(s)ds\right) = 1. \tag{5.27}$$

Using (5.16) to compute $p - q$ next gives

$$p(t) - q(t) = (p(0) - q(0)) \exp\left(\frac{1}{n-1}\int_0^t p(s) + q(s)\,ds\right), \tag{5.28}$$

which shows $p(t) - q(t)$ cannot change sign. By (5.21), $p(t)$ and $q(t)$ consequently keep their signs as long as neither phase fraction collapses. This can alternatively be seen by considering a sketch of u and observing that p and q have opposite signs and can vanish only simultaneously. Thus, without loss of generality, we subsequently assume $p(t) > 0 > q(t)$, for at least some $t \geq 0$.

In the following lemma, we solve the system (5.23), (5.24) implicitly in order to show that two-phase solutions of the type (5.13) exist for all time.

LEMMA 5.1. *Let* $(p(t), q(t))$ *satisfy* (5.23), (5.24) *with initial data* $p(0) > 0 > q(0)$ *(respectively,* $p(0) < 0 < q(0)$*). Then* $(p(t), q(t))$ *exists for all* $t \in (-\infty, \infty)$ *and satisfies* $p(t) > 0 > q(t)$ *(respectively,* $p(t) < 0 < q(t)$*). Further,* $(p(t), q(t)) \to (0, 0)$ *as* $t \to \pm\infty$*, and* $||u(.,t)||_{C^1} + ||\partial_t u(.,t)||_{C^0} \to 0$ *as* $t \to \pm\infty$.

Proof. Writing (5.23) and (5.24) using polar variables $p(t) = r(t)\cos\theta(t)$, $q(t) = r(t)\sin\theta(t)$, $r(t) \geq 0$, leads to the following:

$$\dot{r}(t) = \frac{r^2}{n-1}(\cos^3(\theta(t)) + n(\cos\theta(t) + \sin\theta(t))\cos\theta(t)\sin\theta(t) + \sin^3(\theta(t))), \tag{5.29}$$

and

$$\dot{\theta}(t) = r(\cos\theta(t) - \sin\theta(t))\cos\theta(t)\sin\theta(t). \tag{5.30}$$

In the case $p(0) > 0 > q(0)$, $\theta(0) \in (-\pi/2, 0)$, so by (5.30) $\dot{\theta}(0) < 0$ and, as long as $\theta(t) \in (-\pi/2, 0)$, $\dot{\theta}(t) < 0$.

We will show that $\theta(t) \to -\pi/2$ as $t \to \infty$ ($\theta(t) \to 0$ as $t \to -\infty$) by using (5.29) and (5.30). Integrating the resulting expression for $\frac{d\ln r}{d\theta}$ gives

$$r(\theta) = c|\cos\theta\sin\theta|^{\frac{1}{n-1}}|\cos\theta - \sin\theta|^{-\frac{n+1}{n-1}}, \tag{5.31}$$

where $c > 0$ denotes a generic constant. Inserting this expression for $r(\theta)$ in (5.30) results in

$$\begin{aligned}\dot{\theta}(t) &= c|\cos\theta\sin\theta|^{\frac{1}{n-1}}|\cos\theta - \sin\theta|^{-\frac{n+1}{n-1}}(\cos\theta - \sin\theta)\cos\theta\sin\theta \\ &= -c|\cos\theta\sin\theta|^{\frac{n}{n-1}}|\cos\theta - \sin\theta|^{-\frac{2}{n-1}} \qquad (5.32)\end{aligned}$$

for $\theta(t) \in (-\pi/2, 0)$, and so

$$\int_{\theta(0)}^{\theta(t)} \frac{|\cos\theta - \sin\theta|^{\frac{2}{n-1}}}{|\cos\theta\sin\theta|^{\frac{n}{n-1}}}d\theta = -ct, \ -\frac{\pi}{2} < \theta(0) < 0, \ c > 0. \tag{5.33}$$

Since $\frac{n}{n-1} > 1$, the integral expression diverges, both as $\theta(t) \to -\pi/2$ ($t \to +\infty$) and as $\theta(t) \to 0$ ($t \to -\infty$). Thus $\theta(t)$ and, from (5.31), $r(t)$, are bounded, continuous functions of time, with $\theta(t) \in (-\pi/2, 0)$. By (5.31) then, $r(t) \to 0$ as $t \to \pm\infty$, and, noting that from (5.14), (5.15),

$$\alpha(t) = -\frac{p(t) - q(t)}{2}(\psi(t) - \phi(t))(\phi(0) + \psi(0) - 1)\,,$$

it follows from (5.35) and (5.36) that

$$p(t), q(t), \alpha(t), \text{ and } u(x,t) \to 0 \text{ as } t \to \pm\infty.$$

The remaining conclusions are easily obtained. ∎

Finally, we show that for $c = 0$ the phases remain in the interval $[0, 1]$ for all time.

THEOREM 5.1. *Suppose $c = 0$ and $0 < \phi(0) < \psi(0) < 1$. Then the phases ϕ, ψ stay in $[0, 1]$. In particular*

$$\phi(t) \in [\phi(0), \tfrac{1}{2}(\phi(0) + \psi(0)) \ \textit{and} \ \psi(t) \in (\tfrac{1}{2}(\phi(0) + \psi(0)), \psi(0)]$$

for all $t > 0$. Further, the time asymptotic behavior satisfies

$$\lim_{t\to\infty} \phi(t) = \tfrac{1}{2}(\phi(0) + \psi(0)) = \lim_{t\to\infty} \psi(t).$$

Proof. With (5.15) giving α (for $c = 0$), substituting into (5.18) and (5.20) shows that, by (5.26),

(5.34)

$$\dot{\phi}(t) = (1-\psi(t))^{\cdot} = \frac{p}{2}(\phi + (1-\psi)) = \frac{1}{2}(\phi(0) + (1-\psi(0)))p(t)\exp\left(\int_0^t p(s)ds\right),$$

and the individual phases therefore satisfy

$$\phi(t) = \phi(0) + \frac{1}{2}(\phi(0) + (1-\psi(0)))\left(\exp\left(\int_0^t p(s)ds\right) - 1\right) \tag{5.35}$$

and

$$\psi(t) = \psi(0) - \frac{1}{2}(\phi(0) + (1-\psi(0)))\left(\exp\left(\int_0^t p(s)ds\right) - 1\right). \tag{5.36}$$

Now we examine (5.27). Assuming $q < 0 < p$, the first term is monotonically increasing in time and must converge, for $0 < \phi(0) < \psi(0) < 1$, to a positive limit. The second term is positive but monotonically decreasing, so it may converge, as $t \to \infty$, either to a positive limit or to zero. Formally, setting $0 < \int_0^\infty p(t)dt = L < \infty$ and $-\infty \le \int_0^\infty q(t)dt = M < 0$, (5.27) and (5.28) imply

$$(\phi(0) + (1-\psi(0)))e^L + (\psi(0) - \phi(0))e^M = 1 \tag{5.37}$$

and

$$\lim_{t\to\infty}(p(t) - q(t)) = (p(0) - q(0))e^{\frac{L+M}{n+1}}. \tag{5.38}$$

If M is finite and $p(0) \neq q(0)$, then (5.38), together with the necessity for $p(t)$ to approach zero as $t \to \infty$, means that $\lim_{t\to\infty} q(t) \neq 0$. However, this implies that $M = -\infty$, a contradiction. On the other hand, if $M = -\infty$, then, since $L < \infty$, (5.38) requires that $\lim_{t\to\infty} q(t) = 0$, which is permitted. We conclude that, for smooth solutions $p(t), q(t)$ to exist with $p(0) > 0 > q(0)$, we require that $L = \int_0^\infty p(t)dt < \infty$ and $M = \int_0^\infty q(t)dt = -\infty$. Thus, by (5.37),

$$e^L = \frac{1}{\phi(0) + 1 - \psi(0)}. \tag{5.39}$$

Writing (5.35) in the form

$$\phi(t) = \frac{1}{2}(\phi(0) - (1-\psi(0))) + \frac{1}{2}(\phi(0) + (1-\psi(0)))\exp\int_0^t p(s)ds, \tag{5.40}$$

it follows that

$$\lim_{t\to\infty}\phi(t) = \frac{1}{2}(\phi(0) + \psi(0)) \tag{5.41}$$

and, similarly,

$$\lim_{t\to\infty}\psi(t) = \frac{1}{2}(\phi(0) + \psi(0)). \tag{5.42}$$

By the monoticity in time of $\int_0^t p(s)ds$, therefore $\phi(t) \in [\phi(0), \frac{1}{2}(\phi(0) + \psi(0))$ and $\psi(t) \in (\frac{1}{2}(\phi(0) + \psi(0)), \psi(0)]$ for all $t > 0$.

BREAKING OF SYMMETRICAL PERIODIC SOLUTIONS IN A SINGULARLY PERTURBED KDV MODEL*

ALEXANDER TOVBIS†

Abstract. There are several recent developments in the well-known problem of breaking of homoclinic orbits (splitting of separatrices) of a system that undergoes a singular perturbation. First, survival of a homoclinic orbit is an exceptional situation that can be linked to triviality of the Stokes phenomenon of the underlying "truncated" equation. Second, homoclinic connections to exponentially small periodic orbits survive the perturbation in the generic case. In this paper we consider a different problem: we study deformations of "genuine" periodic orbits of the second order equation $y'' = y + y^2$ that undergoes the singular perturbation $\varepsilon^2 y'''' + (1-\varepsilon^2)y'' = y + y^2$, where $\varepsilon > 0$ is a small parameter. We prove that if the period and the constant of motion do not change too rapidly (in ε), a genuine (nontrivial) periodic solution does not survive the perturbation.

Key words. singular perturbations, periodic solutions, exponentially small phenomena

1. Introduction.

1.1. Breaking of homoclinic connections. Let $y = 0$ be a hyperbolic stationary point of an n-dimensional differential equation $y' = f(y)$, and let W_s, W_u be the stable and unstable manifolds at $y = 0$. It is said that the stationary point $y = 0$ has a homoclinic connection if there exists a phase trajectory, originating and ending at $y = 0$, that lies on $W_s \cap W_u$. For example, the (bounded) separatrix solution

$$y(x) = -\frac{3/2}{\cosh^2(x/2)} \tag{1}$$

to

$$y''(x) = y(x) + y^2(x) \tag{2}$$

corresponds to the homoclinic connection of the stationary point $(0, 0)$ in the phase plane of (2). There exists a general problem to describe how a singular perturbation of the original equation affects the homoclinic (or a heteroclinic) connection. A large number of particular singularly perturbed equations, originating from the corresponding physical or computational problems, have been discussed in the literature (see, for example, [STL] and the references therein). In particular, the singular perturbation

$$\varepsilon^2 y''''(x) + (1-\varepsilon^2)y''(x) = y(x) + y^2(x) \tag{3}$$

of (2) is related to the traveling wave reduction of a fifth order KdV equation that models gravity water waves. Existence or nonexistence of homoclinic connections of (3) has been studied in a number of papers; see, for example, [HM], [PRG], [GJ]. A rigorous proof of nonexistence of such connections was obtained in [AM] (see also

[Eck]) and later on in [To4], where the "asymptotic beyond all orders" approach, first suggested in [KS] for a simple crystal growth model, was put on a rigorous basis. This approach is, in a sense, a natural way to study exponentially small phenomena, such as the mismatch between the stable and the unstable manifolds of (3). The goal of the present paper is to show that a similar argument can be used to prove nonexistence of symmetrical periodic solutions to (3) (see below), subject to some additional requirements.

The approach of [KS] is to rescale (3), which is called the outer equation, to the inner equation

$$v''''(z) + (1-\varepsilon^2)v''(z) = \varepsilon^2 v(z) + v^2(z), \tag{4}$$

where $x = \varepsilon z$ and $v = \varepsilon^2 y$. The main advantage of (4) versus (3) is that the (exponentially small) difference between the stable and unstable solutions is detectable even in the leading order part

$$v''''(z) + v''(z) = v^2(z), \tag{5}$$

of (4), which is called the truncated equation (4). This means that the difference between the stable and unstable solutions to (3) can be studied through the Stokes phenomenon of (5). In fact, in [TP] we considered the family of singular perturbations

$$\varepsilon^2 y^{(\mathrm{iv})} + (1-\varepsilon^2)y'' - y = y^2 + \varepsilon^2\gamma\left(2yy'' + (y')^2\right) \tag{6}$$

of (2), parametrized by $\gamma \in \mathbb{R}$, and found exact conditions for persistence of the homoclinic connection (under the singular perturbation) in terms of the Stokes constant for the corresponding truncated inner equation. The technique developed in [To4] can be modified to consider singularly perturbed problems in other settings. For example, it was used in [To5] to show that the discretized equation (3) does not have a homoclinic connection.

Notice that persistence of the homoclinic connection under singular perturbations (3), (6) is equivalent to existence of a symmetrical (even) stable solution to the corresponding equation. Since the family of stable solutions to (3) (or to (6)) is one-dimensional (translation), we can arrange for $y'(0) = 0$; then the symmetry of the stable solution $y(x)$ is equivalent to $y'''(0) = 0$.

1.2. Deformation of periodic solutions under singular perturbations. The problem of deformations of periodic solutions under singular perturbations has not yet received as much attention as the problem of homoclinic connections. However, it is known that there exist symmetrical periodic solutions to (3) that are exponentially small in ε; see [Lo] and later papers [IL1], [IL2]. We consider such periodic solutions as deformations of a constant solution $y \equiv 0$ of the unperturbed equation (2). Existence of even periodic solutions that are deformations of a trivial solution was also proved in [BPBA] for a certain class of reversible fourth order Hamiltonian systems with zero Hamiltonian. Discussion of even periodic solutions for some fourth order ODEs with nonzero Hamiltonian and cubic nonlinearity ((3) has a quadratic nonlinearity) can be found in [PT].

In the present paper we extended the technique of [To4] to study deformations of a genuine (nonconstant) periodic solution of (2). We limit our attention to periodic solutions inside the potential well of (2). Any such solution is given by the Weierstrass elliptic $\wp$-function with invariants g_2, g_3,

$$y(x) = 6\wp_{g_2,g_3}(x - x_0) - \frac{1}{2}, \tag{7}$$

and has an integral of motion

$$y'^2 = y^2 + \frac{2}{3}y^3 + C, \tag{8}$$

where $x_0 \in \mathbb{C}$ is a translation and $g_2 = \frac{1}{12}$, $g_3 = -\frac{1}{36}(C + \frac{1}{6})$ (see section 1.3). The requirement $C \in (-\frac{1}{3}, 0)$ on the constant of motion (energy) C guarantees that solution $y(x)$ is inside the potential well. (The value $C = 0$ corresponds to the trivial solution and to the separatrix solution of (2), whereas $C = -\frac{1}{3}$ corresponds to the stationary solution $y(x) \equiv -1$.) Solution (7) is a periodic function with finite basic real and purely imaginary periods

$$2\omega_1 = \int_{e_1}^{\infty} \frac{du}{\sqrt{4u^3 - \frac{1}{12}u - g_3}}, \quad 2\omega_3 = i\int_{-\infty}^{e_3} \frac{du}{\sqrt{4u^3 - \frac{1}{12}u - g_3}}, \tag{9}$$

where e_1, e_3 are the largest and the smallest real roots of $4u^3 - \frac{1}{12}u - g_3 = 0$ (see below), respectively. It is also an even function provided that x_0 is an integer linear combination of ω_1, ω_3. It will be convenient for us to choose

$$x_0 = \omega_3, \tag{10}$$

so that the unperturbed solution (7) is bounded, real-valued, symmetrical, and periodic with the period $2\omega_1$ on $x \in \mathbb{R}$. Equivalently, we can consider solution (7) with $x_0 = 0$ along the horizontal line $\omega_3 + \mathbb{R}$ in the complex x-plane.

The perturbed equation (3) also has an integral of motion

$$\varepsilon^2(2y'''y' - y''^2) + (1 - \varepsilon^2)y'^2 - y^2 - \frac{2}{3}y^3 = C(\varepsilon), \tag{11}$$

where $C(\varepsilon)$ is the constant of motion (energy). Since we are interested in deformations of periodic solutions satisfying (8), we require $C(0) = C \in (-\frac{1}{3}, 0)$.

Let $\alpha \geq 1$. We say that a solution $y(x, \varepsilon)$ to the perturbed equation (3) is a C^α-deformation of a periodic solution (7) (in the potential well) to the unperturbed equation (2) under the singular perturbation (3) on interval S if

$$Y(x, \varepsilon) = Y(x, 0) + \varepsilon^\alpha \tilde{Y}(x, \varepsilon), \tag{12}$$

where vector $\tilde{Y}(x, \varepsilon)$ is continuous in ε, uniformly on interval S of the x-axis. Here $Y(x, \varepsilon) = \text{Col}\ (y(x, \varepsilon), y'(x, \varepsilon), y''(x, \varepsilon), y'''(x, \varepsilon))$. Note that a C^α-deformation of a periodic solution (7) has constant of motion (11) satisfying

$$C(\varepsilon) = C + \varepsilon^\alpha \tilde{C}(\varepsilon), \tag{13}$$

where $\tilde{C}(\varepsilon)$ is a continuous function.

Our main result is the following theorem.

THEOREM 1.1. *Let $y(x, 0) = 6\wp_{\frac{1}{12}, g_3}(x - \omega_3) - \frac{1}{2}$, where $|g_3| < 6^{-3}$, be a periodic solution (inside the potential well) of the nonperturbed equation (2). Let $n \in \mathbb{N}$ and $y(x, \varepsilon)$ be a C^α-deformation, $\alpha \geq 1$, of $y(x, 0)$ under the perturbation (3) on some open interval S that contains the segment $[\omega_1, n\omega_1]$. Then the deformation $y(x, \varepsilon)$ does not contain a sequence of symmetric periodic solutions $y(x, \varepsilon_m)$ of (3) with periods $2k\omega_1(\varepsilon_m)$, where $k = 1, 2, \ldots, n$, $\lim_{m\to\infty} \varepsilon_m = 0$, and $\omega_1(\varepsilon)$ is subject to*

$$\omega_1(\varepsilon) - \omega_1 = \varepsilon^{\frac{\alpha}{2}}\tau(\varepsilon), \tag{14}$$

where $\tau(\varepsilon)$ is a continuous function for small $\varepsilon \geq 0$.

Similarly to the homoclinic connection problem, the central idea of our proof here is uniform (in small $\varepsilon \geq 0$) control of an iterative solution of inner equation (4). In a certain sense, though, the homoclinic connection problem is simpler, because the manifolds of stable and unstable solutions to (3) are one-dimensional, whereas deformations of a periodic solution to (2) under the perturbation (3) form a manifold of the full dimension. We rescale the outer equation (3) to the inner equation (4) by $x = \varepsilon z$, $v = \varepsilon^2 y$ and approach the problem through the following sequence of steps: (a) we construct by iterations a two-parameter family $\mathcal{F}_\alpha$ of deformations of the rescaled periodic solution (7), (10), satisfying (4); (b) we show that solutions $v(z, \varepsilon)$ to the inner equation (4) that corresponds to a C^α-deformation $y(x, \varepsilon)$ of a periodic solution (7) with the period $2\omega_1$ belong to the family $\mathcal{F}_\alpha$; and (c) for any $k \in \mathbb{N}$ we prove that the family $\mathcal{F}_\alpha$ does not contain a sequence $\{v(z, \varepsilon_m)\}_1^\infty$ of symmetrical and periodic (with the period $2k\frac{\omega_1(\varepsilon_m)}{\varepsilon_m}$) solutions if $\omega_1(\varepsilon)$ is subject to (14).

The paper is organized in the following way. In the remaining part of this section we describe the Stokes phenomenon for the truncated inner equation (5) and some connections between deformations of homoclinic and periodic orbits of (3). Solution of (3) by iterations, which yields the two-parameter family of solutions $\mathcal{F}_\alpha$, is obtained in sections 2–3. Finally, the proof of Theorem 1.1 is completed in section 4.

1.3. Periodic solutions of the unperturbed equation. It is easy to check that the values C from the interval $(-\frac{1}{3}, 0)$ define periodic solutions of the unperturbed equation (2) within the well of the potential $-y^2 - \frac{2}{3}y^3$. After the change of variables $y = 6X - \frac{1}{2}$, (8) is reduced to

$$X'^2 = 4X^3 - \frac{1}{12}X - g_3, \tag{15}$$

where $g_3 = -\frac{1}{36}(C + \frac{1}{6})$. The solution to this equation is given by the Weierstrass elliptic function $\wp(x) = \wp_{g_2,g_3}(x)$, where the invariant $g_2 = \frac{1}{12}$ and g_3 is defined above. Thus, periodic solutions to the unperturbed equation (2) are given by

$$y(x) = 6\wp_{g_2,g_3}(x) - \frac{1}{2}. \tag{16}$$

The number $\Delta = g_2^3 - 27g_3^2$ is called the discriminant of $\wp_{g_2,g_3}(x)$. The condition $\Delta > 0$ is equivalent to $|g_3| < 6^{-3}$, i.e., to $C \in (-\frac{1}{3}, 0)$. Under this condition the Weierstrass function $\wp$ has real period $2\omega_1$ defined by (9) and purely imaginary period $2\omega_3$, where $\omega_1, -i\omega_3$ are positive numbers (the latter requires correct choice of the branch of the square root in (9)). Using the standard notation, we denote $\omega_2 = \omega_1 + \omega_3$ and $e_j = \wp(\omega_j)$, where $j = 1, 2, 3$. It is well known that (see, for example, [GR]) e_j are the roots of the cubic polynomial in (15),

$$\wp'(\omega_j) = 0,\ j = 1, 2, 3, \quad e_1 + e_2 + e_3 = 0, \qquad \text{and} \qquad e_3 \leq e_2 \leq e_1. \tag{17}$$

When x varies along the real axis, the value of $\wp$ varies between e_1 and $+\infty$ (as $\wp(x)$ is an even function that has a second order pole at the origin with the principle part $\frac{1}{x^2}$); see Figure 1.

This corresponds to the periodic solution of (2), defined by (16), with the range from $\tilde{e}_1$ to infinity outside the potential well, i.e., to the unbounded branch of the periodic orbit (the energy of the motion is fixed). Here $\tilde{e}_j = 6e_j - \frac{1}{2}$, $j = 1, 2, 3$; see Figure 2.

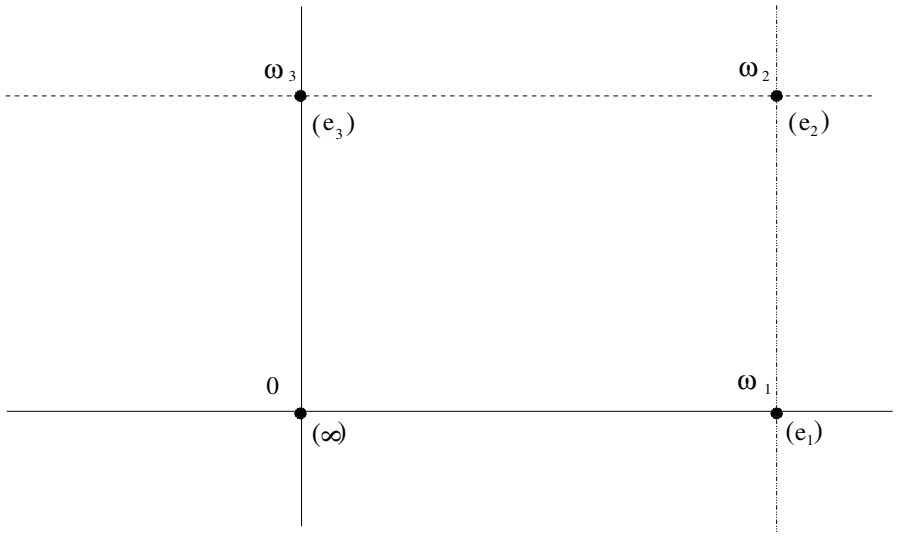

FIG. 1. *Part of the parallelogram of periods* $0\omega_1\omega_2\omega_3$ *for the Weierstrass functions* $\wp(x)$ *in the complex* x*-plane together with the corresponding values of* $\wp$ *shown in the brackets.*

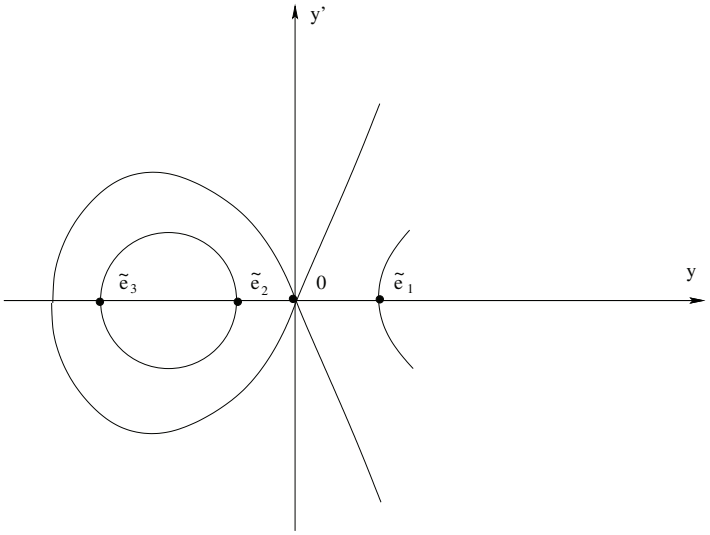

FIG. 2. *Phase portrait of* (2) *showing periodic solutions* ($\Delta > 0$) *of the same period inside (bounded) and outside (unbounded) the potential well. Here* $\tilde{e}_j = 6e_j - \frac{1}{2}$, $j = 1, 2, 3$.

When x varies along the horizontal line $\Im x = \omega_3$, the value of $\wp$ varies between e_3 and e_2. That corresponds to the periodic solution of (2), defined by (16), with the range from $\tilde{e}_3$ to $\tilde{e}_2$ inside the potential well, i.e., to the bounded branch of the periodic orbit. When x varies along the vertical line $\Re x = \omega_1$, the value of $\wp$ varies between e_1 and e_2. That corresponds to the tunneling between the unbounded and bounded branches of the periodic orbit defined by the solution (16); see Figures 1 and 2. For $\Delta < 0$ the periods ω_1 and ω_3 are complex conjugated so that ω_2 is real. In this case the value of $\wp$ varies between e_2 and $+\infty$, which corresponds to infinite periodic motion outside the potential well; see Figure 3.

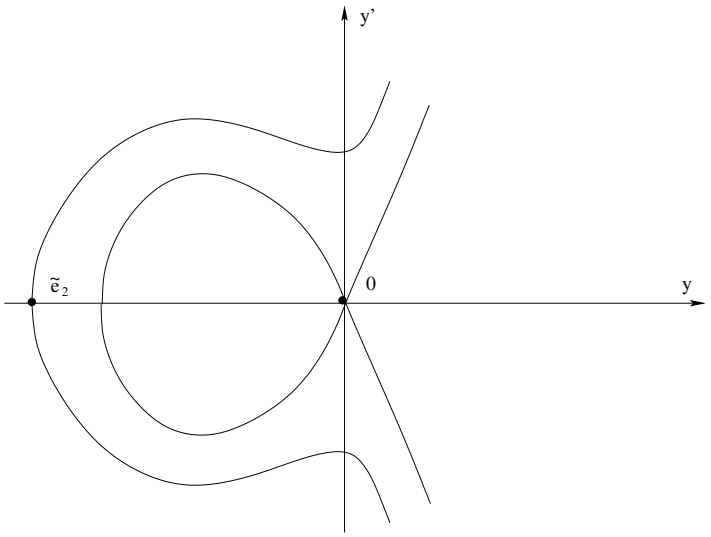

FIG. 3. *Phase portrait of* (2) *showing an unbounded periodic solution* ($\Delta < 0$) *outside the potential well. Here* $\tilde{e}_2 = 6e_2 - \frac{1}{2}$.

Here and henceforth it will be convenient for us to consider x_0 from (7) to be zero. Then we are interested in the behavior of $y(x)$ along the horizontal line $\omega_3(\varepsilon) + \mathbb{R}$.

1.4. Solutions to the perturbed equation. Considering perturbations of the separatrix solution (1) of the original equation, we focus our attention on the stable and unstable solutions of the perturbed equation (3) (those are solutions corresponding to the one-dimensional manifolds W_s and W_u in the phase space of (3)). We define the unstable and stable solutions to (3) as

$$y_{u,s}(x,\varepsilon) = \sum_{k=1}^{\infty} y_k(\varepsilon) e^{\pm kx}, \tag{18}$$

respectively, where $y_1(\varepsilon)$ as an arbitrary continuous positive function and all y_k, $k > 1$, are uniquely defined through y_1 [To4]. The series (18) is convergent in properly chosen left- and right-half planes of the complex x-plane, respectively. It is easy to check that for $\varepsilon = 0$ the choice of $y_1(0) = 6$ yields the unbounded separatrix solution

$$y(x) = \frac{3/2}{\sinh^2(x/2)}, \tag{19}$$

which is related to the bounded separatrix solution (1) through the shift $x \mapsto x + i\pi$. Considering x as a complex variable, now and henceforth we refer to (19) as the separatrix solution of (3).

Perturbations of periodic solutions to the original equation (2) that we are interested in are not as clearly identifiable as solutions (18) in the separatrix case. We start with considering the separatrix solution of (3) as the limit of periodic solutions (16) as $C \to 0^-$. In this limit the real half-period $\omega_1 \to \infty$, and the imaginary half-period $\omega_3 \to i\pi$. Thus, the point $\omega_2 \to i\pi + \infty$ as $C \to 0^-$.

Note that the stable and unstable solutions (18) are symmetrical with respect to $x = 0$ since $y_s(x,\varepsilon) = y_u(-x,\varepsilon)$. Alternatively, we can consider $y_u(x)$ as the

symmetrical continuation of $y_s(x)$ through $x = \infty$ on the compactification of $\mathbb{R}$. The same observation is correct for the horizontal line $\Im x = \pi$ and $x = i\pi + \infty$. The analogue of the point $x = i\pi + \infty$ in the periodic case is $x = \omega_2$. Therefore, by analogy with the separatrix case, we will consider perturbations of the periodic solution (16) that *are symmetrical with respect to the point* $\omega_2(\varepsilon)$. Equivalently, that means that the first and third derivatives of $y(x)$ turn zero at $x_0 = \omega_2$. The remaining two of the total of four conditions to define $y(x, \varepsilon)$ are $y'(\omega_3(\varepsilon), \varepsilon) = 0$ and the integral of motion (11). Thus, $y(x, \varepsilon)$ satisfies third order differential equation (11) with the prescribed energy $C(\varepsilon)$ together with three boundary conditions

$$y'(\omega_3(\varepsilon), \varepsilon) = 0, \quad y'(\omega_2(\varepsilon), \varepsilon) = y'''(\omega_2(\varepsilon), \varepsilon) = 0, \tag{20}$$

where $C(0) = C$ and $2\omega_1(\varepsilon), 2\omega_3(\varepsilon)$ are the fundamental periods of the Weierstrass function $\wp$ in the solution (16) of (8).

It is easy to see that if $f(x)$ is an even (symmetrical at $x = 0$) periodic function with a period $2\omega_1$, then $f(x)$ is symmetrical at any point $x = k\omega_1$, $k \in \mathbb{N}$. Since a solution $y(x, \varepsilon)$ to the BVP (11), (20) is symmetrical at $x = \omega_2(\varepsilon)$ on the horizontal line $\Im x = \Im\omega_3(\varepsilon)$, $y(x, \varepsilon)$ is an even periodic solution if and only if

$$y'''(\omega_3(\varepsilon), \varepsilon) = 0. \tag{21}$$

1.5. The Stokes phenomenon for the inner equation. Periodic solutions (16) to (2) have second order poles at $x = 0$. The asymptotic beyond all orders approach of [KS] suggests blowing up this singularity by rescaling

$$x = \varepsilon z, \quad y(x, \varepsilon) = \varepsilon^{-2} v(z, \varepsilon), \tag{22}$$

where z is a new independent complex variable. The rescaled equation (inner equation) is given by (4), which we can rewrite as

$$(D_z^2 + 1)(D_z^2 - \varepsilon^2)v = v^2. \tag{23}$$

Let $v_+(z, \varepsilon)$ and $v_-(z, \varepsilon)$ denote, respectively, the rescaled solutions to the BVP (11), (20) and to its "symmetrical" problem, where conditions at $\omega_2(\varepsilon)$ are replaced by the same conditions at $-\bar{\omega}_2(\varepsilon) = -\omega_1(\varepsilon) + \omega_3(\varepsilon)$, i.e., $y'(-\bar{\omega}_2(\varepsilon), \varepsilon) = y'''(-\bar{\omega}_2(\varepsilon), \varepsilon) = 0$. Our observation (proved below) is that, similarly to the case of the separatrix solution, the leading order (in ε) of the difference between $v_+(z, \varepsilon)$ and $v_-(z, \varepsilon)$ can be derived from the truncated equation

$$(D_z^2 + 1)D_z^2 v = v^2. \tag{24}$$

Note that $z = \infty$ is the irregular singular point of (24) and that this equation has a unique formal power series solution

$$\hat{v}(z) = \sum_{k=1}^{\infty} \frac{v_k}{z^{2k}}, \tag{25}$$

where $v_1 = 6$.

The inverse Laplace transform $\mathcal{L}^{-1}$ converts the truncated inner equation (24) into the convolution equation

$$(p^4 + p^2)V(p) = V(p) * V(p), \tag{26}$$

where p is a dual variable (called Borel variable), $V(p) = [\mathcal{L}^{-1}v](p)$, and $F(p)*G(p) = \int_0^p F(p-\tau)G(\tau)d\tau$. It is well known that the asymptotic expansion (25) of $v(z)$ yields the corresponding asymptotic expansion in powers of p of $V(p)$ at $p = 0$.

THEOREM 1.2. *Equation* (26) *admits a unique nontrivial power series solution in odd powers of* p. *This solution defines a function* $V(p)$ *that is analytic at the whole* p*-plane except for two vertical rays: from* $p = i$ *upward and from* $p = -i$ *downward. The function* $V(p)$ *is of exponential order* 1 *along any nonvertical ray in this cut* p*-plane.*

This theorem follows from a more general statement (Main Theorem) of [To2].

COROLLARY 1.3. *Let* $v_\pm(z)$ *be defined by*

$$v_\pm(z) = \int_0^{\pm\infty} e^{-zp}V(p)dp. \tag{27}$$

These functions are the only analytic solutions of the truncated inner equation (24) *that satisfy*

$$v_\pm(z) \sim \hat{v}(z) \quad \text{as } z \to \infty, \quad z \in S_\pm, \tag{28}$$

where $S_\pm$ *are sectors*

$$S_+ = \{z : \ |\arg z| < \pi\}, \qquad S_- = \{z : \ |\arg z - \pi| < \pi\}. \tag{29}$$

Moreover,

$$v_+(z) - v_-(z) = -2\pi i s e^{iz}(1 + o(1)) \qquad \text{as} \qquad z \to \infty, \quad 0 < \arg z < \pi, \tag{30}$$

where the constant s *is determined through*

$$s = \lim_{p \to -i} (p + i)V(p). \tag{31}$$

Proof. The Taylor expansion of $V(p)$ at $p = 0$ can be obtained by applying the inverse Laplace transform (Borel transform) to the formal series $\hat{v}(z)$. The function $V(p)$ is analytic on a Riemann surface that has possible branch points of the logarithmic type at $p = ik$, where $k \in \mathbb{Z} \setminus \{0\}$. The statement on the behavior of $V(p)$ at singularities $p = \pm i$ follows from Theorem 2.2 in [To2]. The uniqueness of solutions $v_\pm(z)$ satisfying (28) follows from Theorem 1.2 and properties of the Laplace transform. □

DEFINITION 1.4. *The constant* s *in* (31) *is called the Stokes constant for the truncated inner equation* (24).

PROPOSITION 1.5. *The following three conditions are equivalent:* (i) *the formal power series solution* (25) *has a positive radius of convergence;* (ii) $s = 0$*; and* (iii) $v_+(z) \equiv v_-(z)$.

Proof. The fact that (i) implies (iii) is obvious. The inverse statement follows from the fact that $v(z) = v_+(z) \equiv v_-(z)$ implies that the function $v(z)$ is single-valued near infinity and has asymptotic expansion $\hat{v}(z)$ in the full neighborhood of infinity (see [Wa]). It is also clear that (i) implies (ii), since in this case $\mathcal{L}^{-1}\hat{v}(z)$ is an entire function. Suppose now that $s = 0$. Since $V(p)$ is real-analytic on $\mathbb{R}$, we obtain that $V(p) = o(\frac{1}{p-(\pm i)})$ as $p \to \pm i$. That means, according to Corollary 2.2 in [To2], that $v_+(z)$ coincides with $v_-(z)$ in both the lower and upper z half-planes. Thus (ii) implies (iii). □

Divergence (zero radius of convergence) of the formal power series (25) was proved in [To2, p. 247]. According to Proposition 1.5, this implies that $v_+(z) \not\equiv v_-(z)$. (In fact, nonzero numerical values of s for equations, equivalent to (24), were computed in [PRG], [GJ] by means of formal Borel summation.) This implies, at least at the formal level, that solution $v_+(z,\varepsilon)$ to (23) does not coincide with solution $v_-(z,\varepsilon)$ to (23). To make this statement rigorous, it is sufficient to show that (a)

$$v_\pm(z,\varepsilon) \to v_\pm(z) \tag{32}$$

as $\varepsilon \to 0$ in some regions $R_\pm$ uniformly in $z \in R_\pm$, and (b) intersection $R_+ \cap R_-$ contains some segment of a positive length.

2. Inner equation. In the following theorem (Theorem 2.1) we construct a two-parameter family of solutions to (23) that are symmetrical at $z = \tilde{\omega}_2(\varepsilon)$ and that converge to $v_+(z)$, or to its translation $v_+(z-h)$, $h \in \mathbb{R}$, as $\varepsilon \to 0$ uniformly in the corresponding region (see below) of the complex z-plane. Here $\tilde{\omega}_j(\varepsilon) = \frac{\omega_j(\varepsilon)}{\varepsilon}$, $j = 1, 2, 3$.

This result constitutes an essential part of the method of [KS]; convergence of $v_+(z,\varepsilon)$ to $v_+(z)$ was mentioned only briefly in the original paper [KS] (with regard to a third order equation considered there), but explicit formulations and proofs were omitted. In other papers, connection between solutions of (23) and (24) was considered only on the formal level. The proof of convergence of $v_+(z,\varepsilon)$ to $v_+(z)$ in the separatrix case was given in [To4] (see also [To5] for the discretized equation (2), as well as [TP] for a more general family of singular perturbations of (2)). The major difficulty there was based on the fact that solutions of the full and of the truncated inner equations have different rates of convergence to 0 as $z \to \infty$ (in proper directions): $v_+(z,\varepsilon)$, $\varepsilon > 0$, approaches 0 exponentially fast (in z), while $v_+(z)$ has only power order convergence. One needs to find, however, some uniform majorization that will cover both cases. In order to find such a majorization, we suggested [To4], [To5] linearizing (23) around the unperturbed solution $6q^2$, where $q(z,\varepsilon) = \frac{\varepsilon}{\sinh\frac{\varepsilon z}{2}}$, and applying the contraction mapping principle to the obtained equation. A similar approach will be developed below with the natural choice

$$q(z,\varepsilon) = \varepsilon\sqrt{\wp_{\frac{1}{12},g_3(\varepsilon)}(\varepsilon z) - \frac{1}{12}}, \tag{33}$$

where $g_3 = g_3(\varepsilon)$ is determined through $\omega_1 = \omega_1(\varepsilon)$ by (9).

2.1. Linearized equation. The substitution

$$v(z,\varepsilon) = u(z,\varepsilon) + 6c(\varepsilon)q^2(z,\varepsilon), \tag{34}$$

where $q(z,\varepsilon)$ is given by (33), reduces (23) to

$$(D_z^2+1)(D_z^2-\varepsilon^2)u = u^2 + 12c(\varepsilon)q^2u + f(q). \tag{35}$$

Here $c = c(\varepsilon)$ is a continuous function satisfying $c(0) = 1$. Calculations of f after some algebra yield

$$f(q) = c\left[36(c-1-4\varepsilon^2)q^4 - 6!q^6 - 2\varepsilon^6 J(\varepsilon)\right], \tag{36}$$

where

$$J(\varepsilon) = -36g_3(\varepsilon) - \frac{1}{6} \tag{37}$$

is determined through $\omega_1 = \omega_1(\varepsilon)$. (To simplify notation, we omit the ε dependence in ω_j or $\tilde{\omega}_j$, $j = 1, 2, 3$, provided that such omission cannot cause any misunderstanding.) Note that $\lim_{\varepsilon\to 0} 6c(\varepsilon)q^2(z,\varepsilon) = \frac{6}{z^2}$. This is the leading term of the asymptotic expansion (25) of $v_+(z)$. So, substitution (34) linearizes (23) with respect to the leading term for both positive and zero values of ε.

Let

$$w = (D^2 + 1)u. \tag{38}$$

Then (35) becomes

$$(D^2 - \varepsilon^2)w = \left[(D^2 + 1)^{-1}w\right]^2 + 12cq^2(D^2 + 1)^{-1}w + f(q) \tag{39}$$

or

$$\begin{aligned}[D^2 - (\varepsilon^2 + 12q^2)]w = {} & \left[(D^2 + 1)^{-1}w\right]^2 \\ & + 12cq^2[(D^2 + 1)^{-1} - 1]w - 12q^2(1 - c)w + f(q).\end{aligned} \tag{40}$$

Using the identity

$$(D^2 + 1)^{-1} - 1 = -(D^2 + 1)^{-1}D^2 \tag{41}$$

and solving (39) for D^2w, we finally get

$$\begin{aligned}[D^2 - (\varepsilon^2 + 12q^2)]w = {} & [1 - 12cq^2(D^2 + 1)^{-1}]\left(f(q) + [(D^2 + 1)^{-1}w]^2\right) \\ & - 12q^2(1 - c)w - 12cq^2(D^2 + 1)^{-1}\left[\varepsilon^2 + 12cq^2(D^2 + 1)^{-1}\right]w.\end{aligned} \tag{42}$$

This integrodifferential equation is equivalent to (35), (38). We solve (42) by the contraction mapping principle, considering it as a "perturbation" of the nonhomogeneous linear ODE

$$[D^2 - (\varepsilon^2 + 12q^2)]w = [1 - 12cq^2(D^2 + 1)^{-1}]f(q). \tag{43}$$

The corresponding homogeneous equation

$$[D^2 - (\varepsilon^2 + 12q^2)]w = 0 \tag{44}$$

has two independent solutions $v_1(z)$ and $v_2(z)$, where $v_2(z)$ is symmetric (even) and $v_1(z)$ is antisymmetric (odd) at the origin. Indeed, $v = 6q^2$ is a solution to $(D^2-\varepsilon^2)v = v^2$, which is the rescaled equation (2). Differentiating both sides of the latter equation, we get $(D^2 - \varepsilon^2)v' = 2vv'$. This equation coincides with (44), where $w = v'$. Thus, we obtain

$$v_1(z) = 6\frac{d}{dz}q^2 = 6\varepsilon^3\wp'(\varepsilon z). \tag{45}$$

The second linearly independent solution can be taken as

$$v_2(z) = v_1(z)\int_0^z \frac{d\xi}{v_1^2(\xi)}. \tag{46}$$

Note that $\wp(\varepsilon z)$ is symmetrical and, thus, v_1 is an antisymmetrical (odd) function with respect to any integer combination of half periods $\tilde{\omega}_1$ and $\tilde{\omega}_3$. It will be shown below (section 2.3) that solutions

$$v_{2j}(z) = v_2(z) - \frac{1}{6\varepsilon^7\Delta}\left[\frac{3g_3}{2}\omega_j - g_2\zeta(\omega_j)\right]v_1(z), \qquad j = 1,2,3, \tag{47}$$

to (44), where

$$\zeta(x) = \frac{1}{x} - \int_0^x \left(\wp(y) - \frac{1}{y^2}\right)dy \tag{48}$$

is a "negative antiderivative" of $\wp$, are symmetrical at the points $z = \tilde{\omega}_j$, respectively.

2.2. Formulation of the theorem. Let $g(z)$ be a function, symmetrical (even) with respect to the point $\tilde{\omega}_2(\varepsilon)$, and let $\mathcal{I}_2 = (D^2+1)^{-1}$ denote the operator, inverse to D^2+1 and such that $\mathcal{I}_2 g(z)$ is symmetrical with respect to $\tilde{\omega}_2(\varepsilon)$. The construction of $\mathcal{I}_2$ will be given in section 3.1.

Equation (42) can be written in the operator form as $w = \mathcal{N}w$, where

(49)

$$\mathcal{N}w = \mathcal{I}_1 \circ \left[(1 - 12cq^2\mathcal{I}_2)[f + (\mathcal{I}_2 w)^2] - 12q^2(1-c)w + 12cq^2\mathcal{I}_2(\varepsilon^2 + 12cq^2\mathcal{I}_2)w\right]$$

and

$$\mathcal{I}_1 g(z) = -v_1(z)\int_{\tilde{\omega}_2}^z v_2(\xi)g(\xi)d\xi + v_2(z)\int_{\tilde{\omega}_2}^z v_1(\xi)g(\xi)d\xi. \tag{50}$$

We define iterations

$$w_0 = 0, \quad w_1 = \mathcal{N}w_0 + \varepsilon^6 b(\varepsilon)v_{22}(z), \quad w_n = \mathcal{N}w_{n-1},\ n = 2,3,\dots, \tag{51}$$

and $\Delta w_n = w_n - w_{n-1}$, $n = 1,2,\dots$, where $b(\varepsilon)$ is a continuous function in a vicinity of $\varepsilon = 0$. The following theorem proves uniform convergence of the series $\sum_{n=1}^{\infty}\Delta w_n$ in a region $R_{z_0} \subset \mathbb{C}$, which is defined below. Thus, we obtain a family of solutions to (42), parametrized by $c(\varepsilon)$ and $b(\varepsilon)$, which are symmetrical at $z = \tilde{\omega}_2$.

Consider the parallelogram of periods of the elliptic function $q(z,\varepsilon)$ (the periods are $2\tilde{\omega}_1$ and $2\tilde{\omega}_3$) centered at the origin with the square cut that has vertices $\pm z_0(1+i)$ and $\pm z_0(1-i)$, where $z_0 > 0$ is a positive constant. We require $\varepsilon \in [0, \varepsilon_0]$, where

$$\varepsilon_0 z_0 < \min\{\omega_1, |\omega_3|\}. \tag{52}$$

By R_{z_0} we denote a quarter of this figure, i.e., of the parallelogram of periods with the square cut, that lies in the first quadrant; see Figure 4.

THEOREM 2.1. *Let E be a closed subinterval of $(-\frac{1}{3}, 0)$, and let $J(\varepsilon)$ from (37) be a function, defined on a neighborhood of $\varepsilon = 0$ with the range in E. Let continuous functions $b(\varepsilon), c(\varepsilon)$ satisfy*

$$|b(\varepsilon)| \le l\varepsilon^{\alpha} \qquad \text{and} \qquad |c(\varepsilon) - 1| \le l\varepsilon^{\alpha} \tag{53}$$

for some $l > 0$, $\alpha \ge 1$, and for all nonnegative ε from a vicinity of $\varepsilon = 0$. Then there exist $\varepsilon_0 > 0$, $z_0 > 0$ satisfying (52), which depend only on E and l, and such that the series

$$w(z,\varepsilon) = \sum_{n=1}^{\infty}\Delta w_n(z,\varepsilon) \tag{54}$$

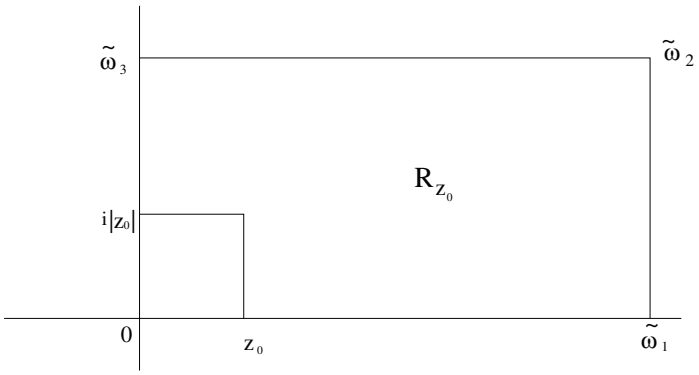

FIG. 4. *Region* R_{z_0}.

converges uniformly in $R_{z_0} \times [0, \varepsilon_0]$.

Remark 2.2. The rectangular "cut" in R_{z_0} can be replaced by a cut of any other shape so that the distance between R_{z_0} and the origin is $O(z_0)$. In fact, it will be replaced by a more convenient triangular "cut" in the course of the proof.

The proof of the theorem is given in section 3.4.

2.3. The second fundamental solution to the linearized equation. Note that, similarly to the separatrix case, the solution v_1 to (44) is an odd function, while the solution v_2 is an even function; see (45)–(46). Moreover, $\wp(\varepsilon z)$ is symmetrical, and, thus, v_1 is an antisymmetrical (odd) function with respect to any integer combination of half-periods $\tilde{\omega}_1$ and $\tilde{\omega}_3$.

Our computation of v_2 is based on the well-known fact (see, for example, [WW]) that the difference between two elliptic functions with the same periods and same principal parts at each singular point is a constant. The only zeros of the function $\wp'(\varepsilon z)$ within the parallelogram of periods are simple zeros at the points $\tilde{\omega}_j$, $j = 1, 2, 3$. Therefore

$$\frac{1}{\wp'^2(\varepsilon z)} = A_0 + \sum_{j=1}^{3} A_j \wp(\varepsilon z - \omega_j) \tag{55}$$

for all z and

$$\int_0^z \frac{d\xi}{\wp'^2(\varepsilon \xi)} = A_0 z - \frac{1}{\varepsilon} \sum_{j=1}^{3} A_j [\zeta(\varepsilon z - \omega_j) + \zeta(\omega_j)], \tag{56}$$

where the constants A_k, $k = 0, 1, 2, 3$, will be discussed below and $\zeta(x)$, defined by (48), is an odd function. The following arguments use some standard facts about the Weierstrass $\wp$-function that can be found, for example, in [WW], [Ha].

Using the "addition theorem" for ζ-function

$$\zeta(\varepsilon z - \omega_j) - \zeta(-\omega_j) = \zeta(\varepsilon z) + \frac{1}{2} \frac{\wp'(\varepsilon z)}{\wp(\varepsilon z) - e_j}, \quad j = 1, 2, 3, \tag{57}$$

we get

$$\int_0^z \frac{d\xi}{\wp'^2(\varepsilon \xi)} = \frac{1}{\varepsilon} \left[A_0 \varepsilon z - \zeta(\varepsilon z) \sum_{j=1}^{3} A_j - \frac{1}{2} \wp'(\varepsilon z) \sum_{j=1}^{3} \frac{A_j}{\wp(\varepsilon z) - e_j} \right]. \tag{58}$$

Constants A_k, $k=0,1,2,3$, are calculated in Lemma 2.3 below. Differential equations

$$\wp'^2 = 4\prod_{j=1}^{3}(\wp - e_j) \quad \text{and} \quad \wp'' = 6\wp^2 - \frac{g_2}{2} \tag{59}$$

for the Weierstrass $\wp$-function and identities

$$e_1e_2 + e_1e_3 + e_2e_3 = -\frac{g_2}{4} \quad \text{and} \quad e_1e_2e_3 = \frac{g_3}{4} \tag{60}$$

are also utilized in this lemma.

LEMMA 2.3.

(61)

$$A_0 = \frac{9g_3}{\Delta}, \quad A_j = \left[\frac{1}{2(e_j-e_i)(e_j-e_k)}\right]^2, \quad j=1,2,3, \quad \text{and} \quad A_+ = \sum_{j=1}^{3} A_j = \frac{6g_2}{\Delta},$$

where the indices i,j,k are a permutation of $1,2,3$.

Proof. The Taylor expansion of $\wp$ at ω_j, $j=1,2,3$, yields

$$\wp(x) = e_j + a_j(x-\omega_j)^2 + O(x-\omega_j)^4. \tag{62}$$

Therefore the principal part of $(\wp')^{-2}$ at ω_j is $\frac{1}{4a_j^2(x-\omega_j)^2}$. According to (59), $a_j = \frac{1}{2}\wp''(\omega_j) = 3e_j^2 - \frac{g_2}{4}$. The principal part of $\wp(x)$ at the origin is $\frac{1}{x^2}$. Thus

$$A_j = \frac{1}{(6e_j^2 - \frac{g_2}{2})^2} = \left[\frac{1}{2(e_j-e_i)(e_j-e_k)}\right]^2, \tag{63}$$

where the indices i,j,k are a permutation of $1,2,3$. The latter expression follows from

$$3e_j^2 - \frac{g_2}{4} = 2e_j^2 + e_j(e_j+e_i) + e_je_k + e_ie_k = 2e_j^2 + e_ie_k = 2(e_i+e_k)^2 + e_ie_k \tag{64}$$

$$= (2e_i+e_k)(2e_k+e_i) = (e_i-e_j)(e_k-e_j),$$

where (17) and (60) were taken into account.

Direct computations, based on (17) and (60), show that

$$\sum_{j=1}^{3} e_j^2 = \frac{g_2}{2}, \quad \sum_{i<k} e_i^2e_k^2 = \frac{g_2^2}{16}, \quad \text{and} \quad \sum_{j=1}^{3} e_j^3 = \frac{3}{4}g_3, \tag{65}$$

where summation in the second expression is taken over all possible pairs i,k such that $1 \le i < k \le 3$. Then

$$\sum_{j=1}^{3} A_j = \frac{\sum_{i<k}(e_i-e_k)^2}{4\prod_{i<k}(e_i-e_k)^2} = \frac{3g_2}{8\prod_{i<k}(e_i-e_k)^2}. \tag{66}$$

Next we compute the denominator, using (60) and (63):

$$-8\prod_{i<k}(e_i-e_k)^2 = \prod_{j=1}^{3}\left(6e_j^2 - \frac{g_2}{2}\right) = -\frac{g_2^3}{8} + 6\frac{g_2^2}{4}\sum_{j=1}^{3} e_j^2 - 18g_2\sum_{i<k} e_i^2e_k^2 \tag{67}$$

$$+ 6^3\prod_{j=1}^{3} e_j^2 = \frac{1}{2}(27g_3^2 - g_2^3) = -\frac{\Delta}{2}.$$

Now the second statement of the lemma follows from (66).

In order to evaluate A_0 we put $z = 0$ at (55). Since $\wp'$ has a pole at the origin, (55) yields

$$A_0 = -\sum_{j=1}^{3} A_j e_j = \frac{\sum_{j=1}^{3} e_j(e_i - e_k)^2}{-4\prod_{i<k}(e_i - e_k)^2}. \tag{68}$$

Using (17) and (65), we calculate the numerator in the latter expression as $-\frac{9}{4}g_3$. Then the first statement of the lemma follows from (67)–(68). □

Now, the combination of (45)–(46) and of (58)–(59) yields

$$v_2(z) = \frac{1}{6\varepsilon^4}\left[[A_0 x - A_+\zeta(x)]\wp'(x) - 2\sum_{j=1}^{3} A_j(\wp(x) - e_i)(\wp(x) - e_k)\right], \tag{69}$$

where for convenience we use the notation $x = \varepsilon z$. The latter sum is a quadratic polynomial in $\wp$, which, according to (17) and (68), can be written as $-2A_+\wp^2 + 2A_0\wp + B$, where the constant $B = -2\sum_{j=1}^{3} A_j e_i e_k$. In order to determine B, note that (46) implies that v_2 is an even function, which has zero of order four at the origin. Using the Laurent expansions of $\wp$, $\wp'$, and ζ at the origin (see [GR]) and equating the constant term of (69) to be zero, we obtain

$$B = -2\sum_{j=1}^{3} A_j e_i e_k = A_+\left(\frac{g_2}{10} + \frac{g_2}{30}\right) + 2A_+\frac{g_2}{10} = \frac{2g_2^2}{\Delta}. \tag{70}$$

Combining the latter equation with (69) and Lemma 2.3 yields

$$\begin{aligned} v_2(z) &= \frac{1}{\varepsilon^4\Delta}\left(\left[\frac{3g_3}{2}\varepsilon z - g_2\zeta(\varepsilon z)\right]\wp'(\varepsilon z) - 2g_2\wp^2(\varepsilon z) + 3g_3\wp(\varepsilon z) + \frac{g_2^2}{3}\right) \\ &= \frac{1}{\varepsilon^4\Delta}\left(\frac{3g_3}{2}\left[\varepsilon z\wp'(\varepsilon z) + 2\wp(\varepsilon z)\right] - \frac{g_2}{3}\left[3\zeta(\varepsilon z)\wp'(\varepsilon z) + 6\wp^2(\varepsilon z) - g_2\right]\right). \end{aligned} \tag{71}$$

Note that $v_2(z)$ is an elliptic function if and only if $\frac{3g_3}{2}x - g_2\zeta(x)$ is doubly periodic with fundamental periods $2\omega_1, 2\omega_3$. Using $\zeta(x + 2\omega_j) = \zeta(x) + 2\zeta(\omega_j)$ for all x in the domain of ζ and $j = 1, 2, 3$ [GR], we can write the condition that v_2 is an elliptic function as

$$3g_3\omega_j - 2g_2\zeta(\omega_j) = 0, \quad j = 1, 3. \tag{72}$$

Considering these equations as a linear system for unknowns $3g_3, -2g_2$, we come to the conclusion that it cannot have nontrivial solutions since its determinant $\omega_1\zeta(\omega_3) - \omega_3\zeta(\omega_1) \equiv -\frac{i\pi}{2}$ [GR]. Thus v_2 is not an elliptic function for any energy $C \in (-\frac{1}{3}, 0)$. Note that in the case of the separatrix solution v_2 is also not a hyperbolic function (see [To4]).

2.4. Estimates for $v_1(z), v_2(z)$. Let T denote trapezoid $ABCD$ in $\mathbb{C}$ with the vertices $A(\tilde{\omega}_1 - \tilde{\omega}_3), B(\tilde{\omega}_1 + 2\tilde{\omega}_3), C(\frac{3}{2}\tilde{\omega}_3), D(-\frac{1}{2}\tilde{\omega}_3)$. We start with the estimate

$$|q^2(z, \varepsilon)| \le \frac{Q}{|z|^2} \tag{73}$$

with some $Q > 0$, which is valid for any $\varepsilon \geq 0$ and for any z in the trapezoid T. The value of the constant Q can be chosen as $Q = 1 + |\omega_2|^2\tilde{Q}$, where $\tilde{Q} = \frac{1}{12} + \max_{x\in\tilde{T}} |\wp(x) - \frac{1}{x^2}|$. Here $\tilde{T}$ denotes the trapezoid in the x-plane, $x = \varepsilon z$, that corresponds to T. Note that ω_2 is defined by the energy $J(\varepsilon)$ of the periodic solution (33). However, we can choose Q such that (73) holds for all $J(\varepsilon) \in E$.

LEMMA 2.4. *There exist positive constants A and B such that the estimates*

$$|v_1(z)| \leq \frac{A}{|z|^3} \qquad \text{and} \qquad |v_2(z)| \leq B|z|^4 \tag{74}$$

are valid in T for any $\varepsilon \geq 0$ and any $J(\varepsilon) \in E$.

Proof. The first estimate follows from (45) and the inequality

$$\left|\wp'(x) + \frac{2}{x^3}\right| \leq A^3 \tag{75}$$

in $\tilde{T}$, similarly to (73).

The second inequality (74) follows from the fact that the expression in the square brackets in the right-hand side of (69) is bounded by $6|x|^4B$ in $\tilde{T}$ with some positive constant B that does not depend on ε and on $J(\varepsilon) \in E$. ∎

3. Solution by iterations.

3.1. Operator $(D^2 + 1)^{-1}$. Let $\omega \in \mathbb{C}$, $a > 0$, and let an analytic function $g(z)$ be real-valued on $\Re z = \Re\omega$ and symmetrical with respect to ω. Note that under these assumptions $g(z)$ is also real-valued along $\Im z = \Im\omega$.

PROPOSITION 3.1. *The operator I_a^ω defined by*

$$I_a^\omega g(z) = \frac{1}{2i}\left[e^{iz}\int_{\omega-ia}^{z} e^{-i\xi}g(\xi)d\xi - e^{-iz}\int_{\omega+ia}^{z} e^{i\xi}g(\xi)d\xi\right] \tag{76}$$

is inverse to $D^2 + 1$, and $I_a^\omega g(z)$ is real-valued on $\Re z = \Re\omega$ and symmetrical with respect to ω.

Proof. The first statement of the proposition is obvious. In order to prove the second statement, we decompose

$$I_a^\omega g(z) = I^\omega g(z) + \frac{1}{2i}\left[e^{iz}\int_{\omega-ia}^{\omega} e^{-i\xi}g(\xi)d\xi - e^{-iz}\int_{\omega+ia}^{\omega} e^{i\xi}g(\xi)d\xi\right], \tag{77}$$

where $I^\omega = I_0^\omega$. Let $ib = \int_\omega^{\omega+ia} e^{i(\xi-\omega)}g(\xi)d\xi$. Since g is real-valued along the path of integration, $b \in \mathbb{R}$ and $-ib = \int_\omega^{\omega-ia} e^{-i(\xi-\omega)}g(\xi)d\xi$. Thus, the second term in (77) is symmetrical and real-valued as it is

$$\frac{1}{2i}[ibe^{i(z-\omega)} + ibe^{-i(z-\omega)}] = b\cos(z-\omega). \tag{78}$$

To complete the proof we observe that

$$\begin{aligned} I^\omega &= \frac{1}{2i}\left[e^{iz}\int_{\omega}^{z} e^{-i\xi}g(\xi)d\xi - e^{-iz}\int_{\omega}^{z} e^{i\xi}g(\xi)d\xi\right] = \int_\omega^z \sin(z-\xi)g(\xi)d\xi \\ &= \sin(z-\omega)\int_\omega^z \cos(\xi-\omega)g(\xi)d\xi - \cos(z-\omega)\int_\omega^z \sin(\xi-\omega)g(\xi)d\xi \end{aligned} \tag{79}$$

is also symmetrical with respect to ω and real-valued. ∎

Using the reflection principle, it is easy to show that the function $g(z)$ of Proposition 3.1 is periodic with real or purely imaginary period $2P$ if and only if it is symmetrical with respect to $\omega + P$. Then Proposition 3.1 shows that there is a (real) one-parameter family of operators I_a^ω, preserving the symmetry of g at ω. The following proposition shows that symmetry can be preserved at both ω and $\omega + P$ if P is not a multiple of π. If P is a multiple of π, one can prove that a symmetrical and periodic $(D^2+1)^{-1}g(z)$ exists if and only if the Fourier expansion of $g(z)$ does not contain a $\cos z$ term.

PROPOSITION 3.2. *Let $g(z)$ be a function, symmetrical with respect to ω and $\omega + P$ and real-valued on $[\omega, \omega + P]$, where P is either real or purely imaginary. If $P \neq k\pi$, $k \in \mathbb{N}$, then there exists an operator I that is inverse to $D^2 + 1$ and such that Ig inherits the abovementioned properties of g.*

Proof. To satisfy the requirements at ω, the operator I has to be of the form $Ig = I^\omega g + d\cos(z-\omega)$, where $d \in \mathbb{R}$ (and depends on g). Then

(80)

$$Ig = I^{\omega+P}g + d\cos(z-\omega) + \frac{1}{2i}\left[e^{i(z-\omega-P)}\int_\omega^{\omega+P} e^{-i(\xi-\omega-P)}g(\xi)d\xi - e^{-i(z-\omega-P)}\int_\omega^{\omega+P} e^{i(\xi-\omega-P)}g(\xi)d\xi\right].$$

Let $A_{1,2}$ denote the (two) terms in the square brackets, respectively, and let $A = \frac{1}{2}(A_1 + A_2)$, $B = \frac{1}{2}(A_1 - A_2)$. Then the square bracket expression in (80) becomes $A\sin(z-\omega-P) - iB\cos(z-\omega-P)$. Therefore

$$Ig = I^{\omega+P}g + (d\cos P - iB)\cos(z-\omega-P) + (A - d\sin P)\sin(z-\omega-P). \tag{81}$$

Using (79) we see that the first two terms in the right-hand side of (81) are symmetrical at $\omega + P$. Thus Ig is symmetrical with respect to $\omega + P$ if and only if

$$d = \frac{2\int_\omega^{\omega+P}\cos(\xi-\omega-P)g(\xi)d\xi}{\sin P}. \tag{82}$$

Equation (82) can be satisfied for any $P \neq k\pi$, $k \in \mathbb{Z}$. Noting that d and iB are real for both real and purely imaginary P concludes the proof. ∎

3.2. Estimates for the operator $\mathcal{I}_2$. Consider the trapezoid T introduced in section 2.4. Given a number $z_1 \in (0, \frac{1}{4}\tilde{\omega}_1)$, which is independent of ε, we cut a triangle near the origin with vertices z_1, z_2, z_3, where z_2, z_3 are the points on the intersection of the imaginary axis and the lines through the points z_1, A and the points z_1, B, respectively. The obtained region is denoted by T_{z_1}. Clearly, for a given $z_0 > 0$ we have $R_{z_0} \subset T_{z_1}$ if z_0 is large enough (i.e., according to (52), if ε_0 is small enough). We define the operator

$$\mathcal{I}_2 = I^{\tilde{\omega}_2}_{-2i\tilde{\omega}_3}. \tag{83}$$

For a given $z \in T_{z_1}$, $\gamma_\pm(z)$ denote contours of integration $[z, B]$ and $[z, A]$, respectively; see Figure 5.

PROPOSITION 3.3. *The inequality*

$$\left|\frac{\xi}{z}\right| > \frac{\omega_1}{\sqrt{\omega_1^2 - \frac{25}{4}\omega_3^2}} \tag{84}$$

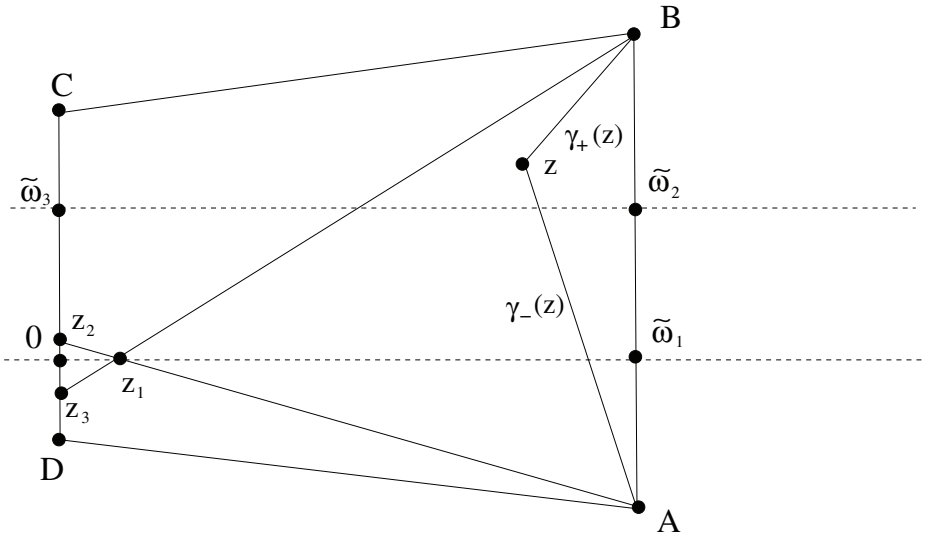

FIG. 5. *Region T_{z_1} and contours $\gamma_\pm(z)$.*

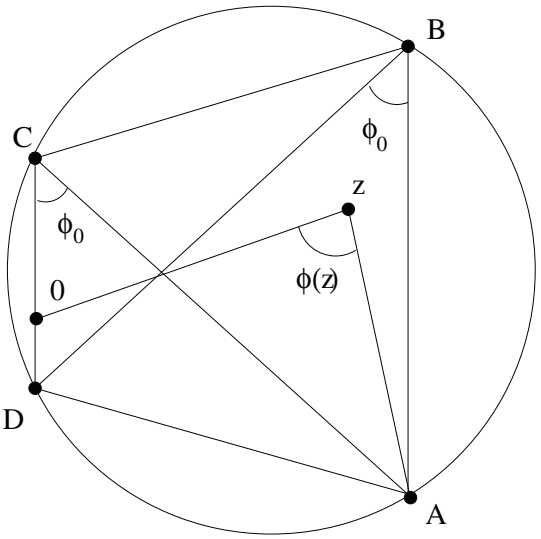

FIG. 6. *Trapezoid $ABCD$ and angles $\phi(z)$, ϕ_0.*

holds for all $z \in T_{z_1}$ and all $\xi \in \gamma_+(z) \cap \gamma_-(z)$.

Proof. For an arbitrary $z \in T_{z_1}$, let $\phi(z)$ denote the angle between the segments $\gamma_-(z)$ and $[0, z]$ (see Figure 6), and let $\alpha(z) = \min_{\xi\in\gamma_-(z)} \frac{|\xi|}{|z|}$. We choose the acute angle for $\phi(\tilde{\omega}_1 + 2\tilde{\omega}_3)$ (at the vertex B) and then define $\phi(z)$ in T_{z_1} by continuity. Clearly $\alpha(z) = 1$ if $\phi(z) \geq \frac{\pi}{2}$ and $\alpha(z) = \sin\phi(z)$ if $\phi(z) < \frac{\pi}{2}$. The latter case can happen only if $\Im z \geq 0$; hence $\alpha(z) = 1$ if $\Im z < 0$. Let ϕ_0 be the acute angle between AB and DB. We show that $\phi(z) \geq \phi_0$ for every $z \in T_{z_1}$.

Indeed, let us inscribe the right trapezoid $ABCD$ into a circle. Then (at the vertex C) $\phi(\frac{3}{2}\tilde{\omega}_3) = \phi_0$. Simple geometrical considerations (see Figure 6) imply that

$\min_{z\in T_{z_1}}\phi(z)$ is attained at $z=\frac{3}{2}\tilde{\omega}_3$. Thus, $\alpha(z)\geq\sin\phi_0$. Therefore

$$\alpha(z)\geq\sin\phi_0=\frac{\omega_1}{\sqrt{\omega_1^2-\frac{25}{4}\omega_3^2}} \tag{85}$$

for any $z\in T_{z_1}$. The same estimate holds for the contour $\gamma_+(z)$. The proof is completed. □

PROPOSITION 3.4. *For any* $z\in T_{z_1}$

$$|\mathcal{I}_2 f(z)|\leq\sqrt{1-4\frac{\omega_1^2}{\omega_3^2}}\max_{\xi\in\gamma_+(z)\cup\gamma_-(z)}|f(\xi)|, \tag{86}$$

where f *is a continuous function on* T_{z_1}.

Proof. According to the construction of γ_+,γ_-,

$$\Re[i(\xi-z)]\leq-\frac{|\omega_3|}{\sqrt{4\omega_1^2-\omega_3^2}}|z-\xi|\quad\text{and}\quad\Re[i(z-\xi)]\leq-\frac{|\omega_3|}{\sqrt{4\omega_1^2-\omega_3^2}}|z-\xi| \tag{87}$$

for all $\xi\in\gamma_\pm(z)$, respectively. Therefore

$$\begin{aligned}|\mathcal{I}_2 f(z)|&\leq\frac{1}{2}\left|\int_{\gamma_-(z)}e^{i(z-\xi)}f(\xi)d\xi+\int_{\gamma_-(z)}e^{i(z-\xi)}f(\xi)d\xi\right|\\&\leq\max_{\xi\in\gamma_+(z)\cup\gamma_-(z)}|f(\xi)|\int_0^\infty e^{-\left(|\omega_3|/\sqrt{4\omega_1^2-\omega_3^2}\right)\lambda}d\lambda,\end{aligned} \tag{88}$$

which implies (86). □

LEMMA 3.5. *If*

$$|f(z)|\leq\frac{1}{|z|^a} \tag{89}$$

in T_{z_1} *with* $a\geq0$, *then*

$$|\mathcal{I}_2 f(z)|\leq\frac{\beta}{|z|^a}, \tag{90}$$

where $\beta=(1-\frac{25\omega_3^2}{4\omega_1^2})^{\frac{1}{2}}(1-4\frac{\omega_1^2}{\omega_3^2})^{\frac{a}{2}}$.

This lemma is a direct consequence of Propositions 3.3 and 3.4.

3.3. Estimates for the operator $\mathcal{I}_1$. Solution $\mathcal{I}_1 g$ to linear differential equation (43), where g denotes the right-hand side of (43), that we consider in the paper is given by (50). In order to estimate $\mathcal{I}_1$, we need the following simple statement.

PROPOSITION 3.6. *Let a ray* λ *on the complex* z*-plane lie outside the disk* $|z|<a$, $a>0$. *Then for any* $\alpha\geq2$

$$\left|\int_\lambda\frac{dz}{z^\alpha}\right|\leq\frac{\pi}{a^{\alpha-1}}. \tag{91}$$

Proof. Let m denote the line containing the ray λ. Suppose m is tangent to the disk $|z|<a$ at the point ω. If $z\in m$, then $|z|^2=a^2+x^2$, where $x=|z-\omega|$. Then

$$\left|\int_\lambda\frac{dz}{z^\alpha}\right|\leq\int_{-\infty}^\infty\frac{dx}{(a^2+x^2)^{\frac{\alpha}{2}}}\leq\frac{2}{a^{\alpha-2}}\int_0^\infty\frac{dx}{(a^2+x^2)}=\frac{\pi}{a^{\alpha-1}}. \tag{92}$$

This estimate will definitely hold if m does not intersect the closed disk $|z| \le a$.

Suppose now that m intersects the disk $|z| < a$. Let ω denote the vertex of the ray λ, and let ζ denote one of the two points which lie on the distance a from both ω and m. Then $|\xi - \zeta| < |\xi|$ for any $\xi \in \lambda$, and we can apply the estimate (92) again, placing the origin at ζ. □

Notice that estimates of Proposition 3.3 are applicable to the contours in (50). Then, using Lemma 2.4 and Proposition 3.6, we can easily establish the following estimates.

LEMMA 3.7. *If $|g(z)| \le K|z|^{-n}$, $n \ge 6$, or if $|g(z)| \le K|z|^{-4}$ in T_{z_1}, then*

$$|\mathcal{I}_1 g(z)| \le \frac{M_1 K}{|z^{n-2}|} \quad \text{and} \quad |\mathcal{I}_1 g(z)| \le \frac{M_2 K}{\varepsilon |z^{-3}|}, \tag{93}$$

respectively, where $M_1 = (1 - \frac{25}{4}\frac{\omega_3^2}{\omega_1^2})^{\frac{n-5}{2}} \pi AB$ and $M_2 = \max\{2|\omega_3|, \sqrt{\omega_1^2 - \frac{9}{4}\omega_3^2}\} AB$.

3.4. Proof of Theorem 2.1. *Proof.* We start with the obvious observation that

$$\varepsilon \le \frac{\sqrt{\omega_1^2 - 4\omega_3^2}}{|z|} \tag{94}$$

if $z \in T_{z_1}$. Using the first inequality in (53), we obtain that $f(q)$ from (36) satisfies

$$|f| \le \tilde{K}_0 |z|^{-6} + \varepsilon \tilde{K}_1 |z|^{-4} \tag{95}$$

in T_{z_1} with some positive constants $\tilde{K}_0, \tilde{K}_1$ that do not depend on ε and $J(\varepsilon) \in E$. Thus, according to (49) and the estimates for $\mathcal{I}_{1,2}$,

$$|\mathcal{N} w_0| \le \frac{K}{2} \left(\frac{\varepsilon^{\alpha - 1}}{|z|^3} + \frac{1}{|z|^4} \right) \tag{96}$$

in T_{z_1} for some constant $K > 0$ that does not depend on ε, $J(\varepsilon)$, and z_1.

Let us now prove by induction that by choosing a sufficiently large $z_1 > 0$ we can find $\delta > 0$, such that the estimate

$$\Delta w_n \le (\delta M)^{n-1} \frac{K}{|z|^3}, \quad \text{where} \quad \delta M \le \frac{1}{2}, \tag{97}$$

holds in T_{z_1} for all $n = 1, 2, \dots$, all $J(\varepsilon) \in E$, and all sufficiently small ε. Here $M = \max\{M_1, M_2\}$, where M_1 is given in Lemma 3.7 with $n = 6$.

According to Lemma 2.4, the estimate for v_{22} for all $z \in T_{z_1}$ and $J(\varepsilon) \in E$ is

$$|v_{22}(z)| \le B|z|^4 + \frac{L}{\varepsilon^7 |z|^3} \tag{98}$$

for some $L > 0$. Then, according to (94), (96), and (53), we can choose $K > 0$ to be so large that $w_1 = \mathcal{N} w_0 + \varepsilon^6 b(\varepsilon) v_{22}$ satisfies

$$|w_1| \le \frac{K}{|z|^3} \tag{99}$$

in T_{z_1} for all $J(\varepsilon) \in E$ and all sufficiently small ε. Thus, for $n = 1$, (97) has been established. Assume that this estimate is true for $k = 1, 2, \dots, n$, and let us establish it for $k = n + 1$. First, we can represent

$$\begin{aligned} \Delta w_{n+1} = \mathcal{I}_1 \circ \big[& (1 - 12cq^2 \mathcal{I}_2)[\mathcal{I}_2(w_n + w_{n-1}) \cdot \mathcal{I}_2 \Delta w_n] - 12q^2(1 - c)\Delta w_n \\ & + 12cq^2 \mathcal{I}_2(\varepsilon^2 + 12cq^2 \mathcal{I}_2)\Delta w_n \big]. \end{aligned} \tag{100}$$

Taking into account (99) and Lemma 3.5, we obtain the estimates

(101)
$$\frac{12Ql\varepsilon^{\alpha}}{|z|}\left|\frac{\Delta w_n}{z}\right|,\ 12cQ\beta\left[\frac{\varepsilon}{|z|}\left|\frac{\varepsilon\Delta w_n}{z}\right|+\frac{12cQ\beta}{|z|}\left|\frac{\Delta w_n}{z^3}\right|\right],\ 4K\beta^2\left(1+\frac{12cQ\beta}{|z|^2}\right)\left|\frac{\Delta w_n}{z^3}\right|$$

for the second, third, and first (nonlinear) terms in the square brackets in (100), respectively. For the latter estimate, observe that both w_n and w_{n-1} are bounded by $\frac{2K}{|z|^3}$ according to (97). (Note that the constants β, K, M are independent of z_1.) Applying operator $\mathcal{I}_1$ to these three terms and utilizing Lemma 3.7, we obtain the estimates

(102)
$$\frac{12Ql}{|z|}\varepsilon^{\alpha-1}M\left|\Delta w_n\right|,\ 12cQ\beta\left[\varepsilon+\frac{12cQ\beta}{|z|}\right]\frac{M}{|z|}\left|\Delta w_n\right|,\ 4K\beta^2\left(1+\frac{12cQ\beta}{|z|^2}\right)\left|\frac{M\Delta w_n}{z}\right|.$$

Factoring $M|\Delta w_n|$, we obtain $|\Delta w_{n+1}|\le\delta M|\Delta w_n|$, where

$$\delta=\frac{12Ql\varepsilon^{\alpha-1}+12cQ\beta\varepsilon}{|z|}+\frac{12^2c^2Q^2\beta^2}{|z|^2}+\frac{4K\beta^2}{|z|}\left(1+\frac{12cQ\beta}{|z|^2}\right). \tag{103}$$

By choosing a sufficiently large $z_1>0$ and sufficiently small $\varepsilon_0>0$, we can guarantee the condition $\delta M\le\frac{1}{2}$ in T_{z_1} for all $\varepsilon\le\varepsilon_0$ and for all $J(\varepsilon)\in E$. Thus, (97) holds for $k=n+1$. We can choose some $z_0\ge z_1$ so that $R_{z_0}\subset T_{z_1}$ and $\varepsilon_0 z_0\le\max\{\omega_1,|\omega_3|\}$ (taking smaller ε_0 if necessary). Thus, inequalities (97) prove convergence of iterations to a solution of (42) that is uniform in $R_{z_0}\times(0,\varepsilon_0]$ for all $J(\varepsilon)\in E$.

In the case $\varepsilon=0$ the region T_{z_1} becomes the right half-plane with the appropriate cut, $q^2=\frac{6}{z^2}$, $f(q)=-\frac{6!}{z^6}$, and the fundamental solutions $v_{1,2}$ to the homogeneous equations (43) become $v_1(z)=\frac{-12}{z^3}$ and $v_2(z)=\frac{-z^4}{84}$. Thus, for the case $\varepsilon=0$ Lemma 2.4 becomes trivial, and the proof of convergence of iterations $w=\sum_1^\infty\Delta w_n$ that solve (42) holds for the case $\varepsilon=0$. (Note that in this case the contours of integration in the integral operators $\mathcal{I}_{1,2}$ are the rays, emanating from z, with the slope $\frac{\Im w}{\Re w}$, where w is the beginning of the corresponding contour in the case $\varepsilon>0$; in other words, $\arg w$ does not depend on ε.) Thus, the proof of Theorem 2.1 is completed. □

Remark 3.8. It is easy to verify that $\alpha>1$ in Theorem 2.1 implies that there exist some $L_n>0$ such that for all $n\in\mathbb{N}$

$$|\Delta w_n|\le L_n|z|^{-n(1+\tilde\alpha)-2} \tag{104}$$

in R_{z_0}, where $\tilde\alpha=\min\{1,\alpha-1\}$. Moreover, for all $n\in\mathbb{N}$ there exist some $K_n>0$ such that

$$\left|\sum_{j=n}^{\infty}\Delta w_n\right|\le K_n|z|^{-n(1+\tilde\alpha)-2}. \tag{105}$$

Let $P\subset T$ denote the triangle with vertices $\tilde\omega_3,\tilde\omega_1$, and $\tilde\omega_1+2\tilde\omega_3$. It is clear that $z\in P$ implies that all the contours of integration in operators $\mathcal{I}_{1,2}$ are in P. Notice that in P

$$\min\{\omega_1,|\omega_3|\}\le\varepsilon|z|\le\sqrt{\omega_1^2-4\omega_3^2}. \tag{106}$$

The latter condition allows us to prove convergence of iterations in P without the requirement (53) in Theorem 2.1.

COROLLARY 3.9. *If instead of* (53) *in Theorem* 2.1 *we require only*

$$\lim_{\varepsilon\to 0} b(\varepsilon) = \lim_{\varepsilon\to 0}[c(\varepsilon)-1] = 0, \tag{107}$$

the statement of Theorem 2.1 *is still valid in* $P\times[0,\varepsilon_0]$*; i.e., there exists some* $\varepsilon_0>0$ *such that the series* (54) *is uniformly convergent in* $P\times[0,\varepsilon_0]$.

Proof. The function

$$h(\varepsilon) = \max\{|b(\varepsilon)|, |c(\varepsilon)-1|\} \tag{108}$$

is continuous and nonnegative, and $\lim_{\varepsilon\to 0} h(\varepsilon) = 0$. Then inequalities (95) and (96) become

$$|f| \le \tilde{K}_0|z|^{-6} + h(\varepsilon)\tilde{K}_1|z|^{-4} \quad \text{and} \quad |\mathcal{N}w_0| \le \frac{K}{2}\left(\frac{h(\varepsilon)}{\varepsilon|z|^3} + \frac{1}{|z|^4}\right), \tag{109}$$

respectively. Then, as in Theorem 2.1, we can choose $K>0$ so large that

$$|w_1| \le \frac{\tilde{h}(\varepsilon)K}{|z|^2} \tag{110}$$

in P, where $\tilde{h}(\varepsilon) = \max\{h(\varepsilon), \varepsilon^2\}$.

As in Theorem 2.1, we will prove convergence of (54) by induction if we show that by choosing a sufficiently small $\varepsilon_0>0$ we can find $\delta>0$, such that the estimate

$$\Delta w_n \le (\delta M)^{n-1}\frac{\tilde{h}(\varepsilon)K}{|z|^2}, \quad \text{where} \quad \delta M \le \frac{1}{2}, \tag{111}$$

holds in P for all $n=1,2,\dots$ and all $J(\varepsilon)\in E$. Taking into account (111) and Lemma 3.5, we obtain the estimates

$$12Ql\tilde{h}(\varepsilon)\left|\frac{\Delta w_n}{z^2}\right|, \tag{112}$$

$$12cQ\beta\left[\left|\frac{\varepsilon^2\Delta w_n}{z^2}\right| + \frac{12cQ\beta}{|z|^2}\left|\frac{\Delta w_n}{z^2}\right|\right], \quad 4\tilde{h}(\varepsilon)K\beta^2\left(1+\frac{12cQ\beta}{|z|^2}\right)\left|\frac{\Delta w_n}{z^2}\right|$$

for the second, third, and first (nonlinear) terms in the square brackets in (100), respectively. Making sure that $\tilde{h}(\varepsilon)$ and $|z^{-2}|$ are sufficiently small by choosing a sufficiently small ε_0 and using Lemma 3.7, we can repeat the arguments of Theorem 2.1 in order to complete the proof of convergence of iterations (54). ∎

Remark 3.10. In fact, we can prove convergence of iterations (54) in larger domains than those stated in Theorem 2.1 and Corollary 3.9. Fix some $n\in\mathbb{N}$. For Theorem 2.1, we replace the trapezoid T with vertices $ABCD$ by the (concave) hexagon $\mathcal{T}$ with vertices $AONBCD$, where $O=\tilde{\omega}_1$, $N=n\tilde{\omega}_1+\tilde{\omega}_3$, and other vertices are the same as in T; see Figure 7. For $z\in\mathcal{T}$, contours of integration in operators $\mathcal{I}_{1,2}$ are the same as before, except for contour $\gamma_-(z)$ that is now the union of segments $[z,O]$ and $[OA]$. For Corollary 3.9, we replace the triangle P with vertices $\tilde{\omega}_3$, $\tilde{\omega}_1$, $\tilde{\omega}_1+2\tilde{\omega}_3$ by a quadrilateral $\mathcal{P}$ with vertices $\tilde{\omega}_1$, $n\tilde{\omega}_1+\tilde{\omega}_3$, $\tilde{\omega}_1+2\tilde{\omega}_3$, $\tilde{\omega}_3$. For $z\in\mathcal{P}$, contours of integration in operators $\mathcal{I}_{1,2}$ are the same as before. It is easy to verify that the estimates for operators $\mathcal{I}_{1,2}$ from Lemmas 3.7 and 3.5 hold in domains $\mathcal{T}$ and $\mathcal{P}$, possibly with larger constants that depend on n. Now proofs of Theorem 2.1 and Corollary 3.9 can be extended to the domains $\mathcal{T}$ and $\mathcal{P}$, respectively.

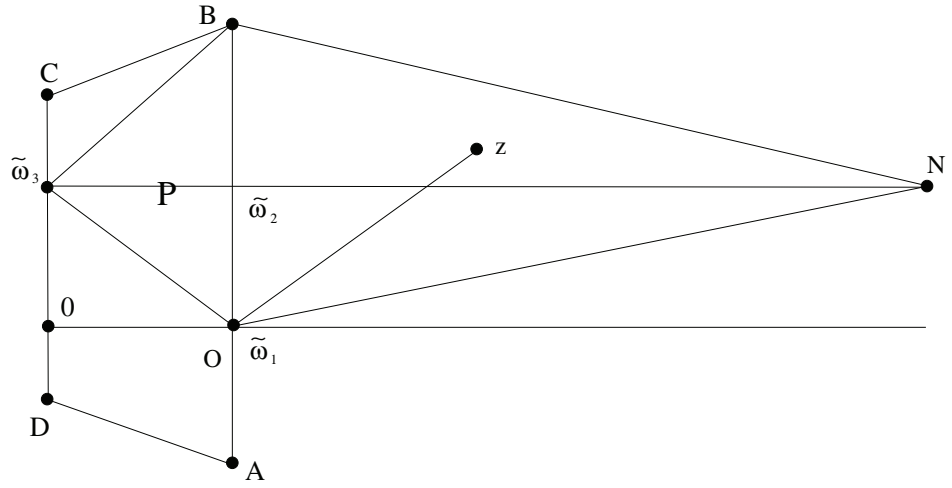

FIG. 7. *Hexagon $\mathcal{T}$ with vertices $AONBCD$. The contour $\gamma_-(z)$ is the union of segments $[z, O]$ and $[OA]$.*

3.5. Symmetry at $\tilde{\omega}_2$. Here we will show that any solution to inner equation (23), obtained through iterations (54), is symmetrical with respect to $z = \tilde{\omega}_2$. Consequently, corresponding solutions to the outer equation (1), connected with (23) via (22), are symmetric at $x = \omega_2$.

The operator $\mathcal{I}_1$ can be represented in the following form.

PROPOSITION 3.11. *If a function $g(z)$ is analytic and bounded in T_{z_1}, then*

$$\mathcal{I}_1 g = v_1(z) \int_{\tilde{\omega}_2}^{z} \frac{\int_{\tilde{\omega}_2}^{t} v_1(\tau) g(\tau) d\tau}{v_1^2(t)} dt. \tag{113}$$

Proof. Using (46) and integration by parts, one gets

$$\begin{aligned} \mathcal{I}_1 g &= -v_1(z) \int_{\tilde{\omega}_2}^{z} \left(v_1(t) g(t) \int_0^t \frac{d\tau}{v_1^2(\tau)} \right) dt + v_2(z) \int_{\tilde{\omega}_2}^{z} v_1(t) g(t) dt \\ &= v_1(z) \times \left[- \int_{\tilde{\omega}_2}^{t} v_1(\tau) g(\tau) d\tau \cdot \int_0^t \frac{d\tau}{v_1^2(\tau)} \Big|_{\tilde{\omega}_2}^{z} \right. \\ &\qquad \left. + \int_{\tilde{\omega}_2}^{z} \frac{\int_{\tilde{\omega}_2}^{t} v_1(\tau) g(\tau) d\tau}{v_1^2(\tau)} dt + \int_0^z \frac{dt}{v_1^2(\tau)} \cdot \int_{\gamma(z)} v_1(t) g(t) dt \right] \\ &= v_1(z) \lim_{\zeta \to \tilde{\omega}_2} \left[\int_{\zeta}^{z} v_1(t) g(t) dt \cdot \int_0^{\zeta} \frac{dt}{v_1^2(\tau)} \right] + v_1(z) \int_{\tilde{\omega}_2}^{z} \frac{\int_{\tilde{\omega}_2}^{t} v_1(\tau) g(\tau) d\tau}{v_1^2(\tau)} dt. \end{aligned} \tag{114}$$

Note that the limit in the latter expression is zero because $\int_{\gamma(\zeta)} v_1(t) g(t) dt$ has a zero of order two at $\tilde{\omega}_2$, whereas $\int_0^{\zeta} \frac{dt}{v_1^2(\tau)}$ has a simple pole there. ∎

Based on (45) and (73), solutions to the homogeneous equation (44) preserving the symmetry at the points $\tilde{\omega}_j$, $j = 1, 2, 3$, are given by

$$v_{2j}(z) = v_2(z) - \frac{1}{6\varepsilon^7 \Delta} \left[\frac{3 g_3}{2} \omega_j - g_2 \zeta(\omega_j) \right] v_1(z), \qquad j = 1, 2, 3, \tag{115}$$

respectively. Indeed, direct calculations show that $D_z v_{2j}(\tilde\omega_j) = 0$. Then, according to (44),

$$D_z^3 v_{2j} = (\varepsilon^2 + 12q^2) D_z v_{2j} + 12(q^2)' v_{2j} = 0 \tag{116}$$

at $z = \tilde\omega_j$. By continuing this argument for higher derivatives, we prove symmetry of v_{2j} at $z = \tilde\omega_j$. Also, note that $v_{2j}(\tilde\omega_j) \in \mathbb{R}$. Then, according to the differential equation for v_{2j}, all even derivatives of v_{2j} at $z = \tilde\omega_j$ are also real.

The fact that operator $\mathcal{I}_1$ preserves the symmetry at the point $\tilde\omega_2$ and real-valuedness along the line $\Im z = \Im\tilde\omega_2$ is a direct consequence of Proposition 3.11. Thus, according to (36), Δw_1 is symmetric with respect to $\tilde\omega_2$ and real-valued on the line $\Im z = \Im\tilde\omega_2$. Then, according to (100) and to Proposition 3.1, the same is true for $w = \sum_1^\infty \Delta w_n$. Now, according to (34), the corresponding solution $v(z,\varepsilon)$ to (23) satisfies

$$v'(\tilde\omega_2, \varepsilon) = v'''(\tilde\omega_2, \varepsilon) = 0 \tag{117}$$

and is real-valued on $\Im z = \Im\tilde\omega_2$.

Thus, in Theorem 2.1 and Corollary 3.9 we have constructed a two-parameter family of solutions to (23), where $b(\varepsilon)$ and $c(\varepsilon)$ are the parameters, that are real along $\Im z = \Im\tilde\omega_2$ and satisfy (117).

3.6. Calculation of $\mathcal{I}_1 f(q)$. In order to calculate $\mathcal{I}_1 f(q)$, we use (36) and (45) to evaluate the integral

$$\begin{aligned}\int_{\tilde\omega_2}^{t} v_1(\tau) f(q(\tau)) d\tau &= \int f(q) d(6q^2) \\ &= c\left[\frac{c-1-4\varepsilon^2}{3}(6q^2)^3 - 5/6(6q^2)^4 - 2\varepsilon^6 C(\varepsilon)(6q^2)\right]\Big|_{\tilde\omega_2}^{z}\end{aligned} \tag{118}$$

in (113). Switching to the original variable $x = \varepsilon z$ and using (113), we obtain

$$\begin{aligned}&\mathcal{I}_1 f = 6\varepsilon^3 c\wp'(x) \\ &\times \int_{\omega_2}^{x} \frac{(6\wp(t) - \frac12)\left[\frac{c-1-4m^2}{3\varepsilon}(6\wp(s) - \frac12)^2 - \frac{5\varepsilon}{6}(6\wp(s) - \frac12)^3 - 2\varepsilon C(\varepsilon)\right]\Big|_{s=\omega_2}^{s=t} dt}{144\prod_1^3(\wp(t) - e_j)}.\end{aligned} \tag{119}$$

The integrand in (119) is nonsingular at $t = \omega_2$ since the numerator has zero at this point. Using this fact, we can cancel the factor $(\wp - e_2)$ in both the numerator and denominator. Then direct calculations show that the integrand in (119) becomes

$$\begin{aligned}&\frac{c-1-4\varepsilon^2}{3\varepsilon} \cdot \frac{\wp^2 + (e_2 - \frac14)\wp + e_2^2 - \frac14 e_2 + \frac{1}{48}}{4(\wp - e_1)(\wp - e_3)} \\ &\qquad - \frac{\frac{5\varepsilon}{6}(6\wp(t) - \frac12)^4}{144\prod_1^3(\wp(t) - e_j)} - \frac{2\varepsilon C(\varepsilon)(6\wp(t) - \frac12)}{144\prod_1^3(\wp(t) - e_j)}.\end{aligned} \tag{120}$$

Let us focus on the first term of (120). Separating the integer part, we can rewrite it as

$$\frac{c-1-4\varepsilon^2}{3\cdot 4\varepsilon}\left[1-\frac{1}{4}\frac{\wp+e_2-\frac{1}{6}}{(\wp-e_1)(\wp-e_3)}\right] = \frac{c-1-4\varepsilon^2}{3\cdot 4\varepsilon}\left[1-\frac{B_0+B_1\wp(t-\omega_1)+B_3\wp(t-\omega_3)}{4}\right], \tag{121}$$

where

$$B_1=-\frac{e_3+\frac{1}{6}}{(e_1-e_3)^2(e_1-e_2)},\quad B_3=\frac{e_1+\frac{1}{6}}{(e_1-e_3)^2(e_2-e_3)},\quad \text{and}\quad B_0=-B_1e_1-B_3e_3. \tag{122}$$

The expressions for B_1, B_3, and B_0 were obtained by evaluating the principal parts of the left-hand side of (122) at $t=\omega_1$, $t=\omega_3$, and $t=0$, respectively.

Using similar calculations, we obtain expressions

$$-\frac{15\varepsilon}{2}\wp(t)+\frac{5\varepsilon}{2}-\frac{5\varepsilon}{24}\left[E_0+E_1\wp(t-\omega_1)+E_3\wp(t-\omega_3)\right]\quad\text{and} \tag{123}$$

$$-\frac{\varepsilon C(\varepsilon)}{12}\left[D_0+D_1\wp(t-\omega_1)+D_3\wp(t-\omega_3)\right]$$

for the second and the third terms of (120), respectively, where

$$D_1=\frac{1}{(e_1-e_3)^2(e_1-e_2)},\quad D_3=-\frac{1}{(e_1-e_3)^2(e_2-e_3)},\quad D_0=-D_1e_1-D_3e_3 \tag{124}$$

and

$$E_3=-\frac{\frac{9}{4}e_3+\frac{3}{2}e_2+36e_2^3-\frac{1}{3}}{(e_1-e_3)^2(e_2-e_3)},\qquad E_0=-E_1e_1-E_3e_3. \tag{125}$$

(The constant E_0 could be calculated similarly to E_3, but we do not need its explicit value.)

Substituting (121)–(125) into (119), we obtain

$$\mathcal{I}_1 f = c\varepsilon^3\wp'(x)\left\{45\varepsilon[\zeta(x)-\zeta(\omega_2)]+6G_1[\zeta(x-\omega_1)-\zeta(\omega_1)]\right. \tag{126}$$

$$\left.+6G_3[\zeta(x-\omega_3)-\zeta(\omega_3)]+\left[-15\varepsilon+(c-1-4\varepsilon^2)(2\varepsilon)^{-1}-6G_1e_1-6G_3e_3\right](x-\omega_2)\right\},$$

where $x=\varepsilon z$ and

$$G_j=-\frac{B_j(c-1-4\varepsilon^2)}{48\varepsilon}-\frac{5\varepsilon}{24}E_j-\frac{\varepsilon C(\varepsilon)}{12}D_j,\qquad j=1,3. \tag{127}$$

3.7. The limit of iterations as $\varepsilon\to 0$. In this subsection we assume that conditions of Theorem 2.1 hold. In the $\varepsilon=0$ case, direct calculation, based on (50) and (49), shows that

$$\Delta w_1(z,0)=-\frac{90}{z^4}+\frac{12\cdot 6!}{7}\left(-z^{-3}\int_\infty^z t^2\mathcal{I}_2[t^{-6}]dt+z^4\int_\infty^z t^{-5}\mathcal{I}_2[t^{-6}]dt\right). \tag{128}$$

It is easy to check that Δw_n, $n = 2, 3, \dots$, is a function, analytic in T_{z_1} and possessing an asymptotic expansion in powers of z^{-2} there, such that

$$\Delta w_n(z) \sim O(z^{-2(n+1)}), \qquad z \to \infty, \ |\arg z| < \frac{\pi}{2}. \tag{129}$$

Then, according to Corollary 1.3, the solution (34) to (23) in the case $\varepsilon = 0$ coincides with $v_+(z)$, i.e., $v(z, 0) = v_+(z)$.

Let $w(z, \varepsilon)$ denote the solution (54) from Theorem 2.1. In order to prove the continuity of $w(z, \varepsilon)$ in ε at $\varepsilon = 0$, we need the following statement.

PROPOSITION 3.12. *Let $g(z, \varepsilon)$ be analytic in z in T_{z_1} and continuous in ε for all sufficiently small $\varepsilon \geq 0$. Moreover, let $g(z, 0) \sim O(z^{-b})$ and $\Delta_\varepsilon g(z, \varepsilon) \sim O(z^{-a})$ in T_{z_1}, the latter uniformly in ε, where $a, b \geq 0$ and $\Delta_\varepsilon g(z, \varepsilon) = g(z, \varepsilon) - g(z, 0)$. Then*

$$\Delta_\varepsilon \mathcal{I}_2 g(z, \varepsilon) = O(z^{-a}) + O(\varepsilon^b), \tag{130}$$

and, if $b > 5$,

$$\Delta_\varepsilon \mathcal{I}_1 g(z, \varepsilon) = O(z^{2-a}) + O(\varepsilon^{b-5} z^{-3}) + O(z^{-b+4}\varepsilon^2), \tag{131}$$

where both (130) *and* (131) *are uniform in T_{z_1} and in small $\varepsilon \geq 0$.*

Proof. Since $g(z, \varepsilon)$ is analytic in T_{z_1},

$$\begin{aligned} \Delta_\varepsilon \mathcal{I}_2 g(z, \varepsilon) = \frac{1}{2i} \left[\int_{\tilde{\omega}_1 - \tilde{\omega}_3}^{z} e^{i(z-\xi)} \Delta_\varepsilon g(\xi, \varepsilon) d\xi - \int_{\tilde{\omega}_1 + 2\tilde{\omega}_3}^{z} e^{-i(z-\xi)} \Delta_\varepsilon g(\xi, \varepsilon) d\xi \right] \\ + \frac{1}{2i} \left[\int_{\infty}^{\tilde{\omega}_1 - \tilde{\omega}_3} e^{i(z-\xi)} g(\xi, 0) d\xi - \int_{\infty}^{\tilde{\omega}_1 + 2\tilde{\omega}_3} e^{-i(z-\xi)} g(\xi, 0) d\xi \right]. \end{aligned} \tag{132}$$

According to Lemma 3.5, estimate (130) follows directly (132).

To prove (131), we first consider $\Delta_\varepsilon q^2(z, \varepsilon)$. Representing $\wp(x) = [\wp(x) - \frac{1}{x^2}] + \frac{1}{x^2} = \Psi(x) + \frac{1}{x^2}$, we note that $\Psi(x)$ is analytic in the trapezoidal region $\tilde{T}$ (vertices at $\omega_1 - \omega_3, \omega_1 + 2\omega_3, \frac{3}{2}\omega_3, -\frac{1}{2}\omega_3$). (The trapezoid $\tilde{T}$ is the image of the trapezoid T under the scaling $x = \varepsilon z$.) Since $q^2(z, 0) = \frac{1}{z^2}$ for any $z \in T$, we have

$$\Delta_\varepsilon q^2(z, \varepsilon) = \varepsilon^2 \left[\Psi(\varepsilon z) - \frac{1}{12} \right] = O(\varepsilon^2) \tag{133}$$

uniformly in T. Similarly, using (45), (46), and (71), we obtain

$$v_1(z, \varepsilon) - v_1(z, 0) = O(\varepsilon^3) \tag{134}$$

and

$$v_2(z, \varepsilon) - v_2(z, 0) = O(\varepsilon^2 z^6) \tag{135}$$

uniformly in T.

Now,

(136)

$$\begin{aligned}\Delta_\varepsilon \mathcal{I}_1 g(z,\varepsilon) = &-\left[v_1(z,\varepsilon)\int_{\tilde\omega_2}^{z} v_2(\xi,\varepsilon)g(\xi,\varepsilon)d\xi - v_1(z,0)\int_{\tilde\omega_2}^{z} v_2(\xi,0)g(\xi,0)d\xi\right]\\ &+\left[v_2(z,\varepsilon)\int_{\tilde\omega_2}^{z} v_1(\xi,\varepsilon)g(\xi,\varepsilon)d\xi - v_2(z,0)\int_{\tilde\omega_2}^{z} v_1(\xi,0)g(\xi,0)d\xi\right]\\ &+\left[-v_1(z,0)\int_{\infty}^{\tilde\omega_2} v_2(\xi,0)g(\xi,0)d\xi + v_2(z,0)\int_{\infty}^{\tilde\omega_2} v_1(\xi,0)g(\xi,0)d\xi\right].\end{aligned}$$

The third term in the right-hand side of (136) is of the order $O(\varepsilon^{b-2})$ as $\varepsilon \to 0$, while the first term can be represented as

(137)

$$\begin{aligned}&- v_1(z,\varepsilon)\int_{\tilde\omega_2}^{z}\left[v_2(\xi,\varepsilon)\Delta_\varepsilon g(\xi,\varepsilon) + g(\xi,0)\Delta_\varepsilon v_2(\xi,\varepsilon)\right]d\xi\\ &- \Delta_\varepsilon v_1(z,\varepsilon)\int_{\tilde\omega_2}^{z} v_2(\xi,0)g(\xi,0)d\xi.\end{aligned}$$

Using Lemma 2.4 together with (134), (135), we obtain estimates

(138)

$$O(z^{2-a}) + O(\varepsilon^2 z^{4-b}) + O(\varepsilon^3 z^{5-b})$$

for the three terms of (137) that are uniform in T and in small $\varepsilon \geq 0$. The second term in the right-hand side of (136) yields the same result. Now (131) follows from (138) and (94). □

THEOREM 3.13. (1) *If in condition* (53) *of Theorem* 2.1 *we require* $\alpha > 1$, *then*

(139)

$$\lim_{\varepsilon\to 0} v(z,\varepsilon) = v_+(z)$$

uniformly on compact subsets of T_{z_1}.

(2) *If condition* (53) *of Theorem* 2.1 *is replaced by*

(140)

$$c(\varepsilon) = 1 + \varepsilon^\alpha \tilde c(\varepsilon) \qquad \text{and} \qquad b(\varepsilon) = \varepsilon^\alpha \tilde b(\varepsilon),$$

where $\alpha = 1$ *and functions* $\tilde c(\varepsilon), \tilde b(\varepsilon)$ *are continuous for small* $\varepsilon \geq 0$, *then*

(141)

$$\lim_{\varepsilon\to 0} v(z,\varepsilon) = v_+(z - z_*)$$

uniformly on compact subsets of T_{z_1}, *where the translation* z_* *depends on* $\tilde b(0), \tilde c(0)$.

Proof. (1) As a consequence of (133), we obtain that (139) is equivalent to

(142)

$$\lim_{\varepsilon\to 0} w(z,\varepsilon) = w(z,0)$$

as $\varepsilon \to 0$ uniformly on compact subsets of T_{z_1}. Since $w(z,\varepsilon) = \sum_{n=1}^{\infty} \Delta w_n(z,\varepsilon)$, where the series converges uniformly for all sufficiently small $\varepsilon \geq 0$ and all $z \in T_{z_1}$, it is sufficient to prove the continuity of each $\Delta w_n(z,\varepsilon)$ in $\varepsilon \geq 0$ in order to prove the continuity of $w(z,\varepsilon)$.

According to (36) and (94),

$$f(z,0) = -6!z^{-6} \quad \text{and} \quad \Delta_\varepsilon f(z,\varepsilon) = O(\varepsilon^\alpha z^{-4}). \tag{143}$$

Then, according to Proposition 3.12,

$$\Delta_\varepsilon \mathcal{I}_1 f(z,\varepsilon) = O(\varepsilon^{\tilde\alpha} z^{-3}), \tag{144}$$

where $\tilde\alpha = \min\{\alpha - 1, 1\}$. Using

$$\Delta_\varepsilon[h(z,\varepsilon)g(z,\varepsilon)] = h(z,\varepsilon)\Delta_\varepsilon g(z,\varepsilon) + \Delta_\varepsilon h(z,\varepsilon) g(z,0) \tag{145}$$

together with (36) and (130), we prove that $\Delta w_1(z,\varepsilon) = w_1(z,\varepsilon)$ also satisfies (144).

Now $\lim_{\varepsilon\to 0} \Delta w_n(z,\varepsilon) = \Delta w_n(z,0)$, $n = 2,3,\dots$, can be proved by induction. Assume that $\Delta_\varepsilon(\Delta w_k(z,\varepsilon))$ satisfies (144) for every $k \in \mathbb{N}$, $k \le n$. We want to prove the statement for $k = n+1$. According to (94), (129), and (130), $\Delta_\varepsilon g(z,\varepsilon) = O(\varepsilon^{\tilde\alpha} z^{-6})$, where $g(z,\varepsilon)$ denotes the argument of $\mathcal{I}_1$ in (100). It is easy to see that $g(z,0) = O(z^{-2(n+3)})$. Then the fact that $\Delta_\varepsilon[\Delta w_{n+1}(z,\varepsilon)]$ satisfies (144) follows from (131). The proof of part (1) is completed.

(2) According to (126), for a given $z \in T_{z_1}$

$$\lim_{\varepsilon\to 0} \mathcal{I}_1 f = -\frac{90}{z^4} + \frac{\tilde c(0)\left\{\sum_{j=1,3} B_j[2\zeta(\omega_j) - \omega_2 e_j] - 4\omega_2\right\}}{4z^3}, \tag{146}$$

where B_j are defined by (122). Similarly,

$$\lim_{\varepsilon\to 0} \varepsilon^7 \tilde b(\varepsilon) v_{22} = -\tilde b(0)\frac{\frac{3g_3}{2}\omega_2 - g_2\zeta(\omega_2)}{3\Delta z^3}. \tag{147}$$

Thus,

$$\lim_{\varepsilon\to 0} w_1(z,\varepsilon) = -\frac{90}{z^4} + \frac{12 z_*}{z^3}, \tag{148}$$

where the constant z_*, which depend on $\tilde b(0), \tilde c(0)$, can be derived from (146), (147).

Now we can repeat the argument of part (1) to show that $\Delta w_n(z,\varepsilon)$ is continuous in ε. It is pretty straightforward to show that $\Delta w_n(z,0) = O(z^{-n-2})$ as $z \to \infty$ and that $\Delta w_n(z,0)$ has asymptotic expansion in z^{-1}. Due to uniform convergence of series (54) in Theorem 2.1, we proved that $\lim_{\varepsilon\to 0} v(z,\varepsilon)$ is a solution of the truncated equation (24) that has asymptotic expansion in z^{-1} as $z \to \infty$ with the leading terms $\frac{6}{z^2} + \frac{12 z_*}{z^3} + \cdots$. Then (141) follows from Corollary 1.3. □

4. Nonexistence of symmetric periodic solutions to (3). Let S be an interval of $\mathbb{R}$ that contains the point $\omega_1 = \omega_1(0)$, and let $y(x,\varepsilon)$ be a C^α-deformation of $y(x,0) = 6\wp_{\frac{1}{12},g_3}(x-\omega_3) - \frac{1}{2}$, where $|g_3| < 6^{-3}$, and where ω_1, ω_3, and g_3 are related through (9). As mentioned earlier, it is more convenient for us to consider $y(x,\varepsilon)$ as a C^α-deformation of $y(x,0) = 6\wp_{\frac{1}{12},g_3}(x) - \frac{1}{2}$ on the interval $S + \omega_3$. Assume that $y(x,\varepsilon)$ contains a sequence $\{y(x,\varepsilon_m)\}_1^\infty$ of solutions that are symmetrical at $x = \omega_3(\varepsilon_m)$ (after a proper translation $\beta(\varepsilon)$) and periodic (along the horizontal line $x = \omega_3(\varepsilon_m) + \mathbb{R}$) with the period $2\omega_1(\varepsilon_m)$, where $\lim_{m\to\infty} \varepsilon_m = 0$ and $\omega_1(\varepsilon_m)$ satisfy (14). Here $\omega_1(\varepsilon), \omega_3(\varepsilon)$, and $g_3(\varepsilon)$ are related through (9).

Let us show that $\beta(\varepsilon_m) = O(\varepsilon_m^\alpha)$. Indeed, since $y(x,\varepsilon)$ is a C^α-deformation of $y(x,0)$, we know that $y'(\omega_2(\varepsilon)+\beta(\varepsilon),\varepsilon) - y'(\omega_2(\varepsilon)+\beta(\varepsilon),0) = O(\varepsilon^\alpha)$ and $\lim_{\varepsilon\to 0}\beta(\varepsilon) =$

0. But solutions $y(x+\beta(\varepsilon_m),\varepsilon_m)$ are symmetrical at $\omega_3(\varepsilon_m)$ and have period $2\omega_1(\varepsilon_m)$, $m\in\mathbb{N}$, so $y'(\omega_2(\varepsilon_m)+\beta(\varepsilon_m),\varepsilon_m)=0$. Thus,

$$y'(\omega_2(\varepsilon_m)+\beta(\varepsilon_m),0)=O(\varepsilon_m^\alpha). \tag{149}$$

Since $y'(\omega_2,0)=0$, then $y'(\omega_2(\varepsilon_m)+\beta(\varepsilon_m),0)=\beta(\varepsilon_m)y''(\omega_2(\varepsilon_m)+\theta(\varepsilon_m)\beta(\varepsilon_m),0)$ by the mean value theorem, where $\theta(\varepsilon_m)\in(0,1)$. Combining this with (149) and the fact that $\wp''$ is separated from zero in a vicinity of ω_2 (see (64)), we obtain $\beta(\varepsilon_m)=O(\varepsilon_m^\alpha)$. Since derivatives of $y(x,0)$ are bounded on the line $\omega_3+\mathbb{R}$, it is easy to show that $y(x+\beta(\varepsilon_m),\varepsilon_m)$ are also C^α-deformations of $y(x,0)$. Thus, without any loss of generality, we will consider only such deformations $y(x,\varepsilon)$ of $y(x,0)$ that are symmetrical at $\omega_2(\varepsilon)$. That means that solutions $v(z,\varepsilon)$ to the inner equation (4), that correspond to such $y(x,\varepsilon)$, are symmetrical at $\tilde\omega_2(\varepsilon)$.

Let us denote by $\mathcal{F}_\alpha$, $\alpha\ge1$, the two-parameter family of solutions constructed in Theorem 2.1 that satisfy an additional assumption: condition (53) in Theorem 2.1 is replaced by (140), where $\alpha\ge1$. The proof of Theorem 1.1 is divided into the following two steps: (1) if $v(z,\varepsilon)$ is the inner solution, symmetrical at $z=\tilde\omega_2(\varepsilon)$, that corresponds to a C^α-deformation $y(x,\varepsilon)$ and if $\omega_1(\varepsilon)$ satisfies (14), then $v(z,\varepsilon)\in\mathcal{F}_\alpha$; (2) if $\omega_1(\varepsilon)$ satisfies (14), then there is no symmetrical and $2\omega_1(\varepsilon)$ periodic solution $v(z,\varepsilon)\in\mathcal{F}_\alpha$. Here and below we use $\tilde\omega_j$ to denote $\tilde\omega_j(\varepsilon)$, $j=1,2,3$, wherever such notation is clear. Additionally, we prove that the BVP

$$2v'''v'-v''^2+(1-\varepsilon^2)v'^2-\varepsilon^2v^2-\frac{2}{3}v^3=\varepsilon^6C(\varepsilon), \tag{150}$$

$$v'(\tilde\omega_3,\varepsilon)=v'(\tilde\omega_2,\varepsilon)=v'''(\tilde\omega_2,\varepsilon)=0$$

has a unique solution in $\mathcal{F}_\alpha$.

If $y(x,\varepsilon)$ is a C^α-deformation of solution (16), then the constant of motion $C(\varepsilon)$ of $y(x,\varepsilon)$, given by (11), satisfies (13). Then the corresponding inner solution $v(z,\varepsilon)$ satisfies (150) and the two latter boundary conditions of (150). It is easy to see that $v(z,\varepsilon)$ is periodic with the period $2\omega_1(\varepsilon)$ and symmetrical if and only if, additionally, $v'(\tilde\omega_3,\varepsilon)=v'''(\tilde\omega_3,\varepsilon)=0$. In other words, a solution $v(z,\varepsilon)$ to the BVP (150) is symmetric and periodic with the period $2\omega_1(\varepsilon)$ if and only if $v'''(\tilde\omega_3,\varepsilon)=0$.

4.1. Solution of BVP (150). Here we prove existence and uniqueness of solution to BVP (150) within the family $\mathcal{F}_\alpha$ using the implicit function theorem.

If $v(z,\varepsilon)$ is a solution to the BVP (150), then the integral of motion (150) evaluated at the points $z=\tilde\omega_2$, $z=\tilde\omega_3$ becomes

$$\varepsilon^2v^2(\tilde\omega_j)+\frac{2}{3}v^3(\tilde\omega_j)+v''^2(\tilde\omega_j)+\varepsilon^6C(\varepsilon)=0, \tag{151}$$

where $j=2,3$. We want to show that for sufficiently small ε there exists a unique $v\in\mathcal{F}_\alpha$ satisfying (151). To this end, we can restrict our attention on the triangle $P\subset T_{z_1}$, which was introduced in section 3.4.

According to (34), (49),

$$v=6q^2+\tilde v=6q^2+6\varepsilon^\alpha\tilde cq^2+\mathcal{I}_2\left[\varepsilon^{6+\alpha}\tilde bv_{22}+\mathcal{I}_1f(q)+\tilde w\right], \tag{152}$$

where

$$\tilde w=-12c\mathcal{I}_1q^2\mathcal{I}_2f(q)+\sum_{n=2}^{\infty}\Delta w_n. \tag{153}$$

It is easy to see that $v(z,\varepsilon) = O(\varepsilon^2)$ uniformly in P as $\varepsilon \to 0$. According to (106), (140), and Remark 3.8, we have $w(z,\varepsilon) = O(\varepsilon^{3+\tilde{\alpha}})$ uniformly in P, where $\tilde{\alpha} = \min\{1, \alpha - 1\}$ as $\varepsilon \to 0$. Then, according to (152) and Lemma 2.4,

$$\tilde{v} \sim O(\varepsilon^{3+\tilde{\alpha}}) \quad \text{and} \quad \tilde{w} \sim O(\varepsilon^{4+2\tilde{\alpha}}) \tag{154}$$

uniformly in P as $\varepsilon \to 0$. Now combining (154) and (39), we see that

$$w'' = \varepsilon^2 w + [\mathcal{I}_2 w]^2 + 12cq^2\mathcal{I}_2 w + f(q) \sim O(\varepsilon^{5+\tilde{\alpha}}) \quad \text{as} \quad \varepsilon \to 0, \tag{155}$$

uniformly on P. Then

$$w'(z,\varepsilon) = \int_{\tilde{\omega}_2}^{z} w''(t,\varepsilon)dt = O(\varepsilon^{4+\tilde{\alpha}}) \tag{156}$$

uniformly in $z \in P$. To estimate v'' in (151) we need the following statement.

PROPOSITION 4.1. *Let $g(z,\varepsilon)$ be a differentiable in $z \in T_{z_1}$ function. If there exists a constant $M > 0$ such that for all small $\varepsilon > 0$ both $|g(z,\varepsilon)|$ and $|g'(z,\varepsilon)|$ are bounded by M in T_{z_1}, then there exists some $\delta_0 > 0$ such that*

$$\mathcal{I}_2 g(z,\varepsilon) = g(z,\varepsilon) - \mathcal{I}_2 g''(z,\varepsilon) + O\left(e^{-\frac{\delta_0}{\varepsilon}\rho(z)}\right) \tag{157}$$

as $\varepsilon \to 0$ uniformly in P, where $\rho(z) = \min\{|z - (\tilde{\omega}_1 + 3\tilde{\omega}_3)|, |z - (\tilde{\omega}_1 - \tilde{\omega}_3)|\}$.

Proof. Integrating by parts $\mathcal{I}_2 g(z,\varepsilon)$, expressed by (76) and (83), twice, we obtain

$$\begin{aligned}\mathcal{I}_2 g(z,\varepsilon) = g(z,\varepsilon) - \mathcal{I}_2 g''(z,\varepsilon) - \frac{1}{2}\, e^{i(z-\xi)}\,[g(\xi,\varepsilon) - ig'(\xi,\varepsilon)]\Big|_{\xi=\tilde{\omega}_1-\tilde{\omega}_3} \\ - \frac{1}{2}\, e^{-i(z-\xi)}\,[g(\xi,\varepsilon) + ig'(\xi,\varepsilon)]\Big|_{\xi=\tilde{\omega}_1+3\tilde{\omega}_3}.\end{aligned} \tag{158}$$

The last two terms of (158) are exponentially small in ε^{-1} according to the construction of T_{z_1}. ∎

Under the assumptions of Proposition 4.1,

$$D^2\mathcal{I}_2 g = g - \mathcal{I}_2 g = \mathcal{I}_2 D^2 g + O\left(e^{-\frac{\delta_0}{\varepsilon}\rho(z)}\right). \tag{159}$$

According to (156), Proposition 4.1 is applicable for $g(z,\varepsilon) = w(z,\varepsilon)$. Thus,

$$v'' = 6c(\varepsilon)(q^2)'' + \mathcal{I}_2 w'' = O(\varepsilon^4) \quad \text{as} \quad \varepsilon \to 0, \tag{160}$$

uniformly on $[\tilde{\omega}_3, \tilde{\omega}_2]$.

Note that $y = \frac{6q^2}{\varepsilon^2}$ is the solution of the unperturbed equation (2) with the constant of motion $J(\varepsilon)$; see (37). Thus,

$$\left(\frac{6q^2}{\varepsilon^2}\right)^2 + \frac{2}{3}\left(\frac{6q^2}{\varepsilon^2}\right)^3 + J(\varepsilon) = 0 \tag{161}$$

at $x = \varepsilon z = \omega_j$, $j = 1, 2, 3$. Notice that (9) and (14) imply that

$$J(\varepsilon) = C + \varepsilon^{\alpha}\tilde{J}(\varepsilon), \tag{162}$$

where $\tilde{J}(\varepsilon)$ is a continuous function. Now substituting $v = 6q^2 + \tilde{v}$ into (151), dividing both sides by $\varepsilon^{7+\tilde{\alpha}}$, and taking into account (161), we obtain

$$2\left(\frac{6q^2}{\varepsilon^2}\right)\breve{v} + \varepsilon^{1+\tilde{\alpha}}\breve{v}^2 + 2\left(\frac{6q^2}{\varepsilon^2}\right)^2\breve{v} + 2\varepsilon^{1+\tilde{\alpha}}\left(\frac{6q^2}{\varepsilon^2}\right)\breve{v}^2 + \frac{2}{3}\varepsilon^{2+2\tilde{\alpha}}\breve{v}^3 + \frac{v''^2}{\varepsilon^{7+\tilde{\alpha}}} + \tilde{C}(\varepsilon) - \tilde{J}(\varepsilon) = 0 \tag{163}$$

at $z = \tilde{\omega}_2, \tilde{\omega}_3$, where

$$\breve{v}(z,\varepsilon) = \frac{\tilde{v}(z,\varepsilon)}{\varepsilon^{3+\tilde{\alpha}}} = \tilde{c}(\varepsilon)\left(\frac{6q^2}{\varepsilon^2}\right) + \varepsilon^4\tilde{b}(\varepsilon)\mathcal{I}_2 v_{22} + \mathcal{I}_2\frac{\mathcal{I}_1 f(q) + \tilde{w}}{\varepsilon^{3+\tilde{\alpha}}}. \tag{164}$$

Equation (163) evaluated at the points $z = \tilde{\omega}_2, \tilde{\omega}_3$ forms a system that we denote by

$$F(\varepsilon, \tilde{b}, \tilde{c}) = 0. \tag{165}$$

LEMMA 4.2. *There exist some $\varepsilon_1 \in (0, \varepsilon_0]$ and functions $\tilde{b}(\varepsilon), \tilde{c}(\varepsilon)$, continuous on $[0, \varepsilon_1]$, such that the system* (165) *holds identically on $[0, \varepsilon_1]$. Moreover, the solution $\tilde{b}(\varepsilon), \tilde{c}(\varepsilon)$ to* (165) *is unique.*

Proof. The proof is based on the implicit function theorem (see, for example, [MB, p. 122]). According to this theorem, we have to show that (a) $F(0, \tilde{b}(0), \tilde{c}(0)) = 0$ for some $\tilde{b}(0), \tilde{c}(0)$; (b) matrix

$$\operatorname{Col}\left(\frac{\partial F}{\partial \tilde{b}}, \frac{\partial F}{\partial \tilde{c}}\right)\Big|_{\varepsilon=0} \tag{166}$$

is not singular; and (c) F and $\frac{\partial F}{\partial \tilde{c}}$, $\frac{\partial F}{\partial \tilde{b}}$ are continuous in all variables in a vicinity of $(0, \tilde{b}(0), \tilde{c}(0))$.

According to (156), we can apply Proposition 4.1 to $\breve{v}(z,\varepsilon) - \tilde{c}(\varepsilon)\frac{6q^2}{\varepsilon^2} = \frac{\mathcal{I}_2 w}{\varepsilon^{3+\tilde{\alpha}}}$. Then

$$\lim_{\varepsilon\to 0}\breve{v}(z,\varepsilon) = \tilde{c}(0)\left(6\wp(\varepsilon z) - \frac{1}{2}\right) + \tilde{b}(0)\lim_{\varepsilon\to 0}\varepsilon^4 v_{22}(z,\varepsilon) + \lim_{\varepsilon\to 0}\frac{\mathcal{I}_1 f(q)}{\varepsilon^{3+\tilde{\alpha}}} + \lim_{\varepsilon\to 0}\frac{\tilde{w}}{\varepsilon^{3+\tilde{\alpha}}} \tag{167}$$

uniformly on $[\tilde{\omega}_3, \tilde{\omega}_2]$. Due to Remark 3.8, the last limit in (167) is zero.

Using (63), (69), (47), and the fact that $v_1(\tilde{\omega}_j) = 0$, we have

$$\lim_{\varepsilon\to 0}\varepsilon^4 v_{22}(\tilde{\omega}_j, \varepsilon) = -\frac{1}{12}\frac{1}{(e_j - e_i)(e_j - e_k)}. \tag{168}$$

Note that $\mathcal{I}_1 f(q)(\tilde{\omega}_2) = 0$. To calculate $\lim_{\varepsilon\to 0}\varepsilon^{-3-\tilde{\alpha}}\mathcal{I}_1 f(q)(\tilde{\omega}_3)$, we notice that

$$\wp'(x - \omega_j) = \left(6e_j^2 - \frac{g_2}{2}\right)(x - \omega_j) + O((x - \omega_j)^2) = 2(e_i - e_j)(e_k - e_j)(x - \omega_j) + O((x - \omega_j)^2) \tag{169}$$

as $x \to \omega_j$, $j = 1, 2, 3$. It follows then from (126) that

$$\varepsilon^{-3}\mathcal{I}_1 f(q)(\omega_3, \varepsilon) = 12c(\varepsilon)(e_1 - e_3)(e_2 - e_3)G_3 = \frac{c(\varepsilon)}{e_1 - e_3}\left\{-\frac{c(\varepsilon) - 1 - 4\varepsilon^2}{4\varepsilon}\left(e_1 + \frac{1}{6}\right) - \frac{5\varepsilon}{2}\left(\frac{9}{4}e_3 + \frac{3}{2}e_2 + 36e_2^3 - \frac{1}{3}\right) + \varepsilon C(\varepsilon)\right\}. \tag{170}$$

Using (126), we obtain

$$\lim_{\varepsilon\to 0}\varepsilon^{-3-\tilde\alpha}\mathcal{I}_1 f(q)(\tilde\omega_3 = -\frac{\tilde c(\varepsilon)(e_1+\frac16)}{4(e_1-e_3)} - \delta_{\tilde\alpha,1}\frac{e_1+\frac16+\frac52\left(\frac94 e_3+\frac32 e_2+36e_2^3-\frac13\right)+36g_3+\frac16}{e_1-e_3} \tag{171}$$

at $z=\tilde\omega_3$, where $\delta_{\tilde\alpha,1}=1$ if $\tilde\alpha=1$ and $\delta_{\tilde\alpha,1}=0$ otherwise. Combining (167)–(171), we obtain

$$\lim_{\varepsilon\to 0}\breve v(\tilde\omega_2) = \left(6e_2-\frac12\right)\tilde c(0)+\frac{\tilde b(0)}{12(e_1-e_2)(e_2-e_3)}, \tag{172}$$

$$\lim_{\varepsilon\to 0}\breve v(\tilde\omega_3) = \left[\left(6e_3-\frac12\right)-\frac{e_1+\frac16}{4(e_1-e_3)}\right]\tilde c(0)-\frac{\tilde b(0)}{12(e_1-e_3)(e_2-e_3)}-\delta_{\tilde\alpha,1}\tilde D,$$

where $\tilde D$ denotes the last fraction in (171).

According to (154) and (160), in the limit $\varepsilon\to 0$ equations (163) become

$$2\left[36\wp^2(\omega_j)-\frac14\right]\lim_{\varepsilon\to 0}\breve v(\tilde\omega_j)+\tilde C(0)-\tilde J(0)=0, \tag{173}$$

where $j=2,3$. Clearly, (172)–(173) form a linear system of equations for the unknowns $\tilde b(0),\tilde c(0)$. Note that the first factor in (173) is different from zero since, otherwise, according to (64), we would have either $C=0$ or $C=-\frac13$, which contradicts our assumption $C\in(-\frac13,0)$. After some algebra, we calculate the determinant of the matrix of linear system (172)–(173) as

(174)

$$\begin{vmatrix} 6e_2-\frac12 & \frac{1}{12(e_1-e_2)(e_2-e_3)}\\ 6e_3-\frac12-\frac{e_1+\frac16}{4(e_1-e_3)} & -\frac{1}{12(e_1-e_3)(e_2-e_3)}\end{vmatrix} = \frac{1}{3\sqrt{\Delta}}\begin{vmatrix}(6e_2-\frac12)(e_1-e_2) & 1\\ (6e_3-\frac12)(e_1-e_3)-\frac{e_1+\frac16}{4} & -1\end{vmatrix}$$

$$= \frac{7(e_1+\frac16)}{12\sqrt{\Delta}},$$

where Δ, defined by (67), is different from zero. This determinant is different from zero since $e_1>0$. Thus, we have established parts (a) and (b) of the lemma; i.e., we have established that $F(0,\tilde b(0),\tilde c(0))=0$ at $z=\tilde\omega_2,\tilde\omega_3$ for some $\tilde b(0),\tilde c(0)$ and that matrix (166) is nonsingular. Continuity of F follows from Theorem 3.13 and the fact that iterations $\Delta w_n(z,\varepsilon)$ in the solution (54) are polynomials in $\tilde b(0),\tilde c(0)$ of degree not exceeding n. Estimates of Theorem 2.1 can be readily adjusted to prove convergence of the series $\sum_{n=1}^\infty\frac{\partial\Delta w_n(z,\varepsilon)}{\partial\tilde c}$ and $\sum_{n=1}^\infty\frac{\partial\Delta w_n(z,\varepsilon)}{\partial\tilde b}$ at $z=\tilde\omega_2$, $z=\tilde\omega_3$. Part (c) and the whole proof are completed. □

THEOREM 4.3. *If $C(\varepsilon)$ and $\omega_1(\varepsilon)$ satisfy* (13) *and* (14)*, respectively, where $\alpha\ge 1$, then the BVP* (150) *has a unique solution in $\mathcal{F}_\alpha$.*

Proof. According to Lemma 4.2, it is sufficient to show that (151) at $z=\tilde\omega_3$ and the rescaled integral of motion (150) imply $v'(\tilde\omega_3)=0$. Indeed, addition of these two equations yields

$$v'(\tilde\omega_3)[2v'''(\tilde\omega_3)+(1-\varepsilon^2)v'(\tilde\omega_3)]=0. \tag{175}$$

That means that $v'(\tilde{\omega}_3) = 0$ or $2v'''(\tilde{\omega}_3) + (1-\varepsilon^2)v'(\tilde{\omega}_3) = 0$. According to (34), and since operators D and D^2+1 commute, this implies $u'(\tilde{\omega}_3) = 0$ or $2w'(\tilde{\omega}_3) = (1+\varepsilon^2)u'(\tilde{\omega}_3)$. If $u'(\tilde{\omega}_3) = 0$, then $v'(\tilde{\omega}_3) = 0$, and the proof is completed. The assumption $u'(\tilde{\omega}_3) \neq 0$ leads to a contradiction. Indeed, on one hand, we have

$$u'(\tilde{\omega}_3) = \frac{2}{1+\varepsilon^2} w'(\tilde{\omega}_3), \tag{176}$$

whereas, on the other hand, according to Proposition 4.1,

$$u'(\tilde{\omega}_3) = \mathcal{I}_2 w'|_{z=\tilde{\omega}_3} = w'(\tilde{\omega}_3) - \mathcal{I}_2 w'''|_{z=\tilde{\omega}_3} + O\left(e^{-\frac{\delta_0}{\varepsilon}}\right). \tag{177}$$

Proposition 4.1 is applicable to $\mathcal{I}_2 w'$ according to (39) and (156). Moreover, differentiating (39), we obtain $w''' = O(\varepsilon^{6+\tilde{\alpha}})$ uniformly on $[\tilde{\omega}_3, \tilde{\omega}_2]$. Thus, (177) contradicts (176). □

4.2. Proof of Theorem 1.1.

Proof. As mentioned in the beginning of section 4, our proof consists of two steps. Step (1) is to show that the inner solution $v(z,\varepsilon) = \varepsilon^2 y(\varepsilon z, \varepsilon)$, corresponding to a C^α-deformation $y(x,\varepsilon)$ of the periodic solution $y(x,0)$, is an $\mathcal{F}_\alpha$ solution. Let us consider first the case $n = 1$.

As discussed above, we can assume without any loss of generality that $v(z,\varepsilon_m)$ is symmetrical with respect to $z = \tilde{\omega}_3(\varepsilon_m)$ and $z = \tilde{\omega}_2(\varepsilon_m)$, where $g_3(\varepsilon_m)$ and $\omega_3(\varepsilon_m)$ are defined by $\omega_1(\varepsilon_m)$ through (9). Then $v'(\tilde{\omega}_2(\varepsilon_m),\varepsilon_m) = v'''(\tilde{\omega}_2(\varepsilon_m),\varepsilon_m) = 0$, so that $v(z,\varepsilon_m)$ is defined by initial conditions $v(\tilde{\omega}_2(\varepsilon_m),\varepsilon_m)$ and $v''(\tilde{\omega}_2(\varepsilon_m),\varepsilon_m)$. In order to show that there is a solution in $\mathcal{F}_\alpha$ with the abovementioned initial conditions at $z = \tilde{\omega}_2(\varepsilon_m)$, we first establish that

$$v(\tilde{\omega}_2(e_n),\varepsilon_m) - \varepsilon_m^2\left(6e_2(0) - \frac{1}{2}\right) = \varepsilon_m^{2+\alpha}\tilde{v}(\varepsilon_m), \tag{178}$$

$$v''(\tilde{\omega}_2(e_n),\varepsilon_m) - \varepsilon_m^4\left(3e_2^2(0) - \frac{1}{48}\right) = \varepsilon_m^{4+\alpha}\tilde{v}''(\varepsilon_m),$$

where $\tilde{v}(\varepsilon)$, $\tilde{v}''(\varepsilon)$ are continuous functions. Indeed, according to our assumptions and taking into account (14),

$$\begin{aligned} y(\omega_2(\varepsilon_m),\varepsilon_m) - y(\omega_2,0) \\ = [y(\omega_2(\varepsilon_m),\varepsilon_m) - y(\omega_2(\varepsilon_m),0)] + [y(\omega_2(\varepsilon_m),0) - y(\omega_2,0)] \\ = \varepsilon_m^\alpha \tilde{y}(\omega_2(\varepsilon_m),\varepsilon_m) + \frac{1}{2}\varepsilon_m^\alpha \tau^2(\varepsilon_m)\wp''(\omega_2(0) + \theta(\omega_1(\varepsilon_m) - \omega_1)), \end{aligned} \tag{179}$$

where $\theta \in (0,1)$. Here we used the mean value theorem and the fact that $\wp'(\omega_2(0)) = 0$. A similar estimate holds for $y''(\omega_2(\varepsilon_m),\varepsilon_m) - y''(\omega_2,0)$. Then, (178) follows from (179).

According to (164), equations (178) in the leading order can be written as

$$\tilde{c}(\varepsilon)\left(\frac{6q^2}{\varepsilon^2}\right)+\varepsilon^4\tilde{b}(\varepsilon)\mathcal{I}_2v_{22}+\mathcal{I}_2\frac{\mathcal{I}_1f(q)+\tilde{w}}{\varepsilon^{3+\tilde{\alpha}}} \tag{180}$$

$$=\tilde{v}(\varepsilon)-\frac{1}{2}\tau^2(\varepsilon)\wp''(\omega_2(0)+\theta(\omega_1(\varepsilon)-\omega_1(0))),$$

$$\tilde{c}(\varepsilon)D_z^2\left(\frac{6q^2}{\varepsilon^2}\right)+\varepsilon^4\tilde{b}(\varepsilon)D_z^2\mathcal{I}_2v_{22}+D_z^2\mathcal{I}_2\frac{\mathcal{I}_1f(q)+\tilde{w}}{\varepsilon^{3+\tilde{\alpha}}}$$

$$=\tilde{v}''(\varepsilon)-\frac{3}{2}(e_2(\varepsilon)+e_2(0))\tau^2(\varepsilon)\wp''(\omega_2(0)+\theta(\omega_1(\varepsilon)-\omega_1(0))).$$

According to (167) and Proposition 4.1, in the limit $\varepsilon\to 0$ equations (180) become

$$\tilde{c}(0)\lim_{\varepsilon\to0}\frac{6q^2}{\varepsilon^2}+\tilde{b}(0)\lim_{\varepsilon\to0}\varepsilon^4v_{22}(\tilde{\omega}_2(\varepsilon),\varepsilon)=\tilde{v}(0)-\frac{1}{2}\tau^2\wp''(\omega_2(0)), \tag{181}$$

$$\tilde{c}(0)\lim_{\varepsilon\to0}\left[\frac{6q^2}{\varepsilon^2}+\frac{36q^4}{\varepsilon^4}\right]+\tilde{b}(0)\lim_{\varepsilon\to0}\left\{\varepsilon^4v_{22}(\tilde{\omega}_2(\varepsilon),\varepsilon)\left[1+\frac{12q^2}{\varepsilon^2}\right]\right\}=\tilde{v}''(0)$$

$$-3e_2(0)\tau^2(0)\wp''(\omega_2(0)).$$

Here we used the fact that $\frac{6q^2}{\varepsilon^2}$ and v_{22} satisfy differential equations (2) and (44), respectively. Calculation of the determinant of the latter system yields

$$\lim_{\varepsilon\to0}\begin{vmatrix}\frac{6q^2}{\varepsilon^2} & \varepsilon^4v_{22}\\ \frac{6q^2}{\varepsilon^2}+\frac{36q^4}{\varepsilon^4} & \left[1+\frac{12q^2}{\varepsilon^2}\right]\varepsilon^4v_{22}\end{vmatrix}=\lim_{\varepsilon\to0}\begin{vmatrix}\frac{6q^2}{\varepsilon^2} & \varepsilon^4v_{22}\\ \frac{36q^4}{\varepsilon^4} & 12q^2\varepsilon^2v_{22}\end{vmatrix} \tag{182}$$

$$=36\lim_{\varepsilon\to0}q^4v_{22}=\frac{3(e_2(0)-\frac{1}{2})^2}{(e_1(0)-e_2(0))(e_2(0)-e_3(0))}\neq0.$$

Following the arguments of Lemma 4.2, we can now use the implicit function theorem to show that the system (180) has a unique solution $\tilde{c}(\varepsilon),\tilde{b}(\varepsilon)$, where $\tilde{c}(\varepsilon),\tilde{b}(\varepsilon)$ are continuous functions. Thus, $v(z,\varepsilon)\in\mathcal{F}_\alpha$. To prove step (1) for the case for general n we simply have to consider the region $\mathcal{P}$ from Remark 3.10 instead of the triangle P and the point $n\tilde{\omega}_1(\varepsilon)+\tilde{\omega}_3(\varepsilon)$ instead of $\tilde{\omega}_2(\varepsilon)$.

To prove step (2), we assume that there is a family of solutions $v(z,\varepsilon_m)\subset\mathcal{F}_\alpha$ to (4), where $\omega_1(\varepsilon)$ satisfies (14), that is symmetrical at $\tilde{\omega}_3(\varepsilon_m)$. However, according to Theorem 3.13,

$$\lim_{m\to\infty}v(z,\varepsilon_m)=v_+(z) \tag{183}$$

uniformly in z on any closed segment of the imaginary axis that belongs to T_{z_1}. Due to the symmetry with respect to the imaginary axis, we also have

$$\lim_{m\to\infty}v(z,\varepsilon_m)=v_-(z) \tag{184}$$

uniformly in z on the same segment of the imaginary axis. But, according to Corollary 1.3, $v_+(z)\not\equiv v_-(z)$. The obtained contradiction proves nonexistence of a family of symmetric periodic solutions $v(z,\varepsilon_m)\subset\mathcal{F}_\alpha$, $\alpha>1$, where $\varepsilon_m\to0$. The same result, according to Theorem 3.13, part (2), holds for the case $\alpha=1$. □

RISE OF CORRELATIONS OF TRANSFORMATION STRAINS IN RANDOM POLYCRYSTALS*

LEONID BERLYAND†, OSCAR BRUNO‡, AND ALEXEI NOVIKOV§

Abstract. We investigate the statistics of the transformation strains that arise in random martensitic polycrystals as boundary conditions cause its component crystallites to undergo martensitic phase transitions. In our laminated polycrystal model the orientation of the n grains (crystallites) is given by an uncorrelated random array of the orientation angles θ_i, $i = 1, \ldots, n$. Under imposed boundary conditions the polycrystal grains may undergo a martensitic transformation. The associated transformation strains $\boldsymbol{\varepsilon_i}$, $i = 1, \ldots, n$ depend on the array of orientation angles, and they can be obtained as a solution to a nonlinear optimization problem. While the random variables θ_i, $i = 1, \ldots, n$ are uncorrelated, the random variables $\boldsymbol{\varepsilon_i}$, $i = 1, \ldots, n$ may be correlated. This issue is central in our considerations. We investigate it in following three different scaling limits: (i) Infinitely long grains (laminated polycrystal of height $L = \infty$); (ii) Grains of finite but large height ($L \gg 1$); and (iii) Chain of short grains ($L = l_0/(2n)$, $l_0 \ll 1$). With references to de Finetti's theorem, Riesz' rearrangement inequality, and near neighbor approximations, our analyses establish that under the scaling limits (i), (ii), and (iii) the arrays of transformation strains arising from given boundary conditions exhibit no correlations, long-range correlations, and exponentially decaying short-range correlations, respectively.

1. Introduction.

We investigate the statistics of the transformation strains (misfits) that arise in random martensitic polycrystals as boundary conditions cause its component crystallites to undergo solid-to-solid (martensitic) phase transitions. Martensitic transformations are shape-deforming phase transitions that can be induced in certain alloys as a result of changes in the imposed strains, stresses, or temperatures. These transitions occur when a crystalline solid transforms between its parent phase (austenite) and any of a number of variants of the product phase (martensite). We focus on a setting that, while sufficiently simple to allow for a complete analytical treatment, provides significant insights on the problem: We study laminated polycrystals that consist of sequences of n of grains of rectangular cross-section—of base $1/n$ and height $L = L(n)$, so that a complete polycrystal is an infinite parallelepiped with rectangular cross-section of base 1 and height L. The goal of this work is to provide a rigorous probabilistic theory for the misfit statistics in such polycrystals and, in particular, to provide a rationale for the approximations implicit in

the numerical algorithms [6, 7, 8] for polycrytalline phase transitions in two- and three-dimensional space.

The microstructure in a laminated polycrystal is described by a sequence of the orientation angles θ_i, $i = 1, \dots, n$; θ_i represents the orientation of the two-dimensional lattice structure in the ith grain. We assume θ_i is a sequence of n independent identically distributed (i.i.d.) random variables. The transformation in the ith grain gives rise to a strain tensor, the transformation strain $\boldsymbol{\varepsilon}_i^{\mathrm{T}}$, $(i = 1, \dots, n)$, which is constant, and it takes one of three *admissible* values: No deformation (the original square lattice remains square), or deformation into one of two rectangular crystalline lattices parallel to the original square lattice. The phase transition in the polycrystal gives rise to a sequence of transformation strains $\boldsymbol{\varepsilon}_i^{\mathrm{T}}$, $i = 1, \dots, n$ obtained by the minimization of the elastic *misfit energy* among all admissible configurations.

We briefly explain the concept of *misfit* using a simple example of a polycrystal with two grains. Assume a rectangular single-crystalline grain, considered separately, can undergo a stress-free (two-dimensional version of the) cubic-to-orthorhombic phase deformation into shapes depicted in Figure 1.1. A polycrystal with two square grains can undergo deformations as depicted in Figure 1.2. The elastic energy of the former transformation is zero, because it is stress-free. In contrast, the latter transformation requires some elastic *misfit energy* that arises because when two crystallites are combined in a polycrystal, their boundaries must remain coherent after the transformation. In general, minimization of misfit energy leads to interactions amongst all of the grains in a polycrystal. Our probabilistic setup allows us to provide a rigorous description of this phenomenology.

The main results of this paper characterize the probability distributions of the random variables $\boldsymbol{\varepsilon}_i^{\mathrm{T}}$ that arise as minimizers of the overall elastic energy for a given i.i.d. distribution of the angle sequence θ_i. Such results are provided in three different cases according to whether the grains are (1) infinitely long ($L = \infty$), (2) of finite but large height ($L = L \gg 1$), and (3) short height ($L = l_0/(2n)$, $l_0 \ll 1$). In case (1) our treatment applies to arbitrary i.i.d. probability measures ρ defining the distribution of angles, and in cases (2) and (3), in turn, we restrict consideration to

i.i.d. distribution of angles with Bernoulli probability measures ρ. Our main results can be briefly described as follows:

1. *Infinitely long grains. Theorem* 5.2. For an arbitrary i.i.d. distribution of angles θ_i, $i = 1, 2, \ldots, n$, under certain technical assumptions, in the limit $n \to \infty$, the transformation strains $\boldsymbol{\varepsilon}_i^{\mathrm{T}}$, $i = 1, 2 \ldots, n$ are also i.i.d. with probability measure μ, where the measure μ is the minimizer of a certain functional ((5.8) below). In particular, in the case of infinitely long grains there are no correlations between transformation strains of any two grains.
2. *Long finite grains. $L \gg 1$. Theorem* 6.4. If θ_i, $i = 1, \ldots, n$ are Bernoulli random variables (4.3), then in the limit $n \to \infty$, $\boldsymbol{\varepsilon}_i^{\mathrm{T}}$, $i = 1, 2 \ldots, n$ have long-range but no short-range correlations.
3. *Short grains. $L = l_0/(2n)$, $l_0 \ll 1$. Theorems* 7.4 *and* 7.5. If θ_i, $i = 1, \ldots, n$ are Bernoulli random variables (4.3), then in the limit $n \to \infty$, $\boldsymbol{\varepsilon}_i^{\mathrm{T}}$, $i = 1, 2 \ldots, n$ have short-range but no long-range correlations.

Results 2 and 3 can be explained as follows. The cornerstone of our study is the maximization of an integral energy functional (see (3.4) below) of the form $\int K_L(x - t) f(x) f(t) dx dt$. Its integral kernel $K_L(x)$ decays on different length scales for long and short grains. For long grains it decays on the length scale of the composite (on $O(1)$ scale), while for short grains it decays on the length scale of a grain (on $O(1/n)$ scale). Maximization with respect to this integral kernel leads to long-range and short-range correlations for long and short grains, respectively. Formally, correlations arise because grains that undergo the stress-free transformation tend to "group together" on the scale of the decay of the integral kernel. We justify this heuristic idea in the case of long grains (see section 6) by applying a randomized version of the Riesz rearrangement inequality. In the case of short grains (see section 7) we show the transforming grains group together—by applying an isoperimetric inequality.

The paper is organized as follows: After describing in section 2 our model of the polycrystal, in section 3 we solve an auxiliary linear elasticity problem, and we obtain an explicit expression for the stored elastic energy for a fixed admissible array of transformation strains. In section 4 we describe our probabilistic model. Our main results are then established in the next three sections, where the nonlinear minimization problem for a random polycrystal is solved. The cases concerning infinitely long grains, finitely long grains, and short grains are studied in sections 5, 6, and 7, respectively.

2. Formulation.

Stress-free transformation. A two-dimensional polycrystal is a collection of grains. In our model, each grain is a single crystal (a crystallite) which can undergo a shape-deforming phase transition that results in a transformation strain. An untransformed grain with a horizontal-vertical square lattice (angle $\theta = 0$) may either elongate in the horizontal direction and remain unchanged in the vertical direction (the upper-right state in Figure 1.1); it may elongate in the vertical direction and remain unchanged in the horizontal direction (the lower right state in Figure 1.1); or, finally, it may not transform at all and thus have its size unchanged (the left state in Figure 1.1). These states correspond to the transformation strains:

$$\boldsymbol{\varepsilon}_0^1 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \ \boldsymbol{\varepsilon}_0^2 = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, \ \boldsymbol{\varepsilon}_0^0 = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}. \tag{2.1}$$

The first and the second state correspond to a nontrivial transformation. The null strain $\boldsymbol{\varepsilon}_0^0$ corresponds to absence of transformation.

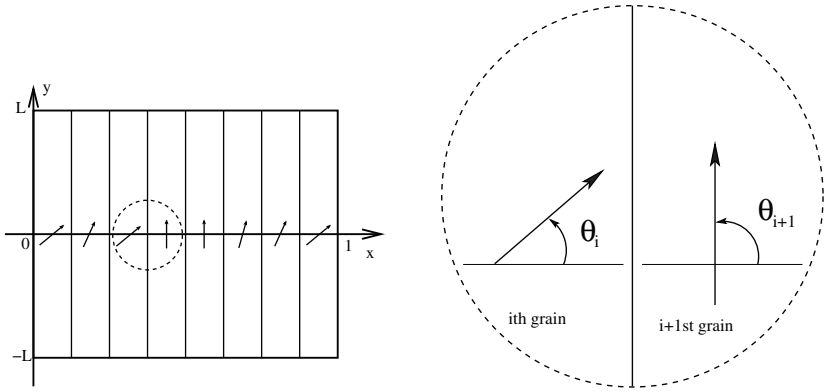

FIG. 2.1. *The laminated polycrystal.*

Mathematical model of a laminated polycrystal. Grains in a polycrystal have a varying orientation of the crystalline lattices. We consider a rectangular polycrystal $\Pi_L = [0,1] \times [-L, L]$ (see Figure 2.1) partitioned into n vertical rectangular layers (the *grains*) of width $1/n$ and height $2L$,

$$\Pi_L = \cup_{i=1}^n \Pi_L^i,\ \Pi_L^i = \left[\frac{i-1}{n}, \frac{i}{n}\right] \times [-L, L].$$

Each grain Π_L^i is occupied by a crystallite obtained by rotation by the *orientation angle*

$$\theta_i,\ 0 \le \theta_i \le \pi/2,$$

of the reference crystallite (see Figure 2.1).

The array of crystallites' orientations is completely determined by the vector of the orientation angles

$$\boldsymbol{\theta} = (\theta_1, \theta_2, \ldots, \theta_n). \tag{2.2}$$

Using the matrix of rotation by an angle θ

$$R = R(\theta) = \begin{pmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{pmatrix},$$

we see that the stress-free transformation strain for the grain Π_L^i must lie in the set

$$\mathcal{S}_{\theta_i} = \left\{\boldsymbol{\varepsilon}^1(\theta_i), \boldsymbol{\varepsilon}^2(\theta_i), \boldsymbol{\varepsilon}^0(\theta_i)\right\},\ 0 \le \theta_i \le \pi/2, \tag{2.3}$$

where

$$\begin{aligned} \boldsymbol{\varepsilon}^1(\theta) &= R\boldsymbol{\varepsilon}^1(0)R^t = \begin{pmatrix} \cos^2(\theta) & \sin(\theta)\cos(\theta) \\ \sin(\theta)\cos(\theta) & \sin^2(\theta) \end{pmatrix}, \\ \boldsymbol{\varepsilon}^2(\theta) &= R\boldsymbol{\varepsilon}^2(0)R^t = \begin{pmatrix} \sin^2(\theta) & -\sin(\theta)\cos(\theta) \\ -\sin(\theta)\cos(\theta) & \cos^2(\theta) \end{pmatrix}, \\ \boldsymbol{\varepsilon}^0(\theta) &= R\boldsymbol{\varepsilon}^0(0)R^t = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}. \end{aligned} \tag{2.4}$$

The superscript t stands for the matrix transpose. The set of all sequences of strains that are admissible for some sequence of angles is denoted by $\tilde{\Omega}_n$:

$$\tilde{\Omega}_n = \left\{ \boldsymbol{\varepsilon}^{\mathrm{T}} | \boldsymbol{\varepsilon}^{\mathrm{T}} = (\boldsymbol{\varepsilon}_1^{\mathrm{T}}, \boldsymbol{\varepsilon}_2^{\mathrm{T}}, \boldsymbol{\varepsilon}_3^{\mathrm{T}}, \ldots, \boldsymbol{\varepsilon}_n^{\mathrm{T}}),\ \boldsymbol{\varepsilon}_i^{\mathrm{T}} \in \mathcal{S}_{\theta_i} \text{ for some } \theta_i \in [0, \pi/2] \right\}. \tag{2.5}$$

The set of all sequences of strains that are admissible for a given sequence $\boldsymbol{\theta}$ will be denoted by

$$\tilde{\Omega}_n(\boldsymbol{\theta}) = \left\{ \boldsymbol{\varepsilon}^{\mathrm{T}} | \boldsymbol{\varepsilon}^{\mathrm{T}} \in \tilde{\Omega}_n \text{ such that } \boldsymbol{\varepsilon}_i^{\mathrm{T}} \in \mathcal{S}_{\theta_i} \right\}. \tag{2.6}$$

Linear elasticity equations for given transformation strains. For a given sequence of the orientation angles $\boldsymbol{\theta} = \{\theta_i, i = 1, \ldots, n\}$ there are up to 3^n corresponding sequences $\boldsymbol{\varepsilon}^{\mathrm{T}} = \{\boldsymbol{\varepsilon}_i^{\mathrm{T}}, i = 1, \ldots, n\}$ in the class $\tilde{\Omega}_n(\boldsymbol{\theta})$ defined in (2.6). Here we introduce the relevant elasticity PDEs on the domain Π_L for a *given* such $\boldsymbol{\varepsilon}^{\mathrm{T}}$. We assume that each grain can be described by isotropic elasticity equations with elastic moduli given by

$$c_{ijkl} = \lambda \delta_{ij} \delta_{kl} + \mathrm{G}(\delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk}), \tag{2.7}$$

where λ and G are the Lamé constants [19].

As an applied displacement is imposed, our polycrystal may acquire microscopic strains $\boldsymbol{\varepsilon}$ which contain combined contributions of elastic and stress-free transformations (see [9]):

$$\boldsymbol{\varepsilon} = \boldsymbol{\varepsilon}^{\text{elastic}} + \boldsymbol{\varepsilon}^{\mathrm{T}}. \tag{2.8}$$

Then Hooke's law $\sigma_{ij} = c_{ijkl}\varepsilon_{kl}^{\text{elastic}}$ yields the stress-strain relation of *linear elasticity* under a given transformation strain $\boldsymbol{\varepsilon}^{\mathrm{T}}$

$$\sigma_{ij} = c_{ijkl}(\varepsilon_{kl} - \varepsilon_{kl}^{\mathrm{T}}). \tag{2.9}$$

Here the strain tensor ε_{kl} is determined by the displacement vector $\boldsymbol{u} = (u_1(x, y), u_2(x, y))$:

$$\varepsilon_{ij} = \frac{1}{2}\left(\partial_i u_j + \partial_j u_i\right) \text{ where } \partial_1 = \frac{\partial}{\partial x},\ \partial_2 = \frac{\partial}{\partial y}. \tag{2.10}$$

The stress tensor satisfies the elasticity equations

$$\partial_j \sigma_{ij} = 0 \text{ for } i = 1, 2. \tag{2.11}$$

The above equation is to be understood in the distributional sense, and thus the traction must be continuous across the interfaces between grains:

$$[\sigma_{i1}](x, y) = 0, \text{ for } i = 1, 2 \text{ and } x = m/n,\ m = 1, 2, \ldots, n-1. \tag{2.12}$$

For such a *given* admissible configuration $\boldsymbol{\varepsilon}_i^{\mathrm{T}}$, we assume a *given* imposed displacement that is chosen in the direction transversal to the laminates:[1]

$$u_1(0, y) = 0,\ u_1(1, y) = U,\ u_2(0, 0) = 0, \tag{2.13}$$

together with the zero-traction boundary conditions

$$\sigma_{12}(0, y) = \sigma_{12}(1, y) = 0,\ \sigma_{i2}(x, \pm L) = 0. \tag{2.14}$$

[1] Other boundary conditions (e.g., shears) could be treated similarly.

It is easy to check that, for a fixed admissible configuration $\boldsymbol{\varepsilon}^{\mathrm{T}}$, (2.11), (2.13), and (2.14) are the Euler–Lagrange equations for the minimizer of the elastic energy

(2.15)
$$W(U,\boldsymbol{\varepsilon}^{\mathrm{T}}) = \frac{1}{E_c}\min_{\boldsymbol{u}}\frac{1}{2L}\int_{\Pi_L}(\varepsilon_{ij}-\varepsilon_{ij}^{\mathrm{T}})c_{ijkl}(\varepsilon_{kl}-\varepsilon_{kl}^{\mathrm{T}})dxdy, \quad \boldsymbol{u} \text{ subject to (2.13)},$$

where

$$E_c = \frac{4\mathrm{G}(\lambda+\mathrm{G})}{\lambda+2\mathrm{G}}, \tag{2.16}$$

is the two-dimensional Young modulus. Thus it can be verified that the boundary value problem (2.11), (2.13), and (2.14) admits a unique solution.

Overall polycrystalline energy. As a displacement (2.13) is imposed on the polycrystal, each grain may undergo a stress-free transformation into one of the three possible stress-free states. The overall energy $\mathcal{W}_n(U,\boldsymbol{\theta})$ in the polycrystal is determined by global minimization of the *misfit energy* $W(U,\boldsymbol{\varepsilon}^{\mathrm{T}})$ of the polycrystal over all admissible configurations [9]

$$\mathcal{W}_n(U,\boldsymbol{\theta}) = \min_{\boldsymbol{\varepsilon}^{\mathrm{T}}\in\tilde{\Omega}_n|_\theta} W(U,\boldsymbol{\varepsilon}^{\mathrm{T}}). \tag{2.17}$$

The (possible nonunique) array(s) of transformations strains that arise in the polycrystal is (are) the minimizer(s) in (2.17).

Simplifying assumptions of our model. The idea that the energy minimization in composites and polycrystals can explain correlations has been long pursued in material science (see, e.g., [16, 22]). In this paper we use a quadratic form of the polycrystal's energy proposed in [9] and further developed analytically in [20, 6] and numerically in [6, 7, 8].

The probabilistic model introduced in this work captures many of the essential features of the general physical phenomenon of misfit and, at the same time, is amenable to rigorous analytical treatment.

Clearly, however, our model is too simple to reflect the rich phenomena that occur in actual three-dimensional polycrystals. For example, we consider isotropic elasticity, whereas typically, the crystalline lattice of each of the martensite variants has less symmetry than that of the austenite. Further, for sufficiently large grains, the lattices associated with the various martensite variants could be combined, giving rise to *twins* and/or higher-rank laminates of two or more different variants of martensite within each grain [21, 4, 15, 5, 17]—an effect that our model does not allow. We also note that, in general, a stress-free transformation is a time-dependent process that involves energy dissipation. Our study assumes that the final state of a polycrystal is determined by minimizers of a time-independent, dissipation-free misfit energy (see, e.g., [9, 6, 8] and references therein). Importantly, however, we do not assume that the grains in the polycrystal transform without elastic stresses (self-accommodation); see, e.g., [3, 2] and references therein.

Although not explicitly considered in this work, related phenomena, including electrical and magnetic polarizations in electro- and magneto-rheological materials and the combined elastic and magnetic-electric misfits arising from magnetostriction and electrostriction in composite materials, could be treated by similar methods.

3. Elasticity kernel. In this section we give a representation for the elastic energy $W(U,\boldsymbol{\varepsilon}^{\mathrm{T}})$ in terms of a certain integral kernel $K_L((x-t))$, and we then present

asymptotics of this kernel under two regimes that are relevant in our studies of the statistics of transformation strains in sections 5, 6, and 7. Denote spatial averages as

$$\langle g\rangle = \frac{1}{|\Pi_L|}\int_{\Pi_L} g(x,y)dxdy = \frac{1}{2L}\int_{\Pi_L} g(x,y)dxdy. \tag{3.1}$$

It turns out that the most convenient mathematical formulation of the elastic energy is in terms of

$$s(x) = \varepsilon^{\mathrm{T}}_{22}(x), \tag{3.2}$$

and the volume fraction of grains that undergo a phase transition[2]

$$f = \langle I\rangle,\ I = \varepsilon^{\mathrm{T}}_{11} + \varepsilon^{\mathrm{T}}_{22}. \tag{3.3}$$

Then the elastic energy

$$W(U,\boldsymbol{\varepsilon}^{\mathrm{T}}) = \langle (U-f+s)^2\rangle - \int_{-1}^{1}\int_{-1}^{1}(s(x)-\langle s\rangle)K_L((x-t))(s(t)-\langle s\rangle)dxdt, \tag{3.4}$$

where K_L is an even, 2-periodic integral kernel whose cosine Fourier coefficients

$$\hat{K}_L(m) = \int_{-1}^{1} K_L(x)\cos(\pi m x)dx \tag{3.5}$$

are explicitly given in Appendix A.1 by formulas (A.5) and (A.6).

The idea of the proof of (3.4) is to decompose the solution $\boldsymbol{u} = (u_1, u_2)$ of the boundary value problem (2.11), (2.13), and (2.14) in the form $\boldsymbol{u} = \tilde{\boldsymbol{u}} + \bar{\boldsymbol{u}}$, where $\tilde{\boldsymbol{u}}$ solves the elasticity equations (2.15) for infinitely long grains ($L = \infty$) and the remainder $\bar{\boldsymbol{u}}$ is the correction for finite L. It turns out that $\tilde{\boldsymbol{u}}$ is a piecewise linear function of the form

$$\begin{cases} \tilde{u}^i_1 = a_i x + f_i, \\ \tilde{u}^i_2 = c_i x + dy + g_i, \end{cases} \tag{3.6}$$

and $\bar{\boldsymbol{u}}$ satisfies the boundary value problem

$$\begin{cases} \partial_j \bar{\sigma}_{ij} = 0 \text{ for } i = 1,2, \\ \bar{u}_1(0,y) = \bar{u}_1(1,y) = 0, \quad \partial_1\bar{u}_2(0,y) = \partial_1\bar{u}_2(1,y) = 0, \\ \bar{\sigma}_{12}(x,\pm L) = 0, \quad \bar{\sigma}_{22}(x,\pm L) = E_c(\varepsilon^{\mathrm{T}}_{22} - \langle\varepsilon^{\mathrm{T}}_{22}\rangle). \end{cases} \tag{3.7}$$

where

$$\begin{cases} \bar{\sigma}_{ij} = c_{ijkl}\bar{\varepsilon}_{kl}, \\ \bar{\varepsilon}_{11} = \partial_1\bar{u}_1, \quad \bar{\varepsilon}_{12} = \bar{\varepsilon}_{21} = (\partial_2\bar{u}_1 + \partial_1\bar{u}_2)/2, \quad \bar{\varepsilon}_{22} = \partial_2\bar{u}_2. \end{cases}$$

Both functions can be computed explicitly: $\tilde{\boldsymbol{u}}$ is obtained from direct computations and $\bar{\boldsymbol{u}}$ is found by the Airy function method. A detailed proof is provided in Appendix A.1. The asymptotics of the convolution kernel in two important limiting

[2]Since the transformation strains defined in (2.4) satisfy $\varepsilon^1_{11} + \varepsilon^1_{22} = 1$, $\varepsilon^2_{11} + \varepsilon^2_{22} = 1$, and $\varepsilon^0_{11} + \varepsilon^0_{22} = 0$, it follows that the quantity f equals the volume fraction of grains that undergo a phase transition.

cases, in turn, are summarized in the following two lemmas. The proofs of the lemmas are provided in Appendices A.2 and A.3, respectively.

LEMMA 3.1 (kernel asymptotics as $L \to \infty$). *$K_L(x)$ can be represented in the form*

$$K_L(x) = \frac{B}{L} K_\infty(x) + O(\exp(-L)), \text{ as } L \to \infty, \tag{3.8}$$

where

$$K_\infty = -\ln|\sin(\pi x/2)|,$$

and

$$B = \frac{5\lambda + 9G}{4\pi(\lambda + 2G)} > 0.$$

We now consider polycrystals for which the height is commensurate with the grain widths $L = l_0/(2n)$. The parameter l_0 is the height-to-width ratio. In particular, when $L = 1/(2n)$, such polycrystals can be viewed as chains of square grains.

LEMMA 3.2 (kernel asymptotics as $L \to 0$). *Suppose $L = l_0/(2n)$, where $l_0 > 0$, and $n \to \infty$. Then for each fixed height-to-width ratio l_0 there exists a positive-definite function $\mathcal{K}_{l_0}(x)$, $x \in \mathbb{R}$ independent of n, such that*

$$||K_L(x) - n\mathcal{K}_{l_0}(nx)||_{L_\infty([-1,1])} \to 0, \text{ as } n \to \infty, \tag{3.9}$$

where $\mathcal{K}_{l_0}(x)$ is even: $\mathcal{K}_{l_0}(-x) = \mathcal{K}_{l_0}(x)$, and

$$|\mathcal{K}_{l_0}(x)| \le \frac{c}{l_0} \exp(-|x|/l_0). \tag{3.10}$$

The constant c in (3.10) *does not depend on n and l_0.*

We will find it useful, especially for chains of rectangular grains, to identify sequences (vectors) $(f_1, \dots . f_n)$ (of real number, matrices, etc.) with the corresponding piecewise constant (real valued, matrix valued, etc.) functions defined in the interval $[0, 1]$ that take the values $f(x) = f_k$ for $x \in \Pi_L^k$, $k = 1, \dots, n$. For example, the argument $\boldsymbol{\varepsilon}^{\mathrm{T}}$ of W in (2.15), which is a matrix-valued function defined in the interval $[0, 1]$, will often be replaced by a sequence of n matrices $(\boldsymbol{\varepsilon}_1^{\mathrm{T}}, \boldsymbol{\varepsilon}_2^{\mathrm{T}}, \boldsymbol{\varepsilon}_3^{\mathrm{T}}, \dots, \boldsymbol{\varepsilon}_n^{\mathrm{T}})$. As another example, note that the dependence on n of the quantity on the left-hand side of (2.17) arises merely from the fact that ε^{T} on the right-hand side of that formula is a piecewise constant function determined by a sequence of n matrices. For a function f defined by a sequence $(f_1, \dots . f_n)$ the spatial average (3.1) is

$$\langle f \rangle = \frac{1}{n} \sum_{i=1}^{n} f_i.$$

Further, on the space of the piecewise constant functions the integral representation of the misfit energy (3.4) can be viewed as an algebraic nonnegative definite quadratic form:

$$W_n(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) = \langle (U - f + s)^2 \rangle - \langle (s - \langle s \rangle) M(n, L)(s - \langle s \rangle) \rangle, \tag{3.11}$$

where $M = M(n, L)$ is a $n \times n$ symmetric Toeplitz matrix with entries $M_{ij}(n, L) = \lambda_{i-j}(n, L)$ defined by

$$(s - \langle s \rangle) M (s - \langle s \rangle) = \int_{-1}^{1} \int_{-1}^{1} (s(x) - \langle s \rangle) K_L(x - t)(s(t) - \langle s \rangle) dx dt \tag{3.12}$$

for piecewise constant functions $s = (s_1, \dots, s_n)$.

As an immediate consequence of Lemma 3.2 we can estimate the decay of the coefficients $\lambda_{i-j}(n, L)$ for a chain of rectangular grains ($L = l_0/(2n)$): As $n \to \infty$, $\lambda_k(n, L) \to \lambda_k(l_0)$ where

$$|\lambda_k(l_0)| \le \frac{c}{n} \exp(-|k|/l_0). \tag{3.13}$$

By (3.13) for a chain of rectangular grains $\lambda_{i-j}(n, L)$ can be accurately approximated by a (truncated) Toeplitz matrix by setting $\lambda_k(n, L) \equiv 0$, for $|k| > k_0$, and the misfit energy is approximately

$$W_n^{k_0}(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) = \langle (U - f + s)^2 \rangle - \sum_{k=-k_0}^{k_0} \sum_{i=1}^{n} \lambda_k(n)(s_i - \langle s \rangle)(s_{i+k} - \langle s \rangle), \tag{3.14}$$

where we define s_{i+k} for $i + k > n$ by periodicity

$$s_{i+k} = \begin{cases} s_{i+k}, \text{ if } i + k \le n, \\ s_{i+k-n}, \text{ if } i + k > n. \end{cases}$$

The approximation (3.14) provides a justification, in a one-dimensional context, of numerical schemes which are used in practical evaluation of the misfit energy [9, 6, 7, 8]. The approximation (3.14) takes into account only interaction with the nearest neighbors. Hence we call (3.14) k_0-nearest neighbors energy. The next proposition shows that for any finite value of n and finite k_0, this k_0-nearest neighbors approximation has an exponential in k_0 error. Therefore the computational complexity of finding the misfit energy can be significantly reduced if (3.11) is replaced by (3.14). In [6, 7, 8] this truncation was implemented for general two- and three-dimensional polycrystals, and the convergence was verified numerically. The following proposition justifies this convergence analytically in the case of chains of rectangular grains, and provides an explicit exponential error estimate.

PROPOSITION 3.3. *For a given U and a given vector of orientation angles $\boldsymbol{\theta}$, suppose $\boldsymbol{\varepsilon}^T(k_0) \in \tilde{\Omega}_n(\boldsymbol{\theta})$ is a minimizer of the k_0-nearest neighbors energy $W_n^{k_0}(U, \boldsymbol{\varepsilon}^T)$ given by* (3.14). *Then there is a universal constant c, independent of n, such that $W_n(U, \boldsymbol{\theta})$, the minimum of the misfit energy* (3.11), *satisfies*

$$|W_n(U, \boldsymbol{\theta}) - W_n^{k_0}(U, \boldsymbol{\varepsilon}^T(k_0))| \le c \exp(-k_0). \tag{3.15}$$

A proof the theorem is given in Appendix A.4. Finally, applying Proposition 3.3 and Lemma 3.2, the misfit energy (3.4) of a chain of short grains becomes

$$\begin{aligned} W_n(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) = \langle (U - f + s)^2 \rangle - \lambda_0 \langle (s - \langle s \rangle)^2 \rangle - \frac{B e^{-1/l_0}}{n} \sum_{i=1}^{n} \\ (s_i - \langle s \rangle)(s_{i+1} - \langle s \rangle) + O(e^{-2/l_0}), \text{ as } l_0 \to 0, \end{aligned} \tag{3.16}$$

where $\lambda_0 > 0$, $B > 0$.[3] Thus, when $l_0 \ll 1$, the misfit energy is approximated by the *nearest neighbor* energy.

[3]From numerical computations λ_k, $k \ge 2$ are negligible even for large $l_0 = 1$: $\sum_{k=2}^{\infty} |\lambda_k| \le .1\lambda_1$, $\lambda_1 \le .17\lambda_0$.

4. A probabilistic model. Our probabilistic model is set to describe energy minimizers within a random setting. In detail, we consider orientation angles θ_i, $i = 1, 2, \dots$ as a sequence of random variables[4]

$$\theta_i : \Omega \to \Omega^\theta = [0, \pi/4]$$

on a common probability space $(\Omega, \mathcal{F}, P)$. We denote by ρ_n the usual induced probability measure of a sequence of the first n orientation angles on $(\Omega_n^\theta, \sigma_n^\theta)$, where $\Omega_n^\theta = \left(\Omega^\theta\right)^n = \Omega^\theta \times \Omega^\theta \times \cdots \times \Omega^\theta$, and σ_n^θ is the Borel σ-algebra on Ω_n^θ.

We may define and work with the probability space $(\tilde{\Omega}_n, \tilde{\sigma}_n, \tilde{\mu}_n)$ of arrays of transformation strains $(\boldsymbol{\varepsilon}_i^{\mathrm{T}})_{i=1}^n$, where we recall that $\tilde{\Omega}_n$ is the set of all sequences of strains that are admissible for some sequence of orientation angles (see (2.5)).

We will, however, work with a different, but equivalent probability space. Recall that the misfit energy (3.4) depends only on a sequence of pairs $\{(s_i, I_i)\}$, $i = 1, \dots, n$, where

$$I_i = \varepsilon_{11,i}^{\mathrm{T}} + \varepsilon_{22,i}^{\mathrm{T}} \in \{0, 1\}, \text{ and } s_i = \varepsilon_{22,i}^{\mathrm{T}} \in [0, 1].$$

Therefore, we will study the probability space

$$\left(\Omega_n^{\mathrm{T}}, \sigma_n^{\mathrm{T}}, \mu_n\right), \ \Omega_n^{\mathrm{T}} = \left(\Omega^{\mathrm{T}}\right)^n = \Omega^{\mathrm{T}} \times \Omega^{\mathrm{T}} \times \cdots \times \Omega^{\mathrm{T}}, \ (s_i, I_i) \in \Omega^{\mathrm{T}} = [0, 1] \times \{0, 1\},$$

where σ_n^{T} is the Borel σ-algebra on Ω_n^{T} and μ_n is a probability measure, which we will define next.

Probability measure in the space of transformation strains. Suppose the applied deformation U is given. For a fixed sequence of orientation angles $\boldsymbol{\theta}$, there are up to 3^n different admissible arrays of transformation strains $(\boldsymbol{\varepsilon}_i^{\mathrm{T}})_{i=1}^n$, $\mathrm{T} = 0, 1, 2$; see (2.6) with (2.3) and (2.4). They correspond to 3^n different arrays of pairs $\{(s_i, I_i)\}$, $i = 1, \dots, n$ using the rule that the matrices $\boldsymbol{\varepsilon}^1(\theta_i), \boldsymbol{\varepsilon}^2(\theta_i)$, and $\boldsymbol{\varepsilon}^0(\theta_i)$ in (2.4) correspond to the pairs $(s_i, I_i) = (\sin^2\theta_i, 1)$, $(s_i, I_i) = (\cos^2\theta_i, 1)$, and $(s_i, I_i) = (0, 0)$, respectively. Some of these arrays $\{(s_i, I_i)\}$, $i = 1, \dots, n$, say a number k of them, minimize the misfit energy (3.4) amongst all admissible arrays. We assume, as it may indeed be natural from a physics perspective, that each of these energy minimizing arrays occurs with equal probability. In other words, we will define the probability measure μ_n in such a way that the conditional probability measure $\mu_n((s_i, I_i)_{i=1}^n | \boldsymbol{\theta})$ satisfies

$$\mu_n((s_i, I_i)_{i=1}^n | \boldsymbol{\theta}) = \begin{cases} 1/k, & \text{if } \boldsymbol{\varepsilon}^{\mathrm{T}} \text{ is a minimizer} \\ 0, & \text{if } \boldsymbol{\varepsilon}^{\mathrm{T}} \text{ is not a minimizer,} \end{cases} \tag{4.1}$$

where k is the number of minimizers of the misfit energy (3.4) for the fixed $\boldsymbol{\theta}$. The probability measure μ_n on the sequences $(s_i, I_i)_{i=1}^n$ is thus defined by

$$\mu_n(A) = \int_{\Omega_n^\theta} \mu_n(A | \boldsymbol{\theta}) \mathrm{d}\rho_n(\boldsymbol{\theta}) \tag{4.2}$$

for any Borel set $A \in \sigma_n^{\mathrm{T}}$.

[4]In principle $\theta \in [0, \pi/2]$. It follows from (2.4) that we are concerned only with $\sin^2\theta$ and $\cos^2\theta$. Since $\sin(\pi/2 - \theta) = \cos\theta$ and $\cos(\pi/2 - \theta) = \sin\theta$, we may and do assume that $\theta \in [0, \pi/4]$. The orientation of a square crystalline lattice can be described uniquely by a value $\theta \in [0, \pi/4]$.

The measure μ_n describes statistics of the transformation strains; the main objective of this paper is to describe it in detail for $n \gg 1$ and for various polycrystal configurations.

Distribution of angles. In the remainder of this paper we will assume that the angles θ_i are independent and identically distributed with the induced probability measure (distribution) ρ on $\Omega^\theta = [0, \pi/4]$—although other types of angle distributions could be considered within the present context. In other words, the probability measure ρ_n on the sequences of the orientation angles will be taken to be a product measure of the form

$$\rho_n = \Pi_{i=1}^n \rho.$$

In particular, to illustrate our theory we will consider two specific probability distributions ρ: (1) the *uniform distribution*, in which ρ is proportional to the Lebesgue measure, and (2) the *Bernoulli trials model* for which ρ is concentrated in two θ values

$$\theta_i = \begin{cases} \alpha, & \text{with probability } q, \\ \beta, & \text{with probability } 1-q, \end{cases} \tag{4.3}$$

$0 \le \beta \le \alpha \le \pi/4$.

5. Statistics of asymptotic energy minimizers 1: Infinitely long grains ($L = \infty$).

5.1. The main theorem. Suppose the grains are infinitely long ($L = \infty$). Then, by Lemma 3.1 the misfit energy for a given admissible sequence of transformation strains on the array of n grains is given by

$$W_n(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) = \langle \left(U - f + \varepsilon_{22}^{\mathrm{T}}\right)^2 \rangle = \langle (U - f + s)^2 \rangle. \tag{5.1}$$

The sequence of measures (4.2) contains convergent subsequences [18]; each such limit $\mu_{\lim}$ is a measure on the set of infinite sequences of transformation strains; the limits along various subsequences may, in principle, not all coincide. In fact, in all cases we consider, however, all such limits do coincide, and the full sequences (4.2) are convergent. For the sake of simplicity, in the subsequent analysis we assume this is the case and we denote $\mu_{\lim} = \lim_{n\to\infty} \mu_n$.

As we shall show the limits $\mu_{\lim}$ are convex combinations of product measures. This is a consequence of the de Finetti's representation theorem (see [13] for a general version of this theorem). In order to motivate the advantages of this observation in our context, we first consider one such limit $\mu_{\lim}$ and we *assume* (this may or may not be true!) that (1) for each finite n the minimizers are unique, and (2) the measure $\mu_{\lim}$ is given by a product of the form

$$\mu_{\lim} = \tilde{\mu} := \Pi_{i=1}^\infty \mu, \tag{5.2}$$

for a certain measure μ so that, according to $\mu_{\lim}$, the random variables $\{(s_i, I_i)\}_{i=1}^\infty$ are i.i.d.

Since, as we have seen above, for each i we must necessarily have $s_i = \sin^2(\theta_i)$ or $s_i = \cos^2(\theta_i)$ whenever $I_i = 1$, under the uniqueness assumption (1) above the measure μ in (5.2) must satisfy

$$\begin{cases} \mu\left(s = \sin^2(\theta) | \theta, I = 1\right) + \mu\left(s(\theta) = \cos^2(\theta) | \theta, I = 1\right) = 1 \\ \mu\left(s = \sin^2(\theta) | \theta, I = 1\right) = 0 \quad \text{or} \quad 1 \quad \text{and} \quad \mu\left(s(\theta) = \cos^2(\theta) | \theta, I = 1\right) = 0 \quad \text{or} \quad 1. \end{cases}$$

Hence, we can define a function $\kappa(\theta)$, $\kappa(\theta) = 0$, or $\kappa(\theta) = 1$ such that

$$\kappa(\theta) = \begin{cases} 1, & \text{if } \mu\left(s = \sin^2(\theta)|\theta, I = 1\right) = 1, \\ 0, & \text{if } \mu\left(s = \cos^2(\theta)|\theta, I = 1\right) = 1. \end{cases} \tag{5.3}$$

By the law of large numbers, as $n \to \infty$ we have for the misfit energy (5.1)

$$W_n(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) \to \int_0^{\pi/4} g(\theta)\chi(\theta)d\rho(\theta) + (U - f)^2(1 - f), \tag{5.4}$$

where $g(\theta) = (U - f + \sin^2\theta)^2\kappa(\theta) + (U - f + \cos^2\theta)^2(1 - \kappa(\theta))$ and where we have set

$$\chi(\theta) = \mu(I = 1|\theta), \ (0 \le \chi(\theta) \le 1), \tag{5.5}$$

and $f = \int_0^{\pi/4} \chi(\theta)d\rho(\theta)$.

Clearly, in the present context the limiting values of the energy function $W_n(U, \boldsymbol{\varepsilon}^{\mathrm{T}})$ are determined uniquely by the functions $\kappa(\theta)$ and $\chi(\theta)$. Since $\mu_{\lim}$ is the limit of probability measures $\{\mu_n\}$ given by (4.1) with (5.1), it follows that the measure μ in (5.2) must minimize (5.4). In other words, under the assumption (5.2), the overall minimization problem has been reduced to the following minimization problem for the functions $\kappa(\theta)$ and $\chi(\theta)$:

$$\begin{aligned} &\min_{\kappa(\theta),\chi(\theta)} \int_0^{\pi/4} g(\theta)\chi(\theta)d\rho(\theta) + (U - f)^2(1 - f) \\ &g(\theta) = (U - f + \sin^2\theta)^2\kappa(\theta) + (U - f + \cos^2\theta)^2(1 - \kappa(\theta)), \\ &f = \int_0^{\pi/4} \chi(\theta)d\rho(\theta), \ 0 \le \chi(\theta) \le 1, \ 0 \le \kappa(\theta) \le 1. \end{aligned} \tag{5.6}$$

One can anticipate that, generally, the assumption (5.2) does not hold. Indeed, even working under the assumption (5.2), we note that a solution μ (i.e., (κ, χ)) to the minimization problem (5.6) may not be unique. If there are two such solutions μ_1 and μ_2 to this problem, then the corresponding infinite products $\tilde{\mu}_1$ and $\tilde{\mu}_2$ could, conceivably, equal to the limit of a subsequence of μ_n. As shown in Theorem 5.2, however, in general $\mu_{\lim}$ will equal a convex combination of such infinite products. The following definition will be useful in these regards.

DEFINITION 5.1. *Consider the set $\mathbb{S}$ of all measures on the set of pairs $(s, I) \in [0, 1] \times \{0, 1\}$. For each measure $\mu \in \mathbb{S}$ define the associated product measure*

$$\tilde{\mu} = \Pi_{i=1}^{\infty}\mu$$

on $\Pi_{i=1}^{\infty}(s_i, I_i)$. A measure γ is called a convex combination of such product measures, if there exists a positive measure $\nu(\mu)$ on the set $\mathbb{S}$, such that

$$\gamma(A) = \int_{\mathbb{S}} \tilde{\mu}(A)d\nu(\mu), \ \int_{\mathbb{S}} d\nu(\mu) = 1. \tag{5.7}$$

THEOREM 5.2. *Consider infinitely long grains and an arbitrary i.i.d. angle distribution with the probability measure ρ, and assume the limit $\mu_{\lim}$ of the sequence*

μ_n defined by (4.2) *and* (4.1) *exists. Then $\mu_{\lim}$ is given by a convex combination of product measures arising from minimization problems. In detail, we have*

$$\mu_{\lim} = \int_{\mathbb{S}} \tilde{\mu} d\nu(\mu), \ \int_{\mathbb{S}} d\nu(\mu) = 1,$$

where $\mathbb{S}$ is the set of product measures: $\tilde{\mu} = \Pi_{i=1}^{\infty}\mu$, and each μ is defined by

$$\mu((s,I)|\theta) = \begin{cases} \chi(\theta)\kappa(\theta), & \text{if } I = 1, \\ 1 - \chi(\theta), & \text{if } I = 0, \end{cases}$$

where $\kappa(\theta)$ and $\chi(\theta)$ are minimizers of

$$\min_{\kappa(\theta),\chi(\theta)} \int_0^{\pi/4} (U - f + s(\theta))^2 \chi(\theta) d\rho(\theta) + (U-f)^2(1-f), \tag{5.8}$$
$$f = \int_0^{\pi/4} \chi(\theta) d\rho(\theta), \ \chi : [0, \pi/4] \to [0,1],$$

$$s(\theta) = \kappa(\theta)\sin^2(\theta) + (1 - \kappa(\theta))\cos^2(\theta), \quad \text{where } \kappa : [0,\pi/4] \to \{0,1\}. \tag{5.9}$$

If the minimizer of (5.8) *is unique, then transformation strains in different grains are independent identically distributed; that is, $\mu_{\lim}$ is a product measure $\mu_{\lim} = \Pi_{i=1}^{\infty}\mu$.*

Proof. A key property of the energy W_n (5.1) in the case of infinitely long grains is that it is *invariant under permutations*; e.g., for a three-grain polycrystal, if $(s_1, I_1), (s_2, I_2), (s_3, I_3)$ is a minimizing sequence for the angles $(\theta_1, \theta_2, \theta_3)$, then $(s_2, I_2), (s_1, I_1), (s_3, I_3)$ is a minimizing sequence for the angles $(\theta_2, \theta_1, \theta_3)$ with the same probability. More generally, the form of the misfit energy and our assumption (4.1) imply that the probability measure μ_n (defined by (4.1), (4.2)) on the minimizers must be symmetric;[5] that is, for any finite permutation $\tau \in S(n)$

$$\mu_n((s_1,I_1) \in A_1 \ldots, (s_n,I_n) \in A_n) = \mu_n((s_{\tau(1)}, I_{\tau(1)}) \in A_1, \ldots, (s_{\tau(n)}, I_{\tau(n)}) \in A_n).$$

As $n \to \infty$, the probability measure μ_n converges to a certain $\mu_{\lim}$. Clearly, $\mu_{\lim}$ must be symmetric as well: For any n and $\tau \in S(n)$

$$\begin{aligned} &\mu_{\lim}\left((s_1,I_1) \in A_1, \ldots, (s_n,I_n) \in A_n, (s_{n+1}, I_{n+1}) \in A_{n+1}, \ldots\right) \\ &= \mu_{\lim}\left((s_{\tau(1)}, I_{\tau(1)}) \in A_1, \ldots, (s_{\tau(n)}, I_{\tau(n)}) \in A_n, (s_{n+1}, I_{n+1}) \in A_{n+1}, \ldots\right). \end{aligned}$$

Hence, we can apply the de Finetti's representation theorem [13], and $\mu_{\lim}$ must be a convex combination of product measures $\tilde{\mu}$:

$$\mu_{\lim} = \int_{\mathbb{S}} \tilde{\mu} d\nu(\mu), \ \int_{\mathbb{S}} d\nu(\mu) = 1, \ \nu(\mu) \geq 0;$$

see Definition 5.1, as claimed.

Let us now show that

$$\begin{aligned} &\lim_{n\to\infty} \int_{\Omega_n^{\mathrm{T}}} W_n(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) d\mu_n \\ &\qquad = \int_{\mathbb{S}} \left[\int_0^{\pi/4} (U - f + s(\theta))^2 \chi(\theta) d\rho(\theta) + (U-f)^2(1-f) \right] d\nu(\mu). \end{aligned} \tag{5.10}$$

[5] Sometimes the term exchangeable is used instead of symmetric.

The key issue here is classical: Given that $\mu_n \to \mu_{\lim}$ *weakly*, we cannot, in general, conclude convergence of $\int W_n d\mu_n$. In our case, however, we can, because the measures μ_n are symmetric. It follows that for an n-grain sample, the functions $\{(s_i, I_i)\}_{i=1}^n$ satisfy, for any i, j, $1 \le i, j \le n$,

$$\int I_i I_j d\mu_n = \begin{cases} \int I_1 I_2 d\mu_n, & i \neq j, \\ \int I_1^2 d\mu_n, & i = j, \end{cases}$$

and similar equalities hold for $s_i I_j$, and $(U - \langle I \rangle + s_i)^2$. Therefore, W_n can be written as

$$\int W_n(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) d\mu_n = \int F(U, s_1, I_1, I_2) d\mu_n + \frac{1}{n} \int G(s_1, I_1, I_2) d\mu_n,$$

where *both* functions $F(U, s_1, I_1, I_2)$ and $G(s_1, I_1, I_2)$ depend *continuously* (they are quadratic polynomials) on the values of s_i and I_i only in two grains $i = 1, 2$ (and, thus, do not depend on n), and they are explicitly given as

$$F = (U + s_1)^2 - 2UI_1 - 2s_1 I_2 + I_1 I_2, \quad G = -2s_1 I_1 + 2s_1 I_2 + I_1^2 - I_1 I_2.$$

Therefore

$$\begin{aligned} \lim_{n\to\infty} \int_{\Omega_n^{\mathrm{T}}} W_n(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) d\mu_n &= \lim_{n\to\infty} \int_{\Omega_n^{\mathrm{T}}} F(U, s_1, I_1, I_2) d\mu_n + \lim_{n\to\infty} \frac{1}{n} \int_{\Omega_n^{\mathrm{T}}} G(s_1, I_1, I_2) d\mu_n \\ &= \int_{\Omega_\infty^{\mathrm{T}}} F(U, s_1, I_1, I_2) d\mu_{\lim}. \end{aligned}$$

Hence it only remains to show that

$$\begin{aligned} &\int_{\Omega_\infty^{\mathrm{T}}} F(U, s_1, I_1, I_2) d\mu_{\lim} \\ &\quad = \int_{\mathbb{S}} \left[\int_0^{\pi/4} (U - f + s(\theta))^2 \chi(\theta) d\rho(\theta) + (U - f)^2 (1 - f) \right] d\nu(\mu). \end{aligned} \tag{5.11}$$

The last equality is obtained by explicit computations provided in Appendix B.1. The proof of the identity (5.10) is now complete.

Further, up to a set of ν-measure zero, each μ must minimize (5.8). Otherwise, we can choose a $\delta > 0$ such that the set

$$A = \left\{ \mu : \int F(U, s_1, I_1, I_2) d\tilde{\mu} - \delta > \min \int F(U, s_1, I_1, I_2) d\tilde{\mu} \right\}$$

has positive measure: $\nu(A) > 0$. Then, if $\nu(\mathbb{S} \setminus A) \neq 0$ we define a new measure $\tilde{\nu}$ by

$$\tilde{\nu}(B) = \nu(B \setminus A)/\nu(\mathbb{S} \setminus A).$$

Clearly

$$\int_{\mathbb{S}} \left[\int F(U, s_1, I_1, I_2) d\tilde{\mu} \right] d\tilde{\nu}(\mu) < \int_{\mathbb{S}} \left[\int F(U, s_1, I_1, I_2) d\tilde{\mu} \right] d\nu(\mu),$$

which contradicts the assumption that ν yields a limit of minimizers of the misfit energy (5.8) as indicated in (5.11). If $\nu(\mathbb{S} \setminus A) \neq 0$, in turn, we can select a single minimizer and assign $\tilde{\nu}$ measure 1 to it, arriving again to a contradiction.

To establish (5.9), note that for a minimizer μ of (5.6), the μ probabilities conditional to a given angle θ and to $I = 1$, satisfy

$$\mu\left(s(\theta) = \cos^2(\theta)|\theta, I = 1\right) = 0, \text{ or } \mu\left(s(\theta) = \sin^2(\theta)|\theta, I = 1\right) = 0.$$

Hence $\kappa(\theta)$ takes only the values 0 and 1 and (5.9) holds.

Finally, suppose (5.8) admits a unique minimizer μ. Since, as established above, the limit $\mu_{\lim}$ must be a convex combination of product measures that minimize (5.8); in the case of uniqueness of solution to (5.8), $\mu_{\lim}$ must be the product measure $\mu_{\lim} = \Pi_{i=1}^{\infty}\mu$, as claimed. □

A few remarks about Theorem 5.2 are in order. Firstly, we are aware of some examples when the minimization problem (5.8) has more than one solution. One of these examples is to consider a deterministic sequence $\theta_i = 0$ and $U = 1$. Then there are two solutions $\kappa_1 \equiv 0$, $\chi_1 \equiv 1$, and $\kappa_2 \equiv 0$, $\chi_2 \equiv 0$ to the minimization problem (5.8), which give rise to corresponding measures μ_1 and μ_2, and, thus, product measures $\tilde{\mu}_1$ and $\tilde{\mu}_2$. For both $i = 1, 2$ we have

$$\int_0^{\pi/4} (U - f_i + s_i(\theta))^2 \chi_i(\theta) d\rho(\theta) + (U - f_i)^2(1 - f_i) = 1.$$

In view of our symmetrization assumption 4.1, the limit of μ_n exists and it is equal to a convex combination of product measures as implied by Theorem (5.2); the convex combination is given by $\tilde{\mu}_1/2 + \tilde{\mu}_2/2$. We expect that generically the minimization problem (5.8) has a unique solution. We give two explicit examples when this measure is unique: Bernoulli trials, Lemma 5.3, and Uniform distribution, Lemma 5.6, in section 5.2.

Secondly, in principle, the (unique) solution to the minimization problem (5.8) may be such that $\chi(\theta)$ takes only two values 0 or 1, i.e., $\chi : [0, \pi/4] \to \{0, 1\}$. This, indeed, happens for uniform distribution (Lemma 5.6 in section 5.2). If we know that $\chi : [0, \pi/4] \to \{0, 1\}$, then the proof of Theorem 5.2 becomes straightforward. However, there are examples, when $0 < \chi(\theta) < 1$ for some θ, and one of them is the Bernoulli trials (Corollary 5.4 in section 5.2).

Finally, if we do not assume the uniform conditional probability (4.1), then $\mu_{\lim}$ may not be unique even if the minimizer of (5.8) is unique. We discuss this issue for Bernoulli trials after the proof of Corollary 5.4 below.

Motivated by the above remarks, we next investigate in more detail how measure μ, a solution to the minimization problem (5.8), depends on the underlying probability measure ρ for two specific probability measures ρ: the Bernoulli trials model and the uniform distribution of θ.

5.2. Bernoulli trials and uniform distribution. For the Bernoulli trials model (4.3), the minimization problem (5.8) from Theorem 5.2 is

$$\begin{aligned} &\min_{q_\alpha, q_\beta, s(\alpha), s(\beta)} W(q_\alpha, q_\beta, s(\alpha), s(\beta)), \\ &W = (U - f + s(\alpha))^2 q_\alpha + (U - f + s(\beta))^2 q_\beta + (U - f)^2(1 - f), \end{aligned} \tag{5.12}$$

with $f = q_\alpha + q_\beta$,

$$0 \le q_\alpha \le q, \ 0 \le q_\beta \le 1 - q, \tag{5.13}$$

$0 \le \beta \le \alpha \le \pi/4$, and $s(\alpha)$, $s(\beta)$ are defined by $s(\theta) = \sin^2\theta$ or $s(\theta) = \cos^2\theta$. In particular, the minimization with respect to χ is reduced to determining the proportions q_α and q_β of grains with angles α and β that do not undergo a stress-free transformation.

LEMMA 5.3. *For the Bernoulli trials model* (4.3) *with* $0 < q < 1$ *the minimizer* (κ, χ) *of* (5.12) *is unique. For the minimizer* $\kappa(\theta) \equiv 1$, *i.e.,*

$$s(\theta) = \sin^2 \theta, \tag{5.14}$$

and χ *depends on* U *and can be described as follows. For a given* U *the total proportion of grains that undergoes a stress-free transformation* $f = f(U)$ *is a (deterministic) nondecreasing function of* U. *For a given* f *we have several cases*

- *if* $f < 1 - q$, *then*

$$q_\alpha = 0,\ 0 \le q_\beta \le 1 - q, \tag{5.15}$$

  i.e., $\chi(\alpha) = 0$, $\chi(\beta) = q_\beta/(1-q)$,
- *if* $f > 1 - q$, *then*

$$0 \le q_\alpha \le q,\ q_\beta = 1 - q, \tag{5.16}$$

  i.e. $\chi(\beta) = q_\alpha/q$, $\chi(\beta) = 1$.

A proof of the Lemma is in Appendix B.2.

COROLLARY 5.4. *The probability distribution*

$$\theta_i = \begin{cases} \pi/4, & \text{with probability } q,\ q \ge 1/2, \\ 0, & \text{with probability } 1 - q \end{cases}$$

is an example, where the minimizer (κ, χ) *of* (5.12) *is unique, but*

$$\chi : [0, \pi/4] \to K \subset [0,1], K \ne \{0,1\}.$$

Indeed, in this case

$$\begin{aligned} &\chi(0) = U, \chi(\pi/4) = 0, \text{ if } U \le 1 - q, \\ &\chi(0) = 1, \chi(\pi/4) = 0, \text{ if } 1 - q \le U \le 5/4 - q, \\ &\chi(0) = 1, \chi(\pi/4) = U - 5/4 + q, \text{ if } 5/4 - q \le U \le 3/4, \text{ or} \\ &\chi(0) = 1, \chi(\pi/4) = 1, \text{ if } 3/4 \le U. \end{aligned}$$

Let us now discuss our final remark that if we do not assume the uniform conditional probability (4.1), then $\mu_{\lim}$ may not be unique even if the minimizer of (5.12) is unique. It depends on whether χ takes more than two values, that is, on whether $\chi : [0, \pi/4] \to K$, but $K \ne \{0,1\}$. For example, consider the Bernoulli trials with $0 < q_\alpha < q$. Then one can choose the grains with $\theta_i = \alpha$, which do not undergo a stress-free transformation, arbitrarily, provided that their total proportion is q_α. Thus, if we remove our assumption of equal probability (4.1), in the case of infinitely long grains there are many minimizers of the misfit energy in addition to minimizers described in Theorem 5.2. Hence, it is possible to construct the limiting measure $\mu_{\lim}$ on the infinite sequence of pairs $\{(s_i, I_i)\}_{i=1}^\infty$ so that it is not a product measure. Moreover, actual construction of the exact minimizers $\boldsymbol{\varepsilon}^{\mathrm{T}}$ of the energy (5.1) (for a given sequence $\{\theta_i\}_{i=1}^n$) in practice [9, 6, 7, 8] is done numerically. Thus it typically results in finding an *almost* minimizer $\tilde{\boldsymbol{\varepsilon}}^{\mathrm{T}}$, such that

$$|W_n(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) - W_n(U, \tilde{\boldsymbol{\varepsilon}}^{\mathrm{T}})| \le \delta,\ \delta > 0. \tag{5.17}$$

Thus, it is natural to ask which characteristic properties of exact minimizers are approximated by characteristic properties of almost minimizers. The property

that $\mu_{\lim}$ is a product measure is *not* characteristic, but the proportion of grains that undergo a stress-free transformation is such property. For example, for Bernoulli trials, $q_\alpha(\boldsymbol{\theta})$ characterizes the proportion of grains with $\theta_i = \alpha$, $i = 1, \dots, n$, which undergo a stress-free transformation (grains for which $I = 1$), and we have the following immediate result.

LEMMA 5.5. *For every $\delta' > 0$ there exists $\delta > 0$ such that an almost minimizer $\tilde{\boldsymbol{\varepsilon}}^T$ in the sense* (5.17) *satisfies*

$$|q_\alpha(\boldsymbol{\theta}) - \tilde{q}_\alpha(\boldsymbol{\theta})| < \delta', \ |q_\beta(\boldsymbol{\theta}) - \tilde{q}_\beta(\boldsymbol{\theta})| < \delta',$$

where $q_\alpha(\boldsymbol{\theta})$ and $\tilde{q}_\alpha(\boldsymbol{\theta})$ correspond to the exact and almost minimizers, respectively ($q_\beta(\boldsymbol{\theta})$ and $\tilde{q}_\beta(\boldsymbol{\theta})$ are defined analogously).

Analogous to the Bernoulli trials model, direct computations show the following result for the uniform distribution.

LEMMA 5.6. *For the uniform distribution of $\theta \in [0, \pi/4]$, the minimizer (κ, χ) of* (5.12) *is unique. For the minimizer $\kappa(\theta) \equiv 1$, hence*

$$s(\theta) = \sin^2 \theta, \tag{5.18}$$

and χ depends on U and can be described as follows. For a given U the total proportion of grains that undergoes a stress-free transformation $f(U)$ is a (deterministic) nondecreasing function of U given by

$$f(U) = \begin{cases} \frac{4\pi}{8+\pi} U + g(U), & \text{if } U \le \frac{1}{4} + \frac{2}{\pi} \approx .88662, \\ 1 & \text{otherwise}, \end{cases}$$

where the small correction $g(U)$ is concave and it satisfies $g(0) = f(1/4 + 2/\pi) = 0$, $-0.055 < g(U) \le 0$. For a given $f < 1$

$$\chi(\theta) = \begin{cases} 1, & \text{if } \sin^2 \theta \le 2(f - U), \\ 0, & \text{otherwise}. \end{cases}$$

If $f = 1$, then $\chi \equiv 1$.

Lemmas 5.3 and 5.6 together with Theorem 5.2 imply the following.

COROLLARY 5.7. *For Bernoulli trials and uniform distribution, the unique minimizing sequence of transformation strains is i.i.d, and, in particular, it is uncorrelated.*

6. Statistics of asymptotic energy minimizers 2: Thin long grains (finite $L \gg 1$).

6.1. Basic definitions and formulation of the main theorem. In contrast to the case of infinitely long grains, if L is large but finite, then each grain may undergo a stress-free transformation which, as we show in this section, is correlated to stress-free transformations of other grains. In particular, for Bernoulli trials in case 1 ($L = \infty$, $n \to \infty$) the minimizers are shown to be i.i.d. (see Corollary 5.7 in the previous section), whereas in case 2 ($n \to \infty$, followed by $L \to \infty$) the minimizers are no longer i.i.d. (see Theorem 6.4 below).[6]

By Lemma 3.1 the misfit energy for $L \gg 1$ has the following asymptotic representation (up to higher order terms):

$$W_n(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) = \langle (U - f + s)^2 \rangle - \frac{B}{L} \bar{W}_n(U, \boldsymbol{\varepsilon}^{\mathrm{T}}), \text{ as } L \to \infty, \tag{6.1}$$

[6] In this sense, we prove that the limits for large n and large L do not commute.

where

$$\bar{W}_n(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) = \int_{-1}^{1}\int_{-1}^{1} (s(x) - \langle s\rangle)(s(t) - \langle s\rangle) K_\infty(x-t)\,dx\,dt, \tag{6.2}$$

$$K_\infty = -\ln|\sin(\pi x/2)| > 0. \tag{6.3}$$

For $L \gg 1$ the second term on the right-hand side of (6.1) amounts to a small correction to the misfit energy of infinitely long grains (5.1) (the first term in (6.1)), a situation that bears connections with the concept of almost minimizers (5.17) introduced in the previous section. In the present context we have:

LEMMA 6.1. *For any $\delta > 0$, there exists a sufficiently large $L_0 > 0$, so that for any $L \geq L_0$*

$$s(\theta) = \sin^2\theta, \tag{6.4}$$

$$|q_\alpha(\boldsymbol{\theta}) - q_\alpha^L(\boldsymbol{\theta})| < \delta,\ |q_\beta(\boldsymbol{\theta}) - q_\beta^L(\boldsymbol{\theta})| < \delta, \tag{6.5}$$

where $q_\alpha(\boldsymbol{\theta})$ and $q_\alpha^L(\boldsymbol{\theta})$ correspond to minimizers of (5.1) *and* (6.1)*, respectively ($q_\beta(\boldsymbol{\theta})$ and $q_\beta^L(\boldsymbol{\theta})$ are defined analogously).*

A proof of Lemma 6.1 is in Appendix C.1. As we pointed out after Corollary 5.4, when $L = \infty$ and $0 < q_\alpha < q$ or $0 < q_\beta < 1 - q$ there is an ambiguity: The solution to the minimization problem (5.1) (the first term in (6.1)) is not unique. We now show that the second term (6.2) plays a role of regularization—it resolves this ambiguity by reducing the number of minimizers, and it gives rise to correlation of transformations in different grains of a laminated polycrystal. The correlations arise from *maximization* of $\bar{W}$ (note the negative sign in front of the second term in (6.1)). We formalize this idea in the next definition.

DEFINITION 6.2. *For a given deformation U and a sequence of angles $\{\theta_i\}_{i=1}^n$, an asymptotic energy minimizer is a pair of piecewise constant functions*

$$(s(x), I(x)) = (s_i, I_i) \text{ if } x \in \left(\frac{i-1}{n}, \frac{i}{n}\right],\ i = 1, 2, \ldots, n,\ s(x), I(x) \in \mathcal{H}_n,$$

which maximizes (6.2) *(the second term in* (6.1)*) amongst all*[7] *minimizers of the misfit energy of infinitely long grains* (5.1) *(the first term in* (6.1)*).*

When the distribution of angles ρ_n is given, we denote by μ_n^a the corresponding probability measure of the distribution of asymptotic energy minimizers $(s_i, I_i)_{i=1}^n$. The behavior of the asymptotic energy minimizers for the distribution of angles ρ_n given by the Bernoulli trials (4.3) model will be described by the Riesz symmetrically rearranged minimizer which we define as follows.

DEFINITION 6.3. *Consider Bernoulli trials* (4.3) *model (θ is α or β with probabilities q or $1-q$). For a given displacement U, let q_α and q_β be the proportion of grains for which $I = 1$ with $\theta = \alpha$ and $\theta = \beta$, respectively,*

$$0 \leq q_\alpha \leq q, \quad 0 \leq q_\beta \leq 1 - q, \tag{6.6}$$

[7]Note that we consider here *all* possible minimizers of the misfit energy of infinitely long grains (5.1) (the first term in (6.1)). In other words, here minimizers of (5.1) may not satisfy our assumption of equal probability (4.1).

as given by Lemma 5.3. *For a given sequence of angles* $\{\theta_i\}_{i=1}^n$ *a Riesz left-rearranged sequence of transformation strains is a pair of functions* $(s_l(x), I_l(x)) \in \mathcal{H}_n$ *given for each* $x \in ((i-1)/n, i/n]$ *as*

$$(s_l(x), I_l(x)) = \left(s_l\left(\frac{i}{n}\right), I_l\left(\frac{i}{n}\right)\right) = \begin{cases} (\sin^2\alpha, 1), \ \text{if } \theta = \alpha, \ 0 \le i/n \le q_\alpha/q, \\ (0,0), \ \text{if } \theta = \alpha, \ q_\alpha/q \le i/n \le 1, \\ (\sin^2\beta, 1), \ \text{if } \theta = \beta, \ 0 \le i/n \le q_\beta/(1-q), \\ (0,0), \ \text{if } \theta = \beta, \ q_\beta/(1-q) \le i/n \le 1. \end{cases}$$

Similarly, a Riesz right-rearranged sequence $(s_r(x), I_r(x)) \in \mathcal{H}_n$ *is determined by*

$$\begin{aligned}(s_r(x), I_r(x)) &= \left(s_r\left(\frac{i}{n}\right), I_r\left(\frac{i}{n}\right)\right) \\ &= \begin{cases} (\sin^2\alpha, 1), \ \text{if } \theta = \alpha, \ 1 - q_\alpha/q \le i/n \le 1, \\ (0,0), \ \text{if } \theta = \alpha, \ 0 \le i/n \le 1 - q_\alpha/q, \\ (\sin^2\beta, 1), \ \text{if } \theta = \beta, \ 1 - q_\beta/(1-q) \le i/n \le 1, \\ (0,0), \ \text{if } \theta = \beta, \ 0 \le i/n \le 1 - q_\beta/(1-q). \end{cases}\end{aligned}$$

We denote by μ_n^l *and* μ_n^r *the corresponding probability measures. A Riesz symmetrically rearranged probability measure* μ_n^s *is the average of right- and left-rearranged measures* $\mu_n^s = 1/2\mu_n^l + 1/2\mu_n^r$. *Finally, the Riesz symmetrically rearranged probability measure* μ^s, *the weak limit of probability measures:* $\mu_n^s \Rightarrow \mu^s$, *as* $n \to \infty$.

The rearranged minimizers quantitatively describe the rise of correlations for *asymptotic energy minimizers* (Definition 6.2), because, as we prove in Lemma 6.7, the asymptotic and rearranged minimizers coincide in the limit as $n \to \infty$. In other words, Definitions 6.2 and 6.3 characterize the same measure as $n \to \infty$. Moreover, the following theorem shows that the minimizer probability measure of the full misfit energy (6.1) converges to the Riesz symmetrically rearranged probability measure when we let $n \to \infty$, and then let $L \to \infty$.

THEOREM 6.4. *Consider the Bernoulli trials* (4.3). *For a given* U, *let* q_α *and* q_β *be defined as in Lemma* 5.3 *by* (5.15) *or* (5.16). *Then as* $n \to \infty$ *and subsequently* $L \to \infty$ *the probability measure of the energy minimizer of the misfit energy* (6.1) *converges weakly to the Riesz symmetrically rearranged probability measure* μ^s.

6.2. Riesz rearrangement inequalities and proof of Theorem 6.4. The key idea of the proof comes from the classical Riesz rearrangement inequality (see e.g., [12], [14]). In particular, this inequality motivated the name for minimizers in Definition 6.3. The simplest form of this inequality, which is sufficient for our purposes is as follows.

LEMMA 6.5. *Riesz rearrangement inequality on a circle.*

Consider two classes of even, bounded, and positive functions on $[-1, 1]$:

$$\mathcal{A}_i = \{f(x) | f(x) = f(-x), 0 \le f(x) \le 1, \int_0^1 f(x)dx = p_i\}, \ i = 1, 2.$$

Let $\chi_{p_i}^1(x) \in \mathcal{A}_i$ *be the characteristic function of the set* $[-p_i, p_i]$ *and* $\chi_{p_i}^2(x) \in \mathcal{A}_i$ *be the characteristic function of the set* $[-1, -1+p_i] \cup [1-p_i, 1]$. *Suppose* $K(x)$ *is an even positive locally integrable* 2*-periodic function on* $\mathbb{R}$ *that decreases on* $[0, 1]$:

(6.7)

$$K(x) \ge 0, \ K(x) = K(-x), \ \int_0^1 K(x)dx < \infty, \ K(x+2) = K(x), \ \text{and } K(x_1) > K(x_2),$$

if $0 < x_1 < x_2 \le 1$. *Then for any* $f(x) \in \mathcal{A}_1$, $g(x) \in \mathcal{A}_2$

$$\int_{-1}^{1}\int_{-1}^{1}(f(x)-p_1)(g(t)-p_2)K(x-t)dxdt$$
$$\le \int_{-1}^{1}\int_{-1}^{1}(\chi^1_{p_1}(x)-p_1)(\chi^1_{p_2}(t)-p_2)K(x-t)dxdt, \tag{6.8}$$

where the equality holds only in the following two cases

$$(a)\ f(x)=\chi^1_{p_1}(x), g(x)=\chi^1_{p_2}(x),\ (b)\ f(x)=\chi^2_{p_1}(x), g(x)=\chi^2_{p_2}(x). \tag{6.9}$$

Moreover, for any $\delta > 0$ *there exists* $\delta' > 0$ *so that if* $\min(e_1, e_2) \ge \delta'$,

$$e_1 = \int_0^1 (|f-\chi^1_{p_1}| + |g-\chi^1_{p_2}|)dx,\ e_2 = \int_0^1 (|f-\chi^2_{p_1}| + |g-\chi^2_{p_2}|)dx, \tag{6.10}$$

then

$$\int_{-1}^{1}\int_{-1}^{1}(f(x)-p_1)(g(t)-p_2)K(x-t)dxdt$$
$$\le \int_{-1}^{1}\int_{-1}^{1}(\chi^1_{p_1}(x)-p_1)(\chi^1_{p_2}(t)-p_2)K(x-t)dxdt-\delta. \tag{6.11}$$

We assumed in this lemma that the functions are bounded from above by one. This assumption can be replaced by any positive number with obvious modifications of the results. The proof of Lemma 6.5 follows from considerations similar to those found in [1]. It basically says that among all possible functions $0 \le f(x) \le 1$, $0 \le g(x) \le 1$ on a circle $[-1, 1]$ (where the endpoints $x = \pm 1$ are identified) the maximum of the integral

$$\int_{-1}^{1}\int_{-1}^{1}(f(x)-p_1)(g(t)-p_2)dxdt, \text{ with } \int_0^1 f(x)dx = p_1, \int_0^1 g(x)dx = p_2 \tag{6.12}$$

is achieved on characteristic functions of the intervals of length $2p_1$ and $2p_2$. The reason why the intervals centered at $x = 0$ and $x = 1$ is due to our assumption that $f(x)$ and $g(x)$ are even. In order to explain how Lemma 6.5 must be modified and applied for our case, we decompose

$$s(x) - \langle s\rangle = \sin^2\alpha\varepsilon_\alpha + \sin^2\beta\varepsilon_\beta,\ \varepsilon_\alpha = (\chi_\alpha\tilde{\chi}_\alpha - q_\alpha),\ \varepsilon_\beta = (\chi_\beta\tilde{\chi}_\beta - q_\beta),$$

where χ_α and χ_β, $\chi_\alpha + \chi_\beta = 1$ are (random) characteristic functions of the angle distributions $\theta = \alpha$ and $\theta = \beta$, respectively; $\tilde{\chi}_\alpha$ and $\tilde{\chi}_\beta$ are the characteristic function of the grains with $\theta = \alpha$ and $\theta = \beta$, respectively, for which $I = 1$.

The term (6.2) (the second term in (6.1)) equals

$$\bar{W}(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) = \sin^4\alpha\int_{-1}^{1}\int_{-1}^{1}\varepsilon_\alpha(x)\varepsilon_\alpha(t)K_\infty(x-t)dxdt$$
$$+ 2\sin^2\alpha\sin^2\beta\int_{-1}^{1}\int_{-1}^{1}\varepsilon_\alpha(x)\varepsilon_\beta(t)K_\infty(x-t)dxdt \tag{6.13}$$
$$+ \sin^4\beta\int_{-1}^{1}\int_{-1}^{1}\varepsilon_\beta(x)\varepsilon_\beta(t)K_\infty(x-t)dxdt.$$

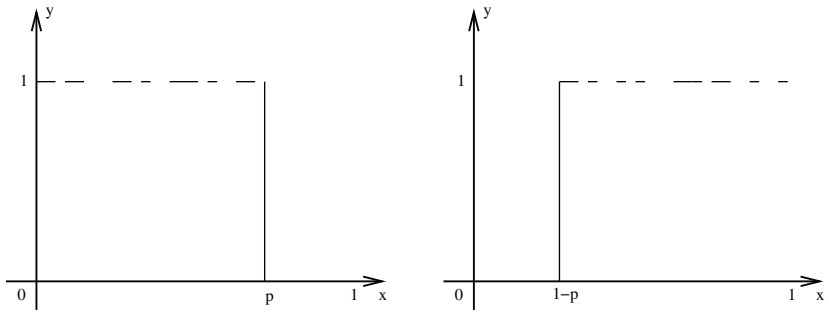

FIG. 6.1. *A sample of two random intervals* $\chi_\alpha(x)\chi^1_{q_\alpha}(x)$ *and* $\chi_\alpha(x)\chi^2_{q_\alpha}(x)$*, where* $p = q_\alpha/q$.

