A SPLIT GODUNOV SCHEME FOR SOLVING ONE-DIMENSIONAL HYPERBOLIC SYSTEMS IN A NONCONSERVATIVE FORM*

GISÈLE MOPHOU† AND PASCAL POULLET†

Abstract. In this paper, we developed a theoretical study for nonconservative sytems in one dimension in order to construct numerical schemes for solving the Riemann problem. The nonconservative form of our model system required the use of a well-adapted theory in order to give us a sense of our problem. We chose a framework of generalized functions for solving a scalar hyperbolic equation with a discontinuous coefficient $\sigma_t + u\sigma_x \approx 0$, where u is the velocity solution of a Burgers's equation. After an explicit solution of the Riemann problem, we derived Godunov split schemes for computing an approximate solution of the Cauchy problem. We applied our study to a system modeling elasticity and a system modeling gas dynamics. Some stability properties of a scheme and its convergence to a generalized solution are proved for the first model. Numerical experiments confirmed this convergence result. For the second model, calculations of flows containing weak-to-moderate shocks showed that conservation errors are reduced when the mesh is refined but were not entirely eliminated.

Key words. Riemann solver, Burgers's equation, splitting method, Godunov scheme, nonconservative system

1. Introduction.

For presenting our study, we first consider the simplified system modeling elasticity in Eulerian coordinates [5, 2]:

$$\left\{ \begin{array}{rcl} \partial_t u(x,t) + u(x,t)\partial_x u(x,t) - \partial_x \sigma(x,t) & \approx & 0, \\ \partial_t \sigma(x,t) + u(x,t)\partial_x \sigma(x,t) - k^2 \partial_x u(x,t) & \approx & 0, \end{array} \right. \tag{1.1}$$

which is a dynamic equation coupled with Hooke's law when the density of the solid is almost equal to one, with u representing the velocity, σ the stress, and k a positive fixed real number.

It is well known that such systems present numerical and physical solutions u and σ which are simultaneously discontinuous functions. Therefore, the term $u\,.\,\partial_x\sigma$ appears in the form of the meaningless product $Y.\delta$ of the Heaviside and the Dirac functions. To remove this ambiguity, J. F. Colombeau developed a mathematical theory by introducing the differential algebra $\mathcal{G}(\mathbb{R}\times\mathbb{R}^+)$ of generalized functions where discontinuous functions are represented by means of classes of $\mathcal{C}^\infty$ functions [4, 2, 5].

Although the Riemann problem (1.1)–(1.2) admits an infinite number of jump conditions for shocks [7], we are interested in seeking its shock solution when the velocity and the stress are written with the same Heaviside function. The decomposition of the Riemann problem (1.1) with the initial data of the form

$$(u_0(x),\, \sigma_0(x)) = \left\{ \begin{array}{ll} (u_l,\, \sigma_l) & \text{if} \quad x < 0, \\ (u_r,\, \sigma_r) & \text{if} \quad x > 0, \end{array} \right. \tag{1.2}$$

†Laboratoire de Mathématiques, Université des Antilles et de la Guyane, Campus de Fouillole, F-97159 Pointe-à-Pitre Cedex, Guadeloupe, French West Indies (Gisele.Mophou@univ-ag.fr, Pascal.Poullet@univ-ag.fr).

achieved by means of a splitting technique [1, 8], permits us to obtain two other Riemann problems which are easier to solve. One of them (propagation terms) is associated with the following linear hyperbolic system:

$$\left\{ \begin{array}{rcl} \partial_t u(x,t) - \partial_x \sigma(x,t) & \approx & 0, \\ \partial_t \sigma(x,t) - k^2 \partial_x u(x,t) & \approx & 0. \end{array} \right. \tag{1.3}$$

The other one is linked to a nonlinear, nonstrictly hyperbolic system (convection terms):

$$\left\{ \begin{array}{rcl} \partial_t u(x,t) + u(x,t)\partial_x u(x,t) & \approx & 0, \\ \partial_t \sigma(x,t) + u(x,t)\partial_x \sigma(x,t) & \approx & 0. \end{array} \right. \tag{1.4}$$

Due to the nonstrictly hyperbolicity of the system (1.4), many authors have already attempted to solve the associated Riemann problem. M. Oberguggenberger in [11] made a theoretical study of the same system by simultaneously solving the two equations. In [6] Colombeau and Le Roux proposed a Godunov scheme for this system by assuming that the variables u and σ moved in phase on the shock. But the case of decreasing initial data when the velocity u has a variable sign was not considered.

Recently, in [13], Remaki studied hyperbolic equations with a discontinuous coefficient depending on the space variable x, which permits us to study the second equation in (1.4), u being known from the first equation. Moreover, a technique of perturbation for solving a degenerated system in conservative formulation has also been introduced by Le Roux and collaborators in [1].

In this paper, we develop two methods for studying the Riemann problem associated with the system of convection terms (1.4). The first one is the approach by perturbation mentioned above. It consists of viewing the system (1.4) as the limit when $\varepsilon \to 0,\ \varepsilon > 0$ of the following well-posed system:

$$\left\{ \begin{array}{rcl} \partial_t u(x,t) + u(x,t)\partial_x u(x,t) - \varepsilon\, \partial_x \sigma(x,t) & = & 0, \\ \partial_t \sigma(x,t) + u(x,t)\partial_x \sigma(x,t) - \varepsilon\, k^2 \partial_x u(x,t) & = & 0. \end{array} \right. \tag{1.5}$$

Proceeding in this way, one shows that its associated Riemann problem presents a shock wave solution when $u_l \geq u_r$; otherwise, a rarefaction wave solution is obtained. Moreover, the Riemann invariants for the systems of convection and propagation terms are the same as those obtained for the original system (1.1).

The second approach consists of substituting this velocity u, which is a solution of the inviscid Burgers's equation, in the second equation of (1.4). Then we study the second equation of the system as a scalar hyperbolic equation with a discontinuous coefficient depending on the variables x and t. Therefore, when we seek the discontinuous solutions of the latter equation, we obtain for $u_l \geq u_r$ a single shock solution and a two shock solution for $u_l < u_r$. (This last equation had not been considered by Colombeau and Le Roux [6].)

Following this analysis, we propose new Godunov schemes to compute an approximate solution of problem (1.4)–(1.2). Then by a splitting method, we construct new Godunov splitted schemes for the system (1.1). Adapting the technique mentioned in [3] for the scheme obtained by the first approach, we prove the stability of the L^∞-norm for the total variation in space and in time (in a Tonnelli–Cesari's sense) and that this scheme is convergent to a generalized solution.

Finally, we consider the gas dynamics system in the nonconservative form [6, 5]:

$$\left\{ \begin{array}{rcl} \partial_t v(x,t) + u(x,t)\partial_x v(x,t) - v(x,t)\partial_x u(x,t) & \approx & 0, \\ \partial_t u(x,t) + u(x,t)\partial_x u(x,t) + v(x,t)\partial_x p(x,t) & \approx & 0, \\ \partial_t p(x,t) + u(x,t)\partial_x p(x,t) + \gamma p(x,t)\partial_x u(x,t) & \approx & 0, \end{array} \right. \tag{1.6}$$

where u, p, and v denote, respectively, the velocity, the pressure, and specific volume.

By the same approach as mentioned above for solving the system of convection terms, we propose split Godunov schemes using the Riemann solver developed by Colombeau–Le Roux [6] for the propagation terms.

It has been proved in [5] that the approximate solution of system (1.6) can cause wrong variations of specific volume, velocity, and pressure. Therefore, we use the modified Godunov scheme for the system of propagation terms which consists of projecting the density, the momentum, and the total energy instead of the specific volume, the velocity, and the pressure.

Consequently, for decreasing initial data where $u_l > 0 > u_r$, our new schemes permit us to compute an acceptable approximate solution either for the elasticity problem or for the gas dynamics Riemann problem, while the Colombeau–Le Roux scheme fails.

Section 2 is devoted to presenting the theoretical and numerical studies of the Riemann problem for the degenerated hyperbolic system (1.4) with the perturbation and the substitution methods. Split schemes for the system modeling elasticity (1.1) are proposed, and the stability properties of the splitted scheme of elasticity obtained with the first approach are proved in section 3. A generalized solution is constructed from the approximate solution in section 4. In section 5 we apply the different approaches to the system of gas dynamics. Numerical results are given in section 6, and concluding remarks are made.

2. Convection problem for the elasticity.

2.1. Resolution by perturbation. The system (1.5) is strictly hyperbolic since the term $\varepsilon\, k^2$ does not vanish. Its matrix has two real eigenvalues $\lambda_1(u, \varepsilon, k) = u - \varepsilon k$ and $\lambda_2(u, \varepsilon, k) = u + \varepsilon k$ associated with two eigenvectors $r_1(k) = (1, k)^t$ and $r_2(k) = (1, -k)^t$, respectively.

As each characteristic field is genuinely nonlinear, we must deal with shock solutions or rarefaction wave solutions to solve the system (1.5). From now on, we set $W = (u,\, \sigma)^t$.

• **Shock wave solution.** If we look for a solution of the form

$$W_\varepsilon(x, t) = W_l + (W_r - W_l)H_\varepsilon(x - ct),$$

one gets $c = c_\varepsilon = \frac{u_l + u_r}{2} \mp \varepsilon\, k$.

When ε tends to 0, c_ε tends to $\frac{u_l + u_r}{2}$, and

$$W(x, t) = W_l + (W_r - W_l)H(x - ct). \tag{2.1}$$

Therefore, the limit of the function u_ε is a solution of Burgers's equation according to the Rankine–Hugoniot condition.

• **Rarefaction wave solution.** Setting $\zeta = \frac{x}{t}$, the self-similar solution of problem (1.5)–(1.2) must satisfy [8, 15] for $i = 1, 2$, the following ordinary differential system:

$$W'(\zeta) = r_i(k), \tag{2.2}$$

with

$$W(\lambda_i(W_l),\, \lambda_i(W_r)) = (W_l,\, W_r).$$

From (2.2) we find the relations

$$\sigma'(\zeta) + k\,u'(\zeta) = 0 \quad \text{or} \quad \sigma'(\zeta) - k\,u'(\zeta) = 0,$$

which give by integration the following Riemann invariants:

$$\left\{ \begin{array}{rcll} \sigma - k\,u & = & \sigma_l - k\,u_l & \text{if } u > u_l, \\ \sigma + k\,u & = & \sigma_r + k\,u_r & \text{if } u < u_r. \end{array} \right. \tag{2.3}$$

The characteristic rays passing through the origin and a general point (x,t) situated inside the fan have the following slopes: $\frac{x}{t} = u - \varepsilon\,k$ or $\frac{x}{t} = u + \varepsilon\,k$. Then, using the Riemann invariants (2.3), one gets as ε tends to zero the value inside the fan:

$$(u,\,\sigma) = \left(\frac{u_l + u_r}{2} + \frac{\sigma_r - \sigma_l}{2\,k},\; \frac{\sigma_l + \sigma_r}{2} + k\frac{u_r - u_l}{2} \right).$$

2.2. Resolution by substitution. We know that Burgers's equation presents discontinuous solutions. Therefore, let us consider in $\mathcal{G}_S(\mathbb{R}\times\mathbb{R}^+)$ the solution of the first equation of system (1.4) under the following form:

$$u(x,t) = u_l + (u_r - u_l)H(x - ct),$$

with the Rankine–Hugoniot condition $c = \frac{(u_l+u_r)}{2}$.

Then, system (1.4) can be written as

$$\left\{ \begin{array}{l} \partial_t\sigma(x,t) + u(x,t)\partial_x\sigma(x,t) \approx 0, \\ u(x,t) = u_l + (u_r - u_l)H(x - ct), \quad \text{with} \quad c = \dfrac{(u_l + u_r)}{2}. \end{array} \right. \tag{2.4}$$

When we add to (2.4) the initial condition

$$\sigma_0(x) = \sigma_l + (\sigma_r - \sigma_l)H(x), \tag{2.5}$$

we obtain a Riemann problem for a scalar equation with the discontinuous coefficient u. From Oberguggenberger [12], the hyperbolic equation (2.4) has a solution in $\mathcal{G}_S(\mathbb{R}\times\mathbb{R}^+)$.

Because u is a piecewise function, one recovers the case of scalar hyperbolic equation with constant coefficient (see [8]) outside the discontinuity. Thus, the characteristic curves are straight lines with slope $\frac{1}{u_l}$ if $x < ct$ and straight lines with slope $\frac{1}{u_r}$ for $x > ct$. To determine the discontinuous solutions of (2.4) we must deal with the sign of $u_l - u_r$.

• *If* $u_l - u_r \geq 0$, we have a shock wave solution

$$\sigma(x,t) = \sigma_l + (\sigma_r - \sigma_l)H(x - ct). \tag{2.6}$$

Moreover, placing (2.6) into (2.4) as $c = \frac{(u_l+u_r)}{2}$, we recover the following classical relation linking a generalized Heaviside function with its derivative:

$$H(x - ct)H'(x - ct) \approx \frac{1}{2}H'(x - ct).$$

• *If* $u_l - u_r < 0$, the function $\sigma(x,t)$ is equal to σ_l if $t > \frac{x}{u_l}$ and equal to σ_r for $t < \frac{x}{u_r}$ (see Figure 1). But in the sector $\frac{x}{u_r} < t < \frac{x}{u_l}$ (which is nonempty because

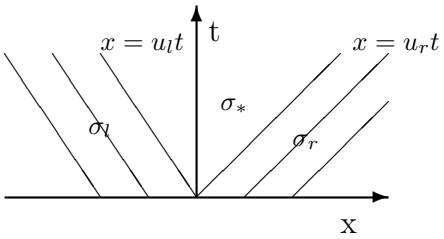

FIG. 1. *Characteristic straight lines when* $u_l - u_r < 0$.

$u_l - u_r < 0$) there is a lack of information. Proceeding as Remaki in [13], we consider a two shock wave solution with an intermediate step value σ_*:

$$\sigma(x,t) = \sigma_l + (\sigma_* - \sigma_l)H(x - u_l t) + (\sigma_r - \sigma_*)H(x - u_r t). \tag{2.7}$$

But, it appears that this function σ verifies (2.4) for all value σ_*.

In fact, a reasonable value of σ_* can derive from the initial condition. Indeed, placing (2.7) into (2.4) and making t tend to 0, one obtains

$$(\sigma_r - \sigma_*)H'(x) + H(x)\{(\sigma_r - \sigma_l)H'(x)\} \approx 0. \tag{2.8}$$

Since $H(x)H'(x) \approx \frac{1}{2}H'(x)$, the relation (2.8) gives $\frac{\sigma_r - \sigma_*}{\sigma_r - \sigma_l} = \frac{1}{2}$; therefore, $\sigma_* = \frac{\sigma_r + \sigma_l}{2}$.

2.3. The Godunov-type numerical schemes. We develop for both approaches a Godunov-type numerical scheme for solving system (1.4). We assume that u_0 and σ_0 are two initial conditions in the space of all bounded variation functions on $\mathbb{R}$. Let $h > 0$ be the space mesh size and $\Delta t = rh$ the time step, with $r > 0$. The discretization of the x-axis is performed by setting for all $i \in \mathbb{Z}$, $x_i = ih$ and $I_i = [x_{i-1/2}, x_{i+1/2}[$. For a given h, the value of the approximate pair (u_h, σ_h) at the point $x_i = ih$ and at the time $t_n = nrh$ is denoted by (u_i^n, σ_i^n), with $i \in \mathbb{Z}$ and $n \in \mathbb{N}$.

The quantities u_i^0 and σ_i^0 are obtained as the mean value of the initial data u_0 and σ_0, respectively, on each I_i. From the knowledge of (u_i^n, σ_i^n) we set $c_{i-1/2}^n = \frac{u_i^n + u_{i-1}^n}{2}$, $i \in \mathbb{Z}$. Then, according to the sign of u_i^n, $i \in \mathbb{Z}$, we compute the value of $(u_i^{n+1}, \sigma_i^{n+1})$ given either by one cell of Table 2.1 for both approaches, or by the formulas (2.17)–(2.18) for the first approach, or by the formula (2.19) for the second approach.

If $u_{i-1}^n < 0 < u_i^n$, then we define for the first approach

$$(\sigma_{i-1/2}^n, u_{i-1/2}^n) = \left(\frac{\sigma_i^n + \sigma_{i-1}^n}{2} + k\frac{u_i^n - u_{i-1}^n}{2}, \frac{u_i^n + u_{i-1}^n}{2} + \frac{\sigma_i^n - \sigma_{i-1}^n}{2\,k} \right),$$

and we obtain

$$\sigma_i^{n+1} = \sigma_i^n - r\left(\frac{u_i^n + u_{i-1/2}^n}{2}\right)(\sigma_i^n - \sigma_{i-1/2}^n), \tag{2.17}$$

$$u_i^{n+1} = u_i^n - r\left(\frac{u_i^n + u_{i-1/2}^n}{2}\right)(u_i^n - u_{i-1/2}^n). \tag{2.18}$$

We set for the second approach

$$\sigma_{i-1/2}^n = \frac{\sigma_i^n + \sigma_{i-1}^n}{2}$$

TABLE 2.1
Approximation of (u, σ) *according to the sign of* $c^n_{i-1/2}$ *and* $c^n_{i+1/2} i \in \mathbb{Z}$.

	$c^n_{i-1/2} \geq 0$	$c^n_{i-1/2} \leq 0$
$c^n_{i+1/2} \geq 0$	(2.9) $\sigma_i^{n+1} = \sigma_i^n - rc^n_{i-1/2}(\sigma_i^n - \sigma_{i-1}^n)$ (2.10) $u_i^{n+1} = \sigma_i^n - rc^n_{i-1/2}(u_i^n - u_{i-1}^n)$	(2.11) $\sigma_i^{n+1} = \sigma_i^n$ (2.12) $u_i^{n+1} = u_i^n$
$c^n_{i-1/2} < 0$	$\sigma_i^{n+1} = \sigma_i^n - rc^n_{i-1/2}(\sigma_i^n - \sigma_{i-1}^n)$ (2.13) $-rc^n_{i+1/2}(\sigma_{i+1}^n - \sigma_i^n)$ $u_i^{n+1} = u_i^n - rc^n_{i-1/2}(u_i^n - u_{i-1}^n)$ (2.14) $-rc^n_{i+1/2}(u_{i+1}^n - u_i^n)$	$\sigma_i^{n+1} = -rc^n_{i+1/2}(\sigma_{i+1}^n - \sigma_i^n) + \sigma_i^n$ (2.15) $u_i^{n+1} = -rc^n_{i+1/2}(u_{i+1}^n - u_i^n) + u_i^n$ (2.16)

and we get the following:

$$\sigma_i^{n+1} = \sigma_i^n - ru_i^n(\sigma_i^n - \sigma_{i-1/2}^n). \tag{2.19}$$

The Courant–Friedrichs–Lewy (CFL) condition, which ensures that two shock waves do not meet inside the mesh, is as follows:

$$\begin{aligned} \max_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}}(|u_i^n|, |u_{i+1/2}^n|) &< \frac{1}{2r} \quad \text{for the first approach,} \\ \max_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}}|u_i^n| &< \frac{1}{2r} \quad \text{for the second approach.} \end{aligned}$$

Note that the Godunov scheme developed for the second approach is based on the sign of u_i^n while the one developed for the first approach is based on the left and right waves of, respectively, speed $C^n_{l,i+1/2} = \frac{u_i^n + u_{i+1/2}^n}{2}$ and $C^n_{r,i+1/2} = \frac{u_{i+1}^n + u_{i+1/2}^n}{2}$. The intermediate step of the velocity is defined above or equals u_i^n or u_{i+1}^n.

3. Godunov scheme by a splitting method for the elasticity. Let u_0, σ_0 be two initial conditions in $\mathcal{BV}(\mathbb{R})$. Discretizing the x-axis and the time space as in subsection 2.3, the procedure consists of two steps.

First, with the assumption that $(\mathbf{u}_i^n, \boldsymbol{\sigma}_i^n)$ is the approximate solution of the system (1.1) at time $t_n = nrh$, we compute an approximate solution $(u_i^{n,1}, \sigma_i^{n,1})$ of the system (1.4) of the convection problem at time $t_{n+1} = (n+1)rh$.

In the second step, solving the linear strictly hyperbolic system (1.3) with the initial data $(u_i^{n,1}, \sigma_i^{n,1})$, the shock waves solutions present two contact discontinuities of, respectively, propagation speed $-k$ and k.

Thanks to the Rankine–Hugoniot jump conditions, for each $i \in \mathbb{Z}$, the intermediate step value of u and σ is given by the same formulas as those obtained from the

Riemann invariants (2.3):

$$\begin{aligned} u_{i+1/2}^{n,1} &= \frac{u_i^{n,1}+u_{i+1}^{n,1}}{2}+\frac{\sigma_{i+1}^{n,1}-\sigma_i^{n,1}}{2k}, \\ \sigma_{i+1/2}^{n,1} &= k\frac{u_{i+1}^{n,1}-u_i^{n,1}}{2}+\frac{\sigma_{i+1}^{n,1}+\sigma_i^{n,1}}{2}. \end{aligned}$$

Then, by projection we construct the approximate solution $(\mathbf{u}_i^{n+1},\, \boldsymbol{\sigma}_i^{n+1})$ of the system (1.1) at time $t_{n+1}=(n+1)rh$:

$$\mathbf{u}_i^{n+1} = u_i^{n,1}+kr(u_{i+1/2}^{n,1}-u_i^{n,1})-kr(u_i^{n,1}-u_{i-1/2}^{n,1}), \tag{3.1}$$

$$\boldsymbol{\sigma}_i^{n+1} = \sigma_i^{n,1}+kr(\sigma_{i+1/2}^{n,1}-\sigma_i^{n,1})-kr(\sigma_i^{n,1}-\sigma_{i-1/2}^{n,1}), \tag{3.2}$$

where the notation $u_i^{n,1}$ and $\sigma_i^{n,1}$ represents the result of the convection step (obtained in subsection 2.3). Moreover, the constant $r>0$ has to fit so that one of the following inequalities holds:

$$\begin{aligned} \max_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}}(|u_i^n|,|u_{i+1/2}^n|,k) &< \frac{1}{2r} \quad \text{for the first approach,} \\ \max_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}}(|u_i^n|,k) &< \frac{1}{2r} \quad \text{for the second approach.} \end{aligned}$$

Let us denote by $\mathcal{B}V(\mathbb{R})$ the space of all bounded variation functions on $\mathbb{R}$ and by $\mathcal{T}V(u)$ the total variation of the function u.

THEOREM 1. *For $u_0,\sigma_0\in\mathcal{B}V(\mathbb{R})\cap L^\infty(\mathbb{R})$ and under the assumption that*

$$\frac{1}{k}\sup_{x\in\mathbb{R}}(|ku_0(x)+\sigma_0(x)|,|ku_0(x)-\sigma_0(x)|)=M, \tag{3.3}$$

$$\max_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} r(|u_i^n|,|u_{i+1/2}^n|,k)<\frac{1}{2}, \tag{3.4}$$

the scheme previously introduced in section 3 is stable for $L^\infty(\mathbb{R})$-norm for the total variation in space and for the total variation in time in the Tonnelli–Cesari's sense.

Therefore, for any $T>0$ it follows from the Banach–Alaoglu–Bourbaki theorem that there exist sequences u_{h_m}, σ_{h_m} (with sequences $(h_m)_{m\in\mathbb{N}}$ tending to 0) which converge for the topology of $L^1_{loc}(\mathbb{R}\times]0,\,T[)$ toward the functions $u,\,\sigma\in L^1_{loc}(\mathbb{R}\times]0,\,T[)\cap\mathcal{B}V(\mathbb{R}\times]0,\,T[)$. The initial condition at $t=0$ is justified as in [3].

Proof of Theorem 1. Let us introduce, for each i, n,

$$R_i^n = ku_i^n+\sigma_i^n, \tag{3.5}$$

$$Q_i^n = ku_i^n-\sigma_i^n, \tag{3.6}$$

$$R_i^{n,1} = ku_i^{n,1}+\sigma_i^{n,1}, \tag{3.7}$$

$$Q_i^{n,1} = ku_i^{n,1}-\sigma_i^{n,1}. \tag{3.8}$$

From (3.1) and (3.2) one has

$$\begin{cases} R_i^{n+1} &= R_i^{n,1}(1-kr)+krR_{i+1}^{n,1}, \quad i\in\mathbb{Z}, \\ Q_i^{n+1} &= Q_i^{n,1}(1-kr)+krQ_{i-1}^{n,1}, \quad i\in\mathbb{Z}. \end{cases} \tag{3.9}$$

We are going to prove that there exists a constant A such that

$$|R_i^n| \leq kM \quad \forall\, i \in \mathbb{Z},\, n \in \mathbb{N}, \tag{3.10}$$

$$\sum_{i\in\mathbb{Z}} |R_{i+1}^n - R_i^n| \leq A \qquad \forall\, n \in \mathbb{N} \tag{3.11}$$

and

$$|Q_i^n| \leq kM \quad \forall\, i \in \mathbb{Z},\, n \in \mathbb{N}, \tag{3.12}$$

$$\sum_{i\in\mathbb{Z}} |Q_{i+1}^n - Q_i^n| \leq A \qquad \forall\, n \in \mathbb{N}. \tag{3.13}$$

We proceed by induction on n. For $n = 0$ we have (3.10) from (3.3), (3.11) from (3.5), and the bounded variation assumption on (u_0, σ_0).

We assume that (3.10) and (3.11) hold for some n. Then, from (3.4) and (3.9) one gets

$$\begin{aligned} |R_i^{n+1}| &\leq (1-kr)|R_i^{n,1}| + kr|R_{i+1}^{n,1}|, \quad i \in \mathbb{Z}, \\ \sum_{i\in\mathbb{Z}} |R_{i+1}^{n+1} - R_i^{n+1}| &\leq (1-kr)\sum_{i\in\mathbb{Z}} |R_{i+1}^{n,1} - R_i^{n,1}| + kr\sum_{i\in\mathbb{Z}} |R_{i+2}^{n,1} - R_{i+1}^{n,1}| \\ &\leq \sum_{i\in\mathbb{Z}} |R_{i+1}^{n,1} - R_i^{n,1}|. \end{aligned}$$

Now we are going to prove that

$$|R_i^{n,1}| \leq kM, \tag{3.14}$$

$$\sum_{i\in\mathbb{Z}} |R_{i+1}^{n,1} - R_i^{n,1}| \leq \sum_{i\in\mathbb{Z}} |R_{i+1}^n - R_i^n|. \tag{3.15}$$

The Riemann invariant $R_i^{n,1}$ is defined with the approximate solution of the convection problem (see subsection 2.3), constructed according to the sign of the velocity u. We start with the case where u has a constant sign; then we treat the case where the velocity has a variable sign.

When $u_i^n < 0$ for all $i \in \mathbb{Z}$, obviously $c_{i+1/2}^n < 0$, and one obtains by projection (see Figure 2)

$$\begin{aligned} \sigma_i^{n,1} &= \sigma_i^n - rc_{i+\frac{1}{2}}^n(\sigma_{i+1}^n - \sigma_i^n), \\ u_i^{n,1} &= u_i^n - rc_{i+\frac{1}{2}}^n(u_{i+1}^n - \sigma_i^n). \end{aligned}$$

Using (3.4) and then shifting the index, it happens that

$$\sum_{i\leq s-1} |R_{i+1}^{n,1} - R_i^{n,1}| \leq \sum_{i\leq s-1} |R_{i+1}^n - R_i^n| - rc_{s+\frac{1}{2}}^n |R_{s+1}^n - R_s^n|, \tag{3.16}$$

$$\sum_{i\geq s} |R_{i+1}^{n,1} - R_i^{n,1}| \leq \sum_{i\geq s} |R_{i+1}^n - R_i^n| + rc_{s+\frac{1}{2}}^n |R_{s+1}^n - R_s^n|, \tag{3.17}$$

and $|R_i^{n,1}| \leq (1 + rc_{i+1/2}^n)|R_i^n| - rc_{i+1/2}^n |R_{i+1}^n| \leq kM$ for all $i \in \mathbb{Z}$.

Moreover, (3.16) and (3.17) give

$$\sum_{i\in\mathbb{Z}} |R_{i+1}^{n,1} - R_i^{n,1}| = \sum_{i\leq s-1} |R_{i+1}^{n,1} - R_i^{n,1}| + \sum_{i\geq s} |R_{i+1}^{n,1} - R_i^{n,1}| \leq \sum_{i\in\mathbb{Z}} |R_{i+1}^n - R_i^n|.$$

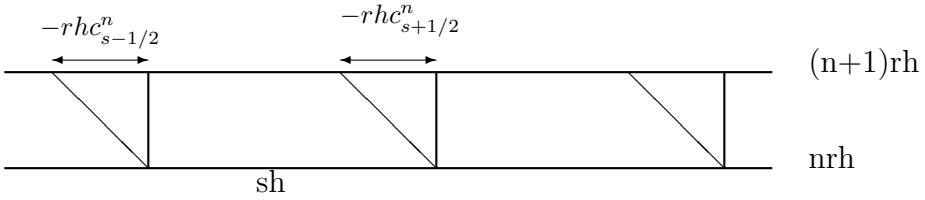

FIG. 2. *Type* 1. $rc^n_{s-1/2} < 0$ *and* $rc^n_{s+1/2} < 0$.

In the case $u^n_i \geq 0$ for all $i \in \mathbb{Z}$, corresponding to type 2, we similarly obtain the same inequalities (3.14) and (3.15).

Since we have chosen a monotonous solution of Burgers's equation, its sign can change only once. Consequently, when u has a variable sign, three cases (types 3, 4, and 5) corresponding to the three pictures Figures 3, 4, and 5 can occur.

Type 3 is the case where there exists $p \in \mathbb{Z}$ such that $u^n_i \leq 0$ for all $i \leq p$ and $u^n_i \geq 0$ for all $i \geq p+1$. We denote by $C^n_{l,i+1/2} = (u^n_i + u^n_{i+1/2})/2$ and $C^n_{r,i+1/2} = (u^n_{i+1} + u^n_{i+1/2})/2$, respectively, the left and the right sound speed between the cells I_p and I_{p+1}.

Thus, by projection (according to Figure 3) and using the CFL condition (3.4) we obtain

$$|R^{n,1}_p| \leq kM \quad \text{and} \quad |R^{n,1}_{p+1}| \leq kM. \tag{3.18}$$

Since the relation (3.14) is valid for $u^n_i \leq 0$ and $u^n_i \geq 0$ for all $i \in \mathbb{Z}$ (types 1 and 2), we have for $i \leq p$ and $i \geq p+2$, $|R^{n,1}_i| \leq kM$. Then with (3.18) one gets $|R^{n,1}_i| \leq kM$, $i \in \mathbb{Z}$.

Moreover,

$$\begin{aligned} |R^{n,1}_p - R^{n,1}_{p-1}| &\leq (1 + rc^n_{p-\frac{1}{2}})|R^n_p - R^n_{p-1}| - rC^n_{l,p+\frac{1}{2}}|R^n_{p+1} - R^n_p|, \\ |R^{n,1}_{p+1} - R^{n,1}_p| &\leq (1 + rC^n_{l,p+\frac{1}{2}})|R^n_{p+1} - R^n_p|, \\ |R^{n,1}_{p+2} - R^{n,1}_{p+1}| &\leq (1 - rc^n_{p+\frac{3}{2}})|R^n_{p+2} - R^n_{p+1}|, \end{aligned} \tag{3.19}$$

and in the case $u^n_i \geq 0$ for all $i \in \mathbb{Z}$,

$$\sum_{i \geq p+2} |R^{n,1}_{i+1} - R^{n,1}_i| \leq \sum_{i \geq p+2} |R^n_{i+1} - R^n_i| + rc^n_{p+\frac{3}{2}}|R^n_{p+2} - R^n_{p+1}|. \tag{3.20}$$

Adding these last estimates (3.20) to (3.19) and to (3.16) with $s = p-1$, one obtains

$$\sum_{i \in \mathbb{Z}} |R^{n,1}_{i+1} - R^{n,1}_i| \leq \sum_{i \in \mathbb{Z}} |R^n_{i+1} - R^n_i|.$$

Type 4 is the case where there exists p such that $u^n_i \leq 0$ for all $i \leq p$ and $u^n_i \geq 0$ for all $i \geq p+2$. Still by projection (according to Figure 4), one obtains

$$|R^{n,1}_{p+1}| = |R^n_{p+1}| \leq kM; \tag{3.21}$$

consequently, in the same way as previously (for type 3), the relation (3.14) is valid for all $i \in \mathbb{Z}$. Moreover,

$$\begin{aligned} |R^m_{p+1} - R^m_p| &= (1 + rc^n_{p+\frac{1}{2}})|R^n_{p+1} - R^n_p|, \\ |R^m_{p+2} - R^m_{p+1}| &= (1 - rc^n_{p+\frac{3}{2}})|R^n_{p+2} - R^n_{p+1}|; \end{aligned} \tag{3.22}$$

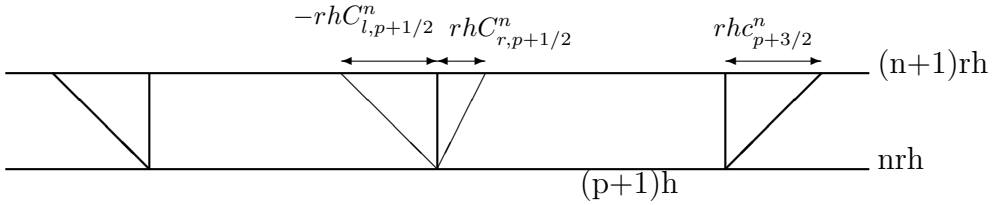

FIG. 3. *Type* 3. $u^n_{p+1} \geq 0$, *and* $u^n_p \leq 0$.

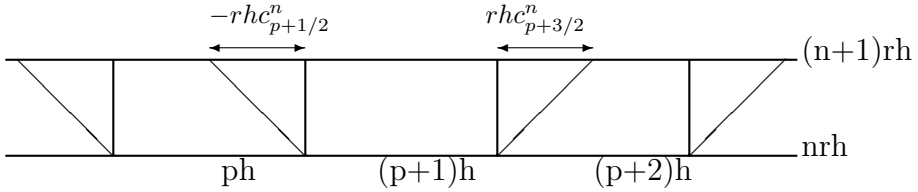

FIG. 4. *Type* 4. $rc^n_{p+1/2} \leq 0$, *and* $rc^n_{p+3/2} \geq 0$.

then adding the above estimates (3.22) to (3.16) for $s = p$ and to (3.20) one gets

$$\sum_{i\in\mathbb{Z}} |R^{n,1}_{i+1} - R^{n,1}_i| \leq \sum_{i\in\mathbb{Z}} |R^n_{i+1} - R^n_i|.$$

Type 5 is the case where there exists p such that $u^n_i \geq 0$ for all $i \leq p$ and $u^n_i \leq 0$ for all $i \geq p+2$. By projection (according to Figure 5), we obtain using the CFL condition (3.4)

$$|R^{n,1}_{p+1}| \leq |R^n_{p+1}|(1 - rc^n_{p+\frac{1}{2}} + rc^n_{p+\frac{3}{2}}) + rc^n_{p+\frac{1}{2}}|R^n_p| - rc^n_{p+\frac{3}{2}}|R^n_{p+2}| \leq kM. \tag{3.23}$$

As the relation (3.14) is valid for $u^n_1 \geq 0$ and $u^n_i \leq 0$ for all $i \in \mathbb{Z}$ (types 1 and 2), we have for $i \leq p$ and $i \geq p+2$, $| R^{n,1}_i | \leq kM$. Then, with (3.23) one gets $|R^{n,1}_i| \leq kM$, $i \in \mathbb{Z}$.

Besides, when $u^n_i \geq 0$ for all $i \in \mathbb{Z}$,

$$\sum_{i\leq p} |R^{n,1}_{i+1} - R^{n,1}_i| \leq \sum_{i\leq p} |R^n_{i+1} - R^n_i| - rc^n_{p+\frac{1}{2}}|R^n_{p+1} - R^n_p|, \tag{3.24}$$

and the following inequalities hold:

$$\begin{aligned} |R^m_{p+1} - R^m_p| &\leq (1 - rc^n_{p+\frac{1}{2}})|R^n_{p+1} - R^n_p| \\ &+ rc^n_{p-\frac{1}{2}}|R^n_p - R^n_{p-1}| - rc^n_{p+\frac{3}{2}}|R^n_{p+2} - R^n_{p+1}|, \\ |R^m_{p+2} - R^m_{p+1}| &\leq (1 + rc^n_{p+\frac{3}{2}})|R^n_{p+2} - R^n_{p+1}| \\ &+ rc^n_{p+\frac{1}{2}}|R^n_{p+1} - R^n_p| - rc^n_{p+\frac{5}{2}}|R^n_{p+3} - R^n_{p+2}|. \end{aligned} \tag{3.25}$$

Adding the above estimates (3.25) to (3.24) and to (3.17) for $s = p+1$, one obtains (3.15).

One similarly obtains the estimates

$$|Q^{n,1}_i| \leq kM \quad \text{and} \quad \sum_{i\in\mathbb{Z}} |Q^{n,1}_{i+1} - Q^{n,1}_i| \leq \sum_{i\in\mathbb{Z}} |Q^n_{i+1} - Q^n_i|, \tag{3.26}$$

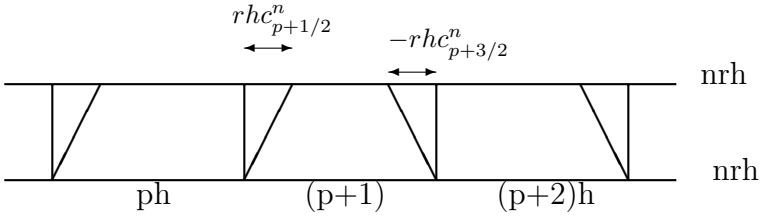

FIG. 5. *Type* 5. $c^n_{p+1/2} \geq 0$, *and* $c^n_{p+3/2} \leq 0$.

from which we deduce the inequalities (3.12) and (3.13).

With the estimations of each Riemann invariant (3.10) and (3.12), one has the stability for the L^∞-norm:

$$|u_i^n| \leq \frac{1}{2k}(|R_i^n| + |Q_i^n|) \leq M \quad \text{and} \quad |\sigma_i^n| \leq \frac{1}{2}(|R_i^n| + |Q_i^n|) \leq kM.$$

Further, from (3.11) and (3.13) one gets the stability for the total variation in space:

$$\begin{aligned} |u_{i+1}^n - u_i^n| &\leq \frac{1}{2k}\left(|R_{i+1}^n - R_i^n| + |Q_{i+1}^n - Q_i^n|\right) \leq \frac{1}{k}A, \\ |\sigma_{i+1}^n - \sigma_i^n| &\leq \frac{1}{2}\left(|R_{i+1}^n - R_i^n| + |Q_{i+1}^n - Q_i^n|\right) \leq A. \end{aligned}$$

To complete the proof of Theorem 1, an easy way to show the stability for total variation in the time property is to observe that the Riemann invariants (3.7) and (3.8), defined with the approximate solutions of the system (1.4), verify the following lemma.

LEMMA 1. *For all* $i \in \mathbb{Z} \quad \exists\, \alpha_i, \beta_i \in \{0, \frac{1}{4}, \frac{1}{2}\}$, *such that*

$$\begin{aligned} |R_i^{n,1} - R_i^n| &\leq \alpha_i |R_{i+1}^n - R_i^n| + \beta_i |R_i^n - R_{i-1}^n|, \\ |Q_i^{n,1} - Q_i^n| &\leq \alpha_i |Q_{i+1}^n - Q_i^n| + \beta_i |Q_i^n - Q_{i-1}^n|. \end{aligned}$$

Proof of Lemma 1. The CFL inequality (3.4) allows us to conclude. ∎

We have from (3.9), (3.26), (3.15), and Lemma 1 that

$$\begin{aligned} \sum_{i\in\mathbb{Z}} |u_i^{n+1} - u_i^n| &\leq \frac{1}{2k}\sum_{i\in\mathbb{Z}} \left(|R_i^{n+1} - R_i^n| + |Q_i^{n+1} - Q_i^n|\right) \\ &\leq \frac{1}{2k}\sum_{i\in\mathbb{Z}} \left(|R_i^{n+1} - R_i^{n,1}| + |R_i^{n,1} - R_i^n|\right) \\ &+ \frac{1}{2k}\sum_{i\in\mathbb{Z}} \left(|Q_i^{n+1} - Q_i^{n,1}| + |Q_i^{n,1} - Q_i^n|\right) \\ &\leq \frac{1}{2k}\sum_{i\in\mathbb{Z}} kr\, \left(|R_{i+1}^{n,1} - R_i^{n,1}| + |Q_i^{n,1} - Q_{i-1}^{n,1}|\right) \\ &+ \frac{1}{2k}\sum_{i\in\mathbb{Z}} (\alpha_i + \beta_{i+1}) \left(|R_{i+1}^n - R_i^n| + |Q_{i+1}^n - Q_i^n|\right) \\ &\leq \frac{1}{2k}\sum_{i\in\mathbb{Z}} (kr + \alpha_i + \beta_{i+1}) \left(|R_{i+1}^n - R_i^n| + |Q_{i+1}^n - Q_i^n|\right). \end{aligned}$$

As $\alpha_i + \beta_{i+1} \leq 1$ for all i in $\mathbb{Z}$ and $k\,r < 1/2$, it follows that

$$\sum_{i\in\mathbb{Z}} |u_{i+1}^{n+1} - u_i^n| \leq \frac{3}{4k}\sum_{i\in\mathbb{Z}} \left(|R_{i+1}^n - R_i^n| + |Q_{i+1}^n - Q_i^n|\right) \leq \frac{3}{2k}A.$$

An analogous estimate holds for $\sum_{i\in\mathbb{Z}} |\sigma_{i+1}^{n+1} - \sigma_i^n|$.

4. A generalized solution of the elasticity problem. Let ρ be a $\mathcal{C}^\infty$ function on $\mathbb{R}$ with compact support and nonnegative values such that $\int \rho(x)\,dx = 1$.

We define two mappings R_u and R_σ from $]0,\,1]\times\mathbb{R}^2$ into $\mathbb{R}$ by

$$\begin{aligned} R_u(\varepsilon,x,t) &= \iint u_\varepsilon(x-\varepsilon^3\zeta, t-\varepsilon^3 r\tau)\rho(\zeta)\rho(\tau)\,d\zeta d\tau, \\ R_\sigma(\varepsilon,x,t) &= \iint \sigma_\varepsilon(x-\varepsilon^3\zeta, t-\varepsilon^3 r\tau)\rho(\zeta)\rho(\tau)\,d\zeta d\tau \end{aligned} \tag{4.1}$$

if $\varepsilon = h_m$ for some m and by

$$R_u(\varepsilon,x,t) = R_u(h_m,x,t) \text{ and } R_\sigma(\varepsilon,x,t) = R_\sigma(h_m,x,t)$$

if $h_{m+1} \le \varepsilon < h_m$.

Since the scheme is stable for the L^∞-norm, there exists $A \in \mathbb{R}_+^*$ such that for all $t > 0$,

$$\sup_\varepsilon ||u_\varepsilon(.,\,t)||_{L^\infty} \le A, \quad \sup_\varepsilon ||\sigma_\varepsilon(.,\,t)||_{L^\infty} \le A,$$

and $R_u,\ R_\sigma \in \mathcal{E}_{M,S}(\mathbb{R}\times\mathbb{R}^+)$. Let U and Σ be the respective classes of R_u and R_σ in $\mathcal{G}_S(\mathbb{R}\times\mathbb{R}^+)$.

THEOREM 2. *The generalized functions* $U,\ \Sigma \in \mathcal{G}_S(\mathbb{R}\times\mathbb{R}^+)$ *are solutions of the system* (1.1) *renamed as follows:*

$$\partial_t U(x,t) + U(x,t)\partial_x U(x,t) - \partial_x \Sigma(x,t) \approx 0, \tag{4.2}$$

$$\partial_t \Sigma(x,t) + U(x,t)\partial_x \Sigma(x,t) - k^2 \partial_x U(x,t) \approx 0. \tag{4.3}$$

The connection between the $U_{|_{t=0}}$, $\Sigma_{|_{t=0}}$ and U, Σ, with the classical functions u_0, σ_0 and u, σ (the weak star limit of the subsequences u_{h_m}, σ_{h_m}), is given by the following proposition.

PROPOSITION 1. $\left(U_{|_{t=0}}, \Sigma_{|_{t=0}}\right)$ *and* (U,Σ) *have, respectively,* (u_0,σ_0) *and* (u,σ) *as macroscopic aspects.*

The proof of Proposition 1 can be found in [3, 2].

Proof of Theorem 2. In order to prove (4.3), by the definition of association we must prove that for all $\psi \in \mathcal{D}(\mathbb{R}\times]0,\,\infty[)$, the quantity

$$\begin{aligned} P_\varepsilon &= \int\int \left(\frac{\partial}{\partial t} R_\sigma(\varepsilon,x,t) - R_u(\varepsilon,x,t)\frac{\partial}{\partial x} R_\sigma(\varepsilon,x,t)\right)\psi(x,t)\,dx\,dt \\ &- \int\int k^2 \frac{\partial}{\partial x} R_u(\varepsilon,x,t)\psi(x,t)\,dx\,dt \end{aligned} \tag{4.4}$$

tends to 0 as $\varepsilon \to 0$.

We adapt the process developed by Cauret in [3] to the case where the velocity sign can change.

If there exists $p \in \mathbb{Z}$ such that $u_p < 0 < u_{p+1}$,

$$E_{p+1}^n = (\sigma_{p+1}^{n+1} - \sigma_{p+1}^n) + rC_{l,p+\frac{1}{2}}^n(\sigma_{p+\frac{1}{2}}^n - \sigma_p^n) + rC_{r,p+\frac{1}{2}}^n(\sigma_{p+1}^n - \sigma_{p+\frac{1}{2}}^n) - rk^2(u_{p+1}^n - u_p^n);$$

otherwise,

$$E_{p+1}^n = (\sigma_{p+1}^{n+1} - \sigma_{p+1}^n) + rc_{p+\frac{1}{2}}^n(\sigma_{p+1}^n - \sigma_p^n) - rk^2(u_{p+1}^n - u_p^n).$$

Let us denote for $i \neq p+1$

$$E_i^n = (\sigma_i^{n+1} - \sigma_i^n) + rc_{i-\frac{1}{2}}^n(\sigma_i^n - \sigma_{i-1}^n) - rk^2(u_i^n - u_{i-1}^n).$$

Setting $\psi_i^n = \psi((i-\frac{1}{2})\varepsilon, r(n-\frac{1}{2})\varepsilon)$, we obtain

$$\left| P_\varepsilon - \sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} (\varepsilon - 2\varepsilon^3)\psi_i^n E_i^n \right| \leq C\varepsilon.$$

Therefore, P_ε tends to 0 when $\varepsilon \to 0$, if $\lim_{\varepsilon\to 0}\sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} (\varepsilon - 2\varepsilon^3)\psi_i^n E_i^n = 0$.

To complete the proof of (4.3), we must prove that the approximate solution is such that the following inequality holds:

$$\begin{aligned}\left|(\varepsilon - 2\varepsilon^3)\sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} \psi_i^n E_i^n\right| &\leq C\varepsilon^2 \sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} |\sigma_{i+1}^n - \sigma_i^n| \left\|\frac{\partial}{\partial x}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)} \\ &+ C\varepsilon^2 \sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} |u_i^n - u_{i-1}^n| \left\|\frac{\partial}{\partial x}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)} \\ &+ C\varepsilon^3 \sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} |\sigma_i^{n,1} + ku_i^n| \left\|\frac{\partial^2}{\partial x^2}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)}. \end{aligned} \tag{4.5}$$

Indeed, as the scheme is stable for the total variation in space and $\psi \in \mathcal{D}(\mathbb{R}\times]0,\infty[)$, one gets

$$\left|(\varepsilon - 2\varepsilon^3)\sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} \psi_i^n E_i^n\right| \leq C\varepsilon.$$

Therefore,

$$(\varepsilon - 2\varepsilon^3)\sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} \psi_i^n E_i^n \to 0 \text{ when } \quad \varepsilon \to 0.$$

Using the classification in different types introduced in the section 3, we are going to prove the estimation (4.5). For type 1 (see Figure 2), we have

$$\begin{aligned}\psi_i^n E_i^n &= \psi_i^n - rc_{i+\frac{1}{2}}^n(\sigma_{i+1}^n - \sigma_i^n)\psi_i^n + rc_{i-\frac{1}{2}}^n(\sigma_i^n - \sigma_{i-1}^n)\psi_i^n \\ &+ \frac{rk^2}{2}\left[-rc_{i+\frac{3}{2}}^n(u_{i+2}^n - u_{i+1}^n)\psi_i^n + rc_{i-\frac{1}{2}}^n(u_i^n - u_{i-1}^n)\psi_i^n\right] \\ &+ \frac{kr}{2}\left[(\sigma_{i+1}^{n,1} + ku_{i+1}^n)\psi_i^n - 2(\sigma_i^{n,1} + ku_i^n)\psi_i^n + (\sigma_{i-1}^{n,1} + ku_{i-1}^n)\psi_i^n\right].\end{aligned}$$

Then using the mean value theorem with the CFL condition (3.4) we achieve

$$\begin{aligned}\left|(\varepsilon - 2\varepsilon^3)\sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} \psi_i^n E_i^n\right| &\leq C\varepsilon^2 \sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} |\sigma_{i+1}^n - \sigma_i^n| \left\|\frac{\partial}{\partial x}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)} \\ &+ C\varepsilon^2 \sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} |u_i^n - u_{i-1}^n| \left\|\frac{\partial}{\partial x}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)} \\ &+ C\varepsilon^3 \sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} |\sigma_i^{n,1} + ku_i^n| \left\|\frac{\partial^2}{\partial x^2}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)}. \end{aligned}$$

Similarly we have for type 2 ($u_i^n \geq 0$ for all $i \in \mathbb{Z}$)

$$\begin{aligned}\left|(\varepsilon - 2\varepsilon^3)\sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} \psi_i^n E_i^n\right| &\leq C\varepsilon^2 \sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} |u_i^n - u_{i-1}^n| \left\|\frac{\partial}{\partial x}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)} \\ &+ C\varepsilon^3 \sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}} |\sigma_i^{n,1} + ku_i^n| \left\|\frac{\partial^2}{\partial x^2}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)}.\end{aligned}$$

For type 3 (see Figure 3) we have

$$\begin{aligned}\sum_{\substack{i\leq p\\ n\in\mathbb{N}}} \psi_i^n E_i^n &= \sum_{\substack{i\leq p-1\\ n\in\mathbb{N}}} rc_{i+1/2}^n(\sigma_{i+1}^n - \sigma_i^n)(\psi_{i+1}^n - \psi_i^n) - rC_{l,p+1/2}^n(\sigma_{p+1/2}^n - \sigma_p^n)\psi_p^n \\ &+ \frac{rk^2}{2}\left[-rC_{l,p+1/2}^n(u_{p+1/2}^n - u_p^n)\psi_{p-1}^n - rC_{r,p+1/2}^n(u_{p+1}^n - u_{p+1/2}^n)\psi_p^n\right] \\ &+ \frac{kr}{2}\left[(\sigma_{p+1}^{n,1} + ku_{p+1}^n)\psi_p^n - 2(\sigma_p^{n,1} + ku_p^n)\psi_p^n + (\sigma_p^{n,1} + ku_p^n)\psi_{p-1}^n\right] \\ &+ \frac{kr}{2}\sum_{\substack{i\leq p-1\\ n\in\mathbb{N}}} (\sigma_i^{n,1} + ku_i^n)(\psi_{i+1}^n - 2\psi_i^n + \psi_{i-1}^n) \\ &+ \frac{rk^2}{2}\sum_{\substack{i\leq p-1\\ n\in\mathbb{N}}} rc_{i+1/2}^n(u_{i+1}^n - u_i^n)(\psi_{i+1}^n - \psi_{i-1}^n),\end{aligned} \tag{4.6}$$

$$\begin{aligned}\psi_{p+1}^n E_{p+1}^n &= rC_{l,p+1/2}^n(\sigma_{p+1/2}^n - \sigma_{p+1}^n)\psi_{p+1}^n \\ &+ \frac{rk^2}{2}\left[rC_{l,p+1/2}^n(u_{p+1/2}^n - u_p^n)\psi_{p+1}^n - rc_{p+3/2}^n(u_{p+2}^n - u_{p+1}^n)\psi_{p+1}^n\right] \\ &+ \frac{kr}{2}\left[(\sigma_{p+2}^{n,1} + ku_{p+2}^n)\psi_{p+1}^n - 2(\sigma_{p+1}^{n,1} + ku_{p+1}^n)\psi_{p+1}^n + (\sigma_p^{n,1} + ku_p^n)\psi_{p+1}^n\right],\end{aligned} \tag{4.7}$$

and

$$\begin{aligned}\sum_{\substack{i\geq p+2\\ n\in\mathbb{N}}} \psi_i^n E_i^n &= \frac{rk^2}{2}\left[rC_{r,p+1/2}^n(u_{p+1}^n - u_{p+1/2}^n)\psi_{p+2}^n + rc_{p+3/2}^n(u_{p+2}^n - u_{p+1}^n)\psi_{p+3}^n\right] \\ &+ \frac{kr}{2}\left[\sum_{\substack{i\geq p+3\\ n\in\mathbb{N}}} (\sigma_i^{n,1} + ku_i^n)(\psi_{i+1}^n - 2\psi_i^n + \psi_{i-1}^n) + (\sigma_{p+1}^{n,1} + ku_{p+1}^n)\psi_{p+2}^n\right] \\ &+ \frac{kr}{2}\left[-2(\sigma_{p+2}^{n,1} + ku_{p+2}^n)\psi_{p+2}^n + (\sigma_{p+2}^{n,1} + ku_{p+2}^n)\psi_{p+3}^n\right] \\ &+ \frac{rk^2}{2}\left[\sum_{\substack{i\geq p+2\\ n\in\mathbb{N}}} rc_{i+1/2}^n(u_{i+1}^n - u_i^n)(\psi_{i+2}^n - \psi_i^n)\right].\end{aligned} \tag{4.8}$$

Therefore, summing (4.6), (4.7), (4.8) and using the mean value theorem with the

CFL condition (3.4) we get

$$\begin{aligned}\left|(\varepsilon-2\varepsilon^3)\sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}}\psi_i^n E_i^n\right| &\le C\varepsilon^2\sum_{\substack{i\le p\\ n\in\mathbb{N}}}|\sigma_{i+1}^n-\sigma_i^n|\left\|\frac{\partial}{\partial x}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)}\\ &+ C\varepsilon^2\sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}}|u_i^n-u_{i-1}^n|\left\|\frac{\partial}{\partial x}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)}\\ &+ C\varepsilon^3\sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}}|\sigma_i^{n,1}+ku_i^n|\left\|\frac{\partial^2}{\partial x^2}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)}.\end{aligned}$$

The computations for getting the estimation (4.5) for types 4 and 5 are similar to those presented for type 3. For type 4, one obtains

$$\begin{aligned}\left|(\varepsilon-2\varepsilon^3)\sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}}\psi_i^n E_i^n\right| &\le C\varepsilon^2\sum_{\substack{i\le p\\ n\in\mathbb{N}}}|\sigma_{i+1}^n-\sigma_i^n|\left\|\frac{\partial}{\partial_x}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)}\\ &+ C\varepsilon^2\sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}}|u_i^n-u_{i-1}^n|\left\|\frac{\partial}{\partial_x}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)}\\ &+ C\varepsilon^3\sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}}|\sigma_i^{n,1}+ku_i^n|\left\|\frac{\partial^2}{\partial x^2}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)},\end{aligned}$$

and for type 5 one gets

$$\begin{aligned}\left|(\varepsilon-2\varepsilon^3)\sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}}\psi_i^n {E_1}_i^n\right| &\le C\varepsilon^2\sum_{\substack{i\ge p+1\\ n\in\mathbb{N}}}|\sigma_{i+1}^n-\sigma_i^n|\left\|\frac{\partial}{\partial_x}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)}\\ &+ C\varepsilon^2\sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}}|u_i^n-u_{i-1}^n|\left\|\frac{\partial}{\partial_x}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)}\\ &+ C\varepsilon^3\sum_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}}|\sigma_i^{n,1}+ku_i^n|\left\|\frac{\partial^2}{\partial x^2}\psi\right\|_{L^\infty(\mathbb{R}\times\mathbb{R}^+)}.\end{aligned}$$

Consequently,

$$P_\varepsilon\to 0 \quad \text{when} \quad \varepsilon\to 0.$$

The association (4.2) can be proved in the same way as (4.3). This ends the proof of Theorem 2. □

Following the study of the model of elasticity in section 2, we use the same approaches for the system of hydrodynamics in the nonconservative form (1.6).

5. A Godunov scheme by a splitting method for a model of hydrodynamics. Let v_0, u_0, σ_0 be the initial conditions in $\mathcal{B}V(\mathbb{R})$. Discretizing the x-axis and the time space and using the same notation as in subsection 2.3, we denote by v_i^0, u_i^0, and p_i^0 the mean value of the initial data v_0, u_0, and p_0, respectively, on each I_i. From our knowledge of (v_i^n, u_i^n, p_i^n), the solution of (1.6), we compute the value $(v_i^{n+1}, u_i^{n+1}, p_i^{n+1})$ in two steps.

First, with $(v_i^n,\, u_i^n,\, p_i^n)$ as initial data, we compute an approximate solution $(v_i^{n,1},\, u_i^{n,1},\, p_i^{n,1})$ of the Riemann problem associated with the convection terms (5.1):

$$\left\{\begin{array}{rcl} \partial_t v(x,t) + u(x,t)\partial_x v(x,t) &=& 0,\\ \partial_t u(x,t) + u(x,t)\partial_x u(x,t) &=& 0,\\ \partial_t p(x,t) + u(x,t)\partial_x p(x,t) &=& 0. \end{array}\right. \tag{5.1}$$

The formulas of the approximate solution for both approaches have the same form as those given in subsection 2.3 for the system (1.4). Only the intermediate step values change, when $u_l < 0 < u_r$.

Using the approach by perturbation, we obtain from the Riemann invariants the following value inside the rarefaction fan:

$$\begin{aligned} u^n_{i-\frac{1}{2}} &= u^n_{i-1} + \frac{u^n_i - u^n_{i-1} + \dfrac{2B^n_i}{\gamma-1}\left(\left(\dfrac{p^n_{i-1}}{p^n_i}\right)^{\frac{\gamma-1}{2\gamma}} - 1\right)}{\left(\dfrac{B^n_i}{B^n_{i-1}}\right)\left(\dfrac{p^n_{i-1}}{p^n_i}\right)^{\frac{\gamma-1}{2\gamma}} + 1},\\ p^n_{i-\frac{1}{2}} &= p^n_{i-1}\left(1 + \frac{\gamma-1}{2B^n_{i-1}}(u^n_{i-1} - u^n_{i-\frac{1}{2}})\right)^{\frac{2\gamma}{\gamma-1}},\\ v^n_{i-\frac{1}{2}} &= v^n_{i-1}\left((1 + \frac{\gamma-1}{2B^n_{i-1}}(u^n_{i-1} - u^n_{i-\frac{1}{2}})\right)^{\frac{2}{1-\gamma}}, \end{aligned}$$

where the sound speed $B^n_i = \sqrt{\gamma\, v^n_i\, p^n_i}$.

Using the approach by substitution, we study the first and the third equation of system (5.1) as the scalar hyperbolic equation (2.4). Then we obtain the following intermediate step values:

$$\begin{aligned} p^n_{i-1/2} &= \frac{p^n_{i-1} + p^n_i}{2},\\ v^n_{i-1/2} &= \frac{v^n_{i-1} + v^n_i}{2}. \end{aligned}$$

Therefore, we approximate the velocity u with the same formulas as in subsection 2.3. Then, as p and v play the role of σ, we substitute them and recover the expressions of the approximate specific volume and approximate pressure.

Second, with the value $(v_i^{n,1},\, u_i^{n,1},\, p_i^{n,1})$ as initial data and considering only the Hugoniot curves, we construct an approximate solution for the system of propagation waves:

$$\left\{\begin{array}{rcl} \partial_t v(x,t) - v(x,t)\partial_x u(x,t) &=& 0,\\ \partial_t u(x,t) + v(x,t)\partial_x p(x,t) &=& 0,\\ \partial_t p(x,t) + \gamma p(x,t)\partial_x u(x,t) &=& 0. \end{array}\right. \tag{5.2}$$

With the Riemann solver developed by Colombeau and Le Roux in [6, p. 30], one

computes the flux across the interface between the cells I_i and I_{i+1} to obtain

$$\begin{aligned}
u^{n,1}_{i+1/2} &= \frac{1}{Z^{n,1}_{l,i+1/2}+Z^{n,1}_{r,i+1/2}}(Z^{n,1}_{l,i+1/2}u^{n,1}_i + Z^{n,1}_{r,i+1/2}u^{n,1}_{i+1} + p^{n,1}_i - p^{n,1}_{i+1}),\\
v^{n,1}_{2,i+1/2} &= \frac{1}{Z^{n,1}_{r,i+1/2}}(u^{n,1}_{i+1} - u^{n,1}_{i+1/2}) + v^n_{i+1},\\
v^{n,1}_{1,i+1/2} &= \frac{1}{Z^{n,1}_{l,i+1/2}}(u^{n,1}_{i+1/2} - u^{n,1}_i) + v^n_i,\\
p^{n,1}_{i+1/2} &= p^n_i - Z^{n,1}_{l,i+1/2}(u^{n,1}_{i+1/2} - u^{n,1}_i),
\end{aligned}$$

where the impedances are as follows:

$$Z^{n,1}_{l,i+1/2} = \sqrt{\gamma\frac{p^{n,1}_{i+1/2}+p^{n,1}_i}{v^{n,1}_{1,i+1/2}+v^{n,1}_i}}, \quad Z^{n,1}_{r,i+1/2} = \sqrt{\gamma\frac{p^{n,1}_{i+1/2}+p^{n,1}_{i+1}}{v^{n,1}_{2,i+1/2}+v^{n,1}_{i+1}}}.$$

Then with the sound speeds

$$C^{n,1}_{l,i+1/2} = -\frac{v^{n,1}_i + \overline{v}^{n,1}_{1,i+1/2}}{2}Z^n_{l,i+1/2}, \quad C^{n,1}_{r,i+1/2} = \frac{v^{n,1}_{i+1} + \overline{v}^{n,1}_{2,i+1/2}}{2}Z^n_{r,i+1/2},$$

we compute by projection

$$\begin{aligned}
u^{n+1}_i &= u^{n,1}_i - rC^{n,1}_{l,i+1/2}(u^{n,1}_{i+1/2} - u^{n,1}_i) - rC^{n,1}_{r,i-1/2}(u^{n,1}_i - u^{n,1}_{i-1/2}),\\
v^{n+1}_i &= v^{n,1}_i - rC^{n,1}_{l,i+1/2}(v^{n,1}_{1,i+1/2} - v^{n,1}_i) - rC^{n,1}_{r,i-1/2}(v^{n,1}_i - v^{n,1}_{2,i-1/2}),\\
p^{n+1}_i &= p^{n,1}_i - rC^{n,1}_{l,i+1/2}(p^{n,1}_{i+1/2} - p^{n,1}_i) - rC^{n,1}_{r,i-1/2}(p^{n,1}_i - p^{n,1}_{i-1/2}).
\end{aligned} \tag{5.3}$$

This latter step is stable if for all $i \in \mathbb{Z},\ n \in \mathbb{N}$

$$1 - rC^{n,1}_{r,i-1/2} + rC^{n,1}_{l,i+1/2} > 0.$$

The CFL condition for the split scheme is ensured as soon as the constant $r > 0$ is adapted so that one of the following inequalities holds:

$$\begin{aligned}
\max_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}}(|C^{n,1}_{l,i+1/2}|, |C^{n,1}_{r,i-1/2}|, |u^n_i|, |u^n_{i+1/2}|) &< 1/2r \quad \text{for the first approach,}\\
\max_{\substack{i\in\mathbb{Z}\\ n\in\mathbb{N}}}(|C^{n,1}_{l,i+1/2}|, |C^{n,1}_{r,i-1/2}|, |u^n_i|) &< 1/2r \quad \text{for the second approach.}
\end{aligned}$$

The formula (5.3) can be at the origin of defects in conservation of mass, momentum, and energy. To lessen this drawback, we use the conservative projection developed by Colombeau in [5, p. 83], which consists of projecting the density instead of the specific volume in the second step.

6. Numerical results. Following the study of the Riemann problem associated with the system (1.1) and (1.6), we are going to present numerical results obtained by the different schemes. We denote by the SHS scheme and the NSHS scheme, respectively, the new schemes obtained with the convection problems by perturbation and by substitution.

From different initial data, we compare the solution obtained by the Colombeau–Le Roux scheme (C-L scheme) with those of the new schemes (SHS scheme and

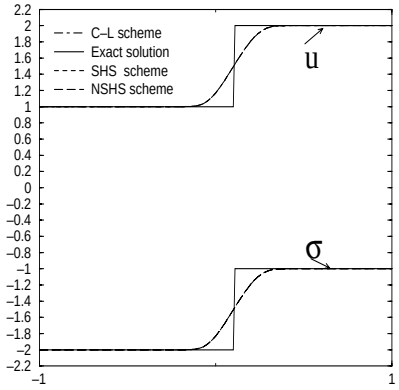

FIG. 6. *Solution of the Riemann problem associated with the system* (1.1)*, when* $(u_l, u_r) = (1, 2)$.

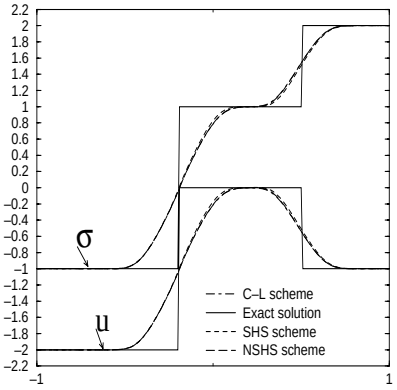

FIG. 7. *Solution of the Riemann problem associated with the system* (1.1)*, when* $(u_l, u_r) = (-1, 2)$.

NSHS scheme). Then, we conduct convergence analysis and study the behavior of conservation errors.

For the numerical tests of both systems, whenever it is not written, the space mesh size h is fixed to a convenient value $h_0 = 0.01$. From now on, the parameter $r = 0.2$ is a fixed real number such that time step $\Delta t = rh$. In order to compare the different schemes, we are interested in the approximate solution after 100 time steps (i.e., the simulation time $T = 0.2$). However, for the convergence tests, we fixed $T = 0.1$.

6.1. Numerical results for the system modeling elasticity. Let $(\sigma_l, \sigma_r) = (-2, -1)$ be the initial data for the stress. Since the exact solution for this problem is known [5], we use it to compare the different schemes between them.

When the velocity has a constant sign (Figure 6) or has a variable sign with an increasing initial data (Figure 7), the C-L scheme and the new schemes give similar numerical solutions.

When $u_l > 0 > u_r$, one can remark that the solution obtained with the C-L scheme is not valid, because none of the intermediate step values is reached (see Figure 8), whereas with the SHS and the NSHS schemes the intermediate step values for u and σ are obtained precisely (see Figure 9).

Because the SHS scheme gives the same solution as the NSHS scheme does, the convergence analysis of the new schemes is done only for the NSHS scheme. For this purpose, only the solution presenting two shocks is considered ($u_l > 0 > u_r$).

In this system modeling elasticity, only the momentum is conserved. Then, as the mass is constant (equals one), one can see that the L^1-norm of the velocity error (equal to the conservation error of the momentum) is reduced by at least one order of magnitude as the mesh decreased (see Figures 10 and 11). One can also observe that the error of the intermediate step value of the stress and that of the velocity converge towards zero (see Figures 11 and 12).

6.2. Numerical results for the system modeling hydrodynamics. Let us denote by AS the exact solution computed with the software CLAWPACK [10], solving the Euler equation in the conservative formulation. The computations are done for different initial data, given by Table 6.1 with $\gamma = 1.4$.

FIG. 11. *Relative error in the intermediate value versus mesh size.* u_h *is the computed momentum and* u_e *the exact momentum,* $T = 0.1$.

Test 1 is the so-called Sod test problem [14]. The other tests, test 2 and test 3, are more general but have been proposed with an aim of finding the better scheme. It is known that the Riemann solution problem of test 1 presents, successively, a left rarefaction wave, a contact discontinuity, and a right shock wave. While the solution of test 2 presents a left and a right rarefaction wave separated by a contact discontinuity. Test 3 has a solution consisting of two shock waves separated by a contact discontinuity.

The Figures 13, 15, and 17 present the solutions of test 1, computed by the Godunov-type schemes (NSHS, SHS, and C-L). Figures 14, 16, and 18 present the solution of test 1 computed by the modified Godunov schemes, obtained by a conservative projection. (We call them the NSHS2, SHS2, and C-L2 schemes.)

One can remark that the solutions of test 1 are similar, though the intermediate step value for the density and the velocity is calculated with more accuracy with the

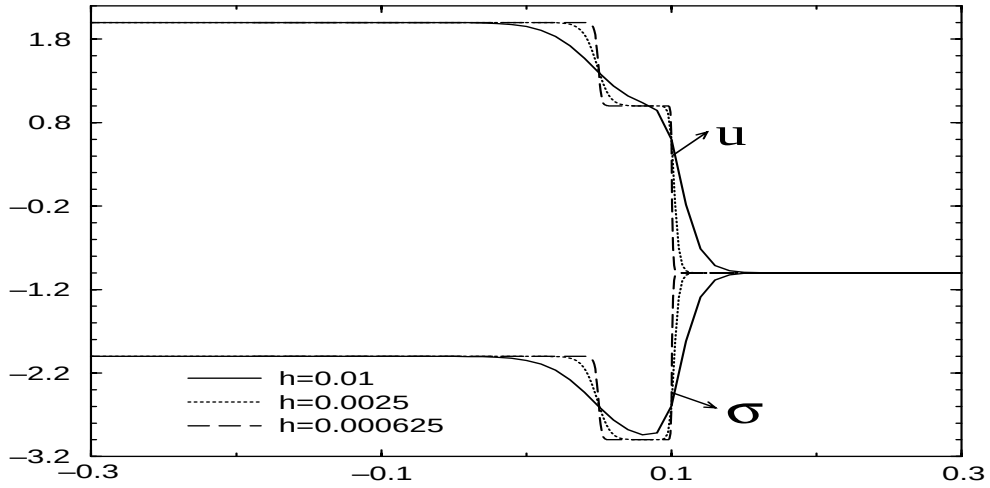

FIG. 12. *Numerical solutions of the Riemann problem with the NSHS scheme for different spatial step,* $(u_l, \sigma_l) = (2, -2)$ *and* $(u_r, \sigma_r) = (-1, -1)$*,* $T = 0.1$*.*

TABLE 6.1
Initial data for the system (1.6).

Initial data	(u_l, u_r)	(p_l, p_r)	(ρ_l, ρ_r)
Test 1	$(0.0, 0.0)$	$(1.0, 0.1)$	$(1.0, 0.125)$
Test 2	$(-1.0, 1.0)$	$(30.0, 10.0)$	$(10.0, 10.0)$
Test 3	$(2.0, -1.0)$	$(30.0, 10.0)$	$(5.0, 5.0)$

schemes using the conservative projection than the others.

We keep the same presentation for the other test problems. Figures 19, 21, and 23 (resp., Figures 25, 27, and 29) are proposed in order to compare the different Godunov-type schemes while the Figures 20, 22, and 24 (resp., Figures 26, 28, and 30) present the different conservative projection schemes.

For test 2, one observes the same behavior in each of the two splitted scheme families. For test 3, one remarks that the schemes using a conservative projection permit us to reach more precisely the intermediate step values. Moreover, this test shows how difficult it is to approximate the density (see Figure 29) by a Godunov-type scheme in the nonconservative formulation. Nevertheless, the new approach by the NSHS2 or SHS2 schemes gives us good enough results while the C-L2 scheme (Figure 30) is significantly less accurate than the new schemes. This phenomenon has already been observed in elasticity when the velocity has the same initial data. As the C-L scheme did not satisfy the CFL condition, we have computed the solution after 100 time steps with a smaller parameter $r = 0.12$ than that used for the other tests.

Unfortunately, one remarks that for each of the tests, the numerical solution computed either with the NSHS2 scheme or with the NSHS scheme presents a surplus of diffusion. And although the NSHS2 scheme is more accurate than the NSHS scheme, the two shocks of test 3 are less well captured when using the NSHS2 scheme (see Figures 25, 27, 29, and 26, 28, 30).

Using the "antidiffusion" process proposed by Colombeau and Le Roux, one reduces the amount of diffusion but the intermediate step values are not reached (cf. [6]).

Following the example of Karni in [9], we conducted a sequence of shock tube tests

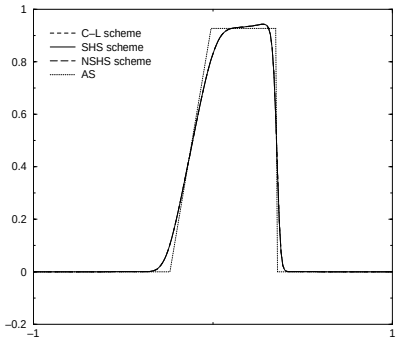

FIG. 13. *Velocity computed by the Godunov scheme for test* 1.

for shock waves of varying strengths involving a single shock. We kept the initial right value $(\rho_r\,, u_r\,, P_r) = (0.125,\, 0.0,\, 0.1)$ and we chose different left values of the initial data for defining a range of shock Mach numbers approximately between 1.1 and 3.1. From Table 6.2, one observes that the conservation error is smaller for the split scheme using the conservative projection than those induced by the split Godunov scheme. Furthermore, the relative error is between 0.6 and 4% for the tests with the NSHS2 scheme, whereas with the NSHS scheme the error varies between 1.6 and 6%.

From Figures 31 and 32, we note that as the mesh decreases, conservation er-

rors decrease almost linearly but are not eliminated. Moreover, we remark that the limit value (with the mesh refinement) of the conservation errors depends on the shock strength. Indeed, the stronger the shock is, the bigger the limit value of the conservation errors becomes.

7. Concluding remarks. We have shown that in the case $u_l.u_r > 0$ our schemes give the same solution as the C-L or C-L2 schemes. In fact, the formula defining the approximate solution of each scheme is the same. But when the sign of

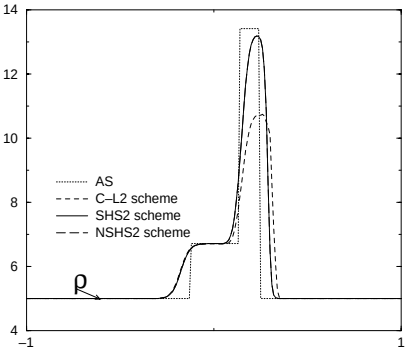

FIG. 30. *Density computed by the conservative projection scheme for test* 3.

the velocity changes, one observes two phenomena.

In the context of increasing initial data, the approximate solutions of the three schemes coincide, even though the scheme expressions are different.

We also have in the context of decreasing initial data that the approximate solution computed by our scheme is valid, whereas the C-L scheme does not permit us to calculate an acceptable solution.

We prove that split Godunov schemes are more efficient when they use the conservative projection step. This is confirmed by conducting convergence tests with regard to the conservation errors. One can develop well-adapted splitted schemes by proceeding in the same way for other systems in nonconservative form—for example, nonconservative systems modeling elastoplasticity or multifluids.

Acknowledgments. The authors are pleased to acknowledge J. F. Colombeau, A.-Y. Le Roux, and A. Méril for their helpful advice and suggestions. They also want to thank an unknown referee who suggested adding a precise convergence analysis.

ORDER ESTIMATES IN TIME OF SPLITTING METHODS FOR THE NONLINEAR SCHRÖDINGER EQUATION*

CHRISTOPHE BESSE†, BRIGITTE BIDÉGARAY‡, AND STÉPHANE DESCOMBES§

Abstract. In this paper, we consider the nonlinear Schrödinger equation $u_t + i\Delta u - F(u) = 0$ in two dimensions. We show, by an operator-theoretic proof, that the well-known Lie and Strang formulae (which are splitting methods) are approximations of the exact solution of order 1 and 2 in time.

1. Introduction.

Let us consider the cubic nonlinear Schrödinger equation

$$\begin{cases} \dfrac{\partial u}{\partial t} + i\Delta u + i\varepsilon|u|^2 u = 0, & x \in \mathbb{R}^2\,,\ t > 0, \\ u(x,0) = u_0(x), & x \in \mathbb{R}^2, \end{cases} \tag{1.1}$$

with $\varepsilon = \pm 1$. A large number of articles are devoted to the numerical study of this equation using many different time discretizations, with or without splitting. The later case is represented by Crank–Nicolson type [4], Runge–Kutta type [1], [12], symplectic (see, for example, [14], [15]), and relaxation [2] methods. Splitting methods are based on a decomposition of the flow of (1.1). More precisely, let us define the flow X^t of the linear Schrödinger equation

$$\begin{cases} \dfrac{\partial v}{\partial t} + i\Delta v = 0, & x \in \mathbb{R}^2\,,\ t > 0, \\ v(x,0) = v_0(x), & x \in \mathbb{R}^2, \end{cases}$$

and the flow Y^t for the differential equation

$$\begin{cases} \dfrac{\partial w}{\partial t} + i\varepsilon|w|^2 w = 0, & x \in \mathbb{R}^2\,,\ t > 0, \\ w(x,0) = w_0(x), & x \in \mathbb{R}^2. \end{cases}$$

The idea of splitting methods is to approximate the flow of (1.1) by combining the two flows X^t and Y^t. Two classical methods are the following: the Lie formula given by $Z_{\mathrm{L}}^t = X^t Y^t$ (or $Y^t X^t$) and the Strang formula [18] $Z_{\mathrm{S}}^t = X^{t/2} Y^t X^{t/2}$ (or $Y^{t/2} X^t Y^{t/2}$); we introduce these four definitions since it is sometimes better to exchange the role of X^t and Y^t when one of the two equations is nonsmooth [17].

This leads to good numerical methods for the periodic problem since the linear part may be computed efficiently by the use of fast Fourier transforms and the nonlinear part is solved exactly [19], [20]. We are interested in showing that the Lie formula is a first order approximation of the flow of (1.1) and the Strang formula is a second order approximation of the flow of (1.1). This result could be obtained formally with the formal Lie algebra theory (explained in the book [14] and in [13]), but here we give a simple proof allowing us to have an idea of the size of the constants.

The linear case has already been studied in [11] and [7] and we extend these results to the nonlinear case.

Following an idea of Donnat [8], we restrict ourselves to the case where the nonlinearity is a Lipschitz function; this may be done by a truncation method on a time interval before a possible blow-up. Thus we consider u the solution to the continuous problem

$$\left\{\begin{array}{ll} \dfrac{\partial u}{\partial t} + i\Delta u - F(u) = 0, & x \in \mathbb{R}^2\,,\ t > 0, \\ u(x,0) = u_0(x), & x \in \mathbb{R}^2, \end{array}\right. \tag{1.2}$$

where we assume that F is a Lipschitz function with constant K such that $F(0) = 0$ and the first four derivatives of F are bounded. We introduce the flow S^t, associated with (1.2) (that is, $u(t,\cdot) = S^t u_0$), and the two flows X^t and Y^t, solutions to

$$\left\{\begin{array}{ll} \dfrac{\partial v}{\partial t} + i\Delta v = 0, & x \in \mathbb{R}^2\,,\ t > 0, \\ v(x,0) = v_0(x), & x \in \mathbb{R}^2, \end{array}\right. \tag{1.3}$$

and

$$\left\{\begin{array}{ll} \dfrac{\partial w}{\partial t} - F(w) = 0, & x \in \mathbb{R}^2\,,\ t > 0, \\ w(x,0) = w_0(x), & x \in \mathbb{R}^2. \end{array}\right. \tag{1.4}$$

In what follows, we call Z^t any of the four splitting schemes when there is no ambiguity. Let us also recall that the semigroup X^t is a unitary operator on all classical Sobolev spaces $H^s = H^s(\mathbb{R}^2)$, $s \in \mathbb{R}$. Let us quote the main result of this article.

THEOREM 4.1. *For all u_0 in H^2 and for all $T > 0$, there exists C and h_0 such that for all $h \in (0, h_0]$, for all n such that $nh \leq T$*

$$\left\| \left(Z_L^h\right)^n u_0 - S^{nh} u_0 \right\| \leq C(\|u_0\|_{H^2}) h \|u_0\|_{H^2}.$$

Moreover, if u_0 belongs to H^4, then

$$\left\| \left(Z_S^h\right)^n u_0 - S^{nh} u_0 \right\| \leq C(\|u_0\|_{H^4}) h^2 \|u_0\|_{H^4}.$$

To prove the convergence order for each splitting scheme, for a small $h > 0$ and all integer n such that $nh \leq T$, we have to estimate the quantity $\|(Z^h)^n u_0 - S^{nh} u_0\|$, where $\|\cdot\|$ denotes the L^2 norm. As noticed in [5], the triangle inequality yields

$$\|(Z^h)^n u_0 - S^{nh} u_0\| \leq \sum_{j=0}^{n-1} \|(Z^h)^{n-j-1} Z^h S^{jh} u_0 - (Z^h)^{n-j-1} S^{(j+1)h} u_0\|.$$

In section 3 we prove that for all the studied schemes there exists a constant C_0 such that for w_0 and $w_0' \in L^2$ and all $t \in [0,1]$

$$\|Z^t w_0 - Z^t w_0'\| \leq (1 + C_0 t)\|w_0 - w_0'\|. \tag{1.5}$$

Therefore

$$\|(Z^h)^n u_0 - S^{nh} u_0\| \leq \sum_{j=0}^{n-1} (1 + C_0 h)^{n-j-1} \left\|(Z^h - S^h) S^{jh} u_0\right\|. \tag{1.6}$$

Thus we may restrict our study to the case for which at each time step the initial data are the same for the continuous model and the splitting scheme and is equal to $v_0 = S^{jh} u_0$. Classical results on solutions to the nonlinear Schrödinger equation allow us to state that $S^{jh} u_0$ is uniformly bounded in H^4 for $jh \leq T$. Now we may write a Duhamel formula for the continuous problem (1.2) that reads as

$$u(t) = X^t v_0 + \int_0^t X^{t-s} F(u(s))\, ds$$

and express the difference of the exact solution and the splitting solution $v(t) = Z^t v_0$ as

$$u(t) - v(t) = \int_0^t X^{t-s} \left[F(u(s)) - F(v(s))\right] ds + R(t),$$

where the fact that F is Lipschitz and X^t is unitary in L^2 leads to

$$\|u(t) - v(t)\| \leq K \int_0^t \|u(s) - v(s)\|\, ds + \|R(t)\|.$$

There remains to show that the remainder $R(t)$ may be estimated as $\|R(t)\| = O(t^{p+1})$ for t small and to use a Gronwall lemma to conclude that the scheme is of order p.

This paper is organized as follows: In section 2, we prove a Gronwall lemma and some estimates on X^t and Y^t. In section 3, we show that each scheme is Lipschitz continuous and we study the local error between Z^t and S^t. Section 4 is devoted to the proof of Theorem 4.1.

2. Some useful estimates.

2.1. A Gronwall lemma.

LEMMA 2.1 (Gronwall). *Let P be a polynomial with positive coefficients and no constant term. We assume that the function ϕ is such that there exists a constant $C \geq 0$ such that for all $t \geq 0$*

$$0 \leq \phi(t) \leq \phi(0) + P(t) + C \int_0^t \phi(s) ds.$$

Then for all $\alpha > 1$ there exists $t_0 > 0$ such that for all $0 \leq t \leq t_0$

$$\phi(t) \leq \phi(0) e^{Ct} + \alpha P(t).$$

Proof. Let us set

$$\psi(t) = \left(\phi(0) + P(t) + C \int_0^t \phi(s) ds\right) e^{-Ct}.$$

Then

$$\psi'(t) = \left(P'(t) + C\phi(t) - C\left(\phi(0) + P(t) + C\int_0^t \phi(s)ds\right)\right) e^{-Ct} \leq P'(t)e^{-Ct};$$

therefore,

$$\psi(t) - \psi(0) \leq \int_0^t P'(s)e^{-Cs}ds,$$

and since $P(0) = 0$, $\psi(0) = \phi(0)$. Hence, because P' is positive,

$$\phi(t) \leq \psi(t)e^{Ct} \leq \phi(0)e^{Ct} + \int_0^t P'(s)e^{C(t-s)}\ ds \leq \phi(0)e^{Ct} + e^{Ct_0}\int_0^t P'(s)\ ds.$$

We choose t_0 such that $e^{Ct_0} \leq \alpha$ and, for all $0 \leq t \leq t_0$,

$$\phi(t) \leq \phi(0)e^{Ct} + \alpha P(t). \qquad \square$$

2.2. Estimates on the Schrödinger flow X^t. From the definition of the Schrödinger flow we first state that

$$\dot{X}^t = i\Delta X^t = iX^t\Delta. \tag{2.1}$$

This leads to the following estimates.

LEMMA 2.2. 1. *For all $w \in H^2$ and all $t \geq 0$,*

$$\|X^t w - w\| \leq t\|w\|_{H^2}. \tag{2.2a}$$

2. *For all $w \in H^4$ and all $t \geq 0$,*

$$\|X^t w - w\|_{H^2} \leq t\|w\|_{H^4}. \tag{2.2b}$$

3. *Let $T > 0$; there exists a constant C such that, for all $w \in \mathcal{C}^1([0,T];H^2) \cap L^\infty([0,T],H^4)$ and $0 \leq t \leq T$,*

$$\left\|\int_0^t \left(X^{t-s}w(s) - X^{t/2}w(s)\right) ds\right\| \leq Ct^3(\|w\|_{\mathcal{C}^1([0,T];H^2)} + \|w\|_{L^\infty([0,T],H^4)}). \tag{2.2c}$$

4. *There exists a constant C such that for all $w \in H^4$,*

$$\left\|X^{t/2}w - \frac{1}{2}X^t w - \frac{1}{2}w\right\| \leq Ct^2\|w\|_{H^4}. \tag{2.2d}$$

Proof. 1. Let $w \in H^2$; we have

$$\|X^t w - w\| = \left\|\int_0^t \dot{X}^s w\ ds\right\| = \left\|\int_0^t X^s\Delta w\ ds\right\| \leq \int_0^t \|\Delta w\|ds \leq t\|w\|_{H^2}.$$

2. If we assume that $w \in H^4$, the estimate may be proved as the previous one replacing the L^2 norm by the H^2 norm.

3. A Taylor expansion gives

$$X^{t-s} - X^{t/2} = (t/2 - s)\dot{X}^{t/2} + \int_{t/2}^{t-s}(t - s - \sigma)\ddot{X}^\sigma\ d\sigma$$

and

$$(X^{t-s} - X^{t/2})w(s) = i(t/2-s)X^{t/2}\Delta w(s) - \int_{t/2}^{t-s}(t-s-\sigma)X^{\sigma}\Delta^2 w(s)\ d\sigma.$$

A simple change of variables implies that

$$\int_0^t (t/2-s)\Delta w(s)\ ds = \int_0^{t/2}(t/2-s)[\Delta w(s) - \Delta w(t-s)]\ ds.$$

The Lipschitz constant of the map $s \mapsto \Delta w(s)$ is estimated using $\|w\|_{\mathcal{C}^1([0,T],H^2)}$ and, therefore,

$$\begin{aligned}
&\left\| \int_0^t \left(X^{t-s}w(s) - X^{t/2}w(s) \right) ds \right\| \\
&\quad \le \left\| \int_0^{t/2} (t/2-s)[\Delta w(s) - \Delta w(t-s)]\ ds \right\| + \left\| \int_0^t \int_{t/2}^{t-s} (t-s-\sigma)X^{\sigma}\Delta^2 w(s) d\sigma ds \right\| \\
&\quad \le 2\|w\|_{\mathcal{C}^1([0,T],H^2)} \int_0^{t/2} (t/2-s)^2 ds + \|w\|_{L^\infty([0,T],H^4)} \int_0^t \int_{t/2}^{t-s} (t-s-\sigma)\ d\sigma\ ds \\
&\quad \le Ct^3(\|w\|_{\mathcal{C}^1([0,T],H^2)} + \|w\|_{L^\infty([0,T],H^4)}).
\end{aligned}$$

4. Once more, Taylor expansions yield

$$X^{t/2} - \frac{1}{2}X^t - \frac{1}{2}X^0 = -\frac{1}{2}\int_0^{t/2} \sigma(\ddot{X}^{\sigma} + \ddot{X}^{t-\sigma})\ d\sigma,$$

and the same arguments as for the last estimates show the result. ∎

2.3. Estimates on the nonlinear flow Y^t. The definition of the nonlinear flow Y^t may also read as

$$Y^t w = w + \int_0^t F(Y^s w)\ ds. \tag{2.3}$$

LEMMA 2.3. *Let $w \in H^2$; then there exists a constant C that depends only on $M = \|w\|_\infty$ such that for all $0 \le t \le 1$*

$$\|Y^t w\| \le e^{Kt}\|w\| \text{ and } \|Y^t w\|_{H^2} \le C\|w\|_{H^2}. \tag{2.4a}$$

Moreover, if $w \in H^4$, then there exists a constant C that depends only on $M = \|w\|_\infty$ such that for all $0 \le t \le 1$

$$\|Y^t w\|_{H^4} \le C\|w\|_{H^4}. \tag{2.4b}$$

Finally, for w_1, $w_2 \in L^2$, there exists a constant C that depends only on F such that for all $0 \le t \le 1$

$$\|Y^t w_1 - Y^t w_2\| \le (1+Ct)\|w_1 - w_2\|. \tag{2.4c}$$

Proof. Equation (2.3) first yields a L^∞ estimate, namely,

$$\|Y^t w\|_\infty \le \|w\|_\infty + K\int_0^t \|Y^s w\|_\infty\ ds.$$

Then the classical Gronwall lemma leads to

$$\|Y^t w\|_\infty \le e^{Kt}\|w\|_\infty.$$

A L^2 estimate also follows from (2.3):

$$\|Y^t w\| \le \|w\| + K\int_0^t \|Y^s w\|\ ds. \tag{2.5}$$

For all first order differential operators D

$$DY^t w = Dw + \int_0^t F'(Y^s w) D(Y^s w)\ ds,$$

and, denoting by M' the maximum for F', we obtain

$$\|DY^t w\| \le \|Dw\| + M'\int_0^t \|DY^s w\|\ ds.$$

Differentiating once more,

$$\Delta Y^t w = \Delta w + \int_0^t \left(F''(Y^s w) D(Y^s w)^2 + F'(Y^s w)\Delta Y^s w\right) ds,$$

and, denoting by M'' the maximum for F'',

$$\|\Delta Y^t w\| \le \|\Delta w\| + \int_0^t \left(M''\|DY^s w\|^2 + M'\|\Delta Y^s w\|\right) ds.$$

Using the Gagliardo–Nirenberg inequality,

$$\|DY^s w\|^2 \le \|Y^s w\|_{H^2}\|Y^s w\|_\infty$$

and

$$\|\Delta Y^t w\| \le \|\Delta w\| + \int_0^t \left(M''\|Y^s w\|_\infty + M'\right)\|Y^s w\|_{H^2}\ ds.$$

Therefore, using the L^∞ estimate, there exists a constant c such that

$$\|Y^t w\|_{H^2} \le \|w\|_{H^2} + c\int_0^t \left(1 + e^{Ks}\right)\|Y^s w\|_{H^2}\ ds.$$

Last, using the Gronwall lemma,

$$\|Y^t w\|_{H^2} \le \|w\|_{H^2} \exp\left(c\int_0^t \left(1 + e^{Ks}\right) ds\right).$$

Equation (2.5) also leads to

$$\|Y^t w\| \le e^{Kt}\|w\|.$$

For $t \le 1$, there exists a constant C such that

$$\exp\left(c\int_0^t \left(1 + e^{Ks}\right) ds\right) \le C$$

and estimate (2.4a) follows. The proof for (2.4b) is similar and left to the reader. Finally, estimate (2.4c) is a simple consequence of the Gronwall lemma. □

3. Lipschitz properties of Z^t and local errors. In this section we more specifically give precise estimates for Lie and Strang formulae. We first show Lipschitz properties on Z^t, i.e., that estimate (1.5) is valid. Next we estimate the remainder $R(t)$ defined in the introduction.

3.1. Lipschitz properties.

- *Lie approximation—case $Z^t = X^t Y^t$.*
  The solution to the Lie approximation with initial data $v_0 \in L^2$ reads as

$$v(t) = Z^t v_0 = X^t v_0 + \int_0^t X^t F(Y^s v_0)\, ds.$$

  Therefore the difference between two solutions for initial data w_0 and w_0' in L^2 is

$$Z^t w_0 - Z^t w_0' = X^t(w_0 - w_0') + \int_0^t X^t (F(Y^s w_0) - F(Y^s w_0'))\, ds,$$

  and using the fact that X^t is unitary in L^2, that F is Lipschitz, and estimate (2.4c), we obtain that there exists a constant C depending only on F such that for $0 \le t \le 1$

$$\|Z^t w_0 - Z^t w_0'\| \le (1 + Ct)\|w_0 - w_0'\|.$$

- *Lie approximation—case $Z^t = Y^t X^t$.*
  Since

$$v(t) = Z^t v_0 = X^t v_0 + \int_0^t F(Y^s X^t v_0)\, ds,$$

  the difference is

$$Z^t w_0 - Z^t w_0' = X^t(w_0 - w_0') + \int_0^t (F(Y^s X^t w_0) - F(Y^s X^t w_0'))\, ds;$$

  thus, using the same tools as above, we obtain that there exists a constant C depending only on F such that for $0 \le t \le 1$

$$\|Z^t w_0 - Z^t w_0'\| \le (1 + Ct)\|w_0 - w_0'\|.$$

- *Strang approximation—case $Z^t = X^{t/2} Y^t X^{t/2}$.*
  Since

$$v(t) = Z^t v_0 = X^t v_0 + \int_0^t X^{t/2} F(Y^s X^{t/2} v_0)\, ds,$$

  we have

$$\begin{aligned} Z^t w_0 - Z^t w_0' &= X^t(w_0 - w_0') \\ &\quad + \int_0^t X^{t/2}(F(Y^s X^{t/2} w_0) - F(Y^s X^{t/2} w_0'))\, ds, \\ \|Z^t w_0 - Z^t w_0'\| &\le (1 + Ct)\|w_0 - w_0'\|. \end{aligned}$$

- *Strang approximation—case* $Z^t = Y^{t/2}X^tY^{t/2}$.
  Since

$$v(t) = Z^t v_0 = X^t Y^{t/2} v_0 + \int_0^{t/2} F(Y^s X^t Y^{t/2} v_0)\, ds,$$

we have

$$\begin{aligned} Z^t w_0 - Z^t w_0' &= X^t Y^{t/2} w_0 - X^t Y^{t/2} w_0' \\ &\quad + \int_0^{t/2} (F(Y^s X^t X^{t/2} w_0) - F(Y^s X^t Y^{t/2} w_0'))\, ds, \\ \|Z^t w_0 - Z^t w_0'\| &\le (1 + Ct)\|w_0 - w_0'\|. \end{aligned}$$

3.2. Local errors.

- *Lie approximation—case* $Z^t = X^tY^t$.
  For $v_0 \in H^2$ and $0 \le t \le 1$, the remainder can be written as

$$R(t) = \int_0^t X^{t-s} F(X^s Y^s v_0)\, ds - \int_0^t X^t F(Y^s v_0)\, ds.$$

Let us define $R_1(s) = F(X^sY^sv_0) - X^sF(Y^sv_0)$; then, using the fact that F is Lipschitz and estimates (2.2a) and (2.4a),

$$\begin{aligned} R_1(s) &= F(X^sY^sv_0) - F(Y^sv_0) + F(Y^sv_0) - X^sF(Y^sv_0), \\ \|R_1(s)\| &\le K\|X^sY^sv_0 - Y^sv_0\| + \|F(Y^sv_0) - X^sF(Y^sv_0)\| \\ &\le s\,(K\|Y^sv_0\|_{H^2} + \|F(Y^sv_0)\|_{H^2}) \\ &\le Cs\|v_0\|_{H^2}. \end{aligned}$$

Therefore, since $R(t) = \int_0^t X^{t-s}R_1(s)ds$,

$$\|R(t)\| \le C\|v_0\|_{H^2} \int_0^t s\, ds = \frac{Ct^2}{2}\|v_0\|_{H^2}.$$

- *Lie approximation—case* $Z^t = Y^tX^t$.
  For $v_0 \in H^2$ and $0 \le t \le 1$, the remainder can be written as

$$R(t) = \int_0^t X^{t-s} F(Y^s X^s v_0)\, ds - \int_0^t F(Y^s X^t v_0)\, ds.$$

In this case $R(t) = \int_0^t R_1(s)ds$, where $R_1 = X^{t-s}F(Y^sX^sv_0) - F(Y^sX^tv_0)$, and using the fact that F is Lipschitz and estimates (2.2a), (2.4a), (2.4c), we obtain

$$\begin{aligned} R_1(s) &= X^{t-s}F(Y^sX^sv_0) - F(Y^sX^sv_0) + F(Y^sX^sv_0) - F(Y^sX^tv_0), \\ \|R_1(s)\| &\le (t-s)\|F(Y^sX^sv_0)\|_{H^2} + K\|X^sv_0 - X^tv_0\| \\ &\le C(t-s)\|v_0\|_{H^2}; \end{aligned}$$

hence

$$\|R(t)\| \le C\|v_0\|_{H^2} \int_0^t (t-s)\, ds = \frac{Ct^2}{2}\|v_0\|_{H^2}.$$

- *Strang approximation—case* $Z^t = X^{t/2}Y^tX^{t/2}$.
  For $v_0 \in H^4$ and $0 \leq t \leq 1$, the remainder can be written as

$$R(t) = \int_0^t X^{t-s}F(X^{s/2}Y^sX^{s/2}v_0)\ ds - \int_0^t X^{t/2}F(Y^sX^{t/2}v_0)\ ds.$$

  We may write $R(t)$ as $R(t) = \int_0^t R_1(s)\ ds + X^{t/2}\int_0^t R_2(s)\ ds$, where

$$R_1(s) = X^{t-s}w(s) - X^{t/2}w(s), \qquad w(s) = F(Y^sX^{t/2}v_0),$$

  and

$$R_2(s) = F(X^{s/2}Y^sX^{s/2}v_0) - F(Y^sX^{t/2}v_0).$$

  Using estimate (2.2c), we obtain that

$$\left\| \int_0^t R_1(s)\ ds \right\| \leq Ct^3\|v_0\|_{H^4}.$$

  A Taylor expansion yields that

$$\begin{aligned} R_2(s) = F'(v_0)\cdot(X^{s/2}Y^sX^{s/2}v_0 - Y^sX^{t/2}v_0) \\ + \int_0^1 (1-\theta)\Big[F''(v_0+\theta(X^{s/2}Y^sX^{s/2}v_0 - v_0)) \\ \cdot (X^{s/2}Y^sX^{s/2}v_0 - v_0)^2 \\ -F''(v_0+\theta(Y^sX^{t/2}v_0 - v_0))\cdot(Y^sX^{t/2}v_0 - v_0)^2\Big]d\theta. \end{aligned}$$

  Using triangle inequalities, estimates (2.2a), (2.4a), formulation (2.3), and the fact that F is Lipschitz, we obtain that

$$\|X^{s/2}Y^sX^{s/2}v_0 - v_0\| \leq Cs\|v_0\|_{H^2}$$

  and

$$\|Y^sX^{t/2}v_0 - v_0\| \leq Ct\|v_0\|_{H^2}.$$

  Besides, we recall that F'' is uniformly bounded by M'', and therefore, using that H^2 is an algebra,

$$\begin{aligned} \left\| \int_0^1 (1-\theta)\Big[F''(v_0+\theta(X^{s/2}Y^sX^{s/2}v_0 - v_0))\cdot(X^{s/2}Y^sX^{s/2}v_0 - v_0)^2 \right. \\ \left. - F''(v_0+\theta(Y^sX^{t/2}v_0 - v_0))\cdot(Y^sX^{t/2}v_0 - v_0)^2\Big]d\theta \right\| \leq Ct^2\|v_0\|^2_{H^4}. \end{aligned}$$

  Moreover, let us define $R_3(s) = X^{s/2}Y^sX^{s/2}v_0 - Y^sX^{t/2}v_0$; formulation (2.3) yields that

$$\begin{aligned} R_3(s) = X^sv_0 - X^{t/2}v_0 + \int_0^s (X^{s/2}F(Y^\sigma X^{s/2}v_0) - F(Y^\sigma X^{s/2}v_0))\ d\sigma \\ + \int_0^s (F(Y^\sigma X^{s/2}v_0) - F(Y^\sigma X^{t/2}v_0))\ d\sigma. \end{aligned}$$

A simple change of variable in lemma (2.2c) proves that

$$\left\| \int_0^t (X^s v_0 - X^{t/2} v_0)\ ds \right\| \leq C t^3 \|v_0\|_{H^4},$$

and using once more estimates (2.2a) and (2.4b) and the fact that F is Lipschitz, we have

$$\left\| \int_0^t \int_0^s (X^{s/2} F(Y^\sigma X^{s/2} v_0) - F(Y^\sigma X^{s/2} v_0))\ d\sigma ds \right\| \leq C t^3 \|v_0\|_{H^2}$$

and, also using (2.2c),

$$\left\| \int_0^t \int_0^s (F(Y^\sigma X^{s/2} v_0) - F(Y^\sigma X^{t/2} v_0))\ d\sigma ds \right\| \leq C t^3 \|v_0\|_{H^2}.$$

Finally, since $X^{t/2}$ is unitary,

$$\left\| X^{t/2} \int_0^t R_2(s)\ ds \right\| \leq C t^3 \|v_0\|_{H^4},$$

and the conclusion is that

$$\|R(t)\| \leq C(1 + \|v_0\|_{H^4}) t^3 \|v_0\|_{H^4}.$$

- *Strang approximation—case $Z^t = Y^{t/2} X^t Y^{t/2}$.*
For $v_0 \in H^4$ and $0 \leq t \leq 1$, the remainder can be written as

$$\begin{aligned} R(t) = &\int_0^t X^{t-s} F(Y^{s/2} X^s Y^{s/2} v_0)\ ds \\ &-\frac{1}{2} \int_0^t X^t F(Y^{s/2} v_0)\ ds - \frac{1}{2} \int_0^t F(Y^{s/2} X^t Y^{t/2} v_0)\ ds. \end{aligned}$$

Taylor expansions yield

$$\begin{aligned} F(Y^{s/2} X^s Y^{s/2} v_0) = &F(v_0) + F'(v_0) \cdot (Y^{s/2} X^s Y^{s/2} v_0 - v_0) \\ &+ \int_0^1 (1-\theta) F''(v_0 + \theta(Y^{s/2} X^s Y^{s/2} v_0 - v_0)) \\ &\qquad \cdot (Y^{s/2} X^s Y^{s/2} v_0 - v_0)^2 d\theta, \\ F(Y^{s/2} v_0) = &F(v_0) + F'(v_0) \cdot (Y^{s/2} v_0 - v_0) \\ &+ \int_0^1 (1-\theta) F''(v_0 + \theta(Y^{s/2} v_0 - v_0)) \\ &\qquad \cdot (Y^{s/2} v_0 - v_0)^2 d\theta, \\ F(Y^{s/2} X^t Y^{t/2} v_0) = &F(v_0) + F'(v_0) \cdot (Y^{s/2} X^t Y^{t/2} v_0 - v_0) \\ &+ \int_0^1 (1-\theta) F''(v_0 + \theta(Y^{s/2} X^t Y^{t/2} v_0 - v_0)) \\ &\qquad \cdot (Y^{s/2} X^t Y^{t/2} v_0 - v_0)^2 d\theta, \end{aligned}$$

and the same sort of estimates as above give

$$\begin{aligned} \|Y^{s/2} X^s Y^{s/2} v_0 - v_0\| &\leq Cs \|v_0\|_{H^4}, \\ \|Y^{s/2} v_0 - v_0\| &\leq Cs \|v_0\|_{H^4}, \\ \|Y^{s/2} X^t Y^{t/2} v_0 - v_0\| &\leq Ct \|v_0\|_{H^4}. \end{aligned}$$

Therefore, the time integral over the interval $[0,t]$ of the integral remainders may be estimated by $Ct^3\|v_0\|_{H^2}^2$. Besides, there remains to estimate $\int_0^t R_1(s)\,ds$ with

$$\begin{aligned}R_1(s) = &\left(X^{t-s} - \frac{1}{2}X^t - \frac{1}{2}\mathrm{Id}\right)F(v_0)\\ &+ (X^{t-s}-\mathrm{Id})F'(v_0)\cdot(Y^{s/2}X^sY^{s/2}v_0 - v_0)\\ &- \frac{1}{2}(X^t-\mathrm{Id})F'(v_0)\cdot(Y^{s/2}v_0 - v_0)\\ &+ F'(v_0)\cdot(Y^{s/2}X^sY^{s/2}v_0 - v_0)\\ &- \frac{1}{2}F'(v_0)\cdot(Y^{s/2}v_0 - v_0) - \frac{1}{2}F'(v_0)\cdot(Y^{s/2}X^tY^{t/2}v_0 - v_0).\end{aligned}$$

The first term is estimated by $Ct^3\|v_0\|_{H^4}$, combining estimates (2.2c) and (2.2d). The two next terms are, respectively, estimated by $CM'(t-s)s\|v_0\|_{H^4}$ and $CM'ts\|v_0\|_{H^2}$.
Last, since $F'(v_0)$ is a linear operator, we have to study $\int_0^t F'(v_0)R_2(s)\,ds$ with

$$\begin{aligned}R_2(s) &= Y^{s/2}X^sY^{s/2}v_0 - \frac{1}{2}Y^{s/2}v_0 - \frac{1}{2}Y^{s/2}X^tY^{t/2}v_0\\ &= X^sv_0 + \frac{1}{2}\int_0^s X^sF(Y^{\sigma/2}v_0)\,d\sigma + \frac{1}{2}\int_0^s F(Y^{\sigma/2}X^sY^{s/2}v_0)\,d\sigma\\ &\quad - \frac{1}{2}v_0 - \frac{1}{4}\int_0^s F(Y^{\sigma/2}v_0)\,d\sigma\\ &\quad - \frac{1}{2}X^tv_0 - \frac{1}{4}\int_0^t X^tF(Y^{\sigma/2}v_0)\,d\sigma - \frac{1}{4}\int_0^t F(Y^{\sigma/2}X^tY^{t/2}v_0)\,d\sigma,\end{aligned}$$

where we have used intensively formulation (2.3). Everywhere where F occurs we subtract and add $F(v_0)$. This leads to terms involving differences which may be estimated by $Ct^2\|v_0\|_{H^2}$, and therefore their time integral is bounded by $Ct^3\|v_0\|_{H^2}$. The only terms that remain are $R_3(s) = X^sv_0 - \frac{1}{2}v_0 - \frac{1}{2}X^tv_0$ and $R_4(s) = \frac{1}{2}\int_0^s X^sF(v_0)d\sigma - \frac{1}{4}\int_0^t X^tF(v_0)d\sigma$. We have

$$R_3(s) = (X^sv_0 - X^{t/2}v_0) + \left(X^{t/2}v_0 - \frac{1}{2}v_0 - \frac{1}{2}X^tv_0\right),$$

$$\left\|\int_0^t R_3(s)\,ds\right\| \le Ct^3\|v_0\|_{H^4};$$

$$R_4(s) = \frac{1}{2}\left(s(X^s - X^t)F(v_0) + \left(s - \frac{t}{2}\right)X^tF(v_0)\right),$$

$$\left\|\int_0^t R_4(s)\,ds\right\| = \left\|\int_0^t s(X^s - X^t)F(v_0)\,ds\right\| \le Ct^3\|v_0\|_{H^2}.$$

Finally, we obtain that

$$\|R(t)\| \le C(1+\|v_0\|_{H^4})t^3\|v_0\|_{H^4}.$$

This last estimate concludes the study of the remainders for the four schemes. Now a consequence of the Gronwall lemma 2.1 is the following lemma.

LEMMA 3.1. *Let $v_0 \in H^2$; there exists $t_0 > 0$ such that for all $0 \le t \le t_0$*

$$\|Z_{\mathrm{L}}^t v_0 - S^t v_0\| \le Ct^2,$$

where C depends on $\|v_0\|_{H^2}$. Moreover, if $v_0 \in H^4$, there exists $t_1 > 0$ such that for all $0 \le t \le t_1$

$$\|Z_{\mathrm{S}}^t v_0 - S^t v_0\| \le Ct^3,$$

where C depends on $\|v_0\|_{H^4}$.

Remark 3.2. In [11], Jahnke and Lubich have shown the first and second order approximation for a linear Schrödinger equation under the weaker regularity conditions $v_0 \in H^1$ and $v_0 \in H^2$. Unfortunately, it is not possible to keep exactly the same hypothesis for the nonlinear case for the following reason: Let us focus on the first order approximation; we can formally extend the results of Jahnke and Lubich in the nonlinear case using Lie commutators. However, the Lie commutator between the Laplace operator and the nonlinear term involves a term containing $(\partial v_0/\partial x)^2$ and $(\partial v_0/\partial y)^2$ (see [13] for more details). To control these two terms, we have two possibilities, either we assume that $v_0 \in H^2$ and we use a Gagliardo–Nirenberg inequality, or we assume that $v_0 \in H^1 \cap W^{1,+\infty}$. Thus, in our lemma, H^2 is not optimal if we also assume that $v_0 \in W^{1,+\infty}$.

4. Order estimate.

THEOREM 4.1. *For all u_0 in H^2 and for all $T > 0$, there exists C and h_0 such that for all $h \in (0, h_0]$, for all n such that $nh \le T$*

$$\left\| \left(Z_L^h\right)^n u_0 - S^{nh} u_0 \right\| \le C(\|u_0\|_{H^2}) h \|u_0\|_{H^2}.$$

Moreover, if u_0 belongs to H^4, then

$$\left\| \left(Z_S^h\right)^n u_0 - S^{nh} u_0 \right\| \le C(\|u_0\|_{H^4}) h^2 \|u_0\|_{H^4}.$$

Proof. As noticed in the introduction, the triangle inequality yields

$$\|(Z^h)^n u_0 - S^{nh} u_0\| \le \sum_{j=0}^{n-1} \|(Z^h)^{n-j-1} Z^h S^{jh} u_0 - (Z^h)^{n-j-1} S^{(j+1)h} u_0\|.$$

In section 3 we have proved that for all the studied schemes there exists a constant C_0 such that for w_0 and $w_0' \in L^2$ and all $t \in [0, 1]$

$$\|Z^t w_0 - Z^t w_0'\| \le (1 + C_0 t)\|w_0 - w_0'\|,$$

and therefore

$$\|(Z^h)^n u_0 - S^{nh} u_0\| \le \sum_{j=0}^{n-1} (1 + C_0 h)^{n-j-1} \|(Z^h - S^h) S^{jh} u_0\|.$$

For the Lie formula when u_0 belongs to H^2, for all j such that $jh \le T$, $S^{jh} u_0$ belongs to H^2 and is uniformly bounded in this space; thus we have

$$\|(Z_{\mathrm{L}}^h - S^h) S^{jh} u_0\| \le C(\|u_0\|_{H^2}) h^2 \|u_0\|_{H^2},$$

and we deduce that

$$\begin{aligned}\|(Z_{\mathrm{L}}^h)^n u_0 - S^{nh}u_0\| &\leq C(\|u_0\|_{H^2})\|u_0\|_{H^2}\sum_{j=0}^{n-1}\exp(C_0h)^{n-j-1}h^2\\ &\leq C(\|u_0\|_{H^2})\|u_0\|_{H^2}\exp(C_0T)nh^2\\ &\leq C(\|u_0\|_{H^2})\|u_0\|_{H^2}h.\end{aligned}$$

For the scheme Z_{S}^h, when u_0 belongs to H^4, for all j such that $jh \leq T$, $S^{jh}u_0$ belongs to H^4 and is uniformly bounded in this space, and we have

$$\begin{aligned}\|(Z_{\mathrm{S}}^h)^n u_0 - S^{nh}u_0\| &\leq C(\|u_0\|_{H^4})\|u_0\|_{H^4}\sum_{j=0}^{n-1}\exp(C_0h)^{n-j-1}h^3\\ &\leq C(\|u_0\|_{H^4})\|u_0\|_{H^4}\exp(C_0T)nh^3\\ &\leq C(\|u_0\|_{H^4})\|u_0\|_{H^4}h^2.\end{aligned}$$

This concludes the proof of Theorem 4.1. ∎

Remark 4.2. Theorem 4.1 shows that the Lie and Strang formulae are approximations of order one and two of the exact solution. We can notice that the proof can be extended to high order splitting formulae. In [9], it is shown that we can construct Nth order approximation ($N \geq 3$) by considering splitting schemes of the form

$$Z_{\mathrm{HO}}^t = X^{c_0 t}Y^{d_1 t}X^{c_1 t}Y^{d_2 t}\cdots Y^{d_{m-1}t}X^{c_{m-1}t}Y^{d_m t}X^{c_m t}, \tag{4.1}$$

but we have to assume that at least one of the coefficient $c_0, \ldots, c_m$ must be negative and at least one of the coefficient $d_1, \ldots, d_m$ must be negative. (This result generalized the fundamental result of [16].) The same result holds if we consider convex combinations of (4.1). For these kinds of formulae, the Lipschitz property is an immediate consequence of their forms, and we notice that we can still use some Taylor formulae for X^t and Y^t to show that the remainder may be estimated as $\|R(t)\| = O(t^{N+1})$ for t small; however, as we have seen for the last scheme studied in the previous proof, it would be very technical.

5. Numerical experiments. We proved in the previous sections that the order p of Lie and Strang formulations are, respectively, 1 and 2 for initial data in H^2 and H^4.

If the numerical order p_{num} given in Table 5.1 does confirm the theoretical orders, it is nevertheless difficult to force the desired regularity for a discretized initial datum. Typically, the regularity of the L^2 initial datum in Figure 5.1 is certainly slightly better.

Let us define $t_n = nh$ and let $\Omega = [-10, 10] \times [-10, 10]$ be the computational domain. The numerical order p_{num} is computed by

$$p_{\mathrm{num}} = \max_{t_n \in [0,T]} \frac{1}{\ln 2}\ln\left(\frac{\|u_2 - u_1\|_{L^2(\Omega)}}{\|u_3 - u_2\|_{L^2(\Omega)}}\right),$$

where u_1 is computed for the time step h, and u_2 and u_3 are, respectively, computed for time steps $h/2$ and $h/4$.

We use initial data displayed in Figure 5.1, and in order to avoid numerical reflections due to boundaries we choose periodic boundary conditions and a FFT method to invert the Laplacian.

TABLE 5.1
Computation of p_{num} for different initial data.

	Lie	Strang
H^2	1.000685	2.000072
H^1	1.001721	2.006374
L^2	1.014480	2.010045

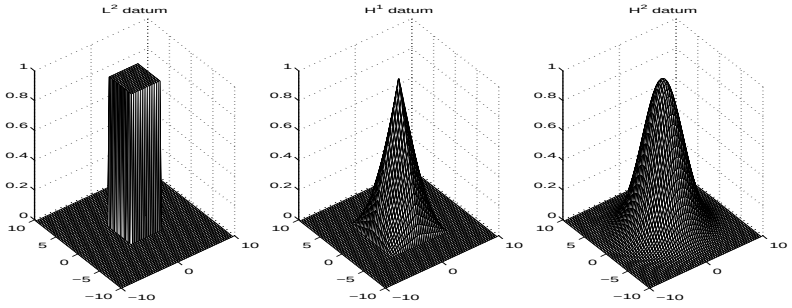

FIG. 5.1. *Initial data used for numerical experiments.*

TABLE 5.2
Computation of p_{num} for different time and space steps.

	$N = 64$	$N = 128$	$N = 256$
$h = 10^{-3}$	2.000016	2.000072	2.000289
$h = 10^{-2}$	2.001637	2.007160	2.030023

The results displayed in Table 5.1 are computed for $h = 10^{-3}$ and $N = 128$ points in both space dimensions.

This results are not much dependent on the choice for the time and space steps. Indeed, for the H^2 initial datum and the Strang formulation, we obtain the results of Table 5.2.

6. Conclusion. We have shown in this paper that, for the nonlinear Schrödinger equation, the Lie and Strang formulae are, respectively, approximations of order 1 and 2. This result could be extended to cover the case of the Schrödinger–Debye equations [3], where one can find a proof for the first order. The case of the nonlinear heat equation could also be treated with the same arguments because we have never used the group property but only the semigroup property of the flow of the linear Schrödinger equation; besides, we may write an equivalent of Lemma 2.2. In particular, this extends also the results of [6]. Our proof may also be extended to the Ginzburg–Landau equation, for which some splitting methods are also used (see, e.g., [10]) since it will use the fact that we are able to perform the proof for both the Schrödinger and the heat equation.

Our analysis does not give any hint on how to choose one splitting scheme among the others. The order of convergence is not the only criterion as stressed in the introduction: in case of stiff terms, the order of the different steps is of consequence. Namely, the last step should be the stiff one which is the nonlinear step Y^t in our context. This fact is hidden in our constants that depend on norms that grow with the size of the exact solution.

SYMMETRIC COUPLING FOR EDDY CURRENT PROBLEMS*

R. HIPTMAIR†

Abstract. In this paper a novel symmetric finite element method-boundary element method-coupling for the **E**-based eddy current model is derived in a rigorous fashion. To that end, the properties of potentials and boundary integral operators arising from a Stratton–Chu-type representation formula for the electric field in the nonconducting region are thoroughly analyzed in a Hilbert-space setting. It yields a variational problem with symmetric bilinear form that is coercive in the natural function spaces. Unknowns are the electric field inside the conductor and the equivalent surface current related to the magnetic field. Existence and uniqueness of solutions and the convergence of a conforming finite element/boundary element Galerkin discretization immediately follows. In particular, schemes based on **curl**-conforming edge elements and divergence-conforming surface elements are examined, and some aspects of implementation are discussed.

Key words. eddy current problem, trace spaces, boundary integral operators, symmetric coupling, edge elements, boundary elements, stream functions, preconditioning

1. Introduction.

The fundamental task in eddy current computation is the following: Given a time-dependent solenoidal exciting current and a conductor of prescribed shape, determine the induced eddy currents in the conductor. To put everything into a mathematical framework, let $\Omega_C \subset \mathbb{R}^3$ designate the space occupied by the conductor. It is to be a bounded domain with piecewise smooth Lipschitz-boundary $\Gamma := \partial\Omega_C$. In other words, Ω_C should be the union of a few (curved) Lipschitz-polyhedra [44, 1.5.2]. Inside Ω_C the conductivity $\sigma \in L^\infty(\Omega_C)$ is uniformly positive, i.e., $\sigma \geq \sigma_0 > 0$ almost everywhere in Ω_C, whereas σ vanishes outside Ω_C in the "air region" $\Omega_E := \mathbb{R}^3 \setminus \bar{\Omega}_C$. The second important material parameter, the magnetic permeability $\mu \in L^\infty(\mathbb{R}^3)$, is uniformly positive everywhere and constant in Ω_E. By a simple scaling we can always get nondimensional equations and achieve $\mu \equiv 1$ in Ω_E. Excitation is provided either by a divergence-free source current $\mathbf{j}_0 \in \boldsymbol{L}^2(\mathbb{R}^3)$ or by prescribing the total current circulating through a loop of the conductor. To begin with, the (generic) case of a given source current $\mathbf{j}_0$ will be the only one considered. Besides, for the sake of simplicity, we assume that $\mathrm{supp}(\mathbf{j}_0) \subset \bar{\Omega}_C$, that there is no flux of $\mathbf{j}_0$ through Γ, and that Ω_E is connected. I stress that it takes only slight alterations to adapt the considerations of this paper to a more general setting.

The eddy current model emerges from Maxwell's equations by formally dropping the displacement currents (magnetoquasistatic approximation). This amounts to neglecting capacitive effects (space charges) and provides a reasonable approximation in the low frequency range and in the presence of high conductivity [3, 40]. In the time harmonic case (frequency domain) the equations of the eddy current model read as

$$\mathbf{curl}\,\mathbf{E} = -i\omega\mu\mathbf{H}, \quad \mathbf{curl}\,\mathbf{H} = \sigma\mathbf{E} + \mathbf{j}_0 \quad \text{in } \mathbb{R}^3\,, \tag{1.1}$$

$$\mathbf{E}(\mathbf{x}) = O(|\mathbf{x}|^{-1}), \quad \mathbf{H}(\mathbf{x}) = O(|\mathbf{x}|^{-1}) \quad \text{for } |\mathbf{x}| \to \infty\,, \tag{1.2}$$

*Received by the editors November 6, 2000; accepted for publication (in revised form) October 18, 2001; published electronically April 12, 2002. This work was supported by DFG as part of SFB 382.

†Sonderforschungsbereich 382, Universität Tübingen, Tübingen, Germany (ralf@hiptmair.de).

where $\omega > 0$ is a fixed angular frequency. Various reformulations of the eddy current problem have been suggested [1, 12], which differ in their choice of the primary unknown. This gives rise to a distinction between approaches zeroing in on the magnetic field ("**H**-based"), the electric field ("**E**-based"), or certain (vector) potentials. I am going to focus on the **E**-based formulation in the frequency domain, which, in the sense of distributions, reads as (cf. [3], $\epsilon_0 \equiv \text{const.} > 0$ in Ω_E)

$$\begin{aligned} &\mathbf{curl}\,\mu^{-1}\,\mathbf{curl}\,\mathbf{E} + i\omega\sigma\mathbf{E} = -i\omega\mathbf{j}_0 \quad \text{in } \mathbb{R}^3\ , \\ &\operatorname{div}(\epsilon_0\mathbf{E}) = 0 \quad \text{in } \Omega_E, \quad \int_{\Gamma_i} \mathbf{E}\cdot\mathbf{n}\,dS = 0\ , i = 1,\ldots,N_C\ , \\ &\mathbf{E}(\mathbf{x}) = O(|\mathbf{x}|^{-1}), \quad \mathbf{curl}\,\mathbf{E}(\mathbf{x}) = O(|\mathbf{x}|^{-1}) \quad \text{for } |\mathbf{x}| \to \infty\ . \end{aligned} \tag{1.3}$$

Here, $\{\Gamma_i\}_{i=1}^{N_C}$ stands for the finitely many connected components of $\Gamma := \partial\Omega_C$, and $\mathbf{n}$ denotes the unit normal vectorfield on Γ, defined almost everywhere and pointing from Ω_C into Ω_E.

In many practical applications the material parameters inside the conductor display substantial spatial variations. Moreover, the permeability μ may even depend on $\mathbf{H}$, which leads to a nonlinear problem. Thus, a viable numerical scheme for eddy current computation has to rely on a complete spatial discretization of the problem inside Ω_C. Starting from the variational formulation (1.3), a finite element scheme (FEM) based on edge elements offers the most attractive option [18, 63]. In fact, their use is mandatory in order to capture the singularities of the fields at material interfaces [37, 11, 19].

However, we also have to deal with the unbounded exterior domain. In many cases, due to the decay properties of the fields, one simply introduces homogeneous boundary conditions for the electric field some distance away from the conductor. Then by extending the finite element mesh to parts of the air region, a satisfactory approximation can be obtained. However, there are many conceivable shapes of Ω_C, where the number of required additional elements much exceeds the number needed to mesh Ω_C.

In this case, BEMs may be used to tackle the unbounded exterior domain, since in Ω_E we face a homogeneous problem with constant coefficients. Then the topic of this paper comes into focus, because the discrete boundary integral equations and the systems of equations arising from the finite element scheme have to be linked properly.

Formally, for second order elliptic problems, the coupling of a finite element discretization with some unbounded exterior domain is achieved by discretizing the Dirichlet-to-Neumann map of the exterior problem. For a self-adjoint differential operator, this map must be self-adjoint, too. However, in the traditional approach employing boundary elements, a nonsymmetric matrix emerges as discrete Dirichlet-to-Neumann map [52]. A breakthrough was accomplished by M. Costabel, who discovered that, by using the full Calderón-projector, symmetry can be restored [34]. In addition, coercive variational problems naturally emerge. The principle can be applied to a wide range of elliptic problems [25] and has recently been adapted to the full Maxwell's equations [4].

The idea of coupled FEM-BEM methods for eddy current computation is by no means new. An early reference is [58], where an **H**-ϕ-approach is discussed. It employs a scalar magnetic potential outside Ω_C, and the coupling makes use of the continuity of tangential components of $\mathbf{H}$ and that of the normal components of $\mu\mathbf{H}$. A similar idea was used in the context of an **A**-ϕ-model in [57] and, along with impedance boundary

conditions, in [75]. Yet this coupling is valid only for simply connected conductors [68, 56].

Field based methods avoid the fundamental difficulties encountered by potential based approaches in the case of complex topologies. Most prominently, the TRIFOU project adopted a coupling strategy based on **H** or **E** [70, 71, 16]. In the former case, scalar potentials still played a role, entailing cutting surfaces to deal with non-simply connected conductors. In the latter case, the concept of a vectorial Dirichlet-to-Neumann map bulked large [17, 15], which, though self-adjoint by nature, was tackled by an inherently unsymmetric indirect boundary integral formulation. A symmetrization of the resulting matrices is performed later on the level of the discrete linear systems, justified by heuristics drawing on the symmetry of the Dirichlet-to-Neumann map [18, sect. 7.4.5] and [72]. Yet, a rigorous mathematical analysis of the impact of this procedure is not available.

This paper is aimed at extending the "TRIFOU-**E**-approach" towards a genuinely symmetric formulation, which is to arise from a thorough mathematical examination of the coupled eddy current problem. We are rewarded by an asymptotically optimal a priori error estimate for the energy norm of the discretization error and linear systems of equations amenable to efficient preconditioning. No restrictions on the topology of Ω_C are imposed. Owing to the lack of strong ellipticity in the case of the eddy current problem, the formal approach to symmetric coupling in the case of second order elliptic boundary value problems cannot be simply copied.

The paper is organized as follows: The following section presents a weak formulation of the eddy current problem. After that, the crucial function spaces of tangential traces are introduced in section 3. Then I examine the relevant Dirichlet and Neumann data for the eddy current problem in Ω_C and Ω_E. The correct coupling conditions are established. In section 5 a representation formula is computed, comprised of several boundary potentials. Their properties and those of related boundary integral operators will be studied in sections 6 and 7. In section 8 I state the symmetric coupled problem in weak form and prove existence and uniqueness of a solution. Section 9 is dedicated to a Galerkin finite element discretization of the coupled problem and the use of discrete stream functions. In the final section the assembly of the discrete operators and iterative solution techniques are examined.

2. Variational formulation and gauging. As the eddy current problem is posed on an unbounded domain, its variational formulation has to rely on the weighted Sobolev space

$$\boldsymbol{W}(\mathbf{curl},\mathbb{R}^3) := \left\{ \mathbf{u} \in \boldsymbol{\mathcal{D}}(\mathbb{R}^3)',\ \frac{\mathbf{u}(\mathbf{x})}{\sqrt{1+|\mathbf{x}|^2}} \in \boldsymbol{L}^2(\mathbb{R}^3),\ \mathbf{curl}\,\mathbf{u} \in \boldsymbol{L}^2(\mathbb{R}^3) \right\},$$

which corresponds to the classical Beppo–Levi spaces. A fairly complete treatment of these spaces is given in [41] and [65, sect. 2.5.4]. The constrained space

$$\mathbf{X}(\mathbb{R}^3) := \left\{ \mathbf{u} \in \boldsymbol{W}(\mathbf{curl},\mathbb{R}^3),\ \operatorname{div}\mathbf{u} = 0 \text{ in } \Omega_E,\ \int_{\Gamma_i} \mathbf{u}_{|\Omega_E} \cdot \mathbf{n}\, dS = 0,\ i = 1,\dots,N_C \right\}$$

offers a suitable setting for the weak eddy current problem: Seek $\mathbf{E} \in \mathbf{X}(\mathbb{R}^3)$ such that for all $\mathbf{v} \in \mathbf{X}(\mathbb{R}^3)$

$$a(\mathbf{E},\mathbf{v}) := \left(\mu^{-1}\,\mathbf{curl}\,\mathbf{E}, \mathbf{curl}\,\mathbf{v}\right)_{0;\mathbb{R}^3} + i\omega\,(\sigma\mathbf{E},\mathbf{v})_{0;\Omega_C} = -i\omega\,(\mathbf{j}_0,\mathbf{v})_{0;\Omega_C}\ . \tag{2.1}$$

THEOREM 2.1. *A solution of the variational problem* (2.1) *exists and is unique.*

Proof. First, I show that the bilinear form $a(\cdot,\cdot)$ of (2.1) is coercive (in the sense of [60, Thm. 2.34]) on

$$\widetilde{\mathbf{X}}(\mathbb{R}^3) := \{\mathbf{u} \in \boldsymbol{W}(\mathbf{curl},\mathbb{R}^3),\, \operatorname{div}\mathbf{u} = 0 \text{ in } \Omega_E\}\,. \tag{2.2}$$

To this end, pick $\mathbf{v} \in \tilde{\mathbf{X}}(\mathbb{R}^3)$, write $\mathbf{v}^C := \mathbf{v}_{|\Omega_C} \in \boldsymbol{H}(\mathbf{curl};\Omega_C)$ and $\tilde{\mathbf{v}} \in \boldsymbol{H}(\mathbf{curl};\mathbb{R}^3)$ for a divergence-free extension of $\mathbf{v}^C$ to $\mathbb{R}^3$. (Extension theorems for $\boldsymbol{H}(\mathbf{curl};\Omega)$ are presented in the next section.) Then define $\mathbf{w} := \mathbf{v} - \tilde{\mathbf{v}} \in \widetilde{\mathbf{X}}(\mathbb{R}^3)$ and observe that $\mathbf{w}$ has vanishing tangential components on Γ. Next, set

$$\mathbf{u} := \mathbf{curl}\,\mathbf{w} \in \boldsymbol{H}_0(\operatorname{div}0;\Omega_E) := \{\mathbf{q} \in \boldsymbol{H}(\operatorname{div};\Omega_E),\, \operatorname{div}\mathbf{q} = 0,\, \mathbf{q}\cdot\mathbf{n} = 0 \text{ on } \Gamma\}\,,$$

and retain the notation $\mathbf{u}$ for its extension by zero into the interior of Ω_C. This will yield $\mathbf{u} \in \boldsymbol{H}(\operatorname{div};\mathbb{R}^3)$ with $\operatorname{div}\mathbf{u} = 0$. According to [41, Thm. 2.5] we can find a unique vector potential $\boldsymbol{\Psi}$ in the vectorial Beppo–Levi space (cf. [65, sect. 2.5.4])

$$\boldsymbol{W}^{1,-1}(\mathbb{R}^3) := \left\{\boldsymbol{\Phi} \in \boldsymbol{\mathcal{D}}(\mathbb{R}^3)',\, \frac{\boldsymbol{\Phi}(\mathbf{x})}{\sqrt{1+|\mathbf{x}|^2}} \in \boldsymbol{L}^2(\mathbb{R}^3),\, D\boldsymbol{\Phi} \in (L^2(\mathbb{R}^3))^{3\times 3}\right\}$$

such that $\mathbf{curl}\,\boldsymbol{\Psi} = \mathbf{u}$, $\operatorname{div}\boldsymbol{\Psi} = 0$, and, with some universal constant $C > 0$,

$$\|\boldsymbol{\Psi}\|_{\boldsymbol{W}^{1,-1}(\mathbb{R}^3)} \le C\,\|\mathbf{u}\|_{\boldsymbol{L}^2(\mathbb{R}^3)}\,.$$

By definition, $\mathbf{curl}\,\boldsymbol{\Psi} = 0$ in Ω_C, which yields the representation

$$\boldsymbol{\Psi} = \operatorname{grad}\phi + \boldsymbol{\eta}, \quad \phi \in H^1(\Omega_C)/\mathbb{R},\, \boldsymbol{\eta} \in \mathbb{H}(\Omega_C)\,,$$

where $\mathbb{H}(\Omega_C) \subset \boldsymbol{L}^2(\Omega_C)$ is the *finite dimensional* space of harmonic Neumann vectorfields on Ω_C, $\boldsymbol{L}^2(\Omega_C)$-orthogonal to $\operatorname{grad} H^1(\Omega_C)$ [5, sect. 3.c]. Then solve the exterior Dirichlet problem

$$\Delta\mu = 0 \quad \text{in } \Omega_E, \quad \mu = \phi \quad \text{on } \Gamma$$

in the Beppo–Levi space $W^{1,-1}(\Omega_E)$ and observe that, with generic constants $C > 0$,

$$\|\mu\|_{W^{1,-1}(\Omega_E)} \le C\left\|\phi_{|\Gamma}\right\|_{H^{\frac12}(\Gamma)} \le C\,\|\phi\|_{H^1(\Omega_C)} \le C\,\|\boldsymbol{\Psi}\|_{\boldsymbol{H}^1(\Omega_C)} \le C\,\|\mathbf{curl}\,\mathbf{w}\|_{\boldsymbol{L}^2(\mathbb{R}^3)}\,.$$

This means for $\boldsymbol{\zeta} := \boldsymbol{\Psi} - \operatorname{grad}\mu - \mathbf{w}$ that

$$\mathbf{curl}\,\boldsymbol{\zeta} = 0 \quad \text{in } \Omega_E, \quad \operatorname{div}\boldsymbol{\zeta} = 0 \quad \text{in } \Omega_E\,. \tag{2.3}$$

On top of that, the tangential components of $\boldsymbol{\zeta}$ on Γ agree with those of vectorfields in $\mathbb{H}(\Omega_C)$. Along with (2.3) this implies that $\boldsymbol{\zeta}$ belongs to a finite dimensional space of harmonic vectorfields on Ω_E. Summing up, we get in Ω_E

$$\mathbf{v} = \mathbf{q} - \boldsymbol{\zeta}, \quad \mathbf{q} := \tilde{\mathbf{v}} + \boldsymbol{\Psi} - \operatorname{grad}\mu$$

and the estimate

$$\begin{aligned}\left\|\frac{\mathbf{q}(\mathbf{x})}{\sqrt{1+|\mathbf{x}|^2}}\right\|_{\boldsymbol{L}^2(\Omega_E)} &\le \|\boldsymbol{\Psi}\|_{\boldsymbol{W}^{1,-1}(\Omega_E)} + \|\tilde{\mathbf{v}}\|_{\boldsymbol{L}^2(\Omega_E)} + \|\mu\|_{W^{1,-1}(\Omega_E)}\\ &\le C\left(\|\mathbf{v}\|_{\boldsymbol{H}(\mathbf{curl};\Omega_C)} + \|\mathbf{curl}\,\mathbf{v}\|_{\boldsymbol{L}^2(\Omega_E)}\right).\end{aligned}$$

We conclude that, with a constant $c > 0$ depending on the material parameters μ, σ, and on Ω_C,

$$|a(\mathbf{v},\mathbf{v})| \geq c \left(\left\| \frac{(\mathbf{v}+\boldsymbol{\zeta})(\mathbf{x})}{\sqrt{1+|\mathbf{x}|^2}} \right\|^2_{\boldsymbol{L}^2(\Omega_E)} + \|\mathbf{v}\|^2_{\boldsymbol{L}^2(\Omega_C)} + \|\mathbf{curl}\,\mathbf{v}\|^2_{\boldsymbol{L}^2(\mathbb{R}^3)} \right) .$$

Recalling that the norm on $\tilde{\mathbf{X}}(\mathbb{R}^3)$ agrees with the norm of $\boldsymbol{W}(\mathbf{curl},\mathbb{R}^3)$ and that $\boldsymbol{\zeta}$ belongs to a finite dimensional space, $a(\cdot,\cdot)$ is immediately seen to be $\tilde{\mathbf{X}}(\mathbb{R}^3)$-coercive, i.e., $\tilde{\mathbf{X}}(\mathbb{R}^3)$-elliptic modulo a compact perturbation.

According to [60, Thm. 2.34], existence of solutions of the weak eddy current problem thus follows from uniqueness. The latter is clear (cf. [3, Thm. 3.2]); as for $\mathbf{u} \in \widetilde{\mathbf{X}}(\mathbb{R}^3)$, the requirement $a(\mathbf{u},\mathbf{u}) = 0$ forces $\mathbf{u}$ to be an exterior Dirichlet vectorfield. However, those are ruled out by the additional constraint in the definition of $\mathbf{X}(\mathbb{R}^3)$. □

It is evident that the constraints in the definition of $\mathbf{X}(\mathbb{R}^3)$ merely serve to enforce the uniqueness of $\mathbf{E}$ outside Ω_C. Dispensing with them will affect neither the magnetic field $\mathbf{H} := -\frac{1}{i\omega\mu}\,\mathbf{curl}\,\mathbf{E}$ in $\mathbb{R}^3$ nor the eddy currents $\mathbf{j} = \sigma\mathbf{E}$ in the conductor. In other words, the constraints on $\mathbf{E}$ are not essential for the validity of the eddy current model. A meaningful model can also be stated in terms of *equivalence classes of electric fields*. It will still supply unique solutions for many interesting quantities. Indeed, frequently the constraints on $\mathbf{E}$ are dropped in numerical schemes [31]. In the spirit of [53], the constraints imposed in (1.3) represent *gauge conditions*, unless one wants to know the true $\mathbf{E}$ in Ω_E.

As my focus is on Ω_C, I am going to relax the constraints on $\mathbf{E}$ in what follows, considering the variational problem only on $\widetilde{\mathbf{X}}(\mathbb{R}^3)$: Seek $\mathbf{u} \in \widetilde{\mathbf{X}}(\mathbb{R}^3)$ such that

$$a(\mathbf{u},\mathbf{v}) = -i\omega\,(\mathbf{j}_0,\mathbf{v})_{0;\Omega_C} \quad \forall \mathbf{v} \in \widetilde{\mathbf{X}}(\mathbb{R}^3)\ . \tag{2.4}$$

Keep in mind that then $\mathbf{u}_{|\Omega_E}$ is merely unique up to contributions from $\mathbb{H}_D(\Omega_E)$, with

$$\mathbb{H}_D(\Omega) := \{\mathbf{v} \in \boldsymbol{L}^2(\Omega),\, \mathbf{curl}\,\mathbf{v} = 0,\, \mathrm{div}\,\mathbf{v} = 0,\, \mathbf{v}\times\mathbf{n} = 0 \text{ on } \partial\Omega\}$$

standing for the finite dimensional space of harmonic Dirichlet vectorfields (cf. [5, sect. 3]). To remind the reader that I am no longer dealing with a physical electric field, this "ungauged" solution will not be denoted by $\mathbf{E}$. Retreating to $\widetilde{\mathbf{X}}(\mathbb{R}^3)$ has to be accompanied by an important caveat: The numerical scheme proposed in the present paper has to be supplemented by some postprocessing in order to yield meaningful values for $\mathbf{E}$ in Ω_E.

Please recall that by means of expansions into spherical harmonics (cf. the proof of Proposition 3.1 in [3]) the following decay properties can be established for any solution $\mathbf{u}$ of (2.4):

$$\mathbf{u}(\mathbf{x}) = O(|\mathbf{x}|^{-1}), \quad \mathbf{curl}\,\mathbf{u}(\mathbf{x}) = O(|\mathbf{x}|^{-2}) \quad \text{uniformly for } |\mathbf{x}| \to \infty\ . \tag{2.5}$$

3. Traces. The boundary integral equations have to be considered in spaces that are closely related to traces of vectorfields in $\boldsymbol{H}(\mathbf{curl};\Omega)$ onto Γ. (Here and in the following, Ω stands for either Ω_C or Ω_E.) On smooth boundaries their theory is well established. I refer to the papers by Paquet [66] and Alonso and Valli [2] and, in particular, to the monographs by Cessenat [26, sect. 2.1] and Nédélec [65, sect. 5.4.1] for a comprehensive exposition. Only recently, these results have been successfully

extended to piecewise smooth boundaries by Buffa [21] and Buffa and Ciarlet [22, 23] and even to Lipschitz-domains in [24]. These articles provide the chief references for the results cited below. Loosely speaking, by judicious generalizations of norms and surface differential operators, the main results for regular surfaces carry over to a nonsmooth setting.

To begin with, we define two different tangential surface trace operators: The *tangential surface trace* $\gamma_{\mathbf{t}}$ is defined for $\mathbf{u} \in C(\bar{\Omega})^3$ by $\gamma_{\mathbf{t}}\mathbf{u}(\mathbf{x}) := \mathbf{n}(\mathbf{x}) \times (\mathbf{u}(\mathbf{x}) \times \mathbf{n}(\mathbf{x}))$ for almost all $\mathbf{x} \in \Gamma$. Accordingly, the *twisted tangential surface trace* $\gamma_{\mathbf{t}}^{\times}$ can be computed through $\gamma_{\mathbf{t}}^{\times}\mathbf{u}(\mathbf{x}) := \mathbf{u}(\mathbf{x}) \times \mathbf{n}(\mathbf{x})$.

Apart from the usual Hilbert spaces of scalar functions and functionals, $H^{1/2}(\Gamma)$ and $H^{-1/2}(\Gamma)$, we will make heavy use of the following Hilbert spaces of *tangential vectorfields* on Γ: $\boldsymbol{L}_{\mathbf{t}}^2(\Gamma)$, $\boldsymbol{H}_{||}^{1/2}(\Gamma)$, and $\boldsymbol{H}_{\perp}^{1/2}(\Gamma)$, where the latter are defined in [22, sect. 1] (and generalized to spaces V_π and V_γ in [24, sect. 2]). The associated dual spaces will be denoted by $\boldsymbol{H}_{||}^{-1/2}(\Gamma)$ and $\boldsymbol{H}_{\perp}^{-1/2}(\Gamma)$, respectively. Sloppily speaking, $\boldsymbol{H}_{||}^{1/2}(\Gamma)$ contains the tangential surface vectorfields that are in $\boldsymbol{H}^{1/2}(F_i)$ for each smooth component F_i of Γ and feature a suitable "weak tangential continuity" across the edges of the F_i. A corresponding "weak normal continuity" is satisfied by surface vectorfields in $\boldsymbol{H}_{\perp}^{1/2}(\Gamma)$. These spaces occur as images of tangential traces of vectorfields.

THEOREM 3.1. *The tangential trace mapping $\gamma_{\mathbf{t}} : \boldsymbol{H}^1_{\mathrm{loc}}(\Omega) \mapsto \boldsymbol{H}_{||}^{1/2}(\Gamma)$ is continuous and surjective and possesses a continuous right inverse.*

The twisted tangential trace mapping $\gamma_{\mathbf{t}}^{\times} : \boldsymbol{H}^1_{\mathrm{loc}}(\Omega) \mapsto \boldsymbol{H}_{\perp}^{1/2}(\Gamma)$ is continuous and surjective and possesses a continuous right inverse.

Proof. See Proposition 1.7 in [22]. ∎

Please recall the definitions of the surface differential operators grad_Γ, $\mathbf{curl}_\Gamma$, curl_Γ, and div_Γ acting on tangential vectorfields (see [24, sect. 3], [22, sect. 2], [23, sect. 1, Defs. 1.1, 1.3], and [65, sect. 2.5.6] for smooth surfaces). I mention that $\mathrm{div}_\Gamma = -\mathrm{grad}_\Gamma^*$ and $\mathbf{curl}_\Gamma = \mathrm{curl}_\Gamma^*$, where $*$ denotes the adjoint with respect to the pivot space $\boldsymbol{L}_{\mathbf{t}}^2(\Gamma)$. The surface differential operators play a role in the definition of the spaces $\boldsymbol{H}_{\perp}^{-1/2}(\mathrm{curl}_\Gamma, \Gamma)$ and $\boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma, \Gamma)$ introduced in [22] by

$$\begin{aligned}\boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\mathrm{curl}_\Gamma, \Gamma) &= \{\mathbf{v} \in \boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\Gamma),\ \mathrm{curl}_\Gamma \mathbf{v} \in H^{-\frac{1}{2}}(\Gamma)\}\ ,\\ \boldsymbol{H}_{||}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma) &= \{\boldsymbol{\zeta} \in \boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma),\ \mathrm{div}_\Gamma \boldsymbol{\zeta} \in H^{-\frac{1}{2}}(\Gamma)\}\ .\end{aligned}$$

These spaces are endowed with the natural graph norms $\|\cdot\|_{\boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\mathrm{curl}_\Gamma,\Gamma)}$ and $\|\cdot\|_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)}$. They are significant as suitable trace spaces for vectorfields in $\boldsymbol{H}(\mathbf{curl}; \Omega)$.

THEOREM 3.2. *The trace mapping $\gamma_{\mathbf{t}} : \boldsymbol{H}(\mathbf{curl}; \Omega) \mapsto \boldsymbol{H}_{\perp}^{-1/2}(\mathrm{curl}_\Gamma, \Gamma)$ is continuous and surjective with a continuous right inverse.*

The trace mapping $\gamma_{\mathbf{t}}^{\times} : \boldsymbol{H}(\mathbf{curl}; \Omega) \mapsto \boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma, \Gamma)$ is continuous and surjective with a continuous right inverse.

Proof. For simply connected Γ this result combines Theorems 2.7 and 2.8 from [22] and Theorem 4.5 in [23]. For general topology see [21]. The statement for smooth domains is made in [65, Thm. 5.4.2]. ∎

These traces occur in the definition of Dirichlet-type boundary conditions for $\boldsymbol{H}(\mathbf{curl}; \Omega)$-elliptic variational problems. Hence, we adopt the alternative notation γ_D for $\gamma_{\mathbf{t}}$ ("Dirichlet trace").

Another result in [23, sect. 4] is that $\boldsymbol{H}_{\perp}^{-1/2}(\mathrm{curl}_\Gamma,\Gamma)$ and $\boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma,\Gamma)$ are dual to each other, when $\boldsymbol{L}_{\mathbf{t}}^2(\Gamma)$ is used as pivot space. More precisely, the usual $\boldsymbol{L}_{\mathbf{t}}^2(\Gamma)$-inner product can be extended to a duality pairing $\langle\cdot,\cdot\rangle_{\boldsymbol{\tau}}$ between $\boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma,\Gamma)$ and $\boldsymbol{H}_{\perp}^{-1/2}(\mathrm{curl}_\Gamma,\Gamma)$.

A couple of weakly defined traces will also be needed in order to deal with Neumann-type boundary conditions: For

$$\mathbf{u}\in\boldsymbol{W}(\mathbf{curl}^2,\Omega):=\{\mathbf{v}\in\boldsymbol{W}(\mathbf{curl},\Omega),\ \mathbf{curl}\,\mathbf{curl}\,\mathbf{v}\in\boldsymbol{L}^2(\Omega)\},$$

we define $\gamma_N\mathbf{u}\in\boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma,\Gamma)$ ("Neumann trace") by

$$\langle\gamma_N\mathbf{u},\gamma_{\mathbf{t}}\mathbf{v}\rangle_{\boldsymbol{\tau}}=\pm\int_\Omega\mathbf{curl}\,\mathbf{u}\cdot\mathbf{curl}\,\overline{\mathbf{v}}-\mathbf{curl}\,\mathbf{curl}\,\mathbf{u}\cdot\overline{\mathbf{v}}\,d\mathbf{x}\quad\forall\mathbf{v}\in\boldsymbol{H}(\mathbf{curl};\Omega)\,,$$

where the positive sign applies to $\Omega=\Omega_C$, the negative to $\Omega=\Omega_E$. An overbar designates complex conjugation. The trace γ_N furnishes a continuous and surjective mapping $\gamma_N:\boldsymbol{W}(\mathbf{curl}^2,\Omega)\mapsto\boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma,\Gamma)$, where $\boldsymbol{W}(\mathbf{curl}^2,\Omega)$ is equipped with the graph norm. Obviously $\gamma_N\mathbf{u}=\gamma_{\mathbf{t}}^{\times}(\mathbf{curl}\,\mathbf{u})$, as this holds for smooth fields.

LEMMA 3.3. *If* $\mathbf{u}\in\boldsymbol{W}(\mathbf{curl}^2,\Omega)$ *satisfies* $\mathbf{curl}\,\mathbf{curl}\,\mathbf{u}=0$ *in* Ω*, there holds*

$$\|\gamma_N\mathbf{u}\|_{\boldsymbol{H}_{||}^{-\frac12}(\mathrm{div}_\Gamma,\Gamma)}\le C\,\|\mathbf{curl}\,\mathbf{u}\|_{\boldsymbol{L}^2(\Omega)}$$

with some constant $C>0$ *independent of* $\mathbf{u}$.

Proof. Set $P_\perp:\boldsymbol{H}_{\perp}^{-1/2}(\mathrm{curl}_\Gamma,\Gamma)\mapsto\boldsymbol{H}(\mathbf{curl};\Omega)$ for the continuous right inverse of $\gamma_{\mathbf{t}}$ from Theorem 3.2. Then the definition of γ_N, straightforward manipulations, and the continuity of the tangential trace show

$$\begin{aligned}\|\gamma_N\mathbf{u}\|_{\boldsymbol{H}_{||}^{-\frac12}(\mathrm{div}_\Gamma,\Gamma)}&=\sup_{\mathbf{v}\in\boldsymbol{H}_{\perp}^{-\frac12}(\mathrm{curl}_\Gamma,\Gamma)}\frac{\langle\gamma_N\mathbf{u},\gamma_D P_\perp\mathbf{v}\rangle_{\boldsymbol{\tau}}}{\|\mathbf{v}\|_{\boldsymbol{H}_{\perp}^{-\frac12}(\mathrm{curl}_\Gamma,\Gamma)}}\\ =\sup_{\mathbf{v}\in\boldsymbol{H}_{\perp}^{-\frac12}(\mathrm{curl}_\Gamma,\Gamma)}\frac{(\mathbf{curl}\,\mathbf{u},\mathbf{curl}\,P_\perp\mathbf{v})_{0;\Omega}}{\|\mathbf{v}\|_{\boldsymbol{H}_{\perp}^{-\frac12}(\mathrm{curl}_\Gamma,\Gamma)}}&\le\sup_{\mathbf{v}\in\boldsymbol{H}_{\perp}^{-\frac12}(\mathrm{curl}_\Gamma,\Gamma)}\frac{\|\mathbf{curl}\,P_\perp\mathbf{v}\|_{\boldsymbol{L}^2(\Omega)}\,\|\mathbf{curl}\,\mathbf{u}\|_{\boldsymbol{L}^2(\Omega)}}{\|\mathbf{v}\|_{\boldsymbol{H}_{\perp}^{-\frac12}(\mathrm{curl}_\Gamma,\Gamma)}}\,.\end{aligned}$$

This amounts to the assertion of the lemma. ∎

The weak normal trace $\gamma_{\mathbf{n}}$ is defined for vectorfields $\mathbf{u}\in\boldsymbol{H}(\mathrm{div};\Omega)$ by

$$\langle\gamma_{\mathbf{n}}\mathbf{u},\phi\rangle_{1/2,\Gamma}=\int_\Omega\overline{\phi}\,\mathrm{div}\,\mathbf{u}+\mathbf{u}\cdot\mathrm{grad}\,\overline{\phi}\,d\mathbf{x}\quad\forall\phi\in H^1(\Omega)$$

with $\langle\cdot,\cdot\rangle_{1/2,\Gamma}$ as duality pairing between $H^{-1/2}(\Gamma)$ and $H^{1/2}(\Gamma)$. $\gamma_{\mathbf{n}}:\boldsymbol{H}(\mathrm{div};\Omega)\mapsto H^{-1/2}(\Gamma)$ is continuous and surjective [42, Thm. 2.5], [65, Thm. 5.4.1].

4. Transmission conditions and Cauchy data. The interface transmission conditions for electromagnetic fields are

$$[\gamma_D\mathbf{u}]_\Gamma=0,\qquad\left[\mu^{-1}\gamma_N\mathbf{u}\right]_\Gamma=0\,. \tag{4.1}$$

I have adopted the notation $[\gamma\cdot]_\Gamma=\gamma^+\cdot-\gamma^-\cdot$ for the jump of some trace γ across Γ. Here, γ^+ refers to the trace from Ω_E and γ^- to the trace from inside. Please be aware

that, in physical terms, (4.1) represents the continuity of the tangential components of the electric and magnetic fields. This ensures the normal continuity of the energy flux given by the Poynting-vector $\mathbf{E} \times \overline{\mathbf{H}}$.

Remark. As only magnetic quantities matter, it is tempting to replace (4.1) by purely magnetic transmission conditions

$$[\gamma_D \mathbf{H}]_\Gamma = 0, \qquad [\gamma_\mathbf{n} \mathbf{B}]_\Gamma = 0 \, .$$

However, for nontrivial topology of Ω_C the resulting coupled problem fails to have a unique solution even for $\mathbf{H}$ [68, 56]: Loop currents in Ω_C can no longer be determined, because Faraday's law is not completely taken into account. Thus, in general, FEM-BEM-coupling for the eddy current problem cannot be based on $\mathbf{A}$-V-formulations [10], V a scalar magnetic potential, unless one is willing to grapple with integrals over cuts in the air region.

Next, we scrutinize the interior eddy current problem in Ω_C. Its strong forms are straightforward: The Dirichlet problem for Dirichlet-data $\mathbf{g} \in \boldsymbol{H}_\perp^{-1/2}(\mathrm{curl}_\Gamma, \Gamma)$ reads

$$\mathbf{curl}\, \frac{1}{\mu}\, \mathbf{curl}\, \mathbf{u} + i\omega\sigma \mathbf{u} = -i\omega \mathbf{j}_0 \quad \text{in } \Omega_C, \quad \gamma_D \mathbf{u} = \mathbf{g} \quad \text{on } \Gamma \, ,$$

whereas the Neumann problem for $\boldsymbol{\lambda} \in \boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma, \Gamma)$ can be stated as

$$\mathbf{curl}\, \mu^{-1}\, \mathbf{curl}\, \mathbf{u} + i\omega\sigma \mathbf{u} = -i\omega \mathbf{j}_0 \quad \text{in } \Omega_C, \quad \mu^{-1} \gamma_N \mathbf{u} = \boldsymbol{\lambda} \quad \text{on } \Gamma \, .$$

Reassuringly, the Cauchy data $(\gamma_D \mathbf{u}, \gamma_N \mathbf{u})$ exactly match the transmission conditions (4.1).

Now, we examine the part of the variational problem (1.3) that is associated with Ω_E. As pointed out in section 2, only relaxed constraints on $\mathbf{E}$ in Ω_E will be considered. Then the weak saddle point formulation of the exterior[1] Dirichlet problem corresponding to (2.4) reads as follows: Given $\mathbf{g} \in \boldsymbol{H}_\perp^{-1/2}(\mathrm{curl}_\Gamma, \Gamma)$, seek $\mathbf{u} \in \boldsymbol{W}(\mathbf{curl}, \Omega_E)$, $\gamma_\mathbf{t} \mathbf{u} = \mathbf{g}$, $p \in W_0^{1,0}(\Omega_E)$, where (cf. [65, sect. 2.5.4])

$$W_0^{1,0}(\Omega) := \{\phi \in L^2(\Omega),\, \sqrt{1+|\mathbf{x}|^2}\, \mathrm{grad}\, \phi(\mathbf{x}) \in \boldsymbol{L}^2(\Omega),\, \phi_{|\partial\Omega} = 0\} \, ,$$

such that

$$\begin{array}{rcccll} (\mathbf{curl}\, \mathbf{u}, \mathbf{curl}\, \mathbf{v})_{0;\Omega_E} & + & (\mathrm{grad}\, p, \mathbf{v})_{0;\Omega_E} & = & 0 & \forall \mathbf{v} \in \boldsymbol{W}_0(\mathbf{curl}, \Omega_E) \, , \\ (\mathbf{u}, \mathrm{grad}\, q)_{0;\Omega_E} & & & = & 0 & \forall q \in W_0^{1,0}(\Omega_E) \, . \end{array}$$

This gives rise to the boundary value problem

$$\mathbf{curl}\, \mathbf{curl}\, \mathbf{u} = 0, \quad \mathrm{div}\, \mathbf{u} = 0 \quad \text{in } \Omega_E, \quad \gamma_\mathbf{t} \mathbf{u} = \mathbf{g} \quad \text{on } \Gamma \, , \tag{4.2}$$

plus decay conditions as in (1.3).

Dropping boundary conditions in the function spaces leads to the Neumann problem: For $\boldsymbol{\lambda} \in \boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma, \Gamma)$, find $\mathbf{u} \in \boldsymbol{W}(\mathbf{curl}, \Omega_E)$, $p \in W^{1,0}(\Omega_E)$ with

$$\begin{array}{rcccll} (\mathbf{curl}\, \mathbf{u}, \mathbf{curl}\, \mathbf{v})_{0;\Omega_E} & + & (\mathrm{grad}\, p, \mathbf{v})_{0;\Omega_E} & = & \langle \boldsymbol{\lambda}, \gamma_\mathbf{t} \mathbf{v} \rangle_{\boldsymbol{\tau}} & \forall \mathbf{v} \in \boldsymbol{W}(\mathbf{curl}, \Omega_E) \, , \\ (\mathbf{u}, \mathrm{grad}\, q)_{0;\Omega_E} & & & = & 0 & \forall q \in W^{1,0}(\Omega_E) \, . \end{array}$$

[1] I keep calling the problem "exterior" even if it may be posed on a bounded domain.

The related boundary value problem can be stated (without decay conditions) as

$$\mathbf{curl}\,\mathbf{curl}\,\mathbf{u} + \operatorname{grad} p = 0 \quad \text{in } \Omega_E, \quad \operatorname{div}\mathbf{u} = 0 \quad \text{in } \Omega_E\ , \tag{4.3}$$

$$\gamma_{\mathbf{n}}\mathbf{u} = 0 \quad \text{on } \Gamma, \qquad \gamma_N\mathbf{u} = \boldsymbol{\lambda} \quad \text{on } \Gamma\ . \tag{4.4}$$

DEFINITION 4.1. *A distribution $\mathbf{u} \in \boldsymbol{\mathcal{D}}(\Omega)'$ is called a solution of the "exterior" eddy current problem in Ω if $\mathbf{curl}\,\mathbf{curl}\,\mathbf{u} = 0$ and $\operatorname{div}\mathbf{u} = 0$. If the domain is not specified, $\Omega = \Omega_C \cup \Omega_E$ is implied.*

Remembering $\operatorname{div}_\Gamma^* = \operatorname{grad}_\Gamma$ and $\operatorname{grad}_\Gamma(\gamma_{\mathbf{t}}\boldsymbol{\Psi}) = \gamma_{\mathbf{t}}(\operatorname{grad}\boldsymbol{\Psi})$, we see from (4.3) that $\operatorname{grad} p = 0$ if and only if $\operatorname{div}_\Gamma\boldsymbol{\lambda} = 0$. This entails a constraint for the Neumann boundary values that produce solutions of the exterior eddy current problem in Ω_E. In sum, we have found $\boldsymbol{H}_\perp^{-1/2}(\operatorname{curl}_\Gamma,\Gamma)$ as the right space for the Dirichlet-data $\gamma_{\mathbf{t}}\mathbf{u}$. Conversely the Neumann-data $(\gamma_N,\gamma_{\mathbf{n}})$ should belong to $\boldsymbol{H}_{||}^{-1/2}(\operatorname{div}_\Gamma 0,\Gamma)\times H^{-1/2}(\Gamma)$, where

$$\boldsymbol{H}_{||}^{-\frac{1}{2}}(\operatorname{div}_\Gamma 0,\Gamma) := \{\boldsymbol{\lambda} \in \boldsymbol{H}_{||}^{-\frac{1}{2}}(\operatorname{div}_\Gamma,\Gamma),\ \operatorname{div}_\Gamma\boldsymbol{\lambda} = 0\}\ .$$

These are the domain and range, respectively, of the Dirichlet-to-Neumann map for the exterior eddy current problem. However, this map is not well defined in the case of relaxed constraints, as the normal trace $\gamma_{\mathbf{n}}$ is nonzero for harmonic Dirichlet fields. However, the trace γ_N is *not* affected and turns out unique for given Dirichlet-data.

The gist of these considerations is that a part of the Neumann data for the exterior eddy current problem is not captured by the transmission conditions. Fittingly, it is exactly that component that is not unique without gauging. This reflects that gauging is redundant as far as the solution in Ω_C is concerned. As we will see in the next section, we have to retain the divergence constraint, nevertheless.

5. Potentials. As usual, the correct boundary integral equations for the exterior eddy current problem emerge from a representation formula. It involves the singular function for the Laplacian in three dimensions:

$$E(\mathbf{x},\mathbf{y}) := \frac{1}{4\pi}\frac{1}{|\mathbf{x}-\mathbf{y}|}\ , \quad \mathbf{x},\mathbf{y} \in \mathbb{R}^3,\ \mathbf{x} \neq \mathbf{y}\ .$$

As in [33, sect. 6.2], for any Lipschitz-domain $\Omega \subset \mathbb{R}^3$ with exterior unit normal $\mathbf{n}$, we arrive at the following representation formula for vectorfields $\mathbf{u} \in C^2(\bar{\Omega})^3$ with $\operatorname{div}\mathbf{u}$ and $\mathbf{curl}\,\mathbf{curl}\,\mathbf{u}$ compactly supported and decaying like $\mathbf{u}(\mathbf{x}) = O(|\mathbf{x}|^{-1})$ and $\mathbf{curl}\,\mathbf{u}(\mathbf{x}) = o(|\mathbf{x}|^{-1})$ uniformly for $|\mathbf{x}| \to \infty$:

$$\begin{aligned}\mathbf{u}(\mathbf{x}) = &-\mathbf{curl}_{\mathbf{x}}\int_\Gamma (\mathbf{n}\times\mathbf{u})(\mathbf{y})E(\mathbf{x},\mathbf{y})\,dS(\mathbf{y}) + \int_\Gamma (\mathbf{n}\times\mathbf{curl}\,\mathbf{u})(\mathbf{y})E(\mathbf{x},\mathbf{y})\,dS(\mathbf{y})\\ &+\operatorname{grad}_{\mathbf{x}}\int_\Gamma (\mathbf{n}\cdot\mathbf{u})(\mathbf{y})E(\mathbf{x},\mathbf{y})\,dS(\mathbf{y}) + \int_\Omega \mathbf{curl}\,\mathbf{curl}\,\mathbf{u}(\mathbf{y})E(\mathbf{x},\mathbf{y})\,d\mathbf{y}\\ &-\int_\Omega \operatorname{div}\mathbf{u}(\mathbf{y})\operatorname{grad}_{\mathbf{x}}E(\mathbf{x},\mathbf{y})\,d\mathbf{y}, \qquad \mathbf{x}\in\Omega\ .\end{aligned} \tag{5.1}$$

It is an analogue to the Stratton–Chu formulas for the full Maxwell's equations (see [33, Thm. 6.1], [59, sect. 2], and [65, sect. 5.5]).