Each of the three integral terms in (6.13) has the form described in the previous Lemma 6.5, because by Lemma 3.1 the integral kernel $K_\infty = -\ln|\sin(\pi x/2)|$, and hence it satisfies all the conditions (6.7). As in Lemma 6.5 we need to maximize the integral (6.13) by varying the characteristic functions $\tilde\chi_\alpha$ and $\tilde\chi_\beta$. The only difference is the additional constraint that χ_α and χ_β are random characteristic functions. This additional constraint, loosely speaking, requires that the maximizers of (6.13) are "random intervals" still centered at $x = 0$ or $x = 1$. More precisely, note that the values of the characteristic functions $\tilde\chi_\alpha$ and $\tilde\chi_\beta$ in (6.13) are important only where $\chi_\alpha = 1$ and $\chi_\beta = 1$, respectively. Hence for a sequence of Bernoulli random variables θ_i, $i = 1, \dots, n$ we can define characteristic functions of random intervals of length $2q_\alpha$ on $[-1, 1]$ centered at $x = 0$ and $x = 1$ as a product of two characteristic functions $\chi_\alpha(x)\chi^1_{q_\alpha}(x)$ and $\chi_\alpha(x)\chi^2_{q_\alpha}(x)$, respectively, where

$$\chi^1_{q_\alpha}(x) = \begin{cases} 1, -\frac{q_\alpha}{q} \le x \le \frac{q_\alpha}{q}, \\ 0, \text{ otherwise}, \end{cases} \qquad \chi^2_{q_\alpha}(x) = \begin{cases} 0, -1 + \frac{q_\alpha}{q} < x < 1 - \frac{q_\alpha}{q}, \\ 1, \text{ otherwise}. \end{cases} \tag{6.14}$$

Similarly, functions $\chi_\alpha(x)\chi^1_{q_\alpha}(x)$ and $\chi_\alpha(x)\chi^2_{q_\alpha}(x)$ are random intervals of length $2q_\beta$ centered at $x = 0$ and $x = 1$ where

$$\chi^1_{q_\beta}(x) = \begin{cases} 1, -\frac{q_\beta}{1-q} \le x \le \frac{q_\beta}{1-q}, \\ 0, \text{ otherwise}, \end{cases} \qquad \chi^2_{q_\beta}(x) = \begin{cases} 0, -1 + \frac{q_\beta}{1-q} < x < 1 - \frac{q_\beta}{1-q}, \\ 1, \text{ otherwise}. \end{cases} \tag{6.15}$$

For an illustration see Figure 6.1. The above discussion is made rigorous by the following.

LEMMA 6.6 (randomized Riesz rearrangement inequality for asymptotic energy minimizers). *Consider Bernoulli trials* (4.3). *Suppose* χ_α *and* χ_β, $\chi_\alpha + \chi_\beta = 1$ *are (random) characteristic functions of the angle distributions* $\theta = \alpha$ *and* $\theta = \beta$, *respectively. Let* $q_\alpha(\boldsymbol{\theta})$ *and* $q_\beta(\boldsymbol{\theta})$ *be random variables of* $\boldsymbol{\theta}$ *with values*

$$0 \le q_\alpha(\boldsymbol{\theta}) \le q, \ 0 \le q_\beta(\boldsymbol{\theta}) \le 1 - q.$$

Suppose $K(x)$ *satisfies* (6.7). *Then for every* $\delta > 0$ *there exists* $\delta' > 0$ *so that if*

$$|q_\alpha(\boldsymbol{\theta}) - q_\alpha| < \delta', \ |q_\beta(\boldsymbol{\theta}) - q_\beta| < \delta' \tag{6.16}$$

for some fixed q_α and q_β, then almost surely[8] *as $n \to \infty$ the maximizers of*

(6.17)
$$\max_{\tilde{\chi}_\alpha, \tilde{\chi}_\beta} \int_{-1}^{1}\int_{-1}^{1} (a\varepsilon_\alpha(x) + b\varepsilon_\beta(x))(a\varepsilon_\alpha(t) + b\varepsilon_\beta(t))K(x-t)dxdt,$$
$$\varepsilon_\alpha = (\chi_\alpha\tilde{\chi}_\alpha - q_\alpha(\boldsymbol{\theta})), \varepsilon_\beta = (\chi_\beta\tilde{\chi}_\beta - q_\beta(\boldsymbol{\theta})), a > 0, b > 0$$
$$\chi^\alpha(x) = \chi^\alpha(-x),\ \chi^\beta(x) = \chi^\beta(-x),\ \int_0^1 \chi^\alpha\tilde{\chi}_\alpha dx = q_\alpha(\boldsymbol{\theta}),\ \int_0^1 \chi^\beta\tilde{\chi}_\beta dx = q_\beta(\boldsymbol{\theta})$$

satisfy

$$\min(e_1, e_2) < \delta, \tag{6.18}$$

where

(6.19)
$$e_1 = \int_0^1 (|\tilde{\chi}_\alpha - \chi^1_{q_\alpha}|\chi_\alpha + |\tilde{\chi}_\beta - \chi^1_{q_\beta}|\chi_\beta)dx, e_2 = \int_0^1 (|\tilde{\chi}_\alpha - \chi^2_{q_\alpha}|\chi_\alpha + |\tilde{\chi}_\beta - \chi^2_{q_\beta}|\chi_\beta)dx,$$

$\chi^i_{q_\alpha}$ and $\chi^i_{q_\beta}$, $i = 1, 2$ are defined in (6.14) *and* (6.15)*, respectively.*

The proof of Lemma 6.6 is by contradiction to the law of large numbers and it is provided in Appendix C.2. The next lemma shows the equivalence of Definitions 6.2 and 6.3 as $n \to \infty$.

LEMMA 6.7. *Consider the Bernoulli trials* (4.3)*. For a given U, let q_α and q_β be defined as in Lemma* 5.3 *by* (5.15) *or* (5.16)*. Then the probability measure μ^a_n of the asymptotic energy minimizer of the misfit energy* (6.1) *(see Definition* 6.2*)) and the probability measure μ^s_n of the Riesz symmetrically rearranged energy minimizer (Definition* 6.3*) have the same weak limit μ^s. Moreover,*

$$\lim_{n\to\infty} e_1 = 0,\ \textit{or}\ \lim_{n\to\infty} e_2 = 0\ \textit{with equal probability}\ 1/2, \tag{6.20}$$

where e_1 and e_2 are defined by (6.19) *in Lemma* 6.17 *above.*

Proof. By Lemmas 5.3 and 5.5, depending on U, the minimizer of the first term in (6.1) satisfies (5.15) or (5.16) for almost every $\boldsymbol{\theta}$ as $n \to \infty$. Since the condition (6.16) of the randomized Riesz rearrangement inequality is satisfied for any $\delta > 0$, by Lemma 6.17 for almost every $\boldsymbol{\theta}$,

$$\lim_{n\to\infty} \min(e_1, e_2) = 0.$$

Hence $\{(s_i, I_i)\}_{i=1}^n$ is either a left-rearranged or right-rearranged sequence almost surely as $n \to \infty$. For every n the measure μ^a_n must be symmetric with respect to the to reflection about the point $x = 1/2$, i.e. with equal probability either $e_1 \to 0$ or $e_2 \to 0$ as $n \to \infty$. This proves (6.20). Clearly (6.20) implies that μ^a_n and the Riesz symmetrically rearranged measure μ^s_n have the same weak limit as $n \to \infty$. ∎

End of proof of Theorem 6.4. Again, by the symmetry of the problem with respect to reflection about the point $x = 1/2$, μ_n also must be similarly symmetric. By Lemma 6.1 the minimizer of (6.1) is an almost minimizer, i.e. for any $\delta > 0$ there is L_0 so that the condition (6.16) of the randomized Riesz rearrangement inequality holds.

[8]Here and in the sequel almost sure convergence is considered in the probability space $(\Omega, \mathcal{F}, P)$ set in the beginning of section 4.

Hence it implies that for sufficiently large L_0 the minimizing sequences $\{(s_i, I_i)\}_{i=1}^n$ for any $L > L_0$ are arbitrarily close to the Riesz symmetrically rearranged minimizing sequences, namely either

(6.21)
$$\int_0^1 (|\tilde{\chi}_\alpha - \chi^1_{q_\alpha}|\chi_\alpha + |\tilde{\chi}_\beta - \chi^1_{q_\beta}|\chi_\beta)dx < \delta, \text{ or } \int_0^1 (|\tilde{\chi}_\alpha - \chi^2_{q_\alpha}|\chi_\alpha + |\tilde{\chi}_\beta - \chi^2_{q_\beta}|\chi_\beta)dx < \delta,$$

with equal probability $1/2$ as $n \to \infty$. If $L_0 \to \infty$, then $\delta \to 0$, and this completes the proof.

It follows from (6.21) that long/short-range correlations in the minimizing sequences $\{(s_i, I_i)\}_{i=1}^n$ are determined by long/short-range correlations of the Riesz symmetrically rearranged minimizing sequences. There is no short-range correlations of the Riesz symmetrically rearranged minimizing sequences. Riesz rearranged measure is, however, correlated on the large-scale: For example, suppose $q_\alpha = q$ and $q_\beta < 1 - q$, then for the right-rearranged measure:

$$(s, I) = \begin{cases} (\sin^2 \alpha, 1), \text{ with probability } q, \\ (\sin^2 \beta, 1), \text{ with probability } 1-q, \text{ if } 1 - q_\beta/(1-q) \le x \le 1, \\ (0, 0), \text{ with probability } 1-q, \text{ if } 0 \le x < 1 - q_\beta/(1-q), \end{cases} \tag{6.22}$$

and for the left-rearranged measure:

$$(s, I) = \begin{cases} (\sin^2 \alpha, 1), \text{ with probability } q, \\ (\sin^2 \beta, 1), \text{ with probability } 1-q, \text{ if } 0 \le x < q_\beta/(1-q), \\ (0, 0), \text{ with probability } 1-q, \text{ if } q_\beta/(1-q) \le x \le 1. \end{cases} \tag{6.23}$$

The long-range correlation of transformation strains for the symmetrically rearranged minimizer probability measure can be read off the formulas (6.22) and (6.23).

7. Statistics of asymptotic energy minimizers 3: Chain of short grains.

7.1. Basic definitions and ideas. In this section we will show how exponentially decaying correlations arise when the scaling of the polycrystal is such that $L = l_0/(2n)$, $l_0 \ll 1$ (short grains). By estimate (3.16) the misfit energy for $l_0 \ll 1$ is given (up to higher order terms) by the nearest neighbor energy

$$W_n(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) = \langle (U - f + s)^2 \rangle - \lambda_0 \langle (s - \langle s \rangle)^2 \rangle - \frac{B l_0}{n} \sum_{i=1}^n (s_i - \langle s \rangle)(s_{i+1} - \langle s \rangle), \tag{7.1}$$

where $B > 0$, $\lambda_0 > 0$. In this case, we show that for Bernoulli trials (4.3) exponentially decaying correlations arise when $n \to \infty$, followed by $l_0 \to 0$.

Qualitatively, the misfit energy $W_n^1(U, \boldsymbol{\varepsilon}^{\mathrm{T}})$ has three terms which are analogous to the case of thin long grains (6.1). The minimization of the first two terms,

$$W_n^0(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) = \langle (U - f + s)^2 \rangle - \lambda_0 \langle (s - \langle s \rangle)^2 \rangle \tag{7.2}$$

determines, as in Lemma 5.3, q_α and q_β, the *total* amount of the grains that undergo a stress-free transformation. The minimizers of (7.2) are, in general, not unique. The third term provides a small correction to (7.2), and, as in section 6, plays a role of regularization, that is it selects the unique minimizer of (7.2) that maximizes

$$\bar{W}_n(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) := \frac{1}{n} \sum_{i=1}^n (s_i - \langle s \rangle)(s_{i+1} - \langle s \rangle). \tag{7.3}$$

Analogous to Definition 6.2, the above considerations motivate the following definition:

DEFINITION 7.1. *For a fixed sequence θ_i, $i = 1, \dots, n$, the asymptotic energy minimizer of the nearest neighbor model* (7.1) *is the sequence (s_i, I_i), $i = 1, \dots, n$ such that it minimizes* (7.2) *and maximizes* (7.3) *among minimizers of* (7.2).

LEMMA 7.2. *For the Bernoulli trials model* (4.3) *the minimizing sequence (s_i, I_i), $i = 1, \dots, n$ of the misfit energy $W_n^0(U, \boldsymbol{\varepsilon}^T)$ given by* (7.2) *satisfies*

$$s(\theta) = \sin^2 \theta, \tag{7.4}$$

and as $n \to \infty$,

$$q_\alpha(\boldsymbol{\theta}) \to q_\alpha, q_\beta(\boldsymbol{\theta}) \to q_\beta$$

almost surely. The values q_α and q_β are determined as follows. For a given U the total proportion of grains that undergoes a stress-free transformation $f = f(U)$ is a (deterministic) nondecreasing function of U. For a given f we have several cases:

- *if $f < 1 - q$, then*

$$q_\alpha = 0,\ 0 \le q_\beta \le 1 - q, \tag{7.5}$$

$\chi(\alpha) = 0$, $\chi(\beta) = q_\beta/(1 - q)$,

- *if $f > 1 - q$, then*

$$0 \le q_\alpha \le q,\ q_\beta = 1 - q, \tag{7.6}$$

$\chi(\beta) = q_\alpha/q$, $\chi(\beta) = 1$.

There are values of α, β, and U for which $0 < q_\beta < 1 - q$ or $0 < q_\alpha < q$.

The proof of this lemma is analogous to Lemma 5.3. Clearly, the function $f(U)$ in Lemma 7.2 is different from the one for the infinitely long grains in Lemma 5.3. However, the characteristic property of the measure that it is determined by q_α and q_β with either (7.5) or (7.6) still holds. One of the consequences of the previous lemma is that there are, again, some values q_α and q_β that determine the proportion of grains that undergo a stress-free transformation and they satisfy $q_\alpha = 0$ or $q_\beta = 1 - q$. This is exactly the characteristic property that we need to be able to prove exponential decay of correlations by applying the isoperimetric inequality (7.8) to the sequences described in Definition 7.1. Following the logic in section 6, we obtain that asymptotic energy minimizer of the nearest neighbor model (7.1) arises in the limit $n \to \infty$, followed by $l_0 \to \infty$. The proof of this statement is similar to the proof of the analogous statement in case 2; see end of the proof of Theorem 6.4 in section 6.2. Hence we only need to find a statistical characterization of maximizers of (7.3) for fixed q_α and q_β found from Lemma 7.2. This is given in Theorems 7.4 and 7.5 below.

7.2. Isoperimetric inequalities and characterization of maximizers of (7.3). Here, it is convenient to characterize any point in the composite $x \in [0, 1]$ as a point that belongs to a (maximal) uninterrupted string of identical values of θ.

DEFINITION 7.3. *For a fixed $\boldsymbol{\theta} = \theta_1, \theta_2, \dots, \theta_n$ we say that a string*

$$\theta_\alpha^m = \theta_{i+1}, \theta_{i+2}, \dots, \theta_{i+m},\ \theta_\alpha^m \subset \boldsymbol{\theta}$$

is a (maximal) uninterrupted string of $\theta = \alpha$ of length m if all $\theta_{i+j} = \alpha$, $i = 1, \dots, m$ and $\theta_i = \theta_{i+1+m} = \beta$. We say that $x \in [0, 1]$ belongs to an uninterrupted string of values α of length m if $x \in \theta_\alpha^m$. The notion $x \in \theta_\beta^m$ is defined analogously.

Recall our notation

$$s(x) - \langle s \rangle = \sin^2 \alpha \varepsilon_\alpha + \sin^2 \beta \varepsilon_\beta,$$

$$\varepsilon_\alpha = (\chi_\alpha \tilde{\chi}_\alpha - q_\alpha), \quad \varepsilon_\beta = (\chi_\beta \tilde{\chi}_\beta - q_\beta),$$

where χ_α and χ_β, $\chi_\alpha + \chi_\beta = 1$ are (random) characteristic functions of the angle distributions $\theta = \alpha$ and $\theta = \beta$, respectively; $\tilde{\chi}_\alpha$ and $\tilde{\chi}_\beta$ are the characteristic function of the grains with $\theta = \alpha$ and $\theta = \beta$, respectively, for which $I = 1$.

By Lemma 7.2, we have two cases: Either $q_\beta = 1 - q$, and then $\tilde{\chi}_\beta \equiv 1$, or $q_\alpha = 0$, and then $\tilde{\chi}_\alpha \equiv 0$. Let us study these two cases separately.

Suppose $q_\alpha = 0$. Let us look at maximization of

$$\frac{1}{n} \sum_{i=1}^{n} s_i s_{i+1}, \ \langle s \rangle = q_\beta \sin^2 \beta \tag{7.7}$$

only. Each of s_i (up to the constant $\sin^2 \beta$) is either 1 or 0; therefore the maximization of the nearest neighbors term (7.7) can be understood as the minimization of the boundary of a set with constant area:

$$\min_{D \in \mathcal{A}} \partial D, \ \mathcal{A} = \left\{ D | D = \{x | s_i(x) \neq 0\}, \int_D dx = q_\beta \right\}. \tag{7.8}$$

Then the usual isoperimetric inequality implies that the maximizer of (7.7) is such that the grains with $\theta_i = \beta$ undergo a stress-free transformation, if they belong to a "long" uninterrupted sequence θ_β^m of the grains with the same $\theta = \beta$. If $\theta_i = \beta$ belongs to a "short" uninterrupted sequence θ_β^m, then it does not undergo a stress-free transformation. Hence there should be short-range correlations. The notion of short and long sequences is relative to the value of the total number of grains that must undergo a stress-free transformation. The above ideas are formulated more precisely in the next theorem.

THEOREM 7.4. *Consider the Bernoulli trials* (4.3). *Denote by* $\tilde{\chi}_\alpha$ *and* $\tilde{\chi}_\beta$ *the characteristic function of the grains with* $\theta = \alpha$ *and* $\theta = \beta$, *respectively, for which* $I = 1$. *Suppose* U *is such that the minimizer of the first term in* (7.1) *satisfies* $q_\alpha = 0$. *Then in the limit* $n \to \infty$ *the sequence* (s_i, I_i), $i = 1, 2, \ldots, n, \ldots$ *is a stationary process with exponentially decaying short-range correlations, long-range correlations are zero, and* $\tilde{\chi}_\alpha \equiv 1$. *Moreover, almost surely as* $n \to \infty$ *the minimizer of the nearest neighbor model* (7.1) *satisfies*

$$\tilde{\chi}_\beta(x) = \begin{cases} 1, \ \textit{if } x \in \theta_\beta^m, \ m > k, \\ 0, \ \textit{if } x \in \theta_\beta^m, \ m < k, \\ 1, \ \textit{with probability } r, \ \textit{if } x \in \theta_\beta^k, \\ 0, \ \textit{with probability } 1 - r, \ \textit{if } x \in \theta_\beta^k, \end{cases}$$

where

$$k = \max(m) \ \textit{such that } q_\beta < (1 - q)^m, \tag{7.9}$$

and r *is found from*

$$q_\beta = rq(1 - q)^k - (1 - q)^{k+1}. \tag{7.10}$$

Proof. By the law of the large numbers, $\tilde{\chi}_\alpha = 0$ and $q_\beta(\boldsymbol{\theta}) \to q_\beta$ almost surely; therefore it is sufficient to study (7.7) or, equivalently, (7.8). By the isoperimetric inequality for every $\boldsymbol{\theta}$ the function $\tilde{\chi}_\beta(x)$ must be such that if $\theta_\beta^{m_1}$, $\theta_\beta^{m_2}$, $\dots$ $\theta_\beta^{m_t}$ are all the (maximal) uninterrupted sequences $\theta_\beta^{m_i} \in \boldsymbol{\theta}$ of values β ordered so that the indices are decreasing $m_1 \geq m_2 \geq \cdots \geq m_t$, then there exists an i: $1 \leq i \leq t$ so that $\tilde{\chi}(x) = 1$, if $x \in \theta_\beta^{m_j}$, $j \leq i$, and $\tilde{\chi}(x) = 0$, if $x \in \theta_\beta^{m_j}$, $j > i$ with the exception of at most one $j \geq i$.

By construction as $n \to \infty$, the process (s_i, I_i), $i = 1, \dots, n, \dots$ is stationary. Since all θ_α^m, θ_β^m are geometrically distributed independent random variables [11], it means explicitly that the probability of a string θ_β^m is given by

$$\rho_\infty(\dots \theta_\beta^m \dots) = q(1-q)^{m-1}.$$

Hence if the total proportion of grains that undergoes a stress-free transformation is q_β, we must have, as $n \to \infty$

$$q_\beta = rq(1-q)^k + \sum_{i=k+1} q(1-q)^i = rq(1-q)^k + (1-q)^{k+1},$$

where, due to our assumption of equal probability (4.1), r is the probability that $\tilde{\chi}(x) = 1$, if $x \in \theta_\beta^k$. Therefore k is found so that $(1-q)^{k+1} \leq q_\beta < (1-q)^k$, i.e., (7.9), and r is found from (7.10).

Since θ_α^m, θ_β^m are independent random variables, the limiting process has exponentially decaying short-range correlations. It implies simultaneously two results: long-range correlations are zero, and short-range correlations decay exponentially with k. These correlations are not zero and can be computed explicitly. □

Suppose $q_\beta = 1 - q$. This case is slightly more technically complicated, but the methods are the same as in the case $q_\alpha = 0$. The main new issue is that s_i may now take *three* values, and, therefore, we have to account for three possible different interfaces. Direct computations show that we have here three different situations, depending on the relative value of α and β. If $\sin^2\alpha > 2\sin^2\beta$, then the maximizer of (7.7) is such that $\tilde{\chi}_\alpha(x) = 1$ if x belongs to the *longest* (maximal) uninterrupted strings θ_α^m. If, however, $\sin^2\alpha < 2\sin^2\beta$, then $\tilde{\chi}_\alpha(x) = 1$ if x belongs to to the *shortest* uninterrupted strings θ_α^m. If $\sin^2\alpha = 2\sin^2\beta$, then there is no difference, and the only statement that is possible to make here is that $\tilde{\chi}_\alpha(x) = \tilde{\chi}_\alpha(y)$, if x and y belong to the same uninterrupted string θ_α^m. Due to our assumption of equal probability (4.1), it is possible to conclude that if $\sin^2\alpha = 2\sin^2\beta$, then there is no correlation at all, therefore we will omit the discussion of this case. Combining these arguments with the arguments in the proof of Theorem 7.4 we have the following result.

THEOREM 7.5. *Consider the Bernoulli trials* (4.3). *Denote by* $\tilde{\chi}_\alpha$ *and* $\tilde{\chi}_\beta$ *the characteristic function of the grains with* $\theta = \alpha$ *and* $\theta = \beta$, *respectively, for which* $I = 1$. *Suppose* U *is such that the minimizer of the first term in* (7.1) *satisfies* $q_\beta = 1 - q$. *Then in the limit* $n \to \infty$ *the sequence* (s_i, I_i), $i = 1, 2, \dots, n, \dots$ *is a stationary process with exponentially decaying short-range correlations; long-range correlations are zero, and* $\tilde{\chi}_\beta \equiv 1$. *Moreover, almost surely as* $n \to \infty$, *the minimizer of the nearest neighbor model* (7.1) *satisfies: If* $\sin^2\alpha > 2\sin^2\beta$, *then*

$$\tilde{\chi}_\alpha(x) = \begin{cases} 1, \text{ if } x \in \theta_\alpha^m, \ m > k, \\ 0, \text{ if } x \in \theta_\alpha^m, \ m < k, \\ 1, \text{ with probability } r, \text{ if } x \in \theta_\alpha^k, \\ 0, \text{ with probability } 1-r, \text{ if } x \in \theta_\alpha^k, \end{cases}$$

where $k = \max(m)$ *such that* $q_\alpha < q^m$ *and* r *solves* $q_\alpha = r(1-q)q^k - q^{k+1}$*; if* $\sin^2\alpha < 2\sin^2\beta$*, then*

$$\tilde{\chi}_\alpha(x) = \begin{cases} 1, \ \textit{if } x \in \theta_\alpha^m, \ m < k, \\ 0, \ \textit{if } x \in \theta_\alpha^m, \ m > k, \\ 1, \ \textit{with probability } r, \ \textit{if } x \in \theta_\alpha^k, \\ 0, \ \textit{with probability } 1-r, \ \textit{if } x \in \theta_\alpha^k, \end{cases}$$

where $k = \max(m)$ *such that* $q - q_\alpha < q^m$ *and* r *solves* $q - q_\alpha = r(1-q)q^k - q^{k+1}$.

Appendix A. Proofs for section 3.

A.1. Proof of formula (3.4). To obtain the representation (3.4) we begin by decomposing $\boldsymbol{u} = (u_1, u_2)$ of the boundary value problem (2.11), (2.13), and (2.14) in the form $\boldsymbol{u} = \tilde{\boldsymbol{u}} + \bar{\boldsymbol{u}}$, where $\tilde{\boldsymbol{u}}$ solves (3.6). The constants a_i, c_i, d, f_i, and g_i are chosen to satisfy the continuity of the displacement $\tilde{\boldsymbol{u}}$ and traction (condition (2.12)) and, denoting

$$\tilde{\sigma}_{ij} = c_{ijkl}(\tilde{\varepsilon}_{kl} - \varepsilon^{\mathrm{T}}_{kl}), \quad \tilde{\varepsilon}_{11} = \partial_1\tilde{u}_1, \quad \tilde{\varepsilon}_{12} = \tilde{\varepsilon}_{21} = (\partial_2\tilde{u}_1 + \partial_1\tilde{u}_2)/2, \quad \tilde{\varepsilon}_{22} = \partial_2\tilde{u}_2,$$

the boundary conditions

$$\tilde{u}_1(0,y) = 0, \ \ \tilde{u}_1(1,y) = U, \ \ \tilde{u}_2(0,0) = 0, \ \ \tilde{\sigma}_{12}(x,y) = 0, \ \text{for } x = 0, 1.$$

The stresses are

$$\begin{aligned} \tilde{\sigma}_{i,11} &= (\lambda + 2\mathrm{G})(a_i - \varepsilon^{\mathrm{T}}_{i,11}) + \lambda(d - \varepsilon^{\mathrm{T}}_{i,22}), \\ \tilde{\sigma}_{i,22} &= (\lambda + 2\mathrm{G})(d - \varepsilon^{\mathrm{T}}_{i,22}) + \lambda(a_i - \varepsilon^{\mathrm{T}}_{i,11}), \\ \tilde{\sigma}_{i,12} &= \mathrm{G}(c_i - 2\varepsilon^{\mathrm{T}}_{i,12}). \end{aligned}$$

Hence $[\tilde{\sigma}_{12}] = 0$, if $c_i = 2\varepsilon^{\mathrm{T}}_{i,12}$. Similarly $[\tilde{\sigma}_{i,11}] = 0$, if

$$a_i = \varepsilon^{\mathrm{T}}_{i,11} + \frac{\lambda}{\lambda + 2\mathrm{G}}\varepsilon^{\mathrm{T}}_{i,22} + \mathrm{Const},$$

where the constant can be found from the condition that the displacement of the right boundary is U:

$$\mathrm{Const} = U - \langle\varepsilon^{\mathrm{T}}_{11}\rangle - \frac{\lambda}{\lambda + 2\mathrm{G}}\langle\varepsilon^{\mathrm{T}}_{22}\rangle.$$

Finally,

$$\begin{aligned} \Big\langle \tilde{\sigma}_{22}\rangle &= \Big\langle (\lambda + 2\mathrm{G})(d - \varepsilon^{\mathrm{T}}_{22}) + \lambda\left(\frac{\lambda}{\lambda + 2\mathrm{G}}\varepsilon^{\mathrm{T}}_{22} + U - \langle\varepsilon^{\mathrm{T}}_{11}\rangle - \frac{\lambda}{\lambda + 2\mathrm{G}}\langle\varepsilon^{\mathrm{T}}_{22}\rangle\right)\Big\rangle \\ &= (\lambda + 2\mathrm{G})(d - \langle\varepsilon^{\mathrm{T}}_{22}\rangle) + \lambda(U - \langle\varepsilon^{\mathrm{T}}_{11}\rangle). \end{aligned}$$

Setting $\langle\tilde{\sigma}_{22}\rangle = 0$ we have

$$d = \langle\varepsilon^{\mathrm{T}}_{22}\rangle - \frac{\lambda}{\lambda + 2\mathrm{G}}(U - \langle\varepsilon^{\mathrm{T}}_{11}\rangle).$$

The values of f_i and g_i in (3.6) are unimportant for our analysis, and we omit them. We have

$$\tilde{\sigma}_{11} = E_c(U - \langle\varepsilon^{\mathrm{T}}_{11}\rangle), \ \tilde{\sigma}_{i,22} = E_c(\langle\varepsilon^{\mathrm{T}}_{22}\rangle - \varepsilon^{\mathrm{T}}_{i,22}), \ \tilde{\sigma}_{12} = 0, \tag{A.1}$$

where the Young's modulus E_c is given by (2.16). The elastic misfit energy associated with $\tilde{\boldsymbol{u}}$ is

$$\frac{1}{E_c}\frac{1}{4L}\int_{-L}^{L}\int_{-1}^{1}\Big[\frac{1}{E_c}((\tilde{\sigma}_{11})^2+(\tilde{\sigma}_{22})^2)-2\frac{\lambda}{4\mathrm{G}(\lambda+\mathrm{G})}\tilde{\sigma}_{11}\tilde{\sigma}_{22}+\frac{1}{2\mathrm{G}}(\tilde{\sigma}_{12})^2\Big]dxdy.$$

Since $\tilde{\sigma}_{12}\equiv 0$, $\tilde{\sigma}_{11}=\text{const}$, and $\tilde{\sigma}_{22}$ is mean-zero, the above equation becomes

$$\frac{1}{E_c^2}\frac{1}{4L}\int_{-L}^{L}\int_{-1}^{1}\left((\tilde{\sigma}_{11})^2+(\tilde{\sigma}_{22})^2\right)dxdy=\langle\left(U-f+\varepsilon_{22}^{\mathrm{T}}\right)^2\rangle=\langle(U-f+s)^2\rangle,$$

which is the first term in (3.4).

Let us now find $\bar{\boldsymbol{u}}$. It solves (3.7) on a bounded domain Π_L. A useful periodic setting for (3.7) is obtained by assuming this equation is posed on an infinite strip $]-\infty,\infty[\times[-L,L]$ with data that is even and periodic in x:

$$\begin{aligned}&(a)\ \theta(-x)=\theta(x),\ \theta(x+2)=\theta(x),\\ &(b)\ \boldsymbol{\varepsilon}^{\mathrm{T}}(x,y)=\boldsymbol{\varepsilon}^{\mathrm{T}}(-x,y),\ \boldsymbol{\varepsilon}^{\mathrm{T}}(x+2,y)=\boldsymbol{\varepsilon}^{\mathrm{T}}(x,y).\end{aligned}\tag{A.2}$$

Thus, $\bar{\boldsymbol{u}}$ equals to the restriction of the solution of (3.7) on an infinite strip $x\in\ ]-\infty,\infty[$, $y\in[-L,L]$ with periodicity conditions defined by (A.2). Since $\bar{\sigma}_{22}(x,\pm L)$ is a periodic, mean-zero, even function, it can be represented as a cosine Fourier series. The solution on the infinite strip with a sinusoidal symmetric stress $\cos(k\pi x)$ at $y=\pm L$ can be computed explicitly for any k by the Airy function method. Namely, since we are given that $\bar{\sigma}_{22}(x,\pm L)$ is a periodic, mean-zero, even function, it can be represented as

$$\bar{\sigma}_{22}(x,\pm L)=E_c\sum_{k=1}^{\infty}c_k\cos(k\pi x),\ E_c=\frac{4\mathrm{G}(\lambda+\mathrm{G})}{\lambda+2\mathrm{G}},$$

where c_k are the corresponding Fourier coefficients of $\varepsilon^{\mathrm{T}}(x)$. The solution for the infinite strip with a sinusoidal symmetric stress $\cos(k\pi x)$ at $y=\pm L$ is given (see [19]) by the Airy function

$$\begin{aligned}&\Phi^k(x,y)\\ &\quad=2\frac{\cos(k\pi x)}{(k\pi)^2}\frac{k\pi y\sinh(k\pi L)\sinh(k\pi y)-[k\pi L\cosh(k\pi L)+\sinh(k\pi L)]\cosh(k\pi y)}{2k\pi L+\sinh(2k\pi L)}.\end{aligned}$$

This Airy function gives rise to the following stresses

$$\begin{aligned}\bar{\sigma}_{11}^k=\frac{\partial^2\Phi^k}{\partial y^2}=d_{11}^k\cos(k\pi x),\ \bar{\sigma}_{12}^k=-\frac{\partial^2\Phi^k}{\partial x\partial y}\\ =d_{12}^k\sin(k\pi x),\ \bar{\sigma}_{22}^k=\frac{\partial^2\Phi^k}{\partial x^2}=d_{22}^k\cos(k\pi x),\end{aligned}$$

where

$$\begin{aligned}d_{11}^k&=2\frac{k\pi y\sinh(k\pi L)\sinh(k\pi y)-[k\pi L\cosh(k\pi L)-\sinh(k\pi L)]\cosh(k\pi y)}{2k\pi L+\sinh(2k\pi L)},\\ d_{12}^k&=2\frac{k\pi y\sinh(k\pi L)\cosh(k\pi y)-k\pi L\cosh(k\pi L)\sinh(k\pi y)}{2k\pi L+\sinh(2k\pi L)},\\ d_{22}^k&=2\frac{-k\pi y\sinh(k\pi L)\sinh(k\pi y)+[k\pi L\cosh(k\pi L)+\sinh(k\pi L)]\cosh(k\pi y)}{2k\pi L+\sinh(2k\pi L)}.\end{aligned}\tag{A.3}$$

Therefore the total stresses are

$$\sigma_{11} = E_c(U - \langle \varepsilon_{11}^{\mathrm{T}} \rangle) + E_c \sum_{k=1}^{\infty} c_k d_{11}^k \cos(k\pi x),$$

$$\sigma_{12} = E_c \sum_{k=1}^{\infty} c_k d_{12}^k \sin(k\pi x), \;\; \sigma_{22} = E_c \sum_{k=1}^{\infty} c_k (d_{22}^k - 1) \cos(k\pi x),$$

where in the last equation we have $d_{22}^k - 1$ instead of d_{22}^k, because (see (A.1))

$$\tilde{\sigma}_{22} = -E_c \sum_{k=1}^{\infty} c_k \cos(k\pi x).$$

By definition

$$W = \frac{1}{E_c} \frac{1}{4L} \int_{-L}^{L} \int_{-1}^{1} \Big[\frac{1}{E_c} ((\sigma_{11})^2 + (\sigma_{22})^2) - 2 \frac{\lambda}{4\mathrm{G}(\lambda + \mathrm{G})} \sigma_{11}\sigma_{22} + \frac{1}{2\mathrm{G}} (\sigma_{12})^2 \Big] dxdy.$$

Since $\int_{-1}^{1} \cos(k\pi x) \cos(m\pi x) dx = \delta_{km}$

$$W(U, \boldsymbol{\varepsilon}^{\mathrm{T}}) = \langle (U - f + \varepsilon_{22}^{\mathrm{T}})^2 \rangle + \sum_{m=1}^{\infty} c_m^2 \hat{K}_L(m),$$

where

$$\text{(A.4)} \quad \hat{K}_L(m) = \frac{1}{4L} \int_{-L}^{L} \Big[(d_{11}^m)^2 + d_{22}^m (d_{22}^m - 2) - \frac{2\lambda d_{11}^m (d_{22}^m - 1)}{\lambda + 2\mathrm{G}} + \frac{2(\lambda + \mathrm{G})(d_{12}^m)^2}{\lambda + 2\mathrm{G}} \Big] dy.$$

Denoting $a = 2\pi mL$ and using Mathematica® we obtain an explicit form of (A.4):

$$\text{(A.5)} \qquad \hat{K}_L(m) = \frac{5\lambda + 9\mathrm{G}}{2(\lambda + 2\mathrm{G})} S_1(a) - \frac{\lambda + \mathrm{G}}{\lambda + 2\mathrm{G}} S_2(a), \;\; a = 2\pi mL, \;\; \text{where}$$

$$\text{(A.6)} \qquad S_1(a) = \frac{(\cosh(a) - 1)}{a(a + \sinh(a))}, \quad S_2(a) = \frac{a^2(2 + \cosh(a))}{6(a + \sinh(a))^2}.$$

A.2. Proof of Lemma 3.1. Using (A.5) and (A.6) from Appendix A.1, direct computations show that the Fourier coefficients of $K_L(x)$ (3.5) are given by

$$\text{(A.7)} \qquad \hat{K}_L(m) = \frac{B}{L} \frac{1}{m} + O(\exp(-L)),$$

so that, defining

$$\text{(A.8)} \qquad K_\infty(x) = \sum_{m=1}^{\infty} \frac{1}{m} \cos(\pi m x),$$

(3.8) is satisfied. A closed form expression for this sum is known: $K_\infty(x) = -\ln|\sin(\pi x/2)|$ (see, e.g., [10]), and the Lemma follows.

A.3. Proof of Lemma 3.2. Set $L = l_0/(2n)$, then for a defined in (A.5) we obtain $a = 2\pi mL = l_0\pi m/n$. Substitute (A.6) into (A.5) and observe that the Fourier coefficients $\hat{K}_L(m)$ depend on the variable $a = l_0\pi m/n$. Thus we can introduce the notation

$$\hat{K}(a) := \hat{K}_L(m),\ a = l_0\pi\frac{m}{n}.$$

In other words the Fourier series of $K_L(x)$ can be written in the form

$$K_L(x) = \sum_{m=-\infty}^{\infty} \hat{K}\left(l_0\pi\frac{m}{n}\right)\cos(\pi m x).$$

For $y = nx$, $y \in [-n, n]$ let

$$K^{(n)}(y) := \frac{1}{n}K_L(y/n) = \frac{1}{n}\sum_{m=-\infty}^{\infty} \hat{K}\left(l_0\pi\frac{m}{n}\right)\cos\left(\pi\frac{m}{n}y\right),$$

and $K^{(n)}(y) = 0$ for $|y| \geq n$. Set

$$\mathcal{K}_{l_0}(y) = \frac{1}{2\pi}\int_{-\infty}^{\infty} \hat{K}\left(l_0\zeta\right)\cos(\zeta y)d\zeta,\ y \in \mathbb{R}.$$

Note that

$$\hat{K}\left(l_0\zeta\right) = \int_{-\infty}^{\infty} \mathcal{K}_{l_0}(y)\cos\left(\zeta y\right)dy,$$

provided $\mathcal{K}_{l_0}(y)$ is smooth and it decays sufficiently fast as $y \to \infty$. The function $\mathcal{K}_{l_0}(y)$ is exactly the limiting function mentioned in Lemma 3.2; that is, $K^{(n)}(y) = K_L(y/n)/n$ converges to $\mathcal{K}_{l_0}(y)$ as $n \to \infty$. Let us first verify properties of $\mathcal{K}_{l_0}$ described in Lemma 3.2 and then establish convergence. Direct calculations using (A.5) show that $\hat{K}(a) > 0$ for all physical choices of the Lamé constants, so that, by Bochner's theorem [18, Vol. 1], $\mathcal{K}_{l_0}$ is positive-definite. We verify (3.10) by applying the Paley–Wiener type Theorems [18, Vol. 1]. Indeed, from (A.6) it follows that the Fourier transform of $\mathcal{K}_{l_0}$ can be analytically extended into a finite strip $|\mathrm{Im}(a)| \leq c_2$ around the real axis provided there is no solution of the equation $a + \sinh(a) = 0$, $a \neq 0$, or, equivalently

$$\text{(A.9)}\quad \mathrm{Re}(a) = -\sinh(\mathrm{Re}(a))\cos(\mathrm{Im}(a)),\ \mathrm{Im}(a) = -\cosh(\mathrm{Re}(a))\sin(\mathrm{Im}(a)), a \neq 0.$$

There is no solution of the last equation in (A.9) at least in the strip $|\mathrm{Im}(a)| \leq \pi$. This implies the exponential decay (3.10) of $\mathcal{K}_{l_0}(y)$ by Paley–Wiener theorems. Finally, for every n consider the $2n$-periodization of $\mathcal{K}_{l_0}(y)$:

$$\mathcal{K}_{l_0}^{(n)}(y) = \sum_{k=-\infty}^{+\infty} \mathcal{K}_{l_0}(y + 2nk).$$

Since $\mathcal{K}_{l_0}(y)$ decays exponentially as $y \to \infty$, we have that $\mathcal{K}_{l_0}^{(n)}(y)$ is a smooth $2n$ periodic function and its Fourier coefficients

$$\begin{aligned}\hat{\mathcal{K}}_{l_0}^{(n)}(m) &= \frac{1}{n}\int_{-n}^{n} \mathcal{K}_{l_0}^{(n)}(y)\cos\left(\pi\frac{m}{n}y\right)dy \\ &= \frac{1}{n}\int_{-n}^{n}\left(\sum_{k=-\infty}^{+\infty}\mathcal{K}_{l_0}(y+2nk)\right)\cos\left(\pi\frac{m}{n}y\right)dy \\ = \frac{1}{n}\int_{-\infty}^{\infty}\mathcal{K}_{l_0}(y)\cos\left(\pi\frac{m}{n}y\right)dy &= \frac{1}{n}\hat{K}\left(l_0\pi\frac{m}{n}\right) = \frac{1}{n}\hat{K}_L(m).\end{aligned}$$

Thus $\mathcal{K}_{l_0}^{(n)}(y) = K_L(y/n)/n = K^{(n)}(y)$ on $[-n,n]$. Therefore

$$\begin{aligned}||K_L(x) - n\mathcal{K}_{l_0}(nx)||_{L_\infty([-1,1])} &= n||K^{(n)}(y) - \mathcal{K}_{l_0}(y)||_{L_\infty([-n,n])} \\ &= n||\mathcal{K}_{l_0}^{(n)}(y) - \mathcal{K}_{l_0}(y)||_{L_\infty([-n,n])} \\ &= n\left\|\sum_{k\neq 0}\mathcal{K}_{l_0}(y+2nk)\right\|_{L_\infty([-n,n])} \leq Cn\sum_{k=1}^{\infty}e^{-ckn} \\ &\leq Cne^{-cn} \to 0,\end{aligned}$$

as $n \to \infty$, and $C = C(l_0) > 0$ is independent of n.

A.4. Proof of Proposition 3.3. For any U and $\boldsymbol{\varepsilon}^{\mathrm{T}}$ we can estimate the error of the truncation (3.14) as

$$\begin{aligned}|W_n(U,\boldsymbol{\varepsilon}^{\mathrm{T}}) - W_n^{k_0}(U,\boldsymbol{\varepsilon}^{\mathrm{T}})| &\leq c\sum_{k>k_0}|\lambda_k(n)|\langle(s-\langle s\rangle)^2\rangle \\ &\leq c\exp(-k_0)\langle(s-\langle s\rangle)^2\rangle \leq c\exp(-k_0).\end{aligned}$$

Since

$$W_n^{k_0}(U,\boldsymbol{\varepsilon}_{k_0}^{\mathrm{T}}) = \min_{\tilde{\boldsymbol{\varepsilon}}^{\mathrm{T}}\in\tilde{\Omega}_n(\theta)} W_n^{k_0}(U,\tilde{\boldsymbol{\varepsilon}}^{\mathrm{T}}),$$

we have

$$W_n(U,\boldsymbol{\varepsilon}^{\mathrm{T}}) \leq \min_{\tilde{\boldsymbol{\varepsilon}}^{\mathrm{T}}\in\tilde{\Omega}_n(\theta)} W_n(U,\tilde{\boldsymbol{\varepsilon}}^{\mathrm{T}}) + c\exp(-k_0) = W_n(U,\boldsymbol{\theta}) + c\exp(-k_0).$$

By definition of the minimizer $W_n(U,\boldsymbol{\theta}) \leq W_n(U,\boldsymbol{\varepsilon}^{\mathrm{T}})$. This implies (3.15).

Appendix B. Proofs for section 5.

B.1. Verification of (5.11). For a given product measure $\tilde{\mu}$ we have

$$\int I_1 I_2 d\tilde{\mu} = \left(\int I_1 d\tilde{\mu}\right)^2, \quad \int s_1 I_2 d\tilde{\mu} = \left(\int s_1 d\tilde{\mu}\right)\left(\int I_1 d\tilde{\mu}\right),$$

because the events in the first and the second grains are independent and identically distributed. Hence

$$\begin{aligned}\int I_1 I_2 d\tilde{\mu} &= \left(\int_0^{\pi/4}\chi(\theta)d\rho(\theta)\right)^2 \\ &= f^2, \quad \int (U+s_1)I_2 d\tilde{\mu} = f\left(\int_0^{\pi/4}(U+s(\theta))\chi(\theta)d\rho(\theta) + (1-f)U\right).\end{aligned}$$

It gives

$$\begin{aligned}
&\int F(U,s_1,I_1,I_2)d\tilde{\mu}\\
&\quad=\int\left((U+s_1)^2-2(U+s_1)I_2+I_1I_2\right)d\tilde{\mu}\\
&\quad=\int_0^{\pi/4}(U+s(\theta))^2\chi(\theta)d\rho(\theta)+(1-f)U^2\\
&\qquad-2f\left(\int_0^{\pi/4}(U+s(\theta))\chi(\theta)d\rho(\theta)+(1-f)U\right)+f^2\\
&\quad=\int_0^{\pi/4}\left((U+s(\theta)-f)^2-f^2\right)\chi(\theta)d\rho(\theta)+(1-f)(U^2-2Uf)+f^2\\
&\quad=\int_0^{\pi/4}(U+s(\theta)-f)^2\chi(\theta)d\rho(\theta)+(U-f)^2(1-f),
\end{aligned}$$

where the last equality is obtained by noting the following identity:

$$f^2=f^2(1-f)+\int_0^{\pi/4}f^2\chi(\theta)d\rho(\theta).$$

B.2. Proof of Lemma 5.3. The proof is the direct evaluation and comparison of all possible scenarios in (5.12). Using (5.12), we simply consider four functions of U, q, q_α, and q_β:

$$\begin{aligned}
W_1&=(U-q_\alpha-q_\beta+\cos^2\alpha)^2q_\alpha\\
&+(U-q_\alpha-q_\beta+\cos^2\beta)^2q_\beta+(U-q_\alpha-q_\beta)^2(1-q_\alpha-q_\beta),\\
W_2&=(U-q_\alpha-q_\beta+\cos^2\alpha)^2q_\alpha\\
&+(U-q_\alpha-q_\beta+\sin^2\beta)^2q_\beta+(U-q_\alpha-q_\beta)^2(1-q_\alpha-q_\beta),\\
W_3&=(U-q_\alpha-q_\beta+\sin^2\alpha)^2q_\alpha\\
&+(U-q_\alpha-q_\beta+\cos^2\beta)^2q_\beta+(U-q_\alpha+q_\beta)^2(1-q_\alpha-q_\beta),\\
W_4&=(U-q_\alpha-q_\beta+\sin^2\alpha)^2q_\alpha\\
&+(U-q_\alpha-q_\beta+\sin^2\beta)^2q_\beta+(U-q_\alpha-q_\beta)^2(1-q_\alpha-q_\beta),
\end{aligned}$$

and compare their values for each fixed U and q, where q_α and q_β are in the range (5.13). It is easy to check that the minimum is always achieved for W_4; hence equation (5.14) is satisfied.

Appendix C. Proofs for section 6.

C.1. Proof of Lemma 6.4. Since the Fourier coefficients of a convolution equal the products of the Fourier coefficients, and since from (A.8) we know the Fourier coefficients of K_∞ are ≤ 1 in absolute value, and in view of Plancherel's theorem, we have

$$\int_{-1}^{1}\int_{-1}^{1}(s(x)-\langle s\rangle)(s(t)-\langle s\rangle)K_\infty(x-t)dxdt \le \int_{-1}^{1}(s(x)-\langle s\rangle)^2dx,$$

and $|s(x)|\le 1$, for any $\delta>0$, there exists $L_0>0$, so that for any $L\ge L_0$

$$\left|\frac{B}{L}\bar{W}_n(U,\boldsymbol{\varepsilon}^{\mathrm{T}})\right|\le\delta.$$

Hence for any $s=\varepsilon_{22}^{\mathrm{T}}$

$$\langle(U-f+s)^2\rangle < W_n(U,\boldsymbol{\varepsilon}^{\mathrm{T}}) \le \langle(U-f+s)^2\rangle+\delta.$$

It follows that

$$\min_{s,f}\langle(U-f+s)^2\rangle < \min_{s,f} W_n(U,\boldsymbol{\varepsilon}^{\mathrm{T}}) \le \min_{s,f}\langle(U-f+s)^2\rangle+\delta$$

for any sequence of angles $\boldsymbol{\theta}$. Applying Lemma 5.5 we complete the proof of (6.5). Equality (6.4) follows from direct computations as in Lemma 5.3.

C.2. Proof of Lemma 6.6. Suppose (6.18) and (6.19) do not hold. It means that there exists $\delta>0$ such that for every $\delta'>0$ there is a sequence of sets $A_{n_k}\in\sigma^{\theta}_{n_k}$, $\{n_k\}\to\infty$ with probability $\rho_{n_k}(A_{n_k})>2C>0$ such that for every fixed $\boldsymbol{\theta}\in A_{n_k}$ (or, equivalently, $(\chi_\alpha,\chi_\beta)\in A_{n_k}$) there is a (at least one) maximizer $\tilde{\chi}_\alpha$, $\tilde{\chi}_\beta$ of (6.17) such that

$$\min(e_1,e_2)>\delta, \tag{C.1}$$

where

(C.2)

$$e_1=\int_0^1(|\tilde{\chi}_\alpha-\chi^1_{q_\alpha}|\chi_\alpha+|\tilde{\chi}_\beta-\chi^1_{q_\beta}|\chi_\beta)dx,\ e_2=\int_0^1(|\tilde{\chi}_\alpha-\chi^2_{q_\alpha}|\chi_\alpha+|\tilde{\chi}_\beta-\chi^2_{q_\beta}|\chi_\beta)dx;$$

$\chi^i_{q_\alpha}$ and $\chi^i_{q_\beta}$ are defined in (6.14) and (6.15), respectively. Since $K(x)\in L^1[-1,1]$ is fixed and $\tilde{\chi}_\alpha\chi_\alpha$, $\tilde{\chi}_\beta\chi_\beta$ are uniformly bounded in $L^\infty[-1,1]$, for any $\delta_1>0$ there exists $h>0$ so that

$$\begin{aligned}
&\left|\int_{-1}^{1}\int_{-1}^{1}\varepsilon_\alpha(x)\varepsilon_\alpha(t)K(x-y)dxdt-\int_{-1}^{1}\int_{-1}^{1}\bar{\varepsilon}_\alpha(x)\bar{\varepsilon}_\alpha(t)K(x-y)|dxdt\right|<\delta_1,\\
&\left|\int_{-1}^{1}\int_{-1}^{1}\varepsilon_\alpha(x)\varepsilon_\beta(t)K(x-y)|dxdt-\int_{-1}^{1}\int_{-1}^{1}\bar{\varepsilon}_\alpha(x)\bar{\varepsilon}_\beta(t)K(x-y)|dxdt\right|<\delta_1,\\
&\left|\int_{-1}^{1}\int_{-1}^{1}\varepsilon_\beta(x)\varepsilon_\beta(t)K(x-y)|dxdt-\int_{-1}^{1}\int_{-1}^{1}\bar{\varepsilon}_\beta(x)\bar{\varepsilon}_\beta(t)K(x-y)|dxdt\right|<\delta_1,
\end{aligned} \tag{C.3}$$

where

$$\bar{\varepsilon}_\alpha(x)=\frac{1}{2h}\int_{-h}^{h}\bar{\varepsilon}_\alpha(x+t)dt,\ \bar{\varepsilon}_\beta(x)=\frac{1}{2h}\int_{-h}^{h}\bar{\varepsilon}_\beta(x+t)dt.$$

By the law of the large numbers, for any $\delta_2 > 0$ there is $\bar{A}_{n_k} \in A_{n_k}$, $\rho_{n_k}(A_{n_k}) > C$ so that for every $\boldsymbol{\theta} \in \bar{A}_{n_k}$ (or, equivalently, $(\chi_\alpha^{n_k}, \chi_\beta^{n_k}) \in \bar{A}_{n_k}$) and $n_k > N_0$, we have

$$\bar{\varepsilon}_\alpha(x) = q\chi_\alpha(x, \boldsymbol{\theta}) - q_\alpha(\boldsymbol{\theta}), \bar{\varepsilon}_\beta(x) = (1-q)\chi_\beta(x, \boldsymbol{\theta}) - q_\alpha(\boldsymbol{\theta}),$$

where (random in $\boldsymbol{\theta} \in \bar{A}_{n_k}$) functions $\chi_\alpha(x, \boldsymbol{\theta})$, $\chi_\beta(x, \boldsymbol{\theta})$ satisfy

$$0 \le \chi_\alpha(x, \boldsymbol{\theta}) \le 1 + \delta_2,\ 0 \le \chi_\beta(x, \boldsymbol{\theta}) \le 1 + \delta_2,$$

and $\min(e_1, e_2) > \delta - \delta_2$ where

$$\begin{aligned} e_1 &= \int_0^1 (|\chi_\alpha(x, \boldsymbol{\theta}) - \chi^1_{q_\alpha}| + |\chi_\beta(x, \boldsymbol{\theta}) - \chi^1_{q_\beta}|)dx,\ e_2 \\ &= \int_0^1 (|\chi_\alpha(x, \boldsymbol{\theta}) - \chi^2_{q_\alpha}| + |\chi_\beta(x, \boldsymbol{\theta}) - \chi^2_{q_\beta}|)dx. \end{aligned}$$

The classical Riesz rearrangement inequality (6.11) implies that when δ_1 and δ_2 are sufficiently small, there is $\delta' > 0$ so that for every $\boldsymbol{\theta} \in \bar{A}_{n_k}$

$$\begin{aligned} &\int_{-1}^1 \int_{-1}^1 (a\varepsilon_\alpha(x) + b\varepsilon_\beta(x))(a\varepsilon_\alpha(t) + b\varepsilon_\beta(t))K(x-t)dxdt \\ &\le \int_{-1}^1 \int_{-1}^1 (a\varepsilon^1_\alpha(x) + b\varepsilon^1_\beta(x))(a\varepsilon^1_\alpha(t) + b\varepsilon^1_\beta(t))K(x-t)dxdt - \delta', \end{aligned}$$

where

$$\varepsilon^1_\alpha(x) = \chi^1_{q_\alpha}\chi_\alpha,\ \varepsilon^1_\alpha(x) = \chi^1_{q_\beta}\chi_\beta.$$

Hence we have that $\tilde{\chi}_\alpha$ and $\tilde{\chi}_\beta$ with (C.1) and (C.2) cannot be maximizers of (6.17). This leads to contradiction with our assumption that (6.18) and (6.19) do not hold.

Acknowledgments. We thank Alexei Borodin and Omri Sarig for useful discussions. We are grateful to anonymous referees for their useful suggestions.

THE PERIODIC UNFOLDING METHOD IN HOMOGENIZATION*

D. CIORANESCU†, A. DAMLAMIAN‡, AND G. GRISO§

Abstract. The periodic unfolding method was introduced in 2002 in [Cioranescu, Damlamian, and Griso, *C.R. Acad. Sci. Paris, Ser.* 1, 335 (2002), pp. 99–104] (with the basic proofs in [*Proceedings of the Narvik Conference* 2004, GAKUTO Internat. Ser. Math. Sci. Appl. 24, Gakkōtosho, Tokyo, 2006, pp. 119–136]). In the present paper we go into all the details of the method and include complete proofs, as well as several new extensions and developments. This approach is based on two distinct ideas, each leading to a new ingredient. The first idea is the change of scale, which is embodied in the unfolding operator. At the expense of doubling the dimension, this allows one to use standard weak or strong convergence theorems in L^p spaces instead of more complicated tools (such as two-scale convergence, which is shown to be merely the weak convergence of the unfolding; cf. Remark 2.15). The second idea is the separation of scales, which is implemented as a macro-micro decomposition of functions and is especially suited for the weakly convergent sequences of Sobolev spaces. In the framework of this method, the proofs of most periodic homogenization results are elementary. The unfolding is particularly well-suited for multiscale problems (a simple backward iteration argument suffices) and for precise corrector results without extra regularity on the data. A list of the papers where these ideas appeared, at least in some preliminary form, is given with a discussion of their content. We also give a list of papers published since the publication [Cioranescu, Damlamian, and Griso, *C.R. Acad. Sci. Paris, Ser.* 1, 335 (2002), pp. 99–104], and where the unfolding method has been successfully applied.

Key words. homogenization, periodic unfolding, multiscale problems

1. Introduction.

The notion of two-scale convergence was introduced in 1989 by Nguetseng in [58], further developed by Allaire in [1] and by Lukkassen, Nguetseng, and Wall in [55] with applications to periodic homogenization. It was generalized to some multiscale problems by Ene and Saint Jean Paulin in [38], Allaire and Briane in [2], Lions et al. in [52] and Lukkassen, Nguetseng, and Wall in [55].

In 1990, Arbogast, Douglas, and Hornung defined a "dilation" operator in [5] to study homogenization for a periodic medium with double porosity. This technique was used again in [16], [3], [4], [48], [49], [50], [51], [54], [20], [21], [22], and [23].

In [24], we expanded on this idea and presented a general and quite simple approach for classical or multiscale periodic homogenization, under the name of "unfolding method." Originally restricted to the case of domains consisting of a union of ε-cells, it was extended to general domains (see the survey of Damlamian [34]). In the present work, we give a complete presentation of this method, including all of the proofs, as well as several new extensions and developments. The relationship of the papers listed above with our work is discussed at the end of this introduction.

The periodic unfolding method is essentially based on two ingredients. The first one is the unfolding operator $\mathcal{T}_\varepsilon$ (similar to the dilation operator), defined in section 2,

§Corresponding author. Laboratoire Jacques-Louis Lions, Université Pierre et Marie Curie, Boîte courrier 187, 4 Place Jussieu, 75252 Paris Cedex 05, France (griso@ann.jussieu.fr).

where its properties are investigated. Let Ω be a bounded open set, and Y a reference cell in $\mathbb{R}^n$. By definition, the operator $\mathcal{T}_\varepsilon$ associates to any function v in $L^p(\Omega)$, a function $\mathcal{T}_\varepsilon(v)$ in $L^p(\Omega \times Y)$. An immediate (and interesting) property of $\mathcal{T}_\varepsilon$ is that it enables one to transform any integral over Ω in an integral over $\Omega \times Y$. Indeed, by Proposition 2.6 below

$$\int_\Omega w(x)\, dx \sim \frac{1}{|Y|} \int_{\Omega \times Y} \mathcal{T}_\varepsilon(w)(x,y)\, dx\, dy \quad \forall w \in L^1(\Omega). \tag{1.1}$$

Proposition 2.14 shows that the two-scale convergence in the $L^p(\Omega)$-sense of a sequence of functions $\{v_\varepsilon\}$ is equivalent to the weak convergence of the sequence of unfolded functions $\{\mathcal{T}_\varepsilon(v_\varepsilon)\}$ in $L^p(\Omega \times Y)$. Thus, the two-scale convergence in Ω is reduced to a mere weak convergence in $L^p(\Omega \times Y)$, which conceptually simplifies proofs.

In section 2 are also introduced a local average operator $\mathcal{M}_\varepsilon$ and an averaging operator $\mathcal{U}_\varepsilon$, the latter being, in some sense, the inverse of the unfolding operator $\mathcal{T}_\varepsilon$.

The second ingredient of the periodic unfolding method consists of separating the characteristic scales by decomposing every function φ belonging to $W^{1,p}(\Omega)$ in two parts. In section 3 it is achieved by using the local average. In section 4, the original proof of this scale-splitting, inspired by the finite element method (FEM), is given. The confrontation of the two methods of sections 3 and 4 is interesting in itself (Theorem 3.5 and Proposition 4.8). In both approaches, φ is written as $\varphi = \varphi_1^\varepsilon + \varepsilon\varphi_2^\varepsilon$, where φ_1^ε is a macroscopic part designed not to capture the oscillations of order ε (if there are any), while the microscopic part φ_2^ε is designed to do so. The main result states that, from any bounded sequence $\{w^\varepsilon\}$ in $W^{1,p}(\Omega)$, weakly convergent to some w, one can always extract a subsequence (still denoted $\{w^\varepsilon\}$) such that $w^\varepsilon = w_1^\varepsilon + \varepsilon w_2^\varepsilon$, with

$$\begin{aligned}
&\text{(i)} \quad w_1^\varepsilon \rightharpoonup w \quad \textit{weakly in } W^{1,p}(\Omega),\\
&\text{(ii)} \quad \mathcal{T}_\varepsilon(w^\varepsilon) \rightharpoonup w \quad \textit{weakly in } L^p(\Omega; W^{1,p}(Y)),\\
&\text{(iii)} \quad \mathcal{T}_\varepsilon(w_2^\varepsilon) \rightharpoonup \widehat{w} \quad \textit{weakly in } L^p(\Omega; W^{1,p}(Y)),\\
&\text{(iv)} \quad \mathcal{T}_\varepsilon(\nabla w^\varepsilon) \rightharpoonup \nabla w + \nabla_y \widehat{w} \quad \textit{weakly in } L^p(\Omega \times Y),
\end{aligned} \tag{1.2}$$

where $\widehat{w}$ belongs to $L^p(\Omega; W^{1,p}_{per}(Y))$.

In section 5 we apply the periodic unfolding method to a classical periodic homogenization problem. We point out that, in the framework of this method, the proof of the homogenization result is elementary. It relies essentially on formula (1.1), on the properties of $\mathcal{T}_\varepsilon$, and on convergences (1.2). It applies directly for both homogeneous Dirichlet or Neumann boundary conditions without hypothesis on the regularity of $\partial\Omega$. For nonhomogenous boundary conditions (or for Robin-type condition), some regularity of $\partial\Omega$ is required for the problem to make sense, in which case the method applies also directly (see Remark 5.12).

Section 6 is devoted to a corrector result, which holds without any additional regularity on the data (contrary to all previous proofs; see [11], [30], and [59]). This result follows from the use of the averaging operator $\mathcal{U}_\varepsilon$. The idea of using averages to improve corrector results first appeared in Dal Maso and Defranceschi [33]. We also give some error estimates and a new corrector result for the case of domains with

a smooth boundary (obtained by Griso in [42], [43], [44], and [45]). These results are explicitely connected to the unfolding method and improve on known classical ones (see [11] and [59]).

The periodic unfolding method is particularly well-suited for the case of multiscale problems. This is shown in section 7 by a simple backward iteration argument. This problem has a long history; one of the first papers on the subject is due to Bruggeman [19]. Its mathematical treatment by homogenization goes back to the book of Bensoussan, Lions, and Papanicolaou [11], where for this problem, the method of asymptotic expansions is used. For more recent references of multiscale homogenization and its applications, we refer to the books of Braides and Defranceschi [17], Milton [57], and the articles by Damlamian and Donato [35], Lukkassen and Milton [54], Lukkassen [53], Braides and Lukkassen [18], Babadjian and Baía [6], and Barchiesi [8].

The final section gives a list of papers where the method has been successfully applied since the publication of [24].

To conclude, let us turn back to the papers quoted at the beginning of this introduction and point out their relationships with our results. The dilation operation from Arbogast, Douglas, and Hornung [5] was defined in a domain which is an exact union of εY-cells. It consists in a change of variables, similar to that used in Definition 2.1 below. By this operation, any integral on Ω can be written as an integral over $\Omega \times Y$. Some elementary properties of the dilation operator in the space L^2 were also contained in Lemma 2 of [5].

The same dilation operator was used by Bourgeat, Luckhaus, and Mikelic in [16] under the name of "periodic modulation." Proposition 4.6 of [16] showed that if a sequence two-scale converges and its periodic modulation converges weakly, they have the same limit.

In the context of two-scale convergence, Allaire and Conca [3] defined a pair of extension and projection operators (suited to Bloch decompositions) which are adjoint of each other. They are similar to our operators $\mathcal{T}_\varepsilon$ and $\mathcal{U}_\varepsilon$ and the equivalent of property (2.12) and Proposition 2.18(ii) below, are proved in Lemma 4.2 of [3]. These properties were exploited by Allaire, Conca, and Vanninathan in [4] for a general bounded domain by extending all functions by zero on its complement.

In [48], Lenczner used the dilation operator (here called "two-scale transformation") in order to treat the homogenization of discrete electrical networks (by nature, the domain is a union of ε-cells). The convergence of the two-scale transform is called two-scale convergence (this would be confusing except that it was shown to be equivalent to the original two-scale convergence). As an aside, a convergence similar to (1.2)(iv) was also treated. In Lenczner and Mercier [49], Lenczner and Senouci-Bereksi [50], and Lenczner, Kader, and Perrier [51], this theory was applied to periodic electrical networks.

Finally, Casado Díaz and Luna-Laynez [21], Casado Díaz, Luna-Laynez, and Martin [22] and [23] used the dilation operator in the case of reticulated structures. In this framework, they obtained the equivalent of (3.7)(i) of Theorem 3.5 below.

2. Unfolding in L^p-spaces.

2.1. The unfolding operator $\mathcal{T}_\varepsilon$. In $\mathbb{R}^n$, let Ω be an open set and Y a reference cell (e.g., $]0,1[^n$, or more generally, a set having the paving property, with respect to a basis $(b_1, \dots, b_n)$ defining the periods).

By analogy with the notation in the one-dimensional case, for $z \in \mathbb{R}^n$, $[z]_Y$ denotes the unique integer combination $\sum_{j=1}^n k_j b_j$ of the periods such that $z - [z]_Y$ belongs

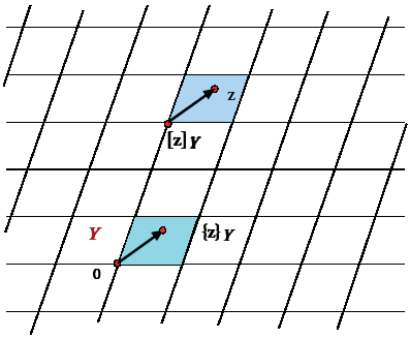

FIG. 1. *Definition of* $[z]_Y$ *and* $\{z\}_Y$.

to Y, and set

$$\{z\}_Y = z - [z]_Y \in Y \quad \text{a.e. for} \quad z \in \mathbb{R}^n.$$

Then for each $x \in \mathbb{R}^n$, one has

$$x = \varepsilon\Big(\Big[\frac{x}{\varepsilon}\Big]_Y + \Big\{\frac{x}{\varepsilon}\Big\}_Y\Big) \quad \text{a.e. for} \quad x \in \mathbb{R}^n \text{ (See Figure 1).}$$

We use the following notations:

$$\begin{cases} \Xi_\varepsilon = \big\{\xi \in \mathbb{Z}^N, \varepsilon(\xi + Y) \subset \Omega\big\}, \\ \widehat{\Omega}_\varepsilon = \text{interior}\Big\{\bigcup_{\xi\in\Xi_\varepsilon} \varepsilon\big(\xi + \overline{Y}\big)\Big\}, \\ \Lambda_\varepsilon = \Omega \setminus \widehat{\Omega}_\varepsilon. \end{cases} \tag{2.1}$$

The set $\widehat{\Omega}_\varepsilon$ is the largest union of $\varepsilon(\xi + \overline{Y})$ cells ($\xi \in \mathbb{Z}^n$) included in Ω, while Λ_ε is the subset of Ω containing the parts from $\varepsilon\big(\xi + \overline{Y}\big)$ cells intersecting the boundary $\partial\Omega$ (see Figure 2).

DEFINITION 2.1. *For ϕ Lebesgue-measurable on Ω, the unfolding operator $\mathcal{T}_\varepsilon$ is defined as follows:*

$$\mathcal{T}_\varepsilon(\phi)(x,y) = \begin{cases} \phi\Big(\varepsilon\Big[\frac{x}{\varepsilon}\Big]_Y + \varepsilon y\Big) & \text{a.e. for} \quad (x,y) \in \widehat{\Omega}_\varepsilon \times Y, \\ 0 & \text{a.e. for} \quad (x,y) \in \Lambda_\varepsilon \times Y. \end{cases}$$

Observe that the function $\mathcal{T}_\varepsilon(\phi)$ is Lebesgue-measurable on $\Omega \times Y$ and vanishes for x outside of the set $\widehat{\Omega}_\varepsilon$.

As in classical periodic homogenization, two different scales appear in the definition of $\mathcal{T}_\varepsilon$: the "macroscopic" scale x gives the position of a point in the domain Ω, while the "microscopic" scale y $(= x/\varepsilon)$ gives the position of a point in the cell Y. The unfolding operator doubles the dimension of the space and puts all of the oscillations in the second variable, in this way separating the two scales (see Figures 3, 4 and Figures 5, 6).

The following property of $\mathcal{T}_\varepsilon$ is a simple consequence of Definition 2.1 for v and w Lebesgue-measurable; it will be used extensively:

$$\mathcal{T}_\varepsilon(vw) = \mathcal{T}_\varepsilon(v)\, \mathcal{T}_\varepsilon(w). \tag{2.2}$$

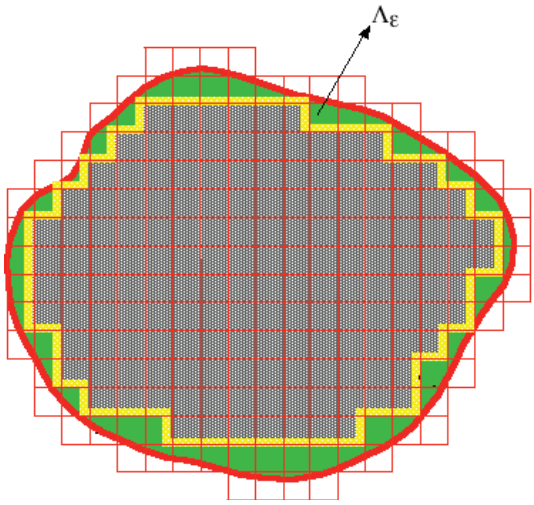

FIG. 2. *The domains* $\widehat{\Omega}_\varepsilon$ *and* Λ_ε.

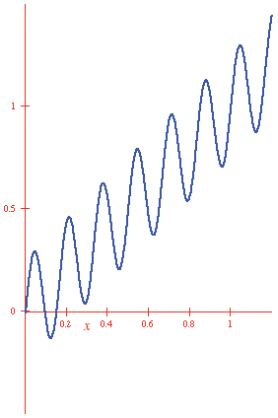

FIG. 3. $f_\varepsilon(x) = \frac{1}{4}\sin(2\pi\frac{x}{\varepsilon}) + x;\ \varepsilon = \frac{1}{6}$.

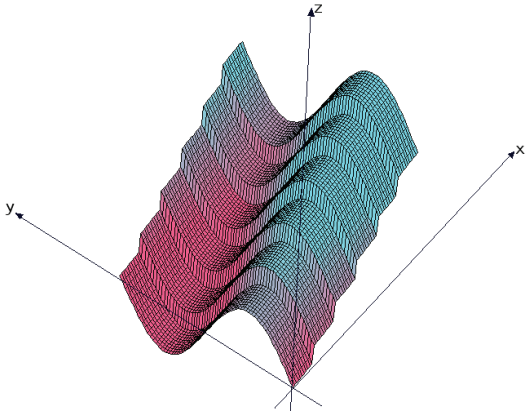

FIG. 4. $\mathcal{T}_\varepsilon(f_\varepsilon)$.

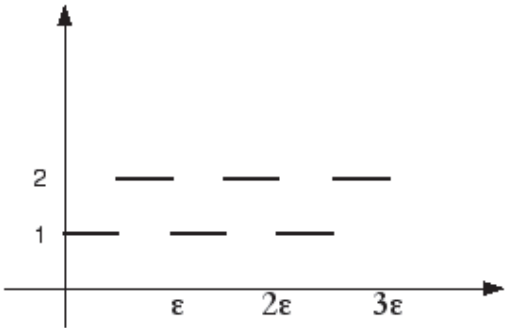

FIG. 5. $f_\varepsilon = f(\{\frac{x}{\varepsilon}\}_Y)$.

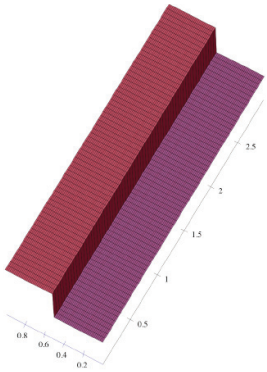

FIG. 6. $\mathcal{T}_\varepsilon(f_\varepsilon)$.

Another simple consequence of Definition 2.1 is the following result concerning highly oscillating functions.

PROPOSITION 2.2. *For f measurable on Y, extended by Y-periodicity to the whole of $\mathbb{R}^n$, define the sequence $\{f_\varepsilon\}$ by*

$$f_\varepsilon(x) = f\left(\frac{x}{\varepsilon}\right) \quad \text{a.e. for } x \in \mathbb{R}^n. \tag{2.3}$$

Then

$$\mathcal{T}_\varepsilon(f_\varepsilon|_\Omega)(x,y) = \begin{cases} f(y) & \text{a.e. for } (x,y) \in \widehat{\Omega}_\varepsilon \times Y, \\ 0 & \text{a.e. for } (x,y) \in \Lambda_\varepsilon \times Y. \end{cases}$$

If f belongs to $L^p(Y)$, $p \in [1, +\infty[$, and if Ω is bounded,

$$\mathcal{T}_\varepsilon(f_\varepsilon|_\Omega) \to f \quad \text{strongly in } L^p(\Omega \times Y). \tag{2.4}$$

Remark 2.3. An equivalent way to define f_ε in (2.3) is to take simply $f_\varepsilon(x) = f(\{\frac{x}{\varepsilon}\}_Y)$. For example, with

$$f(y) = \begin{cases} 1 & \text{for } y \in \left(0, {}^1/_2\right), \\ 2 & \text{for } y \in \left({}^1/_2, 1\right), \end{cases}$$

f_ε is the highly oscillating periodic function, with period ε from Figure 5.

Remark 2.4. Let f in $L^p(Y)$, $p \in [1, +\infty[$, and f_ε be defined by (2.3). It is well-known that $\{f_\varepsilon|_\Omega\}$ converges weakly in $L^p(\Omega)$ to the mean value of f on Y, and not strongly unless f is a constant (see Remark 2.11 below).

The next two results, essential in the study of the properties of the unfolding operator, are also straightforward from Definition 2.1.

PROPOSITION 2.5. *For $p \in [1, +\infty[$, the operator $\mathcal{T}_\varepsilon$ is linear and continuous from $L^p(\Omega)$ to $L^p(\Omega \times Y)$. For every ϕ in $L^1(\Omega)$ and w in $L^p(\Omega)$,*

(i) $\displaystyle \frac{1}{|Y|}\int_{\Omega\times Y} \mathcal{T}_\varepsilon(\phi)(x,y)\,dx\,dy = \int_\Omega \phi(x)\,dx - \int_{\Lambda_\varepsilon} \phi(x)\,dx = \int_{\widehat{\Omega}_\varepsilon} \phi(x)\,dx,$

(ii) $\displaystyle \frac{1}{|Y|}\int_{\Omega\times Y} |\mathcal{T}_\varepsilon(\phi)|\,dxdy \le \int_\Omega |\phi|\,dx,$

(iii) $\displaystyle \left|\int_\Omega \phi\,dx - \frac{1}{|Y|}\int_{\Omega\times Y} \mathcal{T}_\varepsilon(\phi)\,dxdy\right| \le \int_{\Lambda_\varepsilon} |\phi|\,dx,$

(iv) $\|\mathcal{T}_\varepsilon(w)\|_{L^p(\Omega\times Y)} = |\,Y\,|^{\frac{1}{p}}\,\|w\,1_{\widehat{\Omega}_\varepsilon}\|_{L^p(\Omega)} \le |\,Y\,|^{\frac{1}{p}}\,\|w\|_{L^p(\Omega)}.$

Proof. Recalling Definition 2.2 of $\widehat{\Omega}_\varepsilon$, one has

$$\begin{aligned}\frac{1}{|Y|}\int_{\Omega\times Y} \mathcal{T}_\varepsilon(\phi)(x,y)\,dx\,dy &= \frac{1}{|Y|}\int_{\widehat{\Omega}_\varepsilon\times Y} \mathcal{T}_\varepsilon(\phi)(x,y)\,dx\,dy \\ &= \frac{1}{|Y|}\sum_{\xi\in\Xi_\varepsilon}\int_{(\varepsilon\xi+\varepsilon Y)\times Y} \mathcal{T}_\varepsilon(\phi)(x,y)\,dx\,dy.\end{aligned}$$

On each $(\varepsilon\xi+\varepsilon Y)\times Y$, by definition, $\mathcal{T}_\varepsilon(\phi)(x,y) = \phi(\varepsilon\xi+\varepsilon y)$ is constant in x. Hence, each integral in the sum on the right-hand side successively equals

$$\begin{aligned}\int_{(\varepsilon\xi+\varepsilon Y)\times Y} \mathcal{T}_\varepsilon(\phi)(x,y)\,dx\,dy &= |\varepsilon\xi+\varepsilon Y|\int_Y \phi(\varepsilon\xi+\varepsilon y)\,dy \\ &= \varepsilon^n|Y|\int_Y \phi(\varepsilon\xi+\varepsilon y)\,dy = |Y|\int_{(\varepsilon\xi+\varepsilon Y)} \phi(x)\,dx.\end{aligned}$$

By summing over Ξ_ε, the right-hand side becomes $\int_{\widehat{\Omega}_\varepsilon} \phi(x)\,dx$, which gives the result. ∎

Property (iii) in Proposition 2.5 shows that any integral of a function on Ω is "almost equivalent" to the integral of its unfolded on $\Omega \times Y$; the "integration defect" arises only from the cells intersecting the boundary $\partial\Omega$ and is controlled by its integral over Λ_ε.

The next proposition, which we call **unfolding criterion for integrals** (u.c.i.), is a very useful tool when treating homogenization problems.

PROPOSITION 2.6 (u.c.i.). *If $\{\phi_\varepsilon\}$ is a sequence in $L^1(\Omega)$ satisfying*

$$\int_{\Lambda_\varepsilon} |\phi_\varepsilon|\,dx \to 0,$$

then

$$\int_\Omega \phi_\varepsilon\,dx - \frac{1}{|Y|}\int_{\Omega\times Y} \mathcal{T}_\varepsilon(\phi_\varepsilon)\,dxdy \to 0.$$

Based on this result, we introduce the following notation.

Notation. If $\{w_\varepsilon\}$ is a sequence satisfying u.c.i., we write

$$\int_\Omega w_\varepsilon dx \overset{\mathcal{T}_\varepsilon}{\simeq} \frac{1}{|Y|}\int_{\Omega\times Y} \mathcal{T}_\varepsilon(w_\varepsilon)\, dxdy.$$

PROPOSITION 2.7. *Let $\{u_\varepsilon\}$ be a bounded sequence in $L^p(\Omega)$, with $p \in]1,+\infty]$ and $v \in L^{p'}(\Omega)$ $(1/p + 1/p' = 1)$, then*

$$\int_\Omega u_\varepsilon v\, dx \overset{\mathcal{T}_\varepsilon}{\simeq} \frac{1}{|Y|}\int_{\Omega\times Y} \mathcal{T}_\varepsilon(u_\varepsilon)\mathcal{T}_\varepsilon(v)\, dxdy. \tag{2.5}$$

Suppose $\partial\Omega$ is bounded. Let $\{u_\varepsilon\}$ be a bounded sequence in $L^p(\Omega)$ and $\{v_\varepsilon\}$ a bounded sequence in $L^q(\Omega)$, with $1/p + 1/q < 1$, then

$$\int_\Omega u_\varepsilon v_\varepsilon dx \overset{\mathcal{T}_\varepsilon}{\simeq} \frac{1}{|Y|}\int_{\Omega\times Y} \mathcal{T}_\varepsilon(u_\varepsilon)\mathcal{T}_\varepsilon(v_\varepsilon)\, dxdy. \tag{2.6}$$

Proof. Observe that $1_{\Lambda_\varepsilon}(x) \to 0$ for all $x \in \Omega$. Consequently, by the Lebesgue dominated convergence theorem, one gets $\int_{\Lambda_\varepsilon} |v|^{p'}\, dx \to 0$, and then by the Hölder inequality, $\int_{\Lambda_\varepsilon} |u_\varepsilon v|\, dx \to 0$. This proves (2.5). If $\partial\Omega$ is bounded, then one immediately has $|\Lambda_\varepsilon| \to 0$ when $\varepsilon \to 0$, and this implies (2.6). ∎

We now investigate the convergence properties related to the unfolding operator when $\varepsilon \to 0$. For ϕ uniformly continuous on Ω, with modulus of continuity m_ϕ, it is easy to see that

$$\sup_{x\in\widehat{\Omega}_\varepsilon, y\in Y} |\mathcal{T}_\varepsilon(\phi)(x,y) - \phi(x)| \le m_\phi(\varepsilon).$$

So, as ε goes to zero, even though $\mathcal{T}_\varepsilon(\phi)$ is not continuous, it converges to ϕ uniformly on any open set strongly included in Ω. By density, and making use of Proposition 2.5, further convergence properties can be expressed using the mean value of a function defined on $\Omega \times Y$.

DEFINITION 2.8. *The mean value operator $\mathcal{M}_Y : L^p(\Omega \times Y) \mapsto L^p(\Omega)$ for $p \in [1,+\infty]$, is defined as follows:*

$$\mathcal{M}_Y(\Phi)(x) = \frac{1}{|Y|}\int_Y \Phi(x,y)\, dy \quad \text{a.e. for} \quad x \in \Omega. \tag{2.7}$$

Observe that an immediate consequence of this definition is the estimate

$$\|\mathcal{M}_Y(\Phi)\|_{L^p(\Omega)} \le |Y|^{-\frac{1}{p}} \|\Phi\|_{L^p(\Omega\times Y)} \quad \text{for every } \Phi \in L^p(\Omega \times Y).$$

PROPOSITION 2.9. *Let p belong to $[1,+\infty[$.*

(i) *For $w \in L^p(\Omega)$,*

$$\mathcal{T}_\varepsilon(w) \to w \quad \text{strongly in } L^p(\Omega \times Y).$$

(ii) *Let $\{w_\varepsilon\}$ be a sequence in $L^p(\Omega)$ such that*

$$w_\varepsilon \to w \quad \text{strongly in } L^p(\Omega).$$

Then

$$\mathcal{T}_\varepsilon(w_\varepsilon) \to w \quad \text{strongly in } L^p(\Omega \times Y).$$

(iii) *For every relatively weakly compact sequence* $\{w_\varepsilon\}$ *in* $L^p(\Omega)$*, the corresponding* $\{\mathcal{T}_\varepsilon(w_\varepsilon)\}$ *is relatively weakly compact in* $L^p(\Omega \times Y)$*. Furthermore, if*

$$\mathcal{T}_\varepsilon(w_\varepsilon) \rightharpoonup \widehat{w} \quad \text{weakly in } L^p(\Omega \times Y),$$

then

$$w_\varepsilon \rightharpoonup \mathcal{M}_Y(\widehat{w}) \quad \text{weakly in } L^p(\Omega).$$

(iv) *If* $\mathcal{T}_\varepsilon(w_\varepsilon) \rightharpoonup \widehat{w}$ *weakly in* $L^p(\Omega \times Y)$*, then*

$$\|\widehat{w}\|_{L^p(\Omega\times Y)} \le \liminf_{\varepsilon\to 0} |Y|^{\frac{1}{p}} \|w_\varepsilon\|_{L^p(\Omega)}. \tag{2.8}$$

(v) *Suppose* $p > 1$*, and let* $\{w_\varepsilon\}$ *be a bounded sequence in* $L^p(\Omega)$*. Then, the following assertions are equivalent:*

(a) $\mathcal{T}_\varepsilon(w_\varepsilon) \rightharpoonup \widehat{w}$ *weakly in* $L^p(\Omega \times Y)$ *and* $\limsup_{\varepsilon\to 0} |Y|^{\frac{1}{p}} \|w_\varepsilon\|_{L^p(\Omega)} \le \|\widehat{w}\|_{L^p(\Omega\times Y)}$,

(b) $\mathcal{T}_\varepsilon(w_\varepsilon) \to \widehat{w}$ *strongly in* $L^p(\Omega \times Y)$ *and* $\displaystyle\int_{\Lambda_\varepsilon} |w_\varepsilon|^p \, dx \to 0$.

Proof. (i) The result is obvious for any $w \in \mathcal{D}(\Omega)$. If $w \in L^p(\Omega)$, let $\phi \in \mathcal{D}(\Omega)$. Then, by using (iv) from Proposition 2.5,

$$\begin{aligned}\|\mathcal{T}_\varepsilon(w) - w\|_{L^p(\Omega\times Y)} &= \|\mathcal{T}_\varepsilon(w-\phi) + \big(\mathcal{T}_\varepsilon(\phi) - \phi\big) + (\phi - w)\|_{L^p(\Omega\times Y)} \\ &\le 2|Y|^{\frac{1}{p}} \|w-\phi\|_{L^p(\Omega)} + \|\mathcal{T}_\varepsilon(\phi) - \phi\|_{L^p(\Omega\times Y)},\end{aligned}$$

hence,

$$\limsup_{\varepsilon\to 0} \|\mathcal{T}_\varepsilon(w) - w\|_{L^p(\Omega\times Y)} \le 2|Y|^{\frac{1}{p}} \|w-\phi\|_{L^p(\Omega)},$$

from which statement (i) follows by density.

(ii) The following estimate, a consequence of Proposition 2.5(iv), gives the result

$$\|\mathcal{T}_\varepsilon(w_\varepsilon) - \mathcal{T}_\varepsilon(w)\|_{L^p(\Omega\times Y)} \le |\ Y\ |^{\frac{1}{p}} \|w_\varepsilon - w\|_{L^p(\Omega)} \quad \forall w \in L^p(\Omega).$$

(iii) For $p \in]1, +\infty[$, by Proposition 2.5(iv), boundedness is preserved by $\mathcal{T}_\varepsilon$. Suppose that $\mathcal{T}_\varepsilon(w_\varepsilon) \rightharpoonup \widehat{w}$ weakly in $L^p(\Omega \times Y)$, and let $\psi \in L^{p'}(\Omega)$. From Proposition 2.7,

$$\int_\Omega w_\varepsilon(x)\, \psi(x)\, dx \overset{\mathcal{T}_\varepsilon}{\sim} \frac{1}{|Y|} \int_{\Omega\times Y} \mathcal{T}_\varepsilon(w_\varepsilon)(x,y)\, \mathcal{T}_\varepsilon(\psi)(x,y)\, dx\, dy.$$

In view of (i), one can pass to the limit in the right-hand side to obtain

$$\lim_{\varepsilon\to 0} \int_\Omega w_\varepsilon(x)\, \psi(x)\, dx = \int_\Omega \left\{ \frac{1}{|Y|} \int_Y \widehat{w}(x,y)\, dy \right\} \psi(x)\, dx.$$

For $p = 1$, one uses the extra property satisfied by weakly convergent sequences in $L^1(\Omega)$, in the form of the De La Vallée–Poussin criterion (which is equivalent to

relative weak compactness): there exists a continuous convex function $\Phi : \mathbb{R}^+ \mapsto \mathbb{R}^+$ such that

$$\lim_{t\to+\infty} \frac{\Phi(t)}{t} = +\infty, \quad \text{and the set } \left\{ \int_\Omega \big(\Phi \circ |w_\varepsilon|\big)(x)\, dx \right\} \text{ is bounded.}$$

Unfolding the last integral shows that

$$\left\{ \int_{\Omega\times Y} \big(\Phi \circ |\mathcal{T}_\varepsilon(w_\varepsilon)|\big)(x,y)\, dxdy \right\} \text{ is bounded,}$$

which completes the proof of weak compactness of $\{\mathcal{T}_\varepsilon(w_\varepsilon)\}$ in $L^1(\Omega \times Y)$ in the case of Ω with finite measure. For the case where the measure of Ω is not finite, a similar argument shows that the equiintegrability at infinity of the sequence $\{w_\varepsilon\}$ carries over to $\{\mathcal{T}_\varepsilon(w_\varepsilon)\}$.

If $\mathcal{T}_\varepsilon(w_\varepsilon) \rightharpoonup \widehat{w}$ weakly in $L^1(\Omega \times Y)$, let ψ be in $\mathcal{D}(\Omega)$. For ε sufficiently small, one has

$$\int_\Omega w_\varepsilon(x)\, \psi(x)\, dx = \frac{1}{|Y|} \int_{\Omega\times Y} \mathcal{T}_\varepsilon(w_\varepsilon)(x,y)\, \mathcal{T}_\varepsilon(\psi)(x,y)\, dx\, dy.$$

In view of (i), one can pass to the limit in the right-hand side to obtain

$$\lim_{\varepsilon\to 0} \int_\Omega w_\varepsilon(x)\, \psi(x)\, dx = \int_\Omega \left\{ \frac{1}{|Y|} \int_Y \widehat{w}(x,y)\, dy \right\} \psi(x)\, dx.$$

(iv) Inequality (2.8) is a simple consequence of Proposition 2.5(ii).

(v) Proposition 2.5(i) applied to the function $|w_\varepsilon|^p$ gives

$$\frac{1}{|Y|} \|\mathcal{T}_\varepsilon(w_\varepsilon)\|^p_{L^p(\Omega\times Y)} + \int_{\Lambda_\varepsilon} |w_\varepsilon|^p\, dx = \|w_\varepsilon\|^p_{L^p(\Omega)}.$$

This identity implies the required equivalence. □

COROLLARY 2.10. *Let f be in $L^p(Y)$, $p \in [1, +\infty[$, and $\{f_\varepsilon\}$ be the sequence defined by* (2.3). *Then*

$$f_\varepsilon|_\Omega \rightharpoonup \mathcal{M}_Y(f) \quad \textit{weakly in } L^p(\Omega). \tag{2.9}$$

Proof. Proposition 2.2 gives the strong (hence weak) convergenge of $\{\mathcal{T}_\varepsilon(f_\varepsilon|_\Omega)\}$ to f in $L^p(\Omega \times Y)$. Convergence (2.9) follows from Proposition 2.9(iii).[1] □

Remark 2.11. In general, in the case where Λ_ε is not null set (for every ε), the strong (resp. weak) convergence of the sequence $\{\mathcal{T}_\varepsilon(w_\varepsilon)\}$ does not imply the corresponding convergence for the sequence $\{w_\varepsilon\}$, since it gives no control of the sequence $\{w_\varepsilon 1_{\Lambda_\varepsilon}\}$. If $\{w_\varepsilon 1_{\Lambda_\varepsilon}\}$ is bounded in $L^p(\Omega)$ and if $\{\mathcal{T}_\varepsilon(w_\varepsilon)\}$ converges weakly, so does $\{w_\varepsilon\}$ by Proposition 2.9(iii). On the other hand, even if $\{w_\varepsilon 1_{\Lambda_\varepsilon}\}$ converges strongly to 0 in $L^p(\Omega)$, the strong convergence of $\{\mathcal{T}_\varepsilon(w_\varepsilon)\}$ does not imply that of $\{w_\varepsilon\}$ as it is shown by the sequence $\{f_\varepsilon|_\Omega\}$ in Corollary 2.10, unless f is a constant on Y.

COROLLARY 2.12. *Let p belong to $]1, +\infty[$, let $\{u_\varepsilon\}$ be a sequence in $L^p(\Omega)$ such that*

$$\mathcal{T}_\varepsilon(u_\varepsilon) \rightharpoonup u \quad \textit{weakly in } L^p(\Omega \times Y),$$

[1] Note that the proof of convergence (2.9) is really straightforward when using unfolding!

and let $\{v_\varepsilon\}$ *be a sequence in* $L^{p'}(\Omega)$ $(1/p + 1/p' = 1)$*, with*

$$\mathcal{T}_\varepsilon(v_\varepsilon) \to v \quad \textit{strongly in } L^{p'}(\Omega \times Y).$$

Then, for any φ *in* $C_c(\Omega)$*, one has*

$$\int_\Omega u_\varepsilon(x)\, v_\varepsilon(x)\, \varphi(x)dx \to \frac{1}{|Y|} \int_{\Omega\times Y} u(x,y)\, v(x,y)\, \varphi(x)dxdy.$$

Moreover, if

$$\int_{\Lambda_\varepsilon} |v_\varepsilon|^{p'}\, dx \to 0,$$

then, for any φ *in* $C(\overline{\Omega})$*, one has*

$$\int_\Omega u_\varepsilon(x)\, v_\varepsilon(x)\, \varphi(x)dx \to \frac{1}{|Y|} \int_{\Omega\times Y} u(x,y)\, v(x,y)\, \varphi(x)dxdy.$$

Proof. The result follows from the fact that, in both cases, the sequence $\{u_\varepsilon\, v_\varepsilon \phi\}$ satisfies the u.c.i. by the Hölder inequality. □

Remark 2.13. A consequence of (iii) of Proposition 2.9, together with (iv) of Proposition 2.5, is the following. Suppose the sequence $\{w_\varepsilon\}$ converges weakly to w in $L^p(\Omega)$. Then the sequence $\{\mathcal{T}_\varepsilon(w_\varepsilon)\}$ is relatively weakly compact in $L^p(\Omega \times Y)$, and each of its weak-limit points $\widehat{w}$ satisfies $\mathcal{M}_{_Y}(\widehat{w}) = w$.

Now recall the following definition from Nguetseng [58] and Allaire [1].

Two-scale convergence. *Let* $p \in]1, +\infty[$*. A bounded sequence* $\{w_\varepsilon\}$ *in* $L^p(\Omega)$ *two-scale converges to some* w *belonging to* $L^p(\Omega \times Y)$*, whenever, for every smooth function* φ *on* $\Omega \times Y$*, the following convergence holds:*

$$\int_\Omega w_\varepsilon(x) \varphi\Big(x, \frac{x}{\varepsilon}\Big)\, dx \to \frac{1}{|Y|} \int\int_{\Omega\times Y} w(x,y)\, \varphi(x,y)\, dxdy.$$

The next result reduces two-scale convergence of a sequence to a mere weak $L^p(\Omega \times Y)$-convergence of the unfolded sequence.

PROPOSITION 2.14. *Let* $\{w_\varepsilon\}$ *be a bounded sequence in* $L^p(\Omega)$*, with* $p \in]1, +\infty[$*. The following assertions are equivalent:*

(i) $\{\mathcal{T}_\varepsilon(w_\varepsilon)\}$ *converges weakly to* w *in* $L^p(\Omega \times Y)$,

(ii) $\{w_\varepsilon\}$ *two-scale converges to* w*.*

Proof. To prove this equivalence, it is enough to check that, for every φ in a set of admissible test functions for two-scale convergence (for instance, $\mathcal{D}(\Omega, L^q(Y))$), the sequence $\{\mathcal{T}_\varepsilon[\varphi(x, x/\varepsilon)]\}$ converges strongly to φ in $L^q(\Omega \times Y))$. This follows from the definition of $\mathcal{T}_\varepsilon$, indeed

$$\mathcal{T}_\varepsilon\Big[\varphi\Big(x, \frac{x}{\varepsilon}\Big)\Big](x,y) = \varphi\Big(\varepsilon\Big[\frac{x}{\varepsilon}\Big]_{_Y} + \varepsilon y, y\Big). \qquad \square$$

Remark 2.15. Proposition 2.14 shows that the two-scale convergence of a sequence in $L^p(\Omega)$, $p \in]1, +\infty[$, is equivalent to the weak$-L^p(\Omega \times Y)$ convergence of the unfolded sequence. Notice that, by definition, to check the two-scale convergence, one has to use special test functions. To check a weak convergence in the space $L^p(\Omega \times Y)$, one simply makes the use of functions in the dual space $L^{p'}(\Omega \times Y)$. Moreover, due to density properties, it is sufficient to check this convergence only on smooth functions from $\mathcal{D}(\Omega \times Y)$.

2.2. The averaging operator $\mathcal{U}_\varepsilon$. In this section, we consider the adjoint $\mathcal{U}_\varepsilon$ of $\mathcal{T}_\varepsilon$, which we call averaging operator. In order to do so, let v be in $L^p(\Omega\times Y)$, and let u be in $L^{p'}(\Omega)$. We have successively,

$$\begin{aligned}\frac{1}{|Y|}\int_{\Omega\times Y}\mathcal{T}_\varepsilon(u)(x,y)\,v(x,y)\,dxdy &= \frac{1}{|Y|}\int_{\widehat{\Omega}_\varepsilon\times Y}\mathcal{T}_\varepsilon(u)(x,y)\,v(x,y)\,dxdy\\ &=\frac{1}{|Y|}\sum_{\xi\in\Xi_\varepsilon}\int_{\varepsilon(\xi+Y)\times Y}u(\varepsilon\xi+\varepsilon y)\,v(x,y)\,dxdy\\ &=\sum_{\xi\in\Xi_\varepsilon}\frac{1}{|Y|}\int_{Y\times Y}u(\varepsilon\xi+\varepsilon y)\,v(\varepsilon\xi+\varepsilon z,y)\varepsilon^N\,dzdy\\ &=\sum_{\xi\in\Xi_\varepsilon}\frac{1}{|Y|}\int_Y dz\int_{\varepsilon(\xi+Y)}u(x)\,v\Big(\varepsilon\Big[\frac{x}{\varepsilon}\Big]_Y+\varepsilon z,\Big\{\frac{x}{\varepsilon}\Big\}_Y\Big)\,dx\\ &=\int_{\widehat{\Omega}_\varepsilon}u(x)\left(\frac{1}{|Y|}\int_Y v\left(\varepsilon\left[\frac{x}{\varepsilon}\right]_Y+\varepsilon z,\left\{\frac{x}{\varepsilon}\right\}_Y\right)\,dz\right)dx.\end{aligned}$$

This gives the formula for the averaging operator $\mathcal{U}_\varepsilon$.

DEFINITION 2.16. *For p in $[1,+\infty]$, the averaging operator $\mathcal{U}_\varepsilon : L^p(\Omega\times Y)\mapsto L^p(\Omega)$ is defined as*

$$\mathcal{U}_\varepsilon(\Phi)(x)=\begin{cases}\dfrac{1}{|Y|}\displaystyle\int_Y\Phi\Big(\varepsilon\Big[\frac{x}{\varepsilon}\Big]_Y+\varepsilon z,\Big\{\frac{x}{\varepsilon}\Big\}_Y\Big)\,dz & \text{a.e. for } x\in\widehat{\Omega}_\varepsilon,\\ 0 & \text{a.e. for } x\in\Lambda_\varepsilon.\end{cases}$$

Consequently, for $\psi\in L^p(\Omega)$ and $\Phi\in L^{p'}(\Omega\times Y)$, one has

$$\int_\Omega\mathcal{U}_\varepsilon(\Phi)(x)\,\psi(x)\,dx=\frac{1}{|Y|}\int_{\Omega\times Y}\Phi(x,y)\,\mathcal{T}_\varepsilon(\psi)(x,y)\,dxdy.$$

As a consequence of the duality (Hölder's inequality) and of Proposition 2.5(iv), we get the following.

PROPOSITION 2.17. *Let p belong to $[1,+\infty]$. The averaging operator is linear and continuous from $L^p(\Omega\times Y)$ to $L^p(\Omega)$ and*

$$\|\mathcal{U}_\varepsilon(\Phi)\|_{L^p(\Omega)}\le|\,Y\,|^{-\frac{1}{p}}\,\|\Phi\|_{L^p(\Omega\times Y)}. \tag{2.10}$$

The operator $\mathcal{U}_\varepsilon$ maps $L^p(\Omega\times Y)$ into the space $L^p(\Omega)$. It allows one to replace the function $x\mapsto\Phi(x,\{\frac{x}{\varepsilon}\}_Y)$, which is meaningless, in general, by a function which always makes sense. Notice that this implies, in particular, that the largest set of test functions for two-scale convergence is actually the set $\mathcal{U}_\varepsilon(\Phi)$, with Φ in $L^{p'}(\Omega\times Y)$.

It is immediate from its definition that $\mathcal{U}_\varepsilon$ is almost a left-inverse of $\mathcal{T}_\varepsilon$, since

$$\mathcal{U}_\varepsilon\big(\mathcal{T}_\varepsilon(\phi)\big)(x)=\begin{cases}\phi(x) & \text{a.e. for } x\in\widehat{\Omega}_\varepsilon,\\ 0 & \text{a.e. for } x\in\Lambda_\varepsilon,\end{cases} \tag{2.11}$$

for every ϕ in $L^p(\Omega)$, while

$$\mathcal{T}_\varepsilon(\mathcal{U}_\varepsilon(\Phi))(x,y)=\begin{cases}\dfrac{1}{|\,Y\,|}\displaystyle\int_Y\Phi\Big(\varepsilon\Big[\frac{x}{\varepsilon}\Big]_Y+\varepsilon z,y\Big)\,dz & \text{a.e. for } (x,y)\in\widehat{\Omega}_\varepsilon\times Y,\\ 0 & \text{a.e. for } (x,y)\in\Lambda_\varepsilon\times Y,\end{cases} \tag{2.12}$$

for every Φ in $L^p(\Omega\times Y)$.

PROPOSITION 2.18 (properties of $\mathcal{U}_\varepsilon$). *Suppose that p is in $[1,+\infty[$.*

(i) *Let $\{\Phi_\varepsilon\}$ be a bounded sequence in $L^p(\Omega\times Y)$ such that $\Phi_\varepsilon \rightharpoonup \Phi$ weakly in $L^p(\Omega\times Y)$. Then*

$$\mathcal{U}_\varepsilon(\Phi_\varepsilon) \rightharpoonup \mathcal{M}_{_Y}(\Phi) = \frac{1}{|Y|}\int_Y \Phi(\,\cdot\,,y)\,dy \quad \textit{weakly in } L^p(\Omega).$$

In particular, for every $\Phi\in L^p(\Omega\times Y)$,

$$\mathcal{U}_\varepsilon(\Phi) \rightharpoonup \mathcal{M}_{_Y}(\Phi) \quad \textit{weakly in } L^p(\Omega),$$

but not strongly, unless Φ is independent of y.

(ii) *Let $\{\Phi_\varepsilon\}$ be a sequence such that $\Phi_\varepsilon \to \Phi$ strongly in $L^p(\Omega\times Y)$. Then*

$$\mathcal{T}_\varepsilon(\mathcal{U}_\varepsilon(\Phi_\varepsilon)) \to \Phi \quad \textit{strongly in } L^p(\Omega\times Y).$$

(iii) *Suppose that $\{w_\varepsilon\}$ is a sequence in $L^p(\Omega)$. Then, the following assertions are equivalent:*

(a) $\mathcal{T}_\varepsilon(w_\varepsilon) \to \widehat{w}$ *strongly in* $L^p(\Omega\times Y)$,

(b) $w_\varepsilon\, 1_{\widehat{\Omega}_\varepsilon} - \mathcal{U}_\varepsilon(\widehat{w}) \to 0$ *strongly in* $L^p(\Omega)$.

(iv) *Suppose that $\{w_\varepsilon\}$ is a sequence in $L^p(\Omega)$. Then, the following assertions are equivalent:*

(c) $\mathcal{T}_\varepsilon(w_\varepsilon) \to \widehat{w}$ *strongly in* $L^p(\Omega\times Y)$ *and* $\displaystyle\int_{\Lambda_\varepsilon} |w_\varepsilon|^p\,dx \to 0$,

(d) $w_\varepsilon - \mathcal{U}_\varepsilon(\widehat{w}) \to 0$ *strongly in* $L^p(\Omega)$.

Proof. (i) This follows from Proposition 2.9(ii) by duality for $p>1$. It still holds for $p=1$ in the same way as the proof of Proposition 2.9(ii). Indeed, if the De La Vallée–Poussin criterion is satisfied by the sequence $\{\Phi_\varepsilon\}$, it is also satisfied by the sequence $\{\mathcal{U}_\varepsilon(\Phi_\varepsilon)\}$, since for F convex and continuous, Jensen's inequality implies that

$$F(\mathcal{U}_\varepsilon(\Phi_\varepsilon))(x) \le \mathcal{U}_\varepsilon(F(\Phi_\varepsilon))(x).$$

(ii) The proof follows the same lines as that of (i)–(ii) of Proposition 2.9.

(iii) The implication (a)⇒(b) follows from (2.10) applied to $\Phi_\varepsilon = w_\varepsilon\, 1_{\widehat{\Omega}_\varepsilon} - \mathcal{U}_\varepsilon(\widehat{w})$ and from (2.11).

As for the converse (b)⇒(a), Proposition 2.9(ii) implies that

$$\mathcal{T}_\varepsilon(w_\varepsilon\, 1_{\widehat{\Omega}_\varepsilon} - \mathcal{U}_\varepsilon(\widehat{w})) \to 0 \quad \text{strongly in } L^p(\Omega\times Y).$$

Since $\mathcal{T}_\varepsilon(w_\varepsilon) = \mathcal{T}_\varepsilon(w_\varepsilon\, 1_{\widehat{\Omega}_\varepsilon})$, from (ii) above it converges to $\widehat{w}$ strongly in $L^p(\Omega\times Y)$.

(iv) The implication (c)⇒(d) follows from (iii) and the second condition of (c).

Its converse (d)⇒(c) is a consequence of from (iii): since $\mathcal{U}_\varepsilon(\widehat{w})\,1_{\Lambda_\varepsilon} = 0$, (d) implies (b) and $w_\varepsilon\, 1_{\Lambda_\varepsilon} \to 0$ in $L^p(\Omega)$. ∎

Remark 2.19. The statement of Proposition 2.18(iii) does not hold with weak convergences instead of strong ones, contrary to an erroneous statement made in [24]. In view of (2.11) and Proposition 2.18(i), if $\mathcal{T}_\varepsilon(w_\varepsilon) \rightharpoonup \widehat{w}$ weakly in $L^p(\Omega\times Y)$, then $w_\varepsilon\, 1_{\widehat{\Omega}_\varepsilon} - \mathcal{U}_\varepsilon(\widehat{w})$ converges weakly to 0 in $L^p(\Omega)$.

But the converse of this last implication cannot hold. Indeed, choose $\widehat{v}$ with $\mathcal{M}_{_Y}(\widehat{v}) = 0$. By Proposition 2.18(i), $\mathcal{U}_\varepsilon(\widehat{v})$ converges weakly to $\mathcal{M}_{_Y}(\widehat{v}) = 0$. Consequently, the weak limit of $w_\varepsilon\, 1_{\widehat{\Omega}_\varepsilon} - \mathcal{U}_\varepsilon(\widehat{w})$ is also the weak limit of $w_\varepsilon\, 1_{\widehat{\Omega}_\varepsilon} - \mathcal{U}_\varepsilon(\widehat{w}+\widehat{v})$. If the converse were true, it would imply that $\mathcal{T}_\varepsilon(w_\varepsilon)$ converges weakly to both $\widehat{w}$ and $\widehat{w}+\widehat{v}$. So $\widehat{v} = 0$. In other words, $\mathcal{M}_{_Y}(\widehat{v}) = 0$ would imply $\widehat{v} = 0$.

Remark 2.20. Assertions (iii)(b) and (iv)(d) are corrector–type results.

Remark 2.21. The condition (iii)(a) is used by some authors to define the notion of "strong two-scale convergence." From the above considerations, condition (c) of Proposition 2.18(iv) is a better candidate for this definition.

2.3. The local average operator $\mathcal{M}_\varepsilon$. In this section, we consider the classical average operator associated to the partition of Ω by ε-cells Y (setting it to be zero on the cells intersecting the boundary $\partial\Omega$).

DEFINITION 2.22. *The local average operator $\mathcal{M}_\varepsilon : L^p(\Omega) \mapsto L^p(\Omega)$, for $p \in [1,+\infty]$, is defined by*

$$\mathcal{M}_\varepsilon(\phi)(x) = \begin{cases} \dfrac{1}{\varepsilon^N |Y|} \displaystyle\int_\varepsilon \left[\frac{x}{\varepsilon}\right]_y \phi(\zeta)\, d\zeta & \text{if } x \in \widehat{\Omega}_\varepsilon, \\ 0 \qquad \text{if } x \in \Lambda_\varepsilon. \end{cases} \tag{2.13}$$

Remark 2.23. It turns out that the local average $\mathcal{M}_\varepsilon$ is connected to the unfolding operator $\mathcal{T}_\varepsilon$. Indeed, by the usual change of variable cell by cell,

$$\mathcal{M}_\varepsilon(\phi)(x) = \frac{1}{|Y|} \int_Y \mathcal{T}_\varepsilon(\phi)(x,y)\, dy = \mathcal{M}_{_Y}\big(\mathcal{T}_\varepsilon(\phi)\big)(x).$$

Remark 2.24. Note that, for any ϕ in $L^p(\Omega)$, one has $\mathcal{T}_\varepsilon(\mathcal{M}_\varepsilon(\phi)) = \mathcal{M}_\varepsilon(\phi)$ on the set $\Omega \times Y$. Moreover, one also has $\mathcal{U}_\varepsilon(\phi) = \mathcal{M}_\varepsilon(\phi)$.

PROPOSITION 2.25 (properties of $\mathcal{M}_\varepsilon$).

(i) *Suppose that p is in $[1,+\infty]$. For any any ϕ in $L^p(\Omega)$,*

$$\|\mathcal{M}_\varepsilon(\phi)\|_{L^p(\Omega)} \le \|\phi\|_{L^p(\Omega)}.$$

(ii) *Suppose that p is in $[1,+\infty]$. For $\phi \in L^p(\Omega)$ and $\psi \in L^{p'}(\Omega)$,*

$$\int_\Omega \mathcal{M}_\varepsilon(\phi)\, \psi\, dx = \int_\Omega \mathcal{M}_\varepsilon(\phi)\, \mathcal{M}_\varepsilon(\psi)\, dx = \int_\Omega \phi\, \mathcal{M}_\varepsilon(\psi)\, dx. \tag{2.14}$$

(iii) *Suppose that p is in $[1,+\infty[$. Let $\{v_\varepsilon\}$ be a sequence such that $v_\varepsilon \to v$ strongly in $L^p(\Omega)$. Then*

$$\mathcal{M}_\varepsilon(v_\varepsilon) \to v \quad \text{strongly in } L^p(\Omega).$$

In particular, for every $\phi \in L^p(\Omega)$,

$$\mathcal{M}_\varepsilon(\phi) \to \phi \quad \text{strongly in } L^p(\Omega). \tag{2.15}$$

(iv) *Suppose that p is in $[1,+\infty[$. Let $\{v_\varepsilon\}$ be a sequence such that $v_\varepsilon \rightharpoonup v$ weakly in $L^p(\Omega)$. Then*

$$\mathcal{M}_\varepsilon(v_\varepsilon) \rightharpoonup v \quad \text{weakly in } L^p(\Omega).$$

The same holds true for the weak-$*$ topology in $L^\infty(\Omega)$.

Proof. The proofs of (i) and (ii) are straightforward. The proof of (iii) is a simple consequence of (ii) of Proposition 2.9. For the proof of (iv), let ϕ be in $L^{p'}(\Omega)$, with $p' \in [1, +\infty[$ $(p \neq 1)$, and use (2.14) and (2.15) to obtain

$$\int_\Omega \phi\, \mathcal{M}_\varepsilon(v_\varepsilon)\, dx = \int_\Omega \mathcal{M}_\varepsilon(\phi)\, v_\varepsilon\, dx \to \int_\Omega \phi\, v\, dx.$$

For $p = 1$, in the same way as the proof of Proposition 2.9(ii) and Proposition 2.18(i), if the De La Vallée–Poussin criterion is satisfied by the sequence $\{v_\varepsilon\}$, it is also satisfied by the sequence $\{\mathcal{M}_\varepsilon(v_\varepsilon)\}$, since for F convex and continuous, Jensen's inequality implies that

$$F(\mathcal{M}_\varepsilon(v_\varepsilon))(x) \leq \mathcal{M}_\varepsilon(F(v_\varepsilon))(x),$$

which ends the proof. □

COROLLARY 2.26. *Suppose that p is in $[1, +\infty[$. Let w be in $L^p(\Omega)$ and $\{w_\varepsilon\}$ be a sequence in $L^p(\Omega)$ satisfying $\mathcal{T}_\varepsilon(w_\varepsilon) \to w$ strongly in $L^p(\Omega \times Y)$. Then,*

$$w_\varepsilon\, 1_{\widehat{\Omega}_\varepsilon} \to w \quad \text{strongly in } L^p(\Omega).$$

Furthermore, if $\int_{\Lambda_\varepsilon} |w_\varepsilon|^p \to 0$, then, $w_\varepsilon \to w$ strongly in $L^p(\Omega)$.

Proof. Since w does not depend on y, one has $\mathcal{U}_\varepsilon(w) = \mathcal{M}_\varepsilon(w)$ which, by Proposition 2.25(iii), converges strongly to w. The conclusion follows from Proposition 2.18(iii), respectively, (iv). □

3. Unfolding and gradients. This section is devoted to the properties of the restriction of the unfolding operator to the space $W^{1,p}(\Omega)$. Some results require no extra hypotheses, but many others are sensitive to the boundary conditions and the regularity of the boundary itself.

Observe that, for w in $W^{1,p}(\Omega)$, one has

$$\nabla_y(\mathcal{T}_\varepsilon(w)) = \varepsilon \mathcal{T}_\varepsilon(\nabla w), \quad \forall w \in W^{1,p}(\Omega) \quad \text{a.e. for} \quad (x, y) \in \Omega \times Y. \tag{3.1}$$

Then, Proposition 2.5(iv) implies that $\mathcal{T}_\varepsilon$ maps $W^{1,p}(\Omega)$ into $L^p(\Omega; W^{1,p}(Y))$.

For simplicity, we assume that $Y =]0, 1[^n$. Nevertheless, the results we prove here hold true in the case of a general Y, with minor modifications.

PROPOSITION 3.1 (gradient in the direction of a period). *Let k in $[1, \ldots, n]$ and $\{w_\varepsilon\}$ be a bounded sequence in $L^p(\Omega)$, with $p \in]1, +\infty]$, satisfying*

$$\varepsilon \left\| \frac{\partial w_\varepsilon}{\partial x_k} \right\|_{L^p(\Omega)} \leq C. \tag{3.2}$$

Then, there exist a subsequence (still denoted ε) and $\widehat{w}$ in $L^p(\Omega \times Y)$, with $\frac{\partial \widehat{w}}{\partial y_k}$ in $L^p(\Omega \times Y)$ such that

(3.3)

$$\mathcal{T}_\varepsilon(w_\varepsilon) \rightharpoonup \widehat{w} \quad \text{weakly in } L^p(\Omega \times Y),$$

$$\varepsilon \mathcal{T}_\varepsilon\left(\frac{\partial w_\varepsilon}{\partial x_k}\right) = \frac{\partial \mathcal{T}_\varepsilon(w_\varepsilon)}{\partial y_k} \rightharpoonup \frac{\partial \widehat{w}}{\partial y_k} \quad \text{weakly in } L^p(\Omega \times Y), \text{ (weakly-* for } p = +\infty).$$

Moreover, the limit function $\widehat{w}$ is 1-periodic, with respect to the y_k coordinate.

Proof. Convergences (3.3) are a simple consequence of (3.1) and (3.2). It remains to prove the periodicity of $\widehat{w}$. Without loss of generality, assume $k = n$ and write $y = (y', y_n)$, with y' in $Y' \doteq]0,1[^{n-1}$ and $y_n \in]0,1[$.

Let $\psi \in \mathcal{D}(\Omega \times Y')$. Convergences (3.3) imply that the sequence $\{\mathcal{T}_\varepsilon(w_\varepsilon)\}$ is bounded in $L^p(\Omega \times Y'; W^{1,p}(0,1))$ so that $\{\mathcal{T}_\varepsilon(w_\varepsilon)|_{\{y_n=s\}}\}$ is bounded in $L^p(\Omega \times Y')$ for every $s \in [0,1]$. The periodicity with respect to y_n results from the following computation with an obvious change of variable:

$$\begin{aligned}
&\int_{\Omega\times Y'} \big[\mathcal{T}_\varepsilon(w_\varepsilon)(x,(y',1)) - \mathcal{T}_\varepsilon(w_\varepsilon)(x,(y',0)\big]\,\psi(x,y')\,dx\,dy' \\
&\quad= \int_{\Omega\times Y'} \Big\{w_\varepsilon\Big(\varepsilon\Big[\frac{x}{\varepsilon}\Big]_Y + \varepsilon(y',1)\Big) - w_\varepsilon\Big(\varepsilon\Big[\frac{x}{\varepsilon}\Big]_Y + \varepsilon(y',0)\Big)\Big\}\psi(x,y')\,dx\,dy' \\
&\quad= \int_{\Omega\times Y'} w_\varepsilon\Big(\varepsilon\Big[\frac{x}{\varepsilon}\Big]_Y + \varepsilon(y',0)\Big)\big[\psi(x-\varepsilon e_n,y') - \psi(x,y')\big]\,dx\,dy', \\
&\quad= \int_{\Omega\times Y'} \mathcal{T}_\varepsilon(w_\varepsilon)(x,(y',0))\big[\psi(x-\varepsilon e_n,y') - \psi(x,y')\big]\,dx\,dy',
\end{aligned}$$

which goes to zero. ∎

COROLLARY 3.2. *Let $\{w_\varepsilon\}$ be in $W^{1,p}(\Omega)$, with $p \in]1,+\infty[$, and assume that $\{w_\varepsilon\}$ is a bounded sequence in $L^p(\Omega)$ satisfying*

$$\varepsilon\|\nabla w_\varepsilon\|_{L^p(\Omega)} \le C.$$

Then, there exist a subsequence (still denoted ε) and $\widehat{w} \in L^p(\Omega; W^{1,p}(Y))$ such that

$$\begin{aligned}
&\mathcal{T}_\varepsilon(w_\varepsilon) \rightharpoonup \widehat{w} \quad \text{weakly in } L^p(\Omega; W^{1,p}(Y)),\\
&\varepsilon\mathcal{T}_\varepsilon(\nabla w_\varepsilon) \rightharpoonup \nabla_y\widehat{w} \quad \text{weakly in } L^p(\Omega\times Y).
\end{aligned}$$

Moreover, the limit function $\widehat{w}$ is Y-periodic, i.e., belongs to $L^p(\Omega; W^{1,p}_{per}(Y))$, where $W^{1,p}_{per}(Y)$ denotes the Banach space of Y-periodic functions in $W^{1,p}_{loc}(\mathbb{R}^n)$, with the $W^{1,p}(Y)$ norm.

COROLLARY 3.3. *Let p be in $]1,+\infty[$ and $\{w_\varepsilon\}$ be a sequence converging weakly in $W^{1,p}(\Omega)$ to w. Then,*

$$\mathcal{T}_\varepsilon(w_\varepsilon) \rightharpoonup w \quad \text{weakly in } L^p(\Omega; W^{1,p}(Y)).$$

Furthermore, if $\{w_\varepsilon\}$ converges strongly to w in $L^p(\Omega)$, the above convergence is strong (this is the case if, for example, $W^{1,p}(\Omega)$ is compactly embedded in $L^p(\Omega)$).

Proof. Using (3.1), since $\{w_\varepsilon\}$ weakly converges, one has the estimates

$$\begin{aligned}
&\|\mathcal{T}_\varepsilon(w_\varepsilon)\|_{L^p(\Omega\times Y)} \le C,\\
&\|\nabla_y(\mathcal{T}_\varepsilon(w_\varepsilon))\|_{L^p(\Omega\times Y)} \le \varepsilon C,
\end{aligned}$$

so that there exist a subsequence (still denoted ε) and $\widehat{w}$ in $L^p(\Omega; W^{1,p}(Y))$ such that

$$\begin{aligned}
&\mathcal{T}_\varepsilon(w_\varepsilon) \rightharpoonup \widehat{w} \quad \text{weakly in } L^p(\Omega; W^{1,p}(Y)),\\
&\nabla_y(\mathcal{T}_\varepsilon(w_\varepsilon)) \to 0 \quad \text{strongly in } L^p(\Omega\times Y),
\end{aligned} \tag{3.4}$$

and $\nabla_y\widehat{w} = 0$. Consequently, $\widehat{w}$ does not depend on y, and Proposition 2.9(iii) immediately gives $w = \mathcal{M}_Y(\widehat{w}) = \widehat{w}$. Moreover, convergence (3.4) holds for the entire

sequence ε. Finally, if the sequence $\{w_\varepsilon\}$ converges strongly to w in $L^p(\Omega)$, so does the sequence $\{\mathcal{T}_\varepsilon(w_\varepsilon)\}$, thanks to Proposition 2.9(ii). □

PROPOSITION 3.4. *Suppose that p is in $[1,+\infty[$. Let $\{w_\varepsilon\}$ be a sequence which converges strongly to some w in $W^{1,p}(\Omega)$. Then,*

$$\text{(i)}\quad \mathcal{T}_\varepsilon(\nabla w_\varepsilon) \to \nabla w \quad \textit{strongly in } L^p(\Omega\times Y),$$

$$\text{(ii)}\quad \frac{1}{\varepsilon}\Big(\mathcal{T}_\varepsilon(w_\varepsilon) - \mathcal{M}_\varepsilon(w_\varepsilon)\Big) \to y^c\cdot\nabla w \qquad \textit{strongly in } \ L^p(\Omega; W^{1,p}(Y)),$$

where

$$y^c = \left(y_1 - \frac{1}{2},\dots, y_n - \frac{1}{2}\right).$$

Proof. The first asssertion follows from Proposition 2.9(i). To prove (ii), set

$$Z_\varepsilon \doteq \frac{1}{\varepsilon}\Big(\mathcal{T}_\varepsilon(w_\varepsilon) - \mathcal{M}_\varepsilon(w_\varepsilon)\Big),$$

which has mean value zero in Y. Since

$$\nabla_y Z_\varepsilon = \frac{1}{\varepsilon}\nabla_y\big(\mathcal{T}_\varepsilon(w_\varepsilon)\big) = \mathcal{T}_\varepsilon\big(\nabla w_\varepsilon\big),$$

thanks to assertion (i),

$$\nabla_y Z_\varepsilon \to \nabla w \quad \text{ strongly in } L^p(\Omega\times Y).$$

Then recall the Poincaré–Wirtinger inequality in Y:

$$\forall \psi\in W^{1,p}(Y),\quad \big\|\psi - \mathcal{M}_{_Y}(\psi)\big\|_{L^p(Y)} \le C\|\nabla\psi\|_{L^p(Y)}. \tag{3.5}$$

Applying it to the function $Z_\varepsilon - y^c\cdot\nabla w$ (which is of mean value zero) gives

$$\big\|Z_\varepsilon - y^c\cdot\nabla w\big\|_{L^p(\Omega\times Y)} \le C\|\nabla_y Z_\varepsilon - \nabla w\|_{L^p(\Omega\times Y)}, \tag{3.6}$$

and this concludes the proof. □

THEOREM 3.5. *Suppose that p is in $]1,+\infty[$. Let $\{w_\varepsilon\}$ be a sequence converging weakly to some w in $W^{1,p}(\Omega)$. Up to a subsequence, there exists some $\widehat{w}$ in $L^p(\Omega; W^{1,p}_{per}(Y))$ such that*

$$\begin{aligned}&\text{(i)}\quad \mathcal{T}_\varepsilon(\nabla w_\varepsilon) \rightharpoonup \nabla w + \nabla_y\widehat{w} \quad \textit{weakly in } L^p(\Omega\times Y),\\ &\text{(ii)}\quad \frac{1}{\varepsilon}\Big(\mathcal{T}_\varepsilon(w_\varepsilon) - \mathcal{M}_\varepsilon(w_\varepsilon)\Big) \rightharpoonup \widehat{w} + y^c\cdot\nabla w \quad \textit{weakly in } \ L^p(\Omega; W^{1,p}(Y)).\end{aligned} \tag{3.7}$$

Moreover, $\mathcal{M}_{_Y}(\widehat{w}) = 0$.

Proof. Following the same lines as in the previous proof, introduce

$$Z_\varepsilon = \frac{1}{\varepsilon}\Big(\mathcal{T}_\varepsilon(w_\varepsilon) - \mathcal{M}_\varepsilon(w_\varepsilon)\Big),$$

which has mean value zero in Y. Since $\nabla_y Z_\varepsilon = \mathcal{T}_\varepsilon\big(\nabla w_\varepsilon\big)$, (ii) implies (i).

To prove (ii), note that the sequence $\{\nabla_y Z_\varepsilon\}$ is bounded in $L^p(\Omega \times Y)$. By (3.6),

$$\left\| Z_\varepsilon - y^c \cdot \nabla w \right\|_{L^p(\Omega \times Y)} \leq C$$

so that there exists $\widehat{w}$ in $L^p(\Omega; W^{1,p}(Y))$ such that, up to a subsequence,

$$Z_\varepsilon - y^c \cdot \nabla w \rightharpoonup \widehat{w} \quad \text{weakly in} \quad L^p(\Omega; W^{1,p}(Y)).$$

Since, by construction, $\mathcal{M}_Y(y^c)$ vanishes, so does $\mathcal{M}_Y(\widehat{w})$.

It remains to prove the Y-periodicity of $\widehat{w}$. This is obtained in the same way as in the proof of Proposition 3.1 by using a test function $\psi \in \mathcal{D}(\Omega \times Y')$. One has successively,

$$\begin{aligned}
&\int_{\Omega \times Y'} \left[Z_\varepsilon(x,(y',1)) - Z_\varepsilon(x,(y',0)) \right] \psi(x,y')\, dx\, dy' \\
&\quad = \int_{\Omega \times Y'} \frac{1}{\varepsilon} \Big\{ w_\varepsilon\Big(\varepsilon \Big[\frac{x}{\varepsilon}\Big]_Y + \varepsilon(y',1)\Big) - w_\varepsilon\Big(\varepsilon \Big[\frac{x}{\varepsilon}\Big]_Y + \varepsilon(y',0)\Big) \Big\} \psi(x,y')\, dx\, dy' \\
&\quad = \int_{\Omega \times Y'} w_\varepsilon\Big(\varepsilon \Big[\frac{x}{\varepsilon}\Big]_Y + \varepsilon(y',0)\Big) \frac{1}{\varepsilon} \left[\psi(x - \varepsilon e_n, y') - \psi(x,y') \right] dx\, dy', \\
&\quad = \int_{\Omega \times Y'} \mathcal{T}_\varepsilon(w_\varepsilon)(x,(y',0)) \frac{1}{\varepsilon} \left[\psi(x - \varepsilon e_n, y') - \psi(x,y') \right] dx\, dy'.
\end{aligned}$$

By Proposition 2.9(ii), $\{\mathcal{T}_\varepsilon(w_\varepsilon)\}$ converges strongly to w in $L^p(\Omega \times Y)$, and by (3.7) (i), it converges weakly to the same w in $L^p(\Omega; W^{1,p}(Y))$. By the trace theorem in $W^{1,p}(Y)$, the trace of $\mathcal{T}_\varepsilon(w_\varepsilon)$ on $\Omega \times Y'$ converges weakly to w in $L^p(\Omega \times Y')$. Hence, the last integral converges to

$$-\int_{\Omega \times Y'} w(x) \frac{\partial \psi}{\partial x_n}(x,y')\, dx\, dy'. \tag{3.8}$$

Similarly, since $(y^c \cdot \nabla w)(y',1) - (y^c \cdot \nabla w)(y',0) = \frac{\partial w}{\partial x_n}$, we obtain

$$\begin{aligned}
&\int_{\Omega \times Y'} \left[(y^c \cdot \nabla w)(y',1) - (y^c \cdot \nabla w)(y',0) \right] \psi(x,y')\, dx\, dy' \\
&\qquad = \int_{\Omega \times Y'} \frac{\partial w}{\partial x_n}\, \psi(x,y')\, dx\, dy' = -\int_{\Omega \times Y'} w(x) \frac{\partial \psi}{\partial x_n}(x,y')\, dx\, dy'.
\end{aligned}$$

This, together with (3.8) and convergence (3.7)(ii), shows that

$$\int_{\Omega \times Y'} \left[\widehat{w}(x,(y',1)) - \widehat{w}(x,(y',0)) \right] \psi(x,y')\, dx\, dy' = 0,$$

so that $\widehat{w}$ is y_n-periodic. The same holds in the directions of all of the other periods. □

Theorem 3.5 can be generalized to the case of $W^{k,p}(\Omega)$-spaces, with $k \geq 1$ and $p \in]1, +\infty[$. In order to do so, for $r = (r_1, \ldots, r_n) \in \mathbb{N}^n$ with $|r| = r_1 + \cdots + r_n \leq k$, introduce the notation D^r and D^r_y:

$$D^r = \frac{\partial^{|r|}}{\partial x_1^{r_1} \ldots \partial x_n^{r_n}}, \qquad D^r_y = \frac{\partial^{|r|}}{\partial y_1^{r_1} \ldots \partial y_n^{r_n}}.$$

Then the following result holds.

THEOREM 3.6. *Let $\{w_\varepsilon\}$ be a sequence converging weakly in $W^{k,p}(\Omega)$ to w, $k \geq 1$, and $p \in]1, +\infty[$. There exist a subsequence (still denoted ε) and $\widehat{w}$ in the space $L^p(\Omega; W^{k,p}_{per}(Y))$ such that*

$$\begin{cases} \mathcal{T}_\varepsilon(D^l w_\varepsilon) \rightharpoonup D^l w \quad \text{weakly in } L^p(\Omega; W^{k-l,p}(Y)), \quad |l| \leq k-1, \\ \mathcal{T}_\varepsilon(D^l w_\varepsilon) \rightharpoonup D^l w + D^l_y \widehat{w} \quad \text{weakly in } L^p(\Omega \times Y), \quad |l| = k. \end{cases} \tag{3.9}$$

Furthermore, if $\{w_\varepsilon\}$ converges strongly to w in $W^{k-1,p}(\Omega)$, the above convergences are strong in $L^p(\Omega; W^{k-l,p}(Y))$ for $|l| \leq k-1$.

Proof. We give a brief proof for $k = 2$. The same argument generalizes for $k > 2$. If $|l| = 1$, the first convergence in (3.9) follows directly from Corollary 3.3. Set

$$W_\varepsilon = \frac{1}{\varepsilon^2}\Big[\mathcal{T}_\varepsilon(w_\varepsilon) - \mathcal{M}_\varepsilon(w_\varepsilon) - y^c \cdot \mathcal{M}_\varepsilon\big(\nabla w_\varepsilon\big)\Big].$$

The sequence $\{w_\varepsilon\}$ is bounded in $W^{2,p}(\Omega)$, hence proceeding as in the proof of Proposition 2.25(iii), one obtains

$$\big\|W_\varepsilon\big\|_{L^p(\Omega\times Y)} \leq C.$$

Moreover,

$$\nabla_y\big(W_\varepsilon\big) = \frac{1}{\varepsilon^2}\Big(\mathcal{T}_\varepsilon\big(\nabla w_\varepsilon\big) - \mathcal{M}_\varepsilon(\nabla w_\varepsilon)\Big),$$

and

$$D^l_y\big(W_\varepsilon\big) = \mathcal{T}_\varepsilon\big(D^l w_\varepsilon\big), \quad \text{with} \quad |l| = 2.$$

This implies that the sequence $\{W_\varepsilon\}$ is bounded in $L^p(\Omega; W^{2,p}(Y))$. Therefore, there exist a subsequence (still denoted ε) and $\widetilde{w} \in L^p(\Omega; W^{2,p}(Y))$ such that

$$\begin{aligned} &W_\varepsilon \rightharpoonup \widetilde{w} \quad \text{weakly in } L^p(\Omega; W^{2,p}(Y)), \\ &\frac{\partial W_\varepsilon}{\partial y_i} = \frac{1}{\varepsilon^2}\left(\mathcal{T}_\varepsilon\left(\frac{\partial w_\varepsilon}{\partial x_i}\right) - \mathcal{M}_\varepsilon\left(\frac{\partial w_\varepsilon}{\partial x_i}\right)\right) \rightharpoonup \frac{\partial \widetilde{w}}{\partial y_i} \quad \text{weakly in } L^p(\Omega; W^{1,p}(Y)). \end{aligned} \tag{3.10}$$

Consequently,

$$D^l_y(W_\varepsilon) = \mathcal{T}_\varepsilon(D^l w_\varepsilon) \rightharpoonup D^l_y \widetilde{w} \quad \text{weakly in } L^p(\Omega \times Y), \quad |l| = 2. \tag{3.11}$$

Now, apply Theorem 3.5 to each of the derivatives $\frac{\partial w_\varepsilon}{\partial x_i}$, $i \in \{1, \ldots, n\}$. There exist a subsequence (still denoted ε) and $\widehat{w}_i \in L^p(\Omega; W^{1,p}_{per}(Y))$ such that $\mathcal{M}_{_Y}(\widehat{w}_i) \equiv 0$ and

$$\frac{1}{\varepsilon}\left(\mathcal{T}_\varepsilon\left(\frac{\partial w_\varepsilon}{\partial x_i}\right) - \mathcal{M}_\varepsilon\left(\frac{\partial w_\varepsilon}{\partial x_i}\right)\right) \rightharpoonup y^c \cdot \nabla \frac{\partial w}{\partial x_i} + \widehat{w}_i \quad \text{weakly in } L^p(\Omega \times Y).$$

Then (3.10) gives

$$\forall i \in \{1, \ldots, n\}, \qquad \frac{\partial \widetilde{w}}{\partial y_i} = y^c \cdot \nabla \frac{\partial w}{\partial x_i} + \widehat{w}_i. \tag{3.12}$$

Set

$$\widehat{w} = \widetilde{w} - \frac{1}{2}\sum_{i,j=1}^{n} \big(y^c_i\, y^c_j - \mathcal{M}_{_Y}(y^c_i\, y^c_j)\big)\frac{\partial^2 w}{\partial x_i \partial x_j}.$$

By construction, the function $\widehat{w}$ belongs to $L^p(\Omega; W^{2,p}(Y))$. Furthermore,

$$\mathcal{M}_{_Y}(\widehat{w}) = 0, \qquad \frac{\partial \widehat{w}}{\partial y_i} = \frac{\partial \widetilde{w}}{\partial y_i} - y^c \cdot \nabla \left(\frac{\partial w}{\partial x_i} \right) = \widehat{w}_i, \quad \text{and} \quad \mathcal{M}_{_Y}(\nabla_y \widehat{w}) = 0.$$

The last equality implies that $\widehat{w}$ belongs to $L^p(\Omega; W^{2,p}_{per}(Y))$. Finally from (3.12) one gets

$$D^l_y \widetilde{w} = D^l w + D^l_y \widehat{w}, \qquad \text{with} \quad |l| = 2,$$

which together with (3.11), proves the last convergence of (3.9). □

COROLLARY 3.7. *Let $\{w_\varepsilon\}$ be a sequence converging weakly in $W^{2,p}(\Omega)$ to w, and $p \in]1, +\infty[$. Then, there exist a subsequence (still denoted ε) and $\widehat{w}$ in the space $L^p(\Omega; W^{2,p}_{per}(Y))$ such that*

$$\frac{1}{\varepsilon^2}\Big[\mathcal{T}_\varepsilon(w_\varepsilon) - \mathcal{M}_\varepsilon(w_\varepsilon) - y^c \cdot \mathcal{M}_\varepsilon\big(\nabla w_\varepsilon\big)\Big] \rightharpoonup \frac{1}{2} \sum_{i,j=1}^{n} \big(y^c_i\, y^c_j - \mathcal{M}_{_Y}(y^c_i\, y^c_j)\big) \frac{\partial^2 w}{\partial x_i \partial x_j} + \widehat{w}$$

weakly in $L^p(\Omega; W^{2,p}(Y))$, where $\widehat{w}$ is such that $\mathcal{M}_{_Y}(\widehat{w}) = 0$.

Remark 3.8. For the case $Y =]0,1[^n$, y^c was defined in Proposition 3.4. For a general Y, all of the statements of this section hold true, with $y^c = y - \mathcal{M}_{_Y}(y)$.

4. Macro-micro decomposition: The scale-splitting operators $\mathcal{Q}_\varepsilon$ and $\mathcal{R}_\varepsilon$. In this section, we give a different proof of Theorem 3.5, which was the one given originally in [24]. It is based on a scale-separation decomposition which is useful in some specific situations, for example, in the statement of general corrector results (see section 6).

The procedure is based on a splitting of functions ϕ in $W^{1,p}(\Omega)$ (or in $W^{1,p}_0(\Omega)$) for $p \in [1, +\infty]$, in the form

$$\phi = \mathcal{Q}_\varepsilon(\phi) + \mathcal{R}_\varepsilon(\phi),$$

where $\mathcal{Q}_\varepsilon(\phi)$ is an approximation of ϕ having the same behavior as ϕ, while $\mathcal{R}_\varepsilon(\phi)$ is a remainder of order ε. Applied to the sequence $\{w_\varepsilon\}$ converging weakly to w in $W^{1,p}(\Omega)$, it shows that, while $\{\nabla w_\varepsilon\}$, $\{\nabla(\mathcal{Q}_\varepsilon(w_\varepsilon))\}$ and $\{\mathcal{T}_\varepsilon(\nabla \mathcal{Q}_\varepsilon(w_\varepsilon))\}$ have the same weak limit ∇w in $L^p(\Omega)$, respectively, in $L^p(\Omega \times Y)$, the sequence $\mathcal{T}_\varepsilon\big(\nabla(\mathcal{R}_\varepsilon(w_\varepsilon))\big)$ converges weakly in $L^p(\Omega \times Y)$ to $\nabla_y \widehat{w}'$ for some $\widehat{w}'$ in $L^p(\Omega; W^{1,p}_{per}(Y))$.

We will distinguish between the case $W^{1,p}_0(\Omega)$ and the case $W^{1,p}(\Omega)$. For the former, any function ϕ in $W^{1,p}_0(\Omega)$ is extended by zero to the whole of $\mathbb{R}^n$, and this extension is denoted by $\widetilde{\phi}$. In the latter case, we suppose that $\partial\Omega$ is smooth enough so that there exists a continuous extension operator $\mathcal{P} : W^{1,p}(\Omega) \mapsto W^{1,p}(\mathbb{R}^n)$ satisfying

$$\|\mathcal{P}(\phi)\|_{W^{1,p}(\mathbb{R}^n)} \le C \, \|\phi\|_{W^{1,p}(\Omega)}, \quad \forall \phi \in W^{1,p}(\Omega),$$

where C is a constant depending on p and $\partial\Omega$ only.

The construction of $\mathcal{Q}_\varepsilon$ is based on the Q_1 interpolate of some discrete approximation, as is customary in FEM. The idea of using these types of interpolate was already present in Griso [40], [41] for the study of truss-like structures. For the purpose of this paper, it is enough to take the average on $\varepsilon\xi + \varepsilon Y$ to construct the discrete approximations, but the average on $\varepsilon\xi + \varepsilon Y'$, where Y' is any fixed open subset of Y,

or any open subset of a manifold of codimension 1 in Y. The only property which is needed is the Poincaré–Wirtinger inequality, which holds in both of these cases.

DEFINITION 4.1. *The operator $\mathcal{Q}_\varepsilon : L^p(\mathbb{R}^n) \mapsto W^{1,\infty}(\mathbb{R}^n)$, for $p \in [1, +\infty]$, is defined as follows:*

$$\mathcal{Q}_\varepsilon(\phi)(\varepsilon\xi) = \mathcal{M}_\varepsilon(\phi)(\varepsilon\xi) \quad \text{for } \xi \in \varepsilon\mathbb{Z}^n, \tag{4.1}$$

and for any $x \in \mathbb{R}^n$, we set

$$\begin{aligned} &\mathcal{Q}_\varepsilon(\phi)(x) \text{ is the } Q_1 \text{ interpolate of the values of } \mathcal{Q}_\varepsilon(\phi) \text{ at the vertices} \\ &\text{of the cell } \varepsilon\Big[\frac{x}{\varepsilon}\Big]_Y + \varepsilon Y. \end{aligned} \tag{4.2}$$

In the case of the space $W_0^{1,p}(\Omega)$, the operator $\mathcal{Q}_\varepsilon : W_0^{1,p}(\Omega) \mapsto W^{1,\infty}(\Omega)$ is defined by

$$\mathcal{Q}_\varepsilon(\phi) = \mathcal{Q}_\varepsilon(\widetilde{\phi})|_\Omega,$$

where $\mathcal{Q}_\varepsilon(\widetilde{\phi})$ is given by (4.1).

In the case of the space $W^{1,p}(\Omega)$, the operator $\mathcal{Q}_\varepsilon : W^{1,p}(\Omega) \mapsto W^{1,\infty}(\Omega)$ is defined by

$$\mathcal{Q}_\varepsilon(\phi) = \mathcal{Q}_\varepsilon(\mathcal{P}(\phi))|_\Omega,$$

where $\mathcal{Q}_\varepsilon(\mathcal{P}(\phi))$ is given by (4.1).

We start with the following estimates.

PROPOSITION 4.2 (properties of $\mathcal{Q}_\varepsilon$ on $\mathbb{R}^n$). *For ϕ in $L^p(\mathbb{R}^n)$, $p \in [1, +\infty]$, there exists a constant C depending on n and Y only, such that*

$$\text{(i)} \quad \|\mathcal{Q}_\varepsilon(\phi)\|_{L^p(\mathbb{R}^n)} \le C\|\phi\|_{L^p(\mathbb{R}^n)}, \qquad \text{(ii)} \quad \|\nabla\mathcal{Q}_\varepsilon(\phi)\|_{L^p(\mathbb{R}^n)} \le \frac{C}{\varepsilon}\|\phi\|_{L^p(\mathbb{R}^n)},$$

$$\text{(iii)} \quad \|\mathcal{Q}_\varepsilon(\phi)\|_{L^\infty(\mathbb{R}^n)} \le \frac{C}{\varepsilon^{n/p}}\|\phi\|_{L^p(\mathbb{R}^n)}, \qquad \text{(iv)} \quad \|\nabla\mathcal{Q}_\varepsilon(\phi)\|_{L^\infty(\mathbb{R}^n)} \le \frac{C}{\varepsilon^{1+n/p}}\|\phi\|_{L^p(\mathbb{R}^n)}.$$

Furthermore, for any ψ in $L^p(Y)$,

$$\Big\|\mathcal{Q}_\varepsilon(\phi)\psi\Big(\Big\{\frac{\cdot}{\varepsilon}\Big\}_Y\Big)\Big\|_{L^p(\mathbb{R}^n)} \le C\|\phi\|_{L^p(\mathbb{R}^n)}\|\psi\|_{L^p(Y)}; \tag{4.3}$$

if ψ is in $W^{1,p}_{per}(Y)$, then

$$\Big\|\mathcal{Q}_\varepsilon(\phi)\psi\Big(\Big\{\frac{\cdot}{\varepsilon}\Big\}_Y\Big)\Big\|_{W^{1,p}(\mathbb{R}^n)} \le \frac{C}{\varepsilon}\|\phi\|_{L^p(\mathbb{R}^n)}\|\psi\|_{W^{1,p}(Y)}. \tag{4.4}$$

Proof. By definition, the Q_1 interpolate is Lipschitz-continuous and reaches its maximum at some $\varepsilon\xi$. So, to estimate the L^∞ norm of $\mathcal{Q}_\varepsilon(\phi)$, it suffices to estimate the $\mathcal{Q}_\varepsilon(\phi)(\varepsilon\xi)'s$. By (4.1),

$$|\mathcal{Q}_\varepsilon(\phi)(\varepsilon\xi)|^p \le \frac{1}{|Y|}\int_Y |\phi(\varepsilon\xi + \varepsilon z)|^p\, dz = \frac{1}{\varepsilon^n|Y|}\int_{\varepsilon\xi+\varepsilon Y} |\phi(x)|^p\, dx. \tag{4.5}$$

Since

$$\frac{1}{\varepsilon^n|Y|}\int_{\varepsilon\xi+\varepsilon Y} |\phi(x)|^p\, dx \le \frac{1}{\varepsilon^n|Y|}\|\phi\|^p_{L^p(\mathbb{R}^n)},$$

estimate (iii) follows, with $C = \frac{1}{|Y|^{1/p}}$.

The space $Q_1(Y)$ is of dimension 2^n, hence all of the norms are equivalent. So, there are constants c_1, c_2, and c_3 (depending only upon p and Y) such that, for every $\Phi \in Q_1(Y)$,

$$\|\nabla\Phi\|_{L^\infty(Y)} \le c_1 \sum_{\kappa\in\{0,1\}^n} \left|\Phi\left(\sum_{j=1}^n \kappa_j b_j\right)\right|,$$
$$\|\Phi\|_{L^p(Y)} \le c_2 \left(\sum_{\kappa\in\{0,1\}^n} \left|\Phi\left(\sum_{j=1}^n \kappa_j b_j\right)\right|^p\right)^{1/p},$$
$$\|\nabla\Phi\|_{L^p(Y)} \le c_3 \left(\sum_{\kappa\in\{0,1\}^n} \left|\Phi\left(\sum_{j=1}^n \kappa_j b_j\right)\right|^p\right)^{1/p}.$$

Rescaling these inequalities for $\Phi(y) \doteq \mathcal{Q}_\varepsilon(\phi)(\varepsilon\xi + \varepsilon y)$, gives

$$\|\nabla\mathcal{Q}_\varepsilon(\phi)\|_{L^\infty(\varepsilon\xi+\varepsilon Y)} \le \frac{c_1}{\varepsilon} \sum_{\kappa\in\{0,1\}^n} \left|\mathcal{Q}_\varepsilon(\phi)\left(\varepsilon\xi + \varepsilon\sum_{j=1}^n \kappa_j b_j\right)\right|,$$
$$\|\mathcal{Q}_\varepsilon(\phi)\|_{L^p(\varepsilon\xi+\varepsilon Y)} \le c_2\varepsilon^{n/p} \left(\sum_{\kappa\in\{0,1\}^n} \left|\mathcal{Q}_\varepsilon(\phi)\left(\varepsilon\xi + \varepsilon\sum_{j=1}^n \kappa_j b_j\right)\right|^p\right)^{1/p},$$
$$\|\nabla\mathcal{Q}_\varepsilon(\phi)\|_{L^p(\varepsilon\xi+\varepsilon Y)} \le c_3\varepsilon^{n/p-1} \left(\sum_{\kappa\in\{0,1\}^n} \left|\mathcal{Q}_\varepsilon(\phi)\left(\varepsilon\xi + \varepsilon\sum_{j=1}^n \kappa_j b_j\right)\right|^p\right)^{1/p}.$$

Using (4.5), we have

$$\|\nabla\mathcal{Q}_\varepsilon(\phi)\|_{L^\infty(\mathbb{R}^n)} \le \frac{2^n c_1}{\varepsilon^{1+n/p}|Y|^{1/p}} \|\phi\|_{L^p(\mathbb{R}^n)},$$

which gives (iv). Similarly,

$$\|\mathcal{Q}_\varepsilon(\phi)\|^p_{L^p(\varepsilon\xi+\varepsilon Y)} \le \frac{c_2^p}{|Y|} \sum_{\kappa\in\{0,1\}^n} \int_{\varepsilon\xi+\varepsilon\sum_{j=1}^n \kappa_j b_j+\varepsilon Y} |\phi(x)|^p \, dx,$$

which, by summation on $\xi \in \Xi_\varepsilon$, gives (i), with $C = \frac{(2c_2)^{n/p}}{|Y|^{1/p}}$.

Estimate (ii), with $C = \frac{(2c_3)^{n/p}}{|Y|^{1/p}}$, follows by a similar computation.

To prove (4.3), observe first that the function $\mathcal{Q}_\varepsilon(\phi)\psi(\{\frac{\cdot}{\varepsilon}\}_Y)$ belongs to $L^p(\mathbb{R}^n)$, since $\mathcal{Q}_\varepsilon(\phi)$ is in $L^\infty(\mathbb{R}^n)$ and $\psi(\{\frac{\cdot}{\varepsilon}\}_Y)$ is in $L^p(\mathbb{R}^n)$. Moreover,

$$\left\|\psi\left(\left\{\frac{\cdot}{\varepsilon}\right\}_Y\right)\right\|^p_{L^p(\varepsilon\xi+\varepsilon Y)} = \varepsilon^n \|\psi\|^p_{L^p(Y)},$$

while, by (4.5),

$$\|\mathcal{Q}_\varepsilon(\phi)\|^p_{L^\infty(\varepsilon\xi+\varepsilon Y)} \le \sum_{\kappa\in\{0,1\}^n} \frac{1}{\varepsilon^n|Y|} \int_{\varepsilon\xi+\varepsilon Y+\varepsilon\sum_{j=1}^n \kappa_j b_j} |\phi(x)|^p.$$

Using these two estimates and summing on Ξ_ε gives (4.3), with $C = \frac{2^{n/p}}{|Y|^{1/p}}$.

Estimate (4.4) is obtained in a similar fashion, with $C = \frac{(2)^{n/p}+(2c_3)^{n/p}}{|Y|^{1/p}}$. □

COROLLARY 4.3. *For ϕ in $L^p(\mathbb{R}^n)$, $p \in [1, +\infty[$, the following convergences hold:*

$$\mathcal{Q}_\varepsilon(\phi) \to \phi \quad \textit{strongly in} \quad L^p(\mathbb{R}^n),$$
$$\varepsilon \nabla \mathcal{Q}_\varepsilon(\phi) \to 0 \quad \textit{strongly in} \quad (L^p(\mathbb{R}^n))^n.$$

DEFINITION 4.4. *The remainder $\mathcal{R}_\varepsilon(\phi)$ is given by*

$$\mathcal{R}_\varepsilon(\phi) = \phi - \mathcal{Q}_\varepsilon(\phi) \quad \textit{for any } \phi \in W^{1,p}(\Omega).$$

The following proposition is well-known from the FEM.

PROPOSITION 4.5 (properties of $\mathcal{Q}_\varepsilon$ and $\mathcal{R}_\varepsilon$). *For the case $W_0^{1,p}(\Omega)$, one has*

$$\text{(i)} \quad \|\mathcal{Q}_\varepsilon(\phi)\|_{W^{1,p}(\Omega)} \le C\|\phi\|_{W_0^{1,p}(\Omega)},$$
$$\text{(ii)} \quad \|\mathcal{R}_\varepsilon(\phi)\|_{L^p(\Omega)} \le \varepsilon C\|\phi\|_{W_0^{1,p}(\Omega)},$$
$$\text{(iii)} \quad \|\nabla\mathcal{R}_\varepsilon(\phi)\|_{L^p(\Omega)} \le C\|\nabla\phi\|_{L^p(\Omega)}.$$

The constant C depends on Y (via its diameter and its Poincaré–Wirtinger constant) only, and depends neither on Ω nor on ε.

Similarly, for the case $W^{1,p}(\Omega)$, one has

$$\text{(iv)} \quad \|\mathcal{Q}_\varepsilon(\phi)\|_{W^{1,p}(\Omega)} \le C\,\|\mathcal{P}\|\|\phi\|_{W^{1,p}(\Omega)},$$
$$\text{(v)} \quad \|\mathcal{R}_\varepsilon(\phi)\|_{L^p(\Omega)} \le \varepsilon\, C\,\|\mathcal{P}\|\|\phi\|_{W^{1,p}(\Omega)},$$
$$\text{(vi)} \quad \|\nabla\mathcal{R}_\varepsilon(\phi)\|_{L^p(\Omega)} \le C\,\|\mathcal{P}\|\|\nabla\phi\|_{L^p(\Omega)}.$$

Moreover, in both cases,

$$\text{(4.6)} \qquad \left\| \frac{\partial^2 \mathcal{Q}_\varepsilon(\phi)}{\partial x_i \partial x_j} \right\|_{L^p(\Omega)} \le \frac{C'}{\varepsilon}\|\nabla\phi\|_{L^p(\Omega)} \quad \textit{for } i,j \in [1,\dots,n],\ i \ne j,$$

where C' does not depend on ε.

Proof. We start with ϕ in $W^{1,p}(\mathbb{R}^n)$. From Proposition 2.5(i) and inequality (3.5), we get

$$\text{(4.7)} \quad \|\phi - \mathcal{M}_\varepsilon(\phi)\|_{L^p(\mathbb{R}^n)} = |\,Y\,|^{-\frac{1}{p}}\|\mathcal{T}_\varepsilon(\phi) - \mathcal{M}_\varepsilon(\phi)\|_{L^p(\mathbb{R}^n\times Y)} \le \varepsilon C\|\nabla\phi\|_{L^p(\mathbb{R}^n)}.$$

On the other hand, for any $\psi \in W^{1,p}(\text{interior}(\overline{Y \cup (Y+e_i)}))$, $i \in \{1,\dots,n\}$, we have

$$\begin{aligned} |\,\mathcal{M}_{Y+e_i}(\psi) - \mathcal{M}_Y(\psi)\,| &= |\,\mathcal{M}_Y\big(\psi(\cdot+e_i) - \psi(\cdot)\big)\,| \\ &\le \|\psi(\cdot+e_i) - \psi(\cdot)\|_{L^p(Y)} \le C\|\nabla\psi\|_{L^p(Y\cup(Y+e_i))}. \end{aligned}$$

By a scaling argument and using Definition 4.1, this gives

$$\text{(4.8)} \qquad |\mathcal{Q}_\varepsilon(\phi)(\varepsilon\xi) - \mathcal{Q}_\varepsilon(\phi)(\varepsilon\xi + \varepsilon e_i)| \le \varepsilon C\|\nabla\phi\|_{L^p}(\varepsilon(\xi+Y)\cup\varepsilon(\xi+e_i+Y))$$

for all $\xi \in \varepsilon\mathbb{Z}^n$.

Let $x \in \varepsilon\big(\xi + Y\big)$, and set for every $\kappa = (\kappa_1,\dots,\kappa_n) \in \{0,1\}^n$,

$$\overline{x}_l^{(\kappa_l)} = \begin{cases} \dfrac{x_l - \xi_l}{\varepsilon} & \text{if} \quad \kappa_l = 1, \\ 1 - \dfrac{x_l - \xi_l}{\varepsilon} & \text{if} \quad \kappa_l = 0. \end{cases}$$

If $\xi \in \varepsilon\mathbb{Z}^n$, for every $\kappa \in \{0,1\}^n$, by definition we have

$$\mathcal{Q}_\varepsilon\big(\phi\big)(x) = \sum_{\kappa\in\{0,1\}^n} \mathcal{Q}_\varepsilon(\phi)\big(\varepsilon\xi + \varepsilon\kappa\big)\overline{x}_1^{(\kappa_1)} \dots \overline{x}_n^{(\kappa_n)}, \tag{4.9}$$

and so, for example,

$$\frac{\partial \mathcal{Q}_\varepsilon(\phi)}{\partial x_1}(x)$$
$$= \sum_{\kappa_2,\,\dots,\kappa_n} \frac{\mathcal{Q}_\varepsilon(\phi)\big(\varepsilon\xi + \varepsilon(1,\kappa_2,\dots,\kappa_n)\big) - \mathcal{Q}_\varepsilon(\phi)\big(\varepsilon\xi + \varepsilon(0,\kappa_2,\dots,\kappa_n)\big)}{\varepsilon}\overline{x}_2^{(\kappa_2)} \dots \overline{x}_n^{(\kappa_n)},$$

and a same expression for the other derivatives. This last formula and (4.7)–(4.9) imply estimate (i) written in $\mathbb{R}^n$.

Now, from (4.9), we get

$$\phi(x) - \mathcal{Q}_\varepsilon\big(\phi\big)(x) = \sum_{\kappa\in\{0,1\}^n} \Big(\phi(x) - \mathcal{Q}_\varepsilon(\phi)\big(\varepsilon\xi + \varepsilon\kappa\big)\Big)\overline{x}_1^{(\kappa_1)} \dots \overline{x}_n^{(\kappa_n)},$$

and (ii) (in $\mathbb{R}^n$) follows by using estimate (4.7). Estimate (iii) (again in $\mathbb{R}^n$) is straightforward from the previous ones.

If ϕ is in $W_0^{1,p}(\Omega)$, let $\widetilde{\phi}$ be its extension to the whole of $\mathbb{R}^n$. To derive (i)–(iii), it suffices to write down the estimates in $\mathbb{R}^n$ obtained above. Similarly, applying them to $\mathcal{P}(\phi)$ for ϕ in $W^{1,p}(\Omega)$ gives (iv)–(vi).

To finish the proof, it remains to show estimate (4.6) . To do so, it is enough to take the derivative with respect to any x_k, with $k \neq 1$ in the formula of $\frac{\partial \mathcal{Q}_\varepsilon(\phi)}{\partial x_1}$ above, and use estimate (4.8). ∎

Remark 4.6. By construction (see explicit formula (4.9)), the function $\mathcal{Q}_\varepsilon(\phi)$ is separately piecewise linear on each cell. Observe also that, for any $k \in \{1,\dots,n\}$, $\frac{\partial \mathcal{Q}_\varepsilon(\phi)}{\partial x_k}$ is independent of x_k in each cell $\varepsilon\big(\xi + Y\big)$.

PROPOSITION 4.7. *Let $\{w_\varepsilon\}$ be a sequence converging weakly in $W_0^{1,p}(\Omega)$ (resp. $W^{1,p}(\Omega)$) to w. Then, the following convergences hold:*

$$\text{(i)}\quad \mathcal{R}_\varepsilon(w_\varepsilon) \to 0 \quad \textit{strongly in } L^p(\Omega),$$
$$\text{(ii)}\quad \mathcal{Q}_\varepsilon(w_\varepsilon) \rightharpoonup w \quad \textit{weakly in } W^{1,p}(\Omega),$$
$$\text{(iii)}\quad \mathcal{T}_\varepsilon(\nabla \mathcal{Q}_\varepsilon(w_\varepsilon)) \rightharpoonup \nabla w \quad \textit{weakly in } L^p(\Omega\times Y).$$

Proof. Convergence (i) is a direct consequence of estimate (ii) (resp. (v)) of Proposition 4.5, and it implies convergence (ii). Together with (i), Proposition 2.9(ii) implies $\mathcal{T}_\varepsilon(\mathcal{Q}_\varepsilon(w_\varepsilon)) \rightharpoonup w$ weakly in $L^p(\Omega\times Y)$. From (4.5),

$$\left\| \frac{\partial}{\partial x_i}\left(\frac{\partial \mathcal{Q}_\varepsilon(w_\varepsilon)}{\partial x_j}\right)\right\|_{L^p(\Omega)} \leq \frac{C}{\varepsilon} \quad \text{for } i,j \in [1,\dots,n],\ \ i \neq j.$$

Now, by Proposition 3.1, there exist a subsequence (still denoted ε) and $\widehat{w}_j \in L^p(\Omega\times Y)$, with $\frac{\partial \widehat{w}_j}{\partial y_i} \in L^p(\Omega\times Y)$ such that, for $i \neq j$,

$$\mathcal{T}_\varepsilon\left(\frac{\partial \mathcal{Q}_\varepsilon(w_\varepsilon)}{\partial x_j}\right) \rightharpoonup \widehat{w}_j \quad \text{weakly in } L^p(\Omega\times Y),$$
$$\varepsilon\mathcal{T}_\varepsilon\left(\frac{\partial^2 \mathcal{Q}_\varepsilon(w_\varepsilon)}{\partial x_i \partial x_j}\right) \rightharpoonup \frac{\partial \widehat{w}_j}{\partial y_i} \quad \text{weakly in } L^p(\Omega\times Y),$$

where $\widehat{w}_j$ is y_i-periodic for every $i \neq j$. Moreover, from Remark 4.6, the function $\widehat{w}_j$ does not depend on y_j, hence it is Y-periodic. But, by Remark 4.6 again, $\widehat{w}_j$ is also piecewise linear, with respect to any variable y_i. Consequently, $\widehat{w}_j$ is independent of y. On the other hand, from (ii) above we have

$$\frac{\partial \mathcal{Q}_\varepsilon(w_\varepsilon)}{\partial x_j} \rightharpoonup \frac{\partial w}{\partial x_j} \quad \text{weakly in } L^p(\Omega).$$

Now Proposition 2.9(iii) gives $\widehat{w}_j = \frac{\partial w}{\partial x_j}$, and convergence (iii) holds for the whole sequence ε. □

PROPOSITION 4.8 (Theorem 3.5 revisited). *Let $\{w_\varepsilon\}$ be a sequence converging weakly in $W_0^{1,p}(\Omega)$ (resp. in $W^{1,p}(\Omega)$) to w. Then, up to a subsequence there exists some $\widehat{w}'$ in the space $L^p(\Omega; W^{1,p}_{per}(Y))$ such that the following convergences hold:*

$$\frac{1}{\varepsilon}\mathcal{T}_\varepsilon\big(\mathcal{R}_\varepsilon(w_\varepsilon)\big) \rightharpoonup \widehat{w}' \quad \textit{weakly in } L^p(\Omega; W^{1,p}(Y)),$$
$$\mathcal{T}_\varepsilon\big(\nabla \mathcal{R}_\varepsilon(w_\varepsilon)\big) \rightharpoonup \nabla_y \widehat{w}' \quad \textit{weakly in } L^p(\Omega \times Y),$$
$$\mathcal{T}_\varepsilon(\nabla w_\varepsilon) \rightharpoonup \nabla w + \nabla_y \widehat{w}' \quad \textit{weakly in } L^p(\Omega \times Y).$$

Actually, the connection with the $\widehat{w}$ of Theorem 3.5 is given by

$$\widehat{w} = \widehat{w}' - \mathcal{M}_{_Y}(\widehat{w}').$$

Proof. Due to estimates of Proposition 4.5, up to a subsequence, there exists $\widehat{w}'$ in $L^p(\Omega; W^{1,p}_{per}(Y))$ such that

$$\frac{1}{\varepsilon}\mathcal{T}_\varepsilon\big(\mathcal{R}_\varepsilon(w_\varepsilon)\big) \rightharpoonup \widehat{w}' \quad \text{weakly in } L^p(\Omega; W^{1,p}(Y)),$$
$$\mathcal{T}_\varepsilon\big(\nabla \mathcal{R}_\varepsilon(w_\varepsilon)\big) \rightharpoonup \nabla_y \widehat{w}' \quad \text{weakly in } L^p(\Omega \times Y).$$

Combining with convergence (iii) of Proposition 4.7 shows that

$$\mathcal{T}_\varepsilon\big(\nabla w_\varepsilon\big) \rightharpoonup \nabla w + \nabla_y \widehat{w}' \quad \text{weakly in } L^p(\Omega \times Y).$$

So $\nabla_y \widehat{w} \equiv \nabla_y \widehat{w}'$ in $L^p(\Omega \times Y)$. Since $\mathcal{M}_{_Y}(\widehat{w}) = 0$, it follows that $\widehat{w} = \widehat{w}' - \mathcal{M}_{_Y}(\widehat{w}')$. □

Remark 4.9. In the previous proposition, one can actually compute the average of $\widehat{w}'$. One can check that $\mathcal{M}_{_Y}(\widehat{w}') = -\mathcal{M}_{_Y}(y) \cdot \nabla w$, and consequently,

$$\frac{1}{\varepsilon}\Big(\mathcal{T}_\varepsilon(w_\varepsilon) - \mathcal{M}_\varepsilon(w_\varepsilon)\Big) \rightharpoonup y \cdot \nabla w + \widehat{w}' \qquad \text{weakly in } L^p(\Omega; W^{1,p}(Y)).$$

5. Periodic unfolding and the standard homogenization problem.

DEFINITION 5.1. *Let $\alpha, \beta \in \mathbb{R}$, such that $0 < \alpha < \beta$ and $\mathcal{O}$ be an open subset of $\mathbb{R}^n$. Denote by $M(\alpha, \beta, \mathcal{O})$ the set of the $n \times n$ matrices $A = (a_{ij})_{1 \leq i,j \leq n} \in (L^\infty(\mathcal{O}))^{n \times n}$ such that, for any $\lambda \in \mathbb{R}^n$ and a.e. on $\mathcal{O}$,*

$$(A(x)\lambda, \lambda) \geq \alpha|\lambda|^2, \qquad |A(x)\lambda| \leq \beta|\lambda|.$$

Let $A^\varepsilon = (a_{ij}^\varepsilon)_{1\le i,j\le n}$ be a sequence of matrices in $M(\alpha,\beta,\Omega)$. For f given in $H^{-1}(\Omega)$, consider the Dirichlet problem

$$\begin{cases} -\text{div } (A^\varepsilon \nabla u_\varepsilon) = f & \text{in } \Omega, \\ u^\varepsilon = 0 & \text{on } \partial\Omega. \end{cases} \tag{5.1}$$

By the Lax–Milgram theorem, there exists a unique $u^\varepsilon \in H_0^1(\Omega)$ satisfying

$$\int_\Omega A^\varepsilon \nabla u_\varepsilon \, \nabla v \, dx = \langle f, v\rangle_{H^{-1}(\Omega),H_0^1(\Omega)}, \quad \forall v \in H_0^1(\Omega), \tag{5.2}$$

which is the variational formulation of (5.1). Moreover, one has the apriori estimate

$$\|u_\varepsilon\|_{H_0^1(\Omega)} \le \frac{1}{\alpha}\|f\|_{H^{-1}(\Omega)}. \tag{5.3}$$

Consequently, there exist u_0 in $H_0^1(\Omega)$ and a subsequence, still denoted ε, such that

$$u_\varepsilon \rightharpoonup u_0 \quad \text{weakly in } H_0^1(\Omega). \tag{5.4}$$

We are now interested to give a limit problem, the "homogenized" problem, satisfied by u_0. This is called standard homogenization, and the answer, for some classes of A^ε, can be found in many works, starting with the classical book by Bensoussan, Lions, and Papanicolaou [11] (see, for instance, Cioranescu and Donato [30] and the references herein). We now recall it.

THEOREM 5.2 (standard periodic homogenization). *Let $A = (a_{ij})_{1\le i,j\le n}$ belong to $M(\alpha,\beta,Y)$, where $a_{ij} = a_{ij}(y)$ are Y-periodic. Set*

$$A^\varepsilon(x) = \left(a_{ij}\left(\frac{x}{\varepsilon}\right)\right)_{1\le i,j\le n} \quad \text{a.e. on } \Omega. \tag{5.5}$$

Let u_ε be the solution of the corresponding problem (5.1), with f in $H^{-1}(\Omega)$. Then the whole sequence $\{u_\varepsilon\}$ converges to a limit u_0, which is the unique solution of the homogenized problem

$$\begin{cases} -\text{div } (A^0 \nabla u_0) = \displaystyle\sum_{i,j=1}^n a_{ij}^0 \frac{\partial^2 u_0}{\partial x_i \partial x_j} = f & \text{in } \Omega, \\ u_0 = 0 & \text{on } \partial\Omega, \end{cases} \tag{5.6}$$

where the constant matrix $A^0 = (a_{ij}^0)_{1\le i,j\le n}$ is elliptic and given by

$$a_{ij}^0 = \mathcal{M}_Y\left(a_{ij} - \sum_{k=1}^n a_{ik}\frac{\partial \widehat{\chi}_j}{\partial y_k}\right) = \mathcal{M}_Y(a_{ij}) - \mathcal{M}_Y\left(\sum_{k=1}^n a_{ik}\frac{\partial \widehat{\chi}_j}{\partial y_k}\right). \tag{5.7}$$

In (5.7), the functions $\widehat{\chi}_j$ $(j = 1,\dots,n)$, often referred to as correctors, are the solutions of the cell systems

$$\begin{cases} -\displaystyle\sum_{i,k=1}^n \frac{\partial}{\partial y_i}\left(a_{ik}\frac{\partial(\widehat{\chi}_j - y_j)}{\partial y_k}\right) = 0 & \text{in } Y, \\ \mathcal{M}_Y(\widehat{\chi}_j) = 0, \\ \widehat{\chi}_j \quad Y\text{-periodic}. \end{cases} \tag{5.8}$$

As will be seen below, using the periodic unfolding, the proof of this theorem is elementary! Actually, with the same proof, a more general result can be obtained, with matrices A^ε.

THEOREM 5.3 (periodic homogenization via unfolding). *Let u_ε be the solution of problem (5.1), with f in $H^{-1}(\Omega)$, and $A^\varepsilon = (a_{ij}^\varepsilon)_{1\le i,j\le n}$ be a sequence of matrices in $M(\alpha,\beta,\Omega)$. Suppose that there exists a matrix B such that*

$$B^\varepsilon \doteq \mathcal{T}_\varepsilon\big(A^\varepsilon\big) \to B \quad \text{strongly in } [L^1(\Omega\times Y)]^{n\times n}. \tag{5.9}$$

Then there exists $u_0 \in H_0^1(\Omega)$ and $\widehat{u} \in L^2(\Omega; H^1_{per}(Y))$ such that

$$\begin{aligned} &u_\varepsilon \rightharpoonup u_0 \quad \text{weakly in } H_0^1(\Omega),\\ &\mathcal{T}_\varepsilon(u_\varepsilon) \rightharpoonup u_0 \quad \text{weakly in } L^2(\Omega; H^1(Y)),\\ &\mathcal{T}_\varepsilon(\nabla u_\varepsilon) \rightharpoonup \nabla u_0 + \nabla_y \widehat{u} \quad \text{weakly in } L^2(\Omega\times Y), \end{aligned} \tag{5.10}$$

and the pair $(u_0, \widehat{u})$ is the unique solution of the problem

$$\begin{cases} \forall \Psi \in H_0^1(\Omega),\ \forall \Phi \in L^2(\Omega;\, H^1_{per}(Y)),\\ \dfrac{1}{|Y|}\displaystyle\int_{\Omega\times Y} B(x,y)\big[\nabla u_0(x) + \nabla_y \widehat{u}(x,y)\big]\big[\nabla \Psi(x) + \nabla_y \Phi(x,y)\big]\, dxdy \\ \qquad\qquad = \ \langle f, \Psi\rangle_{H^{-1}(\Omega), H_0^1(\Omega)}. \end{cases} \tag{5.11}$$

Remark 5.4. System (5.11) is the unfolded formulation of the homogenized limit problem. It is of standard variational form in the space

$$\mathcal{H} = H_0^1(\Omega) \times L^2(\Omega;\, H^1_{per}(Y)/\mathbb{R}).$$

Remark 5.5. Hypothesis (5.9) implies that $B \in M(\alpha,\beta,\Omega\times Y)$.

Remark 5.6. If A^ε is of the form (5.5), then $B(x,y) = A(y)$. In the case where $A^\varepsilon(x) = A_1(x)A_2(\frac{x}{\varepsilon})$, one has (5.9), with $B(x,y) = A_1(x)A_2(y)$.

Remark 5.7. Let us point out that every matrix $B \in M(\alpha,\beta,\Omega\times Y)$ can be approached by the sequence of matrices A^ε in $M(\alpha,\beta,\Omega)$, with A^ε defined as follows:

$$A^\varepsilon = \begin{cases} \mathcal{U}_\varepsilon(B) & \text{in } \widehat{\Omega}_\varepsilon,\\ \alpha I_n & \text{in } \Lambda_\varepsilon. \end{cases}$$

Proof of Theorem 5.3. Convergences (5.10) follow from estimate (5.3), Corollary 3.3, and Proposition 4.7, respectively.

Let us choose $v = \Psi$, with $\Psi \in H_0^1(\Omega)$ as test function in (5.2). The integration formula (2.5) from Proposition 2.7 gives

$$\frac{1}{|Y|}\int_{\Omega\times Y} B^\varepsilon\ \mathcal{T}_\varepsilon\big(\nabla u_\varepsilon\big)\mathcal{T}_\varepsilon\big(\nabla\Psi\big)\, dxdy \overset{\mathcal{T}_\varepsilon}{\simeq}\ \langle f, \Psi\rangle_{H^{-1}(\Omega), H_0^1(\Omega)}. \tag{5.12}$$

We are allowed to pass to the limit in (5.12), due to (5.9), (5.10), and Proposition 2.9(i), to get

$$\frac{1}{|Y|}\int_{\Omega\times Y} B(x,y)\big[\nabla u_0(x) + \nabla_y \widehat{u}(x,y)\big]\nabla\Psi(x)\, dxdy = \ \langle f, \Psi\rangle_{H^{-1}(\Omega), H_0^1(\Omega)}. \tag{5.13}$$

Now, taking in (5.2), as test function $v^\varepsilon(x) = \varepsilon\Psi(x)\psi(\frac{x}{\varepsilon})$, $\Psi \in \mathcal{D}(\Omega)$, $\psi \in H^1_{per}(Y)$, one has, due to (2.5) and Proposition 2.7,

$$\frac{1}{|Y|}\int_{\Omega\times Y} B^\varepsilon\ \mathcal{T}_\varepsilon\big(\nabla u_\varepsilon\big)\,\varepsilon\psi(y)\mathcal{T}_\varepsilon\big(\nabla\Psi\big)\,dxdy + \frac{1}{|Y|}\int_{\Omega\times Y} B^\varepsilon\ \mathcal{T}_\varepsilon\big(\nabla u_\varepsilon\big)\nabla_y\psi(y)\mathcal{T}_\varepsilon\big(\Psi\big)\,dxdy \overset{\mathcal{T}_\varepsilon}{\simeq}\ \langle f, v_\varepsilon\rangle_{H^{-1}(\Omega),H^1_0(\Omega)}.$$

Since $v^\varepsilon \rightharpoonup 0$ in $H^1_0(\Omega)$, we get at the limit

$$\frac{1}{|Y|}\int_{\Omega\times Y} B(x,y)\big[\nabla u_0(x) + \nabla_y\widehat{u}(x,y)\big]\Psi(x)\nabla_y\psi(y)\,dxdy = 0.$$

By the density of the tensor product $\mathcal{D}(\Omega)\otimes H^1_{per}(Y)$ in $L^2(\Omega; H^1_{per}(Y))$, this holds for all Φ in $L^2(\Omega; H^1_{per}(Y))$. □

Remark 5.8. As in the two-scale method, (5.11) gives $\widehat{u}$ in terms of ∇u_0 and yields the standard form of the homogenized equation, i.e., (5.6). In the simple case where $A(x,y) = A(y) = (a_{ij}(y))_{1\le i,j\le n}$, it is easily seen that

$$\widehat{u} = \sum_{i=1}^n \frac{\partial u_0}{\partial x_i}\widehat{\chi}_i, \tag{5.14}$$

and that the limit B is precisely the matrix A^0 which was defined in Theorem 5.2 by (5.7) and (5.8).

PROPOSITION 5.9 (convergence of the energy). *Under the hypotheses of Theorem* 5.3*,*

$$\begin{cases} \lim\limits_{\varepsilon\to 0}\displaystyle\int_\Omega A^\varepsilon\nabla u_\varepsilon\nabla u_\varepsilon\,dx = \frac{1}{|Y|}\int_{\Omega\times Y} B\big[\nabla u_0 + \nabla_y\widehat{u}\big]\,\big[\nabla u_0 + \nabla_y\widehat{u}\big]\,dx\,dy, \\ \lim\limits_{\varepsilon\to 0}\displaystyle\int_{\Lambda_\varepsilon} |\nabla u_\varepsilon|^2\,dx = 0. \end{cases} \tag{5.15}$$

Proof. By standard weak lower-semicontinuity, one successively obtains

$$\begin{aligned} \frac{1}{|Y|}\int_{\Omega\times Y} B\big[\nabla u_0 + \nabla_y\widehat{u}\big]\,\big[\nabla u_0 + \nabla_y\widehat{u}\big]\,dx\,dy & \\ \le \liminf_{\varepsilon\to 0}\frac{1}{|Y|}\int_{\Omega\times Y} B^\varepsilon\ \mathcal{T}_\varepsilon\big(\nabla u_\varepsilon\big)\mathcal{T}_\varepsilon\big(\nabla u_\varepsilon\big)\,dx\,dy & \\ \le \limsup_{\varepsilon\to 0}\frac{1}{|Y|}\int_{\Omega\times Y} B^\varepsilon\ \mathcal{T}_\varepsilon\big(\nabla u_\varepsilon\big)\mathcal{T}_\varepsilon\big(\nabla u_\varepsilon\big)\,dx\,dy & \\ \le \limsup_{\varepsilon\to 0}\int_\Omega A^\varepsilon\ \nabla u_\varepsilon\nabla u_\varepsilon\,dx = \limsup_{\varepsilon\to 0}\langle f, u_\varepsilon\rangle_{H^{-1}(\Omega),H^1_0(\Omega)} & \\ = \langle f, u_0\rangle_{H^{-1}(\Omega),H^1_0(\Omega)} = \frac{1}{|Y|}\int_{\Omega\times Y} B\big[\nabla u_0 + \nabla_y\widehat{u}\big]\,\big[\nabla u_0 + \nabla_y\widehat{u}\big]\,dx\,dy, & \end{aligned}$$

which gives the first convergence in (5.15), as well as

$$\limsup_{\varepsilon\to 0}\int_{\Lambda_\varepsilon} A^\varepsilon\ \nabla u_\varepsilon\nabla u_\varepsilon\,dx = 0,$$

which implies the second convergence in (5.15). □

Remark 5.10. From the above proof, we also have

$$\lim_{\varepsilon\to 0}\frac{1}{|Y|}\int_{\Omega\times Y} B^\varepsilon\ \mathcal{T}_\varepsilon\big(\nabla u_\varepsilon\big)\mathcal{T}_\varepsilon\big(\nabla u_\varepsilon\big)\ dx\,dy = \frac{1}{|Y|}\int_{\Omega\times Y} B\big[\nabla u_0+\nabla_y\widehat{u}\big]\ \big[\nabla u_0+\nabla_y\widehat{u}\big]\ dx\,dy.$$

COROLLARY 5.11. *The following strong convergence holds:*

$$\mathcal{T}_\varepsilon(\nabla u_\varepsilon)\to\nabla u_0+\nabla_y\widehat{u}\quad \textit{strongly in } L^2(\Omega\times Y). \tag{5.16}$$

Proof. We have successively

$$\begin{aligned}\frac{1}{|Y|}\int_{\Omega\times Y} B^\varepsilon\big[\mathcal{T}_\varepsilon\big(\nabla u_\varepsilon\big)-\nabla u_0-\nabla_y\widehat{u}\big]\big[\mathcal{T}_\varepsilon\big(\nabla u_\varepsilon\big)-\nabla u_0-\nabla_y\widehat{u}\big]\ dx\,dy&\\ = \frac{1}{|Y|}\int_{\Omega\times Y} B^\varepsilon\mathcal{T}_\varepsilon\big(\nabla u_\varepsilon\big)\mathcal{T}_\varepsilon\big(\nabla u_\varepsilon\big)\ dx\,dy&\\ -\frac{1}{|Y|}\int_{\Omega\times Y} B^\varepsilon\big[\nabla u_0+\nabla_y\widehat{u}\big]\mathcal{T}_\varepsilon\big(\nabla u_\varepsilon\big)\ dx\,dy&\\ -\frac{1}{|Y|}\int_{\Omega\times Y} B^\varepsilon\mathcal{T}_\varepsilon\big(\nabla u_\varepsilon\big)\big[\nabla u_0+\nabla_y\widehat{u}\big]\ dx\,dy&\\ +\frac{1}{|Y|}\int_{\Omega\times Y} B^\varepsilon\big[\nabla u_0+\nabla_y\widehat{u}\big]\ \big[\nabla u_0+\nabla_y\widehat{u}\big]\ dx\,dy.&\end{aligned}$$

Each term in the right-hand side converges, the first one due to Remark 5.10, and the others due to (5.10) and hypothesis (5.9). So, the right-hand side term converges to zero. Then convergence (5.16) is a consequence of the ellipticity of B^ε. ∎

Remark 5.12. One can consider problem (5.1) with a homogeneous Neumann boundary condition on $\partial\Omega$ provided a zero order term is added to the operator. This problem is variational on the space $H^1(\Omega)$ without any regularity condition on the boundary. The exact same method applies and gives the corresponding limit problem. In order for a nonhomogeneous Neumann boundary condition (or Robin condition) on $\partial\Omega$ to make sense, a well-behaved trace operator is needed from $H^1(\Omega)$ to $L^2(\Omega)$. In that case, the same method applies.

6. Some corrector results and error estimates. Under additional regularity assumptions on the homogenized solution u_0 and the cell-functions $\widehat{\chi}_j$, the strong convergence for the gradient of u_0 with a corrector is known (cf. [11] Chapter 1, section 5, [30] Chapter 8, section 3 and references therein). More precisely, suppose that $\nabla_y\widehat{\chi}_j\in(L^r(Y))^n,\ j=1,\dots,n$ and $\nabla u^0\in L^s(\Omega)$, with $1\le r,s<+\infty$ and such that $1/r+1/s=1/2$. Then

$$\nabla u_\varepsilon-\nabla u_0-\sum_{j=1}^n\frac{\partial u_0}{\partial x_j}\ \big(\nabla_y\widehat{\chi}_j\big)\Big(\frac{\cdot}{\varepsilon}\Big)\to 0\quad\text{strongly in } L^2(\Omega).$$

Our next result gives a corrector result *without any additional regularity assumption* on $\widehat{\chi}_j$, and its proof reduces to a few lines. We also include a new type of corrector.

THEOREM 6.1. *Under the hypotheses of Theorem* 5.2*, one has*

$$\nabla u_\varepsilon-\nabla u_0-\mathcal{U}_\varepsilon\big(\nabla_y\widehat{u}\big)\to 0\quad \textit{strongly in } L^2(\Omega). \tag{6.1}$$

In the case where $A^\varepsilon(x) = A(\{\frac{x}{\varepsilon}\}_Y)$, *the function* $u_0 + \varepsilon \sum_{i=1}^n \mathcal{Q}_\varepsilon(\frac{\partial u_0}{\partial x_i})\chi_i(\{\frac{\cdot}{\varepsilon}\}_Y)$ *belongs to* $H^1(\Omega)$, *and one has*

$$u_\varepsilon - u_0 - \varepsilon \sum_{i=1}^n \mathcal{Q}_\varepsilon\left(\frac{\partial u_0}{\partial x_i}\right)\chi_i\left(\left\{\frac{\cdot}{\varepsilon}\right\}_Y\right) \to 0 \quad \text{strongly in } H^1(\Omega). \tag{6.2}$$

Proof. From (5.15), (5.16), and Proposition 2.18(iii), one immediately has

$$\nabla u_\varepsilon - \mathcal{U}_\varepsilon\big(\nabla u_0\big) - \mathcal{U}_\varepsilon\big(\nabla_y \widehat{u}\big) \to 0 \quad \text{strongly in } L^2(\Omega).$$

But since ∇u_0 belongs to $L^2(\Omega)$, Corollary 2.26 implies that

$$\mathcal{U}_\varepsilon\big(\nabla u_0\big) \to \nabla u_0 \quad \text{strongly in } L^2(\Omega),$$

whence (6.1). From (4.4) in Proposition 4.2, the function $u_0+\varepsilon \sum_{i=1}^n \mathcal{Q}_\varepsilon(\frac{\partial u_0}{\partial x_i})\chi_i(\{\frac{\cdot}{\varepsilon}\}_Y)$ belongs to $H^1(\Omega)$. From (5.14), we obtain

$$\begin{aligned}
\nabla u_0 + \mathcal{U}_\varepsilon\left(\nabla_y \widehat{u}\right) - \nabla\left[u_0 + \varepsilon \sum_{i=1}^n \mathcal{Q}_\varepsilon\left(\frac{\partial u_0}{\partial x_i}\right)\chi_i\left(\left\{\frac{\cdot}{\varepsilon}\right\}_Y\right)\right] \\
= -\sum_{i=1}^n \left[\mathcal{Q}_\varepsilon\left(\frac{\partial u_0}{\partial x_i}\right) - \mathcal{M}_\varepsilon\left(\frac{\partial u_0}{\partial x_i}\right)\right]\nabla_y \chi_i\left(\left\{\frac{\cdot}{\varepsilon}\right\}_Y\right) \\
- \varepsilon \sum_{i=1}^n \nabla\left[\mathcal{Q}_\varepsilon\left(\frac{\partial u_0}{\partial x_i}\right)\right]\chi_i\left(\left\{\frac{\cdot}{\varepsilon}\right\}_Y\right),
\end{aligned}$$

and using estimate (4.2), Proposition 2.25(iii), and Corollary 4.3, one immediately gets the strong convergence in $L^2(\Omega)$ of the right-hand side in the above equality. Thanks to (6.1), one has (6.2). ∎

We end this section by recalling the error estimates obtained by Griso in [42], [44], and [45] for problem (5.1), with $f \in L^2(\Omega)$.

THEOREM 6.2 (see [42], [44]). *Suppose that* $\partial\Omega$ *is of class* $\mathcal{C}^{1,1}$. *The solution* u_ε *of* (5.1) *satisfies the following estimates:*

$$\left\|\nabla u_\varepsilon - \nabla u_0 - \sum_{i=1}^n \mathcal{Q}_\varepsilon\left(\frac{\partial u_0}{\partial x_i}\right)\nabla_y \widehat{\chi}_i\left(\left\{\frac{\cdot}{\varepsilon}\right\}\right)\right\|_{[L^2(\Omega)]^n} \le C\varepsilon^{1/2}\|f\|_{L^2(\Omega)},$$

$$\|u_\varepsilon - u_0\|_{L^2(\Omega)} + \left\|\rho\left(\nabla u_\varepsilon - \nabla u_0 - \sum_{i=1}^n \mathcal{Q}_\varepsilon\left(\frac{\partial u_0}{\partial x_i}\right)\nabla_y \widehat{\chi}_i\left(\frac{\cdot}{\varepsilon}\right)\right)\right\|_{[L^2(\Omega)]^n} \le C\varepsilon\|f\|_{L^2(\Omega)},$$

where $\widehat{\chi}_i$ *for* $i = 1, \dots, n$ *is defined by* (5.8) *and* $\rho = \rho(x)$ *is the distance between* $x \in \Omega$ *and the boundary* $\partial\Omega$. *The constant* C *depends on* n, A, *and* $\partial\Omega$.

COROLLARY 6.3 (see [44]). *Let* Ω' *be an open set strongly included in* Ω, *then*

$$\left\|u_\varepsilon - u_0 - \varepsilon \sum_{i=1}^n \mathcal{Q}_\varepsilon\left(\frac{\partial u_0}{\partial x_i}\right)\widehat{\chi}_i\left(\frac{\cdot}{\varepsilon}\right)\right\|_{H^1(\Omega')} \le C\varepsilon\|f\|_{L^2(\Omega)}.$$

The constant depends on n, A, Ω', *and* $\partial\Omega$.

In what follows in this paragraph, we suppose that the open set Ω is a bounded domain in $\mathbb{R}^n$, $n = 2$ or 3, of polygonal ($n = 2$) or polyhedral ($n = 3$) boundary. We

assume that Ω is on one side only of its boundary, and that Γ_0 is the union of some edges ($n = 2$) or some faces ($n = 3$) of $\partial\Omega$. Recall that classical regularity results show that the solution u_0 of the homogenized problem (5.6) belongs to $H^{1+s}(\Omega)$ for s in $]1/2, 1[$ ($s = 1$ if the domain is convex) depending only on $\partial\Omega$, on A^0, and satisfies the estimate

$$\|\nabla u_0\|_{H^{1+s}(\Omega)} \leq C\|f\|_{L^2(\Omega)}.$$

The error estimate for this case is given in the following result.

THEOREM 6.4 (see [45]). *The solution u_ε of problem (5.1) satisfies the estimate*

$$\left\|\nabla u_\varepsilon - \nabla u_0 - \sum_{i=1}^{n} \mathcal{Q}_\varepsilon\left(\frac{\partial u_0}{\partial x_i}\right) \nabla_y \widehat{\chi}_i\left(\frac{\cdot}{\varepsilon}\right)\right\|_{[L^2(\Omega)]^n} \leq C\varepsilon^{s/2}\|f\|_{L^2(\Omega)},$$

$$\|u_\varepsilon - u_0\|_{L^2(\Omega)} + \left\|\rho\left(\nabla u_\varepsilon - \nabla u_0 - \sum_{i=1}^{n} \mathcal{Q}_\varepsilon\left(\frac{\partial u_0}{\partial x_i}\right) \nabla_y \widehat{\chi}_i\left(\frac{\cdot}{\varepsilon}\right)\right)\right\|_{[L^2(\Omega)]^n} \leq C\varepsilon^{s}\|f\|_{L^2(\Omega)}.$$

The constants depend on n, A, and $\partial\Omega$.

COROLLARY 6.5 (see [45]). *Let Ω' be an open set strongly included in Ω, then*

$$\left\|u_\varepsilon - u_0 - \varepsilon \sum_{i=1}^{n} \mathcal{Q}_\varepsilon\left(\frac{\partial u_0}{\partial x_i}\right) \widehat{\chi}_i\left(\frac{\cdot}{\varepsilon}\right)\right\|_{H^1(\Omega')} \leq C\varepsilon^{s}\|f\|_{L^2(\Omega)}.$$

The constant depends on n, A, Ω', and $\partial\Omega$.

7. Periodic unfolding and multiscales. As we mentioned in the Introduction, the periodic unfolding method turns out to be particularly well-adapted to multiscales problems. As an example, we treat here a problem with two different small scales.

Consider two periodicity cells Y and Z, both having the properties introduced at the beginning of section 2 (each associated to its set of periods). Suppose that Y is "partitioned" in two nonempty disjoint open subsets Y_1 and Y_2, i.e., such that $Y_1 \cap Y_2 = \emptyset$ and $\overline{Y} = \overline{Y}_1 \cup \overline{Y}_2$.

Let $A^{\varepsilon\delta}$ be a matrix field defined by

$$A^{\varepsilon\delta}(x) = \begin{cases} A_1\left(\left\{\dfrac{x}{\varepsilon}\right\}_Y\right) & \text{for} \quad \left\{\dfrac{x}{\varepsilon}\right\}_Y \in Y_1, \\ A_2\left(\left\{\dfrac{\left\{\frac{x}{\varepsilon}\right\}_Y}{\delta}\right\}_Z\right) & \text{for} \quad \left\{\dfrac{x}{\varepsilon}\right\}_Y \in Y_2, \end{cases}$$

where A_1 is in $M(\alpha, \beta, Y_1)$ and A_2 in $M(\alpha, \beta, Z)$ (cf. Definition 5.1). Here we have two small scales, namely, ε and $\varepsilon\delta$, associated, respectively, to the cells Y and Z (see Figure 7).

Consider the problem

$$\int_\Omega A^{\varepsilon\delta}\nabla u_{\varepsilon\delta}\nabla w \, dx = \int_\Omega f\, w \, dx \qquad \forall w \in H_0^1(\Omega),$$

with f in $L^2(\Omega)$. The Lax–Milgram theorem immediately gives the existence and uniqueness of $u_{\varepsilon\delta}$ in $H_0^1(\Omega)$ satisfying the estimate

$$\|u_{\varepsilon\delta}\|_{H_0^1(\Omega)} \leq \frac{1}{\alpha}\|f\|_{L^2(\Omega)}.$$

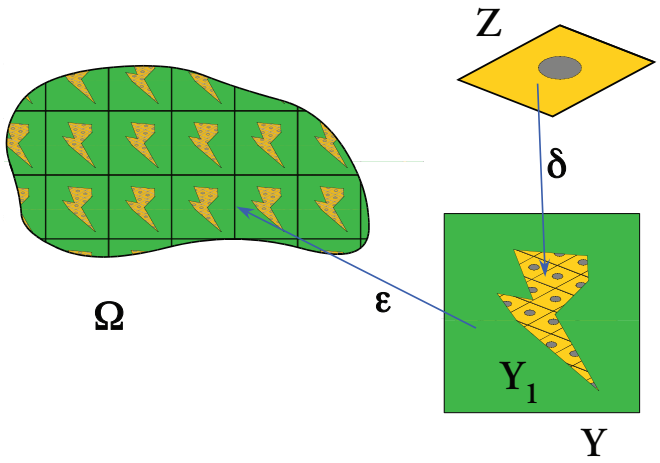

FIG. 7. *A domain with periodic scales ε and $\varepsilon\delta$.*

So, there is some u_0 such that, up to a subsequence,

$$u_{\varepsilon\delta} \rightharpoonup u_0 \quad \text{weakly in } H_0^1(\Omega).$$

Using the unfolding method for scale ε, as before we have

$$\begin{aligned}
&\mathcal{Q}_\varepsilon\big(u_{\varepsilon\delta}\big) \rightharpoonup u_0 \quad \text{weakly in } H_0^1(\Omega),\\
&\mathcal{T}_\varepsilon(u_{\varepsilon\delta}) \rightharpoonup u_0 \quad \text{weakly in } L^2(\Omega;\, H^1(Y)),\\
&\frac{1}{\varepsilon}\mathcal{T}_\varepsilon\big(\mathcal{R}_\varepsilon(u_{\varepsilon\delta})\big) \rightharpoonup \widehat{u} \quad \text{weakly in } L^2(\Omega;\, H^1(Y)),\\
&\mathcal{T}_\varepsilon\big(\nabla u_{\varepsilon\delta}\big) \rightharpoonup \nabla u_0 + \nabla_y \widehat{u} \quad \text{in } L^2(\Omega\times Y).
\end{aligned}$$

These convergences do not see the oscillations at the scale $\varepsilon\delta$. In order to capture them, one considers the restrictions to the set $\Omega\times Y_2$ defined by

$$v_{\varepsilon\delta}(x,y) \doteq \frac{1}{\varepsilon}\mathcal{T}_\varepsilon\big(\mathcal{R}_\varepsilon(u_{\varepsilon\delta})\big)|_{Y_2}.$$

Obviously,

$$v_{\varepsilon\delta} \rightharpoonup \widehat{u}|_{Y_2} \quad \text{weakly in } L^2(\Omega; H^1(Y_2)).$$

Now, we apply to $v_{\varepsilon\delta}$, a similar unfolding operation, denoted $\mathcal{T}_\delta^y$, for the variable y, thus adding a new variable $z\in Z$.

$$\mathcal{T}_\delta^y(v_{\varepsilon\delta})(x,y,z) = v_{\varepsilon\delta}\left(x, \delta\left[\frac{y}{\delta}\right]_Z + \delta z\right) \quad \text{for } x\in\Omega,\ \ y\in Y_2,\ \text{and } z\in Z.$$

It is essential to remark that all of the estimates and weak convergence properties which were shown for the original unfolding $\mathcal{T}_\varepsilon$ still hold for $\mathcal{T}_\delta^y$, with x being a mere parameter. For example, Proposition 4.7 and Theorem 3.5 adapted to this case imply that

$$\begin{aligned}
&\mathcal{T}_\delta^y\big(\nabla_y v_{\varepsilon\delta}\big) \rightharpoonup \nabla_y \widehat{u}|_{\Omega_2} + \nabla_z \widetilde{u} \quad \text{weakly in } L^2(\Omega\times Y_2\times Z),\\
&\mathcal{T}_\delta^y\Big(\mathcal{T}_\varepsilon\big(\nabla u_{\varepsilon\delta}\big)\Big) \rightharpoonup \nabla u_0 + \nabla_y \widehat{u} + \nabla_z \widetilde{u} \quad \text{weakly in } L^2(\Omega\times Y_2\times Z).
\end{aligned}$$

Under these conditions, the limit functions u_0, $\widehat{u}$, and $\widetilde{u}$ are characterized by the following result.

THEOREM 7.1. *The functions*

$$u_0 \in H^1_0(\Omega), \quad \widehat{u} \in L^2(\Omega, H^1_{per}(Y)/\mathbb{R}), \quad \widetilde{u} \in L^2(\Omega \times \Omega_2, H^1_{per}(Z)/\mathbb{R})$$

are the unique solutions of the variational problem

$$\begin{cases} \dfrac{1}{|Y||Z|}\displaystyle\int_\Omega\int_{Y_2}\int_Z A_2(z)\Big\{\nabla u_0 + \nabla_y\widehat{u} + \nabla_z\widetilde{u}\Big\}\Big\{\nabla\Psi + \nabla_y\Phi + \nabla_z\Theta\Big\}\,dx\,dy\,dz \\ \qquad + \dfrac{1}{|Y|}\displaystyle\int_\Omega\int_{Y_1} A_1(y)\Big\{\nabla u_0 + \nabla_y\widehat{u}\Big\}\Big\{\nabla\Psi + \nabla_y\Phi\Big\}\,dx\,dy = \displaystyle\int_\Omega f\,\Psi\,dx, \\ \forall\Psi \in H^1_0(\Omega), \quad \forall\Phi \in L^2(\Omega;\, H^1_{per}(Y)/\mathbb{R}), \forall\Theta \in L^2(\Omega \times \Omega_2, H^1_{per}(Z)/\mathbb{R}). \end{cases}$$

The proof uses test functions of the form

$$\Psi(x) + \varepsilon\Psi_1(x)\Phi_1\left(\frac{x}{\varepsilon}\right) + \varepsilon\delta\Psi_2(x)\Phi_2\left(\left\{\frac{x}{\varepsilon}\right\}_Y\right)\Theta_2\left(\frac{1}{\delta}\left\{\frac{x}{\varepsilon}\right\}_Y\right),$$

where Ψ, Ψ_1, Ψ_2 are in $\mathcal{D}(\Omega)$, Φ_1 in $H^1_{per}(Y)$, $\Phi_2 \in \mathcal{D}(Y_2)$, and $\Theta_2 \in H^1_{per}(Z)$.

Remark 7.2. The same theorem holds true for a general $A^{\varepsilon\delta}$ under the hypotheses

$$\mathcal{T}_\varepsilon(A^{\varepsilon\delta})\,1_{Y_1} \to A_1 \quad \text{strongly in } [L^1(\Omega \times Y_1)]^{n\times n},$$
$$\mathcal{T}^y_\delta\big(\mathcal{T}_\varepsilon(A^{\varepsilon\delta})\,1_{Y_2}\big) \to A_2 \quad \text{strongly in } [L^1(\Omega \times Y_2 \times Z)]^{n\times n}.$$

Proposition 5.9 (convergence of the energy) and Corollary 5.11 extend without any difficulty to the multiscale case.

PROPOSITION 7.3. *The convergence for the energy holds true:*

$$\begin{aligned} \lim_{\varepsilon,\delta\to 0}\int_\Omega A^{\varepsilon\delta}\nabla u_{\varepsilon\delta}\nabla u_{\varepsilon\delta}\,dx &= \frac{1}{|Y||Z|}\int_\Omega\int_{Y_2}\int_Z A_2(z)\Big\{\nabla u_0 + \nabla_y\widehat{u} + \nabla_z\widetilde{u}\Big\}\Big\{\nabla u_0 + \nabla_y\widehat{u} + \nabla_z\widetilde{u}\Big\}\,dx\,dy\,dz \\ &\quad + \frac{1}{|Y|}\int_\Omega\int_{Y_1} A_1(y)\Big\{\nabla u_0 + \nabla_y\widehat{u}\Big\}\Big\{\nabla u_0 + \nabla_y\widehat{u}\Big\}\,dx\,dy. \end{aligned}$$

COROLLARY 7.4. *The following strong convergences hold true:*

$$\mathcal{T}^y_\delta\big(\nabla_y v_{\varepsilon\delta}\big) \rightharpoonup \nabla_y\widehat{u}|_{\Omega_2} + \nabla_z\widetilde{u} \quad \textit{strongly in } L^2(\Omega \times Y_2 \times Z),$$
$$\mathcal{T}^y_\delta\Big(\mathcal{T}_\varepsilon\big(\nabla u_{\varepsilon\delta}\big)\Big) \rightharpoonup \nabla u_0 + \nabla_y\widehat{u} + \nabla_z\widetilde{u} \quad \textit{strongly in } L^2(\Omega \times Y_2 \times Z).$$

Remark 7.5. A corrector result, similar to that of Theorem 6.1, can be obtained.

Remark 7.6. Theorem 7.1 can be extended to the case of any finite number of distinct scales by a simple reiteration.

8. Further developments. The unfolding method has some interesting properties which make it suitable for more general situations than that presented here. In problems which are set on a domain Ω_ε which depends on the parameter ε, it may be difficult to have a good notion of convergence for the sequence of solutions u_ε. The traditional way is to extend the solution by 0 outside Ω_ε; however, this precludes the strong convergence of these extended functions in general. For the case of holes of the

size of order ε distributed ε-periodically, the unfolded sequence lives on a fixed domain. Similarly, for domains with ε-oscillating boundaries, a partial unfolding yields a function which is defined on a fixed domain.

We conclude by giving a list of publications making use of the unfolding method in several of these directions (both for linear and nonlinear problems).

– Reiterated homogenization: Meunier and Van Schaftingen [56].

– Electro-magnetism: Banks et al. [7], Bossavit, Griso, and Miara [15].

– Homogenization of thin piezoelectric shells: Ghergu et al. [39].

– Homogenization of diffusion deformation media: Griso and Rohan [46].

– Homogenization of the Stokes problem in porous media: Cioranescu, Damlamian, and Griso [25].

– Homogenization in perforated domains with Robin boundary conditions: Cioranescu, Donato and Zaki [31], [32].

– Homogenization in domains with oscillating boundaries: Damlamian and Pettersson [36].

– Homogenization of nonlinear integrals of the calculus of variations: Cioranescu, Damlamian, and De Arcangelis [27], [28], and [29].

– Homogenization of multivalued monotone operators of Leray–Lions type: Damlamian, Meunier, and Van Schaftingen [37].

– Thin junctions in linear elasticity: Blanchard, Gaudiello, and Griso [12], [13], Blanchard and Griso [14].

– Thin domains and free boundary problems arising in lubrication theory: Bayada, Martin, and Vazquez [9], [10].

– Elasticity problems in perforated domains: Griso and Sanchez-Rua [47].

– Neumann sieve and Dirichlet shield problems: Onofrei [60], Cioranescu et al. [26]. This last paper treats the case of domains with ε-periodically distributed "very small" holes (their size being a power of ε) on the boundary of which a homogeneous Dirichlet condition is prescribed. This requires the introduction of a rescaled unfolding operator (which originally appeared in the framework of the two-scale convergence in Casado-Díaz [20]).

Aknowledgments. We thank Petru Mironescu and Riccardo De Arcangelis for helpful comments and corrections.

ON THE ASYMPTOTIC STABILITY OF SMALL NONLINEAR DIRAC STANDING WAVES IN A RESONANT CASE*

NABILE BOUSSAID†

Abstract. We study the behavior of perturbations of small nonlinear Dirac standing waves. We assume that the linear Dirac operator of reference $H = D_m + V$ has only two double eigenvalues and that degeneracies are due to a symmetry of H (theorem of Kramers). In this case, we can build a small four-dimensional manifold of stationary solutions tangent to the first eigenspace of H. Then we assume that a resonance condition holds, and we build a center manifold of real codimension 8 around each stationary solution. Inside this center manifold any H^s perturbation of stationary solutions, with $s > 2$, stabilizes towards a standing wave. We also build center-stable and center-unstable manifolds, each one of real codimension 4. Inside each of these manifolds, we obtain stabilization towards the center manifold in one direction of time, while in the other, we have instability. Eventually, outside all of these manifolds, we have instability in the two directions of time. For localized perturbations inside the center manifold, we obtain a nonlinear scattering result.

Key words. Dirac equation, nonlinear PDE, asymptotic stability, Strichartz estimates, smoothness estimates, center manifold

Introduction. We study the asymptotic stability of stationary solutions of a time-dependent nonlinear Dirac equation.

A localized stationary solution of a given time-dependent equation represents a bound state of a particle. Like Rañada [39], we call it a *particle-like solution* (PLS). Many works have been devoted to the proof of the existence of such solutions for a wide variety of equations. Although their stability is a crucial problem (in particular, in a numerical computation or experiment), less attention has been devoted to this issue.

In this paper, we deal with the problem of stability of small PLSs of the following nonlinear Dirac equation:

$$\mathrm{i}\partial_t\psi = (D_m + V)\psi + \nabla F(\psi), \tag{0.1}$$

where ∇F is the gradient of $F : \mathbb{C}^4 \mapsto \mathbb{R}$ for the standard scalar product of $\mathbb{R}^8$. Here, D_m is the usual Dirac operator (see Thaller [48]) acting on $L^2(\mathbb{R}^3, \mathbb{C}^4)$:

$$D_m = \alpha \cdot (-\mathrm{i}\nabla) + m\beta = -\mathrm{i}\sum_{k=1}^{3} \alpha_k \partial_k + m\beta,$$

where $m \in \mathbb{R}_+^*$, $\alpha = (\alpha_1, \alpha_2, \alpha_3)$, and β are $\mathbb{C}^4$ Hermitian matrices satisfying

$$\begin{cases} \alpha_i\alpha_k + \alpha_k\alpha_i = 2\delta_{ik}\mathbf{1}_{\mathbb{C}^4}, & i,k \in \{1,2,3\}, \\ \alpha_i\beta + \beta\alpha_i = \mathbf{0}_{\mathbb{C}^4}, & i \in \{1,2,3\}, \\ \beta^2 = \mathbf{1}_{\mathbb{C}^4}. \end{cases}$$

*Received by the editors March 8, 2007; accepted for publication (in revised form) June 4, 2008; published electronically November 26, 2008. This work was partially supported by EPSRC grant EP/D054621.

http://www.siam.org/journals/sima/40-4/68464.html

†Laboratoire de Mathématiques de Besançon, Université de Franche-Comté, 16 Route de Gray, F-25030 Besançon Cedex, France (nabile.boussaid@univ-fcomte.fr).

Here, we choose

$$\alpha_i = \begin{pmatrix} 0 & \sigma_i \\ \sigma_i & 0 \end{pmatrix} \quad \text{and} \quad \beta = \begin{pmatrix} I_{\mathbb{C}^2} & 0 \\ 0 & -I_{\mathbb{C}^2} \end{pmatrix},$$

$$\text{where } \sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -\mathrm{i} \\ \mathrm{i} & 0 \end{pmatrix}, \quad \text{and} \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

In (0.1), V is the external potential field, and $F : \mathbb{C}^4 \mapsto \mathbb{R}$ is a nonlinearity with the following gauge invariance:

$$\forall (\theta, z) \in \mathbb{R} \times \mathbb{C}^4, \quad F(e^{i\theta} z) = F(z). \tag{0.2}$$

Some additional assumptions on F and V will be made in what follows. Nonlinearity with no potential arises in some Dirac models introduced by physicists to model either extended particles with self-interaction or particles in space-time with geometrical structure. In the latter case, physicists have shown that a relativistic theory sometimes imposes a fourth order nonlinear potential (i.e., a cubic nonlinearity) such as the square of a quadratic form on $\mathbb{C}^4$; see Rañada [39] and the references therein. We added a potential with special features to ensure the existence of small stationary solutions, whose existence and stability are easier to study.

Stationary solutions (PLSs) of (0.1) take the form $\psi(t, x) = e^{-\mathrm{i}Et}\phi(x)$, where ϕ satisfies

$$E\phi = (D_m + V)\phi + \nabla F(\phi). \tag{0.3}$$

We show that there exists a manifold of small solutions to (0.3) tangent to the first eigenspace of $D_m + V$ (see Proposition 1.1 below).

Concerning the asymptotic stability in the Schrödinger equation, the question has been solved in several cases. For small stationary solutions in the simple eigenvalue case it has been studied by Soffer and Weinstein [43, 44], Pillet and Wayne [38], and Gustafson, Nakanishi, and Tsai [22]. For the two eigenvalue case under a resonance condition for an excited state, the problem has been studied by Tsai and Yau [51, 53, 54, 52, 50] and Soffer and Weinstein [45, 46]. Another problem has been studied by Cuccagna [16, 17, 18], who considered the case of a big PLS, when the linearized operator has only one eigenvalue, and obtained the asymptotic stability of the manifold of ground states. Schlag [41] proved that any ground state of the cubic nonlinear Schrödinger equation in dimension 3 is orbitally unstable but possesses a stable manifold of codimension 9.

We also would like to mention the works of Buslaev and Perel'mann [12, 10, 11, 9], Buslaev and Sulem [14, 13], Weder [55], and Krieger and Schlag [31] in the one-dimensional Schrödinger case. Krieger and Schlag [31] proved a result similar to [41] in the one-dimensional case. Concerning two-dimensional nonlinear Schrödinger equations, Mizumachi [35, 36] studied the properties of unstable solutions, while Kirr and Zarnescu [30] proved the existence of small asymptotically stable states in a semilinear case.

In [7], we prove that there are stable directions for the PLS manifold under a nonresonance assumption on the spectrum of $H := D_m + V$. This gives a stable manifold containing the PLS manifold. But we were not able to say anything about solutions starting outside the stable manifold.

The results we present here state the existence of a stable manifold and describe the behavior of solutions starting outside of it. In fact, we prove the instability of the perturbations starting outside the stable manifold. We also prove stabilization towards stationary solutions inside the stable manifold for H^s perturbation with $s > 2$. We have been able to obtain it since we impose a resonance condition (see Assumption 1.5 below), while in [7], we assumed that there is no resonance phenomena.

When the perturbations are localized, we are able to push the analysis further and obtain a nonlinear scattering.

This paper is organized as follows.

In section 1, we present our main results and the assumptions we need. Subsection 1.1 is devoted to the statement of the time decay estimates of the propagator associated with $H = D_m + V$ on the continuous subspace. One estimate is a kind of smoothness result, in the sense of Kato (see, e.g., [27]), and the other is a Strichartz-type result. We prove these estimates with the propagation and dispersive estimates proved in [7]. In subsection 1.2, we state the existence of small stationary states forming a manifold tangent to an eigenspace of H. The study of the dynamics around such states leads us to our main results; see subsection 1.3 and 1.4. In subsection 1.3, we split a neighborhood of a stationary state into different parts, each giving rise to stabilization or instability. In subsection 1.4, we state our scattering result.

To prove our theorems, we consider our nonlinear system as a small perturbation of a linear equation. More precisely, in subsection 2.2, we show that the spectral properties of the linearized operator around a stationary state, presented in section 2, permit us to obtain, as in the linear case, some properties of the dynamics around a stationary state. We obtain center, center-stable, and center-unstable manifolds. In section 3, we obtain, with our time decay estimates, a stabilization towards the PLS manifold for H^s perturbation with $s > 2$ in the center manifold. Section 4 deals with the dynamics outside the center manifold. Eventually in section 5, we conclude our study.

Our results are the analogue, in the Dirac case, of some results of Tsai and Yau [54], Soffer and Weinstein [43], Pillet and Wayne [38], and Gustafson, Nakanishi, and Tsai [22] about the semilinear Schrödinger equation. The point which we did not investigate is the long time behavior of perturbation in the unstable direction. In [51, 53, 54, 52, 50, 45, 46], the authors show that such perturbations relax towards the ground states. Their analyses are based on the asymptotic stability of ground states under a resonance condition. In our case this question is still open and should be investigated. But we believe that the techniques used in the previously cited works will allow us to obtain a similar result. Indeed the phenomenon that leads to this relaxation, namely nonlinear resonance, is not specific to the Shrödinger operator or nonnegative operators. Such a phenomenon comes from the interaction between discrete and continuous modes allowed by the nonlinearity. So a Fermi golden rule assumption should have the same consequences in both Shrödinger and Dirac equations.

We should also mention that four manifolds appear in this paper: the PLS manifold, the center manifold, the center-stable manifold, and the center-unstable manifold. The PLS manifold used to be called center manifold by previous papers on the same subject. The terminology we choose to adopt here comes from dynamical system theory and especially from the center manifold theorem. All these manifolds are invariant manifolds of our equation, at least locally in time. The PLS manifold is a set of stationary solutions, while the center manifold is a set of solutions converging

to the PLS manifold and containing the PLS manifold. The center manifold in turn is the intersection of the center-stable and center-unstable manifolds. The roles of the center-stable and center-unstable manifolds are exchanged when time is reversed.

This paper is devoted to the study of the asymptotic stability of some Dirac equations. So we are investigating convergence of orbits. As far as we know, the question of the orbital stability which requires the orbits to stay close and not necessarily to converge is still open for Dirac equations. In the Schrödinger case, orbital stability results (see, e.g., [15], [56, 57], or [42, 21]) give that any solution stays near the PLS manifold. Unfortunately, orbital stability criteria applied to Schrödinger equations use the fact that Schrödinger operators are bounded from below. Hence the question of orbital stability for Dirac standing waves cannot be solved by a straightforward application of the methods used in the Schrödinger case.

1. Assumptions and statements.

1.1. Time decay estimates. We generalize, to small nonlinear perturbations, stability results for linear systems. These results, as in [7], follow from linear decay estimates. Here we use smoothness-type and Strichartz-type estimates deduced from propagation and dispersive estimates of [7]. Hence, we work within the same assumptions for V and $D_m + V$.

Assumption 1.1. The potential $V : \mathbb{R}^3 \mapsto S_4(\mathbb{C})$ *(self-adjoint* 4×4 *matrices)* is a smooth function such that there exists $\rho > 5$ with

$$\forall \alpha \in \mathbb{N}^3,\ \exists C > 0, \qquad \forall x \in \mathbb{R}^3,\ |\partial^\alpha V|(x) \leq \frac{C}{\langle x\rangle^{\rho+|\alpha|}}.$$

We notice that by the Kato–Rellich theorem, the operator

$$H := D_m + V$$

is essentially self-adjoint on $\mathcal{C}_0^\infty(\mathbb{R}^3, \mathbb{C}^4)$ and self-adjoint on $H^1(\mathbb{R}^3, \mathbb{C}^4)$.

We also mention that Weyl's theorem gives that the essential spectrum of H is $(-\infty, -m] \cup [+m, +\infty)$, and the work of Berthier and Georgescu [5, Theorems 6 and A] gives that there is no embedded eigenvalue. Hence the thresholds $\pm m$ are the only points of the continuous spectrum which can be associated with a wave of zero velocity. These waves perturb the spectral density and diminish the decay rate in the propagation and the dispersive estimates. We will work (as in [7]) within the following assumption.

Assumption 1.2. The operator H presents no resonance at thresholds and no eigenvalue at thresholds.

A resonance is a stationary solution in $H^{1/2}_{-\sigma} \setminus H^{1/2}$ for any $\sigma \in (1/2, \rho - 2)$, where H^t_σ is given by the following definition.

Definition 1.1 (weighted Sobolev space). *The weighted Sobolev space is defined by*

$$H^t_\sigma(\mathbb{R}^3, \mathbb{C}^4) = \left\{ f \in \mathcal{S}'(\mathbb{R}^3),\ \|\langle Q\rangle^\sigma \langle P\rangle^t f\|_2 < \infty \right\}$$

for $\sigma, t \in \mathbb{R}$. *We endow it with the norm*

$$\|f\|_{H^t_\sigma} = \|\langle Q\rangle^\sigma \langle P\rangle^t f\|_2.$$

If $t = 0$, *we write* L^2_σ *instead of* H^0_σ.

We have used the usual notation: $\langle u\rangle = \sqrt{1+u^2}$, $P = -i\nabla$, and Q is the operator of multiplication by x in $\mathbb{R}^3$.

Remark 1.1. Assumption 1.2 is generic in the following sense.

If V does not fulfill Assumption 1.2, then $(1 \pm \varepsilon)V$ does for nonzero small ε. As in [26, section 3] one can prove that resonances and eigenvalues at theresholds at $\pm m$ are in the kernel of $1 + (D_m \mp m)^{-1}V$ in $H^{1/2}_\sigma$ for any $\sigma \in (1/2, \rho - 2)$. Since $(D_m \mp m)^{-1}V$ is a compact operator in $H^{1/2}_\sigma$ (see proof of Lemma 1.1 below) for any $\sigma \in (1/2, \rho - 2)$, its spectrum is discrete, and hence if -1 is in its spectrum, then -1 is not in the spectrum of $\lambda(D_m \mp m)^{-1}V$ for $\lambda \neq 1$ but close to 1. This remark can be extended to any analytic operator valued functions $\lambda \to V(\lambda)$ satisfying Assumption 1.1.

Under the previous assumption one can prove the following lemma.

LEMMA 1.1. *The discrete spectrum of H is finite.*

Proof. To prove this lemma we show that there is no eigenvalue in a neighborhood of the thresholds $\pm m$. Since there is no other possible accumulation point for the discrete spectrum, this will be sufficient.

We will do the proof for m, since it is similar for $-m$. To do so, we show that $(H - z)^{-1}$ exists from $H^{-1/2}_\sigma$ to $H^{1/2}_{-\sigma}$ for any $\sigma \in (1/2, \rho - 2)$ and z close to m and $\Re z < m$. Since isolated eigenvectors belong to $H^{-1/2}_\sigma$ (see [23]), this will give the desired result.

We use the formula

$$H - z = (D_m - z)\left(1 + (D_m - z)^{-1}V\right)$$

for z close to m and $\Re z < m$. From [7, Proposition 2.4] (or [26, Lemma 2.1] and [48, section 1.E]), $z \mapsto (D_m - z)^{-1}$ is a continuous map from $\{z \in \mathbb{C}, \Im z > 0, \Re z > 0\}$ to $\mathcal{B}(H^{-1/2}_\sigma, H^{1/2}_{-\sigma})$ for any $\sigma \in (1/2, \rho - 2)$. The point is to prove the invertibility of $\left(1 + (D_m - z)^{-1}V\right)$ in $H^{-1/2}_\sigma$. Using continuity and Assumption 1.1, we see that it is enough to prove that $\left(1 + (D_m - m)^{-1}V\right)$ is invertible in $H^{-1/2}_\sigma$. This follows from Assumption 1.2 (see [7, Lemma 2.2 and Proof of Proposition 2.3]). ∎

Now let

$$\mathbf{P}_c(H) = \mathbf{1}_{(-\infty, -m|\cup[+m, +\infty)}(H)$$

be the projector associated with the continuous spectrum of H and let $\mathcal{H}_c$ be its range. Using [7, Theorem 1.1], we obtain a limiting absorption principle which gives the H-smoothness of $\langle Q\rangle^{-1}$ in the sense of Kato.

THEOREM 1.1 (Kato smoothness estimates). *If Assumptions* 1.1 *and* 1.2 *hold, then for any $\sigma \geq 1$ and $s \in \mathbb{R}$ one has*

$$\left\| \langle Q\rangle^{-\sigma} e^{-\mathrm{i}tH} \mathbf{P}_c(H)\, \psi \right\|_{L^2_t(\mathbb{R}, H^s)} \leq C \|\psi\|_{H^s}, \tag{1.1}$$

$$\left\| \int_{\mathbb{R}} e^{\mathrm{i}tH} \mathbf{P}_c(H) \langle Q\rangle^{-\sigma} F(t)\, dt \right\|_{H^s} \leq C \|F\|_{L^2_t(\mathbb{R}, H^s)}, \tag{1.2}$$

$$\left\| \int_{s<t} \langle Q\rangle^{-\sigma} e^{-\mathrm{i}(t-s)H} \mathbf{P}_c(H) \langle Q\rangle^{-\sigma} F(s)\, ds \right\|_{L^2_t(\mathbb{R}, H^s)} \leq C \|F\|_{L^2_t(\mathbb{R}, H^s)}. \tag{1.3}$$

Proof. We first prove (1.1). For $s = 0$, it is (see, e.g., [1, Proposition 7.11] or [40, Theorem XIII.25]) a consequence of the limiting absorption principle:

$$\sup_{\Im z\in(0,1)} \left\{ \left\| \langle Q\rangle^{-\sigma} (H-z)^{-1} P_c(H) \langle Q\rangle^{-\sigma} \right\|_2 \right\} < \infty, \tag{1.4}$$

which follows from [7, Theorem 1.1] (or Theorem 3.1 below) for $\sigma > 5/2$ using the fact that the Fourier transform in time of the propagator is the resolvent. Actually, the Fourier transform of

$$\langle Q\rangle^{-\sigma} e^{-\mathrm{i}t(H-\mathrm{i}\varepsilon)} \mathbf{P}_c(H) \mathbf{1}_{\mathbb{R}_+^*}(t) \langle Q\rangle^{-\sigma} f$$

in time is

$$\langle Q\rangle^{-\sigma} (H-\lambda-\mathrm{i}\varepsilon)^{-1} \mathbf{P}_c(H) \langle Q\rangle^{-\sigma} f$$

for $f \in L^2(\mathbb{R}^3, \mathbb{C}^4)$. Then we use the Born expansion

$$(H-z)^{-1} = (D_m-z)^{-1} - (D_m-z)^{-1}V(D_m-z)^{-1} + (D_m-z)^{-1}V(H-z)^{-1}V(D_m-z)^{-1},$$

the limiting absorption in [25, Theorem 2.1(i)] (the authors prove the identity (1.4) for $H = D_m$ when $\sigma = 1$), [7, Proposition 2.3], and the fact that $\|(1-P_c(H))\|_{\mathcal{B}(H^{1/2}_\sigma)}$ is bounded (since the discrete spectrum is finite and eigenvectors are exponentially decaying; see [23]) to obtain (1.4) for $\sigma = 1$. Hence we have concluded the proof for $s = 0$ and $\sigma \geq 1$. For $s \in 2\mathbb{Z}$ and $\sigma \geq 1$ it follows from the previous cases using the boundedness of $\langle H\rangle^s \langle D_m\rangle^{-s}$ and $\langle H\rangle^{-s}\langle D_m\rangle^s$ (which follow from the boundedness of V and its derivatives) and the boundedness of $\langle Q\rangle^{\mp\sigma}[\langle Q\rangle^{\pm\sigma}, H\rangle^s]\langle H\rangle^{-s}$ (which follow from multicommutator estimates; see [24, Appendix B]). The rest of the claim (1.1) follows by interpolation.

Estimates (1.1) and (1.2) are equivalent by duality.

To prove estimate (1.3) when $s = 0$ (the general case will follow in the same way as above), we notice that we have to prove that there exists $C > 0$ such that, for all $F, G \in L^2_t(\mathbb{R}, L^2(\mathbb{R}^3, \mathbb{C}^4))$, we have

$$\left| \iint_{\mathbb{R}^2} \left\langle G(t), \langle Q\rangle^{-\sigma} e^{-\mathrm{i}(t-s)H} \mathbf{P}_c(H) \mathbf{1}_{\mathbb{R}_+^*}(t-s) \langle Q\rangle^{-\sigma} F(s) \right\rangle \, dsdt \right| \leq C \|G\|_{L^2_t(\mathbb{R}, L^2(\mathbb{R}^3,\mathbb{C}^4))} \|F\|_{L^2_t(\mathbb{R}, L^2(\mathbb{R}^3,\mathbb{C}^4))}.$$

We can suppose that F and G are smooth functions with compact support from $\mathbb{R}\times\mathbb{R}^3$ to $\mathbb{C}^4$ and we just need to prove that there exists $C > 0$ such that, for all $\varepsilon > 0$ and for all $F, G \in \mathcal{C}^\infty_0(\mathbb{R}, L^2(\mathbb{R}^3, \mathbb{C}^4))$, we have

$$\left| \iint_{\mathbb{R}^2} \left\langle G(t), \langle Q\rangle^{-\sigma} e^{-\mathrm{i}(t-s)(H-\mathrm{i}\varepsilon)} \mathbf{P}_c(H) \mathbf{1}_{\mathbb{R}_+^*}(t-s) \langle Q\rangle^{-\sigma} F(s) \right\rangle \, dsdt \right| \leq C \|G\|_{L^2_t(\mathbb{R}, L^2(\mathbb{R}^3,\mathbb{C}^4))} \|F\|_{L^2_t(\mathbb{R}, L^2(\mathbb{R}^3,\mathbb{C}^4))}.$$

Then we take the limit as $\varepsilon \to 0$ and conclude using density arguments. Let us write $A_\varepsilon(t)$ for $\langle Q\rangle^{-\sigma} e^{-\mathrm{i}t(H-\mathrm{i}\varepsilon)} \mathbf{P}_c(H) \mathbf{1}_{\mathbb{R}_+^*}(t) \langle Q\rangle^{-\sigma}$; then we have to prove

$$\left| \int_{\mathbb{R}} \langle G(t), (A_\varepsilon * F)(t)\rangle \, dt \right| \leq C \|G\|_{L^2_t(\mathbb{R}, L^2(\mathbb{R}^3,\mathbb{C}^4))} \|F\|_{L^2_t(\mathbb{R}, L^2(\mathbb{R}^3,\mathbb{C}^4))}.$$

Using Plancherel's identity in $L^2_t(\mathbb{R}, L^2(\mathbb{R}^3, \mathbb{C}^4))$ and $A_\varepsilon * F \in L^2_t(\mathbb{R}, L^2(\mathbb{R}^3, \mathbb{C}^4))$, we just need to prove

$$\left| \int_{\mathbb{R}} \left\langle \widehat{G}(\lambda), \widehat{A_\varepsilon * F}(\lambda) \right\rangle \, d\lambda \right| \leq C \left\| \widehat{G} \right\|_{L^2_\lambda(\mathbb{R}, L^2(\mathbb{R}^3, \mathbb{C}^4))} \left\| \widehat{F} \right\|_{L^2_\lambda(\mathbb{R}, L^2(\mathbb{R}^3, \mathbb{C}^4))}.$$

Since the Fourier transform in time of the propagator is the resolvent, F is smooth with compact support, and $\varepsilon > 0$, we obtain

$$\widehat{A_\varepsilon * F}(\lambda) = \langle Q \rangle^{-\sigma} (H - \lambda - \mathrm{i}\varepsilon)^{-1} \mathbf{P}_c(H) \langle Q \rangle^{-\sigma} \widehat{F}(\lambda).$$

Hence we just have to prove

$$\left| \int_{\mathbb{R}} \left\langle \widehat{G}(\lambda), \langle Q \rangle^{-\sigma} (H - \lambda - \mathrm{i}\varepsilon)^{-1} \mathbf{P}_c(H) \langle Q \rangle^{-\sigma} \widehat{F}(\lambda) \right\rangle \, d\lambda \right|$$
$$\leq C \left\| \widehat{G} \right\|_{L^2_\lambda(\mathbb{R}, L^2(\mathbb{R}^3, \mathbb{C}^4))} \left\| \widehat{F} \right\|_{L^2_\lambda(\mathbb{R}, L^2(\mathbb{R}^3, \mathbb{C}^4))}.$$

This in turn follows from the limiting absorption principle (1.4) just proved. ∎

To state the next result, we need the following definition.

DEFINITION 1.2 (Besov space). *For $s \in \mathbb{R}$ and $1 \leq p, q \leq \infty$, the Besov space $B^s_{p,q}(\mathbb{R}^3, \mathbb{C}^4)$ is the space of all $f \in \mathcal{S}'(\mathbb{R}^3, \mathbb{C}^4)$ (dual of the Schwartz space) such that*

$$\|f\|_{B^s_{p,q}} = \left(\sum_{j \in \mathbb{N}} 2^{jsq} \|\varphi_j * f\|_p^q \right)^{\frac{1}{q}} < +\infty$$

with $\widehat{\varphi} \in \mathcal{C}^\infty_0(\mathbb{R}^n \setminus \{0\})$ such that $\sum_{j \in \mathbb{Z}} \widehat{\varphi}(2^{-j}\xi) = 1$ for all $\xi \in \mathbb{R}^3 \setminus \{0\}$, $\widehat{\varphi_j}(\xi) = \widehat{\varphi}(2^{-j}\xi)$ for all $j \in \mathbb{N}^*$ and for all $\xi \in \mathbb{R}^3$, and $\widehat{\varphi_0} = 1 - \sum_{j \in \mathbb{N}^*} \widehat{\varphi_j}$. It is endowed with the natural norm $f \in B^s_{p,q}(\mathbb{R}^3, \mathbb{C}^4) \mapsto \|f\|_{B^s_{p,q}}$.

Using the dispersive estimates of [7, Theorem 1.2] and [29, Theorem 10.1], we obtain the following theorem.

THEOREM 1.2 (Strichartz estimates). *If Assumptions 1.1 and 1.2 hold, then for any $2 \leq p, q \leq \infty$, $\theta \in [0, 1]$, with $(1 - \frac{2}{q})(1 \pm \frac{\theta}{2}) = \frac{2}{p}$ and $(p, \theta) \neq (2, 0)$, and for any reals s, s' with $s' - s \geq \alpha(q)$, where $\alpha(q) = (1 + \frac{\theta}{2})(1 - \frac{2}{q})$, there exists a positive constant C such that*

$$\left\| e^{-\mathrm{i}tH} P_c(H) \psi \right\|_{L^p_t(\mathbb{R}, B^s_{q,2}(\mathbb{R}^3, \mathbb{C}^4))} \leq C \|\psi\|_{H^{s'}(\mathbb{R}^3, \mathbb{C}^4)}, \tag{1.5}$$

$$\left\| \int e^{\mathrm{i}tH} P_c(H) F(t) \, dt \right\|_{H^s} \leq C \|F\|_{L^{p'}_t(\mathbb{R}, B^{s'}_{q',2}(\mathbb{R}^3, \mathbb{C}^4))}, \tag{1.6}$$

$$\left\| \int_{s<t} e^{-\mathrm{i}(t-s)H} P_c(H) F(s) \, ds \right\|_{L^p_t(\mathbb{R}, B^{-s}_{q,2}(\mathbb{R}^3, \mathbb{C}^4))} \leq C \|F\|_{L^{\tilde{p}'}_t(\mathbb{R}, B^{\tilde{s}}_{\tilde{q}',2}(\mathbb{R}^3, \mathbb{C}^4))}, \tag{1.7}$$

for any $r \in [1, \infty]$, $(\tilde{q}, \tilde{p})$ chosen like (q, p), and $s + \tilde{s} \geq \alpha(q) + \alpha(\tilde{q})$.

Proof. This is a consequence of [29, Theorem 10.1] applied to $U(t) = e^{-\mathrm{i}tH} P_c(H)$, using [7, Theorem 1.2] (or Theorem 3.2 below) and

$$B^{(1+\frac{\theta}{2})(1-\frac{2}{q})+s}_{q,2} \hookrightarrow (H^s, B^{1+\theta/2+s}_{1,2})_{2/((1\pm\theta/2)p),2}$$

continuously for $p \geq 2$ ($p \neq 2$ if $\theta = 0$) and $1/q = 1 - 1/((1 \pm \theta/2)p)$. For these embeddings, we refer to the proof of [4, Theorem 6.4.5] as well as the properties of the real interpolation (see [4] or [49]). More precisely, for $\theta = 0$ or 1 it is obvious. In the other cases, we work as in the proof of [4, Theorem 6.4.5(3)].

We use [4, Theorem 6.4.3] ($B^s_{p,2}$ is a retract of $l^s_2(L^p)$ for $s \in \mathbb{R}$ and $p, q \in [1, \infty]$) and [4, Theorem 5.6.2] (about the interpolation of $l^s_2(L^p)$ spaces) with [4, Theorem 5.2.1] (about the interpolation of L^p spaces). Then we conclude using the injection of L^p spaces into some Lorentz spaces [4, section 1.3 and Exercice 1.6.8].

In the case $\theta \neq 0$, the proof is actually simpler. We can prove it using the usual TT^* method and the Hölder inequality instead of the Hardy–Littlewood–Sobolev inequality. □

1.2. The manifold of PLS. We study the nonlinear Dirac equation

$$\begin{cases} \mathrm{i}\partial_t \psi = H\psi + \nabla F(\psi), \\ \psi(0, \cdot) = \psi_0 \end{cases} \tag{1.8}$$

with $\psi \in \mathcal{C}^1(I, H^1(\mathbb{R}^3, \mathbb{C}^4))$ for some real open interval I which contains 0 and $H = D_m + V$. The nonlinearity $F : \mathbb{C}^4 \mapsto \mathbb{R}$ is a differentiable map for the real structure of $\mathbb{C}^4$, and hence the ∇ symbol has to be understood for the real structure of $\mathbb{C}^4$: for the usual Hermitian product of $\mathbb{C}^4$, one has

$$DF(v)h = \Re\langle \nabla F(v), h\rangle.$$

If F has a gauge invariance (see (0.2) or Assumption 1.4), this equation may have stationary solutions, i.e., solutions of the form $e^{-\mathrm{i}Et}\phi_0$, where ϕ_0 satisfies the nonlinear stationary equation

$$E\phi_0 = H\phi_0 + \nabla F(\phi_0).$$

We notice that the Dirac operator D_m has an interesting invariance property due to its matrix structure. This invariance can be shared by some perturbed Dirac operators and gives a consequence of a theorem of Kramers; see [2, 37]. Indeed if we introduce K, the antilinear operator defined by

$$K \begin{pmatrix} \psi \\ \chi \end{pmatrix} = \begin{pmatrix} \sigma_2 \overline{\psi} \\ \sigma_2 \overline{\chi} \end{pmatrix} \quad \text{with } \sigma_2 = \begin{pmatrix} 0 & -\mathrm{i} \\ \mathrm{i} & 0 \end{pmatrix}, \tag{1.9}$$

the operator D_m commutes with K. So if V also commutes with K, we obtain that the eigenspaces of H are always of even dimension. Here we work with the following assumption.

Assumption 1.3. The potential V commutes to K. The operator $H := D_m + V$ has only two double eigenvalues $\lambda_0 < \lambda_1$, with $\{\phi_0, K\phi_0\}$ and $\{\phi_1, K\phi_1\}$ as associated orthonormalized bases.

Remark 1.2. This assumption is fulfilled by $V = \lambda\phi\beta$, where ϕ is a smooth version of the characteristic function of the unit ball and λ is big enough to obtain a first set of double eigenvalues $\pm E$ with E close to m for H but not too much to avoid the appearance of a second set of eigenvalues. Computations have been sketched in [6], and similar ones have been done in detail for $V = \lambda\phi Id_{\mathbb{C}^4}$ in [47].

We also need the next assumption.

Assumption 1.4. The function $F : \mathbb{C}^4 \mapsto \mathbb{R}$ is in $\mathcal{C}^\infty(\mathbb{R}^8, \mathbb{R})$ and satisfies $F(z) = O(|z|^4)$ as $z \to 0$. Moreover, it has the following invariance property:

$$\forall z \in \mathbb{C}^4,\ \forall u_1, u_2 \in \mathbb{C}^2 \text{ with } |u_1|^2 + |u_2|^2 = 1,\ F(u_1 z + u_2 K z) = F(z).$$

Remark 1.3. The invariance property is actually equivalent to both the gauge invariance with respect to the semigroups generated by i and $e^{\mathrm{i}\theta}K$ for all real θ.

We note that this assumption includes the cubic nonlinearity mentionned in the introduction. We were not able to go beyond the cubic order in the present work. This comes from the fact that here orbital stability does not hold or, equivalently, we have no a priori control in the L^2 norm of the perturbation. We bound it with $L^\infty_t H^s$ and $L^2_t B^\beta_{\infty,2}$ ($s > \beta + 2 > 2$) using Duhamel's formula and Theorem 1.2. Our method asks the nonlinearity to be at least cubic; see the proof of Lemma 3.8.

We also note that both the nonlinearity and the potential are smooth. This is not optimal. Concerning the nonlinearity, what we have in mind is a smooth cubic nonlinearity. For instance, a nonlinearity of class $\mathcal{C}^4$ should be enough. It can be improved, but we are not looking for an optimal result in this direction. The advantage of choosing smooth potentials and nonlinearities here is that it allows stationary states to be smooth. It also avoids having to introduce a new parameter giving a bound for the regularity of our solutions.

We obtain the following proposition.

PROPOSITION 1.1 (PLS manifold). *If Assumptions* 1.1–1.4 *hold, then for any* $\sigma \in \mathbb{R}^+$*, there exist* Ω*, a neighborhood of* 0 *in* $\mathbb{C}^2$*; a smooth map*

$$h : \Omega \mapsto \{\phi_0, K\phi_0\}^\perp \cap H^2(\mathbb{R}^3, \mathbb{C}^4) \cap L^2_\sigma(\mathbb{R}^3, \mathbb{C}^4);$$

and a smooth map $E : \Omega \mapsto \mathbb{R}$ *such that* $S((u_1, u_2)) = u_1\phi_0 + u_2 K\phi_0 + h((u_1, u_2))$ *satisfies, for all* $U \in \Omega$*,*

$$HS(U) + \nabla F(S(U)) = E(U)S(U), \tag{1.10}$$

with the following properties:

$$\begin{cases} h((u_1,u_2)) = \left(\frac{u_1}{|(u_1,u_2)|} Id_{\mathbb{C}^4} + \frac{u_2}{|(u_1,u_2)|} K\right) h\left((|(u_1,u_2)|, 0)\right) \quad \forall U = (u_1,u_2) \in \Omega, \\ h(U) = O(|U|^2), \\ E(U) = E(|U|), \\ E(U) = \lambda_0 + O(|U|^2). \end{cases}$$

Proof. This result is adapted from [38, Proposition 2.2] after the reduction due to the invariance of the problem with respect to K. ∎

Moreover, we have the following lemma.

LEMMA 1.2 (exponential decay). *For any* $\beta \in \mathbb{N}^4$*,* $s \in \mathbb{R}^+$*, and* $p, q \in [1, \infty]$*, there exist* $\gamma > 0$*,* $\varepsilon > 0$*, and* $C > 0$ *such that for all* $U \in B_{\mathbb{C}^2}(0, \varepsilon)$ *one has*

$$\|e^{\gamma\langle Q\rangle} \partial^\beta_U S(U)\|_{B^s_{p,q}} \le C \|S(U)\|_2,$$

where

$$\partial^\beta_{(u_1,u_2)} = \frac{\partial^{|\beta|}}{\partial^{\beta_1}\Re u_1 \partial^{\beta_2}\Im u_1 \partial^{\beta_3}\Re u_2 \partial^{\beta_4}\Im u_2}.$$

Proof. This is proved as in [7, Lemma 4.1], where we used ideas from [23]. ∎

1.3. The unstable manifold and the stabilization. Each stationary solution previously introduced has, as in [7], a stable manifold. Under the following assumption, we can prove that a small perturbation of a stationary solution starting outside of this manifold leaves any neighborhood of this stationary solution. We work with the following assumption.

Assumption 1.5. The resonant condition

$$|\lambda_1 - \lambda_0| > \min\{|\lambda_0 + m|, |\lambda_0 - m|\}$$

holds. Moreover, we have the Fermi golden rule

$$\Gamma(\phi) > 0, \tag{1.11}$$

where, for any nonzero eigenvector ϕ associated with λ_0, $\Gamma(\phi)$ is given by

$$\Gamma(\phi) = \lim_{\varepsilon \to 0, \varepsilon > 0} \left\langle d^2F(\phi)\phi_1, \Im\left((H - \lambda_0) + (\lambda_1 - \lambda_0) - \mathrm{i}\varepsilon\right)^{-1} P_c(H) d^2F(\phi)\phi_1 \right\rangle.$$

In this assumption, the notation d^2F denotes the differential of ∇F with respect to the real structure of $\mathbb{C}^4$. Let us introduce the linearized operator $JH(U)$ around a stationary state $S(U)$:

$$H(U) = H + d^2F(S(U)) - E(U).$$

We note that the operator $H(U)$ is not $\mathbb{C}$-linear but only $\mathbb{R}$-linear. Hence we work with the space $L^2(\mathbb{R}^3, \mathbb{R}^4 \times \mathbb{R}^4)$ instead of $L^2(\mathbb{R}^3, \mathbb{C}^4)$ by writing

$$\begin{pmatrix} \Re\phi \\ \Im\phi \end{pmatrix}$$

instead of ϕ. The multiplication by $-\mathrm{i}$ becomes the operator

$$J = \begin{pmatrix} 0 & I_{\mathbb{R}^4} \\ -I_{\mathbb{R}^4} & 0 \end{pmatrix}.$$

Now we mention some spectral properties of the *real operator* $JH(U)$ in $L^2(\mathbb{R}^3, \mathbb{C}^8)$ (the complexification of $L^2(\mathbb{R}^3, \mathbb{R}^4 \times \mathbb{R}^4)$) which are needed to state and to understand our main theorem. These properties will be proved in subsection 2.1.

PROPOSITION 1.2 (spectrum of $JH(U)$). *The operator $JH(U)$ in $L^2(\mathbb{R}^3, \mathbb{C}^4 \times \mathbb{C}^4)$ has a four-dimensional algebraic kernel, and its spectrum is symmetric with respect to the imaginary and real axes.*

Outside the imaginary axis the spectrum is discrete. The sum of the algebraic eigenspaces associated with the right of the imaginary axis (i.e., associated with $\{z \in \mathbb{C}, \Re z > 0\}$) is stable under complex conjugation, and its dimension is 4. The same is true for the left of the imainary axis.

The rest of the spectrum is the essential (or continuous) spectrum. We write $\mathcal{H}_c(U)$ for the space associated with the continuous spectrum. The space $J\mathcal{H}_c(U)$ is the orthogonal of the previous eigenspaces and the geometric kernel of $JH(U)$ and is invariant by the complex conjugation.

Proof. See subsection 2.1 below. □

We will work on the real part of the previous spaces. Let $X_u(U) \subset L^2(\mathbb{R}^3, \mathbb{R}^4 \times \mathbb{R}^4)$ be the real part of the sum of the spectral subspaces associated with $\{z \in \mathbb{C}, \Re z > 0\}$. We introduce a real basis $(\xi_i(U))_{i=1,\dots,4}$ of $X_u(U)$.

We will also work in the real part of the sum of the spectral subspaces associated with $\{z \in \mathbb{C}, \Re z < 0\}$: $X_s(U) \subset L^2(\mathbb{R}^3, \mathbb{R}^4 \times \mathbb{R}^4)$. We introduce a real basis $(\xi_i(U))_{i=5,\dots,8}$ of $X_s(U)$.

We define $\xi(U) = (\xi_i(U))_{i=1,\dots,8}$. We can state our main theorems which will be proved in sections 2–5.

THEOREM 1.3 (central manifold and asymptotic stability). *If Assumptions* 1.1–1.5 *hold, then, for $s > \beta + 2 > 2$ and $\sigma > 3/2$, there exist $\varepsilon > 0$, a continuous map $r : B_{\mathbb{C}^2}(0,\varepsilon) \mapsto \mathbb{R}$ with $r(U) = O(|U|^2)$, $C > 0$, $\mathcal{V}$ a neighborhood of $(0,0)$ in*

$$\mathcal{S} = \{(U,z)\,;\, U \in B_{\mathbb{C}^2}(0,\varepsilon),\ z \in \mathcal{H}_c(U) \cap B_{H^s}(0,r(U))\}$$

endowed with the metric of $\mathbb{C}^2 \times H^s$, and a map $\Psi : \mathcal{V} \mapsto \mathbb{R}^8$, smooth on $\mathcal{V} \setminus (0,0)$, satisfying for any nonzero $U \in B_{\mathbb{C}^2}(0,\varepsilon)$

$$\|\Psi(U,z)\| = O(\|z\|_{H^s}^2)$$

for all $z \in \mathcal{H}_c(U) \cap B_{H^s}(0,r(U))$ with $(U,z) \in \mathcal{V}$ such that the following is true.

For any initial condition of the form

$$\psi_0 = S(U_0) + z_0 + A \cdot \xi(U_0)$$

with $(U_0,z_0) \in \mathcal{V}$ and $A = \Psi(U_0,z_0)$, there exists a solution $\psi \in \cap_{k=0}^2 \mathcal{C}^k\left(\mathbb{R}, H^{s-k}\right)$ of (1.8) *with initial condition ψ_0, and this solution is unique in $L^\infty((-T,T), H^s(\mathbb{R}^3,\mathbb{C}^4))$ for any $T > 0$.*

Moreover, we have for all $t \in \mathbb{R}$

$$\psi(t) = e^{-\mathrm{i}\int_0^t E(U(v))\,dv} S(U(t)) + \varepsilon(t) \tag{1.12}$$

with $\|\dot{U}\|_{L^q(\mathbb{R})} \le C\|z_0\|_{H^s}^2$ for all $q \in [1,\infty]$, $\lim_{t\to\pm\infty} U(t) = U_{\pm\infty}$, and

$$\max\left\{ \|\varepsilon\|_{L^\infty(\mathbb{R}^\pm, H^s)}\,,\ \|\varepsilon\|_{L^2(\mathbb{R}^\pm, H^s_{\pm\sigma})}\,, \|\varepsilon\|_{L^2(\mathbb{R}^\pm, B^\beta_{\infty,2})} \right\} \le C\|z_0\|_{H^s}.$$

Remark 1.4. We mention that to our knowledge the local well-posedness of the Cauchy problem associated with (1.8) has not been obtained for initial data in the energy space H^1. Some results are available for slightly bigger spaces; see, for instance, the work of Escobedo and Vega [19] and Machihara, Nakamura, Nakanishi, and Ozawa [34, 33, 32].

In our case, we work with data in H^s with $s > 2$; this comes from the fact that we use inhomogeneous Strichartz estimates (1.7) with $q = \tilde{q} = \infty$ (see the proof of Lemma 3.8).

THEOREM 1.4 (center-stable and center-unstable manifolds). *With the same assumptions and notation as in Theorem* 1.3, *let $\mathcal{CM}$ be the graph of $(U,z) \in \mathcal{V} \mapsto S(U) + z + \Psi(U,z)\cdot\xi(U)$. Then for the set*

$$\widetilde{\mathcal{S}} = \{(U,z,p)\,;\, U \in B_{\mathbb{C}^2}(0,\varepsilon),\ z \in \mathcal{H}_c(U) \cap B_{H^s}(0,r(U)),\ p \in B_{\mathbb{R}^4}(0,r(U))\}$$

endowed with the metric of $\mathbb{C}^2 \times H^s \times \mathbb{R}^4$, there exist $C > 0$, $\gamma > 0$, neighborhoods $\mathcal{W}_\pm$ of $(0,0,0)$ in $\widetilde{\mathcal{S}}$, and maps $\Phi_\pm : \mathcal{W}_\pm \mapsto \mathbb{R}^4$, smooth on $\mathcal{W}_\pm \setminus \{(0,0,0)\}$ with

$$\|\Phi_\pm(U,z,p)\| = O(\|z\|_{H^s}^2 + \|p\|^2)$$

for all $(U,z,p)\in\mathcal{W}_\pm$*, such that for any initial condition of the form*

$$\psi_0 = S(U_0)+z_0+(p_+,p_-).\xi(U_0)$$

not in $\mathcal{CM}$*, i.e.,*

$$(p_+,p_-)\neq\Psi(U_0,z_0),$$

the following is true.

1. *If* $(U_0,z_0,p_+)\in\mathcal{W}_+$ *and* $p_-=\Phi_+(U_0,z_0,p_+)$ *(resp., if* $(U_0,z_0,p_-)\in\mathcal{W}_-$ *and* $p_+=\Phi_-(U_0,z_0,p_-)$*), then for any small neighborhood* $\mathcal{O}$ *of* $S(U_0)$ *containing* ψ_0 *there exist* $t_+>0$ *(resp.,* $t_->0$*) and a solution*

$$\psi_+\in\cap_{k=0}^2\mathcal{C}^k([-t_+;+\infty),H^{s-k}),$$

respectively,

$$\psi_-\in\cap_{k=0}^2\mathcal{C}^k((-\infty;t_-],H^{s-k}),$$

of (1.8) *with initial condition* ψ_0*, and in* $L^\infty((-T',T),H^s(\mathbb{R}^3,\mathbb{C}^4))$ *this solution is unique for any* $T>0$ *(resp.,* $T\in(0,t_-)$*) and any* $T'\in(0,t_+)$ *(resp.,* $T'<0$*).*
Moreover, there exist $C>0$*,* $\phi_\pm(t)\in\mathcal{CM}$*, and* $\rho_+(t)\in X_s(U_0)$ *(resp.,* $\rho_-(t)\in X_u(U_0)$*) for all* $t>-t_+$ *(resp., for all* $t<t_-$*) such that* $\psi_\pm(t)=\phi_\pm(t)+\rho_\pm(t)$ *with*

$$\|\rho_\pm(t)\|_{H^s}\le C\,\|\rho_\pm(0)\|_{H^s}\,e^{\mp\gamma t}\ \text{ as } t\to\pm\infty\quad\text{ and }\quad\psi_\pm(\mp t_\pm)\notin\mathcal{O}.$$

We also have

$$\phi_\pm(t)=e^{-\mathrm{i}\int_0^t E(U_\pm(v))\,dv}S(U_\pm(t))+\varepsilon_\pm(t)\quad\forall t>t_-\ (\text{resp., }\forall t<-t_+)$$

with

$$\left\|\dot U_+\right\|_{L^q((-t_+,+\infty))}\le C\left(\|z_0\|_{H^s}+\|\rho_\pm(0)\|_{H^s}\right)^2,$$

respectively,

$$\left\|\dot U_-\right\|_{L^q((-\infty,t_-))}\le C\left(\|z_0\|_{H^s}+\|\rho_\pm(0)\|_{H^s}\right)^2,$$

for all $q\in[1,\infty]$*,* $\lim\limits_{t\to\pm\infty}U_\pm(t)=U_{\pm\infty}$*, and*

$$\max\left\{\|\varepsilon_+\|_{L^\infty((-t_+,+\infty),H^s)},\ \|\varepsilon_+\|_{L^2((-t_+,+\infty),H^s_{-\sigma})},\|\varepsilon_+\|_{L^2((-t_+,+\infty),B^\beta_{\infty,2})}\right\}\le C\left(\|z_0\|_{H^s}+\|\rho_\pm(0)\|_{H^s}\right),$$

respectively,

$$\max\left\{\|\varepsilon_-\|_{L^\infty((-\infty,t_-),H^s)},\ \|\varepsilon_-\|_{L^2((-\infty,t_-),H^s_{-\sigma})},\|\varepsilon_-\|_{L^2((-\infty,t_-),B^\beta_{\infty,2})}\right\}\le C\left(\|z_0\|_{H^s}+\|\rho_\pm(0)\|_{H^s}\right).$$

2. *If* $(U_0, z_0, p_+) \in \mathcal{W}_+$ *and* $(U_0, z_0, p_-) \in \mathcal{W}_-$ *with* $p_- \neq \Phi_+(U_0, z_0, p_+)$ *and* $p_+ \neq \Phi_-(U_0, z_0, p_-)$*, then there exist* $t_+(\psi_0) > 0$*,* $t_-(\psi_0) < 0$*, and a unique solution* ψ *of* (1.8) *with initial condition* ψ_0 *such that, for any small neighborhood* $\mathcal{O}$ *of* $S(U_0)$ *containing* ψ_0*,* $\phi \in \cap_{k=0}^{2} \mathcal{C}^k([t_-; t_+], H^{s-k})$ *with* $\psi(t_+) \notin \mathcal{O}$ *and* $\psi(t_-) \notin \mathcal{O}$*. This solution is unique in* $L^\infty((T', T), H^s(\mathbb{R}^3, \mathbb{C}^4))$ *for any* $T \in (0, t_+)$ *and any* $T' \in (t_-, 0)$*.*

Remark 1.5. In Theorem 1.4, we note that when $U_0 = 0$, then $z_0 = 0$ and $p = 0$, and so the theorem does not say anything for this case. In fact, the charge conservation gives the orbital stability of 0. But we cannot extend the previous results to 0 since we can build a manifold of stationary states tangent to the eigenspace associated with λ_1, similarly to Proposition 1.1.

One can also note that the previous result (and the following ones) are still valid when switching the roles of λ_0 and λ_1 as long as the resonance condition, Assumption 1.5, is fulfilled with λ_0 and λ_1 switched. If the resonance condition does not hold, the result in [7] can be applied if the strict nonresonance condition holds:

$$|\lambda_0 - \lambda_1| < \min\{|\lambda_1 + m|, |\lambda_1 - m|\},$$

and we obtain a stable manifold associated with λ_1. As far as we know, the cases

$$|\lambda_0 - \lambda_1| = \min\{|\lambda_1 + m|, |\lambda_1 - m|\} \quad \text{and} \quad |\lambda_1 - \lambda_0| = \min\{|\lambda_0 + m|, |\lambda_0 - m|\}$$

are open.

1.4. The nonlinear scattering. If we choose a localized z_0, we are able to further expand (1.12) as stated by the following theorems that are also proved in sections 2–5.

THEOREM 1.5. *With the assumptions and the notation of Theorem* 1.3*, for the set*

$$\mathcal{S}_\sigma = \left\{(U, z);\ U \in B_{\mathbb{C}^2}(0, \varepsilon),\ z \in \mathcal{H}_c(U) \cap B_{H^s_\sigma}(0, r(U))\right\}$$

endowed with the metric of $\mathbb{C}^2 \times H^s_\sigma$*, there exists a neighborhood* $\mathcal{V}_\sigma$ *of* $(0, 0)$ *in* $\mathcal{S}_\sigma$ *such that the following is true. If* $A = \Psi(U_0, z_0)$ *with* $(U_0, z_0) \in \mathcal{V}_\sigma$*, there exist* $\mathcal{V}^\pm_\sigma$ *open neighborhoods of* $(0, 0)$ *in* $\mathcal{S}_\sigma$ *and* $(V_{\pm\infty}; z_{\pm\infty}) \in \mathcal{V}^\pm_\sigma$*, such that*

$$|V_{\pm\infty} - U_0| \leq C\|z_0\|^2_{H^s_\sigma}, \quad \|z_{\pm\infty} - z_0\|_{H^s} \leq C\|z_0\|^2_{H^s_\sigma},$$

and for all $t \in \mathbb{R}$

$$\psi(t) = e^{-\mathrm{i}tE(V_{\pm\infty})} S(V_\pm(t)) + e^{JtE(V_{\pm\infty})} e^{JtH(V_{\pm\infty})} z_{\pm\infty} + \varepsilon_\pm(t)$$

with

$$\begin{aligned}
\left|\dot V_\pm(t) + \mathrm{i}\,(E(V_\pm(t)) - E(V_{\pm\infty}))\right| &\leq \frac{C}{\langle t\rangle^2}\|z_0\|^2_{H^s_\sigma},\\
|V_\pm(t) - V_{\pm\infty}| &\leq \frac{C}{\langle t\rangle}\|z_0\|_{H^s_\sigma},\\
\max\left\{\|\varepsilon_\pm(t)\|_{H^s},\ \|\varepsilon_\pm(t)\|_{H^{s}_{-\sigma}}, \|\varepsilon_\pm(t)\|_{B^\beta_{\infty,2}}\right\} &\leq \frac{C}{\langle t\rangle^2}\|z_0\|^2_{H^s_\sigma},\\
\text{and} \quad \left\|e^{-JtH(V_{\pm\infty})} e^{J\int_0^t (E(V_\pm(s)) - E(V_{\pm\infty})\,ds} \varepsilon_\pm(t)\right\|_{H^s_{\frac{3}{2}}} &\leq \frac{C}{\langle t\rangle^{\frac{1}{2}}}\|z_0\|^2_{H^s_\sigma}
\end{aligned}$$

for all $t \in \mathbb{R}$.

Moreover, the maps

$$(U_0; z_0) \in \mathcal{V}_\sigma \mapsto (V_{\pm\infty}; z_{\pm\infty}) \in \mathcal{V}_\sigma^\pm$$

are bijective.

Remark 1.6. The fact that z_0 is localized gives us the convergence of

$$\int_0^t E(U(v))\, dv - tE(U_{\pm\infty})$$

as $t \to \pm\infty$ and allows us to obtain an asymptotic profile for the dispersive part of the perturbed solution ϕ. Indeed, to obtain an asymptotic profile for z, we need an asymptotic profile for the phase and hence the existence of

$$\lim_{t\to\pm\infty} \int_0^t E(U(v))\, dv - tE(U_{\pm\infty}) = \int_0^{\pm\infty} \left(E(U(v)) - E(U_{\pm\infty})\right)\, dv. \tag{1.13}$$

But in the present case, we control $\dot{U}$ by the third power of some spatial norm of z. If z belongs just to some Lebesgue space in time, we are able to obtain just that

$$\lim_{t\to\pm\infty} \left(E(U(v)) - E(U_{\pm\infty})\right) = 0,$$

which gives nothing about the existence of (1.13). To obtain this existence, we need pointwise estimates in time for z (see subsection 3.2.4). This requires z_0 to be localized in space. Moreover, we believe that a result similar to [22, Theorem 1.9] showing slow pointwise decay for the perturbation in the nonlocalized case can be adapted here. Such phenomena prevent (1.13) from existing.

What we call the nonlinear scattering result is essentially the fact that the maps

$$(U_0; z_0) \in \mathcal{V}_\sigma \mapsto (U_{\pm\infty}; z_{\pm\infty}) \in \mathcal{V}_\sigma^\pm$$

are well defined and bijective.

Using wave operators for the pair $(JH(U), JD_m)$, we can obtain an expansion of the form $\psi(t) = e^{-\mathrm{i}\int_0^t E(U(v))\, dv} S(U_{\pm\infty}) + e^{-\mathrm{i}tD_m} z_\pm + \varepsilon_\pm(t)$ but will only have

$$\|z_{\pm\infty} - z_0\|_{H^s} \leq C\|z_0\|_{H^s}$$

and

$$\max\left\{ \|\varepsilon_\pm\|_{L^\infty(\mathbb{R}^\pm, H^s)},\ \|\varepsilon_\pm\|_{L^2(\mathbb{R}^\pm, H^s_{-\sigma})}, \|\varepsilon_\pm\|_{L^2(\mathbb{R}^\pm, B^\beta_{\infty,2})} \right\} \leq C\|z_0\|_{H^s}.$$

Or, using wave operators for the pair $(JH(U), JH)$, we can obtain an expansion of the form $\psi(t) = e^{-\mathrm{i}\int_0^t E(U(v))\, dv} S(U_{\pm\infty}) + e^{-\mathrm{i}tH} z_\pm + \varepsilon_\pm(t)$ with

$$\|z_{\pm\infty} - z_0\|_{H^s} \leq C\left(|U_0| + \|z_0\|_{H^s}\right)\|z_0\|_{H^s}$$

and

$$\max\left\{ \|\varepsilon_\pm\|_{L^\infty(\mathbb{R}^\pm, H^s)},\ \|\varepsilon_\pm\|_{L^2(\mathbb{R}^\pm, H^s_{-\sigma})}, \|\varepsilon_\pm\|_{L^2(\mathbb{R}^\pm, B^\beta_{\infty,2})} \right\} \leq C\left(|U_0| + \|z_0\|_{H^s}\right)\|z_0\|_{H^s}.$$

But in these cases, we cannot obtain a nice asymptotic completness statement.

We have (in the previous expansions)

$$\max\left\{\sup_{t\in\mathbb{R}}\left(\left\|e^{JtH(U_{\pm\infty})}z_{\pm\infty}\right\|_{H^s}\right),\ \sup_{t\in\mathbb{R}}\left(\langle t\rangle^{3/2}\left\|e^{JtH(U_{\pm\infty})}z_{\pm\infty}\right\|_{H^s_{-\sigma}}\right),\right.$$
$$\left.\sup_{t\in\mathbb{R}}\left(\langle t\rangle^{3/2}\left\|e^{JtH(U_{\pm\infty})}z_{\pm\infty}\right\|_{B^\beta_{\infty,2}}\right)\right\}\le C\|z_{\pm\infty}\|_{H^s}.$$

This follows from Lemmas 3.13 and 3.14.

Outside the center manifold, we can also have an expansion of the same type. But due to the presence of exponentially stable and unstable directions, one cannot expect a scattering result of the same type. Actually we cannot obtain the injectivity of the corresponding mappings. We have the following theorem.

THEOREM 1.6. *With the assumptions and notation of Theorem* 1.4, *for the sets*

$$\widetilde{\mathcal{S}}_\sigma=\left\{(U,z,p);\ U\in B_{\mathbb{C}^2}(0,\varepsilon),\ z\in\mathcal{H}_c(U)\cap B_{H^s_\sigma}(0,r(U)),\ p\in B_{\mathbb{R}^4}(0,r(U))\right\}$$

endowed with the metric of $\mathbb{C}^2\times H^s_\sigma\times\mathbb{R}^4$, *there exist* $C>0$, $\gamma>0$, *and neighborhoods* $\mathcal{W}^\pm_\sigma$ *of* $(0,0,0)$ *in* $\mathcal{S}_\sigma$ *such that the following is true.*

If $\psi_0\notin\mathcal{CM}$, $(U_0,z_0,p_+)\in\mathcal{W}^+_\sigma$ *and* $p_-=\Phi_+(U_0,z_0,p_+)$ *(resp.,* $(U_0,z_0,p_-)\in\mathcal{W}^-_\sigma$ *and* $p_+=\Phi_-(U_0,z_0,p_-)$*), then there exist* $C>0$, $\phi_\pm(t)\in\mathcal{CM}$, *and* $\rho_\pm(t)\in X_s(U_0)$ *for all* $t>-t_+$ *(resp., for all* $t<t_-$*) such that* $\psi_\pm(t)=\phi_\pm(t)+\rho_\pm(t)$ *with*

$$\|\rho_\pm(t)\|_{H^s}\le C\,\|\rho_\pm(0)\|_{H^s}\,e^{\mp\gamma t}\ \text{ as } t\to\pm\infty\quad\text{ and }\quad\psi(\mp t_\pm)\notin\mathcal{O}.$$

Further, there exist $(V_{\pm\infty};z_{\pm\infty})\in\mathcal{S}$ *such that*

$$|V_{\pm\infty}-U_0|\le C\left(\|z_0\|_{H^s_\sigma}+\|\rho_\pm(0)\|_{H^s}\right)^2,$$
$$\|z_{\pm\infty}-z_0\|_{H^s}\le C\left(\|z_0\|_{H^s_\sigma}+\|\rho_\pm(0)\|_{H^s}\right)^2,$$

and for all $t>-t_+$ *(resp., for all* $t<t_-$*)*

$$\phi_\pm(t)=e^{-\mathrm{i}tE(V_{\pm\infty})}S(V_\pm(t))+e^{JtE(V_{\pm\infty})}e^{JtH(V_{\pm\infty})}z_{\pm\infty}+\varepsilon_\pm(t)$$

with

$$\left|\dot V_\pm(t)+\mathrm{i}\left(E(V_\pm(t))-E(V_{\pm\infty})\right)\right|\le\frac{C}{\langle t\rangle^2}\left(\|z_0\|_{H^s_\sigma}+\|\rho_\pm(0)\|_{H^s}\right)^2,$$
$$|V_\pm(t)-V_{\pm\infty}|\le\frac{C}{\langle t\rangle}\left(\|z_0\|_{H^s_\sigma}+\|\rho_\pm(0)\|_{H^s}\right)^2,$$
$$\max\left\{\|\varepsilon_\pm(t)\|_{H^s},\ \|\varepsilon_\pm(t)\|_{H^s_{-\sigma}},\|\varepsilon_\pm(t)\|_{B^\beta_{\infty,2}}\right\}\le\frac{C}{\langle t\rangle^2}\left(\|z_0\|_{H^s_\sigma}+\|\rho_\pm(0)\|_{H^s}\right)^2,$$
$$\left\|e^{-JtH(V_{\pm\infty})}e^{J\int_0^t(E(V_\pm(s))-E(V_{\pm\infty}))\,ds}\varepsilon_\pm(t)\right\|_{H^s_{\frac{3}{2}}}\le\frac{C}{\langle t\rangle^{\frac12}}\left(\|z_0\|_{H^s_\sigma}+\|\rho_\pm(0)\|_{H^s}\right)^2$$

for all $t>-t_+$ *(resp., for all* $t<t_-$*).*

2. Linearized operator and exponentially stable and unstable manifolds. We study the dynamics associated with (1.8) around a stationary state. We will use spectral properties of the linearized operator around a stationary state.

2.1. The spectrum of the linearized operator. Here we study the spectrum of the linearized operator associated with (1.8) around a stationary state $S(U)$. Let us recall

$$H(U) = H + d^2F(S(U)) - E(U),$$

where d^2F is the differential of ∇F. The operator $H(U)$ is $\mathbb{R}$-linear but not $\mathbb{C}$-linear. Replacing $L^2(\mathbb{R}^3, \mathbb{C}^4)$ by $L^2(\mathbb{R}^3, \mathbb{R}^4 \times \mathbb{R}^4)$ with the inner product obtained by taking the real part of the inner product of $L^2(\mathbb{R}^3, \mathbb{C}^4)$, we obtain a symmetric operator. We then complexify this real Hilbert space and obtain $L^2(\mathbb{R}^3, \mathbb{C}^4 \times \mathbb{C}^4)$ with its natural Hermitian product. This process transforms the operator $-\mathrm{i}$ into

$$J = \begin{pmatrix} 0 & Id_{\mathbb{C}^4} \\ -Id_{\mathbb{C}^4} & 0 \end{pmatrix}.$$

For $\phi \in L^2(\mathbb{R}^3, \mathbb{R}^4 \times \mathbb{R}^4) \subset L^2(\mathbb{R}^3, \mathbb{C}^4 \times \mathbb{C}^4)$, we still write ϕ instead of

$$\begin{pmatrix} \Re\phi \\ \Im\phi \end{pmatrix}.$$

The extension of $H(U)$ to $L^2(\mathbb{R}^3, \mathbb{C}^4 \times \mathbb{C}^4)$ is also written $H(U)$ and is now a real operator. The extension of K (see (1.9)) is also written K.

The linearized operator associated with (1.8) around the stationary state $S(U)$ is given by $JH(U)$. We shall now study its spectrum.

Differentiating (1.10), we have that for $U = (u_1, u_2) \in \Omega$

$$\mathcal{H}_0(u_1, u_2) = \mathrm{span}\left\{ \frac{\partial}{\partial \Re u_1} S(u_1, u_2), \frac{\partial}{\partial \Im u_1} S(u_1, u_2), \frac{\partial}{\partial \Re u_2} S(u_1, u_2), \frac{\partial}{\partial \Im u_2} S(u_1, u_2) \right\}$$

is invariant under the action of $JH(U)$. Differentiating the gauge invariance property for S, we notice that $JS(U) \in \mathcal{H}_0(U)$; differentiating the gauge invariance property for F, we also obtain

$$JH(U)JS(U) = 0;$$

and differentiating (1.10), we obtain for any $\beta \in \mathbb{N}^4$ with $|\beta| = 1$

$$JH(U)\partial_U^\beta S(U) = (\partial_U^\beta E)(U)JS(U).$$

The space $\mathcal{H}_0(U)$ is contained in the algebraic null space of $JH(U)$; in fact, it is exactly the algebraic null space as proved in what follows.

Now we state our results on the spectrum of $JH(U)$. The first deals with the excited states part. Using the function Γ introduced in Assumption 1.5, we have the following proposition.

PROPOSITION 2.1. *If Assumptions* 1.1–1.5 *hold, let*

$$\widetilde{\Gamma}(|U|) = \inf_{V \in \mathbb{C}^2, |V| = |U|} \Gamma(S(V)).$$

For any sufficiently small U, we have

$$\widetilde{\Gamma}(|U|) > 0.$$

There exist continuous maps $E_1^i : B_{\mathbb{C}^2}(0,\varepsilon) \mapsto \mathbb{R}$ *smooth outside* $U = 0$ *with*

$$\begin{cases} \Im E_1^i(U) = (\lambda_1 - E(U)) + O(|U|^4), \\ \Re E_1^i(U) = \Gamma^i(U) + O(|U|^6), \end{cases}$$

where

$$\Gamma^i(U) \geq \frac{1}{2}\widetilde{\Gamma}(|U|)$$

for $i \in \{1,2\}$ *such that* $E_1^i(U)$, $\overline{E_1^i}(U)$, $-E_1^i(U)$, *and* $-\overline{E_1^i}(U)$ *are eigenvalues of* $JH(U)$. *These eigenvalues are simple if* $E_1^1 \neq E_1^2$; *otherwise the associated algebraic eigenspace is of dimension* 2. *We can define maps* $\Phi_\pm^i(U) : B_{\mathbb{C}^2}(0,\varepsilon) \mapsto H^s$ *such that*

- $\{\Phi_+^1(U), \Phi_+^2(U)\}$ *is an orthonormal basis of the sum of the eigenspaces associated with* $E_1^1(U)$ *and* $E_1^2(U)$,
- $\{\overline{\Phi_+^1(U)}, \overline{\Phi_+^2(U)}\}$ *is an orthonormal basis of the eigenspaces associated with* $\overline{E_1^1(U)}$ *and* $\overline{E_1^2(U)}$,
- $\{\Phi_-^1(U), \Phi_-^2(U)\}$ *is an orthonormal basis of the sum of the eigenspaces associated with* $-E_1^1(U)$ *and* $-E_1^2(U)$,
- $\{\overline{\Phi_-^1(U)}, \overline{\Phi_-^2(U)}\}$ *is an orthonormal basis of the sum of the eigenspaces associated with* $-\overline{E_1^1(U)}$ *and* $-\overline{E_1^2(U)}$.

In the case of double eigenvalues $E_1^1(U) = E_1^2(U)$ *one should consider algebraic eigenspaces instead of the sum of the eigenspaces. In any case, the associated projectors are continuous around* $U = 0$ *and smooth outside* $U = 0$.

Moreover, for any $\beta \in \mathbb{N}^4$, $s \in \mathbb{R}^+$ *and* $p, q \in [1,\infty]$. *There exist* $\gamma > 0$, $\varepsilon > 0$, *and* $C > 0$ *such that, for all* $U \in B_{\mathbb{C}^2}(0,\varepsilon) \setminus \{0\}$ *and for any* $i \in \{1,2\}$, *one has*

$$\|e^{\gamma\langle Q\rangle}\partial_U^\beta \Phi_\pm^i(U)\|_{B^s_{p,q}} \leq C\|\Phi_\pm^i(U)\|_2, \tag{2.1}$$

where

$$\partial^\beta_{(u_1,u_2)} = \frac{\partial^{|\beta|}}{\partial^{\beta_1}\Re u_1 \partial^{\beta_2}\Im u_1 \partial^{\beta_1}\Re u_2 \partial^{\beta_2}\Im u_2}.$$

Proof. Using Weyl's sequences, we prove that the essential spectrum of $JH(U)$, for small U, is the essential spectrum of $J(H - E(U))$, i.e., $\mathrm{i}(\mathbb{R} \setminus (-c,c))$ with $c = \min\{m - E(U), m + E(U)\}$. So z with nonzero real part is in the spectrum of $JH(U)$ if and only if it is an isolated eigenvalue with finite multiplicity. The multiplicity of z here is the dimension of the algebraic kernel of $JH(U) - z$.

We now investigate properties of the eigenvalues. To do so, we use ideas from the proof of [54, Theorem 2.2]. The equation to solve for excited states is

$$(JH(U) - z)\,\phi = 0. \tag{2.2}$$

We consider solutions of the form $\phi = (v_1 S_1 + v_2 K S_1) + \eta$, where S_1 is the normalized eigenvector of JH,

$$S_1 = \frac{1}{\sqrt{2}} \begin{pmatrix} \phi_1 \\ -i\phi_1 \end{pmatrix},$$

with $(v_1, v_2) \in \mathbb{C}^2$ such that $|v_1|^2 + |v_2|^2 = 1$ and $\eta \in \{S_1, KS_1\}^\perp$. The orthogonal relation is taken, in fact, with respect to J (but since $JS_1 = \mathrm{i}S_1$ and $JKS_1 = \mathrm{i}KS_1$, we can take it in the usual way). For $z \in \mathbb{C} \setminus \mathrm{i}\mathbb{R}$, we obtain the equation

$$\eta = (J(H - E(U)) - z)^{-1} P_1^\perp W(U) \{(v_1 S_1 + v_2 K S_1) + \eta\} \tag{2.3}$$

with $P_1^\perp$ the orthogonal projector into $\{JS_1\}^\perp = \{S_1\}^\perp$ and $W(U) = JH(U) - J(H - E(U))$. We notice that $\{S_1\}^\perp$ is invariant under the action of $J(H - E(U))$. To solve this equation in η for a fixed U and z, we note that if

$$\Re z > 0 \quad \text{and} \quad |\Im z| \geq c,$$

where $c = \min\{m + E(U), m - E(U)\}$, the series

$$k(U,z)(v_1 S_1 + v_2 K S_1) = (J(H - E(U)) - z)^{-1}$$

$$\times P_1^\perp \sum_{k \geq 0} \left(-W(U) (J(H - E(U)) - z)^{-1} P_1^\perp \right)^k W(U)(v_1 S_1 + v_2 K S_1)$$

is convergent in L^2 for sufficiently small $|U|$ and $|\Re z| = O(|U|^2)$ using the limiting absorption principle (1.4) and the bound of the resolvent $\left\| (H - z')^{-1} \right\| \leq |\Im z'|^{-1}$ in L^2. Hence, we have a solution of (2.3).

Then we solve the equation in z. We obtain from (2.2) the equations

$$\langle (JH(U) - z)\, \phi, S_1 \rangle = 0 \quad \text{and} \quad \langle (JH(U) - z)\, \phi, KS_1 \rangle = 0$$

with $\phi = (v_1 S_1 + v_2 K S_1) + k(U,z)(v_1 S_1 + v_2 K S_1)$. Hence, z is an eigenvalue of the matrix $A(U,z)$ defined by

$$\begin{pmatrix} \langle JH(U)(S_1 + k(U,z)S_1), S_1 \rangle & \langle JH(U)(S_1 + k(U,z)S_1), KS_1 \rangle \\ \langle JH(U)(KS_1 + k(U,z)KS_1), S_1 \rangle & \langle JH(U)(KS_1 + k(U,z)KS_1), KS_1 \rangle \end{pmatrix}$$

in $\mathbb{C}^2$. So we study the zeros of $\det(A(U,z) - z)$. We have that $d_\varepsilon : z \mapsto \det(A(U, z + \varepsilon) - z)$ is an analytic function for z in $\{z \in \mathbb{C}, \Re z > -\varepsilon\}$ for any $\varepsilon \geq 0$, $\det(A(0, z + \varepsilon) - z) = (z - \mathrm{i}(\lambda_1 - \lambda_0))^2$ and $\det(A(U, z + \varepsilon) - z) - \det(A(0, z + \varepsilon) - z) \to 0$ as $U \to 0$ uniformly in z and ε in a bounded set. Since at $(U, \varepsilon) = (0, \varepsilon)$ $(\varepsilon > 0)$ we have a double zero, for $(U, 0)$ close to $(0, 0)$, we have two zeros counted with multiplicity.

Hence if z is a zero of $d_0(U, \cdot)$ and hence an eigenvalue of $A(U,z)$, we have with an associated normalized eigenvector $(v_1, v_2) \in \mathbb{C}^2$ and $\psi = (v_1 S_1 + v_2 K S_1)$

$$z = \mathrm{i}\,(\lambda_1 - \lambda_0) + \langle W(U)\psi, \psi \rangle + \sum_{k \geq 0} \Big\langle JH(U) (J(H - E(U)) - z)^{-1}$$

$$\times P_1^\perp \left(-W(U) (J(H - E(U)) - z)^{-1} P_1^\perp \right)^k W(U)\psi, \psi \Big\rangle$$

$$= \mathrm{i}\,(\lambda_1 - \lambda_0) + \langle W(U)\psi, \psi \rangle$$

$$+ \sum_{k \geq 0} \left\langle P_1^\perp \left(-W(U) (J(H - E(U)) - z)^{-1} P_1^\perp \right)^k W(U)\psi, \psi \right\rangle$$

$$+\sum_{k\geq 0}\Big\langle (W(U)+z)\,(J(H-E(U))-z)^{-1}$$

$$\times\, P_1^{\perp}\Big(-W(U)\,(J(H-E(U))-z)^{-1}P_1^{\perp}\Big)^{k}W(U)\psi,\psi\Big\rangle.$$

Since $P_1^{\perp}(v_1S_1+v_2KS_1)=0$, we introduce the function

$$f(z)=\mathrm{i}\,(\lambda_1-\lambda_0)+\Big\langle W(U)\psi,\psi\Big\rangle+\sum_{k\geq 0}\big\langle W(U)\,(J(H-E(U))-z)^{-1}$$

$$\times\, P_1^{\perp}\left(-W(U)\,(J(H-E(U))-z)^{-1}\,P_1^{\perp}\right)^{k}W(U)\psi,\psi\Big\rangle.$$

Since $J(v_1S_1+v_2KS_1)=-\mathrm{i}(v_1S_1+v_2KS_1)$, we obtain that

$$\Re\,\langle W(U)(v_1S_1+v_2KS_1),(v_1S_1+v_2KS_1)\rangle=0.$$

Thus for $z\in\mathbb{C}\setminus\mathrm{i}\mathbb{R}$, we have

$$\begin{aligned}
&\Re f(z)\\
&=\Re\Big\langle W(U)\,(J(H-E(U))-z)^{-1}\,P_1^{\perp}W(U)(v_1S_1+v_2KS_1),(v_1S_1+v_2KS_1)\Big\rangle\\
&\quad+O(|U|^6)\\
&=\Im\big\langle d^2F(S(U))\,((H-E(U))+zJ)^{-1}\\
&\quad\times P_1^{\perp}d^2F(S(U))(v_1S_1+v_2KS_1),(v_1S_1+v_2KS_1)\big\rangle+O(|U|^6).
\end{aligned}$$

Then using (1.11) and

$$\begin{aligned}
&((H-E(U))+zJ)^{-1}\\
&\qquad=\frac{1}{2}\left(((H-E(U))-\mathrm{i}z)^{-1}\,(I_{C^2}+\mathrm{i}J)+((H-E(U))+\mathrm{i}z)^{-1}\,(I_{C^2}-\mathrm{i}J)\right),
\end{aligned}$$

we obtain

$$\begin{aligned}
&\Im\big\langle d^2F(S(U))((H-E(U))+zJ)^{-1}P_1^{\perp}d^2F(S(U))(v_1S_1+v_2KS_1),(v_1S_1+v_2KS_1)\big\rangle\\
&=\frac{1}{2}\big(\Im\big\langle d^2F(S(U))((H-E(U))-\mathrm{i}z)^{-1}d^2P_1^{\perp}F(S(U))(v_1S_1+v_2KS_1),(v_1S_1+v_2KS_1)\big\rangle\\
&+\Im\big\langle d^2F(S(U))((H-E(U))+\mathrm{i}z)^{-1}P_1^{\perp}d^2F(S(U))(v_1S_1+v_2KS_1),(v_1S_1+v_2KS_1)\big\rangle\big)\\
&-\Im\big\langle d^2F(S(U))\big((H-E(U))^2+z^2\big)^{-1}zJP_1^{\perp}d^2F(S(U))(v_1S_1+v_2KS_1),(v_1S_1+v_2KS_1)\big\rangle,
\end{aligned}$$

and so, using regularity results of the resolvent of [20, Theorem 1.7], we obtain

$$\begin{aligned}
&\Im\big\langle d^2F(S(U))\,((H-E(U))+(\mathrm{i}(\lambda_1-\lambda_0)+0)\,J)^{-1}\\
&\qquad\times P_1^{\perp}d^2F(S(U))(v_1S_1+v_2KS_1),(v_1S_1+v_2KS_1)\big\rangle\\
&=\frac{1}{2}\Im\big\langle d^2F(S(U))\,((H-E(U))+(\lambda_1-\lambda_0)-\mathrm{i}0)^{-1}\\
&\qquad\times P_c(H)d^2F(S(U))(v_1S_1+v_2KS_1),(v_1S_1+v_2KS_1)\big\rangle.
\end{aligned}$$

Using Assumption 1.5, the limiting absorption principle (1.4), and regularity results of [20, Theorem 1.7], we obtain

$$\Re f(z) = \frac{1}{2}\Im\big\langle d^2F(S(U))\left((H-E(U))+(\lambda_1-\lambda_0)-\mathrm{i}0\right)^{-1} \\ \times P_c(H)d^2F(S(U))(v_1S_1+v_2KS_1),(v_1S_1+v_2KS_1)\big\rangle + O(|U|^6)$$

for z in a ball of radius of order $|U|^2$ around $\mathrm{i}\,(\lambda_1-\lambda_0)$ and for small U. We also prove in the same way that

$$\Im f(z) = (\lambda_1-\lambda_0) + O(|U|^4)$$

for z in a ball of radius of order $|U|^2$ around $\mathrm{i}\,(\lambda_1-\lambda_0)$ and for small U.

This proves that the zeros of $A(U,z)$ at the right of the imaginary axis are close to $\mathrm{i}\,(\lambda_1-\lambda_0)$. Hence we have obtained that, for small U, $JH(U)$ has at most two eigenvalues. Counted with algebraic multiplicity, we have that it is exactly two at the right side of the imaginary axis. Indeed, a complex number z is in the resolvent set of $JH(U)$ if and only if $JH(U)-z$ is invertible or if and only if $H(U)+Jz$ is invertible.

Let us consider for $\varepsilon>0$

$$J_\varepsilon = \begin{pmatrix} \frac{\varepsilon}{2} & (1+\mathrm{i}\frac{\varepsilon}{2})Id_{\mathbb{C}^4} \\ (-1-\mathrm{i}\frac{\varepsilon}{2})Id_{\mathbb{C}^4} & \frac{\varepsilon}{2} \end{pmatrix}$$

and the set of z for which the operator

$$H(U) - J_\varepsilon z$$

is invertible. When $U=0$, we have after multiplication by

$$P = \frac{1}{\sqrt{2}}\begin{pmatrix} \mathrm{i} & 1 \\ 1 & \mathrm{i} \end{pmatrix}$$

on the left and by P^{-1} on the right (that is to say, diagonalization of J_ε)

$$\begin{pmatrix} H-\lambda_0+\mathrm{i}z+\mathrm{i}\varepsilon & 0 \\ 0 & H-\lambda_0-\mathrm{i}z \end{pmatrix},$$

which is invertible if

$$z \notin \mathrm{i}\left\{\mathbb{R}\setminus(-m-\lambda_0,m-\lambda_0)\cup\{0,\lambda_1-\lambda_0\}\right\}$$

and

$$z \notin -\mathrm{i}\left\{\mathbb{R}\setminus(-m-\lambda_0,m-\lambda_0)\cup\{0,\lambda_1-\lambda_0\}\right\}-\varepsilon.$$

Since we have closed operators, applying Theorems 3.16 and 5.33 of [28, Chapter IV] to $J_\varepsilon^{-1}H(U)$, we obtain that close to $\mathrm{i}(\lambda_1-\lambda_0)$ the operator $J_\varepsilon^{-1}H(U)$ has two simple eigenvalues or one double (algebraic) eigenvalue when U is small. Now consider ε as a parameter and U fixed, and applying again Theorems 3.16 and 5.33 of [28, Chapter IV], we obtain that, counted with multiplicity, $JH(U)$ has two eigenvalues since the discrete spectrum of $JH(U)=J_0^{-1}H(U)$ close to $\mathrm{i}(\lambda_1-\lambda_0)$ at the right

of the imaginary axis is outside the imaginary axis. Theorems 3.16 and 5.33 of [28, Chapter IV] give as well the continuity with respect to U of the associated projector.

The continuity of eigenvalues follows from the continuity of the zeros of d_ε introduced earlier.

Letting $P_1(U)$ be the spectral projector associated with $\left\{E_1^i(U), i \in \{1,2\}\right\}$, the eigenvalue of $JH(U)$, we have the formula

$$P_1(U) = -\frac{1}{2\mathrm{i}\pi}\int_\Gamma (JH(U) - z)^{-1} dz,$$

where Γ is a positively oriented circle at the right of the imaginary axis around $E_1^1(U')$ and $E_1^2(U')$ for some fixed U' and U sufficiently close to U'; see [28, Formula I.1.16]. Since the resolvent is smooth outside $U = 0$, we have that $P_1(U)$ is smooth outside $U = 0$.

Using complex conjugation, we obtain the corresponding result for the spectrum at the right of the imaginary axis in a neighborhood of $\mathrm{i}\,(\lambda_1 - \lambda_0)$.

Using Weyl's sequences, we prove that the essential spectrum of $(JH(U))^* = -H(U)J$, for small U, is the essential spectrum of $-(H - E(U))J = -J(H - E(U))$. So z with nonzero real part is in the spectrum of $(JH(U))^*$ if and only if it is an isolated eigenvalue; see [28, Theorem IV.5.33]. Then to obtain $-E_1^i(U)$ and $-\overline{E_1^i(U)}$, we notice that $E_1^i(U)$ and $\overline{E_1^i(U)}$ are eigenvalues of $(JH(U))^*$. Using the symmetry $J(JH(U)) = -(JH(U))^*J$, we show that any algebraic eigenvector ϕ of $(JH(U))^*$ associated with λ, $J\phi$ is an algebraic eigenvector of $JH(U)$ associated with $-\lambda$. Hence, repeating the previous proof for $(JH(U))^*$, we also obtain the multiplicity two. Except for the symmetry of the eigenvalues, this can also be obtained by adapting the previous proof to the left part of the complex plane.

The exponential decay works as in Lemma 1.2. □

Remark 2.1. If $F(z)$ is homogeneous of order p, then there exist $\varepsilon, \Gamma_1, \Gamma_2 > 0$ such that for all $U \in B_{\mathbb{C}^2}(0, \varepsilon)$

$$|U|^{p-2}\,\Gamma_1 \le \widetilde{\Gamma}(|U|) \le |U|^{p-2}\,\Gamma_2.$$

We just write $S((u_1, u_2)) = u_1\phi_0 + u_2 K\phi_0 + h((u_1, u_2))$, expand $\Gamma(U)$, and use Assumption 1.5 with the regularity results of the resolvent from [20, Theorem 1.7].

The following proposition deals with the essential spectrum of our linearized operator.

PROPOSITION 2.2. *If Assumptions* 1.1–1.5 *hold, for any sufficiently small nonzero* $U \in \mathbb{C}^2$, *let*

$$\mathcal{H}_1(U) = \operatorname{span}\left\{\Phi_+^1(U), \Phi_+^2(U), \overline{\Phi_+^1(U)}, \overline{\Phi_+^2(U)}, \Phi_-^1(U), \Phi_-^2(U), \overline{\Phi_-^1(U)}, \overline{\Phi_-^2(U)}\right\}.$$

The orthogonal space of $\mathcal{H}_0(U) \oplus \mathcal{H}_1(U)$,

$$\mathcal{H}_c(U) = \{J\mathcal{H}_0(U) \oplus \mathcal{H}_1(U)\}^\perp,$$

is invariant under the action of $JH(U)$.

We also have that, for $\mathbf{P}_c(U)$, *the orthogonal projector onto* $J\mathcal{H}_c(U)$ *is a bounded operator from* $H^s_\sigma(\mathbb{R}^3, \mathbb{C}^8)$ *or* $B^s_{p,q}(\mathbb{R}^3, \mathbb{C}^8)$ *to itself for any reals* $s, \sigma \in \mathbb{R}$ *and* $p, q \in [1, \infty]$, *and for* $U' \in B_{\mathbb{C}^2}(U, \varepsilon)$, *with sufficiently small* $\varepsilon > 0$, *that*

$$\mathbf{P}_c(U)|_{\mathcal{H}_c(U')} : \mathcal{H}_c(U') \mapsto \mathcal{H}_c(U)$$

is an isomorphism and its inverse $R(U',U)$ can be extended to a bounded operator from $H^s_\sigma(\mathbb{R}^3,\mathbb{C}^8)$ or $B^s_{p,q}(\mathbb{R}^3,\mathbb{C}^8)$ to itself for any reals $s,\sigma\in\mathbb{R}$ and $p,q\in[1,\infty]$.

Moreover, there exists $C>0$ such that we have

$$\|\psi\|_X \le C\,\|P_c\psi\|_X \tag{2.4}$$
$$\forall\psi\in\mathcal{H}_c(U)\cap X \text{ with } X=H^s_\sigma(\mathbb{R}^3,\mathbb{C}^8) \text{ or } B^s_{p,q}(\mathbb{R}^3,\mathbb{C}^8),$$
$$\forall s,\sigma\in\mathbb{R},\quad \forall p,q\in[1,\infty];$$

$$\int_{\mathbb{R}} \|\langle Q\rangle^{-\sigma} e^{sJH(U)}\mathbf{P}_c(U)\psi\|_2^2\,ds \le C\|\psi\|_2^2 \tag{2.5}$$
$$\forall\psi\in L^2,\quad \forall\sigma\ge 1;$$

$$\left\|e^{tJH(U)}\mathbf{P}_c(U)\psi\right\|_2 \le C\|\psi\|_2 \tag{2.6}$$
$$\forall t\in\mathbb{R},\quad \forall\psi\in L^2,$$

and $\mathcal{H}_c(U)$ contains no eigenvector.

Remark 2.2. We use the same notation for $\mathcal{H}_c(U)$ and its real part (see definition below) that appears in our main theorems. We just note that $\mathcal{H}_c(U)$ appears when we discuss spectral properties in our proof. Then when we talk about dynamical properties, we deal with its real part. We remind the reader that the real part of $\mathcal{H}_c(U)$ is left invariant by $JH(U)$.

Proof. We prove that there is no other eigenvector by proving that smoothness estimate (2.5) takes place over

$$\mathcal{H}_c(U)=\{J\mathcal{H}_0(U)\oplus\mathcal{H}_1(U)\}^\perp.$$

First we prove that

$$\mathbf{P}_c((U))|_{\mathcal{H}_c(U')}:\mathcal{H}_c(U')\mapsto\mathcal{H}_c(U)$$

is an isomorphism. To prove it, we exhibit an inverse $R(U',U)$ which is the projector onto $\mathcal{H}_c(U')$ associated with the decomposition $\mathcal{H}_0(U)\oplus\mathcal{H}_1(U)\oplus\mathcal{H}_c(U')$ of $L^2(\mathbb{R}^3,\mathbb{C}^8)$. Indeed, we have $\{\mathcal{H}_0(U)\oplus\mathcal{H}_1(U)\}\cap\mathcal{H}_c(U')=\{0\}$ when U' and U are close to one another and $\mathrm{codim}\mathcal{H}_c(U')=\dim\{\mathcal{H}_0(U)\oplus\mathcal{H}_1(U)\}$. We have a decomposition of $L^2(\mathbb{R}^3,\mathbb{C}^8)$ into closed subspaces; hence the associated projectors are continuous. So $R(U',U)$ should be of the form

$$R(U',U)=Id+\sum_i |J\xi_i(U)\rangle\,\langle\alpha_i(U',U)|\,,$$

where $\xi_i(U)$ is a basis of the eigenspaces of $JH(U)$ and $(\alpha_i(U',U))_i$ solve the equations

$$J\xi_j(U')+\sum_i \langle J\xi_i(U),J\xi_j(U')\rangle\,\alpha_i(U',U)=0.$$

Such an α exists because the matrix $(\langle J\xi_i(U),J\xi_j(U')\rangle)_{i,j}$ is invertible. Indeed, if it is not invertible, there exists $\phi\in\mathcal{H}_1(U')=\mathrm{span}\{\xi_j(U')\}$ orthogonal to $\mathcal{H}_1(U)=$

span$\{\xi_j(U)\}$, and hence $\phi \in \mathcal{H}_c(U)$ with $P_c(U')\phi = 0$. But for all $\psi \in \mathcal{H}_c(U)$, we have

$$\|\psi\| \le \|P_c(U')\psi\| + \|(1 - P_c(U'))\psi\| \le \|P_c(U')\psi\| + C|U - U'|\,\|\psi\|,$$

and hence for ϕ this gives a contradiction.

The boundedness of R in $\mathcal{B}(H^s_\sigma(\mathbb{R}^3, \mathbb{C}^8))$ or $\mathcal{B}(B^s_{p,q}(\mathbb{R}^3, \mathbb{C}^8))$ follows from the exponential decay of eigenvectors and their derivatives; see Proposition 1.1, Lemma 1.2, and Proposition 2.1.

Let us now consider the orthogonal projector P_c associated with the continuous subspace of JH. Since the eigenvectors of JH are exponentially decaying, we can extend P_c to obtain an operator of $L^2_{\pm\sigma}$ into itself. The same is true for $P_c(U)$, and hence we can consider the extension of $\mathcal{H}_c(U)$ to $L^2_{\pm\sigma}$. We still call it $\mathcal{H}_c(U)$.

For all $\psi \in \mathcal{H}_c(U)$,

$$\|\psi\|_{L^2_{-\sigma}} \le \|P_c\psi\|_{L^2_{-\sigma}} + \|(1 - P_c)\psi\|_{L^2_{-\sigma}}.$$

Since $1 - P_c$ is the projector into the eigenspaces of H and ψ is orthogonal to the eigenvectors of $JH(U)$, we obtain that

$$\|(1 - P_c)\psi\|_{L^2_{-\sigma}} = \|(1 - P_c(U))\psi\|_{L^2_{-\sigma}} + O(|U|)\|\psi\|_{L^2_{-\sigma}}.$$

Since the components of eigenvectors with respect of $\mathcal{H}_c(U)$ are small with respect to U (see the proof of Lemma 2.1), the projection of ψ in the eigenspaces of H is small. Moreover, for a sufficiently small nonzero U, we obtain estimate (2.4) for $X = L^2_{-\sigma}$ with $\sigma > 0$.

The rest of estimate (2.4) follows in the same way using the exponential decay of eigenvectors (estimate (2.1) and Lemma 1.2).

We infer that

$$\begin{aligned}
&\|\langle Q\rangle^{-\sigma} e^{tJH(U)} \mathbf{P}_c(U)\psi\| \\
&\le C\|\langle Q\rangle^{-\sigma} \mathbf{P}_c e^{tJH(U)} \mathbf{P}_c(U)\psi\| \\
&\le C\|\langle Q\rangle^{-\sigma} \mathbf{P}_c e^{-\mathrm{i}t(H - E(U))} \mathbf{P}_c(U)\psi\| \\
&\quad + C\left\|\langle Q\rangle^{-\sigma} \int_0^t \mathbf{P}_c e^{-\mathrm{i}(t-s)(H-E(U))} D\nabla F(S(U)) e^{sJH(U)} \mathbf{P}_c(U)\psi\, ds\right\|.
\end{aligned}$$

Using estimates (1.1) and (1.3) of Theorem 1.1, we obtain estimate (2.5) for sufficiently small U:

$$\int_{\mathbb{R}} \|\langle Q\rangle^{-\sigma} e^{-sJH(U)} \mathbf{P}_c(U)\psi\|^2\, ds \le C\|\psi\|^2.$$

Hence there is no eigenvector in the range of $P_c(U)$. Using the inequalities (2.5); the conservation law for H; and Duhamel's formula,

$$e^{JtH(U)} = e^{-\mathrm{i}t(H-E(U))} + \int_0^t e^{-\mathrm{i}(t-s)(H-E(U))} Jd^2\nabla F(S(U)) e^{JsH(U)}\, ds,$$

we prove estimate (2.6). ∎

Since $\mathcal{H}_c(U)$ is closed and $\operatorname{codim}\mathcal{H}_c(U) = \dim\{\mathcal{H}_0(U) \oplus \mathcal{H}_1(U)\}$ and $\mathcal{H}_c(U) \cap \{\mathcal{H}_0(U) \oplus \mathcal{H}_1(U)\} = \{0\}$, we obtain $\mathcal{H}_0(U) \oplus \mathcal{H}_1(U) \oplus \mathcal{H}_c(U) = L^2(\mathbb{R}^3, \mathbb{C}^8)$ and the following proposition.

PROPOSITION 2.3. *Suppose that Assumptions* 1.1–1.5 *hold. Then the space* $\mathcal{H}_0(U)$ *is the geometric null space of* $JH(U)$.

2.2. Stable, unstable, and center manifolds. We can now obtain results similar to those of Bates and Jones [3]. We note that we will not prove that the Cauchy problem (1.8) is locally well-posed for an initial condition outside some manifolds (built below). However, this can be proved with the methods we present here or by generalizing to our case the results of Escobedo and Vega [19].

We have that $JH(U)$ as an operator in $L^2(\mathbb{R}^3,\mathbb{R}^8)$ is a closed densely defined operator that generates a continuous semigroup on $L^2(\mathbb{R}^3,\mathbb{R}^8)$. The spectrum of $JH(U)$ in $L^2(\mathbb{R}^3,\mathbb{R}^8)$ is the same as that of $JH(U)$ in $L^2(\mathbb{R}^3,\mathbb{C}^8)$, and so it splits into three parts,

$$\sigma_s(U)=\{\lambda\in\sigma(JH(u)),\ \Re\lambda<0\}=\left\{-E_1^1(U),-E_1^2(U),-\overline{E_1^1(U)},-\overline{E_1^2(U)}\right\},$$
$$\sigma_c(U)=\{\lambda\in\sigma(JH(u)),\ \Re\lambda=0\}=\{0\}\cup \mathrm{i}\left\{\mathbb{R}\setminus(-c,c)\right\},$$
$$\text{where } c=\min\{m+E(U),m-E(U)\},$$
$$\sigma_u(U)=\{\lambda\in\sigma(JH(u)),\ \Re\lambda>0\}=\left\{E_1^1(U),E_1^2(U),\overline{E_1^1(U)},\overline{E_1^2(U)}\right\},$$

each of which is associated with a spectral real subspace, respectively,

$$X_s(U)=\operatorname{span}_{\mathbb{R}}\left\{\Re\Phi_-^1(U),\Im\Phi_-^1(U),\Re\Phi_-^2(U),\Im\Phi_-^2(U)\right\},$$
$$X_u(U)=\operatorname{span}_{\mathbb{R}}\left\{\Re\Phi_+^1(U),\Im\Phi_+^1(U),\Re\Phi_+^2(U),\Im\Phi_+^2(U)\right\},$$
$$X_c(U)=\Re\mathcal{H}_0(U)\oplus\Re\mathcal{H}_c(U),$$

where we used the notation $\Re\Psi=(1/2)\left(\Psi+\overline{\Psi}\right)$, $\Im\Psi=-(\mathrm{i}/2)\left(\Psi-\overline{\Psi}\right)$, and $\Re X=\{\Re\Psi,\Psi\in X\}$, the real part of the space X. The spaces $X_s(U)$ and $X_u(U)$ are finite dimensional. Let us write $\pi^c(U)$, $\pi^s(U)$, and $\pi^u(U)$ for the projectors associated with the decomposition $X_c(U)\oplus X_s(U)\oplus X_u(U)$. Since the eigenvectors also belong to L^2_σ for any $\sigma\in\mathbb{R}$, the projectors $P_c(U)$ and $\pi^c(U)$ can be defined in L^2_σ for any real σ. We can extend, in this way, the spaces $\mathcal{H}_c(U)$ and $X_c(U)$ to L^2_σ for any $\sigma\in\mathbb{R}$. We have the following lemma.

LEMMA 2.1. *If Assumptions* 1.1–1.5 *hold, then, for any* $\sigma\in\mathbb{R}$*, there exist positive reals* r,C_1,C_2 *such that, for all* $t\in\mathbb{R}$*, we have*

$$C_1\frac{1}{f_+(t)}\le\left\|e^{tJH(U)}\pi^s(U)\right\|_{\mathcal{B}(L^2_\sigma)}\le C_2\frac{1}{f_-(t)},\tag{2.7}$$

$$C_1f_-(t)\le\left\|e^{tJH(U)}\pi^u(U)\right\|_{\mathcal{B}(L^2_\sigma)}\le C_2f_+(t),\tag{2.8}$$

$$\left\|e^{tJH(U)}\pi^c(U)\right\|_{\mathcal{B}(L^2_\sigma)}\le C_2\langle t\rangle^r,\tag{2.9}$$

where

$$f_\pm(t)=\begin{cases}e^{\gamma_\pm t} & \text{if } t\ge0,\\ e^{\gamma_\mp t} & \text{if } t\le0,\end{cases}$$

with

$$\gamma_-<\Gamma_-(U)=\min\{\Re E_1^1(U),\Re E_1^2(U)\},$$
$$\gamma_+>\Gamma_+(U)=\max\{\Re E_1^1(U),\Re E_1^2(U)\}.$$

Proof. The statements for the spaces $X^s(U)$ and $X^u(U)$ follow from (2.1).

The statement about $X^c(U)$ is a little more complicated. We note that we are not looking for an optimal r.

First, the result for $e^{-\mathrm{i}t(D_m+V)}$ in L^2_σ with $\sigma \in 2\mathbb{N}$ follows from [48, Theorem 8.5] (see also Proposition 3.1 below), which is based on the charge conservation. The case $\sigma \in \mathbb{R}$ follows by duality and interpolation.

Then for $e^{tJH(U)}\pi^c(U)$, we use Duhamel's formula,

$$e^{JtH(U)}\pi^c(U) = e^{-\mathrm{i}t(H-E(U))}\pi^c(U) + \int_0^t e^{-\mathrm{i}(t-s)(H-E(U))} Jd^2\nabla F(S(U)) e^{JsH(U)}\pi^c(U)\, ds;$$

then the assertion for $e^{tJH(U)}\pi^c(U)$ follows from the assertion for $e^{-\mathrm{i}t(D_m+V)}$, the charge conservation of $e^{tJH(U)}P_c(U)$ (see (2.6)), the fact that $e^{tJH(U)}S(U) = S(U)$, $e^{tJH(U)}\partial_U^\beta S(U) = \partial_U^\beta S(U) + t\partial_U^\beta E(U)S(U)$, and Lemma 1.2. ∎

By now we do not restrict our study to the space $L^2(\mathbb{R}^3,\mathbb{R}^8)$; we extend it to $L^2_\sigma(\mathbb{R}^3,\mathbb{R}^8)$ for any $\sigma \in \mathbb{R}$, but we still write $\mathcal{H}_c(U)$ and $X_c(U)$ for the extensions of these spaces to $L^2_\sigma(\mathbb{R}^3,\mathbb{R}^8)$ for any $\sigma \in \mathbb{R}$.

We now study the behavior of the solutions in L^2_σ of (1.8) centered around $S(U)$:

$$\partial_t\phi = JH(U)\phi + JN(U,\phi), \tag{2.10}$$

where $H(U) = H + d^2F(S(U)) - E(U)$, $N(U,\phi) = \nabla F(S(U)+\phi) - \nabla F(S(U)) - d^2F(S(U))\phi$, and d^2F is the differential of ∇F.

In this subsection, we study a modified equation which coincides with (2.10) as long as the solution stays in a neighborhood of a small $S(U)$:

$$\partial_t\phi = JH(U)\phi + JN_\varepsilon(U,\phi), \tag{2.11}$$

where $N_\varepsilon(U,\eta) = \rho(\varepsilon^{-1}\eta)N(U,\eta)$ and ρ is a smoothed version of the characteristic function of the unit ball of $\mathbb{R}^8$.

We state the following proposition.

PROPOSITION 2.4 (center-stable manifold). *If Assumptions* 1.1–1.5 *hold, then for any sufficiently small nonzero U, there exists around $S(U)$ a unique invariant smooth center-stable manifold $W^{cs}(U)$ for* (2.11) *built as a graph with value in $X_u(U)$ and tangent to $S(U) + X_c(U) \oplus X_s(U)$ at $S(U)$.*

Any solution $\phi \in L^2_\sigma$ of (2.11) *initially in the neighborhood of $S(U)$ tends as $t \to -\infty$ to $W^{cs}(U)$ with*

$$dist_{L^2_\sigma}(\phi(t), W^{cs}(U)) = O(e^{\gamma t}) \text{ as } t \to -\infty$$

for any $\gamma \in (0, \Gamma_-(U))$ and any $s,\sigma \in \mathbb{R}$, and for any sufficiently small neighborhood V of $S(U)$ any solution in V not in $W^{cs}(U)$ leaves V in finite positive time.

Remark 2.3. For any $s \in \mathbb{R}^+$, due to the exponential decay of eigenvectors, if $\phi \notin H^s_\sigma$, there exists $\psi \in W^{cs}(U)$ such that $\phi - \psi \in H^s_\sigma$, and we have

$$dist_{H^s_\sigma}(\phi(t), W^{cs}(U)) = O(e^{\gamma t}) \text{ as } t \to -\infty,$$

as shown in the following proof.

If we consider only small solutions, we obtain a locally invariant manifold for (2.10); that is to say, for any initial condition in the manifold there exists a corresponding solution of (2.10) which stays in this manifold in a small interval of time

around 0. We notice that in the following proofs the size of this invariant manifold, which is given by ε, is a function of U and this function is $O(\Gamma_-(U))$. From now on, we call this function r.

Proof. Our proof is an adaptation of that of Bressan [8], and we refer to it for more details. We make the proof only for the case $\sigma = 0$; the proof in the general case is similar.

First we prove that there is a global solution of (2.11) which does not grow much as $t \to +\infty$. We look for the solution as a fixed point:

$$y(t) = \mathcal{G}_\varepsilon(y_0, y)(t)$$

for any $y_0 \in X_s(U) \oplus X_c(U)$, where for small positive ε

$$\mathcal{G}_\varepsilon(y_0,\eta)(t) = e^{tJH(U)}y_0 + \int_0^t e^{(t-s)JH(U)}\pi^c(U)JN_\varepsilon(U,\eta(s))\,ds$$

$$+\int_0^t e^{(t-s)JH(U)}\pi^s(U)JN_\varepsilon(U,\eta(s))\,ds - \int_t^{+\infty} e^{(t-s)JH(U)}\pi^u(U)JN_\varepsilon(U,\eta(s))\,ds,$$

with $\pi^*(U)$ the projector into $X^*(U)$ with respect to the decomposition $\oplus_{*\in\{c,s,u\}}X^*(U)$.

Let us introduce, for any Γ smaller than $\Gamma_-(U)$, the space

$$Y_\Gamma = \left\{ y : \mathbb{R} \mapsto L^2(\mathbb{R}^3,\mathbb{C}^4),\ \exists C > 0,\ \|y(t)\|_2 \le Ce^{\Gamma|t|}\ \forall t \in \mathbb{R} \right\}.$$

For sufficiently small $\varepsilon > 0$, the map $\mathcal{G}_\varepsilon(y_0,\cdot)$ leaves Y_Γ invariant and is continuous for the norm

$$N_\Gamma : y \mapsto \sup_{t\in\mathbb{R}} \left\{ \|y(t)\|_2 e^{-\Gamma|t|} \right\}.$$

Moreover, it is a strict contraction for sufficiently small U and $\varepsilon > 0$. Actually we choose ε as a function of Γ which is $O(\Gamma)$. In fact, since $Y_\Gamma \subset Y_{\Gamma'}$ for $\Gamma < \Gamma'$, we obtain that ε as a function of U is $O(\Gamma_-(U))$. This proves the existence of the fixed point y.

Then we fix $h^{cs}_U(y_0) = y(0) - y_0$. The invariance of the graph of h^{cs}_U by the flow of (2.11) is immediate.

Now we prove the smoothness property. We have that $N_\varepsilon(U,\eta)$ is l times differentiable in η from $Y_{\Gamma'}$ to Y_Γ if $(l+1)\Gamma' \le \Gamma$ and that $\mathcal{G}_\varepsilon$ is l times differentiable from $X_c(U) \oplus X_s(U) \times Y_{\Gamma''}$ to Y_Γ if $2l\Gamma'' \le \Gamma$ (see [8]). We introduce the family $(\eta_n)_{n\in\mathbb{N}}$ satisfying

$$\eta_0 = 0 \quad \text{and} \quad \eta_{n+1} = \mathcal{G}_\varepsilon(y_0,\eta_n).$$

This sequence converges to y (the fixed point) in Y_Γ. Moreover, as functions of y_0, the convergence is uniform in Y_Γ (endowed with the norm N_Γ) on bounded sets of $X_s(U) \oplus X_c(U)$.

We want to prove that the sequence of their derivatives of order k with respect to η also converges in Y_Γ on bounded sets for any $\Gamma < \gamma(U)$. We prove it by induction in k. So suppose that $(\partial^j\eta_n)_{n\in\mathbb{N}}$ is converging in Y_Γ for all $j < k$ and any $\Gamma < \gamma(U)$. Then we have that for any $k \ge 2$ (see [8])

$$\partial\eta_n = \partial\mathcal{G}_\varepsilon(y_0,\eta_{n-1}) = L + M\left(\partial_\eta N_\varepsilon(U,\eta_{n-1})\partial\eta_{n_1}\right),$$
$$\partial^k\eta_n = \partial^k\mathcal{G}_\varepsilon(y_0,\eta_{n-1}) = M\left(\partial_\eta N_\varepsilon(U,\eta_{n-1})\partial^k\eta_{n-1} + \Psi_k(\eta_{n-1},\dots,\partial^{k-1}\eta_{n-1})\right),$$

with $L = e^{tJH(U)}$,

$$(M\eta)(t) = -\int_0^t e^{(t-s)JH(U)}\pi^{cs}(U)J\eta(s)\,ds + \int_t^{+\infty} e^{(t-s)JH(U)}\pi^{u}(U)J\eta(s)\,ds,$$

and Ψ_k a smooth function of k parameters. Hence since $M \circ \partial_\eta N_\varepsilon(U, y_{n-1})$ is a strict contraction in Y_Γ for sufficiently small ε and U (once more ε is $O(\Gamma_-(U))$), this proves the convergence of the sequence of kth derivatives in Y_Γ on bounded sets for any $\Gamma < \Gamma_-(U)$. Hence the sequences of derivatives of $(\eta_n)_{n\in\mathbb{N}}$ converge in Y_Γ on bounded sets for any $\Gamma < \Gamma_-(U)$. This gives the differentiability at any order of $y(0) = h(y_0)$. This also gives, since $N(U,\eta) = O(|\eta|^2)$ around zero, that $h(y_0) = O(|y_0|^2)$ around zero.

Now we want to prove that $W^{cs}(U)$ is attractive in negative time. In fact, $W^{cs}(U)$ is the graph of a smooth function $h : X^{cs} \mapsto X^u(U)$. Letting η be such that $S(U) + \eta$ is a solution of (1.8), we have

$$\partial_t \eta = JH(U)\eta + JN_\varepsilon(U,\eta),$$

where

$$\eta = y + r = y + h(y) + z$$

with $y = \pi^{cs}(U)\eta$, and we have the following equation for $z \in X^u(U)$:

$$\partial_t z = JH(U)z + M(U,y,z),$$

where

$$\begin{aligned} M(U,y,z) &= \pi^u(U)\left\{JN_\varepsilon(U,\eta) - JN_\varepsilon(U,y+h(y))\right\} \\ &\quad -Dh(y)\pi^{cs}(U)\left\{JN_\varepsilon(U,\eta) - JN_\varepsilon(U,y+h(y))\right\}. \end{aligned}$$

Using Duhamel's formula, we obtain

$$z(t) = e^{tJH(U)}z(0) + \int_0^t e^{(t-s)JH(U)}M(U,y(s),z(s))\,ds.$$

We obtain, since $z \in X^u(U)$,

$$\|z(t)\| \le e^{\gamma(U)t}\|z(0)\| + C\int_0^t e^{(t-s)\gamma(U)}\|M(U,y(s),z(s))\|\,ds,$$

and so for $\gamma \in (0, \Gamma_-(U))$

$$e^{-\gamma t}\|z(t)\| \le \|z(0)\| + C|U|\sup_{s\in[0,t]}\left\{e^{-\gamma s}\|z(s)\|\right\} + o\left(\sup_{s\in[0,t]}\left\{e^{-\gamma s}\|z(s)\|\right\}\right),$$

where C does not depend on U and z. Hence if $z(0)$ and U are small, we have that there exists $c > 0$ such that $\|z(t)\| \le ce^{\gamma t}$ for all $t \le 0$. We notice that, since $X^u(U) \subset H^s_\sigma$ for any $s \in \mathbb{R}^+$ and is finite dimensional (see Lemma 2.1), the time decay in L^2_σ also gives a time decay in H^s_σ gives for any $s \in \mathbb{R}^+$.

Now choose V a sufficiently small neighborhood of 0 and ϕ a solution of (2.11) initially in V but not in $W^{cs}(U)$. Suppose ϕ stays in V in positive time. We obtain that $\phi \in Y_\Gamma$. We have

$$\begin{aligned}\phi(t) &= e^{tJH(U)}\left(\pi^s(U)+\pi^c(U)\right)\phi(0)\\ &+\int_0^t e^{(t-s)JH(U)}\pi^s(U)JN_\varepsilon(U,\phi(s))\,ds+\int_0^t e^{(t-s)JH(U)}\pi^c(U)JN_\varepsilon(U,\phi(s))\,ds\\ &+e^{tJH(U)}\pi^u(U)\left(\pi^u(U)\phi(0)+\int_0^\infty e^{-sJH(U)}\pi^u(U)JN_\varepsilon(U,\phi(s))\,ds\right)\\ &-\int_t^\infty e^{(t-s)JH(U)}\pi^u(U)JN_\varepsilon(U,\phi(s))\,ds\end{aligned}$$

with

$$\pi^u(U)\phi(0)+\int_0^\infty e^{-sJH(U)}\pi^u(U)JN_\varepsilon(U,\phi(s))\,ds\neq 0.$$

Hence we obtain with (2.8) that $\phi(t)$ exponentially tends to infinity in norm. This is a contradiction, so ϕ leaves V in finite time. ∎

Then reversing the time direction, that is to say, replacing H by $-H$ and F by $-F$, we obtain with this theorem a locally invariant center-unstable manifold with the following corresponding properties.

PROPOSITION 2.5 (center-unstable manifold). *If Assumptions* 1.1–1.5 *hold, then for any sufficiently small nonzero U, there exists around $S(U)$ a unique smooth invariant center-unstable manifold $W^{cu}(U)$ for* (2.11)*, built as a graph with value in $X_S(U)$ and tangent to $S(U)+X_c(U)\oplus X_u(U)$ at $S(U)$.*

Any solution $\phi \in L^2_\sigma$ of (2.11) *initially in the neighborhood of $S(U)$ tends as $t\to+\infty$ to $W^{cu}(U)$ with, for any $s\in\mathbb{R}^+$,*

$$dist_{H^s_\sigma}(\phi(t),W^{cu}(U))=O(e^{-\gamma t})\ \text{as}\ t\to+\infty,$$

and for $\gamma\in(0,\Gamma_+(U))$, any $s,\sigma\in\mathbb{R}$, and for any V a sufficiently small neighborhood of $S(U)$, any solution in V not in $W^{cu}(U)$ leaves V in finite negative time.

We can build in the same way a center manifold which is the intersection of the previous two manifolds.

PROPOSITION 2.6 (center manifold). *If Assumptions* 1.1–1.5 *hold, then for any sufficiently small nonzero U, there exists around $S(U)$ a unique smooth invariant center manifold $W^c(U)$ for* (2.11)*, built as a graph with value in $X_s(U)\oplus X_u(U)$ and tangent to $S(U)+X_c(U)$ at $S(U)$.*

Moreover, we have that $W^c(U)=W^{cs}(U)\cap W^{cu}(U)$ and $W^c(U)$ contains the part of the PLS manifold which is in a small neighborhood of $S(U)$.

Proof. We build the center manifold with the same method as in the previous cases. We can also build a center-unstable manifold inside a center-stable manifold. More precisely, let $h^s_U : X_c(U)\oplus X_s(U)\mapsto X_u(U)$ be the map defining the center-stable manifold and let $h^u_U : X_c(U)\oplus X_u(U)\mapsto X_s(U)$ be the map defining the center-unstable manifold. A solution $y=S(U)+y_c+y_s+y_u$ with $y_*\in X_*(U)$ for $*\in\{c,s,u\}$ is in the center-stable manifold if $y_u=h^s_U(y_c,y_s)$. Hence to obtain a center-unstable manifold inside a center-stable manifold one has to solve, for each y_c, the equation

$$y_s=h^u_U(y_c,h^s_U(y_c,y_s)),$$

which can be solved inside a small ball for small y_c and small U by means of the fixed point theorem, since $h^*_U(y_c, z)$ is $O(|y_c|^2 + |z|^2)$ around zero for $* \in \{s, u\}$.

In the same way, we can also build a center-stable manifold inside the center-unstable manifold.

Using the uniqueness of the center manifold, we obtain that these two manifolds are equal to the center manifold and $W^c(U) = W^{cs}(U) \cap W^{cu}(U)$.

Then any stationary states in a small neighborhood of $S(U)$ converge to $W^{cs}(U)$ and $W^{cu}(U)$ using the stabilization results of Propositions 2.4 and 2.5. Hence, we have that it belongs to $W^{cs}(U) \cap W^{cu}(U) = W^c(U)$. ∎

In the following two sections, we study the dynamics inside and outside the center manifold, respectively.

3. The dynamics inside the center manifold. In this section, we prove that the dynamics inside the center manifold around $S(V_0)$, for small nonzero V_0, relaxes towards the PLS manifold. To this end, we use Theorems 1.1 and 1.2 regarding the time decay of the propagator associated with H.

3.1. Decomposition of the system. As in [7], we decompose a solution $\phi \in W^c(V_0)$ of (1.8) with respect to the spectrum of $JH(U)$, with U specified in what follows, and we study the equations for these different parts of the decomposition. We introduce

$$\mathcal{H}_0^{\perp_J}(u_1, u_2) = \Bigg\{ \eta \in L^2(\mathbb{R}^3, \mathbb{C}^8), \Big\langle J\eta, \frac{\partial}{\partial \Re u_1} S(u_1, u_2) \Big\rangle = \Big\langle J\eta, \frac{\partial}{\partial \Im u_1} S(u_1, u_2) \Big\rangle$$
$$= \Big\langle J\eta, \frac{\partial}{\partial \Re u_2} S(u_1, u_2) \Big\rangle = \Big\langle J\eta, \frac{\partial}{\partial \Im u_2} S(u_1, u_2) \Big\rangle = 0 \Bigg\}.$$

In fact, we have

$$\mathcal{H}_0^{\perp_J}(U) = \mathcal{H}_1(U) \oplus \mathcal{H}_c(U),$$

which is invariant under the action of $JH(U)$. We recall that $\mathcal{H}_1(U)$ is defined in Proposition 2.1 and $\mathcal{H}_c(U)$ in Proposition 2.2. We have the following lemma.

LEMMA 3.1. *If Assumptions* 1.1–1.4 *hold, let* $s, \sigma \in \mathbb{R}$. *Then there exist* $\varepsilon, \varepsilon' > 0$ *such that, for the manifold*

$$\Sigma = \Big\{ (U, \eta),\ U \in B_{\mathbb{C}^2}(0, \varepsilon'),\ \eta \in \mathcal{H}_0^{\perp_J}(U) \Big\}$$

endowed with the metric of $\mathbb{C}^2 \times H^s_\sigma$ *and any function* $\phi \in B_{H^s_\sigma}(0, \varepsilon)$, *there exists a unique* $(U, \eta) \in \Sigma$ *with*

$$\phi = S(U) + \eta.$$

Moreover, there exists a neighborhood $\mathcal{O}$ *of* $(0, 0) \in \Sigma$ *such that the mapping* $\phi \mapsto (U, \eta) \in \mathcal{O}$ *is smooth.*

Proof. To prove that Σ is a manifold, we use Proposition 2.2, which gives that it is locally isomorphic to some open subset of $\mathbb{C}^2 \times \mathcal{H}_c$ endowed with the metric of $\mathbb{C}^2 \times H^s_\sigma$. Then we work as in [22, Lemma 2.3]. Indeed we are looking, for all $\phi \in B_{H^s_\sigma}(0, \varepsilon)$, for a solution U in $\mathbb{C}^2 = \mathbb{R}^4$ of the equation

$$F(\phi, U) = (0, 0, 0, 0),$$

where

$$F(\phi,U)=\left(\left\langle J\left(\phi-S(U)\right),\frac{\partial}{\partial\Re u_1}S(u_1,u_2)\right\rangle,\left\langle J\left(\phi-S(U)\right),\frac{\partial}{\partial\Im u_1}S(u_1,u_2)\right\rangle,\right.$$
$$\left.\left\langle J\left(\phi-S(U)\right),\frac{\partial}{\partial\Re u_2}S(u_1,u_2)\right\rangle,\left\langle J\left(\phi-S(U)\right),\frac{\partial}{\partial\Im u_2}S(u_1,u_2)\right\rangle\right)$$

is smooth and satisfies $F(0,0)=0$ and

$$D_UF(0,0)=\begin{pmatrix}0&1&1&1\\1&0&1&1\\1&1&0&1\\1&1&1&0\end{pmatrix},$$

which is invertible in $\mathbb{R}^4$. Hence we apply the implicit function theorem. □

For any solution ϕ of (1.8) on an interval of time I containing 0, we write for $t\in I$

$$\phi(t)=e^{-\mathrm{i}\int_0^t E(U(s))\,ds}\left(S(U(t))+\eta(t)\right),$$

where $\eta(t)\in\mathcal{H}_0^{\perp_J}(U(t))$, and we want to solve the equation

$$\begin{aligned}\mathrm{i}\partial_t\eta&=\left\{H-E(U)\right\}\eta+\left\{\nabla F(S(U)+\eta)-\nabla F(S(U))\right\}-\mathrm{i}dS(U)\dot U\\&=\left\{H+d^2F(S(U))-E(U)\right\}\eta+N(U,\eta)-\mathrm{i}dS(U)\dot U\end{aligned}\tag{3.1}$$

for $\eta(t)\in\mathcal{H}_0^{\perp_J}(U(t))$. Here d^2F is the differential of ∇F and dS is the differential of S in $\mathbb{R}^2$. To close the system, we need the equation for U. This follows from the condition

$$\langle\eta(t),JdS(U(t))\rangle=0.$$

After a time derivation (as in [7]), we obtain the equation

$$\dot U(t)=-A(U(t),\eta(t))\langle N(U(t),\eta(t)),dS(U(t))\rangle,$$

where

$$A(U,\eta)=[\langle JdS(U),dS(U)\rangle-\langle J\eta,d^2S(U)\rangle]^{-1};$$

indeed the matrix $[\langle JdS(U(t)),dS(U(t))\rangle-\langle J\eta(t),d^2S(U(t))\rangle]$ is invertible for small $|U(t)|$ and $\|\eta(t)\|_2$ since we have

$$[\langle JdS(U(t)),dS(U(t))\rangle-\langle J\eta(t),d^2S(U(t))\rangle]=\begin{pmatrix}J&0_2\\0_2&J\end{pmatrix}+O(|U(t)|+\|\eta(t)\|_2).$$

We will need the following lemma.

LEMMA 3.2. *For any $s,s',\sigma\in\mathbb{R}$, any $p,q\in[1,\infty]$, and any $V_0\in\mathbb{C}^2\setminus\{0\}$ sufficiently small, there exist $\varepsilon,\varepsilon'>0$ such that, for the manifold*

$$\mathcal{S}(V_0,\varepsilon)=\left\{(U,z);\ U\in B_{\mathbb{C}^2}(V_0,\varepsilon),z\in\mathcal{H}_c(U)\cap B_{H^{s'}_\sigma}(0,\varepsilon')\right\}$$

endowed with the metric of $\mathbb{C}^2 \times H^{s'}_\sigma$*, there exists a unique map* $g : S(V_0,\varepsilon) \mapsto B^s_{p,q}(\mathbb{R}^3,\mathbb{C}^4)$ *which is smooth and satisfies* $g(U,z) \in \mathcal{H}_1(U)$*,* $z + g(U,z) \in \mathcal{H}_0^{\perp_J}(U)$*, and* $S(U) + z + g(U,z) \in W^c(V_0)$ *for all* $(U,z) \in S(V_0,\varepsilon)$*. Moreover, we have* $\|g(U,z)\|_{B^s_{p,q}} = O(\|z\|^2_{H^{s'}})$*.*

Proof. The fact that $\mathcal{S}(V_0,\varepsilon)$ is a manifold here is proved as in Lemma 3.1.

Let h^c be the function for which $W^c(V_0)$ is the graph. Any $\phi \in L^2(\mathbb{R}^3,\mathbb{R}^8)$ can be written in the form $S(V_0)+\tilde{U}\cdot DS(V_0)+\xi+\rho$ with $\rho \in \mathcal{H}_1(V_0)$ and $\xi \in \mathcal{H}_c(V_0)$. It can also be written in the form $S(U)+z+r$ with $r \in \mathcal{H}_1(U)$ and $z \in \mathcal{H}_c(U)$. These two decompositions in fact define two bijective smooth maps in sufficiently small sets (for the first we have a linear decomposition; for the second see Lemma 3.1). We write Ψ for the first and Φ for the second. Then $f = \Psi \circ \Phi^{-1}$ has three components following the decomposition $\mathcal{H}_0(V_0) \oplus \mathcal{H}_1(V_0) \oplus \mathcal{H}_c(V_0)$; we write them as (f_1, f_2, f_3). Then g is the solution of the implicit equation in r,

$$F(U,z,r) = f_2(U,z,r) - h^c(f_1(U,z,r), f_3(U,z,r)) = 0,$$

which can be solved by the implicit function theorem in $H^{s'}_\sigma$ since $\partial_r F(V_0,0,0)$ is invertible from $\mathcal{H}_1(V_0)$ to itself because $\partial_r f_2(V_0,0,0)$ ($f_2(V_0,r,0) = r$) is invertible from $\mathcal{H}_1(V_0)$ to itself and $Dh_c(0,0) = 0$.

The smoothness of g in the Besov spaces follows from the fact that $g(U,z) \in \mathcal{H}_1(U)$, and the exponential decay for excited states and their derivatives is given by (2.1).

Then we note that, for any U close to V_0, the previous proof can be applied to $W^c(U)$. It shows that $W^c(U)$, $W^c(V_0)$ are, in a neighborhood of $S(V_0)$, graphs of two functions on $\mathcal{S}(V_0,\varepsilon)$, which are equal up to a translation in $\mathbb{C}^2$ of the first parameter. Hence their graphs are equal, so locally $W^c(U) = W^c(V_0)$. The last assertion then follows from the fact that at $S(U)$, $W^c(U)$ is tangent to $S(U)+X^c(U)$ and $X^c(U)\cap\mathcal{H}_1(U) = \{0\}$. ∎

Hence decomposing η with respect to the spectrum of $JH(U)$, we write

$$\eta(t) = g(U(t),z(t)) + z(t)$$

with $z \in \mathcal{H}_c(U) \cap L^2(\mathbb{R}^3,\mathbb{R}^8)$. We obtain the system

$$\begin{cases} \dot{U} = -A(U,\eta)\langle N(U,\eta), dS(U)\rangle, \\ \partial_t z = JH(U)z + \mathbf{P}_c(U)JN(U,\eta) \\ \quad + \mathbf{P}_c(U(v))dS(U(v))A(U(v),\eta(v))\langle N(U(v),\eta(v)), dS(U(v))\rangle \\ \quad + (dP_c(U))A(U,\eta)\langle N(U,\eta), dS(U)\rangle\eta \end{cases}$$

with

$$\eta(t) = z(t) + g\left(U(t),z(t)\right).$$

We note that this equation is defined only *for* z *small with real values and* U *small*. We now study this system.

3.2. The stabilization towards the PLS manifold. We now show that any solution of (1.8) which belongs to the center manifold $W^c(V_0)$, for a small nonzero V_0, stabilizes as $t \to \pm\infty$ towards the manifold of the stationary states inside $W^c(V_0)$. To this end, we will use Theorems 1.1 and 1.2 to prove that z tends to zero in some sense.

Let us define for any ε, $\delta > 0$

$$\mathcal{U}(\varepsilon,\delta) = \left\{ U \in \mathcal{C}^1(\mathbb{R}, B_{\mathbb{C}^2}(V_0,\varepsilon)),\ \|\dot{U}\|_{L^1(\mathbb{R})\cap L^\infty(\mathbb{R})} \leq \delta^2 \right\},$$

and for any $U \in \mathcal{U}(\varepsilon,\delta)$, let s, β *be such that* $s > \beta + 2 > 2$ *and* $\sigma > 3/2$,

$$\mathcal{Z}(U,\delta) = \Big\{ z \in \mathcal{C}(\mathbb{R}, L^2(\mathbb{R}^3,\mathbb{R}^8)),\ z(t) \in \mathcal{H}_c(U(t)),$$

$$\max\left[\|z\|_{L^\infty(\mathbb{R},H^s)}, \|z\|_{L^2(\mathbb{R},H^s_{-\sigma})}, \|z\|_{L^2(\mathbb{R},B^\beta_{\infty,2})} \right] \leq \delta \Big\},$$

and ε, δ are small enough to ensure that for $U \in \mathcal{U}(\varepsilon,\delta)$ and $z \in \mathcal{Z}(U,\delta)$

$$S(U) + z + g(U,z) \in W^c(V_0) \cap B_{H^s}(S(V_0), r(V_0)),$$

where g is defined in Lemma 3.2 and r is defined in Remark 2.3. It will appear later that δ is of the same order as $\|z_0\|_{H^s}$ (see Lemma 3.8).

3.2.1. Some useful lemmas. In the rest of our study, we will need some technical lemmas, which we collect here.

LEMMA 3.3. *If Assumptions* 1.1–1.4 *hold, let* $\sigma, \sigma' \in \mathbb{R}$, $s > 1$, *and* $p, \widetilde{p_1}, p_1, p_2, q$ *in* $[1,\infty]$ *be such that*

$$\frac{1}{p} + \frac{s}{3} \geq \frac{1}{p_1} + \frac{1}{p_2} \geq \frac{1}{p}$$

and

$$\frac{1}{p} + \frac{s}{3} \geq \frac{1}{\widetilde{p_1}}.$$

Then there exist $\varepsilon > 0$ *and* $C > 0$ *such that, for all* $U \in B_{\mathbb{C}}(0,\varepsilon)$ *and* $\eta \in B^s_{p_2,q}(\mathbb{R}^3,\mathbb{R}^8) \cap L^\infty(\mathbb{R}^3,\mathbb{R}^8)$ *with* $\langle Q\rangle^\sigma \eta \in B^s_{p_1,q}(\mathbb{R}^3,\mathbb{R}^8)$ *and* $\langle Q\rangle^{\sigma'}\eta \in B^s_{\widetilde{p_1},q}(\mathbb{R}^3,\mathbb{R}^8)$, *we have*

$$\|\langle Q\rangle^\sigma N(U,\eta)\|_{B^s_{p,q}} \leq C\left(s,F,|U| + \|\eta\|_{L^\infty}\right)|U|\,\|\eta\|_{L^\infty}\left\|\langle Q\rangle^{\sigma'}\eta\right\|_{B^s_{\widetilde{p_1},q}} + C\left(s,F,|U| + \|\eta\|_{L^\infty\cap B^s_{p_2,q}}\right)\|\eta\|^2_{L^\infty}\,\|\langle Q\rangle^\sigma\eta\|_{B^s_{p_1,q}}. \tag{3.2}$$

Proof. We recall the definition

$$N(U,\eta) = \nabla F(S(U)+\eta) - \nabla F(S(U)) - d^2F(S(U))\eta.$$

We have

$$N(U,\eta) = \int_0^1\int_0^1 d^3F(S(U)+\theta'\theta\eta)\cdot\eta\cdot\theta\eta\,d\theta'd\theta$$

or

$$N(U,\eta) = \frac{1}{2}d^3F(S(U))\cdot\eta\cdot\eta + \int_0^1\int_0^1 d^4F(S(U)+\theta''\theta'\theta\eta)\cdot\theta'\theta\eta\cdot\eta\cdot\theta\eta\,d\theta''d\theta'd\theta.$$

Then we use, for $s \in \mathbb{R}^*_+$ and p, p_1, p_2, $q \in [1,\infty]$ such that $\frac{1}{p} + \frac{s}{3} \geq \frac{1}{p_1} + \frac{1}{p_2} \geq \frac{1}{p}$,

$$\|uv\|_{B^s_{p,q}} \leq C\|u\|_{B^s_{p_1,q}}\|v\|_{B^s_{p_2,q}},$$

and for $s > 1$, we use [19, Proposition 2.1]

$$\|d^k F(\psi)\|_{B^s_{p2,q}} \leq C\left(s, F, \|\psi\|_{L^\infty}\right) \|\psi\|_{B^s_{p2,q}}$$

for $k = 3$ or $k = 4$ and $d^4F(z) = O(|z|)$; otherwise we decompose $d^4F(z) = A + O(|z|)$, where A is a constant operator.

Eventually using Lemma 1.2 and

$$\left\| \langle Q\rangle^\sigma |\eta|^l \right\|_{B^s_{p_1,q}} \leq C \|\eta\|^{l-1}_{L^\infty} \|\langle Q\rangle^\sigma \eta\|_{B^s_{p_1,q}}$$

for $l \in \mathbb{N}$, we conclude the proof. □

LEMMA 3.4. *If Assumptions* 1.1–1.4 *hold, let* $\sigma \in \mathbb{R}$, $s > 1$, $p, p_1, p_2, q \in [1, \infty]$, *and* $\sigma_1, \sigma_2 \in \mathbb{R}$ *such that*

$$\frac{1}{p} + \frac{s}{3} \geq \frac{1}{p_1} + \frac{1}{p_2} \geq \frac{1}{p}.$$

Then there exist $\varepsilon > 0$ *and* $C > 0$ *such that, for all* $U \in B_{\mathbb{C}}(0, \varepsilon)$ *and* $\eta \in B^s_{p,q}(\mathbb{R}^3, \mathbb{R}^8) \cap L^\infty(\mathbb{R}^3, \mathbb{R}^8)$ *with* $\langle Q\rangle^{\sigma_1}\eta \in B^s_{p_1,q}(\mathbb{R}^3, \mathbb{R}^8)$ *and* $\langle Q\rangle^{\sigma_2}\eta \in B^s_{p_2,q}(\mathbb{R}^3, \mathbb{R}^8)$, *we have*

$$\begin{aligned}
&\|\langle Q\rangle^\sigma \left(\nabla F(S(U) + \eta) - \nabla F(S(U)) - \nabla F(\eta)\right)\|_{B^s_{p,q}} \\
&\leq C(s, F, |U| + \|\eta\|_{L^\infty}) \left(|U| + \|\langle Q\rangle^{\sigma_1}\eta\|_{B^s_{p_1,q}}\right) |U| \, \|\langle Q\rangle^{\sigma_2}\eta\|_{B^s_{p_2,q}}.
\end{aligned}$$

Proof. The proof is similar to that of Lemma 3.3. □

LEMMA 3.5. *If Assumptions* 1.1–1.4 *hold, let* $\sigma \in \mathbb{R}$, $s > 1$, *and* $p, q \in [1, \infty]$ *such that* $sp \geq 3$. *Then there exist* $\varepsilon > 0$ *and* $C > 0$ *such that, for all* U, $U' \in B_{\mathbb{C}^2}(0, \varepsilon)$ *and* η, $\eta' \in B^s_{p,q}(\mathbb{R}^3, \mathbb{R}^8)$, *we have*

$$\begin{aligned}
\|\langle Q\rangle^\sigma \{N(U, \eta) - N(U', \eta')\}\|_{B^s_{p,q}} &\leq C\left(s, F, |U| + |U'| + \|\eta\|_{B^s_{p,q}} + \|\eta'\|_{B^s_{p,q}}\right) \\
\times \Big\{ &\left(\|\langle Q\rangle^{\sigma_1}\eta\|_{B^s_{p,q}} + \|\langle Q\rangle^{\sigma_1}\eta'\|_{B^s_{p,q}}\right)^2 \left(|U - U'| + \|\langle Q\rangle^{\sigma_2}(\eta - \eta')\|_{B^s_{p,q}}\right) \\
&+ \left(|U| + |U'| + \left\|\langle Q\rangle^{\sigma_1'}\eta\right\|_{B^s_{p,q}} + \left\|\langle Q\rangle^{\sigma_1'}\eta'\right\|_{B^s_{p,q}}\right) \\
&\times \left(\|\langle Q\rangle^{\sigma_2'}\eta\|_{B^s_{p,q}} + \|\langle Q\rangle^{\sigma_2'}\eta'\|_{B^s_{p,q}}\right) \|\langle Q\rangle^{\sigma_3'}(\eta - \eta')\|_{B^s_{p,q}} \Big\},
\end{aligned}$$

with $2\sigma_1 + \sigma_2 = \sigma_1' + \sigma_2' + \sigma_3' = \sigma$ *if* $\langle Q\rangle^w \eta$, $\langle Q\rangle^w \eta' \in B^s_{p,q}(\mathbb{R}^3, \mathbb{R}^8)$ *for* $w \in \{\sigma_1, \sigma_2, \sigma_1', \sigma_2', \sigma_3'\}$.

Proof. Using the identity

$$N(u, \eta) = \int_0^1 \int_0^1 d^3F(S(u) + \theta'\theta\eta) \cdot \eta \cdot \theta\eta \, d\theta' d\theta,$$

we can restrict our study to $d^3F(\phi) - d^3F(\phi')$. If $F = O(|z|^5)$, we have

$$\|\langle Q\rangle^\sigma \left(d^3F(\phi) - d^3F(\phi')\right)\|_{B^s_{p,q}} \leq \int_0^1 \|d^4F(\phi + t(\phi - \phi'))\|_{B^s_{p,q}} \|\langle Q\rangle^\sigma(\phi - \phi')\|_{B^s_{p,q}} \, dt.$$

Then since $s > 1$ and $sp \geq 3$, we use

$$\|d^4F(\psi)\|_{B^s_{p,q}} \leq C(s, F, \|\psi\|_{B^s_{p,q}}).$$

Using Lemma 1.2, we conclude the proof when $F = O(|z|^5)$.

Otherwise, if F is a homogeneous polynomial of order 4, the proof is easily adaptable since d^4F is a constant tensor.

The case $F = O(|z|^4)$ follows by summing the two previous cases since, as a function of $u \in \mathbb{R}^8$, $F(u) = Au^{\otimes 4} + O(|u|^5)$. ∎

LEMMA 3.6. *If Assumptions* 1.1–1.4 *hold, let* $\sigma \in \mathbb{R}$, $s \in \mathbb{R}$, *and* $p, q \in [1, \infty]$. *Then there exist* $\varepsilon > 0$, $M > 0$, *and* $C > 0$ *such that, for all* $U, U' \in B_{\mathbb{C}^2}(0, \varepsilon)$ *and* $\eta, \eta' \in B_{L^2(\mathbb{R}^3, \mathbb{R}^8)}(0, M)$ *with* $\langle Q \rangle^\sigma \{\eta - \eta'\} \in B^s_{p,q}(\mathbb{R}^3, \mathbb{R}^8)$, *one has*

$$|A(U, \eta) - A(U', \eta')| \leq C \left\{ |U - U'| + \|\langle Q \rangle^\sigma \{\eta - \eta'\}\|_{B^s_{p,q}} \right\}. \tag{3.3}$$

Proof. We recall that

$$A(U, \eta) = [\langle JdS(U), dS(U) \rangle - \langle J\eta, d^2 S(U) \rangle]^{-1}.$$

We have

$$\begin{aligned} A(U, \eta) - A(u', \eta') &= -[\langle JdS(U), dS(U) \rangle - \langle J\eta, d^2 S(U) \rangle]^{-1} \\ &\times \left\{ \langle JdS(U), dS(U) \rangle - \langle J\eta, d^2 S(U) \rangle - \langle JdS(U'), dS(U') \rangle + \langle J\eta', d^2 S(U') \rangle \right\} \\ &\times [\langle JdS(U'), dS(U') \rangle - \langle J\eta', d^2 S(U') \rangle]^{-1}. \end{aligned}$$

The lemma then follows from Lemma 1.2. ∎

3.2.2. Global well-posedness for z. Let $U \in \mathcal{U}(\varepsilon, \delta)$ and $z_0 \in \mathcal{H}_c(U(0)) \cap H^s$. Let us write $U_\infty = \lim_{t \to +\infty} U(t)$; then we define $\mathcal{T}_{U, z_0}(z)$ by

$$\begin{aligned} \mathcal{T}_{U,z_0}(z)(t) &= e^{-\mathrm{i}tH + \mathrm{i}\int_0^t E(U(r))\, dr} z_0 \\ &+ \int_0^t e^{-\mathrm{i}(t-v)H + \mathrm{i}\int_v^t E(U(r))\, dr} \mathbf{P}_c(U(v)) J \nabla F(\eta(v))\, dv \\ &+ \int_0^t e^{-\mathrm{i}(t-v)H + \mathrm{i}\int_v^t E(U(r))\, dr} \\ &\quad \times \mathbf{P}_c(U(v)) J \{\nabla F(S(U(v)) + \eta(v)) - \nabla F(S(U(v)) - \nabla F(\eta(v))\}\, dv \\ &+ \int_0^t e^{-\mathrm{i}(t-v)H + \mathrm{i}\int_v^t E(U(r))\, dr} \\ &\quad \times \mathbf{P}_c(U(v)) dS(U(v)) A(U(v), \eta(v)) \langle N(U(v), \eta(v)), dS(U(v)) \rangle\, dv \\ &- \int_0^t e^{-\mathrm{i}(t-v)H + \mathrm{i}\int_v^t E(U(r))\, dr} d\mathbf{P}_c(U(v)) \dot{U}(v) \eta(v)\, dv \end{aligned}$$

with

$$\eta(t) = z(t) + g\left(U(t), z(t)\right).$$

First, we have a local well-posedness result for z with the following lemma.

LEMMA 3.7. *If Assumptions* 1.1–1.5 *hold, then there exist* $\varepsilon_0 > 0$ *and* $\delta_0 > 0$ *such that for any* $\varepsilon \in (0, \varepsilon_0)$, $\delta \in (0, \delta_0)$, $U \in \mathcal{U}(\delta, \varepsilon)$, *and* $z_0 \in B_{H^s(0,\delta)} \cap \mathcal{H}_c(U(0))$ *there are* $T^\pm(z_0, U) > 0$ *and a solution*

$$z \in \cap_{k=0}^2 \mathcal{C}^k((-T^-(z_0, U); +T^+(z_0, U)), H^{s-k}(0, \delta))$$

of the equation

$$\begin{cases} \partial_t z = JH(U)z + \mathbf{P}_c(U)JN(u,\eta) - (d\mathbf{P}_c(U))\dot{U}\eta, \\ z(0) = z_0, \end{cases} \tag{3.4}$$

where $\eta(t) = z(t) + g\,(U(t), z(t))$.

Moreover, z *is unique in* $L^\infty((-T', T), H^s)$ *for any* $T \in (0, T^+(z_0, U))$ *and* $T' \in (0, T^-(z_0, U))$, *and we have that if* $T^+(z_0, U) < +\infty$, *then*

$$\lim_{t \to T^+(z_0,U)} \|z(t)\|_{H^s} \geq \delta,$$

and if $T^-(z_0, U) = +\infty$, *then*

$$\lim_{t \to -T^-(z_0,U)} \|z(t)\|_{H^s} \geq \ \delta.$$

Proof. The proof is a consequence of the fixed point theorem applied to $\mathcal{T}_{U,z_0}$.

Using Lemmas 3.3, 3.5, and 3.6 with the estimate (2.7)–(2.9) and the properties of g given by Lemma 3.2, we obtain that $\mathcal{T}_{U,z_0}$ leaves a small ball in H^s invariant and is a contraction inside this ball.

Hence there exists a unique solution defined on the interval $[-T, T]$. Classical arguments permit us to extend the solution over a maximal interval $(-T^-(z_0, U), T^+(z_0, U))$ such that if $T^+(z_0, U) < \infty$, then necessarily the solution should leave a small ball in H^s at time $T^+(z_0, U)$. ∎

We now have a global well-posedness result as stated in the following lemma.

LEMMA 3.8. *If Assumptions* 1.1–1.5 *hold, there exist* $\varepsilon_0 > 0$, $\delta_0 > 0$, *and* $C > 0$ *such that for any* $\varepsilon \in (0, \varepsilon_0)$, $\delta \in (0, \delta_0)$, $U \in \mathcal{U}(\varepsilon, \delta)$, *and* $z_0 \in B_{H^s}(0, \delta) \cap \mathcal{H}_c(U(0))$ *we obtain, for the Cauchy problem* (3.4), $T^+(U, z_0) = +\infty$, $T^-(U, z_0) = +\infty$, $z \in \mathcal{Z}(U, \delta)$, *and*

$$\max\left[\|z\|_{L^\infty(\mathbb{R},H^s)}, \|z\|_{L^2(\mathbb{R},H^s_{-\sigma})}, \|z\|_{L^2(\mathbb{R},B^\beta_{\infty,2})}\right] \leq C\,\|z_0\|_{H^s}\,.$$

Proof. We have $(1 - P_c(U))z \equiv 0$ because $(1 - P_c(U(0)))z(0) = 0$ and its time derivative is zero.

Let us introduce for any $0 < T < T^+(U, z_0)$ the function

$$m(T) = \sup_{t \in (-T,T)} \left\{ \|z\|_{L^\infty((-T,T),H^s)}\,,\ \|z\|_{L^2((-T,T),H^s_{-\sigma})}\,,\ \|z\|_{L^2((-T,T),B^\beta_{\infty,2})} \right\}.$$

First, we study the estimation of $L^2((-T, T), H^s_{-\sigma})$. We use estimate (2.4) and the estimates of Theorem 1.1:

$$\begin{aligned} &\|z\|_{L^2((-T,T),H^s_{-\sigma})} \\ &\leq C_0\,\|z_0\|_{H^s} + C\left\|\mathbf{P}_c\int_0^t e^{-\mathrm{i}(t-v)H + \mathrm{i}\int_v^t E(U(r))\,dr}\mathbf{P}_c(U(v))J\nabla F(\eta(v))\,dv\right\|_{L^2((-T,T),H^s_{-\sigma})} \\ &\quad + C\,\|\nabla F(S(U)+\eta) - \nabla F(S(U) - \nabla F(\eta)\|_{L^2((-T,T),H^s_\sigma)} \\ &\quad + C\,\|dS(U)A(U,\eta)\langle N(U,\eta), dS(U)\rangle\|_{L^2((-T,T),H^s_\sigma)} \\ &\quad + C\left\|(d\mathbf{P}_c(U)\dot{U}\eta\right\|_{L^2((-T,T),H^s_\sigma)}. \end{aligned}$$

We now study the estimation of the third term of the right-hand side:

$$\left\| \int_0^t e^{-\mathrm{i}(t-v)H+\mathrm{i}\int_v^t E(U(r))\,dr} \mathbf{P}_c \mathbf{P}_c(U(v)) J\nabla F(\eta(v))\,dv \right\|_{L^2_t((-T,T),H^s_{-\sigma})}$$

$$\leq \int_{-T}^T \left\| e^{-\mathrm{i}(t-v)H+\mathrm{i}\int_v^t E(U(r))\,dr} \mathbf{P}_c \mathbf{P}_c(U(v)) J\nabla F(\eta(v)) \right\|_{L^2_t((-T,T),H^s_{-\sigma})} dv$$

$$\leq C(U) \left\| \nabla F(\eta) \right\|_{L^1((-T,T),H^s)}$$

$$\leq C(U) \left\| \eta \right\|^2_{L^2((-T,T),L^\infty)} \left\| \eta \right\|_{L^\infty((-T,T),H^s)},$$

where we used Theorem 1.1, estimate (1.2). Hence for the $L^2H^s_{-\sigma}$ estimate, we obtain

$$\begin{aligned} \left\| z \right\|_{L^2((-T,T),H^s_{-\sigma})} \leq{}& C_0 \left\| z_0 \right\|_{H^s} + C \left\| \eta \right\|^2_{L^2((-T,T),L^\infty)} \left\| \eta \right\|_{L^\infty((-T,T),H^s)} \\ &+ C \left(\left\| U \right\|_\infty + \left\| \eta \right\|_{L^\infty((-T,T),H^s_{-\sigma})} \right) \left\| U \right\|_\infty \left\| \eta \right\|_{L^2((-T,T),H^s_{-\sigma})} \\ &+ C \left\| \eta \right\|^2_{L^2((-T,T),L^\infty)} + C \left\| \dot{U} \right\|_{L^2} \left\| \eta \right\|_{L^\infty((-T,T),H^s)}. \end{aligned}$$

Using Lemma 3.2, we obtain

$$\left\| z \right\|_{L^2((-T,T),H^s_{-\sigma})} \leq C_0 \left\| z_0 \right\|_{H^s} + Cm(T)^3 + Cm(T)^2 + C\varepsilon m(T) + C\delta^2 m(T),$$

where C depends on $\left\| U \right\|_\infty$ and $\left\| \eta \right\|_{L^\infty((-T,T),H^s)}$.

Then, we estimate the H^s norm. Using estimate (2.4), we have

$$\begin{aligned} \left\| z(t) \right\|_{H^s} \leq{}& \left\| z_0 \right\|_{H^s} + \int_{-T}^T \left\| \nabla F(\eta(v)) \right\|_{H^s} dv \\ &+ \Bigg\| \int_0^t e^{-\mathrm{i}(t-v)H+\mathrm{i}\int_v^t E(U(r))\,dr} \mathbf{P}_c(U(v)) \\ &\quad \times J\{\nabla F(S(U(v))+\eta(v)) - \nabla F(S(U(v))) - \nabla F(\eta(v))\}\,dv \Bigg\|_{H^s} \\ &+ \int_{-T}^T \left\| dS(U(v)) A(U(v),\eta(v)) \langle N(U(v),\eta(v)), dS(U(v)) \rangle \right\|_{H^s} dv \\ &+ \int_{-T}^T \left\| d\mathbf{P}_c(U(v)) \dot{U}(v) \eta(v) \right\|_{H^s} dv. \end{aligned}$$

To estimate the third term of the right-hand side, we use the H-smoothness estimates,

more precisely, Theorem 1.1, estimate (1.1), and then we use Lemma 3.4:

$$\begin{aligned}
&\Big\| \int_0^t e^{-\mathrm{i}(t-v)H+\mathrm{i}\int_v^t E(U(r))\,dr} \\
&\qquad \times \mathbf{P}_c(U(v))J\{\nabla F(S(U(v))+\eta(v)) - \nabla F(S(U(v))) - \nabla F(\eta(v))\}\,dv \Big\|_{H^s} \\
&\le \Big\| \int_0^t e^{\mathrm{i}vH-\mathrm{i}\int_0^v E(U(r))\,dr} \\
&\qquad \times \mathbf{P}_c(U(v))J\{\nabla F(S(U(v))+\eta(v)) - \nabla F(S(U(v))) - \nabla F(\eta(v))\}\,dv \Big\|_{H^s} \\
&\le C\left\|\nabla F(S(U)+\eta) - \nabla F(S(U)) - \nabla F(\eta)\right\|_{L^2((-T,T),H^s_\sigma)} \\
&\le C\left(\|U\|_\infty + \|\eta(v)\|_{L^\infty((-T,T),H^s)}\right)\|U\|_\infty \|\eta\|_{L^2((-T,T),H^s_{-\sigma})}.
\end{aligned}$$

Hence for the $L^\infty H^s$ estimate, we obtain

$$\begin{aligned}
&\|z(t)\|_{H^s} \le \|z_0\|_{H^s} + C\|\eta\|_{L^\infty((-T,T),H^s)}\|\eta\|^2_{L^2((-T,T),L^\infty)} \\
&+ C\left(\|U\|_{L^\infty((-T,T))} + \|\eta(v)\|_{L^\infty((-T,T),H^s)}\right)\|U\|_{L^\infty((-T,T))}\|\eta\|_{L^2((-T,T),H^s_{-\sigma})} \\
&+ C\|\eta\|^2_{L^2((-T,T),L^\infty)} + \left\|\dot U\right\|_{L^1((-T,T))}\|\eta\|_{L^\infty((-T,T),H^s)}.
\end{aligned}$$

Using Lemma 3.2, we obtain

$$\|z(t)\|_{H^s} \le \|z_0\|_{H^s} + Cm(T)^3 + Cm(T)^2 + C\varepsilon m(T) + C\delta^2 m(T),$$

where C depends on $\|U\|_\infty$ and $\|\eta\|_{L^\infty((-T,T),H^s)}$.

For the $L^2B^\beta_{\infty,2}$ estimate, by Proposition 2.2 and Theorem 1.2, we have for any $\delta>0$, any $p_\delta > 3/\delta$, and $\theta_\delta = \frac{4}{p_\delta - 2}$

$$\begin{aligned}
\|z\|_{L^2((-T,T),B^\beta_{\infty,2})} &\le \|z\|_{L^2((-T,T),B^{\beta+\delta}_{p_\delta,2})} \\
&\le C_0\|z_0\|_{H^{\beta+1+\delta+\theta_\delta/2}} + C\left\|d^2F(S(U))\cdot\eta\right\|_{L^2((-T,T),B^{\beta+2+\delta+\theta_\delta}_{p'_\delta,2})} \\
&\quad + C\|N(U,\eta)\|_{L^1((-T,T),H^{\beta+1+\delta+\theta_\delta/2})} \\
&\quad + C\|dS(U)A(U,\eta)\langle N(U,\eta), dS(U)\rangle\|_{L^1((-T,T),H^{\beta+1+\delta+\theta_\delta/2})} \\
&\quad + C\left\|(d\mathbf{P}_c(U))\dot U\eta\right\|_{L^1((-T,T),H^{\beta+1+\delta+\theta_\delta/2})}\,dv.
\end{aligned}$$

With Lemmas 3.3 and 3.4, we infer that

$$\begin{aligned}
&\|z\|_{L^2(\mathbb{R},B^\beta_{\infty,2})} \le C_0\|z_0\|_{H^{\beta+1+\delta+\theta_\delta/2}} + C|U|_\infty\|\eta\|_{L^2((-T,T),H^{\beta+2+\delta+\theta_\delta}_{-\sigma})} \\
&+ C|U|_\infty\|z\|_{L^2((-T,T),L^\infty)}\|z\|_{L^2((-T,T),H^{\beta+1+\delta+\theta_\delta/2})} \\
&+ C(|U|_\infty + \|\eta\|_{L^\infty((-T,T),H^{\beta+1+\delta+\theta_\delta/2})})\|\eta\|^2_{L^2((-T,T),L^\infty)}\|z\|_{L^\infty((-T,T),H^{\beta+1+\delta+\theta_\delta/2})}
\end{aligned}$$

$$+ C(|U|_\infty + \|\eta\|_{L^\infty((-T,T),H^{\beta+1+\delta+\theta_\delta/2})}) \|\eta\|_{L^2((-T,T),H^{\beta+1+\delta+\theta_\delta/2}_{-\sigma})}$$

$$\times \|\eta\|_{L^\infty((-T,T),H^{\beta+1+\delta+\theta_\delta/2})}$$

$$+ C\|\dot{U}\|_{L^1} \|\eta\|_{L^\infty((-T,T),H^{\beta+1+\delta+\theta_\delta/2})}.$$

Since for small $\delta > 0$, $s \geq \beta + 2 + \delta + \theta_\delta$ and using Lemma 3.2, we infer that

$$\|z\|_{L^2((-T,T),B^\beta_{\infty,2})} \leq C_0\|z_0\|_{H^{\beta+1+\delta+\theta_\delta/2}} + Cm(T)^3 + Cm(T)^2 + C\varepsilon m(T) + C\delta^2 m(T).$$

Hence we obtain

$$m(T) \leq C_0\|z_0\|_{H^{\beta+1+\delta+\theta_\delta/2}} + C\varepsilon m(T) + C\delta^2 m(T) + Cm(T)^3 + Cm(T)^2,$$

where C_0 does not depend on m and C is a nondecreasing function of $\|z\|_{L^\infty((-T,T),H^s)}$ and $\|U\|_\infty$ and hence can be bounded by a nondecreasing function of m.

If $\|z_0\|_{H^s}$ is small, then $m(0)$ is small and $m(T)$ stays small. Therefore we have that $z \in \mathcal{Z}(U,\delta)$ if $\|z_0\|_{H^s}, \delta$, and ε are small enough; moreover,

$$\max\left[\|z\|_{L^\infty(\mathbb{R},H^s)}, \|z\|_{L^2(\mathbb{R},H^s_{-\sigma})}, \|z\|_{L^2(\mathbb{R},B^\beta_{\infty,2})}\right] \leq f(\|z_0\|_{H^s}),$$

where f is such that there exists $C > 0$ with

$$f(\|z_0\|_{H^s}) \leq C\|z_0\|_{H^s}. \qquad \square$$

The solution z just found is a function of z_0 and U; writing it $z[z_0, U]$, we have the following important property given by the following lemma.

LEMMA 3.9. *If Assumptions* 1.1–1.5 *hold, then for any $T > 0$, there exist $\varepsilon_0 > 0$, $\delta_0 > 0$, $C > 0$, and $\kappa \in (0,1)$ such that for any $\varepsilon \in (0,\varepsilon_0)$, $\delta \in (0,\delta_0)$, U, $U' \in \mathcal{U}(\varepsilon,\delta)$, $z_0 \in \mathcal{H}_c(U(0))$, $z_0' \in \mathcal{H}_c(U'(0))$, $z \in \mathcal{Z}(U,\delta)$, and $z' \in \mathcal{Z}(U',\delta)$, one has*

$$\|z[z_0',U'] - z[z_0,U]\|_{L^\infty((-T;T),H^s)\cap L^2((-T;T),L^\infty)\cap L^2((-T;T),H^s_{-\sigma})} \leq C\|z_0 - z_0'\|_{H^s} + \kappa\left\{\|U - U'\|_{L^\infty((-T;T))} + \left\|\dot{U} - \dot{U}'\right\|_{L^\infty((-T;T))}\right\}.$$

Proof. We use the techniques of the previous lemma. $\square$

3.2.3. Global well-posedness for U and its stabilization. Here we want to solve the equation for U. We note that z has been built in the previous section and is a function of U and $z_0 \in \mathcal{H}_c(U(0))$. Let us introduce for any $U_0 \in B_{\mathbb{C}}(0,\varepsilon)$ the function on $\mathcal{U}(\varepsilon,\delta)$:

$$f_{U_0}(U)(t) = U_0 - \int_0^t A(U(v),\eta(v))\langle N(U(v),\eta(v)), dS(U(v))\rangle\, dv,$$

where $\eta = z(t) + g[U(t),z(t)]$. We have the following lemma.

LEMMA 3.10. *If Assumptions* 1.1–1.5 *hold, there exist $\varepsilon_0 > 0$ and $\delta_0 > 0$ such that, for any $\varepsilon \in (0,\varepsilon_0)$, $\delta \in (0,\delta_0)$, the function f_{U_0} maps $\mathcal{U}(\varepsilon,\delta)$ into itself if U_0 and $z_0 \in H^s \cap \mathcal{H}_c(U_0)$ are small enough.*

Proof. By means of Lemma 3.3, we obtain

$$\|\partial_t f_{U_0}(U)\|_{L^1(\mathbb{R})\cap L^\infty(\mathbb{R})} \leq C \|N(U(v),\eta(v))\|_{L^1(\mathbb{R},H^s_{-\sigma})\cap L^\infty(\mathbb{R},H^s)} \leq \delta^2$$

and

$$\|f_{U_0}(U)\|_{L^\infty(\mathbb{R})} \leq |U_0| + C \|N(U(v),\eta(v))\|_{L^1(\mathbb{R},H^s)} \leq |U_0| + \delta^2;$$

hence for sufficiently small U_0 and δ, we obtain the lemma. ∎

The function f_{U_0} also has a local Lipschitz property, as stated by the following lemma.

LEMMA 3.11. *If Assumptions* 1.1–1.5 *hold, for any* $T > 0$, *there exist* $\varepsilon_0 > 0$, $\delta_0 > 0$, *and* $\kappa \in (0,1)$ *such that for any* $\varepsilon \in (0,\varepsilon_0)$, $\delta \in (0,\delta_0)$, U, $U' \in \mathcal{U}(\varepsilon,\delta)$, *for any* $z_0 \in \mathcal{H}_c(U(0)) \cap H^s$, *for any* $z_0' \in \mathcal{H}_c(U'(0)) \cap H^s$ *small enough, and for* U_0, U_0' *small enough, one has*

$$\begin{aligned}&\left|f_{U_0}(U) - f_{U_0'}(U')\right|_{L^\infty((-T;T))} + \left|\partial_t f_{U_0}(U) - \partial_t f_{U_0'}(U')\right|_{L^1((-T;T))}\\ &\leq |U_0 - U_0'| + \kappa\left(\|U - U'\|_{L^\infty((-T;T))} + \|\dot U - \dot U'\|_{L^1((-T;T))} + \|z_0 - z_0'\|_{H^s}\right).\end{aligned}$$

Proof. The proof is a straightforward consequence of Lemmas 3.5, 3.6, and 3.9. ∎

We now obtain the following lemma.

LEMMA 3.12. *If Assumptions* 1.1–1.5 *hold, there exist* $\varepsilon > 0$ *and* $\delta > 0$ *such that, for any* $U_0 \in \mathbb{C}$ *small and* $z_0 \in \mathcal{H}_c(U_0) \cap H^s_\sigma$ *small, the equation*

$$\left\{\begin{array}{lcl}\dot U &=& -A(U,\eta)\langle N(U,\eta), dS(U)\rangle,\\ U(0) &=& U_0,\end{array}\right. \tag{3.5}$$

where $\eta(t) = z(t) + g\,[U(t),z(t)]$, *has a unique solution in* $\mathcal{U}(\delta,\varepsilon)$. *Moreover, there exists* $C > 0$ *such that*

$$|U_{\pm\infty} - U_0| \leq C \|z_0\|^2_{H^s}.$$

Proof. This is also a fixed point result for f_{U_0}. Let us fix $T > 0$ and consider, for any $V \in \mathcal{U}(\delta,\varepsilon)$ with sufficiently small $\delta > 0$ and $\varepsilon > 0$, the sequence

$$\left\{\begin{array}{l}V_{n+1} = f_{U_0}(V_n) \quad \forall n \in \mathbb{N},\\ V_0 = V\end{array}\right.$$

for any $n \in \mathbb{N}$, $V_n \in \mathcal{U}(\delta,\varepsilon)$. With Lemma 3.11, the fixed point theorem gives us the convergence for the norms of $L^\infty((-T,T))$ and $\dot W^{1,1}((-T,T))$ of $(V_n)_{n\in\mathbb{N}}$.

Then we notice that, for any $T' \in \mathbb{R}$, we have

$$V_{n+1}(t) = f_{f_{U_0}(V_n)(T')}(V_n)(t - T').$$

Since for $T' \in (-T;T)$, $(f_{U_0}(V_n)(T'))$ is a Cauchy sequence, Lemma 3.11 gives us the convergence of (V_n) for the norms of $L^\infty((T'-T;T'+T))$ and $\dot W^{1,1}((T'-T;T'+T))$.

Iterating this process, we obtain that the sequence converges uniformly locally in time and we prove the lemma since the other statements are classical. We note just that the last statement follows from the fact that there exists $C > 0$ such that

$$\int_{\mathbb{R}^\pm} \left|\dot U(v)\right| \, dv \leq \int_{\mathbb{R}^\pm} |A(U(v),\eta(v))\langle N(U(v),\eta(v)), dS(U(v))\rangle| \, dv \leq C \|z_0\|^2_{H^s}. \qquad ∎$$

3.2.4. The asymptotic profile of z. In this section, our aim is to specify the asymptotic profile of z when z_0 is localized. First we state the following proposition.

PROPOSITION 3.1. *There exists $\varepsilon > 0$ such that for all $U \in B_{\mathbb{C}^2}(0,\varepsilon)$ and $\alpha \in \mathbb{R}^+$ there exists $C > 0$ such that*

$$\left\| \langle Q \rangle^{\alpha} e^{JtH(U)} P_c(U) \psi \right\| \leq C_\alpha \sum_{\beta=0}^{\alpha} \langle t \rangle^{\beta} \left\| \langle Q \rangle^{\alpha-\beta} \psi \right\|$$

for any $\psi \in L^2(\mathbb{R}^3, \mathbb{C}^8)$.

Proof. From Proposition 2.2, we obtain the lemma for $\alpha = 0$; then we just need the estimate

$$\left\| Q^{\alpha} e^{JtH(U)} \psi \right\|^2 \leq C_\alpha^2 \sum_{0 \leq \beta \leq \alpha} |t|^{2|\beta|} \left\| Q^{\alpha-\beta} \psi \right\|^2$$

for any $\psi \in L^2(\mathbb{R}^3, \mathbb{C}^8)$, $\alpha \in \mathbb{N}^3$, and some $C > 0$ independent of ψ. The rest of the proposition will follow by interpolation.

For $U = 0$, this follows by an iterated proof from the identity

$$\frac{d}{dt} e^{\mathrm{i}tH} Q e^{-\mathrm{i}tH} = e^{\mathrm{i}tH} \alpha e^{-\mathrm{i}tH},$$

where α is the 3-vector of Dirac–Pauli matrices defined in the introduction. For $U \neq 0$, we use the same proof with the exponential decay of Proposition 1.1. ∎

We can improve Lemma 3.13 if we use [7, Theorem 1.1] and [7, Theorem 1.2], which we repeat in what follows.

THEOREM 3.1 (Theorem 1.1 of [7]: propagation for perturbed Dirac dynamics). *Assume that Assumptions* 1.1 *and* 1.2 *hold, and let $\sigma > \frac{5}{2}$. Then one has*

$$\| e^{-\mathrm{i}tH} \mathbf{P}_c(H) \|_{B(L^2_\sigma, L^2_{-\sigma})} \leq C \langle t \rangle^{-\frac{3}{2}}.$$

We also have the following proposition.

PROPOSITION 3.2 (Proposition 2.2 of [7]: propagation far from thresholds). *Suppose that Assumption* 1.1 *holds. Then, for any $\chi \in \mathcal{C}^\infty(\mathbb{R}^3, \mathbb{C}^4)$ bounded with support in $\mathbb{R} \setminus (-m; m)$ and for any $\sigma \geq 0$, there is $C > 0$ such that*

$$\| e^{-\mathrm{i}tH} \chi(H) \|_{B(L^2_\sigma, L^2_{-\sigma})} \leq C \langle t \rangle^{-\sigma}.$$

Using Duhamel's formula as in Proposition 2.2 and interpolating with estimate (2.6), we obtain the following corollary.

COROLLARY 3.1. *Assume that Assumptions* 1.1 *and* 1.2 *hold, and let $\theta \geq 0$ and $\sigma > \frac{5}{2}\theta$. Then there exists $\varepsilon > 0$ such that for all $U \in B_{\mathbb{C}^2}(0,\varepsilon)$ one has*

$$\| e^{JtH(U)} \mathbf{P}_c(U) \|_{B(L^2_\sigma, L^2_{-\sigma})} \leq C \langle t \rangle^{-\frac{3\theta}{2}}.$$

THEOREM 3.2 (Theorem 1.2 of [7]: dispersion for perturbed Dirac dynamics). *Assume that Assumptions* 1.1 *and* 1.2 *hold. Then for $p \in [1,2]$, $\theta \in [0,1]$, $s - s' \geq (2+\theta)(\frac{2}{p} - 1)$, and $q \in [1,\infty]$ there exists a constant $C > 0$ such that*

$$\| e^{-\mathrm{i}tH} \mathbf{P}_c(H) \|_{B^s_{p,q}, B^{s'}_{p',q}} \leq C (K(t))^{\frac{2}{p}-1}$$

with $\frac{1}{p}+\frac{1}{p'}=1$, *and*

$$K(t)=\begin{cases} |t|^{-1+\theta/2} & \text{if } |t|\in(0,1],\\ |t|^{-1-\theta/2} & \text{if } |t|\in[1,\infty). \end{cases}$$

Using Duhamel's formula once more, Theorem 3.1, and Corollary 3.1, we obtain the following corollary.

COROLLARY 3.2. *Assume that Assumptions* 1.1 *and* 1.2 *hold, and let* $p\in[1,2]$, $\theta\in[0,1]$, $s-s'\geq(2+\theta)(\frac{2}{p}-1)$, $q\in[1,\infty]$, *and* $\sigma>\max\{\frac{3}{2},(\frac{2}{p}-1)(1+\frac{\theta}{2})\}$. *Then there exists* $\varepsilon>0$ *such that for all* $U\in B_{\mathbb{C}^2}(0,\varepsilon)$ *one has*

$$\|e^{JtH(U)}\mathbf{P}_c(U)\|_{H^s_\sigma,B^{s'}_{p',q}}\leq C\,(K(t))^{\frac{2}{p}-1}$$

with $\frac{1}{p}+\frac{1}{p'}=1$, *and*

$$K(t)=\begin{cases} |t|^{-1+\theta/2} & \text{if } |t|\in(0,1],\\ |t|^{-1-\theta/2} & \text{if } |t|\in[1,\infty). \end{cases}$$

Proof. We first prove this for $U=0$. We have to study the high and low energy parts in a different manner. For the low energy part, we iterate twice Duhamel's formula with respect to D_m in order to use Theorems 3.1 and 3.2 for the free case.

In the high energy part, we use also Duhamel's formula but with Theorem 3.2 for the free case and Proposition 3.2.

Then for $U\neq 0$, we work as for estimate (2.6). ∎

We obtain the following lemma.

LEMMA 3.13. *If Assumptions* 1.1–1.5 *hold, there exist* $\varepsilon_0>0$, $\delta_0>0$, *and* $C>0$ *such that for any* $\varepsilon\in(0,\varepsilon_0)$, $\delta\in(0,\delta_0)$, $U_0\in B_{\mathbb{C}^2}(0,\varepsilon)$, *and* $z_0\in B_{H^s_\sigma}(0,\delta)\cap\mathcal{H}_c(U_0)$ *we obtain for the Cauchy problem* (3.4) *(with* U *the solution of* (3.5)) *a global solution* z *such that*

$$\max\Big[\sup_{t\in\mathbb{R}}(\|z(t)\|_{H^s}),\ \sup_{t\in\mathbb{R}}(\langle t\rangle^{3/2}\|z(t)\|_{H^s_{-\sigma}}),$$

$$\sup_{t\in\mathbb{R}}(\langle t\rangle^{3/2}\|z(t)\|_{B^\beta_{\infty,2}}),\ \sup_{t\in\mathbb{R}}(\langle t\rangle^{-3/2}\|z(t)\|_{H^s_{3/2}})\Big]\leq C\,\|z_0\|_{H^s_\sigma}.$$

Proof. The proof is similar to that of Lemma 3.8 with some adaptations involving the norm H^s_σ; we also refer to the proof of [7, Lemma 5.5]. Indeed, we work in the spaces

$$\widetilde{\mathcal{U}}(\varepsilon,\delta)=\Big\{U\in\mathcal{C}^1(\mathbb{R},B_{\mathbb{C}^2}(V_0,\varepsilon)),\ \|\dot V(t)\|\leq\frac{\delta^2}{\langle t\rangle^3}\Big\}$$

and

$$\mathcal{Z}(U,\delta)=\Big\{z\in\mathcal{C}(\mathbb{R},L^2(\mathbb{R}^3,\mathbb{R}^8)),\ z(t)\in\mathcal{H}_c(U(t)),$$

$$\max\Big[\sup_{t\in\mathbb{R}}(\|z(t)\|_{H^s}),\ \sup_{t\in\mathbb{R}}(\langle t\rangle^{3/2}\|z(t)\|_{H^s_{-\sigma}}),$$

$$\sup_{t\in\mathbb{R}}(\langle t\rangle^{3/2}\|z(t)\|_{B^\beta_{\infty,2}}),\ \sup_{t\in\mathbb{R}}(\langle t\rangle^{-3/2}\|z(t)\|_{H^s_{3/2}})\Big]\leq\delta\Big\}.$$

Let

$$t \mapsto \xi_\pm(t) = e^{J\int_0^t (E(U(v))-E(U_{\pm\infty}))\,dv} z(t)$$

and

$$t \mapsto V_\pm(t) = e^{-\mathrm{i}\int_0^t (E(U(v))-E(U_{\pm\infty}))\,dv} U(t).$$

We have that $V_{\pm\infty} \lim_{\pm\infty} V_\pm(t)$ exist and we use exactly the same method as that of Lemma 3.8, applied to

$$\begin{aligned}
\xi_\pm(t) &= e^{JtH(V_{\pm\infty})} z_0 \\
&+ \int_0^t e^{J(t-s)H(V_{\pm\infty})} \mathbf{P}_c(V_\pm(v)) J \left(d^2F(S(V_\pm(v))) - d^2F(S(V_{\pm\infty})) \right) \xi_\pm(v)\,dv \\
&+ \int_0^t e^{J(t-s)H(V_{\pm\infty})} \mathbf{P}_c(V_\pm(v)) J N(V_\pm(v), \tilde\eta_\pm(v))\,dv \\
&+ \int_0^t e^{J(t-s)H(V_{\pm\infty})} \mathbf{P}_c(V_\pm(v)) dS(V(v)) A(V_\pm(v), \tilde\eta_\pm(v)) \\
&\qquad \times \langle N(V_\pm(v), \tilde\eta_\pm(v)), dS(V_\pm(v)) \rangle\,dv \\
&- \int_0^t e^{J(t-s)H(V_{\pm\infty})} (d\mathbf{P}_c(V_\pm(v))) A(V_\pm(v), \tilde\eta_\pm(v)) \\
&\qquad \times \langle N(V_\pm(v), \tilde\eta_\pm(v)), dS(V_\pm(v)) \rangle \tilde\eta_\pm(v)\,dv,
\end{aligned}$$

with $\tilde\eta_\pm(t) = e^{J\int_0^t (E(U(v))-E(U_{\pm\infty}))\,dv} (z(t) + g(U(t), z(t)))$, but using the previous time decay estimates.

There are two differences from the proof of Lemma 3.8:

One is in the estimate of the $H^s_{-\sigma}$ norm. In fact, before using the time decay estimates for $e^{-\mathrm{i}tH} P_c(H)$, we split the space associated with the continuous spectrum into two parts: one associated with energy close to the thresholds and one associated with the rest of the spectrum. In the first part, we use the fact that $\sigma > 3/2$ to estimate the $H^s_{-\sigma}$ by the $B^\beta_{\infty,2}$ norm since we work with bounded energies. In the second part, since we work far from thresholds, we use Proposition 3.2 after estimating the $H^s_{-\sigma}$ by the $H^s_{-3/2}$ norm.

The other difference is in the estimation of the $B^\beta_{\infty,2}$ norm. We use Corollary 3.2 for $e^{JtH(V_{\pm\infty})} z_0$ and Theorem 3.2 for the integrals. □

We have that $\lim_{\pm\infty} U = U_{\pm\infty}$ exist. If $z_0 \in H^s_\sigma$, then the associated solution U satisfies

$$\left|\dot U\right| \le \frac{C}{\langle t\rangle^3} \left\| z_0 \right\|_{H^s_\sigma},$$

and we have

$$\int_0^t \left(E(U(v)) - E(U_{\pm\infty})\right)\,dv \to E_{\pm\infty} \quad \text{as } t \to \pm\infty$$

for some real $E_{\pm\infty}$. We introduce

$$V_\pm(t) = e^{-\mathrm{i}\int_0^t (E(U(v))-E(U_{\pm\infty}))\,dv} U(t),$$

which have a limit as $t \to \pm\infty$, respectively, as being

$$V_{\pm\infty} = e^{-\mathrm{i}E_{\pm\infty}} U_{\pm\infty}.$$

Then we note that we can also obtain an asymptotic profile for $e^{\mathrm{i}tH+\mathrm{i}tE(U_\infty)}z(t)$ if z_0 is localized. But we prefer to obtain a scattering result with respect to $e^{JtH(V_\infty))}$. We have the following lemma.

LEMMA 3.14. *If Assumptions* 1.1–1.5 *hold, then there exist* $\varepsilon_0 > 0$, $\delta_0 > 0$ *such that for any* $\varepsilon \in (0, \varepsilon_0)$, $\delta \in (0, \delta_0)$, $U_0 \in B_{\mathbb{C}^2}(0, \varepsilon)$, *and* $z_0 \in B_{H^s_\sigma}(0, \delta) \cap \mathcal{H}_c(U_0)$ *and for the solution* z *of* (3.4) *(with* U *the solution of* (3.5)*) given in Lemma* 3.7, *the limit*

$$z_{\pm\infty} = \lim_{t\to\pm\infty} e^{-JtH(V_{\pm\infty})} e^{J\int_0^t (E(U(v))-E(U_{\pm\infty}))\,dv} z(t)$$

exists in H^s. *Moreover, we have* $z_{\pm\infty} \in \mathcal{H}_c(V_{\pm\infty}) \cap H^s_\sigma$, *and there exists* $C > 0$ *such that*

$$\max\Big\{ \|e^{-J\int_0^t (E(U(v))-E(U_{\pm\infty}))\,dv} e^{JtH(V_{\pm\infty})\,dr} z_{\pm\infty} - z(t)\|_{H^s},$$
$$\|e^{-J\int_0^t (E(U(v))-E(U_{\pm\infty}))\,dv} e^{JtH(V_{\pm\infty})\,dr} z_{\pm\infty} - z(t)\|_{H^s_{-\sigma}},$$
$$\|e^{-J\int_0^t (E(U(v))-E(U_{\pm\infty}))\,dv} e^{JtH(V_{\pm\infty})\,dr} z_{\pm\infty} - z(t)\|_{B^\beta_{\infty,2}} \Big\} \le \tfrac{C}{\langle t\rangle^2} \|z_0\|^2_{H^s_\sigma}$$

and

$$\|z_{\pm\infty} - e^{-JtH(V_{\pm\infty})} e^{J\int_0^t (E(U(v))-E(U_{\pm\infty}))\,dv} z(t)\|_{H^s_{3/2}} \le \frac{C}{\langle t\rangle^{\frac12}} \|z_0\|^2_{H^s_\sigma}.$$

Proof. Let

$$t \mapsto \xi_\pm(t) = e^{J\int_0^t (E(U(v))-E(U_{\pm\infty}))\,dv} z(t)$$

and

$$t \mapsto V_\pm(t) = e^{-\mathrm{i}\int_0^t (E(U(v))-E(U_{\pm\infty}))\,dv} U(t).$$

Using exactly the same method as that of Lemma 3.8, applied to

$$\begin{aligned}
e^{-JtH(V_{\pm\infty})}\xi_\pm(t) &= z_0 \\
&+ \int_0^t e^{\quad -JsH(V_{\pm\infty})} \mathbf{P}_c(V_\pm(v)) J \left(d^2F(S(V_\pm(v))) - d^2F(S(V_{\pm\infty})) \right) \xi_\pm(v)\,dv \\
&+ \int_0^t e^{\quad -JsH(V_{\pm\infty})} \mathbf{P}_c(V_\pm(v)) J N(V_\pm(v), \tilde\eta_\pm(v))\,dv \\
&+ \int_0^t e^{-JsH(V_{\pm\infty})} \mathbf{P}_c(V_\pm(v)) dS(V(v)) A(V_\pm(v), \tilde\eta_\pm(v)) \\
&\qquad \times \langle N(V_\pm(v), \tilde\eta_\pm(v)), dS(V_\pm(v))\rangle\,dv \\
&- \int_0^t e^{-JsH(V_{\pm\infty})} (d\mathbf{P}_c(V_\pm(v))) A(V_\pm(v), \tilde\eta_\pm(v)) \\
&\qquad \times \langle N(V_\pm(v), \tilde\eta_\pm(v)), dS(V_\pm(v))\rangle \tilde\eta_\pm(v)\,dv,
\end{aligned}$$

with $\tilde{\eta}_\pm(t) = e^{J\int_0^t (E(U(v))-E(U_{\pm\infty}))\,dv}\,(z(t)+g(U(t),z(t)))$, we prove that the limits

$$\lim_{t\to\pm\infty} e^{-JtH(V_{\pm\infty})}\xi_\pm(t) = z_{\pm\infty}$$

exist. If we use the method of Lemma 3.13, we obtain the estimates on the convergence of $e^{JtH(V_{\pm\infty})}z_{\pm\infty} - \xi_\pm(t)$. Then multiplying by $e^{-J\int_0^t (E(U(v))-E(U_{\pm\infty}))\,dv}$, we obtain the estimates and the convergence of

$$e^{-J\int_0^t (E(U(v))-E(U_{\pm\infty}))\,dv} e^{-JtH(V_{\pm\infty})}z_{\pm\infty} - z(t).$$

Then since $(1-P_c(U(t)))\,z(t) = 0$, we have $(1-P_c(V_{\pm\infty}))\,z_{\pm\infty} = 0$, and hence $z_{\pm\infty}$ belongs to $\mathcal{H}_c(V_{\pm\infty})$. □

4. The dynamics outside the center manifold. We can make the same study in the center-stable manifold and the center-unstable manifold but only in one direction of time. Let us explain it for the center-stable manifold in positive time since it is similar for the center-unstable manifold. Actually it is equivalent if we revert the time direction.

We give just a sketch of the proof since it is similar to the previous study. Using the idea of the proof of exponential stabilization for Proposition 2.4, we write any solution ψ in the form $\phi+\rho+f(\phi,\rho)$ with ϕ in the center manifold, $\rho\in X_s(V_0)$, and f a function to be specified and which ensures that ϕ is in the center stable manifold.

Indeed, $W^c(V_0)$ is the graph of a smooth function $h^c : X_c(V_0)\mapsto X_s(V_0)\oplus X_u(V_0)$, and $W^{cs}(V_0)$ is the graph of a smooth function $h^u : X_c(V_0)\oplus X_s(V_0)\mapsto X_u(V_0)$. Let ν be such that $\psi = S(V_0)+\nu$ satisfies (1.8); then we have

$$\begin{aligned}
\partial_t\nu &= JH(V_0)\nu + JN(V_0,\nu),\\
\nu &= y + h_c(y) + \rho + h^u(y, h^c(y)+\rho)\\
&= \phi(y) - S(V_0) + (\rho - \pi^s(V_0)h^c(y)) + (h^u(y,h^c(y)+\rho) - \pi^u(V_0)h^c(y))\\
&= \phi(y) - S(V_0) + \rho + f(y,\rho)
\end{aligned}$$

with $y = \pi^c(V_0)\nu = \pi^c(V_0)\,(\psi - S(V_0))$, $\phi(y) = S(V_0) + y + h^c(y)$ in the center manifold, and $\rho\in X_s(V_0)$. We have the following equation for ρ:

$$\partial_t\rho = JH(V_0)\rho + M(V_0,y,\rho), \tag{4.1}$$

where

$$\begin{aligned}
M(V_0,y,\rho) &= \pi^s(V_0)\left\{JN(V_0,y+h^c(y)+\rho+f(y,\rho)) - JN(V_0,y+h^c(y))\right\}\\
&- \pi^s(V_0)Dh^c(y)\pi^c(V_0)\left\{JN(V_0,y+h^c(y)+\rho+f(y,\rho)) - JN(V_0,y+h^c(y))\right\}.
\end{aligned}$$

Then we obtain for ϕ the equation

$$\begin{aligned}
\partial_t\phi &= JH\phi + J\nabla F(\phi) + R(\phi,\rho),\\
R(\phi,\rho) &= J\nabla F(\phi+\rho+f(y,\rho)) - J\nabla F(\phi)\\
&\quad - Jd^2F(S(V_0))\rho - M(V_0,\pi^c(V_0)(\phi - S(V_0)),\rho),
\end{aligned}$$

noting that $|R(\phi,\rho)|\le C(\|\phi\|_{H^s},\|\rho\|_{L^\infty})|\rho|$.

Working as in section 3, we write $\phi = S(U) + \eta$ with $\eta = z + g(U, z)$ and we have the following equations for U and z:

$$\begin{cases} \dot{U} = -A(U,\eta)\langle N(U,\eta) - JR(U,\eta,\rho), dS(U)\rangle, \\ \partial_t z = JH(U)z + \mathbf{P}_c(U)JN(U,\eta) \\ + \mathbf{P}_c(U(v))dS(U(v))A(U(v),\eta(v))\langle N(U(v),\eta(v)) - JR(U,\eta,\rho), dS(U(v))\rangle \\ + (dP_c(U))A(U,\eta)\langle N(U,\eta) - JR(U,\eta,\rho), dS(U)\rangle\eta + \mathbf{P}_c(U)R(U,\eta,\rho) \end{cases}$$

with

$$\eta(t) = z(t) + g\left(U(t), z(t)\right),$$

where g is defined by Lemma 3.2 and

$$R(U,\eta,\rho) = R(S(U) + \eta, \rho).$$

These equations are similar to those we have studied but with an extra term coming from R which is exponentially decaying in positive time. Indeed, let us introduce for any $T_0 < 0$, $\gamma \in (0, \gamma(V_0))$, and $\delta > 0$ the set

$$\mathcal{R}_{T_0,\gamma}(\delta) = \left\{\rho \in \mathcal{C}((T_0, +\infty), X_s(V_0)),\ |\rho(t)|_{H^s} \leq \delta e^{-\gamma t}\ \forall t > T_0\right\}.$$

We study (4.1) in $\mathcal{R}_{T_0,\gamma}(\delta)$ with small initial condition ρ_0. We also define for any $\varepsilon > 0$

$$\mathcal{U}_{T_0}(\varepsilon,\delta) = \left\{U \in \mathcal{C}^1((T_0,+\infty), B_{\mathbb{C}^2}(V_0,\varepsilon)),\ \|\dot{U}\|_{L^1((T_0,+\infty))\cap L^\infty((T_0,+\infty))} \leq \delta^2\right\},$$

and for any $U \in \mathcal{U}_{T_0}(\varepsilon)$, let s, β be such that $s > \beta + 2 > 2$ and $\sigma > 3/2$,

$$\mathcal{Z}_{T_0}(U,\delta) = \big\{z \in \mathcal{C}((T_0,+\infty), L^2(\mathbb{R}^3,\mathbb{R}^8)),\ z(t) \in \mathcal{H}_c(U(t)),$$
$$\max\left[\|z\|_{L^\infty((T_0,+\infty),H^s)}, \|z\|_{L^2((T_0,+\infty),H^s_{-\sigma})}, \|z\|_{L^2((T_0,+\infty),B^\beta_{\infty,2})}\right] \leq \delta\big\},$$

and ε, δ are small enough to ensure that for $U \in \mathcal{U}(\varepsilon,\delta)$ and $z \in \mathcal{Z}(U,\delta)$

$$S(U) + z + g(U,z) \in W^c(V_0) \cap B_{H^s}(S(V_0), r(V_0)).$$

For a sufficiently small T_0, we solve the equation for z first, then the one for ρ, and eventually the one for U using the method of section 3. This gives us the desired exponential decay for ρ as well as similar results for U and z.

We note that instead of Lemma 3.9, we obtain the following lemma.

LEMMA 4.1. *If Assumptions* 1.1–1.5 *hold, then for any $T > 0$, there exist $T_0 > 0$, $\varepsilon_0 > 0$, $\delta_0 > 0$, $C > 0$, and $\kappa \in (0,1)$ such that for any $\varepsilon \in (0,\varepsilon_0)$, $\delta \in (0,\delta_0)$, $U, U' \in \mathcal{U}_{T_0}(\varepsilon,\delta)$, $\rho, \rho' \in \mathcal{R}_{T_0,\gamma}$, $z_0 \in \mathcal{H}_c(U(0))$, $z_0' \in \mathcal{H}_c(U'(0))$, $z \in \mathcal{Z}_{T_0}(U,\delta)$, and $z' \in \mathcal{Z}_{T_0}(U',\delta)$, one has*

$$\begin{aligned} &\|z[z_0', U', \rho'] - z[z_0, U, \rho]\|_{L^\infty((T_0,T),H^s)\cap L^2((T_0,T),L^\infty)\cap L^2((T_0,T),H^s_{-\sigma})} \\ &\quad \leq C\left\|z_0 - z_0'\right\|_{H^s} + \kappa\big\{\left\|U - U'\right\|_{L^\infty((T_0,T),\mathbb{C}^2)} + \left\|\dot{U} - \dot{U}'\right\|_{L^\infty((T_0,T),\mathbb{C}^2)} \\ &\qquad + \|e^{\gamma t}(\rho - \rho')(t)\|_{L^\infty_t((T_0,T),X^s(V_0))}\big\}. \end{aligned}$$

Then for ρ as a function of U, z_0, and ρ_0 (the initial condition for ρ), we obtain the following lemma.

LEMMA 4.2. *If Assumptions* 1.1–1.5 *hold, then for any* $T > 0$ *there exist* $T_0 > 0$, $\varepsilon_0 > 0$, $\delta_0 > 0$, $C > 0$, *and* $\kappa \in (0,1)$ *such that for any* $\varepsilon \in (0, \varepsilon_0)$, $\delta \in (0, \delta_0)$, $U, U' \in \mathcal{U}_{T_0}(\varepsilon, \delta)$, $r_0, r_0' \in X_s(V_0)$, $z_0 \in \mathcal{H}_c(U(0))$, $z_0' \in \mathcal{H}_c(U'(0))$, $z \in \mathcal{Z}_{T_0}(U, \delta)$, *and* $z' \in \mathcal{Z}_{T_0}(U', \delta)$ *one has*

$$\begin{aligned}&\|e^{\gamma t}\left(\rho[z_0', U', \rho_0'] - \rho[z_0, U, \rho_0]\right)\|_{L_t^\infty((T_0,T),X^s(V_0))}\\ &\leq C\|z_0 - z_0'\|_{H^s} + \kappa\big\{\,\|U - U'\|_{L^\infty((T_0,T),\mathbb{C}^2)}) + \big\|\dot U - \dot U'\big\|_{L^\infty((T_0,T),\mathbb{C}^2)} + \|\rho_0 - \rho_0'\|_{L^2}\,\big\}.\end{aligned}$$

We also note that the proof gives the well-posedness of (4.1) in $\mathcal{R}_{T_0,\gamma}(\delta)$ with small initial condition ρ_0 and that there exists $C > 0$ such that the solution ρ satisfies

$$\|\rho(t)\|_{H^s} \leq C\,\|\rho_\pm(0)\|\,e^{-\gamma t} \quad \forall t > T_0.$$

The asymptotic behaviors of U and z are obtained as in the previous section when z_0 is localized.

5. End of the proof of main theorems. We note that the small *locally invariant* center manifold built in section 2.2 for (2.10) is now a small *invariant* (globally in time) center manifold. Indeed, we have just proved the stabilization towards the PLS manifold; this ensures that a solution in the center manifold will stay inside this manifold in the two directions of time.

Now let us consider $\mathcal{C}M$ as being the union of all these small globally invariant center manifolds and 0. Using the uniqueness of the center manifold and Lemma 3.2, we prove that $\mathcal{C}M \setminus \{0\}$ is a manifold. Now we generalize Lemma 3.2 by the following lemma.

LEMMA 5.1. *For any* $s, s', \sigma \in \mathbb{R}$ *and* $p, q \in [1, \infty]$, *there exist* $\varepsilon > 0$, *a continuous map* $r : B^2_{\mathbb{C}}(0,\varepsilon) \mapsto \mathbb{R}^+$ *with* $r(U) = O(\Gamma(U))$, *and a continuous map* $\Psi : S \mapsto \mathcal{C}M$, *where*

$$\mathcal{S}_\sigma = \big\{(U,z);\ U \in B_{\mathbb{C}^2}(0,\varepsilon),\ z \in \mathcal{H}_c(U) \cap B_{H^{s'}_\sigma}(0, r(U))\big\}$$

is endowed with the metric of $\mathbb{C}^2 \times H^{s'}_\sigma$.

Moreover, Ψ *is bijective from* $\mathcal{S}$ *to an open neigborhood of* $(0,0)$ *in* $\mathcal{C}M$ *and smooth on* $\mathcal{S} \setminus \{(0,0)\}$. *For all* $U \in B_{\mathbb{C}^2}(0,\varepsilon)$, *there exists* $C > 0$ *such that, for all* $z \in \mathcal{H}_c(U) \cap B_{H^{s'}}(0, r(U))$, $\Psi(U,z) \in \mathcal{H}_1(U)$, $z + \Psi(U,z) \in \mathcal{H}_0(U)^\perp$, *and* $S(U) + z + \Psi(U,z) \in \mathcal{C}M$. *For sufficiently small nonzero* U, *we have* $\|\Psi(U,z)\|_{B^s_{p,q}} = O(\|z\|^2_{H^{s'}})$ *for* $z \in H^{s'}$ *such that* $(U,z) \in \mathcal{S}$.

Proof. The proof works like that of Lemma 3.2. The statements for r follow from Remark 2.3. ∎

The scattering result follows from a one-to-one correspondence of the initial profile with the asymptotic profile as stated in the following proposition.

PROPOSITION 5.1. *If Assumptions* 1.1–1.5 *hold, there exist* $\varepsilon > 0$ *and a continuous map* $r : B^2_{\mathbb{C}}(0,\varepsilon) \mapsto \mathbb{R}^+$ *with* $r(U) = O(\Gamma(U))$ *and* $\mathcal{V}_\sigma$, $\mathcal{V}_\pm$ *neighborhoods of* $(0,0)$ *in*

$$S_\sigma = \big\{(U,z);\ U \in \mathbb{C}^2,\ z \in \mathcal{H}_c(U) \cap B_{H^s_\sigma}(0, r(U))\big\}$$

endowed with the norm of $\mathbb{C}^2 \times H^s_\sigma$ *such that the maps*

$$\mathcal{P}_\pm : \begin{pmatrix} U_0 \\ z_0 \end{pmatrix} \in \mathcal{V}_\sigma \mapsto \begin{pmatrix} V_{\pm\infty} \\ z_{\pm\infty} \end{pmatrix} \in \mathcal{V}_\pm$$

are bijections and are smooth on $\mathcal{V}_0 \setminus \{(0,0)\}$.

Proof. We choose, for example,

$$\mathcal{V}_\sigma = \left\{(U,z)\,;\, U \in B_{\mathbb{C}^2}(0,\varepsilon),\ z \in \mathcal{H}_c(U) \cap B_{H^s_\sigma}(0,r(U))\right\}$$

for some positive ε, and we work on the manifold $\mathcal{V}_\sigma \setminus \{(0,0)\}$ which is locally isomorphic to an open set of $\mathbb{C}^2 \times \mathcal{H}_c(U) \cap H^s_\sigma$. We write

$$\mathcal{P}^{U_0}_\pm (U,z) = (U,z) + \mathcal{R}^{U_0}_\pm (U,z)\,.$$

Since

$$\|(U_\infty, z_\infty) - (U_0, z_0)\|_{H^s_\sigma} = O\left(|U_0|^2 + \|z_0\|^2_{H^s_\sigma}\right),$$

we need only prove the statement locally. Hence we prove that, in a neighborhood of $(U_0,0)$, the maps $\mathcal{P}^{U_0}_\pm (U,z) \mapsto (Id_{\mathbb{C}^2}, P_c(U_0))\mathcal{P}_\pm (U, R(U,U_0)z)$ are bijective (P_c and R are defined in Proposition 2.2).

To prove that $\mathcal{P}^{U_0}_\pm$ is bijective (i.e., the scattering exists), let us prove it for $\mathcal{P}^{U_0}_+$ (it is similar for $\mathcal{P}^{U_0}_-$). It is enough to prove that the following system has a unique solution in an open neighborhood of $(0,0)$ in $\mathcal{S}_\sigma$:

$$\begin{aligned}
&V_\pm(t) = V_{\pm\infty} \\
&+\int_t^\infty A(V_\pm(v), e^{JsH(V_{\pm\infty})}\tilde\eta_\pm(v))\langle N(U(v), e^{JsH(V_{\pm\infty})}\tilde\eta_\pm(v)), dS(V_\pm(v))\rangle\, dv
\end{aligned}$$

and

$$\begin{aligned}
\tilde\xi_+(t) &= z_\infty - \int_t^\infty e^{-JsH(V_{+\infty})} \\
&\quad\times \mathbf{P}_c(V_+(v)) J\left(d^2F(S(V_+(v))) - d^2F(S(V_{+\infty}))\right) e^{JsH(V_{+\infty})}\tilde\xi_+(v)\, dv \\
&-\int_t^\infty e^{-JsH(V_{+\infty})} \\
&\quad\times \mathbf{P}_c(V_+(v)) JN(V_+(v), e^{JsH(V_{+\infty})}\tilde\eta_+(v))\, dv \\
&-\int_t^\infty e^{-JsH(V_{+\infty})}\mathbf{P}_c(V_+(v)) dS(V(v)) A(V_+(v), e^{JsH(V_{+\infty})}\tilde\eta_+(v)) \\
&\quad\times\langle N(V_+(v), e^{JsH(V_{+\infty})}\tilde\eta_+(v)), dS(V_+(v))\rangle\, dv \\
&+\int_t^\infty e^{-JsH(V_{+\infty})}(d\mathbf{P}_c(V_+(v))) A(V_+(v), e^{JsH(V_{+\infty})}\tilde\eta_+(v)) \\
&\quad\times\langle N(V_+(v), e^{JsH(V_{+\infty})}\tilde\eta_+(v)), dS(V_+(v))\rangle e^{JsH(V_{+\infty})}\tilde\eta_+(v)\, dv
\end{aligned}$$

with $\tilde\eta_+(t) = \tilde\xi_+(t) + e^{-JsH(V_{+\infty})} g\big(V_+(t), e^{JsH(V_{+\infty})}\tilde\xi_+(t)\big)$.

This system can be solved by a fixed point argument in the set of functions such that

$$\begin{aligned}
&\max\Bigg[\sup_{t\in\mathbb{R}}(\|z_{+\infty} - \tilde\xi_+(t)\|_{H^s}),\ \sup_{t\in\mathbb{R}}(\langle t\rangle^{3/2}\|z_{+\infty} - \tilde\xi_+(t)\|_{H^s_{-\sigma}}), \\
&\sup_{t\in\mathbb{R}}(\langle t\rangle^{3/2}\|z_{+\infty} - \tilde\xi_+(t)\|_{B^\beta_{\infty,2}}),\ \sup_{t\in\mathbb{R}}(\langle t\rangle^{-3/2}\|z_{+\infty} - \tilde\xi_+(t)\|_{H^s_{3/2}})\Bigg]
\end{aligned}$$

and

$$\langle t\rangle^2 \left|V_+(t) - V_{+\infty}\right|$$

are small with the method we used in Lemma 3.14. □

For the same reasons, the small locally invariant center-stable manifold built in section 2.2 is invariant in positive time. We can also consider the union of these manifolds, and we can obtain a map Φ_+ similar to the map Ψ built in Lemma 5.1.

The instability in negative time is, in fact, a consequence of Proposition 2.5.

The corresponding conclusion holds for the center-unstable manifold.

The statements on the instability outside these manifolds follow from Propositions 2.4 and 2.5.

Acknowledgments. I would like to thank Éric Séré for fruitful discussions and advice during the preparation of this work. I am indebted to Galina Perel'man for her careful reading and her comments and suggestions, to Michael Levitin for his advice, to Sylvain Golénia for having checked some proofs, to Matthieu Brassart for his answers to my questions, and to Mathieu Lewin for all his help. I am grateful to the referees for their careful reading, corrections, and remarks.

ANALYSIS OF MODEL EQUATIONS FOR STRESS-ENHANCED DIFFUSION IN COAL LAYERS. PART I: EXISTENCE OF A WEAK SOLUTION*

ANDRO MIKELIĆ† AND HANS BRUINING‡

Abstract. This paper is motivated by the study of the sorption processes in the coal. They are modeled by a nonlinear degenerate pseudoparabolic equation for stress-enhanced diffusion of carbon dioxide (CO_2) in coal, $\partial_t \phi = \partial_x \left\{ D(\phi)\, \partial_x \phi + \frac{D(\phi)\phi}{B} \partial_x \left(e^{-m\phi} \partial_t \phi \right) \right\}$, where B, m are positive constants and the diffusion coefficient $D(\phi)$ has a small value when the CO_2 volume fraction ϕ is $0 \leq \phi < \phi_c$, representative of coal in the glass state and orders of magnitude higher value for $\phi > \phi_c$, when coal is in the rubber-like state. These types of equations arise in a number of cases when nonequilibrium thermodynamics or extended nonequilibrium thermodynamics is used to compute the flux. For this equation, existence of the travelling wave–type solutions was extensively studied. Nevertheless, the existence seems to be known only for a sufficiently short time. We use the corresponding entropy functional in order to get existence, for any time interval, of an appropriate weak solution with square integrable first derivatives and satisfying uniform L^∞-bounds. Due to the degeneracy, we obtain square integrability of the mixed second order derivative only in the region where the concentration ϕ is strictly positive. In obtaining the existence result it was crucial to have the regularized entropy as unknown for the approximate problem and not the original unknown (the concentration).

Key words. degenerate pseudoparabolic equation, entropy methods, stress-enhanced diffusion

1. Introduction.

One of the promising methods for reducing the discharge of the "greenhouse gas" carbon dioxide (CO_2) into the atmosphere is its sequestration in unminable coal seams. A typical procedure is the injection of CO_2 via deviated wells drilled inside the coal seams. CO_2 displaces the methane adsorbed on the internal surface of the coal. A production well gathers the methane as free gas. This process, known as CO_2-enhanced coal bed methane production (CO_2-ECBM), is a producer of energy and at the same time reduces greenhouse concentrations as about two CO_2 molecules displace one molecule of methane. Worldwide application of ECBM can reduce greenhouse gas emissions by a few percent. Coal has an extensive fracturing system called the cleat system. In fact, it is possible to discern a number of cleat

This author's research was supported by Shell International Exploration and Production B.V., NWO-Novem, and the Greenhouse-gas Removal Apprenticeship and Student Program (GRASP) funded by the EC. The idea of stress-enhanced diffusion [29], [30] for coal, worked out in the doctoral thesis of Mazumder [23], was the inspiration for this work.

systems at different scales. In the end, the matrix blocks between the smallest cleat systems typically have diameters of a few tens of microns [13].

The matrix blocks have a polymeric structure (dehydrated cellulose [32]), which provides the adsorption sites for the gases. At low temperatures or low sorption concentration the coal structure behaves like a rigid glassy polymer, in which movement is difficult. At high temperatures or high sorption concentrations, the glassy structure is converted to the less rigid and open rubber-like (swollen) structure [29], [30]. As coal is less dense in the rubber-like state, a conversion from the glassy state to the rubber-like state exhibits swelling. Therefore modeling of diffusion is not only relevant for modeling transport into the matrix blocks, but also for the modeling of swelling, which affects the permeability of the coal seam.

Ritger and Peppas [29], [30] distinguish between transport by Fickean diffusion and a process that occurs on the interface between the glass state and the rubber-like state. Ritger and Peppas state that the conversion process from the glass to the rubber state is controlled by a rate-limiting relaxation phenomenon (see also [2]). Thomas and Windle [31] (see also [16], [17], [19]), however, suggested in their classic paper that the diffusion transport was enhanced by stress gradients that resulted from the accommodation of large molecules in the small cavities providing the adsorption sites. For this, Alfrey, Gurnee, and Lloyd [1] coined the term superdiffusion or case II diffusion. At a critical concentration of the penetrants the glassy polymer is transformed to a rubber state, where the diffusion coefficient is of the order of a factor 1000 larger than in the glassy state.

This paper is the first of a series in which the model equations for case II diffusion [31], [16], [17], [19] will be analyzed. Our longtime interest is to investigate the one-dimensional sorption rate behavior, i.e., whether the equations indeed lead to a rate faster than the square root of time. In this paper, we establish existence of a weak solution for all times.

Nonlinear diffusion equations with a pseudoparabolic regularizing term being the Laplacian of the time derivative are considered in [25] and [26]. Global existence of a strong solution is proved by writing the problem as a linear elliptic operator, acting on the time derivative, equal to the nonlinear diffusion term. Then the linear elliptic operator, acting on the time derivative, is inverted, and the standard geometric theory of nonlinear parabolic equations (see, e.g., [15]) is applicable.

In our situation the physical model leads to a degenerate nonlinear second order elliptic operator, acting on the time derivative, in place of the Laplacian. The invertibility of this nonlinear elliptic operator is not clear anymore and depends on the solution itself. The same type of equation can occur in models that use classical irreversible thermodynamics (CIT) or extended irreversible thermodynamics (EIT). An important example is the model of the two-phase flow through porous media introduced in [14], where the capillary pressure relation is extended with a dynamic term, which contains the time derivative of the saturation. We also refer the reader to [5] for the modeling. This application to multiphase and unsaturated flows through porous media motivated a number of recent papers. In [18] one finds a detailed study of possible travelling wave solutions and in particular of the behavior of such travelling waves near fronts where the concentration is zero. Further studies of the travelling waves are in [8] and [7]. The small- and waiting-time behavior of the equations is studied in [20]. Study of the viscosity limit for the linear relaxation model of the dynamic term is in [10]. Nevertheless, the study of existence of a solution to the nonlinear model from [14] is undertaken only in [4] and [5], where the nondegeneracy is supposed and existence is local in time. Another existence result, also local in

time, is in the paper [9] by Düll, where a related pseudoparabolic equation modeling solvent uptake in polymeric solids is studied. Düll proved the short-time existence of a solution for the problem in $\mathbb{R}$, supposing nonnegative compactly supported initial datum. Contrary to our approach, the problem was written as a system containing a linear elliptic equation and an evolution equation. With such an approach, we did not manage to get estimates as good as those with the entropy approach undertaken in this paper. For studies of travelling waves and sharp fronts in case II diffusion models, we refer the reader to [17] and [33].

We consider the evolution problem

$$\partial_t \phi = \partial_x \left\{ D(\phi)\, \partial_x \phi + \frac{D(\phi)\, \phi}{B} \partial_x \left(e^{-m\phi} \partial_t \phi \right) \right\} \quad \text{in } (0, L) \times (0, T), \tag{1}$$

$$D(\phi)\, \partial_x \phi + \frac{D(\phi)\, \phi}{B} \partial_x \left(e^{-m\phi} \partial_t \phi \right) = 0 \quad \text{on } \{x = L\} \times (0, T), \tag{2}$$

$$\phi(0, t) = \phi_g(t) \quad \text{on } (0, T), \quad \phi = 0 \quad \text{on } (0, L) \times \{0\}. \tag{3}$$

Our goal is to obtain a global existence of a weak solution, for any time interval, as was obtained in [3] for a degenerate pseudoparabolic regularization of a nonlinear forward-backward heat equation. Our PDE allows a natural generalization of the classic Kullback entropy, and its integrand is given by

$$\mathcal{E}(\varphi) = \int_0^{\varphi} \frac{\varphi - \xi}{\xi} \left(e^{-m\xi} \frac{1}{D(\xi)} - \frac{1}{D(0)} \right) d\xi + \frac{1}{D(0)} (\varphi \log \varphi - \varphi). \tag{4}$$

As in [24], we will use $\mathcal{E}'(\varphi)$ as a test function, with the hope of obtaining a convenient a priori estimate. Formal calculation gives the equality

$$\begin{aligned} &\partial_t \int_0^L \left\{ \mathcal{E}(\phi) - \varphi \mathcal{E}'(\varphi_g) + \frac{1}{2B} (e^{-m\phi} \partial_x \phi)^2 \right\} dx \\ &\quad + \int_0^L \left(\frac{1}{\phi} e^{-m\phi} (\partial_x \phi)^2 + \phi \partial_t \mathcal{E}'(\varphi_g) \right) dx = 0. \end{aligned} \tag{5}$$

The presence of the initial and boundary conditions leads to unbounded nonintegrable $\mathcal{E}'$. The equality (5) cannot be used directly, and we do not get the entropy estimates as in [12]. We had to obtain an additional estimate for the time derivative, and our calculations are more complicated than in the literature.

Existence is proved by showing that the "energy" of the system remains bounded during the time evolution of the system. The "energy" equation is derived from the differential equation by multiplying with an appropriate test function and integrating over the domain. The choice of the test function depends strongly on the choice of the nonlinearities. With an appropriate approximation, this can also be the basis of a numerical scheme that leads to an implicit first order nonlinear system of ODEs. The implicit dependence on the time derivative makes its solvability nontrivial. Solvability of our system of ODEs depends strongly on the initial conditions. The fact that the "energy" is bounded means that the numerical scheme is stable. If convergence can be proved, it shows that at least one solution exists.

As already stated, in this case an appropriate test function is $\Phi(\phi)$, where

$$\Phi'(\xi) = \frac{e^{-m\xi}}{\xi D(\xi)},$$

is, however, singular for $\xi = 0$. Another problem of the test function is that for large values of ξ, Φ' is exponentially small. In order to prove existence we need Φ that is bijective from $\mathbb{R}$ to $\mathbb{R}$. Concerning the diffusion coefficient D, we extend it by setting $D(\xi) = D(-\xi)$ for $\xi < 0$.

We introduce Φ_δ by

$$\Phi'_\delta := \frac{e^{-m\min\{|\xi|,1/\delta\}}}{(|\xi|+\delta)\,D(\xi)}, \quad \delta > 0,\ \xi \in \mathbb{R}, \tag{6}$$

and

$$\Phi_\delta(\phi) := \begin{cases} \displaystyle\int_0^\phi \frac{e^{-m\min\{\xi,1/\delta\}}}{(\xi+\delta)D(\xi)}\,d\xi, & \phi > 0, \\ \displaystyle -\int_\phi^0 \frac{e^{-m\min\{-\xi,1/\delta\}}}{(-\xi+\delta)D(-\xi)}\,d\xi, & \phi < 0. \end{cases} \tag{7}$$

Obviously, Φ_δ is odd and strictly increasing on $\mathbb{R}_+$.

In order to obtain an existence result for problem (1)–(3) we study the following regularized problem in $Q_T = (0,L)\times(0,T)$:

$$\partial_t\phi = \partial_x\left\{D(\phi)\,\partial_x\phi + \frac{D(\phi)(|\phi|+\delta)}{B}\partial_x\left(e^{-m\min\{|\phi|,1/\delta\}}\partial_t\phi\right)\right\} \tag{8}$$

with boundary condition at $x = L$,

$$D(\phi)\,\partial_x\phi + \frac{D(\phi)(|\phi|+\delta)}{B}\partial_x\left(e^{-m\min\{|\phi|,1/\delta\}}\partial_t\phi\right)\Big|_{x=L} = 0, \tag{9}$$

and boundary and initial conditions (3).

We start by introducing a variational solution for the problem (8), (9), and (3).

Definition 1. *Let*

$$\mathcal{V} := \{z \in C^\infty[0,L],\ z|_{x=0} = 0\} \quad \textit{and} \quad \mathcal{H} := \{C^\infty[0,T],\ h(T) = 0\}. \tag{10}$$

Then the variational formulation corresponding to the problem (3), (8), *and* (9) *is*

$$\begin{aligned} &-\int_0^T\int_0^L \phi(x,t)\,g(x)\,\partial_t h(t)\,dx\,dt + \int_0^T\int_0^L D(\phi)\,\partial_x\phi(x,t)\,\partial_x g(x)h(t)\,dx\,dt \\ &+\int_0^T\int_0^L \frac{D(\phi)(|\phi|+\delta)}{B}\partial_x g(x)\,h(t)\,\partial_x\left(e^{-m\min\{|\phi|,1/\delta\}}\partial_t\phi\right)dx\,dt = 0 \end{aligned} \tag{11}$$

for all $g \in \mathcal{V}$ and for all $h \in \mathcal{H}$, and at the boundary $x = 0$ we have

$$\phi - \phi_g = 0. \tag{12}$$

Our goal is to prove existence for (11)–(12). In order to have the entropy estimate, we should formulate the approximate problem in terms of it. Otherwise it *would not be possible to use it as a test function* for the approximate problem, which is finite dimensional. Getting a priori estimates without this approach is not clear.

Let $z := \Phi_\delta(\phi)$, $\phi = \Phi_\delta^{-1}(z)$, $z|_{x=0} = \Phi_\delta(\phi_g(t))$. We reformulate the problem (3), (8), and (9) in terms of z:

$$\frac{1}{\Phi_\delta'\left(\Phi_\delta^{-1}(z)\right)}\partial_t z = \partial_x\left\{\frac{D\left(\Phi_\delta^{-1}(z)\right)}{\Phi_\delta'\left(\Phi_\delta^{-1}(z)\right)}\partial_x z\right.$$

$$\left. + \frac{D\left(\Phi_\delta^{-1}(z)\right)\left(\left|\Phi_\delta^{-1}(z)\right|+\delta\right)}{B}\partial_x\left(D\left(\Phi_\delta^{-1}(z)\right)\left(\left|\Phi_\delta^{-1}(z)\right|+\delta\right)\partial_t z\right)\right\} \quad \text{in } Q_T. \tag{13}$$

Moreover we can express the boundary and initial conditions in z as

$$z(0,t) = \Phi_\delta(\phi_g(t)) \quad \text{on } (0,T), \quad z(x,t=0) = \Phi_\delta(0) = 0 \quad \text{on } (0,L), \tag{14}$$

$$\frac{1}{\Phi_\delta'\left(\Phi_\delta^{-1}(z)\right)}\partial_x z + \frac{\left(\left|\Phi_\delta^{-1}(z)\right|+\delta\right)}{B}\partial_x\left(D\left(\Phi_\delta^{-1}(z)\right)\left(\left|\Phi_\delta^{-1}(z)\right|+\delta\right)\partial_t z\right) = 0 \quad \text{at } x = L. \tag{15}$$

Our paper is organized as follows: section 2 describes the physical model, first proposed in [31]. We repeat the derivations from [16], [17], [19] for reasons of easy reference and unified notation.

In section 3 we introduce the discretization of the problem (13)–(15). We get the Cauchy problem for an implicit first order system of ODEs. Next the solvability of the discretized problem is proved, and the uniform L^2 a priori estimates for the first derivatives and the mixed second derivative are obtained for a small time interval $(0, T_0)$. They imply the short-time existence for the regularized problem.

We continue with section 4 where we use the entropy to establish the existence of a solution for the regularized problem for all times. Next, we establish L^∞-bounds independent of the regularization parameter.

The last section 5 concerns the existence for the original problem. Using the entropy, the estimates for the time derivative, and the L^∞-bounds again, we are able to pass to the limit when the regularization parameter tends to zero and prove the existence of at least one solution for the original problem.

2. Model equation for stress-induced diffusion. Consider a coal particle between the fractured cleat systems in coal. The matrix block can be considered as a small (30 μm diameter) cubical particle consisting of glassy coal. The coal face is exposed to the penetrant, in our case CO_2. The coal face of the particle and the mechanism of the sorption process is shown schematically in Figure 1. The coal originates from a cellulose-like polymeric structure [32], with the chemical formula $C_n(H_2O)_m$, from which part of the hydrogen and oxygen have disappeared during the coalification process, which took millions of years. The remaining structure behaves like a glassy polymer, which contains holes (sites) that can accommodate CO_2, CH_4, etc. In other words, sorption of gases by coal is more a dissolution process than is adsorption of gases at a coal surface. The holes receiving the CO_2 are originally too small to accommodate the molecule and need to expand. Consequently, the expanded hole exerts a stress on the neighboring molecules constituting the polymeric coal. Therefore the penetration of CO_2 will lead to both a stress gradient and a concentration gradient. The concentration will be expressed as a volume fraction ϕ, i.e., $\phi = c/\Omega$, where c is the molecular concentration and Ω is the molecular volume. As the CO_2 likes to move toward a region of smaller stress, the transport of the molecule will be caused by both a concentration gradient and a stress gradient. When the stresses become too high, a deformation occurs, in which the glassy polymeric structure is converted to a rubber-like (swollen) structure, which is much more open. Consequently the diffusion coefficient in the rubber-like structure is much higher (more

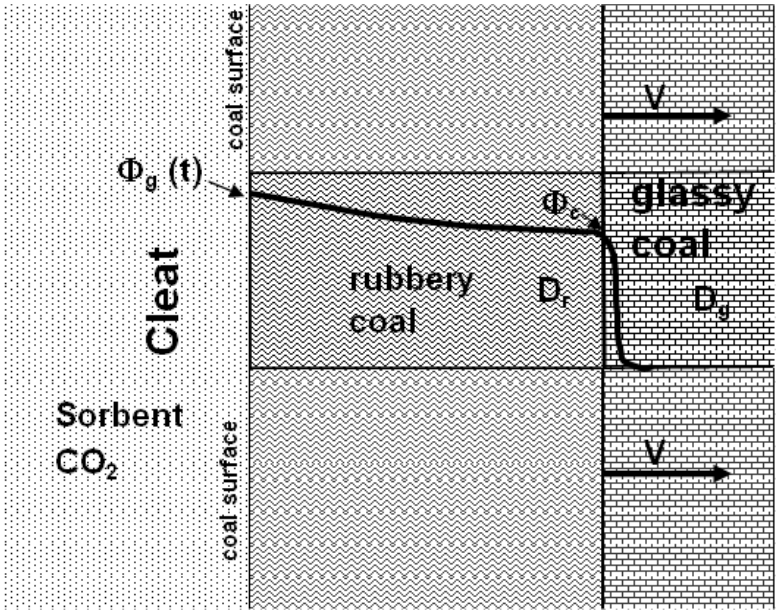

FIG. 1. *A coal face exposed to a sorbent (CO_2). To the far right is the virgin coal, which behaves as a glassy polymer. As the sorbent penetrates in the coal, a reorientation of the polymeric coal structure occurs, and the coal becomes rubber-like. The diffusion coefficient in the rubber-like structure is much higher ($> 1000\times$) than in the glassy structure. The rubber-like structure has also a lower density leading to swelling.*

than 1000 times) than the diffusion coefficient in the glassy structure. The stresses are considered to depend on the CO_2 concentration in the coal, and conversion to the rubber-like structure occurs instantaneously when a certain critical concentration is exceeded.

These ideas were formulated for the first time by Thomas and Windle [31], and the derivation of the model equations will be explained below.

2.1. Derivation of model equations. The salient features of the Thomas and Windle model [31] are well summarized by Hui et al. [16], [17]. We summarize the derivation here with the help of the article by Hui et al. and the book of Landau and Lifshitz [21]; i.e., the molar (diffusive) flux J is not only driven by the volume fraction (ϕ) (concentration) gradient, but also by the stress (P_{xx}) gradient, i.e.,

$$J = -D\left(\frac{\partial \phi}{\partial x} + \frac{\Omega\phi}{kT}\frac{\partial P_{xx}}{\partial x}\right), \tag{16}$$

where k is the Boltzmann constant. As opposed to the equation in [21], which contains a scalar pressure gradient, the idea here is extended in [19] with the use of the stress gradient $\partial_x P_{xx}$. Hui (see [16], [17]) interprets P as the osmotic pressure. Note that J is the flux of a volume fraction and behaves as a velocity. The diffusion coefficient depends on the concentration. Below a critical volume fraction ϕ_c, a diffusion coefficient $D_g > 0$ characteristic of a glassy state is used, and above ϕ_c the diffusion coefficient $D_r > 0$ characteristic of the rubber (swollen) state is used. It can be expected that $D_r/D_g \gg 1$. In the model an abrupt change of the diffusion coefficients at ϕ_c is used, but D_r and D_g are considered constant for $\phi > \phi_c$ and $\phi < \phi_c$, respectively:

$$D(\xi) := \begin{cases} D_g, & 0 \le \xi < \phi_c - \kappa, \\ D_g + (D_r - D_g)(\xi - \phi_c + \kappa)/(2\kappa), & \phi_c - \kappa \le \xi \le \phi_c + \kappa, \\ D_r, & \phi_c + \kappa < \xi < +\infty, \end{cases} \tag{17}$$

where $\kappa > 0$ is a small parameter. Extended nonequilibrium thermodynamics [19] suggests that vice versa also the stress (P_{xx}) is related to the volumetric flux gradient as

$$P_{xx} = -\eta_l \frac{\partial J}{\partial x} = \eta_l \frac{\partial \phi}{\partial t}, \tag{18}$$

where the second equality follows from a mass conservation law that assumes incompressible flow,

$$\frac{\partial \phi}{\partial t} + \frac{\partial J}{\partial x} = 0. \tag{19}$$

With η_l we denote the elongational velocity [6], i.e., the resistance of movement due to a velocity gradient $\frac{\partial J}{\partial x}$ in the direction of flow. Elongational viscosity is caused by a resistance force of a fluid to accelerate. Hence, the force is proportional to the component of the gradient of the velocity in the flow direction. Elongational viscosity η_l is always larger than the shear viscosity η_s, e.g., in Newtonian fluids $\eta_l = 3\eta_s$. In this case the "fluid CO_2" is moving in the coal medium. The resistance to flow is largely determined by the coal-CO_2 interaction and not, as in the usual definition of viscosity, as CO_2-CO_2 interaction. Hence here we deal with an apparent or pseudoviscosity. With increasing CO_2 concentration the coal becomes more rubberlike, i.e., it acquires a more open structure, and the apparent viscosity decreases with increasing concentration (see (20)). The elongational viscosity η_l is supposed to depend on the volume fraction of the penetrant as

$$\eta_l = \eta_o \exp(-m\phi), \tag{20}$$

where m is a material constant and η_0 is the volumetric viscosity of the unswollen coal sample.

Substituting expression (16) for the flux into the mass balance equation (19), where we also use (18), we obtain

$$\partial_t \phi = \partial_x \left\{ D(\phi)\, \partial_x \phi + \frac{D(\phi)\,\phi}{B} \partial_x \left(e^{-m\phi} \partial_t \phi \right) \right\}, \tag{21}$$

where the constant $B = k_B T/(\eta_o \Omega)$. This equation is defined in $Q_T = (0, L) \times (0, T)$.

As initial condition we have that the concentration is

$$\phi(x, t = 0) = 0 \quad \text{on } (0, T). \tag{22}$$

The boundary condition at $x = 0$ must be derived from thermodynamic arguments. The final equilibrium concentration is reached when the coal has swollen to make the stress $P_{xx} = P^0_{xx}$ equal to zero. In this case the volume fraction of CO_2 in the coal is in equilibrium with the CO_2 in the fluid phase outside the coal. Also the CO_2 in the stressed coal is in equilibrium with the CO_2 in the fluid phase. The change in chemical potential is $d\mu = \Omega\, dP_{xx} + k_B T\, d\ln\phi$. Equating the chemical potential in the unstressed and stressed state leads to

$$\Omega P_{xx} + k_B T \ln\phi = \Omega P^0_{xx} + k_B T \ln\phi_o, \tag{23}$$

where ϕ_o is the volume fraction at the coal boundary that would be in equilibrium with the CO_2 in the gas phase if the coal has relaxed to the rubber state with $P^0_{xx} = 0$.

Substituting (18) and (20) into (23) leads to

$$t = -\phi_o \frac{\eta_0 \Omega}{k_B T} \int_0^{\phi/\phi_o} \frac{\exp(-m\phi_o y)}{\ln y}\, dy, \tag{24}$$

where we use the initial condition that $\phi = 0$ at $t = 0$. Singularity of the integrand at $y = 1$ guarantees that ϕ remains bounded by ϕ_o for all times.

At $x = L$ we have the boundary condition on $(0, T)$,

$$D(\phi)\left(\partial_x \phi + \frac{1}{B}\phi \partial_x \left(\exp(-m\phi)\, \partial_t \phi\right)\right)_{x=L} = 0. \tag{25}$$

In summary, we have one initial condition equation (22), one boundary condition at $x = L$, viz. (25), and the implicit boundary condition equation (24), which specifies $\phi(x = 0, t)$ as

$$\phi(0, t) = \phi_g(t). \tag{26}$$

ϕ_g satisfies the conditions

$$0 \le \phi_g \le A_0, \quad \phi_g(0) = 0. \tag{27}$$

Remark 2. Equations like (21) can occur in many transport problems in which the flux is calculated using CIT or EIT. A well-known example for CIT in porous media flow is that the deviation of the capillary pressure P_c from its equilibrium value at a given oil saturation S_o, i.e., $P_c^o = P_c^o(S_o)$, is a driving force leading to a rate of change of the saturation (scalar flux). This leads [14], [27], [28], [22] to $\partial_t S_o = L(P_c - P_c^o)$ and to the transport equation for counter current imbibition:

$$\begin{aligned}\varphi \partial_t S_o &= \partial_x \left(\Lambda(S_o)\, \partial_x P_c\right) \\ &= \partial_x \left(\Lambda(S_o)\, \partial_x P_c^o(S_o)\right) + \partial_x \left(\Lambda(S_o)\, \partial_x \frac{1}{L(S_o)} \partial_t S_o\right).\end{aligned}$$

EIT [19] differs from CIT as it characterizes a system not only by its local thermodynamic variables (pressure, temperature, and concentration) but also by its gradients. The explanation in [19] is difficult to follow by nonspecialists as many thermodynamic relations are considered to be known by the reader. In isothermal systems and in the absence of other applied fields, e.g., electric fields, the volumetric flux J is, according to EIT, given by the following system of equations:

$$\tau_1 \partial_t J + J = -D\left(\frac{\partial \phi}{\partial x} + \frac{\Omega \phi}{kT} \frac{\partial P_{xx}}{\partial x}\right), \tag{28}$$

$$\tau_2 \partial_t P_{xx} + P_{xx} = -\eta_l \frac{\partial J}{\partial x}. \tag{29}$$

Reference [19] uses a mass flux instead of a volumetric flux and therefore uses a factor υ_1, being the partial volume per unit mass. Here τ_1, τ_2 are time constants, which are small with respect to L^2/D. The first terms on the left-hand sides of (28) and (29) appear only in EIT and not in CIT. The first terms on the left are of interest for

short-time behavior and are omitted from the model discussed here. Another example from EIT is the Taylor dispersion problem (see equation 10.34 in [19]), where there is an "xxt" derivative in the concentration, apart from many other terms. Hence, EIT or CIT can lead to transport equations of the form of (21).

3. Short-time existence for the regularized problem. In this section, we first introduce an approximate problem corresponding to (13)–(15). It is a first order system of ODEs for expansion coefficients, with implicit dependence on the time derivatives. First we prove the solvability on some interval $(0, T_N)$, where N is the parameter describing discretization in space. Then, we use the entropy to prove the solvability on interval $(0, T_0)$, where T_0 does not depend on N. Finally, we pass to the limit $N \to +\infty$ and prove that the problem (13)–(15) itself has a solution on $(0, T_0)$.

Let $V := \left\{ g \in H^1(0,L) \mid g(0) = 0 \right\}$ be the closure of $\mathcal{V}$ in $H^1(0,L)$, and let $\{\alpha_j\}_{j\in\mathbb{N}}$ be a C^∞-basis for V. We set $V_N := \operatorname{span}\{\alpha_1, \dots, \alpha_N\}$ and introduce the following coefficients:

$$d_1(z) := \frac{1}{\left(\Phi_\delta'\left(\Phi_\delta^{-1}(z)\right)\right)}, \quad d_2(z) := \frac{D\left(\Phi_\delta^{-1}(z)\right)}{\left(\Phi_\delta'\left(\Phi_\delta^{-1}(z)\right)\right)}, \quad \text{and}$$

$$d(z) := D\left(\Phi_\delta^{-1}(z)\right)\left(\left|\Phi_\delta^{-1}(z)\right| + \delta\right). \tag{30}$$

The coefficients d_1 and d_2 are continuous, nonnegative, and bounded functions of z. d is a continuous function of z, bounded away from zero.

We start study of the initial boundary problem (13)–(15) by constructing an approximate solution for every N. It is defined as follows.

Approximate problem 3. *For $q \in (2, +\infty)$, find $z_N = \sum_{j=1}^N c_j(t)\,\alpha_j(x) + \Phi_\delta(\phi_g(t)) \in W^{1,q}([0,T]; V_N)$ such that*

$$\int_0^L \partial_t z_N d_1(z_N)\,\alpha_k\,dx + \int_0^L d_2(z_N)\,\partial_x z_N \partial_x \alpha_k\,dx$$

$$+ \int_0^L \frac{1}{B} d(z_N)\,\partial_x\left(d(z_N)\,\partial_t z_N\right)\partial_x\alpha_k\,dx = 0 \text{ for } k = 1, \dots, N, \quad \text{and} \tag{31}$$

$$z_N|_{t=0} = P_N\left(z|_{t=0} - \Phi_\delta(\phi_g(0))\right) = 0, \tag{32}$$

where $P : V \to V_N$ is the projector $P_N(f)(x) := \sum_{j=1}^N \alpha_j(x)\,(f, \alpha_j)_V$.

Let the vector valued function $\mathbf{F}$ be given by $F_\kappa(t, \mathbf{c}, \partial_t \mathbf{c}) =$ left-hand side of (31) and let $\mathbf{c}$ be the column vector consisting of elements $(c_1(t) \dots c_N(t))$; then (31), (32) are equivalent to the following Cauchy problem in $\mathbb{R}^N$:

$$\begin{cases} \mathbf{F}(t, \mathbf{c}, \partial_t \mathbf{c}) = 0, \\ \mathbf{c}|_{t=0} = 0. \end{cases} \tag{33}$$

The Cauchy problem (33) is difficult to solve, since the dependence of $\mathbf{F}$ on $\partial_t \mathbf{c}$ is implicit. It is crucial to reduce it to an ordinary Cauchy problem of the form $\partial_t \mathbf{c} = \varrho(t, \mathbf{c})$.