Evidently, information on the divergence is crucial in the derivation of the representation formula. This is the fundamental reason why we have to keep the zero divergence constraint for the exterior eddy current problem.

We recall the definition of the scalar single layer potential [27, Chap. 6]:

$$\Psi_V(\phi)(\mathbf{x}) := \int_\Gamma \phi(\mathbf{y}) E(\mathbf{x},\mathbf{y})\, dS(\mathbf{y}) , \quad \mathbf{x} \notin \Gamma . \tag{5.2}$$

It is well known that it can be extended to a continuous mapping $\Psi_V : H^{-1/2}(\Gamma) \mapsto H^1_{\mathrm{loc}}(\mathbb{R}^3)$, that it satisfies certain jump relations, and that it induces a Hermitian $H^{-1/2}(\Gamma)$-elliptic bilinear form [39, Chap. XI, sect. 2, Thm. 3]. We aim to establish similar results for the potentials occurring in (5.1), too. To this end we closely follow the approach in [35]. First, for a tangential vectorfield $\boldsymbol{\lambda}$ on Γ, we define the vectorial single layer potential by

$$\boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda})(\mathbf{x}) := \int_\Gamma \boldsymbol{\lambda}(\mathbf{y}) E(\mathbf{x},\mathbf{y})\, dS(\mathbf{y}) , \quad \mathbf{x} \notin \Gamma . \tag{5.3}$$

Introducing the vectorial Newton-potential as

$$\mathbf{G}(\boldsymbol{\lambda})(\mathbf{x}) := \int_{\mathbb{R}^3} \boldsymbol{\lambda}(\mathbf{y}) E(\mathbf{x},\mathbf{y})\, d\mathbf{y} , \tag{5.4}$$

which defines a continuous mapping $\mathbf{G} : \boldsymbol{H}^{-1}_{\mathrm{comp}}(\mathbb{R}^3) \mapsto \boldsymbol{H}^1_{\mathrm{loc}}(\mathbb{R}^3)$, we formally get for a smooth compactly supported test field $\boldsymbol{\Phi} \in \boldsymbol{\mathcal{D}}(\mathbb{R}^3)$

$$\begin{aligned}\int_{\mathbb{R}^3} \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda})(\mathbf{x}) \cdot \overline{\boldsymbol{\Phi}(\mathbf{x})}\, d\mathbf{x} &= \int_{\mathbb{R}^3} \int_\Gamma E(\mathbf{x},\mathbf{y}) \boldsymbol{\lambda}(\mathbf{y}) \cdot \overline{\boldsymbol{\Phi}(\mathbf{x})}\, dS(\mathbf{y})\, d\mathbf{x} \\ &= \int_\Gamma \boldsymbol{\lambda}(\mathbf{y}) \cdot \overline{\mathbf{G}(\boldsymbol{\Phi})(\mathbf{y})}\, dS(\mathbf{y}) .\end{aligned}$$

We conclude

$$(\boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda}), \boldsymbol{\Phi})_{0;\mathbb{R}^3} = (\boldsymbol{\lambda}, \gamma_{\mathbf{t}} \mathbf{G}(\boldsymbol{\Phi}))_{0;\Gamma} = (\gamma_{\mathbf{t}}{}^* \boldsymbol{\lambda}, \mathbf{G}(\boldsymbol{\Phi}))_{0;\mathbb{R}^3} = (\mathbf{G}(\gamma_{\mathbf{t}}{}^* \boldsymbol{\lambda}), \boldsymbol{\Phi})_{0;\mathbb{R}^3} ,$$

which means, by density,

$$\boldsymbol{\Psi}_{\mathbf{A}}^* = \gamma_{\mathbf{t}} \circ \mathbf{G} \quad \Leftrightarrow \quad \boldsymbol{\Psi}_{\mathbf{A}} = \mathbf{G} \circ \gamma_{\mathbf{t}}{}^* . \tag{5.5}$$

THEOREM 5.1. $\boldsymbol{\Psi}_{\mathbf{A}} : \boldsymbol{H}_{||}^{-1/2}(\Gamma) \mapsto \boldsymbol{H}^1_{\mathrm{loc}}(\mathbb{R}^3)$ *is a continuous operator.*

Proof. By Theorem 3.1, the L^2-adjoint $\gamma_{\mathbf{t}}{}^* : \boldsymbol{H}_{||}^{-1/2}(\Gamma) \mapsto \boldsymbol{H}^{-1}(\mathbb{R}^3)$ is continuous. Then the assertion is immediate from (5.5). ∎

The next lemma supplies an important auxiliary relationship.

LEMMA 5.2. *For* $\boldsymbol{\lambda} \in \boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma, \Gamma)$ *we have*

$$\mathrm{div}\, \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda}) = \Psi_V(\mathrm{div}_\Gamma \boldsymbol{\lambda}) \quad \textit{in } \boldsymbol{L}^2(\mathbb{R}^3) .$$

Proof. Cf. the proof of Lemma 2.3 in [59]. ∎

From the decay properties of the kernel we infer $\boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda}) \in W^{1,-1}(\mathbb{R}^3)$. Now, we confine ourselves to $\boldsymbol{\lambda} \in \boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma 0, \Gamma)$. According to the previous lemma, this implies $\mathrm{div}\, \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda}) = 0$, and, since $\Delta \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda}) = 0$ away from Γ, $\mathbf{curl}\,\mathbf{curl}\, \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda})$ is seen to vanish in $\mathbb{R}^3 \setminus \Gamma$ as well. Thus, $\gamma_N \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda})$ is well defined from both sides of Γ.

Now we can apply Green's formula to Ω_C and Ω_E separately and add up the expressions: For all $\boldsymbol{\Phi} \in \boldsymbol{\mathcal{D}}(\mathbb{R}^3)$

$$\int_{\mathbb{R}^3} \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda}) \cdot \mathbf{curl}\,\mathbf{curl}\, \boldsymbol{\Phi}\, d\mathbf{x} = \langle [\gamma_D \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda})]_\Gamma, \gamma_N \boldsymbol{\Phi} \rangle_{\boldsymbol{\tau}} - \langle [\gamma_N \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda})]_\Gamma, \gamma_D \boldsymbol{\Phi} \rangle_{\boldsymbol{\tau}} .$$

On the other hand, using $\operatorname{div} \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda}) = 0$, we get

$$\begin{aligned}\int_{\mathbb{R}^3} \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda})(\mathbf{x}) \cdot \mathbf{curl}\,\mathbf{curl}\,\boldsymbol{\Phi}(\mathbf{x})\,d\mathbf{x} &= -\int_{\mathbb{R}^3} \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda})(\mathbf{x}) \cdot \boldsymbol{\Delta}\boldsymbol{\Phi}(\mathbf{x})\,d\mathbf{x} \\ &= -\left\langle \boldsymbol{\lambda}, (\boldsymbol{\Psi}_{\mathbf{A}}^* \circ \boldsymbol{\Delta})\boldsymbol{\Phi} \right\rangle_{\boldsymbol{\tau}} = \left\langle \boldsymbol{\lambda}, \gamma_D \boldsymbol{\Phi} \right\rangle_{\boldsymbol{\tau}}.\end{aligned}$$

We have made use of (5.5), i.e., $\boldsymbol{\Psi}_{\mathbf{A}}^* = \gamma_{\mathbf{t}} \circ \mathbf{G}$, and $\mathbf{G} \circ \Delta = -Id$. Next, we see from the regularity result of Theorem 5.1 that $[\gamma_D \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda})]_\Gamma = 0$. Subtracting the previous equation, we establish

$$[\gamma_N \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda})]_\Gamma = -\boldsymbol{\lambda} \quad \text{in } \boldsymbol{H}_{||}^{-\frac{1}{2}}(\operatorname{div}_\Gamma, \Gamma), \tag{5.6}$$

thanks to the density of $\boldsymbol{\mathcal{D}}(\mathbb{R}^3)_{|\Gamma}$ in $\boldsymbol{H}_{||}^{-1/2}(\operatorname{div}_\Gamma, \Gamma)$. This is the desired *jump relation* for the vectorial single layer potential.

The vectorial double layer potential for a tangential vectorfield $\mathbf{u}$ is given by

$$\boldsymbol{\Psi}_{\mathbf{M}}(\mathbf{u}) := \mathbf{curl}\,\boldsymbol{\Psi}_{\mathbf{A}}(R\mathbf{u}), \quad R\mathbf{u} := \mathbf{n} \times \mathbf{u}\,. \tag{5.7}$$

From the regularity of the vectorial single layer potential (Theorem 5.1) and the fact that $R : \boldsymbol{H}_{||}^{-1/2}(\Gamma) \mapsto \boldsymbol{H}_{\perp}^{-1/2}(\Gamma)$ is an isometry, we can infer that $\boldsymbol{\Psi}_{\mathbf{M}}$ is a continuous mapping from $\boldsymbol{H}_{\perp}^{-1/2}(\Gamma)$ to $\boldsymbol{H}(\operatorname{div}; \mathbb{R}^3)$.

Armed with these regularity results and the continuity of the trace mappings, we can extend the representation formula (5.1) to vectorfields $\mathbf{u} \in \boldsymbol{W}(\mathbf{curl}, \mathbb{R}^3)$ decaying according to (2.5) and satisfying $\operatorname{div} \mathbf{u}_{|\Omega_C} \in L^2(\Omega_C)$, $\operatorname{div} \mathbf{u}_{|\Omega_E} \in L^2(\Omega_E)$ compactly supported, $\mathbf{curl}\,\mathbf{curl}\,\mathbf{u}_{|\Omega_C} \in \boldsymbol{L}^2(\Omega_C)$, and $\mathbf{curl}\,\mathbf{curl}\,\mathbf{u}_{|\Omega_E} \in \boldsymbol{L}^2(\Omega_E)$ compactly supported: We get the *transmission formula*

$$\begin{aligned}\mathbf{u} = &-\mathbf{G}(\mathbf{curl}\,\mathbf{curl}\,\mathbf{u}) + \operatorname{grad}\mathbf{G}(\operatorname{div}\mathbf{u}) + \boldsymbol{\Psi}_{\mathbf{M}}([\gamma_D\mathbf{u}]_\Gamma) \\ &- \boldsymbol{\Psi}_{\mathbf{A}}([\gamma_N\mathbf{u}]_\Gamma) - \operatorname{grad}\Psi_V([\gamma_{\mathbf{n}}\mathbf{u}]_\Gamma).\end{aligned} \tag{5.8}$$

Let us write $\mathfrak{S} : \boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\operatorname{curl}_\Gamma, \Gamma) \mapsto \boldsymbol{W}(\mathbf{curl}^2, \Omega) \cap \boldsymbol{H}(\operatorname{div} 0; \Omega)$ for a continuous solution operator for the Dirichlet problem (4.2) on both sides of Γ. It fulfills (for $\mathbf{g} \in \boldsymbol{H}_{\perp}^{-1/2}(\operatorname{curl}_\Gamma, \Gamma)$)

$$\begin{aligned}\mathfrak{S}\,\mathbf{g} &= \boldsymbol{\Psi}_{\mathbf{M}}(\mathbf{g}) - \boldsymbol{\Psi}_{\mathbf{A}}(\gamma_N\,\mathfrak{S}\,\mathbf{g}) - \operatorname{grad}\Psi_V(\gamma_{\mathbf{n}}\,\mathfrak{S}\,\mathbf{g}) \quad \text{in } \Omega_E\,, \\ \mathfrak{S}\,\mathbf{g} &= -\boldsymbol{\Psi}_{\mathbf{M}}(\mathbf{g}) + \boldsymbol{\Psi}_{\mathbf{A}}(\gamma_N\,\mathfrak{S}\,\mathbf{g}) + \operatorname{grad}\Psi_V(\gamma_{\mathbf{n}}\,\mathfrak{S}\,\mathbf{g}) \quad \text{in } \Omega_C\,.\end{aligned} \tag{5.9}$$

Of course, the introduction of $\mathfrak{S}$ entails some gauging of $\mathfrak{S}\,\mathbf{g}$ to render it well defined. As the kind of gauging involved ultimately turns out to be immaterial, we do not have to bother about its details.

THEOREM 5.3. *$\boldsymbol{\Psi}_{\mathbf{M}}$ is a continuous mapping from $\boldsymbol{H}_{\perp}^{-1/2}(\operatorname{curl}_\Gamma, \Gamma)$ to $\boldsymbol{H}(\operatorname{div} 0; \Omega) \cap \boldsymbol{H}(\mathbf{curl}; \Omega)$, for both $\Omega = \Omega_C$ and $\Omega = \Omega_E$.*

Proof. Equations (5.9) mean that, e.g., in Ω_E, $\boldsymbol{\Psi}_{\mathbf{M}} = (Id - \boldsymbol{\Psi}_{\mathbf{A}} \circ \gamma_N + \operatorname{grad} \circ \Psi_V \circ \gamma_{\mathbf{n}}) \circ \mathfrak{S}$. Employing the continuity properties of the other potentials and of the trace operators, we get the result. ∎

We may plug an (arbitrarily gauged) solution of the Dirichlet problem (4.2) into the transmission formula and extend $\mathbf{u}$ to the other side of Γ by solving a Neumann problem (4.3) such that $[\gamma_{\mathbf{n}}\mathbf{u}]_\Gamma = 0$ and $[\gamma_N\mathbf{u}]_\Gamma = 0$. In the end, we have $\mathbf{u} = \boldsymbol{\Psi}_{\mathbf{M}}([\gamma_D\mathbf{u}]_\Gamma)$ and can state $\operatorname{Im}(\boldsymbol{\Psi}_{\mathbf{M}}) \subset \boldsymbol{W}(\mathbf{curl}^2, \Omega_C) \times \boldsymbol{W}(\mathbf{curl}^2, \Omega_E)$. So it is legal to evaluate the Neumann trace γ_N for the vectorial double layer potential.

Next, we aim to establish the jump relations for $\boldsymbol{\Psi}_{\mathbf{M}}$. Note that from (5.5)

$$\boldsymbol{\Psi}_{\mathbf{M}} = \mathbf{curl} \circ \boldsymbol{\Psi}_{\mathbf{A}} \circ R = \mathbf{curl} \circ \mathbf{G} \circ {\gamma_{\mathbf{t}}}^* \circ R = \mathbf{curl} \circ \mathbf{G} \circ (\gamma_{\mathbf{t}}^{\times})^*,$$

where I used $R^* = -R$. By virtue of $\mathbf{curl}\,\mathbf{curl}\,\mathbf{curl} = -\,\mathbf{curl} \circ \boldsymbol{\Delta}$ and $\mathbf{curl}^* = \mathbf{curl}$, this implies

$$\mathbf{curl}\,\mathbf{curl}\,\boldsymbol{\Psi}_{\mathbf{M}} = -\,\mathbf{curl} \circ (\boldsymbol{\Delta} \circ \mathbf{G}) \circ (\gamma_{\mathbf{t}}^{\times})^* = (\gamma_{\mathbf{t}}^{\times} \circ \mathbf{curl})^* = \gamma_N^* \tag{5.10}$$

in the sense of distributions. As above, we get from Green's formula for $\boldsymbol{\Phi} \in \boldsymbol{\mathcal{D}}(\mathbb{R}^3)$

$$\int_{\mathbb{R}^3} \boldsymbol{\Psi}_{\mathbf{M}}(\mathbf{u}) \cdot \mathbf{curl}\,\mathbf{curl}\,\overline{\boldsymbol{\Phi}}\, d\mathbf{x} = \langle [\gamma_D \boldsymbol{\Psi}_{\mathbf{M}}(\mathbf{u})]_\Gamma, \gamma_N \boldsymbol{\Phi} \rangle_{\boldsymbol{\tau}} - \langle [\gamma_N \boldsymbol{\Psi}_{\mathbf{M}}(\mathbf{u})]_\Gamma, \gamma_D \boldsymbol{\Phi} \rangle_{\boldsymbol{\tau}} .$$

Combining this with (5.10) confirms that for all $\boldsymbol{\Phi} \in \boldsymbol{\mathcal{D}}(\mathbb{R}^3)$

$$\langle [\gamma_D \boldsymbol{\Psi}_{\mathbf{M}}(\mathbf{u})]_\Gamma - \mathbf{u}, \gamma_N \boldsymbol{\Phi} \rangle_{\boldsymbol{\tau}} - \langle [\gamma_N \boldsymbol{\Psi}_{\mathbf{M}}(\mathbf{u})]_\Gamma, \gamma_D \boldsymbol{\Phi} \rangle_{\boldsymbol{\tau}} = 0 . \tag{5.11}$$

As we can see along the lines of the proof of Lemma 1.5.39 in [43], $\boldsymbol{\mathcal{D}}(\Omega)$ is dense in $\boldsymbol{W}(\mathbf{curl}^2, \Omega)$. This means that we can equivalently state (5.11) to hold for all $\boldsymbol{\Phi} \in \boldsymbol{W}(\mathbf{curl}^2, \Omega)$. Finally, let $\mathbf{p} \in \boldsymbol{W}(\mathbf{curl}^2, \Omega)$ be a solution of the Dirichlet problem

$$\mathbf{curl}\,\mathbf{curl}\,\mathbf{p} = \mathbf{f} \text{ in } \Omega, \quad \operatorname{div} \mathbf{p} = 0 \text{ in } \Omega, \quad \gamma_D \mathbf{p} = 0 \text{ on } \Gamma ,$$

with $\mathbf{f} \in \boldsymbol{H}(\operatorname{div} 0; \Omega)$ compactly supported. On top of that, define $\boldsymbol{\eta} \in \boldsymbol{W}(\mathbf{curl}^2, \Omega)$ as a solution of the Dirichlet problem

$$\mathbf{curl}\,\mathbf{curl}\,\boldsymbol{\eta} = 0 \text{ in } \Omega, \quad \operatorname{div} \boldsymbol{\eta} = 0 \text{ in } \Omega, \quad \gamma_D \boldsymbol{\eta} = [\gamma_D \boldsymbol{\Psi}_{\mathbf{M}}(\mathbf{u})]_\Gamma - \mathbf{u} \text{ on } \Gamma .$$

By using the definition of the Neumann trace operator γ_N,

$$\begin{aligned} 0 &= \langle \gamma_D \boldsymbol{\eta}, \gamma_N \mathbf{p} \rangle_{\boldsymbol{\tau}} = \langle \gamma_D \boldsymbol{\eta}, \gamma_N \mathbf{p} \rangle_{\boldsymbol{\tau}} - \langle \gamma_N \boldsymbol{\eta}, \gamma_D \mathbf{p} \rangle_{\boldsymbol{\tau}} \\ &= (\mathbf{curl}\,\mathbf{curl}\,\boldsymbol{\eta}, \mathbf{p})_{0;\Omega} - (\boldsymbol{\eta}, \mathbf{curl}\,\mathbf{curl}\,\mathbf{p})_{0;\Omega} = -\,(\boldsymbol{\eta}, \mathbf{f})_{0;\Omega} . \end{aligned}$$

Hence, $\boldsymbol{\eta}$ must vanish, as $\operatorname{div} \boldsymbol{\eta} = 0$. At this stage, we already know

$$[\gamma_D \boldsymbol{\Psi}_{\mathbf{M}}(\mathbf{u})]_\Gamma = \mathbf{u} \quad \text{in } \boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\operatorname{curl}_\Gamma, \Gamma) , \tag{5.12}$$

and from (5.11) $[\gamma_N \boldsymbol{\Psi}_{\mathbf{M}}(\mathbf{u})]_\Gamma = 0$ is readily available. This finishes the proof of the jump relations for the vectorial double layer potential.

6. Boundary integral operators. The regularity properties demonstrated in the previous section pave the way for defining related boundary integral operators

$$\begin{aligned} \mathbf{A}\boldsymbol{\lambda} &:= \gamma_D \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda}), & \mathbf{B}\boldsymbol{\lambda} &:= \gamma_N^+ \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda}) , \\ \mathbf{C}\mathbf{u} &:= \gamma_D^+ \boldsymbol{\Psi}_{\mathbf{M}}(\mathbf{u}), & \mathbf{N}\mathbf{u} &:= \gamma_N \boldsymbol{\Psi}_{\mathbf{M}}(\mathbf{u}) , \\ \mathbf{S}\phi &:= \gamma_D^+(\operatorname{grad} \Psi_V(\phi)). \end{aligned}$$

Alternatively, we could have written $\mathbf{S}\phi := \operatorname{grad}_\Gamma \Psi_V(\phi)$. The continuity of the potential mappings and that of the trace operators bear out the following theorem.

THEOREM 6.1. *The mappings*

$$\begin{aligned} &\mathbf{A} : \boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma) \mapsto \boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma), & &\mathbf{B} : \boldsymbol{H}_{||}^{-\frac{1}{2}}(\operatorname{div}_\Gamma, \Gamma) \mapsto \boldsymbol{H}_{||}^{-\frac{1}{2}}(\operatorname{div}_\Gamma, \Gamma) , \\ &\mathbf{C} : \boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\operatorname{curl}_\Gamma, \Gamma) \mapsto \boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\operatorname{curl}_\Gamma, \Gamma), & &\mathbf{N} : \boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\operatorname{curl}_\Gamma, \Gamma) \mapsto \boldsymbol{H}_{||}^{-\frac{1}{2}}(\operatorname{div}_\Gamma, \Gamma) , \\ &\mathbf{S} : H^{-\frac{1}{2}}(\Gamma) \mapsto \boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\Gamma) \end{aligned}$$

are continuous.

Next, pick arbitrary $\mathbf{p},\mathbf{q} \in \boldsymbol{H}_{\perp}^{-1/2}(\mathrm{curl}_\Gamma,\Gamma)$, $\boldsymbol{\zeta},\boldsymbol{\eta} \in \boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma 0,\Gamma)$ and define solutions to the transmission problem for the exterior eddy current problem by

$$\begin{aligned}\mathbf{u} &:= \boldsymbol{\Psi}_{\mathbf{M}}(\mathbf{p}) + \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\zeta}), \quad \text{in } \Omega_C \cup \Omega_E\ ,\\ \mathbf{v} &:= \boldsymbol{\Psi}_{\mathbf{M}}(\mathbf{q}) + \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\eta}), \quad \text{in } \Omega_C \cup \Omega_E\ .\end{aligned}$$

By definition,

$$\begin{aligned}\gamma_D^+\mathbf{u} &= \mathbf{C}(\mathbf{p}) + \mathbf{A}(\boldsymbol{\zeta}), \quad \gamma_N^+\mathbf{u} = \mathbf{N}(\mathbf{p}) + \mathbf{B}(\boldsymbol{\zeta})\ ,\\ \gamma_D^+\mathbf{v} &= \mathbf{C}(\mathbf{q}) + \mathbf{A}(\boldsymbol{\eta}), \quad \gamma_N^+\mathbf{v} = \mathbf{N}(\mathbf{q}) + \mathbf{B}(\boldsymbol{\eta})\ ,\end{aligned}$$

and from the jump relations we get

$$\begin{aligned}\gamma_D^-\mathbf{u} &= \mathbf{C}(\mathbf{p}) - \mathbf{p} + \mathbf{A}(\boldsymbol{\zeta}), \quad \gamma_N^-\mathbf{u} = \mathbf{N}(\mathbf{p}) + \mathbf{B}(\boldsymbol{\zeta}) + \boldsymbol{\zeta}\ ,\\ \gamma_D^-\mathbf{v} &= \mathbf{C}(\mathbf{q}) - \mathbf{q} + \mathbf{A}(\boldsymbol{\eta}), \quad \gamma_N^-\mathbf{v} = \mathbf{N}(\mathbf{q}) + \mathbf{B}(\boldsymbol{\eta}) + \boldsymbol{\eta}.\end{aligned}$$

As $\mathbf{curl}\,\mathbf{curl}\,\mathbf{u} = 0$ and $\mathbf{curl}\,\mathbf{curl}\,\mathbf{v} = 0$ in $\mathbb{R}^3\backslash\Gamma$, Green's formula implies the identities

$$\left\langle \gamma_N^+\mathbf{v}, \gamma_D^+\mathbf{u}\right\rangle_{\boldsymbol{\tau}} = -\left(\mathbf{curl}\,\mathbf{u}, \mathbf{curl}\,\mathbf{v}\right)_{0;\Omega_E} = \overline{\left\langle \gamma_N^+\mathbf{u}, \gamma_D^+\mathbf{v}\right\rangle_{\boldsymbol{\tau}}}\ , \tag{6.1}$$

$$\left\langle \gamma_N^-\mathbf{v}, \gamma_D^-\mathbf{u}\right\rangle_{\boldsymbol{\tau}} = \left(\mathbf{curl}\,\mathbf{u}, \mathbf{curl}\,\mathbf{v}\right)_{0;\Omega_C} = \overline{\left\langle \gamma_N^-\mathbf{u}, \gamma_D^-\mathbf{v}\right\rangle_{\boldsymbol{\tau}}}\ . \tag{6.2}$$

By setting $\boldsymbol{\zeta} = 0$, $\boldsymbol{\eta} = 0$, we deduce

$$\begin{aligned}(6.1) \quad \Rightarrow \qquad \left\langle \mathbf{N}(\mathbf{q}), \mathbf{C}(\mathbf{p})\right\rangle_{\boldsymbol{\tau}} &= \overline{\left\langle \mathbf{N}(\mathbf{p}), \mathbf{C}(\mathbf{q})\right\rangle_{\boldsymbol{\tau}}}\ ,\\ (6.2) \quad \Rightarrow \qquad \left\langle \mathbf{N}(\mathbf{q}), (\mathbf{C}-Id)(\mathbf{p})\right\rangle_{\boldsymbol{\tau}} &= \overline{\left\langle \mathbf{N}(\mathbf{p}), (\mathbf{C}-Id)(\mathbf{q})\right\rangle_{\boldsymbol{\tau}}}\ ,\end{aligned}$$

which directly leads to

$$\left\langle \mathbf{N}(\mathbf{q}), \mathbf{p}\right\rangle_{\boldsymbol{\tau}} = \overline{\left\langle \mathbf{N}(\mathbf{p}), \mathbf{q}\right\rangle_{\boldsymbol{\tau}}}\ . \tag{6.3}$$

As we admitted any $\mathbf{p},\mathbf{q} \in \boldsymbol{H}_{\perp}^{-1/2}(\mathrm{curl}_\Gamma,\Gamma)$, this shows that $\mathbf{N}$ is self-adjoint. In a parallel fashion, by setting $\mathbf{p} = 0$, $\mathbf{q} = 0$, it can be proved that

$$\left\langle \boldsymbol{\eta}, \mathbf{A}(\boldsymbol{\zeta})\right\rangle_{\boldsymbol{\tau}} = \overline{\left\langle \boldsymbol{\zeta}, \mathbf{A}(\boldsymbol{\eta})\right\rangle_{\boldsymbol{\tau}}} \quad \forall \boldsymbol{\zeta},\boldsymbol{\eta} \in \boldsymbol{H}_{||}^{-\frac{1}{2}}(\mathrm{div}_\Gamma 0,\Gamma)\ . \tag{6.4}$$

Finally, we choose $\mathbf{p} = 0$, $\boldsymbol{\eta} = 0$ and observe

$$\begin{aligned}(6.1) \quad \Rightarrow \qquad \left\langle \mathbf{N}(\mathbf{q}), \mathbf{A}(\boldsymbol{\zeta})\right\rangle_{1/2,\Gamma} &= \overline{\left\langle \mathbf{B}(\boldsymbol{\zeta}), \mathbf{C}(\mathbf{q})\right\rangle_{\boldsymbol{\tau}}}\ ,\\ (6.2) \quad \Rightarrow \qquad \left\langle \mathbf{N}(\mathbf{q}), \mathbf{A}(\boldsymbol{\zeta})\right\rangle_{1/2,\Gamma} &= \overline{\left\langle (\mathbf{B}+Id)(\boldsymbol{\zeta}), (\mathbf{C}-Id)(\mathbf{q})\right\rangle_{\boldsymbol{\tau}}}\ ,\end{aligned}$$

which implies

$$\left\langle \mathbf{B}(\boldsymbol{\zeta}), \mathbf{q}\right\rangle_{\boldsymbol{\tau}} = \left\langle \boldsymbol{\zeta}, (\mathbf{C}-Id)\mathbf{q}\right\rangle_{\boldsymbol{\tau}} \quad \forall \mathbf{q} \in \boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\mathrm{curl}_\Gamma,\Gamma), \boldsymbol{\zeta} \in \boldsymbol{H}_{||}^{-\frac{1}{2}}(\mathrm{div}_\Gamma 0,\Gamma)\ . \tag{6.5}$$

The main properties of the operators $\mathbf{A}$ and $\mathbf{N}$, including "ellipticity," are summed up in the following theorems.

THEOREM 6.2. *The bilinear form on* $\boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma 0,\Gamma)$ *induced by the operator* $\mathbf{A}$ *is symmetric and there is a constant* $c>0$ *depending on* Γ *such that*

$$\langle \boldsymbol{\lambda}, \mathbf{A}\boldsymbol{\lambda}\rangle_{\boldsymbol{\tau}} \geq c\,\|\boldsymbol{\lambda}\|^2_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} \qquad \forall \boldsymbol{\lambda} \in \boldsymbol{H}_{||}^{-\frac{1}{2}}(\mathrm{div}_\Gamma 0,\Gamma)\ .$$

Proof. Symmetry can be concluded from (6.4). Pick $\boldsymbol{\lambda} \in \boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma 0,\Gamma)$ and set $\mathbf{u} := \boldsymbol{\Psi}_{\mathbf{A}}(\boldsymbol{\lambda})$, which provides a solution of the exterior eddy current problem in $\Omega_C \cup \Omega_E$. We apply Green's formula on both domains separately and also resort to the jump relations (5.6) for the vectorial simple layer potential:

$$\|\mathbf{curl}\,\mathbf{u}\|^2_{\boldsymbol{L}^2(\Omega_C\cup\Omega_E)} = -\langle [\gamma_N \mathbf{u}]_\Gamma, \gamma_D \mathbf{u}\rangle_{\boldsymbol{\tau}} = \langle \boldsymbol{\lambda}, \mathbf{A}\boldsymbol{\lambda}\rangle_{1/2,\Gamma}\ .$$

Thus, Lemma 3.3 justifies the contention of the theorem. ∎

The examination of the operator $\mathbf{N}$ will rely on the following equivalent expression.

LEMMA 6.3. *For all* $\mathbf{u},\mathbf{v} \in \boldsymbol{H}_{\perp}^{-1/2}(\mathrm{curl}_\Gamma,\Gamma)$

$$\langle \mathbf{N}(\mathbf{u}),\mathbf{v}\rangle_{\boldsymbol{\tau}} = -\langle \mathrm{curl}_\Gamma \mathbf{v}, V(\mathrm{curl}_\Gamma \mathbf{u})\rangle_{1/2,\Gamma}$$

holds, where $V : H^{-\frac{1}{2}}(\Gamma) \mapsto H^{\frac{1}{2}}(\Gamma)$ *is the ordinary scalar single layer potential operator on* Γ.

Proof. I refer to the derivation of formula (2.86) in [32]. ∎

THEOREM 6.4. *The bilinear form induced by the boundary integral operator* $\mathbf{N}$ *on* $\boldsymbol{H}_{\perp}^{-1/2}(\mathrm{curl}_\Gamma,\Gamma)$ *is symmetric and negative semidefinite. In particular*

$$-\langle \mathbf{N}(\mathbf{u}),\mathbf{u}\rangle_{\boldsymbol{\tau}} \geq c\,\|\mathrm{curl}_\Gamma \mathbf{u}\|^2_{H^{-\frac{1}{2}}(\Gamma)} \qquad \forall \mathbf{u} \in \boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\mathrm{curl}_\Gamma,\Gamma)\ ,$$

for some constant $c>0$.

Proof. Symmetry is a consequence of (6.3). For the estimate we simply rely upon the well-known $H^{-1/2}(\Gamma)$-ellipticity of V and use Lemma 6.3. ∎

Remark. The boundary integral operator that has been investigated in a Sobolev space setting in this section can also be considered in spaces of Hölder-continuous functions. This was done (for similar boundary integral operators) in [33, 32, 54].

7. Symmetric coupling. By setting $\mathbf{u} \equiv 0$ in Ω_C, the transmission formula (5.8) is turned into a representation formula for the (arbitrarily gauged) solutions $\mathbf{u}$ of the exterior eddy current problem in Ω_E:

$$\mathbf{u} = \boldsymbol{\Psi}_{\mathbf{M}}(\gamma_D^+\mathbf{u}) - \boldsymbol{\Psi}_{\mathbf{A}}(\gamma_N^+\mathbf{u}) - \mathrm{grad}\,\Psi_V(\gamma_{\mathbf{n}}^+\mathbf{u})\ . \tag{7.1}$$

Formally applying both trace operators γ_D^+ and γ_N^+ to (7.1), we arrive at

$$\gamma_D^+\mathbf{u} = \mathbf{C}(\gamma_D^+\mathbf{u}) - \mathbf{A}(\gamma_N^+\mathbf{u}) - \mathbf{S}(\gamma_{\mathbf{n}}^+\mathbf{u})\ , \tag{7.2}$$

$$\gamma_N^+\mathbf{u} = \mathbf{N}(\gamma_D^+\mathbf{u}) - \mathbf{B}(\gamma_N^+\mathbf{u})\ . \tag{7.3}$$

The first equation is set in $\boldsymbol{H}_{\perp}^{-1/2}(\mathrm{curl}_\Gamma,\Gamma)$ and the second in $\boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma 0,\Gamma)$, which are the appropriate spaces of Dirichlet and Neumann data, as explained in section 3. The goal is to extract a *Calderón-projector* [27, sect. 4.5], [38] from (7.2) and (7.3). In a straightforward fashion, this is not possible, foiled by the presence of the extra Neumann data $\gamma_{\mathbf{n}}^+\mathbf{u}$. The idea is to get the equivalent of a weak Calderón-projector.

We attempt to achieve this goal by testing (7.2) against functions in $\boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma 0,\Gamma)$ only. Apparently this sacrifices a lot of information: Whereas the dual space of $\boldsymbol{H}_{\perp}^{-1/2}(\mathrm{curl}_\Gamma,\Gamma)$ is the entire space $\boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma,\Gamma)$, the dual of $\boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma 0,\Gamma)$ is the orthogonal complement of $\mathrm{grad}_\Gamma H^{1/2}(\Gamma)$ in $\boldsymbol{H}_{\perp}^{-1/2}(\mathrm{curl}_\Gamma,\Gamma)$. (Orthogonality has to be understood with respect to the duality pairing $\langle\cdot,\cdot\rangle_{\boldsymbol{\tau}}$.) On the other hand, the reward is clear from the observation

$$\langle \boldsymbol{\zeta}, \mathbf{S}(\phi)\rangle_{\boldsymbol{\tau}} = 0 \quad \forall \boldsymbol{\zeta} \in \boldsymbol{H}_{||}^{-\frac{1}{2}}(\mathrm{div}_\Gamma 0,\Gamma) \tag{7.4}$$

because $\mathbf{S}(\phi) \in \mathrm{grad}_\Gamma H^{1/2}(\Gamma)$. It reveals that, after all, the test space $\boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma 0,\Gamma)$ suppresses the impact of gauging because (7.4) can be used to get rid of the "artificial" Neumann data $\gamma_{\mathbf{n}}^+\mathbf{u}$ due to the gauge condition. Thus, we can derive the following variational equations from (7.2) and (7.3):

$$\begin{array}{rcccll} \langle \boldsymbol{\zeta}, \gamma_D^+\mathbf{u}\rangle_{\boldsymbol{\tau}} & = & \langle \boldsymbol{\zeta}, \mathbf{C}(\gamma_D^+\mathbf{u})\rangle_{\boldsymbol{\tau}} & - & \langle \boldsymbol{\zeta}, \mathbf{A}(\gamma_N^+\mathbf{u})\rangle_{\boldsymbol{\tau}} & \forall \boldsymbol{\zeta} \in \boldsymbol{H}_{||}^{-\frac{1}{2}}(\mathrm{div}_\Gamma 0,\Gamma)\,, \\ \langle \gamma_N^+\mathbf{u}, \mathbf{w}\rangle_{\boldsymbol{\tau}} & = & \langle \mathbf{N}(\gamma_D^+\mathbf{u}), \mathbf{w}\rangle_{\boldsymbol{\tau}} & - & \langle \mathbf{B}(\gamma_N^+\mathbf{u}), \mathbf{w}\rangle_{\boldsymbol{\tau}} & \forall \mathbf{w} \in \boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\mathrm{curl}_\Gamma,\Gamma)\,, \end{array} \tag{7.5}$$

which are satisfied by all solutions $\mathbf{u} \in \boldsymbol{W}(\mathbf{curl}^2,\Omega_E)$ of the exterior eddy current problem. This is the desired Calderón-projector in weak form.

Now, we can pursue the classical policy due to Costabel [34] in order to couple the interior problem in Ω_C with (7.5). Given a solution $\mathbf{u} \in \boldsymbol{W}(\mathbf{curl},\mathbb{R}^3) \cap \boldsymbol{W}(\mathbf{curl}^2,\Omega_E)$ of the full eddy current problem (1.3), we find through Green's formula and the coupling conditions (4.1) that

$$q(\mathbf{u},\mathbf{v}) - \langle \gamma_N^+\mathbf{u}, \gamma_D\mathbf{v}\rangle_{\boldsymbol{\tau}} = -i\omega\,(\mathbf{j}_0,\mathbf{v})_{0;\Omega_C} \tag{7.6}$$

for all $\mathbf{v} \in \boldsymbol{H}(\mathbf{curl};\Omega_C)$. For the sake of brevity I have set

$$q(\mathbf{u},\mathbf{v}) := \left(\tfrac{1}{\mu}\,\mathbf{curl}\,\mathbf{u}, \mathbf{curl}\,\mathbf{v}\right)_{0;\Omega_C} + i\omega\,(\sigma\mathbf{u},\mathbf{v})_{0;\Omega_C}\ .$$

Equation (7.6) with $\gamma_N^+\mathbf{u}$ replaced by $\boldsymbol{\lambda}$ is added to the second equation of (7.5) tested with $\gamma_D\mathbf{v}$. The first equation of (7.5) completes the coupled variational problem: Seek $\mathbf{u} \in \boldsymbol{H}(\mathbf{curl};\Omega_C)$, $\boldsymbol{\lambda} \in \boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma 0,\Gamma)$ such that

$$\begin{array}{rcccll} q(\mathbf{u},\mathbf{v}) - \langle \mathbf{N}(\gamma_D\mathbf{u}), \gamma_D\mathbf{v}\rangle_{\boldsymbol{\tau}} & + & \langle \mathbf{B}\boldsymbol{\lambda}, \gamma_D\mathbf{v}\rangle_{\boldsymbol{\tau}} & = & -i\omega\,(\mathbf{j}_0,\mathbf{v})_{0;\Omega_C}\,, \\ \langle \boldsymbol{\zeta}, (Id-\mathbf{C})\gamma_D\mathbf{u}\rangle_{\boldsymbol{\tau}} & + & \langle \boldsymbol{\zeta}, \mathbf{A}\boldsymbol{\lambda}\rangle_{\boldsymbol{\tau}} & = & 0 \end{array} \tag{7.7}$$

for all $\mathbf{v} \in \boldsymbol{H}(\mathbf{curl};\Omega_C)$, $\boldsymbol{\zeta} \in \boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma 0,\Gamma)$.

For ease of presentation, I am going to write $\mathbf{d}(\cdot,\cdot)$ for the sesquilinear form on $\mathcal{W} := \boldsymbol{H}(\mathbf{curl};\Omega_C) \times \boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma 0,\Gamma)$ spawning the variational problem (7.7). The right-hand side will be designated by $f \in \boldsymbol{H}(\mathbf{curl};\Omega_C)'$. Existence and uniqueness of a solution $(\mathbf{u},\boldsymbol{\lambda})$ of (7.7) follow from the next theorem by the Lax–Milgram lemma.

THEOREM 7.1. *The sesquilinear form* $\mathbf{d}$ *is* $\mathcal{W}$*-elliptic and continuous.*

Proof. The continuity of the sesquilinear form is an immediate consequence of the continuity of the boundary integral operators (Theorem 6.1) and that of the traces (Theorem 3.2). Owing to (6.5), the operator in (7.7) is block skew-symmetric:

$$\begin{aligned}
&|\mathbf{d}((\mathbf{v},\boldsymbol{\zeta}),(\mathbf{v},\boldsymbol{\zeta}))|\\
&= \left|q(\mathbf{v},\mathbf{v}) - \langle \mathbf{N}(\gamma_D\mathbf{v}),\gamma_D\mathbf{v}\rangle_{\boldsymbol{\tau}} + \langle \mathbf{B}\boldsymbol{\zeta},\gamma_D\mathbf{v}\rangle_{\boldsymbol{\tau}} + \langle \boldsymbol{\zeta},(Id-\mathbf{C})\gamma_D\mathbf{v}\rangle_{\boldsymbol{\tau}} + \langle \boldsymbol{\zeta},\mathbf{A}\boldsymbol{\zeta}\rangle_{1/2,\Gamma}\right|\\
&= \left|q(\mathbf{v},\mathbf{v}) - \langle \mathbf{N}(\gamma_D\mathbf{v}),\gamma_D\mathbf{v}\rangle_{\boldsymbol{\tau}} + \langle \mathbf{A}\boldsymbol{\zeta},\boldsymbol{\zeta}\rangle_{1/2,\Gamma}\right|\\
&\geq c\left(\left(\tfrac{1}{\mu}\,\mathbf{curl}\,\mathbf{v},\mathbf{curl}\,\mathbf{v}\right)_{0;\Omega_C} + (\sigma\mathbf{v},\mathbf{v})_{0;\Omega_C} + \|\mathrm{curl}_\Gamma\,\gamma_D\mathbf{v}\|^2_{H^{-\frac{1}{2}}(\Gamma)} + \|\boldsymbol{\zeta}\|^2_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)}\right)\\
&\geq c\left(\|\mathbf{v}\|^2_{\boldsymbol{H}(\mathbf{curl};\Omega_C)} + \|\boldsymbol{\zeta}\|^2_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)}\right),
\end{aligned}$$

with generic constants $c > 0$ independent of $\mathbf{v} \in \boldsymbol{H}(\mathbf{curl};\Omega_C)$ and $\boldsymbol{\zeta} \in \boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma 0,\Gamma)$. The estimates relied on Theorems 6.2 and 6.4 and used the uniform boundedness of μ and σ (the latter in Ω_C). ∎

Uniqueness of the solution for the coupled problem ultimately justifies our approach. We know that, taking $\mathbf{u} := \mathbf{E}$ from (2.1), $\mathbf{u}_{|\Omega_C}$ and $\gamma_N\mathbf{u}$ are unique (even independent of gauging). The derivation of (7.7) ensures that a solution of (2.1) will always give rise to a corresponding solution of the coupled problem. Uniqueness guarantees that we get the one correct answer.

Remark. The unknown $\boldsymbol{\lambda}$ corresponds to the equivalent surface current density $\mathbf{H}\times\mathbf{n}$ scaled by $-i\omega$.

Remark. In the case of good conductors, smooth surfaces, and high frequency ω, a skin-effect approximation is feasible, which neglects the interior of the conductors. Instead, impedance boundary conditions $\gamma_{\mathbf{t}}\mathbf{E} = \eta\gamma_{\mathbf{t}}^{\times}\mathbf{H}$ are imposed on Γ, where $\eta := (1+i)\sqrt{\omega\mu/2\sigma} \in L^\infty(\Gamma)$ is the surface impedance expressed through the material parameters that are expected to prevail on Γ [75] and [32, sect. 4.7]. In this case we should replace (7.6) with

$$\left(\eta^{-1}\gamma_D\mathbf{u},\mathbf{v}\right)_{0;\Gamma} - \left\langle\gamma_N^+\mathbf{u},\gamma_D\mathbf{v}\right\rangle_{\boldsymbol{\tau}} = 0 \quad \forall\mathbf{v}\in\boldsymbol{H}_\perp^{-\frac{1}{2}}(\mathrm{curl}_\Gamma,\Gamma)\;. \tag{7.8}$$

This will give an analogue of the coupled problem (7.7) with $\boldsymbol{\lambda}$ and $\gamma_D\mathbf{u}$ as unknowns. Of course, the sources $\mathbf{j}_0$ are no longer meaningful, but prescribing total currents in conducting loops continues to make sense.

Yet, (7.8) is pointless without higher regularity of $\gamma_D\mathbf{u}$ so that we have to seek $\gamma_D\mathbf{u}$ in the space $\boldsymbol{L}^2(\Gamma)$. After this alteration, all the above considerations carry over to the skin-effect model, because $\Re\eta > 0$.

8. Discretization. The domain Ω_C is equipped with a triangulation Ω_h in the sense of [29, Chap. 2, sect. 2.2], which may consist of tetrahedra, hexahedra, and prisms. It induces a surface mesh Γ_h of Γ composed of triangles and quadrangles.

As conforming finite element space for approximation in $\boldsymbol{H}(\mathbf{curl};\Omega_C)$, we use edge elements [64, 14] and adopt the notation $\boldsymbol{\mathcal{NED}}_1(\Omega_h)$ for the resulting finite element space. Edge elements can be regarded as discrete 1-forms [13] and they match the tangential continuity of the electric field. In the presence of re-entrant edges of Ω_C or discontinuous material parameters their use is mandatory, because the fields might not belong to $\boldsymbol{H}^1(\Omega_C)$ [37, 36].

The Neumann data $\boldsymbol{\lambda} \in \boldsymbol{H}_{||}^{-1/2}(\mathrm{div}_\Gamma 0, \Gamma)$ require an approximation by means of solenoidal div_Γ-conforming surface finite elements. They are supplied by the space $\boldsymbol{\mathcal{RT}}_0^0(\Gamma_h) := \{\boldsymbol{\lambda}_h \in \boldsymbol{\mathcal{RT}}_0(\Gamma_h),\, \mathrm{div}_\Gamma \boldsymbol{\lambda}_h = 0\}$ of divergence-free lowest order Raviart–Thomas elements on Γ_h [67]. It is worth noting that both kinds of finite elements form affine equivalent families in the sense of [29] based on suitable co- and contravariant transformations of vectorfields [64, 20]. These transformations also make it possible to extend the definition of the finite element spaces to curved elements of Ω_h and Γ_h [9].

Setting $\mathcal{W}_h := \boldsymbol{\mathcal{ND}}_1(\Omega_h) \times \boldsymbol{\mathcal{RT}}_0^0(\Gamma_h) \subset \mathcal{W}$ for the discrete approximation space, the discrete problem can be stated as follows: Seek $(\mathbf{u}_h, \boldsymbol{\lambda}_h) \in \mathcal{W}_h$ such that

$$\mathbf{d}((\mathbf{u}_h, \boldsymbol{\lambda}_h), (\mathbf{v}_h, \boldsymbol{\zeta}_h)) = f(\mathbf{v}_h) \quad \forall (\mathbf{v}_h, \boldsymbol{\zeta}_h) \in \mathcal{W}_h \,. \tag{8.1}$$

As before, we get existence and uniqueness of a discrete solution $(\mathbf{u}_h, \boldsymbol{\lambda}_h)$, and from Theorem 7.1 we conclude the a priori error estimate

$$\begin{aligned} &\|\mathbf{u} - \mathbf{u}_h\|_{\boldsymbol{H}(\mathbf{curl};\Omega_C)} + \|\boldsymbol{\lambda} - \boldsymbol{\lambda}_h\|_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)} \\ &\qquad \leq C \inf_{(\mathbf{v}_h, \boldsymbol{\zeta}_h) \in \mathcal{W}_h} \left\{ \|\mathbf{u} - \mathbf{v}_h\|_{\boldsymbol{H}(\mathbf{curl};\Omega_C)} + \|\boldsymbol{\lambda} - \boldsymbol{\zeta}_h\|_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)} \right\} , \end{aligned} \tag{8.2}$$

with a constant $C > 0$ depending only on the geometry and the material parameters σ and μ. A more concrete estimate is also available.

THEOREM 8.1. *Let $h > 0$ be the meshwidth of Ω_h and assume that the solution $\mathbf{u}$ of the eddy current problem is as regular as $\mathbf{u} \in \boldsymbol{H}^s(\Omega_C)$, $\mathbf{curl}\,\mathbf{u} \in \boldsymbol{H}^s(\Omega_C)$, $\mathbf{curl}\,\mathbf{curl}\,\mathbf{u} \in \boldsymbol{H}^s(\Omega_C)$ for some $s > \frac{1}{2}$. Then*

$$\begin{aligned} &\|\mathbf{u} - \mathbf{u}_h\|_{\boldsymbol{H}(\mathbf{curl};\Omega_C)} + \|\boldsymbol{\lambda} - \boldsymbol{\lambda}_h\|_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)} \\ &\qquad \leq C' h^{\min\{s,1\}} \left(\|\mathbf{u}\|_{\boldsymbol{H}^s(\Omega_C)} + \|\mathbf{curl}\,\mathbf{u}\|_{\boldsymbol{H}^s(\Omega_C)} + \|\mathbf{curl}\,\mathbf{curl}\,\mathbf{u}\|_{\boldsymbol{H}^s(\Omega_C)} \right) , \end{aligned}$$

where $C' > 0$ depends on C from (8.2) *and the shape-regularity constants* (*cf.* [29, *Chap.* 3, *sect.* 3.1]) *of the triangulation Ω_h.*

Proof. Recall the canonical interpolation operators Π and Π^Γ for the spaces $\boldsymbol{\mathcal{ND}}_1(\Omega_h)$ and $\boldsymbol{\mathcal{RT}}_0(\Gamma_h)$ [64, 20]. Π is well defined for vectorfields satisfying the assumptions of the theorem (cf. [5, Lemma 4.7]) and there holds (cf. [30, Lemmas 3.2, 3.3])

$$\|\mathbf{u} - \Pi\,\mathbf{u}\|_{\boldsymbol{H}(\mathbf{curl};\Omega_C)} \leq C h^{\min\{s,1\}} \left(\|\mathbf{u}\|_{\boldsymbol{H}^s(\Omega_C)} + \|\mathbf{curl}\,\mathbf{u}\|_{\boldsymbol{H}^s(\Omega_C)} \right) , \tag{8.3}$$

with a constant merely depending on the shape-regularity of the mesh. Hence, we may choose $\mathbf{v}_h = \Pi\,\mathbf{u}$ on the right-hand side of (8.2).

We set $\mathbf{q}_h := \Pi\,\mathbf{curl}\,\mathbf{u}$, which is also well defined for the given $\mathbf{u}$. We may then pick $\boldsymbol{\zeta}_h := \gamma_\mathbf{t}^\times \mathbf{q}_h$ because we have the commuting relationship $\gamma_\mathbf{t}^\times \circ \Pi = \Pi^\Gamma \circ \gamma_\mathbf{t}^\times$ for sufficiently smooth vectorfields (cf. [49]). Since $\mathrm{div}_\Gamma(\gamma_N \mathbf{u}) = 0$ on Γ, $\gamma_\mathbf{n}(\mathbf{curl}\,\mathbf{curl}\,\mathbf{u}) = 0$, too. Then we may use the commuting diagram property [49, Thm. 13]

$$\mathrm{div}_\Gamma \circ \Pi^\Gamma \circ \gamma_\mathbf{t}^\times = Q^\Gamma \circ \mathrm{div}_\Gamma \circ \gamma_\mathbf{t}^\times = Q^\Gamma \circ \gamma_\mathbf{n} \circ \mathbf{curl}\,,$$

where Q^Γ stands for the $L^2(\Gamma)$-orthogonal projection onto the space of piecewise constants with respect to Γ_h. In short, we get $\mathrm{div}_\Gamma \boldsymbol{\zeta}_h = 0$; i.e., $\boldsymbol{\zeta}_h \in \boldsymbol{\mathcal{RT}}_0^0(\Gamma_h)$.

Next, denote by $P : \boldsymbol{H}_{||}^{1/2}(\Gamma) \mapsto \boldsymbol{H}^1(\Omega_C)$ the continuous extension operator mentioned in Theorem 3.1. Then we can evaluate $\|\boldsymbol{\lambda} - \boldsymbol{\zeta}_h\|_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)}$ by

$$\|\boldsymbol{\lambda} - \boldsymbol{\zeta}_h\|_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)} = \sup_{\boldsymbol{\Psi}\in\boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma)} \frac{(\boldsymbol{\lambda} - \boldsymbol{\zeta}_h, \boldsymbol{\Psi})_{0;\Gamma}}{\|\boldsymbol{\Psi}\|_{\boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma)}} = \sup_{\boldsymbol{\Psi}\in\boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma)} \frac{\left(\gamma_N \mathbf{u} - \gamma_{\mathbf{t}}^\times \mathbf{q}_h, \gamma_{\mathbf{t}} P\boldsymbol{\Psi}\right)_{0;\Gamma}}{\|\boldsymbol{\Psi}\|_{\boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma)}}$$

$$= \sup_{\boldsymbol{\Psi}\in\boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma)} \frac{1}{\|\boldsymbol{\Psi}\|_{\boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma)}} \int_{\Omega_C} \mathbf{curl}(P\overline{\boldsymbol{\Psi}}) \cdot (\mathbf{curl}\,\mathbf{u} - \mathbf{q}_h) - \mathbf{curl}(\mathbf{curl}\,\mathbf{u} - \mathbf{q}_h) \cdot (P\overline{\boldsymbol{\Psi}})\, d\mathbf{x}$$

$$\leq \sup_{\boldsymbol{\Psi}\in\boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma)} \frac{\|P\boldsymbol{\Psi}\|_{\boldsymbol{H}^1(\Omega_C)}}{\|\boldsymbol{\Psi}\|_{\boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma)}} \|\mathbf{curl}\,\mathbf{u} - \mathbf{q}_h\|_{\boldsymbol{H}(\mathbf{curl};\Omega_C)} \leq C \|\mathbf{curl}\,\mathbf{u} - \mathbf{q}_h\|_{\boldsymbol{H}(\mathbf{curl};\Omega_C)} .$$

Applying (8.3) for $\mathbf{curl}\,\mathbf{u}$ instead of $\mathbf{u}$ and using (8.2) finishes the proof. □

Still one issue looms large, namely, how to deal with the subspace $\boldsymbol{\mathcal{RT}}_0^0(\Gamma_h)$ of solenoidal surface Raviart–Thomas vectorfields. If Γ was simply connected, we could exploit $\boldsymbol{\mathcal{RT}}_0^0(\Gamma_h) = \mathbf{curl}_\Gamma \mathcal{S}_1(\Gamma_h)$, where $\mathcal{S}_1(\Gamma_h)$ is the space of scalar, continuous, piecewise linear finite element functions on Γ_h [49] ("stream functions," "loop currents" [51]). Yet, as we allowed more general topology of Ω_C, harmonic surface vectorfields can also contribute to the kernel of div_Γ.

The attack on the problem starts from the results of [55, sect. III] and [45, Chap. 3]: They show that there exists an orientable cutting surface $\Sigma_1, \ldots, \Sigma_L$ in Ω_E such that in $\widetilde{\Omega}_E := \Omega_E \setminus (\Sigma_1 \cup \cdots \cup \Sigma_L)$ each irrotational vectorfield has a single valued scalar potential (i.e., the cohomology group $H^1(\widetilde{\Omega}_E, \mathbb{R})$ is trivial). Their number L equals the first Betti-number of Ω_E. Moreover, $\partial\Sigma_k \subset \Gamma$, $k = 1, \ldots, L$, and none of the Σ_k is tangent to Γ. In addition, under the current assumptions on Ω_C, these surfaces can be chosen to be piecewise smooth and Lipschitz-continuous, and their boundaries can be 1-cycles (i.e., closed paths) of edges in Γ_h. Collect these paths in the set $\mathfrak{C} := \{\gamma_1, \ldots, \gamma_L\}$.

As Ω_E is connected, the first Betti-numbers of Ω_E and Ω_C coincide. Thus we can find orientable and piecewise smooth cutting surfaces $\Sigma_1', \ldots, \Sigma_L'$ that render the cohomology group $H^1(\widetilde{\Omega}_C, \mathbb{R})$ trivial: $\widetilde{\Omega}_C := \Omega_C \setminus (\Sigma_1' \cup \cdots \cup \Sigma_L')$. Their boundaries can also be 1-cycles of edges in Γ_h, again, and give the set $\mathfrak{C}' := \{\gamma_1', \ldots, \gamma_L'\}$. The union $\mathfrak{C} \cup \mathfrak{C}'$ is a set of generators of the homology group $H_1(\Gamma_h, \mathbb{Z})$, when Γ_h is regarded as cell complex (cf. [45, Chap. 2]).

The cutting surfaces can be chosen in a way that renders $\mathfrak{C}$ and $\mathfrak{C}'$ dual to each other. This means that $\mathfrak{C} \cup \mathfrak{C}' \setminus \{\gamma_k'\}$ is a set of generators of $H_1(\Gamma_h \setminus \{\gamma_k\}, \mathbb{Z})$, and $\mathfrak{C} \cup \mathfrak{C}' \setminus \{\gamma_k\}$ a set of generators of $H_1(\Gamma \setminus \{\gamma_k'\}, \mathbb{Z})$, $k = 1, \ldots, L$. The simplest example for dual 1-cycles are the "large" and "small" circle of a torus. Without loss of generality, dual edge cycles may intersect in one point only.

Let me cite a simple observation: As $\gamma_k \in \mathfrak{C}$, $k = 1, \ldots, L$, is the boundary of $\Sigma_k \subset \Omega_E$, we get from Stokes' theorem (Σ_k is orientable!)

$$\int_{\gamma_k} R\gamma_N \mathbf{u} \cdot d\vec{s} = \int_{\Sigma_k} \mathbf{curl}\,\mathbf{curl}\,\mathbf{u} \cdot \mathbf{n}\, dS = 0 ,$$

where R is defined in (5.7). We have this, first, for smooth solutions of the exterior eddy current problem and then, by continuity, for all. This means that in the discrete variational problem (8.1) we can confine ourselves to those $\boldsymbol{\lambda}_h \in \boldsymbol{\mathcal{RT}}_0^0(\Gamma_h)$ that satisfy

$$\int_\gamma R\boldsymbol{\lambda}_h \cdot d\vec{s} = 0 \quad \forall \gamma \in \mathfrak{C} \, .$$

The space of vectorfields in $\boldsymbol{\mathcal{RT}}_0^0(\Gamma_h)$ complying with this constraint will be denoted by $\widehat{\boldsymbol{\mathcal{RT}}}_0^0(\Gamma_h)$.

For each $\gamma_k \in \mathfrak{C}$, $k = 1, \ldots, L$, pick a function $\phi_k \in L^2(\Gamma)$ that is piecewise linear with respect to Γ_h and continuous except for a jump of size 1 across γ_k. Then, setting $\boldsymbol{\eta}_k := \widetilde{\mathbf{curl}}_\Gamma \phi_k$, where $\widetilde{\mathbf{curl}}_\Gamma$ is the surface-**curl** on $\Gamma \setminus \gamma_k$, we find $\boldsymbol{\eta}_k \in \boldsymbol{\mathcal{RT}}_0^0(\Gamma_h)$. Duality of the cycles implies

$$\int_{\gamma_k'} R\boldsymbol{\eta}_k \cdot d\vec{s} = [\phi_k]_{\gamma_k} = 1 \, .$$

A $\boldsymbol{\kappa}_h \in \boldsymbol{\mathcal{RT}}_0(\Gamma_h)$ is in $\mathbf{curl}_\Gamma \mathcal{S}_1(\Gamma_h)$ if and only if $\int_\gamma R\boldsymbol{\kappa}_h \cdot d\vec{s} = 0$ for all closed paths γ: Just define the stream function by $\phi_h(\mathbf{x}) := \int_{\gamma(\mathbf{x}_0,\mathbf{x})} R\boldsymbol{\kappa}_h \cdot d\vec{s}$, $\mathbf{x}, \mathbf{x}_0 \in \Gamma$ ($\mathbf{x}_0$ arbitrary, but fixed), where the path $\gamma(\mathbf{x}_0, \mathbf{x})$ links $\mathbf{x}$ and $\mathbf{x}_0$. Then $\mathbf{curl}_\Gamma \phi_h = \boldsymbol{\kappa}_h$ and $\phi_h \in \mathcal{S}_1(\Gamma_h)$ by plain computations.

Now, given $\boldsymbol{\zeta}_h \in \widehat{\boldsymbol{\mathcal{RT}}}_0^0(\Gamma_h)$, the circulation of $R\tilde{\boldsymbol{\zeta}}_h$ with

$$\tilde{\boldsymbol{\zeta}}_h := \boldsymbol{\zeta}_h - \sum_{k=1}^{L} \int_{\gamma_k'} R\boldsymbol{\zeta}_h \cdot d\vec{s} \; \cdot \; \boldsymbol{\eta}_k$$

vanishes for all closed paths, because any closed path is bounding in Γ relative to $\mathfrak{C} \cup \mathfrak{C}'$. Finally, we have found

$$\widehat{\boldsymbol{\mathcal{RT}}}_0^0(\Gamma_h) = \mathbf{curl}_\Gamma \mathcal{S}_1(\Gamma_h) + \operatorname{Span}\{\boldsymbol{\eta}_1, \ldots, \boldsymbol{\eta}_L\} \, . \tag{8.4}$$

We can now phrase the discrete variational problem (8.1): Seek $\mathbf{u}_h \in \boldsymbol{\mathcal{ND}}_1(\Omega_h)$, $\phi_h \in \mathcal{S}_1(\Gamma_h)$, $\alpha_1, \ldots, \alpha_L \in \mathbb{C}$ such that

$$\begin{aligned}
q(\mathbf{u}_h, \mathbf{v}_h) + (V(\operatorname{curl}_\Gamma \gamma_{\mathbf{t}} \mathbf{u}_h), \operatorname{curl}_\Gamma \gamma_{\mathbf{t}} \mathbf{v}_h)_{0;\Gamma} + (\mathbf{B}(\mathbf{curl}_\Gamma \phi_h), \gamma_{\mathbf{t}} \mathbf{v}_h)_{0;\Gamma} & \\
+ \sum_{k=1}^{L} \alpha_k \, (\mathbf{B}\boldsymbol{\eta}_k, \gamma_{\mathbf{t}} \mathbf{v}_h)_{0;\Gamma} &= -i\omega \, (\mathbf{j}_0, \mathbf{v})_{0;\Omega_C} \, , \\
- (\mathbf{B}(\mathbf{curl}_\Gamma \psi_h), \gamma_{\mathbf{t}} \mathbf{u}_h)_{0;\Gamma} + (\mathbf{A}(\mathbf{curl}_\Gamma \phi_h), \mathbf{curl}_\Gamma \psi_h)_{0;\Gamma} & \\
+ \sum_{k=1}^{L} \alpha_k \, (\mathbf{A}\boldsymbol{\eta}_k, \mathbf{curl}_\Gamma \psi_h)_{0;\Gamma} &= 0 \, , \\
- \big(\mathbf{B}\boldsymbol{\eta}_j, \gamma_{\mathbf{t}} \mathbf{u}_h\big)_{0;\Gamma} + \big(\mathbf{A}(\mathbf{curl}_\Gamma \phi_h), \boldsymbol{\eta}_j\big)_{0;\Gamma} & \\
+ \sum_{k=1}^{L} \alpha_k \, \big(\mathbf{A}\boldsymbol{\eta}_k, \boldsymbol{\eta}_j\big)_{0;\Gamma} &= 0
\end{aligned} \tag{8.5}$$

for all $\mathbf{v}_h \in \boldsymbol{\mathcal{ND}}_1(\Omega_h)$, $\psi_h \in \mathcal{S}_1(\Gamma_h)$, and $j = 1, \ldots, L$. Of course, the solution for ϕ_h is unique only up to a constant.

Remark. Exciting total loop currents in the conductor can be easily coped with: Let the cycles $\gamma_1, \ldots, \gamma_K \in \mathfrak{C}$ belong to those loops. Write I_l, $l = 1, \ldots, K$, for the total current in loop $\#l$. Then, thanks to Ampere's law,

$$I_l = \int_{\Sigma_l'} \mathbf{j} \cdot \mathbf{n} \, dS = \int_{\gamma_l'} -\tfrac{1}{\mu i\omega} \, \mathbf{curl}\, \mathbf{E} \cdot d\vec{s} = -\tfrac{1}{i\omega} \int_{\gamma_l'} R(\tfrac{1}{\mu} \gamma_N^- \mathbf{E}) \cdot d\vec{s} = -\tfrac{1}{i\omega} \int_{\gamma_l'} R\boldsymbol{\lambda} \cdot d\vec{s} \, .$$

Hence, the jump of the stream function across γ_l must be set to $-i\omega I_l$. This amounts to fixing $\alpha_l = -i\omega I_l$, $l = 1, \ldots, K$, in (8.5), while $-i\omega\,(\mathbf{j}_0, \mathbf{v})_{0;\Omega_C}$ is dropped. Only $L - K$ jumps $\alpha_{K+1}, \ldots, \alpha_L$ remain as unknowns.

9. Implementation. The choice of local basis functions for the spaces $\boldsymbol{\mathcal{NP}}_1(\Omega_h)$ and $\mathcal{S}_1(\Gamma_h)$ is canonical. They are associated with the edges of Ω_h and the vertices of Γ_h, respectively. The assembly of the linear system of equations related to (8.5) poses no unusual difficulties. First, we note that $\operatorname{curl}_\Gamma \gamma_{\mathbf{t}}\mathbf{v}_h$, $\operatorname{curl}_\Gamma \gamma_{\mathbf{t}}\mathbf{u}_h$, $\mathbf{curl}_\Gamma\psi_h$, $\mathbf{curl}_\Gamma\phi_h$, and $\boldsymbol{\eta}_k$ are piecewise constant on Γ_h and $\gamma_{\mathbf{t}}\mathbf{u}_h$, $\gamma_{\mathbf{t}}\mathbf{v}_h$ piecewise (bi-)linear. On top of that, all boundary integral operators are structurally equal to those for second order elliptic problems. For instance (see [68]),

$$\begin{aligned}(\mathbf{B}\boldsymbol{\zeta}_h, \mathbf{v}_h)_{0;\Gamma} = \quad & \int_\Gamma \int_\Gamma \boldsymbol{\zeta}_h(\mathbf{y}) \cdot \overline{\mathbf{v}}_h(\mathbf{x}) \frac{\partial E(\mathbf{x},\mathbf{y})}{\partial \mathbf{n}(\mathbf{x})}\, dS(\mathbf{y}) dS(\mathbf{x}) \\ & - \int_\Gamma \int_\Gamma \operatorname{grad}_{\mathbf{x}} E(\mathbf{x},\mathbf{y}) (\boldsymbol{\zeta}_h(\mathbf{y}) \cdot \mathbf{n}(\mathbf{x})) \cdot \overline{\mathbf{v}}_h(\mathbf{x})\, dS(\mathbf{y}) dS(\mathbf{x}) \\ & - \frac{1}{2} \int_\Gamma \boldsymbol{\zeta}_h(\mathbf{x}) \cdot \overline{\mathbf{v}}_h(\mathbf{x})\, dS(\mathbf{x})\ .\end{aligned}$$

Even more striking, [39, Chap. XI, sect. 2, Thm. 7] reveals that

$$(\mathbf{A}(\mathbf{curl}_\Gamma\phi_h), \mathbf{curl}_\Gamma\psi_h)_{0;\Gamma} = \langle D\phi_h, \psi_h\rangle_{1/2,\Gamma} \quad \forall \phi_h, \psi_h \in \mathcal{S}_1(\Gamma_h)\ ,$$

where $D : H^{1/2}(\Gamma) \mapsto H^{-1/2}(\Gamma)$ is the hypersingular operator for the Laplacian.

This permits us to apply all the sophisticated techniques developed for Galerkin boundary element methods for second order elliptic problems. In particular, the same quadrature rules [73] and panel-clustering techniques [47] may be used in an implementation.

When the linear system has been built, it must be solved iteratively, because the sheer dimension of $\boldsymbol{\mathcal{NP}}_1(\Omega_h)$ will usually overwhelm any direct solver. Let us first study the case of trivial topology of Ω_C, i.e., $L = 0$. Then, in compact notation, the variational problem related to (8.5) is characterized by the bilinear form

$$\widetilde{\mathbf{d}}((\mathbf{u}_h, \phi_h), (\mathbf{v}_h, \psi_h)) := \mathbf{d}((\mathbf{u}_h, \mathbf{curl}_\Gamma\phi_h), (\mathbf{v}_h, \mathbf{curl}_\Gamma\psi_h))\ ,$$

with $\mathbf{u}_h, \mathbf{v}_h \in \boldsymbol{\mathcal{NP}}_1(\Omega_h)$, $\phi_h, \psi_h \in \mathcal{S}_1(\Gamma_h)$. Setting $\boldsymbol{\mathcal{U}}_h := \boldsymbol{\mathcal{NP}}_1(\Omega_h) \times \mathcal{S}_1(\Gamma_h)$ with seminorm

$$\|(\mathbf{v}_h, \psi_h)\|^2_{\boldsymbol{\mathcal{U}}} := \left(\frac{1}{\mu}\,\mathbf{curl}\,\mathbf{v}_h, \mathbf{curl}\,\mathbf{v}_h\right)_{0;\Omega_C} + \omega\,(\sigma\mathbf{v}_h, \mathbf{v}_h)_{0;\Omega_C} + \langle D\psi_h, \psi_h\rangle_{1/2,\Gamma}\,,$$

the proof of Theorem 7.1 teaches that

$$\frac{1}{\sqrt{2}}\,\|(\mathbf{u}_h, \phi_h)\|_{\boldsymbol{\mathcal{U}}} \le \|\mathcal{P}_h(\mathbf{u}_h, \phi_h)\|_{\boldsymbol{\mathcal{U}}'} \le \overline{c}\,\|(\mathbf{u}_h, \phi_h)\|_{\boldsymbol{\mathcal{U}}} \quad \forall (\mathbf{u}_h, \phi_h) \in \boldsymbol{\mathcal{U}}_h\ . \tag{9.1}$$

Here, $\mathcal{P}_h : \boldsymbol{\mathcal{U}}_h \mapsto \boldsymbol{\mathcal{U}}_h'$ is the operator associated with $\widetilde{\mathbf{d}}$, and $\overline{c}$ is a positive constant that is utterly independent of the choice of conforming finite element/boundary element spaces. More precisely, as can be seen from the proof of Theorem 7.1, it depends only on the norm bound for the boundary integral operators $\mathbf{N}, \mathbf{B}, \mathbf{C}$.

As exposed in [6, sect. 7] and [28, sect. 4], (9.1) means that solving discrete variational problems connected with the inner product on $\boldsymbol{\mathcal{U}}$ will supply a good preconditioner for $\mathcal{P}_h$. Thus we define the symmetric positive definite operator $\widehat{\mathcal{P}}_h : \boldsymbol{\mathcal{U}}_h' \mapsto \boldsymbol{\mathcal{U}}_h$ by $\widehat{\mathcal{P}}(f_\Re + if_\Im, \rho_\Re + i\rho_\Im) = (\mathbf{v}_\Re + i\mathbf{v}_\Im, \psi_\Re + i\psi_\Im) \in \boldsymbol{\mathcal{U}}_h$ with $(* = \Re, \Im)$

(9.2)
$$\begin{aligned} \left(\tfrac{1}{\mu}\,\mathbf{curl}\,\mathbf{v}_*, \mathbf{curl}\,\mathbf{q}_h\right)_{0;\Omega_C} + \omega\,(\sigma\mathbf{v}_*, \mathbf{q}_h)_{0;\Omega_C} &= f_*(\mathbf{q}_h) \quad \forall \mathbf{q}_h \in \boldsymbol{\mathcal{NP}}_1(\Omega_h)\;, \\ \langle D\psi_*, \eta_h\rangle_{1/2,\Gamma} &= \rho_*(\eta_h) \quad \forall \eta_h \in \mathcal{S}_1(\Gamma_h)\;. \end{aligned}$$

Here, subscripts $\Re$ and $\Im$ tag the (real valued) real and imaginary parts of functionals and functions. Consequently, the ansatz and test functions in the above variational formulation are real valued, too. Besides, we have to demand that ρ_* vanishes for constants. As the right-hand sides of the discrete systems are consistent and the preconditioner is applied to residuals, this trivially holds. Altogether, we infer from (9.1) that the spectrum of $\widehat{\mathcal{P}_h}\mathcal{P}_h$ is contained in $[-\overline{c}, -\frac{1}{2}\sqrt{2}] \cup \{0\} \cup [\frac{1}{2}\sqrt{2}, \overline{c}]$. This carries over to the spectrum of the product $\widehat{\mathsf{P}}\mathsf{P}$ of the matrices representing $\widehat{\mathcal{P}}_h$ and $\mathcal{P}_h$ with respect to some basis of $\boldsymbol{\mathcal{U}}_h$.

However, solving either equation in (9.2) is still prohibitively expensive. A second stage is required in the following way: To determine an approximation for $\mathbf{v}_*$, I suggest to use a symmetric V-cycle of the multigrid method for edge elements presented in [50, sect. 6], if a hierarchy of nested regularly refined meshes, whose finest is Ω_h, is at one's disposal. This amounts to solving the modified variational problem

$$b(\mathbf{v}_*, \mathbf{q}_h) = f_*(\mathbf{q}_h) \quad \forall \mathbf{q}_h \in \boldsymbol{\mathcal{NP}}_1(\Omega_h)\;,$$

with a bilinear form $b : \boldsymbol{\mathcal{NP}}_1(\Omega_h) \times \boldsymbol{\mathcal{NP}}_1(\Omega_h) \mapsto \mathbb{R}$ that fulfills

$$\underline{c}_b\,\|(\mathbf{v}_h, 0)\|^2_{\boldsymbol{\mathcal{U}}} \le b(\mathbf{v}_h, \mathbf{v}_h) < \|(\mathbf{v}_h, 0)\|^2_{\boldsymbol{\mathcal{U}}} \quad \forall \mathbf{v}_h \in \boldsymbol{\mathcal{NP}}_1(\Omega_h)\;. \tag{9.3}$$

Here, $\underline{c}_b$ is uniformly bounded away from zero (cf. [50, sect. 5]), way above $\frac{1}{2}$, as numerical evidence suggests. In case a hierarchy of meshes is not available, one may resort to algebraic multigrid methods [8, 69]. Yet, theoretical estimates like (9.3) are elusive in this case.

The second equation of (9.2) can be tackled following the recipe of [74]. The idea is to use the scalar single layer potential operator V as a preconditioner for D (see also [62, 61]): We know

$$\underline{k}\,\|\psi_h\|^2_{L^2(\Gamma)} \le \langle VD\psi_h, \psi_h\rangle_{1/2,\Gamma} \le \overline{k}\,\|\psi_h\|^2_{L^2(\Gamma)} \quad \forall \psi_h \in \mathcal{S}_1(\Gamma_h)/\mathbb{R}$$

with constants $\underline{k}, \overline{k} > 0$ that can be chosen independently of $\mathcal{S}_1(\Gamma_h)$. $\mathcal{S}_1(\Gamma_h)/\mathbb{R}$ designates the subspace of $\mathcal{S}_1(\Gamma_h)$ containing only functions with zero mean. Thus, an efficient way to determine an approximation for ψ_* from (9.2) is to use a small number of steps of a damped linear or (nonlinear) gradient-type iteration preconditioned by V. As alternatives, domain decomposition or multilevel methods might be used [76, 48].

This practical preconditioner can then be used to accelerate the conjugate residual method [46, sect. 9.5] applied to the symmetric linear system

$$\mathsf{P}\vec{\mathbf{x}} := \begin{pmatrix} \mathsf{M}_\Re & -\mathsf{M}_\Im & \mathsf{B}^T & 0 \\ -\mathsf{M}_\Im & -\mathsf{M}_\Re & 0 & -\mathsf{B}^T \\ \mathsf{B} & 0 & -\mathsf{D} & 0 \\ 0 & -\mathsf{B} & 0 & \mathsf{D} \end{pmatrix} \begin{pmatrix} \vec{\mathbf{u}}_\Re \\ \vec{\mathbf{u}}_\Im \\ \vec{\phi}_\Re \\ \vec{\phi}_\Im \end{pmatrix} = \begin{pmatrix} \vec{f}_\Re \\ \vec{f}_\Im \\ \vec{\rho}_\Re \\ \vec{\rho}_\Im \end{pmatrix} [=: \vec{\mathbf{y}}]. \tag{9.4}$$

Here, $\vec{\mathbf{u}}_\Re, \vec{\mathbf{u}}_\Im, \vec{\phi}_\Re, \vec{\phi}_\Im$ are the vectors of the real/imaginary components of degrees of freedom in $\boldsymbol{\mathcal{ND}}_1(\Omega_h)$ and $\mathcal{S}_1(\Gamma_h)$, respectively. The matrices $\mathsf{M}_\Re$, $\mathsf{M}_\Im$, B, and D arise from a discretization of $\widetilde{\mathbf{d}}$ in a straightforward manner. Thus, $\mathsf{D} = \mathsf{D}^T$ and $\mathsf{M}_* = \mathsf{M}_*^T$. The right-hand sides can be deduced from (8.5). Note that, compared to (8.5), signs in the second equation have been flipped to achieve a symmetric system.

If $L > 0$, we face the system

$$\begin{pmatrix} \mathsf{P} & \mathsf{F} \\ \mathsf{F}^T & \mathsf{H} \end{pmatrix} \begin{pmatrix} \vec{\mathbf{x}} \\ \vec{\alpha} \end{pmatrix} = \begin{pmatrix} \vec{\mathbf{y}} \\ \vec{\rho} \end{pmatrix} ,$$

where $\mathsf{H} \in \mathbb{R}^{2L,2L}$ is symmetric, positive definite. Switching to the Schur-complement system

$$\mathsf{S}\vec{\mathbf{x}} := (\mathsf{P} - \mathsf{F}\mathsf{H}^{-1}\mathsf{F}^T)\vec{\mathbf{x}} = \vec{\mathbf{y}} - \mathsf{F}\mathsf{H}^{-1}\vec{\rho},$$

we realize that it can be considered a rank-$2L$ perturbation of (9.4). The spectrum of $\widehat{\mathsf{P}}\mathsf{S}$ will still lie in $[-\bar{c}, -\frac{1}{2}\sqrt{2}] \cup \{0\} \cup [\frac{1}{2}\sqrt{2}, \bar{c}]$, except for $2L$ eigenvalues. However, as is typical of gradient-type schemes [7], the convergence of the conjugate residual method after at most $2L$ steps will no longer be affected by these eigenvalues. As L is moderate (typically 1 or 2), that many steps are not too expensive to conduct.

NATURAL BOUNDARY ELEMENT METHODS FOR THE ELECTRIC FIELD INTEGRAL EQUATION ON POLYHEDRA*

R. HIPTMAIR† AND C. SCHWAB‡

Abstract. We consider the electric field integral equation on the surface of polyhedral domains and its Galerkin discretization by means of divergence-conforming boundary elements. With respect to a Hodge decomposition, the continuous variational problem is shown to be coercive. However, this does not immediately carry over to the discrete setting, as discrete Hodge decompositions fail to possess essential regularity properties. Introducing an intermediate semidiscrete Hodge decomposition, we can bridge the gap and come up with asymptotically optimal a priori error estimates. Until now, those had been elusive, in particular for nonsmooth boundaries.

Key words. electric field integral equation, Rumsey's principle, Raviart–Thomas elements, Hodge decomposition, discrete coercivity

1. Introduction.

One of the main tasks in computational electromagnetism is the computation of the scattering of electromagnetic waves at a perfectly conducting body $\Omega \subset \mathbb{R}^3$. It boils down to solving the time-harmonic Maxwell's equations in the exterior $\Omega' = \mathbb{R}^3 \backslash \overline{\Omega}$ of Ω for a fixed frequency, subject to a vanishing tangential trace of the total electric field on the surface of the scatterer and the Silver–Müller radiation conditions at ∞. It is known that the exterior scattering problem for Maxwell's equations has a unique solution (see, e.g., [26, Chap. 6] and [23]). In most technical applications, the boundary Γ of Ω will be only piecewise smooth.

Starting from the Stratton–Chu representation formulas in Ω' (see, e.g., [19, sect. 3]), an indirect method yields the well-known electrical field boundary integral equation (EFIE) for the unknown jump $\mathbf{j}$ of the magnetic field [19, sect. 4]. Cast in variational form, this integral equation is sometimes referred to as Rumsey's principle [9] and reads as follows: Find a complex amplitude $\mathbf{j} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ such that

$$\langle V_\varsigma \mathrm{div}_\Gamma \mathbf{j}, \mathrm{div}_\Gamma \mathbf{v} \rangle_{\frac{1}{2},\Gamma} - \varsigma^2 \langle \mathbf{A}_\varsigma \mathbf{j}, \mathbf{v} \rangle_{||,\Gamma} = f(\mathbf{v}) \quad \forall \mathbf{v} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma). \tag{1.1}$$

Here, $\varsigma \in \mathbb{R}_+$ is the nondimensional wavenumber, the continuous linear functional $f : \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{curl}_\Gamma, \Gamma) \mapsto \mathbb{C}$ represents the excitation due to an incident wave, and $V_\varsigma, \mathbf{A}_\varsigma$ stand for scalar and vectorial single layer potential integral operators, respectively. In (1.1), the (sesquilinear) duality pairings $\langle \cdot, \cdot \rangle_{\frac{1}{2},\Gamma}$ and $\langle \cdot, \cdot \rangle_{||,\Gamma}$ coincide with the usual $H^{1/2}(\Gamma) \times H^{-1/2}(\Gamma)$ duality when Γ is smooth. On polyhedra, however, there are several nonequivalent definitions of these dualities. Details will be explained below. For the well-posedness of the integral equation formulation (1.1), we adopt the following assumption throughout this paper.

ASSUMPTION 1.1. *The wavenumber ς is bounded away from the spectrum of the interior Maxwell's problem.*

*Received by the editors April 9, 2001; accepted for publication (in revised form) November 19, 2001; published electronically April 12, 2002.

This implies the injectivity of the boundary integral operator in (1.1).

Recalling the derivation of (1.1), the unknown $\mathbf{j}$ emerges as the jump of tangential traces $\mathbf{H}\times\mathbf{n}$ of magnetic field solutions for the full Maxwell's equations in the interior and exterior of Ω. When Maxwell's equations are concisely stated in the language of differential forms [6, 13], the magnetic field is modeled by a twisted 1-form. The same will hold for its trace on Γ. This suggests that two-dimensional discrete twisted 1-forms built upon a triangulation of Γ should be used to approximate $\mathbf{j}$. Those are provided by the boundary element counterparts of the two-dimensional Raviart–Thomas $\boldsymbol{H}(\mathrm{div};\Omega)$-conforming finite elements. We could also reason in an entirely discrete setting: it is no longer a moot point that a suitable discretization of magnetic fields is provided by $\boldsymbol{H}(\mathbf{curl};\Omega)$-conforming edge elements [44], which are discrete 1-forms in three dimensions. Taking a look at their tangential traces, again, we discover Raviart–Thomas elements mapped onto the surface [35]. Thus, we argue that the latter offer a "natural" boundary element discretization of (1.1) as follows: Find $\mathbf{j}_h \in \boldsymbol{\mathcal{RT}}_0(\Gamma_h)$ such that

$$\langle V_\varsigma \mathrm{div}_\Gamma \mathbf{j}_h, \mathrm{div}_\Gamma \mathbf{v}_h\rangle_{\frac{1}{2},\Gamma} - \varsigma^2 \langle \mathbf{A}_\varsigma \mathbf{j}_h, \mathbf{v}_h\rangle_{||,\Gamma} = f(\mathbf{v}_h) \quad \forall \mathbf{v}_h \in \boldsymbol{\mathcal{RT}}_0(\Gamma_h), \tag{1.2}$$

where $\boldsymbol{\mathcal{RT}}_0(\Gamma_h)$ denotes the lowest order Raviart–Thomas boundary element space on a triangulation Γ_h on Γ.

The Galerkin discretization (1.2) is commonplace in engineering codes. The first convergence analysis of this scheme was given by Bendali in [7, 8] and was based on a saddle point formulation and elliptic regularization, which is inherently confined to smooth surfaces. Using parametric variants of the Raviart–Thomas boundary elements, he established asymptotic a priori convergence estimates. Attempts to adapt his approach to nonsmooth surfaces have not been successful. Recently, Buffa, Costabel, and Schwab [19] succeeded in showing convergence of a mixed discretization of (1.1) which, however, is different from the "natural" scheme (1.2) used in engineering.

Obstructions of convergence analysis on nonsmooth surfaces are threefold. First, the correct function spaces and relevant surface differential operators have to be properly characterized. For smooth domains, using smooth charts and trace theorems for the entire scale of Sobolev spaces, this is not hard to do [2, 23]. It becomes a challenge in a nonsmooth setting, as is vividly conveyed in the introduction of [20]. The situation on polyhedral boundaries Γ was clarified only recently by Buffa and Ciarlet [17, 18, 15], and general Lipschitz boundaries were presented in [20]. We emphasize that it is these results only that made possible the progress reported in the current paper.

Second, with (1.1) we recognize the typical difficulty faced when dealing with variational problems arising from Maxwell's equations: owing to the large kernel of the surface divergence operator div_Γ, it becomes impossible to assign one term the role of a principal part and, thus, the sesquilinear form of (1.1) fails to be coercive. A remedy was first found in the case of Maxwell's differential equations [42, 39] and it is marked by the use of *Hodge decompositions*. Also, for boundary integral equations this idea is fruitful and in fact was exploited many times to recover coercive problems [31, 19, 3].

Unfortunately, Hodge decompositions and the divergence-conforming boundary elements do not match easily. This is the third obstacle and it is also faced in the analysis of $\boldsymbol{H}(\mathbf{curl};\Omega)$-conforming finite element schemes. In that context, a solution has been devised relying on judiciously combining discrete and continuous Hodge decompositions. This idea was successful in the analysis of multigrid methods for

edge elements [36, 4, 38] and in the numerical analysis of schemes for Maxwell's eigenproblems that are free of spurious modes [10, 12, 11, 43, 22].

It is this idea that permits us to launch a successful attack on Galerkin discretizations of the EFIE (1.1) on polyhedral domains. Yet, numerous adjustments of this technique are necessary to cope with the low regularity of the function spaces of interest on Γ. Whereas for problems on domains $\subset \mathbb{R}^3$ all fields are at least square integrable, here we find that surface vectorfields in $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ do not necessarily have this property. In this paper we aim to elucidate how to handle this difficulty. Christiansen [24] pursues a policy partly similar to ours, but with a different objective, suboptimal results, and confinement to smooth domains. Other related publications are [21] and [16].

The paper is organized as follows. In the next section we summarize important results about spaces of tangential vectorfields on polyhedra. The third and fourth sections establish the coercivity of the continuous variational problem with respect to a Hodge decomposition of $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$. In the fifth section we introduce divergence-conforming boundary elements and review their main properties. In the sixth section we define and scrutinize mappings that create a link between discrete and continuous Hodge decompositions. The seventh section is dedicated to proving a discrete inf-sup condition. The final section covers asymptotic a priori estimates of the discretization error.

It was our objective to keep the treatment as focused and self-contained as possible. To that end we forgo any generalizations and investigate only the lowest order Raviart–Thomas boundary elements and Lipschitz polyhedra with plane faces. By and large, generalizations are straightforward. Numerical experiments are skipped, since the Galerkin discretization of the EFIE by Raviart–Thomas boundary elements is widely and successfully used in electrical engineering.

2. Spaces. The domain $\Omega \subset \mathbb{R}^3$ is assumed to be a Lipschitz polyhedron (cf. the introduction of [29]). In particular, we assume that the Lipschitz boundary Γ can be written as a union of a finite number of plane faces Γ_j, $j = 1, \ldots, N_\Gamma$, i.e., $\bar{\Gamma} = \bigcup_i \bar{\Gamma}_j$. For each face Γ_j we find a constant unit normal vector $\mathbf{n}_i$ pointing into the exterior of Ω. These vectors can be blended into an exterior unit normal vectorfield $\mathbf{n} \in L^\infty(\Gamma)$, defined almost everywhere on Γ. In addition, we can fix two orthogonal unit vectors $\mathbf{e}_j^1, \mathbf{e}_j^2$ that span the tangential plane for Γ_i. It goes without saying that each Γ_j can be identified with a bounded subset of $\mathbb{R}^2$.

Next, we introduce two different tangential surface trace operators [20, sect. 2]. The tangential components trace $\pi_{\mathbf{t}}$ is defined for $\mathbf{u} \in \boldsymbol{C}^\infty(\bar{\Omega})$ by $\pi_{\mathbf{t}}\mathbf{u}(\mathbf{x}) := \mathbf{n}(\mathbf{x}) \times (\mathbf{u}(\mathbf{x}) \times \mathbf{n}(\mathbf{x}))$ for almost all $\mathbf{x} \in \Gamma$. Accordingly, the tangential surface trace $\gamma_{\mathbf{t}}$ can be computed through $\gamma_{\mathbf{t}}\mathbf{u}(\mathbf{x}) := \mathbf{u}(\mathbf{x}) \times \mathbf{n}(\mathbf{x})$. The same traces from Ω' are ${\pi_{\mathbf{t}}}'$ and $\gamma_{\mathbf{t}}'$. To begin with, the trace operators supply functions in

$$\boldsymbol{L}_{\mathbf{t}}^2(\Gamma) := \{\mathbf{u} \in (L^2(\Gamma))^3, \mathbf{u} \cdot \mathbf{n} = 0\}.$$

The usual Sobolev spaces of scalar functions and related functionals, $H^s(\Gamma)$ and $H^{-s}(\Gamma)$, can be defined invariantly for $0 \le s \le 1$ [34, sect. 1.3.3]. For indices $s > 1$ we resort to the piecewise definition

$$H^s(\Gamma) := \{u \in H^1(\Gamma),\, u_{|\Gamma_j} \in H^s(\Gamma_j),\, j = 1, \ldots, N_\Gamma\}.$$

We equip this space with the graph norm

$$\|u\|^2_{H^s(\Gamma)} := \|u\|^2_{H^1(\Gamma)} + \sum_{j=1}^{N_\Gamma} \|u\|^2_{H^s(\Gamma_j)}\,.$$

Using the local coordinate systems introduced above, spaces of tangential vectorfields that feature certain Sobolev regularity in a piecewise sense are readily available:

$$\boldsymbol{H}^s_{\mathbf{t}}(\Gamma) := \{\mathbf{u} \in \boldsymbol{L}^2_{\mathbf{t}}(\Gamma),\, \mathbf{u}_{|\Gamma_j} \cdot \mathbf{e}^i_j \in H^s(\Gamma_j),\, j = 1,\ldots,N_\Gamma,\, i = 1,2\}.$$

By localization to Γ_j we can define the tangential surface gradient $\mathbf{grad}_\Gamma$ [20, Def. 3.1]. Its continuity as a mapping $H^{s+1}(\Gamma) \mapsto \boldsymbol{H}^s_{\mathbf{t}}(\Gamma)$, $s \geq 0$, is straightforward. The surface divergence is obtained as a formal $\boldsymbol{L}^2_{\mathbf{t}}(\Gamma)$-adjoint $\mathrm{div}_\Gamma : \boldsymbol{L}^2_{\mathbf{t}}(\Gamma) \mapsto H^{-1}_*(\Gamma)$. Its range space is

$$H^{-s}_*(\Gamma) := \{\phi \in H^{-s}(\Gamma),\, \langle \chi, \phi\rangle_{s,\Gamma} = 0\, \forall \chi \in Z\}, \tag{2.1}$$

where Z is the space of piecewise constants on connected components of Γ and $\langle\cdot,\cdot\rangle_{s,\Gamma}$ denotes the $H^s(\Gamma) \times H^{-s}(\Gamma)$ duality pairing.

The two operators can be used to define the surface Laplace–Beltrami operator $\Delta_\Gamma : H^1(\Gamma) \mapsto H^{-1}_*(\Gamma)$ by $\Delta_\Gamma := \mathrm{div}_\Gamma \mathbf{grad}_\Gamma$. This will be a key tool, because it possesses the following lifting property shown in Theorem 5.3 of [19].

THEOREM 2.1. *If $f \in H^s_*(\Gamma)$ for $s \geq -1$, then the (unique) solution $u \in H^1(\Gamma)/Z$ of $-\Delta_\Gamma u = f$ belongs to $H^{1+r}(\Gamma)$ for $0 \leq r \leq \min\{s+1, s^*\}$, where $s^* > 0$ depends on the geometry of Γ in neighborhoods of vertices only.*

In other words, with $\tilde{C} = \tilde{C}(t,\Gamma)$ and $0 \leq r \leq \min\{s+1, s^*\}$,

$$f \in H^s_*(\Gamma), \quad -\Delta_\Gamma u = f \quad \Rightarrow \quad \|u\|_{H^{r+1}(\Gamma)/Z} \leq \tilde{C}\, \|f\|_{H^s(\Gamma)}\,. \tag{2.2}$$

We adopt the convention that C and c stand for generic positive constants, whose values might be different between different occurrences, but must not depend on any concrete function. When tagged with a tilde on top, they may depend only on ς, continuous function spaces, and the geometry of Γ.

Note that there exist polyhedral vertices for which $s^* > 0$ is arbitrarily small (see [19]). Nevertheless, reasonable geometries will allow for s^* to be well bounded above zero. For instance, if only three edges meet at a vertex O, we find $s^* = 2\pi/(\varphi_1+\varphi_2+\varphi_3) - \varepsilon$ for any $\varepsilon > 0$, where $\varphi_1, \varphi_2, \varphi_3$ are the opening angles at vertex O of the three plane faces Γ_j meeting at O.

Owing to Theorem 2.1, the space

$$H^{-\frac{1}{2}}(\Delta_\Gamma, \Gamma) := \{u \in H^1(\Gamma),\, \Delta_\Gamma u \in H^{-\frac{1}{2}}(\Gamma)\}$$

will actually be embedded in $H^{1+r}(\Gamma)$ for all $0 \leq r \leq \min\{\frac{3}{2}, s^*\}$. Based on div_Γ, we get the Hilbert spaces ($s \geq 0$)

$$\boldsymbol{H}^s(\mathrm{div}_\Gamma; \Gamma) := \{\mathbf{u} \in \boldsymbol{H}^s_{\mathbf{t}}(\Gamma),\, \mathrm{div}_\Gamma \mathbf{u} \in H^s(\Gamma)\}.$$

Tangential traces of vectorfields in $\boldsymbol{H}^1_{\mathrm{loc}}(\Omega)$ form the spaces $\boldsymbol{H}^{\frac{1}{2}}_{||}(\Gamma)$ and $\boldsymbol{H}^{\frac{1}{2}}_{\perp}(\Gamma)$ which were characterized in [17, Prop. 1.6]. Loosely speaking, $\boldsymbol{H}^{\frac{1}{2}}_{||}(\Gamma)$ contains the tangential surface vectorfields that are in $\boldsymbol{H}^{\frac{1}{2}}(\Gamma_i)$ for each smooth component Γ_i of Γ and feature

a suitable "weak tangential continuity" across the edges of the Γ_i. A corresponding "weak normal continuity" is satisfied by surface vectorfields in $\boldsymbol{H}_{\perp}^{\frac{1}{2}}(\Gamma)$. For smooth Γ these spaces coincide with the spaces of tangential surface vectorfields in $\boldsymbol{H}_{\mathbf{t}}^{\frac{1}{2}}(\Gamma)$. The associated dual spaces will be denoted by $\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)$ and $\boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\Gamma)$, respectively, where the duality pairings are taken with $\boldsymbol{L}_{\mathbf{t}}^2(\Gamma)$ as pivot space. Further, we denote by $\langle\cdot,\cdot\rangle_{||,\Gamma}$ and $\langle\cdot,\cdot\rangle_{\perp,\Gamma}$ the respective duality pairings. A fundamental result of [17] asserts that the tangential trace mapping $\pi_{\mathbf{t}} : \boldsymbol{H}_{\mathrm{loc}}^1(\Omega) \mapsto \boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma)$ is continuous, surjective, and possesses a continuous right inverse (see Proposition 1.7 in [17]).

One of the crucial insights gained in [17] and [20] was that the tangential surface gradient $\mathbf{grad}_\Gamma : H^1(\Gamma) \mapsto \boldsymbol{L}_{\mathbf{t}}^2(\Gamma)$ can be both extended and restricted to continuous, *closed*, and *injective* linear operators

$$\mathbf{grad}_\Gamma : \tilde{H}^{\frac{3}{2}}(\Gamma)/Z \mapsto \boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma), \quad \mathbf{grad}_\Gamma : H^{\frac{1}{2}}(\Gamma)/Z \mapsto \boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\Gamma)$$

(cf. Propositions 3.4 and 3.6 in [20]), where $\tilde{H}^{\frac{3}{2}}(\Gamma)$ is the space of traces of functions in $H^2(\Omega)$. Consequently, div_Γ also can be read as a continuous and *surjective* operator

$$\mathrm{div}_\Gamma : \boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma) \mapsto \tilde{H}_*^{-\frac{3}{2}}(\Gamma), \quad \mathrm{div}_\Gamma : \boldsymbol{H}_{\perp}^{\frac{1}{2}}(\Gamma) \mapsto H_*^{-\frac{1}{2}}(\Gamma).$$

This is important for the definition of the space $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$, introduced in [17], as

$$\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) = \{\mathbf{v} \in \boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma),\, \mathrm{div}_\Gamma \mathbf{v} \in H^{-\frac{1}{2}}(\Gamma)\}.$$

It is endowed with the natural graph norm $\|\cdot\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)}$.

The key role of *Hodge decompositions* was emphasized in the introduction. The following theorem reveals the nature of the Hodge decomposition that we will need. More details are given in [20, sect. 5], [18], and [15].

THEOREM 2.2. *The space* $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$ *has the direct and stable decomposition*

$$\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) := \mathbf{grad}_\Gamma\, H^{-\frac{1}{2}}(\Delta_\Gamma,\Gamma) \oplus (\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) \cap \mathrm{Ker}(\mathrm{div}_\Gamma)).$$

Moreover, when restricted to $\boldsymbol{L}_{\mathbf{t}}^2(\Gamma) \cap \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$ *the decomposition is* $\boldsymbol{L}_{\mathbf{t}}^2(\Gamma)$*-orthogonal.*

Proof. Any function in $\mathbf{grad}_\Gamma\, H^{-\frac{1}{2}}(\Delta_\Gamma,\Gamma) \cap \mathrm{Ker}(\mathrm{div}_\Gamma)$ must be the gradient of a function in the kernel of Δ_Γ on Γ. The latter contains only piecewise constants with respect to the connected components of Γ and, therefore, the decomposition is direct.

Next, pick some $\mathbf{v} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$. Since $\mathrm{div}_\Gamma : \boldsymbol{H}_{\perp}^{\frac{1}{2}}(\Gamma) \mapsto H_*^{-\frac{1}{2}}(\Gamma)$ is surjective, we can find $\boldsymbol{\psi} \in \boldsymbol{H}_{\perp}^{\frac{1}{2}}(\Gamma)$ such that $\mathrm{div}_\Gamma \boldsymbol{\psi} = \mathrm{div}_\Gamma \mathbf{v} \in H_*^{-\frac{1}{2}}(\Gamma)$. Define φ by

$$\varphi \in H^1(\Gamma)/Z: \quad (\mathbf{grad}_\Gamma \varphi, \mathbf{grad}_\Gamma \eta)_{0;\Gamma} = (\boldsymbol{\psi}, \mathbf{grad}_\Gamma \eta)_{0;\Gamma} \quad \forall \eta \in H^1(\Gamma)/Z,$$

that is, as the unique weak solution of $\Delta_\Gamma \varphi = \mathrm{div}_\Gamma \boldsymbol{\psi}$. This yields the decomposition

$$\mathbf{v} = \mathbf{grad}_\Gamma \varphi + (\boldsymbol{\psi} - \mathbf{grad}_\Gamma \varphi + \mathbf{v} - \boldsymbol{\psi}),$$

whose second part is readily seen to be divergence free. Since div_Γ is surjective, the open mapping theorem ensures that $\boldsymbol{\psi}$ can be chosen such that

$$\|\boldsymbol{\psi}\|_{\boldsymbol{H}_{\perp}^{\frac{1}{2}}(\Gamma)} \leq \tilde{C}\, \|\mathrm{div}_\Gamma \boldsymbol{\psi}\|_{H^{-\frac{1}{2}}(\Gamma)}\,.$$

This implies

$$\|\mathbf{grad}_\Gamma\,\varphi\|_{\boldsymbol{L}^2(\Gamma)} \le \|\boldsymbol{\psi}\|_{\boldsymbol{L}^2(\Gamma)} \le \|\boldsymbol{\psi}\|_{\boldsymbol{H}^{\frac12}_\perp(\Gamma)} \le \tilde{C}\,\|\mathrm{div}_\Gamma\boldsymbol{\psi}\|_{H^{-\frac12}(\Gamma)}\,,$$

which confirms the stability of the decomposition. For $\mathbf{v} \in \boldsymbol{L}^2_{\mathbf{t}}(\Gamma) \cap \boldsymbol{H}^{-\frac12}(\mathrm{div}_\Gamma,\Gamma)$, the $\boldsymbol{L}^2_{\mathbf{t}}(\Gamma)$-orthogonality is immediate from the definition of div_Γ. ∎

In what follows, we write

$$\mathbf{X} := \mathbf{grad}_\Gamma\, H^{-\frac12}(\Delta_\Gamma,\Gamma) \quad \text{and} \quad \mathbf{N} := \boldsymbol{H}^{-\frac12}(\mathrm{div}_\Gamma,\Gamma) \cap \mathrm{Ker}(\mathrm{div}_\Gamma).$$

From the stability of the Hodge decomposition, we conclude that both $\mathbf{X}$ and $\mathbf{N}$ are closed subspaces of $\boldsymbol{H}^{-\frac12}(\mathrm{div}_\Gamma,\Gamma)$.

LEMMA 2.3. *If* $\mathbf{v} \in \mathbf{X}$ *satisfies* $\mathrm{div}_\Gamma\mathbf{v} \in H^s(\Gamma)$ *for some* $s \ge -\frac12$*, then for all* $0 \le r \le \min\{s+1, s^*\}$*,*

$$\mathbf{v} \in \boldsymbol{H}^r_{\mathbf{t}}(\Gamma) \quad \textit{and} \quad \|\mathbf{v}\|_{\boldsymbol{H}^r(\Gamma)} \le \tilde{C}\,\|\mathrm{div}_\Gamma\mathbf{v}\|_{H^s(\Gamma)}\,,$$

with a constant $\tilde{C} = \tilde{C}(r,s)$ *and* $s^* > 0$ *as in Theorem* 2.1.

Proof. $\mathbf{v} \in \mathbf{X}$ means $\mathbf{v} = \mathbf{grad}_\Gamma\,\varphi$ for some $\varphi \in H^1(\Gamma)$. By definition of $\mathbf{X}$, we see $\Delta_\Gamma\varphi = \mathrm{div}_\Gamma\mathbf{v}$, and the assertion follows from Theorem 2.1. ∎

In particular, we conclude that

$$\|\mathbf{v}\|_{\boldsymbol{H}^{-\frac12}_{||}(\Gamma)} \le \|\mathbf{v}\|_{\boldsymbol{L}^2(\Gamma)} \le \tilde{C}\,\|\mathrm{div}_\Gamma\mathbf{v}\|_{H^{-\frac12}(\Gamma)} \quad \forall\mathbf{v} \in \mathbf{X}. \tag{2.3}$$

3. Continuous variational problem. We recall the scalar single layer potential $\Psi^V_\varsigma : H^{-\frac12}(\Gamma) \mapsto H^1_{\mathrm{loc}}(\mathbb{R}^3)$ for the Helmholtz operator $\Delta + \varsigma^2$. Its relative, the vectorial Helmholtz single layer potential $\boldsymbol{\Psi}^{\mathbf{A}}_\varsigma(\mathbf{v})$ for $\mathbf{v} \in \boldsymbol{H}^{-\frac12}_{||}(\Gamma)$, is given by

$$\boldsymbol{\Psi}^{\mathbf{A}}_\varsigma(\mathbf{v})(\mathbf{x}) := \int_\Gamma \Phi_\varsigma(\mathbf{x},\mathbf{y})\mathbf{v}(\mathbf{y}), \quad \Phi_\varsigma(\mathbf{x},\mathbf{y}) := \frac{\exp(i\varsigma|\mathbf{x}-\mathbf{y}|)}{4\pi|\mathbf{x}-\mathbf{y}|}\,.$$

For every $\mathbf{v} \in \boldsymbol{H}^{-\frac12}_{||}(\Gamma)$, it defines a function in $\mathbf{H}^1_{\mathrm{loc}}(\mathbb{R}^3)$ and, as a consequence of the trace theorem for $\pi_{\mathbf{t}}$, we can introduce the vectorial single layer boundary operator

$$\mathbf{A}_\varsigma : \boldsymbol{H}^{-\frac12}_{||}(\Gamma) \mapsto \boldsymbol{H}^{\frac12}_{||}(\Gamma), \quad \mathbf{A}_\varsigma := \pi_{\mathbf{t}} \circ \boldsymbol{\Psi}^{\mathbf{A}}_\varsigma\,,$$

in analogy to the scalar single layer integral operator

$$V_\varsigma : H^{-1/2}(\Gamma) \mapsto H^{\frac12}(\Gamma), \quad V_\varsigma := \gamma \circ \Psi^V_\varsigma,$$

where $\gamma : H^1_{\mathrm{loc}}(\mathbb{R}^3) \mapsto H^{\frac12}(\Gamma)$ is the standard trace operator. In the static case, i.e., at wavenumber $\varsigma = 0$, these operators are coercive.

LEMMA 3.1. *The operators* V_0 *and* $\mathbf{A}_0$ *are continuous, self-adjoint, and elliptic; i.e., there are constants* $\tilde{c}_1, \tilde{c}_2 > 0$ *depending only on* Γ *such that for all* $\mu \in H^{-\frac12}(\Gamma)$ *and all* $\boldsymbol{\mu} \in \boldsymbol{H}^{-\frac12}_{||}(\Gamma)$*,* $\mathrm{div}_\Gamma\boldsymbol{\mu} = 0$*,*

$$\langle V_0\mu,\mu\rangle_{\frac12,\Gamma} \ge \tilde{c}_1\,\|\mu\|^2_{H^{-\frac12}(\Gamma)}\,, \quad \langle \mathbf{A}_0\boldsymbol{\mu},\boldsymbol{\mu}\rangle_{||,\Gamma} \ge \tilde{c}_2\,\|\boldsymbol{\mu}\|^2_{\boldsymbol{H}^{-\frac12}_{||}(\Gamma)}\,.$$

Proof. See Corollary 8.13 in [41], or Theorem 3 in [30, Vol. IV, Chap. XI, sect. 2], and Theorem 6.2 in [37] or Proposition 4.1 in [19]. ∎

Along with the following result, this lemma yields the coercivity of V_ς and $\mathbf{A}_\varsigma$ (cf. the proof of Theorem 4.4 in [19]).

LEMMA 3.2. *The following operators are compact:*

$$\delta V_\varsigma := V_\varsigma - V_0 : H^{-\frac{1}{2}}(\Gamma) \mapsto H^{\frac{1}{2}}(\Gamma), \qquad \delta \mathbf{A}_\varsigma := \mathbf{A}_\varsigma - \mathbf{A}_0 : \boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma) \mapsto \boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma).$$

Proof. We write G_ς for the Green's operator in $\mathbb{R}^3$ for the Helmholtz equation defined by $(G_\varsigma\varphi)(\mathbf{x}) = \int_{\mathbf{y}\in\mathbb{R}^3} \Phi_\varsigma(\mathbf{x},\mathbf{y})\varphi(\mathbf{y})d\mathbf{y}$ for $\varphi \in C_0^\infty(\mathbb{R}^3)$. With γ^* denoting a right inverse of the trace operator and appealing to the continuity of the trace map $\gamma : H^s_{loc}(\mathbb{R}^3) \to H^{s-1/2}(\Gamma)$, $s \in (1/2, 3/2)$ (see Lemma 3.6 in [27]), we find $\delta V_\varsigma = \gamma\circ(G_\varsigma - G_0)\circ\gamma^* : H^{-1/2}(\Gamma) \to H^{1/2}(\Gamma)$ compactly, since the kernel $\Phi_\varsigma(\mathbf{x},\mathbf{y}) - \Phi_0(\mathbf{x},\mathbf{y})$ of the operator $G_\varsigma - G_0$ has essentially bounded derivatives in $\mathbf{x}$ and $\mathbf{y}$. The vectorial case follows in the same way. ∎

The main tool in the analysis of variational problem (1.1) is Hodge decompositions according to Theorem 2.2 (cf. [19, sect. 4.3]). Based on Theorem 2.2, we Hodge decompose $\mathbf{j} := \mathbf{j}^\perp + \mathbf{j}^0$, $\mathbf{j}^\perp \in \mathbf{X}$, $\mathbf{j}^0 \in \mathbf{N}$, and $\mathbf{v} := \mathbf{u}^\perp + \mathbf{v}^0$, $\mathbf{v}^\perp \in \mathbf{X}$, $\mathbf{v}^0 \in \mathbf{N}$, in (1.1). In this way, we end up with the following equivalent variational problem: Find $\mathbf{j}^\perp \in \mathbf{X}$, $\mathbf{j}^0 \in \mathbf{N}$ such that for all $\mathbf{v}^\perp \in \mathbf{X}$, $\mathbf{v}^0 \in \mathbf{N}$,

$$\begin{aligned} \left\langle V_\varsigma \mathrm{div}_\Gamma \mathbf{j}^\perp, \mathrm{div}_\Gamma \mathbf{v}^\perp \right\rangle_{\frac{1}{2},\Gamma} - \varsigma^2 \left\langle \mathbf{A}_\varsigma \mathbf{j}^\perp, \mathbf{v}^\perp \right\rangle_{||,\Gamma} - \quad & \varsigma^2 \left\langle \mathbf{A}_\varsigma \mathbf{j}^0, \mathbf{v}^\perp \right\rangle_{||,\Gamma} \;=\; f(\mathbf{v}^\perp), \\ \varsigma^2 \left\langle \mathbf{A}_\varsigma \mathbf{j}^\perp, \mathbf{v}^0 \right\rangle_{||,\Gamma} \qquad\qquad + \quad & \varsigma^2 \left\langle \mathbf{A}_\varsigma \mathbf{j}^0, \mathbf{v}^0 \right\rangle_{||,\Gamma} \;=\; -f(\mathbf{v}^0). \end{aligned} \tag{3.1}$$

Remember that $\langle .,. \rangle_{||,\Gamma}$ stands for the $\boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma) \times \boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)$ duality pairing.

The natural setting for formulation (3.1) is the Hilbert space $\boldsymbol{\mathcal{G}} := \mathbf{X} \oplus \mathbf{N}$ endowed with the graph norm

$$\left\| (\mathbf{v}^\perp, \mathbf{v}^0) \right\|_{\boldsymbol{\mathcal{G}}}^2 := \left\| \mathbf{v}^\perp \right\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)}^2 + \left\| \mathbf{v}^0 \right\|_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)}^2, \quad (\mathbf{v}^\perp, \mathbf{v}^0) \in \boldsymbol{\mathcal{G}}.$$

Thanks to Theorem 2.2, the space $\boldsymbol{\mathcal{G}}$ is isomorphic to $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ algebraically and topologically. The sesquilinear form $a : \boldsymbol{\mathcal{G}} \times \boldsymbol{\mathcal{G}} \mapsto \mathbb{C}$ that belongs to (3.1) reads

$$\begin{aligned} a((\mathbf{j}^\perp, \mathbf{j}^0), (\mathbf{v}^\perp, \mathbf{v}^0)) := & \left\langle V_\varsigma \mathrm{div}_\Gamma \mathbf{j}^\perp, \mathrm{div}_\Gamma \mathbf{v}^\perp \right\rangle_{\frac{1}{2},\Gamma} \\ & - \varsigma^2 \left\langle \mathbf{A}_\varsigma \mathbf{j}^\perp, \mathbf{v}^\perp \right\rangle_{||,\Gamma} - \varsigma^2 \left\langle \mathbf{A}_\varsigma \mathbf{j}^0, \mathbf{v}^\perp \right\rangle_{||,\Gamma} \\ & + \varsigma^2 \left\langle \mathbf{A}_\varsigma \mathbf{j}^\perp, \mathbf{v}^0 \right\rangle_{||,\Gamma} + \varsigma^2 \left\langle \mathbf{A}_\varsigma \mathbf{j}^0, \mathbf{v}^0 \right\rangle_{||,\Gamma} \end{aligned} \tag{3.2}$$

and is continuous, i.e.,

$$|a(\boldsymbol{\varphi}, \boldsymbol{\eta})| \le \tilde{C}_a \, \|\boldsymbol{\varphi}\|_{\boldsymbol{\mathcal{G}}} \, \|\boldsymbol{\eta}\|_{\boldsymbol{\mathcal{G}}} \quad \forall \boldsymbol{\varphi}, \boldsymbol{\eta} \in \boldsymbol{\mathcal{G}}. \tag{3.3}$$

Using the form $a(\cdot,\cdot)$, we can express variational problem (3.1) succinctly as follows: Find $\boldsymbol{\iota} \in \boldsymbol{\mathcal{G}}$ such that

$$a(\boldsymbol{\iota}, \boldsymbol{\eta}) = f(\boldsymbol{\eta}) \quad \forall \boldsymbol{\eta} \in \boldsymbol{\mathcal{G}}, \tag{3.4}$$

where $f(\boldsymbol{\eta}) := f(\mathbf{v}^\perp) - f(\mathbf{v}^0)$, $\boldsymbol{\eta} := (\mathbf{v}^\perp, \mathbf{v}^0)$. We point out that (3.4) is entirely equivalent to (1.1) in the sense that, if $\mathbf{j} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ is a solution of (1.1), then $\boldsymbol{\iota} := (\mathbf{j}^\perp, \mathbf{j}^0) \in \boldsymbol{\mathcal{G}}$ will solve (3.4). In particular, assertions on existence and uniqueness of solutions of (1.1) instantly carry over to (3.4) and vice versa.

4. Strong ellipticity. To establish strong ellipticity of the form $a(\cdot,\cdot)$ in (3.4), we proceed as in [19] and write $a = a_0 - k_0$, where $k_0 : \boldsymbol{\mathcal{G}} \times \boldsymbol{\mathcal{G}} \mapsto \mathbb{C}$ reads

$$k_0((\mathbf{j}^\perp,\mathbf{j}^0),(\mathbf{v}^\perp,\mathbf{v}^0)) := -\left\langle \delta V_\varsigma \mathrm{div}_\Gamma \mathbf{j}^\perp, \mathrm{div}_\Gamma \mathbf{v}^\perp \right\rangle_{\frac{1}{2},\Gamma} + \varsigma^2 \left\langle \delta \mathbf{A}_\varsigma \mathbf{j}^\perp, \mathbf{v}^\perp \right\rangle_{||,\Gamma} + \varsigma^2 \left\langle \delta \mathbf{A}_\varsigma \mathbf{j}^0, \mathbf{v}^\perp \right\rangle_{||,\Gamma} - \varsigma^2 \left\langle \delta \mathbf{A}_\varsigma \mathbf{j}^\perp, \mathbf{v}^0 \right\rangle_{||,\Gamma} - \varsigma^2 \left\langle \delta \mathbf{A}_\varsigma \mathbf{j}^0, \mathbf{v}^0 \right\rangle_{||,\Gamma},$$

and where $a_0 : \boldsymbol{\mathcal{G}} \times \boldsymbol{\mathcal{G}} \mapsto \mathbb{C}$ emerges from a by replacing V_ς with V_0 and A_ς with A_0. The next lemma is crucial for establishing the strong ellipticity of variational problem (3.4).

LEMMA 4.1. *The operator* $L : \mathbf{X} \mapsto \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)'$, *defined by* $L\mathbf{u}^\perp(\mathbf{z}) := \left\langle \mathbf{A}_0 \mathbf{u}^\perp, \mathbf{z} \right\rangle_{||,\Gamma}$ *for all* $\mathbf{u}^\perp \in \mathbf{X}$, $\mathbf{z} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$, *is compact.*

Proof. Consider a bounded sequence $(\mathbf{u}_n^\perp)_{n\in\mathbb{N}}$ in $\mathbf{X}$. By Lemma 2.3 it is also bounded in $\boldsymbol{H}_{\mathbf{t}}^{\frac{1}{2}}(\Gamma)$. By Rellich's theorem we can find a subsequence, also designated by $(\mathbf{u}_n^\perp)_n$, that converges in $\boldsymbol{L}_{\mathbf{t}}^2(\Gamma)$. Observe that, due to the continuity of the vectorial single layer boundary integral operator,

$$\left\| L\mathbf{z}^\perp \right\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)'} = \sup_{\mathbf{v}\in\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} \frac{|(L\mathbf{z}^\perp)(\mathbf{v})|}{\|\mathbf{v}\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)}} \leq \sup_{\mathbf{v}\in\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} \frac{|\left\langle \mathbf{A}_0 \mathbf{z}^\perp, \mathbf{v} \right\rangle_{||,\Gamma}|}{\|\mathbf{v}\|_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)}} \leq \left\| \mathbf{A}_0 \mathbf{z}^\perp \right\|_{\boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma)} \leq \tilde{C} \left\| \mathbf{z}^\perp \right\|_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)} \leq \tilde{C} \left\| \mathbf{z}^\perp \right\|_{\boldsymbol{L}^2(\Gamma)}.$$

Thus $(L\mathbf{u}_n^\perp)_n$ will converge in $\mathbf{X}'$. ∎

At once, from $\mathbf{X} \subset \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$ and $\mathbf{N} \subset \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$, we deduce that $L : \mathbf{X} \mapsto \mathbf{X}'$ and $L : \mathbf{X} \mapsto \mathbf{N}'$ are compact as well.

To establish the strong ellipticity of the form $a(\cdot,\cdot)$, we accordingly split $a_0(\cdot,\cdot)$ as $a_0 = d - k_1$, where the sesquilinear form $k_1 : \boldsymbol{\mathcal{G}} \times \boldsymbol{\mathcal{G}} \mapsto \mathbb{C}$ is defined by

$$k_1((\mathbf{j}^\perp,\mathbf{j}^0),(\mathbf{v}^\perp,\mathbf{v}^0)) := \varsigma^2 \left\langle \mathbf{A}_0 \mathbf{j}^\perp, \mathbf{v}^\perp \right\rangle_{||,\Gamma} + \varsigma^2 \left\langle \mathbf{A}_0 \mathbf{j}^0, \mathbf{v}^\perp \right\rangle_{||,\Gamma} - \varsigma^2 \left\langle \mathbf{A}_0 \mathbf{j}^\perp, \mathbf{v}^0 \right\rangle_{||,\Gamma},$$

and the definite part $d : \boldsymbol{\mathcal{G}} \times \boldsymbol{\mathcal{G}} \mapsto \mathbb{C}$ reads

$$d((\mathbf{j}^\perp,\mathbf{j}^0),(\mathbf{v}^\perp,\mathbf{v}^0)) := \left\langle V_0 \mathrm{div}_\Gamma \mathbf{j}^\perp, \mathrm{div}_\Gamma \mathbf{v}^\perp \right\rangle_{\frac{1}{2},\Gamma} + \varsigma^2 \left\langle \mathbf{A}_0 \mathbf{j}^0, \mathbf{v}^0 \right\rangle_{||,\Gamma}.$$

THEOREM 4.2. *The sesquilinear form* $a : \boldsymbol{\mathcal{G}} \times \boldsymbol{\mathcal{G}} \mapsto \mathbb{C}$ *is coercive; that is, it can be written as the difference of a* $\boldsymbol{\mathcal{G}}$*-elliptic sesquilinear form* d *and a compact sesquilinear form* $k : \boldsymbol{\mathcal{G}} \times \boldsymbol{\mathcal{G}} \mapsto \mathbb{C}$.

Proof. Recall $a = a_0 - k_0$. Lemma 3.2 reveals that k_0 is a compact perturbation of a_0. Further, $a_0 = d - k_1$, and Lemma 4.1 implies that k_1 is a compact perturbation of d. From the ellipticity of the single layer boundary integral operators in Lemma 3.1, we immediately get

$$|d((\mathbf{v}^\perp,\mathbf{v}^0),(\mathbf{v}^\perp,\mathbf{v}^0))| = |\left\langle V_0 \mathrm{div}_\Gamma \mathbf{v}^\perp, \mathrm{div}_\Gamma \mathbf{v}^\perp \right\rangle_{\frac{1}{2},\Gamma} + \varsigma^2 \left\langle \mathbf{A}_0 \mathbf{v}^0, \mathbf{v}^0 \right\rangle_{||,\Gamma}| \geq \tilde{c}_1 \left\| \mathrm{div}_\Gamma \mathbf{v}^\perp \right\|^2_{H^{-\frac{1}{2}}(\Gamma)} + \tilde{c}_2 \varsigma^2 \left\| \mathbf{v}^0 \right\|^2_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)}$$

for all $(\mathbf{v}^\perp,\mathbf{v}^0) \in \boldsymbol{\mathcal{G}}$. Now, we can appeal to (2.3) and obtain

$$|d(\boldsymbol{\varphi},\boldsymbol{\varphi})| \geq \tilde{c}_d \|\boldsymbol{\varphi}\|^2_{\boldsymbol{\mathcal{G}}} \quad \forall \boldsymbol{\varphi} \in \boldsymbol{\mathcal{G}}.$$

Setting $k = k_0 + k_1$ yields $a = d - k$ with a principal part d, which is positive on $\boldsymbol{\mathcal{G}}$, and a compact perturbation k, as claimed. ∎

The strong ellipticity of the form $a(\cdot,\cdot)$ together with its injectivity ensured by Assumption 1.1 implies, as usual, the unique solvability of the EFIE (3.4) (and hence of (1.1)) for any admissible right-hand side. Moreover, there holds the continuous inf-sup condition for $a(\cdot,\cdot)$,

$$\sup_{\boldsymbol{\nu}\in\boldsymbol{\mathcal{G}}} \frac{|a(\boldsymbol{\varphi},\boldsymbol{\nu})|}{\|\boldsymbol{\nu}\|_{\boldsymbol{\mathcal{G}}}} \geq \tilde{c}_a \|\boldsymbol{\varphi}\|_{\boldsymbol{\mathcal{G}}} \quad \forall \boldsymbol{\varphi} \in \boldsymbol{\mathcal{G}}. \tag{4.1}$$

5. Boundary element spaces. We equip Γ with a family of shape-regular, quasi-uniform triangulations $(\Gamma_h)_{h>0}$ [25] comprising only flat triangles. The parameter h designates the meshwidth, that is, the length of the longest edge. Let $\mathbb{H}$ stand for the collection of meshwidths occurring in $(\Gamma_h)_{h\in\mathbb{H}}$ and assume that $\mathbb{H} \subset \mathbb{R}^+$ forms a decreasing sequence converging to zero. The set $\mathcal{T}_h$ will include all triangles of Γ_h, and $\mathcal{E}_h$ stands for the set of edges of Γ_h.

Using the local coordinate systems on the faces Γ_j, $j = 1,\ldots,N_\Gamma$, each $T \in \mathcal{T}_h$ can be embedded in $\mathbb{R}^2$. Then we can define the local spaces (cf. [45])

$$\boldsymbol{\mathcal{RT}}_0(T) := \{\mathbf{x} \mapsto \mathbf{a} + \beta\mathbf{x},\, \mathbf{a} \in \mathbb{C}^2,\, \beta \in \mathbb{C}\}, \quad T \in \mathcal{T}_h.$$

They give rise to the global boundary element space

$$\boldsymbol{\mathcal{RT}}_0(\Gamma_h) := \{\mathbf{v} \in \boldsymbol{H}(\mathrm{div}_\Gamma;\Gamma),\, \mathbf{v}_{|T} \in \boldsymbol{\mathcal{RT}}_0(T)\, \forall T \in \mathcal{T}_h\}.$$

Keep in mind that this definition is based on a weak notion of div_Γ. So Green's formula applied to the surface triangles can be used to confirm that the "edge-normal" components of the tangential vectorfields in $\boldsymbol{\mathcal{RT}}_0(\Gamma_h)$ must be continuous across interelement edges. This renders the following degrees of freedom well-defined:

$$\phi_e : \boldsymbol{\mathcal{RT}}_0(\Gamma_h) \mapsto \mathbb{C}, \qquad \phi_e(\mathbf{v}_h) := \int_e (\mathbf{v}_h \times \mathbf{n}_j) \cdot d\vec{s}, \quad e \in \mathcal{E}_h\ ,$$

where $\mathbf{n}_j$ is the normal of a face Γ_j in whose closure e is contained. Given the degrees of freedom, we have nodal interpolation operators Π_h onto $\boldsymbol{\mathcal{RT}}_0(\Gamma_h)$ at our disposal. To begin with, those can be declared for $\{\Gamma_j\}$-piecewise continuous tangential surface vectorfields whose edge-normal components are continuous, too. It turns out that this is not enough, and we badly need to apply Π_h to less regular surface vectorfields. A first step towards this goal is the following lemma (cf. formula (3.40) in [14]).

LEMMA 5.1. *For any $s > 0$ the local interpolation operator $\Pi_T : \boldsymbol{H}^s(T) \cap \boldsymbol{H}(\mathrm{div};T) \mapsto \boldsymbol{\mathcal{RT}}_0(T)$, $T \in \mathcal{T}_h$, is continuous.*

Proof. Only the case $s \leq \frac{1}{2}$ is of interest. We consider a single degree of freedom on T as follows: Pick an edge $e \subset \partial T$ and regard its characteristic function χ_e as an element in $W_q^{1-\frac{1}{q}}(e)$ for $q := 1+s$. As $1 < q < 2$, Theorem 1.4.5.2 of [34] reveals that extension by zero of χ_e onto all of ∂T will provide a function $\tilde{\psi}$ in $W_q^{1-\frac{1}{q}}(\partial T)$. Then we can use the trace theorem [34, Thm. 1.5.1.3] to extend $\tilde{\psi}$ to a function $\psi \in W_q^1(T)$ in a continuous fashion. Using Green's formula, extended by continuity, we estimate for any smooth vectorfield $\mathbf{v}$ that

$$\begin{aligned}\int_e \mathbf{v}\cdot\mathbf{n}_e\, ds &= \int_{\partial T} \tilde{\psi}\mathbf{v}\cdot\mathbf{n}\, ds = \int_T (\mathbf{grad}\,\psi\cdot\mathbf{v} + \psi\,\mathrm{div}\,\mathbf{v})\, d\mathbf{x}\\ &\leq \|\mathbf{grad}\,\psi\|_{L^q(T)}\,\|\mathbf{v}\|_{L^p(T)} + \|\psi\|_{L^2(T)}\,\|\mathrm{div}\,\mathbf{v}\|_{\boldsymbol{L}^2(T)}\,,\end{aligned}$$

where p is the exponent conjugate to q, i.e., $p^{-1} + q^{-1} = 1$. The Sobolev embedding theorem [1, Thm. 4.5] gives the continuous inclusions $W_q^1(T) \hookrightarrow L^2(T)$ and $\boldsymbol{H}^s(T) \hookrightarrow \boldsymbol{L}^p(T)$. This implies, with $\tilde{C} = \tilde{C}(s,T)$,

$$\int_e \mathbf{v} \cdot \mathbf{n}_e \, ds \leq \tilde{C} \left(\|\mathbf{grad}\, \psi\|^2_{L^q(T)} + \|\psi\|^2_{W_q^1(T)} \right)^{\frac{1}{2}} \left(\|\mathbf{v}\|^2_{\boldsymbol{H}^s(T)} + \|\mathrm{div}\, \mathbf{v}\|^2_{\boldsymbol{L}^2(T)} \right)^{\frac{1}{2}}$$

for all $\mathbf{v} \in \boldsymbol{H}^s(T) \cap \boldsymbol{H}(\mathrm{div}; T)$ and the assertion of the lemma, since ψ is fixed. ∎

The importance of the interpolation operators Π_h can be traced back to the *commuting diagram property* as follows [14, Prop. 3.7]:

$$\mathrm{div}_\Gamma \Pi_h \mathbf{v} = Q_h \mathrm{div}_\Gamma \mathbf{v} \quad \forall \mathbf{v} \in \boldsymbol{H}(\mathrm{div}; \Gamma) \cap \mathrm{Dom}(\Pi_h), \tag{5.1}$$

where Q_h is the $L^2(\Gamma)$-orthogonal projection onto the space

$$\mathcal{Q}_0(\Gamma_h) := \{\mu \in L^2(\Gamma),\, \mu_{|T} = \text{const.}\, \forall T \in \mathcal{T}_h\}.$$

Identity (5.1) is a simple consequence of the definition of the degrees of freedom and Gauss's theorem applied to elements. An important consequence is that

$$\mathrm{div}_\Gamma \mathbf{v} = 0 \quad \wedge \quad \mathbf{v} \in \mathrm{Dom}(\Pi_h) \qquad \Rightarrow \quad \mathrm{div}_\Gamma(\Pi_h \mathbf{v}) = 0.$$

The relationship (5.1) also reveals that $\mathrm{div}_\Gamma \boldsymbol{\mathcal{RT}}_0(\Gamma_h) = \mathcal{Q}_0(\Gamma_h)$.

Remark. The reader should be aware that we have restricted ourselves to lowest order Raviart–Thomas elements only for the sake of simplicity. All other $\boldsymbol{H}(\mathrm{div}; \Omega)$-conforming finite elements in two dimensions that provide valid discrete 1-forms could be used as well. A rich collection is offered in [14, sect. III.3]. All arguments in what follows will carry over to these elements with only slight alterations.

The Raviart–Thomas elements form an affine family of finite elements in the sense of [25] with respect to Piola's transformation [14, sect. III.1.3],

$$\mathfrak{P}_T : \boldsymbol{L}^2(\widehat{T}) \mapsto \boldsymbol{L}^2_{\mathbf{t}}(T)\,, \quad \mathfrak{P}_T(\widehat{\mathbf{v}}_h)(\mathbf{x}) := |\det D\boldsymbol{\Phi}_T|^{-1} D\boldsymbol{\Phi}_T \widehat{\mathbf{v}}_h(\boldsymbol{\Phi}_T^{-1}(\mathbf{x})), \quad \mathbf{x} \in T,$$

where $\widehat{T}$ is the reference triangle $\widehat{T} := \{\mathbf{x} \in \mathbb{R}^2,\, x_1, x_2 > 0,\, x_1 + x_2 < 1\}$, $T \in \mathcal{T}_h$, and $\boldsymbol{\Phi}_T$ the unique affine mapping that takes $\widehat{T}$ to T. The Piola transform preserves the values of degrees of freedom. Shape regularity and quasi-uniformity guarantee that $|\det D\boldsymbol{\Phi}_T| \asymp h^2$ and $\|D\boldsymbol{\Phi}_T\| \asymp h$ uniformly in $T \in \mathcal{T}_h$ and $h \in \mathbb{H}$. Here and in what follows, we use the symbol $\asymp$ to indicate equivalence up to constants that may depend on Γ and the shape regularity of $\{\Gamma_h\}_h$, but are independent of h. The same is understood of all generic constants unless they bear a tilde.

Now, using standard affine equivalence techniques, the effect of Piola's transform on fractional Sobolev norms can be controlled as shown below.

LEMMA 5.2. *The Piola transform $\mathfrak{P}_T$, $T \in \mathcal{T}_h$, satisfies, for $0 \leq s \leq 1$,*

$$|\widehat{\mathbf{u}}|_{\boldsymbol{H}^s(\widehat{T})} \asymp h^s \, |\mathfrak{P}_T \widehat{\mathbf{u}}|_{\boldsymbol{H}^s(T)} \quad \forall \widehat{\mathbf{u}} \in \boldsymbol{H}^s(\widehat{T}),$$

with constants depending only on the shape regularity of T.

Proof. See Lemma 3 in [45] for the cases $s = 0$ and $s = 1$. The rest follows by interpolation. ∎

Remark. Using Piola's transform, one easily constructs parametric divergence-conforming surface elements [8, 32] for piecewise smooth Γ. Thus, our approach can be instantly extended to curved Lipschitz polyhedra.

6. Hodge mapping. Coercivity of the sesquilinear form related to (1.1) could only be established in the split space $\boldsymbol{\mathcal{G}}$ arising from the Hodge decomposition. This means that, though the boundary element spaces $\boldsymbol{\mathcal{RT}}_0(\Gamma_h)$ are conforming and natural for the EFIE (1.1), Theorem 4.2, i.e., the validity of a Gårding inequality on the continuous level, gives no immediate information about the convergence of the Galerkin discretization. The reason is that we would need conforming finite element subspaces of both $\mathbf{X}$ and $\mathbf{N}$ in order to apply the usual results (cf., e.g., [47, sect. 2.3]) about the convergence of Galerkin schemes for strongly elliptic variational problems.

A discrete $\boldsymbol{L}^2_{\mathbf{t}}(\Gamma)$-orthogonal Hodge decomposition

$$\boldsymbol{\mathcal{RT}}_0(\Gamma_h) = \mathbf{X}_h \oplus \mathbf{N}_h, \quad \mathbf{N}_h := \mathrm{Ker}(\mathrm{div}_\Gamma) \cap \boldsymbol{\mathcal{RT}}_0(\Gamma_h), \tag{6.1}$$

yields $\mathbf{N}_h \subset \mathbf{N}$, but generally we cannot expect $\mathbf{X}_h \subset \mathbf{X}$. In short, $\mathbf{X}_h$ provides only a *nonconforming* discretization of $\mathbf{X}$, and a discrete inf-sup condition does not follow from the strong ellipticity of the continuous problem. On the other hand, no modification of the sesquilinear form $a(\cdot,\cdot)$ is necessary if we consider the variational problem (3.4) over $\boldsymbol{\mathcal{G}}_h := \mathbf{X}_h \times \mathbf{N}_h$. This is simply due to the fact that everything remains perfectly conforming in $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$. In particular, $\boldsymbol{\mathcal{G}}_h$ can be equipped with the graph norm $\|\cdot\|_{\boldsymbol{\mathcal{G}}}$ of $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma) \times \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$. However, embedding and regularity properties of $\mathbf{X}$ (cf. Lemmas 2.3 and 4.1) are crucial and the space $\mathbf{X}_h$ lacks them. We deal with this by introducing semidiscrete spaces arising from the *continuous* Hodge decomposition of the discrete boundary element space as follows: We split $\mathbf{v}_h \in \boldsymbol{\mathcal{RT}}_0(\Gamma_h)$ in two ways,

$$\mathbf{v}_h = \mathbf{v}_h^\perp + \mathbf{v}_h^0, \quad \mathbf{v}_h^\perp \in \mathbf{X}_h,\, \mathbf{v}_h^0 \in \mathbf{N}_h \quad \text{and} \quad \mathbf{v}_h = \mathbf{v}^\perp + \mathbf{v}^0, \quad \mathbf{v}^\perp \in \mathbf{X},\, \mathbf{v}^0 \in \mathbf{N}.$$

The discrete field $\mathbf{v}_h^\perp$ is a genuine boundary element function, but only the *semidiscrete* field $\mathbf{v}^\perp$ has the desired properties. We have labeled it semidiscrete because $\mathrm{div}_\Gamma \mathbf{v}^\perp = \mathrm{div}_\Gamma \mathbf{v}_h$ is still piecewise constant and, hence, $\mathbf{v}^\perp$ still depends on the triangulation. To bridge the gap between $\mathbf{v}_h^\perp$ and $\mathbf{v}^\perp$, we need the following device (cf. Def. 4.1 in [38]).

DEFINITION 6.1. *We define the* Hodge mapping $H_h : \boldsymbol{\mathcal{RT}}_0(\Gamma_h) \mapsto \mathbf{X}$ *by*

$$H_h \mathbf{v}_h \in \mathbf{X}: \quad \mathrm{div}_\Gamma H_h \mathbf{v}_h := \mathrm{div}_\Gamma \mathbf{v}_h, \quad \mathbf{v}_h \in \boldsymbol{\mathcal{RT}}_0(\Gamma_h).$$

Owing to (2.3), H_h is well defined. The Hodge mappings are uniformly continuous with respect to $h \in \mathbb{H}$. They create the desired link between $\mathbf{X}_h$ and $\mathbf{X}$ (cf. Lemma 4.2 in [38]) as follows.

LEMMA 6.2. *For any $s \geq -\frac{1}{2}$, the Hodge mappings satisfy the estimate*

$$\|\mathbf{v}_h - H_h \mathbf{v}_h\|_{\boldsymbol{L}^2(\Gamma)} \leq C h^r \, \|\mathrm{div}_\Gamma \mathbf{v}_h\|_{H^s(\Gamma)} \quad \forall \mathbf{v}_h \in \mathbf{X}_h \; \forall h \in \mathbb{H}$$

with $0 \leq r \leq \min\{s+1, 1, s^*\}$ and constants depending only on s, r, Γ, and the shape regularity of the surface triangulations.

Proof. We follow the proof of Lemma 4.2 from [38], pick $\mathbf{u}_h \in \boldsymbol{\mathcal{RT}}_0(\Gamma_h)$, and focus on a single triangle $T \in \Gamma_h$. Take $H_h \mathbf{u}_{h|T}$ to the reference element and set $\widehat{\mathbf{w}} := \mathfrak{P}_T^{-1} H_h \mathbf{u}_h$. By (2.3), we see $\widehat{\mathbf{w}} \in \boldsymbol{H}^r(\widehat{T})$ so that the assumptions of Lemma 5.1 are satisfied. We have for any $r > 0$

$$\|\hat{\Pi}\widehat{\mathbf{w}}\|_{\boldsymbol{L}^2(\widehat{T})} \leq \tilde{C}(r) \left(\|\widehat{\mathbf{w}}\|_{\boldsymbol{H}^r(\widehat{T})} + \|\mathrm{div}\, \widehat{\mathbf{w}}\|_{L^2(\widehat{T})} \right),$$

where $\hat{\Pi}$ is the local interpolation operator on $\widehat{T}$. Remember that $\operatorname{div}_\Gamma H_h \mathbf{u}_h$ is piecewise constant, which renders $\operatorname{div} \widehat{\mathbf{w}}$ constant. Exploiting the equivalence of all norms on finite-dimensional spaces, we can easily bound $\|\operatorname{div} \widehat{\mathbf{w}}\|_{L^2(\widehat{T})}$ and arrive at

$$\|\hat{\Pi}\widehat{\mathbf{w}}\|_{\boldsymbol{L}^2(\widehat{T})} \leq \tilde{C}(r) \, \|\widehat{\mathbf{w}}\|_{\boldsymbol{H}^r(\widehat{T})} .$$

Constant vectorfields on $\widehat{T}$ are preserved by the interpolation $\hat{\Pi}$. Thus, for any $\mathbf{p} \in \mathbb{C}^2$,

$$\|\widehat{\mathbf{w}} - \hat{\Pi}\widehat{\mathbf{w}}\|_{\boldsymbol{L}^2(\widehat{T})} = \|\widehat{\mathbf{w}} - \mathbf{p} - \hat{\Pi}(\widehat{\mathbf{w}} - \mathbf{p})\|_{\boldsymbol{L}^2(\widehat{T})} \leq \|\widehat{\mathbf{w}} - \mathbf{p}\|_{\boldsymbol{L}^2(\widehat{T})} + \tilde{C}(r) \, \|\widehat{\mathbf{w}} - \mathbf{p}\|_{\boldsymbol{H}^r(\widehat{T})} .$$

From the definition of the fractional Sobolev norm [34, Def. 1.3.2.1] and $0 \leq r \leq 1$, it is immediate that

$$\|\widehat{\mathbf{w}} - \mathbf{p}\|^2_{\boldsymbol{H}^r(\widehat{T})} = \|\widehat{\mathbf{w}} - \mathbf{p}\|^2_{\boldsymbol{L}^2(\widehat{T})} + |\widehat{\mathbf{w}}|^2_{\boldsymbol{H}^r(\widehat{T})} .$$

As, according to Proposition 6.1 in [33], a Bramble–Hilbert-type estimate of the form

$$\inf_{c \in \mathbb{R}} \|f - c\|_{L^2(\widehat{T})} \leq \tilde{C}(r) \, |f|_{H^r(\widehat{T})} \quad \forall f \in H^r(\widehat{T})$$

also holds in fractional Sobolev spaces, we end up with the estimate

$$\|\widehat{\mathbf{w}} - \hat{\Pi}\widehat{\mathbf{w}}\|_{\boldsymbol{L}^2(\widehat{T})} \leq \tilde{C}(r) \, |\widehat{\mathbf{w}}|_{H^r(\widehat{T})} .$$

Since interpolation and the Piola transform commute, we may use Lemma 5.2 to pull the estimate back to the element T,

$$\|H_h \mathbf{u}_h - \Pi_h H_h \mathbf{u}_h\|_{\boldsymbol{L}^2(T)} \leq C h^r \, \|H_h \mathbf{u}_h\|_{\boldsymbol{H}^r(T)} .$$

At this stage, shape regularity starts affecting the constants. Squaring and summing over all elements yields

$$\|H_h \mathbf{u}_h - \Pi_h H_h \mathbf{u}_h\|_{\boldsymbol{L}^2(\Gamma)} \leq C h^r \, \|H_h \mathbf{u}_h\|_{\boldsymbol{H}^r(\Gamma)} ,$$

which, in light of Lemma 2.3, involves

$$\|H_h \mathbf{u}_h - \Pi_h H_h \mathbf{u}_h\|_{\boldsymbol{L}^2(\Gamma)} \leq C h^r \, \|\operatorname{div}_\Gamma \mathbf{u}_h\|_{H^s(\Gamma)} . \tag{6.2}$$

By the commuting diagram property of Π_h, we conclude from $\operatorname{div}_\Gamma(\mathbf{u}_h - H_h \mathbf{u}_h) = 0$ that also $\operatorname{div}_\Gamma(\mathbf{u}_h - \Pi_h H_h \mathbf{u}_h) = 0$. This means $\mathbf{u}_h - \Pi_h H_h \mathbf{u}_h \in \mathbf{N}_h$ and makes it possible for us to apply Nédélec's trick [44, sect. 3.3],

$$\begin{aligned} \|\mathbf{u}_h - H_h \mathbf{u}_h\|^2_{\boldsymbol{L}^2(\Gamma)} &= (\mathbf{u}_h - H_h \mathbf{u}_h, \mathbf{u}_h - \Pi_h H_h \mathbf{u}_h + \Pi_h H_h \mathbf{u}_h - H_h \mathbf{u}_h)_{0;\Gamma} \\ &= (\mathbf{u}_h - H_h \mathbf{u}_h, \Pi_h H_h \mathbf{u}_h - H_h \mathbf{u}_h)_{0;\Gamma} . \end{aligned}$$

Together with (6.2) this shows the assertion of the lemma. ∎

Now, we *fix* $t \leq \min\{\frac{1}{2}, s^*\}$ and keep it constant for the remainder of this paper. A legal choice for r in the previous lemma is $r = t$ for $s = -\frac{1}{2}$, and we denote the associated constant by C_3.

LEMMA 6.3. *The decomposition* $\boldsymbol{\mathcal{RT}}_0(\Gamma_h) = \mathbf{X}_h \oplus \mathbf{N}_h$ *is uniformly* $\boldsymbol{H}^{-\frac{1}{2}}(\operatorname{div}_\Gamma, \Gamma)$*-stable.*

Proof. For $\mathbf{u}_h \in \mathbf{X}_h$ we can use the Hodge mapping and the previous lemma to estimate

$$\|\mathbf{u}_h\|_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)} \leq \|\mathbf{u}_h - H_h\mathbf{u}_h\|_{\boldsymbol{L}^2(\Gamma)} + \|H_h\mathbf{u}_h\|_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)} \leq C(h^t+1)\,\|\mathrm{div}_\Gamma \mathbf{u}_h\|_{H^{-\frac{1}{2}}(\Gamma)},$$

as $H_h\mathbf{u}_h \in \mathbf{X}$. Since $\mathrm{div}_\Gamma H_h\mathbf{u}_h = \mathrm{div}_\Gamma \mathbf{u}_h$ and $\mathbb{H}$ is bounded, the proof is finished. ∎

We also shall require the following right inverse of the Hodge mapping.

DEFINITION 6.4. *We define the linear continuous mappings $T_h : \mathbf{X} \mapsto \mathbf{X}_h$, $h \in \mathbb{H}$, by*

$$T_h\mathbf{w} \in \mathbf{X}_h : \quad \mathrm{div}_\Gamma T_h\mathbf{w} = Q_h^{-\frac{1}{2}}\mathrm{div}_\Gamma \mathbf{w} \quad \forall \mathbf{w} \in \mathbf{X},$$

where $Q_h^{-\frac{1}{2}} : H^{-\frac{1}{2}}(\Gamma) \mapsto \mathcal{Q}_0(\Gamma_h)$ are the $H^{-\frac{1}{2}}(\Gamma)$-orthogonal projections.

Note that it is only due to the preceding stability result that this definition makes real sense. In addition, Lemma 6.3 guarantees that the family of operators $(T_h)_{h\in\mathbb{H}}$ is uniformly continuous, as

$$\|T_h\mathbf{w}\|_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)} \leq C\,\|\mathrm{div}_\Gamma T_h\mathbf{w}\|_{H^{-\frac{1}{2}}(\Gamma)} \leq C\,\|\mathrm{div}_\Gamma \mathbf{w}\|_{H^{-\frac{1}{2}}(\Gamma)}.$$

LEMMA 6.5. *For any fixed $\mathbf{w} \in \mathbf{X}$ we have*

$$\lim_{h\to 0} \|\mathbf{w} - T_h\mathbf{w}\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} = 0.$$

Proof. We resort to the same trick as in the proof of Lemma 6.3 and use $H_hT_h\mathbf{w} - \mathbf{w} \in \mathbf{X}$,

$$\begin{aligned}
\|T_h\mathbf{w} - \mathbf{w}\|_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)} &\leq \|H_hT_h\mathbf{w} - T_h\mathbf{w}\|_{\boldsymbol{L}^2(\Gamma)} + \|H_hT_h\mathbf{w} - \mathbf{w}\|_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)} \\
&\leq C_3h^t\,\|\mathrm{div}_\Gamma T_h\mathbf{w}\|_{H^{-\frac{1}{2}}(\Gamma)} + \tilde{C}\,\|\mathrm{div}_\Gamma(H_hT_h\mathbf{w} - \mathbf{w})\|_{H^{-\frac{1}{2}}(\Gamma)} \\
&\leq Ch^t\,\|\mathrm{div}_\Gamma \mathbf{w}\|_{H^{-\frac{1}{2}}(\Gamma)} + \tilde{C}\inf_{\mu_h\in\mathcal{Q}_0(\Gamma_h)} \|\mathrm{div}_\Gamma \mathbf{w} - \mu_h\|_{H^{-\frac{1}{2}}(\Gamma)}.
\end{aligned}$$

As $\bigcup_{h\in\mathbb{H}} \mathcal{Q}_0(\Gamma_h)$ is dense in $L^2(\Gamma)$, which, in turn, is dense in $H^{-\frac{1}{2}}(\Gamma)$, the lemma holds true. ∎

Remark. The operator T_h of Definition 6.4 is closely related to the so-called *Fortin projector* for edge elements introduced by Boffi [10].

7. Stability of the Galerkin scheme. Galerkin discretization of (3.4) leads to the following discrete variational problem: Seek $\boldsymbol{\iota}_h \in \boldsymbol{\mathcal{G}}_h$ such that

$$a(\boldsymbol{\iota}_h, \boldsymbol{\eta}_h) = f(\boldsymbol{\eta}_h) \quad \forall \boldsymbol{\eta}_h \in \boldsymbol{\mathcal{G}}_h. \tag{7.1}$$

The discrete Hodge decomposition (6.1) shows (7.1) to be equivalent to the Galerkin discretization (1.2) of the EFIE (1.1). From Theorem 4.2, we saw that problem (3.4) is strongly elliptic, i.e., $a = d - k$, with a $\boldsymbol{\mathcal{G}}$-elliptic sesquilinear form d and a $\boldsymbol{\mathcal{G}}$-compact form k. Discretization of (3.4) by a dense and conforming family of finite-dimensional subspaces would therefore imply quasi-optimal asymptotic convergence of the approximate solutions. The problem here is that $\boldsymbol{\mathcal{G}}_h$ is generally nonconforming, i.e., $\boldsymbol{\mathcal{G}}_h \not\subset \boldsymbol{\mathcal{G}}$. Therefore, coercivity in the discrete setting must be established by

a separate argument. For the proof, we draw on an idea of Schatz [46]. A similar strategy is pursued in [21, sect. 4].

To get compact formulas, we replace bilinear forms by the associated Riesz operators. First, $A : \boldsymbol{\mathcal{G}} \mapsto \boldsymbol{\mathcal{G}}'$ is associated to the sesquilinear form a. Next, the operator $K : \boldsymbol{\mathcal{G}} \mapsto \boldsymbol{\mathcal{G}}'$ is associated with the sesquilinear form k defined in the proof of Theorem 4.2. Both operators are continuous from $\boldsymbol{\mathcal{G}} \mapsto \boldsymbol{\mathcal{G}}'$. However, since $\boldsymbol{\mathcal{G}}_h$ is nonconforming, these operators are not defined on $\boldsymbol{\mathcal{G}}_h$ a priori. To extend them, we use Hodge mappings on $\boldsymbol{\mathcal{G}}_h$ which are defined through

$$\mathbf{H}_h : \boldsymbol{\mathcal{G}}_h \mapsto \boldsymbol{\mathcal{G}}, \quad \mathbf{H}_h(\mathbf{v}_h^\perp, \mathbf{v}_h^0) := (H_h \mathbf{v}_h^\perp, \mathbf{v}_h^0) \in \boldsymbol{\mathcal{G}}, \quad (\mathbf{v}_h^\perp, \mathbf{v}_h^0) \in \boldsymbol{\mathcal{G}}_h.$$

Lemma 6.2 ensures the uniform boundedness in h of this family of operators. We also define the extension $\mathbf{T}_h : \boldsymbol{\mathcal{G}} \mapsto \boldsymbol{\mathcal{G}}_h$ to $\boldsymbol{\mathcal{G}}_h$ of the right inverses T_h, $h \in \mathbb{H}$, of the Hodge mappings from Definition 6.4:

$$\mathbf{T}_h(\mathbf{v}^\perp, \mathbf{v}^0) := (T_h \mathbf{v}^\perp, \mathbf{Q}_h^{-\frac{1}{2}} \mathbf{v}^0) \in \boldsymbol{\mathcal{G}}_h, \quad (\mathbf{v}^\perp, \mathbf{v}^0) \in \boldsymbol{\mathcal{G}},$$

where $\mathbf{Q}_h^{-\frac{1}{2}}$ is the $\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)$-orthogonal projection $\mathbf{N} \mapsto \mathbf{N}_h$. The operator $\mathbf{T}_h$ is well defined, since $\mathbf{N}_h \subset \mathbf{N}$ and $\mathbf{N}$ is a closed subspace of $\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)$. Density of $\bigcup_{h\in\mathbb{H}} \mathbf{N}_h$ in $\mathbf{N}$ and Lemma 6.5 confirm pointwise convergence

$$\lim_{h\to 0} \|\boldsymbol{\varphi} - \mathbf{T}_h \boldsymbol{\varphi}\|_{\boldsymbol{\mathcal{G}}} = 0 \quad \forall \boldsymbol{\varphi} \in \boldsymbol{\mathcal{G}}. \tag{7.2}$$

Next, we consider the operator $S : \boldsymbol{\mathcal{G}}' \mapsto \boldsymbol{\mathcal{G}}$ defined as the solution operator of the $\boldsymbol{\mathcal{G}}$-elliptic variational problem

$$\boldsymbol{\eta}' \in \boldsymbol{\mathcal{G}}' : \quad d(S\boldsymbol{\eta}', \boldsymbol{\varphi}) = \boldsymbol{\eta}'(\boldsymbol{\varphi}) \quad \forall \boldsymbol{\varphi} \in \boldsymbol{\mathcal{G}}.$$

Continuity and ellipticity of the sesquilinear form d ensure that S is well defined and give

$$\tilde{C}_d^{-1} \|\boldsymbol{\eta}'\|_{\boldsymbol{\mathcal{G}}'} \le \|S\boldsymbol{\eta}'\|_{\boldsymbol{\mathcal{G}}} \le \tilde{c}_d^{-1} \|\boldsymbol{\eta}'\|_{\boldsymbol{\mathcal{G}}'} \quad \forall \boldsymbol{\eta}' \in \boldsymbol{\mathcal{G}}', \tag{7.3}$$

where $\tilde{C}_d := \|d\|$. Note also that the operator S is confined to the continuous setting.

LEMMA 7.1. *There is a decreasing function $b : \mathbb{H} \mapsto \mathbb{R}^+$ with $b(h) \to 0$ as $h \to 0$ such that*

$$\|(\mathbf{T}_h - Id)SK\boldsymbol{\eta}\|_{\boldsymbol{\mathcal{G}}} \le b(h) \|\boldsymbol{\eta}\|_{\boldsymbol{\mathcal{G}}} \quad \forall \boldsymbol{\eta} \in \boldsymbol{\mathcal{G}}.$$

Proof. We follow the ideas of the proof of Corollary 10.4 in [40]. Set $B_1(\boldsymbol{\mathcal{G}}) := \{\boldsymbol{\varphi} \in \boldsymbol{\mathcal{G}} : \|\boldsymbol{\varphi}\|_{\boldsymbol{\mathcal{G}}} \le 1\}$. As $K : \boldsymbol{\mathcal{G}} \mapsto \boldsymbol{\mathcal{G}}'$ is compact, the set $KB_1(\boldsymbol{\mathcal{G}})$ is precompact in $\boldsymbol{\mathcal{G}}'$. Thanks to the continuity of S, the closure w.r.t. the $\|\cdot\|_{\boldsymbol{\mathcal{G}}}$-norm $M := \overline{SKB_1(\boldsymbol{\mathcal{G}})}$ is compact in $\boldsymbol{\mathcal{G}}$. Pick some $\epsilon > 0$ and write $B_\epsilon(\boldsymbol{\nu})$ for the ϵ-neighborhood of $\boldsymbol{\nu}$ in $\boldsymbol{\mathcal{G}}$. We can find finitely many $\boldsymbol{\nu}_1, \ldots, \boldsymbol{\nu}_L$, $L = L(\epsilon) \in \mathbb{N}$, in M such that $M \subset \bigcup_l B_\epsilon(\boldsymbol{\nu}_l)$. From (7.2) we learn that there is $h_0 = h_0(\epsilon) \in \mathbb{H}$ such that

$$\|\mathbf{T}_h \boldsymbol{\nu}_l - \boldsymbol{\nu}_l\|_{\boldsymbol{\mathcal{G}}} \le \epsilon \quad \forall h < h_0, \qquad l = 1, \ldots, L.$$

For any $\boldsymbol{\eta} \in M$, there exists a $\boldsymbol{\nu}_l$ such that $\boldsymbol{\eta} \in B_\epsilon(\boldsymbol{\nu}_l)$. Hence,

$$\|\mathbf{T}_h \boldsymbol{\eta} - \boldsymbol{\eta}\|_{\boldsymbol{\mathcal{G}}} \le \|\mathbf{T}_h \boldsymbol{\eta} - \mathbf{T}_h \boldsymbol{\nu}_l\|_{\boldsymbol{\mathcal{G}}} + \|\mathbf{T}_h \boldsymbol{\nu}_l - \boldsymbol{\nu}_l\|_{\boldsymbol{\mathcal{G}}} + \|\boldsymbol{\nu}_l - \boldsymbol{\eta}\|_{\boldsymbol{\mathcal{G}}} \le (\|\mathbf{T}_h\|_{\boldsymbol{\mathcal{G}} \mapsto \boldsymbol{\mathcal{G}}} + 2)\epsilon$$

if $h < h_0$. Undoing the substitutions, we get

$$\|(\mathbf{T}_h - Id)SK\boldsymbol{\eta}\|_{\boldsymbol{\mathcal{G}}} \leq (\|\mathbf{T}_h\|_{\boldsymbol{\mathcal{G}}\mapsto\boldsymbol{\mathcal{G}}} + 2)\epsilon \quad \forall \boldsymbol{\eta} \in B_1(\boldsymbol{\mathcal{G}}), \qquad h < h_0.$$

A homogeneity argument finishes the proof. □

Next, we prove the discrete inf-sup condition for the form $a(\cdot,\cdot)$: Given $\boldsymbol{\eta}_h \in \boldsymbol{\mathcal{G}}_h$, we set

$$\boldsymbol{\varphi}_h := (Id - \mathbf{T}_h SK\mathbf{H}_h)\boldsymbol{\eta}_h \in \boldsymbol{\mathcal{G}}_h.$$

The uniform boundedness with respect to h of the operators involved ensures that there is $C_4 > 0$ independent of $h \in \mathbb{H}$ and $\boldsymbol{\eta}_h$ such that

$$\|\boldsymbol{\varphi}_h\|_{\boldsymbol{\mathcal{G}}} \leq C_4 \|\boldsymbol{\eta}_h\|_{\boldsymbol{\mathcal{G}}}. \tag{7.4}$$

We therefore estimate

$$\begin{aligned}
|a(\boldsymbol{\eta}_h, \boldsymbol{\varphi}_h)| &= |a(\boldsymbol{\eta}_h, (Id - \mathbf{T}_h SK\mathbf{H}_h)\boldsymbol{\eta}_h)| \\
&= |a(\boldsymbol{\eta}_h, ((Id - \mathbf{T}_h)(SK\mathbf{H}_h) + (Id - SK\mathbf{H}_h))\boldsymbol{\eta}_h)| \\
&\geq |a(\boldsymbol{\eta}_h, (Id - SK\mathbf{H}_h)\boldsymbol{\eta}_h)| - |a(\boldsymbol{\eta}_h, (Id - \mathbf{T}_h)SK\mathbf{H}_h\boldsymbol{\eta}_h)| \\
&\geq |a(\boldsymbol{\eta}_h, (Id - SK\mathbf{H}_h)\boldsymbol{\eta}_h)| - \tilde{C}_a \|\boldsymbol{\eta}_h\|_{\boldsymbol{\mathcal{G}}} \|(Id - \mathbf{T}_h)SK\mathbf{H}_h\boldsymbol{\eta}_h\|_{\boldsymbol{\mathcal{G}}} \\
&\geq |a(\boldsymbol{\eta}_h, (Id - SK\mathbf{H}_h)\boldsymbol{\eta}_h)| - b(h)\tilde{C}_a \|\boldsymbol{\eta}_h\|^2_{\boldsymbol{\mathcal{G}}},
\end{aligned}$$

the final inequality being a consequence of Lemma 7.1. Further, we estimate the first term,

$$\begin{aligned}
|a(\boldsymbol{\eta}_h, (Id - SK\mathbf{H}_h)\boldsymbol{\eta}_h)| &= |a(\boldsymbol{\eta}_h, ((Id - \mathbf{H}_h) + (Id - SK)\mathbf{H}_h)\boldsymbol{\eta}_h)| \\
&\geq |a(\boldsymbol{\eta}_h, (Id - SK)\mathbf{H}_h\boldsymbol{\eta}_h)| - |a(\boldsymbol{\eta}_h, (Id - \mathbf{H}_h)\boldsymbol{\eta}_h)| \\
&\geq |a(\boldsymbol{\eta}_h, S(S^{-1} - K)\mathbf{H}_h\boldsymbol{\eta}_h)| - \tilde{C}_a \|\boldsymbol{\eta}_h\|_{\boldsymbol{\mathcal{G}}} \|(Id - \mathbf{H}_h)\boldsymbol{\eta}_h\|_{\boldsymbol{\mathcal{G}}} \\
&\geq |a(\boldsymbol{\eta}_h, S(S^{-1} - K)\mathbf{H}_h\boldsymbol{\eta}_h)| - \tilde{C}_a C_3 h^t \|\boldsymbol{\eta}_h\|^2_{\boldsymbol{\mathcal{G}}},
\end{aligned}$$

by Lemma 6.2. Now, we note that $\boldsymbol{\psi} := S(S^{-1} - K)\boldsymbol{\lambda} \in \boldsymbol{\mathcal{G}}$, $\boldsymbol{\lambda} \in \boldsymbol{\mathcal{G}}$, satisfies

$$d(\boldsymbol{\psi}, \boldsymbol{\nu}) = \big\langle (S^{-1} - K)\boldsymbol{\lambda}, \boldsymbol{\nu} \big\rangle = d(\boldsymbol{\lambda}, \boldsymbol{\nu}) - k(\boldsymbol{\lambda}, \boldsymbol{\nu}) = a(\boldsymbol{\lambda}, \boldsymbol{\nu})$$

for all $\boldsymbol{\nu} \in \boldsymbol{\mathcal{G}}$ ($\langle\cdot,\cdot\rangle$ stands for the duality pairing $\boldsymbol{\mathcal{G}} \times \boldsymbol{\mathcal{G}}' \mapsto \mathbb{C}$). In short, $S(S^{-1} - K) = SA$. This enables us to continue the estimates

$$\begin{aligned}
|a(\boldsymbol{\eta}_h, S(S^{-1} - K)\mathbf{H}_h\boldsymbol{\eta}_h)| &= |a(\boldsymbol{\eta}_h - \mathbf{H}_h\boldsymbol{\eta}_h + \mathbf{H}_h\boldsymbol{\eta}_h, SA\mathbf{H}_h\boldsymbol{\eta}_h)| \\
&\geq |a(\mathbf{H}_h\boldsymbol{\eta}_h, SA\mathbf{H}_h\boldsymbol{\eta}_h)| - \tilde{C}_a \|(Id - \mathbf{H}_h)\boldsymbol{\eta}_h\|_{\boldsymbol{\mathcal{G}}} \|SA\mathbf{H}_h\boldsymbol{\eta}_h\|_{\boldsymbol{\mathcal{G}}} \\
&\geq |d(SA\mathbf{H}_h\boldsymbol{\eta}_h, SA\mathbf{H}_h\boldsymbol{\eta}_h)| - \tilde{C}_a^2 \tilde{c}_d^{-1} C_3 h^t \|\boldsymbol{\eta}_h\|^2_{\boldsymbol{\mathcal{G}}}.
\end{aligned}$$

For the last time we target the first term

$$\begin{aligned}
|d(SA\mathbf{H}_h\boldsymbol{\eta}_h, SA\mathbf{H}_h\boldsymbol{\eta}_h)| &\geq \tilde{c}_d \|SA\mathbf{H}_h\boldsymbol{\eta}_h\|^2_{\boldsymbol{\mathcal{G}}} \geq \tilde{c}_d \tilde{C}_d^{-1} \|A\mathbf{H}_h\boldsymbol{\eta}_h\|^2_{\boldsymbol{\mathcal{G}}'} \\
&\geq \tilde{c}_d \tilde{C}_d^{-1} \tilde{c}_a \|\boldsymbol{\eta}_h - (Id - \mathbf{H}_h)\boldsymbol{\eta}_h\|^2_{\boldsymbol{\mathcal{G}}} \\
&\geq \tilde{c}_4 (\|\boldsymbol{\eta}_h\|^2_{\boldsymbol{\mathcal{G}}} - \|(Id - \mathbf{H}_h)\boldsymbol{\eta}_h\|^2_{\boldsymbol{\mathcal{G}}}) \\
&\geq \tilde{c}_4 \|\boldsymbol{\eta}_h\|^2_{\boldsymbol{\mathcal{G}}} - \tilde{c}_4 C_3^2 h^{2t} \|\boldsymbol{\eta}_h\|^2_{\boldsymbol{\mathcal{G}}},
\end{aligned}$$

with $\tilde{c}_4 := \tilde{c}_d \tilde{C}_d^{-1} \tilde{c}_a$. Summing up, we have obtained

$$|a(\boldsymbol{\eta}_h, \boldsymbol{\varphi}_h)| \geq \left(\tilde{c}_4 - (\tilde{c}_4 C_3 h^t + \tilde{C}_a^2 \tilde{c}_d^{-1} + \tilde{C}_a) C_3 h^t - \tilde{C}_a b(h) \right) \|\boldsymbol{\eta}_h\|_{\boldsymbol{\mathcal{G}}}^2 .$$

If $h < h_*$ with $(\tilde{c}_4 C_3 h_*^t + \tilde{C}_a^2 \tilde{c}_d^{-1} + \tilde{C}_a) C_3 h_*^t + \tilde{C}_a b(h_*) < \frac{1}{2} \tilde{c}_4$, then we obtain the lower bound

$$|a(\boldsymbol{\eta}_h, \boldsymbol{\varphi}_h)| \geq \frac{1}{2} \tilde{c}_4 \|\boldsymbol{\eta}_h\|_{\boldsymbol{\mathcal{G}}}^2 \quad \forall h < h_*.$$

This is valid for any $\boldsymbol{\eta}_h$. Recalling (7.4), an immediate consequence is the discrete inf-sup condition

$$\sup_{\boldsymbol{\varphi}_h \in \boldsymbol{\mathcal{G}}_h} \frac{|a(\boldsymbol{\eta}_h, \boldsymbol{\varphi}_h)|}{\|\boldsymbol{\varphi}_h\|_{\boldsymbol{\mathcal{G}}}} \geq \frac{\tilde{c}_4}{2C_4} \|\boldsymbol{\eta}_h\|_{\boldsymbol{\mathcal{G}}} \quad \forall \boldsymbol{\eta}_h \in \boldsymbol{\mathcal{G}}_h, \qquad h < h_*. \tag{7.5}$$

Based on this discrete stability condition, stability (4.1) of the continuous problem, and the continuity (3.3) of the bilinear forms involved, we obtain quasi-optimal asymptotic convergence for the sequence of Galerkin solutions.