We note that

$$F_k := \sum_{j=1}^N \left\{ \int_0^L d_1(z_N)\,\alpha_k\alpha_j\,dx + \int_0^L \frac{1}{B} d(z_N)\,\partial_x\left(d(z_N)\,\alpha_j\right)\partial_x\alpha_k\,dx \right\} \frac{dc_j}{dt}$$

$$+ \sum_{j=1}^N \left\{ \int_0^L d_2(z_N)\,\partial_x\alpha_j\partial_x\alpha_k\,dx \right\} c_j + \int_0^L d_1(z_N)\,\alpha_k \partial_t \Phi_\delta(\phi_g(t))\,dx. \tag{34}$$

Then, after introducing the matrices $\mathcal{A}(\mathbf{c})$ and $\mathcal{B}(\mathbf{c})$ and the vector $\mathbf{f}(\mathbf{c})$ by

$$\mathcal{A}_{kj}(\mathbf{c}) := \int_0^L d_1(z_N)\,\alpha_k\alpha_j\,dx + \int_0^L \frac{1}{B} d(z_N)\,\partial_x\left(d(z_N)\,\alpha_j\right)\partial_x\alpha_k\,dx, \tag{35}$$

$$\mathcal{B}_{kj}(\mathbf{c}) := \int_0^L d_2(z_N)\,\partial_x\alpha_j\partial_x\alpha_k\,dx, \quad \text{and} \quad f_k(\mathbf{c}) = \int_0^L d_1(z_N)\,\alpha_k\partial_t\Phi_\delta(\phi_g(t))\,dx, \tag{36}$$

$1 \le k, j \le N$, we see that the problem (31)–(32) is equivalent to the following Cauchy problem:

$$\text{Find} \quad \mathbf{c} \in W^{1,q}(0,T)^N \quad \text{such that}$$
$$\mathcal{A}(\mathbf{c})\frac{d\mathbf{c}}{dt} = -\mathcal{B}(\mathbf{c})\mathbf{c} - \mathbf{f}(\mathbf{c}) \ \text{ a.e. in } \ (0,T); \quad \mathbf{c}|_{t=0} = 0. \tag{37}$$

PROPOSITION 4. *There is a $T_N > 0$ such that the problem* (31)–(32) *has a unique solution $z_N \in W^{1,q}(0,T_N;V_N)$ for all $q < +\infty$.*

Proof. It is enough to prove that the Cauchy problem (37) has a solution.

Obviously, $\mathcal{A}$, $\mathcal{B}$, and $\mathbf{f}$ are smooth functions of $\mathbf{c}$. Because of the singularity of $\partial_t\varphi_g$ at $t = 0$, $\mathbf{f}(\mathbf{c}) \in L^q(0,T)$ for all $q < +\infty$, but it is not bounded. Hence, the only property to check is the invertibility of the matrix $\mathcal{A}$. Let $\mathbf{b}$ be an arbitrary vector from $\mathbb{R}^N$ and let $b_\alpha(x) = \mathbf{b}\cdot\alpha(x) = \sum_{j=1}^N b_j\alpha_j(x)$. Then we have

$$\begin{aligned}(\mathcal{A}\mathbf{b})\cdot\mathbf{b} = \sum_{k,j=1}^N \mathcal{A}_{k,j}b_kb_j &= \int_0^L d_1(z_N)(b_\alpha)^2\,dx + \frac{1}{B}\int_0^L d(z_N)\partial_x b_\alpha\partial_x(d(z_N)b_\alpha)\,dx \\ &= \int_0^L d_1(z_N)(b_\alpha)^2\,dx + \frac{1}{B}\int_0^L (d(z_N)\partial_x b_\alpha)^2\,dx \\ &\quad + \frac{1}{B}\int_0^L d(z_N)\partial_x b_\alpha b_\alpha d'(z_N)\partial_x z_N\,dx \\ &\ge \int_0^L \left\{d_1(z_N) - \frac{1}{4B}(d'(z_N))^2(\partial_x z_N)^2\right\}(b_\alpha)^2\,dx. \end{aligned} \tag{38}$$

Since $\partial_x z_N(x,0) = 0$ and functions $\{\alpha_j\}_{j\in\mathbb{N}}$ are linearly independent, the matrix $\mathcal{A}$ is by (38) invertible in a neighborhood of $t = 0$. Then by the classical theory, the problem (37) has a unique solution on some interval $(0,T_N)$. ∎

Next, we want to prove that the existence interval does not depend on N.

PROPOSITION 5. *There is a constant C, independent of N, such that*

$$\|\partial_x z_N\|_{L^\infty(0,T_N;L^2(0,L))} \le C. \tag{39}$$

Consequently, the vector valued function $\mathbf{c}$ *remains bounded at $t = T_N$.*

Proof. In (31) we can replace α_k by $z_N - \Phi_\delta(\phi_g)$. Then after using that $\partial_x\left(d(z_N)\,\partial_t z_N\right) = \partial_t\left(d(z_N)\,\partial_x z_N\right)$, we get

$$\begin{aligned}&\int_0^L d_1(z_N)\,z_N\partial_t z_N\,dx + \int_0^L d_2(z_N)\,(\partial_x z_N)^2\,dx \\ &\quad + \int_0^L \frac{1}{B}\partial_t\left(d(z_N)\,\partial_x z_N\right)d(z_N)\,\partial_x z_N\,dx\end{aligned} \tag{40}$$

$$= \int_0^L d_1(z_N)\,\Phi_\delta(\phi_g)\,\partial_t z_N\,dx = \partial_t \int_0^L \Phi_\delta(\phi_g)(t) \int_0^{z_N} d_1(\xi)\,d\xi\,dx$$
$$- \partial_t \Phi_\delta(\phi_g)(t) \int_0^L \int_0^{z_N} d_1(\xi)\,d\xi\,dx.$$

Integrating over t leads to

$$\int_0^L \left(\int_0^{z_N(x,t)} d_1(\xi)\,\xi\,d\xi \right) dx + \int_0^t \int_0^L d_2(z_N)(\partial_x z_N)^2\,dx\,d\tau + \frac{1}{2B}\int_0^L d(z_N)^2(\partial_x z_N)^2\,dx \tag{41}$$
$$= \int_0^L \left(\int_0^{z_N(x,t)} d_1(\xi)\,d\xi \right) dx\,\Phi_\delta(\phi_g)(t) - \int_0^t \partial_\tau \Phi_\delta(\phi_g)(\tau) \left(\int_0^L \int_0^{z_N} d_1(\xi)\,d\xi\,dx \right) d\tau.$$

We easily find out that

$$\int_0^z d_1(\xi)\,\xi\,d\xi = \int_0^{\Phi_\delta^{-1}(z)} \Phi_\delta(\eta)\,d\eta \quad \text{and} \quad \int_0^z d_1(\xi)\,d\xi = \Phi_\delta^{-1}(z). \tag{42}$$

The growth of the terms in (42) indicates that it will be possible to control the two terms on the right-hand side of (41) by the first term on the left-hand side of (41).

Let $M_\phi := \max_{0\le t\le T} |\Phi_\delta(\phi_g(t))|$. Then by the definition of $\Phi_\delta(\varphi)$, we have $C_0(\delta)\log(1+\varphi/\delta) \le \Phi_\delta(\varphi)$ for all $\varphi \ge 0$. Hence $\int_0^z d_1(\xi)\,\xi\,d\xi \ge C_0(\delta)((|\Phi_\delta^{-1}(z)| + \delta)\log(1+|\Phi_\delta^{-1}(z)|/\delta) - |\Phi_\delta^{-1}(z)|)$, and there is a large enough constant $C_\varphi = C_\varphi(M_\phi,\delta)$ such that $g(z) = C_0(\delta)((|\Phi_\delta^{-1}(z)|+\delta)\log(1+|\Phi_\delta^{-1}(z)|/\delta) - |\Phi_\delta^{-1}(z)|) - M_\phi|\Phi_\delta^{-1}(z)| + C_\varphi > |\Phi_\delta^{-1}(z)|$ for all z. The equality (41) now implies

$$\int_0^L g(z_N(x,t))\,dx + \int_0^t \int_0^L d_2(z_N)(\partial_x z_N)^2\,dx\,d\tau + \frac{1}{2B}\int_0^L d(z_N)^2(\partial_x z_N(t))^2\,dx$$
$$\le C_\varphi(M_\phi,\delta)\,L + \int_0^t |\partial_\tau \Phi_\delta(\phi_g)(\tau)| \left(\int_0^L g(z_N(x,\tau))\,dx \right) d\tau. \tag{43}$$

Since $\partial_\tau \Phi_\delta(\phi_g) \in L^1(0,T)$, we apply Gronwall's inequality, and estimate (39) follows. Hence $\mathbf{c}$ remains bounded at $t = T_N$. ∎

Nevertheless, since the matrix $\mathcal{A}$ could degenerate, some components of $\frac{\partial \mathbf{c}}{\partial t}$ could blow up at $t = T_N$. In order to exclude this possibility and to prove that the maximal solution for (33) exists on $[0,T]$, we need an estimate for the time derivatives. Furthermore, if we want to pass to the limit $N \to +\infty$ in (31), estimate (39) is not sufficient. Our strategy is to obtain an estimate, uniform with respect to N, for $\partial_{xt} z_N$ in $L^2(Q_T)$.

THEOREM 6. *There exists $T_0 > 0$, independent of N, such that*

$$\|\partial_x z_N\|_{L^\infty(0,T_0;L^2(0,L))} \le C, \tag{44}$$
$$\|\partial_t z_N\|_{L^2(0,T_0;L^2(0,L))} \le C, \tag{45}$$
$$\|\partial_{xt} z_N\|_{L^2(0,T_0;L^2(0,L))} \le C, \tag{46}$$
$$\left\| \partial_{xt} \int_0^{z_N} d(\xi)\,d\xi \right\|_{L^2((0,T_0)\times(0,L))} \le C, \tag{47}$$

with constants independent of N. Consequently, the maximal solution for (33) *exists on* $[0,T_0]$.

Proof. We replace α_k in (31) by $\partial_t z_N - \partial_t \Phi_\delta(\phi_g)$. This yields

$$\int_0^L d_1(z_N)(\partial_t z_N)^2\,dx + \int_0^L d_2(z_N)\,\partial_x z_N \partial_{xt} z_N\,dx$$
$$+\frac{1}{B}\int_0^L d(z_N)\,\partial_t\left(d(z_N)\,\partial_x z_N\right)\partial_{xt} z_N\,dx = \int_0^L d_1(z_N)\,\partial_t z_N \partial_t \Phi_\delta(\phi_g)\,dx. \tag{48}$$

In the estimates which follow we will use the fact that integrability of higher order derivatives implies continuity and boundedness in x or in t. We recall that for one-dimensional Sobolev embeddings Morrey's theorem applies and $H^1(0,t)$ (respectively, $H^1(0,L)$) is continuously embedded into the Hölder space $C^{0,1/2}[0,t]$ (respectively, into $C^{0,1/2}[0,L]$). See, e.g., [11] for more details. In our particular situation, we use the explicit dependence of the embedding constant on the length of the time interval and we prefer to derive the estimates directly.

First, as $\partial_x z_N \in L^2\left(0,L;H^1(0,t)\right)$ and $\partial_x z_N|_{\tau=0}=0$, we have for a.e. $x\in(0,L)$ and for every $\tau\in(0,t)$

$$|\partial_x z_N(x,\tau)| = \left|\int_0^\tau \partial_\xi \partial_x z_N(x,\xi)\,d\xi\right| \le \sqrt{\tau}\sqrt{\int_0^\tau |\partial_\xi \partial_x z_N(x,\xi)|^2\,d\xi}. \tag{49}$$

Next, as $\partial_\tau z_N \in L^2\left(0,t;H^1(0,L)\right)$ and $\partial_\tau z_N|_{\tau=0} = \partial_\tau \Phi(\phi_g)$, we have for a.e. $\tau\in(0,t)$ and for every $x\in(0,L)$

$$|\partial_\tau z_N(x,\tau)| \le |\partial_\tau \Phi(\phi_g(\tau))| + \left|\int_0^x \partial_\xi \partial_\tau z_N(\xi,\tau)\,d\xi\right|$$
$$\le |\partial_\tau \Phi(\phi_g(\tau))| + \sqrt{L}\sqrt{\int_0^L |\partial_\xi \partial_\tau z_N(\xi,\tau)|^2\,d\xi}. \tag{50}$$

Estimates (49)–(50) imply

$$\int_0^L\int_0^t |\partial_\tau z_N(x,\tau)|^2\,|\partial_x z_N(x,\tau)|^2\,dx\,d\tau$$
$$\le 2\int_0^L\int_0^t \tau\left(\int_0^t |\partial_\xi \partial_x z_N(x,\xi)|^2\,d\xi\right)\left(|\partial_\tau\Phi(\phi_g(\tau))|^2 + L\int_0^L |\partial_\xi\partial_\tau z_N(\xi,\tau)|^2\,d\xi\right)d\tau\,dx$$
$$\le 2Lt\,\|\partial_{x\tau} z_N\|^4_{L^2((0,t)\times(0,L))} + 2\,\|\partial_{x\tau} z_N\|^2_{L^2((0,t)\times(0,L))}\int_0^t \tau|\Phi'_\delta(\phi_g)|^2|\partial_\tau\phi_g|^2\,d\tau$$
$$\le \left(2\sqrt{L}\sqrt{t}\,\|\partial_{x\tau} z_N\|^2_{L^2((0,t)\times(0,L))} + \frac{1}{\sqrt{2L}}\int_0^t \tau^{1/2}|\Phi'_\delta(\phi_g)|^2|\partial_\tau\phi_g|^2\,d\tau\right)^2. \tag{51}$$

Now we integrate (48) with respect to time, over $(0,t)$, and estimate the obtained terms. The second term is estimated as follows:

$$\left|\int_0^t\int_0^L d_2(z_N)\,\partial_x z_N \partial_{x\tau} z_N\,dx\,d\tau\right| \le C\int_0^t \|\partial_{x\tau} z_N(\tau)\|_{L^2(0,L)}\,\|\partial_x z_N(\tau)\|_{L^2(0,L)}\,d\tau$$
$$\le C\sqrt{\int_0^t \|\partial_{x\tau} z_N(\tau)\|^2_{L^2(0,L)}\,d\tau}\sqrt{\int_0^t\int_0^L (\partial_x z_N)^2\,dx\,d\tau} \le C\,\|\partial_{x\tau} z_N\|_{L^2((0,t)\times(0,L))}, \tag{52}$$

where we have used the estimate (39). We rewrite the third term of (48), omitting the $1/B$ factor, as

$$\int_0^t\int_0^L d(z_N)\partial_\tau\left(d(z_N)\partial_x z_N\right)\partial_{x\tau}z_N\,dx\,d\tau = \int_0^t\int_0^L d(z_N)\left(\partial_{x\tau}z_N\right)^2 dx\,d\tau$$

$$+\int_0^t\int_0^L d(z_N)d'(z_N)\partial_\tau z_N\partial_x z_N\partial_{x\tau}z_N\,dx\,d\tau. \tag{53}$$

The last term in (53) is cubic in derivatives of z_N. Our idea is to use the estimate (51), showing that for small times it enters with a small coefficient and then controlling it using other terms. Using the estimate (51), we find out that it satisfies the following inequality:

$$\left|\int_0^t\int_0^L d(z_N)\partial_{x\tau}z_N\,d'(z_N)\partial_\tau z_N\partial_x z_N\,dx\,d\tau\right| \le C\left\|\partial_{x\tau}z_N\right\|_{L^2(Q_t)}\left\|\partial_\tau z_N\partial_x z_N\right\|_{L^2(Q_t)}$$

$$\le C\sqrt{t}\left(\left\|\partial_{x\tau}z_N\right\|^3_{L^2(Q_t)}+\left\|\tau^{1/6}\Phi'_\delta(\phi_g)\partial_\tau\phi_g\right\|^3_{L^3(0,t)}\right), \tag{54}$$

where $Q_t=(0,t)\times(0,L)$. Let $X^2(t):=\int_0^t\int_0^L\left|\partial_{x\tau}z_N\right|^2dx\,d\tau$. Since $\partial_\tau\Phi_g(\phi_g)\in L^2(0,t)$, estimates (39), (52), (53), and (54) imply

$$\left\|\sqrt{d_1(z_N)}\partial_\tau z_N\right\|^2_{L^2((0,t)\times(0,L))}+X^2(t)-C_1\sqrt{t}X^3(t)\le C_o, \tag{55}$$

where C_o depends on $\left\|\partial_\tau\Phi_\delta(\phi_g)\right\|_{L^2(0,t)}$ and on the constant from estimate (39). We note that the last term on the left-hand side corresponds to the lower bound for the cubic term, corresponding to the stress gradient part of the diffusive flux. Inequality (55) is satisfied for $t=0$. The function $\varrho(X)=X^2-C_1\sqrt{t}X^3$ has its maximum on $(0,+\infty)$ in the point $X_o=3/\left(2C_1\sqrt{t}\right)$. If $C_o<\varrho(X_o)$, then inequality (55) gives an estimate for $X(t)$. We note that $C_o<\varrho(X_o)$ if $t<\frac{4}{27C_1^2C_o}$. Hence for $T\le\frac{4}{27C_1^2C_o}=T_0$ we have estimates (44)–(46).

From (44)–(46) it follows that $\partial_x z_N\partial_t z_N\in L^2\left(0,T_0;L^2(0,L)\right)\le C$, and we have (47) as well. □

The estimates (44)–(47) allow us to pass to the limit $N\to+\infty$. Using classical compactness and weak compactness arguments and due to the a priori estimates (44)–(47), we can extract a subsequence of z_N, denoted by the same subscripts, which converges to an element $z\in H^1((0,T_0)\times(0,L))$, $\partial_{xt}z\in L^2((0,T_0)\times(0,L))$, in the following sense:

$$z_N\to z \text{ strongly in } L^2((0,T_0)\times(0,L)) \text{ and a.e. on } (0,T_0)\times(0,L), \tag{56}$$

$$\partial_x z_N\rightharpoonup\partial_x z \text{ weakly in } L^2((0,T_0)\times(0,L)), \tag{57}$$

$$\partial_t z_N\rightharpoonup\partial_t z \text{ weakly in } L^2((0,T_0)\times(0,L)), \tag{58}$$

$$\partial_{xt} z_N\rightharpoonup\partial_{xt} z \text{ weakly in } L^2((0,T_0)\times(0,L)), \tag{59}$$

$$\partial_{xt}\int_0^{z_N} d(\xi)\,d\xi\rightharpoonup\partial_{xt}\int_0^{z} d(\xi)\,d\xi \text{ weakly in } L^2((0,T_0)\times(0,L)). \tag{60}$$

Now passing to the limit $N\to\infty$ in (31) does not pose problems, and we conclude that z satisfies (13)–(15).

We summarize the results in the following theorem.

THEOREM 7. *Let $\phi_g \in H^1(0,T)$. Then there exists $T_0 > 0$ such that problem* (13)–(15) *has at least one variational solution $z \in H^1((0,T_0)\times(0,L))$, $\partial_{xt} z \in L^2((0,T_0)\times(0,L))$.*

COROLLARY 8. *Let $\phi_g \in H^1(0,T)$. Then there exists $T_0 > 0$ such that the variational formulation* (11)–(12) *of the problem* (8), (9), *and* (3) *has at least one solution $\phi = \Phi_\delta^{-1}(z) \in H^1((0,T_0)\times(0,L))$, $\partial_{xt}\phi \in L^2((0,T_0)\times(0,L))$.*

4. Existence of the regularized problem. In this section, we first use the regularized entropy function to prove the global existence for the problem (8), (9), and (3) (i.e., for the regularized problem). Then we establish the L^∞-bounds for the solution, independent of the regularization parameter.

Let us prove that any solution ϕ for the problem (8), (9), and (3), constructed in Corollary 8, could be extended from $(0,T_0)$ to arbitrary time interval $(0,T)$. First we test (11) by $\Phi_\delta(\phi) - \Phi_\delta(\phi_g(t))$. We have

$$\int_0^t\int_0^L \partial_\tau\phi\Phi_\delta(\phi)\,dx\,d\tau + \int_0^t\int_0^L D(\phi)\,\partial_x\phi\partial_x\Phi_\delta(\phi)\,dx\,d\tau + \int_0^t\int_0^L \frac{D(\phi)(|\phi|+\delta)}{B}\partial_x\left(e^{-m\min\{|\phi|,1/\delta\}}\partial_\tau\phi\right)\partial_x\Phi_\delta(\phi)\,dx\,d\tau = \int_0^t\int_0^L \partial_\tau\phi\Phi_\delta(\phi_g)\,dx\,d\tau,$$

and it follows that

$$\int_0^L\left(\int_0^{\phi(t)}\Phi_\delta(\xi)\,d\xi\right)dx + \int_0^t\int_0^L \frac{1}{2B}\partial_\tau\left(e^{-m\min\{|\phi|,1/\delta\}}\partial_x\phi\right)^2 dx\,d\tau + \int_0^t\int_0^L D(\phi)\Phi_\delta'(\phi)(\partial_x\phi)^2\,dx\,d\tau = \int_0^L \phi(t)\Phi_\delta(\phi_g(t))\,dx - \int_0^t\int_0^L \phi\partial_\tau\Phi_\delta(\phi_g)\,dx\,d\tau$$

and we get as in the proof of Proposition 5

$$\|\partial_x\phi\|_{L^\infty(0,t;L^2(0,L))} \le C. \tag{61}$$

This estimate implies the boundedness of ϕ. We note that C does not depend on the smoothing of D at $\phi = \phi_c$.

Next we test (11) by

$$e^{-m\min\{|\phi|,1/\delta\}}\partial_t\phi - e^{-m\min\{|\phi_g|,1/\delta\}}\partial_t\phi_g$$

and get

$$\int_0^t\int_0^L (\partial_\tau\phi)^2 e^{-m\min\{|\phi|,1/\delta\}}\,dx\,d\tau + \int_0^t\int_0^L D(\phi)\,\partial_x\phi\partial_x\left(e^{-m\min\{|\phi|,1/\delta\}}\partial_\tau\phi\right)dx\,d\tau + \int_0^t\int_0^L \frac{D(\phi)(|\phi|+\delta)}{2B}\left(\partial_{x\tau}\int_0^\phi e^{-m\min\{|\xi|,1/\delta\}}\,d\xi\right)^2 dx\,d\tau$$

$$= \int_0^t \int_0^L \partial_\tau \phi \, e^{-m \min\{|\phi_g|, 1/\delta\}} \partial_\tau \phi_g \, dx \, d\tau.$$

Then, as in the proof of Proposition 5, by estimating the second and the fourth terms and after using (61), we conclude that

$$\|\partial_\tau \phi\|_{L^2((0,t)\times(0,L))} \le C, \tag{62}$$

$$\left\| \partial_{x\tau} \int_0^\phi e^{-m \min\{|\xi|, 1/\delta\}} \, d\xi \right\|_{L^2((0,t)\times(0,L))} \le C, \tag{63}$$

and from this it follows that

$$\|\partial_{x\tau} \phi\|_{L^2((0,t)\times(0,L))} \le C. \tag{64}$$

Therefore, we arrive at the following theorem.

THEOREM 9. *Let $\phi_g \in H^1(0,T)$. Then for all $T > 0$ there exists a weak solution $\phi \in H^1((0,T)\times(0,L))$, $\partial_{xt}\phi \in L^2((0,T)\times(0,L))$ for the variational formulation* (11)–(12) *of the problem* (8), (9), *and* (3).

We conclude this section by establishing uniform L^∞-bounds for ϕ. We have the following proposition.

PROPOSITION 10. *Let $\phi_g \in H^1(0,T)$ and $\phi_g \ge 0$. Then any weak solution ϕ of the problem* (8), (9), *and* (3), *obtained in Theorem* 9, *satisfies $\phi(x,t) \ge 0$ a.e. on Q_T.*

Proof. Let $a_- = -\inf\{a, 0\}$ and $a_+ = \sup\{a, 0\}$. Then $a = a_+ - a_-$ and $\Phi_\delta((\phi_g)_-) = \Phi_\delta(0) = 0$. We test (11) by $\Phi_\delta(\phi_-)$. Note that $\Phi_\delta(\phi_-)|_{x=0} = 0$ and $\Phi_\delta(\phi_-) \ge 0$. Then we have

$$\int_0^t \int_0^L (\partial_\tau \phi) \, \Phi_\delta(\phi_-) \, dx \, d\tau + \int_0^t \int_0^L D(\phi) \, \partial_x \phi \partial_x \Phi_\delta(\phi_-) \, dx \, d\tau$$
$$+ \int_0^t \int_0^L \frac{D(\phi)(|\phi| + \delta)}{B} \partial_x \left(e^{-m \min\{|\phi|, 1/\delta\}} \partial_\tau \phi \right) \Phi_\delta'(\phi_-) \, \partial_x \phi_- \, dx \, d\tau = 0.$$

Since $\phi_-|_{t=0} = 0$, $\phi_+ \phi_- = 0$, and $|\phi| \, \phi_- = \phi_-^2$, we get

$$\int_0^L \left(\int_0^{\phi_-(x,t)} \Phi_\delta(\xi) \, d\xi \right) dx + \int_0^t \int_0^L D(\phi_-) \, \Phi_\delta'(\phi_-) \, (\partial_x \phi_-)^2 \, dx \, d\tau$$
$$+ \int_0^L \frac{D(\phi)(|\phi| + \delta)}{2B} \left(e^{-m \min\{|\phi|, 1/\delta\}} \partial_x \phi_- \right)^2 (t) \, dx = 0.$$

It follows that $\partial_x \phi_- = 0$ and $\phi_-|_{x=0} = 0$. Therefore $\phi_- = 0$, and consequently $\phi = \phi_+ \ge 0$. ∎

In the uniform bounds which follow, we use, for given positive constants m and δ, the function

$$G(z) := \int_0^z \exp\{-m \min\{\xi, 1/\delta\}\} \, d\xi, \quad z \ge 0. \tag{65}$$

Then we have the following bounds.

PROPOSITION 11. *Let $\phi_g \in H^1(0,T)$, $\phi_g \ge 0$ and $\partial_t \phi_g \ge 0$ a.e. on $(0,T)$. Then any weak solution ϕ of the problem* (8), (9), *and* (3), *obtained in Theorem* 9, *satisfies $\phi_g(t) \ge \phi(x,t)$ a.e. on Q_T.*

Proof. Let G be given by (65). We test (11) by $(G(\phi)-G(\phi_g))_+$. Note that $(G(\phi)-G(\phi_g))_+\big|_{x=0}=0$. Then we have

$$\int_0^t\int_0^L \partial_\tau\phi\,(G(\phi)-G(\phi_g))_+\,dx\,d\tau+\int_0^t\int_0^L D(\phi)\,\partial_x\phi\partial_x\,(G(\phi)-G(\phi_g))_+\,dx\,d\tau$$

(66)

$$+\int_0^t\int_0^L \frac{D(\phi)(|\phi|+\delta)}{B}\partial_x\left(e^{-m\min\{|\phi|,1/\delta\}}\partial_\tau\phi\right)\partial_x\,(G(\phi)-G(\phi_g))_+\,dx\,d\tau=0.$$

Note that

(67)

$$\partial_\tau\phi\,(G(\phi)-G(\phi_g))_+=\partial_\tau\left(\int_0^\phi (G(\xi)-G(\phi_g))_+\,d\xi\right)+G'(\phi_g)\partial_\tau\phi_g\,(\phi-\phi_g)_+$$

and

$$\frac{D(\phi)(|\phi|+\delta)}{B}\partial_\tau\partial_x G(\phi)\partial_x\,(G(\phi)-G(\phi_g))_+=\partial_\tau\left(\frac{D(\phi)(|\phi|+\delta)}{2B}(\partial_x\,(G(\phi)\right.$$

(68)

$$\left.-G(\phi_g))_+)^2\right)-(\partial_x\,(G(\phi)-G(\phi_g))_+)^2\partial_\tau\left(\frac{D(\phi)(|\phi|+\delta)}{2B}\right).$$

Then using the monotonicity of ϕ_g and G we obtain from (66), (67), and (68) the following inequality:

$$\int_0^L\left(\int_0^{\phi(x,t)}(G(\xi)-G(\phi_g))_+\,d\xi\right)dx+\int_0^t\int_0^L\frac{D(\phi)}{G'(\phi)}\left(\partial_x\,(G(\phi)-G(\phi_g))_+\right)^2dx\,d\tau$$

$$+\int_0^L\frac{D(\phi)(|\phi|+\delta)}{2B}(\partial_x\,(G(\phi)-G(\phi_g))_+)^2\,dx$$

$$\le\int_0^t\int_0^L(\partial_x\,(G(\phi)-G(\phi_g))_+)^2\partial_\tau\left(\frac{D(\phi)(|\phi|+\delta)}{2B}\right)dx\,d\tau.$$

Since $\partial_\tau\left(\frac{D(\phi)(|\phi|+\delta)}{2B}\right)\in L^2(0,T;L^\infty(0,L))$, we apply Gronwall's lemma and conclude that $(G(\phi)-G(\phi_g))_+=0$, from which it follows that $G(\phi)\le G(\phi_g)$. Inversion of this equation leads to $\phi(x,t)\le\phi_g(t)$ a.e. on Q_T. ∎

PROPOSITION 12. *Let $\phi_g\in H^1(0,T)$, and let us suppose in addition that there are constants $A_0>0$, $\alpha>0$, and $C_0>0$ such that*

$$A_0\ge\phi_g(t)\ge C_0t^\alpha\quad\forall t\in[0,T]. \tag{69}$$

Then any weak solution ϕ of the problem (8), (9), *and* (3), *obtained in Theorem* 9, *satisfies $A_0\ge\phi(x,t)\ge C_0t^\alpha$ a.e. on Q_T.*

Proof. The proof follows the lines of Proposition 11. It is enough to prove the lower bound. We test (11) by $(G(C_0t^\alpha)-G(\phi))_-$. Note that $(G(C_0t^\alpha)-G(\phi))_-\big|_{x=0}=0$. Then as in the proof of Proposition 11 we have

$$\int_0^t\int_0^L\partial_\tau\phi\,(G(C_0\tau^\alpha)-G(\phi))_-\,dx\,d\tau \tag{70}$$

$$+\int_0^t\int_0^L D(\phi)\,\partial_x\phi\partial_x\,(G(C_0\tau^\alpha)-G(\phi))_-\,dx\,d\tau$$

$$+\int_0^t\int_0^L\frac{D(\phi)(|\phi|+\delta)}{B}\partial_x\left(e^{-m\min\{|\phi|,1/\delta\}}\partial_\tau\phi\right)\partial_x\,(G(C_0\tau^\alpha)-G(\phi))_-\,dx\,d\tau=0.$$

Note that

$$G(\phi) = G(C_0 t^\alpha) - \left(G\left(C_0 t^\alpha\right) - G\left(\phi\right)\right)_+ + \left(G\left(C_0 t^\alpha\right) - G\left(\phi\right)\right)_-, \tag{71}$$

$$\partial_\tau \phi \left(G\left(C_0 \tau^\alpha\right) - G\left(\phi\right)\right)_- = \frac{\partial_\tau G(C_0 \tau^\alpha)}{G'(\phi)} \left(G\left(C_0 \tau^\alpha\right) - G\left(\phi\right)\right)_-$$

$$+ \frac{1}{2G'(\phi)} \partial_\tau \left(G\left(C_0 \tau^\alpha\right) - G\left(\phi\right)\right)_-^2 \geq \frac{1}{2G'(\phi)} \partial_\tau \left(G\left(C_0 \tau^\alpha\right) - G\left(\phi\right)\right)_-^2, \tag{72}$$

and

$$\frac{D\left(\phi\right)\left(|\phi| + \delta\right)}{B} \partial_\tau \partial_x G(\phi)\, \partial_x \left(G\left(C_0 \tau^\alpha\right) - G\left(\phi\right)\right)_-$$

$$= \partial_\tau \left(\frac{D\left(\phi\right)\left(|\phi| + \delta\right)}{2B} \left(\partial_x \left(G\left(C_0 \tau^\alpha\right) - G\left(\phi\right)\right)_-\right)^2 \right)$$

$$- \left(\partial_x \left(G\left(C_0 \tau^\alpha\right) - G\left(\phi\right)\right)_-\right)^2 \partial_\tau \left(\frac{D\left(\phi\right)\left(|\phi| + \delta\right)}{2B} \right). \tag{73}$$

Then using the monotonicity of G we obtain from (70), (72), and (73) the following inequality:

$$\int_0^L \frac{\left(G\left(C_0 t^\alpha\right) - G\left(\phi\right)\right)_-^2}{2G'(\phi)}\, dx + \int_0^t \int_0^L \frac{D\left(\phi\right)}{G'\left(\phi\right)} \left(\partial_x \left(G\left(C_0 \tau^\alpha\right) - G\left(\phi\right)\right)_-\right)^2 dx\, d\tau$$

$$+ \int_0^L \frac{D\left(\phi\right)\left(|\phi| + \delta\right)}{2B} \left(\partial_x \left(G\left(C_0 t^\alpha\right) - G\left(\phi\right)\right)_-\right)^2 dx$$

$$\leq \int_0^t \int_0^L \left(\partial_x \left(G\left(C_0 \tau^\alpha\right) - G\left(\phi\right)\right)_-\right)^2 \partial_\tau \frac{1}{2G'(\phi)}\, dx\, d\tau$$

$$+ \int_0^t \int_0^L \left(G\left(C_0 \tau^\alpha\right) - G\left(\phi\right)\right)_-^2 \partial_\tau \left(\frac{D\left(\phi\right)\left(|\phi| + \delta\right)}{2B} \right) dx\, d\tau.$$

Since $\partial_t \left(\frac{D(\phi)(|\phi|+\delta)}{2B}\right)$ and $\partial_t \frac{1}{2G'(\phi)}$ are elements of $L^2(0,T;L^\infty(0,L))$, we apply Gronwall's lemma to the function

$$\int_0^t \left\|\partial_\tau \phi(\tau)\right\|_{L^\infty(0,L)} \left\|\left(G\left(C_0 \tau^\alpha\right) - G\left(\phi(\tau)\right)\right)_-\right\|_{H^1(0,L)}^2 d\tau$$

and conclude that $\left(G\left(C_0 t^\alpha\right) - G\left(\phi\right)\right)_- = 0$, from which it follows that $G\left(\phi\right) \geq G\left(C_0 t^\alpha\right)$. Inversion of G leads to $\phi(x,t) \geq C_0 t^\alpha$ a.e. on Q_T. ∎

THEOREM 13. *Let $\phi_g \in H^1(0,T)$, $A_0 = \max_{0\leq t\leq T} \phi_g(t)$, $A_0 \geq \phi_g \geq C_0 t^\alpha$, and $\alpha > 1$. Then there exists a weak solution ϕ, $C_0 t^\alpha \leq \phi\left(x,t\right) \leq A_0$, $\partial_{xt}\phi \in L^2\left((0,T)\times(0,L)\right)$, $\phi \in H^1\left((0,T)\times(0,L)\right)$, for the problem* (8), (9), *and* (3).

Remark 14.

- By choosing $\delta < 1/A_0$, we can replace $e^{-m\min\{|\phi|,1/\delta\}}$ by $e^{-m\phi}$ and $|\phi| + \delta$ by $\phi + \delta$.
- In addition to the assumptions of Theorem 13 let us suppose that $\partial_t \phi_g \geq 0$. Then there exists a weak solution ϕ, $C_0 t^\alpha \leq \phi\left(x,t\right) \leq \phi_g(t)$, $\partial_{xt}\phi \in L^2\left((0,T)\times(0,L)\right)$, $\phi \in H^1\left((0,T)\times(0,L)\right)$, for the problem (8), (9), and (3).

5. Existence for the original problem. It remains to pass to the limit $\delta \to 0$. This limit will give us the solvability of the starting problem (1)–(3).

After Theorem 13, we are free to replace the nonlinearity $\exp\{-m\phi\}$ by $h(\xi) = e^{-m}\min\{\xi, A_0\}$, $\xi \geq 0$. We have existence for the system (11)–(12); i.e., for every $g \in L^2(0,T;V)$, $V = \{g \in H^1(0,L) \mid g(0) = 0\}$, we have

(74)
$$\int_0^T\int_0^L \partial_t\phi_\delta\, g\, dx\, dt + \int_0^T\int_0^L D(\phi_\delta)\left\{\partial_x\phi_\delta + \frac{(\phi_\delta+\delta)}{B}\partial_x\left(h(\phi_\delta)\,\partial_t\phi_\delta\right)\right\}\partial_x g\, dx\, dt = 0,$$

(75)
$$\phi_\delta|_{x=0} = \phi_g(t) \qquad \text{and} \qquad \phi_\delta|_{t=0} = 0,$$

and we want to pass to the limit $\delta \to 0$.

Let

$$\Psi_\delta'(\xi) := \frac{h(\xi)}{D(\xi)(\xi+\delta)}, \quad \xi \geq 0, \tag{76}$$

and

$$\Psi_\delta(\phi) := \int_0^\phi \frac{1}{\xi+\delta}\left(\frac{h(\xi)}{D(\xi)} - \frac{h(0)}{D(0)}\right)d\xi + \frac{h(0)}{D(0)}\log(\phi+\delta) \quad \text{for} \quad \phi \geq 0. \tag{77}$$

It should be noted that $\Psi_\delta(0) = \frac{h(0)}{D(0)}\log\delta < 0$, which would cause some complications.

THEOREM 15. *Let $\alpha > 0$, C_0, and A_0 be positive constants and let*

$$\phi_g \in H^1(0,T), \quad C_0 t^\alpha \leq \phi_g \leq A_0 \quad \textit{and} \quad \log\phi_g \in L^2(0,T). \tag{78}$$

Then problem (1)–(3) *has at least one weak solution $\phi \in H^1((0,T)\times(0,L))$ such that $\sqrt{\phi}\,\partial_x\left(e^{-m\phi}\partial_t\phi\right) \in L^2((0,T)\times(0,L))$ and $C_0 t^\alpha \leq \phi \leq A_0$.*

Proof.

Step 1 (a priori estimates uniform in δ). We test (74) by $\Psi_\delta(\phi_\delta) - \Psi_\delta(\phi_g)$ and get

$$\begin{aligned}\int_0^t\int_0^L \partial_t\phi_\delta\,\Psi_\delta(\phi_\delta)\,dx\,d\tau + \int_0^t\int_0^L \frac{h(\phi_\delta)}{\phi_\delta+\delta}\left(\partial_x\phi_\delta\right)^2 dx\,d\tau \\ + \frac{1}{B}\int_0^t\int_0^L D(\phi_\delta)(\phi_\delta+\delta)\,\partial_t\left(h(\phi_\delta)\,\partial_x\phi_\delta\right)\frac{h(\phi_\delta)\,\partial_x\phi_\delta}{D(\phi_\delta)(\phi_\delta+\delta)}\,dx\,d\tau \\ = \int_0^t\int_0^L \partial_t\phi_\delta\,\Psi_\delta(\phi_g)\,dx\,d\tau.\end{aligned}$$

This yields

$$\begin{aligned}\int_0^L\left(\int_0^{\phi_\delta(t)}\Psi_\delta(\xi)\,d\xi + \frac{1}{2B}\left(h(\phi_\delta)\,\partial_x\phi_\delta\right)^2\right)dx + \int_0^t\int_0^L \frac{h(\phi_\delta)}{\phi_\delta+\delta}\left(\partial_x\phi_\delta\right)^2 dx\,d\tau \\ = \int_0^t\int_0^L \partial_t\phi_\delta\,\Psi_\delta(\phi_g)\,dx\,d\tau.\end{aligned} \tag{79}$$

In order to get a useful estimate we should find a bound for the first term on the left-hand side of (79). First we note that $\int_0^{\phi_\delta}\int_0^\xi \frac{1}{\eta+\delta}\left(\frac{h(\eta)}{D(\eta)} - \frac{h(0)}{D(0)}\right)d\eta\,d\xi$ defines a continuous function of ϕ_δ. Since ϕ_δ takes values between 0 and A_0, it is bounded independently of δ. Hence

(80)
$$\left|\int_0^L \int_0^{\phi_\delta(t)} \Psi_\delta(\xi)\, d\xi\, dx\right| \le \int_0^L \frac{h(0)}{D(0)} \left|\{\phi_\delta+\delta\}\log\{\phi_\delta+\delta\} - \phi_\delta - \delta\log\delta\right| dx + C.$$

Next $(\phi_\delta(t)+\delta)\log(\phi_\delta(t)+\delta) - \phi(t) - \delta\log\delta$ takes value zero at $t=0$. It is a continuous function of ϕ_δ. Obviously $|(\phi(t)+\delta)\log(\phi(t)+\delta) - \phi(t) - \delta\log\delta| \le \max\{1-\delta+\delta\log\delta,\ (A_0+\delta)\log(A_0+\delta) - A_0 - \delta\log\delta\}$, and it is uniformly bounded with respect to δ.

With (80), (79) leads to

$$\int_0^t \int_0^L \frac{h(\phi_\delta)}{\phi_\delta+\delta} \left(\partial_x\phi_\delta\right)^2 dx\, d\tau \le C + \left|\int_0^t \int_0^L \partial_t\phi_\delta\, \Psi_\delta(\phi_g)\, dx\, d\tau\right|. \tag{81}$$

Next we test (74) by $h(\phi_\delta)\partial_t\phi_\delta - h(\phi_g)\partial_t\phi_g$ and get

$$\int_0^t \int_0^L h(\phi_\delta)\left(\partial_\tau\phi_\delta\right)^2 dx\, d\tau + \int_0^t \int_0^L D(\phi_\delta)\partial_x\phi_\delta\partial_x\left(h(\phi_\delta)\partial_\tau\phi_\delta\right) dx\, d\tau$$
$$+ \frac{1}{B}\int_0^t \int_0^L D(\phi_\delta)(\phi_\delta+\delta)\left(\partial_x\left(h(\phi_\delta)\partial_\tau\phi_\delta\right)\right)^2 dx\, d\tau = \int_0^t \int_0^L \partial_t\phi_\delta\, h(\phi_g)\partial_\tau\phi_g\, dx\, d\tau,$$

and from this

$$\int_0^t \int_0^L h(\phi_\delta)\left(\partial_\tau\phi_\delta\right)^2 dx\, d\tau + \frac{1}{B}\int_0^t \int_0^L D(\phi_\delta)(\phi_\delta+\delta)\left(\partial_x\left(h(\phi_\delta)\partial_\tau\phi_\delta\right)\right)^2 dx\, d\tau$$
$$\le B\int_0^t \int_0^L \frac{D(\phi_\delta)}{\phi_\delta+\delta}\left(\partial_x\phi_\delta\right)^2 dx\, d\tau + \int_0^t \int_0^L \frac{h^2(\phi_g)}{h(\phi_\delta)}\left(\partial_\tau\phi_g\right)^2 dx\, d\tau. \tag{82}$$

Let $h_{\min} = e^{-mA_0}$. Then inserting (81) into (82) yields

$$\int_0^t \int_0^L h(\phi_\delta)\left(\partial_\tau\phi_\delta\right)^2 dx\, d\tau + \frac{1}{B}\int_0^t \int_0^L D(\phi_\delta)(\phi_\delta+\delta)\left(\partial_x\left(h(\phi_\delta)\partial_\tau\phi_\delta\right)\right)^2 dx\, d\tau$$
$$\le C + \frac{BD_r}{h_{\min}}\left|\int_0^t \int_0^L \partial_\tau\phi_\delta\Psi_\delta(\phi_g)\, dx\, d\tau\right| + \int_0^t \int_0^L \frac{h^2(\phi_g)}{h(\phi_\delta)}\left(\partial_\tau\phi_g\right)^2 dx\, d\tau \le C$$
$$+ \frac{1}{2}\int_0^t \int_0^L h(\phi_\delta)\left(\partial_\tau\phi_\delta\right)^2 dx\, d\tau + \frac{B^2\left(D_r\right)^2}{2h_{\min}^3}\left\|\Psi_\delta(\phi_g)\right\|^2_{L^2((0,t)\times(0,L))}$$
$$+ \frac{1}{h_{\min}}\int_0^t \int_0^L \left(\partial_\tau\phi_g\right)^2 dx\, d\tau.$$

Step 2 (weak and strong compactness). From the above a priori estimate and assumptions (78) on ϕ_g, we conclude that

$$\left\|\partial_t\phi_\delta\right\|_{L^2((0,T)\times(0,L))} + \left\|\frac{1}{\sqrt{\phi_\delta+\delta}}\,\partial_x\phi_\delta\right\|_{L^2((0,T)\times(0,L))} \le C, \tag{83}$$

$$\left\|\sqrt{\phi_\delta+\delta}\,\partial_x\left(h(\phi_\delta)\partial_t\phi_\delta\right)\right\|_{L^2((0,T)\times(0,L))} \le C. \tag{84}$$

Hence there are a $\phi \in H^1((0,T)\times(0,L))$ and a subsequence $\{\phi_\delta\}$, denoted by the same subscripts, such that

$$\phi_\delta \to \phi \quad \text{strongly in } L^2((0,T)\times(0,L)) \text{ and a.e. on } \quad (0,T)\times(0,L), \tag{85}$$

$$\partial_t \phi_\delta \rightharpoonup \partial_t \phi \quad \text{weakly in } \quad L^2((0,T)\times(0,L)), \tag{86}$$

$$\partial_x \phi_\delta \rightharpoonup \partial_x \phi \quad \text{weakly in } \quad L^2((0,T)\times(0,L)). \tag{87}$$

With the part of the flux containing the second order operator, the situation is more complicated. Obviously, there is $F \in L^2((0,T)\times(0,L))$ such that

$$\sqrt{\phi_\delta+\delta}\,\partial_{xt}\int_0^{\phi_\delta} h(\xi)\,d\xi \rightharpoonup F \quad \text{weakly in } \quad L^2((0,T)\times(0,L)). \tag{88}$$

Using the lower bound $\phi_\delta \geq C_0 t^\alpha$, we get from the estimate (84) and convergence (85) that

$$\partial_{xt}\int_0^{\phi_\delta} h(\xi)\,d\xi \rightharpoonup \partial_{xt}\int_0^{\phi} h(\xi)\,d\xi \quad \text{weakly in } \quad L^2((0,T)\times(0,L)). \tag{89}$$

The convergences (85) and (89) imply that F in (88) is given by $F = \sqrt{\phi}\,\partial_{xt}\int_0^{\phi} h(\xi)\,d\xi$.

Step 3 (passing to the limit). Consequently for every $g \in L^2(0,T;V)$ we have

$$\int_0^T\int_0^L \partial_t\phi_\delta\, g\,dx\,dt \to \int_0^T\int_0^L \partial_t\phi\, g\,dx\,dt \quad \text{for } \delta\to 0, \tag{90}$$

$$\int_0^T\int_0^L D(\phi_\delta)\,\partial_x\phi_\delta\,\partial_x g\,dx\,dt \to \int_0^T\int_0^L D(\phi)\,\partial_x\phi\,\partial_x g\,dx\,dt \quad \text{for } \delta\to 0, \tag{91}$$

$$\begin{aligned}&\int_0^T\int_0^L \frac{D(\phi_\delta)}{B}(\phi_\delta+\delta)\,\partial_x\left(h(\phi_\delta)\,\partial_t\phi_\delta\right)\partial_x g\,dx\,dt\\ &\qquad\to \int_0^T\int_0^L \frac{D(\phi)}{B}\phi\,\partial_x\left(h(\phi)\,\partial_t\phi\right)\partial_x g\,dx\,dt \quad \text{for } \delta\to 0.\end{aligned} \tag{92}$$

Furthermore, for every $\zeta \in C^\infty([0,L]\times[0,T])$, such that $\zeta(L,t)=0$ on $[0,T]$, we have

$$\int_0^T \phi|_{x=0}\zeta|_{x=0}\,dt = \int_0^T \phi_g(t)\zeta|_{x=0}\,dt - \int_0^T\int_0^L \partial_x\left((\phi-\phi_\delta)\zeta\right)dx\,dt,$$

and, using the convergences (85) and (87), we obtain that the trace of ϕ at $x=0$ satisfies the boundary condition (26). Hence, we conclude that ϕ satisfies the system (1)–(3). □

Acknowledgment. The authors are grateful to the (anonymous) referees for their careful reading of the manuscript and helpful remarks.

ASYMPTOTIC STABILITY OF THE STATIONARY SOLUTION FOR A HYPERBOLIC FREE BOUNDARY PROBLEM MODELING TUMOR GROWTH*

SHANGBIN CUI†

Abstract. In this paper we study the asymptotic behavior of solutions for a free boundary problem modeling the growth of tumors containing two species of cells: proliferating cells and quiescent cells. This tumor model was proposed by Pettet, Please, and McElwain [*Bull. Math. Biol.*, 63 (2001), pp. 231–257]. By using a functional approach and the C_0 semigroup theory, we prove that the unique stationary solution of this model ensured by the work of Cui and Friedman [*Trans. Amer. Math. Soc.*, 355 (2003), pp. 3537–3590] is locally asymptotically stable in certain function spaces. Key techniques used in the proof include an improvement of the linear estimate obtained by the work of Chen, Cui, and Friedman [*Trans. Amer. Math. Soc.*, 357 (2005), pp. 4771–4804] and a similarity transformation.

Key words. free boundary problem, hyperbolic equations, tumor growth, stationary solution, asymptotic stability

1. Introduction.

During the past thirty years, an increasing number of free boundary problems of partial differential equations have been proposed by groups of researchers to model the growth of various in vivo and in vitro tumors; cf. the reviewing articles [1], [15], [16], and [22] and the references cited therein. Such free boundary problems usually contain one or more reaction-diffusion equations describing the distribution of nutrient and inhibitory materials, and several first-order nonlinear partial differential equations or nonlinear conservation laws with source terms describing the evolution and movement of various tumor cells (proliferating cells, quiescent cells, and dead cells). Rigorous analysis of such tumor models is evidently a significant topic of research and has drawn great attention during the past few years. The main concern of this topic is the dynamics or the long-term behavior of the solutions of such free boundary problems.

Based on the applications of the well-established theories of elliptic and parabolic partial differential equations, parabolic differential equations in Banach spaces (i.e., differential equations in Banach spaces that are treatable with the analytic semigroup theory), and the bifurcation theory, rigorous analysis of models for the growth of tumors containing only one species of tumor cells has achieved great success; cf. [2], [3], [6], [7], [9], [10], [11], [17], [18], [19], [23], [24], and the references cited therein. As far as models for tumors containing more than one species of tumor cells are concerned, however, the results are much less. This is caused by the fact that such tumor models are much more difficult to analyze because they contain nonlinear conservation laws whose dynamical behavior is very hard to grasp.

In this paper we study the following free boundary problem modeling the growth of an in vitro tumor containing two species of cells—proliferating cells and quiescent

cells:

$$\nabla^2 C = F(C) \quad \text{for } x \in \Omega(t), \ t \geq 0, \tag{1.1}$$

$$C = C_0 \quad \text{for } x \in \partial\Omega(t), \ t \geq 0, \tag{1.2}$$

$$\frac{\partial P}{\partial t} + \nabla \cdot (\vec{u}P) = \big[K_B(C) - K_Q(C)\big]P + K_P(C)Q \quad \text{for } x \in \Omega(t), \ t \geq 0, \tag{1.3}$$

$$\frac{\partial Q}{\partial t} + \nabla \cdot (\vec{u}Q) = K_Q(C)P - \big[K_D(C) + K_P(C)\big]Q \quad \text{for } x \in \Omega(t), \ t \geq 0, \tag{1.4}$$

$$P + Q = N \quad \text{for } x \in \Omega(t), \ t \geq 0, \tag{1.5}$$

$$\frac{dR}{dt} = \vec{u} \cdot \vec{\nu} \quad \text{for } x \in \partial\Omega(t), \ t \geq 0. \tag{1.6}$$

Here C denotes the concentration of nutrient (with all nutrient materials regarded as one species), P and Q denote the densities of proliferating cells and quiescent cells, respectively, whose mixture makes up the tumor tissue and has a constant density N, $\vec{u}$ denotes the velocity of the cell movement, R denotes the radius of the tumor, $\Omega(t) = \{x \in \mathbb{R}^3 : r = |x| < R(t)\}$ is the domain occupied by the tumor at time t, and $\vec{\nu}$ is the unit outward normal of $\partial\Omega(t)$. Besides, C_0 is a positive constant reflecting the constant nutrient supply that the tumor receives from its surface, $F(C)$ is the nutrient consumption rate function, and $K_B(C)$, $K_D(C)$, $K_P(C)$, and $K_Q(C)$ are the birth rate of proliferating cells, the death rate of quiescent cells, the transferring rate of proliferating cells to quiescent cells, and the transferring rate of quiescent cells to proliferating cells, respectively. We shall only consider radially symmetric solutions of the above problem, so that C, P, and Q are functions of the radial space variable $r = |x|$ and the time variable t, and $\vec{u} = u(r,t)r^{-1}x$, where u is a scalar function. Note that in the above problem, the unknowns are C, P, Q, u, and R, and all of the rest of the constants and functions are given.

The above tumor model was proposed by Pettet et al. in the literature [21]. Its global well-posedness has been established by Cui and Friedman in [12]. A challenging task concerning this free boundary problem is the study of the asymptotic behavior of its solutions as time goes to infinity. For the corresponding model of the growth of tumors with one species of cells, it is known that there exists a unique stationary solution and that all time-dependent solutions converge to it as time goes to infinity, or, in other words, this unique stationary solution is globally asymptotically stable; cf. [7] and [18]. Since the above problem is a natural extension of such one species tumor model to the two species case, we are naturally led to the conjecture that a similar result holds for it. The advancement of the study toward this goal is as follows. In [13], Cui and Friedman proved that the problem (1.1)–(1.6) has a unique stationary solution. In [5], Chen, Cui, and Friedman further proved that this stationary solution is linearly asymptotically stable, namely, the trivial solution of the linearization of (1.1)–(1.6) at the stationary solution is asymptotically stable. However, this last-mentioned result does not imply that the stationary solution of (1.1)–(1.6) is asymptotically stable. In fact, the asymptotic stability of this stationary solution of (1.1)–(1.6), which is one of a number of interesting open problems raised in [15] and [16], is a very difficult problem due to a number of reasons. Firstly, since the problem (1.1)–(1.6) is of the hyperbolic type, not of the parabolic type, there is not a well-developed geometric theory like that for parabolic problems used in [6], [7], [9], [10], [11], [23], [24] to study this problem. Secondly, the stationary solution of this problem does not have an explicit expression, and, in particular, it possibly possesses a singularity at the point $r = 0$ (see Lemma 3.1 below for this point). It follows that

the method of linearized stability as in [3] and [17] (tempted by [5]) does not work. Thirdly, the commonly used characteristic method for hyperbolic conservation laws also does not apply to this problem, because all of its characteristic curves approach to the same point $r = 0$ as $t \to \infty$, and, consequently, analysis along characteristic curves does not give us much information of the asymptotic behavior of the solution. Finally, it is our experience that the other commonly used methods for investigating the asymptotic behavior of the solutions of partial differential equations, such as upper and lower solutions and so on (as either explicitly or implicitly discussed in [5]), also do not work. In order to solve this problem, we have to use some new ideas and develop some new techniques.

In this paper we shall prove that the unique stationary solution of (1.1)–(1.6) ensured by [13] is locally asymptotically stable. Recall that conditions given in [13], which ensure that (1.1)–(1.6) has a unique stationary solution are as follows:

$$\text{(1.7)}\quad F(C),\ K_B(C),\ K_D(C),\ K_P(C) \text{ and } K_Q(C) \text{ are analytic for } 0 \le C \le C_0;$$

$$\text{(1.8)}\quad F(0) = 0, \quad F'(C) > 0 \quad \text{for } 0 \le C \le C_0;$$

$$\text{(1.9)}\quad \begin{cases} K_B'(C) > 0 \text{ and } K_D'(C) < 0 \text{ for } 0 \le C \le C_0,\ K_B(0) = 0 \text{ and } K_D(C_0) = 0; \\ K_P(C) \text{ and } K_Q(C) \text{ satisfy the same conditions as } K_B(C) \text{ and } K_D(C), \\ \qquad \text{respectively}; \\ K_B'(C) + K_D'(C) > 0 \text{ for } 0 \le C \le C_0. \end{cases}$$

The main result of this paper is the following.

THEOREM 1.1. *Assume that the conditions* (1.7)–(1.9) *are satisfied. Let* $(C_*, P_*, Q_*, \vec{u}_*, R_*)$ *be the unique stationary solution of the problem* (1.1)–(1.6), *and let* $(C, P, Q, \vec{u}, R)$ *be a time-dependent solution of it such that* $P|_{t=0} = P_0$, $Q|_{t=0} = Q_0$, *and* $R|_{t=0} = R_0$, *where* P_0, Q_0, *and* R_0 *are given initial data satisfying* $0 \le P_0 \le N$, $0 \le Q_0 \le N$, *and* $P_0 + Q_0 = N$. *Then there exist positive constants* μ, ε, *and* K *such that if* P_0, Q_0, *and* R_0 *satisfy*

$$\max_{0\le r\le 1} \{|P_0(rR_0) - P_*(rR_*)| + |Q_0(rR_0) - Q_*(rR_*)|\} < \varepsilon,$$

$$\sup_{0<r<1} r(1-r) \left\{ \left| \frac{d}{dr} \left(P_0(rR_0) - P_*(rR_*)\right) \right| + \left| \frac{d}{dr} \left(Q_0(rR_0) - Q_*(rR_*)\right) \right| \right\} < \varepsilon,$$

and $|R_0 - R_*| < \varepsilon$; *then, for all* $t \ge 0$, *we have*

$$\max_{0\le r\le 1} \{|P(rR(t),t) - P_*(rR_*)| + |Q(rR(t),t) - Q_*(rR_*)|\} < K\varepsilon e^{-\mu t},$$

$$\sup_{0<r<1} r(1-r) \left\{ \left| \frac{\partial}{\partial r} \left(P(rR(t),t) - P_*(rR_*)\right) \right| + \left| \frac{\partial}{\partial r} \left(Q(rR(t),t) - Q_*(rR_*)\right) \right| \right\} < K\varepsilon e^{-\mu t},$$

and $|R(t) - R_*| < K\varepsilon e^{-\mu t}$.

We shall use a functional approach to prove the above theorem. More precisely, we shall first reduce the problem (1.1)–(1.6) into a differential equation for the unknown $U = (p, z)$ in the Banach space $X = C[0,1] \times \mathbb{R}$, where $p = p(r,t) = P(rR(t),t)$ and $z = z(t) = \log R(t)$. The reduced equation is of the hyperbolic type in the sense of Pazy [20] and is quasi-linear. We next use the Banach fixed point theorem to prove that, for any $U_0 = (p_0, z_0)$ sufficiently closed to the stationary point $U_* = (p_*, z_*)$, where $p_* = p_*(r) = P_*(rR_*)$ and $z_* = \log R_*$, this differential equation imposed, with the initial condition $U|_{t=0} = U_0$ and the decay estimate $\sup_{t\ge 0} e^{\mu t} \|U(t) - U_*\|_{X_0} < \infty$, where X_0 is a subspace of X, has a unique solution in the space $C([0,\infty), X_0)$

(endowed with the norm $|||U||| = \sup_{t\geq 0} e^{\mu t}\|U(t)\|_{X_0}$). To attain this goal we shall use some abstract results for hyperbolic differential equations in Banach spaces presented in [20]. In particular, a family of evolution systems for the linear equations related to the semilinearization of the reduced equation are obtained and applied to convert the semilinearized equations into integral equations. The main difficult and key step in the proof of Theorem 1.1 is the establishment of a uniform decay estimate for the family of evolution systems. In order to obtain such an estimate, we first use a localization technique to get an improvement of the linear estimate established in [5], removing the singularities at $r = 0$ contained in that estimate, and next use a special technique—similarity transformation—to extend this improved linear estimate to the family of evolution systems mentioned above. The similarity transformation technique is the core of this paper. It enables us to transform a transport equation of the form $\partial u/\partial t + w(r,t)\partial u/\partial r = f(r,t)$, where $0 < r < 1$ and $w(0,t) = w(1,t) = 0$, into a similar equation of the form $\partial\widetilde{u}/\partial t + w_*(r)\partial\widetilde{u}/\partial r = \widetilde{f}(r,t)$, where $w_*(0) = w_*(1) = 0$. See section 5 for details of this transformation.

An interesting question raised by one of the referees is: can the above result be extended to the radially nonsymmetric version of the problem (1.1)–(1.6)? Up to now we do not have an answer to this question. A basic difficulty encountered in answering this question is that $P_*, Q_*, \vec{u}_*$ are possibly singular at the center point $r = 0$. More precisely, we know only that P_* is continuous at $r = 0$, but we do not know if it is smooth at $r = 0$ (in fact, we even do not know if it is differentiable at $r = 0$). This possibly existing singularity of the stationary solution induces many obstacles in the analysis of its asymptotic stability for nonradial perturbations. Our conjecture is that $P_*, Q_*, \vec{u}_*$ are smooth for all $r \leq R_*$, and a similar result as that in [11] proved for the one-species model also holds for the radially nonsymmetric version of the problem (1.1)–(1.6).

The structure of the rest part is as follows. In the following section we reduce the problem (1.1)–(1.6) into a differential equation in the Banach space $X = C[0,1]\times\mathbb{R}$. In section 3 we summarize some basic properties of the stationary solution. In section 4 we study a linear equation obtained from semilinearizing the reduced equation and prove that its solution operator is an evolution system so that the semilinearized equation can be converted into an integral equation. Section 5 aims at developing the similarity transformation technique mentioned above. In section 6 we first derive an improvement of the linear estimate established in [5] and next use the similarity transformation technique to extend this estimate to the evolution systems obtained in section 4. After these preparations, in the last section we use the Banach fixed point theorem to prove Theorem 1.1.

Throughout this paper the notation "$'$" denotes both the ordinary derivatives of functions in $\mathbb{R}$ and the Fréchet derivatives of mappings between Banach spaces.

Finally, to end this introduction, we would like to refer the reader to see [4], [8], and [14] for other work related with the problem (1.1)–(1.6).

2. Reduction of the problem. In this section we reduce the system of equations (1.1)–(1.6) into a differential equation in the Banach space $X = C[0,1]\times\mathbb{R}$.

We first note that, by summing up (1.3), (1.4), and using (1.5), we get the following equation:

$$\nabla\cdot\vec{u} = \frac{1}{N}\big[K_B(C)P - K_D(C)Q\big]. \tag{2.1}$$

Conversely, from (1.3), (1.5), and (2.1) we immediately obtain (1.4). Hence, the two groups of equations (1.3), (1.4), (1.5), and (1.3), (1.5), (2.1) are equivalent. We recall that $\vec{u} = u(r,t)r^{-1}x$ for some scalar function u.

By rescaling the space and time variables, setting

$$\bar{c}(\bar{r},t)=\frac{C\left(\bar{r}e^{z(t)},t\right)}{C_0},\quad \bar{p}(\bar{r},t)=\frac{P\left(\bar{r}e^{z(t)},t\right)}{N},$$
$$\bar{u}(\bar{r},t)=u\left(\bar{r}e^{z(t)},t\right)e^{-z(t)},\quad R(t)=e^{z(t)},$$

and using the equivalence of (1.3), (1.4), and (1.5) with (1.3), (1.5), and (2.1), we see that the problem (1.1)–(1.6) can be reformulated into the following problem (for the simplicity of the notation we omit all bars):

$$\frac{\partial^2 c}{\partial r^2}+\frac{2}{r}\frac{\partial c}{\partial r}=e^{2z}F(c)\quad \text{for } 0<r\le 1,\ t\ge 0, \tag{2.2}$$

$$\frac{\partial c}{\partial r}\Big|_{r=0}=0,\quad c|_{r=1}=1\quad \text{for } t\ge 0, \tag{2.3}$$

$$\frac{\partial p}{\partial t}+[u(r,t)-ru(1,t)]\frac{\partial p}{\partial r}=K_P(c)+\big[K_M(c)-K_N(c)\big]p-K_M(c)p^2 \quad \text{for } 0\le r\le 1,\ t\ge 0, \tag{2.4}$$

$$\frac{\partial u}{\partial r}+\frac{2}{r}u=-K_D(c)+K_M(c)p\quad \text{for } 0<r\le 1 \text{ and } u|_{r=0}=0,\ t\ge 0, \tag{2.5}$$

$$\frac{dz}{dt}=u(1,t)\quad \text{for } t\ge 0, \tag{2.6}$$

where $K_M(c)=K_B(c)+K_D(c)$, $K_N(c)=K_P(c)+K_Q(c)$, and $F(c)$, $K_B(c)$, $K_D(c)$, $K_P(c)$, and $K_Q(c)$ are the rescaled forms of the corresponding functions appearing in (1.1)–(1.6).

Clearly, (2.2) and (2.3) can be solved to get c as a function of z. Thus, instead of $c(r,t)$, later on we use the notation $c(r,z(t))$, or simply $c(r,z)$, to denote the solution of (2.2) and (2.3). Similarly, (2.5) can be solved to get u as a functional of p and z. Thus, later on we use the notation $u_{p,z}$ to redenote u. By a simple computation, we have

$$u_{p,z}(r,t)=\frac{1}{r^2}\int_0^r[-K_D(c(\rho,z(t)))+K_M(c(\rho,z(t)))p(\rho,t)]\rho^2 d\rho \tag{2.7}$$

for $0<r\le 1$, $t\ge 0$, and $u_{p,z}(0,t)=0$ for $t\ge 0$. We also denote

$$w_{p,z}(r,t)=u_{p,z}(r,t)-ru_{p,z}(1,t). \tag{2.8}$$

Then (2.2)–(2.6) reduces into the following system of equations:

$$\begin{cases}\dfrac{\partial p}{\partial t}+w_{p,z}(r,t)\dfrac{\partial p}{\partial r}=f(r,p,z)\quad \text{for } 0\le r\le 1,\ t>0,\\[2mm] \dfrac{dz}{dt}=u_{p,z}(1,t)\quad \text{for } t>0,\end{cases} \tag{2.9}$$

where

$$f(r,p,z)=K_P(c(r,z))+\big[K_M(c(r,z))-K_N(c(r,z))\big]p-K_M(c(r,z))p^2.$$

In what follows we rewrite (2.9) as a differential equation in the Banach space $X=C[0,1]\times\mathbb{R}$. To this end we denote $X_0=C_V^1[0,1]\times\mathbb{R}$, where $C_V^1[0,1]$ is the function space

$$C_V^1[0,1]=\big\{p\in C[0,1]\cap C^1(0,1):\ r(1-r)p'(r)\in C[0,1]\big\}$$

endowed with the norm

$$\|p\|_{C_V^1[0,1]} = \max_{0\le r\le 1} |p(r)| + \sup_{0<r<1} |r(1-r)p'(r)| \quad \text{for } p \in C_V^1[0,1].$$

Clearly, endowed with the product norm, X_0 is a Banach space densely and continuously embedded into X. We introduce a mapping $\mathbb{F} : X_0 \to X$ as follows. First, for given $p \in C[0,1]$ and $z \in \mathbb{R}$, let $\mathcal{A}_0(p,z) : C_V^1[0,1] \to C(0,1)$ be the following linear operator: For any $q \in C_V^1[0,1]$,

$$\mathcal{A}_0(p,z)q(r) = -w_{p,z}(r)q'(r) \quad \text{for } 0 < r < 1.$$

Here and hereafter, $w_{p,z}(r)$ represents the function defined by similar formulations as in (2.7) and (2.8), with $p(r,t)$ and $z(t)$ there replaced by $p(r)$ and z, respectively. Later on we shall use the convention that, for a function $f \in C(0,1)$, if both limits $\lim_{r\to 0^+} f(r)$ and $\lim_{r\to 1^-} f(r)$ exist and are finite, then we write $f \in C[0,1]$. Furthermore, when we are concerned with the values of f at $r = 0$ and $r = 1$, we mean that $f(0) = \lim_{r\to 0^+} f(r)$ and $f(1) = \lim_{r\to 1^-} f(r)$. Using this convention, we see easily that, for any $p \in C[0,1]$ and $z \in \mathbb{R}$, we have $w_{p,z}(r)/r(1-r) \in C[0,1]$. It follows that, for any $q \in C_V^1[0,1]$, both limits $\lim_{r\to 0^+} w_{p,z}(r)q'(r)$ and $\lim_{r\to 1^-} w_{p,z}(r)q'(r)$ exist so that $\mathcal{A}_0(p,z)q \in C[0,1]$. It can also be easily seen that $\mathcal{A}_0(p,z) \in L(C_V^1[0,1], C[0,1])$, and

$$\|\mathcal{A}_0(p,z)\|_{L(C_V^1[0,1],C[0,1])} \le \sup_{0<r<1} \left| \frac{w_{p,z}(r)}{r(1-r)} \right|.$$

Next we denote by $\mathcal{F} : C[0,1] \times \mathbb{R} \to C[0,1]$ and $\mathcal{G} : C[0,1] \times \mathbb{R} \to \mathbb{R}$, respectively, the following nonlinear operators:

$$\mathcal{F}(p,z)(r) = f(r, p(r), c(r,z)),$$
$$\mathcal{G}(p,z) = \int_0^1 [-K_D(c(r,z)) + K_M(c(r,z))p(r)]r^2\,dr.$$

We now define $\mathbb{F} : X_0 \to X$ to be the following nonlinear operator:

$$\mathbb{F}(U) = \big(\mathcal{A}_0(p,z)p + \mathcal{F}(p,z), \mathcal{G}(p,z)\big) \quad \text{for } U = (p,z) \in X_0.$$

It is obvious that $\mathbb{F} \in C^\infty(X_0, X)$. Later on we shall also regard $\mathbb{F}$ as an unbounded nonlinear operator in X with domain X_0.

With the above notations, we see that (2.9) can be rewritten as the following differential equation in the Banach space X:

$$\frac{dU}{dt} = \mathbb{F}(U). \tag{2.10}$$

Here $U = U(t)$ represents an X_0-valued unknown function for $t \ge 0$, and the left-hand side denotes the Fréchet derivative of $U = U(t)$ regarded as a mapping from $[0,\infty)$ to the X space.

The equation (2.10) has a quasi-linear structure. To see this we define $\mathbb{A}_0 : X \to L(X_0, X)$ and $\mathbb{F}_0 : X \to X$ as follows: For $U = (p,z) \in X$ and $V = (q,y) \in X_0$, we let

$$\mathbb{A}_0(U)V = \big(\mathcal{A}_0(p,z)q, 0\big) \quad \text{and} \quad \mathbb{F}_0(U) = \big(\mathcal{F}(p,z), \mathcal{G}(p,z)\big).$$

Then we have

$$\mathbb{F}(U) = \mathbb{A}_0(U)U + \mathbb{F}_0(U) \quad \text{for } U \in X_0.$$

Clearly, $\mathbb{A}_0 \in C^\infty(X, L(X_0, X))$ and $\mathbb{F}_0 \in C^\infty(X, X) \cap C^\infty(X_0, X_0)$. Hence, the desired assertion follows. Later on, for given $U \in X$, we shall also regard $\mathbb{A}_0(U)$ as an unbounded linear operator in X with domain X_0.

From [13] we know that under the assumptions (1.7)–(1.9), the problem (2.2)–(2.6) has a unique stationary solution which we denote as (c_*, p_*, u_*, z_*). By definition, $(c_*, p_*, u_*, z_*) = (c_*(r), p_*(r), u_*(r), z_*)$ $(0 \le r \le 1)$ is the solution of the following problem:

$$c_*'' + \frac{2}{r}c_*' = e^{2z_*}F(c_*) \quad \text{for } 0 < r \le 1, \tag{2.11}$$

$$c_*'(0) = 0, \quad c_*(1) = 1, \tag{2.12}$$

$$u_*p_*' = f(r, p_*, z_*) \quad \text{for } 0 \le r \le 1, \tag{2.13}$$

$$u_*' + \frac{2}{r}u_* = -K_D(c_*) + K_M(c_*)p_* \quad \text{for } 0 < r \le 1, \tag{2.14}$$

$$u_*(0) = 0, \quad u_*(1) = 0. \tag{2.15}$$

Let $U_* = (p_*, z_*)$. Then $U_* \in X_0$ (see Lemma 2.1 below), and, by the equivalence of the system (2.2)–(2.6) with the equation (2.10), it follows that U_* is the unique equilibrium of (2.10), i.e., $\mathbb{F}(U_*) = 0$ or $\mathbb{A}_0(U_*)U_* + \mathbb{F}_0(U_*) = 0$. Hence, to study the asymptotic stability of the stationary solution (c_*, p_*, u_*, z_*) of the problem (2.2)–(2.6), we need only to study the asymptotic stability of the stationary solution U_* of (2.10). For this purpose, we rewrite (2.10) into an equivalent equation for the difference $V = U - U_*$. Let $\mathbb{A} : X \to L(X_0, X)$ and $\mathbb{G} : X \to X$ be the following operators:

$$\begin{aligned}\mathbb{A}(V)W &= \mathbb{A}_0(U_* + V)W + [\mathbb{A}_0'(U_*)W]U_* + \mathbb{F}_0'(U_*)W \quad \text{for } V \in X,\ W \in X_0,\\ \mathbb{G}(V) &= [\mathbb{A}_0(U_* + V) - \mathbb{A}_0(U_*) - \mathbb{A}_0'(U_*)V]U_*\\ &\quad + [\mathbb{F}_0(U_* + V) - \mathbb{F}_0(U_*) - \mathbb{F}_0'(U_*)V] \quad \text{for } V \in X.\end{aligned}$$

Then clearly (2.10) is equivalent to the following equation for $V = U - U_*$:

$$\frac{dV}{dt} = \mathbb{A}(V)V + \mathbb{G}(V). \tag{2.16}$$

Later on we shall concentrate our attention on (2.16).

The above deduction leads to the following preliminary result.

LEMMA 2.1. *The system* (2.2)–(2.6) *is equivalent to* (2.16), *and the asymptotic stability of the stationary solution* (c_*, p_*, u_*, z_*) *of* (2.2)–(2.6) *is equivalent to the asymptotic stability of the trivial solution of* (2.16). *Moreover, the assertion of Theorem* 1.1 *is equivalent to the following assertion for* (2.16): *There exist positive constants* K, μ, *and* ε *such that if the solution* $V = V(t)$ *of* (2.16) *satisfies* $\|V(0)\|_{X_0} \le \varepsilon$, *then it also satisfies*

$$\|V(t)\|_{X_0} \le K\varepsilon e^{-\mu t} \quad \textit{for all } t \ge 0. \tag{2.17}$$ □

Since it has been proved (see [12]) that the initial value problem of the system (2.2)–(2.6) is globally well-posed for any C^1 initial data, by the equivalence of (2.2)–(2.6) with (2.16), it follows that, for any $V_0 \in X_0$, (2.16) has a unique solution

$V = V(t)$ for all $t \geq 0$ such that $V(0) = V_0$. Our analysis later on is to prove that (2.17) holds provided $\|V_0\|_{X_0} \leq \varepsilon$.

We note that $\mathbb{A} \in C^\infty(X, L(X_0, X))$, $\mathbb{G} \in C^\infty(X, X)$, and, by using the Taylor expansions up to second-order for Fréchet derivatives of $\mathbb{A}_0$ and $\mathbb{F}_0$, we have

$$\|\mathbb{G}(V)\|_X = O\left(\|V\|_X^2\right) \quad \text{as } \|V\|_X \to 0. \tag{2.18}$$

We also note that, by introducing an operator $\mathbb{B} : X \to X$ by

$$\mathbb{B}W = [\mathbb{A}_0'(U_*)W]U_* + \mathbb{F}_0'(U_*)W \quad \text{for } W \in X,$$

we have

$$\mathbb{A}(0) = \mathbb{F}'(U_*) = \mathbb{A}_0(U_*) + \mathbb{B} \quad \text{and} \quad \mathbb{A}(V) = \mathbb{A}_0(U_* + V) + \mathbb{B}.$$

Note that as an immediate consequence of the facts that $\mathbb{A}_0 \in C^\infty(X, L(X_0, X))$ and $\mathbb{F}_0 \in C^\infty(X, X)$, we have $\mathbb{B} \in L(X)$. Finally, we note that $[V \to \mathbb{A}_0(U_* + V)] \in C^\infty(X, L(X_0, X))$. These facts will play an important role in later analysis.

A simple computation shows that if we denote

$$\begin{aligned} a(r) &= K_M(c_*(r)) - K_N(c_*(r)) - 2K_M(c_*(r))p_*(r), \\ b(r) &= \left\{K_P'(c_*(r)) + [K_M'(c_*(r)) - K_N'(c_*(r))]p_*(r) - K_M'(c_*(r))p_*^2(r)\right\} c_z(r) \end{aligned} \tag{2.19}$$

$$+ rp_*'(r)\left[\int_0^1 g_c(\rho)c_z(\rho)\rho^2 d\rho - \frac{1}{r^3}\int_0^r g_c(\rho)c_z(\rho)\rho^2 d\rho\right], \tag{2.20}$$

$$\mathcal{B}q(r) = rp_*'(r)\left[\int_0^1 g_p(\rho)q(\rho)\rho^2 d\rho - \frac{1}{r^3}\int_0^r g_p(\rho)q(\rho)\rho^2 d\rho\right], \tag{2.21}$$

$$\mathcal{F}(q) = \int_0^1 g_p(\rho)q(\rho)\rho^2 d\rho, \tag{2.22}$$

$$\kappa = \int_0^1 g_c(\rho)c_z(\rho)\rho^2 d\rho, \tag{2.23}$$

where

$$g_p(r) = K_M(c_*(r)), \quad g_c(r) = -K_D'(c_*(r)) + K_M'(c_*(r))p_*(r), \quad c_z(r) = \frac{\partial c}{\partial z}(r, z_*),$$

then we have

$$\mathbb{B} = \begin{pmatrix} a(r) + \mathcal{B} & b(r) \\ \mathcal{F} & \kappa \end{pmatrix}. \tag{2.24}$$

Here and hereafter, when we write $\mathbb{M} = \begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix}$ for bounded linear operators $M_{11} \in L(X_1, Y_1)$, $M_{12} \in L(X_2, Y_1)$, $M_{21} \in L(X_1, Y_2)$, and $M_{22} \in L(X_2, Y_2)$, where X_1, X_2, Y_1, and Y_2 are Banach spaces, we mean that $\mathbb{M}$ is the bounded linear operator from $X_1 \times X_2$ to $Y_1 \times Y_2$ defined by $\mathbb{M}(x_1, x_2) = (M_{11}x_1 + M_{12}x_2, M_{21}x_1 + M_{22}x_2)$ for $(x_1, x_2) \in X_1 \times X_2$. Using this notation we see that

$$\mathbb{A}_0(U_*) = \begin{pmatrix} \mathcal{L}_0 & 0 \\ 0 & 0 \end{pmatrix} \quad \text{and} \quad \mathbb{A}_0(U_* + V) = \begin{pmatrix} \mathcal{L}_V & 0 \\ 0 & 0 \end{pmatrix}, \tag{2.25}$$

where $\mathcal{L}_0 = \mathcal{A}_0(p_*, z_*)$ and $\mathcal{L}_V = \mathcal{A}_0(p_* + \varphi, z_* + \zeta)$ for $V = (\varphi, \zeta) \in X$. Finally, we recall that $a(r) < 0$ for all $0 \leq r \leq 1$; see (2.7) in section 2 of [5].

3. Some basic facts. In this section we summarize some basic properties of the functions $c_*(r) = c(r, z_*)$, $c_z(r) = \frac{\partial c}{\partial z}(r, z_*)$, $p_*(r)$, and $u_*(r)$. These properties will play an important role in later discussions.

LEMMA 3.1. *We have the following assertions:*

(1) $c_*,\ c_z \in C^\infty[0,1]$, *and*

(3.1)
$$0 < c_*(0) \le c_*(r) \le 1 \quad \textit{for } 0 \le r \le 1, \quad c_*'(r) > 0 \quad \textit{for } 0 < r \le 1, \quad c_*'(0) = 0.$$

(2) $p_* \in C[0,1] \cap C^\infty(0,1]$,

$$0 < p_*(0) \le p_*(r) \le 1 \quad \textit{for } 0 \le r \le 1, \quad p_*'(r) > 0 \quad \textit{for } 0 < r \le 1, \tag{3.2}$$

and either $p_* \in C^1[0,1]$ *or there exists* $0 < \gamma < 1$ *such that* $\lim_{r\to 0^+} r^\gamma p_*'(r)$ *exists and is finite, so that* $r^\gamma p_*'(r) \in C[0,1]$. *Moreover,*

$$\lim_{r\to 0^+} r p_*'(r) = 0, \quad \lim_{r\to 0^+} r^2 p_*''(r) = 0, \quad \lim_{r\to 0^+} r^3 p_*'''(r) = 0. \tag{3.3}$$

(3) $u_* \in C^1[0,1] \cap C^\infty(0,1]$, *and there exist positive constants* C_1, C_2 *such that*

$$-C_1 r(1-r) \le u_*(r) \le -C_2 r(1-r) \quad \textit{for } \ 0 \le r \le 1. \tag{3.4}$$

Besides, either $u_* \in C^2[0,1]$ *or there exists* $0 < \gamma < 1$ *such that* $\lim_{r\to 0^+} r^\gamma u_*''(r)$ *exists and is finite, so that* $r^\gamma u_*''(r) \in C[0,1]$. *Moreover,*

$$\lim_{r\to 0^+} r u_*''(r) = 0, \quad \lim_{r\to 0^+} r^2 u_*'''(r) = 0. \tag{3.5}$$

Proof. The assertions that $c_*, c_z \in C^\infty[0,1]$ and relations in (3.1) are immediate. The assertions that $p_* \in C[0,1] \cap C^\infty(0,1]$, $u_* \in C^1[0,1] \cap C^\infty(0,1]$, and relations in (3.2) follow from Theorem 2.1 of [13], by which we also know that $u_*(r) < 0$ for $0 < r < 1$. The last assertion combined with the facts that $u_*'(0) < 0$ and $u_*'(1) > 0$ (see Theorem 7.1 of [13]) immediately yields (3.4). To prove (3.3) we compute

$$\lim_{r\to 0} u_*(r) p_*'(r) = K_P(c_*(0)) + [K_M(c_*(0)) - K_N(c_*(0))] p_*(0) - K_M(c_*(0)) p_*^2(0) = 0$$

(see (8.4) in section 8 of [13]), so that

$$\lim_{r\to 0} r p_*'(r) = \lim_{r\to 0} \frac{r}{u_*(r)} \cdot \lim_{r\to 0} u_*(r) p_*'(r) = 0,$$

and

$$\begin{aligned}\lim_{r\to 0} u_*(r) r p_*''(r) = \lim_{r\to 0} r\big\{ & K_P'(c_*(r)) + [K_M'(c_*(r)) - K_N'(c_*(r))] p_*(r) \\ & - K_M'(c_*(r)) p_*^2(r)\big\} c_*'(r) + \lim_{r\to 0}\{[K_M(c_*(r)) - K_N(c_*(r))] \\ & - 2K_M(c_*(r)) p_*(r)\} r p_*'(r) - \lim_{r\to 0} u_*'(r) r p_*'(r) = 0,\end{aligned}$$

so that

$$\lim_{r\to 0} r^2 p_*''(r) = \lim_{r\to 0} \frac{r}{u_*(r)} \cdot \lim_{r\to 0} u_*(r) r p_*''(r) = 0.$$

This proves the first two relations in (3.3). The proof of the third relation is similar and is omitted. Next, from (2.14) we can easily deduce that

$$\begin{aligned} u_*''(r) &= [-K_D'(c_*(r)) + K_M'(c_*(r))p_*(r)]c_*'(r) \\ &\quad + K_M(c_*(r))p_*'(r) + \frac{2}{r}[K_D(c_*(r)) - K_M(c_*(r))p_*(r)] \\ &\quad + \frac{6}{r^4}\int_0^r [-K_D(c_*(\rho)) + K_M(c_*(\rho))p_*(\rho)]\rho^2 d\rho \\ &= [-K_D'(c_*(r)) + K_M'(c_*(r))p_*(r)]c_*'(r) + \frac{6}{r^4}\int_0^r [K_D(c_*(r)) - K_D(c_*(\rho))]\rho^2 d\rho \\ &\quad + K_M(c_*(r))p_*'(r) - \frac{6}{r^4}\int_0^r [K_M(c_*(r))p_*(r) - K_M(c_*(\rho))p_*(\rho)]\rho^2 d\rho. \end{aligned} \tag{3.6}$$

From this expression and the first relation in (3.3) we readily obtain the first relation in (3.5). The proof of the second relation in (3.5) is similar and is omitted. Finally, by Theorems 5.3 and 5.4 of [13], we know that either $p_* \in C^1[0,1]$ or there exist constants $-1 < \alpha < 0$ and C such that[1]

$$p_*'(r) = Cr^\alpha + O(1) \quad \text{for } r \to 0. \tag{3.7}$$

Suppose that it is the second case. Then, by letting $\gamma = |\alpha|$, we see that $0 < \gamma < 1$ and $r^\gamma p_*'(r) \in C[0,1]$. Finally, from (3.7) we see that

$$p_*(r) = p_*(0) + C(1+\alpha)^{-1} r^{1+\alpha} + O(r) \quad \text{for } r \to 0. \tag{3.8}$$

Substituting (3.7) and (3.8) into (3.6), we get $r^\gamma u_*''(r) \in C[0,1]$. This completes the proof of Lemma 3.1. ∎

COROLLARY 3.2. *Let $a, b, \mathcal{B}, \mathcal{F}$, and $\mathbb{B}$ be as in* (2.19)–(2.22) *and* (2.24). *Then we have $a, b \in C_V^1[0,1], \mathcal{B} \in L(C[0,1], C_V^1[0,1]) \subseteq L(C[0,1]) \cap L(C_V^1[0,1]), \mathcal{F} \in L(C[0,1], \mathbb{R})$, and $\mathbb{B} \in L(X) \cap L(X_0)$. Moreover, we also have $r^2(1-r)^2 a''(r)$, $r^2(1-r)^2 b''(r) \in C[0,1]$.* ∎

COROLLARY 3.3. *$\mathbb{G} \in C^\infty(X,X) \cap C^\infty(X_0, X_0)$ and in addition to* (2.18), *we also have*

$$\|\mathbb{G}(V)\|_{X_0} = O\left(\|V\|_{X_0}^2\right) \quad \text{as } \|V\|_{X_0} \to 0. \tag{3.9}$$

Proof. We have $\mathbb{G}(V) = \mathbb{G}_1(V) + \mathbb{G}_2(V)$, where $\mathbb{G}_1(V) = [\mathbb{A}_0(U_* + V) - \mathbb{A}_0(U_*) - \mathbb{A}_0'(U_*)V]U_*$ and $\mathbb{G}_2(V) = \mathbb{F}_0(U_* + V) - \mathbb{F}_0(U_*) - \mathbb{F}_0'(U_*)V$. Since $\mathbb{F}_0 \in C^\infty(X_0, X_0)$, it is evident that $\mathbb{G}_2 \in C^\infty(X_0, X_0)$ and $\|\mathbb{G}_2(V)\|_{X_0} = O(\|V\|_{X_0}^2)$ as $\|V\|_{X_0} \to 0$. Next, let $V = (\varphi, \zeta)$ and $(p, z) = (p_* + \varphi, z_* + \zeta)$. Then, by (2.25), we have $\mathbb{A}_0(U_* + V)U_* = (-w_{p,z}(r)p_*'(r), 0)$. Using this expression and the first two relations in (3.3), we can easily show that, for every $V \in X$, we have $\mathbb{A}_0(U_* + V)U_* \in X_0$, and the mapping $V \to \mathbb{A}_0(U_* + V)U_*$ belongs to $C^\infty(X, X_0)$. Hence we have $\mathbb{G}_1 \in C^\infty(X, X_0) \subseteq C^\infty(X_0, X_0)$ and $\|\mathbb{G}_1(V)\|_{X_0} = O(\|V\|_X^2) = O(\|V\|_{X_0}^2)$ as $\|V\|_{X_0} \to 0$. Combining these assertions together, we see that the desired assertion follows. ∎

4. Evolution system. In this section we study the following initial value problem:

$$\frac{dU}{dt} = \mathbb{A}(V(t))U + F(t) \quad \text{for } t > 0, \quad U(0) = U_0, \tag{4.1}$$

[1] In the notation of Theorem 5.4 of [13], we have $\alpha = \alpha(\lambda)$ and $C = (1 + \alpha(\lambda))\omega$.

where $V \in C([0,\infty), X)$, $F \in C([0,\infty), X_0)$, and $U_0 \in X_0$ are given. For a small $\varepsilon > 0$, we denote

$$S_\varepsilon = \{V = (\varphi, \zeta) \in X = C[0,1] \times \mathbb{R} : \ \|\varphi\|_\infty \le \varepsilon, \ |\zeta| \le \varepsilon\}.$$

We want to prove that given $V \in C([0,\infty), X)$ such that $V(t) \in S_\varepsilon$ for all $t \ge 0$, the problem (4.1) has a unique solution $U \in C([0,\infty), X_0) \cap C^1([0,\infty), X)$, and there exists a family of bounded linear operators $\{\mathbb{U}(t,s,V) : t \ge s \ge 0\}$ on X_0, the so-called *evolution system* determined by the family of operators $\{\mathbb{A}(V(t)) : t \ge 0\}$, such that the solution of this problem is given by

$$U(t) = \mathbb{U}(t,0,V)U_0 + \int_0^t \mathbb{U}(t,s,V)F(s)ds \quad \text{for } \ t \ge 0. \tag{4.2}$$

For this purpose we shall prove that the family of operators $\{\mathbb{A}(V) : V \in S_\varepsilon\}$ is a stable family of the infinitesimal generators of C_0 semigroups on X, and its part in X_0 is a stable family of the infinitesimal generators of C_0 semigroups on X_0. When these assertions are proved, the desired assertion then follows from the results of sections 5.2–5.5 and 6.4 of [20].

In what follows, for $V \in S_\varepsilon$, we denote by $\tilde{\mathbb{A}}(V)$ the part of $\mathbb{A}(V)$ in X_0. Recall that $\mathrm{Dom}(\tilde{\mathbb{A}}(V)) = \{U \in X_0 : \mathbb{A}(V)U \in X_0\}$, and $\tilde{\mathbb{A}}(V)U = \mathbb{A}(V)U$ for $U \in \mathrm{Dom}(\tilde{\mathbb{A}}(V))$.

Let $w \in C^1[0,1]$ and assume that it satisfies the following condition: There exist positive constants C_1 and C_2 such that

$$-C_1 r(1-r) \le w(r) \le -C_2 r(1-r) \quad \text{for } \ 0 \le r \le 1. \tag{4.3}$$

Note that this assumption particularly implies that $w(0) = w(1) = 0$, $w'(0) < 0$ and $w'(1) > 0$. For a such w, we denote by $\mathcal{L}_0$ the bounded linear operator from $C^1_V[0,1]$ to $C[0,1]$ defined by

$$\mathcal{L}_0 q(r) = -w(r)q'(r) \quad \text{for } \ 0 < r < 1, \quad \text{for } \ q \in C^1_V[0,1].$$

Later on we shall also regard $\mathcal{L}_0$ as an unbounded linear operator in $C[0,1]$ with domain $C^1_V[0,1]$. Note that if $w = u_*$, then $\mathcal{L}_0 = \mathcal{A}_0(p_*, z_*)$.

LEMMA 4.1. *Let the notation and assumption be as above. Then $\mathcal{L}_0$ generates a C_0 semigroup of contractions $e^{t\mathcal{L}_0}$ on $C[0,1]$, i.e.,*

$$\|e^{t\mathcal{L}_0}\|_{L(C[0,1])} \le 1 \quad \textit{for } \ t \ge 0. \tag{4.4}$$

Moreover, $C^1_V[0,1]$ is $\mathcal{L}_0$-admissible,[2] and the restriction of $e^{t\mathcal{L}_0}$ on $C^1_V[0,1]$ is a uniformly bounded C_0 semigroup on $C^1_V[0,1]$, i.e., there exists constant $C > 0$ depending only on the constants C_1 and C_2 in (4.3) such that

$$\|e^{t\mathcal{L}_0}\|_{L(C^1_V[0,1])} \le C \quad \textit{for } \ t \ge 0. \tag{4.5}$$

[2]Recall that for a C_0 semigroup $T(t)$ $(t \ge 0)$ on a Banach space X generated by an unbounded linear operator A in X, a linear subspace Y of X is called *A-admissible* if it is an invariant subspace of $T(t)$ for all $t \ge 0$ and the restriction of $T(t)$ $(t \ge 0)$ to Y is a C_0 semigroup in Y. A necessary and sufficient condition for Y to be A-admissible is that (1) Y is an invariant subspace of $R(\lambda, A)$ for all $\lambda > \omega$, and (2) the part $\bar{A}$ of A in Y is an infinitesimal generator of a C_0 semigroup on Y. In this case we have $e^{t\bar{A}} = e^{tA}|_Y$. See Theorem 5.5 in Chapter 4 of [20].

Proof. Let $\lambda \in \mathbb{C}$ be such that $\mathrm{Re}\lambda > 0$, and let $f \in C[0,1]$. Consider the equation

$$-w(r)q'(r) - \lambda q(r) = f(r) \quad \text{for } 0 < r < 1. \tag{4.6}$$

By using some similar arguments as in section 2 of [8], we can easily show that this equation has a unique solution defined and bounded for $0 < r < 1$, given by

$$q(r) = e^{-\lambda \int_{r_0}^{r} \frac{d\rho}{w(\rho)}} \int_r^1 \frac{f(\eta)}{w(\eta)} e^{\lambda \int_{r_0}^{\eta} \frac{d\rho}{w(\rho)}} d\eta, \quad 0 < r < 1, \tag{4.7}$$

where r_0 is an arbitrarily chosen number in $(0,1)$. Clearly $q \in C^1(0,1)$. By using the L'Hospital's rule, we can easily verify that $q(r)$ has finite limits as $r \to 0^+$ and $r \to 1^-$, so that $q \in C[0,1] \cap C^1(0,1)$. Furthermore, since $r(1-r)/w(r) \in C[0,1]$, from (4.6) we see that also $r(1-r)q'(r) \in C[0,1]$, so that $q \in C_V^1[0,1]$, and, moreover,

$$\begin{aligned} |q(r)| &\le \|f\|_\infty e^{(\mathrm{Re}\lambda) \int_{r_0}^{r} \frac{d\rho}{|w(\rho)|}} \int_r^1 \frac{1}{|w(\eta)|} e^{-(\mathrm{Re}\lambda) \int_{r_0}^{\eta} \frac{d\rho}{|w(\rho)|}} d\eta \\ &= \frac{\|f\|_\infty}{\mathrm{Re}\lambda} \Big[1 - e^{-(\mathrm{Re}\lambda) \int_r^1 \frac{d\rho}{|w(\rho)|}} \Big] \le \frac{\|f\|_\infty}{\mathrm{Re}\lambda} \quad \text{for } 0 < r < 1. \end{aligned} \tag{4.8}$$

This proves that, for any $\lambda \in \mathbb{C}$ with $\mathrm{Re}\lambda > 0$, we have $\lambda \in \rho(\mathcal{L}_0)$ and $\|R(\lambda, \mathcal{L}_0)\|_{L(C[0,1])} \le 1/\mathrm{Re}\lambda$. Thus, by the Hille–Yosida theorem, we see that $\mathcal{L}_0$ generates a strongly continuous semigroup $e^{t\mathcal{L}_0}$ on $C[0,1]$, which satisfies the estimate (4.4).

Next we prove that $C_V^1[0,1]$ is $\mathcal{L}_0$-admissible. Clearly, $C_V^1[0,1]$ is an invariant subspace of $R(\lambda, \mathcal{L}_0)$ for all $\lambda \in \mathbb{C}$, with $\mathrm{Re}\lambda > 0$. Let $\tilde{\mathcal{L}}_0$ be the part of $\mathcal{L}_0$ in $C_V^1[0,1]$. Since $r(1-r)/w(r)$, $w(r)/r(1-r) \in C[0,1]$, we see that, for $q \in C[0,1] \cap C^1(0,1)$, $r(1-r)q'(r) \in C[0,1]$ if and only if $w(r)q'(r) \in C[0,1]$, and there exist positive constants C_1 and C_2 such that

$$C_1 \sup_{0<r<1} |w(r)q'(r)| \le \sup_{0<r<1} |r(1-r)q'(r)| \le C_2 \sup_{0<r<1} |w(r)q'(r)|.$$

By the above assertion, it follows easily that

$$\mathrm{Dom}\left(\tilde{\mathcal{L}}_0\right) = \left\{ q \in C[0,1] \cap C^2(0,1) :\ w(r)q'(r) \in C[0,1],\ w^2(r)q''(r) \in C[0,1] \right\}, \tag{4.9}$$

and $\|q\|'_{C_V^1[0,1]} = \|q\|_\infty + \|wq'\|_\infty$ is an equivalent norm in $C_V^1[0,1]$. For $q \in \mathrm{Dom}(\tilde{\mathcal{L}}_0)$, we have, by definition, $\tilde{\mathcal{L}}_0 q = \mathcal{L}_0 q$. Now let $f \in C_V^1[0,1]$ and $\mathrm{Re}\lambda > 0$. Let q be the solution of (4.6). Using (4.9) we can easily verify that $q \in \mathrm{Dom}(\tilde{\mathcal{L}}_0)$, so that it is the solution of the equation $\tilde{\mathcal{L}}_0 q - \lambda q = f$. Moreover, a simple computation shows that $wq' = R(\mathcal{L}_0, \lambda)(wf')$. Thus, by (4.8), we have

$$\begin{aligned} \|q\|'_{C_V^1[0,1]} &= \|q\|_\infty + \|wq'\|_\infty = \|R(\mathcal{L}, \lambda)f\|_\infty + \|R(\mathcal{L}, \lambda)(wf')\|_\infty \\ &\le \frac{1}{\mathrm{Re}\lambda}\|f\|_\infty + \frac{1}{\mathrm{Re}\lambda}\|wf'\|_\infty = \frac{1}{\mathrm{Re}\lambda}\|f\|'_{C_V^1[0,1]}. \end{aligned}$$

Hence, $\lambda \in \rho(\tilde{\mathcal{L}}_0)$ and $\|R(\lambda, \tilde{\mathcal{L}}_0)\|'_{C_V^1[0,1]} \le (\mathrm{Re}\lambda)^{-1}$. The desired assertion then follows from the Hille–Yosida theorem and footnote 2. ∎

Given $V = (\varphi, \zeta) \in S_\varepsilon$, we set $p(r) = p_*(r) + \varphi(r)$, $z = z_* + \zeta$, and, as before, we denote

$$u_{p,z}(r) = \frac{1}{r^2} \int_0^r [-K_D(c(\rho, z)) + K_M(c(\rho, z))p(\rho)]\rho^2 d\rho, \quad w_{p,z}(r) = u_{p,z}(r) - r u_{p,z}(1).$$

Since $\|\varphi\|_\infty \le \varepsilon$ and $|\zeta| \le \varepsilon$, by a simple computation, we see that

$$-C\varepsilon r(1-r) \le w_{p,z}(r) - u_*(r) \le C\varepsilon r(1-r) \quad \text{for } 0 \le r \le 1. \tag{4.10}$$

Since $-C_1 r(1-r) \le u_*(r) \le -C_2 r(1-r)$, it follows that, for ε sufficiently small, we have

$$-C_1 r(1-r) \le w_{p,z}(r) \le -C_2 r(1-r) \quad \text{for } 0 \le r \le 1. \tag{4.11}$$

Later on we shall also use the notation $w_V(r)$ to redenote $w_{p,z}(r)$. We note that all constants C, C_1, and C_2 that appear in (4.10)–(4.11) are independent of V and ε.

LEMMA 4.2. *$\{\mathbb{A}(V) : V \in S_\varepsilon\}$ is a stable family of the infinitesimal generators of C_0 semigroups on $X = C[0,1] \times \mathbb{R}$, and $\{\tilde{\mathbb{A}}(V) : V \in S_\varepsilon\}$ is a stable family of the infinitesimal generators of C_0 semigroups on X_0.*

Proof. Let $\mathcal{L}_V q(r) = -w_V(r) q'(r)$. Then, by Lemma 4.1, we see that, for any $V \in S_\varepsilon$, $\mathcal{L}_V$ is an infinitesimal generator of a C_0 semigroup of contractions on $C[0,1]$. From this assertion and the second expression in (2.25), we easily infer that, for any $V \in S_\varepsilon$, $\mathbb{A}_0(U_* + V)$ is an infinitesimal generator of a C_0 semigroup of contractions on $X = C[0,1] \times \mathbb{R}$. Hence, $\{\mathbb{A}_0(U_* + V) : V \in S_\varepsilon\}$ is a stable family of the infinitesimal generators of C_0 semigroups on X, with stability constants $(M, \omega) = (1, 0)$. Since $\mathbb{A}(V) = \mathbb{A}_0(U_* + V) + \mathbb{B}$ and $\mathbb{B}$ is a bounded linear operator on X independent of V, by a standard perturbation result (see, e.g., Theorem 2.3 in section 5.2 of [20]), we see immediately that $\{\mathbb{A}(V) : V \in S_\varepsilon\}$ is a stable family of the infinitesimal generators of C_0 semigroups on $X = C[0,1] \times \mathbb{R}$, with stability constants $(M, \omega) = (1, \|\mathbb{B}\|)$.

In order to prove that $\{\tilde{\mathbb{A}}(V) : V \in S_\varepsilon\}$ is a stable family of the infinitesimal generators of a C_0 semigroup on $X_0 = C_V^1[0,1] \times \mathbb{R}$, we first establish an estimate for the semigroup $e^{t\tilde{\mathcal{L}}_V}$ on $C_V^1[0,1]$ different from (4.5), where $\tilde{\mathcal{L}}_V$ represents the part of $\mathcal{L}_V$ in $C_V^1[0,1]$. Let $q_0 \in C_V^1[0,1]$ and $q = e^{t\tilde{\mathcal{L}}_V} q_0 = e^{t\mathcal{L}_V} q_0$. Then q is the solution of the problem

$$\frac{\partial q}{\partial t} + w_V(r)\frac{\partial q}{\partial r} = 0 \quad \text{for } 0 \le r \le 1 \text{ and } t > 0, \quad q|_{t=0} = q_0.$$

Let $l(r,t) = r(1-r)\frac{\partial q(r,t)}{\partial r}$ and $l_0(r) = r(1-r)q_0'(r)$. Formally differentiating the above equation in r and multiplying it with $r(1-r)$, we get

$$\frac{\partial l}{\partial t} + w_V(r)\frac{\partial l}{\partial r} = a_V(r) l \quad \text{for } 0 \le r \le 1 \text{ and } t > 0, \quad l|_{t=0} = l_0,$$

where $a_V(r) = (1-2r)\frac{w_V(r)}{r(1-r)} - w_V'(r)$. Since $w_V \in C^1[0,1], w_V(0) = w_V(1) = 0$, and $a_V \in C[0,1]$, by a standard characteristics argument, we can easily show that this problem has a unique solution $l \in C([0,1] \times [0,\infty))$ such that $[\frac{\partial}{\partial t} + w_V(r)\frac{\partial}{\partial r}]l \in C([0,1] \times [0,\infty))$. Thus, the above formal computation makes sense. Clearly, there exists a nonnegative constant c_0 independent of V such that $a_V(r) \le c_0$ for $0 < r < 1$, for all $V \in S_\varepsilon$. Using this fact and the characteristics argument, we can easily obtain $\|l(\cdot,t)\|_\infty \le \|l_0\|_\infty e^{c_0 t}$ for $t \ge 0$. Combining this estimate with $\|q(\cdot,t)\|_\infty \le \|q_0\|_\infty$ ensured by (4.4), we get $\|q(\cdot,t)\|_{C_V^1[0,1]} \le \|q_0\|_{C_V^1[0,1]} e^{c_0 t}$ for $t \ge 0$, or

$$\|e^{t\tilde{\mathcal{L}}_V}\|_{L(C_V^1[0,1])} \le e^{c_0 t} \quad \text{for } t \ge 0, \quad \text{for all } V \in S_\varepsilon.$$

Hence, $\{\tilde{\mathcal{L}}_V : V \in S_\varepsilon\}$ is a stable family of the infinitesimal generators of C_0 semigroups on $C_V^1[0,1]$, with stability constants $(M, \omega) = (1, c_0)$. Using this assertion and

the second expression in (2.25), we see easily that $\{\tilde{\mathbb{A}}_0(U_* + V) : V \in S_\varepsilon\}$, the part of $\{\mathbb{A}_0(U_* + V) : V \in S_\varepsilon\}$ on $X_0 = C[0,1] \times \mathbb{R}$, is a stable family of the infinitesimal generators of C_0 semigroups on X_0, with stability constants $(M, \omega) = (1, c_0)$. Since $\tilde{\mathbb{A}}(V) = \tilde{\mathbb{A}}_0(U_* + V) + \mathbb{B}$, and, by Corollary 3.2, $\mathbb{B}$ is a bounded linear operator on X_0 independent of V, we conclude, as before, that $\{\mathbb{A}(V) : V \in S_\varepsilon\}$ is a stable family of the infinitesimal generators of C_0 semigroups on $X_0 = C^1_V[0,1] \times \mathbb{R}$, with stability constants $(M, \omega) = (1, c_0 + \|\mathbb{B}\|_{L(C^1_V[0,1])})$. This completes the proof of Lemma 4.2. ∎

Since $\mathbb{A} \in C^\infty(X, L(X_0, X))$, by Lemma 4.2, we see that, for any $V \in C([0,\infty), X)$ such that $V(t) \in S_\varepsilon$ for all $t \geq 0$, $\{\mathbb{A}(V(t)) : t \geq 0\}$ satisfies the conditions (H_1)–(H_3) in section 5.3 of [20]. It follows by Theorem 3.1 in section 5.3 of [20] that given such a function $V = V(t)$, there exists an evolution system determined by $\{\mathbb{A}(V(t)) : t \geq 0\}$, which we denote as $\mathbb{U}(t, s, V)$. By definition, this means that

(1) for any $t \geq s \geq 0$, $\mathbb{U}(t, s, V)$ is a bounded linear operator on X;
(2) $\mathbb{U}(s, s, V) = \mathrm{id}$ for all $s \geq 0$, $\mathbb{U}(t, s, V)\mathbb{U}(s, r, V) = \mathbb{U}(t, r, V)$ for all $t \geq s \geq r$; and
(3) the mapping $(t, s) \to \mathbb{U}(t, s, V)$ is strongly continuous for $t \geq s \geq 0$.

However, the theory developed in [20] does not ensure that $U = \mathbb{U}(t, s, V)U_0$ is a solution of the problem

$$\frac{dU}{dt} = \mathbb{A}(V(t))U \quad \text{for } t > s, \quad U|_{t=s} = U_0, \tag{4.12}$$

even if $U_0 \in X_0$, unless some other conditions are satisfied by $\mathbb{U}(t, s, V)$. These conditions are as follows (see conditions (E_4) and (E_5) in Theorem 4.3 in section 5.4 of [20]):

(4) $\mathbb{U}(t, s, V)X_0 \subseteq X_0$ for any $t \geq s \geq 0$; and
(5) For any $U_0 \in X_0$, the mapping $(t, s) \to \mathbb{U}(t, s, V)U_0$ is continuous in X_0 for $t \geq s \geq 0$.

In the following lemma we shall directly prove that, for any $U_0 \in X_0$, the problem (4.12) has a unique solution $U = U_s(t) \in C([s,\infty), X_0) \cap C^1([s,\infty), X)$. By Theorem 4.2 in section 5.4 of [20], it then follows that $U_s(t) = \mathbb{U}(t, s, V)U_0$, and consequently, the conditions (4) and (5) above are satisfied.

LEMMA 4.3. *Given $V \in C([0,\infty), X)$ such that $V(t) \in S_\varepsilon$ for all $t \geq 0$, for any $s \geq 0$ and any $U_0 \in X_0$, the problem* (4.12) *has a unique solution $U = U_s(t) \in C([s,\infty), X_0) \cap C^1([s,\infty), X)$.*

Proof. Let $U = (q, y)$ and $U_0 = (q_0, y_0)$. Then (4.12) can be rewritten as follows:

$$\begin{cases} \dfrac{\partial q}{\partial t} + w_V(r,t)\dfrac{\partial q}{\partial r} = a(r)q + \mathcal{B}(q) + b(r)y \quad \text{for } 0 \leq r \leq 1, \ t > s, \\ \dfrac{dy}{dt} = \mathcal{F}(q) + \kappa y \quad \text{for } t > s, \\ q|_{t=s} = q_0(r) \quad \text{for } 0 \leq r \leq 1, \quad \text{and} \quad y|_{t=s} = y_0. \end{cases} \tag{4.13}$$

Using the characteristic method and the Banach fixed point theorem, we can easily show that this problem has a unique local solution (q, y), with $q \in C([0,1] \times [0,\delta])$ and $y \in C^1[0,\delta]$ for some $\delta > 0$. Since $w_V(0,t) = w_V(1,t) = 0$ for all $t \geq 0$, we see that the two lines $r = 0$ and $r = 1$ are characteristic curves. It follows that all characteristic curves starting from the open interval $(0,1)$ always lie in it, so that the solution of the above problem exists for all $t \geq s$. It remains to prove that $q \in C([0,\infty), C^1_V[0,1])$. To this end we formally differentiate the first equation in (4.13) in r and multiply it

with $r(1-r)$, which gives, by letting $l(r,t) = r(1-r)\frac{\partial q(r,t)}{\partial r}$, that

$$\frac{\partial l}{\partial t} + w_V(r,t)\frac{\partial l}{\partial r} = a_1(r,t)u + f_1(r,t) \quad \text{for } 0 \le r \le 1, \ \ t > 0, \tag{4.14}$$

where $a_1(r,t) = a(r) + (1-2r)\frac{w_V(r,t)}{r(1-r)} - \frac{\partial w_V(r,t)}{\partial r}$, and

$$f_1(r,t) = r(1-r)a'(r)q(r,t) + r(1-r)\frac{\partial \mathcal{B}q(r,t)}{\partial r} + r(1-r)b'(r)y(t).$$

Clearly, $a_1 \in C([0,1]\times[0,\infty))$. By Corollary 3.2, we see that also $f_1 \in C([0,1]\times[0,\infty)$. Thus, by using the characteristic method, we can easily prove that (4.14) imposed with the initial condition $l(r,0) = r(1-r)q_0'(r)$ has a unique solution $l \in C([0,1]\times[0,\infty))$ such that $[\frac{\partial}{\partial t} + w_V(r,t)\frac{\partial}{\partial r}]l \in C([0,1]\times[0,\infty))$. Thus, the above formal computation makes sense, and consequently, $q \in C([0,\infty), C_V^1[0,1]) \cap C^1([0,\infty), C[0,1])$. The desired assertion now becomes immediate. □

By the above results and Theorems 4.2 and 5.2 in sections 5.4 and 5.5 of [20], we get the following.

COROLLARY 4.4. *Let $V \in C([0,\infty), X)$ be as in Lemma* 4.3, *and let $F \in C([0,\infty), X_0)$. Then, for any $U_0 \in X_0$, the initial value problem* (4.1) *has a unique solution $U \in C([0,\infty), X_0) \cap C^1([0,\infty), X)$, and it is given by* (4.2). □

5. Similarity transformation. In the previous section we proved that given $V \in C([0,\infty), X)$ such that $V(t) \in S_\varepsilon$ for all $t \ge 0$, the family of operators $\{\mathbb{A}(V(t)) : t \ge 0\}$ determines an evolution system $\mathbb{U}(t,s,V)$ $(t \ge s \ge 0)$, so that the solution of (4.1) can be expressed as (4.2). However, the deduction in the previous section does not provide us with an estimate of the form $\|\mathbb{U}(t,s,V)\| \le Ce^{-\mu(t-s)}$, which, however, is essential in order to establish the estimate (2.17). To establish such an estimate, we shall follow a different approach as follows: For $V \equiv 0$, the desired estimate will be obtained by improving the linear estimate established in [5]. For a general $V = V(t)$, we shall use a special transformation, which we call *similarity transformation,* to transform the problem into an equivalent problem which can be estimated by using the estimate for the case $V \equiv 0$. The similarity transformation is a family of C^1 diffeomorphisms $\bar{r} = T(r,t,s)$ of the unit interval $0 \le r \le 1$ to itself, where $t \ge s \ge 0$ are parameters. The aim of this section is to establish this transformation.

Let $w \in C([0,\infty), C^1[0,1])$. We assume that w satisfies the following condition: For some small parameter $\varepsilon > 0$,

$$-C\varepsilon r(1-r)e^{-\mu t} \le w(r,t) - u_*(r) \le C\varepsilon r(1-r)e^{-\mu t} \quad \text{for } 0 \le r \le 1, \ \ t \ge 0, \tag{5.1}$$

where C is a positive constant independent of ε and w. Since $-C_1 r(1-r) \le u_*(r) \le -C_2 r(1-r)$, we see that

$$\sup_{0<r<1}\Big|\frac{w(r,t)}{u_*(r)} - 1\Big| \le C\varepsilon e^{-\mu t} \quad \text{for } 0 \le r \le 1, \ \ t \ge 0, \tag{5.2}$$

and, for ε sufficiently small, $w(r,t)$ satisfies (4.3) for all $t \ge 0$.

Let $0 \le \xi \le 1$ and $s \ge 0$. Consider the following initial value problem:

$$\frac{dr}{dt} = u_*(r) \quad \text{for } t > s, \quad r|_{t=s} = \xi. \tag{5.3}$$

Since $u_* \in C^1[0,1]$, $u_*(r) < 0$ for $0 < r < 1$, and, in particular, $u_*(0) = u_*(1) = 0$, it can be easily shown that this problem has a unique solution $r = \Phi_*(\xi, t, s)$ for all $t \geq s \geq 0$, satisfying the following properties (A):

$$\Phi_*(\xi,t,s) \text{ is continuously differentiable in } (\xi,t,s),$$
$$\Phi_*(0,t,s) = 0, \quad \Phi_*(1,t,s) = 1 \quad \text{for } t \geq s \geq 0,$$
$$0 < \Phi_*(\xi,t,s) < 1 \quad \text{for } 0 < \xi < 1, \ t \geq s \geq 0,$$
$$\frac{\partial \Phi_*(\xi,t,s)}{\partial \xi} > 0, \quad \frac{\partial \Phi_*(\xi,t,s)}{\partial t} < 0 \quad \text{for } 0 < \xi < 1, \ t \geq s \geq 0,$$
$$\Phi_*(\xi,s,s) = \xi \quad \text{for } 0 \leq \xi \leq 1, \ s \geq 0.$$

From these properties we see that, for any $s \geq 0$ and $t \geq s$, the mapping $\xi \to r = \Phi_*(\xi,t,s)$ is a C^1 diffeomorphism of $[0,1]$ to itself. Let $\xi = \Psi_*(r,t,s)$ be the inverse of this mapping. Clearly, Ψ_* also satisfies the properties (A) (with ξ replaced by r). Furthermore, from the relation $\Psi_*(\Phi_*(\xi,t,s),t,s) = \xi$ (for $0 \leq \xi \leq 1$ and $t \geq s \geq 0$), it can be easily shown that $\xi = \Psi_*(r,t,s)$ is the unique solution of the following initial value problem:

$$\frac{\partial \xi}{\partial t} + u_*(r)\frac{\partial \xi}{\partial r} = 0 \quad \text{for } t > s, \quad \xi|_{t=s} = r. \tag{5.4}$$

Next, let $r = \Phi(\xi,t,s)$ $(0 \leq \xi \leq 1,\ t \geq s \geq 0)$ be the solution of the following problem:

$$\frac{dr}{dt} = w(r,t) \quad \text{for } t > s, \quad r|_{t=s} = \xi. \tag{5.5}$$

Similarly as before, $\Phi(\xi,t,s)$ is well-defined for all $0 \leq \xi \leq 1$ and $t \geq s \geq 0$, and it also satisfies the properties (A). It follows that, for any $s \geq 0$ and $t \geq s$, the mapping $\xi \to r = \Phi(\xi,t,s)$ is a C^1 diffeomorphism of $[0,1]$ to itself. Let $\xi = \Psi(r,t,s)$ be the inverse of this mapping. Clearly, Ψ also satisfies the properties (A) (with ξ replaced by r). Furthermore, from the relation $\Psi(\Phi(\xi,t,s),t,s) = \xi$ (for $0 \leq \xi \leq 1$ and $t \geq s \geq 0$), it can be easily shown that $\xi = \Psi(r,t,s)$ is the unique solution of the following initial value problem:

$$\frac{\partial \xi}{\partial t} + w(r,t)\frac{\partial \xi}{\partial r} = 0 \quad \text{for } t > s, \quad \xi|_{t=s} = r. \tag{5.6}$$

In what follows we consider the following initial value problem:

$$\begin{cases} \dfrac{\partial \bar{r}}{\partial t} + w(r,t)\dfrac{\partial \bar{r}}{\partial r} = u_*(\bar{r}) \quad \text{for } 0 \leq r \leq 1, \ t > s, \\ \bar{r}|_{t=s} = r \quad \text{for } 0 \leq r \leq 1. \end{cases} \tag{5.7}$$

LEMMA 5.1. *For any $0 \leq r \leq 1$ and $s \geq 0$, the problem* (5.7) *has a unique solution $\bar{r} = T(r,t,s)$ for all $t \geq s$, and the following relation holds:*

$$T(r,t,s) = \Phi_*(\Psi(r,t,s),t,s) \quad \textit{for } 0 \leq r \leq 1, \ t \geq s \geq 0. \tag{5.8}$$

Proof. Using (5.3) and (5.6) we can easily verify that $\bar{r} = \Phi_*(\Psi(r,t,s),t,s)$ is a solution of the problem (5.7). Thus, (5.8) follows by the uniqueness of the solution. ∎

By (5.8), it is evident that, for any $s \geq 0$ and $t \geq s$, the mapping $r \to \bar{r} = T(r,t,s)$ is a C^1 diffeomorphism of $[0,1]$ to itself, satisfying $T(0,t,s) = 0$, $T(1,t,s) = 1$ for $t \geq s \geq 0$, and $\partial T(r,t,s)/\partial r > 0$ for $0 < r < 1$, $t \geq s$. We denote by $r = S(\bar{r},t,s)$ the inverse of this mapping. By (5.8), it is clear that

$$S(\bar{r},t,s) = \Phi(\Psi_*(\bar{r},t,s),t,s) \quad \text{for } 0 \leq \bar{r} \leq 1, \ \ t \geq s \geq 0. \tag{5.9}$$

It is also clear that $S(\bar{r},t,s)$ satisfies $S(0,t,s) = 0$, $S(1,t,s) = 1$ for $t \geq s \geq 0$ and that $\partial S(\bar{r},t,s)/\partial \bar{r} > 0$ for $0 < \bar{r} < 1$, $t \geq s \geq 0$.

T and S can be expressed in more explicit formulations. To show this we introduce a function F_* as follows:

$$F_*(r) = -\int_{\frac{1}{2}}^{r} \frac{d\eta}{u_*(\eta)} = \int_{\frac{1}{2}}^{r} \frac{d\eta}{|u_*(\eta)|} \quad \text{for } 0 < r < 1. \tag{5.10}$$

Clearly, $F_* \in C^1(0,1)$, $F_*'(r) > 0$ for all $0 < r < 1$, and $\lim_{r\to 0^+} F_*(r) = -\infty$, $\lim_{r\to 1^-} F_*(r) = \infty$. Hence, $\bar{r} = F_*(r)$ is a C^1 diffeomorphism of the open unit interval $(0,1)$ onto the real line $(-\infty,\infty)$. From (5.3) we easily obtain $F_*(\Phi_*(\xi,t,s)) - F_*(\xi) = -t + s$. Thus, we have

$$\Phi_*(\xi,t,s) = F_*^{-1}(F_*(\xi) - t + s), \tag{5.11}$$

and consequently,

$$\Psi_*(r,t,s) = F_*^{-1}(F_*(r) + t - s). \tag{5.12}$$

Next, let

$$g(\xi,t,s) = G(\Phi(\xi,t,s),t), \quad \text{where} \quad G(r,t) = \frac{w(r,t)}{u_*(r)} - 1.$$

Since $w(r,t) = [1 + G(r,t)]u_*(r)$, from (5.5) we see that $r = \Phi(\xi,t,s)$ is a solution of the following problem:

$$\frac{dr}{dt} = [1 + g(\xi,t,s)]u_*(r) \quad \text{for } t > s, \quad r|_{t=s} = \xi. \tag{5.13}$$

Thus, similarly, as before, we have $F_*(\Phi(\xi,t,s)) - F_*(\xi) = -t + s - \int_s^t g(\xi,\tau,s)d\tau$, so that

$$\Phi(\xi,t,s) = F_*^{-1}\left(F_*(\xi) - t + s - \int_s^t g(\xi,\tau,s)d\tau\right), \tag{5.14}$$

$$\Psi(r,t,s) = F_*^{-1}\left(F_*(r) + t - s + \int_s^t g(\Psi(r,t,s),\tau,s)d\tau\right). \tag{5.15}$$

Combining (5.8), (5.9), (5.11), (5.12), (5.14), and (5.15), we see that

$$T(r,t,s) = F_*^{-1}\left(F_*(r) + \int_s^t g(\Psi(r,t,s),\tau,s)d\tau\right), \tag{5.16}$$

$$S(\bar{r},t,s) = F_*^{-1}\left(F_*(\bar{r}) - \int_s^t g(\Psi_*(\bar{r},t,s),\tau,s)d\tau\right). \tag{5.17}$$

LEMMA 5.2. *Assume that $|\zeta| \le C$. Then there exist positive constants C_1 and C_2 depending only on C such that, for any $0 < r < 1$, we have*

$$C_1 r(1-r) \le F_*^{-1}(F_*(r)+\zeta)\left[1 - F_*^{-1}(F_*(r)+\zeta)\right] \le C_2 r(1-r). \tag{5.18}$$

Proof. Since $-C \le \zeta \le C$, by the monotonicity of F_*, we have

$$F_*^{-1}(F_*(r)-C) \le F_*^{-1}(F_*(r)+\zeta) \le F_*^{-1}(F_*(r)+C).$$

Thus,

$$\frac{F_*^{-1}(F_*(r)+\zeta)}{r} \le \frac{F_*^{-1}(F_*(r)+C)}{r} \quad \text{and}$$
$$\frac{1-F_*^{-1}(F_*(r)+\zeta)}{1-r} \le \frac{1-F_*^{-1}(F_*(r)-C)}{1-r}.$$

Moreover, using the facts that $u_*(r) = u_*'(0)r[1+O(r^\beta)]$ as $r \to 0^+$ for some $0 < \beta \le 1$ (see Assertion (3) of Lemma 3.1) and that $u_*(r) = -u_*'(1)(1-r)[1+O(1-r)]$ as $r \to 1^-$, we can easily show that

$$\lim_{r\to 0^+} \frac{F_*^{-1}(F_*(r)+C)}{r} = e^{C|u_*'(0)|} \quad \text{and} \quad \lim_{r\to 1^-} \frac{1-F_*^{-1}(F_*(r)-C)}{1-r} = e^{Cu_*'(1)}.$$

From these relations we immediately obtain the second inequality in (5.18). The proof for the first inequality in (5.18) is similar. ∎

COROLLARY 5.3. *For ε sufficiently small, we have*

$$C_1 r(1-r) \le T(r,t,s)[1-T(r,t,s)] \le C_2 r(1-r), \tag{5.19}$$
$$C_1 \bar{r}(1-\bar{r}) \le S(\bar{r},t,s)[1-S(\bar{r},t,s)] \le C_2 \bar{r}(1-\bar{r}). \tag{5.20}$$

Proof. Let $\zeta = \int_s^t g(\Psi(r,t,s),\tau,s)d\tau$. By (5.2), we have

$$|\zeta| \le \int_s^t |g(\Psi(r,t,s),\tau,s)|d\tau \le C\varepsilon \int_s^t e^{-\mu\tau}d\tau \le C\varepsilon \int_0^\infty e^{-\mu\tau}d\tau \le C\varepsilon \le C.$$

Hence, (5.19) follows from (5.16) and (5.18). Similarly, (5.20) follows from (5.17) and (5.18). ∎

As an immediate consequence of Corollary 5.3, we see that there exists a constant $C > 1$ such that, for ε sufficiently small, we have $C^{-1} \le T(r,t,s)/r \le C$ and $C^{-1} \le S(\bar{r},t,s)/\bar{r} \le C$.

COROLLARY 5.4. *For ε sufficiently small, we have the following inequalities:*

$$C_1\Psi_*(r,t,s)[1-\Psi_*(r,t,s)] \le \Psi(r,t,s)[1-\Psi(r,t,s)] \le C_2\Psi_*(r,t,s)[1-\Psi_*(r,t,s)], \tag{5.21}$$
$$C_1\Phi_*(\bar{r},t,s)[1-\Phi_*(\bar{r},t,s)] \le \Phi(\bar{r},t,s)[1-\Phi(\bar{r},t,s)] \le C_2\Phi_*(\bar{r},t,s)[1-\Phi_*(\bar{r},t,s)]. \tag{5.22}$$

Proof. Let $\bar{r} = \Psi_*(r,t,s)$ and $\zeta = \int_s^t g(\Psi(r,t,s),\tau,s)d\tau$. Then, by (5.12) and (5.15), we have $\Psi(r,t,s) = F_*^{-1}(F_*(\bar{r})+\zeta)$. By this expression and (5.18), we immediately obtain (5.21). The proof of (5.22) is similar. ∎

As an immediate consequence of Corollary 5.4, we see that there exists a constant $C > 1$ such that, for ε sufficiently small, we have $C^{-1} \le \Psi(r,t,s)/\Psi_*(r,t,s) \le C$ and $C^{-1} \le \Phi(\bar{r},t,s)/\Phi_*(\bar{r},t,s) \le C$.

LEMMA 5.5. *We have the following inequalities:*

$$|T(r,t,s) - r| \le C\varepsilon\big(e^{-\mu s} - e^{-\mu t}\big)r(1-r), \tag{5.23}$$

$$|S(\bar{r},t,s) - \bar{r}| \le C\varepsilon\big(e^{-\mu s} - e^{-\mu t}\big)\bar{r}(1-\bar{r}). \tag{5.24}$$

Proof. Similarly as in the proof of Corollary 5.3, we have

$$\int_s^t |g(\Psi(r,t,s),\tau,s)|d\tau \le C\varepsilon\int_s^t e^{-\mu\tau} \le C\varepsilon\Big(e^{-\mu s} - e^{-\mu t}\Big).$$

Thus, by noticing that $\frac{dF_*^{-1}(\eta)}{d\eta} = \frac{1}{F_*'(F_*^{-1}(\eta))} = |u_*(F_*^{-1}(\eta))|$, we see that

$$\begin{aligned}
|T(r,t,s) - r| &= \left|F_*^{-1}\left(F_*(r) + \int_s^t g(\Psi(r,t,s),\tau,s)d\tau\right) - F_*^{-1}(F_*(r))\right| \\
&\le \int_0^1 \left|u_*\left(F_*^{-1}(F_*(r)+\zeta_\theta)\right)\right| d\theta \cdot \int_s^t |g(\Psi(r,t,s),\tau,s)|d\tau \\
&\le C\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right)\cdot\int_0^1 \left|u_*\left(F_*^{-1}(F_*(r)+\zeta_\theta)\right)\right| d\theta,
\end{aligned}$$

where $\zeta_\theta = \theta\int_s^t g(\Psi(r,t,s),\tau,s)d\tau$. Since $|\zeta_\theta| \le C$ and $|u_*(\eta)| \le C\eta(1-\eta)$, by Lemma 5.2, we have

$$\left|u_*\left(F_*^{-1}(F_*(r)+\zeta_\theta)\right)\right| \le CF_*^{-1}(F_*(r)+\zeta_\theta)\left[1 - F_*^{-1}(F_*(r)+\zeta_\theta)\right] \le Cr(1-r).$$

Substituting this estimate into the above inequality, we see that (5.23) follows. The proof of (5.24) is similar. ∎

COROLLARY 5.6. *We have the following inequalities:*

$$|\Phi(\xi,t,s) - \Phi_*(\xi,t,s)| \le C\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right)\Phi_*(\xi,t,s)[1-\Phi_*(\xi,t,s)], \tag{5.25}$$

$$|\Psi(r,t,s) - \Psi_*(r,t,s)| \le C\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right)\Psi_*(r,t,s)[1-\Psi_*(r,t,s)]. \tag{5.26}$$

Proof. Let $r = \Phi(\xi,t,s)$. Then $\xi = \Psi(r,t,s)$ and $\Phi_*(\xi,t,s) = \Phi_*(\Psi(r,t,s),t,s) = T(r,t,s)$. Thus, by (5.23), we have

$$|\Phi(\xi,t,s) - \Phi_*(\xi,t,s)| = |r - T(r,t,s)| \le C\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right)r(1-r).$$

Substituting $r = \Phi(\xi,t,s)$ into the right-hand side of the last inequality and using (5.22), we see that (5.25) follows. The proof of (5.26) is similar. ∎

LEMMA 5.7. *Assume that, in addition to* (5.2)*, there also holds*

$$\max_{0\le r\le 1}\left|\frac{\partial w(r,t)}{\partial r} - u_*'(r)\right| \le C\varepsilon e^{-\mu t}. \tag{5.27}$$

Then we have the following estimates:

$$e^{-C\varepsilon\left(e^{-\mu s}-e^{-\mu t}\right)} \le \frac{\partial T(r,t,s)}{\partial r} \le e^{C\varepsilon\left(e^{-\mu s}-e^{-\mu t}\right)}, \tag{5.28}$$

$$e^{-C\varepsilon\left(e^{-\mu s}-e^{-\mu t}\right)} \le \frac{\partial S(\bar{r},t,s)}{\partial \bar{r}} \le e^{C\varepsilon\left(e^{-\mu s}-e^{-\mu t}\right)}. \tag{5.29}$$

Proof. Recalling that $T(r,t,s) = \Phi_*(\Psi(r,t,s),t,s)$, we have

$$\begin{aligned}\frac{\partial T(r,t,s)}{\partial r} &= \frac{\partial \Phi_*}{\partial \xi}(\Psi(r,t,s),t,s)\frac{\partial \Psi(r,t,s)}{\partial r}\\ &= \frac{\partial \Phi_*}{\partial \xi}(\Psi(r,t,s),t,s)\left[\frac{\partial \Phi}{\partial \xi}(\Psi(r,t,s),t,s)\right]^{-1}\\ &= \exp\left(\int_s^t \left[u_*'(\Phi_*(\xi,\tau,s)) - \frac{\partial w}{\partial r}(\Phi(\xi,\tau,s),\tau)\right]d\tau\right)\Bigg|_{\xi=\Psi(r,t,s)}. \qquad (5.30)\end{aligned}$$

We write

$$\begin{aligned}u_*'(\Phi_*(\xi,\tau,s)) - \frac{\partial w}{\partial r}(\Phi(\xi,\tau,s),\tau) &= [u_*'(\Phi_*(\xi,\tau,s)) - u_*'(\Phi(\xi,\tau,s))]\\ &\quad + \left[u_*'(\Phi(\xi,\tau,s)) - \frac{\partial w}{\partial r}(\Phi(\xi,\tau,s),\tau)\right].\end{aligned}$$

From assumption (5.27) we see that

$$\sup_{\xi\in\mathbb{R}}\left|u_*'(\Phi(\xi,\tau,s)) - \frac{\partial w}{\partial r}(\Phi(\xi,\tau,s),\tau)\right| \le \sup_{0<r<1}\left|u_*'(r) - \frac{\partial w}{\partial r}(r,\tau)\right| \le C\varepsilon e^{-\mu\tau}.$$

Next, by assertion (3) of Lemma 3.1, we know that there exists $0 \le \gamma < 1$ such that $r^\gamma u_*''(r) \in C[0,1]$. With this fact in mind, we use the mean value theorem to compute

$$\begin{aligned}&|u_*'(\Phi_*(\xi,\tau,s)) - u_*'(\Phi(\xi,\tau,s))|\,\big|_{\xi=\Psi(r,t,s)}\\ &= |u_*''(\zeta)|\,|\Phi_*(\xi,\tau,s) - \Phi(\xi,\tau,s)|\,\big|_{\xi=\Psi(r,t,s)}\\ &= |\zeta^\gamma u_*''(\zeta)|\cdot\left[\left(\frac{\Phi(\xi,\tau,s)}{\zeta}\right)^\gamma\cdot(\Phi(\xi,\tau,s))^{-\gamma}\,|\Phi_*(\xi,\tau,s) - \Phi(\xi,\tau,s)|\right]\Bigg|_{\xi=\Psi(r,t,s)},\end{aligned}$$

where $\zeta = \theta\Phi_*(\xi,\tau,s) + (1-\theta)\Phi(\xi,\tau,s)$ for some $0 < \theta < 1$ (depending on ξ, τ, s). Since there exists a constant $0 < c < 1$ such that $\frac{\Phi_*(\xi,\tau,s)}{\Phi(\xi,\tau,s)} \ge c$ for ε sufficiently small, we have $\zeta \ge c\Phi(\xi,\tau,s)$. Thus,

$$\begin{aligned}&\Big|u_*'(\Phi_*(\xi,\tau,s)) - u_*'(\Phi(\xi,\tau,s))\Big|\Big|_{\xi=\Psi(r,t,s)}\\ &\le C\big(\Phi(\xi,\tau,s)\big)^{-\gamma}\big|\Phi_*(\xi,\tau,s) - \Phi(\xi,\tau,s)\big|\big|_{\xi=\Psi(r,t,s)}\\ &\le C\varepsilon\big(e^{-\mu s} - e^{-\mu\tau}\big)\big(\Phi(\xi,\tau,s)\big)^{-\gamma}\Phi_*(\xi,\tau,s)[1-\Phi_*(\xi,\tau,s)]\big|_{\xi=\Psi(r,t,s)}\\ &\le C\varepsilon\big(e^{-\mu s} - e^{-\mu\tau}\big)\big(\Phi(\xi,\tau,s)\big)^{1-\gamma}[1-\Phi(\xi,\tau,s)]\big|_{\xi=\Psi(r,t,s)}\\ &= C\varepsilon\big(e^{-\mu s} - e^{-\mu\tau}\big)\big(\Psi(r,t,\tau)\big)^{1-\gamma}[1-\Psi(r,t,\tau)].\end{aligned}$$

In getting the last equality, we used the following relation:

$$\Phi(\Psi(r,t,s),\tau,s) = \Psi(r,t,\tau) \quad \text{for } 0 \le r \le 1,\ \ s \le \tau \le t. \qquad (5.31)$$

The proof of this relation is as follows: From (5.6) we know that $\rho = \Psi(r,t,\tau)$ is a solution of the following problem:

$$\frac{\partial \rho}{\partial t} + w(r,t)\frac{\partial \rho}{\partial r} = 0 \quad \text{for } 0 \le r \le 1,\ \ t > \tau, \quad \rho|_{t=\tau} = r.$$

But it is easy to verify that $\rho = \Phi(\Psi(r,t,s),\tau,s)$ is also a solution of this problem. Hence, by uniqueness, we have (5.31). Hence, using (5.21) and (5.12), we get

$$\begin{aligned}
&\left|u_*'(\Phi_*(\xi,\tau,s)) - \frac{\partial w}{\partial r}(\Phi(\xi,\tau,s),\tau)\right|\Big|_{\xi=\Psi(r,t,s)} \\
&\le C\varepsilon\left(e^{-\mu s} - e^{-\mu\tau}\right)\left(\Psi_*(r,t,\tau)\right)^{1-\gamma}\left[1-\Psi_*(r,t,\tau)\right] + C\varepsilon e^{-\mu\tau} \\
&= C\varepsilon\left(e^{-\mu s} - e^{-\mu\tau}\right)\left[F_*^{-1}(F_*(r)+t-\tau)\right]^{1-\gamma}\left[1-F_*^{-1}(F_*(r)+t-\tau)\right] + C\varepsilon e^{-\mu\tau}.
\end{aligned}$$

It follows that

$$\begin{aligned}
&\int_s^t \left|u_*'(\Phi_*(\xi,\tau,s)) - \frac{\partial w}{\partial r}(\Phi(\xi,\tau,s),\tau)\right|\Big|_{\xi=\Psi(r,t,s)} d\tau \\
&\le C\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right)\int_s^t \left[F_*^{-1}(F_*(r)+t-\tau)\right]^{1-\gamma}\left[1-F_*^{-1}(F_*(r)+t-\tau)\right] d\tau \\
&\quad + C\varepsilon\int_s^t e^{-\mu\tau}d\tau \\
&= C\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right)\int_{F_*(r)}^{F_*(r)+t-s}\left(F_*^{-1}(\xi)\right)^{1-\gamma}[1-F_*^{-1}(\xi)]d\xi + C\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right) \\
&\quad \left(\xi = F_*(\eta), \quad d\xi = F_*'(\eta)d\eta = \frac{d\eta}{|u_*(\eta)|}\right) \\
&= C\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right)\int_r^{F_*^{-1}(F_*(r)+t-s)} \frac{\eta^{1-\gamma}(1-\eta)}{|u_*(\eta)|}d\eta + C\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right) \\
&\le C\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right)\int_0^1 \eta^{-\gamma}d\eta + C\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right) = C\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right).
\end{aligned}$$

Combining this result with (5.30), we see that (5.28) follows. Finally, (5.29) is an immediate consequence of (5.28). □

COROLLARY 5.8. *Under the assumption of Lemma* 5.7, *for* ε *sufficiently small, we have*

$$\left|\frac{\partial T(r,t,s)}{\partial r} - 1\right| \le C\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right), \quad \left|\frac{\partial S(\bar r,t,s)}{\partial \bar r} - 1\right| \le C\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right),$$

and

$$C^{-1} \le \frac{\partial T(r,t,s)}{\partial r} \le C, \quad C^{-1} \le \frac{\partial S(\bar r,t,s)}{\partial \bar r} \le C. \qquad \square$$

LEMMA 5.9. *Assume that* $a \in C_V^1[0,1]$, *and the assumption of Lemma* 5.7 *holds. Then*

$$\|a(S(\cdot,t,s)) - a\|_\infty \le C\|a\|_1\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right), \tag{5.32}$$

where $\|a\|_1 = \max_{0\le r\le 1} r(1-r)|a'(r)|$. *If further* $r^2(1-r)^2a''(r) \in C[0,1]$, *then we also have*

$$\|a(S(\cdot,t,s)) - a\|_{C_V^1[0,1]} \le C\|a\|_2\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right), \tag{5.33}$$

where $\|a\|_2 = \|a\|_1 + \max_{0\le r\le 1} r^2(1-r)^2|a''(r)|$.

Proof. We have

$$\begin{aligned}|a(S(r,t,s)) - a(r)| &= |a'(\eta)||S(r,t,s) - r| \\ &\le C\varepsilon\eta(1-\eta)|a'(\eta)| \cdot \frac{r(1-r)}{\eta(1-\eta)}\left(e^{-\mu s} - e^{-\mu t}\right) \\ &\le C\|a\|_1\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right),\end{aligned}$$

where $\eta = (1-\theta)r + \theta S(r,t,s)$ for some $0 < \theta < 1$ (depending on r, t, and s). In getting the last inequality, we used the inequality $\eta(1-\eta) \ge Cr(1-r)$ for $0 \le r \le 1$, which follows from (5.20) and the following identity:

$$\eta(1-\eta) = (1-\theta)r(1-r) + \theta S(r,t,s)[1 - S(r,t,s)] + \theta(1-\theta)[r - S(r,t,s)]^2.$$

Hence, (5.32) is proved. Next, we compute

$$\begin{aligned}r(1-r)\left|\frac{\partial a(S(r,t,s))}{\partial r} - a'(r)\right| &= r(1-r)\left|a'(S(r,t,s))\frac{\partial S(r,t,s)}{\partial r} - a'(r)\right| \\ &\le r(1-r)|a'(S(r,t,s))|\left|\frac{\partial S(r,t,s)}{\partial r} - 1\right| \\ &\quad + r(1-r)|a'(S(r,t,s)) - a'(r)|.\end{aligned}$$

By Corollaries 5.3 and 5.8, we see that the first term on the right-hand side is bounded by $C\|a\|_1 \cdot C\varepsilon(e^{-\mu s} - e^{-\mu t})$, and, by a similar argument as before, we can easily show that the second term on the right-hand side is bounded by $C(\max_{0\le r\le 1} r^2(1-r)^2|a''(r)|)\varepsilon(e^{-\mu s} - e^{-\mu t})$. Hence, (5.33) follows. ∎

LEMMA 5.10. *Given $a \in C[0,1]$, we define a bounded linear operator L in $C[0,1]$ by*

$$L(q)(r) = \frac{1}{r^3}\int_0^r a(\rho)q(\rho)\rho^2 d\rho \quad \text{for } q \in C[0,1], \quad 0 < r \le 1,$$

and $L(q)(0) = \lim_{r\to 0^+} L(q)(r) = \frac{1}{3}a(0)q(0)$. Let $\bar r = T(r,t,s)$ and $r = S(\bar r,t,s)$ be as before, and let $\widetilde L$ be the following bounded linear operator in $C[0,1]$:

$$\widetilde L(q)(\bar r) = \frac{1}{r^3}\int_0^r a(\rho)q(T(\rho,t,s))\rho^2 d\rho\Big|_{r=S(\bar r,t,s)} \quad \text{for } q \in C[0,1], \quad 0 < \bar r \le 1,$$

and $\widetilde L(q)(0) = \lim_{\bar r\to 0^+}\widetilde L(q)(\bar r) = \frac{1}{3}a(0)q(0)$. Assume that $a \in C_V^1[0,1]$, and the assumption of Lemma 5.7 holds. Then both L and $\widetilde L$ are bounded linear operators from $C[0,1]$ to $C_V^1[0,1]$, and we have

$$\left\|\widetilde L - L\right\|_{L(C[0,1],C_V^1[0,1])} \le C\|a\|_{C_V^1[0,1]}\varepsilon\left(e^{-\mu s} - e^{-\mu t}\right). \tag{5.34}$$

Proof. We give only the proof of (5.34), because the proof of the assertion that both L and $\widetilde L$ are bounded linear operators from $C[0,1]$ to $C_V^1[0,1]$ follows by a similar argument.

We first note that, for $q \in C[0,1]$ and $0 < \bar r \le 1$, $\widetilde L(q)(\bar r)$ can be rewritten as follows:

$$\widetilde L(q)(\bar r) = \frac{1}{[S(\bar r,t,s)]^3}\int_0^{\bar r} a(S(\rho,t,s))q(\rho)\left[\frac{S(\rho,t,s)}{\rho}\right]^2\frac{\partial S(\rho,t,s)}{\partial\rho}\rho^2 d\rho.$$

Thus,

$$\begin{aligned}\widetilde{L}(q)(\bar{r})-L(q)(\bar{r})=&\left[\frac{\bar{r}}{S(\bar{r},t,s)}\right]^3\cdot\frac{1}{\bar{r}^3}\int_0^{\bar{r}}a(S(\rho,t,s))q(\rho)\\&\left[\frac{S(\rho,t,s)}{\rho}\right]^2\left[\frac{\partial S(\rho,t,s)}{\partial\rho}-1\right]\rho^2d\rho\\&+\left[\frac{\bar{r}}{S(\bar{r},t,s)}\right]^3\cdot\frac{1}{\bar{r}^3}\int_0^{\bar{r}}a(S(\rho,t,s))q(\rho)\left\{\left[\frac{S(\rho,t,s)}{\rho}\right]^2-1\right\}\rho^2d\rho\\&+\left[\frac{\bar{r}}{S(\bar{r},t,s)}\right]^3\cdot\frac{1}{\bar{r}^3}\int_0^{\bar{r}}[a(S(\rho,t,s))-a(\rho)]q(\rho)\rho^2d\rho\\&+\left\{\left[\frac{\bar{r}}{S(\bar{r},t,s)}\right]^3-1\right\}\cdot\frac{1}{\bar{r}^3}\int_0^{\bar{r}}a(\rho)q(\rho)\rho^2d\rho.\end{aligned}$$

From Corollary 5.3, Lemma 5.5, Corollary 5.8, and Lemma 5.9, we know that

$$\begin{aligned}\left|\frac{\bar{r}}{S(\bar{r},t,s)}\right|\le C,\quad&\left|\frac{\bar{r}}{S(\bar{r},t,s)}-1\right|\le C\varepsilon\left(e^{-\mu s}-e^{-\mu t}\right),\\\left|\frac{S(\rho,t,s)}{\rho}\right|\le C,\quad&\left|\frac{\partial S(\rho,t,s)}{\partial\rho}-1\right|\le C\varepsilon\left(e^{-\mu s}-e^{-\mu t}\right),\\|a(S(\rho,t,s))-a(\rho)|\le C\|a\|_1\varepsilon&\left(e^{-\mu s}-e^{-\mu t}\right).\end{aligned}$$

Using the above estimates, we see easily that

$$\max_{0\le\bar{r}\le1}\left|\widetilde{L}(q)(\bar{r})-L(q)(\bar{r})\right|\le C\varepsilon\left(e^{-\mu s}-e^{-\mu t}\right)\|a\|_{C_V^1[0,1]}\|q\|_\infty. \tag{5.35}$$

Next, by a simple computation, we have

$$\begin{aligned}\bar{r}(1-\bar{r})L(q)'(\bar{r})=&(1-\bar{r})a(\bar{r})q(\bar{r})-\frac{3(1-\bar{r})}{\bar{r}^3}\int_0^{\bar{r}}a(\rho)q(\rho)\rho^2d\rho,\\\bar{r}(1-\bar{r})\widetilde{L}(q)'(\bar{r})=&\frac{\bar{r}(1-\bar{r})}{S(\bar{r},t,s)}a(S(\bar{r},t,s))q(\bar{r})\frac{\partial S(\bar{r},t,s)}{\partial\bar{r}}\\&-\frac{3\bar{r}(1-\bar{r})}{[S(\bar{r},t,s)]^4}\frac{\partial S(\bar{r},t,s)}{\partial\bar{r}}\int_0^{\bar{r}}a(S(\rho,t,s))q(\rho)\\&\left[\frac{S(\rho,t,s)}{\rho}\right]^2\frac{\partial S(\rho,t,s)}{\partial\rho}\rho^2d\rho.\end{aligned}$$

Using these expressions and a similar argument as before, we have

$$\sup_{0<\bar{r}<1}\bar{r}(1-\bar{r})\left|\widetilde{L}(q)'(\bar{r})-L(q)'(\bar{r})\right|\le C\varepsilon\left(e^{-\mu s}-e^{-\mu t}\right)\|a\|_{C_V^1[0,1]}\|q\|_\infty. \tag{5.36}$$

To save space, we omit the details here. By (5.35) and (5.36), we see that (5.34) follows. □

6. Decay estimates. In this section we establish a decay estimate for the evolution system $\{\mathbb{U}(t,s,V):t\ge s\ge0\}$ obtained in section 4, where $V=V(t)\in C([0,\infty),S_\varepsilon)$, under an additional assumption that $V(t)$ is exponentially decaying as $t\to\infty$.

We first consider the special case where $V = 0$. In this case we have $\mathbb{U}(t, s, V) = e^{(t-s)\mathbb{A}(0)}$. The main result, Theorem 5.1 of [5], gives a decay estimate for $e^{t\mathbb{A}(0)}$ (see (6.8) below). But that estimate contains some singularity at $r = 0$, so that it does not meet our requirement. In what follows we use the fact that $\lim_{r\to 0^+} rp'_*(r) = 0$ ensured by Lemma 3.1 to establish an improved estimate. To this end we need a preliminary lemma, which gives an estimate for the semigroup generated by the following operator $\mathcal{L} = \mathcal{L}_0 + a$:

$$\mathcal{L}q(r) = -w(r)q'(r) + a(r)q(r) \quad \text{for } 0 \le r \le 1,$$

where w and a are given functions.

LEMMA 6.1. *Assume that $w \in C^1[0,1]$ and satisfies (4.3), and $a \in C^1_V[0,1]$. Then $\mathcal{L}$ generates a C_0 semigroup $e^{t\mathcal{L}}$ on $C[0,1]$ satisfying the following estimate:*

$$\left\|e^{t\mathcal{L}}\right\|_{L(C[0,1])} \le e^{\omega_0 t} \quad \textit{for } t \ge 0, \tag{6.1}$$

where $\omega_0 = \max_{0\le r\le 1} a(r)$. Moreover, $C^1_V[0,1]$ is $\mathcal{L}$-admissible, and, for any $\omega > \omega_0$, we have

$$\left\|e^{t\mathcal{L}}\right\|_{L(C^1_V[0,1])} \le C_\omega e^{\omega t} \quad \textit{for } t \ge 0. \tag{6.2}$$

Here, C_ω is independent of the function w.

The proof is similar to that of Lemma 4.1, so that is omitted. □

LEMMA 6.2. *There exists a constant $\mu^* > 0$ such that, for any $0 < \mu < \mu^*$, the semigroup $e^{t\mathbb{A}(0)}$ $(t \ge 0)$ generated by $\mathbb{A}(0)$ satisfies the following estimate:*

$$\left\|e^{t\mathbb{A}(0)}\right\|_{L(C[0,1])} \le Ce^{-\mu t} \quad \textit{for } t \ge 0. \tag{6.3}$$

Proof. Given $U_0 = (\phi_0, \zeta_0) \in X$, let $U(t) = e^{t\mathbb{A}(0)}U_0 = (\phi(r,t), \zeta(t))$. Then (ϕ, ζ) is the unique solution of the following initial value problem:

$$\partial_t\phi + u_*(r)\partial_r\phi = a(r)\phi + \mathcal{B}(\phi) + b(r)\zeta \quad \text{for } 0 \le r \le 1, \ t > 0, \tag{6.4}$$

$$\frac{d\zeta}{dt} = \mathcal{F}(\phi) + \kappa\zeta \quad \text{for } t > 0, \tag{6.5}$$

$$\phi(r,0) = \phi_0(r) \quad \text{for } 0 \le r \le 1, \quad \zeta(0) = \zeta_0, \tag{6.6}$$

where $a(r), b(r), \mathcal{B}(\phi), \mathcal{F}(\phi)$, and κ are given in (2.19)–(2.23). By Theorem 5.1 of [5] and the remark in the end of section 8 of [5], we know that there exists a constant $\sigma^* > 0$ and a function $\hat\phi \in C^1(0,1]$ satisfying

$$\hat\phi(r) > 0 \quad \text{for } 0 < r \le 1, \quad \hat\phi(r) \sim Cr^{-\theta} \quad \text{for } r \to 0 \tag{6.7}$$

for some constants $1 \le \theta < 3$ and $C > 0$, such that the solution of the above problem satisfies the following estimate:

$$|\zeta(t)| + \sup_{0<r\le 1}\left|\frac{\phi(r,t)}{\hat\phi(r)}\right| \le C\left(|\zeta_0| + \sup_{0<r\le 1}\left|\frac{\phi_0(r)}{\hat\phi(r)}\right|\right)(1+t)^2e^{-\sigma^* t} \quad \text{for } t \ge 0. \tag{6.8}$$

This particularly implies that, for any $0 < \sigma < \sigma^*$ and $\delta \in (0,1)$, we have

$$|\zeta(t)| + \sup_{\delta\le r\le 1}|\phi(r,t)| \le C\left(|\zeta_0| + \sup_{0\le r\le 1}|\phi_0(r)|\right)e^{-\sigma t} \quad \text{for } t \ge 0, \tag{6.9}$$

because $1/\hat{\phi}(r)$ has a positive lower bound for $\delta \le r \le 1$ and a finite upper bound for $0 \le r \le 1$. In what follows we prove that, for δ sufficiently small, there also holds

$$\sup_{0\le r\le\delta} |\phi(r,t)| \le Ce^{-\mu t} \quad \text{for } t \ge 0 \tag{6.10}$$

for some $\mu > 0$.

Take a nonnegative cut-off function $\varphi \in C[0,1]$ such that

$$\varphi(r) \le 1 \quad \text{for } 0 \le r \le 1, \quad \varphi(r) = 1 \quad \text{for } 0 \le r \le \delta, \quad \varphi(r) = 0 \quad \text{for } 2\delta \le r \le 1.$$

We split $\mathcal{B}$ into a sum of two operators as follows:

$$\mathcal{B}(q) = \mathcal{B}_1(q) + \mathcal{B}_2(q) \quad \text{for } q \in C[0,1], \tag{6.11}$$

where

$$\mathcal{B}_1(q) = -rp'_*(r)\varphi(r)\cdot\frac{1}{r^3}\int_0^{\min\{r,\delta\}} g_p(\rho)q(\rho)\rho^2 d\rho,$$

$$\mathcal{B}_2(q) = rp'_*(r)\int_0^1 g_p(\rho)q(\rho)\rho^2 d\rho - r^{-2}p'_*(r)[1-\varphi(r)]\int_0^{\min\{r,\delta\}} g_p(\rho)q(\rho)\rho^2 d\rho$$
$$- r^{-2}p'_*(r)\int_{\min\{r,\delta\}}^r g_p(\rho)q(\rho)\rho^2 d\rho$$

and introduce $f(r,t) = \mathcal{B}_2(\phi(\cdot,t))(r) + b(r)\zeta(t)$. By (6.4) and (6.11), we see that ϕ is the solution of the equation

$$\partial_t\phi + u_*(r)\partial_r\phi = a(r)\phi + \mathcal{B}_1(\phi) + f(r,t) \quad \text{for } 0 \le r \le 1, \ \ t > 0 \tag{6.12}$$

subject to the initial condition $\phi(r,0) = \phi_0(r)$. Introducing operators $\mathcal{L}(q) = -u_*q' + aq$, we see that (6.12) can be rewritten as the following differential equation in $C[0,1]$:

$$\frac{d\phi(\cdot,t)}{dt} = (\mathcal{L}+\mathcal{B}_1)(\phi(\cdot,t)) + f(\cdot,t). \tag{6.13}$$

Using Lemma 6.1 we see that the operator $\mathcal{L}$ generates a strongly continuous semigroup $e^{t\mathcal{L}}$ on $C[0,1]$, and $\|e^{t\mathcal{L}}\| \le e^{-\omega t}$ for all $t \ge 0$ where $\omega = \min_{0\le r\le 1}|a(r)| > 0$ and using the facts that $\lim_{r\to 0} rp'_*(r) = 0$ and $\varphi(r) = 0$ for $r \ge 2\delta$, we can easily deduce that, for any given $\varepsilon > 0$, there exists corresponding $\delta > 0$ such that $\|\mathcal{B}_1(q)\|_\infty \le \varepsilon\|q\|_\infty$, or, in other words, $\mathcal{B}_1$ is a bounded linear operator on $C[0,1]$, with norm dorminated by ε. Thus, the operator $\mathcal{L}+\mathcal{B}_1$ also generates a strongly continuous semigroup $e^{t(\mathcal{L}+\mathcal{B}_1)}$ on $C[0,1]$, and it satisfies

$$\|e^{t(\mathcal{L}+\mathcal{B}_1)}\| \le e^{-(\omega-\varepsilon)t} \quad \text{for all } \ t \ge 0. \tag{6.14}$$

In what follows we assume that ε is sufficiently small such that $\omega - \varepsilon > 0$. By (6.13), we have

$$\phi(\cdot,t) = e^{t(\mathcal{L}+\mathcal{B}_1)}\phi_0 + \int_0^t e^{(t-\tau)(\mathcal{L}+\mathcal{B}_1)} f(\cdot,\tau)d\tau. \tag{6.15}$$

Using (6.7), (6.8), and (6.9), we can easily show that $\|f(\cdot,t)\|_\infty \le C_\delta\|U_0\|e^{-\sigma t}$ for $t \ge 0$. Hence, from (6.15) and (6.14) we see that, for any $0 < \mu < \min\{\sigma, \omega-\varepsilon\}$, there holds

$$\|\phi(\cdot,t)\|_\infty \le \|\phi_0\|_\infty e^{-(\omega-\varepsilon)t} + C\|U_0\|e^{-\mu t} \quad \text{for } \ t \ge 0,$$

from which (6.10) immediately follows.

Combining (6.9) and (6.10), we get (6.3). This completes the proof. □

LEMMA 6.3. *Let μ^* be as in Lemma 6.2. Then, for any $0 < \mu < \mu^*$, in addition to (6.3), we also have the following estimate:*

$$\left\|e^{t\mathbb{A}(0)}\right\|_{L(C_V^1[0,1])} \le Ce^{-\mu t} \quad \text{for } t \ge 0. \tag{6.16}$$

Proof. We first show that $\mathcal{B}$ and $\mathcal{F}$ satisfy the following properties: For any $q \in C_V^1[0,1]$,

$$\|\mathcal{B}(u_*q')\|_\infty + \|u_*\mathcal{B}(q)'\|_\infty \le C\|q\|_\infty, \tag{6.17}$$

$$|\mathcal{F}(u_*q')| \le C\|q\|_\infty. \tag{6.18}$$

Using the facts that $\lim_{r\to 0} rp_*'(r) = 0$ and $\lim_{r\to 0} r^2p_*''(r) = 0$ (see (3.3)), we can easily prove that $\|u_*\mathcal{B}(q)'\|_\infty \le C\|q\|_\infty$ for $q \in C[0,1]$. To estimate $\|\mathcal{B}(u_*q')\|_\infty$, we compute

$$\frac{1}{r^3}\int_0^r g_p(\rho)u_*(\rho)q'(\rho)\rho^2 d\rho = \frac{1}{r}u_*(r)g_p(r)q(r) - \frac{1}{r^3}\int_0^r m(\rho)q(\rho)\rho^2 d\rho,$$

where $m(\rho) = g_p'(\rho)u_*(\rho) + g_p(\rho)u_*'(\rho) + \frac{2}{\rho}u_*(\rho)g_p(\rho)$. Taking $r = 1$ we particularly obtain

$$\int_0^1 g_p(\rho)u_*(\rho)q'(\rho)\rho^2 d\rho = u_*(1)g_p(1)q(1) - \int_0^1 m(\rho)q(\rho)\rho^2 d\rho.$$

Since $g_p \in C^1[0,1]$, $u_* \in C^1[0,1]$, and $u_*(0) = 0$, we see that $\frac{1}{r}u_*g_p$ and m both belong to $C[0,1]$. Hence, from the above expressions we see immediately that

$$\begin{aligned}\|\mathcal{B}(u_*q')\|_\infty &= \sup_{0<r<1}\left|rp_*'(r)\left[\int_0^1 g_p(\rho)u_*(\rho)q'(\rho)\rho^2 d\rho - \frac{1}{r^3}\int_0^r g_p(\rho)u_*(\rho)q'(\rho)\rho^2 d\rho\right]\right| \\ &\le C\|q\|_\infty.\end{aligned}$$

Similarly we have $|\mathcal{F}(u_*q')| = |\int_0^1 g_p(\rho)u_*(\rho)q'(\rho)\rho^2 d\rho| \le C\|q\|_\infty$. This proves (6.17) and (6.18).

We now proceed to prove (6.16). Let $U_0 \in X_0$ and $U = e^{t\mathbb{A}(0)}U_0$. From the proof of Lemma 4.2 we know that $U \in C([0,\infty), X_0) \cap C^1([0,\infty), X)$. Let $U_0 = (q_0, y_0)$ and $U = (q, y)$. Then (q, y) is the solution of the following problem:

$$\begin{cases} \dfrac{\partial q}{\partial t} + u_*(r)\dfrac{\partial q}{\partial r} = a(r)q + \mathcal{B}(q) + b(r)y \quad \text{for } 0 \le r \le 1, \ t > 0, \\ \dfrac{dy}{dt} = \mathcal{F}(q) + \kappa y \quad \text{for } t > 0, \\ q|_{t=0} = q_0(r) \quad \text{for } 0 \le r \le 1, \quad \text{and} \quad y|_{t=0} = y_0. \end{cases}$$

Let $l(r,t) = u_*(r)\frac{\partial q(r,t)}{\partial r}$. By formally differentiating the first equation above in r and multiplying it with $u_*(r)$, we see that (l, y) is a formal solution of the following problem:

$$\begin{cases} \dfrac{\partial l}{\partial t} + u_*(r)\dfrac{\partial l}{\partial r} = a(r)l + \mathcal{B}(l) + b(r)y + f_1(r,t) \quad \text{for } 0 \le r \le 1, \ t > 0, \\ \dfrac{dy}{dt} = \mathcal{F}(l) + \kappa y + c_1(t) \quad \text{for } t > 0, \\ l|_{t=0} = l_0(r) \quad \text{for } 0 \le r \le 1, \quad \text{and} \quad y|_{t=0} = y_0, \end{cases}$$

where $l_0(r) = u_*(r)q_0'(r)$, $c_1(t) = \mathcal{F}(q) - \mathcal{F}(u_*\frac{\partial q}{\partial r})$, and

$$f_1(r,t) = u_*(r)a'(r)q(r,t) - \mathcal{B}\left(u_*\frac{\partial q}{\partial r}\right) + u_*(r)\frac{\partial \mathcal{B}(q)}{\partial r} + [u_*(r)b'(r) - b(r)]y(t).$$

We denote $W(t) = (l(\cdot,t), y(t))$, $W_0 = (l_0, y_0)$, and $F_1(t) = (f_1(\cdot,t), c_1(t))$. Then the above problem can be rewritten as follows:

$$\frac{dW}{dt} = \mathbb{A}(0)W + F_1(t) \quad \text{for } t > 0, \quad W(0) = W_0.$$

Using the fact that $U \in C^1([0,\infty), X)$, Corollary 3.2, (6.17), and (6.18), we can easily prove that $F_1 \in C^1([0,\infty), X)$. Thus, by a standard result, we see that the above problem has a unique mild solution, and consequently, the above formal computation makes sense. Moreover, we have

$$W(t) = e^{t\mathbb{A}(0)}W_0 + \int_0^t e^{(t-s)\mathbb{A}(0)}F_1(s)ds \quad \text{for } t \geq 0.$$

From this expression and Lemma 6.2 we see that, for any given $0 < \mu < \mu_*$, we have

$$\|W(t)\|_X \leq Ce^{-\mu t}\|W_0\|_X + C\int_0^t e^{-\mu(t-s)}\|F_1(s)\|_X ds \quad \text{for } t \geq 0.$$

Using (6.17), (6.18), and the fact that $\|U(t)\|_X \leq Ce^{-\mu t}\|U_0\|_X$ ensured by (6.3), we see that

$$\|F_1(t)\|_X \leq C\|U(t)\|_X \leq Ce^{-\mu t}\|U_0\|_X \quad \text{for } t \geq 0.$$

Substituting this estimate into the above inequality and noticing that $W(t) = (u_*\frac{\partial q(\cdot,t)}{\partial r}, y(t))$ and $W_0 = (u_*q_0', y_0)$, we obtain

$$\|U(t)\|_{X_0} \leq C(1+t)e^{-\mu t}\|U_0\|_{X_0} \quad \text{for } t \geq 0.$$

Now, for any given $0 < \mu < \mu_*$, we arbitrarily take a $\bar{\mu} \in (\mu, \mu_*)$ and first use the above estimate to $\bar{\mu}$ and next use the elementary inequality $(1+t)e^{-\bar{\mu}t} \leq Ce^{-\mu t}$, we see that (6.16) follows. This completes the proof. □

In what follows we consider the evolution system $\mathbb{U}(t,s,V)$ for a general $V = V(t) \in C([0,\infty), X)$ satisfying the following condition: For some positive constants $\bar{\mu}$, ε and C_0,

$$\|V(t)\|_X \leq C_0\varepsilon e^{-\bar{\mu}t} \quad \text{for } t \geq 0. \tag{6.19}$$

LEMMA 6.4. *Assume that $V = V(t) \in C([0,\infty), X)$, and it satisfies* (6.19). *Let μ^* be as in Lemma* 6.2. *Then, for any $0 < \mu < \mu^*$, there exists corresponding $\varepsilon_0 > 0$ (depending on μ, $\bar{\mu}$, and C_0) such that if $0 < \varepsilon \leq \varepsilon_0$, then the following estimates hold:*

$$\|\mathbb{U}(t,s,V)\|_{L(X)} \leq C_1e^{-\mu t} \quad \textit{for } t \geq 0, \tag{6.20}$$

$$\|\mathbb{U}(t,s,V)\|_{L(X_0)} \leq C_2e^{-\mu t} \quad \textit{for } t \geq 0, \tag{6.21}$$

where C_1 and C_2 are positive constants depending only on μ and independent of $\bar{\mu}$ and C_0.

Proof. Given $0 < \mu < \mu^*$ we take a $\mu_1 \in (\mu, \mu^*)$ and fix it. By Lemmas 6.2 and 6.3, we have the following estimates:

$$\left\|e^{t\mathbb{A}(0)}\right\|_{L(C[0,1])} \le C_1 e^{-\mu_1 t} \quad \text{for } t \ge 0, \tag{6.22}$$

$$\left\|e^{t\mathbb{A}(0)}\right\|_{L(C^1_V[0,1])} \le C_2 e^{-\mu_1 t} \quad \text{for } t \ge 0. \tag{6.23}$$

Let $U_0 = (q_0, s_0)$ be an arbitrary point in X, and let $U = \mathbb{U}(t, s, V)U_0$. By definition, U is the solution of the problem (4.12). Let $U = (q, y)$. Then (4.12) can be rewritten as follows:

$$\begin{cases} \dfrac{\partial q}{\partial t} + w_V(r,t)\dfrac{\partial q}{\partial r} = a(r)q + \mathcal{B}q + b(r)y \quad \text{for } 0 \le r \le 1, \ \ t > s, \\ \dfrac{dy}{dt} = \mathcal{F}(q) + \kappa y \quad \text{for } t > s, \\ q|_{t=s} = q_0(r) \quad \text{for } 0 \le r \le 1, \quad \text{and} \quad y|_{t=s} = y_0. \end{cases} \tag{6.24}$$

Let $\bar r = T(r,t,s)$ and $r = S(\bar r, t, s)$ be as defined in section 5, and let $\widetilde q(\bar r, t, s) = q(S(\bar r, t, s), t)$, or, equivalently, $q(r,t) = \widetilde q(T(r,t,s), t, s)$. Then by using (5.7), we see that (6.24) is transformed into the following problem:

$$\begin{cases} \dfrac{\partial \widetilde q}{\partial t} + u_*(\bar r)\dfrac{\partial \widetilde q}{\partial \bar r} = \widetilde a(\bar r, t, s)\widetilde q + \widetilde{\mathcal{B}}\widetilde q + \widetilde b(\bar r, t, s)s \quad \text{for } 0 \le \bar r \le 1, \ \ t > s, \\ \dfrac{ds}{dt} = \widetilde{\mathcal{F}}(\widetilde q)(t,s) + \kappa s \quad \text{for } t > s, \\ \widetilde q|_{t=s} = q_0(\bar r) \quad \text{for } 0 \le \bar r \le 1, \quad \text{and} \quad s|_{t=s} = s_0, \end{cases} \tag{6.25}$$

where $\widetilde a(\bar r, t, s) = a(S(\bar r, t, s))$, $\widetilde b(\bar r, t, s) = b(S(\bar r, t, s))$,

$$\widetilde{\mathcal{B}}\widetilde q = rp'_*(r)\left[\int_0^1 g_p(\rho)\widetilde q(T(\rho,t,s),t,s)\rho^2 d\rho - \frac{1}{r^3}\int_0^r g_p(\rho)\widetilde q(T(\rho,t,s),t,s)\rho^2 d\rho\right]\Bigg|_{r=S(\bar r,t,s)},$$

and $\widetilde{\mathcal{F}}(\widetilde q)(t,s) = \int_0^1 g_p(\rho)\widetilde q(T(\rho,t,s),t,s)\rho^2 d\rho$. We define a family of bounded linear operators $\widetilde{\mathbb{B}}(t,s,V) : X \to X$ $(t \ge s \ge 0)$ as follows:

$$\widetilde{\mathbb{B}}(t,s,V) = \begin{pmatrix} \widetilde a(\cdot,t,s) + \widetilde{\mathcal{B}} & \widetilde b(\cdot,t,s) \\ \widetilde{\mathcal{F}} & \kappa \end{pmatrix}.$$

We also denote $\widetilde U = (\widetilde q, y)$. Then (6.25) can be rewritten as follows:

$$\frac{d\widetilde U}{dt} = \mathbb{A}_0(U_*)\widetilde U + \widetilde{\mathbb{B}}(t,s,V)\widetilde U \quad \text{for } t > s, \quad \widetilde U|_{t=s} = U_0. \tag{6.26}$$

Recalling that $\mathbb{A}(0) = \mathbb{A}_0(U_*) + \mathbb{B}$ and denoting

$$\widetilde{\mathbb{E}}(t,s,V) = \widetilde{\mathbb{B}}(t,s,V) - \mathbb{B} = \begin{pmatrix} \widetilde a(\cdot,t,s) - a + \widetilde{\mathcal{B}} - \mathcal{B} & \widetilde b(\cdot,t,s) - b \\ \widetilde{\mathcal{F}} - \mathcal{F} & 0 \end{pmatrix},$$

we see that

$$\mathbb{A}_0(U_*) + \widetilde{\mathbb{B}}(t,s,V) = \mathbb{A}_0(U_*) + \mathbb{B} + \widetilde{\mathbb{E}}(t,s,V) = \mathbb{A}(0) + \widetilde{\mathbb{E}}(t,s,V).$$

Hence, (6.26) can be further rewritten as follows:

$$\frac{d\widetilde{U}}{dt} = \mathbb{A}(0)\widetilde{U} + \widetilde{\mathbb{E}}(t,s,V)\widetilde{U} \quad \text{for } t > s, \quad \widetilde{U}|_{t=s} = U_0. \tag{6.27}$$

We know that (6.27) is equivalent to the following integral equation:

$$\widetilde{U}(t,s) = e^{(t-s)\mathbb{A}(0)}U_0 + \int_s^t e^{(t-\tau)\mathbb{A}(0)}\widetilde{\mathbb{E}}(\tau,s,V)\widetilde{U}(\tau,s) \quad \text{for } t \geq s. \tag{6.28}$$

It can be easily shown that, under the assumption (6.19), w_V satisfies the estimates (5.1) and (5.27) (with μ replaced by $\bar{\mu}$). Hence, by Corollary 3.2 and Lemma 5.9, we have

$$\|\widetilde{a}(\cdot,t,s) - a\|_{C_V^1[0,1]} \leq C\varepsilon, \qquad \big\|\widetilde{b}(\cdot,t,s) - b\big\|_{C_V^1[0,1]} \leq C\varepsilon,$$

and by Corollary 3.2, Lemma 5.9, and Lemma 5.10, we have

$$\big\|\widetilde{\mathcal{B}} - \mathcal{B}\big\|_{L(C[0,1])} \leq C\varepsilon, \quad \big\|\widetilde{\mathcal{B}} - \mathcal{B}\big\|_{L(C_V^1[0,1])} \leq C\varepsilon, \quad \big\|\widetilde{\mathcal{F}} - \mathcal{F}\big\|_{L(C[0,1],\mathbb{R})} \leq C\varepsilon.$$

It follows that

$$\big\|\widetilde{\mathbb{E}}(\tau,s,V)\big\|_{L(X)} \leq C\varepsilon, \quad \big\|\widetilde{\mathbb{E}}(\tau,s,V)\big\|_{L(X_0)} \leq C\varepsilon. \tag{6.29}$$

From (6.22), (6.23), (6.28), and (6.29) we obtain

$$\big\|\widetilde{U}(t,s)\big\|_X \leq C_1 e^{-\mu_1(t-s)}\|U_0\|_X + C\varepsilon\int_s^t e^{-\mu_1(t-\tau)}\big\|\widetilde{U}(\tau,s)\big\|_X,$$

$$\big\|\widetilde{U}(t,s)\big\|_{X_0} \leq C_2 e^{-\mu_1(t-s)}\|U_0\|_{X_0} + C\varepsilon\int_s^t e^{-\mu_1(t-\tau)}\big\|\widetilde{U}(\tau,s)\big\|_{X_0}.$$

By the Gronwall lemma, these inequalities yield

$$\big\|\widetilde{U}(t,s)\big\|_X \leq C_1 e^{-(\mu_1 - C\varepsilon)t}\|U_0\|_X, \quad \big\|\widetilde{U}(t,s)\big\|_{X_0} \leq C_2 e^{-(\mu_1 - C\varepsilon)t}\|U_0\|_{X_0}.$$

Hence, by taking ε sufficiently small such that $\mu_1 - C\varepsilon \geq \mu$, we obtain (6.20) and (6.21). This completes the proof. □

7. The proof of Theorem 1.1. In order to prove Theorem 1.1, we let μ^* be as in Lemma 6.2 and arbitrarily fix a number $0 < \mu < \mu^*$. Let ε be a positive number to be specified later. For any fixed $U_0 \in X_0$ satisfying $\|U_0\|_{X_0} \leq \varepsilon$, we denote by $\mathbf{M}$ the set of all functions $V = V(t) \in C([0,\infty), X)$ satisfying the following conditions:

$$V(0) = U_0, \quad \|V(t)\|_X \leq 2C_1\varepsilon e^{-\mu t} \quad \text{for } t \geq 0, \tag{7.1}$$

where C_1 is the constant appearing in (6.20). We introduce a metric d on $\mathbf{M}$ by defining $d(V_1,V_2) = \sup_{t\geq 0} e^{\mu t}\|V_1(t) - V_2(t)\|_X$ for $V_1, V_2 \in \mathbf{M}$. It is evident that $(\mathbf{M}, d)$ is a complete metric space. Given $V \in \mathbf{M}$, we consider the following initial value problem:

$$\frac{dU(t)}{dt} = \mathbb{A}(V(t))U(t) + \mathbb{G}(U(t)) \quad \text{for } t > 0, \quad U(0) = U_0. \tag{7.2}$$

LEMMA 7.1. *If ε is sufficiently small, then, for any $V \in \mathbf{M}$, problem (7.2) has a unique solution $U \in C([0,\infty), X_0) \cap C^1([0,\infty), X)$, which satisfies the following estimates:*

(7.3)
$$\|U(t)\|_X \le 2C_1\varepsilon e^{-\mu t}, \quad \|U(t)\|_{X_0} \le C\varepsilon e^{-\mu t}, \quad \|U'(t)\|_X \le C\varepsilon e^{-\mu t} \quad \text{for } t \ge 0,$$

where C_1 is as before, and C is another constant independent of V.

Proof. We denote

$$\widetilde{\mathbf{M}} = \{U \in C([0,\infty), X_0) : \|U(t)\|_X \le 2C_1\varepsilon e^{-\mu t} \text{ and } \|U(t)\|_{X_0} \le 2C_2\varepsilon e^{-\mu t} \text{ for } t \ge 0\}$$

and introduce a metric d on it by defining $d(U_1, U_2) = \sup_{t\ge 0} e^{\mu t}\|U_1(t) - U_2(t)\|_{X_0}$ for $U_1, U_2 \in \widetilde{\mathbf{M}}$. Here, C_1 and C_2 are positive constants appearing in (6.20) and (6.21), respectively. $(\widetilde{\mathbf{M}}, d)$ is clearly a complete metric space. Given $U \in \widetilde{\mathbf{M}}$, we consider the following initial value problem:

$$\frac{d\widetilde{U}(t)}{dt} = \mathbb{A}(V(t))\widetilde{U}(t) + \mathbb{G}(U(t)) \quad \text{for } t > 0, \quad \widetilde{U}(0) = U_0. \tag{7.4}$$

Since $U(t) \in C([0,\infty), X_0)$, by Corollary 3.3, we have $\mathbb{G}(U(t)) \in C([0,\infty), X_0)$. It follows by Corollary 4.4 that the above problem has a unique solution $\widetilde{U} \in C([0,\infty), X_0) \cap C^1([0,\infty), X)$ and is given by

$$\widetilde{U}(t) = \mathbb{U}(t,0,V)U_0 + \int_0^t \mathbb{U}(t,s,V)\mathbb{G}(U(s))ds. \tag{7.5}$$

Using this expression and Lemma 6.4 and (2.18) we have

$$\begin{aligned}\left\|\widetilde{U}(t)\right\|_X &\le C_1 e^{-\mu t}\|U_0\|_X + C_1\int_0^t e^{-\mu(t-s)}\|\mathbb{G}(U(s))\|_X ds \\ &\le C_1\varepsilon e^{-\mu t} + C\int_0^t e^{-\mu(t-s)}\|U(s)\|_X^2 ds \le 2C_1\varepsilon e^{-\mu t},\end{aligned}$$

when ε is sufficiently small. Similarly, by using Lemma 6.4 and (3.9), we also have $\|\widetilde{U}(t)\|_{X_0} \le 2C_2\varepsilon e^{-\mu t}$, when ε is sufficiently small. Hence, $\widetilde{U} \in \widetilde{\mathbf{M}}$. We now define a mapping $\widetilde{\mathbf{S}} : \widetilde{\mathbf{M}} \to \widetilde{\mathbf{M}}$ by setting $\widetilde{\mathbf{S}}(U) = \widetilde{U}$ for every $U \in \widetilde{\mathbf{M}}$. We claim that $\widetilde{\mathbf{S}}$ is a contraction mapping. Indeed, for any $U_1, U_2 \in \widetilde{\mathbf{M}}$, let $\widetilde{U}_1 = \mathbf{S}(U_1)$, $\widetilde{U}_2 = \mathbf{S}(U_2)$, and $W = \widetilde{U}_1 - \widetilde{U}_2$. Then W satisfies

$$\frac{dW(t)}{dt} = \mathbb{A}(V(t))W(t) + [\mathbb{G}(U_1(t)) - \mathbb{G}(U_2(t))] \quad \text{for } t > 0, \quad W(0) = 0,$$

so that $W(t) = \int_0^t \mathbb{U}(t,s,V)[\mathbb{G}(U_1(s)) - \mathbb{G}(U_2(s))]ds$. It follows that

$$\begin{aligned}\|W(t)\|_{X_0} &\le C_2\int_0^t e^{-\mu(t-s)}\|\mathbb{G}(U_1(s) - \mathbb{G}(U_2(s)))\|_{X_0} ds \\ &\le C_2\int_0^t e^{-\mu(t-s)}\|U_1(s) - U_2(s)\|_{X_0} \\ &\quad \left(\int_0^1 \|\mathbb{G}'(\theta U_1(s) + (1-\theta)U_2(s))\|_{L(X_0)} d\theta\right) ds \\ &\le C\int_0^t e^{-\mu(t-s)}\|U_1(s) - U_2(s)\|_{X_0}\left(\int_0^1 \|\theta U_1(s) + (1-\theta)U_2(s)\|_{X_0} d\theta\right) ds,\end{aligned}$$

which yields $\|W(t)\|_{X_0} \le C\varepsilon d(U_1,U_2)e^{-\mu t}$. Thus, for ε sufficiently small, we have $d(\widetilde{U}_1,\widetilde{U}_2) = \sup_{t\ge 0} e^{\mu t}\|W(t)\|_{X_0} \le \frac{1}{2}d(U_1,U_2)$, showing that $\widetilde{\mathbf{S}}$ is a contraction mapping, as we claimed. Thus, by the Banach fixed point theorem, we see that $\widetilde{\mathbf{S}}$ has a unique fixed point in $\widetilde{\mathbf{M}}$, which is clearly a solution of the problem (7.2) in $C([0,\infty),X_0)$. The uniqueness of the solution follows from a standard argument.

From the above argument we see that the solution U of (7.2) satisfies the first two inequalities in (7.3), and $U \in C^1([0,\infty),X)$. It remains to prove that U also satisfies the last inequality in (7.3). The argument is as follows. First, it is straightforward to deduce from condition (7.1) that, for sufficiently small $\varepsilon > 0$, we have $w_V(r,t)/r(1-r) \in C[0,1]$, and there exist positive constants C_1 and C_2 independent of V such that

$$-C_1 r(1-r) \le w_V(r,t) \le -C_2 r(1-r) \quad \text{for } 0 \le r \le 1 \text{ and } t \ge 0. \tag{7.6}$$

It follows that, for the solution $U = (q,s)$ of (7.2), we have

$$\sup_{0\le r\le 1}\left|w_V(r,t)\frac{\partial q(r,t)}{\partial r}\right| \le C \sup_{0\le r\le 1}\left|r(1-r)\frac{\partial q(r,t)}{\partial r}\right| \le C\|q(\cdot,t)\|_{C^1_V[0,1]}.$$

Using this result and (7.2), we see that

$$\|U'(t)\|_X \le \|\mathbb{A}(V(t))U(t)\|_X + \|\mathbb{G}(U(t)\|_X \le C\|U(t)\|_{X_0} + C\|U(t)\|_X^2 \le C\varepsilon e^{-\mu t}$$

for all $t \ge 0$. This completes the proof of Lemma 7.1. ∎

Lemma 7.1, in particular, implies that, for every V in $\mathbf{M}$, the solution U of (7.2) also belongs to $\mathbf{M}$. Thus we can define a mapping $\mathbf{S} : \mathbf{M} \to \mathbf{M}$ as follows: For any $V \in \mathbf{M}$,

$$\mathbf{S}(V) = U = \text{the solution of (7.2)}.$$

LEMMA 7.2. *For ε sufficiently small, $\mathbf{S}$ is a contraction mapping.*

Proof. Let $V_1, V_2 \in \mathbf{M}$ and denote $U_1 = \mathbf{S}(V_1)$, $U_2 = \mathbf{S}(V_2)$, and $W = U_1 - U_2$. Then W satisfies

$$\frac{dW(t)}{dt} = \mathbb{A}(V_1(t))W(t) + [\mathbb{A}(V_1(t)) - \mathbb{A}(V_2(t))]U_2(t) + [\mathbb{G}(U_1(t)) - \mathbb{G}(U_2(t))]$$

for $t > 0$, and $W(0) = 0$. Thus

$$\begin{aligned} W(t) &= \int_0^t \mathbb{U}(t,s,V_1)[\mathbb{A}(V_1(s)) - \mathbb{A}(V_2(s))]U_2(s)ds \\ &\quad + \int_0^t \mathbb{U}(t,s,V_1)[\mathbb{G}(U_1(s)) - \mathbb{G}(U_2(s))]ds. \end{aligned} \tag{7.7}$$

Since the first component of $[\mathbb{A}(V_1(s)) - \mathbb{A}(V_2(s))]U_2(s)$ is $[w_{V_2}(r,s) - w_{V_1}(r,s)]q_2'(r,s)$ and the second component is zero, we have

$$\begin{aligned} \|[\mathbb{A}(V_1(s)) - \mathbb{A}(V_2(s))]U_2(s)\|_X &= \max_{0\le r\le 1}|[w_{V_1}(r,s) - w_{V_2}(r,s)]q_2'(r,s)| \\ &\le \sup_{0\le r\le 1}\left|\frac{w_{V_1}(r,s) - w_{V_2}(r,s)}{r(1-r)}\right| \max_{0\le r\le 1}|r(1-r)q_2'(r,s)| \\ &\le C\|V_1(s) - V_2(s)\|_X \|U_2(s)\|_{X_0}. \end{aligned} \tag{7.8}$$

Besides, from (2.18) we have

$$\|\mathbb{G}(U_1(s)) - \mathbb{G}(U_2(s))\|_X = \left\| \int_0^1 \mathbb{G}'(\theta U_1(s) + (1-\theta)U_2(s))[U_1(s) - U_2(s)]d\theta \right\|_X$$
$$\leq C\left(\|U_1(s)\|_X + \|U_2(s)\|_X\right)\|U_1(s) - U_2(s)\|_X. \tag{7.9}$$

From (7.7)–(7.9) and Lemma 6.4 we get

$$\begin{aligned}\|U_1(t) - U_2(t)\|_X &\leq C\int_0^t e^{-\mu(t-s)}\|V_1(s) - V_2(s)\|_X\|U_2(s)\|_{X_0}ds \\ &\quad + C\int_0^t e^{-\mu(t-s)}\left(\|U_1(s)\|_X + \|U_2(s)\|_X\right)\|U_1(s) - U_2(s)\|_X ds \\ &\leq C\varepsilon e^{-\mu t}d(V_1, V_2) + C\varepsilon e^{-\mu t}d(U_1, U_2),\end{aligned}$$

which yields $d(U_1, U_2) \leq C\varepsilon d(V_1, V_2) + C\varepsilon d(U_1, U_2)$. From this inequality the desired assertion easily follows. □

By Lemma 7.2, if ε is sufficiently small, then the mapping $\mathbf{S}$ has a unique fixed point U in $\mathbf{M}$. Clearly, U is a global solution of (2.16) subject to the initial condition $U(0) = U_0$. Moreover, by Lemma 7.1, we know that the image of $\mathbf{S}$ is contained in $\widetilde{\mathbf{M}}$ so that U satisfies (7.3). From this result and Lemma 2.1 we see that the assertion of Theorem 1.1 follows. This completes the proof of Theorem 1.1.

Acknowledgments. Part of this work was prepared when the author was visiting the Ecole Normale Superieur (ENS) during June 1–August 28, 2007. He wishes to acknowledge his gratefulness to all staff and faculty of the Department of Mathematics and Applications of ENS, particularly Prof. Perthame and Prof. Rosso, for their hospitality, and the French Ministry of Foreign Affairs, particularly the Section of Science and Technology of the French Consulate at Guangzhou, for financial support for his visit. WELL-POSEDNESS AND CONVERGENCE TO THE STEADY STATE FOR A MODEL OF MORPHOGEN TRANSPORT*

PIOTR KRZYŻANOWSKI†, PHILIPPE LAURENÇOT‡, AND DARIUSZ WRZOSEK†

Abstract. Well-posedness and large time convergence to the unique steady state are shown for a model which describes the spreading of morphogens by a nonlinear transport mechanism (transcytosis) and couples a quasilinear parabolic partial differential equation with an ordinary differential equation. A simpler model which assumes linear transport is also investigated for comparison. The analysis of both models requires the construction of specific Liapunov functionals. The study is supplemented by numerical simulations of the sensitivity of the models to the variation of their parameters.

Key words. degenerate parabolic system, Liapunov functional, steady state

1. Introduction.

Morphogens are signaling molecules that play an important role in the process of cell differentiation, as different morphogen concentrations induce distinct cell fates. In fact, during cell development, spatial gradients of morphogen concentration form while the morphogens move away from a spatially localized source. It is, however, yet unclear whether the spreading of morphogens occurs by passive diffusion in the extracellular medium or by more complex mechanisms such as planar transcytosis (see, e.g., [5, 11] and the references therein). Planar transcytosis explains the transport of morphogens across the tissue as the consequence of repeated cycles of internalization of morphogens inside the cell (endocytosis) and release of morphogens outside the cell (exocytosis) together with the binding and unbinding of morphogens to receptors located at the surface of the cell. A related model accounting only for the latter mechanism was introduced in [6].

A model for the transport of morphogens by passive diffusion was recently derived in [8, Model B] and describes the space and time evolution of the concentrations of free morphogens ℓ and bound receptors s: in dimensionless form, it reads

$$\partial_t \ell = D\, \partial_x^2 \ell + \delta\, s - \ell\,(1-s), \quad (t,x) \in (0,\infty)\times(0,1), \tag{1.1}$$

$$\partial_t s = \ell\,(1-s) - (\delta+\varepsilon)\, s, \quad (t,x) \in (0,\infty)\times(0,1), \tag{1.2}$$

supplemented by suitable boundary and initial conditions. In this model, the total number of receptors (free + bound) per cell is assumed to be constant and normalized to one. The reaction terms account for the depletion of free morphogens resulting from the binding with free receptors ($-\ell\,(1-s)$), the release of free morphogens after unbinding from the receptors ($\delta\, s$), and the degradation of bound receptors ($-\varepsilon\, s$), respectively. An attempt to take into account planar transcytosis is made in

[3, 7]: it gives a system of two equations similar to (1.1)–(1.2), with the noticeable difference that it includes a nonconstant diffusion coefficient in the equation for the free morphogens. It describes the fact that free receptors have to be available for the transport of morphogens to take place. Depending on the assumptions made during the derivation, the equation for the free morphogens might also contain an additional drift term of the form $\partial_x (\chi(\ell, s)\ \partial_x s)$. Let us mention here that such a drift term also shows up in the related model proposed in [9]. We will, however, focus in this paper on a model which does not include an additional drift term of the above-mentioned form but accounts for transcytosis by a nonconstant diffusion coefficient which depends on the concentration of bound receptors and vanishes if no free receptor is available ($s = 1$).

More precisely, the model derived in [7] reads, in dimensionless form,

$$\partial_t \ell = D\ \partial_x \left((1-s)\ \partial_x \ell\right) + \delta\ s - \ell\ (1-s), \quad (t,x) \in (0,\infty) \times (0,1), \tag{1.3}$$

$$\partial_t s = \ell\ (1-s) - (\delta + \varepsilon)\ s, \quad (t,x) \in (0,\infty) \times (0,1), \tag{1.4}$$

$$D\ (1 - s(t,0))\ \partial_x \ell(t,0) + \nu = \ell(t,1) = 0, \quad t \in (0,\infty), \tag{1.5}$$

$$(\ell, s)(0,x) = (\ell_0, s_0)(x), \quad x \in (0,1), \tag{1.6}$$

with $D > 0$, $\delta > 0$, $\varepsilon \ge 0$, and $\nu > 0$. The strength of the diffusion is clearly related to the concentration of bound receptors s and no diffusion takes place in the absence of free receptors. As for the reaction terms, they are the same as for (1.1)–(1.2) though their biological meaning is different: Indeed, the term $(-\ell\ (1-s))$ accounts for the endocytosis process, which combines the binding of a free morphogen with a receptor followed by its internalization, and the term (δs) for the exocytosis process, which includes an externalization step and a dissociation step. Finally, the boundary condition at $x = 0$ accounts for a source of morphogens localized on one side of the tissue. We refer to [7] for a complete derivation of the model, and some additional information as well.

The aim of this paper is to supplement the qualitative study of (1.3)–(1.6) performed in [7] with that of mathematical properties, namely, well-posedness and large time behavior. We first point out that, as (1.3)–(1.6) couples a quasilinear parabolic partial differential equation with an ordinary differential equation, it cannot be studied with the usual techniques for systems of parabolic partial differential equations. Nevertheless, a general theory has been developed in [1] to study this kind of system: applying this theory in a suitable functional framework allows us to establish the local well-posedness of (1.3)–(1.6). A Liapunov functional is then constructed from which we deduce the global well-posedness.

More precisely, we assume that

$$(\ell_0, s_0) \in V \times V \quad \text{with} \quad \ell_0 \ge 0 \quad \text{and} \quad 0 \le s_0 < 1, \tag{1.7}$$

where $V := \{v \in H^1(0,1) \ \text{ such that } \ v(1) = 0\}$ and V' denotes the topological dual of V.

THEOREM 1. *Given initial data (ℓ_0, s_0) satisfying (1.7) the initial-boundary value problem (1.3)–(1.6) possesses a unique weak solution*

$$(\ell, s) \in \mathcal{C}([0,\infty); V \times V) \cap \mathcal{C}^1([0,\infty); V' \times V)$$

such that $\partial_t \ell \in L^2((0,T) \times (0,1))$ for every $T > 0$,

$$0 \le \ell(t,x) \quad \textit{and} \quad 0 \le s(t,x) < 1 \quad \textit{for} \quad (t,x) \in [0,\infty) \times [0,1],$$

and

$$\langle \partial_t \ell(t), \psi \rangle_{V',V} + D \int_0^1 (1 - s(t))\ \partial_x \ell(t)\ \partial_x \psi\ dx = \nu\ \psi(0) + \int_0^1 (\delta s(t) - \ell(t)(1 - s(t)))\ \psi\ dx,$$

$$\partial_t s(t) = -(\delta + \varepsilon) s(t) + \ell(t)(1 - s(t))$$

for $\psi \in V$ *and* $t \in [0, \infty)$. *Furthermore, for each* $t > 0$,

$$\mathcal{L}(s(t), \partial_t \sigma(t)) + \int_0^t \mathcal{D}(s(\tau), \partial_t \sigma(\tau))\ d\tau = \mathcal{L}(s_0, \partial_t \sigma(0)), \tag{1.8}$$

where $\sigma := -\ln(1 - s)$ *and*

$$\mathcal{L}(v, w) := \mathcal{L}_0(v) + \frac{1}{2} \int_0^1 w(x)^2\ dx, \tag{1.9}$$

$$\mathcal{L}_0(v) := \int_0^1 \left\{ \frac{D(\delta + \varepsilon)}{2}\ |\partial_x \Sigma_I(v)(x)|^2 + \varepsilon\ (\Sigma_I(v) - v)(x) - \nu\ \Sigma_I(v)(0) \right\} dx, \tag{1.10}$$

$$\mathcal{D}(v, w) := \int_0^1 \left(1 - v(x) + \frac{\delta + \varepsilon}{1 - v(x)}\right)\ w(x)^2\ dx + D \int_0^1 (1 - v(x))\ |\partial_x w(x)|^2\ dx, \tag{1.11}$$

the function Σ_I *being defined by* $\Sigma_I(r) := -\ln(1 - r)$ *for* $r \in [0, 1)$.

We now turn to the behavior for large times of weak solutions to (1.3)–(1.6) and first recall from [7] that (1.3)–(1.5) has a single stationary solution.

PROPOSITION 2. *There is a unique stationary solution* $(\ell_\infty, s_\infty) \in \mathcal{C}([0, 1]; \mathbb{R}^2)$ *to* (1.3)–(1.5) *satisfying the natural constraints*

$$\ell_\infty(x) \geq 0 \quad \textit{and} \quad 0 \leq s_\infty(x) < 1 \quad \textit{for} \quad x \in [0, 1]. \tag{1.12}$$

The function s_∞ *is the unique solution to the boundary value problem*

$$\begin{aligned} -D\ \partial_x^2 \Sigma_I(s_\infty) + \frac{\varepsilon}{\delta + \varepsilon}\ s_\infty = 0 \quad \textit{in} \quad (0, 1), \\ D\ \partial_x \Sigma_I(s_\infty)(0) + \frac{\nu}{\delta + \varepsilon} = s_\infty(1) = 0, \end{aligned} \tag{1.13}$$

while ℓ_∞ *is given by* $\ell_\infty(x) = (\delta + \varepsilon) s_\infty(x)/(1 - s_\infty(x))$ *for* $x \in [0, 1]$.

With this notation, our second result reads as follows.

THEOREM 3. *Consider* (ℓ_0, s_0) *satisfying* (1.7) *and let* (ℓ, s) *be the corresponding weak solution to the initial-boundary value problem* (1.3)–(1.6). *Then* $(\ell(t), s(t))$ *converges (strongly) towards* (ℓ_∞, s_∞) *in* $L^2(0, 1) \times H^1(0, 1)$ *as* $t \to \infty$.

Roughly speaking, the only piece of information on the convergence that can be retrieved from (1.8) is that $\partial_t \Sigma_I(s)$ vanishes as $t \to \infty$ and so does $\partial_t s$. Therefore, by (1.4), $\ell(1 - s) - (\delta + \varepsilon) s$ vanishes for large times, which somehow means that s gets closer and closer to $\ell/(\ell + \delta + \varepsilon)$ as time goes by. However, no information is available

on ℓ at this stage. Nevertheless, it seems reasonable to guess that ℓ behaves as the solution λ to

$$\partial_t \lambda = \partial_x \left(\frac{\delta+\varepsilon}{\lambda+\delta+\varepsilon}\, \partial_x \lambda \right) - \frac{\varepsilon}{\delta+\varepsilon}\, \frac{\lambda}{\lambda+\delta+\varepsilon}, \quad (t,x) \in (0,\infty)\times(0,1), \tag{1.14}$$

$$D\, \frac{\partial_x \lambda(t,0)}{\lambda(t,0)+\delta+\varepsilon} + \frac{\nu}{\delta+\varepsilon} = \lambda(t,1) = 0, \quad t \in (0,\infty), \tag{1.15}$$

obtained from (1.3)–(1.5) by replacing s by $\ell/(\ell+\delta+\varepsilon)$. Noting that ℓ_∞ is also a stationary solution to (1.14)–(1.15) allows us to construct another Liapunov functional for (1.3)–(1.6) resembling that available for (1.14)–(1.15) and providing the needed information on ℓ.

The large time convergence towards the steady state is proved in section 3 after establishing the well-posedness in $V \times V$ in section 2. In section 4, we return to the model (1.1)–(1.2) of morphogen transport by passive diffusion and show that it is also well-posed in $V \times V$ once supplemented by the boundary and initial conditions (1.5)–(1.6). To this end we construct a Liapunov function for this problem which turns out to provide much more information than $\mathcal{L}$. In particular, exponential convergence to the steady state can be proved for (1.1)–(1.2). Finally, we devote section 5 to numerical simulations, where we show that the solutions of both models converge to the steady state at an exponential rate and that this rate cannot be arbitrarily large regardless of the choice of the parameters.

Throughout the paper, C_i, $i \ge 1$, denotes any positive constant depending only on ℓ_0, s_0, D, δ, ε, and ν. For a real number $r \in \mathbb{R}$, $r_+ := \max\{r,0\}$ denotes the positive part of r and we set $\mathrm{sign}_+(r) := 1$ for $r > 0$ and $\mathrm{sign}_+(r) := 0$ for $r \le 0$.

2. Well-posedness. We first show that the Liapunov functional $\mathcal{L}$ is bounded from below.

LEMMA 4. *For $v \in V$, $0 \le v < 1$, we have*

$$\mathcal{L}_0(v) \ge \mathcal{L}_0(s_\infty) + \frac{D(\delta+\varepsilon)}{2} \int_0^1 \left| \partial_x \left(\Sigma_I(v) - \Sigma_I(s_\infty) \right)(x) \right|^2 dx. \tag{2.1}$$

In particular,

$$\mathcal{L}_0(s_\infty) = \min_{v \in V} \{ \mathcal{L}_0(v) \}.$$

Proof. Let $v \in V$, $0 \le v < 1$. It follows from (1.13) by a straightforward computation that

$$\begin{aligned} \mathcal{L}_0(v) - \mathcal{L}_0(s_\infty) = {} & \frac{D(\delta+\varepsilon)}{2} \int_0^1 \left| \partial_x \left(\Sigma_I(v) - \Sigma_I(s_\infty) \right)(x) \right|^2 dx \\ & + \varepsilon \int_0^1 \left\{ (1-s_\infty)\, \left(\Sigma_I(v) - \Sigma_I(s_\infty) \right) - v + s_\infty \right\}(x)\, dx. \end{aligned}$$

Since $s_\infty < 1$ by Proposition 2 we observe that

$$(1-s_\infty)\left(\Sigma_I(v)-\Sigma_I(s_\infty)\right) - v + s_\infty = (1-s_\infty)\left[\Sigma_I(v)-\Sigma_I(s_\infty)-\Sigma_I'(s_\infty)\,(v-s_\infty)\right] \ge 0$$

by the convexity of Σ_I, and (2.1) follows. ∎

Proof of Theorem 1. By [1, Theorem 6.4] (with $G = \mathbb{R} \times (-\infty, 1)$) the initial-boundary value problem (1.3)–(1.6) possesses a unique maximal weak solution

$$(\ell, s) \in \mathcal{C}([0,T_m); V \times H^1(0,1)) \cap \mathcal{C}^1([0,T_m); V' \times H^1(0,1)) \tag{2.2}$$

such that

$$s(t,x) < 1, \quad (t,x) \in [0,T_m) \times [0,1], \tag{2.3}$$

and

$$\begin{aligned} &\langle \partial_t \ell(t), \psi \rangle_{V',V} + D \int_0^1 (1-s(t))\ \partial_x \ell(t)\ \partial_x \psi\ dx \\ &\qquad = \nu\ \psi(0) + \int_0^1 (\delta s(t) - \ell(t)(1-s(t)))\ \psi\ dx, \end{aligned} \tag{2.4}$$

$$\partial_t s(t) = -(\delta+\varepsilon) s(t) + \ell(t)(1-s(t)) \tag{2.5}$$

for $\psi \in V$ and $t \in [0,T_m)$. In addition, $T_m = \infty$ if, for each $T > 0$,

$$(\ell, s) \in \mathcal{BUC}([0,T] \cap [0,T_m); V \times H^1(0,1)) \tag{2.6}$$

and there is $\vartheta_T \in (0,1)$ such that

$$\max_{x\in[0,1]} \{s(t,x)\} \le \vartheta_T \quad \text{for every} \quad t \in [0,T] \cap [0,T_m). \tag{2.7}$$

We first establish the nonnegativity of (ℓ, s). For that purpose we notice that since $1 - s \ge 0$, the right-hand side of (1.3)–(1.4) satisfies

$$\begin{aligned} &[\delta s - \ell(1-s)]\ \operatorname{sign}_+(-\ell) + [\ell(1-s) - (\delta+\varepsilon)s]\ \operatorname{sign}_+(-s) \\ &\ge -\delta(-s)_+ + (1-s)(-\ell)_+ - (1-s)(-\ell)_+ + (\delta+\varepsilon)(-s)_+ \\ &\ge 0. \end{aligned}$$

We may then use classical approximations of $r \mapsto r_+$ to deduce from (2.4) and (2.5) that

$$\int_0^1 [(-\ell)_+(t) + (-s)_+(t)]\ dx \le \int_0^1 [(-\ell_0)_+ + (-s_0)_+]\ dx = 0$$

for $t \in [0,T_m)$. Consequently

$$\ell(t,x) \ge 0 \quad \text{and} \quad s(t,x) \ge 0, \quad (t,x) \in [0,T_m) \times [0,1]. \tag{2.8}$$

It also follows from (1.7), (2.2), and (2.5) that $\partial_t s(t,1) = -(\delta+\varepsilon) s(t,1)$ with $s(0,1) = 0$, whence

$$s(t,1) = 0 \quad \text{and} \quad s(t) \in V \quad \text{for} \quad t \in [0,T_m). \tag{2.9}$$

We next turn to the identity (1.8): owing to (2.2), (2.3), and (2.9), the function $\sigma := \Sigma_I(s) = -\ln(1-s)$ is well-defined in $[0,T_m) \times [0,1]$ and belongs to $\mathcal{C}^1([0,T_m); V)$ with

$$\partial_t \sigma = \frac{\partial_t s}{1-s} \quad \text{and} \quad \partial_x \sigma = \frac{\partial_x s}{1-s}.$$

Furthermore (2.5) also reads

$$\partial_t \sigma = \ell - (\delta+\varepsilon)\ \frac{s}{1-s}, \tag{2.10}$$

which, together with (2.2), ensures that $\partial_t\sigma$ belongs to $\mathcal{C}([0,T_m);V)$ and $\mathcal{C}^1([0,T_m);V')$. For $t\in[0,T_m)$, $\partial_t\sigma(t)$ is then an admissible test function in (2.4) and it follows from (2.4) and (2.5) that

$$\begin{aligned}&\langle\partial_t\ell(t),\partial_t\sigma(t)\rangle_{V',V}+D\int_0^1(1-s(t))\,\partial_x\ell(t)\,\partial_x\partial_t\sigma(t)\,dx\\&=-\int_0^1\left(\partial_t s(t)+\varepsilon\,s(t)\right)\,\partial_t\sigma(t)\,dx+\nu\,\partial_t\sigma(t,0).\end{aligned}$$

On the one hand, expressing ℓ in terms of σ and s with the help of (2.10) yields

$$\langle\partial_t\ell(t),\partial_t\sigma(t)\rangle_{V',V}=\frac{1}{2}\,\frac{d}{dt}\int_0^1|\partial_t\sigma(t)|^2\,dx+(\delta+\varepsilon)\int_0^1\frac{|\partial_t\sigma(t)|^2}{1-s(t)}\,dx.$$

On the other hand, using once more (2.10), we obtain

$$\begin{aligned}D\int_0^1(1-s(t))\,\partial_x\ell(t)\,\partial_x\partial_t\sigma(t)\,dx&=D\int_0^1(1-s(t))\,|\partial_x\partial_t\sigma(t)|^2\,dx\\&\quad+\frac{D(\delta+\varepsilon)}{2}\,\frac{d}{dt}\int_0^1|\partial_x\sigma(t)|^2\,dx.\end{aligned}$$

Combining the above three identities we end up with

$$\frac{d}{dt}\mathcal{L}(s(t),\partial_t\sigma(t))+\mathcal{D}(s(t),\partial_t\sigma(t))=0,\quad t\in[0,T_m),$$

whence

$$\mathcal{L}(s(t),\partial_t\sigma(t))+\int_0^t\mathcal{D}(s(\tau),\partial_t\sigma(\tau))\,d\tau=\mathcal{L}(s_0,\partial_t\sigma(0)),\quad t\in[0,T_m).\tag{2.11}$$

We then deduce from (1.9), (2.11), (2.1), and the nonnegativity of $\mathcal{D}(s,\partial_t\sigma)$ that

$$\frac{D(\delta+\varepsilon)}{2}\int_0^1\left|\partial_x\left(\sigma(t)-\Sigma_I(s_\infty)\right)\right|^2\,dx+\frac{1}{2}\int_0^1|\partial_t\sigma(t)|^2\,dx\le C_0,\tag{2.12}$$

with $C_0:=-\mathcal{L}_0(s_\infty)+\mathcal{L}(s_0,\partial_t\sigma(0))$. Since $\sigma(t)\in V$ for $t\in[0,T_m)$ it follows from (2.12) and the Poincaré inequality

$$\|v\|_2\le\|v\|_\infty\le\|\partial_x v\|_2,\quad v\in V,\tag{2.13}$$

that there is a constant $C_1>0$ such that

$$\|\sigma(t)\|_{H^1}\le C_1,\quad t\in[0,T_m).\tag{2.14}$$

In particular, $\|\sigma(t)\|_\infty\le C_1$, from which we readily deduce that

$$s(t,x)\le 1-e^{-C_1},\quad (t,x)\in[0,T_m)\times[0,1].\tag{2.15}$$

Since $\partial_x s=e^{-\sigma}\,\partial_x\sigma$ and $\sigma\ge 0$ we further obtain from (2.14) and (2.15) that

$$\|s(t)\|_{H^1}\le 1+C_1,\quad t\in[0,T_m).\tag{2.16}$$

We next establish a similar estimate for ℓ and first proceed in a formal way. A rigorous proof based on an approximation argument will be sketched at the end of the proof of Theorem 1. We take $\psi = \partial_t \ell$ in (2.4) and use (2.3), (2.5), (2.12), (2.15), and the nonnegativity of ℓ to obtain

$$\begin{aligned}
&\int_0^1 |\partial_t \ell|^2 \, dx + \frac{D}{2} \, \frac{d}{dt} \int_0^1 (1-s) \, |\partial_x \ell|^2 \, dx - \nu \, \partial_t \ell(0) \\
&= -\frac{D}{2} \int_0^1 \partial_t s \, |\partial_x \ell|^2 \, dx - \int_0^1 (\partial_t s + \varepsilon \, s) \, \partial_t \ell \, dx \\
&\le \frac{D}{2} \, (\delta + \varepsilon) \int_0^1 s \, |\partial_x \ell|^2 \, dx + \frac{1}{2} \, \|\partial_t \ell\|_2^2 + \frac{1}{2} \, \|(1-s) \, \partial_t \sigma + \varepsilon \, s\|_2^2 \\
&\le \frac{D(\delta+\varepsilon) e^{C_1}}{2} \int_0^1 (1-s) \, |\partial_x \ell|^2 \, dx + \frac{1}{2} \, \|\partial_t \ell\|_2^2 + \|\partial_t \sigma\|_2^2 + \varepsilon \\
&\le \frac{D(\delta+\varepsilon) e^{C_1}}{2} \int_0^1 (1-s) \, |\partial_x \ell|^2 \, dx + \frac{1}{2} \, \|\partial_t \ell\|_2^2 + 2C_0 + \varepsilon.
\end{aligned}$$

Consequently, there is a constant $C_2 > 0$ such that

$$\int_0^1 |\partial_t \ell|^2 \, dx + \frac{d}{dt} \left\{ \int_0^1 D \, (1-s) \, |\partial_x \ell|^2 \, dx - \nu \, \ell(0) \right\} \le C_2 \, \left(1 + \int_0^1 (1-s) \, |\partial_x \ell|^2 \, dx \right),$$

whence

$$\begin{aligned}
&D \int_0^1 (1 - s(t)) \, |\partial_x \ell(t)|^2 \, dx - \nu \, \ell(t,0) + \int_0^t \int_0^1 |\partial_t \ell(\tau)|^2 \, dx d\tau \\
&\qquad \le (1 + D \, \|\ell_0\|_{H^1}^2) \, e^{C_2 t}
\end{aligned} \tag{2.17}$$

for $t \in [0, T_m)$. Recalling (2.15) we readily deduce from (2.17) and the Poincaré inequality (2.13) that

$$\|\ell(t)\|_{H^1}^2 + \int_0^t \|\partial_t \ell(\tau)\|_2^2 \, d\tau \le C_3 \, e^{C_3 t} \tag{2.18}$$

for $t \in [0, T_m)$. According to (2.16) and (2.18), we have shown so far that, given $T > 0$, there is a positive constant M_T depending only on ℓ_0, s_0, D, δ, ε, ν, and T such that

$$\|\ell(t)\|_{H^1} + \|s(t)\|_{H^1} \le M_T \quad \text{for} \quad t \in [0,T] \cap [0, T_m).$$

It remains to improve this estimate to a uniform bound on the modulus of continuity with respect to time for ℓ and s in $H^1(0,1)$ as required by (2.6). To this end, we first notice that (2.5) and (2.18) entail that

$$\|\partial_t s(t)\|_{H^1} \le 2 \, \|\ell(t)\|_{H^1} \, \|(1-s)(t)\|_{H^1} + (\delta + \varepsilon) \, \|s(t)\|_{H^1} \le C_4 \, e^{C_4 t} \quad \text{for } t \in [0, T_m). \tag{2.19}$$

It next follows from (2.4) that $\xi := \partial_t \ell$ formally solves

$$\begin{aligned}
\partial_t \xi &= D \, \partial_x \left((1-s) \, \partial_x \xi - \partial_t s \, \partial_x \ell \right) \\
&\qquad + (\ell + \delta) \, \partial_t s - \xi \, (1-s), \quad (t,x) \in (0, T_m) \times (0,1),
\end{aligned} \tag{2.20}$$

$$(1 - s(t,0)) \, \partial_x \xi(t,0) - \partial_t s(t,0) \, \partial_x \ell(t,0) = \xi(t,1) = 0, \quad t \in (0, T_m). \tag{2.21}$$

We multiply (2.20) by ξ and integrate over $(0,1)$ to obtain, thanks to (2.21),

$$\begin{aligned}\frac{1}{2}\,\frac{d}{dt}\|\xi(t)\|_2^2 &= -D\,\int_0^1 \partial_x\xi\,\left((1-s)\,\partial_x\xi-\partial_t s\,\partial_x\ell\right)\,dx\\ &\quad+\int_0^1(\ell+\delta)\,\partial_t s\,\xi\,dx-\int_0^1(1-s)\,\xi^2\,dx\\ &\le -D\,\int_0^1(1-s)\,|\partial_x\xi|^2\,dx-\int_0^1(1-s)\,\xi^2\,dx\\ &\quad+D\,\|\partial_t s\|_\infty\,\|\partial_x\ell\|_2\,\|\partial_x\xi\|_2+(\|\ell\|_\infty+\delta)\,\|\partial_t s\|_2\,\|\xi\|_2.\end{aligned}$$

Recalling (2.15), (2.18), (2.19), and the continuous embedding of $H^1(0,1)$ in $L^\infty(0,1)$, we deduce from the Young inequality that

$$\begin{aligned}\frac{1}{2}\,\frac{d}{dt}\|\xi(t)\|_2^2 &\le -D\,e^{-C_1}\,\|\partial_x\xi\|_2^2-e^{-C_1}\,\|\xi\|_2^2+D\,e^{-C_1}\,\|\partial_x\xi\|_2^2\\ &\quad+e^{-C_1}\,\|\xi\|_2^2+C_5\,\|\partial_t s\|_{H^1}^2\,\left(\|\ell\|_{H^1}+\delta\right)^2\\ &\le C_6\,e^{C_6 t},\end{aligned}$$

whence

$$\|\xi(t)\|_2^2\le\|\xi(\tau)\|_2^2+2\,e^{C_6 t},\quad 0\le\tau\le t<T_m.$$

Integrating with respect to τ over $(0,t)$ and using (2.18), we end up with

$$\begin{aligned}t\,\|\xi(t)\|_2^2&\le\int_0^t\|\xi(\tau)\|_2^2\,d\tau+2\,t\,e^{C_6 t},\\ \|\xi(t)\|_2^2&\le C_7\,\left(1+\frac{1}{t}\right)\,e^{C_7 t},\quad t\in(0,T_m).\end{aligned}\tag{2.22}$$

We next infer from (1.3) and (2.16) that

$$\partial_x^2\ell=\frac{\partial_t\ell}{D\,(1-s)}+\frac{\ell}{D}-\frac{\delta}{D}\,\frac{s}{1-s}+\partial_x\sigma\,\partial_x\ell.$$

Therefore, by (2.14), (2.15), (2.18), (2.22), and the interpolation inequality

$$\|\partial_x w\|_\infty\le C_8\,\|w\|_{H^2}^{3/4}\,\|w\|_2^{1/4},\quad w\in H^2(0,1),$$

we have

$$\begin{aligned}\|\partial_x^2\ell(t)\|_2&\le\frac{e^{C_1}}{D}\,\|\partial_t\ell(t)\|_2+\frac{\|\ell(t)\|_2}{D}+\frac{\delta\,e^{C_1}}{D}+\|\partial_x\sigma(t)\|_2\,\|\partial_x\ell(t)\|_\infty\\ &\le\frac{\sqrt{C_7}\,e^{C_1}}{D}\,\left(1+\frac{1}{t}\right)^{1/2}\,e^{C_7 t/2}+\frac{\sqrt{C_3}\,e^{C_3 t/2}}{D}\\ &\quad+\frac{\delta\,e^{C_1}}{D}+C_1\,C_8\,\|\ell(t)\|_{H^2}^{3/4}\,\|\ell(t)\|_2^{1/4}\\ &\le C_9\,\left(1+\frac{1}{\sqrt{t}}\right)\,e^{C_9 t}+\frac{1}{2}\,\|\ell(t)\|_{H^2}\\ &\le C_9\,\left(1+\frac{1}{\sqrt{t}}\right)\,e^{C_9 t}+\frac{1}{2}\,\sqrt{C_3}\,e^{C_3 t/2}+\frac{1}{2}\,\|\partial_x^2\ell(t)\|_2,\end{aligned}$$

whence

$$\|\ell(t)\|_{H^2} \le C_{10}\ \left(1+\frac{1}{\sqrt{t}}\right)\ e^{C_{10}t}, \quad t\in(0,T_m). \tag{2.23}$$

Consider next $t_1\in(0,T_m)$ and $t_2\in(t_1,T_m)$. It follows from (2.18), (2.23), and the interpolation inequality

$$\|\partial_x w\|_2 \le C_{11}\ \|w\|_{H^2}^{1/2}\ \|w\|_2^{1/2}, \quad w\in H^2(0,1),$$

that

$$\begin{aligned}
\|\ell(t_2)-\ell(t_1)\|_{H^1}^2 &\le C_{11}^2\ \|\ell(t_2)-\ell(t_1)\|_{H^2}\ \|\ell(t_2)-\ell(t_1)\|_2\\
&\le C_{11}^2\ \left(\|\ell(t_2)\|_{H^2}+\|\ell(t_1)\|_{H^2}\right)\ \int_{t_1}^{t_2}\|\partial_t\ell(\tau)\|_2\ d\tau\\
&\le 2\ C_{10}\ C_{11}^2\ \left(1+\frac{1}{\sqrt{t_1}}\right)\ e^{C_{10}t_2}\ (t_2-t_1)^{1/2}\ \left(\int_{t_1}^{t_2}\|\partial_t\ell(\tau)\|_2^2\ d\tau\right)^{1/2}\\
&\le C_{12}\ \left(1+\frac{1}{\sqrt{t_1}}\right)\ e^{C_{12}t_2}\ (t_2-t_1)^{1/2},
\end{aligned}$$

$$\|\ell(t_2)-\ell(t_1)\|_{H^1} \le C_{13}\ \left(1+t_1^{-1/4}\right)\ e^{C_{13}t_2}\ (t_2-t_1)^{1/4}. \tag{2.24}$$

Since ℓ belongs to $\mathcal{BC}([0,T]\cap[0,T_m);H^1(0,1))$ for any $T>0$ by (2.2) and (2.18), it readily follows from (2.24) that

$$\ell\in\mathcal{BUC}([0,T]\cap[0,T_m);H^1(0,1)) \quad \text{for any} \quad T>0. \tag{2.25}$$

Recalling (2.16) and (2.19), we also have

$$s\in\mathcal{BUC}([0,T]\cap[0,T_m);H^1(0,1)) \quad \text{for any} \quad T>0,$$

which, together with (2.15) and (2.25), allows us to conclude that $T_m=\infty$ by (2.6) and (2.7). The proof of Theorem 1 is then complete, provided we can justify the above computations.