THEOREM 7.2. *There exists a meshwidth $h_* \in \mathbb{H}$ depending only on Γ, ς, and on the shape regularity of the triangulations Γ_h such that for any $h < h_*$ the Galerkin discretization of variational problem* (1.1) *in $\boldsymbol{\mathcal{RT}}_0(\Gamma_h)$ possesses a unique solution $\mathbf{j}_h$. It converges quasi-optimally according to*

$$\|\mathbf{j} - \mathbf{j}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)} \leq C \inf_{\mathbf{v}_h \in \boldsymbol{\mathcal{RT}}_0(\Gamma_h)} \|\mathbf{j} - \mathbf{v}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)}$$

with $C > 0$ independent of $\mathbf{j}$ and h.

Proof. We denote by $\hat{a}(\mathbf{j}, \mathbf{v}) := \langle V_\varsigma \mathrm{div}_\Gamma \mathbf{j}, \mathrm{div}_\Gamma \mathbf{v} \rangle_{\frac{1}{2}, \Gamma} - \varsigma^2 \langle \mathbf{A}_\varsigma \mathbf{j}, \mathbf{v} \rangle_{||, \Gamma}$ the bilinear form in (1.1) and (1.2). Since $\boldsymbol{\mathcal{RT}}_0(\Gamma_h)$ is $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$-conforming, the $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$-stable Hodge decompositions $\boldsymbol{\mathcal{RT}}_0(\Gamma_h) = \mathbf{X}_h \oplus \mathbf{N}_h$, $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma) = \mathbf{X} \oplus \mathbf{N}$ and the equivalence of (1.1) with (3.4) and of (1.2) with (7.1) imply that for every $(\mathbf{v}_h^\perp, \mathbf{v}_h^0) \in \boldsymbol{\mathcal{G}}_h$, $(\mathbf{z}_h^\perp, \mathbf{z}_h^0) \in \boldsymbol{\mathcal{G}}_h$, the sums $\mathbf{v}_h := \mathbf{v}_h^\perp + \mathbf{v}_h^0, \mathbf{z}_h := \mathbf{z}_h^\perp + \mathbf{z}_h^0$ belong to $\boldsymbol{\mathcal{RT}}_0(\Gamma_h)$. Further, there holds

$$a((\mathbf{z}_h^\perp, \mathbf{z}_h^0), (\mathbf{v}_h^\perp, -\mathbf{v}_h^0)) = \hat{a}(\mathbf{j}, \mathbf{v}_h). \tag{7.6}$$

From Lemma 6.3, we conclude the h-uniform equivalence of norms

$$\left\|(\mathbf{z}_h^\perp, \mathbf{z}_h^0)\right\|_{\boldsymbol{\mathcal{G}}} \asymp \|\mathbf{z}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)}, \quad \left\|(\mathbf{v}_h^\perp, \mathbf{v}_h^0)\right\|_{\boldsymbol{\mathcal{G}}} \asymp \|\mathbf{v}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)}$$

with constants independent of h and the functions. Thus, by (7.6), the h-uniform discrete inf-sup condition for $\hat{a}$ on $\boldsymbol{\mathcal{RT}}_0(\Gamma_h)$,

$$\sup_{\mathbf{v}_h \in \boldsymbol{\mathcal{RT}}_0(\Gamma_h)} \frac{|\hat{a}(\mathbf{z}_h, \mathbf{v}_h)|}{\|\mathbf{v}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)}} \geq C \|\mathbf{z}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)} \quad \forall \mathbf{z}_h \in \boldsymbol{\mathcal{RT}}_0(\Gamma_h), \tag{7.7}$$

immediately follows from (7.5). Taking the cue from the standard approach of [5], we

resort to Galerkin orthogonality $\hat{a}(\mathbf{j}-\mathbf{j}_h,\mathbf{v}_h)=0$ for all $\mathbf{v}_h\in\boldsymbol{\mathcal{RT}}_0(\Gamma_h)$ and get

$$\begin{aligned}\|\mathbf{j}-\mathbf{j}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} &\le \|\mathbf{j}-\mathbf{z}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} + \|\mathbf{z}_h-\mathbf{j}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)}\\ &\le \|\mathbf{j}-\mathbf{z}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} + C\sup_{\mathbf{v}_h\in\boldsymbol{\mathcal{RT}}_0(\Gamma_h)}\frac{|\hat{a}(\mathbf{z}_h-\mathbf{j}_h,\mathbf{v}_h)|}{\|\mathbf{v}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)}}\\ &\le \|\mathbf{j}-\mathbf{z}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} + C\sup_{\mathbf{v}_h\in\boldsymbol{\mathcal{RT}}_0(\Gamma_h)}\frac{|\hat{a}(\mathbf{z}_h-\mathbf{j},\mathbf{v}_h)|}{\|\mathbf{v}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)}}\\ &\le (1+C\|\hat{a}\|)\,\|\mathbf{j}-\mathbf{z}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)}\end{aligned}$$

for any $\mathbf{z}_h\in\boldsymbol{\mathcal{RT}}_0(\Gamma_h)$. Here, $\|\hat{a}\|$ stands for the norm of $\hat{a}$ on $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$. Thus, we get the assertion of the theorem. ∎

8. Convergence rates. Quantitative estimates of rates of convergence of $\mathbf{j}_h$ towards $\mathbf{j}$ hinge on extra smoothness of $\mathbf{j}$. Under corresponding assumptions the asymptotic decay of the error of best $\boldsymbol{\mathcal{RT}}_0(\Gamma_h)$-approximations in $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$ can be quantified.

LEMMA 8.1. *If $\mathbf{z}\in\boldsymbol{H}^\sigma(\mathrm{div}_\Gamma;\Gamma)$, $\sigma>0$, then for any $\epsilon>0$,*

$$\inf_{\mathbf{u}_h\in\boldsymbol{\mathcal{RT}}_0(\Gamma_h)}\|\mathbf{z}-\mathbf{u}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} \le Ch^{\min\{\frac{3}{2}-\epsilon,\sigma+\frac{1}{2}-\epsilon,1+s^*,\sigma+s^*\}}\,\|\mathbf{z}\|_{\boldsymbol{H}^\sigma(\mathrm{div}_\Gamma;\Gamma)}\,,$$

with $C>0$ depending on Γ, s^*, ϵ, and the shape regularity of the meshes Γ_h.

Proof. The proof is based on duality techniques used to deal with the negative norms occurring in the definition of $\|\cdot\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)}$ as follows: Pick any $\mathbf{z}\in\boldsymbol{H}^\sigma(\mathrm{div}_\Gamma;\Gamma)$ and $\epsilon>0$. We consider the following mixed variational problem: Seek $\mathbf{u}\in\boldsymbol{H}(\mathrm{div};\Gamma)$, $p\in\boldsymbol{L}^2(\Gamma)/Z$ such that

$$\begin{array}{ccccccc}(\mathbf{u},\mathbf{v})_{0;\Gamma} & + & (\mathrm{div}_\Gamma\mathbf{v},p)_{0;\Gamma} & = & (\mathbf{z},\mathbf{v})_{0;\Gamma} & & \forall\mathbf{v}\in\boldsymbol{H}(\mathrm{div};\Gamma),\\ (\mathrm{div}_\Gamma\mathbf{u},q)_{0;\Gamma} & & & = & (\mathrm{div}_\Gamma\mathbf{z},q)_{0;\Gamma} & & \forall q\in L^2(\Gamma)/Z.\end{array}\tag{8.1}$$

The usual techniques employed for the analysis of mixed variational formulations for second order elliptic boundary value problems [14, sect. IV.1.2] in conjunction with Theorem 2.1 confirm the existence and uniqueness of solutions of this variational problem. Evidently, we have

$$\mathbf{u}=\mathbf{z}\quad\text{and}\quad p=0.$$

Now, we look at a conforming Galerkin discretization of (8.1). Seek $\mathbf{u}_h\in\boldsymbol{\mathcal{RT}}_0(\Gamma_h)$, $p_h\in\mathcal{Q}_0(\Gamma_h)/Z$ with

$$\begin{array}{ccccccc}(\mathbf{u}_h,\mathbf{v}_h)_{0;\Gamma} & + & (\mathrm{div}_\Gamma\mathbf{v}_h,p_h)_{0;\Gamma} & = & (\mathbf{z},\mathbf{v}_h)_{0;\Gamma} & & \forall\mathbf{v}_h\in\boldsymbol{\mathcal{RT}}_0(\Gamma_h),\\ (\mathrm{div}_\Gamma\mathbf{u}_h,q_h)_{0;\Gamma} & & & = & (\mathrm{div}_\Gamma\mathbf{z},q_h)_{0;\Gamma} & & \forall q_h\in\mathcal{Q}_0(\Gamma_h)/Z.\end{array}$$

For each $q_h\in\mathcal{Q}_0(\Gamma_h)/Z$ we can find a solution $\psi\in H^{1+s^*}(\Gamma)/Z$, s^* from Theorem 2.1, of $\Delta_\Gamma\psi=q_h$ on Γ. By Lemma 5.1, the interpolant $\Pi_h\,\mathbf{grad}_\Gamma\,\psi$ is well defined. The commuting diagram property (5.1) involves

$$\mathrm{div}_\Gamma\Pi_h\,\mathbf{grad}_\Gamma\,\psi=Q_h\mathrm{div}_\Gamma\,\mathbf{grad}_\Gamma\,\psi=Q_hq_h=q_h$$

and continuity means

$$\|\Pi_h \,\mathbf{grad}_\Gamma\,\psi\|_{\boldsymbol{L}^2(\Gamma)} \leq C\left(\|\mathbf{grad}_\Gamma\,\psi\|_{\boldsymbol{H}^{s^*}(\Gamma)} + \|\mathrm{div}_\Gamma\,\mathbf{grad}_\Gamma\,\psi\|_{L^2(\Gamma)}\right) \leq \tilde{C}\,\|q_h\|_{L^2(\Gamma)}\,.$$

We owe the second estimate to Theorem 2.1. Now we are in a position to establish the crucial uniform discrete Ladyshenskaya–Babuška–Brezzi condition [14, sect. II.2.1]

$$\begin{aligned}\sup_{\mathbf{v}_h\in\boldsymbol{\mathcal{RT}}_0(\Gamma_h)} \frac{(\mathrm{div}_\Gamma\mathbf{v}_h, q_h)_{0;\Gamma}}{\|\mathbf{v}_h\|_{\boldsymbol{H}(\mathrm{div};\Gamma)}} &\geq \frac{(\mathrm{div}_\Gamma\Pi_h\,\mathbf{grad}_\Gamma\,\psi, q_h)_{0;\Gamma}}{\sqrt{\|\Pi_h\,\mathbf{grad}_\Gamma\,\psi\|^2_{\boldsymbol{L}^2(\Gamma)} + \|\mathrm{div}_\Gamma\Pi_h\,\mathbf{grad}_\Gamma\,\psi\|^2_{L^2(\Gamma)}}}\\ &\geq \frac{1}{1+\tilde{C}}\,\|q_h\|_{L^2(\Gamma)}\,.\end{aligned}$$

Along with $\mathrm{div}_\Gamma\boldsymbol{\mathcal{RT}}_0(\Gamma_h) = \mathcal{Q}_0(\Gamma_h)/Z$, this settles the issue of existence, uniqueness, and asymptotic quasi-optimality of discrete solutions $\mathbf{u}_h$, p_h [14, Prop. 2.6]. In particular, plain interpolation error estimates based on affine equivalence techniques and a Bramble–Hilbert-type result (cf. the proof of Lemma 6.2) give us

$$\|\mathbf{z}-\mathbf{u}_h\|_{\boldsymbol{H}(\mathrm{div};\Gamma)} \leq C \inf_{\mathbf{v}_h\in\boldsymbol{\mathcal{RT}}_0(\Gamma_h)} \|\mathbf{z}-\mathbf{v}_h\|_{\boldsymbol{H}(\mathrm{div};\Gamma)} \leq Ch^{\min\{1,\sigma\}}\,\|\mathbf{z}\|_{\boldsymbol{H}^\sigma(\mathrm{div}_\Gamma;\Gamma)}\,. \tag{8.2}$$

Next, pick $\mathbf{q}\in\boldsymbol{H}^s(\Gamma)$, $s := \max\{0, \frac{1}{2}-\epsilon\}$, and fix $\varphi\in H^1(\Gamma)/Z$ by

$$-\Delta_\Gamma\varphi = \mathrm{div}_\Gamma\mathbf{q} \in H^{s-1}_*(\Gamma).$$

From Theorem 2.1, we learn that $\varphi\in H^{r+1}(\Gamma)$, $r := \min\{s, s^*\}$, $0 < r < \frac{1}{2}$, and

$$\|\varphi\|_{H^{r+1}(\Gamma)} \leq C\,\|\mathrm{div}_\Gamma\mathbf{q}\|_{H^{s-1}(\Gamma)}\,.$$

Set $\mathbf{w} := \mathbf{q} + \mathbf{grad}_\Gamma\,\varphi \in \boldsymbol{H}^r(\Gamma)$ and observe $\mathrm{div}_\Gamma\mathbf{w} = 0$. Immediately we have the estimate

$$\begin{aligned}\|\mathbf{w}\|_{\boldsymbol{H}^r(\Gamma)} &\leq \|\mathbf{q}\|_{\boldsymbol{H}^r(\Gamma)} + \|\mathbf{grad}_\Gamma\,\varphi\|_{\boldsymbol{H}^r(\Gamma)}\\ &\leq \|\mathbf{q}\|_{\boldsymbol{H}^r(\Gamma)} + C\,\|\mathrm{div}_\Gamma\mathbf{q}\|_{H^{s-1}(\Gamma)} \leq C\,\|\mathbf{q}\|_{\boldsymbol{H}^s(\Gamma)}\,.\end{aligned} \tag{8.3}$$

The ultimate goal is to get information about the error $\mathbf{z}-\mathbf{u}_h$. To that end we note that Galerkin orthogonality implies

$$\begin{array}{rcrcll}(\mathbf{z}-\mathbf{u}_h, \mathbf{v}_h)_{0;\Gamma} & - & (\mathrm{div}_\Gamma\mathbf{v}_h, p_h)_{0;\Gamma} & = & 0 & \forall\mathbf{v}_h\in\boldsymbol{\mathcal{RT}}_0(\Gamma_h),\\ (\mathrm{div}_\Gamma(\mathbf{z}-\mathbf{u}_h), q_h)_{0;\Gamma} & & & = & 0 & \forall q_h\in\mathcal{Q}_0(\Gamma_h)/Z.\end{array} \tag{8.4}$$

This has two obvious consequences. First, we see from the usual interpolation estimates for the $L^2(\Gamma)$-orthogonal projections Q_h that for all $\eta\in H^t(\Gamma)$, $0\leq t\leq 1$,

$$\begin{aligned}|\,(\mathrm{div}_\Gamma(\mathbf{z}-\mathbf{u}_h), \eta)_{0;\Gamma}\,| &= |\,(\mathrm{div}_\Gamma(\mathbf{z}-\mathbf{u}_h), \eta - Q_h\eta)_{0;\Gamma}\,|\\ &\leq Ch^t\,\|\mathrm{div}_\Gamma(\mathbf{z}-\mathbf{u}_h)\|_{L^2(\Gamma)}\,\|\eta\|_{H^t(\Gamma)}\,.\end{aligned} \tag{8.5}$$

This immediately yields the duality estimate

$$\|\mathrm{div}_\Gamma(\mathbf{z}-\mathbf{u}_h)\|_{H^{-\frac{1}{2}}(\Gamma)} \leq Ch^{\frac{1}{2}}\,\|\mathrm{div}_\Gamma(\mathbf{z}-\mathbf{u}_h)\|_{L^2(\Gamma)}\,. \tag{8.6}$$

Second, (8.4) and the error estimates for Π_h lead to

$$\begin{aligned} |\,(\mathbf{z}-\mathbf{u}_h,\mathbf{w})_{0;\Gamma}\,| &= |\,(\mathbf{z}-\mathbf{u}_h,\Pi_h\mathbf{w})_{0;\Gamma}+(\mathbf{z}-\mathbf{u}_h,\mathbf{w}-\Pi_h\mathbf{w})_{0;\Gamma}\,| \\ &= |\,(\mathrm{div}_\Gamma\Pi_h\mathbf{w},p_h)_{0;\Gamma}+(\mathbf{z}-\mathbf{u}_h,\mathbf{w}-\Pi_h\mathbf{w})_{0;\Gamma}\,| \\ &\le Ch^r\,\|\mathbf{z}-\mathbf{u}_h\|_{\boldsymbol{L}^2(\Gamma)}\,\|\mathbf{w}\|_{\boldsymbol{H}^r(\Gamma)}\,. \end{aligned}$$

The last step relied on the commuting diagram property (5.1), which implies $\mathrm{div}_\Gamma\Pi_h\mathbf{w} = Q_h\mathrm{div}_\Gamma\mathbf{w} = 0$. Estimate (8.5)—more precisely, the case $t=1$ with η replaced by φ—and (8.3) can be combined with what we have just obtained. This yields

$$\begin{aligned} |\,(\mathbf{z}-\mathbf{u}_h,\mathbf{q})_{0;\Gamma}\,| &= |\,(\mathbf{z}-\mathbf{u}_h,\mathbf{w}-\mathbf{grad}_\Gamma\,\varphi)_{0;\Gamma}\,| \\ &= |\,(\mathbf{z}-\mathbf{u}_h,\mathbf{w})_{0;\Gamma}+(\mathrm{div}_\Gamma(\mathbf{z}-\mathbf{u}_h),\varphi)_{0;\Gamma}\,| \\ &\le Ch^r\,\|\mathbf{z}-\mathbf{u}_h\|_{\boldsymbol{H}(\mathrm{div};\Gamma)}\,\|\mathbf{q}\|_{\boldsymbol{H}^s(\Gamma)}\,. \end{aligned}$$

By definition of the dual norm for $0\le s<\frac{1}{2}$, this means

$$\|\mathbf{z}-\mathbf{u}_h\|_{\boldsymbol{H}^{-s}(\Gamma)} = \sup_{\mathbf{q}\in\boldsymbol{H}^s(\Gamma)}\frac{(\mathbf{z}-\mathbf{u}_h,\mathbf{q})_{0;\Gamma}}{\|\mathbf{q}\|_{\boldsymbol{H}^s(\Gamma)}} \le Ch^r\,\|\mathbf{z}-\mathbf{u}_h\|_{\boldsymbol{H}(\mathrm{div};\Gamma)}\,.$$

To finish the proof we have only to recall (8.2) and (8.6). ∎

Combined with Theorem 7.2, the preceding lemma instantly translates into an asymptotic convergence estimate for the electric field integral equation discretized by means of lowest order Raviart–Thomas elements.

THEOREM 8.2. *Provided that* $\mathbf{j}\in\boldsymbol{H}^\sigma(\mathrm{div}_\Gamma;\Gamma)$, $\sigma>0$, *and* $h<h_*$, *the discretization error encountered when using lowest order Raviart–Thomas surface elements for the Galerkin discretization of the electric field integral equation* (1.1) *behaves like*

$$\|\mathbf{j}-\mathbf{j}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} \le Ch^{\min\{\frac{3}{2}-\epsilon,\sigma+\frac{1}{2}-\epsilon,1+s^*,\sigma+s^*\}}\,\|\mathbf{j}\|_{\boldsymbol{H}^\sigma(\mathrm{div}_\Gamma;\Gamma)}\,,$$

where $C>0$ *may depend only on* Γ, ς, $\epsilon>0$, *and the shape regularity of the surface triangulations.*

Remark. From the discussion of s^* after Theorem 2.1, it is clear that $s^*\ge\frac{1}{2}$ if at most three edges of Γ meet at a vertex.

Remark. As $\mathbf{j}$ is the jump of traces of magnetic field solutions of Maxwell's equations on both sides of Γ, the regularity theory of [28] illustrates that the regularity requirements of Theorem 8.2 will always be satisfied. However, $\sigma\ge\frac{1}{2}$ cannot be expected for nonsmooth Γ, since any edge of Γ will appear as a re-entrant when seen from either inside or outside.

Remark. Why is the case $\epsilon=0$ not covered by Lemma 8.1 in general? The reason is that in this case we would have to choose $\mathbf{q}\in\boldsymbol{H}^{\frac{1}{2}}_{\perp}(\Gamma)$ in order to achieve $\mathrm{div}_\Gamma\mathbf{q}\in H^{-\frac{1}{2}}(\Gamma)$. However, we would need $\mathbf{q}\in\boldsymbol{H}^{\frac{1}{2}}_{||}(\Gamma)$ to gain information about the dual norm $\|\mathbf{z}-\mathbf{u}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}_{||}(\Gamma)}$. This mismatch foils the proof for $\epsilon=0$. Yet, for smooth surface Γ the spaces $\boldsymbol{H}^{\frac{1}{2}}_{||}(\Gamma)$ and $\boldsymbol{H}^{\frac{1}{2}}_{\perp}(\Gamma)$ coincide, and the best approximation estimate remains true for $\epsilon=0$.

Remark. Lemma 8.1 easily can be extended to kth order Raviart–Thomas boundary elements, $k\ge0$, yielding asymptotic convergence of order $\min\{k+\frac{3}{2}-\epsilon,\frac{1}{2}+\sigma-\epsilon,1+k+s^*,\sigma+s^*\}$.

Remark. In [19] an equivalent mixed formulation of (1.1) is proposed that takes the variational problem to classical Sobolev spaces. In this setting, duality techniques are available that give slightly better rates of asymptotic convergence (not reduced by ϵ), provided that s^* is sufficiently large. In [16], an alternative approach to the error estimates of section 8 is presented which shows that the convergence estimates in Theorem 8.2 are not limited by s^* but only by the regularity of the solution $\mathbf{j}$.

ERROR ANALYSIS FOR APPROXIMATION OF STOCHASTIC DIFFERENTIAL EQUATIONS DRIVEN BY POISSON RANDOM MEASURES*

ERIKA HAUSENBLAS†

Abstract. Let X_t be the solution of a stochastic differential equation (SDE) with starting point x_0 driven by a Poisson random measure. Additive functionals are of interest in various applications. Nevertheless they are often unknown and can only be found by simulation on computers. We investigate the quality of the Euler approximation. Our main emphasis is on SDEs driven by an α-stable process, $0 < \alpha < 2$, where we study the approximation of the Monte Carlo error $\mathbb{E}[f(X_T)]$, f belonging to L^∞. Moreover, we treat the case where the time equals $T \wedge \tau$, where τ is the first exit time of some interval.

Key words. stochastic differential equations, Euler scheme, Poisson random measure, α-stable process, Malliavin calculus, first exit time

1. Introduction.

Let X_t be a real valued process and solution to

$$X_t(x_0) = x_0 + \int_0^t \int \sigma(X_{s^-}, z)(\mu - \gamma)(dz, ds) + \int_0^t b(X_{s^-})ds, \tag{1.1}$$

where μ is a Poisson random measure satisfying certain conditions and γ is its compensator. Assume that $b : \mathbb{R} \mapsto \mathbb{R}$ and $\sigma : \mathbb{R} \times \mathbb{R} \mapsto \mathbb{R}$ are Lipschitz continuous in x. Then the stochastic differential equation (SDE) admits a unique solution and the solution is a semimartingale. Cinlar and Jacod [7] have shown that up to a random time change, every Hunt process (right continuous and quasi-left continuous) can be represented as a solution of an SDE driven by a Wiener process, a Lebesgue measure, and a compensated Poisson random measure. Thus, a large class of stochastic processes can be covered by considering SDEs driven by Brownian motion and Poisson random measures.

In contrast to the Brownian case, the Poissonian case is barely investigated. Kurtz and Protter [14] have studied the convergence in law of the normalized error for the path-by-path Euler scheme, and $\mathcal{L}^p$ estimates of the Euler scheme are given by Kohatsu-Higa and Protter [13]. Protter and Talay [16] investigate the weak error $\mathbb{E}[f(X_T)]$, which has to be evaluated at a fixed time T; the diffusion coefficient $\sigma(x, z)$ is of the form $\sigma_0(x)h(z)$; and f, σ, and b are supposed to be four times differentiable. In contrast, we assume f to be only measurable but $\sigma : \mathbb{R}\times\mathbb{R} \to \mathbb{R}$ and $b : \mathbb{R} \to \mathbb{R}$ to be five times differentiable. Additionally, we consider the approximation of $\mathbb{E}[f(X_{T\wedge\tau})]$, where τ denotes the first hitting time of zero ($\wedge$ denotes the minimum).

We proceed as in Bally and Talay [1], in which the Brownian case is treated. Moreover, Bally and Talay [2] give an expansion of the density for the Brownian case

in terms of $\frac{1}{n}$. We do not treat this case, but we conjecture that the same procedure can be applied to treat the Poissonian case to get an expansion.

Let X_t^n be the approximation of X_t by the Euler scheme with step size $\frac{1}{n}$ defined by

$$\left\{ \begin{array}{rcl} X_0^n & = & x_0, \\ X_t^n & = & X_{[t]_n}^n + b(X_{[t]_n}^n)(t-[t]_n) + \int_{[t]_n}^t \int \sigma(X_{[t]_n}^n, z)(\mu-\gamma)(ds,dz), \end{array} \right.$$

where $[t]_n = [tn]/n$. The entity $\mathbb{E}[f(X_T)]$ will be approximated by a finite sum over a large number N of independent trajectories, i.e.,

$$\mathbb{E}[f(X_T)] \quad \approx \quad \frac{1}{N}\sum_{i=1}^N f(X_T^n(\omega_i)).$$

The resulting error $e(n,N)$ depends on the sample size N and on the step size $\frac{1}{n}$, i.e.,

$$e(n,N) \leq \left| \frac{1}{N}\sum_{i=1}^N f(X_T^n(\omega_i)) - \mathbb{E}[f(X_T^n)] \right| + \left| \mathbb{E}[f(X_T^n)] - \mathbb{E}[f(X_T)] \right| \ = \mathrm{I} + \mathrm{II}.$$

If the driving process has finite variance, an upper bound for (I) can be found by the central limit theorem or deviation results. The main result of our paper is an error bound for the entity (II) under appropriate hypotheses for σ and b.

We suppose that μ is a random measure generated by a Poisson point process whose characteristic measure is Lebesgue, γ its compensator. Let X_t be a solution of (1.1).

Definition 1.1 (Bass and Cranston [3, p. 513]). *Let us call $\sigma(x,z)$ quasi-stable of order k between the indices α^- and α^+ if there exist $0 \leq z_0 < \infty$ and $0 < c_1, c_2 < \infty$ such that*

$$c_1|z|^{-\frac{1}{\alpha^-}-i} \leq |\partial_z^i \sigma(x,z)| \leq c_2|z|^{-\frac{1}{\alpha^+}-i} \tag{1.2}$$

for $i = 0, \ldots, k$, $|z| > z_0$, and all x.

Theorem 1.2. *Let X_t be a solution of the SDE (1.1), where $\sigma(x,z)$ is quasi-stable of order five between the indices α^- and α^+, $0 < \alpha^- \leq \alpha^+ < 2$, such that $\sigma_z(x,z) \geq 0$. Moreover, assume that there exist constants $1 \leq M < \infty$ and $1 \leq m_b \ll M$ such that σ and b satisfy each of the following hypotheses:*

- (H0) *For j, $0 < j \leq 5$, $x \in \mathbb{R}$, and $i = 1, \ldots, 5-j$, either $\partial_x^j \sigma(x,z) = 0$ or estimate (1.2) holds for $\partial_x^j \sigma(x,z)$.*
- (H1) *For all x, z the quantities $|\partial_z^i \partial_x^j \sigma(x,z)|$ are bounded uniformly by M in z and x for all i and j, $i + j \leq 5$, $j \neq 0$.*
- (H2) *$\sup_x |\partial_x^i b(x)|$, $i = 1, \ldots, 5$, is bounded by m_b and $\sup_x |\partial_x^i \sigma(x,z)|$, $i = 1, \ldots, 5$, is bounded by $h_\sigma(z)$ such that $|h_\sigma|_p \leq M$ for all $p \geq 2$.*
- (H3) *Let $\bar{z} = \sup_z\{|\sigma_x(x,z)| > \frac{1}{4} \text{ for all } x\}$. The functions $\left(\partial_x + \frac{\sigma_x(x,z)}{\sigma_z(x,z)}\partial_z\right)^i \sigma_x(x,z)$, $i = 1,2,3,4$, are then uniformly bounded by M in x for all $|z| < \bar{z}$ with the convention that $0/0 = 0$.*

If X_t is approximated by the Euler scheme, i.e., by X_t^n, then we have for $f \in L^\infty$

$$|E[f(X_T)] - E[f(X_T^n)]| \leq C(T) \cdot \frac{1}{n} \cdot M^{21} \cdot \left(1 + \exp(M^{16})\right).$$

REMARK 1.1. *If $\sigma(x,z)$ is quasi-stable of order six, and the indices five and four, respectively, are replaced by six and five, respectively, in* (H0), (H1), (H2), *and* (H3), *then for a Dirac-function $f=\delta$, we have*

$$|E[\delta(X_T)]-E[\delta(X_T^n)]| \le C\cdot\frac{1}{n}\cdot M^{28}\cdot\left(1+\exp(M^{16})\right).$$

If $\sigma(x,z)$ is quasi-stable of order i, $i=2,3,4$, and the indices five and four, respectively, are replaced by i and $i-1$, respectively, in (H0), (H1), (H2), *and* (H3), *then we have for $f\in C_b^{5-i}(\mathbb{R})$*

$$|E[f(X_T)]-E[f(X_T^n)]| \le C\cdot|f^{(5-i)}|_\infty\cdot\frac{1}{n}\cdot M^{c_i}\cdot\left(\exp(M^{2^{5-i}})+\exp(M^{16})\right),$$

and if $2/\alpha^+ > (i-1)/\alpha^- - 1$,

$$|E[f(X_T)]-E[f(X_T^n)]| \le C\cdot|f^{(5-i)}|_\infty\cdot\frac{1}{n}\cdot M^{c_i}\cdot\exp(M^{2^{5-i}}),$$

where $c_2=6$ and $c_i=c_{i-1}+i+1$ for $i>2$.

If the driving process has infinite variance, e.g., if it is an α-stable process, the case is more complicated. (I) is given by the percentiles of an α-stable variable, and to handle (II), we first truncate the driving process, i.e., we throw away all jumps larger than an integer M, and then we apply the result stated above to get the following error bounds:

- Let $f\in C_b^i(\mathbb{R})$, $i=2,3,4$. Then we have for any integer $M\ge 1$

$$|(II)| \le C_1(T)\cdot\frac{1}{n}\cdot M^{c_i}\left(1+\exp(M^{2^{5-i}})\right)+C_2\cdot\left(1-\exp(TM^{-\alpha})\right),$$

  where c_i is defined by $c_2=6$, $c_i=c_{i-1}+i+1$ for $i>2$, and $\alpha>i-3$.
- $f\in L^\infty$, and $\lim_{x\to\infty}\frac{|\sigma(x,z)|}{x^p} < C|z|^{-\frac{1}{\alpha}}$, where $C<\infty$, for all $p\ge 1$: the error bound of (II) is given by $|(II)|\le C\,\frac{1}{n}$.

C_1, C_2, and C are constants. Let $\tau=\inf_{t\ge0}\{X_t=0\}$ and $\tau^n=\inf_{t\ge0}\{X_t^n=0\}$ and $M=1$. Finally we show for $2/\alpha^+ > (i-1)/\alpha^- - 1$ and $f\in C_b^{5-i}(\mathbb{R})$, $i=2,3,4$,

$$|E[f(X_{T\wedge\tau})]-E[f(X^n_{T\wedge\tau^n})]| \le C_1(T)1/\sqrt{n}+C_2(T)|f^{(5-i)}|_\infty\cdot\frac{1}{n}M^{c_i}\exp(M^{2^{5-i}}).$$

The paper is organized as follows: In the second section, we give some preliminaries on point processes and Malliavin calculus. The third section is concerned with the main result, i.e., the error bound for $f\in L^\infty$. After that we give some additional remarks and consider the remaining cases.

2. Preliminaries. In this section we recall some basic facts about point processes, α-stable processes, and the Malliavin calculus. For details on point processes, α-stable processes, and semimartingales, see Bertoin [4] and Cinlar et al. [8].

Let $\mathcal{F}_t$ be a filtration satisfying the usual conditions. Let $\mathcal{Z}$ be a measurable space. A point process with state space $\mathcal{Z}$ is a countable collection of adapted random variables $(Z_i,T_i)\in\mathcal{Z}\times\mathbb{R}^+$. Given a point process, one usually works with the associated random measure μ defined by $\mu(A\times[0,t])(\omega)=\sum_{T_i\le t}1_A(Z_i(\omega))$. A random measure μ has a random measure γ as compensator if γ is predictable and $\mu(A\times[0,t])-\gamma(A\times[0,t])$ is a local martingale in t for all Borel sets A such that $\mathbb{E}[\gamma(A\times[0,t])]<\infty$ for all $t>0$.

A point process is a Poisson point process with characteristic measure ν on $\mathcal{Z}$ if for each Borel set A with $\nu(A) < \infty$ and for each t the counting measure of the set $A \times [0,t]$ is Poisson with parameter $\nu(A)\,t$. It follows that μ has independent increments and that $\mu(A \times [0,t])$ and $\mu(B \times [0,t])$ are independent for $A \cap B = \emptyset$. If the compensator $\gamma(dz,ds)$ of the random measure μ is of the form $\gamma(dz,ds) = \nu(dz)ds$ for some σ-finite measure ν on $\mathcal{Z}$, then the process $t \mapsto \mu(A \times [0,t])$ is called a Poisson point process with characteristic measure ν mentioned above, and the law of the point process is uniquely determined.

In analogy to the Wiener case, we can define a stochastic integral with respect to a Poisson measure. Let $h(s,z,\omega)$ be a simple, càdlàg, and predictable process; i.e., $h(s,z,\omega) = \sum_{i=1}^{n} 1_{(t_{i-1},t_i]}(s) 1_{A_i}(z) H_i(\omega)$, where $0 = t_1 < \cdots < t_n < \infty$ is a finite sequence of stopping times, H_i is bounded and adapted to $\mathcal{F}_{t_i}$, and $\nu(A_i) < \infty$ for all $i = 1, \ldots, n$. The stochastic integral is defined by the Stieltjes integral

$$\int_0^t \int_{\mathcal{Z}} h(s,z,\omega)(\mu-\gamma)(dz,ds) = \sum_{i=1}^{n} H_i(\omega)(\mu-\gamma)(A_i \times (t_{i-1} \wedge t, t_i \wedge t]).$$

The above definition can be extended by $\mathcal{L}^2$ limits to $\mathcal{M}^2 = \{h : h \text{ predictable}, \mathbb{E}[\int_0^t \int_{\mathcal{Z}} h^2(s,z,\omega)\gamma(dz,ds)] < \infty\}$. In what follows we omit ω and $\mathcal{Z}$ for simplicity if there is no danger of confusion.

A purely discontinuous martingale is one where $\mathbb{E}[M_t^2] - \mathbb{E}[M_0^2] = \mathbb{E}[\sum_{s \le t} \Delta M_s^2]$ with $\Delta M_t = M_t - M_{t^-}$. In this case, let $[M,M]_t = \sum_{s \le t} \Delta M_s^2$. One can show that $M_t = \int_0^t \int h(s,z)(\mu-\gamma)(dz,ds)$ is a purely discontinuous (local) martingale with $[M,M]_t = \int_0^t \int h^2(s,z)\mu(dz,ds)$ for $h \in \mathcal{M}^2$. In particular,

$$\mathbb{E}[M_t^2] = \mathbb{E}\left[\int_0^t \int h^2(s,z)\mu(dz,ds)\right] = \mathbb{E}\left[\int_0^t \int h^2(s,z)\gamma(dz,ds)\right].$$

We will suppose throughout the remainder of this paper that $\mathcal{Z} = \mathbb{R} \setminus \{0\}$, and μ is a random measure generated by a Poisson point process whose characteristic measure is Lebesgue, denoted by λ, and γ is its compensator.

REMARK 2.1. *Suppose that $Z_t = \int_0^t \int h(z)\mu(dz,ds)$ is of finite variation on compacts, i.e., the Lévy measure defined by $\nu_h([y,\infty)) = \lambda\{h(z) > y\}$ for $y > 0$ and $\nu_h(x,(-\infty,y]) = \lambda\{h(z) < y\}$ for $y < 0$ satisfies $\int (1 \wedge |x|)\nu_h(dx) < \infty$. It follows (see, e.g., Bertoin* [4, *Proposition* III.8]*) that $t^{-1}\,Z_t$ tends to a constant a.s. as t tends to zero. By Billingsley* [6, *p.* 25] *we know that $t^{-1}\|Z_t\|_p$ is uniformly bounded as t tends to zero for all Z_t, where $\|Z_t\|_p < \infty$.*

REMARK 2.2. *Let $Z_t = \int_0^t \int h(z)\mu(dz,ds)$ with Lévy measure ν_h (cf. Remark* 2.1*). If $\overline{\{z|h(z) \neq 0\}}$ is compact in $\mathcal{Z}$, ν_h has finite total mass and Z_t is a compound Poisson process. Let us define $Y_t = \int_0^t \int \sqrt{|h(z)|}\,\mu(dz,ds)$. It follows that Y_t is also a compound Poisson process and we have a.s. $Z_t \le \sum_{s \le t} |\Delta Z_s| = \sum_{s \le t} \Delta Y_s^2 = [Y,Y]_t$. Since Y_t has finite variation on compacts, $t^{-p}\|Y_t\|_p^p$ is bounded for $t \to 0$ (see Remark* 2.1*). On the other hand, we have for $p \ge 1$ (see Barlow, Jacka, and Yor* [11]*) $C(p)\,t^{-2p}\|Y_t\|_{2p}^{2p} \ge t^{-2p}\|[Y,Y]_t\|_p^p \ge t^{-2p}\|Z_t\|_p^p$ a.s. and therefore $t^{-2}\|Z_t\|_p$ is bounded as t tends to zero. By iterating we see that $t^{-n}\|Z_t\|_p$ is bounded as $t \to 0$ for $n = 2^k$ $k \in \mathbb{N}$.*

REMARK 2.3. *Suppose that $Z_t = \int_0^t \int h(z)\mu(dz,ds)$ has finite Lévy measure with $\nu_h(\mathcal{Z}) = C_h$ and $\sup_z |h(z)| = h_{max} < \infty$. We are interested in an upper bound for $t^{-1}\|Z_t\|_p$. Note that $Z_t \le h_{max}R$, where $R = \int_0^t \int \mu(dz,ds)$ is an exponential*

distributed random variable with parameter $t\,\nu_h(A)$ *and moments* $(t\,\nu_h(A))^k$, $k \in \mathbb{N}$. *It follows that*

$$t^{-p}\|Z_t\|_p^p \le h_{max}^p \mathbb{E}\left[\frac{R^p}{t^p}\right] = t^{-p}\, h_{max}^p \nu_h(A)^p,$$

and therefore $\sup_{0<t\le T} t^{-1}\|Z_t\|_p \le h_{max}\nu_h(A)$.

2.1. Stable processes. In Definition 1.1 we introduced the notion of quasi-stable processes to the class of processes which are the solution to $X_t = \int_0^t \int \sigma(X_{s^-}, z)$ $(\mu-\gamma)(dz, ds)$ for some $\sigma : \mathbb{R}\times\mathcal{Z}\to\mathbb{R}$. Assume that X_t is well defined and consider the process $Z_t = \int_0^t \int_{\mathcal{Z}} \sigma^Z(X_{s^-}, z)\mu(dz, ds)$, where $|z|^{-\frac{1}{\alpha^-}} \le |\sigma^Z(x, z)| \le |z|^{-\frac{1}{\alpha^+}}$ for $0 < \alpha^- \le \alpha^+ < 2$ and for all z, where $|z| \ge z_0$ for some $0 < z_0 < \infty$. Obviously, the driving process $\sigma^Z(X_{s^-}, z)$ behaves like a quasi-stable process of order zero with indices α^- and α^+ but does not necessarily belong to the class of processes for which Definition 1.1 is given. Thus, in order to also consider these cases, we extend the notation of quasi-stable processes to a more general class of processes.

Definition 2.1. *Let* $h : \mathbb{R}^+\times\mathcal{Z}\times\Omega\to\mathbb{R}$ *be adapted. We call* $h(t, z, \omega)$ *quasi-stable of order* k *between the indices* α^- *and* α^+ *if there exist* $z_0 < \infty$ *and* $c_1, c_2 < \infty$ *such that*

$$c_1|z|^{-\frac{1}{\alpha^-}-k} \le |\partial_z^k h(t, z, \omega)| \le c_2|z|^{-\frac{1}{\alpha^+}-k}$$

for $|z| > z_0$ *uniformly for all* $\omega\in\Omega$ *and* $t\in\mathbb{R}^+$.

Remark 2.4. *In Definition* 1.1 *we introduced quasi-stable processes for the solution to* $X_t = \int_0^t \int \sigma(X_{s^-}, z)\,(\mu-\gamma)(dz, ds)$. *Now* $\sigma(X_{s^-}, z)$ *can also be written as* $h(s, z, \omega) = \sigma(X_{s^-}(\omega), z)$, *i.e.,* $X_t = \int_0^t \int h(s, z, \omega)(\mu-\gamma)(dz, ds)$. *The above* $h(s, z, x)$ *can be regarded as quasi-stable in the sense of both Definition* 1.1 *and Definition* 2.1.

Remark 2.5. *In contrast to Bass and Cranston* [3] *we include the* k*th derivative. The number* k *depends on the highest order of the Malliavin derivative involved.*

Since the function $h : \mathbb{R}\to\mathbb{R} : z\mapsto |z|^{-1/\alpha}$ does not belong to $L^2(\mathcal{Z})$ for $0 < \alpha < 2$, we define the truncated α-stable process Z_t^m by throwing away all jumps larger than m, i.e., for $0 < \alpha < 2$, $Z_t^m = \int_0^t \int (|z|^{-1/\alpha}\wedge m)(\mu-\gamma)(dz, ds)$. Furthermore, if $0 < \alpha < 1$, we can also define the truncated α-stable subordinator by

$$Z_t^m = \int_0^t \int (|z|^{-1/\alpha}\wedge m)\mu(dz, ds). \tag{2.1}$$

Proposition 2.1. *Let* $Z_t = \int_0^t \int h(s, z, \omega)\mu(dz, ds)$, *where* h *is bounded and belongs to* $\mathcal{M}^2$ *such that* $h(s, z, \omega)$ *is a quasi-stable process of order zero between the indices* α^- *and* α^+ *with* $0 < \alpha^- \le \alpha^+ < 1$.

(i) *Define* $\sigma^+ := \sup_{(s,z,\omega)} |z|^{\frac{1}{\alpha^+}}\,|h(s, z, \omega)|$, *and*

$$m = (\sigma^+)^{-1} \sup_{(s,z,\omega)} \left(1\vee|z|^{\frac{1}{\alpha}}\right)|h(s, z, \omega)|,$$

where $\vee$ *denotes the maximum. Let* $Z_t^{m,+}$ *be defined by* (2.1), *where* α *is replaced by* α^+. *Then* $\|Z_t\|_p \le \sigma^+\|Z_t^{m,+}\|_p$ *for* $p\ge 1$ *and* $t\in\mathbb{R}^+$.

(ii) *Assume that* $h(s, z, \omega)$ *is positive a.s. and define* $\sigma^- = \inf_{(s,z,\omega)} |z|^{\frac{1}{\alpha^-}}\, h(s, z, \omega)$. *Then* $\sigma^-\|Z_t^{m,-}\|_p \le \|Z_t\|_p$ *for* $p\ge 1$ *and* $t\in\mathbb{R}^+$, *where* $Z_t^{m,-} = \int_0^t \int 1_{(-\infty,-1]\cup[1,\infty)}(z)\; |z|^{-\frac{1}{\alpha^-}}\; \mu(dz)$.

Proof. For (i) note that from $|h(s,z,\omega)| \leq \sigma^+(m \wedge |z|^{-\frac{1}{\alpha^+}})$ it follows that $|\Delta Z_s| \leq \Delta Z_s^{m,+}$ and therefore

$$|Z_t| = \Big|\sum_{s\leq t} \Delta Z_s\Big| \leq \sum_{s\leq t} |\Delta Z_s| \leq \sigma^+ \sum_{s\leq t} \Delta Z_s^{m,+} \leq \sigma^+ Z_t^{m,+} \quad a.s.$$

Thus, we obtain $\|Z_t\|_p \leq \sigma^+ \|Z_t^{m,+}\|_p$. Part (ii) can be proved in an analogous way because $h(s,z,\omega) \geq \sigma^- |z|^{-\frac{1}{\alpha^-}}$. □

PROPOSITION 2.2. *Let $Z_t^m = \int_0^t \int_{\mathcal{Z}} (|z|^{-\frac{1}{\alpha}} \wedge m)\, \mu(dz,ds)$, where $0 < \alpha < 1$ and $0 < t \leq 1$, and let $V_t = \int_0^t \int 1_{(-\infty,-1]\cup[1,\infty)}(z)\, |z|^{-\frac{1}{\alpha}} \mu(dz,ds)$. Then the following conditions are satisfied:*

1. *for $\beta > \alpha$, $t^{-\frac{1}{\beta}} \|Z_t^m\| \leq c(p)\,(m + \|Z_1^m\|_p)$, and*
2. *for $\beta \leq \alpha$, $V_1 \leq t^{-\frac{1}{\beta}} Z_t^m$.*

Proof. To show (i), we decompose Z_t into two processes, i.e.,

$$Z_t^m = \sum_{s\leq t} 1_{\{\Delta Z_s^m < t^{\frac{1}{\beta}}\}} \Delta Z_s^m + \sum_{s\leq t} 1_{\{\Delta Z_s^m \geq t^{\frac{1}{\beta}}\}} \Delta Z_s^m =: \tilde{V}_t^t + \tilde{K}_t^t,$$

where $\tilde{V}_s^t$ and $\tilde{K}_s^t$ are defined by $\tilde{V}_s^t = \int_0^s \int_{\mathcal{Z}} 1_{(-\infty,-t^{-\frac{\alpha}{\beta}})\cup(t^{-\frac{\alpha}{\beta}},\infty)}(z)\, |z|^{-\frac{1}{\alpha}}\, \mu(dz,dr)$ and $\tilde{K}_s^t = \int_0^s \int_{\mathcal{Z}} 1_{[-t^{-\frac{\alpha}{\beta}}, t^{-\frac{\alpha}{\beta}}]}(z)\, (m \wedge |z|^{-\frac{1}{\alpha}})\, \mu(dz,dr)$. Note that since $\mathcal{Z} = \mathbb{R} \setminus \{0\}$, the process $\tilde{K}_s^t$ is well defined. A short calculation shows that the Laplace transform $\Psi(\lambda)$ of $\tilde{V}_t^t / t^{\frac{1}{\beta}}$ is $\Psi(\lambda) = \exp(t \int_0^{t^{\frac{1}{\beta}}} e^{-\lambda x / t^{\frac{1}{\beta}}}\, \bar{\nu}(dx))$, where

$$\bar{\nu}(x) = \nu(x,\infty) = \begin{cases} x^{-\alpha}, & x < m^{-\alpha}, \\ 0, & m^{-\alpha} \leq x. \end{cases}$$

Substitution yields $\Psi(\lambda) = \exp(t \int_0^1 e^{-\lambda x} \bar{\nu}(t^{\frac{1}{\beta}} dx))$. It is easy to see that $\bar{\nu}(tx) \leq t^{-\alpha} \bar{\nu}(x)$ for $0 < x < m$. Thus it follows $\Psi(\lambda) \leq \exp(t^{1-\frac{\alpha}{\beta}} \int_0^1 e^{-\lambda x} \bar{\nu}(dx))$, and therefore $\tilde{V}_t^t / t^{\frac{1}{\beta}} \leq \tilde{V}_1^1 = V_1 \leq Z_1^m$ a.s. It remains to calculate $t^{-\frac{1}{\beta}} \|\tilde{K}_t^t\|_p$. We take k such that $k - 1 < \frac{1}{\beta} \leq k$. Fix $k_0 = 2^{n_0}$ for some fixed $n_0 \in \mathbb{N}$ such that $k_0(1 - \frac{\alpha}{\beta}) \geq k$. Let

$$K_s^{i,t} = \int_0^s \int_{\mathcal{Z}} 1_{[-t^{-\frac{\alpha}{\beta}}, t^{-\frac{\alpha}{\beta}}]}(z) \left(m^{\frac{1}{2^i}} \wedge |z|^{-\frac{1}{2^i \alpha}}\right) \mu(dz,dr), \quad i = 1, \ldots, n_0.$$

Note that $K_s^{i,t}$ has Lévy measure with total mass $C\, t^{-\frac{\alpha}{\beta}}$. Therefore, $K_s^{i,t}$ is a compound Poisson process for $0 < t \leq 1$ and Remark 2.2 implies, for $p \geq 1$,

$$\left\|\tilde{K}_s^t\right\|_p^p = \left\|\left[K^{1,t}, K^{1,t}\right]_s\right\|_p^p \leq c_1(p) \left\|K_s^{1,t}\right\|_{2p}^{2p}.$$

Iteration yields

$$\begin{aligned} \left\|\tilde{K}_s^t\right\|_p &\leq c_1(p) \left\|K_s^{1,t}\right\|_{2p}^2 \leq \cdots \leq c_{i-1}(p) \left\|K_s^{i-1,t}\right\|_{2^{i-1}p}^{2^{i-1}} \\ &= c_{i-1}(p) \left\|\left[K^{i,t}, K^{i,t}\right]_s\right\|_{2^{i-1}p}^{2^{i-1}} \\ &\leq c_i(p) \left\|K_s^{i,t}\right\|_{2^i p}^{2^i} \leq \cdots \leq c_{n_0}(p) \left\|K_s^{n_0,t}\right\|_{k_0 p}^{k_0}. \end{aligned}$$

By letting $s = t$ and Remark 2.3 we see that $t^{-1}\|K_t^{n_0,t}\|_p \le m^{\frac{1}{k_0}} t^{-\frac{\alpha}{\beta}}$ and therefore

$$t^{-\frac{1}{\beta}}\|\tilde{K}_t^t\|_p \le t^{-k}\|\tilde{K}_t^t\|_p \le c_{n_0}(p)\, t^{-k}\, \|K_s^{n_0,t}\|_{k_0 p}^{k_0} = m\, t^{-k_0\frac{\alpha}{\beta}-k+k_0} \le m,$$

since $-k + k_0 - \frac{\alpha}{\beta}k_0 \ge 0$. Thus $t^{-\frac{1}{\beta}}\|Z_t^m\|_p \le C(p)\,(m + \|Z_1^m\|_p) \le C(p)\, m$. To show (ii), let $\beta \le \alpha$. Proceeding as above, we see that the Laplace transform of $\tilde{V}_t^t/t^{\frac{1}{\beta}}$ is $\Psi(\lambda) = \exp(t^{1-\frac{\alpha}{\beta}} \int_0^1 e^{-\lambda x}\bar{\nu}(dx))$. Because $\tilde{K}_t^t$ has only positive jumps, $V_1 \le \tilde{V}_t^t/t^{\frac{1}{\beta}} \le t^{-\frac{1}{\beta}} Z_t^m$ for $\beta \le \alpha$. □

REMARK 2.6. *Let A_t be defined as in Bass and Cranston* [3, Lemma 6.1]*, i.e., $A_t = \int_0^t \int \exp(-|z|/p_0)\mu(dz, ds)$. Since $|z|^{-1/\alpha} \ge \exp(-|z|/p_0)$ for all $|z| \ge z_0$, z_0 large enough, $CZ_t \ge A_t$ a.s. for a constant $C > 0$, and therefore $Z_t^{-1} \le CA_t^{-1}$ a.s. Because A_t^{-1} is in $\mathcal{L}^{p_0}$, the inverse Z_t^{-1} is also in $\mathcal{L}^{p_0}$. Analyzing the proof of Bass and Cranston, we see for a truncated, quasi-stable subordinator (see* (2.1)*) that $\|Z_t^{m-1}\|_p \le C\,\frac{1}{\alpha}\,\Gamma(\frac{1+p}{\alpha} - 1)$, and therefore we can give a threshold of $\|Z_t^{m-1}\|_p$ independent of m.*

REMARK 2.7. *Let Z_t^m be defined as in* (2.1)*. Combining Proposition* 2.2 *and Remark* 2.6*, we obtain an estimate for the inverse of Z_t^m, i.e., $\|(Z_t^m)^{-1}\|_p \le C\, t^{-\frac{1}{\beta}}$, where $\beta \le \alpha$.*

2.2. The Doléans–Dade exponential. Let us now introduce the stochastic exponential, or Doléans–Dade exponential, and its generalization. Since it is necessary for our computations, we list some properties. The proofs can be found in Protter [15, Chapter II.8].

Let X_t be a semimartingale whose martingale part is purely discontinuous. The stochastic exponential $\mathcal{E}(X)_t$ is defined by

$$\mathcal{E}(X)_t = \exp(X_t - X_0) \prod_{s\le t} [(1 + \Delta X_s)\exp(-\Delta X_s)].$$

Before giving an estimate of $\|\mathcal{E}(X)_t\|_p$, $p \ge 2$, we state the following lemmas.

LEMMA 2.2 (Bass and Cranston [3, Lemma 5.2]). *Let $n \ge 1$ and $p = 2^n$. Suppose that $h(s,z)$ is predictable and $|h(s,z)| \le K_s \bar{h}(z)$, where $\bar{h}$ is a deterministic bounded function that is in $L^2(\nu)$. Suppose that $Z_t = \int_0^t \int h(s,z)(\mu - \gamma)(dz, ds)$ and let $Z_t^* = \sup_{0\le s\le t} |Z_s|$. Then we have $\mathbb{E}[Z_t^{*p}] \le c^*(p, \bar{h}, t) \int_0^t \mathbb{E}[\,|K_s|^p]\, ds$ and $\mathbb{E}[Z_t^p] \le c(p, \bar{h}, t) \int_0^t \mathbb{E}[|K_s|^p]\, ds$.*

REMARK 2.8. *Analyzing the proof of* [3, Lemma 5.2]*, we see that*

$$c^*(p, \bar{h}, t) \le \bar{c}(t) c(2^n) \Big(2^{p-1} c(2^{n-1}) \Big(2^{p-1} \dots \Big(2^{p-1} c(4) \times \Big(c(2)|\bar{h}|_{2^n}^{2^n} + |\bar{h}|_{2^{n-1}}^{2^n}\Big) + |\bar{h}|_{2^{n-2}}^{2^n}\Big) + \cdots\Big) + |\bar{h}|_2^{2^n}\Big),$$

where the constant $c(p)$ arises by the Burkholder–Gundy inequality, $\bar{c}(t) \ge 1$ and increasing in t. Thus, if $|\bar{h}|_q \le \bar{m}$ for all $q \ge 2$, then $c^*(p, \bar{h}, t) \le c(p,t)\,\bar{m}^p$ for a constant $c(p,t)$ depending only on p and t. Further, we have $c(p, \bar{h}, t) \le c(t)\, 2^{np} \sum_{k=1}^n |h|_{2^k}^{2^n}$.

Proof. For the first part see [3, Lemma 5.2]. For the second part, the only difference is that we use the isometry of the stochastic integral instead of the Burkholder inequality. □

COROLLARY 2.3. *Let X_t be a solution of $X_t = x_0 + \int_0^t \int \sigma(X_{s^-}, z)\,(\mu-\gamma)(dz, ds) + \int_0^t b(X_{s^-})\,ds$, where $\sup_x \sigma(x,z)$ is bounded by a bounded deterministic function $\bar{h}(z)$ in $L^2(\nu)$. Furthermore, assume that $b(x)$ is bounded by m_b. Then for $n \geq 1$ and $p = 2^n$,*

$$\|\mathcal{E}(X)_t^*\|_p^p \leq 2^{p-1}\,\exp(x_0 p)\,\exp\left(2^{p-1}\left[c^*(p,\bar{h},t) + m_b^p\right]\,t\right)$$

and

$$\|\mathcal{E}(X)_t\|_p^p \leq 2^{p-1}\,\exp(x_0 p)\,\exp\left(2^{p-1}\left[c(p,\bar{h},t) + m_b^p\right]\,t\right),$$

where the constants $c^*(p,\bar{h},t)$ and $c(p,\bar{h},t)$ coincide with those in Lemma 2.2.

Proof. Note that $\mathbb{E}\left[X_t^{*p}\right]^{\frac{1}{p}}$ is a norm for $p \geq 2$ (see Protter [15, Chapter V.2]). By Lemma 2.2 we have

$$\mathbb{E}\left[\left|\mathcal{E}(X)_t - \exp(x_0) - \int_0^t \mathcal{E}(X)_{s^-} b(X_{s^-})\,ds\right|^{*\,p}\right] \leq c^*(p,\bar{h},t)\int_0^t \mathbb{E}\left[|\mathcal{E}(X)_s|^p\right]\,ds.$$

The triangle inequality yields

$$\mathbb{E}\left[\mathcal{E}(X)_t^{*p}\right]^{\frac{1}{p}} \leq \exp(x_0) + m_b\left(\int_0^t \mathbb{E}\left[\mathcal{E}(X)_s^{*p}\right]\,ds\right)^{\frac{1}{p}} + \left(c^*(p,\bar{h},t)\int_0^t \mathbb{E}\left[\mathcal{E}(X)_s^{*p}\right]\,ds\right)^{\frac{1}{p}}$$

and therefore

$$\mathbb{E}\left[|\mathcal{E}(X)_t|^{*p}\right] \leq 2^{p-1}\left(\exp(px_0) + \left(c^*(p,\bar{h},t) + m_b^p\right)\int_0^t \mathbb{E}\left[\mathcal{E}(X)_s^{*p}\right]\,ds\right).$$

Gronwall's lemma then yields the assertion. The proof of the second inequality is in analogy. □

Let H_t be a càdlàg and adapted semimartingale and suppose that X_t satisfies the assumption of Corollary 2.3. The generalization of the stochastic exponential is the solution of the SDE $Z_t = H_t + \int_0^t Z_{s^-}\,dX_s$, which is explicitly given by $Z_t = \mathcal{E}_H(X)_t = \mathcal{E}(X)_t(H_0 + \int_0^t \mathcal{E}(X)_s^{-1} dH_s)$. Suppose that $H_0 = 0$. As above, we can show that for $n \geq 1$ and $p = 2^n$ we have

$$\left\|Z_t - H_t - \int_0^t b(X_{s^-})Z_{s^-}\,ds\right\|_p^p \leq c(p,\bar{h},t)\int_0^t \|Z_s\|_p^p\,ds.$$

The triangle inequality implies

$$\|\mathcal{E}_H(X)_t\|_p = \|Z_t\|_p \leq \|H_t\|_p + m_b\left(\int_0^t \|Z_s\|_p^p\,ds\right)^{\frac{1}{p}} + \left(c(p,\bar{h},t)\int_0^t \|Z_s\|_p^p\,ds\right)^{\frac{1}{p}}.$$

Therefore we get

$$\|\mathcal{E}_H(X)_t\|_p^p \leq 2^{p-1}\|H_t\|_p^p + 2^{p-1}\left(c(p,\bar{h},t) + m_b^p\right)\int_0^t \|\mathcal{E}_H(X)_s\|_p^p\,ds. \tag{2.2}$$

Proceeding as above, we also obtain

$$\|\mathcal{E}_H(X)_t^*\|_p^p \leq 2^{p-1}\|H_t\|_p^p + 2^{p-1}\left(c^*(p,\bar{h},t) + m_b^p\right)\int_0^t \|\mathcal{E}_H(X)_s^*\|_p^p\,ds. \tag{2.3}$$

If $\|H_t\|_p$ in (2.2) or (2.3) is of polynomial growth in t, i.e., $\|H_t\|_p = O(t^\delta)$ for some $\delta \in \mathbb{R}$, $\delta \geq 0$, we can apply the following modification of Gronwall's lemma to obtain an estimate of $\mathcal{E}_H(X)_t$.

LEMMA 2.4 (modification of Gronwall's lemma). *Suppose that g is a continuous function satisfying $0 \leq g(t) \leq a\,t^\delta + \beta \int_0^t g(s)ds$ for $0 \leq t \leq T$ with $\beta > 0$, $\delta \in \mathbb{R}$, $\delta \geq 0$. Then $g(t) \leq a\,t^\delta \exp(\beta t)$ for $0 \leq t \leq T$.*

Proof. Using Gronwall's lemma and integration by parts, the proof is done by direct calculations. □

Now assume that $\|H_t\|_p = O(t^\delta)$ for some $\delta \in \mathbb{R}$, $\delta \geq 0$. A combination of Lemma 2.4 and (2.2) leads to the estimate

$$\|\mathcal{E}_H(X)_t\|_p^p \leq 2^{p-1}\, t^{\delta p} \exp\left(2^{p-1}\ \left(c(p,\bar{h},t) + m_b^p\right)\ t\right). \tag{2.4}$$

We now investigate the inverse of $\mathcal{E}(X)_t$ and $\mathcal{E}_H(X)_t$, where X_t satisfies the assumption of Corollary 2.3. First we have to make sure that the jump sizes are not too large. For this we additionally assume that there exists a $0 < \rho \leq 1$ such that there are no jumps ΔX_s smaller than $-(1-\rho)$ and larger than one. Since for fixed ω there is only a finite number of s such that $|\Delta X_s| \geq \frac{1}{2}$ on each compact interval, it is sufficient to show that

$$V_t = \prod_{0<s\leq t} \left(1 + \Delta X_s 1_{\{|\Delta X_s| \leq \frac{1}{2}\}}\right) \exp\left(-\Delta X_s 1_{\{|\Delta X_s| \leq \frac{1}{2}\}}\right)$$

converges and is of finite variation. But since $|\ln(1+x) - x|, |\ln(1-x) + x| \leq x^2/2$ for $|x| \leq 1/2$, it follows that both V_t and V_t^{-1} are bounded by $\exp([X,X]_t)$ (see also Bass and Cranston [3, p. 510]). Now, consider

$$U_t = \prod_{0<s\leq t} \left(1 + \Delta X_s 1_{\{|\Delta X_s| > \frac{1}{2}\}}\right) \exp\left(-\Delta X_s 1_{\{|\Delta X_s| > \frac{1}{2}\}}\right).$$

Because $\left(1 + \Delta X_s 1_{\{|\Delta X_s| > \frac{1}{2}\}}\right)^{-1} \leq \rho^{-1}$ and $|x| \leq 2x^2$ for $|x| \geq \frac{1}{2}$, U_t^{-1} is bounded by $\exp(2[X,X]_t)/\rho$. Thus we have $\mathcal{E}(X)_t^{-1} \leq C \cdot \exp(|X|_t^*) \exp(2[X,X]_t)$ a.s. Since $\sup_x \sigma(x,z)$ is bounded by a bounded deterministic function, Lemma 2.1 [3] shows that $\|\mathcal{E}(X)_t^{-1}\|_p$ is finite. Now, let $Z_t = \mathcal{E}_H(X)_t$, where X_t is defined in Corollary 2.3 and the jumps are bounded from below by $-(1-\rho)$, $0 < \rho < 1$, and from above by one. Then we have (see Bass and Cranston [3, p. 510]) $Z_t \geq \mathcal{E}(X)_t (\inf_{s\leq t} \mathcal{E}(X)_s^{-1}) H_t$, and, if H_t is invertible, $Z_t^{-1} \leq \mathcal{E}(X)_t^{-1} \mathcal{E}(X)_t^* (H_t)^{-1}$. Assume furthermore that X_t and σ, respectively, are quasi-stable of order zero between the indices α^+ and α^-, $0 < \alpha^- \leq \alpha^+ < 2$. We then obtain

$$\|\mathcal{E}(X)_t^{-1}\|_p^p \leq C(t, q_1, \bar{h}, m_b)\, \|H_t^{-1}\|_{q_2},$$

where $1/q_1 + 1/q_2 = 1/p$.

2.3. Malliavin calculus. In this section we recall briefly some main features of the Malliavin calculus for Poisson random measures. For details see Bass and Cranston [3] (we use the notation of this article) or the book of Bichteler, Gravereaux, and Jacod [5].

In the Wiener case, the key ingredient in the Malliavin calculus, or calculus of variations, is the introduction of a symmetric linear operator $\mathcal{L}$ defined on a dense subspace of the Hilbert space of $\mathcal{L}^2$ functionals, together with a bilinear form $\Gamma(\cdot,\cdot)$

defined by $\Gamma(X,Y) := \mathcal{L}(XY) - \mathcal{L}XY - X\mathcal{L}Y$, X, Y in the domain of $\mathcal{L}$. These operations satisfy that if X and Y are in the domain of $\mathcal{L}$ and ϕ is a C^1 function, then $\phi \circ X$ is also in the domain of $\mathcal{L}$ and $\mathbb{E}[\Gamma(\phi(X), Y)] = -\mathbb{E}[\phi'(X)\Gamma(X,Y)]$. This formula is also called the "integration by parts setting," and if $\Gamma(X,Y)$ is invertible, we can give an estimate of the quantity $\mathbb{E}[\phi'(X)F]$ for some $\mathcal{L}^2$ functional F. Bass and Cranston [3] transferred this idea to the Poissonian case to prove the existence of the local time for certain Lévy processes. To show the convergence of the Euler scheme we have to show that $\mathbb{E}[\phi^{(IV)}(X)Y]$ is bounded, where X is the solution to (1.1) and $Y \approx X - x_0$. In the following we recall the main results of the Malliavin calculus for quasi-stable processes.

One approach of the Malliavin calculus is due to Bismut and is based on a perturbation argument. In contrast to the Wiener case, infinitely many jumps have to be perturbed simultaneously—this essentially requires that the jump times of μ be left unchanged and that only the jump size be modified. We can do it as follows.

Define $\mathcal{M}_\infty^2 = \{h : h \text{ is predictable, and we have for some bounded deterministic function } H(z) \in \mathcal{L}^2(\mu)\colon\ |h(s,z,\omega)| \le H(z) \text{ for all } s,\ z \text{ a.s.}\}$. Suppose that $l \in \mathcal{M}_\infty^2$ with $|l(s,z)| \le 1$ a.s., and let

$$v(s,z) = \int_0^z l(s,y)dy. \tag{2.5}$$

Now the process X_t will be perturbed in direction l by shifting the random measure μ as $\mu^\epsilon(B \times [0,T]) = \int_0^t \int 1_B(z + \epsilon v(s,z))\mu(dz,ds)$, and

$$L_t = \int_0^t \int l(s,z)(\mu - \gamma)(dz,ds). \tag{2.6}$$

By the Girsanov transformation we can construct a martingale M_t^ϵ such that $\mu^\epsilon(B,[0,t]) - t\nu(B)$ is a local martingale. The martingale M_t^ϵ is given by the stochastic exponential of ϵL_t. The associated probability measure Q_t^ϵ is defined by its Radon–Nikodým derivative.

In the Wiener case, the Malliavin derivative is the Fréchet derivative of the perturbed path with respect to ϵ at $\epsilon = 0$. Analogously, the derivative for a functional G of μ in the direction of l is given in the following definition.

DEFINITION 2.5. *A functional G of μ will be called $\mathcal{L}^p(P)$ smooth with derivative $D_lG(\mu) \in \mathcal{L}^p(P)$ if for every $l \in \mathcal{M}_\infty^2$, $\mathbb{E}[|\epsilon^{-1}[G(\mu^\epsilon) - G(\mu) - \epsilon D_lG(\mu)]|^p] \longrightarrow 0$ as $\varepsilon \to 0$.*

Then the following theorem gives the integration by parts setting.

THEOREM 2.6 (Bass and Cranston [3, Theorem 3.4]). *Suppose that G is an $\mathcal{L}^1(P)$ smooth functional of μ and belongs to $\mathcal{L}^p(P)$ for some $p > 1$. Suppose that $l \in \mathcal{M}_\infty^2$, and L_t is defined by* (2.6). *Then $\mathbb{E}[G(\mu)L_t] = -\mathbb{E}[D_lG(\mu)]$.*

Let $h \in C^2$ with compact support and set $G(\mu) = h(Y)$. Suppose that Y is $\mathcal{L}^1$ smooth. From

$$\begin{aligned}|h(Y(\mu^\varepsilon)) - h(Y) - \epsilon h'(Y)D_lY| \le\ & |h(Y(\mu^\varepsilon)) - h(Y) - h'(Y)(Y(\mu^\epsilon) - Y)| \\ & + \|h'\| \cdot |Y(\mu^\epsilon) - Y - \epsilon D_lY|,\end{aligned}$$

and since $\epsilon^{-1}(Y(\mu^\epsilon) - Y(\mu))$ tends to $D_lY(\mu)$ as ϵ tends to zero in $\mathcal{L}^1$, we can conclude that $h(Y)$ is $\mathcal{L}^1(P)$ smooth with derivative $h'(Y)D_lY$. Moreover, thanks to Theorem 2.6 we know $\mathbb{E}[h'(Y)D_lY] = -\mathbb{E}[h(Y)L]$. Assume that D_lY is strictly positive. Let

F be a functional of μ. Setting $h_0(\mu) = h(Y(\mu))\ F(\mu)\ (D_lY)^{-1}(\mu)$ we obtain

$$\begin{aligned}\mathbb{E}[h_0(\mu)L] &= -\mathbb{E}[D_l h_0(\mu)] \\ &= -\mathbb{E}[h'(Y)F(\mu) + h(Y)D_lF(\mu)(D_lY)^{-1} + h(Y)F(\mu)(D_lY)^{-2}D_l^2Y],\end{aligned}$$

and therefore

$$\mathbb{E}[h'(Y)F(\mu)] = -\mathbb{E}[h(Y)H_Y\,[F(\mu)]], \tag{2.7}$$

where $H_Y\,[F(\mu)] := (D_lY)^{-1}((D_lY)^{-1}D_l^2YF(\mu) + F(\mu)L + D_lF(\mu))$.

Suppose that X_t satisfies the hypothesis of Theorem 5.1 [3] and l belongs to $\mathcal{M}_\infty^2$. Then X_t is $\mathcal{L}^p(P)$ smooth for all $p \geq 1$ and the derivative D_lX_t is a solution to

$$\begin{aligned}D_lX_t = &\int_0^t \int \sigma_x(X_{s^-}, z)D_lX_{s^-}(\mu - \gamma)(dz, ds) + \int_0^t b_x(X_{s^-})D_lX_{s^-}ds \\ &+ \int_0^t \int \sigma_z(X_{s^-}, z)v(s, z)\mu(dz, ds),\end{aligned} \tag{2.8}$$

where v is given by (2.5).

Fix $k_0 \in \mathbb{N}$. Suppose in the next paragraph that $D_l^kX_t$ is well defined for $0 \leq k \leq k_0$ and $D_lX_t^{-1}$ exists. Until now we have investigated the forward variable. But considering $\mathbb{E}^x[f(X_t)] =: \mathbb{E}[f(X_t(x))]$ it is easy to see how the Malliavin calculus can be applied to the study of the backward variable x. We use the method of Gihman and Skorokhod [9, Chapter II.2.8] (see also Bichteler, Gravereaux, and Jacod [5, Proof of Theorem 28, resp., Chapter 4-c]), i.e.,

$$\partial_k^x\mathbb{E}[f(X_t)] = \sum_{i=1}^k \mathbb{E}^x\left[(\partial_{k-i+1}^y f)(y)\big|_{y=X_t}\nabla^i X_t\right],$$

where ∇X_t satisfies

$$\nabla X_t = 1 + \int_0^t \int \sigma_x(X_{s^-}, z)\nabla X_{s^-}(\mu - \gamma)(dz, ds) + \int_0^t b_x(X_{s^-})\nabla X_{s^-}\,ds, \tag{2.9}$$

and $\nabla^i X_t = \nabla^{i-1}\nabla X_t$. Now it follows from (2.7) that

$$\partial_k^x\mathbb{E}^x[f(X_t)] = \sum_{i=1}^k \mathbb{E}^x\left[f(X_t)H_X^{k-i+1}\left[\nabla_l^i X_t\right]\right]. \tag{2.10}$$

Now, assume that X_t is a solution of (1.1), where σ is quasi-stable of order one between indices α^- and α^+ with $\sigma_z(x, z)$ positive. Furthermore, assume that $\sigma : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ and $b : \mathbb{R} \to \mathbb{R}$ satisfy the following hypotheses for some constants M and m_b (compare also Bass and Cranston [3, Theorem 4.4]):

- (H0*) The function $\sigma_x(x, z)$ satisfies inequality (1.2) uniformly in x for $i = 0$ and $|z| > z_0$, $0 \leq z_0 < \infty$.
- (H1*) $\sup_{(x,z)} |\sigma_z(x, z)| \leq M$.
- (H2*) (i) $\sup_x |b_x(x)| \leq m_b$.
  (ii) $\sup_{x,z} |\sigma_x(x, z)| \leq M$ and $\sup_x |\sigma_x(x, \cdot)|_p \leq M$.
- (H3*) Let $z_0(x) = \sup_z\{|\sigma_x(x, z)| > \frac{1}{4}\}$. Then $|\sigma_x(x, z)/\sigma_z(x, z)|$ is bounded by M for all $|z| < z_0(x)$, with the convention that $0/0 = 0$.

Next we have also to specify the direction of the derivative, i.e., the function l. Of course, there are many choices of l, but l should be chosen so that $D_l X_t$ is invertible and $\|D_l X_t\|_p$ is not too large. Our choice is

$$l(s,z) = \frac{\partial}{\partial z}\left(\frac{z^2}{1+|z|^{1+\frac{1}{p_0}}}\right) - \frac{\partial}{\partial z}\left(\frac{\sigma_x(X_{s^-},z)}{\sigma_z(X_{s^-},z)}\varphi\left(\sigma_x(X_{s^-},z)\right)\right) D_l X_{s^-}, \tag{2.11}$$

where $\frac{1}{2} < p_0 < \frac{2}{3}$ and $\varphi \in C^3(\mathbb{R})$ such that $\varphi^{(i)}(x) \leq 40$, $i = 1,2,3,4$, and

$$\varphi(x)\begin{cases} = & 0, & x \in \left(-\frac{1}{4}, \frac{3}{4}\right), \\ \in & (0,1), & x \in \left(-\frac{3}{4}, -\frac{1}{4}\right) \cup \left(\frac{3}{4}, 1\right), \\ = & 1, & x \in \left(-\infty, -\frac{3}{4},\right) \cup (1, \infty). \end{cases}$$

In fact, $l(s,z)$ does not belong to $\mathcal{M}_\infty^2$. But as in Bass and Cranston [3, Proof of Theorem 4.4, p. 509] we can show under the hypothesis (H0*), (H1*), (H2*), and (H3*) and a limit argument that this choice is valid. For simplicity, we write $v(s,z) = v_1(z) + v_2(s,z)$.

Remark 2.9. *Defining $\phi(x,z) := (\varphi \circ \sigma_x)(x,z)$ and taking* (H0*) *into account, we see that the set $\cup_{x\in\mathbb{R}}\{z \in \mathbb{R};\, \phi(x,z) \neq 0\}$ has finite mass. Analogously, defining $\phi'(x,z) := (\varphi' \circ \sigma_x)(x,z)$, the set $\cup_{x\in\mathbb{R}}\{z \in \mathbb{R};\, \phi'(x,z) \neq 0\}$ has finite mass.*

The process $D_l X_t = Y_t$ can also be written as a Doléans–Dade exponential, i.e., $Y_t = \int_0^t Y_{s^-}\, dK_s + H_t$, where K_t and H_t are given by

$$\begin{aligned} K_t &= \int_0^t \int \sigma_x(X_{s^-},z)(\mu-\gamma)(dz,ds) + \int_0^t b_x(X_{s^-})ds \\ &\quad - \int_0^t \int \sigma_x(X_{s^-},z)\varphi(\sigma_x(X_{s^-},z))\mu(dz,ds), \end{aligned} \tag{2.12}$$

$$H_t = \int_0^t \int \sigma_z(X_{s^-},z)v_1(z)\mu(dz,ds). \tag{2.13}$$

Our next objective is to give an upper bound of the derivative $D_l X_t$. For clarity, we set $\alpha = \alpha^+$. Since $\gamma(dz,ds) = \nu(dz)\,ds = dz\,ds$, we can write for K_t

$$\begin{aligned} K_t &= \int_0^t \int \sigma_x(X_{s^-},z)\left[1-\varphi(\sigma_x(X_{s^-},z))\right](\mu-\gamma)(dz,ds) \\ &\quad - \int_0^t \int \sigma_x(X_{s^-},z)\varphi(\sigma_x(X_{s^-},z))\,dz\,ds + \int_0^t b_x(X_{s^-})ds. \end{aligned} \tag{2.14}$$

Let $h_K(z) := \sup_x \sigma_x(x,z)\left[1-\varphi(\sigma_x(x,z))\right]$. Note that $h_K(z)$ is bounded from below by $-\frac{3}{4}$ and from above by one. Moreover, by Remark 2.9 the function $\sigma_x(x,\cdot)\varphi(\sigma_x(x,\cdot))$ has a uniformly bounded support in x, and since $\sup_{x,z}|\sigma_x(x,z)|$ is bounded, the integral $\int \sigma_x(x,z)\varphi(\sigma_x(x,z))\,dz$ is bounded uniformly for all x. Setting $C_a = \sup_x\left|\int \sigma_x(x,z)\ \varphi(\sigma_x(x,z))\,dz\right|$, we obtain by (2.3)

$$\|D_l X_t^*\|_p^p \leq 2^{p-1}\|H_t\|_p^p + 2^{p-1}\left(c^*(p,h_K,t) + (m_b + C_a)^p\right)\int_0^t \|D_l X_s^*\|_p^p\,ds,$$

where $p = 2^n$ for some $n \geq 1$ and H_t is given by (2.13). Let us define

$$\sigma_H^+ = \sup_{x,z}|z|^{-\frac{1}{\alpha}-\frac{1}{p_0}}|\sigma_z(x,z)v_1(z)| \quad \text{and} \quad m_H = {\sigma_H^+}^{-1}\sup_{x,z}\left(|\sigma_z(x,z)v_1(z)| \vee 1\right).$$

Since $\sigma(x,z)$ is quasi-stable of order one, we know that $\sigma_H^+ < \infty$ and σ_H^+ is strictly larger than zero. Therefore and by (H1*), it follows that $m_H < \infty$. Proposition 2.1 leads to $\|H_t\|_p \le \sigma_H^+ \|Z_t^H\|_p$, where

$$Z_t^H = \int_0^t \int \left(m_H \wedge |z|^{-\frac{1}{\alpha}-\frac{1}{p_0}} \right) \mu(dz,ds).$$

By Proposition 2.2 we obtain $t^{-\delta_H}\|Z_t^H\|_p \le C(T)\,\sigma_H^+ m_H \le C(T)\,M$ for $0<t<T$ and $1/p_0 + 1/\alpha > \delta_H$. It follows by a generalization of Gronwall's lemma 2.4 (see also (2.4)) that

$$t^{-\delta_H}\|D_l X_t^*\|_p^p \le C(T)\,M^p\,2^{p-1}\,\exp\left(2^{p-1}\left(c^*(p,h_K,t) + (m_b + C_a)^p\right)\,t\right). \tag{2.15}$$

Assume $\sigma(x,z)$ is a quasi-stable process with indices α^+ and α^- of order five satisfying the hypotheses of Theorem 1.2. Our next objective is to compute the Malliavin derivative $D_l^2 X_t$. The second derivative $D_l^2 X$ satisfies the SDE

$$\begin{aligned}
D_l^2 X_t = &\int_0^t \int \left[\sigma_{xx}(X_{s^-},z) D_l X_{s^-}^2 + \sigma_x(X_{s^-},z) D_l^2 X_{s^-}\right](\mu-\gamma)(dz,ds) \\
&+ \int_0^t \left[b_{xx}(X_{s^-}) D_l X_{s^-}^2 + b_x(X_{s^-}) D_l^2 X_{s^-}\right] ds \\
&- \int_0^t \int \partial_x\left(\sigma_x(X_{s^-},z)\varphi(\sigma_x(X_{s^-},z))\right) D_l X_{s^-}^2\,\mu(dz,ds) \\
&- \int_0^t \int \sigma_x(X_{s^-},z)\varphi(\sigma_x(X_{s^-},z)) D_l^2 X_{s^-}\,\mu(ds,dz) \\
&+ \int_0^t \int \sigma_{xz}(X_{s^-},z) D_l X_{s^-} v_1(z)\mu(dz,ds) \\
&+ \int_0^t \int \Big[\sigma_{xz}(X_{s^-},z) D_l X_{s^-} + \partial_z\left(\sigma_x(X_{s^-},z)\varphi(\sigma_x(X_{s^-},z))\right) D_l X_{s^-} \\
&\qquad + \partial_z\left(\sigma_z(X_{s^-},z) v_1(z)\right)\Big] v(s,z)\,\mu(dz,ds).
\end{aligned}$$

Analogously to $D_l X_t$, we can write $D_l^2 X_t$ as a generalized stochastic exponential with $\bar{H}$ and K defined by (2.14) and

$$\begin{aligned}
\bar{H}_t = &\int_0^t \int \sigma_{xx}(X_{s^-},z) D_l X_{s^-}^2 (\mu-\gamma)(dz,ds) + \int_0^t b_{xx}(X_{s^-}) D_l X_{s^-}^2\,ds \\
&+ \int_0^t \int 2 D_l X_{s^-}\sigma_{xz}(X_{s^-},z) v_1(z)\mu(dz,ds) \\
&+ \int_0^t \int \sigma_z(X_{s^-},z) v_1(z) v_{1\,z}(z) + \sigma_{zz}(X_{s^-},z) v_1^2(z)\,\mu(dz,ds) \\
&+ \int_0^t \int \left\{a_1(X_{s^-},z) D_l X_{s^-}^2 + a_2(X_{s^-},z) D_l X_{s^-}\right\}\mu(dz,ds),
\end{aligned} \tag{2.16}$$

where

$$\begin{aligned}
a_1(x,z) &= \frac{\sigma_{xz}(x,z)}{\sigma_z(x,z)}\sigma_x(x,z)\phi(x,z) - \partial_x\big(\sigma_x(x,z)\phi(x,z)\big) \\
&\qquad + \partial_z\big(\sigma_x(x,z)\phi(x,z)\big)\frac{\sigma_x(x,z)}{\sigma_z(x,z)}\phi(x,z), \\
a_2(x,z) &= \partial_z\big(\sigma_z(x,z)v_1(z)\big)\frac{\sigma_x(x,z)}{\sigma_z(x,z)}\phi(x,z).
\end{aligned}$$

Note that we set $\phi(x,z) := (\varphi \circ \sigma_x)(x,z)$ and $\phi'(x,z) = (\varphi' \circ \sigma_x)(x,z)$.

REMARK 2.10. *Set*

$$A_{1t} = \int_0^t \int a_1(X_{s^-}, z)\, \mu(dz, ds),$$
$$A_{2t} = \int_0^t \int a_2(X_{s^-}, z)\, \mu(dz, ds).$$

By Remark 2.9 *we know the processes* A_{1t} *and* A_{2t} *are compound Poisson processes. Thanks to condition* (H3)*, the quantities* $\sup_{x,z} |a_1(x,z)|$ *and* $\sup_{x,z} |a_2(x,z)|$ *are bounded by* CM^2 *and by* M*. Combining Remarks* 2.2 *and* 2.3 *yields* $t^{-n}\|A_{1t}\|_p \leq \frac{3}{4}\, C(T)\, M^2$ *and* $t^{-n}\|A_{2t}\|_p \leq \frac{3}{4}\, C(T)\, M$ *for* $0 < t \leq T$ *and* $n = 2^k$*,* $k \in \mathbb{N}$.

Analogous to (2.3), we obtain

$$\|D_l^2 X_t^*\|_p^p \leq 2^{p-1}\, \|\bar{H}_t\|_p^p + 2^{p-1}\, (c^*(p, h_K, t) + (m_b + C_a)^p) \int_0^t \|D_l^2 X_s^*\|_p^p\, ds. \tag{2.17}$$

Defining $J_t = \int_0^t \int \sigma_{xz}(X_{s^-}, z) v_1(z)\, \mu(dz, ds)$ and $V_t = \int_0^t \int \sigma_z(X_{s^-}, z) v_1(z) v_{1z}(z) + \sigma_{zz}(X_{s^-}, z) v_1^2(z)\, \mu(dz, ds)$, we can write for $\bar{H}_t$

$$\begin{aligned}\bar{H}_t = &\int_0^t \int \sigma_{xx}(X_{s^-}, z) D_l X_{s^-}^2 (\mu - \gamma)(dz, ds) + \int_0^t b_{xx}(X_{s^-}) D_l X_{s^-}^2\, ds \\ &+ \int_0^t D_l X_{s^-}\, dJ_t + V_t + \int_0^t D_l X_{s^-}^2\, dA_{1s} + \int_0^t D_l X_{s^-}\, dA_{2s}.\end{aligned}$$

Applying Lemma 2.2 to the first summand and Emery's inequality to the third, fifth, and sixth summands, we obtain

$$\begin{aligned}\|\bar{H}_t\|_p^p \leq (c\,(p,t)\; M^p + m_b^p) &\int_0^t \|D_l X_s^2\|_p^p\, ds + \|D_l X_t^*\|_{q_1}^p \|J_t\|_{q_2}^p + \|V_t\|_p^p \\ &+ \|D_l X_t^{*2}\|_{2q_1}^p \|A_{1t}\|_{q_2}^p + \|D_l X_t^*\|_{q_1}^p \|A_{2t}\|_{q_2}^p,\end{aligned}$$

where $1/q_1 + 1/q_2 = 1/p$. Let σ_J^+ and σ_V^+ be two constants given by $\sigma_J^+ = \sup_{(x,z)} |z|^{\frac{1}{\alpha} + \frac{1}{p_0}} |\sigma_{xz}(x,z) v_1(z)|$ and $\sigma_V^+ = \sup_{(x,z)} |z|^{\frac{1}{\alpha} + \frac{2}{p_0}} |\sigma_z(x,z) v_1(z) v_{1z}(z) + \sigma_{zz}(x,z) v_1^2(z)|$, respectively. The suprema exist and are finite, because we have first (see (2.11)) $\sup_z |z|^{\frac{1}{p_0}} v_1(z) \leq C \cdot z$ for some $C > 0$ and second, by condition (H1), $\sup_{(x,z)} |z|^{\frac{1}{\alpha}+1} \sigma_{xz}(x,z) \leq C$. Note that the constant C may vary from line to line. Thus, we have $\sup_{(x,z)} |z|^{\frac{1}{\alpha} + \frac{1}{p_0}} \sigma_{xz}(x,z) v_1(z) \leq C < \infty$, and therefore σ_J^+ exists and is finite. To show the existence of σ_V^+, we have to take into account that $\sigma(x,z)$ is quasi-stable at least of order two. Let

$$m_J = \big(\sigma_J^+\big)^{-1} \sup_{x,z} \big(|\sigma_{xz}(x,z) v_1(z)| \vee 1\big),$$

and

$$m_V = (\sigma_Z^+)^{-1} \sup_{x,z} \big(|\sigma_z(x,z) v_1(z) v_{1z}(z) + \sigma_{zz}(x,z) v_1^2(z)| \vee 1\big).$$

Setting $h_J(s,z,\omega) = \sigma_{xz}(X_{s^-}(\omega), z) v_1(z)$ and

$$h_V(s,z,\omega) = \sigma_z(X_{s^-}(\omega), z) v_1(z) v_{1z}(z) + \sigma_{zz}(X_{s^-}(\omega), z) v_1^2(z),$$

we know

$$\sup_{(s,z,\omega)} |z|^{\frac{1}{\alpha}+\frac{1}{p_0}} h_J(s,z,\omega) \le \sigma_J^+ \quad \text{and} \quad \sup_{(s,z,\omega)} |z|^{\frac{1}{\alpha}+\frac{2}{p_0}} h_V(s,z,\omega) \le \sigma_V^+,$$

respectively, and therefore h_J and h_V are quasi-stable of order zero with above indices $(1/\alpha + 1/p_0)^{-1}$ and $(1/\alpha + 2/p_0)^{-1}$, respectively. Further, let $Z_t^J = \int_0^t \int (m_J \wedge |z|^{-\frac{1}{\alpha}-\frac{1}{p_0}})\mu(dz,ds)$ and $Z_t^V = \int_0^t \int (m_V \wedge |z|^{-\frac{1}{\alpha}-\frac{2}{p_0}})\mu(dz,ds)$. Since $(1/\alpha+1/p_0)^{-1} < 1$ and $(1/\alpha+2/p_0)^{-1} < 1$, we can apply Proposition 2.1 in order to get $\|J_t\|_p \le \sigma_J^+ \|Z_t^J\|_p$ and $\|V_t\|_p \le \sigma_V^+ \|Z_t^V\|_p$, respectively. Proposition 2.2 yields $t^{-\delta_J}\|Z_t^J\|_p \le C(T)\,\sigma_J^+ m_J \le C(T)\,M$ for $1/p_0 + 1/\alpha > \delta_J = \delta_H$ and $t^{-\delta_V}\|Z_t^V\|_p \le C(T)\,\sigma_V^+ m_V \le C(T)\,M$ for $2/p_0 + 1/\alpha > \delta_V$ and $0 < t \le T$, respectively. Thus, we can conclude for $\bar{H}_t$ and $0 < t \le T$ that

$$\begin{aligned}
t^{-\delta_V p}\|\bar{H}_t\|_p^p &\le \left(c(p,t)\,M^p + m_b^p\right)\, t^{-\delta_V p}\, 2^{2p-1} \\
&\quad \times \int_0^t s^{2\delta_H p} \exp\left(2^{2p-1}\left(c(2p,h_K,t) + (m_b+C_a)^{2p}\right)s\right)\, ds \\
&\quad + M^p\, 2^{2p-1} \exp\left(2^{2p-1}\left(c^*(2p,h_K,t) + (m_b+C_a)^{2p}\right)t\right)\, \underbrace{t^{-\delta_J p}\|J_t\|_p^p}_{\le C(T)M^p} + \underbrace{t^{-\delta_V p}\|V_t\|_p^p}_{\le C(T)M^p} \\
&\quad + \|D_l X_t^{*2}\|_{2q_1}^p \underbrace{t^{-\delta_V p}\|A_{1t}\|_{q_2}^p}_{\le C(T)\,M^{2p}} + \|D_l X_t^*\|_{q_1}^p \underbrace{t^{-\delta_V p}\|A_{2t}\|_{q_2}^p}_{\le C(T)\,M^p}.
\end{aligned}$$

Substituting $\bar{H}_t$ in (2.17) and applying Lemma 2.4 we get for $q_1 = q_2 = 2p$

$$\begin{aligned}
t^{-\delta_V p}\|D_l^2 X_t^*\|_p^p &\le C\left(M^{4p} + m_b^p\right) \\
&\quad \times \exp\left(2^{2p-1}\left(c^*(4p,h_K,t) + (m_b+C_a)^{4p}\right)t\right). \qquad (2.18)
\end{aligned}$$

Therefore $t^{-\delta_V}\|D_l^2 X_t^*\|_p$ is uniformly bounded by $C(T)\,M^4$ in t on $(0,T]$. Iterating (2.18) we obtain that $D_l^3 X_t$ equals $\mathcal{E}_{\hat{H}}(K)_t$, where K_t is given by (2.12) and

$$\begin{aligned}
\hat{H}_t &= \int_0^t \int \left[3\sigma_{xx}(X_{s^-},z) D_l X_{s^-} D_l^2 X_{s^-} + \sigma_{xxx}(X_{s^-},z) D_l X_{s^-}^3\right](\mu-\gamma)(dz,ds) \\
&+ \int_0^t \left[3b_{xx}(X_{s^-}) D_l X_{s^-} D_l^2 X_{s^-} + b_{xxx}(X_{s^-}) D_l X_{s^-}^3\right] ds \\
&+ \int_0^t \int \left\{3\sigma_{xz}(X_{s^-},z) v_1(z) D_l^2 X_{s^-} + \cdots + \sigma_z(X_{s^-},z) v_{1z}^2\right\}\mu(dz,ds) \\
&+ \int_0^t \int \left[\hat{a}_1(X_{s^-},z) D_l X_{s^-}^3 + \hat{a}_2(X_{s^-},z) D_l X_{s^-} D_l^2 X_{s^-} + \hat{a}_3(X_{s^-},z) D_l^2 X_{s^-}\right. \\
&\qquad \left. + \hat{a}_4(X_{s^-},z) D_l X_{s^-}^2 + \hat{a}_5(X_{s^-},z) D_l X_{s^-}\right]\mu(dz,ds), \qquad (2.19)
\end{aligned}$$

where $\hat{a}_i(x,z)$ $i = 1,\ldots,5$, have bounded support (see condition (H3)). Observe that $\hat{a}_1(x,z) = \partial_x^2(\sigma_x(x,z)\phi(x,z)) + \cdots \le C\,M^3$, $\hat{a}_2(x,z) \le C\,M^3$, $\hat{a}_3(x,z), \hat{a}_4(x,z) \le C\,M^2$, and $\hat{a}_5(x,z) \le C\,M$. Further we have the identity $D_l^4 X_t = \mathcal{E}_{\tilde{H}}(K)_t$, where K_t is given in (2.12) and

$$\tilde{H}_t = \int_0^t \int \left\{4\sigma_{xx}(X_{s^-},z) D_l^3 X_{s^-} D_l X_{s^-} + \cdots + \sigma_z(X_{s^-},z) v_1(z) v_{1z}^3(z)\right\}\mu(dz,ds)$$

$$+\int_0^t\int\Big[\tilde a_1(X_{s^-},z)D_lX_{s^-}^4+\tilde a_2(X_{s^-},z)D_lX_{s^-}^3D_lX_{s^-}\\ +\cdots+\hat a_9(X_{s^-},z)D_lX_{s^-}\Big]\mu(dz,ds).$$

Next, we investigate in the norm of $D_l^3X_t$. Defining $\hat A_{it}=\int_0^t\int\hat a_1(X_{s^-},z)\mu(dz,ds)$, we know

$$\begin{aligned}\|\hat H_t\|_p^p\le C\ (M^p+m_b^p)\ \Big[\|D_lX_t^3\|_p^p+\|D_lX_t^2\|_{2p}^p\|D_lX_t\|_{2p}^p\Big]\,ds\\ +\|D_lX_t^{2*}\|_{2p}^p\ \|J_t^1\|_{2p}^p\|D_l^2X_t^*\|_{2p}^p\ \|J_t^2\|_{2p}^p\\ +\|D_lX_t{}^*\|_{2p}^p\ \|V_t\|_{2p}^p+\|W_t\|_p^p+\|D_lX_t^{3*}\|_{2p}^p\|\hat A_{1t}\|_{2p}^p\\ +\|D_l^2X_t{}^*\|_{3p}^p\|D_lX_t{}^*\|_{3p}^p\ \|\hat A_{2t}\|_{3p}^p+\cdots+\|D_lX_t{}^*\|_{2p}^p\ \|\hat A_{9t}\|_{2p}^p,\end{aligned}\tag{2.20}$$

where $J_t^1=\int_0^t\int 2\sigma_{xxz}(X_{s^-},z)v_1(z)\mu(dz,ds)$, $J_t^2=\int_0^t\int 3\sigma_{xz}(X_{s^-},z)v_1(z)\mu(dz,ds)$, $V_t=\int_0^t\int 3\big(\sigma_{xzz}(X_{s^-},z)v_1(z)+\sigma_{xz}(X_{s^-},z)v_{1z}(z)\big)v_1(z)\mu(dz,ds)$, and

$$\begin{aligned}W_t&=\int_0^t\int\partial_z\big(\partial_z\big(\sigma_z(X_{s^-},z)v_1(z)\big)v_1(z)\big)v_1(z)\mu(dz,ds)\\ &=:\int_0^t\int h_W(s,z,\omega)\mu(dz,ds).\end{aligned}\tag{2.21}$$

By the same arguments as above and Proposition 2.1, we can conclude that $\|J_t^i\|_p\le C_i(T)\,\|Z_t^{m_i}\|_p$ for $i=1,2$, for $0<t\le T$, and for some C_i and m_i such that $C_im_i\le M$. Applying Proposition 2.2 yields that $t^{-\delta_H}\|J_t^i\|_p$ and $t^{-\delta_V}\|V_t\|_p^p$ are uniformly bounded by $C(T)\,M$ as t tends to zero, $i=1,2$. It remains to tackle W_t. Since $\sigma(x,z)$ is quasi-stable at least of order three, we know that $\sup_{x,z}|z|^{\frac1\alpha}\sigma_{zzz}(x,z)\le C\,|z|^3$. By definition of $v_1(z)$, we know that $\sup_z|z|^{\frac1{p_0}}|v_1(z)|\le C|z|$ and $\sup_z|z|^{\frac1{p_0}}|v_{1z}(z)|\le C|z|^2$. Therefore we have $\sup_{x,z}|z|^{\frac3{p_0}+\frac1\alpha}|\sigma_{zzz}(v_1^2(z)+v_{1z}(z))v_1(z)|\le C<\infty$. Analogously, we can show $\sup_{x,z}|z|^{\frac3{p_0}+\frac1\alpha}|\sigma_{zz}(X_{s^-},z)\partial_z(v_1^2(z)+v_{1z}(z))v_1(z)|\le C<\infty$. Thus, $\sigma_W^+=\sup_{x,z}|z|^{\frac3{p_0}+\frac1\alpha}|\partial_z(\partial_z(\sigma_z(x,z)v_1(z))v_1(z))v_1(z)|$ is finite and strictly larger than zero. Let $m_W=\sigma_W^{+\,-1}(\sup_{x,z}|\partial_z(\partial_z(\sigma_z(x,z)v_1(z))v_1(z))v_1(z)|\vee1)$. By Proposition 2.1 we know $W_t\le\sigma_W^+\int_0^t\int\big(m_W\wedge|z|^{-\frac3{p_0}-\frac1\alpha}\big)\mu(dz,ds)$, and by Proposition 2.2 $t^{-\delta_W}\|W_t\|_p$ is uniformly bounded on $[0,T]$ by $C(T)\,M$ for $3/p_0+1/\alpha>\delta_W$.

REMARK 2.11. *Note, concerning the processes $\hat A_{it}$, that the process which possesses the highest exponent in M is $\int_0^t\int D_lX_{s^-}D_l^2X_{s^-}d\hat A_{2\,s}$. To be more precise, we know $t^{-3p}\ \|\tilde A_{2t}\|_{3p}\ \|D_lX_t{}^*\|_{3p}\|D_l^2X_t{}^*\|_{3p}\le C\,M^8$ and that the other summands are at least of the same order.*

Combining (2.19), (2.4), and (2.20) we get

$$\begin{aligned}&t^{-\delta_W p}\|\hat H_t\|_p^p\le 2^{4p-1}\,C_1\ (M+m_b^p)\int_0^t\ \exp\Big(2^{4p-1}\Big(c^*(4p,h_K,t)+m_b^{4p}\Big)\,s\Big)\,ds\\ &+C_2\,M^{4p}\ \exp\Big(2^{4p-1}\Big(c(4p,h_K)+m_b^{4p}\Big)\,t\Big)\ t^{-i\delta_Hp}\ \big(\|J_t^1\|_{2p}^p+\|J_t^2\|_{2p}^p\big)\\ &+M^p\,C_3\ \exp\Big(2^{2p-1}\Big(c(2p,h_K)+m_b^{2p}\Big)\,t\Big)\ t^{-\delta_Vp}\|V_t\|_{2p}^p+C_4\ t^{-\delta_Wp}\|W_t^3\|_p^p\\ &+C_5M^{8p}\ \exp\Big(2^{2p-1}\Big(c(6p,h_K)+m_b^{2p}\Big)\,t\Big)\end{aligned}$$

as t tends to zero. Thus, we have

$$t^{-\delta_W p}\|D_l^3 X_t^*\|_p^p \le C(T)\, M^{8p}\ \exp\left(2^{8p-1}\left(c^*(8p,h_k,t)+m_b^{4p}\right)t\right). \tag{2.22}$$

REMARK 2.12. *Observe that the function h_K is bounded from above by one and from below by $-\frac{3}{4}$. Therefore since $|\sigma_x(x,z)| \le C|z|^{-\frac{1}{\alpha}}$ for z large enough, $|h_K|_p \le C(p)$ and the term $c^*(8p,h_K,t)$ is bounded by a constant $C(p,t)$ depending only on p and t.*

REMARK 2.13. *Analyzing the proof of the estimates* (2.15), (2.18), *and* (2.22) *we see (see also Remark* 2.11*) that the worst term is $\int_0^t D_l^{i-1} X_{s^-} D_l X_{s^-} d\dot{A}_{2s}$, where $\dot{A}$ equals A in the case of $i=2$, equals $\hat{A}$ in the case of $i=3$, and equals $\tilde{A}$ and in the case of $i=4$. A short calculation shows that the norm is bounded by M^{k_i}, where $k_i = k_{i-1}+1+i$, $k_2=4$.*

Analogously to the computations of $\|D_l^4 X_t^*\|$ and taking into account Remarks 2.12 and Remark 2.13, we obtain

$$\|D_l^4 X_t^*\|_p^p \le C(t)\, M^{13p}\ \exp\left(2^{16p}\left(c^*(16p,h_K,t)+m_b^{16p}\right)t\right) \le C(p,t,m_b)M^{13p}, \tag{2.23}$$

$$\|D_l^5 X_t^*\|_p^p \le C(t)\, M^{19p}\ \exp\left(2^{32p}\left(c^*(32p,h_K,t)+m_b^{32p}\right)t\right) \le C(p,t,m_b)M^{19p}. \tag{2.24}$$

Finally we have to investigate some estimates of $\|D_l^i \nabla^j X_t\|_p$, where $i+j \le 4$ and $\nabla^j X_t$ is given in (2.9). First, ∇X_t is the Doléans–Dade exponential $\mathcal{E}(K)_t$ with

$$K_t = \int_0^t \int \sigma_x(X_{s^-},z)(\mu-\gamma)(dz,ds) + \int_0^t b_x(X_{s^-})\,ds,$$

and norm $\|\mathcal{E}(K)_t^*\|_p \le \exp(\frac{1}{p}(c^*(p,t,\sigma_x)+m_b)t) \le \exp\left(c(p,t)\left(M^p+m_b\right)\right)$ for $p \ge 2$. Recursively applied, (2.9) yields $\nabla^i X_t = \mathcal{E}_{H_i}(K)_t$, where

$$\begin{aligned} H_{it} = &\sum \int_0^t \int \partial_x^j \sigma(X_{s^-},z)\nabla^{|I_1|}X_{s^-}\ldots\nabla^{|I_n|}X_{s^-}\,(\nu-\gamma)(dz,ds)\\ &+\sum \int_0^t \partial_x^j b(X_{s^-},z)\nabla^{|I_1|}X_{s^-}\ldots\nabla^{|I_n|}X_{s^-}\,ds, \end{aligned}$$

where the sum runs over the set of all partitions with length larger than 1 of $\{1,\ldots,i\} = I_1 \cup \cdots \cup I_\nu$ and $|\cdot|$ denotes the length. A short calculation yields

$$\begin{aligned} H_{2t} &= \int_0^t \int \sigma_{xx}(X_{s^-},z)\nabla X_{s^-}^2\,(\mu-\gamma)(dz,ds) + \int_0^t b_{xx}(X_{s^-},z)\nabla X_{s^-}^2\,ds,\\ &\ldots \quad \ldots\\ H_{4t} &= \int_0^t \int \left(\sigma_{xxxx}(X_{s^-},z)\nabla X_{s^-}^4 + \cdots + \sigma_{xx}(X_{s^-},z)\nabla^3 X_{s^-}\nabla X_{s^-}\right)(\mu-\gamma)(dz,ds)\\ &\quad + \int_0^t \left(b_{xxxx}(X_{s^-},z)\nabla X_{s^-}^4 + \cdots + b_{xx}(X_{s^-},z)\nabla^3 X_{s^-}\nabla X_{s^-}\right)ds. \end{aligned}$$

Applying [3, Lemma 2.1] we get for $p \ge 2$

$$\begin{aligned} &\|\nabla^2 X_t\|_p \le \exp\left(\frac{1}{p}(c(p,t,\sigma_x)+m_b)t\right)\cdot\|\nabla X_t^2\|_p \le \exp\left(C(p,t)(M^{2p}+m_b)\right),\\ &\|\nabla^3 X_t\|_p \le \exp\left(C(p,t)(M^{4p}+m_b)\right),\\ &\|\nabla^4 X_t\|_p \le \exp\left(C(p,t)(M^{8p}+m_b)\right). \end{aligned} \tag{2.25}$$

Obviously $D_l\nabla X_t$ is the generalized Doléans–Dade exponential $\mathcal{E}_H(K)_t$ with

$$H_t = \int_0^t \int \sigma_{xx}(X_{s^-},z) D_l X_{s^-} \nabla X_{s^-} (\mu-\gamma)(dz,ds)$$
$$+ \int_0^t \int \sigma_{xz}(X_{s^-},z) \left(v_1(z) + D_l X_{s^-} \frac{\sigma_x(X_{s^-},z)}{\sigma_z(X_{s^-},z)} \varphi(\sigma_x(X_{s^-},z)) \right) \nabla X_{s^-} v(s,z) \mu(dz,ds).$$

Remark 2.12 and hypotheses (H0), (H1), (H2), and (H3) lead to

$$\|H_t\| \leq C(p,t) \cdot M \cdot \int_0^t \|D_l X_s\|_{2p} \|\nabla X_s\|_{2p}\, ds,$$

and therefore

$$\|D_l \nabla X_t\|_p \leq C(p,t)\, M \, \exp\left(\frac{1}{p} \left(c^*(p,t,\sigma_x) + m_b \right) t \right) \cdot \|D_l X_t^*\|_{2p} \cdot \|\nabla X_t^*\|_{2p}$$
$$\leq C(t,p) \cdot M \cdot \exp\left(c(t,p)(M^{2p} + m_b) \right). \tag{2.26}$$

Iterating (2.18) yields

$$\|D_l^2 \nabla X_t\|_P \leq \exp\left(\frac{1}{p} \left(c(p,t,\sigma_x) + m_b \right) t \right) \|\nabla X_t\|_{2p} \left(M^2 \|D_l X_t^2\|_{2p} + M \|D_l^2 X_t\|_{2p} \right),$$
$$\leq C(t,p) M^5 \exp\left(c(t,p)(M^{2p} + m_b) \right),$$
$$\|D_l^3 \nabla X_t\|_P \leq C(t,p) M^9 \exp\left(c(t,p)(M^{2p} + m_b) \right),$$

and

$$\|D_l^4 \nabla X_t\|_P \leq C(t,p) M^{14} \exp\left(c(t,p)(M^{2p} + m_b) \right)$$

for $M \geq 1$. Finally we have for $D_l \nabla^4 X_t$

$$\|D_l \nabla^4 X_t\|_p \leq C(p,t) M \exp\left(c(t,p)(M^{8p} + m_b) \right). \tag{2.27}$$

As our last point we give an estimate of $\|L_t\|_p$ and $\|D_l^i L_t\|_p$, $i = 1, \ldots, 4$. Combining (2.6) and (2.11), we obtain

$$L_t = \int_0^t \int \frac{\partial}{\partial z} \left(\frac{z^2}{1+|z|^{1+\frac{1}{p_0}}} \right) (\mu-\gamma)(dz,ds) - \int_0^t \int \phi(x,z) D_l X_{s^-} \, (\mu-\gamma)(dz,ds)$$
$$=: L_t^1 - L_t^2.$$

A short calculation shows $t^{-\frac{1}{p_0}} \|L_t^1\|_p \leq C(p)$. Further, by the Emery and Burkholder–Gundy inequality it follows for L_t^2 and $p \geq 2$ that $t^{-\frac{1}{p_0}} \|L_t^2\|_p \leq M \|D_l X_t^*\|_p$ and therefore

$$t^{-\frac{1}{p_0}} \|L_t\|_p \leq (M^2 + 1). \tag{2.28}$$

Evaluating $D_l L_t$ we get

$$D_l L_t = \int_0^t \int \frac{\partial}{\partial x} \phi(x,z) D_l X_{s^-}^2 \, (\mu-\gamma)(dz,ds) + \int_0^t \int \phi(x,z) D_l^2 X_{s^-}^2 \, (\mu-\gamma)(dz,ds)$$
$$+ \int_0^t \int \frac{\partial^2}{\partial z^2} \left(\frac{z^2}{1+|z|^{1+\frac{1}{p_0}}} \right) \left(v_1(z) + \phi(s,z) D_l X_{s^-} \right) \mu(dz,ds),$$

and therefore

$$\|D_l L_t\|_p \leq c_1(p) M \|D_l X_t^{*\,2}\|_p + c_2(p) M \|D_l^2 X_t^*\|_p + c_3(p) + c_4(p) M \|D_l X_t^*\|_p$$
$$\leq C(p)\, M^5. \tag{2.29}$$

3. Proof of Theorem 1.2. Suppose that X_t is a solution of the SDE (1.1) and X_t^n is its Euler approximation, and for the sake of simplicity, let $T = \frac{m}{n}$. Following Bally and Talay [1], we define the functional $u(x,t) = \mathbb{E}_x[f(X_{T-t}^n)]$. Then we can write

$$
\begin{aligned}
(3.1)\qquad & |\mathbb{E}_{x_0}[f(X_T)] - \mathbb{E}_{x_0}[f(X_T^n)]| = |\mathbb{E}_{x_0}[u(X_T,T) - u(x_0,0)]| \\
&= \left|\sum_{k=1}^{m} \mathbb{E}_{x_0}\left[u\left(X_{\frac{k}{n}}, \frac{k}{n}\right) - u\left(X_{\frac{k-1}{n}}, \frac{k-1}{n}\right)\right]\right| =: \left|\sum_{k=1}^{m} \mathbb{E}_{x_0}[\delta_k^n]\right|.
\end{aligned}
$$

For simplicity we consider only δ_1^n and omit the index x_0. Applying the Dynkin formula, we get

$$
\begin{aligned}
&\mathbb{E}[\delta_1^n] = \mathbb{E}\left[u\left(X_{\frac{1}{n}}, \frac{1}{n}\right) - u(x_0,0)\right] \\
&= \mathbb{E}\left[\int_0^{\frac{1}{n}} \left(\partial_x u(X_{s^-},s)b(X_{s^-}) + R(u(X_{s^-},s),X_{s^-}) + \partial_t u(X_{s^-},t)\Big|_{t=s}\right) ds\right],
\end{aligned}
$$

where $R(f(\cdot),x) = \int_{|y|\le 1}(f(\cdot+y) - f(\cdot) - f'(\cdot)y)\nu(x,dy)$, with $\nu(x,[y,\infty)) = \inf_z\{\sigma(x,z) \le y\}$. Applying the Dynkin formula to $\partial_t u(x,t)$, we get

$$
\begin{aligned}
\mathbb{E}[\delta_1^n] &= \mathbb{E}\Bigg[\int_0^{\frac{1}{n}} \partial_x u(X_{s^-},s)b(X_{s^-}) - \partial_x u(X_{s^-},s)b(x_0) + R(u(X_{s^-},s),X_{s^-}) \\
&\qquad - R(u(X_{s^-},s),x_0)\, ds\Bigg] \\
&= \mathbb{E}\Bigg[\int_0^{\frac{1}{n}} \partial_x u(X_{s^-},s)b(X_{s^-}) - \partial_x u(x_0,0)b(x_0) - \partial_x u(X_{s^-},s)b(x_0) \\
&\qquad + \partial_x u(x_0,0)b(x_0) + R(u(X_{s^-},s),X_{s^-}) - R(u(X_{s^-},s),x_0) \\
&\qquad + R(u(x_0,0),x_0) - R(u(X_{s^-},s),X_{s^-})\, ds\Bigg].
\end{aligned}
$$

Applying the Dynkin formula a third and fourth time, we get

$$
\begin{aligned}
&\mathbb{E}[\delta_1^n] = \mathbb{E}\Bigg[\int_0^{\frac{1}{n}}\int_0^{s} \partial_x\Big(\partial_x u(X_{r^-},r)(b(X_{r^-}) - b(x_0))\Big)(b(X_{r^-}) - b(x_0)) \\
&+ R\Big(\partial_x u(X_{r^-},r)(b(X_{r^-}) - b(x_0)), X_{r^-}\Big) \\
&- R\Big(\partial_x u(X_{r^-},r)(b(X_{r^-}) - b(x_0)), x_0\Big) \\
&\partial_x\Big(R(u(X_{r^-},r),X_{r^-}) - R(u(X_{r^-},r),x_0)\Big)(b(X_{r^-}) - b(X_0)) \\
&+ R\Big(R(u(X_{r^-},r),X_{r^-}) - R(u(X_{r^-},r),x_0), X_{r^-}\Big) \\
(3.2)\qquad &- R\Big(R(u(X_{r^-},r),X_{r^-}) - R(u(X_{r^-},r),x_0), x_0\Big)\, dr\, ds\Bigg].
\end{aligned}
$$

Before continuing, we investigate the operator R. By the Taylor formula, we know that for the remainder term we have

$$
f(\cdot + y) - f(\cdot) - f'(\cdot)\cdot y = \int_0^y z f''(\cdot + y + z)dz.
$$

Set $h_x(z) = \sigma(x,z)$. A short calculation shows that $\nu(x,dy) = g(x,y)dy$, where $g(x,y) = 1/[h'_x(h_x^{-1}(y)]$. What happens if the operator R is applied to the product $u(x)g(x)$? Set $f(x) = (ug)(x)$. Then we have

$$\begin{aligned} f(x+y) - f(x) - f'(x)\cdot y &= \big(u(x+y) - u(x) - u_x(x)\cdot y\big)g(x) \\ &\quad + u(x+y)\big(g(x+y) - g(x)\big) - g_x(x)u(x)y \\ &= \Big(\int_0^y z u_{xx}(x+y+z)dz\Big)\, g(x) \\ &\quad + \big(u(x+y)\big(g(x+y) - g(x)\big) - g_x(x)u(x)y\big). \end{aligned} \tag{3.3}$$

Set $x = X_{r^-}$ and $g(x) = b(x) - b(x_0)$ or $g(x) = g(x,y) - g(x_0,y)$. Taking the expectation, obviously the second summand of (3.3) is bounded, because no derivative of u appears. Thus, we have

$$\begin{aligned} \mathbb{E}[\delta_1^n] = \int_0^{\frac{1}{n}} \int_0^s \Big\{ &\mathbb{E}\big[u_{xx}(X_{r^-},r)\big(b(X_{r^-}) - b(x_0)\big)^2 \\ &\quad + u_x(X_{r^-},r)b_x(X_{r^-})\big(b(X_{r^-}) - b(x_0)\big)\big] \\ &+ \int_{|y|\le 1}\int_0^y \mathbb{E}\big[2u_{xxx}(X_{r^-}+y+z,r)\cdot z \\ &\qquad \times \big(b(X_{r^-}) - b(x_0)\big)\big(g(X_{r^-},y) - g(x_0,y)\big)\big]\, dy\, dz \\ &+ \int_{|y_1|\le 1}\int_0^{y_1}\int_{|y_2|\le 1}\int_0^{y_2} \mathbb{E}[u_{xxxx}(X_{r^-}+y_1+z_1+y_2+z_2,r)\cdot z \\ &\quad \times \big(g(X_{r^-},y_1) - g(x_0,y_1)\big)\big(g(X_{r^-},y_2) - g(x_0,y_2)\big)\big]\, dy_1\, dz_1\, dy_2\, dz_2 \\ &+ C\Big\}\, dr\, ds. \end{aligned} \tag{3.4}$$

Due to (H1) we know that $g(x,y)$ is differentiable with respect to x; i.e., $g_x(x,y) = -h'_x(z)^{-2}\ (\sigma_{xz}(x,z)\ +\sigma_{zz}(x,z)\partial_x z)$, where $z = h_x^{-1}(y)$. Thus $g(x,y) - g(x_0,y) = (x-x_0)g_x(\xi_{x,x_0},y)$ for some $\xi_{x,x_0} \in (x,x_0)$. It follows for $R(\cdot,\cdot)$ that

$$R(f(\cdot),x) - R(f(\cdot),x_0) = (x-x_0)\int_{|y|\le 1}\int_0^y z f''(\cdot + y - z) g_x(\xi_{x,x_0},y)\, dz\, dy.$$

Setting $j=1$ in condition (H3), we know $\int |y^2 g_x(x,y)|dy$ to be uniformly bounded in x and therefore $|R(f(\cdot),x) - R(f(\cdot),x_0)| \le C\,|x-x_0|$. Going back to (3.4) we have to show that the terms

(1) $\mathbb{E}\big[u_{xx}(X_{r^-},r)\big(b(X_{r^-}) - b(x_0)\big)^2 + u_x(X_{r^-},r)b_x(X_{r^-})\big(b(X_{r^-}) - b(x_0)\big)\big]$,
(2) $\mathbb{E}\big[2u_{xxx}(X_{r^-}+y,r)\big(b(X_{r^-}) - b(x_0)\big)\big(g(X_{r^-},y) - g(x_0,y)\big)\big]$,
(3) $\mathbb{E}\big[u_{xxxx}(X_{r^-}+y,r)\big(g(X_{r^-},y_1) - g(x_0,y_1)\big)\big(g(X_{r^-},y_2) - g(x_0,y_2)\big)\big]$

are bounded for all y with $|y| \le 2$.

Next, analogously to Bally and Talay we distinguish in the following small t from large t. If t is large, i.e., $t/2 \le t \le T$, we get rid of the derivatives of $u(t,x)$ using Malliavin's integration by parts formula with respect to the functional $X_t(x)$ and apply formula (2.7). For small t, i.e., $0 \le t \le t/2$, we apply formula (2.10).

The case $T/2 \le t \le T$. Picking up the worst case, we must show $|\mathbb{E}[\partial_x^4 \bar{f}(X_t))]| \le C(T)M^{21}$ for $\bar{f}(x) = u(x,t)$. Define $H_X[Y] = (D_lX)^{-1}(YL + D_l^2 X D_l X^{-1} Y + D_l Y) = D_l(D_l X^{-1} Y) + LY D_l X^{-1}$, where L is defined by (2.6) and (2.11). First, note that we have chosen l so that $D_l X_t$ is invertible (see Remarks 2.6 and 2.7). By the integration by parts formula (2.7), we know $\mathbb{E}[\partial_x g(X)Y] = \mathbb{E}[g(X)H_X[Y]]$. Applying integration by parts and $u(x,\cdot) \le |f|_\infty$ to the inner part of (3.4), we get

$$
\begin{aligned}
|\mathbb{E}[\delta_1^n]| \le \int_0^{\frac{1}{n}} \int_0^t \big(& |f|_\infty \mathbb{E}\big[|H_X^4[(b(X) - b(x_0))^2]_s + H_X^4[(g(\cdot, X) - g(\cdot, x_0))^2]_s \\
& + 2\, H_X^4[(b(X) - b(x_0))(g(\cdot, X) - g(\cdot, x_0))|\big]_s + C \big)\, ds\, dt.
\end{aligned} \tag{3.5}
$$

The worst case is due to the summand $H_X^4[(g(\cdot, X) - g(\cdot, x_0))^2]$. Thus we restrict ourselves to this case and define $Y_t = b(X_t) - b(x_0)$ and $R(\cdot, X_t) - R(\cdot, x_0)$. For clarity, we omit the index t if it is obvious and write G for $L + D_l X^{-1} D_l^2 X$. Define the operator $\widehat{H}_X[Y] = D_l Y + (L + D_l X^{-1} D_l^2 X)Y$. Obviously, we have $H_X[Y] = D_l X^{-1} \widehat{H}_X[Y]$. Next we evaluate $H_X^4[Y^2]$:

$$
\widehat{H}_X^4[Y^2] = D_l^2(\hat{H}_X^2[Y^2]) + 2G D_l(\hat{H}_X^2[Y^2]) + (D_l G + G^2)\hat{H}_X^2[Y^2].
$$

After some computations we get

$$
\begin{aligned}
\widehat{H}_X^4[Y^2] &= Y^2\big(G^4 + D_l^3 G + 6G^2 D_l G + 3(D_l G)^2 + 4G D_l^2 G\big) \\
&\quad + 8 D_l Y Y \big(3 D_l G G + G^3 + D_l^2 G\big) + 12\big(D_l^2 Y Y + (D_l Y)^2\big)(G^2 + D_l G) \\
&\quad + 8G\big(D_l^3 Y Y + 3 D_l^2 Y D_l Y\big) + 2\big(D_l^4 Y Y + 4 D_l^3 Y D_l Y + 3(D_l^2 Y)^2\big) \\
&= L^4 Y^2 + 6L^2 Y^2 D_l L + 3Y^2 D_l L^2 + 8L^3 Y D_l Y + \cdots \\
&\qquad + 8 D_l X^{-1} Y D_l Y D_l^4 X + 2Y D_l^4 Y + D_l X^{-1} Y^2 D_l^5 X.
\end{aligned} \tag{3.6}
$$

Set $Y = b(X) - b(x_0)$. Since b is four times boundedly differentiable, $D_l Y = b'(X) D_l X, \ldots, D_l^4 Y = \sum b^{(4)}(X) D_l X^4 + \cdots + b^{(1)}(X) D_l^4 X$ are bounded by $D_l X, \ldots, \sum_{i=1}^4 D_l^i X$. In the case of the operator R, we can set $Y \sim X$.

Next we investigate (3.6) term by term and show that the terms are, when multiplied by $D_l X_t^{-4}$, bounded by $C(T)M^{21}$. Note that thanks to Remark 2.6 we have an upper bound of $\|D_l X_t^{-1}\|_p$ independent of M. The first term we consider is $Y^2 L^4$. Using (2.28) we get

$$
\begin{aligned}
\|Y_t^2 L_t^4 D_l X_t^{-4}\|_1 &\le \|Y_t^2\|_4 \|L_t^4\|_4 \|D_l X_t^{-4}\|_2 \\
&\le t^{-Q}\, C(t) \cdot M^2 \cdot M^8 \;=\; t^{-Q}\, C(t) \cdot M^{10}
\end{aligned}
$$

for $t \in [T/2, T]$ and $Q < \infty$. Since $T > t > T/2$, the right side is uniformly bounded by $C(T)\, M^{10}$ for all $t \in [T/2, T]$. Analyzing term by term we get, by Remark 2.12 and the estimates (2.15), (2.18), (2.22), (2.23), (2.24), (2.28), and (2.29),

$$
\begin{aligned}
\|D_l X_t^{-4} L_t^2 Y_t^2 D_l L_t\|_1 &\le \|D_l X_t^{-4}\|_3 \cdot \|L_t^2\|_4 \cdot \|Y_t^2\|_6 \|D_l L_t\|_4 \\
&\le t^{-Q}\, C(t) \cdot M^4 \cdot M^2 \cdot M^5 \;=\; t^{-Q}\, C(t) \cdot M^{11}, \\
\|D_l X_t^{-4} Y_t^2 D_l L_t^2\|_1 &\le \|D_l X_t^{-4}\|_4 \cdot \|Y_t^2\|_4 \cdot \|D_l L_t^2\|_2 \\
&\le t^{-Q}\, C(t) \cdot M^2 \cdot M^{10} \;\le\; t^{-Q}\, C(t) \cdot M^{14}, \\
&\quad \vdots \\
\cdots &\quad \vdots \quad \cdots
\end{aligned}
$$

$$\begin{aligned}\|D_l X_t^{-4} Y_t\big(8D_l X_t^{-1} D_l Y_t D_l^4 Y_t + 2D_l^4 Y_t + D_l X_t^{-1} Y_t D_l^5 X_t\big)\|_1 \\ &\le t^{-Q}\, C(t)\cdot M\cdot\big(MM^{13}+M^{13}+MM^{19}\big)\\ &\le t^{-Q}\, C(t)\cdot M^{21}\,.\end{aligned}$$

Collecting all together, we get for $t\in[T/2,T]$

$$\mathbb{E}[|H^4[Y^2]_t|] = \|H^4[Y^2]_t\|_1 \le C(T)\cdot M^{21}.$$

The case $0 < t \le T/2$. Here, we have to apply formula (2.10) with time $r = T-t > T/2$. A short calculation shows that the terms $\mathbb{E}\left[\mathbb{E}\left[H_X[\nabla^4 X_r]|\mathcal{F}_t\right] Y_t^2\right]$, $\mathbb{E}\left[\mathbb{E}\left[H_X^2[\nabla^2 X_r^2]|\mathcal{F}_t\right] Y_t^2\right]$, $\mathbb{E}\left[\mathbb{E}\left[H_X^2[\nabla^3 X_t \nabla X_r]|\mathcal{F}_t\right] Y_t^2\right]$, $\mathbb{E}\left[\mathbb{E}\left[H_X^3[\nabla X_r^2 \nabla^2 X_r]|\mathcal{F}_t\right] Y_t^2\right]$, and $\mathbb{E}\left[\mathbb{E}\left[H_X^4[\nabla X_r^4]|\mathcal{F}_t\right] Y_t^2\right]$ have to be bounded by $r^{-Q}\, C(r)\cdot M^4\cdot\exp(M^{16})$ for some $Q<\infty$ and $C(r)$ is uniformly bounded on $[0,T]$. But the estimates given in equations (2.15), (2.18), and (2.22)–(2.29) lead to

$$\begin{aligned}\|H_X[\nabla^4 X_r]\|_1 &\le \|D_l X_r^{-1}\big(D_l\nabla^4 X_r + \nabla^4 X_r L_t + \nabla^4 X_r D_l^2 X_r D_l X_r^{-1}\big)\|_1\\ &\le r^{-Q}\, C(r)\cdot\exp(M^{16})\cdot\big(M+M^2+M^4\big)\,,\\ \|H_X^2[\nabla^2 X_r^2]\|_1 &\le \|D_l X_r^{-2}\big(L_r^2\nabla^2 X_r^2 + D_l L_r \nabla^2 X_r^2 + \cdots + D_l X_r^{-1}\nabla^2 X_r^2 D_l^3 X_r\big)\|_1\\ &\le r^{-Q}\, C(r)\cdot\exp(M^8)\cdot\big(M^4+M^5+\cdots+\exp(M^4)+M^8\big)\,,\\ &\cdots\quad\cdots\\ \|H_X^4[\nabla X_r^4]\|_t &\le \|D_l X_r^{-4}\big(L_r^4\nabla X_r^4 + 6L_r^2\nabla X_r^4 D_l L_t + \cdots + \nabla X_t^4 D_l^5 X_t\big)\|_1\\ &\le\ r^{-Q}\, C(r)\cdot(\exp(M^{16})M^8 + 6\exp(M^{16})M^4M^5 + \cdots + M^{19}\exp(M^{16})).\end{aligned}$$

Integration of (3.4) and applying the same localization argument as Bally and Talay [1] completes the proof. □

4. Conclusions and additional remarks.

REMARK 4.1. *To handle the case where f is a Delta function, we have to investigate the upper bound of $\|H^5[Y^2]\|_1$, $M^2\,\|H_X^5[\nabla X_t^5]_t\|_1$, and $M^2\|H_X[\nabla^5 X]_t\|_1$. But analyzing the preceding proof it is obvious that the worst term in the first case is $\|D_l^6 X_t Y_t^2 D_l X_t^{-5}\|_1$, which is of order M^{28}. In the second and third case the worst term is $\|H_X^5[\nabla X^5]\|M^2$, which is of order $M^{28}\exp(M^{32})$.*

REMARK 4.2. *Assume that f belongs to $C_b^1(\mathbb{R})$ and consider $u(x,t)=\mathbb{E}^x[f(X_{T-t}^n)]$ $\approx \mathbb{E}^x[f(X_{T-t})]$. To give an upper bound of $\partial_{x^4}^4 u(x,t)$, we have again to distinguish between small t and large t.*

Let $T/2\le t\le T$. Note that formula (2.10) leads to $\partial_x u(x,t)=\mathbb{E}^x[f'(X_{T-t})\nabla X_{T-t}]$ and therefore $|\partial_x u(x,t)|_\infty \le |f'|_\infty \sup_x \|\nabla X_{T-t}(x)\|_1 \le |f'|_\infty \exp\big((T-t)M^2\big)$. To get rid of the remaining derivatives, we have to apply the operator $H_X[\cdot]$ only three times to Y^2:

$$\begin{aligned}H_X^3[Y^2]_t = D_l X_t^{-3}\Big\{&L_t^3 Y_t^2 + 3L_t Y_t^2 D_l L_t + 6L_t^2 Y_t D_l Y_t + \cdots\\ &+ 6Y_t D_l Y_t D_l^3 X_t D_l X_t^{-2} + 2Y_t D_l^3 Y_t + Y_t^2 D_l^4 X_t D_l X_t^{-1}\Big\}.\end{aligned}\tag{4.1}$$

The worst factor is $Y_t^2 D_l^4 X_t D_l X_t^{-4}$. But $\|Y_t^2 D_l^4 X_t D_l X_t^{-4}\|_1 \le M^2 M^{13} \le C(T)M^{15}$, and therefore $\mathbb{E}[\partial_x^4 u(t,x)] \le |f'|_\infty \exp\big(TM^2\big)\, M^{15}$.

Let $0 \le t \le T/2$. Then we have

$$\begin{aligned}
&\left|\partial_x^4 u(t,x)\right| = \left|\mathbb{E}^x\left[f^{(4)}(X_{T-t})\nabla X_t^4 + \cdots + f'(X_{T-t})\nabla^4 X_t\right]\right| \\
&= \left|\mathbb{E}^x\left[f'(X_{T-t})H_X^3[\nabla X^4]_t + \cdots + f'(X_{T-t})\nabla^4 X_t\right]\right| \\
&\le |f'|_\infty\big(\|H_X^3[\nabla X^4]_t\|_1 + \cdots + \|\nabla^4 X_t\|_1\big) \\
&\le C\,|f'|_\infty\big(\|L_t^3\nabla X_t^4 D_l X_t^{-3}\|_1 + \cdots + \|\nabla X_t^4 D_l^4 X_t D_l X_t^{-3}\|_1 + \cdots + \|\nabla^4 X_t\|_1\big) \\
&\le C\,|f'|_\infty\big(M^6\exp(M^{16}) + \cdots + M\exp(2M^8) + \exp(M^{16})\cdot M^{13} + \cdots + \exp(M^{16})\big).
\end{aligned}$$

Collecting all together, we get as an error bound

$$|\mathbb{E}\left[f(X_t)\right] - \mathbb{E}\left[f(X_t^n)\right]| \le |f'|_\infty \frac{C}{n} M^{15}\,\left(\exp(M^2) + \exp(M^{16})\right).$$

REMARK 4.3. *Assume that $2/\alpha^+ > 3/\alpha^- - 1$ and $f \in C^1(\mathbb{R})$. Without any restriction on α^+ and α^-, we can see by the scaling properties that the right-hand side of* (4.1) *tends to infinity as t tends to zero. But with the restriction above on α^+ and α^-, the right-hand side of* (4.1) *is of order $O(t^\delta)$, where $\delta > -1$. Integration leads to the error bound*

$$|\mathbb{E}\left[f(X_t)\right] - \mathbb{E}\left[f(X_t^n)\right]| \le |f'|_\infty \frac{C}{n} M^{15}\,\exp(M^2).$$

It remains to show the right-hand side of (4.1) *is of order $O(t^\delta)$, i.e., $\|H_X^3[Y^2]_t\|_1 \le O(t^\delta)$. Analyzing term by term by the estimates* (2.15), (2.18), (2.22), (2.23), (2.24), (2.28), *and* (2.29) *we see that the leading term in* (4.1) *is the worst. Thus, we pick it up and show $\|D_l X_t^{-3} Y_t^2 L_t^3\|_1 \le O(t^\delta)$, where $\delta > -1$. As t tends to zero we know by Proposition* 2.2 *and Remark* 2.7 *that $\|D_l X_t^{-3}\|_p \le c(p)\,t^{-\frac{3}{\alpha^-}-\frac{3}{p_0}}$ and $\|Y_t^2\|_p \le C(M)\,t^{\delta_Y}$, where $\alpha^+ > 2\delta_Y$. Thanks to estimate* (2.28), *we see that $\int_0^T \|H_X^3[Y^2]_t\|_1\,dt$ is bounded for $\frac{2}{\alpha^+} > \frac{3}{\alpha^-} - 1$. To get the exact threshold of $\|H_X^3[Y^2]_t\|_1$, we have to investigate the last summand of* (4.1), *i.e., $\|D_l X_t^{-4} D_l^4 X_t Y_t^2\|_1$, which is of $O(M^{15})$.*

REMARK 4.4. *Assume that f is in $C_b^2(\mathbb{R})$. To show*

$$|\mathbb{E}\left[f(X_t)\right] - \mathbb{E}\left[f(X_t^n)\right]| \le |f''|_\infty \frac{C}{n} M^{10}\,\left(\exp(M^4) + \exp(M^{16})\right), \tag{4.2}$$

we have again to distinguish between large and small t.

Let $T/2 \le t \le T$. Then we have $\partial_x^2 u(x,t) = \mathbb{E}^x[f''(X_{T-t})\nabla^2 X_{T-t}]$ and $|\partial_x^2 u(x,t)|_\infty \le |f''|_\infty \exp\big((T-t)M^4\big)$. To get rid of the two remaining derivatives, we have to apply the operator $H_X[\cdot]$ only twice to Y^2, i.e.,

$$H_X^2[Y^2]_t = D_l X_t^{-2}\Big\{L_t^2 Y_t^2 + Y_t^2 D_l L_t + \cdots + 2Y_t D_l^2 Y_t - Y_t^2 D_l^3 X_t D_l X_t^{-1}\Big\}. \tag{4.3}$$

But we have $\|Y_t^2 D_l^3 X_t D_l X_t^{-3}\|_t \le C(T)\,M^{10}$.

Let $0 \le t \le T/2$ and set $r = T - t$. Analogous to Remark 4.2 *we have*

$$\begin{aligned}
&\left|\partial_x^4 u(t,x)\right| = \left|\mathbb{E}^x\left[f^{(4)}(X_{T-t})\nabla X_t^4 + \cdots + f'(X_{T-t})\nabla^4 X_t\right]\right| \\
&= \left|\mathbb{E}^x\left[f^{(2)}(X_{T-t})H_X^2[\nabla X^4]_t + \cdots + f^{(2)}(X_{T-t})\nabla^4 X_t\right]\right| \\
&\le |f''|_\infty\big(\|H_X^2[\nabla X^4]_t\|_1 + \cdots + \|\nabla^4 X_t\|_1\big) \le C\,|f''|_\infty\exp(M^{16})\cdot M^8.
\end{aligned}$$

Collecting all together, we get (4.2).

REMARK 4.5. *Assume that* $2/\alpha^+ > 3/\alpha^- - 1$ *and* $f \in C_b^2(\mathbb{R})$. *Without any restriction on* α^+ *and* α^- *we can see by the scaling properties that the right-hand side of* (4.1) *tends to infinity as* t *tends to zero. But with the restriction above on* α^+ *and* α^-, *the right-hand side of* (4.3) *is of order* $O(t^\delta)$, *where* $\delta > -1$. *Integration leads to the error bound*

$$|\mathbb{E}\left[f(X_t)\right] - \mathbb{E}\left[f(X_t^n)\right]| \leq |f''|_\infty \frac{C}{n} M^{10} \exp(M^4).$$

It remains to show the right-hand side of (4.3) *is of order* $O(t^\delta)$, *i.e.,* $\|H_X^2[Y^2]_t\|_1 \leq O(t^\delta)$. *The worst term in* (4.3) *is the leading term. Thus, we have to show* $\|D_l X_t^{-2} Y_t^2 L_t^2\|_1 \leq O(t^\delta)$, *where* $\delta > -1$. *As* t *tends to zero we know by Proposition* 2.2 *and Remark* 2.7 *that* $\|D_l X_t^{-2}\|_p \leq c(p)\, t^{-\frac{2}{\alpha^-} - \frac{2}{p_0}}$ *and* $\|Y_t^2\|_p \leq C(M)\, t^{\delta_Y}$, *where* $\alpha^+ > 2\delta_Y$. *Thanks to estimate* (2.28), *we see that* $\int_0^T \|H_X^3[Y^2]_t\|_1\, dt$ *is bounded for* $\frac{2}{\alpha^+} > \frac{2}{\alpha^-} - 1$. *To get the exact threshold of* $\|H_X^2[Y^2]_t\|_1$, *we have to investigate the last summand of* (4.3), *which is of order* $O(M^{10})$.

REMARK 4.6. *Analogous to Remarks* 4.2 *and* 4.4 *we can show*

$$|\mathbb{E}\left[f(X_t)\right] - \mathbb{E}\left[f(X_t^n)\right]| \leq |f'''|_\infty \frac{C}{n} M^6 \left(\exp(M^8) + \exp(M^{16})\right)$$

for $f \in C_b^3(\mathbb{R})$. *If* $\frac{2}{\alpha^+} > \frac{1}{\alpha^-} - 1$, *the same consideration as in Remarks* 4.3 *and* 4.5 *yields*

$$|\mathbb{E}\left[f(X_t)\right] - \mathbb{E}\left[f(X_t^n)\right]| \leq |f'''|_\infty \frac{C}{n} M^6 \exp(M^8).$$

REMARK 4.7. *If the driving process is* α*-stable, i.e.,* $\sigma(x,z)$ *can be written as* $\sigma_0(x) z^{-1/\alpha}$, *we have to truncate the process before applying Theorem* 1.2. *To be more exact, we call* X_t^m *the truncated process if* X_t^m *is a solution to* (1.1), *where* $\sigma(x,z)$ *is replaced by* $\sigma_0(x)(z^{-1/\alpha} \wedge m)$. *The error now splits into three parts:*

$$\begin{aligned}|\mathbb{E}[f(X_T) - f(X_t^n)]| \leq{}& |\mathbb{E}[f(X_T) - f(X_T^m)]| + |\mathbb{E}[f(X_T^m) - f(X_T^{m,n})]| \\ &+ |\mathbb{E}[f(X_T^m) - f(X_T^{m,n})]| =: \mathrm{I} + \mathrm{II} + \mathrm{III}.\end{aligned}$$

Given an estimate of (II), *we can apply Theorem* 1.2. *Further, we have*

$$(\mathrm{I}) \leq |\mathbb{E}[f(X_T) - f(X_T^m) 1_{\{T^m \leq T\}}]| \leq 2|f|_\infty \mathbb{P}(T^m \leq T),$$

where $T^m = \inf_{t>0}\{|\Delta Z| > m\}$. *Hence the counting process of* $[m,\infty)$ *is Poisson distributed with parameter* $\mu([m,\infty))$ *(see section* 2 *or Protter and Talay* [15, Proposition 4.5]*); it follows that* $\mathbb{P}(T^m \leq T) = (1 - \exp(Tm^{-\alpha}))$. *Therefore, setting* $M = m$, *the error is given by*

$$|\mathbb{E}[f(X_T) - f(X_T^n)]| \leq C(T) \frac{1}{n} \cdot \left(m^{21} + m^4 \exp(m^{16})\right) + \left(1 - \exp\left(Tm^{-\alpha}\right)\right).$$

REMARK 4.8. *Let* X_t *be a solution to* (1.1), *where* σ *and* b *satisfy the assumption of Theorem* 1.2 *with* $M = 1$. *Proceeding as Kanagawa* [12] *(see also Talay* [17, Proposition 2.1]*) we can show that* $\|X_t^n - X_t\|_2 \leq C/\sqrt{n}$. *Let* $t = [t]_n$. *Using condition* (H3), *an induction on* k *shows that for any* $n \in \mathbb{N}$,

$$\mathbb{E}\left[\sup_{t\in[0,T]} |X_t^n|^2\right] \leq K(T)(1 + x_0^2)\exp(K(T)) \tag{4.4}$$

for some increasing function $K(\cdot)$. For $t \in (k/n, (k+1)/n]$ consider the process

$$\varepsilon_t := X_{\frac{k}{n}} - X^n_{\frac{k}{n}} + \int_{\frac{k}{n}}^t (b(X_{s^-}) - b(X^n_{\frac{k}{n}}))ds + \int_{\frac{k}{n}}^t (\sigma(X_{s^-}, z) - \sigma(X^n_{\frac{k}{n}}, z))(\mu - \gamma)(dz, ds).$$

Apply the Itô formula to $(\varepsilon_t)^2$ between $t = k/n$ and $t = (k+1)/n$: Standard computations, condition (H3)*, and* (4.4) *show that we have, for an increasing function $K(\cdot)$,*

$$\mathbb{E}[\varepsilon^2_{\frac{k+1}{n}}] \le \mathbb{E}[\varepsilon^2_{\frac{k}{n}}] \left(1 + \frac{K(T)}{n}\right) + \frac{1}{n^2}.$$

Noting that $\varepsilon_0 = 0$, an induction on k provides the estimate

$$\sup_{0 \le k \le n} \mathbb{E}\left[\varepsilon^2_{\frac{k+1}{n}}\right] \le C \exp(K(T)).$$

To conclude, it remains to use (4.4) *again.*

REMARK 4.9. *Let X_t be a solution to* (1.1)*, where σ and b satisfy the assumption of Theorem* 1.2 *with $M = 1$ and $f \in C^1_b(\mathbb{R})$, $2/\alpha^+ < 3/\alpha^- - 1$. Let $T > 0$ fixed, $\tau = \inf_{t \le 0}\{X_t = 0\}$, and $\tau^n = \inf_{t \le 0}\{X^n_t = 0\}$. Now, the error taken at the stopping time $T \wedge \tau$ equals*

$$\begin{aligned}|\mathbb{E}[f(X_{\tau \wedge T})] - \mathbb{E}[f(X^n_{\tau \wedge T})]| \le{}& |\mathbb{E}[f(X_{\tau \wedge T})] - \mathbb{E}[f(X^n_{\tau \wedge T})]| \\ &+ |\mathbb{E}[f(X^n_{\tau \wedge T})] - \mathbb{E}[f(X^n_{\tau^n \wedge T})]|.\end{aligned}$$

Replacing the first summand we can write

$$|E1| = \left|\sum_{k=1}^m \mathbb{E}_{x_0}\left[u\left(X_{\frac{k}{n} \wedge \tau}, \frac{k}{n} \wedge \tau\right) - u\left(X_{\frac{k-1}{n} \wedge \tau}, \frac{k-1}{n} \wedge \tau\right)\right]\right| =: \left|\sum_{k=1}^m \mathbb{E}_{x_0}[\delta^n_k]\right|,$$

and therefore we have to show that

$$|\mathbb{E}[\delta^n_1]| \le \int_0^{\frac{1}{n} \wedge \tau} \int_0^s \mathbb{E}\left[\sum_{i=2}^4 C_i H^i[Y^2]_t + C\right] dr\, ds$$

is bounded. But in Remark 4.3 *we have seen that $H^i[Y^2]_t$, $i = 2, 3$, is uniformly bounded in $t \in [0, T]$ for $Y = b(X) - b(x_0)$ or $Y = R(u, X) - R(u, x_0)$, respectively (see Remarks* 4.2 *and* 4.4*). It remains to investigate $E2$. Suppose that $F : \mathbb{R} \to \mathbb{R}$ is Lipschitz with $F(x) > 0$ for $x > 0$ and $F(x) = 0$ for $x \le 0$. By the same arguments as Gobet* [10]*, we can conclude for the second summand $S2$ that*

$$|S2| \le |f|_\infty \int_0^T |\mathbb{P}(t < \tau) - \mathbb{P}(t < \tau^n)|\, dt \;=\; |f|_\infty T\, |\mathbb{1}_{T<\tau} - \mathbb{1}_{t<\tau^n}|.$$

Continuing we get

$$\begin{aligned}|\mathbb{1}_{T<\tau} - \mathbb{1}_{t<\tau^n}| = {}& \big(\mathbb{1}_{\inf_{t\in[0,T]} F(X_t)=0} \mathbb{1}_{\inf_{t\in[0,T]} F(X^n_t)>0} + \mathbb{1}_{\inf_{t\in[0,T]} F(X_t)>0} \\ & \mathbb{1}_{\inf_{t\in[0,T]} F(X^n_t)=0}\big) \cdot \big(\mathbb{1}_{\inf_{t\in[0,T]} F(X_t)>\delta} + \mathbb{1}_{\inf_{t\in[0,T]} F(X_t)\le\delta}\big) \times \big(\mathbb{1}_{\inf_{t\in[0,T]} F(X^n_t)>\delta} \\ & + \mathbb{1}_{\inf_{t\in[0,T]} F(X^n_t)\le\delta}\big) \le |\mathbb{1}_{|\inf_{t\in[0,T]} F(X_t) - \inf_{t\in[0,T]} F(X^n_t)|>\delta}\end{aligned}$$

$$+ \mathbb{1}_{\inf_{t\in[0,T]} F(X_t)=0} \cdot \mathbb{1}_{0<\inf_{t\in[0,T]} F(X_t^n)\leq\delta} + \mathbb{1}_{\inf_{t\in[0,T]} F(X_t^n)=0} \cdot \mathbb{1}_{0<\inf_{t\in[0,T]} F(X_t)\leq\delta}$$
$$\leq \mathbb{P}\left(\left|\inf_{t\in[0,T]} F(X_t) - \inf_{t\in[0,T]} F(X_t^n)\right| > \delta\right) + \mathbb{P}\left(0 < \inf_{t\in[0,T]} F(X_t) \leq \delta\right)$$
$$+ \mathbb{P}\left(0 < \inf_{t\in[0,T]} F(X_t^n) \leq \delta\right).$$

Using the Chebyshev inequality and Remark 4.8 *we get*

$$\mathbb{P}\left(\left|\inf_{t\in[0,T]} F(X_t) - \inf_{t\in[0,T]} F(X_t^n)\right| > \delta\right) \leq \mathbb{P}\left(\inf_{t\in[0,T]} |F(X_t) - F(X_t^n)| > \delta\right)$$
$$\leq \frac{1}{\delta} \cdot \|F(X_t) - F(X_t^n)\|_2^2 \leq \frac{1}{\delta} \cdot \frac{1}{n}.$$

Moreover, since X_t *has a continuous density (see Bass and Cranston* [3, *Theorem* 4.1]*) we have* $\mathbb{P}(0 < \inf_{t\in[0,T]} F(X_t) \leq \delta) \leq C\delta$. *Set* $\delta \sim n^{-1/2}$. *Collecting all together, we get*

$$|\mathbb{E}[f(X_{\tau\wedge T})] - \mathbb{E}[f(X^n_{\tau\wedge T})]| \leq C_1(T)\,\frac{1}{\sqrt{n}} + |f'|_\infty\, C_2(T)\,\frac{M^{15}\exp(M^2)}{n}.$$

REMARK 4.10. *If an interval* I *is bounded, the jumps of an* α*-stable process are bounded by the length of* I *and we can apply Remark* 1.1*, setting* $M = |I|$ *to handle the quality of approximation for the first exit time.*

REMARK 4.11. *If* X_t *is driven by an* α*-stable process, the solution* X_t *does not belong to* $\mathcal{L}^2$ *in general. But, e.g., if* σ *is flat of order* q *at infinity, i.e.,* $\lim_{x\to\infty}\sigma(x,z)/x^q < C|z|^{-\frac{1}{\alpha}}$*, the solution* X *belongs to* $\cap_{p<\alpha(q+1)}\mathcal{L}^p$. *Thus, if* σ *is flat at infinity of all orders, the stochastic exponential belongs to* $\mathcal{L}^p$, $p \geq 1$, *and we do not need to truncate the driving process before applying Theorem* 1.2.

THE ZEROS OF SPECIAL FUNCTIONS FROM A FIXED POINT METHOD*

JAVIER SEGURA†

Abstract. A scheme for the computation of the zeros of special functions and orthogonal polynomials is developed. We study the structure of the first order difference-differential equations (DDEs) satisfied by two fundamental sets of solutions of second order ODEs $y_n''(x)+A_n(x)y_n(x)=0$, n being the order of the solutions and $A_n(x)$ a family of continuous functions. It is proved that, with a convenient normalization of the solutions, $T_{\pm1}(z)=z\pm\operatorname{sign}(d)\arctan(y_n(x(z))/y_{n\pm1}(x(z)))$ are globally convergent iterations with fixed points $z(x_n^{(i)})$, $x_n^{(i)}$ being the zeros of $y_n(x)$; d is one of the coefficients in the DDEs and $z(x)$ is a primitive of d. The structure of the DDEs is also used to set global bounds on the differences between adjacent zeros of functions of consecutive orders and to find iteration steps which guarantee that all the zeros inside a given interval can be found with certainty. As an illustration, we describe how to implement this scheme for the calculation of the zeros of arbitrary solutions of the Bessel, Coulomb, Legendre, Hermite, and Laguerre equations.

Key words. special functions, zeros, fixed point iteration, second order ODE, recurrence relations

1. Introduction.

The literature concerning the evaluation of the real zeros of special functions is extensive, with special emphasis on the zeros of Bessel functions [2, 11, 20, 21, 23, 27, 28, 24]. There exist several algorithms with different characteristics [13, 22, 28] and a great variety of papers dealing with properties of the zeros of cylinder functions (see, for instance, [3, 5, 9, 17]). However, little is known regarding the real zeros of other special functions. Methods for the computation of the zeros of first kind Bessel functions [2, 10, 20, 21, 22, 24, 28], second kind Bessel functions [20, 22, 24, 28], Airy functions [26, 22, 6], and regular Coulomb wave functions [10, 2] have been described. Only matrix methods [10] have been applied for finding zeros of special functions other than Bessel or related functions (Airy functions).

The main task when evaluating zeros of a given function is usually the bracketing of the roots (with the exception of matrix eigenvalue methods [10]). After this, bisection or other standard methods can be used. However, the distribution of zeros changes drastically from one family of functions to another and from one set of values or parameters (like the order of Bessel functions) to another. In addition, the distribution of zeros may be highly nonuniform. Thus, bracketing is generally a difficult issue which requires, for instance, the use of the concept of topological degree [12]. Bracketing can be avoided if initial approximations for the roots [24, 20, 19] are available which allow local methods (such as the Newton–Raphson method) to converge.

We will build a single and simple numerical method which can be applied to all the previously mentioned functions as well as to more general cases. No bracketing is needed; instead we provide iterative relations between consecutive zeros. The method

applies for special functions (and orthogonal polynomials) which are solutions of a second order ODE and satisfy systems of difference-differential equations (DDEs) of the type

$$\begin{aligned} y_n'(x) &= a_n(x)y_n(x) + d_n(x)y_{n-1}(x), \\ y_{n-1}'(x) &= b_n(x)y_{n-1}(x) + e_n(x)y_n(x), \end{aligned} \tag{1.1}$$

with continuous coefficients a_n, b_n, d_n, e_n. The method is able to find the zeros of any solution of the Bessel equation (including Airy functions), of any Coulomb wave function (not necessarily the regular Coulomb wave function, as matrix methods require [10, 2]), of any Legendre function, and so on.

Our method makes use of information regarding the distribution of the zeros that is carried by the coefficients of the DDEs. The main ingredients of the method consist of globally convergent fixed point iterations (FPIs) together with prescriptions, based on global bounds on the distance between adjacent zeros, to compute with certainty all the zeros inside a given interval. These global bounds on differences of consecutive and adjacent zeros apply to a broad family of special functions and orthogonal polynomials.

The structure of the paper is as follows. In section 2 we describe the properties of the coefficients in the DDEs, satisfied by the solutions of a second order ODE $y_k'' + A_k(x)y_k = 0$, under the assumption that such coefficients are continuous functions. The DDEs relating y_n' and y_{n-1}' with y_n and y_{n-1} for two sets of fundamental solutions exist and are unique [15]. The properties shown will be thus quite general. With these properties, we will show (section 3) that the ratios $y_n(x(z))/y_{n\pm1}(x(z))$ satisfy nonlinear first order ODEs resembling the equation for the function $\tan(z(x))$; $z = z(x)$ is a change of variables given by a primitive of one of the coefficients of the DDEs. We will use this similarity to build a globally convergent FPI in section 4. This FPI, together with bounds on the distance between the zeros of y_n and the adjacent zeros of $y_{n\pm1}$, will be used to build a global method to find with certainty all the roots inside a given interval (section 5). The method is monotonically convergent except for two possible exceptions which are treated in section 6. In section 7, we give explicit algorithms to compute with certainty all the zeros inside a given interval. Finally (section 8), we compile the analytical information needed to apply the method to arbitrary solutions of the Bessel, Coulomb, Legendre, Hermite, and Laguerre differential equations.

2. Structure of the DDEs. We will consider the solutions of second order ODEs in normal form,

$$y_k''(x) + A_k(x)y_k(x) = 0, \tag{2.1}$$

which are defined for all x in an interval I, where $A_k(x)$ is a family of continuous functions. The solutions $y_k(x)$ have continuous second derivative in I. This is a common situation: most special functions and orthogonal polynomials satisfy second order differential equations, reducible to the normal form (2.1), in which $A_k(z)$ is an analytic function in the complex plane except for a few singularities. The results in this paper apply to real intervals free of singularities of A_k.

Given a solution corresponding to a given value $k = n$, y_n, we will say that n is the order of the solution.

Let $\{y_k^{(1)}(x)\}$ and $\{y_k^{(2)}(x)\}$ be two families of independent solutions of (2.1) in I, i.e., two families of solutions with Wronskians different from zero,

$$W[y_k^{(1)}, y_k^{(2)}] = y_k^{(1)} y_k^{(2)\prime} - y_k^{(1)\prime} y_k^{(2)} \equiv w_k \neq 0. \tag{2.2}$$

It is obvious from (2.1) that the Wronskians are constant.

Following [15, Thm. 1], it can be proved that for every fixed pair of sequences $\{y_k^{(1)}(x)\}$, $\{y_k^{(2)}(x)\}$ of fundamental solutions of (2.1), there exists a unique pair of DDEs, relating y_k with y_{k-1} and its first derivative and y_{k-1} with y_k and its first derivative, which is valid for both fundamental sets of solutions (and hence for any linear combination of them with constant coefficients).

Let us consider two orders $k = n, n-1$ and write these relations in the form

$$\begin{aligned} y_n'(x) &= a_n(x) y_n(x) + d_n(x) y_{n-1}(x), \\ y_{n-1}'(x) &= b_n(x) y_{n-1}(x) + e_n(x) y_n(x). \end{aligned} \tag{2.3}$$

Let us now denote by $Z_n(x)$ the determinant

$$Z_n(x) = \begin{vmatrix} y_n^{(1)} & y_{n-1}^{(1)} \\ y_n^{(2)} & y_{n-1}^{(2)} \end{vmatrix}. \tag{2.4}$$

It is easy to prove that $Z_n(x)$ cannot be identically zero [15, Thm. 1]; see also [14]. By expressing the coefficients a_n, b_n, d_n, e_n in terms of $y_n^{(1)}$, $y_n^{(2)}$, $y_{n-1}^{(1)}$, $y_{n-1}^{(2)}$, and their derivatives, the following result can be easily proved.

LEMMA 2.1. *Let relations* (2.3) *be satisfied by solutions* $\{y_n^{(1)}, y_{n-1}^{(1)}\}$ *and* $\{y_n^{(2)}, y_{n-1}^{(2)}\}$, *where* $\{y_n^{(1)}, y_n^{(2)}\}$ *and* $\{y_{n-1}^{(1)}, y_{n-1}^{(2)}\}$ *are independent solutions of second order ODEs in normal form. Then*

1. $d_n(x) \neq 0$, $e_n(x) \neq 0$.
2. $d_n(x)/e_n(x) \equiv c_n \neq 0$ *is a constant.*
3. $a_n(x)$,$b_n(x)$,$d_n(x)$,$e_n(x)$ *are continuous* $\iff$ $a_n(x)$,$b_n(x)$,$d_n(x)$,$e_n(x)$ *are differentiable* $\iff$ $Z_n(x) \neq 0\ \forall x \in I$.

Proof. Writing the first equation of (2.3) for $\{y_n^{(1)}, y_{n-1}^{(1)}\}$ and $\{y_n^{(2)}, y_{n-1}^{(2)}\}$ and solving the resulting system, we get $Z_n(x) d_n(x) = w_n$, w_n being the Wronskian (2.2). Similarly, from the second equation in (2.3) we get $Z_n(x) e_n(x) = -w_{n-1}$. Considering these relations, the first two properties follow because the solutions of (2.1) and their first derivatives are continuous in I and the Wronskians are constant and different from zero. It is also evident that d_n and e_n are continuous in I if and only if $Z_n(x)$ does not vanish in I; obviously, the same is true for a_n and b_n. In addition, the coefficients are differentiable when $Z_n(x) \neq 0$, because the solutions of the differential equation are at least twice differentiable in I. ∎

By taking into account that both sets of solutions satisfy the second order ODE (2.1) we can obtain relations between the coefficients appearing in relations (2.3).

LEMMA 2.2. *Let relations* (2.3), *with continuous coefficients in* I, *be satisfied by solutions* $\{y_n^{(1)}, y_{n-1}^{(1)}\}$ *and* $\{y_n^{(2)}, y_{n-1}^{(2)}\}$, *where* $\{y_n^{(1)}, y_n^{(2)}\}$ *and* $\{y_{n-1}^{(1)}, y_{n-1}^{(2)}\}$ *are independent solutions of second order ODEs in normal form* (2.1). *Then, the following relations hold:*

1. $d_n/e_n = c_n \neq 0$ *with* c_n *constant and* $d_n(x) \neq 0\, \forall x$.
2. $a_n + b_n = -d_n'/d_n$.