To this end we note that s belongs to $\mathcal{C}^1([0,T_m);H^1(0,1))$ by (2.2). Setting $\alpha_1:=e^{-C_1}/2$, classical approximation arguments ensure that, for each $\alpha\in(0,\alpha_1)$ and $T\in(0,T_m)$, there is a function $s_{\alpha,T}\in\mathcal{C}^\infty([0,T]\times[0,1])$ such that

$$\|s_{\alpha,T}-s\|_{\mathcal{C}^1([0,T];H^1(0,1))}+\|s_{\alpha,T}-s\|_{\mathcal{C}([0,T]\times[0,1])}\le\alpha. \tag{2.26}$$

Owing to (2.15) and (2.26) we have $1-s_{\alpha,T}\ge\alpha_1>0$ and the initial-boundary value problem

$$\begin{aligned}
&\partial_t\ell_{\alpha,T}-D\ \partial_x\left((1-s_{\alpha,T})\ \partial_x\ell_{\alpha,T}\right)=\delta\ s_{\alpha,T}-(1-s_{\alpha,T})\ \ell_{\alpha,T}, \quad (t,x)\in(0,T)\times(0,1),\\
&D\ (1-s_{\alpha,T}(t,0))\ \partial_x\ell_{\alpha,T}(t,0)+\nu=\ell_{\alpha,T}(t,1)=0, \quad t\in(0,T),\\
&\ell_{\alpha,T}(0,x)=\ell_0(x), \quad x\in(0,1),
\end{aligned}$$

has a unique nonnegative classical solution $\ell_{\alpha,T}\in\mathcal{C}([0,T]\times[0,1])\cap\mathcal{C}^\infty((0,T]\times[0,1])$. On the one hand it is rather straightforward to check that

$$\sup_{t\in[0,T]}\left\{\|(\ell_{\alpha,T}-\ell)(t)\|_2^2\right\}\le\alpha\ \int_0^T\left(D^2\ \|\partial_x\ell(t)\|_2^2+\delta^2+\|\ell(t)\|_2^2\right)\ dt. \tag{2.27}$$

On the other hand, the smoothness of $\ell_{\alpha,T}$ allows us to proceed as in the derivation of (2.17) and obtain that

$$\|\partial_x \ell_{\alpha,T}(t)\|_2^2 + \int_0^t \|\partial_t \ell_{\alpha,T}(\tau)\|_2^2 \, d\tau \le C_{14} \, e^{C_{14} t}, \quad t \in [0,T]. \tag{2.28}$$

Owing to (2.27) we may let $\alpha \to 0$ in (2.28) and deduce by weak convergence arguments that $\ell \in L^\infty(0,T;V)$ and $\partial_t \ell \in L^2((0,T)\times(0,1))$ and satisfy an inequality similar to (2.18). Still proceeding as above, we next show that $\ell_{\alpha,T}$ enjoys the properties (2.22) and (2.23), and we use once more weak compactness arguments to provide a rigorous proof of the $\mathcal{BUC}$-estimate (2.25). ∎

3. Convergence to the steady state. As a first step towards the proof of Theorem 3, we derive the following information on s and $\sigma := \Sigma_I(s)$ from (1.8).

LEMMA 5. *There is a real number $\vartheta \in (0,1)$ such that*

$$0 \le s(t,x) \le 1 - \vartheta \quad \textit{for all} \quad (t,x) \in [0,\infty) \times [0,1] \tag{3.1}$$

and

$$\sigma \in L^\infty(0,\infty;H^1(0,1)), \qquad \partial_t \sigma \in L^2(0,\infty;H^1(0,1)). \tag{3.2}$$

Proof. By (1.8) and (2.1) we have

$$\mathcal{L}_0(s_\infty) + \frac{D(\delta+\varepsilon)}{2} \, \|\partial_x \sigma(t) - \partial_x \Sigma_I(s_\infty)\|_2^2 \le \mathcal{L}(s(t), \partial_t \sigma(t)) \le \mathcal{L}(s_0, \partial_t \sigma(0))$$

for all $t \ge 0$, from which we readily conclude that $\partial_x \sigma$ belongs to $L^\infty(0,\infty;L^2(0,1))$. Since $\sigma(t,1) = 0$ for every $t \ge 0$, the Poincaré inequality (2.13) entails that σ belongs to $L^\infty(0,\infty;H^1(0,1))$, which gives the first assertion in (3.2). The space $H^1(0,1)$ being continuously embedded in $L^\infty(0,1)$, we further deduce that σ belongs to $L^\infty((0,\infty)\times(0,1))$, whence (3.1).

Next, since $r + (\delta+\varepsilon)/r \ge 2(\delta+\varepsilon)^{1/2} \ge 2\delta^{1/2}$ for $r \ge 0$ and $1 - s \ge \vartheta > 0$ by (3.1), we have

$$\mathcal{D}(s, \partial_t \sigma) \ge 2\delta^{1/2} \, \|\partial_t \sigma\|_2^2 + \vartheta D \, \|\partial_x \partial_t \sigma\|_2^2,$$

and we infer from (1.8) and (2.1) that

$$\mathcal{L}_0(s_\infty) + \int_0^t \left(2\delta^{1/2} \, \|\partial_t \sigma\|_2^2 + \vartheta D \, \|\partial_x \partial_t \sigma\|_2^2 \right) \, d\tau \le \mathcal{L}(s_0, \partial_t \sigma(0))$$

for all $t \ge 0$, which gives the second assertion in (3.2). ∎

We next turn to ℓ and establish the following inequality.

LEMMA 6. *For $t \ge 0$ we have*

$$\mathcal{L}_1(\ell(t)) + \int_0^t \mathcal{D}_1(\ell, s) \, d\tau \le \mathcal{L}_1(\ell_0) + C_{15} \, \int_0^t \left\| \partial_x \ln\left(\frac{\ell + \delta + \varepsilon}{\ell_\infty + \delta + \varepsilon} \right) \right\|_2 \, \|\partial_t \sigma\|_2 \, d\tau \tag{3.3}$$

with

$$\mathcal{L}_1(u) := \int_0^1 \left[(u + \delta + \varepsilon) \, \left(\ln\left(\frac{u + \delta + \varepsilon}{\ell_\infty + \delta + \varepsilon} \right) - 1 \right) + \ell_\infty + \delta + \varepsilon \right] \, dx \ge 0$$

and

$$\mathcal{D}_1(u,v) := D\ \int_0^1 (1-v)\ (u+\delta+\varepsilon)\ \left|\partial_x \ln\left(\frac{u+\delta+\varepsilon}{\ell_\infty+\delta+\varepsilon}\right)\right|^2\ dx$$
$$+\ \varepsilon(\delta+\varepsilon)\ \int_0^1 \frac{u-\ell_\infty}{(u+\delta+\varepsilon)(\ell_\infty+\delta+\varepsilon)}\ \ln\left(\frac{u+\delta+\varepsilon}{\ell_\infty+\delta+\varepsilon}\right)\ dx \geq 0.$$

Proof. We put $\Lambda := \ln(\ell+\delta+\varepsilon)$ and $\Lambda_\infty := \ln(\ell_\infty+\delta+\varepsilon)$. By (1.4) we have

$$1-s = (\delta+\varepsilon+\partial_t s)\ e^{-\Lambda} \quad \text{and} \quad s = (\ell-\partial_t s)\ e^{-\Lambda}. \tag{3.4}$$

Let $\psi \in V$. Using (1.4) and (3.4) the weak formulation of (1.3) reads

$$\begin{aligned}
&\langle \partial_t \ell, \psi\rangle_{V',V} + D\ \int_0^1 (\delta+\varepsilon+\partial_t s)\ e^{-\Lambda}\ \partial_x \ell\ \partial_x \psi\ dx \\
&\qquad = \nu\ \psi(0) - \int_0^1 (\partial_t s + \varepsilon\ s)\ \psi\ dx \\
&\qquad = \nu\ \psi(0) - \int_0^1 \left(\partial_t s + \varepsilon\ (\ell-\partial_t s)\ e^{-\Lambda}\right)\ \psi\ dx \\
&\qquad = \nu\ \psi(0) - \int_0^1 \left(1-\varepsilon\ e^{-\Lambda}\right)\ \partial_t s\ \psi\ dx - \varepsilon\ \int_0^1 \left(1-(\delta+\varepsilon)\ e^{-\Lambda}\right)\ \psi\ dx.
\end{aligned}$$

Similarly, as (ℓ_∞, s_∞) is also a weak solution to (1.3)–(1.5), we have

$$\begin{aligned}
&D\ \int_0^1 (\delta+\varepsilon)\ e^{-\Lambda_\infty}\ \partial_x \ell_\infty\ \partial_x \psi\ dx \\
&\qquad = \nu\ \psi(0) - \varepsilon\ \int_0^1 \left(1-(\delta+\varepsilon)\ e^{-\Lambda_\infty}\right)\ \psi\ dx.
\end{aligned}$$

Subtracting the above two identities gives

$$\begin{aligned}
&\langle \partial_t \ell, \psi\rangle_{V',V} + D\ \int_0^1 (\delta+\varepsilon+\partial_t s)\ \partial_x(\Lambda-\Lambda_\infty)\ \partial_x \psi\ dx \\
&\qquad + \varepsilon(\delta+\varepsilon)\ \int_0^1 \left(e^{-\Lambda_\infty} - e^{-\Lambda}\right)\ \psi\ dx \\
&\qquad = -D\ \int_0^1 \partial_t s\ \partial_x \Lambda_\infty\ \partial_x \psi\ dx - \int_0^1 \left(1-\varepsilon\ e^{-\Lambda}\right)\ \partial_t s\ \psi\ dx.
\end{aligned} \tag{3.5}$$

Clearly, $\Lambda-\Lambda_\infty$ belongs to V and we may thus take $\psi = \Lambda-\Lambda_\infty$ in (3.5) to obtain

$$\begin{aligned}
&\langle \partial_t \ell, \Lambda-\Lambda_\infty\rangle_{V',V} + D\ \int_0^1 (\delta+\varepsilon+\partial_t s)\ |\partial_x(\Lambda-\Lambda_\infty)|^2\ dx \\
&\qquad + \varepsilon(\delta+\varepsilon)\ \int_0^1 \left(e^{-\Lambda_\infty} - e^{-\Lambda}\right)\ (\Lambda-\Lambda_\infty)\ dx \\
&\qquad = -D\ \int_0^1 \partial_t s\ \partial_x \Lambda_\infty\ \partial_x(\Lambda-\Lambda_\infty)\ dx - \int_0^1 \left(1-\varepsilon\ e^{-\Lambda}\right)\ \partial_t s\ (\Lambda-\Lambda_\infty)\ dx.
\end{aligned}$$

On the one hand, we have

$$\langle \partial_t \ell, \Lambda-\Lambda_\infty\rangle_{V',V} = \frac{d}{dt}\int_0^1 (\ell+\delta+\varepsilon)\ (\ln(\ell+\delta+\varepsilon) - 1 - \Lambda_\infty)\ dx = \frac{d}{dt}\mathcal{L}_1(\ell).$$

On the other hand, $\partial_x\Lambda_\infty$ clearly belongs to $L^\infty(0,1)$ and

$$\begin{aligned}
&-D\int_0^1 \partial_t s\ \partial_x\Lambda_\infty\ \partial_x(\Lambda-\Lambda_\infty)\ dx - \int_0^1 \left(1-\varepsilon\ e^{-\Lambda}\right)\ \partial_t s\ (\Lambda-\Lambda_\infty)\ dx \\
&\le D\ \|\partial_x\Lambda_\infty\|_\infty\ \|\partial_t s\|_2\ \|\partial_x(\Lambda-\Lambda_\infty)\|_2 + \|\partial_t s\|_2\ \|\Lambda-\Lambda_\infty\|_2 \\
&\le C_{16}\ \|\partial_t s\|_2\ \|\partial_x(\Lambda-\Lambda_\infty)\|_2,
\end{aligned}$$

the last inequality being a consequence of the Poincaré inequality (2.13) which can be applied here since $\Lambda(t)-\Lambda_\infty\in V$ for all $t\ge 0$. Therefore,

$$\frac{d}{dt}\mathcal{L}_1(\ell)+\mathcal{D}_1(\ell,s)\le C_{16}\ \|\partial_t s\|_2\ \|\partial_x(\Lambda-\Lambda_\infty)\|_2.$$

Integrating the above inequality with respect to time and using the fact that $|\partial_t s| = |(1-s)\ \partial_t\sigma|\le|\partial_t\sigma|$ complete the proof of (3.3). □

Several bounds on ℓ may be deduced from (3.3) and are listed now.

LEMMA 7. *Introducing the space $W:=H^2(0,1)\cap V$ and denoting its topological dual by W', we have*

$$\ell\ \ln(1+\ell)\in L^\infty(0,\infty;L^1(0,1)), \tag{3.6}$$

$$(\ell+\delta+\varepsilon)^{1/2}\ \partial_x\ln\left(\frac{\ell+\delta+\varepsilon}{\ell_\infty+\delta+\varepsilon}\right)\in L^2((0,\infty)\times(0,1)), \tag{3.7}$$

$$\frac{1}{\ell+\delta+\varepsilon}-\frac{1}{\ell_\infty+\delta+\varepsilon}\in L^2((0,\infty)\times(0,1)), \tag{3.8}$$

$$\partial_t\ell\in L^2(0,\infty;W'). \tag{3.9}$$

Proof. Keeping the notation $\Lambda:=\ln(\ell+\delta+\varepsilon)$ and $\Lambda_\infty:=\ln(\ell_\infty+\delta+\varepsilon)$, we infer from (3.1), the nonnegativity of ℓ, and the inequalities $\left|e^{-\Lambda_\infty}-e^{-\Lambda}\right|\le|\Lambda-\Lambda_\infty|$ and $\ell+\delta+\varepsilon\ge(\ell+2\delta+\varepsilon)/2$ that

$$\mathcal{D}_1(\ell,s)\ge\frac{\vartheta D}{2}\ \int_0^1(\ell+2\delta+\varepsilon)\ |\partial_x(\Lambda-\Lambda_\infty)|_2^2\ dx+\varepsilon(\delta+\varepsilon)\ \left\|e^{-\Lambda_\infty}-e^{-\Lambda}\right\|_2^2.$$

It then follows from (3.3) and the Young inequality that

$$\begin{aligned}
&\mathcal{L}_1(\ell(t))+\frac{\vartheta D}{2}\ \int_0^t\int_0^1(\ell+2\delta+\varepsilon)\ |\partial_x(\Lambda-\Lambda_\infty)|_2^2\ dxd\tau \\
&+\varepsilon(\delta+\varepsilon)\ \int_0^t\left\|e^{-\Lambda_\infty}-e^{-\Lambda}\right\|_2^2\ d\tau \\
&\le\mathcal{L}_1(\ell(t))+\int_0^t\mathcal{D}_1(\ell,s)\ d\tau \\
&\le\mathcal{L}_1(\ell_0)+\frac{\vartheta D\delta}{2}\ \int_0^t\|\partial_x(\Lambda-\Lambda_\infty)\|_2^2\ d\tau+C_{17}\ \int_0^t\|\partial_t\sigma\|_2^2\ d\tau,
\end{aligned}$$

hence

$$\begin{aligned}
&\mathcal{L}_1(\ell(t))+\frac{\vartheta D}{2}\ \int_0^t\int_0^1(\ell+\delta+\varepsilon)\ |\partial_x(\Lambda-\Lambda_\infty)|_2^2\ dxd\tau \\
&+\varepsilon(\delta+\varepsilon)\ \int_0^t\left\|e^{-\Lambda_\infty}-e^{-\Lambda}\right\|_2^2\ d\tau \\
&\le C_{18}\ \left(1+\int_0^t\|\partial_t\sigma\|_2^2\ d\tau\right).
\end{aligned}$$

Recalling that $\partial_t\sigma \in L^2((0,\infty)\times(0,1))$ by Lemma 5, we readily deduce from the previous inequality, the Poincaré inequality (2.13), and the nonnegativity of $\mathcal{L}_1$ that $\mathcal{L}_1(\ell)$ belongs to $L^\infty(0,\infty)$ and that (3.7) and (3.8) hold true. In turn, the L^∞-bound on $\mathcal{L}_1(\ell)$ gives (3.6).

It remains to check (3.9). For that purpose, consider $\psi \in W$. Since $\delta+\varepsilon+\partial_t s = (1-s)(\ell+\delta+\varepsilon)$ by (1.4), it follows from (3.5) and the Hölder inequality that

$$\begin{aligned}
|\langle \partial_t \ell, \psi\rangle_{V',V}| &\le D \int_0^1 (1-s)(\ell+\delta+\varepsilon)\ |\partial_x(\Lambda-\Lambda_\infty)|\ |\partial_x\psi|\ dx \\
&\quad + \varepsilon(\delta+\varepsilon)\ \left\|e^{-\Lambda_\infty}-e^{-\Lambda}\right\|_2\ \|\psi\|_2 + \|\partial_t s\|_2\ \left(D\ \|\partial_x\Lambda_\infty\|_\infty + 1\right)\|\psi\|_{H^1} \\
&\le D\left(\int_0^1 (\ell+\delta+\varepsilon)|\partial_x(\Lambda-\Lambda_\infty)|^2\ dx\right)^{1/2}\left(\int_0^1 (\ell+\delta+\varepsilon)\ dx\right)^{1/2}\|\partial_x\psi\|_\infty \\
&\quad + \varepsilon(\delta+\varepsilon)\ \left\|e^{-\Lambda_\infty}-e^{-\Lambda}\right\|_2\ \|\psi\|_2 + C_{19}\ \|\partial_t\sigma\|_2\ \|\psi\|_{H^1}.
\end{aligned}$$

Thanks to (3.2), (3.6), (3.7), (3.8), and the continuous embedding of W in $W^{1,\infty}(0,1)$, we deduce from the above inequality that

$$\int_0^t |\langle \partial_t\ell,\psi\rangle_{V',V}|^2\ d\tau \le C_{20}\ \|\psi\|_{H^2},$$

which implies the claim (3.9). □

Proof of Theorem 3. Let $(t_n)_{n\ge1}$ be a sequence of positive times such that $t_n\to\infty$ as $n\to\infty$. It follows from (3.1), (3.2), (3.6), and the Dunford–Pettis theorem that $(\ell(t_n))_{n\ge1}$ is weakly compact in $L^1(0,1)$ and $(s(t_n))_{n\ge1}$ is weakly compact in $H^1(0,1)$. There are thus $\ell_*\in L^1(0,1)$, $s_*\in H^1(0,1)$, and a subsequence of $(\ell(t_n),s(t_n))_{n\ge1}$ (not relabeled) such that

$$\ell(t_n) \rightharpoonup \ell_* \quad\text{in}\quad L^1(0,1), \tag{3.10}$$

$$s(t_n) \rightharpoonup s_* \quad\text{in}\quad H^1(0,1). \tag{3.11}$$

Owing to the compactness of the embedding of $H^1(0,1)$ in $\mathcal{C}([0,1])$, we further obtain

$$s(t_n) \longrightarrow s_* \quad\text{in}\quad \mathcal{C}([0,1]). \tag{3.12}$$

We now aim at showing that $(\ell_*,s_*)=(\ell_\infty,s_\infty)$. For that purpose, we introduce as usual the functions $(\ell_n,s_n)\in\mathcal{C}([0,1];V\times V)$ defined by

$$(\ell_n(t,x),s_n(t,x)) := (\ell(t_n+t,x),s(t_n+t,x)) \quad\text{for}\quad (t,x)\in[0,1]^2 \quad\text{and}\quad n\ge1,$$

and claim that

$$\ell_n \longrightarrow \ell_* \quad\text{in}\quad \mathcal{C}([0,1];L^1_w(0,1)), \tag{3.13}$$

$$s_n \longrightarrow s_* \quad\text{in}\quad \mathcal{C}([0,1]\times[0,1]), \tag{3.14}$$

$L^1_w(0,1)$ denoting the usual space $L^1(0,1)$ endowed with its weak topology. Indeed, on the one hand, the continuous embedding of $H^1(0,1)$ in $L^\infty(0,1)$ and the Hölder inequality entail that

$$\begin{aligned}
\|s_n(t)-s_n(0)\|_\infty &\le \int_{t_n}^{t_n+t}\|\partial_t s\|_\infty\ d\tau \le \int_{t_n}^{t_n+t}\|\partial_t\sigma\|_\infty\ d\tau \\
&\le \left(\int_{t_n}^{t_n+t}\|\partial_t\sigma\|_{H^1}^2\ d\tau\right)^{1/2}
\end{aligned}$$

for $t \in [0,1]$, so that

$$\sup_{t\in[0,1]} \|s_n(t) - s_n(0)\|_\infty \le \left(\int_{t_n}^\infty \|\partial_t \sigma\|_{H^1}^2 \, d\tau \right)^{1/2}.$$

By (3.2), the right-hand side of the above inequality converges to zero as $n \to \infty$, which, together with (3.12), gives the claim (3.14). On the other hand, if $\psi \in W = H^2(0,1) \cap V$ (defined in Lemma 7) and $t \in [0,1]$,

$$\begin{aligned}
\left| \int_0^1 (\ell_n(t) - \ell_n(0)) \, \psi \, dx \right| &= \left| \int_{t_n}^{t_n+1} \langle \partial_t \ell(\tau), \psi \rangle_{V',V} \, d\tau \right| \\
&\le \int_{t_n}^{t_n+1} \|\partial_t \ell(\tau)\|_{W'} \, \|\psi\|_W \, d\tau \\
&\le \|\psi\|_W \, \left(\int_{t_n}^{t_n+1} \|\partial_t \ell(\tau)\|_{W'}^2 \, d\tau \right)^{1/2} \\
&\le \|\psi\|_W \, \left(\int_{t_n}^{\infty} \|\partial_t \ell(\tau)\|_{W'}^2 \, d\tau \right)^{1/2}.
\end{aligned}$$

Owing to (3.9) and (3.10), we pass to the limit as $n \to \infty$ in the above inequality to conclude that

$$\lim_{n\to\infty} \sup_{t\in[0,1]} \left| \int_0^1 (\ell_n(t) - \ell_*) \, \psi \, dx \right| = 0 \quad \text{for all} \quad \psi \in W.$$

A classical approximation combined with (3.6) allows us to extend the above convergence to every $\psi \in L^\infty(0,1)$ and completes the proof of (3.13).

We next infer from (3.8) that

$$\begin{aligned}
&\lim_{n\to\infty} \int_0^1 \left\| \frac{1}{\ell_n(t) + \delta + \varepsilon} - \frac{1}{\ell_\infty + \delta + \varepsilon} \right\|_2^2 dt \\
&= \lim_{n\to\infty} \int_{t_n}^{t_n+1} \left\| \frac{1}{\ell(t) + \delta + \varepsilon} - \frac{1}{\ell_\infty + \delta + \varepsilon} \right\|_2^2 dt \\
&= 0.
\end{aligned}$$

Consequently, after extracting a further subsequence if necessary, we may assume that

$$\ell_n \longrightarrow \ell_\infty \quad \text{a.e. in} \quad (0,1) \times (0,1). \tag{3.15}$$

Recalling (3.13) we readily conclude from (3.15) that $\ell_* = \ell_\infty$.

Next, (3.1) and (3.14) imply that $0 \le s_*(x) \le 1 - \vartheta < 1$ for $x \in [0,1]$, and we infer from (1.4), (3.2), (3.13), and (3.14) that, if $\psi \in L^\infty(0,1)$,

$$\begin{aligned}
\left| \int_0^1 \left(\ell_* - (\delta+\varepsilon) \, \frac{s_*}{1-s_*} \right) \psi \, dx \right| &= \left| \lim_{n\to\infty} \int_0^1 \int_0^1 \left(\ell_n(t) - (\delta+\varepsilon) \, \frac{s_n(t)}{1-s_n(t)} \right) \psi(x) \, dxdt \right| \\
&= \left| \lim_{n\to\infty} \int_0^1 \partial_t \sigma(t_n + t) \, \psi \, dxdt \right| \\
&\le \|\psi\|_\infty \, \left(\lim_{n\to\infty} \int_{t_n}^{t_n+1} \|\partial_t \sigma(t)\|_2^2 \, dt \right)^{1/2} \\
&= 0.
\end{aligned}$$

Therefore, $(\delta+\varepsilon) s_*/(1-s_*) = \ell_* = \ell_\infty$ a.e. in $(0,1)$ and thus $s_* = s_\infty$.

We have actually shown that (ℓ_∞, s_∞) is the unique cluster point of $(\ell(t), s(t))$ as $t \to \infty$ for the weak topology of $L^1(0,1)\times H^1(0,1)$. The trajectory $\{(\ell(t), s(t));\ t \ge 0\}$ being relatively compact for that topology by (3.2), (3.6), and the Dunford–Pettis theorem, we conclude that

$$(\ell(t), s(t)) \rightharpoonup (\ell_\infty, s_\infty) \quad \text{in} \quad L^1(0,1) \times H^1(0,1)$$

as $t \to \infty$. The embedding of $H^1(0,1)$ in $L^2(0,1)$ being compact, we further obtain that

$$s(t) \longrightarrow s_\infty \quad \text{in} \quad L^2(0,1). \tag{3.16}$$

Let us finally improve the topology in which the convergence to the steady state takes place. For $\psi \in V$ it follows from the weak formulation of (1.3) and Proposition 2 that

$$\begin{aligned} &\langle \partial_t \ell, \psi \rangle_{V',V} + D \int_0^1 (1-s)\ \partial_x(\ell - \ell_\infty)\ \partial_x \psi\ dx \\ &= D \int_0^1 (s - s_\infty)\ \partial_x \ell_\infty\ \partial_x \psi\ dx + \int_0^1 \left[(\ell_\infty + \delta)\ (s - s_\infty) - (1-s)\ (\ell - \ell_\infty) \right]\ \psi\ dx. \end{aligned}$$

Since $\ell - \ell_\infty$ belongs to V, we may take $\psi = \ell - \ell_\infty$ and use the fact that ℓ_∞ does not depend on time to obtain

$$\begin{aligned} &\frac{1}{2}\ \frac{d}{dt} \|\ell - \ell_\infty\|_2^2 + \int_0^1 (1-s)\ \left(D\ \left| \partial_x (\ell - \ell_\infty) \right|^2 + |\ell - \ell_\infty|^2 \right)\ dx \\ &\le \|s - s_\infty\|_2\ \left(\|\partial_x \ell_\infty\|_\infty\ \left\| \partial_x (\ell - \ell_\infty) \right\|_2 + (\delta + \|\ell_\infty\|_\infty)\ \|\ell - \ell_\infty\|_2 \right) \\ &\le \frac{D\vartheta}{2}\ \left\| \partial_x (\ell - \ell_\infty) \right\|_2^2 + \frac{\vartheta}{2}\ \|\ell - \ell_\infty\|_2^2 + C_{21}\ \|s - s_\infty\|_2^2, \end{aligned}$$

the last inequality following from the boundedness of ℓ_∞ and $\partial_x \ell_\infty$ and the parameter ϑ being defined in Lemma 5. Using (3.1) to bound from below $(1-s)$ in the second term on the left-hand side of the above inequality we get

$$\frac{d}{dt} \|\ell - \ell_\infty\|_2^2 + D\vartheta\ \left\| \partial_x (\ell - \ell_\infty) \right\|_2^2 + \vartheta\ \|\ell - \ell_\infty\|_2^2 \le 2C_{21}\ \|s - s_\infty\|_2^2. \tag{3.17}$$

We next infer from (1.4) and Proposition 2 that

$$\partial_t s = (1-s)\ (\ell - \ell_\infty) - (\ell_\infty + \delta + \varepsilon)\ (s - s_\infty).$$

We differentiate the above identity with respect to x and take the scalar product in $L^2(0,1)$ of the result with $\partial_x(s - s_\infty)$. Recalling the Poincaré inequality (2.13) and the bound (3.2) we obtain

$$\begin{aligned} &\frac{1}{2}\ \frac{d}{dt}\ \left\| \partial_x (s - s_\infty) \right\|_2^2 + \int_0^1 (\ell_\infty + \delta + \varepsilon)\ \left| \partial_x (s - s_\infty) \right|_2^2\ dx \\ &\le \|\partial_x s\|_2\ \|\ell - \ell_\infty\|_\infty\ \left\| \partial_x (s - s_\infty) \right\|_2 + \left\| \partial_x (\ell - \ell_\infty) \right\|_2\ \left\| \partial_x (s - s_\infty) \right\|_2 \\ &+ \|\partial_x \ell_\infty\|_\infty\ \|s - s_\infty\|_2\ \left\| \partial_x (s - s_\infty) \right\|_2 \\ &\le \|(1-s)\ \partial_x \sigma\|_2\ \left\| \partial_x (\ell - \ell_\infty) \right\|_2\ \left\| \partial_x (s - s_\infty) \right\|_2 + \left\| \partial_x (\ell - \ell_\infty) \right\|_2\ \left\| \partial_x (s - s_\infty) \right\|_2 \\ &+ \|\partial_x \ell_\infty\|_\infty\ \|s - s_\infty\|_2\ \left\| \partial_x (s - s_\infty) \right\|_2 \\ &\le C_{22}\ \left(\left\| \partial_x (\ell - \ell_\infty) \right\|_2 + \|s - s_\infty\|_2 \right)\ \left\| \partial_x (s - s_\infty) \right\|_2 \\ &\le \frac{\delta}{2}\ \left\| \partial_x (s - s_\infty) \right\|_2^2 + \frac{C_{23}}{2}\ \left(\left\| \partial_x (\ell - \ell_\infty) \right\|_2^2 + \|s - s_\infty\|_2^2 \right). \end{aligned}$$

Since ℓ_∞ and ε are nonnegative we end up with

$$\frac{d}{dt}\,\|\partial_x\,(s-s_\infty)\|_2^2+\delta\;\|\partial_x\,(s-s_\infty)\|_2^2\le C_{23}\;\left(\|\partial_x\,(\ell-\ell_\infty)\|_2^2+\|s-s_\infty\|_2^2\right). \tag{3.18}$$

We now multiply (3.18) by $D\vartheta/C_{23}$ and add the result to (3.17) to obtain

$$\begin{aligned}\frac{d}{dt}\left(\|\ell-\ell_\infty\|_2^2+\frac{D\vartheta}{C_{23}}\,\|\partial_x\,(s-s_\infty)\|_2^2\right)+\vartheta\;\|\ell-\ell_\infty\|_2^2\\ +\;\frac{D\vartheta\delta}{C_{23}}\,\|\partial_x\,(s-s_\infty)\|_2^2\le C_{24}\;\|s-s_\infty\|_2^2.\end{aligned}$$

Introducing $\omega:=\min\{\vartheta,\delta\}>0$ and integrating the above differential inequality give

$$\begin{aligned}\left(\|\ell(t)-\ell_\infty\|_2^2+\frac{D\vartheta}{C_{23}}\,\|\partial_x\,(s(t)-s_\infty)\|_2^2\right)\le\left(\|\ell_0-\ell_\infty\|_2^2+\frac{D\vartheta}{C_{23}}\,\|\partial_x\,(s_0-s_\infty)\|_2^2\right)\;e^{-\omega t}\\ +\,C_{24}\;\int_0^t\|s(\tau)-s_\infty\|_2^2\;e^{\omega(\tau-t)}\;d\tau\end{aligned}$$

for $t\ge0$. Since $\|s(\tau)-s_\infty\|_2\longrightarrow0$ as $\tau\to\infty$ by (3.16), we deduce from the above inequality that both $\|\ell(t)-\ell_\infty\|_2$ and $\|\partial_x\,(s(t)-s_\infty)\|_2$ converge to zero as $t\to\infty$, and the proof of Theorem 3 is complete. □

4. Well-posedness of (1.1)–(1.2). In this section, we consider the initial-boundary value problem

$$\partial_t\ell=D\;\partial_x^2\ell+\delta\;s-\ell\;(1-s),\quad(t,x)\in(0,\infty)\times(0,1), \tag{4.1}$$

$$\partial_t s=\ell\;(1-s)-(\delta+\varepsilon)\;s,\quad(t,x)\in(0,\infty)\times(0,1), \tag{4.2}$$

$$D\;\partial_x\ell(t,0)+\nu=\ell(t,1)=0,\quad t\in(0,\infty), \tag{4.3}$$

$$(\ell,s)(0,x)=(\ell_0,s_0)(x),\quad x\in(0,1), \tag{4.4}$$

with $D>0$, $\delta>0$, $\varepsilon\ge0$, and $\nu>0$.

THEOREM 8. *Given initial data (ℓ_0,s_0) satisfying (1.7) the initial-boundary value problem (4.1)–(4.4) possesses a unique weak solution*

$$(\ell,s)\in\mathcal{C}([0,\infty);V\times V)\cap\mathcal{C}^1([0,\infty);V'\times V)$$

such that $\partial_t\ell\in L^2((0,T)\times(0,1))$ for every $T>0$,

$$0\le\ell(t,x)\quad\textit{and}\quad0\le s(t,x)<1\quad\textit{for}\quad(t,x)\in[0,\infty)\times[0,1], \tag{4.5}$$

and

$$\begin{aligned}\langle\partial_t\ell(t),\psi\rangle_{V',V}+D\;\int_0^1\partial_x\ell(t)\;\partial_x\psi\;dx\\ =\nu\;\psi(0)+\int_0^1\left(\delta s(t)-\ell(t)(1-s(t))\right)\;\psi\;dx,\end{aligned}$$

$$\partial_t s(t)=-(\delta+\varepsilon)s(t)+\ell(t)(1-s(t))$$

for $\psi\in V$ and $t\in[0,\infty)$. Furthermore, for each $t>0$,

$$\Lambda(\ell(t),s(t))+\int_0^t\mathcal{D}_\Lambda(\ell(\tau),s(\tau))\;d\tau=\Lambda(\ell_0,s_0), \tag{4.6}$$

where

$$\Lambda(u,v) := \frac{1}{2}\ \|u-\ell_\infty\|_2^2 + \Lambda_0(u,v),$$

$$\Lambda_0(u,v) := \int_0^1 (1-s_\infty)\ (\ell_\infty+\delta+2\varepsilon)\ \left[\Sigma_I(v)-\Sigma_I(s_\infty)-\frac{v-s_\infty}{1-s_\infty}\right]\ dx \ge 0,$$

$$\mathcal{D}_\Lambda(u,v) := D\ \|\partial_x(u-\ell_\infty)\|_2^2 + \int_0^1 \frac{|\partial_t v|^2+\varepsilon\ (\ell_\infty+\delta+\varepsilon)\ (v-s_\infty)^2}{1-v}\ dx,$$

$s_\infty := \ell_\infty/(\ell_\infty+\delta+\varepsilon)$, *and* ℓ_∞ *denotes the unique solution to the boundary-value problem*

$$-D\ \partial_x^2\ell_\infty + \frac{\varepsilon\ \ell_\infty}{\ell_\infty+\delta+\varepsilon} = 0 \quad in \quad (0,1), \quad D\ \partial_x\ell_\infty(0)+\nu = \ell_\infty(1) = 0. \tag{4.7}$$

We first point out that the nonnegativity of Λ_0 is a consequence of the convexity of Σ_I. We next observe that Λ differs strongly from $\mathcal{L}$ and provide valuable information on the large time behavior. In fact, exponential convergence to the steady state can be shown; see Proposition 9 below.

Proof. The local well-posedness of (4.1)–(4.4) in $V\times V$ and the bounds (4.5) for (ℓ,s) on the maximal existence time interval $[0,T_m)$ are established as in the proof of Theorem 1 by employing the abstract theory developed in [1]. In addition, since $u\longmapsto \varepsilon u/(u+\delta+\varepsilon)$ is a nondecreasing function, the existence and uniqueness of the solution ℓ_∞ to (4.7) are proved by classical arguments [2, 4].

We next turn to the proof of the identity (4.6) for $t\in[0,T_m)$. For that purpose, we take $\psi=\ell-\ell_\infty$ in the weak formulation of (4.1) and (4.7) for ℓ and ℓ_∞ and use (4.2) for s and s_∞ to obtain

$$\frac{1}{2}\ \frac{d}{dt}\|\ell-\ell_\infty\|_2^2 + D\ \|\partial_x(\ell-\ell_\infty)\|_2^2 = -\int_0^1 (\partial_t s+\varepsilon\ (s-s_\infty))\ (\ell-\ell_\infty)\ dx. \tag{4.8}$$

Owing to (4.2) we have

$$\ell-\ell_\infty = \frac{\partial_t s}{1-s} + (\delta+\varepsilon)\ \frac{s-s_\infty}{(1-s)\ (1-s_\infty)}.$$

Consequently,

$$\begin{aligned}
&-\int_0^1 (\partial_t s+\varepsilon\ (s-s_\infty))\ (\ell-\ell_\infty)\ dx\\
&= -\int_0^1 \frac{|\partial_t s|^2}{1-s}\ dx - \int_0^1 \left[\varepsilon+\frac{\delta+\varepsilon}{1-s_\infty}\right]\ (s-s_\infty)\ \frac{\partial_t s}{1-s}\ dx\\
&\quad -\varepsilon(\delta+\varepsilon)\ \int_0^1 \frac{(s-s_\infty)^2}{(1-s)\ (1-s_\infty)}\ dx\\
&= -\int_0^1 \frac{|\partial_t s|^2}{1-s}\ dx - \int_0^1 (\ell_\infty+\delta+2\varepsilon)\ \partial_t\left((1-s_\infty)\ \Sigma_I(s)-s\right)\ dx\\
&\quad -\varepsilon\ \int_0^1 (\ell_\infty+\delta+\varepsilon)\ \frac{(s-s_\infty)^2}{1-s}\ dx,
\end{aligned}$$

where we have used $(\delta+\varepsilon)/(1-s_\infty)=\ell_\infty+\delta+\varepsilon$ to deduce the last equality. Inserting the previous equality in (4.8) gives (4.6) for $t\in[0,T_m)$ after integration with respect to time.

A useful consequence of (4.6) is that

$$\|\ell(t)\|_2 \le \|\ell_\infty\|_2 + \sqrt{2\ \Lambda(\ell_0,s_0)}, \quad t\in[0,T_m). \tag{4.9}$$

We next proceed as in the proof of (2.18) and take $\psi=\partial_t\ell$ in the weak formulation of (4.1) (recall that a regularization procedure has to be used to justify this step as $\partial_t\ell\notin V$). This gives

$$\|\partial_t\ell\|_2^2 + \frac{D}{2}\ \frac{d}{dt}\|\partial_x\ell\|_2^2 = \int_0^1 \partial_t\ell\ (\delta\ s-\ell\ (1-s))\ dx \le \frac{1}{2}\ \|\partial_t\ell\|_2^2 + \left(\delta+\|\ell\|_2^2\right).$$

We then infer from (4.9) that

$$\int_0^t \|\partial_t\ell(\tau)\|_2^2\ d\tau + D\ \|\partial_x\ell(t)\|_2^2 \le C_{25}\ (1+t), \quad t\in[0,T_m). \tag{4.10}$$

We next differentiate (4.2) to obtain the equation solved by $\partial_x s$ and deduce from (4.10) that

$$\|\partial_x s(t)\|_2 \le C_{26}\ (1+t), \quad t\in[0,T_m). \tag{4.11}$$

Finally, we infer from (4.2), (4.5), (4.9), (4.10), (4.11), and the continuous embedding of $H^1(0,1)$ in $L^\infty(0,1)$ that

$$s\in W^{1,\infty}([0,T]\cap[0,T_m);H^1(0,1)) \quad\text{and}\quad \delta\ s-\ell\ (1-s)\in L^2((0,T)\cap(0,T_m);H^1(0,1))$$

for all $T>0$. Combining this last property with (4.1) and [10, Theorem 4.3.1] ensures that

$$\ell\in\mathcal{C}^{1/2}((0,T]\times(0,T_m);H^1(0,1)) \quad\text{for all}\quad T>0.$$

Collecting the above information allows us to conclude that $T_m=\infty$ and complete the proof. □

We next turn to the large time behavior and prove the following result.

PROPOSITION 9. *Consider initial data (ℓ_0,s_0) satisfying (1.7) and denote by (ℓ,s) the corresponding weak solution to (4.1)–(4.4) given by Theorem 8. Then, for $t\ge 0$,*

$$\|\ell(t)-\ell_\infty\|_2^2 + (\delta+\varepsilon)\ \|s(t)-s_\infty\|_2^2 \le 2\ \Lambda(\ell_0,s_0)\ e^{-\chi t} \tag{4.12}$$

with

$$\chi := \min\left\{D, \frac{D\ (\delta+\varepsilon)}{2(D+2)} + \frac{\varepsilon}{2}\right\}. \tag{4.13}$$

Proposition 9 is a simple consequence of (4.6) and the following two functional inequalities.

LEMMA 10. *Under the assumptions and notation of Proposition 9 we have for all $t\ge 0$*

$$\mathcal{D}_\Lambda(\ell(t),s(t)) \ge \chi\ \Lambda(\ell(t),s(t)), \tag{4.14}$$

$$\Lambda_0(s(t)) \ge \frac{\delta+\varepsilon}{2}\ \|s(t)-s_\infty\|_2^2. \tag{4.15}$$

Proof. By the elementary inequality $a^2 \le ((D+2)/D)\ (a-b)^2 + ((D+2)/2)\ b^2$ we have

$$\begin{aligned}
&\int_0^1 \left(\frac{\delta+\varepsilon}{1-s_\infty}\right)^2 \ \frac{(s-s_\infty)^2}{1-s}\ dx \\
&\le \frac{D+2}{D}\ \int_0^1 (1-s)\ \left[\frac{\delta+\varepsilon}{1-s_\infty}\ \frac{s-s_\infty}{1-s} - (\ell-\ell_\infty)\right]^2\ dx \\
&+ \frac{D+2}{2}\ \int_0^1 (1-s)\ (\ell-\ell_\infty)^2\ dx \\
&\le \frac{D+2}{D}\ \left\{\int_0^1 (1-s)\ \left(\frac{\partial_t s}{1-s}\right)^2\ dx + \frac{D}{2}\ \|\ell-\ell_\infty\|_2^2\right\}, \qquad (4.16)
\end{aligned}$$

the last inequality following from the identities $\ell+\delta+\varepsilon = (\partial_t s+\delta+\varepsilon)/(1-s)$ and

$$\frac{\delta+\varepsilon}{1-s_\infty} = \ell_\infty+\delta+\varepsilon \ge \delta+\varepsilon. \qquad (4.17)$$

We next infer from the Poincaré inequality (2.13), (4.16), and (4.17) that

$$\begin{aligned}
\mathcal{D}_\Lambda(\ell,s) &\ge D\ \|\ell-\ell_\infty\|_2^2 + \int_0^1 \frac{|\partial_t s|^2}{1-s}\ dx + \varepsilon\ (\delta+\varepsilon)\ \int_0^1 \frac{(s-s_\infty)^2}{(1-s)(1-s_\infty)}\ dx \\
&\ge \frac{D}{2}\ \|\ell-\ell_\infty\|_2^2 + \frac{D}{D+2}\ \int_0^1 \left(\frac{\delta+\varepsilon}{1-s_\infty}\right)^2\ \frac{(s-s_\infty)^2}{1-s}\ dx \\
&\quad + \varepsilon\ (\delta+\varepsilon)\ \int_0^1 \frac{(s-s_\infty)^2}{(1-s)(1-s_\infty)}\ dx, \\
\mathcal{D}_\Lambda(\ell,s) &\ge \frac{D}{2}\ \|\ell-\ell_\infty\|_2^2 + (\delta+\varepsilon)\ \left(\frac{D(\delta+\varepsilon)}{D+2}+\varepsilon\right)\ \int_0^1 \frac{(s-s_\infty)^2}{(1-s)(1-s_\infty)}\ dx. \qquad (4.18)
\end{aligned}$$

We next claim that

$$\frac{(z-a)^2}{2} \le \Sigma_I(z)-\Sigma_I(a)-\frac{z-a}{1-a} \le \frac{1}{2}\ \frac{1+a}{1-a}\ \frac{(z-a)^2}{1-z}, \quad (a,z)\in[0,1)\times[0,1). \qquad (4.19)$$

Indeed, the first inequality in (4.19) follows from the convexity of Σ_I, while the second can be shown by studying the variation of the function

$$z \longmapsto (1-z)\ \left[\Sigma_I(z)-\Sigma_I(a)-\frac{z-a}{1-a}\right] - \frac{1}{2}\ \frac{1+a}{1-a}\ (z-a)^2,$$

the real number a being fixed in $[0,1)$. Using the second inequality in (4.19) with $z=s(t,x)$ and $a=s_\infty(x)$ gives

$$\int_0^1 \frac{(s-s_\infty)^2}{(1-s)(1-s_\infty)}\ dx \ge \int_0^1 \frac{2(\delta+\varepsilon)}{1+s_\infty}\left(\Sigma_I(s)-\Sigma_I(s_\infty)-\frac{s-s_\infty}{1-s_\infty}\right)\ dx.$$

Using once more (4.17) we realize that

$$\begin{aligned}
\frac{2(\delta+\varepsilon)}{1+s_\infty} &= \frac{2(\delta+\varepsilon)}{1+s_\infty}\ \frac{(1-s_\infty)\ (\ell_\infty+\delta+2\varepsilon)}{\delta+\varepsilon+\varepsilon(1-s_\infty)} \\
&\ge (\delta+\varepsilon)\ \frac{(1-s_\infty)\ (\ell_\infty+\delta+2\varepsilon)}{\delta+2\varepsilon} \\
&\ge \frac{(1-s_\infty)\ (\ell_\infty+\delta+2\varepsilon)}{2},
\end{aligned}$$

so that

$$\int_0^1 \frac{(s-s_\infty)^2}{(1-s)(1-s_\infty)}\,dx \geq \frac{1}{2}\,\Lambda_0(s).$$

Inserting the previous inequality in (4.18) gives

$$\mathcal{D}_\Lambda(\ell,s) \geq \frac{D}{2}\,\|\ell-\ell_\infty\|_2^2 + \frac{1}{2}\left(\frac{D(\delta+\varepsilon)}{D+2}+\varepsilon\right)\Lambda_0(s) \geq \chi\,\Lambda(\ell,s),$$

and hence (4.14).

Inequality (4.15) readily follows from (4.17) and the first inequality in (4.19). ∎

5. Numerical simulations. Above, we have developed a theory which provides insight into the stationary states and large time behavior of two models of morphogen transport. It is therefore interesting to verify the dependence on the parameters of both the properties of these stationary solutions and the convergence rate to the equilibrium. For this, we have performed numerical simulations on an x86-64 machine under MATLAB 7.2. All source files are available upon request.

We discuss certain qualitative properties of (1.3)–(1.6) and (4.1)–(4.4) for a range of their parameters with default values $D=\nu=\delta=1$ and $\varepsilon=0$. For an evaluation of the two models for biologically relevant parameter values, see [7]. In all experiments, we supply zero initial data, $\ell_0(x)=s_0(x)=0$. For clarity, in what follows we shall refer to (1.3)–(1.6) as the nonlinear diffusion (ND) model and to (4.1)–(4.4) as the linear diffusion (LD) model.

Discretization. To discretize the system (1.3)–(1.6) we employ a finite difference scheme in the spatial variable on a regular mesh with $N=240$ nodes. Introducing $\ell_i(t)\approx\ell(t,ih)$, $s_i(t)\approx s(t,ih)$, where h is the mesh size and using the first order flux approximation,

$$j_i = \left(1-\frac{s_{i+1}+s_i}{2}\right)\frac{\ell_{i+1}-\ell_i}{h},$$

we arrive at a system of $2N$ ordinary differential equations (ODEs)

$$\frac{d\ell_i}{dt} = \frac{j_i-j_{i-1}}{h} + \delta s_i - \ell_i\,(1-s_i)\,, \tag{5.1a}$$

$$\frac{ds_i}{dt} = -(\delta+\varepsilon)s_i + \ell_i\,(1-s_i) \tag{5.1b}$$

for $i=1,\ldots,N$. This discretization has the truncation error of second order with respect to h and is supplemented by a first order approximation of the flux boundary condition. In order to solve (5.1) we use a stiff ODE solver `ode15s` from MATLAB. Since we trace the behavior of the solution up to very small time derivatives, we adjust the absolute and relative error tolerance parameters in `ode15s` to the value of 10^{-13}. Model LD is discretized and solved analogously.

Steady state computation. As observed in [7], without degradation ($\varepsilon=0$) one has explicit formulas for the stationary states, since from (1.13) it follows that for the ND model there holds

$$\ell_\infty(x) = \delta\,\left(\exp\left(\frac{\nu}{\delta D}(1-x)\right)-1\right), \tag{5.2}$$

$$s_\infty(x) = 1-\exp\left(-\frac{\nu}{\delta\,D}\,(1-x)\right), \tag{5.3}$$

while for the LD model, according to Theorem 8,

$$\ell_\infty(x) = \frac{\nu}{D}(1-x), \tag{5.4}$$

$$s_\infty(x) = 1 - \frac{1}{1 + (\nu/(\delta\, D))\,(1-x)}. \tag{5.5}$$

But when $\varepsilon > 0$ there is no closed formula and we have to approximate the steady states numerically. To this end, we either run the simulation until the L^2 norm of the right-hand side of the discrete ODE system drops (unless otherwise stated) below 10^{-6} or we solve the nonlinear system (5.1), where we replace time derivatives with zeros. Note, however, that although in practice the first procedure turns out to be more robust, none of these procedures guarantees that the obtained solution is sufficiently close to the stationary state, particularly when s_∞ is too close to 1; see [7] for a more detailed discussion.

5.1. Dependence of the convergence rate on the parameters. According to Theorem 3, the solutions of the ND model converge to the stationary state. From Proposition 9 we know that for the LD model the distance between the solution and the equilibrium decays at least at an exponential rate. It may therefore be interesting to identify the actual convergence rate of the two models under consideration for several values of the parameters. In order to do so, we investigate the L^2 norm of the relative difference between the stationary solution (ℓ_∞, s_∞) and the solution at time t,

$$d_{rel}(t) = \frac{||(\ell, s)(t) - (\ell_\infty, s_\infty)||_2}{||(\ell_\infty, s_\infty)||_2}.$$

We stop the analysis when d_{rel} drops below 10^{-5}; otherwise the results would have been polluted with the discretization error.

We consider four cases, when only one of the parameters ε, ν, D, or δ is allowed to vary, while the others are kept at their default values.

The convergence to the stationary state seems to occur indeed at an exponential rate; see the top plots in Figures 1–4. Therefore, we can next compare the dependence of the rates on various parameters of the models. To this end, we introduce an approximate measure of the convergence rate ζ as the mean value of the ratios

$$\zeta_i = -\frac{\ln(d_{rel}(t_{i+1})) - \ln(d_{rel}(t_i))}{t_{i+1} - t_i}$$

for several subsequent t_i at which d_{rel} was measured.

As could be expected by comparing the diffusive parts, the LD model always converges faster than the ND model for the same parameter set. From the modeling point of view, as the constants D and δ have different interpretation in each of the two models [7], it is worth mentioning that for moderate values of D, an approximately tenfold increase of D in the nonlinear diffusion model is needed to recover the convergence speed of the linear diffusion model (see Figure 3). Although in the absence of degradation the stationary states of the two models depend only on the ratio $\nu/(\delta\, D)$, the convergence rate may be different for the same ratios of $\nu/(\delta\, D)$, as indicated in Figures 2–4.

Both models show similar dependence of the convergence speed ζ on the degradation rate ε, the unbinding parameter δ, and the diffusion coefficient D. However,

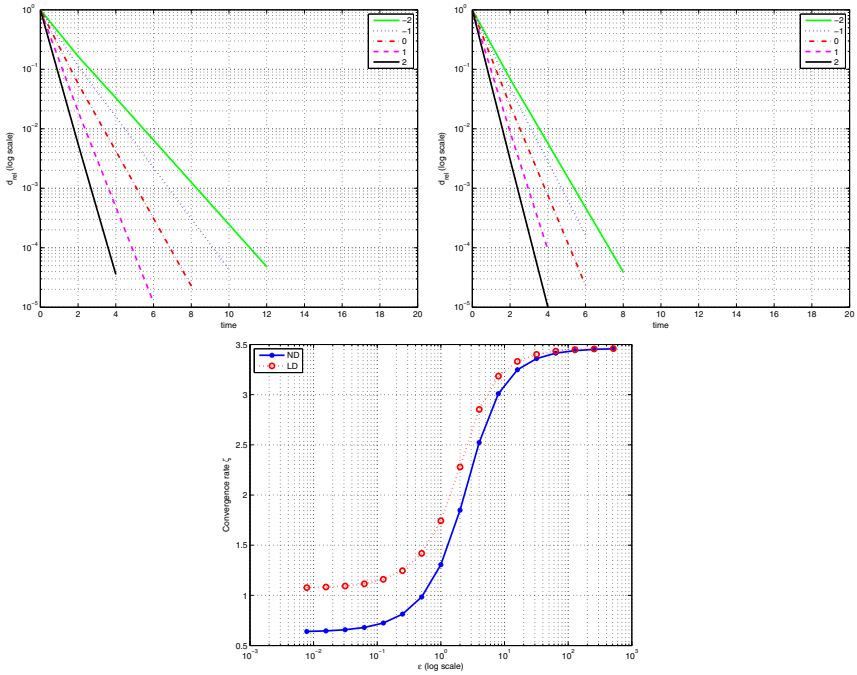

FIG. 1. *Convergence to the equilibrium for different values of ε. The ND model (top left) vs. the LD model (top right) for $\varepsilon = 2^k$, $k = -2, \dots, 2$. The comparison of the convergence rates ζ for a broader range of ε (bottom).*

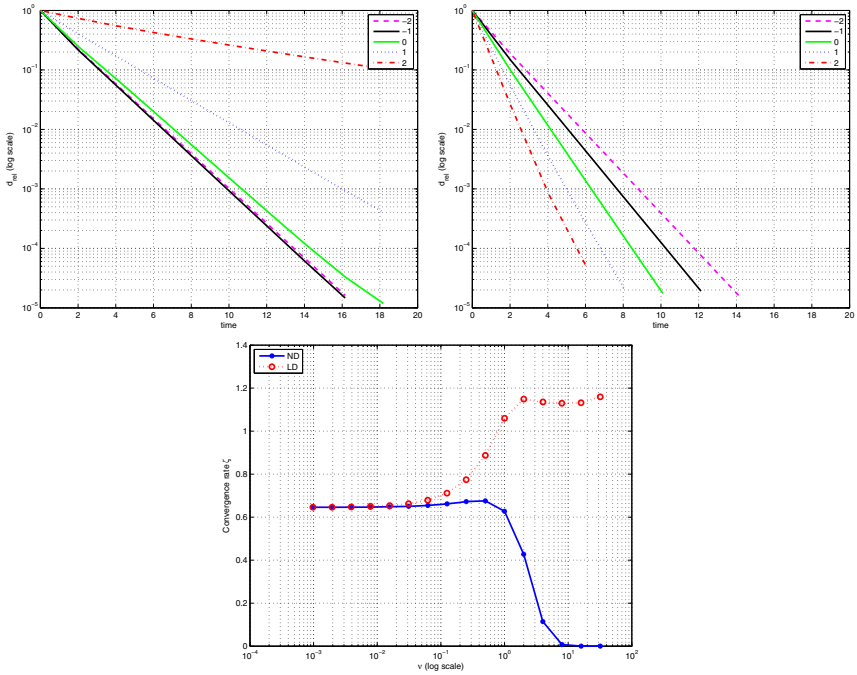

FIG. 2. *Convergence to the equilibrium for different values of ν. The ND model (top left) vs. the LD model (top right) for $\nu = 2^k$, $k = -2, \dots, 2$. The comparison of the convergence rates ζ for a broader range of ν (bottom).*

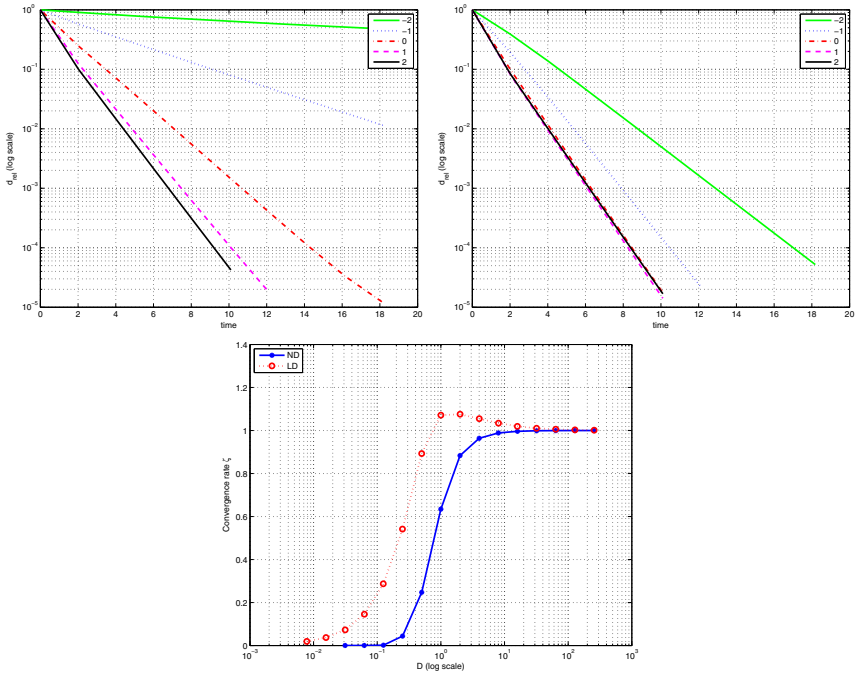

FIG. 3. *Convergence to the equilibrium for different values of D. The ND model (top left) vs. the LD model (top right) for $D = 2^k$, $k = -2, \ldots, 2$. The comparison of the convergence rates ζ for a broader range of D (bottom).*

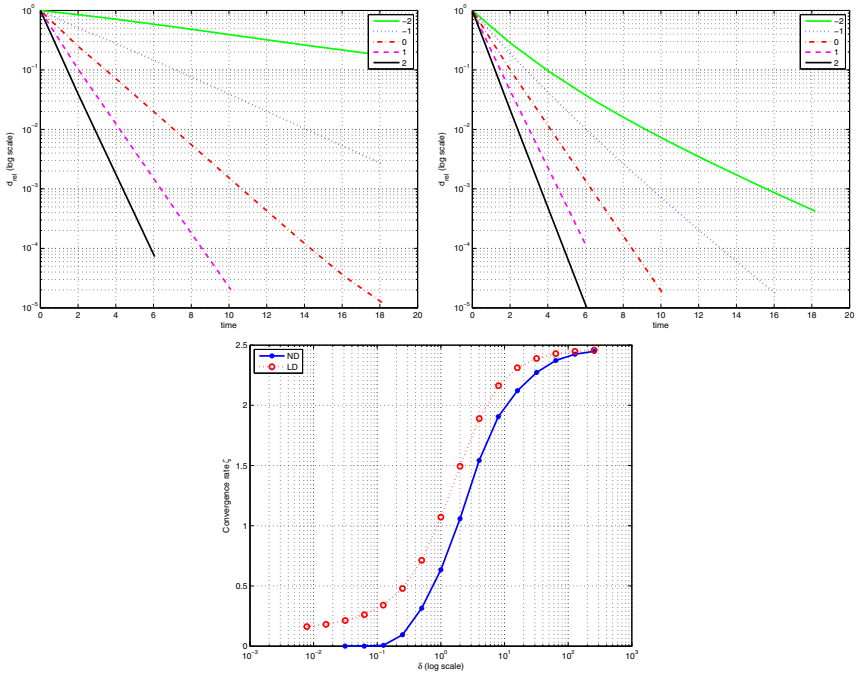

FIG. 4. *Convergence to the equilibrium for different values of δ. The ND model (top left) vs. the LD model (top right) for $\delta = 2^k$, $k = -2, \ldots, 2$. The comparison of the convergence rates ζ for a broader range of δ (bottom).*

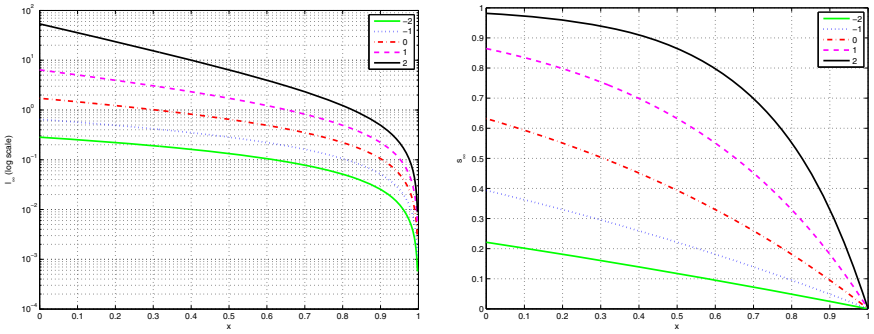

FIG. 5. *Stationary states of the ND model,* $\nu = 2^k$, $k = -2, -1, 0, 1, 2$, *without degradation.*

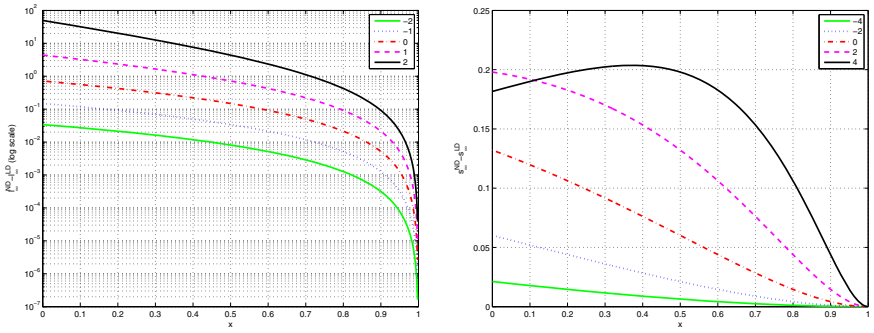

FIG. 6. *Difference between the stationary states of the ND and LD models,* $\nu = 2^k$, $k = -2, -1, 0, 1, 2$, *without degradation.*

the two models differ significantly with respect to their sensitivity to the injection parameter ν: the convergence speed increases with ν for the LD model, while the effect of ν on the convergence of the ND model is opposite; cf. Figure 2 (bottom). This is explained by looking at the stationary states of the latter model; see Figures 5 and 6. The stationary solution reaches, in the case of nonlinear diffusion, higher values than in the linear diffusion case. Indeed, from (5.2) and (5.4) it follows that $\|\ell_\infty\|_\infty = \delta \ (\exp(\nu/(\delta D)) - 1)$ for the ND model which clearly exceeds by far the L^∞ norm ν/D of ℓ_∞ of the LD model. The closer s_∞ gets to 1, the smaller the diffusion, and thus it takes more time for the solution to evolve to the steady state.

It is important to notice that due to the nonlinear effects, both models cannot converge to (ℓ_∞, s_∞) arbitrarily fast, as can be concluded from the bottom parts of Figures 1–4. For each of varying parameters, there is some threshold value of ζ, which cannot be surpassed regardless of the value of the parameter.

Let us observe that for sufficiently large values of D, ε, δ, or $1/\nu$, the convergence speed of both models stabilizes at almost an identical level. On one hand, the similarity in the convergence rates can easily be explained by noticing that the s_∞-component of the steady state of the nonlinear model is so close to zero that the fluxes for both models are nearly the same. On the other hand, the convergence rate stabilization effect is in full agreement with our previous discussion of the Liapunov function for the LD model in the case of varying D. Indeed, denoting by (ℓ^D, s^D) the solution to the LD model for some prescribed D, it follows from (4.6) and (4.7) that

$\ell^D \to 0$ in $L^2(0,T;H^1(0,1))$ as $D \to \infty$. Hence we deduce that s^D converges towards S, solving $\partial_t S = -(\delta+\varepsilon)S$, which exponentially decays to zero at rate $\delta+\varepsilon$ (cf. Figure 3, where $\delta+\varepsilon=1$), to be compared with the L^2 norm decay rate $\chi/2 = \delta/4+\varepsilon/2$ obtained in the limit $D \to \infty$ from (4.13).

5.2. Dependence of the stationary solutions on the parameters. As confirmed by Figures 5–6 and experiments for other parameters not reported here (see also [7]), for identical set of parameters, the two models produce stationary solutions of quite similar shape. There is a difference in how the ν parameter affects the stationary states of the two models; cf. Figures 5–6. The ℓ_∞-component of the stationary solution of the nonlinear diffusion model shows more sensitivity to large values of ν than its linear diffusion counterpart. This is because for large ν, the x-derivative of ℓ is much larger in the nonlinear diffusion case, due to higher saturation level of s. The stationary states of the two models are much less sensitive to the changes in the degradation rate ε. There is only a limited range of ε, close to 1, for which large relative change in ε results in a similar large change in the stationary solutions.

Acknowledgments. Part of this research was carried out during P. Krzyżanowski's and D. Wrzosek's visits to the Institut de Mathématiques de Toulouse and during Ph. Laurençot's visit to the Institute of Applied Mathematics at Warsaw University. The authors thank both institutions for their hospitality. They also thank an anonymous referee for pointing out a gap in the original proof of Theorem 1.

ON THE WHITHAM EQUATIONS FOR THE DEFOCUSING COMPLEX MODIFIED KDV EQUATION*

YUJI KODAMA†, V. U. PIERCE†, AND FEI-RAN TIAN†

Abstract. We study the Whitham equations for the defocusing complex modified KdV (mKdV) equation. These Whitham equations are quasi-linear hyperbolic equations and describe the averaged dynamics of the rapid oscillations which appear in the solution of the mKdV equation when the dispersive parameter is small. The oscillations are referred to as dispersive shocks. The Whitham equations for the mKdV equation are neither strictly hyperbolic nor genuinely nonlinear. We are interested in the solutions of the Whitham equations when the initial values are given by a step-like function. We also compare the results with those of the defocusing nonlinear Schrödinger (NLS) equation. For the NLS equation, the Whitham equations are strictly hyperbolic and genuinely nonlinear. We show that the weak hyperbolicity of the mKdV–Whitham equations is responsible for some new structure in the dispersive shocks which has not been found in the NLS case.

Key words. Whitham equations, non-strictly hyperbolic equations, dispersive shocks

1. Introduction.

In [11, 12], Pierce and Tian studied the self-similar solutions of the Whitham equations which describe the zero dispersion limits of the KdV hierarchy. The main feature of the Whitham equations for the higher members of the hierarchy, of which the KdV equation is the first member, is that these Whitham equations are neither strictly hyperbolic nor genuinely nonlinear. This is in sharp contrast to the case of the KdV equation whose Whitham equations are strictly hyperbolic and genuinely nonlinear [8]. In this paper, we extend their studies to the case of the complex modified KdV (mKdV) equation, which is the second member of the defocusing nonlinear Schrödinger (NLS) hierarchy. The Whitham equations for the defocusing NLS equation are strictly hyperbolic and genuinely nonlinear, and they have been studied extensively (see, for example, [4, 6, 7, 10, 14]). However, for the mKdV equation, the Whitham equations are neither strictly hyperbolic nor genuinely nonlinear.

Let us begin with a brief description of the zero dispersion limit of the solution of the NLS equation

$$\sqrt{-1}\,\epsilon\frac{\partial\psi}{\partial t}+2\epsilon^2\frac{\partial^2\psi}{\partial x^2}-4|\psi|^2\psi=0, \tag{1.1}$$

with the initial data

$$\psi(x,0)=A_0(x)\exp\left(\sqrt{-1}\,\frac{S_0(x)}{\epsilon}\right).$$

Here $A_0(x)$ and $S_0(x)$ are real functions that are independent of ϵ. Writing the solution $\psi(x,t;\epsilon)=A(x,t;\epsilon)\exp(\sqrt{-1}\,\frac{S(x,t;\epsilon)}{\epsilon})$ and using the notation $\rho(x,t;\epsilon)=A^2(x,t;\epsilon)$,

$v(x,t;\epsilon) = \partial S(x,t;\epsilon)/\partial x$, one obtains the conservation form of the defocusing NLS equation,

$$\begin{cases} \dfrac{\partial \rho}{\partial t} + \dfrac{\partial}{\partial x}(4\rho v) = 0, \\ \dfrac{\partial}{\partial t}(\rho v) + \dfrac{\partial}{\partial x}\left(4\rho v^2 + 2\rho^2\right) = \epsilon^2 \dfrac{\partial}{\partial x}\left(\rho \dfrac{\partial^2}{\partial x^2} \ln \rho\right). \end{cases} \tag{1.2}$$

The mass density $\rho = |\psi|^2$ and momentum density $\rho v = \frac{\sqrt{-1}}{2}(\psi\psi_x^* - \psi^*\psi_x)$ have weak limits as $\epsilon \to 0$ [6]. These limits satisfy a 2×2 system of hyperbolic equations

$$\begin{cases} \dfrac{\partial \rho}{\partial t} + \dfrac{\partial}{\partial x}(4\rho v) = 0, \\ \dfrac{\partial}{\partial t}(\rho v) + \dfrac{\partial}{\partial x}\left(4\rho v^2 + 2\rho^2\right) = 0 \end{cases} \tag{1.3}$$

until its solution develops a shock. System (1.3) can be rewritten in the diagonal form for $\rho \neq 0$,

$$\frac{\partial}{\partial t}\begin{pmatrix} \alpha \\ \beta \end{pmatrix} + 2\begin{pmatrix} 3\alpha + \beta & 0 \\ 0 & \alpha + 3\beta \end{pmatrix} \frac{\partial}{\partial x}\begin{pmatrix} \alpha \\ \beta \end{pmatrix} = 0, \tag{1.4}$$

where the Riemann invariants α and β are given by

$$\alpha = \frac{v}{2} + \sqrt{\rho}, \quad \beta = \frac{v}{2} - \sqrt{\rho}. \tag{1.5}$$

As a simple example, we consider the case with $\alpha = a =$ constant. System (1.4) reduces to a single equation

$$\frac{\partial \beta}{\partial t} + 2(a + 3\beta)\frac{\partial \beta}{\partial x} = 0. \tag{1.6}$$

The solution is given by the implicit form

$$\beta(x,t) = h(x - 2(a + 3\beta)t),$$

where $h(x) = \beta(x,0)$ is the initial function for β. One can easily see that if $\beta(x,0)$ decreases in some region, then $\beta(x,t)$ develops a shock in a finite time; i.e., $\partial\beta/\partial x$ becomes singular.

After the shock formation in the solution of (1.3) or (1.4), the weak limits are described by the NLS–Whitham equations, which can also be put in the Riemann invariant form [4, 6, 7, 10]

$$\frac{\partial u_i}{\partial t} + \lambda_{g,i}(u_1, \ldots, u_{2g+2})\frac{\partial u_i}{\partial x} = 0, \quad i = 1, 2, \ldots, 2g+2, \tag{1.7}$$

where $\lambda_{g,i}$ are expressed in terms of complete hyperelliptic integrals of genus g [8]. Here the number g is exactly the number of phases in the NLS oscillations with small dispersion. Accordingly, the zero phase $g = 0$ corresponds to no oscillations, and single and higher phases $g \geq 1$ correspond to the NLS oscillations. System (1.4) is viewed as the zero phase Whitham equations. The solution of the Whitham equations (1.7) for $g \geq 1$ then describes the averaged motion of the oscillations appearing in the solution of (1.1) (see, e.g., [7]).

Let us discuss the most important $g = 1$ case in more detail. We note that it is well known that the KdV oscillatory solution, in the single phase regime, can be approximately described by the KdV periodic solution when the dispersive parameter is small [1, 5, 16]. It is very possible to use the method of [1, 16] to show that the solution of the NLS equation (1.1) for small ϵ can be approximately described, in the single phase regime, by the periodic solution of the NLS equation. The NLS periodic solution has the form

$$\tilde{\rho}(x,t;\epsilon) = \rho_3 + (\rho_2 - \rho_3)\,\mathrm{sn}^2\left(\sqrt{\rho_1 - \rho_3}\;\frac{\theta(x,t)}{\epsilon}, s\right) \tag{1.8}$$

with $\theta(x,t) = x - V_1 t - Q$, where $V_1 = V_1(\rho_1,\rho_2,\rho_3)$ and Q is the phase shift. Here ρ_i's are determined by the equation obtained from (1.2)

$$\frac{\epsilon^2}{4}\left(\frac{d\rho}{d\theta}\right)^2 = (\rho-\rho_1)(\rho-\rho_2)(\rho-\rho_3)$$

with $\rho_1 > \rho_2 > \rho_3$, and $\mathrm{sn}(z,s)$ is the Jacobi elliptic function with the modulus $s = (\rho_2 - \rho_3)/(\rho_1 - \rho_3)$. We can also write ρ_i's as [3]

$$\begin{cases} \rho_1 = \dfrac{1}{4}(u_1 + u_2 - u_3 - u_4)^2, \\ \rho_2 = \dfrac{1}{4}(u_1 - u_2 + u_3 - u_4)^2, \\ \rho_3 = \dfrac{1}{4}(u_1 - u_2 - u_3 + u_4)^2 \end{cases} \tag{1.9}$$

with $u_1 > u_2 > u_3 > u_4$. The velocity V_1 is then given by

$$V_1 = 2(u_1 + u_2 + u_3 + u_4).$$

It can also be shown that the flow velocity of the periodic solution (1.8) is given by [3]

$$\tilde{v}(x,t;\epsilon) = \frac{V_1}{4} + \frac{\sqrt{\rho_1\rho_2}}{2\rho}\,(u_1 - u_2 - u_3 + u_4). \tag{1.10}$$

For constants u_1, u_2, u_3, and u_4, formula (1.8) gives the well-known elliptic solution of the NLS equation. To describe the solution $\rho(x,t;\epsilon)$ of the NLS equation (1.2), the quantities u_1, u_2, u_3, and u_4, are instead functions of x and t and evolve according to the single phase Whitham equations (1.7) for $g = 1$. The phase shift Q is also a function of u_1, u_2, u_3, u_4, and depends on the initial values of system (1.2). Suppose the initial function for system (1.4) is given by

$$\alpha(x,0) = a, \quad \beta(x,0) = \beta_0(x), \tag{1.11}$$

where a is a constant and $\beta_0(x)$ is a monotone function. The Whitham solution of (1.7) has the property that $u_1 = a$ and that only u_2, u_3, u_4 are nontrivial functions of (x,t). Then the phase shift $Q(u_1,u_2,u_3,u_4)$ with $u_1 = a$ is the unique solution of the boundary value problem for the Euler–Poisson–Darboux equations

$$2(u_i - u_j)\frac{\partial^2 Q}{\partial u_i \partial u_j} = \frac{\partial Q}{\partial u_i} - \frac{\partial Q}{\partial u_j}, \quad i,j = 2,3,4, \tag{1.12}$$

$$Q(a,u,u,u) = f(u), \tag{1.13}$$

where boundary value $f(u)$ is the inverse of the initial function $\beta_0(x)$ (see Appendix C for details). If, instead, $\beta(x,0)$ is a constant and $\alpha(x,0)$ is given by a monotone function, the phase shift Q is determined by a similar boundary value problem for the Euler–Poisson–Darboux equations.

The weak limit of $\rho(x,t;\epsilon)$ of the NLS equation (1.1) as $\epsilon \to 0$ can be expressed in terms of ρ_1, ρ_2, ρ_3, and ρ_4 [6] as

$$\overline{\rho(x,t)} = \rho_1 - (\rho_1 - \rho_3)\frac{E(s)}{K(s)}, \tag{1.14}$$

where $K(s)$ and $E(s)$ are the complete elliptic integrals of the first and second kind, respectively. This weak limit can also be viewed as the average value of the periodic solution $\tilde{\rho}(x,t;\epsilon)$ of (1.8) over its period $L = 2\epsilon K(s)/\sqrt{\rho_1 - \rho_3}$.

In order to see how a single phase Whitham solution appears, we consider the following step-like initial data for system (1.4):

$$\alpha(x,0) = a, \quad \beta(x,0) = \begin{cases} b, & x < 0, \\ c, & x > 0, \end{cases} \tag{1.15}$$

where $a > b$, $a > c$, $b \neq c$. The solution of (1.4) develops a shock if and only if $b > c$ (cf. (1.6)). After the formation of a shock, the Whitham equations (1.7) with $g = 1$ kick in. For instance, we consider the Whitham equations with the initial data [7]

$$u_1(x,0) = a, \quad u_2(x,0) = b, \quad u_3(x,0) = \begin{cases} b, & x < 0, \\ c, & x > 0, \end{cases} \quad u_4(x,0) = c. \tag{1.16}$$

Now notice that the Whitham equations (1.7) for $g = 1$ with the initial data (1.16) can be reduced to a single equation $u_{3t} + \lambda_{1,3}(a,b,u_3,c)u_{3x} = 0$. The equation has a global self-similar solution, which is implicitly given by $x/t = \lambda_3(a,b,u_3,c)$. The x-t plane is then divided into *three* parts:

$$(1)\ \frac{x}{t} < \gamma, \quad (2)\ \gamma < \frac{x}{t} < 2a + 4b + 2c, \quad (3)\ \frac{x}{t} > 2a + 4b + 2c,$$

where $\gamma = 2(a+b+2c) - 8(a-c)(b-c)/(a+b-2c)$ (see (2.7) and (2.8) for the derivation). The solution of system (1.4) occupies the first and third parts; i.e.,

(1) for $x/t < \gamma$,

$$\alpha(x,t) = a, \quad \beta(x,t) = b,$$

(3) for $x/t > 2a + 4b + 2c$,

$$\alpha(x,t) = a, \quad \beta(x,t) = c.$$

The Whitham solution of (1.7) with $g = 1$ lives in the second part; i.e.,

(2) for $\gamma < x/t < 2a + 4b + 2c$,

$$u_1(x,t) = a, \quad u_2(x,t) = b, \quad \frac{x}{t} = \lambda_{1,3}(a,b,u_3,c), \quad u_4(x,t) = c,$$

where the solution u_3 can be obtained as a function of the self-similarity variable x/t if

$$\frac{\partial \lambda_{1,3}}{\partial u_3}(a,b,u_3,c) \neq 0.$$

Indeed, it has been shown that the Whitham equations (1.7) are genuinely nonlinear [6, 7]; i.e.,

$$\frac{\partial \lambda_{1,i}}{\partial u_i}(u_1, u_2, u_3, u_4) > 0, \quad i = 1, 2, 3, 4, \tag{1.17}$$

for $u_1 > u_2 > u_3 > u_4$.

In Figure 1.1, we plot the self-similar solution of the Whitham equations (1.7) with $g = 1$ for the NLS equation and the corresponding periodic oscillatory solution (1.8) for the initial data (1.15) with $a = 4$, $b = 1$, and $c = -1$. The oscillations describe a dispersive shock of the NLS equation under a small dispersion. Note here that the oscillations have uniform structure, which is due to an almost linear profile of the Whitham solution u_3. This will be seen to be in sharp contrast to the case of the mKdV equation, which we will discuss later (cf. Figure 1.2).

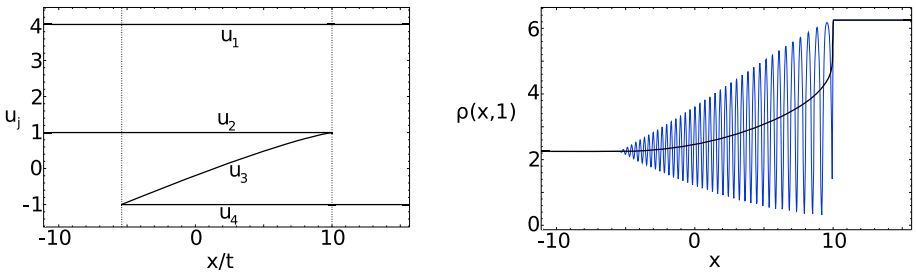

FIG. 1.1. *Self-similar solution of the NLS–Whitham equation* (1.7) *with* $g = 1$ *and the corresponding oscillatory solution* (1.8) *of the NLS equation with* $\epsilon = 0.3$ *at* $t = 1$. *The dark line in the middle of the oscillations is the weak limit* $\overline{\rho(x,t)}$ *given by* (1.14) *at* $t = 1$. *The initial data are given by* (1.15) *with* $a = 4$, $b = 1$, *and* $c = -1$.

Most of the figures in this paper have the same form: On the left-hand side is a plot of the solution of the Whitham equations as a function of the self-similarity variable x/t, which is exact, other than a numerical method used to implement the inverse function theorem. On the right-hand side is the oscillatory solution given by (1.8) at $t = 1$ (respectively, (1.25) for mKdV), while the dark plot is the weak limit (1.14) of the oscillatory solution; both plots on the right are also exact. For all the step-like initial data that we study in this paper, the resulting phase shift Q, which is determined by (1.12) and (1.13), is always zero for both NLS and mKdV. This is due to the fact that our step-like initial function has a jump discontinuity at the origin, which implies that $f \equiv 0$.

In the plots on the left-hand sides of Figures 1.1 and 1.2, we demark the region where the single phase Whitham equations govern the solution and label the four functions $u_1 > u_2 > u_3 > u_4$. The demarcation and labeling are similar in the other figures, and we will omit them for brevity.

The defocusing NLS equation is just the first member of the defocusing NLS hierarchy; the second is the (defocusing) complex mKdV equation

$$\frac{\partial \psi}{\partial t} + \frac{3}{2}\,|\psi|^2 \frac{\partial \psi}{\partial x} - \frac{\epsilon^2}{4}\frac{\partial^3 \psi}{\partial x^3} = 0. \tag{1.18}$$

We again use $\psi(x,t;\epsilon) = A(x,t;\epsilon)\exp(\sqrt{-1}\,\frac{S(x,t;\epsilon)}{\epsilon})$ and notation $\rho(x,t;\epsilon) = A^2(x,t;\epsilon)$, $v(x,t;\epsilon) = \partial S(x,t;\epsilon)/\partial x$ to obtain the conservation form of the mKdV

equation

$$\begin{cases} \dfrac{\partial \rho}{\partial t} + \dfrac{\partial}{\partial x}\left(\dfrac{3}{4}\rho^2 + \dfrac{3}{4}\rho v^2\right) = \epsilon^2 \dfrac{\partial}{\partial x}\left(\rho^{3/4}\dfrac{\partial^2}{\partial x^2}\rho^{1/4}\right), \\ \dfrac{\partial}{\partial t}(\rho v) + \dfrac{\partial}{\partial x}\left(\dfrac{3}{2}\rho^2 v + \dfrac{3}{4}\rho v^3\right) = \dfrac{\epsilon^2}{4}\ \dfrac{\partial}{\partial x}\left[\dfrac{\partial^2}{\partial x^2}(\rho v) - \dfrac{3}{2}R\right], \end{cases} \tag{1.19}$$

where

$$R = \frac{3v}{2\rho}\left(\frac{\partial \rho}{\partial x}\right)^2 + \frac{\partial v}{\partial x}\frac{\partial \rho}{\partial x} - v\frac{\partial^2 \rho}{\partial x^2}.$$

The mass density ρ and momentum density ρv for the mKdV equation also have weak limits as $\epsilon \to 0$ [6]. As in the NLS case, the weak limits satisfy

$$\begin{cases} \dfrac{\partial}{\partial t}\rho + \dfrac{\partial}{\partial x}\left(\dfrac{3}{4}\rho^2 + \dfrac{3}{4}\rho v^2\right) = 0, \\ \dfrac{\partial}{\partial t}(\rho v) + \dfrac{\partial}{\partial x}\left(\dfrac{3}{2}\rho^2 v + \dfrac{3}{4}\rho v^3\right) = 0, \end{cases} \tag{1.20}$$

until the solution of (1.20) forms a shock. One can rewrite equations (1.20) as

$$\frac{\partial}{\partial t}\begin{pmatrix}\alpha \\ \beta\end{pmatrix} + \frac{3}{8}\begin{pmatrix}5\alpha^2 + 2\alpha\beta + \beta^2 & 0 \\ 0 & \alpha^2 + 2\alpha\beta + 5\beta^2\end{pmatrix}\frac{\partial}{\partial x}\begin{pmatrix}\alpha \\ \beta\end{pmatrix} = 0, \tag{1.21}$$

where the Riemann invariants α and β are again given by formula (1.5).

Let us again consider the simplest case $\alpha(x,0) = a$, where a is constant, to see how the solution of system (1.21) develops a shock. In this case, the system reduces to a single equation

$$\frac{\partial \beta}{\partial t} + \frac{3}{8}\left(a^2 + 2a\beta + 5\beta^2\right)\frac{\partial \beta}{\partial x} = 0.$$

As in the NLS case, we consider the initial function given by $\beta(x,0) = b$ for $x < 0$ and $\beta(x,0) = c$ for $x > 0$. We recall that, in the NLS case, the zero phase solution of (1.4) develops a shock if and only if $b > c$. However, the solution in the mKdV case develops a shock for $b > c$ if and only if $a + 5b > 0$. In addition, if $b < c$, the solution in the mKdV case develops a shock if and only if $a + 5b < 0$. These differences between the mKdV and NLS cases are due to the weak hyperbolicity of the system (1.21) (note that, for the eigenspeed $\lambda = \frac{3}{8}(\alpha^2 + 2\alpha\beta + 5\beta^2)$ for β, we have $\partial\lambda/\partial\beta = \frac{3}{4}(\alpha + 5\beta)$ which can change sign). As will be shown below, this leads to new structure in the dispersive shocks for the mKdV case.

As in the case of the NLS equation, immediately after the shock formation in the solution of (1.20), the weak limits are described by the mKdV–Whitham equations

$$\frac{\partial u_i}{\partial t} + \mu_{g,i}(u_1, \ldots, u_{2g+2})\frac{\partial u_i}{\partial x} = 0, \quad i = 1, 2, \ldots, 2g+2, \tag{1.22}$$

where $\mu_{g,i}$ can also be expressed in terms of complete hyperelliptic integrals of genus g [6].

In this paper, we study the solution of the Whitham equations (1.22) with $g = 1$ when the initial mass density $\rho(x,0)$ and momentum density $\rho(x,0)v(x,0)$ are

step-like functions. In view of (1.5), this amounts to requiring α and β of system (1.21) to have step-like initial data. We are interested in the following two cases:

(i) $\alpha(x,0)$ is a constant, and

$$\alpha(x,0)=a,\quad \beta(x,0)=\begin{cases} b, & x<0,\\ c, & x>0,\end{cases}\qquad a>b,\ a>c,\ b\neq c, \tag{1.23}$$

(ii) $\beta(x,0)$ is a constant, and

$$\alpha(x,0)=\begin{cases} b, & x<0,\\ c, & x>0,\end{cases}\quad \beta(x,0)=a,\quad b>a,\ c>a,\ b\neq c. \tag{1.24}$$

In the case of the NLS equation, the genuine nonlinearity of the single phase Whitham equations (see (1.17)) warrants that the solution is found by the implicit function theorem. However, the mKdV–Whitham equations (1.22) generally are not genuinely nonlinear; that is, a property like (1.17) is not available (see Appendix B). Our construction of solutions of the Whitham equations (1.22) with $g=1$ makes use of the non-strict hyperbolicity of the equations. For the NLS case, it is known from [6, 7] that the Whitham equations (1.7) with $g=1$ are strictly hyperbolic; that is,

$$\lambda_{1,1}>\lambda_{1,2}>\lambda_{1,3}>\lambda_{1,4}$$

for $u_1>u_2>u_3>u_4$. For the mKdV–Whitham equations (1.22) with $g=1$, the eigenspeeds $\mu_{1,i}(u_1,u_2,u_3,u_4)$ may coalesce in the region $u_1>u_2>u_3>u_4$.

Let us now describe one of our main results (see Theorem 3.1) for the single phase mKdV–Whitham equations with step-like initial function (1.23) for $a=4$, $b=1$, and $c=-1$. In this case, the space time is divided into *four* regions (see Figure 1.2) instead of *three* in the case of the NLS equation (cf. Figure 1.1):

$$(1)\ \frac{x}{t}<c_1,\quad (2)\ c_1<\frac{x}{t}<c_2,\quad (3)\ c_2<\frac{x}{t}<c_3,\quad (4)\ \frac{x}{t}>c_3,$$

where c_1, c_2, and c_3 are some constants. In the first and fourth regions, the solution of the 2×2 system (1.21) governs the evolution:

(1) for $x/t<c_1$,

$$\alpha(x,t)=4,\quad \beta(x,t)=1;$$

(4) for $x/t>c_3$,

$$\alpha(x,t)=4,\quad \beta(x,t)=-1.$$

The Whitham solution of the 4×4 system (1.22) with $g=1$ lives in the second and third regions:

(2) for $c_1<x/t<c_2$,

$$u_1(x,t)=4,\quad u_2(x,t)=1,\quad \frac{x}{t}=\mu_{1,3}(4,1,u_3,u_4),\quad \frac{x}{t}=\mu_{1,4}(4,1,u_3,u_4);$$

(3) for $c_2<x/t<c_3$,

$$u_1(x,t)=4,\quad u_2(x,t)=1,\quad \frac{x}{t}=\mu_{1,3}(4,1,u_3,-1),\quad u_4(x,t)=-1.$$

Note that, in the second region, we have

$$\mu_{1,3}(4,1,u_3,u_4) = \mu_{1,4}(4,1,u_3,u_4)$$

on a curve in the region $-1 < u_4 < u_3 < 1$. This implies the non-strict hyperbolicity of the mKdV–Whitham equations (1.22) for $g = 1$.

It is again possible to use the method of [1, 16] to show that the solution of the mKdV equation (1.18) can be approximately described, in the single phase regime, by the periodic solution of the mKdV when ϵ is small. The periodic solution has the same form as (1.8) of the NLS, i.e.,

$$\tilde{\rho}(x,t;\epsilon) = \rho_3 + (\rho_2 - \rho_3)\,\mathrm{sn}^2\left(\sqrt{\rho_1 - \rho_3}\;\frac{\theta(x,t)}{\epsilon}, s\right). \tag{1.25}$$

However, $\theta(x,t)$ is now given by $\theta = x - V_2 t - Q$ with the velocity V_2 (see, e.g., [9]):

$$V_2 = \frac{3}{8}\sigma_1^2 - \frac{1}{2}\sigma_2,$$

where $\sigma_1 = \sum_{j=1}^{4} u_j$ and $\sigma_2 = \sum_{i<j} u_i u_j$ are the elementary symmetric functions of degree one and two, respectively. The functions ρ_1, ρ_2, and ρ_3 are also given by formula (1.9), and the flow velocity formula (1.10) is still valid for the mKdV. If u_1, u_2, u_3, and u_4 are constants, formula (1.25) gives the periodic solution of the mKdV equation. To describe the solution $\rho(x,t;\epsilon)$ of the mKdV equation (1.18), the quantities u_1, u_2, u_3, and u_4 must satisfy the single phase mKdV-Whitham equations (1.22) for $g = 1$. The phase shift Q is still determined by (1.12) and (1.13) if the initial function of system (1.21) is given by (1.11). The weak limit of $\rho(x,t;\epsilon)$ of the mKdV equation is also given by formula (1.14).

In Figure 1.2, we plot the self-similar solution of the Whitham equations (1.22) for $g = 1$ and the corresponding periodic oscillatory solution (1.25). We note here that the pattern of the oscillations in this case has two different kinds of structure: one corresponds to the region (2), $c_1 < x/t < c_2$, and the other corresponds to the region (3), $c_2 < x/t < c_3$. In Figure 1.2, those regions are separated by a dashed-dotted line. This is in sharp contrast to the NLS case where the oscillations have uniform structure (cf. Figure 1.1). We also note that the weak limit $\overline{\rho(x,t)}$ and the envelope of the oscillations are not C^1 smooth at $x/t = c_2 \approx 3.67$, while they are smooth (even analytic) everywhere within the oscillatory region in the NLS case. Finally, the shapes of the envelopes of the oscillations are quite different: the one on the right of Figure 1.2 looks like a Bordeaux glass and that of Figure 1.1 resembles a martini glass.

As we will show below, for other values of a, b, and c, the solutions of (1.21) and (1.22) with $g = 1$ will be seen to be quite different from the above.

The Whitham equations (1.22) with $g = 1$ for the mKdV equation are analogous to the Whitham equations for the fifth order KdV equation [11]; both Whitham equations are neither strictly hyperbolic nor genuinely nonlinear. For all the step-like initial shock data, the single phase Whitham solutions for the fifth order KdV are also constructed using the non-strict hyperbolicity of the equations. In the case of KdV, the Whitham equations are strictly hyperbolic and genuinely nonlinear, and the oscillations (dispersive shock) have uniform structure. However, in the case of the fifth order KdV, new structure has been found in the dispersive shocks. This structure is similar to the one found here in the dispersive shocks of the mKdV equation.

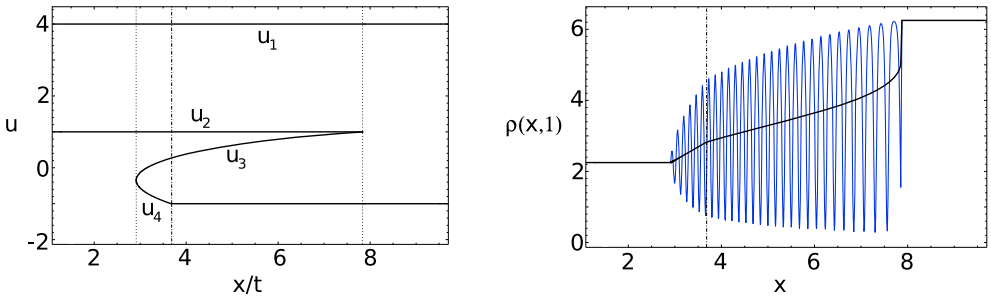

FIG. 1.2. *Self-similar solution of the mKdV–Whitham equation* (1.22) *with* $g = 1$ *and the corresponding oscillatory solution* (1.25) *of the mKdV equation with* $\epsilon = 0.1$. *The initial data are given by* (1.23) *with* $a = 4$, $b = 1$, *and* $c = -1$. *There are two different kinds of structure in the oscillations, and they are separated by* $x/t \approx 3.67$. *Both the weak limit and the envelope of the oscillations have a drastic change at* $x/t \approx 3.67$.

There are still some significant differences between the mKdV oscillations and the fifth order KdV oscillations. The biggest difference lies in the fact that, in the former case, the zero phase Whitham equations (1.21) form a system of two equations, while in the latter case, the zero phase Whitham equation is a scalar equation. In this paper, we consider initial functions (1.23) and (1.24) in which either $\alpha(x,0)$ or $\beta(x,0)$ is a constant; thus equations (1.21) reduce to a single equation. However, the constant initial function $\alpha(x,0) = a$ of (1.23) or $\beta(x,0) = a$ of (1.24) still has a significant effect on the behavior of the Whitham solutions (cf. Figures 3.1 and 4.1). Another difference is that mKdV solution ρ can have points (x,t) at which $\rho(x,t;\epsilon) = 0$ for a sequence of vanishing ϵ (see section 5). These points put the mKdV dispersive approximation (1.19) at stake. This phenomenon does not occur in the fifth order KdV case.

The Whitham equations for the higher members of the KdV hierarchy are again neither strictly hyperbolic nor genuinely nonlinear. However, step-like initial shock data will, in general, generate a mixture of single, double, or even higher phases in the higher order KdV oscillations. It has been an open problem to construct such multiphase Whitham solutions. Only rather special step-like initial shock data will produce merely single phase oscillations in the higher order KdV case. Some of these initial data have been studied in [12]. The analogues of inequalities (2.15) and (2.16), which play a crucial role in the fifth order KdV case, are not valid anymore in the higher order KdV case. As a consequence, the approach in [12] is quite different from that in [11]. Indeed, the calculations in [12] are considerably more difficult than in [11].

The Whitham equations for the higher members of the KdV hierarchy are supposed to be analogous to the Whitham equations for the higher members of the (defocusing) NLS hierarchy. It would be very interesting to see how step-like initial shock data generate multiphases in the higher order NLS oscillations.

The organization of the paper is as follows. In section 2, we will study the eigenspeeds $\mu_{g,1}$, $\mu_{g,2}$, $\mu_{g,3}$, and $\mu_{g,4}$ of the Whitham equations (1.22) for $g = 1$. In section 3, we will construct the self-similar solutions of the single phase Whitham equations for the initial function (1.23) with $a > b > c$. In section 4, we will construct the self-similar solution of the Whitham equations for the initial function (1.23) with $a > c > b$. In section 5, we will study those points (x,t) at which the mKdV solution $\rho(x,t;\epsilon) = 0$ for a sequence of vanishing ϵ. In section 6, we will briefly discuss how to handle the other step-like initial data (1.24).

2. The Whitham equations. In this section we define the eigenspeeds $\lambda_{g,i}$ and $\mu_{g,i}$ of the Whitham equations (1.7) and (1.22) with $g = 1$ for the NLS and the mKdV equations. For simplicity, we suppress the subscript $g = 1$ in the notation $\lambda_{g,i}$ and $\mu_{g,i}$ in the rest of the paper.

We first introduce the polynomials of ξ for $n = 0, 1, 2, \dots$ [2, 4, 10]:

$$P_n(\xi, u_1, u_2, u_3, u_4) = \xi^{n+2} + a_{n,1}\xi^{n+1} + \cdots + a_{n,n+2}, \tag{2.1}$$

where the coefficients $a_{n,1}, a_{n,2}, \dots, a_{n,n+2}$ are uniquely determined by the two conditions

$$\frac{P_n(\xi, u_1, u_2, u_3, u_4)}{\sqrt{(\xi - u_1)(\xi - u_2)(\xi - u_3)(\xi - u_4)}} = \xi^n + \mathcal{O}(\xi^{-2}) \quad \text{for large } |\xi|$$

and

$$\int_{u_2}^{u_1} \frac{P_n(\xi, u_1, u_2, u_3, u_4)}{\sqrt{(u_1 - \xi)(\xi - u_2)(\xi - u_3)(\xi - u_4)}} d\xi = 0.$$

The coefficients of P_n can be expressed in terms of complete elliptic integrals.

The eigenspeeds of the Whitham equations (1.7) with $g = 1$ for the NLS equation are defined in terms of P_0 and P_1 of (2.1) [4, 6, 10],

$$\lambda_i(u_1, u_2, u_3, u_4) = 8\, \frac{P_1(u_i, u_1, u_2, u_3, u_4)}{P_0(u_i, u_1, u_2, u_3, u_4)}, \quad i = 1, 2, 3, 4,$$

which give

$$\lambda_i(u_1, u_2, u_3, u_4) = 2\left(\sigma_1(u_1, u_2, u_3, u_4) - \frac{I(u_1, u_2, u_3, u_4)}{\partial_{u_i} I(u_1, u_2, u_3, u_4)}\right). \tag{2.2}$$

Here $\sigma_1 := \sum_{j=1}^4 u_j$, and $I(u_1, u_2, u_3, u_4)$ is given by a complete elliptic integral [14]

$$I(u_1, u_2, u_3, u_4) = \int_{u_2}^{u_1} \frac{d\eta}{\sqrt{(u_1 - \eta)(\eta - u_2)(\eta - u_3)(\eta - u_4)}}. \tag{2.3}$$

The function I can be rewritten as a contour integral. Hence,

$$2(u_i - u_j)\frac{\partial^2 I}{\partial u_i \partial u_j} = \frac{\partial I}{\partial u_i} - \frac{\partial I}{\partial u_j}, \quad i, j = 1, 2, 3, 4, \tag{2.4}$$

since the integrand satisfies the same equations for each $\eta \neq u_i$ (cf. (1.12)). This contour integral connection also allows us to give another formulation of I,

$$I(u_1, u_2, u_3, u_4) = \int_{u_4}^{u_3} \frac{d\eta}{\sqrt{(u_1 - \eta)(u_2 - \eta)(u_3 - \eta)(\eta - u_4)}}. \tag{2.5}$$

It follows from (2.2), (2.3), and (2.5) that

$$\lambda_4 - 2\sigma_1 < \lambda_3 - 2\sigma_1 < 0 < \lambda_2 - 2\sigma_1 < \lambda_1 - 2\sigma_1 \tag{2.6}$$

for $u_4 < u_3 < u_2 < u_1$. This implies the strict hyperbolicity of the NLS–Whitham equation (1.7) for $g = 1$.

The eigenspeeds λ_i have the following values [14]: At $u_3 = u_4$, we have

$$\begin{cases} \lambda_1 = 6u_1 + 2u_2, \\ \lambda_2 = 2u_1 + 6u_2, \\ \lambda_3 = \lambda_4 = 2(u_1 + u_2 + 2u_4) - \frac{8(u_1-u_4)(u_2-u_4)}{u_1+u_2-2u_4}, \end{cases} \tag{2.7}$$

and at $u_2 = u_3$,

$$\begin{cases} \lambda_1 = 6u_1 + 2u_4, \\ \lambda_2 = \lambda_3 = 2u_1 + 4u_3 + 2u_4, \\ \lambda_4 = 2u_1 + 6u_4. \end{cases} \tag{2.8}$$

Notice that the eigenspeed $\lambda_2 = \lambda_3$ at $u_2 = u_3$ is the same as the velocity of the periodic solution (1.8), i.e., $V_1 = 2\sigma_1 = 2(u_1 + 2u_3 + u_4)$.

The eigenspeeds of the mKdV–Whitham equations (1.22) with $g = 1$ are [6]

$$\mu_i(u_1, u_2, u_3, u_4) = 3\,\frac{P_2(u_i, u_1, u_2, u_3, u_4)}{P_0(u_i, u_1, u_2, u_3, u_4)}, \quad i = 1, 2, 3, 4. \tag{2.9}$$

They can be expressed in terms of λ_1, λ_2, λ_3, and λ_4 of the NLS–Whitham equations (1.7) with $g = 1$.

LEMMA 2.1. *The eigenspeeds $\mu_i(u_1, u_2, u_3, u_4)$ of* (2.9) *can be expressed in the form*

$$\mu_i = \frac{1}{2}\,(\lambda_i - 2\sigma_1)\,\frac{\partial q}{\partial u_i} + q, \quad i = 1, 2, 3, 4, \tag{2.10}$$

where $\sigma_1 = \sum_{j=1}^{4} u_j$ and $q = q(u_1, u_2, u_3, u_4)$ is the solution of the boundary value problem of the Euler–Poisson–Darboux equations (cf. (1.12) *and* (2.4)*)*

$$2(u_i - u_j)\frac{\partial^2 q}{\partial u_i \partial u_j} = \frac{\partial q}{\partial u_i} - \frac{\partial q}{\partial u_j}, \quad i, j = 1, 2, 3, 4, \tag{2.11}$$

$$q(u, u, u) = 3u^2.$$

Also the μ_i satisfy the overdetermined systems

$$\frac{1}{\mu_i - \mu_j}\,\frac{\partial \mu_i}{\partial u_j} = \frac{1}{\lambda_i - \lambda_j}\,\frac{\partial \lambda_i}{\partial u_j}, \qquad i \neq j. \tag{2.12}$$

We omit the proof since it is very similar to the proof of an analogous result for the KdV hierarchy [13].

The boundary value problem (2.11) has a unique solution. The solution is a symmetric quadratic function of u_1, u_2, u_3, and u_4:

$$q = \frac{3}{8}\sigma_1^2 - \frac{1}{2}\sigma_2, \tag{2.13}$$

where $\sigma_2 = \sum_{i>j} u_i u_j$ is the elementary symmetric polynomial of degree two. Notice that q gives the velocity of the periodic solution (1.25) for the mKdV equation, i.e., $V_2 = q$.

For NLS, λ_i satisfy [14]

$$\frac{\partial\lambda_4}{\partial u_4} < \frac{3}{2}\frac{\lambda_3-\lambda_4}{u_3-u_4} < \frac{\partial\lambda_3}{\partial u_3} \tag{2.14}$$

for $u_4 < u_3 < u_2 < u_1$. Similar results also hold for the mKdV–Whitham equations (1.22) with $g = 1$.

LEMMA 2.2.

$$\frac{\partial\mu_3}{\partial u_3} > \frac{3}{2}\ \frac{\mu_3-\mu_4}{u_3-u_4} \quad \textit{if}\ \ \frac{\partial q}{\partial u_3} > 0, \tag{2.15}$$

$$\frac{\partial\mu_4}{\partial u_4} < \frac{3}{2}\ \frac{\mu_3-\mu_4}{u_3-u_4} \quad \textit{if}\ \ \frac{\partial q}{\partial u_4} > 0 \tag{2.16}$$

for $u_4 < u_3 < u_2 < u_1$.

Proof. We use (2.10) and (2.14) to obtain

$$\begin{aligned}\frac{\partial\mu_3}{\partial u_3} &= \frac{1}{2}\frac{\partial\lambda_3}{\partial u_3}\frac{\partial q}{\partial u_3} + \frac{1}{2}(\lambda_3-2\sigma_1)\frac{\partial^2 q}{\partial u_3^2}\\ &> \frac{3}{4}\frac{\lambda_3-\lambda_4}{u_3-u_4}\frac{\partial q}{\partial u_3} + \frac{1}{2}(\lambda_4-2\sigma_1)\frac{\partial^2 q}{\partial u_3^2}\end{aligned} \tag{2.17}$$

and

$$\begin{aligned}\mu_3-\mu_4 &= \frac{1}{2}\,(\lambda_3-\lambda_4)\,\frac{\partial q}{\partial u_3} + \frac{1}{2}(\lambda_4-2\sigma_1)\left(\frac{\partial q}{\partial u_3}-\frac{\partial q}{\partial u_4}\right)\\ &= \frac{1}{2}\,(\lambda_3-\lambda_4)\,\frac{\partial q}{\partial u_3} + (\lambda_4-2\sigma_1)(u_3-u_4)\frac{\partial^2 q}{\partial u_3\partial u_4}\\ &= \frac{2}{3}(u_3-u_4)\left(\frac{3}{4}\,\frac{\lambda_3-\lambda_4}{u_2-u_3}\,\frac{\partial q}{\partial u_3} + \frac{3}{2}(\lambda_4-2\sigma_1)\frac{\partial^2 q}{\partial u_3\partial u_4}\right),\end{aligned} \tag{2.18}$$

where we have used (2.11)

$$\frac{\partial q}{\partial u_3}-\frac{\partial q}{\partial u_4} = 2(u_3-u_4)\frac{\partial^2 q}{\partial u_3\partial u_4}.$$

Differentiating this equation with respect to u_3 yields

$$\frac{\partial^2 q}{\partial u_3^2} - 3\frac{\partial^2 q}{\partial u_3\partial u_4} = 2(u_3-u_4)\frac{\partial^3 q}{\partial u_3^2\partial u_4}.$$

It is here we exploit the fact that q is a quadratic polynomial and conclude that

$$3\frac{\partial^2 q}{\partial u_3\partial u_4} = \frac{\partial^2 q}{\partial u_3^2},$$

which, along with (2.17) and (2.18), proves (2.15). Inequality (2.16) can be proved in the same way. ∎

The following calculations will be useful in the subsequent sections. Using formula (2.10) for μ_3 and μ_4 and formula (2.2) for λ_3 and λ_4, we obtain

$$\begin{aligned}\mu_3 - \mu_4 &= \frac{I}{(\partial_{u_3} I)(\partial_{u_4} I)}\left[\frac{\partial q}{\partial u_4}\frac{\partial I}{\partial u_3} - \frac{\partial q}{\partial u_3}\frac{\partial I}{\partial u_4}\right] \\ &= \frac{I}{(\partial_{u_3} I)(\partial_{u_4} I)}\left[\frac{\partial q}{\partial u_4}\left(\frac{\partial I}{\partial u_3} - \frac{\partial I}{\partial u_4}\right) - \left(\frac{\partial q}{\partial u_3} - \frac{\partial q}{\partial u_4}\right)\frac{\partial I}{\partial u_4}\right] \\ &= \frac{2I(u_3 - u_4)}{(\partial_{u_3} I)(\partial_{u_4} I)}\ M, \qquad (2.19)\end{aligned}$$

where

$$M = \frac{\partial q}{\partial u_4}\ \frac{\partial^2 I}{\partial u_3 \partial u_4} - \frac{\partial^2 q}{\partial u_3 \partial u_4}\ \frac{\partial I}{\partial u_4}.$$

Here we have used equations (2.4) for I and equations (2.11) for q in equality (2.19). Since q of (2.13) is quadratic, we obtain

$$\frac{\partial M}{\partial u_3} = \frac{\partial q}{\partial u_4}\ \frac{\partial^3 I}{\partial u_3^2 \partial u_4}. \qquad (2.20)$$

We note that another expression for M is

$$M = \frac{\partial q}{\partial u_3}\ \frac{\partial^2 I}{\partial u_3 \partial u_4} - \frac{\partial^2 q}{\partial u_3 \partial u_4}\ \frac{\partial I}{\partial u_3}.$$

Hence, we get

$$\frac{\partial M}{\partial u_4} = \frac{\partial q}{\partial u_3}\ \frac{\partial^3 I}{\partial u_3 \partial u_4^2}. \qquad (2.21)$$

We next evaluate $M(u_1, u_2, u_3, u_4)$ when $u_3 = u_4$. Using the integral formula (2.3) for the function I and applying the change of variable $\eta = (u_1 - u_2)\nu + u_2$, we obtain

$$\begin{aligned}M\Big|_{u_3=u_4} &= \frac{\frac{\partial q}{\partial u_4}}{4(u_2 - u_4)^3}\int_0^1 \frac{d\nu}{(1 + \frac{u_1 - u_2}{u_2 - u_4}\nu)^3\sqrt{\nu(1-\nu)}} \\ &\quad - \frac{\frac{\partial^2 q}{\partial u_3 \partial u_4}}{2(u_2 - u_4)^2}\int_0^1 \frac{d\nu}{(1 + \frac{u_1 - u_2}{u_2 - u_4}\nu)^2\sqrt{\nu(1-\nu)}}.\end{aligned}$$

The two integrals can be evaluated exactly as

$$\int_0^1 \frac{d\nu}{(1+\gamma\nu)^3\sqrt{\nu(1-\nu)}} = \frac{\pi(8 + 8\gamma + 3\gamma^2)}{8(1+\gamma)^{\frac{5}{2}}}, \quad \int_0^1 \frac{d\nu}{(1+\gamma\nu)^2\sqrt{\nu(1-\nu)}} = \frac{\pi(2+\gamma)}{2(1+\gamma)^{\frac{3}{2}}}$$

for $\gamma > -1$. We finally get

$$M\Big|_{u_3=u_4} = \frac{\pi U(u_1, u_2, u_4)}{128[(u_2 - u_4)(u_1 - u_4)]^{\frac{5}{2}}}, \qquad (2.22)$$

where

$$U(u_1,u_2,\xi) = [8(u_2-\xi)^2 + 8(u_2-\xi)(u_1-u_2) + 3(u_1-u_2)^2](u_1+u_2+4\xi)$$

$$- 8(u_1-\xi)(u_2-\xi)(u_1+u_2-2\xi). \tag{2.23}$$

Similarly to (2.19) for μ_3 and μ_4, we have

$$\mu_2 - \mu_3 = \frac{2I(u_2-u_3)}{(\partial_{u_2} I)(\partial_{u_3} I)}\ N, \tag{2.24}$$

where

$$N = \frac{\partial q}{\partial u_2}\ \frac{\partial^2 I}{\partial u_2 \partial u_3} - \frac{\partial^2 q}{\partial u_2 \partial u_3}\ \frac{\partial I}{\partial u_2}.$$

Since q of (2.13) is quadratic, we obtain

$$\frac{\partial N}{\partial u_3} = \frac{\partial q}{\partial u_2}\ \frac{\partial^3 I}{\partial u_2 \partial u_3^2}. \tag{2.25}$$

Finally, we use (2.7) and (2.10) to calculate

$$(\mu_2-\mu_3)\Big|_{u_3=u_4} = \frac{1}{2}[\lambda_2 - 2(u_1+u_2+2u_4)]\frac{\partial q}{\partial u_2} - \frac{1}{2}[\lambda_3 - 2(u_1+u_2+2u_4)]\frac{\partial q}{\partial u_3}$$

$$= \frac{(u_2-u_4)}{2(u_1+u_2-2u_4)}\ V(u_1,u_2,u_4), \tag{2.26}$$

where

$$V(u_1,u_2,u_4) = 3u_1^2 + 3u_2^2 - 12u_4^2 + 6u_1u_2 + 6u_1u_4 - 6u_2u_4. \tag{2.27}$$

3. Self-similar solutions. In this section, we construct self-similar solutions of the Whitham equations (1.22) with $g=1$ for the initial function (1.23) with $a>b>c$. The case with $a>c>b$ will be studied in next section. The solution of the zero phase Whitham equations (1.21) does not develop a shock when $a+5b\le 0$. We are therefore interested only in the case $a+5b>0$.

We first study the ξ-zero of the cubic polynomial equation

$$U(a,b,\xi) = 0, \tag{3.1}$$

where U is given by (2.23). It is easy to prove that, for each pair of a and b satisfying $a>b$ and $a+5b>0$, $U(a,b,\xi)=0$ has only one simple real root. Denoting this zero by $\xi(a,b)$, we then deduce that $U(a,b,\xi)$ is positive for $\xi>\xi(a,b)$ and negative for $\xi<\xi(a,b)$. Since $U(a,b,-(a+b)/4)<0$ in view of (2.23), we must have

$$\xi(a,b) > -\frac{a+b}{4}. \tag{3.2}$$

For initial function (1.23) with $a>b>c$ and $a+5b>0$, we now classify the resulting Whitham solutions into four types:

I. $\xi(a,b)\le c$ with any $a>b>c$,
II. $\xi(a,b)>c$ with $a+5b>3(b-c)>0$,
III. $\xi(a,b)>c$ with $a+5b=3(b-c)>0$,
IV. $\xi(a,b)>c$ with $0<a+5b<3(b-c)$.

In Figure 3.1, we illustrate this classification by scaling $a>0$ to $a=4$ and plotting regions for types I–IV in the b-c plane.

We will study the second type first.

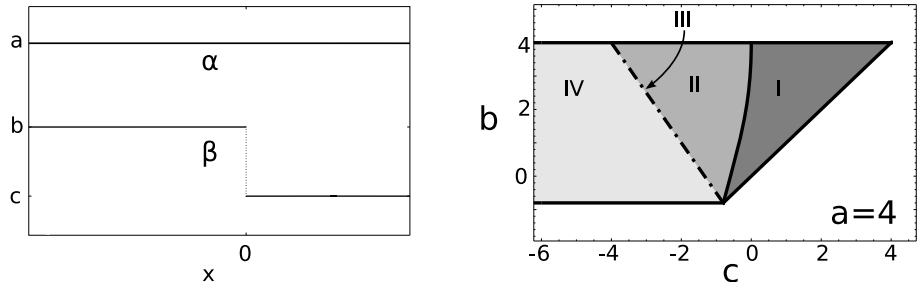

FIG. 3.1. *Graph of the step-like initial shock data* (1.23) *with* $a > b > c$ *and* $a + 5b > 0$*, and diagram of regions for types* I–IV*, where* $a > 0$ *has been scaled to* $a = 4$*. The region for type* IV *is unbounded from the left.*

3.1. Type II. Here we consider the step-like initial function (1.23) satisfying $\xi(a, b) > c$ and $a + 5b > 3(b - c) > 0$.

THEOREM 3.1 (see Figure 1.2). *For the step-like initial data* (1.23) *with* $a > b > c$*,* $a + 5b > 3(b - c)$*, and* $\xi(a, b) > c$*, the solution* (α, β) *of the zero phase Whitham equations* (1.21) *and the solution* (u_1, u_2, u_3, u_4) *of the single phase Whitham equations* (1.22) *with* $g = 1$ *are given as follows:*

(1) *For* $x/t \le \mu_3(a, b, \xi(a, b), \xi(a, b))$,

$$\alpha = a, \quad \beta = b. \tag{3.3}$$

(2) *For* $\mu_3(a, b, \xi(a, b), \xi(a, b)) < x/t < \mu_3(a, b, u^{**}, c)$,

$$u_1 = a, \quad u_2 = b, \quad \frac{x}{t} = \mu_3(a, b, u_3, u_4), \quad \frac{x}{t} = \mu_4(a, b, u_3, u_4), \tag{3.4}$$

where u^{**} *is the unique solution* u_3 *of* $\mu_3(a, b, u_3, c) = \mu_4(a, b, u_3, c)$ *in the interval* $c < u_3 < b$.

(3) *For* $\mu_3(a, b, u^{**}, c) \le x/t < \mu_3(a, b, b, c)$,

$$u_1 = a, \quad u_2 = b, \quad \frac{x}{t} = \mu_3(a, b, u_3, c), \quad u_4 = c. \tag{3.5}$$

(4) *For* $x/t \ge \mu_3(a, b, b, c)$,

$$\alpha = a, \quad \beta = c. \tag{3.6}$$

The boundaries $x/t = \mu_3(a, b, \xi(a, b), \xi(a, b))$ and $x/t = \mu_3(a, b, b, c)$ are called the trailing and leading edges, respectively. They separate the solutions of the single phase Whitham equations (1.22) with $g = 1$ and the zero phase Whitham equations (1.21). The single phase Whitham solution matches the zero phase Whitham solution in the following fashion (see Figure 1.2):

$$(u_1, u_2) = \text{the solution } (\alpha, \beta) \text{ of (1.21) defined outside the region,} \tag{3.7}$$

$$u_3 = u_4, \tag{3.8}$$

at the trailing edge;

$$(u_1, u_4) = \text{the solution } (\alpha, \beta) \text{ of (1.21) defined outside the region,} \tag{3.9}$$

$$u_2 = u_3, \tag{3.10}$$

at the leading edge.

The proof of Theorem 3.1 is based on a series of lemmas: We first show that the solutions defined by formulae (3.4) and (3.5) indeed satisfy the Whitham equations (1.22) for $g = 1$ [2, 15].

LEMMA 3.2.

(1) *The functions u_1, u_2, u_3, and u_4 determined by equations* (3.4) *give a solution of the Whitham equations* (1.22) *with $g = 1$ as long as u_3 and u_4 can be solved from* (3.4) *as functions of x and t.*

(2) *The functions u_1, u_2, u_3, and u_4 determined by equations* (3.5) *give a solution of the Whitham equations* (1.22) *with $g = 1$ as long as u_3 can be solved from* (3.5) *as a function of x and t.*

Proof. (1) u_1 and u_2 obviously satisfy the first two equations of (1.22) for $g = 1$. To verify the third and fourth equations, we observe that

$$\frac{\partial \mu_3}{\partial u_4} = \frac{\partial \mu_4}{\partial u_3} = 0 \tag{3.11}$$

on the solution of (3.4). To see this, we use (2.12) to calculate

$$\frac{\partial \mu_3}{\partial u_4} = \frac{\frac{\partial \lambda_3}{\partial u_4}}{\lambda_3 - \lambda_4} (\mu_3 - \mu_4) = 0.$$

The second part of (3.11) can be shown in the same way. We then calculate the partial derivatives of the third equation of (3.4) with respect to x and t,

$$1 = \frac{\partial \mu_3}{\partial u_3} tu_{3x}, \quad 0 = \frac{\partial \mu_3}{\partial u_3} tu_{3t} + \mu_3,$$

which give the third equation of (1.22) with $g = 1$. The fourth equation of (1.22) with $g = 1$ can be verified in the same way.

(2) The second part of Lemma 3.2 can easily be proved. □

We now determine the trailing edge. Eliminating x and t from the last two equations of (3.4) yields

$$\mu_3(a, b, u_3, u_4) - \mu_4(a, b, u_3, u_4) = 0. \tag{3.12}$$

Since it degenerates at $u_3 = u_4$, we replace (3.12) by

$$F(a, b, u_3, u_4) := \frac{\mu_3(a, b, u_3, u_4) - \mu_4(a, b, u_3, u_4)}{u_3 - u_4} = 0. \tag{3.13}$$

Therefore, at the trailing edge where $u_3 = u_4$, (3.13), in view of formulae (2.19) and (2.22), reduces to

$$U(a, b, u_4) = 0. \tag{3.14}$$

Noting that $\xi(a, b)$ is the unique solution of (3.1), we then deduce that $u_4 = \xi(a, b)$.

LEMMA 3.3. *Equation* (3.13) *has a unique solution satisfying $u_3 = u_4$. The solution is $u_3 = u_4 = \xi(a, b)$. The rest of equations* (3.4) *at the trailing edge are $u_1 = a$, $u_2 = b$, and $x/t = \mu_3(a, b, \xi(a, b), \xi(a, b))$.*

Having located the trailing edge, we now solve equations (3.4) in the neighborhood of the trailing edge. We first consider (3.13). We use (2.19) to write F of (3.13) as

$$F(a, b, u_3, u_4) = \frac{2I}{(\partial_{u_3} I)(\partial_{u_3} I)} M(a, b, u_3, u_4).$$

We note that, at the trailing edge $u_3 = u_4 = \xi(a,b)$, we have $M(a,b,\xi(a,b),\xi(a,b)) = 0$ because of (2.22) and (3.14). We then use (2.20) and (2.21) to differentiate F at the trailing edge

$$\frac{\partial F(a,b,\xi(a,b),\xi(a,b))}{\partial u_3} = \frac{\partial F(a,b,\xi(a,b),\xi(a,b))}{\partial u_4}$$

$$= \frac{I}{2(\partial_{u_3} I)(\partial_{u_3} I)}\ [a+b+4\xi(a,b)]\ \frac{\partial^3 I}{\partial u_3^2 \partial u_4} > 0,$$

where we have used the expression (2.13) for q in the last equation and (3.2) in the inequality. These show that (3.13) or, equivalently, (3.12) can be inverted to give u_4 as a decreasing function of u_3,

$$u_4 = A(u_3), \tag{3.15}$$

in a neighborhood of $u_3 = u_4 = \xi(a,b)$.

We now extend the solution $A(u_3)$ of (3.12) in the region $c < u_4 < \xi(a,b) < u_3 < b$ as far as possible. We first claim that

$$\frac{\partial q(a,b,u_3,u_4)}{\partial u_3} > 0, \quad \frac{\partial q(a,b,u_3,u_4)}{\partial u_4} > 0 \tag{3.16}$$

on the extension. To see this, we first observe that inequalities (3.16) are true at the trailing edge $u_3 = u_4 = \xi(a,b)$. This follows from (2.13) and (3.2). Therefore, inequalities (3.16) hold in a neighborhood of the trailing edge. To prove that (3.16) remains true on the extension, we use formula (2.10) for μ_3 and μ_4 to rewrite (3.12) as

$$\frac{1}{2}[\lambda_3 - 2(a+b+u_3+u_4)]\frac{\partial q}{\partial u_3} = \frac{1}{2}[\lambda_4 - 2(a+b+u_3+u_4)]\frac{\partial q}{\partial u_4}.$$

Since the two terms in the two sets of parentheses are both negative in view of (2.6) and since $\frac{\partial q}{\partial u_3} - \frac{\partial q}{\partial u_4} = (u_3 - u_4)/4 > 0$ in view of (2.13), neither $\frac{\partial q}{\partial u_3}$ nor $\frac{\partial q}{\partial u_4}$ can vanish on the extension. This proves inequalities (3.16).

We deduce from Lemma 2.2 that

$$\frac{\partial \mu_3}{\partial u_3} > 0, \quad \frac{\partial \mu_4}{\partial u_4} < 0 \tag{3.17}$$

on the solution of (3.12). Because of (3.11) and (3.17), solution (3.15) of (3.12) can be extended as long as $c < u_4 < \xi(a,b) < u_3 < b$.

There are two possibilities: (1) u_3 touches b before or simultaneously as u_4 reaches c and (2) u_4 touches c before u_3 reaches b. It follows from (2.8), (2.10), and (2.13) that

$$\mu_3(a,b,b,u_4) - \mu_4(a,b,b,u_4) = \frac{1}{2}\ (b-u_4)(a+2b+3u_4) > 0 \quad \text{for } c \le u_4 < b, \tag{3.18}$$

where we have used $a+2b+3c > 0$ in the inequality. This shows that (1) is unattainable. Hence, u_4 will touch c before u_3 reaches b. When this happens, (3.12) becomes

$$\mu_3(a,b,u_3,c) = \mu_4(a,b,u_3,c). \tag{3.19}$$

LEMMA 3.4. *Equation* (3.19) *has a simple zero in the interval* $c < u_3 < b$, *counting multiplicities. If we denote the zero by* u^{**}, *then* $\mu_3(a,b,u_3,c) - \mu_4(a,b,u_3,c)$ *is positive for* $u_3 > u^{**}$ *and negative for* $u_3 < u^{**}$.

Proof. We use (2.19) and (2.20) to prove the lemma. In both formulae, $\partial_{u_3} I$, $\partial_{u_4} I$, and $\partial^2_{u_3 u_4} I$ are all positive functions. By (2.20),

$$\frac{\partial M(a,b,u_3,c)}{\partial u_3} = \frac{(a+b+u_3+3c)}{4} \frac{\partial^3 I}{\partial u_3^2 \partial u_4} \quad \text{for } c < u_3 < b. \tag{3.20}$$

We claim that

$$M(a,b,u_3,c) < 0 \quad \text{when } u_3 = c \qquad \text{and} \qquad M(a,b,u_3,c) > 0 \quad \text{for } u_3 \text{ near } b.$$

The second inequality follows from (2.19) and (3.18). The first inequality can be deduced from formula (2.22):

$$M(a,b,c,c) = \frac{\pi U(a,b,c)}{128[(b-c)(a-c)]^{\frac{5}{2}}} < 0 \quad \text{for } c < \xi(a,b).$$

Therefore, $M(a,b,u_3,c)$ has a zero in the interval $c < u_3 < b$. The uniqueness of the zero follows from (3.20) in that $M(a,b,u_3,c)$ increases or changes from decreasing to increasing as u_3 increases. This zero is exactly u^{**}, and the rest of the theorem can be proved easily. □

Having solved (3.12) for u_4 as a decreasing function of u_3 for $c < u_4 < \xi(a,b) < u_3 < b$, we turn to equations (3.4). Because of (3.11) and (3.17), the third equation of (3.4) gives u_3 as an increasing function of x/t for $\mu_3(a,b,\xi(a,b),\xi(a,b)) < x/t < \mu_3(a,b,u^{**},c)$. Consequently, u_4 is a decreasing function of x/t in the same interval.

LEMMA 3.5. *The last two equations of* (3.4) *can be inverted to give* u_3 *and* u_4 *as increasing and decreasing functions, respectively, of the self-similarity variable* x/t *in the interval* $\mu_3(a,b,\xi(a,b),\xi(a,b)) < x/t < \mu_3(a,b,u^{**},c)$, *where* u^{**} *is given in Lemma* 3.4.

We now turn to equations (3.5). We want to solve the third equation when $x/t > \mu_3(a,b,u^{**},c)$ or, equivalently, when $u_3 > u^{**}$. According to Lemma 3.4, $\mu_3(a,b,u_3,c) - \mu_4(a,b,u_3,c) > 0$ for $u^{**} < u_3 < b$. In view of (3.16), $\partial_{u_3} q(a,b,u_3,c) = (a+b+3u_3+c)/4$ is positive at $u_3 = u^{**}$, and, hence, it remains positive for $u_3 > u^{**}$. By (2.15), we have

$$\frac{\partial \mu_3(a,b,u_3,c)}{\partial u_3} > 0.$$

Hence, the third equation of (3.5) can be solved for u_3 as an increasing function of x/t as long as $u^{**} < u_3 < b$. When u_3 reaches b, we have $x/t = \mu_3(a,b,b,c)$. We have therefore proved the following result.

LEMMA 3.6. *The third equation of* (3.5) *can be inverted to give* u_3 *as an increasing function of* x/t *in the interval* $\mu_3(a,b,u^{**},c) \le x/t \le \mu_3(a,b,b,c)$.

We are ready to conclude the proof of Theorem 3.1. The solutions (3.3) and (3.6) are obvious. According to Lemma 3.5, the last two equations of (3.4) determine u_3 and u_4 as functions of x/t in the region $\mu_3(a,b,\xi(a,b),\xi(a,b)) \le x/t \le \mu_3(a,b,u^{**},c)$. By the first part of Lemma 3.2, the resulting u_1, u_2, u_3, and u_4 satisfy the Whitham equations (1.22) with $g = 1$. Furthermore, the boundary conditions (3.7) and (3.8) are satisfied at the trailing edge $x = \mu_3(a,b,\xi(a,b),\xi(a,b))$.

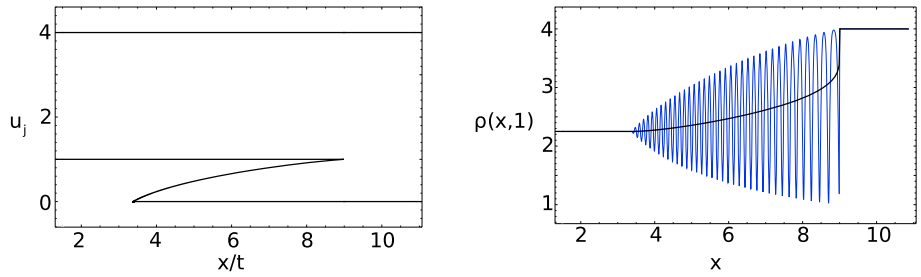

FIG. 3.2. *Self-similar solution of the Whitham equations* (1.22) *with* $g = 1$ *and the corresponding oscillatory solution* (1.25) *of the mKdV equation with* $\epsilon = 0.07$. *The initial data are given by* (1.23) *with* $a = 4$, $b = 1$, *and* $c = 0$ *of type* I.

Similarly, by Lemma 3.6, the third equation of (3.5) determines u_3 as a function of x/t in the region $\mu_3(a, b, u^{**}, c) \le x/t \le \mu_3(a, b, b, c)$. It then follows from the second part of Lemma 3.2 that u_1, u_2, u_3, and u_4 of (3.5) satisfy the Whitham equations (1.22) for $g = 1$. They also satisfy the boundary conditions (3.9) and (3.10) at the leading edge $x/t = \mu_3(a, b, b, c)$. We have therefore completed the proof of Theorem 3.1.

A graph of the Whitham solution (u_1, u_2, u_3, u_4) is given in Figure 1.2. It is obtained by plotting the exact solutions of (3.4) and (3.5).

3.2. Type I. Here we consider the initial function (1.23) satisfying $\xi(a, b) \le c$ with $b > c$ and $a + 5b > 0$.

We will present our proofs only briefly, since they are, more or less, similar to those in section 3.1. The main feature of this case is that the ξ-zero point does not appear in the solution u_3, and the Whitham equations (1.22) with $g = 1$ are strictly hyperbolic on the solution.

THEOREM 3.7 (see Figure 3.2). *For the step-like initial data* (1.23) *with* $a > b > c$, $a + 5b > 0$, *and* $\xi(a, b) \le c$, *the solution of the Whitham equations* (1.22) *with* $g = 1$ *is given by*

$$u_1 = a, \quad u_2 = b, \quad \frac{x}{t} = \mu_3(a, b, u_3, c), \quad u_4 = c$$

for $\mu_3(a, b, c, c) < x/t < \mu_3(a, b, b, c)$. *Outside this interval, the solution of* (1.21) *is given by*

$$\alpha = a, \quad \beta = b \qquad \textit{for} \quad \frac{x}{t} \le \mu_3(a, b, c, c)$$

and

$$\alpha = a, \quad \beta = c \qquad \textit{for} \quad \frac{x}{t} \ge \mu_3(a, b, b, c).$$

Proof. It suffices to show that $\mu_3(a, b, u_3, c)$ is an increasing function of u_3 for $c < u_3 < b$. Substituting (2.13) for q into (2.20) yields

$$\frac{\partial M(a, b, u_3, c)}{\partial u_3} = \frac{1}{4}[a + b + u_3 + 3c] \, \frac{\partial^3 I}{\partial u_3^2 \partial u_4} \ge \frac{1}{4}[a + b + 4\xi(a, b)] \, \frac{\partial^3 I}{\partial u_3^2 \partial u_4} > 0$$

for $c < u_3 < b$, where we have used $\xi(a, b) \le c$ in the first inequality and (3.2) in the second. We now use formula (2.22) to calculate the value of $M(a, b, u_3, c)$ at

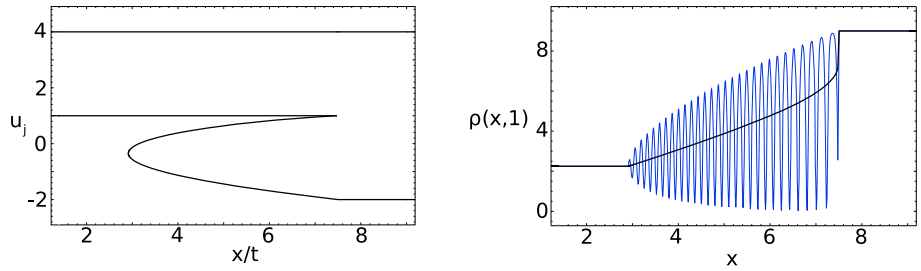

FIG. 3.3. *Self-similar solution of the Whitham equations* (1.22) *with* $g = 1$ *and the corresponding oscillatory solution* (1.25) *of the mKdV equation with* $\epsilon = 0.1$. *The initial data are given by* (1.23) *with* $a = 4$, $b = 1$, $c = -2$ *of type* III.

$u_3 = c$:

$$M(a,b,c,c) = \frac{\pi U(a,b,c)}{128[(b-c)(a-c)]^{\frac{5}{2}}} \geq 0 \quad \text{for } \xi(a,b) \leq c$$

because $U(a,b,\xi) \geq 0$ for $\xi \geq \xi(a,b)$. Therefore, $M(a,b,u_3,c) > 0$ for $c < u_3 < b$. It then follows from (2.19) that $\mu_3(a,b,u_3,c) - \mu_4(a,b,u_3,c) > 0$. Since $\frac{\partial q}{\partial u_3}(a,b,u_3,c) = (a+b+3u_3+c)/4 > (a+b+3\xi(a,b))/4 > 0$ because of (3.2), we conclude from Lemma 2.2 that

$$\frac{d\mu_3(a,b,u_3,c)}{du_3} > 0$$

for $c < u_3 < b$. □

3.3. Type III. Here we consider the step-like initial function (1.23) satisfying $\xi(a,b) > c$ with $a + 5b = 3(b-c) > 0$.

THEOREM 3.8 (see Figure 3.3). *For the step-like initial data* (1.23) *with* $a > b > c$, $\xi(a,b) > c$, *and* $a + 5b = 3(b-c)$, *the solution of the* $g = 1$ *Whitham equations* (1.22) *with* $g = 1$ *is given by*

$$u_1 = a, \quad u_2 = b, \quad \frac{x}{t} = \mu_3(a,b,u_3,u_4), \quad \frac{x}{t} = \mu_4(a,b,u_3,u_4)$$

for $\mu_3(a,b,\xi(a,b),\xi(a,b)) < x/t < \mu_3(a,b,b,c)$. *Outside the region, the solution of* (1.21) *is given by*

$$\alpha = a, \quad \beta = b \quad \textit{for} \quad \frac{x}{t} \leq \mu_3(a,b,\xi(a,b),\xi(a,b))$$

and

$$\alpha = a, \quad \beta = c \quad \textit{for} \quad \frac{x}{t} \geq \mu_3(a,b,b,c).$$

Proof. It suffices to show that u_3 and u_4 of $\mu_2(a,b,u_3,u_4) - \mu_3(a,b,u_3,u_4) = 0$ reaches b and c, respectively, simultaneously. To see this, we deduce from calculation (3.18) that

$$\mu_3(a,b,b,u_4) - \mu_4(a,b,b,u_4) = \frac{1}{2}(b-u_4)(a+2b+3u_4) \tag{3.21}$$

vanishes at $u_4 = (-a-2b)/3 = c$. □

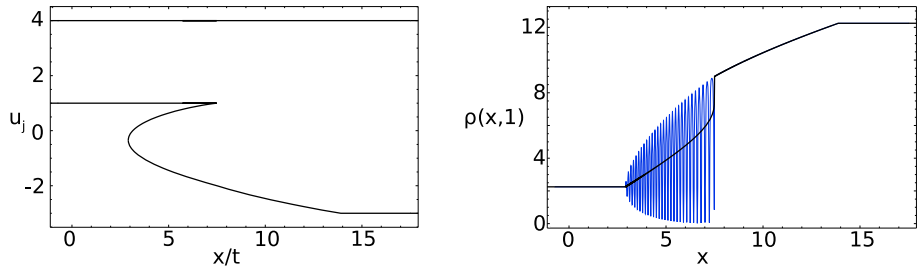

FIG. 3.4. *Self-similar solution of the Whitham equations* (1.22) *with* $g = 1$ *and the corresponding oscillatory solution* (1.25) *of the mKdV equation with* $\epsilon = 0.1$. *The initial data are given by* (1.23) *with* $a = 4$, $b = 1$, *and* $c = -3$ *of type* IV. *The solution in the region* $7.5 < x/t < 111/8$ *represents a rarefaction wave. The weak limit* $\overline{\rho(x,t)}$ *is not* C^1 *smooth at* $x/t = 111/8$.

3.4. Type IV. Here we consider the step-like initial function (1.23) satisfying $\xi(a,b) > c$ with $0 < a + 5b < 3(b-c)$.

THEOREM 3.9 (see Figure 3.4). *For the step-like initial data* (1.23) *with* $a > b > c$, $\xi(a,b) > c$, *and* $0 < a+5b < 3(b-c)$, *the solution of the Whitham equations* (1.18) *is given by*

$$u_1 = a, \quad u_2 = b, \quad \frac{x}{t} = \mu_2(a,b,u_3,u_4), \quad x = \mu_3(a,b,u_3,u_4)\ t$$

for $\mu_3(a,b,\xi(a,b),\xi(a,b)) < x/t < \mu_3(a,b,b,-(a+2b)/3)$. *Outside the region, the solution of* (1.21) *is divided into the three regions:*

(1) *For* $x/t \le \mu_3(a,b,\xi(a,b),\xi(a,b))$,

$$\alpha = a, \quad \beta = b.$$

(2) *For* $\mu_3(a,b,b,-(a+2b)/3) \le \frac{x}{t} \le \frac{3}{8}\left(a^2+2ac+5c^2\right)$,

$$\alpha = a, \quad \beta = -\frac{1}{5}a - \sqrt{\frac{8}{15}\frac{x}{t} - \frac{4}{25}a^2}.$$

(3) *For* $x/t \ge \frac{3}{8}\left(a^2+2ac+5c^2\right)$,

$$\alpha = a, \quad \beta = c.$$

Proof. By calculation (3.21), when u_3 of $\mu_3(a,b,u_3,u_4) - \mu_4(a,b,u_3,u_4) = 0$ touches b, the corresponding u_4 reaches $-(a+2b)/3$, which is above c. Hence, the equations

$$\frac{x}{t} = \mu_3(a,b,u_3,u_4), \quad \frac{x}{t} = \mu_4(a,b,u_3,u_4)$$

can be inverted to give u_3 and u_4 as functions of x/t in the region $\mu_3(a,b,\xi(a,b),\xi(a,b)) < x/t < \mu_3(a,b,b,-(a+2b)/3)$. In region (2), (1.21) has a rarefaction wave solution. ∎

4. More self-similar solutions. In this section, we construct self-similar solutions of the $g = 1$ Whitham equations (1.22) for the initial function (1.23) with $a > c > b$. The solution of (1.21) does not develop a shock for $a + 5b \ge 0$. We are therefore interested only in the case $a + 5b < 0$. We classify the resulting Whitham solution into four types:

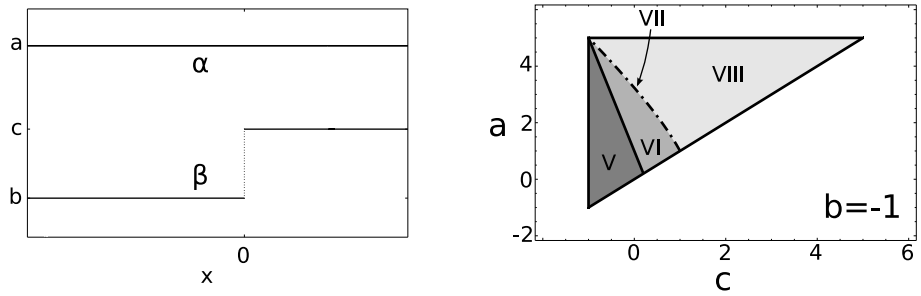

FIG. 4.1. *Graph of the step-like initial shock data* (1.23) *with* $a > c > b$ *and* $a + 5b < 0$, *and diagram of regions for types* V–VIII, *where* $b < 0$ *has been scaled to* $b = -1$.

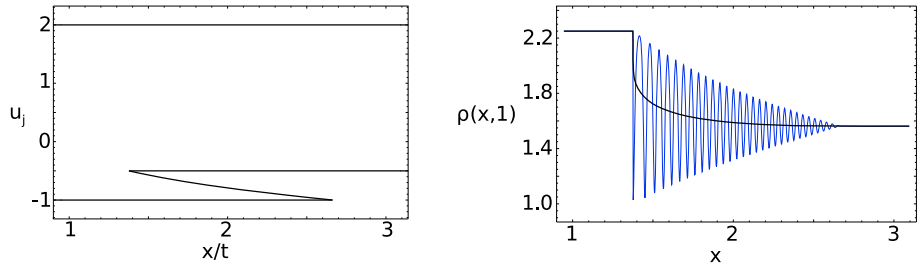

FIG. 4.2. *Self-similar solution of the Whitham equations* (1.22) *with* $g = 1$ *and the corresponding oscillatory solution* (1.25) *of the mKdV equation with* $\epsilon = 0.014$. *The initial data are given by* (1.23) *with* $a = 2$, $b = -1$, *and* $c = -1/2$ *of type* V.

V. $a + 5b \le -4(c - b) < 0$,
VI. $0 > a + 5b > -4(c - b)$ with $V(a, c, b) < 0$,
VII. $0 > a + 5b > -4(c - b)$ with $V(a, c, b) = 0$,
VIII. $0 > a + 5b > -4(c - b)$ with $V(a, c, b) > 0$,

where V is a quadratic polynomial given by (2.27). In Figure 4.1, we illustrate this classification by scaling $b < 0$ to $b = -1$ and plotting regions for types V–VIII in the a-c plane.

4.1. Type V. Here we consider the step-like initial function (1.23) satisfying $a + 5b \le -4(c - b) < 0$.

THEOREM 4.1 (see Figure 4.2). *For the step-like initial data* (1.23) *with* $a > c > b$, $a+5b \le -4(c-b)$, *the solution of the Whitham equations* (1.22) *with* $g = 1$ *is given by*

$$u_1 = a, \quad u_2 = c, \quad \frac{x}{t} = \mu_3(a, c, u_3, b), \quad u_4 = b$$

for $\mu_3(a, c, c, b) < x/t < \mu_3(a, c, b, b)$. *Outside this interval, the solution of* (1.21) *is given by*

$$\alpha = a, \quad \beta = b \quad \textit{for} \quad \frac{x}{t} \le \mu_3(a, c, c, b)$$

and

$$\alpha = a, \quad \beta = c \quad \textit{for} \quad \frac{x}{t} \ge \mu_3(a, c, b, b).$$

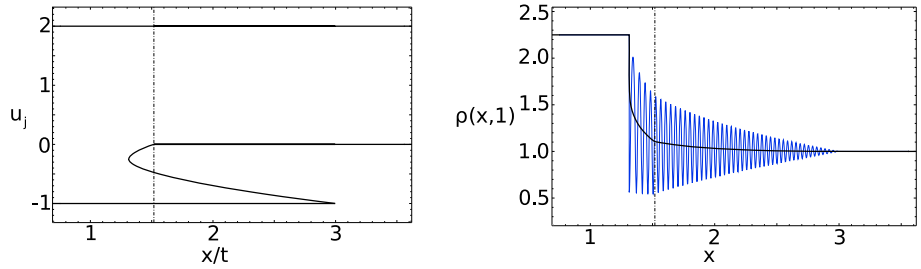

FIG. 4.3. *Self-similar solution of the Whitham equations* (1.22) *with* $g = 1$ *and the corresponding periodic oscillatory solution* (1.25) *of the mKdV equation with* $\epsilon = 0.018$. *The initial data are given by* (1.23) *with* $a = 2$, $b = -1$, *and* $c = 0$ *of type* VI. *The oscillations have two different kinds of structure, which are separated by* $x/t \approx 1.51$. *The weak limit* $\overline{\rho(x,t)}$ *and the envelope of the oscillations have noticeable corners at* $x/t \approx 1.51$.

Proof. It suffices to show that $\mu_3(a, c, u_3, b)$ is a decreasing function of u_3 for $b < u_3 < c$. By (2.10), we have

$$\frac{\partial \mu_3(a,c,u_3,b)}{\partial u_3} = \frac{1}{2}\frac{\partial \lambda_3}{\partial u_3}\frac{\partial q}{\partial u_3} + \frac{1}{2}[\lambda_3 - 2(a+c+u_3+b)]\frac{\partial^2 q}{\partial u_3^2}.$$

The second term is negative because of (2.6) and $\frac{\partial^2 q}{\partial u_2^2} = 3/8 > 0$. The first term is also negative: Its first factor is positive in view of (1.17), while its second factor is

$$\frac{\partial q}{\partial u_3} = \frac{1}{4}(a + c + 3u_3 + b) < 0$$

for $b < u_3 < c$, as we have that $a + b + 4c \le 0$. ∎

4.2. Type VI. Here we consider the step-like initial function (1.23) satisfying $0 > a + 5b > -4(c - b)$ with $V(a, c, b) < 0$.

THEOREM 4.2 (see Figure 4.3). *For the step-like initial data* (1.23) *with* $0 > a + 5b > -4(c - b)$ *and* $V(a, c, b) < 0$, *the solution of the Whitham equations* (1.22) *with* $g = 1$ *is given by*

$$u_1 = a, \quad \frac{x}{t} = \mu_2(a, u_2, u_3, b), \quad \frac{x}{t} = \mu_3(a, u_2, u_3, b), \quad u_4 = b \tag{4.1}$$

for $\mu_3(a, -(a+b)/4, -(a+b)/4, b) < x/t \le \mu_3(a, u^{***}, u^{***}, b)$ *and by*

$$u_1 = a, \quad u_2 = c, \quad \frac{x}{t} = \mu_3(a, c, u_3, b), \quad u_4 = b \tag{4.2}$$

for $\mu_3(a, u^{***}, u^{***}, b) \le x/t < \mu_3(a, c, b, b)$, *where* u^{***} *is the unique solution* u_3 *of* $\mu_2(a, c, u_3, b) = \mu_3(a, c, u_3, b)$ *in the interval* $b < u_3 < c$. *Outside the region* $\mu_3(a, -(a+b)/4, -(a+b)/4, b) < x/t < \mu_3(a, c, b, b)$, *the solution of* (1.21) *is given by*

$$\alpha = a, \quad \beta = b \quad \textit{for} \quad \frac{x}{t} \le \mu_3(a, -(a+b)/4, -(a+b)/4, b)$$

and

$$\alpha = a, \quad \beta = c \quad \textit{for} \quad \frac{x}{t} \ge \mu_3(a, c, b, b).$$

Proof. We first locate the "leading" edge, i.e., the solution of (4.1) at $u_2 = u_3$. Eliminating x/t from the first two equations of (4.1) yields

$$\mu_2(a, u_2, u_3, b) - \mu_3(a, u_2, u_3, b) = 0. \tag{4.3}$$

Since it degenerates at $u_2 = u_3$, we replace (4.3) by

$$G(a, u_2, u_3, b) := \frac{\mu_2(a, u_2, u_3, b) - \mu_3(a, u_2, u_3, b)}{(u_2 - u_3)\sqrt{(u_1 - u_3)(u_2 - u_4)}I(a, u_2, u_3, b)} = 0. \tag{4.4}$$

In Appendix A, we show that, at the "leading" edge $u_2 = u_3$, we have

$$G(a, u_3, u_3, b) = 2\left(\frac{\partial q}{\partial u_2} + \frac{\partial q}{\partial u_3}\right) = 0$$

in view of (A.6), which along with (2.13) gives $u_2 = u_3 = -(a+b)/4$. Having located the "leading" edge, we solve (4.4) near $u_2 = u_3 = -(a+b)/4$. We use formula (A.8) to obtain

$$\frac{\partial G(a, -(a+b)/4, -(a+b)/4, b)}{\partial u_2} = \frac{\partial G(a, -(a+b)/4, -(a+b)/4, b)}{\partial u_3} = 2.$$

These show that (4.4) gives u_2 as a decreasing function of u_3,

$$u_2 = B(u_3), \tag{4.5}$$

in a neighborhood of $u_2 = u_3 = -(a+b)/4$.

We now extend the solution (4.5) of (4.3) as far as possible in the region $b < u_3 < -(a+b)/4 < u_2 < c$. We use formula (2.10) to obtain

$$\frac{\partial \mu_2}{\partial u_2} = \frac{1}{2}\frac{\partial \lambda_2}{\partial u_2}\frac{\partial q}{\partial u_2} + \frac{1}{2}[\lambda_2 - 2(a + u_2 + u_3 + b)]\frac{\partial^2 q}{\partial u_2^2},$$

$$\frac{\partial \mu_3}{\partial u_3} = \frac{1}{2}\frac{\partial \lambda_3}{\partial u_3}\frac{\partial q}{\partial u_3} + \frac{1}{2}[\lambda_3 - 2(a + u_2 + u_3 + b)]\frac{\partial^2 q}{\partial u_3^2}.$$

In view of (1.17) and (2.6), we have

$$\frac{\partial \mu_2}{\partial u_2} > 0 \quad \text{if} \quad \frac{\partial q}{\partial u_2} > 0,$$

$$\frac{\partial \mu_3}{\partial u_3} < 0 \quad \text{if} \quad \frac{\partial q}{\partial u_3} < 0.$$

We claim that

$$\frac{\partial q}{\partial u_2} > 0, \quad \frac{\partial q}{\partial u_3} < 0 \tag{4.6}$$

on the solution of (4.3) in the region $b < u_3 < -(a+b)/4 < u_2 < c$. To see this, we use formula (2.10) to rewrite (4.3) as

$$\frac{1}{2}[\lambda_2 - 2(a + u_2 + u_3 + b)]\frac{\partial q}{\partial u_2} = \frac{1}{2}[\lambda_3 - 2(a + u_2 + u_3 + b)]\frac{\partial q}{\partial u_3}.$$

This, together with

$$\frac{\partial q}{\partial u_2} - \frac{\partial q}{\partial u_3} = 2(u_2 - u_3)\frac{\partial^2 q}{\partial u_2 \partial u_3} = \frac{1}{2}(u_2 - u_3) > 0$$

for $u_2 > u_3$ and inequalities (2.6), proves (4.6).

Hence, the solution (4.5) can be extended as long as $b < u_3 < -(a+b)/4 < u_2 < c$. There are two possibilities: (1) u_2 touches c before u_3 reaches b, and (2) u_3 touches b before or simultaneously as u_2 reaches c.

Possibility (2) is unattainable. To see this, we use (2.26) to write

$$\mu_2(a, u_2, b, b) - \mu_3(a, u_2, b, b) = \frac{(u_2 - b)}{2(a + u_2 - 2b)}\, V(a, u_2, b), \tag{4.7}$$

which is negative for $b < u_2 \le c$ since $V(a, u_2, b)$ of (2.27) is an increasing function of u_2 and since $V(a, c, b) < 0$. Therefore, u_2 will touch c before u_3 reaches b. When this happens, we have

$$\mu_2(a, c, u_3, b) - \mu_3(a, c, u_3, b) = 0. \tag{4.8}$$

LEMMA 4.3. *Equation* (4.8) *has a simple zero, counting multiplicities, in the interval* $b < u_3 < c$. *If we denote this zero by* u^{***}, *then* $\mu_2(a, c, u_3, b) - \mu_3(a, c, u_3, b)$ *is positive for* $u_3 > u^{***}$ *and negative for* $u_3 < u^{***}$.

The proof, which involves formulae (2.24) and (2.25), is rather similar to the proof of Lemma 3.19. We will omit it.

We now continue to prove Theorem 4.2. Having solved (4.3) for u_2 as a decreasing function of u_3 for $u^{***} < u_3 < -(a+b)/4$, we can then use the middle two equations of (4.1) to determine u_2 and u_3 as functions of x/t in the interval $\mu_2(a, -(a+b)/4, -(a+b)/4, b) < x/t < \mu_2(a, c, u^{***}, b)$.

We finally turn to equations (4.2). We want to solve the third equation of (4.2), $x/t = \mu_3(a, c, u_3, b)$, for $u_3 < u^{***}$. It is enough to show that $\mu_3(a, c, u_3, b)$ is a decreasing function of u_3 for $u_3 < u^{***}$. According to Lemma 4.3, $\mu_2(a, c, u_3, b) - \mu_3(a, c, u_3, b) < 0$ for $u_3 < u^{***}$. Using formula (2.10) for μ_2 and μ_3, we have

$$\frac{1}{2}[\lambda_2 - 2(a + c + u_3 + b)]\frac{\partial q}{\partial u_2} < \frac{1}{2}[\lambda_3 - 2(a + c + u_3 + b)]\frac{\partial q}{\partial u_3}.$$

This, together with

$$\frac{\partial q}{\partial u_2} - \frac{\partial q}{\partial u_3} = \frac{1}{2}(c - u_3) > 0$$

for $u_3 < c$ and inequalities (2.6), proves that

$$\frac{\partial q(a, c, u_3, b)}{\partial u_3} < 0$$

for $u_3 < u^{***}$. Hence,

$$\frac{\partial \mu_3}{\partial u_3} = \frac{1}{2}\frac{\partial \lambda_3}{\partial u_3}\frac{\partial q}{\partial u_3} + \frac{1}{2}[\lambda_3 - 2(a + c + u_3 + b)]\frac{\partial^2 q}{\partial u_3^2} < 0,$$

where we have used inequality (1.17). □

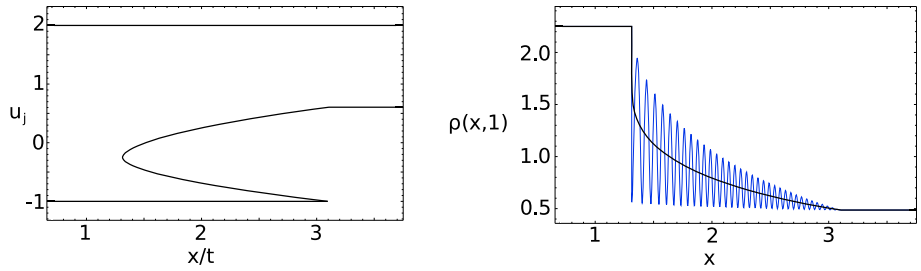

FIG. 4.4. *Self-similar solution of the Whitham equations* (1.22) *with* $g = 1$ *and the corresponding oscillatory solution* (1.25) *of the mKdV equation with* $\epsilon = 0.03$. *The initial data are given by* (1.23) *with* $a = 2$, $b = -1$, *and* $c = -3 + \sqrt{13}$ *of type* VII.

4.3. Type VII. Here we consider the step-like initial function (1.23) satisfying $0 > a + 5b > -4(c - b)$ with $V(a, c, b) = 0$.

THEOREM 4.4 (see Figure 4.4). *For the step-like initial data* (1.23) *with* $0 > a + 5b > -4(c - b)$ *and* $V(a, c, b) = 0$, *the solution of the Whitham equations* (1.22) *with* $g = 1$ *is given by*

$$u_1 = a, \quad \frac{x}{t} = \mu_2(a, u_2, u_3, b), \quad \frac{x}{t} = \mu_3(a, u_2, u_3, b), \quad u_4 = c$$

for $\mu_3(a, -(a + b)/4, -(a + b)/4, b) < x/t < \mu_3(a, c, b, b)$. *Outside the region, the solution of* (1.21) *is given by*

$$\alpha = a, \quad \beta = b \qquad \textit{for} \quad \frac{x}{t} \le \mu_3(a, -(a + b)/4, -(a + b)/4, b)$$

and

$$\alpha = a, \quad \beta = c \qquad \textit{for} \quad \frac{x}{t} \ge \mu_3(a, c, b, b).$$

Proof. It suffices to show that u_2 and u_3 of $\mu_2(a, u_2, u_3, b) - \mu_3(a, u_2, u_3, b) = 0$ reaches c and b, respectively, simultaneously. To see this, we deduce from (4.7) that

$$\mu_2(a, c, b, b) - \mu_3(a, c, b, b) = \frac{(c - b)}{2(a + c - 2b)} \, V(a, c, b) \tag{4.9}$$

vanishes when $V(a, c, b) = 0$. ∎

4.4. Type VIII. Here we consider the step-like initial function (1.23) satisfying $0 > a + 5b > -4(c - b)$ with $V(a, c, b) > 0$.

THEOREM 4.5 (see Figure 4.5). *For the step-like initial data* (1.23) *with* $0 > a + 5b > -4(c - b)$ *and* $V(a, c, b) > 0$, *the solution of the Whitham equations* (1.22) *with* $g = 1$ *is given by*

(1) *For* $x/t \le \mu_3(a, -(a+b)/4, -(a+b)/4, b)$,

$$\alpha = a, \quad \beta = b.$$

(2) *For* $\mu_2(a, \hat{u}, b, b) \le x/t \le \frac{3}{8}\left(a^2 + 2ac + 5c^2\right)$,

$$\alpha = a, \quad \beta = -\frac{1}{5}a + \sqrt{\frac{8}{15}\frac{x}{t} - \frac{4}{25}a^2}.$$

(3) *For* $x/t \ge \frac{3}{8}\left(a^2 + 2ac + 5c^2\right)$,

$$\alpha = a, \quad \beta = c.$$

Proof. By the calculation (4.9), when u_3 of $\mu_2(a, u_2, u_3, b) - \mu_3(a, u_2, u_3, b) = 0$ touches b, the corresponding u_2 reaches $\hat{u}$, where $V(a, \hat{u}, b) = 0$. Obviously, $\hat{u} < c$. Hence, equations

$$\frac{x}{t} = \mu_2(a, u_2, u_3, b), \qquad \frac{x}{t} = \mu_3(a, u_2, u_3, b)$$

can be inverted to give u_2 and u_3 as functions of x/t in the region $\mu_2(a, -(a + b)/4, -(a+b)/4, b) < x/t < \mu_2(a, \hat{u}, \hat{u}, b)$. To the right of this region, equations (1.21) have a rarefaction wave solution. ∎

5. Vacuum points. The nonnegative function $\rho(x, t; \epsilon)$ has to be positive in order for the mKdV dispersive approximation (1.19) (or (1.2) for NLS) to make sense. It is therefore interesting to study those points (x, t) at which $\rho(x, t; \epsilon) = 0$ for a sequence of vanishing ϵ. These points are referred to as the vacuum points in [3].

Since the solution $\rho(x, t; \epsilon)$ of (1.19) can be approximated by the periodic solution (1.25) in the single phase regime, we instead study the vacuum points of the latter solution.

Since $\rho_2 \ge \rho_3$ because of (1.9) for $u_1 \ge u_2 \ge u_3 \ge u_4$, it follows from formula (1.25) that (x, t) is a vacuum point if and only if $\rho_3(x, t) = 0$, which, in view of (1.9), is equivalent to

$$u_1(x,t) - u_2(x,t) - u_3(x,t) + u_4(x,t) = 0. \tag{5.1}$$

For types I–IV, equality (5.1) can occur only if $u_1 - u_2 \le u_3 - u_4$ at the leading edge of the Whitham solution (see Figures 1.2, 3.2, 3.3, and 3.4). This inequality leads to $a + b \le 2b$ for types I and II and gives $a \le 4b$ for types III and IV. Hence,

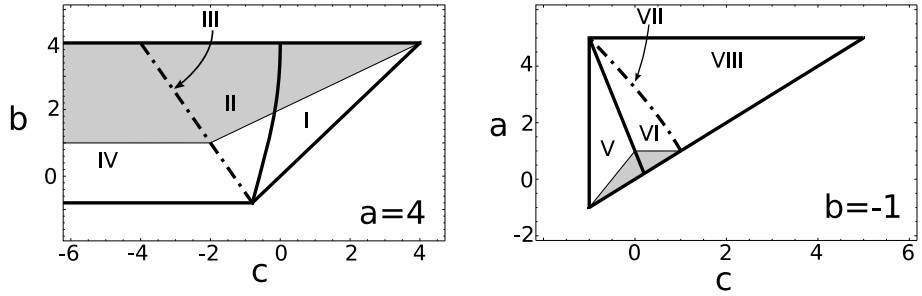

FIG. 5.1. *Diagram of regions for the initial data* (1.23) *which generate oscillatory solutions with vacuum points. The parameters* (c, b) *or* (c, a) *form the shaded region.*

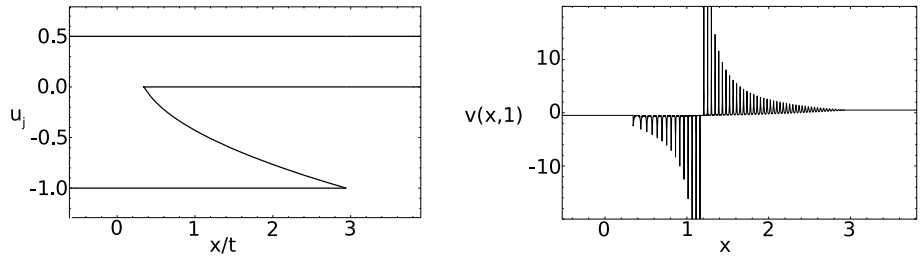

FIG. 5.2. *Self-similar solution of the Whitham equations* (1.22) *with* $g = 1$ *and the flow velocity* (1.10) *of the oscillatory solution of the mKdV equation with* $\epsilon = 0.014$. *The initial data are given by* (1.24) *of type* V *with parameters* $a = 0.5$, $b = -1$, *and* $c = 0$. *A vacuum point is located at* $x/t \approx 1.16$.

step-like initial shock data of types I–IV with $4b \geq a > b > c$ and $a + c \leq 2b$ will generate mKdV oscillatory solutions with vacuum points (cf. Figure 5.1).

Similarly, step-like initial shock data of types V and VI with $-b \geq a > c > b$ and $a + b \leq 2c$ will produce mKdV oscillatory solutions with vacuum points. Types VII and VIII oscillatory solutions cannot have any vacuum point (cf. Figure 5.1).

Types I–V oscillatory solutions have at most one vacuum point. To see this, note that the corresponding Whitham solutions have the property that $u_1(x, t)$ and $u_2(x, t)$ are constants and that $u_3(x, t) - u_4(x, t)$ are strictly monotone functions of x/t in the single phase region; so is the left-hand side of (5.1). Hence, (5.1) has at most one solution x/t. Figure 5.2 shows an example of oscillatory solutions with a unique vacuum point. Notice that the velocity $v(x, t; \epsilon)$ has a huge change at this point.

Type VI oscillatory solutions can have more than one vacuum point. They can even have a continuum of vacuum points. Namely, there exists an interval such that (5.1) holds at each point of the interval.

THEOREM 5.1. *For step-like initial data* (1.24) *of type* VI *satisfying condition* $a+b = 0$, *all the points on the closed interval* $\mu_3(a, -(a+b)/4, -(a+b)/4, b) \leq x/t \leq \mu_3(a, u^{***}, u^{***}, b)$, *where* u^{***} *is given in Theorem* 4.2, *are vacuum points.*

Proof. According to Theorem 4.2, the Whitham solution has the property that $u_1 = a$ and $u_4 = b$. Since $a + b = 0$, it follows from (5.1) that it suffices to show that $u_2 = -u_3$ over the closed interval mentioned in Theorem 5.1.

The functions u_2 and u_3 of the Whitham solution satisfies (4.3), which has a unique solution (4.5) with the property that $B(0) = 0$ in the case of $a + b = 0$. It

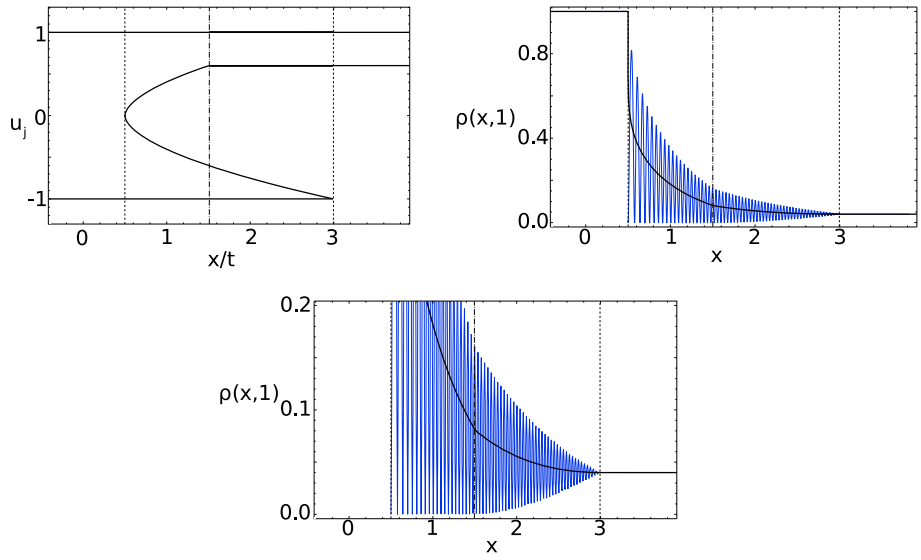

FIG. 5.3. *Self-similar solution of the Whitham equations* (1.22) *with* $g = 1$ *and the oscillatory solutions* (1.25) *of the mKdV equation with* $\epsilon = 0.04$. *The initial data are given by* (1.23) *with* $a = 1$, $b = -1$, *and* $c = 0.6$ *of type* VI. *The vacuum points occupy the whole interval* $0.5 \le \frac{x}{t} \le 1.50$.

follows from formula (2.10) for μ_2 and μ_3, formula (2.13) for q, and formulae (A.2–A.3) for λ_2 and λ_3 that $\mu_2(a, -u_3, u_3, b) = \mu_3(a, -u_3, u_3, b)$. Hence, $u_2 = -u_3$ is the unique solution of (4.3). □

Figure 5.3 is an illustration of such a solution, where rather than a vacuum point we now have a vacuum interval. It follows from formula (1.10) that $V(x, t; \epsilon) = (u_1 + u_2 + u_3 + u_4)/4 = 0$ at each point of the interval.

We close this section with a remark on the NLS case, which has been used to describe the nonlinear pulse propagation in an optical fiber [7]. The NLS oscillations with step-like initial shock data (1.15), $b > c$, have at most one vacuum point [3]. For more complicated step-like initial shock data, the NLS oscillations can also have a continuum of vacuum points. Indeed, consider the initial data

$$\alpha(x, 0) = \begin{cases} a, & x < 0, \\ b, & x > 0, \end{cases} \qquad \beta(x, 0) = \begin{cases} c, & x < 0, \\ d, & x > 0, \end{cases}$$

with $a > c > b > d$ and $a - b = c - d$. It can easily be shown that there is an interval within the single phase regime where all the u_i of the Whitham solution of (1.7) with $g = 1$ are constants. More precisely, $u_1 = a$, $u_2 = c$, $u_3 = b$, and $u_4 = d$ for $\lambda_3(a, c, b, d) \le x/t \le \lambda_2(a, c, b, d)$, where λ_2 and λ_3 are the second and third eigenspeeds of the NLS–Whitham equations (1.7) for $g = 1$. Since $a - b = c - d$, (5.1) holds at each point of the interval; hence, this is a vacuum interval. From the point of view of nonlinear optics, the optical wave has trivial frequency chirp in this region, and the region may be considered as a vacuum.

6. Other initial data. We conclude the paper by showing how to handle the initial data (1.24). Inequalities (2.14) are replaced by

$$\frac{\partial \lambda_2}{\partial u_2} < \frac{3}{2} \frac{\lambda_1 - \lambda_2}{u_1 - u_2} < \frac{\partial \lambda_1}{\partial u_1}$$

for $u_4 < u_3 < u_2 < u_1$. Results similar to those of Lemma 2.2 can then be easily proved. The rest of the calculations are similar to those in sections 3 and 4.

Appendix A. Leading edge calculations. The function $I(u_1, u_2, u_3, u_4)$ of (2.3) can be written in terms of the complete elliptic integral of the first kind $K(s)$; i.e.,

$$I = \frac{K(s)}{\sqrt{(u_1 - u_3)(u_2 - u_4)}}, \tag{A.1}$$

where

$$s = \frac{(u_1 - u_2)(u_3 - u_4)}{(u_1 - u_3)(u_2 - u_4)}.$$

Using the derivative formula

$$\frac{dK(s)}{ds} = \frac{E(s) - (1-s)K(s)}{2s(1-s)},$$

where $E(s)$ is the complete elliptic integral of the second kind, we calculate λ_2 and λ_3 of (2.2):

$$\lambda_2 = 2\sigma_1 - 4\,\frac{u_1 - u_2}{1 - \frac{u_1 - u_3}{u_2 - u_3}\,\frac{E}{K}}, \tag{A.2}$$

$$\lambda_3 = 2\sigma_1 + 4\,\frac{u_3 - u_4}{1 - \frac{u_2 - u_4}{u_2 - u_3}\,\frac{E}{K}}. \tag{A.3}$$

We then use (2.10) to write $\mu_2 - \mu_3$ as

$$-2(u_2 - u_3)K(s)\left[\frac{u_1 - u_2}{(u_2 - u_3)K - (u_1 - u_3)E}\,\frac{\partial q}{\partial u_2} + \frac{u_3 - u_4}{(u_2 - u_3)K - (u_2 - u_4)E}\,\frac{\partial q}{\partial u_3}\right].$$

Hence, $G(u_1, u_2, u_3, u_4)$ of (4.4) becomes

$$G = -2\left[\frac{u_1 - u_2}{(u_2 - u_3)K - (u_1 - u_3)E}\,\frac{\partial q}{\partial u_2} + \frac{u_3 - u_4}{(u_2 - u_3)K - (u_2 - u_4)E}\,\frac{\partial q}{\partial u_3}\right]. \tag{A.4}$$

We now use the asymptotics of $K(s)$ and $E(s)$ as s is close to 1,

$$K(s) \approx \frac{1}{2}\log\frac{16}{1-s}, \quad E(s) \approx 1 + \frac{1}{4}(1-s)\left(\log\frac{16}{1-s} - 1\right), \tag{A.5}$$

to calculate the $u_2 = u_3$ limit

$$G = 2\left(\frac{\partial q}{\partial u_2} + \frac{\partial q}{\partial u_3}\right). \tag{A.6}$$

Finally, we can also use the expression (2.13) and the derivative formulae

$$\frac{dE(s)}{ds} = \frac{E(s) - K(s)}{2s}, \quad \frac{dK(s)}{ds} = \frac{E(s) - (1-s)K(s)}{2s(1-s)} \tag{A.7}$$

to evaluate the partial derivatives of G in the $u_2 = u_3$ limit

$$\frac{\partial G}{\partial u_2}\Big|_{u_2=u_3} = 2 + \frac{(u_1-u_4)(u_1+4u_3+u_4)}{4(u_1-u_3)(u_4-u_3)}, \tag{A.8}$$

$$\frac{\partial G}{\partial u_3}\Big|_{u_2=u_3} = 2 - \frac{(u_1-u_4)(u_1+4u_3+u_4)}{4(u_1-u_3)(u_4-u_3)}.$$

Appendix B. Loss of genuine nonlinearity. In this appendix, we will show that the Whitham equations (1.22) with $g = 1$ are not genuinely nonlinear. Again, we suppress the subscript $g = 1$ in the notation $\lambda_{g,i}$ and $\mu_{g,i}$.

PROPOSITION B.1. *For fixed $u_1 > u_2 > u_4$ satisfying conditions*

$$u_1 + 4u_2 + u_4 > 0, \quad U(u_1, u_2, u_4) < 0,$$

where the function U is given in (2.23)*, the derivative*

$$\frac{\partial \mu_3(u_1, u_2, u_3, u_4)}{\partial u_3}$$

changes sign as u_3 increases from u_4 to u_2.

Proof. We first use formula (A.3) for λ_3, derivative formulae (A.7), and asymptotics (A.5) to calculate

$$\frac{\partial \lambda_3}{\partial u_3}\Big|_{u_3=u_2} = +\infty, \tag{B.1}$$

$$\frac{\partial \lambda_3}{\partial u_3}\Big|_{u_3=u_4} = \frac{24(u_2-u_4)^2 + 24(u_1-u_2)(u_2-u_4) + 9(u_1-u_2)^2}{(u_1+u_2-2u_4)^2}. \tag{B.2}$$

In the calculation of the last equation, we have also used the asymptotics of $K(s)$ and $E(s)$ near $s = 0$,

$$K(s) = \frac{\pi}{2}\left[1 + \frac{s}{4} + \frac{9}{64}s^2 + \cdots + \left(\frac{1\cdot 3\cdots(2n-1)}{2\cdot 4\cdots 2n}\right)^2 s^n + \cdots\right],$$

$$E(s) = \frac{\pi}{2}\left[1 - \frac{s}{4} - \frac{3}{64}s^2 - \cdots - \frac{1}{2n-1}\left(\frac{1\cdot 3\cdots(2n-1)}{2\cdot 4\cdots 2n}\right)^2 s^n - \cdots\right].$$

Differentiating formula (2.10) for μ_3 and using formula (2.13) for q, we obtain

$$\frac{\partial \mu_3(u_1, u_2, u_3, u_4)}{\partial u_3} = \frac{1}{8}(u_1+u_2+3u_3+u_4)\,\frac{\partial \lambda_3}{\partial u_3} + \frac{3}{8}[\lambda_3 - 2\sigma_1].$$

We then use the boundary values (2.7) and (2.8) for λ_3 and boundary values (B.1) and (B.2) for $\partial_{u_3}\lambda_3$ to calculate

$$\frac{\partial \mu_3}{\partial u_3}\Big|_{u_3=u_2} = +\infty \quad \text{if } u_1 + 4u_2 + u_4 > 0,$$

and

$$\frac{\partial \mu_3}{\partial u_3}\Big|_{u_3=u_4} = \frac{3U(u_1, u_2, u_4)}{8(u_1+u_2-2u_4)} < 0 \quad \text{if } U(u_1, u_2, u_4) < 0.$$

These two boundary values for $\partial_{u_3}\mu_3$ prove the proposition. □

The conditions of the proposition can easily be verified. For example, for the initial data (1.23) of types II and III, we have $\xi(a,b) > c$ and $a + 5b \geq 3(b-c) > 0$, which imply $U(a,b,c) < 0$ and $a + 4b + c > 0$. By Proposition B.1, the derivative

$$\frac{\partial \mu_3(a,b,u_3,c)}{\partial u_3}$$

must change sign as u_3 increases from c to b.

Appendix C. Phase shift. In this appendix, we will verify that Q given by (1.12) and (1.13) is the right phase shift for both the NLS and mKdV. We will study only the NLS case; the mKdV case can be handled in the same way.

For the NLS periodic wave train (1.8), the wave number and frequency are

$$k = \frac{\pi\sqrt{\rho_1 - \rho_3}}{\epsilon K(s)}, \quad w = kV_1.$$

The rapid phase is then given by

$$\Theta(x,t;\epsilon) = k\theta(x,t) = k[x - V_1\ t - Q]. \tag{C.1}$$

To verify that Q of (1.12) and (1.13) is indeed the phase shift, it suffices to show that Θ satisfies the generalized wave number and frequency relations

$$\frac{\partial \Theta}{\partial x} = k, \quad \frac{\partial \Theta}{\partial t} = -w. \tag{C.2}$$

We first observe that the compatibility condition for (C.2) is

$$\frac{\partial k}{\partial t} + \frac{\partial w}{\partial x} = 0,$$

which is the conservation of waves. This equation can be viewed as an additional conservation law satisfied by the solutions of the Whitham equations (1.7). Hence, the eigenspeeds λ_i of the Whitham equations can be calculated using k and w; i.e.,

$$\lambda_i = \frac{\partial_{u_i} w}{\partial_{u_i} k}. \tag{C.3}$$

We can also rewrite the wave number k in terms of I of (A.1) as

$$k = \frac{\pi}{\epsilon I},$$

which along with formula (2.2) for λ_i gives

$$\frac{k}{\partial_{u_i} k} = -\frac{I}{\partial_{u_i} I} = \frac{1}{2}(\lambda_i - 2\sigma_1). \tag{C.4}$$

Differentiating (C.1) with respect to x and using the property that $u_1 = a$, we obtain

$$\begin{aligned} \frac{\partial \Theta}{\partial x} &= k + \sum_{i=2}^{4} \left[x\frac{\partial k}{\partial u_i} - t\frac{\partial w}{\partial u_i} - k\frac{\partial Q}{\partial u_i} - Q\frac{\partial k}{\partial u_i} \right] u_{ix} \\ &= k + \sum_{i=2}^{4} \frac{\partial k}{\partial u_i}\ u_{ix} \left[x - \lambda_i t - \frac{1}{2}(\lambda_i - 2\sigma_1)\frac{\partial Q}{\partial u_i} - Q \right], \end{aligned} \tag{C.5}$$

where we have used formulae (C.3) and (C.4) in the last equality.

It is known that if $Q(a, u_2, u_3, u_4)$ satisfies (1.12) and (1.13), then

$$x = \lambda_i t + \frac{1}{2}(\lambda_i - 2\sigma_1)\frac{\partial Q}{\partial u_i} + Q$$

is the hodograph solution of the Whitham equations (1.7) [14]. Hence, we deduce from (C.5) the first equation of (C.2). The second equation of (C.2) can be shown in the same way.

Acknowledgment. We thank the referees for many valuable suggestions.

PERSISTENCE OF ROLL WAVES FOR THE SAINT VENANT EQUATIONS*

PASCAL NOBLE†

Abstract. The purpose of the article is to study the linear and nonlinear "stability" of roll-waves that are periodic and discontinuous entropic travelling wave solutions of the Saint Venant equations. More precisely, we prove that the Cauchy problem with initial data close to a roll-wave and satisfying suitable compatibility conditions has a solution on a sufficiently small interval.

Key words. roll-waves, shallow water, Cauchy problem, hyperbolic equations

AMS subject classifications. 35L45, 35L67, 35B10, 76H05, 35Q35

DOI. 10.1137/07070810X

1. Introduction.

Roll-waves are well-known nonlinear patterns appearing in shallow waters under the effect of gravity and bottom friction. This type of flow is commonly modeled by the "shallow water equations" that can be formally derived from the Navier–Stokes system. This is a hyperbolic system for the fluid height h and the average velocity u that is similar to the isentropic Euler equations. An empiric friction term, so-called Chezy friction term, is added to the momentum equation to model the friction of the bottom; see [7] for more details on the derivation of such models. In [3], Dressler proved the existence of periodic travelling waves that are mathematical solutions of the shallow water equations: those travelling waves are discontinuous, the discontinuity being a Lax shock. Similarly to shocks in hyperbolic systems, several questions arise at this stage: first, the existence of continuous roll-wave solutions of a viscous perturbation of the shallow water equations, the convergence to the inviscid roll-waves in the vanishing viscosity limit and their stability. The existence of continuous travelling waves for viscous shallow water equations follows from a classical Hopf bifurcation argument [9]. More involved is the question of the convergence of those solutions in the vanishing viscosity limit: one can prove, using geometric singular perturbation arguments (Fenichel theorems) that continuous roll-waves are ε close to an inviscid roll-wave with spatial period T and wave speed c_0 for a suitable wave speed $c(\varepsilon, T)$ with ε, the size of the viscosity [10], [11]. Only partial results are known concerning the stability of viscous roll-waves: those patterns are proved to be spectrally stable under large wavelength and small wavelength perturbations and are linearly stable provided that they are strongly spectrally stable; see [12] for more details.

In order to obtain more information on stability of viscous roll-waves, at least in the vanishing viscosity limit, we shall consider the inviscid case. In the case of a shock wave, the connection between the viscous and inviscid shocks has been established by Rousset [15] in the one-dimensional ($1D$) case and Gues and coworkers [6] in the multidimensional case. In the hyperbolic setting, the question of the "stability" of inviscid roll-waves then arises either under $1D$ or multidimensional perturbations.

In that paper and in order to make the connection with the viscous case, we shall focus on small *smooth* perturbations of roll-waves. Due to the presence of an infinite number of shocks, even the formulation of the stability problem is a hard task. In the case of a single shock, one formulates the stability problem among the piecewise smooth functions with a single discontinuity that is close to the shock: working in the reference frame attached to that discontinuity, one can reduce the stability problem to the analysis of an initial boundary value problem. In the case of roll-waves, it is natural to work among the functions that are piecewise regular with discontinuities that are close to the discontinuities of the roll-waves. Here it is not sufficient to work in the reference frame attached to *one* discontinuity; in that case, this would mean that we restrict our attention to *periodic* perturbations of the roll-waves. In that setting, Tamada and Tougou [17] proved that, for suitable large wavelength, roll-waves are spectrally stable. In order to handle more general perturbations, we need to fix *all* the discontinuities; this is done through a Lipschitz change of variable. The author proved in that case that for large wavelength, the spectral problem has no unstable eigenvalue [13]. Due to the hyperbolic nature of the problem, it seems hard to obtain a stability result in that case; we shall consider here the question of the "persistence" of roll-waves.

Similarly to the persistence of shocks, we shall prove here that the Cauchy problem with initial data that are close to a roll-wave and satisfy suitable compatibility conditions is well posed. First, we formulate the "stability" problem among the space of piecewise regular functions with discontinuities close to the roll-waves discontinuities: the shocks are fixed through a Lipschitz change of variable, and we write both the shallow water equations and the Rankine–Hugoniot jump conditions in that setting. Then we linearize that set of equations and analyze the spectral problem. In order to tackle the Cauchy problem, we shall only consider the high-frequency perturbations; we briefly analyze an analogous equation of the Lopatinskii determinant for shocks. Then, following the approach for shocks, we derive a priori estimates on the linear problem and for a linearized problem around an approximate solution. For an initial data satisfying suitable compatibility conditions, we can construct an approximate solution of the shallow water equations on a sufficiently small time interval. We obtain the existence of a solution to the Cauchy problem through a fixed point argument around the approximate solution with the a priori estimates on the linearized problem.

This method introduced by Majda [4] for compact shocks and generalized by Métivier [5] is suitable for *multimensional perturbations*. Though *valid in the multidimensional case*, the principal results obtained in this paper are written in *the* $1D$ *setting*. Indeed, in order to simplify the presentation, we have chosen to emphasize the periodic nature of the problem and the new issues that have to be handled with, in particular, the formulation of the stability problem and the presence of a sonic point in the interior that complicates higher-order estimates. In this particular setting, the energy estimates are derived easily without the microlocal analysis. We briefly discuss at the end of the paper how to extend the analysis proposed here to multidimensional perturbations. Moreover, this approach shall be generalized and developed in a forthcoming paper to handle roll-waves in generalized hyperbolic systems obtained recently by the author in [14].

The paper is organized as follows: in section 2, we recall the Dressler construction of roll-waves and formulate the boundary value problem associated to the persistence problem. In section 3, we linearize the equations around a roll-wave and perform the spectral analysis of that linear problem. We also obtain a priori estimates for

the solutions of that problem. We then consider the linearized problem around an approximate solution: we first obtain a priori estimates on solutions of that linear problem and deduce the well posedness of those equations in suitable functional spaces. Section 4 is devoted to the analysis of the full nonlinear problem: we first obtain compatibility conditions for initial data and construct an approximate solution of the shallow water equations coupled with Rankine–Hugoniot jump conditions. The well posedness of the Cauchy problem is then obtained through a fixed point argument.

2. Formulation of the problem. In this section, we give a short proof of the existence of inviscid roll-waves. Then, we introduce the functional spaces adapted to the stability analysis of that kind of pattern: these are piecewise regular functions with discontinuities close to the discontinuities of a roll-wave. We then perform the Lipschitz change of variable that fixes *all* the shocks and write the shallow water equations and the Rankine–Hugoniot conditions in the reference frame.

2.1. Existence of roll-waves. We briefly recall Dressler analysis for the existence of roll-wave solutions of the Saint Venant system. Let us start with the nondimensional Saint Venant equations

$$\begin{aligned} &h_t + (hu)_x = 0, \\ &(hu)_t + \left(\frac{h^2}{2F} + hu^2\right)_x = h - u^2, \end{aligned} \tag{1}$$

where h is the height of the fluid, u is the average fluid speed, and F is the Froude number. In [3], Dressler looks for periodic travelling wave solutions in the form

$$(h,u)(x,t) = (H,U)(x-ct)$$

of the inviscid Saint Venant equations: these yield a first order differential system. Eliminating U from the system reduces the problem to finding periodic solutions of the scalar equation

$$H' = \frac{H - (c - \frac{q}{H})^2}{\frac{H}{F} - \frac{q^2}{H^2}} = P_1(H), \tag{2}$$

where $q = H(c-U) > 0$, a constant, is the relative discharge rate. Integrating (2) in the form $\xi = \xi_0 + \int \frac{dh}{P_1(h)}$, it is proved that (2) has no continuous periodic solution [3]. Thus, we are looking for periodic solutions with discontinuities that satisfy admissibility conditions. The hyperbolic part of the system being similar to the isentropic Euler equations and the admissibility conditions for a discontinuity located at $x = x(t)$ are the Rankine–Hugoniot conditions

$$[hu] = \dot{x}[h], \quad \left[\frac{h^2}{2F} + hu^2\right] = \dot{x}[hu], \tag{3}$$

where $[u] = \lim_{\epsilon \to 0} u(x(t)+\epsilon) - u(x(t)-\epsilon)$ and a Lax shock condition

$$u_+ + \sqrt{\frac{h_+}{F}} < \dot{x} < u_- + \sqrt{\frac{h_-}{F}}.$$

Dressler proved the following result.

THEOREM 1. *Given any $F > 4$, $L > 0$, and $c > 0$, there exists a piecewise C^1 periodic travelling wave, with wave speed c and wavelength L, entropic solution of the inviscid Saint Venant equations* (1).

We recall the proof for completeness.

Proof. Let H_- (resp. H_+) be the fluid height before (resp. after) a shock. The entropic shock must satisfy the Rankine–Hugoniot jump conditions

$$\frac{H_+^2}{2F} + \frac{q^2}{H_+} = \frac{H_-^2}{2F} + \frac{q^2}{H_-}. \tag{4}$$

The Saint Venant equations are similar to the isentropic Euler equations for an ideal gas with $\gamma = 2$, where h plays the role of the density ρ. The entropy condition is equivalent to the Lax shock condition (see [18] for more details):

$$U_+ + \sqrt{\frac{H_+}{F}} < c < U_- + \sqrt{\frac{H_-}{F}}.$$

Since the relative discharge rate $H(c-U) = q$ is a constant, we obtain

$$\sqrt{\frac{H_+}{F}} - \frac{q}{H_+} < 0 < \sqrt{\frac{H_-}{F}} - \frac{q}{H_-}.$$

Hence, $H_+ < H_-$ and there exists a "sonic" point H_0 so that $H_+ < H_0 < H_-$ and

$$\frac{H_0}{F} - \frac{q^2}{H_0^2} = 0.$$

In order to satisfy the entropy condition, we must have $\frac{dH}{d\xi}|_{H_0} > 0$ or equivalently, $F > 4$. The denominator of the fraction in (2) vanishes at point H_0. To pass continuously through this value, the numerator must also vanish at this point H_0:

$$H_0 - \left(c - \frac{q}{H_0}\right)^2 = 0.$$

We simplify the fraction in (2):

$$\frac{dH}{d\xi} = F\frac{H^2 + \left(H_0 - c^2\right)H + \frac{H_0^2}{F}}{H^2 + H_0 H + H_0^2} = P_1(H). \tag{5}$$

The construction of a periodic solution with an arbitrary wavelength L is, at this point, straightforward. Let $H(\xi)$ be the special solution of (5) so that $H(0) = H_0$: it is defined implicitly by $H(\xi) = h \Leftrightarrow \xi = f_1(h)$, where f_1 is the primitive of $\frac{1}{P_1}$ such that $f_1(H_0) = 0$. The function f_1 is given by

$$\begin{aligned} Ff_1(h) = h - H_0 &+ \frac{H_a^2 + H_0 H_a + H_0^2}{H_a - H_b} \ln\left(\frac{h - H_a}{H_0 - H_a}\right) \\ &- \frac{H_b^2 + H_0 H_b + H_0^2}{H_a - H_b} \ln\left(\frac{h - H_b}{H_0 - H_b}\right), \end{aligned}$$

and $H_a > H_b$ are the zeros of P_1. Define $H_n(\xi) = H(\xi - nL)$. We fit H_n and H_{n+1} together by means of an entropic shock. Eliminating the solution $H_+ = H_-$, the Rankine–Hugoniot condition (4) now reads

$$H_+ + H_- = \frac{2H_0^3}{H_+ H_-}. \tag{6}$$

We determine the position of the nth shock ξ_c^n, with $H_n(\xi_c^n) = H_-$ and $H_{n+1}(\xi_c^n) = H_+$. This is equivalent to the relation

$$\int_{H_0}^{H^-} \frac{dh}{P_1(h)} = L + \int_{H_0}^{H_+} \frac{dh}{P_1(h)}. \tag{7}$$

Now, eliminating H_+ between (6) and (7) yields L as a function of H_-. Then we have obtained periodic and entropic solutions of the Saint Venant equations (1). □

In what follows, we rescale space variables and unknowns by H_0 in the variable $H := H_0 h$ and $\xi := H_0 \xi$: we get the nondimensional equation of profile

$$h' = F \frac{h^2 + \left(1 - \left(1 + \frac{1}{\sqrt{F}}\right)^2\right) h + \frac{1}{F}}{h^2 + h + 1} = P(h).$$

Denote $H_+ = H_0 h_+$ and $H_- = H_0 h_-$. The nondimensional Rankine–Hugoniot conditions reads

$$h_+ + h_- = \frac{2}{h_+ h_-}.$$

We can easily describe the asymptotic profile of the roll-waves as $L \to \infty$. Indeed, when $L \to \infty$, the minimum height h_+ converges to h_a given by

$$h_a = \frac{H_a}{H_0} = \frac{1}{2F}\left(1 + 2\sqrt{F} + \sqrt{1 + 4\sqrt{F}}\right).$$

Then the family of roll-waves converges to a solitary wave with a single shock as $L \to \infty$. Denote $h_m > h_a$ so that $h_a + h_m = \frac{2}{h_a h_m}$. Before the shock, the profile $\tilde{h}$ of the solitary wave is given by the special solution $\tilde{h} = h$, $h \in (h_a, h_m)$, and after the shock, it is a constant $\tilde{h} = h_a$. The description of the roll-wave solutions of the Saint Venant system is complete, and we are now in a position to formulate the stability problem.

2.2. Formulation of the stability problem. In this section, we recall the method, introduced in [13], of studying the stability of Dressler roll-waves that possess an infinite number of shocks . These roll-waves are parametrized by the wavelength L and the wave speed c. When these parameters are fixed, denote H_+ (resp. H_-) the minimum (resp. maximum) height of the roll-wave. This is also the height after (resp. before) a shock. We first write the Saint Venant system (1) into a diagonalized form and introduce the Riemann invariants

$$r = u + 2\sqrt{\frac{h}{F}}, \quad s = u - 2\sqrt{\frac{h}{F}}.$$

The shallow water equations (1) read

$$r_t + \lambda_1(r,s) r_x = Q(r,s), \quad s_t + \lambda_2(r,s) s_x = Q(r,s), \tag{8}$$

where $\lambda_k, k = 1, 2$ and Q are defined by

$$\lambda_1(r,s) = \frac{3r}{4} + \frac{s}{4}, \quad \lambda_2(r,s) = \frac{3s}{4} + \frac{r}{4}, \quad Q(r,s) = 1 - \frac{4}{F}\left(\frac{r+s}{r-s}\right)^2.$$

For a discontinuity located at $x = x(t)$, the Rankine–Hugoniot conditions in these variables reads

$$\begin{aligned} \left[(r+s)(r-s)^2)\right] &= 2\,\dot{x}\,\left[(r-s)^2\right], \\ \left[(r-s)^4 + 8(r-s)^2(r+s)^2\right] &= 16\,\dot{x}\,\left[(r+s)(r-s)^2\right]. \end{aligned} \tag{9}$$

The derivation of the spectral problem is inspired by the method introduced by Majda for studying the stability of multidimensional shocks in hyperbolic systems [4]. In what follows, we consider a Dressler roll-wave (H, U) (or equivalently, R, S) with wavespeed c and wavelength L: the location of the shocks are given by $x_i(t) = ct + iL$, $i \in \mathbb{Z}$. We consider small perturbations of that solution: we can suppose it is piecewise C^1 functions with discontinuities at positions $X_i(t) = ct + iL + \varepsilon_i(t)$, $i \in \mathbb{Z}$. The ε_i are supposed to be small. The Rankine–Hugoniot conditions (9) are then given by

$$\begin{aligned} \left[(r+s)(r-s)^2)\right]_{X_i} &= 2\dot{X}_i\,\left[(r-s)^2\right]_{X_i}, \\ \left[(r-s)^4 + 8(r-s)^2(r+s)^2\right]_{X_i} &= 16\dot{X}_i\,\left[(r+s)(r-s)^2\right]_{X_i} \end{aligned} \qquad \forall i \in \mathbb{Z}. \tag{10}$$

In [4], working in the reference frame attached to the discontinuity made the shock steady. In our case, because of the existence of an *infinite* distribution of shocks, we have to fix *all* the discontinuities in order to make the roll-wave steady, just as Majda did in the case of the stability of planar shocks [4]. In that case, a perturbation of a planar shock has a discontinuity front at points $x_n = \psi(y,t)$, with $y = (x_1, \dots, x_{n-1})$ the transverse variable, and one introduces a new variable $\xi = x_n - \psi(y,t)$ that fixes *all* the front shock and not only a variable $\xi = x_n - \psi(t)$ that fixes only the shock at $y = 0$. In the case of roll-waves, we fix all the shocks by working in the new system of coordinates $(\xi = \xi(x,t), t)$ such that $\xi(X_i(t), t) = iL\ \forall i \in \mathbb{Z}$. The function ξ has the form

$$\forall x \in]X_i(t), X_{i+1}(t)[,\ \xi(x,t) = \frac{x - X_i(t)}{X_{i+1}(t) - X_i(t)} L + iL\ \forall i \in \mathbb{Z}. \tag{11}$$

Remark. Considering $|\varepsilon_i| << 1$, we prove that $\xi(x,t) \approx x - ct$ up to first order; it looks like a change of reference frame.

Note that in the case of the stability of roll-waves, we have a sort of multidimensional stability issue where the transverse "variable" is $i \in \mathbb{Z}$. The function ξ is Lipschitz and the system is of order one, so this change of coordinates is licit and does not change the Rankine–Hugoniot jump conditions. We make the change of coordinates $(r,s)(x,t) = (\overline{r}, \overline{s})(\xi(x,t), t)$, where $(\overline{r}, \overline{s})$ are piecewise C^1 functions with discontinuities located at points $\{iL, i \in \mathbb{Z}\}$. The derivation rules are given by

$$\begin{aligned} \frac{\partial r}{\partial x} &= \frac{\partial \overline{r}}{\partial \xi} \frac{L}{X_{i+1} - X_i}, \\ \frac{\partial r}{\partial t} &= \frac{\partial \overline{r}}{\partial t} - \frac{L}{X_{i+1} - X_i} \left(\dot{X}_i + \frac{\xi - iL}{L} \left(\dot{X}_{i+1} - \dot{X}_i \right) \right) \frac{\partial \overline{r}}{\partial \xi}. \end{aligned} \tag{12}$$

Substituting (12) into the shallow water equations (8) and dropping the overlines into the equations, the system (8) reads for all $x \in (iL, (i+1)L)$,

$$\begin{aligned} r_t + \frac{L}{X_{i+1} - X_i} \left(\lambda_1(r,s) - \left(\dot{X}_i + \gamma_i(x) \left(\dot{X}_{i+1} - \dot{X}_i \right) \right) \right) r_x &= Q(r,s), \\ s_t + \frac{L}{X_{i+1} - X_i} \left(\lambda_2(r,s) - \left(\dot{X}_i + \gamma_i(x) \left(\dot{X}_{i+1} - \dot{X}_i \right) \right) \right) s_x &= Q(r,s), \end{aligned} \tag{13}$$

with $\gamma_i(x) = \frac{x-iL}{L} \in (0,1)$. The Rankine–Hugoniot conditions (10) remain unchanged and are given by

$$[hu]_{X_i} = \dot{X}_i[h]_{X_i}, \quad \left[\frac{h^2}{2F} + hu^2\right]_{X_i} = \dot{X}_i[hu]_{X_i}, \tag{14}$$

where h, u have to be understood as functions of r, s. The particular solution $(R, S, X_i(t) = ct + iL)$ computed by Dressler is now a steady solution of (13) and (14).

In this paper, we deal with the problem of the *persistence* of a roll-wave solution: Given any initial condition (r_0, s_0) which has the same structure as a roll-wave solution with discontinuities at points x_i^0, $i \in \mathbb{Z}$, we are going to prove that, for initial conditions close to a roll-wave solution and satisfying suitable compatibility conditions, there exists a solution of the Cauchy problem (13), (14) with the initial conditions $(r,s)(.,0) = (r_0, s_0)$ on a sufficiently small interval $(0, T^*)$ that conserves a structure similar to the roll-wave structure. This result is in some sense a result of the *stability* of roll waves. Due to the hyperbolic nature of the problem, we expect the apparition of new discontinuities that breaks the roll-wave structure. To deal with this problem, we follow the approach initiated by Majda [4] to prove the existence of compact shocks and developed by Metivier [5] for the stability of multidimensonal shocks: In order to deal with the full nonlinear problem, the first task is to prove the well posedness of the linearized equations around an approximate solution, which will be assumed to be close to a roll wave solution. Then, under suitable compatibility conditions, we are able to prove the existence of an approximate solution of (13), (14), and using a fixed point argument in the neighborhood of this approximate solution, we prove the existence of a solution of the full Cauchy problem.

3. Well posedness of the linearized equations. In this section, we prove the well posedness of the linear equations obtained by the linearization of (13), (14) in the neighborhood of an approximate solution close to a roll-wave. This is done by energy estimates on the linear problem and on an adjoint problem. We start with the analysis of the spectral problem associated to the linear equations obtained by linearization of (13), (14) around the *roll-wave solution* and then perform a priori estimates of solutions of that problem and the adjoint of that problem. We prove that these estimates remain true for the solutions of the linear equations obtained by linearization around a function "close" to a roll-wave. We deduce from the energy estimates that the linearized problem around an approximate solution is well posed in suitable functional spaces.

3.1. Energy estimates on the "exact" linearized problem. In what follows, we linearize shallow water equations and Rankine–Hugoniot conditions around an exact roll-wave solution and obtain energy estimates for that linearized problem: we shall deduce estimates for the linearized problem around an approximate solution.

3.1.1. Formulation of the linearized problem. The linearization of the equation in the neighborhood of the roll-wave solution yields the following, after time rescaling $t := H_0\, t$:

$$\begin{matrix} \partial_t\, r_i + a(h)\partial_x\, r_i \\ \partial_t\, s_i + b(h)\partial_x\, s_i \end{matrix} + L^0(h) \begin{pmatrix} r_i \\ s_i \end{pmatrix} = \mathcal{F}_i \quad \forall (x,i) \in (0,L) \times \mathbb{Z}, \tag{15}$$

with $a(h) = \sqrt{h} - h^{-1}$, $b(h) = -\sqrt{h} - h^{-1}$, $(r_i, s_i) = (r, s)_{|(iL, iL+L)}$,

$$\mathcal{F}_i = \left(\dot\varepsilon_i + \frac{x}{L}\left(\dot\varepsilon_{i+1} - \dot\varepsilon_i\right)\right) P(h) \begin{pmatrix} h^{-2} + h^{-\frac12} \\ h^{-2} - h^{-\frac12} \end{pmatrix} - \frac{c(\varepsilon_{i+1} - \varepsilon_i)P(h)}{L\left(1 + \sqrt{F}\right)} \begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

and

$$\begin{aligned}
L^0_{11} &= \frac34\left(h^{-2} + h^{-\frac12}\right) P(h) - h^{-\frac32}\left(1 + \sqrt{F} - h^{-1}\right)\left(1 + \sqrt{F} - h^{-1} - 2h^{\frac12}\right), \\
L^0_{12} &= \frac14\left(h^{-2} + h^{-\frac12}\right) P(h) + h^{-\frac32}\left(1 + \sqrt{F} - h^{-1}\right)\left(1 + \sqrt{F} - h^{-1} + 2h^{\frac12}\right), \\
L^0_{21} &= \frac14\left(h^{-2} - h^{-\frac12}\right) P(h) - h^{-\frac32}\left(1 + \sqrt{F} - h^{-1}\right)\left(1 + \sqrt{F} - h^{-1} - 2h^{\frac12}\right), \\
L^0_{22} &= \frac34\left(h^{-2} - h^{-\frac12}\right) P(h) + h^{-\frac32}\left(1 + \sqrt{F} - h^{-1}\right)\left(1 + \sqrt{F} - h^{-1} + 2h^{\frac12}\right).
\end{aligned}$$

Here h has to be understood as $h = h(x)$, the equation of profile of the roll-wave. The linearized Rankine–Hugoniot conditions are given by

$$\begin{aligned}
2[h]_{iL}\dot\varepsilon_i &= \left[\left(h - h^{-\frac12}\right) r + \left(h + h^{-\frac12}\right) s\right]_{iL}, \\
2[h]_{iL}\dot\varepsilon_i &= \left[\left(h - h^{-\frac12} + \frac{1}{1 + \sqrt{F}}\left(h^{\frac32} + h^{-\frac32} - 2\right)\right) r\right. \\
&\qquad \left. + \left(h + h^{-\frac12} - \frac{1}{1 + \sqrt{F}}\left(h^{\frac32} + h^{-\frac32} + 2\right)\right) s\right]_{iL} \quad \forall i \in \mathbb{Z},
\end{aligned} \tag{16}$$

with $[h]_{iL} = h_+ - h_-$. In order to simplify the notations, we introduce the matrix $M(h)$ so that (16) reads

$$2[h]\dot\varepsilon \begin{pmatrix} 1 \\ 1 \end{pmatrix} = \left[M(h) \begin{pmatrix} r \\ s \end{pmatrix}\right]_{iL}.$$

Equivalently, system (16) can be written

$$\begin{aligned}
2[h]\dot\varepsilon_i &= \left[\left(h - h^{-\frac12}\right) r + \left(h + h^{-\frac12}\right) s\right]_{iL}, \\
0 &= \left[\left(h^{\frac32} + h^{-\frac32} - 2\right) r - \left(h^{\frac32} + h^{-\frac32} + 2\right) s\right]_{iL}
\end{aligned} \qquad \forall i \in \mathbb{Z}. \tag{17}$$

In order to eliminate the derivatives of ε_i in the interior equations (15), one can, as usual, introduce the "good" unknowns:

$$\begin{aligned}
\overline{r}_i &= r_i + \left(\varepsilon_i + \frac{x}{L}(\varepsilon_{i+1} - \varepsilon_i)\right) P(h)\left(h^{-2} + h^{-\frac12}\right), \\
\overline{s}_i &= s_i + \left(\varepsilon_i + \frac{x}{L}(\varepsilon_{i+1} - \varepsilon_i)\right) P(h)\left(h^{-2} - h^{-\frac12}\right).
\end{aligned}$$

Dropping the overlines, this yields the system

$$\begin{aligned}
\partial_t r_i + a(h)\partial_x r_i &= \overline{\mathcal{F}}_i \quad \forall (x, i) \in (0, L) \times \mathbb{Z}, \\
\partial_t s_i + b(h)\partial_x s_i &
\end{aligned} \tag{18}$$

where $\overline{\mathcal{F}}_i$ contains only zeroth order terms. More precisely, $\overline{\mathcal{F}}_i$ is written

$$\begin{aligned}\overline{\mathcal{F}}_i = &- L^0 \begin{pmatrix} r_i \\ s_i \end{pmatrix} - \varepsilon_i P(h) L^0 \begin{pmatrix} h^{-2}+h^{-\frac{1}{2}} \\ h^{-2}-h^{-\frac{1}{2}} \end{pmatrix} \\ &- \frac{x}{L}(\varepsilon_{i+1}-\varepsilon_i) P(h) L^0 \begin{pmatrix} h^{-2}+h^{-\frac{1}{2}} \\ h^{-2}-h^{-\frac{1}{2}} \end{pmatrix} \\ &- \varepsilon_i \mathrm{diag}\,(a(h),b(h))\,\partial_x \begin{pmatrix} P(h)\big(h^{-2}+h^{-\frac{1}{2}}\big) \\ P(h)\big(h^{-2}-h^{-\frac{1}{2}}\big) \end{pmatrix} \\ &- (\varepsilon_{i+1}-\varepsilon_i)\mathrm{diag}(a(h),b(h))\partial_x \begin{pmatrix} \frac{x\,P(h)}{L}\big(h^{-2}+h^{-\frac{1}{2}}\big) \\ \frac{x\,P(h)}{L}\big(h^{-2}-h^{-\frac{1}{2}}\big) \end{pmatrix}.\end{aligned}$$

The Rankine–Hugoniot jump conditions are given by

$$\begin{aligned} 2[h]\dot{\varepsilon}_i &= \left[\left(h-h^{-\frac{1}{2}}\right) r + \left(h+h^{-\frac{1}{2}}\right) s\right]_{iL}, \\ -\left[P(h)\left(h-h^{-2}\right)\right]\varepsilon_i &= \left[\left(h^{\frac{3}{2}}+h^{-\frac{3}{2}}-2\right) r - \left(h^{\frac{3}{2}}+h^{-\frac{3}{2}}+2\right) s\right]_{iL}. \end{aligned} \tag{19}$$

As usual, we consider the linear boundary value problem dropping the zeroth order term from (18, 19):

$$\begin{aligned} &\partial_t r_i + a(h)\partial_x r_i = F_i^1, \\ &\partial_t s_i + b(h)\partial_x s_i = F_i^2 \end{aligned} \qquad \forall i \in \mathbb{Z}, x \in (0,L), \tag{20}$$

with the linearized Rankine–Hugoniot conditions

$$\begin{aligned} 2[h]\dot{\varepsilon}_i &= \left[\left(h-h^{-\frac{1}{2}}\right) r + \left(h+h^{-\frac{1}{2}}\right) s\right]_{iL} + a_{1,i}, \\ \left[\left(h^{\frac{3}{2}}+h^{-\frac{3}{2}}-2\right) r - \left(h^{\frac{3}{2}}+h^{-\frac{3}{2}}+2\right) s\right]_{iL} &= a_{2,i} \end{aligned} \qquad \forall i \in \mathbb{Z}. \tag{21}$$

These conditions can be interpreted as transmission conditions at the point of discontinuities between (r_i, s_i) and (r_{i+1}, s_{i+1}). Indeed, a jump of a function f of r, s at point $x = iL$ can be written

$$[f(r,s)]_{iL} = f(r_i(0), s_i(0)) - f(r_{i-1}(L), s_{i-1}(L)).$$

3.1.2. Normal mode analysis. We carry out a similar analysis made in the stability of multidimensional shocks and search for possible unstable eigenmodes. We make a Laplace transform in time and Fourier transform in discrete space (that yields Fourier series) of (20, 21):

$$\lambda \overline{r} + a(h)\overline{r}' = 0, \;\; \lambda \overline{s} + b(h)\overline{s}' = 0 \; \forall x \in (0,L),$$

with

$$\overline{r}(\lambda, \theta, x) = \sum_{k \in \mathbb{Z}} e^{ik\theta} \int_{-\infty}^{\infty} e^{\lambda t} r_k(x,t)\, dt.$$

The linearized Rankine–Hugoniot conditions reads

$$2\lambda(h_- - h_+)\overline{\varepsilon} \begin{pmatrix} 1 \\ 1 \end{pmatrix} = e^{i\theta} M(h_-) \begin{pmatrix} \overline{r}(L) \\ \overline{s}(L) \end{pmatrix} - M(h_+) \begin{pmatrix} \overline{r}(0) \\ \overline{s}(0) \end{pmatrix}.$$

Here the space $\mathbb{E}^s$ of functions decreasing to 0 at infinity used in the analysis of multidimensional shocks is replaced by the space $\mathbb{E}^a$ of *bounded* functions at the point of singularity x_0 such that $h(x_0) = 1$. A basis of solutions for the differential system (3.1.2) is given by

$$V_1 = \left((x-x_0)^{-\frac{\lambda}{a'(x_0)}} Z(x), 0\right), \; V_2 = \left(0, e^{-\lambda \int_{x_0}^x \frac{ds}{b(h(s))}}\right),$$

where Z is an analytic (thus bounded) function on the interval $(0, L)$ that is unique if we choose $Z(0) = 1$. When $\Re(\lambda) > 0$, it is easily seen that $\mathbb{E}^a = \langle V_2 \rangle$ so that the analogous equation of the Lopatinskii determinant is an Evans function given by

$$\Delta(\lambda, \theta) = \frac{2[h]}{1+\sqrt{F}} \lambda \left(\left(h_+^{\frac{3}{2}} + h_+^{-\frac{3}{2}} + 2 \right) - \left(h_-^{\frac{3}{2}} + h_-^{-\frac{3}{2}} + 2 \right) e^{i\theta - \lambda \int_0^L \frac{ds}{b(h(s))}} \right).$$

The function $h \mapsto h^{\frac{3}{2}} + h^{-\frac{3}{2}} + 2$ is decreasing on the interval (0, 1), is increasing on (1, $+\infty$), and is invariant under the function $\mapsto \frac{1}{h}$. The Rankine–Hugoniot jump conditions for the roll-wave $h_+ + h_- = \frac{2}{h_+ h_-}$ imply that $h_- = *10 \frac{1}{2}(\sqrt{h_+^2 + \frac{8}{h_+}} - h_+) < \frac{1}{h_+}$ for any $h_+ < 1$. Then we find that $h_+^{\frac{3}{2}} + h_+^{-\frac{3}{2}} + 2 > h_-^{\frac{3}{2}} + h_-^{-\frac{3}{2}} + 2$. As a consequence, on the half plane $\Re(\lambda) > 0$, the Evans function Δ vanishes either when $\lambda = 0$ (for any θ) and for

$$-\Re(\lambda) \int_0^L \frac{ds}{b(h(s))} = \log \left(\frac{h_+^{\frac{3}{2}} + h_+^{-\frac{3}{2}} + 2}{h_-^{\frac{3}{2}} + h_-^{-\frac{3}{2}} + 2} \right), \; \theta = \Im(\lambda) \int_0^L \frac{ds}{b(h(s))} \; [2\pi].$$

We obtain a full line of unstable eigenmodes with a positive growth rate $\Re(\lambda)$ in time, since $b(h) < 0$ and $h_+^{\frac{3}{2}} + h_+^{-\frac{3}{2}} + 2 > h_-^{\frac{3}{2}} + h_-^{-\frac{3}{2}} + 2$.