3. $W[d_n, g_n] \equiv d_n g_n' - d_n' g_n = (A_n - A_{n-1}) d_n$, *where* $g_n \equiv b_n - a_n$.
4. $a_n' + a_n^2 = -A_n - e_n d_n$

Conversely, given two DDEs verifying relations 1, 2, 3, *and* 4 *for all* n, *there exist two sets of independent solutions* $\{y_k^{(1)}\}$, $\{y_k^{(2)}\}$ *which verify the DDEs and are solutions of the differential equation* (2.1) *for each* k.

Proof. The first relation was already shown in Lemma 2.1. Taking the derivative of the first DDE and using $y_{n-1} = \frac{1}{d_n}(y_n' - a_n y_n)$ to eliminate y_{n-1} (recall that $d_n \neq 0$), we find

$$y_n'' = \left[a_n + \frac{d_n'}{d_n} + b_n\right] y_n' + \left[a_n' + d_n e_n - a_n \frac{d_n'}{d_n} - a_n b_n\right] y_n,$$

and given that y_n satisfies $y_n'' + A_n y_n = 0$, by subtracting we have

$$\left[a_n + \frac{d_n'}{d_n} + b_n\right] y_n' + \left[a_n' + d_n e_n - a_n \frac{d_n'}{d_n} - a_n b_n + A_n\right] y_n = 0.$$

We demand that this equation be satisfied by two independent functions $y_n^{(1)}$ and $y_n^{(2)}$, and therefore

$$\begin{aligned} &a_n + b_n + \frac{d_n'}{d_n} = 0, \\ &a_n' + d_n e_n - a_n \frac{d_n'}{d_n} - a_n b_n + A_n = 0. \end{aligned} \tag{2.5}$$

Proceeding in a similar way, starting from the second equation in (2.3), we find

$$\begin{aligned} &a_n + b_n + \frac{e_n'}{e_n} = 0, \\ &b_n' + d_n e_n - b_n \frac{e_n'}{e_n} - a_n b_n + A_{n-1} = 0. \end{aligned} \tag{2.6}$$

Subtracting the first equations in (2.5) and (2.6), we obtain

$$\frac{d_n'}{d_n} - \frac{e_n'}{e_n} = 0, \tag{2.7}$$

which implies, as already known, that d_n/e_n is a constant (and d_n and e_n never vanish, as we know from Lemma 2.1).

Combining the two equations in (2.5), we have

$$a_n' + a_n^2 = -A_n - e_n d_n, \tag{2.8}$$

and proceeding in a similar way with (2.6), obtain

$$b_n' + b_n^2 = -A_{n-1} - e_n d_n. \tag{2.9}$$

Subtracting these last two equations and using the first equation in (2.5), we get the third equation of the theorem.

Conversely, given the two DDEs with coefficients satisfying relations 1, 2, 3, and 4, the sets of functions satisfying such DDEs automatically satisfy second order ODEs in normal form. Furthermore, one can always generate two sets of fundamental solutions by iterative application of the DDEs: take two sets of independent solutions of the ODE for one order (let's say $y_{m-1}^{(1)}$ and $y_{m-1}^{(2)}$) and use the second DDE to obtain $y_m^{(1)}$

and $y_m^{(2)}$, which necessarily satisfy the first DDE on account of the relations between coefficients. $y_m^{(1)}$ and $y_m^{(2)}$ are necessarily independent because $d_m/e_m = -w_m/w_{m-1}$, $d_m \neq 0$, $e_m \neq 0$, and $w_{m-1} = W[y_{m-1}^{(1)}, y_{m-1}^{(2)}] \neq 0$; this implies that $w_m \neq 0$. □

Further properties of the coefficients of the DDEs are obtained in Corollary 2.3 and Lemma 2.4.

COROLLARY 2.3. *Let A_n, A_{n-1}, a_n, b_n, d_n, and e_n be continuous in I. If $A_n(x) - A_{n-1}(x) \neq 0\, \forall x \in I$, then $a_n - b_n$ can have only one zero in I.*

Proof. Let us define the function $f(x) = (b_n(x) - a_n(x))/d_n(x)$, which is differentiable in I. By taking the derivative and considering relation 3 of Lemma 2.2 we get $f' = (A_n - A_{n-1})/d_n$.

Thus, f is monotonic in I because neither d_n nor $A_n - A_{n-1}$ change sign in I. Therefore, f can have no more than one zero in I. □

An additional property satisfied by the coefficients is the fact that the coefficients d_n and e_n have opposite signs. This property is a key ingredient of the global method that we will describe.

LEMMA 2.4. *Let y_n and y_{n-1} be two nontrivial solutions of* (2.1), *for $k = n$ and $k = n-1$, such that they satisfy* (2.3) *with continuous d_n. If one of these functions has, at least, two zeros in I, then*

1. *the zeros of y_n, y_{n-1} are simple.*
2. *y_n and y_{n-1} cannot vanish simultaneously.*
3. *the zeros of y_n and y_{n-1} are interlaced.*
4. *$e_n(x)d_n(x) < 0\ \forall x \in I$.*

Proof. 1. This is an immediate consequence of the existence and uniqueness theorem for linear homogeneous ODEs.

2. If $y_n(x_0) = y_{n-1}(x_0) = 0$, then by virtue of the DDEs and the continuity of the coefficients, $y_n'(x_0) = y_{n-1}'(x_0) = 0$. Then both solutions would be trivial: $y_n(x) = y_{n-1}(x) = 0$.

3. Let x_1, x_2 be two consecutive zeros of y_n. Given that y_n is differentiable, we have $y_n'(x_1)y_n'(x_2) < 0$. By virtue of the first DDE (2.3) and the fact that $d_n(x)$ does not change sign, we get $y_{n-1}(x_1)y_{n-1}(x_2) < 0$; however, y_{n-1} is continuous and therefore there is at least one $\bar{x}_1 \in (x_1, x_2)$ such that $y_{n-1}(\bar{x}_1) = 0$. Since we can prove in a similar way (using the second difference-differential relation) that between two zeros of y_{n-1} there is at least one zero of y_n, then there can be no more zeros of y_{n-1} in (x_1, x_2): if there were two zeros of y_{n-1} in (x_1, x_2), then there would be a zero of y_n in this interval, and x_1 and x_2 would not be consecutive zeros, in contrast to our hypothesis.

This proves that between two zeros of y_n there is exactly one zero of y_{n-1}. In the same way, between two zeros of y_{n-1} there is exactly one zero of y_n.

4. Let x_1, x_2, and $\bar{x}_1$ be defined as before. Let us take $y_n(\bar{x}_1) > 0$ (for $y_n(\bar{x}_1) < 0$ the proof is analogous). This assumption implies that $y_n'(x_1) > 0$ and $y_n'(x_2) < 0$ because the zeros are simple. Considering the first DDE, we get $\operatorname{sign}(d_n)y_{n-1}(x_1) > 0$, $\operatorname{sign}(d_n)y_{n-1}(x_2) < 0$, and so

$$\operatorname{sign}(d_n)y_{n-1}'(\bar{x}_1) < 0.$$

Considering the second DDE and given that we assumed that $\operatorname{sign}(y_n(\bar{x}_1)) > 0$, we have

$$\operatorname{sign}(y_{n-1}'(\bar{x}_1)) = \operatorname{sign}(e_n).$$

Therefore, $e_n d_n < 0$. □

The following theorem summarizes the main results of this section.

THEOREM 2.5. *Let $y_k'' + A_k(x)y_k(x) = 0$, where $A_k(x)$ are continuous functions in I. Let $\{y_n^{(1)}, y_n^{(2)}\}$,$\{y_{n-1}^{(1)}, y_{n-1}^{(2)}\}$ be two sets of independent solutions in I for $k = n$ and $k = n-1$. Then, both sets $\{y_n^{(1)}, y_{n-1}^{(1)}\}$ and $\{y_n^{(2)}, y_{n-1}^{(2)}\}$ satisfy the relations*

$$\begin{aligned} y_n'(x) &= a_n(x)y_n(x) + d_n(x)y_{n-1}(x), \\ y_{n-1}'(x) &= b_n(x)y_{n-1}(x) + e_n(x)y_n(x), \end{aligned} \tag{2.10}$$

where the coefficients $a_n(x)$, $b_n(x)$, $d_n(x)$, and $e_n(x)$ have the same discontinuities in I. If these coefficients are continuous, then the following properties hold:

1. *The coefficients are differentiable in I.*
2. *$d_n(x) \neq 0\ \forall x \in I$, $d_n/e_n = c_n \neq 0$, c_n constant.*
3. *$a_n + b_n = -d_n'/d_n$.*
4. *$W[d_n, g_n] \equiv d_n g_n' - d_n' g_n = (A_n - A_{n-1})d_n$, where $g_n \equiv b_n - a_n$.*
5. *$a_n' + a_n^2 = -A_n - e_n d_n$.*
6. *If at least one of the solutions (for n or $n-1$) has two (or more) zeros in I, we can set $d_n(x) = -e_n(x)$ after a convenient normalization of the solutions.*
7. *If $A_n(x) - A_{n-1}(x)$ does not change sign in I, then $a_n(x) - b_n(x)$ can have only one zero in I.*

Conversely, given two DDEs (2.3) *verifying the first* 5 *conditions for all n, there exist two sets of fundamental solutions $\{y_k^{(1)}\}$, $\{y_k^{(2)}\}$ which are solutions of the differential equation* (2.1) *for each k.*

Proof. It is known that the DDEs relating y_n' and y_{n-1}' with y_n and y_{n-1} for two sets of fundamental solutions of the ODE exist and are unique [15]. The rest of the theorem, except property 6, is a compilation of the results presented in Lemmas 2.1, 2.2, 2.4, and Corollary 2.3.

The only thing left to prove is that from the initial fundamental sets of solutions, one of them having at least two zeros in I, one can build other fundamental sets such that $d_n = -e_n$. Note that $e_n d_n < 0$ (Lemma 2.4) and that d_n/e_n is a constant. Therefore, the relation $d_n = -e_n$ can be indeed trivially accomplished by renormalizing the solutions through constant factors. Of course, such a renormalization does not change the a_n and b_n coefficients or any other result in this theorem and the previous ones. ∎

Although we have considered equations in normal form so far, these results apply more generally. The following result for ODEs in canonical form can be easily proved.

COROLLARY 2.6. *Let $y_n''(x) + B(x)y_n'(x) + A_n(x)y_n(x) = 0$ with $A_n(x)$ continuous and $B(x)$ not depending on n and with continuous derivative in I. If the coefficients of the DDEs are continuous in I, then the following properties hold:*

1. *The coefficients of the DDEs are differentiable in I.*
2. *$d_n(x) \neq 0\ \forall x \in I$, $d_n/e_n = c_n \neq 0$, c_n constant.*
3. *If there is a solution of order n or $n-1$ with at least two zeros in I, then $d_n(x) = -e_n(x)$ with a convenient normalization of the solutions.*
4. *$W[d_n, g_n] \equiv d_n g_n' - d_n' g_n = (A_n - A_{n-1})d_n$ being $g_n \equiv b_n - a_n$.*
5. *If $A_n(x) - A_{n-1}(x)$ does not change sign in I, then $a_n(x) - b_n(x)$ can have only one zero in I.*

Proof. Transform the ODE to the normal form by the change $y(x) = \nu(x)\bar{y}(x)$, $\nu(x) = \exp(-\frac{1}{2}\int B(x)dx)$. In this way,

$$\bar{y}_n'' + \bar{A}_n \bar{y}_n = 0 \text{ with } \bar{A}_n = A_n - B^2/4 - B'/2,$$

and $\bar{A}_n$ is continuous in I. Then apply Theorem 2.5. □

The rest of the properties in Theorem 2.5 must be slightly modified but the main properties that will be used in what follows (2, 3, and 5 of Corollary 2.6) remain invariant. Hence, the methods that we will develop can be directly applied for solutions of these types of equations.

On the other hand, if $B(x)$ also depends on the order n, these results are no longer valid. For instance, d_n/e_n is not necessarily a constant. However, one can transform the ODEs to the normal form by applying changes of the dependent variables depending on the order. We would write $y_k = \nu_k(x)\bar{y}_k$, $k = n, n-1$, where $\nu_k = \exp\left(-\frac{1}{2}\int B_k(x)dx\right)$ and the DDEs for the functions $\{\bar{y}_k\}$, with the same zeros as the functions $\{y_k\}$, satisfy all the relations between coefficients of Theorem 2.5.

3. Ratios of consecutive functions and the change of variables $z(x)$. From now on, we will consider functions normalized in such a way that $d_n = -e_n$ (Theorem 2.5).

We define

$$H_n(x) = \text{sign}(d_n)y_n/y_{n-1}. \tag{3.1}$$

$H_n(x)$ has the same zeros as y_n because the zeros of y_n and y_{n-1} are interlaced. This ratio will be the basis of our root-finding scheme.

Taking the derivative and using the DDEs, we have

$$H_n'(x) = \text{sign}(d_n)\left(\frac{y_n'}{y_{n-1}} - \frac{y_n}{y_{n-1}}\frac{y_{n-1}'}{y_{n-1}}\right) = |d_n| + (a_n - b_n)H_n + |d_n|H_n^2 \ .$$

If relations (2.3), with the conditions of Theorem 2.5, hold with the replacement $n \to n+1$, which is the usual situation, we can write

$$\begin{aligned} y_{n+1}'(x) &= a_{n+1}(x)y_{n+1}(x) + d_{n+1}(x)y_n(x), \\ y_n'(x) &= b_{n+1}(x)y_n(x) - d_{n+1}(x)y_{n+1}(x), \end{aligned} \tag{3.2}$$

and we can define a second ratio with the same roots as y_n:

$$H_{n,+1}(x) = -\text{sign}(d_{n+1})\frac{y_n(x)}{y_{n+1}(x)} \ . \tag{3.3}$$

Taking the derivative, we obtain

$$H_{n,+1}'(x) = |d_{n+1}|(1 + H_{n,+1}^2) - (a_{n+1} - b_{n+1})H_{n,+1}. \tag{3.4}$$

In a more compact form, we define

$$H_{n,i}(x) = -i\text{sign}(d)\frac{y_n}{y_{n+i}} \tag{3.5}$$

and we have that

$$H_{n,i}'(x) = |d|(1 + H_{n,i}^2) + i(b - a)H_{n,i}, \tag{3.6}$$

where $i = \pm 1$, and the orders of the coefficients a, b, and d are n for $i = -1$ and $n+1$ for $i = +1$.

We observe that the functions $H_{n,i}(x)$ satisfy the same differential equation as $\tan x$ if $|d| = 1$ and if the linear term is missing. This linear term prevents the $H_{n,i}$ functions from being monotonic in general. Monotonic functions (except at the zeros of y_{n+i}) can be obtained from the functions $H_{n,i}$, as similarly shown in [21], by exponentiation of the coefficient of the linear term:

$$f_{n,i}(x) = \exp\left(i \int (a-b)dx\right) H_{n,i}(x).$$

These functions can be used to build globally convergent Newton iterations. However, we will see how the properties satisfied by the function $H_{n,i}$ are enough to find a fixed point method which implies, as a weaker result, the global convergence of the Newton iterations based on $f_{n,i}$.

Let us introduce the changes of variables (one different change for each value of i):

$$z(x) = \int |d(x)|\, dx. \tag{3.7}$$

Denoting

$$H_i(z) \equiv H_{n,i}(x(z)) \tag{3.8}$$

and $\frac{dH_i}{dz} \equiv \dot{H}_i$, we find that

$$\dot{H}_i = (1 + H_i^2) - 2\eta_i H_i, \tag{3.9}$$

where

$$\eta_i = i\frac{a-b}{2|d|}. \tag{3.10}$$

These expressions are quite similar to those obtained for the particular case of the Bessel functions [21, 23], the main difference being that $(b-a)/d$ may change sign (only once if $A_n - A_{n-1}$ never vanishes), while this phenomenon was absent for Bessel functions. η_i are monotonic functions if $A_n - A_{n-1}$ never cancels (see the proof of Corollary 2.3).

4. Globally convergent fixed point method. The starting point of the fixed point method for the evaluation of the zeros of $Y_n(z) \equiv y_n(x(z))$ is the first derivative of H_i (see (3.9)).

We will discuss the evaluation of the zeros of $Y_n(z) \equiv y_n(x(z))$. Obviously, if z_n is a zero of Y_n, then $z^{-1}(z_n)$ is a zero of y_n and vice versa. We will assume that all hypotheses of Theorem 2.5 are met.

If we were given a guess value z_0 to obtain a zero z_n of Y_n and η_i was identically zero (which is the case for Bessel functions of order $n = 1/2$), the obvious answer would be

$$z_n = T_i(z_0) = z_0 - \arctan(H_i(z_0)).$$

When $\eta_i \neq 0$, we will show that $T_i(z)$ can be used to evaluate zeros by taking successive iterations of this function.

It is important to bear in mind that, if $A_n(x) - A_{n-1}(x) \neq 0 \, \forall x \in I$, η_i can change sign only once in I (see Theorem 2.5, properties 2 and 7, and (3.10)). The value $z \equiv z_\eta$ for which $\eta_i(z_\eta) = 0$ will be called the transition point (TP).

We will first prove the global convergence for the iteration in case η_i does not change sign, and we will consider the other situation later.

Let us first introduce some notation:

1. We denote by Y_k the functions $Y_k(z) \equiv y_k(x(z))$.
2. Let us consider that z_n is a zero of Y_n. We will denote by $z_{n+i}^{(j)}$ the closest zero of Y_{n+i} to z_n which is smaller than z_n (if it exists). Similarly, we denote by $z_{n+i}^{(j+1)}$ the closest zero of Y_{n+i} to z_n which is greater than z_n (if it exists).
3. We will denote by J_i an open interval such that there is exactly one zero of Y_n in J_i ($z_n \in J_i$) and such that J_i is the largest interval in which there are no zeros of Y_{n+i}.

It is important to bear in mind the following result.

LEMMA 4.1. *Let J_i be an interval as defined above. Then H_i is continuous in J_i. If $z \in J_i$, then* $\operatorname{sign}(H_i) = \operatorname{sign}(z - z_n)$. *If $z_{n+i}^{(j)}$ exists, then* $\lim_{z \to z_{n+i}^{(j)+}} H_i = -\infty$. *If $z_{n+i}^{(j+1)}$ exists, then* $\lim_{z \to z_{n+i}^{(j+1)-}} H_i = +\infty$.

Proof. H_i is continuous in J_i because Y_{n+i} does not vanish in I. In addition, (3.9) implies that $\dot{H}_i(z_n) = 1$ because $H_i(z_n) = 0$. Given that the only zero of Y_n in J_i is z_n and H_i is increasing at z_n, then H_i is positive for $z > z_n$ and negative for $z < z_n$ for values of z in J_i. ∎

The following lemma will lead to the definition of subintervals of monotonic convergence.

LEMMA 4.2. *Let $T_i(z) = z - \arctan(H_i(z))$.*

1. *If $\eta_i > 0 \; \forall z_0 \in (z_n, z') \subset J_i$, then $z_n < T_i(z_0) < z_0$ and $\lim_{p\to\infty} T_i^{(p)}(z_0) = z_n$ $\forall z_0 \in (z_n, z')$.*
2. *If $\eta_i < 0 \; \forall z_0 \in (z'', z_n) \subset J_i$, then $z_0 < T_i(z_0) < z_n$ and $\lim_{p\to\infty} T_i^{(p)}(z_0) = z_n \; \forall z_0 \in (z'', z_n)$.*

In both cases the FPI converges monotonically.

Proof. The only fixed point of the iteration T_i in J_i is z_n. Therefore, convergence to z_n is guaranteed once we have proved that the successive iterations of T_i form monotonic sequences which approach z_n and are bounded by z_n.

From (3.9) we have

$$\dot{H}_i = (1 + H_i^2) - 2\eta_i H_i \; . \tag{4.1}$$

Rearranging (4.1) gives

$$\operatorname{sign}(\eta_i)\operatorname{sign}(H_i) \left(\frac{\dot{H}_i}{1 + H_i^2} - 1 \right) = -2|\eta_i| \frac{|H_i|}{1 + H_i^2} \leq 0, \tag{4.2}$$

where the equality holds only for $z = z_n$.

Now, since $\operatorname{sign}(H_i(z)) = \operatorname{sign}(z - z_n) \; \forall z \in J_i$ (see Lemma 4.1),

$$\operatorname{sign}(\eta_i) \int_z^{z'} \left(\frac{\dot{H}_i}{1 + H_i^2} - 1 \right) dz < 0 \tag{4.3}$$

for all $z, z' \in J_i$ such that $z_n \leq z < z'$ or $z_n \geq z > z'$.

Integrating, we obtain

$$\operatorname{sign}(\eta_i)(\arctan(H_i(z')) - \arctan(H_i(z)) - (z' - z)) < 0, \tag{4.4}$$

and taking $z = z_n$ gives

$$\operatorname{sign}(\eta_i)(\arctan(H_i(z')) - (z' - z_n)) < 0, \qquad z' \in J_i \setminus \{z_n\}. \tag{4.5}$$

Therefore, if $\eta_i > 0$ $\forall z \in (z_n, z') \equiv K \subset J_i$, then we have that $H_i(z) > 0$ in K (Lemma 4.1), and given a value $z_0 \in K$, we have $T_i(z_0) = z_0 - \arctan(H_i(z_0)) < z_0$; in addition, from (4.5) it follows that $z_n < T_i(z_0)$. This proves the first case of the lemma; the second case can be proved in a similar way. ∎

This lemma suggests the following definition.

DEFINITION 4.3. *When $\eta_i > 0$ in $(z_n, z_{n+i}^{(j+1)}) \subset J_i$ (first case of Lemma 4.2), we say that z_n has a subinterval of monotonic convergence (SMC) on the right. The interval $(z_{n+i}^{(j)}, z_n) \subset J_i$ when $\eta_i > 0$ is called a subinterval of conditioned convergence (SCC).*

z_n has an SMC on the left when $\eta_i < 0$ holds in an interval $(z_{n+i}^{(j)}, z_n)$ (second case of Lemma 4.2). There is an SCC on the right if $\eta_i < 0$ in $(z_n, z_{n+i}^{(j+1)})$.

Lemma 4.2 can be used to show that, whenever $z_{n+i}^{(j)}$ and $z_{n+i}^{(j+1)}$ exist and η_i does not change sign in $(z_{n+i}^{(j)}, z_{n+i}^{(j+1)})$, the FPI converges for any starting value in such an interval. Before this, it is convenient to set bounds on the lengths of SMCs and SCCs.

COROLLARY 4.4 (lengths of SCCs and SMCs). *Let $z_{n+i}^{(j)}$ and $z_{n+i}^{(j+1)}$ be two consecutive zeros of Y_{n+i} and let z_n be the zero of Y_n in $J_i = (z_{n+i}^{(j)}, z_{n+i}^{(j+1)})$. Let $\eta_i \neq 0$ $\forall z \in J_i$. Then*

1. *the length of the SMC is larger than $\pi/2$,*
2. *the length of the SCC is smaller than $\pi/2$.*

Proof. Considering (4.5) and taking into account Lemma 4.1, we have

$$\operatorname{sign}(\eta_i)\operatorname{sign}(z' - z_n)(|\arctan(H_i(z'))| - |z' - z_n|) < 0 \ \forall z' \in J_i \setminus z_n. \tag{4.6}$$

Taking the limit $z' \to z_{n+i}$, where $z_{n+i} = z_{n+i}^{(j)}$ or $z_{n+i} = z_{n+i}^{(j+1)}$, gives

$$\operatorname{sign}(\eta_i)\operatorname{sign}(z_{n+i} - z_n)\left(\frac{\pi}{2} - |z_{n+i} - z_n|\right) < 0. \tag{4.7}$$

However, the values between z_n and z_{n+i} form an SMC if and only if $\operatorname{sign}(\eta_i)\operatorname{sign}(z_{n+i} - z_n) > 0$, and they are an SCC if and only if $\operatorname{sign}(\eta_i)\operatorname{sign}(z_{n+i} - z_n) < 0$ (see Lemma 4.2 and Definition 4.3). ∎

COROLLARY 4.5. *The distance between two consecutive zeros of Y_n or Y_{n+i} is greater than $\pi/2$.*

We can now prove the global convergence in the intervals $(z_{n+i}^{(j)}, z_{n+i}^{(j+1)})$.

THEOREM 4.6. *Let $z_{n+i}^{(j)}$ and $z_{n+i}^{(j+1)}$ be two consecutive zeros of Y_{n+i} and let z_n be the zero of Y_n on $J_i = (z_{n+1}^{(j)}, z_{n+1}^{(j+1)})$. Assume that η_i does not change sign in J_i. Let $T_i(z) = z - \arctan(H_i)$. Then*

$$\lim_{p \to \infty} T_i^{(p)}(z_0) = z_n \ \forall z \in (z_{n+i}^{(j)}, z_{n+i}^{(j+1)}).$$

Proof. Given that η_i does not change sign, there is an SMC on either the left or on the right of z_n (Lemma 4.2). Let us consider that the SMC is on the right, which means that $\eta_i > 0$ (the case $\eta_i < 0$ is proved in a similar way). From (4.5) we have that $z_n < T_i(z) = z - \arctan(H_i(z))\,\forall z \in J_i$. As discussed in Lemma 4.2 this implies monotonic convergence to z_n for all the starting values z_0 in the SMC $(z_n, z_{n+i}^{(j+1)})$. For initial values z_0 in the SCC $(z_{n+i}^{(j)}, z_n)$, given that $z_0 < z_n < z_1 \equiv T_i(z_0) < z_0 + \pi/2$ (see (4.5)), the value of z after the first iteration (z_1) is greater than z_n and in fact lies in the SMC; this is so because the length of the SMC, $z_{n+i}^{(j+1)} - z_n$, is larger than $\pi/2$ while $z_1 - z_0 < \pi/2$. The next iterations starting from z_1 will therefore converge monotonically. ∎

The preceding proof illustrates how the convergence for starting values in an SCC inside an interval J_i is conditioned to the existence of an adjacent SMC in J_i.

Remark. Given that the zeros of Y_n and Y_{n+i} are interlaced, the preceding theorem guarantees (except for a trivial exception) convergence to a zero of Y_n for any starting value in an interval (z_{n+i}, z'_{n+i}), z_{n+i} and z'_{n+i} being any two zeros of Y_{n+i}, not necessarily consecutive. The trivial exception to this result comes from the fact that $H_i(z)$ is not defined at the zeros of Y_{n+i}. However, this "overflow problem" in the evaluation of H_i is easy to handle numerically. Let us avoid this circumstance by defining $T_i(z_{n+i}) = \pi/2$; then, convergence in intervals (z_{n+i}, z'_{n+i}) is global without exception.

The convergence theorems established so far, as well as all the following results, also apply to the Newton iteration based on the monotonic functions f_i. This iteration is given by

$$\hat{T}_i(z) = z - \frac{f_i}{\dot{f}_i} = z - \frac{H_i}{1 + H_i^2} \equiv z - R_i(z).$$

However, $\operatorname{sign}(R_i(z)) = \operatorname{sign}(\arctan(H_i(z)))$ and $|R_i(z)| < |\arctan(H_i(z))|$ and therefore this Newton iteration is also globally convergent.

5. Finding the zeros inside an interval. In order to compute with certainty all the zeros of Y_n inside an interval $I \subset (z_{n+i}, z'_{n+i})$, with z_{n+i}, z'_{n+i} zeros of Y_{n+i}, we need to find a step Δz such that, once a zero of Y_n (z_n) is known, the starting value $z_0 = z_n + \Delta z$ (or $z_0 = z_n - \Delta z$) will lead to convergence to a zero Y_n consecutive to z_n. This is provided by the following proposition.

PROPOSITION 5.1. *Let $I = [z_1, z_2] \subset (z_{n+i}^{(1)}, z_{n+i}^{(M)})$, where $z_{n+i}^{(1)}$, $z_{n+i}^{(2)}$, …, $z_{n+i}^{(M)}$ denote M consecutive zeros of Y_{n+i}; η_i is such that $\eta_i \neq 0\,\forall z \in I$. All the zeros of Y_n in I can be found by applying one of the following algorithms:*

1. *If $\eta_i < 0\,\forall z \in I$, then $z_n^{(1)} = \lim_{p\to\infty} T_i^{(p)}(z_1)$ is a zero of Y_n and the successive consecutive zeros $z_n^{(1)} < z_n^{(2)} \ldots$ are recursively obtained in the following way: $z_n^{(k+1)} = \lim_{p\to\infty} T_i^{(p)}(z_n^{(k)} + \pi/2)$. The convergence to the zeros $z_n^{(k)}$, $k > 1$, is always monotonic. The process is repeated until an m is reached for which $z_n^{(m)} + \pi/2 > z_2$.*
2. *If $\eta_i > 0\,\forall z \in I$, then $z_n^{(1)} = \lim_{p\to\infty} T_i^{(p)}(z_2)$ is a zero of Y_n and the successive consecutive zeros $z_n^{(1)} > z_n^{(2)} \ldots$ are recursively obtained in the following way: $z_n^{(k+1)} = \lim_{p\to\infty} T_i^{(p)}(z_n^{(k)} - \pi/2)$. The convergence to the zeros $z_n^{(k)}$, $k > 1$, is always monotonic. The process is repeated until an m is reached for which $z_n^{(m)} - \pi/2 < z_1$.*

Proof. 1. If $\eta_i < 0$, then the SMCs are on the left of the zeros of Y_n and the SCCs are on the right. By Theorem 4.6, the FPI with starting value z_1 converges to a zero $z_n^{(1)}$ of Y_n.

Given a zero of Y_n, $z_n^{(k)} \in (z_{n+i}^{(j)}, z_{n+i}^{(j+1)})$, the right subinterval $(z_n^{(k)}, z_{n+i}^{(j+1)})$ is an SCC, with length smaller than $\pi/2$, and therefore $z_n^{(k)} + \pi/2$ "jumps" outside this SCC and falls into the next SMC $(z_{n+i}^{(j+1)}, z_n^{(k+1)})$, which guarantees monotonic convergence to the next zero of Y_n, $z_n^{(k+1)}$. This shows that the step $\Delta z = \pi/2$ guarantees convergence to the successive zeros of Y_n.

Because the algorithm always evaluates successive values of z in increasing order, except, perhaps, when calculating the first zero, after $z_n^{(m)} + \pi/2 > z_2$ for some m, the iteration can be stopped since the next zero of Y_n would be larger than z_2.

2. The proof for $\eta_i > 0$ is very similar and it is omitted. □

6. Special cases. In order to circumvent the limitations present in Proposition 5.1 and to thus be able to build a general algorithm which will find all the real roots inside any real interval $[z_1, z_2]$, we must study the convergence of the method when

1. the starting value lies in an interval which is not contained in an interval $(z_{n+i}^{(1)}, z_{n+i}^{(M)})$.
2. η_i changes sign in an interval $(z_{n+i}^{(j)}, z_{n+i}^{(j+1)})$. We will say that $(z_{n+i}^{(j)}, z_{n+i}^{(j+1)})$ is a transition subinterval.

The potential problems will be avoided by choosing starting values which guarantee monotonic convergence.

It is easy to prove the following result regarding convergence in transition subintervals.

PROPOSITION 6.1 (transition subintervals). *Let $J_i \equiv (z_{n+i}^{(j)}, z_{n+i}^{(j+1)})$, $z_{n+i}^{(j)}$ and $z_{n+i}^{(j+1)}$ being two consecutive zeros of Y_{n+i}, and let z_η be the zero of η_i in J_i. If $\lim_{z \to z_{n+i}^{(j)}} \eta_i > 0$ and $\lim_{z \to z_{n+i}^{(j+1)}} \eta_i < 0$, then the following hold:*

1. $\lim_{p \to \infty} T_i^{(p)}(z_\eta) = z_n$, *where z_n is the zero of Y_n inside J_i.*
2. *If $z_\eta \le z_n$, then $z_\eta - \pi/2 < z_{n+i}^{(j)}$ and $z_n + \pi/2 > z_{n+i}^{(j+1)}$.*
3. *If $z_\eta \ge z_n$, then $z_n - \pi/2 < z_{n+i}^{(j)}$ and $z_\eta + \pi/2 > z_{n+i}^{(j+1)}$.*

Proof. 1. η_i is negative between z_η and z_n if $z_\eta < z_n$, while η_i will be positive between z_η and z_n if $z_\eta > z_n$; in both cases, by Lemma 4.2, there is monotonic convergence for all starting values between z_η and z_n (including both values).

2. $\eta_i < 0$ for $z \in (z_n, z_{n+i}^{(j+1)})$; thus, z_n has an SCC on the right and hence $z_n + \pi/2 > z_{n+i}^{(j+1)}$ (Corollary 4.4). On the other hand, $\eta_i > 0$ in $(z_{n+i}^{(j)}, z_\eta)$, where H_i is negative (such as for an SCC); by using similar arguments to those in Corollary 4.4 (applying (4.3)) one can show that $z_\eta - \pi/2 < z_{n+i}^{(j)}$.

3. The proof is analogous to the previous case. □

This result will be applied when η_i is a decreasing function with a zero z_η (recall that η_i is monotonic and cannot have more than one zero when $A_n - A_{n+i} \neq 0\ \forall x$). The algorithm is said to be expansive, because the zeros are evaluated in increasing order on the right of z_η and in decreasing order on the left. This proposition gives a recipe for finding the zero in the transition subinterval and for starting the forward and backward sweeps outside this subinterval.

Regarding convergence in intervals that are not contained in intervals $(z_{n+i}^{(1)}, z_{n+i}^{(M)})$, the most important case is for intervals of the type $[z_1, z_{n+i})$ or $(z_{n+i}, z_2]$. We have the following result.

PROPOSITION 6.2 (first and last subintervals). *Let J_i be an interval where there is no zero of Y_{n+i}.*

1. *If $J_i = [z_1, z_{n+i})$ and $\eta_i < 0$ in J_i, then we have the following:*
   (a) *If $H_i(z_1) > 0$, then there is no zero of Y_n in J_i and $z_1 + \pi/2 > z_{n+i}$.*
   (b) *If $H_i(z_1) < 0$, then there is a zero, z_n, of Y_n in J_i; $\lim_{p\to\infty} T^{(p)}(z_1) = z_n$ (monotonically) and $z_n + \pi/2 > z_{n+i}$.*
2. *If $J_i = (z_{n+i}, z_2]$ and $\eta_i > 0$ in J_i, then we have the following:*
   (a) *If $H_i(z_1) < 0$, then there is no zero of Y_n in J_i and $z_2 - \pi/2 < z_{n+i}$.*
   (b) *If $H_i(z_1) > 0$, then there is a zero, z_n, of Y_n in J_i; $\lim_{p\to\infty} T^{(p)}(z_2) = z_n$ (monotonically) and $z_n - \pi/2 < z_{n+i}$.*

Proof. 1(a) There can be no zero of Y_n in J_i because H_i is increasing at the zeros. Equation (4.4) can be used to prove that $z_1 + \pi/2 > z_{n+i}$.

1(b) There is a zero in J_i as a consequence of Lemma 4.1. Convergence is guaranteed by Lemma 4.2, and Corollary 4.4 proves that $z_n^{(1)} + \pi/2 > z_{n+i}$. (There is an SCC on the right of $z_n^{(1)}$.)

Cases 2(a) and 2(b) can be proved in the same way. □

This result will be useful when evaluating the smallest (largest) zero when $\eta_i < 0$ ($\eta_i > 0$) inside an interval $[z_1, z_2]$. Monotonic convergence is guaranteed.

Propositions 6.1 and 6.2 provide convergence results for the zeros of the first and last subintervals and transition subintervals, as well as steps to abandon such subintervals. It is important to note that such steps ($\Delta z = \pi/2$) guarantee monotonic convergence once such subintervals are abandoned.

7. Algorithms. We will build explicit algorithms to compute with certainty all the zeros inside an interval. These algorithms implement Propositions 5.1, 6.1, and 6.2.

We will first consider evaluation of the zeros inside an interval $[z_1, z_2]$, where η_i does not change sign. The algorithm computes zeros in increasing order if $\eta_i < 0$ and in decreasing order in the other case (similarly to Proposition 5.1). Both forward ($\eta_i < 0$) and backward ($\eta_i > 0$) sweeps can be summarized in a single algorithm as follows. We use FORTRAN-like syntax.

ALGORITHM 1. FORWARD AND BACKWARD SWEEPS. *Let $[z_1, z_2]$ be an interval where η_i does not change sign. Let $H(z) \equiv H_i(z)$. The zeros of Y_n in this interval can be found with certainty using the following algorithm:*

Input: $j = -\text{sign}(\eta_i)$ *(+1 forward sweep; −1 backward); z_1;z_2;$\epsilon \equiv$ relative precision*
Output: *i (number of zeros); $z(1), \ldots, z(i)$: zeros in the interval*

```
(0)   SUBROUTINE SWEEP(j,z1,z2,ϵ,i,z(i))
(1)   NOTERM = 1
(2)   z̄1 = (z1 + z2)/2 + j((z1 − z2)/2)
(3)   z = z̄1
(4)   z̄2 = (z1 + z2)/2 − j((z1 − z2)/2)
(5)   IF (jH(z) > 0) THEN z = z + jπ/2
(6)   i = 0
(7)   DO WHILE (j(z − z̄2) < 0)
(8)        CALL FIXEDPOINT(z,z̄2,ϵ,zn,NOTERM)
(9)        IF(NOTERM = 1) THEN
(10)            z(j i) = zn
(11)            i = i + 1
(12)            z = zn + jπ/2
```

(13) *ELSE*
(14) $z = \bar{z}_2 + j$
(15) *ENDIF*
(16) *END WHILE*
(17) *END*

($0'$) *SUBROUTINE FIXEDPOINT*(z,$\bar{z}_2$,ϵ,z_n,*NOTERM*)
($1'$) $Err = 1 + \epsilon$
($2'$) *DO WHILE* (*NOTERM* $= 1$) AND ($Err > \epsilon$)
($3'$) $z_p = z$
($4'$) $z = z - \arctan(H(z))$
($5'$) $Err = |1 - z/z_p|$
($6'$) *IF* ($j(z - \bar{z}_2) > 0$) *THEN NOTERM* $= 0$
($7'$) *END WHILE*
($8'$) $z_n = z$
($9'$) *END*

and the zeros generated in a forward sweep are stored in the positive positions of the array $z(i)$ $(z(1), z(2), \ldots)$, *while those generated in a backward sweep are stored in the negative positions* $(z(-1),\ z(-2), \ldots)$.

Lines ($0'$)–($9'$) implement the fixed point iteration T_i. Lines (0)–(17) implement Proposition 5.1, complemented with Proposition 6.2 (line (5)).

Let us, for instance, discuss how the algorithm works in the case of a forward sweep ($j = +1$) in an interval $[z_1, z_2]$; for a backward sweep, the description is very similar. The first 4 lines are used to set the initial and final values for the sweep. In the case we are considering (forward), the starting value for the process is $\bar{z}_1 = z_1$ and the algorithm stops when, at any stage of the process, a value of z is reached which is greater than $\bar{z}_2 = z_2$ (lines ($6'$) and (7) test whether this condition is reached).

Line (5) tests whether there is a zero of Y_n between z_1 and the first zero of Y_{n+i} in $[z_1, z_2]$; if there is no such zero ($jH(z) < 0$), the instruction $z = z + j\pi/2$ sets a new starting value z to compute the smallest zero of Y_n in $[z_1, z_2]$ (see Proposition 6.2).

Lines (7)–(17) implement Proposition 5.1.

Note that all successive values of z generated in the process form an increasing sequence because convergence is always monotonic. This explains why the process can be stopped when a value of z outside this interval is reached. When this happens, we can be sure that all the zeros in the interval have been found.

The previous algorithm always can be applied when η_i does not change sign inside the interval under consideration; however, when η_i changes sign in I, we have to combine the forward and backward sweeps. If η_i is negative on the left of the interval and positive on the right, then we can use an algorithm which approaches the TP from both sides of the interval.

ALGORITHM 2. CONTRACTIVE SWEEP. *Let* $[z_1, z_2]$ *be an interval where* η_i *changes sign in such a way that* $\eta_i < 0$ *as* $z \to z_1$. *Let* z_η *be such that* $\eta_i(z_\eta) = 0$. *The zeros of* Y_n *in such an interval can be found with certainty using the following two successive calls*:
CALL SWEEP($+1$,z_1,z_η,ϵ,i,$z(i)$)
CALL SWEEP(-1,z_η,z_2,ϵ,i,$z(i)$)

If η_i is negative on the right of the interval and positive on the left, then the sweep starts from the TP and propagates away from it (expansive sweep). Convergence

starting from any value z in an interval $(z_{n+i}^{(j)}, z_{n+i}^{(j+1)})$ with a TP is not guaranteed because there is no SMC in such an interval. However, given the way η_i changes sign, Proposition 6.1 tells us that the starting value z_η ensures convergence to the zero of Y_n near the TP. In addition, the same proposition gives the recipe for abandoning the region of convergence to this zero. These are the main characteristics of the following algorithm.

ALGORITHM 3. EXPANSIVE SWEEP. *Let $[z_1, z_2]$ be a real interval where η_i changes sign in such a way that $\eta_i > 0$ as $z \to z_1$. Let z_η be such that $\eta_i(z_\eta) = 0$. The zeros of Y_n in such an interval can be found with certainty using the following algorithm*:

(0) *SUBROUTINE EXPANSIVE*(z_1,z_2,z_η,ϵ,$z(i)$)
(1) $z = z_\eta$
(2) $Err = 1 + \epsilon$
(3) *DO WHILE* $(Err > \epsilon)$ *AND* $(NOTERM = 1)$
(4) $\quad z_p = z$
(5) $\quad z = z - \arctan(H(z))$
(6) $\quad$ *IF* $(z > z_2)$ *OR* $(z < z_1)$ $NOTERM = 0$
(7) $\quad Err = |1 - z/z_p|$
(8) *END WHILE*
(9) $z_{tp} = z$
(10) *IF NOTERM*$= 1$ *THEN*
(11) $\quad z(0) = z$
(12) $\quad$ *IF* $(z_{tp} > z_\eta)$ *THEN*
(13) $\quad\quad$ *CALL SWEEP*($+1$,$z(0) + \pi/2$,z_2,ϵ,i,$z(i)$)
(14) $\quad\quad$ *CALL SWEEP*(-1,z_1,$z_\eta - \pi/2$,ϵ,i,$z(i)$)
(15) $\quad$ *ELSE*
(16) $\quad\quad$ *CALL SWEEP*($+1$,$z_\eta + \pi/2$,z_2,ϵ,i,$z(i)$)
(17) $\quad\quad$ *CALL SWEEP*(-1,z_1,$z(0) - \pi/2$,ϵ,i,$z(i)$)
(18) $\quad\quad$ *ENDIF*
(19) *ENDIF*
(20) *END*

$z(0)$ *is the zero of Y_n in the transition subinterval.*

The three algorithms described are sufficient to find all the zeros of any solution of a second order ODE $y_n''(x) + B(x)y_n'(x) + A_n(x)y_n(x) = 0$, $A_n(x) - A_{n-1}(x) \neq 0\,\forall x$ satisfying general DDEs (satisfied by two fundamental sets) with continuous coefficients. The forward and backward (or expansive and contractive) sweeps are most often simultaneously available given that we will normally have two iterations to choose, one with $\eta_{-1} = -(a_n - b_n)/2d_n$ and another with $\eta_{+1} = (a_{n+1} - b_{n+1})/2d_{n+1}$.

The condition $A_n(x) - A_{n-1}(x) \neq 0\,\forall x$ was used to show that η_i can change sign only once. However, if this condition is not met, strategies combining contractive and expansive sweeps can be developed. In any case, as we will see, this condition is met with great generality.

8. Applications. Considering that we started from basic ingredients, it is not surprising that the method developed is valid for a wide spectrum of special functions. The method can be applied to any combination of fundamental solutions of the ODE. In contrast, matrix eigenvalue methods apply only to orthogonal polynomials and to minimal solutions of three term recurrence relations

$$y_{n+1} + \alpha_n y_n + \beta_n y_{n-1} = 0. \tag{8.1}$$

The matrix methods for minimal solutions were developed by Grad and Zakrajsek [8], enhanced by Ikebe et al. (see [10, 11, 16] and references therein), and later revisited by Ball [2].

The fixed point method described here becomes especially simple to implement for minimal solutions of the recurrence (8.1) related to (2.3). The reason is that Pincherles's theorem [4, 18] guarantees the existence of continued fractions for the ratios of minimal solutions y_n/y_{n-1} and y_n/y_{n+1}, which are the only evaluations needed in our method. In this case, the method is based solely on the coefficients of the recurrence relations, as happens with matrix methods [10], with the advantage that the fixed point method is not affected by truncation errors, which need to be estimated. The fixed point method is not restricted to minimal solutions; for any dominant solution, the method still can be applied by using an alternative method for calculating $y_n/y_{n\pm1}$.

We are now explicitly showing how to implement these algorithms for general solutions of the Bessel, Coulomb, and Legendre equations (with emphasis on conical functions and Legendre polynomials) as well as for general solutions of second order ODEs satisfied by some classical orthogonal polynomials (Hermite, Laguerre). Computational details are given in [7].

8.1. Bessel equation (cylinder functions). The Bessel equation is

$$y_n''(x) + B(x)y_n'(x) + A_n(x)y_n(x) = 0, \tag{8.2}$$

with $B(x) = 1/x$, $A_n(x) = 1 - n^2/x^2$, and $A_n(x) - A_{n-1}(x) = \dfrac{2n-1}{x^2}$ which is only zero for $n = 1/2$. This case is trivial: $y_n(x) \propto \cos(x + \phi)$. The coefficients of the DDEs are

$$a_n = -n/x\,; \quad b_n = (n-1)/x\,; \quad d_n = -e_n = 1, \tag{8.3}$$

and then $\eta_i = -i\frac{n_i - 1/2}{x}$, with $i = \pm1$, $n_{+1} = n + 1$, and $n_{-1} = n$. There are no TPs ($x = 0$ is a regular singular point and our analysis is only for intervals where all the solutions are continuous). No change of variable $z(x)$ is required. The DDEs are satisfied by general cylinder functions; therefore, the algorithm can be applied to combinations of first and second kind Bessel functions, including Airy functions.

8.2. Coulomb equation (Coulomb wave functions). The coefficient $A_n(x)$ for the Coulomb equation (which is an equation in normal form) is $A_n(x) = 1 - 2\gamma/x - n(n+1)/x^2$; we use n instead of the more standard notation L, γ instead of η, and x instead of ρ (see [1, 25]). n and γ are parameters.

We can take $n > -1$ because $A_{-n-1} = A_n$. Observe that $A_n(x) - A_{n-1}(x) = -2n/x$ which equals zero only for $n = 0$. $n = 0$ is a special case only in the sense that the iteration with $i = -1$ has no meaning because y_0 and y_{-1} are not independent solutions (but the iteration for $i = +1$ always can be used).

The coefficients for the DDEs (see [1, eqs. (14.2.1) and (14.2.2)]) are

$$a_n = -b_n = -\frac{1}{n}\left(\frac{n^2}{x} + \gamma\right); \qquad d_n = -e_n = \frac{\sqrt{n^2 + \gamma^2}}{n}\ . \tag{8.4}$$

We need only consider positive zeros because the negative ones are positive zeros of the functions with the sign of γ reversed. The change of variables can be chosen as $z = \int d_{n_i}(x)dx = d_{n_i}x$ (again, $n_i = n$ for $i = -1$ and $n_i = n + 1$ for $i = +1$).

We have that $\eta_i = -i(n_i^2 + \gamma x)/(x\sqrt{n_i^2 + \gamma^2})$. Thus, there is a TP at $z_\eta = -d_n n^2/\gamma$ which is positive for $n \in (-1, 0)$ and $\gamma > 0$ as well as for $n > 0$ and $\gamma < 0$.

If there is no positive TP, then the forward sweep ($i = +1$) always can be used and the backward sweep ($i = -1$) can be used except for $n = 0$. When there is a TP, we can use both contractive and expansive sweeps (except for the case $n = 0$, for which only the expansive sweep can be used).

The DDEs are satisfied by both the regular and irregular Coulomb wave functions; the algorithm applies to any combination of them (general solutions of the differential equation).

8.3. Legendre equation (conical functions). Conical functions are chosen to illustrate the application of the fixed point method to Legendre functions P_m^n, Q_m^n, which are solutions of a differential equation $y_n''(x) + B(x)y_n'(x) + A_n(x)y_n(x) = 0$ with coefficients

$$B(x) = 2x/(x^2 - 1);\ A_n(x) = -[m(m+1) + n^2/(x^2 - 1)](x^2 - 1). \tag{8.5}$$

We have reversed the use of m and n with respect to the standard notation [1] in order to be consistent with our own notation. We will consider the case $x > 1$.

We have $A_n - A_{n-1} = (-2n + 1)/(x^2 - 1)^2$ which vanishes (identically) only for $n = 1/2$; this is, as for Bessel functions with $n = 1/2$, a trivial case.

Conical functions are defined by $m = -1/2 + i\tau$ with real τ. The corresponding coefficients of the difference-differential relations are

$$a_n = \frac{-nx}{x^2 - 1}, \quad b_n = \frac{(n-1)x}{x^2 - 1}, \quad d_n = -\frac{\lambda_n^2}{\sqrt{x^2 - 1}}, \quad e_n = \frac{1}{\sqrt{x^2 - 1}}, \tag{8.6}$$

with

$$\lambda_n = \sqrt{(n - 1/2)^2 + \tau^2}\ . \tag{8.7}$$

In order to set $d_n = -e_n$ we need to renormalize the solutions. We then use new functions $\bar{y}$: $y_p = K_p \bar{y}_p$ with $K_n = \sqrt{(n - 1/2)^2 + \tau^2} K_{n-1}$. With this, the new coefficients d_n and e_n are $d_n = -e_n = -\lambda_n/\sqrt{x^2 - 1}$ and the change of variables $z(x)$ can be taken as $z(x) = \int |d_{n_i}(x)| dx = \lambda_{n_i} \ln(x + \sqrt{x^2 - 1})$, which means that $x(z) = \cosh(z/\lambda_{n_i})$.

The iterations read $T_i(z) = z - \arctan(H_i(z))$ with

$$\begin{aligned} H_{-1}(z) &= \mathrm{sign}(d_n)\frac{\bar{y}_n(x(z))}{\bar{y}_{n-1}(x(z))} = -\frac{1}{\lambda_n}\frac{y_n(x(z))}{y_{n-1}(x(z))}, \\ H_{+1}(z) &= -\mathrm{sign}(d_{n+1})\frac{\bar{y}_n(x(z))}{\bar{y}_{n+1}(x(z))} = \lambda_{n+1}\frac{y_n(x(z))}{y_{n+1}(x(z))}. \end{aligned} \tag{8.8}$$

From the coefficients we get $\eta_i = i(-n_i + 1/2)x/(\lambda_{n_i}\sqrt{x^2 - 1})$, with n_i as defined before. There are no TP for $x > 1$. However, η_i vanishes identically for $n_i = 1/2$. This is a trivial case because $\dot{H}_i = 1 + H_i^2$.

Forward and backward sweeps are possible.

The same DDEs are satisfied by first kind ($P^n_{-1/2+i\tau}$) and second kind ($Q^n_{-1/2+i\tau}$) conical functions and therefore the algorithm also applies to any linear combination.

8.4. Legendre equation (Legendre polynomials). Differential equation: $(1-x^2)P_n(x) - 2xP_n'(x) + n(n+1)P_n(x) = 0$, $|x| < 1$.

Coefficients in the DDEs: $a_n = -b_n = -\frac{nx}{1-x^2}$, $d_n = -e_n = \frac{n}{1-x^2}$.

Change of variable: $z(x) = \frac{n_i}{2}\ln\frac{1+x}{1-x}$; $x(z) = \tanh(z/n_i)$. Range of z: $(-\infty, +\infty)$.

TPs: $\eta_i = -ix$; TP at $x_\eta = 0 = z(x_\eta) \equiv z_\eta$.

Applicable algorithms: expansive from $z = 0$; contractive is not appropriate given the range of z. Only the positive z-roots of Legendre polynomials need to be calculated because they are symmetric around $x = 0$ and $z(-x) = -z(x)$; thus, a forward sweep from $z = 0$ is sufficient to find all the zeros.

The algorithms apply to any solution of the differential equation, satisfying the same DDEs. Then we can use them for $\cos\alpha P_n - \sin\alpha Q_n$ for any α.

8.5. Hermite equation (Hermite polynomials). Differential equation: $y_n'' - 2xy_n' + 2ny_n = 0$.

Coefficients in the DDEs: $a_n = 0$, $b_n = 2x$, $d_n = 2n$, $e_n = -1$.

Normalization: We must renormalize Hermite polynomials by $y_p = k_p\bar{y}_p$ with $k_n = \sqrt{2n}k_{n-1}$ $(n > 0)$.

Renormalized coefficients: same as before except that $d_n = -e_n = \sqrt{2n}$.

Change of variable: $z(x) = \sqrt{2n_i}x$. Range of z: $(-\infty, +\infty)$.

TPs: $\eta_i = -ix(z)/\sqrt{2n_i}$; TP at $x_\eta = 0 = z(x_\eta) \equiv z_\eta$.

Applicable algorithms: same as for Legendre polynomials.

The functions $e^{-x^2/2}y_n(x)$ satisfy an equation in normal form and two DDEs with $A_n(x) = 1 - x^2 + 2n$, $a_n = -b_n = -x$, $d_n = 2n$, $e_n = -1$ which satisfy all the conditions of Lemma 2.2. Thus, the DDEs are satisfied by general solutions (with a convenient normalization). The algorithms apply to arbitrary solutions of the ODE.

8.6. Laguerre equation (generalized Laguerre polynomials). Differential equation: $xy_n'' + (\alpha + 1 - x)y_n' + ny_n = 0$, $x > 0$.

Coefficients: $a_n = n/x$, $b_n = 1 - (n+\alpha)/x$, $d_n = -(n+\alpha)/x$, $e_n = n/x$.

Normalization: We must renormalize Laguerre polynomials by $y_p = k_p\bar{y}_p$ with $k_n = \sqrt{(n+\alpha)/n}k_{n-1}$.

Renormalized coefficients: same as before except that $d_n = -e_n = -\frac{1}{x}\sqrt{(n+\alpha)n}$.

Change of variable: $z(x) = \sqrt{(n_i+\alpha)n_i}\ln x$. Range of z: $(-\infty, +\infty)$.

TPs: $\eta_i = i(n_i + \alpha/2 - x/2)/\sqrt{n_i(n_i+\alpha)}$; TP at $x_\eta = 2n_i + \alpha$, $z_\eta = z(x_\eta) = \sqrt{n_i(n_i+\alpha)}\ln(2n_i+\alpha)$.

Applicable algorithms: expansive or contractive from z_η. Given the range of z, expansive is more appropriate.

Writing the differential equation in normal form and using Lemma 2.2 we conclude that the algorithms apply to arbitrary solutions of the ODE.

9. Conclusions and perspectives. The method described here can be applied to any oscillating special function when DDEs (with continuous coefficients) satisfied by two sets of fundamental solutions are available. We also require that A_n and A_{n+i} are never equal (which is a condition generally met).

The method has several advantages with respect to matrix methods: not only can the zeros of minimal solutions be obtained, but also the zeros of general solutions. The zeros in any interval (x_1, x_2) can be found, and not necessarily the first n zeros. The method can be used to investigate the existence of zeros in a given interval (where perhaps there is no zero at all). In addition, although fast (see [22] for a similar method for Bessel functions), the method admits improvements when there is

additional information on the zeros of a function (like asymptotic [24] or Chebyshev approximations for the zeros of Bessel functions), in contrast to matrix methods. Finally, the fixed point method is not affected by matrix truncation errors, which are function dependent [16, 2]. With respect to more general purpose methods [12], the fixed point method has the advantage of being much more simple to implement. Besides, it proves to be faster: the global Newton method for Bessel functions in [22] compared favorably with respect to [28] and the speed of convergence of this Newton method [21] is improved by the implementation of the fixed point method described in this paper. More computational details are given in [7].

The main difficulty when evaluating zeros of a given function is usually the bracketing of the roots, given that the distribution of zeros can change drastically from one set of parameters to another. The fixed point method here presented does not require bracketing. A good example of this variability are Coulomb functions, which present very rapid oscillations for $\gamma < 0$, large $|\gamma|$, and not too large x and oscillate slowly for large and positive n and/or γ and not too large x. It is observed that the number of iterations needed by the algorithm to converge to the different zeros is quite stable with varying parameters [7]. For instance, for Coulomb functions we have experienced that around 10 iterations are enough to get a precision of 10^{-8} for moderate values of n and γ and that as n and γ increase this number is quite stable, reaching 20–30 for values as large as 500 (in spite of the fact that the spacing between the first zeros increases considerably).

Not only can the spacing between zeros vary for different parameter selection but also, for a fixed function, the spacing between zeros can vary drastically for different ranges of x. The change of variable $z(x)$ tends to smooth this variation; for instance, this is observed for conical functions, which oscillate very fast for x close to 1 and slow down for large x. The change of variables $z(x)$ (see the previous section) automatically sets a much more uniform distribution of zeros with respect to z, which explains why the fixed point method has a fairly uniform behavior regarding convergence to all the zeros.

Both the method and the bonus information regarding the distances between zeros have the property of being valid for a broad family of special functions, which is a rather singular event. In future papers, we plan to investigate how broad this class of functions is and to provide a comprehensive lexicon for its application.

Also, the zeros of the derivatives of this class of functions can be investigated using similar techniques. Given a family of functions $\{y_n\}$ satisfying a second order linear ODE in normal form, after a change of the dependent variable one can write a second order linear ODE for $z_n \propto y_n'$, together with first order DDEs; the main difficulty consists of finding analytic expressions for the change of variable $z(x)$ and its inverse. An alternative consists of realizing that for positive A_n the zeros of y_n and y_n' are interlaced. This suggests that fixed point methods based on the logarithmic derivative of y_n are more appropriate, as discussed in [7].

WEAK ILL-POSEDNESS OF SPATIAL DISCRETIZATIONS OF ABSORBING BOUNDARY CONDITIONS FOR SCHRÖDINGER-TYPE EQUATIONS*

ISAÍAS ALONSO-MALLO† AND NURIA REGUERA‡

Abstract. When we wish to solve numerically a differential problem defined on an infinite domain, it is necessary to consider a finite subdomain and to use artificial boundary conditions in such a way that the solutions in the finite subdomain approximate the original solution. These boundary conditions are called absorbing when small reflections to the interior domain are allowed. In this paper, we develop a general class of absorbing boundary conditions for Schrödinger-type equations by using rational approximations to the transparent boundary conditions. With this approach, previous absorbing boundary conditions in the literature are included in this class. We use the method of lines for the discretization of the initial boundary value problems obtained this way. We show that the ordinary differential systems that arise after the spatial discretization are weakly ill-posed, explaining a previous conjecture of Fevens and Jiang. The time discretization is carried out with A-stable Runge–Kutta methods, where the high order ones may be used to compensate for the possible troubles present in the problems semidiscretized in space.

Key words. Schrödinger equation, absorbing boundary conditions, initial boundary value problems, method of lines

1. Introduction.

The numerical solution of initial value problems on unbounded domains arises in a wide variety of differential equations. In order to obtain a manageable problem, it is necessary to consider a finite subdomain $[x_l, x_r]$ and to impose artificial boundary conditions. When the solution of this new problem is equal to the restriction to the subdomain of the original solution, we say that the boundary condition is *transparent* (TBC). However, when the transparent boundary conditions are nonlocal it is convenient to use local *absorbing* boundary conditions (ABCs), permitting that the computed solution presents some reflections.

The TBCs and ABCs and their discretizations are widely studied (see [5, 9, 23] for hyperbolic problems, [4, 8] for parabolic ones). In this paper, we are interested in the study of ABCs for the equation

$$\partial_t u = -\frac{i}{c}(\partial_x^2 u + V(x,t)u), \quad x \in \mathbf{R},\ t > 0, \tag{1.1}$$

where c is a real constant and V is the potential. (In this paper, we suppose without loss of generality that $c > 0$. The case $c < 0$ is analogous.) This equation arises in two well-known cases: the one-dimensional time dependent Schrödinger equation for

a particle with mass m,

$$i\hbar\partial_t\Psi = -\frac{\hbar^2}{2m}\partial_x^2\Psi + V(x,t)\Psi,$$

and the Fresnel equation for the evolution of a paraxial electrical field E along the z-direction in a Cartesian coordinate system [17, 24],

$$2in_0k_0\partial_z E = \partial_x^2 E + (n^2(x) - n_0^2)k_0^2 E, \tag{1.2}$$

where $n(x)$ is the refractive index ($n = 1$ if the solution propagates in a vacuum) and n_0 the reference index. We suppose in this paper that the potential V is constant or almost constant. With these hypotheses, it is possible to obtain an expression for the TBCs. Equation (1.1) along with these TBCs give rise to a well-posed problem when the support of the initial condition is contained in the domain $[x_l, x_r]$. But these TBCs are nonlocal and thus their practical interest is limited. Baskakov and Popov [2] considered these TBCs, using for their implementation linear approximations of the solution in the time intervals. However, such an approach may cause instabilities, as is proved in [15].

As an alternative, Schmidt and Yevick [19] proposed a TBC for the Fresnel equation discretized in time with the θ-method and another one for the fully discretized problem. As they are transparent, we can expect very small reflections at the boundary. Nevertheless, these boundary conditions have some troubles: they are nonlocal and thus the computational cost is high, and they are specific to the method used for the discretization in time (θ-method) and also in space in the case of the fully discretized ones. In this way, we cannot use other different numerical schemes in the interior domain. Previously, Schmidt and Deuflhard [18] had already obtained these boundary conditions for the Fresnel equation discretized in time with variable coefficients.

Several works have been done to develop local ABCs for the Schrödinger equation. Di Menza [3] considered the Schrödinger equation without potential in several dimensions. In order to get local ABCs from the transparent ones, he obtains the expression analogous to (2.3) below for the TBCs in Fourier variables, and he uses interpolating rational functions whose numerator and denominator are both polynomials of the same degree. The interpolatory nodes are chosen in order to obtain least squares approximations to the Fourier symbol of the TBCs in a given interval.

In a recent work, Fevens and Jiang [6] have developed the following ABCs for the Schrödinger equation:

$$\prod_{l=1}^{p}\left(i\partial_x - \frac{a_l c}{2}\right)u = 0. \tag{1.3}$$

This boundary condition is developed in order to absorb completely the components of the wave solutions that travel with group velocities a_l, $l = 1, \ldots, p$. They showed how Shibata's boundary conditions [20] is equivalent to (1.3) with $p = 2$ and so is Kuska's [13] for $p = 3$ and $a_1 = a_2 = a_3$.

In this paper, we define a general class of ABCs considering interpolating rational functions, as Di Menza did, but here the degree of the numerator and denominator is not necessarily the same, and we do not fix the interpolatory nodes in any way. However, we show what is the optimal choice in order to absorb the solution when it is a plane wave. These ABCs are denoted ABC(j_1, j_2), where j_1, j_2 are the degrees of the

polynomials in the numerator and denominator of the rational function, respectively. We will call order of absorption the value $j_1 + j_2 + 1$.

We prove that the ABCs obtained are a generalization of ABCs in [6]. However, a well-posedness study in a similar way to the one carried out in [6] shows that the initial boundary value problem that arises by using these ABCs may be well-posed only for the ABCs obtained in [6].

We study the discretization of the ABCs by using the method of lines. First, we discretize in space, obtaining a system of ordinary differential equations. We use the same standard finite differences discretization used in [6, 19] for the interior domain, together with several implementations at the boundary, depending on the ABCs that we use.

With our analysis, we can prove that the semidiscrete problems that arise after the spatial discretization are weakly ill-posed. In fact, these problems are dissipative when we use an adequate weighted norm. However, the bound depends on the parameter of the spatial discretization and this may lead to a growth of this bound when the spatial grid is refined. We prove this fact for the case of ABC(1,0), showing that the ill-posedness is very weak. Therefore, the ABC(1,0) may be useful in practical applications, although they are not very absorbing. Moreover, we show numerically that the semidiscrete problems associated with higher order ABCs are worse posed. This explains why in some cases we can get better results with ABCs of smaller order of absorption, as is conjectured in [6]. On the other hand, when the solution is a wave traveling with a concrete group velocity, the worse behavior of ABCs of higher order can be canceled because of the greater absorption at the boundary.

Second, we use a Runge–Kutta method for the time integration, although other time integration methods can be considered. Since the problem discretized in space is weakly ill-posed, it is very important to use a high order method for the time integration to compensate for the troubles in space, allowing a moderate time stepsize. Therefore, it is crucial to use an algorithm obtained by using the method of lines.

The organization of the paper is the following. The ABCs are studied in section 2, together with the relations with other ABCs previously proposed in the literature. Section 3 is devoted to the spatial discretization of the case ABC(1,0). Some theorems of linear algebra, which are necessary to show the weak ill-posedness of the semidiscrete problems, are proved in section 4. In section 5 we study the time discretization by using Runge–Kutta methods. In section 6 we analyze the discretization of ABCs of higher order, showing numerically the weak ill-posedness. The higher-dimensional case is studied in section 7. Finally, section 8 presents some numerical experiments showing results previously obtained.

2. Absorbing boundary conditions. Let us suppose $x_r = 0$ and consider the right exterior domain $x > 0$. In order to obtain an expression for the TBCs, we use an argument similar to the one in [19]. Let us denote by $\hat{u}(x,\omega)$ the Fourier–Laplace transform of $u(x,t)$, where $\omega = \Re(\omega) + i\Im(\omega)$ with $\Im(\omega) < 0$. From (1.1), we get

$$\partial_x^2 \hat{u} - \lambda^2 \hat{u} = 0, \tag{2.1}$$

where $\lambda^2 = -(V + c\omega)$, and since we are interested in solutions that go to 0 as $x \to \infty$, it should be

$$\hat{u}(x,\omega) = \hat{u}(0,\omega) e^{-\lambda x} \tag{2.2}$$

with $\lambda = \sqrt{-(V + c\omega)}$ ($\sqrt{\ }$ is the square root with positive real part). If $\hat{U}(p,\omega)$ denotes the Laplace transform of $\hat{u}(x,\omega)$, in view of (2.2), it is $\hat{U}(p,\omega) = \hat{u}(0,\omega)/(p +$

λ), and then $\hat{U}(\lambda,\omega) < \infty$. On the other hand, if we take Laplace transform in (2.1), we obtain

$$\hat{U}(p,\omega) = \frac{p\hat{u}(0,\omega) + \partial_x \hat{u}(0,\omega)}{(p^2 - \lambda^2)}.$$

So in order for $\hat{U}(p,\omega)$ to be finite at $p = \lambda$, the numerator in the previous expression should be 0 for this value of p. We have developed the expression for the TBCs:

$$i\sqrt{V + c\omega}\,\hat{u}(x_r,\omega) + \partial_x \hat{u}(x_r,\omega) = 0. \tag{2.3}$$

An analogous expression can be obtained for the left boundary. Our purpose is to approximate these nonlocal boundary conditions by local ones. We are going to consider approximations

$$\sqrt{V + c\omega} \approx q(V + c\omega), \tag{2.4}$$

where $q(s)$ is a rational function that interpolates $\sqrt{s}$. This is a generalization of [1] where we considered as q the Taylor expansion of first order. We use the notation ABC(j_1, j_2) when $q(s) = p_1(s)/p_2(s)$, where p_1 and p_2 are relatively prime polynomials with degrees j_1 and j_2, respectively. We recall that $j_1 + j_2 + 1$ is the order of absorption. Notice that the ABC also depends on the interpolatory nodes, but this dependence is not displayed in our notation.

We will not consider the cases ABC(0,j) for $j \geq 0$, since with a study similar to the one made later in this section, we see that ABC(0,1) and ABC(0,2) cannot give rise to a well-posed problem, and although this does not happen for ABC(0,0), its order of absorption is too small. The simplest cases are the following.

ABC(1,0). Let us consider in (2.4) the polynomial $q(s)$ that interpolates $\sqrt{s}$ at the points s_1^2 and s_2^2 (with $s_1, s_2 > 0$),

$$q(s) = \frac{s_1 s_2}{s_1 + s_2} + \frac{s}{s_1 + s_2}. \tag{2.5}$$

Then the differential operator associated with the symbol obtained in (2.3) by considering the approximation (2.4) is

$$\beta_0 \partial_t u(x_r,t) + \beta_1 u(x_r,t) + \partial_x u(x_r,t) = 0, \tag{2.6}$$

where $\beta_0 = c/(s_1 + s_2)$, $\beta_1 = i(s_1 s_2 + V)/(s_1 + s_2)$. In the particular case when $s_1^2 = s_2^2 = b$, the approximation (2.4) reduces to the Taylor expansion of first order of $\sqrt{V + c\omega}$ at $\omega = \omega^*$, with $\omega^* = (b - V)/c$.

ABC(1,1). We can also replace $\sqrt{V + c\omega}$ by $q(V + c\omega)$, where $q(s) = (\alpha_0 + \alpha_1 s)/(1 + \alpha_2 s)$ is a rational function that interpolates $\sqrt{s}$ at s_1^2, s_2^2, and s_3^2. This gives rise to

$$\beta_0 u(x_r,t) + \beta_1 \partial_t u(x_r,t) + \beta_2 \partial_x u(x_r,t) + \beta_3 \partial_{tx} u(x_r,t) = 0 \tag{2.7}$$

for certain coefficients β_j depending on s_1, s_2, and s_3. In particular, when $s_1^2 = s_2^2 = s_3^2 = b$, the approximation considered reduces to the Padé(1,1) expansion of $\sqrt{V + c\omega}$ at $\omega = \omega^*$.

ABC(2,1). Let us now consider $q(s) = (\alpha_0 + \alpha_1 s + \alpha_2 s^2)/(1 + \alpha_3 s)$ so that it interpolates $\sqrt{s}$ at the points s_1^2, s_2^2, s_3^2, and s_4^2. In this way, we get

$$\beta_0 u(x_r,t) + \beta_1 \partial_t u(x_r,t) + \beta_2 \partial_t^2 u(x_r,t) + \beta_3 \partial_x u(x_r,t) + \beta_4 \partial_{tx} u(x_r,t) = 0 \tag{2.8}$$

for certain coefficients β_j that depend on s_1, s_2, s_3, and s_4. The special case $s_1^2 = s_2^2 = s_3^2 = s_4^2 = b$ corresponds to a Padé(2,1) approximation of $\sqrt{V + c\omega}$ at $\omega = \omega^*$.

ABC(3,2). Finally, let $q(s) = p_1(s)/q_1(s)$ with $p_1(s)$ and $q_1(s)$ of degree 3, 2, respectively, interpolate $\sqrt{s}$ at the points s_1^2, s_2^2, s_3^2, s_4^2, and s_5^2. With a similar reasoning as in previous cases, we obtain

$$0 = \beta_0 u(x_r,t) + \beta_1 \partial_t u(x_r,t) + \beta_2 \partial_t^2 u(x_r,t) + \beta_3 \partial_t^3 u(x_r,t) + \beta_4 \partial_x u(x_r,t) + \beta_5 \partial_{tx} u(x_r,t) + \beta_6 \partial_{ttx} u(x_r,t). \tag{2.9}$$

ABC(2,0). We can also consider the second order polynomial $q(s)$ that interpolates $\sqrt{s}$ at three points. Nevertheless, the ABC obtained is useless for practice as we will see later on.

Let us now see which should be the value for the interpolatory nodes. Consider the equation in the interior domain along with a solution of kind $u(x,t) = \exp i(kx - \omega(k)t)$, where $\omega(k) = (V - k^2)/c$. When we use the ABC obtained by considering the approximation (2.4) in (2.3), we need $\sqrt{V + c\omega} - q(V + c\omega)$ to be small when $\omega = -\omega(k)$, that is, when $V + c\omega = k^2$. This way, the approximation should be good when at least one of the nodes of interpolation is $s_1^2 = k^2$.

Let us now study the relation between our ABCs and the ones proposed in [6]. Because of the derivatives of the solution appearing in the ABCs, only ABC($j+1$,j) and ABC(j,j) for a natural number j could coincide with (1.3). If we take $s_j = a_j c/2$, $j = 1, 2$ in ABC(1,0), we obtain the ABCs proposed in [6] for $p = 2$. Similarly, ABC(1,1) coincides with the one in [6] for $p = 3$ and $s_j = a_j c/2$, $j = 1, 2, 3$. In the same way, ABC(2,1) is that of [6] for $p = 4$ and $s_j = a_j c/2$, $j = 1, 2, 3, 4$.

The study in a rigorous way of the well-posedness of the initial boundary value problems obtained with these ABC is not the purpose of this paper. However, the theory of well-posedness for hyperbolic problems of Kreiss [12, 21] provides necessary conditions for the study of well-posedness for these problems (cf. [10]). In this way, in [6] it is checked whether there exist solutions $\Psi(s) = \exp(st + \eta x)$ of the equation and the ABCs with $\Re(s) \geq 0$, concluding that the only solution of this kind satisfies $\Re(s) = 0$. For our ABC(1,0) (that coincides with the one of [6] for $p = 2$), these solutions should satisfy

$$ics - V = \eta^2, \qquad \beta_0 s + \beta_1 + \eta = 0,$$

and then the only possibilities for s are $s = i(s_j^2 - V)/c$, for $j = 1, 2$, both imaginary. The group velocities associated with these solutions are $2s_j/c > 0$ and as we are considering the right boundary, this will not produce a reflected wave. We have obtained similar conclusions for ABC(1,1), ABC(2,1), ABC(2,2), and ABC(3,2). For ABC(2,0) and ABC(1,2) there exists a value of s that although it is imaginary, it gives rise to a solution with negative group velocity. For ABC(3,0) and ABC(1,3) there exists s with $\Re(s) > 0$ such that $\exp(st + \eta x)$ is a solution of the equation and the ABCs, giving rise to an exponentially unstable problem. We see that among the ABCs previously mentioned, the only ones that could give rise to a well-posed problem are those of the form ABC($j+1$,j) and ABC(j,j), that is, particular cases of [6].

3. Spatial discretization of ABC(1,0). Let $\{x^j : 0 \leq j \leq N\}$ be a uniform mesh of the interval $[x_l, x_r]$, where $x^j = x_l + jh$, $0 \leq j \leq N$ with $h = L/N$ and $L = x_r - x_l$. We will denote by $u^j(t)$ an approximation of $u(x^j, t)$. We have considered,

as in [6, 19], finite differences for the discretization in space of the equation in the interior domain $[x_l, x_r]$:

$$\frac{d}{dt}u^j(t) = \widetilde{m}_1(h)u^{j-1}(t) + \widetilde{m}_2(h)u^j(t) + \widetilde{m}_1(h)u^{j+1}(t), \quad 1 \le j \le N-1, \tag{3.1}$$

with $\widetilde{m}_1(h) = -i/ch^2$, $\widetilde{m}_2(h) = i(2 - Vh^2)/ch^2$.

Let us study now how to discretize the equation at the right boundary when we consider ABC(1,0) given by (2.6). An analogous reasoning is valid for the left boundary. Let us consider, as an approximation to $\partial_x^2 u$ at the right boundary x^N,

$$\partial_x^2 u(x^N, t) \approx \frac{2}{h^2}(u^{N-1}(t) - u^N(t) + h\partial_x u(x^N, t)) \tag{3.2}$$

so that, along with (2.6), we can develop the following discretization of the equation at x^N:

$$\begin{aligned}\frac{d}{dt}u^N(t) &\approx \frac{-i}{c}(\partial_x^2 u(x^N, t) + Vu^N(t)) \\ &\approx \frac{-2i}{ch^2}\left(u^{N-1}(t) - u^N(t) - h\beta_0\frac{d}{dt}u^N(t) - h\beta_1 u^N(t)\right) - \frac{iV}{c}u^N(t).\end{aligned}$$

We have obtained $du^N(t)/dt \approx \widetilde{\alpha}(h)u^N(t) + \widetilde{\beta}(h)u^{N-1}(t)$ this way, where

$$\widetilde{\alpha}(h) = \frac{i(2 - h^2V)(s_1 + s_2) - 2h(s_1s_2 + V)}{ch(-2i + hs_1 + hs_2)}, \quad \widetilde{\beta}(h) = \frac{-2i}{ch^2\left(1 - \frac{2i}{h(s_1+s_2)}\right)}.$$

For the left boundary, we have a similar expression. With this implementation of ABC(1,0), we have obtained a first order ordinary differential system

$$U'(t) = M(h)U(t) \tag{3.3}$$

with $U(t) = \left[u^0(t), u^1(t), \ldots, u^{N-1}(t), u^N(t)\right]^T$ and

$$M(h) = \begin{bmatrix} \widetilde{\alpha} & \widetilde{\beta} & 0 & 0 & \cdots & 0 \\ \widetilde{m}_1 & \widetilde{m}_2 & \widetilde{m}_1 & 0 & \cdots & 0 \\ \vdots & & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & \widetilde{m}_1 & \widetilde{m}_2 & \widetilde{m}_1 \\ 0 & \cdots & 0 & 0 & \widetilde{\beta} & \widetilde{\alpha} \end{bmatrix} \in \mathcal{M}_{(N+1)\times(N+1)}, \tag{3.4}$$

where we omit the dependence on h in the notation of the elements of $M(h)$. The solution of (3.3) is

$$U(t) = \exp(M(h)t)U(0).$$

Our following objective is to study the well-posedness in the Euclidean norm of (3.3), with the corresponding scalar product denoted by $\langle\cdot,\cdot\rangle$. We have

$$\frac{d}{dt}\|U\|^2 = \frac{d}{dt}\langle U, U\rangle = 2\Re\langle U, U'\rangle = 2\Re\langle U, M(h)U\rangle.$$

TABLE 3.1

Let $\mu_2(M(h))$ be the logarithmic norm of $M(h)$, i.e., the largest eigenvalue of $(M(h) + M(h)^*)/2$. From the estimate [7]

$$\Re\langle y, M(h)y\rangle \leq \mu_2(M(h))\|y\|^2, \tag{3.5}$$

the solution decays in the Euclidean norm (i.e., (3.3) is dissipative) when $\mu_2(M(h)) \leq 0$. But a straightforward calculation shows that $\mu_2(M(h)) > 0$ and $\mu_2(M(h)) = 1/(2ch^2) + O(h^{-1})$, providing a bound that permits an exponential instability when h goes to 0.

Since the numerical experiments do not show this catastrophic behavior, and $\mu_2(M(h))$ is the smallest number satisfying (3.5) [7], some kind of weak well-posedness must be present. In fact, the following result is proved in section 4.

THEOREM 3.1. *For every $h > 0$, all the eigenvalues of the matrix $M(h)$ have negative real part.*

A first consequence of Theorem 3.1 is that the solution $U(t)$ of (3.3) goes to zero as $t \to \infty$. However, the matrix $M(h)$ is nonnormal and it is known that in this case the eigenanalysis is not always an efficient means to determine the behavior of an exponential matrix [16, 22]. In fact, for small values of t it is possible that $U(t)$ is unbounded when h goes to zero. To examine this growth, we first make use of the analysis of the ϵ-pseudospectrum, defined in [22] by

$$\Lambda_\epsilon(M(h)) = \{\mu_\epsilon \in \mathbf{C} : \mu_\epsilon \text{ is an eigenvalue of } M(h) + E \text{ for some } E \text{ with } \|E\| \leq \epsilon\}.$$

From Theorem 5.1 in [16], when the estimate

$$\|\exp(tM(h))\| \leq C\exp(\omega t)$$

holds for all $t \geq 0$, we have the following bound for the real parts of the ϵ-pseudoeigenvalues μ_ϵ of $M(h)$:

$$\Re\mu_\epsilon \leq \omega + C\epsilon$$

for all $\epsilon \geq 0$. We have computed these ϵ-pseudoeigenvalues for some typical values of ϵ for an example of section 8 with a moderate size of h ($h = 1/80$). The maximum of the real parts are displayed in the second column of Table 3.1. Notice that all these values are negative and vary slowly for $\epsilon = 10^{-3}, 10^{-6}, 10^{-9}, 10^{-12}$, showing that the nonnormality of $M(h)$ is mild for the h considered.

However, it is necessary to estimate the initial growth of the solution of (3.3) when h goes to zero. Suppose that $M(h)$ is diagonalizable for $h > 0$. Let $P(h)$ be

an invertible matrix such that $M(h) = P(h)D(h)P(h)^{-1}$, where $D(h)$ is the diagonal matrix of eigenvalues. Therefore,

$$\begin{aligned}\|\exp(M(h)t)\| &= \left\|P(h)\exp(D(h)t)P(h)^{-1}\right\| \\ &\le \|P(h)\|\,\|\exp(D(h)t)\|\,\left\|P(h)^{-1}\right\| \le \|P(h)\|\,\left\|P(h)^{-1}\right\| = \kappa_h,\end{aligned}$$

where κ_h is the condition number of $P(h)$.

If $M(h)$ is not diagonalizable, the analysis of the behavior of $U(t)$ may be more complicated (see, for example, [11]). However, the diagonalizable case can be considered as generic. Moreover, since $\widetilde{\alpha}(h) = O(h^{-1})$ and $\widetilde{\beta}(h) = O(h^{-1})$ while the rest of the elements of $M(h)$ are $O(h^{-2})$, $M(h)$ can be considered as a perturbation of the diagonalizable matrix M_0, defined as the tridiagonal matrix such that $M_0(j,j) = 2i/ch^2$, $M_0(j,j+1) = M_0(j,j-1) = -i/ch^2$, and the first and last rows vanish. For this matrix, it is straightforward to prove that $M_0 = P_0 D_0 P_0^{-1}$, where D_0 is the diagonal matrix of eigenvalues, with $\sigma(M_0) = \left\{(2i/ch^2)(1-\cos(j\pi/N)) : j = 1,\dots,N-1\right\}\cup\{0\}$. Therefore,

$$\|\exp(M_0 t)\| = \left\|P_0\exp(D_0 t)P_0^{-1}\right\| \le \kappa_0,$$

where $\kappa_0 = \|P_0\|\,\left\|P_0^{-1}\right\|$ is the condition number of the matrix P_0 whose columns are the eigenvectors of M_0. Therefore,

$$P_0 = \begin{bmatrix} \frac{1}{\sqrt{N+1}} & \mathbf{0} & 0 \\ \frac{\mathbf{e}}{\sqrt{N+1}} & C_0 & \frac{\mathbf{d}}{s_N} \\ \frac{1}{\sqrt{N+1}} & \mathbf{0} & \frac{N}{s_N} \end{bmatrix}, \quad P_0^{-1} = \begin{bmatrix} \sqrt{N+1} & \mathbf{0} & 0 \\ \mathbf{a} & C_0 & \mathbf{b} \\ -\frac{s_N}{N} & \mathbf{0} & \frac{s_N}{N} \end{bmatrix},$$

where C_0 is the unitary matrix with elements $C_0(l,j) = \sqrt{2/N}\sin(lj\pi/N)$, $1 \le l,j \le N-1$, $s_N = \sqrt{N(N+1)(2N+1)/6}$, $\mathbf{e} = [1,\dots,1]^T$, $\mathbf{d} = [1,2,\dots,N-1]^T$, $\mathbf{a} = -\frac{1}{N}C_0[N-1,N-2,\dots,1]^T$, and $\mathbf{b} = -\frac{1}{N}C_0\mathbf{d}$.

Now, it is possible to prove that $\|P_0\| = O(1)$ and $\left\|P_0^{-1}\right\| = O(N^{1/2})$, and we deduce that $\kappa_0 = O(N^{1/2})$. By considering κ_0 as an approximation of κ_h, it is reasonable to suppose that $\kappa_h = O(h^{-1/2})$. We have numerically checked this value with an example used in section 8 (see Figure 3.1), obtaining this behavior for κ_h. The matrices $M(h)$ of these numerical tests were always diagonalizable because the eigenvalues were distinct.

4. Results on the eigenvalues of a certain class of matrices. Let us consider a matrix M_{N+1} of dimension $(N+1)\times(N+1)$ with the structure of (3.4) with $\widetilde{\alpha} = \alpha$, $\widetilde{\beta} = \beta$, $\widetilde{m}_j = m_j$, $j = 1,2$, where α, β, m_1, and m_2 are, at first, arbitrary nonzero complex numbers. If λ is an eigenvalue of this matrix with eigenvector $\mathbf{x} = [x_0,\dots,x_N]^T$, the following equation must be satisfied:

$$m_1 x_{j-1} + (m_2 - \lambda)x_j + m_1 x_{j+1} = 0, \quad 1 \le j \le N-1.$$

The solutions of this equation are $x_j = Ay_1^j + By_2^j$ for certain constants A, B, where y_1, y_2 are the roots of

$$y^2 + \frac{m_2 - \lambda}{m_1}y + 1 = 0, \tag{4.1}$$

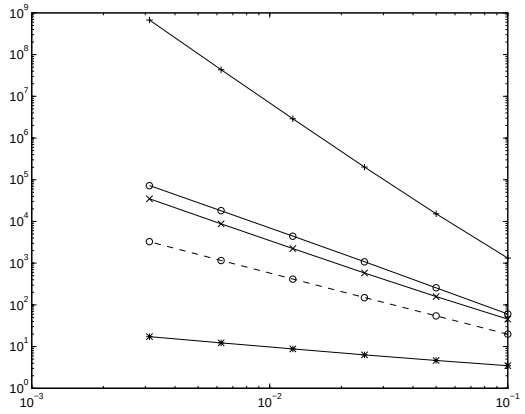

FIG. 3.1. *Condition number as a function of h:* $-*$ $ABC(1,0)$, $-\circ$ $ABC(1,1)$, $-\,-\circ$ $ABC(1,1)$ *(second implementation),* $-\times$ $ABC(2,1)$, $-+$ $ABC(3,2)$.

and then $\lambda = m_2 + m_1(y_1 + y_2)$. The following system also has to be satisfied:

$$\begin{aligned}(\alpha-\lambda)(A+B)+\beta(Ay_1+By_2)=0,\\ \beta(Ay_1^{N-1}+By_2^{N-1})+(\alpha-\lambda)(Ay_1^N+By_2^N)=0.\end{aligned} \tag{4.2}$$

In order that this system has nontrivial solutions A, B, the determinant of its coefficients should vanish. In this way, taking into account that $y_1y_2 = 1$, we obtain

$$(\alpha-\lambda)^2(y_1^N-y_2^N)+2\beta(\alpha-\lambda)(y_1^{N-1}-y_2^{N-1})+\beta^2(y_1^{N-2}-y_2^{N-2})=0. \tag{4.3}$$

Let A_{N-1} be the tridiagonal matrix obtained from M_{N+1} by eliminating the first and last rows and columns. It is a well-known fact that $\sigma(A_{N-1}) = \{m_2+2m_1\cos(\pi j/N) : j = 1,\dots,N-1\}$. Notice that $\sigma(A_{N-1}) \cap \sigma(A_N) = \emptyset$, $N > 0$. Let us denote $R_{N-1}(\lambda) = \det(A_{N-1} - \lambda I_{N-1})$ (where I_{N-1} is the identity matrix of dimension $N-1$). It is clear that

$$\begin{aligned}\det(M_{N+1}-\lambda I_{N+1}) &= (\alpha-\lambda)^2R_{N-1}(\lambda)\\ &\quad -2m_1(\alpha-\lambda)\beta R_{N-2}(\lambda)+\beta^2m_1^2R_{N-3}(\lambda).\end{aligned} \tag{4.4}$$

Notice that $R_N(\lambda) = m_1^N P_N((m_2-\lambda)/m_1)$, where $P_N(x)$ is the monic polynomial of degree N:

$$P_N(x)=\det\begin{bmatrix} x & 1 & 0 & \cdots & 0\\ 1 & x & 1 & \cdots & 0\\ \vdots & \ddots & \ddots & \ddots & \vdots\\ 0 & \cdots & 0 & 1 & x\end{bmatrix}.$$

From this expression we deduce that the following recurrence formula is satisfied:

$$P_n(x) = xP_{n-1}(x) - P_{n-2}(x), \quad n = 1,2,\dots, \tag{4.5}$$

with $P_0(x) = 1$ and $P_{-1}(x) = 0$. $R_{N-1}(\lambda)$ and $R_N(\lambda)$ have no common roots, so the same is true for the polynomials $P_N(x)$. Finally, (4.4) reduces to

$$\det(M_{N+1}-\lambda I_{N+1}) = m_1^{N-1}Q_{N+1}\left(\frac{m_2-\lambda}{m_1}\right),$$

where

$$Q_{N+1}(x) = (\alpha - m_2 + m_1 x)^2 P_{N-1}(x) - 2\beta(\alpha - m_2 + m_1 x)P_{N-2}(x) + \beta^2 P_{N-3}(x). \tag{4.6}$$

So we can conclude that λ is an eigenvalue of M_{N+1} iff

$$Q_{N+1}\left(\frac{m_2 - \lambda}{m_1}\right) = 0.$$

In the rest of this section, we will assume that the coefficients m_1 and m_2 of M_{N+1} are $m_1 = -i$, $m_2 = i(2-\delta)$.

LEMMA 4.1. *Let us consider the matrix M_{N+1} previously defined, with α, $\beta \in \mathbf{C}$ and $\delta \in \mathbf{R}$. We shall use the notation $\alpha_r = \Re(\alpha)$, $\alpha_i = \Im(\alpha)$, $\beta_r = \Re(\beta) \neq 0$, $\beta_i = \Im(\beta) \neq 0$, where these coefficients satisfy one of the following properties:*

$$|\beta| \leq |\alpha_r|, \tag{4.7}$$

$$|\beta| > |\alpha_r| \quad \textit{and} \quad \sqrt{|\beta|^2 - \alpha_r^2} < \delta + \alpha_i < 4 - \sqrt{|\beta|^2 - \alpha_r^2}. \tag{4.8}$$

We will also assume the following hypotheses:

$$\delta + \alpha_i < \frac{\alpha_r \beta_i}{\beta_r}, \tag{4.9}$$

$$(\delta + \alpha_i)(2 + \beta_i) < -\alpha_r\beta_r - 2\beta_i. \tag{4.10}$$

Then the matrix M_{N+1} has no imaginary eigenvalues.

Proof. Let us suppose there exists an imaginary eigenvalue λ of M, $\lambda = i\lambda_0$ with λ_0 real. The Gersgorin disks are $D_1 = \{x \in \mathbf{C} : |x - i(2-\delta)| \leq 2\}$ and $D_2 = \{x \in \mathbf{C} : |x - \alpha| \leq |\beta|\}$. If (4.7) is satisfied, D_2 has no imaginary eigenvalues except maybe $i\alpha_i$. But if this point was an eigenvalue of M_{N+1}, it should be also in the boundary of D_1 (M_{N+1} is irreducible; see the theorem of Taussky [14]). Therefore, $-\delta \leq \lambda_0 \leq 4 - \delta$. Otherwise, if $|\beta| > |\alpha_r|$, D_2 intersects the imaginary axis at the points $i(\alpha_i \pm \sqrt{|\beta|^2 - \alpha_r^2})$ that are in D_1 because of (4.8), then we obtain this way the same condition for λ_0, $-\delta \leq \lambda_0 \leq 4 - \delta$.

On the other hand, as we have already seen, if λ is an eigenvalue of M_{N+1}, $Q_{N+1}(X_0) = 0$, where $X_0 = -2 + \delta + \lambda_0 \in \mathbf{R}$, so X_0 should satisfy $-2 \leq X_0 \leq 2$. Making use of the recurrence formula (4.5) in (4.6),

$$\begin{aligned} Q_{N+1}(x) = {} & (-\beta^2 + (\alpha_r - i\gamma)^2 - 2i(\alpha_r - i\gamma)x - x^2)P_{N-1}(x) \\ & - (2\beta(\alpha_r - i\gamma) - (2i\beta + \beta^2)x)P_{N-2}(x), \end{aligned}$$

where $\gamma = 2 - \delta - \alpha_i$. We can write $Q_{N+1}(x) = Q^r_{N+1}(x) + iQ^i_{N+1}(x)$ where $Q^r_{N+1}(x)$ and $Q^i_{N+1}(x)$ are real polynomials. Since X_0 is a real root of $Q_{N+1}(x)$, it will be a root of $Q^r_{N+1}(x)$ and $Q^i_{N+1}(x)$:

$$\begin{aligned} 0 = Q^r_{N+1}(X_0) = {} & (-\beta_r^2 + \beta_i^2 + \alpha_r^2 - \gamma^2 - 2\gamma X_0 - X_0^2)P_{N-1}(X_0) \\ & - (2\alpha_r\beta_r + 2\gamma\beta_i - (-2\beta_i + \beta_r^2 - \beta_i^2)X_0)P_{N-2}(X_0), \end{aligned} \tag{4.11}$$

$$\begin{aligned} 0 = Q^i_{N+1}(X_0) = {} & 2(-\beta_r\beta_i - \alpha_r\gamma - \alpha_r X_0)P_{N-1}(X_0) \\ & - 2(\alpha_r\beta_i - \gamma\beta_r - (\beta_r + \beta_r\beta_i)X_0)P_{N-2}(X_0). \end{aligned} \tag{4.12}$$

As we have previously mentioned, $P_{N-1}(x)$ and $P_{N-2}(x)$ have no common roots. If we consider (4.11)–(4.12) as a system with variables $P_{N-1}(X_0)$ and $P_{N-2}(X_0)$, in order that it has a nontrivial solution, it should be

$$\begin{aligned}(4.13)\quad 0 &= (-\beta_r^2+\beta_i^2+\alpha_r^2-\gamma^2-2\gamma X_0-X_0^2)(\alpha_r\beta_i-\gamma\beta_r-(\beta_r+\beta_r\beta_i)X_0)\\ &\quad-(2\alpha_r\beta_r+2\gamma\beta_i-(-2\beta_i+\beta_r^2-\beta_i^2)X_0)(-\beta_r\beta_i-\alpha_r\gamma-\alpha_r X_0).\end{aligned}$$

Let us suppose first that $\beta_i\neq -1$. The roots of this equation are

$$X_0^a=-\gamma-\frac{\alpha_r\beta_i}{\beta_r},\quad X_0^{b,c}=\frac{A\pm\sqrt{A^2-B}}{D}$$

with $A=\alpha_r\beta_r-\gamma(2+\beta_i)$, $B=4(1+\beta_i)(\alpha_r^2+\beta_i^2+\beta_r^2+\gamma^2)$, $D=2(1+\beta_i)$.

Because of (4.9), $X_0^a<-2$, which is not possible. If $A^2-B<0$, $X_0^{b,c}\notin\mathbf{R}$, concluding the proof. Let us suppose then that $A^2-B\geq 0$. We consider first the case $\beta_i+1>0$. Let us prove $X_0^b<-2$, which is equivalent to $A+2D<-\sqrt{A^2-B}$. Making use of (4.10), we see that $A+2D<0$, and then

$$A+2D<-\sqrt{A^2-B}\quad\text{iff}\quad A^2+4AD+4D^2=|A+2D|^2>A^2-B.$$

It remains only to prove that

$$4AD+4D^2+B=4(1+\beta_i)\phi_1(\delta)>0,$$

where $\phi_1(\delta)=(\alpha_i+\beta_i)^2+(\alpha_r+\beta_r)^2+2\delta(\alpha_i+\beta_i)+\delta^2$. Notice that $\phi_1(\delta)$ goes to ∞ as $\delta\to\pm\infty$. The roots of $\phi_1(\delta)$ are $-\alpha_i-\beta_i\pm\sqrt{-(\alpha_r+\beta_r)^2}$. If $|\beta|\leq|\alpha_r|$, since $\beta_i\neq 0$, it should be $\alpha_r+\beta_r\neq 0$, and then $\phi_1(\delta)>0$ for all $\delta\in\mathbf{R}$. Otherwise, if (4.8) is satisfied, we see that the only case when we cannot guarantee that $\phi_1(\delta)>0$ is for $\delta=-\alpha_i-\beta_i$ when $\alpha_r+\beta_r=0$. But then $\sqrt{|\beta|^2-\alpha_r^2}=|\beta_i|\not<\delta+\alpha_i=-\beta_i$, which goes against hypothesis (4.8). So we obtain that $\phi_1(\delta)>0$, and then $X_0^b<-2$, which is not possible. Similarly, $X_0^c<-2$ iff $A+2D<\sqrt{A^2-B}$ which is true since $A+2D<0$ from (4.10).

Let us now consider the case $\beta_i+1<0$. It can be proved that $X_0^b<-2$ with a reasoning analogous to that for $\beta_i+1>0$. Let us see $X_0^c>2$, which is equivalent to $A-2D<\sqrt{A^2-B}$. If $A-2D<0$, this is trivially true. Otherwise,

$$A-2D<\sqrt{A^2-B}\quad\text{iff}\quad -4AD+4D^2+B=4(1+\beta_i)\phi_2(\delta)<0,$$

where $\phi_2(\delta)=(4-\alpha_i)^2+(\alpha_r-\beta_r)^2+8\beta_i-2\alpha_i\beta_i+\beta_i^2+2(\alpha_i-4-\beta_i)\delta+\delta^2$. It can be proved that $\phi_2(\delta)>0$ in a manner similar to that for ϕ_1, concluding $X_0^c>2$.

Finally, if $\beta_i=-1$, (4.13) reduces to

$$\begin{aligned}(4.14)\qquad 0 &= (-\beta_r^2+1+\alpha_r^2-\gamma^2-2\gamma X_0-X_0^2)(-\alpha_r-\gamma\beta_r)\\ &\quad-(2\alpha_r\beta_r-2\gamma-(1+\beta_r^2)X_0)(\beta_r-\alpha_r\gamma-\alpha_r X_0),\end{aligned}$$

whose roots are

$$X_0^d=\frac{\alpha_r}{\beta_r}-\gamma,\qquad X_0^e=\frac{1+\alpha_r^2+\beta_r^2+\gamma^2}{\alpha_r\beta_r-\gamma}.$$

From hypothesis (4.9) for $\beta_i=-1$, we deduce that $X_0^d<-2$. Let us see that $X_0^e<-2$. Taking into account (4.10), we have that $\alpha_r\beta_r-\gamma<0$, so $X_0^e<-2$ iff

$$1+\alpha_r^2+\beta_r^2+\gamma^2+2\alpha_r\beta_r-2\gamma=(\alpha_r+\beta_r)^2+(1-\gamma)^2>0,$$

which is true unless $\alpha_r = -\beta_r$ and $\delta + \alpha_i = 1$. It can be seen that this cannot happen if (4.7) or (4.8) is satisfied. Therefore, (4.14) cannot be satisfied, and then M_{N+1} cannot have any imaginary eigenvalues. ∎

LEMMA 4.2. *Let $M_{N+1}(h)$ be the matrix M_{N+1} where the coefficients $\alpha(h)$, $\beta(h)$, $\delta(h)$ are functions regular enough in a neighborhood $\mathcal{V}$ of zero and the dimension of the matrix is independent of h. Let us suppose that there exist $a_1, b_1, d_1 \in \mathbf{R}$ such that*

$$\alpha(h) = h\alpha_0 + h^2\alpha_1(h), \quad \textit{where} \quad \alpha_0 < 0, \quad \alpha_1(0) = ia_1, \tag{4.15}$$

$$\beta(h) = -h\alpha_0 + h^2\beta_1(h), \quad \textit{where} \quad \beta_1(0) = ib_1, \tag{4.16}$$

$$\delta(h) = h^2\delta_1(h) \in \mathbf{R}, \quad \textit{where} \quad \delta_1(0) = d_1, \tag{4.17}$$

$$0 > a_1 + b_1 + d_1, \tag{4.18}$$

$$0 > \alpha_0(1-N)(a_1 + b_1 + d_1) + 2\Re(\alpha_1'(0) + \beta_1'(0)). \tag{4.19}$$

Then there exists $h_0 > 0$ such that for all $h \in (0, h_0)$, the eigenvalues of $M_{N+1}(h)$ have negative real part.

Proof. Let λ be an eigenvalue of $M_{N+1}(h)$ with eigenvector $\mathbf{x} = [x_0, \dots, x_N]^T$. As we have remarked previously, $x_j = Ay_1^j + By_2^j$ where y_1 and y_2 are the roots of (4.1) and $\lambda = i(2 - \delta(h) - y_1 - y_2)$. We observe this way that

$$\Re(\lambda) = \Im(y_1)\left(1 - \frac{1}{|y_1|^2}\right) < 0 \quad \text{iff} \quad \begin{cases} \Im(y_1) < 0 & \text{and} \quad |y_1| > 1 \quad \text{or} \\ \Im(y_1) > 0 & \text{and} \quad |y_1| < 1, \end{cases} \tag{4.20}$$

where we have used that $y_1 y_2 = 1$. Equation (4.3) also has to be satisfied (where the coefficients now depend on h). If we multiply this expression by y_1^{N+2}, we obtain $T(y_1, h) = 0$, with

$$\begin{aligned} T(y,h) = {} & \alpha(h)^2(y^{2N+2} - y^2) - 2i\alpha(h)((2-\delta(h))y - y^2 - 1)(y^{2N+1} - y) \\ & - ((2-\delta(h))y - y^2 - 1)^2(y^{2N} - 1) + 2\alpha(h)\beta(h)(y^{2N+1} - y^3) \\ & - 2i\beta(h)((2-\delta(h))y - y^2 - 1)(y^{2N} - y^2) + \beta(h)^2(y^{2N} - y^4). \end{aligned}$$

Our purpose is to study whether the roots of $T(y,h)$ satisfy (4.20) for h small enough. Let us notice that $T(y,0) = -(y-1)^4(y^{2N} - 1)$, and therefore, the roots of $T(y,0)$ are $y = 1$ and $\{\exp(i\pi j/N) : j = 0, \dots, 2N-1\}$. Taking into account that $\alpha(0) = \beta(0) = \delta(0) = 0$, we get

$$\partial_y T(y,0) = -2N(y-1)^4 y^{2N-1} + 4(y-1)^3(1 - y^{2N}),$$

so for $j \in \{1, \dots, 2N-1\}$, $T(\exp(i\pi j/N), 0) = 0$ and $\partial_y T(\exp(i\pi j/N), 0) \neq 0$. Then we can apply the implicit function theorem: there exist neighborhoods $\mathcal{A}_j \subset \mathcal{V}$ of 0 and $\mathcal{B}_j$ of $\exp(i\pi j/N)$ and a unique regular function $y_j : \mathcal{A}_j \to \mathcal{B}_j$ such that

$$T(y_j(h), h) = 0 \quad \text{for all} \quad h \in \mathcal{A}_j \quad \text{and} \quad y_j(0) = \exp(i\pi j/N).$$

In a neighborhood of 0, $y_j(h) = \exp(i\pi j/N) + hy_j'(0) + O(h^2)$. Therefore,

$$\begin{aligned} |y_j(h)|^2 &= |\exp(i\pi j/N) + hy_j'(0) + O(h^2)|^2 \\ &= 1 + 2h(\Re(y_j'(0))\cos(\pi j/N) + \Im(y_j'(0))\sin(\pi j/N)) + O(h^2). \end{aligned}$$

Let us now study $y_j'(0)$. Taking into account that $\beta'(0) = -\alpha'(0)$, $\delta'(0) = 0$, $y_j(0)^{2N} = 1$, and $y_j(0)^{-1} = \bar{y}_j(0)$,

$$y_j'(0) = \frac{-\partial_h T(y_j(0),0)}{\partial_y T(y_j(0),0)} = \frac{-2i\alpha'(0)(y_j(0)+y_j(0)^{2N})}{-2N(y_j(0)-1)y_j(0)^{2N-1}+4(1-y_j(0)^{2N})}$$

$$= \frac{i\alpha'(0)(y_j(0)+1)}{N(y_j(0)-1)y_j(0)^{-1}} = \frac{i\alpha_0(y_j(0)+1)}{N(1-\bar{y}_j(0))} = \frac{i\alpha_0(1-y_j(0)^2)}{N|1-\bar{y}_j(0)|^2},$$

and then

$$\Re(y_j'(0)) = \frac{2\alpha_0\cos(\pi j/N)\sin(\pi j/N)}{N|1-\bar{y}_j(0)|^2}, \quad \Im(y_j'(0)) = \frac{2\alpha_0\sin^2(\pi j/N)}{N|1-\bar{y}_j(0)|^2}.$$

Since $\alpha_0 < 0$ from (4.15), we deduce that $\Im(y_j'(0)) < 0$ for $0 < j < 2N$, $j \neq N$.

If $0 < j < \lfloor \frac{N}{2} \rfloor$, $\cos(\pi j/N)\sin(\pi j/N) > 0$ and then $\Re(y_j'(0)) < 0$. We have $\Re(y_j'(0))\cos(\pi j/N) + \Im(y_j'(0))\sin(\pi j/N) < 0$ this way, and therefore, $|y_j(h)|^2 < 1$ and $\Im(y_j(h)) > 0$ for h small enough. Reasoning this way for the rest of the cases, we can conclude that there exists $h_0 > 0$ such that, for all $h \in (0, h_0)$,

(i) if $0 < j < N$, $\Im(y_j(h)) > 0$ and $|y_j(h)| < 1$;
(ii) if $N < j < 2N$, $\Im(y_j(h)) < 0$ and $|y_j(h)| > 1$.

For $j = N$, $y_j(0) = -1$. It can be checked that $T(-1,h) = 0$, so $y_N \equiv -1$ because of the uniqueness of y_N. Nevertheless, it does not correspond to an eigenvalue of $M_{N+1}(h)$. Otherwise, the associated eigenvalue $\lambda = i(2-\delta(h)) + 2i = 4i - i\delta(h)$ would have the eigenvector $\mathbf{x}$ with $x_j = (-1)^j(A+B)$, and from (4.2),

$$(\alpha(h) - \lambda)(A+B) - \beta(h)(A+B) = 0,$$

so $A + B = 0$, since $\alpha(h) - \lambda - \beta(h) = -4i + 2h\alpha_0 + h^2(\alpha_1(h) + i\delta_1(h) - \beta_1(h)) \neq 0$ for h small enough.

Finally, let us consider the zero $y = 1$ of $T(y,0)$. We cannot use the implicit function theorem directly because $\partial_y T(1,0) = 0$. Let us define r such that $y = 1 + rh$, obtaining in this way the function $t(r,h)$ defined by

$$\begin{aligned} t(r,h) = \frac{1}{h^4}T(1+rh,h) &= (r^2 + (1+rh)(i\alpha_0 r - i\alpha_1(h) - i\beta_1(h)(1+rh) + \delta_1(h)))^2 \\ &\quad - (1+hr)^{2N}(-i\alpha_0 r + r^2 - i\beta_1(h) + (1+rh)(-i\alpha_1(h) + \delta_1(h)))^2 \\ &= 4i\alpha_0 r(a_1 + b_1 + d_1 + r^2) + h(-2nr(a_1 + b_1 + d_1 - i\alpha_0 r + r^2)^2 \\ &\quad + 2r(2b_1 + i\alpha_0 r)(a_1 + b_1 + d_1 + r^2) + 2i\alpha_0 r(2a_1 r + 2b_1 r + 2d_1 r + i\alpha_0 r^2) \\ &\quad + 2i\alpha_0 r(-2i\alpha_1'(0) - 2i\beta_1'(0) + 2\delta_1(0))) + O(h^2). \end{aligned} \tag{4.21}$$

We are going to use the implicit function theorem for $t(r,h)$. The roots of $t(r,0)$ are $r_0 = 0$, $r_1 = \sqrt{-a_1 - b_1 - d_1}$, and $r_2 = -\sqrt{-a_1 - b_1 - d_1}$. Making use of (4.18),

$$\partial_r t(r_0,0) = 4\alpha_0(\alpha_1(0) + \beta_1(0) + i\delta_1(0)) = 4i\alpha_0(a_1 + b_1 + d_1) \neq 0,$$

$$\partial_r t(r_1,0) = \partial_r t(r_2,0) = -8i\alpha_0(a_1 + b_1 + d_1) \neq 0.$$

Therefore, for $j = 0, 1, 2$, there exist neighborhoods $\mathcal{U}_j \subset \mathcal{V}$ of zero and $\mathcal{W}_j$ of r_j and a unique regular function $r_j : \mathcal{U}_j \to \mathcal{W}_j$ such that

$$t(r_j(h), h) = 0 \quad \text{for all} \quad h \in \mathcal{U}_j, \quad \text{and} \quad r_j(0) = r_j.$$

Let us define $\phi_j(h) = 1 + hr_j(h)$ for $j = 0, 1, 2$. For these functions,

$$T(\phi_j(h), h) = T(1 + hr_j(h), h) = h^4 t(r_j(h), h) = 0 \quad \text{and} \quad \phi_j(0) = 1.$$

For $j = 0, 1, 2$, $\phi_j(h) = 1 + h\phi_j'(0) + (h^2/2)\phi_j''(0) + O(h^3)$. Let us study each of the cases:

1. $\phi_1(h) = 1 + hr_1(h)$. Taking into account (4.21), (4.18), (4.19), and $\delta_1(h) \in \mathbf{R}$,

$$\phi_1'(0) = r_1(0) = \sqrt{-a_1 - b_1 - d_1} > 0,$$

$$\Im(\phi_1''(0)) = \Im(2r_1'(0)) = -\Im\left(\frac{2\partial_h t(r_1, 0)}{\partial_r t(r_1, 0)}\right) = \frac{-\Re(\partial_h t(r_1, 0))}{4\alpha_0(a_1 + b_1 + d_1)}$$

$$= \frac{\alpha_0(1 - N)(a_1 + b_1 + d_1) + 2\Re(\alpha_1'(0) + \beta_1'(0))}{2\sqrt{-a_1 - b_1 - d_1}} < 0.$$

Therefore, for $h > 0$ small enough, $\Im(\phi_1(h)) < 0$ and

$$|\phi_1(h)|^2 = \left|1 + h\phi_1'(0) + \frac{h^2}{2}\phi_1''(0) + O(h^3)\right|^2 = 1 + 2h\phi_1'(0) + O(h^2) > 1.$$

2. Similarly for $\phi_2(h) = 1 + hr_2(h)$, we obtain $\Im(\phi_2(h)) > 0$ and $|\phi_2(h)|^2 < 1$ for $h > 0$ small enough.

3. Finally, notice that $t(0, h) = 0$ for all h, so $r_0 \equiv 0$ and $\phi_0 \equiv 1$. Nevertheless, the root $y = 1$ of $T(y, h)$ does not give rise to any eigenvalue of $M_{N+1}(h)$. This can be proved similarly as we have done previously for the root $y = -1$. ∎

THEOREM 4.3. *With the notation of Lemma* 4.2 *let us consider the matrix* $M_{N+1}(h)$ *whose coefficients satisfy* (4.15)–(4.19)*, and let us suppose that the hypotheses of Lemma* 4.1 *are satisfied for all* $h > 0$ *(where now the coefficients are functions of* h*). Then, for every* $h > 0$*, all the eigenvalues of* $M_{N+1}(h)$ *have negative real part.*

Proof. Lemma 4.2 asserts that there exists h_0 such that for $h \in (0, h_0)$, all the eigenvalues of $M_{N+1}(h)$ have negative real part. Lemma 4.1 asserts that for $h > 0$, $M_{N+1}(h)$ has not imaginary eigenvalues. On the other hand, the eigenvalues of $M_{N+1}(h)$ are continuous functions of h, so if there were $h^* \geq h_0$ such that $M_{N+1}(h^*)$ had an eigenvalue with real part greater or equal to zero, there should exist $h \in [h_0, h^*]$ such that $M_{N+1}(h)$ had an imaginary eigenvalue, which is not possible. ∎

Proof of Theorem 3.1. It suffices to prove that all the eigenvalues of $ch^2 M(h)$ have negative real part. Notice that $ch^2 M(h)$ is the matrix $M_{N+1}(h)$ previously considered with $\alpha(h) = ch^2\widetilde{\alpha}(h)$, $\beta(h) = ch^2\widetilde{\beta}(h)$, and $\delta(h) = h^2 V$. These coefficients satisfy (4.15)–(4.17) for

$$\alpha_0 = -(s_1 + s_2) < 0,\ a_1 = \frac{s_1^2 + s_2^2}{2} - V \in \mathbf{R},\ b_1 = \frac{-(s_1 + s_2)^2}{2} \in \mathbf{R},\ d_1 = V \in \mathbf{R}.$$

We also have

$$\alpha_1'(0) = \frac{1}{4}(s_1^3 + s_1^2 s_2 + s_1 s_2^2 + s_2^3), \quad \beta_1'(0) = -\frac{1}{4}(s_1 + s_2)^3.$$

Then, hypotheses (4.18) and (4.19) are satisfied,

$$a_1 + b_1 + d_1 = -s_1 s_2 < 0,$$

$$\alpha_0(1 - N)(a_1 + b_1 + d_1) + 2\Re(\alpha_1'(0) + \beta_1'(0)) = -N s_1 s_2 (s_1 + s_2) < 0.$$

Let us see now that the hypotheses of Lemma 4.1 are satisfied. With the previous notation,

$$\alpha_r(h) = \frac{-2h(s_1+s_2)(2+s_1s_2h^2)}{4+h^2(s_1+s_2)^2}, \quad \alpha_i(h) = \frac{h^2(2(s_1^2+s_2^2)-4V-h^2V(s_1+s_2)^2)}{4+h^2(s_1+s_2)^2},$$

$$\beta_r(h) = \frac{4}{h(s_1+s_2)+\frac{4}{h(s_1+s_2)}}, \quad \beta_i(h) = \frac{-2}{1+\frac{4}{h^2(s_1+s_2)^2}}.$$

For these coefficients we have, omitting the dependence on h in the notation,

$$|\beta|^2 - |\alpha_r|^2 = \frac{4h^4(s_1+s_2)^2((s_1-s_2)^2-h^2s_1^2s_2^2)}{(4+h^2(s_1+s_2)^2)^2},$$

so $|\beta| \le |\alpha_r|$ for $h \ge |s_1-s_2|/s_1s_2$ and (4.7) is satisfied. Let us see (4.8) is satisfied if $0 < h < |s_1-s_2|/s_1s_2$. It can be checked that $\delta - 4 + \alpha_i < 0$; therefore, $\delta - 4 + \alpha_i < -\sqrt{|\beta|^2-\alpha_r^2}$ iff $(\delta-4+\alpha_i)^2 > |\beta|^2 - \alpha_r^2$, which is satisfied:

$$(\delta-4+\alpha_i)^2 - |\beta|^2 + \alpha_r^2 = \frac{4(4+s_1s_2h^2)^2}{4+h^2(s_1+s_2)^2} > 0.$$

Similarly, $-\alpha_i + \sqrt{|\beta|^2-\alpha_r^2} < \delta$ iff $(\delta+\alpha_i)^2 > |\beta|^2 - \alpha_r^2$, which is true:

$$(\delta+\alpha_i)^2 - |\beta|^2 + \alpha_r^2 = \frac{4s_1^2s_2^2h^4}{4+h^2(s_1+s_2)^2} > 0.$$

Therefore, (4.8) is satisfied.

The following relations are true for every h:

$$\delta + \alpha_i - \frac{\alpha_r\beta_i}{\beta_r} = -h^2s_1s_2 < 0,$$

$$(\delta+\alpha_i)(2+\beta_i) + \alpha_r\beta_r + 2\beta_i = \frac{-4h^2(s_1^2+4s_1s_2+s_2^2)}{4+h^2(s_1+s_2)^2} < 0.$$

Therefore, hypotheses (4.9) and (4.10) are satisfied.

Therefore, Theorem 4.3 asserts that for all $h > 0$ the eigenvalues of $M(h)$ (where $h = L/N$) have negative real part. □

5. Time discretization. We now study the full discrete method obtained by using the method of lines. For this, it is necessary to apply a time integration method to solve numerically the ordinary differential system (3.3). Although there are many available integration schemes, notice that (3.3) is stiff and the stiffness grows when h, the parameter of the spatial discretization, goes to zero. Moreover, there exist several eigenvalues of the matrix $M(h)$ with real part nearly 0 but with large imaginary parts. Therefore, it is convenient to use A-stable methods. As a consequence, the widely used backward differentiation formulae methods are not suited to solve (3.3), and we consider only implicit Runge–Kutta methods in this paper.

Let us take a Runge–Kutta method of order p and denote by $r(z)$ its stability function. We suppose that the Runge–Kutta method is A-stable, i.e., $|r(z)| \le 1$ for $\Re(z) \le 0$. Moreover, since the order is p, $r(z)$ is a rational approximation to $\exp(z)$ of order p, i.e.,

$$\exp(z) - r(z) = Cz^{p+1} + O(z^{p+2}) \quad \text{as} \quad z \to 0,$$

where $C \neq 0$ is the error constant. We remark that this constant may be dependent on the parameter k, causing the well-known order reduction phenomenon [7]. Therefore, the order observed in practice is smaller than the classical order p when the time stepsize is not small enough. We do not study in detail this problem here; nevertheless, we remark that the semidiscrete problems arising when we use higher order ABCs are usually stiffer.

By applying the Runge–Kutta method with stepsize k to (3.3), we obtain approximations $U_n = r^n(kM(h))U(0)$ to the values $U(nk) = U(t_n) = \exp(t_n M(h))U(0)$, $0 \leq n \leq N$, with U being the solution of (3.3). Our main objective is to study the troubles caused by the weak ill-posedness of the semidiscrete problems (3.3) to the convergence of these approximations. Notice that we do not take into account the error due to the spatial approximation and the ABCs.

We denote by $e_n = U(t_n) - r^n(kM(h))U(0)$ the global errors and by $\rho_n = U(t_n) - r(kM(h))U(t_{n-1})$ the local errors. Then

$$\begin{aligned} e_{n+1} &= U(t_{n+1}) - r(kM(h))U(t_n) + r(kM(h))U(t_n) - r^{n+1}(kM(h))U(0) \\ &= \rho_{n+1} + r(kM(h))e_n, \end{aligned}$$

and, assuming that $M(h)$ is diagonalizable and by using a recursion argument, we deduce that

$$\begin{aligned} e_n &= \sum_{j=1}^{n} r^{n-j}(kM(h))\rho_j = \sum_{j=1}^{n} r^{n-j}(kM(h))(U(t_j) - r(kM(h))U(t_{j-1})) \\ &= \sum_{j=1}^{n} r^{n-j}(kM(h))(\exp(kM(h)) - r(kM(h)))\exp(t_{j-1}M(h))U(0) \\ &= \sum_{j=1}^{n} P(h)r^{n-j}(kD(h))(\exp(kD(h)) - r(kD(h)))\exp(t_{j-1}D(h))P(h)^{-1}U(0). \end{aligned}$$

Taking the Euclidean norm, we deduce

$$\begin{aligned} \|e_n\| &\leq \kappa_h \sum_{j=1}^{n} \|r^{n-j}(kD(h))(\exp(kD(h)) - r(kD(h)))\exp(t_{j-1}D(h))\|\|U(0)\| \\ &\leq \kappa_h \sum_{j=1}^{n} \sup_{\Re z \leq 0} \{|r^{n-j}(z)||\exp(t_{j-1}z)|\} \sup_{z\in\sigma(D(h))} |\exp(kz) - r(kz)|\|U(0)\| \\ &\leq \kappa_h \sum_{j=1}^{n} \sup_{z\in\sigma(D(h))} \{|\exp(kz) - r(kz)|\}\|U(0)\| = O(\kappa_h k^p). \end{aligned}$$

From this estimate, we conclude that the global error may grow when h goes to zero and k is fixed because of the growth of κ_h. Nevertheless, this possible growth is made up for the presence of the factor k^p, which goes to zero when the stepsize k goes to zero. Therefore, it is very convenient to use Runge–Kutta methods of high order when the factor κ_h is ill-behaved. Otherwise, the stepsize k must be very small.

6. Discretization of other ABC. We are going to propose spatial approximations of some ABC defined in section 2. Notice that it is possible to consider several spatial approximations for each one. Therefore, the properties of the corresponding ordinary differential system analogous to (3.3) depend on both the ABCs and the spatial discretization. As an example, we propose two different discretizations of ABC(1,1).

ABC(1,1). First, let us define the new function $v(x,t) = \partial_t u(x,t)$ and denote by $v^N(t)$ an approximation of $v(x^N,t)$. Taking ABC(1,1) and (3.2) into account,

$$\begin{aligned} v^N &\approx \frac{d}{dt}u^N \approx \frac{-i}{c}(\partial_x^2 u(x^N,t) + Vu^N) \\ &\approx \frac{-2i}{ch^2}\left(u^{N-1} - u^N - \frac{h}{\beta_2}(\beta_0 u^N + \beta_1 v^N + \beta_3 \partial_x v(x^N,t))\right) - \frac{iV}{c}u^N, \end{aligned}$$

where we have omitted the dependence on t in the notation. This allows us to obtain $\partial_x v(x^N,t) \approx \gamma_0 u^{N-1} + \gamma_1 u^N + \gamma_2 v^N$. Finally, making use of this expression,

$$\begin{aligned} \frac{d}{dt}v^N &\approx \frac{-i}{c}(\partial_x^2 v(x^N,t) + Vv^N) \approx \frac{-2i}{ch^2}\left(\frac{d}{dt}u^{N-1} - v^N + h\partial_x v(x^N,t)\right) - \frac{iV}{c}v^N \\ &\approx \frac{-2i}{ch^2}(\tilde{m}_1(u^{N-2}+u^N) + \tilde{m}_2 u^{N-1} - v^N + h(\gamma_0 u^{N-1} + \gamma_1 u^N + \gamma_2 v^N)) \\ &\quad - \frac{iV}{c}v^N = \delta_0 v^N + \delta_1 u^N + \delta_2 u^{N-1} + \delta_3 u^{N-2} \end{aligned}$$

for certain coefficients δ_j. We have obtained in this way a system $U' = MU$ with $U = [v^0, u^0, \ldots, u^N, v^N]^T$ and

$$M = \begin{bmatrix} \delta_0 & \delta_1 & \delta_2 & \delta_3 & 0 & \cdots & 0 \\ 1 & 0 & 0 & 0 & 0 & \cdots & 0 \\ 0 & \tilde{m}_1 & \tilde{m}_2 & \tilde{m}_1 & 0 & \cdots & 0 \\ \vdots & & \ddots & \ddots & \ddots & & \vdots \\ 0 & \cdots & 0 & \tilde{m}_1 & \tilde{m}_2 & \tilde{m}_1 & 0 \\ 0 & \cdots & 0 & 0 & 0 & 0 & 1 \\ 0 & \cdots & 0 & \delta_3 & \delta_2 & \delta_1 & \delta_0 \end{bmatrix}. \tag{6.1}$$

Let us implement ABC(1,1) in a different way. As for the previous implementation, we consider (3.2) so that

$$\frac{d}{dt}u^N \approx \frac{-2i}{ch^2}\left(u^{N-1} - u^N - \frac{h}{\beta_2}\left(\beta_0 u^N + \beta_1 \frac{d}{dt}u^N + \beta_0 \partial_{xt} u(x^N,t)\right)\right) - \frac{iV}{c}u^N.$$

Using the approximation

$$\partial_{xt} u(x^N,t) \approx \frac{3\frac{d}{dt}u^N - 4\frac{d}{dt}u^{N-1} + \frac{d}{dt}u^{N-2}}{2h}$$

and taking (3.1) into account, we obtain

$$\frac{d}{dt}u^N = \gamma_0 u^N + \gamma_1 u^{N-1} + \gamma_2 u^{N-2} + \gamma_3 u^{N-3}$$

for certain coefficients γ_j. Therefore, in this case, we have a system with matrix

$$M = \begin{bmatrix} \gamma_0 & \gamma_1 & \gamma_2 & \gamma_3 & 0 & \cdots & 0 \\ \tilde{m}_1 & \tilde{m}_2 & \tilde{m}_1 & 0 & 0 & \cdots & 0 \\ \vdots & & \ddots & \ddots & \ddots & & \vdots \\ 0 & \cdots & 0 & 0 & \tilde{m}_1 & \tilde{m}_2 & \tilde{m}_1 \\ 0 & \cdots & 0 & \gamma_3 & \gamma_2 & \gamma_1 & \gamma_0 \end{bmatrix}. \tag{6.2}$$

A study similar to the one done previously for ABC(1,0) could be done for ABC(1,1). We have checked numerically that matrices (6.1) and (6.2) have their eigenvalues with negative real part and the ϵ-pseudoeigenvalues are close to the eigenvalues for some typical values of ϵ. These numerical results are displayed in Table 3.1. Nevertheless, the condition number κ_h of the corresponding matrix P_h behaves with h worse than it did for matrix (3.4). In Figure 3.1, we can observe that for matrix (6.1) κ_h is approximately $O(h^{-2})$ and for (6.2) it is $O(h^{-3/2})$.

ABC(2,1). Continuing this approach and using the notation $v(x,t) = \partial_t u(x,t)$, for the ABC(2,1) we have

$$v^N \approx \frac{-i}{c}(\partial_x^2 u(x^N,t) + Vu^N) \approx \frac{-2i}{ch^2}\Bigg(u^{N-1} - u^N - \frac{h}{\beta_3}\left(\beta_0 u^N + \beta_1 v^N + \beta_2 \frac{d}{dt}v^N + \beta_4 \partial_x v(x^N,t)\right)\Bigg) - \frac{iV}{c}u^N.$$

Solving last equation for $\partial_x v^N$, we get

$$\partial_x v(x^N,t) \approx \gamma_0 u^{N-1} + \gamma_1 u^N + \gamma_2 v^N + \gamma_3 \frac{d}{dt}v^N$$

for certain coefficients γ_j. This expression allows us to obtain

$$\frac{d}{dt}v^N \approx \frac{-i}{c}(\partial_x^2 v(x^N,t) + Vv^N) \approx \frac{-2i}{ch^2}\left(\frac{d}{dt}u^{N-1} - v^N + h\partial_x v(x^N,t)\right) - \frac{iV}{c}v^N$$

$$\approx \frac{-2i}{ch^2}\Bigg(\tilde{m}_1(u^{N-2} + u^N) + \tilde{m}_2 u^{N-1} - v^N + h\left(\gamma_0 u^{N-1} + \gamma_1 u^N + \gamma_2 v^N + \gamma_3 \frac{d}{dt}v^N\right)\Bigg) - \frac{iV}{c}v^N,$$

where an approximation similar to (3.2) has been used for $\partial_x^2 v(x^N,t)$. Finally, we obtain

$$\frac{d}{dt}v^N = \delta_0 v^N + \delta_1 u^N + \delta_2 u^{N-1} + \delta_3 u^{N-2}.$$

Similar to previous cases, after discretization in space, we have to solve a system whose matrix is of the form (6.1) (with different coefficients). We have checked numerically (see Table 3.1) that all the ϵ-pseudoeigenvalues of this matrix have negative real part for some typical values of ϵ smaller or equal to 1.0d-3, and in Figure 3.1 we can observe that $\kappa_h = O(h^{-2})$.

For the discretization in time of these ordinary differential systems, we may use the same analysis of section 5. We remember that it is convenient to use higher order Runge–Kutta methods for the more ill-behaved problems semidiscretized in space. This fact will be clear in section 8.

7. Higher dimensions. We extend the ABCs obtained in section 2 to the two-dimensional case (the three-dimensional case is analogous). Consider the equation

$$\partial_t u(x,y,t) = \frac{-i}{c}(\partial_x^2 u(x,y,t) + \partial_y^2 u(x,y,t) + Vu(x,y,t)), \quad (x,y) \in \mathbf{R}^2,\ t>0. \tag{7.1}$$

Let us take the finite subdomain $[x_l, x_r] \times [y_l, y_r]$, where we will impose artificial boundary conditions. We consider the boundary $x = x_r$. Let us call $\hat{u}(x,\xi,\omega)$ the Fourier–Laplace transform in time and Fourier transform in variable y of $u(x,y,t)$. From (7.1) we obtain

$$\partial_x^2 \hat{u}(x,\xi,\omega) - \lambda^2 \hat{u}(x,\xi,\omega) = 0,$$

which is analogous to (2.1) with $\lambda^2 = -V - c\omega + \xi^2$. With an argument similar to that of the one-dimensional case, we obtain the TBC for the right boundary,

$$i\sqrt{V + c\omega - \xi^2}\,\hat{u}(x_r,\xi,\omega) + \partial_x \hat{u}(x_r,\xi,\omega) = 0. \tag{7.2}$$

In order to approximate this nonlocal boundary condition, we consider the approximation $\sqrt{V + c\omega - \xi^2} \approx q(V + c\omega - \xi^2)$, where, as in section 2, $q(s)$ is a rational interpolatory function of $\sqrt{s}$. In this way, we may consider the following simplest cases (other ABC of higher order can be obtained with a similar argument).

ABC(1,0). We take the rational function given by (2.5), and we deduce the ABC

$$\beta_0 \partial_t u(x_r,y,t) + \beta_1 u(x_r,y,t) + \beta_2 \partial_y^2 u(x_r,y,t) + \partial_x u(x_r,y,t) = 0, \tag{7.3}$$

where $\beta_0 = c/(s_1+s_2)$, $\beta_1 = i(s_1 s_2 + V)/(s_1+s_2)$, and $\beta_2 = i/(s_1+s_2)$. In a similar way, we obtain the following ABC for the boundary $y = y_r$:

$$\beta_0 \partial_t u(x,y_r,t) + \beta_1 u(x,y_r,t) + \beta_2 \partial_x^2 u(x,y_r,t) + \partial_y u(x,y_r,t) = 0. \tag{7.4}$$

ABC(1,1). We now approximate $\sqrt{s}$ by $q(s) = (\alpha_0 + \alpha_1 s)/(1+\alpha_2 s)$. In this case, the ABC is of the form

$$\begin{aligned} 0 = {} & \beta_0 u(x_r,y,t) + \beta_1 \partial_t u(x_r,y,t) + \beta_2 \partial_y^2 u(x_r,y,t) + \beta_3 \partial_x u(x_r,y,t) \\ & + \beta_4 \partial_{xt} u(x_r,y,t) + \beta_5 \partial_{xyy} u(x_r,y,t) \end{aligned} \tag{7.5}$$

for certain coefficients β_j. In fact, when $q(s)$ is the Padé(1,1) approximation to $\sqrt{s}$, (7.5) coincides with the ABC given by Kuska in [13] and by Fevens and Jiang in [6].

Let us consider the spatial discretization of (7.1) with ABC(1,0). Without loss of generality, we suppose that $x_r - x_l = y_r - y_l$. We consider a uniform grid of $[x_l, x_r] \times [y_l, y_r]$ given by $\{(x^j, y^m) : 0 \le j,m \le N\}$, where $x^j = x_l + jh$, $y^m = y_l + mh$ with $h = (x_r - x_l)/N = (y_r - y_l)/N$, and we denote by $u^{j,m}(t)$ the numerical approximation of $u(x^j, y^m, t)$. For the discretization of (7.1) in the interior domain, we consider the finite difference scheme

$$\frac{d}{dt}u^{j,m} = \frac{-i}{c}\left(\frac{u^{j-1,m} - 2u^{j,m} + u^{j+1,m}}{h^2} + \frac{u^{j,m-1} - 2u^{j,m} + u^{j,m+1}}{h^2} + Vu^{j,m}\right).$$

Now, we consider the spatial discretization at the boundary $x = x_r$. We take the node (x^N, y^m) with $0 < m < N$. First, we consider the approximation

$$\frac{d}{dt}u^{N,m} \approx \frac{-i}{c}\left(\frac{2}{h^2}(u^{N-1,m} - u^{N,m} + h\partial_x u(x^N,y^m,t)) + \partial_y^2 u(x^N,y^m,t) + Vu^{N,m}\right),$$

and taking into account the ABC(1,0) given by (7.3),

$$\frac{d}{dt}u^{N,m} \approx \frac{i}{c}\left(\frac{-2}{h^2}u^{N-1,m} - \left(V - \frac{2}{h^2} - \frac{2\beta_1}{h}\right)u^{N,m} - \left(1 - \frac{2\beta_2}{h}\right)\partial_y^2 u(x^N, y^m, t) + \frac{2\beta_0}{h}\frac{d}{dt}u^{N,m}\right).$$

Finally, using the approximation $\partial_y^2 u(x^N, y^m, t) \approx (u^{N,m-1} - 2u^{N,m} + u^{N,m+1})/h^2$,

$$\frac{d}{dt}u^{N,m} = \alpha_0 u^{N-1,m} + \alpha_1 u^{N,m-1} + \alpha_1 u^{N,m+1} + \alpha_2 u^{N,m}$$

for certain coefficients α_j. Similar expressions are obtained for $du^{j,N}/dt$, $du^{0,m}/dt$, and $du^{j,0}/dt$, $1 \le j, m \le N-1$.

Let us see now the spatial discretization for the corner (x^N, y^N). We consider the approximation

$$\partial_x^2 u(x^N, y^N, t) \approx \frac{2}{h^2}\left(u^{N-1,N} + u^{N,N} - h\left(\beta_0\frac{d}{dt}u^{N,N} + \beta_1 u^{N,N} + \beta_2\partial_y^2 u(x^N, y^N, t)\right)\right), \tag{7.6}$$

where we have used ABC(1,0) given by (7.3). Similarly, taking into account (7.4),

$$\partial_y^2 u(x^N, y^N, t) \approx \frac{2}{h^2}\left(u^{N,N-1} + u^{N,N} - h\left(\beta_0\frac{d}{dt}u^{N,N} + \beta_1 u^{N,N} + \beta_2\partial_x^2 u(x^N, y^N, t)\right)\right). \tag{7.7}$$

Adding expressions (7.6) and (7.7), we obtain

$$\partial_x^2 u(x^N, y^N, t) + \partial_y^2 u(x^N, y^N, t) \approx \epsilon_0 u^{N-1,N} + \epsilon_0 u^{N,N-1} + \epsilon_1 u^{N,N} + \epsilon_2\frac{d}{dt}u^{N,N}$$

for certain coefficients ϵ_j. Finally, making use of this expression in

$$\frac{d}{dt}u^{N,N} \approx \frac{-i}{c}(\partial_x^2 u(x^N, y^N, t) + \partial_y^2 u(x^N, y^N, t) + V u^{N,N}),$$

we obtain

$$\frac{d}{dt}u^{N,N} \approx \delta_0 u^{N,N} + \delta_1 u^{N,N-1} + \delta_1 u^{N-1,N}$$

for certain coefficients δ_j. Analogous expressions are obtained for the spatial discretization of $du^{N,0}/dt$, $du^{0,N}/dt$, and $du^{0,0}/dt$.

We have obtained a first order ordinary differential system

$$U'(t) = M(h)U(t), \tag{7.8}$$

where $U(t) = [u^{0,0}(t), u^{0,1}(t), \ldots, u^{0,N}(t), u^{1,0}(t), \ldots, u^{N,N}(t)]^T$ and $M(h)$ is a matrix of dimension $(N+1)^2 \times (N+1)^2$ with coefficients depending on h. This matrix

TABLE 7.1
Maximum of the real part of the ϵ-pseudoeigenvalues for ABC$(1,0)$ 2-dimensional.

ϵ =1.0d-1	ϵ =1.0d-3	ϵ =1.0d-6	ϵ =1.0d-9	ϵ =1.0d-12
-2.3324d-01	-2.2152d-01	-2.2172d-01	-2.2172d-01	-2.2172d-01

is nonnormal as in the one-dimensional case. In order to study the behavior of the solutions of (7.8), we have carried out an analysis of the ϵ-pseudospectrum of $M(h)$. In Table 7.1 we show an example of the maximum real part of the ϵ-eigenvalues for some values of ϵ. As in section 3, we deduce from this table that the nonnormality of $M(h)$ is mild. We have also computed for some examples the condition number κ_h of the matrix $P(h)$ such that $M(h) = P(h)D(h)P(h)^{-1}$ with $D(h)$ diagonal. The growth of κ_h observed is approximately $O(h^{-1})$.

8. Numerical experiments. Like Schmidt and Yevick in [19], we will consider for the numerical experiments the Fresnel equation (1.2) with $n = 1$, $\beta = 21.8°$, $n_0 = \cos(\beta)$, $\lambda = 0.832$, $k_0 = 2\pi/\lambda$. This case is a generalization of the two test cases of [25] associated with optical beam propagation in the Fresnel approximation. In order to obtain a solution describing an angle α with respect to the t-axis, we are going to consider the initial condition

$$u_0(x) = \exp\left(-((x - L/2)/\sigma)^2\right) \exp(i\eta(x - L/2)), \quad x \in [0, L], \tag{8.1}$$

with $\eta = -\cos(\beta)k_0 \tan(\alpha)$.

We will compare the results, in terms of reflection, obtained when we consider ABC(1,0), ABC(1,1), and ABC(2,1) using the spatial discretizations previously discussed. In the case of ABC(1,1) we will use the discretization in space that gives rise to a system with matrix (6.1). We will also consider ABC(3,2) using a spatial discretization similar to the one of ABC(2,1). In every case, the interpolatory nodes s_j^2 are considered equal to a unique positive number b. As we have already said, with the initial condition (8.1) we will hope to obtain optimal results if $b = \eta^2$.

Let us consider first an initial condition (8.1) with $\alpha = 10°$, $\sigma = 10$, and $L = 200$ so that it is 0 at the boundary. (This is very important, as we will discuss later.) In Figure 8.1(a) we have represented the reflection (the discrete L^2-norm of the solution remaining inside the computational window) as a function of time when we consider the optimal value $b = \eta^2$ and $h = 0.025$. The integration in time has been carried out with the implicit midpoint rule using a stepsize $k = 0.4$. It is clear that the behavior observed in Figure 8.1(a) is due to the order of absorption of the ABCs. Nevertheless, this is not the only thing we should take into account to compare the different ABC. As we have already remarked, the semidiscrete problems associated with these ABC are weakly ill-posed and are worse posed for higher order absorbing boundary conditions. This bad behavior is not visible in Figure 8.1(a) because the initial condition is 0 at the boundary and as the solution is a wave traveling with a concrete group velocity, this bad behavior of high order ABCs is canceled because of the greater absorption at the boundary.

Let us see the influence of taking an initial condition (8.1) which is not zero at the boundary, although this should not be done in practice since the interior domain must be long enough to contain the support of the initial condition. Let us consider (8.1) with $\sigma = 10$, $\alpha = 20°$, and $L = 40$. We will take the optimal value $b = \eta^2$ and the same discretization and stepsizes as in the previous experiment. Notice that

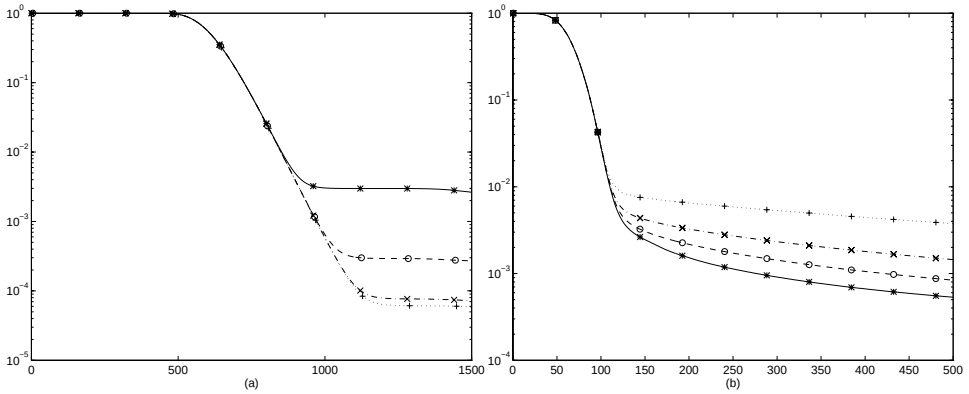

FIG. 8.1. *Reflection as a function of time:* $-*$ $ABC(1,0)$, $--\circ$ $ABC(1,1)$, $-\cdot-\times$ $ABC(2,1)$, $\cdots+$ $ABC(3,2)$. (a) *Initial value vanishing at the boundary.* (b) *Initial value nonvanishing at the boundary.*

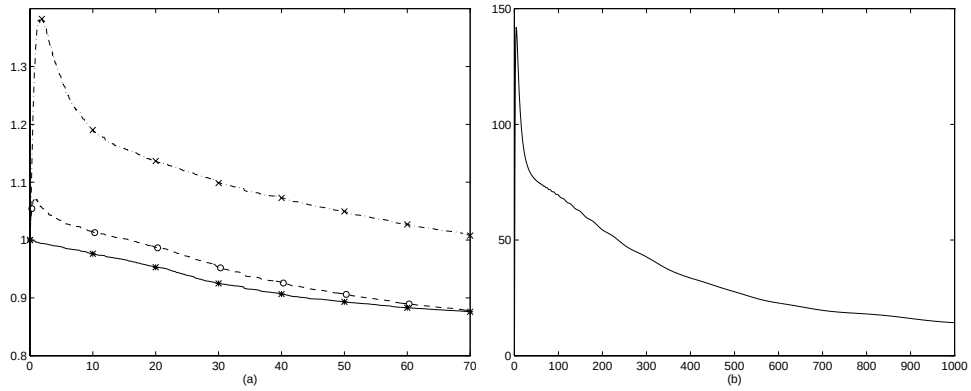

FIG. 8.2. *Reflection as a function of time. Random initial value nonvanishing at the boundary.* (a) $-*$ $ABC(1,0)$, $--\circ$ $ABC(1,1)$, $-\cdot-\times$ $ABC(2,1)$. (b) $ABC(3,2)$

$u_0(x)$ is approximately 0.018 at the boundary. This way, in Figure 8.1(b) the worse behavior of high ABCs due to its weak ill-posedness (see Figure 3.1) is present. We observe that ABCs with high order of absorption produce more reflection than the less absorbing ones. We remark that a similar behavior is present in the numerical experiments in [6]. The authors take as initial condition a single Gaussian distribution $w_0(x) = \exp\left(-(x-\xi)^2/2\sigma_0^2\right)\exp(iK_0x)$, $x \in [0,L]$, with $L = 10$, $\xi = 3L/4$, and $\sigma_0 = L/10$. They also consider a narrow Gaussian pulse distribution $z_0(x)$ taking $\xi = 3L/4$, $\sigma_0 = L/100$, and $L = 10$, concluding that although for the initial condition $w_0(x)$ the ABC given by (1.3) with $p = 4$ behaves worse that the one with $p = 3$; for $z_0(x)$ the higher order ABC is more effective. Taking into account our previous analysis, this behavior is due to the fact that $w_0(x)$ is not 0 at the boundary.

In the previous examples we have considered only regular solutions. In order to see that the weak ill-posedness does not produce unbounded growths when the solution is not regular, we consider now a random initial condition. The discretization of the equation is done as in the previous experiment with $h = 0.025$ and $k = 0.1$. We observe in Figure 8.2 that although for all ABC the norm of the solution goes to 0

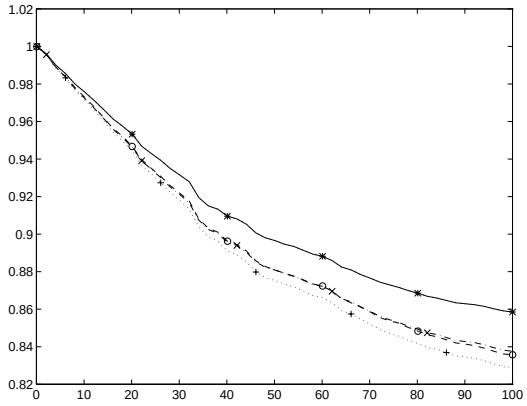

FIG. 8.3. *Reflection as a function of time. Random initial value vanishing at the boundary:* $-*$ $ABC(1,0)$, $--\circ$ $ABC(1,1)$, $-\cdot-\times$ $ABC(2,1)$, $\cdots+$ $ABC(3,2)$.

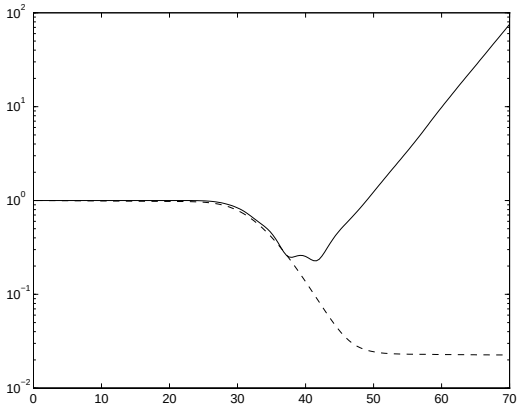

FIG. 8.4. *Reflection as a function of time. Nonoptimal value of* b *and very small spatial stepsize:* $ABC(3,2)$, *– IMPR, – – DIRK order* 3.

as $t \to \infty$, for ABC(1,1), ABC(2,1), and ABC(3,2) there is an initial growth due to the condition number of the semidiscrete systems in space associated with these ABC (see Figure 3.1). In the case of ABC(3,2), this condition number is $O(h^{-4})$ and the norm of the solutions grows initially to 140. This behavior is more accentuated the smaller h is.

Let us see how important it is to consider an initial condition which is 0 at the boundary. In Figure 8.3 we have considered the same random initial condition but with vanishing values for the four first and last nodes. For the same values of h and k as in Figure 8.2, the worse behavior of high order ABCs is not visible.

The fact that we have used the method of lines is very important since the problem discretized in space is weakly ill-posed. We can consider this way a high order method for the time integration that compensates for the troubles in space. This can be seen in Figure 8.4. We have considered ABC(3,2), taking as initial condition (8.1) with

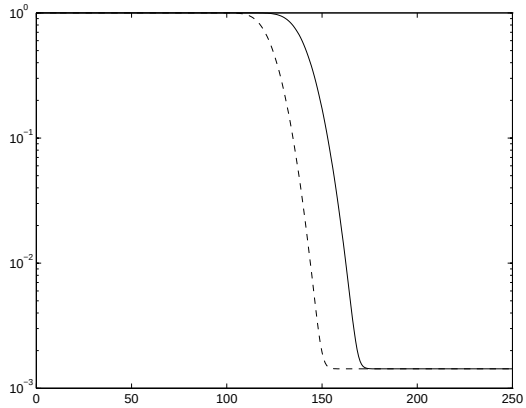

FIG. 8.5. *Reflection as a function of time. Comparison of the velocity in the interior domain:* $ABC(1,0)$ *– IMPR,* – – *2-stage Gauss.*

$\alpha = 30°$, $\sigma = 3$, and $L = 36$ (notice that it is 0 at the boundary). We have not chosen the optimal value of b for this solution but rather the optimal value for a wave traveling with a velocity $\tan(10°)$, so that the weak ill-posedness of the semidiscrete problem is not canceled because the great absorption of this ABC. We have integrated the semidiscrete problem with two different methods: the implicit midpoint rule and a diagonally implicit Runge–Kutta of order 3. In both cases we have considered the very small value $h = 36/76800$ and the time stepsize $k = 0.4$. In Figure 8.4 we can observe that with the implicit midpoint rule the instability in space makes the norm of the solution grow, while with the method of order 3 this behavior is not present.

The possibility of using different integrators in time is also important for the integration of the solution in the interior domain. Let us see the result of taking as initial condition (8.1) with $\alpha = 40°$, $\sigma = 10$, and $L = 200$. We have considered ABC(1,0) using for the integration in time first the implicit midpoint rule, and second the 2-stage Gauss method. In both cases we have taken $h = 0.025$ and $k = 0.4$. In Figure 8.5 we observe that with the implicit midpoint rule the numerical solution does not travel with the right velocity (describing an angle $\alpha = 40°$ with respect to the t-axis) because k is not small enough, while this does not happen for the 2-stage Gauss method. The possibility of considering high order methods for the time integration allows us to use bigger stepsizes.

DUAL-PRIMAL FETI METHODS FOR THREE-DIMENSIONAL ELLIPTIC PROBLEMS WITH HETEROGENEOUS COEFFICIENTS*

AXEL KLAWONN†, OLOF B. WIDLUND‡, AND MAKSYMILIAN DRYJA§

Abstract. In this paper, certain iterative substructuring methods with Lagrange multipliers are considered for elliptic problems in three dimensions. The algorithms belong to the family of dual-primal finite element tearing and interconnecting (FETI) methods which recently have been introduced and analyzed successfully for elliptic problems in the plane. The family of algorithms for three dimensions is extended and a full analysis is provided for the new algorithms. Particular attention is paid to finding algorithms with a small primal subspace since that subspace represents the only global part of the dual-primal preconditioner. It is shown that the condition numbers of several of the dual-primal FETI methods can be bounded polylogarithmically as a function of the dimension of the individual subregion problems and that the bounds are otherwise independent of the number of subdomains, the mesh size, and jumps in the coefficients. These results closely parallel those of other successful iterative substructuring methods of primal as well as dual type.

1. Introduction.

The finite element tearing and interconnecting (FETI) methods are domain decomposition methods of iterative substructuring type. They are thus a special type of preconditioned conjugate gradient methods which have been developed for solving the often huge algebraic systems of equations which arise in finite element computations. The dual-primal FETI (FETI-DP) methods were introduced recently by Farhat et al. [9]. Their work was followed by a significant contribution to the theory of two-dimensional second and fourth order problems by Mandel and Tezaur [17]; by Farhat, Lesoinne, and Pierson [10], who specifically address an algorithm for three-dimensional problems; and by Pierson [19], who has also recently used his codes to solve very difficult and huge problems. The algorithm presented in [10, 19] uses constraints on the averages over edges and faces in a way similar to that of the algorithms considered in this paper. Our contribution is to both the extension of the family of algorithms for problems in three dimensions and the analysis. We also show that good convergence bounds can be maintained even for quite general coefficients such as those that model highly heterogeneous materials. Our work has

been inspired by that of Mandel and Tezaur and is also based on our own earlier work, in particular, [5, 6], and [13].

It is well known that domain decomposition algorithms cannot be scalable, i.e., have a rate of convergence which is independent of the number of subregions, unless a coarse space component is included. We note that the underlying coarse spaces for three-dimensional problems are often more complicated than the quite simple constructions that work well for problems in the plane; see [24] for a discussion. We will construct several of our FETI-DP methods using relatively exotic coarse spaces. Thus, our Algorithms B and C in section 4 are closely related to certain interpolation operators and coarse spaces known from earlier work on primal iterative substructuring methods; see [5, 6]. Both of these methods have relatively large global, primal subspaces.

The term dual-primal refers to the idea of enforcing some continuity constraints across the interface between the subregions, throughout the iteration, as in a primal method, while all other constraints are enforced by using dual variables, i.e., Lagrange multipliers, as in a dual method. We will see that the FETI-DP methods differ in several important respects from the strictly dual FETI methods, in particular, the one-level FETI method which is described in section 3. In fact, from both an algorithmic and an analytic point of view, the FETI-DP methods are closer to the primal iterative substructuring methods than the FETI methods previously developed. While the global part of the preconditioner for a strictly dual FETI method is directly associated with the dual variables, that of a FETI-DP method is not.

We note that primal iterative substructuring methods have been studied quite extensively (see, e.g., [6, 8], and [5]) well before a similarly complete, and quite challenging, mathematical theory was developed for the FETI methods (see [16, 21], and [13]; FETI algorithms using inexact subdomain solvers also have been developed and analyzed by two of the authors in [12]). We note that primal iterative substructuring methods have been developed extensively even for elliptic systems, e.g., in [18], and that we believe we have many of the tools necessary to extend our current results and algorithms to the systems of linear elasticity; cf. also [12]. We also note that, algorithmically, some of the FETI-DP methods that we consider have certain features in common with very early work on iterative substructuring methods for problems with many substructures; cf. the studies on Neumann–Dirichlet algorithms by Dryja, Proskurowski, and Widlund [4] and the contributions of Dryja [3] and Widlund [23] to the first international symposium on domain decomposition. We note, in particular, that the Neumann subsystems of these early algorithms are nonsingular; there are no floating subregions because of a device very similar to that used in the FETI-DP methods. The use of Lagrange multipliers, in a special context, was also suggested in [23].

The remainder of this paper is organized as follows. In section 2, we introduce our scalar elliptic equation, which can have very different coefficients in different subregions and which has served as a standard, nontrivial model problem in many studies of iterative substructuring methods. We also introduce a simple finite element space, the decomposition of our region, and our variational problem. In section 3, we give a brief description of a one-level FETI method to provide a necessary background. In section 4, we introduce our four FETI-DP methods; we note that we have recently analyzed still another FETI-DP algorithm in [14]. In section 5, we provide, with a few proofs, some auxiliary results, many of which have been previously developed for the analysis of primal iterative substructuring methods. In section 6, we prove

almost optimal bounds on the condition number of three of the methods. They are independent of the number of substructures and grow only polylogarithmically with the number of degrees of freedom associated with the individual substructures.

2. Elliptic model problem, finite elements, and geometry. Let $\Omega \subset \mathbf{R}^3$ be a bounded, polyhedral region; let $\partial\Omega_D \subset \partial\Omega$ be a closed set of positive measure, and let $\partial\Omega_N := \partial\Omega \setminus \partial\Omega_D$ be its complement. We impose homogeneous Dirichlet and general Neumann boundary conditions, respectively, on these two subsets and introduce the Sobolev space $H^1_0(\Omega, \partial\Omega_D) := \{v \in H^1(\Omega) : v = 0 \text{ on } \partial\Omega_D\}$.

For simplicity, we will consider only a piecewise linear, conforming finite element approximation of the following scalar, second order model problem: Find $u \in H^1_0(\Omega, \partial\Omega_D)$, such that

$$a(u, v) = f(v) \quad \forall v \in H^1_0(\Omega, \partial\Omega_D), \tag{2.1}$$

where

$$a(u, v) := \int_\Omega \rho(x)\nabla u \cdot \nabla v dx, \qquad f(v) := \int_\Omega f v dx \; + \; \int_{\partial\Omega_N} g_N v ds, \tag{2.2}$$

and where g_N is the Neumann boundary data defined on $\partial\Omega_N$; it provides, together with the volume load f, the contributions to the load vector of the finite element problem. The coefficient $\rho(x) > 0$ for $x \in \Omega$.

We decompose Ω into nonoverlapping subdomains $\Omega_i, i = 1, \ldots, N$, also known as substructures, and each of which is the union of shape-regular elements with the finite element nodes on the boundaries of neighboring subdomains matching across the interface $\Gamma := \overline{(\bigcup_{i=1}^N \partial\Omega_i) \setminus \partial\Omega}$. The interface Γ is composed of subdomain faces, regarded as open sets, which are shared by two subregions; of edges which are shared by more than two subregions; and of vertices which are endpoints of edges. If Γ intersects $\partial\Omega_N$ along an edge common to the boundaries of only two subdomains, we will regard it as part of the face common to this pair of subdomains. We denote the faces of Ω_i by $\mathcal{F}^{ij}$, its edges by $\mathcal{E}^{ik}$, and its vertices by $\mathcal{V}^{i\ell}$.

We denote the standard finite element space of continuous, piecewise linear functions on Ω_i by $W^h(\Omega_i)$; we always assume that these functions vanish on $\partial\Omega_D$. For simplicity, we assume that the triangulation of each subdomain is quasi-uniform. The diameter of Ω_i is H_i or, generically, H. We denote the corresponding finite element trace spaces by $W_i := W^h(\partial\Omega_i \cap \Gamma), i = 1, \ldots, N$, and the associated product space by $W := \prod_{i=1}^N W_i$. We will often consider elements of W which are discontinuous across the interface.

The finite element approximation of the elliptic problem is continuous across Γ and we denote the corresponding subspace of W by $\widehat{W}$. We note that while the stiffness matrix K and Schur complement S, which correspond to the product space W, generally are singular, those of $\widehat{W}$ are not.

We also will use additional, intermediate subspaces $\widetilde{W}$ of W for which only a relatively small number of continuity constraints is enforced across the interface. One of the benefits of working in $\widetilde{W}$, rather than in W, will be that certain related Schur complements, $\widetilde{S}$ and S_Δ, are strictly positive definite; see sections 3 and 4.

We assume that possible jumps of $\rho(x)$ are aligned with the subdomain boundaries and, for simplicity, that on each subregion Ω_i, $\rho(x)$ has the constant value $\rho_i > 0$. Our bilinear form and load vector can then be written, in terms of contributions from

individual subregions, as

$$a(u,v) = \sum_{i=1}^{N} \rho_i \int_{\Omega_i} \nabla u \cdot \nabla v dx, \qquad f(v) = \sum_{i=1}^{N} \left(\int_{\Omega_i} f v dx \; + \; \int_{\partial\Omega_i \cap \partial\Omega_N} g_N v ds \right). \tag{2.3}$$

In our theoretical analysis, we assume that each subregion Ω_i is the union of a number of shape-regular tetrahedral coarse elements and that the number of such tetrahedra is uniformly bounded for each subdomain. Thus, the subregions are not very thin and we also can easily show that the diameters of any pair of neighboring subdomains are comparable. We also assume that if a face of a subdomain intersects $\partial\Omega_D$, then the measure of this set is comparable to that of the face. Similarly, if an edge of a subdomain intersects $\partial\Omega_D$, we assume that the length of this intersection is bounded from below in terms of the length of the edge as a whole. The sets of nodes on $\partial\Omega, \partial\Omega_i$, and Γ are denoted by $\partial\Omega_h, \partial\Omega_{i,h}$, and Γ_h, respectively.

As in previous work on Neumann–Neumann and FETI algorithms, a crucial role is played by *the weighted counting functions* μ_i, which are associated with the individual subdomain boundaries $\partial\Omega_i$; cf. [5, 8, 15, 20]. In this paper they will be used in the definition of certain diagonal scaling matrices. These functions are defined for $\gamma \in [1/2, \infty)$ and for $x \in \Gamma_h \cup \partial\Omega_h$ by a sum of contributions from Ω_i and its relevant neighbors

$$\mu_i(x) = \begin{cases} \sum\limits_{j \in \mathcal{N}_x} \rho_j^{\gamma}(x) & x \in \partial\Omega_{i,h} \cap \partial\Omega_{j,h}, \\ \rho_i^{\gamma}(x) & x \in \partial\Omega_{i,h} \cap (\partial\Omega_h \setminus \Gamma_h), \\ 0 & x \in (\Gamma_h \cup \partial\Omega_h) \setminus \partial\Omega_{i,h}. \end{cases} \tag{2.4}$$

Here, $\mathcal{N}_x$ is the set of indices of the subregions which have x on their boundaries. We note that any node of Γ_h either belongs to two faces, belongs to at least three edges, or is a vertex of several substructures. The μ_i are continuous, piecewise discrete harmonic functions; for a definition see section 3. The pseudoinverses $\mu_i^{\dagger}$, which belong to the same class of functions, are defined for $x \in \Gamma_h \cup \partial\Omega_h$ by

$$\mu_i^{\dagger}(x) = \begin{cases} \mu_i^{-1}(x) & \text{if } \mu_i(x) \neq 0, \\ 0 & \text{if } \mu_i(x) = 0. \end{cases} \tag{2.5}$$

We note that these functions provide a partition of unity:

$$\sum_i \rho_i^{\gamma}(x) \mu_i^{\dagger}(x) \equiv 1 \quad \forall x \in \Gamma_h \cup \partial\Omega_h. \tag{2.6}$$

3. One-level FETI methods. In this section, we will introduce some notation and certain other aspects of the older one-level FETI methods which we will use in the rest of this paper. We begin by defining a stiffness matrix K for the entire product space $\prod_{i=1}^{N} W^h(\Omega_i)$. K is a direct sum of local stiffness matrices $K^{(i)}$ which correspond to the subdomains $\Omega_i, i = 1, \ldots, N$, and to the appropriate terms in the first formula of (2.3). The local load vectors are obtained similarly; see the second formula of (2.3).

Any nodal variable not associated with Γ_h is called interior and belongs only to one substructure; the nodal values on $\partial\Omega_N \backslash \Gamma$ also belong to this set. The interior variables of any subdomain can be eliminated by block Gaussian elimination in work which

clearly can be parallelized across the subdomains. The resulting reduced matrices are the Schur complements

$$S^{(i)} = K^{(i)}_{\Gamma\Gamma} - K^{(i)}_{\Gamma I}(K^{(i)}_{II})^{-1}K^{(i)}_{I\Gamma}, \qquad i = 1, \ldots, N.$$

Here Γ and I represent the interface and interior, respectively. We note that the $S^{(i)}$, and their inverses or pseudoinverses, are needed only in terms of matrix-vector products and that their elements therefore need not be explicitly computed. We also obtain a reduced load vector for each subdomain. The one originating in Ω_i is denoted by f_i, and the local vector of interface nodal values, which can be regarded as a component of an element of the product space W, is denoted by u_i.

The elimination of the interior variables of a substructure also can be viewed in terms of an orthogonal projection, with respect to the bilinear form $\langle K^{(i)}\cdot, \cdot\rangle$, onto the subspace of vectors with components that vanish at all the nodes of $\overline{\partial\Omega_i \setminus \partial\Omega_N}$. Here $\langle\cdot,\cdot\rangle$ denotes the ℓ_2-inner product. We note that these vectors represent elements of $W^h(\Omega_i) \cap H^1_0(\Omega_i, \overline{\partial\Omega_i \setminus \partial\Omega_N})$. These local subspaces are orthogonal, in this energy inner product, to the space of discrete harmonic vectors which represent discrete harmonic finite element functions with v_Γ and w_Γ vectors of interface values, such a vector $w = (w_I, w_\Gamma)$ is defined by

$$\langle K^{(i)}w, v\rangle = 0 \quad \forall v \ \text{ such that } \ v_\Gamma = 0 \tag{3.1}$$

on the subdomain Ω_i, or, equivalently, by

$$K^{(i)}_{II}w_I + K^{(i)}_{I\Gamma}w_\Gamma = 0. \tag{3.2}$$

We can regard w_Γ as a vector of Dirichlet data given on $\partial\Omega_{i,h} \cap \Gamma_h$ and note that a piecewise discrete harmonic function is completely defined by its values on the interface.

The Schur complement $S^{(i)}$ satisfies the following minimum property: For all $w \in W_i$,

$$\langle S^{(i)}w, w\rangle = \min\langle K^{(i)}v, v\rangle, \tag{3.3}$$

where the minimum is taken over all $v = (v_I, v_\Gamma) \in W^h(\Omega_i)$ such that $v_\Gamma = w$.

We note that we can view the Schur complement $S^{(i)}$ as the restriction of the stiffness matrix $K^{(i)}$ to the space of discrete harmonic functions. In what follows, we will work almost exclusively with functions in the trace spaces W_i and, whenever convenient, consider such an element as representing a discrete harmonic function in Ω_i. We also note that it is this piecewise discrete harmonic part of the solution, representing an element of $\widehat{W}$, that is determined by any iterative substructuring method; the other, interior, parts of the solution are computed locally as indicated above.