Contrary to the case of multidimensional shocks where there is only one shock, this *does not* imply strong instability since the Evans function is not homogeneous; the growth rate of the unstable eigenmodes is *bounded*, whereas in the case of a single shocks, a full line of eigenvalues with an arbitrary large real part is found. This is due to the fact that in the case of shocks, the equations are invariant under the hyperbolic scaling $(x, t) \mapsto (\mu x, \mu t)$ for any $\mu > 0$. As a consequence, an unstable mode is accompanied with a full line of unstable modes that are more and more unstable as the frequency goes to infinity. This is not the case here due to the periodic nature of the problem. Moreover, it is easily seen that when $L \to \infty$, $\mathrm{Re}(\lambda) \to 0$: the zeroth order terms have an importance in the stability issue as pointed out in [13].

3.1.3. Energy estimates. In this section, we obtain energy estimates for solutions of the linear problem (20), (21). We multiply the first (resp. second) equation of (20) by r_i (resp. s_i), integrate on (0, L), and sum for $i \in \mathbb{Z}$:

$$\partial_t \sum_{i\in\mathbb{Z}} \int_0^L \left(r_i^2 + s_i^2\right) dx + \sum_{i\in\mathbb{Z}} \int_0^L a(h)\partial_x r_i^2 + b(h)\partial_x s_i^2 = 2 \sum_{i\in\mathbb{Z}} \int_0^L F_i^1 r_i + F_i^2 r_i dx.$$

An integration by parts on the second integral yields

$$\int_0^L a(h)\partial_x r_i^2 + b(h)\partial_x s_i^2 = \left[a(h) r_i^2 + b(h) s_i^2\right]_0^L - \int_0^L \partial_x a \, r_i^2 + \partial_x b \, s_i^2 \, dx.$$

We change the indices of summation in the boundary terms and find that

$$\partial_t \sum_{i\in\mathbb{Z}} \int_0^L \left(r_i^2 + s_i^2\right) dx - \sum_{i\in\mathbb{Z}} \left[a(h)r^2 + b(h)s^2\right]_{iL} = 2\sum_{i\in\mathbb{Z}} \int_0^L F_i^1 r_i + F_i^2 s_i dx + \sum_{i\in\mathbb{Z}} \int_0^L \partial_x a(h)\, r_i^2 + \partial_x b(h)\, s_i^2. \tag{22}$$

Equation (22) can be written in the form

$$\partial_t \int_{\mathbb{R}} r^2 + s^2\, dx - \sum_{i\in\mathbb{Z}} \left[a(r)\, r^2 + b(h)\, s^2\right]_{iL} = 2\int_{\mathbb{R}} F\, r + G\, s\, dx + \int_{\mathbb{R}} \partial_x\, a(h)\, r^2 + \partial_x\, b(h)\, s^2\, dx. \tag{23}$$

Next, we have to obtain an estimate on the boundary terms. For that purpose, we show that the boundary condition

$$f_- r_i^- - f_+ r_i^+ = g_- s_i^- - g_+ s_i^+,$$

with

$$f_\pm = f(h_\pm),\ g_\pm = g(h_\pm),\ f(h) = h^{\frac{3}{2}} + h^{-\frac{3}{2}} - 2,\ g(h) = h^{\frac{3}{2}} + h^{-\frac{3}{2}} + 2,$$

is maximal dissipative. More precisely, we prove that

$$B\left(r_i^+, r_i^-, s_i^+, s_i^-\right) = 0 \ \Rightarrow \mathcal{Q}\left(r_i^+, r_i^-, s_i^+, s_i^-\right) \geq 0,$$

with $Bu = \langle rh, u\rangle$, rh being the vector $rh =^t (f_+, -f_-, -g_+, g_-)$ and $\mathcal{Q}$ is the quadratic form

$$\mathcal{Q}\left(r_i^+, r_i^-, s_i^+, s_i^-\right) = a_-\left(r_i^-\right)^2 + b_-\left(s_i^-\right)^2 - a_+\left(r_i^+\right)^2 - b_+\left(s_i^+\right)^2,$$

with $a_\pm = a(h_\pm), b_k = b(h_\pm)$. This property is necessarily maximal, since $\dim(\mathrm{KerB}) = 3$ and $b_- < 0$, whereas $-b_+, a_-, -a_+ > 0$. The restriction of the quadratic form $\mathcal{Q}$ to KerB is represented by the symmetric matrix $\mathcal{A}$:

$$\mathcal{A} = \begin{pmatrix} a_- g_+^2 - b_+ f_-^2 & b_+ f_- g_- & b_+ f_+ f_- \\ b_+ f_- g_- & b_- g_+^2 - b_+ g_-^2 & -b_+ f_+ g_- \\ b_+ f_+ f_- & -b_+ f_+ g_- & -a_+ g_+^2 - b_+ f_+^2 \end{pmatrix}.$$

The matrix $\mathcal{A}$ is definite positive provided that all the principal determinants Δ_i, $i = 1, 2, 3$ are strictly nonnegative. Let us check that condition. First, $\Delta_1 = a_- g_+^2 - b_+ f_-^2 \geq 0$ since $a_-, -b_+ \geq 0$, and $\Delta_1 \neq 0$ provided that there is a real shock $h_+ < 1 < h_-$ (otherwise, it is just the stationary solution). A straightforward computation shows that

$$\Delta_2 = g_+^2\left(a_- b_- g_+^2 - b_+\left(a_- g_-^2 + b_- f_-^2\right)\right),$$

and $\Delta_2 > 0$ if and only if the following condition is satisfied:

$$h_+\left(1 + h_+^{\frac{3}{2}}\right)\left(1 + h_+^{-\frac{3}{2}}\right)^2 < 6h_- + \frac{2}{h_-^2}. \tag{24}$$

It is easily proved that this relation is satisfied for *small amplitude* roll-waves when $h_+ < 1 < h_-$ lie in the neighborhood of $h = 1$. In the large amplitude case, recall that $h_a < h_+ < 1$, where $h_a = \frac{1}{2F}(1+2\sqrt{F}+\sqrt{1+4\sqrt{F}})$ and $h_+ + h_- = \frac{2}{h_+ h_-}$. We write the Rankine–Hugoniot jump condition for the roll wave as

$$h_- = RH(h_+) = \frac{1}{2}\left(\sqrt{h_+^2 + \frac{8}{h_+}} - h_+\right)$$

and inserting that relation into (24), the problem is reduced to the analysis of the sign of

$$C(h_+) = 6RH(h_+) + \frac{2}{RH(h_+)^2} - h_+\left(1+h_+^{\frac{3}{2}}\right)\left(1+h_+^{-\frac{3}{2}}\right)^2$$

when $h_+ \in (h_a, 1)$. It is a lengthly but straightforward computation to prove that $C(h_+) > 0$ for all $h_+ \in (h_a, 1)$ provided that $4 < F \leq F_c$, with $F_c \geq 18$. Thus, when $4 < F \leq F_c$, the relation $\Delta_2 > 0$ is satisfied for *all* roll-wave solutions and for larger Froude numbers; there exists $h_c(F) > h_a$ so that $\Delta_2 > 0$ is satisfied for all $h_+ \in (h_c(F), 1)$. Next, we consider the last condition $\Delta_3 > 0$. One can show that

$$\Delta_3 = g_+^4\left(\left(a_- g_-^2 + b_- f_-^2\right)a_+ b_+ - \left(a_+ g_+^2 + b_+ f_+^2\right)a_- b_-\right)$$

and $\Delta_3 > 0$ if and only if

$$3h_- + \frac{1}{h_-^2} > 3h_+ + \frac{1}{h_+^2}.$$

Then it is an easy calculation to prove that this condition is satisfied for *all* roll-wave solutions if $4 < F \leq F_c$, with $F_c \geq 12$. As a conclusion, the matrix $\mathcal{A}$ is definite positive if $4 < F \leq F_c$ ($F_c \geq 12$). Suppose that this assumption is satisfied. The quadratic form $\mathcal{Q}_{|\mathrm{KerB}}$ is definite positive. Denote $w = (r_i^+, r_i^-, s_i^+, s_i^-)$. We deduce that there exist $\kappa > 0$ and $C > 0$ so that

$$\mathcal{Q}(w) \geq \kappa\|w\|^2 - C\|Bw\|^2$$

and substituting that relation into (23), we deduce the estimate

$$\begin{aligned}\partial_t\|(r,s)\|_2^2 + \kappa\sum_{i\in\mathbb{Z}}\left|\left(r_i^\pm, s_i^\pm\right)\right|^2 \\ \leq 2\int_{\mathbb{R}} F^1\, r + F^2\, s\, dx + C\|(r,s)\|^2 + \|a_2\|_{l^2(\mathbb{Z})}^2,\end{aligned} \tag{25}$$

where $\|(r,s)\|_2^2 = \int_{\mathbb{R}} r^2 + s^2\, dx$ is the classical $\left(L^2(\mathbb{R})\right)^2$-norm. From the Rankine–Hugoniot condition, one can easily estimate $\varepsilon_i, \dot{\varepsilon}_i$:

$$|\dot{\varepsilon}_i|^2 \leq C\left(\left|\left(r_i^\pm, s_i^\pm\right)\right|^2 + a_{1,i}^2\right).$$

We compute estimates in weighted functional spaces. For $\gamma > 0$ sufficiently large (that depends on $\|(R,S)\|_{W^{1,\infty}(0,L)}$) and using Young's type inequalities, we obtain the following proposition.

PROPOSITION 1. *Assume that the Froude number F satisfies $0 < F < F_c$ (with $F_c > 12$). Then there exists γ_c (depending on $\|(R,S)\|_{W^{1,\infty}(0,L)}$) such that for all $\gamma > \gamma_c$, the following estimate holds true:*

$$\begin{aligned}&\gamma \int_{\mathbb{R}} e^{-2\gamma t}\|(r,s)\|_2^2 + \int_{\mathbb{R}} e^{-2\gamma t}\sum_{i\in\mathbb{Z}} \left|\left(r_i^{\pm}, s_i^{\pm}\right)\right|^2 + \left(\varepsilon_i^2 + \dot\varepsilon_i^2\right)\, dt\\ &\le C\left(\frac{1}{\gamma}\int_{\mathbb{R}} e^{-2\gamma t}\left\|\left(F^1,F^2\right)\right\|_2^2 dt + \int_{\mathbb{R}} e^{-2\gamma t}\left(\|a_1\|_{l^2(\mathbb{Z})}^2 + \|a_2\|_{l^2(\mathbb{Z})}^2\right) dt\right).\end{aligned} \tag{26}$$

We are now in a position to make the energy estimates on the linearized problem around an approximate solution close to a roll-wave. In what follows, we shall assume that the assumption $0 < F < F_c$ is satisfied.

3.2. Energy estimates for the "approximate" linearized problem. In order to tackle the full nonlinear problem, we consider the linearization of the Saint Venant system (13) in the neighborhood of an approximate solution (R_i, S_i, X_i) that is close to the original roll-wave $(R, S, ct+iL)$. In what follows, we shall prove that the estimates (26) obtained in the previous section remain true for (R_i, S_i, X_i) sufficiently "close" to the roll-wave solution $(R, S, ct + iL)$.

3.2.1. Formulation of the problem. We consider an approximate "solution" $(R_i, S_i, X_i) \approx (R, S, ct + iL)$ and linearize the shallow water equations and Rankine–Hugoniot jump conditions around that function:

$$\begin{aligned}&\partial_t r_i + \frac{L}{X_{i+1} - X_i}\Lambda_1^i \partial_x r_i = \overline{F}_i^1,\\ &\partial_t s_i + \frac{L}{X_{i+1} - X_i}\Lambda_2^i \partial_x s_i = \overline{F}_i^2\end{aligned} \qquad \forall (x,i) \in (0,L)\times\mathbb{Z}, \tag{27}$$

where the function $F_k^i, k = 1, 2$ are defined by

$$\begin{aligned}\overline{F}_i^1 &= \frac{\partial Q}{\partial r}(R_i,S_i)r_i + \frac{\partial Q}{\partial s}(R_i,S_i)s_i + \frac{L(\varepsilon_{i+1}-\varepsilon_i)}{(X_{i+1}-X_i)^2}\Lambda_1^i\\ &\quad - \frac{L}{X_{i+1}-X_i}\left(\lambda_1(r_i,s_i) - \left(\dot\varepsilon_i + \frac{x}{L}\left(\dot\varepsilon_{i+1} - \dot\varepsilon_i\right)\right)\right)\partial_x R_i\\ \overline{F}_i^2 &= \frac{\partial Q}{\partial r}(R_i,S_i)r_i + \frac{\partial Q}{\partial s}(R_i,S_i)s_i + \frac{L(\varepsilon_{i+1}-\varepsilon_i)}{(X_{i+1}-X_i)^2}\Lambda_2^i\\ &\quad - \frac{L}{X_{i+1}-X_i}\left(\lambda_2(r_i,s_i) - \left(\dot\varepsilon_i + \frac{x}{L}\left(\dot\varepsilon_{i+1} - \dot\varepsilon_i\right)\right)\right)\partial_x S_i\end{aligned}$$

and $\Lambda_k^i, k = 1, 2, i \in \mathbb{Z}$ denotes $\Lambda_k^i = \lambda_k(R_i, S_i) - (\dot X_i + \frac{x}{L}(\dot X_{i+1} - \dot X_i))$. The linearized Rankine–Hugoniot jump conditions are given by

$$\begin{aligned}[\mathbb{Q}(R_i,S_i)]\dot\varepsilon_i &= \left[\left(\frac{\partial \mathbb{F}}{\partial R} - \dot X_i\frac{\partial \mathbb{Q}}{\partial R}\right)r + \left(\frac{\partial \mathbb{F}}{\partial S} - \dot X_i\frac{\partial \mathbb{Q}}{\partial S}\right)s\right]_{iL}\\ &\quad + \frac{L\varepsilon_i}{X_{i+1}-X_i}\left[\partial_x\left(\mathbb{F} - \dot X_i\mathbb{Q}\right)\right]_{iL},\\ [H(R_i,S_i)]\dot\varepsilon_i &= \left[\left(\frac{\partial \mathbb{Q}}{\partial R} - \dot X_i\frac{\partial H}{\partial R}\right)r + \left(\frac{\partial \mathbb{Q}}{\partial S} - \dot X_i\frac{\partial H}{\partial S}\right)s\right]_{iL}\\ &\quad + \frac{L\varepsilon_i}{X_{i+1}-X_i}\left[\partial_x\left(\mathbb{Q} - \dot X_i H\right)\right]_{iL},\end{aligned} \tag{28}$$

where the functions $\mathbb{Q} = HU, \mathbb{F} = \frac{H^2}{2F} + HU^2$ shall be considered as functions of R, S. One can introduce the "good" unknowns to drop the derivatives of ε_i in the interior equation (27). Similarly to the previous section, we analyse the linear problem obtained after dropping zeroth order terms in (27), (28):

$$\begin{aligned} &\partial_t r_i + \frac{L}{X_{i+1} - X_i} \Lambda_1^i \, \partial_x r_i = F_i^1, \\ &\partial_t s_i + \frac{L}{X_{i+1} - X_i} \Lambda_2^i \, \partial_x s_i = F_i^2 \end{aligned} \qquad \forall x \in (0, L) \; \forall i \in \mathbb{Z}. \tag{29}$$

The system (29) is completed with the linearized Rankine–Hugoniot conditions

$$\begin{aligned} [\mathbb{Q}(R_i, S_i)]\dot{\varepsilon}_i &= \left[\left(\frac{\partial \mathbb{F}}{\partial R} - \dot{X}_i \frac{\partial \mathbb{Q}}{\partial R} \right) r + \left(\frac{\partial \mathbb{F}}{\partial S} - \dot{X}_i \frac{\partial \mathbb{Q}}{\partial S} \right) s \right]_{iL} + a_{1,i}, \\ [H(R_i, S_i)]\dot{\varepsilon}_i &= \left[\left(\frac{\partial \mathbb{Q}}{\partial R} - \dot{X}_i \frac{\partial H}{\partial R} \right) r + \left(\frac{\partial \mathbb{Q}}{\partial S} - \dot{X}_i \frac{\partial H}{\partial S} \right) s \right]_{iL} + a_{2,i} \end{aligned} \qquad \forall i \in \mathbb{Z}. \tag{30}$$

3.2.2. Energy estimates. In what follows, we shall prove the following result.

PROPOSITION 2. *There exists $\eta > 0$ so that for all $m > 0$, there exists a constant C and γ_0 depending on m and for any Lipschitz continuous and bounded function $(R_i, S_i, X_i)_{i \in \mathbb{Z}}$ satisfying*

$$\begin{aligned} &\max_{i \in \mathbb{Z}} \left(\left\| \dot{X}_i - c \right\|_\infty + \| X_{i+1} - X_i - L \|_\infty + \| R_i - R, S_i - S \|_\infty \right) \leq \eta, \\ &\max_{i \in \mathbb{Z}} \left(|\partial_x (R_i, S_i)|_\infty + \left| \dot{X}_i \right|_\infty \right) \leq m, \end{aligned}$$

and for all $\gamma \geq \gamma_0$, $(F^1, F^2) \in \mathcal{D}(\mathbb{R}/\{iL\} \times \mathbb{R})$, $(a_1, a_2) \in l^2(\mathbb{Z}, \mathcal{D}(\mathbb{R}))$, then a solution $(r_i, s_i, \varepsilon_i)_{i \in \mathbb{Z}}$ of (29), (30) satisfies

$$\begin{aligned} &\gamma \left\| e^{-\gamma t}(r, s) \right\|^2_{L^2(\mathbb{R}/\{iL\} \times \mathbb{R})} + \left\| e^{-\gamma t} \left(r_i^\pm, s_i^\pm \right) \right\|^2_{l^2(\mathbb{Z}, L^2(\mathbb{R}))} + \left\| e^{-\gamma t} \varepsilon_i \right\|_{l^2(\mathbb{Z}, H^1(\mathbb{R}))} \\ &\leq C \left(\frac{1}{\gamma} \| e^{-\gamma t} \left(F^1, F^2 \right) \|^2_{L^2(\mathbb{R}/\{iL\} \times \mathbb{R})} + \left\| e^{-\gamma t} (a_1, a_2) \right\|_{l^2(\mathbb{Z}, L^2(\mathbb{R}))} \right). \end{aligned}$$

Proof. Similarly to the previous case, we multiply the first (resp. second) equation of (29) by r_i (resp. s_i), integrate on $(0, L)$, and sum for $i \in \mathbb{Z}$:

$$\begin{aligned} &\partial_t \int_{\mathbb{R}} r^2 + s^2 \, dx + \sum_{i \in \mathbb{Z}} \frac{L}{X_{i+1} - X_i} \left[\Lambda_1^i \, r_i^2 + \Lambda_2^i \, s_i^2 \right]_0^L \\ &= 2 \int_{\mathbb{R}} F^1 \, r + F^2 \, s \, dx + \sum_{i \in \mathbb{Z}} \frac{L}{X_{i+1} - X_i} \int_0^L \partial_x \Lambda_1^i \; r_i^2 + \partial_x \Lambda_2^i \; s_i^2 \, dx. \end{aligned}$$

It is a straightforward computation to prove that the boundary terms satisfy

$$\begin{aligned} \sum_{i \in \mathbb{Z}} \frac{L}{X_{i+1} - X_i} \left[\Lambda_1^i \, r_i^2 + \Lambda_2^i \, s_i^2 \right]_0^L \geq &- \sum_{i \in \mathbb{Z}} \left[a(h) \, r^2 + b(h) \, s^2 \right]_{iL} \\ &- \| \delta \|_{l^\infty(\mathbb{Z})} \sum_i \left| \left(r_i^\pm, s_i^\pm \right) \right|^2, \end{aligned}$$

where $(r_i^{\pm}, s_i^{\pm})$ denotes the vector $(r_i^+, r_i^-, s_i^+, s_i^-)$ and $(\delta_i)_{i\in\mathbb{Z}}$ satisfies

$$\delta_i = \mathcal{O}\left(\left\|\dot{X}_i - c\right\|_\infty + \|X_{i+1} - X_i - L\|_\infty + \|R_i - R, S_i - S\|_\infty\right).$$

On the other hand, for $\max_i(\|R-R_i, S-S_i\|_\infty)$ sufficiently small, we obtain $[H(R_i, S_i)] \neq 0$, and we can write the Rankine–Hugoniot jump conditions in the form

$$\dot{\varepsilon}_i = [\mathcal{L}_1^i(r,s)]_{iL} + L_1^i(a_i, b_i), \quad [\mathcal{L}_2^i(r,s)]_{iL} = L_2^i(a_i, b_i),$$

so that

$$[\mathcal{L}_2^i(r,s)]_{iL} = \left[\left(h^{\frac{3}{2}} + h^{-\frac{3}{2}} - 2\right) r + \left(h^{\frac{3}{2}} + h^{-\frac{3}{2}} + 2\right) s\right]_{iL} + \mu_i \left|\left(r_i^{\pm}, s_i^{\pm}\right)\right|,$$

and the real numbers μ_i are estimated by

$$\mu_i = \mathcal{O}\left(\left\|\dot{X}_i - c\right\|_\infty + \|X_{i+1} - X_i - L\|_\infty + \|R_i - R, S_i - S\|_\infty\right).$$

Moreover, the linear operators L_k^i are uniformly bounded:

$$|L_k^i(a,b)| \leq C|(a,b)| \ \forall i \in \mathbb{Z},\ k = 1, 2.$$

Choosing μ_i, δ_i sufficiently small and for

$$\max_{i\in\mathbb{Z}}\left(\|R_i, S_i\|_{W^{1,\infty}(0,L)}\right) < m, \quad \max_{i\in\mathbb{Z}}\left(\left|\dot{X}_i\right|\right) < m, \quad m < \infty,$$

we deduce the following estimate:

$$\begin{aligned}
&\gamma \int_{\mathbb{R}} e^{-2\gamma t}\|(r,s)\|_2^2\, dt + \int_{\mathbb{R}} e^{-2\gamma t} \sum_i \left|\left(r_i^{\pm}, s_i^{\pm}\right)\right|^2 + \dot{\varepsilon}_i^2 + \varepsilon_i^2\, dt \\
&\leq C\left(\frac{1}{\gamma}\int_{\mathbb{R}} e^{-2\gamma t}\left\|\left(F^1, F^2\right)\right\|_2^2\, dt + \int_{\mathbb{R}} e^{-2\gamma t}\left(\|a_1\|_{l^2(\mathbb{Z})}^2 + \|a_2\|_{l^2(\mathbb{Z})}^2\right) dt\right)
\end{aligned}$$

for any $\gamma \geq \gamma_0 > 0$, where γ_0 depends on $\|\delta\|_{l^\infty(\mathbb{Z})}$ and m. This completes the proof of the proposition. ∎

3.3. The adjoint problem. In this section, we formulate the adjoint problem of the linearized equations around the roll-wave and around an approximate solution that is close to a roll-wave. We obtain energy estimates for that adjoint problem that shall be useful to prove the existence of weak solutions to the linearized equations.

3.3.1. The adjoint problem of the "exact" linearized equations. We multiply the first equation (resp. second) of (20) by p_i (resp. q_i), integrate over $(0, L)\times\mathbb{R}$, and sum on $i \in \mathbb{Z}$:

$$\begin{aligned}
&\int_{\mathbb{R}} \sum_i \int_0^L \partial_t\, r_i\, p_i + \partial_t\, s_i\, q_i + a(h)\partial_x\, r_i\, p_i + b(h)\partial_x\, s_i\, q_i\, dxdt \\
&\qquad = \int_{\mathbb{R}} \sum_i \int_0^L F_i^1\, p_i + F_i^2\, q_i.
\end{aligned}$$

An integration by parts on the interval $(0, L)$ and $t \in \mathbb{R}$ yields

$$\begin{aligned}
&-\int_{\mathbb{R}} \sum_i \int_0^L (p_{i,t} + (a(h)p_i)_x) r_i + (q_{i,t} + (b(h)q_i)_x) s_i\, dx \\
&\quad - \int_{\mathbb{R}} \sum_i [a(h)p\, r + b(h)q\, s]_{iL} = \int_{\mathbb{R}} \sum_i \int_0^L F_i^1\, p_i + F_i^2\, q_i\, dxdt.
\end{aligned}$$

The boundary terms can be written

$$-[a(h)p\,r + b(h)q\,s]_{iL} =^t \left(p_i^\pm, q_i^\pm\right) A \left(r_i^\pm, s_i^\pm\right),$$

with $A = \mathrm{diag}(-a_+, a_-, -b_+, b_-)$. We write the Rankine–Hugoniot conditions (21) in the form

$$\begin{pmatrix} \dot{\underline{\varepsilon}}_i \\ 0 \end{pmatrix} = \underline{B}\left(r_i^\pm, s_i^\pm\right) + \begin{pmatrix} a_{1,i} \\ a_{2,i} \end{pmatrix},$$

with $\underline{\varepsilon}_i = 2[h]\varepsilon_i$ and $\underline{B}$ is defined by

$$\underline{B} = \begin{pmatrix} h_+ - h_+^{-\frac{1}{2}} & -h_- + h_-^{-\frac{1}{2}} & h_+ + h_+^{\frac{1}{2}} & -h_- - h_-^{-\frac{1}{2}} \\ 2 - h_+^{\frac{3}{2}} - h_+^{-\frac{3}{2}} & h_-^{\frac{3}{2}} + h_-^{-\frac{3}{2}} - 2 & h_+^{\frac{3}{2}} + h_+^{-\frac{3}{2}} + 2 & -h_-^{\frac{3}{2}} - h_-^{-\frac{3}{2}} - 2 \end{pmatrix}.$$

We decompose $\underline{B}$ in the form $\underline{B} = (A_1\ A_2) = \binom{B_1}{B_2}$, with $A_i \in M_2(\mathbb{R})$ and ${}^t B_i \in \mathbb{R}^4$. It is a straightforward computation to prove that

$$\det(A_1) = \left(h_- - h_-^{-\frac{1}{2}}\right)\left(h_+ - h_+^{-\frac{1}{2}}\right)\left(\left(h_+^{\frac{1}{2}} - h_+^{-1}\right) - \left(h_-^{\frac{1}{2}} - h_-^{-1}\right)\right) \neq 0,$$

provided that $h_+ < 1 < h_-$. This condition is clearly satisfied for roll-wave solutions (otherwise, there is no roll-wave). Thus, $\mathrm{Ker}\,\underline{B}$ is two-dimensional ($2D$) and possesses a basis of vectors: $\langle {}^t B_1^\perp, {}^t B_2^\perp \rangle$. We can apply Lemma 9.4, p. 255 in [1]: there exists $N_1 \in M_{2,4}(\mathbb{R})$ so that $\mathbb{R}^4 = \mathrm{Ker}\underline{B} \oplus \mathrm{Ker}N_1$ and there exist $C, N_2 \in M_{2,4}(\mathbb{R})$ so that $\mathbb{R}^4 = \mathrm{Ker}C \oplus \mathrm{Ker}N_2$ and $A =^t N_2\,\underline{B} +^t C\,N_1$. As a consequence, the boundary terms can be written in the form

$$\begin{aligned}
&\int_{\mathbb{R}} \sum_i {}^t\left(p_i^\pm, q_i^\pm\right) A \left(r_i^\pm, s_i^\pm\right) \\
&\qquad = \int_{\mathbb{R}} \sum_i {}^t\left(N_2\left(p_i^\pm, q_i^\pm\right)\right) \underline{B}\left(r_i^\pm, s_i^\pm\right) + {}^t\left(C\left(p_i^\pm, q_i^\pm\right)\right) N_1\left(r_i^\pm, s_i^\pm\right) \\
&\qquad = \int_{\mathbb{R}} \sum_i {}^t\left(C\left(p_i^\pm, q_i^\pm\right)\right) N_1\left(r_i^\pm, s_i^\pm\right) + {}^t\left(N_2\left(p_i^\pm, q_i^\pm\right)\right) \begin{pmatrix} a_{1,i} - \dot{\varepsilon}_i \\ a_{2,i} \end{pmatrix} \\
&\qquad = \int_{\mathbb{R}} \sum_i {}^t\left(N_2\left(p_i^\pm, q_i^\pm\right)\right) \begin{pmatrix} a_{1,i} \\ a_{2,i} \end{pmatrix} dt + \partial_t\left(N_2\left(p_i^\pm, q_i^\pm\right)_1\right) \varepsilon_i\, dt \\
&\qquad\quad + \int_{\mathbb{R}} \sum_i {}^t\left(C\left(p_i^\pm, q_i^\pm\right)\right) N_1\left(r_i^\pm, s_i^\pm\right) dt.
\end{aligned}$$

The adjoint problem of the linearized equations around a roll-wave is written in the form

$$\begin{array}{l} -\partial_t\, p_i - \partial_x(a(h)p_i) = 0, \\ -\partial_t\, q_i - \partial_x(b(h)q_i) = 0, \end{array} \quad \forall (x,i) \in (0,L) \times \mathbb{Z},$$

with the boundary conditions

$$\partial_t\left(N_2\left(p_i^\pm, q_i^\pm\right)_1\right) = 0, \quad C\left(p_i^\pm, q_i^\pm\right) = 0 \quad \forall i \in \mathbb{Z}.$$

In what follows, we compute energy estimates for solutions of the linear problem:

$$\begin{array}{l} -\partial_t\, p_i - \partial_x\left(a(h)p_i\right) = F_i^1, \\ -\partial_t\, q_i - \partial_x\left(b(h)q_i\right) = F_i^2 \end{array} \quad \forall i \in \mathbb{Z},\ x \in (0,L), \tag{31}$$

with the boundary equations

$$\partial_t \left(N_2 \left(p_i^\pm, q_i^\pm \right)_1 \right) = a_{1,i}, \quad C \left(p_i^\pm, q_i^\pm \right) = a_{2,i} \quad \forall i \in \mathbb{Z}. \tag{32}$$

We multiply the first equation of (31) by p_i and the second by q_i:

$$\begin{aligned} -\partial_t \int_{\mathbb{R}} p^2 + q^2 \, dx + \sum_i \left[a(h)\, p^2 + b(h)\, q^2 \right]_{iL} &= 2 \int_{\mathbb{R}} F^1\, p + F^2\, q \, dxdt \\ &+ \int_{\mathbb{R}} \partial_x a(h)\, p^2 + \partial_x b(h)\, q^2 \, dx, \end{aligned} \tag{33}$$

where (p, q) is the function $(p, q) = \sum_{i \in \mathbb{Z}} (p_i, q_i) 1_{(iL,(i+1)L}$. We note $\tilde{a}_{1,i}$, the unique exponentially decreasing solution of $\partial_t \tilde{a}_{1,i} = a_{1,i}$. The boundary conditions (32) now read

$$\begin{aligned} N_2 \left(p_i^\pm, q_i^\pm \right)_1 &= \tilde{a}_{1,i}, \\ N_2 \left(p_i^\pm, q_i^\pm \right)_2 &= N_2 \left(p_i^\pm, q_i^\pm \right)_2 \ \forall\, i \in \mathbb{Z}, \\ C \left(p_i^\pm, q_i^\pm \right) &= a_{2,i}. \end{aligned} \tag{34}$$

We recall that $A =^t N_2 \underline{B} +^t C_1$, and (34) is written

$$A \left(p_i^\pm, q_i^\pm \right) = \left(N_2 \left(p_i^\pm, q_i^\pm \right)_2 \right)^t B_2 + \tilde{a}_{1,i}\, {}^t B_1 +^t N_1\, a_{i,2}.$$

The matrix A is invertible with a bounded inverse so that

$$\left| \left(p_i^\pm, q_i^\pm \right) \right|^2 \leq C \left(\left| N_2 \left(p_i^\pm, q_i^\pm \right)_2 \right|^2 + |(\tilde{a}_{1,i}, 0, a_{2,i})|^2 \right).$$

As a consequence, there remains to estimate the term $N_2(p_i^\pm, q_i^\pm)_2$. For that purpose, we write the boundary terms in (33) in the form

$$\begin{aligned} -\mathcal{Q} \left(p_i^\pm, q_i^\pm \right) = &- \left| N_2 \left(p_i^\pm, q_i^\pm \right)_2 \right|^2 \, B_2\, A^{-1}\, {}^t B_2 \\ &- 2 N_2 \left(p_i^\pm, q_i^\pm \right)_2 \left(A^{-1}\, {}^t B_2; A^{-1} \left({}^t \underline{B}, {}^t \, N_1 \right) \begin{pmatrix} \tilde{a}_{1,i} \\ 0 \\ a_{2,i} \end{pmatrix} \right) \\ &- \left(A^{-1} \left({}^t \underline{B}, {}^t \, N_1 \right) \begin{pmatrix} \tilde{a}_{1,i} \\ 0 \\ a_{2,i} \end{pmatrix}; \left({}^t \underline{B}, {}^t \, N_1 \right) \begin{pmatrix} \tilde{a}_{1,i} \\ 0 \\ a_{2,i} \end{pmatrix} \right). \end{aligned}$$

Then, we deduce from (33) that

$$\begin{aligned} -\partial_t \int_{\mathbb{R}} p^2 + q^2 - \sum_i \left| N_2 \left(p_i^\pm, q_i^\pm \right)_2 \right|^2 \, B_2\, A^{-1}\, {}^t B_2 \\ = 2 \int_{\mathbb{R}} F^1\, p + F^2\, q + \mathcal{O} \left(\sum_i \tilde{a}_{1,i}^2 + |a_{2,i}|^2 \right) \\ + \mathcal{O} \left(\sum_i \left| N_2 \left(p_i^\pm, q_i^\pm \right)_2 \right| \, |(\tilde{a}_{1,i}, 0, a_{2,i})| \right). \end{aligned}$$

Next, we show that $B_2\, A^{-1}\, {}^t B_2 < 0$. It is an easy commputation to prove that

$$B_2\, A^{-1}\, {}^t B_2 = 2 \left(\left(3h_+ + \frac{1}{h_+^2} \right) - \left(3h_- + \frac{1}{h_-^2} \right) \right) < 0.$$

The inequality is satisfied, since we have already assumed that the Froude number F is such that $0 < F < F_c$, and thus

$$3h_- + \frac{1}{h_-} > 3h_+ + \frac{1}{h_+}$$

(see the proof of Proposition 1) so that the boundary conditions are maximal dissipative and obtain energy estimates on the linearized problem. We work in weighted spaces in time: integrating on $t \in \mathbb{R}$ and using Young's inequalities, we get for $\gamma \geq \gamma_0$ (γ_0 depending on $\|(R,S)\|_{W^{1,\infty}(0,L)}$) that

$$\begin{aligned} &\gamma \int_{\mathbb{R}} e^{2\gamma t} \|(p,q)\|_2^2 \, dt + \kappa \int_{\mathbb{R}} e^{2\gamma t} \sum_i \left| \left(p_i^{\pm}, q_i^{\pm}\right) \right|^2 \\ &\leq C \left(\frac{1}{\gamma} \int_{\mathbb{R}} e^{2\gamma t} \left\| \left(F^1, F^2\right) \right\|^2 \, dt + \int_{\mathbb{R}} e^{2\gamma t} \sum_i |a_{1,i}|^2 + |a_{2,i}|^2 \right), \end{aligned} \tag{35}$$

with $\kappa, C > 0$ constant.

3.3.2. The "approximate" adjoint problem. In this section, we compute the adjoint problem of the linearized problem around an approximate solution and a priori estimates on that linear problem. Recall that the linearized equations around an approximate solution are given by

$$\begin{aligned} &\partial_t r_i + \frac{L}{X_{i+1} - X_i} \Lambda_1^i \partial_x r_i = F_i \\ &\partial_t s_i + \frac{L}{X_{i+1} - X_i} \Lambda_2^i \partial_x s_i = G_i \end{aligned} \qquad \forall x \in (0,L), i \in \mathbb{Z}, \tag{36}$$

with $\Lambda_k^i = \lambda_k(R^i, S^i) - (\dot{X}_i + \frac{x}{L}(\dot{X}_{i+1} - \dot{X}_i))$. We multiply the first (resp. second) equation of (36) by p_i (resp. q_i), integrate on $(0,\, L) \times \mathbb{R}$, and sum on $i \in \mathbb{Z}$:

$$\begin{aligned} \int_{\mathbb{R}} \sum_i \int_0^L F_i \, p_i + G_i \, q_i = &- \int_{\mathbb{R}} \sum_i \int_0^L \partial_t \, p_i \, r_i + \partial_t \, q_i \, s_i \\ &- \int_{\mathbb{R}} \sum_i \int_0^L \partial_x \big(\Lambda_1^i \, p_i\big) r_i + \partial_x \big(\Lambda_2^i \, q_i\big) s_i \\ &+ \int_{\mathbb{R}} \sum_i {}^t \left(p_i^{\pm}, q_i^{\pm}\right) A_i \left(r_i^{\pm}, s_i^{\pm}\right), \end{aligned} \tag{37}$$

with

$$\begin{aligned} A_i = \operatorname{diag}\Bigg(&- \frac{L}{X_{i+1} - X_i} \left(\lambda_1 \left(R_i^+, S_i^+\right) - \dot{X}_i\right), \frac{L}{X_i - X_{i-1}} \left(\lambda_1(R_i^-, S_i^-) - \dot{X}_i\right), \\ &- \frac{L}{X_{i+1} - X_i} \left(\lambda_2 \left(R_i^+, S_i^+\right) - \dot{X}_i\right), \frac{L}{X_i - X_{i-1}} \left(\lambda_2 \left(R_i^-, S_i^-\right) - \dot{X}_i\right) \Bigg). \end{aligned}$$

It is a straightforward computation to prove that $A_i = A + \mathcal{O}(\eta)$, where η is given by

$$\eta = \max_{i \in \mathbb{Z}} \left(\left| \dot{X}_i - x \right|_\infty, |X_{i+1} - X_i - L|_\infty, |(R - R_i, S - S_i)|_\infty \right).$$

We consider the boundary terms in (37): recall that, under the assumption of Proposition 2, the linearized Rankine–Hugoniot conditions can be written in the form

$$\begin{pmatrix} \dot{\varepsilon}_i \\ 0 \end{pmatrix} = \underline{B}_i \left(r_i^{\pm}, s_i^{\pm}\right) + \begin{pmatrix} a_{1,i} \\ a_{2,i} \end{pmatrix}.$$

We can prove easily that $\underline{B}_i = \underline{B} + \mathcal{O}(\eta)$. Following the computation of the dual problem in the previous section, we decompose $\underline{B}_i$ in the form $\underline{B}_i = (A_{1,i}\ A_{2,i}) = \binom{B_{1,i}}{B_{2,i}}$, with $A_{k,i} \in M_2(\mathbb{R})$ and ${}^t B_{k,i} \in \mathbb{R}^4$. It is a straightforward computation to prove that, for η sufficiently small,

$$\det(A_{1,i}) = \det(A_1) + \mathcal{O}(\eta) \neq 0.$$

Thus, $\mathrm{Ker}\,\underline{B}_i$ is $2D$ and possesses a basis of vectors: $\langle {}^t B_{1,i}^{\perp}, {}^t B_{2,i}^{\perp} \rangle$. We can apply Lemma 9.4, p. 255 in [1]: there exists $N_{1,i} \in M_{2,4}(\mathbb{R})$ so that $\mathbb{R}^4 = \mathrm{Ker}\underline{B}_i \oplus \mathrm{Ker}N_{1,i}$ and there exist $C_i\,, N_{2,i} \in M_{2,4}(\mathbb{R})$ so that $\mathbb{R}^4 = \mathrm{Ker}C_i \oplus \mathrm{Ker}N_{2,i}$ and $A_i = {}^t N_{2,i}\,\underline{B}_i + {}^t C_i\,N_{1,i}$. At this stage, the formulation of the adjoint problem is straightforward, and one finds

$$\begin{aligned} &-\partial_t p_i - \frac{L}{X_{i+1} - X_i}\partial_x \left(\Lambda_i^1\, p_i\right) = 0, \\ &-\partial_t q_i - \frac{L}{X_{i+1} - X_i}\partial_x \left(\Lambda_i^2\, q_i\right) = 0 \end{aligned} \qquad \forall (x,i) \in (0,\, L) \times \mathbb{Z},$$

with the boundary conditions

$$\partial_t \left(N_{2,i}\left(p_i^{\pm}, q_i^{\pm}\right)_1\right) = 0 \quad C_i\left(p_i^{\pm}, q_i^{\pm}\right) = 0 \quad \forall i \in \mathbb{Z}.$$

Next we consider the linear problem

$$\begin{aligned} &-\partial_t p_i - \frac{L}{X_{i+1} - X_i}\partial_x (\Lambda_i^1\, p_i) = F_i^1, \\ &-\partial_t q_i - \frac{L}{X_{i+1} - X_i}\partial_x (\Lambda_i^2\, q_i) = F_i^2 \end{aligned} \qquad \forall (x,i) \in (0,\, L) \times \mathbb{Z}, \tag{38}$$

with the boundary conditions

$$\partial_t \left(N_{2,i}(p_i^{\pm}, q_i^{\pm})_1\right) = a_{1,i} \quad C_i(p_i^{\pm}, q_i^{\pm}) = a_{2,i} \quad \forall i \in \mathbb{Z}. \tag{39}$$

Following the method of proof of the energy estimates for the adjoint problem associated to the linearization of shallow water equations around roll-waves, one can prove the following result.

PROPOSITION 3. *Under the hypothesis $0 < F < F_c$, there exists $\eta > 0$ so that for all $m > 0$, there exists a constant C and γ_0 depending on m and for any Lipschitz continuous and bounded function $(R_i, S_i, X_i)_{i\in\mathbb{Z}}$ satisfying*

$$\begin{aligned} &\max_{i\in\mathbb{Z}} \left(\left\| \dot{X}_i - c \right\|_{\infty} + \|X_{i+1} - X_i - L\|_{\infty} + \|R_i - R, S_i - S\|_{\infty} \right) \leq \eta, \\ &\max_{i\in\mathbb{Z}} \left(|\partial_x (R_i, S_i)|_{\infty} + \left| \dot{X}_i \right|_{\infty} \right) \leq m, \end{aligned}$$

and for all $\gamma \geq \gamma_0$, $(F^1, F^2) \in \mathcal{D}(\mathbb{R}/\{iL\} \times \mathbb{R})$, $(a_1, a_2) \in l^2(\mathbb{Z}, \mathcal{D}(\mathbb{R}))$, then a solution $(p_i, q_i)_{i\in\mathbb{Z}}$ of (38), (39) satisfies

$$\begin{aligned} &\gamma \|e^{\gamma t}(p,q)\|^2_{L^2(\mathbb{R}/\{iL\}\times\mathbb{R})} + \|e^{-\gamma t}(p_i^{\pm}, q_i^{\pm})\|^2_{l^2(\mathbb{Z}, L^2(\mathbb{R}))} \\ &\quad \leq C \left(\frac{1}{\gamma} \left\| e^{\gamma t} \left(F^1, F^2\right) \right\|^2_{L^2(\mathbb{R}/\{iL\}\times\mathbb{R})} + \|e^{\gamma t}(a_1, a_2)\|_{l^2(\mathbb{Z}, L^2(\mathbb{R}))} \right). \end{aligned}$$

As a conclusion, we have obtained energy estimates for the linearized problem around an approximate solution, we have formulated an adjoint problem, and we computed estimates on that problem. This is the first step towards the well posedness of the linearized equations.

3.4. Well posedness of the linear differential boundary value problem. In what follows, we prove the well posedness of the linear boundary value problem without any initial condition: The method of proof is based on a weak formulation of the linearized equations that define an adjoint problem. Using the Riesz representation theorem, we prove the existence of a weak solution that is proved to enjoy more regularity using a mollifying operator in the "transverse" t-direction. At this step, there is a difference with the shock case. In that latter case, the convection matrix in front of the x-derivatives is nonsingular, and we easily get estimates on those derivatives. In the case of roll-waves, the matrix that is in front of the x-derivatives is *singular* in the neighborhood of the sonic point. As a consequence, we also need a regularization step in the interior equations in the neighborhood of the sonic point. In what follows, the presentation of the well posedness results for a linearized problem follows the presentation made in [1] for the persistence of shocks: in the proofs of those results, we shall emphasize the difference between the shock case and the roll-wave case.

In order to simplify the notations, we introduce $\tilde{\Lambda}_i^k = \frac{L}{X_{i+1}-X_i}\Lambda_i^k$ and denote $\Omega = \mathbb{R} \setminus \{iL,\, i \in \mathbb{Z}\} \times \mathbb{R}$. We shall also note $L^2_\gamma(\Omega)$ the Hilbert space of functions f so that $e^{-\gamma t} f \in L^2(\Omega)$. We first prove the following result (see Theorem 12.4, p. 360 in [1] for the shock case).

PROPOSITION 4. *There exists $\eta > 0$ and $\gamma_0 = \gamma_0(m)$ such that if*

$$\max_{i\in\mathbb{Z}} \left(\left\|\dot{X}_i - c\right\|_\infty, \|X_{i+1} - X_i - L\|_\infty, \left\|R_i - \overline{R}\right\|_\infty, \left\|S_i - \overline{S}\right\|_\infty \right) \leq \eta,$$
$$\max_{i\in\mathbb{Z}} \left(\left\|\dot{X}_{i+1} - \dot{X}_i\right\|_\infty, \|R_i\|_{W^{1,\infty}}, \|S_i\|_{W^{1,\infty}} \right) \leq m,$$

then for all $\gamma \geq \gamma_0$, $f \in L^2_\gamma(\Omega)^2$, $g \in l^2(\mathbb{Z}, L^2_\gamma(\mathbb{R}))^2$, there is one and only one $((r,s),\varepsilon) \in L^2_\gamma(\Omega)^2 \times l^2(\mathbb{Z}, H^{\frac{1}{2}}_\gamma(\mathbb{R}))$ such that

$$\mathcal{L}(r,s) = \begin{cases} \partial_t r_i + \widetilde{\Lambda}_i^1 \partial_x r_i = f_i^1, \\ \partial_t s_i + \widetilde{\Lambda}_i^2 \partial_x s_i = f_i^2 \end{cases} \qquad \forall\, i \in \mathbb{Z}, (x,t) \in]0, L[\times\mathbb{R}$$

and satisfies the boundary conditions

$$\begin{pmatrix} \dot{\varepsilon}_i \\ 0 \end{pmatrix} = \underline{B}_i \left(r_i^\pm, s_i^\pm \right) + \begin{pmatrix} g_i^1 \\ g_i^2 \end{pmatrix} \ \forall\, i \in \mathbb{Z}, t \in \mathbb{R}.$$

Furthermore, $(r_i^\pm, s_i^\pm)_{i\in\mathbb{Z}} \in l^2(\mathbb{Z}, L^2_\gamma(\mathbb{R})^4)$ and $\varepsilon \in l^2(\mathbb{Z}, H^1_\gamma(\mathbb{R}))$, and we have the estimate

$$\gamma \|(r,s)\|^2_{L^2_\gamma(\Omega)^2} + \left\| \left(r^\pm, s^\pm\right) \right\|^2_{l^2(\mathbb{Z}, L^2_\gamma(\mathbb{R})^4)} + \|\varepsilon\|^2_{l^2(\mathbb{Z}, H^1_\gamma(\mathbb{R}))}$$
$$\leq C \left(\frac{1}{\gamma} \|f\|^2_{L^2_\gamma(\Omega)} + \|g\|^2_{l^2(\mathbb{Z}, L^2_\gamma(\mathbb{R}))} \right).$$

Proof. Let us first prove the existence of a weak solution with a duality argument. With the notations of Proposition 3, denote $\mathcal{E}$ the space of functions $(p,q) \in \mathcal{D}(\Omega)^2$ so that

$$\partial_t N^t_{2,i}(p_i^\pm, q_i^\pm)_1 - \gamma\, N^t_{2,i}(p_i^\pm, q_i^\pm)_1 = 0, \quad C_i(p_i^\pm, q_i^\pm) = 0.$$

We define the adjoint operator $\mathcal{L}_\gamma^*$ of $\mathcal{L}_\gamma = \mathcal{L} + \gamma\, Id$ as

$$\mathcal{L}_\gamma^*(p,q) = \begin{cases} -\partial_t\, p_i - \partial_x \left(\widetilde{\Lambda}_i^1\, p_i\right) + \gamma\, p_i, \\ -\partial_t\, q_i - \partial_x \left(\widetilde{\Lambda}_i^2\, q_i\right) + \gamma\, q_i. \end{cases}$$

Let $(f,g) \in L^2(\Omega)^2 \times l^2(\mathbb{Z}, L^2(\mathbb{R}))$ and define a bounded linear form l on $\mathcal{L}_\gamma^*\mathcal{E}$ as

$$l\Big(\mathcal{L}_\gamma^*(p,q)\Big) = \sum_{i\in\mathbb{Z}} \int_{\mathbb{R}} \int_0^L p_i\, f_i^1 + q_i\, f_i^2\, dx + \left(N_{2,i}(p_i^\pm, q_i^\pm)\right) \begin{pmatrix} g_i^1 \\ g_i^2 \end{pmatrix} dt.$$

We deduce from Proposition 3 on the adjoint problem that $\forall (p,q) \in \mathcal{E}$,

$$\begin{aligned} \left| l\left(\mathcal{L}_\gamma^*(p,q)\right)\right| &\le C(\|f\|, \|g\|) \left(\|(p,q)\|_{L^2(\Omega)} + \|(p^\pm, q^\pm)\|_{l^2(\mathbb{Z}, L^2(\mathbb{R}))^4}\right) \\ &\le C\left(\frac{1}{\gamma}\|f\| + \frac{1}{\sqrt{\gamma}}\|g\|\right) \|\mathcal{L}_\gamma^*(p,q)\|_{L^2(\Omega)}. \end{aligned}$$

Therefore, by the Hahn–Banach theorem, the linear form l extends to a continuous form on $L^2(\Omega)^2$ and using the Riesz representation theorem, there exists $(r,s) \in L^2(\Omega)^2$ so that

$$l\left(\mathcal{L}_\gamma^*(p,q)\right) = \sum_{i\in\mathbb{Z}} \int_{\mathbb{R}} \int_0^L (r_i, s_i)^t\, \mathcal{L}_\gamma^*(p_i, q_i) dx dt \quad \forall (p,q) \in \mathcal{E}.$$

Then, by the definition of l, we find that

$$\sum_{i\in\mathbb{Z}} \int_{\mathbb{R}} \int_0^L (r_i, s_i)^t\, \mathcal{L}_\gamma^*(p_i, q_i) - \left(f_i^1, f_i^2\right)^t (p_i, q_i) dx dt = 0 \quad \forall (p,q) \in \mathcal{D}(\Omega)^2,$$

and $\mathcal{L}_\gamma(r,s) = (f^1, f^2)$ in the sense of distribution. For all $(p,q) \in \mathcal{E}$, one can prove that

$$\begin{aligned} \sum_{i\in\mathbb{Z}} \int_{\mathbb{R}} \int_0^L (r_i, s_i)^t . \mathcal{L}_\gamma^*(p_i, q_i) - \mathcal{L}_\gamma(r_i, s_i)^t . \begin{pmatrix} p_i \\ q_i \end{pmatrix} dx\, dt & \\ = \sum_{i\in\mathbb{Z}} \int_{\mathbb{R}} N_{2,i}(p_i^\pm, q_i^\pm)^t . \begin{pmatrix} g_i^1 \\ g_i^2 \end{pmatrix} dt & \\ = \sum_{i\in\mathbb{Z}} \int_{\mathbb{R}} N_{2,i}(p_i^\pm, q_i^\pm)^t . \underline{B}_i \begin{pmatrix} r_i^\pm \\ s_i^\pm \end{pmatrix} dt. & \end{aligned}$$

As a consequence, we find that

$$\sum_{i\in\mathbb{Z}} \int_{\mathbb{R}} N_{2,i}(p_i^\pm, q_i^\pm)^t \left(\underline{B}_i \left(r_i^\pm, s_i^\pm\right) - \begin{pmatrix} g_i^1 \\ g_i^2 \end{pmatrix}\right) dt = 0 \quad \forall (p,q) \in \mathcal{E}. \tag{40}$$

By density, this property holds true for all $(p,q) \in H^1(\Omega)$ such that

$$C_i^t(p_i^\pm, q_i^\pm) = 0, \quad \partial_t\, N_{2,i}(p_i^\pm, q_i^\pm)_1 - \gamma\, N_{2,i}(p_i^\pm, q_i^\pm)_1 = 0.$$

Let $(\theta^1,\theta^2)\in l^2(\mathbb{Z},H^{\frac12}(\mathbb{R})^2)$ and $(p_i^\pm,q_i^\pm)_{i\in\mathbb{Z}}\in l^2(\mathbb{Z},H^{\frac12}(\mathbb{R})^2)$ so that

$$N_{2,i}^t(p_i^\pm,q_i^\pm)=\begin{pmatrix}\theta_i^1\\ \theta_i^2\end{pmatrix},\quad C_i^t(p_i^\pm,q_i^\pm)=\begin{pmatrix}0\\0\end{pmatrix}\quad\forall i\in\mathbb{Z},t\in\mathbb{R}.$$

The sequence $(p_i^\pm,q_i^\pm)_{i\in\mathbb{Z}}$ exists, is unique, and lies in $l^2(\mathbb{Z},H^{\frac12}(\mathbb{R})^2)$, since the matrix $(N_{2,i},C_i)$ is invertible under the assumption of Proposition 3. Now with a standard trace-lifting argument, choose $(p,q)\in,H^1(\Omega)$ so that $p(iL)^\pm=p_i^\pm,q(iL)^\pm=q_i^\pm$. Then we deduce from (40) that for all $\theta\in l^2(\mathbb{Z},H^{\frac12}(\mathbb{R})^2)$ such that $\frac{d\theta_i^1}{dt}-\gamma\theta_i^1=0$,

$$\sum_{i\in\mathbb{Z}}\left\langle\begin{pmatrix}\theta_i^1\\ \theta_i^2\end{pmatrix},\underline{B}_i\left(r_i^\pm,s_i^\pm\right)-\begin{pmatrix}g_i^1\\ g_i^2\end{pmatrix}\right\rangle_{\left(H^{\frac12}(\mathbb{R}),H^{-\frac12}(\mathbb{R})\right)}=0.$$

Thus, there exists $\varepsilon\in l^2(\mathbb{Z},H^{\frac12}(\mathbb{R}))$ so that

$$\begin{pmatrix}\dot\varepsilon_i+\gamma\varepsilon_i\\0\end{pmatrix}=\underline{B}_i\left(r_i^\pm,s_i^\pm\right)+\begin{pmatrix}g_i^1\\g_i^2\end{pmatrix}\ \forall i\in\mathbb{Z}.$$

Let us now prove that $(r,s),\varepsilon$ is a strong solution. This is just a matter of smoothing the solution and using the estimates of the first part. We consider a mollifying operator R_δ^t in the t-direction, and we define a regularization (r^δ,s^δ), ε^δ of (r,s,ε). Let us first deal with the equation on s. Denote $s_i^\delta=R_\delta^t\,s_i$, we easily obtain

$$\partial_t\,s_i^\delta+\widetilde{\Lambda}_i^2\partial_x\,s_i^\delta=\widetilde{\Lambda}_i^2\left(R_\delta^t\left(\frac{f_i^2}{\widetilde{\Lambda}_i^2}\right)+\left[\frac{1}{\widetilde{\Lambda}_i^2}\partial_t,R_\delta^t\right]s_i\right).$$

Due to the presence of a *sonic point* $x_i(t)$ so that $\widetilde{\Lambda}_1^i(x_i(t),t)=0$, we cannot directly do the same regularization on r_i. In that case, we do not obtain any information on the derivatives of r_i in the x-direction. Nevertheless, under the assumptions of Proposition 3, there exists $L_1>0$ and a constant $C(m)$ so that for all $i\in\mathbb{Z}$, $iL+2L_1\leq x_i(t)\leq(i+1)L-2L_1$ and $|\widetilde{\Lambda}_1^i(x,t)|^{-1}\leq C(m)\ \forall\ x\in[0,L_1]\bigcup[L-L_1,L]$. Let $\overline{\phi}\in,C_c^\infty(0,L)$ so that $\overline{\phi}=1$ on $[2L_1,\,L-2L_1]$ and $\overline{\phi}=0$ on $[0,L_1]\bigcup[L-L_1,L]$ and define $\phi=1-\overline{\phi}$. We multiply the equation on r_i by ϕ. We find

$$\partial_t(\phi\,r_i)+\widetilde{\Lambda}_i^1\partial_x(\phi\,r_i)=\phi f_i^1+\widetilde{\Lambda}_i^1\partial_x\phi\,r_i.$$

Then we regularize that equation the same way we did with the equation on s_i:

$$\partial_t\left(\phi\,r_i\right)^\delta+\widetilde{\Lambda}_i^1\partial_x\left(\phi\,r_i\right)^\delta=\widetilde{\Lambda}_i^1\left(R_\delta^t\left(\frac{\phi\,f_i^1}{\widetilde{\Lambda}_i^1}+\partial_x\phi\,r_i\right)+\left[\frac{1}{\widetilde{\Lambda}_i^1}\partial_t,R_\delta^t\right](\phi\,r_i)\right).$$

We multiply the equation on r_i by $(1-\phi)$ and choose a mollifying operator R_δ^x in the x direction with $\delta\leq L_1$:

$$\begin{aligned}\partial_t\,R_\delta^x((1-\phi)r_i)+\widetilde{\Lambda}_i^1\partial_x\,R_\delta^x((1-\phi)r_i)&=R_\delta^x\Big((1-\phi)f_1^i-\widetilde{\Lambda}_i^1\partial_x\phi\,r_1^i\Big)\\&\quad+\left[\widetilde{\Lambda}_i^1\partial_x,R_\delta^x\right]((1-\phi)r_i).\end{aligned}$$

We define r^δ so that $r^\delta_{|[iL,(i+1)L]}=R_\delta^t(\phi\,r_i)+R_\delta^x((1-\phi)r_i)$. By construction, both r^δ and s^δ lie in $H^1(\Omega)$. On the other hand, we find that r^δ,s^δ, and ε^δ satisfy the boundary conditions

$$\begin{pmatrix}\dot\varepsilon_i^\delta\\0\end{pmatrix}=\underline{B}_i\left(r_i^{\delta,\pm},s_i^{\delta,\pm}\right)+\begin{pmatrix}R_\delta^t\,g_i^1\\R_\delta^t\,g_i^2\end{pmatrix}+\left[\underline{B}_i,R_\delta^t\right]\left(r_i^\pm,s_i^\pm\right).$$

We can apply Proposition 2 as follows:

$$\begin{aligned}\gamma\left\| \left(r^\delta, s^\delta\right)\right\|^2_{L^2_\gamma(\Omega)^2} + \left\| \left(r^{\delta,\pm}, s^{\delta,\pm}\right)\right\|^2_{l^2(\mathbb{Z},L^2_\gamma(\mathbb{R})^4)} + \left\|\varepsilon^\delta\right\|^2_{l^2(\mathbb{Z},H^1_\gamma(\mathbb{R}))}\\ \leq C\left(\frac{1}{\gamma}\left\|f^\delta\right\|^2_{L^2_\gamma(\Omega)} + \left\|g^\delta\right\|^2_{l^2(\mathbb{Z},L^2_\gamma(\mathbb{R}))}\right),\end{aligned} \tag{41}$$

with

$$\begin{aligned}f^\delta_{i,1} &= R^x_\delta\left((1-\phi)f^1_i - \widetilde{\Lambda}^1_i\partial_x\phi\, r_i\right) + \left[\widetilde{\Lambda}^1_i\partial_x, R^x_\delta\right]((1-\phi)r_i)\\ &\quad + \widetilde{\Lambda}^1_i\left(R^t_\delta\left(\frac{\phi\, f^1_i}{\widetilde{\Lambda}^1_i} + \partial_x\phi\, r_i\right) + \left[\frac{1}{\widetilde{\Lambda}^1_i}\partial_t, R^t_\delta\right](\phi\, r_i)\right),\\ f^\delta_{i,2} &= \widetilde{\Lambda}^2_i\left(R^t_\delta\left(\frac{f^2_i}{\widetilde{\Lambda}^2_i}\right) + \left[\frac{1}{\widetilde{\Lambda}^2_i}\partial_t, R^t_\delta\right](s)\right)\\ g^\delta_i &= \begin{pmatrix} R^t_\delta\, g^1_i\\ R^t_\delta\, g^2_i\end{pmatrix} + \left[\underline{B}_i, R^t_\delta\right]\left(r^\pm_i, s^\pm_i\right).\end{aligned}$$

One can prove the following convergence properties (see [1] for more details):

$$\lim_{\delta\to 0}\left\|f^\delta - f\right\|_{L^2_\gamma(\Omega)} + \left\|g^\delta - g\right\|_{l^2(\mathbb{Z},L^2_\gamma(\mathbb{R}))} = 0.$$

By linearity of the equations, these estimates also apply to

$$r^\delta - r^{\delta'}, \quad s^\delta - s^{\delta'}, \quad \varepsilon^\delta - \varepsilon^{\delta'}.$$

Together with the convergence properties, this shows that $r^{\delta,\pm}, s^{\delta,\pm}$, and ε^δ are, respectively, Cauchy sequences in $l^2(\mathbb{Z}, L^2_\gamma(\mathbb{R})^4)$ and $l^2(\mathbb{Z}, H^1_\gamma(\mathbb{R}))$. By uniqueness of the limit in the sense of distribution, the sequences $(r^{\delta,\pm}, s^{\delta,\pm})$ and ε^δ converge to $r^\pm, s^\pm$, and ε in these norms. Then passing to the limit $\delta \to 0$ in (41), one finds

$$\begin{aligned}\gamma\|(r,s)\|^2_{L^2_\gamma(\Omega)^2} + \left\| \left(r^\pm, s^\pm\right)\right\|^2_{l^2(\mathbb{Z},L^2_\gamma(\mathbb{R})^4)} + \|\varepsilon\|^2_{l^2(\mathbb{Z},H^1_\gamma(\mathbb{R}))}\\ \leq C\left(\frac{1}{\gamma}\|f\|^2_{L^2_\gamma(\Omega)} + \|g\|^2_{l^2(\mathbb{Z},L^2_\gamma(\mathbb{R}))}\right).\end{aligned}$$

This completes the proof of the proposition. ∎

We can prove more regularity on the solution (r, s, ε) under the condition that f, g, and the coefficients R_i, S_i, X_i enjoy more regularity. Similarly to the L^2 estimates, we introduce weighted Sobolev norms:

$$\|u\|_{\mathcal{H}^k_\gamma} = \sum_{|\alpha|\leq k}\gamma^{2(k-|\alpha|)}\|e^{-\gamma t}u\|_{L^2}.$$

The regularity result on (r, s, ε) is formulated as follows (see Theorem 12.5, p. 364 in [1] in the shock case).

PROPOSITION 5. *Under the assumptions of Proposition* 4 *and that* R_i, S_i, X_i *enjoy more regularity,*

$$\begin{aligned}\|R - R_i, S - S_i\|_{l^2(\mathbb{Z},H^k((0,L)\times\mathbb{R}))} &\leq \mu,\\ \|R^\pm_i - R^\pm, S^\pm_i - S^\pm\|_{l^2(\mathbb{Z},H^k(\mathbb{R}))} &\leq \mu,\\ \|\dot{X}_i - c, X_{i+1} - X_i - L\|_{l^2(\mathbb{Z},H^k(\mathbb{R}))} &\leq \mu,\end{aligned}$$

with $k > 2$, the solution (r, s, ε) found in Proposition 4 is such that $(r, s) \in H^k(\Omega)$, $(r^\pm, s^\pm) \in l^2(\mathbb{Z}, H^k(\mathbb{R}))$, and $\varepsilon \in l^2(\mathbb{Z}, H^{k+1}(\mathbb{R}))$ and, for any $\gamma \geq \gamma_k(\mu) \geq 1$, satisfy the estimate

$$\begin{aligned} \gamma\|(r,s)\|^2_{\mathcal{H}^k_\gamma(\Omega)} + \left\|\left(r^\pm, s^\pm\right)\right\|^2_{l^2(\mathbb{Z},\mathcal{H}^k_\gamma(\mathbb{R}))} + \|\varepsilon\|^2_{l^2(\mathbb{Z},\mathcal{H}^{k+1}_\gamma(\Omega))} \\ \leq C(k,\mu)\left(\frac{1}{\gamma}\|f\|^2_{\mathcal{H}^k_\gamma(\Omega)} + \|g\|^2_{l^2(\mathbb{Z},\mathcal{H}^k_\gamma(\mathbb{R}))}\right). \end{aligned} \tag{42}$$

Proof. We prove that proposition in two steps. The first step is to extend the a priori L^2 estimates obtained in Proposition 2. For all (r, s) and ε compactly supported and smooth functions, the following estimate holds true:

$$\begin{aligned} \gamma\|(r,s)\|^2_{\mathcal{H}^k_\gamma(\Omega)} + \left\|\left(r^\pm, s^\pm\right)\right\|^2_{l^2(\mathbb{Z},\mathcal{H}^k_\gamma(\mathbb{R}))} + \|\varepsilon\|^2_{l^2(\mathbb{Z},\mathcal{H}^{k+1}_\gamma(\Omega))} \\ \leq C(k,\mu)\left(\frac{1}{\gamma}\|f\|^2_{\mathcal{H}^k_\gamma(\Omega)} + \|g\|^2_{l^2(\mathbb{Z},\mathcal{H}^k_\gamma(\mathbb{R}))}\right), \end{aligned} \tag{43}$$

where $f = \mathcal{L}(r, s)$ and g is defined by

$$g_i = \begin{pmatrix} \dot{\varepsilon}_i \\ 0 \end{pmatrix} - \underline{B}_i\left(r_i^\pm, s_i^\pm\right).$$

In order to prove that estimate, we decompose in the form $r_i = \phi\, r_i + (1-\phi) r_i$, with ϕ defined in Proposition 4. Deriving the equation satisfied by $\phi r_i, s_i$ in the t-direction and applying Proposition 2, we get estimates for derivatives in the t-direction. We recover the derivatives in the x-direction with

$$\partial_x(\phi r_i) = \frac{1}{\widetilde{\lambda}_i^1}\left(f_i^1 + \partial_x\phi r_i - \partial_t(\phi r_i)\right), \quad \partial_x s_i = \frac{1}{\widetilde{\Lambda}_i^2}\left(f_i^2 - \partial_t s_i\right).$$

The obtention of estimates for $(1-\phi)r_i$ is straightforward, since it is trace-free on the discontinuity points iL, $i \in \mathbb{Z}$.

Now we come back to the solution obtained in Proposition 4. The next step is to prove enough regularity on (r, s, ε) in order to apply the a priori estimate (43). We first consider that the coefficients $R_i - R, S_i - S, X_i - (ct + iL)$ are smooth and compactly supported: the regularity of (r, s, ε) is then obtained by induction (see [1, p. 366] for the details of the proof). We then construct a family $(r^\delta, s^\delta, \varepsilon^\delta)$ of compactly supported functions that converges to (r, s, ε) in Sobolev H^k_γ norms. The regularized functions $(r^\delta, s^\delta, \varepsilon^\delta)$ satisfy the a priori estimate (43) and passing to the limit $\delta \to 0$ as in Proposition 4, we prove that (r, s, ε) satisfies the energy estimates (42). For the more general case, $R_i - R, S_i - S, X_i - (ct + iL)$ lying in Sobolev spaces, it is just a matter of smoothing the coefficients and passing to the limit. This completes the proof of that proposition. ∎

Next, we consider the well posedness of the linearized equation with zero initial data. Let $T \in \mathbb{R}$, I_T the interval $I_T =]-\infty, T]$, and $\Omega_T = \mathbb{R} \setminus \{iL,\, i \in \mathbb{Z}\} \times I_T$. One can prove that, under the assumptions of Proposition 4 and for all $f \in L^2(\mathbb{R} \setminus \{iL, i \in \mathbb{Z}\} \times I_T, \mathbb{R}^2)$ and $g \in l^2(\mathbb{Z}, L^2(I_T)^2)$ such that $f_{|t<0} = 0, \quad g_{|t<0} = 0$, there exists a unique function $(r, s) \in L^2(\Omega_T)$ and $\varepsilon \in l^2(\mathbb{Z}, H^1(I_T))$ so that

$$\begin{aligned} &\partial_t\, r_i + \widetilde{\Lambda}_i^1 \partial_x\, r_i = f_i^1, \\ &\partial_t\, s_i + \widetilde{\Lambda}_i^2 \partial_x\, s_i = f_i^2 \end{aligned} \quad \forall\, i \in \mathbb{Z}, (x,t) \in]0, L[\times I_T,$$

and

$$\begin{pmatrix} \dot{\varepsilon}_i \\ 0 \end{pmatrix} = \underline{B}_i \left(r_i^{\pm}, s_i^{\pm}\right) + \begin{pmatrix} g_i^1 \\ g_i^2 \end{pmatrix} \quad \forall\, i \in \mathbb{Z}, t \in I_T.$$

Furthermore, we have $r_{|t<0} = s_{|t<0} = 0, \quad \varepsilon_{|t<0} = 0$, $(r_i^{\pm}, s_i^{\pm})_{i\in\mathbb{Z}}$ belongs $l^2(\mathbb{Z}, L^2_\gamma(I_T)^4)$, and the solution (r, s, ε) satisfies the following estimate,

$$\begin{aligned}\gamma\|(r,s)\|^2_{L^2_\gamma(\Omega_T)^2} + \left\|\left(r^{\pm}, s^{\pm}\right)\right\|^2_{l^2(\mathbb{Z},L^2_\gamma(I_T)^4)} + \|\varepsilon\|^2_{l^2(\mathbb{Z},H^1_\gamma(I_T))} \\ \leq C\left(\frac{1}{\gamma}\|f\|^2_{L^2_\gamma(\Omega_T)} + \|g\|^2_{l^2(\mathbb{Z},L^2_\gamma(I_T))}\right).\end{aligned}$$

In the case of smoother coefficients, the solution (r, s, ε) of the linearized problem with zero initial data enjoys more regularity. One can prove the following result that shall be useful in the proof of the well posedness of the Cauchy problem for the full nonlinear problem.

PROPOSITION 6. *Assume that the hypotheses of Proposition* 4 *are satisfied, and the coefficients enjoy the following regularity properties:*

$$\begin{aligned}&\|(R_i - R, S_i - S)\|_{l^2(\mathbb{Z},H^k((0,L)\times I_T))} \leq \mu,\\ &\left\|\left(R_i^{\pm} - R^{\pm}, S_i^{\pm} - S^{\pm}\right)\right\|_{l^2(\mathbb{Z},H^k(I_T))} \leq \mu,\\ &\left\|\dot{X}_i - c, X_{i+1} - X_i - L\right\|_{l^2(\mathbb{Z},H^k(I_T))} \leq \mu.\end{aligned}$$

Furthermore, suppose that, for some $\tau < T$,

$$R_i - R_{|t<\tau} = S_i - S_{|t<\tau} = 0, \quad \left(\dot{X}_i - c, X_{i+1} - X_i - L\right)_{|t<\tau} = 0.$$

Then, for any $f \in H^k(\Omega_T)$ *and* $g \in l^2(\mathbb{Z}, H^k(I_T))$ *such that* $f_{|t<0} = 0, \quad g_{|t<0} = 0$, *the solution* (r, s) *belongs to* $H^k(\Omega_T)$, $(r^{\pm}, s^{\pm})$ *belongs to* $l^2(\mathbb{Z}, H^k(I_T))$ *and* ε *to* $l^2(\mathbb{Z}, H^{k+1}(I_T))$ *with the estimate*

$$\begin{aligned}\frac{1}{T}\|(r,s)\|^2_{H^k(\Omega_T)} + \left\|r^{\pm}, s^{\pm}\right\|_{l^2(\mathbb{Z},H^k(I_T))} + \|\varepsilon\|^2_{l^2(\mathbb{Z},H^{k+1}(I_T))} \\ \leq C(k,\mu)\left(T\,\|f\|^2_{H^k(\Omega_T)} + \|g\|^2_{l^2(\mathbb{Z},H^k(I_T))}\right).\end{aligned}$$

4. The nonlinear problem. In this section, we solve the full nonlinear Cauchy problem with prescribed initial data (r_0, s_0, X_0). To actually solve that problem, we need compatibility conditions on (r_0, s_0, X_0). Under suitable compatibility conditions, we shall prove the existence of an approximate solution $(r^{(a)}, s^{(a)}, X^{(a)})$ on a time interval $(0, T^0)$ for a sufficiently small interval. We can prove the well posedness of the full Cauchy problem through an iterative scheme based on the approximate linear problem introduced in the previous section. That scheme is proved to converge to a solution of the Cauchy problem with the energy estimates obtained previously.

4.1. Construction of an approximate solution. In what follows, we shall construct an approximate solution of the shallow water equations coupled with the Rankine–Hugoniot jump condition for an initial data (r_0, s_0, X_0) that satisfies some compatibility conditions. In what follows, we write compatibility conditions for the shallow water equations.

4.1.1. Compatibility conditions. After the change of variable introduced in section 2, the shallow water system is written as

$$\begin{aligned} &\partial_t r_i + \Lambda_i^1 \, \partial_x r_i = Q(r_i, s_i), \\ &\partial_t s_i + \Lambda_i^2 \, \partial_x s^i = Q(r_i, s_i) \end{aligned} \qquad \forall (x,i) \in (0,L) \times \mathbb{Z}, \tag{44}$$

where the Λ_i^k are defined by

$$\Lambda_i^k = \frac{L}{X_{i+1} - X_i} \left(\lambda_k(r_i, s_i) - \left(\dot{X}_i + \frac{x}{L} \left(\dot{X}_{i+1} - \dot{X}_i \right) \right) \right),$$

whereas the Rankine–Hugoniot jump conditions are given by

$$\dot{X}_i = F\left(r_i^+, r_i^-, s_i^+, s_i^-\right), \quad G\left(r_i^+, r_i^-, s_i^+, s_i^-\right) = 0 \quad \forall i \in \mathbb{Z}, \tag{45}$$

with

$$\begin{aligned} F\left(r_i^\pm, s_i^\pm\right) &= \left[(r-s)^4 + 8(r-s)^2(r+s)^2\right]_{iL} \left[(r-s)^2\right]_{iL} - 8\left[(r+s)(r-s)^2\right]_{iL}^2, \\ G\left(r_i^\pm, s_i^\pm\right) &= \frac{1}{2}\left[(r+s)(r-s)^2\right]_{iL} \left[(r-s)^2\right]_{iL}^{-1}. \end{aligned}$$

Suppose that both (r,s) and X are smooth enough: applying Faa di Bruno's formula to the jump conditions (45), we obtain

$$\frac{d^{p+1} X_i}{dt^{p+1}} = \sum_{i=1}^{p} \sum_{i_1 + \cdots + i_m = p} c_{i_1 \ldots i_m} d^m F\left(r_i^\pm, s_i^\pm\right) . \left(\frac{d^{i_1}}{dt^{i_1}} \begin{pmatrix} r_i^\pm \\ s_i^\pm \end{pmatrix}, \ldots, \frac{d^{i_m}}{dt^{i_m}} \begin{pmatrix} r_i^\pm \\ s_i^\pm \end{pmatrix} \right). \tag{46}$$

Furthermore, we derive the interior equations (44) with the Faa di Bruno formula:

$$\begin{aligned} \partial_t^{p+1} r_i &= \partial_t^p \, Q(r_i, s_i) - \sum_{l=0}^{p} C_p^l \, \partial_t^l \, \Lambda_i^1 \, \partial_x \partial_t^{p-l} r_i, \\ \partial_t^{p+1} s_i &= \partial_t^p \, Q(r_i, s_i) - \sum_{l=0}^{p} C_p^l \, \partial_t^l \, \Lambda_i^2 \, \partial_x \partial_t^{p-l} s_i. \end{aligned} \tag{47}$$

It is a straightforward computation to prove that

$$\partial_t^p \, Q(r_i, s_i) = \sum_{m=1}^{p} \sum_{i_1 + \cdots i_m = p} c_{i_1 \ldots i_m} d^m Q(r_i, s_i) . \left(\partial_t^{i_1} \begin{pmatrix} r_i \\ s_i \end{pmatrix}, \ldots, \partial_t^{i_m} \begin{pmatrix} r_i \\ s_i \end{pmatrix} \right).$$

Moreover, for $l = 1, \ldots, p-1$, we easily obtain

$$\begin{aligned} \partial_t^l \Lambda_i^k = &\sum_{m=1}^{l} \sum_{i_1 + \cdots + i_m = l} c_{i_1 \ldots i_m} d_{1,4}^m \Lambda_i^k . \left(\partial_t^{i_1} \begin{pmatrix} r_i \\ s_i \\ X_i \\ X_{i+1} \end{pmatrix}, \ldots, \partial_t^{i_m} \begin{pmatrix} r_i \\ s_i \\ X_i \\ X_{i+1} \end{pmatrix} \right) \\ &+ \sum_{m=1}^{l} \sum_{i_1 + \cdots + i_m = l} c_{i_1 \ldots i_m} d_{5,6}^m \Lambda_i^k . \left(\partial_t^{i_1} \begin{pmatrix} \dot{X}_i \\ \dot{X}_{i+1} \end{pmatrix}, \ldots, \partial_t^{i_m} \begin{pmatrix} \dot{X}_i \\ \dot{X}_{i+1} \end{pmatrix} \right), \end{aligned}$$

where $d_{1,4}\Lambda_i^k$ denotes the differential of Λ_i^k with respect to (r, s, X_i, X_{i+1}) and $d_{5,6}\Lambda_i^k$ denotes the differential with respect to $(\dot{X}_i, \dot{X}_{i+1})$. Here, the derivatives in X_i are no

larger than p. For $l = p$, one finds

$$\begin{aligned}\partial_t^p \Lambda_k^i = &\sum_{m=1}^{p} \sum_{i_1+\cdots+i_m=p} c_{i_1\dots i_m} d_{1,4}^m \Lambda_k . \left(\partial_t^{i_1} \begin{pmatrix} r_i \\ s_i \\ X_i \\ X_{i+1} \end{pmatrix}, \dots, \partial_t^{i_m} \begin{pmatrix} r_i \\ s_i \\ X_i \\ X_{i+1} \end{pmatrix} \right) \\ &+ \sum_{m=2}^{p} \sum_{i_1+\cdots+i_m=p} c_{i_1\dots i_m} d_{5,6}^m \Lambda_k . \left(\partial_t^{i_1} \begin{pmatrix} \dot{X}_i \\ \dot{X}_{i+1} \end{pmatrix}, \dots, \partial_t^{i_m} \begin{pmatrix} \dot{X}_i \\ \dot{X}_{i+1} \end{pmatrix} \right) \\ &+ \nabla_{5,6} \Lambda_k . \partial_t^{p+1} \begin{pmatrix} X_i \\ X_{i+1} \end{pmatrix}.\end{aligned}$$

The derivatives of X_i up to order $p+1$ are replaced by the expressions found in (46) involving derivatives of order $j \le p$. Following the definitions of compatibility conditions introduced in [1, p. 370] (see the definition of "compatibility conditions to order s"), we define the compatibility conditions for a pair of initial data (r_0, s_0, X_0).

We fix (r_0, s_0, X_0) an initial data and define the functions (r_p, s_p) and X_p so that

$$\begin{aligned} X_{1,i} &= F\left(r_{0,i}^{\pm}, s_{0,i}^{\pm}\right), \\ r_{1,i} &= Q(r_{0,i}, s_{0,i}) - \Lambda_{0,i}^1 \partial_x \, r_{0,i}, \\ s_{1,i} &= Q(r_{0,i}, s_{0,i}) - \Lambda_{0,i}^2 \partial_x \, s_{0,i}, \end{aligned} \tag{48}$$

and

$$\begin{aligned} X_{p+1,i} = &\sum_{i=1}^{p} \sum_{i_1+\cdots+i_m=p} c_{i_1\dots i_m} d^m \, F\left(r_{0,i}^{\pm}, s_{0,i}^{\pm}\right) . \left(\begin{pmatrix} r_{i_1,i}^{\pm} \\ s_{i_1,i}^{\pm} \end{pmatrix}, \dots, \begin{pmatrix} r_{i_m,i}^{\pm} \\ s_{i_m,i}^{\pm} \end{pmatrix} \right), \\ r_{p+1,i} = &\sum_{m=1}^{p} \sum_{i_1+\cdots i_m=p} c_{i_1\dots i_m} d^m Q(r_{0,i}, s_{0,i}) . \left(\begin{pmatrix} r_{i_1,i} \\ s_{i_1,i} \end{pmatrix}, \dots, \begin{pmatrix} r_{i_m,i} \\ s_{i_m,i} \end{pmatrix} \right) \\ &- \sum_{l=0}^{p} C_p^l \, \Lambda_{l,i}^1 \partial_x \, r_{p-l,i}, \\ s_{p+1,i} = &\sum_{m=1}^{p} \sum_{i_1+\cdots i_m=p} c_{i_1\dots i_m} d^m Q(r_{0,i}, s_{0,i}) . \left(\begin{pmatrix} r_{i_1,i} \\ s_{i_1,i} \end{pmatrix}, \dots, \begin{pmatrix} r_{i_m,i} \\ s_{i_m,i} \end{pmatrix} \right) \\ &- \sum_{l=0}^{p} C_p^l \, \Lambda_{l,i}^2 \partial_x \, s_{p-l,i}, \end{aligned} \tag{49}$$

where $\Lambda_{l,i}^k$ are defined, for any $l = 0, \dots, p-1$, by

$$\begin{aligned} \Lambda_{0,i}^k &= \frac{L}{X_{0,i+1} - X_{0,i}} \left(\lambda_k(r_{0,i}, s_{0,i}) - \left(X_{1,i} + \frac{x}{L}(X_{1,i+1} - X_{1,i}) \right) \right), \\ \Lambda_{l,i}^k &= \sum_{m=1}^{l} \sum_{i_1+\cdots+i_m=l} c_{i_1\dots i_m} d_{1,4}^m \Lambda_i^k . \left(\begin{pmatrix} r_{i_1,i} \\ s_{i_1,i} \\ X_{i_1,i} \\ X_{i_1,i+1} \end{pmatrix}, \dots, \begin{pmatrix} r_{i_m,i} \\ s_{i_m,i} \\ X_{i_m,i} \\ X_{i_m,i+1} \end{pmatrix} \right) \\ &+ \sum_{m=1}^{l} \sum_{i_1+\cdots+i_m=l} c_{i_1\dots i_m} d_{5,6}^m \Lambda_i^k . \left(\begin{pmatrix} X_{i_1+1,i} \\ X_{i_1+1,i+1} \end{pmatrix}, \dots, \begin{pmatrix} X_{i_m+1,i} \\ X_{i_m+1,i+1} \end{pmatrix} \right), \end{aligned}$$

and, for $l = p$,

$$\Lambda^k_{p,i} = \sum_{m=1}^{p} \sum_{i_1+\cdots+i_m=p} c_{i_1\dots i_m} d^m_{1,4}\Lambda^k_i . \left(\begin{pmatrix} r_{i_1,i} \\ s_{i_1,i} \\ X_{i_1,i} \\ X_{i_1,i+1} \end{pmatrix}, \dots, \begin{pmatrix} r_{i_m,i} \\ s_{i_m,i} \\ X_{i_m,i} \\ X_{i_m,i+1} \end{pmatrix} \right)$$
$$+ \sum_{m=2}^{p} \sum_{i_1+\cdots+i_m=p} c_{i_1\dots i_m} d^m_{5,6}\Lambda^k_i . \left(\begin{pmatrix} X_{i_1+1,i} \\ X_{i_1+1,i+1} \end{pmatrix}, \dots, \begin{pmatrix} X_{i_m+1,i} \\ X_{i_m+1,i+1} \end{pmatrix} \right)$$
$$+ \nabla_{5,6}\Lambda^k_i . \begin{pmatrix} X_{p+1,i} \\ X_{p+1,i+1} \end{pmatrix}.$$

For the definition of the sequence (r_p, s_p, X_p), we have not used the jump condition $G(r^\pm_i, s^\pm_i) = 0$. In order to obtain a solution to the Cauchy problem, the sequence (r_p, s_p, X_p) shall satisfy some compatible conditions. We define here those compatibility conditions.

DEFINITION 1. *A pair of initial data (r_0, s_0) and X_0 is said to be compatible up to order s if, for all $p \in \{0, \dots, s\}$, the functions (r_p, s_p, X_p) defined by (49) satisfy*

$$0 = \sum_{m=1}^{p} \sum_{i_1+\cdots+i_m=p} c_{i_1,\dots,i_m} d^m \, G\left(r^\pm_{0,i}, s^\pm_{0,i}\right) . \left(\begin{pmatrix} r^\pm_{i_1,i} \\ s^\pm_{i_1,i} \end{pmatrix}, \dots, \begin{pmatrix} r^\pm_{i_m,i} \\ s^\pm_{i_m,i} \end{pmatrix} \right).$$

4.1.2. Approximate solution. The purpose of this section is to prove that, under the compatibility conditions defined above, one can construct an approximate solution of the full Cauchy problem. Denote $\Omega = \mathbb{R} \setminus \{iL,\, i \in \mathbb{Z}\}$. We show the following result.

PROPOSITION 7. *Let (r_0, s_0) and X_0 be an initial data so that $(r_0, s_0) \in (R, S) + H^{m+\frac{1}{2}}(\Omega)$ and $(X_{0,i} - iL)_{i\in\mathbb{Z}} \in l^2(\mathbb{Z})$, with $m > 2$ an integer that is compatible up to order $m-1$ and such that*

$$\|(r_0, s_0) - (R, S)\|_{L^\infty(\Omega)} \le \rho, \quad \max_{i\in\mathbb{Z}} \left(|X_{0,i+1} - X_{0,i} - L|\right) \le \rho.$$

Then for ρ sufficiently small, there exists $T_0 > 0$ and

$$(r_a, s_a) \in (R, S) + H^{m+1}(\Omega), \quad (X_{a,i} - (ct + iL)) \in l^2\left(\mathbb{Z}, H^{m+1}(\mathbb{R})\right),$$

with both $(r_a, s_a) - (R, S)$ and $X_{a,i} - (ct + iL)$ vanishing for $|t| \ge 2T_0$, so that $(r_a, s_a)_{|t=0} = (r_0, s_0)$, $X_{a,i}(0) = X_{0,i}$ and for all $(x, t) \in \Omega \times [-T_0, T_0]$,

$$\|(r_a - r_0, s_a - s_0)\| \le \frac{\rho}{2}, \quad |X_{a,i} - X_{0,i}| \le \frac{\rho}{2}.$$

Furthermore, the functions f_a and g_a defined as

$$f^1_{a,i} = \partial_t r_{a,i} + \Lambda^1_{a,i}\partial_x r_{a,i} - Q(r_{a,i}, s_{a,i}),$$
$$f^2_{a,i} = \partial_t s_{a,i} + \Lambda^2_{a,i}\partial_x s_{a,i} - Q(r_{a,i}, s_{a,i}),$$

and $g^1_{a,i} = \dot{X}_{a,i} - F(r^\pm_{a,i}, s^\pm_{a,i})$, $g^2_{a,i} = G(r^\pm_{a,i}, s^\pm_{a,i})$ are such that

$$\partial^p_t f_{a|t=0} = 0, \quad \partial^p_t g_{a|t=0} = 0 \ \forall p \in \{0, \dots, m-1\}.$$

The function f_a belongs to $H^m(\Omega\times\mathbb{R})$, g_a lies in $l^2(\mathbb{Z},H^m(\mathbb{R}))$, and both vanish for $|t|\geq 2T_0$.

Proof. For $k=1\dots m-1$, we construct a sequence $(r_k,s_k)\in H^{m+\frac{1}{2}-k}(\Omega)$, X_k so that $X_{1,i}-c\in l^2(\mathbb{Z})$ and $X_{k,i}\in l^2(\mathbb{Z})$ $(k\geq 2)$ that satisfies the compatibility conditions (49). Then, by trace lifting, we find $(r_a,s_a)\in(R,S)+H^{m+1}(\Omega\times\mathbb{R})$ and $X_a\in(ct+iL)+l^2(\mathbb{Z},H^{m+1}(\mathbb{R}))$ so that

$$\begin{aligned}\|r_a-R,s_a-S\|_{H^{m+1}(\Omega\times\mathbb{R})}&\leq C\|r_0-R,s_0-S\|_{H^{m+1}(\Omega)},\\ \|X_a-(ct+iL)\|_{l^2(\mathbb{Z},H^{m+1}(\mathbb{R}))}&\leq C\|X_0-iL\|_{l^2(\mathbb{Z})},\end{aligned}$$

and $\partial_t^k(r_{a,i},s_{a,i})_{|t=0}=(r_{k,i},s_{k,i})$, $\partial_t^k(X_{a,i})_{|t=0}=X_{k,i}\forall k\in\{0,\dots,m-1\}$. By Sobolev embeddings, we find $T_0>0$ so that

$$\|(r_a-r_0,s_a-s_0)\|\leq\frac{\rho}{2},\quad \|X_a-X_0\|\leq\frac{\rho}{2}$$

for $|t|\leq T_0$. In order to obtain functions f_a,g_a that vanish for $|t|\geq 2T_0$, we choose $\phi\in\mathcal{D}(\mathbb{R})$ a cut-off function so that $\phi(t)=1$ if $|t|\leq T_0$ and $\phi(t)=0$ if $|t|\geq 2T_0$. Then, substitute (r_a,s_a) and X_a, respectively, by $\phi(r_a,s_a)+(1-\phi)(R,S)$ and $\phi X_{a,i}+(1-\phi)(ct+iL)$. Then, one can prove that f_a belongs to $H^m(\Omega\times\mathbb{R})$ and $g^{(a)}$ lies in $l^2(\mathbb{Z},H^m(\mathbb{R}))$, and both vanish for $|t|\geq 2T_0$. Finally, according to the compatibility conditions that are satisfied up to order $m-1$, the derivatives of these functions vanish at $t=0$. The proof of the proposition is then completed. ∎

4.2. The fixed point argument. In this section, we prove the main theorem of this paper on the persistence of roll-waves.

THEOREM 2. *Assume that the Froude number F satisfies $0<F<F_c$. There exists $\rho>0$ so that for any $(r_0,s_0)\in(R,S)+H^{m+\frac{1}{2}}(\Omega)$, with $m>2$ and $(X_{0,i}-iL)_{i\in\mathbb{Z}}\in l^2(\mathbb{Z})$, compatible up to order $m-1$ and such that*

$$\|(r_0,s_0)-(R,S)\|_{L^\infty(\Omega)}\leq\rho,\quad \|X_{0,i+1}-X_{0,i}-L\|_{l^\infty(\mathbb{Z})}\leq\rho,$$

there is $T>0$ and a solution (r,s) and X of the shallow water system (8) *coupled with the Rankine–Hugoniot jump conditions* (9) *so that*

$$(r,s)_{|t=0}=(r_0,s_0),\quad X_i(t=0)=X_{0,i},$$

and (r,s) belongs to $(R,S)+H^m(\Omega\times[0,T])$, whereas $(X_i-(ct+iL))_{i\in\mathbb{Z}}$ lies in $l^2(\mathbb{Z},H^{m+1}(0,T))$.

Proof. The method of proof is based on an interative scheme: We search the solution in the form $(r,s)=(r_a,s_a)+(\overline{r},\overline{s})$, $X=X_a+\varepsilon$, where (r_a,s_a,X_a) is the approximate solution associated to the initial data (r_0,s_0,X_0) and defined in Proposition (7). For that purpose, we introduce the iterative scheme $r^{(0)}=s^{(0)}=0$, $\varepsilon^{(0)}=0$, and $(r^{(k)},s^{(k)})$, $\varepsilon^{(k)}$ is defined inductively as the unique solution, with zero initial data, of the system

$$\partial_t r_i^{(k)}+\Lambda_i^{1,(k-1)}\partial_x r_i^{(k)}=f_i^{1,(k-1)},\quad \partial_t s_i^{(k)}+\Lambda_i^{2,(k-1)}\partial_x s_i^{(k)}=f_i^{2,(k-1)},\tag{50}$$

where the functions $f_i^{n,(k-1)}$, $n=1,2$ are defined by

$$\begin{aligned}f_i^{1,(k-1)}&=Q_i^{(k-1)}-\partial_t r_i^{(k-1)}-\Lambda_i^{1,(k-1)}\partial_x r_i^{(k-1)},\\ f_i^{2,(k-1)}&=Q_i^{(k-1)}-\partial_t s_i^{(k-1)}-\Lambda_i^{2,(k-1)}\partial_x s_i^{(k-1)},\end{aligned}$$

with $Q_i^{(k)} = Q(r_{a,i} + r^{(k)}, s_{a,i} + s^{(k)})$ and

$$\Lambda_i^{n,(k)} = \frac{L}{X_{a,i+1} - X_{a,i} + \varepsilon_{i+1}^{(k)} - \varepsilon_i^{(k)}} \Big(\lambda^n \left(r_{a,i} + r^{(k)} s_{a,i} + s^{(k)} \right) - \left(\dot{X}_{a,i} + \dot{\varepsilon}_i^{(k)} + \frac{x}{L} \left(\dot{X}_{a,i+1} - \dot{X}_{a,i} + \dot{\varepsilon}_{i+1}^{(k)} - \dot{\varepsilon}_i^{(k)} \right) \right) \Big).$$

Equations (50) are supplemented by boundary conditions that read

$$\begin{pmatrix} \dot{\varepsilon}_i^{(k)} \\ 0 \end{pmatrix} = \underline{B}_i^{(k-1)} \left(r_i^{(k),\pm}, s_i^{(k),\pm} \right) + \begin{pmatrix} g_i^{1,(k-1)} \\ g_i^{2,(k-1)} \end{pmatrix}, \tag{51}$$

where the functions $g_i^{n,(k)}$ are defined by

$$\begin{pmatrix} g_i^{1,(k)} \\ g_i^{2,(k)} \end{pmatrix} = \begin{pmatrix} -\dot{X}_{a,i} + F \left(r_{a,i}^{\pm} + r_i^{(k),\pm}, s_{a,i}^{\pm} + s_i^{(k),\pm} \right) \\ G \left(r_{a,i}^{\pm} + r_i^{(k),\pm}, s_{a,i}^{\pm} + s_i^{(k),\pm} \right) \end{pmatrix} - \underline{B}_i^{(k)} \left(r_i^{(k),\pm}, s_i^{(k),\pm} \right).$$

We estimate the nonlinear terms $f_i^{n,(k-1)}$ and $g_i^{n,(k-1)}$. One can prove that there exists $M > 0$ so that for any $T \in (0, T_0)$, and if $r^{(k-1)}, s^{(k-1)}$ belongs to $H^m(\Omega) \times I_T)$, $r^{(k-1),\pm}, s^{(k-1),\pm}$ lies in $l^2(\mathbb{Z}, H^m(I_T))$ and $\varepsilon^{(k-1)}$ to $l^2(\mathbb{Z}, H^{m+1}(I_T))$, vanish for $t < 0$ and are such that

$$\begin{aligned} \left\| r^{(k-1)}, s^{(k-1)} \right\|_{H^m(\Omega \times I_T)} &\leq M, \\ \left\| r^{(k-1),\pm}, s^{(k-1),\pm} \right\|_{l^2(\mathbb{Z}, H^m(I_T))} &\leq M, \\ \left\| \varepsilon^{(k-1)} \right\|_{l^2(\mathbb{Z}, H^{m+1}(I_T))} &\leq M, \end{aligned} \tag{52}$$

then $f^{n,(k-1)}$ lies in $H^m(\Omega \times I_T)$, $g^{n,(k-1)}$ in $l^2(\mathbb{Z}, H^m(I_T))$ and satisfy the estimates

$$\left\| f^{n,(k-1)} \right\|_{H^m(\Omega \times I_T)} \leq C(M), \quad \left\| g^{n,(k-1)} \right\|_{l^2(\mathbb{Z}, H^m(I_T))} \leq C(M)T + \eta(T),$$

with $\eta(T) \to 0$ as $T \to 0$ and $M \longmapsto C(M)$ is a continuous function. The function $(r^{(0)}, s^{(0)}), \varepsilon^{(0)}$ satisfies all the assumptions. We can apply the Proposition 6: There exists a unique solution $(r^{(1)}, s^{(1)}) \in H^m(\Omega \times I_T)$ and $\varepsilon^{(1)} \in l^2(\mathbb{Z}, H^{m+1}(I_T))$ solution of (50), (51) with $k = 1$. Moreover, diminishing T if necessary, one can prove, using the energy estimate in Proposition 6, that

$$\begin{aligned} \left\| r^{(1)}, s^{(1)} \right\|_{H^m(\Omega \times I_T)} &\leq M, \\ \left\| r^{(1),\pm}, s^{(1),\pm} \right\|_{l^2(\mathbb{Z}, H^m(I_T))} &\leq M, \\ \left\| \varepsilon^{(1)} \right\|_{l^2(\mathbb{Z}, H^{m+1}(I_T))} &\leq M. \end{aligned}$$

By induction, one can construct $(r^{(k)}, s^{(k)}) \in H^m(\Omega \times I_T)$ and $\varepsilon^{(k)} \in l^2(\mathbb{Z}, H^{m+1}(I_T))$ that satisfy (52) for $k \geq 1$. Now using the fact that $W^{1,\infty}(\mathbb{R}) \hookrightarrow H^m(\mathbb{R})$, we obtain uniform estimates on $\|(r^{(k)}, s^{(k)}\|_{W^{1,\infty}}(\mathbb{R})$. We write the equations satisfied by $(r^{(k)} - r^{(k-1)}, s^{(k)} - s^{(k-1)})$ that is denoted $u^{(k)}$ in what follows, and $\varepsilon^{(k)} - \varepsilon^{(k-1)}$. Using the L^2 energy estimate of Proposition 4, we prove that, for T sufficiently small,

$$\begin{aligned} \left\| u^{(k+1)} \right\|_{L^2(\Omega \times I_T)} &\leq \frac{1}{2} \left\| u^{(k)} \right\|_{L^2(\Omega \times I_T)}, \\ \left\| u^{(k+1),\pm} \right\|_{l^2(\mathbb{Z}, L^2(I_T))} &\leq \frac{1}{2} \left\| u^{(k),\pm} \right\|_{l^2(\mathbb{Z}, L^2(I_T))}, \\ \left\| \varepsilon^{(k+1)} - \varepsilon^{(k)} \right\|_{l^2(\mathbb{Z}, H^1(I_T))} &\leq \frac{1}{2} \left\| \varepsilon^{(k)} - \varepsilon^{(k-1)} \right\|_{l^2(\mathbb{Z}, H^1(I_T))}. \end{aligned}$$

Then, $(r^{(k)}, s^{(k)})$, $(r^{(k),\pm}, s^{(k)}, \pm)$, and $\varepsilon^{(k)}$ are, respectively, Cauchy sequences in $L^2(\Omega \times I_T)$, $l^2(\mathbb{Z}, L^2(I_T))$, and $l^2(\mathbb{Z}, H^1(I_T))$ and converge in that space. We denote $\overline{r}, \overline{s}$, and $\overline{\varepsilon}$ the limits of $(r^{(k)}, s^{(k)})$ and $\varepsilon^{(k)}$ as $k \to \infty$. Necessarily, $(\overline{r}, \overline{s})$ lies in $H^m(\Omega \times I_T)$, $(\overline{r}^{\pm}, \overline{s}^{\pm})$ in $l^2(\mathbb{Z}, H^m(I_T))$, and $\overline{\varepsilon}$ belongs to $l^2(\mathbb{Z}, H^{m+1}(I_T))$. By standard interpolation arguments, we obtain strong convergence in appropriate Sobolev spaces so that we can make $k \to \infty$ in (50),(51). As a result, the function $(r_a + \overline{r}, s_a + \overline{s})$ and $X_a + \overline{\varepsilon}$ solves the full Cauchy problem (8), (9) on the interval $(0, T)$. This concludes the proof of the theorem and the persistence of roll-waves for suitable initial data. ∎

5. Conclusion. In this paper, we proved the well posedness of the shallow water equations in the neighborhood of roll-wave solutions for initial conditions that satisfy suitable compatibility conditions. The main issue here is to formulate the stability problem in the presence of an infinite number of shocks. This is done through a Lipschitz change of variable that fixes *all* the discontinuities of functions that are close to roll-waves. Writing the shallow water equations with Riemann invariants, we diagonalize the shallow water system; in that case, it is easier to obtain estimates on the linearized problems. We prove the existence of weak solutions to the linearized problem through the formulation of an adjoint problem just as in the shock case. We then prove regularity properties on that solution. The main difference with the shock case is the presence of a singularity in the interior equations due to the presence of a sonic point: a regularization in the transverse direction is not sufficient here, and we regularize the solution also in the direction of propagation. The existence of a solution to the full nonlinear problem is then obtain through a fixed point argument. A key assumption is that the Froude number F (that measures whether a the flow of the channel is fluvial or torrential) has to be smaller than a critical value F_c: this suggests that in the super critical regime $F > F_c$, the roll-wave structure may be destroyed. This would be an interesting question to see what happens in that regime even from a numerical point of view.

Though written in a $1D$ setting, we claim that the results obtained in this paper hold true in the *multidimensional setting*. We briefly discuss the method of proof. Indeed, in the $2D$ case, one shall consider a transverse coordinate y and a transverse speed v; the hyperbolic part of the equations is nothing but the isentropic Euler equations. Here we shall assume that the shocks are located at the positions $\Psi_i(t, y) \approx iT$, $i \in \mathbb{Z}$. Next we perform a change of variable similar to the one used in this paper, and one can easily formulate the linearized equations. The main difference with the $1D$ case is the obtention of energy estimates for the linearized (exact and approximated) equations. However, once the linearization procedure is performed, we are left with an infinite but discrete number of Lax shocks that can be treated separately. For each Lax shock, one can use Kreiss symmetrizers to obtain energy estimates and then sum all the contributions over $i \in \mathbb{Z}$. The end of the proof is then completely similar to the $1D$ case presented here. This method shall be developped in a forthcoming paper on the persistence of roll-waves in general hyperbolic systems with discontinuities satisfying Lax shock conditions obtained recently by the author[14]. We shall also consider the persistence of roll-waves with characteristic discontinuities. This is of interest from a physical point of view, since they may appear when the pressure term in shallow water equations is not convex like in stratified flows (see [2] for more details).

At this stage, several questions arise. First, we have restricted our analysis to *smooth* perturbations: in the $1D$ case, because of the progress made in the analysis of the $1D$ problem, it seems relevant to consider more general perturbations. In the case of shock waves, the persistence of shocks satisfying the Majda–Liu stability condition

under small perturbations with a bounded variation (BV) using the Glimm scheme or the front tracking method has been established (see [16], [8] for more details). It is thus a natural question whether roll-waves persist under BV perturbations, though it may be a very difficult problem in the case of roll-waves. Another interesting question is the stability of viscous roll-waves that are close to Dressler roll-waves in the vanishing viscosity limit [10, 11]; that question has been treated recently in the shock case for multidimensional perturbations [6]. Moreover, the linear stability of viscous roll-waves has been proved under strong spectral stability [12]. Energy estimates have been obtained through Green functions that blow up in the vanishing viscosity case, just as in the shock case. It would be interesting here to adapt the method introduced by Metivier and coworkers [6] to the roll-wave case: the main issue would be the presence of an infinite number of viscous shocks. This question is an open problem that is postponed to a forthcoming work.

Acknowledgment. The author wishes to thank Prof. Sylvie Benzoni for many useful discussions on the multidimensional stability of shock waves.

A NONLOCAL p-LAPLACIAN EVOLUTION EQUATION WITH NONHOMOGENEOUS DIRICHLET BOUNDARY CONDITIONS*

F. ANDREU†, J. M. MAZÓN‡, J. D. ROSSI§, AND J. TOLEDO‡

Abstract. In this paper we study the nonlocal p-Laplacian-type diffusion equation $u_t(t,x) = \int_{\mathbb{R}^N} J(x-y)|u(t,y)-u(t,x)|^{p-2}(u(t,y)-u(t,x))\,dy$, $(t,x) \in]0,T[\times\Omega$, with $u(t,x) = \psi(x)$ for $(t,x) \in]0,T[\times(\mathbb{R}^N \setminus \Omega)$. If $p > 1$, this is the nonlocal analogous problem to the well-known local p-Laplacian evolution equation $u_t = \operatorname{div}(|\nabla u|^{p-2}\nabla u)$ with Dirichlet boundary condition $u(t,x) = \psi(x)$ on $(t,x) \in]0,T[\times\partial\Omega$. If $p = 1$, this is the nonlocal analogous to the total variation flow. When $p = +\infty$ (this has to be interpreted as the limit as $p \to +\infty$ in the previous model) we find an evolution problem that can be seen as a nonlocal model for the formation of sandpiles (here $u(t,x)$ stands for the height of the sandpile) with prescribed height of sand outside of Ω. We prove, as main results, existence, uniqueness, a contraction property that gives well posedness of the problem, and the convergence of the solutions to solutions of the local analogous problem when a rescaling parameter goes to zero.

Key words. nonlocal diffusion, p-Laplacian, nonhomogeneous Dirichlet boundary conditions, total variation flow, sandpiles

1. Introduction.

In this paper we study the nonlocal diffusion equation

$$u_t(t,x) = \int_{\mathbb{R}^N} J(x-y)|u(t,y)-u(t,x)|^{p-2}(u(t,y)-u(t,x))\,dy \qquad (t,x) \in]0,T[\times\Omega,$$

where Ω is a bounded domain and u is prescribed in $\mathbb{R}^N \setminus \Omega$ as $u(t,x) = \psi(x)$ for $(t,x) \in]0,T[\times(\mathbb{R}^N \setminus \Omega)$. We consider $1 < p < +\infty$ as well as the extreme cases $p = 1$ and the limit $p \nearrow +\infty$. Throughout the paper, we assume that $J : \mathbb{R}^N \to \mathbb{R}$ is a nonnegative, radial, continuous function, strictly positive in $B(0,1)$, vanishing in $\mathbb{R}^N \setminus B(0,1)$ and such that $\int_{\mathbb{R}^N} J(z)\,dz = 1$.

First, let us briefly introduce the prototype of nonlocal problem that will be considered along this work. Nonlocal evolution equations of the form

$$u_t(t,x) = (J * u - u)(t,x) = \int_{\mathbb{R}^N} J(x-y)u(t,y)\,dy - u(t,x), \tag{1.1}$$

and variations of it, have been recently widely used to model diffusion processes. More precisely, as stated in [31], if $u(t,x)$ is thought of as a density at the point x at time t and $J(x-y)$ is thought of as the probability distribution of jumping from location y to

location x, then $\int_{\mathbb{R}^N} J(y-x)u(t,y)\,dy = (J*u)(t,x)$ is the rate at which individuals are arriving at position x from all other places and $-u(t,x) = -\int_{\mathbb{R}^N} J(y-x)u(t,x)\,dy$ is the rate at which they are leaving location x to travel to all other sites. This consideration, in the absence of external or internal sources, leads immediately to the fact that the density u satisfies (1.1). For recent references on nonlocal diffusion, see [4], [5], [6], [9], [11], [12], [20], [21], [22], [23], [24], [25], [26], [27], [31], [33], [36] and references therein.

The first goal of this paper is to study the following nonlocal nonlinear diffusion problem:

$$P_p^J(u_0,\psi)\begin{cases} u_t(t,x) = \displaystyle\int_\Omega J(x-y)|u(t,y)-u(t,x)|^{p-2}(u(t,y)-u(t,x))\,dy \\ \qquad\qquad + \displaystyle\int_{\Omega_J\setminus\overline{\Omega}} J(x-y)|\psi(y)-u(t,x)|^{p-2}(\psi(y)-u(t,x))\,dy, \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad (t,x)\in]0,T[\times\Omega, \\ u(0,x) = u_0(x), \quad x\in\Omega. \end{cases}$$

Here $\Omega_J = \Omega + \operatorname{supp}(J)$ and ψ is a given function $\psi : \Omega_J \setminus \overline{\Omega} \to \mathbb{R}$.

Observe that we can rewrite $P_p^J(u_0,\psi)$, setting $u(t,x) = \psi(x)$ in $\Omega_J \setminus \overline{\Omega}$, as

$$\begin{cases} u_t(t,x) = \displaystyle\int_{\Omega_J} J(x-y)|u(t,y)-u(t,x)|^{p-2}(u(t,y)-u(t,x))\,dy, \quad (t,x)\in]0,T[\times\Omega, \\ u(t,x) = \psi(x), \quad (t,x)\in]0,T[\times\left(\Omega_J\setminus\overline{\Omega}\right), \\ u(0,x) = u_0(x), \quad x\in\Omega, \end{cases}$$

and we call it the *nonlocal p-Laplacian problem with Dirichlet boundary condition*. Note that we are prescribing the values of u outside the domain Ω and not only on its boundary. This is due to the nonlocal character of the problem.

Let us state the precise definition of solution. Solutions to $P_p^J(u_0,\psi)$ will be understood in the following sense.

DEFINITION 1.1. *Let $1 < p < +\infty$. A solution of $P_p^J(u_0,\psi)$ in $[0,T]$ is a function*

$$u \in C\left([0,T];L^1(\Omega)\right) \cap W^{1,1}\left(]0,T[;L^1(\Omega)\right),$$

which satisfies $u(0,x) = u_0(x)$ a.e. $x\in\Omega$ and

$$u_t(t,x) = \int_\Omega J(x-y)|u(t,y)-u(t,x)|^{p-2}(u(t,y)-u(t,x))\,dy + \int_{\Omega_J\setminus\overline{\Omega}} J(x-y)|\psi(y)-u(t,x)|^{p-2}(\psi(y)-u(t,x))\,dy,$$

for a.e. $t\in]0,T[$ and a.e. $x\in\Omega$.

Our first result shows existence and uniqueness of a global solution for this problem. Moreover, a contraction principle holds.

THEOREM 1.2. *Assume $p > 1$ and let $u_0 \in L^p(\Omega)$, $\psi \in L^p(\Omega_J\setminus\overline{\Omega})$. Then, there exists a unique solution to $P_p^J(u_0,\psi)$ in the sense of Definition 1.1. Moreover, if $u_{i0}\in L^1(\Omega)$ and u_i is a solution in $[0,T]$ of $P_p^J(u_{i0},\psi)$, $i=1,2$, respectively. Then*

$$\int_\Omega (u_1(t)-u_2(t))^+ \le \int_\Omega (u_{10}-u_{20})^+ \qquad \text{for every } t\in[0,T].$$

If $u_{i0} \in L^p(\Omega)$, $i = 1, 2$, *then*

$$\|u_1(t) - u_2(t)\|_{L^p(\Omega)} \le \|u_{10} - u_{20}\|_{L^p(\Omega)} \qquad \text{for every } t \in [0, T].$$

Our next step is to rescale the kernel J appropriately and take the limit as the scaling parameter goes to zero. To be more precise, for $p > 1$, we consider the local p-Laplace evolution equation with Dirichlet boundary condition

$$D_p(u_0, \tilde{\psi}) \quad \begin{cases} u_t = \Delta_p u & \text{in }]0, T[\times\Omega, \\ u = \tilde{\psi} & \text{on }]0, T[\times\partial\Omega, \\ u(0, x) = u_0(x) & \text{in } \Omega, \end{cases}$$

where the boundary datum $\tilde{\psi}$ is assumed to be the trace of a function defined in a larger domain and the operator in the equation, $\Delta_p u = \operatorname{div}(|\nabla u|^{p-2}\nabla u)$, is the usual local p-Laplacian.

We prove that the solutions of this local problem can be approximated by solutions of a sequence of nonlocal *p-Laplacian* problems of the form P_p^J. Indeed, for given $p \ge 1$ and J we consider the rescaled kernels

$$J_{p,\varepsilon}(x) := \frac{C_{J,p}}{\varepsilon^{p+N}} J\left(\frac{x}{\varepsilon}\right), \qquad \text{where} \qquad C_{J,p}^{-1} := \frac{1}{2}\int_{\mathbb{R}^N} J(z)|z_N|^p \, dz \tag{1.2}$$

is a normalizing constant in order to obtain the p-Laplacian in the limit instead of a multiple of it, and we obtain the following result.

THEOREM 1.3. *Let* Ω *be a smooth bounded domain in* $\mathbb{R}^N$ *and* $\tilde{\psi} \in W^{1/p',p}(\partial\Omega) \cap L^\infty(\partial\Omega)$. *Let* $\psi \in W^{1,p}(\Omega_J) \cap L^\infty(\Omega_J)$ *such that the trace* $\psi|_{\partial\Omega} = \tilde{\psi}$. *Assume* $J(x) \ge J(y)$ *if* $|x| \le |y|$. *Let* $T > 0$ *and* $u_0 \in L^p(\Omega)$. *Let* u_ε *be the unique solution of* $P_p^{J_{p,\varepsilon}}(u_0, \psi)$ *and* u *the unique solution of* $D_p(u_0, \tilde{\psi})$ *(see section* 2.2*). Then*

$$\lim_{\varepsilon\to 0} \sup_{t\in[0,T]} \|u_\varepsilon(t, .) - u(t, .)\|_{L^p(\Omega)} = 0. \tag{1.3}$$

Note that the above result says that P_p^J is a nonlocal problem analogous to the p-Laplacian with Dirichlet boundary condition.

The second goal of this paper is to study the Dirichlet problem for $p = 1$, called the nonlocal total variation flow, which can be written formally as

$$P_1^J(u_0, \psi) \begin{cases} u_t(t, x) = \displaystyle\int_\Omega J(x - y)\frac{u(t, y) - u(t, x)}{|u(t, y) - u(t, x)|}\, dy \\ \qquad\qquad + \displaystyle\int_{\Omega_J\setminus\overline{\Omega}} J(x - y)\frac{\psi(t, y) - u(t, x)}{|\psi(t, y) - u(t, x)|}\, dy, \quad (t, x) \in]0, T[\times\Omega, \\ u(0, x) = u_0(x), \quad x \in \Omega. \end{cases}$$

We give the following definition of what we understand by a solution of $P_1^J(u_0, \psi)$.

DEFINITION 1.4. *A solution of* $P_1^J(u_0, \psi)$ *in* $[0, T]$ *is a function*

$$u \in C\left([0, T]; L^1(\Omega)\right) \cap W^{1,1}\left(]0, T[; L^1(\Omega)\right),$$

which satisfies $u(0, x) = u_0(x)$ *a.e.* $x \in \Omega$ *and*

$$u_t(t, x) = \int_{\Omega_J} J(x - y)g(t, x, y)\, dy \quad \text{a.e. in }]0, T[\times\Omega,$$

for some $g \in L^\infty(0,T;L^\infty(\Omega_J \times \Omega))$ *with* $\|g\|_\infty \le 1$ *such that for almost every* $t \in]0,T[$, $g(t,x,y) = -g(t,y,x)$ *and*

$$J(x-y)g(t,x,y) \in J(x-y)\mathrm{sign}(u(t,y)-u(t,x)), \qquad (x,y) \in \Omega \times \Omega,$$

$$J(x-y)g(t,x,y) \in J(x-y)\mathrm{sign}(\psi(y)-u(t,x)), \qquad (x,y) \in \Omega \times \left(\Omega_J \setminus \overline{\Omega}\right).$$

Here, sign is the multivalued function defined by

$$\mathrm{sign}(r) := \begin{cases} 1 & \text{if } r > 0 \\ [-1,1] & \text{if } r = 0 \\ -1 & \text{if } r < 0. \end{cases}$$

We use sign_0 to denote the univalued function

$$\mathrm{sign}_0(r) := \begin{cases} 1 & \text{if } r > 0 \\ 0 & \text{if } r = 0 \\ -1 & \text{if } r < 0. \end{cases}$$

To get the existence and uniqueness of these kinds of solutions, the idea is to take the limit as $p \searrow 1$ of solutions to P_p^J with $p > 1$.

THEOREM 1.5. *Let* $u_0 \in L^1(\Omega)$ *and* $\psi \in L^1(\Omega_J \setminus \overline{\Omega})$. *Then, there exists a unique solution to* $P_1^J(u_0)$ *in the sense of Definition* 1.4. *Moreover, if* $u_{i0} \in L^1(\Omega)$ *and* u_i *are solutions in* $[0,T]$ *of* $P_1^J(u_{i0})$, $i = 1,2$. *Then*

$$\int_\Omega (u_1(t) - u_2(t))^+ \le \int_\Omega (u_{10} - u_{20})^+ \quad \text{for every } t \in [0,T].$$

In this case we can rescale the kernel as in (1.2) in order to obtain convergence of the solutions of the corresponding rescaled problem to the solution of the Dirichlet problem for the total variational flow, that is,

$$D_1(u_0,\tilde{\psi}) \quad \begin{cases} u_t = \mathrm{div}\left(\frac{Du}{|Du|}\right) & \text{in }]0,T[\times\Omega, \\ u = \tilde{\psi} & \text{on }]0,T[\times\partial\Omega, \\ u(0,x) = u_0(x) & \text{in } \Omega. \end{cases}$$

THEOREM 1.6. *Let* Ω *be a smooth bounded domain in* $\mathbb{R}^N$. *Assume* $J(x) \ge J(y)$ *if* $|x| \le |y|$. *Let* $T > 0$, $u_0 \in L^1(\Omega)$, $\tilde{\psi} \in L^\infty(\partial\Omega)$, *and* $\psi \in W^{1,1}(\Omega_J \setminus \overline{\Omega}) \cap L^\infty(\Omega_J \setminus \overline{\Omega})$ *such that the trace* $\psi|_{\partial\Omega} = \tilde{\psi}$. *Let* u_ε *be the unique solution of* $P_1^{J_{1,\varepsilon}}(u_0,\psi)$. *Then, if* u *is the unique solution of* $D_1(u_0,\tilde{\psi})$ *(see section* 3.2*),*

$$\lim_{\varepsilon\to 0} \sup_{t\in[0,T]} \|u_\varepsilon(t,.) - u(t,.)\|_{L^1(\Omega)} = 0.$$

Finally, the third goal of this paper is to study the limit case $p = +\infty$, which has to be understood as the limit of our nonlocal evolution problems as $p \to +\infty$ (see section 4). In this case we recover a nonlocal model for the evolution of sandpiles which is the nonlocal version of the Prigozhin model [35]. Then, the nonlocal limit problem with source for $p = +\infty$ can be written as

$$P_\infty^J(u_0,\psi,f) \quad \begin{cases} f(t,\cdot) - u_t(t,\cdot) \in \partial G^J_{\infty,\psi}(u(t)), & \text{a.e. } t \in]0,T[, \\ u(0,x) = u_0(x), \end{cases}$$

where $G^J_{\infty,\psi}$ is the functional

$$G^J_{\infty,\psi}(u) = \begin{cases} 0 & \text{if } |u(x)-u(y)| \le 1, \text{ for } x,y \in \Omega \\ & \text{and } |\psi(y)-u(x)| \le 1, \quad \text{for } x \in \Omega, y \in \Omega_J \setminus \overline{\Omega}, \\ & \text{with } x-y \in \operatorname{supp}(J) \\ +\infty & \text{in the other case,} \end{cases}$$

that is, $G^J_{\infty,\psi} = I_{K^J_{\infty,\psi}}$, the indicator function of the set

$$K^J_{\infty,\psi} := \left\{ u \in L^2(\Omega) \ : \ \begin{array}{l} |u(x)-u(y)| \le 1, x, y \in \Omega \\ \text{and } |\psi(y)-u(x)| \le 1, \quad \text{for } x \in \Omega, y \in \Omega_J \setminus \overline{\Omega}, \\ \text{with } x-y \in \operatorname{supp}(J) \end{array} \right\}.$$

More precisely, we obtain the following result.

THEOREM 1.7. *Let $\psi \in L^\infty(\Omega_J \setminus \overline{\Omega})$ such that $K^J_{\infty,\psi} \neq \emptyset$. Let $T > 0$, $f \in L^2(0,T; \cap_{q\ge 2} L^q(\Omega))$, $u_0 \in \cap_{q\ge 2} L^q(\Omega)$ such that $u_0 \in K^J_{\infty,\psi}$, and u_p, $p \ge 2$, the unique solution of the nonlocal p-Laplacian with a source term f, $P^J_p(u_0,\psi,f)$ (see section 4). Then, if u_∞ is the unique solution to $P^J_\infty(u_0,\psi,f)$,*

$$\lim_{p\to\infty} \sup_{t\in[0,T]} \|u_p(t,\cdot) - u_\infty(t,\cdot)\|_{L^2(\Omega)} = 0.$$

Our next step is to rescale the kernel J appropriately and take the limit as the scaling parameter goes to zero. We will suppose that Ω is convex and ψ verifies $\|\nabla\psi\|_\infty \le 1$. For $\varepsilon > 0$, we rescale the functional $G^J_{\infty,\psi}$ as follows:

$$G^\varepsilon_{\infty,\psi}(u) = \begin{cases} 0 & \text{if } |u(x)-u(y)| \le \varepsilon, \text{ for } x,y \in \Omega \\ & \text{and } |\psi(y)-u(x)| \le \varepsilon, \quad \text{for } x \in \Omega, y \in \Omega_J \setminus \overline{\Omega}, \\ & \text{with } |x-y| \le \varepsilon \\ +\infty & \text{in the other case,} \end{cases}$$

that is, $G^\varepsilon_{\infty,\psi} = I_{K^\varepsilon_{\infty,\psi}}$, where

$$K^\varepsilon_{\infty,\psi} := \left\{ u \in L^2(\Omega) \ : \ \begin{array}{l} |u(x)-u(y)| \le \varepsilon, x, y \in \Omega \\ \text{and } |\psi(y)-u(x)| \le \varepsilon, \quad \text{for } x \in \Omega, y \in \Omega_J \setminus \overline{\Omega}, \\ \text{with } |x-y| \le \varepsilon \end{array} \right\}.$$

Consider the gradient flow associated to the functional $G^\varepsilon_{\infty,\psi}$

$$P^\varepsilon_\infty(u_0,\psi,f) \quad \begin{cases} f(t,\cdot) - u_t(t,\cdot) \in \partial I_{K^\varepsilon_{\infty,\psi}}(u(t)), & \text{a.e. } t \in]0,T[, \\ u(0,x) = u_0(x), & \text{in } \Omega, \end{cases}$$

and the limit problem

$$P_\infty(u_0,\psi,f) \quad \begin{cases} f(t,\cdot) - u_{\infty,t} \in \partial I_{K_\psi}(u_\infty), & \text{a.e. } t \in]0,T[, \\ u_\infty(0,x) = u_0(x), & \text{in } \Omega, \end{cases}$$

where

$$K_\psi := \left\{ u \in W^{1,\infty}(\Omega) \ : \ \|\nabla u\|_\infty \le 1, \ u|_{\partial\Omega} = \psi|_{\partial\Omega} \right\}.$$

Now we state our result concerning the limit as $\varepsilon \to 0$ for the sandpile model ($p = +\infty$).

THEOREM 1.8. *Assume Ω is a convex bounded domain in $\mathbb{R}^N$. Let $T > 0$, $f \in L^2(0,T;L^2(\Omega))$, $\psi \in W^{1,\infty}(\Omega_J \setminus \overline{\Omega})$ such that $\|\nabla \psi\|_\infty \le 1$, $u_0 \in W^{1,\infty}(\Omega)$ such that $\|\nabla u_0\|_\infty \le 1$ and $u_0|_{\partial\Omega} = \psi|_{\partial\Omega}$ (this means $u_0 \in K_\psi$), and consider $u_{\infty,\varepsilon}$ the unique solution of $P^\varepsilon_\infty(u_0,\psi,f)$. Then, if v_∞ is the unique solution of $P_\infty(u_0,\psi,f)$, we have*

$$\lim_{\varepsilon\to 0} \sup_{t\in[0,T]} \|u_{\infty,\varepsilon}(t,\cdot) - v_\infty(t,\cdot)\|_{L^2(\Omega)} = 0.$$

Closely related to the present work are [5] and [6] where the homogeneous Neumann problem and its limit as p goes to infinity or to one are considered. The difference here is that we are now considering Dirichlet boundary conditions, not only the homogeneous case, but also the nonhomogeneous case, and this introduces new difficulties specially when one tries to recover the local models when $\varepsilon \to 0$. Remark that in our nonlocal formulation we are not imposing any continuity between the values of u inside Ω and outside it, ψ. However, when dealing with local problems usually the boundary datum is taken in the sense of traces, that is, $u|_{\partial\Omega} = \psi$. Recovering this condition as $\varepsilon \to 0$ is one of the main contributions of the present work.

Note that, as it happens for the local p-Laplacian, the Dirichlet problem can be written as a Neumann problem with a particular flux that depends on the solution itself. Indeed, the problem $P^J_p(u_0,\psi)$ can be written as

$$\begin{cases} u_t(t,x) = \displaystyle\int_\Omega J(x-y)|u(t,y)-u(t,x)|^{p-2}(u(t,y)-u(t,x))\,dy + \varphi(x,u(x)) \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad (t,x) \in]0,T[\times\Omega, \\ u(0,x) = u_0(x), \quad x \in \Omega, \end{cases}$$

where

$$\varphi(x,u(x)) = \int_{\Omega_J\setminus\overline{\Omega}} J(x-y)|\psi(t,y)-u(t,x)|^{p-2}(\psi(t,y)-u(t,x))\,dy.$$

In the homogeneous case, $\psi \equiv 0$,

$$\varphi(x,u(x)) = -\left(\int_{\Omega_J\setminus\overline{\Omega}} J(x-y)\,dy\right)|u(t,x)|^{p-2}u(t,x).$$

This problem is a nonhomogeneous Neumann problem (see [5]) with a prescribed flux given by φ.

Let us finish the introduction by collecting some notations and results that will be used in the sequel. Following [7] (see also [2]), let

$$X(\Omega) = \left\{ z \in L^\infty(\Omega,\mathbb{R}^n) \ : \ \mathrm{div}(z) \in L^1(\Omega) \right\}. \tag{1.4}$$

If $z \in X(\Omega)$ and $w \in BV(\Omega)\cap L^\infty(\Omega)$, we define the functional $(z,Dw) : C_0^\infty(\Omega) \to \mathbb{R}$ by the formula

$$\langle (z,Dw),\varphi\rangle = -\int_\Omega w\,\varphi\,\mathrm{div}(z)\,dx - \int_\Omega w\,z\cdot\nabla\varphi\,dx. \tag{1.5}$$

Then (z, Dw) is a Radon measure in Ω,

$$\int_\Omega (z, Dw) = \int_\Omega z \cdot \nabla w \, dx \tag{1.6}$$

for all $w \in W^{1,1}(\Omega) \cap L^\infty(\Omega)$ and

$$\left| \int_B (z, Dw) \right| \leq \int_B |(z, Dw)| \leq \|z\|_\infty \int_B \|Dw\| \tag{1.7}$$

for any Borel set $B \subseteq \Omega$.

In [7], a weak trace on $\partial\Omega$ of the normal component of $z \in X(\Omega)$ is defined. Concretely, it is proved that there exists a linear operator $\gamma : X(\Omega) \to L^\infty(\partial\Omega)$ such that

$$\|\gamma(z)\|_\infty \leq \|z\|_\infty,$$

and

$$\gamma(z)(x) = z(x) \cdot \nu(x) \quad \text{for all } x \in \partial\Omega \text{ if } z \in C^1\left(\overline{\Omega}, \mathbb{R}^N\right).$$

We shall denote $\gamma(z)(x)$ by $[z, \nu](x)$. Moreover, the following *Green's formula*, relating the function $[z, \nu]$ and the measure (z, Dw), for $z \in X(\Omega)$ and $w \in BV(\Omega) \cap L^\infty(\Omega)$, is established:

$$\int_\Omega w \, \operatorname{div}(z) \, dx + \int_\Omega (z, Dw) = \int_{\partial\Omega} [z, \nu] w \, d\mathcal{H}^{N-1}. \tag{1.8}$$

Organization of the paper. The rest of the paper is organized as follows. In the second section we prove the existence and uniqueness of strong solutions for the nonlocal p-Laplacian problem with Dirichlet boundary conditions for $p > 1$ and we show that our model approaches local p-Laplacian evolution equation with Dirichlet boundary condition. In section 3 we study the Dirichlet problem for the nonlocal total variation flow, proving convergence to the local model when the problem is rescaled appropriately as well. Finally, in section 4 we study the case $p = \infty$, obtaining a model for sandpiles with Dirichlet boundary conditions.

2. The case $p > 1$.

2.1. Existence of solutions for the nonlocal problems. We first study $P_p^J(u_0, \psi)$ from the point of view of nonlinear semigroup theory ([15], [28]). For that we introduce in $L^1(\Omega)$ the following operator associated with our problem.

DEFINITION 2.1. For $1 < p < +\infty$ and $\psi : \Omega_J \setminus \overline{\Omega} \to \mathbb{R}$, such that $|\psi|^{p-1} \in L^1(\Omega_J \setminus \overline{\Omega})$, we define in $L^1(\Omega)$ the operator $B_{p,\psi}^J$ by

$$\begin{aligned} B_{p,\psi}^J(u)(x) \quad &= -\int_\Omega J(x-y)|u(y)-u(x)|^{p-2}(u(y)-u(x))\,dy \\ &\quad -\int_{\Omega_J \setminus \overline{\Omega}} J(x-y)|\psi(y)-u(x)|^{p-2}(\psi(y)-u(x))\,dy, \qquad x \in \Omega. \end{aligned}$$

Remark 2.2. (i). We will set overall the section,

$$u_\psi(x) := \begin{cases} u(x) & \text{if } x \in \Omega, \\ \psi(x) & \text{if } x \in \Omega_J \setminus \overline{\Omega}, \\ 0 & \text{if } x \notin \Omega_J. \end{cases}$$

Therefore, we can rewrite

$$B^J_{p,\psi}(u)(x) = -\int_{\Omega_J} J(x-y)|u_\psi(y)-u(x)|^{p-2}(u_\psi(y)-u(x))\,dy, \qquad x\in\Omega.$$

(ii) If $\psi = 0$, then

$$B^J_{p,0}(u)(x) = -\int_{\Omega} J(x-y)|u(y)-u(x)|^{p-2}(u(y)-u(x))\,dy + \left(\int_{\Omega_J\setminus\overline{\Omega}} J(x-y)dy\right)\ |u(x)|^{p-2}u(x)\,, \qquad x\in\Omega.$$

Remark 2.3. It is easy to see that
(i) If $\psi = 0$, $B^J_{p,0}$ is positively homogeneous of degree $p-1$,
(ii) $L^{p-1}(\Omega)\subset \mathrm{Dom}(B^J_{p,\psi})$, if $p>2$.
(iii) For $1<p\le 2$, $\mathrm{Dom}(B^J_{p,\psi}) = L^1(\Omega)$ and $B^J_{p,\psi}$ is closed in $L^1(\Omega)\times L^1(\Omega)$.
We have the following monotonicity lemma, whose proof is straightforward.

LEMMA 2.4. *Let $1<p<+\infty$, $\psi:\Omega_J\setminus\overline{\Omega}\to\mathbb{R}$, $|\psi|^{p-1}\in L^1(\Omega_J\setminus\overline{\Omega})$, and $T:\mathbb{R}\to\mathbb{R}$ a nondecreasing function. Then,*

(i) *for every u, $v\in L^p(\Omega)$ such that $T(u-v)\in L^p(\Omega)$, it holds*

$$\begin{aligned}&\int_\Omega \left(B^J_{p,\psi}u(x) - B^J_{p,\psi}v(x)\right)T(u(x)-v(x))dx\\ &= \frac{1}{2}\int_{\Omega_J}\int_{\Omega_J} J(x-y)\left(T(u_\psi(y)-v_\psi(y)) - T(u_\psi(x)-v_\psi(x))\right)\\ &\qquad\times\left(|u_\psi(y)-u_\psi(x)|^{p-2}(u_\psi(y)-u_\psi(x))\right.\\ &\qquad\quad\left.-|v_\psi(y)-v_\psi(x)|^{p-2}(v_\psi(y)-v_\psi(x))\right)dydx.\end{aligned} \tag{2.1}$$

(ii) *Moreover, if T is bounded,* (2.1) *holds for u, $v\in Dom(B^J_{p,\psi})$.*

We have the following Poincaré's type inequality.

PROPOSITION 2.5. *Given Ω a bounded domain in $\mathbb{R}^N$, $J:\mathbb{R}^N\to\mathbb{R}$ a nonnegative, radial, continuous function, such that $\int_{\mathbb{R}^N} J(z)\,dz>0$, $p\ge 1$ and $\psi\in L^p(\Omega_J\setminus\overline{\Omega})$, there exists $\lambda=\lambda(J,\Omega,p)>0$ such that*

$$\lambda\int_\Omega |u(x)|^p\,dx \le \int_\Omega\int_{\Omega_J} J(x-y)|u_\psi(y)-u(x)|^p\,dy\,dx + \int_{\Omega_J\setminus\overline{\Omega}}|\psi(y)|^p\,dy \tag{2.2}$$

for all $u\in L^p(\Omega)$.

Proof. First, let us assume that there exist $r,\alpha>0$ such that $J(x)\ge\alpha$ in $B(0,r)$. Let

$$B_0 = \{x\in\Omega_J\setminus\overline{\Omega}\ :\ d(x,\Omega)\le r/2\},$$
$$B_1 = \{x\in\Omega\ :\ d(x,B_0)\le r/2\},$$
$$B_j = \left\{x\in\Omega\setminus\cup_{k=1}^{j-1}B_k\ :\ d(x,B_{j-1})\le r/2\right\},\quad j=2,3,\dots$$

Observe that we can cover Ω by a finite number of nonnull sets $\{B_j\}_{j=1}^{l_r}$. Now

$$\int_\Omega\int_{\Omega_J} J(x-y)|u_\psi(y)-u(x)|^p\,dy\,dx \ge \int_{B_j}\int_{B_{j-1}} J(x-y)|u_\psi(y)-u(x)|^p\,dy\,dx,$$

$j = 1, \dots, l_r$, and

$$\begin{aligned}
&\int_{B_j}\int_{B_{j-1}} J(x-y)|u_\psi(y)-u(x)|^p\,dy\,dx \\
&\geq \frac{1}{2^p}\int_{B_j}\int_{B_{j-1}} J(x-y)|u(x)|^p\,dy\,dx - \int_{B_j}\int_{B_{j-1}} J(x-y)|u_\psi(y)|^p\,dy\,dx \\
&= \frac{1}{2^p}\int_{B_j}\left(\int_{B_{j-1}} J(x-y)\,dy\right)|u(x)|^p\,dx - \int_{B_{j-1}}\left(\int_{B_j} J(x-y)\,dx\right)|u_\psi(y)|^p\,dy \\
&\geq \frac{1}{2^p}\min_{x\in\overline{B}_j}\int_{B_{j-1}} J(x-y)dy\int_{B_j}|u(x)|^p\,dx - \beta\int_{B_{j-1}}|u_\psi(y)|^p\,dy,
\end{aligned}$$

where $\beta = \int_{\mathbb{R}^N} J(x)dx$. Hence

$$\int_\Omega\int_{\Omega_J} J(x-y)|u_\psi(y)-u(x)|^p\,dy\,dx \geq \alpha_j\int_{B_j}|u(x)|^p\,dx - \beta\int_{B_{j-1}}|u_\psi(y)|^p\,dy,$$

where

$$\alpha_j = \frac{1}{2^p}\min_{x\in\overline{B}_j}\int_{B_{j-1}} J(x-y)dy > 0.$$

Therefore, since $u_\psi(y) = \psi(y)$ if $y \in B_0$, $u_\psi(y) = u(y)$ if $y \in B_j$, $j = 1, \dots, l_r$, $B_j \cap B_i = \emptyset$, for all $i \neq j$ and $|\Omega \setminus \cup_{j=1}^{j_r} B_j| = 0$, it is easy to see that there exists $\hat{\lambda} = \hat{\lambda}(J, \Omega, p) > 0$ such that

$$\int_\Omega |u|^p \leq \hat{\lambda}\int_\Omega\int_{\Omega_J} J(x-y)|u_\psi(y)-u(x)|^p\,dy\,dx + \hat{\lambda}\int_{B_0}|\psi|^p.$$

The proof is finished by taking $\lambda = \hat{\lambda}^{-1}$.

In the general case we have that there exist $\mathtt{a} \geq 0$ and $r, \alpha > 0$ such that

$$J(x) \geq \alpha \text{ in the annulus } A(0, \mathtt{a}, r). \tag{2.3}$$

In this case we proceed as before with the same choice of the sets B_j for $j \geq 0$ and

$$B_{-j} = \left\{x \in \Omega_J \setminus \left(\Omega \cup \cup_{k=0}^{j-1} B_{-k}\right) \;:\; d(x, B_{-j+1}) \leq r/2\right\}, \quad j = 1, 2, 3, \dots$$

Observe that for each B_j, $j \geq 1$, there exists B_{j^e} with $j^e < j$ and such that

$$|(x + A(0, \mathtt{a}, r)) \cap B_{j^e}| > 0 \quad \forall x \in \overline{B}_j. \tag{2.4}$$

With this choice of B_j and taking into account (2.3) and (2.4), as before, we obtain

$$\begin{aligned}
\int_\Omega\int_{\Omega_J} J(x-y)|u_\psi(y)-u(x)|^p\,dy\,dx &\geq \int_{B_j}\int_{B_{j^e}} J(x-y)|u_\psi(y)-u(x)|^p\,dy\,dx \\
&\geq \alpha_j\int_{B_j}|u(x)|^p\,dx - \beta\int_{B_{j^e}}|u_\psi(y)|^p\,dy,
\end{aligned}$$

$j = 1, \dots, l_r$, where

$$\alpha_j = \frac{1}{2^p}\min_{x\in\overline{B}_j}\int_{B_{j^e}} J(x-y)dy > 0$$

and $\beta = \int_{\mathbb{R}^N} J(x)dx$. And we conclude as before. ∎

Remark 2.6. Note that in [5] it is proved a Poincare's type inequality for Neumann boundary conditions, but assuming that $J(0) > 0$ (otherwise there is a counterexample). Surprisingly, for the Dirichlet problem we do not need positivity at the origin for J. This is due to the fact that for the Dirichlet problem the outside values influence the inside values.

In the next result we prove that $B^J_{p,\psi}$ is a completely accretive operator (see [14]) and verifies a range condition. In short, this means that for any $\phi \in L^p(\Omega)$ there is a unique solution of the problem $u + B^J_{p,\psi}u = \phi$ and the resolvent $(I + B^J_{p,\psi})^{-1}$ is a contraction in $L^q(\Omega)$ for all $1 \le q \le +\infty$.

THEOREM 2.7. *Let $1 < p < +\infty$. For $\psi \in L^p(\Omega_J \setminus \overline{\Omega})$, the operator $B^J_{p,\psi}$ is completely accretive and verifies the range condition*

$$L^p(\Omega) \subset Ran\left(I + B^J_{p,\psi}\right). \tag{2.5}$$

Proof. Given $u_i \in \mathrm{Dom}(B^J_{p,\psi})$, $i = 1, 2$, by the monotonicity Lemma 2.4, for any $q \in C^\infty(\mathbb{R})$, $0 \le q' \le 1$, $\mathrm{supp}(q')$ compact, $0 \notin \mathrm{supp}(q)$, we have that

$$\int_\Omega \left(B^J_{p,\psi}u_1(x) - B^J_{p,\psi}u_2(x)\right) q(u_1(x) - u_2(x))\, dx \ge 0,$$

from where it follows that $B^J_{p,\psi}$ is a completely accretive operator (see [14]).

To show that $B^J_{p,\psi}$ satisfies the range condition we have to prove that for any $\phi \in L^p(\Omega)$ there exists $u \in \mathrm{Dom}(B^J_{p,\psi})$ such that $\phi = u + B^J_{p,\psi}u$.

Assume first $p \ge 2$. Let $\phi \in L^p(\Omega)$ and set

$$K = \left\{w \in L^p(\Omega_J) \ : \ w = \psi \text{ in } \Omega_J \setminus \overline{\Omega}\right\}.$$

We consider the continuous monotone operator $A : K \to L^{p'}(\Omega_J)$ defined by

$$A(w)(x) := w(x) - \int_{\Omega_J} J(x-y)|w(y) - w(x)|^{p-2}(w(y) - w(x))\, dy.$$

A is coercive in $L^p(\Omega_J)$. In fact, by Proposition 2.5, for any $w \in K$,

$$\begin{aligned}
&\int_{\Omega_J} A(w)w = \int_{\Omega_J} w^2 - \int_{\Omega_J}\int_{\Omega_J} J(x-y)|w(y) - w(x)|^{p-2}(w(y) - w(x))\, dy w(x) dx \\
&\ge \frac{1}{2}\int_{\Omega_J}\int_{\Omega_J} J(x-y)|w(y) - w(x)|^p\, dy dx \\
&\ge \frac{1}{2}\int_{\Omega}\int_{\Omega_J} J(x-y)|w_\psi(y) - w(x)|^p\, dy dx \ge \frac{\lambda}{2}\|w\|^p_{L^p(\Omega)} - \frac{1}{2}\int_{\Omega_J\setminus\overline{\Omega}} |\psi|^p.
\end{aligned}$$

Therefore,

$$\lim_{\substack{\|w\|_{L^p(\Omega_J)} \to +\infty \\ w \in K}} \frac{\displaystyle\int_{\Omega_J} A(w)w}{\|w\|_{L^p(\Omega_J)}} = +\infty.$$

Now, since $p \ge 2$, we have the function $\phi_\psi \in L^{p'}(\Omega_J)$. Then, applying [32, Corollary III.1.8] to the operator $B(w) := A(w) - \phi_\psi$, we get there exists $w \in K$, such that

$$w(x) - \int_{\Omega_J} J(x-y)|w(y) - w(x)|^{p-2}(w(y) - w(x))\, dy = \phi_\psi(x) \qquad \text{for all } \ x \in \Omega_J.$$

Hence, $u := w_{|\Omega}$ satisfies

$$u(x) - \int_{\Omega_J} J(x-y)|u_\psi(y) - u(x)|^{p-2}(u_\psi(y) - u(x))\,dy = \phi(x) \qquad \text{for all } \ x \in \Omega,$$

and, consequently, $\phi = u + B^J_{p,\psi}u$.

Suppose now $1 < p < 2$. By the results in [5], we know that the operator

$$B^J_p u(x) = -\int_\Omega J(x-y)|u(y) - u(x)|^{p-2}(u(y) - u(x))\,dy$$

is m-accretive in $L^1(\Omega)$ and satisfies what is called property (M_0); that is, for any $q \in C^\infty(\mathbb{R})$, $0 \le q' \le 1$, $\operatorname{supp}(q')$ compact, $0 \notin \operatorname{supp}(q)$, and $(u, v) \in B^J_p$,

$$\int_\Omega q(u)v \ge 0.$$

On the other hand,

$$\varphi(x, r) = -\int_{\Omega_J \setminus \overline{\Omega}} J(x-y)|\psi(y) - r|^{p-2}(\psi(y) - r)\,dy$$

is continuous and nondecreasing in r for almost every $x \in \Omega$, and an $L^1(\Omega)$ function for all r. Therefore, by [3, Theorem 3.1], $B^J_{p,\psi}u(x) = B^J_p u(x) + \varphi(x, u(x))$ is m-accretive in $L^1(\Omega)$. □

Remark 2.8. If $\mathcal{B}^J_{p,\psi}$ denotes the closure of $B^J_{p,\psi}$ in $L^1(\Omega)$, by Theorem 2.7, we have $\mathcal{B}^J_{p,\psi}$ is m-completely accretive in $L^1(\Omega)$ (see [14]). Therefore, by the nonlinear semigroup theory (see [15] and [14]), there exists an unique mild-solution of the abstract Cauchy problem

$$\begin{cases} u'(t) + B^J_{p,\psi}u(t) = 0, & t \in (0, T), \\ u(0) = u_0, \end{cases} \tag{2.6}$$

given by the Crandall–Liggett exponential formula

$$\mathrm{e}^{-t\mathcal{B}^J_{p,\psi}}u_0 = \lim_n \left(I + \frac{t}{n}\mathcal{B}^J_{p,\psi}\right)^{-n} u_0.$$

Now, due to regularity results for mild solutions, under certain hypothesis, this mild solution is a strong solution of the abstract Cauchy problem (2.6) (see [14]) which means, for our problem $P^J_p(u_0, \psi)$, a solution in the sense of Definition 1.1.

The following result states the existence and uniqueness results for $P^J_p(u_0, \psi)$. From it, Theorem 1.2 can be derived.

THEOREM 2.9. *Assume $p > 1$. Let $T > 0$, $\psi \in L^p(\Omega_J \setminus \overline{\Omega})$, and $u_0 \in L^1(\Omega)$. Then, there exists a unique mild-solution u of* (2.6). *Moreover,*

(1) *if $u_0 \in L^p(\Omega)$, the unique mild solution u of* (2.6) *is a solution of $P^J_p(u_0, \psi)$ in the sense of Definition* 1.1. *If $1 < p \le 2$, this is true for any $u_0 \in L^1(\Omega)$ and any ψ such that $|\psi|^{p-1} \in L^1(\Omega_J \setminus \overline{\Omega})$.*

(2) *Let $u_{i0} \in L^1(\Omega)$ and u_i a solution in $[0, T]$ of $P^J_p(u_{i0})$, $i = 1, 2$. Then*

$$\int_\Omega (u_1(t) - u_2(t))^+ \le \int_\Omega (u_{10} - u_{20})^+ \quad \text{for every } t \in]0, T[.$$

Moreover, for $q \in [1, +\infty]$, if $u_{i0} \in L^q(\Omega)$, $i = 1, 2$, then

$$\|u_1(t) - u_2(t)\|_{L^q(\Omega)} \le \|u_{10} - u_{20}\|_{L^q(\Omega)} \quad \text{for every } t \in]0, T[.$$

Proof. As a consequence of Theorem 2.7 we get the existence of mild solution of (2.6) (see Remark 2.8). Now, due to the complete accretivity of $B^J_{p,\psi}$ and the range condition (2.5), by regularity results for mild solutions (see [14]), $u(t)$ is a strong solution, that is, a solution of $P^J_p(u_0, \psi)$ in the sense of Definition 1.1. Moreover, in the case $1 < p \le 2$, since $\mathrm{Dom}(B^J_{p,\psi}) = L^1(\Omega)$ and $B^J_{p,\psi}$ is closed in $L^1(\Omega) \times L^1(\Omega)$, the result holds for L^1-data. Finally, the contraction principle is a consequence of the general nonlinear semigroup theory ([15], [28]). □

2.2. Convergence to the *p*-Laplacian. Our main goal in this section is to show that the solution to the Dirichlet problem for the p-Laplacian equation $D_p(u_0, \tilde{\psi})$ can be approximated by solutions to suitable nonlocal Dirichlet problems $P^J_p(u_0, \psi)$.

Let us first recall the following result from [5]. For a function g defined in a set D, we define

$$\overline{g}(x) = \begin{cases} g(x) & \text{if } x \in D, \\ 0 & \text{otherwise,} \end{cases}$$

and we denote by χ_D the characteristic function of D.

PROPOSITION 2.10 ([5]). *Let $1 \le q < +\infty$, D a bounded domain in $\mathbb{R}^N$, $\rho : \mathbb{R}^N \to \mathbb{R}$ a nonnegative continuous radial function with compact support, nonidentically zero, and $\rho_n(x) := n^N \rho(nx)$. Let $\{f_n\}$ be a sequence of functions in $L^q(D)$ such that*

$$\int_D \int_D |f_n(y) - f_n(x)|^q \rho_n(y - x)\, dx\, dy \le M \frac{1}{n^q}. \tag{2.7}$$

1. *If $\{f_n\}$ is weakly convergent in $L^q(D)$ to f, then*
   (i) *if $q > 1$, $f \in W^{1,q}(D)$ and moreover*

$$(\rho(z))^{1/q} \chi_D \left(x + \frac{1}{n} z\right) \frac{\overline{f}_n\left(x + \frac{1}{n} z\right) - f_n(x)}{1/n} \rightharpoonup (\rho(z))^{1/q}\, z \cdot \nabla f(x)$$

weakly in $L^q(D) \times L^q(\mathbb{R}^N)$;
   (ii) *if $q = 1$, $f \in BV(D)$ and moreover*

$$\rho(z) \chi_D \left(\cdot + \frac{1}{n} z\right) \frac{\overline{f}_n\left(\cdot + \frac{1}{n} z\right) - f_n(\cdot)}{1/n} \rightharpoonup \rho(z) z \cdot Df$$

weakly as measures.

2. *Assume D is a smooth bounded domain in $\mathbb{R}^N$ and $\rho(x) \ge \rho(y)$ if $|x| \le |y|$. Then $\{f_n\}$ is relatively compact in $L^q(D)$ and, consequently, there exists a subsequence $\{f_{n_k}\}$ such that*
   (i) *if $q > 1$, $f_{n_k} \to f$ in $L^q(D)$ with $f \in W^{1,q}(D)$;*
   (ii) *If $q = 1$, $f_{n_k} \to f$ in $L^1(D)$ with $f \in BV(D)$.*

Let us now recall some results about the p-Laplacian equation

$$D_p(u_0, \tilde{\psi}) \quad \begin{cases} u_t = \Delta_p u & \text{in }]0, T[\times\Omega, \\ u = \tilde{\psi} & \text{on }]0, T[\times\partial\Omega, \\ u(0, x) = u_0(x) & \text{in } \Omega. \end{cases}$$

In the case $\tilde{\psi} \in W^{1/p',p}(\partial\Omega)$, associated to the p-Laplacian with nonhomogeneous Dirichlet boundary condition, in [2] it is defined the operator $A_{p,\psi} \subset L^1(\Omega) \times L^1(\Omega)$ as $(u,\hat{u}) \in A_{p,\tilde{\psi}}$ if and only if $\hat{u} \in L^1(\Omega)$, $u \in W^{1,p}_{\tilde{\psi}}(\Omega) := \{u \in W^{1,p}(\Omega) : u|_{\partial\Omega} = \tilde{\psi}\ \mathcal{H}^{N-1} - a.e.\ \text{on } \partial\Omega\}$ and

$$\int_\Omega |\nabla u|^{p-2}\nabla u \cdot \nabla(u-v) \le \int_\Omega \hat{u}(u-v) \quad \text{for every} \quad v \in W^{1,p}_{\tilde{\psi}}(\Omega) \cap L^\infty(\Omega).$$

This inequality is equivalent to

$$\int_\Omega |\nabla u|^{p-2}\nabla u \cdot \nabla w = \int_\Omega \hat{u}w \quad \text{for every} \quad w \in W^{1,p}_0(\Omega) \cap L^\infty(\Omega).$$

Moreover, for $\tilde{\psi} \in W^{1/p',p}(\partial\Omega) \cap L^\infty(\partial\Omega)$, $A_{p,\tilde{\psi}}$ is proved to be a completely accretive operator in $L^1(\Omega)$, satisfying the range condition $L^\infty(\Omega) \subset \mathrm{Ran}(I + A_{p,\tilde{\psi}})$, and it is easy to see that $\overline{\mathrm{D}(A_{p,\tilde{\psi}})}^{L^1(\Omega)} = L^1(\Omega)$. Therefore, its closure $\mathcal{A}_{p,\tilde{\psi}}$ in $L^1(\Omega) \times L^1(\Omega)$ is an m-completely accretive operator in $L^1(\Omega)$. Consequently, for any $u_0 \in L^1(\Omega)$ there exists a unique mild solution $u(t) = e^{-t\mathcal{A}_{p,\tilde{\psi}}}u_0$ of the abstract Cauchy problem associated to $D_p(u_0,\tilde{\psi})$, given by Crandall–Liggett's exponential formula. Due to the complete accretivity of the operator $\mathcal{A}_{p,\tilde{\psi}}$, in the case $u_0 \in D(\mathcal{A}_{p,\tilde{\psi}})$ this mild solution is the unique strong solution of problem $D_p(u_0,\tilde{\psi})$.

In the homogeneous case $\tilde{\psi} = 0$, due to the results in [13], we can say that for any $u_0 \in L^1(\Omega)$, the mild solution $u(t) = e^{-t\mathcal{A}_{p,0}}u_0$ is the unique entropy solution of problem $D_p(u_0,0)$.

For given $p > 1$ and J, we consider the rescaled kernels

$$J_{p,\varepsilon}(x) := \frac{C_{J,p}}{\varepsilon^{p+N}} J\left(\frac{x}{\varepsilon}\right), \qquad \text{where} \qquad C^{-1}_{J,p} := \frac{1}{2}\int_{\mathbb{R}^N} J(z)|z_N|^p\,dz$$

is a normalizing constant in order to obtain the p-Laplacian in the limit instead of a multiple of it.

PROPOSITION 2.11. *Let Ω be a smooth bounded domain in $\mathbb{R}^N$ and let $\tilde{\psi} \in W^{1/p',p}(\partial\Omega) \cap L^\infty(\partial\Omega)$. Let $\psi \in W^{1,p}(\Omega_J) \cap L^\infty(\Omega_J)$ such that $\psi|_{\partial\Omega} = \tilde{\psi}$. Assume $J(x) \ge J(y)$ if $|x| \le |y|$. Then, for any $\phi \in L^\infty(\Omega)$,*

$$\left(I + B^{J_{p,\varepsilon}}_{p,\psi}\right)^{-1}\phi \to \left(I + A_{p,\tilde{\psi}}\right)^{-1}\phi \quad \text{in } L^p(\Omega) \text{ as } \varepsilon \to 0. \tag{2.8}$$

Proof. We denote

$$\Omega_\varepsilon := \Omega_{J_{p,\varepsilon}} = \Omega + \mathrm{supp}(J_{p,\varepsilon}).$$

For $\varepsilon > 0$ small, let $u_\varepsilon = \left(I + B^{J_{p,\varepsilon}}_{p,\psi}\right)^{-1}\phi$. Then,

$$\int_\Omega u_\varepsilon v - \frac{C_{J,p}}{\varepsilon^{p+N}} \int_\Omega\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y) - u_\varepsilon(x)|^{p-2} \times ((u_\varepsilon)_\psi(y) - u_\varepsilon(x))\,dy\,v(x)\,dx = \int_\Omega \phi v \tag{2.9}$$

for every $v \in L^\infty(\Omega)$.

Let $M := \max\{\|\phi\|_{L^\infty(\Omega)}, \|\psi\|_{L^\infty(\Omega_J)}\}$. Taking $v = (u_\varepsilon - M)^+$ in (2.9), we get

$$\int_\Omega u_\varepsilon(x)(u_\varepsilon(x)-M)^+dx - \frac{C_{J,p}}{\varepsilon^{p+N}}\int_\Omega\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-u_\varepsilon(x)|^{p-2} \times ((u_\varepsilon)_\psi(y)-u_\varepsilon(x))\,dy(u_\varepsilon(x)-M)^+\,dx = \int_\Omega \phi(x)(u_\varepsilon(x)-M)^+\,dx.$$

Now,

$$-\frac{C_{J,p}}{\varepsilon^{p+N}}\int_\Omega\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-u_\varepsilon(x)|^{p-2}((u_\varepsilon)_\psi(y)-u_\varepsilon(x))\,dy \times (u_\varepsilon(x)-M)^+dx$$
$$= -\frac{C_{J,p}}{\varepsilon^{p+N}}\int_{\Omega_\varepsilon}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|^{p-2}((u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x))\,dy \times ((u_\varepsilon)_\psi(x)-M)^+dx$$
$$= \frac{C_{J,p}}{2\varepsilon^{p+N}}\int_{\Omega_\varepsilon}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|^{p-2}((u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)) \times (((u_\varepsilon)_\psi(y)-M)^+-((u_\varepsilon)_\psi(x)-M)^+)\,dy\,dx$$
$$\geq 0.$$

Therefore,

$$\int_\Omega u_\varepsilon(x)(u_\varepsilon(x)-M)^+dx \leq \int_\Omega \phi(x)(u_\varepsilon(x)-M)^+\,dx.$$

Consequently, we have

$$\int_\Omega (u_\varepsilon(x)-M)(u_\varepsilon(x)-M)^+dx \leq \int_\Omega (\phi(x)-M)(u_\varepsilon(x)-M)^+\,dx \leq 0,$$

and $u_\varepsilon(x) \leq M$ for almost all $x \in \Omega$. Analogously, we can obtain $-M \leq u_\varepsilon(x)$ for almost all $x \in \Omega$. Thus

$$\|u_\varepsilon\|_{L^\infty(\Omega)} \leq M \qquad \text{for all } \epsilon > 0, \tag{2.10}$$

and, therefore, there exists a sequence $\varepsilon_n \to 0$ such that

$$u_{\varepsilon_n} \rightharpoonup u \quad \text{weakly in } L^1(\Omega).$$

Taking $v = u_\varepsilon - \psi$ in (2.9) we get

$$\int_\Omega u_\varepsilon(u_\varepsilon-\psi) - \frac{C_{J,p}}{\varepsilon^{p+N}}\int_{\Omega_\varepsilon}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|^{p-2} \times ((u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x))\,dy\,((u_\varepsilon)_\psi(x)-\psi(x))\,dx = \int_\Omega \phi(u_\varepsilon-\psi). \tag{2.11}$$

Now, by (2.11) and (2.10),

$$\frac{C_{J,p}}{2\varepsilon^N}\int_{\Omega_\varepsilon}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)\frac{|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|^p}{\varepsilon^p}\,dy\,dx$$
$$\leq \frac{C_{J,p}}{2\varepsilon^N}\int_{\Omega_\varepsilon}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)\frac{|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|^{p-1}}{\varepsilon^{p-1}}\frac{|\psi(y)-\psi(x)|}{\varepsilon}dy\,dx + M_1.$$

Since $\psi \in W^{1,p}(\Omega_J)$, using Young's inequality, we obtain

$$\frac{1}{\varepsilon^N}\int_{\Omega_\varepsilon}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)\frac{|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|^p}{\varepsilon^p}\,dy\,dx \le M_2.$$

Moreover,

$$\begin{aligned}
&\int_{\Omega_J}\int_{\Omega_J}\frac{1}{\varepsilon^N}J\left(\frac{x-y}{\varepsilon}\right)\left|\frac{(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)}{\varepsilon}\right|^p dx\,dy\\
&=\int_{\Omega_\varepsilon}\int_{\Omega_\varepsilon}\frac{1}{\varepsilon^N}J\left(\frac{x-y}{\varepsilon}\right)\left|\frac{(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)}{\varepsilon}\right|^p dx\,dy\\
&\quad+2\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon}\int_{\Omega_\varepsilon}\frac{1}{\varepsilon^N}J\left(\frac{x-y}{\varepsilon}\right)\left|\frac{\psi(y)-(u_\varepsilon)_\psi(x)}{\varepsilon}\right|^p dx\,dy\\
&\quad+\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon}\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon}\frac{1}{\varepsilon^N}J\left(\frac{x-y}{\varepsilon}\right)\left|\frac{\psi(y)-\psi(x)}{\varepsilon}\right|^p dx\,dy\\
&=\int_{\Omega_\varepsilon}\int_{\Omega_\varepsilon}\frac{1}{\varepsilon^N}J\left(\frac{x-y}{\varepsilon}\right)\left|\frac{(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)}{\varepsilon}\right|^p dx\,dy\\
&\quad+2\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon}\int_{\Omega_\varepsilon\setminus\overline{\Omega}}\frac{1}{\varepsilon^N}J\left(\frac{x-y}{\varepsilon}\right)\left|\frac{\psi(y)-\psi(x)}{\varepsilon}\right|^p dx\,dy\\
&\quad+\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon}\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon}\frac{1}{\varepsilon^N}J\left(\frac{x-y}{\varepsilon}\right)\left|\frac{\psi(y)-\psi(x)}{\varepsilon}\right|^p dx\,dy \le M_3.
\end{aligned}\tag{2.12}$$

Therefore, by Proposition 2.10, there exists a subsequence, denoted as above, and $w \in W^{1,p}(\Omega_J)$ such that

$$(u_{\varepsilon_n})_\psi \to w \quad \text{strongly in } L^p(\Omega_J).$$

Hence, $w = u$ in Ω and, by [18, Proposition IX.18] and the properties of the trace, $u \in W^{1,p}_{\tilde{\psi}}(\Omega)$. Moreover, by Proposition 2.10,

$$\left(\frac{C_{J,p}}{2}J(z)\right)^{1/p}\chi_\Omega(x+\varepsilon_n z)\frac{(u_{\varepsilon_n})_\psi(x+\varepsilon_n z)-(u_{\varepsilon_n})_\psi(x)}{\varepsilon_n} \rightharpoonup \left(\frac{C_{J,p}}{2}J(z)\right)^{1/p} z\cdot\nabla u(x)\tag{2.13}$$

weakly in $L^p(\Omega)\times L^p(\mathbb{R}^N)$ (observe that $\chi_\Omega(x+\varepsilon_n z)(u_{\varepsilon_n})_\psi(x+\varepsilon_n z) = \chi_\Omega(x+\varepsilon_n z)\overline{u}_{\varepsilon_n}(x+\varepsilon_n z)$). We can also assume that

$$\begin{aligned}
(J(z))^{1/p'}&\left|\frac{(u_{\varepsilon_n})_\psi(x+\varepsilon_n z)-(u_{\varepsilon_n})_\psi(x)}{\varepsilon_n}\right|^{p-2}\chi_{\Omega_{\varepsilon_n}}(x+\varepsilon_n z)\\
&\times\frac{(u_{\varepsilon_n})_\psi(x+\varepsilon_n z)-(u_{\varepsilon_n})_\psi(x)}{\varepsilon_n} \rightharpoonup (J(z))^{1/p'}\chi(x,z)
\end{aligned}$$

weakly in $L^{p'}(\Omega_J)\times L^{p'}(\mathbb{R}^N)$, for some function $\chi \in L^{p'}(\Omega_J)\times L^{p'}(\mathbb{R}^N)$.

Passing to the limit in (2.9) for $\varepsilon = \varepsilon_n$, we get

$$\int_\Omega uv + \int_{\mathbb{R}^N}\int_\Omega \frac{C_{J,p}}{2}J(z)\chi(x,z)\,z\cdot\nabla v(x)\,dx\,dz = \int_\Omega \phi v\tag{2.14}$$

for every v smooth with support in Ω and by approximation for every $v \in W^{1,p}_0(\Omega)$.

Finally, working as in Proposition 3.3. of [5], we can prove

$$\int_{\mathbb{R}^N}\int_\Omega \frac{C_{J,p}}{2} J(z)\chi(x,z)z\cdot\nabla v(x)\,dx\,dz = \int_\Omega |\nabla u|^{p-2}\nabla u\cdot\nabla v \tag{2.15}$$

and the proof is finished. □

From the above Proposition, by the standard results of the nonlinear semigroup theory (see [19] or [15]), we obtain Theorem 1.3.

3. The nonlocal total variation flow. The case $p = 1$.

3.1. Existence of solutions for the nonlocal problem. This section deals with the existence and uniqueness of solutions for the nonlocal 1-Laplacian problem with Dirichlet boundary condition,

$$P_1^J(u_0,\psi)\quad \begin{cases} u_t(t,x) = \displaystyle\int_\Omega J(x-y)\frac{u(t,y)-u(t,x)}{|u(t,y)-u(t,x)|}\,dy. \\ \qquad\qquad + \displaystyle\int_{\Omega_J\setminus\overline{\Omega}} J(x-y)\frac{\psi(y)-u(t,x)}{|\psi(y)-u(t,x)|}\,dy, \qquad x\in\Omega. \\ u(0,x) = u_0(x). \end{cases}$$

As in the case $p > 1$, to prove existence and uniqueness of solutions of $P_1^J(u_0,\psi)$ we use the Nonlinear Semigroup Theory, so we start by introducing the following operator in $L^1(\Omega)$.

DEFINITION 3.1. *Given $\psi \in L^1(\Omega_J\setminus\overline{\Omega})$, we define the operator $B_{1,\psi}^J$ in $L^1(\Omega)\times L^1(\Omega)$ by $\hat{u}\in B_{1,\psi}^J u$ if and only if $u,\hat{u}\in L^1(\Omega)$, there exists $g\in L^\infty(\Omega_J\times\Omega_J)$, $g(x,y) = -g(y,x)$ for almost all $(x,y)\in\Omega_J\times\Omega_J$, $\|g\|_\infty\le 1$,*

$$\hat{u}(x) = -\int_{\Omega_J} J(x-y)g(x,y)\,dy \quad \text{a.e. } x\in\Omega, \tag{3.1}$$

and

$$J(x-y)g(x,y)\in J(x-y)\,\mathrm{sign}(u(y)-u(x)) \quad \text{a.e. } (x,y)\in\Omega\times\Omega, \tag{3.2}$$

$$J(x-y)g(x,y)\in J(x-y)\,\mathrm{sign}(\psi(y)-u(x)) \quad \text{a.e. } (x,y)\in\Omega\times(\Omega_J\setminus\overline{\Omega}). \tag{3.3}$$

Remark 3.2. Observe that

(i) we can rewrite (3.2) + (3.3) as

$$J(x-y)g(x,y)\in J(x-y)\,\mathrm{sign}(u_\psi(y)-u(x)) \quad \text{a.e. } (x,y)\in\Omega\times\Omega_J, \tag{3.4}$$

where we set as above, and overall the section,

$$u_\psi(x) := \begin{cases} u(x) & \text{if } x\in\Omega, \\ \psi(x) & \text{if } x\in\Omega_J\setminus\overline{\Omega}, \\ 0 & \text{if } x\notin\Omega_J. \end{cases}$$

(ii) It holds $L^1(\Omega) = \mathrm{Dom}(B_{1,\psi}^J)$ and $B_{1,\psi}^J$ is closed in $L^1(\Omega)\times L^1(\Omega)$.

(iii) It is not difficult to see that, if $g\in L^\infty(\Omega_J\times\Omega_J)$, $g(x,y) = -g(y,x)$ for almost all $(x,y)\in\Omega_J\times\Omega_J$, $\|g\|_\infty\le 1$,

$$J(x-y)g(x,y)\in J(x-y)\ \ \mathrm{sign}(z(y)-z(x)) \quad \text{a.e. } (x,y)\in\Omega_J\times\Omega_J$$

is equivalent to

$$-\int_{\Omega_J}\int_{\Omega_J} J(x-y)g(x,y)\,dy\,z(x)\,dx = \frac{1}{2}\int_{\Omega_J}\int_{\Omega_J} J(x-y)|z(y)-z(x)|\,dy\,dx.$$

THEOREM 3.3. *Let $\psi \in L^1(\Omega_J \setminus \overline{\Omega})$. The operator $B^J_{1,\psi}$ is completely accretive and satisfies the range condition*

$$L^\infty(\Omega) \subset Ran\left(I + B^J_{1,\psi}\right).$$

Proof. Let $\hat{u}_i \in B^J_{1,\psi}u_i$, $i = 1, 2$, and set $u_i(y) = \psi(y)$ in $\Omega_J \setminus \overline{\Omega}$. Then, there exist $g_i \in L^\infty(\Omega_J \times \Omega_J)$, $\|g_i\|_\infty \le 1$, $g_i(x,y) = -g_i(y,x)$, $J(x-y)g_i(x,y) \in J(x-y)\text{sign}(u_i(y)-u_i(x))$ for almost all $(x,y) \in \Omega \times \Omega_J$, such that

$$\hat{u}_i(x) = -\int_{\Omega_J} J(x-y)g_i(x,y)\,dy \quad a.e.\ x \in \Omega$$

for $i = 1, 2$. Given $q \in C^\infty(\mathbb{R})$, $0 \le q' \le 1$, $\text{supp}(q')$ compact, $0 \notin \text{supp}(q)$, we have

$$\begin{aligned}
&\int_\Omega (\hat{u}_1(x) - \hat{u}_2(x))q(u_1(x)-u_2(x))\,dx \\
&= \frac{1}{2}\int_\Omega\int_\Omega J(x-y)(g_1(x,y)-g_2(x,y))\left(q(u_1(y)-u_2(y)) - q(u_1(x)-u_2(x))\right)\,dxdy \\
&\quad - \int_\Omega\int_{\Omega_J\setminus\overline{\Omega}} J(x-y)(g_1(x,y)-g_2(x,y)\left(q(u_1(x)-u_2(x))\right)\,dx\,dy \\
&\ge \frac{1}{2}\int_\Omega\int_\Omega J(x-y)(g_1(x,y)-g_2(x,y))\left(q(u_1(y)-u_2(y)) - q(u_1(x)-u_2(x))\right)\,dxdy.
\end{aligned}$$

Now, by the mean value theorem

$$\begin{aligned}
&J(x-y)(g_1(x,y)-g_2(x,y))\left[q(u_1(y)-u_2(y)) - q(u_1(x)-u_2(x))\right] \\
&= J(x-y)(g_1(x,y)-g_2(x,y))q'(\xi)\left[(u_1(y)-u_2(y)) - (u_1(x)-u_2(x))\right] \\
&= J(x-y)q'(\xi)\left[g_1(x,y)(u_1(y)-u_1(x)) - g_1(x,y)(u_2(y)-u_2(x))\right] \\
&\qquad -J(x-y)q'(\xi)\left[g_2(x,y)(u_1(y)-u_1(x)) - g_1(x,y)(u_2(y)-u_2(x))\right] \ge 0,
\end{aligned}$$

since

$$J(x-y)g_i(x,y)(u_i(y)-u_i(x)) = J(x-y)|u_i(y)-u_i(x)|, \quad i = 1, 2,$$

and

$$-J(x-y)g_i(x,y)(u_j(y)-u_j(x)) \ge -J(x-y)|u_j(y)-u_j(x)|, \quad i \ne j.$$

Hence

$$\int_\Omega (\hat{u}_1(x) - \hat{u}_2(x))q(u_1(x)-u_2(x))\,dx \ge 0,$$

from which it follows that $B^J_{1,\psi}$ is a completely accretive operator.

To show that $B^J_{1,\psi}$ satisfies the range condition, let us see that for any $\phi \in L^\infty(\Omega)$,

$$\lim_{p\to 1+}\left(I + B^J_{p,\psi}\right)^{-1}\phi = \left(I + B^J_{1,\psi}\right)^{-1}\phi \quad \text{weakly in } L^1(\Omega).$$

We prove this in several steps.

Step 1. Let us first suppose that $\psi \in L^\infty(\Omega_J \setminus \overline{\Omega})$. For $1 < p < +\infty$, by Theorem 2.7, there is u_p such that $u_p = (I + B^J_{p,\psi})^{-1}\phi$, that is,

$$u_p(x) - \int_{\Omega_J} J(x-y)\,|(u_p)_\psi(y) - u_p(x)|^{p-2}((u_p)_\psi(y) - u_p(x))\,dy = \phi(x), \tag{3.5}$$

a.e. $x \in \Omega$. It is easy to see that $\|u_p\|_\infty \le \sup\{\|\phi\|_\infty, \|\psi\|_\infty\}$. Therefore, there exists a sequence $p_n \to 1$ such that

$$u_{p_n} \rightharpoonup u \quad \text{weakly in } L^2(\Omega).$$

On the other hand, we also have

$$\frac{1}{2}\int_{\Omega_J}\int_{\Omega_J} J(x-y)\,|(u_{p_n})_\psi(y) - (u_{p_n})_\psi(x)|^{p_n}\,dy\,dx \le M_2, \qquad \forall\, n \in \mathbb{N}.$$

Consequently, for any measurable subset $E \subset \Omega_J \times \Omega_J$, we have

$$\begin{aligned}\left|\int\int_E J(x-y)|(u_{p_n})_\psi(y) - (u_{p_n})_\psi(x)|^{p_n-2}\,((u_{p_n}(y))_\psi - (u_{p_n})_\psi(x))\right| \\ \le \int\int_E J(x-y)|(u_{p_n})_\psi(y) - (u_{p_n})_\psi(x)|^{p_n-1} \le M_2|E|^{\frac{1}{p_n}}.\end{aligned}$$

Hence, by the Dunford–Pettis theorem we may assume that there exists $g(x,y)$ such that

$$J(x-y)|(u_{p_n})_\psi(y) - (u_{p_n})_\psi(x)|^{p_n-2}\,((u_{p_n})_\psi(y) - (u_{p_n})_\psi(x)) \rightharpoonup J(x-y)g(x,y),$$

weakly in $L^1(\Omega_J \times \Omega_J)$, $g(x,y) = -g(y,x)$ for almost all $(x,y) \in \Omega_J \times \Omega_J$, and $\|g\|_\infty \le 1$.

Therefore, by (3.5),

$$u(x) - \int_{\Omega_J} J(x-y)g(x,y)\,dy = \phi(x) \qquad \text{a.e. } x \in \Omega. \tag{3.6}$$

Then, to finish the proof it is enough to show that

$$\begin{aligned}-\int_{\Omega_J}\int_{\Omega_J} J(x-y)g(x,y)\,dy\,u_\psi(x)\,dx \\ = \frac{1}{2}\int_{\Omega_J}\int_{\Omega_J} J(x-y)|u_\psi(y) - u_\psi(x)|\,dy\,dx.\end{aligned} \tag{3.7}$$

In fact, by (3.5) and (3.6),

$$\begin{aligned}
&\frac{1}{2}\int_{\Omega_J}\int_{\Omega_J} J(x-y)\,|(u_{p_n})_\psi(y)-(u_{p_n})_\psi(x)|^{p_n}\,dy\,dx = \int_\Omega \phi u_{p_n} - \int_\Omega u_{p_n}u_{p_n}\\
&-\int_{\Omega_J\setminus\overline{\Omega}}\int_{\Omega_J} J(x-y)\,|\psi(y)-(u_{p_n})_\psi(x)|^{p_n-2}\,(\psi(y)-(u_{p_n})_\psi(x))\,dy\,\psi(x)\,dx\\
&=\int_\Omega \phi u - \int_\Omega uu - \int_\Omega \phi(u-u_{p_n}) + \int_\Omega 2u(u-u_{p_n}) - \int_\Omega (u-u_{p_n})(u-u_{p_n})\\
&\qquad-\int_{\Omega_J\setminus\overline{\Omega}}\int_{\Omega_J} J(x-y)\,|\psi(y)-(u_{p_n})_\psi(x)|^{p_n-2}\,(\psi(y)-(u_{p_n})_\psi(x))\,dy\,\psi(x)\,dx\\
&\le -\int_{\Omega_J}\int_{\Omega_J} J(x-y)g(x,y)\,dy\,u(x)\,dx - \int_\Omega \phi(u-u_{p_n}) + \int_\Omega 2u(u-u_{p_n})\\
&\qquad+\int_{\Omega_J\setminus\overline{\Omega}}\int_{\Omega_J} J(x-y)g(x,y)\,dy\,\psi(x)\,dx\\
&\qquad-\int_{\Omega_J\setminus\overline{\Omega}}\int_{\Omega_J} J(x-y)\,|\psi(y)-(u_{p_n})_\psi(x)|^{p_n-2}\,(\psi(y)-(u_{p_n})_\psi(x))\,dy\,\psi(x)\,dx,
\end{aligned}$$

and so,

$$\begin{aligned}
\limsup_{n\to+\infty}\frac{1}{2}\int_{\Omega_J}\int_{\Omega_J} J(x-y)\,|u_{p_n}(y)-u_{p_n}(x)|^{p_n}\,dy\,dx\\
\le -\int_\Omega\int_\Omega J(x-y)g(x,y)\,dy\,u(x)\,dx.
\end{aligned}$$

Now, by the monotonicity Lemma 2.4, for all $\rho\in L^\infty(\Omega)$,

$$\begin{aligned}
&-\int_{\Omega_J}\int_{\Omega_J} J(x-y)|\rho(y)-\rho(x)|^{p_n-2}(\rho(y)-\rho(x))\,dy\,(u_{p_n}(x)-\rho(x))\,dx\\
&\le -\int_{\Omega_J}\int_{\Omega_J} J(x-y)|u_{p_n}(y)-u_{p_n}(x)|^{p_n-2}(u_{p_n}(y)-u_{p_n}(x))dy(u_{p_n}(x)-\rho(x))dx.
\end{aligned}$$

Taking limits,

$$\begin{aligned}
-\int_{\Omega_J}\int_{\Omega_J} J(x-y)\,\mathrm{sign}_0(\rho(y)-\rho(x))\,dy\,(u(x)-\rho(x))\,dx\\
\le -\int_{\Omega_J}\int_{\Omega_J} J(x-y)g(x,y)\,dy\,(u(x)-\rho(x))\,dx.
\end{aligned}$$

Taking now, $\rho = u\pm\lambda u$, $\lambda>0$, and letting $\lambda\to 0$, we get (3.7), and the proof is finished for this class of data.

Step 2. Let us now suppose that ψ^- is bounded. Let $\psi_n = T_n(\psi)$, n large enough such that $\psi_n^- = \psi^-$. Then, $\{\psi_n\}$ is a nondecreasing sequence that converges in L^1 to ψ. By *Step* 1, there exists $u_n = (I+B^J_{1,\psi_n})^{-1}\phi$, that is, there exists $g_n\in L^\infty(\Omega_J\times\Omega_J)$, $g_n(x,y) = -g_n(y,x)$ for almost all $(x,y)\in\Omega_J\times\Omega_J$, $\|g_n\|_\infty\le 1$,

$$u_n(x) - \int_{\Omega_J} J(x-y)g_n(x,y)\,dy = \phi(x) \qquad \text{a.e. } x\in\Omega \tag{3.8}$$

and

$$\begin{aligned}
&-\int_{\Omega_J}\int_{\Omega_J} J(x-y)g_n(x,y)\,dy\,(u_n)_{\psi_n}(x)\,dx\\
&=\frac{1}{2}\int_{\Omega_J}\int_{\Omega_J} J(x-y)|(u_n)_{\psi_n}(y)-(u_n)_{\psi_n}(x)|\,dy\,dx.
\end{aligned} \tag{3.9}$$

Therefore, by monotonicity,

$$\int_{\Omega_J}\int_{\Omega_J}\left((u_n)_{\psi_n}-(u_{n+1})_{\psi_{n+1}}\right)\left((u_n)_{\psi_n}-(u_{n+1})_{\psi_{n+1}}\right)^+\le 0,$$

which implies $u_n\le u_{n+1}$. Since $\{u_n\}$ is bounded in L^∞ we have $\{u_n\}$ converges to a function u in L^2. On the other hand, we can suppose that $J(x-y)g_n(x,y)$ converges weakly in L^2 to $J(x-y)g(x,y)$, $g(x,y)=-g(y,x)$ for almost all $(x,y)\in\Omega_J\times\Omega_J$, and $\|g\|_\infty\le 1$. Hence, passing to the limit in (3.8) and (3.9) we obtain $u=(I+B^J_{1,\psi})^{-1}\phi$.

Step 3. For a general $\psi\in L^1(\Omega_J\setminus\overline{\Omega})$, apply *Step* 2 to $\psi_n=\sup\{\psi,-n\}$ and use monotonicity in a similar way to finish the proof. ∎

Proof of Theorem 1.5. As a consequence of the above results, we have that the abstract Cauchy problem

$$\begin{cases}u'(t)+B^J_{1,\psi}u(t)\ni 0, & t\in(0,T),\\ u(0)=u_0\end{cases}\tag{3.10}$$

has a unique mild solution u for every initial datum $u_0\in L^1(\Omega)$ and $T>0$ (see [15]). Moreover, due to the complete accretivity of the operator $B^J_{1,\psi}$, the mild solution of (3.10) is a strong solution ([14]). Consequently, the proof is concluded. ∎

3.2. Convergence to the total variation flow. Let us start recalling some results from [1] (see also [2]) about the Dirichlet problem for the total variational flow, that is,

$$D_1(u_0,\tilde\psi)\quad\begin{cases}u_t=\operatorname{div}\left(\frac{Du}{|Du|}\right) & \text{in }]0,T[\times\Omega,\\ u=\tilde\psi & \text{on }]0,T[\times\partial\Omega,\\ u(0,x)=u_0(x) & \text{in } \Omega,\end{cases}$$

with $\tilde\psi\in L^1(\partial\Omega)$.

THEOREM 3.4 ([1]). *Let $T>0$ and $\tilde\psi\in L^1(\partial\Omega)$. For any $u_0\in L^1(\Omega)$ $(L^2(\Omega))$ there exists a unique entropy (strong) solution $u(t)$ of $D_1(u_0,\tilde\psi)$.*

Associated to $-\operatorname{div}(\frac{Du}{|Du|})$ with Dirichlet boundary conditions, in [1] it is defined the operator $\mathcal{A}_{\tilde\psi}\subset L^1(\Omega)\times L^1(\Omega)$ as follows: $(u,v)\in\mathcal{A}_{\tilde\psi}$ if and only if $u,v\in L^1(\Omega)$, $q(u)\in BV(\Omega)$ for all $q\in\mathcal{P}:=\{q\in W^{1,\infty}(\mathbb{R}):q'\ge 0,\operatorname{supp}(q')\text{ is compact}\}$, and there exists $\zeta\in X(\Omega)$ (where $X(\Omega)$ is defined by (1.4)), with $\|\zeta\|_\infty\le 1$, $v=-\operatorname{div}(\zeta)$ in $\mathcal{D}'(\Omega)$ such that

$$\int_\Omega (w-q(u))v\le\int_\Omega(\zeta,Dw)-|Dq(u)|+\int_{\partial\Omega}|w-q\left(\tilde\psi\right)|-\int_{\partial\Omega}|q(u)-q\left(\tilde\psi\right)|\tag{3.11}$$

for every $w\in BV(\Omega)\cap L^\infty(\Omega)$ and every $q\in\mathcal{P}$. Also in [1] it is proved that the following assertions are equivalent:

(a) $(u,v)\in\mathcal{A}_{\tilde\psi}$,

(b) $u,v\in L^1(\Omega)$, $q(u)\in BV(\Omega)$ for all $q\in\mathcal{P}$, and there exists $\zeta\in X(\Omega)$, with $\|\zeta\|_\infty\le 1$, $v=-\operatorname{div}(\zeta)$ in $\mathcal{D}'(\Omega)$ such that

$$\int_\Omega(\zeta,Dq(u))=|Dq(u)|\qquad\forall\ q\in\mathcal{P},\tag{3.12}$$

$$[\zeta,\nu]\in\operatorname{sign}\left(q\left(\tilde\psi\right)-q(u)\right)\quad\mathcal{H}^{N-1}-a.e.\ \text{ on }\ \partial\Omega,\ \ \forall\ q\in\mathcal{P}.\tag{3.13}$$

Moreover, it is shown that $\mathcal{A}_{\tilde{\psi}}$ is an m-completely accretive operator in $L^1(\Omega)$ with dense domain and that for any $u_0 \in L^1(\Omega)$, the unique entropy solution $u(t)$ of problem $D_1(u_0, \tilde{\psi})$ coincides with the unique mild solution $e^{-t\mathcal{A}_{\tilde{\psi}}}u_0$ given by Crandall–Liggett's exponential formula.

Now, given J, we consider the rescaled kernels

$$J_{1,\varepsilon}(x) := \frac{C_{J,1}}{\varepsilon^{1+N}} J\left(\frac{x}{\varepsilon}\right), \qquad \text{with} \quad C_{J,1}^{-1} := \frac{1}{2}\int_{\mathbb{R}^N} J(z)|z_N|\,dz,$$

that is, a normalizing constant in order to obtain the 1-Laplacian in the limit instead of a multiple of it.

PROPOSITION 3.5. *Let Ω be a smooth bounded domain in $\mathbb{R}^N$ and $\tilde{\psi} \in L^\infty(\partial\Omega)$. Let $\psi \in W^{1,1}(\Omega_J \setminus \overline{\Omega}) \cap L^\infty(\Omega_J \setminus \overline{\Omega})$ such that $\psi|_{\partial\Omega} = \tilde{\psi}$. Assume $J(x) \geq J(y)$ if $|x| \leq |y|$. Then, for any $\phi \in L^\infty(\Omega)$,*

$$\left(I + B_{1,\psi}^{J_{1,\varepsilon}}\right)^{-1}\phi \to \left(I + \mathcal{A}_{\tilde{\psi}}\right)^{-1}\phi \quad \textit{strongly in } L^1(\Omega) \textit{ as } \varepsilon \to 0. \tag{3.14}$$

Proof. Given $\varepsilon > 0$ small, we set $u_\varepsilon = (I + B_{1,\psi}^{J_{1,\varepsilon}})^{-1}\phi$ and denote

$$\Omega_\varepsilon := \Omega_{J_{1,\varepsilon}} = \Omega + \operatorname{supp}(J_{1,\varepsilon}).$$

Then, there exists $g_\epsilon \in L^\infty(\Omega_\varepsilon \times \Omega_\varepsilon)$, $g_\varepsilon(x,y) = -g_\varepsilon(y,x)$ for almost all $(x,y) \in \Omega_\varepsilon \times \Omega_\varepsilon$, $\|g_\varepsilon\|_\infty \leq 1$, such that

$$J\left(\frac{x-y}{\varepsilon}\right) g_\varepsilon(x,y) \in J\left(\frac{x-y}{\varepsilon}\right) \operatorname{sign}(u_\varepsilon(y) - u_\varepsilon(x)) \qquad \text{a.e. } (x,y) \in \Omega \times \Omega,$$

$$J\left(\frac{x-y}{\varepsilon}\right) g_\varepsilon(x,y) \in J\left(\frac{x-y}{\varepsilon}\right) \operatorname{sign}(\tilde{\psi}(y) - u_\varepsilon(x)) \qquad \text{a.e. } (x,y) \in \Omega \times (\Omega_\epsilon \setminus \overline{\Omega})$$

and

$$u_\varepsilon(x) - \frac{C_{J,1}}{\varepsilon^{1+N}}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right) g_\varepsilon(x,y)\,dy = \phi(x) \quad \textit{a.e. } x \in \Omega. \tag{3.15}$$

Therefore, for $v \in L^\infty(\Omega_J)$, we can write

$$\begin{aligned}\int_\Omega u_\varepsilon(x)v(x)\,dx - \frac{C_{J,1}}{\varepsilon^{1+N}}\int_\Omega\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right) g_\varepsilon(x,y)v(x)\,dy\,dx \\ = \int_\Omega \phi(x)v(x)\,dx.\end{aligned} \tag{3.16}$$

Observe that we can extend g_ε to a function in $L^\infty(\Omega_J \times \Omega_J)$, $g_\varepsilon(x,y) = -g_\varepsilon(y,x)$ for almost all $(x,y) \in \Omega_J \times \Omega_J$, $\|g_\varepsilon\|_{L^\infty(\Omega_J)} \leq 1$, such that

$$J\left(\frac{x-y}{\varepsilon}\right) g_\varepsilon(x,y) \in J\left(\frac{x-y}{\varepsilon}\right) \operatorname{sign}((u_\varepsilon)_\psi(y) - (u_\varepsilon)_\psi(x)) \quad \text{a.e. } (x,y) \in \Omega_J \times \Omega_J.$$

Let $M := \max\{\|\phi\|_{L^\infty(\Omega)}, \|\psi\|_{L^\infty(\Omega_J \setminus \overline{\Omega})}\}$. Taking $v = (u_\varepsilon - M)^+$ in (3.16), we get

$$\begin{aligned}&\int_\Omega u_\varepsilon(x)(u_\varepsilon(x) - M)^+ dx - \frac{C_{J,1}}{\varepsilon^{1+N}}\int_\Omega\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right) g_\varepsilon(x,y)(u_\varepsilon(x) - M)^+\,dy\,dx \\ &= \int_\Omega \phi(x)(u_\varepsilon(x) - M)^+\,dx.\end{aligned}$$

Now

$$
\begin{aligned}
&-\frac{C_{J,1}}{\varepsilon^{1+N}}\int_{\Omega_\varepsilon}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right) g_\varepsilon(x,y)((u_\varepsilon)_\psi(x)-M)^+\,dy\,dx\\
&=\frac{C_{J,1}}{2\varepsilon^{1+N}}\int_{\Omega_\varepsilon}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right) g_\varepsilon(x,y)(((u_\varepsilon)_\psi(y)-M)^+-\left((u_\varepsilon)_\psi(x)-M\right)^+)\,dy\,dx\\
&\geq 0.
\end{aligned}
$$

Hence, we get

$$\int_\Omega u_\varepsilon(x)(u_\varepsilon(x)-M)^+dx\leq\int_\Omega \phi(x)(u_\varepsilon(x)-M)^+dx.$$

Consequently,

$$0\leq\int_\Omega (u_\varepsilon(x)-M)(u_\varepsilon(x)-M)^+dx\leq\int_\Omega(\phi(x)-M)(u_\varepsilon(x)-M)^+dx\leq 0,$$

and we deduce $u_\varepsilon(x)\leq M$ for almost all $x\in\Omega$. Analogously, we can obtain $-M\leq u_\varepsilon(x)$ for almost all $x\in\Omega$. Thus

$$\|u_\varepsilon\|_{L^\infty(\Omega)}\leq M\qquad\text{for all }\epsilon>0; \tag{3.17}$$

from here, we can assume there exists a sequence $\varepsilon_n\to 0$ such that

$$u_{\varepsilon_n}\rightharpoonup u\quad\text{weakly in } L^1(\Omega).$$

Taking $v=u_\varepsilon$ in (3.16), we have

$$\int_\Omega u_\varepsilon(x)u_\varepsilon(x)\,dx-\frac{C_{J,1}}{\varepsilon^{1+N}}\int_\Omega\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right) g_\varepsilon(x,y)\,dyu_\varepsilon(x)\,dx=\int_\Omega\phi(x)u_\varepsilon(x)dx. \tag{3.18}$$

Observe that

$$
\begin{aligned}
&-\frac{C_{J,1}}{\varepsilon^{1+N}}\int_\Omega\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right) g_\varepsilon(x,y)dyu_\varepsilon(x)\,dx\\
&=-\frac{C_{J,1}}{\varepsilon^{1+N}}\int_{\Omega_\varepsilon}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right) g_\varepsilon(x,y)dy(u_\varepsilon)_\psi(x)\,dx\\
&\quad+\frac{C_{J,1}}{\varepsilon^{1+N}}\int_{\Omega_\varepsilon\setminus\overline{\Omega}}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right) g_\varepsilon(x,y)dy\psi(x)\,dx.
\end{aligned}
$$

Then

$$
\begin{aligned}
&\left|\frac{C_{J,1}}{\varepsilon^{1+N}}\int_{\Omega_\varepsilon\setminus\overline{\Omega}}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right) g_\varepsilon(x,y)dy\psi(x)dx\right|\\
&\leq\frac{C_{J,1}}{\varepsilon^{1+N}}\int_{\Omega_\varepsilon\setminus\overline{\Omega}}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right) dy|\psi(x)|dx\\
&\leq\frac{C_{J,1}}{\varepsilon}M\int_{\Omega_\varepsilon\setminus\overline{\Omega}}\left(\frac{1}{\varepsilon^N}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right) dy\right)dx\\
&\leq\frac{C_{J,1}}{\varepsilon}M|\Omega_\varepsilon\setminus\Omega|\leq M_1.
\end{aligned}
$$

On the other hand,

$$-\frac{C_{J,1}}{\varepsilon^{1+N}}\int_{\Omega_\varepsilon}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right) g_\varepsilon(x,y)dy(u_\varepsilon)_\psi(x)dx$$
$$=\frac{C_{J,1}}{2\varepsilon^{1+N}}\int_{\Omega_\varepsilon}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|\,dy\,dx.$$

Consequently, from (3.17) and (3.18), it follows that

$$\frac{C_{J,1}}{2\varepsilon^{1+N}}\int_{\Omega_\varepsilon}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|\,dy\,dx\le M_2. \tag{3.19}$$

Let us compute,

$$\begin{aligned}
&\frac{C_{J,1}}{2\varepsilon^{1+N}}\int_{\Omega_J}\int_{\Omega_J} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|\,dy\,dx\\
&=\frac{C_{J,1}}{2\varepsilon^{1+N}}\int_{\Omega_\varepsilon}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|\,dy\,dx\\
&\quad+\frac{C_{J,1}}{2\varepsilon^{1+N}}\int_{\Omega_\varepsilon}\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|\,dy\,dx\\
&\quad+\frac{C_{J,1}}{2\varepsilon^{1+N}}\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|\,dy\,dx\\
&\quad+\frac{C_{J,1}}{2\varepsilon^{1+N}}\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon}\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|\,dy\,dx.
\end{aligned}$$

Now, since $\psi\in W^{1,1}(\Omega_J\setminus\overline{\Omega})$, we get

$$\frac{C_{J,1}}{2\varepsilon^{1+N}}\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon}\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|\,dy\,dx$$
$$=\frac{C_{J,1}}{2\varepsilon^{N}}\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon}\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)\frac{|\psi(y)-\psi(x)|}{\varepsilon}dydx\le M_3.$$

On the other hand, we have

$$\begin{aligned}
&\frac{C_{J,1}}{2\varepsilon^{1+N}}\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|\,dy\,dx\\
&=\frac{C_{J,1}}{2\varepsilon^{N}}\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon}\int_{\Omega_\varepsilon\setminus\overline{\Omega}} J\left(\frac{x-y}{\varepsilon}\right)\frac{|\psi(y)-\psi(x)|}{\varepsilon}\,dy\,dx\\
&\le M_4\frac{C_{J,1}}{2}\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon}\left(\frac{1}{\varepsilon^N}\int_{\Omega_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)dy\right)dx\le M_5.
\end{aligned}$$

With similar arguments we obtain

$$\frac{C_{J,1}}{2\varepsilon^{1+N}}\int_{\Omega_\varepsilon}\int_{\Omega_J\setminus\overline{\Omega}_\varepsilon} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|\,dy\,dx\le M_6.$$

Therefore,

$$\frac{C_{J,1}}{2\varepsilon^{1+N}}\int_{\Omega_J}\int_{\Omega_J} J\left(\frac{x-y}{\varepsilon}\right)|(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)|\,dy\,dx\le M_7. \tag{3.20}$$

In particular, we get

$$\int_{\Omega_J}\int_{\Omega_J}\frac{1}{2}\frac{C_{J,1}}{\varepsilon^N}J\left(\frac{x-y}{\varepsilon}\right)\left|\frac{(u_\varepsilon)_\psi(y)-(u_\varepsilon)_\psi(x)}{\varepsilon}\right|dx\,dy\le M_7\qquad\forall\, n\in\mathbb{N}.$$

By Proposition 2.10, there exists a subsequence, denote equal, and $w\in BV(\Omega_J)$ such that

$$(u_{\varepsilon_n})_\psi\to w\qquad\text{strongly in } L^1(\Omega_J)$$

and

$$\frac{C_{J,1}}{2}J(z)\chi_\Omega(\cdot+\varepsilon_n z)\frac{(u_{\varepsilon_n})_\psi(\cdot+\varepsilon_n z)-(u_{\varepsilon_n})_\psi(\cdot)}{\varepsilon_n}\rightharpoonup\frac{C_{J,1}}{2}J(z)z\cdot Dw \tag{3.21}$$

weakly as measures. Hence, it is easy to obtain that

$$w(x)=u_\psi(x)=\begin{cases}u(x) & \text{in } x\in\Omega,\\ \psi(x) & \text{in } x\in\Omega_J\setminus\overline{\Omega},\end{cases}$$

and $u\in BV(\Omega)$.

Moreover, we can also assume that

$$J(z)\chi_{\Omega_J}(x+\varepsilon_n z)\overline{g}_{\varepsilon_n}(x,x+\varepsilon_n z)\rightharpoonup\Lambda(x,z) \tag{3.22}$$

weakly* in $L^\infty(\Omega_J)\times L^\infty(\mathbb{R}^N)$ for some function $\Lambda\in L^\infty(\Omega_J)\times L^\infty(\mathbb{R}^N)$, $\Lambda(x,z)\le J(z)$ almost everywhere in $\Omega_J\times\mathbb{R}^N$. Taking in (3.16) $v\in\mathcal{D}(\Omega)$, we get for $\varepsilon=\varepsilon_n$ small enough

$$\begin{aligned}\int_\Omega u_{\varepsilon_n}(x)v(x)dx-\frac{C_{J,1}}{{\varepsilon_n}^{1+N}}\int_\Omega\int_\Omega J\left(\frac{x-y}{\varepsilon_n}\right)g_{\varepsilon_n}(x,y)v(x)\,dy\,dx\\ =\int_\Omega\phi(x)v(x)\,dx.\end{aligned} \tag{3.23}$$

Changing variables and taking into account (3.23), we can write

$$\begin{aligned}&\frac{C_{J,1}}{2}\int_{\mathbb{R}^N}\int_\Omega J(z)\chi_\Omega(x+\varepsilon_n z)\overline{g}_{\varepsilon_n}(x,x+\varepsilon_n z)\,dz\frac{\overline{v}(x+\varepsilon_n z)-v(x)}{\varepsilon_n}\,dx\\ &=-\frac{C_{J,1}}{\varepsilon_n}\int_{\mathbb{R}^N}\int_\Omega J(z)\chi_\Omega(x+\varepsilon_n z)\overline{g}_{\varepsilon_n}(x,x+\varepsilon_n z)\,dz\,v(x)\,dx\\ &=\int_\Omega(\phi(x)-u_{\varepsilon_n}(x))v(x)\,dx.\end{aligned} \tag{3.24}$$

By (3.22), passing to the limit in (3.24), we get

$$\frac{C_{J,1}}{2}\int_{\mathbb{R}^N}\int_\Omega\Lambda(x,z)z\cdot\nabla v(x)\,dx\,dz=\int_\Omega(\phi(x)-u(x))v(x)\,dx \tag{3.25}$$

for all $v\in\mathcal{D}(\Omega)$. We set $\zeta=(\zeta_1,\dots,\zeta_N)$, the vector field defined by

$$\zeta_i(x):=\frac{C_{J,1}}{2}\int_{\mathbb{R}^N}\Lambda(x,z)z_i\,dz,\qquad i=1,\dots,N.$$

Then, $\zeta \in L^\infty(\Omega_J, \mathbb{R}^N)$, and from (3.25),

$$-\mathrm{div}(\zeta) = \phi - u \quad \text{in } \mathcal{D}'(\Omega).$$

Let us see that

$$\|\zeta\|_{L^\infty(\Omega_J)} \le 1.$$

Given $\xi \in \mathbb{R}^N \setminus \{0\}$, let R_ξ be the rotation such that $R_\xi^t(\xi) = \mathbf{e}_1|\xi|$. If we make the change of variables $z = R_\xi(y)$, we obtain

$$\begin{aligned}\zeta(x)\cdot\xi &= \frac{C_{J,1}}{2}\int_{\mathbb{R}^N}\Lambda(x,z)z\cdot\xi\,dz = \frac{C_{J,1}}{2}\int_{\mathbb{R}^N}\Lambda(x,R_\xi(y))R_\xi(y)\cdot\xi\,dy\\ &= \frac{C_{J,1}}{2}\int_{\mathbb{R}^N}\Lambda(x,R_\xi(y))y_1|\xi|\,dy.\end{aligned}$$

On the other hand, since J is a radial function and $\Lambda(x,z) \le J(z)$ almost everywhere,

$$C_{J,1}{}^{-1} = \frac{1}{2}\int_{\mathbb{R}^N} J(z)|z_1|\,dz$$

and

$$|\zeta(x)\cdot\xi| \le \frac{C_{J,1}}{2}\int_{\mathbb{R}^N} J(y)|y_1|\,dy|\xi| = |\xi| \quad \text{a.e. } x \in \Omega_J.$$

Therefore, $\|\zeta\|_{L^\infty(\Omega_J)} \le 1$.

To finish the proof, that is, to show that $u = (I + \mathcal{A}_{\tilde\psi})^{-1}\phi$, since $u \in L^\infty(\Omega)$ and $\tilde\psi \in L^\infty(\partial\Omega)$, we need only to prove that

$$(\zeta, Du) = |Du| \quad \text{as measures in } \Omega \tag{3.26}$$

and

$$[\zeta,\nu] \in \mathrm{sign}\left(\tilde\psi - u\right) \quad \mathcal{H}^{N-1}\text{-a.e. on } \partial\Omega. \tag{3.27}$$

Given $0 \le \varphi \in \mathcal{D}(\Omega)$, taking $\varepsilon = \varepsilon_n$ and $v = \varphi u_{\varepsilon_n}$ in (3.16), we get

$$\begin{aligned}&-\frac{C_{J,1}}{{\varepsilon_n}^{1+N}}\int_\Omega\int_\Omega J\left(\frac{x-y}{\varepsilon_n}\right)g_{\varepsilon_n}(x,y)u_{\varepsilon_n}(x)\varphi(x)\,dy\,dx\\ &= \frac{C_{J,1}}{2{\varepsilon_n}^{1+N}}\int_\Omega\int_\Omega J\left(\frac{x-y}{\varepsilon_n}\right)g_{\varepsilon_n}(x,y)(u_{\varepsilon_n}(y)\varphi(y) - u_{\varepsilon_n}(x)\varphi(x))\,dy\,dx\\ &= \int_\Omega(\phi(x) - u_{\varepsilon_n}(x))u_{\varepsilon_n}(x)\varphi(x)\,dx.\end{aligned} \tag{3.28}$$

Now, we decompose the double integral as follows,

$$I_n := \frac{C_{J,1}}{2{\varepsilon_n}^{1+N}}\int_\Omega\int_\Omega J\left(\frac{x-y}{\varepsilon_n}\right)g_{\varepsilon_n}(x,y)(u_{\varepsilon_n}(y)\varphi(y) - u_{\varepsilon_n}(x)\varphi(x))\,dy\,dx = I_n^1 + I_n^2,$$

where

$$\begin{aligned}I_n^1 &:= \frac{C_{J,1}}{2{\varepsilon_n}^{1+N}}\int_\Omega\int_\Omega J\left(\frac{x-y}{\varepsilon_n}\right)|u_{\varepsilon_n}(y) - u_{\varepsilon_n}(x)|\varphi(y)\,dy\,dx\\ &= \frac{C_{J,1}}{2}\int_\Omega\int_\Omega J(z)\,\chi_\Omega(x+\varepsilon_n z)\frac{|\overline{u}_{\varepsilon_n}(x+\varepsilon_n z) - u_{\varepsilon_n}(x)|}{\varepsilon_n}\overline{\varphi}(x+\varepsilon_n z)\,dz\,dx\end{aligned}$$

and

$$I_n^2 := \frac{C_{J,1}}{2{\varepsilon_n}^{1+N}} \int_\Omega \int_\Omega J\left(\frac{x-y}{\varepsilon_n}\right) g_{\varepsilon_n}(x,y) u_{\varepsilon_n}(x)(\varphi(y)-\varphi(x))\,dy\,dx$$
$$= \frac{C_{J,1}}{2} \int_\Omega \int_\Omega J(z)\chi_\Omega(x+\varepsilon_n z)\overline{g}_{\varepsilon_n}(x,x+\varepsilon_n z) u_{\varepsilon_n}(x) \frac{\overline{\varphi}(x+\varepsilon_n z)-\varphi(x)}{\varepsilon_n}\,dz\,dx.$$

Having in mind (3.21), it follows that

$$\lim_{n\to\infty} I_n^1 \geq \frac{C_{J,1}}{2} \int_\Omega \int_\Omega J\left(z\right)\varphi(x)|z\cdot Du| = \int_\Omega \varphi\,|Du|.$$

On the other hand, since

$$u_{\varepsilon_n} \to u \qquad \text{strongly in } L^1(\Omega),$$

by (3.22), we get

$$\lim_{n\to\infty} I_n^2 = \frac{C_{J,1}}{2} \int_\Omega \int_{\mathbb{R}^N} u(x)\Lambda(x,z) z\cdot\nabla\varphi(x)\,dz\,dx = \int_\Omega u(x)\zeta(x)\cdot\nabla\varphi(x)\,dx.$$

Therefore, taking $n\to+\infty$ in (3.28), we obtain

$$\int_\Omega \varphi\,|Du| + \int_\Omega u(x)\zeta(x)\cdot\nabla\varphi(x)\,dx \leq \int_\Omega (\phi(x)-u(x))u(x)\varphi(x)\,dx. \tag{3.29}$$

By Green's formula,

$$\int_\Omega (\phi(x)-u(x))u(x)\varphi(x)dx = -\int_\Omega \operatorname{div}(\zeta)u\varphi\,dx = \int_\Omega (\zeta, D(\varphi u))$$
$$= \int_\Omega \varphi(\zeta,Du) + \int_\Omega u(x)\zeta(x)\cdot\nabla\varphi(x)\,dx.$$

Since $|(\zeta,Du)|\leq|Du|$, the last identity and (3.29) give (3.26).

Finally, we show that (3.27) holds. We take $w_m\in W^{1,1}(\Omega)\cap C(\Omega)$ such that $w_m=\tilde{\psi}\,\mathcal{H}^{N-1}$-a.e. on $\partial\Omega$, and $w_m\to u$ in $L^1(\Omega)$. Taking $v=v_{m,n}:=(u_{\varepsilon_n})_\psi-(w_m)_\psi$ in (3.16), we get

$$\begin{aligned}
&\int_\Omega (\phi(x)-u_{\varepsilon_n}(x))(u_{\varepsilon_n}(x)-w_m(x))\,dx\\
&= -\frac{C_{J,1}}{{\varepsilon_n}^{1+N}} \int_{\Omega_J}\int_{\Omega_J} J\left(\frac{x-y}{\varepsilon_n}\right) g_{\varepsilon_n}(x,y) v_{m,n}(x)\,dy\,dx\\
&= \frac{C_{J,1}}{2{\varepsilon_n}^{1+N}} \int_{\Omega_J}\int_{\Omega_J} J\left(\frac{x-y}{\varepsilon_n}\right) g_{\varepsilon_n}(x,y)(v_{m,n}(x)-v_{m,n}(x))\,dy\,dx\\
&= H_n^1 + H_{m,n}^1,
\end{aligned} \tag{3.30}$$

where

$$H_n^1 = \frac{C_{J,1}}{2} \int_{\Omega_J}\int_{\mathbb{R}^N} J(z)\chi_{\Omega_J}(x+\varepsilon_n z)\left|\frac{(u_{\varepsilon_n})_\psi(x+\varepsilon_n z)-(u_{\varepsilon_n})_\psi(x)}{\varepsilon_n}\right| dz\,dx$$

and

$$H_{m,n}^2 = -\frac{C_{J,1}}{2} \int_{\Omega_J}\int_{\mathbb{R}^N} J(z)\chi_{\Omega_J}(x+\varepsilon_n z)\overline{g}_{\varepsilon_n}(x,x+\varepsilon_n z)$$
$$\times \frac{(w_m)_\psi(x+\varepsilon_n z)-(w_m)_\psi(x)}{\varepsilon_n}\,dz\,dx.$$

Arguing as before,

$$\lim_{n\to\infty} H_n^1 \geq \int_{\Omega_J} |Du_\psi| = \int_\Omega |Du| + \int_{\partial\Omega} \left|u-\tilde{\psi}\right| d\mathcal{H}^{N-1} + \int_{\Omega_J\setminus\overline{\Omega}} |\nabla\psi|.$$

On the other hand, since $(w_m)_\psi \in W^{1,1}(\Omega_J)$, by (3.22),

$$\lim_{n\to\infty} H_{m,n}^2 = -\frac{C_{J,1}}{2}\int_{\Omega_J}\int_{\mathbb{R}^N} \Lambda(x,z) z\cdot\nabla(w_m)_\psi(x)\,dz\,dx = -\int_{\Omega_J} \zeta(x)\cdot\nabla(w_m)_\psi(x)\,dx.$$

Consequently, taking $n\to\infty$ in (3.30), we get

$$\begin{aligned}(3.31)\qquad &\int_\Omega (\phi(x)-u(x))(u(x)-w_m(x))\,dx\\ &\geq \int_\Omega |Du| + \int_{\partial\Omega}\left|u-\tilde{\psi}\right| d\mathcal{H}^{N-1} + \int_{\Omega_J\setminus\overline{\Omega}} |\nabla\psi| - \int_{\Omega_J}\zeta(x)\cdot\nabla(w_m)_\psi(x)\,dx.\end{aligned}$$

Now,

$$\begin{aligned}-\int_{\Omega_J}\zeta(x)\cdot\nabla(w_m)_\psi(x)\,dx &= -\int_\Omega \zeta(x)\cdot\nabla w_m(x)\,dx - \int_{\Omega_J\setminus\overline{\Omega}}\zeta(x)\cdot\nabla\psi(x)\,dx\\ &= \int_\Omega \mathrm{div}\zeta(x) w_m(x)\,dx - \int_{\partial\Omega}[\zeta,\nu]\tilde{\psi}\,d\mathcal{H}^{N-1} - \int_{\Omega_J\setminus\overline{\Omega}}\zeta(x)\cdot\nabla\psi(x)\,dx.\end{aligned}$$

Since

$$\int_{\Omega_J\setminus\overline{\Omega}} |\nabla\psi| - \int_{\Omega_J\setminus\overline{\Omega}}\zeta(x)\cdot\nabla\psi(x)\,dx \geq 0,$$

from (3.31), we have

$$\begin{aligned}&\int_\Omega (\phi(x)-u(x))(u(x)-w_m(x))\,dx\\ &\quad\geq \int_\Omega |Du| + \int_{\partial\Omega}\left|u-\tilde{\psi}\right| d\mathcal{H}^{N-1} + \int_\Omega \mathrm{div}\zeta(x) w_m(x)\,dx - \int_{\partial\Omega}[\zeta,\nu]\tilde{\psi}\,d\mathcal{H}^{N-1}.\end{aligned}$$

Letting $m\to\infty$, and using Green's formula, we deduce

$$\begin{aligned}0 &\geq \int_\Omega |Du| + \int_{\partial\Omega}\left|u-\tilde{\psi}\right| d\mathcal{H}^{N-1} + \int_\Omega \mathrm{div}\zeta(x)u(x)\,dx - \int_{\partial\Omega}[\zeta,\nu]\tilde{\psi}\,d\mathcal{H}^{N-1}\\ &= \int_\Omega |Du| + \int_{\partial\Omega}\left|u-\tilde{\psi}\right| d\mathcal{H}^{N-1} - \int_\Omega (\zeta, Du) + \int_{\partial\Omega}[\zeta,\nu]u\,d\mathcal{H}^{N-1}\\ &\qquad - \int_{\partial\Omega}[\zeta,\nu]\tilde{\psi}\,d\mathcal{H}^{N-1}.\end{aligned}$$

By (3.26), we obtain

$$\int_{\partial\Omega}\left|u-\tilde{\psi}\right| d\mathcal{H}^{N-1} \leq \int_{\partial\Omega}[\zeta,\nu]\big(\tilde{\psi}-u\big)\,d\mathcal{H}^{N-1} \leq \int_{\partial\Omega}\left|u-\tilde{\psi}\right| d\mathcal{H}^{N-1}.$$

Therefore,

$$[\zeta,\nu]\in \mathrm{sign}\big(\tilde{\psi}-u\big) \quad \mathcal{H}^{N-1}-\text{a.e. on } \partial\Omega,$$

and the proof is finished. □

From the above Proposition, by standard results of the Nonlinear Semigroup Theory (see, [19] or [15]), we obtain Theorem 1.6.

4. Limit as $p \to +\infty$. A model for sandpiles.

4.1. A model for sandpiles. Let sand be poured out onto a rigid surface, $y = u_0(x)$, given in a bounded open subset Ω of $\mathbb{R}^2$ with Lipschitz boundary $\partial\Omega$. If the support boundary is open and we assume that the angle of stability is equal to $\frac{\pi}{4}$, a model for pile surface evolution was proposed by Prigozhin [35] as

$$\partial_t u + \operatorname{div} \mathbf{q} = f, \qquad u|_{t=0} = u_0, \qquad u|_{\partial\Omega} = u_0|_{\partial\Omega}, \tag{4.1}$$

where $u(t,x)$ is the unknown pile surface, $f(t,x) \geq 0$ is the given source density, and $\mathbf{q}(t,x)$ is the unknown horizontal projection of the flux of sand pouring down the pile surface. If the support has no slopes steeper than the sand angle of repose, $\|\nabla u_0\|_\infty \leq 1$, Prigozhin ([35], see also [10], [29], and the references therein) proposed to take $\mathbf{q} = -m\nabla u$, where $m \geq 0$ is the Lagrange multiplier related to the constraint $\|\nabla u\|_\infty \leq 1$ and satisfies $m(\|\nabla u\|^2 - 1) = 0$ and reformulated this model as the following variational inequality:

$$\begin{cases} f(t,\cdot) - u_t(t) \in \partial I_{K(u_0)}(u(t)), & \text{a.e. } t \in]0,T[, \\ u(0,x) = u_0(x), \end{cases} \tag{4.2}$$

where

$$K(u_0) := \left\{ v \in W^{1,\infty}(\Omega) \ : \ \|\nabla v\|_\infty \leq 1, \ v|_{\partial\Omega} = u_0|_{\partial\Omega} \right\}.$$

Our aim is to approximate the Prigozhin model for the sandpile by a nonlocal model (Theorem 1.8) obtained as the limit as $p \to +\infty$ of the nonlocal p-Laplacian problem with Dirichlet boundary condition (Theorem 1.7).

To identify the limit as $p \to +\infty$ of the solutions u_p of problem $P_p^J(u_0, \psi)$ we will use the methods of convex analysis, and so we first recall some terminology (see [30], [17], and [8]). If H is a real Hilbert space with inner product $(\ ,\ )$ and $\Psi : H \to (-\infty, +\infty]$ is convex, then the subdifferential of Ψ is defined as the multivalued operator $\partial\Psi$ given by

$$v \in \partial\Psi(u) \iff \Psi(w) - \Psi(u) \geq (v, w-u) \quad \forall\, w \in H.$$

The epigraph of Ψ is defined by $\operatorname{Epi}(\Psi) = \{(u,\lambda) \in H \times \mathbb{R} \ : \ \lambda \geq \Psi(u)\}$.

Given K a closed convex subset of H, the indicator function of K is defined by

$$I_K(u) = \begin{cases} 0 & \text{if } \ u \in K, \\ +\infty & \text{if } \ u \notin K. \end{cases}$$

Then it is easy to see that the subdifferential is characterized as follows:

$$v \in \partial I_K(u) \iff u \in K \ \text{ and } \ (v, w-u) \leq 0 \quad \forall\, w \in K.$$

In case the convex functional $\Psi : H \to (-\infty, +\infty]$ is proper, lower-semicontinuous, and $\min \Psi = 0$, it is well known (see [17]) that the abstract Cauchy problem

$$\begin{cases} u'(t) + \partial\Psi(u(t)) \ni f(t), & \text{a.e. } t \in]0,T[, \\ u(0) = u_0, \end{cases}$$

has a unique strong solution for any $f \in L^2(0,T;H)$ and $u_0 \in \overline{D(\partial\Psi)}$.

The following convergence was studied by Mosco in [34] (see [8]). Suppose X is a metric space and $A_n \subset X$. We define

$$\liminf_{n\to\infty} A_n = \{x \in X \ : \ \exists x_n \in A_n,\ x_n \to x\}$$

and

$$\limsup_{n\to\infty} A_n = \{x \in X \ : \ \exists x_{n_k} \in A_{n_k},\ x_{n_k} \to x\}.$$

In the case X is a normed space, we note by $s-\lim$ and $w-\lim$ the above limits associated, respectively, to the strong and to the weak topology of X.

Given a sequence $\Psi_n, \Psi : H \to (-\infty, +\infty]$ of convex lower-semicontinuous functionals, we say that Ψ_n converges to Ψ in the sense of Mosco if

$$w - \limsup_{n\to\infty} \mathrm{Epi}(\Psi_n) \subset \mathrm{Epi}(\Psi) \subset s - \liminf_{n\to\infty} \mathrm{Epi}(\Psi_n). \tag{4.3}$$

It is easy to see that (4.3) is equivalent to the two following conditions:

$$\forall\, u \in D(\Psi)\ \ \exists u_n \in D(\Psi_n)\ :\ u_n \to u \ \text{ and } \ \Psi(u) \geq \limsup_{n\to\infty} \Psi_n(u_n); \tag{4.4}$$

$$\text{for every subsequence } n_k, \text{ when } u_k \rightharpoonup u, \text{ it holds } \Psi(u) \leq \liminf_{k} \Psi_{n_k}(u_k). \tag{4.5}$$

As a consequence of the results in [19] and [8] we can write the following result.

THEOREM 4.1. *Let $\Psi_n, \Psi : H \to (-\infty, +\infty]$ convex lower-semicontinuous functionals. Then the following statements are equivalent.*

(i) *Ψ_n converges to Ψ in the sense of Mosco.*

(ii) *$(I + \lambda\partial\Psi_n)^{-1}u \to (I + \lambda\partial\Psi)^{-1}u, \quad \forall\, \lambda > 0,\ u \in H.$*

Moreover, any of these two conditions (i) *or* (ii) *imply that*

(iii) *for every $u_0 \in \overline{D(\partial\Psi)}$ and $u_{0,n} \in \overline{D(\partial\Psi_n)}$ such that $u_{0,n} \to u_0$, and every $f_n, f \in L^2(0,T;H)$ with $f_n \to f$, if $u_n(t)$, $u(t)$ are the strong solutions of the abstract Cauchy problems*

$$\begin{cases} u_n'(t) + \partial\Psi_n(u_n(t)) \ni f_n, & \text{a.e. } t \in]0,T[, \\ u_n(0) = u_{0,n}, \end{cases}$$

and

$$\begin{cases} u'(t) + \partial\Psi(u(t)) \ni f, & \text{a.e. } t \in]0,T[, \\ u(0) = u_0, \end{cases}$$

respectively, then

$$u_n \to u \qquad \text{in } C([0,T] : H).$$

4.2. Limit as $p \to +\infty$. Let us consider the *nonlocal p-Laplacian evolution problem* with source

$$P_p^J(u_0,\psi,f) \begin{cases} u_t(t,x) = \displaystyle\int_\Omega J(x-y)|u(t,y)-u(t,x)|^{p-2}(u(t,y)-u(t,x))dy + f(t,x), \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad (t,x) \in]0,T[\times\Omega, \\ u(t,x) = \psi(x), \quad (t,x) \in]0,T[\times(\Omega_J \setminus \overline{\Omega}), \\ u(0,x) = u_0(x), \quad x \in \Omega. \end{cases}$$

This problem is associated to the energy functional

$$G^J_{p,\psi}(u) = \frac{1}{2p}\int_\Omega\int_\Omega J(x-y)|u(y)-u(x)|^p\,dy\,dx + \frac{1}{p}\int_\Omega\int_{\Omega_J\setminus\overline{\Omega}} J(x-y)|\psi(y)-u(x)|^p\,dy\,dx.$$

With a formal calculation, taking limit as $p\to+\infty$, we arrive to the functional

$$G^J_{\infty,\psi}(u) = \begin{cases} 0 & \text{if } |u(x)-u(y)|\le 1, \text{ for } x,y\in\overline{\Omega} \\ & \text{and } |\psi(y)-u(x)|\le 1, \quad \text{for } x\in\Omega, y\in\Omega_J\setminus\overline{\Omega}, \\ & \text{with } x-y\in\operatorname{supp}(J) \\ +\infty & \text{in the other case.} \end{cases}$$

Hence, if we define

$$K^J_{\infty,\psi} := \left\{ u\in L^2(\Omega) \;:\; \begin{array}{l} |u(x)-u(y)|\le 1, x,y\in\Omega \\ \text{and } |\psi(y)-u(x)|\le 1, \quad \text{for } x\in\Omega, y\in\Omega_J\setminus\overline{\Omega}, \\ \text{with } x-y\in\operatorname{supp}(J) \end{array} \right\},$$

we have that the functional $G^J_{\infty,\psi}$ is given by the indicator function of $K^J_{\infty,\psi}$; that is, $G^J_{\infty,\psi} = I_{K^J_{\infty,\psi}}$. Then, the *nonlocal limit problem* can be written as

$$P^J_\infty(u_0,\psi,f) \quad \begin{cases} f(t,\cdot) - u_t(t) \in \partial I_{K^J_{\infty,\psi}}(u(t)), & \text{a.e. } t\in]0,T[, \\ u(0,x) = u_0(x). \end{cases}$$

Proof of Theorem 1.7. Let $T>0$. By Theorem 4.1, to prove the result it is enough to show that the functionals

$$G^J_{p,\psi}(u) = \frac{1}{2p}\int_\Omega\int_\Omega J(x-y)|u(y)-u(x)|^p\,dy\,dx + \frac{1}{p}\int_\Omega\int_{\Omega_J\setminus\overline{\Omega}} J(x-y)|\psi(y)-u(x)|^p\,dy\,dx$$

converge to

$$G^J_{\infty,\psi}(u) = \begin{cases} 0 & \text{if } |u(x)-u(y)|\le 1, \text{ for } x,y\in\Omega \\ & \text{and } |\psi(y)-u(x)|\le 1, \quad \text{for } x\in\Omega, y\in\Omega_J\setminus\overline{\Omega}, \\ & \text{with } x-y\in\operatorname{supp}(J) \\ +\infty & \text{in the other case} \end{cases}$$

as $p\to+\infty$, in the sense of Mosco. First, let us check that

$$\operatorname{Epi}\left(G^J_{\infty,\psi}\right) \subset s-\liminf_{p\to+\infty}\operatorname{Epi}\left(G^J_{p,\psi}\right). \tag{4.6}$$

To this end let $(u,\lambda)\in\operatorname{Epi}(G^J_{\infty,\psi})$. We can assume that $u\in K^J_{\infty,\psi}$ and $\lambda\ge 0$ (as $G^J_{\infty,\psi}(u)=0$). Now take

$$v_p = u \qquad \text{and} \qquad \lambda_p = G^J_{p,\psi}(u)+\lambda. \tag{4.7}$$

Then, as $\lambda \geq 0$ we have $(v_p, \lambda_p) \in \mathrm{Epi}(G^J_{p,\psi})$. Obviously, $v_p = u \to u$ in $L^2(\Omega)$, and as $u \in K^J_{\infty,\psi}$,

$$\begin{aligned} G^J_{p,\psi}(u) &= \frac{1}{2p}\int_\Omega\int_\Omega J(x-y)|u(y)-u(x)|^p\,dydx \\ &\quad + \frac{1}{p}\int_\Omega\int_{\Omega_J\setminus\overline{\Omega}} J(x-y)|\psi(y)-u(x)|^p\,dy\,dx \\ &\leq \frac{1}{2p}\int_\Omega\int_\Omega J(x-y)\,dydx + \frac{1}{p}\int_\Omega\int_{\Omega_J\setminus\overline{\Omega}} J(x-y)\,dy\,dx \to 0 \end{aligned}$$

as $p \to +\infty$. Therefore, we get (4.6). Finally, let us prove that

$$w - \limsup_{p\to+\infty} \mathrm{Epi}\left(G^J_{p,\psi}\right) \subset \mathrm{Epi}\left(G^J_{\infty,\psi}\right). \tag{4.8}$$

To this end, let us consider a sequence $(u_{p_j}, \lambda_{p_j}) \in \mathrm{Epi}(G^J_{p_j,\psi})$; that is, $G^J_{p_j,\psi}(u_{p_j}) \leq \lambda_{p_j}$, with

$$u_{p_j} \rightharpoonup u, \qquad \text{and} \qquad \lambda_{p_j} \to \lambda.$$

Since, $0 \leq G^J_{p_j,\psi}(u_{p_j}) \leq \lambda_{p_j} \to \lambda$, $0 \leq \lambda$. On the other hand, we have that there exists a constant $C > 0$ such that

$$\begin{aligned} (p_jC)^{1/p_j} \geq \left(p_jG^J_{p,\psi}(u_{p_j})\right)^{1/p_j} &= \left(\frac{1}{2}\int_\Omega\int_\Omega J(x-y)|u_{p_j}(y)-u_{p_j}(x)|^{p_j}\,dy\,dx \right. \\ &\quad \left. + \int_\Omega\int_{\Omega_J\setminus\overline{\Omega}} J(x-y)|\psi(y)-u_{p_j}(x)|^{p_j}\,dy\,dx\right)^{1/p_j}. \end{aligned}$$

Then, by the above inequality,

$$\begin{aligned} &\left(\int_\Omega\int_\Omega J\,(x-y)\left|u_{p_j}(y)-u_{p_j}(x)\right|^q\,dy\,dx\right)^{1/q} \\ &\quad\leq \left(\int_\Omega\int_\Omega J\,(x-y)\,dy\,dx\right)^{(p_j-q)/p_jq} \\ &\qquad\times\left(\int_\Omega\int_\Omega J\,(x-y)\left|u_{p_j}(y)-u_{p_j}(x)\right|^{p_j}\,dy\,dx\right)^{1/p_j} \\ &\quad\leq \left(\int_\Omega\int_\Omega J\,(x-y)\,dy\,dx\right)^{(p_j-q)/p_jq}(Cp_j)^{1/p_j}. \end{aligned}$$

Hence, we can extract a subsequence (if necessary) and let $p_j \to +\infty$ to obtain

$$\left(\int_\Omega\int_\Omega J\,(x-y)\,|u(y)-u(x)|^q\,dy\,dx\right)^{1/q} \leq \left(\int_\Omega\int_\Omega J\,(x-y)\,dy\,dx\right)^{1/q}.$$

Now, just taking $q \to +\infty$, we get

$$|u(x)-u(y)| \leq 1 \qquad \text{a.e. } (x,y) \in \Omega\times\Omega,\ x-y \in \mathrm{supp}(J).$$

With a similar argument we obtain

$$|u(x)-\psi(y)| \leq 1 \qquad \text{a.e. } x \in \Omega,\ y \in \Omega_J\setminus\overline{\Omega},\ \text{with}\ \ x-y \in \mathrm{supp}(J).$$

Hence, we conclude that $u \in K^J_{\infty,\psi}$. This ends the proof. □

4.3. Rescaling. We will assume now that Ω is convex and ψ verifies $\|\nabla\psi\|_\infty \le 1$. For $\varepsilon > 0$, we rescale the functional $G^J_{\infty,\psi}$ as follows:

$$G^\varepsilon_{\infty,\psi}(u) = \begin{cases} 0 & \text{if } |u(x)-u(y)| \le \varepsilon, \text{ for } x,y \in \Omega \\ & \text{and } |\psi(y)-u(x)| \le \varepsilon, \quad \text{for } x \in \Omega, y \in \Omega_J \setminus \overline{\Omega}, \\ & \text{with } |x-y| \le \varepsilon \\ +\infty & \text{in the other case.} \end{cases}$$

In other words, $G^\varepsilon_{\infty,\psi} = I_{K^\varepsilon_{\infty,\psi}}$, where

$$K^\varepsilon_{\infty,\psi} := \left\{ u \in L^2(\Omega) \ : \ \begin{array}{l} |u(x)-u(y)| \le \varepsilon, x, y \in \Omega \\ \text{and } |\psi(y)-u(x)| \le \varepsilon, \quad \text{for } x \in \Omega, y \in \Omega_J \setminus \overline{\Omega}, \\ \text{with } |x-y| \le \varepsilon \end{array} \right\}.$$

Consider the gradient flow associated to the functional $G^\varepsilon_{\infty,\psi}$

$$P^\varepsilon_\infty(u_0,\psi,f) \quad \begin{cases} f(t,\cdot) - u_t(t,\cdot) \in \partial I_{K^\varepsilon_{\infty,\psi}}(u(t)), & \text{a.e. } t \in]0,T[, \\ u(0,x) = u_0(x), & \text{in } \Omega, \end{cases}$$

and the problem

$$P_\infty(u_0,\psi,f) \quad \begin{cases} f(t,\cdot) - u_{\infty,t} \in \partial I_{K_\psi}(u_\infty), & \text{a.e. } t \in]0,T[, \\ u_\infty(0,x) = u_0(x), & \text{in } \Omega, \end{cases}$$

where

$$K_\psi := \left\{ u \in W^{1,\infty}(\Omega) \ : \ \|\nabla u\|_\infty \le 1, \ u|_{\partial\Omega} = \psi|_{\partial\Omega} \right\}.$$

Observe that if $u \in K_\psi$, $\|\nabla u\|_\infty \le 1$. Then, since $\|\nabla\psi\|_\infty \le 1$ and Ω is convex, we have $|u(x)-u(y)| \le |x-y|$ and $|u(x)-\psi(y)| \le |x-y|$, from where it follows that $u \in K^\varepsilon_{\infty,\psi}$, that is, $K_\psi \subset K^\varepsilon_{\infty,\psi}$.

With all these definitions and notations, we can proceed with the limit as $\varepsilon \to 0$ for the sandpile model ($p = +\infty$).

Proof of Theorem 1.8. Since $u_0 \in K_\psi$, $u_0 \in K^\varepsilon_{\infty,\psi}$ for all $\varepsilon > 0$. Again we are using that $\|\nabla\psi\|_\infty \le 1$. Consequently, there exists $u_{\infty,\varepsilon}$ the unique solution of $P^\varepsilon_\infty(u_0,\psi,f)$.

By Theorem 4.1, to prove the result it is enough to show that $I_{K^\varepsilon_{\infty,\psi}}$ converges to I_{K_ψ} in the sense of Mosco. Using that $\|\nabla\psi\|_\infty \le 1$ it is easy to obtain that

$$K^{\varepsilon_1}_{\infty,\psi} \subset K^{\varepsilon_2}_{\infty,\psi}, \quad \text{if } \ \varepsilon_1 \le \varepsilon_2. \tag{4.9}$$

Since $K_\psi \subset K^\varepsilon_{\infty,\psi}$ for all $\varepsilon > 0$, we have

$$K_\psi \subset \bigcap_{\varepsilon>0} K^\varepsilon_{\infty,\psi}.$$

On the other hand, if

$$u \in \bigcap_{\varepsilon>0} K^\varepsilon_{\infty,\psi},$$

we have

$$|u(y)-u(x)| \le |y-x|, \quad \text{a.e. } x,y \in \Omega,$$

and moreover

$$|u(y)-\psi(x)| \le |y-x|, \quad \text{a.e. } x \in \Omega_J \setminus \overline{\Omega},\ y \in \Omega,$$

from where it follows that $u \in K_\psi$. Therefore, we have

$$K_\psi = \bigcap_{\varepsilon>0} K^\varepsilon_{\infty,\psi}. \tag{4.10}$$

Note that

$$\mathrm{Epi}(I_{K_\psi}) = K_\psi \times [0,\infty[, \quad \mathrm{Epi}\left(I_{K^\varepsilon_{\infty,\psi}}\right) = K^\varepsilon_{\infty,\psi} \times [0,\infty[\ \ \forall\, \varepsilon>0. \tag{4.11}$$

By (4.10) and (4.11),

$$\mathrm{Epi}\left(I_{K_\psi}\right) \subset s-\liminf_{\varepsilon\to 0} \mathrm{Epi}\left(I_{K^\varepsilon_{\infty,\psi}}\right). \tag{4.12}$$

On the other hand, given $(u,\lambda) \in w-\limsup_{\varepsilon\to 0} \mathrm{Epi}(I_{K^\varepsilon_{\infty,\psi}})$ there exists $(u_{\varepsilon_k},\lambda_k) \in K_{\varepsilon_k,\psi} \times [0,\infty[$, such that $\varepsilon_k \to 0$ and

$$u_{\varepsilon_k} \rightharpoonup u \quad \text{in } L^2(\Omega), \quad \lambda_k \to \lambda \ \text{ in } \mathbb{R}.$$

By (4.9), given $\varepsilon>0$, there exists k_0, such that $u_{\varepsilon_k} \in K^\varepsilon_{\infty,\psi}$ for all $k \ge k_0$. Then, since $K^\varepsilon_{\infty,\psi}$ is a closed convex set, we get $u \in K^\varepsilon_{\infty,\psi}$, and, by (4.10), we obtain that $u \in K_0$. Consequently,

$$w-\limsup_{n\to\infty} \mathrm{Epi}\left(I_{K^\varepsilon_{\infty,\psi}}\right) \subset \mathrm{Epi}\left(I_{K_\psi}\right). \tag{4.13}$$

Finally, by (4.12), (4.13), and having in mind (4.3), we obtain that $I_{K^\varepsilon_{\infty,\psi}}$ converges to I_{K_ψ} in the sense of Mosco. □

4.4. Explicit solutions. Our goal now is to show some explicit examples that illustrate the behavior of the solutions when $p=+\infty$.

Remark 4.2. There is a natural upper bound (and of course also a natural lower bound) for the solutions with boundary datum ψ outside Ω (regardless the source term f). Indeed, given a bounded domain $\Omega \subset \mathbb{R}^N$ let us define inductively

$$\Omega_1 = \left\{x \in \Omega \ :\ |x-y|<1 \text{ for some } y \in \Omega_J \setminus \overline{\Omega}\right\}$$

and, for $j \ge 2$,

$$\Omega_j = \left\{x \in \Omega \setminus \cup_{i=1}^{j-1}\Omega_i \ :\ |x-y|<1 \text{ for some } y \in \Omega_{j-1}\right\}.$$

Then, since $u(t) \in K^J_{\infty,\psi}$ we must have

$$u(t,x) \le \psi(y)+1 \qquad \text{if } \ |x-y| \le 1,\ x \in \Omega_1,\ y \in \Omega_J \setminus \overline{\Omega},$$

and for any $j \ge 2$

$$u(t,x) \le u(t,y)+1 \qquad \text{if } \ |x-y| \le 1,\ x \in \Omega_j,\ y \in \Omega_{j-1} \setminus \Omega_j.$$

Therefore we have an upper bound for $u(t,x)$ in the whole Ω,

$$u(t,x) \le \Psi_1(x),$$

where Ψ_1 is defined by the inductive formula,

$$\Psi_1(x) = \max\left\{\psi(y)+1 \ : \ y \in \Omega_J \setminus \overline{\Omega},\ |x-y| \le 1\right\},\ \text{for } x \in \Omega_1,$$

and

$$\Psi_1(x) = \max\left\{\Psi_1(y)+1 \ : \ y \in \Omega_{j-1},\ |x-y| \le 1\right\},\ \text{for } x \in \Omega_j,\ \text{if } j \ge 2.$$

Analogously, we can obtain a lower bound for $u(t,x)$,

$$u(t,x) \ge \Phi_1(x),$$

where Φ_1 is defined by the inductive formula,

$$\Phi_1(x) = \min\left\{\psi(y)-1 \ : \ y \in \Omega_J \setminus \overline{\Omega},\ |x-y| \le 1\right\},\ \text{for } x \in \Omega_1,$$

and

$$\Phi_1(x) = \min\left\{\Phi_1(y)-1 \ : \ y \in \Omega_{j-1},\ |x-y| \le 1\right\},\ \text{for } x \in \Omega_j,\ \text{ if } j \ge 2.$$

With this remark in mind we show some explicit examples of solutions to

$$P^J_\infty(u_0,\psi,f) \quad \begin{cases} f(t,x) - u_t(t,x) \in \partial G^J_{\infty,\psi}(u(t)), & \text{a.e. } t \in]0,T[, \\ u(0,x) = u_0(x), & \text{in } \Omega, \end{cases}$$

where

$$G^J_{\infty,\psi}(u) = \begin{cases} 0 & \text{if } u \in L^2(\Omega),\ |u(x)-u(y)| \le 1,\ \text{for } x,y \in \Omega,\ |x-y| \le 1, \\ & \text{and } |u(x)-\psi(y)| \le 1, \text{for } x \in \Omega,\ y \in \Omega_J \setminus \overline{\Omega},\ |x-y| \le 1, \\ +\infty & \text{in the other case.} \end{cases}$$

In order to verify that a function $u(t,x)$ is a solution to $P^J_\infty(u_0,\psi,f)$, we need to check that

$$G^J_{\infty,\psi}(v) \ge G^J_{\infty,\psi}(u) + \langle f - u_t,\ v-u\rangle, \qquad \text{for all } v \in L^2(\Omega). \tag{4.14}$$

To this end we can assume that $v \in K^J_{\infty,\psi}$ (otherwise $G^J_{\infty,\psi}(v) = +\infty$ and then (4.14) becomes trivial). Therefore, we need to check that

$$u(t,\cdot) \in K^J_{\infty,\psi} \tag{4.15}$$

and, by (4.14), that

$$\int_\Omega (f(t,x) - u_t(t,x))(v(x)-u(t,x))\,dx \le 0 \tag{4.16}$$

for every $v \in K^J_{\infty,\psi}$.

Example 1. Let us consider a nonnegative source f and as initial condition the upper bound defined in the previous remark, $u_0(x) = \Psi_1(x)$. Then the solution to $P^J_\infty(u_0,\psi,f)$ is given by

$$u(t,x) \equiv \Psi_1(x)$$

for every $t > 0$. Indeed, $\Psi_1(x) \in K^J_{\infty,\psi}$ and for every $v \in K^J_{\infty,\psi}$ we have that $v(x) \le \Psi_1(x)$, and therefore

$$\int_\Omega (f(t,x) - u_t(t,x))(v(x) - u(t,x))\,dx = \int_\Omega f(t,x)(v(x) - \Psi_1(x))\,dx \le 0,$$

as we have to show.

In general, given a nonnegative source f supported in $D \subset \Omega$, any initial condition $u_0 \in K^J_{\infty,\psi}$ that verifies $u_0(x) = \Psi_1(x)$ in D produces a stationary solution $u(t,x) \equiv u_0(x)$.

Analogously, it can be shown that $u(t,x) \equiv \Phi_1(x)$ when $u_0(x) = \Phi_1(x)$ and $f(t,x) \le 0$.

Example 2. Now, let us assume that we are in an interval $\Omega = (-L, L)$, $\psi = 0$, $\varepsilon = L/n$, $n \in \mathbf{N}$, $u_0 = 0$ which belongs to $K_{\varepsilon,0}$, and the source f is an approximation of a delta function,

$$f(t,x) = f_\eta(t,x) = \frac{1}{\eta}\chi_{[-\frac{\eta}{2},\frac{\eta}{2}]}(x), \quad 0 < \eta \le 2\varepsilon.$$

Using the same ideas of [6], it is easy to verify the following general formula that describes the solution of $P^\varepsilon_\infty(u_0,\psi,f)$ for every $t \ge 0$. For any given integer $l \ge 0$ we have

$$u(t,x) = \begin{cases} l\varepsilon + k_l(t - t_l), & x \in [-\frac{\eta}{2}, \frac{\eta}{2}], \\ (l-1)\varepsilon + k_l(t - t_l), & x \in [-\frac{\eta}{2} - \varepsilon, \frac{\eta}{2} + \varepsilon] \setminus [-\frac{\eta}{2}, \frac{\eta}{2}], \\ \dots & \\ k_l(t - t_l), & x \in [-\frac{\eta}{2} - l\varepsilon, \frac{\eta}{2} + l\varepsilon] \setminus [-\frac{\eta}{2} - (l-1)\varepsilon, \frac{\eta}{2} + (l-1)\varepsilon], \\ 0, & x \notin [-\frac{\eta}{2} - l\varepsilon, \frac{\eta}{2} + l\varepsilon], \end{cases}$$

for $t \in [t_l, t_{l+1})$, where

$$k_l = \frac{1}{2l\varepsilon + \eta} \quad \text{and} \quad t_{l+1} = t_l + \frac{\varepsilon}{k_l}, \quad t_0 = 0.$$

This general formula is valid until the time at which the solution verifies $u(t,x) = \Psi_\varepsilon(x)$ for $x \in [-\frac{\eta}{2}, \frac{\eta}{2}]$ (the support of f), that is, until $T = t_{l^*+1}$, where

$$l^* \text{ is the first } l \text{ such that } l\varepsilon + k_l(t_{l+1} - t_l) = \Psi_\varepsilon(0)$$

and

$$\Psi_\varepsilon \text{ is the natural upper bound defined in Remark 4.2}$$

for the corresponding rescaled kernel. Observe that for this l^*, $\frac{\eta}{2} + l^*\varepsilon \le L$. From that time on the solution is stationary, that is, $u(t,x) = u(T,x)$ for all $t > T$.

From the above formula, taking limits as $\eta \to 0$, we get that the expected solution to $P^\varepsilon_\infty(u_0,\psi,\delta_0)$ is given, for any given integer $l \ge 1$, by

$$u(t,x) = \begin{cases} (l-1)\varepsilon + k_l(t - t_l), & x \in [-\varepsilon, \varepsilon], \\ (l-2)\varepsilon + k_l(t - t_l), & x \in [-2\varepsilon, 2\varepsilon] \setminus [-\varepsilon, \varepsilon], \\ \dots & \\ k_l(t - t_l), & x \in [-l\varepsilon, l\varepsilon] \setminus [-(l-1)\varepsilon, (l-1)\varepsilon], \\ 0, & x \notin [-l\varepsilon, l\varepsilon], \end{cases} \tag{4.17}$$

for $t \in [t_l, t_{l+1})$, where $k_l = \frac{1}{2l\varepsilon}$, $t_{l+1} = t_l + \frac{\varepsilon}{k_l}$, $t_1 = 0$, until $T = t_{l^*+1}$, where

$$l^* \text{ is the first } l \text{ such that } l\varepsilon + k_l(t_{l+1} - t_l) = \Psi_\varepsilon(0).$$

And from that time on the solution is stationary, that is, $u(t,x) = u(T,x)$ for all $t > T$.

Remark that, since the space of functions $K^\varepsilon_{\infty,\psi}$ is not contained into $C(\mathbb{R})$, the formulation (4.16) with $f = \delta_0$ does not make sense. Hence the function $u(t,x)$ described by (4.17) is to be understood as a *generalized solution* to $P^\varepsilon_\infty(u_0, \psi, \delta_0)$ (it is obtained as a limit of solutions to approximating problems).

Note that the function $u(T,x)$ is a "regular and symmetric pyramid" composed by squares of side ε which is one step below the upper profile Ψ_ε.

Recovering the sandpile model as $\varepsilon \to 0$. Now, to recover the sandpile model, take the limit as $\varepsilon \to 0$ in the previous example to get that $u(t,x) \to v(t,x)$, where

$$v(t,x) = (l - |x|)^+ \qquad \text{for } t = l^2,$$

until the time at which $t = L^2$, and from that time the solution is stationary.

A similar argument shows that, for any $a \in (0, L)$, the *generalized solution* to $P^\varepsilon_\infty(0, 0, \delta_a)$ converges as $\varepsilon \to 0$ to $v(t,x)$, where

$$v(t,x) = (l - |x - a|)^+ \qquad \text{for } t = l^2,$$

until the time at which $t = (L - a)^2$, and from that time the solution is stationary.

These concrete examples illustrate the general convergence result in Theorem 1.8.

Acknowledgments. We want to thank the referees for their help to improve the manuscript. Part of this work was performed during a visit of JDR to Univ. de Valencia. He is thankful for the warm hospitality and the stimulating working atmosphere found there.

GROW-UP RATE AND REFINED ASYMPTOTICS FOR A TWO-DIMENSIONAL PATLAK–KELLER–SEGEL MODEL IN A DISK*

NIKOS I. KAVALLARIS† AND PHILIPPE SOUPLET‡

Abstract. We consider a special case of the Patlak–Keller–Segel system in a disc, which arises in the modeling of chemotaxis phenomena. For a critical value of the total mass, the solutions are known to be global in time but with density becoming unbounded, leading to a phenomenon of mass-concentration in infinite time. We establish the precise grow-up rate and obtain refined asymptotic estimates of the solutions. Unlike in most of the similar, recently studied, grow-up problems, the rate is neither polynomial nor exponential. In fact, the maximum of the density behaves like $e^{\sqrt{2t}}$ for large time. In particular, our study provides a rigorous proof of a behavior suggested by Sire and Chavanis [*Phys. Rev. E* (3), 66 (2002), 046133] on the basis of formal arguments.

Key words. chemotaxis system, critical mass, grow-up, sub-/supersolutions

1. Introduction.

1.1. The complete Patlak–Keller–Segel model. Out of the many mathematical models that have been proposed to deal with particular aspects of chemotaxis, that proposed by Patlak in 1953 (cf. [40]) and Keller and Segel in 1970 (cf. [32]) has received particular attention. The so-called (two-dimensional) Patlak–Keller–Segel model consists of two equations, describing the evolution of the population density $\rho(x,t)$ of bacteria and the concentration $c(x,t)$ of a chemical attracting substance in a bounded domain $\Omega \subset \mathbb{R}^2$ and in a time interval $[0,T]$:

$$\frac{\partial \rho}{\partial t} = \nabla \cdot (D_1 \nabla \rho - \chi \rho \nabla c), \tag{1.1}$$

$$\theta \frac{\partial c}{\partial t} = \Delta c - ac + \rho. \tag{1.2}$$

More precisely, the first equation describes the random (Brownian) diffusion of the population of cells, which is biased in the direction of a drift velocity, proportional to the gradient of the concentration of the chemoattractant. The diffusion coefficient is denoted by $D_1 > 0$, and the proportionality coefficient of the drift (mobility parameter) is denoted by $\chi > 0$. According to the second equation, the chemoattractant, which is directly emitted by the cells, diffuses with a diffusion coefficient $D_2 = 1/\theta > 0$ on the substrate, while it is generated proportionally to the density of cells and at the same time is degraded with a rate equal to $a/\theta \geq 0$. In order for system (1.1)–(1.2) to be well posed, it should be supplemented with some initial conditions

$$\rho(x,0) = \rho_0(x) \geq 0, \quad c(x,0) = c_0(x) \geq 0, \tag{1.3}$$

along with conditions on the boundary $\partial\Omega$. A natural boundary condition, since it guarantees the conservation of total mass, is the no-flux–type condition for ρ, namely,

$$\frac{\partial \rho}{\partial \nu} - \rho \frac{\partial c}{\partial \nu} = 0 \quad \text{on } \partial\Omega, \tag{1.4}$$

where ν stands for the outer unit normal vector at $\partial\Omega$. As for c, a Dirichlet-type boundary condition is assumed, i.e.,

$$c = 0 \quad \text{on } \partial\Omega; \tag{1.5}$$

cf. [7, 46]. Note that the parabolic system (1.1)–(1.2) preserves the nonnegativity of the initial conditions, i.e., $\rho, c \geq 0$ for $t > 0$, which is also expected to be true for the physical problem. For simplicity, D_1, χ are considered to be constant and under suitable scaling can be taken as $D_1 = \chi = 1$.

In view of experimental facts, the coefficients θ and a are assumed to be small, and a simplified form of the Patlak–Keller–Segel system is obtained (in fact, this corresponds to the case when the diffusion and production of c are much faster than the dynamics of ρ and the degradation of c). Namely, by considering the limiting case $\theta, a \to 0+$, the parabolic-parabolic system (1.1)–(1.5) is reduced to the elliptic-parabolic system

$$\frac{\partial \rho}{\partial t} = \nabla \cdot (\nabla \rho - \rho \nabla c), \quad x \in \Omega,\ t \in (0, T), \tag{1.6}$$

$$-\Delta c = \rho, \quad x \in \Omega,\ t \in (0, T), \tag{1.7}$$

$$\frac{\partial \rho}{\partial \nu} - \rho \frac{\partial c}{\partial \nu} = 0, \quad x \in \partial\Omega,\ t \in (0, T), \tag{1.8}$$

$$c = 0, \quad x \in \partial\Omega,\ t \in (0, T), \tag{1.9}$$

$$\rho(x, 0) = \rho_0(x) \geq 0, \quad x \in \Omega. \tag{1.10}$$

Note that in order for (1.6)–(1.10) to be well posed, only the initial data $\rho(x, 0) = \rho_0(x)$ must be prescribed. Moreover, owing to the boundary condition (1.8), the total (mass) population of cells is conserved; that is,

$$||\rho(\cdot, t)||_1 = ||\rho_0||_1 =: \Lambda \quad \text{for } t > 0.$$

For a more detailed analysis regarding the modeling as well as the behavior of solutions of chemotaxis systems, see the review papers [24, 28, 29] as well as the monograph [48]. Here, it should be noticed that system (1.6)–(1.10) is also known as the Smoluchowski–Poisson system and can describe the motion of the mean field of many self-gravitating particles [13, 1, 2, 7, 46, 49, 50] or that of polymer molecules [16]. The behavior of the solution to (1.6)–(1.10) strongly depends on the parameter Λ. In fact, if $\Lambda > 8\pi$ and $\Omega = B(0, R)$, $R > 0$, then solutions of (1.6)–(1.10) blow up in a finite time $T^*(\rho_0)$; that is,

$$\lim_{t \to T^*} ||\rho(\cdot, t)||_{H^1} = \lim_{t \to T^*} ||\rho(\cdot, t)||_{L^p} = \lim_{t \to T^*} \int_\Omega (\rho \log \rho)(x, t)\, dx = \infty$$

for every $p > 1$; see [9, Theorem 2(i)], [2, Theorem 2]. On the other hand, for $\Lambda < 8\pi$, all solutions of system (1.6)–(1.10) are global in time; cf. [7, Theorem 2 (iv)]. In the critical case $\Lambda = 8\pi$ an infinite-time blow-up (grow-up) occurs, i.e., $||\rho(\cdot, t)||_\infty \to \infty$ as $t \to \infty$; cf. [39, Theorem 3], [5, Proposition 3.2]. Finite- or infinite-time blow-up can

be accompanied by the occurrence of a δ-function formation in the blow-up set (this represents the trend of populations to concentrate to form sporae) and is known in the literature as *chemotactic collapse*. This phenomenon was conjectured by Childress and Percus [14] and Nanjundiah [38] and was first verified, via matched asymptotics arguments, for a radially symmetric simplified Patlak–Keller–Segel system in [25]. A result regarding the infinite-time Dirac mass formation for ρ can be found in [39], where some characterization of grow-up (mass-concentration) points together with more grow-up results for different types of boundary conditions are also obtained [39, Theorems 2 and 3]. For blow-up results concerning a variation of system (1.6)–(1.10) but with Neumann boundary conditions for both ρ and c, see [30, 35, 3, 36, 44].

1.2. The simplified Patlak–Keller–Segel model in the radial case. In the case when Ω is the ball $B(0,R)$, $R>0$, and the initial data $\rho_0(x)=\rho_0(r)$ is radially symmetric, the solution of system (1.6)–(1.10) is radially symmetric, i.e., $\rho(x,t)=\rho(r,t)$, with $r=|x|$. In this case the elliptic-parabolic system (1.6)–(1.10) can be greatly simplified. Namely, by introducing the cumulative mass distribution

$$Q(r,t):=\int_{B(0,r)}\rho(x,t)\,dx=2\pi\int_0^r s\rho(s,t)\,ds,$$

which is equal to the mass contained in the sphere $B(0,r)$, the system reduces to a single equation

$$Q_t=Q_{rr}-\frac{1}{r}Q_r+\frac{1}{2\pi r}QQ_r,\quad 0<r<R,\ t>0, \tag{1.11}$$

$$Q(0,t)=0,\quad Q(R,t)=\Lambda. \tag{1.12}$$

By the definition of Q, the function

$$Q(r,0)=Q_0(r) \tag{1.13}$$

is positive nondecreasing and satisfies the compatibility conditions $Q_0(0)=0$ and $Q_0(R)=\Lambda$.

As mentioned in [4, 7], the formulation (1.11)–(1.13) allows the consideration of some initial data for the density ρ which could be either unbounded or singular (such as measures)—a case that seems rather realistic. This means that the initial data Q_0 for problem (1.11)–(1.13) could have unbounded derivatives $Q_{0,r}$ or even be discontinuous. Moreover, using formulation (1.11)–(1.13), we have the comparison principle at hand, which is not available for system (1.6)–(1.10). Due to the scaling properties of (1.11), we can assume without loss of generality that problem (1.11)–(1.13) is posed in the unit ball $B(0,1)$. (Indeed, it is easily seen that if $Q(r,t)$ is a solution of (1.11)–(1.13), then $Q(Rr,R^2t)$ is also a solution.)

Using the new variable $x=r^2$ (no confusion with the original variable x in (1.6)–(1.10) should occur) and defining $N(x,t)=Q(r,t)$, we are led to the problem

$$N_t=4xN_{xx}+\frac{1}{\pi}NN_x,\quad 0<x<1,\ t>0, \tag{1.14}$$

$$N(0,t)=0,\quad N(1,t)=\Lambda, \tag{1.15}$$

$$N(x,0)=N_0(x),\quad 0<x<1. \tag{1.16}$$

Note that (1.14) differs from the Burgers equation only by the variable coefficient x in the diffusion term. The above problem, although it degenerates at $x=0$, may be

handled more easily than (1.11)–(1.13) since it contains fewer terms and at the same time does not have any singular coefficients in the first order terms.

As expected, the behavior of the solution of problem (1.14)–(1.16) (which is well defined for suitable initial data) depends on Λ. For $\Lambda > 8\pi$ the solution N ceases to exist in a finite time T^*; more precisely, the boundary condition $N(0,t) = 0$ is no longer fulfilled at $t = T^*$. Moreover, a "gradient blow-up" occurs at $t = T^*$ in the sense that $N_x(0,t) \to \infty$ as $t \to T^*$ and the density ρ also becomes unbounded at time T^*; cf. [8, Theorem 2(i)]. On the other hand, for $0 < \Lambda < 8\pi$ and any (admissible) initial data there is a unique global-in-time solution $N \in C([0,\infty); L^2(0,1)) \cap C^{2,1}((0,1)\times(0,\infty))$. Furthermore, N converges to the unique steady state solution:

$$N(\cdot,t) \to N_d = 8\pi \frac{x}{x+d} \quad \text{as } t \to \infty \tag{1.17}$$

in $L^p(\Omega)$, $p \geq 1$, and even in $L^\infty(\Omega)$ provided that $\sup_{t\geq 0} |N_x|_\infty < \infty$, where $d = \frac{8\pi}{\Lambda} - 1 > 0$; cf. [5]. In this case the rate of the L^1-convergence of $N(\cdot,t)$ to N_d is shown to be exponential.

In the borderline case $\Lambda = 8\pi$, the situation is still different and the problem exhibits a typical critical behavior. Namely, it is proved in [5] that there exists a global-in-time solution N, which converges to the "singular" steady state $\widetilde{N}(x) \equiv 8\pi$ (note that $\widetilde{N}$ does not satisfy the boundary condition at $x = 0$). Actually, as was proven in [39, Theorem 3], an infinite-time Dirac mass formation at the origin $r = 0$ of the ball occurs in this case. However, neither an estimation of the grow-up rate nor the asymptotic profile of the grow-up are provided in [39]. On the other hand, the authors in [5, Proposition 3.2] obtain the decay estimate

$$||N(\cdot,t) - 8\pi||_{L^1} \leq \frac{8\pi}{t} \quad \text{for} \quad t \geq 1. \tag{1.18}$$

Estimate (1.18) seems to be far from optimal since formal asymptotics performed in [46] suggest a temporal decay estimate of order

$$||N(\cdot,t) - 8\pi||_{L^1} \approx O\big(e^{-\sqrt{2t}}\big) \quad \text{as } t \to \infty. \tag{1.19}$$

Remarks 1.1. (a) The (nonradial) Patlak–Keller–Segel system has also been studied in the whole plane $\mathbb{R}^2$. Again, the behavior of solutions depends on the initial mass of the system, and a dichotomy is found [11, 17]. More precisely, assuming $0 \leq (1+|x|^2)\rho_0$ and $\rho_0 \log \rho_0 \in L^1$, there exists a critical value of the mass $N_c := 8\pi$ such that if $0 < ||\rho_0||_1 < N_c$ (subcritical case), only global-in-time solutions exist, while if $||\rho_0||_1 > N_c$ (supercritical case), the solutions blow up in finite time [11, 41]. Moreover, in the subcritical case, solutions converge to a self-similar profile as $t \to \infty$ [6, 11]. Finally, for the critical case $N = N_c$, which was studied in [10], the solution is global-in-time and grows up as a Dirac mass at the center of mass as $t \to \infty$.

(b) The only previous mathematical study of grow-up rates for a system of Patlak–Keller–Segel type concerns high dimensions, namely, $n \geq 11$, and was performed recently in [45]. There, some radial global unbounded solutions were constructed in a ball and an infinite sequence of polynomial grow-up rates was obtained (for a suitable sequence of initial data). On the contrary, our results in the present paper for $n = 2$ exhibit a grow-up rate independent of the initial data.

(c) Concerning the parabolic-parabolic Patlak–Keller–Segel system in a bounded domain with Neumann conditions, interesting results can be found in [26, 27] and [19,

37], respectively, on the asymptotics of finite-time blow-up and on global existence and the convergence of global bounded solutions.

(d) Problem (1.14)–(1.16) is in fact independent of the boundary condition (1.9) for c. Of course the boundary condition for c has to be taken into account if one wants to determine c, and not only ρ, from N.

(e) In the case where the diffusion of cells is very slow as compared to the diffusion of the chemoattractant, i.e., when $D_1 \ll D_2$ in (1.1)–(1.2), the complete system (1.1)–(1.5) is reduced to a single but nonlocal equation; cf. [51]. The global existence (subcritical case) and the finite-time blow-up (supercritical case) of solutions of the derived nonlocal equation in the two-dimensional case are studied in [31].

1.3. Heuristic description of the results and methods. Our aim is to prove rigorously the decay rate (1.19) as well as to provide a refined asymptotic profile for $N(x,t)$ as $t \to \infty$. To normalize the constants arising in the calculations we shall work with the equivalent problem

$$u_t = xu_{xx} + 2uu_x, \qquad 0 < x < 1,\ t > 0, \tag{1.20}$$

$$u(0,t) = 0, \qquad u(1,t) = \xi := \frac{\Lambda}{8\pi}, \qquad t > 0, \tag{1.21}$$

$$u(x,0) = u_0(x), \qquad 0 < x < 1, \tag{1.22}$$

which is obtained from (1.14)–(1.16) by setting $N(x,t) = 8\pi u(x,4t)$.

It is clear that the stationary part $xu_{xx} + 2uu_x = 0$ of the parabolic equation (1.20) is invariant under the rescaling $u(x) \mapsto u(kx)$ $(k > 0)$. Moreover, the steady state solution for $\xi < 1$ is given by

$$U_a(x) = 1 - \frac{1}{ax+1} = \frac{ax}{ax+1}$$

for $a = U_a'(0) = \frac{\xi}{1-\xi} > 0$. Rewriting (1.17) in terms of u, we have

$$u(x,t) \to U_a(x) \quad \text{as } t \to \infty.$$

Also, observe that $U_a(x)$ converges in a monotone increasing way to the "singular" steady state $U \equiv 1$ as $a \to \infty$ $(\xi \to 1)$.

Motivated by the above considerations, we shall look for sub- and supersolutions of problem (1.20)–(1.22), which are perturbations of a moving family of steady states

$$U_{a(t)}(x), \tag{1.23}$$

the perturbation being defined in terms of the self-similar variable $y = a(t)x$. Here, a is a function of time, diverging to infinity, which is a priori unknown and will be eventually identified by a suitable "matching" procedure (see Remark 1.3). Note that such a form was used in [46] to construct "approximate solutions" leading to the formal asymptotics mentioned above. However, the expansions in [46] contained only a correction term at the first order, while those that we here construct involve first and second order terms (see Lemmas 4.1 and 4.2). This seems necessary to obtain (rigorous) sub- and supersolutions living "close" to the actual solution and eventually provides us with the desired decay rate as well as a good description of the asymptotic profile.

As a consequence of this construction, we shall derive an infinite-time boundary gradient grow-up result, with the grow-up rate

(1.24)
$$u_x(0,t) = A(t)\Big(1 + O\big(t^{-1/2}\log t\big)\Big) \quad \text{as } t \to \infty, \quad \text{where } A(t) = \exp\left[\frac{5}{2} + \sqrt{2t}\right].$$

In terms of the solution of the original system (1.6)–(1.10), (1.24) gives an estimate of the central density of bacteria, since $\rho(0,t) = 8u_x(0,4t)$. Note that (1.24) was also predicted by formal arguments in [46]. At the same time, we show the C^1 regularity of u up to the boundary for all finite time intervals, hence ruling out the possibility of $\sup_{x\in[0,1]} u_x(x,t)$ blowing up in finite time. This problem was left open in [5]. Moreover, we obtain a precise asymptotic expansion of the solution (see formula (2.8) in Theorem 2.1). It expresses the solution as the sum of a quasi-stationary profile (cf. (1.23)) and a correction term which becomes significant only for x bounded away from 0. As a consequence, we obtain the decay

$$\|u(\cdot,t) - 1\|_{L^1(0,1)} = \Big(1 + O\big(t^{-1/2}\log t\big)\Big)\sqrt{2t}\exp\left[-\frac{5}{2} - \sqrt{2t}\right] \quad \text{as } t \to \infty,$$

again in accordance with the predictions in [46].

Remark 1.2. The study of unbounded global classical solutions of superlinear parabolic problems and their asymptotic behavior has recently attracted substantial mathematical interest. Particular effort has been devoted to the reaction-diffusion equation

$$u_t - \Delta u = u^p, \tag{1.25}$$

where such solutions are known to exist for suitable $p > 1$. Let us mention the works [33, 18, 22] for the Dirichlet problem in a ball and [42, 20, 21, 34] for the Cauchy problem. See also [43, sections 22 and 29] for related questions. The case of the Frank–Kamenetskii equation (with nonlinearity e^u instead of u^p) is also studied in [18]. As for the diffusive Hamilton–Jacobi equation

$$u_t - u_{xx} = |u_x|^p, \tag{1.26}$$

with $p > 2$, results of this kind can be found in [47]. A common feature in all these examples is the stabilization of the solution to a singular steady state, the growing-up quantity being $\|u(t)\|_\infty$ (resp., $\|u_x(t)\|_\infty$) for (1.25) (resp., (1.26)). It has to be noted that the grow-up rates, as $t \to \infty$, usually behave like either $e^{\mu t}$ or t^k. The only known exception (see [22]) seems to be the case of (1.25) with zero boundary conditions, in a ball of $\mathbb{R}^4$ with critical Sobolev exponent ($p = 3$). In this situation, unlike in spatial dimensions $n \neq 4$, there holds $\log\|u(t)\|_\infty \sim 2\sqrt{t}$, thus leading to a rate similar to that in our problem.

Remark 1.3. Let us point out that our determination of the grow-up rate for problem (1.20)–(1.22) is achieved through the matching of (sub- or super-) solutions with the imposed boundary condition at the right endpoint $x = 1$, an idea also present in [22]. This is different from what is done in [18, 20, 21, 47], where the grow-up rate is determined by the matching between inner and outer (sub-/super-) solutions. In those works, the inner solution corresponds to a self-similar, quasi-stationary evolution along a continuum of regular steady states (similar to (1.23)), but the outer solution is obtained by a linearization around the singular steady state. Here, on the contrary,

the behavior of u in the inner and outer regions is unified through a single self-similar variable $y = a(t)x$ (cf. formulae (4.1) and (4.27) below). Moreover, we point out that, in our case, a linearization around the "singular" steady state $U \equiv 1$ would not give the desired grow-up rate (1.24) but only a nonoptimal exponential upper bound based on an associated eigenvalue problem.

The paper is organized as follows. In section 2 we state the main results. Section 3 contains a number of preliminary results: In subsection 3.1, we recall the basic facts concerning local existence and comparison. In subsections 3.2 and 3.3, we show that a control on the slope at $x = 0$ is enough to prevent gradient blow-up (Lemma 3.2), and we obtain preliminary estimates of solutions for small time, which will be useful in section 4 to initialize the comparison with the main sub-/supersolutions (Lemmas 3.3 and 3.4). Subsection 3.4 is devoted to the study of a second order ordinary differential operator which plays a key role in the subsequent construction of sub-/supersolutions. The proofs of the main results are given in section 4: Subsections 4.1 and 4.2 are devoted to the construction of the main sub- and supersolutions, respectively; the proofs of Theorem 2.1 and Corollary 2.2 are finally completed in subsection 4.3.

2. Main results. Consider the problem

$$u_t - xu_{xx} = 2uu_x, \quad 0 < x < 1,\ t > 0, \tag{2.1}$$

$$u(0,t) = 0, \quad t > 0, \tag{2.2}$$

$$u(1,t) = 1, \quad t > 0, \tag{2.3}$$

$$u(x,0) = u_0(x), \quad 0 \le x \le 1. \tag{2.4}$$

Concerning the initial data, we assume that

$$u_0 \in C([0,1]), \quad u_0(0) = 0, \quad u_0(1) = 1, \quad u_0 \text{ is nondecreasing}, \tag{2.5}$$

and that

$$u_0(x) \le Kx, \quad 0 < x < 1, \quad \text{for some } K \ge 1. \tag{2.6}$$

Problem (2.1)–(2.4) admits a unique global solution, with $u \in C([0,1] \times [0,\infty))$, $u \in C^{2,1}((0,1] \times (0,\infty))$ (see [5] and section 3.1 below). Moreover, it was shown in [5] that $0 \le u \le 1$, u is nondecreasing in x, and

$$\lim_{t\to\infty} u(x,t) = 1, \quad \text{uniformly for } x \text{ in compact subsets of } (0,1]. \tag{2.7}$$

Our main results are the following.

THEOREM 2.1. *Let u_0 satisfy* (2.5) *and* (2.6)*, and denote by u the global solution of problem* (2.1)–(2.4)*. Then there holds*

$$1 - u(x,t) = \frac{1 - x + O\big(t^{-1/2}\log t\big)}{1 + A(t)x} \quad \textit{uniformly in } [0,1],\ \textit{as } t \to \infty, \tag{2.8}$$

with

$$A(t) = \exp\left[\frac{5}{2} + \sqrt{2t}\right]. \tag{2.9}$$

Moreover, we have the regularity property

$$u_x \in C\big([0,1] \times (0,\infty)\big) \tag{2.10}$$

and the estimate

$$u_x(0,t) = A(t)\Big(1 + O\big(t^{-1/2}\log t\big)\Big) \quad \text{as } t \to \infty. \tag{2.11}$$

COROLLARY 2.2. *Let u_0 satisfy (2.5) and (2.6), denote by u the global solution of problem (2.1)–(2.4), and let $A(t)$ be given by (2.9).*

(i) *The solution u satisfies the inner layer expansion (quasi-stationary behavior)*

$$1 - u(x,t) = \frac{1 + o(1)}{1 + A(t)x} \quad \text{uniformly in any region } x \le o(1), \text{ as } t \to \infty.$$

(ii) *We have the L^1-decay rate*

$$\|u(\cdot,t) - 1\|_{L^1(0,1)} = \Big(1 + O\big(t^{-1/2}\log t\big)\Big)\sqrt{2t}\exp\left[-\frac{5}{2} - \sqrt{2t}\right] \quad \text{as } t \to \infty.$$

3. Preliminaries.

3.1. Local existence and comparison principle. By [5, Theorem 2.1], we know that for any u_0 satisfying (2.5), problem (2.1)–(2.4) admits a global solution u in the following sense:

$$u \in C\big([0,\infty); L^1(0,1)\big), \tag{3.1}$$

$$u \in C^{2,1}\big((0,1] \times (0,\infty)\big), \tag{3.2}$$

$$u_x \ge 0, \quad 0 < x \le 1,\ t > 0, \tag{3.3}$$

and

$$u_t - xu_{xx} = 2uu_x, \quad 0 < x < 1,\ t > 0, \tag{3.4}$$

$$\lim_{x \to 0^+} u(x,t) = 0 \quad \text{for a.e. } t > 0, \tag{3.5}$$

$$u(1,t) = 1, \quad t > 0, \tag{3.6}$$

$$u(\cdot,0) = u_0 \quad \text{in } L^1(0,1). \tag{3.7}$$

Note that the solution is obtained in [5] as a limit of solutions of regularized problems, where xu_{xx} is replaced by $(x+\varepsilon)u_{xx}$, $\varepsilon > 0$. Also, for each $T > 0$, u is the unique local solution of (3.1)–(3.7) on $(0,T)$. If, moreover, u_0 satisfies (2.6), then

$$u \in C\big([0,1] \times [0,\infty)\big);$$

see also [8, Theorem 1 (i)]. The continuity for $t > 0$ and $x = 0$ follows from [5, Propositions 2.4 and 2.5]. For $t = 0$ and $x \in [0,1]$, the continuity can be established by comparison with simple barrier functions.

The following proposition provides a comparison principle suitable to our needs.

PROPOSITION 3.1. *Let $\tau > 0$ and the functions u, v satisfy the following regularity conditions:*

$$u, v \in C\big([0,\tau); L^1(0,1)\big), \tag{3.8}$$

$$u, v \in C^{2,1}\big((0,1] \times (0,\tau)\big), \tag{3.9}$$

$$u_x, v_x \in L^1_{loc}\big([0,1] \times (0,\tau)\big), \tag{3.10}$$

$$u, v \in L^\infty_{loc}\big([0,1] \times (0,\tau)\big). \tag{3.11}$$

Assume that

$$u_t - xu_{xx} - 2uu_x \le v_t - xv_{xx} - 2vv_x, \quad 0 < x < 1,\ 0 < t < \tau, \tag{3.12}$$

$$\lim_{x\to 0^+} u(x,t) \le \lim_{x\to 0^+} v(x,t) \quad \textit{for a.e. } t \in (0,\tau), \tag{3.13}$$

$$u(1,t) \le v(1,t), \quad 0 < t < \tau, \tag{3.14}$$

$$u(\cdot,0) \le v(\cdot,0) \quad \textit{a.e. in } (0,1). \tag{3.15}$$

Then $u \le v$ *in* $(0,1)\times(0,\tau)$.

Observe that (3.10) implies that the limits in (3.13) exist for a.e. $t \in (0,\tau)$. Note also that for any u_0 satisfying (2.5), the solution u of problem (3.1)–(3.7) satisfies conditions (3.10) and (3.11) as a consequence of (3.3), (3.5), and (3.6).

Proof of Proposition 3.1. The proof is a modification of the stability proof in [5, Theorem 3.1]. Let $z = u - v$. By (3.12), we have

$$z_t \le xz_{xx} + 2uu_x - 2vv_x = \partial_x\big(xz_x + z(u+v-1)\big), \quad 0 < x < 1,\ 0 < t < \tau. \tag{3.16}$$

For $\delta \in (0,1)$ we define the following C^1 (and piecewise C^2) convex approximations of the function $s \to s_+ = \max(s,0)$:

$$\phi_\delta(s) = \begin{cases} 0 & \text{if} \quad -\infty < s \le \delta, \\ (2\delta)^{-1}(s-\delta)^2 & \text{if} \quad \delta \le s \le 2\delta, \\ s - 3\delta/2 & \text{if} \quad 2\delta < s < \infty. \end{cases}$$

Fix $0 < t_1 < t_2 < \tau$ and $\delta \in (0,1)$. Then, for any $\varepsilon \in (0,1)$, multiplying (3.16) by $\phi_\delta'(z)$, integrating by parts, and using (3.11), (3.14), $0 \le \phi_\delta' \le 1$, and $\phi_\delta'' \ge 0$, we obtain

$$\begin{aligned}
&\int_\varepsilon^1 \phi_\delta(z(x,t_2))\,dx - \int_\varepsilon^1 \phi_\delta(z(x,t_1))\,dx \\
&= \int_{t_1}^{t_2}\int_\varepsilon^1 \phi_\delta'(z) z_t\,dx\,dt \le \int_{t_1}^{t_2}\int_\varepsilon^1 \phi_\delta'(z)\partial_x\big(xz_x + z(u+v-1)\big)\,dx\,dt \\
&= \int_{t_1}^{t_2}\Big[\phi_\delta'(z)\big(xz_x + z(u+v-1)\big)\Big]_\varepsilon^1 dt - \int_{t_1}^{t_2}\int_\varepsilon^1 \phi_\delta''(z)\big(xz_x + z(u+v-1)\big)z_x\,dx\,dt \\
&\le \varepsilon\int_{t_1}^{t_2} |z_x(\varepsilon,t)|\,dt + C\int_{t_1}^{t_2}\phi_\delta'(z(\varepsilon,t))\,dt - \int_{t_1}^{t_2}\int_\varepsilon^1 \phi_\delta''(z)(u+v-1)zz_x\,dx\,dt \\
&\equiv I_\varepsilon + J_\varepsilon + K_\varepsilon,
\end{aligned}$$

where C depends on t_1, t_2 but is independent of ε (and δ). Owing to (3.10), there exists a sequence $\varepsilon_n \to 0+$ such that $\lim_{n\to\infty} I_{\varepsilon_n} = 0$. Next, since $\lim_{n\to\infty}\phi_\delta'(z(\varepsilon_n,t)) = 0$ for a.e. $t \in (t_1,t_2)$ due to (3.13) and the definition of ϕ_δ, we deduce that $\lim_{n\to\infty} J_{\varepsilon_n} = 0$ by dominated convergence. Consequently,

$$\begin{aligned}
\int_0^1 \phi_\delta(z(x,t_2))\,dx - \int_0^1 \phi_\delta(z(x,t_1))\,dx &\le -\int_{t_1}^{t_2}\int_0^1 \phi_\delta''(z)(u+v-1)zz_x\,dx\,dt \\
&\le C\int_{t_1}^{t_2}\int_0^1 |z\phi_\delta''(z)||z_x|\,dx\,dt.
\end{aligned}$$

Now, observe that $\lim_{\delta\to 0}\phi_\delta(s) = s_+$ and $\lim_{\delta\to 0} s\phi_\delta''(s) = 0$ for each $s \in \mathbb{R}$. Using $0 \le \phi_\delta(s) \le s_+$, (3.10), and (3.11), we may pass to the limit $\delta \to 0$ by dominated

convergence in the preceding inequality, and we obtain

$$\int_0^1 z_+(x,t_2)\,dx - \int_0^1 z_+(x,t_1)\,dx \le 0.$$

Letting $t_1 \to 0+$ and using (3.8) and (3.15), we conclude that $\int_0^1 z_+(x,t_2)\,dx = 0$ for all $t_2 \in (0,\tau)$; hence $u \le v$ in $(0,1)\times(0,\tau)$. □

3.2. Sufficient condition for C^1 regularity. As noted in, e.g., [12, section 2.2] and [23, section 2], by means of the transformation

$$w(r,t) := \frac{8}{r^2}u(r^2,4t) = \frac{1}{\pi r^2}\int_{B_r}\rho(y,4t)\,dy$$

(and $w_0(r) := 8r^{-2}u_0(r^2)$), problem (2.1)–(2.4) becomes equivalent to

$$w_t - \tilde{\Delta}w = w^2 + \tfrac{r}{2}\,w\,w_r, \quad 0<r<1,\ t>0, \tag{3.17}$$

$$w_r(0,t) = 0, \quad t>0, \tag{3.18}$$

$$w(1,t) = 8, \quad t>0, \tag{3.19}$$

$$w(r,0) = w_0(r), \quad 0<r<1, \tag{3.20}$$

where $\tilde{\Delta}w := w_{rr} + \frac{3}{r}w_r$, which in turn corresponds to the radial Laplacian in four space dimensions. It should be noticed that w has the same scale invariance as ρ but is smoother than ρ. Problem (3.17)–(3.20) turns out to be convenient regarding the study of C^1 regularity of u up to the boundary, which was left open in [5]. Namely, using this transformation, one can show the following additional properties for u.

LEMMA 3.2. *Let u_0 satisfy* (2.5) *and* (2.6)*, and denote by u the global solution of problem* (2.1)–(2.4)*. For any given $T>0$, if*

$$\sup_{0<x<1,\,0<t<T}\frac{u(x,t)}{x} < \infty, \tag{3.21}$$

then

$$u_x \in C\big([0,1]\times(0,T]\big) \tag{3.22}$$

and

$$u_x(0,t) > 0, \quad 0<t\le T. \tag{3.23}$$

Note that the assumption (3.21) (for all $T>0$) will be shown in section 4 (see Lemma 4.3(ii)) as a consequence of our main supersolution construction, hence leading to the global C^1 regularity property (2.10) in Theorem 2.1.

Proof of Lemma 3.2. Since the semilinear parabolic equation in (3.17) has only linear growth with respect to the gradient, standard arguments based on the variation-of-constants formula (see, e.g., [43, Example 51.30] or [15, p. 889]) show that problem (3.17)–(3.20) is locally well posed in the space of (radial, nonnegative) L^∞-functions. More precisely, for any $0 \le w_0 \in L^\infty(0,1)$, there exists a unique, maximal (radial, nonnegative) classical solution w of (3.17)–(3.20), with $w \in C^{2,1}\big([0,1]\times(0,T_m)\big)$ and $w \in C\big([0,T_m);L^q(0,1)\big)$ for all finite $q \le 1$. Moreover,

$$T_m < \infty \Longrightarrow \lim_{t\to T_m}\|w(t)\|_\infty = \infty. \tag{3.24}$$

Now, if u_0 satisfies (2.5)–(2.6), then $w_0(r) := 8r^{-2}u_0(r^2)$ verifies $0 \le w_0 \in L^\infty(0,1)$. Denote by w the corresponding maximal solution of (3.17)–(3.20), and let

$$\tilde{u}(x,t) = \frac{x}{8} w(\sqrt{x}, t/4), \qquad 0 \le x \le 1,\ 0 \le t < 4T_m.$$

We see that $\tilde{u}$ satisfies the regularity conditions in (3.8), (3.9), and (3.11) with $\tau = 4T_m$. Also, since

$$\tilde{u}_x(x,t) = \frac{1}{8} w(\sqrt{x}, t/4) + \frac{\sqrt{x}}{16}\, w_r(\sqrt{x}, t/4), \qquad 0 < x \le 1,\ 0 < t < 4T_m,$$

we have

$$\tilde{u} \in C^{1,0}([0,1] \times (0, 4T_m)) \tag{3.25}$$

and hence in particular (3.10) with $\tau = 4T_m$. Then one easily checks that $\tilde{u}$ solves (2.1)–(2.3) on $[0, 4T_m)$, along with (3.7). We may thus apply Proposition 3.1 to deduce that $\tilde{u} = u$ on $(0, T_0)$ with $T_0 = \min(T, 4T_m)$.

We claim that $T_m > T/4$. Indeed, if $T_m \le T/4$, then (3.24) implies

$$\lim_{t \to 4T_m} \sup_{0<x<1} \frac{u(x,t)}{x} = \infty,$$

contradicting (3.21). Consequently, property (3.22) follows from (3.25). Moreover, $w > 0$ in $[0,1] \times (0, T_m)$ by the strong maximum principle, which readily implies (3.23). □

3.3. Small time estimates. Throughout the paper, we denote by $\mathcal{P}$ the parabolic operator defined by

$$\mathcal{P}v := v_t - x v_{xx} - 2 v v_x. \tag{3.26}$$

The following two lemmas will be useful to initialize the comparison between u and the main sub-/supersolutions constructed in section 4.

LEMMA 3.3. *Let u_0 satisfy* (2.5) *and* (2.6)*, and denote by u the global solution of problem* (2.1)–(2.4)*. Then there exist $\tau, \eta > 0$ such that*

$$u(x,t) \le 2Kx, \qquad 0 \le x \le 1,\ 0 \le t \le \tau, \tag{3.27}$$

and

$$u(x,\tau) \le 1 - \eta(1-x), \qquad 0 \le x \le 1.$$

Proof. Define

$$\overline{v}(x,t) = \frac{Kx}{1-2Kt}, \qquad 0 \le x \le 1,\ 0 \le t < 1/2K.$$

Since

$$\mathcal{P}\overline{v} = \frac{2K^2 x}{(1-2Kt)^2} - \frac{2K^2 x}{(1-2Kt)^2} = 0$$

and $\overline{v}(1,t) \ge K \ge 1$, the comparison principle guarantees that

$$u(x,t) \le \overline{v}(x,t) \le 2Kx, \qquad 0 \le x \le 1,\ 0 < t \le 1/4K.$$

Fix $\tau = 1/4K$. By Hopf's lemma, we have $u_x(1,\tau) > 0$. Since $u(\cdot,\tau)$ is nondecreasing in x, this implies $u(x,\tau) \le 1-\eta(1-x)$, $0 \le x \le 1$, for $\eta > 0$ sufficiently small, and the conclusion follows. ∎

LEMMA 3.4. *Let u_0 satisfy* (2.5) *and* (2.6)*, and denote by u the global solution of problem* (2.1)–(2.4)*. For any given $\delta \in (0,1)$, there exists $T_\delta > 0$ such that*

$$u(x,T_\delta) \ge \min(1-\delta, x/\delta), \qquad 0 \le x \le 1.$$

Proof. By Lemma 3.2, we may fix a small $\tau > 0$ such that $u_x(\cdot,\tau) \in C([0,1])$ and $u_x(0,\tau) > 0$. Therefore, $u(x,\tau) \ge \eta x$ for all $x \in [0,1]$ and some $\eta \in (0,1)$. Since $\mathcal{P}[\eta x] \le 0$ and $\eta < 1 = u(1,t)$, the comparison principle implies that

$$u(x,t) \ge \eta x, \qquad 0 \le x \le 1,\ t \ge \tau. \tag{3.28}$$

On the other hand, by (2.7), there exists $T > \tau$ such that

$$u(x,t) \ge 1-\delta, \qquad (1-\delta)\delta \le x \le 1,\ t \ge T. \tag{3.29}$$

Define

$$\underline{v}(x,t) = \big(\eta + 2\eta^2(t-T)\big)x, \qquad 0 \le x \le 1,\ t \ge T. \tag{3.30}$$

We have

$$\mathcal{P}\underline{v} = 2\eta^2 x - 2\big(\eta + 2\eta^2(t-T)\big)^2 x \le 0 \tag{3.31}$$

and, due to (3.28),

$$u(x,T) \ge \underline{v}(x,T), \qquad 0 \le x \le 1. \tag{3.32}$$

Since $\eta < 1 < 1/\delta$, we may find $T_\delta > T$ such that

$$\eta + 2\eta^2(T_\delta - T) = 1/\delta. \tag{3.33}$$

In view of (3.29), (3.30), and (3.33), we have

$$u\big((1-\delta)\delta, t\big) \ge 1-\delta \ge \underline{v}\big((1-\delta)\delta, t\big), \qquad T \le t \le T_\delta. \tag{3.34}$$

It then follows from (3.31), (3.32), (3.34), and the comparison principle that

$$u(x,T_\delta) \ge x/\delta, \qquad 0 \le x \le (1-\delta)\delta.$$

Using $\mathcal{P}[x/\delta] \le 0$ and (3.29), we deduce that

$$u(x,t) \ge x/\delta, \qquad 0 \le x \le (1-\delta)\delta,\ t \ge T_\delta.$$

This combined with (3.29) yields the desired conclusion. ∎

3.4. ODE lemmas. We consider the differential operator

$$\mathcal{L}w := yw'' + \frac{2yw'}{1+y} + \frac{2w}{(1+y)^2}.$$

First, the expression for the operator $\mathcal{L}$ reads

$$\mathcal{L}w = \left[\left(\frac{y}{y+1}\right)^2 \left(\frac{(y+1)^2}{y} w\right)'\right]'.$$

If $\psi \in C([0,\infty))$ satisfies $\psi(y) = O(y)$ as $y \to 0$, then the problem

$$\begin{aligned} \mathcal{L}w &= \psi, \quad y > 0, \\ w(0) &= 0,\ w'(0) = 0 \end{aligned}$$

admits a unique solution w, and w can be represented as

$$w(y) = \mathcal{L}_0^{-1}\psi := \frac{y}{(y+1)^2}\int_0^y \left(\frac{t+1}{t}\right)^2 \int_0^t \psi(s)\,ds\,dt$$

(note that the integral is convergent due to the assumption on ψ). In particular,

$$\psi \geq 0 \text{ on } [0,\infty) \implies \mathcal{L}_0^{-1}\psi \geq 0 \text{ on } [0,\infty). \tag{3.35}$$

On the other hand, $w_0(y) = \frac{y}{(y+1)^2}$ solves

$$\begin{aligned} \mathcal{L}w &= 0, \quad y > 0, \\ w(0) &= 0,\ w'(0) = 1. \end{aligned}$$

In the next section, to construct our main sub- and supersolutions, we will need to know the asymptotic behavior of the action of the operator $\mathcal{L}_0$ on some particular functions as $y \to \infty$. More precisely, let us define

$$\begin{aligned} f &= \left(I + \mathcal{L}_0^{-1}\right)\left(\frac{y}{(y+1)^2}\right), \\ \tilde{f} &= 2ff' - yf' + f, \\ g &= \mathcal{L}_0^{-1}\tilde{f}, \end{aligned}$$

and

$$h = \mathcal{L}_0^{-1}(\tilde{f} + M\varphi) = g + M\mathcal{L}_0^{-1}\varphi,$$

where $M > 0$ and

$$\varphi \in C^1([0,\infty)), \qquad \varphi(0) = 0, \qquad \varphi(y) = \frac{1}{\log y},\ y \geq 2.$$

We have the following lemmas.

LEMMA 3.5. *As $y \to \infty$, the function f satisfies*

$$\text{(i)} \qquad f(y) = \log y - 2 + O\left(\frac{\log^2 y}{y}\right);$$

$$\text{(ii)} \qquad f'(y) = \frac{1}{y} + O\left(\frac{\log^2 y}{y^2}\right).$$

LEMMA 3.6. *As $y \to \infty$, the functions g and h satisfy*

$$\text{(i)} \qquad g(y) = \frac{y\log y}{2} - \frac{9y}{4} + O\left(\log^3 y\right);$$

$$\text{(ii)} \qquad g'(y) = \frac{\log y}{2} - \frac{7}{4} + O\left(\frac{\log^3 y}{y}\right);$$

$$\text{(iii)} \qquad h(y) = \frac{y\log y}{2} - \frac{9y}{4} + O\left(\frac{y}{\log y}\right);$$

$$\text{(iv)} \qquad h'(y) = \frac{\log y}{2} - \frac{7}{4} + O\left(\frac{1}{\log y}\right).$$

Proof of Lemma 3.5.

(i) Using

$$\log(y+1) = \log y + O(1/y) \quad \text{as } y \to \infty, \tag{3.36}$$

we obtain

$$\begin{aligned} f(y) &= \frac{y}{(y+1)^2}\left[1 + \int_0^y \left(\frac{t+1}{t}\right)^2 \int_0^t \left(\frac{1}{s+1} - \frac{1}{(s+1)^2}\right) ds\, dt\right] \\ &= \frac{y}{(1+y)^2}\left[1 + \int_0^y \left\{\left(1 + \frac{2}{t} + \frac{1}{t^2}\right)\left(\log(t+1) - \frac{t}{t+1}\right)\right\} dt\right] \\ &= \frac{y}{(1+y)^2}\left[y\log y - 2y + O\big(\log^2 y\big)\right] \\ &= \log y - 2 + O\left(\frac{\log^2 y}{y}\right) \quad \text{as } y \to \infty. \end{aligned}$$

(ii) Now, using (i), we deduce

$$\begin{aligned} f'(y) &= \left[\frac{1}{y} - \frac{2}{y+1}\right] f(y) + \frac{1}{y}\left(\log(y+1) - \frac{y}{y+1}\right) \\ &= \left(-\frac{1}{y} + O\left(\frac{1}{y^2}\right)\right)\left(\log y - 2 + O\left(\frac{\log^2 y}{y}\right)\right) + \frac{\log(y+1)}{y} - \frac{1}{y+1} \\ &= \frac{1}{y} + O\left(\frac{\log^2 y}{y^2}\right) \quad \text{as } y \to \infty. \qquad \square \end{aligned}$$

To show Lemma 3.6, we first note that, due to Lemma 3.5 and (3.36), we have

$$\tilde{f}(y) = f_1(y) - 3f_2(y) + O(f_3(y)) \quad \text{as } y \to \infty,$$

where

$$f_1(y) = \log(y+1), \quad f_3(y) = \frac{\log^2(y+1)}{y+1},$$

and

$$f_2 \in C^1([0,\infty)), \qquad f_2(0) = 0, \qquad f_2(y) = 1,\ y \geq 1.$$

Denote $g_i = \mathcal{L}_0^{-1} f_i$ for $i = 1,2,3$ and $g_4 = \mathcal{L}_0^{-1}\varphi$. Lemma 3.6 will then be an immediate consequence of the following lemma.

LEMMA 3.7. *As $y \to \infty$, the functions g_i satisfy*

(i) $g_1(y) = \dfrac{y\log y}{2} - \dfrac{3y}{4} + O(\log y)$ *and* $g_1'(y) = \dfrac{\log y}{2} - \dfrac{1}{4} + O\left(\dfrac{\log y}{y}\right)$;

(ii) $g_2(y) = \dfrac{y}{2} + O(1)$ *and* $g_2'(y) = \dfrac{1}{2} + O\left(\dfrac{1}{y}\right)$;

(iii) $g_3(y) = O\left(\log^3 y\right)$ *and* $g_3'(y) = O\left(\dfrac{\log^3 y}{y}\right)$;

(iv) $g_4(y) = O\left(\dfrac{y}{\log y}\right)$ *and* $g_4'(y) = O\left(\dfrac{1}{\log y}\right)$.

Proof.

(i) As $y \to \infty$, we have

$$\begin{aligned} g_1(y) &= \frac{y}{(y+1)^2}\int_0^y \left(\frac{t+1}{t}\right)^2 \big((t+1)\log(t+1)-t\big)\,dt \\ &= \frac{y}{(1+y)^2}\int_0^y \left[(t+1)\log(t+1)-t+O\left(\log(t+1)\right)\right]dt \\ &= \left[\frac{1}{y}+O\left(\frac{1}{y^2}\right)\right]\left[\frac{y^2\log y}{2}-\frac{3y^2}{4}+O\left(y\log y\right)\right] \\ &= \frac{y\log y}{2}-\frac{3y}{4}+O\left(\log y\right); \end{aligned}$$

hence

$$\begin{aligned} g_1'(y) &= \left[\frac{1}{y}-\frac{2}{y+1}\right]g_1(y)+\frac{1}{y}\int_0^y \log(s+1)\,ds \\ &= \left(-\frac{1}{y}+O\left(\frac{1}{y^2}\right)\right)\left(\frac{y\log y}{2}-\frac{3y}{4}+O\left(\log y\right)\right)+\frac{(y+1)\log(y+1)-y}{y} \\ &= \frac{\log y}{2}-\frac{1}{4}+O\left(\frac{\log y}{y}\right). \end{aligned}$$

(ii) Due to the definition of g_2, there exist constants $C_1, C_2 \in \mathbb{R}$ such that, for $y > 1$,

$$\begin{aligned} g_2(y) &= \frac{y}{(y+1)^2}\left[\int_0^1 \left(\frac{t+1}{t}\right)^2 \int_0^t f_2(s)\,ds\,dt+\int_1^y \left(\frac{t+1}{t}\right)^2 (C_1+t)\,dt\right] \\ &= \frac{y}{(y+1)^2}\left[C_2+\frac{y^2}{2}+O(y)\right] = \frac{y}{2}+O(1) \quad \text{as } y\to\infty. \end{aligned}$$

Therefore, for $y > 1$,

$$\begin{aligned} g_2'(y) &= \left[\frac{1}{y}-\frac{2}{y+1}\right]g_2(y)+\frac{y}{(y+1)^2}\left(\frac{y+1}{y}\right)^2 (C_1+y) \\ &= \left[\frac{1}{y}-\frac{2}{y+1}\right]g_2(y)+1+O\left(\frac{1}{y}\right) = \frac{1}{2}+O\left(\frac{1}{y}\right) \quad \text{as } y\to\infty. \end{aligned}$$

(iii) As $y \to \infty$, we have

$$\begin{aligned} g_3(y) &= \frac{y}{3(y+1)^2}\int_0^y \left(\frac{t+1}{t}\right)^2 \log^3(t+1)\,dt \\ &= \frac{y}{3(1+y)^2}\int_0^y O\left(\log^3(t+1)\right)dt \\ &= \frac{y}{3(1+y)^2}\,O\left((y+1)\log^3(y+1)\right) = O\left(\log^3 y\right); \end{aligned}$$

hence

$$\begin{aligned} g_3'(y) &= \left[\frac{1}{y}-\frac{2}{y+1}\right]g_3(y)+\frac{1}{y}\int_0^y \frac{\log^2(t+1)}{(t+1)}\,dt \\ &= \left(-\frac{1}{y}+O\left(\frac{1}{y^2}\right)\right)O\left(\log^3 y\right)+\frac{\log^3(y+1)}{3y} = O\left(\frac{\log^3 y}{y}\right). \end{aligned}$$

(iv) Similarly to (ii), in this case we have, for $y > 2$,

$$\begin{aligned} g_4(y) &= \frac{y}{(y+1)^2}\left[\int_0^2 \left(\frac{t+1}{t}\right)^2 \int_0^t \varphi(s)\,ds\,dt + \int_2^y \left(\frac{t+1}{t}\right)^2 \left(C_1 + \int_2^t \frac{ds}{\log s}\right) dt\right] \\ &= \frac{y}{(y+1)^2}\left[C_2 + \int_2^y \left(\frac{t+1}{t}\right)^2 O\left(\frac{t}{\log t}\right) dt\right] \\ &= \frac{y}{(y+1)^2} O\left(\frac{y^2}{\log y}\right) = O\left(\frac{y}{\log y}\right) \quad \text{as } y \to \infty. \end{aligned}$$

Therefore, for $y > 2$,

$$\begin{aligned} g_4'(y) &= \left[\frac{1}{y} - \frac{2}{y+1}\right] g_4(y) + \frac{y}{(y+1)^2}\left(\frac{y+1}{y}\right)^2 \left(C_1 + \int_2^y \frac{ds}{\log s}\right) \\ &= O\left(\frac{1}{\log y}\right) \quad \text{as } y \to \infty. \qquad \square \end{aligned}$$

4. Proof of the main results.

4.1. Construction of a subsolution. Motivated by the idea of an asymptotic expansion around (moving) steady states and based on a self-similar variable (see subsection 1.3), we make the following ansatz:

$$\underline{u}(x,t) = 1 - \frac{1}{y+1} + b(t)f(y) - b^2(t)g(y), \qquad y = a(t)x,$$

where the functions a, b, f, g have to be determined. Note that the variable y now ranges into the time-dependent interval $[0, a(t)]$. Here, a and b are expected to satisfy

$$a(t) \sim u_x(0,t), \quad \lim_{t\to\infty} a(t) = \infty, \quad \text{and} \quad \lim_{t\to\infty} b(t) = 0.$$

LEMMA 4.1. *The problem*

$$\begin{aligned} &\underline{u}_t - x\underline{u}_{xx} \le 2\,\underline{u}\,\underline{u}_x, \quad 0 < x < 1,\ t > 0, \\ &\underline{u}(0,t) = 0, \quad t \ge 0, \\ &\underline{u}(1,t) < 1, \quad t \ge 0, \end{aligned}$$

admits a solution of the form

$$\underline{u}(x,t) = 1 - \frac{1}{y+1} + b(t)f(y) - b^2(t)g(y), \qquad y = a(t)x, \tag{4.1}$$

where the smooth functions $a > 0$, $b > 0$, $f \ge 0$, and g have the following properties:

$$f(y) \sim \log y, \quad g(y) \sim \frac{y \log y}{2} \quad \text{as } y \to \infty,$$

$$f(0) = g(0) = f'(0) = g'(0) = 0, \tag{4.2}$$

$$a(t) = \left(1 + O\big(t^{-1/2}\log t\big)\right) \exp\left[\frac{5}{2} + \sqrt{2t}\right] \quad \text{as } t \to \infty, \tag{4.3}$$

$$b(t) = \frac{1 + O\big(t^{-1/2}\big)}{a(t)\log a(t)} \quad \text{as } t \to \infty, \tag{4.4}$$

and, moreover,

$$\underline{u}_x > 0, \quad 0 \le x \le 1,\ t \ge 0. \tag{4.5}$$

Proof. Step 1. *Construction of the subsolution.* In what follows we shall omit the variables t and/or y when no confusion is likely. We take $\underline{u}$ as in (4.1) where we assume

$$a > 0 \quad \text{and} \quad \lim_{t\to\infty} a(t) = \infty. \tag{4.6}$$

We compute

$$\underline{u}_x = \frac{a}{(1+y)^2} + baf'(y) - b^2 a g'(y), \tag{4.7}$$

$$\underline{u}_{xx} = \frac{-2a^2}{(1+y)^3} + ba^2 f''(y) - b^2 a^2 g''(y),$$

and

$$\underline{u}_t = \frac{a'x}{(1+y)^2} + \left[b'f(y) + ba'xf'(y) - 2bb'g(y) - b^2a'xg'(y)\right];$$

hence

$$\underline{u}_t = \frac{a'}{a}\frac{y}{(1+y)^2} + \left[b'f(y) + \frac{ba'}{a}yf'(y) - 2bb'g(y) - \frac{b^2a'}{a}yg'(y)\right].$$

Recall that the operator $\mathcal{P}$ is defined in (3.26). It follows that

$$\begin{aligned}\mathcal{P}\underline{u} = {} & \frac{a'}{a}\frac{y}{(1+y)^2} + \left[b'f + \frac{ba'}{a}yf' - 2bb'g - \frac{b^2a'}{a}yg'\right] \\ & + 2a\,\frac{y}{(1+y)^3} - ba\,yf'' + b^2a\,yg'' \\ & - 2a\left[\frac{y}{1+y} + bf - b^2g\right]\left[\frac{1}{(1+y)^2} + bf' - b^2g'\right].\end{aligned}$$

Collecting terms of the same order in b yields

$$\begin{aligned}\mathcal{P}\underline{u} = {} & \frac{a'}{a}\frac{y}{(1+y)^2} + \left[b'f + \frac{ba'}{a}yf' - 2bb'g - \frac{b^2a'}{a}yg'\right] - ab\left[yf'' + \frac{2f}{(1+y)^2} + \frac{2yf'}{1+y}\right] \\ & + ab^2\left[yg'' + \frac{2g}{(1+y)^2} + \frac{2yg'}{1+y} - 2ff'\right] + 2ab^3\left[f'g + fg'\right] - 2ab^4gg'.\end{aligned} \tag{4.8}$$

The natural scaling of the equation leads to the choice

$$b := \frac{a'}{a^2}, \tag{4.9}$$

so that in the right-hand side (RHS) of (4.8), the first term will be of the same order as the terms in the second bracket. Assuming

$$a' > 0, \tag{4.10}$$

we also denote

$$\gamma := \left(\frac{a}{a'}\right)' \tag{4.11}$$

and observe that

$$\frac{a'}{a} = ab, \qquad b' = -(1+\gamma)ab^2, \tag{4.12}$$

where the last equality comes from

$$\gamma = \left(\frac{a}{a'}\right)' = \left(\frac{1}{ab}\right)' = -\frac{b'}{ab^2} - \frac{a'}{a^2 b} = -\frac{b'}{ab^2} - 1.$$

To make things clear, let us already stress that the final choice of a will guarantee

$$\gamma \geq 0 \quad \text{and} \quad \lim_{t\to\infty} \gamma(t) = 0.$$

Using (4.12), we can recast identity (4.8) in the form

$$\begin{aligned}\mathcal{P}\underline{u} &= ab\left[\frac{y}{(1+y)^2} - yf'' - \frac{2f}{(1+y)^2} - \frac{2yf'}{1+y}\right] \\ &\quad + ab^2\left[yg'' + \frac{2g}{(1+y)^2} + \frac{2yg'}{1+y} - 2ff' + yf' - (1+\gamma)f\right] \\ &\quad + ab^3\left[2f'g + 2fg' - yg' + 2(1+\gamma)g\right] - 2ab^4 gg';\end{aligned}$$

hence

$$\begin{aligned}\mathcal{P}\underline{u} &= ab\left[\frac{y}{(1+y)^2} - \mathcal{L}f\right] + ab^2\left[\mathcal{L}g - 2ff' + yf' - (1+\gamma)f\right] \\ &\quad + ab^3\left[2f'g + 2fg' - yg' + 2(1+\gamma)g\right] - 2ab^4 gg'.\end{aligned} \tag{4.13}$$

Let us now choose

$$f := (I + \mathcal{L}_0^{-1})\left(\frac{y}{(1+y)^2}\right) \geq \frac{y}{(1+y)^2} \geq 0, \tag{4.14}$$

which solves $\mathcal{L}f = y/(1+y)^2$ for $y > 0$, with $f(0) = 0$ and $f'(0) = 1$ (cf. subsection 3.4). Dividing by ab^2, we see that $\mathcal{P}\underline{u}$ has the same sign as the quantity

$$A := \left[\mathcal{L}g - 2ff' + yf' - (1+\gamma)f\right] + b\left[2f'g + 2fg' - yg' + 2(1+\gamma)g\right] - 2b^2 gg'.$$

Next we choose

$$g := \mathcal{L}_0^{-1}\big(2ff' - yf' + f\big).$$

Therefore,

$$A = -\gamma f + b\left[2f'g + 2fg' - yg' + 2(1+\gamma)g\right] - 2b^2 gg'.$$

We now proceed to show that the quantity A is nonpositive for large t by considering separately the regions $y_0 \le y \le a(t)$ and $0 \le y \le y_0$ for some large y_0 independent of t. At this point, we make the additional assumptions that

$$\gamma \sim \frac{1}{\log a} \quad \text{as } t \to \infty \tag{4.15}$$

and

$$a' \sim \frac{a}{\log a}; \quad \text{hence} \quad b \sim \frac{1}{a \log a} \quad \text{as } t \to \infty \tag{4.16}$$

(which will be verified on the final choice of the function a; actually more precise expansions of γ and b will be needed in the final matching process). By Lemmas 3.5 and 3.6, we have

$$f \sim \log y, \quad f'g = o(g), \quad fg' = o(g), \quad \text{and} \quad yg' \sim g \sim \frac{y \log y}{2} \quad \text{as } y \to \infty.$$

Consequently, fixing $\delta > 0$ and taking y_0 and t_0 large enough, we have, for $y_0 \le y \le a(t)$ and $t \ge t_0$,

$$-\gamma f \le (-1+\delta)\frac{\log y}{\log a}, \qquad g, g' \ge 0,$$

and

$$\begin{aligned} 2f'g + 2fg' - yg' + 2(1+\gamma)g &\le \delta\, y \log y - \frac{1}{2} y \log y + 2(1+\gamma)\left(\frac{1}{2}+\delta\right) y \log y \\ &\le \left(\frac{1}{2} + 4\delta\right) y \log y. \end{aligned}$$

Taking $\delta = 1/12$ and also using (4.16), we thus obtain

$$A \le (-1+\delta)\frac{\log y}{\log a} + \frac{1}{a \log a}\left(\frac{1}{2}+5\delta\right) y \log y = \frac{\log y}{\log a}\left(-1+\delta+\left(\frac{1}{2}+5\delta\right)\frac{y}{a}\right) \le 0$$

for $y_0 \le y \le a(t)$ and $t \ge t_0$ (possibly larger). Next, for $0 \le y \le y_0$, (4.14) implies

$$f(y) \ge c_1 y, \quad 0 \le y \le y_0,$$

whereas $f(0) = g(0) = 0$ yields

$$|2f'g + 2fg' - yg'| + 4|g| + |gg'| \le c_2 y, \quad 0 \le y \le y_0,$$

with $c_1, c_2 > 0$. Consequently,

$$A \le -c_1 \gamma(t) y + c_2 b(t) y = \left[-c_1 + c_2 \frac{b(t)}{\gamma(t)}\right] \gamma(t) y \le 0$$

on $[0, y_0]$ for t large enough, due to (4.15) and (4.16).

We have thus proved that, under conditions (4.6), (4.10), (4.15), and (4.16), there holds $\mathcal{P}\underline{u} \le 0$ in $(0,1) \times (T, \infty)$ for T large enough. By a time shift we may obviously take $T = 0$.

Step 2. *Determination of $a(t)$ by matching at the outer boundary.* Next, the determination of $a(t)$ will be done by "matching" with the boundary condition at $x = 1$, i.e., by writing

$$\underline{u}(1,t) < 1,$$

which is equivalent to

$$bf(a) - b^2 g(a) < \frac{1}{a+1}. \tag{4.17}$$

It is of course sufficient to check (4.17) for large t (thanks to the possibility of shifting time). Let us first sketch the resolution of (4.17) in a rough way. Using (4.9) and applying Lemmas 3.5(i) and 3.6(i) at leading order, we are left with

$$\frac{a'}{a^2}\left(\log a - \frac{a'}{a^2}\frac{a\log a}{2}\right) \lesssim \frac{1}{a+1} \quad \text{as } t \to \infty. \tag{4.18}$$

We expect the second term in the bracket of the left-hand side (LHS) of the preceding relation to be much smaller than the first one as $a \to \infty$. If we ignore it, we obtain the differential inequality

$$a' \lesssim \frac{a}{\log a} \quad \text{as } t \to \infty, \tag{4.19}$$

which implies that

$$a(t) \lesssim e^{\sqrt{2t}} \quad \text{as } t \to \infty.$$

However, the latter estimation is not accurate enough to show the desired estimate, and we thus add a correction term in (4.19). More precisely, we look for $a(t)$ as the solution of

$$a' = \frac{a}{\log a}(1+\eta), \quad t > 0, \qquad a(0) = 2, \tag{4.20}$$

where the correction term $\eta = \eta(a)$ has the form

$$\eta = \frac{5}{2\log a} + \frac{K}{\log^2 a}, \quad K > 0. \tag{4.21}$$

Now plugging (4.20) into (4.17), recalling also (4.9), and using the exact asymptotic behavior of $f(a), g(a)$ as $a \to \infty$, provided by Lemmas 3.5(i) and 3.6(i), we are reduced to the condition

$$\frac{1+\eta}{a\log a}\left[\log a - 2 + O\left(\frac{\log^2 a}{a}\right) - \frac{1+\eta}{a\log a}\left(\frac{a\log a}{2} - \frac{9a}{4} + O\left(\log^3 a\right)\right)\right] < \frac{1}{a+1}$$

as $t \to \infty$ or

$$(1+\eta)\left[1 - \frac{5+\eta}{2\log a} + \frac{9}{4\log^2 a} + \frac{9\eta}{4\log^2 a} + O\left(\frac{\log a}{a}\right)\right] < \frac{a}{a+1} \quad \text{as } t \to \infty. \tag{4.22}$$

Plugging (4.21) into (4.22), we first obtain

$$\left(1 + \frac{5}{2\log a} + \frac{K}{\log^2 a}\right)\left[1 - \frac{5}{2\log a} + \frac{1}{\log^2 a} + O\left(\frac{1}{\log^3 a}\right)\right] < 1 - \frac{1}{a+1} \quad \text{as } t \to \infty$$

and finally

$$1+\frac{4K-21}{4\log^2 a}+O\left(\frac{1}{\log^3 a}\right)<1-\frac{1}{a+1}\quad \text{as } t\to\infty. \tag{4.23}$$

In order for (4.23) to be satisfied, we choose $K<\frac{21}{4}$, and we then obtain the following ODE for a:

$$a'=\frac{a}{\log a}\left(1+\frac{5}{2\log a}+\frac{K}{\log^2 a}\right),\quad t>0,\qquad a(0)=2. \tag{4.24}$$

Here we should mention that the same form for η, given by (4.21), will also be considered for the supersolution, with a different constant K; see the next subsection. Equation (4.24) implies that

$$a'=\frac{a}{\log a-5/2}\left(1+O\big(\log^{-2} a\big)\right)\quad \text{as } t\to\infty,$$

and, integrating with respect to t, we get

$$\log^2 a-5\log a=2t+O\left(\int_0^t\frac{ds}{\log^2(a(s))}\right)\quad \text{as } t\to\infty.$$

Solving the quadratic polynomial in $\log a$ and noting that $\log a(s)\ge\sqrt{2s}$ by (4.24), we end up with (4.3). As for (4.4), it follows from

$$\begin{aligned} b=\frac{a'}{a^2}&=\frac{1}{a\log a}\left(1+\frac{5}{2\log a}+\frac{K}{\log^2 a}\right)=\frac{1+O\left(\log^{-1} a\right)}{a\log a}\\ &=\frac{1+O\left(t^{-1/2}\right)}{a\log a}\quad \text{as } t\to\infty, \end{aligned} \tag{4.25}$$

where we used (4.24) and $\log a\ge\sqrt{2t}$ as $t\to\infty$. On the other hand, denoting $G(s)=s+(5/2)s^2+Ks^3$ and using (4.24), we see that $\gamma=(a/a')'$ satisfies

$$\gamma=\left[\frac{1}{G\big(1/\log a\big)}\right]'=\frac{a'}{a\log^2 a}\frac{G'\big(1/\log a\big)}{G^2\big(1/\log a\big)}=\frac{G'\big(1/\log a\big)}{\log^2 a\,G\big(1/\log a\big)}=H\big(1/\log a\big), \tag{4.26}$$

where $H(s)=s(1+5s+3Ks^2)(1+(5/2)s+Ks^2)^{-1}$. Finally, the assumed properties (4.6), (4.10), (4.15), and (4.16) of a,b,γ are immediate consequences of (4.24), (4.25), and (4.26).

Step 3. *Proof of* (4.5). By (4.7) we have

$$a^{-1}\underline{u}_x=\frac{1}{(1+y)^2}+bf'(y)-b^2g'(y).$$

By Lemma 3.6 and (4.16), taking y_1 and t_1 large enough, we have, for $t\ge t_1$ and $y_1\le y\le a(t)$,

$$a^{-1}\underline{u}_x\ge\frac{1}{2a^2}-\frac{\log y}{a^2\log^2 a}\ge\frac{1}{a^2}\left(\frac{1}{2}-\frac{1}{\log a}\right)>0.$$

Now, for $0\le y\le y_1$ and $t\ge t_1$ possibly larger, we get

$$a^{-1}\underline{u}_x\ge\frac{1}{(1+y_1)^2}-Cb(t)-Cb^2(t)>0.$$

By a time shift we may obviously take $t_1 = 0$, and (4.5) is proved. ∎

Remark 4.1. It is still possible to obtain a qualitatively correct subsolution with just a two-term expansion, for instance, by making the simple choice $f(y) = \log(1+y)$, $g = 0$ in (4.1). However, this yields only the lower grow-up rate up to a multiplicative constant, i.e., $u_x(0,t) \geq Ce^{\sqrt{2t}}$, and does not enable one to deduce an expansion of the form (2.8).

4.2. Construction of a supersolution. The form (4.1) does not seem to be sufficient to construct an accurate supersolution (i.e., leading to a function $a(t)$ fulfilling (4.3)). We need a slight perturbation, corresponding to the modified ansatz

$$\overline{u}(x,t) = 1 - \frac{1}{y+1} + b(t)f(y) - b^2(t)\tilde{g}(y,t), \qquad y = a(t)x, \tag{4.27}$$

where

$$\tilde{g}(y,t) = (1+\varepsilon(t))h(y), \tag{4.28}$$

and $\varepsilon(t)$ goes to 0 as $t \to \infty$.

LEMMA 4.2. *The problem*

$$\begin{aligned} &\overline{u}_t - x\overline{u}_{xx} \geq 2\,\overline{u}\,\overline{u}_x, \quad 0 < x < 1,\ t > 0,\\ &\overline{u}(0,t) = 0, \quad t \geq 0,\\ &\overline{u}(1,t) \geq 1, \quad t \geq 0, \end{aligned}$$

admits a solution of the form

$$\overline{u}(x,t) = 1 - \frac{1}{y+1} + b(t)f(y) - (1+\varepsilon(t))b^2(t)h(y), \qquad y = a(t)x,$$

where the smooth functions $a(t), b(t), f(y), h(y)$ have the following properties:

$$f(y) \sim \log y, \quad h(y) \sim \frac{y\log y}{2} \quad \text{as } y \to \infty,$$

$$f(0) = h(0) = f'(0) = h'(0) = 0,$$

$$a(t) = \Big(1 + O\big(t^{-1/2}\log t\big)\Big)\exp\left[\frac{5}{2} + \sqrt{2t}\right] \quad \text{as } t \to \infty, \tag{4.29}$$

$$b(t) = \frac{1 + O\big(t^{-1/2}\big)}{a(t)\log a(t)} \quad \text{as } t \to \infty, \tag{4.30}$$

$$\varepsilon(t) \sim (2t)^{-1/2} \quad \text{as } t \to \infty. \tag{4.31}$$

Proof. Step 1. *Construction of the supersolution.* Taking $\overline{u}$ as defined in (4.27), (4.28), the expression for $\mathcal{P}\overline{u}$ is similar to (4.13), except that g, g', g'' are now replaced with $\tilde{g}, \tilde{g}_y, \tilde{g}_{yy}$ and an additional term $-b^2\varepsilon' h$ is added, which is inherited from $\overline{u}_t$. As in the proof of Lemma 4.1, b and γ are defined through (4.9) and (4.11), and we assume (4.6), (4.10), (4.15), and (4.16). This leads to

$$\begin{aligned} \mathcal{P}\overline{u} = {}& ab\left[\frac{y}{(1+y)^2} - \mathcal{L}f\right] + ab^2\left[\mathcal{L}\tilde{g} - 2ff' + yf' - (1+\gamma)f - \frac{\varepsilon'}{a}h\right]\\ &+ ab^3\left[2f'\tilde{g} + 2f\tilde{g}_y - y\tilde{g}_y + 2(1+\gamma)\tilde{g}\right] - 2ab^4\tilde{g}\tilde{g}_y. \end{aligned}$$

Replacing $\tilde{g}(y,t)$ with $(1+\varepsilon(t))h(y)$, we obtain

$$\mathcal{P}\overline{u} = ab\left[\frac{y}{(1+y)^2} - \mathcal{L}f\right] + ab^2\left[(1+\varepsilon)\mathcal{L}h - 2ff' + yf' - (1+\gamma)f - \frac{\varepsilon'}{a}h\right] + (1+\varepsilon)ab^3\left[2f'h + 2fh' - yh' + 2(1+\gamma)h\right] - 2(1+\varepsilon)^2ab^4hh'. \tag{4.32}$$

Denote

$$B_0 := (1+\varepsilon)\mathcal{L}h - 2ff' + yf' - (1+\gamma)f - \frac{\varepsilon'}{a}h.$$

As in Lemma 4.1, we first choose

$$f := (I + \mathcal{L}_0^{-1})\left(\frac{y}{(1+y)^2}\right).$$

Dividing identity (4.32) by ab^2, we see that $\mathcal{P}\overline{u}$ has the same sign as the quantity

$$B := B_0 + (1+\varepsilon)b\left[2f'h + 2fh' - yh' + 2(1+\gamma)h\right] - 2(1+\varepsilon)^2b^2hh'.$$

Next we choose

$$h = \mathcal{L}_0^{-1}\big(2ff' - yf' + f + M\varphi\big),$$

where φ satisfies

$$\varphi(0) = 0, \qquad \varphi'(0) > 0, \qquad \varphi(y) > 0 \ \text{ for } 0 < y < 2, \qquad \varphi(y) = 1/\log y \ \text{ for } y \geq 2. \tag{4.33}$$

Note that, taking $M > 2$ suitably large, we have

$$2ff' - yf' + f + M\varphi \geq 0, \quad y \geq 0,$$

by Lemma 3.5; hence

$$h(y) \geq 0, \quad y \geq 0, \tag{4.34}$$

due to (3.35). We compute

$$\begin{aligned} B_0 &= (1+\varepsilon)\big(2ff' - yf' + f + M\varphi\big) - 2ff' + yf' - (1+\gamma)f - \frac{\varepsilon'}{a}h \\ &= \varepsilon\big(2ff' - yf'\big) + M(1+\varepsilon)\varphi + (\varepsilon - \gamma)f - \frac{\varepsilon'}{a}h. \end{aligned}$$

At this point, we choose

$$\varepsilon = \gamma, \tag{4.35}$$

where γ is defined by (4.11), and we assume again (4.15) and (4.16) along with

$$\gamma' \leq 0 \tag{4.36}$$

(these assumptions will be verified on the final choice of the function a). By (4.34) and (4.36) we have

$$B_0 \geq \gamma\big(2ff' - yf'\big) + M(1+\gamma)\varphi,$$

and it follows that

(4.37)
$$(1+\gamma)^{-1}B \ge \left[\frac{\gamma}{1+\gamma}\big(2ff'-yf'\big)+M\varphi\right]+b\Big[2f'h+2fh'-yh'+2(1+\gamma)h\Big]-2(1+\gamma)b^2hh'.$$

To show that the RHS of (4.37) is nonnegative for large t, we again consider separately the regions $y_0 \le y \le a(t)$ and $0 \le y \le y_0$ for some large y_0 independent of t. By the estimates in Lemma 3.5, we have

$$f \sim \log y, \quad f' \sim \frac{1}{y}, \quad \text{and} \quad yh' \sim h \sim \frac{y\log y}{2} \quad \text{as } y \to \infty. \tag{4.38}$$

Consequently, fixing $\delta > 0$, using (4.15), and taking y_0 and t_0 large enough, we have, for $y_0 \le y \le a(t)$ and $t \ge t_0$,

$$\frac{\gamma}{1+\gamma}\big(2ff'-yf'\big)+M\varphi \ge -\frac{3}{2}\gamma+\frac{M}{\log y} \ge -\frac{2}{\log a}+\frac{M}{\log y} \ge \frac{M-2}{\log y},$$

$$2f'h+2fh'-yh'+2(1+\gamma)h \ge -\left(\frac{1}{2}+\delta\right)y\log y+2(1+\gamma)\left(\frac{1}{2}-\delta\right)y\log y \ge \left(\frac{1}{2}-4\delta\right)y\log y,$$

and

$$2(1+\gamma)hh' \le y\log^2 y.$$

Assuming $M \ge 3$, taking $\delta = 1/8$, and also using (4.16), we infer that

$$(1+\gamma)^{-1}B \ge \frac{1}{\log a}-\frac{y\log^2 y}{a^2\log^2 a}=\frac{1}{\log a}\left(1-\frac{y\log^2 y}{a^2\log a}\right) \ge \frac{1}{\log a}\left(1-\frac{\log a}{a}\right) \ge 0$$

for $y_0 \le y \le a(t)$ and $t \ge t_0$. Next, for $0 \le y \le y_0$, (4.33) implies

$$M\varphi(y) \ge c_1 y,$$

whereas $f(0) = h(0) = 0$ yields

$$2ff'-yf' \ge -c_2 y, \quad 2f'h+2fh'-yh'+2(1+\gamma)h \ge -c_2 y, \quad 2(1+\gamma)hh' \le c_2 y,$$

with $c_1, c_2 > 0$. Therefore,

$$(1+\gamma)^{-1}B \ge -\gamma(t)c_2 y+c_1 y-b(t)c_2 y-b^2(t)c_2 y=\Big[c_1-c_2\big(\gamma(t)+b(t)+b^2(t)\big)\Big]\,y \ge 0$$

on $[0, y_0]$ for t large enough.

We have thus proved that $\mathcal{P}\overline{u} \ge 0$ in $(0,1)\times(T,\infty)$ for T large enough. By a time shift we may obviously take $T = 0$.

Step 2. *Determination of $a(t)$ by matching at the outer boundary.* The determination of $a(t)$ will be done again by "matching" with the boundary condition at $x = 1$. Imposing that

$$\underline{u}(1,t) \ge 1,$$

we obtain

$$bf(a)-b^2(1+\varepsilon)h(a) \ge \frac{1}{a+1},$$

and taking (4.9) into account, we end up with

$$\frac{a'}{a^2}\left(f(a)-\frac{a'}{a^2}(1+\varepsilon)h(a)\right)\geq\frac{1}{a+1}. \tag{4.39}$$

Again it suffices to check (4.39) for large t. Following the same reasoning as in the case of a subsolution, we again look for $a(t)$ as a solution of

$$a'=\frac{a}{\log a}(1+\eta)\quad\text{as } t\to\infty, \tag{4.40}$$

where the correction term $\eta=\eta(a)$ is given by (4.21) with K a constant to be determined.

Plugging (4.40) into (4.39) and using the exact asymptotic behavior of $f(a),h(a)$ as $a\to\infty$, given by Lemmas 3.5 and 3.6, we arrive at

$$\frac{1+\eta}{a\log a}\left[\log a-2+O\left(\frac{\log^2 a}{a}\right)-\frac{(1+\eta)(1+\varepsilon)}{a\log a}\left(\frac{a\log a}{2}-\frac{9a}{4}+O\left(\frac{a}{\log a}\right)\right)\right]\geq\frac{1}{a+1}$$

or

$$(1+\eta)\left[1-\frac{2}{\log a}+O\left(\frac{\log a}{a}\right)-\frac{(1+\eta)(1+\varepsilon)}{\log a}\left(\frac{1}{2}-\frac{9}{4\log a}+O\left(\frac{1}{\log^2 a}\right)\right)\right]\geq\frac{a}{a+1} \tag{4.41}$$

as $t\to\infty$. Denote by Γ the quantity in the bracket in the LHS of (4.41). Using (4.21) and (4.41), we obtain

$$\begin{aligned}\Gamma&=1-\frac{2}{\log a}+O\left(\frac{\log a}{a}\right)\\&\quad-\left(1+\frac{5}{2\log a}+\frac{K}{\log^2 a}\right)\left(1+\frac{1}{\log a}+\frac{5}{2\log^2 a}\right)\left(\frac{1}{2\log a}-\frac{9}{4\log^2 a}+O\left(\frac{1}{\log^3 a}\right)\right)\\&=1-\frac{5}{2\log a}+\frac{1}{2\log^2 a}+O\left(\frac{1}{\log^3 a}\right)\quad\text{as } t\to\infty.\end{aligned}$$

Then (4.41) becomes equivalent to

$$\left(1+\frac{5}{2\log a}+\frac{K}{\log^2 a}\right)\left(1-\frac{5}{2\log a}+\frac{1}{2\log^2 a}+O\left(\frac{1}{\log^3 a}\right)\right)\geq 1-\frac{1}{a+1}\quad\text{as } t\to\infty;$$

that is,

$$1+\frac{4K-23}{4\log^2 a}+O\left(\frac{1}{\log^3 a}\right)\geq 1-\frac{1}{a+1}\quad\text{as } t\to\infty. \tag{4.42}$$

For (4.42) to be satisfied we choose $K>\frac{23}{4}$, and we again take a to be the solution of the ODE (4.24). Then, by the end of step 2 of the proof of Lemma 4.1, we obtain (4.29) and (4.30) as well as the assumed properties (4.6), (4.10), (4.15), and (4.16) of a,b,γ. Finally, we note that (4.15), (4.29), and (4.35) guarantee (4.31), and that (4.26) implies

$$\gamma'=\frac{-a'}{a\log^2 a}H'\big(1/\log a\big)=\frac{-1}{\log^2 a}(H'G)\big(1/\log a\big)\sim\frac{-1}{\log^3 a}\quad\text{as } t\to\infty$$

and hence (4.36) (after a further time shift). ∎

4.3. Proofs of Theorem 2.1 and Corollary 2.2. Let u be the solution of (2.1)–(2.4) and let $\underline{u}, \overline{u}$ be the sub-/supersolutions provided by Lemmas 4.1 and 4.2. The asymptotic expansion (2.8)–(2.9) in Theorem 2.1 will be an immediate consequence of the following two Lemmas. The first one guarantees that u lies between suitable time-shifts of $\underline{u}$ and $\overline{u}$. The second one shows that (shifted versions of) $\underline{u}$ and $\overline{u}$ satisfy the required asymptotic behavior.

LEMMA 4.3.

(i) *There exists $T_1 > 0$ such that*

$$u(\cdot,t) \ge \underline{u}(\cdot,t-T_1), \qquad t \ge T_1. \tag{4.43}$$

(ii) *Let τ be as in Lemma* 3.3. *Then there exists $T_2 > 0$ such that*

$$u(\cdot,t) \le \overline{u}(\cdot,t+T_2), \qquad t \ge \tau.$$

Proof. (i) Since $\underline{u}(\cdot,0) \in C^1([0,1])$ with $\underline{u}(0,0) = 0$, $\underline{u}(1,0) < 1$, and $\underline{u}_x(\cdot,0) > 0$, it follows from Lemma 3.4 that $u(\cdot,T_1) \ge \underline{u}(\cdot,0)$ for some $T_1 > 0$. The assertion then follows from the comparison principle.

(ii) Due to (4.38), (4.14), and $h(0) = 0$, we have

$$f(y) \ge c_1 \log(y+1) \quad \text{and} \quad h(y) \le c_2\,(y+1)\log(y+1), \qquad y \ge 0,$$

for some $c_1, c_2 > 0$. This along with (4.29)–(4.31) implies that, for all $t \ge t_2$ large enough and all $x \in [0,1]$,

$$\begin{aligned}
\overline{u}(x,t) &= \frac{ax}{ax+1} + bf(ax) - (1+\varepsilon(t))b^2 h(ax) \\
&\ge \frac{ax}{ax+1} + b\log(ax+1)\big(c_1 - 2c_2(ax+1)b\big) \\
&\ge \frac{ax}{ax+1} + b\log(ax+1)\left(c_1 - 3c_2\frac{a+1}{a\log a}\right) \ge \frac{ax}{ax+1}.
\end{aligned}$$

Take τ, η as in Lemma 3.3 and set $x_0 = 1/4K$. For all $x \in [0,x_0]$ and $t \ge t_2$, with $t_2 \ge \tau$ possibly larger, we have $a/2K \ge ax+1$; hence

$$\overline{u}(x,t) \ge \frac{ax}{ax+1} \ge 2Kx \ge u(x,\tau), \qquad 0 \le x \le x_0,\ t \ge t_2.$$

On the other hand, (4.38) implies that

$$f'(y) \le c_3 \quad \text{and} \quad |h'(y)| \le c_3 + \log(y+1), \qquad y \ge 0,$$

for some $c_3 > 0$. For all $x \in (x_0,1]$ and $t \ge t_2$ (possibly larger), we thus have

$$\begin{aligned}
\overline{u}_x &= \frac{a}{(1+ax)^2} + baf'(ax) - (1+\varepsilon(t))b^2 a h'(ax) \\
&\le \frac{a}{(1+ax_0)^2} + c_3 ba + 2(c_3 + \log(a+1))b^2 a \le \eta,
\end{aligned}$$

due to (4.29) and (4.30); hence

$$\overline{u}(x,t) \ge 1 - \eta(1-x) \ge u(x,\tau), \qquad x_0 < x \le 1,\ t \ge t_2.$$

Therefore, $\overline{u}(\cdot,t_2) \ge u(\cdot,\tau)$ in $[0,1]$. The assertion, with $T_2 = t_2 - \tau$, thus follows from the comparison principle. ∎

LEMMA 4.4. *Let*

$$A(t) = \exp\left[\frac{5}{2} + \sqrt{2t}\right].$$

Then, for any $T \in \mathbb{R}$, each of the functions $w = \underline{u}$ and $w = \overline{u}$ satisfies

$$1 - w(x, t+T) = \frac{1}{1 + A(t)x}\left[1 - x + O\big(t^{-1/2}\log t\big)\right]$$

as $t \to \infty$, uniformly in $[0,1]$.

Proof. We shall give the proof for $w = \underline{u}$, the other case being completely similar. Set $\tilde{a}(t) = a(t+T)$ and $\tilde{b}(t) = b(t+T)$. We first note that, by (4.3), we have

$$\tilde{a}(t) = \Big(1 + O\big(t^{-1/2}\log t\big)\Big)A(t)$$

and

$$\log \tilde{a}(t) = \log A(t) + O\big(t^{-1/2}\log t\big) = \Big(1 + O\big(t^{-1}\log t\big)\Big)\log A(t). \tag{4.44}$$

Also, by (4.4), we have

$$\tilde{b}(t) = \frac{1 + O\big(t^{-1/2}\big)}{\tilde{a}\log\tilde{a}}. \tag{4.45}$$

Moreover, due to Lemma 3.5, there exists $C > 0$ such that

$$|f(y) - \log(1+y)| \le C, \quad y \ge 0. \tag{4.46}$$

Now, using (4.45), (4.46), and (4.44), we compute

$$\begin{aligned}
\frac{1}{1+\tilde{a}x} - \tilde{b}f(\tilde{a}x) &= \frac{1}{1+\tilde{a}x}\left[1 - \frac{(1+\tilde{a}x)f(\tilde{a}x)}{\tilde{a}\log\tilde{a}}\Big(1 + O\big(t^{-1/2}\big)\Big)\right] \\
&= \frac{1}{1+\tilde{a}x}\left[1 - \frac{(1+\tilde{a}x)\log(1+\tilde{a}x)}{\tilde{a}\log\tilde{a}}\Big(1 + O\big(t^{-1/2}\big)\Big)\right] \\
&= \frac{1}{1+\tilde{a}x}\left[1 - \frac{x\log(1+\tilde{a}x)}{\log\tilde{a}} + O\big(t^{-1/2}\big)\right] \\
&= \frac{1}{1+\tilde{a}x}\left[1 - x + R(x,t) + O\big(t^{-1/2}\big)\right],
\end{aligned}$$

where

$$R(x,t) := \frac{x\big(\log\tilde{a} - \log(1+\tilde{a}x)\big)}{\log\tilde{a}}.$$

Here and in what follows, the O's are uniform in $[0,1]$. To control R we note that, if $\tilde{a}x \ge 1$, then

$$\log(\tilde{a}x) \le \log(1+\tilde{a}x) \le \log(\tilde{a}x) + \log 2,$$

and hence

$$|R(x,t)| \le \frac{x\big(|\log x| + \log 2\big)}{\log\tilde{a}} \le \frac{C}{\log\tilde{a}},$$

whereas, if $\tilde{a}x < 1$, then $|R(x,t)| \le x \le 1/\tilde{a}$. It follows that $\sup_{x\in[0,1]} |R(x,t)| = O(t^{-1/2})$ as $t \to \infty$. Since, by (4.3), we have

$$1 + \tilde{a}x = (1 + Ax)\left[1 + \frac{(\tilde{a} - A)x}{1 + Ax}\right] = (1 + Ax)\left[1 + \frac{O\big(t^{-1/2}\log t\big)Ax}{1 + Ax}\right]$$
$$= (1 + Ax)\big(1 + O\big(t^{-1/2}\log t\big)\big),$$

we deduce that

$$\frac{1}{1 + \tilde{a}x} - \tilde{b}f(\tilde{a}x) = \frac{1 + O\big(t^{-1/2}\log t\big)}{1 + Ax}\left(1 - x + O\big(t^{-1/2}\big)\right),$$

and hence

$$\frac{1}{1 + \tilde{a}x} - \tilde{b}f(\tilde{a}x) = \frac{1 - x + O\big(t^{-1/2}\log t\big)}{1 + Ax}. \tag{4.47}$$

On the other hand, due to Lemma 3.6 and $g(0) = 0$, there exists $C_1 > 0$ such that

$$|g(y)| \le C_1(1 + y)\log(1 + y), \quad y \ge 0.$$

Consequently, using also (4.45), we obtain, for $t \to \infty$,

$$(1 + Ax)\tilde{b}^2|g(\tilde{a}x)| \le 2C_1\,\frac{(1 + \tilde{a}x)^2\log(1 + \tilde{a}x)}{\tilde{a}^2\log^2\tilde{a}} \le \frac{3C_1}{\log\tilde{a}} = O\big(t^{-1/2}\big). \tag{4.48}$$

Combining (4.47) and (4.48) finally yields

$$1 - \underline{u}(x, t + T) = \frac{1}{1 + \tilde{a}x} - \tilde{b}f(\tilde{a}x) + \tilde{b}^2 g(\tilde{a}x) = \frac{1 - x + O\big(t^{-1/2}\log t\big)}{1 + Ax}. \qquad \square$$

Proof of (2.10) *and* (2.11). First notice that estimate (3.27) in Lemma 3.3 and Lemma 4.3(ii) guarantee the control of the slope at $x = 1$, namely, (3.22), for any finite $T > 0$. The C^1 regularity property (2.10) is then a consequence of Lemma 3.2. To show (2.11), note that $\underline{u}_x(0,t) = a(t)$ due to (4.7) and (4.2). The lower estimate corresponding to (2.11) is then a consequence of (4.43) and (4.3). The proof of the upper part is similar by using $\overline{u}$. $\square$

Proof of Corollary 2.2. Assertion (i) is an immediate consequence of (2.8) and (2.9). To show (ii), it suffices to observe that, due to (2.9),

$$\int_0^1 \frac{dx}{1 + A(t)x} = \left[\frac{\log\big(1 + A(t)x\big)}{A(t)}\right]_0^1 = \frac{\log(1 + A(t))}{A(t)}$$
$$= \big(1 + O\big(t^{-1/2}\big)\big)\sqrt{2t}\exp\left[-\frac{5}{2} - \sqrt{2t}\right]$$

as $t \to \infty$ and to use

$$\int_0^1 \frac{x\,dx}{1 + A(t)x} \le \frac{1}{A(t)}. \qquad \square$$

Acknowledgments. This research was performed while Nikos I. Kavallaris was a visitor at the Laboratoire Analyse Géométrie et Applications in Université Paris-Nord. He is grateful to this institution for its hospitality and stimulating atmosphere. He would like to express his sincere thanks to Piotr Biler, who introduced him to the chemotaxis problem, and to Andrew A. Lacey for stimulating discussions.

MATHEMATICAL RESULTS ON EXISTENCE FOR VISCOELASTODYNAMIC PROBLEMS WITH UNILATERAL CONSTRAINTS*

ADRIEN PETROV† AND MICHELLE SCHATZMAN‡

Abstract. This paper focuses on a damped wave equation and the evolution of a Kelvin–Voigt viscoelastic material, both problems being subject to unilateral boundary conditions. Under appropriate regularity assumptions on the initial data, both problems possess a weak solution which is obtained as the limit of a sequence of solutions of penalized problems; the functional properties of all the traces are precisely identified through Fourier analysis, and this enables us to infer the existence of a strong solution, i.e., a solution satisfying almost everywhere the unilateral conditions.

Key words. viscoelasticity, Signorini conditions, penalty method, traces, variational inequality, convolution

1. Introduction and notation.

This paper aims to give some new mathematical results on existence for a damped wave equation with an obstacle and for full viscoelasticity in the particular case of a Kelvin–Voigt material with unilateral boundary conditions.

We consider in section 2 a damped wave equation taking place in a half-space, with an obstacle at the boundary. Let $u(x,t)$ be the displacement at time t of the material point of spatial coordinate $x = (x_1, x') \in (-\infty, 0] \times \mathbb{R}^{d-1}$ at rest with $d \geq 2$. We will agree that if we write a function of space and time as a function of three variables, then the first variable is the normal space variable x_1, the second variable is the tangential space variable x', and the last variable is time. Let $f(x_1, x', t)$ denote a density of external forces, depending on space and time. Define $\Omega \stackrel{\text{def}}{=} (-\infty, 0] \times \mathbb{R}^{d-1}$, and let α be a positive number. The mathematical problem is formulated as follows:

$$u_{tt} - \Delta u - \alpha \Delta u_t = f, \quad x \in \Omega, \quad t > 0, \tag{1.1}$$

with Cauchy initial data

$$u(\cdot, 0) = u_0 \quad \text{and} \quad u_t(\cdot, 0) = u_1 \tag{1.2}$$

and Signorini boundary conditions at $x_1 = 0$, $t > 0$,

$$0 \leq u \perp u_{x_1} + \alpha u_{x_1 t} \geq 0, \tag{1.3}$$

where $(\cdot)_t \stackrel{\text{def}}{=} \frac{\partial}{\partial t}(\cdot)$ and $(\cdot)_{x_1} \stackrel{\text{def}}{=} \frac{\partial}{\partial x_1}(\cdot)$. The orthogonality has the natural meaning: if we have enough regularity, it means that the product $u(u_{x_1} + \alpha u_{x_1 t})$ vanishes almost everywhere on the boundary. If we do not have enough regularity, the above inequality

is integrated on an appropriate set of test functions, yielding a weak formulation for the unilateral condition. The main result of section 2 is that, indeed, (1.3) holds almost everywhere on the boundary; i.e., we have a strong solution to our problem.

We suppose that the initial position u_0 belongs to the Sobolev space $\mathrm{H}^2(\Omega)$ and satisfies the compatibility condition $u_0(0,\cdot,\cdot) \geq 0$, the initial velocity u_1 belongs to $\mathrm{H}^1(\Omega)$, and the density of forces f belongs to $\mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$. The choice of a function f defined for all nonnegative time is justified by the use of a Fourier transform in the latter part of the article. This is not a significant restriction as we can always extend f by 0 if it is defined only for finite times.

Let us describe the weak formulation of the problem. Denote by K the convex set

$$K \stackrel{\text{def}}{=} \big\{ v \in \mathrm{H}^1_{\mathrm{loc}}(\Omega \times [0,\infty)) : \nabla v_t \in \mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega)),\ v|_{\{0\}\times\mathbb{R}^{d-1}} \geq 0 \big\}.$$

This unusual convex set has been devised in order to write a weak formulation of our problem. Since we expect to find a scalar product $(\nabla u_t, \nabla w)$, we require ∇u_t to be square integrable. Thus, the weak formulation associated to (1.1)–(1.3) is obtained by multiplying (1.1) by $v-u$, $v \in K$, and by integrating formally over $\Omega \times (0,\tau)$. Then, we get

$$\begin{cases} \text{find } u \in K \text{ such that for all } v \in K \text{ and for all } \tau \in (0,\infty), \\ \displaystyle\int_\Omega (u_t(v-u))\big|_0^\tau \,\mathrm{d}x - \int_0^\tau \int_\Omega u_t(v_t - u_t)\,\mathrm{d}x\,\mathrm{d}t \\ \displaystyle + \int_0^\tau \int_\Omega (\nabla u + \alpha \nabla u_t)(\nabla v - \nabla u)\,\mathrm{d}x\,\mathrm{d}t \geq \int_0^\tau \int_\Omega f(v-u)\,\mathrm{d}x\,\mathrm{d}t. \end{cases} \tag{1.4}$$

We approximate this problem by a regularized problem, and the bulk of our work is to get enough regularity to obtain traces of the tangential first derivatives of the solution on the boundary. This is done essentially through an analysis of the Dirichlet to Neumann operator for the damped wave equation. For this purpose, one must go to tangential Fourier variables and perform an estimate on a pseudodifferential term.

In section 3, we treat the evolution of a Kelvin–Voigt material (see [DaL90]) occupying a three dimensional half-space, satisfying Signorini conditions at the boundary and Cauchy data at $t=0$. We make the assumptions of small deformations. Let $\varepsilon_{ij}(u) \stackrel{\text{def}}{=} (u_{j,x_i} + u_{i,x_j})/2$ be the strain tensor, and let there be given two Hooke tensors, a^n_{ijkl}, $n=0,1$. We define the two stress tensors σ^n_{ij} corresponding, respectively, to the elastic and the viscous parts of the stress:

$$\sigma^n_{ij}(u) \stackrel{\text{def}}{=} a^n_{ijkl}\varepsilon_{kl}(u); \tag{1.5}$$

here, we have used the summation convention on repeated indices. The displacement field u satisfies the system

$$\rho u_{i,tt} = \sigma^0_{ij,x_j}(u) + \sigma^1_{ij,x_j}(u_t) + f_i, \quad x \in \Omega, \quad t > 0. \tag{1.6}$$

The initial data are given by

$$u(\cdot,0) = v_0 \quad \text{and} \quad u_t(\cdot,0) = v_1. \tag{1.7}$$

The components of the unit external normal are δ_{1j} (δ is the Kronecker symbol), and a basis of tangential vectors can be taken as $\tau_j = \delta_{2j}$ and $\tau'_j = \delta_{3j}$. Denote by

$\Sigma = \{0\} \times \mathbb{R}^{d-1}$ the boundary of Ω. Then, the boundary conditions on $\Sigma \times [0, \infty)$ are

$$0 \geq u_1 \perp \sigma^0_{11}(u) + \sigma^1_{11}(u_t) \leq 0, \tag{1.8a}$$

$$\sigma^0_{12}(u) + \sigma^1_{12}(u_t) = 0, \quad \text{and} \quad \sigma^0_{13}(u) + \sigma^1_{13}(u_t) = 0. \tag{1.8b}$$

One of the main results of section 3 is to show that (1.8a) holds almost everywhere, because the relevant traces exist.

In order to simplify the problem, we have considered a homogeneous and isotropic material; then, the Hooke tensors a^n_{ijkl} are defined with the help of Lamé constants λ^n and μ^n:

$$a^n_{ijkl} \stackrel{\text{def}}{=} \lambda^n \delta_{ij}\delta_{kl} + 2\mu^n \delta_{ik}\delta_{jl}, \quad n = 0, 1.$$

We define two elasticity operators A^n by

$$A^n u \stackrel{\text{def}}{=} a^n_{ijkl} \partial_j \varepsilon_{kl}(u), \quad n = 0, 1.$$

Then, the problem (1.6)–(1.8) can be rewritten as follows:

$$\rho u_{tt} - A^0 u - A^1 u_t = f, \quad x \in \Omega, \quad t > 0, \tag{1.9a}$$

$$0 \geq u_1 \perp \big(\sigma^0_{11}(u) + \sigma^1_{11}(u_t)\big) \leq 0 \quad \text{on} \quad \Sigma \times [0, \infty), \tag{1.9b}$$

$$\sigma^0_{12}(u) + \sigma^1_{12}(u_t) = 0 \quad \text{and} \quad \sigma^0_{13}(u) + \sigma^1_{13}(u_t) = 0 \quad \text{on} \quad \Sigma \times [0, \infty), \tag{1.9c}$$

$$u(\cdot, 0) = v_0 \quad \text{and} \quad u_t(\cdot, 0) = v_1. \tag{1.9d}$$

Let us describe now the functional hypotheses on the data; if X is a space of scalar functions, the bold-face notation $\mathbf{X}$ denotes the space X^d. For the final result, we require v_0 to belong to $\mathbf{H}^{5/2}(\Omega)$, v_1 to $\mathbf{H}^{3/2}(\Omega)$, and f to $\mathbf{H}^1_{\text{loc}}([0, \infty); \mathrm{L}^2(\Omega))$. The initial data must satisfy the compatibility condition $(v_0)_1(0, x') \leq 0$ for all $x' \in \Sigma$. Let K be the convex set defined by

$$K \stackrel{\text{def}}{=} \big\{ v \in \mathbf{H}^1(\Omega \times (0, \tau)) : \nabla v_t \in \mathbf{L}^2(\Omega \times (0, \tau)),\ v(0, \cdot) \leq 0 \big\}.$$

Define two bilinear forms by

$$a^0(u, v) \stackrel{\text{def}}{=} \int_\Omega a^0_{ijkl} \varepsilon_{ij}(u) \varepsilon_{kl}(v)\, \mathrm{d}x \quad \text{and} \quad a^1(u, v) \stackrel{\text{def}}{=} \int_\Omega a^1_{ijkl} \varepsilon_{ij}(u) \varepsilon_{kl}(v)\, \mathrm{d}x.$$

We obtain a weak formulation of the problem (1.9) as follows: we multiply (1.9a) by $v - u$, $v \in K$, and we formally integrate the result over $\Omega \times (0, \tau)$; we obtain then the variational inequality

$$\begin{cases} \text{find } u \in K \text{ such that for all } v \in K \text{ and for all } \tau \in (0, \infty), \\ \displaystyle\int_0^\tau \int_\Omega \rho u_{tt} \cdot (v - u)\, \mathrm{d}x\, \mathrm{d}t + \int_0^\tau a^0(u, u - v)\, \mathrm{d}t \\ \displaystyle + \int_0^\tau a^1(u_t, v - u)\, \mathrm{d}t \geq \int_0^\tau \int_\Omega f \cdot (v - u)\, \mathrm{d}x\, \mathrm{d}t. \end{cases} \tag{1.10}$$

The existence result for (1.1)–(1.3) is easily established by the penalty method and was already proved by Jarušek et al. [JM*92] in the case of distributed constraints.

Jarušek has also proved in [Jar96] an existence result for (1.9), in a much more general and complicated case, since it allows for contact, a given friction at the boundary, a nonlinear constitutive law for viscoelasticity, and a general geometry. However,

the boundary conditions must be understood in the sense of duality, since the traces themselves are defined by duality. The reader can also refer to [KuS04a]. Moreover, notice that [KuS04b] contains some regularity results for a Signorini problem with normal compliance.

The reader may wonder why our proofs of existence for weak solutions are longer than other known proofs; the reason is that we prove more estimates in order to get more information. Hence, we cannot reuse previous proofs of existence of weak solutions. In particular, we need stronger results on the regularity of solutions, and these cannot be deduced from former results on regularity, which use stronger assumptions.

In the present paper, for both problems, we penalize the obstacle constraint, we construct a solution of the penalized problem, and we show the existence of a weak solution by passing to the limit with respect to the penalty parameter. Then, under appropriate regularity conditions on the data, we prove that the penalized solution has traces, which can be estimated, and therefore the limiting weak solution that we obtained is a strong solution.

We have chosen to limit ourselves to homogeneous and, in the case of viscoelasticity, isotropic media, since we use a Fourier transform and some calculus in the dual variables for obtaining the traces. We believe that more general cases could be considered, namely, variable coefficients and curved boundary. The method is probably straightforward, but it is exacting, since one would probably have to use the full technology of pseudodifferential operators.

Observe that nothing is known about uniqueness.

These two problems are treated in the same article, because they are quite close. Proofs for the second problem are shortened when very close to proofs for the first one. Nevertheless, there are substantial differences in detail, since the second problem is much more complicated than the first. In particular, the bulk of the proof in section 3 consists in obtaining a solution of a linear system through Fourier–Laplace transform and then in estimating this solution in anisotropic Sobolev spaces.

2. The damped wave equation with Signorini boundary conditions.

2.1. The penalized problem. We approximate (1.1)–(1.3) by the penalty method. This means that we replace the rigid constraint (1.3) by a very stiff response. When the constraint is active, the response is linear, and it vanishes when the constraint is not active. More precisely, letting $r^- \stackrel{\text{def}}{=} -\min(r,0)$, we replace u by u^ϵ, which satisfies

$$u^\epsilon_{tt} - \Delta u^\epsilon - \alpha \Delta u^\epsilon_t = f, \quad x \in \Omega, \quad t > 0, \tag{2.1}$$

with initial data

$$u^\epsilon(\cdot,0) = u_0 \quad \text{and} \quad u^\epsilon_t(\cdot,0) = u_1 \tag{2.2}$$

and boundary condition

$$(u^\epsilon_{x_1} + \alpha u^\epsilon_{x_1 t})(0,\cdot,\cdot) = (u^\epsilon(0,\cdot,\cdot))^-/\epsilon. \tag{2.3}$$

Notice that (2.3) is the so-called *normal compliance condition* introduced by Martins and Oden [MaO88].

Define the following sets:

$$\forall \tau \in (0,\infty), \quad Q_\tau \stackrel{\text{def}}{=} \Omega \times (0,\tau) \quad \text{and} \quad I_\tau \stackrel{\text{def}}{=} \Sigma \times (0,\tau). \tag{2.4}$$

THEOREM 2.1. *Let* $\mathrm{W}_{\mathrm{loc}} \stackrel{\mathrm{def}}{=} \{u \in \mathrm{H}^1_{\mathrm{loc}}([0,\infty)\times\Omega) : \nabla u_t \in \mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))\}$. *Assume that* u_0 *and* u_1 *belong to* $\mathrm{H}^1(\Omega)$, *and* f *belongs to* $\mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$; *then for every* $\epsilon > 0$ *there exists a unique weak solution* $u^\epsilon \in \mathrm{W}_{\mathrm{loc}}$ *of the problem* (2.1)–(2.3) *such that*

$$u^\epsilon \in \mathrm{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{H}^1(\Omega)), \tag{2.5a}$$

$$u^\epsilon_t \in \mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{H}^1(\Omega)), \tag{2.5b}$$

$$u^\epsilon_{tt} \in \mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega)), \tag{2.5c}$$

and for every $\tau \in (0,T)$ *and for all* $v \in \mathrm{W}_{\mathrm{loc}}$, *the following variational equality is satisfied:*

$$\begin{aligned}\int_\Omega ((u^\epsilon_t v)(\cdot,\tau) - u_1 v(\cdot,0))\,\mathrm{d}x - \int_{Q_\tau} u^\epsilon_t v_t\,\mathrm{d}x\,\mathrm{d}t + \int_{Q_\tau} \nabla u^\epsilon \nabla v\,\mathrm{d}x\,\mathrm{d}t \\ + \alpha\int_{Q_\tau} \nabla u^\epsilon_t \nabla v\,\mathrm{d}x\,\mathrm{d}t - \frac{1}{\epsilon}\int_{I_\tau} (u^\epsilon)^- v\,\mathrm{d}x'\,\mathrm{d}t = \int_{Q_\tau} f v\,\mathrm{d}x\,\mathrm{d}t.\end{aligned} \tag{2.6}$$

Proof. The theorem is proved by the standard Galerkin method, and the reader can refer to [GGZ74] or the appendix of [JM*92]. □

2.2. A priori estimates. We establish here estimates up to the boundary and interior estimates which will enable us later to infer the existence of a weak solution to (1.1)–(1.3).

LEMMA 2.2. *Assume that* f *belongs to* $\mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, u_0 *to* $\mathrm{H}^1(\Omega)$, *and* u_1 *to* $\mathrm{L}^2(\Omega)$. *Then* u^ϵ_t *and* ∇u^ϵ *are bounded in* $\mathrm{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, ∇u^ϵ_t *is bounded in* $\mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, *and* $(u^\epsilon(0,\cdot,\cdot))^-/\sqrt{\epsilon}$ *is bounded in* $\mathrm{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\mathbb{R}^-))$ *independently of* $\epsilon > 0$. *If, moreover,* u_0 *belongs to* $\mathrm{H}^2(\Omega)$, Δu^ϵ *is bounded in* $\mathrm{L}^\infty_{\mathrm{loc}}(0,\infty;L^2(\Omega))$ *independently of* ϵ.

Proof. These estimates result from an application of the Gronwall lemma to the energy identity. We multiply (2.1) by u^ϵ_t, and we integrate this expression over Q_τ to get

$$\int_{Q_\tau} u^\epsilon_{tt} u^\epsilon_t\,\mathrm{d}x\,\mathrm{d}t - \int_{Q_\tau} \Delta u^\epsilon u^\epsilon_t\,\mathrm{d}x\,\mathrm{d}t - \alpha\int_{Q_\tau} \Delta u^\epsilon_t u^\epsilon_t\,\mathrm{d}x\,\mathrm{d}t = \int_{Q_\tau} f u^\epsilon_t\,\mathrm{d}x\,\mathrm{d}t.$$

We integrate the first integral in time in the above relation, we use Green's formula for the second and third, and, with the help of the boundary conditions (2.3), we obtain

$$\begin{aligned}&\frac{1}{2}\int_\Omega \left(|u^\epsilon_t(\cdot,\tau)|^2 + |\nabla u^\epsilon(\cdot,\tau)|^2\right)\mathrm{d}x + \alpha\int_{Q_\tau} |\nabla u^\epsilon_t|^2\,\mathrm{d}x\,\mathrm{d}t + \frac{1}{2\epsilon}\int_\Sigma \left((u^\epsilon(0,\cdot,\cdot))^-\right)^2\Big|_0^\tau \mathrm{d}x' \\ &= \int_{Q_\tau} f u^\epsilon_t\,\mathrm{d}x\,\mathrm{d}t + \frac{1}{2}\int_\Omega \left(|\nabla u_0|^2 + |u_1|^2\right)\mathrm{d}x.\end{aligned}$$

We may deduce from the classical Gronwall lemma that u^ϵ_t and ∇u^ϵ are bounded in $\mathrm{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, ∇u^ϵ_t is bounded in $\mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, and $(u^\epsilon(0,\cdot,\cdot))^-/\sqrt{\epsilon}$ is bounded in $\mathrm{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\mathbb{R}^{d-1}))$ independently of $\epsilon > 0$.

For the bound on Δu^ϵ, we multiply (2.1) by $\mathrm{e}^{t/\alpha}$, and we integrate from 0 to τ. After an integration by parts on the term

$$\int_0^\tau u^\epsilon_{tt}\mathrm{e}^{t/\alpha}\,\mathrm{d}t,$$

we find the identity

$$\begin{aligned}\Delta u^\epsilon(\cdot,\tau) &= \Delta u_0 \mathrm{e}^{-\tau/\alpha} + \alpha^{-1}\big(u_t^\epsilon(\cdot,\tau) - u_1 \mathrm{e}^{-\tau/\alpha}\big)\\ &\quad - \alpha^{-2}\int_0^\tau u_t^\epsilon(\cdot,t)\mathrm{e}^{(t-\tau)/\alpha}\,\mathrm{d}t - \alpha^{-1}\int_0^\tau f\mathrm{e}^{(t-\tau)/\alpha}\,\mathrm{d}t.\end{aligned} \tag{2.7}$$

The end of the proof is straightforward. □

Remark 2.3. If we suppose that f vanishes for t large, then, independently of $\epsilon > 0$, u_t^ϵ, ∇u^ϵ, and Δu^ϵ are bounded in $\mathrm{L}^\infty([0,\infty);\mathrm{L}^2(\Omega))$ and ∇u_t^ϵ is bounded in $\mathrm{L}^2([0,\infty);\mathrm{L}^2(\Omega))$. These properties can be proved using the arguments given in the proof of Lemma 2.2, with the origin of time moved to T if $f(\cdot,t)$ vanishes for $t \geq T$; since the integral involving f vanishes, the conclusion is clear for u_t^ϵ, ∇u^ϵ, and ∇u_t^ϵ. For Δu^ϵ, we use the identity (2.7), with 0 replaced by $T \leq \tau$, and the conclusion is clear.

LEMMA 2.4. *Assume the hypotheses of Lemma* 2.2. *Then for all nonnegative, continuously differentiable, and compactly supported* ψ *on* $\mathbb{R}^{d-1}$ *and for all* $\tau \in [0,T]$,

$$\int_{I_\tau} \frac{(u^\epsilon)^-}{\epsilon}\,\psi\,\mathrm{d}x'\,\mathrm{d}t$$

is bounded independently of $\epsilon > 0$. *In particular,* $(u^\epsilon(0,\cdot,\cdot))^-/\epsilon$ *is a bounded measure on* I_τ.

Proof. Let ϕ be a continuous function with compact support in $\mathbb{R}^d$; we multiply (2.1) by ϕ and integrate over Q_τ; thanks to the boundary conditions (2.3) and Green's formula, we obtain

$$\int_\Omega \phi u_t^\epsilon(\cdot,t)\big|_0^\tau\,\mathrm{d}x + \int_{Q_\tau}\nabla\phi(\nabla u^\epsilon + \alpha\nabla u_t^\epsilon)\,\mathrm{d}x\,\mathrm{d}t - \frac{1}{\epsilon}\int_{I_\tau}(u^\epsilon)^-\phi\,\mathrm{d}x'\,\mathrm{d}t = \int_{Q_\tau}\phi f\,\mathrm{d}x\,\mathrm{d}t.$$

Since the product $|zy|$ can be estimated by $|z|^2/2 + |y|^2/2$, we get the following inequality:

$$\begin{aligned}&\frac{1}{\epsilon}\int_{I_\tau}(u^\epsilon)^-\phi\,\mathrm{d}x'\,\mathrm{d}t \leq \frac{1}{2}\int_\Omega\big(|u_t^\epsilon(\cdot,\tau)|^2 + |u_1|^2\big)\,\mathrm{d}x + \int_\Omega|\phi|^2\,\mathrm{d}x\\ &+\int_{Q_\tau}|\nabla\phi\nabla u^\epsilon|\,\mathrm{d}x\,\mathrm{d}t + \alpha\int_{Q_\tau}|\nabla\phi\nabla u_t^\epsilon|\,\mathrm{d}x\,\mathrm{d}t + \int_{Q_\tau}|\phi f|\,\mathrm{d}x\,\mathrm{d}t.\end{aligned} \tag{2.8}$$

The right-hand side of (2.8) is bounded since f belongs to $\mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, u_1 to $\mathrm{L}^2(\Omega)$, and u_t^ϵ, ∇u^ϵ, and ∇u_t^ϵ to $\mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$. Moreover, $(u^\epsilon(0,\cdot,\cdot))^-$ is nonnegative; if the trace ψ of ϕ over Σ is nonnegative, the inequality is clear. The last statement of the theorem is obtained by a classical approximation argument. Write $\mu^\epsilon = (u^\epsilon(0,\cdot,\cdot))^-/\epsilon$. Let ψ_n be an increasing sequence of nonnegative, continuously differentiable, and compactly supported functions on Σ, which are at most equal to ψ. Then the integrals of ψ_n against μ^ϵ converge to the integral of $\lim_n \psi_n$ against μ^ϵ, so that the integral of any nonnegative, continuous, and compactly supported function against μ^ϵ is nonnegative, and this is precisely the definition of a nonnegative measure on Σ. □

Let us turn now to interior estimates.

LEMMA 2.5. *Assume the hypotheses of Lemma* 2.2. *Then for all* $\beta > 0$, u_{tt}^ϵ *and* Δu_t^ϵ *are bounded in* $\mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2((-\infty,-\beta)\times\Sigma))$, *independently of* $\epsilon > 0$.

Proof. The idea of the proof is twofold: we multiply u^ϵ by a truncation function $\varphi \in \mathrm{C}_0^\infty(\mathbb{R})$, and we define $v^\epsilon \overset{\text{def}}{=} \varphi u^\epsilon$; we will observe that $w^\epsilon \overset{\text{def}}{=} v_t^\epsilon$ satisfies a heat equation, whose right-hand side will be estimated thanks to the previous lemmas. Let us now go into the details.

Let φ be a truncation function which is equal to 1 if $x_1 \leq -\beta$ and to 0 if $x_1 \geq -\beta/2$ ($\beta > 0$). Then, we multiply u^ϵ by φ, which enables us to forget about the strongly nonlinear boundary conditions. Define

$$v^\epsilon(x_1, \cdot, \cdot) \overset{\text{def}}{=} \varphi(x_1) u^\epsilon(x_1, \cdot, \cdot). \tag{2.9}$$

The derivatives of v^ϵ are given by

$$v_{tt}^\epsilon = \varphi u_{tt}^\epsilon, \tag{2.10a}$$

$$\Delta v^\epsilon = \varphi \Delta u^\epsilon + 2\varphi_{x_1} \nabla u^\epsilon + \varphi_{x_1 x_1} u^\epsilon, \tag{2.10b}$$

$$\Delta v_t^\epsilon = \varphi \Delta u_t^\epsilon + 2\varphi_{x_1} \nabla u_t^\epsilon + \varphi_{x_1 x_1} u_t^\epsilon. \tag{2.10c}$$

Observe that, thanks to relations (2.1) and (2.10), we have

$$v_{tt}^\epsilon - \Delta v^\epsilon - \alpha \Delta v_t^\epsilon = \widetilde{g}^\epsilon, \tag{2.11}$$

where $\widetilde{g}^\epsilon \overset{\text{def}}{=} \varphi f - 2\varphi_{x_1}(\nabla u^\epsilon + \alpha \nabla u_t^\epsilon) - \varphi_{x_1 x_1}(u^\epsilon + \alpha u_t^\epsilon)$. Since f, u_t^ϵ, ∇u^ϵ, ∇u_t^ϵ, and u^ϵ are bounded in $\mathrm{L}^2_{\mathrm{loc}}([0,\infty); \mathrm{L}^2(\Omega))$, $\widetilde{g}^\epsilon$ is bounded in $\mathrm{L}^2_{\mathrm{loc}}([0,\infty); \mathrm{L}^2(\Omega))$. Let us define

$$w^\epsilon \overset{\text{def}}{=} v_t^\epsilon \quad \text{and} \quad g^\epsilon \overset{\text{def}}{=} \widetilde{g}^\epsilon + \Delta v^\epsilon. \tag{2.12}$$

Substituting (2.12) into (2.11), we obtain

$$w_t^\epsilon - \alpha \Delta w^\epsilon = g^\epsilon. \tag{2.13}$$

Let us prove now that w_t^ϵ is bounded in $\mathrm{L}^2_{\mathrm{loc}}([0,\infty); \mathrm{L}^2(\Omega))$. For this purpose, we multiply (2.13) by w_t^ϵ; we integrate this expression over Ω:

$$\int_\Omega |w_t^\epsilon|^2 \, \mathrm{d}x - \alpha \int_\Omega \Delta w^\epsilon w_t^\epsilon \, \mathrm{d}x = \int_\Omega g^\epsilon \, w_t^\epsilon \, \mathrm{d}x.$$

We use Green's formula in the second term on the left-hand side of the above expression, thus getting the following equality:

$$\int_\Omega |w_t^\epsilon|^2 \, \mathrm{d}x + \alpha \int_\Omega \nabla w_t^\epsilon \nabla w^\epsilon \, \mathrm{d}x = \int_\Omega g^\epsilon w_t^\epsilon \, \mathrm{d}x. \tag{2.14}$$

We integrate (2.14) over $(0,\tau)$, we observe that the product $|g^\epsilon w_t^\epsilon|$ can be estimated by $|g^\epsilon|^2/2 + |w_t^\epsilon|^2/2$, and we obtain

$$\begin{aligned} &\frac{1}{2} \int_{Q_\tau} |w_t^\epsilon|^2 \, \mathrm{d}x \, \mathrm{d}t + \alpha \int_\Omega |\nabla w^\epsilon(\cdot, \tau)|^2 \, \mathrm{d}x \\ &\leq \alpha \int_\Omega |\nabla w^\epsilon(\cdot, 0)|^2 \, \mathrm{d}x + \frac{1}{2} \int_{Q_\tau} |g^\epsilon|^2 \, \mathrm{d}x \, \mathrm{d}t. \end{aligned} \tag{2.15}$$

Since u_1 belongs to $\mathrm{H}^1(\Omega)$ and φ belongs to $\mathrm{C}_0^\infty(\mathbb{R})$, $\nabla w^\epsilon(\cdot, 0) = \varphi_{x_1} u_1 + \varphi \nabla u_1$ is bounded in $\mathrm{L}^2(\Omega)$. Moreover, g^ϵ is bounded in $\mathrm{L}^2_{\mathrm{loc}}([0,\infty); \mathrm{L}^2(\Omega))$ because Δv^ϵ and $\widetilde{g}^\epsilon$ are bounded in $\mathrm{L}^2_{\mathrm{loc}}([0,\infty); \mathrm{L}^2(\Omega))$. Therefore, (2.9), (2.12), and (2.15) enable us to

deduce that u^ϵ_{tt} is bounded in $\mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2((-\infty,-\beta)\times\Sigma))$. We use analogous arguments to show that Δu^ϵ_t is bounded in $\mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2((-\infty,-\beta)\times\Sigma))$. We multiply (2.13) by Δw^ϵ, we integrate over Q_τ, and, thanks to Green's formula, we obtain

$$-\frac{1}{2}\int_\Omega |\nabla w^\epsilon|^2\big|_0^\tau \,\mathrm{d}x - \alpha\int_{Q_\tau}|\Delta w^\epsilon|^2\,\mathrm{d}x\,\mathrm{d}t = \int_{Q_\tau} g^\epsilon \Delta w^\epsilon\,\mathrm{d}x\,\mathrm{d}t. \tag{2.16}$$

The product $|g^\epsilon\Delta w^\epsilon|$ can be estimated by $|g^\epsilon|^2/(2\gamma)+\gamma|\Delta w^\epsilon|^2/2$, and if we choose $\gamma\in(0,2\alpha)$, we obtain the following inequality:

$$\Big(\alpha-\frac{\gamma}{2}\Big)\int_{Q_\tau}|\Delta w^\epsilon|^2\,\mathrm{d}x\,\mathrm{d}t \le \frac{1}{2\gamma}\int_{Q_\tau}|g^\epsilon|^2\,\mathrm{d}x\,\mathrm{d}t + \frac{1}{2}\int_\Omega|\nabla w^\epsilon(\cdot,0)|^2\,\mathrm{d}x. \tag{2.17}$$

Since g^ϵ and $\nabla w^\epsilon(\cdot,0)$ are, respectively, bounded in $\mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$ and $\mathrm{L}^2(\Omega)$, according to (2.9), (2.12), and (2.17), we infer that Δu^ϵ_t is bounded in the space $\mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2((-\infty,-\beta)\times\Sigma))$. ∎

2.3. Existence of a weak solution. In this section, we show that it is possible to pass to the limit in the variational formulation of the penalized problem to obtain a weak solution of (1.1)–(1.3). There is a minor subtlety due to the unboundedness of Ω.

THEOREM 2.6. *Assume the hypotheses of Lemma* 2.2. *Then there exists a solution of the variational inequality* (1.4)*; this solution can be obtained as a limit of a subsequence of the penalty approximation defined by* (2.1)–(2.3).

Proof. Let v belong to K and φ be a function belonging to $\mathrm{C}^\infty_0(\bar\Omega\times[0,\infty))$, which takes its values in $[0,1]$. Multiplying (2.1) by $(v-u^\epsilon)\varphi$ and integrating over Q_τ and then observing that

$$\int_{I_\tau}\big((u^\epsilon)^-\varphi(v-u^\epsilon)\big)\,\mathrm{d}x'\,\mathrm{d}t = \int_{I_\tau}\big(\big((u^\epsilon)^-\big)^2\varphi\big)\,\mathrm{d}x'\,\mathrm{d}t + \int_{I_\tau}\big((u^\epsilon)^-\varphi v\big)\,\mathrm{d}x'\,\mathrm{d}t$$

is nonnegative, we may deduce the following inequality:

$$\begin{aligned}&\int_\Omega u^\epsilon_t\varphi(v-u^\epsilon)\big|_0^\tau\,\mathrm{d}x - \int_{Q_\tau}u^\epsilon_t(\varphi(v-u^\epsilon))_t\,\mathrm{d}x\,\mathrm{d}t\\ &+\int_{Q_\tau}(\nabla u^\epsilon+\alpha\nabla u^\epsilon_t)\nabla(\varphi(v-u^\epsilon))\,\mathrm{d}x\,\mathrm{d}t \ge \int_{Q_\tau} f\varphi(v-u^\epsilon)\,\mathrm{d}x\,\mathrm{d}t.\end{aligned} \tag{2.18}$$

We infer from Lemmas 2.2 and 2.4 that it is possible to extract a subsequence, still denoted by u^ϵ, such that

$$u^\epsilon \rightharpoonup u \quad\text{in}\quad \mathrm{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega)) \quad\text{weak}\quad *, \tag{2.19a}$$

$$u^\epsilon_t \rightharpoonup u_t \quad\text{in}\quad \mathrm{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega)) \quad\text{weak}\quad *, \tag{2.19b}$$

$$\nabla u^\epsilon \rightharpoonup \nabla u \quad\text{in}\quad \mathrm{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega)) \quad\text{weak}\quad *, \tag{2.19c}$$

$$\Delta u^\epsilon \rightharpoonup \Delta u \quad\text{in}\quad \mathrm{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega)) \quad\text{weak}\quad *, \tag{2.19d}$$

$$\nabla u^\epsilon_t \rightharpoonup \nabla u_t \quad\text{in}\quad \mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega)) \quad\text{weak}. \tag{2.19e}$$

Define the set $Q_R \overset{\text{def}}{=} \{x : x_1 < 0,\ |x'|\le R\}\times[0,R]$. Thanks to the classical compactness properties of injections of Sobolev spaces on bounded open sets, we see that for all $R>0$, the restrictions of u^ϵ and ∇u^ϵ to Q_R converge strongly to their

respective limits in $\mathrm{L}^2(Q_R)$; therefore, we can pass to the limit in all the terms of (2.18) except possibly the first two terms.

Let us prove that u_t is continuous from $[0,\infty)$ to $\mathrm{L}^2(\Omega)$ equipped with the weak topology: we infer from the estimates of Lemma 2.5 that for all $\beta > 0$, u^ϵ_{tt} restricted to $x_1 < -\beta$ is bounded in $\mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2((-\infty,-\beta]\times\Sigma))$; therefore, u^ϵ_t converges to a function u_t whose restriction to $x_1 < -\beta$ is continuous from $[0,\infty)$ to $\mathrm{L}^2((-\infty,-\beta]\times\Sigma)$. Let $t_j \in [0,\infty)$ be a sequence converging to $t_\infty < \infty$; as u_t belongs to $\mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, we may extract a subsequence, still denoted by t_j, such that

$$u^\epsilon_t(\cdot,t_j) \rightharpoonup z \quad \text{in} \quad \mathrm{L}^2(\Omega) \quad \text{weak}.$$

But since, for all $\beta > 0$,

$$u^\epsilon_t(\cdot,t_j)1_{\{x_1<-\beta\}} \to u_t(\cdot,t_\infty)1_{\{x_1<-\beta\}} \quad \text{in} \quad \mathrm{L}^2(\Omega),$$

we see that z must coincide with $u_t(\cdot,t_\infty)$ and that the whole sequence converges strongly to $u_t(\cdot,t_\infty)$; this proves that u_t is continuous from $[0,\infty)$ to $\mathrm{L}^2(\Omega)$ weak.

Let us prove now that $u^\epsilon_t(\cdot,t)$ converges weakly to $u_t(\cdot,t)$ for all $t > 0$: let γ be an arbitrary positive number; let z belong to $\mathrm{L}^2(\Omega)$; and denote by C_1 an upper bound for $|u^\epsilon_t|_{\mathrm{L}^\infty([0,T];\mathrm{L}^2(\Omega))}$ with T fixed. We choose β so small that

$$\left(\int_{-\beta<x_1<0} |z|^2\,\mathrm{d}x\right)^{1/2} \le \frac{\gamma}{4C_1};$$

then, for $t \in [0,T]$,

$$\begin{aligned}\left|\int_\Omega (u^\epsilon_t(\cdot,t)-u_t(\cdot,t))z\,\mathrm{d}x\right| &\le \left|\int_{x_1<-\beta} (u^\epsilon_t(\cdot,t)-u_t(\cdot,t))z\,\mathrm{d}x\right| \\ &+ \left(\int_{-\beta<x_1<0} |z|^2\,\mathrm{d}x\right)^{1/2}\left(\int_{-\beta<x_1<0} |u^\epsilon_t(\cdot,t)-u_t(\cdot,t)|^2\,\mathrm{d}x\right)^{1/2}.\end{aligned} \tag{2.20}$$

By definition of C_1, the second term on the right-hand side of (2.20) is estimated by $C_1\gamma/(2C_1) = \gamma/2$. As $u^\epsilon_t|_{(-\infty,-\beta)\times I_T}$ is bounded in $\mathrm{H}^1((-\infty,-\beta)\times I_T)$, we see that

$$\int_{-\infty}^{-\beta}\int_\Sigma u^\epsilon_t z\,\mathrm{d}x \quad \text{converges} \quad \text{to} \quad \int_{-\infty}^{-\beta}\int_\Sigma u_t z\,\mathrm{d}x$$

uniformly with respect to $t \in [0,T]$. It suffices therefore to choose ϵ so small that the first term on the right-hand side of (2.20) is estimated by $\gamma/2$. This proves that the convergence of $\int_\Omega u^\epsilon_t z\,\mathrm{d}x$ to $\int_\Omega u_t z\,\mathrm{d}x$ is uniform on compact sets in time. In particular, as ϵ tends to 0, it is plain that for all $\tau > 0$,

$$\int_\Omega u^\epsilon_t\varphi(v-u^\epsilon)\,\mathrm{d}x \to \int_\Omega u_t\varphi(v-u)\,\mathrm{d}x.$$

Let us turn now to the term

$$\int_{Q_\tau} u^\epsilon_t(\varphi_t(v-u^\epsilon)+\varphi(v_t-u^\epsilon_t))\,\mathrm{d}x\,\mathrm{d}t.$$

It is clear that

$$\int_{Q_\tau} u^\epsilon_t(\varphi_t(v-u^\epsilon)+\varphi v_t)\,\mathrm{d}x\,\mathrm{d}t \to \int_{Q_\tau} u_t(\varphi_t(v-u)+\varphi v_t)\,\mathrm{d}x\,\mathrm{d}t.$$

There remains to prove the convergence

$$\int_{Q_\tau} |u_t^\epsilon|^2 \varphi \,\mathrm{d}x\,\mathrm{d}t \to \int_{Q_\tau} |u_t|^2 \varphi \,\mathrm{d}x\,\mathrm{d}t.$$

We observe that

$$\int_{Q_\tau} |u_t^\epsilon - u_t|^2 \varphi \,\mathrm{d}x\,\mathrm{d}t \le \int_0^\tau \int_\Sigma \int_{x_1 \le -\beta} |u_t^\epsilon - u_t|^2 \varphi \,\mathrm{d}x\,\mathrm{d}t + \int_0^\tau \int_\Sigma \int_{-\beta \le x_1 \le 0} |u_t^\epsilon - u_t|^2 \varphi \,\mathrm{d}x\,\mathrm{d}t.$$

Let γ be any positive number. One can deduce from the estimates of $|u_t^\epsilon|_{\mathrm{L}^2(I_\tau)}$ and $|\nabla u_t^\epsilon|_{\mathrm{L}^2(Q_\tau)}$ that there exists a constant C_2 independent from ϵ such that

$$|u_t^\epsilon(x_1, \cdot, \cdot)|_{\mathrm{L}^2(\Sigma \times (0,\tau))} \le C_2.$$

Therefore,

$$\int_0^\tau \int_\Sigma \int_{-\beta \le x_1 \le 0} |u_t^\epsilon - u_t|^2 \varphi \,\mathrm{d}x\,\mathrm{d}t \le C_2^2 \beta.$$

We choose β so small that $C_2^2 \beta \le \gamma/2$; then we know from the estimates of Lemmas 2.2 and 2.5 that the restriction of u^ϵ to $\{x_1 < -\beta\}$ intersected with a ball containing the support of φ is bounded in H^2 of that set; therefore, for ϵ small enough,

$$\int_{Q_\tau} |u_t^\epsilon - u_t|^2 \varphi \,\mathrm{d}x\,\mathrm{d}t \le \frac{\gamma}{2},$$

and the convergence of the first two terms of (2.18) is proved. We observe now that since u, u_t, ∇u, and ∇u_t belong to $\mathrm{L}^2_{\mathrm{loc}}([0,\infty); \mathrm{L}^2(\Omega))$, we may replace φ by φ_R in the variational inequality where φ_R is equal to 1 over the set Q_R and vanishes outside of Q_{R+1}. It is plain that as $R \to \infty$ all the terms in (2.18) converge to their limit; thus we have proved the existence of the desired weak solution. ∎

Remark 2.7. Nothing is known about uniqueness.

2.4. Auxiliary results on the damped wave equation with Dirichlet boundary conditions. We establish a priori estimates on the damped wave equation with Dirichlet boundary conditions. These estimates will enable us to give some properties on the trace spaces which we use in the next subsection.

LEMMA 2.8. *Assume u_0 belongs to $\mathrm{H}^{5/2}(\Omega)$; then, there exists a function $z \in \mathrm{H}^3(\Omega \times [0,\infty))$ with compact support in t such that the trace of z on Ω is equal to u_0.*

Proof. We extend u_0 into a function belonging to $\mathrm{H}^{5/2}(\mathbb{R}^d)$: as the boundary of Ω is smooth, this extension is a consequence of classical results on Sobolev spaces. Then there exists a function Z belonging to $\mathrm{H}^3(\mathbb{R}^d \times [0,\infty))$ whose trace is u_0. It suffices now to select a cut-off function $\varphi \in \mathrm{C}^\infty([0,\infty))$ which is equal to 1 on $[0,1]$ and to 0 on $[2,\infty)$ and to define z as the restriction of φZ to $\Omega \times [0,\infty)$. ∎

LEMMA 2.9. *Assume u_0 belongs to $\mathrm{H}^{5/2}(\Omega)$, u_1 belongs to $\mathrm{H}^1(\Omega)$, and f belongs to $\mathrm{L}^2_{\mathrm{loc}}([0,\infty); \mathrm{L}^2(\Omega))$. Define z as in Lemma 2.8, and let $\bar{u}$ be the solution of (1.1) with the initial data (1.2) and boundary condition $\bar{u}(0,\cdot,\cdot) = z(0,\cdot,\cdot)$. Then the trace $\bar{g} \overset{\mathrm{def}}{=} -(\bar{u}_{x_1} + \alpha \bar{u}_{x_1 t})(0,\cdot,\cdot)$ is well defined and belongs to $\mathrm{L}^2_{\mathrm{loc}}([0,\infty); \mathrm{L}^2(\mathbb{R}^{d-1}))$. Moreover, if f is compactly supported in time,*

$$\int_0^\tau |\bar{g}(\cdot,t)|^2_{\mathrm{L}^2(\Sigma)} \,\mathrm{d}t$$

increases at most polynomially with respect to τ.

Proof. The function $\zeta \overset{\text{def}}{=} \bar{u} - z$ satisfies the equation

$$\zeta_{tt} - \Delta\zeta - \alpha\Delta\zeta_t = F, \quad x \in \Omega, \quad t > 0, \tag{2.21}$$

where $F \overset{\text{def}}{=} f - z_{tt} + \Delta z + \alpha\Delta z_t$, with initial data

$$\zeta(\cdot, 0) = 0 \quad \text{and} \quad \zeta_t(\cdot, 0) = u_1$$

and the Dirichlet boundary condition $\zeta(0, \cdot, \cdot) = 0$. If we multiply (2.21) by ζ_t and integrate, and if we suppose that f and F are compactly supported in time, we may easily deduce that ζ_t, $\nabla\zeta$ are bounded in $\mathrm{L}^\infty_{\mathrm{loc}}([0,\infty); \mathrm{L}^2(\Omega))$ and $\nabla\zeta_t$ is bounded in $\mathrm{L}^2_{\mathrm{loc}}([0,\infty); \mathrm{L}^2(\Omega))$. In order to get more information, we multiply (2.21) by $\Delta\zeta_t$; since the boundary term vanishes, we get immediately the identity

$$\begin{aligned}&\alpha \int_{Q_\tau} |\Delta\zeta_t|^2 \,\mathrm{d}x\,\mathrm{d}t + \frac{1}{2}\int_\Omega |\Delta\zeta(\cdot,\tau)|^2 \,\mathrm{d}x + \int_\Omega |\nabla\zeta_t(\cdot,\tau)|^2 \,\mathrm{d}x \\ &= \int_\Omega |\nabla\zeta_t(\cdot,0)|^2 \,\mathrm{d}x - \int_{Q_\tau} F\Delta\zeta_t \,\mathrm{d}x\,\mathrm{d}t.\end{aligned}$$

The product $F\Delta\zeta_t$ can be estimated by $\alpha|\Delta\zeta_t|^2/2 + |F|^2/(2\alpha)$; then $\Delta\zeta_t$ is bounded in $\mathrm{L}^2_{\mathrm{loc}}([0,\infty); \mathrm{L}^2(\Omega))$, and $\Delta\zeta$ and $\nabla\zeta_t$ are bounded in $\mathrm{L}^\infty_{\mathrm{loc}}([0,\infty); \mathrm{L}^2(\Omega))$. In particular, if the support in time of F is bounded, $\Delta\zeta_t$ is bounded in $\mathrm{L}^2([0,\infty); \mathrm{L}^2(\Omega))$ and $\Delta\zeta$ and $\nabla\zeta_t$ are bounded in $\mathrm{L}^\infty([0,\infty); \mathrm{L}^2(\Omega))$. Hence $\zeta_{x_1 t}(0,\cdot,\cdot)$ and $\zeta_{x_1}(0,\cdot,\cdot)$ belong, respectively, to $\mathrm{L}^2_{\mathrm{loc}}([0,\infty); \mathrm{H}^{1/2}(\mathbb{R}^{d-1}))$ and to $\mathrm{L}^\infty_{\mathrm{loc}}([0,\infty); \mathrm{H}^{1/2}(\mathbb{R}^{d-1}))$, and if the support in time of f is bounded, the local character of these spaces may be removed. ∎

2.5. Regularity of the trace. We characterize the trace spaces using Fourier analysis, and we prove that u is a strong solution of (1.1)–(1.3). Here, we mean by strong solution that all the traces can be defined.

Let ν be a positive number. Denote by $v^\epsilon \overset{\text{def}}{=} \mathrm{e}^{-\nu t}(u^\epsilon - \bar{u})$ a solution of

$$(\nu + \partial_t)^2 v^\epsilon - (1 + \alpha(\nu + \partial_t))\Delta v^\epsilon = 0, \quad x \in \Omega, \quad t > 0, \tag{2.22a}$$

$$(1 + \alpha(\nu + \partial_t))v^\epsilon_{x_1}(0,\cdot,\cdot) = \mathrm{e}^{-\nu t}\bar{g} - (v^\epsilon(0,\cdot,\cdot) + \mathrm{e}^{-\nu t}\bar{u}(0,\cdot,\cdot))^-/\epsilon, \tag{2.22b}$$

$$v^\epsilon(\cdot, 0) = 0 \quad \text{and} \quad v^\epsilon_t(\cdot, 0) = 0. \tag{2.22c}$$

We denote by $\xi \overset{\text{def}}{=} (\xi_2, \dots, \xi_d)^{\mathsf{T}}$ and ω, respectively, the dual variables to $x' \overset{\text{def}}{=} (x_2, \dots, x_d)^{\mathsf{T}}$ and t. The Fourier transform of $u(0, x', t)$ is $\widehat{u}(0, \xi, \omega)$, where the convention for the Fourier transform is

$$\widehat{u}(0,\xi,\omega) = \int_{\mathbb{R}^d} \mathrm{e}^{-i(\xi\cdot x' + \omega t)} u(0, x', t) \,\mathrm{d}x'\,\mathrm{d}t.$$

Then $u(0, x', t)$ belongs to the Sobolev space $\mathrm{H}^{a,b}_{\mathrm{loc}}(\mathbb{R}^{d-1}\times[0,\infty))$, $(a, b) \in \mathbb{R}^2$, iff $|\xi|^a\widehat{u}(0,\xi,\omega)$ and $|\omega|^b\widehat{u}(0,\xi,\omega)$ belong to $\mathrm{L}^2(\mathbb{R}^d)$.

We apply a partial Fourier transform in the tangential variable to (2.22a), and we get the following differential equation:

$$\widehat{v}^\epsilon_{x_1 x_1} = \left(|\xi|^2 + \frac{(\nu + i\omega)^2}{1 + \alpha(\nu + i\omega)}\right)\widehat{v}^\epsilon. \tag{2.23}$$

Define $\widehat{\lambda}$ to be

$$\widehat{\lambda}(\xi,\omega) \stackrel{\text{def}}{=} \sqrt{|\xi|^2 + \frac{(\nu+i\omega)^2}{1+\alpha(\nu+i\omega)}};$$

thus $\widehat{\lambda}$ is holomorphic in the lower half-plane $\Im(\omega) < 0$ and $\Re\widehat{\lambda} \geq 0$ for $\Im(\omega) = 0$. The general solution of (2.23) is given by $\widehat{a}^\epsilon \mathrm{e}^{\widehat{\lambda}x_1} + \widehat{b}^\epsilon \mathrm{e}^{-\widehat{\lambda}x_1}$; since we performed a Fourier transform on v^ϵ, we assumed implicitly that v^ϵ and $\widehat{v}^\epsilon$ are tempered, respectively, in (x',t) and (ξ,ω). We remark that the term $\widehat{b}^\epsilon \mathrm{e}^{-\widehat{\lambda}x_1}$ can be tempered only if $\widehat{b}^\epsilon$ decays at infinity very quickly, and since this must be true for all x_1, it implies that $\widehat{b}^\epsilon$ vanishes; the proof is similar to that given in [PeS02]. We deduce that the solution of (2.23) is $\widehat{a}^\epsilon \mathrm{e}^{\widehat{\lambda}x_1}$. In particular,

$$((1+\alpha(\nu+\partial_t))v^\epsilon_{x_1})\widehat{\ }(0,\xi,\omega) = \widehat{\lambda}_1 \widehat{v}^\epsilon(0,\xi,\omega), \tag{2.24}$$

where $\widehat{\lambda}_1 \stackrel{\text{def}}{=} (1+\alpha(\nu+i\omega))\widehat{\lambda}$. Define

$$g(x',t) \stackrel{\text{def}}{=} \mathrm{e}^{-\nu t}\bar{g}(x',t) \quad \text{and} \quad h(x',t) \stackrel{\text{def}}{=} \mathrm{e}^{-\nu t}\bar{u}(0,x',t).$$

If we let $w^\epsilon(x',t)$ be the trace $v^\epsilon(0,x',t)$, (2.22) can now be written as

$$\lambda_1 * w^\epsilon = g + (w^\epsilon + h)^-/\epsilon, \tag{2.25}$$

where w^ϵ vanishes for all $t \leq 0$.

Remark 2.10. It is clear that $\widehat{\lambda}$ is a holomorphic function in $\Im(\omega) < 0$, and thus we may deduce that λ_1 is a causal distribution.

LEMMA 2.11. *Let u^ϵ be the solution of* (2.1)–(2.3). *Then we may extract a subsequence, still denoted by u^ϵ, such that*

$$u^\epsilon(0,\cdot,\cdot) \rightharpoonup u(0,\cdot,\cdot) \quad \textit{weakly} \quad \textit{in} \quad \mathrm{H}^{1/2,5/4}_{\mathrm{loc}}(\mathbb{R}^{d-1}\times[0,\infty)).$$

Moreover, u is a strong solution of (1.1)–(1.3).

Proof. Formally, we multiply (2.25) by $\alpha(\nu w^\epsilon + w^\epsilon_t) + w^\epsilon$, and we estimate the pseudodifferential term in the Fourier variable; we obtain

$$\begin{aligned} &\frac{1}{(2\pi)^d}\,\Re\int_{\mathbb{R}^d} \widehat{\lambda}_1 \widehat{w}^\epsilon \overline{(1+\alpha(\nu+i\omega))\widehat{w}^\epsilon}\,\mathrm{d}\omega\,\mathrm{d}\xi \\ &= \frac{1}{(2\pi)^d}\,\Re\int_{\mathbb{R}^d} \widehat{g}\overline{(1+\alpha(\nu+i\omega))\widehat{w}^\epsilon}\,\mathrm{d}\omega\,\mathrm{d}\xi \\ &+ \frac{1}{\epsilon}\int_0^\infty \int_{\mathbb{R}^{d-1}} (w^\epsilon+h)^-(1+\alpha(\nu+\partial_t))w^\epsilon\,\mathrm{d}x'\,\mathrm{d}t. \end{aligned} \tag{2.26}$$

Since $(u^\epsilon(0,\cdot,\cdot))^-/\sqrt{\epsilon}$ is bounded in $\mathrm{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\mathbb{R}^{d-1}))$, the absolute value of the second integral in the right-hand side of (2.26) is bounded, and we infer that there exists $C_1 > 0$ such that

$$\Re\int_{\mathbb{R}^d} \widehat{\lambda}_1 |\widehat{w}^\epsilon|^2 \overline{(1+\alpha(\nu+i\omega))}\,\mathrm{d}\omega\,\mathrm{d}\xi \leq C_1 + \Re\int_{\mathbb{R}^d} \widehat{g}\overline{(1+\alpha(\nu+i\omega))\widehat{w}^\epsilon}\,\mathrm{d}\omega\,\mathrm{d}\xi. \tag{2.27}$$

On the other hand, we have

$$\Re\widehat{\lambda}^2 = |\xi|^2 + \frac{\nu^2(1+\alpha\nu) + (-1+\alpha\nu)\omega^2}{|1+\alpha(\nu+i\omega)|^2} \quad \text{and} \quad \Im\widehat{\lambda}^2 = \frac{2\nu\omega + \alpha\omega(\nu^2+\omega^2)}{|1+\alpha(\nu+i\omega)|^2}.$$

We may choose ν such that $\nu\alpha = 1$; we get then

$$\Re\widehat{\lambda}^2 = |\xi|^2 + \frac{2}{\alpha^2|2+i\alpha\omega|^2} \quad \text{and} \quad \Im\widehat{\lambda}^2 = \frac{\omega(3+\alpha^2\omega^2)}{\alpha|2+i\alpha\omega|^2}. \tag{2.28}$$

Therefore, we infer that

$$\arg\widehat{\lambda} = \frac{1}{2}\arctan\left(\frac{|\xi|^2|2+i\alpha\omega|^2+2}{\alpha\omega(3+\alpha^2\omega^2)}\right).$$

According to (2.28), $\arg\widehat{\lambda}$ belongs to $[0,\pi/4]$, and since $\widehat{\lambda}$ is never equal to zero, we get for $|\xi|+|\omega| \gg 1$ the following inequality:

$$\Re\widehat{\lambda} \geq C\big(1+|\xi|+\sqrt{|\omega|}\big). \tag{2.29}$$

Therefore, we obtain

$$C\int_{\mathbb{R}^d} |2+i\alpha\omega|^2\big(1+|\xi|+\sqrt{|\omega|}\big)|\widehat{w}^\epsilon|^2\,\mathrm{d}\omega\,\mathrm{d}\xi \leq C_1 + \int_{\mathbb{R}^d} |2+i\alpha\omega||\widehat{g}||\widehat{w}^\epsilon|\,\mathrm{d}\omega\,\mathrm{d}\xi.$$

We estimate the product $|zy|$ by $|z|^2/(2\gamma)+\gamma|y|^2/2$, $\gamma>0$; we see that

$$\begin{aligned}&\Big(C-\frac{\gamma}{2}\Big)\int_{\mathbb{R}^d} |2+i\alpha\omega|^2\big(1+|\xi|+\sqrt{|\omega|}\big)|\widehat{w}^\epsilon|^2\,\mathrm{d}\omega\,\mathrm{d}\xi\\ &\leq C_1 + \frac{1}{2\gamma}\int_{\mathbb{R}^d}\frac{|\widehat{g}|^2}{1+|\xi|+\sqrt{|\omega|}}\,\mathrm{d}\omega\,\mathrm{d}\xi.\end{aligned} \tag{2.30}$$

We choose γ such that $\gamma < 2C$; since g belongs to $\mathrm{L}^2([0,\infty);\mathrm{H}^{1/2}(\mathbb{R}^{d-1}))$, then it is easy to deduce from (2.30) that $u^\epsilon(0,\cdot,\cdot)$ is bounded in $\mathrm{H}^{1/2,5/4}_{\mathrm{loc}}(\mathbb{R}^{d-1}\times[0,\infty))$. Moreover, it is clear that $(u_{x_1}+\alpha u_{x_1 t})(0,\cdot,\cdot)$ is bounded in $\mathrm{H}^{-1/2,-1/4}_{\mathrm{loc}}(\mathbb{R}^{d-1}\times[0,\infty))$. Therefore, all the traces are defined, and we may deduce that u is a strong solution of (2.1)–(2.3). ∎

Remark 2.12. We have been unable to establish that the energy loss is purely viscous as in the case of the one dimensional viscously damped wave equation on the half-line and with unilateral boundary conditions [PeS02, PeS08].

3. The evolution of a Kelvin–Voigt material with Signorini boundary conditions. As for the damped wave equation with unilateral boundary conditions, a priori estimates on the penalized problem and care relative due to the unboundedness of Ω enable us to pass to the limit in the penalized variational formulation and to deduce the existence of a solution to (1.9). Korn's inequality plays an important role here. If we denote by $\bar{u}$ the solution of (1.9a) with initial data (1.9d) and Dirichlet boundary data at $x_1 = 0$, then we establish that the trace $-(a^0_{11kl}\varepsilon_{kl}(\bar{u}) + a^1_{11kl}\varepsilon_{kl}(\bar{u}_t))|_{\Sigma\times[0,\infty)}$ increases exponentially with time in $\mathrm{L}^2_{\mathrm{loc}}(\Sigma\times[0,\infty))$ and not polynomially as in the case of the damped wave equation with Dirichlet boundary conditions studied in subsection 2.4. We determine the trace spaces using analogous techniques already developed in section 2.5, but here we perform a Fourier transform in the tangential variables (x_2,x_3,t) and a Laplace transform in x_1.

3.1. The penalized problem. We approximate (1.9) as in section 2.1. More precisely, letting $r^+ \stackrel{\mathrm{def}}{=} \max(r,0)$, we replace u by u^ϵ which is a solution of the following penalized problem:

$$\rho u^\epsilon_{tt} - A^0 u^\epsilon - A^1 u^\epsilon_t = f, \quad x\in\Omega, \quad t>0, \tag{3.1}$$

with initial data

$$u^\epsilon(\cdot,0) = v_0 \quad \text{and} \quad u_t^\epsilon(\cdot,0) = v_1 \tag{3.2}$$

and boundary conditions

$$a^0_{11kl}\varepsilon_{kl}(u^\epsilon) + a^1_{11kl}\varepsilon_{kl}(u_t^\epsilon) = -(u_1^\epsilon)^+/\epsilon, \tag{3.3a}$$

$$a^0_{12kl}\varepsilon_{kl}(u^\epsilon) + a^1_{12kl}\varepsilon_{kl}(u_t^\epsilon) = 0, \quad \text{and} \quad a^0_{13kl}\varepsilon_{kl}(u^\epsilon) + a^1_{13kl}\varepsilon_{kl}(u_t^\epsilon) = 0. \tag{3.3b}$$

Recall that Q_τ and I_τ were defined by (2.4).

THEOREM 3.1. *Let* $\mathrm{W} \stackrel{\text{def}}{=} \{u \in \mathbf{H}^1_{\mathrm{loc}}([0,\infty)\times\Omega) : \nabla u_t \in \mathbf{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))\}$. *Then for each* $\epsilon > 0$ *there exists a unique weak solution* $u^\epsilon \in \mathrm{W}$ *of the problem* (3.1)–(3.3) *such that*

$$\begin{aligned} u^\epsilon &\in \mathbf{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{H}^1(\Omega)),\\ u_t^\epsilon &\in \mathbf{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{H}^1(\Omega)),\\ u_{tt}^\epsilon &\in \mathbf{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega)), \end{aligned}$$

and for every $\tau \in (0,T)$ *and for all* $v \in \mathrm{W}$, *the following variational equality is satisfied:*

$$\begin{aligned} &\int_{Q_\tau} \rho u_{tt}^\epsilon \cdot v \,\mathrm{d}x\,\mathrm{d}t + \int_0^\tau \left(a^0(u^\epsilon, v) + a^1(u_t^\epsilon, v)\right)\mathrm{d}t\\ &+ \int_{I_\tau} \frac{(u_1^\epsilon)^+}{\epsilon} v_1 \,\mathrm{d}x'\,\mathrm{d}t \geq \int_{Q_\tau} f\cdot v\,\mathrm{d}x\,\mathrm{d}t. \end{aligned} \tag{3.4}$$

Proof. We leave the verification of the proof to the reader as it is analogous to the one developed in [Jar96]. ∎

3.2. Estimates on the penalized solution. We establish a priori estimates which are essential to prove the existence of a weak solution to (3.1)–(3.3). These estimates are obtained thanks to the techniques already developed in section 2.2 for the damped wave equation and to Korn's inequality.

LEMMA 3.2. *Assume that* f *belongs to* $\mathbf{L}^2_{\mathrm{loc}}\big([0,\infty);\mathrm{L}^2(\Omega)\big)$, v_0 *to* $\mathbf{H}^1(\Omega)$, *and* v_1 *to* $\mathbf{L}^2(\Omega)$. *Then* u_t^ϵ *and* ∇u^ϵ *are bounded in* $\mathbf{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, ∇u_t^ϵ *is bounded in* $\mathbf{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, *and* $(u_1^\epsilon(0,\cdot,\cdot))^+/\sqrt{\epsilon}$ *is bounded in* $\mathrm{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\mathbb{R}^{d-1}))$, *independently of* $\epsilon > 0$.

Proof. These estimates are a simple application of the Gronwall lemma to the energy estimate. We multiply (3.1) by u_t^ε and integrate this expression over Q_τ to get

$$\begin{aligned} &\frac{1}{2}\int_\Omega \left(\rho|u_t^\epsilon|^2 + a^0_{ijkl}\varepsilon_{ij}(u^\epsilon)\varepsilon_{kl}(u^\epsilon)\right)\Big|_0^\tau \mathrm{d}x + \int_{Q_\tau} a^1_{ijkl}\varepsilon_{ij}(u_t^\epsilon)\varepsilon_{kl}(u_t^\epsilon)\,\mathrm{d}x\,\mathrm{d}t\\ &+ \frac{1}{2\epsilon}\int_\Sigma \left((u_1^\epsilon)^+\right)^2\Big|_0^\tau \mathrm{d}x' = \int_{Q_\tau} f\cdot u^\epsilon\,\mathrm{d}x\,\mathrm{d}t. \end{aligned} \tag{3.5}$$

According to Korn's inequality, it is possible to infer that there exist two positive constants C_1 and C_2 such that

$$\int_\Omega a^n_{ijkl}\varepsilon_{kl}(z)\varepsilon_{ij}(z)\,\mathrm{d}z \geq C_1\int_\Omega |\nabla z|^2\,\mathrm{d}z - C_2\int_\Omega |z|^2\,\mathrm{d}z, \quad n = 0,1.$$

As fu_t^ϵ can be estimated by $|f|^2/(2\gamma)+\gamma|u_t^\epsilon|^2/2$, $\gamma>0$, and using the above inequality, we deduce from (3.5) that

$$\begin{aligned}&\frac{1}{2}\int_\Omega \big(\rho|u_t^\epsilon|^2+C_1|\nabla u^\epsilon|^2\big)(\cdot,\tau)\,\mathrm{d}x+C_1\int_{Q_\tau}|\nabla u_t^\epsilon|^2\,\mathrm{d}x\,\mathrm{d}t+\frac{1}{2\epsilon}\int_\Sigma\big((u_1^\epsilon)^+\big)\big|_0^\tau\,\mathrm{d}x'\\&\le\frac{C_2}{2}\int_\Omega|u^\epsilon(\cdot,\tau)|^2\,\mathrm{d}x+\Big(C_2+\frac{\gamma}{2}\Big)\int_{Q_\tau}|u_t^\epsilon|^2\,\mathrm{d}x\,\mathrm{d}t+\frac{1}{2\gamma}\int_{Q_\tau}|f|^2\,\mathrm{d}x\,\mathrm{d}t\\&+\frac{1}{2}\int_\Omega\big(\rho|v_1|^2+a^0_{ijkl}\varepsilon_{ij}(v_0)\varepsilon_{kl}(v_0)\big)\,\mathrm{d}x.\end{aligned}$$

A classical Gronwall lemma enables us to deduce that u_t^ϵ and ∇u^ϵ are bounded in the space $\mathbf{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, ∇u_t^ϵ is bounded in $\mathbf{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, and $(u_1^\epsilon(0,\cdot,\cdot))^+/\sqrt{\epsilon}$ is bounded in $\mathrm{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\mathbb{R}^{d-1}))$. ∎

Remark 3.3. If we suppose that f vanishes for large t, then, independently of $\epsilon>0$,

$$\operatorname*{ess\,sup}_{0\le t\le T}|u^\epsilon(\cdot,t)|_{\mathrm{H}^1}\le C(1+T)$$

and

$$\left(\int_0^T|u_t^\epsilon(\cdot,t)|^2_{\mathrm{H}^1}\,\mathrm{d}t\right)^{1/2}\le C(1+T).$$

These properties can be proved using the arguments given in the proof of Lemma 3.2, with the origin of time moved to T if f vanishes for $t\ge T$; since the integral involving f vanishes, the conclusion is clear.

LEMMA 3.4. *Assume that f belongs to $\mathbf{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, v_0 to $\mathbf{H}^1(\Omega)$, and v_1 to $\mathbf{L}^2(\Omega)$. Then, independently of $\epsilon>0$, the trace $(u_1^\epsilon(0,\cdot,\cdot))^+/\epsilon$ is bounded in the space of measures on I_T.*

Proof. Let φ be a cut-off function which belongs to $\mathbf{C}^1(\mathbb{R}^{d-1})$, is equal to 1 in the sphere of center 0 and radius $R>0$, and vanishes outside of a sphere of radius $R+1$. We multiply (3.1) by φ and we integrate over Q_τ; due to the boundary conditions (3.3), we obtain

$$\begin{aligned}&\int_\Omega\rho u_t^\epsilon\cdot\varphi\big|_0^\tau\,\mathrm{d}x+\frac{1}{\epsilon}\int_{I_\tau}(u_1^\epsilon)^+\varphi_1\,\mathrm{d}x'\,\mathrm{d}t+\int_{Q_\tau}\sigma^0_{ij}(u^\epsilon)\varepsilon_{ij}(\varphi)\,\mathrm{d}x\,\mathrm{d}t\\&+\int_{Q_\tau}\sigma^1_{ij}(u_t^\epsilon)\varepsilon_{ij}(\varphi)\,\mathrm{d}x\,\mathrm{d}t=\int_{Q_\tau}f\cdot\varphi\,\mathrm{d}x\,\mathrm{d}t.\end{aligned}$$

As the product $|zy|$ can be estimated by $|z|^2/2+|y|^2/2$, we get the following inequality:

$$\begin{aligned}&\frac{1}{\epsilon}\int_{I_\tau}(u_1^\epsilon)^+\varphi_1\,\mathrm{d}x'\,\mathrm{d}t\le\frac{\rho}{2}\int_\Omega\big(|u_t^\epsilon(\cdot,\tau)|^2+|v_1|^2\big)\,\mathrm{d}x+\rho\int_\Omega|\varphi|^2\,\mathrm{d}x\\&+\int_{Q_\tau}\big|\big(\sigma^0_{ij}(u^\epsilon)+\sigma^1_{ij}(u_t^\epsilon)\big)\varepsilon_{ij}(\varphi)\big|\,\mathrm{d}x\,\mathrm{d}t+\int_{Q_\tau}|f\cdot\varphi|\,\mathrm{d}x\,\mathrm{d}t.\end{aligned}\tag{3.6}$$

We may deduce that the right-hand side of (3.6) is bounded using the Lemma 3.2. Since $(u_1^\epsilon(0,\cdot,\cdot))^+$ is nonnegative, the conclusion is clear. ∎

LEMMA 3.5. *Assume that f, v_0, and v_1 belong, respectively, to $\mathbf{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, $\mathbf{H}^2(\Omega)$, and $\mathbf{L}^2(\Omega)$. Then A^0u^ϵ and A^1u^ϵ are bounded in $\mathbf{L}^\infty_{\mathrm{loc}}([0,\infty),\mathrm{L}^2(\Omega))$, independently of $\epsilon>0$.*

Proof. Once again, we use energy techniques, but now we multiply relation (3.1) by A^1u^ϵ and we integrate over Q_τ to obtain

$$\begin{aligned}\frac{1}{2}\int_\Omega |A^1u^\epsilon(\cdot,\tau)|^2\,\mathrm{d}x &= \frac{1}{2}\int_\Omega |A^1v_0|^2\,\mathrm{d}x + \int_{Q_\tau}\rho u^\epsilon_{tt}\cdot(A^1u^\epsilon)\,\mathrm{d}x\,\mathrm{d}t\\ &- \int_{Q_\tau}(A^0u^\epsilon)\cdot(A^1u^\epsilon)\,\mathrm{d}x\,\mathrm{d}t - \int_{Q_\tau} f\cdot(A^1u^\epsilon)\,\mathrm{d}x\,\mathrm{d}t.\end{aligned} \tag{3.7}$$

Notice that

$$\begin{aligned}\int_{Q_\tau}\rho u^\epsilon_{tt}\cdot(A^1u^\epsilon)\,\mathrm{d}x\,\mathrm{d}t &= \rho\int_\Omega u^\epsilon_t\cdot(A^1u^\epsilon)\big|_0^\tau\,\mathrm{d}x\\ &- \rho\int_{I_\tau} u^\epsilon_{1,t}\sigma^1_{1j}(u^\epsilon)\,\mathrm{d}x'\,\mathrm{d}t + \int_{Q_\tau} a^1_{ijkl}\varepsilon_{ij}(u^\epsilon_t)\varepsilon_{kl}(u^\epsilon_t)\,\mathrm{d}x\,\mathrm{d}t.\end{aligned} \tag{3.8}$$

Carrying (3.8) into (3.7) and using the boundary conditions (3.3), we obtain

$$\begin{aligned}\frac{1}{2}\int_\Omega |A^1u^\epsilon(\cdot,\tau)|^2\,\mathrm{d}x &= \frac{1}{2}\int_\Omega |A^1v_0|^2\,\mathrm{d}x - \int_{Q_\tau}(A^0u^\epsilon)\cdot(A^1u^\epsilon)\,\mathrm{d}x\,\mathrm{d}t\\ &- \int_{Q_\tau} f\cdot(A^1u^\epsilon)\,\mathrm{d}x\,\mathrm{d}t + \rho\int_\Omega u^\epsilon_t\cdot(A^1u^\epsilon)\big|_0^\tau\,\mathrm{d}x + \frac{\rho}{\epsilon}\int_{I_\tau} u^\epsilon_{1,t}(u^\epsilon_1)^+\,\mathrm{d}x'\,\mathrm{d}t\\ &+ \rho\int_{I_\tau} u^\epsilon_{1,t}\sigma^0_{1j}(u^\epsilon)\,\mathrm{d}x'\,\mathrm{d}t + \int_{Q_\tau} a^1_{ijkl}\varepsilon_{ij}(u^\epsilon_t)\varepsilon_{kl}(u^\epsilon_t)\,\mathrm{d}x\,\mathrm{d}t.\end{aligned} \tag{3.9}$$

On the other hand, we observe that

$$\int_{I_\tau}|\sigma^0_{1j}(u^\epsilon)|^2\,\mathrm{d}x'\,\mathrm{d}t \le C\left(\int_{Q_\tau}|u^\epsilon|^2\,\mathrm{d}x\,\mathrm{d}t + \int_{Q_\tau}|A^1u^\epsilon|^2\,\mathrm{d}x\,\mathrm{d}t\right), \tag{3.10}$$

and for all v belonging to $\mathbf{H}^1(\Omega)$ and A^1v belonging to $\mathbf{L}^2(\Omega)$, we get

$$|A^0v|_{\mathrm{L}^2(\Omega)} \le C|v|_{\mathrm{L}^2(\Omega)} + |A^1v|_{\mathrm{L}^2(\Omega)}. \tag{3.11}$$

Define

$$F(t) \stackrel{\mathrm{def}}{=} \int_\Omega |A^1u^\epsilon(\cdot,t)|^2\,\mathrm{d}x. \tag{3.12}$$

According to (3.10)–(3.12) and since $u^\epsilon_t\cdot(A^1u^\epsilon)$ can be estimated by $|u^\epsilon_t|^2/(2\gamma) + \gamma|A^1u^\epsilon|^2/2$, $\gamma>0$, it is possible to infer from (3.9) the following inequality:

$$\begin{aligned}&\left(\frac{1}{2}-\frac{\rho\gamma}{2}\right)F(\tau) \le \frac{1}{2}F(0) + (2+C)\int_0^\tau F(t)\,\mathrm{d}t + \frac{1}{2}\int_{Q_\tau}|f|^2\,\mathrm{d}x\,\mathrm{d}t\\ &+ \frac{\rho}{2\gamma}\int_\Omega |u^\epsilon_t(\cdot,\tau)|^2\,\mathrm{d}x + \rho\int_\Omega |v_1\cdot(A^1v_0)|\,\mathrm{d}x + \int_{Q_\tau} a^1_{ijkl}\varepsilon_{ij}(u^\epsilon_t)\varepsilon_{kl}(u^\epsilon_t)\,\mathrm{d}x\,\mathrm{d}t\\ &+ \frac{\rho}{2\varepsilon}\int_\Sigma \big(u^\epsilon_1(\cdot,\tau)\big)^+\,\mathrm{d}x' + (1+C)\int_{Q_\tau}|u^\epsilon|^2\,\mathrm{d}x\,\mathrm{d}t + \int_{I_\tau}|u^\epsilon_t|^2\,\mathrm{d}x'\,\mathrm{d}t.\end{aligned}$$

If we choose γ such that $\rho\gamma<1$, we may infer using Lemma 3.2 and a classical Gronwall inequality that F is bounded in $\mathrm{L}^\infty_{\mathrm{loc}}([0,\infty))$. This proves the lemma. ∎

Remark 3.6. If we suppose that f vanishes for t large, then, independently of $\epsilon > 0$, $A^0 u^\epsilon$ and $A^1 u^\epsilon$ increase polynomially. These properties can be proved using the arguments given in Remark 3.3.

Let us turn now to interior estimates.

LEMMA 3.7. *Assume that f belongs to $\mathbf{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, v_0 to $\mathbf{H}^2(\Omega)$, and v_1 to $\mathbf{L}^2(\Omega)$. Then for all $\beta > 0$, u^ϵ_{tt} and $A^1 u^\epsilon_t$ are bounded in $\mathbf{L}^2([0,\infty);\mathrm{L}^2((-\infty,-\beta)\times\Sigma))$, independently of $\epsilon > 0$.*

Proof. As for the proof of Lemma 2.5, we use a truncation function which enables us to forget about the strongly nonlinear boundary conditions. More precisely, we multiply u^ϵ by a cut-off function $\varphi(x_1) \in \mathrm{C}^\infty([0,\infty))$ which is equal to 0 on $x_1 \le -\beta$ and to 1 on $x_1 \ge -\beta/2$, $\beta > 0$. Define

$$v^\epsilon(x_1,\cdot,\cdot) \stackrel{\mathrm{def}}{=} \varphi(x_1) u^\epsilon(x_1,\cdot,\cdot). \tag{3.13}$$

The derivatives of v^ϵ are given by

$$v^\epsilon_{tt} = \varphi u^\epsilon_{tt}, \tag{3.14a}$$

$$\varepsilon_{kl,x_j}(v^\epsilon) = \varphi\varepsilon_{kl,x_j}(u^\epsilon) + 2\varphi_{x_1}\varepsilon_{kl}(u^\epsilon) + \varphi_{x_1x_1}u^\epsilon_k, \tag{3.14b}$$

$$\varepsilon_{kl,x_j}(v^\epsilon_t) = \varphi\varepsilon_{kl,x_j}(u^\epsilon_t) + 2\varphi_{x_1}\varepsilon_{kl}(u^\epsilon_t) + \varphi_{x_1x_1}u^\epsilon_{k,t}. \tag{3.14c}$$

Notice that thanks to relations (3.1) and (3.14), we have

$$v^\epsilon_{tt} - A^0 v^\epsilon - A^1 v^\epsilon = \widetilde{g}^\epsilon, \tag{3.15}$$

where $\widetilde{g}^\varepsilon_i \stackrel{\mathrm{def}}{=} \varphi f_i - 2\varphi_{x_1}(a^0_{ijkl}\varepsilon_{kl}(u^\epsilon) + a^1_{ijkl}\varepsilon_{kl}(u^\epsilon_t)) - \varphi_{x_1x_1}(a^0_{ijkl}u^\epsilon_k + a^1_{ijkl}u^\epsilon_{k,t})$. Thanks to Lemma 3.2, we deduce that $\widetilde{g}^\varepsilon$ is bounded in $\mathbf{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$. Define

$$w^\epsilon \stackrel{\mathrm{def}}{=} v^\epsilon_t \quad \text{and} \quad g^\epsilon \stackrel{\mathrm{def}}{=} \widetilde{g}^\epsilon + A^0 v^\epsilon. \tag{3.16}$$

We substitute (3.16) into (3.15) and obtain

$$w^\epsilon_t - A^1 w^\epsilon = g^\epsilon. \tag{3.17}$$

We will prove that w^ε_t is bounded in $\mathbf{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$. For this purpose, we multiply (3.17) by w^ε_t; we integrate this expression over Q_τ to obtain

$$\int_{Q_\tau} |w^\epsilon_t|^2 \,\mathrm{d}x\,\mathrm{d}t - \int_{Q_\tau} (A^1 w^\epsilon)\cdot w^\epsilon_t \,\mathrm{d}x\,\mathrm{d}t = \int_{Q_\tau} g^\epsilon \cdot w^\epsilon_t \,\mathrm{d}x\,\mathrm{d}t.$$

As

$$\int_{Q_\tau} (A^1 w^\epsilon)\cdot w^\epsilon_t \,\mathrm{d}x\,\mathrm{d}t = -\frac{1}{2}\int_\Omega a^1_{ijkl}\varepsilon_{ij}(w^\epsilon)\varepsilon_{kl}(w^\epsilon)\big|_0^\tau \,\mathrm{d}x, \tag{3.18}$$

we infer that

$$\begin{aligned} &\int_{Q_\tau} |w^\epsilon_t|^2 \,\mathrm{d}x\,\mathrm{d}t + \frac{1}{2}\int_\Omega a^1_{ijkl}\varepsilon_{ij}(w^\epsilon)\varepsilon_{kl}(w^\epsilon)\big|_{t=\tau}\,\mathrm{d}x \\ &= \frac{1}{2}\int_\Omega a^1_{ijkl}\varepsilon_{ij}(w^\epsilon)\varepsilon_{kl}(w^\epsilon)\big|_{t=0}\,\mathrm{d}x + \int_{Q_\tau} g^\epsilon\cdot w^\epsilon_t \,\mathrm{d}x\,\mathrm{d}t. \end{aligned} \tag{3.19}$$

According to Korn's inequality, we infer that there exist C_1 and C_2 such that

$$\int_\Omega a^1_{ijkl}\varepsilon_{ij}(w^\epsilon)\varepsilon_{kl}(w^\epsilon)\,\mathrm{d}x \ge C_1\int_\Omega |\nabla w^\epsilon|^2\,\mathrm{d}x - C_2\int_\Omega |w^\epsilon|^2\,\mathrm{d}x. \tag{3.20}$$

Carrying the above inequality into (3.19) and observing that $g^\epsilon \cdot w_t^\epsilon$ can be estimated by $|g^\epsilon|^2/2 + |w_t^\epsilon|^2/2$, we get

$$\begin{aligned}&\int_{Q_\tau} |w_t^\epsilon|^2 \,\mathrm{d}x\,\mathrm{d}t + C_1 \int_\Omega |\nabla w^\epsilon(\cdot,\tau)|^2 \,\mathrm{d}x \\ &\le \int_\Omega a^1_{ijkl}\varepsilon_{ij}(w^\epsilon)\varepsilon_{kl}(w^\epsilon)\big|_{t=0}\,\mathrm{d}x + C_2 \int_\Omega |w^\epsilon(\cdot,\tau)|^2 \,\mathrm{d}x + \int_{Q_\tau} |g^\epsilon|^2 \,\mathrm{d}x\,\mathrm{d}t.\end{aligned} \tag{3.21}$$

As v_0 belongs to $\mathbf{H}^2(\Omega)$, v_1 belongs to $\mathbf{H}^1(\Omega)$, φ belongs to $\mathrm{C}_0^\infty(\mathbb{R})$, and g^ε is bounded in $\mathbf{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, we infer that the right-hand side of (3.21) is bounded. Therefore, using identities (3.13) and (3.16), it is possible to deduce that u^ε_{tt} is bounded in $\mathbf{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2((-\infty,-\beta)\times\Sigma))$.

We will show that $A^1 w^\epsilon$ is bounded in $\mathbf{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$ using an analogous method. We multiply (3.17) by $A^1 w^\epsilon$, we integrate over Q_τ, and we obtain

$$\int_{Q_\tau} w_t^\epsilon \cdot (A^1 w^\epsilon)\,\mathrm{d}x\,\mathrm{d}t - \int_{Q_\tau} |A^1 w^\epsilon|^2 \,\mathrm{d}x\,\mathrm{d}t = \int_{Q_\tau} g^\epsilon \cdot (A^1 w^\epsilon)\,\mathrm{d}x\,\mathrm{d}t. \tag{3.22}$$

Carrying (3.18) and (3.20) into (3.22), $g^\epsilon \cdot (A^1 w^\epsilon)$ being estimated by $|g^\epsilon|^2/2 + |A^1 w^\epsilon|^2/2$, we obtain

$$\begin{aligned}&\int_{Q_\tau} |A^1 w^\epsilon|^2 \,\mathrm{d}x\,\mathrm{d}t + C_1 \int_\Omega |\nabla w^\epsilon(\cdot,\tau)|^2 \,\mathrm{d}x \\ &\le \int_\Omega a^1_{ijkl}\varepsilon_{ij}(w^\epsilon)\varepsilon_{kl}(w^\epsilon)\big|_{t=0}\,\mathrm{d}x + C_2 \int_\Omega |w^\epsilon(\cdot,\tau)|^2 \,\mathrm{d}x + \int_{Q_\tau} |g^\epsilon|^2 \,\mathrm{d}x\,\mathrm{d}t.\end{aligned} \tag{3.23}$$

Thanks to (3.13) and (3.16), we may deduce from (3.23) that $A^1 u_t^\epsilon$ is bounded in $\mathbf{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2((-\infty,-\beta)\times\Sigma))$. □

3.3. Existence of a weak solution. Thanks to the estimates obtained in section 3.2, we are able to pass to the limit in the variational formulation associated to the penalized problem (3.1)–(3.3). Therefore, it is routine to deduce that there exists a solution to (1.9).

Because Ω is an unbounded set, the proof will be technical but similar to the one developed in section 2.3.

THEOREM 3.8. *Assume that f belongs to $\mathbf{L}^2_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, v_0 to $\mathbf{H}^2(\Omega)$, and v_1 to $\mathbf{L}^2(\Omega)$. Then there exists a solution to the variational inequality* (1.10)*; this solution is the limit of a subsequence of the penalty approximation defined by* (3.1)–(3.3).

Proof. Let $\varphi \in \mathrm{C}_0^\infty(\bar\Omega \times [0,\infty))$ be a function which takes its values between 0 and 1. We suppose here that v belongs to K. Multiplying (3.1) by $(v - u^\epsilon)\varphi$ and integrating over Q_τ,

$$\int_{I_\tau} (u_1^\epsilon)^+(\varphi(v_1 - u_1^\epsilon))\,\mathrm{d}x'\,\mathrm{d}t = -\int_{I_\tau} \big((u_1^\epsilon)^+\big)^2\varphi\,\mathrm{d}x'\,\mathrm{d}t + \int_{I_\tau} (u_1^\epsilon)^+\varphi v_1\,\mathrm{d}x'\,\mathrm{d}t$$

being negative, we get the following inequality:

$$\begin{aligned}&\int_\Omega \rho u_t^\epsilon \cdot (\varphi(v-u^\epsilon))|_0^\tau\,\mathrm{d}x - \int_{Q_\tau} \rho u_t^\epsilon \cdot (\varphi(v-u^\epsilon))_t\,\mathrm{d}x\,\mathrm{d}t \\ &+ \int_{Q_\tau} (a^0_{ijkl}\varepsilon_{kl}(u^\epsilon)\varepsilon_{ij}(u^\epsilon) + a^1_{ijkl}\varepsilon_{kl}(u_t^\epsilon)\varepsilon_{ij}(u^\epsilon))(\varphi(v_i - u_i^\epsilon))\,\mathrm{d}x\,\mathrm{d}t \\ &\ge \int_{Q_\tau} f \cdot \big(\varphi(v-u^\epsilon)\big)\,\mathrm{d}x\,\mathrm{d}t.\end{aligned} \tag{3.24}$$

We may deduce from Lemmas 3.2 and 3.5 that there exists a subsequence, still denoted by u^ϵ, such that

$$u^\epsilon \rightharpoonup u \quad \text{in} \quad \mathbf{L}^2_{\text{loc}}([0,\infty);\mathrm{L}^2(\Omega)) \quad \text{weak} \quad *, \tag{3.25a}$$

$$u^\epsilon_t \rightharpoonup u_t \quad \text{in} \quad \mathbf{L}^\infty_{\text{loc}}([0,\infty);\mathrm{L}^2(\Omega)) \quad \text{weak} \quad *, \tag{3.25b}$$

$$\nabla u^\epsilon \rightharpoonup \nabla u \quad \text{in} \quad \mathbf{L}^2_{\text{loc}}([0,\infty);\mathrm{L}^2(\Omega)) \quad \text{weak} \quad *, \tag{3.25c}$$

$$A^n u^\epsilon \rightharpoonup A^n u \quad \text{in} \quad \mathbf{L}^\infty_{\text{loc}}([0,\infty);\mathrm{L}^2(\Omega)) \quad \text{weak} \quad *, \quad n=0,1, \tag{3.25d}$$

$$\nabla u^\epsilon_t \rightharpoonup \nabla u_t \quad \text{in} \quad \mathbf{L}^2_{\text{loc}}([0,\infty);\mathrm{L}^2(\Omega)) \quad \text{weak} \quad *. \tag{3.25e}$$

Thanks to the classical compactness properties of Sobolev space injections on bounded open sets, we see that for all $R>0$, the restrictions of u^ϵ and $a^n_{ijkl}\varepsilon_{kl}(u^\epsilon)$, $n=0,1$, to $Q_R=\{x : x_1<0,\ |x'|\le R\}\times[0,R]$ (a set which has already been defined in section 2.3) converge strongly to their respective limits in $\mathbf{L}^2(Q_R)$. On the other hand, using the same techniques as those of section 2.3, we may prove that u^ϵ converges strongly to u in $\mathbf{L}^2_{\text{loc}}([0,\infty);\mathrm{L}^2(\Omega))$. The complete proof can be found in [Pet02, pp. 113–115].

We observe now that since u and u_t belong to $\mathbf{L}^2_{\text{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, we may replace φ by φ_R in the variational inequality where φ_R is equal to 1 over the set Q_R and vanishes outside of Q_{R+1}. When R tends to infinity all the terms in (3.24) converge to their limit; thus we have proved the existence of a weak solution. ∎

Remark 3.9. As for the damped wave equation with Signorini boundary conditions, the uniqueness is still an open problem.

3.4. Preliminary results. In this section, we establish estimates on the problem (1.9a) with initial data (1.9d) and the Dirichlet boundary condition which enable us to characterize the trace spaces in the next section.

LEMMA 3.10. *Assume v_0 and v_1 belong, respectively, to $\mathbf{H}^{5/2}(\Omega)$ and $\mathbf{H}^{3/2}(\Omega)$; then, there exists a function with compact support in t such that the traces of z and z_t on Σ are, respectively, v_0 and v_1.*

Proof. We extend v_0 and v_1 into functions belonging, respectively, to $\mathbf{H}^{5/2}(\mathbb{R}^d)$ and $\mathbf{H}^{3/2}(\mathbb{R}^d)$. Then there exists a function Z belonging to $\mathbf{H}^3(\mathbb{R}^d\times[0,\infty))$ such that $Z|_{\mathbb{R}^d\times\{0\}}=v_0$ and $Z_t|_{\mathbb{R}^d\times\{0\}}=v_1$. We select a cut-off function $\varphi\in\mathrm{C}^\infty([0,\infty))$ which is equal to 1 on $[0,1]$ and to 0 on $[2,\infty)$, and we define z as the restriction of $\varphi(x)Z(x,t)$ to $\Omega\times[0,\infty)$. ∎

LEMMA 3.11. *Assume v_0 belongs to $\mathbf{H}^{5/2}(\Omega)$, v_1 belongs to $\mathbf{H}^1(\Omega)$, and f belongs to $\mathbf{L}^2_{\text{loc}}([0,\infty);\mathrm{L}^2(\Omega))$. Define z as in Lemma* 3.10*, and let $\bar u$ be the solution of* (1.9a) *with initial data* (1.9d) *and boundary condition $\bar u(0,\cdot,\cdot)=z(0,\cdot,\cdot)$. Then the trace $\bar g \stackrel{\text{def}}{=} -(a^0_{11kl}\varepsilon_{kl}(\bar u)+a^1_{11kl}\varepsilon_{kl}(\bar u_t))\big|_{\Sigma\times[0,\infty)}$ is well defined and belongs to the space $\mathrm{L}^2_{\text{loc}}([0,\infty);\mathrm{L}^2(\Sigma))$. Moreover, there exists $K>0$ such that $\mathrm{e}^{-Kt}\bar g\in\mathrm{L}^2(\Sigma\times[0,\infty))$.*

Proof. Let $\zeta\stackrel{\text{def}}{=}\bar u - z$ be the solution of the following problem:

$$\rho\zeta_{tt}-A^0\zeta-A^1\zeta_t=F,\quad x\in\Omega,\quad t>0, \tag{3.26}$$

where $F\stackrel{\text{def}}{=} f-\rho z_{tt}+A^0z+A^1z_t$ with initial data $\zeta(\cdot,0)=\zeta_t(\cdot,0)=0$ and boundary condition $\zeta(0,\cdot,\cdot)=0$. Multiplying (3.26) by ζ_t and integrating over Q_τ, Korn's inequality enables us to deduce that ζ_t and $\nabla\zeta$ are bounded in $\mathbf{L}^\infty_{\text{loc}}([0,\infty);\mathrm{L}^2(\Omega))$ and $\nabla\zeta_t$ is bounded in $\mathbf{L}^2_{\text{loc}}([0,\infty);\mathrm{L}^2(\Omega))$. If we multiply (3.26) by $A^1\zeta$, we may deduce that $A^0\zeta$ and $A^1\zeta$ are bounded in $\mathbf{L}^\infty_{\text{loc}}([0,\infty);\mathrm{L}^2(\Omega))$, arguing as in the proof of Lemma 3.5. On the other hand, we have

$$\int_{Q_\tau} \zeta_{tt}\cdot(A^1\zeta_t)\,\mathrm{d}x\,\mathrm{d}t = -\frac{1}{2}\int_\Omega a^1_{ijkl}\varepsilon_{kl}(\zeta_t)\varepsilon_{ij}(\zeta_t)\big|_0^\tau\,\mathrm{d}x.$$

Therefore, we multiply (3.26) by $A^1\zeta_t$, we integrate over Q_τ, and, thanks to the above identity, we get

$$\begin{aligned}&\frac{\rho}{2}\int_\Omega a^1_{ijkl}\varepsilon_{kl}(\zeta_{tt})\varepsilon_{ij}(\zeta_t)\big|_{t=\tau}\,\mathrm{d}x + \int_{Q_\tau}|A^1\zeta_t|^2\,\mathrm{d}x\,\mathrm{d}t + \frac{1}{2}\int_\Omega (A^0\zeta)\cdot(A^1\zeta)\big|_0^\tau\,\mathrm{d}x\\ &= \frac{\rho}{2}\int_\Omega a^1_{ijkl}\varepsilon_{kl}(\zeta_t)\varepsilon_{ij}(\zeta_t)\big|_{t=0}\,\mathrm{d}x - \int_{Q_\tau} F\cdot(A^1\zeta_t)\,\mathrm{d}x\,\mathrm{d}t.\end{aligned}$$

According to Gronwall's lemma, there exists $K>0$ such that

$$\int_{Q_\tau}|A^1\zeta_t|^2\,\mathrm{d}x\,\mathrm{d}t \le C\mathrm{e}^{K\tau}\left(|F|^2_{\mathrm{L}^2(0,\tau;\mathrm{L}^2(\Omega))} + |\xi_t(\cdot,0)|^2_{\mathrm{H}^1(\Omega)} + |\xi|^2_{\mathrm{L}^2(0,\tau;\mathrm{L}^2(\Omega))}\right).$$

The lemma is now clear. □

3.5. The trace spaces. We proceed as in section 2.5. A Fourier–Laplace transform and Lemma 3.11 enable us to infer that all the traces can be defined. Therefore, it is plain that a weak solution of (1.9) is also a strong one.