We now briefly review a part of the derivation of the traditional FETI methods prior to showing in the next section how matters change in the FETI-DP case. We begin by reformulating the finite element problem, reduced to the interface Γ, as a minimization problem with constraints given by the requirement of continuity across Γ: find $u \in W$, such that

$$\left.\begin{array}{c} J(u) := \frac{1}{2}\langle Su, u\rangle - \langle f, u\rangle \rightarrow \ \min \\ Bu = 0 \end{array}\right\}, \tag{3.4}$$

where $u = [u_1, \ldots, u_N]^t$, $f = [f_1, \ldots, f_N]^t$, and $S = \mathrm{diag}_i(S^{(i)})$.

The matrix $B = [B^{(1)}, \ldots, B^{(N)}]$ is constructed from $\{0, 1, -1\}$ such that the values of the solution u, associated with more than one subdomain, coincide when $Bu = 0$. Here, as in [13, sections 5 and 4], we can work with either fully redundant or nonredundant constraints, i.e., with either all possible or the smallest possible number of constraints for each node of Γ_h. The local Schur complement matrices $S^{(i)}$ are positive semidefinite and, in fact, in many cases, there are floating subdomains, i.e., subregions for which the $S^{(i)}$ are singular. Problem (3.4) is uniquely solvable if and only if $\ker(S) \cap \ker(B) = \{0\}$, i.e., S is invertible on the null space of B. This condition holds since the original finite element model is elliptic.

In a standard one-level FETI method, a vector of Lagrange multipliers λ is introduced to enforce all the constraints $Bu = 0$, and we obtain a saddle point formulation of (3.4): find $(u, \lambda) \in W \times U$ such that

$$\left.\begin{array}{rcrcl} Su & + & B^t\lambda & = & f \\ Bu & & & = & 0 \end{array}\right\}. \tag{3.5}$$

In this paper, we will work exclusively with fully redundant sets of Lagrange multipliers. The matrix B^t then has a null space and, to ensure uniqueness, it is appropriate to restrict the choice of Lagrange multipliers to $\mathrm{range}(B)$. In fact, in the one-level FETI methods the space of Lagrange multipliers is chosen as a subspace of $\mathrm{range}(B)$, since further constraints on the Lagrange multipliers must be introduced in order to ensure the solvability of the first equation of (3.5); see, e.g., [11, 16, 13].

We also will use a full column rank matrix R built from all of the null space elements of S; these elements are associated with individual subdomains (the rigid body motions in the case of elasticity) and are continued by zero outside the subregion in question. Thus, $\mathrm{range}(R) = \ker(S)$. We note that no subdomain with a boundary which intersects $\partial\Omega_D$ contributes to R. We also note that the case of linear elasticity is somewhat more complicated. There also can be contributions to R from subdomains with boundaries intersecting $\partial\Omega$ for which there are not enough essential boundary conditions to fully eliminate the entire space of rigid body motions.

The solution of the first equation in (3.5) exists if and only if $f - B^t\lambda \in \mathrm{range}(S)$; this constraint leads to the introduction of an orthogonal projection P from U onto $\ker(G^t)$ with $G := BR$. We note that we do not need any such projection in the FETI-DP methods defined in the next section.

Eliminating the primal variables from (3.5) and considering the component orthogonal to $\mathrm{range}(G)$, we obtain

$$\left.\begin{array}{rcl} P^tF\lambda & = & P^td \\ G^t\lambda & = & e \end{array}\right\} \tag{3.6}$$

with $F := BS^\dagger B^t$, $d := BS^\dagger f$, $S^\dagger$ a pseudoinverse of S, and $e := R^t f$; this last constraint ensures that the first equation of (3.5) is solvable.

The original FETI method is a conjugate gradient method applied to

$$P^tF\lambda = P^td, \qquad \lambda \in \lambda_0 + \mathrm{range}(P), \tag{3.7}$$

with an initial approximation λ_0 chosen such that $G^t\lambda_0 = e$; this constraint guarantees that the first equation of (3.5) is consistent.

We will not describe the preconditioners used in the solution of this dual problem but will postpone this topic to the next section; there are no essential differences

between the two cases as far as preconditioners are concerned. For a more detailed description and analysis of a number of one-level FETI algorithms, see Klawonn and Widlund [13].

4. FETI-DP methods. In previous studies of FETI-DP methods for problems in two dimensions (see Farhat et al. [9] and Mandel and Tezaur [17]), the constraints on the degrees of freedom associated with the vertices of the substructures are enforced in each iteration; i.e., the corresponding degrees of freedom belong to the primal set of variables, while all the constraints associated with the edge nodes are fully enforced only at the convergence of the iterative method. A linear system of algebraic equations is solved exactly in each step of the iteration. All unknowns except those of the subdomain vertices can be eliminated at a modest expense, and in parallel across the subdomains, resulting in a Schur complement for the vertex variables. In this first step, we can take full advantage of a high quality sparse matrix Cholesky solver when solving the individual subdomain problems, which in fact are Neumann problems on the individual subregions except for a Dirichlet condition at the subdomain vertices. The order of the Schur complement equals the number of subdomain vertices which do not belong to $\partial\Omega_D$. It is sparse since it can be shown quite easily that no nonzero off-diagonal elements exist in the reduced system matrix except those that correspond to pairs of vertices which belong to the same substructure.

In their recent paper, Mandel and Tezaur [17] established a condition number bound of the form $C(1+\log(H/h))^2$ for the resulting FETI-DP method, in two dimensions, and if it is equipped with a Dirichlet preconditioner similar to those used for some of the older FETI methods; cf. Farhat, Mandel, and Roux [11]. This preconditioner is built from local solvers on the subregions with zero Dirichlet conditions at the vertices of the subregions. This algorithm is scalable in the sense that the constant C is independent of the number of subregions, the subdomain diameters, as well as the mesh size h of the finite element model. Mandel and Tezaur also established a corresponding result for a fourth order elliptic problem in the plane. Their proof in [17] for the second order equation uses linear algebra arguments and a lemma from a classical paper by Bramble, Pasciak, and Schatz [2, Lem. 3.5].

The same algorithm, our Algorithm A, also can be defined for the three-dimensional case but it does not perform well; see Farhat et al. [9, sect. 5]. This is undoubtedly related to the poor performance of *vertex-based* iterative substructuring methods; see [6, sect. 6.1]. A condition number estimate for this algorithm is given in Remark 2 at the end of the paper.

In the present study, as well as in others of FETI-DP methods, we work with subspaces $\widetilde{W} \subset W$ for which sufficiently many constraints are enforced so that the resulting leading diagonal block of the saddle point problem, though no longer block diagonal, is strictly positive definite. We also introduce two subspaces, $\widehat{W}_\Pi \subset \widehat{W}$ and $\widetilde{W}_\Delta$, corresponding to a primal and a dual part of the space $\widetilde{W}$. These subspaces will play an important role in the description and analysis of our iterative method. The direct sum of these spaces equals $\widetilde{W}$, i.e.,

$$\widetilde{W} = \widehat{W}_\Pi \oplus \widetilde{W}_\Delta. \tag{4.1}$$

The second subspace, $\widetilde{W}_\Delta$, is the direct sum of local subspaces $\widetilde{W}_{\Delta,i}$ of $\widetilde{W}$, where each subdomain Ω_i contributes a subspace $\widetilde{W}_{\Delta,i}$; only its ith component in the sense of the product space $\widetilde{W}$ is nontrivial.

In the descriptions of our algorithms, we will need certain standard finite element cutoff functions $\theta_{\mathcal{E}^{ik}}$, $\theta_{\mathcal{F}^{ij}}$, and $\theta_{\mathcal{V}^{i\ell}}$. The first two are the discrete harmonic functions

which equal 1 on $\mathcal{E}_h^{ik}$ and $\mathcal{F}_h^{ij}$, respectively, and which vanish elsewhere on Γ_h; $\theta_{\mathcal{V}^{i\ell}}$ denotes the piecewise discrete harmonic extension of the standard nodal basis function associated with the vertex $\mathcal{V}^{i\ell}$. These cutoff functions also will be used in the analysis of the methods; see sections 5 and 6.

We are now ready to define our algorithms in terms of pairs of subspaces.

ALGORITHM A. *The primal subspace, $\widehat{W}_\Pi$, is spanned by the nodal finite element basis functions $\theta_{\mathcal{V}^{i\ell}}$. The local subspace $\widetilde{W}_{\Delta,i}$ is defined as the subspace of W_i of elements which vanish at the subdomain vertices, i.e., by*

$$\widetilde{W}_{\Delta,i} := \{u \in W_i : u(\mathcal{V}^{i\ell}) = 0 \ \forall \mathcal{V}^{i\ell} \in \partial\Omega_i\}.$$

Hence, $\widetilde{W} = \widetilde{W}_A$ is the subspace of W of functions that are continuous at the subdomain vertices.

ALGORITHM B. *The primal subspace, $\widehat{W}_\Pi$, is spanned by the vertex nodal finite element basis functions $\theta_{\mathcal{V}^{i\ell}}$ and the cutoff functions $\theta_{\mathcal{E}^{ik}}$ and $\theta_{\mathcal{F}^{ij}}$ associated with all the edges and faces, respectively, of the interface. The local subspace $\widetilde{W}_{\Delta,i}$ is defined as the subspace of W_i, where the values at the subdomain vertices vanish, together with the averages $\overline{u}_{\mathcal{E}^{ik}}$ and $\overline{u}_{\mathcal{F}^{ij}}$, i.e., by*

$$\widetilde{W}_{\Delta,i} := \{u \in W_i : u(\mathcal{V}^{i\ell}) = 0, \overline{u}_{\mathcal{E}^{ik}} = 0, \overline{u}_{\mathcal{F}^{ij}} = 0 \ \forall \mathcal{V}^{i\ell}, \mathcal{E}^{ik}, \mathcal{F}^{ij} \subset \partial\Omega_i\}.$$

Here,

$$\overline{u}_{\mathcal{E}^{ik}} = \frac{\int_{\mathcal{E}^{ik}} u ds}{\int_{\mathcal{E}^{ik}} 1 ds} \quad \text{and} \quad \overline{u}_{\mathcal{F}^{ij}} = \frac{\int_{\mathcal{F}^{ij}} u dx}{\int_{\mathcal{F}^{ij}} 1 dx}. \tag{4.2}$$

Hence, $\widetilde{W} = \widetilde{W}_B$ is the subspace of W of functions that are continuous at the subdomain vertices and that have the same values of $\overline{u}_{\mathcal{E}^{ik}}$ and $\overline{u}_{\mathcal{F}^{ij}}$. These functions are independent of the component of $u \in \widetilde{W}_B$ that is used in the evaluation of these averages.

ALGORITHM C. *The primal subspace, $\widehat{W}_\Pi$, is spanned by the vertex nodal finite element basis functions $\theta_{\mathcal{V}^{i\ell}}$ and the cutoff functions $\theta_{\mathcal{E}^{ik}}$ of all the edges of Γ. The local subspace $\widetilde{W}_{\Delta,i}$ is defined as the subspace of W_i, where the values at the subdomain vertices vanish together with the averages $\overline{u}_{\mathcal{E}^{ik}}$, i.e., by*

$$\widetilde{W}_{\Delta,i} := \{u \in W_i : u(\mathcal{V}^{i\ell}) = 0, \overline{u}_{\mathcal{E}^{ik}} = 0 \ \forall \mathcal{V}^{i\ell}, \mathcal{E}^{ik} \subset \partial\Omega_i\}.$$

Hence, $\widetilde{W} = \widetilde{W}_C$ is the subspace of W of functions that are continuous at the subdomain vertices and have common averages $\overline{u}_{\mathcal{E}^{ik}}$ for all the edges. The number of degrees of freedom of the corresponding primal subspace $\widehat{W}_\Pi$ is therefore equal to the sum of the number of vertices and the number of edges; this $\widehat{W}_\Pi$ will be of lower dimension than the primal space of Algorithm B.

The number of constraints enforced in all the iterations of Algorithms B and C is substantially larger than when only the vertex constraints are satisfied, as in Algorithm A, but we are still able to work with a uniformly bounded number of such constraints for each substructure. In order to put this in perspective, we consider Algorithms B and C in the very regular case of cubic substructures. There are then seven global variables for each interior substructure in the case of Algorithm B since there are eight vertices, each shared by eight cubes; twelve edges, each shared by four cubes; and six faces, each shared by a pair of substructures. The count for Algorithm

C is four. We note that the counts would be different, relative to the number of substructures, in the case of tetrahedral subregions.

It is useful to distinguish between the continuity constraints at the vertices and the other constraints. The latter are sometimes called optional constraints since they are not needed to guarantee solvability of the subproblems if there are enough vertex constraints. The optional constraints could be handled as the vertex variables after a change of basis. Another possibility, which we advocate, is to introduce an additional set of Lagrange multipliers which are computed exactly in each iteration to enforce the required optional constraints of the primal subspace; see Farhat, Lesoinne, and Pierson [10], where this approach is used; for a more detailed description, see section 4.2, especially formulae (24)–(28), of that paper.

We are able to show as strong a result for Algorithm C as for Algorithm B. It is therefore natural to attempt to drop additional constraints, i.e., further decrease the primal subspace $\widehat{W}_\Pi$ while preserving the fast convergence of the FETI-DP method. This leads to the introduction of our final algorithm.

ALGORITHM D. *The primal subspace, $\widehat{W}_\Pi$, is defined in terms of constraints associated with a subset of the edges and vertices of the interface. Our recipe for selecting such primal edges and vertices is relatively complicated and can only be fully understood by carefully reading the proof of Lemma* 10 *in section* 6.

We first describe the requirements on a minimal set of primal constraints which we have found necessary to give a complete proof of a good bound for Algorithm D. For each face, we should have at least one designated, primal edge. Additionally, for all pairs of substructures Ω_i, Ω_j, which have an edge in common, we must have an acceptable *edge path* between the two subdomains. An acceptable edge path is a path from Ω_i to Ω_j, possibly via several other subdomains, Ω_k, which have the edge $\mathcal{E}^{ij}$ in common and such that their coefficients satisfy $TOL*\rho_k \geq \min(\rho_i, \rho_j)$ for some chosen tolerance TOL. The path can only pass from one subdomain to another through an edge designated as primal. Finally, we consider all pairs of substructures which have in common a vertex $\mathcal{V}^{i\ell}$ but not a face or an edge. Then, we assume either that $\mathcal{V}^{i\ell}$ is a primal vertex or that we have an acceptable edge path of the same nature as above, except that we can be more lenient and insist only on $TOL*\rho_k \geq (h_k/H_k)\min(\rho_i, \rho_j)$. We also note that we could allow our edge paths to stray somewhat further away from the edge $\mathcal{E}^{ij}$, or the vertex $\mathcal{V}^{i\ell}$, and that in fact a careful examination of the proof of Lemma 10 would reveal that alternative, more liberal rules concerning the paths could be adopted.

We now give a description of a possible way of selecting the set of primal constraints. We start by choosing enough edges so that for each face of the interface there is at least one designated, primal edge which is part of the boundary of the face. In addition, we can exercise an option of designating some of the vertices of the substructures as primal; this is not strictly necessary but if constraints are enforced at enough vertices throughout the computation, then the related Schur complement can be made invertible even without any edge constraints. As pointed out above, this can be an advantage in the implementation of the method.

After this initial phase, which in the case of hexagonal substructures can involve as few as three edge constraints per subdomain, and hence a very small primal space, we consider the effects of the possibly very large variation of the coefficients ρ_i; if there are no great variations in the coefficients, we need do nothing more. We examine one by one each edge $\mathcal{E}^{ij}$ not previously designated as primal. We consider all pairs of subdomains that have this edge in common and try to find an acceptable edge path

between the two subdomains Ω_i and Ω_j. If no such path can be found, we add the edge $\mathcal{E}^{ij}$ to the set of designated edges; a trivial, acceptable edge path is then created. We also note that since two subdomains that share a face always have at least one designated edge in common, we need not consider any such pairs of subdomains in this step.

Finally, we consider, one by one, all vertices which so far have not been designated as primal. We consider pairs of substructures that have such a vertex $\mathcal{V}^{i\ell}$ in common but which do not have a face or edge in common. For each vertex inspected, we try to find an acceptable edge path subject only to the more lenient condition on the coefficients. If we fail to find such a path, we mark the vertex $\mathcal{V}^{i\ell}$ as primal, i.e., a vertex where the constraints should be exactly satisfied throughout the FETI iteration.

We note that we are free to add any other vertex, edge, or face constraints to our definition of the primal space; the bounds on the condition numbers will only improve. If all edges and vertices are primal, we are back to Algorithm C.

We can now formulate our FETI-DP algorithms. Each is expressed in terms of a Schur complement $\widetilde{S}$ related to the dual space $\widetilde{W}_\Delta$. We can arrive at this reduced problem by eliminating the primal variables associated with the interior nodes, the vertex nodes designated as primal, as well as the Lagrange multipliers related to the optional constraints. This Schur complement $\widetilde{S}$ can be equally well defined by a variational problem: for all $w_\Delta \in \widetilde{W}_\Delta$,

$$\langle \widetilde{S} w_\Delta, w_\Delta \rangle = \min \langle Sw, w \rangle, \tag{4.3}$$

where we take the minimum over all $w \in \widetilde{W}$ of the form $w = w_\Pi + w_\Delta, w_\Pi \in \widehat{W}_\Pi$. We note that any Schur complement of a positive definite, symmetric matrix is always associated with such a variational problem. We also obtain, analogously, a reduced right-hand side $\tilde{f}_\Delta$ from the load vectors associated with the individual subdomains.

We now reformulate the original finite element problem, reduced to the degrees of freedom of the second subspace $\widetilde{W}_\Delta$, as a minimization problem with constraints given by the requirement of continuity across all of Γ_h: find $u_\Delta \in \widetilde{W}_\Delta$, such that

$$\left.\begin{array}{c} J(u_\Delta) := \frac{1}{2}\langle \widetilde{S} u_\Delta, u_\Delta \rangle - \langle \tilde{f}_\Delta, u_\Delta \rangle \rightarrow \min \\ B_\Delta u_\Delta = 0 \end{array}\right\}. \tag{4.4}$$

The matrix B_Δ is constructed from $\{0, 1, -1\}$ in a way very similar to the matrix B discussed in section 3 and in such a way that the values of the solution u_Δ, associated with more than one subdomain, coincide when $B_\Delta u_\Delta = 0$. Again, these constraints are very simple and just express that the nodal values coincide across the interface; in comparison with the FETI method described in the previous section, we can drop some of the constraints, in particular, those associated with the vertex nodes of the primal space. However, we will otherwise use all possible constraints and thus work with a fully redundant set of Lagrange multipliers as in [13, sect. 5].

By introducing a set of Lagrange multipliers $\lambda \in V := \text{range}\,(B_\Delta)$ to enforce the constraints $B_\Delta u_\Delta = 0$, we obtain a saddle point formulation of (4.4), as in (3.5). Since $\widetilde{S}$ is invertible, we can eliminate the subvector u_Δ, and we obtain the following system for the dual variables:

$$F\lambda = d := B_\Delta \widetilde{S}^{-1} \tilde{f}_\Delta, \tag{4.5}$$

where

$$F := B_\Delta \widetilde{S}^{-1} B_\Delta^t.$$

Algorithmically, the matrix $\widetilde{S}$ is needed only in terms of $\widetilde{S}^{-1}$ times a vector, and such an operation can be computed relatively inexpensively. While it is natural to describe a Schur complement in terms of a second set of variables and resulting from the elimination of a first set, the action of its inverse on a vector can often be obtained advantageously by solving the entire linear system from which it originates after augmenting the given right-hand side with zeros. Full advantage can then be taken of algorithms that symmetrically reorder the larger matrix so as to preserve sparsity. In the case at hand, it is thus advantageous to group together all the interior and dual variables of each subdomain and to factor the resulting blocks in parallel across the subdomains using a good ordering algorithm. The contributions to the remaining Schur complement, of the primal variables, can also be computed locally prior to subassembly and factorization of this final, global part of the linear system of equations.

The operator F will obviously depend on the choice of the subspaces $\widehat{W}_\Pi$ and $\widetilde{W}_\Delta$, and we denote the operators of the resulting linear systems by F_A, F_B, F_C, and F_D, respectively. To define the FETI-DP Dirichlet preconditioner, we need to introduce an additional set of local Schur complement matrices, $S_\Delta^{(i)}$, which is obtained by restricting $S^{(i)}$ to the space $\widetilde{W}_{\Delta,i}$; in the case of Algorithm A, we simply remove the rows and columns corresponding to the subdomain vertices from $S^{(i)}$. The associated block-diagonal matrix is given by

$$S_\Delta := \operatorname{diag}_{i=1}^N(S_\Delta^{(i)}).$$

We can compute S_Δ times a vector $w_\Delta \in \widetilde{W}_\Delta$ by solving a local Dirichlet problem with a solution in $\widetilde{W}_{\Delta,i},\ i = 1, \ldots, N$, and then multiplying it by the stiffness matrix of its subdomains. Such solutions are constrained to vanish at designated subdomain vertices and to have zero edge and face averages, as required by the algorithm in question.

We also introduce diagonal scaling matrices $D_\Delta^{(i)}$ that operate on the Lagrange multiplier spaces. Each of their diagonal elements corresponds to a Lagrange multiplier which enforces continuity between the nodal values of some $w_i \in \widetilde{W}_i$ and $w_j \in \widetilde{W}_j$ at some point $x \in \Gamma_h$; it is given by $\rho_j^\gamma(x)\mu_j^\dagger(x)$. Finally, we define a scaled jump operator by

$$B_{D,\Delta} := \left[D_\Delta^{(1)} B_\Delta^{(1)}, \ldots, D_\Delta^{(N)} B_\Delta^{(N)}\right].$$

As in Klawonn and Widlund [13, sect. 5], we solve the dual system (4.5) using the preconditioned conjugate gradient algorithm with the preconditioner

$$M^{-1} := B_{D,\Delta} S_\Delta B_{D,\Delta}^t. \tag{4.6}$$

The FETI-DP method is the standard preconditioned conjugate gradient algorithm for solving the preconditioned system

$$M^{-1} F\lambda = M^{-1} d.$$

This definition of M clearly depends on the choice of the subspaces $\widehat{W}_\Pi$ and $\widetilde{W}_\Delta$ for the different algorithms. The resulting preconditioners are denoted by $M_A^{-1}, M_B^{-1}, M_C^{-1}$, and M_D^{-1}, respectively.

5. Some auxiliary lemmas. The purpose of this section is to provide, in most cases without proofs, the few auxiliary results that are required for a complete proof of Lemmas 9 and 10, which provide the core of the proofs of our main results. Some of these results are borrowed from [6, 8, 7]; see also [25] for similar material. Here, we formulate them using trace spaces on the subdomain boundaries, i.e., $H^{1/2}(\partial\Omega_i)$ instead of the spaces $H^1(\Omega_i)$ and discrete harmonic extensions; given the well-known equivalence of the norms, nothing essentially new needs to be proven. In our proofs, we will work with the S-norm defined by $|u|_S^2 = \sum_{i=1}^N |u_i|_{S^{(i)}}^2$ and $|u_i|_{S^{(i)}}^2 = \langle S^{(i)}u_i, u_i\rangle$. A proof of the equivalence of $S^{(i)}$- and $H^{1/2}(\partial\Omega_i)$-seminorms of elements of W_i can be found in [1] for the case of piecewise linear elements and two dimensions. The tools necessary to extend this result to more general finite elements are provided in [22]; in our case, we of course have to multiply $|u_i|_{H^{1/2}(\partial\Omega_i)}^2$ by the factor ρ_i.

We also recall that we can define the $H_{00}^{1/2}(\tilde\Gamma)$-norm, $\tilde\Gamma \subset \partial\Omega_i$, of an element of W_i which is supported in $\tilde\Gamma$, as the $H^{1/2}(\partial\Omega_i)$-norm of the function extended by zero onto $\partial\Omega_i \setminus \tilde\Gamma$.

The first lemma can, essentially, be found in Dryja, Smith, and Widlund [6, Lem. 4.4].

LEMMA 1. *Let $\theta_{\mathcal{F}^{ij}}$ be the finite element function that is equal to* 1 *at the nodal points on the face $\mathcal{F}^{ij}$, which is common to two subregions Ω_i and Ω_j, and that vanishes on $(\partial\Omega_{i,h} \cup \partial\Omega_{j,h}) \setminus \mathcal{F}_h^{ij}$. Then,*

$$|\theta_{\mathcal{F}^{ij}}|_{H^{1/2}(\partial\Omega_i)}^2 \leq C(1+\log(H_i/h_i))H_i.$$

The same bounds also hold for the other subregion Ω_j.

The following result can, essentially, be found in Dryja, Smith, and Widlund [6, Lem. 4.5] or in Dryja [3, Lem. 3].

LEMMA 2. *Let $\theta_{\mathcal{F}^{ij}}$ be the function introduced in Lemma* 1 *and let I^h denote the interpolation operator onto the finite element space $W^h(\Omega_i)$. Then, for all $u \in W_i$,*

$$\|I^h(\theta_{\mathcal{F}^{ij}}u)\|_{H_{00}^{1/2}(\mathcal{F}^{ij})}^2 \leq C(1+\log(H_i/h_i))^2\left(|u|_{H^{1/2}(\mathcal{F}^{ij})}^2 + \frac{1}{H_i}\|u\|_{L_2(\mathcal{F}^{ij})}^2\right).$$

We will also need two additional results which are used to estimate the contributions to our bounds from the edges of Ω_i. For the next lemma, see Dryja, Smith, and Widlund [6, Lem. 4.7].

LEMMA 3. *Let $\theta_{\mathcal{E}^{ik}}$ be the cutoff function associated with the edge $\mathcal{E}^{ik}$. Then, for all $u \in W_i$,*

$$|I^h(\theta_{\mathcal{E}^{ik}}u)|_{H^{1/2}(\partial\Omega_i)}^2 \leq C\|u\|_{L_2(\mathcal{E}^{ik})}^2.$$

This result follows by an elementary estimate of the energy norm of the zero extension of the boundary values and by noting that the harmonic extension has a smaller energy.

We will also need a Sobolev-type inequality for finite element functions; see Dryja and Widlund [7, Lem. 3.3] or Dryja [3, Lem. 1].

LEMMA 4. *Let $\mathcal{E}^{ik}$ be any edge of Ω_i which forms part of the boundary of a face $\mathcal{F}^{ij} \subset \partial\Omega_i$. Then, for all $u \in W_i$,*

$$\|u\|_{L_2(\mathcal{E}^{ik})}^2 \leq C(1+\log(H_i/h_i))\left(|u|_{H^{1/2}(\mathcal{F}^{ij})}^2 + \frac{1}{H_i}\|u\|_{L_2(\mathcal{F}^{ij})}^2\right).$$

We also state a nonstandard version of Friedrichs' inequality that is given in a somewhat different form in [8, Lem. 6].

LEMMA 5. *Let $\mathcal{E}^{ik}$ be an edge of $\mathcal{F}^{ij}$. Then, for all $u \in W_i$ that vanish on $\mathcal{E}^{ik}$,*

$$\|u\|^2_{L_2(\mathcal{F}^{ij})} \leq CH_i(1+\log(H_i/h_i))|u|^2_{H^{1/2}(\mathcal{F}^{ij})}.$$

The proof of the main results in Mandel and Tezaur [17] is based on a bound for a certain interpolation operator. In our proofs, we also could use a different interpolation operator for each of our algorithms. Although these operators now play no direct role in the proofs of our main results, they are nevertheless of independent interest. They also illustrate how, in the cases of Algorithms B and C, we can approximate an arbitrary element in $\widetilde{W}_B$ and $\widetilde{W}_C$, respectively, by a continuous interpolant which is almost uniformly stable in the energy norm; concerning $\widetilde{W}_D$, see Remark 1.

The first interpolation operator, I^h_A, is given by the continuous piecewise linear interpolant on the coarse triangulation of Γ used in the definition of the Ω_i.

Our second interpolation operator I^h_B is defined, for all $u \in \widetilde{W}_B$, by sums over all the vertices, edges, and faces of Γ:

$$I^h_B u(x) = \sum_{\mathcal{V}^{i\ell}\in\Gamma} u(\mathcal{V}^{i\ell})\theta_{\mathcal{V}^{i\ell}}(x) + \sum_{\mathcal{E}^{ik}\subset\Gamma} \overline{u}_{\mathcal{E}^{ik}}\theta_{\mathcal{E}^{ik}}(x) + \sum_{\mathcal{F}^{ij}\subset\Gamma} \overline{u}_{\mathcal{F}^{ij}}\theta_{\mathcal{F}^{ij}}(x). \tag{5.1}$$

The operator I^h_B, a modification of an operator introduced in [6, p. 1690], has almost optimal stability properties. We note that the values of $I^h_B u(x)$ on $\partial\Omega_i$ depend only on the W_i component of u.

We also introduce a third interpolation operator, I^h_C, which provides an alternative to I^h_B:

$$I^h_C u(x) = \sum_{\mathcal{V}^{i\ell}\in\Gamma} u(\mathcal{V}^{i\ell})\theta_{\mathcal{V}^{i\ell}}(x) + \sum_{\mathcal{E}^{ik}\subset\Gamma} \overline{u}_{\mathcal{E}^{ik}}\theta_{\mathcal{E}^{ik}}(x) + \sum_{\mathcal{F}^{ij}\subset\Gamma} \overline{u}_{\partial\mathcal{F}^{ij}}\theta_{\mathcal{F}^{ij}}(x). \tag{5.2}$$

Here the average $\overline{u}_{\mathcal{E}^{ik}}$ is defined as in (4.2), and $\overline{u}_{\partial\mathcal{F}^{ij}}$ is given by

$$\overline{u}_{\partial\mathcal{F}^{ij}} = \frac{\int_{\partial\mathcal{F}^{ij}} u ds}{\int_{\partial\mathcal{F}^{ij}} 1 ds}.$$

This average is a convex combination of the values of the $\overline{u}_{\mathcal{E}^{ik}}$ of the face in question. This interpolant is well defined for any element $u \in \widetilde{W}_C$.

The next lemma provides L_2- and $H^{1/2}$-estimates for the vertex-based interpolation operator I^h_A. This is essentially Lemma 4.1 of Dryja, Smith, and Widlund [6]. The proof follows directly from Poincaré's inequality and a standard discrete Sobolev inequality; see also [6, sect. 4].

LEMMA 6. *The vertex-based interpolation operator I^h_A satisfies*

$$|I^h_A u|^2_{H^{1/2}(\mathcal{F}^{ij})} \leq C\,(H_i/h_i)\,|u|^2_{H^{1/2}(\mathcal{F}^{ij})} \quad \forall u \in W_i$$

and

$$\|u - I^h_A u\|^2_{L_2(\mathcal{F}^{ij})} \leq C\,(H_i/h_i)\,H_i\,|u|^2_{H^{1/2}(\mathcal{F}^{ij})} \quad \forall u \in W_i.$$

Here the constant C is independent of the diameter H_i of Ω_i and the mesh size h_i.

We have better results for the interpolation operators I^h_B and I^h_C, introduced in (5.1) and (5.2), respectively. A bound for I^h_B can be found in a somewhat different

form in Dryja, Smith, and Widlund [6, pp. 1689–1690]. We note that our L_2-estimate is now improved in comparison to [6, p. 1690] since our estimate of the interpolation error contains no logarithmic factor.

LEMMA 7. *The interpolation operators I_B^h and I_C^h, defined in* (5.1) *and* (5.2), *respectively, satisfy*

$$|I_B^h u|^2_{H^{1/2}(\mathcal{F}^{ij})} \leq C(1+\log(H_i/h_i))|u|^2_{H^{1/2}(\mathcal{F}^{ij})} \quad \forall u \in W_i,$$
$$|I_C^h u|^2_{H^{1/2}(\mathcal{F}^{ij})} \leq C(1+\log(H_i/h_i))|u|^2_{H^{1/2}(\mathcal{F}^{ij})} \quad \forall u \in W_i$$

and

$$\|u - I_B^h u\|^2_{L_2(\mathcal{F}^{ij})} \leq CH_i|u|^2_{H^{1/2}(\mathcal{F}^{ij})} \quad \forall u \in W_i,$$
$$\|u - I_C^h u\|^2_{L_2(\mathcal{F}^{ij})} \leq CH_i(1+\log(H_i/h_i))|u|^2_{H^{1/2}(\mathcal{F}^{ij})} \quad \forall u \in W_i.$$

Here the constant C is independent of the diameter H_i of Ω_i and the mesh size h_i.

6. Convergence analysis. Our analysis borrows ideas from the recent paper by Mandel and Tezaur [17] and from our own paper [13]. In the latter, fast one-level FETI algorithms and a theory for the elliptic problem of the class defined by (2.3) were developed for an arbitrary choice of the ρ_i.

As in [17], the two different Schur complements, $\widetilde{S}$ and S_Δ, introduced in section 4 play an important role in the analysis of the dual-primal iterative algorithm. Both operate on the second subspace $\widetilde{W}_\Delta$, and we also recall that $\widetilde{S}$ represents a global problem while S_Δ does not.

Let $V := \text{range}\,(B_\Delta)$ be the space of Lagrange multipliers. As in [13, sect. 5], we introduce a projection

$$P_\Delta := B_{D,\Delta}^t B_\Delta.$$

A simple computation shows (see [13, Lem. 4.2]) that P_Δ preserves the jump of any function $u_\Delta \in \widetilde{W}_\Delta$, i.e., $B_\Delta P_\Delta u_\Delta = B_\Delta u_\Delta$, and we also have $P_\Delta u = 0$ for all $u \in \widehat{W}$.

Analogous to [13, Lem. 5.2], we have the following.

LEMMA 8. *For any $\mu \in V$, there exists a $w_\Delta \in \text{range}\,(P_\Delta)$ such that $\mu = B_\Delta w_\Delta$.*

Proof. We note that for any $\mu \in V = \text{range}\,(B_\Delta)$, there exists a w'_Δ such that $\mu = B_\Delta w'_\Delta$. Choosing $w_\Delta := P_\Delta w'_\Delta$, we have $B_\Delta w_\Delta = B_\Delta w'_\Delta = \mu$. ∎

Let $x \in \Gamma_h$ and let $w_\Delta \in \widetilde{W}_\Delta$. We borrow the following formula from [13]:

$$P_\Delta w_\Delta(x) \;=\; \sum_{j \in \mathcal{N}_{\Delta,x}} \rho_j^\gamma \mu_j^\dagger (w_{\Delta,i}(x) - w_{\Delta,j}(x)), x \in \partial\Omega_{i,h} \cap \Gamma_h. \tag{6.1}$$

Here, $\mathcal{N}_{\Delta,x}$ is the set of indices of the subregions which have the node x on their boundaries. We note that the coefficients in this expression are constant on the set of the nodal points of each face and each edge of $\partial\Omega_i$ and that this formula is independent of the particular choice of B_Δ.

We first analyze Algorithm B and begin by proving the following core estimate.

LEMMA 9 (Algorithm B). *For all $w_\Delta \in \widetilde{W}_{\Delta,B}$, we have*

$$|P_\Delta w_\Delta|^2_{S_\Delta} \leq C\,(1+\log(H/h))^2 |w_\Delta|^2_{\widetilde{S}},$$

where $C > 0$ is independent of h, H, γ, and the ρ_i.

Proof. We consider an arbitrary $w_\Delta \in \widetilde{W}_{\Delta,B}$. In order to compute its $\widetilde{S}$-norm (cf. (4.3)), we determine the element $w = w_\Pi + w_\Delta \in \widetilde{W}_B, w_\Pi \in \widehat{W}_{\Pi,B}$, with the correct minimal property. Then, by the definition of $\widetilde{S}$, $|w_\Delta|_{\widetilde{S}} = |w|_S$. We next note that we can subtract any continuous function from w_Δ without changing the values of $P_\Delta w_\Delta$; thus, $P_\Delta w = P_\Delta w_\Delta$. It is also easy to see, by carrying out a simple computation and by using formula (6.1), that $P_\Delta w_\Delta \in \widetilde{W}_{\Delta,B}$. We also recall that the S_Δ-norm of any element of $\widetilde{W}_\Delta$ equals its S-norm.

We model our proof on [13, Lem. 4.7 and 5.4] but note that the arguments need to be modified to some extent. We also note that we have contributions only from faces and edges since all elements in $\widetilde{W}_B$ are continuous at the vertices. Here, in contrast to the proof in [13], we do not need to assume that there is no subdomain, with boundaries, that intersects $\partial\Omega_D$ only in isolated points.

We introduce the notation $(v_i)_{i=1,\dots,N} := P_\Delta w$. Then, we have to estimate

$$|P_\Delta w|_S^2 = \sum_{i=1}^N |v_i|_{S^{(i)}}^2.$$

We can therefore focus on the estimate of the contribution from a single subdomain Ω_i. We first assume that its boundary and the boundaries of its relevant neighbors do not intersect $\partial\Omega_D$.

We cut the function v_i, using the functions $\theta_{\mathcal{F}^{ij}}$ and $\theta_{\mathcal{E}^{ik}}$, and write it as a sum of terms which vanish at all the interface nodes outside individual faces and edges; cf., e.g., [6, 8, 7]. We then have, since v_i vanishes at the subdomain vertices,

$$v_i = \sum_{\mathcal{F}^{ij}\subset\partial\Omega_i} I^h(\theta_{\mathcal{F}^{ij}} v_i) + \sum_{\mathcal{E}^{ik}\subset\partial\Omega_i} I^h(\theta_{\mathcal{E}^{ik}} v_i).$$

We find that the face $\mathcal{F}^{ij}$ contributes

$$I^h(\theta_{\mathcal{F}^{ij}} \rho_j^\gamma \mu_j^\dagger (w_i - w_j))$$

and we have to estimate its $H_{00}^{1/2}(\mathcal{F}^{ij})$-norm; this formula follows from (6.1).

With $\gamma \geq 1/2$, we can easily prove that

$$\rho_i(\rho_j^\gamma \mu_j^\dagger)^2 \leq \min(\rho_i, \rho_j). \tag{6.2}$$

We note that $\rho_j^\gamma \mu_j^\dagger$ is constant on $\mathcal{F}_h^{ij}$ and that w has common face averages, i.e., $\overline{w}_{i,\mathcal{F}^{ij}} = \overline{w}_{j,\mathcal{F}^{ij}}$. Using inequality (6.2), these observations, and Lemma 2, we obtain

(6.3)

$$\begin{aligned}
&\rho_i \|I^h(\theta_{\mathcal{F}^{ij}} \rho_j^\gamma \mu_j^\dagger (w_i - w_j))\|^2_{H_{00}^{1/2}(\mathcal{F}^{ij})} \\
&= \rho_i \|I^h(\theta_{\mathcal{F}^{ij}} \rho_j^\gamma \mu_j^\dagger ((w_i - \overline{w}_{i,\mathcal{F}^{ij}}) - (w_j - \overline{w}_{j,\mathcal{F}^{ij}})))\|^2_{H_{00}^{1/2}(\mathcal{F}^{ij})} \\
&\leq C\,(1 + \log(H_i/h_i))^2 \min(\rho_i, \rho_j) \Big(|w_i - w_j|^2_{H^{1/2}(\mathcal{F}^{ij})} \\
&\qquad\qquad + \frac{1}{H_i} \|(w_i - \overline{w}_{i,\mathcal{F}^{ij}}) - (w_j - \overline{w}_{j,\mathcal{F}^{ij}})\|^2_{L_2(\mathcal{F}^{ij})} \Big).
\end{aligned}$$

We can estimate this expression by

$$C\,(1 + \log(H_i/h_i))^2 \left(\rho_i |w_i|^2_{H^{1/2}(\mathcal{F}^{ij})} + \rho_j |w_j|^2_{H^{1/2}(\mathcal{F}^{ij})} \right),$$

as desired, by applying a Poincaré inequality. We note that, by assumption, H_j and H_i are comparable and so are h_j and h_i, since the triangulations of Ω_i and Ω_j are quasi-uniform.

By using Lemma 3, we can estimate the contributions of the edges of Ω_i to the energy of v_i in terms of L_2-norms over the edges. These L_2-terms are then estimated by using Lemma 4. If four subdomains, e.g., $\Omega_i, \Omega_j, \Omega_k$, and Ω_ℓ, have an edge $\mathcal{E}^{ik}$ in common, then, according to (6.1), there are three contributions to the estimate of the contribution of Ω_i to $|P_\Delta w|_S^2$, namely,

$$\begin{aligned}\rho_i \, \|I^h(\rho_j^\gamma \, \mu_j^\dagger \, \theta_{\mathcal{E}^{ik}}(w_i - w_j))\|^2_{L_2(\mathcal{E}^{ik})} \; &+ \; \rho_i \, \|I^h(\rho_k^\gamma \, \mu_k^\dagger \, \theta_{\mathcal{E}^{ik}}(w_i - w_k))\|^2_{L_2(\mathcal{E}^{ik})} \\ &+ \; \rho_i \, \|I^h(\rho_\ell^\gamma \, \mu_\ell^\dagger \, \theta_{\mathcal{E}^{ik}}(w_i - w_\ell))\|^2_{L_2(\mathcal{E}^{ik})}.\end{aligned} \tag{6.4}$$

We first consider the second term in detail, assuming that Ω_i shares a face with each of Ω_j and Ω_ℓ but only an edge with Ω_k. In the next estimate, we use $|\overline{w}_{i,\mathcal{E}^{ik}}|^2 \leq 1/H_i \|w_i\|^2_{L_2(\mathcal{E}^{ik})}$ and $\|\theta_{\mathcal{E}^{ik}}\|^2_{L_2(\mathcal{E}^{ik})} \leq C\, H_i$. Using formula (6.2), Lemma 4, and the fact that w has common edge averages, i.e., $\overline{w}_{i,\mathcal{E}^{ik}} = \overline{w}_{k,\mathcal{E}^{ik}}$, we obtain

$$\begin{aligned}
& \rho_i \, \|I^h(\rho_k^\gamma \mu_k^\dagger \theta_{\mathcal{E}^{ik}}(w_i - w_k))\|^2_{L_2(\mathcal{E}^{ik})} \\
= \; & \rho_i \, \|I^h(\rho_k^\gamma \mu_k^\dagger (\theta_{\mathcal{E}^{ik}}(w_i - \overline{w}_{i,\mathcal{E}^{ik}}) - \theta_{\mathcal{E}^{ik}}(w_k - \overline{w}_{k,\mathcal{E}^{ik}})))\|^2_{L_2(\mathcal{E}^{ik})} \\
\leq \; & 2 \left(\rho_i \|I^h(\theta_{\mathcal{E}^{ik}}(w_i - \overline{w}_{i,\mathcal{E}^{ik}}))\|^2_{L_2(\mathcal{E}^{ik})} + \rho_k \|I^h(\theta_{\mathcal{E}^{ik}}(w_k - \overline{w}_{k,\mathcal{E}^{ik}}))\|^2_{L_2(\mathcal{E}^{ik})} \right) \\
\leq \; & C \left(\rho_i \|w_i\|^2_{L_2(\mathcal{E}^{ik})} + \rho_k \|w_k\|^2_{L_2(\mathcal{E}^{ik})} \right) \\
\leq \; & C(1 + \log(H/h)) \left(\rho_i \left(|w_i|^2_{H^{1/2}(\mathcal{F}^{ij})} + \tfrac{1}{H_i} \|w_i\|^2_{L_2(\mathcal{F}^{ij})} \right) \right. \\
& \qquad \left. + \rho_k \left(|w_k|^2_{H^{1/2}(\mathcal{F}^{kj})} + \tfrac{1}{H_k} \|w_k\|^2_{L_2(\mathcal{F}^{kj})} \right) \right) \\
\leq \; & C(1 + \log(H/h)) \left(\rho_i |w_i|^2_{H^{1/2}(\mathcal{F}^{ij})} + \rho_k |w_k|^2_{H^{1/2}(\mathcal{F}^{kj})} \right),
\end{aligned} \tag{6.5}$$

with $\mathcal{F}^{ij}$ a face of Ω_i and $\mathcal{F}^{kj}$ a face of Ω_k, both of which have the edge $\mathcal{E}^{ik}$ in common. The last inequality follows from the shift invariance of the expressions on the third line; i.e., we can add constants to w_i and w_k without changing the value of the expressions and then use Poincaré's inequality.

Since Ω_i and Ω_j, as well as Ω_i and Ω_ℓ, have a face in common, the argument given above could be simplified for the first and third edge contributions; they can be reduced to estimates for face terms directly.

Finally, we have to consider boundary subregions which have a nonempty intersection with $\partial\Omega_D$ and show that we can obtain bounds of the same quality. We then need different arguments to eliminate the $L_2(\mathcal{F}^{ij})$ terms. In case this intersection is a face or an edge, we can use exactly the same arguments as in [13, p. 71] which include using Lemma 5. If the boundary of a substructure intersects $\partial\Omega_D$ in just one or a few single points, the shifting can be done exactly as above for the face and edge terms of an interior subregion. ∎

We now prove our condition number estimate for Algorithm B, which only depends polylogarithmically on the dimension of the subproblems.

THEOREM 1 (Algorithm B). *The condition number satisfies*

$$\kappa(M_B^{-1} F_B) \leq C \, (1 + \log(H/h))^2.$$

Here, C is independent of h, H, γ, and the values of the ρ_i.

Proof. We have to estimate the smallest eigenvalue $\lambda_{min}(M_B^{-1}F_B)$ from below and the largest eigenvalue $\lambda_{max}(M_B^{-1}F_B)$ from above. We will show that

$$\langle M_B\lambda,\lambda\rangle \leq \langle F_B\lambda,\lambda\rangle \leq C\,(1+\log(H/h))^2\langle M_B\lambda,\lambda\rangle \quad \forall \lambda\in V. \tag{6.6}$$

Lower bound. This bound is derived using purely algebraic arguments. As in the analysis of the one-level FETI methods, we can use the following formula (see Mandel and Tezaur [16] or Klawonn and Widlund [13, p. 73]):

$$\langle F_B\lambda,\lambda\rangle = \sup_{0\neq v_\Delta\in\widetilde{W}_\Delta} \frac{\langle\lambda, B_\Delta v_\Delta\rangle^2}{|v_\Delta|^2_{\widetilde{S}}}.$$

Let $\mu\in V$ be arbitrary. It then follows from Lemma 8 that there exists a $w_\Delta\in$ range (P_Δ) with $\mu = B_\Delta w_\Delta$. Since $w_\Delta = P_\Delta w_\Delta$ and $|u_\Delta|_{\widetilde{S}}\leq |u_\Delta|_{S_\Delta}$ for all $u_\Delta\in\widetilde{W}_\Delta$, we obtain

$$\langle F_B\lambda,\lambda\rangle \geq \frac{\langle\lambda,B_\Delta w_\Delta\rangle^2}{|w_\Delta|^2_{\widetilde{S}}} \geq \frac{\langle\lambda,B_\Delta w_\Delta\rangle^2}{|w_\Delta|^2_{S_\Delta}} = \frac{\langle\lambda,\mu\rangle^2}{|B^t_{D,\Delta}\mu|^2_{S_\Delta}} = \frac{\langle\lambda,\mu\rangle^2}{\langle M_B^{-1}\mu,\mu\rangle}.$$

The left inequality of (6.6) follows by choosing $\mu := M_B\lambda$.

Upper bound. Using Lemma 9, we obtain, for all $\lambda\in V$,

$$\begin{aligned}
\langle F_B\lambda,\lambda\rangle &= \sup_{0\neq w_\Delta\in\widetilde{W}_\Delta} \frac{\langle\lambda,B_\Delta w_\Delta\rangle^2}{|w_\Delta|^2_{\widetilde{S}}} \\
&\leq C\,(1+\log(H/h))^2 \sup_{w_\Delta\neq 0} \frac{\langle\lambda,B_\Delta w_\Delta\rangle^2}{|P_\Delta w_\Delta|^2_{S_\Delta}} \\
&= C\,(1+\log(H/h))^2 \sup_{w_\Delta\neq 0} \frac{\langle\lambda,B_\Delta w_\Delta\rangle^2}{\langle M_B^{-1}B_\Delta w_\Delta, B_\Delta w_\Delta\rangle} \\
&= C\,(1+\log(H/h))^2 \sup_{\mu\in V} \frac{\langle\lambda,\mu\rangle^2}{\langle M_B^{-1}\mu,\mu\rangle} = C\,(1+\log(H/h))^2\langle M_B\lambda,\lambda\rangle. \qquad \square
\end{aligned}$$

We now turn to the analysis of Algorithms C and D.

LEMMA 10 (Algorithms C and D). *For all $w_\Delta\in\widetilde{W}_{\Delta,C}$, we have*

$$|P_\Delta w_\Delta|^2_{S_\Delta} \leq C\,(1+\log(H/h))^2|w_\Delta|^2_{\widetilde{S}}.$$

For all $w_\Delta\in\widetilde{W}_{\Delta,D}$, we have

$$|P_\Delta w_\Delta|^2_{S_\Delta} \leq C\,\max(1,TOL)\,(1+\log(H/h))^2|w_\Delta|^2_{\widetilde{S}}.$$

In both cases, $C>0$ is independent of h, H, γ, and the ρ_i.

Proof. We can proceed as in the proof of Lemma 9; we will use the same notation and discuss only details that are technically different. We note that in Algorithm D all vertices are not necessarily constrained and that therefore we have to estimate terms of $P_\Delta w(x)$ related to the vertices which are not primal.

We cut the function v_i using the functions $\theta_{\mathcal{F}^{ij}}$, $\theta_{\mathcal{E}^{ik}}$, and $\theta_{\mathcal{V}^{il}}$ and write it as a sum of terms which vanish at all the interface nodes outside individual faces, edges, and vertices, respectively; cf., e.g., [6, 8, 7]. We then have

$$v_i = \sum_{\mathcal{F}^{ij}\subset\partial\Omega_i} I^h(\theta_{\mathcal{F}^{ij}}v_i) + \sum_{\mathcal{E}^{ik}\subset\partial\Omega_i} I^h(\theta_{\mathcal{E}^{ik}}v_i) + \sum_{\mathcal{V}^{il}\in\partial\Omega_i} \theta_{\mathcal{V}^{il}}v_i(\mathcal{V}^{il}).$$

As in [13] and the proof of Lemma 9, we find that the face $\mathcal{F}^{ij}$ contributes

$$I^h(\theta_{\mathcal{F}^{ij}}\rho_j^\gamma\mu_j^\dagger(w_i-w_j))$$

and we have to estimate its $H_{00}^{1/2}(\mathcal{F}^{ij})$-norm. Using inequality (6.2) and the fact that $\rho_j^\gamma\mu_j^\dagger$ is constant on $\mathcal{F}_h^{ij}$, we obtain

$$\begin{aligned}
&\rho_i\|I^h(\theta_{\mathcal{F}^{ij}}\rho_j^\gamma\mu_j^\dagger(w_i-w_j))\|^2_{H_{00}^{1/2}(\mathcal{F}^{ij})}\\
=\;&\rho_i\|I^h(\theta_{\mathcal{F}^{ij}}\rho_j^\gamma\mu_j^\dagger((w_i-\overline{w}_{i,\mathcal{F}^{ij}})-(w_j-\overline{w}_{j,\mathcal{F}^{ij}})\\
&\qquad+(\overline{w}_{i,\mathcal{F}^{ij}}-\overline{w}_{j,\mathcal{F}^{ij}})))\|^2_{H_{00}^{1/2}(\mathcal{F}^{ij})}\\
\le\;&2\min(\rho_i,\rho_j)\left(\|I^h(\theta_{\mathcal{F}^{ij}}((w_i-\overline{w}_{i,\mathcal{F}^{ij}})-(w_j-\overline{w}_{j,\mathcal{F}^{ij}})))\|^2_{H_{00}^{1/2}(\mathcal{F}^{ij})}\right.\\
&\qquad\left.+\|(\overline{w}_{i,\mathcal{F}^{ij}}-\overline{w}_{j,\mathcal{F}^{ij}})\theta_{\mathcal{F}^{ij}}\|^2_{H_{00}^{1/2}(\mathcal{F}^{ij})}\right).
\end{aligned}\tag{6.7}$$

The first term can be estimated as in (6.3) by

$$C\,(1+\log(H_i/h_i))^2\left(\rho_i|w_i|^2_{H^{1/2}(\mathcal{F}^{ij})}+\rho_j|w_j|^2_{H^{1/2}(\mathcal{F}^{ij})}\right),$$

as desired, by applying a Poincaré inequality. There remains to estimate $\|((\overline{w}_{i,\mathcal{F}^{ij}}-\overline{w}_{j,\mathcal{F}^{ij}})\theta_{\mathcal{F}^{ij}}\|^2_{H_{00}^{1/2}(\mathcal{F}^{ij})}$. Let $\mathcal{E}^{ik}\subset\partial\mathcal{F}^{ij}$ be a designated, primal edge. Then, we have

$$|\overline{w}_{i,\mathcal{F}^{ij}}-\overline{w}_{j,\mathcal{F}^{ij}}|^2\le 2\left(|\overline{w}_{i,\mathcal{F}^{ij}}-\overline{w}_{i,\mathcal{E}^{ik}}|^2+|\overline{w}_{j,\mathcal{F}^{ij}}-\overline{w}_{j,\mathcal{E}^{ik}}|^2\right).$$

It is sufficient to consider the first term on the right-hand side. The shift invariance allows us to assume that $\overline{w}_{i,\mathcal{F}^{ij}}=0$. Using $|\overline{w}_{\mathcal{E}^{ik}}|^2\le C/H_i\|w_i\|^2_{L_2(\mathcal{E}^{ik})}$ and Lemmas 1 and 4, we obtain

$$\|(\overline{w}_{i,\mathcal{F}^{ij}}-\overline{w}_{j,\mathcal{F}^{ij}})\theta_{\mathcal{F}^{ij}}\|^2_{H_{00}^{1/2}(\mathcal{F}^{ij})}\le C\,(1+\log(H/h))^2\left(|w_i|^2_{H^{1/2}(\mathcal{F}^{ij})}+|w_j|^2_{H^{1/2}(\mathcal{F}^{ij})}\right).$$

The remainder of the proof of the result for Algorithm C can be carried out as in the proof of Lemma 9. However, for Algorithm D, we need to do some further work.

Proceeding as in the proof of Lemma 9, we can estimate the contributions of the edges of Ω_i to the energy of v_i in terms of L_2-norms over the edges. We first consider the second term of (6.4) in detail, again assuming that Ω_i shares a face with each of Ω_j and Ω_ℓ but only an edge with Ω_k. If we have a trivial, acceptable edge path, i.e., the common edge is designated as primal, we can proceed exactly as in (6.5). Otherwise assume that we have a nontrivial, acceptable edge path through the subdomain Ω_j via the edges $\mathcal{E}^{ij}$ and $\mathcal{E}^{jk}$; in general the acceptable edge path could be more complicated but such a case could be analyzed similarly. We obtain

$$\begin{aligned}
&\rho_i\,\|\rho_k^\gamma\mu_k^\dagger I^h(\theta_{\mathcal{E}^{ik}}(w_i-w_k))\|^2_{L_2(\mathcal{E}^{ik})}\\
=\;&\rho_i\,\|\rho_k^\gamma\mu_k^\dagger\left(I^h(\theta_{\mathcal{E}^{ik}}(w_i-\overline{w}_{i,\mathcal{E}^{ij}}))+\theta_{\mathcal{E}^{ik}}(\overline{w}_{j,\mathcal{E}^{ij}}-\overline{w}_{j,\mathcal{E}^{jk}})\right.\\
&\qquad\left.-I^h(\theta_{\mathcal{E}^{ik}}(w_k-\overline{w}_{k,\mathcal{E}^{jk}}))\right)\|^2_{L_2(\mathcal{E}^{ik})}\\
\le\;&C\min(\rho_i,\rho_k)\left(\|I^h(\theta_{\mathcal{E}^{ik}}(w_i-\overline{w}_{i,\mathcal{E}^{ij}}))\|^2_{L_2(\mathcal{E}^{ik})}+H_j\,|\overline{w}_{j,\mathcal{E}^{ij}}-\overline{w}_{j,\mathcal{E}^{jk}}|^2\right.\\
&\qquad\left.+\|I^h(\theta_{\mathcal{E}^{ik}}(w_k-\overline{w}_{k,\mathcal{E}^{jk}}))\|^2_{L_2(\mathcal{E}^{ik})}\right).
\end{aligned}\tag{6.8}$$

The terms of the last expression can be estimated as in (6.5). The only difference is that, additionally, we have to use $TOL * \rho_j \geq \min(\rho_i, \rho_k)$. We obtain

$$\rho_i \, \|\rho_k^\gamma \mu_k^\dagger I^h(\theta_{\mathcal{E}^{ik}}(w_i - w_k))\|^2_{L_2(\mathcal{E}^{ik})} \leq C(1+\log(H/h)) \left(\rho_i |w_i|^2_{H^{1/2}(\mathcal{F}^{ij})} + \rho_k |w_k|^2_{H^{1/2}(\mathcal{F}^{ik})} + TOL * \rho_j \left(|w_j|^2_{H^{1/2}(\mathcal{F}^{ij})} + |w_j|^2_{H^{1/2}(\mathcal{F}^{jk})}\right)\right).$$

Since Ω_i and Ω_j, as well as Ω_i and Ω_ℓ, have a face in common, the argument given above could be simplified for the first and third edge contributions (see (6.4)); they can be reduced to estimates of face terms.

Finally, we consider the terms resulting from the vertices. We have, according to (6.1),

$$\begin{aligned} &\rho_i |\theta_{\mathcal{V}^{i\ell}} v_i(\mathcal{V}^{i\ell})|^2_{H^{1/2}(\partial\Omega_i)} \\ &\leq C \sum_{j \in \mathcal{N}_{\Delta,\mathcal{V}^{i\ell}}} \rho_i (\rho_j^\gamma \mu_j^\dagger)^2 |\theta_{\mathcal{V}^{i\ell}}|^2_{H^{1/2}(\partial\Omega_i)} |w_i(\mathcal{V}^{i\ell}) - w_j(\mathcal{V}^{i\ell})|^2 \\ &\leq C \sum_{j \in \mathcal{N}_{\Delta,\mathcal{V}^{i\ell}}} \min(\rho_i, \rho_j) h_i |w_i(\mathcal{V}^{i\ell}) - w_j(\mathcal{V}^{i\ell})|^2. \end{aligned}$$

We now consider each pair of substructures separately. Let Ω_i, Ω_l be such a pair and assume that we have an acceptable edge path through Ω_j via the edges $\mathcal{E}^{ij}$ and $\mathcal{E}^{jl}$ with the condition

$$TOL * \rho_j \geq \frac{h_j}{H_j} \min(\rho_i, \rho_l). \tag{6.9}$$

We can proceed as in the analysis of the edge terms and obtain

$$\begin{aligned} &\min(\rho_i, \rho_l) h_i |w_i(\mathcal{V}^{il}) - w_l(\mathcal{V}^{il})|^2 \\ &\leq 3 \, \min(\rho_i, \rho_l) h_i \left(|w_i(\mathcal{V}^{il}) - \overline{w}_{i,\mathcal{E}^{ij}}|^2 + |\overline{w}_{j,\mathcal{E}^{ij}} - \overline{w}_{j,\mathcal{E}^{jl}}|^2 + |w_l(\mathcal{V}^{il}) - \overline{w}_{l,\mathcal{E}^{jl}}|^2\right). \end{aligned}$$

It is sufficient to estimate the first term on the last line; the third term can be treated in exactly the same way, and the second term can be estimated as above with the only difference of an additional factor h_j/H_j which is accounted for in (6.9). Using $h_i |w_i(\mathcal{V}^{il})|^2 \leq C \|w_i\|^2_{L_2(\mathcal{E}^{ij})}$ and Lemma 4, and estimating $|\overline{w}_{i,\mathcal{E}^{ij}}|$ as before, we obtain

$$\begin{aligned} |w_i(\mathcal{V}^{il}) - \overline{w}_{i,\mathcal{E}^{ij}}|^2 &\leq 2 \left(|w_i(\mathcal{V}^{il})|^2 + |\overline{w}_{i,\mathcal{E}^{ij}}|^2\right) \\ &\leq C(1+\log(H_i/h_i)) h_i^{-1} \left(|w_i|^2_{H^{1/2}(\mathcal{F}^{ij})} + 1/H_i \|w_i\|^2_{L_2(\mathcal{F}^{ij})}\right) \\ &\leq C(1+\log(H_i/h_i)) h_i^{-1} |w_i|^2_{H^{1/2}(\mathcal{F}^{ij})}. \end{aligned}$$

Here, the last line follows again from the shift invariance of the first expression. Using (6.9), we finally obtain

$$\begin{aligned} &\min(\rho_i, \rho_l) h_i |w_i(\mathcal{V}^{il}) - w_l(\mathcal{V}^{il})|^2 \\ &\leq C \, (1+\log(H/h)) \left(\rho_i |w_i|^2_{H^{1/2}(\mathcal{F}^{ij})} + \rho_\ell |w_\ell|^2_{H^{1/2}(\mathcal{F}^{j\ell})} + TOL * \rho_j \left(|w_j|^2_{H^{1/2}(\mathcal{F}^{ij})} + |w_j|^2_{H^{1/2}(\mathcal{F}^{j\ell})}\right)\right). \end{aligned}$$

The boundary subregions can again be treated as in the proof of Lemma 9. ∎

We can now prove our condition number estimates for Algorithms C and D, which are as strong as those in Theorem 1. The proof can be carried out exactly as for Theorem 1, using Lemma 10 instead of Lemma 9.

THEOREM 2 (Algorithms C and D). *The condition numbers satisfy*

$$\kappa(M_C^{-1}F_C) \leq C\,(1+\log(H/h))^2$$

and

$$\kappa(M_D^{-1}F_D) \leq C\,\max(1,TOL)\,(1+\log(H/h))^2.$$

Here, C is independent of h, H, γ, and the values of the ρ_i.

Remark 1. It is possible to define a fourth interpolation operator I_D^h, based on the weights ρ_i, the pseudoinverses $\mu_i^\dagger$, and the averages over the subdomain boundaries, by

$$I_D^h u(x) = \sum_i \overline{u}_{\partial\Omega_i}\rho_i^\gamma(x)\mu_i^\dagger(x). \tag{6.10}$$

Here the average $\overline{u}_{\partial\Omega_i}$ is defined by

$$\overline{u}_{\partial\Omega_i} = \frac{\int_{\partial\Omega_i} u ds}{\int_{\partial\Omega_i} 1 ds},$$

where we use the component in W_i when computing this average. This operator naturally appears in studies of Neumann–Neumann algorithms. We can establish the same type of bounds as for I_C^h in Lemma 7, provided that we introduce the same constraints as for Algorithm D.

Remark 2. It is already known from the numerical results in [9, 10] that Algorithm A is not competitive. We can prove that the condition number of Algorithm A satisfies the weaker bound,

$$\kappa(M_A^{-1}F_A) \leq C\,(H/h)\,(1+\log(H/h))^2,$$

in the same way as Theorem 1, using Lemma 6 and a variant of Lemma 10. Here, C is independent of h, H, γ, and the values of the ρ_i.

A STABLE AFFINE-APPROXIMATE FINITE ELEMENT METHOD*

K. ARUNAKIRINATHAR† AND B. D. REDDY‡

Abstract. The notion of the affine figure closest to a given quadrilateral can be given a precise mathematical definition. The resulting figure is referred to as the equivalent parallelogram associated with a quadrilateral. Equipped with such a concept, it is then feasible to consider finite element approximations in which the original quadrilateral elements are replaced by their equivalent parallelograms. The idea is appealing, not least because of the resulting economy arising from computations performed on an element generated by an affine map. Furthermore, numerical experiments reported recently indicate that highly efficient and accurate schemes result when such a concept is combined with the enhanced strain method or the method of incompatible modes. The purpose of this work is to analyze finite element schemes resulting from approximation of quadrilaterals by their equivalent parallelograms. The focus is on low-order (bilinear) elements, and the analysis is carried out in the context of linear elasticity for standard approximations as well as for those which use enhanced strains. The affine approximation applies only to the element map, and the primary unknown (the displacement vector in the context of elasticity) is approximated by conventional piecewise bilinear functions. The analysis confirms convergence at the optimal rate, provided that the deviations of the quadrilaterals from their equivalent parallelograms are at most $O(h)$.

Key words. equivalent parallelogram, affine approximations, four-noded quadrilateral, error estimates

1. Introduction.

The use of low-order elements in finite element analyses of complex problems carries with it significant advantages. Most particularly, such schemes are highly economical and for this reason are attractive.

Finite element analyses based on four-noded quadrilaterals in two dimensions, and on eight-noded hexahedral elements in three, are widely used. Unfortunately, they are not without their drawbacks. In problems of solid mechanics in which bending deformations dominate, analyses based on these elements exhibit poor accuracy, at least when coarse meshes are used. In addition, in the incompressible limit, or when the compressibility is small, locking behavior is experienced.

There is a vast literature that is devoted to the construction of methods which are intended to overcome the problems referred to, while retaining the advantages of using low-order elements. One commonly used set of remedies is that based on a combination of underintegration plus stabilization (see, for example, the work of [4] and [8]). The great advantage of this approach is its efficiency, in that only a single integration point is used. However, the eigenvalues of the stiffness matrix are required in the process, and it is not possible to evaluate these without a relatively high degree of effort, for nonaffine elements.

Another popular approach is that associated with the enrichment or enhancement of the strain by the addition of suitably chosen basis functions. The key work dealing with enhanced strain formulations is [14], which in turn contains as a special case

the nonconforming method of incompatible modes due to Wilson, Taylor, Doherty, and Ghaboussi [17] for rectangular elements and extended by Taylor, Beresford, and Wilson [16] to incorporate arbitrary quadrilaterals. The method has been successfully extended to nonlinear problems (see, for example, [15]). Reddy and Simo [11] have shown, for linear problems and for affine elements, that the enhanced strain method is stable and convergent, while Arunakirinathar and Reddy [3] have extended that work to include the case of arbitrary quadrilaterals.

The enhanced strain method is still not without its drawbacks. For example, the quality of approximations for arbitrary elements declines with an increase in distortion of the elements. Consideration of this shortcoming, together with a desire to improve the efficiency of computations associated with arbitrary quadrilaterals or hexahedra, leads naturally to the notion of replacing the arbitrary quadrilateral by the affine element that is closest to it, in a manner that can be made precise. Such an affine element is known as the equivalent parallelogram in two dimensions, and the equivalent parallelepiped in three. It is important to bear in mind that the affine approximation applies only to the element map and that the primary unknown (the displacement vector in the context of elasticity) is still approximated by piecewise bilinear functions in two dimensions and by piecewise trilinear functions in three.

It has been shown in [2] that the interpolation error obtained by using the equivalent parallelogram instead of the original quadrilateral is of the same order as that corresponding to the usual interpolation error. The element stiffness matrices associated with the equivalent elements are therefore admissible alternatives to the "exact" stiffness matrices of the original elements, while at the same time they are far easier to construct. This set of ideas has been proposed, and then tested numerically, first in the context of problems of linear elasticity in [9] and subsequently for problems involving nonlinearly elastic materials in [12, 13]. In all cases the numerical results are encouraging and suggest a significant improvement in efficiency and accuracy when this approach is used, particularly in circumstances in which element distortions are significant.

The purpose of this work is to carry out a detailed analysis of these affine-approximate finite element methods, for linear problems. The analysis is confined to plane problems but can be extended to three dimensions with little difficulty, though the details are messy. The analysis includes treatment of finite elements without and with the inclusion of enhanced strains. The key results, with respect to both classes of approximations, is that the method converges at the optimal rate provided that the element distortion is sufficiently small—more precisely, provided that deviation of the quadrilateral from the equivalent parallelogram is of the order of mesh size. This notion will be made precise in what follows.

The plan of the remainder of this work is as follows. In section 2 the problem is formulated. Finite element approximations are introduced in section 3, as is the notion of the equivalent parallelogram. The analysis of the affine-approximate method is carried in section 4 for the problem without enhancement, while section 5 is devoted to an analysis of the problem with enhancement.

2. The boundary-value problem of elasticity. The model problem of relevance is the displacement boundary-value problem of linear elasticity. Suppose that a linear elastic body occupies a region $\Omega \subset \mathbb{R}^d$ $(d = 2, 3)$. The body has boundary Γ. Then the governing equations which are required to hold on Ω are the equation of equilibrium

$$-\operatorname{div} \boldsymbol{\sigma} = \boldsymbol{b}, \tag{1}$$

the strain-displacement relation

$$\boldsymbol{\epsilon}(\boldsymbol{u}) = \tfrac{1}{2}(\nabla \boldsymbol{u} + [\nabla \boldsymbol{u}]^T), \tag{2}$$

and the elastic constitutive equation

$$\boldsymbol{\sigma} = \mathbb{C}[\boldsymbol{\epsilon}]. \tag{3}$$

Here $\boldsymbol{\sigma}$ is the symmetric Cauchy stress tensor, $\boldsymbol{\epsilon}$ is the infinitesimal strain tensor, $\boldsymbol{u}$ is the displacement vector, $\mathbb{C}$ is the fourth-order elasticity tensor, and $\boldsymbol{b}$ is a prescribed body force vector.

For convenience we assume that the displacement satisfies the homogeneous Dirichlet boundary condition, that is,

$$\boldsymbol{u} = \boldsymbol{0} \quad \text{on } \Gamma. \tag{4}$$

The tensor $\mathbb{C}$ has the symmetries

$$\mathbb{C}_{ijkl} = \mathbb{C}_{jikl} = \mathbb{C}_{ijlk} = \mathbb{C}_{klij} \tag{5}$$

and is assumed to be pointwise stable, in the sense that there exists a constant $c_0 > 0$ such that

$$\mathbb{C}_{ijkl} M_{ij} M_{kl} \geq c_0 M_{ij} M_{ij} \tag{6}$$

for all symmetric matrices $\boldsymbol{M}$, the summation convention for repeated indices being invoked here and henceforth. In addition, the components of $\mathbb{C}$ are assumed to be bounded measurable functions; that is,

$$\mathbb{C}_{ijkl} \in L^\infty(\Omega) \tag{7}$$

for all indices i, j, k, l ranging over 1 to d, with

$$c_\infty := \max_{i,j,k,l} \operatorname{ess\,sup}\{\mathbb{C}_{ijkl}(\boldsymbol{x}) : \ \boldsymbol{x} \in \Omega \ \}. \tag{8}$$

For isotropic elastic materials the elasticity tensor takes the simple form

$$\mathbb{C}[\boldsymbol{\epsilon}] = \lambda \operatorname{tr} \boldsymbol{\epsilon} + 2\mu\, \boldsymbol{\epsilon},$$

in which λ and μ are the Lamé constants. Pointwise stability of $\mathbb{C}$ is equivalent to the condition that the Lamé constants satisfy the inequalities [10]

$$\mu > 0 \quad \text{and} \quad \lambda > -\tfrac{2}{3}\mu.$$

We will make use of the space $L^2(\Omega)$ of square-integrable functions defined on Ω. The inner product and norm on this space are denoted, respectively, by $(\cdot, \cdot)_0$ and $\| \cdot \|_0$. We recall also the definition of the Sobolev spaces $H^m(\Omega)$, where m is an integer; for nonnegative m, these are equivalence classes of functions which, together with their generalized derivatives up to and including those of order m, are members of $L^2(\Omega)$. The Sobolev spaces are Hilbert spaces with inner product and associated norm given by

$$(u, v)_m = \int_\Omega \sum_{|\alpha| \leq m} D^\alpha u(\boldsymbol{x}) D^\alpha v(\boldsymbol{x}) \, d\boldsymbol{x}, \quad \|u\|_m = (u, u)_m^{1/2}$$

for all $u, v \in H^m(\Omega)$. Here $\alpha = (\alpha_1, \ldots, \alpha_d)$ is a multi-index whose components α_i are nonnegative integers, $|\alpha| = \alpha_1 + \cdots + \alpha_d$, and $D^\alpha = \partial^{|\alpha|}/\partial x_1^{\alpha_1} \cdots \partial x_d^{\alpha_d}$. The seminorm $|\cdot|_m$ on $H^m(\Omega)$ is defined by

$$|u|_m = \int_\Omega \sum_{|\alpha|=m} D^\alpha u(\boldsymbol{x}) D^\alpha v(\boldsymbol{x})\ d\boldsymbol{x}.$$

We define the space $H_0^m(\Omega)$ of functions in $H^m(\Omega)$ which, together with their derivatives of order up to and including those of order $m-1$, vanish on the boundary in the sense of traces. The seminorm $|\cdot|_m$ is a norm on $H_0^m(\Omega)$, equivalent to the standard norm $\|\cdot\|_m$. Finally, the space $H^{-m}(\Omega)$, for m a nonnegative integer, may be identified with the topological dual space of $H_0^m(\Omega)$.

We are now in a position to define the standard variational problem in linear elasticity. For this purpose we denote by $V := [H_0^1(\Omega)]^d$ the space of admissible displacements and define the bilinear form $a(\cdot,\cdot)$ and linear functional $\ell(\cdot)$ by

$$a : V \times V \to \mathbb{R}, \qquad a(\boldsymbol{u}, \boldsymbol{v}) = \int_\Omega \mathbb{C}\boldsymbol{\epsilon}(\boldsymbol{u}) : \boldsymbol{\epsilon}(\boldsymbol{v})\ d\boldsymbol{x}, \tag{9}$$

$$\ell : V \to \mathbb{R}, \qquad \ell(\boldsymbol{v}) = \int_\Omega \boldsymbol{b} \cdot \boldsymbol{v}\ d\boldsymbol{x}. \tag{10}$$

The properties of $\mathbb{C}$ guarantee that $a(\cdot,\cdot)$ is symmetric, continuous, and V-elliptic; that is, $a(\boldsymbol{v}, \boldsymbol{u}) = a(\boldsymbol{u}, \boldsymbol{v})$, and there exist positive constants M and α such that

$$|a(\boldsymbol{u}, \boldsymbol{v})| \le M\|\boldsymbol{u}\|_V \|\boldsymbol{v}\|_V \quad \text{and} \quad a(\boldsymbol{v}, \boldsymbol{v}) \ge \alpha \|\boldsymbol{v}\|_V^2$$

for all $\boldsymbol{u}$, $\boldsymbol{v} \in V$.

The topological dual of V is denoted by V'.

The standard variational problem is as follows.

Problem S. Given $\boldsymbol{b} \in V'$, find $\boldsymbol{u} \in V$ which satisfies

$$a(\boldsymbol{u}, \boldsymbol{v}) = \ell(\boldsymbol{v}) \tag{11}$$

for all $\boldsymbol{v} \in V$.

It is well known (see, for example, [7]) that Problem S has a unique solution, which satisfies the bound

$$\|\boldsymbol{u}\|_V \le (1/\alpha)\, \|\ell\|_{V'}. \tag{12}$$

3. Finite element approximations. We confine attention to plane situations, so that $d = 2$. The domain Ω is assumed to be polygonal, and a finite element mesh $\mathcal{T}$ of quadrilateral elements is constructed on Ω in the usual manner. A typical element K in $\mathcal{T}$ is generated by an isoparametric map F from a reference element $\hat{K} \equiv (-1,1) \times (-1,1)$. The mesh parameter h is defined by

$$h = \max_{K \in \mathcal{T}} \sup\{|\boldsymbol{x} - \boldsymbol{y}| : \quad \boldsymbol{x}, \boldsymbol{y} \in K\}. \tag{13}$$

We define basis functions $\hat{N}_A \quad (A = 1, \ldots, 4)$ on $\hat{K}$ by

$$\hat{N}_A(\boldsymbol{\xi}) = \tfrac{1}{4}(1 + \xi\xi_A)(1 + \eta\eta_A),$$

where $\boldsymbol{\xi}_A \equiv (\xi_A, \eta_A)$ are the nodal coordinates on $\hat{K}$ with $(\xi_1 \cdots \xi_4) = (1\ -1\ -1\ 1)$ and $(\eta_1 \cdots \eta_4) = (1\ 1\ -1\ -1)$. Denote by Q_1 the space of bilinear functions spanned by $\hat{N}_A$. Then it is convenient to express the map F in the form

$$F : \hat{K} \to K, \qquad \boldsymbol{x} = F(\boldsymbol{\xi}) = \sum_{A=1}^{4} \boldsymbol{x}_A \hat{N}_A(\boldsymbol{\xi}), \tag{14}$$

in which $\boldsymbol{x}_A$ are the nodal points of K.

The Jacobian matrix $\boldsymbol{J}$ is defined to be the gradient of the map F and is the matrix with components

$$J_{ij} = \frac{\partial F_i(\boldsymbol{\xi})}{\partial \xi_j}, \quad i, j = 1, 2.$$

We also set

$$j = \det \boldsymbol{J}.$$

Next we define the space V^h by

$$V^h = \{\boldsymbol{v}_h \in V : \ (v_h)_i|_K \circ F \in Q_1\}. \tag{15}$$

In other words, if we define the function $\hat{\boldsymbol{v}}$ on $\hat{K}$ by

$$\hat{\boldsymbol{v}}(\boldsymbol{\xi}) = \boldsymbol{v}|_K(\boldsymbol{x}),$$

in which $\boldsymbol{\xi}$ and $\boldsymbol{x}$ are related through (14), then $\hat{\boldsymbol{v}} \in Q_1$.

The standard discrete variational problem takes the following form.

Problem $\mathrm{S^h}$. Given $\boldsymbol{b} \in V'$, find $\boldsymbol{u}_h \in V^h$ which satisfies

$$a(\boldsymbol{u}_h, \boldsymbol{v}_h) = \ell(\boldsymbol{v}_h) \tag{16}$$

for all $\boldsymbol{v}_h \in V^h$.

It is well known (see [7]) that Problem $\mathrm{S^h}$ has a unique solution, and furthermore, provided that $\boldsymbol{u} \in [H^2(\Omega)]^2$, there exists a constant $C > 0$, depending on Ω and on u, but independent of h, such that

$$\|\boldsymbol{u} - \boldsymbol{u}_h\|_V \leq Ch.$$

It is instructive, and relevant to the developments that follow, to note that the bilinear form and linear functional appearing in (16) are usually evaluated on the reference element. In order to do this it is necessary to carry out transformations of the functions appearing in $a(\cdot, \cdot)$ and $\ell(\cdot)$. Thus, if we define $\hat{\boldsymbol{v}}$ as above, the chain rule gives

$$\frac{\partial \hat{v}_i}{\partial \xi_j} = \sum_{k=1}^{2} \frac{\partial v_i}{\partial x_k} \frac{\partial F_k}{\partial \xi_j},$$

or if we define the tensors or matrices $\boldsymbol{L}$ and $\hat{\boldsymbol{L}}$ by

$$L_{ij} = \frac{\partial v_i}{\partial x_j}, \quad \hat{L}_{ij} = \frac{\partial \hat{v}_i}{\partial \xi_j},$$

then

$$\hat{\boldsymbol{L}} = \boldsymbol{L}\boldsymbol{J}.$$

The transformation of the strain tensor may now be easily carried out, and we have, using an obvious notation,

$$\begin{aligned} \boldsymbol{\epsilon}(\boldsymbol{v}) &= \tfrac{1}{2}(\boldsymbol{L} + \boldsymbol{L}^T) \\ &= \tfrac{1}{2}(\hat{\boldsymbol{L}}\boldsymbol{J}^{-1} + \boldsymbol{J}^{-T}\hat{\boldsymbol{L}}^T) := \hat{\boldsymbol{\epsilon}}(\hat{\boldsymbol{v}}). \end{aligned} \tag{17}$$

Hence the bilinear form may be evaluated according to

$$a(\boldsymbol{u}_h, \boldsymbol{v}_h) = \sum_{K \in \mathcal{T}} a_K(\boldsymbol{u}_h, \boldsymbol{v}_h) \tag{18}$$

in which

$$\begin{aligned} a_K(\boldsymbol{u}_h, \boldsymbol{v}_h) &= \int_K \mathbb{C}[\boldsymbol{\epsilon}(\boldsymbol{u}_h)] : \boldsymbol{\epsilon}(\boldsymbol{v}_h)\ dxdy \\ &= \int_{\hat{K}} \hat{\mathbb{C}}[\hat{\boldsymbol{\epsilon}}(\hat{\boldsymbol{u}}_h)] : \hat{\boldsymbol{\epsilon}}(\hat{\boldsymbol{v}}_h)\ j\, d\xi d\eta \end{aligned} \tag{19}$$

and where $\hat{\mathbb{C}} = \mathbb{C} \circ F$.

3.1. The equivalent parallelogram. The notion of the equivalent parallelogram associated with a quadrilateral arises naturally when one seeks to define the parallelogram that is closest to the quadrilateral in a sense that can be made mathematically precise. Assuming that such a parallelogram can be constructed, the quadrilateral can then be viewed as a perturbation of the parallelogram.

This problem was considered by Arunakirinathar and Reddy [2], who showed that the equivalent parallelogram can be constructed as follows. Suppose that the map from the reference element $\hat{K}$ to an arbitrary quadrilateral K is given by (14); then the equivalent parallelogram $\tilde{K}$ associated with K is defined by the *affine* map $\tilde{F}$ obtained simply by discarding the bilinear terms in (14). That is, if we define the vector $\boldsymbol{k}$ by

$$\boldsymbol{k} = \tfrac{1}{4}(\boldsymbol{x}_1 - \boldsymbol{x}_2 + \boldsymbol{x}_3 - \boldsymbol{x}_4),$$

then the map $\tilde{F}$ may be expressed in the form

$$\begin{aligned} \tilde{F}(\boldsymbol{\xi}) &= F(\boldsymbol{\xi}) - \boldsymbol{k}\xi\eta \\ &= \sum_{A=1}^{4} N_A(\boldsymbol{\xi})\tilde{\boldsymbol{x}}_A, \end{aligned}$$

in which the nodal points $\tilde{\boldsymbol{x}}_A$ of the equivalent parallelogram are defined by

$$\tilde{\boldsymbol{x}}_A = \tfrac{3}{4}\boldsymbol{x}_A + \tfrac{1}{4}(\boldsymbol{x}_{A+1} - \boldsymbol{x}_{A+2} + \boldsymbol{x}_{A+3}), \quad A = 1, \ldots, 4 \text{ (modulo 4)}.$$

These notions are illustrated in Figure 1.

The equivalent parallelogram has some interesting properties [2]: for example, K and $\tilde{K}$ have the same areas, their sides intersect at midpoints, and the lengths of the corresponding diagonals are equal. These last two properties are evident in Figure 1.

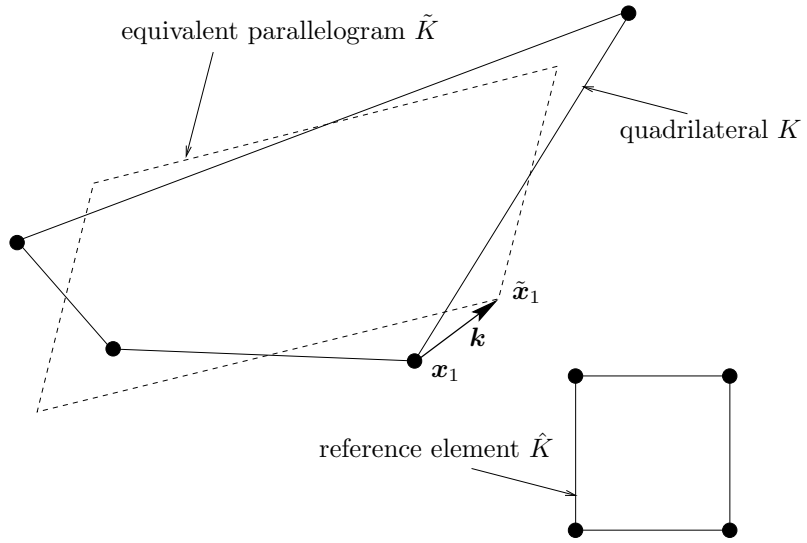

FIG. 1. *The equivalent parallelogram associated with a quadrilateral.*

It is necessary to characterize mathematically the relationship between the quadrilateral and its equivalent parallelogram; more particularly, we need to characterize the notion of closeness between K and $\tilde{K}$. Suppose that the affine map from $\hat{K}$ to $\tilde{K}$ takes the form

$$\tilde{\boldsymbol{x}} = \boldsymbol{C}\boldsymbol{\xi} + \boldsymbol{c}, \tag{20}$$

in which $\boldsymbol{C}$ and $\boldsymbol{c}$ are, respectively, a constant matrix and vector; then the *distortion parameter* τ_K for element K is defined by

$$\tau_K = |\boldsymbol{C}^{-1}\boldsymbol{k}|. \tag{21}$$

The distortion is thus measured by mapping the vector $\boldsymbol{k}$ back to the reference element $\hat{K}$, using $\boldsymbol{C}^{-1}$. From Figure 1 and the definition of $\boldsymbol{k}$ it is clear that $\boldsymbol{k} = \boldsymbol{0}$, and $\tau_K = 0$, if and only if K is a parallelogram.

The distortion parameter associated with a finite element mesh may now be defined by

$$\tau = \max_{K \in \mathcal{T}} |\tau_K|. \tag{22}$$

We will also require the notion of an *h-regular mesh*, which is defined to be a finite element mesh for which $\tau = O(h)$.

The role played by τ_K in characterizing the difference between K and $\tilde{K}$ may be seen more clearly by examining the properties of the map $G : \tilde{K} \to K$ from the parallelogram to the quadrilateral. If we set $\boldsymbol{J}' = DG$ and $j' = \det \boldsymbol{J}'$, then since

$$\boldsymbol{x} = G(\tilde{\boldsymbol{x}}) = \tilde{\boldsymbol{x}} + \boldsymbol{k}\xi\eta,$$

it is straightforward to show, also using (20), that

$$\boldsymbol{J}' = \boldsymbol{I} + \boldsymbol{C}^{-1}\boldsymbol{k} \otimes \boldsymbol{l}$$

and

$$j' = 1 + \boldsymbol{C}^{-1}\boldsymbol{k} \cdot \boldsymbol{l},$$

in which $\boldsymbol{l} = (\eta, \xi)$. It follows from (21) that

$$\sup_{\boldsymbol{x} \in K} |j'(\boldsymbol{x})| := \|j'\|_\infty \leq 1 + \sqrt{2}\,\tau_K. \tag{23}$$

If $|\boldsymbol{A}| = (\sum_{i,j=1}^{2} A_{ij}A_{ij})^{1/2}$ for any matrix $\boldsymbol{A}$, then

$$\begin{aligned} |\boldsymbol{J}'| &\leq |\boldsymbol{I}| + |\boldsymbol{C}^{-1}\boldsymbol{k} \otimes \boldsymbol{l}| \\ &\leq |\boldsymbol{I}| + |\boldsymbol{C}^{-1}\boldsymbol{k}|\,|\boldsymbol{l}| \\ &\leq \sqrt{2}\,(1 + \tau_K). \end{aligned} \tag{24}$$

The inverse of the map $\boldsymbol{J}'$ is given by

$$(\boldsymbol{J}')^{-1} = \boldsymbol{I} - \boldsymbol{R}, \tag{25}$$

in which

$$\boldsymbol{R} = \frac{\boldsymbol{C}^{-1}\boldsymbol{k} \otimes \boldsymbol{l}}{1 + \boldsymbol{C}^{-1}\boldsymbol{k} \cdot \boldsymbol{l}}. \tag{26}$$

It follows from (21) that

$$|\boldsymbol{R}| \leq \frac{|\boldsymbol{C}^{-1}\boldsymbol{k}|\,|\boldsymbol{l}|}{|1 + \boldsymbol{C}^{-1}\boldsymbol{k} \cdot \boldsymbol{l}|} \leq \frac{\sqrt{2}\tau_K}{1 - \sqrt{2}\tau_K}. \tag{27}$$

Likewise, using the identity

$$\det(\boldsymbol{I} + \boldsymbol{B}) = 1 + \det \boldsymbol{B}(1 + \operatorname{tr} \boldsymbol{B}^{-1}) + \operatorname{tr} \boldsymbol{B}$$

and (25) and (26), we find that

$$\begin{aligned} (j')^{-1} &= \det((\boldsymbol{J}')^{-1}) \\ &= 1 - \frac{\boldsymbol{C}^{-1}\boldsymbol{k} \cdot \boldsymbol{l}}{1 + \boldsymbol{C}^{-1}\boldsymbol{k} \cdot \boldsymbol{l}} \\ &\leq \frac{1}{1 - \sqrt{2}\tau_K} \end{aligned}$$

so that

$$\|(j')^{-1}\|_\infty \leq \frac{1}{1 - \sqrt{2}\tau_K}. \tag{28}$$

Thus, roughly, it is seen that the Jacobians of $\tilde{K}$ and K differ by a term that is $O(\tau_K)$.

Finally, a transformation similar to that in (17) may be obtained by defining on $\tilde{K}$ a coordinate system $\tilde{\boldsymbol{x}} = (\tilde{x}, \tilde{y})$ and by defining the gradient $\tilde{\nabla}$ and strain $\tilde{\boldsymbol{\epsilon}}$ relative to this coordinate system by

$$(\tilde{\nabla}\tilde{\boldsymbol{v}})_{ij} = \frac{\partial \tilde{v}_i}{\partial \tilde{x}_j}, \quad \tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}) = \frac{1}{2}(\tilde{\nabla}\tilde{\boldsymbol{v}} + [\tilde{\nabla}\tilde{\boldsymbol{v}}]^T). \tag{29}$$

For convenience we set

$$\tilde{\boldsymbol{L}}(\tilde{\boldsymbol{v}}) = \tilde{\nabla}\tilde{\boldsymbol{v}};$$

then we have

$$\tilde{\boldsymbol{L}}(\tilde{\boldsymbol{v}}) = \boldsymbol{L}(\boldsymbol{v})\tilde{\boldsymbol{J}}. \tag{30}$$

4. Affine finite element approximations. Since the equivalent parallelogram associated with a quadrilateral is "close" to that quadrilateral, it is natural to enquire whether approximate solutions to Problem S of the desired degree of accuracy might be obtained if Problem S^{h} were modified by replacing the integral in (18) with an integral over $\tilde{K}$ for each element K in the mesh. Such a procedure would have the advantage that, since the map from K to $\tilde{K}$ is affine, the associated Jacobian matrix and determinant are constant, and the integrals can be evaluated exactly, for homogeneous materials at least, for which case $\mathbb{C}$ is constant.

We now show that such a procedure does in fact lead to finite element approximations that converge at the usual rate. Numerical results presented by Küssner and Reddy [9] in the case of linear elasticity and by Reese and coworkers [12, 13] for problems involving nonlinear elasticity and finite deformations show in addition that, when this concept is applied to enhanced assumed strain formulations, the results represent in many cases an improvement over those obtained by the conventional approach.

From (25), (29), and (30), we have

$$\begin{aligned}\boldsymbol{\epsilon}(\boldsymbol{v}) &= \tfrac{1}{2}(\boldsymbol{L}(\boldsymbol{v}) + \boldsymbol{L}^T(\boldsymbol{v})) \\ &= \tfrac{1}{2}(\tilde{\boldsymbol{L}}(\boldsymbol{J}')^{-1} + (\boldsymbol{J}')^{-T}\tilde{\boldsymbol{L}}^T) \\ &= \tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}) - \Delta(\tilde{\boldsymbol{v}}),\end{aligned} \tag{31}$$

in which

$$\Delta(\tilde{\boldsymbol{v}}) := \tfrac{1}{2}[\tilde{\boldsymbol{L}}\boldsymbol{R} + \boldsymbol{R}^T\tilde{\boldsymbol{L}}^T], \tag{32}$$

and $\boldsymbol{R}$ is defined by (26).

Next, for continuous functions $\tilde{\boldsymbol{u}}$ and $\tilde{\boldsymbol{v}}$ on $\tilde{K}$ we define the bilinear form $a_{\tilde{K}}(\cdot,\cdot)$ and linear functional $\ell_{\tilde{K}}(\cdot)$ by

$$a_{\tilde{K}}(\tilde{\boldsymbol{u}},\tilde{\boldsymbol{v}}) = \int_{\tilde{K}} \tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{u}})] : \tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}})\; d\tilde{x}d\tilde{y}, \quad \ell_{\tilde{K}}(\tilde{\boldsymbol{v}}) = \int_{\tilde{K}} \boldsymbol{b}\cdot\tilde{\boldsymbol{v}}\; d\tilde{x}d\tilde{y}. \tag{33}$$

Here, and henceforth, $\tilde{\mathbb{C}}(\tilde{\boldsymbol{x}}) := \mathbb{C}(G(\tilde{\boldsymbol{x}}))$, and we write $d\tilde{x}d\tilde{y}$ for dx_1dx_2 for convenience. Likewise, for functions $\boldsymbol{u}$, $\boldsymbol{v} \in V$ we set

$$\tilde{a}(\boldsymbol{u},\boldsymbol{v}) = \sum_{K\in\mathcal{T}} a_{\tilde{K}}(\tilde{\boldsymbol{u}},\tilde{\boldsymbol{v}}), \quad \tilde{\ell}(\boldsymbol{v}) = \sum_{K\in\mathcal{T}} \ell_{\tilde{K}}(\tilde{\boldsymbol{v}}), \tag{34}$$

where it is to be understood that $\tilde{\boldsymbol{u}}$ and $\tilde{\boldsymbol{v}}$ are the maps to $\tilde{K}$ of the restrictions $\boldsymbol{u}|_K$ and $\boldsymbol{v}|_K$. In particular, in what follows, for any function $\boldsymbol{v}_h \in V^h$ we set

$$\tilde{\boldsymbol{v}}_h := \boldsymbol{v}_h|_K \circ G^{-1}.$$

We are now in a position to define the affine-approximate problem.

Problem $\tilde{\mathrm{S}}^{\mathrm{h}}$. Given $\boldsymbol{b} \in V'$, find $\boldsymbol{w}_h \in V^h$ which satisfies

$$\tilde{a}(\boldsymbol{w}_h,\boldsymbol{v}_h) = \tilde{\ell}(\boldsymbol{v}_h) \tag{35}$$

for all $\boldsymbol{v}_h \in V^h$.

Remark. It is important to note that Problem $\tilde{\mathrm{S}}^{\mathrm{h}}$ is defined not by *transforming* the integrals in (18) onto $\tilde{K}$ but rather by *replacing* the integrals over K with those over $\tilde{K}$. Thus the relevant functions are mapped from K to $\tilde{K}$, after which the appropriate gradients are evaluated on $\tilde{K}$. So, for example, the integrals in the definitions of $a_{\tilde{K}}$ and $\ell_{\tilde{K}}$ contain no Jacobian determinants.

LEMMA 1. *The bilinear form $\tilde{a}$ is V^h-elliptic; that is, there exists a constant $\tilde{\alpha} > 0$, independent of τ, such that*

$$\tilde{a}(\boldsymbol{v}_h, \boldsymbol{v}_h) \geq \tilde{\alpha}(1 + \tau + \tau^2)\|\boldsymbol{v}_h\|_V^2 \quad \text{for all } \boldsymbol{v}_h \in V^h, \tag{36}$$

where τ is defined by (22).

Proof. From the V^h-ellipticity of $a(\cdot,\cdot)$ we have

$$\alpha \|\boldsymbol{v}_h\|_V^2 \leq a(\boldsymbol{v}_h, \boldsymbol{v}_h) = \sum_{K \in \mathcal{T}} a_K(\boldsymbol{v}_h, \boldsymbol{v}_h), \tag{37}$$

where $a_K(\cdot,\cdot)$ is given by

$$a_K(\boldsymbol{u}, \boldsymbol{v}) := \int_K \mathbb{C}[\boldsymbol{\epsilon}(\boldsymbol{u})] : \boldsymbol{\epsilon}(\boldsymbol{v})\, dxdy. \tag{38}$$

Using (31) we have

$$a_K(\boldsymbol{v}_h, \boldsymbol{v}_h) = \int_{\tilde{K}} \tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h) - \Delta(\tilde{\boldsymbol{v}}_h)] : (\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h) - \Delta(\tilde{\boldsymbol{v}}_h))\, j'\, d\tilde{x}d\tilde{y}. \tag{39}$$

We now examine each of the terms on the right-hand side of (39) in turn.

We set

$$(\boldsymbol{E}, \boldsymbol{F})_{\mathbb{C},\tilde{K}} := \int_{\tilde{K}} \tilde{\mathbb{C}}[\boldsymbol{E}] : \boldsymbol{F}\, d\tilde{x}d\tilde{y}$$

for any $\boldsymbol{E}$, $\boldsymbol{F} \in \mathbb{L}^2(\tilde{K})$, and we note that this is an inner product on $\mathbb{L}^2(\tilde{K})$, equivalent to the standard inner product, as a result of the properties (6) and (7) of $\mathbb{C}$. We will also make use of the symmetry property $\mathbb{C}[\boldsymbol{E}] : \boldsymbol{F} = \mathbb{C}[\boldsymbol{F}] : \boldsymbol{E}$, which follows from (5).

Now, setting $\tilde{\boldsymbol{L}}\boldsymbol{R} := \boldsymbol{A}$ in the definition (32) of Δ, consider the expression

$$\begin{aligned}
\text{(I)} &:= \int_{\tilde{K}} \tilde{\mathbb{C}}[\Delta] : \Delta\, j'\, d\tilde{x}d\tilde{y} \\
&\leq \|j'\|_\infty (\Delta, \Delta)_{\mathbb{C},\tilde{K}} \\
&= \tfrac{1}{4}\|j'\|_\infty (\boldsymbol{A} + \boldsymbol{A}^T, \boldsymbol{A} + \boldsymbol{A}^T)_{\mathbb{C},\tilde{K}} \\
&= \tfrac{1}{2}\|j'\|_\infty \left(\|\boldsymbol{A}\|_{\mathbb{C},\tilde{K}}^2 + (\boldsymbol{A}, \boldsymbol{A}^T)_{\mathbb{C},\tilde{K}} \right) \\
&\leq \|j'\|_\infty \|\boldsymbol{A}\|_{\mathbb{C},\tilde{K}}^2. \qquad (40)
\end{aligned}$$

Next, from the definition of $\boldsymbol{A}$ we have

$$\|\boldsymbol{A}\|_{\mathbb{C},\tilde{K}} \leq \|\tilde{\boldsymbol{L}}\|_{\mathbb{C},\tilde{K}} \|\boldsymbol{R}\|_{\mathbb{C},\tilde{K}}. \tag{41}$$

Furthermore, we have, using the definition of the norm $\|\cdot\|_{\mathbb{C},\tilde{K}}$, (8), and (27),

$$\begin{aligned}\|\boldsymbol{R}\|^2_{\mathbb{C},\tilde{K}} &\le c_\infty \mu_K \max_{\tilde{\boldsymbol{x}}\in\tilde{K}} |\boldsymbol{R}|^2(\tilde{\boldsymbol{x}}) \\ &\le \frac{2c_\infty \mu_K \tau_K^2}{(1-\sqrt{2}\,\tau_K)^2}, \end{aligned} \tag{42}$$

in which μ_K is the area of K (and of $\tilde{K}$).

We also have

$$\begin{aligned}\|\tilde{\boldsymbol{L}}\|^2_{\mathbb{C},\tilde{K}} &= \int_{\tilde{K}} \tilde{\mathbb{C}}[\tilde{\boldsymbol{L}}] : \tilde{\boldsymbol{L}}\; d\tilde{x}d\tilde{y} \\ &= \int_{\tilde{K}} \tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}] : \tilde{\boldsymbol{\epsilon}}\; d\tilde{x}d\tilde{y} \\ &= a_{\tilde{K}}(\tilde{\boldsymbol{v}}_h, \tilde{\boldsymbol{v}}_h). \end{aligned} \tag{43}$$

From (41)–(43), it follows that

$$\text{(I)} \le c_K^2\, a_{\tilde{K}}(\tilde{\boldsymbol{v}}_h, \tilde{\boldsymbol{v}}_h), \tag{44}$$

where the constant c_K is defined by

$$c_K = \tau_K(1-\sqrt{2}\,\tau_K)^{-1}\sqrt{2c_\infty\mu_K(1+\sqrt{2}\,\tau_K)}. \tag{45}$$

Next, consider the expression

$$\begin{aligned}\text{(II)} &:= \int_{\tilde{K}} \tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h)] : \tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h) j'\; d\tilde{x}d\tilde{y} \\ &\le (1+\sqrt{2}\,\tau_K)\int_{\tilde{K}} \tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}] : \tilde{\boldsymbol{\epsilon}}\; d\tilde{x}d\tilde{y} \\ &= (1+\sqrt{2}\,\tau_K) a_{\tilde{K}}(\tilde{\boldsymbol{v}}_h, \tilde{\boldsymbol{v}}_h), \end{aligned} \tag{46}$$

where we have used the positivity of the integrand and (23).

Finally, consider the term

$$\begin{aligned}\text{(III)} &:= -\int_{\tilde{K}} \left[\tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h)] : \Delta(\tilde{\boldsymbol{v}}_h) + \tilde{\mathbb{C}}[\Delta(\tilde{\boldsymbol{v}}_h)] : \tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h)\right] j'\; d\tilde{x}d\tilde{y} \\ &= -2\int_{\tilde{K}} \tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h)] : \Delta(\tilde{\boldsymbol{v}}_h) j'\; d\tilde{x}d\tilde{y} \\ &= -2(j'\tilde{\boldsymbol{\epsilon}}, \Delta)_{\mathbb{C},\tilde{K}} \\ &\le 2\|j'\|_\infty \left|(\tilde{\boldsymbol{\epsilon}}, \Delta)_{\mathbb{C},\tilde{K}}\right| \\ &= 2\|j'\|_\infty \left|(\tilde{\boldsymbol{\epsilon}}, \boldsymbol{A})_{\mathbb{C},\tilde{K}}\right| \\ &\le 2\|j'\|_\infty \|\tilde{\boldsymbol{\epsilon}}\|_{\mathbb{C},\tilde{K}} \|\boldsymbol{A}\|_{\mathbb{C},\tilde{K}}, \end{aligned}$$

where we have used the representation $\Delta = \frac{1}{2}(\boldsymbol{A} + \boldsymbol{A}^T)$ and the Cauchy–Schwarz inequality. Now we know that $\|\tilde{\boldsymbol{\epsilon}}\|_{\mathbb{C},\tilde{K}} = \sqrt{a_{\tilde{K}}(\tilde{\boldsymbol{v}}_h, \tilde{\boldsymbol{v}}_h)}$ and, from (41)–(43),

$$\|\boldsymbol{A}\|^2_{\mathbb{C},\tilde{K}} \le c_K^2(1+\sqrt{2}\,\tau_K)^{-1} a_{\tilde{K}}(\tilde{\boldsymbol{v}}_h, \tilde{\boldsymbol{v}}_h).$$

So we have

$$\text{(III)} \le 2c_K\sqrt{1+\sqrt{2}\,\tau_K}\,a_{\tilde{K}}(\tilde{\boldsymbol{v}}_h,\tilde{\boldsymbol{v}}_h). \tag{47}$$

Expanding (39) and substituting the estimates for (I), (II), and (III), we have

$$\begin{aligned}\alpha\|\boldsymbol{v}_h\|_V^2 \le a(\boldsymbol{v}_h,\boldsymbol{v}_h) &= \sum_{K\in\mathcal{T}} a_K(\boldsymbol{v}_h,\boldsymbol{v}_h)\\ &\le \sum_{K\in\mathcal{T}} \text{(I)}+\text{(II)}+\text{(III)}\\ &\le \sum_{K\in\mathcal{T}}\left[c_K+\sqrt{1+\sqrt{2}\,\tau_K}\right]^2 a_{\tilde{K}}(\tilde{\boldsymbol{v}}_h,\tilde{\boldsymbol{v}}_h)\\ &\le \gamma\,\tilde{a}(\boldsymbol{v}_h,\boldsymbol{v}_h),\end{aligned}$$

where the constant γ is given by

$$\gamma = [1+\sqrt{2c_\infty}\,(1-\sqrt{2}\,\tau_K)^{-1}h\tau]^2(1+\sqrt{2}\,\tau).$$

It follows that $\tilde{a}(\cdot,\cdot)$ is V^h-elliptic. □

Since $\tilde{a}$ and $\tilde{\ell}$ are clearly continuous, it follows therefore that Problem $\tilde{\mathrm{S}}^h$ has a unique solution $\boldsymbol{w}_h$.

Remark. The consistency and convergence of the solution to Problem S^{h} depends in a fundamental way on the following lemma, which is analogous to the first Strang lemma (see [7, Theorem 4.4.1]) associated with errors induced by numerical quadrature in finite element approximations.

LEMMA 2. *There exists a positive constant C, independent of h, such that*

$$\begin{aligned}\|\boldsymbol{u}-\boldsymbol{w}_h\|_V \le C\Bigg(&\inf_{\boldsymbol{v}_h\in V^h}\left\{\|\boldsymbol{u}-\boldsymbol{v}_h\|_V+\sup_{\boldsymbol{z}_h\in V^h}\frac{|a(\boldsymbol{v}_h,\boldsymbol{z}_h)-\tilde{a}(\boldsymbol{v}_h,\boldsymbol{z}_h)|}{\|\boldsymbol{z}_h\|_V}\right\}\\ &+\sup_{\boldsymbol{z}_h\in V^h}\frac{|\ell(\boldsymbol{z}_h)-\tilde{\ell}(\boldsymbol{z}_h)|}{\|\boldsymbol{z}_h\|_V}\Bigg).\end{aligned} \tag{48}$$

Proof. The proof follows that of the Strang lemma very closely, and we therefore merely sketch the details. Using the V^h-ellipticity of $\tilde{a}$, we have

$$\begin{aligned}\tilde{\alpha}\|\boldsymbol{w}_h-\boldsymbol{v}_h\|_V^2 &\le \tilde{a}(\boldsymbol{w}_h-\boldsymbol{v}_h,\boldsymbol{w}_h-\boldsymbol{v}_h)\\ &= a(\boldsymbol{u}-\boldsymbol{v}_h,\boldsymbol{w}_h-\boldsymbol{v}_h)+[a(\boldsymbol{v}_h,\boldsymbol{w}_h-\boldsymbol{v}_h)-\tilde{a}(\boldsymbol{v}_h,\boldsymbol{w}_h-\boldsymbol{v}_h)]\\ &\quad+[\tilde{\ell}(\boldsymbol{w}_h-\boldsymbol{v}_h)-\ell(\boldsymbol{w}_h-\boldsymbol{v}_h)].\end{aligned} \tag{49}$$

Here we have used (11) and (35). Now

$$\frac{a(\boldsymbol{v}_h,\boldsymbol{w}_h-\boldsymbol{v}_h)-\tilde{a}(\boldsymbol{v}_h,\boldsymbol{w}_h-\boldsymbol{v}_h)}{\|\boldsymbol{w}_h-\boldsymbol{v}_h\|_V} \le \sup_{\boldsymbol{z}_h\in V^h}\frac{|a(\boldsymbol{v}_h,\boldsymbol{z}_h)-\tilde{a}(\boldsymbol{v}_h,\boldsymbol{z}_h)|}{\|\boldsymbol{z}_h\|_V}, \tag{50}$$

and a similar inequality exists for $\ell-\tilde{\ell}$. The triangle inequality gives

$$\|\boldsymbol{u}-\boldsymbol{w}_h\|_V \le \|\boldsymbol{u}-\boldsymbol{v}_h\|_V+\|\boldsymbol{w}_h-\boldsymbol{v}_h\|_V. \tag{51}$$

We divide throughout in (49) by $\|\boldsymbol{w}_h-\boldsymbol{v}_h\|_V$ and make use of the continuity of a in the first term on the right-hand side of (49); next, we use (50) and the corresponding expression for $|\ell-\tilde{\ell}|$ and take the supremum of the terms in square brackets in

(49). Finally, (48) is obtained by using (51) and by taking the infimum over all $\boldsymbol{v}_h \in V^h$. ∎

Next, we address the task of estimating the expression

$$\sup_{\boldsymbol{z}_h \in V^h} \frac{|a(\boldsymbol{v}_h, \boldsymbol{z}_h) - \tilde{a}(\boldsymbol{v}_h, \boldsymbol{z}_h)|}{\|\boldsymbol{z}_h\|_V}.$$

From (33) and (39) we have

$$\begin{aligned}
&a_K(\boldsymbol{v}_h, \boldsymbol{z}_h) - a_{\tilde{K}}(\tilde{\boldsymbol{v}}_h, \tilde{\boldsymbol{z}}_h) \\
&\quad = \int_K \mathbb{C}[\boldsymbol{\epsilon}(\boldsymbol{v}_h)] : \boldsymbol{\epsilon}(\boldsymbol{z}_h)\, dxdy - \int_{\tilde{K}} \tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h)] : \tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{z}}_h)\, d\tilde{x}d\tilde{y} \\
&\quad = \int_{\tilde{K}} \tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h)] : \tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{z}}_h) j'\, d\tilde{x}d\tilde{y} - \int_{\tilde{K}} \tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h)] : \Delta(\tilde{\boldsymbol{z}}_h)\, j'\, d\tilde{x}d\tilde{y} \\
&\qquad - \int_{\tilde{K}} \tilde{\mathbb{C}}[\Delta(\tilde{\boldsymbol{v}}_h)] : \tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{z}}_h)\, j'\, d\tilde{x}d\tilde{y} + \int_{\tilde{K}} \tilde{\mathbb{C}}[\Delta(\tilde{\boldsymbol{v}}_h)] : \Delta(\tilde{\boldsymbol{z}}_h)\, j'\, d\tilde{x}d\tilde{y} \\
&\qquad - \int_{\tilde{K}} \tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h)] : \tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{z}}_h)\, d\tilde{x}d\tilde{y} \\
&\quad = \int_{\tilde{K}} \tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h)] : \tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{z}}_h)(j'-1)\, d\tilde{x}d\tilde{y} - \int_{\tilde{K}} \tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h)] : \Delta(\tilde{\boldsymbol{z}}_h) j'\, d\tilde{x}d\tilde{y} \\
&\qquad - \int_{\tilde{K}} \tilde{\mathbb{C}}[\Delta(\tilde{\boldsymbol{v}}_h)] : \tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{z}}_h) j'\, d\tilde{x}d\tilde{y} + \int_{\tilde{K}} \tilde{\mathbb{C}}[\Delta(\tilde{\boldsymbol{v}}_h)] : \Delta(\tilde{\boldsymbol{z}}_h) j'\, d\tilde{x}d\tilde{y} \\
&\quad \le \sqrt{2}\,\tau_K\, a_{\tilde{K}}(\tilde{\boldsymbol{v}}_h, \tilde{\boldsymbol{z}}_h) + \sqrt{a_{\tilde{K}}(\tilde{\boldsymbol{v}}_h, \tilde{\boldsymbol{v}}_h) a_{\tilde{K}}(\tilde{\boldsymbol{z}}_h, \tilde{\boldsymbol{z}}_h)} \left[c_K^2 + 2c_K \sqrt{1 + \sqrt{2}\,\tau_K} \right]. \qquad (52)
\end{aligned}$$

Here we have used the estimates leading to (44) and (47).

Now

$$a_{\tilde{K}}(\tilde{\boldsymbol{v}}_h, \tilde{\boldsymbol{z}}_h) \le M_{\tilde{K}}\, \|\tilde{\boldsymbol{v}}_h\|_{H^1(\tilde{K})} \|\tilde{\boldsymbol{z}}_h\|_{H^1(\tilde{K})}$$

for some positive constant $M_{\tilde{K}}$, independent of h_K and τ_K, and, using (24), (28), and (30), we have

$$\begin{aligned}
\|\tilde{\boldsymbol{v}}_h\|^2_{H^1(\tilde{K})} &= \int_{\tilde{K}} \left(|\tilde{\boldsymbol{v}}_h|^2 + |\tilde{\nabla} \tilde{\boldsymbol{v}}_h|^2 \right) d\tilde{x}d\tilde{y} \\
&= \int_K [|\boldsymbol{v}_h|^2 + |(\nabla \boldsymbol{v}_h)\boldsymbol{J}'|^2](j')^{-1}\, dxdy \\
&\le C_K \|\boldsymbol{v}_h\|^2_{H^1(K)},
\end{aligned}$$

where $C_K = 2(1+\tau_K)^2(1-\sqrt{2}\,\tau_K)^{-1}$.

Hence

$$\begin{aligned}
&\frac{|a(\boldsymbol{v}_h, \boldsymbol{z}_h) - \tilde{a}(\boldsymbol{v}_h, \boldsymbol{z}_h)|}{\|\boldsymbol{z}_h\|_V} \\
&\le \frac{\sum_{K \in \mathcal{T}} M_{\tilde{K}} C_K \left[\left(c_K + \sqrt{1 + \sqrt{2}\,\tau_K} \right)^2 - 1 \right] \|\boldsymbol{v}_h\|_{H^1(K)} \|\boldsymbol{z}_h\|_{H^1(K)}}{\|\boldsymbol{z}_h\|_V} \\
&\le C\tau \frac{\sum_{K \in \mathcal{T}} \|\boldsymbol{v}_h\|_{H^1(K)} \|\boldsymbol{z}_h\|_{H^1(K)}}{\|\boldsymbol{z}_h\|_V} \\
&\le C\tau \|\boldsymbol{v}_h\|_V, \qquad (53)
\end{aligned}$$

where the constant C is independent of h and τ.

Choosing $\boldsymbol{v}_h = \Pi_h \boldsymbol{u}$, where Π_h is the interpolation operator onto V^h, and noting that $\|\Pi_h \boldsymbol{u}\|_V \leq \|\boldsymbol{u}\|_V + \|\boldsymbol{u} - \Pi_h \boldsymbol{u}\|_V \leq ch|\boldsymbol{u}|_{H^2} + \|\boldsymbol{u}\|_V$, we finally obtain

$$\inf_{\boldsymbol{v}_h \in V^h} \sup_{\boldsymbol{z}_h \in V^h} \frac{|a(\boldsymbol{v}_h, \boldsymbol{z}_h) - \tilde{a}(\boldsymbol{v}_h, \boldsymbol{z}_h)|}{\|\boldsymbol{z}_h\|} \leq C\tau,$$

where the constant C depends on the geometry and on the solution $\boldsymbol{u}$. In exactly the same way we can derive the estimate

$$\inf_{\boldsymbol{v}_h \in V^h} \sup_{\boldsymbol{z}_h \in V^h} \frac{|\ell(\boldsymbol{z}_h) - \tilde{\ell}(\boldsymbol{z}_h)|}{\|\boldsymbol{z}_h\|} \leq C\tau,$$

where again C depends on the geometry and on $\boldsymbol{u}$. We therefore have the following result.

THEOREM 3. *Let $\mathcal{T}$ be an h-regular finite element mesh of quadrilaterals, with the maximum distortion of quadrilaterals being bounded in the sense that $\tau \leq ch$ for some constant c, independent of h, as $h \to 0$. Then problem $\tilde{\mathrm{S}}^h$ has a unique solution $\boldsymbol{w}_h$ which satisfies*

$$\|\boldsymbol{u} - \boldsymbol{w}_h\|_V \leq Ch,$$

the constant C depending on the geometry and the solution $\boldsymbol{u}$ to the continuous problem, but not on h.

5. The enhanced strain problem. In the context of the finite element method, the enhanced strain method refers to an approach proposed by Simo and Rifai [14], in which the discrete strain $\boldsymbol{\epsilon}_h$ takes the form

$$\boldsymbol{\epsilon}_h = \boldsymbol{\epsilon}(\boldsymbol{u}_h) + \boldsymbol{\eta}_h, \tag{54}$$

the first term on the right-hand side being evaluated as in (2), while the second term on the right-hand side is the enhanced strain, which is required to have the property $\boldsymbol{\eta}_h \to \mathbf{0}$ as $h \to 0$.

In order to formulate the problem in weak form it is necessary to add to the spaces already defined the space Γ^h of enhanced strains, which is defined by

$$\Gamma^h := \left\{ \boldsymbol{\gamma} = (\gamma_{ij}) : \ \gamma_{ij} \in L^2(\Omega), \ \gamma_{ji} = \gamma_{ij}, \ \int_K \mathbb{C}\boldsymbol{\gamma}|_K \, dxdy = \mathbf{0} \text{ for all } K \in \mathcal{T} \right\}. \tag{55}$$

In practice Γ^h will comprise functions of the form $\boldsymbol{\gamma} = j^{-1}\hat{\boldsymbol{\gamma}}$ on each element, in which the components of $\hat{\boldsymbol{\gamma}}$ are simple polynomials defined on the reference element $\hat{K}$. A consequence of this definition is that $\int_{\hat{K}} \mathbb{C}\hat{\boldsymbol{\gamma}} \, d\xi d\eta = \mathbf{0}$ [3]. Concrete examples of bases for Γ^h, together with applications, may be found in [14, 1].

We set $\boldsymbol{\phi}_h = (\boldsymbol{u}_h, \boldsymbol{\eta}_h)$ and $\boldsymbol{\psi}_h = (\boldsymbol{v}_h, \boldsymbol{\gamma}_h)$ for $\boldsymbol{u}_h$, $\boldsymbol{v}_h \in V^h$ and $\boldsymbol{\eta}_h$, $\boldsymbol{\gamma}_h \in \Gamma^h$. Also, we define the product space

$$\Psi^h := V^h \times \Gamma^h,$$

which is a Hilbert space with the natural norm

$$\|\boldsymbol{\psi}_h\|_\Psi := \left(\|\boldsymbol{v}_h\|_V^2 + \|\boldsymbol{\gamma}_h\|_{L^2}^2 \right)^{1/2}.$$

The bilinear form $A : \Psi^h \times \Psi^h \longrightarrow \mathbb{R}$ is defined by

$$A(\boldsymbol{\phi}_h, \boldsymbol{\psi}_h) = \int_\Omega \mathbb{C}(\boldsymbol{\epsilon}(\boldsymbol{u}_h) + \boldsymbol{\eta}_h) : (\boldsymbol{\epsilon}(\boldsymbol{v}_h) + \boldsymbol{\gamma}_h)\, dxdy, \tag{56}$$

and we recall the definition (10) of the linear functional ℓ.

The weak formulation of the problem then takes the following form [11, 14].

Problem E^{h}. Find $(\boldsymbol{u}_h, \boldsymbol{\eta}_h) \in V^h \times \Gamma^h$ such that

$$A(\boldsymbol{\phi}_h, \boldsymbol{\psi}_h) = \ell(\boldsymbol{v}_h) \quad \text{for all } \boldsymbol{\psi}_h \in \Psi^h. \tag{57}$$

We have the following result, proved in [11] for affine-equivalent meshes (see also [5]) and in [3] for isoparametric meshes and stated here for the special case in which V^h is chosen as in (15).

THEOREM 4. *Let $\mathcal{T}$ be a regular mesh of quadrilaterals on a bounded polygonal domain $\Omega \in \mathbb{R}^2$. Let the space V^h be defined by* (15) *and the space Γ^h by* (55). *Assume, in addition, that*

(a) $\boldsymbol{\epsilon}(V^h) \cap \Gamma^h = \{\boldsymbol{0}\}$,

(b) *there exists a constant c_1 with $0 < c_1 < 1$ such that, for any $\boldsymbol{\gamma}_h \in \Gamma^h$, $\|P\boldsymbol{\gamma}_h\|_\Gamma \le c_1\|\boldsymbol{\gamma}_h\|$, where P is the L^2-orthogonal projection onto $\boldsymbol{\epsilon}(V^h)$.*

Then there exists a unique solution to Problem E^{h}. *Furthermore, if $\boldsymbol{u} \in [H^2(\Omega)]^2$, then there exists a constant $C > 0$, independent of h, such that*

$$\|\boldsymbol{u} - \boldsymbol{u}_h\|_V + \|\boldsymbol{\eta}_h\|_\Gamma \le Ch|\boldsymbol{u}|_{H^2}.$$

We now consider the affine-approximate problem analogous to Problem $\tilde{\mathrm{S}}^h$.

Define

$$A_{\tilde{K}}(\tilde{\boldsymbol{\chi}}_h, \tilde{\boldsymbol{\psi}}_h) = \int_{\tilde{K}} \tilde{\mathbb{C}}(\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{w}}_h) + \tilde{\boldsymbol{\beta}}_h) : (\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h) + \tilde{\boldsymbol{\gamma}}_h)\, d\tilde{x}d\tilde{y} \tag{58}$$

and

$$\ell_{\tilde{K}}(\tilde{\boldsymbol{\psi}}_h) = \int_{\tilde{K}} \boldsymbol{b} \cdot \tilde{\boldsymbol{v}}_h\, d\tilde{x}d\tilde{y}, \tag{59}$$

where $\boldsymbol{\chi}_h = (\boldsymbol{w}_h, \boldsymbol{\beta}_h)$ and superposed tildes have the same interpretation as previously. Set

$$\tilde{A}(\boldsymbol{\chi}_h, \boldsymbol{\psi}_h) = \sum_{K \in \mathcal{T}} A_{\tilde{K}}(\tilde{\boldsymbol{\chi}}_h, \tilde{\boldsymbol{\psi}}_h) \tag{60}$$

and

$$\tilde{\ell}(\boldsymbol{\psi}_h) = \sum_{K \in \mathcal{T}} \ell_{\tilde{K}}(\tilde{\boldsymbol{\psi}}_h). \tag{61}$$

Problem $\tilde{\mathrm{E}}^{\mathrm{h}}$. Given $\boldsymbol{b} \in V'$, find $\boldsymbol{\chi}_h := (\boldsymbol{w}_h, \boldsymbol{\beta}_h) \in V^h \times \Psi^h$ which satisfy

$$\tilde{A}(\boldsymbol{\chi}_h, \boldsymbol{\psi}_h) = \tilde{\ell}(\boldsymbol{\psi}_h) \tag{62}$$

for all $\boldsymbol{\psi}_h \in \Psi^h$.

We need to show that $\tilde{A}$ is Ψ^h-elliptic. We proceed as in the case of Lemma 1, beginning with the observation that $A(\cdot,\cdot)$ is Ψ^h-elliptic (see [11]), from which it follows that

$$\begin{aligned} \alpha_A \|\boldsymbol{\psi}_h\|_\Psi^2 &\le A(\boldsymbol{\psi}_h, \boldsymbol{\psi}_h) \\ &= \sum_{K\in\mathcal{T}} A_K(\boldsymbol{\psi}_h, \boldsymbol{\psi}_h). \end{aligned} \tag{63}$$

Now we have, from the positivity of the integrand of A_K and the symmetry of $\mathbb{C}$,

$$\begin{aligned} A_K(\boldsymbol{\psi}_h, \boldsymbol{\psi}_h) &= \int_K \mathbb{C}(\boldsymbol{\epsilon}(\boldsymbol{v}_h) + \boldsymbol{\gamma}_h) : (\boldsymbol{\epsilon}(\boldsymbol{v}_h) + \boldsymbol{\gamma}_h)\ dxdy \\ &= \int_{\tilde{K}} \mathbb{C}(\boldsymbol{\epsilon}(\boldsymbol{v}_h) + \boldsymbol{\gamma}_h) : (\boldsymbol{\epsilon}(\boldsymbol{v}_h) + \boldsymbol{\gamma}_h)\ j'\, d\tilde{x}d\tilde{y} \\ &\le \|j'\|_\infty \int_{\tilde{K}} \mathbb{C}(\boldsymbol{\epsilon}(\boldsymbol{v}_h) + \boldsymbol{\gamma}_h) : (\boldsymbol{\epsilon}(\boldsymbol{v}_h) + \boldsymbol{\gamma}_h)\ d\tilde{x}d\tilde{y} \\ &= \|j'\|_\infty \int_{\tilde{K}} \tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h) - \Delta(\tilde{\boldsymbol{v}}_h) + \tilde{\boldsymbol{\gamma}}_h) : (\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h) - \Delta(\tilde{\boldsymbol{v}}_h) + \tilde{\boldsymbol{\gamma}}_h)\ d\tilde{x}d\tilde{y} \\ &= \|j'\|_\infty \Bigg[A_{\tilde{K}}(\tilde{\boldsymbol{\psi}}_h, \tilde{\boldsymbol{\psi}}_h) \underbrace{-2\int_{\tilde{K}} \tilde{\mathbb{C}}[\Delta(\tilde{\boldsymbol{v}}_h)] : [\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h) - \tfrac{1}{2}\Delta(\tilde{\boldsymbol{v}}_h) + \tilde{\boldsymbol{\gamma}}_h]\ d\tilde{x}d\tilde{y}}_{\mathcal{F}} \\ &\qquad + 2\int_{\tilde{K}} \tilde{\mathbb{C}}[\tilde{\boldsymbol{\gamma}}_h] : (\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h) + \tfrac{1}{2}\tilde{\boldsymbol{\gamma}}_h)\ d\tilde{x}d\tilde{y} \Bigg] \\ &\le \|j'\|_\infty \Big[A_{\tilde{K}}(\tilde{\boldsymbol{\psi}}_h, \tilde{\boldsymbol{\psi}}_h) + 2(\tilde{\boldsymbol{\epsilon}}, \tilde{\boldsymbol{\gamma}})_{\mathbb{C},\tilde{K}} + (\tilde{\boldsymbol{\gamma}}, \tilde{\boldsymbol{\gamma}})_{\mathbb{C},\tilde{K}} + \mathcal{F}(\tilde{\boldsymbol{v}}_h, \tilde{\boldsymbol{\gamma}}_h, \tau_K) \Big]. \end{aligned}$$

Here the term $\mathcal{F}$ is of the form $\mathcal{F} = c_K \cdot [\text{terms depending on } (\tilde{\boldsymbol{v}}_h,\ \tilde{\boldsymbol{\gamma}}_h,\ \tau_K)]$, as can be deduced by a series of manipulations similar to those carried out in (44)–(46). From the definition of $A_{\tilde{K}}$ it follows therefore that

$$A_K(\boldsymbol{\psi}_h, \boldsymbol{\psi}_h) \le (1 + \sqrt{2}\,\tau_K)[2A_{\tilde{K}}(\tilde{\boldsymbol{\psi}}_h, \tilde{\boldsymbol{\psi}}_h) + \mathcal{F}(\tilde{\boldsymbol{v}}_h, \tilde{\boldsymbol{\gamma}}_h, \tau_K)].$$

We therefore have the following result.

LEMMA 5. *The bilinear form $\tilde{A}$ is Ψ^h-elliptic for sufficiently small τ. Furthermore, Problem $\tilde{\mathrm{E}}^h$ has a unique solution $\boldsymbol{\chi}_h = (\boldsymbol{w}_h, \boldsymbol{\beta}_h)$ in Ψ^h.*

Next, we have the following counterpart to Lemma 2.

LEMMA 6. *Set $\boldsymbol{\phi} = (\boldsymbol{u}, \boldsymbol{0})$, where $\boldsymbol{u}$ is the solution to Problem* S*, and denote the solution to Problem $\tilde{\mathrm{E}}^{\mathrm{h}}$ by $\boldsymbol{\chi}_h = (\boldsymbol{w}_h, \boldsymbol{\beta}_h)$. Then there exists a constant C, independent of h, such that*

$$\|\boldsymbol{\phi} - \boldsymbol{\chi}_h\|_\Psi \le C \left[\inf_{\boldsymbol{\psi}_h \in \Psi^h} \left\{ \|\boldsymbol{\phi} - \boldsymbol{\psi}_h\|_\Psi + \sup_{\boldsymbol{\omega}_h = (\boldsymbol{z}_h, \boldsymbol{\rho}_h) \in \Psi^h} \frac{\diamond}{\|\boldsymbol{\omega}_h\|_\Psi} \right\} \right], \tag{64}$$

where $\diamond$ is given by

$$\diamond = |A(\boldsymbol{\psi}_h, \boldsymbol{\omega}_h) - \tilde{A}(\boldsymbol{\psi}_h, \boldsymbol{\omega}_h)| + |\ell(\boldsymbol{\psi}_h) - \tilde{\ell}(\boldsymbol{\psi}_h)| + \left| \int_\Omega \mathbb{C}\boldsymbol{\epsilon}(\boldsymbol{u}) : \boldsymbol{\gamma}_h\ dxdy \right|. \tag{65}$$

Proof. From the Ψ^h-ellipticity of $\tilde{A}$, we have

$$\begin{aligned}\tilde{\alpha}\|\boldsymbol{\chi}_h-\boldsymbol{\psi}_h\|_\Psi^2 &\le \tilde{A}(\boldsymbol{\chi}_h-\boldsymbol{\psi}_h,\boldsymbol{\chi}_h-\boldsymbol{\psi}_h)\\ &= A(\boldsymbol{\phi}-\boldsymbol{\psi}_h,\boldsymbol{\chi}_h-\boldsymbol{\psi}_h)+[A(\boldsymbol{\psi}_h,\boldsymbol{\chi}_h-\boldsymbol{\psi}_h)-\tilde{A}(\boldsymbol{\psi}_h,\boldsymbol{\chi}_h-\boldsymbol{\psi}_h)]\\ &\quad - A(\boldsymbol{\phi},\boldsymbol{\chi}_h-\boldsymbol{\psi}_h)+\tilde{A}(\boldsymbol{\chi}_h,\boldsymbol{\chi}_h-\boldsymbol{\psi}_h)\\ &= A(\boldsymbol{\phi}-\boldsymbol{\psi}_h,\boldsymbol{\chi}_h-\boldsymbol{\psi}_h)+[A(\boldsymbol{\psi}_h,\boldsymbol{\chi}_h-\boldsymbol{\psi}_h)-\tilde{A}(\boldsymbol{\psi}_h,\boldsymbol{\chi}_h-\boldsymbol{\psi}_h)]\\ &\quad +[\tilde{\ell}(\boldsymbol{\chi}_h-\boldsymbol{\psi}_h)-\ell(\boldsymbol{\chi}_h-\boldsymbol{\psi}_h)]+[\ell(\boldsymbol{\chi}_h-\boldsymbol{\psi}_h)-A(\boldsymbol{\phi},\boldsymbol{\chi}_h-\boldsymbol{\psi}_h)].\end{aligned}$$

The rest of the proof proceeds in much the same way as the proof of Lemma 2. ∎

Finally, the expression $\diamond$ in (64) must be estimated. We have, from (58) and (64),

$$\begin{aligned}&A_K(\boldsymbol{\psi}_h,\boldsymbol{\omega}_h)-A_{\tilde{K}}(\tilde{\boldsymbol{\psi}}_h,\tilde{\boldsymbol{\omega}}_h)\\ &= a_K(\boldsymbol{v}_h,\boldsymbol{z}_h)-a_{\tilde{K}}(\tilde{\boldsymbol{v}}_h,\tilde{\boldsymbol{z}}_h)\quad\text{(i)}\\ &\quad+\int_K(\mathbb{C}[\boldsymbol{\epsilon}(\boldsymbol{v}_h)]:\boldsymbol{\rho}_h+\mathbb{C}[\boldsymbol{\epsilon}(\boldsymbol{z}_h)]:\boldsymbol{\gamma}_h)\,dxdy\\ &\quad-\int_{\tilde{K}}(\tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h)]:\tilde{\boldsymbol{\rho}}_h-\tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{z}}_h)]:\tilde{\boldsymbol{\gamma}}_h)\,d\tilde{x}d\tilde{y}\quad\text{(ii)}\\ &\quad+\int_K\mathbb{C}[\boldsymbol{\gamma}_h]:\boldsymbol{\rho}_h\,dxdy-\int_{\tilde{K}}\tilde{\mathbb{C}}[\tilde{\boldsymbol{\gamma}}_h]:\tilde{\boldsymbol{\rho}}_h\,d\tilde{x}d\tilde{y}.\quad\text{(iii)}\end{aligned}\tag{66}$$

We now examine the expressions (i)–(iii) in (66) in turn. First, we see that (i) is estimated in (52). Next, we have

$$\begin{aligned}\text{(ii)} &\le \int_{\tilde{K}}(j'-1)\tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h)]:\tilde{\boldsymbol{\rho}}_h\,d\tilde{x}d\tilde{y}+\int_{\tilde{K}}(j'-1)\tilde{\mathbb{C}}[\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{z}}_h)]:\tilde{\boldsymbol{\gamma}}_h\,d\tilde{x}d\tilde{y}\\ &\quad-\int_{\tilde{K}}\tilde{\mathbb{C}}[\Delta(\tilde{\boldsymbol{v}}_h)]:\tilde{\boldsymbol{\rho}}_h\,\tilde{j}\,d\tilde{x}d\tilde{y}-\int_{\tilde{K}}\tilde{\mathbb{C}}[\Delta(\tilde{\boldsymbol{z}}_h)]:\tilde{\boldsymbol{\gamma}}_h\,\tilde{j}\,d\tilde{x}d\tilde{y}\\ &\le \left[\sqrt{2}\tau_K+\sqrt{1+\sqrt{2}\tau_K}\,c_K\right]\left\{\|\tilde{\boldsymbol{\rho}}_h\|_{\mathbb{C},\tilde{K}}\|\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{v}}_h)\|_{\mathbb{C},\tilde{K}}+\|\tilde{\boldsymbol{\gamma}}_h\|_{\mathbb{C},\tilde{K}}\|\tilde{\boldsymbol{\epsilon}}(\tilde{\boldsymbol{z}}_h)\|_{\mathbb{C},\tilde{K}}\right\}.\end{aligned}\tag{67}$$

Here we have used (23) and the manipulations leading to (44). Finally,

$$\text{(iii)}\le\sqrt{2}\tau_K\|\tilde{\boldsymbol{\rho}}_h\|_{\mathbb{C},\tilde{K}}\|\tilde{\boldsymbol{\gamma}}_h\|_{\mathbb{C},\tilde{K}}.\tag{68}$$

It is not difficult to see, from the arguments leading to (53) and from (67) and (68), that

$$\sup_{\boldsymbol{\omega}_h\in\Psi^h}\frac{A(\boldsymbol{\psi}_h,\boldsymbol{\omega}_h)-\tilde{A}(\tilde{\boldsymbol{\psi}}_h,\tilde{\boldsymbol{\omega}}_h)}{\|\boldsymbol{\omega}_h\|_\Psi}\le C\tau,\tag{69}$$

in which the constant C depends on the geometry and on the solution $\boldsymbol{u}$ but not on h nor on τ. In the same way, one may derive an estimate of the form (69) for the second term in the definition (65) of $\diamond$.

Finally, the last term on the right-hand side of (65) is shown in [11] to be bounded, up to a constant, by $h|\boldsymbol{u}|_1$.

THEOREM 7. *Let $\mathcal{T}$ be an h-regular finite element mesh of quadrilaterals, with the maximum distortion of quadrilaterals being bounded in the sense that $\tau\le ch$ for*

some constant c, independent of h, as $h \to 0$. Let $\boldsymbol{\phi} = (\boldsymbol{u}, \mathbf{0}) \in \Psi$, where $\boldsymbol{u}$ is the solution to Problem S. *Then Problem* $\tilde{\mathrm{E}}^{\mathrm{h}}$ *has a unique solution $\boldsymbol{\chi}_h$ which satisfies*

$$\|\boldsymbol{\phi} - \boldsymbol{\chi}_h\|_\Psi \leq Ch,$$

the constant C depending on the geometry, on the material tensor $\mathbb{C}$, and on $\boldsymbol{u}$, but not on h.

Remark. The analysis presented here has been carried out for the case of compressible materials, for which the components of $\mathbb{C}$ are bounded. A modified approach, such as that presented in [11, section 5] or in [6], is required for the limiting cases of incompressibility or near incompressibility. Such an analysis would combine the approaches presented here and in those works.

ERROR ANALYSIS OF A FINITE ELEMENT–INTEGRAL EQUATION SCHEME FOR APPROXIMATING THE TIME-HARMONIC MAXWELL SYSTEM*

G. C. HSIAO†, P. B. MONK†, AND N. NIGAM‡

Abstract. In 1996 Hazard and Lenoir suggested a variational formulation of Maxwell's equations using an overlapping integral equation and volume representation of the solution [*SIAM J. Math. Anal.,* 27 (1996), pp. 1597–1630]. They suggested a numerical scheme based on this approach, but no error analysis was provided. In this paper, we provide a convergence analysis of an edge finite element scheme for the method. The analysis uses the theory of collectively compact operators. Its novelty is that a perturbation argument is needed to obtain error estimates for the solution of the discrete problem that is best suited for implementation.

Key words. Maxwell system, edge finite element, integral representation, error estimate

1. Introduction.

A key feature of scattering problems is that they are typically posed as exterior boundary value problems. When using finite element methods to compute approximate solutions to these problems, the truncation of the computational domain needs to be done carefully. The truncated problem should be chosen to provide a convenient and accurate approximation of the true problem. In [25], Hazard and Lenoir proposed a new variational approach to the time-harmonic scattering problem for Maxwell's equations that can be used as the basis of a finite element method. This was extended to layered media in [19]. Hazard and Lenoir suggested the use of standard continuous finite elements, which are known to require special care if the scatterer has corners [4, 17, 21]. In this paper, we propose the use of edge elements [31, 32] to approximate the problem. A direct application of this approach leads to unwieldy matrices. Thus we apply flux-recovery procedures [35, 5, 6, 7] in the discretization of the Hazard–Lenoir method resulting in a fully discrete problem that is better suited to implementation. We then provide the first error analysis of the discrete Hazard–Lenoir scheme for Maxwell's equations (see [18] for convergence studies of the method applied to the time-harmonic Helmholtz problem).

For simplicity we will not describe the general scattering problem discussed in [19]. Instead, we shall confine ourselves to time-harmonic scattering from a bounded perfect conductor. The finite element scheme applies in the more general case, but some estimates in the analysis still need to be performed. The plan for the paper is as follows. In the next subsection we describe the continuous problem and introduce a

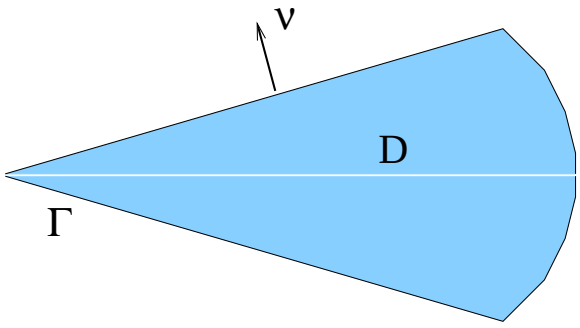

FIG. 1.1. *The perfectly conducting scatterer, D.*

truncated boundary value problem based on an integral representation of the scattered field. In section 2 we describe the finite elements to be used, and in section 3 we provide an error analysis of the method without discretizing the integral operator. In section 4 we provide an analysis of the fully discrete scheme and discuss briefly the solution of the discrete problem, and we draw some conclusions in section 5.

1.1. Problem description. We consider a perfectly conducting scatterer, which occupies a bounded, Lipschitz, polyhedral region D in $\mathbb{R}^3$. We assume that the boundary of the scatterer, Γ, is connected and we denote by $\boldsymbol{\nu}$ the unit outward normal (see Figure 1.1). For simplicity we shall also assume that both D and $\mathbb{R}^3 \setminus \bar{D}$ are simply connected. We wish to approximate the total electric field $\mathbf{E} = \mathbf{E}(\mathbf{x})$, $\mathbf{x} \in \mathbb{R}^3 \setminus D$, where this field satisfies the time-harmonic Maxwell's equation,

$$\nabla \times \nabla \times \mathbf{E} - k^2 \mathbf{E} = 0 \quad \text{in } \mathbb{R}^3 \setminus \overline{D}, \tag{1.1}$$

and the boundary condition appropriate for a perfect conductor,

$$\boldsymbol{\nu} \times \mathbf{E} = 0 \quad \text{on } \Gamma. \tag{1.2}$$

The real parameter $k > 0$ is called the wave number of the time-harmonic field. The total field $\mathbf{E}$ is given by

$$\mathbf{E} = \mathbf{E}^i + \mathbf{E}^s \quad \text{in } \mathbb{R}^3 \setminus D, \tag{1.3}$$

where the given incident field $\mathbf{E}^i$ satisfies Maxwell's equation (1.1) in all of $\mathbb{R}^3$, and $\mathbf{E}^s$ is the unknown scattered field. A typical choice for the incident field is a plane wave, in which case

$$\mathbf{E}^i = \mathbf{p} \exp(ik\mathbf{d} \cdot \mathbf{x}),$$

where the real vectors $\mathbf{p}$ (polarization) and $\boldsymbol{d}$ satisfy $|\mathbf{p}| = |\mathbf{d}| = 1$ and $\mathbf{p} \cdot \mathbf{d} = 0$.

In order to uniquely determine the scattered field, we need to impose the Silver–Müller radiation condition,

$$\lim_{|x| \to \infty} (\nabla \times \mathbf{E}^s) \times \mathbf{x} - ik|\mathbf{x}|\mathbf{E}^s_T = 0, \tag{1.4}$$

uniformly in $\hat{\mathbf{x}} = \mathbf{x}/|\mathbf{x}|$, where

$$\mathbf{E}^s_T = (\hat{\mathbf{x}} \times \mathbf{E}^s) \times \hat{\mathbf{x}}.$$

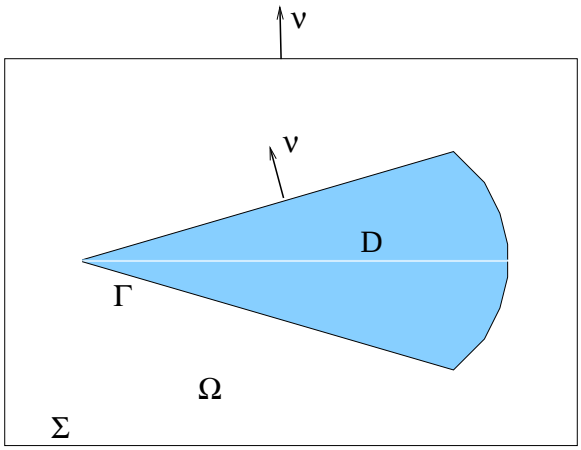

FIG. 1.2. *The truncated computational domain,* $\Omega := D_\Sigma \setminus D$.

More generally, for a sufficiently smooth vector function $\mathbf{u}$, we use the notation

$$\mathbf{u}_T := (\boldsymbol{\nu} \times \mathbf{u}|_S) \times \boldsymbol{\nu}$$

to denote the tangential component of $\mathbf{u}$ on a given surface S with normal $\boldsymbol{\nu}$. Equations (1.1)–(1.4) are uniquely solvable in appropriate function spaces which will be given shortly.

1.2. Truncation of the problem. As stated in the previous section, the scattering problem is posed on an infinite region. In order to apply a finite element method, we need to truncate the domain. Following Hazard and Lenoir, we introduce a simply connected, Lipschitz, polyhedral surface Σ, with interior D_Σ, such that $\overline{D} \subset D_\Sigma$. The outward unit normal on Σ is again denoted $\boldsymbol{\nu}$. For technical reasons associated with the proof of Lemma 3.3, we restrict Σ to be a right parallelepiped. We expect that a more general polyhedral surface also would be appropriate. A smooth surface such as a sphere might also be used, but the analysis of such a scheme would involve the use of curvilinear finite elements which is outside the scope of this paper. We define the truncated computational domain

$$\Omega := D_\Sigma \setminus \overline{D}.$$

Our assumptions imply that the boundary of Ω consists of two disjoint, connected components Σ and Γ, and the region Ω is simply connected (see Figure 1.2). The goal is to use finite elements on Ω to approximate $\mathbf{E}$, but we need a boundary condition on Σ. This is provided by recalling the Stratton–Chu formula that gives a representation of classical solutions of (1.1)–(1.4) away from Γ (see [15]). More precisely, let

$$\mathbb{G}(\mathbf{x}, \mathbf{y}) = \Phi(\mathbf{x}, \mathbf{y})\mathbb{I} + k^{-2}\mathrm{Hess}(\Phi)(\mathbf{x}, \mathbf{y}),$$

where $\mathbb{I}$ is the identity matrix, $\Phi(\mathbf{x}, \mathbf{y})$ is the fundamental solution of the Helmholtz equation in $\mathbb{R}^3$, given by

$$\Phi(\mathbf{x}, \mathbf{y}) := \frac{e^{ik|\mathbf{x}-\mathbf{y}|}}{4\pi|\mathbf{x}-\mathbf{y}|},$$

and Hess$(\cdot)$ is the Hessian operator defined by

$$\mathrm{Hess}(\Phi)_{l,m} = \frac{\partial^2 \Phi}{\partial y_l \partial y_m}, \qquad 1 \le l,\, m \le 3.$$

For $\mathbf{x} \in \mathbb{R}^3 \setminus \overline{D}$, we have

$$\begin{aligned} \mathbf{E}^s(\mathbf{x}) &= \int_\Gamma \left\{ \mathbb{G}(\mathbf{x},\mathbf{y})^T \left(\boldsymbol{\nu}_y \times (\nabla \times \mathbf{E}^s(\mathbf{y}))\right) \right. \\ &\qquad \left. (\nabla_y \times \mathbb{G}(\mathbf{x},\mathbf{y}))^T (\boldsymbol{\nu}_y \times \mathbf{E}^s(\mathbf{y})) \right\} dA(\mathbf{y}) \\ &=: \mathcal{I}(\mathbf{E}^s), \end{aligned} \tag{1.5}$$

where $\nabla_y \times \mathbb{G}(\mathbf{x},\mathbf{y})$ is the columnwise curl of $\mathbb{G}$ with respect to $\mathbf{y}$. Using the fact that $\mathbf{E}^i$ is a regular solution of Maxwell's equations inside D, we have $\mathcal{I}(\mathbf{E}^i) = 0$ in Ω, and thus

$$\mathbf{E} = \mathbf{E}^i + \mathcal{I}(\mathbf{E}) \quad \text{in } \Omega,$$

provided $\mathbf{E}$ is regular enough for $\mathcal{I}(\mathbf{E})$, defined in (1.5), to be well defined.

1.3. A modified integral representation. Unfortunately, the regularity requirement implicit in (1.5) is not met by edge finite elements. We therefore need to extend the definition of $\mathcal{I}$ to allow for less regular arguments $\mathbf{E}^s$. In order to do this, we first recall that

$$H(\mathrm{curl};\Omega) = \left\{ \mathbf{u} \in (L^2(\Omega))^3 |\ \nabla \times \mathbf{u} \in (L^2(\Omega))^3 \right\}$$

and define the subspace

$$X := \left\{ \mathbf{u} \in H(\mathrm{curl};\Omega) |\ \boldsymbol{\nu} \times \mathbf{u} = 0 \,\mathrm{on}\, \Gamma, \text{ and } \boldsymbol{\nu} \times \mathbf{u}|_\Sigma \in (L^2(\Sigma))^3 \right\}.$$

The space X is equipped with the norm

$$\|\mathbf{u}\|_X^2 = \|\mathbf{u}\|_{H(\mathrm{curl};\Omega)}^2 + \|\mathbf{u}_T\|_{(L^2(\Sigma))^3}^2, \tag{1.6}$$

where $\|\cdot\|_{H(\mathrm{curl};\Omega)}$ is the standard norm on $H(\mathrm{curl};\Omega)$, and $\|\cdot\|_{(L^2(\Sigma))^3}$ is the $(L^2(\Sigma))^3$ norm.

Let $\chi \in C_0^\infty(D_\Sigma)$ denote a cutoff function such that $\chi = 1$ on Γ, and define $\widetilde{\mathbb{G}}(\mathbf{x},\cdot) \in H(\mathrm{curl};\Omega)$ by

$$\widetilde{\mathbb{G}}(\mathbf{x},\mathbf{y}) = \chi(\mathbf{y}) \mathbb{G}(\mathbf{x},\mathbf{y}). \tag{1.7}$$

We can now define the integral operator

$$\begin{aligned} \mathcal{I}^R(\mathbf{E}^s) := &\int_\Omega \left((\nabla_y \times \widetilde{\mathbb{G}})^T \nabla \times \mathbf{E}^s - k^2 \widetilde{\mathbb{G}}^T \mathbf{E}^s \right) dV(\mathbf{y}) \\ &+ \int_\Gamma (\nabla_y \times \mathbb{G})^T \boldsymbol{\nu}_y \times \mathbf{E}^s \, dA(\mathbf{y}), \end{aligned} \tag{1.8}$$

where the curl is taken with respect to $\mathbf{y}$ and the integral is evaluated for $\mathbf{x}$ outside the support of the cutoff function χ (in particular, for $\mathbf{x} \in \Sigma$). Using integration by parts we can verify that for a smooth solution $\mathbf{E}^s$ of (1.1)–(1.4),

$$\mathcal{I}^R(\mathbf{E}^s) = \mathcal{I}(\mathbf{E}^s),$$

and thus

$$\mathbf{E} = \mathbf{E}^i + \mathcal{I}^R(\mathbf{E}).$$

Note also that since $\mathcal{I}^R(\mathbf{E})$ is evaluated outside the support of χ (for example, on Σ), a further integration by parts, and the use of the perfect conducting boundary condition on Γ, show that

$$\mathcal{I}^R(\mathbf{E}) = \int_\Omega \left(\nabla \times (\nabla \times \widetilde{\mathbb{G}}) - k^2 \widetilde{\mathbb{G}}\right)^T \mathbf{E}\, dV(\mathbf{y}). \tag{1.9}$$

This is the form of $\mathcal{I}^R$ we shall use for the first part of the analysis.

Before stating the variational problem for Maxwell's equations, we define one further operator. For a sufficiently smooth field $\mathbf{u}$, we can define a tangential boundary operator on Σ as follows:

$$T(\mathbf{u}) := (\nabla \times \mathbf{u})|_\Sigma \times \boldsymbol{\nu} - ik\mathbf{u}_T, \tag{1.10}$$

where $\mathbf{u}_T$ is the tangential component of $\mathbf{u}$ on Σ. With this notation, the truncated version of problem (1.1)–(1.4) is to find $\mathbf{E} \in X$ such that

$$\begin{aligned} &\int_\Omega \nabla \times \mathbf{E} \cdot \nabla \times \bar{\boldsymbol{\phi}} - k^2 \mathbf{E} \cdot \bar{\boldsymbol{\phi}}\, dV \\ &- \int_\Sigma ik\mathbf{E}_T \cdot \bar{\boldsymbol{\phi}}_T\, dA - \int_\Sigma T(\mathcal{I}^R(\mathbf{E})) \cdot \bar{\boldsymbol{\phi}}_T\, dA = \int_\Sigma T(\mathbf{E}^i) \cdot \bar{\boldsymbol{\phi}}_T\, dA \quad \forall \boldsymbol{\phi} \in X. \end{aligned} \tag{1.11}$$

Hazard and Lenoir show [25] that problem (1.11) has a unique solution for every $k > 0$ and given incident field $\mathbf{E}^i$. It is also easy to see that the solution does not depend on the choice of χ. Indeed, (1.11) is identical to (4.12) of [25], allowing for differences in notation and with $\tau = t = \infty$, $\xi_0 = 1$, $\xi = 1$, $\lambda = ik$, and $\zeta^{-1} = 1$. The space X is H^E_τ from [25] but without the constraint on $\nabla \cdot \mathbf{E}$. As we shall see, this constraint is implied directly by the variational equation (1.11).

We shall use (1.11) as the basis of the finite element method we shall analyze. There are several advantages to this formulation compared to other finite element formulations. One advantage is that, unlike methods which use standard absorbing boundary conditions, the convergence of the formulation in this paper can be verified as the mesh size decreases; moreover, the method can be easily applied to a layered medium. Further, compared to a standard coupled finite element–boundary element scheme, the advantage of this method is that no singular integrals must be approximated (since $\mathbf{x} \neq \mathbf{y}$ in (1.5)). The main disadvantages relate to the matrices arising from the discrete problem. We shall discuss these issues more at the end of the paper, but mention here that the matrices have dense blocks.

2. The finite element method. We describe a method based on the tetrahedral edge elements of Nédélec [31] which we summarize next. Results for the hexahedral elements discussed in the same paper follow in the same way and will not be detailed here. In addition, smooth curved boundaries can be handled using the mapping scheme described in [22], but only for elements of the lowest order.

We suppose that Ω has been covered by a regular, quasi-uniform mesh τ_h consisting of tetrahedra of maximum diameter h. Let P_ℓ denote the set of all polynomials in x_1, x_2, and x_3 of maximum degree ℓ, and let $\widetilde{P}_\ell$ denote the set of homogeneous

polynomials of degree ℓ in x_1, x_2, and x_3. On each tetrahedron $K \in \tau_h$, the finite element functions are taken from the set

$$R_\ell = (P_{\ell-1})^3 \oplus S_\ell$$

for some $\ell = 1, 2, \ldots$, where

$$S_\ell = \{\mathbf{p} \in \widetilde{P}_\ell^3 \mid \mathbf{p}(\mathbf{x}) \cdot \mathbf{x} = 0 \quad \forall \mathbf{x}\}.$$

Using these basis functions, we can define

$$V_h = \{\mathbf{u}_h \in H(\mathrm{curl}; \Omega) \mid \mathbf{u}_h|_K \in R_\ell \quad \forall K \in \tau_h\}$$

and

$$X_h = \{\mathbf{u}_h \in V_h \mid \mathbf{u}_h \times \boldsymbol{\nu} = 0 \quad \text{on } \Gamma\}. \tag{2.1}$$

Following [2], we can define an interpolation operator. We proceed by recalling the standard degrees of freedom for these tetrahedral elements. Let K be an element and suppose that $\mathbf{u} \in (H^{\frac{1}{2}+\epsilon}(K))^3$, $\epsilon > 0$, and $\nabla \times \mathbf{u} \in (L^q(K))^3$, $q > 2$. Then the following degrees of freedom on K are well defined. Let e be any edge of K with unit tangent vector $\boldsymbol{\tau}$ and let $\boldsymbol{\nu}$ denote the outward normal to K for any face f. Then let

$$M_e(\mathbf{u}) = \left\{ \int_e \mathbf{u} \cdot \boldsymbol{\tau}\, q\, ds \quad \forall q \in P_{\ell-1}(e),\ \forall \text{ edges } e \text{ of } K \right\}, \tag{2.2a}$$

$$M_f(\mathbf{u}) = \left\{ \int_f \mathbf{u} \times \boldsymbol{\nu} \cdot \mathbf{q}\, dA \quad \forall \mathbf{q} \in (P_{\ell-2}(f))^2,\ \forall \text{ faces } f \text{ of } K \right\}, \tag{2.2b}$$

$$M_K(\mathbf{u}) = \left\{ \int_K \mathbf{u} \cdot \mathbf{q}\, dV \quad \forall \mathbf{q} \in (P_{\ell-3}(K))^3 \right\}. \tag{2.2c}$$

The set $M_\ell(\mathbf{u}) \cup M_f(\mathbf{u}) \cup M_K(\mathbf{u})$ is unisolvent for R_l and curl-conforming (see [31]). Thus, we can define an interpolant π_h elementwise by requiring that $\pi_h \mathbf{u}\big|_K \in R_\ell$ and

$$M_e(\mathbf{u} - \pi_h \mathbf{u}) = M_f(\mathbf{u} - \pi_h \mathbf{u}) = M_K(\mathbf{u} - \pi_h \mathbf{u}) = \{0\}.$$

Error estimates can be proved by scaling to a reference element. In [1] it is shown that

$$\|\mathbf{u} - \pi_h \mathbf{u}\|_{H(\mathrm{curl};\Omega)} \le C h^{\ell'} \left(\|\mathbf{u}\|_{(H^{\ell'}(\Omega))^3} + \|\nabla \times \mathbf{u}\|_{(H^{\ell'}(\Omega))^3} \right) \tag{2.3}$$

for any ℓ' with $\ell \ge \ell' > \frac{1}{2}$.

Now suppose that $\mathbf{u}$ is such that $\nabla \times \mathbf{u}|_K \in (P_\ell)^3$ for each element $K \in \tau_h$. Then using a standard scaling argument like the one proving the above estimate, and using the equivalence of norms for piecewise polynomials on the reference element as in the proof of equation (2.4) of [3], we obtain that for $0 < \epsilon \le \frac{1}{2}$,

$$\|\mathbf{u} - \pi_h \mathbf{u}\|_{(L^2(\Omega))^3} \le C \left(h^{\frac{1}{2}+\epsilon} \|\mathbf{u}\|_{(H^{\frac{1}{2}+\epsilon}(\Omega))^3} + h \|\nabla \times \mathbf{u}\|_{(L^2(\Omega))^2} \right). \tag{2.4}$$

For later use we need to discretize the operator $\mathcal{I}^R$ defined in (1.8). Let $\widetilde{\mathbb{G}}_h(\mathbf{x}, \cdot)$ denote the matrix function such that if $\tilde{\mathbf{g}}_{h,m}(\mathbf{x}, \cdot)$ is the mth column of $\widetilde{\mathbb{G}}_h(\mathbf{x}, \cdot)$ and $\tilde{\mathbf{g}}_m(\mathbf{x}, \cdot)$ is the mth column of $\widetilde{\mathbb{G}}(\mathbf{x}, \cdot)$, then (recalling that $\mathbf{x} \in \Sigma$)

1. $\tilde{\mathbf{g}}_{h,m}(\mathbf{x},\cdot) \in V_h$, $1 \le m \le 3$;
2. $(\tilde{\mathbf{g}}_{h,m}(\mathbf{x},\cdot))_T$ interpolates $(\mathbf{g}_m(\mathbf{x},\cdot))_T$ on Γ (using edge and face degrees of freedom (2.2a) and (2.2b));
3. $(\tilde{\mathbf{g}}_{h,i}(\mathbf{x},\cdot))_T = 0$ on all tetrahedra having a face or edge on Σ.

Obviously, this discretization of $\widetilde{\mathbb{G}}(\mathbf{x},\mathbf{y})$ is not uniquely determined. For computational convenience, we use $(\tilde{\mathbf{g}}_{h,m})$, $m = 1,2,3$, that decay to zero rapidly away from Γ. This minimizes the support of $\widetilde{\mathbb{G}}_h$ and is the reason for discretizing $\widetilde{\mathbb{G}}$.

We can then define the discretized version of the integral operator defined in (1.8), denoted by $\mathcal{I}_h(\mathbf{u})$, for $\mathbf{u} \in H(\operatorname{curl}\Omega)$ and $\mathbf{x}$ outside the support of $\widetilde{\mathbb{G}}_h$ (in particular, for $\mathbf{x} \in \Sigma$) by

$$\mathcal{I}_h(\mathbf{u})(\mathbf{x}) = \int_\Omega \Big((\nabla \times \widetilde{\mathbb{G}}_h(\mathbf{x},\mathbf{y}))^T \nabla \times \mathbf{u}(\mathbf{y}) - k^2 (\widetilde{\mathbb{G}}_h(\mathbf{x},\mathbf{y}))^T \mathbf{u}(\mathbf{y}) \Big)\, dV(\mathbf{y}). \tag{2.5}$$

As long as $\mathbf{x}$ is on Σ, $\mathcal{I}_h(\mathbf{u})$ is a smooth function of $\mathbf{x}$. Hence $T(\mathcal{I}_h(\mathbf{u}))$ is a well defined and smooth (tangential) vector field on each face on Σ.

The finite element analogue of (1.11) is to find $\mathbf{E}_h \in X_h$ such that

$$\begin{aligned} &\int_\Omega \nabla \times \mathbf{E}_h \cdot \nabla \times \overline{\boldsymbol{\phi}}_h - k^2 \mathbf{E}_h \cdot \overline{\boldsymbol{\phi}}_h \, dV - \int_\Sigma (ik \mathbf{E}_{h,T} + T(\mathcal{I}_h(\mathbf{E}_h))) \cdot \overline{\boldsymbol{\phi}}_{h,T} \, dA \\ &\quad = \int_\Sigma T(\mathbf{E}^i) \cdot \overline{\boldsymbol{\phi}}_h \, dA \quad \forall \boldsymbol{\phi}_h \in X_h. \end{aligned} \tag{2.6}$$

Unfortunately, we have been unable to prove directly that $\mathbf{E}_h$ converges to $\mathbf{E}$. Instead we first analyze the convergence of the solution of the following intermediate problem of finding $\tilde{\mathbf{E}}_h \in X_h$ such that

$$\begin{aligned} &\int_\Omega \nabla \times \tilde{\mathbf{E}}_h \cdot \nabla \times \overline{\boldsymbol{\phi}}_h - k^2 \tilde{\mathbf{E}}_h \cdot \overline{\boldsymbol{\phi}}_h \, dV - \int_\Sigma \Big(ik \tilde{\mathbf{E}}_{h,T} + T(\mathcal{I}^R(\tilde{\mathbf{E}}_h)) \Big) \cdot \overline{\boldsymbol{\phi}}_{h,T} \, dA \\ &\quad = \int_\Sigma T(\mathbf{E}^i) \cdot \overline{\boldsymbol{\phi}}_h \, dA \quad \forall \boldsymbol{\phi}_h \in X_h. \end{aligned} \tag{2.7}$$

Here the operator $\mathcal{I}^R$ is not discretized.

In the next section we shall show that $\tilde{\mathbf{E}}_h$ is well defined and converges to the true solution $\mathbf{E}$. In principle, we could implement (2.7) but the integral operator $\mathcal{I}^R$ would become increasingly more expensive to evaluate as the mesh size decreases, since a volume integral over a fixed volume must be evaluated. Hence we prefer to compute with (2.6) since $\mathcal{I}_h$ can be constructed to involve only a skin of tetrahedra that share an edge with Γ.

Another justification for the use of (2.6) is that the solution $\mathbf{E}_h$ is independent of the choice of $\widetilde{\mathbb{G}}_h$ (provided the conditions mentioned earlier in this section are satisfied). In order to show this, we state the following lemma, which also partially justifies our choice of $\widetilde{\mathbb{G}}_h$. The proof of this lemma is straightforward and is postponed until the appendix.

LEMMA 2.1. *Suppose* (2.6) *has a unique solution for each* $\widetilde{\mathbb{G}}_h$ *satisfying requirements* (1)–(3) *discussed earlier in this section. Then the solution is independent of the choice of* $\widetilde{\mathbb{G}}_h$.

From this lemma it suffices to prove existence and uniqueness for a particular choice of $\widetilde{\mathbb{G}}_h$ to then conclude the result for any $\widetilde{\mathbb{G}}_h$.

3. Analysis of the scheme. We will prove that as the mesh size h decreases, the solutions of the discrete problem (2.7) approach the exact solution of (1.11). In order to prove this, we first need to carefully describe the function spaces we will be working with. This is done in subsection 3.1. In subsection 3.2, we rewrite both the continuous and the discrete problems in a convenient operator form. In subsection 3.3, we show that the operator equations are of Fredholm type. We also demonstrate the convergence (in some suitable norm) of the discrete operators to their continuous analogues as the mesh size decreases.

Subsection 3.5 concerns a collective compactness result. We follow the general approach of [34] in that we verify convergence of some operation using the theory of collectively compact operators. The main property of edge elements relevant to this approach is the discrete compactness property (see [27, 28, 29, 34]). Subsection 3.6 combines all these results into our first theorem about the finite element scheme.

An alternative approach to proving the operator convergence via the theory of mixed methods has been employed by Boffi [9] and Boffi, Brezzi, and Gastaldi [10, 11]. So far this approach has been aimed at proving convergence in $(L^2(\Omega))^3$ which is appropriate for eigenvalue problems. In that case, Boffi proved the equivalence of the mixed method and the discrete compactness approaches [8] (see also [14]), so the choice of which method to use is immaterial.

For the remainder of the paper we shall assume that Γ and Σ are each connected, so $\partial\Omega = \Gamma \cup \Sigma$ and $\Gamma \cap \Sigma = \phi$. We could allow both boundaries to be disconnected if necessary at the cost of using more notation and complexity.

3.1. Some function spaces and estimates. In this subsection, we define useful function spaces, which shall be used in the remainder of the paper. Convenient decompositions and properties of these spaces are also listed. Let

$$S = \left\{ p \in H^1(\Omega) \mid p = 0 \text{ on } \Gamma \text{ and } p = \text{ constant on } \Sigma \right\}. \tag{3.1}$$

Then $\nabla S \subset X$ and is a closed subspace of X. Hence we may write, using the $(L^2(\Omega))^3$ inner product,

$$X = X_0 \oplus \nabla S \tag{3.2}$$

and

$$X_0 = \left\{ \mathbf{u} \in X \;\middle|\; \int_\Omega \mathbf{u} \cdot \nabla\xi \, dV = 0 \quad \forall \xi \in S \right\}. \tag{3.3}$$

Using Costabel's regularity result [16] we know that the injection $X_0 \to (L^2(\Omega))^3$ is compact. Furthermore, suppose $\mathbf{u} \in X_0$, $\nabla \times \mathbf{u} = 0$ in Ω and $\mathbf{u}_T = 0$ on Σ. Then since $\nabla \times \mathbf{u} = 0$, and Ω is simply connected, there is a scalar potential $p \in H^1(\Omega)$ such that

$$\mathbf{u} = \nabla p.$$

The tangential components of $\mathbf{u}$ vanish on Γ and Σ, and thus we can take $p \in S$. The fact that $\mathbf{u} \in \nabla S$ and $\mathbf{u} \in X_0$ then implies $\mathbf{u} = 0$. Thus, using the compactness result above, for $\mathbf{u} \in X_0$ there is a constant $C > 0$ such that

$$\|\mathbf{u}\|_X \le C \left(\|\nabla \times \mathbf{u}\|_{(L^2(\Omega))^3} + \|\mathbf{u}_T\|_{(L^2(\Sigma)^3)} \right). \tag{3.4}$$

We can also decompose X_h. It is well known (see [31]) that if

$$S_h = \{p_h \in S \mid p_h|_K \in P_\ell \quad \forall K \in \tau_h\}, \tag{3.5}$$

then

$$\nabla S_h \subset X_h, \tag{3.6}$$

and we may write (again using the $(L^2(\Omega))^3$ inner product)

$$X_h = X_{0,h} \oplus \nabla S_h, \tag{3.7}$$

where

$$X_{0,h} = \left\{ \mathbf{u}_h \in X_h \;\middle|\; \int_\Omega \mathbf{u}_h \cdot \nabla \xi_h \, dV = 0 \quad \forall \xi_h \in S_h \right\} \tag{3.8}$$

is the space of discrete divergence-free fields. The main difficulty with the analysis of the error is that $X_{0,h} \not\subset X_0$.

3.2. An operator equation. In order to use the Fredholm alternative in the analysis of the finite element formulation, we rewrite the continuous variational problem (1.11) and the discrete finite element problem (2.6) as operator equations. We introduce some convenient notation to be used in the remainder of this section. For $\mathbf{u}, \mathbf{v} \in X$ we denote

$$a(\mathbf{u}, \mathbf{v}) = \int_\Omega \nabla \times \mathbf{u} \cdot \nabla \times \bar{\mathbf{v}} + k^2 \mathbf{u} \cdot \overline{\mathbf{v}} \, dV - ik \int_\Sigma \mathbf{u}_T \cdot \overline{\mathbf{v}}_T \, dA. \tag{3.9}$$

Note that $|a(\mathbf{u}, \mathbf{u})|$ is a norm equivalent to $\|\mathbf{u}\|_X$. Define the operator $A : (L^2(\Omega))^3 \to (L^2(\Omega))^3$ such that for all $\mathbf{f} \in (L^2(\Omega))^3$, $A\mathbf{f} \in X_0 \subset (L^2(\Omega))^3$ satisfies

$$a(A\mathbf{f}, \boldsymbol{\phi}) = -2k^2 \int_\Omega \mathbf{f} \cdot \overline{\boldsymbol{\phi}} \, dV - \int_\Sigma T(\mathcal{I}^R(\mathbf{f})) \cdot \overline{\boldsymbol{\phi}}_T dA \quad \forall \boldsymbol{\phi} \in X_0. \tag{3.10}$$

By the Lax–Milgram lemma this problem is well posed. In particular, using the expression for $\mathcal{I}^R$ in (1.9) shows that

$$\|T(\mathcal{I}^R(\mathbf{u}))\|_{(L^2(\Sigma))^3} \leq C \|\mathbf{u}\|_{(L^2(\Omega))^3}$$

which allows us to prove the continuity of the right-hand side of (3.10).

Similarly, we define $\mathbf{F} \in X_0$ by

$$a(\mathbf{F}, \boldsymbol{\phi}) = \int_\Sigma T(\mathbf{E}^i) \cdot \bar{\phi} dA \quad \forall \boldsymbol{\phi} \in X_0. \tag{3.11}$$

We proceed to show that the operator problem of finding $\mathbf{E} \in (L^2(\Omega))^3$ such that

$$\mathbf{E} + A\mathbf{E} = \mathbf{F} \tag{3.12}$$

is exactly equivalent to solving the Hazard–Lenoir equation (1.11). Any solution of (1.11) is divergence free, and thus if we pick a test function $\boldsymbol{\phi} \in X_0$, then (1.11) can be recast as follows: *Find* $\mathbf{E} \in X_0$ *such that*

$$a(\mathbf{E} + A\mathbf{E} - \mathbf{F}, \boldsymbol{\phi}) = 0 \quad \forall \boldsymbol{\phi} \in X_0.$$

Hence, $\mathbf{E} + A\mathbf{E} - \mathbf{F} = 0$ in X_0 and this certainly implies equality in $(L^2(\Omega))^3$. Conversely, if we have a solution $\mathbf{E} \in (L^2(\Omega))^3$ of

$$\mathbf{E} + A\mathbf{E} = \mathbf{F},$$

then since $\mathbf{E} = \mathbf{F} - A\mathbf{E}$, we know that $\mathbf{E} \in X_0$. Therefore $\mathbf{E}$ satisfies

$$a(\mathbf{E} + A\mathbf{E} - \mathbf{F}, \boldsymbol{\xi}) = 0 \quad \forall \boldsymbol{\xi} \in X,$$

which is the Hazard–Lenoir equation (1.11). This shows the equivalence of the operator equation (3.12) and the Hazard–Lenoir equation (1.11). The existence and uniqueness of solutions to (3.12) now follow from those of (1.11) (see [25]).

3.3. The Fredholm alternative. Hazard and Lenoir proved the compactness of A as an operator from X_0 to X_0. We need to perform the analysis in $(L^2(\Omega))^3$ since $X_{0,h} \not\subset X_0$. In fact, A is compact as a map from $(L^2(\Omega))^3$ to $(L^2(\Omega))^3$, as the next lemma shows.

LEMMA 3.1. *The map $A : (L^2(\Omega))^3 \to (L^2(\Omega))^3$ is compact.*

Proof. By the Lax–Milgram lemma, A is well defined and bounded as a map from $(L^2(\Omega))^3$ into X_0. The extension of Weber's compactness theorem due to Costabel [16] proves that X_0 is compactly embedded in $(L^2(\Omega))^3$. This proves the compactness of A. ∎

Using this lemma we can see that (3.12) is a Fredholm equation on $(L^2(\Omega))^3$ and hence, via Hazard and Lenoir's uniqueness result, (3.12) has a unique solution $\mathbf{E}$ in $(L^2(\Omega))^3$.

Now we write the discrete problem (2.7) as an operator equation. We define the operator $\tilde{A}_h : (L^2(\Omega))^3 \to (L^2(\Omega))^3$ as the straightforward discrete analogue of A. By this we mean that for a given $\mathbf{f} \in (L^2(\Omega))^3$, $\tilde{A}_h\mathbf{f} \in X_{0,h}$ satisfies

$$a(\tilde{A}_h\mathbf{f}, \boldsymbol{\xi}_h) = -2k^2 \int_\Omega \mathbf{f} \cdot \bar{\boldsymbol{\xi}}_h \, dV - \int_\Sigma T(\mathcal{I}^R(\mathbf{f})) \cdot \bar{\boldsymbol{\xi}}_{h,T} \, dA \quad \forall \boldsymbol{\xi}_h \in X_{0,h}. \tag{3.13}$$

We can also define $\mathbf{F}_h \in X_{0,h}$ by

$$a(\mathbf{F}_h, \boldsymbol{\xi}_h) = \int_\Sigma T(\mathbf{E}^i) \cdot \overline{\boldsymbol{\xi}}_{h,T} \, dA \quad \forall \boldsymbol{\xi}_h \in X_{0,h}. \tag{3.14}$$

The operator $\tilde{A}_h$ and vector $\mathbf{F}_h$ are well defined by the Lax–Milgram lemma.

We can then pose the problem of finding $\tilde{\mathbf{E}}_h \in (L^2(\Omega))^3$ such that

$$\tilde{\mathbf{E}}_h + \tilde{A}_h\tilde{\mathbf{E}}_h = \mathbf{F}_h. \tag{3.15}$$

Assuming such a solution can be found, we have

$$\tilde{\mathbf{E}}_h = \mathbf{F}_h - \tilde{A}_h\tilde{\mathbf{E}}_h \in X_{0,h}.$$

As a first step in our analysis of this problem, we now need to demonstrate that as the mesh size h decreases, the discrete operator $\tilde{A}_h$ converges to A. This is the content of the next lemma, the proof of which is rather classical (see [26]).

LEMMA 3.2. *For fixed $\mathbf{f} \in (L^2(\Omega))^3$, $\tilde{A}_h\mathbf{f} \to A\mathbf{f}$ in X as $h \to 0$.*

Proof. We rewrite the problem defining A, (3.10), as the mixed problem of finding $A\mathbf{f} \in X$ and $p \in S$ such that

$$\begin{aligned} a(A\mathbf{f}, \boldsymbol{\xi}) + \int_\Omega \boldsymbol{\xi} \cdot \nabla \bar{p} \, dV &= -2k^2 \int_\Omega \mathbf{f} \cdot \bar{\boldsymbol{\xi}} \, dV - \int_\Sigma T(\mathcal{I}_R(\mathbf{f})) \cdot \bar{\boldsymbol{\xi}}_T \, dA \quad \forall \boldsymbol{\xi} \in X, \\ \int_\Omega A\mathbf{f} \cdot \nabla \bar{\phi} \, dV &= 0 \quad \forall \phi \in S. \end{aligned}$$

Since $a(\cdot,\cdot)$ is coercive on X and $\nabla S \subset X$, we can easily verify the Babuška–Brezzi condition and conclude that this is a well-posed problem (taking $\boldsymbol{\xi} \in X_0$ shows it reduces to (3.10) in this case).

Similarly, the discrete problem (3.13) may be written as

$$a(\tilde{A}_h\mathbf{f},\boldsymbol{\xi}_h) + \int_\Omega \boldsymbol{\xi}_h \cdot \nabla \bar{p}_h \, dV = -2k^2 \int_\Omega \mathbf{f}\cdot\bar{\boldsymbol{\xi}}_h \, dV - \int_\Sigma T(\mathcal{I}_R(\mathbf{f}))\cdot\bar{\boldsymbol{\xi}}_{h,T}\, dA \quad \forall \boldsymbol{\xi}_h \in X_h,$$

$$\int_\Omega \tilde{A}_h\mathbf{f}\cdot\nabla\bar{\phi}_h \, dV = 0 \quad \forall \phi_h \in S_h. \tag{3.16}$$

The coercivity of $a(\cdot,\cdot)$ and the fact that $\nabla S_h \subset X_h$ allows us to verify the discrete Babuška–Brezzi condition, and we conclude that the following estimate holds (see [13]):

$$\begin{aligned}\|A\mathbf{f} - \tilde{A}_h\mathbf{f}\|_X + \|\nabla(p-p_h)\|_{(L^2(\Omega))^3} \\ \le c\left\{\inf_{\chi_h\in X_h}\|A\mathbf{f}-\chi_h\|_X + \inf_{\xi_h\in S_h}\|\nabla(p-\xi_h)\|_{(L^2(\Omega))^3}\right\}.\end{aligned} \tag{3.17}$$

The theorem follows from standard arguments using the density of S_h in S and X_h in X. ∎

The pointwise convergence of $\tilde{A}_h$ to A is not sufficient to conclude that the operator $(I+\tilde{A}_h)$ is invertible. Before proving this invertibility we need to prove a technical regularity result.

3.4. A regularity result. Before stating and proving our main compactness result we need the following regularity result. This result claims that if a vector field $\mathbf{u} \in X$ and a discrete field $\mathbf{u}_h \in X_h$ have curls which agree in Ω, and if the tangential components of the fields agree on the boundary, then $\mathbf{u}$ possesses some extra regularity. The proof of this lemma proceeds by considering a decomposition of $\mathbf{u}$ and establishing a regularity result for each component.

LEMMA 3.3. *Let $\mathbf{u}_h \in X_{0,h}$ and suppose $\mathbf{u} \in X_0$ satisfies*

$$\begin{aligned}\nabla\times\mathbf{u} &= \nabla\times\mathbf{u}_h \text{ in } \Omega,\\ \boldsymbol{\nu}\times\mathbf{u} &= \boldsymbol{\nu}\times\mathbf{u}_h \text{ on } \partial\Omega.\end{aligned}$$

Then there is an $\epsilon_{max} > 0$ such that $\mathbf{u} \in (H^s(\Omega))^3$, for $1/2 \le s < 1/2+\epsilon_{max}$, and

$$\|\mathbf{u}\|_{(H^s(\Omega))^3} \le C\left(\|\nabla\times\mathbf{u}\|_{(L^2(\Omega))^3} + \|\boldsymbol{\nu}\times\mathbf{u}\|_{(H^{s-1/2}(\Sigma))^3}\right).$$

Remark 1. (1) In [16] this result is proved for $S = 1/2$, and in [2] the result is proved when $\boldsymbol{\nu}\times\mathbf{u} = 0$ on $\partial\Omega$ (including Σ). The result here is possible because $\boldsymbol{\nu}\times\mathbf{u}_h$ is a piecewise polynomial on Γ and Σ and hence is smoother than just square integrable on Γ and Σ. The proof we shall give combines those in [2] and [16].

(2) It is in the proof of this theorem that we use the fact that Σ is a parallelepiped. This is a hypothesis for an extension result given in Lemma A.2. Note that extension results of this type are valid for arbitrary Lipschitz polygons in $\mathbb{R}^2$ (see [24, Thm. 1.5.2.3], for example). Dauge (in private communication) suggested that the same is true in $\mathbb{R}^3$. Assuming this is so, the proofs in this paper are valid for more general outer boundaries Σ.

Proof. In this proof we shall use the spaces $H^l(\Sigma)$ for $l > 0$. We define (on Σ here, but using obvious notation also on Γ)

$$H^l(\Sigma) = \left\{g = \xi|_\Sigma \mid \xi \in H^{l+1/2}(\Omega)\right\}$$

with the norm

$$\|g\|_{H^l(\Sigma)} = \inf_{\xi \in H^{l+1/2}(\Omega),\ \xi|_\Sigma = g} \|\xi\|_{H^{l+1/2}(\Omega)}.$$

This definition makes sense for all $l > 0$ and agrees with the trace space defined in terms of intrinsic norms for $l \leq 1$.

As in [16], let $\mathcal{O}$ denote a smooth, bounded, connected domain with simply connected boundary $\partial\mathcal{O}$ containing $\bar{\Omega}$ in its interior (see Figure 3.1). First we construct a vector potential $\mathbf{w} \in (H^1(\mathcal{O}))^3$ such that

$$\left.\begin{array}{rcl} \nabla \times \mathbf{w} & = & \nabla \times \mathbf{u} \\ \nabla \cdot \mathbf{w} & = & 0 \end{array}\right\} \text{ in } \Omega. \tag{3.18}$$

Let $\mathbf{z}$ be defined on $\mathcal{O}$ by

$$\mathbf{z} = \begin{cases} 0 & \text{in } D, \\ \nabla \times \mathbf{u} & \text{in } \Omega, \\ \nabla \xi & \text{in } \mathcal{O} \setminus \overline{(\Omega \cup D)}, \end{cases}$$

where $\xi \in H^1(\mathcal{O} \setminus \overline{(\Omega \cup D)})/\mathbb{R}$ solves the boundary value problem

$$\begin{aligned} &\Delta \xi = 0 \text{ in } \mathcal{O} \setminus \overline{(\Omega \cup D)}, \\ &\frac{\partial \xi}{\partial \nu} = \boldsymbol{\nu} \cdot \nabla \times \mathbf{u} \text{ on } \Sigma, \\ &\frac{\partial \xi}{\partial \nu} = 0 \text{ on } \partial\mathcal{O}. \end{aligned}$$

Note that $\boldsymbol{\nu} \cdot \nabla \times \mathbf{u} \in H^{-1/2}(\Sigma)$ since $\nabla \cdot (\nabla \times \mathbf{u}) = 0$ and that this also implies the necessary compatibility condition for solvability.

Of course, $\boldsymbol{\nu} \cdot \nabla \times \mathbf{u} = 0$ on Γ since the boundary condition is perfectly conducting. Thus $\mathbf{z}$ has a continuous normal component across Σ and Γ, $\nabla \cdot \mathbf{z} = 0$ in $\mathcal{O}$. Hence Lemma 3.5 of [2] ensures that there is a function $\mathbf{w} \in (H^1(\mathcal{O}))^3$ such that

$$\nabla \times \mathbf{w} = \mathbf{z} \text{ and } \nabla \cdot \mathbf{w} = 0 \text{ in } \mathcal{O}.$$

Hence $\mathbf{w}$ verifies the desired properties in (3.18).

As $\nabla \times (\mathbf{u} - \mathbf{w}) = 0$, in Ω there is a scalar potential $p \in H^1(\Omega)$ such that

$$\mathbf{u} - \mathbf{w} = \nabla p.$$

The fact that $\nabla \cdot (\mathbf{u} - \mathbf{w}) = 0$ then implies that

$$\Delta p = 0 \text{ in } \Omega.$$

We need to demonstrate that p possesses extra regularity in order to establish the smoothness of $\mathbf{u}$. This can be done following [2]. Inside D we have $\nabla \times \mathbf{w} = 0$, and since $\mathbf{w} \in (H^1(\mathcal{O}))^3$, there is a scalar potential $\eta \in H^2(D)$ such that $\mathbf{w} = \nabla \eta$ in D. On the boundary Γ, we have

$$(\boldsymbol{\nu} \times (\mathbf{u} - \mathbf{w})) \times \boldsymbol{\nu} = (\boldsymbol{\nu} \times \nabla p) \times \boldsymbol{\nu}.$$

We now use the boundary condition on Γ and the fact that $\mathbf{w} = \nabla \eta$ in D to obtain

$$\nabla_\Gamma p = -\nabla_\Gamma \eta,$$

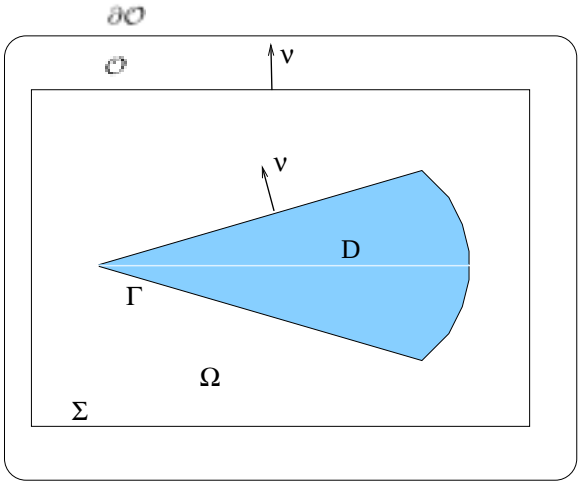

FIG. 3.1. *The configuration of the smooth enclosing domain O.*

where we have used the notation $\nabla_\Gamma p = (\boldsymbol{\nu} \times \nabla p) \times \boldsymbol{\nu}$ so that ∇_Γ is the surface gradient. Since $\eta \in H^{3/2}(\Gamma)$, we can conclude $p \in H^{3/2}(\Gamma)$.

For the outer boundary Σ, we follow [16]. Clearly $p|_\Sigma \in H^{1/2}(\Sigma)$ and $\mathbf{w}|_\Sigma \in (H^{1/2}(\Sigma))^3$. Furthermore, on Σ,

$$(\boldsymbol{\nu} \times (\mathbf{u} - \mathbf{w})) \times \boldsymbol{\nu} = (\boldsymbol{\nu} \times \nabla p) \times \boldsymbol{\nu}.$$

Thus, on Σ,

$$\mathbf{u}_T - \mathbf{w}_T = \nabla_\Sigma p.$$

Unlike the boundary condition on Γ, now $\mathbf{u}_T$ does not vanish on Σ, since

$$\mathbf{u}_T = \mathbf{u}_{h,T}.$$

The polyhedral nature of Σ implies that on each face F of the surface, we have that $\boldsymbol{\nu}$ is a constant vector, and $\mathbf{u}_h$ is a piecewise polynomial, so

$$\mathbf{u}_{h,T} = (\boldsymbol{\nu} \times \mathbf{u}_h) \times \boldsymbol{\nu} \in (H^\epsilon(F))^3$$

for $0 \le \epsilon < 1/2$. Thus $\nabla_\Sigma p \in (H^\epsilon(F))^3$ and hence $p \in H^{1+\epsilon}(F)$. Moreover, since $p \in H^{1/2}(\Sigma)$ it cannot have line discontinuities, so in fact p is continuous on Σ.

We are thus assured that p is continuous at each edge of Σ, and $p \in H^{1+\epsilon}(F)$ for each face F. Hence, via Lemma A.2 there is an extension denoted $\tilde{p} \in H^{3/2+\epsilon}(\Omega)$. Then using this extension and considering $p - \tilde{p}$, we can conclude, using Corollary 18.15 of Dauge [20], that there is an ϵ_{max} with $0 < \epsilon_{max} < 1/2$ such that $p \in H^{3/2+\epsilon}(\Omega)$ for $0 \le \epsilon < \epsilon_{max}$. Using the fact that $\mathbf{u} = \mathbf{w} + \nabla p$ completes the proof. ∎

3.5. A collective compactness result. Let Λ be a countable set of positive real numbers whose only accumulation point is at zero. We assume that the mesh size $h \in \Lambda$ and hence that there is a sequence of mesh sizes $h_n \to 0$ as $n \to \infty$.

LEMMA 3.4. *The set of operators* $\{\tilde{A}_h : (L^2(\Omega))^3 \to (L^2(\Omega))^3\}_{h\in\Lambda}$ *is collectively compact.*

Remark 2. This is essentially the discrete compactness property (for a full discussion of this property see [27, 28, 29, 9]).

Proof. Let $U \subset (L^2(\Omega))^3$ be a bounded set and define

$$\mathcal{A}(U) = \{\mathbf{w} \in (L^2(\Omega))^3 \mid \mathbf{w} = \tilde{A}_h(\mathbf{u}) \text{ for some } \mathbf{u} \in U \text{ and } h \in \Lambda\}.$$

To prove collective compactness, we need to show that $\mathcal{A}(U)$ is precompact in $(L^2(\Omega))^3$. Let $\{\mathbf{w}_n\} \subset \mathcal{A}(U)$ be a sequence. Then for each n there is an h_n and $\mathbf{u}_n \in U$ such that

$$\mathbf{w}_n = \tilde{A}_{h_n}(\mathbf{u}_n) \in X_{0,h_n}.$$

Without loss of generality, we can assume $h_n \to 0$ as $n \to \infty$ (otherwise we are in a finite-dimensional vector space, and a convergent subsequence of $\{\mathbf{w}_n\}$ is guaranteed).

Let $p^n \in S$ satisfy

$$\int_\Omega \nabla p^n \cdot \nabla \overline{\xi}\, dV = \int_\Omega \mathbf{w}_n \cdot \nabla \overline{\xi}\, dV \quad \forall \xi \in S.$$

We can decompose $\mathbf{w}_n \in (L^2(\Omega))^3$ by defining $\mathbf{w}^n$ as

$$\mathbf{w}^n = \mathbf{w}_n - \nabla p^n.$$

Clearly, $\mathbf{w}^n \in X_0$. Since $\{\mathbf{w}_n\}$ is a bounded subset of X, we can conclude $\{\mathbf{w}^n\}$ is a bounded subset in X_0. Thus, using the compactness result of [16], there is a subsequence, still denoted $\{\mathbf{w}^n\}$, and an element $\mathbf{w} \in X_0$, such that

$$\mathbf{w}^n \longrightarrow \mathbf{w} \text{ as } n \to \infty \begin{cases} \text{weakly} & \text{in} \quad X, \\ \text{strongly} & \text{in} \quad (L^2(\Omega))^3. \end{cases}$$

Moreover, the definition of $\mathbf{w}^n$ reveals that since $\mathbf{w}_n$ is a finite element function,

$$\nabla \times \mathbf{w}^n = \nabla \times \mathbf{w}_n \in (L^q(\Omega))^3,$$

and $\boldsymbol{\nu} \times \mathbf{w}^n = \boldsymbol{\nu} \times \mathbf{w}_n$ on Σ (and Γ).

Hence by Lemma 3.3, $\mathbf{w}^n \in (H^{\frac{1}{2}+\epsilon}(\Omega))^3$ for some $\epsilon > 0$. Since $\nabla \times \mathbf{w}^n \in (L^q(\Omega))^3$ for any $q \geq 2$, we can conclude that the interpolant $\pi_{h_n}\mathbf{w}^n$ is well defined. The interpolant of $\mathbf{w}_n$, and hence the interpolant of ∇p^n, is also well defined. Thus,

$$\pi_{h_n}\mathbf{w}^n = \pi_{h_n}(\mathbf{w}_n - \nabla p^n) = \mathbf{w}_n - \nabla p_n$$

for some $p_n \in S_{h_n}$. The relation

$$\pi_{h_n} \nabla p = \nabla p_n \quad \text{for some } p_n \in S_{h_n}$$

follows from properties of edge elements (see [23]). Hence, using the fact that $\mathbf{w} \in X_0$ and $\mathbf{w}_n \in X_{0,h_n}$, we have

$$\begin{aligned} \int_\Omega (\mathbf{w} - \mathbf{w}_n) \cdot \overline{(\mathbf{w}^n - \mathbf{w}_n)}\, dV &= \int_\Omega (\mathbf{w} - \mathbf{w}_n) \cdot \overline{(\mathbf{w}^n - \pi_{h_n}\mathbf{w}^n - \nabla p_n)}\, dV \\ &= \int_\Omega (\mathbf{w} - \mathbf{w}_n) \cdot \overline{(\mathbf{w}^n - \pi_{h_n}\mathbf{w}^n)}\, dV \end{aligned}$$

so that

$$\|\mathbf{w}-\mathbf{w}_n\|_{(L^2(\Omega))^3} \le \|\mathbf{w}-\mathbf{w}^n\|_{(L^2(\Omega))^3} + \|\mathbf{w}^n-\pi_{h_n}\mathbf{w}^n\|_{(L^2(\Omega))^3}.$$

Now we can use the estimate (2.4) to conclude (using the fact that $\nabla\times\mathbf{w}^n = \nabla\times\mathbf{w}_n$) that

$$\begin{aligned}\|\mathbf{w}-\mathbf{w}_n\|_{(L^2(\Omega))^3} \le{}& \|\mathbf{w}-\mathbf{w}^n\|_{(L^2(\Omega))^3}\\ &+C\left(h^{1/2+\epsilon}\|\mathbf{w}^n\|_{(H^{1/2+\epsilon}(\Omega))^3} + h\|\nabla\times\mathbf{w}_n\|_{(L^2(\Omega))^3}\right).\end{aligned}$$

Using this estimate, the a priori estimate in Lemma 3.3, and the following inverse estimate for fractional power Sobolev spaces norms of piecewise polynomial functions on quasi-uniform meshes proved in [12]:

$$\|\boldsymbol{\nu}\times\mathbf{w}_n\|_{(H^{\epsilon}(\Sigma))^3} \le Ch^{-\epsilon}\|\boldsymbol{\nu}\times\mathbf{w}_n\|_{(L^2(\Sigma))^3},$$

we have that

$$\|\mathbf{w}-\mathbf{w}_n\|_{(L^2(\Omega))^3} \le \|\mathbf{w}-\mathbf{w}^n\|_{(L^2(\Omega))^3} + Ch^{1/2}\|\mathbf{w}_n\|_X.$$

The first term on the right-hand side tends to zero by construction, and the second term tends to zero since $h_n \to 0$ as $n\to\infty$. Hence we have proved the desired result. ∎

3.6. Error estimates. We can now analyze the operator based problems (3.12) and (3.15) which are to find $\mathbf{E}\in(L^2(\Omega))^3$ and $\mathbf{E}_h\in(L^2(\Omega))^3$ such that

$$\begin{aligned}(I+A)\mathbf{E} &= \mathbf{F},\\ (I+\tilde{A}_h)\tilde{\mathbf{E}}_h &= \mathbf{F}_h,\end{aligned}$$

for $h\in\Lambda$. We have the following theorem.

THEOREM 3.5. *For $h\in\Lambda$ sufficiently small, $(I+\tilde{A}_h)^{-1}$ exists and is uniformly bounded as a map from $(L^2(\Omega))^3$ to $(L^2(\Omega))^3$. The error estimate*

$$\begin{aligned}\|\tilde{\mathbf{E}}_h-\mathbf{E}\|_{(L^2(\Omega))^3} \le c\Big(&\|\mathbf{F}-\mathbf{F}_h\|_{(L^2(\Omega))^3} + \|(A-\tilde{A}_h)\mathbf{F}\|_{(L^2(\Omega))^3}\\ &+\|(A-\tilde{A}_h)A\mathbf{E}\|_{(L^2(\Omega))^3}\Big)\end{aligned}$$

holds with c independent of h, $\mathbf{E}$, and $\mathbf{F}$.

Proof. We start with a slight modification of the proof of Theorem 10.9 of [30]. From that theorem we know that if $h\in\Lambda$ is small enough, then $(I+\tilde{A}_h)$ is invertible with a uniformly bounded inverse as a map from $(L^2(\Omega))^3$ to $(L^2(\Omega))^3$ (because $\{A_h\}_{h\in\Lambda}$ is a collectively compact and pointwise convergent sequence of operators). Thus $\tilde{\mathbf{E}}_h$ is well defined.

Then

$$\mathbf{E}-\tilde{\mathbf{E}}_h = (I+\tilde{A}_h)^{-1}(\mathbf{F}-\mathbf{F}_h) + \left((I+A)^{-1}-(I+\tilde{A}_h)^{-1}\right)\mathbf{F}$$

and the following error estimate follows from the bound on $((I+A)^{-1}-(I+\tilde{A}_h)^{-1})$ in [30]:

$$\begin{aligned}\|\tilde{\mathbf{E}}_h-\mathbf{E}\|_{(L^2(\Omega))^3} \le c\Big(&\|\mathbf{F}-\mathbf{F}_h\|_{(L^2(\Omega))^3} + \|(A-\tilde{A}_h)\mathbf{F}\|_{(L^2(\Omega))^3}\\ &+ \|(A-\tilde{A}_h)A\mathbf{E}\|_{(L^2(\Omega))^3}\Big).\end{aligned} \tag{3.19}$$

∎

THEOREM 3.6. *Provided $h \in \Lambda$ is small enough, the discrete variational problem* (2.7) *has a unique solution $\tilde{\mathbf{E}}_h \in X_h$. Furthermore,*

$$\|\tilde{\mathbf{E}}_h - \mathbf{E}\|_X \le C \left(\inf_{\boldsymbol{\chi}_h \in X_h} \|\mathbf{F} - \boldsymbol{\chi}_h\|_X + \inf_{\boldsymbol{\phi}_h \in X_h} \|A\mathbf{F} - \boldsymbol{\phi}_h\|_X + \inf_{\boldsymbol{\psi}_h \in X_h} \|A\mathbf{E} - \boldsymbol{\psi}_h\|_X \right).$$

In general, $\tilde{\mathbf{E}}_h \to \mathbf{E}$ in X as $h \to 0$.

Proof. From the previous theorem, $\mathbf{E}_h$ is proved to exist uniquely, and it remains to estimate the error in X. From (3.12) and (3.15),

$$\begin{aligned} \|\mathbf{E} - \tilde{\mathbf{E}}_h\|_X &= \|A\mathbf{E} - \tilde{A}_h\tilde{\mathbf{E}}_h + \mathbf{F} - \mathbf{F}_h\|_X \\ &\le \|(A - \tilde{A}_h)\mathbf{E}\|_X + \|\tilde{A}_h(\mathbf{E} - \tilde{\mathbf{E}}_h)\|_X + \|\mathbf{F} - \mathbf{F}_h\|_X. \end{aligned}$$

However, using the definition of $\tilde{A}_h$,

$$\|\tilde{A}_h(\mathbf{E} - \tilde{\mathbf{E}}_h)\|_X \le C\|\mathbf{E} - \tilde{\mathbf{E}}_h\|_{(L^2(\Omega))^3}.$$

Hence, via the previous theorem (and using the fact that the $(L^2(\Omega))^3$ norm is bounded by the X norm),

$$\begin{aligned} \|\mathbf{E} - \tilde{\mathbf{E}}_h\|_X \le C \Big(&\|(A - \tilde{A}_h)\mathbf{E}\|_X + \|\mathbf{F} - \mathbf{F}_h\|_X \\ &+ \|(A - \tilde{A}_h)\mathbf{F}\|_{(L^2(\Omega))^3} + \|(A - \tilde{A}_h)A\mathbf{E}\|_{(L^2(\Omega))^3} \Big). \end{aligned}$$

Since $A\mathbf{E} = \mathbf{F} - \mathbf{E}$, this can be rewritten

$$\|\mathbf{E} - \tilde{\mathbf{E}}_h\|_X \le C \left(\|(A - \tilde{A}_h)\mathbf{E}\|_X + \|\mathbf{F} - \mathbf{F}_h\|_X + \|(A - \tilde{A}_h)\mathbf{F}\|_{(L^2(\Omega))^3} \right).$$

Now we can estimate each term. Via the estimates for the mixed method used previously, we get

$$\|\mathbf{F} - \mathbf{F}_h\|_X \le C \inf_{\boldsymbol{\chi}_h \in X_h} \|\mathbf{F} - \boldsymbol{\chi}_h\|_X.$$

Since $\mathbf{E} \in X_0$, the potential p_h in (3.16) vanishes when $\mathbf{F} = \mathbf{E}$. Therefore,

$$\|(A - \tilde{A}_h)\mathbf{E}\|_X \le C \inf_{\boldsymbol{\phi}_h \in X_h} \|A\mathbf{E} - \boldsymbol{\phi}_h\|_X.$$

In the same way, since $\mathbf{F} \in X_0$,

$$\|(A - \tilde{A}_h)\mathbf{F}\|_X \le C \inf_{\boldsymbol{\xi}_h \in X_h} \|A\mathbf{F} - \boldsymbol{\xi}_h\|_X.$$

The convergence result now follows from a density argument. ∎

This result can be made more specific provided the solution is regular enough. Let

$$\begin{aligned} H^s(\text{curl};\, \Omega) = \big\{ &\mathbf{u} \in (H^s(\Omega))^3 \mid \nabla \times \mathbf{u} \in (H^s(\Omega))^3,\ \boldsymbol{\nu} \times \mathbf{u} \in (H^s(f))^3 \\ &\text{for each face } f \text{ of } \Sigma \big\} \end{aligned}$$

for some $s \ge 0$ with norm

$$\|\mathbf{u}\|^2_{H^s(\text{curl};\, \Omega)} := \|\mathbf{u}\|^2_{H^s(\Omega)} + \|\nabla \times \mathbf{u}\|^2_{H^s(\Omega)} + \sum_{f \in \Sigma} \|\boldsymbol{\nu} \times \mathbf{u}\|^2_{H^s(f)}.$$

Then, the error estimate of Theorem 3.6 can be written as shown below.

COROLLARY 3.7. *If* $\mathbf{F}, A\mathbf{F}, A\mathbf{E} \in H^s(\text{curl};\ \Omega)$ *for some* $s > \frac{1}{2}$, *then*

$$\|\mathbf{E} - \tilde{\mathbf{E}}_h\|_X \leq ch^{\min(s,\ell)},$$

where the norm on X *is given by* (1.6).

Remark 3. For a Lipschitz polyhedral domain, the best we can generally expect is that the above regularity requirements hold for some s with $\frac{1}{2} < s$ but possibly with s less than 1.

4. The fully discrete problem. The discretization we have considered up to this point is not optimal for implementation since $\mathcal{I}^R$ is expensive to compute. We prefer to use (2.6) in place of (2.7). Let us define $A_h : (L^2(\Omega))^3 \to (L^2(\Omega))^3$ such that if $\mathbf{f} \in (L^2(\Omega))^3$, then $A_h\mathbf{f} \in X_{0,h}$ satisfies

$$a(A_h\mathbf{f}, \boldsymbol{\xi}_h) = -2k^2 \int_\Omega \mathbf{f} \cdot \bar{\boldsymbol{\xi}}_h \, dV - \int_\Sigma T(\mathcal{I}_h(\mathbf{f})) \cdot \bar{\boldsymbol{\xi}}_{h,T} \, dA \quad \forall \boldsymbol{\xi}_h \in X_{0,h}. \tag{4.1}$$

Then (2.6) is equivalent to solving

$$(I + A_h)\mathbf{E}_h = \mathbf{F}_h. \tag{4.2}$$

In order to prove convergence we make a specific choice of $\widetilde{\mathbb{G}}_h$. We choose $\widetilde{\mathbb{G}}_h$ to interpolate $\widetilde{\mathbb{G}}$ on Ω (as a function of $\mathbf{y}$). Using this choice we can prove the following lemma.

LEMMA 4.1. *There is a constant* C *such that for any* $\mathbf{u} \in X$,

$$\|(A_h - \tilde{A}_h)\mathbf{u}\|_X \leq Ch^l \|\mathbf{u}\|_X.$$

Proof. By the definition of A_h and $\tilde{A}_h$,

$$a((A_h - \tilde{A}_h)\mathbf{u}, (A_h - \tilde{A}_h)\mathbf{u}) = -\int_\Sigma T(\mathcal{I}_h(\mathbf{u}) - \mathcal{I}^R(\mathbf{u})) \cdot \overline{(A_h - \tilde{A}_h)\mathbf{u}} \, dA.$$

Thus

$$\|(A_h - \tilde{A}_h)\mathbf{u}\|_X \leq C\|T(\mathcal{I}_h(\mathbf{u}) - \mathcal{I}^R(\mathbf{u}))\|_{(L^2(\Sigma))^3}.$$

However, for any derivative D_x with respect to $\mathbf{x}$, for any $\mathbf{x} \in \Sigma$,

$$\begin{aligned} \left|D_x(\mathcal{I}_h(\mathbf{u}) - \mathcal{I}^R(\mathbf{u}))\right| &= \left| \int_\Omega (\nabla \times D_x(\widetilde{\mathbb{G}}_h - \widetilde{\mathbb{G}}))^T \nabla \times \mathbf{u} - k^2 D_x(\widetilde{\mathbb{G}}_h - \widetilde{\mathbb{G}})^T \mathbf{u} \, dV \right| \\ &\leq C\|D_x(\widetilde{\mathbb{G}}_h - \widetilde{\mathbb{G}})\|_X \|\mathbf{u}\|_X. \end{aligned}$$

But since $D_x\mathbb{G}$ is smooth when $\mathbf{x} \neq \mathbf{y}$, and $\widetilde{\mathbb{G}}_h$ interpolates $\widetilde{\mathbb{G}}$, we may use the interpolation estimate (2.3) to show that

$$\|D_x(\widetilde{\mathbb{G}}_h - \widetilde{\mathbb{G}})\|_X \leq Ch^l,$$

and we are done. ∎

Next we verify that $(I + \tilde{A}_h)$ is invertible as a map from X to X.

LEMMA 4.2. *The operator* $(I + \tilde{A}_h)$ *is invertible with a uniformly bounded inverse as a map from* X *to* X.

Proof. We have already seen that this lemma holds with $(L^2(\Omega))^3$ in place of X. Now let $\mathbf{u} \in (L^2(\Omega))^3$ solve

$$\mathbf{u} + \tilde{A}_h \mathbf{u} = \mathbf{F}$$

for some $\mathbf{F} \in X$; then since $\mathbf{u} = \mathbf{F} - \tilde{A}_h \mathbf{u} \in X$,

$$\begin{aligned} \|\mathbf{u}\|_X &\le \|\mathbf{F}\|_X + \|\tilde{A}_h \mathbf{u}\|_X \\ &\le \|\mathbf{F}\|_X + C\|\mathbf{u}\|_{(L^2(\Omega))^3} \\ &\le \|\mathbf{F}\|_X + C\|\mathbf{F}\|_{(L^2(\Omega))^3}. \end{aligned}$$

Thus

$$\|(I + \tilde{A}_h)^{-1}\mathbf{F}\|_X \le C\|\mathbf{F}\|_X,$$

and we are done. ∎

Now we can prove that (4.2) has a unique solution that is close to the solution $\tilde{\mathbf{E}}_h$ of (2.7).

THEOREM 4.3. *Provided h is sufficiently small,* (4.2) (*or equivalently,* (2.6)) *has a unique solution $\mathbf{E}_h \in X_h$, and if $\tilde{\mathbf{E}}_h$ is the solution of* (2.7)*, then*

$$\|\mathbf{E}_h - \tilde{\mathbf{E}}_h\|_X \le Ch^l \|\mathbf{E}_h\|_X.$$

Remark 4. As a result of this theorem we can conclude that $\mathbf{E}_h$ satisfies the error estimates in Theorem 3.6 and Corollary 3.7.

Proof. We have already verified (Lemma 4.2) that $(I + \tilde{A}_h)$ is invertible as a map from X to X and that the inverse is uniformly bounded. Since

$$\mathbf{E}_h + \tilde{A}_h \mathbf{E}_h + (A_h - \tilde{A}_h)\mathbf{E}_h = \mathbf{F}_h,$$

we have

$$(I + C_h)\mathbf{E}_h = (I + \tilde{A}_h)^{-1}\mathbf{F}_h,$$

where $C_h = (I + \tilde{A}_h)^{-1}(A_h - \tilde{A}_h)$ and hence, using Lemma 4.1, $\|C_h\|_{L(X,X)} \le Ch^l < 1$ for h sufficiently small. This implies that $(I + C_h)$ is invertible with bounded inverse in X, and hence $\mathbf{E}_h$ exists.

Furthermore,

$$(I + \tilde{A}_h)(\mathbf{E}_h - \tilde{\mathbf{E}}_h) = (\tilde{A}_h - A_h)\mathbf{E}_h$$

so that by using Lemma 4.1 and the boundedness of $(I + \tilde{A}_h)^{-1}$ we have

$$\|\mathbf{E}_h - \tilde{\mathbf{E}}_h\|_X \le C\|(\tilde{A}_h - A_h)\mathbf{E}_h\|_X \le Ch^l \|\mathbf{E}_h\|_X.$$

Thus we can conclude that Theorem 3.6 holds for $\mathbf{E}_h$. ∎

Now we shall show why (2.6) helps in the discretization of this problem. Let $\{\boldsymbol{\xi}_i\}_{i=1}^{N_h}$ be a basis for X_h. Usually this basis would be constructed using the degrees of freedom (2.2), but other choices are possible [32]. Then we can express $\mathbf{E}_h \in X_h$ as

$$\mathbf{E}_h = \sum_{i=1}^{N_h} E_i \boldsymbol{\xi}_i,$$

and we may write the variational equation (2.6) as a matrix equation. Let $\vec{E} = (E_1, \ldots, E_{N_h})^T$, and let S and L be $N_h \times N_n$ matrices with

$$S_{i,j} = \int_\Omega \nabla \times \boldsymbol{\xi}_j \cdot \nabla \times \bar{\boldsymbol{\xi}}_i - k^2 \boldsymbol{\xi}_j \cdot \bar{\boldsymbol{\xi}}_i \, dV - ik \int_\Sigma \boldsymbol{\xi}_{j,T} \cdot \bar{\boldsymbol{\xi}}_{i,T} \, dA,$$
$$L_{ij} = -\int_\Sigma T(\mathcal{I}_h(\boldsymbol{\xi}_j)) \cdot \bar{\boldsymbol{\xi}}_i \, dA.$$

Let $\vec{F}$ be the vector with

$$F_j = \int_\Sigma T(\mathbf{E}^i) \cdot \bar{\boldsymbol{\xi}}_j \, dA.$$

Then

$$(S + L)\vec{E} = \vec{F}. \tag{4.3}$$

Our analysis guarantees that $S + L$ is invertible for h sufficiently small, but $S + L$ is not particularly well structured from the point of view of numerical linear algebra. It is nondefinite and nonsymmetric.

The matrix S is somewhat better behaved than L. It is sparse and symmetric (but not Hermitian). It corresponds to the standard discretization of an interior boundary value problem for Maxwell's equations and is also invertible for h sufficiently small. In general, S has $O(N_h)$ nonzero entries.

If we choose $\widetilde{\mathbb{G}}_h$ to interpolate zero away from Γ, then $\mathcal{I}_h(\boldsymbol{\xi}_j)$ vanishes when $\boldsymbol{\xi}_j$ is zero on all tetrahedra sharing an edge with Γ. Thus $L_{ij} \neq 0$ only if $\boldsymbol{\xi}_i$ is associated with an edge or face on Σ and if $\boldsymbol{\xi}_j$ is associated with a tetrahedron touching Γ. For a quasi-uniform mesh, we expect $O(N_h^{\frac{2}{3}})$ edges and faces on Σ, and $O(N_h^{\frac{2}{3}})$ tetrahedra to touch Γ. Hence L has $O(N_h^{\frac{4}{3}})$ nonzero entries which is far more than S. Thus L is very expensive to compute and store. This suggests that (4.3) should be solved by an iterative technique (Bi-CGSTAB has worked well for us when applying similar methods to the Helmholtz equation) and then only the action of L needs to be computed. We expect that this can be computed rapidly using the fast multipole method [33] to yield a fast overall solver.

5. Conclusion. We have proved convergence of the combined finite element–integral equation technique under fairly general conditions on the scatterer and the auxiliary boundary. When the domain is well behaved so that the exact solution is regular, we can even obtain optimal order estimates.

The scheme results in a large dense submatrix in the overall matrix for the discrete problem. This suggests the necessity of using the fast multipole scheme to evaluate the integral operator $\mathcal{I}_h(\mathbf{f})$. We are now programming the combined scheme and hope to report numerical results and algorithmic details in the near future.

Appendix. In this appendix, we provide a proof of Lemma 2.1 and an extension theorem for functions defined on a parallelepiped (Lemma A.2). Let $\widetilde{\mathbb{G}}_h(\mathbf{x}, \cdot)$ denote the matrix function such that if $\tilde{\mathbf{g}}_{h,l}(\mathbf{x}, \cdot)$ is the lth column of $\widetilde{\mathbb{G}}_h(\mathbf{x}, \cdot)$ and $\mathbf{g}_l(\mathbf{x}, \cdot)$ is the lth column of $\mathbb{G}(\mathbf{x}, \cdot)$, then

(a) $\tilde{\mathbf{g}}_{h,l}(\mathbf{x}, \cdot) \in V_h, \quad 1 \leq l \leq 3$;
(b) $(\tilde{\mathbf{g}}_{h,l}(\mathbf{x}, \cdot))_T$ interpolates $(\mathbf{g}_l(\mathbf{x}, \cdot))_T$ on Γ (using edge and face freedoms (2.2a) and (2.2b));
(c) $(\tilde{\mathbf{g}}_{h,l}(\mathbf{x}, \cdot))_T = 0$ on all tetrahedra sharing an edge or face with Σ.

LEMMA A.1. *Suppose* (2.6) *has a unique solution for each given* $\widetilde{\mathbb{G}}_h$ *satisfying the properties assumed in section* 2. *Then the solution is independent of the choice of* $\widetilde{\mathbb{G}}_h$.

Proof. Suppose $\mathbf{E}_h^{(i)}$ is the solution of (2.6) corresponding to $\widetilde{\mathbb{G}}_h^{(i)}$, $i = 1, 2$. Let $\mathcal{I}_h^{(i)}$, $i = 1, 2$, denote the operator in (2.5) using $\widetilde{\mathbb{G}}_h^{(i)}$. Since solutions of the finite element formulation (2.6) are unique, it suffices to show that

$$\mathcal{I}_h^{(2)}(\mathbf{E}_h^{(1)}) = \mathcal{I}_h^{(1)}(\mathbf{E}_h^{(1)}).$$

By definition,

$$\begin{aligned}&\left(\mathcal{I}_h^{(2)}(\mathbf{E}_h^{(1)}) - \mathcal{I}_h^{(1)}(\mathbf{E}_h^{(1)})\right)^T \\ &\quad = \int_\Omega \left\{(\nabla \times \mathbf{E}_h^{(1)})^T \nabla \times (\widetilde{\mathbb{G}}_h^{(2)} - \widetilde{\mathbb{G}}_h^{(1)}) - k^2 (\mathbf{E}_h^{(1)})^T (\widetilde{\mathbb{G}}_h^{(2)} - \widetilde{\mathbb{G}}_h^{(1)})\right\} dV.\end{aligned}$$

Now the lth column of $\widetilde{\mathbb{G}}_h^{(2)} - \widetilde{\mathbb{G}}_h^{(1)}$ is

$$(\widetilde{\mathbb{G}}_h^{(2)} - \widetilde{\mathbb{G}}_h^{(1)})_l = \tilde{\mathbf{g}}_{h,l}^{(2)} - \tilde{\mathbf{g}}_{h,l}^{(1)},$$

and since $\mathbf{g}_{h,l}^{(j)}$, $j = 1, 2$, interpolates $\mathbf{g}_l$ on Γ, the tangential component of the difference vanishes there. Hence $\tilde{\mathbf{g}}_{h,l}^{(2)} - \tilde{\mathbf{g}}_{h,l}^{(1)} \in X_h$. Since $(\mathbf{g}_{h,i}^{(2)} - \mathbf{g}_{h,i}^{(1)})_T = 0$ on Σ we have, from the definition of $\mathbf{E}_h^{(1)}$ in (2.6) and using the test function $\boldsymbol{\phi}_h = \overline{(\tilde{\mathbf{g}}_{h,l}^{(2)} - \tilde{\mathbf{g}}_{h,l}^{(1)})}$,

$$\int_\Omega \left\{(\nabla \times \mathbf{E}_h^{(1)}) \cdot \nabla \times (\tilde{\mathbf{g}}_{h,l}^{(2)} - \tilde{\mathbf{g}}_{h,l}^{(1)}) - k^2 \mathbf{E}_h^{(1)} \cdot (\tilde{\mathbf{g}}_{h,l}^{(2)} - \tilde{\mathbf{g}}_{h,l}^{(1)})\right\} dV = 0.$$

This implies $\mathcal{I}_h^{(2)}(\mathbf{E}_h^{(1)}) = \mathcal{I}_h^{(1)}(\mathbf{E}_h^{(1)})$. Thus $\mathbf{E}_h^{(1)}$ satisfies (2.6) with $\mathcal{I}_h = \mathcal{I}_h^{(2)}$. The assumed uniqueness of $\mathbf{E}_h^{(2)}$ then implies $\mathbf{E}_h^{(2)} = \mathbf{E}_h^{(1)}$. ∎

LEMMA A.2. *Suppose* Σ *is the surface of a right parallelepiped, that there is a function* $u \in H^1(\Sigma)$ *such that on each face* f *of* Σ, $u \in H^{1+\epsilon}(\Sigma)$, $0 \le \epsilon < 1/2$, *and that* u *is continuous at the edges of the face of* Σ. *Then there is an extension* $u \in H^{3/2+\epsilon}(P)$, *where* P *denotes the interior of the parallelepiped.*

Remark 5. The proof is similar to that of Theorem 1.5.2.4 of [24].

Proof. By a partition of unity we need only consider the problem in the neighborhood of a corner. Suppose the corner is at $(0, 0, 0)$ and that the planes $x = 0$, $y = 0$, and $z = 0$ meet there. Furthermore, suppose we wish to extend u to the octant $x > 0$, $y > 0$, and $z > 0$.

Let $u = g_1$ on the quarter plane $\{0\} \times \mathbb{R}_+ \times \mathbb{R}_+$, $u = g_2$ on the quarter plane $\mathbb{R}_+ \times \{0\} \times \mathbb{R}_+$, and $u = g_3$ on the quarter plane $\mathbb{R}_+ \times \mathbb{R}_+ \times \{0\}$. We can assume g_1, g_2, and g_3 vanish outside a sphere of radius R around $(0, 0, 0)$ (because of the partition of unity).

Using the standard extension theorem we can extend g_1 to a function $\tilde{g}_1 \in H^{1+\epsilon}(\{0\} \times \mathbb{R} \times \mathbb{R})$. This can then be extended to a function $G_1 \in H^{3/2+\epsilon}(\mathbb{R}^3)$ such that $G_1|_{x=0} = \tilde{g}_1$.

Now consider $v = u - G_1$. Clearly, $v = 0$ on $\{0\} \times \mathbb{R}_+ \times \mathbb{R}_+$, $v = g_2 - G_1$ on $\mathbb{R}_+ \times \{0\} \times \mathbb{R}_+$, and $v = g_3 - G_1$ on $\mathbb{R}_+ \times \mathbb{R}_+ \times \{0\}$. In particular, $v = 0$ on the line

$x = 0$, $z = 0$, $y > 0$. Define a function w by

$$w(x,y) = \begin{cases} v(x,y,0) & \text{if } x > 0, y > 0, \\ -v(-x,y,0) & \text{if } x < 0, y > 0, \\ v(x,-y,0) & \text{if } x > 0, y < 0, \\ -v(-x,-y,0) & \text{if } x < 0, y < 0. \end{cases}$$

Clearly, w is continuous on the whole plane $z = 0$ and is antisymmetric in x. Since it is continuous we can conclude $w \in H^{1+\epsilon}(\mathbb{R} \times \mathbb{R} \times \{0\})$. Using this as Dirichlet data for solving Laplace's equation (with zero data on the hemisphere of radius R in the upper half-space) shows that there is a function $G_2 \in H^{3/2+\epsilon}(\mathbb{R} \times \mathbb{R} \times \mathbb{R}_+)$ such that $v = G_2$ on the plane $z = 0$. The odd symmetry of the data is maintained by the solution and so G_2 vanishes on the plane $x = 0$. Hence if $p = v - G_2$, then we can conclude $p = 0$ on $\{0\} \times \mathbb{R}_+ \times \mathbb{R}_+$, $p = g_2 - G_1 - G_2$ on $\mathbb{R}_+ \times \{0\} \times \mathbb{R}_+$, and $p = 0$ on $\mathbb{R}_+ \times \mathbb{R}_+ \times \{0\}$.

Now we again extend p to the plane $y = 0$ by reflection. Let q be defined for $y = 0$ by

$$q(x,z) = \begin{cases} p(x,0,z) & \text{if } x > 0, z > 0, \\ -p(-x,0,z) & \text{if } x < 0, z > 0, \\ -p(x,0,-z) & \text{if } x > 0, z < 0, \\ p(-x,0,-z) & \text{if } x < 0, z < 0. \end{cases}$$

Now $q \in H^{1+\epsilon}(\mathbb{R} \times \{0\} \times \mathbb{R})$ and is antisymmetric about the lines $y = z = 0$ and $y = x = 0$. Thus, again using this as boundary data for the Dirichlet problem for Laplace's equation (again with zero Dirichlet data on the hemisphere in the appropriate half-space), we can conclude that there is a function G_3 such that $p = G_3|_{y=0}$ and that G_3 vanishes on $x = 0$ and $z = 0$. Thus the function

$$u = G_1 + G_2 + G_3$$

is the required extension with the required smoothness. □

EFFICIENT COMPUTATION OF SENSITIVITIES FOR ORDINARY DIFFERENTIAL EQUATION BOUNDARY VALUE PROBLEMS*

RADU SERBAN† AND LINDA R. PETZOLD‡

Abstract. For models described by ordinary differential equation boundary value problems (ODE BVPs), we derive adjoint equations for sensitivity analysis, giving explicit forms for the boundary conditions of the adjoint boundary value problem. The solutions of the adjoint equations are used to efficiently compute gradients of both integral-form and pointwise constraints. Existence and stability results are given for the adjoint system and its numerical solution. The use of the method is demonstrated for a simple example, where it is seen that the method is particularly advantageous for problems with more than a few parameters.

Key words. sensitivity analysis, ODE boundary value problem, adjoint method

1. Introduction.

Sensitivity analysis generates essential information for design optimization, parameter estimation, optimal control, data assimilation, process sensitivity, and experimental design. Virtually any scientific or engineering problem can take advantage of sensitivity analysis, for example, problems in chemical engineering applications, multibody mechanical systems, structural engineering, materials science, electric and electronic circuit simulation, and weather prediction models.

There is a large body of work on methods and software for forward sensitivity analysis of initial value problems (IVPs) for ordinary differential equation (ODE) systems [16] and differential-algebraic equation (DAE) systems [11, 22]. Recent research [21, 25] has demonstrated that forward sensitivities can be computed reliably and efficiently via automatic differentiation [4] in combination with ODE/DAE/PDE solution techniques designed to exploit the structure of the sensitivity system.

Forward sensitivity analysis has been shown to be very efficient for problems in which the sensitivities of a (potentially) very large number of quantities, with respect to relatively few parameters, are needed. However, for problems where the number of uncertain parameters is large, the forward sensitivity method becomes computationally intractable. The adjoint (reverse) method is advantageous in the complementary situation, where the sensitivities of a few quantities, with respect to a large number of parameters, are needed. Adjoint sensitivity analysis is particularly attractive for boundary value problems (BVPs). In contrast to the situation for IVPs, where the adjoint method requires considerable memory resources above what is required for the solution of the original problem, the solution values required by

the adjoint method for BVPs are naturally available from the solution of the original problem.

Adjoint sensitivity analysis raises a set of entirely new issues ranging from existence of adjoint operators [3, 5, 6, 20] to construction of adjoint models [10, 17, 18], derivation of boundary conditions for the adjoint states [5], and algorithm implementation [13]. Adjoint sensitivity analysis for BVPs has focused mainly on models described by partial differential equations (PDEs). We cite here the work of Cacuci [5, 6] on general sensitivity theory for nonlinear systems, that of Ghione and Filicori on sensitivity of semiconductor devices [12], the work of Giles and Pierce [14] on adjoint equations in computational fluid dynamics, and that of Machiels, Maclay, and Patera [23, 24] on the use of adjoint methods to obtain a posteriori finite element output bounds.

In [5, 6, 26], adjoint operators are constructed for general nonlinear systems, and results are given for solvability of the original and adjoint systems. However, because of the generality of this setting, boundary conditions for the adjoint problem cannot be explicitly constructed. Instead, for each particular example, proper boundary conditions are obtained by imposing the condition that the Lagrange identity is satisfied. For the adjoint equations for inviscid and viscous compressible flow, Giles and Pierce [14] constructed correct boundary conditions for adjoint problems used in evaluating integral-form quantities. In computational fluid dynamics, most quantities of interest are in integral form. However, in other engineering areas, point quantities such as maximum stresses and/or deformations in structural analysis are of major concern. Being able to efficiently compute gradients of such quantities is thus of high interest.

In the present work we derive adjoint equations for sensitivity analysis of models described by ODE BVPs. For a general form ODE BVP, which is assumed to be well conditioned and to have a unique solution, we derive in section 2 adjoint systems for which we explicitly construct proper boundary conditions. Our goals are to demonstrate that the adjoint method offers an efficient means of computing ODE BVP sensitivities, particularly if there are many parameters, and to show how the adjoint method is formulated for ODE BVPs for different classes of derived functions. Thus we derive adjoint equations to efficiently evaluate not only gradients of integral-form quantities, but also (using the Leibnitz integral rule) gradients of pointwise constraints. In section 3 we establish that, for the problems considered here, the adjoint problems are well-posed and inherit the stability of the original system. We show that numerical stability of the midpoint method for the original system implies numerical stability for the adjoint system. In section 4 we illustrate the computation of sensitivities via the adjoint method on a simple example.

2. Derivation of the adjoint BVP. Consider a state vector $\mathbf{x} \in R^N$ that satisfies the BVP depending on parameters $\mathbf{p} \in R^{N_p}$,

$$\begin{aligned} \mathbf{F}(\dot{\mathbf{x}}, \mathbf{x}, \mathbf{p}, t) &= \mathbf{0}, \\ \mathbf{h}(\mathbf{x}(a), \mathbf{x}(b), \mathbf{p}) &= \mathbf{0}, \end{aligned} \tag{1}$$

and the function $g(\mathbf{x}, \mathbf{p}, t)$ whose gradient with respect to $\mathbf{p}$, $dg/d\mathbf{p}$ is to be evaluated at some time $\tau \in [a, b]$. We assume that the Jacobian of $\mathbf{F}$ with respect to the vector $\dot{\mathbf{x}}$ is nonsingular (meaning that (1) represents a system of ODEs and not DAEs) and that $\mathbf{h}$ represents a set of N independent equations. Note that if g also depends on the time derivatives $\dot{\mathbf{x}}$, then the first set of relations (1) can be used to express g as a function of only $\mathbf{x}$, $\mathbf{p}$, and t. We assume also that (1) is well conditioned and has a unique solution.

In section 2.1 we derive the gradient $(dg/d\mathbf{p})$ at $\tau \in (a,b)$. Using the resulting expressions, the particular case of computing $(dg/d\mathbf{p})$ at $\tau = b$ is analyzed in section 2.2.

2.1. Gradients of g between the integration bounds. We start by deriving the gradient $(dg/d\mathbf{p})$ at some $\tau \in (a,b)$. The derivation closely follows the IVP case [7], with differences arising from the definition of proper boundary conditions for the adjoint equations.

First, define the function

$$G^\tau(\mathbf{p}) = \int_a^\tau g(\mathbf{x},\mathbf{p},t)dt.$$

The gradient of G^τ with respect to $\mathbf{p}$ is then simply

$$\frac{dG^\tau}{d\mathbf{p}} = \int_a^\tau \frac{dg}{d\mathbf{p}}(\mathbf{x},\mathbf{p},t)dt = \int_a^\tau \left(g_\mathbf{p} + g_\mathbf{x}\mathbf{x}_\mathbf{p}\right) dt, \tag{2}$$

where subscripts represent partial differentiation. Applying the Leibnitz integral rule we obtain

$$\frac{d}{d\tau}\frac{dG^\tau}{d\mathbf{p}} = \left.\frac{dg}{d\mathbf{p}}\right|_\tau.$$

Thus $(dg/d\mathbf{p})|_\tau$ can be computed as

$$\left.\frac{dg}{d\mathbf{p}}\right|_\tau = \frac{d}{d\tau}\left(\int_a^\tau \left(g_\mathbf{p} + g_\mathbf{x}\mathbf{x}_\mathbf{p}\right) dt\right).$$

The challenge of adjoint sensitivity analysis is now to compute the above quantity without solving for the sensitivities $\mathbf{x}_\mathbf{p}$. To do this, we first form the linear sensitivity problem from the BVP (1),

$$\begin{aligned} \mathbf{F}_{\dot{\mathbf{x}}}\dot{\mathbf{x}}_\mathbf{p} + \mathbf{F}_\mathbf{x}\mathbf{x}_\mathbf{p} + \mathbf{F}_\mathbf{p} &= \mathbf{0}, \\ \mathbf{A}\mathbf{x}_\mathbf{p}(a) + \mathbf{B}\mathbf{x}_\mathbf{p}(b) + \mathbf{h}_\mathbf{p} &= \mathbf{0}, \end{aligned} \tag{3}$$

where $\mathbf{A} = \mathbf{h}_{\mathbf{x}_0}(\mathbf{x}(a),\mathbf{x}(b),\mathbf{p})$ and $\mathbf{B} = \mathbf{h}_{\mathbf{x}_1}(\mathbf{x}(a),\mathbf{x}(b),\mathbf{p})$. Then, for arbitrary $\boldsymbol{\lambda}_1, \boldsymbol{\lambda}_2 \in R^N$, the following holds:

$$0 \equiv \int_a^\tau \boldsymbol{\lambda}_1^* \left(\mathbf{F}_{\dot{\mathbf{x}}}\dot{\mathbf{x}}_\mathbf{p} + \mathbf{F}_\mathbf{x}\mathbf{x}_\mathbf{p} + \mathbf{F}_\mathbf{p}\right) dt + \int_\tau^b \boldsymbol{\lambda}_2^* \left(\mathbf{F}_{\dot{\mathbf{x}}}\dot{\mathbf{x}}_\mathbf{p} + \mathbf{F}_\mathbf{x}\mathbf{x}_\mathbf{p} + \mathbf{F}_\mathbf{p}\right) dt, \tag{4}$$

where * indicates the transposed conjugate. Integrating by parts, the first term in the first integral in the above relation becomes

$$\int_a^\tau \boldsymbol{\lambda}_1^*\mathbf{F}_{\dot{\mathbf{x}}}\dot{\mathbf{x}}_\mathbf{p}dt = \left(\boldsymbol{\lambda}_1^*\mathbf{F}_{\dot{\mathbf{x}}}\mathbf{x}_\mathbf{p}\right)|_a^\tau - \int_a^\tau \left(\dot{\boldsymbol{\lambda}}_1^*\mathbf{F}_{\dot{\mathbf{x}}} + \boldsymbol{\lambda}_1^*\frac{d\mathbf{F}_{\dot{\mathbf{x}}}}{dt}\right)\mathbf{x}_\mathbf{p}dt,$$

where

$$\boldsymbol{\lambda}_1^*\frac{d\mathbf{F}_{\dot{\mathbf{x}}}}{dt} = \left[\left(\frac{d\mathbf{F}_{\dot{\mathbf{x}}}}{dt}\right)^*\boldsymbol{\lambda}_1\right]^* = \left(\mathbf{F}_{\dot{\mathbf{x}}}^*\bar{\boldsymbol{\lambda}}_1\right)_t^* + \left[\left(\mathbf{F}_{\dot{\mathbf{x}}}^*\bar{\boldsymbol{\lambda}}_1\right)_\mathbf{x}\dot{\mathbf{x}}\right]^* + \left[\left(\mathbf{F}_{\dot{\mathbf{x}}}^*\bar{\boldsymbol{\lambda}}_1\right)_{\dot{\mathbf{x}}}\ddot{\mathbf{x}}\right]^*. \tag{5}$$

A bar over a variable indicates that the variable is held fixed for the purpose of the current differentiation. Without loss of generality, we can assume that $\mathbf{F}$ depends

linearly on $\dot{\mathbf{x}}$ and that therefore, the last term in (5) is zero. Indeed, any other case can be reduced to this one by introducing the additional variables $\mathbf{y} = \dot{\mathbf{x}}$. So from now on, we calculate $\boldsymbol{\lambda}_1^* \left(d\mathbf{F}_{\dot{\mathbf{x}}}/dt\right)$ by

$$\boldsymbol{\lambda}_1^* \frac{d\mathbf{F}_{\dot{\mathbf{x}}}}{dt} = \left(\mathbf{F}_{\dot{\mathbf{x}}}^* \bar{\boldsymbol{\lambda}}_1\right)_t^* + \left[\left(\mathbf{F}_{\dot{\mathbf{x}}}^* \bar{\boldsymbol{\lambda}}_1\right)_{\mathbf{x}} \dot{\mathbf{x}}\right]^*.$$

Thus we have from (4) that

$$\begin{aligned} 0 \equiv\ & \left(\boldsymbol{\lambda}_1^* \mathbf{F}_{\dot{\mathbf{x}}} \mathbf{x}_{\mathbf{p}}\right)\big|_a^\tau + \left(\boldsymbol{\lambda}_2^* \mathbf{F}_{\dot{\mathbf{x}}} \mathbf{x}_{\mathbf{p}}\right)\big|_\tau^b - \int_a^\tau \left(\dot{\boldsymbol{\lambda}}_1^* \mathbf{F}_{\dot{\mathbf{x}}} - \boldsymbol{\lambda}_1^* \mathbf{F}_{\mathbf{x}} + \boldsymbol{\lambda}_1^* \frac{d\mathbf{F}_{\dot{\mathbf{x}}}}{dt}\right) \mathbf{x}_{\mathbf{p}} dt \\ & - \int_\tau^b \left(\dot{\boldsymbol{\lambda}}_2^* \mathbf{F}_{\dot{\mathbf{x}}} - \boldsymbol{\lambda}_2^* \mathbf{F}_{\mathbf{x}} + \boldsymbol{\lambda}_2^* \frac{d\mathbf{F}_{\dot{\mathbf{x}}}}{dt}\right) \mathbf{x}_{\mathbf{p}} dt + \int_a^\tau \boldsymbol{\lambda}_1^* \mathbf{F}_{\mathbf{p}} dt + \int_\tau^b \boldsymbol{\lambda}_2^* \mathbf{F}_{\mathbf{p}} dt. \end{aligned} \tag{6}$$

A suitable choice for $\boldsymbol{\lambda}_1$ and $\boldsymbol{\lambda}_2$ to compute $dG^\tau/d\mathbf{p}$ is given by the following.

PROPOSITION 1. *If $\boldsymbol{\lambda}_1$ and $\boldsymbol{\lambda}_2$ satisfy*

$$\begin{gathered} \dot{\boldsymbol{\lambda}}_1^* \mathbf{F}_{\dot{\mathbf{x}}} - \boldsymbol{\lambda}_1^* \left(\mathbf{F}_{\mathbf{x}} - \frac{d\mathbf{F}_{\dot{\mathbf{x}}}}{dt}\right) = g_{\mathbf{x}}, \\ \dot{\boldsymbol{\lambda}}_2^* \mathbf{F}_{\dot{\mathbf{x}}} - \boldsymbol{\lambda}_2^* \left(\mathbf{F}_{\mathbf{x}} - \frac{d\mathbf{F}_{\dot{\mathbf{x}}}}{dt}\right) = \mathbf{0}, \\ \bar{\mathbf{A}} \mathbf{F}_{\dot{\mathbf{x}}}^*(a) \boldsymbol{\lambda}_1(a) + \bar{\mathbf{B}} \mathbf{F}_{\dot{\mathbf{x}}}^*(b) \boldsymbol{\lambda}_2(b) = \mathbf{0}, \\ \boldsymbol{\lambda}_1(\tau) - \boldsymbol{\lambda}_2(\tau) = \mathbf{0}, \end{gathered} \tag{7}$$

where $\bar{\mathbf{A}}$ and $\bar{\mathbf{B}}$ are such that

$$\textit{span} \begin{bmatrix} \bar{\mathbf{A}}^T \\ \bar{\mathbf{B}}^T \end{bmatrix} = \textit{null}\left[-\mathbf{A}|\mathbf{B}\right], \tag{8}$$

that is, the rows of $[\bar{\mathbf{A}}|\bar{\mathbf{B}}]$ span the null space of $[-\mathbf{A}|\mathbf{B}]$, then

$$\frac{dG^\tau}{d\mathbf{p}} = -\boldsymbol{\alpha}^* \mathbf{h}_{\mathbf{p}} + \int_a^\tau \left(g_{\mathbf{p}} + \boldsymbol{\lambda}_1^* \mathbf{F}_{\mathbf{p}}\right) dt + \int_\tau^b \boldsymbol{\lambda}_2^* \mathbf{F}_{\mathbf{p}} dt, \tag{9}$$

where $\boldsymbol{\alpha} = \left(\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*\right)^{-1} \left(-\mathbf{A}(\mathbf{F}_{\dot{\mathbf{x}}}^* \boldsymbol{\lambda}_1)(a) + \mathbf{B}(\mathbf{F}_{\dot{\mathbf{x}}}^* \boldsymbol{\lambda}_2)(b)\right)$.

Proof. First note that the requirement that the boundary conditions in (1) represent N linearly independent equations is equivalent to $[\mathbf{A}|\mathbf{B}]$ (as well as $[-\mathbf{A}|\mathbf{B}]$) having full row rank. As a consequence, the matrix $\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*$ is invertible. The definition (8) of $\bar{\mathbf{A}}$ and $\bar{\mathbf{B}}$ implies that the rows of $[-\mathbf{A}|\mathbf{B}]$ span the null space of $[\bar{\mathbf{A}}|\bar{\mathbf{B}}]$. On the other hand, the third relation in (7) imposes that the vector $[(\mathbf{F}_{\dot{\mathbf{x}}}^* \boldsymbol{\lambda}_1)(a), (\mathbf{F}_{\dot{\mathbf{x}}}^* \boldsymbol{\lambda}_2)(b)]$ is in the null space of $[\bar{\mathbf{A}}|\bar{\mathbf{B}}]$. Therefore, there exists a vector $\boldsymbol{\alpha} \in R^N$ such that

$$\begin{aligned} (\mathbf{F}_{\dot{\mathbf{x}}}^* \boldsymbol{\lambda}_1)(a) &= -\mathbf{A}^* \boldsymbol{\alpha}, \\ (\mathbf{F}_{\dot{\mathbf{x}}}^* \boldsymbol{\lambda}_2)(b) &= \mathbf{B}^* \boldsymbol{\alpha}, \end{aligned} \tag{10}$$

and thus

$$\begin{gathered} \left(\boldsymbol{\lambda}_1^* \mathbf{F}_{\dot{\mathbf{x}}} \mathbf{x}_{\mathbf{p}}\right)\big|_a^\tau + \left(\boldsymbol{\lambda}_2^* \mathbf{F}_{\dot{\mathbf{x}}} \mathbf{x}_{\mathbf{p}}\right)\big|_\tau^b = \left(\boldsymbol{\lambda}_1(\tau) - \boldsymbol{\lambda}_2(\tau)\right)^* \left(\mathbf{F}_{\dot{\mathbf{x}}} \mathbf{x}_{\mathbf{p}}\right)(\tau) \\ - \left(\boldsymbol{\lambda}_1^* \mathbf{F}_{\dot{\mathbf{x}}}\right)(a) \mathbf{x}_{\mathbf{p}}(a) + \left(\boldsymbol{\lambda}_2^* \mathbf{F}_{\dot{\mathbf{x}}}\right)(b) \mathbf{x}_{\mathbf{p}}(b) = \boldsymbol{\alpha}^* \left(\mathbf{A}\mathbf{x}_{\mathbf{p}}(a) + \mathbf{B}\mathbf{x}_{\mathbf{p}}(b)\right) = -\boldsymbol{\alpha}^* \mathbf{h}_{\mathbf{p}}, \end{gathered}$$

where the second relation in (3) and the last relation in (7) have been used. Since $[\mathbf{A}|\mathbf{B}]$ has full row rank, the $N \times N$ matrix $\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*$ is nonsingular, and $\boldsymbol{\alpha}$ can be computed from (10) as

$$\boldsymbol{\alpha} = (\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*)^{-1} \left(-\mathbf{A}(\mathbf{F}^*_{\dot{\mathbf{x}}}\boldsymbol{\lambda}_1)(a) + \mathbf{B}(\mathbf{F}^*_{\dot{\mathbf{x}}}\boldsymbol{\lambda}_2)(b)\right).$$

Substituting this result together with the first two relations of (7) into (6), we have

$$0 = -\boldsymbol{\alpha}^*\mathbf{h}_{\mathbf{p}} - \int_a^\tau g_{\mathbf{x}}\mathbf{x}_{\mathbf{p}}dt + \int_a^\tau \boldsymbol{\lambda}_1^*\mathbf{F}_{\mathbf{p}}dt + \int_\tau^b \boldsymbol{\lambda}_2^*\mathbf{F}_{\mathbf{p}}dt$$

and therefore

$$\frac{dG^\tau}{d\mathbf{p}} = \int_a^\tau \left(g_{\mathbf{p}} + g_{\mathbf{x}}\mathbf{x}_{\mathbf{p}}\right)dt = -\boldsymbol{\alpha}^*\mathbf{h}_{\mathbf{p}} + \int_a^\tau \left(g_{\mathbf{p}} + \boldsymbol{\lambda}_1^*\mathbf{F}_{\mathbf{p}}\right)dt + \int_\tau^b \boldsymbol{\lambda}_2^*\mathbf{F}_{\mathbf{p}}dt. \qquad \square$$

Returning to the problem of computing $dg/d\mathbf{p}$ at τ, by taking the total derivative with respect to τ in (9) we obtain

$$\frac{d}{d\tau}\frac{dG^\tau}{d\mathbf{p}} = \frac{d}{d\tau}\left(-\boldsymbol{\alpha}^*\mathbf{h}_{\mathbf{p}} + \int_a^\tau \left(g_{\mathbf{p}} + \boldsymbol{\lambda}_1^*\mathbf{F}_{\mathbf{p}}\right)dt + \int_\tau^b \boldsymbol{\lambda}_2^*\mathbf{F}_{\mathbf{p}}dt\right)$$

and therefore

$$\left.\frac{dg}{d\mathbf{p}}\right|_\tau = -\boldsymbol{\alpha}_\tau^T\mathbf{h}_{\mathbf{p}} + g_{\mathbf{p}}(\tau) + \int_a^\tau \boldsymbol{\mu}_1^*\mathbf{F}_{\mathbf{p}}dt + \int_\tau^b \boldsymbol{\mu}_2^*\mathbf{F}_{\mathbf{p}}dt, \tag{11}$$

where we have used $\boldsymbol{\lambda}_1(\tau) = \boldsymbol{\lambda}_2(\tau)$. The quantities $\boldsymbol{\mu}_1 = (\boldsymbol{\lambda}_1)_\tau$ and $\boldsymbol{\mu}_2 = (\boldsymbol{\lambda}_2)_\tau$ are the solution of the following sensitivity system, obtained by direct differentiation of (7):

$$\begin{aligned}
\dot{\boldsymbol{\mu}}_1^*\mathbf{F}_{\dot{\mathbf{x}}} - \boldsymbol{\mu}_1^*\left(\mathbf{F}_{\mathbf{x}} - \frac{d\mathbf{F}_{\dot{\mathbf{x}}}}{dt}\right) &= \mathbf{0},\\
\dot{\boldsymbol{\mu}}_2^*\mathbf{F}_{\dot{\mathbf{x}}} - \boldsymbol{\mu}_2^*\left(\mathbf{F}_{\mathbf{x}} - \frac{d\mathbf{F}_{\dot{\mathbf{x}}}}{dt}\right) &= \mathbf{0},\\
\bar{\mathbf{A}}\mathbf{F}^*_{\dot{\mathbf{x}}}(a)\boldsymbol{\mu}_1(a) + \bar{\mathbf{B}}\mathbf{F}^*_{\dot{\mathbf{x}}}(b)\boldsymbol{\mu}_2(b) &= \mathbf{0},\\
\boldsymbol{\mu}_1(\tau) + \dot{\boldsymbol{\lambda}}_1(\tau) - \boldsymbol{\mu}_2(\tau) - \dot{\boldsymbol{\lambda}}_2(\tau) &= \mathbf{0}.
\end{aligned}$$

The last boundary condition is obtained by taking the total derivative with respect to τ of the boundary condition $\boldsymbol{\lambda}_1(\tau) - \boldsymbol{\lambda}_2(\tau) = 0$ and taking into account all dependencies on τ. These can be better seen if $\boldsymbol{\lambda}_1$ and $\boldsymbol{\lambda}_2$ are considered as functions of two arguments, $\boldsymbol{\lambda}_1(t,\tau)$ and $\boldsymbol{\lambda}_2(t,\tau)$. In this case, direct differentiation of

$$\boldsymbol{\lambda}(t,\tau)|_{t=\tau} - \boldsymbol{\lambda}(t,\tau)|_{t=\tau} = \mathbf{0}$$

yields

$$\boldsymbol{\lambda}_{1t}(\tau,\tau) + \boldsymbol{\lambda}_{1\tau}(\tau,\tau) - \boldsymbol{\lambda}_{2t}(\tau,\tau) - \boldsymbol{\lambda}_{2\tau}(\tau,\tau) = 0,$$

that is,

$$\dot{\boldsymbol{\lambda}}_1(\tau) + \boldsymbol{\mu}_1(\tau) - \dot{\boldsymbol{\lambda}}_2(\tau) + \boldsymbol{\mu}_2(\tau) = 0.$$

Note that, upon substitution of $\dot{\boldsymbol{\lambda}}_1(\tau)$ and $\dot{\boldsymbol{\lambda}}_2(\tau)$, this boundary condition can be further simplified to

$$\boldsymbol{\mu}_1(\tau) - \boldsymbol{\mu}_2(\tau) + \left(g_{\mathbf{x}}\mathbf{F}_{\dot{\mathbf{x}}}^{-1}\right)^*(\tau) = \mathbf{0}.$$

The quantity $\boldsymbol{\alpha}_\tau$ is obtained by taking the total derivative of $\boldsymbol{\alpha}$ with respect to τ:

$$\boldsymbol{\alpha}_\tau = \left(\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*\right)^{-1}\left(-\mathbf{A}(\mathbf{F}_{\dot{\mathbf{x}}}^*\boldsymbol{\mu}_1)(a) + \mathbf{B}(\mathbf{F}_{\dot{\mathbf{x}}}^*\boldsymbol{\mu}_2)(b)\right).$$

2.2. Gradients of g at the integration bounds. The gradient of $G^b = \int_a^b g(\mathbf{x},\mathbf{p},t)dt$ can be derived by applying a similar procedure, leading to

$$\frac{dG^b}{d\mathbf{p}} = -\boldsymbol{\alpha}^*\mathbf{h}_{\mathbf{p}} + \int_a^b \left(g_{\mathbf{p}} + \boldsymbol{\lambda}^*\mathbf{f}_{\mathbf{p}}\right)dt, \tag{12}$$

where $\boldsymbol{\lambda}$ is the solution of

$$\dot{\boldsymbol{\lambda}}^*\mathbf{F}_{\dot{\mathbf{x}}} - \boldsymbol{\lambda}^*\left(\mathbf{F}_{\mathbf{x}} - \frac{d\mathbf{F}_{\dot{\mathbf{x}}}}{dt}\right) = g_{\mathbf{x}},$$
$$\bar{\mathbf{A}}\mathbf{F}_{\dot{\mathbf{x}}}^*(a)\boldsymbol{\lambda}(a) + \bar{\mathbf{B}}\mathbf{F}_{\dot{\mathbf{x}}}^*(b)\boldsymbol{\lambda}(b) = \mathbf{0},$$

and $\boldsymbol{\alpha} = \left(\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*\right)^{-1}\left(-\mathbf{A}(\mathbf{F}_{\dot{\mathbf{x}}}^*\boldsymbol{\lambda})(a) + \mathbf{B}(\mathbf{F}_{\dot{\mathbf{x}}}^*\boldsymbol{\lambda})(b)\right)$.

The gradient of g at $t = b$ could, in principle, be obtained as in the previous section by taking the total derivative of (12) with respect to b. Such an approach would be considerably complicated by the fact that g now depends on b implicitly through x. However, if we take

$$\left.\frac{dg}{d\mathbf{p}}\right|_b = \lim_{\tau\to b}\left.\frac{dg}{d\mathbf{p}}\right|_\tau,$$

then these difficulties can be circumvented. Indeed, if we specify $\tau = b$ in (11), we obtain

$$\left.\frac{dg}{d\mathbf{p}}\right|_b = -\boldsymbol{\alpha}_b^*\mathbf{h}_{\mathbf{p}} + g_{\mathbf{p}}(b) + \int_a^b \boldsymbol{\mu}^*\mathbf{F}_{\mathbf{p}}dt, \tag{13}$$

where $\boldsymbol{\mu} = \boldsymbol{\lambda}_b$ is the solution of

$$\dot{\boldsymbol{\mu}}^*\mathbf{F}_{\dot{\mathbf{x}}} - \boldsymbol{\mu}^*\left(\mathbf{F}_{\mathbf{x}} - \frac{d\mathbf{F}_{\dot{\mathbf{x}}}}{dt}\right) = \mathbf{0},$$
$$\bar{\mathbf{A}}\mathbf{F}_{\dot{\mathbf{x}}}^*(a)\boldsymbol{\mu}(a) + \bar{\mathbf{B}}\mathbf{F}_{\dot{\mathbf{x}}}^*(b)\left(\boldsymbol{\mu}(b) + \left(g_{\mathbf{x}}\mathbf{F}_{\dot{\mathbf{x}}}^{-1}\right)^*(b)\right) = \mathbf{0},$$

or, rearranging the boundary condition, is the solution of

$$\dot{\boldsymbol{\mu}}^*\mathbf{F}_{\dot{\mathbf{x}}} - \boldsymbol{\mu}^*\left(\mathbf{F}_{\mathbf{x}} - \frac{d\mathbf{F}_{\dot{\mathbf{x}}}}{dt}\right) = \mathbf{0},$$
$$\bar{\mathbf{A}}\mathbf{F}_{\dot{\mathbf{x}}}^*(a)\boldsymbol{\mu}(a) + \bar{\mathbf{B}}\mathbf{F}_{\dot{\mathbf{x}}}^*(b)\boldsymbol{\mu}(b) = -\bar{\mathbf{B}}g_{\dot{\mathbf{x}}}^*(b).$$

The expression of $\boldsymbol{\alpha}_b$ in (13) can be derived as

$$\boldsymbol{\alpha}_b = \left(\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*\right)^{-1}\left(-\mathbf{A}(\mathbf{F}_{\dot{\mathbf{x}}}^*\boldsymbol{\mu})(a) + \mathbf{B}(\mathbf{F}_{\dot{\mathbf{x}}}^*\boldsymbol{\mu} + g_{\dot{\mathbf{x}}}^*)(b)\right).$$

3. On existence and stability of the adjoint solution. Consider a linear implicit ODE BVP of the form (3), written here as

$$\begin{aligned} \mathbf{M}(t)\dot{\mathbf{x}} + \mathbf{K}(t)\mathbf{x} + \mathbf{q}(t) &= \mathbf{0}, \\ \mathbf{A}\mathbf{x}(a) + \mathbf{B}x(b) + \mathbf{c} &= \mathbf{0}, \end{aligned} \tag{14}$$

whose adjoint BVP can be written as

$$\begin{aligned} \frac{d}{dt}\left(\mathbf{M}^*(t)\boldsymbol{\lambda}\right) - \mathbf{K}^*(t)\boldsymbol{\lambda} + \mathbf{r}(t) &= \mathbf{0}, \\ \bar{\mathbf{A}}\mathbf{M}^*(a)\boldsymbol{\lambda}(a) + \bar{\mathbf{B}}\mathbf{M}^*(b)\boldsymbol{\lambda}(b) &= \mathbf{0}, \end{aligned} \tag{15}$$

where $\bar{\mathbf{A}}$ and $\bar{\mathbf{B}}$ are defined as before.

In this section we investigate the stability of the adjoint system. More precisely, if the original system is stable, will the adjoint system also be stable? If we consider the adjoint system (15), the answer may be negative. Indeed, consider the following IVP example [7]:

$$e^t\dot{x} + \frac{1}{2}e^t x = 0, \tag{16}$$

with some initial condition at $t = a$. This system is equivalent to

$$\dot{x} + \frac{1}{2}x = 0,$$

so it is stable to integration from the left. However, the adjoint system (15) for (16) is

$$e^t\dot{\lambda} - \frac{1}{2}e^t\lambda + e^t\lambda = 0 \quad \Rightarrow \quad \dot{\lambda} + \frac{1}{2}\lambda = 0. \tag{17}$$

Note that the adjoint system must be solved in a backward direction. Thus the adjoint system (17) is unstable.

Denoting $\bar{\boldsymbol{\lambda}}(t) = \mathbf{M}^*(t)\boldsymbol{\lambda}(t)$, we can form the *augmented adjoint system* for (15),

$$\begin{aligned} \dot{\bar{\boldsymbol{\lambda}}} - \mathbf{K}^*(t)\boldsymbol{\lambda} + \mathbf{r}(t) &= \mathbf{0}, \\ \bar{\boldsymbol{\lambda}} - \mathbf{M}^*(t)\boldsymbol{\lambda} &= \mathbf{0}, \\ \bar{\mathbf{A}}\mathbf{M}^*(a)\boldsymbol{\lambda}(a) + \bar{\mathbf{B}}\mathbf{M}^*(b)\boldsymbol{\lambda}(b) &= \mathbf{0}. \end{aligned} \tag{18}$$

If, instead of (17), we solve the augmented adjoint system (18), then $\bar{\boldsymbol{\lambda}}$ satisfies

$$\dot{\bar{\boldsymbol{\lambda}}} - \frac{1}{2}\bar{\boldsymbol{\lambda}} = 0,$$

which is stable to integration from the right. We will show that, in general, if the original system (14) is stable, then the augmented adjoint system (18) for $\bar{\boldsymbol{\lambda}}$ is stable. First, note that since $\mathbf{M}$ is nonsingular, $\bar{\boldsymbol{\lambda}}$ satisfies

$$\begin{aligned} \dot{\bar{\boldsymbol{\lambda}}} - \mathbf{K}^*(t)\left(\mathbf{M}^*(t)\right)^{-1}\bar{\boldsymbol{\lambda}} + \mathbf{r}(t) &= \mathbf{0}, \\ \bar{\mathbf{A}}\bar{\boldsymbol{\lambda}}(a) + \bar{\mathbf{B}}\bar{\boldsymbol{\lambda}}(b) &= \mathbf{0}. \end{aligned}$$

In other words, for the implicit ODE BVP, the augmented adjoint system for $\bar{\boldsymbol{\lambda}}$ is the same as the adjoint system of the explicit ODE BVP equivalent to the original

system (14). Therefore it is sufficient to investigate stability of the adjoint system for the explicit ODE BVP,

$$\begin{aligned} \dot{\mathbf{x}} &= \mathbf{C}(t)\mathbf{x} + \mathbf{q}(t), \\ \mathbf{A}\mathbf{x}(a) + \mathbf{B}x(b) &= \mathbf{c}, \end{aligned} \tag{19}$$

whose adjoint BVP can be written as

$$\begin{aligned} \dot{\boldsymbol{\lambda}} &= -\mathbf{C}^*(t)\boldsymbol{\lambda} + \mathbf{r}(t), \\ \bar{\mathbf{A}}\boldsymbol{\lambda}(a) + \bar{\mathbf{B}}\boldsymbol{\lambda}(b) &= \mathbf{0}. \end{aligned} \tag{20}$$

We begin by deriving the relationship between fundamental solutions of these two problems. This is given by the following.

LEMMA 1. *Let* $\mathbf{X}$ *and* $\boldsymbol{\Lambda}$ *be any fundamental solutions of* (19) *and* (20), *respectively. Then, for any* $t, s \in [a, b]$, $\boldsymbol{\Lambda}^*(t)\mathbf{X}(t) = \boldsymbol{\Lambda}^*(s)\mathbf{X}(s)$.

Proof. Consider $\mathbf{Z}(t) = \boldsymbol{\Lambda}^*(t)\mathbf{X}(t)$. Then

$$\dot{\mathbf{Z}} = \dot{\boldsymbol{\Lambda}}^*(t)\mathbf{X}(t) + \boldsymbol{\Lambda}^*(t)\dot{\mathbf{X}}(t) = \left(-\mathbf{C}^*(t)\boldsymbol{\Lambda}(t)\right)^* \mathbf{X}(t) + \boldsymbol{\Lambda}^*(t)\left(\mathbf{C}(t)\mathbf{X}(t)\right) = \mathbf{0}.$$

Therefore $\boldsymbol{\Lambda}^*(t)\mathbf{X}(t) = \boldsymbol{\Lambda}^*(s)\mathbf{X}(s)$ for all $t, s \in [a, b]$; in particular, $\boldsymbol{\Lambda}^*(t)\mathbf{X}(t) = \boldsymbol{\Lambda}^*(a)\mathbf{X}(a) = \boldsymbol{\Lambda}^*(b)\mathbf{X}(b)$ for any $t \in [a, b]$. ∎

As a direct consequence of Lemma 1, $\|\boldsymbol{\Lambda}(t)\boldsymbol{\Lambda}^{-1}(s)\| = \|\mathbf{X}(s)\mathbf{X}^{-1}(t)\|$ for all $s \geq t$. This proves the following.

THEOREM 1. *The adjoint system* (20) *of an (asymptotically) stable linear ODE IVP* (19) *is (asymptotically) stable.*

We now concentrate on the ODE BVP. We first show the following.

THEOREM 2. *If the BVP* (19) *has a unique solution, then a solution for the adjoint BVP* (20) *exists and is unique.*

Proof. Consider the fundamental solution $\mathbf{X}(t)$ of the homogeneous equivalent of (19) which satisfies $\mathbf{X}(a) = \mathbf{I}$. Then the matrix $\mathbf{Q} = \mathbf{A} + \mathbf{B}\mathbf{X}(b)$ is nonsingular [2]. Similarly, let $\boldsymbol{\Lambda}(t)$ be the fundamental solution of the homogeneous equivalent of (20), which satisfies $\boldsymbol{\Lambda}(b) = \mathbf{I}$, and construct the matrix $\bar{\mathbf{Q}} = \bar{\mathbf{A}}\boldsymbol{\lambda}(a) + \bar{\mathbf{B}}$. From Lemma 1 we have that $\boldsymbol{\Lambda}(a) = \mathbf{X}^*(b)$. Then

$$\mathbf{Q}\bar{\mathbf{A}}^* = \mathbf{A}\bar{\mathbf{A}}^* + \mathbf{B}\mathbf{X}(b)\bar{\mathbf{A}}^* = \mathbf{B}\bar{\mathbf{B}}^* + \mathbf{B}\boldsymbol{\Lambda}^*(a)\bar{\mathbf{A}}^* = \mathbf{B}\bar{\mathbf{Q}}^*$$

and

$$\begin{aligned} \mathbf{Q}\mathbf{X}^{-1}(b)\bar{\mathbf{B}}^* &= \mathbf{A}\mathbf{X}^{-1}(b)\bar{\mathbf{B}}^* + \mathbf{B}\bar{\mathbf{B}}^* = \mathbf{A}\left(\boldsymbol{\Lambda}^*(a)\right)^{-1}\bar{\mathbf{B}}^* + \mathbf{A}\bar{\mathbf{A}}^* \\ &= \mathbf{A}\left(\boldsymbol{\Lambda}^*(a)\right)^{-1}\bar{\mathbf{Q}}^* = \mathbf{A}\mathbf{X}^{-1}(b)\bar{\mathbf{Q}}^*, \end{aligned}$$

where we have used $\mathbf{A}\bar{\mathbf{A}}^* = \mathbf{B}\bar{\mathbf{B}}^*$. Since $\mathbf{Q}$ is invertible, we can write

$$\begin{aligned} \bar{\mathbf{A}}^* &= \mathbf{Q}^{-1}\mathbf{B}\bar{\mathbf{Q}}^*, \\ \bar{\mathbf{B}}^* &= \mathbf{X}(b)\mathbf{Q}^{-1}\mathbf{A}\mathbf{X}^{-1}(b)\bar{\mathbf{Q}}^*. \end{aligned}$$

Thus

$$\begin{bmatrix} \bar{\mathbf{A}}^* \\ \bar{\mathbf{B}}^* \end{bmatrix} = \begin{bmatrix} \mathbf{Q}^{-1}\mathbf{B} \\ \mathbf{X}(b)\mathbf{Q}^{-1}\mathbf{A}\mathbf{X}^{-1}(b) \end{bmatrix} \bar{\mathbf{Q}}^*.$$

Since $[\bar{\mathbf{A}}|\bar{\mathbf{B}}]$ has full row rank, it follows that $\bar{\mathbf{Q}}^*$ has full rank. Therefore, $\bar{\mathbf{Q}}$ is invertible and (20) has a unique solution. ∎

Stability results for the adjoint problem are given by the following [9].

THEOREM 3. *If the BVP* (19) *is well conditioned, then its adjoint BVP* (20) *is well conditioned.*

We now consider numerical stability for the adjoint system. As a consequence of Theorem 3, zero-stability (i.e., stability as the stepsize $h \to 0$ and the number of steps $n \to \infty$) for the adjoint BVP (20) is inherited from zero-stability of the original BVP (19). Here we are concerned with the question of whether a numerical method which is stable for the original system (19) on the mesh

$$\pi : a = t_0 < t_1 < \cdots < t_{N-1} < t_N = b$$

is also stable for the adjoint system (20). We consider the midpoint method for which we show the following.

THEOREM 4. *Numerical stability of the midpoint method for the original system on some mesh π implies numerical stability for the adjoint system on the same mesh.*

Proof. Discretizing the original system (19) with the midpoint rule, we obtain

$$\begin{aligned} \frac{\mathbf{x}_n - \mathbf{x}_{n-1}}{h_n} &= \mathbf{C}(t_{n-1/2})\frac{\mathbf{x}_n + \mathbf{x}_{n-1}}{2} + \mathbf{q}(t_{n-1/2}), \qquad n = 1, \ldots, N, \\ \mathbf{A}\mathbf{x}_0 + \mathbf{B}\mathbf{x}_N &= -\mathbf{c}, \end{aligned} \tag{21}$$

where $h_n = t_n - t_{n-1}$. The first N relations in (21) can be written as

$$-\mathbf{S}_n\mathbf{x}_{n-1} + \mathbf{R}_n\mathbf{x}_n = \mathbf{q}(t_{n-1/2}), \qquad n = 1, \ldots, N,$$

where

$$\begin{aligned} \mathbf{S}_n &= \frac{1}{h_n}\mathbf{I} + \frac{1}{2}\mathbf{C}(t_{n-1/2}), \\ \mathbf{R}_n &= \frac{1}{h_n}\mathbf{I} - \frac{1}{2}\mathbf{C}(t_{n-1/2}). \end{aligned}$$

Thus we have that $[\mathbf{x}_0^*; \mathbf{x}_N^*]$ is the solution of a linear system of the form

$$\begin{bmatrix} \mathbf{P} & -\mathbf{I} \\ \mathbf{A} & \mathbf{B} \end{bmatrix} \begin{bmatrix} \mathbf{x}_0 \\ \mathbf{x}_N \end{bmatrix} = \begin{bmatrix} \hat{\mathbf{q}} \\ -\mathbf{c} \end{bmatrix} \tag{22}$$

for some right-hand side $\hat{\mathbf{q}}$, where $\mathbf{P} = \mathbf{R}_N^{-1}\mathbf{S}_N\mathbf{R}_{N-1}^{-1}\mathbf{S}_{N-1}\cdots\mathbf{R}_1^{-1}\mathbf{S}_1$.

The midpoint method applied to the adjoint problem (20) yields the linear equations

$$\mathbf{S}_n^*\boldsymbol{\lambda}_n - \mathbf{R}_n^*\boldsymbol{\lambda}_{n-1} = \mathbf{r}(t_{n-1/2}), \qquad n = 1, \ldots, N.$$

Since $\mathbf{S}_n$ and $\mathbf{R}_n^{-1}$ commute, it follows that $[\boldsymbol{\lambda}_N^*; \boldsymbol{\lambda}_0^*]$ is the solution of a linear system

$$\begin{bmatrix} \mathbf{P}^* & -\mathbf{I} \\ \bar{\mathbf{B}} & \bar{\mathbf{A}} \end{bmatrix} \begin{bmatrix} \boldsymbol{\lambda}_N \\ \boldsymbol{\lambda}_0 \end{bmatrix} = \begin{bmatrix} \hat{\mathbf{r}} \\ \mathbf{0} \end{bmatrix} \tag{23}$$

for some right-hand side $\hat{\mathbf{r}}$. We show next that with $\bar{\mathbf{A}}$ and $\bar{\mathbf{B}}$ defined by (8), solving linear system (23) is equivalent to solving linear system (22). Indeed, system (22) can be solved as

$$\begin{aligned}(\mathbf{A}+\mathbf{BP})\mathbf{x}_0 &= \mathbf{B}\hat{\mathbf{q}}-\mathbf{c},\\ \mathbf{x}_N &= \mathbf{P}\mathbf{x}_0-\hat{\mathbf{q}}.\end{aligned}$$

On the other hand, by construction, there exists a vector $\boldsymbol{\alpha}$ defined as in (10). Thus system (23) can be solved as

$$\begin{aligned}(\mathbf{P}^*\mathbf{B}^*+\mathbf{A}^*)\boldsymbol{\alpha} &= \hat{\mathbf{r}},\\ \boldsymbol{\lambda}_0 &= -\mathbf{A}^*\boldsymbol{\alpha},\\ \boldsymbol{\lambda}_N &= \mathbf{B}^*\boldsymbol{\alpha}.\end{aligned}$$

Noting that $\|(\mathbf{P}^*\mathbf{B}^*+\mathbf{A}^*)^{-1}\| = \|(\mathbf{A}+\mathbf{BP})^{-1}\|$, this concludes the proof. ∎

4. Numerical example. As an example we consider the following ODE BVP:

$$\begin{aligned}(J+ml^2)\ddot{\theta} &= u(t)-mgl\cos(\theta),\\ \theta(a) &= \theta_0,\\ \theta(b) &= \theta_1,\end{aligned} \tag{24}$$

which describes the motion of a 2-D pendulum of length $2l$, mass m, and inertia J under the action of gravity (g) and a time varying applied torque $u(t)$. The position of the pendulum is imposed at the initial and final times. Considering the torque $u(t)$ parameterized by $p \in R^{N_p}$, we wish to estimate the sensitivity with respect to p of the energy $g(\theta,\dot{\theta},p,t) = \frac{1}{2}(J+ml^2)\dot{\theta}^2 + mgl\sin(\theta)$ at some time $t \in (a,b)$, as well as the sensitivity of the total energy $G^\tau(p) = \int_a^\tau g(\theta,\dot{\theta},p,t)dt$ over the interval $[a,\tau]$.

As an alternative to using adjoint sensitivity analysis for the solution of these problems, one could generate the sensitivity ODE BVP systems (3) by the following forward method: For each of the parameters p_i, compute the sensitivities of the trajectories $(\theta(t),\dot{\theta}(t))$ and then, using the chain rule of differentiation, evaluate the gradients of g and G^τ. However, such an approach is computationally expensive, especially if the dimension N_p of the parameterization of $u(t)$ is very large.

We first transform (24) into a first order ODE BVP:

$$\begin{aligned}\dot{x}_1 &= x_2,\\ \dot{x}_2 &= \frac{1}{J+ml^2}\left(u(t)-mgl\cos(x_1)\right),\\ x_1(a) &= \theta_0,\\ x_1(b) &= \theta_1,\end{aligned} \tag{25}$$

in which case

$$g(x,p,t) = \frac{1}{2}(J+ml^2)x_2^2 + mgl\sin(x_1) \tag{26}$$

and

$$G^\tau(p) = \int_a^\tau \left(\frac{1}{2}(J+ml^2)x_2^2 + mgl\sin(x_1)\right)dt. \tag{27}$$

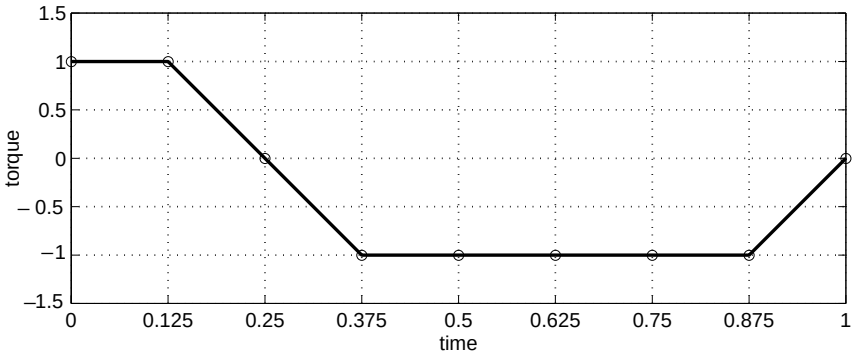

FIG. 1. *Torque $u(t)$ for the pendulum example ($N = 8$, $N_p = 9$).*

Consider a piecewise linear approximation of u given by

$$u(t) = -p_k \frac{t - k\Delta t}{\Delta t} + p_{k+1} \frac{t - (k-1)\Delta t}{\Delta t}; \tag{28}$$
$$(k-1)\Delta t \le t \le k\Delta t, \qquad k = 1, 2, \ldots, N,$$

where $\Delta t = (b-a)/N$. This gives $N_p = N + 1$ parameters p. Let $N = 8$ and let u be as in Figure 1. For $a = 0$, $b = 1$, $\theta_0 = 0$, $\theta_1 = 0$, $\tau = 0.25$, and $m = g = l = J = 1$, we compare gradients of g and G^τ at both $\tau \in (a, b)$ and $\tau = b$ obtained by the adjoint sensitivity analysis presented in the previous sections with gradients computed through forward sensitivity analysis. Differences in gradients computed with the two methods are summarized in Table 1.

TABLE 1

6	$1.875241 \cdot 10^{-05}$	$-8.563900 \cdot 10^{-11}$
7	$1.879674 \cdot 10^{-05}$	$-7.838902 \cdot 10^{-11}$
8	$1.893979 \cdot 10^{-05}$	$-4.928702 \cdot 10^{-11}$
9	$9.530949 \cdot 10^{-06}$	$-1.530841 \cdot 10^{-06}$

All ODE BVPs involved in both adjoint and forward computations were numerically solved with COLSYS [1]. We note that the version of COLSYS that we used has a limit of 20 on the number of differential equations, thus limiting the number of parameters that we could include for the forward sensitivity system to $N_p = 9$. Of course, when using the adjoint approach this is not an issue, as only one additional BVP of the same size as the original problem must be solved to evaluate gradients with respect to an array of parameters of any size. The other obvious advantage of using adjoint sensitivity versus forward sensitivity is, of course, computational efficiency. Indeed, solution of the BVP (original + adjoint) required by the adjoint approach was 15 times faster than solution of the BVP (original + N_p forward sensitivities) required by the forward approach. In all fairness, we must note that a careful implementation of forward sensitivity analysis (which takes advantage of the special structure of the sensitivity systems and the fact that they share the same Jacobian matrices with the original BVP) will lead to a speedup of only about $(1 + N_p)/(1 + 1) = 5$. Since COLSYS does not provide a sensitivity analysis capability, the overhead computations (especially in the linear algebra) explain the much higher speedup obtained.

AUGMENTED LAGRANGE-SQP METHODS WITH LIPSCHITZ-CONTINUOUS LAGRANGE MULTIPLIER UPDATES*

E. SACHS† AND S. VOLKWEIN‡

Abstract. Augmented Lagrangian-SQP methods using Lipschitz-continuous Lagrange multiplier updates are analyzed. Kantorovich-style convergence results are proved and applied to the discretization of optimal control problems. The existence of stationary points for the discretized problems is also discussed.

Key words. nonlinear programming, multiplier methods, Lipschitz-continuous multiplier methods, Burgers equation

1. Introduction.

This paper is concerned with an optimization problem of the following type:

$$\text{minimize } J(x) \text{ subject to } e(x) = 0, \tag{1.1}$$

where $J : X \to \mathbb{R}$ and $e : X \to Y$ are sufficiently smooth functions and X, Y are real Hilbert spaces. These types of problems occur, for example, in the optimal control of systems described by partial differential equations. In many applications (1.1) is solved by variants of SQP methods. The principal idea of these algorithms is to replace J and e by a quadratic approximation of the Lagrangian and a linearization of the constraint. The resulting augmented Lagrangian-SQP method is as follows [GMW81, pp. 225–233].

ALGORITHM 1.

(a) *Choose* $(x^0, \lambda^0) \in X \times Y$, $c \geq 0$, *and set* $n = 0$.

(b) *Solve the following quadratic minimization problem for* s:

$$\text{(QP)} \quad \min L_c'(x^n, \lambda^n)s + \frac{1}{2} L_c''(x^n, \lambda^n)(s, s) \text{ subject to } e'(x^n)s + e(x^n) = 0,$$

where L_c *denotes the augmented Lagrangian*

$$L_c(x, \lambda) = J(x) + \langle e(x), \lambda \rangle_Y + \frac{c}{2} \|e(x)\|_Y^2 \quad \text{for } c \geq 0. \tag{1.2}$$

(c) *Set* $x^{n+1} = x^n + s$, $\lambda^{n+1} = \Lambda(x^n, \lambda^n)$, *and go back to step* (b).

The parameter c is called the augmentation or penalty parameter. Versions of the augmented Lagrangian-SQP methods differ in the choice of the multiplier update $\Lambda(x, \lambda)$. We refer the reader to [FST87] for a review of multiplier updates in finite

dimensions. It is well known that different multiplier updates lead to different rates of convergence. If Λ is the Newton multiplier update, i.e.,

$$\Lambda_N(x,\lambda) = \left(e'(x)L_c''(x,\lambda)^{-1}e'(x)^\star\right)^{-1}\left(e(x) - e'(x)L_c''(x,\lambda)^{-1}L_c'(x,\lambda)\right), \tag{1.3}$$

then Algorithm 1 coincides with the augmented Lagrangian Newton-SQP method. This method was analyzed by Ito and Kunisch in [IK96]. In this paper we consider Lipschitz-continuous update formulas for the Lagrange multiplier that depend only on the x-variable. We assume that $\lambda^n = \Lambda(x^n)$, where $\lambda : X \to Y$ satisfies

$$\|\Lambda(x) - \Lambda(\bar{x})\|_Y \le \gamma_\Lambda \|x - \bar{x}\|_X \tag{1.4}$$

for all $x, \bar{x}$ in an appropriate neighborhood of the starting point and a constant $\gamma_\Lambda \ge 0$ such that as an example, consider the least-squares multipliers [Kle97], i.e., the solution of

$$\text{minimize } \|J'(x^{n+1}) + e'(x^{n+1})^\star\lambda\|_X \text{ over } \lambda \in Y.$$

The least-squares solution is given by

$$\lambda^{n+1} = -\left(e'(x^{n+1})e'(x^{n+1})^\star\right)^{-1} e'(x^{n+1})J'(x^{n+1}), \tag{1.5}$$

where $e'(x^{n+1})^\star$ denotes the adjoint of the operator $e'(x^{n+1})$. Another example is given by the update of Kunisch and Sachs in [KS92]. Note that, in contrast, the Newton multiplier update (1.3) does not generally satisfy the Lipschitz continuity condition (1.4).

In this paper we prove convergence results using the Kantorovich theory. As is well known, the advantage of this theory is that the existence of a stationary point is not required. This is particularly useful in the case of discretized infinite-dimensional optimization problems arising in optimal control. In addition to proving that the iterates converge, we show that stationary points for the discretized problem exist. In [KV97] and [Vol00a] the convergence of the augmented Lagrangian-SQP method is considered in terms of the pair (x, λ). In this paper we sharpen the convergence statement by considering only the variable x. This requires the definition of a new fixed point map in order to prove contraction properties only for x. This approach is presented for Lipschitz-continuous multiplier updates. We keep the update rule as general as possible and impose additional assumptions such as $\Lambda(x^*) = \lambda^*$ at a later stage.

The paper is organized as follows. In section 2 an example of a constrained optimal control problem is presented. In the next section the augmented Lagrangian-SQP method is formulated with a Lipschitz-continuous update. We prove under certain conditions that the first-order necessary optimality conditions for (1.1) have a solution x^*. Therefore, we need not assume that $\Lambda(x^*) = \lambda^*$, where λ^* is the Lagrange multiplier associated with x^*. In section 4 these results are applied to discretized problems. If the infinite-dimensional first-order necessary optimality conditions have a solution, it can be shown that the discretized optimality conditions also have a solution. Finally, a numerical example is presented in section 5.

We introduce some notation that will be used throughout the paper. Let $(V, \|\cdot\|_V)$ and $(W, \|\cdot\|_W)$ be normed linear spaces. The set $B(v; r)$ denotes an open ball of radius $r > 0$ centered at the point $x \in X$. By $\mathcal{L}(V, W)$ we denote the normed linear space of all bounded linear operators from V into W and write $\mathcal{L}(V) = \mathcal{L}(V, V)$. By $\langle \cdot, \cdot \rangle_{V',V}$

we denote the dual pair associated with V and its dual. For $\mathcal{A} \in \mathcal{L}(V,W)$ the set $N(\mathcal{A}) = \{v \in V : \mathcal{A}(v) = 0\}$ denotes the null space of $\mathcal{A}$. Let X and Y be two real Hilbert spaces with inner products $\langle \cdot\,, \cdot \rangle_X$ and $\langle \cdot\,, \cdot \rangle_Y$, respectively, and $\mathcal{A} \in \mathcal{L}(X,Y)$. The (Hilbert space) adjoint $\mathcal{A}^\star \in \mathcal{L}(Y,X)$ of $\mathcal{A}$ is defined by

$$\langle \mathcal{A}^\star(\lambda), x \rangle_X = \langle \lambda, \mathcal{A}(x) \rangle_Y \quad \text{for all } x \in X, \lambda \in Y.$$

2. Formulation of the problem. Let us consider the following constrained optimal control problem:

$$\text{(P)} \qquad \text{minimize } J(x) \text{ subject to } e(x) = 0,$$

where $J : X \to \mathbb{R}$, $e : X \to Y$, and X, Y are real Hilbert spaces. Note that we do not distinguish between a functional in the dual space and its Riesz representation in the Hilbert space. The Hilbert space $X \times Y$ is endowed with the Hilbert space product topology. The Fréchet-derivatives with respect to the variable x are denoted by primes. We start with an example that motivates the material of later sections. We also refer to [KV97] and [Vol00a], where further examples were presented.

Example 2.1. Let $\Omega = (0,1) \subset \mathbb{R}$, $\Omega_\circ \subseteq \Omega$ with positive measure, and $f \in H^{-1}(\Omega)$. For a control $u \in L^2(\Omega_\circ)$ the state $y \in H_0^1(\Omega)$ is given by the variational solution of the steady-state Burgers equation

$$-\nu y'' + yy' = f + \mathcal{E}(u) \quad \text{in } H^{-1}(\Omega), \tag{2.1}$$

where $\mathcal{E} \in \mathcal{L}(L^2(\Omega_\circ), H^{-1}(\Omega))$ is the extension operator

$$\mathcal{E}(u) = \langle u, \cdot \rangle_{L^2(\Omega_\circ)}. \tag{2.2}$$

Equation (2.1) is a second-order approximation to the one-dimensional steady-state Navier–Stokes equations [Lig56]. In the general case $f \in H^{-1}(\Omega)$ would be a force density, y a velocity field, and $\nu > 0$ a viscosity parameter. Note that for $u \in L^2(\Omega_\circ)$, $\mathcal{E}(u)$ belongs to $L^2(\Omega_\circ)'$, which can be identified with $L^2(\Omega_\circ)$. We equip $H_0^1(\Omega)$ with the inner product

$$\langle \varphi, \psi \rangle_{H_0^1} = \int_\Omega \varphi' \psi' \, dx \quad \text{for } \varphi, \psi \in H_0^1(\Omega).$$

It is proved in [Vol00b] that for all $u \in L^2(\Omega_\circ)$ there exists at least one $y \in H_0^1(\Omega)$ satisfying

$$\int_\Omega \nu y' \varphi' + yy' \varphi \, dx = \langle f + \mathcal{E}(u), \varphi \rangle_{H^{-1}, H_0^1} \quad \text{for all } \varphi \in H_0^1(\Omega),$$

i.e., (2.1) has at least one variational solution. The cost function is of the tracking type:

$$J(y,u) = \frac{1}{2} \int_\Omega |y - z|^2 \, dt + \frac{\alpha}{2} \int_{\Omega_\circ} |u|^2 \, dt,$$

where $z \in L^2(\Omega)$ denotes a desired state and $\alpha > 0$ is fixed. We introduce the nonlinear operator $e = H_0^1(\Omega) \times L^2(\Omega_\circ) \to H_0^1(\Omega)$ such that

$$e(y,u) = (-\Delta)^{-1}\big(-\nu y'' + yy' - f - \mathcal{E}(u) \big),$$

where Δ is the Laplace operator from $H_0^1(\Omega)$ to $H^{-1}(\Omega)$; i.e., for $\tilde{f} \in H^{-1}(\Omega)$ $v = (-\Delta)^{-1}(\tilde{f})$ solves

$$\int_\Omega v'\varphi'\,dt = \langle \tilde{f}, \varphi \rangle_{H^{-1},H_0^1} \quad \text{for all } \varphi \in H_0^1(\Omega).$$

The resulting optimal control problem is of the form (P) with $X = H_0^1(\Omega) \times L^2(\Omega_\circ)$ and $Y = H_0^1(\Omega)$.

For SQP methods in Hilbert spaces the following smoothness assumptions are imposed on J and e.

Assumption 1. J and e are twice continuously Fréchet-differentiable, and the mappings J'' and e'' are Lipschitz-continuous in a neighborhood $U(x^0)$ of some given point $x^0 \in X$.

Remark 2.2. In Example 2.1 both J and e are twice continuously Fréchet-differentiable in $X = H_0^1(\Omega) \times L^2(\Omega_\circ)$. In particular, for $(y,u) \in X$ we have

$$\begin{aligned}
J'(y,u) &= \begin{pmatrix} (-\Delta)^{-1}\big(\langle y - z, \cdot\rangle_{L^2}\big) \\ \alpha u \end{pmatrix} \in X, \\
J''(y,u)(v,q) &= \begin{pmatrix} (-\Delta)^{-1}\big(\langle v, \cdot\rangle_{L^2}\big) \\ \alpha q \end{pmatrix} \in X, \\
e'(y,u)(v,q) &= (-\Delta)^{-1}\big(-\nu v'' + (yv)' - \mathcal{E}(q)\big) \in Y, \\
e''(y,u)(v,q)(w,p) &= (-\Delta)^{-1}\big(\langle (vw)', \cdot\rangle_{L^2}\big) \in Y
\end{aligned} \tag{2.3}$$

for $(v,q),(w,p) \in X$. Since the second Fréchet-derivatives of J and e do not depend on (y,u), J'' and e'' are Lipschitz-continuous in the whole space X.

The Lagrange multiplier rule holds for (1.5) if the following regularity condition is true.

Assumption 2. The Fréchet derivative $e'(x^0)$ is surjective.

Remark 2.3. In [Vol00b] it was shown that for Example 2.1 the operator $e'(y,u)$ is surjective for all $(y,u) \in X$. In particular, Assumption 2 is satisfied.

Assumption 3. Let $\Lambda : X \to Y$ denote a continuous mapping with a uniform Lipschitz-constant $\gamma_\Lambda \geq 0$ on the set $U(x^0)$, i.e.,

$$\|\Lambda(x) - \Lambda(\bar{x})\|_Y \leq \gamma_\Lambda \|x - \bar{x}\|_X \quad \text{for all } x, \bar{x} \in U(x^0). \tag{2.4}$$

The function Λ denotes the Lipschitz-continuous update for the Lagrange multiplier.

Remark 2.4. In case of the least-squares update (1.5) we have

$$\Lambda(x) = -\left(e'(x)e'(x)^\star\right)^{-1} e'(x)J'(x). \tag{2.5}$$

Under Assumptions 1 and 2 we conclude that Λ is Lipschitz-continuous in a neighborhood of x^0. In fact, Assumption 2 implies that $e'(x)^\star$ is injective in a neighborhood of x^0. It follows from the closed range theorem [Bre87, p. 29] that there exists a $\beta > 0$ such that

$$\langle e'(x)e'(x)^\star\lambda, \lambda\rangle_X = \|e'(x)^*\lambda\|_X^2 \geq \beta\,\|\lambda\|_Y^2 \quad \text{for all } \lambda \in Y.$$

Hence, $e'(x)e'(x)^\star$ is a positive operator and thus invertible.

Remark 2.5. We specify (2.5) for Example 2.1. Let $(y,u) \in X$ and let v be the solution of the Poisson problem

$$-v'' = y - z \text{ in } H^{-1}(\Omega), \quad v(0) = v(1) = 0.$$

Using (2.3) we set

$$q = (-\Delta)^{-1}\left(e'(y,u)J'(y,u)\right) = -\nu v'' + (yv)' - \alpha\mathcal{E}(u) \in H^{-1}(\Omega). \tag{2.6}$$

Note that the adjoint of $(-\Delta)^{-1}$ is given by its inverse operator $-\Delta$. It follows that for $\lambda \in H_0^1(\Omega)$,

$$\begin{aligned}(-\Delta)^{-1}e'(y,u)e'(y,u)^\star\lambda &= (-\Delta)^{-1}e'(y,u)\left((-\Delta)^{-1}(-\nu\lambda'' - y\lambda'), \quad \mathcal{E}^\star(-\Delta)(\lambda)\right)\\ &= -\nu\tilde{\lambda}'' + (y\tilde{\lambda})' - \mathcal{E}\mathcal{E}^\star(-\Delta)(\lambda),\end{aligned}$$

where $\tilde{\lambda} = (-\Delta)^{-1}(-\nu\lambda'' - y\lambda') \in H_0^1(\Omega)$. The adjoint $\mathcal{E}^\star$ of $\mathcal{E}$ is given by $\mathcal{E}^\star(f) = [(-\Delta)^{-1}(f)]\big|_{\Omega_\circ} \in L^2(\Omega_\circ)$ for any $f \in H^{-1}(\Omega)$. Then $\lambda = \Lambda(y,u)$ is the unique solution $(\lambda,\tilde{\lambda}) \in H_0^1(\Omega)\times H_0^1(\Omega)$ of the linear system

$$\left\{\begin{array}{lcll} -\nu\tilde{\lambda}'' + (y\tilde{\lambda})' + \mathcal{E}\mathcal{E}^\star(\lambda'') &=& -q & \text{in } H^{-1}(\Omega),\\ -\tilde{\lambda}'' + \nu\lambda'' + y\lambda' &=& 0 & \text{in } H^{-1}(\Omega).\end{array}\right. \tag{2.7}$$

We give a sufficient condition that the first-order necessary optimality conditions for problem (P),

$$L_c'(x,\lambda) = 0, \quad e(x) = 0 \quad \text{for } c \geq 0, \tag{2.8}$$

have a solution. Note that L_c' is the derivative of the augmented Lagrangian (1.2) with respect to x.

Define the vector

$$R_c(x) = \begin{pmatrix} L_c'(x,\Lambda(x)) \\ e(x)\end{pmatrix}$$

and matrix

$$M_c(x) = \nabla_{(x,\lambda)}\begin{pmatrix} L_c'(x,\lambda) \\ e(x)\end{pmatrix}\Big|_{\lambda=\Lambda(x)} = \begin{pmatrix} L_c''(x,\Lambda(x)) & e'(x)^\star \\ e'(x) & 0\end{pmatrix} \tag{2.9}$$

for all $x \in U(x^0)$ and for $c \geq 0$. Since Λ, e, L_c', e', and L_c'' are Lipschitz-continuous in $U(x^0)$, the maps R_c and M_c are also Lipschitz-continuous with Lipschitz-constants $\gamma_R > 0$ and $\gamma_M > 0$. For convenience, we assume that γ_M is also the Lipschitz-constant for

$$\nabla_{(x,\lambda)}\begin{pmatrix} L_c'(x,\lambda) \\ e(x)\end{pmatrix} = \begin{pmatrix} L_c''(x,\lambda) & e'(x)^\star \\ e'(x) & 0\end{pmatrix}$$

in a neighborhood of $(x^0,\Lambda(x^0))$. To guarantee the invertibility of the matrix M_c at x^0 we need Assumption 2 and the following condition.

Assumption 4. The operator $L_0''(x^0,\Lambda(x^0))$ is coercive on the null space of $e'(x^0)$, i.e., there exists a constant $\kappa > 0$ such that

$$L_0''(x^0,\Lambda(x^0))(\phi,\phi) \geq \kappa\,\|\phi\|_X^2 \quad \text{for all } \phi \in N(e'(x^0)).$$

Remark 2.6. In case $x^0 = x^*$ and $\lambda^* = \Lambda(x^*)$, this assumption includes the usual second-order sufficient optimality condition. However, other choices are also possible. For example, in the case $\Lambda(x^0) = 0$ Assumption 4 means $J''(x^0)$ must be positive definite on the null space of $e'(x^0)$.

Remark 2.7. We discuss Assumption 4 for the least-squares update applied to Example 2.1. Let $x^0 = (y^0, u^0) \in X$. For arbitrary $\phi = (v, q) \in N(e'(x^0))$

$$\begin{aligned} L_0''(x^0, \Lambda(x^0))(\phi, \phi) &= \|v\|_{L^2}^2 + \alpha \|q\|_{L^2(\Omega_\circ)}^2 + 2 \int_\Omega v v' \Lambda(x^0)\, dx \\ &\geq \alpha \|q\|_{L^2(\Omega_\circ)}^2 - 2 \int_\Omega v v' \left(e'(x^0) e'(x^0)^\star \right)^{-1} e'(x^0) J'(x^0)\, dx. \end{aligned}$$

Note that there exists a constant $C_1 > 0$ such that $\|(e'(x^0)e'(x^0)^\star)^{-1}\|_{\mathcal{L}(H_0^1)} \leq C_1$. This bound and the Hölder inequality imply that

$$L_0''(x^0, \Lambda(x^0))(\phi, \phi) \geq \alpha \|q\|_{L^2(\Omega_\circ)}^2 - 2C_1 \|v\|_{L^\infty} \|v'\|_{L^2} \|e'(x^0)J'(x^0)\|_{H_0^1}. \tag{2.10}$$

Here we also use the estimate $\|v\|_{L^\infty} \leq \|v\|_{H_0^1}$ which holds for all $v \in H_0^1(\Omega)$. It may be inferred from (2.6) that

$$\|e'(x^0)J'(x^0)\|_{H_0^1} = \| - \nu w'' + (wy^0)' - \alpha \mathcal{E}(u^0)\|_{H^{-1}},$$

where we put $w = (-\Delta)^{-1}(\langle y^0 - z, \cdot \rangle_{L^2})$. Since $\phi = (v, q) \in N(e'(x^0))$, we obtain that $-\nu v'' + (y^0 v)' - \mathcal{E}(q) = 0$ in $H^{-1}(\Omega)$, which leads to

$$\int_\Omega \nu v' \varphi' + (y^0 v)' \varphi \, dx = \int_{\Omega_\circ} q \varphi \, dx \quad \text{for all } \varphi \in H_0^1(\Omega).$$

Using Remark B.4 of the appendix, there exists a constant $C_2 > 0$ with

$$\|v\|_{H_0^1}^2 \leq C_2 \|q\|_{L^2(\Omega_\circ)}^2.$$

Thus, we have

$$L_0''(x^0, \Lambda(x^0))(\phi, \phi) \geq \frac{\alpha}{2} \|q\|_{L^2(\Omega_\circ)}^2 + \left(\frac{\alpha}{2C_2} - 2C_1 \|e'(x^0)J'(x^0)\|_{H_0^1} \right) \|v\|_{H_0^1}^2. \tag{2.11}$$

If the inequality

$$\| - \nu w'' + (wy^0)' - \alpha \mathcal{E}(u^0)\|_{H^{-1}} < \frac{\alpha}{4C_1 C_2} \tag{2.12}$$

holds, it follows that

$$\kappa = \min \left(\frac{\alpha}{2}, \frac{\alpha}{2C_2} - 2C_1 \|e'(x^0)J'(x^0)\|_{H_0^1} \right) > 0$$

and from (2.11) we obtain

$$L_0''(x^0, \Lambda(x^0))(\phi, \phi) \geq \kappa \|\phi\|_X^2 \quad \text{for all } \phi \in N(e'(x^0)).$$

Condition (2.12) can be deduced from (2.10) if the residual $\|(y^0 - z, \alpha u^0)\|_{L^2 \times L^2(\Omega_\circ)}$ is sufficiently small.

Assumption 4 implies the existence of a constant $\eta_c > 0$ depending on c, such that

$$\|M_c(x^0)^{-1}\|_{\mathcal{L}(X \times Y)} \leq \eta_c. \tag{2.13}$$

Moreover, there exists a neighborhood $V(x^0) \subseteq U(x^0)$ such that, for all $x \in V(x^0)$,

(a) $J(x)$ and $e(x)$ are twice Fréchet-differentiable and their second Fréchet-derivatives are Lipschitz-continuous in $\overline{V(x^0)}$;
(b) $e'(x)$ is surjective; and
(c) $L_0''(x, \Lambda(x))$ is coercive on the null space of $e'(x)$.

3. The augmented Lagrangian-SQP method with Lipschitz-continuous Lagrange multiplier update. If the Newton multiplier update (1.3) is used in Algorithm 2, then the rate of convergence results hold for the pair of iterates (x, λ) [IK96, KS97]. If one uses a Lipschitz-continuous multiplier update, the dependence on λ^n is eliminated and we derive convergence estimates that depend only on the variable x. We consider the map $x^n \mapsto x^{n+1}$ and omit λ. Note that the solution to (QP) is given by the first component of $M_c(x^n)^{-1}R_c(x^n) \in X \times Y$ [Kle97]. Therefore, we introduce the linear and bounded projection $\mathcal{P} : X \times Y \to X$ defined by $\mathcal{P}(x, \lambda) = x$ for all $(x, \lambda) \in X \times Y$. We formulate Algorithm 2 using a Lipschitz-continuous multiplier update.

ALGORITHM 2.

(a) *Choose* $x^0 \in V(x^0)$, $c \geq 0$, *and set* $n = 0$.

(b) *Compute*

$$x^{n+1} = x^n - \mathcal{P}\left(M_c(x^n)^{-1}R_c(x^n)\right). \tag{3.1}$$

(c) *Set* $n = n + 1$ *and go back to* (b).

Define the nonlinear operator $\Phi_c : X \to X$ such that

$$\Phi_c(x) = x - \mathcal{P}\left(M_c(x)^{-1}R_c(x)\right) \quad \text{for } c \geq 0.$$

The computation (3.1) can be written as a fixed-point iteration $x^{n+1} = \Phi_c(x^n)$ for $n = 0, 1, \ldots$.

In (1.3) we introduced the Newton multiplier update Λ_N. On the neighborhood $V(x^0)$ of x^0 the element $\Lambda_N(x, \Lambda(x))$ is well defined and there exists a constant $\gamma_N > 0$ satisfying

$$\|\Lambda_N(x, \Lambda(x)) - \Lambda_N(\bar{x}, \Lambda(\bar{x}))\|_Y \leq \gamma_N \|x - \bar{x}\|_X \quad \text{for all } x, \bar{x} \in V(x^0).$$

In particular, $\Lambda_N(x, \Lambda(x))$ satisfies

$$M_c(x)\begin{pmatrix} \Phi_c(x) - x \\ \Lambda_N(x, \Lambda(x)) \end{pmatrix} = -R_c(x). \tag{3.2}$$

Remark 3.1. From (3.2) and (2.13) we infer that

$$\|x^1 - x^0\|_X = \|\Phi_c(x^0) - x^0\|_X = \|\mathcal{P}(M_c(x^0)^{-1}R_c(x^0))\|_X \leq \eta_c \|R_c(x^0)\|_{X\times Y}$$

holds. Thus we conclude that $\|x^1 - x^0\|_X$ is small if $\|R_c(x^0)\|_{X\times Y}$ is sufficiently small.

The following theorem is of the Kantorovich type since it makes assumptions only on the initial iterate and some problem data rather than on an unknown solution of the problem.

THEOREM 3.2. *Let Assumptions* 1–4 *at some* $x^0 \in X$ *be valid. Assume that*

$$\|\Lambda_N(x^0, \Lambda(x^0))\|_Y \leq \frac{1}{4\gamma_M \eta_c} \tag{3.3}$$

and

$$\|\Phi_c(x^0) - x^0\|_X \leq \frac{1}{16p_1} \tag{3.4}$$

with $p_1 = \eta_c\gamma_M((1+\gamma_\Lambda^2)^2 + 2\gamma_\Lambda)/2$. *Then the iterates defined by Algorithm* 2 *lie in*

$$D = V(x^0) \cap \left\{x \in X : \|x - x^0\|_X < \varrho\right\},$$

where $\varrho = \min\left((\gamma_M\eta_c)^{-1}, (2\gamma_N\gamma_M\eta_c)^{-1}, p_1^{-1}\right)/2$, *and converge to a fixed point* $x^* \in D$ *satisfying*

$$x^* = \Phi_c(x^*), \tag{3.5}$$

i.e., x^* *solves* $\mathcal{P}(M_c(x^*)^{-1}R_c(x^*)) = 0$.

Proof. To prove the claim we want to apply Lemma A.2; see Appendix A. Therefore, we have to estimate $\|\Phi_c(\Phi_c(x)) - \Phi_c(x)\|_X$ for $x, \Phi_c(x) \in D$. First we show that Φ_c is well defined on D. We have for all $x \in D$

$$\|M_c(x) - M_c(x^0)\|_{\mathcal{L}(X\times Y)} \le \gamma_M \, \|x - x^0\|_X < \gamma_M\varrho < \frac{1}{2\eta_c} < \frac{1}{\eta_c}. \tag{3.6}$$

It follows from (2.13) and (3.6) that

$$\|M_c(x^0)^{-1}\|_{\mathcal{L}(X\times Y)} \, \|M_c(x) - M_c(x^0)\|_{\mathcal{L}(X\times Y)} < 1.$$

Now the Banach lemma [OR70, p. 45] gives

$$\|M_c(x)^{-1}\|_{\mathcal{L}(X\times Y)} \le \frac{\eta_c}{1 - \eta_c\gamma_M \, \|x - x^0\|_X} \le 2\eta_c \quad \text{for all } x \in D. \tag{3.7}$$

This implies that Φ_c is well defined on D. Now we proceed by deriving an estimate of the form (A.1). For that purpose let $x, \Phi_c(x) \in D$. Then we have

(3.8)

$$\begin{aligned}
&\|\Phi_c(\Phi_c(x)) - \Phi_c(x)\|_X \\
&= \|\mathcal{P}\big[M_c(\Phi_c(x))^{-1}R_c(\Phi_c(x))\big]\|_X \\
&= \Bigg\|\mathcal{P}\Bigg[M_c(\Phi_c(x))^{-1}\Bigg\{R_c(\Phi_c(x)) - R_c(x) - M_c(x)\begin{pmatrix} \Phi_c(x) - x \\ \Lambda(\Phi_c(x)) - \Lambda(x) \end{pmatrix} \\
&\qquad + (M_c(x) - M_c(\Phi_c(x)))\begin{pmatrix} 0 \\ \Lambda(\Phi_c(x)) - \Lambda(x) - \Lambda_N(x, \Lambda(x)) \end{pmatrix} \\
&\qquad + M_c(\Phi_c(x))\begin{pmatrix} 0 \\ \Lambda(\Phi_c(x)) - \Lambda(x) - \Lambda_N(x, \Lambda(x)) \end{pmatrix}\Bigg\}\Bigg]\Bigg\|_X.
\end{aligned}$$

From the expression

$$\begin{aligned}
&R_c(\Phi(x)) - R_c(x) - M_c(x)\begin{pmatrix} \Phi_c(x) - x \\ \Lambda(\Phi_c(x)) - \Lambda(x) \end{pmatrix} \\
&\quad = \begin{pmatrix} L_c'(\Phi_c(x), \Lambda(\Phi_c(x))) \\ e(\Phi_c(x)) \end{pmatrix} - \begin{pmatrix} L_c'(x, \Lambda(x)) \\ e(x) \end{pmatrix} \\
&\qquad - \nabla_{(x,\lambda)}\begin{pmatrix} L_c'(x,\lambda) \\ e(x) \end{pmatrix}\Bigg|_{\lambda=\Lambda(x)}\begin{pmatrix} \Phi_c(x) - x \\ \Lambda(\Phi_c(x)) - \Lambda(x) \end{pmatrix}
\end{aligned}$$

and Lemma 3.2.12 in [OR70, p. 73] we obtain that

$$\begin{aligned}
&\left\|R_c(\Phi(x)) - R_c(x) - M_c(x)\begin{pmatrix} \Phi_c(x) - x \\ \Lambda(\Phi_c(x)) - \Lambda(x) \end{pmatrix}\right\|_{X\times Y} \\
&\quad \le \frac{\gamma_M}{2} \, \|(\Phi_c(x) - x, \Lambda(\Phi_c(x)) - \Lambda(x))\|_{X\times Y}^2 \\
&\quad \le \frac{\gamma_M}{2}\,(1 + \gamma_\Lambda^2) \, \|\Phi_c(x) - x\|_X^2.
\end{aligned} \tag{3.9}$$

Furthermore,

$$\mathcal{P}\left[M_c(\Phi_c(x))^{-1}M_c(\Phi_c(x))\begin{pmatrix} 0 \\ \Lambda(\Phi_c(x)) - \Lambda(x) - \Lambda_N(x,\Lambda(x)) \end{pmatrix}\right] = 0. \tag{3.10}$$

Since $\mathcal{P}$ is linear, we derive from (3.8), (3.9), and (3.10) that

$$\begin{aligned} &\|\Phi_c(\Phi_c(x)) - \Phi_c(x)\|_X \\ &\quad \le \|M_c(\Phi_c(x))^{-1}\|_{\mathcal{L}(X\times Y)}\left(\frac{\gamma_M}{2}(1+\gamma_\Lambda^2) + \gamma_\Lambda\gamma_M\right)\|\Phi_c(x) - x\|_X^2 \\ &\qquad + \|M_c(\Phi_c(x))^{-1}\|_{\mathcal{L}(X\times Y)}\gamma_M\|\Lambda_N(x,\Lambda(x))\|_Y\|\Phi_c(x) - x\|_X. \end{aligned} \tag{3.11}$$

Using (3.3) the term $\|\Lambda_N(x,\Lambda(x))\|_Y$ can be estimated as follows:

$$\begin{aligned} \|\Lambda_N(x,\Lambda(x))\|_Y &\le \|\Lambda_N(x^0,\Lambda(x^0))\|_Y + \|\Lambda_N(x,\Lambda(x)) - \Lambda_N(x^0,\Lambda(x^0))\|_Y \\ &\le \frac{1}{4\gamma_M\eta_c} + \gamma_N\ \|x - x^0\|_X < \frac{1}{4\gamma_M\eta_c} + \gamma_N\varrho \le \frac{1}{2\gamma_M\eta_c}. \end{aligned}$$

Define $p_2 = 1/2$ and $p_3 = 2p_1$. Then, we have $p_3 \ge \gamma_M\eta_c$ such that we conclude from (3.7) and (3.11) that

$$\|\Phi_c(\Phi_c(x)) - \Phi_c(x)\|_X \le \frac{p_1\ \|\Phi_c(x) - x\|_X^2 + p_2\ \|\Phi_c(x) - x\|_X}{1 - p_3\ \|\Phi_c(x) - x^0\|_X} \tag{3.12}$$

for all $x, \Phi_c(x) \in D$. Note that $\|\Phi_c(x) - x^0\|_X < \varrho \le 1/p_3$. Thus (A.1) holds with

$$\varphi : [0,\infty) \times \left[0, \frac{1}{p_3}\right) \to \mathbb{R}, \quad (t,s) \mapsto \frac{p_1t^2 + p_2t}{1 - p_3s}.$$

Obviously, φ is monotonically increasing in both variables. Note that $p_1 > 0$, $p_2 \ge 0$, and $2p_1 = p_3$. Hence p_1, p_2, and p_3 satisfy the hypotheses of Lemma A.3. Using Lemmas A.2 and A.3 we have proved the theorem. ∎

Remark 3.3. From Theorem 3.2, the iterates $x^{n+1} = \Phi_c(x^n)$, $n \le 1$, lie in D. Applying estimate (3.12) for $x^{n+1} \in D$ leads to

$$\|x^{n+1} - x^n\|_X \le \frac{p_1\ \|x^n - x^{n-1}\|_X^2 + p_2\ \|x^n - x^{n-1}\|_X}{1 - p_3\ \|x^n - x^0\|_X} \quad \text{for } n \ge 1.$$

If $\|x^n - x^0\|_X \le 1/(2p_3)$, we obtain

$$\|x^{n+1} - x^n\|_X \le \frac{p_1}{2}\ \|x^n - x^{n-1}\|_X^2 + \frac{p_2}{2}\ \|x^n - x^{n-1}\|_X \quad \text{for } n \ge 1.$$

This is an estimate for the iterates of the sequence $\{x^n\}_{n\in\mathbb{N}}$. To prove the quadratic convergence of the fixed-point iteration we need, in addition, that $\lambda^* = \Lambda(x^*)$ is satisfied; see Theorem 3.6 below.

Theorem 3.2 yields not only the existence of a fixed point x^* but also the existence of a pair $(x^*,\lambda^*) \in D \times Y$ that solves the first-order necessary optimality conditions (2.8) for problem (P).

COROLLARY 3.4. *Under the hypotheses of Theorem* 3.2 *the multiplier* $\lambda^* = \Lambda_N(x^*,\Lambda(x^*)) + \Lambda(x^*) \in Y$ *satisfies together with* x^* *the first-order necessary optimality conditions for problem* (P).

Proof. Equations (2.9), (3.2), and (3.5) give

$$e'(x^*)^\star \Lambda_N(x^*, \Lambda(x^*)) = -L_c'(x^*, \Lambda(x^*)), \tag{3.13}$$

$$0 = -e(x^*). \tag{3.14}$$

From (3.14) we have $e(x^*) = 0$. Equation (3.13) implies that

$$L_c'(x^*, \Lambda_N(x^*, \Lambda(x^*)) + \Lambda(x^*)) = 0 \quad \text{for } c \geq 0.$$

Setting $\lambda^* = \Lambda_N(x^*, \Lambda(x^*)) + \Lambda(x^*) \in Y$ we conclude that $L_c'(x^*, \lambda^*) = 0$. ∎

COROLLARY 3.5. *Let all hypotheses of Theorem* 3.2 *hold. In case of the least-squares update we have* $\lambda^* = \Lambda(x^*)$. *Furthermore,* x^* *is a solution to* (P).

Proof. From (3.13) and $e(x^*) = 0$ we obtain that

$$\begin{aligned} e'(x^*)^\star \Lambda_N(x^*, \Lambda(x^*)) &= -J'(x^*) - e'(x^*)^\star \Lambda(x^*) \\ &= -J'(x^*) + e'(x^*)^\star (e'(x^*)e'(x^*)^\star)^{-1} e'(x^*) J'(x^*). \end{aligned}$$

Since $e'(x^*)$ is surjective, we have $(e'(x^*)e'(x^*)^\star)^{-1} \in \mathcal{L}(Y)$. Hence, $\Lambda_N(x^*, \Lambda(x^*)) = 0$ and $\lambda^* = \Lambda_N(x^*, \Lambda(x^*)) + \Lambda(x^*) = \Lambda(x^*)$. The rest follows directly from the second-order sufficient optimality condition (Remark 2.6). ∎

If $\lambda^* = \Lambda(x^*)$ for a Lipschitz-continuous multiplier update is used in Algorithm 2, then it is possible to recover the q-quadratic rate of convergence in the iterates x^n. For the proof we refer to [KS97].

THEOREM 3.6. *Let all hypotheses of Theorem* 3.2 *and* $\lambda^* = \Lambda(x^*)$ *hold. Then there exists* $\varepsilon > 0$ *such that for all* $x^0 \in B(x^*, \varepsilon)$ *the sequence* $x^{n+1} = \Phi_c(x^n)$ *converges to* x^* *and*

$$\|x^{n+1} - x^*\|_X \leq C \|x^n - x^*\|_X^2 \quad \textit{for } n = 0, 1, \ldots \tag{3.15}$$

and

$$\|\lambda^{n+1} - \lambda^*\|_X \leq \gamma_\Lambda C \|x^n - x^*\|_X^2 \quad \textit{for } n = 0, 1, \ldots$$

for a constant $C > 0$, *which is independent of* n.

4. Application for discretization methods. Let X and Y be infinite-dimensional Hilbert spaces. The goal of this section is to prove convergence of the discretized version of Algorithm 3 to a solution of the discrete first-order necessary optimality conditions. The existence of such a solution can also be demonstrated by Theorem 3.2.

We assume the following: the constrained minimization problem (**P**) has a local solution x^*; J and e are twice continuously Fréchet-differentiable; the mappings J'' and e'' are Lipschitz-continuous; $e'(x)$ is surjective in the neighborhood $U(x^*)$ of x^*; and $L_0''(x, \Lambda(x))$ is coercive on the null space of $e'(x)$ in $U(x^*)$ of x^* (see the Assumptions 1–4).

Since $e'(x^*)$ is surjective, there exists an element $\lambda^* \in Y$ satisfying the first-order necessary optimality conditions

$$L_c'(x^*, \lambda^*) = L'(x^*, \lambda^*) = 0 \text{ and } e(x^*) = 0 \quad \text{for all } c \geq 0. \tag{4.1}$$

In addition to (2.4) we assume that the multiplier update Λ satisfies

$$\Lambda(x^*) = \lambda^*. \tag{4.2}$$

Remark 4.1. In Remark 2.4 we introduced the least-squares update

$$\Lambda(x) = -\left(e'(x)e'(x)^\star\right)^{-1} e'(x)J'(x).$$

Using (4.1) we get $J'(x^*) = -e'(x^*)^\star\lambda^*$. Thus, (4.2) holds for the least-squares update.

Since X and Y are infinite-dimensional real Hilbert spaces, they have to be discretized for a numerical solution of (P). For this purpose we suppose that we are given finite-dimensional spaces $\{X_h\}_h$ and $\{Y_h\}_h$ approximating X and Y, respectively.

Let $p_h^X \in \mathcal{L}(X_h, X)$ and $p_h^Y \in \mathcal{L}(Y_h, Y)$ be given injective prolongations. In addition, we introduce surjective restrictions $r_h^X \in \mathcal{L}(X, X_h)$ and $r_h^Y \in \mathcal{L}(Y, Y_h)$. For brevity we set $p_h = (p_h^X, p_h^Y)$ and $r_h = (r_h^X, r_h^Y)$.

In many applications it turns out that the solution (x^*, λ^*) of (4.1) as well as the iterates x^n of Algorithm 2 have "better smoothness" than the elements of $X \times Y$ and X, respectively. This is a motivation for the following assumption.

Assumption 5. *There are bounded subsets $V^* \subset X$ such that*

$$x^*,\, x^n,\, x^n - x^*,\, x^{n+1} - x^n \in V^* \tag{4.3}$$

hold for all $n = 0, 1, \ldots$.

Let e_h, L_h', L_h'', and e_h' denote Lipschitz-continuous discretizations of the operators e, L_0', L_0'', and e', respectively. We refer the reader to [Vol00a], where Lipschitz-continuous discretizations are introduced as internal approximations of the infinite-dimensional operators, for instance, $e_h = (p_h^Y)^\star \circ e \circ p_h^X$. Further, we define $\Lambda_h = r_h^Y \circ \Lambda \circ p_h^X$.

We make the following assumptions on the discretization method.

Assumption 6. The discretization methods are described by a family of quadruples

$$\{R_{c,h}, M_{c,h}, p_h, r_h\} \text{ for } h > 0, \tag{4.4}$$

where the operators

$$R_{c,h} : U_h \subseteq X_h \to X_h \times Y_h, \quad M_{c,h} : U_h \subseteq X_h \to \mathcal{L}(X_h \times Y_h) \quad \text{for } h > 0$$

are given by

$$R_{c,h}(x_h) = \begin{pmatrix} L_0'(x_h, \Lambda_h(x_h)) \\ e_h(x_h) \end{pmatrix}, \quad M_{c,h}(x_h) = \begin{pmatrix} L_0''(x_h, \Lambda_h(x_h)) & e_h'(x_h)^\star \\ e_h'(x_h) & 0 \end{pmatrix},$$

and

$$r_h^X(U(x^*) \cap V^*) \subseteq U_h \quad \text{for } h > 0. \tag{4.5}$$

The discretization (4.4) is Lipschitz-uniform with respect to h, i.e., there exist constants $r > 0$, $\Gamma_R > 0$, and $\Gamma_M > 0$ independent of h such that

$$B_h = \{x_h \in X_h : \|x_h - r_h^X x^*\|_X \le r\} \subseteq U_h \quad \text{for } h > 0 \tag{4.6}$$

and

$$\begin{aligned} \|R_{c,h}(x_h) - R_{c,h}(\bar{x}_h)\|_{X\times Y} &\le \Gamma_R \|x_h - \bar{x}_h\|_X, \\ \|M_{c,h}(x_h) - M_{c,h}(\bar{x}_h)\|_{\mathcal{L}(X_h\times Y_h)} &\le \Gamma_M \|x_h - x_h\|_X \end{aligned} \tag{4.7}$$

for all $x_h, \bar{x}_h \in B_h$. Moreover, the discretization family $\{R_{c,h}, M_{c,h}, p_h, r_h\}_{h>0}$ is

(1) uniformly bounded, i.e., there exists a constant $\mu > 0$ independent of h such that

$$\|p_h\|_{\mathcal{L}(X_h \times Y_h, X \times Y)} \leq \mu \text{ and } \|r_h\|_{\mathcal{L}(X \times Y, X_h \times Y_h)} \leq \mu; \tag{4.8}$$

(2) stable in U_h, i.e.,

$$\|M_{c,h}(x_h)^{-1}\|_{\mathcal{L}(X_h \times Y_h)} \leq \sigma_c \quad \text{for all } x_h \in U_h,$$

where the constant $\eta_c > 0$ does not depend on h; and

(3) consistent of order $s > 0$, i.e., there is a constant $\bar{C} > 0$ independent of h such that

$$\|R_{c,h}(r_h^X x) - (p_h)^\star R_c(x)\|_{X \times Y} \leq \bar{C} h^s$$

for all $x \in U(x^*) \cap V^*$.

We derive from (2.4) and (4.8) that

$$\|\Lambda_h(r_h^X x) - \Lambda_h(r_h^X \bar{x})\|_Y = \|r_h^Y \left(\Lambda(p_h^X r_h^X x) - \Lambda(p_h^X r_h^X \bar{x})\right)\|_Y \leq \mu^2 \gamma_\Lambda \|r_h^X x - r_h^X \bar{x}\|_X$$

for all $x, \bar{x} \in U(x^*)$. Hence, $\Gamma_\Lambda = \mu^2 \gamma_\Lambda$ is a uniform Lipschitz-constant for Λ_h.

To formulate the discretization of Algorithm 2 we need the following linear and bounded projection $\mathcal{P}_h : X_h \times Y_h \to X_h$ defined by $\mathcal{P}_h(x_h, \lambda_h) = x_h$ for all $(x_h, \lambda_h) \in X_h \times Y_h$.

ALGORITHM 3.

(a) *Choose* $c \geq 0, x_h^0 \in U_h$, *and* $n = 0$.

(b) *Compute*

$$x_h^{n+1} = \Phi_{c,h}(x_h^n) = x_h^n - \mathcal{P}_h \left(M_{c,h}(x_h^n)^{-1} R_{c,h}(x_h^n)\right). \tag{4.9}$$

(c) *Set* $n = n + 1$ *and go back to* (b).

THEOREM 4.2. *Let Assumptions* 1–6 *hold. Then there exists an* $\bar{h} \in [0, 1]$ *such that for all* $h \in (0, \bar{h}]$ *the operators* $\Phi_{c,h}$ *possess fixed points* x_h^* *satisfying*

$$\|x_h^* - r_h^X x^*\|_X = O(h^s). \tag{4.10}$$

If in addition $\|x^0 - x^*\|_X$ *is sufficiently small, then there exists an* $\tilde{h} \in (0, \bar{h}]$ *such that for all* $h \in (0, \tilde{h}]$ *the sequence* $x_h^{n+1} = \Phi_{c,h}(x_h^n)$ *with the starting value* $x_h^0 = r_h^X x^*$ *converges to* x_h^*.

Proof. We apply Theorem 3.2 to prove this claim. In the constants p_1 and ϱ of Theorem 3.2 we replace γ_M and γ_Λ by the Lipschitz-constants of $M_{c,h}$ and Λ_h, i.e.,

$$p_1 = \frac{1}{2} \sigma_c \Gamma_M \left((1 + \Gamma_\Lambda^2)^2 + 2\Gamma_\Lambda\right).$$

Further, define the constant

$$\rho = \min\left(\frac{1}{8\sigma_c^2 \Gamma_R \Gamma_M}, \frac{1}{2p_1}\right)$$

and the set

$$D_h = \left\{x \in B_h : \|x_h - r_h^X x^*\|_{X_h} < \rho\right\}.$$

We prove that the claim holds for

$$\bar{h} = \min\left(\left(\frac{1}{8\sigma_c^2\bar{C}\Gamma_M}\right)^{1/s}, \left(\frac{1}{16p_1\sigma_c\bar{C}}\right)^{1/s}\right). \tag{4.11}$$

By applying Assumption 6 we find that

$$\|M_{c,h}(x_h^0)^{-1}\|_{\mathcal{L}(X_h\times Y_h)} \le \sigma_c$$

for a constant $\eta_c > 0$ independent of h. This is the estimate (2.13). Condition (3.3) has the form

$$\|\Lambda_{N,h}(x_h^0, \Lambda_h(x^0))\|_Y < \frac{1}{4\Gamma_M\sigma_c}, \tag{4.12}$$

where $\Lambda_{N,h}(x_h^0, \Lambda_h(x^0)) \in Y_h$ satisfies

$$M_{c,h}(x_h^0)\begin{pmatrix} \Phi_{c,h}(x_h^0) - x_h^0 \\ \Lambda_{N,h}(x_h^0, \Lambda_h(x^0)) \end{pmatrix} = -R_{c,h}(x_h^0).$$

We find that

$$\|\Lambda_{N,h}(x_h^0, \Lambda_h(x^0))\|_Y \le \sigma_c \, \|R_{c,h}(x_h^0)\|_{X\times Y}. \tag{4.13}$$

From $R_c(x^*) = 0$ and Assumption 6 we deduce that for $x_h \in D_h$

$$\begin{aligned}\|R_{c,h}(x_h)\|_{X\times Y} &= \|R_{c,h}(x_h) - R_{c,h}(r_h^X x^*)\|_{X\times Y} \\ &\qquad + \|R_{c,h}(r_h^X x^*) - (p_h)^\star R_c(x^*)\|_{X\times Y} \\ &\le \Gamma_R \, \|x_h - r_h^X x^*\|_X + \bar{C}h^s \\ &< \frac{1}{8\sigma_c^2\Gamma_M} + \bar{C}h^s.\end{aligned}$$

Thus (4.13) and (4.11) yield (4.12):

$$\|\Lambda_{N,h}(x_h^0, \Lambda_h(x^0))\|_Y \le \frac{1}{8\sigma_c\Gamma_M} + \sigma_c\bar{C}\bar{h}^s \le \frac{1}{4\Gamma_M\sigma_c}.$$

From Assumption 6, $R_c(x^*) = 0$, and $x_h^0 = r_h^X x^0$ we conclude that

$$\begin{aligned}&\|\Phi_{c,h}(x_h^0) - x_h^0\|_X \\ &\quad \le \|M_{c,h}(x_h^0)^{-1}\|_{\mathcal{L}(X_h\times Y_h)} \, \|R_{c,h}(r_h^X x^*) - (p_h)^\star R_c(x^*)\|_{X\times Y} \\ &\quad \le \sigma_c\bar{C}\bar{h}^s \le \frac{1}{16p_1}.\end{aligned} \tag{4.14}$$

This is the estimate (3.4). Applying Theorem 3.2 leads to the existence of (x_h^*, λ_h^*) which solve the first-order necessary optimality condition of (P_h).

We now verify (4.10). Let $p_2 = 1/2$ and $p_3 = 2p_1$. From Lemmas A.2 and A.3 and (4.14) it follows that

$$\begin{aligned}\|x_h^* - r_h^X x^*\|_X = t^* &\le \frac{1}{p_3}\left(1 - p_2 - \sqrt{(1-p_2)^2 - 4p_1\,\|\Phi_{c,h}(x_h^0) - x_h^0\|_X}\right) \\ &= \frac{4p_1\,\|\Phi_{c,h}(x_h^0) - x_h^0\|_X}{p_3\left(1 - p_2 + \sqrt{(1-p_2)^2 - 4p_1\,\|\Phi_{c,h}(x_h^0) - x_h^0\|_X}\right)} \\ &\le \frac{4p_1\,\|\Phi_{c,h}(x_h^0) - x_h^0\|_X}{p_3(1-p_2)} \le \frac{4p_1\sigma_c\bar{C}}{p_3(1-p_2)}\,h^s,\end{aligned}$$

which gives (4.10). ∎

Remark 4.3. From Theorem 4.2 and Corollary 3.4 there exists $\lambda_h^* \in Y_h$ such that (x_h^*, λ_h^*) solves the first-order necessary optimality conditions for (P_h). If $\lambda_h^* = \Lambda_h(x_h^*)$ holds, the q-quadratic convergence follows for the iterates $x_h^{n+1} = \Phi_{c,h}(x_h^n)$ analogous to the proof of Theorem 3.6.

5. Application to Example 2.1. This section is devoted to the discussion of the assumptions of Theorem 4.2 for Example 2.1.

It was proved in [Vol00b] that (P) has a solution, and that $e'(y^*, u^*)$ is surjective, if $f \in L^2(\Omega)$ holds. Moreover, $L_0''(y^*, u^*, \lambda^*)$ is coercive on the null space of $e'(y^*, u^*)$ if $\|y^* - z\|_{L^2}$ is sufficiently small.

To approximate the Hilbert spaces X and Y in case of Example 2.1 we set $h = \frac{1}{m+1}$, $x_j = jh$ for $j = 0, \dots, m+1$ and introduce piecewise linear functions $\varphi_1, \dots, \varphi_m \in H_0^1(\Omega)$ satisfying $\varphi_i(x_j) = \delta_{ij}$. We restrict our discussion to the case where the set $\Omega_\circ = (a, b) \subseteq \Omega$ is an open nonempty interval. The numbers $i_a, i_b \in \{1, \dots, m\}$ are defined by

$$0 \le a < x_{i_a} < x_{i_a+1} < \cdots < x_{i_b} < b \le 1.$$

For the approximation of X and Y we set

$$X_h = \mathrm{Span}\,\{\varphi_1, \dots, \varphi_m\} \times \mathrm{Span}\,\{\varphi_{i_a}, \dots, \varphi_{i_b}\}, \quad Y_h = \mathrm{Span}\,\{\varphi_1, \dots, \varphi_m\}.$$

To define the prolongations and restrictions we set

$$p_h(y_h, u_h, \lambda_h) = (y_h, u_h, \lambda_h) \quad \text{for } (y_h, u_h) \in X_h \text{ and } \lambda_h \in Y_h$$

and

$$r_h(y, u, \lambda) = \left(\sum_{i=0}^{m} y(x_i)\varphi_i, \frac{1}{h} \sum_{i=i_a}^{i_b} \int_{x_i - \frac{h}{2}}^{x_i + \frac{h}{2}} u\, dx\, \varphi_i, \left(\sum_{i=1}^{m-1} \lambda(x_i)\varphi_i, \mu \right) \right)$$

for $(y, u) \in X$ and $(\lambda, \mu) \in Y$. The Hilbert spaces X_h and Y_h are endowed with the inner products in X and Y, respectively. It follows directly that p_h is a linear injective operator satisfying $\|p_h\|_{\mathcal{L}(X_h \times Y_h, X \times Y)} = 1$ and that r_h is linear and surjective.