Let us remark first that the problem (3.3) can be written under an equivalent form: let us extend by 0 for $t\le 0$ the difference $v^\epsilon \stackrel{\text{def}}{=} \mathrm{e}^{-\nu t}(u^\epsilon - \bar u)$; then it satisfies

$$\begin{aligned}&\rho(\nu+\partial_t)^2 v_i^\epsilon - ((\lambda^0+\mu^0)+(\lambda^1+\nu^1)(\nu+\partial_t))\,\mathrm{div}\,v^\epsilon\\ &-(\mu^0+\mu^1(\nu+\partial_t))\Delta v_i^\epsilon = 0,\quad x\in\Omega,\quad t>0,\end{aligned}\tag{3.27}$$

with boundary conditions at $\{x_1=0\}$

$$(\mu^0+\nu\mu^1)(v^\epsilon_{j,x_1}+v^\epsilon_{1,x_j}) + \mu^1(v^\epsilon_{j,x_1t}+v^\epsilon_{1,x_jt}) = 0,\quad j=2,3,\tag{3.28a}$$

$$(\lambda^0+\lambda^1(\nu+\partial_t))\,\mathrm{div}\,v^\epsilon + 2(\mu^0+\mu^1(\nu+\partial_t))v^\epsilon_{x_1} = \mathrm{e}^{-\nu t}\bar g - \frac{(v_1^\epsilon - \mathrm{e}^{-\nu t}\bar u)^+}{\epsilon}\tag{3.28b}$$

and with initial data

$$v^\epsilon(\cdot,0)=0 \quad\text{and}\quad v^\epsilon_t(\cdot,0)=0.\tag{3.29}$$

If v^ϵ is a tempered distribution, we may perform a Fourier transform in the tangential variable (x',t) and a Laplace transform in x_1. Denoting by ξ and ω the dual variables of x' and t and by η the dual variable of x_1, we are led to the system

$$\begin{aligned}&\rho(\nu+i\omega)^2\widehat{v}^\epsilon - ((\lambda^0+\mu^0)+(\lambda^1+\mu^1)(\nu+i\omega))\begin{pmatrix}\eta\\ i\xi\end{pmatrix}(\eta, i\xi^{\mathsf T})\widetilde{v}^\epsilon\\ &+(\mu^0+\mu^1(\nu+i\omega))(|\xi|^2-\eta^2)\widetilde{v}^\epsilon = 0.\end{aligned}\tag{3.30}$$

Equation (3.30) is a linear system of equations; we seek its eigenvalues η_i and its eigenvectors ϕ_i:

$$\eta_1^2 = |\xi|^2 + \frac{\rho(\nu+i\omega)^2}{\mu^0+\mu^1(\nu+i\omega)}\quad\text{and}\quad \phi_1 = \begin{pmatrix}0\\ i\xi^\perp\end{pmatrix},\tag{3.31a}$$

$$\eta_2^2 = |\xi|^2 + \frac{\rho(\nu+i\omega)^2}{\mu^0+\mu^1(\nu+i\omega)}\quad\text{and}\quad \phi_2 = \begin{pmatrix}1\\ 0\end{pmatrix},\tag{3.31b}$$

$$\eta_3^2 = |\xi|^2 + \frac{\rho(\nu+i\omega)^2}{\lambda^0+2\mu^0+(\lambda^1+2\mu^1)(\nu+i\omega)}\quad\text{and}\quad \phi_3 = \begin{pmatrix}\eta_3\\ i\xi\end{pmatrix},\tag{3.31c}$$

where $\xi^\perp$ is obtained from ξ by a rotation of $\pi/2$. We choose η_i to be the causal determination of the square root of η_i^2; therefore, η_i is holomorphic in the lower half-plane $\Im(\omega) < 0$. Let us denote by $\widehat{v}^\epsilon$ the partial Fourier transform of v^ϵ with respect to the tangential variables. As v^ϵ and $\widetilde{v}^\epsilon$ are tempered distributions, $\widehat{v}^\epsilon$ is also tempered; therefore, it can include only factors of the form $\mathrm{e}^{\eta_i x_1}$, and thus, it must be of the form

$$\widehat{v}^\epsilon(x_1,\xi,\omega) = \sum_{i=1}^{3} \theta_i(\xi,\omega)\phi_i \mathrm{e}^{\eta_i x_1}. \tag{3.32}$$

Our goal now is to determine the θ_i's. Define $v^\epsilon \overset{\text{def}}{=} (v_1^\epsilon, (v^\epsilon)')$. If we apply a partial Fourier transform in the tangential variable to the boundary condition (3.28a), we obtain

$$(\widehat{v}^\epsilon)'_{x_1}(0,\xi,\omega) = -i\xi\widehat{v}_1^\epsilon(0,\xi,\omega). \tag{3.33}$$

Carrying (3.32) into (3.33), we infer that at $x_1 = 0$,

$$i\xi^\perp\eta_2\theta_1 + i\xi\eta_3\theta_3 = -i\xi(\theta_2 + \eta_3\theta_3);$$

thus it is clear that $\theta_1 = 0$ and $\theta_2 = -2\eta_3\theta_3$. Furthermore, relation (3.32) taken at $x_1 = 0$ enables us to deduce that $\theta_3 = -\widehat{v}_1^\epsilon(0,\xi,\omega)/\eta_3$. Finally, we obtain

$$\widehat{v}^\epsilon(x_1,\xi,\omega) = 2\widehat{v}_1^\epsilon(0,\xi,\omega)\phi_2\mathrm{e}^{\eta_2 x_1} - \widehat{v}_1^\epsilon(0,\xi,\omega)\phi_3\mathrm{e}^{\eta_3 x_1}/\eta_3. \tag{3.34}$$

At last, using (3.34), we can write the left-hand side of (3.28b) as a product of convolution: if we perform a Fourier transform of the left-hand side of (3.28b) and since

$$\widehat{v}^\epsilon_{1,x_1}(0,\xi,\omega) = (2\eta_2 - \eta_3)\widehat{v}_1^\epsilon(0,\xi,\omega) \quad \text{and} \quad (\widehat{v}^\epsilon)'(0,\xi,\omega) = -i\xi\widehat{v}_1^\epsilon(0,\xi,\omega)/\eta_3,$$

we obtain

$$((\lambda^0 + \lambda^1(\nu+\partial_t))\operatorname{div} v^\epsilon + 2(\mu^0 + \mu^1(\nu+\partial_t))v^\epsilon_{1,x_1})\widehat{\ }(0,\xi,\omega) = \widehat{b}\widehat{v}_1^\epsilon(0,\xi,\omega),$$

where

$$\widehat{b} \overset{\text{def}}{=} (\lambda^0 + 2\mu^0 + (\lambda^1 + 2\mu^1)(\nu + i\omega))(2\eta_2 - \eta_3) + (\lambda^0 + \lambda^1(\nu+i\omega))|\xi|^2/\eta_3.$$

Let $w^\epsilon(x',t)$ be the trace $v^\epsilon(0,x',t)$; then (3.28b) can now be written as

$$b * w_1^\epsilon = \mathrm{e}^{-\nu t}\bar{g} - \frac{\left(w_1^\epsilon - \mathrm{e}^{-\nu t}\bar{u}_1(0,\cdot,\cdot)\right)^+}{\epsilon}. \tag{3.35}$$

LEMMA 3.12. *Let $u^\epsilon = (u_1^\epsilon, u_2^\epsilon, u_3^\epsilon)^\mathsf{T}$ be the solution of* (3.1)–(3.3a). *Then we may extract a subsequence, still denoted by u_1^ϵ, such that*

$$u_1^\epsilon(0,\cdot,\cdot) \rightharpoonup u_1(0,\cdot,\cdot) \quad \textit{weakly} \quad \textit{in} \quad \mathrm{H}^{1/2,5/4}_{\mathrm{loc}}(\mathbb{R}^{d-1}\times[0,\infty)).$$

Moreover, u is a strong solution of (1.9).

Proof. We denote by $\widehat{\psi}$ and $\widehat{g}$ the respective Fourier transforms of $\psi \stackrel{\text{def}}{=} \lambda^0+2\mu^0+(\lambda^1+2\mu^1)(\nu+\partial_t)$ and $g \stackrel{\text{def}}{=} \mathrm{e}^{-\nu t}\bar{g}$. Multiplying (3.35) by ψw_1^ϵ and using the Plancherel identity, we obtain

$$\begin{aligned}&\frac{1}{(2\pi)^d}\,\Re\int_{\mathbb{R}^d}\overline{\widehat{\psi}}\,\widehat{b}|\widehat{w}_1^\epsilon|^2\,\mathrm{d}\xi\,\mathrm{d}\omega\\&=\frac{1}{(2\pi)^d}\,\Re\int_{\mathbb{R}^d}\widehat{g}\overline{\widehat{\psi}\widehat{w}_1^\epsilon}\,\mathrm{d}\xi\,\mathrm{d}\omega-\int_0^\infty\int_{\mathbb{R}^{d-1}}\frac{\bigl(w_1^\epsilon-\mathrm{e}^{-\nu t}\bar{u}_1(0,\cdot,\cdot)\bigr)^+}{\epsilon}\,\psi w_1^\epsilon\,\mathrm{d}x'\,\mathrm{d}t.\end{aligned}$$

According to the Cauchy–Schwarz inequality and since $(u_1^\epsilon(0,\cdot,\cdot))^+/\sqrt{\epsilon}$ is bounded in $\mathrm{L}^\infty_{\mathrm{loc}}([0,\infty);\mathrm{L}^2(\mathbb{R}^{d-1}))$, the absolute value of the second integral on the right-hand side of the above inequality is bounded by C_1; therefore, we get

$$\frac{1}{(2\pi)^d}\,\Re\int_{\mathbb{R}^d}\overline{\widehat{\psi}}\,\widehat{b}|\widehat{w}_1^\epsilon|^2\,\mathrm{d}\xi\,\mathrm{d}\omega\le C_1+\frac{1}{(2\pi)^d}\,\Re\int_{\mathbb{R}^d}\widehat{g}\overline{\widehat{\psi}\widehat{w}_1^\epsilon}\,\mathrm{d}\xi\,\mathrm{d}\omega.\tag{3.36}$$

Define

$$\begin{aligned}\kappa&\stackrel{\text{def}}{=}\frac{-\rho(\nu+i\omega)^2-2|\xi|^2(\mu^0+(\nu+i\omega)\mu^1)}{-\rho(\nu+i\omega)^2-|\xi|^2\bigl(\lambda^0+2\mu^0+(\nu+i\omega)(\lambda^1+2\mu^1)\bigr)},\\x_0&\stackrel{\text{def}}{=}\sqrt{\frac{2\rho(\lambda^0+\nu\lambda^1)}{4\lambda^1\mu^1+(\lambda^1)^2}}.\end{aligned}$$

Then $\widehat{b}=\widehat{\psi}(2\eta_2-\kappa\eta_3)$, and we remark also that it is sufficient to find a function h which depends on ξ and ω such that $\Re(2\eta_2-\kappa\eta_3)\ge|h|$. If we assume that $|\xi|+|\omega|\gg1$, we have two cases to consider according to the values taken by $|\xi|$. We suppose first that $|\xi|^2+2\rho(\nu\mu^1-\mu^0)/(\mu^1)^2\ge0$; then η_2 can be approximated by $\widetilde{\eta}_2$ defined as follows:

$$|\widetilde{\eta}_2^2|^2=\left(|\xi|^2+\frac{\rho(\nu\mu^1-\mu^0)}{(\mu^1)^2}\right)^2+\left(\frac{\rho\mu^1\omega}{(\mu^1)^2}\right)^2.$$

Therefore, it is easy to deduce that $|\widetilde{\eta}_2^2|^2\ge|\xi|^4/4+\rho^2\omega^2/(\mu^1)^2$, and then, in the case $|\xi|^2+2\rho(\nu\mu^1-\mu^0)/(\mu^1)^2\ge0$, we obtain the following estimate:

$$\Re\eta_2\ge\cos\bigl(\pi/4\bigr)|\eta_2|\ge\frac{1}{\sqrt{2}}\left(\frac{|\xi|^4}{4}+\frac{\rho^2\omega^2}{(\mu^1)^2}\right)^{1/4}.\tag{3.37}$$

In the other case, we suppose $|\xi|^2+2\rho(\nu\mu^1-\mu^0)/(\mu^1)^2\le0$; then, it is plain that

$$|\Re\eta_2^2|\le\frac{3\rho(\nu\mu^1+\mu^0)}{(\mu^1)^2}\quad\text{and}\quad|\Im\eta_2^2|\ge\frac{\rho\mu^1|\omega|}{(\mu^1+\nu\mu^0)^2+(\mu^0)^2},$$

which implies that there exists $C>0$ such that

$$|\operatorname{arc\,cotan}\eta_2^2|\le\frac{3(\nu\mu^1+\mu^0)\bigl((\mu^1+\nu\mu^0)^2+(\mu^0)^2\bigr)}{(\mu^1)^3|\omega|}\le\frac{C}{|\omega|}.$$

We deduce from the above inequality and from $|\eta_2|^2\ge C|\omega|$ that $|\arg\eta_2^2|\le\pi/2+C/|\omega|$ and thus $\cos(\arg\eta_2)\ge1/2$. In the case $|\xi|^2+2\rho(\nu\mu^1-\mu^0)/(\mu^1)^2\le0$, we get

$$\Re\eta_2\ge C\sqrt{|\omega|}/2.\tag{3.38}$$

Therefore, in both cases, we infer from (3.37) and (3.38) that there exists $M > 0$ such that

$$\Re\eta_2 \geq M\left(\omega^2 + |\xi|^4\right)^{1/4}. \tag{3.39}$$

Furthermore, there exists $C > 0$ such that $|\kappa|^2 \leq 1 + C1_{\{|\xi|\leq x_0\}}/|\omega|^2$ and for $|\xi|$ large enough, $|\eta_2| \geq |\eta_3|$. Then (3.39) enables us to deduce

$$\Re(2\eta_2 - \kappa\eta_3) \geq M\left(\omega^2 + |\xi|^4\right)^{1/4}. \tag{3.40}$$

Carrying (3.40) into (3.36), we obtain

$$M\int_{\mathbb{R}^d} |\widehat{\psi}|^2\left(\omega^2 + |\xi|^4\right)^{1/4} |\widehat{w}_1^\varepsilon|^2\,\mathrm{d}\xi\,\mathrm{d}\omega \leq C_1 + \int_{\mathbb{R}^d} |\widehat{g}||\widehat{\psi}||\widehat{w}_1^\epsilon|\,\mathrm{d}\xi\,\mathrm{d}\omega. \tag{3.41}$$

We estimate the product zy by $|z|^2/(2\gamma) + \gamma|y|^2/2$, $\gamma > 0$, and we see that

$$\left(M - \frac{\gamma}{2}\right)\int_{\mathbb{R}^d} |\omega|^2\left(\omega^2 + |\xi|^4\right)^{1/4} |\widehat{w}_1^\varepsilon|^2\,\mathrm{d}\xi\,\mathrm{d}\omega \leq C_1 + \frac{1}{2\gamma}\int_{\mathbb{R}^d} \frac{|\widehat{g}|^2}{\left(\omega^2 + |\xi|^4\right)^{1/4}}\,\mathrm{d}\xi\,\mathrm{d}\omega.$$

We choose γ such that $\gamma < 2M$. On the other hand, $\mathrm{e}^{-Kt}\bar{g}(\cdot,t)$ is bounded in $\mathrm{L}^2(\Sigma\times[0,\infty))$, so that $g(\cdot,t)$ is bounded in $\mathrm{L}^2(\Sigma\times[0,\infty))$ if we choose $\nu > K$. Therefore, u_1^ϵ is bounded in $\mathrm{H}^{1/2,5/4}_{\mathrm{loc}}(\Sigma\times[0,\infty))$. In particular, $(\lambda^0+\lambda^1(\nu+\partial_t))\,\mathrm{div}\,v^\epsilon + 2(\mu^0+\mu^1(\nu+\partial_t))v^\epsilon_{x_1}$ is bounded in $\mathrm{H}^{-1/2,-1/4}_{\mathrm{loc}}(\Sigma\times[0,\infty))$. We conclude that u is a strong solution of (1.9) because all the traces can be defined. ∎

L^2 DECAY OF SOLUTIONS TO A MICRO-MACRO MODEL FOR POLYMERIC FLUIDS NEAR EQUILIBRIUM*

LINGBING HE† AND PING ZHANG‡

Abstract. In this paper, we consider the long time decay of the L^2 norm to the global solutions (u, ψ) constructed in [F.-H. Lin, C. Liu, and P. Zhang, *Comm. Pure Appl. Math.*, 60 (2007), pp. 838–866] for a micro-macro model of polymeric fluids near equilibrium $(0, M)$. Under the additional assumption that $u_0 \in \dot{H}^{-\kappa}(\mathbf{R}^3)$, $(\psi_0 - M)/\sqrt{M} \in L^2(\mathbf{R}^3_q; \dot{H}^{-\kappa}(\mathbf{R}^3_x))$, we prove that $(u(t), \psi(t))$ tends to $(0, M)$ as t goes to infinity with decaying rate $\|u(t)\|_{L^2} \le C(1+t)^{-\frac{b}{2}}$ and $\|\frac{\psi(t)-M}{\sqrt{M}}\|_{L^2} \le C(1+t)^{-\frac{b+1}{2}}$ for $b = \min(\kappa, \frac{3}{2})$. In general, without this additional assumption, we shall present an explicit long time decaying formula for $\|u(t)\|_{L^2}$ and $\|\frac{\psi(t)-M}{\sqrt{M}}\|_{L^2}$.

1. Introduction.

In this paper, we consider the long time behavior to the global solutions constructed in [10] for a coupled microscopic-macroscopic model for polymeric fluid near equilibrium. The micro-mechanical models for polymeric liquids usually consist of beads joined by springs or rods [1, 6]. In the simplest case, a molecule configuration can be described by its end-to-end vector q. Taking into account the elastic effect together with the thermo-fluctuation, the distribution function $\psi(t, x, q)$ of molecule orientations q satisfies a Fokker–Planck equation. The convection velocity u satisfies the Navier–Stokes equations with an elastic stress which reflects the microscopic contribution of the polymer molecules to the overall macroscopic flow fields. Mathematically, this system reads (one may check [10] for a formal energetic variational derivation) as

$$\begin{cases} u_t + u \cdot \nabla u + \nabla p = \mu \triangle u + \nabla \cdot \tau, \quad x \in \mathbf{R}^3, \\ \nabla \cdot u = 0, \quad x \in \mathbf{R}^3, \\ \psi_t + u \cdot \nabla \psi = \sigma \triangle_q \psi - \nabla_q \cdot (\nabla u q \psi - \sigma \nabla_q U \psi), \quad (x, q) \in \mathbf{R}^3 \times \mathbf{R}^3, \end{cases} \tag{1.1}$$

where the polymer stress τ is given by

$$\tau = \int_{\mathbf{R}^3} \nabla_q U \otimes q \psi dq, \tag{1.2}$$

with $U(q) = U(|q|^2)$ being the potential function.

Existence results for micro-macro models of polymeric fluids are usually limited to small time existence [7, 17, 13] and uniqueness of strong solutions or global existence

of weak solutions [12]. In the setting when the last equation of (1.1) is formulated as a stochastic PDE, we refer to [7] (see also [17] for a polynomial force). Concerning the general coupled PDE system, some preliminary studies were made in the earlier work [13].

In a recent work [10], Lin, Liu, and Zhang studied the global existence of smooth solutions to (1.1) near equilibrium, which is a sort of extension to a related result of the Oldroyd model [9, 3], and which corresponds to the Hooke dumbbell model. In two space dimensions, Constantin et al. [4] proved the global existence of smooth solutions to a coupled nonlinear Fokker–Planck and Navier–Stokes system when the convection velocity u in the Fokker–Planck equation is replaced by a sort of time averaged one. Later this assumption was removed by Constantin and Masmoudi [5]. Meanwhile Lin, Zhang, and Zhang [11] independently proved the global regularity for the two-dimensional corotational FENE model with smooth initial data.

On the other hand, in [8], Jourdain et al. investigated the long time behavior of both Hookean models and FENE models for various special flows in a bounded domain with suitable boundary conditions. The main aim of this paper is to consider the long time decay rate for the global solutions to (1.1) constructed in [10].

Before we proceed, let us introduce some basic notation that will be used throughout this paper. Similarly to [10], after renormalization, we assume that $\int_{\mathbf{R}^3} \exp\{-U\}\, dq = 1$; furthermore,

$$
\begin{aligned}
&|q| \le C(|\nabla_q U| + 1), \quad \Delta_q U \le C + \delta |\nabla_q U|^2, \text{ with } \delta < 1,\\
&\int_{\mathbf{R}^3} |\nabla_q U|^2 e^{-U}\, dq \le C, \quad \int_{\mathbf{R}^3} |q|^4 e^{-U}\, dq \le C,
\end{aligned} \tag{1.3}
$$

and

$$
\begin{aligned}
&|\nabla_q^k (q \nabla_q U)| \le C(|q||\nabla_q U| + 1), \quad \int_{\mathbf{R}^3} |\nabla_q^k (q \nabla_q U e^{-\frac{U}{2}})|^2\, dq \le C,\\
&\left| \nabla_q^k \left(\Delta_q U - \frac{|\nabla_q U|^2}{2} \right) \right| \le C(1 + |\nabla_q U|^2),
\end{aligned} \tag{1.4}
$$

where the positive integer $0 \le k \le s$, which will be fixed in the later sections.

In what follows, for any given function $\phi(x, q)$, we denote

$$
|\phi|_{H^s} = \left\{ \int_{\mathbf{R}^3} \int_{\mathbf{R}^3} \sum_{|\alpha| \le s} |\nabla_x^\alpha \phi|^2\, dq dx \right\}^{\frac{1}{2}},
$$

and $\|\phi\|_{H^s}$ the standard Sobolev norm of ϕ. We shall use the convention (f, g) to stand for both the inner product on $\mathbf{R}^3$, $\int_{\mathbf{R}^3} fg\, dx$, and on $\mathbf{R}^3 \times \mathbf{R}^3$, $\int_{\mathbf{R}^3} \int_{\mathbf{R}^3} fg\, dq dx$. And we will denote ∇^s to be any of ∇_x^α, where α is any multiple indices with $|\alpha| = s$. And we use similar notation for ∇_q^s.

It is easy to check that $(0, e^{-U})$ is a stationary solution to the system (1.1). In [10], Lin, Liu, and Zhang considered solutions of (1.1) with ψ being of the form

$$
\psi = e^{-U} + e^{-U/2} f \overset{\text{def}}{=} M + \sqrt{M} f. \tag{1.5}
$$

As we assume that $\int_{\mathbf{R}^3} \psi_0(x, q) dq = 1$, there holds $\int_{\mathbf{R}^3} \psi(t, x, q) dq = 1$, which together with (1.5) yields

$$
\int_{\mathbf{R}^3} \sqrt{M} f\, dq = 0. \tag{1.6}
$$

Moreover, plugging (1.5) into (1.1), we obtain the following system for (u, f):

$$
\begin{cases}
u_t + u\cdot\nabla u + \nabla p = \mu\triangle u + \nabla\cdot\left(\int_{\mathbf{R}^3}\sqrt{M}\nabla_q U\otimes q f\, dq\right), & x\in\mathbf{R}^3,\\
f_t + u\cdot\nabla f + \nabla u q\cdot\nabla_q f - \sigma\left(\triangle_q f + \frac{\triangle_q U}{2} f - \frac{|\nabla_q U|^2}{4} f\right)\\
\qquad = \sqrt{M}\nabla u q\cdot\nabla_q U + \frac{1}{2}\nabla u q\cdot\nabla_q U f, & (x,q)\in\mathbf{R}^3\times\mathbf{R}^3,\\
\text{div } u = 0, \quad x\in\mathbf{R}^3,
\end{cases}
\tag{1.7}
$$

together with the initial conditions

$$
u|_{t=0} = u_0, \qquad f|_{t=0} = f_0, \quad \text{for} \quad (x,q)\in\mathbf{R}^3\times\mathbf{R}^3,
\tag{1.8}
$$

where f_0 satisfies (1.6) and div $u_0 = 0$.

For the reader's convenience, we first recall the following result from [10].

THEOREM 1.1. *Let $s \geq 7$ be an integer, f_0 satisfy* (1.6), *and $\psi_0 = M + \sqrt{M} f_0 > 0$. Then, there exists a sufficiently small constant ε such that if*

$$
\frac{1}{2}\|u_0\|_{L^2}^2 + \int_{\mathbf{R}^3}\int_{\mathbf{R}^3}[\psi_0\ln\psi_0 + U\psi_0]\,dq\,dx \leq \varepsilon^{1+a}\mu\sigma\min(\mu,\sigma),
$$

$$
\|u_0\|_{H^s}^2 + \|f_0\|_{H^s}^2 + |q f_0|_{H^4}^2 \leq \varepsilon\min(\mu,\sigma),
$$

where $a > 0$ is a small positive constant, then (1.7) *and* (1.8) *has a unique global classical solution (u,ψ) with $\psi = M + \sqrt{M} f > 0$, and*

$$
\begin{aligned}
&\sup_{0\leq t<\infty}\left(\|u(t)\|_{H^s}^2 + |qf|_{H^4}^2 + \|f(t)\|_{H^s}^2\right)\\
&\quad + \int_0^t\left[\mu\|\nabla u\|_{H^s}^2 + \sigma\left(\left\|q\right|\left(\nabla_q f + \frac{1}{2}\nabla_q U f\right)\right|_{H^4}^2 + \left\|\nabla_q f + \frac{1}{2}\nabla_q U f\right\|_{H^s}^2\right)\right]d\tau\\
&\quad \leq C\varepsilon\min(\mu,\sigma).
\end{aligned}
\tag{1.9}
$$

The main aim of this paper is to prove that the solution (u, f) constructed in Theorem 1.1 decays to $(0, 0)$ as t goes to ∞. More precisely, motivated by [14, 15] and with the additional assumption on the low frequency part of (u_0, f_0), we obtain the following decay rates for the L^2 norm of (u, f).

THEOREM 1.2. *Under the assumptions of Theorem* 1.1, *we assume further that there exists $\kappa, C > 0$ and a small enough number $c > 0$ such that*

$$
\int_{|\xi|\leq c}|\xi|^{-2\kappa}|\hat{u}_0|^2\,d\xi, \quad \int_{\mathbf{R}^3}\int_{|\xi|\leq c}|\xi|^{-2\kappa}|\mathcal{F}_x(f_0)(\xi,q)|^2\,d\xi\,dq \leq C.
\tag{1.10}
$$

Then the L^2 norm of (u, f) decays to $(0, 0)$ according to

$$
\|u(t)\|_{L^2} \leq C(1+t)^{-\frac{b}{2}}, \quad \|f(t)\|_{L^2} \leq C(1+t)^{-\frac{b+1}{2}},
\tag{1.11}
$$

with $b = \min(\kappa, \frac{3}{2})$.

In general, without the additional assumptions (1.10), to study the precise long time decay rates for (u, f), we need some basic facts from the Littlewood–Paley theory. One may check [2] and [16] for more details.

Let $\mathcal{C} \overset{\text{def}}{=} \{\xi \in \mathbf{R}^3,\ \frac{3}{4} \le |\xi| \le \frac{8}{3}\}$. Let $\varphi \in C_c^\infty(\mathcal{C})$, which satisfies

$$\sum_{j\in\mathbf{Z}} \varphi(2^{-j}\xi) = 1 \quad \forall\, \xi \in \mathbf{R}^3 \setminus \{0\}.$$

We denote $h \overset{\text{def}}{=} \mathcal{F}^{-1}\varphi$; then the Littlewood–Paley operators $\dot{\Delta}_j$ and $\dot{\mathcal{S}}_j$ can be defined as follows:

$$\dot{\Delta}_j f \overset{\text{def}}{=} \varphi(2^{-j}D)f = 2^{3j}\int_{\mathbf{R}^3} h(2^j y) f(x-y)dy \quad \text{for} \quad j \in \mathbf{Z},$$

$$\dot{\mathcal{S}}_j f \overset{\text{def}}{=} \sum_{j' \le j-1} \dot{\Delta}_{j'} f. \tag{1.12}$$

With the introduction of $\dot{\Delta}_j$, we present the following decay estimates for the solution (u, f) constructed in Theorem 1.1.

THEOREM 1.3. *Under the assumptions of Theorem* 1.1, *the global solutions* (u, f) *constructed in Theorem* 1.1 *decay to* $(0, 0)$ *by*

$$\|u(t)\|_{L^2}^2 \le C\Big[(1+t)^{-\frac{1}{2}} + \sum_{j<0}(\|\dot{\Delta}_j u_0\|_{L^2} + \|\dot{\Delta}_j f_0\|_{L^2})e^{-c2^{2j}t}\Big], \tag{1.13}$$

$$\|f(t)\|_{L^2}^2 \le C\Big[(1+t)^{-\frac{3}{2}} + \sum_{j<0}(\|\dot{\Delta}_j u_0\|_{L^2} + \|\dot{\Delta}_j f_0\|_{L^2})2^{2j}e^{-c2^{2j}t}\Big] \tag{1.14}$$

for some $c > 0$. *Moreover, for any* $j \in \mathbf{Z}$,

$$\|(1-\dot{\mathcal{S}}_j)u(t)\|_{L^2}^2 \le C_j(1+t)^{-\frac{1}{2}}, \qquad \|(1-\dot{\mathcal{S}}_j)f(t)\|_{L^2}^2 \le C_j(1+t)^{-\frac{3}{2}}. \tag{1.15}$$

Remark 1.1. (i) The estimates (1.13) and (1.14) can be improved when $\|u(t)\|_{L^2} \le C(1+t)^{-\frac{1}{4}}$. The main reason lies in the fact that in this case $\|u(t)\|_{L^2}$ belongs to L^p for $p > 4$. One may check the proof of Proposition 2.1 for details. Then under the assumption (1.10), we can recover Theorem 1.2 from Theorem 1.3 by using the fact that

$$\sup_{t\ge 0}\left\{\sum_{j\in\mathbf{Z}}(2^{2j}t)^\kappa e^{-c2^{2j}t}\right\} \le C.$$

(ii) The estimate (1.13) implies that $\|u(t)\|_{L^2}$ tends to 0 as t goes to ∞. While thanks to [2, 16], we have

$$\|f(t)\|_{L^2}^2 \le \frac{\varrho(t)}{1+t},$$

where $\varrho(t) \to 0$ as $t \to \infty$.

(iii) Without (1.10), Theorem 1.3 provides a more precise decay estimate for the L^2 norm of $u(t)$ and $f(t)$. For instance, let ϕ be a smooth function with low frequency part satisfying

$$(\mathcal{F}\phi)(\xi)\big|_{|\xi|\le\frac{1}{2}} = \big|\log|\xi|\big|^{-1}|\xi|^{-\frac{3}{2}}. \tag{1.16}$$

It is easy to check that $\phi \notin \dot{H}^{-\kappa}(\mathbf{R}^3)$ for any positive κ. While for any $j < 0$, we have

$$\|\dot{\Delta}_j \phi\|_{L^2}^2 \approx j^{-2}.$$

Let $\omega(t) \overset{\text{def}}{=} \sum_{j>0} j^{-2} e^{-c2^{-2j}t}$ and $\varpi(t) \overset{\text{def}}{=} \sum_{j>0} j^{-2} 2^{-2j} e^{-c2^{-2j}t}$; then there exist $N, C_N > 0$ such that

$$\begin{aligned}
\omega(2^{2k}) &= \sum_{j>0} j^{-2} e^{-c2^{2(k-j)}} \\
&= \sum_{j>k} j^{-2} e^{-c2^{2(k-j)}} + \sum_{0<j\le k} 2^{-2\log_2 j} e^{-c2^{2(k-j)}} \\
&\le \int_k^\infty x^{-2} dx + k^{-2} C_N \sum_{0<j\le k} 2^{2(\log_2 k - \log_2 j)} 2^{-2N(k-j)} \\
&\le C_N k^{-1}.
\end{aligned}$$

By the monotone property of $\omega(t)$ and $\varpi(t)$, we conclude that

$$\omega(t) \le C(\log t)^{-1}, \quad \varpi(t) \le C(1+t)^{-1}(\log t)^{-\frac{3}{2}}.$$

On the other hand, it is easy to construct examples so that the low frequency part of u_0 coincides with $\varepsilon\phi$, and the low frequency part of f_0 coincides with $\varepsilon\phi(x)\psi(q)$ with $\psi \in \mathcal{S}(\mathbf{R}^3)$. Then for ε sufficiently small, let (u, f) be the unique solution of (1.7) and (1.8) obtained in Theorem 1.1. The above calculations show that $u(t)$ has the logarithm decay, while $f(t)$ has a better decay rate than $(1+t)^{-1}(\log t)^{-1}$, which can be obtained by directly using Schonbek's devices [14, 15].

(iv) Under the assumptions of Theorem 1.1, we can provide an explicit decay rate for $\|u(t)\|_{L^p}$ and $\|f(t)\|_{L^p}$ for $p > 2$ (see Corollary 2.1).

Remark 1.2. We can study the decay rates for the global smooth solutions to the Oldroyd model in [10, 3] by using exactly the same procedure as that in this paper. We omit the details here.

2. The proof of Theorem 1.2. Motivated by [14, 15], we shall present the proof of Theorem 1.2 in this section. However, compared with [14, 15], the source term in the Navier–Stokes equations of (1.7) does not decay as fast as what is required in [14, 15]. To deal with this term, we need to use the coupling effect between u and f in (1.7).

Let us first recall the following lemma from [10], which shall be of constant use in what follows.

LEMMA 2.1. *Let f satisfy $\int_{\mathbf{R}^3} f\sqrt{M}\, dq = 0$, and let U satisfy* (1.3). *Then there hold*

$$\begin{aligned}
&\|f\|_{L^2} \le C \left\| \nabla_q f + \frac{1}{2} \nabla_q U f \right\|_{L^2}, \\
&\|\nabla_q U f\|_{L^2} \le C \left\| \nabla_q f + \frac{1}{2} \nabla_q U f \right\|_{L^2}, \\
&\|\nabla_q U q f\|_{L^2} \le C \|(1+|q|^2)^{\frac{1}{2}} \left(\nabla_q f + \frac{1}{2} \nabla_q U f \right) \|_{L^2}.
\end{aligned}$$

Moreover, for any integer $s_1 \geq 0$ and $s_2 \geq 1$, there holds

$$\|\nabla_q U \nabla^{s_1} \nabla_q^{s_2} f\|_{L^2} \leq C \sum_{k=0}^{s_2} \left\| \nabla_q \nabla^{s_1} \nabla_q^k f + \frac{1}{2} \nabla_q U \nabla^{s_1} \nabla_q^k f \right\|_{L^2},$$

$$\|\nabla^{s_1} \nabla_q^{s_2} f\|_{L^2} \leq C \sum_{k=0}^{s_2-1} \left\| \nabla_q \nabla^{s_1} \nabla_q^k f + \frac{1}{2} \nabla_q U \nabla^{s_1} \nabla_q^k f \right\|_{L^2}.$$

As a first step in the proof of Theorem 1.2, we shall prove the following L^2 decay estimate for (u, f).

PROPOSITION 2.1. *Under the assumptions of Theorem* 1.2, *the L^2 norm of the global classical solutions (u, f) to* (1.7) *constructed in Theorem* 1.1 *decay to* $(0, 0)$ *as t goes to ∞ according to*

$$\|u(t)\|_{L^2}^2 + \|f(t)\|_{L^2}^2 \leq C(1+t)^{-b}, \tag{2.1}$$

with $b = \min(\kappa, \frac{3}{2})$.

Proof. We first get by using standard energy estimation to (1.7) that

$$\begin{aligned} &\frac{d}{dt}(\|u\|_{L^2}^2 + \|f\|_{L^2}^2) + 2\mu\|\nabla u\|_{L^2}^2 + 2\sigma \left\| \nabla_q f + \frac{1}{2} \nabla_q U f \right\|_{L^2}^2 \\ &\quad = (\nabla u q \cdot \nabla_q U f,\ f) \leq |qf|_{H^4} \|\nabla u\|_{L^2} \|\nabla_q U f\|_{L^2}, \end{aligned}$$

which together with Lemma 2.1 and Theorem 1.1 applied gives

$$\frac{d}{dt}(\|u\|_{L^2}^2 + \|f\|_{L^2}^2) + \mu\|\nabla u\|_{L^2}^2 + \sigma \left\| \nabla_q f + \frac{1}{2} \nabla_q U f \right\|_{L^2}^2 \leq 0. \tag{2.2}$$

Thanks to (2.2), to use Schonbek's strategy in [14, 15], we need to split the phase space into two time-dependent domains. More precisely, we decompose $\|\nabla u\|_{L^2}^2$ as

$$\|\nabla u\|_{L^2}^2 = \int_{S(t)} |\xi|^2 |\hat{u}(\xi)|^2 d\xi + \int_{S(t)^c} |\xi|^2 |\hat{u}(\xi)|^2 d\xi,$$

where $S(t) \overset{\text{def}}{=} \{\xi : |\xi| \leq C^{\frac{1}{2}}(1+t)^{-\frac{1}{2}}\}$ and the constant C will be chosen later on. Then, thanks to (2.2), we have

$$\frac{d}{dt}(\|u\|_{L^2}^2 + \|f\|_{L^2}^2) + \frac{C\mu}{1+t}\|u\|_{L^2}^2 + \sigma \left\| \nabla_q f + \frac{1}{2} \nabla_q U f \right\|_{L^2}^2 \leq \frac{C\mu}{1+t} \int_{S(t)} |\hat{u}(\xi)|^2 d\xi. \tag{2.3}$$

In what follows, we shall focus on the L^2 estimate to the low frequency part of u. In order to do so, we take Fourier transform with respect to x variables in (1.7) to get

$$\begin{cases} \hat{u}_t + \mathcal{F}_x(u \cdot \nabla u) + i\xi\, \hat{p} = -\mu|\xi|^2 \hat{u} + i\xi \cdot (\int_{\mathbf{R}^3} \sqrt{M} \nabla_q U \otimes q \hat{f}\ dq), \\ \hat{f}_t + \mathcal{F}_x(u \cdot \nabla f) + \mathcal{F}_x(\nabla u q \cdot \nabla_q f) - \sigma(\triangle_q \hat{f} + \frac{\triangle_q U}{2} \hat{f} - \frac{|\nabla_q U|^2}{4} \hat{f}) \\ \qquad = i(\xi_j \hat{u}_i)(\nabla_q U \otimes q\sqrt{M}) + \frac{1}{2}\mathcal{F}_x(\nabla u q \cdot \nabla_q U f), \\ \xi \cdot \hat{u} = \xi \cdot \bar{\hat{u}} = 0, \end{cases} \tag{2.4}$$

where $\hat{f}(\xi,q,t) \overset{\text{def}}{=} \mathcal{F}_x(f)(\xi,q,t)$. Notice that $\xi\cdot\hat{u}=\xi\cdot\bar{\hat{u}}=0$. By multiplying the first equation of (2.4) by $\bar{\hat{u}}(t,\xi)$ and taking the resulting real part we get that

$$\begin{aligned}(2.5)\qquad &\frac{1}{2}\frac{d}{dt}|\hat{u}(\xi,t)|^2+\mathcal{R}e[\mathcal{F}_x(u\cdot\nabla u)\cdot\bar{\hat{u}}(\xi,t)]\\ &\quad=-\mu|\xi|^2|\hat{u}(\xi,t)|^2+\mathcal{R}e\left[i\xi\otimes\bar{\hat{u}}(\xi,t):\left(\int_{\mathbf{R}^3}\sqrt{M}\nabla_q U\otimes q\hat{f}\;dq\right)\right].\end{aligned}$$

A similar process applied to the microscopic equation of (2.4) gives

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\mathbf{R}^3}|\hat{f}(\xi,q,t)|^2dq+\mathcal{R}e\left[\int_{\mathbf{R}^3}\left(\mathcal{F}_x(u\cdot\nabla f)\bar{\hat{f}}(\xi,q,t)+\mathcal{F}_x(\nabla uq\cdot\nabla_q f)\bar{\hat{f}}(\xi,q,t)\right)dq\right]\\ &(2.6)\quad+\sigma\left\|\nabla_q\hat{f}+\frac{1}{2}\nabla_q U\hat{f}\right\|^2_{L^2_q}\\ &=\mathcal{R}e\left[i\xi\otimes\hat{u}(\xi,t):\left(\int_{\mathbf{R}^3}\sqrt{M}\nabla_q U\otimes q\bar{\hat{f}}(\xi,q,t)\;dq\right)\right]\\ &\quad+\frac{1}{2}\mathcal{R}e\left[\int_{\mathbf{R}^3}\mathcal{F}_x(\nabla uq\cdot\nabla_q Uf)\,\bar{\hat{f}}(\xi,q,t)dq\right].\end{aligned}$$

Thanks to (2.5)–(2.6), we obtain that for any $\delta>0$, there is a C_δ such that

$$\begin{aligned}&\frac{d}{dt}\left(|\hat{u}(\xi,t)|^2+\int_{\mathbf{R}^3}|\hat{f}(\xi,q,t)|^2dq\right)+\mu|\xi|^2|\hat{u}(\xi,t)|^2+2\sigma\left\|\nabla_q\hat{f}+\frac{1}{2}\nabla_q U\hat{f}\right\|^2_{L^2_q}\\ &\quad\le C|\mathcal{F}_x(u\otimes u)|^2+C_\delta\int_{\mathbf{R}^3}(|\mathcal{F}_x(u\cdot\nabla f)|^2+|\mathcal{F}_x(\nabla uq\cdot\nabla_q f)|^2\\ &\qquad+|\mathcal{F}_x(\nabla uq\cdot\nabla_q Uf)|^2)\,dq+\delta\int_{\mathbf{R}^3}|\bar{\hat{f}}(\xi,q,t)|^2dq,\end{aligned}$$

from which we deduce that

$$\begin{aligned}&|\hat{u}(\xi,t)|^2+\int_{\mathbf{R}^3}|\hat{f}(\xi,q,t)|^2dq+2\sigma\int_0^t\int_{\mathbf{R}^3}e^{-\mu|\xi|^2(t-s)}\left|\nabla_q\hat{f}+\frac{1}{2}\nabla_q U\hat{f}\right|^2dqds\\ &\quad\le e^{-\mu|\xi|^2t}\left(|\hat{u_0}(\xi)|^2+\int_{\mathbf{R}^3}|\hat{f}_0(\xi,q)|^2dq\right)\\ &\qquad+\int_0^t\int_{\mathbf{R}^3}e^{-\mu|\xi|^2(t-s)}(\mu|\xi|^2+\delta)|\hat{f}(\xi,q,s)|^2dqds\\ &\quad+C\int_0^t|\mathcal{F}_x(u\otimes u)|^2ds+C_\delta\int_0^t\int_{\mathbf{R}^3}(|\mathcal{F}_x(u\cdot\nabla f)(\xi,q,s)|^2\\ &(2.7)\qquad+|\mathcal{F}_x(\nabla uq\cdot\nabla_q f)(\xi,q,s)|^2+|\mathcal{F}_x(\nabla uq\cdot\nabla_q Uf)(\xi,q,s)|^2)\,dq\,ds.\end{aligned}$$

Now we are in a position to estimate the right-hand side of (2.3). First, it is easy to observe that

$$\int_0^t \int_{\mathbf{R}^3} \int_{S(t)} e^{-|\xi|^2(t-s)}(\mu|\xi|^2+\delta)|\hat{f}(\xi,q,s)|^2 d\xi\, dq\, ds$$

$$\leq \left(\frac{C\mu}{1+t}+\delta\right)\int_0^t \int_{\mathbf{R}^3} \int_{S(t)} e^{-\mu|\xi|^2(t-s)}|\hat{f}(\xi,q,s)|^2 d\xi dq ds.$$

While noticing that $\int_{\mathbf{R}^3} \sqrt{M}\hat{f} dq = 0$, applying Lemma 2.1 gives

$$\int_{\mathbf{R}^3} \int_{S(t)} e^{-\mu|\xi|^2(t-s)}|\hat{f}(\xi,q,s)|^2 d\xi dq = \int_{S(t)} e^{-\mu|\xi|^2(t-s)} \int_{\mathbf{R}^3} |\hat{f}|^2\, dq\, d\xi$$

$$\leq C\int_{\mathbf{R}^3} \int_{S(t)} e^{-\mu|\xi|^2(t-s)} \left|\nabla_q \hat{f} + \frac{1}{2}\nabla_q U \hat{f}\right|^2 d\xi dq.$$

To deal with the remaining terms (2.7), we introduce $\phi \in \mathcal{S}(\mathbf{R}^3)$, the Fourier transform of which satisfies

$$\hat{\phi}(\xi) = \begin{cases} 1, & |\xi| \leq 2C^{\frac{1}{2}}, \\ 0, & |\xi| \geq 3C^{\frac{1}{2}}, \end{cases}$$

and we denote $\phi_t(x) \overset{\text{def}}{=} (1+t)^{-\frac{3}{2}}\phi((1+t)^{-\frac{1}{2}}x)$. Then, by using Young's inequality and (1.9) we get that

$$\int_0^t \int_{S(t)} |\mathcal{F}_x(u\otimes u)|^2 d\xi ds \leq \int_0^t \int_{\mathbf{R}^3} |(u\otimes u) * \phi_t|^2\, dx\, ds$$

$$\leq C(1+t)^{-\frac{3}{2}} \int_0^t \|u\otimes u\|_{L^1}^2 ds \leq C(1+t)^{-\frac{3}{2}} \int_0^t \|u\|_{L^2}^4 ds$$

$$\leq C(1+t)^{-\frac{1}{2}}. \tag{2.8}$$

While thanks to Minkowski's inequality and (1.9), we obtain

$$\int_0^t \int_{\mathbf{R}^3} \int_{S(t)} |\mathcal{F}_x(u\cdot\nabla f)|^2\, d\xi\, dq\, ds \leq \int_0^t \int_{\mathbf{R}^3} \int_{\mathbf{R}^3} |(u\cdot\nabla f) * \phi_t|^2 dx dq ds$$

$$\leq \int_0^t \int_{\mathbf{R}^3} \Big| (|u|\|\nabla f\|_{L^2_q}) * |\phi_t| \Big|^2 dx ds \leq C(1+t)^{-\frac{3}{2}} \int_0^t \Big\| |u|\|\nabla f\|_{L^2_q} \Big\|_{L^1_x}^2 ds$$

$$\leq C(1+t)^{-\frac{3}{2}} \int_0^t \|u\|_{L^2}^2 \|\nabla f\|_{L^2}^2 ds \leq C(1+t)^{-\frac{3}{2}} \int_0^t |\nabla_q f + \frac{1}{2}\nabla_q U f|_{H^4}^2 ds$$

$$\leq C(1+t)^{-\frac{3}{2}}.$$

A similar argument for the last two terms in (2.7) yields

$$\int_0^t \int_{\mathbf{R}^3} \int_{S(t)} |\mathcal{F}_x(\nabla u q \cdot \nabla_q f)|^2 d\xi dq ds \le C(1+t)^{-\frac{3}{2}} \int_0^t \Big\| |\nabla u| \|q \nabla_q f\|_{L^2_q} \Big\|^2_{L^1_x} ds$$

$$\le C(1+t)^{-\frac{3}{2}} \int_0^t \|q\nabla_q f\|^2_{L^2} ds \le C(1+t)^{-\frac{3}{2}} \int_0^t \Big\| (1+|q|^2)^{\frac{1}{2}} \Big(\nabla_q f + \frac{1}{2} \nabla_q U f \Big) \Big\|^2_{L^2} ds$$

$$\le C(1+t)^{-\frac{3}{2}}$$

and

$$\int_0^t \int_{\mathbf{R}^3} \int_{S(t)} |\mathcal{F}_x(\nabla u q \cdot \nabla_q U f)|^2 d\xi dq ds \le C(1+t)^{-\frac{3}{2}}.$$

Therefore, thanks to (2.7), we obtain

$$\int_{S(t)} |\hat{u}(\xi,t)|^2 d\xi \le \int_{S(t)} e^{-\mu|\xi|^2 t} |\hat{u}(\xi,0)|^2 d\xi + \int_{S(t)} \int_{\mathbf{R}^3} e^{-\mu|\xi|^2 t} |\hat{f}(\xi,q,0)|^2 d\xi dq$$
$$+ C(1+t)^{-\frac{1}{2}}$$

for t large enough. Then with the additional assumption (1.10), we conclude

$$\int_{S(t)} |\hat{u}(\xi,t)|^2 d\xi \le C(1+t)^{-\kappa} + C(1+t)^{-\frac{1}{2}}, \tag{2.9}$$

for t large enough. This together with (2.3) ensures that

$$\frac{d}{dt}(\|u\|^2_{L^2} + \|f\|^2_{L^2}) + \frac{C\mu}{1+t}\|u\|^2_{L^2} + \sigma \left\| \nabla_q f + \frac{1}{2}\nabla_q U f \right\|^2_{L^2} \le \frac{C\mu}{1+t}(1+t)^{-b},$$

where $b = \min(\kappa, \frac{1}{2})$, from which we deduce that

$$\|u(t)\|^2_{L^2} + \|f(t)\|^2_{L^2} \le C(1+t)^{-b}. \tag{2.10}$$

With the above decay estimate for $\|u(t)\|_{L^2}$, we can improve the estimate in (2.8). Suppose that $\kappa > \frac{1}{2}$; then $b = \frac{1}{2}$ in (2.10) and

$$\int_0^t \int_{S(t)} |\mathcal{F}_x(u \otimes u)|^2 d\xi ds \le C(1+t)^{-\frac{3}{2}} \int_0^t \|u\|^4_{L^2} ds$$

$$\le C(1+t)^{-\frac{7}{6}} \left(\int_0^t \|u\|^6_{L^2} ds \right)^{\frac{2}{3}}$$

$$\le C(1+t)^{-\frac{7}{6}}.$$

Then the proof of (2.9) implies that

$$\int_{S(t)} |\hat{u}(\xi,t)|^2 d\xi \le C(1+t)^{-\kappa} + C(1+t)^{-\frac{7}{6}},$$

for t large enough, from which, with the proof of (2.10), we deduce that

$$\|u(t)\|^2_{L^2} + \|f(t)\|^2_{L^2} \le C(1+t)^{-b}, \tag{2.11}$$

with $b=\min(\kappa,\frac{7}{6})$. Now if $\kappa>\frac{7}{6}$, then by using (2.11) we get that

$$\int_0^t\int_{S(t)}|\mathcal{F}_x(u\otimes u)|^2d\xi ds\le C(1+t)^{-\frac{3}{2}}\int_0^t\|u\|_{L^2}^4ds$$
$$\le C(1+t)^{-\frac{3}{2}}.$$

Then the proof of (2.9) yields

$$\int_{S(t)}|\hat{u}(\xi,t)|^2d\xi\le C(1+t)^{-\kappa}+C(1+t)^{-\frac{3}{2}},$$

from which, with the proof of (2.10), we obtain

$$\|u(t)\|_{L^2}^2+\|f(t)\|_{L^2}^2\le C(1+t)^{-b},$$

with $b=\min(\kappa,\frac{3}{2})$. This completes the proof of the proposition. □

With Proposition 2.1, to complete the proof of Theorem 1.2, we still need to improve the decay rate for the L^2 norm of f. In order to do so, we shall first prove the L^2 decays for the derivatives of u and f, which, in particular, implies a sort of L^p decay estimate for u,f without any additional assumption on the initial data.

PROPOSITION 2.2. *Under the assumptions of Theorem* 1.1, *we have the following decay estimate for* $\nabla u,\nabla f$, *and* f*:*

$$\|\nabla u(t)\|_{L^2}^2+\|\nabla f(t)\|_{L^2}^2+\|f(t)\|_{L^2}^2\le C(1+t)^{-1}. \tag{2.12}$$

Proof. Taking ∇ to (1.7), by a standard energy estimation we get that

$$\frac{d}{dt}(\|\nabla u\|_{L^2}^2+\|\nabla f\|_{L^2}^2)+2\mu\|\nabla^2u\|_{L^2}^2+2\sigma\left\|\nabla_q\nabla f+\frac{1}{2}\nabla_qU\nabla f\right\|_{L^2}^2$$
$$=-2(\nabla(u\cdot\nabla u),\nabla u)-2(\nabla(u\cdot\nabla f),\nabla f)$$
$$-2(\nabla(\nabla uq\cdot\nabla_qf),\nabla f)+(\nabla(\nabla uq\cdot\nabla_qUf),\ \nabla f) \tag{2.13}$$

Thanks to (1.9), we have

$$|(\nabla(u\cdot\nabla u),\nabla u)|=|(\nabla(u\otimes u),\nabla\nabla u)|$$
$$\le C\|u\|_{L^3}\|\nabla u\|_{L^6}\|\nabla^2u\|_{L^2}\le C\epsilon\|\nabla^2u\|_{L^2}^2.$$

Similarly, as $\operatorname{div}u=0$ and $\operatorname{div}_q(\nabla uq)=0$, we have

$$|(\nabla(u\cdot\nabla f),\nabla f)|=|((\nabla u)\cdot\nabla f,\nabla f)|\le\|\nabla u\|_{H^2}\|\nabla f\|_{L^2}^2,$$
$$|(\nabla(\nabla uq\cdot\nabla_qf),\nabla f)|=|((\nabla\nabla u)q\cdot\nabla_qf,\nabla f)|$$
$$\le\|\nabla_qf\|_{H^4}\|\nabla^2u\|_{L^2}\|q\nabla f\|_{L^2},$$

and

$$|(\nabla(\nabla uq\cdot\nabla_qUf),\nabla f)|$$
$$=|(\nabla(\nabla u)q\cdot\nabla_qUf,\nabla f)+(\nabla uq\cdot\nabla_qU(\nabla f),\nabla f)|$$
$$\le|qf|_{H^4}\|\nabla^2u\|_{L^2}\|\nabla_qU\nabla f\|_{L^2}+\|\nabla u\|_{H^2}\|q\nabla f\|_{L^2}\|\nabla_qU\nabla f\|_{L^2}.$$

Then we deduce from (1.9), (2.13) that

$$\frac{d}{dt}(\|\nabla u\|_{L^2}^2+\|\nabla f\|_{L^2}^2)+\mu\|\nabla^2u\|_{L^2}^2+\sigma\left\|\nabla_q\nabla f+\frac{1}{2}\nabla_qU\nabla f\right\|_{L^2}^2\le0. \tag{2.14}$$

Then Schonbek's strategy [14, 15] applied to (2.14) gives

$$\frac{d}{dt}(\|\nabla u\|_{L^2}^2+\|\nabla f\|_{L^2}^2)+\frac{C\mu}{1+t}\|\nabla u\|_{L^2}^2 + \sigma\left\|\nabla_q(\nabla f)+\frac{1}{2}\nabla_q U(\nabla f)\right\|_{L^2}^2 \le \frac{C\mu}{1+t}\int_{S(t)}|\xi|^2|\hat{u}(\xi,t)|^2 d\xi, \tag{2.15}$$

from which we deduce that

$$\|\nabla u(t)\|_{L^2}^2+\|\nabla f(t)\|_{L^2}^2 \le C(1+t)^{-1}. \tag{2.16}$$

With (2.16), we now turn to the proof of the L^2 decay of f. First by a standard energy estimation we get that

$$\frac{1}{2}\frac{d}{dt}\|f\|_{L^2}^2+\sigma\left\|\nabla_q f+\frac{1}{2}\nabla_q U f\right\|_{L^2}^2 \le \|\nabla u\|_{L^2}\|\sqrt{M}\nabla_q U\|_{L^2}\|qf\|_{L^2}+|qf|_{H^4}\|\nabla u\|_{L^2}\|\nabla_q U f\|_{L^2}.$$

Then thanks to Lemma 2.1 and (1.9), we obtain

$$\frac{d}{dt}\|f\|_{L^2}^2+\sigma\|f\|_{L^2}^2 \le C\|\nabla u\|_{L^2}^2 \le C(1+t)^{-1}, \tag{2.17}$$

from which we deduce that

$$\|f(t)\|_{L^2}^2 \le C\|f_0\|_{L^2}^2 e^{-\sigma t}+\int_0^t e^{-\sigma(t-s)}(1+s)^{-1}ds. \le C(1+t)^{-1},$$

which together with (2.16) gives (2.12). This completes the proof of Proposition 2.2. □

Remark 2.1. Assume that $\|u(t)\|_{L^2}^2 \le C(1+t)^{-b}$; then, thanks to (2.15), we can improve (2.16) to $\|\nabla u(t)\|_{L^2}^2+\|\nabla f(t)\|_{L^2}^2 \le C(1+t)^{-b-1}$, which, in turn, implies that $\|f(t)\|_{L^2}^2 \le C(1+t)^{-b-1}$.

An immediate corollary of Proposition 2.2 and Sobolev imbedding is the following corollary.

COROLLARY 2.1. *Under the assumption of Theorem* 1.1, *we have*

$$\|u(t)\|_{L^p}^2+\|f(t)\|_{L_q^2(L_x^p)}^2 \le \begin{cases} C_p(1+t)^{-\frac{6}{p}} & \text{if} \quad 6\le p\le\infty, \\ C_p(1+t)^{-\frac{3(p-2)}{2p}} & \text{if} \quad 2<p\le 6. \end{cases}$$

Now we are in a position to complete the proof of Theorem 1.2.

Proof of Theorem 1.2. Combining Proposition 2.1 and Remark 2.1, we complete the proof of the theorem. □

3. The proof of Theorem 1.3. In this section, we consider the L^2 decay of u without the additional assumption (1.10). It is easy to observe from the proof of Theorem 1.2 that the low frequency part of initial data makes this problem difficult. To get rid of this difficulty, we are going to study the decay of solution to the linearized

problem of (1.7) first, then we estimate the difference between the solution of the linearized equation (3.1) and that of (1.7).

The linearized equation of (1.7) reads as

$$(3.1)\quad \begin{cases} v_t + \nabla h = \mu\triangle v + \nabla\cdot(\int_{\mathbf{R}^3}\sqrt{M}\nabla_q U\otimes qg\ dq), & x\in\mathbf{R}^3,\\ g_t - \sigma(\triangle_q g + \frac{\triangle_q U}{2}g - \frac{|\nabla_q U|^2}{4}g) = \sqrt{M}\nabla v q\cdot\nabla_q U, & (x,q)\in\mathbf{R}^3\times\mathbf{R}^3,\\ \text{div } v = 0, \quad x\in\mathbf{R}^3, \end{cases}$$

together with the initial condition

$$(3.2)\qquad v|_{t=0} = u_0, \qquad g|_{t=0} = f_0 \quad \text{for} \quad (x,q)\in\mathbf{R}^3\times\mathbf{R}^3\,.$$

Notice from (3.1) that

$$\frac{d}{dt}\int_{\mathbf{R}^3} g\sqrt{M}dq = 0,$$

which together with the fact that $\int_{\mathbf{R}^3} f_0\sqrt{M}dq = 0$ ensures that

$$\int_{\mathbf{R}^3} g\sqrt{M}dq = 0,$$

so that Lemma 2.1 can still be applied for g.

PROPOSITION 3.1. *Under the assumptions of Theorem* 1.1, (3.1)–(3.2) *has a unique solution* (v,g) *so that*

$$(3.3)\quad \sup_{0\le t<\infty}\Big(\|v(t)\|_{H^s}^2 + |qg|_{H^4}^2 + \|g(t)\|_{H^s}^2\Big) + \int_0^t\Big[\mu\|\nabla v\|_{H^s}^2 + \sigma\Big(||q|\Big(\nabla_q g + \frac{1}{2}\nabla_q U g\Big)|_{H^4}^2 + \Big\|\nabla_q g + \frac{1}{2}\nabla_q U g\Big\|_{H^s}^2\Big)\Big]d\tau \le C\varepsilon\min(\mu,\sigma).$$

Furthermore, there holds

$$\||D|^\lambda v\|_{L^2}^2 \le C_\lambda(1+t)^{-\lambda},$$

$$(3.4)\qquad \||D|^\lambda g\|_{L^2}^2 + \||D|^\lambda\nabla_q g\|_{L^2}^2 + \||q||D|^\lambda g\|_{L^2}^2 \le C_\lambda(1+t)^{-\lambda-1},$$

for $\lambda\in[0,s]$, *where* $|D|^\lambda$ *is the Fourier multiplier with the symbol* $|\xi|^\lambda$.

Proof. A standard functional analysis method can be applied to prove the global existence of a smooth solution to (3.1). Furthermore, a similar proof of (1.9) in [10] ensures that (v,g) satisfies (3.3). We omit the details here.

Now let us turn to the long time behavior of (v,g). First, let $\lambda\in\mathbf{N}$. We get by using standard energy estimation that

$$\frac{d}{dt}(\|\nabla^\lambda v\|_{L^2}^2 + \|\nabla^\lambda g\|_{L^2}^2) + 2\mu\|\nabla\nabla^\lambda v\|_{L^2}^2 + 2\sigma\Big\|\nabla_q(\nabla^\lambda g) + \frac{1}{2}\nabla_q U(\nabla^\lambda g)\Big\|_{L^2}^2 = 0.$$

Schonbek's strategy applied gives

$$\frac{d}{dt}(\|\nabla^\lambda v\|_{L^2}^2 + \|\nabla^\lambda g\|_{L^2}^2) + \frac{\lambda+1}{1+t}\|\nabla^\lambda v\|_{L^2}^2 + 2\sigma\Big\|\nabla_q(\nabla^\lambda g) + \frac{1}{2}\nabla_q U(\nabla^\lambda g)\Big\|_{L^2}^2 \le \frac{\lambda+1}{1+t}\int_{|\xi|\le(\lambda+1)^{\frac12}(1+t)^{-\frac12}}|\mathcal{F}(\nabla^\lambda v)(\xi)|^2 d\xi \le C_\lambda(1+t)^{-\lambda-1},$$

from which we deduce that

$$\|\nabla^\lambda v\|_{L^2}^2 + \|\nabla^\lambda g\|_{L^2}^2 \le C_\lambda (1+t)^{-\lambda}. \tag{3.5}$$

On the other hand, by applying ∇^λ and $\nabla^\lambda \nabla_q$ to the microscopic equation (3.1) and taking the L^2 inner product of the resulting equations with $\nabla^\lambda g$ and $\nabla^\lambda \nabla_q g$, respectively, we obtain

$$\frac{d}{dt}\|\nabla^\lambda g\|_{L^2}^2 + \sigma \left\| \nabla_q(\nabla^\lambda g) + \frac{1}{2}\nabla_q U(\nabla^\lambda g)\right\|_{L^2}^2 \le C\|\nabla\nabla^\lambda v\|_{L^2}^2$$

and

$$\begin{aligned}
&\frac{d}{dt}\|\nabla^\lambda \nabla_q g\|_{L^2}^2 + \sigma \left\| \nabla_q(\nabla^\lambda \nabla_q g) + \frac{1}{2}\nabla_q U(\nabla^\lambda \nabla_q g)\right\|_{L^2}^2 \\
&\quad \le C(\|\nabla_q U \nabla^\lambda g\|_{L^2}\|\nabla_q U \nabla^\lambda \nabla_q g\|_{L^2} + \|\nabla^\lambda g\|_{L^2}\|\nabla^\lambda \nabla_q g\|_{L^2}) \\
&\qquad + \|\nabla\nabla^\lambda v\|_{L^2}\|\nabla^\lambda \nabla_q g\|_{L^2},
\end{aligned}$$

where we used (1.3) and (1.4) in the estimate of the second inequality.

In order to get the estimate for $\||q|\nabla^\lambda g\|_{L^2}$, we apply ∇^λ to the microscopic equation (3.1) and then take the L^2 inner product of the resulting equation with $|q|^2\nabla^\lambda g$ to get

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\||q|\nabla^\lambda g\|_{L^2}^2 + \sigma \left\| |q|\left(\nabla_q(\nabla^\lambda g) + \frac{1}{2}\nabla_q U(\nabla^\lambda g)\right)\right\|_{L^2}^2 \\
&\quad \le \|\nabla^\lambda g\|_{L^2}^2 + \int_{\mathbf{R}^3\times\mathbf{R}^3} |\nabla_q U q||\nabla^\lambda g|^2 dqdx \\
&\qquad + \|\nabla^{1+\lambda} v\|_{L^2}\left(\int_{\mathbf{R}^3} (M|q|^2)dq\right)^{\frac{1}{2}} \|q\nabla_q U\nabla^\lambda g\|_{L^2}.
\end{aligned}$$

Therefore, by using Lemma 2.1 we get that

$$\begin{aligned}
&\frac{d}{dt}\left(\|\nabla^\lambda g\|_{L^2}^2 + c\|\nabla^\lambda \nabla_q g\|_{L^2}^2 + c\||q|\nabla^\lambda g\|_{L^2}^2\right) + \sigma\left(\left\| \nabla_q(\nabla^\lambda g) + \frac{1}{2}\nabla_q U(\nabla^\lambda g)\right\|_{L^2}^2 \right. \\
&\quad \left. + c\left\| \nabla_q(\nabla^\lambda \nabla_q g) + \frac{1}{2}\nabla_q U(\nabla^\lambda \nabla_q g)\right\|_{L^2}^2 + c\left\| |q|\left(\nabla_q(\nabla^\lambda g) + \frac{1}{2}\nabla_q U(\nabla^\lambda g)\right)\right\|_{L^2}^2\right) \\
&\le C\|\nabla\nabla^\lambda v\|_{L^2}^2,
\end{aligned}$$

by taking c sufficiently small, which implies

$$\|\nabla^\lambda g(t)\|_{L^2}^2 + \|\nabla^\lambda \nabla_q g(t)\|_{L^2}^2 + \||q|\nabla^\lambda g(t)\|_{L^2}^2 \le C_\lambda (1+t)^{-\lambda-1}. \tag{3.6}$$

With (3.5) and (3.6), we complete the proof of (3.4) via a trivial interpolation argument. □

Remark 3.1. Plugging the second inequality of (3.4) into the v equation of (3.1) and using Schonbek's strategy in [14, 15], we cannot obtain an improved decay estimate for v. In particular, the decay rate of $\|v(t)\|_{L^2}$ is not as good as that in [14, 15].

The main reason lies in the fact that elastic stress τ defined in (3.1) does not decay as fast as the source term in [14, 15]. A similar remark applies to (1.7) as well.

PROPOSITION 3.2. *Let (u, f) be the unique solution of* (1.7) *and* (1.8) *obtained in Theorem* 1.1, *and let (v, g) be the unique solution of* (3.1) *and* (3.2) *obtained in Proposition* 3.1. *Then there hold*

$$\|(u-v)(t)\|_{L^2}^2 \le C(1+t)^{-\frac{1}{2}},$$

$$\|(f-g)(t)\|_{L^2}^2 \le C(1+t)^{-\frac{3}{2}}. \tag{3.7}$$

Proof. Thanks to (1.7) and (3.1), we obtain

(3.8)
$$\begin{cases} (u-v)_t + u\cdot\nabla u + \nabla(p-h) \\ \quad = \mu\triangle(u-v) + \nabla\cdot\left(\displaystyle\int_{\mathbf{R}^3}\sqrt{M}\nabla_q U\otimes q(f-g)\,dq\right), \quad x\in\mathbf{R}^3, \\ (f-g)_t + u\cdot\nabla f + \nabla u q\cdot\nabla_q f - \sigma\left(\triangle_q(f-g) + \dfrac{\triangle_q U}{2}(f-g) - \dfrac{|\nabla_q U|^2}{4}(f-g)\right) \\ \quad = \sqrt{M}\nabla(u-v)q\cdot\nabla_q U + \dfrac{1}{2}\nabla u q\cdot\nabla_q U f, \qquad (x,q)\in\mathbf{R}^3\times\mathbf{R}^3, \\ \text{div }(u-v) = 0, \quad x\in\mathbf{R}^3. \end{cases}$$

Note that as $\operatorname{div} u = 0$ and $\operatorname{div} v = 0$, by standard energy estimates we get that

$$\begin{aligned} &\frac{d}{dt}(\|u-v\|_{L^2}^2 + \|f-g\|_{L^2}^2) + 2\mu\|\nabla(u-v)\|_{L^2}^2 + 2\sigma\left\|\nabla_q(f-g) + \frac{1}{2}\nabla_q U(f-g)\right\|_{L^2}^2 \\ &\quad = -2(u\cdot\nabla u, u-v) - 2(u\cdot\nabla f, f-g) - 2(\nabla u q\cdot\nabla_q f, f-g) \\ &\qquad + (\nabla u q\cdot\nabla_q U f,\ f-g) \\ &\quad = 2(u\cdot\nabla v, u-v) + 2(u\cdot\nabla g, f-g) + 2(\nabla u q\cdot\nabla_q g, f-g) \\ &\qquad + (\nabla u q\cdot\nabla_q U(f-g),\ f-g) + (\nabla u q\cdot\nabla_q U g,\ f-g). \end{aligned}$$

Thanks to (1.9) and Lemma 2.1, we have

$$\begin{aligned} |(\nabla u q\cdot\nabla_q U(f-g),\ f-g)| &\le \|\nabla u\|_{H^2}\|q(f-g)\|_{L^2}\|\nabla_q U(f-g)\|_{L^2} \\ &\le \epsilon\min\{\mu,\sigma\}\left\|\nabla_q(f-g) + \frac{1}{2}\nabla_q U(f-g)\right\|_{L^2}^2. \end{aligned}$$

Then by taking ϵ small enough we get

$$\begin{aligned} &\frac{d}{dt}(\|u-v\|_{L^2}^2 + \|f-g\|_{L^2}^2) + \mu\|\nabla(u-v)\|_{L^2}^2 + \sigma\left\|\nabla_q(f-g) + \frac{1}{2}\nabla_q U(f-g)\right\|_{L^2}^2 \\ &\quad \le 2|(u\cdot\nabla v, u-v)| + 2|(u\cdot\nabla g, f-g)| + 2|(\nabla u q\cdot\nabla_q g, f-g)| \\ &\qquad + |(\nabla u q\cdot\nabla_q U g,\ f-g)|. \end{aligned} \tag{3.9}$$

In what follows, we shall deal with the right-hand side of (3.9) term by term. Our main idea is to make full use of the decay estimate to the solutions of the linear system

(3.4). First of all, thanks to (1.9), (2.12), and (3.4), we have

$$\begin{aligned}|(u\cdot\nabla v, u-v)| &\le C\|u\|_{L^4}\|v\|_{L^4}\|\nabla(u-v)\|_{L^2}\\ &\le C_\delta\|u\|^2_{\dot H^{\frac34}}\|v\|^2_{\dot H^{\frac34}}+\delta\|\nabla(u-v)\|^2_{L^2}\\ &\le C_\delta(1+t)^{-\frac32}+\delta\|\nabla(u-v)\|^2_{L^2},\end{aligned}$$

for any $\delta>0$. A similar procedure applied to the remaining terms in (3.9) gives

$$\begin{aligned}|(u\cdot\nabla g, f-g)| &\le C\int_{\mathbf{R}^3}\|u\|_{L^4}\|f-g\|_{L^2_x}\|\nabla g\|_{L^4_x}dq\\ &\le C\|u\|_{\dot H^{\frac34}}\|f-g\|_{L^2}|g|_{\dot H^{\frac74}}\le C_\delta(1+t)^{-\frac52}+\delta\|f-g\|^2_{L^2},\end{aligned}$$

$$\begin{aligned}|(\nabla uq\cdot\nabla_q g, f-g)| &\le C\|\nabla u\|_{\dot H^{\frac34}}|\nabla_q g|_{\dot H^{\frac34}}\|q(f-g)\|_{L^2}\\ &\le C_\delta(1+t)^{-2}+\delta\|q(f-g)\|^2_{L^2},\end{aligned}$$

and

$$\begin{aligned}|(\nabla uq\cdot\nabla_q Ug, f-g)| &\le C\|\nabla u\|_{\dot H^{\frac34}}|qg|_{\dot H^{\frac34}}\|\nabla_q U(f-g)\|_{L^2}\\ &\le C_\delta(1+t)^{-2}+\delta\|\nabla_q U(f-g)\|^2_{L^2}.\end{aligned}$$

Then taking δ small enough, we deduce from (3.9) and Schonbek's strategy in [14, 15] that

$$\begin{aligned}&\frac{d}{dt}(\|u-v\|^2_{L^2}+\|f-g\|^2_{L^2})+\frac{C\mu}{t+1}\|u-v\|^2_{L^2}+\sigma\left\|\nabla_q(f-g)+\frac12\nabla_q U(f-g)\right\|^2_{L^2}\\ &\le\frac{C\mu}{t+1}\int_{S(t)}|\mathcal{F}(u-v)(\xi)|^2d\xi+C(1+t)^{-\frac32}.\end{aligned}\tag{3.10}$$

Now we repeat the procedure in section 2 to estimate the low frequency of $u-v$. First, thanks to (3.8), we have

$$\begin{aligned}&\frac{d}{dt}|\mathcal{F}(u-v)(\xi,t)|^2+\frac{d}{dt}\int_{\mathbf{R}^3}|\mathcal{F}_x(f-g)(\xi,q,t)|^2dq\\ &\quad+\mu|\xi|^2|\mathcal{F}(u-v)(\xi,t)|^2+2\sigma\left|\nabla_q\mathcal{F}_x(f-g)+\frac12\nabla_q U\mathcal{F}_x(f-g)\right|^2_{L^2_q}\\ &\le C|\mathcal{F}(u\otimes u)|^2+C_\delta\int_{\mathbf{R}^3}\Big(|\mathcal{F}_x(u\cdot\nabla f)|^2+|\mathcal{F}_x(\nabla uq\cdot\nabla_q f)|^2\\ &\quad+|\mathcal{F}_x(\nabla uq\cdot\nabla_q Uf)|^2\Big)dq+\delta\int_{\mathbf{R}^3}|\mathcal{F}(f-g)(\xi,q,t)|^2dq,\end{aligned}$$

which implies

$$
\begin{aligned}
&|\mathcal{F}(u-v)(\xi,t)|^2+\int_{\mathbf{R}^3}|\mathcal{F}_x(f-g)(\xi,q,t)|^2dq\\
&\quad+2\sigma\int_0^t\int_{\mathbf{R}^3}e^{-\mu|\xi|^2(t-s)}\left|\nabla_q\mathcal{F}_x(f-g)+\frac{1}{2}\nabla_qU\mathcal{F}_x(f-g)\right|^2dqds\\
&\le\int_0^t\int_{\mathbf{R}^3}e^{-|\xi|^2(t-s)}(\delta+\mu|\xi|^2)|\mathcal{F}(f-g)(\xi,q,s)|^2\,dq\,ds+C\int_0^t|\mathcal{F}(u\otimes u)|^2ds\\
&\quad+C\int_0^t\int_{\mathbf{R}^3}(|\mathcal{F}_x(u\cdot\nabla f)(\xi,q,s)|^2+|\mathcal{F}_x(\nabla uq\cdot\nabla_qf)(\xi,q,s)|^2\\
&\quad+|\mathcal{F}_x(\nabla uq\cdot\nabla_qUf)(\xi,q,s)|^2)\,dqds,
\end{aligned}
$$

from which, with the proof of Proposition 2.1, we deduce that

$$
\int_{S(t)}|\mathcal{F}(u-v)(\xi,t)|^2d\xi\le C(1+t)^{-\frac{1}{2}}. \tag{3.11}
$$

Plugging (3.11) into (3.10), we get for large enough t that

$$
\frac{d}{dt}\left((1+t)^{C\mu}\|u-v\|_{L^2}^2+(1+t)^{C\mu}\|f-g\|_{L^2}^2\right)\le C(1+t)^{C\mu-\frac{3}{2}}.
$$

Let us choose C in the definition of $S(t)$ to be large enough so that $C\mu\ge 2$. Then, we obtain

$$
\|(u-v)(t)\|_{L^2}^2+\|(f-g)(t)\|_{L^2}^2\le C(1+t)^{-\frac{1}{2}}. \tag{3.12}
$$

A similar procedure applied to $\nabla(u-v)$ and $\nabla(f-g)$ gives

$$
\|\nabla(u-v)(t)\|_{L^2}^2+\|\nabla(f-g)(t)\|_{L^2}^2\le C(1+t)^{-\frac{3}{2}}. \tag{3.13}
$$

With (3.12) and (3.13), we are in a position to prove (3.7). In fact, standard energy estimation applied to the microscopic equation of (3.8) yields

$$
\begin{aligned}
&\frac{d}{dt}\|f-g\|_{L^2}^2+2\sigma\left\|\nabla_q(f-g)+\frac{1}{2}\nabla_qU(f-g)\right\|_{L^2}^2\\
&\quad=-2(u\cdot\nabla f,f-g)+2(\sqrt{M}\nabla(u-v)q\cdot\nabla_qU,f-g)\\
&\qquad-2(\nabla uq\cdot\nabla_qf,f-g)+(\nabla uq\cdot\nabla_qUf,\ f-g)\\
&\quad=2(u\cdot\nabla g,f-g)+2(\sqrt{M}\nabla(u-v)q\cdot\nabla_qU,f-g)+(\nabla uq\cdot\nabla_qg,f-g)\\
&\qquad+(\nabla uq\cdot\nabla_qU(f-g),\ f-g)+(\nabla uq\cdot\nabla_qUg,\ f-g),
\end{aligned}
$$

from which, with the arguments from (3.9) to (3.10), we obtain

$$
\|(f-g)(t)\|_{L^2}^2\le C(1+t)^{-\frac{3}{2}}.
$$

This together with (3.12) completes the proof of (3.7). □

Now we present the proof of Theorem 1.3.

Proof of Theorem 1.3. Thanks to Proposition 3.2, we only need to take care of the decay estimate of the L^2 norm of (v, g). In order to do so, we first act $\dot{\Delta}_j$ to (3.1), then use the micro-local energy estimate to get

$$\frac{d}{dt}(\|\dot{\Delta}_j v\|_{L^2}^2 + \|\dot{\Delta}_j g\|_{L^2}^2) + 2\mu\|\nabla\dot{\Delta}_j v\|_{L^2}^2 + 2\sigma\left\|\nabla_q(\dot{\Delta}_j g) + \frac{1}{2}\nabla_q U(\dot{\Delta}_j g)\right\|_{L^2}^2 = 0,$$

from which we deduce that there exists some small positive constant c such that

$$\frac{d}{dt}(\|\dot{\Delta}_j v\|_{L^2}^2 + \|\dot{\Delta}_j g\|_{L^2}^2) + c\|\dot{\Delta}_j v\|_{L^2}^2 + c\|\dot{\Delta}_j g\|_{L^2}^2 \le 0 \qquad \text{for} \quad j \ge 0,$$

and

$$\frac{d}{dt}(\|\dot{\Delta}_j v\|_{L^2}^2 + \|\dot{\Delta}_j g\|_{L^2}^2) + c2^{2j}\|\dot{\Delta}_j v\|_{L^2}^2 + c2^{2j}\|\dot{\Delta}_j g\|_{L^2}^2 \le 0 \qquad \text{for} \quad j < 0.$$

Then applying Gronwall's inequality gives

$$\|\dot{\Delta}_j v(t)\|_{L^2}^2 + \|\dot{\Delta}_j g(t)\|_{L^2}^2 \le (\|\dot{\Delta}_j u_0\|_{L^2}^2 + \|\dot{\Delta}_j f_0\|_{L^2}^2)e^{-ct} \quad \text{for} \quad j \ge 0,$$

$$\|\dot{\Delta}_j v(t)\|_{L^2}^2 + \|\dot{\Delta}_j g(t)\|_{L^2}^2 \le (\|\dot{\Delta}_j u_0\|_{L^2}^2 + \|\dot{\Delta}_j f_0\|_{L^2}^2)e^{-c2^{2j}t} \quad \text{for} \quad j < 0. \tag{3.14}$$

Next, let us turn to the decay estimate of $\|\Delta_j g(t)\|_{L^2}$. First by using a micro-local energy estimate to the microscopic equation of (3.1) we get that

$$\frac{d}{dt}\|\dot{\Delta}_j g\|_{L^2}^2 + 2\sigma\left\|\nabla_q(\dot{\Delta}_j g) + \frac{1}{2}\nabla_q U(\dot{\Delta}_j g)\right\|_{L^2}^2 \le \|\nabla(\dot{\Delta}_j v)\|_{L^2}\|q\sqrt{M}\nabla_q U\|_{L^2_q}\|\dot{\Delta}_j g\|_{L^2},$$

from which, with (3.14) and (2.1), we deduce that

$$\|\dot{\Delta}_j g(t)\|_{L^2}^2 \le C(\|\dot{\Delta}_j u_0\|_{L^2}^2 + \|\dot{\Delta}_j f_0\|_{L^2}^2)2^{2j}e^{-c2^{2j}t}. \tag{3.15}$$

On the other hand, thanks to [2, 16], we have $\|u\|_{L^2}^2 \equiv \sum_{j\in\mathbf{Z}}\|\Delta_j u\|_{L^2}^2$. Therefore, thanks to (3.7) and (3.14), we obtain

$$\begin{aligned}\|u(t)\|_{L^2}^2 &\le C\Big(\|u(t) - v(t)\|_{L^2}^2 + \sum_{j\in\mathbf{Z}}\|\Delta_j v(t)\|_{L^2}^2\Big)\\ &\le C\Big[(1+t)^{-\frac{1}{2}} + \sum_{j\le 0}(\|\dot{\Delta}_j u_0\|_{L^2}^2 + \|\dot{\Delta}_j f_0\|_{L^2}^2)e^{-c2^{2j}t}\Big].\end{aligned}$$

This proves (1.13) and the first part of (1.15). A similar argument gives (1.14) and the second part of (1.15). This completes the proof of Theorem 1.3. ∎

ANISOTROPIC INHOMOGENEOUS RECTANGULAR THIN-WALLED BEAMS*

LORENZO FREDDI†, FRANÇOIS MURAT‡, AND ROBERTO PARONI§

Abstract. This paper is devoted to the asymptotic analysis of the problem of linear elasticity for an anisotropic and inhomogeneous body occupying, in its reference configuration, a cylindrical domain with a rectangular cross section with sides proportional to ε and ε^2 and clamped on one of its bases. The sequence of solutions u^ε of the equilibrium problem is shown to converge in an appropriate topology, as ε goes to zero, to the solution of a problem for a beam in which the extensional, flexural, and torsional effects are all coupled together.

Key words. asymptotic analysis, calculus of variations, thin-walled beams, dimension reduction, variational convergence, linear elasticity

1. Introduction.

Geometrically, a thin-walled beam is a slender structural element whose length is much larger than the diameter of the cross section which, on its hand, is larger than the thickness of the thin wall. These kinds of beams have been used for a long time in civil and mechanical engineering and, most of all, in flight vehicle structures because of their high ratio between maximum strength and weight. More recently, their importance has increased because of the introduction of fiber-reinforced composite materials in structural components. These materials are finding more and more applications for their high resistance to corrosion and high strength. Composite beams are usually made up by fiber-reinforced laminates and, hence, are anisotropic and inhomogeneous, even in cross-section planes. These peculiarities make classical thin-walled beam theories not applicable. The problem though has attracted the interest of several researchers and by now a huge number of articles can be found on the subject; see, for instance, [11] and the references therein. This is strongly remarked also in the first sentences of the abstract of [12]: "There is no lack of composite beam theories. Quite to the contrary, there might be too many of them. Different approaches, notations, etc., are used by the authors of those theories, so it is not always straightforward to compare the assumptions made and to assess the quantitative consequences of those assumptions."

The problem under study has a huge technological interest. One very suggestive, mentioned in [2], concerns the rotor blades of helicopters. The blades are composite beams and, hence, anisotropic and inhomogeneous. The anisotropy and the inhomogeneity introduce, as we shall also deduce, structural couplings between bending, extension, and twisting behaviors. It has been observed experimentally that these

couplings have a powerful influence on blade dynamics including vibrations and the aeroelastic stability; see [2]. If a model of composite beams that accurately describes the structural couplings was at our disposal, then we could try to vary the anisotropy and inhomogeneity so as to minimize undesired effects like, for instance, vibrations. Through the control of lamination parameters (ply orientation and stacking sequence), it would then be possible for industry to minimize the undesired effects.

Our aim here is to deduce a "rigorous" model for a composite thin-walled beam, that is, a inhomogeneous and anisotropic beam. We shall achieve our goal by means of well-established asymptotic methods starting from the three-dimensional linear theory of elasticity.

This paper is devoted to the asymptotic analysis of the linearized system of equilibrium equations of a body which occupies, in its reference configuration, a cylindrical domain with a rectangular cross section with sides proportional to ε and ε^2 and clamped on one of its two bases. In particular, we study the compactness properties of the sequence of solutions u^ε of the equilibrium problems and, letting ε go to zero, we are concerned with the identification of the limit problem. The same problem has been studied from the point of view of Γ-convergence: in [4] in the simpler setting of homogeneous and isotropic material and in [3] in the case of an anisotropic material which is inhomogeneous only along the longitudinal axis and subject to residual stress. Trabucho and Viano [9] also studied the same problem by superimposing two asymptotic analyses where the lengths of the two sides of the cross section go to zero independently.

Besides the material properties of the body, our treatment differs from the preceding works also in the topology used in the passage from the three-dimensional problem to the one-dimensional: the one used in the present paper delivers much more information on the deformation of the beam. The approach is close to the one developed in a recent paper of Murat and Sili [8] for a thin cylinder of radius ε. The lack of isotropy or homogeneity assumptions leads to a limit problem where the extensional, flexural, and torsional effects are coupled together. In fact, we prove that the limit problem can be written as a system of five equations in a 5-tuple of unknowns (u, v, w, p, q) (see Theorem 6.1) and that $u^\varepsilon - (u + \varepsilon v + \varepsilon^2 w + \varepsilon^3 p + \varepsilon^4 q)$ converges strongly to zero in $H^1(\Omega)$, under some regularity assumptions on v, w, p, and q (see Corollary 6.1). We also derive the set of Euler equations of the variational limit problem, that is, the system of equilibrium differential equations, in the fully general case. Then we show that a strong simplification and a partial decoupling occurs when the material is homogeneous, and a complete decoupling is obtained for a homogeneous orthotropic material.

Notation. Throughout this paper Ω_1, Ω_2, and Ω_3 will denote the following three intervals:

$$\Omega_\alpha := (-a_\alpha/2, +a_\alpha/2) \quad \text{for } \alpha = 1, 2 \quad \text{and } \Omega_3 := (0, \ell),$$

where a_1, a_2, and ℓ are three positive real numbers. Also, for $i, j = 1, 2, 3$ we set

$$\Omega_{ij} := \Omega_i \times \Omega_j$$

and

$$\Omega := \Omega_1 \times \Omega_2 \times \Omega_3.$$

Unless otherwise specified, we use the Einstein summation convention. Moreover, we use the following convention for indexing vector and tensor components: Greek indices α and β take their values in the set $\{1,2\}$ and Latin indices i, j, and k in the set $\{1,2,3\}$. With a little abuse of notation, and because this is a common practice and does not give rise to any mistakes, we call "sequences" even those families indicized by a continuous parameter $\varepsilon \in (0,1)$. The component k of a vector v will be denoted either with $(v)_k$ or v_k, and an analogous notation will be used to denote tensor components. $\mathcal{E}_{\alpha\beta}$ denotes the Ricci's symbol, that is, $\mathcal{E}_{11} = \mathcal{E}_{22} = 0$, $\mathcal{E}_{12} = 1$, and $\mathcal{E}_{21} = -1$. Since usually $x = (x_1, x_2, x_3)$, we shall then denote by $x' := (x_1, x_2)$. A wide use will be made of vector valued distributions and Sobolev spaces; for a brief account of which and for the current notation we refer the reader to the book of Le Dret [5]. Throughout this paper C will denote a constant which may change line by line.

2. The three-dimensional problem. We consider a body which occupies, in its reference configuration, the region

$$\Omega_\varepsilon := \varepsilon^2\Omega_1 \times \varepsilon\Omega_2 \times \Omega_3 \subset \mathbb{R}^3.$$

We denote by $E(u)$ the strain of the displacement u, whose components are

$$E_{ij}(u) = \frac{1}{2}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right).$$

The elasticity tensor, with respect to the reference configuration Ω_ε, of the material will be denoted by $\mathbb{C}^\varepsilon$. We assume it to be essentially bounded,

$$\mathbb{C}^\varepsilon \in L^\infty(\Omega_\varepsilon; \mathbb{R}^{3\times3\times3\times3});$$

to have the minor symmetries,

$$\mathbb{C}^\varepsilon_{ijkl} = \mathbb{C}^\varepsilon_{jikl} = \mathbb{C}^\varepsilon_{ijlk};$$

and to be positive definite. That is, there exists a constant $c > 0$ such that

$$\mathbb{C}^\varepsilon A \cdot A \geq c|A|^2, \tag{1}$$

for all three by three symmetric matrices A and for all ε. We consider the body clamped on $\Gamma^\varepsilon_b := \partial\Omega_\varepsilon \cap \{x_3 = 0\}$ and we denote by

$$H^1_{dn}(\Omega_\varepsilon; \mathbb{R}^3) := \left\{\varphi \in H^1(\Omega_\varepsilon; \mathbb{R}^3) : \varphi = 0 \text{ on } \Gamma^\varepsilon_b\right\}.$$

The weak form of the equilibrium problem can be written as

$$\begin{cases} \tilde{u}^\varepsilon \in H^1_{dn}(\Omega_\varepsilon; \mathbb{R}^3), \\ \displaystyle\int_{\Omega_\varepsilon} \mathbb{C}^\varepsilon E(\tilde{u}^\varepsilon) \cdot E(\varphi)\, dv = \int_{\Omega_\varepsilon} \tilde{F}^\varepsilon \cdot E(\varphi)\, dv \quad \forall \varphi \in H^1_{dn}(\Omega_\varepsilon; \mathbb{R}^3), \end{cases} \tag{2}$$

where the matrix field $\tilde{F}^\varepsilon$, which takes into account the presence of external forces, is assumed to be an element of $L^2(\Omega_\varepsilon; \mathbb{R}^{3\times3}_{\text{sym}})$.

If $\tilde{F}^\varepsilon$ is not just in $L^2(\Omega_\varepsilon; \mathbb{R}^{3\times3}_{\text{sym}})$ but in

$$H(\text{div}, \Omega_\varepsilon) := \{T \in L^2(\Omega_\varepsilon; \mathbb{R}^{3\times3}_{\text{sym}}) : \text{div}\, T \in L^2(\Omega_\varepsilon; \mathbb{R}^3)\},$$

then the previous problem can be seen as the weak form of the following problem:

$$\begin{cases} \operatorname{div} \mathbb{C}^\varepsilon E(\tilde{u}^\varepsilon) + \tilde{b}^\varepsilon = 0 & \text{in } \Omega_\varepsilon, \\ \mathbb{C}^\varepsilon E(\tilde{u}^\varepsilon) n^\varepsilon = \tilde{c}^\varepsilon & \text{on } \Gamma_c^\varepsilon, \\ \tilde{u}^\varepsilon = 0 & \text{on } \Gamma_b^\varepsilon, \end{cases} \tag{3}$$

where $\Gamma_c^\varepsilon := \partial\Omega_\varepsilon \backslash \Gamma_b^\varepsilon$, and n^ε denotes the unit outward normal vector to Ω_ε, while the *body loads* $\tilde{b}^\varepsilon$ and the *contact loads* $\tilde{c}^\varepsilon$ are simply given by

$$\tilde{b}^\varepsilon := -\operatorname{div} \tilde{F}^\varepsilon \quad \text{in } \Omega_\varepsilon, \qquad \tilde{c}^\varepsilon := \tilde{F}^\varepsilon n^\varepsilon \quad \text{in } \Gamma_c^\varepsilon. \tag{4}$$

Note that given $\tilde{b}^\varepsilon \in L^2(\Omega_\varepsilon; \mathbb{R}^3)$ and $\tilde{c}^\varepsilon \in H^{-1/2}(\partial\Omega_\varepsilon; \mathbb{R}^3)$ it is always possible to find an $\tilde{F}^\varepsilon \in H(\operatorname{div}, \Omega_\varepsilon)$ which satisfies (4).

3. The rescaled problem. It is convenient to work with the domain Ω instead of the domain Ω_ε. We therefore rescale the problem by means of the scaling map $s_\varepsilon : \Omega \to \Omega_\varepsilon$,

$$s_\varepsilon(x_1, x_2, x_3) = (\varepsilon^2 x_1, \varepsilon x_2, x_3).$$

Let $\tilde{u}^\varepsilon$ be the solution of (2); then we define the "rescaled solution" u^ε by

$$u_1^\varepsilon := \varepsilon^2 \tilde{u}_1^\varepsilon \circ s_\varepsilon, \quad u_2^\varepsilon := \varepsilon \tilde{u}_2^\varepsilon \circ s_\varepsilon, \quad u_3^\varepsilon := \tilde{u}_3^\varepsilon \circ s_\varepsilon.$$

Let E^ε be the "rescaled strain" defined by

$$E^\varepsilon(\varphi) := \begin{pmatrix} \frac{1}{\varepsilon^4} E_{11}(\varphi) & \frac{1}{\varepsilon^3} E_{12}(\varphi) & \frac{1}{\varepsilon^2} E_{13}(\varphi) \\ \frac{1}{\varepsilon^3} E_{21}(\varphi) & \frac{1}{\varepsilon^2} E_{22}(\varphi) & \frac{1}{\varepsilon} E_{23}(\varphi) \\ \frac{1}{\varepsilon^2} E_{31}(\varphi) & \frac{1}{\varepsilon} E_{32}(\varphi) & E_{33}(\varphi) \end{pmatrix}. \tag{5}$$

It follows that $E^\varepsilon(u^\varepsilon) = E(\tilde{u}^\varepsilon) \circ s_\varepsilon$.

We further assume that there exists a $\mathbb{C} \in L^\infty(\Omega; \mathbb{R}^{3\times3\times3\times3})$ such that

$$\mathbb{C}^\varepsilon = \mathbb{C} \circ s_\varepsilon,$$

and we denote with $F^\varepsilon = \tilde{F}^\varepsilon \circ s_\varepsilon^{-1} \in L^2(\Omega; \mathbb{R}^{3\times3}_{\mathrm{sym}})$. With this notation u^ε turns out to be the unique solution of

$$\begin{cases} u^\varepsilon \in H^1_{dn}(\Omega; \mathbb{R}^3), \\ \displaystyle\int_\Omega \mathbb{C} E^\varepsilon(u^\varepsilon) \cdot E^\varepsilon(\varphi)\, dx = \int_\Omega F^\varepsilon \cdot E^\varepsilon(\varphi)\, dx \quad \forall \varphi \in H^1_{dn}(\Omega; \mathbb{R}^3), \end{cases} \tag{6}$$

where $\Gamma_b := \partial\Omega \cap \{x_3 = 0\}$ and

$$H^1_{dn}(\Omega; \mathbb{R}^3) := \Big\{ \varphi \in H^1(\Omega; \mathbb{R}^3) : \varphi = 0 \text{ on } \Gamma_b \Big\}.$$

By taking $\varphi = u^\varepsilon$ and using (1), we find

$$c \|E^\varepsilon(u^\varepsilon)\|_{L^2(\Omega)} \le \|F^\varepsilon\|_{L^2(\Omega)}. \tag{7}$$

Thus a uniform bound on $\|F^\varepsilon\|_{L^2(\Omega)}$ would lead to rescaled strains uniformly bounded in ε. We augment this requirement by assuming

$$F^\varepsilon \to F \quad \text{in } L^2(\Omega; \mathbb{R}^{3\times3}_{\mathrm{sym}}). \tag{8}$$

Remark 3.1. Let $S^\varepsilon := \operatorname{diag}(1/\varepsilon^2, 1/\varepsilon, 1)$; then $E^\varepsilon(\varphi) = S^\varepsilon E(\varphi) S^\varepsilon$. If we assume $F^\varepsilon \in H(\operatorname{div}, \Omega)$, then we can write

$$\begin{aligned}\int_\Omega F^\varepsilon \cdot E^\varepsilon(\varphi)\,dx &= \int_\Omega S^\varepsilon F^\varepsilon S^\varepsilon \cdot E(\varphi)\,dx \\ &= -\int_\Omega \operatorname{div}(S^\varepsilon F^\varepsilon S^\varepsilon)\cdot\varphi\,dx + \langle S^\varepsilon F^\varepsilon S^\varepsilon n, \varphi\rangle_{\partial\Omega},\end{aligned}$$

for all $\varphi \in H^1_{dn}(\Omega;\mathbb{R}^3)$, and conclude that instead of considering F^ε we could have been using the following body and contact forces

$$b^\varepsilon := -\operatorname{div}(S^\varepsilon F^\varepsilon S^\varepsilon) \quad \text{in } \Omega \quad \text{and} \quad c^\varepsilon := S^\varepsilon F^\varepsilon S^\varepsilon n \quad \text{in } \Gamma_c.$$

Note that if $F^\varepsilon = S^{\varepsilon^{-1}} F^{(0)} S^{\varepsilon^{-1}}$ for some $F^{(0)} \in H(\operatorname{div}, \Omega)$ the body and the contact forces would be independent of ε. Since $S^{\varepsilon^{-1}} = \operatorname{diag}(\varepsilon^2, \varepsilon, 1)$, the sequence $\{S^{\varepsilon^{-1}} F^{(0)} S^{\varepsilon^{-1}}\}$, with $F^{(0)} \in H(\operatorname{div}, \Omega)$, strongly converges in $L^2(\Omega; \mathbb{R}^{3\times 3}_{\mathrm{sym}})$ and hence satisfies assumption (8). Assumption (8) though allows us to consider "stronger" forces than $F^\varepsilon = S^{\varepsilon^{-1}} F^{(0)} S^{\varepsilon^{-1}}$, like $F^\varepsilon = F^{(0)}$ or, more generally,

$$F^\varepsilon = F^{(0)} + \varepsilon F^{(1)} + \varepsilon^2 F^{(2)} + \varepsilon^3 F^{(3)} + \varepsilon^4 F^{(4)},$$

with $F^{(i)} \in H(\operatorname{div}, \Omega)$ for $i = 0, 1, \dots, 4$, where, for instance, the term $\varepsilon^4 F^{(4)}_{11}$ would lead to the definition of body and contact forces independent of ε.

4. Partial Korn's inequalities. In this section we state and prove several Korn's inequalities. The proofs of Theorems 4.2 and 4.3 follow some of the lines of that of Theorem 4.4, which is due to Monneau, Murat, and Sili [7].

THEOREM 4.1. *There exists a constant C such that*

$$\Big\| u_1 - \fint_{\Omega_1} u_1\,dx_1 \Big\|_{L^2(\Omega)} \le C \Big\| \frac{\partial u_1}{\partial x_1} \Big\|_{L^2(\Omega)}$$

for every $u_1 \in H^1(\Omega_1; L^2(\Omega_{23}))$.

Proof. By density we may restrict ourselves to considering $u_1 \in C^1(\bar\Omega)$. For every x_2 and x_3 there exists a $\xi = \xi(x_2, x_3)$ such that $u_1(\xi, x_2, x_3) = \fint_{\Omega_1} u_1(s, x_2, x_3)\,ds$ and

$$u_1(x_1, \cdot, \cdot) - u_1(\xi, \cdot, \cdot) = \int_\xi^{x_1} \frac{\partial u_1}{\partial x_1}(s, \cdot, \cdot)\,ds.$$

Taking squares and applying Jensen's inequality we conclude the proof. ∎

THEOREM 4.2. *There exists a constant C such that*

$$\begin{aligned}\Big\| u_2 - \Big(\fint_{\Omega_1} u_2\,dx_1 - x_1 \frac{\partial}{\partial x_2} \fint_{\Omega_1} u_1\,dx_1 \Big) \Big\|_{H^{-1}(\Omega_2; L^2(\Omega_{13}))} \\ \le C \left(\big\| E_{11}(u) \big\|_{L^2(\Omega)} + \big\| E_{12}(u) \big\|_{L^2(\Omega)} \right)\end{aligned}$$

for every $u \in H^1(\Omega; \mathbb{R}^2)$.

Proof. Let

$$\bar u_1 := u_1 - \fint_{\Omega_1} u_1\,dx_1, \quad \bar u_2 := u_2 - \fint_{\Omega_1} u_2\,dx_1 + x_1 \frac{\partial}{\partial x_2} \fint_{\Omega_1} u_1\,dx_1,$$

and note that $⨍_{\Omega_1} \bar{u}_2\,dx_1 = 0$ and $\bar{u}_2 \in H^1(\Omega_1; L^2(\Omega_{23}))$. Let $\psi \in H^1_0(\Omega_2)$; then

$$\begin{aligned}\frac{\partial}{\partial x_1}\int_{\Omega_2}\psi\bar{u}_2\,dx_2 &= \int_{\Omega_2}\psi\left(\frac{\partial u_2}{\partial x_1}+\frac{\partial}{\partial x_2}⨍_{\Omega_1}u_1\,dx_1\right)dx_2\\ &= \int_{\Omega_2}\psi\left(2E_{12}(u)-\frac{\partial\bar{u}_1}{\partial x_2}\right)dx_2\\ &= \int_{\Omega_2}2\psi E_{12}(u)+\bar{u}_1\frac{d\psi}{dx_2}\,dx_2.\end{aligned}$$

Since $\int_{\Omega_2}\psi\bar{u}_2\,dx_2 \in H^1(\Omega_1; L^2(\Omega_{23}))$ and $\int_{\Omega_1}\int_{\Omega_2}\psi\bar{u}_2\,dx_2dx_1 = 0$, by Theorem 4.1 and the above equation we deduce

$$\begin{aligned}\left\|\int_{\Omega_2}\psi\bar{u}_2\,dx_2\right\|_{L^2(\Omega)} &\le C\left\|\frac{\partial}{\partial x_1}\int_{\Omega_2}\psi\bar{u}_2\,dx_2\right\|_{L^2(\Omega)}\\ &\le C\,\|\psi\|_{H^1(\Omega_2)}(\|E_{12}(u)\|_{L^2(\Omega)}+\|\bar{u}_1\|_{L^2(\Omega)})\\ &\le C\,\|\psi\|_{H^1(\Omega_2)}(\|E_{12}(u)\|_{L^2(\Omega)}+\|E_{11}(u)\|_{L^2(\Omega)}).\end{aligned}$$

Let $\varphi \in L^2(\Omega_{13})$; then

$$\begin{aligned}\left|\int_\Omega\varphi\psi\bar{u}_2\,dx\right| &\le \|\varphi\|_{L^2(\Omega_{13})}\left\|\int_{\Omega_2}\psi\bar{u}_2\,dx_2\right\|_{L^2(\Omega_{13})}\\ &\le C\,\|\varphi\|_{L^2(\Omega_{13})}\|\psi\|_{H^1(\Omega_2)}(\|E_{11}(u)\|_{L^2(\Omega_{13})}+\|E_{12}(u)\|_{L^2(\Omega)}).\end{aligned}$$

A density argument concludes the proof. Indeed, let $\{\varphi_n\}$ be an orthonormal basis of $L^2(\Omega_{13})$ and for any $v \in H^1_0(\Omega_2; L^2(\Omega_{13}))$, let

$$\psi_n(x_2) := \int_{\Omega_{13}}\varphi_n(x_1,x_3)v(x)\,dx_1dx_3 \in H^1_0(\Omega_2).$$

Then for $v_N := \sum_{n=1}^N \psi_n\varphi_n$ we have

$$\left|\int_\Omega v_N\bar{u}_2\,dx\right| \le \|v_N\|_{H^1_0(\Omega_2;L^2(\Omega_{13}))}(\|E_{11}(u)\|_{L^2(\Omega)}+\|E_{12}(u)\|_{L^2(\Omega)}),$$

and letting N go to infinity we conclude the proof. □

Remark 4.1. In spite of the fact that the left-hand side belongs to $L^2(\Omega)$, the inequality of Theorem 4.2 does not hold true if one replaces the norm H^{-1} with the norm of L^2, because of the following counterexample, which is inspired by an example contained in [7] in a quite similar framework.

Consider two scalar smooth functions $\varphi_\alpha \in C^\infty(\bar{\Omega}_\alpha)$ with φ_1 satisfying

$$\int_{\Omega_1}\varphi_1\,dx_1 = \int_{\Omega_1}\frac{\partial\varphi_1}{\partial x_1}\,dx_1 = 0.$$

Define

$$u_1 := -\varphi_2\frac{\partial\varphi_1}{\partial x_1},\quad u_2 := \varphi_1\frac{\partial\varphi_2}{\partial x_2},\quad u_3 := 0.$$

Then $u \in H^1(\Omega;\mathbb{R}^3)$, and the inequality of Theorem 4.2 reduces to

$$\left\|\varphi_1\frac{\partial\varphi_2}{\partial x_2}\right\|_{H^{-1}(\Omega_2;L^2(\Omega_1))} \le C\left\|\varphi_2\frac{\partial^2\varphi_1}{\partial x_1^2}\right\|_{L^2(\Omega)},$$

which cannot be true if we replace H^{-1} by L^2 because in such a case, taking $\|\varphi_1\|_{L^2(\Omega_1)} = \|\partial^2\varphi_1/\partial x_1^2\|_{L^2(\Omega_1)}$ would imply that

$$\left\|\frac{\partial\varphi_2}{\partial x_2}\right\|_{L^2(\Omega)} \le C\|\varphi_2\|_{L^2(\Omega)}$$

for any $\varphi_2 \in C^\infty(\bar\Omega_2)$, which is clearly impossible.

Define (using the summation convention)

$$rd_2 = \{r \in L^2(\Omega_{12};\mathbb{R}^2) : \exists\, c \in \mathbb{R},\, d \in \mathbb{R}^2 \text{ such that } r_\alpha(y) = \mathcal{E}_{\beta\alpha}\, x_\beta\, d + c_\alpha\},$$

where $\mathcal{E}$ denotes the Ricci's symbol. The elements of rd_2 are the infinitesimal rigid displacements on Ω_{12}. It is easy to see that $rd_2 \subset H^1(\Omega_{12};\mathbb{R}^2)$; moreover, being finite-dimensional, it is closed in $L^2(\Omega_{12};\mathbb{R}^2)$. Thus, the orthogonal projection operator of $L^2(\Omega_{12};\mathbb{R}^2)$ on rd_2, which will be denoted by $\wp$, is well defined. Given a vector function $v \in L^2(\Omega_{12},\mathbb{R}^m)$ with $m \ge 2$, we define

$$\vartheta(v) := \frac{1}{I_O}\int_{\Omega_{12}} (x_1 v_2 - x_2 v_1)\, dx', \text{ where } I_O = \int_{\Omega_{12}} (x_1^2 + x_2^2)\, dx'. \tag{9}$$

If $v \in L^2(\Omega_{12};\mathbb{R}^2)$, then the components of $\wp$ turn out to be

$$\wp_\alpha(v) = \mathcal{E}_{\beta\alpha}\, x_\beta \vartheta(v) + \fint_{\Omega_{12}} v_\alpha\, dx'. \tag{10}$$

Furthermore, the two-dimensional Korn's inequality can be written as

$$\|v - \wp(v)\|_{H^1(\Omega_{12};\mathbb{R}^2)} \le C \sum_{\alpha,\beta} \|E_{\alpha\beta}(v)\|_{L^2(\Omega_{12};\mathbb{R}^{2\times 2})} \tag{11}$$

for all $v \in H^1(\Omega_{12};\mathbb{R}^2)$ with a constant C which is independent of v.

Similarly, given a vector function $u \in L^2(\Omega_3; L^2(\Omega_{12},\mathbb{R}^m))$ with $m \ge 2$, we analogously define $\vartheta(u) \in L^2(\Omega_3)$ and $\wp_\alpha(u)$. The operator $\wp$ associates to any $u \in L^2(\Omega_3; L^2(\Omega_{12},\mathbb{R}^m))$ a function $\wp(u) \in L^2(\Omega_3; L^2(\Omega_{12},\mathbb{R}^2))$ which is an infinitesimal rigid displacement on Ω_{12} for almost every $x_3 \in \Omega_3$.

Let us observe that the orthogonal complement, with respect to the $L^2(\Omega_{12};\mathbb{R}^2)$ inner product, of rd_2 in $H^1(\Omega_{12};\mathbb{R}^2)$ can be then characterized as

$$rd_2^\perp = \{v \in H^1(\Omega_{12};\mathbb{R}^2) \ :\ \wp(v) = 0\} = \{v \in H^1_m(\Omega_{12};\mathbb{R}^2) \ :\ \vartheta(v) = 0\}.$$

Moreover, we denote by

$$RD_2^\perp(\Omega) = \{v \in L^2(\Omega_3; H^1_m(\Omega_{12};\mathbb{R}^2)) \ :\ \vartheta(v) = 0 \text{ a.e. } x_3 \in \Omega_3\}. \tag{12}$$

Hereafter, for any $u \in L^2(\Omega_3; H^1(\Omega_{12};\mathbb{R}^m))$, $m \ge 2$, we set

$$\tilde u_\alpha := u_\alpha - \wp_\alpha(u). \tag{13}$$

Of course $\tilde u \in L^2(\Omega_3; H^1(\Omega_{12};\mathbb{R}^2))$ and $\fint_{\Omega_{12}} \tilde u\, dx_1 dx_2 = 0$ and $\vartheta(\tilde u) = 0$ a.e. in Ω_3, where the latter follows from the linearity of ϑ and the fact that $\vartheta(u) = \vartheta(\wp(u))$. Thus $\tilde u \in RD_2^\perp(\Omega)$.

LEMMA 4.1. *There exists a constant C such that*

$$\|\tilde u\|_{L^2(\Omega_3;H^1(\Omega_{12};\mathbb{R}^2))} \le C \sum_{\alpha,\beta} \|E_{\alpha\beta}(u)\|_{L^2(\Omega_3;L^2(\Omega_{12}))}$$

for every $u \in L^2(\Omega_3; H^1(\Omega_{12};\mathbb{R}^m))$, $m \ge 2$.

Proof. Since $u_\alpha(\cdot,\cdot,x_3) \in L^2(\Omega_{12})$ for almost every $x_3 \in \Omega_3$, from (10) and (11) we have that the relations

$$\wp_\alpha(u) = \mathcal{E}_{\beta\alpha}\, x_\beta\, \vartheta(u) + \frac{1}{|\Omega_{12}|}\int_{\Omega_{12}} u_\alpha\, dx', \tag{14}$$

$$\|\tilde{u}\|_{H^1(\Omega_{12};\mathbb{R}^2)} \le C \sum_{\alpha,\beta} \|E_{\alpha\beta}(u)\|_{L^2(\Omega_{12})} \tag{15}$$

hold for almost every x_3 in Ω_3, and the claimed inequality follows by integration. □

A different proof of the lemma above can be found in Le Dret [6].

PROPOSITION 4.1. *$RD_2^\perp(\Omega)$ is a Hilbert space with the norm*

$$\|v\|_{RD_2^\perp(\Omega)} := \left(\sum_{\alpha,\beta} \|E_{\alpha\beta}(v)\|^2_{L^2(\Omega)}\right)^{1/2}.$$

Proof. We have only to prove that $\|v\|_{RD_2^\perp(\Omega)}$ is equivalent to the norm induced on $RD_2^\perp(\Omega)$ by $L^2(\Omega_3;H^1(\Omega_{12};\mathbb{R}^2))$ since the former space is a closed subspace of the latter. For any $v \in RD_2^\perp(\Omega)$, recalling that $\wp(v) = 0$, so that $v = \tilde{v}$, and using Lemma 4.1, we then have

$$\|v\|_{L^2(\Omega_3;H^1(\Omega_{12};\mathbb{R}^2))} = \|\tilde{v}\|_{L^2(\Omega_3;H^1(\Omega_{12};\mathbb{R}^2))} \le C\|v\|_{RD_2^\perp(\Omega)}$$

while the opposite inequality is trivially satisfied. □

THEOREM 4.3. *There exists a constant C such that*

$$\left\| u_3 - \left(x_1 x_2 \frac{d\vartheta(u)}{dx_3} - x_1 \frac{d}{dx_3} \fint_{\Omega_{12}} u_1\, dx' + \fint_{\Omega_1} u_3\, dx_1 \right) \right\|_{H^{-1}(\Omega_3;L^2(\Omega_{12}))} \le C \left(\sum_{\alpha,\beta} \|E_{\alpha\beta}(u)\|_{L^2(\Omega)} + \|E_{13}(u)\|_{L^2(\Omega)} \right)$$

for every $u \in H^1(\Omega;\mathbb{R}^3)$.

Proof. Let $\tilde{u}_\alpha := u_\alpha - \wp_\alpha(u)$ as in (13) and

$$\tilde{u}_3 := u_3 - \left(x_1 x_2 \frac{d\vartheta(u)}{dx_3} - x_1 \frac{d}{dx_3} \fint_{\Omega_{12}} u_1\, dx' + \fint_{\Omega_1} u_3\, dx_1 \right).$$

Since $E_{13}(u) = E_{13}(\tilde{u})$,

$$\frac{\partial \tilde{u}_3}{\partial x_1} = 2E_{13}(u) - \frac{\partial \tilde{u}_1}{\partial x_3}.$$

Let $\psi \in H_0^1(\Omega_3)$; then

$$\begin{aligned} \frac{\partial}{\partial x_1}\int_{\Omega_3} \psi \tilde{u}_3\, dx_3 &= \int_{\Omega_3} \psi\Big(2E_{13}(u) - \frac{\partial \tilde{u}_1}{\partial x_3}\Big)\, dx_3 \\ &= \int_{\Omega_3} 2\Big(\psi E_{13}(u) + \tilde{u}_1 \frac{d\psi}{dx_3}\Big)\, dx_3. \end{aligned}$$

Since $\int_{\Omega_3} \psi\tilde{u}_3\,dx_3 \in H^1(\Omega)$ and $\int_{\Omega_1}\int_{\Omega_3} \psi\tilde{u}_3\,dx_3dx_1 = 0$, by Theorem 4.1, Lemma 4.1, and the previous equality we deduce

$$\begin{aligned}\left\|\int_{\Omega_3}\psi\tilde{u}_3\,dx_3\right\|_{L^2(\Omega)} &\le C\left\|\frac{\partial}{\partial x_1}\int_0^\ell \psi\tilde{u}_3\,dx_3\right\|_{L^2(\Omega)}\\ &\le C\|\psi\|_{H^1(\Omega_3)}(\|E_{13}(u)\|_{L^2(\Omega)} + \|\tilde{u}_1\|_{L^2(\Omega)})\\ &\le C\|\psi\|_{H^1(\Omega_3)}(\|E_{13}(u)\|_{L^2(\Omega)} + \textstyle\sum_{\alpha,\beta}\|E_{\alpha\beta}(u)\|_{L^2(\Omega)}).\end{aligned}$$

Let $\varphi \in L^2(\Omega_{12})$; then

$$\begin{aligned}\left|\int_\Omega \varphi\psi\tilde{u}_3\,dx\right| &= \left|\int_{\Omega_{12}}\varphi\int_{\Omega_3}\psi\tilde{u}_3\,dx_3dx'\right| \le \|\varphi\|_{L^2(\Omega_{12})}\left\|\int_{\Omega_3}\psi\tilde{u}_3\,dx_3\right\|_{L^2(\Omega_{12})}\\ &\le C\|\varphi\|_{L^2(\Omega_{12})}\|\psi\|_{H^1(\Omega_3)}\left(\|E_{13}(u)\|_{L^2(\Omega)} + \sum_{\alpha,\beta}\|E_{\alpha\beta}(u)\|_{L^2(\Omega)}\right).\end{aligned}$$

Arguing as in the proof of Theorem 4.2, we conclude the proof. □

Remark 4.2. As in Remark 4.1, in spite of the fact that the left-hand side belongs to $L^2(\Omega)$, the inequality of Theorem 4.3 does not hold true if one replaces the norm H^{-1} with the norm of L^2, because of the following counterexample.

Consider three scalar smooth functions $\varphi_i \in C^\infty(\bar{\Omega}_i)$ with φ_α satisfying

$$\int_{\Omega_\alpha}\varphi_\alpha\,dx_\alpha = \int_{\Omega_\alpha}\frac{\partial\varphi_\alpha}{\partial x_\alpha}\,dx_\alpha = 0.$$

Define

$$u_1 := -\varphi_2\frac{\partial\varphi_1}{\partial x_1}\varphi_3, \quad u_2 := -\varphi_1\frac{\partial\varphi_2}{\partial x_2}\varphi_3, \quad u_3 := +\varphi_1\varphi_2\frac{\partial\varphi_3}{\partial x_3}.$$

Then $u \in H^1(\Omega;\mathbb{R}^3)$, and the inequality of Theorem 4.3 reduces to

$$\left\|\varphi_1\varphi_2\frac{\partial\varphi_3}{\partial x_3}\right\|_{H^{-1}(\Omega_2;L^2(\Omega_1))} \le C\left\|\varphi_3\left(\frac{\partial^2\varphi_1}{\partial x_1^2}\varphi_2 + \varphi_1\frac{\partial^2\varphi_2}{\partial x_2^2}\right)\right\|_{L^2(\Omega)},$$

which cannot be true if we replace H^{-1} by L^2, because in such a case taking $\|\varphi_\alpha\|_{L^2(\Omega_\alpha)} = \|\partial^2\varphi_\alpha/\partial x_1^\alpha\|_{L^2(\Omega_\alpha)}$ would imply that

$$\left\|\frac{\partial\varphi_3}{\partial x_3}\right\|_{L^2(\Omega)} \le C\|\varphi_3\|_{L^2(\Omega)}$$

for any $\varphi_3 \in C^\infty(\bar{\Omega}_3)$, which is clearly impossible.

The next partial Korn's inequality is proved in Monneau, Murat, and Sili [7].

THEOREM 4.4. *There exists a constant C such that*

$$\begin{aligned}&\left\|u_3 - \left(\fint_{\Omega_{12}} u_3\,dx' - x_\alpha\frac{d}{dx_3}\fint_{\Omega_{12}} u_\alpha\,dx'\right)\right\|_{H^{-1}(\Omega_3;L^2(\Omega_{12}))}\\ &\qquad\le C\left(\sum_{\alpha\beta}\|E_{\alpha\beta}(u)\|_{L^2(\Omega)} + \sum_\alpha\|E_{\alpha3}(u)\|_{L^2(\Omega)}\right)\end{aligned}$$

for every $u \in H^1_{dn}(\Omega;\mathbb{R}^3)$.

5. Limit strain characterization. Let

$$\begin{aligned} H^1_m(\Omega_{12}) &:= \{z \in H^1(\Omega_{12}) : \textstyle\int_{\Omega_{12}} z\,dx' = 0\},\\ H^1_{m_1}(\Omega_1; L^2(\Omega_{23})) &:= \{z \in H^1(\Omega_1; L^2(\Omega_{23})) : \textstyle\int_{\Omega_1} z\,dx_1 = 0 \text{ a.e. in } \Omega_{23}\},\\ H^{-1}_{m_1}(\Omega_3; L^2(\Omega_{12})) &:= \{v \in H^{-1}(\Omega_3; L^2(\Omega_{12})) : \langle z_3, \varphi\rangle = 0 \\ &\qquad\qquad \forall\, \varphi \in H^1_0(\Omega_3; L^2(\Omega_2))\}, \end{aligned}$$

where the bracket in the last definition has to be understood in the sense of the duality $H^{-1}(\Omega_3; L^2(\Omega_{12})) \times H^1_0(\Omega_3; L^2(\Omega_{12}))$.

Let (u^ε) be the sequence of solutions to problems (6). From (7) and assumption (8) it follows that

$$\sup_\varepsilon \|E^\varepsilon(u^\varepsilon)\|_{L^2(\Omega)} < +\infty. \tag{16}$$

Hence, possibly passing to a subsequence, we have that

$$E^\varepsilon(u^\varepsilon) \rightharpoonup E \quad \text{in } L^2(\Omega; \mathbb{R}^{3\times 3}_{\rm sym})$$

for some $E \in L^2(\Omega; \mathbb{R}^{3\times 3}_{\rm sym})$.

In this section we characterize the limit strain E. For clarity we state several lemmas.

LEMMA 5.1 (component 33). *There exists a function $\bar u$ in the set of the so-called Bernoulli–Navier displacements*

$$\mathscr{U} := \{u \in H^1_{dn}(\Omega; \mathbb{R}^3) : E_{\alpha i}(u) = 0\}$$

such that

$$E_{33} = \frac{\partial \bar u_3}{\partial x_3} = E_{33}(\bar u).$$

Proof. From (16), the structure of E^ε, and Korn's inequality, we have that

$$C \geq \|E^\varepsilon(u^\varepsilon)\|_{L^2(\Omega)} \geq \|E(u^\varepsilon)\|_{L^2(\Omega)} \geq C_K \|u^\varepsilon\|_{H^1(\Omega)},$$

where C is a constant independent of ε and C_K is Korn's constant. Hence, up to a subsequence $u^\varepsilon \rightharpoonup \bar u$ in $H^1(\Omega; \mathbb{R}^3)$, for some $\bar u \in H^1_{dn}(\Omega; \mathbb{R}^3)$. The claim follows by noticing that $\|E_{\alpha i}(u^\varepsilon)\|_{L^2(\Omega)} \leq C\varepsilon$, and $E^\varepsilon_{33}(u^\varepsilon) = \partial u^\varepsilon_3/\partial x_3$. In fact it follows that $\bar u \in \{u \in H^1_{dn}(\Omega; \mathbb{R}^3) : E_{\alpha i}(u) = 0\}$. ∎

Remark 5.1 (representation of the space $\mathscr{U}$). It is well known (see, for instance, Le Dret [5]) that the space of Bernoulli–Navier displacements admits the following representation:

$$\mathscr{U} := \Big\{ u \in H^2_{dn}(\Omega)^2 \times H^1_{dn}(\Omega) : \text{exists } \zeta \in H^2_{dn}(\Omega_3)^2 \times H^1_{dn}(\Omega_3) \text{ such that } u_1 = \zeta_1,\ u_2 = \zeta_2,\ u_3 = \zeta_3 - x_1 \frac{d\zeta_1}{dx_3} - x_2 \frac{d\zeta_2}{dx_3} \Big\}.$$

Moreover, $\mathscr{U}$ is a Hilbert space with the norm

$$\|u\|_{\mathscr{U}} := \|E_{33}(u)\|_{L^2(\Omega)},$$

which is equivalent to that induced by $H^1_{dn}(\Omega; \mathbb{R}^3)$ (see [8]).

LEMMA 5.2 (component 23). *There exists a function $\bar{v}$ in the space*

$$\mathscr{V} := \Big\{ v \in H^1_{dn}(\Omega)^2 \times L^2(\Omega_3; H^1_m(\Omega_{12})) : \textit{exist } \vartheta \in H^1(\Omega_3) \textit{ such that } \vartheta(0) = 0$$
$$\textit{and } \varrho \in L^2(\Omega_3; H^1(\Omega_2)) \textit{ such that } v_1(x) = -x_2\vartheta(x_3),\ v_2(x) = x_1\vartheta(x_3),$$
$$v_3(x) = x_1x_2\frac{d\vartheta}{dx_3}(x_3) + \varrho(x_2, x_3)\Big\}$$

such that

$$E_{23} = E_{23}(\bar{v}).$$

Proof. Let $v_i^\varepsilon := \frac{1}{\varepsilon}u_i^\varepsilon$ and $\vartheta^\varepsilon := \vartheta(v^\varepsilon)$ (see (9)).

First of all, by adapting an argument of [4] and Lemmas 4.4 and 4.5, we prove that there exists $\vartheta \in H^1(\Omega_3)$ with $\vartheta(0) = 0$, such that, up to subsequences,

$$\vartheta^\varepsilon \to \vartheta \text{ in } L^2(\Omega_3). \tag{17}$$

Applying Lemma 4.1, there exists a constant C such that

$$\|\tilde{v}^\varepsilon\|_{L^2(\Omega_3;H^1(\Omega_{12};\mathbb{R}^2))} \le C\sum_{\alpha,\beta}\|E_{\alpha\beta}(v^\varepsilon)\|_{L^2(\Omega_3;L^2(\Omega_{12}))}. \tag{18}$$

Since, furthermore,

$$E_{11}(v^\varepsilon)_{11} = \varepsilon^3E^\varepsilon_{11}(u^\varepsilon),\ E_{12}(v^\varepsilon) = \varepsilon^2E^\varepsilon_{12}(u^\varepsilon),\ E_{22}(v^\varepsilon) = \varepsilon E^\varepsilon_{22}(u^\varepsilon),$$

and using (16) we have

$$\|E_{\alpha\beta}(v^\varepsilon)\|_{L^2(\Omega)} \le \varepsilon\|E^\varepsilon_{\alpha\beta}(u^\varepsilon)\|_{L^2(\Omega)} \le C\,\varepsilon. \tag{19}$$

From (18) we get

$$\|\tilde{v}^\varepsilon\|_{L^2(\Omega_3;H^1(\Omega_{12};\mathbb{R}^2))} \le C\varepsilon; \tag{20}$$

hence

$$\tilde{v}^\varepsilon \to 0 \text{ in } L^2(\Omega_3; H^1(\Omega_{12};\mathbb{R}^2)). \tag{21}$$

Now let $\eta \in C^\infty_c(\Omega_{12})$ be such that

$$\int_{\Omega_{12}} \eta\, dx' = -\frac{I_O}{2}.$$

Then, taking into account (14), we have

$$
\begin{aligned}
I_O\vartheta^\varepsilon &= -2\vartheta^\varepsilon \int_{\Omega_{12}} \eta\, dx' = -\vartheta^\varepsilon \int_{\Omega_{12}} \eta D_\alpha x_\alpha\, dx' \\
&= \vartheta^\varepsilon \int_{\Omega_{12}} D_\alpha\eta\, x_\alpha\, dx' = \vartheta^\varepsilon \int_{\Omega_{12}} \mathcal{E}_{\alpha\gamma}\mathcal{E}_{\beta\gamma} D_\alpha\eta\, x_\beta\, dx' \\
&= \int_{\Omega_{12}} \mathcal{E}_{\alpha\gamma} D_\alpha\eta \mathcal{E}_{\beta\gamma} x_\beta \vartheta^\varepsilon\, dx' \\
&= \int_{\Omega_{12}} \mathcal{E}_{\alpha\gamma} D_\alpha\eta \Big(\wp_\gamma(v^\varepsilon) - \frac{1}{|\Omega_{12}|}\int_{\Omega_{12}} v^\varepsilon_\gamma\, dx'\Big)\, dx' \\
&= \int_{\Omega_{12}} \mathcal{E}_{\alpha\gamma} D_\alpha\eta\, \wp_\gamma(v^\varepsilon)\, dx' \\
&= \int_{\Omega_{12}} \mathcal{E}_{\alpha\gamma} D_\alpha\eta\, v^\varepsilon_\gamma\, dx' - \int_{\Omega_{12}} \mathcal{E}_{\alpha\gamma} D_\alpha\eta \big(v^\varepsilon - \wp_\gamma(v^\varepsilon)\big)\, dx'.
\end{aligned}
$$

Hence, denoting by

$$
\tilde\vartheta^\varepsilon = \frac{1}{I_O}\int_{\Omega_{12}} \mathcal{E}_{\alpha\gamma} D_\alpha\eta\, w^\varepsilon_\gamma\, dx'
$$

and recalling (21), we find

$$
\vartheta^\varepsilon - \tilde\vartheta^\varepsilon \to 0 \ \text{ in } L^2(\Omega_3). \tag{22}
$$

We now show that $D_3\tilde\vartheta^\varepsilon$ is bounded in L^2. Since $\mathcal{E}_{\alpha\gamma}D_\alpha D_\gamma\eta = 0$ everywhere in Ω_3 and $D_\alpha\eta = 0$ on $\partial\Omega_3$, we have

$$
I_O D_3\tilde\vartheta^\varepsilon = \int_{\Omega_{12}} \mathcal{E}_{\alpha\gamma} D_\alpha\eta\, D_3 v^\varepsilon_\gamma\, dx' = 2\int_{\Omega_{12}} \mathcal{E}_{\alpha\gamma} D_\alpha\eta\, E_{\gamma 3}(v^\varepsilon)\, dx',
$$

but $E_{13}(v^\varepsilon) = \varepsilon E^\varepsilon_{13}(u^\varepsilon)$ and $E_{23}(v^\varepsilon) = E^\varepsilon_{23}(u^\varepsilon)$, and therefore $D_3\tilde\vartheta^\varepsilon$ is bounded in $L^2(\Omega_3)$. Since $\tilde\vartheta^\varepsilon(0) = 0$, $\tilde\vartheta^\varepsilon$ is then bounded in $H^1(\Omega_3)$ so that there exists $\vartheta \in H^1(\Omega_3)$ with $\vartheta(0) = 0$, such that, up to subsequences,

$$
\tilde\vartheta^\varepsilon \rightharpoonup \vartheta \text{ in } H^1(\Omega_3).
$$

Thus, from (22) we obtain (17).

Let us now set

$$
\bar v^\varepsilon_1 := v^\varepsilon_1 - \fint_{\Omega_{12}} v^\varepsilon_1\, dx', \quad \bar v^\varepsilon_2 := v^\varepsilon_2 - \fint_{\Omega_{12}} v^\varepsilon_2\, dx',
$$

and

$$
\bar v^\varepsilon_3 := v^\varepsilon_3 - \Big(\fint_{\Omega_{12}} v^\varepsilon_3\, dx' - x_\alpha \frac{d}{dx_3}\fint_{\Omega_{12}} v^\varepsilon_\alpha\, dx'\Big).
$$

Observing that, by the definitions,

$$
\bar v^\varepsilon_1 = \tilde v^\varepsilon_1 - x_2\vartheta^\varepsilon, \quad \bar v^\varepsilon_2 = \tilde v^\varepsilon_2 + x_1\vartheta^\varepsilon,
$$

from (17) and (21) we have that

$$\bar{v}_1^\varepsilon \to -x_2\vartheta, \qquad \bar{v}_2^\varepsilon \to +x_1\vartheta \qquad \text{in } L^2(\Omega_3; H^1(\Omega_{12})).$$

By Theorem 4.4, we have that

$$\|\bar{v}_3^\varepsilon\|_{H^{-1}(\Omega_3;L^2(\Omega_{12}))} \le C,$$

and hence there exists $\bar{v}_3 \in H^{-1}(\Omega_3; L^2(\Omega_{12}))$ such that, up to subsequences,

$$\bar{v}_3^\varepsilon \rightharpoonup : \bar{v}_3 \text{ in } H^{-1}(\Omega_3; L^2(\Omega_{12})). \tag{23}$$

Moreover, let us set

$$\bar{v}_1 = -x_2\vartheta, \quad \bar{v}_2 = +x_1\vartheta,$$

and check that the vector field $\bar{v}$ so defined satisfies the properties claimed in the statement of Lemma 4.1. A simple computation shows that

$$E_{13}(\bar{v}^\varepsilon) = E_{13}(v^\varepsilon) \quad \text{and} \quad E_{23}(\bar{v}^\varepsilon) = E_{23}(v^\varepsilon).$$

Noticing that $E_{13}(v^\varepsilon) = \varepsilon E_{13}^\varepsilon(u^\varepsilon) \to 0$ in $L^2(\Omega)$ and $E_{13}(\bar{v}^\varepsilon) \to E_{13}(\bar{v})$ in $\mathscr{D}'(\Omega)$, we obtain that $E_{13}(\bar{v}) = 0$. Hence,

$$\frac{\partial \bar{v}_3}{\partial x_1} = -\frac{\partial \bar{v}_1}{\partial x_3} = x_2 \frac{d\vartheta}{dx_3}$$

and, integrating with respect to x_1,

$$\bar{v}_3 = x_1 x_2 \frac{d\vartheta}{dx_3} + \varrho(x_2, x_3)$$

for some function $\varrho \in L^2(\Omega_3; H^1(\Omega_2))$. Moreover, $\bar{v}_3 \in L^2(\Omega_3; H^1(\Omega_{12}))$ and, from (23) and the fact that $\bar{v}_3$, $\bar{v}_3^\varepsilon \in L^2(\Omega)$, we then obtain easily that $⨍_{\Omega_{12}} \bar{v}_3 dx' = 0$, which concludes the proof. □

LEMMA 5.3 (characterization of the space $\mathscr{V}$). *The space $\mathscr{V}$ admits the following characterization:*

$$\begin{aligned}\mathscr{V} = \{v \in H^1_{dn}(\Omega)^2 \times L^2(\Omega_3; H^1_m(\Omega_{12})) : E_{\alpha\beta}(v) = 0,\ E_{13}(v) = 0,\\ E_{23}(v) \in L^2(\Omega) \text{ and } \textstyle\int_{\Omega_{12}} v_\alpha\, dx' = 0 \text{ a.e.}\}.\end{aligned} \tag{24}$$

Moreover, it is a Hilbert space with the norm

$$\|v\|_{\mathscr{V}} := \|W_{13}(v)\|_{L^2(\Omega)} + \|E_{23}(v)\|_{L^2(\Omega)},$$

where

$$W_{13}(v) = \frac{1}{2}\left(\frac{\partial v_1}{\partial x_3} - \frac{\partial v_3}{\partial x_1}\right).$$

Proof. Let us call V the space at the right-hand side of equality (24) and let $\mathscr{V}$ be as in the statement of Lemma 5.2. It is trivial to check that $\mathscr{V} \subseteq V$. Let us prove the opposite inclusion. Let $v \in V$. Since $v_\alpha \in H^1_{dn}(\Omega)$ and $E_{\alpha\beta}(v) = 0$, by integration there exists $\vartheta \in L^2(\Omega_3)$ such that

$$v_1 = -x_2\vartheta(x_3) + a_1(x_3), \quad v_2 = x_1\vartheta(x_3) + a_2(x_3),$$

and since $\int_{\Omega_{12}} v_\alpha \, dx' = 0$, we have $a_1 = a_2 = 0$ a.e.. From the resulting expression of v_α it follows that $\vartheta \in H^1_{dn}(\Omega)$ and $\vartheta(0) = 0$.

Since $E_{13}(v) = 0$ we obtain that $\partial v_3/\partial x_1 = x_2 \vartheta'(x_3)$. Then there exists $\varrho \in L^2(\Omega_{23})$ such that

$$v_3 = x_1 x_2 \vartheta'(x_3) + \varrho(x_2, x_3),$$

from which it follows also that $\varrho \in L^2(\Omega_3; H^1_m(\Omega_2))$ and that $E_{23}(v) \in L^2(\Omega)$.

The last part of the claim follows from the fact that $L^2(\Omega_3; H^1_m(\Omega_{12})$ is a Hilbert space with the scalar product

$$\langle u_3, v_3 \rangle_{L^2(\Omega_3; H^1_m(\Omega_{12}))} = \int_{\Omega_3} \langle u_3(x_3), v_3(x_3) \rangle_{H^1_m(\Omega_{12})} \, dx_3,$$

and $\mathscr{V}$ is a closed subspace of $H^1_{dn}(\Omega)^2 \times L^2(\Omega_3; H^1_m(\Omega_{12}))$ which is Hilbert with the product norm

$$\|v_1\|_{H^1_{dn}(\Omega)} + \|v_2\|_{H^1_{dn}(\Omega)} + \|v_3\|_{L^2(\Omega_3; H^1_m(\Omega_{12}))}$$

induced by $H^1_{dn}(\Omega)^2 \times L^2(\Omega_3; H^1_m(\Omega_{12}))$. The proof that this norm is equivalent to $\|v\|_{\mathscr{V}}$ is an easy consequence of the Poincaré inequality, the representation lemma, Lemma 5.2, and the characterization of the space $\mathscr{V}$ proved above. ∎

LEMMA 5.4 (components 22 and 13). *There exists a function $\bar{w}$ in the space*

$$\mathscr{W} = \{ w \in RD^\perp_2(\Omega) \times H^{-1}_{m_1}(\Omega_3; L^2(\Omega_{12})) \ : \ E_{11}(w) = E_{12}(w) = 0, \ E_{13}(w) \in L^2(\Omega) \}$$

such that

$$E_{22} = \frac{\partial \bar{w}_2}{\partial x_2} = E_{22}(\bar{w}), \quad E_{13} = \frac{1}{2}\left(\frac{\partial \bar{w}_1}{\partial x_3} + \frac{\partial \bar{w}_3}{\partial x_1} \right) = E_{13}(\bar{w}).$$

Moreover, $\mathscr{W}$ is a Hilbert space with the norm

$$\|w\|_{\mathscr{W}} := \|E_{22}(w)\|_{L^2(\Omega)} + \|E_{13}(w)\|_{L^2(\Omega)} + \|w_3\|_{H^{-1}_{m_1}(\Omega_3; L^2(\Omega_{12}))}.$$

Proof. Let

$$w^\varepsilon := \frac{1}{\varepsilon^2} u^\varepsilon;$$

then

$$\begin{aligned} &\|E_{11}(w^\varepsilon)\|_{L^2(\Omega)} \le C\varepsilon^2, \qquad \|E_{12}(w^\varepsilon)\|_{L^2(\Omega)} \le C\varepsilon, \\ &\|E_{22}(w^\varepsilon)\|_{L^2(\Omega)} \le C, \qquad \|E_{13}(w^\varepsilon)\|_{L^2(\Omega)} \le C. \end{aligned} \tag{25}$$

Let us recall that $\tilde{w}^\varepsilon_\alpha := w^\varepsilon_\alpha - \wp_\alpha(w^\varepsilon)$. By Lemma 4.1 and using (25), we have

$$\|\tilde{w}^\varepsilon\|_{L^2(\Omega_3; H^1(\Omega_{12}; \mathbb{R}^2))} \le C \sum_{\alpha,\beta} \|E_{\alpha\beta}(w^\varepsilon)\|_{L^2(\Omega)} \le C,$$

$⨍_{\Omega_{12}} \tilde{w}^\varepsilon \, dx' = 0$, and $\vartheta(\tilde{w}^\varepsilon) = 0$. Thus, up to a subsequence,

$$\tilde{w}^\varepsilon_\alpha \rightharpoonup \bar{w}_\alpha \quad \text{in } L^2(\Omega_3; H^1(\Omega_{12})) \text{ for } \alpha = 1, 2; \tag{26}$$

moreover, a.e.,

$$\fint_{\Omega_{12}} \bar{w}_\alpha dx' = 0,\ \vartheta(\bar{w}) = 0. \tag{27}$$

Hence $(\bar{w}_1, \bar{w}_2) \in RD_2^\perp(\Omega)$ (see (12)). Using (25) we also obtain

$$E_{11}(\bar{w}) = E_{12}(\bar{w}) = 0.$$

Moreover,

$$E_{22}^\varepsilon(u^\varepsilon) = E_{22}(w^\varepsilon) = E_{22}(\tilde{w}^\varepsilon) \rightharpoonup E_{22}(\bar{w}) \text{ in } L^2(\Omega).$$

Let

$$\tilde{w}_3^\varepsilon := w_3^\varepsilon - \left(x_1 x_2 \frac{d\vartheta(w^\varepsilon)}{dx_3} - x_1 \frac{d}{dx_3} \fint_{\Omega_{12}} w_1^\varepsilon \, dx' + \fint_{\Omega_1} w_3^\varepsilon \, dx_1 \right).$$

By Theorem 4.3 we have that

$$\|\tilde{w}_3^\varepsilon\|_{H^{-1}(\Omega_3; L^2(\Omega_{12}))} \le C \left(\sum_{\alpha,\beta} \|E_{\alpha\beta}(w^\varepsilon)\|_{L^2(\Omega)} + \|E_{13}(w^\varepsilon)\|_{L^2(\Omega)} \right) \le C.$$

Hence, up to a subsequence,

$$\tilde{w}_3^\varepsilon \rightharpoonup w_3 \quad \text{ in } H^{-1}(\Omega_3; L^2(\Omega_{12})).$$

Taking into account that (see (16))

$$\wp_1(w^\varepsilon) = \fint_{\Omega_{12}} w_1^\varepsilon \, dx' - x_2 \vartheta(w^\varepsilon), \quad \wp_2(w^\varepsilon) = \fint_{\Omega_{12}} w_2^\varepsilon \, dx' + x_1 \vartheta(w^\varepsilon),$$

we easily deduce that $E_{13}^\varepsilon(u^\varepsilon) = E_{13}(w^\varepsilon) = E_{13}(\tilde{w}^\varepsilon)$ and hence that

$$E_{13} = \frac{1}{2} \left(\frac{\partial \bar{w}_1}{\partial x_3} + \frac{\partial \bar{w}_3}{\partial x_1} \right).$$

Finally, since $\fint_{\Omega_1} \tilde{w}_3^\varepsilon \, dx_1 = 0$, we have that

$$\langle \bar{w}_3, \varphi \rangle_{H^{-1}(\Omega_3; L^2(\Omega_{12})) \times H_0^1(\Omega_3; L^2(\Omega_{12}))} = 0$$

for all $\varphi \in H_0^1(\Omega_3; L^2(\Omega_2))$.

The last part of the claim follows from the fact that $\mathscr{W}$ is a closed subspace of

$$\{ z \in RD_2^\perp(\Omega) \times H_{m_1}^{-1}(\Omega_3; L^2(\Omega_{12})) \ : \ E_{13}(z) \in L^2(\Omega) \}$$

which, in turn, is a Hilbert space under the scalar product

$$\langle z, \zeta \rangle := \langle z, \zeta \rangle_{RD_2^\perp(\Omega) \times H_{m_1}^{-1}(\Omega_3; L^2(\Omega_{12}))} + \int_\Omega E_{13}(z) E_{13}(\zeta) \, dx$$

and from an application of Proposition 4.1. □

LEMMA 5.5 (representation of the space $\mathscr{W}$). *The space $\mathscr{W}$ admits the following representation:*

$$\mathscr{W} = \Big\{ w \in L^2(\Omega_3; H^1(\Omega_{12}))^2 \times H^{-1}_{m_1}(\Omega_3; L^2(\Omega_{12})) \ : \ E_{13}(w) \in L^2(\Omega),$$

there exists $\eta_1 \in L^2(\Omega_3; H^2(\Omega_2))$ and $\eta_2 \in L^2(\Omega_3; H^1(\Omega_2))$ such that

$$w_1(x) = \eta_1(x_2, x_3), \quad w_2(x) = -x_1 \frac{\partial \eta_1}{\partial x_2}(x_2, x_3) + \eta_2(x_2, x_3), \tag{28}$$

$$\int_{\Omega_2} \eta_\alpha \, dx_2 = 0, \quad \int_{\Omega_2} \left(\frac{a_1^2}{12} \frac{\partial \eta_1}{\partial x_2} + x_2 \eta_1 \right) dx_2 = 0 \Big\}.$$

Proof. Let us call W the set on the right-hand side of equality (28), and let $\mathscr{W}$ be as in the statement of Lemma 5.4. Then it is trivial to check that $W \subseteq \mathscr{W}$. Let us prove the converse inequality. Let $w \in \mathscr{W}$ as in Lemma 5.4. Since $E_{11}(w) = E_{12}(w) = 0$, by integration we deduce that there exist $\eta_1 \in L^2(\Omega_3; H^2(\Omega_2))$ and $\eta_2 \in L^2(\Omega_3; H^1(\Omega_2))$ such that

$$w_1(x) = \eta_1(x_2, x_3), \quad w_2(x) = -x_1 \frac{\partial \eta_1}{\partial x_2}(x_2, x_3) + \eta_2(x_2, x_3).$$

Since

$$⨍_{\Omega_{12}} w_\alpha dx' = 0, \quad \vartheta(w) = 0, \tag{29}$$

we have that

$$\int_{\Omega_2} \eta_\alpha \, dx_2 = 0 \quad \text{a.e. for } \alpha = 1, 2,$$

and

$$\int_{\Omega_2} \left(\frac{a_1^2}{12} \frac{\partial \eta_1}{\partial x_2} + x_2 \eta_1 \right) dx_2 = 0,$$

a.e.. □

LEMMA 5.6 (component 12). *There exists a vector function $\bar{p}$ in the set*

$$\mathscr{P} = \{0\} \times H^1_{m_1}(\Omega_1; L^2(\Omega_{23})) \times \{0\}$$

such that

$$E_{12} = \frac{1}{2} \frac{\partial \bar{p}_2}{\partial x_1} = E_{12}(\bar{p}). \tag{30}$$

Moreover, $\mathscr{P}$ is a Hilbert space with the norm

$$\|p\|_{\mathscr{P}} := \|E_{12}(p)\|.$$

Proof. Let

$$p^\varepsilon_\alpha := \frac{1}{\varepsilon^3} u^\varepsilon_\alpha \quad \text{for } \alpha = 1, 2,$$

and

$$\bar{p}^\varepsilon_1 := p^\varepsilon_1 - ⨍_{\Omega_1} p^\varepsilon_1 \, dx_1, \quad \bar{p}^\varepsilon_2 := p^\varepsilon_2 - ⨍_{\Omega_1} p^\varepsilon_2 \, dx_1 + x_1 \frac{\partial}{\partial x_2} ⨍_{\Omega_1} p^\varepsilon_1 \, dx_1.$$

Then $E_{11}(\bar{p}^\varepsilon) = E_{11}(p^\varepsilon) = \varepsilon E^\varepsilon_{11}(u^\varepsilon)$; hence, by Theorem 4.1 we have

$$\bar{p}^\varepsilon_1 \to 0, \quad \frac{\partial \bar{p}^\varepsilon_1}{\partial x_1} \to 0 \quad \text{in } L^2(\Omega).$$

Since $E_{12}(\bar{p}^\varepsilon) = E_{12}(p^\varepsilon) = E^\varepsilon_{12}(u^\varepsilon)$, by Theorem 4.2 we also have that, up to subsequences,

$$\bar{p}^\varepsilon_2 \rightharpoonup \bar{p}_2 \text{ in } H^{-1}(\Omega_2; L^2(\Omega_{13})).$$

Setting $\bar{p} := (0, \bar{p}_2, 0)$, we have

$$E_{12} = E_{12}(\bar{p}) = \frac{1}{2}\frac{\partial \bar{p}_2}{\partial x_1},$$

that is, (30). It remains then to prove that $\bar{p}_2 \in H^1(\Omega_1; L^2(\Omega_{23}))$ and that $⨍_{\Omega_1} \bar{p}_2 \, dx_1 = 0$.

Since $\bar{p}_2 \in H^{-1}(\Omega_2; L^2(\Omega_{13}))$, for any $\varphi \in H^1_0(\Omega_2)$ and any $\psi \in L^2(\Omega_{13})$ the product $\varphi \otimes \psi$ belongs to $H^1_0(\Omega_2; L^2(\Omega_{13}))$, and the linear map

$$P_\varphi : L^2(\Omega_{13}) \to \mathbb{R}, \quad \langle P_\varphi, \psi \rangle := \langle \bar{p}_2, \varphi \otimes \psi \rangle$$

satisfies the estimate

$$|\langle P_\varphi, \psi \rangle| \le \|\bar{p}_2\|_{H^{-1}} \|\varphi\|_{H^1_0} \|\psi\|_{L^2}.$$

Thus $P_\varphi \in L^2(\Omega_{13})$. Moreover, from the definition of P_φ and the fact that $\frac{\partial \bar{p}_2}{\partial x_1} \in L^2(\Omega)$, we obtain that $\frac{\partial P_\varphi}{\partial x_1} \in L^2(\Omega_{13})$ and also that

$$\frac{\partial P_\varphi}{\partial x_1} = \int_{\Omega_2} \frac{\partial \bar{p}_2}{\partial x_1} \varphi \, dx_2. \tag{31}$$

Since $⨍_{\Omega_1} \bar{p}^\varepsilon_2 \, dx_1 = 0$ it follows from the definitions that

$$⨍_{\Omega_1} P_\varphi(s, x_3) \, ds = \langle \bar{p}_2, \varphi \rangle = 0 \tag{32}$$

for almost every $x_3 \in \Omega_3$; using this fact, the following Poincaré inequality holds:

$$\|P_\varphi(\cdot, x_3)\|_{L^2(\Omega_1)} \le C \left\| \frac{\partial P_\varphi}{\partial x_1}(\cdot, x_3) \right\|_{L^2(\Omega_1)},$$

where the constant C depends only on the domain Ω_1 and is therefore independent of x_3. By substituting (31) inside the Poincaré inequality, we obtain that

$$\|P_\varphi\|_{L^2(\Omega_{13})} \le C \left\| \frac{\partial \bar{p}_2}{\partial x_1} \right\|_{L^2(\Omega)} \|\varphi\|_{L^2(\Omega_2)}. \tag{33}$$

Using the density of $C^\infty_c(\Omega_2) \otimes C^\infty_c(\Omega_{13})$ in $L^2(\Omega)$ (see, for instance, Treves [10, Theorem 39.2 and subsequent Corollary 3]), the fact that $P_\varphi \in L^2(\Omega_{13})$, and inequality (33), we have that

$$\begin{aligned}
\|\bar{p}_2\|_{L^2(\Omega)} &= \sup_{\varphi \in C^\infty_c(\Omega_2),\ \psi \in C^\infty_c(\Omega_{13})} \frac{|\langle \bar{p}_2, \varphi\psi \rangle|}{\|\varphi\|_{L^2(\Omega_2)} \|\psi\|_{L^2(\Omega_{13})}} \\
&= \sup_{\varphi \in C^\infty_c(\Omega_2),\ \psi \in C^\infty_c(\Omega_{13})} \frac{|\langle P_\varphi, \psi \rangle|}{\|\varphi\|_{L^2(\Omega_2)} \|\psi\|_{L^2(\Omega_{13})}} \\
&\le \sup_{\varphi \in C^\infty_c(\Omega_2)} \frac{\|P_\varphi\|_{L^2(\Omega_{13})}}{\|\varphi\|_{L^2(\Omega_2)}} \le C \left\| \frac{\partial \bar{p}_2}{\partial x_1} \right\|_{L^2(\Omega)};
\end{aligned}$$

hence $\bar{p}_2 \in L^2(\Omega)$. Thus $\bar{p}_2 \in H^1(\Omega_1; L^2(\Omega_{23}))$, and (32) implies $⨍_{\Omega_1} \bar{p}_2\, dx_1 = 0$.

The last part of the claim follows from the fact that $H^1_{m_1}(\Omega_1; L^2(\Omega_{23}))$ is a Hilbert space with the norm

$$\|p\|_{H^1_{m_1}(\Omega_1;L^2(\Omega_{23}))} := \left\| \frac{\partial p_2}{\partial x_1} \right\|_{L^2(\Omega)},$$

which, by Theorem 4.1, turns out to be equivalent to the canonical one. ∎

LEMMA 5.7 (component 11). *There exists a function $\bar{q}$ in the space*

$$\mathscr{Q} := H^1_{m_1}(\Omega_1; L^2(\Omega_{23})) \times \{0\}^2$$

such that

$$E_{11} = \frac{\partial \bar{q}_1}{\partial x_1} = E_{11}(\bar{q}).$$

Moreover, $\mathscr{Q}$ is a Hilbert space with the norm

$$\|q\|_{\mathscr{Q}} := \|E_{11}(q)\|.$$

Proof. Let

$$q_1^\varepsilon := \frac{1}{\varepsilon^4}\left(u_1^\varepsilon - ⨍_{\Omega_1} u_1^\varepsilon dx_1 \right);$$

then

$$\sup_\varepsilon \left\| \frac{\partial q_1^\varepsilon}{\partial x_1} \right\|_{L^2(\Omega)} = \sup_\varepsilon \|E_{11}^\varepsilon(u^\varepsilon)\|_{L^2(\Omega)} \le C,$$

and by Theorem 4.1 we have $\sup_\varepsilon \|q_1^\varepsilon\|_{L^2(\Omega)} \le C$. Then, up to a subsequence, $q_1^\varepsilon \rightharpoonup \bar{q}_1$ in $L^2(\Omega)$, and $E_{11}^\varepsilon(u^\varepsilon) = \partial \bar{q}_1^\varepsilon / \partial x_1 \rightharpoonup \partial \bar{q}_1 / \partial x_1$ in $L^2(\Omega)$ for some $\bar{q}_1 \in L^2(\Omega)$.

The last part of the claim follows from the fact that $H^1_{m_1}(\Omega_1; L^2(\Omega_{23}))$ is a Hilbert space with the norm

$$\|q\|_{H^1_{m_1}(\Omega_1;L^2(\Omega_{23}))} := \|q_{1,1}\|_{L^2(\Omega)},$$

which, by Theorem 4.1, turns out to be equivalent to the canonical one. ∎

6. The limit problem. Let us consider the space $\mathscr{A} := \mathscr{U} \times \mathscr{V} \times \mathscr{W} \times \mathscr{P} \times \mathscr{Q}$. According to the notation and the results proved in the previous section, $\mathscr{A}$ is a Hilbert space when endowed with the product norm

$$\|(u, v, w, p, q)\|_{\mathscr{A}} := \|u\|_{\mathscr{U}} + \|v\|_{\mathscr{V}} + \|w\|_{\mathscr{W}} + \|p\|_{\mathscr{P}} + \|q\|_{\mathscr{Q}}.$$

Given a 5-tuple of vector valued distributions $(u, v, w, p, q) \in \mathcal{D}'(\Omega; \mathbb{R}^3)^5$, let us define

$$E(u, v, w, p, q) := \begin{pmatrix} E_{11}(q) & E_{12}(p) & E_{13}(w) \\ & E_{22}(w) & E_{23}(v) \\ \text{Sym.} & & E_{33}(u) \end{pmatrix}. \tag{34}$$

We are now in a position to state the main result of this paper.

THEOREM 6.1. *Let $\mathbb{C}$ be a positive definite fourth order tensor field on Ω with the minor symmetries, i.e., $\mathbb{C}_{ijkl} = \mathbb{C}_{jikl} = \mathbb{C}_{ijlk}$. Let F^ε be a second order symmetric tensor field which belongs to $L^2(\Omega;\mathbb{R}^{3\times 3})$. Then problem* (6)*, that is,*

$$\text{(35)}\qquad \begin{cases} u^\varepsilon \in H^1_{dn}(\Omega;\mathbb{R}^3), \\ \displaystyle\int_\Omega \mathbb{C}E^\varepsilon(u^\varepsilon)\cdot E^\varepsilon(\varphi)\,dx = \int_\Omega F^\varepsilon \cdot E^\varepsilon(\varphi)\,dx \quad \forall \varphi \in H^1_{dn}(\Omega;\mathbb{R}^3), \end{cases}$$

admits a unique solution u^ε. Moreover, if $F^\varepsilon \to F$ in $L^2(\Omega;\mathbb{R}^{3\times 3})$, then we have the following:

1. *the problem*

$$\text{(36)}\qquad \int_\Omega \mathbb{C}E(\bar u,\bar v,\bar w,\bar p,\bar q)\cdot E(u,v,w,p,q)\,dx = \int_\Omega F\cdot E(u,v,w,p,q)\,dx \quad \forall\,(u,v,w,p,q)\in \mathscr{A}$$

   admits a unique solution $(\bar u,\bar v,\bar w,\bar p,\bar q)\in\mathscr{A}$;
2. *$u^\varepsilon \rightharpoonup \bar u$ in $H^1(\Omega;\mathbb{R}^3)$;*
3. *$E^\varepsilon(u^\varepsilon)\to E(\bar u,\bar v,\bar w,\bar p,\bar q)$ in $L^2(\Omega;\mathbb{R}^{3\times 3})$.*

The following corollary can be seen as a corrector result.

COROLLARY 6.1. *If the solution $(\bar u,\bar v,\bar w,\bar p,\bar q)$ of problem* (36) *is such that*

$$\text{(37)}\qquad \frac{\partial \bar v_3}{\partial x_3},\ E_{23}(\bar w),\ \frac{\partial \bar w_3}{\partial x_3},\ \frac{\partial \bar q_1}{\partial x_2},\ \frac{\partial \bar q_1}{\partial x_3},\ \frac{\partial \bar p_2}{\partial x_2},\ \frac{\partial \bar p_2}{\partial x_3} \in L^2(\Omega),$$

then

$$\|E^\varepsilon(u^\varepsilon) - E^\varepsilon(\bar u^\varepsilon)\|_{L^2(\Omega;\mathbb{R}^{3\times 3})}\to 0,$$

where

$$\bar u^\varepsilon := \bar u + \varepsilon\bar v + \varepsilon^2\bar w + \varepsilon^3\bar p + \varepsilon^4\bar q.$$

Proof. Since

$$E^\varepsilon(\bar u^\varepsilon) = E(\bar u,\bar v,\bar w,\bar p,\bar q) + \varepsilon\begin{pmatrix} 0 & E_{12}(\bar q) & 0 \\ & E_{22}(\bar p) & E_{23}(\bar w) \\ \text{Sym.} & & E_{33}(\bar v)\end{pmatrix} + \varepsilon^2\begin{pmatrix} 0 & 0 & E_{13}(\bar q) \\ & 0 & E_{23}(\bar p) \\ \text{Sym.} & & E_{33}(\bar w)\end{pmatrix}$$

the additional regularity assumptions imply that $E^\varepsilon(\bar u^\varepsilon)\in L^2(\Omega;\mathbb{R}^{3\times 3})$ and

$$\|E^\varepsilon(\bar u^\varepsilon) - E(\bar u,\bar v,\bar w,\bar p,\bar q)\|_{L^2(\Omega;\mathbb{R}^{3\times 3})}\to 0.$$

Then the claim follows from step 3 of Theorem 6.1. ∎

In order to prove Theorem 6.1, we introduce the subspaces of $H^1_{dn}(\Omega;\mathbb{R}^3)$,

$$\hat{\mathscr{U}} := \{u\in H^1_{dn}(\Omega;\mathbb{R}^3)\ :\ E_{\alpha\beta}(u) = E_{\alpha 3}(u) = 0\},$$
$$\hat{\mathscr{V}} := \{v\in H^1_{dn}(\Omega;\mathbb{R}^3)\ :\ E_{\alpha\beta}(v) = E_{13}(v) = 0\},$$
$$\hat{\mathscr{W}} := \{w\in H^1_{dn}(\Omega;\mathbb{R}^3)\ :\ E_{1\beta}(w) = 0\},$$
$$\hat{\mathscr{P}} := \{p\in H^1_{dn}(\Omega;\mathbb{R}^3)\ :\ E_{11}(p) = 0\},$$
$$\hat{\mathscr{Q}} := H^1_{dn}(\Omega;\mathbb{R}^3),$$

and define $\hat{\mathscr{A}} := \hat{\mathscr{U}} \times \hat{\mathscr{V}} \times \hat{\mathscr{W}} \times \hat{\mathscr{P}} \times \hat{\mathscr{Q}}$.

Let us note that $\mathscr{U} = \hat{\mathscr{U}}$, but similar equalities are not true for the spaces $\mathscr{V}$, $\mathscr{W}$, $\mathscr{P}$, and $\mathscr{Q}$. Nevertheless, for such spaces we can prove the following approximation lemma.

LEMMA 6.1. *For every $v \in \mathscr{V}$, $w \in \mathscr{W}$, $p \in \mathscr{P}$, and $q \in \mathscr{Q}$ there exist sequences $(\hat{v}^n)$ in $\hat{\mathscr{V}}$, $(\hat{w}^n)$ in $\hat{\mathscr{W}}$, $(\hat{p}^n)$ in $\hat{\mathscr{P}}$, and $(\hat{q}^n)$ in $\hat{\mathscr{Q}}$ such that the following convergences hold in the norm of $L^2(\Omega)$:*

(i) $E_{23}(\hat{v}^n) \to E_{23}(v)$,
(ii) $E_{13}(\hat{w}^n) \to E_{13}(w)$ *and* $E_{22}(\hat{w}^n) \to E_{22}(w)$,
(iii) $E_{12}(\hat{p}^n) \to E_{12}(p)$,
(iv) $E_{11}(\hat{q}^n) \to E_{11}(q)$.

Proof. Let us prove (i). Since $v \in \mathscr{V}$ (see Lemma 5.2), there exist $\vartheta \in H^1(\Omega_3)$ with $\vartheta(0) = 0$ and $\varrho \in L^2(\Omega_3; H^1(\Omega_2))$ such that

$$v_1(x) = -x_2\vartheta(x_3), \quad v_2(x) = x_1\vartheta(x_3),$$
$$v_3(x) = x_1x_2\frac{d\vartheta}{dx_3}(x_3) + \varrho(x_2, x_3).$$

Then there exist sequences $\vartheta_n \in H^2_{dn}(\Omega_3)$ and $\varrho_n \in H^1_{dn}(\Omega_{23})$ such that

$$\vartheta_n \to \vartheta \text{ in } H^1(\Omega_3), \quad \varrho_n \to \varrho \text{ in } L^2(\Omega_3; H^1(\Omega_2)).$$

Setting

$$\hat{v}^n_1(x) = -x_2\vartheta_n(x_3), \quad \hat{v}^n_2(x) = x_1\vartheta_n(x_3),$$
$$\hat{v}^n_3(x) = x_1x_2\frac{d\vartheta_n}{dx_3}(x_3) + \varrho_n(x_2, x_3),$$

we obtain the claim.

Let us prove (ii). As $w \in \mathscr{W}$ (see Lemma 5.4), there exist $\eta_1 \in L^2(\Omega_3; H^2(\Omega_2))$ and $\eta_2 \in L^2(\Omega_3; H^1(\Omega_2))$ such that

$$w_1(x) = \eta_1(x_2, x_3), \quad w_2(x) = -x_1\frac{\partial\eta_1}{\partial x_2}(x_2, x_3) + \eta_2(x_2, x_3).$$

Then, there exist a sequence $\eta^n_1 \in H^2_{dn}(\Omega)$ with $\partial\eta^n_1/\partial x_1 = 0$ such that

$$\eta^n_1 \to \eta_1 \quad \text{in } L^2(\Omega_3; H^2(\Omega_2))$$

and a sequence $\eta^n_2 \in H^1_{dn}(\Omega)$ with $\partial\eta^n_2/\partial x_1 = 0$ such that

$$\eta^n_2 \to \eta_2 \quad \text{in } L^2(\Omega_3; H^1(\Omega_2)).$$

Since $\partial w_3/\partial x_1 = 2E_{13}(w) - \partial\eta_1/\partial x_3$ and $E_{13}(w) \in L^2(\Omega)$, by integration, there exists $G_{13} \in H^1(\Omega_1; L^2(\Omega_{23}))$ such that

$$\frac{\partial G_{13}}{\partial x_1} = E_{13}(w) \quad \text{and} \quad w_3 = 2G_{13} - x_1\frac{\partial\eta_1}{\partial x_3},$$

where we have also used the fact that η_1 does not depend on x_1.

We may also find a sequence $G^n_{13} \in H^1_{dn}(\Omega)$ such that

$$G^n_{13} \to G_{13} \quad \text{in } H^1(\Omega_1; L^2(\Omega_{23}))$$

and define

$$\hat{w}_1^n := \eta_1^n, \quad \hat{w}_2^n := -x_1 \frac{\partial \eta_1^n}{\partial x_2} + \eta_2^n, \quad \hat{w}_3^n := G_{13}^n - x_1 \frac{\partial \eta_1^n}{\partial x_3}.$$

Then $\hat{w}^n \in H^1_{dn}(\Omega)$, $E_{11}(\hat{w}^n) = \partial \eta_1^n / \partial x_1 = 0$, and $E_{12}(\hat{w}^n) = 0$ so that $\hat{w}^n \in \hat{\mathscr{W}}$. Moreover,

$$E_{13}(\hat{w}^n) = \frac{\partial G_{13}^n}{\partial x_1} \rightarrow \frac{\partial G_{13}}{\partial x_1} = E_{13}(w) \quad \text{in } L^2(\Omega),$$

and

$$E_{22}(\hat{w}^n) = \frac{\partial \hat{w}_2^n}{\partial x_2} = -x_1 \frac{\partial^2 \eta_1^n}{\partial x_2^2} + \frac{\partial \eta_2^n}{\partial x_2} \rightarrow \frac{\partial \hat{w}_2}{\partial x_2} = E_{22}(\hat{w}) \quad \text{in } L^2(\Omega).$$

To prove (iii) it is enough to consider, for a given $p = (0, p_2, 0) \in \mathscr{P}$, a sequence $\hat{p}_2^n \in H^1_{dn}(\Omega)$, which converges to p_2 in the norm of $H^1(\Omega_1; L^2(\Omega_{23}))$, and set $\hat{p}^n = (0, \hat{p}_2^n, 0)$. Finally, claim (iv) simply follows from the density of $H^1_{dn}(\Omega)$ in $H^1_{m_1}(\Omega_1; L^2(\Omega_{23}))$. □

Proof of Theorem 6.1. The existence and uniqueness of the solution of problem (36) follows from an application of the Lax–Milgram lemma to the symmetric bilinear form defined on $\mathscr{A}$ by

$$a[(u, v, w, p, q), (\hat{u}, \hat{v}, \hat{w}, \hat{p}, \hat{q})] := \int_\Omega \mathbb{C} E(u, v, w, p, q) \cdot E(\hat{u}, \hat{v}, \hat{w}, \hat{p}, \hat{q})\, dx,$$

which is continuous and coercive with respect to the Hilbertian norm on $\mathscr{A}$ defined at the beginning of this section.

Part 2 of the statement of Theorem 6.1 is actually a consequence of step 3. Let us now prove part 3. According to the results proved in the previous section, we have

$$E^\varepsilon(u^\varepsilon) \rightharpoonup E \text{ in } L^2(\Omega; \mathbb{R}^{3\times 3}), \tag{38}$$

and there exists a $(\bar{u}, \bar{v}, \bar{w}, \bar{p}, \bar{q}) \in \mathscr{A}$ such that

$$E = \begin{pmatrix} E_{11}(\bar{q}) & E_{12}(\bar{p}) & E_{13}(\bar{w}) \\ & E_{22}(\bar{w}) & E_{23}(\bar{v}) \\ \text{Sym.} & & E_{33}(\bar{u}) \end{pmatrix} = E(\bar{u}, \bar{v}, \bar{w}, \bar{p}, \bar{q}).$$

The result will be achieved in two steps: (i) we prove that $(\bar{u}, \bar{v}, \bar{w}, \bar{p}, \bar{q})$ satisfies equality (36) and therefore coincides with the unique solution of the variational problem, and (ii) we show that the convergence in (38) is indeed strong.

Let $(\hat{u}, \hat{v}, \hat{w}, \hat{p}, \hat{q}) \in \hat{\mathscr{A}}$ and set

$$\hat{\varphi}^\varepsilon := \hat{u} + \varepsilon \hat{v} + \varepsilon^2 \hat{w} + \varepsilon^3 \hat{p} + \varepsilon^4 \hat{q};$$

then $\hat{\varphi}^\varepsilon \in H^1_{dn}(\Omega; \mathbb{R}^3)$ and an easy computation shows that, as $\varepsilon \rightarrow 0$,

$$E^\varepsilon(\hat{\varphi}^\varepsilon) \rightarrow \begin{pmatrix} E_{11}(\hat{q}) & E_{12}(\hat{p}) & E_{13}(\hat{w}) \\ & E_{22}(\hat{w}) & E_{23}(\hat{v}) \\ \text{Sym.} & & E_{33}(\hat{u}) \end{pmatrix} = E(\hat{u}, \hat{v}, \hat{w}, \hat{p}, \hat{q}) \tag{39}$$

in the norm convergence of $L^2(\Omega;\mathbb{R}^{3\times 3})$. Taking $\varphi = \hat{\varphi}^\varepsilon$ in (35) and passing to the limit we find

$$\int_\Omega \mathbb{C}E(\bar{u},\bar{v},\bar{w},\bar{p},\bar{q})\cdot E(\hat{u},\hat{v},\hat{w},\hat{p},\hat{q})\,dx = \int_\Omega F\cdot E(\hat{u},\hat{v},\hat{w},\hat{p},\hat{q})\,dx,$$

for every $(\hat{u},\hat{v},\hat{w},\hat{p},\hat{q}) \in \hat{\mathscr{A}}$. This equality holds in fact for any $(u,v,w,p,q) \in \mathscr{A}$ in place of $(\hat{u},\hat{v},\hat{w},\hat{p},\hat{q}) \in \hat{\mathscr{A}}$ because of the approximation Lemma 6.1 which ensures that there exists a sequence $(u,\hat{v}^n,\hat{w}^n,\hat{p}^n,\hat{q}^n) \in \hat{\mathscr{A}}$ such that

$$\|(u,\hat{v}^n,\hat{w}^n,\hat{p}^n,\hat{q}^n) - (u,v,w,p,q)\|_{\mathscr{A}} \to 0.$$

To show that the convergence in (38) is indeed strong, it suffices to prove that $\lim_{\varepsilon\to 0}\|E^\varepsilon(u^\varepsilon)\|_{L^2(\Omega;\mathbb{R}^{3\times 3})} = \|E(\bar{u},\bar{v},\bar{w},\bar{p},\bar{q})\|_{L^2(\Omega;\mathbb{R}^{3\times 3})}$ or, equivalently, that

$$\begin{aligned}\lim_{\varepsilon\to 0}\int_\Omega \mathbb{C}E^\varepsilon(u^\varepsilon)\cdot E^\varepsilon(u^\varepsilon)\,dx &= \lim_{\varepsilon\to 0}\int_\Omega F^\varepsilon\cdot E^\varepsilon(u^\varepsilon)\,dx\\ &= \int_\Omega F\cdot E(\bar{u},\bar{v},\bar{w},\bar{p},\bar{q})\,dx\\ &= \int_\Omega \mathbb{C}E(\bar{u},\bar{v},\bar{w},\bar{p},\bar{q})\cdot E(\bar{u},\bar{v},\bar{w},\bar{p},\bar{q})\,dx,\end{aligned}$$

where we passed to the limit thanks to the strong convergence of F^ε. □

7. Equilibrium differential equations. In this last section we derive the differential formulation of the limit problem. For simplicity we assume here that the elasticity tensor also satisfies the major symmetries; that is, $\mathbb{C}_{ijkl} = \mathbb{C}_{klij}$ for any i,j,k,l. Nevertheless, the same computation can be performed also in the general case.

To make (36) more explicit and to keep the notation compact, in writing the elasticity tensor components $\mathbb{C}_{ijkl}$ we associate to a pair of components ij a single component s following the rule $11\mapsto 1, 22\mapsto 2, 33\mapsto 3, 23\mapsto 4, 13\mapsto 5, 12\mapsto 6$, and we write, for instance, c_{14} for $\mathbb{C}_{1123}$; see Auld [1] for more details on the notation used. Clearly $c_{ij} = c_{ji}$. Still, for brevity, define $\bar{e}_1 = E_{11}(\bar{q})$, $\bar{e}_2 = E_{22}(\bar{w})$, $\bar{e}_3 = E_{33}(\bar{u})$, $\bar{e}_4 = 2E_{23}(\bar{v})$, $\bar{e}_5 = 2E_{13}(\bar{w})$, $\bar{e}_6 = 2E_{12}(\bar{p})$. Letting

$$\mathscr{L}(u,v,w,p,q) := \int_\Omega F\cdot E(u,v,w,p,q)\,dx,$$

we can then rewrite (36) as

$$\begin{aligned}\int_\Omega \sum_{j=1}^6 \big[&c_{1j}\bar{e}_j E_{11}(q) + c_{2j}\bar{e}_j E_{22}(w) + c_{3j}\bar{e}_j E_{33}(u) + 2c_{4j}\bar{e}_j E_{23}(v)\\ &+ 2c_{5j}\bar{e}_j E_{13}(w) + 2c_{6j}\bar{e}_j E_{12}(p)\big]\,dx = \mathscr{L}(u,v,w,p,q),\end{aligned}$$

for every $(u,v,w,p,q)\in\mathscr{A}$. Thus

$$\int_\Omega \sum_{j=1}^{6} c_{1j}\bar{e}_j E_{11}(q)\,dx = \mathscr{L}(0,0,0,0,q), \tag{40}$$

$$\int_\Omega \sum_{j=1}^{6} 2c_{6j}\bar{e}_j E_{12}(p)\,dx = \mathscr{L}(0,0,0,p,0), \tag{41}$$

$$\int_\Omega \sum_{j=1}^{6} \left[c_{2j}\bar{e}_j E_{22}(w) + 2c_{5j}\bar{e}_j E_{13}(w)\right] dx = \mathscr{L}(0,0,w,0,0), \tag{42}$$

$$\int_\Omega \sum_{j=1}^{6} 2c_{4j}\bar{e}_j E_{23}(v)\,dx = \mathscr{L}(0,v,0,0,0), \tag{43}$$

$$\int_\Omega \sum_{j=1}^{6} c_{3j}\bar{e}_j E_{33}(u)\,dx = \mathscr{L}(u,0,0,0,0). \tag{44}$$

In this section, for simplicity, we assume

$$\begin{gathered}\mathscr{L}(0,0,\cdot,\cdot,\cdot)=0,\quad \mathscr{L}(0,v,0,0,0)=\int_0^\ell m(x_3)\vartheta(x_3)\,dx_3,\\ \mathscr{L}(u,0,0,0,0)=\int_\Omega b\cdot u\,dx+\int_{\Gamma_\ell} s\cdot u\,d\mathscr{H}^2,\end{gathered} \tag{45}$$

where $\Gamma_\ell=\partial\Omega\cap\{x_3=\ell\}$; $u\in\mathscr{U}$; $b\in L^2(\Omega)$; $s\in L^2(\Gamma_\ell)$; $v\in\mathscr{V}$; $\vartheta\in H^1(\Omega_3)$, $\vartheta(0)=0$, is related to v as in Lemma 5.2; and $m\in L^2(\Omega_3)$. Such assumptions are quite often satisfied in engineering applications.

We now derive the equilibrium equations in differential form. Let $\psi\in L^2(\Omega)$ and define

$$q_1 := \int_{-a_1/2}^{x_1} \psi(s,\cdot,\cdot)\,ds - \fint_{\Omega_1}\int_{-a_1/2}^{x_1} \psi(s,\cdot,\cdot)\,ds\,dx_1.$$

Then $q:=(q_1,0,0)\in\mathscr{Q}$ and $E_{11}(q)=\psi$; hence, from (40) and (45) we deduce

$$\sum_{j=1}^{6} c_{1j}\bar{e}_j = 0 \quad \text{a.e..} \tag{46}$$

With the same argument it follows from (41) that

$$\sum_{j=1}^{6} c_{6j}\bar{e}_j = 0 \quad \text{a.e..} \tag{47}$$

From (46) and (47) we deduce, since $c_{11}c_{66}-c_{16}^2>0$, that

$$\bar{e}_1 = E_{11}(\bar{q}) = -\sum_{j=2}^{5} \frac{c_{66}c_{1j}-c_{16}c_{6j}}{c_{11}c_{66}-c_{16}^2}\,\bar{e}_j \quad \text{a.e.,} \tag{48}$$

$$\bar{e}_6 = 2E_{12}(\bar{p}) = -\sum_{j=2}^{5} \frac{c_{11}c_{6j}-c_{16}c_{1j}}{c_{11}c_{66}-c_{16}^2}\,\bar{e}_j \quad \text{a.e..} \tag{49}$$

Using (45), (48), and (49) we can rewrite (42), after setting

$$\tilde{c}_{ij} = c_{ij} - c_{i1}\frac{c_{66}c_{1j} - c_{16}c_{6j}}{c_{11}c_{66} - c_{16}^2} - c_{i6}\frac{c_{11}c_{6j} - c_{16}c_{1j}}{c_{11}c_{66} - c_{16}^2},$$

for $i, j = 2, \dots, 5$, as

$$\int_\Omega \sum_{j=2}^{5} \left[\tilde{c}_{2j}\bar{e}_j E_{22}(w) + 2\tilde{c}_{5j}\bar{e}_j E_{13}(w)\right] dx = \mathscr{L}(0,0,w,0,0) = 0. \tag{50}$$

Since $w \in \mathscr{W}$, it then admits the representation given in Lemma 5.5 in terms of functions η_1 and η_2. Choosing $\eta_1 = \eta_2 = 0$, so that $E_{22}(w) = 0$, and w_3 like it has been chosen q_1 previously, we find from (50) that

$$\sum_{j=2}^{5} \tilde{c}_{5j}\bar{e}_j = 0 \quad \text{a.e..} \tag{51}$$

Let $\psi \in L^2(\Omega_{23})$. Taking $\eta_1 = w_3 = 0$ and

$$\eta_2 := \int_{-a_2/2}^{x_2} \psi(s,\cdot)\, ds - \fint_{\Omega_2} \int_{-a_2/2}^{x_2} \psi(s,\cdot)\, ds\, dx_2$$

so that $E_{22}(w) = \psi$, we find from (50) that

$$\sum_{j=2}^{5} \int_{\Omega_1} \tilde{c}_{2j}\bar{e}_j\, dx_1 = 0 \quad \text{a.e..} \tag{52}$$

Taking instead $\eta_2 = w_3 = 0$ and

$$\eta_1 := \int_{-a_2/2}^{x_2} \int_{-a_2/2}^{t} \psi(s,\cdot)\, ds\, dt - K_1 x_2 - K_2,$$

where the constants K_1 and K_2 are chosen in order to satisfy the mean integral conditions required on η_1 by (28), we have $E_{22}(w) = -x_1\psi$, and hence, from (50) we deduce

$$\sum_{j=2}^{5} \int_{\Omega_1} x_1\tilde{c}_{2j}\bar{e}_j\, dx_1 = 0 \quad \text{a.e..} \tag{53}$$

From (51), and observing that the positive definiteness of the elastic tensor implies $\tilde{c}_{55} > 0$, we find

$$\bar{e}_5 = 2E_{13}(\bar{w}) = -\sum_{j=2}^{4} \frac{\tilde{c}_{5j}}{\tilde{c}_{55}}\, \bar{e}_j \quad \text{a.e..} \tag{54}$$

To solve (52) and (53) we need to write explicitly $\bar{e}_2 = E_{22}(\bar{w})$. Since $\bar{w} \in \mathscr{W}$, by Lemma 5.5, we can write

$$\bar{w}_1(x) = \bar{\eta}_1(x_2, x_3), \quad \bar{w}_2(x) = -x_1\frac{\partial\bar{\eta}_1}{\partial x_2}(x_2, x_3) + \bar{\eta}_2(x_2, x_3),$$

where $\bar{\eta}_1$ and $\bar{\eta}_2$ belong to the appropriate spaces. Since

$$\bar{e}_2 = -x_1 \frac{\partial^2 \bar{\eta}_1}{\partial x_2^2} + \frac{\partial \bar{\eta}_2}{\partial x_2} \tag{55}$$

and using (54), we can rewrite (52) and (53) as

$$s_{1;22} \frac{\partial^2 \bar{\eta}_1}{\partial x_2^2} - s_{0;22} \frac{\partial \bar{\eta}_2}{\partial x_2} = \sum_{j=3}^{4} \fint_{\Omega_1} \hat{c}_{2j} \bar{e}_j \, dx_1,$$

$$s_{2;22} \frac{\partial^2 \bar{\eta}_1}{\partial x_2^2} - s_{1;22} \frac{\partial \bar{\eta}_2}{\partial x_2} = \sum_{j=3}^{4} \fint_{\Omega_1} x_1 \hat{c}_{2j} \bar{e}_j \, dx_1,$$

where we have set

$$\hat{c}_{ij} := \frac{\tilde{c}_{55}\tilde{c}_{ij} - \tilde{c}_{i5}\tilde{c}_{j5}}{\tilde{c}_{55}}, \qquad s_{k;ij} := \fint_{\Omega_1} x_1^k \, \hat{c}_{ij} \, dx_1, \tag{56}$$

for $i, j = 2, 3, 4$ and $k = 0, 1, 2$. From these equations we find

$$\frac{\partial^2 \bar{\eta}_1}{\partial x_2^2} = \frac{1}{s_{0;22}s_{2;22} - s_{1;22}^2} \biggl(s_{0;22} \sum_{j=3}^{4} \fint_{\Omega_1} x_1 \hat{c}_{2j} \bar{e}_j \, dx_1 - s_{1;22} \sum_{j=3}^{4} \fint_{\Omega_1} \hat{c}_{2j} \bar{e}_j \, dx_1 \biggr),$$

$$\frac{\partial \bar{\eta}_2}{\partial x_2} = \frac{1}{s_{0;22}s_{2;22} - s_{1;22}^2} \biggl(s_{1;22} \sum_{j=3}^{4} \fint_{\Omega_1} x_1 \hat{c}_{2j} \bar{e}_j \, dx_1 - s_{2;22} \sum_{j=3}^{4} \fint_{\Omega_1} \hat{c}_{2j} \bar{e}_j \, dx_1 \biggr),$$

and then by integration $\bar{\eta}_1$ and $\bar{\eta}_2$ (the fact that $s_{0;22}s_{2;22} - s_{1;22}^2 > 0$ can be checked, for instance, by using Hölder's inequality; see Wheeden and Zygmund [13, Chapter 8, Exercise 4]).

According to Remark 5.1 and Lemma 5.2, we let

$$\bar{e}_3 = \bar{\zeta}_3' - x_1 \bar{\zeta}_1'' - x_2 \bar{\zeta}_2'', \qquad \bar{e}_4 = 2x_1 \bar{\vartheta}' + \frac{\partial \bar{\varrho}}{\partial x_2}. \tag{57}$$

Setting

$$S_{mpqr}^{ijkl} := \frac{s_{i;2j}s_{k;2l} - s_{m;2p}s_{q;2r}}{s_{0;22}s_{2;22} - s_{1;22}^2},$$

we then have

$$\frac{\partial^2 \bar{\eta}_1}{\partial x_2^2} = S_{0312}^{0213} \bigl(\bar{\zeta}_3' - x_2 \bar{\zeta}_2'' \bigr) - S_{1213}^{0223} \bar{\zeta}_1'' + 2S_{1214}^{0224} \bar{\vartheta}' + S_{0412}^{0214} \frac{\partial \bar{\varrho}}{\partial x_2},$$

$$\frac{\partial \bar{\eta}_2}{\partial x_2} = S_{0322}^{1213} \bigl(\bar{\zeta}_3' - x_2 \bar{\zeta}_2'' \bigr) - S_{2213}^{1223} \bar{\zeta}_1'' + 2S_{1422}^{1224} \bar{\vartheta}' + S_{0422}^{1214} \frac{\partial \bar{\varrho}}{\partial x_2},$$

and taking into account the relations (48), (49), (54), (55), and (57), we find

$$\begin{aligned} \sum_{j=1}^{6} c_{ij} \bar{e}_j = {} & \bigl(\hat{c}_{i3} - x_1 \hat{c}_{i2} S_{0312}^{0213} + \hat{c}_{i2} S_{0322}^{1213} \bigr) \bigl(\bar{\zeta}_3' - x_2 \bar{\zeta}_2'' \bigr) \\ & - \bigl(x_1 \hat{c}_{i3} - x_1 \hat{c}_{i2} S_{1213}^{0223} + \hat{c}_{i2} S_{2213}^{1223} \bigr) \bar{\zeta}_1'' \\ & + 2 \bigl(x_1 \hat{c}_{i4} - x_1 \hat{c}_{i2} S_{1214}^{0224} + \hat{c}_{i2} S_{1422}^{1224} \bigr) \bar{\vartheta}' \\ & + \bigl(\hat{c}_{i4} - x_1 \hat{c}_{i2} S_{0412}^{0214} + \hat{c}_{i2} S_{0422}^{1214} \bigr) \frac{\partial \bar{\varrho}}{\partial x_2}, \end{aligned} \tag{58}$$

for $i = 3, 4$. Now let $v \in \mathscr{V}$ and ϑ and ϱ be as in Lemma 5.2. With $\psi \in L^2(\Omega_{23})$ and $\vartheta = 0$ and

$$\varrho := \int_{-a_2/2}^{x_2} \psi(s,\cdot)\,ds - \fint_{\Omega_2} \int_{-a_2/2}^{x_2} \psi(s,\cdot)\,ds\,dx_2,$$

we find from (43) that

$$\fint_{\Omega_1} \sum_{j=1}^{6} c_{4j}\bar{e}_j\,dx_1 = 0.$$

It then follows that

$$\begin{aligned} 0 = {} & \big(s_{0;43} - s_{1;42}S^{0213}_{0312} + s_{0;42}S^{1213}_{0322}\big)\big(\bar{\zeta}_3' - x_2\bar{\zeta}_2''\big) \\ & -\big(s_{1;43} - s_{1;42}S^{0223}_{1213} + s_{0;42}S^{1223}_{2213}\big)\bar{\zeta}_1'' \\ & +2\big(s_{1;44} - s_{1;42}S^{0224}_{1214} + s_{0;42}S^{1224}_{1422}\big)\bar{\vartheta}' \\ & +\big(s_{0;44} - s_{1;42}S^{0214}_{0412} + s_{0;42}S^{1214}_{0422}\big)\frac{\partial\bar{\varrho}}{\partial x_2}, \end{aligned}$$

and provided that the last coefficient $s_{0;44} - s_{1;42}S^{0214}_{0412} + s_{0;42}S^{1214}_{0422} \neq 0$, one finds

$$\begin{aligned} \frac{\partial\bar{\varrho}}{\partial x_2} = {} & \frac{-1}{s_{0;44} - s_{1;42}S^{0214}_{0412} + s_{0;42}S^{1214}_{0422}} \\ & \cdot\Big[\big(s_{0;43} - s_{1;42}S^{0213}_{0312} + s_{0;42}S^{1213}_{0322}\big)\big(\bar{\zeta}_3' - x_2\bar{\zeta}_2''\big) \\ & - \big(s_{1;43} - s_{1;42}S^{0223}_{1213} + s_{0;42}S^{1223}_{2213}\big)\bar{\zeta}_1'' \\ & + \big(s_{1;44} - s_{1;42}S^{0224}_{1214} + s_{0;42}S^{1224}_{1422}\big)2\bar{\vartheta}'\Big]. \end{aligned}$$

We may rewrite (58) as

$$\sum_{j=1}^{6} c_{ij}\bar{e}_j = F_{i3}\bar{\zeta}_3' - F_{i2}\bar{\zeta}_2'' - F_{i1}\bar{\zeta}_1'' + F_{i4}\bar{\vartheta}' \tag{59}$$

for $i = 3, 4$, where

$$\begin{aligned} F_{i1} = {} & (x_1\hat{c}_{i3} - x_1\hat{c}_{i2}S^{0223}_{1213} + \hat{c}_{i2}S^{1223}_{2213}) \\ & -\frac{(\hat{c}_{i4} - x_1\hat{c}_{i2}S^{0214}_{0412} + \hat{c}_{i2}S^{1214}_{0422})\big(s_{1,43} - s_{1,42}S^{0223}_{1213} + s_{0,42}S^{1223}_{2213}\big)}{s_{0,44} - s_{1,42}S^{0214}_{0412} + s_{0,42}S^{1214}_{0422}}, \\ F_{i2} = {} & x_2F_{i3}, \\ F_{i3} = {} & (\hat{c}_{i3} - x_1\hat{c}_{i2}S^{0213}_{0312} + \hat{c}_{i2}S^{1213}_{0322}) \\ & -\frac{(\hat{c}_{i4} - x_1\hat{c}_{i2}S^{0214}_{0412} + \hat{c}_{i2}S^{1214}_{0422})(s_{0,43} - s_{1,42}S^{0213}_{0312} + s_{0,42}S^{1213}_{0322})}{s_{0,44} - s_{1,42}S^{0214}_{0412} + s_{0,42}S^{1214}_{0422}}, \\ F_{i4} = {} & 2(x_1\hat{c}_{i4} - x_1\hat{c}_{i2}S^{0224}_{1214} + \hat{c}_{i2}S^{1224}_{1422}) \\ & -2\frac{(\hat{c}_{i4} - x_1\hat{c}_{i2}S^{0214}_{0412} + \hat{c}_{i2}S^{1214}_{0422})(s_{1,44} - s_{1,42}S^{0224}_{1214} + s_{0,42}S^{1224}_{1422})}{s_{0,44} - s_{1,42}S^{0214}_{0412} + s_{0,42}S^{1214}_{0422}}. \end{aligned}$$

Let

$$A_{ij}(x_3) := \int_{\Omega_{12}} F_{ij}(\cdot,\cdot,x_3)\,dx_1dx_2$$

and

$$K_{ij}(x_3) := \int_{\Omega_{12}} x_1F_{ij}(\cdot,\cdot,x_3)\,dx_1dx_2, \quad L_{ij}(x_3) := \int_{\Omega_{12}} x_2F_{ij}(\cdot,\cdot,x_3)\,dx_1dx_2.$$

Then, from (43), (44), and (59) we finally deduce the following system of equilibrium differential equations:

$$\left\{\begin{array}{l} (A_{33}\bar{\zeta}_3' - A_{31}\bar{\zeta}_1'' - A_{32}\bar{\zeta}_2'' + A_{34}\bar{\vartheta}')' = -p_3,\\ (K_{33}\bar{\zeta}_3' - K_{31}\bar{\zeta}_1'' - K_{32}\bar{\zeta}_2'' + K_{34}\bar{\vartheta}')'' = -p_1,\\ (L_{33}\bar{\zeta}_3' - L_{31}\bar{\zeta}_1'' - L_{32}\bar{\zeta}_2'' + L_{34}\bar{\vartheta}')'' = -p_2,\\ 2(K_{43}\bar{\zeta}_3' - K_{41}\bar{\zeta}_1'' - K_{42}\bar{\zeta}_2'' + K_{44}\bar{\vartheta}')' = -m, \end{array}\right. \tag{60}$$

where

$$\begin{aligned} p_1 &= \left(\int_{\Omega_{12}} x_1b_3\,dx_1dx_2\right)' + \int_{\Omega_{12}} b_1\,dx_1dx_2,\\ p_2 &= \left(\int_{\Omega_{12}} x_2b_3\,dx_1dx_2\right)' + \int_{\Omega_{12}} b_2\,dx_1dx_2,\\ p_3 &= \int_{\Omega_{12}} b_3\,dx_1dx_2. \end{aligned}$$

The system (60) should then be completed with the suitable boundary conditions.

7.1. The homogeneous beam. In the general inhomogeneous and anisotropic case, the torsional, flexional, and extensional problems are all coupled together in the equilibrium differential system (60). A partial decoupling occurs already in the homogeneous fully anisotropic case. Indeed, in this case, from (56), we have

$$s_{0;ij} = \hat{c}_{ij}, \qquad s_{1;ij} = 0, \qquad s_{2;ij} = \frac{a_1^3}{12}\hat{c}_{ij},$$

and therefore

$$S_{0312}^{0213} = S_{2213}^{1223} = S_{0412}^{0214} = S_{1422}^{1224} = 0, \qquad S_{1213}^{0223} = \frac{\hat{c}_{23}}{\hat{c}_{22}}, \qquad S_{0322}^{1213} = -\frac{\hat{c}_{23}}{\hat{c}_{22}}, \qquad S_{1422}^{1214} = \frac{\hat{c}_{24}}{\hat{c}_{22}},$$

which causes many of the coefficients of the system A_{ij}, K_{ij}, and L_{ij} to be zero. In this case, the system (60) simply rewrites as

$$\left\{\begin{array}{l} A_{33}\bar{\zeta}_3'' = -p_3,\\ (-K_{31}\bar{\zeta}_1'' + K_{34}\bar{\vartheta}')'' = -p_1,\\ -L_{32}\bar{\zeta}_2^{(iv)} = -p_2,\\ 2(-K_{41}\bar{\zeta}_1'' + K_{44}\bar{\vartheta}')' = -m, \end{array}\right. \tag{61}$$

where

$$A_{33} = a_1 a_2 \left[\frac{\hat{c}_{22}\hat{c}_{33} - \hat{c}_{23}^2}{\hat{c}_{22}} + \frac{(\hat{c}_{22}\hat{c}_{34} - \hat{c}_{23}\hat{c}_{24})^2}{\hat{c}_{22}(\hat{c}_{22}\hat{c}_{44} - \hat{c}_{24}^2)} \right],$$

$$K_{31} = \frac{a_1^3 a_2}{12} \frac{\hat{c}_{22}\hat{c}_{33} - \hat{c}_{23}^2}{\hat{c}_{22}}, \; K_{34} = \frac{a_1^3 a_2}{6} \frac{\hat{c}_{22}\hat{c}_{34} - \hat{c}_{23}\hat{c}_{24}}{\hat{c}_{22}},$$

$$K_{41} = \frac{a_1^3 a_2}{12} \frac{\hat{c}_{22}\hat{c}_{34} - \hat{c}_{23}\hat{c}_{24}}{\hat{c}_{22}}, \; K_{44} = \frac{a_1^3 a_2}{6} \frac{\hat{c}_{22}\hat{c}_{44} - \hat{c}_{24}^2}{\hat{c}_{22}},$$

$$L_{32} = \frac{a_1 a_2^3}{12} \left[\frac{\hat{c}_{22}\hat{c}_{33} - \hat{c}_{23}^2}{\hat{c}_{22}} + \frac{(\hat{c}_{22}\hat{c}_{34} - \hat{c}_{23}\hat{c}_{24})^2}{\hat{c}_{22}(\hat{c}_{22}\hat{c}_{44} - \hat{c}_{24}^2)} \right].$$

Thus for a fully anisotropic but homogeneous beam there is only coupling between twisting and bending in direction 1.

7.2. The homogeneous orthotropic/isotropic beam. When the material is orthotropic a complete decoupling occurs. Indeed, for orthotropic material we have that $c_{ki} = 0$ for $k = 1, 2, 3$ and $i = 4, 5, 6$, and $c_{45} = c_{46} = c_{56} = 0$. It then follows that $K_{34} = K_{41} = 0$ and the system (61) reduces to

$$\text{(62)} \qquad \begin{cases} A_{33}\bar{\zeta}_3'' = -p_3, \\ -K_{31}\bar{\zeta}_1^{(iv)} = -p_1, \\ -L_{32}\bar{\zeta}_2^{(iv)} = -p_2, \\ 2K_{44}\bar{\vartheta}'' = -m. \end{cases}$$

Finally, if the material is isotropic, that is, if it is orthotropic and $c_{12} = c_{23} = c_{13} =: \lambda$, $c_{44} = c_{55} = c_{66} =: \mu$, and $c_{11} = c_{22} = c_{33} = \lambda + 2\mu$, where λ and μ are the Lamé moduli, then we have that

$$A_{33} = a_1 a_2 E, \quad K_{31} = \frac{a_1^3 a_2}{12} E, \quad 2K_{44} = \frac{a_1^3 a_2}{3}\mu, \quad L_{32} = \frac{a_1 a_2^3}{12} E,$$

where $E := \mu\frac{3\lambda+2\mu}{\lambda+\mu}$ is the Young modulus of the material. Hence, in the isotropic and homogeneous case we recover the usual form of the differential system of equilibrium equations.

CORRECTORS FOR THE HOMOGENIZATION OF A CLASS OF HYPERBOLIC EQUATIONS WITH IMPERFECT INTERFACES*

PATRIZIA DONATO†, LUISA FAELLA‡, AND SARA MONSURRÒ§

Abstract. We present here some corrector results for the homogenization of the wave equation in a two-component composite with ε-periodic connected inclusions which complete the homogenization results proved in [P. Donato, L. Faella, and S. Monsurrò, *J. Math. Pures Appl.*, 87 (2007), pp. 119–143] by the authors. On the interface separating the two components we prescribe a jump of the solution proportional to the conormal derivatives via a function of order ε^γ, with $-1 < \gamma \leq 1$. Due to different expressions of the energies of the limit problems, the cases $-1 < \gamma < 1$ and $\gamma = 1$ need to be treated separately. The second one, where a memory effect appears in the homogenized problem, is the most interesting. For this critical case, displaying lack of compactness, we in particulur establish the central upper semicontinuity type inequalities by splitting a related energy term into a compact part and a part vanishing in appropriate norms.

Key words. homogenization, correctors, hyperbolic equations

1. Introduction.

In this paper we prove some corrector results for the homogenization of a linear hyperbolic problem in a domain Ω of $\mathbb{R}^n$ made up of two components, a connected one $\Omega_{1\varepsilon}$ and a disconnected one $\Omega_{2\varepsilon}$, which is a union of ε-periodic connected inclusions of size ε. The conditions prescribed on the interface $\Gamma^\varepsilon := \partial\Omega_{2\varepsilon}$ between the two components are the continuity of the conormal derivatives and a jump of the solution proportional to the conormal derivatives via a function of order ε^γ. We suppose here that $-1 < \gamma \leq 1$. This work completes the corresponding homogenization results proved by the authors in [9].

Let A be a periodic, symmetric, bounded, and elliptic matrix field and h a bounded and periodic function. We consider the following problem:

$$\begin{cases} u_\varepsilon'' - \operatorname{div}(A^\varepsilon \nabla u_\varepsilon) = f_\varepsilon \quad \text{in } (\Omega_{1\varepsilon} \times \Omega_{2\varepsilon}) \times]0,T[, \\ [A^\varepsilon \nabla u_\varepsilon] \cdot n_{1\varepsilon} = 0 \quad \text{on } \Gamma^\varepsilon \times]0,T[, \\ A^\varepsilon \nabla u_{1\varepsilon} \cdot n_{1\varepsilon} = -\varepsilon^\gamma h^\varepsilon [u_\varepsilon] \quad \text{on } \Gamma^\varepsilon \times]0,T[, \\ u_\varepsilon = 0 \quad \text{on } \partial\Omega \times]0,T[, \\ u_\varepsilon(0) = U_\varepsilon^0 \quad \text{in } \Omega, \\ u_\varepsilon'(0) = U_\varepsilon^1 \quad \text{in } \Omega, \end{cases} \tag{1.1}$$

where $A^\varepsilon(x) := A(x/\varepsilon)$, $h^\varepsilon(x) := h(x/\varepsilon)$, $u_\varepsilon = (u_{1\varepsilon}, u_{2\varepsilon})$ is defined in $\Omega_{1\varepsilon} \times \Omega_{2\varepsilon}$, $[\,\cdot\,]$ denotes the jump trough Γ^ε, and $n_{i\varepsilon}$ is the unitary outward normal to $\Omega_{i\varepsilon}$, $i = 1, 2$.

This problem models the wave propagation in a medium made up of two materials with very different coefficients of propagation, which gives rise to the jump in the boundary condition on the interface. For the physical model we refer to [4], where these kinds of interface conditions are derived.

The homogenization results proved in [9] (recalled in section 2) show two different asymptotic behaviors for $-1 < \gamma < 1$ and $\gamma = 1$, the last case being the most interesting one, since a memory effect appears at the limit (see also Remark 2.7).

When $-1 < \gamma < 1$, under suitable assumptions on the data (see Theorem 2.3), we have, as $\varepsilon \to 0$, the following convergences:

$$\begin{cases} P_1^\varepsilon u_{1\varepsilon} \rightharpoonup u_1 & \text{weakly* in } L^\infty\left(0,T;H_0^1(\Omega)\right), \\ P_1^\varepsilon u'_{1\varepsilon} \rightharpoonup u'_1 & \text{weakly* in } L^\infty\left(0,T;L^2(\Omega)\right), \end{cases}$$

while

$$\begin{cases} \widetilde{u_{2\varepsilon}} \rightharpoonup \theta_2 u_1 & \text{weakly* in } L^\infty\left(0,T;L^2(\Omega)\right), \\ \widetilde{u'_{2\varepsilon}} \rightharpoonup \theta_2 u'_1 & \text{weakly* in } L^\infty\left(0,T;L^2(\Omega)\right), \end{cases}$$

and

$$\begin{cases} A^\varepsilon \widetilde{\nabla u_{1\varepsilon}} \rightharpoonup A^0 \nabla u_1 & \text{weakly* in } L^\infty\left(0,T;\left[L^2(\Omega)\right]^n\right), \\ A^\varepsilon \widetilde{\nabla u_{2\varepsilon}} \rightharpoonup 0 & \text{weakly* in } L^\infty\left(0,T;\left[L^2(\Omega)\right]^n\right), \end{cases} \tag{1.2}$$

where P_1^ε is a suitable extension operator, θ_2 is the proportion of material occupying the inclusions, $\widetilde{\ }$ denotes the zero extension to the whole of Ω, and u_1 is the solution of the homogenized problem

$$\begin{cases} u_1'' - \operatorname{div}\left(A^0 \nabla u_1\right) = f_1 + f_2 & \text{in } \Omega\times]0,T[, \\ u_1 = 0 & \text{on } \partial\Omega\times]0,T[, \\ u_1(0) = U_0 & \text{in } \Omega, \\ u_1'(0) = U_1 & \text{in } \Omega. \end{cases}$$

The matrix field A^0 is the same constant positive definite matrix obtained by Cioranescu and Saint Jean Paulin (see [7] and also [6]) for the homogenization of the elliptic problem in the perforated domain $\Omega_{1\varepsilon}$, with a Neumann condition on the boundary of the holes.

All of these convergences are weak, but sufficient, to obtain the homogenized problem. At this point, the question is how to improve them, in particular give more information on the gradient and on the first time derivative of the solution. Such results are known in standard homogenization as corrector results. The aim of this paper is precisely to answer the above questions.

The corrector result given in Theorem 2.4 states that, under some additional assumptions,

$$\begin{cases} \widetilde{u'_{1\varepsilon}} + \widetilde{u'_{2\varepsilon}} \to u'_1 \text{ strongly in } C^0(0,T;L^2(\Omega)), \\ \lim\limits_{\varepsilon\to 0} \|\nabla u_{1\varepsilon} - C^\varepsilon \nabla u_1\|_{C^0(0,T;[L^1(\Omega_{1\varepsilon})]^n)} = 0, \\ \lim\limits_{\varepsilon\to 0} \|\nabla u_{2\varepsilon}\|_{C^0(0,T;[L^2(\Omega_{2\varepsilon})]^n)} = 0, \end{cases}$$

where C^ε is the same corrector matrix of the problem studied in [7].

The additional assumptions concern the data. We assume strong convergence for both f_ε and U_ε^1, and we suppose that U_ε^0 solves the particular elliptic equation given by (2.10). These assumptions are needed for the convergence of the energy of problem (1.1) to that of the homogenized one. This convergence is necessary to prove the corrector results, as already evidenced in the classical homogenization of the wave equation (see [2]) or in a perforated domain with a Neumann condition on the boundaries of the holes (see [18]).

If $\gamma = 1$, the situation is more complicated since the limit problem consists in a p.d.e. coupled with an o.d.e., as proved in [9]. One still has the convergences

$$\begin{cases} P_1^\varepsilon u_{1\varepsilon} \rightharpoonup u_1 & \text{weakly* in } L^\infty\left(0,T;H_0^1(\Omega)\right), \\ P_1^\varepsilon u'_{1\varepsilon} \rightharpoonup u'_1 & \text{weakly* in } L^\infty\left(0,T;L^2(\Omega)\right), \end{cases}$$

and

$$\begin{cases} \widetilde{u_{2\varepsilon}} \rightharpoonup u_2 & \text{weakly* in } L^\infty\left(0,T;L^2(\Omega)\right), \\ \widetilde{u'_{2\varepsilon}} \rightharpoonup u'_2 & \text{weakly* in } L^\infty\left(0,T;L^2(\Omega)\right), \end{cases}$$

but u_2 is not $\theta_2 u'_1$ anymore. In this case (see Theorem 2.6), (u_1, u_2) is the unique solution of the coupled problem

$$\begin{cases} \theta_1 u_1'' - \operatorname{div}\left(A^0 \nabla u_1\right) + c_h(\theta_2 u_1 - u_2) = f_1 & \text{in } \Omega\times]0,T[, \\ u_2'' - c_h(\theta_2 u_1 - u_2) = f_2 & \text{in } \Omega\times]0,T[, \\ u_1 = 0 & \text{on } \partial\Omega\times]0,T[, \\ u_1(x,0) = U^0, \quad u_2(x,0) = \theta_2 U^0 & \text{in } \Omega, \\ u'_1(x,0) = U^1, \quad u'_2(x,0) = \theta_2 U^1 & \text{in } \Omega, \end{cases}$$

where $\theta_1 = 1 - \theta_2$ and c_h is a constant depending on the function h. Furthermore, convergences (1.2) still hold. Let us mention that in [9, Remark 2.11] the limit function u_2 is explicitly computed in terms of u_1 and it is shown that u_1 is the solution of a linear hyperbolic problem with a linear memory effect.

Under the same assumptions as in the previous case, the corrector result for $\gamma = 1$ (Theorem 2.8) states the convergences

$$\begin{cases} \lim\limits_{\varepsilon\to 0} \|u'_{1\varepsilon} - u'_1\|_{C^0(0,T;L^2(\Omega_{1\varepsilon}))} = 0, \\ \lim\limits_{\varepsilon\to 0} \|u'_{2\varepsilon} - \theta_2^{-1} u'_2\|_{C^0(0,T;L^2(\Omega_{2\varepsilon}))} = 0, \\ \lim\limits_{\varepsilon\to 0} \|\nabla u_{1\varepsilon} - C^\varepsilon \nabla u_1\|_{C^0(0,T;[L^1(\Omega_{1\varepsilon})]^n)} = 0, \\ \lim\limits_{\varepsilon\to 0} \|\nabla u_{2\varepsilon}\|_{C^0(0,T;[L^2(\Omega_{2\varepsilon})]^n)} = 0. \end{cases}$$

The corrector results are proved in section 5 for $-1 < \gamma < 1$ and in section 6 for $\gamma = 1$.

Let us point out the main difficulties of our situation due to the presence of the interface. The first concerns the study of the convergence of the energy associated to problem (1.1). This is in general straightforward, but here the expression of the energy of problem (1.1) is more complicated than usual, since it contains a boundary term. Moreover, for $\gamma = 1$, the energy of the homogenized coupled system contains also a zero order term which is a linear combination of u_1 and u_2. This can be seen comparing formulas (4.5) (case $-1 < \gamma < 1$) and (4.8) (case $\gamma = 1$). We can prove in section 4 (Theorems 4.3 and 4.4) that in both cases the energy converges to those of the homogenized problems.

The second and more difficult point consists in proving two upper semicontinuity type inequalities given for the two cases in Propositions 5.1 and 6.1, respectively. They require specific arguments and are crucial, since they allow us to end, by a density argument, the proof of the corrector result. Let us mention that usually in the literature one obtains a convergence, which gives rise to an equality for the limit (see Remark 5.2), but here we can only obtain an inequality on an upper limit. Nevertheless, this is enough to conclude.

Let us briefly describe Proposition 6.1 concerning the case $\gamma = 1$, which is the most interesting one. It states that if we set, for $\Phi, \Psi \in C^\infty([0,T], \mathcal{D}(\Omega))$,

$$\hat{X}_\varepsilon = \frac{1}{2}\Big[\int_{\Omega_{1\varepsilon}} |u'_{1\varepsilon} - \Phi'|^2 \, dx + \int_{\Omega_{2\varepsilon}} |u'_{2\varepsilon} - \Psi'|^2 \, dx + \int_{\Omega_{1\varepsilon}} A^\varepsilon \left(\nabla u_{1\varepsilon} - C^\varepsilon \nabla \Phi\right)\left(\nabla u_{1\varepsilon} - C^\varepsilon \nabla \Phi\right) \, dx + \int_{\Omega_{2\varepsilon}} A^\varepsilon \nabla u_{2\varepsilon} \nabla u_{2\varepsilon} \, dx \Big],$$

then

$$\limsup_{\varepsilon \to 0} \left\| \hat{X}_\varepsilon \right\|_{C^0([0,T])} \le \left\| \hat{X} \right\|_{C^0([0,T])}, \tag{1.3}$$

where

$$\hat{X} = \frac{1}{2}\left[\theta_1 \| u'_1 - \Phi' \|^2_{L^2(\Omega)} + \theta_2^{-1} \| u'_2 - \theta_2 \Psi' \|^2_{L^2(\Omega)} + \int_\Omega A^0 (\nabla u_1 - \nabla \Phi)(\nabla u_1 - \nabla \Phi) \, dx \right].$$

The main difficulty when proving this result is due to the boundary term in the energy associated to problem (1.1). Indeed, we cannot have estimates for the time derivative of $\hat{X}_\varepsilon$ so that we cannot derive any compactness of $\hat{X}_\varepsilon$ in $C^0([0,T])$. To overcome this difficulty, in Step 4 of the proof of Proposition 6.1 we decompose $\hat{X}_\varepsilon$ as a sum of two terms and we show that the first one is compact and the second one goes to zero in $C^0([0,T])$ (see also Remarks 6.2 and 6.3 for details). This allows us to prove (1.3).

The correctors for the corresponding elliptic case have been studied by the first author in [8]. The first homogenization result for these kinds of boundary conditions was done in the elliptic case, for some values of the parameter γ, by Auriault and Ene [1] by the multiple scales method. We refer to Lipton [15] for the study of the limit problem when $\gamma = 0$, to S. Monsurrò [17] for the case $\gamma \le -1$, and to [10] for the case $\gamma > -1$. For similar elliptic homogenization problems we refer also to [3], [12], [13], [16], [19].

2. Formulation of the problem and main results. Along this paper, Ω will denote an open bounded subset of $\mathbb{R}^n$ and $\{\varepsilon\}$ a sequence of positive real numbers converging to zero.

Let $Y =]0, l_1[\times \cdots \times]0, l_n[$ be a reference cell in $\mathbb{R}^n$ and Y_1 and Y_2 be two nonempty open and disjoint subsets of Y such that

$$Y = Y_1 \cup \overline{Y_2},$$

with Y_1 connected and $\Gamma := \partial Y_2$ of class C^2.

For any $k \in Z^n$ we denote

$$Y_i^k := \; k_l + Y_i, \qquad \Gamma_k := \; k_l + \Gamma,$$

where $k_l = (k_1 l_1, \ldots, k_n l_n)$ and $i = 1, 2$, and we suppose that

$$\partial\Omega \cap \left(\cup_{k \in Z^n} (\varepsilon \Gamma_k) \right) := \emptyset. \tag{2.1}$$

We introduce then, for any ε, the two components of Ω and the interface, respectively, by

$$\Omega_{i\varepsilon} := \Omega \cap \left\{\cup_{k\in K_\varepsilon} \varepsilon Y_i^k\right\},\ i=1,2, \quad \text{and} \quad \Gamma^\varepsilon := \partial\Omega_{2\varepsilon},$$

where K_ε is the set of the n-tuples such that $\varepsilon\Gamma_k$ is included in Ω, namely,

$$K_\varepsilon := \{k \in Z^n |\ \varepsilon\Gamma_k \cap \Omega \neq \emptyset\},$$

so that $\partial\Omega \cap \Gamma^\varepsilon = \emptyset$.

Due to (2.1), the set $\Omega_{1\varepsilon}$ is connected while $\Omega_{2\varepsilon}$ is a union of $c\varepsilon^{-n}$ disjoint translated sets of εY_2, c being a constant independent of ε.

In what follows, we will denote by χ_ω the characteristic function of any open set $\omega \subset \mathbb{R}^n$. We know that (see, for instance, [6])

$$\chi_{\Omega_{i\varepsilon}} \rightharpoonup \theta_i := \frac{|Y_i|}{|Y|} \quad \text{weakly in } L^2(\Omega), \qquad i=1,2. \tag{2.2}$$

We define the normed space V^ε by

$$V^\varepsilon := \{v_1 \in H^1(\Omega_{1\varepsilon}) |\ v_1 = 0\}$$

endowed with the norm

$$\|v_1\|_{V^\varepsilon} := \|\nabla v_1\|_{L^2(\Omega_{1\varepsilon})}.$$

Remark 2.1. Since we do not assume any regularity on $\partial\Omega$, the condition on $\partial\Omega$ in the definition of V^ε has to be understood in a density sense. More precisely, V^ε is the closure with respect to the $H^1(\Omega_{1\varepsilon})$-norm of the set of the functions of $C^\infty(\Omega_{1\varepsilon})$ with a compact support contained in Ω. This make sense because of (2.1).

As in [9], we also define, for every $\gamma \in \mathbb{R}$,

$$H^\varepsilon_\gamma := \left\{v = (v_1, v_2) \mid v_1 \in V^\varepsilon \quad \text{and} \quad v_2 \in H^1(\Omega_{2\varepsilon})\right\}$$

equipped with the norm

$$\|v\|^2_{H^\varepsilon_\gamma} := \|\nabla v_1\|^2_{L^2(\Omega_{1\varepsilon})} + \|\nabla v_2\|^2_{L^2(\Omega_{2\varepsilon})} + \varepsilon^\gamma \|v_1 - v_2\|^2_{L^2(\Gamma^\varepsilon)}.$$

Obviously, if $0 < \varepsilon < 1$ and $\gamma_1 \leq \gamma_2$, then

$$\|v\|_{H^\varepsilon_{\gamma_2}} \leq \|v\|_{H^\varepsilon_{\gamma_1}}.$$

Moreover, as shown in [17, Lemmas 2.7 and 2.8 and their proofs], for every fixed ε the norms of H^ε_γ and $V^\varepsilon \times H^1(\Omega_{2\varepsilon})$ are equivalent.

To introduce the coefficient matrix, we define, for $\alpha, \beta \in \mathbb{R}$ with $0 < \alpha < \beta$, the set $M(\alpha, \beta, Y)$ of the $n \times n$ Y-periodic matrix-valued functions in $L^\infty(Y)$ such that

$$(A(x)\lambda, \lambda) \geq \alpha|\lambda|^2, \quad |A(x)\lambda| \leq \beta\lambda$$

for any $\lambda \in \mathbb{R}^n$ and a.e. in Y.

We assume that

$$A \in M(\alpha, \beta, Y), \quad A \text{ symmetric}, \tag{2.3}$$

and we set, for any $\varepsilon > 0$,

$$A^\varepsilon(x) := A(x/\varepsilon). \tag{2.4}$$

Moreover, we consider a Y-periodic function h such that

$$h \in L^\infty(\Gamma) \text{ and } \exists\, h_0 \in \mathbb{R} \text{ such that } 0 < h_0 < h(y) \text{ a.e. in } \Gamma$$

and set

$$h^\varepsilon(x) := h\left(\frac{x}{\varepsilon}\right). \tag{2.5}$$

Throughout this work, we suppose $T > 0$ be given and $-1 < \gamma \leq 1$. We consider the following problem:

$$\begin{cases} u''_{1\varepsilon} - \operatorname{div}(A^\varepsilon \nabla u_{1\varepsilon}) = f_{1\varepsilon} \quad \text{in } \Omega_{1\varepsilon} \times]0,T[, \\ u''_{2\varepsilon} - \operatorname{div}(A^\varepsilon \nabla u_{2\varepsilon}) = f_{2\varepsilon} \quad \text{in } \Omega_{2\varepsilon} \times]0,T[, \\ A^\varepsilon \nabla u_{1\varepsilon} \cdot n_{1\varepsilon} = -A^\varepsilon \nabla u_{2\varepsilon} \cdot n_{2\varepsilon} \quad \text{on } \Gamma^\varepsilon \times]0,T[, \\ A^\varepsilon \nabla u_{1\varepsilon} \cdot n_{1\varepsilon} = -\varepsilon^\gamma h^\varepsilon (u_{1\varepsilon} - u_{2\varepsilon}) \quad \text{on } \Gamma^\varepsilon \times]0,T[, \\ u_{1\varepsilon} = 0 \quad \text{on } \partial\Omega \times]0,T[, \\ u_{1\varepsilon}(0) = U^0_{1\varepsilon} \quad \text{in } \Omega_{1\varepsilon}, \qquad u_{2\varepsilon}(0) = U^0_{2\varepsilon} \quad \text{in } \Omega_{2\varepsilon}, \\ u'_{1\varepsilon}(0) = U^1_{\varepsilon\,|\Omega_{1\varepsilon}} \quad \text{in } \Omega_{1\varepsilon}, \qquad u'_{2\varepsilon}(0) = U^1_{\varepsilon\,|\Omega_{2\varepsilon}} \quad \text{in } \Omega_{2\varepsilon}, \end{cases} \tag{2.6}$$

where $n_{i\varepsilon}$ is the unitary outward normal to $\Omega_{i\varepsilon}$, $i = 1, 2$, and

$$\begin{cases} \text{(i) } f_\varepsilon := (f_{1\varepsilon|\Omega_{1\varepsilon}}, f_{2\varepsilon|\Omega_{2\varepsilon}}) \text{ with } f_{i\varepsilon} \in L^2\left(0,T; L^2(\Omega)\right),\ i = 1,2, \\ \text{(ii) } U^0_\varepsilon := \left(U^0_{1\varepsilon}, U^0_{2\varepsilon}\right) \in V^\varepsilon \times H^1(\Omega_{2\varepsilon}), \\ \text{(iii) } U^1_\varepsilon \in L^2(\Omega). \end{cases} \tag{2.7}$$

Its variational (weak) formulation is