We discuss Assumption 5 in the case of Example 2.1. We prove that there exists a bounded subset V^* in $H^2(\Omega) \times H^1(\Omega_\circ)$ such that (4.3) holds. By Theorem 3.6 there exists $\varepsilon > 0$ such that

$$\lim_{n \to \infty} \|(y^n, u^n) - (y^*, u^*)\|_X = 0$$

for all initial values $(y^0, u^0) \in B((y^*, u^*); \varepsilon)$. Hence,

$$\|(y^n, u^n)\|_X \le C_3 \quad \text{for all } n, \tag{5.1}$$

where $C_3 > 0$ does not depend on n. This implies that

$$\|\Lambda(y^n, u^n)\|_{H_0^1} \le \|\Lambda(y^n, u^n) - \Lambda(y^*, u^*)\|_{H_0^1} + \|\lambda^*\|_{H_0^1} \le C_4 \quad \text{for all } n, \tag{5.2}$$

where $C_4 = \gamma_g C_3 + \|(y^*, u^*)\|_X + \|\lambda^*\|_Y$ is independent of n. Let $y^0 \in H^2(\Omega)$ and $u^0 \in H^1(\Omega_\circ)$. Then both (5.1) and (5.2) hold with $n = 0$ and $n = 1$. If $(\bar{y}, \bar{u}, \bar{\lambda})$ is the solution of the linear system

$$M_c(y^0, u^0) \begin{pmatrix} \bar{y} \\ \bar{u} \\ \bar{\lambda} \end{pmatrix} = -R_c(y^0, u^0) + M_c(y^0, u^0) \begin{pmatrix} y^0 \\ u^0 \\ \Lambda(y^0, u^0) \end{pmatrix},$$

then the new iterate $(y^1, u^1) = \Phi_c(y^0, u^0)$ is given by $(y^1, u^1) = (\bar{y}, \bar{u})$. This implies that

$$-\nu\bar{\lambda}'' - y^n\bar{\lambda}' = -\bar{y} + \Lambda(y^n, u^n)'\bar{y} + z - y^n\Lambda(y^n, u^n)', \tag{5.3}$$

$$\alpha\bar{u} = \bar{\lambda}, \tag{5.4}$$

$$-\nu\bar{y}'' = -(y^n\bar{y})' + \mathcal{E}(\bar{u}) + f + y^n(y^n)'. \tag{5.5}$$

Since $y^{n+1} \in L^\infty(\Omega)$, we have $-\nu\lambda'' - y^n\lambda' \in L^2(\Omega)$. As (5.1) holds for all n, we have $\|\bar{y}\|_{H_0^1} \le C_3$. To show that $\bar{\lambda}'' \in L^2(\Omega)$ we estimate the right-hand side of (5.3):

$$\begin{aligned} &\| -\bar{y} + \Lambda(y^0, u^0)'\bar{y} + z - y^0\Lambda(y^0, u^0)'\|_{L^2} \\ &\quad \le \|\bar{y}\|_{L^2} + \|\Lambda(y^0, u^0)\|_{H_0^1}\|\bar{y}\|_{L^\infty} + \|z\|_{L^2} + \|y^0\|_{L^\infty}\|\Lambda(y^0, u^0)\|_{H_0^1} \\ &\quad \le C_3 + C_4C_3 + \|z\|_{L^2} + C_3C_4 =: C_5. \end{aligned} \tag{5.6}$$

Hence $\bar{\lambda}'' \in L^2(\Omega)$ and we can apply the Sturm–Liouville theory in Appendix B. We obtain from Remark B.2, (5.1), and (5.6) that

$$\begin{aligned} \|\bar{\lambda}\|_{H_0^1} &\le \frac{1}{\nu}\exp\left(\frac{2}{\nu}\|y^0\|_{L^1}\right)\| -\bar{y} + \Lambda(y^0, u^0)'\bar{y} + z - y^0\Lambda(y^0, u^0)'\|_{L^2} \\ &\le \frac{1}{\nu}\exp\left(\frac{2C_3}{\nu}\right)C_5 =: C_6. \end{aligned} \tag{5.7}$$

Thus, we infer from (5.4) that

$$\|\bar{u}'\|_{L^2(\Omega_\circ)} = \frac{1}{\alpha}\|\bar{\lambda}'\|_{L^2(\Omega_\circ)} \le \frac{1}{\alpha}\|\bar{\lambda}\|_{H_0^1} \le \frac{C_6}{\alpha}. \tag{5.8}$$

By (5.5) and (5.8) we find that

$$\begin{aligned} \|\bar{y}''\|_{L^2} &\le \frac{1}{\nu}\left(2\|y^0\|_{H_0^1}\|\bar{y}\|_{H_0^1} + \|\bar{u}\|_{L^2(\Omega_\circ)} + \|f\|_{L^2} + \|y^0\|_{H_0^1}^2\right) \\ &\le \frac{1}{\nu}\left(2C_3^2 + C_3 + \|f\|_{L^2} + C_3^2\right) =: C_7. \end{aligned} \tag{5.9}$$

Hence, $(y^1, u^1) \in H^2(\Omega) \times H^1(\Omega_\circ)$ and for $C_8 = \max(C_6/\alpha, C_7)$ it follows that

$$\|(y^1)''\|_{L^2} \le C_8 \text{ and } \|(u^1)'\|_{L^2(\Omega_\circ)} \le C_8. \tag{5.10}$$

Now let (y^n, u^n) be given for $n \ge 0$. Then (5.1) and (5.2) hold. As in the case $n = 0$ we derive that

$$\|(y^{n+1})''\|_{L^2} \le C_8 \text{ and } \|(u^{n+1})'\|_{L^2(\Omega_\circ)} \le C_8$$

hold, where C_8 is the same constant as in (5.10). The first-order necessary optimality conditions for Example 2.1 are given by

$$\begin{aligned} y^* - z - \nu(\lambda^*)'' - y^*(\lambda^*)' = 0 \quad &\text{in } \Omega \quad \text{(the adjoint equation)}, \\ \alpha u^* - \lambda^* = 0 \quad &\text{in } \Omega_\circ \text{ (the optimality condition)}, \\ -\nu(y^*)'' + y^*(y^*)' - f - \mathcal{E}(u^*) = 0 \quad &\text{in } \Omega \quad \text{(the state equation)}. \end{aligned}$$

By using Remark B.2, the adjoint equation, and $\|y^*\|_{H_0^1} \le C_3$ it can be shown that

$$\|\lambda^*\|_{H_0^1} \le \frac{1}{\nu}\exp\left(\frac{2}{\nu}\|y^*\|_{L^2}\right)\|y^* - z\|_{L^2} \le C_6,$$

where the constant $C_6 > 0$ is given by estimate (5.7). Thus, from the optimality condition we infer that $\|(u^*)'\|_{L^2(\Omega_\circ)} \le C_6/\alpha$, which coincides with estimate (5.8). The state equation gives

$$\|(y^*)''\|_{L^2} \le \frac{1}{\nu}\left(2\,\|y^*\|_{L^\infty}\,\|y^*\|_{H_0^1} + \|u^*\|_{L^2(\Omega_\circ)} + \|f\|_{L^2}\right) \le C_7,$$

where the constant $C_7 > 0$ is given by estimate (5.9). We set

$$V^* = \left\{(v,q) \in H^2(\Omega) \times H^1(\Omega_\circ) : \|v''\|_{L^2} \le 2C_8 \text{ and } \|q'\|_{L^2(\Omega_\circ)} \le 2C_8\right\}. \tag{5.11}$$

Thus, we obtain that

$$(y^*,u^*), (y^n,u^n), (y^n,u^n) - (y^*,u^*), (y^{n+1},u^{n+1}) - (y^n,u^n) \in V^*.$$

Now let us discuss Assumption 6 in case of Example 2.1.

(a) We have $\|p_h\|_{\mathcal{L}(X_h \times Y_h, X \times Y)} = 1$. It was proved in [Aub72, p. 38] that

$$\lim_{h\to\infty} \|((y,u),\lambda) - r_h((y,u),\lambda)\|_{X\times Y} = 0 \quad \text{for all } ((y,u),\lambda) \in X \times Y.$$

Hence $\|r_h((y,u),\lambda)\|_{X\times Y}$ is bounded for all $((y,u),\lambda) \in X \times Y$. According to the principle of uniform boundedness [Wou79, p. 112], there exists a constant $C_9 > 0$ such that $\|r_h\|_{\mathcal{L}(X\times Y, X_h \times Y_h)} \le C_9$. Thus, the discretization family is uniformly bounded.

(b) If we define the operator $R_{c,h}$ by the internal approximation of R_c, i.e., $R_{c,h} = (p_h)^\star \circ R_c \circ p_h^X$, then it follows from $\|p_h^\star\|_{\mathcal{L}(X\times Y, X_h \times Y_h)} = 1$ that

$$\|R_{c,h}(y_h,u_h) - R_{c,h}(\bar y_h,\bar u_h)\|_{X_h\times Y_h} \le \gamma_R\,\|(y_h,u_h) - (\bar y_h,\bar u_h)\|_{X\times Y}.$$

Analogously, if we define $M_{c,h}(\cdot) = (p_h)^\star \circ M_c(p_h^X(\cdot)) \circ p_h^X$, we find that

$$\|M_{c,h}(y_h,u_h) - M_{c,h}(\bar y_h,\bar u_h)\|_{\mathcal{L}(X_h\times Y_h)} \le \gamma_M\,\|(y_h,u_h) - (\bar y_h,\bar u_h)\|_{X\times Y}.$$

Thus, (4.7) follows with $\Gamma_R = \gamma_R$ and $\Gamma_M = \gamma_M$.

(c) The discretization family is stable in U_h if the uniform sufficient optimality condition

$$L_h''(y_h,u_h,\Lambda_h(y_h,u_h))(\phi_h,\phi_h) \ge \kappa^*\,\|\phi_h\|_X^2 \quad \text{for all } \phi_h \in N(e_h'(y_h,u_h)) \tag{5.12}$$

and the uniform Babuška–Brezzi condition

$$\inf_{\lambda_h \in Y_h\setminus\{0\}} \sup_{\phi_h \in X_h\setminus\{0\}} \frac{\langle e_h'(y_h,u_h)^\star\lambda_h, \phi_h\rangle_X}{\|\phi_h\|_X\,\|\lambda_h\|_Y} \ge \beta^* \tag{5.13}$$

hold for all $(y_h,u_h) \in U_h$ and constants $\kappa^* \ge 0$ and $\beta^* > 0$ that do not depend on h; see [GR86, p. 114]. If we define $L_h'' = (p_h^X)^\star \circ L_0''(p_h(\cdot)) \circ p_h^X$ and use (a), then (5.12) leads to

$$L''(y_h,u_h,\Lambda_h(y_h,u_h))(\phi_h,\phi_h) \ge \kappa^*\,\|\phi_h\|_X^2 \quad \text{for all } \phi_h \in N(e_h'(y_h,u_h)).$$

Hence, (5.12) follows if L_0'' is coercive in the whole space X. It is proved in [Vol00b] that (5.13) holds if the mesh-size is sufficiently small and if (y_h,u_h) is sufficiently close to $r_h^X(x^*,u^*)$.

TABLE 1

n	$R_{c,h}(y_h^n, u_h^n)$ for Λ_N	$R_{c,h}(y_h^n, u_h^n)$ for Λ
1	1.56e-01	1.62e-01
2	5.98e-02	4.33e-02
3	7.30e-03	9.15e-03
4	1.31e-03	1.29e-03
5	1.04e-04	5.26e-06
6	1.56e-09	1.37e-09
7	6.42e-14	5.87e-14

(d) In (5.11) we introduced the set V^*. Standard estimates for finite elements (see, for instance, [Hac92]) lead to

$$\|(y,u) - r_h^X(y,u)\|_X \le C_{10} h \quad \text{for all } (y,u) \in V^*.$$

Thus,

$$\begin{aligned}\|R_{c,h}(r_h^X(y,u)) - (p_h)^\star R_c(y,u)\|_{X\times Y} &\le \gamma_R \|p_h^X r_h^X(y,u) - (\bar y, \bar u)\|_{X\times Y} \\ &\le \gamma_R C_{10} h = C_{11} h,\end{aligned}$$

with $C_{11} = \gamma_R C_{10}$, so that the discretization family is consistent of order $s = 1$.

6. Numerical example. Let us consider the optimal control problem

$$\text{minimize } J(y,u) = \frac{1}{2}\,\|y - z\|_{L^2}^2 + \frac{\alpha}{2}\,\|u\|_{L^2(\Omega_\circ)}^2$$

with $z(x) = \sin(2\pi x)$, $\Omega = (0,1)$, $\Omega_\circ = (0, 0.5)$, and $\alpha = 0.001$

$$\text{subject to } -\nu y'' + yy' = \mathcal{E}(u) \quad \text{in } \Omega \text{ and } y(0) = 0, y(1) = 0,$$

where $\nu = 0.01$. The codes are written in MATLAB 5.3 and executed on a 550 MHz PC Pentium III. We apply the augmented Lagrangian-SQP method with $c = 1$ and compare the Newton update Λ_N with the least-squares update Λ given in (2.5). The two algorithms are stopped if

$$\|R_c(y_h^n, u_h^n)\|_{X\times Y} < 10^{-10}.$$

As initial iterates we choose $y_h^0 = z$ and $u_h^0 = 0$, and the step-size h is set equal to $\frac{1}{150}$. It turns out that both updates behave similarly; see Table 1.

Further, the second-order convergence rate in the variables (y_h^n, u_h^n) can be observed empirically in both cases. For this purpose we define

$$e_h(n) = \frac{\|(y_h^n, u_h^n) - (y_h^*, u_h^*)\|_{H^1\times L^2}}{\|(y_h^{n-1}, u_h^{n-1}) - (y_h^*, u_h^*)\|_{H^1\times L^2}^2} \quad \text{for } n \ge 2.$$

Then we observe in Table 2 that the term $e_h(n)$ is bounded, which yields the quadratic convergence rate of convergence.

An important feature of iterative approximation schemes for infinite-dimensional problems is mesh-independence. It asserts that the number or iterations to reach a

certain approximation quality $\varepsilon > 0$ is independent of the mesh-size. Let us introduce the following notation:

$$n_h(\varepsilon) = \min \left\{ n_\circ | n \geq n_\circ : \|R_{c,h}(x_h^n)\|_{X \times Y} < \varepsilon \right\}.$$

From Table 3 one can observe empirically that Algorithm 3 has a mesh-independent behavior. For a proof we refer the reader to [Vol01].

7. Conclusions. In this paper we prove convergence results of the Kantorovich type for Lagrange-SQP methods. The theory is extended to the case of Lipschitz-continuous multiplier updates and is applied to obtain convergence rates for the discretized optimization problems. In addition, we obtain the existence of stationary points for the discretized problems. The assumptions are verified for an optimal control problem for the steady-state Burgers equation, and a numerical example illustrates the theoretical results. Numerical examples for the augmented Lagrange-SQP methods with Lipschitz-continuous Lagrange multiplier updates exhibit mesh-independence.

Appendix A. Nonlinear majorants. For more details and for the proofs we refer the reader to [OR70, Part V].

DEFINITION A.1. *Let* $\{x^n\}_{n \in \mathbb{N}}$ *be any sequence in a real Hilbert space* X. *Then a sequence* $\{t^n\}_{n \in \mathbb{N}} \subset [0, \infty)$ *for which*

$$\|x^{n+1} - x^n\|_X \leq t^{n+1} - t^n, \qquad n = 0, 1, \dots,$$

holds is a majorizing sequence *for* $\{x^n\}_{n \in \mathbb{N}}$.

Note that any majorizing sequence is necessarily monotonically increasing. In the proof of Theorem 3.2 a majorizing sequence occurs as the solution of a certain nonlinear difference equation. It is based on an estimate for $\Phi(\Phi(x)) - \Phi(x)$. The idea is presented in the following lemma.

LEMMA A.2. *Let X be a real Hilbert space, $\Phi : D \subseteq X \to X$, and $\varphi : J_1 \times J_2 \subset \mathbb{R}^2 \to [0,\infty)$, where each J_i is an interval of the form $[0,\alpha]$, $[0,\alpha)$, or $[0,\infty)$ and φ is monotonically increasing in each variable. Suppose that there is an element $x^0 \in D$ such that*

$$\|\Phi(\Phi(x)) - \Phi(x)\|_X \le \varphi\left(\|\Phi(x) - x\|_X, \|\Phi(x) - x^0\|_X\right) \tag{A.1}$$

holds whenever $x, \Phi(x) \in D$, and that with $t^0 = 0$, $t^1 = \|\Phi(x^0) - x^0\|_X$ the solution of the difference equation

$$t^{n+1} - t^n = \varphi(t^n - t^{n-1}, t^n), \qquad n = 1, 2, \dots, \tag{A.2}$$

exists and converges to $t^* < \infty$. Finally, assume that $B(x^0, t^*) \subset D$. Then the iterates $x^{n+1} = \Phi(x^n)$, $n = 0, 1, \dots$, are well defined, lie in $\overline{B(x^0, t^*)}$, converge to some $x^* \in \overline{B(x^0, t^*)}$, and satisfy

$$\|x^* - x^n\|_X \le t^* - t^n \quad \text{for all } n = 0, 1, \dots .$$

If $x^* \in D$ and Φ is continuous at x^*, then $x^* = \Phi(x^*)$.

Using (3.12) the difference equation (A.2) has the form

$$t^{n+1} - t^n = \frac{p_1\ (t^n - t^{n-1})^2 + p_2\ (t^n - t^{n-1})}{1 - p_3\ t^n} \quad \text{for all } n = 0, 1, \dots . \tag{A.3}$$

The following lemma gives sufficient conditions for the convergence of the sequence satisfying (A.3).

LEMMA A.3. *Assume that $p_1 > 0$, $1 > p_2 \ge 0$, $2p_1 = p_3$, and $0 \le \|\Phi(x^0) - x^0\|_X \le (1 - p_2)^2 (4p_1)^{-1}$. Then the sequence $\{t^n\}_{n\in\mathbb{N}}$ of (A.3) with initial values $t^0 = 0$ and $t^1 = \|\Phi(x^0) - x^0\|_X$ is strictly increasing unless $\|\Phi(x^0) - x^0\|_X = 0$, and*

$$\lim_{n\to\infty} t^n = t^* = \frac{1}{p_3}\left(1 - p_2 - \sqrt{(1 - p_2)^2 - 4p_1\ \|\Phi(x^0) - x^0\|_X}\right).$$

Appendix B. Linear boundary value problems of second order. Let $f \in L^2(\Omega)$, $y \in C(\overline{\Omega})$, and $\nu > 0$. We consider the linear boundary value problem

$$v'' + \frac{y}{\nu}\, v' = f \quad \text{in } \Omega, \quad v(0) = v(1) = 0. \tag{B.1}$$

Let

$$\varphi_0(x) = -\int_0^x \exp\left(-\frac{1}{\nu}\int_0^t y(s)\, ds\right) dt, \quad \varphi_1(x) = \int_x^1 \exp\left(-\frac{1}{\nu}\int_0^t y(s)\, ds\right) dt.$$

Observe that φ_0 and φ_1 are two linear independent fundamental solutions of the homogeneous problem $v'' + \frac{y}{\nu}\, v' = 0$ with $\varphi_0(0) = 0$ and $\varphi_1(1) = 0$. The Green's function associated with problem (B.2) is given by

$$G(x,t) = \begin{cases} \dfrac{\varphi_0(x)\varphi_1(t)}{\varphi_1(0)}, & 0 \le x \le t \le 1, \\[2ex] \dfrac{\varphi_0(t)\varphi_1(x)}{\varphi_1(0)}, & 0 \le t \le x \le 1. \end{cases} \tag{B.2}$$

For the proof of the next result we refer the reader to [Con78, p. 51].

PROPOSITION B.1. *Let $f \in L^2(\Omega)$ and let G denote the Green's function given by* (B.2). *Then there exists a unique solution $v \in H^2(\Omega) \cap H_0^1(\Omega)$ of* (B.1), *with the integral representation*

$$v(x) = \int_\Omega G(x,t) f(t)\, dt \quad \text{for } x \in \overline{\Omega}. \tag{B.3}$$

Remark B.2. Proposition B.1 allows us to give an H_0^1-estimate for the solution of (B.1):

$$\|v\|_{H_0^1} \le \frac{1}{|\varphi_1(1)|} \|\varphi_0\, \varphi_1\|_{L^\infty} \|f\|_{L^2} \le \exp\left(\frac{2}{\nu} \|y\|_{L^1}\right) \|f\|_{L^2}.$$

For $y \in C^1(\overline{\Omega})$ we consider the linear boundary value problem

$$v'' - \frac{1}{\nu}(yv)' = f \quad \text{in } \Omega, \quad v(0) = v(1) = 0. \tag{B.4}$$

Let

$$\varphi_0(x) = -\exp\left(\int_0^x \frac{y(s)}{\nu}\, ds\right) \int_0^x \exp\left(\int_t^0 \frac{y(s)}{\nu}\, ds\right) dt,$$

$$\varphi_1(x) = \exp\left(\int_0^x \frac{y(s)}{\nu}\, ds\right) \int_0^1 \exp\left(\int_t^1 \frac{y(s)}{\nu}\, ds\right) dt - \exp\left(\int_0^1 \frac{y(s)}{\nu}\, ds\right)$$
$$\cdot \exp\left(\int_0^x \frac{y(s)}{\nu}\, ds\right) \int_0^x \exp\left(-\int_0^t \frac{y(s)}{\nu}\, ds\right) dt.$$

Note that φ_0 and φ_1 are linear independent fundamental solutions of the homogeneous problem $v'' \frac{1}{\nu}(yv)' = 0$ with $\varphi_0(0) = 0$ and $\varphi_1(1) = 0$. Let the Green's function associated with problem (B.4) be given by

$$G(x,t) = \begin{cases} \dfrac{\varphi_0(x)\varphi_1(t)}{\varphi_1(1)}, & 0 \le x \le t \le 1, \\ \dfrac{\varphi_0(t)\varphi_1(x)}{\varphi_1(1)}, & 0 \le t \le x \le 1. \end{cases} \tag{B.5}$$

PROPOSITION B.3. *Let $f \in L^2(\Omega)$ and let G denote the Green's function given by* (B.5). *Then there exists a unique solution $v \in H^2(\Omega \cap H_0^1(\Omega)$ of* (B.4) *with the integral representation*

$$v(x) = \int_\Omega G(x,t) f(t)\, dt \quad \text{for } x \in \overline{\Omega}.$$

Remark B.4. Proposition B.3 allows us to give an estimate for the solution of (B.4) in the H_0^1-norm:

$$\|v\|_{H_0^1} \le \max_{(x,t)\in[0,1]^2} |G_x(x,t)|\, \|f\|_{L^2} \le c_\circ \|f\|_{L^2},$$

where

$$c_\circ = \exp\left(\frac{3}{\nu} \|y\|_{L^1}\right) \left(1 + \frac{\|y\|_{L^\infty}}{\nu}\right)^2 \left[1 + \frac{1}{|\varphi_1(1)|} \exp\left(\frac{2}{\nu} \|y\|_{L^1}\right)\right].$$

Acknowledgments. The authors thank both referees for helpful comments on the paper.

AN ANALYSIS OF SMOOTHING EFFECTS OF UPWINDING STRATEGIES FOR THE CONVECTION-DIFFUSION EQUATION*

HOWARD C. ELMAN† AND ALISON RAMAGE‡

Abstract. Using a technique for constructing analytic expressions for discrete solutions to the convection-diffusion equation, we examine and characterize the effects of upwinding strategies on solution quality. In particular, for grid-aligned flow and discretization based on bilinear finite elements with streamline upwinding, we show precisely how the amount of upwinding included in the discrete operator affects solution oscillations and accuracy when different types of boundary layers are present. This analysis provides a basis for choosing a streamline upwinding parameter which also gives accurate solutions for problems with non-grid-aligned and variable speed flows. In addition, we show that the same analytic techniques provide insight into other discretizations, such as a finite difference method that incorporates streamline diffusion and the isotropic artificial diffusion method.

1. Introduction.

There are many discretization strategies available for the linear convection-diffusion equation

$$\begin{aligned} -\epsilon\nabla^2 u(x,y) + \mathbf{w}\cdot\nabla u(x,y) &= f(x,y) \qquad \text{in} \quad \Omega, \\ u(x,y) &= g(x,y) \qquad \text{on} \quad \delta\Omega, \end{aligned} \tag{1.1}$$

where the small parameter ϵ and divergence-free convective velocity field $\mathbf{w} = (w_1(x,y), w_2(x,y))$ are given. In this paper, we analyze some well-known methods which involve the addition of upwinding to stabilize the discretization for problems involving boundary layers. In particular, we focus on characterizing exactly how this upwinding affects the resulting discrete solutions.

A standard discretization technique is the Galerkin finite element method (see, for example, [5], [9], [10], [11], [13]). This is based on seeking a solution u of the weak form of (1.1),

$$\epsilon(\nabla u, \nabla v) + (\mathbf{w}.\nabla u, v) = (f, v) \qquad \forall\, v \in V,$$

where the test functions v are in the Sobolev space $V = \mathcal{H}_0^1(\Omega)$. Restricting this to a finite-dimensional subspace V_h of V gives

$$\epsilon(\nabla u_h, \nabla v) + (\mathbf{w}.\nabla u_h, v) = (f_h, v) \qquad \forall\, v \in V_h, \tag{1.2}$$

where f_h is the $L^2(\Omega)$ orthogonal projection of f into V_h and h is a discretization parameter. Choosing the test functions equal to a set of basis functions for V_h (usually

‡Department of Mathematics, University of Strathclyde, Glasgow G1 1XH, Scotland (ar@maths.strath.ac.uk). The work of this author was supported by the Leverhulme Trust.

continuous piecewise polynomials with local support) leads to a sparse linear system whose solution can be used to recover the discrete solution u_h.

One quantity which has an important effect on the quality of the resulting discrete solution is the mesh Péclet number

$$P_e^{el} = \frac{h^{el}|\mathbf{w}|}{2\epsilon},$$

where h^{el} is a measure of element size and $|\mathbf{w}|$ represents the strength of the convective field within an element. In particular, if the mesh Péclet number is greater than one, then the discrete solution obtained from the Galerkin method may exhibit nonphysical oscillations. For the one-dimensional analogue of (2.1), this is well understood (see, for example, [10, p. 14]); for an analysis of the Galerkin discretization of the two-dimensional case, see [2]. An approach for minimizing the deleterious effects of these oscillations, especially in areas of the domain away from boundary layers, is to stabilize the discrete problem by using an upwind discretization. A particularly effective implementation of this idea is via the streamline diffusion method (see, e.g., [8], [9, sect. 9.7]). For linear or bilinear elements, the weak form (1.2) is replaced by

$$\epsilon(\nabla u_h, \nabla v) + (\mathbf{w}.\nabla u_h, v) + \sum \alpha^{el}(\mathbf{w}\cdot\nabla u_h, \mathbf{w}\cdot\nabla v)_{el} = (f_h, v) + \sum \alpha^{el}(f_h, \mathbf{w}\cdot\nabla v)_{el} \quad \forall v \in V_h, \tag{1.3}$$

where the sums are taken over all elements in the discretization. The stabilization parameters α^{el} are given by

$$\alpha^{el} = \frac{\delta^{el} h^{el}}{|\mathbf{w}|}, \tag{1.4}$$

where $\delta^{el} \geq 0$ are parameters to be chosen. Note that setting $\delta^{el} = 0$ on each element reduces (1.3) to the standard Galerkin case (1.2): this is the usual practice when $P_e^{el} < 1$. Formulation (1.3) has additional coercivity in the local flow direction, resulting in improved stability. More on the motivation behind this method can be found in [6, p. 289]. However, the best way of choosing δ^{el} for a general convection-diffusion problem is not known: for a discussion of this difficulty, see, for example, [13, Remark 3.34, p. 234].

In [2], we developed an analytic technique for characterizing the nature of oscillations in discrete solutions arising from the Galerkin discretization (1.2). More specifically, for the case of grid-aligned flow, we presented an analytic representation of the discrete solution, enabling isolation of any oscillatory behavior in the direction of the flow. Using this framework, we studied the dependence of solution behavior on the mesh Péclet number in some detail.

In this paper, we apply the tools developed in [2] to various upwinding strategies for discretizing (1.1). For the most part, we focus on the streamline diffusion method (1.3), examining the effect of stabilization on the quality of the resulting discrete solutions. In section 2, we summarize the Fourier analysis presented in [2] and derive an explicit formula for the discrete streamline diffusion solution for a model problem with constant grid-aligned flow. Section 3 contains the details of this process in the case of bilinear finite elements. The resulting formulae allow us to investigate various issues which influence the choice of stabilization parameters. In section 4, we characterize the effect of stabilization on oscillations in the discrete solution in the flow direction for three test problems whose solutions exhibit different types of

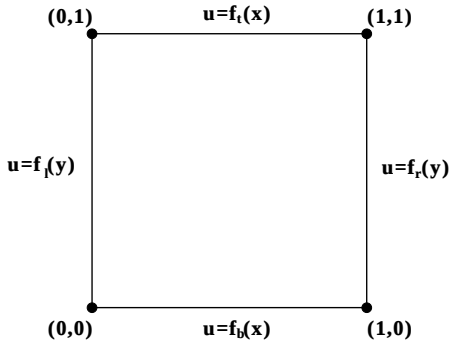

FIG. 1. *Boundary conditions.*

boundary layers. The implications of this analysis for solution accuracy are examined in section 5. In section 6, we discuss the relevance of our results for problems with non-grid-aligned and variable flow and present our recommended choice for the streamline diffusion parameters. Finally, in section 7, we illustrate how the same approach can be used to understand other discretization methods. We analyze an analogous streamline diffusion (upwind) discretization for a finite difference stencil and explain the comparative lack of effectiveness of isotropic artificial diffusion.

2. Summary of Fourier analysis. In this section, we summarize the Fourier techniques used in [2] to construct an analytic expression for the entries in the discrete solution vector $\mathbf{u}$.

Setting $\mathbf{w} = (0, 1)$ and $f = 0$ in (1.1), we obtain the "vertical wind" model problem

$$-\epsilon\nabla^2 u + \frac{\partial u}{\partial y} = 0 \qquad \text{in } \Omega = (0,1) \times (0,1), \tag{2.1}$$

with Dirichlet boundary conditions as shown in Figure 1. Using a natural ordering of the unknowns on a uniform grid of square bilinear elements with $N = 1/h$ elements in each dimension, both (1.2) and (1.3) give rise to a linear system

$$A\mathbf{u} = \mathbf{f}, \tag{2.2}$$

where the coefficient matrix A is of order $(N-1)^2$. Denoting the coefficients of the computational molecule by

$$\begin{array}{ccccc} m_4 & & m_3 & & m_4 \\ & \nwarrow & \uparrow & \nearrow & \\ m_2 & \leftarrow & m_1 & \rightarrow & m_2 \\ & \swarrow & \downarrow & \searrow & \\ m_6 & & m_5 & & m_6 \end{array}, \tag{2.3}$$

the matrix A can be written as

$$A = \begin{bmatrix} M_1 & M_2 & & & 0 \\ M_3 & M_1 & M_2 & & \\ & \ddots & \ddots & \ddots & \\ & & M_3 & M_1 & M_2 \\ 0 & & & M_3 & M_1 \end{bmatrix}, \tag{2.4}$$

where $M_1 = \text{tridiag}(m_2, m_1, m_2)$, $M_2 = \text{tridiag}(m_4, m_3, m_4)$, and $M_3 = \text{tridiag}(m_6, m_5, m_6)$ are all tridiagonal matrices of order $N-1$. Given that the eigenvalues and eigenvectors of the blocks of A satisfy

$$\begin{aligned} M_1\mathbf{v}_j &= \lambda_j \mathbf{v}_j, \qquad \lambda_j = m_1 + 2m_2 \cos\tfrac{j\pi}{N}, \\ M_2\mathbf{v}_j &= \sigma_j \mathbf{v}_j, \qquad \sigma_j = m_3 + 2m_4 \cos\tfrac{j\pi}{N}, \\ M_3\mathbf{v}_j &= \gamma_j \mathbf{v}_j, \qquad \gamma_j = m_5 + 2m_6 \cos\tfrac{j\pi}{N} \end{aligned} \tag{2.5}$$

for $j = 1, \ldots, N-1$, where the eigenvectors are

$$\mathbf{v}_j = \sqrt{\frac{2}{N}} \left[\sin\frac{j\pi}{N}, \quad \sin\frac{2j\pi}{N}, \quad \ldots, \sin\frac{(N-1)j\pi}{N} \right]^T, \tag{2.6}$$

we may obtain the decomposition

$$A = (\mathcal{V}P)T(\mathcal{V}P)^T, \tag{2.7}$$

where $\mathcal{V} = \text{diag}(V, V, \ldots, V)$ is a block diagonal matrix with each block V having the $N-1$ eigenvectors (2.6) as its columns, and P is a permutation matrix of order $(N-1)^2$. The matrix T is also block diagonal, with diagonal blocks $T_i = \text{tridiag}(\gamma_i, \lambda_i, \sigma_i)$, $i = 1, \ldots, N-1$. Using this decomposition and observing that P and V are both orthogonal, (2.2) implies

$$\mathbf{u} = \mathcal{V}P\mathbf{y}, \tag{2.8}$$

where the vector $\mathbf{y}$ is the solution to the linear system

$$T\mathbf{y} = P^T\mathcal{V}^T\mathbf{f} \equiv \hat{\mathbf{f}}. \tag{2.9}$$

As T is block diagonal, this system can be partitioned into $N-1$ independent systems of the form

$$T_i\mathbf{y}_i = \hat{\mathbf{f}}_i, \tag{2.10}$$

where T_i is defined above and $\mathbf{y}$ and $\hat{\mathbf{f}}$ are partitioned in the obvious way. Because T_i is a Toeplitz matrix, each of these systems can be considered as a three-term recurrence relation which can be solved analytically to give an expression for each entry y_{ik} of $\mathbf{y}_i$, $k = 1, \ldots, N-1$, in (2.10). Finally, to obtain an explicit formula for the entries of $\mathbf{u}$, we permute and transform these entries via (2.8) to get

$$u_{jk} = \sqrt{\frac{2}{N}} \sum_{i=1}^{N-1} \sin\frac{ij\pi}{N} y_{ik} \tag{2.11}$$

for $j, k = 1, \ldots, N-1$.

To obtain an expression for the entries y_{ik} in (2.11), we must consider the vectors $\hat{\mathbf{f}}_i$. As $f = 0$ in (2.1), the only nonzero entries in the original right-hand side vector $\mathbf{f}$ in (2.2) involve sums of certain matrix coefficients times boundary values, which are transformed and permuted to obtain $\hat{\mathbf{f}}$ in (2.9). The details of this process can be found in [2]. Here we simply state that each right-hand side vector $\hat{\mathbf{f}}_i$, $i = 1, \ldots, N-1$, in (2.10) can be written as

$$\hat{\mathbf{f}}_i = \begin{bmatrix} \bar{b}_i + \bar{s}_i \\ \bar{s}_i \\ \vdots \\ \bar{s}_i \\ \bar{t}_i + \bar{s}_i \end{bmatrix}_{N-1},$$

where $\bar{b}_i$ involves data from the bottom boundary values, $\bar{t}_i$ involves data from the top boundary values, and $\bar{s}_i$ combines information from the left and right boundary values. We will make the same assumption as in [2] that the functions $f_l(y)$ and $f_r(y)$ on the left and right boundaries are constant. This simplifies the presentation of the analysis.

The solution of each system (2.10) is now the solution of a three-term recurrence relation with constant coefficients whose auxiliary equation has roots

$$\mu_1(i) = \frac{-\lambda_i + \sqrt{\lambda_i^2 - 4\sigma_i\gamma_i}}{2\sigma_i}, \qquad \mu_2(i) = \frac{-\lambda_i - \sqrt{\lambda_i^2 - 4\sigma_i\gamma_i}}{2\sigma_i}. \tag{2.12}$$

The solution of this recurrence relation can be written as

$$y_{ik} = F_3(i) + [F_1(i) - F_3(i)]\, G_1(i,k) + [F_2(i) - F_3(i)]\, G_2(i,k), \tag{2.13}$$

where

$$G_1(i,k) = \frac{\mu_1^k - \mu_2^k}{\mu_1^N - \mu_2^N},$$
$$G_2(i,k) = (1 - \mu_1^k) - (1 - \mu_1^N)\left[\frac{\mu_1^k - \mu_2^k}{\mu_1^N - \mu_2^N}\right],$$

and the functions

$$F_1(i) = -\frac{\bar{t}_i}{\sigma_i}, \qquad F_2(i) = \frac{\bar{s}_i}{\sigma_i + \lambda_i + \gamma_i}, \qquad F_3(i) = -\frac{\bar{b}_i}{\gamma_i}$$

involve the coefficient matrix entries and boundary condition information (see [2] for details).

We emphasize that the functions $F_m(i)$, $m = 1, 2, 3$, in (2.13) are independent of the vertical grid index k: for fixed i, the behavior of $\mathbf{y}$ in the streamline (vertical) direction depends only on the functions $G_1(i,k)$ and $G_2(i,k)$. In addition, as $F_1(i)$ is related to the top boundary values, $F_2(i)$ is related to the sum of the left and right boundary values (which have been assumed to be constant for this analysis), and $F_3(i)$ is related to the bottom boundary values, (2.13) shows that different boundary conditions will dictate how the functions $G_1(i,k)$ and $G_2(i,k)$ combine to produce different two-dimensional recurrence relation solutions y_{ik}. In the next section, we analyze the behavior of these solutions in some detail for the streamline diffusion finite element discretization (1.3) with bilinear elements.

3. Streamline diffusion discretization. In [2], an explicit expression for (2.13) for the Galerkin finite element method with bilinear elements was derived and analyzed. Here we present the equivalent analysis for the streamline diffusion finite element discretization (1.3) with a view to precisely characterizing the effect of the extra diffusion on the oscillations that occur with the Galerkin method when $P_e^{el} > 1$. We again use bilinear elements. Note that for a uniform grid and constant grid-aligned flow, $\delta = \delta^{el}$ is constant over all elements.

3.1. The recurrence relation solution. The coefficients in stencil (2.3) for a streamline diffusion discretization (1.3) using bilinear finite elements are given by

$$m_1 = \tfrac{4}{3}(\delta h + 2\epsilon), \qquad m_2 = \tfrac{1}{3}(\delta h - \epsilon), \qquad m_3 = -\tfrac{1}{3}[(2\delta - 1)h + \epsilon],$$

$$m_4 = -\tfrac{1}{12}[(2\delta - 1)h + 4\epsilon], \quad m_5 = -\tfrac{1}{3}[(2\delta + 1)h + \epsilon], \quad m_6 = -\tfrac{1}{12}[(2\delta + 1)h + 4\epsilon].$$

For convenience, we introduce the notation

$$C_i = \cos\frac{i\pi}{N}$$

and write the eigenvalues (2.5) as

$$\begin{aligned}
\gamma_i &= \frac{1}{6}\{-2[\delta h(2+C_i)+\epsilon(1+2C_i)]-h(2+C_i)\},\\
\lambda_i &= \frac{2}{3}\{[\delta h(2+C_i)+\epsilon(1+2C_i)]+3\epsilon(1-C_i)\},\\
\sigma_i &= \frac{1}{6}\{-2[\delta h(2+C_i)+\epsilon(1+2C_i)]+h(2+C_i)\},
\end{aligned}$$

$i = 1, \ldots, N-1$. Substituting these into (2.12) gives the expressions

$$\mu_{1,2} = \frac{-2\delta - \left[\dfrac{4-C_i}{2+C_i}\right]\dfrac{1}{P_e} \pm \sqrt{1+\dfrac{12\delta(1-C_i)}{(2+C_i)}\dfrac{1}{P_e}+\dfrac{3(5+C_i)(1-C_i)}{(2+C_i)^2}\dfrac{1}{P_e^2}}}{-2\delta+1-\left[\dfrac{1+2C_i}{2+C_i}\right]\dfrac{1}{P_e}} \tag{3.1}$$

for the auxiliary equation roots in (2.13).

3.2. Oscillations in the recurrence relation solution. We know from [2, Thm 5.1] that if $P_e > 1$, then the recurrence relation solution $\mathbf{y}$ and the related discrete solution $\mathbf{u}$ to the pure Galerkin problem (1.2) usually exhibit oscillations. In this section we address the question of how the streamline diffusion parameter δ can be chosen to eliminate oscillations in the recurrence relation solution $\mathbf{y}$. The issue of how this affects the resulting $\mathbf{u}$ will be discussed in section 3.3.

THEOREM 3.1. *If $P_e > 1$, then for any value of $i \in S_N \equiv \{1, \ldots, N-1\}$ there exists a parameter*

$$\delta_i^c = \frac{1}{2}\left(1 - \left[\frac{1+2C_i}{2+C_i}\right]\frac{1}{P_e}\right) \tag{3.2}$$

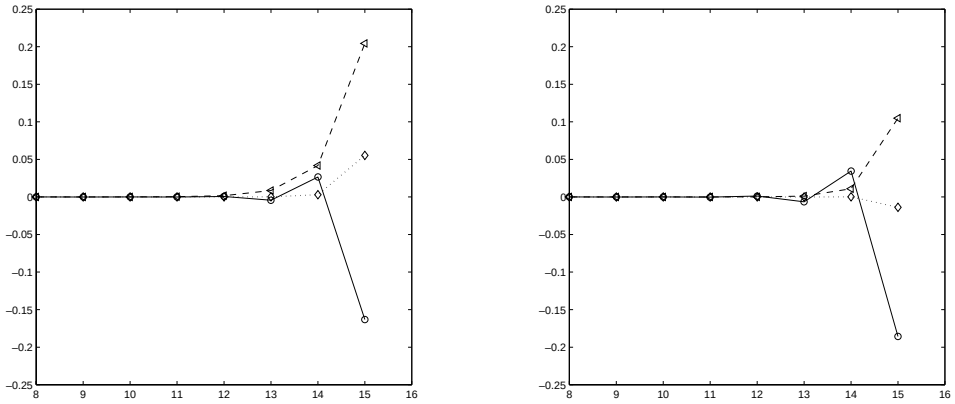
such that $\delta > \delta_i^c$ implies that $G_1(i,k)$ and $G_2(i,k)$ in (2.13) are nonoscillatory functions of k.

Proof. We have

$$G_1(i,k) = \frac{\mu_1^k - \mu_2^k}{\mu_1^N - \mu_2^N} = \left[\frac{\left(\dfrac{\mu_1}{\mu_2}\right)^k - 1}{\left(\dfrac{\mu_1}{\mu_2}\right)^N - 1}\right]\mu_2^{k-N} = \Theta(i,k)\,\mu_2^{k-N}.$$

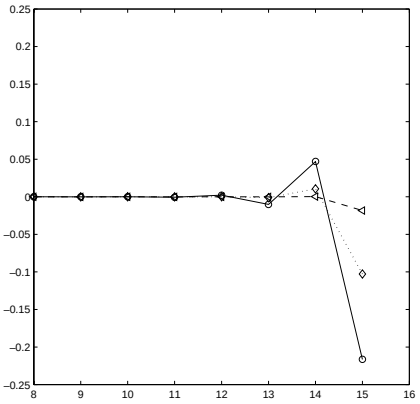
As $|\mu_1/\mu_2| < 1$, $\Theta(i,k)$ is always positive. Hence if μ_2 is negative, $G_1(i,k)$ alternates in sign as k goes from 1 to $N-1$, that is, $G_1(i,k)$ is oscillatory for fixed $i \in S_N$. From (3.1), the numerator of μ_2 is always negative so, for δ_i^c given by (3.2), we have the conditions

$$\begin{cases}
\delta > \delta_i^c \;\Rightarrow\; \mu_2 > 0,\ G_1(i,k) \text{ is nonoscillatory,}\\[2ex]
\delta < \delta_i^c \;\Rightarrow\; \mu_2 < 0,\ G_1(i,k) \text{ is oscillatory.}
\end{cases}$$



(a) $i = 1$.

(b) $i = N/2$.



(c) $i = N - 1$.

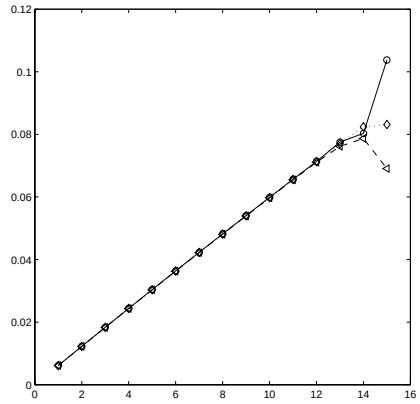
FIG. 2. *Plots of $G_1(i,k)$ against k for fixed i with $\delta = 0.2$ (solid, o), $\delta = 0.4$ (dotted, $\diamondsuit$), and $\delta = 0.6$ (dashed, $\triangle$).*

In addition, it can be shown that $0 < \mu_1 < 1$ so that if $G_1(i,k)$ is nonoscillatory, then $G_2(i,k) = (1-\mu_1^k) - (1-\mu_1^N)G_1(i,k)$ must also be nonoscillatory. □

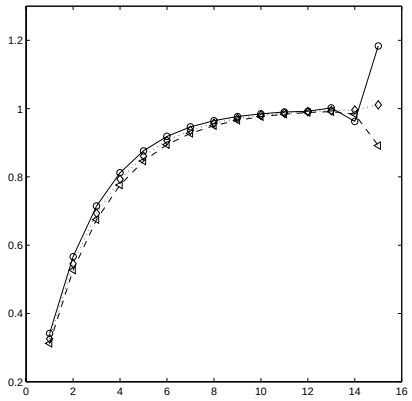
Sample plots of $G_1(i,k)$ for various values of $i \in S_N$ when $N = 16$ and $P_e = 3.125$ are given in Figure 2. Only the right half of the range of k has been plotted in each case to magnify the area of interest. Each subplot shows the behavior for three distinct values of δ, namely $\delta = 0.2$ (solid line, o), $\delta = 0.4$ (dotted line, $\diamondsuit$), and $\delta = 0.6$ (dashed line, $\triangle$). Given the relevant critical values $\delta_1^c \simeq 0.34$, $\delta_{N/2}^c \simeq 0.42$, and $\delta_{N-1}^c \simeq 0.65$ for this problem, the dependence of oscillations on the value of δ is clear. For $\delta = 0.2$ (that is, $\delta < \delta_i^c$ for all $i \in S_N$), all functions $G_1(i,k)$ are oscillatory; for $\delta = 0.4$, $G_1(1,k)$ is nonoscillatory (as $\delta > \delta_1^c$) and $G_1(N/2,k)$ is only very mildly oscillatory; for $\delta = 0.6$, only $G_1(N-1,k)$ is oscillatory (as $\delta > \delta_i^c$ for $i = 1, N/2$). Analogous behavior is seen in Figure 3 for $G_2(i,k)$ with the same parameter values, although the oscillations here occur about the function $1 - \mu_1^k$ rather than zero.

We now define

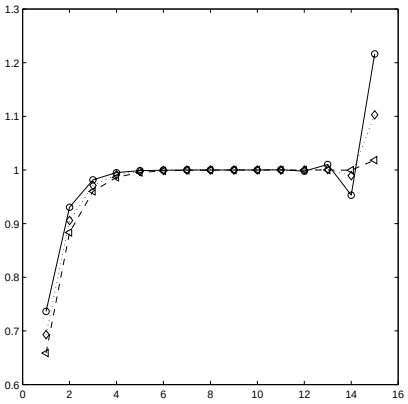
$$\delta_* = \frac{1}{2}\left(1 - \frac{1}{P_e}\right), \qquad \delta^* = \frac{1}{2}\left(1 + \frac{1}{P_e}\right) \tag{3.3}$$



(a) $i = 1$.



(b) $i = N/2$.



(c) $i = N - 1$.

FIG. 3. *Plots of $G_2(i,k)$ against k for fixed i with $\delta = 0.2$ (solid, o), $\delta = 0.4$ (dotted, $\diamondsuit$), and $\delta = 0.6$ (dashed, $\triangle$).*

(as in [3]) so that

$$\delta_* < \delta_i^c < \delta^* \tag{3.4}$$

for all values of $i \in S_N$. If $\delta \geq \delta^*$, then $\delta > \delta_i^c$ for each $i \in S_N$ and all of the functions $G_1(i,k)$ and $G_2(i,k)$ will be nonoscillatory in terms of k. We therefore have the following corollary to Theorem 3.1.

COROLLARY 3.2. *For any value of δ such that $\delta \geq \delta^*$, the functions $G_1(i,k)$ and $G_2(i,k)$ in* (2.13) *are nonoscillatory functions of k for every $i \in S_N$. Hence the recurrence relation solution $\mathbf{y}$ is a sum of smooth functions and will not exhibit oscillations in the streamline direction.*

The case $\delta = \delta_i^c$ requires special attention. With this value, $\sigma_i = 0$ in (2.5) and the resulting matrix T_i in (2.10) is bidiagonal. This leads to a two-term recurrence relation with auxiliary equation root

$$\rho = \frac{1}{1 + \dfrac{3(1 - C_i)}{2 + C_i} \dfrac{1}{P_e}}$$

and solution

$$y_{ik} = F_3(i)\rho^k + F_2(i)(1-\rho^k). \tag{3.5}$$

As $0 < \rho < 1$ for any $i \in S_N$, y_{ik} is nonoscillatory in the streamline direction. In addition, $\rho \to 1$ as $P_e \to \infty$, giving the solution $y_{ik} = F_3(i)$. Looking ahead to section 3.3, applying transformation (2.11) gives $u_{jk} = f_b(x_j)$ (see (3.8)). This is the solution to the reduced problem (obtained by setting $\epsilon = 0$ in (2.1)) where the bottom boundary values are simply transported in the direction of the flow without any diffusion present. That is, with the choice $\delta = \delta_i^c$ for each i, the discrete solution is exact at every interior node in the limit as $P_e \to \infty$.

3.3. Oscillations in the discrete solution. In this section we consider the impact of transformation (2.11) on the recurrence relation solution $\mathbf{y}$, with a view to choosing δ to obtain an oscillation-free discrete solution $\mathbf{u}$. We begin by considering the functions $F_m(i)$, $m = 1, 2, 3$, in (2.13). Following the analysis of [2, sect. 4.4 and appendix] we can derive the following expressions

$$\begin{aligned} F_1(i) &= \sqrt{\frac{2}{N}} \sum_{s=1}^{N-1} f_t(x_s) \sin \frac{si\pi}{N}, \\ F_2(i) &= f_l \sqrt{\frac{2}{N}} \sum_{s=1}^{N-1} \sin \frac{si\pi}{N}, \\ F_3(i) &= \sqrt{\frac{2}{N}} \sum_{s=1}^{N-1} f_b(x_s) \sin \frac{si\pi}{N} \end{aligned} \tag{3.6}$$

for the streamline diffusion weight functions in the special case where the constant left and right boundary values f_l and f_r are equal. From (2.13), we therefore have

$$\begin{aligned} y_{ik} = &\sqrt{\frac{2}{N}} \sum_{s=1}^{N-1} f_b(x_s) \sin \frac{si\pi}{N} + \sqrt{\frac{2}{N}} \sum_{s=1}^{N-1} [f_t(x_s) - f_b(x_s)] \sin \frac{si\pi}{N} G_1(i,k) \\ &+ \sqrt{\frac{2}{N}} \sum_{s=1}^{N-1} [f_l - f_b(x_s)] \sin \frac{si\pi}{N} G_2(i,k) \end{aligned} \tag{3.7}$$

[2, Thm 4.2]. Note that the expressions in (3.6) hold for any stencil of the form (2.3) whose entries sum to zero. In particular, this implies that the functions in (3.6) are the same for discretizations (1.2) and (1.3).

We now apply transformation (2.11) to (3.7) to obtain an expression for the entries of the discrete solution vector $\mathbf{u}$. As in [2], for the first term we have

$$\sqrt{\frac{2}{N}} \sum_{i=1}^{N-1} \sin \frac{ij\pi}{N} \left\{ \sqrt{\frac{2}{N}} \sum_{s=1}^{N-1} f_b(x_s) \sin \frac{si\pi}{N} \right\} = f_b(x_j), \tag{3.8}$$

where $f_b(x)$ is the bottom boundary function in Figure 1. Applying (2.11) to the full expression (3.7) therefore gives

$$u_{jk} = f_b(x_j) + \frac{2}{N} \sum_{i=1}^{N-1} \left[a_{ij} G_1(i,k) + b_{ij} G_2(i,k) \right], \tag{3.9}$$

where

$$a_{ij} = \sin\frac{ij\pi}{N}\sum_{s=1}^{N-1}[f_t(x_s) - f_b(x_s)]\sin\frac{si\pi}{N},$$

(3.10)

$$b_{ij} = \sin\frac{ij\pi}{N}\sum_{s=1}^{N-1}[f_l - f_b(x_s)]\sin\frac{si\pi}{N}.$$

That is, along a streamline (j fixed), $\mathbf{u}$ consists of the bottom boundary value on that line plus a linear combination of the functions $G_1(i,k)$ and $G_2(i,k)$ for $i \in S_N$. Note that $a_{i(N-j)} = a_{ij}$ and $b_{i(N-j)} = b_{ij}$, so that if $f_b(x)$ is symmetric about the center vertical line of the grid, then so is $\mathbf{u}$.

We can use the representation (3.9) to obtain insight into the effect of δ on the quality of the solution in the streamline direction. Recall from section 3.2 that if $\delta \geq \delta_i^c$ in (3.2), then the functions $G_1(i,k)$ and $G_2(i,k)$ are nonoscillatory in the streamline direction for that particular $i \in S_N$. It follows from Corollary 3.2 that if $\delta \geq \delta^*$ in (3.3), then (3.9) is a sum of smooth functions. We have therefore established a sufficient condition for the discrete solution to be nonoscillatory.

THEOREM 3.3. *For a streamline diffusion discretization of* (2.1) *with bilinear finite elements, the discrete solution* $\mathbf{u}$ *does not exhibit oscillations in the streamline direction when* $\delta \geq \delta^*$.

4. Analysis of boundary layer effects. In practice, it turns out that the restriction on δ given by Theorem 3.3 is too harsh, and better solutions can be obtained using values of δ smaller than δ^* due to the "smoothing" nature of transformation (2.11). The precise effect of this transformation in the context of the behavior of the Galerkin finite element solution for different mesh Péclet numbers was studied in [2]. Here we present a discussion of the effects of varying δ in the streamline diffusion method. We illustrate the ideas with three examples containing different types of boundary layers. The first two examples contain an exponential layer at the outflow and parabolic layers along the characteristic (vertical) boundaries, respectively. The third example has a Neumann boundary condition at the outflow, and we show that the analysis generalizes to this case.

Throughout this section we will use notation based on considering u_{jk} in (3.9) as a sum of smooth and oscillatory parts. That is, letting i^* be the lowest value of $i \in S_N$ such that $\delta < \delta_i^c$, we write

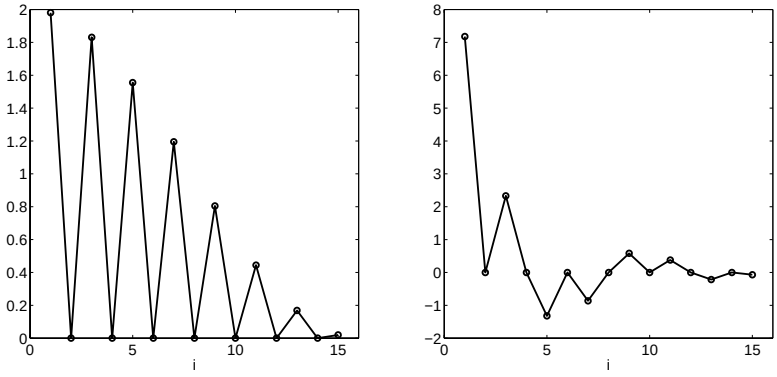
(4.1)

$$\begin{aligned} u_{jk} &= f_b(x_j) + \frac{2}{N}\left(\sum_{i=1}^{i^*-1}[a_{ij}G_1(i,k) + b_{ij}G_2(i,k)] + \sum_{i=i^*}^{N-1}[a_{ij}G_1(i,k) + b_{ij}G_2(i,k)]\right) \\ &= f_b(x_j) + S_{\text{smooth}} + S_{\text{osc}}. \end{aligned}$$

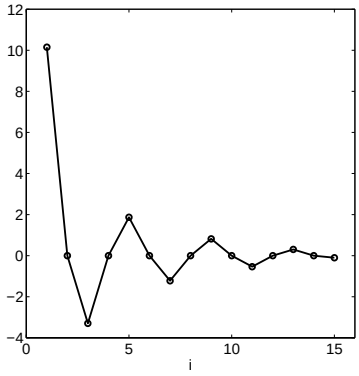
Note that the preceding analysis implies $S_{\text{smooth}} = 0$ when $\delta \leq \delta_*$ and $S_{\text{osc}} = 0$ when $\delta \geq \delta^*$. As δ increases from δ_*, i^* will increase so that S_{smooth} contains more and more of the terms, with the overall smoothness of $\mathbf{u}$ dependent on the relative size of the two sums S_{smooth} and S_{osc}.

Problem I. In this example we apply the Dirichlet boundary conditions

$$f_t(x) = 1, \qquad f_b(x) = f_l(y) = f_r(y) = 0,$$



(a) $j = 1$. (b) $j = N/4$.



(c) $j = N/2$.

FIG. 4. *Plots of coefficients a_{ij} against i for $N = 16$.*

as per Figure 1, so that the solution has an exponential boundary layer of width ϵ along the top boundary. For this problem, (3.7) implies

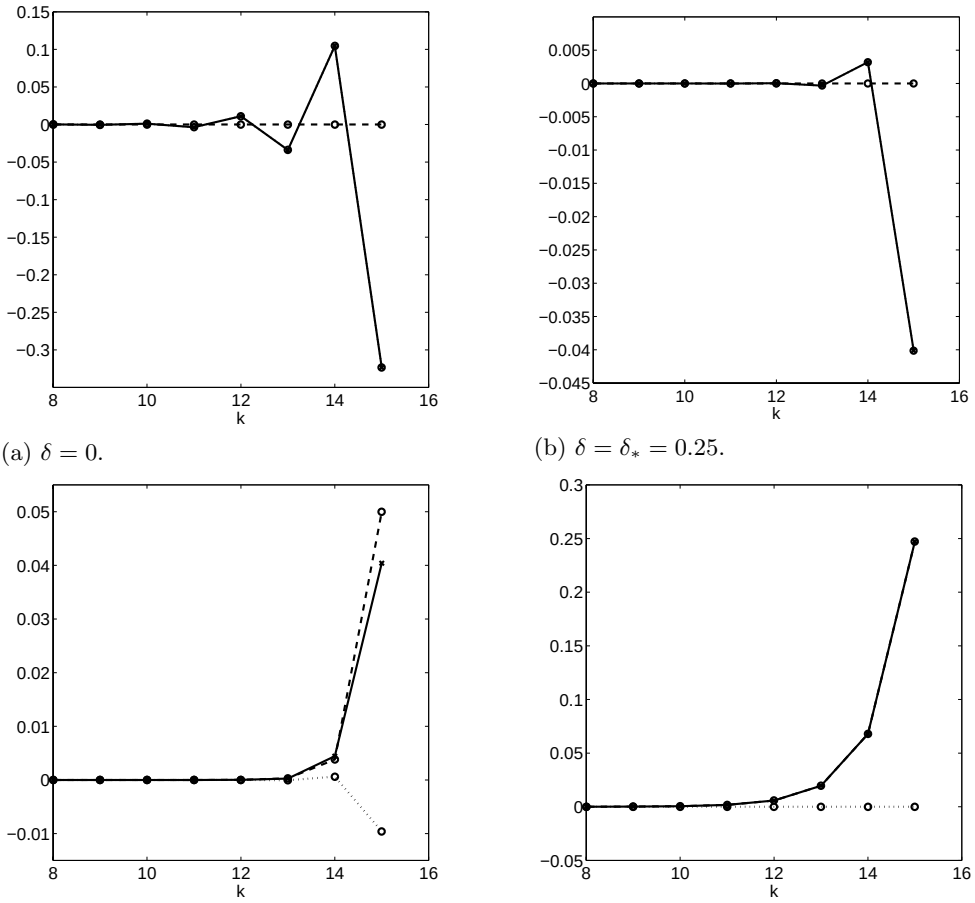
$$y_{ik} = \sqrt{\frac{2}{N}} \sum_{s=1}^{N-1} \sin \frac{si\pi}{N} G_1(i,k) \tag{4.2}$$

so the coefficients in (3.10) simplify to

$$a_{ij} = \sin \frac{ij\pi}{N} \sum_{s=1}^{N-1} \sin \frac{si\pi}{N}, \qquad b_{ij} = 0, \tag{4.3}$$

with the magnitude of each a_{ij} decreasing rapidly as i goes from 1 to $N-1$ as shown in Figure 4 (taken from [2]). This means that the contributions to u_{jk} from the functions $G_1(i,k)$ are much larger for small indices i, so that the smoothness of $G_1(i,k)$ for small i plays a much more important role. In particular, it is not necessary for $G_1(i,k)$ to be nonoscillatory for all $i \in S_N$ in order for $|S_{\text{smooth}}|$ to dominate $|S_{\text{osc}}|$ and the resulting function $\mathbf{u}$ to be smooth.

We illustrate these ideas in Figures 5 and 6 for this example problem with $N = 16$ and $P_e = 2$. The first figure shows u_{1k} (or, equivalently, $u_{(N-1)k}$) plotted against k. This is the vertical cross-section of the solution obtained by fixing $j = 1$, which is



(a) $\delta = 0$.

(b) $\delta = \delta_* = 0.25$.

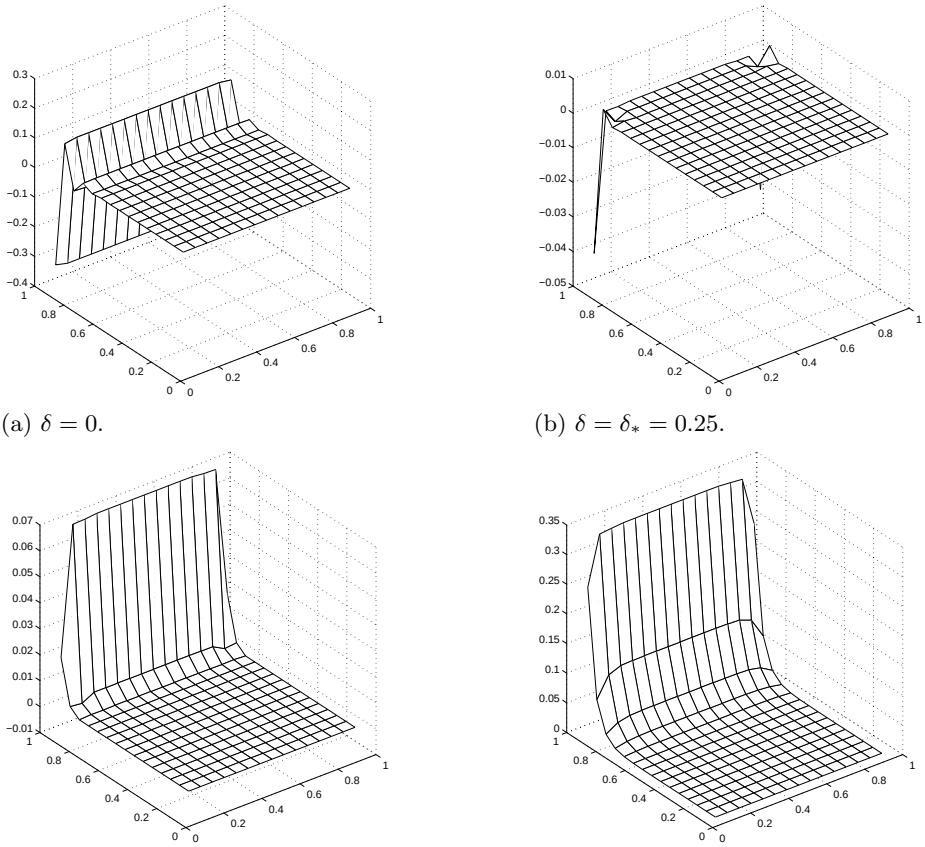
(c) $\delta = \delta_{\rm s} = 0.354$.

(d) $\delta = \delta^* = 0.75$.

FIG. 5. *Comparison of* $S_{\rm smooth}$ *(dashed line, o) and* $S_{\rm osc}$ *(dotted line, o) with* u_{1k} *(solid line, x) for Problem* I.

the most oscillatory of the vertical cross-sections for this problem. Each plot shows a comparison of $S_{\rm smooth}$ (dotted line, o) and $S_{\rm osc}$ (dashed line, o) with u_{1k} (solid line, x) for a different value of δ, where again only the right half of the range of k has been plotted to magnify the area of interest. For this example, $\delta_* = 0.25$ and $\delta^* = 0.75$. Plot (a) shows the Galerkin case ($\delta = 0$) where all of the functions $G_1(i,k)$ are oscillatory and $S_{\rm smooth}$ is zero. This is still true in plot (b), where $\delta = \delta_*$, but the magnitude and extent of the oscillations has been reduced considerably. The result of choosing $\delta = \delta^*$ according to Theorem 3.3 to guarantee an oscillation-free discrete solution by ensuring a nonoscillatory $\mathbf{y}$ is shown in plot (d). Here too much extra diffusion has been added. Plot (c) shows u_{1k} for $\delta = \delta_{\rm s} = 0.354$, which lies in the interval (δ_7^c, δ_8^c), that is, $i^* = 8$. This is the lowest value of i^* such that $S_{\rm smooth}$ dominates (3.9) for this problem and u_{1k} is nonoscillatory.

The corresponding full two-dimensional solutions $\mathbf{u}$ are shown in Figure 6, where the boundary values have been omitted so that the fine detail of each solution is visible. The overall behavior corresponds to that seen from the cross-sections: the severe oscillations present when $\delta = 0$ are almost eliminated by choosing $\delta = \delta_*$, and



(a) $\delta = 0$.

(b) $\delta = \delta_* = 0.25$.

(c) $\delta = \delta_s = 0.354$.

(d) $\delta = \delta^* = 0.75$.

FIG. 6. *Discrete solution at interior node points for Problem* I *with* $N = 16$, $P_e = 2$.

setting $\delta = \delta^*$ gives a smooth but overly diffuse solution. For $\delta = \delta_s$, the oscillations along the lines u_{1k} and $u_{(15)k}$ have just been eliminated to give a completely smooth solution in the flow direction.

Problem II. Next we consider the Dirichlet boundary conditions

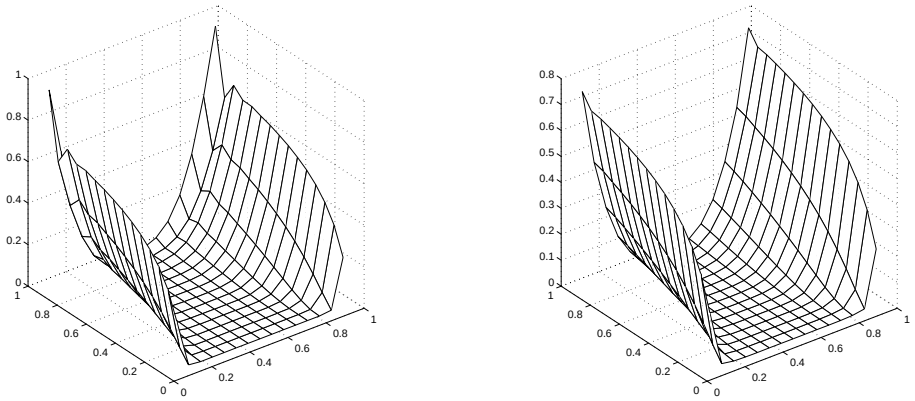
$$f_b(x) = f_t(x) = 0, \qquad f_l(y) = f_r(y) = 1,$$

which result in a solution which has parabolic layers on both vertical sides of the domain. The recurrence relation solution is

$$y_{ik} = \sqrt{\frac{2}{N}} \sum_{s=1}^{N-1} \sin \frac{si\pi}{N} G_2(i,k), \tag{4.4}$$

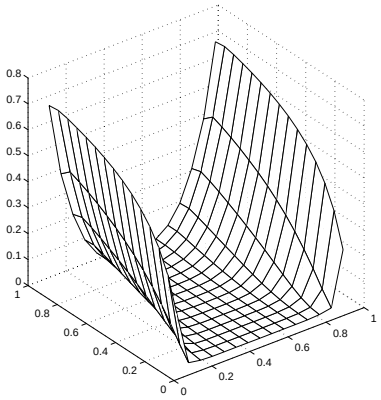
which is the same as for Problem I, except with G_2 in place of G_1 (see (4.2)). In addition, the coefficients in the full solution (3.10) are identical to those in Problem I as given by (4.3). The analysis for this problem is therefore very similar. In particular, as observed in section 3.2, G_2 is oscillatory if and only if G_1 is oscillatory, so exactly the same argument applies as to the effect of δ on solution quality.

Sample solutions for $N = 16$ with $P_e = 2$ are shown in Figure 7. These plots

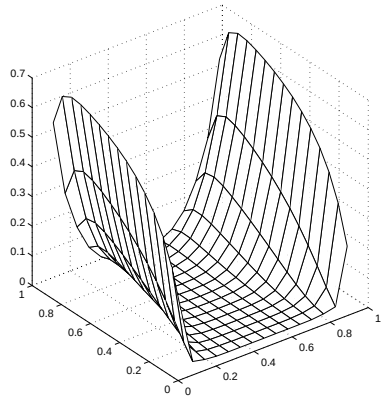


(a) $\delta = 0$.

(b) $\delta = \delta_* = 0.25$.



(c) $\delta = \delta_s = 0.354$.



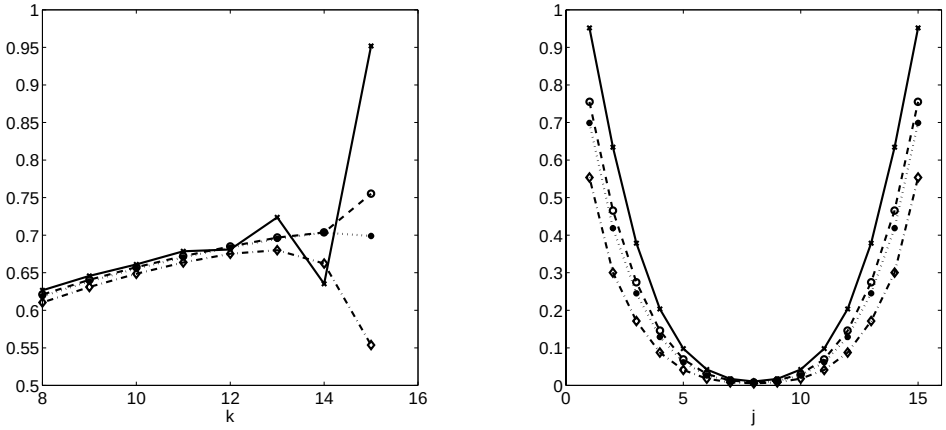
(d) $\delta = \delta^* = 0.75$.

FIG. 7. *Discrete solution at interior node points for Problem* II *with* $N = 16$, $P_e = 2$.

show the effect of increasing δ on the solution in the streamline direction: again, the solutions with $\delta = 0$ and $\delta = \delta_*$ exhibit oscillations while the solution with $\delta = \delta^*$ is overly diffuse. The value δ_s is the first for which the smooth part dominates to give a smooth solution. Figure 8 shows cross-sections of these plots for fixed values $j = 1$ on the left and $k = 15$ on the right.

It is known that parabolic layers such as those exhibited by the solution of this problem are wider than the exponential layers of the previous example (the widths are proportional to $\sqrt{\epsilon}$ and ϵ, respectively [13]). Oscillations transverse to the flow caused by inadequate resolution of parabolic layers will occur, but only for mesh Péclet numbers much larger than in the examples shown. However, the results given here demonstrate that *streamwise* effects also cause difficulties for problems with parabolic layers. The analysis shows that these are manifested in Problem II by the presence of G_2 in the solution and that streamline upwinding ameliorates these difficulties by making $G_2(i, \cdot)$ smoother for enough indices i. The right-hand plot in Figure 8 also shows that excessive diffusivity in the streamline direction gives the appearance of smearing of the characteristic layers.

Problem III. For this example, we replace the Dirichlet boundary condition $u = f_t(x)$ on the top boundary in Problem I by the Neumann boundary condition $\frac{\partial u}{\partial n} = 1$.



(a) $j = 1$. (b) $k = N - 1$.

FIG. 8. *Cross-sections of solutions to Problem* II *for* $N = 16$*;* $P_e = 2$ *for* $\delta = 0$ *(solid line,* $\times$*),* $\delta = \delta_*$ *(dashed line,* $\circ$*),* $\delta = \delta_s$ *(dotted line,* $*$*), and* $\delta = \delta^*$ *(dot-dash line,* $\diamondsuit$*).*

The other Dirichlet boundary conditions remain the same. The analysis of section 2 needs to be modified slightly to handle this case. There are now $N(N-1)$ unknowns, and the coefficient matrix A in (2.4) is replaced by

$$A^\star = \begin{bmatrix} M_1 & M_2 & & & 0 \\ M_3 & M_1 & M_2 & & \\ & \ddots & \ddots & \ddots & \\ & & M_3 & M_1 & M_2 \\ 0 & & & M_3 & M_1^\star \end{bmatrix},$$

where there are N rows of $(N-1) \times (N-1)$ blocks. For bilinear finite elements on a square mesh, $M_1^\star = \text{tridiag}(m_2^\star, m_1^\star, m_2^\star)$ with entries

$$m_1^\star = \frac{1}{3}[(2\delta + 1)h + 4\epsilon], \qquad m_2^\star = -\frac{1}{12}[(2\delta - 1)h + 2\epsilon].$$

As the vectors $\mathbf{v}_j$ in (2.6) are eigenvectors of $M_1^\star$, we may construct a matrix $\mathcal{V}^\star$ with N copies of V on its diagonal and a permutation matrix $P^\star$ of order $N(N-1)$ such that a decomposition of type (2.7) exists. The associated block tridiagonal matrix $T^\star$ has $N-1$ diagonal blocks, each one of the form

$$T_i^\star = \begin{bmatrix} \lambda_i & \sigma_i & & & 0 \\ \gamma_i & \lambda_i & \sigma_i & & \\ & \ddots & \ddots & \ddots & \\ & & \gamma_i & \lambda_i & \sigma_i \\ 0 & & & \gamma_i & \lambda_i^\star \end{bmatrix}_{N \times N},$$

where

$$\lambda_i^\star = m_1^\star + 2m_2^\star \cos\frac{i\pi}{N}, \qquad i = 1, \ldots, N-1,$$

are the eigenvalues of $M_1^\star$. Similarly, the transformed right-hand side vector $\hat{\mathbf{f}}^\star$ can be partitioned into $N-1$ vectors of length N to give $N-1$ independent systems

$$T_i^\star \mathbf{y}_i = \hat{\mathbf{f}}_i^\star. \tag{4.5}$$

For this specific example, the vectors $\hat{\mathbf{f}}_i^\star$ are given by

$$\hat{\mathbf{f}}_i^\star = \epsilon h \begin{bmatrix} 0 \\ \vdots \\ 0 \\ \sqrt{\frac{2}{N}} \sum_{s=1}^{N-1} \sin \frac{si\pi}{N} \end{bmatrix}_N .$$

The solution of each system (4.5) is therefore the solution of the same constant-coefficient recurrence relation as in the Dirichlet case, but with the right-hand boundary condition now of Neumann type. The roots of the auxiliary equation are given by (2.12), and the recurrence relation solution is

$$y_{ik}^\star = \epsilon h \sqrt{\frac{2}{N}} \sum_{s=1}^{N-1} \sin \frac{si\pi}{N} G_1^\star(i,k), \tag{4.6}$$

where

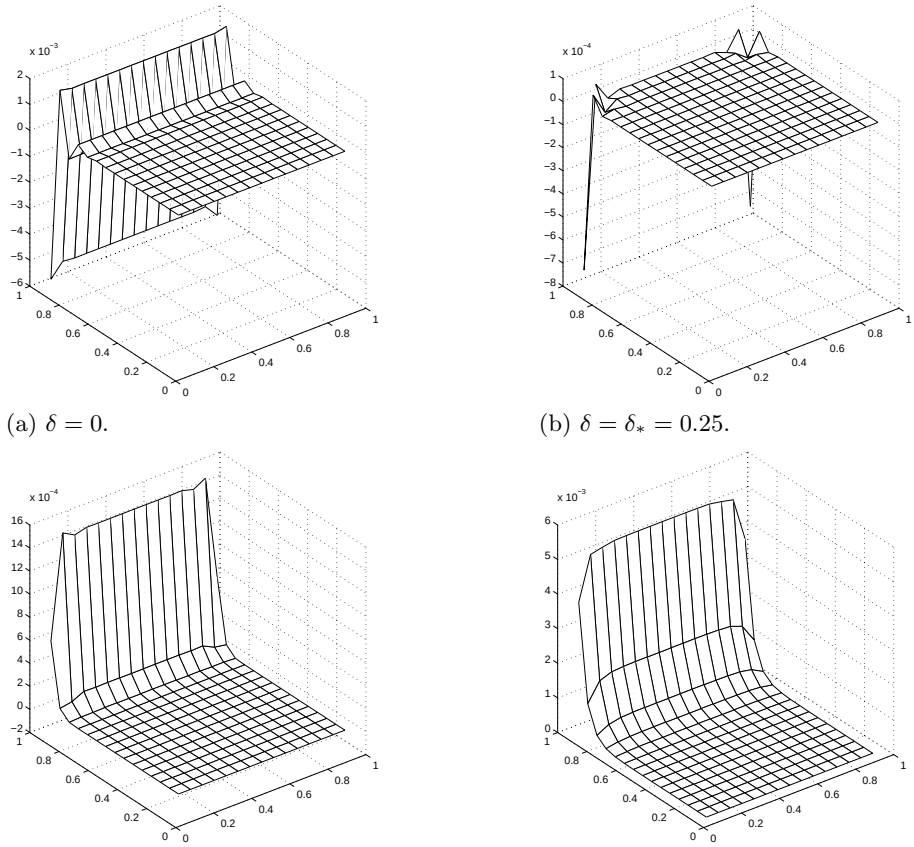
$$G_1^\star(i,k) = \frac{\mu_1^k - \mu_2^k}{(\gamma_i + \lambda_i^\star \mu_1)\mu_1^{N-1} - (\gamma_i + \lambda_i^\star \mu_2)\mu_2^{N-1}}.$$

This expression compares with (4.2) in the Dirichlet case. The most significant difference is the factor of ϵh in front of the Neumann solution: this means that for this problem the oscillations will be much smaller than those in the Dirichlet case. Because of the nature of $G_1^\star$ and G_1, however, the effect of changing δ will be very similar in both cases. This is borne out by the plots of the Neumann solution shown in Figure 9 (for $N = 16$ and $P_e = 2$ so that $\epsilon h = 9.8 \times 10^{-4}$). As predicted by the analysis, these solutions are almost identical in shape to those obtained for the Dirichlet problem (see Figure 6), but any oscillations are much smaller in magnitude.

5. Solution accuracy. We have now characterized the effect of δ on oscillations in the flow direction. One important question which remains is how the choice of δ affects the overall accuracy of the discrete solution. To investigate this, we begin with the example problems of the previous section. In each case, we compare solutions on a 16×16 grid with $\epsilon = 1/64$ (so $P_e = 2$) with a reference solution for the same value of ϵ on a 256×256 grid. On this fine grid, we use the Galerkin method ($\delta = 0$) as $P_e = 0.125 \ll 1$ and there are no oscillations. In what follows, we will denote the fine grid nodal solution vector by $\mathbf{u}_{256}$ and its associated finite element solution by u_{256}, likewise for the coarse grid solutions $\mathbf{u}_{16}^\delta$ and u_{16}^δ.

Figure 10 shows the variation with δ of the error for our test problems measured in two different norms. In all cases the norm of the error is plotted against δ for $0 \le \delta \le 1$ with the values of δ_* (o), δ_s ($\diamondsuit$), and δ^* (x) highlighted. For $P_e = 6.25$ ($\epsilon = 1/200$), $\delta_* = 0.42$, $\delta_s = 0.468$, and $\delta^* = 0.58$. The solid line represents the discrete $L_\infty[0,1]$ norm defined by

$$\|\mathbf{u}_{256} - \mathbf{u}_{16}^\delta\|_\infty = \max_{i,j} |\mathbf{u}_{256}(x_i, y_j) - \mathbf{u}_{16}^\delta(x_i, y_j)|,$$



(a) $\delta = 0$.

(b) $\delta = \delta_* = 0.25$.

(c) $\delta = \delta_s = 0.354$.

(d) $\delta = \delta^* = 0.75$.

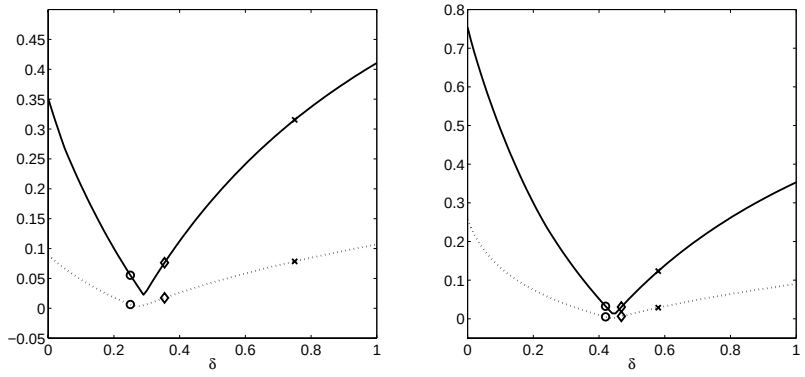
FIG. 9. *Discrete solution at interior node points for Problem* III *with* $N = 16$, $P_e = 2$.

where the points $(x_i, y_j) = (ih, jh)$ are the nodes of the 16×16 grid. When using the finite element method, it may be more natural to work with the L_2 norm

$$\|u_{256} - u_{16}^{\delta}\|_2 = \left\{ \int_{\Omega} \left(u_{256} - u_{16}^{\delta} \right)^2 \right\}^{\frac{1}{2}}. \tag{5.1}$$

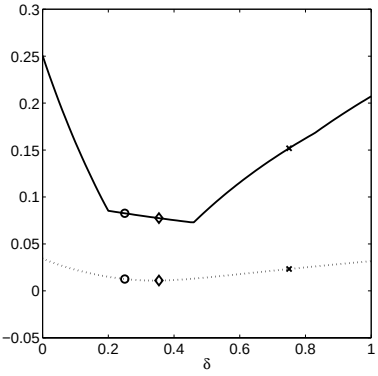
However, this measure leads to misleading results for certain singular perturbation problems of this type where the overall error is heavily dominated by the error in the boundary layer, which we cannot hope to resolve on a 16×16 uniform grid using low order elements. For Problems I and III, a more meaningful measure of the error for our purposes is obtained using the L_2 norm of the error away from the boundary layer; that is, in these cases, we omit the top row of coarse grid elements from the region of integration in (5.1) and integrate over $(0,1) \times (0, 0.9375)$ instead of $\Omega = (0,1) \times (0,1)$. This norm is represented by a dotted line in the error plots. We note in passing that in all of the examples, this curve is very similar to that obtained for the discrete L_2 norm defined by

$$\|\mathbf{u}_{256} - \mathbf{u}_{16}^{\delta}\|_2 = \left\{ \sum_{i,j=0}^{N} \left(u_{256}(x_i, y_j) - u_{16}^{\delta}(x_i, y_j) \right)^2 \right\}^{\frac{1}{2}},$$

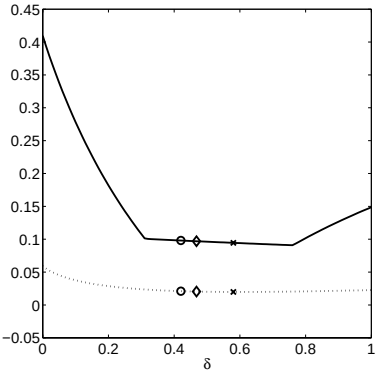


(a) Problem I: $P_e = 2$.

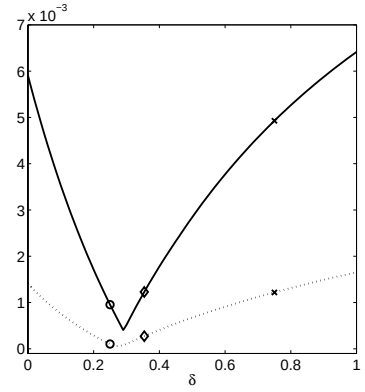
(d) Problem I: $P_e = 6.25$.



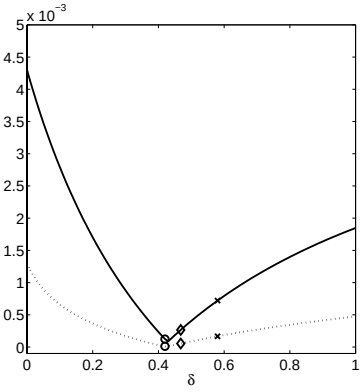
(b) Problem II: $P_e = 2$.



(e) Problem II: $P_e = 6.25$.



(c) Problem III: $P_e = 2$.



(f) Problem III: $P_e = 6.25$.

FIG. 10. *Error variation with δ in the discrete L_∞ norm (solid) and L_2 norm (dotted) for $N = 16$.*

where (x_i, y_j) is again a node of the coarse grid.

From Figure 10, we see that the optimal choice of δ in terms of solution accuracy depends on the norm in which the error is measured, although in most cases both δ_* and δ_s are closer than δ^* to the optimal choice. Note that setting $\delta = \delta_s$ to produce a completely oscillation-free discrete solution $\mathbf{u}$ does not result in the most accurate solution.

6. Guidelines for choosing the streamline diffusion parameter in practice. In sections 2–4, we presented model problem analysis which enabled us to characterize the behavior of the discrete finite element solutions. Three highlighted values of δ play important roles in this analysis: δ_*, where the solution is oscillatory but the oscillations are extremely small; δ_s, which is the smallest value of δ such that the solution is found by numerical experiment to be oscillation free; and δ^*, where the solution is guaranteed to be oscillation free via Theorem 3.3. The analysis, based on Fourier techniques, is restricted to grid-aligned flow. (This is needed for the tridiagonal matrices M_1, M_2, and M_3 of (2.4) to be symmetric and have a common set of eigenvectors.) In this section, we consider several more complex problems and make some observations about choosing δ in practice.

First, we observe that although with $\delta = \delta^*$ we have a way of guaranteeing that there are no oscillations, the resulting discrete solutions are overly diffuse and inaccurate: both δ_* and $\delta_{\rm s}$ are in general much better values to use. The choice $\delta = \delta_{\rm s}$ produces a completely oscillation-free solution but $\delta_{\rm s}$ is not readily determined even for the model problems considered above. However, we know that δ_s lies between δ_* and δ^*, and the empirical results for Problems I–III suggest that the computable expression

$$\delta_\bullet = \frac{1}{2}\left(1 - \frac{0.8}{P_e}\right) \tag{6.1}$$

is a good approximation to it. Note that in the limit as $P_e \to \infty$, both δ_* and $\delta_\bullet$ tend to 0.5.

We now introduce three new test problems with non-grid-aligned or variable winds. For these problems, we use a stabilization strategy which fixes δ^{el} locally on each element by using the local element mesh Péclet number

$$P_e^{el} = \frac{h^{el}\|\mathbf{w}^{el}\|_2}{2\epsilon}$$

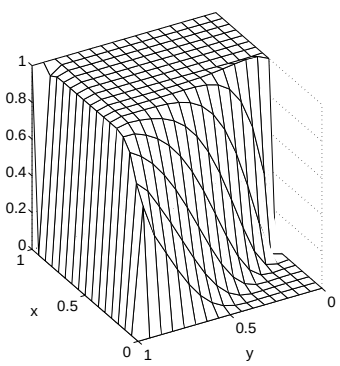
in formulae (3.3) and (6.1). This is calculated using the discrete L_2 norm of the wind value at the element center $\mathbf{w}^{el}$, with the local grid size value h^{el} taken as the distance across the element measured in the direction of the wind. In what follows, these element-based values of δ will be denoted using the superscript el. In all cases, the value of the stabilization parameter used is $\max(\delta^{el}, 0)$ on each element.

Problem IV. Here we impose the Dirichlet boundary conditions

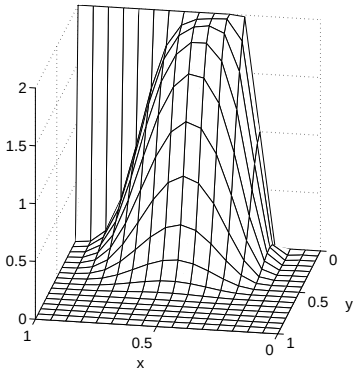
$$f_b(x) = \begin{cases} 0, & 0 < x \le \frac{1}{2}, \\ 1, & \frac{1}{2} < x < 1, \end{cases} \qquad f_t(x) = f_l(y) = 0, \quad f_r(y) = 1$$

on the domain in Figure 1 and apply the wind $\mathbf{w} = (\cos 115^\circ, \sin 115^\circ)$ which has constant magnitude and direction but is not aligned with the grid. This problem has an exponential boundary layer on a portion of the outflow boundary and an internal layer along the characteristic caused by the discontinuity on the inflow boundary. A sample solution with $N = 16$, $\epsilon = 1/200$, and $\delta = \delta_*^{el}$ is shown in Figure 11 (a).

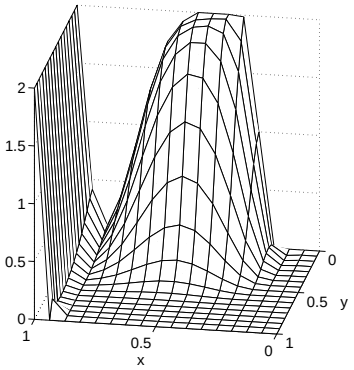
Error calculations carried out as described in the previous section lead to the plots in Figure 12 (a) and (d), where the values δ_*^{el} ($\circ$), $\delta^{el,*}$ ($\times$), and $\delta_\bullet^{el}$ ($\diamondsuit$) have been highlighted. When $\delta = 0$, the error is dominated by difficulties associated with the exponential layers at the outflow. As δ is increased so that these layers begin to be resolved, the error is then dominated by the effect of the discontinuity in the



(a) Problem IV.



(b) Problem V.



(c) Problem VI.

FIG. 11. *Sample solutions with* $N = 16$, $\epsilon = 1/200$, *and* $\delta = \delta_*^{el}$.

inflow boundary condition which is relatively insensitive to the value of δ, causing the middle of the plots to look fairly flat.

Problem V. Our two variable wind test problems are variants of the "IAHR/CEGB" test problem proposed in [14]. In this first case, we solve (1.1) on the unit square with

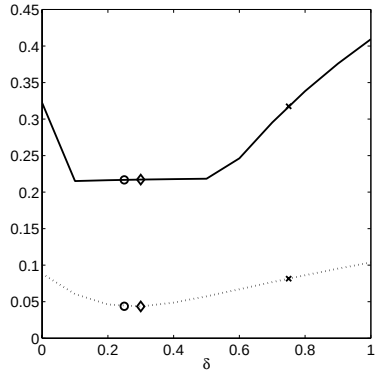
$$\mathbf{w} = (2y(1-(2x-1)^2), -2(2x-1)(1-y^2)). \tag{6.2}$$

The Dirichlet boundary conditions are given by

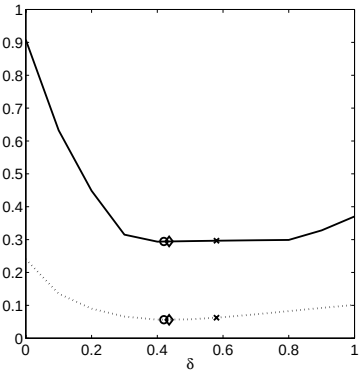
$$u(x,0) = 1 + \tanh[10 + 20(2x-1)] \tag{6.3}$$

on the inflow boundary (the interval $0 \le x \le 0.5$, $y = 0$) and $u(x,0) = 2$ on the outflow boundary (the interval $0.5 < x \le 1$, $y = 0$). On the remaining boundaries, we impose $f_t(x) = f_l(y) = f_r(y) = 0$. The Dirichlet boundary conditions at the bottom $y = 0$ are continuous but there is an exponential layer at the outflow portion, i.e., where $x \ge 1/2$. A sample solution for $N = 16$ and $\epsilon = 1/200$ is shown in Figure 11 (b).

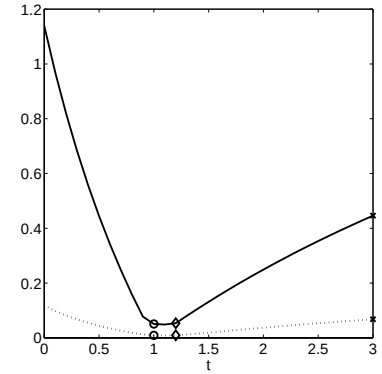
As the wind now varies in magnitude and direction from element to element, we cannot identify a single parameter δ which can be varied for the purposes of comparing errors as in the previous examples. However, we can compare various strategies for choosing δ^{el} locally within elements by considering the parameterized version of δ^{el}



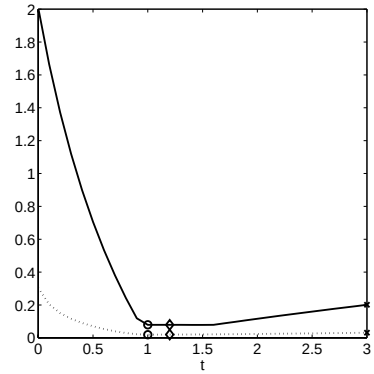
(a) Problem IV: $\epsilon = 1/64$.



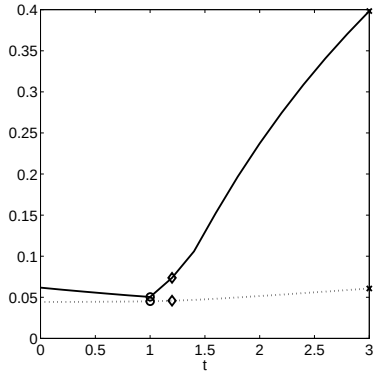
(d) Problem IV: $\epsilon = 1/200$.



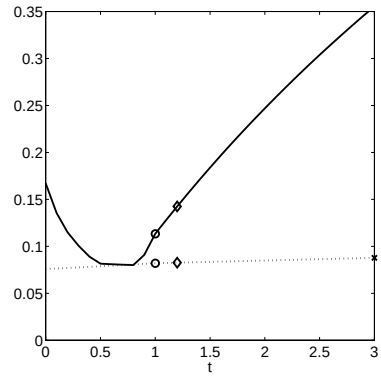
(b) Problem V: $\epsilon = 1/64$.



(e) Problem V: $\epsilon = 1/200$.



(c) Problem VI: $\epsilon = 1/64$.



(f) Problem VI: $\epsilon = 1/200$.

FIG. 12. *Error variation with δ in the discrete L_∞ norm (solid) and L_2 norm (dotted) for $N = 16$.*

given by

$$\delta^{el} = \begin{cases} \dfrac{t}{2}\left(1 - \dfrac{1}{P_e^{el}}\right), & 0 \le t \le 1, \\ \dfrac{1}{2}\left(1 + (t-2)\dfrac{1}{P_e^{el}}\right), & 1 < t \le 3. \end{cases} \tag{6.4}$$

As t varies from 0 to 3, the value of δ^{el} on each element first increases linearly from 0 to δ_*^{el} (at $t = 1$) and then varies linearly between δ_*^{el} and $\delta^{el,*}$. The variation with t of the error for this problem for $N = 16$ with two different values of ϵ is shown in Figure 12 (b) and (e). The errors are again calculated as described in section 5. The values δ_*^{el} ($\circ$), $\delta^{el,*}$ ($\times$), and $\delta_\bullet^{el}$ ($\diamondsuit$) are highlighted. The error is dominated by problems caused by the exponential layer along the outflow boundary in a similar way to Problem I.

Problem VI. Our final test problem also has a variable wind given by (6.2) but the boundary conditions are now of mixed type. We again impose the Dirichlet condition (6.3) on the inflow boundary but now the condition imposed on the outflow boundary is a homogeneous Neumann one. The Dirichlet boundary conditions on the remaining boundaries are $f_t(x) = f_l(y) = 0$, $f_r(y) = 2$. This results in the formation of a characteristic boundary layer along the right-hand wall. A sample solution for $N = 16$ and $\epsilon = 1/200$ is shown in Figure 11 (c). Error plots for this problem with δ parameterized by t as in (6.4) are shown in Figure 12 (c) and (f). This problem features a characteristic layer, so we expect the effects of changing δ to be less pronounced, as for Problem II. This is supported by the error plots: increasing δ helps to resolve the characteristic layer until the error becomes dominated by the effects of boundary discontinuities.

The results in these experiments are essentially the same as those for the model problems. We have not displayed oscillations here, but in all of the examples, the solutions for $\delta = \delta_*$ contain slight oscillations near layers, and the choice $\delta = \delta_\bullet$ reduces but does not eliminate them in these examples. There is little difference between these values in terms of solution quality obtained, and both choices are generally better than δ^*, which adds too much diffusion. Although it is tempting to use the interpolated value $\delta_\bullet$ to produce a qualitatively smoother solution, in our view δ_* is a better choice. The oscillations it produces indicate that in fact the layers are *not* fully resolved and that mesh refinement is needed where they occur; the smoothing of these effects will be misleading (see, e.g., [4]). Streamline diffusion alone cannot completely resolve this issue, and the choice δ_* adds the right amount of diffusion to keep the errors small in most of the domain. Note that this value has previously been recommended as a good choice in [1] and was shown to be good for efficient solution of the resulting linear system by the GMRES iterative method [3]. We also remark that although the analysis of sections 2–4 does not apply to linear elements, we have performed a few experiments which indicate that δ_* yields more accurate solutions than $\delta_\bullet$ in the linear case and that the latter choice adds excessive diffusion in this setting.

7. Application to other discretizations. To conclude, we emphasize that analysis of this type can be applied to any discretization whose stencil is of the form (2.3). We comment on two particular cases of interest here.

7.1. Finite differences with streamline diffusion. The usual central finite difference discretization of (1.1) can also be stabilized using streamline diffusion; see, for example, [12, p. 1465]. Specifically, we apply the finite difference method to the differential equation

$$-(\epsilon\nabla^2 + \nabla \cdot D\nabla)u(x,y) + \mathbf{w} \cdot \nabla u(x,y) = f(x,y),$$

where diffusion in the streamline direction is added using

$$D = \alpha \begin{bmatrix} c^2 & cs \\ cs & s^2 \end{bmatrix}$$

with

$$c = \frac{w_1}{\|\mathbf{w}\|_2}, \qquad s = \frac{w_2}{\|\mathbf{w}\|_2},$$

and α as in (1.4). Assuming for convenience that $\|\mathbf{w}\|_2 = 1$, the full computational molecule is given by

$$\begin{array}{ccc} \frac{w_1 w_2 \delta}{2h} & -\frac{\epsilon}{h^2} + \frac{w_2}{2h} - \frac{w_2^2 \delta}{h} & -\frac{w_1 w_2 \delta}{2h} \\ \nwarrow & \uparrow & \nearrow \\ -\frac{\epsilon}{h^2} - \frac{w_1}{2h} - \frac{w_1^2 \delta}{h} \leftarrow & \frac{4\epsilon}{h^2} + \frac{2\delta}{h} & \rightarrow -\frac{\epsilon}{h^2} + \frac{w_1}{2h} - \frac{w_1^2 \delta}{h} \\ \swarrow & \downarrow & \searrow \\ -\frac{w_1 w_2 \delta}{2h} & -\frac{\epsilon}{h^2} - \frac{w_2}{2h} - \frac{w_2^2 \delta}{h} & \frac{w_1 w_2 \delta}{2h} \end{array}.$$

This simplifies to a stencil of standard five-point type for our model problem (2.1) with grid-aligned flow. Using the notation of (2.3), the stencil entries are

$$m_1 = \frac{4\epsilon}{h^2} + \frac{2\delta}{h}, \qquad m_2 = -\frac{\epsilon}{h^2}, \qquad m_3 = -\frac{\epsilon}{h^2} + \frac{1}{2h} - \frac{\delta}{h},$$

$$m_4 = 0, \qquad m_5 = -\frac{\epsilon}{h^2} - \frac{1}{2h} - \frac{\delta}{h}, \qquad m_6 = 0$$

with related eigenvalues

$$\gamma_i = \frac{1}{h^2}\left[-(\epsilon + \delta h) - \frac{h}{2}\right], \qquad \lambda_i = \frac{1}{h^2}\left[2(\epsilon + \delta h) + 2\epsilon(1 - C_i)\right],$$

$$\sigma_i = \frac{1}{h^2}\left[-(\epsilon + \delta h) + \frac{h}{2}\right].$$

This results in the expressions

$$\mu_{1,2} = \frac{-2\delta - [2 - C_i]\frac{1}{P_e} \pm \sqrt{1 + 4\delta(1 - C_i)\frac{1}{P_e} + (1 - C_i)(3 - C_i)\frac{1}{P_e^2}}}{-2\delta + 1 - \frac{1}{P_e}}$$

for the roots of the recurrence relation which appear in (2.13).

Here the sign of μ_2 (and hence the nature of the corresponding functions $G_1(i,k)$ and $G_2(i,k)$, $i \in S_N$) is independent of i: as the numerator of μ_2 is always negative, we simply have the conditions

$$\begin{cases} \delta > \delta_* & \Rightarrow \quad \mu_2 > 0,\ G_1(i,k) \text{ is nonoscillatory,} \\ \delta < \delta_* & \Rightarrow \quad \mu_2 < 0,\ G_1(i,k) \text{ is oscillatory,} \end{cases}$$

where δ_* is given by (3.3). Hence the result equivalent to Theorem 3.1 is given by the following theorem.

THEOREM 7.1. *For a streamline diffusion finite difference discretization with $P_e > 1$, $\delta > \delta_*$ implies that $G_1(i,k)$ and $G_2(i,k)$ in* (2.13) *are nonoscillatory functions of k for any value of $i \in S_N$.*

The special case $\delta = \delta_*$ leads to the two-term recurrence with auxiliary equation root

$$\rho = \frac{1}{1 + \dfrac{(1 - C_i)}{P_e}}$$

and solution (3.5). Because $\rho < 1$, this solution is nonoscillatory in the streamline direction for all $i \in S_N$ and, as in the finite element case, tends to the nodally exact solution in the limit as $P_e \to \infty$.

The fact that there is one critical parameter (independent of i) here means that there is no issue about selecting a global parameter δ as we had in the finite element case. Furthermore, the analysis of the effect of transforming from $\mathbf{y}$ to $\mathbf{u}$ (cf. section 3.3) is greatly simplified. In particular, for the same specific example problem with $f_t = 1$ and $f_b = f_l = f_r = 0$ studied in section 3.3, the equivalent expression to (4.2) using finite differences has $S_{\text{smooth}} = 0$ when $\delta < \delta_*$ and $S_{\text{osc}} = 0$ when $\delta > \delta_*$. Thus we immediately have the following theorem (cf. Theorem 3.3).

THEOREM 7.2. *For a streamline diffusion finite difference discretization of* (2.1), *the discrete solution* $\mathbf{u}$ *does not exhibit oscillations in the streamline direction when $\delta \geq \delta_*$.*

That is, in contrast to the finite element case, there is no "smoothing" introduced by the Fourier transformation: the same single parameter governs the presence of oscillations in both the recurrence relation solution $\mathbf{y}$ and the discrete two-dimensional solution $\mathbf{u}$.

7.2. Artificial diffusion. So far we have focused on adding smoothing in the streamline direction only, which is just one of the many stabilization methods available. In this section we analyze the artificial diffusion method (see, for example, [7, pp. 218–219]) with a view to comparing its smoothing effect with that of streamline diffusion. The artificial diffusion method works by adding diffusion in an isotropic way which does not take account of flow direction, and it is well known that this can result in smearing of internal layers. We can use the analytical techniques presented in this paper to confirm that the streamline diffusion method avoids this problem.

We again consider a vertical wind model problem using bilinear finite elements on a uniform grid. The idea of the artificial diffusion method is to replace equation (2.1) with

$$-(\epsilon + \delta h)\nabla^2 u + \frac{\partial u}{\partial y} = 0 \qquad \text{in } \Omega = (0,1) \times (0,1), \tag{7.1}$$

with δ once again a stabilization parameter to be chosen. When $P_e < 1$, we set $\delta = 0$ as before. Galerkin discretization using bilinear finite elements results in a matrix of the form (2.4), which is therefore covered by our analysis. The stencil entries in this

case are given by

$$m_1 = \frac{8}{3}(\delta h + \epsilon), \qquad m_2 = -\frac{1}{3}(\delta h + \epsilon), \qquad m_3 = -\frac{1}{3}[(\delta - 1)h + \epsilon],$$

$$m_4 = -\frac{1}{12}[(4\delta - 1)h + 4\epsilon], \quad m_5 = -\frac{1}{3}[(\delta + 1)h + \epsilon], \quad m_6 = -\frac{1}{12}[(4\delta + 1)h + 4\epsilon],$$

so the roots (2.12) of the corresponding recurrence relation are given by

$$\mu_{1,2} = \frac{-\left(2\delta + \frac{1}{P_e}\right)\left[\frac{4 - C_i}{2 + C_i}\right] \pm \sqrt{1 + \frac{3(1 - C_i)(5 + C_i)}{(2 + C_i)^2}\left(2\delta + \frac{1}{P_e}\right)^2}}{1 - \left(2\delta + \frac{1}{P_e}\right)\left[\frac{1 + 2C_i}{2 + C_i}\right]}. \tag{7.2}$$

First we briefly consider the issue of oscillations in the streamline direction. Here, as in section 3.2, the sign of μ_2 (and hence the presence of oscillations in the recurrence relation solution) depends on the value of $i \in S_N$. Defining the new critical value

$$\tilde{\delta}_i^c = \frac{1}{2}\left(\left[\frac{2 + C_i}{1 + 2C_i}\right] - \frac{1}{P_e}\right),$$

we have different conditions for two sets of i values, namely

$$1 \le i \le \tfrac{2}{3}N: \quad \begin{cases} \delta > \tilde{\delta}_i^c & \Rightarrow \quad \mu_2 > 0,\ G_1(i,k) \text{ is nonoscillatory,} \\ \delta < \tilde{\delta}_i^c & \Rightarrow \quad \mu_2 < 0,\ G_1(i,k) \text{ is oscillatory,} \end{cases}$$

$$\tfrac{2}{3}N < i \le N - 1: \quad \mu_2 < 0,\ G_1(i,k) \text{ is oscillatory.}$$

Notice that this is different from the streamline diffusion case (cf. Theorem 3.1) in that there is no choice of δ which will make the recurrence relation solution oscillation free, as some of the contributing functions $G_1(i,k)$ are always oscillatory. However, it can be seen using an argument of the type presented in section 3.3 that the transformed solution is again dominated by contributions from functions pertaining to lower values of i. Hence, despite the fact that $G_1(i,k)$ is always oscillatory for large i, it is still possible to obtain a nonoscillatory discrete solution $\mathbf{u}$. Note that inequality (3.4) is satisfied with δ_c^i replaced by $\tilde{\delta}_c^i$. For the particular (i-independent) choice $\delta = \delta_*$ from (3.3), equation (7.1) (and hence the artificial diffusion solution) is independent of ϵ.

To gain insight into the main difference between this method and the streamline diffusion technique, we must examine solution behavior in the "crosswind" direction, that is, perpendicular to the direction of the flow. To fix ideas, we will use the discontinuous boundary conditions

$$f_b(x) = \begin{cases} 0, & x < 0.5, \\ 1, & x \ge 0.5, \end{cases} \qquad f_r(y) = 1, \quad f_t(x) = f_l(y) = 0$$

so that the solution has an internal layer along $x = 0.5$ as well as a boundary layer along the right half of the top boundary. The internal layer derives from propagation of the bottom boundary condition through the domain and, as $\epsilon \to 0$, the width of this layer tends to zero. Ideally, this phenomenon should be reproduced by a discretization method, that is, we would like to obtain a set of discrete solutions $\mathbf{u}$ in

this limit whose variation from the bottom boundary function is independent of j for fixed k. We now show that while the streamline diffusion method has this property, the artificial diffusion method does not.

Consider the recurrence relation solution vector $\mathbf{y}$ for this problem. From (2.13), its entries are given by

$$y_{ik} = F_3(i)\,(1 - G_1(i,k)) + [F_2(i) - F_3(i)]\,G_2(i,k) \tag{7.3}$$

with

$$F_2(i) = \sqrt{\frac{2}{N}}\left[\frac{(-1)^{i+1}\sin\dfrac{i\pi}{N}}{2\left(1-\cos\dfrac{i\pi}{N}\right)}\right]$$

[2, appendix] and $F_3(i)$ as in (3.6). As the functions $F_2(i)$ and $F_3(i)$ are the same for both discretizations, any difference in solution behavior must come from a difference in the behavior of the functions $G_1(i,k)$ and $G_2(i,k)$ associated with the two methods. We therefore now focus on how these functions vary with $i \in S_N$ as $\epsilon \to 0$ ($P_e \to \infty$) for $k \in S_N$ fixed. To simplify the presentation of this analysis, we will assume that δ is fixed independent of P_e, with $\delta \neq 0, 0.5$.

With the streamline diffusion discretization, neglecting terms of $O(P_e^{-1})$ and higher in (3.1) gives the approximations

$$\mu_1 \simeq 1, \qquad \mu_2 \simeq \frac{2\delta+1}{2\delta-1} \equiv \beta$$

so that

$$\begin{aligned} G_1(i,k) &= \frac{\mu_1^k - \mu_2^k}{\mu_1^N - \mu_2^N} \simeq \frac{1-\beta^k}{1-\beta^N} \equiv G_1^a(k), \\ G_2(i,k) &= (1-\mu_1^k) - (1-\mu_1^N)G_1(i,k) \simeq 0. \end{aligned}$$

Thus, in the limit as $P_e \to \infty$, both functions are independent of i. We then have

$$y_{ik} \simeq F_3(i)(1 - G_1^a(k));$$

hence, using (2.8),

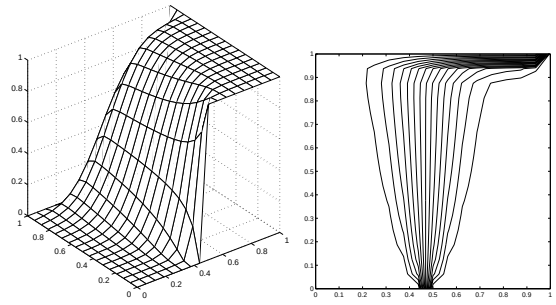
$$u_{jk} \simeq f_b(x_j)(1 - G_1^a(k)).$$

That is, the variation of u_{jk} from the bottom boundary function is independent of j in this limit. For the artificial diffusion discretization, however, neglecting terms of $O(P_e^{-1})$ and higher in (7.2) gives

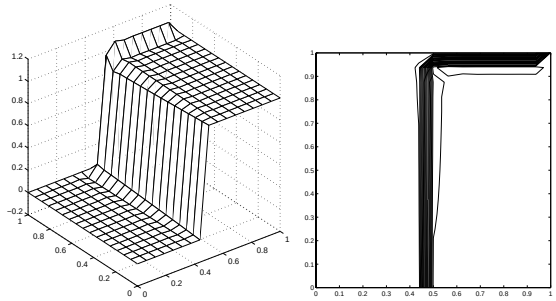
$$\mu_{1,2} \simeq \frac{-2\delta(4-C_i) \pm \sqrt{4(1+15\delta^2) + 4(1-12\delta^2)C_i + (1-12\delta^2)C_i^2}}{2(1-\delta) + (1-4\delta)C_i},$$

leading to approximations for $G_1(i,k)$ and $G_2(i,k)$ which depend on i through C_i. From (7.3) the solution is therefore

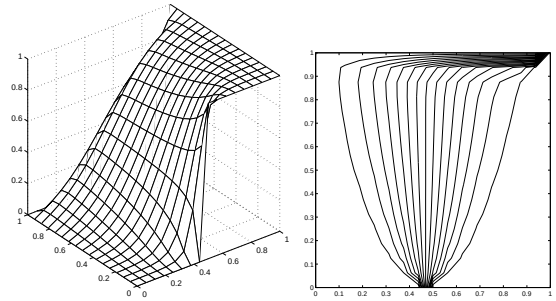
$$u_{jk} \simeq f_b(x_j) - \sqrt{\frac{2}{N}} \sum_{i=1}^{N-1} \sin\frac{ij\pi}{N}\left(F_3(i)G_1(i,k) - [F_2(i) - F_3(i)]\,G_2(i,k)\right).$$



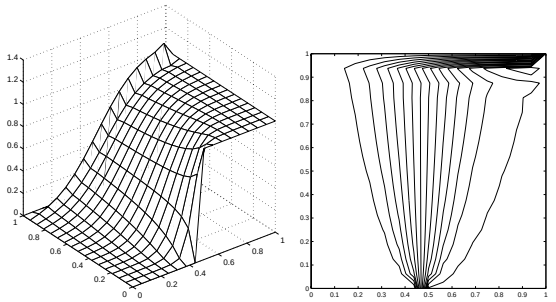
(a) Streamline diffusion: $P_e = 2$.



(b) Streamline diffusion: $P_e = 200$.



(c) Artificial diffusion: $P_e = 2$.



(d) Artificial diffusion: $P_e = 200$.

FIG. 13. *Solutions and contour plots for* $\delta = 0.4$ *and* $N = 16$.

This has a j-dependence which the continuous solution in this limit does not.

This fundamental difference between the discretizations is demonstrated pictorially in Figure 13, which shows streamline and artificial diffusion approximations (and associated contour plots) for this example problem with two values of ϵ, $\delta = 0.4$,

and $N = 16$. Plots (a) and (b) show that the streamline diffusion method captures the narrowing of the internal layer exhibited by the continuous solution as $\epsilon \to 0$ ($P_e \to \infty$). The equivalent artificial diffusion approximation does not, as shown in plots (c) and (d).

8. Summary. In this study, we have performed a Fourier analysis of model problems with grid-aligned flow that identifies the effects of upwinding in discretizations of the convection-diffusion equation. Our emphasis is on streamline-diffusion discretization with bilinear elements, where we show how the choice of streamline diffusion parameter affects the qualitative behavior of the solution with respect to oscillations. This analysis gives theoretical justification for the choice

$$\delta = \delta_* = \frac{1}{2}\left(1 - \frac{1}{P_e^{el}}\right).$$

Our analysis also shows that δ_* is the optimal choice for finite difference discretizations, provides insight into the method of isotropic artificial diffusion, and yields qualitatively good solutions in a variety of computational experiments.

ERROR ESTIMATES FOR SEMIDISCRETE FINITE ELEMENT APPROXIMATIONS OF LINEAR AND SEMILINEAR PARABOLIC EQUATIONS UNDER MINIMAL REGULARITY ASSUMPTIONS*

K. CHRYSAFINOS† AND L. S. HOU†

Abstract. Semidiscrete finite element error estimates for linear parabolic equations are derived under minimal regularity with the help of L^2 projectors. Then, analogous minimal regularity semidiscrete error estimates for semilinear parabolic equations are derived.

Key words. parabolic equations, finite element methods, semidiscrete error estimates, boundary value problems

1. Introduction.

Semidiscrete finite element approximations of linear parabolic equations have been studied extensively. [38] offers an excellent review of the main results and mathematical techniques of this subject and contains a comprehensive list of references. Here, we provide a brief summary along with some representative (but certainly not exhaustive) citations for each type of semidiscrete error estimate available in the literature.

- $L^2(\Omega)$ error estimates—either $L^\infty(0,T;L^2(\Omega))$ or $L^2(0,T;L^2(\Omega))$—[7], [18], [43], [22, Theorems 4.1–4.3], and [38, Theorems 1.2, 2.3, 2.5, 2.6];
- $H^1(\Omega)$ error estimates—either $L^\infty(0,T;H^1(\Omega))$ or $L^2(0,T;H^1(\Omega))$—[7], [18], [22, Theorems 4.1–4.3], and [38, Theorems 1.4, 2.4];
- $L^\infty(\Omega)$ error estimates—[33], [29], [30], [34], [40], [12], [16], [17], [10], [42], [41], [7], and [38, Theorems 5.2–5.5];
- Negative spatial norm error estimates for $u-u^h$ and $\partial_t u-\partial_t u^h$ and superconvergence results—[7], [37], [19], and [38, Theorems 6.2–6.6];
- Semidiscrete error estimates with nonsmooth initial data—[36], [37], [31], [27], [15], [25], and [38, Theorems 3.1–3.6].

There is also an abundant literature on fully discrete approximations; see, e.g., [4], [3], [18], [6], [8], [20], [32], [44], and [38]. In this paper, we will concern ourselves only with semidiscrete approximations.

Notwithstanding the vast number of papers and books devoted to semidiscrete approximations of solutions of parabolic equations, the literature seems to lack $L^2(\Omega)$ and $H^1(\Omega)$ convergence results for parabolic problems under minimal regularity assumptions. The goal of this work is to establish the convergence and derive error estimates in the norm of the solution space under minimal regularity assumptions on the solution. Such results will be established for both linear and semilinear parabolic problems.

The linear problem we consider is the parabolic initial boundary value problem

$$\partial_t u - \operatorname{div}\left[A(\mathbf{x})\nabla u\right] = f \qquad \text{in } [0,T]\times\Omega\,, \tag{1.1}$$

$$u\big|_{(0,T)\times\partial\Omega} = 0\,, \tag{1.2}$$

and

$$u(0) = u_0 \qquad \text{in } \Omega\,, \tag{1.3}$$

where $\partial_t u = \partial u/\partial t$, Ω is a bounded spatial domain in $\mathbb{R}^d$ ($d = 2$ or 3), and the matrix function $A \in \mathbf{L}^\infty(\mathbb{R}^d; \mathbb{R}^{d\times d})$ is uniformly positive definite. In the standard weak formulation of (1.1)–(1.3) (see, e.g., [21]) the solution u is sought in the space

$$X \equiv L^2(0,T; H_0^1(\Omega)) \cap H^1(0,T; H^{-1}(\Omega)).$$

Of course, the minimal regularity of u for showing the X-norm convergence of semidiscrete finite element approximations is that $u \in X$. The assumption $u \in X$ is equivalent to the requirements that the forcing term $f \in L^2(0,T; H^{-1}(\Omega))$ and the initial condition $u_0 \in L^2(\Omega)$; see, e.g., [21, p. 356, Theorem 3]. The X-norm convergence results in the literature generally assume higher regularity than the minimal regularity $u \in X$. For instance, the estimates in [38] typically require $\partial_t u \in L^2(0,T; L^2(\Omega))$ and those in [43] require $\nabla u \in L^\infty(0,T; L^\infty(\Omega))$.

To derive $\mathcal{O}(h^m)$ ($m \geq 0$) error estimates in the X-norm, the minimal regularity assumption on u should be $u \in L^2(0,T; H^{m+1}(\Omega)) \cap H^1(0,T; H^{m-1}(\Omega))$. We indeed will prove $\mathcal{O}(h^m)$ error estimates under such minimal regularity assumptions. $\mathcal{O}(h^m)$ error estimates in the literature generally require higher regularity than what this paper assumes. We note that the assumption $u \in L^2(0,T; H^{m+1}(\Omega)) \cap H^1(0,T; H^{m-1}(\Omega))$ is essentially equivalent to the assumptions $u_0 \in H^m(\Omega)$ and $f \in L^2(0,T; H^{m-1}(\Omega))$ plus certain compatibility conditions; see, e.g., [28, p. 287, Theorem 2.10] (for all m) and [21, p. 365] (for odd m).

In addition to showing the convergence and deriving the error estimates under the minimal regularity assumptions explained above, we will also establish a parabolic Cea's lemma and a parabolic Aubin–Nitsche's lemma. The collection of these results comprises a semidiscrete finite element theory for parabolic problems that parallels classical finite element theories for elliptic problems.

A further linear result of this paper is the derivation of some pointwise-in-time error estimates under slightly weaker regularity requirements compared to similar results in the literature (e.g., [38, Theorem 2.4]).

It should be pointed out that a key element of our proof is the use of the $L^2(\Omega)$- and generalized $L^2(\Omega)$-projectors instead of the usual elliptic projector. Though some properties of the L^2-projections are well known (see, e.g., [38], [5], and [14] for interior L^2-projections and [24] for boundary L^2-projections), we include in this paper some detailed discussions of the approximation properties of $L^2(\Omega)$- and generalized $L^2(\Omega)$-projectors.

It also should be noted that the nonminimal regularity assumptions in the literature for showing convergence and error estimates are partly tied to the nonlinearities appearing in the equations. For instance, if the equation contains a term $\operatorname{div}[A(u)\nabla u]$, then for $u(t) \in H^1(\Omega)$ and $v \in H^1(\Omega)$ it is not guaranteed that $\int_\Omega A(u)(\nabla u)\cdot(\nabla v) < \infty$. In this case, an assumption such as $u(t) \in L^\infty(\Omega)$ is needed. For this reason the results of this paper do not apply to the approximations of nonlinear equations involving $\operatorname{div}[A(u)\nabla u]$. It can be checked that many nonminimal regularity assumptions in the literature could be weakened when the underlying equations are linear, e.g., the results of [43] and [22]. However, error estimates for

nonlinear equations under nonminimal regularity do not trivially lead to the minimal regularity error estimates of this paper when the nonlinearity is dropped. For instance, one may find in [38] a number of linear results under nonminimal regularity assumptions.

The semilinear problem we consider consists of the partial differential equation

$$\partial_t u - \operatorname{div}[A(\mathbf{x})\nabla u] + \mathbf{b}(t,\mathbf{x})\cdot\nabla u + \phi(u) = f \qquad \text{in } [0,T]\times\Omega\,, \tag{1.4}$$

with boundary-initial conditions (1.2)–(1.3), where $\mathbf{b} \in L^\infty(0,T;L^\gamma(\Omega))$ ($\gamma > d$, $d = 2$ or 3 is the space dimension) and ϕ satisfies certain power growth conditions. We extend the linear results to the semilinear case. Namely, we prove the X-norm convergence of semidiscrete finite element solutions if $u \in X$ and we derive X-norm error estimates under minimal regularity assumptions on u. Compared to the results of [38] and [39] for semilinear parabolic equations, our results not only assume merely minimal regularity but also allow for a slightly larger exponent in the growth conditions for $\phi(u)$.

In our study of the semilinear problems the linear theory of this paper and the approximation theory of Brezzi–Rappaz–Raviart both play a crucial role. Other worthmentioning technicalities for our semilinear theory involve (i) the proof of an embedding theorem for X and (ii) the choice of a merely continuously embedded subspace (as opposed to the choice of a compactly embedded subspace that is typical of the applications of Brezzi–Rappaz–Raviart theory).

The plan of the paper is as follows. In section 2, we introduce some notations and discuss the approximation properties of $L^2(\Omega)$- and generalized $L^2(\Omega)$-projectors. In section 3, we derive semidiscrete error estimates for finite element approximations of linear parabolic equations under minimal regularity assumptions on the solutions. Finally, in section 4, we derive error estimates for semidiscrete approximations of semilinear parabolic equations, again under minimal regularity assumptions on the solutions.

2. Notations and some properties of L^2-projections onto finite element spaces. We assume that Ω is a convex polygon in $\mathbb{R}^2$ or a convex polyhedron in $\mathbb{R}^3$. Throughout, we use standard notations (see, e.g., [1]) for the Sobolev spaces $H^r(\Omega)$ and $H^s(\Gamma)$ for all real r and s, with norms denoted by $\|\cdot\|_r$ and $\|\cdot\|_{s,\Gamma}$, respectively. We use $H_0^r(\Omega)$ to denote the completion of $C_0^\infty(\Omega)$ in the $H^r(\Omega)$-norm. We denote the inner products on $H^r(\Omega)$ and $H^s(\Gamma)$ by $(\cdot,\cdot)_r$ and $(\cdot,\cdot)_{s,\Gamma}$, respectively. Note that $H^0(\Omega) = L^2(\Omega)$ and we omit the subscript 0 for the $L^2(\Omega)$-norm and $L^2(\Omega)$ inner product, i.e., $(\cdot,\cdot)_0 = (\cdot,\cdot)$ and $\|\cdot\|_0 = \|\cdot\|$. The duality pairing between $H^{-1}(\Omega)$ and $H_0^1(\Omega)$ is denoted by $\langle\cdot,\cdot\rangle$, which we assume is generated from the $L^2(\Omega)$ inner product, i.e.,

$$\langle v, w\rangle = (v, w) \qquad \forall\, v, w \in L^2(\Omega).$$

Also, C denotes a generic constant whose value changes with context.

Let V^h be a family of finite element subspaces of $H_0^1(\Omega)$ with the following approximation properties:

$$\inf_{v^h\in V^h} \|v - v^h\|_s \to 0 \quad \text{as } h \to 0 \quad \forall\, v \in H^s(\Omega)\,,\ s = -1, 0, 1. \tag{2.1}$$

In order to properly state some additional approximation properties for functions in V^h having zero boundary values, we introduce, for all real r, the spaces $\Phi_0^r(\Omega) =$

$H_0^{\min\{1,r\}}(\Omega)$ equipped with the $H^{\min\{1,r\}}(\Omega)$-norm, i.e.,

$$\Phi_0^r(\Omega) = \begin{cases} H_0^1(\Omega) & \text{if } r \geq 1\,, \\ H_0^r(\Omega) & \text{if } 1/2 < r < 1\,, \\ H^r(\Omega) & \text{if } r \leq 1/2\,. \end{cases}$$

Note that we have used the result that $H^r(\Omega) = H_0^r(\Omega)$ for $r \leq 1/2$; see [26, p. 55]. Also, when $r > 1$, r is no longer the differentiability index in $\Phi_0^r(\Omega)$. The space $\Phi_0^r(\Omega)$ simply unifies the notation used below for stating relevant approximation properties.

We assume that V^h has the following additional approximation properties:

$$\inf_{v^h \in V^h} \|v - v^h\|_{-1} \leq Ch^{m+2}\|v\|_{m+1} \quad \forall\, v \in H^{m+1}(\Omega) \cap \Phi_0^{m+1}(\Omega),\ -2 \leq m \leq k\,, \tag{2.2}$$

$$\inf_{v^h \in V^h} \|v - v^h\| \leq Ch^{m+1}\|v\|_{m+1} \quad \forall\, v \in H^{m+1}(\Omega) \cap \Phi_0^{m+1}(\Omega), \quad -1 \leq m \leq k\,, \tag{2.3}$$

and

$$\inf_{v^h \in V^h} \|v - v^h\|_1 \leq Ch^{m}\|v\|_{m+1} \quad \forall\, v \in H^{m+1}(\Omega) \cap H_0^1(\Omega), \quad 0 \leq m \leq k\,. \tag{2.4}$$

In (2.2)–(2.4), C is independent of v and h and k is a positive integer that is usually determined by the order of the piecewise polynomials used to define V^h.

We also assume the following inverse inequalities:

$$\|v^h\|_1 \leq \frac{C}{h}\|v^h\|_0 \qquad \forall\, v^h \in V^h. \tag{2.5}$$

For a thorough discussion of the properties (2.1)–(2.5) and the construction of finite element spaces having these properties, see, e.g., [2] and [11].

We denote by P^h the $L^2(\Omega)$-projection from $L^2(\Omega)$ onto V^h, R^h the $H^1(\Omega)$-projection from $H_0^1(\Omega)$ onto V^h, and S^h the $H^{-1}(\Omega)$-projection from $H^{-1}(\Omega)$ onto V^h. Namely, for each $v \in L^2(\Omega)$,

$$(P^h v, w^h) = (v, w^h) \qquad \forall\, w^h \in V^h\,; \tag{2.6}$$

for each $v \in H_0^1(\Omega)$,

$$(R^h v, w^h)_1 = (v, w^h)_1 \qquad \forall\, w^h \in V^h\,; \tag{2.7}$$

and for each $v \in H^{-1}(\Omega)$,

$$(S^h v, w^h)_{-1} = (v, w^h)_{-1} \qquad \forall\, w^h \in V^h\,. \tag{2.8}$$

We also define the *generalized $L^2(\Omega)$-projection* operator $Q^h : H^{-1}(\Omega) \to V^h$ as follows: for each $v \in H^{-1}(\Omega)$,

$$\langle Q^h v, w^h \rangle = \langle v, w^h \rangle \qquad \forall\, w^h \in V^h\,. \tag{2.9}$$

Remark. One can easily show that Q^h is well defined by introducing a basis $\{e_i\}_{i=1}^M$ for V^h and examining the solvability of a $v^h = \sum_{j=1}^M c_j e_j$ from the equations $\langle \sum c_j e_j, e_i \rangle = \langle v, e_i \rangle$ for $i = 1, \ldots, M$. Also, it is evident that $Q^h v = P^h v$ whenever $v \in L^2(\Omega)$; thus, $Q^h : H^{-1}(\Omega) \to V^h$ can be thought of as the generalization of the operator $P^h : L^2(\Omega) \to V^h$ into an operator from $H^{-1}(\Omega)$ to V^h. ∎

It is trivial that $P^h v$ is the best approximation in the $L^2(\Omega)$-norm to $v \in L^2(\Omega)$. We will show that $P^h v$ is *a quasi-best* approximation to v in the $H^1(\Omega)$-norm and $Q^h v$ is *a quasi-best* approximation to v in the $H^{-1}(\Omega)$-norm in the sense of the following two propositions.

PROPOSITION 2.1. *Let $P^h : L^2(\Omega) \to V^h$ be defined by* (2.6) *and $R^h : H_0^1(\Omega) \to V^h$ be defined by* (2.7)*. Then there exists a constant C, independent of v and h, such that*

$$\|v - P^h v\|_1 \le C\|v - R^h v\|_1 \qquad \forall\, v \in H_0^1(\Omega)\,. \tag{2.10}$$

Proof. Let $v \in H_0^1(\Omega)$ be given. The inverse inequality (2.5) yields

$$\|R^h v - P^h v\|_1 \le \frac{C}{h}\|R^h v - P^h v\|\,.$$

The best approximation property of the projection operators gives

$$\|v - P^h v\| \le \|v - R^h v\|\,.$$

As Ω is assumed to be convex, the Aubin–Nitsche lemma (see, e.g., [11, p. 137]) implies

$$\|R^h v - v\| \le Ch\|R^h v - v\|_1\,.$$

Using triangle inequalities and the last three relations we obtain

$$\begin{aligned}\|v - P^h v\|_1 &\le \|v - R^h v\|_1 + \|R^h v - P^h v\|_1 \le \|v - R^h v\|_1 + \frac{C}{h}\|R^h v - P^h v\| \\ &\le \|v - R^h v\|_1 + \frac{C}{h}\Big(\|R^h v - v\| + \|v - P^h v\|\Big) \le \|v - R^h v\|_1 + \frac{2C}{h}\|R^h v - v\| \\ &\le C\|v - R^h v\|_1\,. \qquad \square\end{aligned}$$

Remark. The key elements of the proof of Proposition 2.1 can be found in, among others, [38]. We include this proposition and its proof here for completeness. $\square$

PROPOSITION 2.2. *Let $S^h : H^{-1}(\Omega) \to V^h$ and $Q^h : H^{-1}(\Omega) \to V^h$ be defined by* (2.8) *and* (2.9)*, respectively. Then, there exists a constant C, independent of v and h, such that*

$$\|v - Q^h v\|_{-1} \le C\|v - S^h v\|_{-1} \qquad \forall\, v \in H^{-1}(\Omega)\,. \tag{2.11}$$

Proof. Let $v \in H^{-1}(\Omega)$ be given. Then

$$\begin{aligned}\|v - Q^h v\|_{-1} &= \sup_{w \in H_0^1(\Omega), \|w\|_1 = 1} \langle v - Q^h v, w\rangle \\ &= \sup_{w \in H_0^1(\Omega), \|w\|_1 = 1} \langle v - Q^h v, w - P^h w\rangle = \sup_{w \in H_0^1(\Omega), \|w\|_1 = 1} \langle v, w - P^h w\rangle \\ &= \sup_{w \in H_0^1(\Omega), \|w\|_1 = 1} \langle v - S^h v, w - P^h w\rangle \le \|v - S^h v\|_{-1} \sup_{w \in H_0^1(\Omega), \|w\|_1 = 1} \|w - P^h w\|_1\,.\end{aligned}$$

From Proposition 2.1, we see that

$$\|w - P^h w\|_1 \le C\|w - R^h w\|_1 \le C\|w\|_1\,.$$

Thus, (2.11) is obtained trivially by combining the last two relations. $\square$

Remark. As a consequence of Propositions 2.1 and 2.2, approximation properties (2.1) with $s = -1$ and (2.2) can be proved from the inverse inequality (2.5) and approximation properties (2.1) with $s = 0, 1$ and (2.3)–(2.4). Indeed, if $v \in H^{k+1}(\Omega) \cap \Phi_0^{k+1}(\Omega)$,

$$\|v - S^h v\|_{-1} \le \|v - P^h v\|_{-1} = \sup_{\phi \in H_0^1(\Omega)} \frac{\langle v - P^h v, \phi \rangle}{\|\phi\|_1}$$

$$= \sup_{\phi \in H_0^1(\Omega)} \frac{\langle v - P^h v, \phi - P^h \phi \rangle}{\|\phi\|_1}$$

$$\le \|v - P^h v\| \cdot \sup_{\phi \in H_0^1(\Omega)} \frac{\|\phi - P^h \phi\|}{\|\phi\|_1} \le C h^{k+1} \|v\|_{k+1} \cdot h.$$

For $v \in H^{-1}(\Omega) \cap \Phi_0^{-1}(\Omega) = H^{-1}(\Omega)$,

$$\|v - S^h v\|_{-1} \le 2\|v\|_{-1}.$$

Thus (2.1) with $s = -1$ and (2.2) follows from these estimates. □

Next we examine approximation properties on time-space function spaces. If B is a spatial function space such as $H^r(\Omega)$ for a real r, then we denote by $L^2(0, T; B)$ and $H^1(0, T; B)$ the time-space function spaces such that

$$\|v\|^2_{L^2(0,T;B)} \equiv \int_0^T \|v(t)\|_B^2 \, dt < \infty \qquad \forall\, v \in L^2(0, T; B)$$

and

$$\|v\|^2_{H^1(0,T;B)} \equiv \int_0^T \left(\|v(t)\|_B^2 + \|\partial_t v(t)\|_B^2 \right) dt < \infty \qquad \forall\, v \in H^1(0, T; B),$$

respectively. If B^h is a finite dimensional subspace of B, the norm of $L^2(0, T; B^h)$ and $H^1(0, T; B^h)$ is taken to be that of $L^2(0, T; B)$ and $H^1(0, T; B)$, respectively.

Based on the approximation properties of V^h, we may derive the following approximation properties of the semidiscrete function spaces $L^2(0, T; V^h)$ and $H^1(0, T; V^h)$.

PROPOSITION 2.3. *Let V^h be a family of finite element subspaces of $H_0^1(\Omega)$ satisfying* (2.1)–(2.5). *Then, the following convergence properties hold as $h \to 0$:*

$$\inf_{v^h \in L^2(0,T;V^h)} \|v - v^h\|_{L^2(0,T;H^s(\Omega))} \to 0 \quad \forall\, v \in L^2(0, T; H^s(\Omega)),\ s = -1, 0, 1. \tag{2.12}$$

Moreover, the following approximation properties hold:

$$\inf_{v^h \in L^2(0,T;V^h)} \|v - v^h\|_{L^2(0,T;H^s(\Omega))} \le C h^{m+1-s} \|v\|_{L^2(0,T;H^{m+1}(\Omega))}$$
$$\forall\, v \in L^2(0, T; H^{m+1}(\Omega) \cap \Phi_0^{m+1}(\Omega)),\ -2 \le m \le k\,,\ s = -1, 0, 1. \tag{2.13}$$

Proof. We will prove (2.12) and (2.13) for the case $s = -1$ only; the cases when $s = 0$ or 1 can be proved in a similar manner.

To prove (2.13) when $s = -1$, we need only to verify it for the cases $m = k$ and $m = -2$ thanks to interpolation theorems. Let $v \in L^2(0, T; H^{k+1}(\Omega) \cap \Phi_0^{k+1}(\Omega))$ be given and let $S^h v(t)$ be defined by (2.8) for almost every $t \in (0, T)$, i.e.,

$$(S^h v(t), w^h)_{-1} = (v(t), w^h)_{-1} \qquad \forall\, w^h \in V^h,\ \text{a.e. } t\,.$$

It follows from $v \in L^2(0,T;H^{k+1}(\Omega)\cap\Phi_0^{k+1}(\Omega))$ that $S^h v \in L^2(0,T;V^h)$. Using (2.2), we see that for almost every $t\in(0,T)$,

$$\|v(t)-S^h v(t)\|_{-1} \le Ch^{k+2}\|v(t)\|_{k+1} \qquad \text{a.e. } t$$

so that integration in t yields

$$\|v-S^h v\|_{L^2(0,T;H^{-1}(\Omega))} \le Ch^{k+2}\|v(t)\|_{L^2(0,T;H^{k+1}(\Omega))}\,. \tag{2.14}$$

Let $v\in L^2(0,T;H^{-1}(\Omega)) = L^2(0,T;H^{-1}(\Omega)\cap\Phi_0^{-1}(\Omega))$ be given and let $S^h v(t)$ be defined by (2.8) again for almost every t. The best approximation property of projection operators implies

$$\|v(t)-S^h v(t)\|_{-1} \le C\|v(t)\|_{-1} \qquad \text{a.e. } t$$

so that integration in t leads to

$$\|v-S^h v\|_{L^2(0,T;H^{-1}(\Omega))} \le C\|v(t)\|_{L^2(0,T;H^{-1}(\Omega))}\,. \tag{2.15}$$

Interpolation of (2.14) and (2.15) yields (2.13).

We now proceed to prove (2.12) when $s=-1$. Let $v\in L^2(0,T;H^{-1}(\Omega))$ be given. For each $\epsilon>0$, we may choose a $v_\epsilon\in C([0,T];H^{-1}(\Omega))$ such that

$$\|v-v_\epsilon\|_{L^2(0,T;H^{-1}(\Omega))} < \epsilon/3\,.$$

Then, using triangle inequalities and the fact that $\|S^h w\|_{-1}\le\|w\|_{-1}$, we have that

$$\begin{aligned}
&\|v-S^h v\|_{L^2(0,T;H^{-1}(\Omega))}\\
&\le \|v-v_\epsilon\|_{L^2(0,T;H^{-1}(\Omega))} + \|v_\epsilon - S^h v_\epsilon\|_{L^2(0,T;H^{-1}(\Omega))} + \|S^h v_\epsilon - S^h v\|_{L^2(0,T;H^{-1}(\Omega))}\\
&\le 2\|v-v_\epsilon\|_{L^2(0,T;H^{-1}(\Omega))} + \sqrt{T}\max_{t\in[0,T]}\|v_\epsilon(t)-S^h v_\epsilon(t)\|_{-1}\\
&< 2\epsilon/3 + \sqrt{T}\,\|v_\epsilon(t_0)-S^h v_\epsilon(t_0)\|_{H^{-1}(\Omega)}
\end{aligned}$$

for some $t_0\in[0,T]$. The approximation property (2.1) implies that there exists an $h_0>0$ such that, for all $h\in(0,h_0)$,

$$\|v_\epsilon(t_0)-S^h v_\epsilon(t_0)\|_{-1} \le \epsilon/(3\sqrt{T})\,.$$

Combining the last two relations, we have that, for all $h\in(0,h_0)$,

$$\|v-S^h v\|_{L^2(0,T;H^{-1}(\Omega))} < \epsilon\,.$$

This completes the proof of (2.12) when $s=-1$. ∎

Similar to Propositions 2.1 and 2.2, we can establish the *best approximation* properties of the $L^2(\Omega)$-projector P^h in $L^2(0,T;H_0^1(\Omega))$ and of the generalized $L^2(\Omega)$-projector Q^h in $L^2(0,T;H^{-1}(\Omega))$.

PROPOSITION 2.4. *Let V^h be a family of finite element subspaces of $H_0^1(\Omega)$ satisfying* (2.1)–(2.5). *Then, the following approximation properties hold:*

$$\|v-P^h v\|_{L^2(0,T;H^1(\Omega))}\to 0 \quad \text{as } h\to 0 \quad \forall\, v\in L^2(0,T;H_0^1(\Omega))\,, \tag{2.16}$$

$$\|v-Q^h v\|_{L^2(0,T;H^{-1}(\Omega))}\to 0 \quad \text{as } h\to 0 \quad \forall\, v\in L^2(0,T;H^{-1}(\Omega))\,, \tag{2.17}$$

$$\|v - P^h v\|_{L^2(0,T;H^1(\Omega))} \le Ch^m \|v\|_{L^2(0,T;H^{m+1}(\Omega))} \quad \forall\, v \in L^2(0,T;H^{m+1}(\Omega)\cap H_0^1(\Omega)),\ 0 \le m \le k\,, \tag{2.18}$$

and

$$\|v - Q^h v\|_{L^2(0,T;H^{-1}(\Omega))} \le Ch^{m+2} \|v\|_{L^2(0,T;H^{m+1}(\Omega))} \quad \forall\, v \in L^2(0,T;H^{m+1}(\Omega)\cap \Phi_0^{m+1}(\Omega)),\ -1 \le m \le k\,. \tag{2.19}$$

Moreover, the following inequalities hold:

$$\|v - P^h v\|_{L^2(0,T;H^1(\Omega))} \le C\|v - v^h\|_{L^2(0,T;H^1(\Omega))} \quad \forall\, v \in L^2(0,T;H_0^1(\Omega))\ \forall\, v^h \in L^2(0,T;V^h) \tag{2.20}$$

and

$$\|v - Q^h v\|_{L^2(0,T;H^{-1}(\Omega))} \le C\|v - v^h\|_{L^2(0,T;H^{-1}(\Omega))} \quad \forall\, v \in L^2(0,T;H^{-1}(\Omega))\ \forall\, v^h \in L^2(0,T;V^h)\,. \tag{2.21}$$

Proof. Let $v \in L^2(0,T;H_0^1(\Omega))$ be given. From (2.10) we see that

$$\|v(t) - P^h v(t)\|_1 \le C\|v(t) - R^h v(t)\|_1 \qquad \text{a.e. } t\,.$$

Squaring both sides and integrating in t we obtain

$$\|v - P^h v\|_{L^2(0,T;H^1(\Omega))} \le C\|v - R^h v\|_{L^2(0,T;H^1(\Omega))}\,. \tag{2.22}$$

Also, it is evident from the best approximation properties of R^h in the $\|\cdot\|_1$-norm that

$$\|v(t) - R^h v(t)\|_{L^2(0,T;H^1(\Omega))} = \inf_{v^h \in V^h} \|v - v^h\|_{L^2(0,T;H^1(\Omega))}\,.$$

Thus, (2.16) and (2.18) follow from (2.12) (with $s = 1$), (2.13) (with $s = 1$), and the last two relations.

Let $v \in L^2(0,T;H^{-1}(\Omega))$ be given. From (2.11) we see that

$$\|v(t) - Q^h v(t)\|_{-1} \le C\|v(t) - S^h v(t)\|_{-1} \qquad \text{a.e. } t\,.$$

Squaring both sides and integrating in t we obtain

$$\|v - Q^h v\|_{L^2(0,T;H^{-1}(\Omega))} \le C\|v - S^h v\|_{L^2(0,T;H^{-1}(\Omega))}\,. \tag{2.23}$$

Also, it is evident from the best approximation properties of S^h in the $\|\cdot\|_{-1}$-norm that

$$\|v - S^h v\|_{L^2(0,T;H^{-1}(\Omega))} = \inf_{v^h \in V^h} \|v - v^h\|_{L^2(0,T;H^{-1}(\Omega))}\,.$$

Thus, (2.17) and (2.19) follow from (2.12), (2.13), and the last two relations.

Inequalities (2.20) and (2.21) are trivial consequences of (2.22) and (2.23), respectively. ∎

Remark. Note that using (2.6) and (2.8), we can prove that P^h is the L^2-projection from $L^2(0,T;L^2(\Omega))$ onto $L^2(0,T;V^h)$. ∎

3. Semidiscrete error estimates for linear parabolic equations. We assume in what follows that the data

$$f \in L^2(0,T;H^{-1}(\Omega)) \quad \text{and} \quad u_0 \in L^2(\Omega)$$

or, equivalently, the solution $u \in X$, where X is as introduced in section 1, is the space

$$X = L^2(0,T;H_0^1(\Omega)) \cap H^1(0,T;H^{-1}(\Omega))$$

equipped with the norm

$$\|v\|_X^2 = \|v\|_{L^2(0,T;H^1(\Omega))}^2 + \|\partial_t v\|_{L^2(0,T;H^{-1}(\Omega))}^2 .$$

Whenever further regularity assumptions on the solution u (or equivalently on the data f and u_0) are used, they will be explicitly stated. In this section we consider the approximations of the linear parabolic problem

$$\partial_t u - \operatorname{div}[A(\mathbf{x})\nabla u] = f \qquad \text{in } (0,T)\times\Omega\,, \tag{3.1}$$

$$u\big|_{(0,T)\times\partial\Omega} = 0\,, \tag{3.2}$$

and

$$u(0) = u_0 \qquad \text{in } \Omega\,. \tag{3.3}$$

We introduce a bilinear form

$$a(v,w) = \int_\Omega [A(\mathbf{x})\nabla v(\mathbf{x})]\cdot[\nabla w(\mathbf{x})]\,d\mathbf{x} \qquad \forall\, v,w \in H^1(\Omega).$$

We assume that $A : \Omega \to \mathbb{R}^{d\times d}$ is uniformly positive definite and essentially bounded so that

$$a(v,v) \geq C_0\|v\|_1^2 \qquad \forall\, v \in H_0^1(\Omega) \tag{3.4}$$

and

$$a(v,w) \leq C_1\|v\|_1\|w\|_1 \qquad \forall\, v,w \in H^1(\Omega). \tag{3.5}$$

We define a weak formulation of (3.1)–(3.3) as follows: find

$$u \in X \tag{3.6}$$

such that

$$\langle \partial_t u(t), v\rangle + a(u(t),v) = \langle f(t), v\rangle \qquad \forall\, v \in H_0^1(\Omega),\ \text{a.e. } t, \tag{3.7}$$

and

$$(u(0), z) = (u_0, z) \qquad \forall\, z \in L^2(\Omega)\,. \tag{3.8}$$

Here, a.e. t means "for almost every $t \in (0,T)$."

Throughout this paper, V^h denotes a family of finite element subspaces of $H_0^1(\Omega)$ satisfying (2.1)–(2.5). The semidiscrete finite element approximation of the weak formulation (3.6)–(3.8) is defined by

$$u^h \in H^1(0,T;V^h)\,, \tag{3.9}$$

$$(\partial_t u^h(t), v^h) + a(u^h(t), v^h) = \langle f(t), v^h\rangle \qquad \forall\, v^h \in V^h,\ \text{a.e. } t\,, \tag{3.10}$$

and

$$u^h(0) = u_0^h\,, \tag{3.11}$$

where $u_0^h \in V^h$ is a suitable approximation of u_0.

The initial conditions (3.8) and (3.11) make sense because of part (i) of the following embedding results.

LEMMA 3.1. *The following two embedding results hold for X:*

(i) *X is continuously embedded into $C([0,T];L^2(\Omega))$. Furthermore, for $v \in X$, the mapping $t \mapsto \|v(t)\|$ is absolutely continuous on $[0,T]$ with*

$$\frac{1}{2}\frac{d}{dt}\|v(t)\|^2 = \langle v'(t), v(t)\rangle \qquad \text{a.e. } t \in [0,T]\,.$$

(ii) *X is compactly embedded into $L^2(0,T;L^2(\Omega))$.*

Proof. See, e.g., [21, p. 287] for part (i) and [35, p. 271, p. 274] for part (ii). ∎

Parallel to standard finite element theories for elliptic problems, we will derive error estimates in the norm of the solution space for the parabolic weak formulation and establish parabolic Cea's lemma and Aubin–Nitsche's lemma. (For the elliptic version of Cea's lemma and Aubin–Nitsche's lemma, see, e.g., [11].) We will also prove some additional estimates.

3.1. Semidiscrete error estimates in the norm of the solution space. We will estimate the errors in the X-norm by estimating $u-u^h$ and $\partial_t u - \partial_t u^h$ separately. We have the following error estimates for $u - u^h$.

THEOREM 3.2. *Let $u \in X$ be the solution of* (3.7)–(3.8) *and $u^h \in H^1(0,T;V^h)$ be the solution of* (3.10)–(3.11). *Assume that*

$$\|u_0 - u_0^h\| \to 0 \quad \text{as } h \to 0\,. \tag{3.12}$$

Then, for every $t \in [0,T]$,

$$\|u(t) - u^h(t)\|^2 + \int_0^T \|u(s) - u^h(s)\|_1^2\, ds \to 0 \quad \text{as } h \to 0\,. \tag{3.13}$$

If, in addition,

$$u \in L^2(0,T;H^{m+1}(\Omega)) \cap H^1(0,T;H^{m-1}(\Omega)) \qquad \text{for some } m \in [0,k] \tag{3.14}$$

and $u_0^h = P^h u_0$, then

$$\begin{aligned}\|u(t) - u^h(t)\|^2 &+ \int_0^T \|u(s) - u^h(s)\|_1^2\, ds \\ &\le Ch^{2m}\Big(\|u\|^2_{L^2(0,T;H^{m+1}(\Omega))} + \|\partial_t u\|^2_{L^2(0,T;H^{m-1}(\Omega))}\Big).\end{aligned} \tag{3.15}$$

Proof. By subtracting (3.10) from (3.7) we obtain the "orthogonality" condition

$$\langle \partial_t u(t) - \partial_t u^h(t), v^h\rangle + a(u(t)-u^h(t), v^h) = 0 \qquad \forall\, v^h \in V^h,\ \text{a.e. } t\,. \tag{3.16}$$

This leads to the relation

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\|u(t)-u^h(t)\|^2 + a(u(t)-u^h(t), u(t)-u^h(t)) \\ &\quad = \langle \partial_t u(t) - \partial_t u^h(t), u(t)-u^h(t)\rangle + a(u(t)-u^h(t), u(t)-u^h(t)) \\ &\quad = \langle \partial_t u(t) - \partial_t u^h(t), u(t)-v^h(t)\rangle + a(u(t)-u^h(t), u(t)-v^h(t)) \end{aligned} \tag{3.17}$$

for every $v^h(t) \in H^1(0,T;V^h)$ and almost every $t \in (0,T)$. Let $P^h u(t)$ be defined through (2.6) for almost every t. Then, we see that $P^h u$ has the same regularity as u, i.e., $P^h u \in L^2(0,T;H_0^1(\Omega)) \cap H^1(0,T;H^{-1}(\Omega))$. Using repeatedly the fact that

$$(u(t) - P^h u(t), w^h) = 0 \qquad \forall\, w^h \in V^h,\ \text{a.e. } t\,,$$

we obtain

$$\begin{aligned} &\langle \partial_t u(t) - \partial_t u^h(t), u(t) - P^h u(t)\rangle = \langle \partial_t u(t), u(t) - P^h u(t)\rangle \\ &= \langle \partial_t u(t) - \partial_t P^h u(t), u(t) - P^h u(t)\rangle = \frac{1}{2}\frac{d}{dt}\|u(t) - P^h u(t)\|^2 \qquad \text{a.e. } t\,. \end{aligned} \tag{3.18}$$

Thus, by setting $v^h(t) = P^h u(t)$ in (3.17) and with the help of (3.18), (3.4), and (3.5), we are led to

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\|u(t)-u^h(t)\|^2 + C_0\|u(t)-u^h(t)\|_1^2 \\ &\le \frac{1}{2}\frac{d}{dt}\|u(t)-u^h(t)\|^2 + a(u(t)-u^h(t), u(t)-u^h(t)) \\ &= \frac{1}{2}\frac{d}{dt}\|u(t)-P^h u(t)\|^2 + a(u(t)-u^h(t), u(t)-P^h u(t)) \\ &\le \frac{1}{2}\frac{d}{dt}\|u(t)-P^h u(t)\|^2 + \frac{C_0}{2}\|u(t)-u^h(t)\|_1^2 + C\|u(t)-P^h u(t)\|_1^2 \end{aligned} \tag{3.19}$$

for almost every t. Integrating (3.19) in t and eliminating the factor $(1/2)$ we obtain

$$\begin{aligned} &\|u(t)-u^h(t)\|^2 + C_0\int_0^t \|u(s)-u^h(s)\|_1^2\, ds \\ &\quad \le \|u_0 - u^h(0)\|^2 + \|u(t)-P^h u(t)\|^2 - \|u(0)-P^h u(0)\|^2 \\ &\qquad + C\int_0^t \|u(s)-P^h u(s)\|_1^2\, ds \\ &\quad \le \|u_0 - u_0^h\|^2 + \|u(t_1)-P^h u(t_1)\|^2 - \|u(0)-P^h u(0)\|^2 \\ &\qquad + C\int_0^t \|u(s)-P^h u(s)\|_1^2\, ds \qquad \forall\, t \in [0,T]\,, \end{aligned} \tag{3.20}$$

where $t_1 \in [0,T]$ satisfies $\|u(t_1)-P^h u(t_1)\|^2 = \max_{t\in[0,T]}\|u(t)-P^h u(t)\|^2$. Note that (3.20) makes sense for all t because of Lemma 3.1. Also, we note that (3.14) implies $u \in C([0,T];H^m(\Omega))$ so that $u_0 \in H^m(\Omega)$. Thus, (3.13) follows from (3.20), (3.12), (2.1) with $s=0$, and (2.16).

If $u_0^h = P^h u_0$, then (3.20) simplifies to

$$\begin{aligned}(3.21)\qquad &\|u(t)-u^h(t)\|^2 + C_0\int_0^t \|u(s)-u^h(s)\|_1^2\,ds \\ &\qquad \le \|u(t_1)-P^h u(t_1)\|^2 + C\int_0^T \|u(s)-P^h u(s)\|_1^2\,ds \qquad \forall\, t\in[0,T]\end{aligned}$$

so that under the assumption $u \in L^2(0,T;H^{m+1}(\Omega)) \cap H^1(0,T;H^{m-1}(\Omega))$, (3.15) follows from (3.21), (2.3), Lemma 3.1, and (2.18). □

Remark. Note that (3.14) implies that $u \in C([0,T];H^m(\Omega))$ so that u_0 necessarily satisfies $u_0 \in H^m(\Omega)$. Using the differential equation we also deduce that $f \in L^2(0,T;H^{m-1}(\Omega))$. On the other hand, if we assume $f \in L^2(0,T;H^{m-1}(\Omega))$ and $u_0 \in H^m(\Omega)$, we need certain compatibility conditions and some further conditions on f in order to deduce that $u \in L^2(0,T;H^{m+1}(\Omega)) \cap H^1(0,T;H^{m-1}(\Omega))$; see, e.g., [21, p. 365] and [28, pp. 386–387]. In Theorem 3.2 and the remaining theorems in this paper concerning the order of error estimates, we simply assume (3.14) holds without stating precisely the compatibility conditions and the conditions on f. Based on [21, p. 365] and [28, pp. 386–387], we see that regularity assumption (3.14) on u not only is nonvacuous, but holds quite generally. □

Remark. The use of the L^2-projection $P^h u(t)$ played an important role in the treatment of the $\partial_t u - \partial_t u^h$ term. [18, Theorem 3.1] derived an estimate seemingly similar to the first inequality in (3.20). However, that estimate contained an extra term, $\|\partial_t u - \partial_t u^h\|^2_{L^2(0,T;L^2(\Omega))}$, that cannot be estimated under the minimal regularity $\partial_t u \in L^2(0,T;H^{-1}(\Omega))$. [22, Theorem 4.1] derived an estimate involving the term $\|\partial_t u - \partial_t v^h\|^2_{L^2(0,T;H^{-1}(\Omega))}$ which is in the minimal regularity norm. However, that estimate by itself does not directly yield the convergence results or error estimates of this paper under minimal regularity; see [22, Theorem 4.3]. □

Now we turn to the convergence proof and the estimate for the error $\partial_t u - \partial_t u^h$ in $L^2(0,T;H^{-1}(\Omega))$.

THEOREM 3.3. *Let $u \in X$ be the solution of* (3.7)–(3.8) *and $u^h \in H^1(0,T;V^h)$ be the solution of* (3.10)–(3.11). *Assume that* (3.12) *holds. Then,*

$$(3.22)\qquad \|\partial_t u - \partial_t u^h\|_{L^2(0,T;H^{-1}(\Omega))} \to 0 \quad \text{as } h\to 0\,.$$

If, in addition, (3.14) *holds and $u_0^h = P^h u_0$, then*

$$\begin{aligned}(3.23)\qquad &\|\partial_t u - \partial_t u^h\|_{L^2(0,T;H^{-1}(\Omega))} \\ &\qquad \le Ch^m\Big(\|u\|_{L^2(0,T;H^{m+1}(\Omega))} + \|\partial_t u\|_{H^1(0,T;H^{m-1}(\Omega))}\Big).\end{aligned}$$

Proof. Using the orthogonality condition (3.16), we have

$$\begin{aligned}\langle \partial_t u(t) - \partial_t u^h(t), v\rangle &= \langle \partial_t u(t) - \partial_t u^h(t), Q^h v\rangle + \langle \partial_t u(t) - \partial_t u^h(t), v - Q^h v\rangle \\ &= -a(u(t)-u^h(t), Q^h v) + \langle \partial_t u(t) - \partial_t u^h(t), v - Q^h v\rangle\,.\end{aligned}$$

Note that $\langle \partial_t u^h(t), v - Q^h v\rangle = 0 = \langle Q^h \partial_t u(t), v - Q^h v\rangle$ so that the previous equality can be rewritten as

$$\begin{aligned}\langle \partial_t u(t) - \partial_t u^h(t), v\rangle &= -a(u(t)-u^h(t), Q^h v) + \langle \partial_t u(t) - Q^h\partial_t u(t), v - Q^h v\rangle \\ &\le C\|u(t)-u^h(t)\|_1\,\|Q^h v\|_1 + \|\partial_t u(t) - Q^h\partial_t u(t)\|_{-1}\|v - Q^h v\|_1 \qquad \text{a.e. } t\,.\end{aligned}$$

Taking the supremum over $v \in H_0^1(\Omega)$ with $\|v\|_1 = 1$ and noting that $\|P^h v - v\|_1 \le C\|R^h v - v\|_1 \le C\|v\|_1$, $\|P^h v\|_1 \le \|P^h v - v\|_1 + \|v\|_1 \le C\|R^h v - v\|_1 + \|v\|_1 \le C\|v\|_1$, and $P^h v = Q^h v$, we obtain

$$\begin{aligned} &\|\partial_t u(t) - \partial_t u^h(t)\|_{-1} \\ &\qquad \le C\|u(t) - u^h(t)\|_1 + C\|\partial_t u(t) - Q^h \partial_t u(t)\|_{-1} \qquad \text{a.e. } t\,. \end{aligned} \tag{3.24}$$

Integration in t in (3.24) yields

$$\begin{aligned} &\|\partial_t u - \partial_t u^h\|_{L^2(0,T;H^{-1}(\Omega))} \\ &\qquad \le C\|u - u^h\|_{L^2(0,T;H_0^1(\Omega))} + C\|\partial_t u - Q^h \partial_t u\|_{L^2(0,T;H^{-1}(\Omega))}\,. \end{aligned} \tag{3.25}$$

Thus, (3.22) follows from (3.25), (3.13), and (2.17), and (3.23) follows from (3.25), (3.15), and (2.19). ∎

3.2. Parabolic Cea's lemma and Aubin–Nitsche's lemma. As an immediate consequence of (2.20), (2.21), (3.21), and (3.25), we obtain the following parabolic version of Cea's lemma.

THEOREM 3.4. *Let $u \in X$ be the solution of* (3.7)–(3.8) *and $u^h \in H^1(0,T;V^h)$ be the solution of* (3.10)–(3.11). *Assume $u_0^h = P^h u_0$. Then*

$$\|u - u^h\|_X \le C\|u - v^h\|_X \qquad \forall\, v^h \in H^1(0,T;V^h),$$

i.e.,

$$\begin{aligned} &\|u(t) - u^h(t)\|_{L^2(\Omega)} + \|u - u^h\|_{L^2(0,T;H_0^1(\Omega))} + \|\partial_t u - \partial_t u^h\|_{L^2(0,T;H^{-1}(\Omega))} \\ &\le C\Big(\|u(t) - v^h(t)\|_{L^2(\Omega)} + \|u - v^h\|_{L^2(0,T;H_0^1(\Omega))} + \|\partial_t u - \partial_t v^h\|_{L^2(0,T;H^{-1}(\Omega))}\Big) \end{aligned}$$

for every $v^h \in H^1(0,T;V^h)$. Furthermore,

$$\begin{aligned} &\|u(t) - u^h(t)\|_{L^\infty(0,T;L^2(\Omega))} + \|u - u^h\|_{L^2(0,T;H_0^1(\Omega))} + \|\partial_t u - \partial_t u^h\|_{L^2(0,T;H^{-1}(\Omega))} \\ &\le C\Big(\|u - v^h\|_{L^\infty(0,T;L^2(\Omega))} + \|u - w^h\|_{L^2(0,T;H_0^1(\Omega))} + \|\partial_t u - \partial_t z^h\|_{L^2(0,T;H^{-1}(\Omega))}\Big) \end{aligned}$$

for every $v^h, w^h, z^h \in H^1(0,T;V^h)$. ∎

Remark. Thanks to Lemma 3.1, we may freely add or delete the term

$$\|v\|_{L^\infty(0,T;L^2(\Omega))}$$

in the definition of the norm for X. ∎

Next we prove a parabolic Aubin–Nitsche lemma.

THEOREM 3.5. *Let $u \in X$ be the solution of* (3.7)–(3.8) *and $u^h \in H^1(0,T;V^h)$ be the solution of* (3.10)–(3.11). *Assume that $u_0^h = P^h u_0$. Then*

$$\|u - u^h\|_{L^2(0,T;L^2(\Omega))} \le Ch\|u - u^h\|_{L^2(0,T;H^1(\Omega))}. \tag{3.26}$$

Proof. Using the embedding

$$L^2(0,T;H_0^1(\Omega)) \cap H^1(0,T;H^{-1}(\Omega)) \hookrightarrow C([0,T];L^2(\Omega))$$

we have that $u \in C([0,T];L^2(\Omega))$ and $u^h \in C([0,T];L^2(\Omega))$. Thus for every $t \in [0,T]$ we may define $z(t) \in H_0^1(\Omega)$ and $z^h(t) \in V^h$ as the solutions of the following continuous and discrete elliptic problems, respectively:

$$a(z(t), v) = (u(t) - u^h(t), v) \qquad \forall\, v \in H_0^1(\Omega) \tag{3.27}$$

and

$$a(z^h(t), v^h) = (u(t) - u^h(t), v^h) \qquad \forall\, v^h \in V^h. \tag{3.28}$$

Setting $v = u(t) - u^h(t)$ in (3.27) we obtain

$$\begin{aligned}\|u(t) - u^h(t)\|_0^2 &= a(z(t), u(t) - u^h(t)) \\ &= a(z(t) - z^h(t), u(t) - u^h(t)) + a(z^h(t), u(t) - u^h(t)),\end{aligned}$$

which, upon an application of the "orthogonality condition" (3.16), can be rewritten as

$$\|u(t) - u^h(t)\|_0^2 = a(z(t) - z^h(t), u(t) - u^h(t)) - \langle \partial_t u(t) - \partial_t u^h(t), z^h(t)\rangle. \tag{3.29}$$

Differentiating (3.28) and then setting $v^h = z^h(t)$ yield

$$\frac{1}{2}\frac{d}{dt} a(z^h(t), z^h(t)) = a(\partial_t z^h(t), z^h(t)) = \langle \partial_t u(t) - \partial_t u^h(t), z^h(t)\rangle \quad \text{a.e. } t. \tag{3.30}$$

Substitution of (3.30) into (3.29) and integration over $t \in [0, T]$ lead us to

$$\begin{aligned}\|u - u^h\|^2_{L^2(0,T;L^2(\Omega))} \le C\|z - z^h\|_{L^2(0,T;H^1(\Omega))}\, \|u - u^h\|_{L^2(0,T;H^1(\Omega))} \\ - \frac{1}{2} a(z^h(T), z^h(T)) + \frac{1}{2} a(z^h(0), z^h(0)).\end{aligned} \tag{3.31}$$

From (3.28) at $t = 0$ we see that

$$a(z^h(0), z^h(0)) = (u(0) - u^h(0), z^h(0)) = (u(0) - P^h u(0), z^h(0)) = 0.$$

Also obviously,

$$a(z^h(T), z^h(T)) \ge 0.$$

Elliptic regularity on convex domains implies that $z(t) \in H^2(\Omega)$ with the estimate $\|z(t)\|_2 \le C\|u(t) - u^h(t)\|_0$. Standard error estimates for the finite element approximations of elliptic problems yield

$$\|z(t) - z^h(t)\|_1 \le Ch\, \|z(t)\|_2 \le Ch\, \|u(t) - u^h(t)\|_0. \tag{3.32}$$

By combining (3.31)–(3.32) we derive

$$\|u - u^h\|^2_{L^2(0,T;L^2(\Omega))} \le Ch\|u - u^h\|_{L^2(0,T;L^2(\Omega))}\, \|u - u^h\|_{L^2(0,T;H^1(\Omega))},$$

which yields (3.26) upon cancelling the common factor $\|u - u^h\|_{L^2(0,T;L^2(\Omega))}$. ∎

3.3. Pointwise-in-time error estimates. If we make stronger regularity assumptions on u, i.e., $u \in L^2(0, T; H^3(\Omega)) \cap H^1(0, T; H^1(\Omega))$, then we may obtain pointwise-in-time error estimates for $\|\partial_t u(t) - \partial_t u^h(t)\|_{-1}$ and $\|u(t) - u^h(t)\|_1$. We may also obtain an error estimate for $\|\partial_t u - \partial_t u^h\|_{L^2(0,T;L^2(\Omega))}$.

THEOREM 3.6. *Let $u \in X$ be the solution of* (3.7)–(3.8) *and $u^h \in H^1(0, T; V^h)$ be the solution of* (3.10)–(3.11). *Assume that $k \ge 2$,*

$$u \in L^2(0, T; H^{m+1}(\Omega)) \cap H^1(0, T; H^{m-1}(\Omega)) \qquad \textit{for some } m \in [2, k]\,, \tag{3.33}$$

and $u_0^h = P^h u_0$. *Then*

$$\|\partial_t u - \partial_t u^h\|_{L^2(0,T;L^2(\Omega))} \to 0 \quad \text{as } h \to 0\,, \tag{3.34}$$

$$\|u(t) - u^h(t)\|_1 \to 0 \quad \text{as } h \to 0 \quad \forall\, t \in [0,T]\,, \tag{3.35}$$

$$\|\partial_t u(t) - \partial_t u^h(t)\|_{-1} \to 0 \quad \text{as } h \to 0 \quad \forall\, t \in [0,T]\,, \tag{3.36}$$

$$\begin{aligned} &\|\partial_t u - \partial_t u^h\|_{L^2(0,T;L^2(\Omega))} \\ &\qquad \le C h^{m-1}\Big(\|u\|_{L^2(0,T;H^{m+1}(\Omega))} + \|\partial_t u\|_{H^1(0,T;H^{m-1}(\Omega))}\Big)\,, \end{aligned} \tag{3.37}$$

$$\begin{aligned} &\|u(t) - u^h(t)\|_1 \\ &\qquad \le C h^{m-1}\Big(\|u\|_{L^2(0,T;H^{m+1}(\Omega))} + \|\partial_t u\|_{H^1(0,T;H^{m-1}(\Omega))}\Big) \qquad \forall\, t \in [0,T]\,, \end{aligned} \tag{3.38}$$

and

$$\begin{aligned} &\|\partial_t u(t) - \partial_t u^h(t)\|_{-1} \\ &\qquad \le C h^{m-1}\Big(\|u\|_{L^2(0,T;H^{m+1}(\Omega))} + \|\partial_t u\|_{H^1(0,T;H^{m-1}(\Omega))}\Big) \qquad \forall\, t \in [0,T]\,. \end{aligned} \tag{3.39}$$

Proof. From (3.33) we deduce that $u_0 \in H^m(\Omega)$ and that $u \in L^2(0,T;H^3(\Omega)) \cap H^1(0,T;H^1(\Omega))$ so that $\partial_t u \in L^2(0,T;H^1(\Omega))$. Using the orthogonality condition (3.16) we obtain

$$(\partial_t u(t) - \partial_t u^h(t), P^h \partial_t u(t)) + a(u(t) - u^h(t), P^h \partial_t u(t)) = 0 \qquad \text{a.e. } t \tag{3.40}$$

and

$$(\partial_t u(t) - \partial_t u^h(t), \partial_t u^h(t)) + a(u(t) - u^h(t), \partial_t u^h(t)) = 0 \qquad \text{a.e. } t\,. \tag{3.41}$$

With the help of (3.40)–(3.41) we obtain

$$\begin{aligned} &\|\partial_t u(t) - \partial_t u^h(t)\|^2 + \frac{1}{2}\frac{d}{dt} a(u(t) - u^h(t), u(t) - u^h(t)) \\ &\quad = (\partial_t u(t) - \partial_t u^h(t), \partial_t u(t) - \partial_t u^h(t)) + a(u(t) - u^h(t), \partial_t u(t) - \partial_t u^h(t)) \\ &\quad = (\partial_t u(t) - \partial_t u^h(t), \partial_t u(t)) + a(u(t) - u^h(t), \partial_t u(t)) \\ &\quad = (\partial_t u(t) - \partial_t u^h(t), \partial_t u(t) - P^h \partial_t u(t)) + a(u(t) - u^h(t), \partial_t u(t) - P^h \partial_t u(t)) \end{aligned}$$

for almost every $t \in [0,T]$. Then, from the defining equation of P^h, i.e., (2.6), we see that

$$(\partial_t u^h(t), \partial_t u(t) - P^h \partial_t u(t)) = 0 = (P^h \partial_t u(t), \partial_t u(t) - P^h \partial_t u(t)) \qquad \text{a.e. } t\,.$$

Combining the last two equations we arrive at

$$\begin{aligned} &\|\partial_t u(t) - \partial_t u^h(t)\|^2 + \frac{1}{2}\frac{d}{dt} a(u(t) - u^h(t), u(t) - u^h(t)) \\ &= (\partial_t u(t) - P^h \partial_t u(t), \partial_t u(t) - P^h \partial_t u(t)) + a(u(t) - u^h(t), \partial_t u(t) - P^h \partial_t u(t)) \\ &\le \|\partial_t u(t) - P^h \partial_t u(t)\|^2 + C\|u(t) - u^h(t)\|_1^2 + C\|\partial_t u(t) - P^h \partial_t u(t)\|_1^2\,. \end{aligned}$$

Integration in t yields

$$\begin{aligned}
&\int_0^t \|\partial_t u(s) - \partial_t u^h(s)\|^2\,ds + \frac{1}{2}a(u(t)-u^h(t),u(t)-u^h(t)) \\
&\quad\le \frac{1}{2}a(u(0)-u^h(0),u(0)-u^h(0)) + \int_0^T \|\partial_t u(t) - P^h\partial_t u(t)\|^2\,dt \\
&\qquad + C\int_0^T \|u(t)-u^h(t)\|_1^2\,dt + C\int_0^T \|\partial_t u(t) - P^h\partial_t u(t)\|_1^2\,dt \\
&\quad\le \frac{1}{2}\|u_0 - P^h u_0\|_1^2 + \int_0^T \|\partial_t u(t) - P^h\partial_t u(t)\|^2\,dt \\
&\qquad + C\int_0^T \|u(t)-u^h(t)\|_1^2\,dt + C\int_0^T \|\partial_t u(t) - P^h\partial_t u(t)\|_1^2\,dt\,.
\end{aligned} \tag{3.42}$$

Thus, (3.34) and (3.35) follow from (3.42), (2.10), (2.1) with $s=1$, (2.12) with $s=0$, (3.13), and (2.16). Relations (3.37) and (3.38) follow from (3.42), (2.10), (2.4), (2.13) with $s=0$, (3.15), and (2.18). Also, (3.36) follows from (3.24), (3.35), (2.11), and (2.1). Finally, (3.39) follows from (3.24), (3.38), (2.11), and (2.2). ∎

Remark. The $H^1(\Omega)$-norm of $P^h\partial_t u(t)$ was used in the proof of Theorem 3.4. For this reason we need $k \ge m \ge 2$. ∎

Remark. We used the fact that $P^h\partial_t u = \partial_t P^h u$, which can be easily verified. ∎

Remark. (3.42) seems to suggest that, for pointwise-in-time estimate, one should assume $u \in L^2(0,T;H^{m+1}(\Omega)) \cap H^1(0,T;H^m(\Omega))$ instead of $u \in L^2(0,T;H^{m+1}(\Omega)) \cap H^1(0,T;H^{m-1}(\Omega))$. Under the former regularity together with the assumption $u_0 \in H^{m+1}(\Omega)$, (3.42) yields $\mathcal{O}(h^m)$ estimates instead of $\mathcal{O}(h^{m-1})$ estimates. ∎

4. Semidiscrete error estimates for semilinear parabolic equations. In this section, we derive error estimates for the semidiscrete finite element approximations of the semilinear parabolic problem

$$\partial_t u - \operatorname{div}[A(\mathbf{x})\nabla u] + \mathbf{b}(t,\mathbf{x})\cdot(\nabla u) + \phi(u) = f \qquad \text{in } (0,T)\times\Omega\,, \tag{4.1}$$

$$u\big|_{(0,T)\times\partial\Omega} = 0\,, \tag{4.2}$$

and

$$u(0) = u_0 \qquad \text{in } \Omega \tag{4.3}$$

under minimal regularity assumptions on u. Throughout this section we assume that $A(\mathbf{x})$ possesses sufficient smoothness that guarantees the validity of the regularity theorem [21, p. 360, Theorem 5] for the linear parabolic equation.

The error estimates to be derived in section 4.2 make use of results of [9] (see also [23] and [13]) concerning the approximation of a class of nonlinear problems. These results imply that, under certain hypotheses, the error of approximation of solutions of certain nonlinear problems is basically the same as the error of approximation of solutions of related linear problems. Here, for the sake of completeness, we state the relevant results, specialized to our needs.

4.1. Quotation of results concerning the approximation of a class of nonlinear problems. The nonlinear problems considered in [9] and [23] are of the following type. We seek a $\psi \in \mathcal{X}$ such that

$$\psi + \mathcal{T}\mathcal{G}(\psi) = 0\,, \tag{4.4}$$

where $\mathcal{T} \in \mathcal{L}(\mathcal{Y};\mathcal{X})$, $\mathcal{G}$ is a C^2 mapping from $\mathcal{X}$ into $\mathcal{Y}$, and $\mathcal{X}$ and $\mathcal{Y}$ are Banach spaces. We say that ψ is a *regular solution* if $\psi + T\mathcal{G}_\psi(\psi)$ is an isomorphism from $\mathcal{X}$ into $\mathcal{X}$. Here, $\mathcal{G}_\psi(\cdot)$ (or $\mathcal{G}'$ or $D\mathcal{G}$) denotes the Fréchet derivative of $\mathcal{G}(\cdot)$. We assume that there exists another Banach space $\mathcal{Z}$, contained in $\mathcal{Y}$, with continuous embedding, such that

$$\mathcal{G}_\psi(\psi) \in \mathcal{L}(\mathcal{X};\mathcal{Z}) \quad \forall\, \psi \in \mathcal{X}\,. \tag{4.5}$$

Approximations are defined by introducing a subspace $\mathcal{X}^h \subset \mathcal{X}$ and an approximating operator $\mathcal{T}^h \in \mathcal{L}(\mathcal{Y};\mathcal{X}^h)$. We seek a $\psi^h \in \mathcal{X}^h$ such that

$$\psi^h + \mathcal{T}^h\mathcal{G}(\psi^h) = 0\,. \tag{4.6}$$

Concerning the linear operator $\mathcal{T}^h$, we assume the approximation properties

$$\lim_{h\to 0} \|(\mathcal{T}^h - \mathcal{T})\omega\|_{\mathcal{X}} = 0 \quad \forall\, \omega \in \mathcal{Y} \tag{4.7}$$

and

$$\lim_{h\to 0} \|\mathcal{T}^h - \mathcal{T}\|_{\mathcal{L}(\mathcal{Z};\mathcal{X})} = 0\,. \tag{4.8}$$

Note that whenever the imbedding $\mathcal{Z} \subset \mathcal{Y}$ is compact, (4.8) follows from (4.7) and, moreover, (4.5) implies that the operator $\mathcal{T}\mathcal{G}_\psi(\psi) \in \mathcal{L}(\mathcal{X};\mathcal{X})$ is compact.

We can now state the result of [9] (see also [23]) that will be used in section 4.2. In the statement of the theorem, $D^2\mathcal{G}$ represents the second Fréchet derivatives of $\mathcal{G}$.

THEOREM 4.1. *Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces. Assume that $\mathcal{G}$ is a C^2 mapping from $\mathcal{X}$ into $\mathcal{Y}$ and that $D^2\mathcal{G}$ is bounded on all bounded sets of $\mathcal{X}$. Assume that* (4.5), (4.7), *and* (4.8) *hold and that ψ is a regular solutions of* (4.4). *Then there exists a neighborhood $\mathcal{O}$ of the origin in $\mathcal{X}$ and, for $h \le h_0$ small enough, a unique $\psi^h \in \mathcal{X}^h$ such that ψ^h is a regular solution of* (4.6) *and $\psi^h - \psi \in \mathcal{O}$. Moreover, there exists a constant $C > 0$, independent of h, such that*

$$\|\psi^h - \psi\|_{\mathcal{X}} \le C\|(\mathcal{T}^h - \mathcal{T})\mathcal{G}(\psi)\|_{\mathcal{X}}\,. \qquad \square \tag{4.9}$$

4.2. Recasting the semilinear problem into the Brezzi–Rappaz–Raviart framework. We define the following weak form for the semilinear problem (4.1)–(4.3): find

$$u \in X \tag{4.10}$$

such that

$$\begin{aligned} \langle \partial_t u(t), v\rangle + a(u(t),v) + (\mathbf{b}(t)\cdot\nabla u(t), v) + \big(\phi(u(t)), v\big) \\ = \langle f(t), v\rangle \qquad \forall\, v \in H_0^1(\Omega),\ \text{a.e. } t \end{aligned} \tag{4.11}$$

and

$$(u(0), z) = (u_0, z) \qquad \forall\, z \in L^2(\Omega)\,. \tag{4.12}$$

Certain conditions must be imposed on ϕ in order to guarantee the existence of a solution for (4.10)–(4.12) in X. In this paper, we limit ourselves to finite element analysis only. Thus, we will simply assume the existence of a solution for (4.10)–(4.12) and then try to derive error estimates for its semidiscrete finite element solution. Of course, there are many choices of ϕ (e.g., $\phi(u) = u^{11/5}$) that guarantee a solution to (4.10)–(4.12) so that our error estimation is not vacuous.

Let V^h be a family of finite element subspaces of $H_0^1(\Omega)$ satisfying (2.1)–(2.5). We define a semidiscrete finite element approximation of the weak formulation (4.10)–(4.12) by

$$u^h \in H^1(0,T;V^h)\,, \tag{4.13}$$

$$\begin{aligned}(\partial_t u^h(t), v^h) + a(u^h(t), v^h) + (\mathbf{b}(t)\cdot\nabla u^h(t), v^h) + (\phi(u^h(t), v^h)\\ = \langle f(t), v^h\rangle \quad \forall\, v^h \in V^h, \text{ a.e. } t\,,\end{aligned} \tag{4.14}$$

and

$$(u^h(0), z^h) = (u_0, z^h) \qquad \forall\, z^h \in V^h\,. \tag{4.15}$$

Error estimates for such approximations were derived in [38, Chapter 14] and [39] under certain smoothness assumptions on the solution. We will derive error estimates under minimal regularity in the sense we described in section 1, and we determine the largest growth exponent for the derivative of the semilinear term that guarantees a solution with the minimal regularity. For the same order error estimates as those of [38, Chapter 14] and [39], we assume less smoothness on the solution than what was required in [38] or [39]. Also, we obtain an estimate for $\partial_t u - \partial_t u^h$ which was absent from [38] or [39].

To derive error estimates for the semidiscrete approximations of the semilinear problem, we first fit the problem into the Brezzi–Rappaz–Raviart framework described in section 4.1. Then by verifying all assumptions of the Brezzi–Rappaz–Raviart theory we obtain the desired error estimates.

We set

$$\mathcal{X} = X \equiv L^2(0,T;H_0^1(\Omega)) \cap H^1(0,T;H^{-1}(\Omega))$$

with the norm $\|v\|_{\mathcal{X}}^2 = \|v\|_{L^2(0,T;H_0^1(\Omega))}^2 + \|\partial_t v\|_{L^2(0,T;H^{-1}(\Omega))}^2$ for all $v \in \mathcal{X}$ and

$$\mathcal{Y} = L^2(0,T;H^{-1}(\Omega)) \times L^2(\Omega)$$

with the norm $\|(y_1,y_2)\|_{\mathcal{Y}}^2 = \|y_1\|_{L^2(0,T;H^{-1}(\Omega))}^2 + \|y_2\|^2$ for all $y = (y_1,y_2) \in \mathcal{Y}$. We introduce the linear operator $\mathcal{T} : \mathcal{Y} \to \mathcal{X}$ to be the solution operator for the linear parabolic problem, i.e., $\mathcal{T}(\widetilde{f},\widetilde{u}_0) = \widetilde{u}$ for $(\widetilde{f},\widetilde{u}_0) \in \mathcal{Y}$ and $\widetilde{u} \in \mathcal{X}$ if and only if

$$\langle \partial_t \widetilde{u}(t), v\rangle + a(\widetilde{u}(t), v) = \langle \widetilde{f}(t), v\rangle \qquad \forall\, v \in H_0^1(\Omega), \text{ a.e. } t,$$

and

$$(\widetilde{u}(0), z) = (\widetilde{u}_0, z) \qquad \forall\, z \in L^2(\Omega)\,.$$

We define $\mathcal{G} : \mathcal{X} \to \mathcal{Y}$ by $\mathcal{G}(v) = (-f + \mathbf{b}\cdot\nabla v + \phi(v), -u_0)$ for all $v \in \mathcal{X}$.

Let $\mathcal{X}^h = H^1(0,T;V^h)$. We define the linear operator $\mathcal{T}^h : \mathcal{Y} \to \mathcal{X}^h$ to be the semidiscrete solution operator for the linear parabolic problem, i.e., $\mathcal{T}^h(\widetilde{f},\widetilde{u}_0) = \widetilde{u}^h$ for $(\widetilde{f},\widetilde{u}_0) \in \mathcal{Y}$ and $\widetilde{u}^h \in \mathcal{X}^h$ if and only if

$$(\partial_t \widetilde{u}^h(t), v^h) + a(\widetilde{u}^h(t), v^h) = \langle \widetilde{f}(t), v^h \rangle \qquad \forall\, v^h \in V^h, \text{ a.e. } t,$$

and

$$(\widetilde{u}^h(0), z^h) = (\widetilde{u}_0, z^h) \qquad \forall\, z^h \in V^h\,.$$

Clearly, (4.11)–(4.12) is equivalent to

$$u + \mathcal{T}\mathcal{G}(u) = 0,$$

and (4.14)–(4.15) is equivalent to

$$u^h + \mathcal{T}^h\mathcal{G}(u^h) = 0\,.$$

In other words, we have recast the semilinear problem and its approximation into the form of (4.4) and (4.6).

4.3. Semidiscrete error estimates for the approximation of semilinear parabolic equations. Our goal is to obtain convergence and error estimates in the X-norm for finite element approximations of the semilinear problem. We first examine conditions on ϕ that will guarantee the meaningfulness of the term $\phi(u)$ when $u \in X$. We consider the three-dimensional case only ($\Omega \subset \mathbb{R}^3$). Note that $L^2(0,T;H_0^1(\Omega)) \subset L^2(0,T;L^6(\Omega))$. If $\phi(s) = O(|s|^\alpha)$, then in order for the term $\phi(u) = O(|u|^\alpha)$ to make sense in the function space $L^2(0,T;H^{-1}(\Omega))$, we need $|u|^\alpha \in L^2(0,T;L^{6/5}(\Omega))$, which is equivalent to $u \in L^{2\alpha}(0,T;L^{6\alpha/5}(\Omega))$. The next lemma determines the largest value of allowable α when $\Omega \subset \mathbb{R}^3$.

LEMMA 4.2. *Assume $\Omega \subset \mathbb{R}^3$ and let $\overline{\alpha} \equiv 7/3$. Then the embedding*

$$L^2(0,T;H_0^1(\Omega)) \cap H^1(0,T;H^{-1}(\Omega)) \subset L^{2\alpha_1}(0,T;L^{6\alpha_2/5}(\Omega)) \tag{4.16}$$

is continuous for all $\alpha_1, \alpha_2 \in [1,\overline{\alpha}]$ and compact for all $\alpha_1, \alpha_2 \in [1,\overline{\alpha})$.

Proof. To show (4.16) is a continuous embedding for all $\alpha_1, \alpha_2 \in [1,\overline{\alpha}]$, it suffices to show that the embedding

$$\begin{aligned} &L^2(0,T;H_0^1(\Omega)) \cap H^1(0,T;H^{-1}(\Omega)) \\ &\qquad \subset L^{2\overline{\alpha}}(0,T;L^{\frac{6\overline{\alpha}}{5}}(\Omega)) = L^{\frac{14}{3}}(0,T;L^{\frac{14}{5}}(\Omega)) \end{aligned} \tag{4.17}$$

is continuous. It is well known that the embeddings

$$L^2(0,T;H_0^1(\Omega)) \cap H^1(0,T;H^{-1}(\Omega)) \subset L^2(0,T;L^6(\Omega))$$

and

$$L^2(0,T;H_0^1(\Omega)) \cap H^1(0,T;H^{-1}(\Omega)) \subset L^\infty(0,T;L^2(\Omega))$$

are continuous. For each $y \in L^2(0,T;H_0^1(\Omega)) \cap H^1(0,T;H^{-1}(\Omega))$ the interpolation of L^6 and L^2 yields

$$\|y(t)\|_{L^q(\Omega)} \le C\|y(t)\|_{L^6(\Omega)}^{1-\theta}\,\|y(t)\|_{L^2(\Omega)}^{\theta}$$

for all $\theta \in [0,1]$ with $q \in [2,6]$ determined by

$$\frac{1}{q} = \frac{1-\theta}{6} + \frac{\theta}{2}\,. \tag{4.18}$$

This leads to

$$\|y(t)\|^{\frac{2}{1-\theta}}_{L^q(\Omega)} \le C\|y(t)\|^2_{L^6(\Omega)}\,\|y(t)\|^{\frac{2\theta}{1-\theta}}_{L^2(\Omega)}$$

so that

$$\|y\|_{L^{\frac{2}{1-\theta}}(0,T;L^q(\Omega))} \le C\|y\|^{\theta}_{L^\infty(0,T;L^2(\Omega))}\,\|y\|^{1-\theta}_{L^2(0,T;L^6(\Omega))}\,.$$

Thus, the embedding

$$L^2(0,T;H^1_0(\Omega)) \cap H^1(0,T;H^{-1}(\Omega)) \subset L^{\frac{2}{1-\theta}}(0,T;L^q(\Omega)) \tag{4.19}$$

is continuous for all $\theta \in [0,1]$ with q determined by (4.18). By choosing $\theta = 4/7$ in (4.19), we see that the embedding (4.17) is continuous.

Next, we show the embedding (4.16) is compact for all $\alpha_1, \alpha_2 \in [1,\overline{\alpha})$. Let $\alpha_1, \alpha_2 \in [1,\overline{\alpha})$ be given. For each $y \in L^2(0,T;H^1_0(\Omega)) \cap H^1(0,T;H^{-1}(\Omega))$ the interpolation of $L^{2\overline{\alpha}}(0,T;L^{\frac{6\alpha_2}{5}}(\Omega))$ and $L^2(0,T;L^{\frac{6\alpha_2}{5}}(\Omega))$ yields

$$\begin{aligned}&\left(\int_0^T \|y(t)\|^{2\alpha_1}_{L^{\frac{6\alpha_2}{5}}(\Omega)}\,dt\right)^{\frac{1}{2\alpha_1}}\\ &\quad\le C\left(\int_0^T \|y(t)\|^{2\overline{\alpha}}_{L^{\frac{6\alpha_2}{5}}(\Omega)}\,dt\right)^{\frac{1-\theta_1}{2\overline{\alpha}}}\left(\int_0^T \|y(t)\|^2_{L^{\frac{6\alpha_2}{5}}(\Omega)}\,dt\right)^{\frac{\theta_1}{2}},\end{aligned} \tag{4.20}$$

where θ_1 satisfies

$$\frac{1}{2\alpha_1} = \frac{1-\theta_1}{2\overline{\alpha}} + \frac{\theta_1}{2}\,.$$

The interpolation of $L^{\frac{6\overline{\alpha}}{5}}(\Omega)$ and $L^2(\Omega)$ and Holder's inequality imply

$$\begin{aligned}\int_0^T \|y(t)\|^2_{L^{\frac{6\alpha_2}{5}}(\Omega)}\,dt &\le C\int_0^T \|y(t)\|^{2(1-\theta_2)}_{L^{\frac{6\overline{\alpha}}{5}}(\Omega)}\,\|y(t)\|^{2\theta_2}_{L^2(\Omega)}\,dt\\ &\le C\left(\int_0^T \|y(t)\|^2_{L^{\frac{6\overline{\alpha}}{5}}(\Omega)}\,dt\right)^{1-\theta_2}\left(\int_0^T \|y(t)\|^2_{L^2(\Omega)}\,dt\right)^{\theta_2},\end{aligned} \tag{4.21}$$

where θ_2 satisfies

$$\frac{5}{6\alpha_2} = \frac{5(1-\theta_2)}{6\overline{\alpha}} + \frac{\theta_2}{2}.$$

Substituting (4.21) into (4.20), we obtain

$$\begin{aligned}&\|y\|_{L^{2\alpha_1}(0,T;L^{\frac{6\alpha_2}{5}}(\Omega))}\\ &\le C\left|\int_0^T \|y(t)\|^{2\overline{\alpha}}_{L^{\frac{6\alpha_2}{5}}(\Omega)}\,dt\right|^{\frac{1-\theta_1}{2\overline{\alpha}}}\left|\int_0^T \|y(t)\|^2_{L^{\frac{6\overline{\alpha}}{5}}(\Omega)}\,dt\right|^{\frac{\theta_1(1-\theta_2)}{2}}\left|\int_0^T \|y(t)\|^2_{L^2(\Omega)}\,dt\right|^{\frac{\theta_1\theta_2}{2}}\\ &= C\|y\|^{1-\theta_1}_{L^{2\overline{\alpha}}(0,T;L^{\frac{6\alpha_2}{5}}(\Omega))}\|y\|^{\theta_1(1-\theta_2)}_{L^2(0,T;L^{\frac{6\overline{\alpha}}{5}}(\Omega))}\|y\|^{\theta_1\theta_2}_{L^2(0,T;L^2(\Omega))}\,.\end{aligned} \tag{4.22}$$

Let $\{y_n\}$ be a weakly convergent sequence in $L^2(0,T;H_0^1(\Omega)) \cap H^1(0,T;H^{-1}(\Omega))$. Then $\{y_n\}$ is bounded in $L^{2\overline{\alpha}}(0,T;L^{\frac{6\alpha_2}{5}}(\Omega))$ and in $L^2(0,T;L^{\frac{6\overline{\alpha}}{5}}(\Omega))$ (because of the continuous imbedding (4.17)), and $\{y_n\}$ converges strongly in $L^2(0,T;L^2(\Omega))$ (see Lemma 3.1, part (ii)). Thus, (4.22) implies that $\{y_n\}$ converges strongly in $L^{2\alpha_1}(0,T;L^{\frac{6\alpha_2}{5}}(\Omega))$. ∎

Based on the recast problems in section 4.2, we now verify all assumptions of Theorem 4.1 and derive the following error estimates for the semidiscrete solution u^h of the semilinear problem.

THEOREM 4.3. *Let $u \in X$ be a regular solution of (4.10)–(4.12). Assume that $\mathbf{b} \in L^\infty(0,T;\mathbf{L}^\gamma(\Omega))$ for some $\gamma > d$ ($d = 2$ or 3 being the space dimension), $\phi \in C^2(\mathbb{R};\mathbb{R})$,*

$$|\phi'(s)| \le C|s|^{\alpha-1} \quad \text{and} \quad |\phi''(s)| \le C|s|^{\alpha-2} \qquad \forall\, s \in \mathbb{R} \tag{4.23}$$

for an $\alpha \in [2, 7/3)$ when $d = 3$ or for an $\alpha \in [2,\infty)$ when $d = 2$. Then there exists a sufficiently small $h_0 > 0$ such that for all $h \in (0, h_0)$, (4.13)–(4.15) has a unique regular solution $u^h \in H^1(0,T;V^h)$ satisfying

$$\begin{aligned}\|u(t) - u^h(t)\|^2 + \|u - u^h\|^2_{L^2(0,T;H^1(\Omega))} + \|\partial_t u - \partial_t u^h\|^2_{L^2(0,T;H^{-1}(\Omega))} \\ \to 0 \quad \text{as } h \to 0\ \forall\, t \in [0,T]\,.\end{aligned} \tag{4.24}$$

If, in addition, $u \in L^2(0,T;H^{m+1}(\Omega)) \cap H^1(0,T;H^{m-1}(\Omega))$ for some $m \in [0,k]$, then

$$\begin{aligned}&\|u(t) - u^h(t)\|^2 + \|u - u^h\|^2_{L^2(0,T;H^1(\Omega))} + \|\partial_t u - \partial_t u^h\|^2_{L^2(0,T;H^{-1}(\Omega))} \\ &\quad \le Ch^{2m}\Big(\|u\|^2_{L^2([0,T;H^{m+1}(\Omega))} + \|\partial_t u\|^2_{L^2([0,T;H^{m-1}(\Omega))}\Big) \qquad \forall\, t \in [0,T]\,.\end{aligned} \tag{4.25}$$

Proof. We will treat the three-dimensional case only; the two-dimensional case can be handled similarly and more easily.

Let $\mathcal{X}$ and $\mathcal{Y}$ be the spaces defined in section 4.2 and let $\mathcal{T}$, $\mathcal{T}^h$, and $\mathcal{G}$ be the operators defined in section 4.2. Since $\alpha < 7/3 = \overline{\alpha}$, $\gamma > 3$, $\beta_\epsilon \equiv (6-\epsilon)/(5-\epsilon) \to 6/5$ as $\epsilon \to 0$, and $(12-2\epsilon)/(4-\epsilon) \to 3$ as $\epsilon \to 0$, we may fix a sufficiently small $\epsilon > 0$ such that $\beta_\epsilon \alpha < 6\overline{\alpha}/5$ and $(12-2\epsilon)/(4-\epsilon) < \gamma$. For this fixed ϵ, we set $\epsilon_1 = \epsilon/(12-2\epsilon)$ and $\mathcal{Z} = L^2(0,T;H^{-1+\epsilon_1}(\Omega)) \times H_0^{\epsilon_1}(\Omega)$. Note that ϵ_1 is so chosen to guarantee the continuous embedding $H^{1-\epsilon_1}(\Omega) \subset L^{6-\epsilon}(\Omega)$.

Theorems 3.2 and 3.3 imply that

$$\|(\mathcal{T} - \mathcal{T}^h)(\widetilde{f}, \widetilde{u}_0)\|_{\mathcal{X}} \to 0 \quad \text{as } h \to 0$$

for all $(\widetilde{f}, \widetilde{u}_0) \in \mathcal{Y}$.

For any $(\widetilde{f}, \widetilde{u}_0) \in \mathcal{Z} = L^2(0,T;H^{-1+\epsilon_1}(\Omega)) \times H_0^{\epsilon_1}(\Omega)$, a regularity theorem (see [21, p. 360, Theorem 5]) for the solution of the heat equation and interpolation theorems imply that $\widetilde{u} = T(\widetilde{f}, \widetilde{u}_0) \in L^2(0,T,H^{1+\epsilon_1}(\Omega)) \cap H^1(0,T;H^{-1+\epsilon_1}(\Omega))$ and

$$\|\widetilde{u}\|_{L^2(0,T,H^{1+\epsilon_1}(\Omega))} + \|\partial_t \widetilde{u}\|_{L^2(0,T,H^{-1+\epsilon_1}(\Omega))} \le C\Big(\|\widetilde{f}\|_{L^2(0,T,H^{-1+\epsilon_1}(\Omega))} + \|\widetilde{u}_0\|_{H^{\epsilon_1}(\Omega)}\Big)\,.$$

Thus, Theorems 3.2 and 3.3 with $m = \epsilon_1$ give

$$\begin{aligned}\|(\mathcal{T} - \mathcal{T}^h)(\widetilde{f}, \widetilde{u}_0)\|_{\mathcal{X}} &= \|\widetilde{u} - \widetilde{u}^h\|_{\mathcal{X}} \\ &\le Ch^{\epsilon_1}\Big(\|\widetilde{u}\|_{L^2(0,T,H^{1+\epsilon_1}(\Omega))} + \|\partial_t \widetilde{u}\|_{L^2(0,T,H^{-1+\epsilon_1}(\Omega))}\Big) \\ &\le Ch^{\epsilon_1}\Big(\|\widetilde{f}\|_{L^2(0,T,H^{-1+\epsilon_1}(\Omega))} + \|\widetilde{u}_0\|_{H^{\epsilon_1}(\Omega)}\Big) = Ch^{\epsilon_1}\|(\widetilde{f}, \widetilde{u}_0)\|_{\mathcal{Z}}\end{aligned}$$

so that by taking the supremum over $(\widetilde{f},\widetilde{u}_0)\in\mathcal{Z}$, we obtain

$$\|\mathcal{T}-\mathcal{T}^h\|_{\mathcal{L}(\mathcal{Z},\mathcal{X})}\le Ch^{\epsilon_1}\to 0\quad\text{as } h\to 0\,.$$

Next we verify (4.5). Let $v,w\in\mathcal{X}$ be given. A simple calculation reveals

$$[D\mathcal{G}(v)]w=(\mathbf{b}\cdot\nabla w+\phi'(v)w,0).$$

We recall the generalized Holder's inequality

$$\Big|\int_E f_1\,f_2\,f_3\,dE\Big|\le\|f_1\|_{L^{r_1}(E)}\,\|f_2\|_{L^{r_2}(E)}\,\|f_3\|_{L^{r_3}(E)}\,, \tag{4.26}$$

where E is a measurable set of any dimension and $(1/r_1)+(1/r_2)+(1/r_3)=1$. Using (4.26) with $r_1=\alpha\beta_\epsilon/(\alpha-1)$, $r_2=\alpha\beta_\epsilon$, and $r_3=6-\epsilon$, where $\beta_\epsilon=(6-\epsilon)/(5-\epsilon)$ (recall that ϵ was chosen such that $\beta_\epsilon\alpha<\overline{\alpha}$), we obtain

$$\begin{aligned}&\int_0^T\int_\Omega|v|^{\alpha-1}|w|\,|y|\,d\mathbf{x}\,dt\\&\le\int_0^T\|v(t)\|^{\alpha-1}_{L^{\alpha\beta_\epsilon}(\Omega)}\,\|w(t)\|_{L^{\alpha\beta_\epsilon}(\Omega)}\,\|y(t)\|_{L^{6-\epsilon}(\Omega)}\,dt\;\forall\,y\in L^2(0,T;H^{1-\epsilon_1}(\Omega))\,.\end{aligned}\tag{4.27}$$

Applying to (4.27) the inequality (4.26) with $r_1=2\alpha/(\alpha-1)$, $r_2=2\alpha$, and $r_3=2$ we have

$$\begin{aligned}&\int_0^T\int_\Omega|v|^{\alpha-1}|w|\,|y|\,d\mathbf{x}\,dt\\&\quad\le C\|v\|^{\alpha-1}_{L^{2\alpha}(0,T;L^{\alpha\beta_\epsilon}(\Omega))}\,\|w\|_{L^{2\alpha}(0,T;L^{\alpha\beta_\epsilon}(\Omega))}\,\|y\|_{L^2(0,T;L^{6-\epsilon}(\Omega))}\\&\quad\le C\|v\|^{\alpha-1}_{L^{2\alpha}(0,T;L^{\alpha\beta_\epsilon}(\Omega))}\,\|w\|_{L^{2\alpha}(0,T;L^{\alpha\beta_\epsilon}(\Omega))}\,\|y\|_{L^2(0,T;H^{1-\epsilon_1}(\Omega))}\end{aligned}$$

for every $y\in L^2(0,T;H^{1-\epsilon_1}(\Omega))$. Taking the supremum in the last estimate over all $y\in L^2(0,T;H^{1-\epsilon_1}(\Omega))$ we see that

$$\big\||v|^{\alpha-1}w\big\|_{L^2(0,T;H^{-1+\epsilon_1}(\Omega))}\le C\|v\|^{\alpha-1}_{L^{2\alpha}(0,T;L^{\alpha\beta_\epsilon}(\Omega))}\,\|w\|_{L^{2\alpha}(0,T;L^{\alpha\beta_\epsilon}(\Omega))}.\tag{4.28}$$

We can also estimate the term $\mathbf{b}\cdot\nabla w$ as follows:

$$\begin{aligned}&\int_0^T\int_\Omega|\mathbf{b}||\nabla w|\,|y|\,d\mathbf{x}\,dt\\&\quad\le\int_0^T\|\mathbf{b}\|_{\mathbf{L}^{(12-2\epsilon)/(4-\epsilon)}(\Omega)}\,\|\nabla w(t)\|_{L^2(\Omega)}\,\|y(t)\|_{L^{6-\epsilon}(\Omega)}\,dt\\&\quad\le\|\mathbf{b}\|_{L^\infty(0,T;\mathbf{L}^\gamma(\Omega))}\|w\|_{L^2(0,T;H^1(\Omega))}\|y\|_{L^2(0,T;H^{1-\epsilon_1}(\Omega))}\quad\forall\,y\in L^2(0,T;H^{1-\epsilon_1}(\Omega))\end{aligned}$$

so that

$$\big\|\mathbf{b}\cdot\nabla w\big\|_{L^2(0,T;H^{-1+\epsilon_1}(\Omega))}\le C\|\mathbf{b}\|_{L^\infty(0,T;\mathbf{L}^\gamma(\Omega))}\|w\|_{L^2(0,T;H^1(\Omega))}.\tag{4.29}$$

Thus, (4.28), Lemma 4.2, and (4.29) imply that $D\mathcal{G}(v)\in\mathcal{L}(\mathcal{X},\mathcal{Z})$ for every $v\in\mathcal{X}$.

Similarly, we may use the growth condition for ϕ'' to prove that $D^2\mathcal{G}$ is locally bounded.

Hence all the assumptions in Theorem 4.1 are verified, and we conclude from that theorem that

$$\|u - u^h\|_{\mathcal{X}} \leq \|(\mathcal{T} - \mathcal{T}^h)\mathcal{G}(u)\|_{\mathcal{X}} \to 0 \quad \text{as } h \to 0,$$

and if, in addition, $u \in L^2(0,T;H^{m+1}(\Omega)) \cap H^1(0,T;H^{m-1}(\Omega))$,

$$\|u - u^h\|_{\mathcal{X}} \leq Ch^m \Big(\|u\|_{L^2(0,T;H^{m+1}(\Omega))} + \|\partial_t u\|_{L^2(0,T;H^{m-1}(\Omega))} \Big).$$

Thus, the desired estimates (4.24) and (4.25) follow from the definition of $\|\cdot\|_{\mathcal{X}}$, Lemma 3.1, and the last two relations. ∎

Remark. The proof of Theorem 4.3 used a regularity theorem of [21, p. 360] which was proved with the help of an elliptic regularity theorem. Thus, the convexity assumption on the domain Ω played a role here. Also, since we need only the regularity $L^2(0,T;H^{1+\epsilon_1}(\Omega)) \cap H^1(0,T;H^{-1+\epsilon_1}(\Omega))$ for solutions of the linear equation, we expect that the convexity assumption on Ω can be weakened. ∎

Remark. If $\alpha \in [1,2)$, then we have to use a modified version of Theorem 4.1, namely to replace the assumptions $\mathcal{G} \in C^2$ and $D^2\mathcal{G}$ being locally bounded by the assumptions $\mathcal{G} \in C^1$ and $D\mathcal{G}$ being uniformly continuous. This modified version of Theorem 4.1 can be easily proved upon a routine examination of the proof of [23, p. 307, Theorem 3.3]. Also, (4.23) should be replaced by $\phi'(s) = O(|s|^{\alpha-1})$ and ϕ' is uniformly continuous. For example, for $\phi(s) = s^{3/2}$ we have that $\phi'(s) = (3/2)\sqrt{s}$. The function $\sqrt{s}$ is obviously uniformly continuous away from 0. But on any neighborhood of $s = 0$, $\sqrt{s}$ is also uniformly continuous so that ϕ' is uniformly continuous on its entire domain. ∎

Acknowledgment. The authors thank Oleg Emanouilov for suggesting the ideas for the proof of Lemma 4.2.

THE DISCRETE FIRST-ORDER SYSTEM LEAST SQUARES: THE SECOND-ORDER ELLIPTIC BOUNDARY VALUE PROBLEM*

ZHIQIANG CAI† AND BYEONG CHUN SHIN‡

Abstract. In [Z. Cai, T. Manteuffel, and S. F. McCormick, *SIAM J. Numer. Anal.*, 34 (1997), pp. 425–454], an L^2-norm version of first-order system least squares (FOSLS) was developed for scalar second-order elliptic partial differential equations. A limitation of this approach is the requirement of sufficient smoothness of the original problem, which is used for the equivalence of spaces between $(H^1)^d$ and $H(\text{div}\,) \cap H(\text{curl})$-type, where $d = 2$ or 3 is the dimension. By directly approximating $H(\text{div}\,) \cap H(\text{curl})$-type space based on the Helmholtz decomposition, this paper develops a discrete FOSLS approach in two dimensions. Under general assumptions, we establish error estimates in the L^2 and H^1 norms for the vector and scalar variables, respectively. Such error estimates are optimal with respect to the required regularity of the solution. A preconditioner for the algebraic system arising from this approach is also considered.

1. Introduction.

Recently, there has been substantial interest in the use of least-squares principles for numerical approximations of elliptic partial differential equations and systems (see the recent review article [1] and references therein). In [5], Cai, Manteuffel, and McCormick developed an L^2-norm version of first-order system least squares (FOSLS) for scalar second-order elliptic partial differential equations in $d = 2$ or 3 dimensions. It was shown that the homogeneous FOSLS functional is equivalent to a $\mathcal{V} \times H^1(\Omega)$ norm with $\mathcal{V} = H(\text{div}\,;\Omega) \cap H(\text{curl}\,A;\Omega)$ under general assumptions, where A is the diffusion coefficient and Ω is the domain of the underlying problem. Moreover, such a norm was shown to be in fact an $H^1(\Omega)^{d+1}$ norm under the assumption that the original problem is H^2-regular. This product H^1 equivalence means that the minimization process amounts to solving a loosely coupled system of Poisson-like scalar equations. This in turn implies that standard finite element discretization and standard multigrid solution methods admit optimal H^1-like performance.

The limitation of this L^2-norm FOSLS is the requirement of sufficient smoothness of the underlying problem. Such smoothness guarantees the equivalence of norms between $\mathcal{V}$ and $H^1(\Omega)^d$ so that it can be approximated by standard continuous finite element space as in [5]. In general, when the domain Ω is not smooth or not convex or the coefficient A is not continuous, these two spaces are not equivalent. In fact, $\mathcal{V}$ is equal to $H^1(\Omega)^d$ plus a finite-dimensional space which consists of singular functions associated with corners of the boundary and interfaces. Therefore, standard continuous finite element spaces are not good approximations to $\mathcal{V}$ in general. In this paper,

we will construct an appropriate approximation space for $\mathcal{V}$ based on the Helmholtz decomposition. Since our approximation space is discontinuous and is not contained in $\mathcal{V}$, we then modify the FOSLS functional to accommodate such discontinuity and nonconformity of finite element spaces. An alternative for overcoming such a limitation is the inverse-norm version of FOSLS (see [2]), but at the expense of rather awkward norm evaluation requirements.

The paper is organized as follows. The second-order elliptic boundary value problem and the L^2-norm version of the FOSLS approach are introduced in section 2, along with some notations. The discrete FOSLS approach is developed in section 3, and its error estimate is established in section 4. In section 5, we discuss preconditioners for the resulting system of linear equations.

2. First-order system least squares (FOSLS). Let Ω be a bounded, open, and simply connected domain in $\Re^2$ with Lipschitz boundary $\partial\Omega$. We consider the following scalar second-order elliptic boundary value problem:

$$\left\{\begin{array}{rcll} -\nabla\cdot(A\nabla p)+\mathbf{b}\cdot\nabla p+cp &=& f & \text{in } \Omega,\\ p &=& 0 & \text{on } \Gamma_D,\\ \mathbf{n}\cdot(A\nabla p) &=& 0 & \text{on } \Gamma_N, \end{array}\right. \tag{2.1}$$

where the symbols $\nabla\cdot$ and ∇ stand for the divergence and gradient operators, respectively; A is a 2×2 symmetric matrix of functions in $L^\infty(\Omega)$; $\mathbf{b}$ and c are the respective vector and scalar of functions in $L^\infty(\Omega)$; $f\in L^2(\Omega)$ is a given scalar function; $\partial\Omega=\Gamma_D\cup\Gamma_N$ is the partition of the boundary of Ω; and $\mathbf{n}$ is the outward unit vector normal to the boundary. For simplicity, assume that both Γ_D and Γ_N are nonempty, with the obvious generalization to quotient spaces when one of them is empty in the subsequent sections. We assume that A is uniformly symmetric positive definite and scaled appropriately; that is, there exist positive constants

$$0<\lambda\le 1\le\Lambda$$

such that

$$\lambda\boldsymbol{\xi}^T\boldsymbol{\xi}\le\boldsymbol{\xi}^T A\boldsymbol{\xi}\le\Lambda\boldsymbol{\xi}^T\boldsymbol{\xi} \tag{2.2}$$

for all $\boldsymbol{\xi}\in\Re^2$ and almost all $x\in\bar{\Omega}$.

We use standard notation and definitions for the Sobolev spaces $H^s(\Omega)^2$, associated inner products $(\cdot,\cdot)_s$, and respective norms $\|\cdot\|_s$, $s\ge 0$. (We suppress the designation Ω on the inner products and norms because dependence on region is clear by context.) $H^0(\Omega)^2$ coincides with $L^2(\Omega)^2$, in which case the norm and inner product will be denoted by $\|\cdot\|$ and $(\cdot,\cdot)$, respectively. Define subspaces of $H^1(\Omega)$:

$$H^1_D(\Omega)=\{q\in H^1(\Omega):\ q=0 \text{ on } \Gamma_D\} \text{ and } H^1_N(\Omega)=\{q\in H^1(\Omega):\ q=0 \text{ on } \Gamma_N\}.$$

Let $H_D^{-1}(\Omega)$ denote the dual of $H^1_D(\Omega)$ with the norm defined by

$$\|\phi\|_{H_D^{-1}(\Omega)}=\sup_{0\ne\psi\in H^1_D(\Omega)}\frac{(\phi,\,\psi)}{\|\psi\|_1}.$$

Denote the curl operator in $\Re^2$ by

$$\nabla\times=(-\partial_2,\,\partial_1)$$

and its formal adjoint by

$$\nabla^{\perp} = \begin{pmatrix} \partial_2 \\ -\partial_1 \end{pmatrix}.$$

Let

$$H(\operatorname{div} A^{\frac{1}{2}};\Omega) = \{\mathbf{v} \in L^2(\Omega)^2 : \nabla \cdot (A^{\frac{1}{2}}\mathbf{v}) \in L^2(\Omega)\}$$

and

$$H(\operatorname{curl} A^{-\frac{1}{2}};\Omega) = \{\mathbf{v} \in L^2(\Omega)^2 : \nabla\times(A^{-\frac{1}{2}}\mathbf{v}) \in L^2(\Omega)\},$$

which are Hilbert spaces under norms

$$\|\mathbf{v}\|_{H(\operatorname{div} A^{\frac{1}{2}};\Omega)} = \left(\|\mathbf{v}\|^2 + \left\|\nabla \cdot \left(A^{\frac{1}{2}}\mathbf{v}\right)\right\|^2\right)^{\frac{1}{2}}$$

and

$$\|\mathbf{v}\|_{H(\operatorname{curl} A^{-\frac{1}{2}};\Omega)} = \left(\|\mathbf{v}\|^2 + \left\|\nabla\times \left(A^{-\frac{1}{2}}\mathbf{v}\right)\right\|^2\right)^{\frac{1}{2}},$$

respectively. When A is the identity matrix, we use the simpler notations $H(\operatorname{div};\Omega)$ and $H(\operatorname{curl};\Omega)$. Define the subspaces

$$H_0(\operatorname{div} A^{\frac{1}{2}};\Omega) = \{\mathbf{v} \in H(\operatorname{div} A^{\frac{1}{2}};\Omega) : \mathbf{n} \cdot (A^{\frac{1}{2}}\mathbf{v}) = 0 \text{ on } \Gamma_N\},$$

$$H_0(\operatorname{curl} A^{-\frac{1}{2}};\Omega) = \{\mathbf{v} \in H(\operatorname{curl} A^{-\frac{1}{2}};\Omega) : \boldsymbol{\tau} \cdot (A^{-\frac{1}{2}}\mathbf{v}) = 0 \text{ on } \Gamma_D\},$$

and denote

$$\mathcal{U} = H_0(\operatorname{div} A^{\frac{1}{2}};\Omega) \cap H_0(\operatorname{curl} A^{-\frac{1}{2}};\Omega),$$

where $\boldsymbol{\tau}$ represents the unit vector tangent to the boundary oriented counterclockwise.

Introducing an independent vector variable

$$\mathbf{u} = A^{\frac{1}{2}}\,\nabla p,$$

by using the homogeneous Dirichlet boundary condition on Γ_D we have that

$$\nabla\times(A^{-\frac{1}{2}}\mathbf{u}) = 0 \quad \text{in } \Omega \quad \text{and} \quad \boldsymbol{\tau} \cdot (A^{-\frac{1}{2}}\mathbf{u}) = 0 \quad \text{on } \Gamma_D.$$

Then an equivalent extended system for problem (2.1) is

$$\left\{\begin{array}{rcll} \mathbf{u} - A^{\frac{1}{2}}\nabla p &=& \mathbf{0} & \text{in } \Omega, \\ -\nabla \cdot (A^{\frac{1}{2}}\mathbf{u}) + \mathbf{b} \cdot (A^{-\frac{1}{2}}\mathbf{u}) + cp &=& f & \text{in } \Omega, \\ \nabla \times (A^{-\frac{1}{2}}\mathbf{u}) &=& 0 & \text{in } \Omega, \\ p &=& 0 & \text{on } \Gamma_D, \\ \mathbf{n} \cdot (A^{\frac{1}{2}}\mathbf{u}) &=& 0 & \text{on } \Gamma_N, \\ \boldsymbol{\tau} \cdot (A^{-\frac{1}{2}}\mathbf{u}) &=& 0 & \text{on } \Gamma_D. \end{array}\right. \tag{2.3}$$

Define the FOSLS functional as follows (see [5] or [6] for Poisson's equations):

$$G(\mathbf{v},q;f) = \|\mathbf{v} - A^{\frac{1}{2}}\nabla q\|^2 + \|f + \nabla \cdot (A^{\frac{1}{2}}\mathbf{v}) - \mathbf{b} \cdot (A^{-\frac{1}{2}}\mathbf{v}) - cq\|^2 + \|\nabla \times (A^{-\frac{1}{2}}\mathbf{v})\|^2$$

for $(\mathbf{v},q) \in \mathcal{U} \times H^1_D(\Omega)$. Then the FOSLS variational problem for (2.1) is to minimize the quadratic functional $G(\mathbf{v},q;f)$ over $\mathcal{U} \times H^1_D(\Omega)$: find $(\mathbf{u},q) \in \mathcal{U} \times H^1_D(\Omega)$ such that

$$G(\mathbf{u},p;f) = \inf_{(\mathbf{v},q)\in\mathcal{U}\times H^1_D(\Omega)} G(\mathbf{v},q;f). \tag{2.4}$$

3. Discrete FOSLS. The least-squares approach defined in the previous section was proposed and analyzed in [5]. In particular, it was shown in [5] that the homogeneous functional is elliptic in the $H^1(\Omega)^3$ norm under certain H^2 regularity assumptions. This implies optimal H^1-like performance for standard finite element discretization and standard multigrid solution methods. An unfortunate limitation of this FOSLS approach is that this product H^1 equivalence generally requires sufficient smoothness of the original problem. Such a requirement is needed for the equivalence between the spaces $H^1(\Omega)^2$ and $\mathcal{U} = H_0(\operatorname{div} A^{\frac{1}{2}};\Omega) \cap H_0(\operatorname{curl} A^{-\frac{1}{2}};\Omega)$ and the quasi-optimality of finite element approximations in the H^1 norm for each variable. To overcome such a difficulty, we use discontinuous approximation spaces for the vector variable and modify this FOSLS functional to accommodate such a discontinuity of finite element spaces. Extension of the approach proposed in this section to the least-squares functional studied in [4, 8] is straightforward.

Discontinuous approximation spaces that we will employ are motivated by the following Helmholtz decomposition, for any $\mathbf{u} \in \mathcal{U}$:

$$\mathbf{u} = A^{\frac{1}{2}}\nabla s + A^{-\frac{1}{2}}\nabla^{\perp} t, \tag{3.1}$$

where $s \in H^1_D(\Omega)$ is the unique solution of

$$\left\{\begin{array}{rcccl} \nabla\cdot(A\nabla s) & = & \nabla\cdot(A^{\frac{1}{2}}\mathbf{u}) & \text{in} & \Omega, \\ s & = & 0 & \text{on} & \Gamma_D, \\ \mathbf{n}\cdot(A\nabla s) & = & 0 & \text{on} & \Gamma_N \end{array}\right.$$

and $t \in H^1_N(\Omega)$ is the unique solution of

$$\left\{\begin{array}{rcccl} \nabla\times(A^{-1}\nabla^{\perp} t) & = & \nabla\times(A^{-\frac{1}{2}}\mathbf{u}) & \text{in} & \Omega, \\ \boldsymbol{\tau}\cdot(A^{-1}\nabla^{\perp} t) & = & 0 & \text{on} & \Gamma_D, \\ t & = & 0 & \text{on} & \Gamma_N. \end{array}\right.$$

It is then natural to approximate the scalar functions $s \in H^1_D(\Omega)$ and $t \in H^1_N(\Omega)$ by standard continuous piecewise polynomials.

Let $\mathcal{T}_h$ be a partition of the domain Ω into finite elements; i.e., $\Omega = \cup_{K\in\mathcal{T}_h} K$ with $h = \max\{h_K = \operatorname{diam}(K) : K \in \mathcal{T}_h\}$. Assume that the triangulation $\mathcal{T}_h$ is regular (see [7]). Let $\mathcal{P}^h_{m-1}$ be a finite-dimensional space consisting of continuous piecewise polynomials of degree at most $m-1$ with respect to the triangulation $\mathcal{T}_h$. Denote standard finite element spaces by

$$\mathcal{S}^h_D = H^1_D(\Omega) \cap \mathcal{P}^h_{m-1} \quad \text{and} \quad \mathcal{S}^h_N = H^1_N(\Omega) \cap \mathcal{P}^h_{m-1}$$

and define the approximation space for the vector variable by

$$\mathcal{U}^h = \big(A^{\frac{1}{2}}\nabla\mathcal{S}^h_D\big) \oplus \big(A^{-\frac{1}{2}}\nabla^{\perp}\mathcal{S}^h_N\big).$$

It is an immediate consequence of the integration by parts and homogeneous boundary conditions that two subspaces $A^{\frac{1}{2}}\nabla\mathcal{S}^h_D$ and $A^{-\frac{1}{2}}\nabla^{\perp}\mathcal{S}^h_N$ are orthogonal with respect to the L^2 inner product. That is,

$$(A^{\frac{1}{2}}\nabla s,\, A^{-\frac{1}{2}}\nabla^{\perp} t) = 0 \tag{3.2}$$

for any $s \in \mathcal{S}^h_D$ and any $t \in \mathcal{S}^h_N$.

Note that $\mathcal{U}^h$ is not contained in $\mathcal{U}$ and, hence, the FOSLS functional $G(\cdot\,;\cdot)$ defined in the previous section is not well defined on $\mathcal{U}^h \times \mathcal{S}_D^h$. Therefore, we need to replace the divergence and curl operators in the $G(\cdot\,;\cdot)$ by the corresponding discrete operators. To this end, define the discrete divergence operator, $\nabla_h \cdot : L^2(\Omega)^2 \longrightarrow \mathcal{S}_D^h$, for given $\mathbf{v} \in L^2(\Omega)^2$ by $\phi = \nabla_h \cdot \mathbf{v} \in \mathcal{S}_D^h$ satisfying

$$(\phi,\, q) = -(\mathbf{v},\, \nabla q) \quad \forall\, q \in \mathcal{S}_D^h$$

and the discrete curl operator, $\nabla_h \times : L^2(\Omega)^2 \longrightarrow \mathcal{S}_N^h$, for given $\mathbf{v} \in L^2(\Omega)^2$ by $\psi = \nabla_h \times \mathbf{v} \in \mathcal{S}_N^h$ satisfying

$$(\psi,\, q) = (\mathbf{v}, \nabla^{\perp} q) \quad \forall\, q \in \mathcal{S}_N^h.$$

Finally, we denote Q_h the L^2-projection operator onto $\mathcal{S}_D^h$.

Now, we are ready to define the discrete FOSLS functional:

$$\begin{aligned} G_h(\mathbf{v}, q; f) = {} & \|\mathbf{v} - A^{\frac{1}{2}} \nabla q\|^2 + \|f + \nabla_h \cdot (A^{\frac{1}{2}} \mathbf{v}) - Q_h\big(\mathbf{b} \cdot (A^{-\frac{1}{2}} \mathbf{v})\big) - cq\|^2 \\ & + \|\nabla_h \times (A^{-\frac{1}{2}} \mathbf{v})\|^2 \end{aligned}$$

for $(\mathbf{v}, q) \in \mathcal{U}^h \times \mathcal{S}_D^h$. Our discrete FOSLS finite element approximation for (2.1) is then to minimize the quadratic functional $G_h(\mathbf{v}, q; f)$ over $\mathcal{U}^h \times \mathcal{S}_D^h$: find $(\mathbf{u}_h,\, p_h) \in \mathcal{U}^h \times \mathcal{S}_D^h$ such that

$$G_h(\mathbf{u}_h,\, p_h; f) = \inf_{(\mathbf{v},q) \in \mathcal{U}^h \times \mathcal{S}_D^h} G_h(\mathbf{v},\, q; f). \tag{3.3}$$

Denote the norm over $\mathcal{U}^h \times \mathcal{S}_D^h$ by

$$|||(\mathbf{v}, q)||| = \Big(\|q\|_1^2 + \|\mathbf{v}\|^2 + \|\nabla_h \cdot (A^{\frac{1}{2}} \mathbf{v})\|^2 + \|\nabla_h \times (A^{-\frac{1}{2}} \mathbf{v})\|^2 \Big)^{\frac{1}{2}}.$$

THEOREM 3.1. *The homogeneous functional $G_h(\cdot\,; 0)$ is uniformly elliptic and continuous in $\mathcal{U}^h \times \mathcal{S}_D^h$; i.e., for any $(\mathbf{v}, q) \in \mathcal{U}^h \times \mathcal{S}_D^h$, there exists a positive constant C such that*

$$\frac{1}{C} |||(\mathbf{v}, q)|||^2 \le G_h(\mathbf{v}, q; 0) \le C |||(\mathbf{v}, q)|||^2. \tag{3.4}$$

Proof. The upper bound in (3.4) is an immediate consequence of the triangle inequality and the boundedness of coefficients A, $\mathbf{b}$, c and the L^2-projection operator Q_h. To show the validity of the lower bound in (3.4), we first establish the following inequality: there exists a positive constant C such that

$$\frac{1}{C} |||(\mathbf{v}, q)|||^2 \le \tilde{G}(\mathbf{v}, q) \quad \forall\, (\mathbf{v}, q) \in \mathcal{U}^h \times \mathcal{S}_D^h, \tag{3.5}$$

where

$$\begin{aligned} \tilde{G}(\mathbf{v}, q) &= \|\mathbf{v} - A^{\frac{1}{2}} \nabla q\|^2 + \|\nabla_h \cdot (A^{\frac{1}{2}} \mathbf{v}) - Q_h(\mathbf{b} \cdot \nabla q) - cq\|^2 + \|\nabla_h \times (A^{-\frac{1}{2}} \mathbf{v})\|^2 \\ &= \left\| \begin{pmatrix} I & -A^{\frac{1}{2}} \nabla \\ \nabla_h \cdot A^{\frac{1}{2}} & -Q_h \mathbf{b} \cdot \nabla - cI \end{pmatrix} \begin{pmatrix} \mathbf{v} \\ q \end{pmatrix} \right\|^2 + \|\nabla_h \times (A^{-\frac{1}{2}} \mathbf{v})\|^2. \end{aligned}$$

Then the lower bound in (3.4) follows from the fact that

$$G_h(\mathbf{v},q;0) = \left\| \begin{pmatrix} I & 0 \\ -Q_h\mathbf{b}\cdot A^{-\frac{1}{2}} & I \end{pmatrix} \begin{pmatrix} I & -A^{\frac{1}{2}}\nabla \\ \nabla_h\cdot A^{\frac{1}{2}} & -Q_h\mathbf{b}\cdot\nabla - cI \end{pmatrix} \begin{pmatrix} \mathbf{v} \\ q \end{pmatrix} \right\|^2 + \|\nabla_h \times (A^{-\frac{1}{2}}\mathbf{v})\|^2$$

and that the largest and smallest singular values of the transformation matrix

$$\begin{pmatrix} I & 0 \\ -Q_h\mathbf{b}\cdot A^{-\frac{1}{2}} & I \end{pmatrix}$$

are bounded.

To prove the validity of (3.5), let $Xq = Q_h(\mathbf{b}\cdot\nabla q) + cq$ for convenience. Since $\|Q_h\| = 1$, (2.2) and the triangle and Poincaré–Friedrichs inequalities yield

$$\|Xq\| \le C\|A^{\frac{1}{2}}\nabla q\|.$$

It now follows from the definition of the discrete divergence operator and the Cauchy–Schwarz inequality that

$$\begin{aligned} \|A^{\frac{1}{2}}\nabla q\|^2 &= (A^{\frac{1}{2}}\nabla q - \mathbf{v}, A^{\frac{1}{2}}\nabla q) + (A^{\frac{1}{2}}\mathbf{v}, \nabla q) \\ &= (A^{\frac{1}{2}}\nabla q - \mathbf{v}, A^{\frac{1}{2}}\nabla q) - \big(\nabla_h\cdot(A^{\frac{1}{2}}\mathbf{v}), q\big) \\ &= (A^{\frac{1}{2}}\nabla q - \mathbf{v}, A^{\frac{1}{2}}\nabla q) - \big(\nabla_h\cdot(A^{\frac{1}{2}}\mathbf{v}) - Xq, q\big) - (Xq, q) \\ &\le \|A^{\frac{1}{2}}\nabla q - \mathbf{v}\|\,\|A^{\frac{1}{2}}\nabla q\| + \|\nabla_h\cdot(A^{\frac{1}{2}}\mathbf{v}) - Xq\|\,\|q\| + \|Xq\|\,\|q\|, \end{aligned}$$

which, together with the Poincaré–Friedrichs inequality, implies that

$$\|A^{\frac{1}{2}}\nabla q\| \le C\left(\|A^{\frac{1}{2}}\nabla q - \mathbf{v}\| + \|\nabla_h\cdot(A^{\frac{1}{2}}\mathbf{v}) - Q_h(\mathbf{b}\cdot\nabla q) - cq\| + \|q\|\right). \tag{3.6}$$

The triangle and Poincaré–Friedrichs inequalities and (3.6) give that

$$|||(\mathbf{v},q)|||^2 \le C\left(\tilde{G}(\mathbf{v},q) + \|q\|^2\right).$$

Now, (3.5) is a consequence of the standard compactness argument. This completes the proof of the theorem. ∎

4. Error estimates. This section establishes error estimates in the L^2 norm for the vector variable and the H^1 norm for the scalar variable (see Theorem 4.1). Such error estimates are optimal with respect to the required regularity of the solution.

Let $(\mathbf{u}_h, p_h) \in \mathcal{U}^h \times \mathcal{S}_D^h$ be the solution of the discrete problem in (3.3). The corresponding variational form of (3.3) is to find $(\mathbf{u}_h, p_h) \in \mathcal{U}^h \times \mathcal{S}_D^h$ such that

$$b_h(\mathbf{u}_h, p_h; \mathbf{v}, q) = \big(f, -\nabla_h\cdot(A^{\frac{1}{2}}\mathbf{v}) + Q_h(\mathbf{b}\cdot(A^{-\frac{1}{2}}\mathbf{v})) + cq\big) \quad \forall\,(\mathbf{v},q) \in \mathcal{U}^h \times \mathcal{S}_D^h, \tag{4.1}$$

where the bilinear form $b_h(\cdot,\cdot)$ is induced from the quadratic form $G_h(\cdot;0)$:

$$\begin{aligned} b_h(\mathbf{u}_h, p_h; \mathbf{v}, q) &= \big(\mathbf{u}_h - A^{\frac{1}{2}}\nabla p_h, \mathbf{v} - A^{\frac{1}{2}}\nabla q\big) + \big(\nabla_h\times(A^{-\frac{1}{2}}\mathbf{u}_h), \nabla_h\times(A^{-\frac{1}{2}}\mathbf{v})\big) \\ &+\big(\nabla_h\cdot(A^{\frac{1}{2}}\mathbf{u}_h) - Q_h(\mathbf{b}\cdot(A^{-\frac{1}{2}}\mathbf{u}_h)) - cp_h, \nabla_h\cdot(A^{\frac{1}{2}}\mathbf{v}) - Q_h(\mathbf{b}\cdot(A^{-\frac{1}{2}}\mathbf{v})) - cq\big). \end{aligned} \tag{4.2}$$

To deduce the error equation, we need the following lemma.

LEMMA 4.1. *Let $(\mathbf{u}, p) \in \mathcal{U} \times H_D^1(\Omega)$ be the solution of first-order system (2.3). Then it satisfies the following equations:*

$$\big(-\nabla_h \cdot (A^{\frac{1}{2}}\mathbf{u}) + Q_h(\mathbf{b} \cdot (A^{-\frac{1}{2}}\mathbf{u})) + cp, q \big) = (f, q) \quad \forall\, q \in \mathcal{S}_D^h \tag{4.3}$$

and

$$\big(\nabla_h \times (A^{-\frac{1}{2}}\mathbf{u}), r\big) = 0 \quad \forall\, r \in \mathcal{S}_N^h. \tag{4.4}$$

Proof. It follows from the definitions of the discrete divergence and curl operators and the L^2-projection and integration by parts that, for any $q \in \mathcal{S}_D^h$,

$$\big(\nabla_h \cdot (A^{\frac{1}{2}}\mathbf{u}), q\big) = \big(\nabla \cdot (A^{\frac{1}{2}}\mathbf{u}), q\big) \quad \text{and} \quad \big(Q_h(\mathbf{b} \cdot (A^{\frac{1}{2}}\mathbf{u})), q\big) = \big(\mathbf{b} \cdot (A^{\frac{1}{2}}\mathbf{u}), q\big)$$

and that, for any $r \in \mathcal{S}_N^h$,

$$\big(\nabla_h \times (A^{-\frac{1}{2}}\mathbf{u}), r\big) = \big(\nabla \times (A^{-\frac{1}{2}}\mathbf{u}), r\big) = 0,$$

which, together with the second and third equations in (2.3), imply equalities (4.3) and (4.4). ∎

For any $(\mathbf{v}, q) \in \mathcal{U}^h \times \mathcal{S}_D^h$, by (4.3) and (4.4) it is easy to see that

$$\begin{aligned} b_h(\mathbf{u}, p; \mathbf{v}, q) &= \big(f, -\nabla_h \cdot (A^{\frac{1}{2}}\mathbf{v}) + Q_h(\mathbf{b} \cdot (A^{-\frac{1}{2}}\mathbf{v})) + cq\big) \\ &\quad + \big(\nabla \cdot (A^{\frac{1}{2}}\mathbf{u}) - \nabla_h \cdot (A^{\frac{1}{2}}\mathbf{u}), cq\big) - \big((I - Q_h)(\mathbf{b} \cdot (A^{-\frac{1}{2}}\mathbf{u})), cq\big). \end{aligned} \tag{4.5}$$

The difference of equations (4.5) and (4.2) gives the following error equation:

$$\begin{aligned} &b_h(\mathbf{u} - \mathbf{u}_h, p - p_h; \mathbf{v}, q) \\ &= \big(\nabla \cdot (A^{\frac{1}{2}}\mathbf{u}) - \nabla_h \cdot (A^{\frac{1}{2}}\mathbf{u}), cq\big) - \big((I - Q_h)(\mathbf{b} \cdot (A^{-\frac{1}{2}}\mathbf{u})), cq\big) \end{aligned} \tag{4.6}$$

for all $(\mathbf{v}, q) \in \mathcal{U}^h \times \mathcal{S}_D^h$.

LEMMA 4.2. *For any $q \in H^{\alpha-2}(\Omega)$ with $\alpha \geq 2$, let $m-1$, the degree of the finite element space defined in section 3, be the smallest integer greater than or equal to $\alpha - 1$; we then have that*

$$\|(I - Q_h)q\|_{H_D^{-1}(\Omega)} \leq C\, h^{\alpha-1} \|q\|_{\alpha-2}. \tag{4.7}$$

Proof. It follows from the definitions of the $H_D^{-1}(\Omega)$ norm and the L^2-projection, the Cauchy–Schwarz inequality, and the approximation property that

$$\begin{aligned} \|(I - Q_h)q\|_{H_D^{-1}(\Omega)} &= \sup_{r \in H_D^1(\Omega)} \frac{\big((I - Q_h)q, r\big)}{\|r\|_1} = \sup_{r \in H_D^1(\Omega)} \frac{\big((I - Q_h)q, (I - Q_h)r\big)}{\|r\|_1} \\ &\leq C\, h\, \|(I - Q_h)q\| \leq C\, h^{\alpha-1}\, \|q\|_{\alpha-2}. \end{aligned}$$

This completes the proof of the lemma. ∎

Now, we are ready to establish error estimates in the L^2 and H^1 norms for the vector and scalar variables, respectively, which are optimal with respect to the required regularity of the solution. Note that the norm for $\mathbf{u}$ in the error estimate in (4.8) is L^2 only but H^1 in [5]. This contributes to the less smoothness requirement of the original problem here than in [5].

THEOREM 4.1. *Assume that* $(\mathbf{u}, p)$ *is in* $H^{\alpha-1}(\Omega)^2 \times H^{\alpha}(\Omega)$ *with* $\alpha > 1$, *and let* $m-1$, *the degree of the finite element space defined in section* 3, *be the smallest integer greater than or equal to* $\alpha - 1$. *Then the following error estimate holds:*

$$\|\mathbf{u} - \mathbf{u}_h\| + \|p - p_h\|_1 \le C\, h^{\alpha-1}\big(\|p\|_\alpha + \|\mathbf{u}\|_{\alpha-1}\big). \tag{4.8}$$

Proof. Let p_I be an interpolant of p in $\mathcal{S}_D^h$; one then has

$$\|p_I - p\|_1 \le C\, h^{\alpha-1}\, \|p\|_\alpha. \tag{4.9}$$

To establish the error bound in (4.8), by the triangle inequality, it suffices to show that there exists a $\tilde{\mathbf{u}}_h \in \mathcal{U}^h$ such that

$$\|\mathbf{u} - \tilde{\mathbf{u}}_h\| \le C\, h^{\alpha-1}\, \|\mathbf{u}\|_{\alpha-1} \tag{4.10}$$

and that

$$\|\tilde{\mathbf{u}}_h - \mathbf{u}_h\| + \|p_I - p_h\|_1 \le C\, h^{\alpha-1}\, \big(\|p\|_\alpha + \|\mathbf{u}\|_{\alpha-1}\big). \tag{4.11}$$

Note that $\mathbf{u}$ has the decomposition of the form

$$\mathbf{u} = A^{\frac{1}{2}} \nabla s + A^{-\frac{1}{2}} \nabla^\perp t,$$

where $s \in H_D^1(\Omega)$ and $t \in H_N^1(\Omega)$ are the unique solutions of

$$\big(A \nabla s, \nabla q\big) = \big(A^{\frac{1}{2}} \mathbf{u}, \nabla q\big) \quad \forall\, q \in H_D^1(\Omega) \tag{4.12}$$

and

$$\big(A^{-1} \nabla^\perp t, \nabla^\perp r\big) = \big(A^{-\frac{1}{2}} \mathbf{u}, \nabla^\perp r\big) \quad \forall\, r \in H_N^1(\Omega), \tag{4.13}$$

respectively. Let $\tilde{s}_h \in \mathcal{S}_D^h$ and $\tilde{t}_h \in \mathcal{S}_N^h$ be the respective finite element approximations of s and t; i.e., they satisfy the following equations:

$$\big(A \nabla \tilde{s}_h, \nabla q\big) = \big(A^{\frac{1}{2}} \mathbf{u}, \nabla q\big) \quad \forall\, q \in \mathcal{S}_D^h \tag{4.14}$$

and

$$\big(A^{-1} \nabla^\perp \tilde{t}_h, \nabla^\perp r\big) = \big(A^{-\frac{1}{2}} \mathbf{u}, \nabla^\perp r\big) \quad \forall\, r \in \mathcal{S}_N^h, \tag{4.15}$$

respectively. Assume that Poisson equations (4.12) and (4.13) have the following regularity estimates:

$$\|s\|_\alpha \le C\, \|\nabla \cdot (A^{\frac{1}{2}} \mathbf{u})\|_{\alpha-2} \quad \text{and} \quad \|t\|_\alpha \le C\, \|\nabla \times (A^{-\frac{1}{2}} \mathbf{u})\|_{\alpha-2},$$

respectively. Then standard finite element error bounds give that

$$\|A^{\frac{1}{2}} \nabla (s - \tilde{s}_h)\| \le C\, h^{\alpha-1}\, \|s\|_\alpha \le C\, h^{\alpha-1}\, \|\nabla \cdot (A^{\frac{1}{2}} \mathbf{u})\|_{\alpha-2}$$

and

$$\|A^{-\frac{1}{2}} \nabla^\perp (t - \tilde{t}_h)\| \le C\, h^{\alpha-1}\, \|t\|_\alpha \le C\, h^{\alpha-1}\, \|\nabla \times (A^{-\frac{1}{2}} \mathbf{u})\|_{\alpha-2}.$$

Hence, choosing

$$\tilde{\mathbf{u}}_h = A^{\frac{1}{2}} \nabla \tilde{s}_h + A^{-\frac{1}{2}} \nabla^\perp \tilde{t}_h,$$

by orthogonality (3.2) we have that

$$\begin{aligned}\|\mathbf{u}-\tilde{\mathbf{u}}_h\| &= \left(\|A^{\frac{1}{2}}\nabla(s-\tilde{s}_h)\|^2+\|A^{-\frac{1}{2}}\nabla^{\perp}(t-\tilde{t}_h)\|^2\right)^{\frac{1}{2}}\\ &\le C\,h^{\alpha-1}\,\left(\|\nabla\cdot(A^{\frac{1}{2}}\mathbf{u})\|_{\alpha-2}+\|\nabla\times(A^{-\frac{1}{2}}\mathbf{u})\|_{\alpha-2}\right).\end{aligned}$$

This completes the proof of inequality (4.10).

To show the validity of inequality (4.11), by the definition of the discrete divergence and curl operators, notice first that (4.14) and (4.15) imply

$$\nabla_h\cdot(A\nabla\tilde{s}_h)=\nabla_h\cdot(A^{\frac{1}{2}}\mathbf{u})\quad\text{and}\quad\nabla_h\times(A^{-1}\nabla^{\perp}\tilde{t}_h)=\nabla_h\times(A^{-\frac{1}{2}}\mathbf{u}),$$

respectively. Since $\nabla_h\cdot\nabla^{\perp}\tilde{t}_h=\nabla_h\times\nabla\tilde{s}_h=0$, we then have that

$$\nabla_h\cdot(A^{\frac{1}{2}}\tilde{\mathbf{u}}_h)=\nabla_h\cdot(A^{\frac{1}{2}}\mathbf{u})\quad\text{and}\quad\nabla_h\times(A^{-\frac{1}{2}}\tilde{\mathbf{u}}_h)=\nabla_h\times(A^{-\frac{1}{2}}\mathbf{u}). \tag{4.16}$$

It follows from Theorem 3.1 and error equation (4.6) that

$$\begin{aligned}&\frac{1}{C}|||(\tilde{\mathbf{u}}_h-\mathbf{u}_h,p_I-p_h)|||^2\\ &\le G_h(\tilde{\mathbf{u}}_h-\mathbf{u}_h,p_I-p_h;0)=b_h(\tilde{\mathbf{u}}_h-\mathbf{u}_h,p_I-p_h;\tilde{\mathbf{u}}_h-\mathbf{u}_h,p_I-p_h)\\ &=b_h(\tilde{\mathbf{u}}_h-\mathbf{u},p_I-p;\tilde{\mathbf{u}}_h-\mathbf{u}_h,p_I-p_h)-\big(\nabla\cdot(A^{\frac{1}{2}}\mathbf{u})-\nabla_h\cdot(A^{\frac{1}{2}}\mathbf{u}),c(p_I-p_h)\big)\\ &\quad+\big((I-Q_h)(\mathbf{b}\cdot(A^{-\frac{1}{2}}\mathbf{u})),c(p_I-p_h)\big).\end{aligned} \tag{4.17}$$

Now, we bound each term in the above inequality. First, by the definitions of the discrete divergence operator, the L^2-projection, and $H_D^{-1}(\Omega)$ norm, we have that

$$\begin{aligned}&\big(\nabla\cdot(A^{\frac{1}{2}}\mathbf{u})-\nabla_h\cdot(A^{\frac{1}{2}}\mathbf{u}),c(p_I-p_h)\big)\\ &=\big(\nabla\cdot(A^{\frac{1}{2}}\mathbf{u}),c(p_I-p_h)\big)-\big(\nabla_h\cdot(A^{\frac{1}{2}}\mathbf{u}),Q_hc(p_I-p_h)\big)\\ &=\big(\nabla\cdot(A^{\frac{1}{2}}\mathbf{u}),c(p_I-p_h)\big)-\big(\nabla\cdot(A^{\frac{1}{2}}\mathbf{u}),Q_hc(p_I-p_h)\big)\\ &=\big((I-Q_h)\nabla\cdot(A^{\frac{1}{2}}\mathbf{u}),c(p_I-p_h)\big)\\ &\le C\,\|(I-Q_h)\nabla\cdot(A^{\frac{1}{2}}\mathbf{u})\|_{H_D^{-1}(\Omega)}\|p_I-p_h\|_1.\end{aligned} \tag{4.18}$$

Second, it follows from the Cauchy–Schwarz and triangle inequalities, equalities in (4.16), and the boundedness of the L^2-projection and coefficients A, $\mathbf{b}$, and c that

$$\begin{aligned}&b_h(\tilde{\mathbf{u}}_h-\mathbf{u},p_I-p;\tilde{\mathbf{u}}_h-\mathbf{u}_h,p_I-p_h)\\ &\le\left(\|\tilde{\mathbf{u}}_h-\mathbf{u}\|+\|A^{\frac{1}{2}}\nabla(p_I-p)\|\right)\left(\|\tilde{\mathbf{u}}_h-\mathbf{u}_h\|+\|A^{\frac{1}{2}}\nabla(p_I-p_h)\|\right)\\ &\quad+\left(\|Q_h\big(\mathbf{b}\cdot A^{-\frac{1}{2}}(\tilde{\mathbf{u}}_h-\mathbf{u})\big)\|+\|c(p_I-p)\|\right)\cdot\\ &\qquad\left(\|\nabla_h\cdot(A^{\frac{1}{2}}(\tilde{\mathbf{u}}_h-\mathbf{u}_h))\|+\|Q_h\big(\mathbf{b}\cdot A^{-\frac{1}{2}}(\tilde{\mathbf{u}}_h-\mathbf{u}_h)\big)\|+\|c(p_I-p_h)\|\right)\\ &\le C\,\left(\|\tilde{\mathbf{u}}_h-\mathbf{u}\|+\|p_I-p\|_1\right)|||(\tilde{\mathbf{u}}_h-\mathbf{u}_h,p_I-p_h)|||.\end{aligned} \tag{4.19}$$

Substituting (4.18) and (4.19) into (4.17) implies that

$$\begin{aligned}\|\tilde{\mathbf{u}}_h-\mathbf{u}_h\|+\|p_I-p_h\|_1\le C\Big(&\|\tilde{\mathbf{u}}_h-\mathbf{u}\|+\|p_I-p\|_1+\|(I-Q_h)\big(\nabla\cdot(A^{\frac{1}{2}}\mathbf{u})\big)\|_{H_D^{-1}(\Omega)}\\ &+\|(I-Q_h)\big(\mathbf{b}\cdot(A^{-\frac{1}{2}}\mathbf{u})\big)\|_{H_D^{-1}(\Omega)}\Big).\end{aligned}$$

Now, (4.11) is an immediate consequence of (4.9), (4.10), and Lemma 4.2. This completes the proof of the theorem. ∎

5. Preconditioners. In this section, we discuss a spectrally equivalent preconditioner for the system of linear equations arising from the FOSLS discretization which is uniform in the mesh size.

The equivalence in Theorem 3.1 do not give us an immediate preconditioner since $|||(\mathbf{v},p)|||^2$ involves the (discrete) divergence and curl operators. Instead of working with $\mathbf{v}\in\mathcal{U}^h$, we explicitly make use of its representation:

$$\mathbf{v} = A^{\frac{1}{2}}\nabla s + A^{-\frac{1}{2}}\nabla^{\perp} t, \quad \text{where } s\in\mathcal{S}_D^h,\ t\in\mathcal{S}_N^h. \tag{5.1}$$

Now, $|||(\mathbf{v},p)|||^2 = |||(s,t,p)|||^2$ would be equivalent to some weighted Sobolev norm in terms of (s,t,q) which gives indications on how to construct preconditioners. To this end, by the definitions of the discrete divergence and curl operators, we first note that

$$\nabla_h\cdot(\nabla^{\perp}t) = 0 \quad \text{in } \Omega \quad \text{and} \quad \nabla_h\times(\nabla s) = 0 \quad \text{in } \Omega \tag{5.2}$$

for any $t\in\mathcal{S}_N^h$ and any $s\in\mathcal{S}_D^h$, respectively. We then introduce two discrete diffusion operators, $\Delta_{h,A}:\mathcal{S}_D^h\longrightarrow\mathcal{S}_D^h$ and $\hat{\Delta}_{h,A}:\mathcal{S}_N^h\longrightarrow\mathcal{S}_N^h$. For a given $s\in\mathcal{S}_D^h$, define $\Delta_{h,A}s\in\mathcal{S}_D^h$ to be the solution of

$$(\Delta_{h,A}s,\, q) = -(A\nabla s,\,\nabla q) \quad \forall\ q\in\mathcal{S}_D^h, \tag{5.3}$$

and for a given $t\in\mathcal{S}_D^h$, define $\hat{\Delta}_{h,A}t\in\mathcal{S}_N^h$ to be the solution of

$$(\hat{\Delta}_{h,A}t,\, q) = (A^{-1}\nabla^{\perp}t,\,\nabla^{\perp}q) \quad \forall\ q\in\mathcal{S}_N^h. \tag{5.4}$$

It is easy to see that

$$\Delta_{h,A} = \nabla_h\cdot A\nabla \quad \text{and} \quad \hat{\Delta}_{h,A} = \nabla_h\times A^{-1}\nabla^{\perp}.$$

By using (3.2), we then have that

$$|||(\mathbf{v},p)|||^2 = |||(s,t,p)|||^2 = \|p\|_1^2 + |||s|||^2 + |||t|||^2, \tag{5.5}$$

where

$$|||s|||^2 = \|s\|^2 + \|A^{\frac{1}{2}}\nabla s\|^2 + \|\Delta_{h,A}s\|^2 \quad \text{and} \quad |||t|||^2 = \|t\|^2 + \|A^{-\frac{1}{2}}\nabla^{\perp}t\|^2 + \|\hat{\Delta}_{h,A}t\|^2.$$

Before discussing the preconditioner based on $|||(s,t,q)|||^2$, we restate our discrete FOSLS approach in terms of functions (s,t,q). Our FOSLS functional is as follows:

$$\begin{aligned} G_h(s,t,q;f) =& \|A^{\frac{1}{2}}\nabla s + A^{-\frac{1}{2}}\nabla^{\perp}t - A^{\frac{1}{2}}\nabla q\|^2 \\ &+ \|f + \Delta_{h,A}s - Q_h\big(\mathbf{b}\cdot(\nabla s + A^{-1}\nabla^{\perp}t)\big) - cq\|^2 + \|\hat{\Delta}_{h,A}t\|^2, \end{aligned} \tag{5.6}$$

and the FOSLS minimization problem is to find $(\phi_h,\psi_h,p_h)\in\mathcal{S}_D^h\times\mathcal{S}_N^h\times\mathcal{S}_D^h$ such that

$$G_h(\phi_h,\psi_h,p_h;f) = \inf_{(s,t,q)\in\mathcal{S}_D^h\times\mathcal{S}_N^h\times\mathcal{S}_D^h} G_h(s,t,q;f) \tag{5.7}$$

with $\mathbf{u}_h = A^{\frac{1}{2}}\nabla\phi_h + A^{-\frac{1}{2}}\nabla^{\perp}\psi_h$. The corresponding variational problem is to find $(\phi_h,\psi_h,p_h)\in\mathcal{S}_D^h\times\mathcal{S}_N^h\times\mathcal{S}_D^h$ such that

$$b_h(\phi_h,\psi_h,p_h;s,t,q) = f_h(s,t,q) \quad \forall\ (s,t,q)\in\mathcal{S}_D^h\times\mathcal{S}_N^h\times\mathcal{S}_D^h, \tag{5.8}$$

where the bilinear and linear forms are given by

$$\begin{aligned}
&b_h(\phi_h,\psi_h,p_h;s,t,q)\\
&=\big(A^{\frac12}\nabla\phi_h+A^{-\frac12}\nabla^\perp\psi_h-A^{\frac12}\nabla p_h,\ A^{\frac12}\nabla s+A^{-\frac12}\nabla^\perp t-A^{\frac12}\nabla q\big)+\big(\hat\Delta_{h,A}\psi_h,\ \hat\Delta_{h,A}t\big)\\
&+\big(\Delta_{h,A}\phi_h-Q_h\big(\mathbf{b}\cdot(\nabla\phi_h+A^{-1}\nabla^\perp\psi_h)\big)-cp,\ \Delta_{h,A}s-Q_h\big(\mathbf{b}\cdot(\nabla s+A^{-1}\nabla^\perp t)\big)-cq\big)
\end{aligned}$$

and

$$f_h(s,t,q)=\big(f,\ -\Delta_{h,A}s+Q_h\big(\mathbf{b}\cdot(\nabla s+A^{-1}\nabla^\perp t)\big)+cq\big).$$

THEOREM 5.1. *For any $(s,t,q)\in\mathcal{S}_D^h\times\mathcal{S}_N^h\times\mathcal{S}_D^h$, there exists a positive constant C such that*

$$\frac1C\,|||(s,t,q)|||^2\le G_h(s,t,q;0)=b_h(s,t,q;s,t,q)\le C\,|||(s,t,q)|||^2. \tag{5.9}$$

Proof. It is a direct consequence of Theorem 3.1 and equality (5.5). ∎

Theorem 5.1 indicates that the quadratic form $b_h(s,t,q;s,t,q)$ can be preconditioned well by the diagonal quadratic form $|||(s,t,q)|||^2$ because they are spectrally equivalent uniformly in the mesh size (see (5.9)). We further replace these diagonal blocks of $|||(s,t,q)|||^2$ by some multigrid preconditioners. To this end, note first that $\|q\|_1^2$ is uniformly equivalent to

$$\|q\|^2+\|A^{\frac12}\nabla q\|^2=\big((I-\Delta_{h,A})q,\,q\big)$$

by using (2.2) and the definitions of the discrete divergence and diffusion operators. Similarly, $|||s|||^2$ and $|||t|||^2$ are uniformly equivalent to

$$\begin{aligned}
&\|s\|^2+2\|A^{\frac12}\nabla s\|^2+\|\Delta_{h,A}s\|^2=\big((I-\Delta_{h,A})^2s,\,s\big)\\
\text{and}\quad&\|t\|^2+2\|A^{-\frac12}\nabla^\perp s\|^2+\|\hat\Delta_{h,A}t\|^2=\big((I-\hat\Delta_{h,A})^2t,\,t\big),
\end{aligned}$$

respectively. Let P_1 be a preconditioner based on a symmetric multigrid V-cycle applied to the diffusion problem: find $v\in\mathcal{S}_D^h$ such that

$$(A\nabla v,\,\nabla\xi)+(v,\,\xi)=0\quad\forall\,\xi\in\mathcal{S}_D^h.$$

It is well known that P_1 is spectrally equivalent to $I-\Delta_{h,A}$ uniformly in the mesh size. Since the solution of

$$(I-\Delta_{h,A})^2s=g$$

for a given $g\in\mathcal{S}_D^h$ can be obtained successively by solving two discrete diffusion equations, i.e.,

$$(I-\Delta_{h,A})\hat s=g\quad\text{and}\quad(I-\Delta_{h,A})s=\hat s,$$

it is then natural to precondition $(I-\Delta_{h,A})^2$ by P_1^2. For further discussions and numerical experiments on P_1^2 as a preconditioner for $(I-\Delta_{h,A})^2$, see [3]. Similarly, we precondition $(I-\hat\Delta_{h,A})^2$ by P_2^2, where P_2 is a preconditioner based on a symmetric multigrid V-cycle applied to the diffusion problem: find $v\in\mathcal{S}_N^h$ such that

$$(A^{-1}\nabla^\perp v,\,\nabla^\perp\xi)+(v,\,\xi)=0\quad\forall\,\xi\in\mathcal{S}_N^h.$$

LOCAL DISCONTINUOUS GALERKIN METHODS FOR THE STOKES SYSTEM*

BERNARDO COCKBURN†, GUIDO KANSCHAT‡, DOMINIK SCHÖTZAU§, AND CHRISTOPH SCHWAB¶

Abstract. In this paper, we introduce and analyze local discontinuous Galerkin methods for the Stokes system. For a class of shape regular meshes with hanging nodes we derive a priori estimates for the L^2-norm of the errors in the velocities and the pressure. We show that *optimal*-order estimates are obtained when polynomials of degree k are used for each component of the velocity and polynomials of degree $k-1$ for the pressure, for any $k \geq 1$. We also consider the case in which *all* the unknowns are approximated with polynomials of degree k and show that, although the orders of convergence remain the same, the method is more efficient. Numerical experiments verifying these facts are displayed.

Key words. finite elements, discontinuous Galerkin methods, Stokes system

1. Introduction.

In this paper, we introduce and analyze local discontinuous Galerkin (LDG) methods for the Stokes system

$$\begin{aligned} -\Delta \boldsymbol{u} + \nabla p &= \boldsymbol{f} && \text{in } \Omega, \\ \nabla \cdot \boldsymbol{u} &= 0 && \text{in } \Omega, \\ \boldsymbol{u} &= \boldsymbol{g}_{\mathcal{D}} && \text{on } \partial\Omega, \end{aligned} \tag{1.1}$$

where Ω is a bounded domain of $\mathbb{R}^d$ and the Dirichlet datum satisfies the usual compatibility condition $\int_{\partial\Omega} \boldsymbol{g}_{\mathcal{D}} \cdot \boldsymbol{n}\, ds = 0$, with $\boldsymbol{n}$ denoting the outward unit normal to $\partial\Omega$. We thus continue the study of LDG methods as applied to diffusion-dominated problems started by Castillo, Cockburn, Perugia, and Schötzau [8], who carried out the analysis of general LDG methods for the Laplacian on general triangulations, and by Cockburn, Kanschat, Perugia, and Schötzau [13], who obtained superconvergence results for Cartesian grids and a special LDG method. Our long-term goal is to study LDG methods for the *incompressible* Navier–Stokes equations; the analysis of the Stokes system is thus a necessary intermediate step.

¶Seminar für Angewandte Mathematik (SAM), ETHZ, CH-8092 Zürich, Switzerland (schwab@sam.math.ethz.ch).

There are mainly two motivations for using LDG methods for the Navier–Stokes equations. The first one is that these methods can easily handle meshes with hanging nodes, elements of general shapes, and local spaces of different types; this makes them ideally suited for *hp*-adaptivity. The second one, of no less importance, is that with their carefully devised *numerical fluxes* inherited from the corresponding discontinuous Galerkin (DG) discretizations of nonlinear hyperbolic conservation laws—see the work by Cockburn and Shu [16, 17, 19], Cockburn, Hou, and Shu [12], and Cockburn, Lin, and Shu [15]—the LDG methods weakly enforce the conservation laws element-by-element and in a *conservative* way. This last property is highly appreciated by the practitioners of computational fluid dynamics, especially in situations where there are shocks, steep gradients, or boundary layers. In fact, it was for the convection-dominated *compressible* Navier–Stokes equations that the DG discretization techniques were applied for the first time by Bassi and Rebay in [4] with excellent results; the LDG method was then introduced by Cockburn and Shu in [18] as an extension of Bassi and Rebay's method to general convection-diffusion problems. To give the reader a flavor of the LDG methods proposed in this paper, we briefly compare them with other methods.

• **Interior penalty methods.** In the framework of the Stokes system, the main difficulty in obtaining numerical approximations is the enforcement of the incompressibility condition on the velocity. For continuous approximations of the velocity, it is well known that a pointwise enforcement could yield an overconstrained velocity and the only divergence-free function might turn out to be identically zero; this is the so-called *locking* phenomenon. However, in 1990, Baker, Jureidini, and Karakashian [2] showed how to enforce the incompressibility condition pointwise *inside* each element and still obtain optimal error estimates. They achieved this by using interior penalty (IP) methods, that is, methods that take the velocity approximation to be *discontinuous* and penalize the size of its discontinuity jumps across the element boundaries; see also the recent extension of this method to the incompressible Navier–Stokes equations by Karakashian and Katsaounis [28]. Arnold, Brezzi, Cockburn, and Marini [1] briefly review IP methods for purely elliptic problems and then relate and compare them to the LDG and other DG methods. A similar comparison can easily be developed for the Stokes system, but here we restrict ourselves to pointing out that, like the IP method of Baker, Jureidini, and Karakashian, the LDG methods use a discontinuous approximate velocity whose discontinuity jumps across the element boundaries are also penalized. However, unlike the IP method of Baker, Jureidini, and Karakashian, the LDG methods use discontinuous pressure approximations and (at least in this paper) do not try to impose the incompressibility condition pointwise inside the elements; instead, like in standard mixed methods, this condition is imposed weakly.

• **Standard mixed methods.** In his review of standard mixed methods for the Navier–Stokes equations, Fortin [21] points out that the use of discontinuous approximations for the pressure ensures a better conservation of mass in comparison with the use of continuous approximations and refers to the work of Pelletier, Fortin, and Camarero [30] for situations that illustrate this point. This is a property that these methods have in common with the LDG methods, not only because of the use of discontinuous approximations of the pressure, but also because the LDG methods ensure mass conservation. Indeed, to obtain the LDG methods, we first rewrite the Stokes system as the following collection of conservation laws:

$$\underline{\sigma} = \nabla \boldsymbol{u} \qquad \text{in } \Omega, \tag{1.2}$$

$$-\nabla \cdot \underline{\sigma} + \nabla p = \boldsymbol{f} \qquad \text{in } \Omega, \tag{1.3}$$

$$\nabla \cdot \boldsymbol{u} = 0 \qquad \text{in } \Omega, \tag{1.4}$$

$$\boldsymbol{u} = \boldsymbol{g}_{\mathcal{D}} \qquad \text{on } \partial\Omega. \tag{1.5}$$

Then we discretize them by using the DG technique, that is, element-by-element and in a conservative way; this is what ensures mass conservation. Note that to achieve this, we introduced the stress tensor $\underline{\sigma}$. This could be considered a disadvantage of the LDG methods with respect to the classical mixed methods, but this is not so because $\underline{\sigma}$ can be eliminated independently and in parallel on each grid cell, as we shall see.

Let us briefly digress to point out that the issue of the possible advantages of methods that, like the LDG methods, enforce the conservation laws locally and in a conservative way over finite element methods which cannot do that, and are typically based on continuous approximations, is the subject of an ongoing discussion which is far from being exhausted. Although it has been firmly established that this property is certainly desirable for convection-dominated problems, its possible advantages in other situations still remain to be thoroughly explored. About this very point, see the review of DG methods by Cockburn, Karniadakis, and Shu [14] and the paper by Hughes, Engel, Mazzei, and Larson [25] where a comparison of discontinuous and continuous Galerkin methods is carried out.

• **Stabilized mixed methods.** Finally, let us emphasize that for the LDG methods, the approximation spaces for the velocity and the pressure can be chosen almost arbitrarily; only a mild local condition has to be satisfied. This is so because the LDG methods can be considered to be *stabilized* mixed methods; for a review of stabilized mixed methods, see the article by Franca, Hughes, and Stenberg [22]. They are thus related to the Galerkin least squares (GLS) mixed methods introduced in 1986/1987 by Hughes, Franca, and Balestra [27] and Hughes and Franca [26], who used the jumps of the pressures across boundary elements and residuals inside the elements to render them stable. However, unlike these methods, LDG methods use discontinuous approximations to the velocity and employ stabilization terms which involve jumps across the element boundaries only. Variations of the LDG methods we study here could be easily constructed which are closely related to the "locally" stabilized methods introduced and numerically studied in 1989 by Silvester and Kechkar [31] and then analyzed in 1992 by Kechkar and Silvester [29]; however, this subject will not be considered in this paper. Finally, we must also point out that in the GLS methods, one has, in particular for velocities which are piecewise quadratic or of higher degree, and also for curvilinear mapped elements, to evaluate the GLS stabilization terms which are quite costly due to the appearance of, e.g., the Laplacian in the bilinear forms. The LDG methods achieve, as we prove here, the same stabilization effect but as a rule do this without recourse to domain integrals of second-order derivatives of finite element functions. Rather, only edge/face integrals of jumps are evaluated.

Now, let us briefly describe our results. We show that if we use polynomials of degree k to approximate the pressure p, the stresses $\underline{\sigma}$, and the velocity $\boldsymbol{u}$, the order of convergence of k is obtained for the L^2-norm of p and $\underline{\sigma}$, and of $k+1$ for the L^2-norm of the velocity. These orders of convergence are *sharp*, as they are observed in our numerical experiments. We also explore the situation in which polynomials of degree $k-1$ are used to approximate the pressure p and the stress tensor $\underline{\sigma}$. In this case, we prove that the above mentioned orders of convergence remain *invariant*; in

other words, in this case the error estimates are *optimal*. Our numerical experiments confirm this fact; moreover, they also show that this choice of approximating spaces gives rise to a method which is *less efficient* than the one obtained by using the same approximation spaces for all the variables. In Table 1.1, we summarize our theoretical results and compare them with the orders of convergence obtained for the IP method of Baker, Jureidini, and Karakashian [2] and the stabilized mixed methods of Hughes and Franca [26]. (See also Franca and Stenberg [23] for a unified error analysis.) Note that when the approximations are continuous, the jumps across elements are zero and the corresponding penalization term vanishes; we indicate this by writing "none."

TABLE 1.1
Theoretical orders of convergence for $k \geq 1$.

Method		Penalization of the jumps of velocity and pressure		$\|\boldsymbol{u} - \boldsymbol{u}_N\|_0$	$\|p - p_N\|_0$
LDG		$\mathcal{O}(h^{-1})$	$\mathcal{O}(h)$	$k+1$	k
IP	[2]	$\mathcal{O}(h^{-1})$	none	$k+1$	k
Stabilized mixed	[26, 23]	none	$\mathcal{O}(h)$	$k+1$	k

Finally, let us point out that the technique we use in our analysis is an extension of that used in [8] for the Laplacian. One of the contributions in this paper is that we make the technique work for local spaces that might be different for different unknowns. In fact, in *all* previous error analyses of LDG methods involving second-order operators (see [18, 7, 9, 11, 8, 13, 20]), the local spaces for both the auxiliary stresses and the main unknowns have been taken to be identical. The second contribution is that we show how to obtain the inf-sup condition, which is nonstandard given the discontinuous nature of our elements, in order to obtain error estimates for the pressure. Note that, unlike the analysis technique used by Hughes, Franca, and Balestra [27] and Hughes and Franca [26], who obtained error estimates of the pressure in certain mesh-dependent norms, we obtain an error of the pressure in the L^2-norm by using an inf-sup condition; in this respect, our technique is closer to that employed in 1991 by Franca and Stenberg [23].

The paper is organized as follows. In section 2, we introduce the method, show that it determines a unique approximate solution, and then state and discuss our main results. Finally, a brief overview of its proof is given which is then completed in full detail in section 3. Section 4 is devoted to numerical experiments devised to verify our theoretical results and to compare the effect that the use of different spaces has on the quality of the LDG approximate solution. We end in section 5 by describing extensions of our analysis and giving some concluding remarks.

2. The main results. In this section, we formulate the LDG method and show that it possesses a well-defined solution. We then state and discuss our main results, and finally, we present an abstract framework upon which our error analysis is based.

We assume throughout this section, in order to avoid unnecessary technicalities, that the exact solution $(\boldsymbol{u}, p)$ of (1.1) belongs at least to $H^2(\Omega)^d \times H^1(\Omega)$.

2.1. Definition of the LDG method. To define the LDG method, we consider the system of first-order conservation laws (1.2)–(1.5). We use the standard notation $(\nabla \boldsymbol{v})_{ij} = \partial_j v_i$ and $(\nabla \cdot \underline{\sigma})_i = \sum_{j=1}^d \partial_j \sigma_{ij}$. We also denote by $\boldsymbol{v} \otimes \boldsymbol{n}$ the matrix whose

ijth component is $v_i\, n_j$ and write

$$\underline{\sigma} : \underline{\tau} := \sum_{i,j=1}^{d} \sigma_{ij}\tau_{ij}, \qquad\qquad \boldsymbol{v} \cdot \underline{\sigma} \cdot \boldsymbol{n} := \sum_{i,j=1}^{d} v_i \sigma_{ij} n_j = \underline{\sigma} : (\boldsymbol{v} \otimes \boldsymbol{n}).$$

Multiplying (1.2), (1.3), and (1.4) by arbitrary, smooth test functions $\underline{\tau}$, $\boldsymbol{v}$, and q, respectively, and integrating by parts over an arbitrary subset K of the domain Ω, we obtain

$$\int_K \underline{\sigma} : \underline{\tau}\, d\boldsymbol{x} = -\int_K \boldsymbol{u} \cdot \nabla \cdot \underline{\tau}\, d\boldsymbol{x} + \int_{\partial K} \boldsymbol{u} \cdot \underline{\tau} \cdot \boldsymbol{n}_K\, ds, \tag{2.1}$$

$$\int_K \underline{\sigma} : \nabla \boldsymbol{v}\, d\boldsymbol{x} - \int_{\partial K} \underline{\sigma} : (\boldsymbol{v} \otimes \boldsymbol{n}_K) ds - \int_K p\, \nabla \cdot \boldsymbol{v}\, d\boldsymbol{x} + \int_{\partial K} p\, \boldsymbol{v} \cdot \boldsymbol{n}_K ds$$

$$= \int_K \boldsymbol{f} \cdot \boldsymbol{v}\, d\boldsymbol{x}, \tag{2.2}$$

$$-\int_K \boldsymbol{u} \cdot \nabla q\, d\boldsymbol{x} + \int_{\partial K} \boldsymbol{u} \cdot \boldsymbol{n}_K\, q\, ds = 0, \tag{2.3}$$

where $\boldsymbol{n}_K$ is the outward unit normal to ∂K. This is the weak form of the Stokes system that we shall use to define the LDG method. We enforce the above equations on each element K of a general triangulation $\mathcal{T}$ of Ω which can have hanging nodes and elements of various shapes. Thus, since the above equations are well defined for any functions $(\underline{\sigma}, \boldsymbol{u}, p)$ and $(\underline{\tau}, \boldsymbol{v}, q)$ in $\underline{\Sigma} \times \boldsymbol{V} \times Q$, where

$$\underline{\Sigma} := \{\underline{\sigma} \in L^2(\Omega)^{d^2} \ : \sigma_{ij}\big|_K \in H^1(K)\ \forall K \in \mathcal{T},\ 1 \le i,j \le d\},$$
$$\boldsymbol{V} := \{\boldsymbol{v} \in L^2(\Omega)^d \ : v_i\big|_K \in H^1(K)\ \forall K \in \mathcal{T},\ 1 \le i \le d\},$$
$$Q := \left\{ q \in L^2(\Omega) \ : \int_\Omega q\, d\boldsymbol{x} = 0,\ q\big|_K \in H^1(K)\ \forall K \in \mathcal{T} \right\},$$

we seek to approximate the exact solution $(\underline{\sigma}, \boldsymbol{u}, p)$ with functions $(\underline{\sigma}_N, \boldsymbol{u}_N, p_N)$ in the finite element space $\underline{\Sigma}_N \times \boldsymbol{V}_N \times Q_N \subset \underline{\Sigma} \times \boldsymbol{V} \times Q$, where

$$\underline{\Sigma}_N := \{\underline{\sigma} \in L^2(\Omega)^{d^2} \ : \sigma_{ij}\big|_K \in \mathcal{S}(K)\ \forall K \in \mathcal{T},\ 1 \le i,j \le d\},$$
$$\boldsymbol{V}_N := \{\boldsymbol{v} \in L^2(\Omega)^d \ : v_i\big|_K \in \mathcal{V}(K)\ \forall K \in \mathcal{T},\ 1 \le i \le d\},$$
$$Q_N := \left\{ q \in L^2(\Omega) \ : \int_\Omega q\, d\boldsymbol{x} = 0,\ q\big|_K \in \mathcal{Q}(K)\ \forall K \in \mathcal{T} \right\},$$

and the *local* finite element spaces $\mathcal{S}(K)$, $\mathcal{V}(K)$, and $\mathcal{Q}(K)$ typically consist of polynomials.

The approximate solution $(\underline{\sigma}_N, \boldsymbol{u}_N, p_N)$ is now defined by imposing that for all $K \in \mathcal{T}$, for all $(\underline{\tau}, \boldsymbol{v}, q) \in \mathcal{S}(K)^{d^2} \times \mathcal{V}(K)^d \times \mathcal{Q}(K)$,

$$\int_K \underline{\sigma}_N : \underline{\tau}\, d\boldsymbol{x} = -\int_K \boldsymbol{u}_N \cdot \nabla \cdot \underline{\tau}\, d\boldsymbol{x} + \int_{\partial K} \widehat{\boldsymbol{u}}_{N,\sigma} \cdot \underline{\tau} \cdot \boldsymbol{n}_K\, ds, \tag{2.4}$$

$$\int_K \underline{\sigma}_N : \nabla \boldsymbol{v}\, d\boldsymbol{x} - \int_{\partial K} \widehat{\underline{\sigma}}_N : (\boldsymbol{v} \otimes \boldsymbol{n}_K)\, ds - \int_K p_N\, \nabla \cdot \boldsymbol{v}\, d\boldsymbol{x} + \int_{\partial K} \widehat{p}_N\, \boldsymbol{v} \cdot \boldsymbol{n}_K\, ds$$

$$= \int_K \boldsymbol{f} \cdot \boldsymbol{v}\, d\boldsymbol{x}, \tag{2.5}$$

$$-\int_K \boldsymbol{u}_N \cdot \nabla q\, d\boldsymbol{x} + \int_{\partial K} \widehat{\boldsymbol{u}}_{N,p} \cdot \boldsymbol{n}_K\, q\, ds = 0. \tag{2.6}$$

Here, $\widehat{\boldsymbol{u}}_{N,\sigma}$, $\widehat{\underline{\sigma}}_N$, $\widehat{p}_N$, and $\widehat{\boldsymbol{u}}_{N,p}$ are the so-called *numerical fluxes*, which are discrete approximations to traces on the boundary of the elements. Note how the numerical fluxes $\widehat{\boldsymbol{u}}_{N,\sigma}$ and $\widehat{\boldsymbol{u}}_{N,p}$ arise naturally from the weak formulation; although both are approximations to the trace of the velocity $\boldsymbol{u}$, they are defined in very different ways since they are associated with different conservation laws.

To define these numerical fluxes, we need to introduce some notation associated with traces. Let K^+ and K^- be two adjacent elements of $\mathcal{T}$; let $\boldsymbol{x}$ be an arbitrary point of the set $e = \partial K^+ \cap \partial K^-$, which is assumed to have a nonzero $(d-1)$-dimensional measure; and let $\boldsymbol{n}^+$ and $\boldsymbol{n}^-$ be the corresponding outward unit normals at that point. Let $(\underline{\sigma}, \boldsymbol{u}, p)$ be a function smooth inside each element $K^\pm$ and let us denote by $(\underline{\sigma}^\pm, \boldsymbol{u}^\pm, p^\pm)$ the traces of $(\underline{\sigma}, \boldsymbol{u}, p)$ on e from the interior of $K^\pm$. Then we define the mean values $\{\!\{\cdot\}\!\}$ and jumps $[\![\cdot]\!]$ at $\boldsymbol{x} \in e$ as

$$\{\!\{p\}\!\} := (p^+ + p^-)/2, \qquad \{\!\{\boldsymbol{u}\}\!\} := (\boldsymbol{u}^+ + \boldsymbol{u}^-)/2, \qquad \{\!\{\underline{\sigma}\}\!\} := (\underline{\sigma}^+ + \underline{\sigma}^-)/2,$$
$$[\![p]\!] := p^+\,\boldsymbol{n}^+ + p^-\,\boldsymbol{n}^-, \qquad [\![\boldsymbol{u}]\!] := \boldsymbol{u}^+ \cdot \boldsymbol{n}^+ + \boldsymbol{u}^- \cdot \boldsymbol{n}^-, \qquad [\![\underline{\sigma}]\!] := \underline{\sigma}^+ \cdot \boldsymbol{n}^+ + \underline{\sigma}^- \cdot \boldsymbol{n}^-.$$

Note that the jumps $[\![p]\!]$ and $[\![\underline{\sigma}]\!]$ are both vectors whereas the jump $[\![\boldsymbol{u}]\!]$ is a scalar. We also need to define a jump of the velocity $\boldsymbol{u}$ which is a matrix, namely,

$$\underline{[\![\boldsymbol{u}]\!]} := \boldsymbol{u}^+ \otimes \boldsymbol{n}^+ + \boldsymbol{u}^- \otimes \boldsymbol{n}^-.$$

In components, we have $\underline{[\![\boldsymbol{u}]\!]}^2 = \sum_{i=1}^d (u_i^+ - u_i^-)^2$ and $(\boldsymbol{u}^\pm \otimes \boldsymbol{n}^\pm)^2 = \sum_{i=1}^d (u_i^\pm)^2$. Also, we remark that, since $[\![\boldsymbol{u}]\!] = \sum_{i=1}^d (u_i^+ - u_i^-)\, n_i^+$, we have $[\![\boldsymbol{u}]\!]^2 \le \underline{[\![\boldsymbol{u}]\!]}^2$, that is, the norm of the scalar-valued jump of the velocity can be controlled by the norm of the matrix-valued jump.

We are now ready to introduce the numerical fluxes. We begin by defining the numerical fluxes $\widehat{\underline{\sigma}}$ and $\widehat{\boldsymbol{u}}_\sigma$ associated with the Laplacian. We pick a *direct* extension of the choice of numerical fluxes for the Laplace operator considered in [8] and [13]. That is, on a face e inside the domain Ω, we take

$$\begin{bmatrix} \widehat{\underline{\sigma}} \\ \widehat{\boldsymbol{u}}_\sigma \end{bmatrix} := \begin{bmatrix} \{\!\{\underline{\sigma}\}\!\} \\ \{\!\{\boldsymbol{u}\}\!\} \end{bmatrix} - \begin{bmatrix} C_{11} \underline{[\![\boldsymbol{u}]\!]} + [\![\underline{\sigma}]\!] \otimes \boldsymbol{C}_{12} \\ -\underline{[\![\boldsymbol{u}]\!]} \cdot \boldsymbol{C}_{12} \end{bmatrix}, \tag{2.7}$$

and if e lies on the boundary, we take

$$\begin{bmatrix} \widehat{\underline{\sigma}} \\ \widehat{\boldsymbol{u}}_\sigma \end{bmatrix} := \begin{bmatrix} \underline{\sigma}^+ - C_{11}\,(\boldsymbol{u}^+ - \boldsymbol{g}_{\mathcal{D}}) \otimes \boldsymbol{n}^+ \\ \boldsymbol{g}_{\mathcal{D}} \end{bmatrix}. \tag{2.8}$$

The numerical fluxes associated with the incompressibility constraint, $\widehat{\boldsymbol{u}}_p$ and $\widehat{p}$, are defined by using an analogous recipe. If the face e is on the interior of Ω, we take

$$\begin{bmatrix} \widehat{\boldsymbol{u}}_p \\ \widehat{p} \end{bmatrix} := \begin{bmatrix} \{\!\{\boldsymbol{u}\}\!\} \\ \{\!\{p\}\!\} \end{bmatrix} + \begin{bmatrix} D_{11}\,[\![p]\!] + \boldsymbol{D}_{12}\,[\![\boldsymbol{u}]\!] \\ -\boldsymbol{D}_{12} \cdot [\![p]\!] \end{bmatrix}, \tag{2.9}$$

and if e lies on the boundary, we take

$$\begin{bmatrix} \widehat{\boldsymbol{u}}_p \\ \widehat{p} \end{bmatrix} := \begin{bmatrix} \boldsymbol{g}_{\mathcal{D}} \\ p^+ \end{bmatrix}. \tag{2.10}$$

The parameters C_{11}, $\boldsymbol{C}_{12}$ and D_{11}, $\boldsymbol{D}_{12}$ depend on $\boldsymbol{x} \in e$. This completes the definition of the LDG method for the Stokes system (1.1).

We would like to stress the following points about this method:

• Note that since the numerical flux $\widehat{\boldsymbol{u}}_\sigma$ is independent of the variable $\underline{\sigma}$, it is possible to use (2.4) to solve $\underline{\sigma}_N$ in terms of $\boldsymbol{u}_N$ only, element-by-element. This local solvability, which allows us to *eliminate* the stresses $\underline{\sigma}_N$ from the equations, gives the name to the LDG method. (See [8, 18] for more details.)

• The numerical fluxes are consistent in the sense that equations (2.4)–(2.6) coincide with (2.1)–(2.3) for the exact solution $(\underline{\sigma}, \boldsymbol{u}, p)$. Note also that the boundary condition is taken into consideration *only* through the numerical fluxes $\widehat{\boldsymbol{u}}_\sigma$ and $\widehat{\boldsymbol{u}}_p$ on the boundary.

• The purpose of the coefficients C_{11} and D_{11} is to ensure the stability of the method. They are thus referred to as the stabilization coefficients. As we shall see, they can also affect the accuracy of the method. The parameters $\boldsymbol{C}_{12}$ and $\boldsymbol{D}_{12}$ can be chosen so as to reduce the sparsity of the matrices and, in special cases, to enhance the accuracy of the method; see the case of the Laplacian treated in [13]. In this paper, we simply assume that they are of order one.

• Note that if we rewrite the conservation law (1.3) as

$$-\nabla \cdot (\underline{\sigma} - p\, \underline{I}) = \boldsymbol{f} \qquad \text{in } \Omega,$$

where $\underline{I}$ is the identity tensor, we see that we need to define a single numerical flux for $(\underline{\sigma} - p\ \underline{I})$ which, in fact, has been taken to be $\widehat{\underline{\sigma}} - \widehat{p}\ \underline{I}$. We could have taken the following more general ansatz for the numerical flux for the pressure $\widehat{p} = \{\!\{p\}\!\} - \boldsymbol{D}_{12} \cdot [\![p]\!] + D_{22}\, [\![\boldsymbol{u}]\!]$, but this would result in

$$\widehat{\underline{\sigma}} - \widehat{p}\, \underline{I} \;=\; \{\!\{\underline{\sigma}\}\!\} - \{\!\{p\}\!\}\, \underline{I} \;+\; \boldsymbol{D}_{12} \cdot [\![p]\!]\, \underline{I} - \Big(C_{11} \underline{[\![\boldsymbol{u}]\!]} + D_{22}\, [\![\boldsymbol{u}]\!]\, \underline{I} \Big).$$

Since, as we shall see, the role of the term $C_{11}\, [\![\boldsymbol{u}]\!]$ is to control *all* the discontinuity jumps of the velocity $\boldsymbol{u}$ but the term $D_{22}\, [\![\boldsymbol{u}]\!]\, \underline{I}$ can induce a control on the jumps of only the *normal* component of the velocity, it is clear that we can always take $D_{22} \equiv 0$.

2.2. The mixed setting. The study of the LDG method is greatly facilitated if we recast its formulation in a classical mixed finite element setting. To do that, we denote by $\mathcal{E}_i$ the *union* of all interior faces of the triangulation $\mathcal{T}$ and by $\mathcal{E}_\mathcal{D}$ the union of faces lying on $\partial\Omega$. By summing (2.4), (2.5), and (2.6) over all elements and after simple algebraic manipulations, the LDG method can be reformulated more compactly as follows. Find $(\underline{\sigma}_N, \boldsymbol{u}_N, p_N) \in \underline{\Sigma}_N \times \boldsymbol{V}_N \times Q_N$ such that

$$\begin{aligned} a(\underline{\sigma}_N, \underline{\tau}) + b(\boldsymbol{u}_N, \underline{\tau}) &= f(\underline{\tau}), \\ -b(\boldsymbol{v}, \underline{\sigma}_N) + c(\boldsymbol{u}_N, \boldsymbol{v}) + d(\boldsymbol{v}, p_N) &= g(\boldsymbol{v}), \\ -d(\boldsymbol{u}_N, q) + e(p_N, q) &= h(q) \end{aligned} \tag{2.11}$$

for all $(\underline{\tau}, \boldsymbol{v}, q) \in \underline{\Sigma}_N \times \boldsymbol{V}_N \times Q_N$.

Here,

$$
\begin{aligned}
a(\underline{\sigma},\underline{\tau}) &:= \int_\Omega \underline{\sigma} : \underline{\tau}\, d\boldsymbol{x},\\
b(\boldsymbol{u},\underline{\tau}) &:= \sum_{K\in\mathcal{T}} \int_K \boldsymbol{u}\cdot\nabla\cdot\underline{\tau}\, d\boldsymbol{x} - \int_{\mathcal{E}_i} (\{\!\{\boldsymbol{u}\}\!\} + \underline{[\![\boldsymbol{u}]\!]}\cdot \boldsymbol{C}_{12})\cdot [\![\underline{\tau}]\!]\, ds,\\
c(\boldsymbol{u},\boldsymbol{v}) &:= \int_{\mathcal{E}_i} C_{11}\underline{[\![\boldsymbol{u}]\!]} : \underline{[\![\boldsymbol{v}]\!]}\, ds + \int_{\mathcal{E}_\mathcal{D}} C_{11}(\boldsymbol{u}\otimes\boldsymbol{n}) : (\boldsymbol{v}\otimes\boldsymbol{n})\, ds,\\
d(\boldsymbol{v},p) &:= -\sum_{K\in\mathcal{T}} \int_K p\nabla\cdot\boldsymbol{v}\, d\boldsymbol{x} + \int_{\mathcal{E}_i} (\{\!\{p\}\!\} - \boldsymbol{D}_{12}\cdot[\![p]\!])[\![\boldsymbol{v}]\!]\, ds + \int_{\mathcal{E}_\mathcal{D}} p\boldsymbol{v}\cdot\boldsymbol{n}\, ds,\\
e(p,q) &:= \int_{\mathcal{E}_i} D_{11}[\![p]\!]\cdot[\![q]\!]\, ds
\end{aligned}
$$

and

$$
\begin{aligned}
f(\underline{\tau}) &:= \int_{\mathcal{E}_\mathcal{D}} \boldsymbol{g}_\mathcal{D}\cdot\underline{\tau}\cdot\boldsymbol{n}\, ds,\\
g(\boldsymbol{v}) &:= \int_\Omega \boldsymbol{f}\cdot\boldsymbol{v}\, d\boldsymbol{x} + \int_{\mathcal{E}_\mathcal{D}} C_{11}(\boldsymbol{g}_\mathcal{D}\otimes\boldsymbol{n}) : (\boldsymbol{v}\otimes\boldsymbol{n})\, ds,\\
h(q) &:= -\int_{\mathcal{E}_\mathcal{D}} \boldsymbol{g}_\mathcal{D}\cdot\boldsymbol{n}\, q\, ds.
\end{aligned}
$$

Note that, by integration by parts, the forms b and d can also be expressed as

$$
\begin{aligned}
b(\boldsymbol{u},\underline{\tau}) &= -\sum_{K\in\mathcal{T}} \int_K \nabla\boldsymbol{u} : \underline{\tau}\, d\boldsymbol{x} + \int_{\mathcal{E}_i} (\{\!\{\underline{\tau}\}\!\} - [\![\underline{\tau}]\!]\otimes\boldsymbol{C}_{12}) : \underline{[\![\boldsymbol{u}]\!]}\, ds + \int_{\mathcal{E}_\mathcal{D}} \underline{\tau} : (\boldsymbol{u}\otimes\boldsymbol{n})\, ds,\\
d(\boldsymbol{v},p) &= \sum_{K\in\mathcal{T}} \int_K \boldsymbol{v}\cdot\nabla p\, d\boldsymbol{x} - \int_{\mathcal{E}_i} (\{\!\{\boldsymbol{v}\}\!\} + \boldsymbol{D}_{12}[\![\boldsymbol{v}]\!])\cdot[\![p]\!]\, ds.
\end{aligned}
$$

Finally, in order to analyze the method, we write the mixed system (2.11) in the following equivalent form: Find $(\underline{\sigma}_N,\boldsymbol{u}_N,p_N)\in\underline{\Sigma}_N\times\boldsymbol{V}_N\times Q_N$ such that

$$
\mathcal{A}(\underline{\sigma}_N,\boldsymbol{u}_N,p_N;\underline{\tau},\boldsymbol{v},q) = \mathcal{F}(\underline{\tau},\boldsymbol{v},q) \tag{2.12}
$$

for all $(\underline{\tau},\boldsymbol{v},q)\in\underline{\Sigma}_N\times\boldsymbol{V}_N\times Q_N$ by setting

$$
\begin{aligned}
\mathcal{A}(\underline{\sigma},\boldsymbol{u},p;\underline{\tau},\boldsymbol{v},q) &:= a(\underline{\sigma},\underline{\tau}) + b(\boldsymbol{u},\underline{\tau}) - b(\boldsymbol{v},\underline{\sigma}) + c(\boldsymbol{u},\boldsymbol{v}) + d(\boldsymbol{v},p) - d(\boldsymbol{u},q) + e(p,q),\\
\mathcal{F}(\underline{\tau},\boldsymbol{v},q) &:= f(\underline{\tau}) + g(\boldsymbol{v}) + h(q).
\end{aligned}
$$

2.3. Existence and uniqueness of LDG solutions. Next, we show that the LDG method defines a unique approximate solution provided that for each element $K\in\mathcal{T}$ the following mild conditions on the local spaces hold:

$$
u\in\mathcal{V}(K) : \int_K \nabla u\cdot\boldsymbol{v}\, d\boldsymbol{x} = 0 \quad \forall\boldsymbol{v}\in\mathcal{S}^d(K) \quad \text{implies} \quad \nabla u\equiv\boldsymbol{0} \text{ on } K, \tag{2.13}
$$

$$
q\in\mathcal{Q}(K) : \int_K \boldsymbol{v}\cdot\nabla q\, d\boldsymbol{x} = 0 \quad \forall\boldsymbol{v}\in\mathcal{V}^d(K) \quad \text{implies} \quad \nabla q\equiv\boldsymbol{0} \text{ on } K. \tag{2.14}
$$

See [8] for simple examples of local spaces not satisfying the above conditions.

PROPOSITION 2.1 (well-posedness of the LDG method). *Consider the* LDG *method defined by the weak formulation* (2.4)–(2.6) *and by the numerical fluxes given by* (2.7)–(2.10). *Suppose that the coefficients* C_{11} *and* D_{11} *are positive. Finally, assume that the conditions* (2.13) *and* (2.14) *on the local spaces are satisfied. Then the* LDG *method defines a unique approximate solution* $(\underline{\sigma}_N, \boldsymbol{u}_N, p_N) \in \underline{\Sigma}_N \times \boldsymbol{V}_N \times Q_N$.

Proof. It is enough to show that the only possible solution to the system (2.11) with $\boldsymbol{f} = \boldsymbol{0}$ and $\boldsymbol{g}_{\mathcal{D}} = \boldsymbol{0}$ is $(\underline{\sigma}_N, \boldsymbol{u}_N, p_N) = (\underline{0}, \boldsymbol{0}, 0)$. Indeed, taking $\underline{\tau} = \underline{\sigma}_N$, $\boldsymbol{v} = \boldsymbol{u}_N$, $q = p_N$ in (2.11) and adding the three equations yields

$$a(\underline{\sigma}_N, \underline{\sigma}_N) + c(\boldsymbol{u}_N, \boldsymbol{u}_N) + e(p_N, p_N) = 0,$$

which implies $\underline{\sigma}_N = \underline{0}$, $\underline{[\![\boldsymbol{u}_N]\!]} = \underline{0}$ on $\mathcal{E}_i$, $\boldsymbol{u}_N = \boldsymbol{0}$ on $\mathcal{E}_{\mathcal{D}}$, and $[\![p_N]\!] = 0$ on $\mathcal{E}_i$ since the coefficients C_{11} and D_{11} are positive. Consequently, the first equation in (2.11) reads as

$$\sum_{K \in \mathcal{T}} \int_K \nabla \boldsymbol{u}_N : \underline{\tau}\, d\boldsymbol{x} = 0 \qquad \forall \underline{\tau} \in \underline{\Sigma}_N.$$

Assumption (2.13) implies that $\nabla \boldsymbol{u}_N = \underline{0}$ on every $K \in \mathcal{T}$, and, since $\underline{[\![\boldsymbol{u}_N]\!]} = \underline{0}$ on $\mathcal{E}_i$ and $\boldsymbol{u}_N = \boldsymbol{0}$ on $\mathcal{E}_{\mathcal{D}}$, we must have $\boldsymbol{u}_N = \boldsymbol{0}$.

Taking $\underline{\sigma}_N = \underline{0}$ and $\boldsymbol{u}_N = \boldsymbol{0}$, the second equation in (2.11) becomes

$$\sum_{K \in \mathcal{T}} \int_K \boldsymbol{v} \cdot \nabla p_N \, d\boldsymbol{x} = 0 \qquad \forall \boldsymbol{v} \in \boldsymbol{V}_N.$$

Analogously, we conclude from assumption (2.14) that $\nabla p_N = \boldsymbol{0}$ on every $K \in \mathcal{T}$ and, since $[\![p_N]\!] = 0$, that p_N is a constant. Since we also require that $\int_\Omega p_N \, d\boldsymbol{x} = 0$, we conclude that $p_N = 0$. ∎

2.4. A priori estimates. In this section we state and discuss our a priori error bounds for the LDG method. We assume that every element K of the triangulation $\mathcal{T}$ is *affinely equivalent* (see [10, section 2.3]) to one of several reference elements in an arbitrary but fixed set; this allows us to use elements of various shapes with possibly curved boundaries. For each $K \in \mathcal{T}$, we denote by h_K the diameter of K and by ρ_K the diameter of the biggest ball included in K; we set, as usual, $h := \max_{K \in \mathcal{T}} h_K$. The triangulations we consider can have hanging nodes but have to be *regular*; that is, there exists a positive constant σ_1 such that

$$\frac{h_K}{\rho_K} \leq \sigma_1 \qquad \forall\, K \in \mathcal{T} \tag{2.15}$$

(see [10, section 3.1]). Moreover, we let the maximum number of neighbors of a given element K be arbitrary but fixed. To formally state this property, we need to introduce the set $\langle K, K' \rangle$ defined as

$$\langle K, K' \rangle = \begin{cases} \emptyset & \text{if } \mathrm{meas}_{(d-1)}(\partial K \cap \partial K') = 0, \\ \text{interior of } \partial K \cap \partial K' & \text{otherwise.} \end{cases}$$

Thus, we assume that there exists a positive constant $\sigma_2 < 1$ such that, for each element $K \in \mathcal{T}$,

$$\sigma_2 \leq \frac{h_{K'}}{h_K} \leq \sigma_2^{-1} \qquad \forall K' : \langle K, K' \rangle \neq \emptyset\,. \tag{2.16}$$

These three hypotheses allow for quite general triangulations and are not restrictive in practice.

We assume that the local finite element spaces satisfy the following *inclusions* for $i = 1, \dots, d$:

$$\partial_i \mathcal{V}(K) \subseteq \mathcal{S}(K), \quad \partial_i \mathcal{S}(K) \subseteq \mathcal{V}(K), \quad \partial_i \mathcal{V}(K) \subseteq \mathcal{Q}(K), \quad \partial_i \mathcal{Q}(K) \subseteq \mathcal{V}(K). \tag{2.17}$$

Note that (2.17) also implies the assumptions (2.13) and (2.14) on the local spaces.

We denote by $P^\kappa(K)$ the set of all polynomials of degree at most κ on K and by $Q^\kappa(K)$ the polynomials of degree at most κ in each variable. Then, in order to guarantee certain approximation properties of the local spaces, we assume that they contain at least the following polynomial spaces:

$$P^k(K) \subseteq \mathcal{V}(K), \qquad P^l(K) \subseteq \mathcal{S}(K), \qquad P^m(K) \subseteq \mathcal{Q}(K), \tag{2.18}$$

with approximation orders $k \geq 1$ and $l, m \geq 0$. Since $\partial_i P^k(K) \subset P^{k-1}(K)$ and $\partial_i Q^k(K) \subset Q^k(K)$, conditions (2.17) and (2.18) are satisfied, for example, by

$$\mathcal{V}(K) = P^k(K), \qquad \mathcal{S}(K) = P^l(K), \qquad \mathcal{Q}(K) = P^m(K), \tag{2.19}$$

with $k \geq 1$, $l = k$ or $l = k - 1$, and $m = k$ or $m = k - 1$, or by

$$\mathcal{V}(K) = Q^k(K), \qquad \mathcal{S}(K) = Q^k(K), \qquad \mathcal{Q}(K) = Q^k(K), \qquad k \geq 1. \tag{2.20}$$

Next, we introduce a seminorm that appears in a natural way in the analysis of LDG methods. We denote by $H^s(D)$, D being a domain in $\mathbb{R}^d$, the Sobolev spaces of integer orders, and by $\|\cdot\|_{s,D}$ and $|\cdot|_{s,D}$ the usual norms and seminorms in $H^s(D)$, $H^s(D)^d$, and $H^s(D)^{d^2}$; we omit the dependence on the domain in the norms whenever $D = \Omega$. We define

$$|\!|\!| (\underline{\sigma}, \boldsymbol{u}, p) |\!|\!|_{\mathcal{A}}^2 := \|\underline{\sigma}\|_0^2 + \Theta^2(\boldsymbol{u}, p),$$

where

$$\Theta^2(\boldsymbol{u}, p) = \int_{\mathcal{E}_i} \left(C_{11} \underline{[\![\boldsymbol{u}]\!]}^2 + D_{11} [\![p]\!]^2 \right) ds + \int_{\mathcal{E}_\mathcal{D}} C_{11} (\boldsymbol{u} \otimes \boldsymbol{n})^2 \, ds.$$

We assume that the stabilization coefficients C_{11} and D_{11} defining the numerical fluxes in (2.7) and (2.9) are given by

$$C_{11}(\boldsymbol{x}) = \begin{cases} c_{11} \max\{h_{K^+}^{-1}, h_{K^-}^{-1}\} & \text{if } \boldsymbol{x} \in \langle K^+, K^- \rangle, \\ c_{11} h_{K^+}^{-1} & \text{if } \boldsymbol{x} \in \partial K^+ \cap \partial\Omega, \end{cases} \tag{2.21}$$

$$D_{11}(\boldsymbol{x}) = d_{11} \max\{h_{K^+}, h_{K^-}\}, \qquad \boldsymbol{x} \in \langle K^+, K^- \rangle, \tag{2.22}$$

with c_{11} and $d_{11} > 0$ independent of the meshsize and $|\boldsymbol{C}_{12}|$ as well as $|\boldsymbol{D}_{12}|$ of order one.

We are now ready to state our a priori error estimates for the LDG method. The first result is concerned with the error in the seminorm $|\!|\!| \cdot |\!|\!|_{\mathcal{A}}$ and the L^2-error in the pressure.

THEOREM 2.2. *Let* $(\underline{\sigma}, \boldsymbol{u}, p)$ *be the solution of* (1.2)–(1.5) *and let* $(\underline{\sigma}_N, \boldsymbol{u}_N, p_N)$ *be the approximate solution given by the* LDG *method* (2.4)–(2.6) *with numerical fluxes* (2.7)–(2.10). *Assume the hypotheses* (2.15), (2.16) *on the triangulations, the*

hypotheses (2.17), (2.18) *on the local spaces, with approximation orders* $k \geq 1$ *and* $l, m \geq 0$, *and the hypotheses* (2.21), (2.22) *on the form of the stabilization parameters. For* $\underline{\sigma} \in H^{l+1}(\Omega)^{d^2}$, $\boldsymbol{u} \in H^{k+1}(\Omega)^d$, *and* $p \in H^{m+1}(\Omega)$, *we have that the errors* $\underline{e}_\sigma = \underline{\sigma} - \underline{\sigma}_N$, $\boldsymbol{e}_u = \boldsymbol{u} - \boldsymbol{u}_N$, *and* $e_p = p - p_N$ *satisfy*

$$|\,(\underline{e}_\sigma, \boldsymbol{e}_u, e_p)\,|_{\mathcal{A}} + \|e_p\|_0 \leq C\Big[h^{l+1}\|\underline{\sigma}\|_{l+1} + h^k\|\boldsymbol{u}\|_{k+1} + h^{m+1}\|p\|_{m+1}\Big],$$

where the constant C *solely depends on* Ω, σ_1, σ_2, c_{11}, d_{11}, d, *and the dimensions of the local spaces but is independent of the meshsize* h.

To prove a priori bounds for the L^2-error in $\boldsymbol{u}$, we assume elliptic regularity, that is, we assume that the solution $(\boldsymbol{z}, q)$ of the homogeneous Stokes problem

$$-\Delta \boldsymbol{z} + \nabla q = \boldsymbol{\lambda} \qquad \text{in } \Omega, \tag{2.23}$$

$$\nabla \cdot \boldsymbol{z} = 0 \qquad \text{in } \Omega, \tag{2.24}$$

$$\boldsymbol{z} = \boldsymbol{0} \qquad \text{on } \partial\Omega \tag{2.25}$$

with right-hand side $\boldsymbol{\lambda} \in L^2(\Omega)^d$ satisfies the estimate

$$\|\boldsymbol{z}\|_2 + \|q\|_1 \leq C\|\boldsymbol{\lambda}\|_0 \tag{2.26}$$

for a constant $C > 0$ just depending on Ω. For the inequality (2.26) to hold, certain restrictions on Ω are necessary; see, for example, Proposition 2.3 in Témam [32].

THEOREM 2.3. *Under the same assumptions as in Theorem* 2.2 *and the elliptic regularity assumption* (2.26), *we have that*

$$\|\boldsymbol{e}_u\|_0 \leq C\Big[h^{l+2}\|\underline{\sigma}\|_{l+1} + h^{k+1}\|\boldsymbol{u}\|_{k+1} + h^{m+2}\|p\|_{m+1}\Big]$$

with a constant C *that depends solely on* Ω, σ_1, σ_2, c_{11}, d_{11}, d, *the dimensions of the local spaces, and the constant in* (2.26) *but that is independent of the meshsize* h.

Let us briefly discuss the results of Theorems 2.2 and 2.3:

• When P^k- or Q^k-elements with $k \geq 1$ are used for all field variables, i.e, the local spaces are chosen as in (2.19) with $l = k$ and $m = k$ or as in (2.20), we obtain for smooth solutions $\underline{\sigma} \in H^{k+1}(\Omega)^{d^2}$, $\boldsymbol{u} \in H^{k+1}(\Omega)$, $p \in H^{k+1}(\Omega)$ the error bounds

$$|\,(\underline{e}_\sigma, \boldsymbol{e}_u, e_p)\,|_{\mathcal{A}} + \|e_p\|_0 \leq Ch^k, \qquad \|\boldsymbol{e}_u\|_0 \leq Ch^{k+1}.$$

Although these rates are sharp in the sense that they are actually observed in the numerical experiments of section 4, they are not optimal in terms of the approximation properties of the finite element spaces.

• If the P-elements used for $\underline{\sigma}$ and p are of one order lower than the ones used for the velocities $\boldsymbol{u}$, i.e., if we consider P-elements as in (2.19) with $l = m = k - 1$ and $k \geq 1$, then an *optimal*-order error estimate is obtained: for $\underline{\sigma} \in H^k(\Omega)^{d^2}$, $\boldsymbol{u} \in H^{k+1}(\Omega)^d$, and $p \in H^k(\Omega)$ we again have

$$|\,(\underline{e}_\sigma, \boldsymbol{e}_u, e_p)\,|_{\mathcal{A}} + \|e_p\|_0 \leq Ch^k, \qquad \|\boldsymbol{e}_u\|_0 \leq Ch^{k+1},$$

which is optimal in terms of the approximation properties and of the regularity requirements of the exact solution.

• The stabilization parameters C_{11} and D_{11} are taken to be of order $\mathcal{O}(1/h)$ and $\mathcal{O}(h)$, respectively. As can be inferred from our analysis, this choice maximizes the

rates of convergence. For different selections of C_{11} and D_{11}, the obtained orders of convergence are summarized in Table 2.1 for smooth solutions and P^k- or Q^k-elements. On the other hand, our numerical results in Table 5.1 below indicate that for C_{11} and D_{11} of order one the parameters $\boldsymbol{C}_{12}$ and $\boldsymbol{D}_{12}$ can be chosen in such a way that the LDG method superconverges on Cartesian grids and for tensor product polynomials; we rigorously proved this result in [13] for the Laplacian. The extension of the study there to the Stokes system will be addressed in future work.

TABLE 2.1
Orders of convergence for P^k- or Q^k-elements in dependence of C_{11} and D_{11}.

C_{11}	D_{11}	$\lvert\!\lvert\!\lvert (\underline{e}_\sigma, \boldsymbol{e}_u, e_p) \rvert\!\rvert\!\rvert_{\mathcal{A}}$	$\lVert e_p \rVert_0$	$\lVert \boldsymbol{e}_u \rVert_0$
$\mathcal{O}(1), \mathcal{O}(1/h)$	$\mathcal{O}(1)$	k	k	$k+1/2$
$\mathcal{O}(1)$	$\mathcal{O}(h)$	k	k	$k+1/2$
$\mathcal{O}(1/h)$	$\mathcal{O}(h)$	k	k	$k+1$

2.5. The setting for the error analysis. The purpose of this section is to display as clearly as possible the main ingredients of the proof of our a priori results in section 2.4. To do so, we base our analysis on an abstract setting similar to the one introduced in [8] for the Laplacian.

We split the error $(\underline{e}_\sigma, \boldsymbol{e}_u, e_p) = (\underline{\sigma} - \underline{\sigma}_N, \boldsymbol{u} - \boldsymbol{u}_N, p - p_N)$ into the following sum:

$$(\underline{e}_\sigma, \boldsymbol{e}_u, e_p) = (\underline{\sigma} - \underline{\Pi}\underline{\sigma}, \boldsymbol{u} - \boldsymbol{\Pi}\boldsymbol{u}, p - \Pi p) + (\underline{\Pi}\underline{e}_\sigma, \boldsymbol{\Pi}\boldsymbol{e}_u, \Pi e_p),$$

where $\underline{\Pi} : \underline{\Sigma} \to \underline{\Sigma}_N$, $\boldsymbol{\Pi} : \boldsymbol{V} \to \boldsymbol{V}_N$, and $\Pi : Q \to Q_N$ are fixed projections onto the corresponding finite element spaces.

The basic ingredients. The basic ingredients of our error analysis are two. The first one is, as it is classical in finite element error analysis, the so-called Galerkin orthogonality property, namely,

$$\mathcal{A}(\underline{e}_\sigma, \boldsymbol{e}_u, e_p; \underline{\tau}, \boldsymbol{v}, q) = 0 \qquad \forall (\underline{\tau}, \boldsymbol{v}, q) \in \underline{\Sigma}_N \times \boldsymbol{V}_N \times Q_N. \tag{2.27}$$

This property is a straightforward consequence of the consistency of the numerical fluxes and is valid since $(\boldsymbol{u}, p) \in H^2(\Omega)^d \times H^1(\Omega)$.

The second ingredient is a couple of inequalities that reflect the approximation properties of the projections $\underline{\Pi}$, $\boldsymbol{\Pi}$, and Π; namely, we assume that there exist error bounds $K_{\mathcal{A}}$ and $K_{\mathcal{B}}$ such that

$$\lvert\!\lvert\!\lvert \mathcal{A}(\underline{\sigma} - \underline{\Pi}\underline{\sigma}, \boldsymbol{u} - \boldsymbol{\Pi}\boldsymbol{u}, p - \Pi p; \underline{\tau} - \underline{\Pi}\underline{\tau}, \boldsymbol{v} - \boldsymbol{\Pi}\boldsymbol{v}, q - \Pi q) \rvert\!\rvert\!\rvert \le C K_{\mathcal{A}}(\underline{\sigma}, \boldsymbol{u}, p; \underline{\tau}, \boldsymbol{v}, q) \tag{2.28}$$

for any $(\underline{\sigma}, \boldsymbol{u}, p)$, $(\underline{\tau}, \boldsymbol{v}, q) \in \underline{\Sigma} \times \boldsymbol{V} \times Q$, and

$$\lvert\!\lvert\!\lvert \mathcal{A}(\underline{\sigma} - \underline{\Pi}\underline{\sigma}, \pm(\boldsymbol{u} - \boldsymbol{\Pi}\boldsymbol{u}), p - \Pi p; \underline{\tau}, \pm\boldsymbol{v}, q) \rvert\!\rvert\!\rvert \le C \lvert\!\lvert\!\lvert (\underline{\tau}, \boldsymbol{v}, q) \rvert\!\rvert\!\rvert_{\mathcal{A}} \, K_{\mathcal{B}}(\underline{\sigma}, \boldsymbol{u}, p) \tag{2.29}$$

for any $(\underline{\tau}, \boldsymbol{v}, q) \in \underline{\Sigma}_N \times \boldsymbol{V}_N \times Q_N$ and $(\underline{\sigma}, \boldsymbol{u}, p) \in \underline{\Sigma} \times \boldsymbol{V} \times Q$ and with constants C which are independent of the meshsize (specific forms for $K_{\mathcal{A}}$ and $K_{\mathcal{B}}$ shall be provided below). As we show next, all the error estimates we are interested in can be obtained in terms of $K_{\mathcal{A}}$ and $K_{\mathcal{B}}$.

Error in the $\mathcal{A}$-seminorm. The error in $|\cdot|_{\mathcal{A}}$ can be estimated as follows.

LEMMA 2.4. *We have*

$$|\,(\underline{e}_\sigma, \boldsymbol{e}_u, e_p)\,|_{\mathcal{A}} \le CK_{\mathcal{A}}^{1/2}(\underline{\sigma}, \boldsymbol{u}, p; \underline{\sigma}, \boldsymbol{u}, p) + CK_{\mathcal{B}}(\underline{\sigma}, \boldsymbol{u}, p),$$

with C independent of the meshsize.

Proof. This is a straightforward extension of [8, Lemma 2.3]. We present the proof for the sake of completeness. Since $|\,(\cdot,\cdot,\cdot)\,|_{\mathcal{A}}$ is a seminorm, we have

$$|\,(\underline{e}_\sigma, \boldsymbol{e}_u, e_p)\,|_{\mathcal{A}} \le |\,(\underline{\sigma} - \underline{\Pi\sigma}, \boldsymbol{u} - \boldsymbol{\Pi u}, p - \Pi p)\,|_{\mathcal{A}} + |\,(\underline{\Pi e}_\sigma, \boldsymbol{\Pi e}_u, \Pi e_p)\,|_{\mathcal{A}}.$$

By the definition of $\mathcal{A}$ in (2.12), by Galerkin orthogonality (2.27), and by assumption (2.29),

$$\begin{aligned}|\,(\underline{\Pi e}_\sigma, \boldsymbol{\Pi e}_u, \Pi e_p)\,|_{\mathcal{A}}^2 =& \mathcal{A}(\underline{\Pi e}_\sigma, \boldsymbol{\Pi e}_u, \Pi e_p; \underline{\Pi e}_\sigma, \boldsymbol{\Pi e}_u, \Pi e_p)\\ =& \mathcal{A}(\underline{\Pi\sigma} - \underline{\sigma}, \boldsymbol{\Pi u} - \boldsymbol{u}, \Pi p - p; \underline{\Pi e}_\sigma, \boldsymbol{\Pi e}_u, \Pi e_p)\\ \le& C|\,(\underline{\Pi e}_\sigma, \boldsymbol{\Pi e}_u, \Pi e_p)\,|_{\mathcal{A}} K_{\mathcal{B}}(\underline{\sigma}, \boldsymbol{u}, p),\end{aligned}$$

we have that

$$|\,(\underline{\Pi e}_\sigma, \boldsymbol{\Pi e}_u, \Pi e_p)\,|_{\mathcal{A}} \le CK_{\mathcal{B}}(\underline{\sigma}, \boldsymbol{u}, p), \tag{2.30}$$

and so

$$|\,(\underline{e}_\sigma, \boldsymbol{e}_u, e_p)\,|_{\mathcal{A}} \le |\,(\underline{\sigma} - \underline{\Pi\sigma}, \boldsymbol{u} - \boldsymbol{\Pi u}, p - \Pi p)\,|_{\mathcal{A}} + CK_{\mathcal{B}}(\underline{\sigma}, \boldsymbol{u}, p).$$

The estimate now follows from a simple application of assumption (2.28). This completes the proof. ∎

Error in the pressure. To obtain an error estimate in the pressure, we shall prove a stability result which allows us to measure the error of the pressure in the L^2-norm. It can be viewed as a discrete counterpart of the standard continuous inf–sup condition for the Stokes problem (see, e.g., [6, 24]), adapted to the discontinuous spaces considered here. Its proof is obtained by following the techniques used by Franca and Stenberg [23] in section 3.4 below.

PROPOSITION 2.5. *There exist positive constants κ_1 and κ_2 independent of the meshsize such that for all $(\underline{\tau}, \boldsymbol{v}, q) \in \underline{\Sigma}_N \times \boldsymbol{V}_N \times Q_N$ there is a $\boldsymbol{w} \in \boldsymbol{V}_N$ with*

$$\mathcal{A}(\underline{\tau}, \boldsymbol{v}, q; \underline{0}, \boldsymbol{w}, 0) \ge \kappa_1 \|q\|_0^2 - \kappa_2 |\,(\underline{\tau}, \boldsymbol{v}, q)\,|_{\mathcal{A}}^2, \quad |\,(\underline{0}, \boldsymbol{w}, 0)\,|_{\mathcal{A}} = \Theta(\boldsymbol{w}, 0) \le \|q\|_0. \tag{2.31}$$

Based on this inf-sup condition we obtain the following estimate for e_p.

LEMMA 2.6. *We have*

$$\|e_p\|_0 \le \|p - \Pi p\|_0 + CK_{\mathcal{B}}(\underline{\sigma}, \boldsymbol{u}, p),$$

with C independent of the meshsize.

Proof. We only have to find an estimate for $\|\Pi e_p\|_0$, since we trivially have $\|p - p_N\|_0 \le \|p - \Pi p\|_0 + \|\Pi e_p\|_0$. To do that, we see that by Proposition 2.5 there exists a test function $\boldsymbol{w} \in \boldsymbol{V}_N$ such that (2.31) is satisfied for $(\underline{\tau}, \boldsymbol{v}, q) = (\underline{\Pi e}_\sigma, \boldsymbol{\Pi e}_u, \Pi e_p)$. By

(2.31), Galerkin orthogonality (2.27), assumption (2.29), estimate (2.30), the Cauchy–Schwarz inequality, and the properties of $\boldsymbol{w}$, we obtain

$$\begin{aligned}\kappa_1\|\Pi e_p\|_0^2 &\le \mathcal{A}(\underline{\Pi e}_\sigma, \boldsymbol{\Pi e}_u, \Pi e_p; \underline{0}, \boldsymbol{w}, 0) + \kappa_2 |\,(\underline{\Pi e}_\sigma, \boldsymbol{\Pi e}_u, \Pi e_p)\,|_{\mathcal{A}}^2 \\ &= \mathcal{A}(\underline{\Pi\sigma} - \underline{\sigma}, \boldsymbol{\Pi u} - \boldsymbol{u}, \Pi p - p; 0, \boldsymbol{w}, 0) + \kappa_2 |\,(\underline{\Pi e}_\sigma, \boldsymbol{\Pi e}_u, \Pi e_p)\,|_{\mathcal{A}}^2 \\ &\le C_1 |\,(\underline{0}, \boldsymbol{w}, 0)\,|_{\mathcal{A}} K_{\mathcal{B}}(\underline{\sigma}, \boldsymbol{u}, p) + C_2 K_{\mathcal{B}}(\underline{\sigma}, \boldsymbol{u}, p)^2 \\ &\le \frac{C_1}{2\varepsilon}\|\Pi e_p\|_0^2 + \Big(C_1\frac{\varepsilon}{2} + C_2\Big) K_{\mathcal{B}}(\underline{\sigma}, \boldsymbol{u}, p)^2\end{aligned}$$

for all $\varepsilon > 0$. We can now choose ε in such a way that

$$\|\Pi e_p\|_0 \le C K_{\mathcal{B}}(\underline{\sigma}, \boldsymbol{u}, p)$$

with a constant C depending on C_1 and C_2. The assertion follows. ∎

Error in the velocity. The estimate for the error $\|\boldsymbol{e}_u\|_0$ is based on a duality argument similar to the one used in [8].

LEMMA 2.7. *Assume that the elliptic regularity inequality* (2.26) *holds. Then we have*

$$\|\boldsymbol{e}_u\|_0 \le C \sup_{\boldsymbol{\lambda}\in L^2(\Omega)^d} \frac{K_{\mathcal{A}}(\underline{\sigma}, \boldsymbol{u}, p; \underline{\zeta}, \boldsymbol{z}, \widetilde{q})}{\|\boldsymbol{\lambda}\|_0} + C K_{\mathcal{B}}(\underline{\sigma}, \boldsymbol{u}, p) \sup_{\boldsymbol{\lambda}\in L^2(\Omega)^d} \frac{K_{\mathcal{B}}(\underline{\zeta}, \boldsymbol{z}, \widetilde{q})}{\|\boldsymbol{\lambda}\|_0}, \tag{2.32}$$

with $(\boldsymbol{z}, q)$ *denoting the solution of* (2.23)–(2.25) *with right-hand side* $\boldsymbol{\lambda}$ *and* $\underline{\zeta} = -\nabla\boldsymbol{z}$, $\widetilde{q} = -q$.

Proof. We introduce the linear functional $\Lambda(\boldsymbol{u}) = (\boldsymbol{\lambda}, \boldsymbol{u})$, where $(\cdot,\cdot)$ denotes the $L^2(\Omega)^d$-inner product. Then we have

$$\|\boldsymbol{e}_u\|_0 = \sup_{\boldsymbol{\lambda}\in L^2(\Omega)^d} \frac{\Lambda(\boldsymbol{e}_u)}{\|\boldsymbol{\lambda}\|_0}. \tag{2.33}$$

Now, let $(\boldsymbol{z}, q)$ be the solution of the adjoint equation (2.23)–(2.25) with right-hand side $\boldsymbol{\lambda}$. It is easy to verify that, if we set $\underline{\zeta} = -\nabla\boldsymbol{z}$, $\widetilde{q} = -q$, we have

$$\mathcal{A}(-\underline{\zeta}, \boldsymbol{z}, -\widetilde{q}; -\underline{\tau}, \boldsymbol{w}, -r) = \Lambda(\boldsymbol{w})$$

for all $(\underline{\tau}, \boldsymbol{w}, r) \in \underline{\Sigma} \times \boldsymbol{V} \times Q$. Taking $(\underline{\tau}, \boldsymbol{w}, r) = (\underline{e}_\sigma, \boldsymbol{e}_u, e_p)$, we get by the definition of $\mathcal{A}$ in (2.12) and by Galerkin orthogonality (2.27)

$$\begin{aligned}\Lambda(\boldsymbol{e}_u) =& \mathcal{A}(-\underline{\zeta}, \boldsymbol{z}, -\widetilde{q}; -\underline{e}_\sigma, \boldsymbol{e}_u, -e_p) \\ =& \mathcal{A}(\underline{e}_\sigma, \boldsymbol{e}_u, e_p; \underline{\zeta}, \boldsymbol{z}, \widetilde{q}) \\ =& \mathcal{A}(\underline{e}_\sigma, \boldsymbol{e}_u, e_p; \underline{\zeta} - \underline{\Pi\zeta}, \boldsymbol{z} - \boldsymbol{\Pi z}, \widetilde{q} - \Pi\widetilde{q}) \\ =& \mathcal{A}(\underline{\Pi e}_\sigma, \boldsymbol{\Pi e}_u, \Pi e_p; \underline{\zeta} - \underline{\Pi\zeta}, \boldsymbol{z} - \boldsymbol{\Pi z}, \widetilde{q} - \Pi\widetilde{q}) \\ &+ \mathcal{A}(\underline{\sigma} - \underline{\Pi\sigma}, \boldsymbol{u} - \boldsymbol{\Pi u}, p - \Pi p; \underline{\zeta} - \underline{\Pi\zeta}, \boldsymbol{z} - \boldsymbol{\Pi z}, \widetilde{q} - \Pi\widetilde{q}).\end{aligned}$$

We obtain with assumption (2.29) and estimate (2.30)

$$\begin{aligned}&|\,\mathcal{A}(\underline{\Pi e}_\sigma, \boldsymbol{\Pi e}_u, \Pi e_p; \underline{\zeta} - \underline{\Pi\zeta}, \boldsymbol{z} - \boldsymbol{\Pi z}, \widetilde{q} - \Pi\widetilde{q})| \\ &= |\,\mathcal{A}(\underline{\zeta} - \underline{\Pi\zeta}, -(\boldsymbol{z} - \boldsymbol{\Pi z}), \widetilde{q} - \Pi\widetilde{q}; \underline{\Pi e}_\sigma, -\boldsymbol{\Pi e}_u, \Pi e_p)\,| \le C K_{\mathcal{B}}(\underline{\sigma}, \boldsymbol{u}, p)\, K_{\mathcal{B}}(\underline{\zeta}, \boldsymbol{z}, \widetilde{q}),\end{aligned}$$

and hence

$$|\,\Lambda(\boldsymbol{e}_u)\,| \le CK_{\mathcal{B}}(\underline{\sigma},\boldsymbol{u},p)\,K_{\mathcal{B}}(\underline{\zeta},\boldsymbol{z},\widetilde{q}\,) + |\,\mathcal{A}(\underline{\sigma}-\underline{\Pi\sigma},\boldsymbol{u}-\boldsymbol{\Pi u},p-\Pi p;\underline{\zeta}-\underline{\Pi\zeta},\boldsymbol{z}-\boldsymbol{\Pi z},\widetilde{q}-\Pi\widetilde{q}\,)\,|.$$

The estimate now follows from a simple application of assumption (2.28) and from the characterization (2.33) of the L^2-norm. ∎

Conclusion. Thus, in order to prove our a priori estimates, all we need to do is to obtain the functionals $K_{\mathcal{A}}$ and $K_{\mathcal{B}}$ as well as the stability estimate in Proposition 2.5; this will be carried out in the next section. Then Theorems 2.2 and 2.3 will immediately follow after a simple application of Lemmas 2.4, 2.6, and 2.7.

3. Proofs. In this section, we prove our main results in the setting of section 2.5. We proceed as follows. After presenting some preliminary results, we obtain the functional $K_{\mathcal{A}}$ for general projection operators $\underline{\Pi}$, $\boldsymbol{\Pi}$, and Π. To obtain the functional $K_{\mathcal{B}}$, the projections $\underline{\Pi}$, $\boldsymbol{\Pi}$, and Π are chosen as L^2-projections.

3.1. Preliminaries. The following two lemmas contain all the information we actually use about our finite elements. The first one is a standard approximation result, valid for any linear continuous and polynomial preserving operator Π from $H^{s+1}(K)$ onto a finite-dimensional space $\mathcal{N}(K) \supset P^\kappa(K)$; it can be easily obtained by using the techniques of [10]. The second one is a standard inverse inequality.

LEMMA 3.1. *Let Π be a linear continuous operator from $H^{s+1}(K)$, $s \ge 0$, onto $\mathcal{N}(K) \supset P^\kappa(K)$ such that $\Pi w = w$ for all $w \in P^\kappa(K)$, $\kappa \ge 0$. Then we have*

$$|w-\Pi w|_{r,K} \le Ch_K^{\min(s,\kappa)+1-r}\|w\|_{s+1,K}, \qquad r=0,1,$$
$$\|w-\Pi w\|_{0,\partial K} \le Ch_K^{\min(s,\kappa)+\frac{1}{2}}\|w\|_{s+1,K}$$

for some constant C that solely depends on σ_1 in inequality (2.15)*, the dimension of $\mathcal{N}(K)$, d, and s.*

LEMMA 3.2. *There exists a positive constant C_{inv} that depends solely on σ_1 in inequality* (2.15)*, the dimension of $\mathcal{N}(K)$, and d such that for all $s \in \mathcal{N}(K)$ we have $\|s\|_{0,\partial K} \le C_{\mathrm{inv}}h_K^{-1/2}\|s\|_{0,K}$ for all $K \in \mathcal{T}$.*

Let $\underline{\Pi} : \underline{\Sigma} \to \underline{\Sigma}_N$, $\boldsymbol{\Pi} : \boldsymbol{V} \to \boldsymbol{V}_N$, and $\Pi : Q \to Q_N$ be projection operators onto the corresponding finite element spaces satisfying (componentwise) the assumptions in Lemma 3.1. We will make use of the following shorthand notation:

$$\underline{\xi}_\sigma = \underline{\sigma}-\underline{\Pi\sigma}, \qquad \boldsymbol{\xi}_u = \boldsymbol{u}-\boldsymbol{\Pi u}, \qquad \xi_p = p-\Pi p$$

for $(\underline{\sigma},\boldsymbol{u},p) \in \underline{\Sigma}\times\boldsymbol{V}\times Q$. We also define the quantities

$$\underline{C}_{11}^{\partial K} := \inf\{C_{11}(\boldsymbol{x}) : \boldsymbol{x} \in \partial K\}, \qquad \overline{C}_{11}^{\partial K} := \sup\{C_{11}(\boldsymbol{x}) : \boldsymbol{x} \in \partial K\},$$
$$\underline{D}_{11}^{\partial K} := \inf\{D_{11}(\boldsymbol{x}) : \boldsymbol{x} \in \partial K \setminus \partial\Omega\}, \qquad \overline{D}_{11}^{\partial K} := \sup\{D_{11}(\boldsymbol{x}) : \boldsymbol{x} \in \partial K \setminus \partial\Omega\}.$$

3.2. The functional $K_{\mathcal{A}}$. Using Cauchy–Schwarz's inequality, the approximation properties in Lemma 3.1 and the assumptions (2.15) and (2.16) on the meshes, we can prove, in exactly the same way as in [8, section 3.2], the following approximation results for the LDG forms.

LEMMA 3.3. *Assume* (2.15)*,* (2.16)*, and* (2.18)*. Let $\underline{\Pi}$, $\boldsymbol{\Pi}$, and Π be projection operators satisfying (componentwise with $\kappa = k$, $\kappa = l$, and $\kappa = m$, respectively) the*

assumptions in Lemma 3.1. *Let* $\underline{\sigma} \in H^{r+1}(\Omega)^{d^2}$, $\underline{\tau} \in H^{\overline{r}+1}(\Omega)^{d^2}$, $\boldsymbol{u} \in H^{s+1}(\Omega)^d$, $\boldsymbol{v} \in H^{\overline{s}+1}(\Omega)^d$, $p \in H^{t+1}(\Omega)$, *and* $q \in H^{\overline{t}+1}(\Omega)$ *for* r, $\overline{r}$, s, $\overline{s}$, t, $\overline{t} \geq 0$. *Then we have*

$$|a(\underline{\xi}_\sigma, \underline{\xi}_\tau)| \leq C \left(\sum_{K\in\mathcal{T}} h_K^{2\min(r,l)+2} \|\underline{\sigma}\|_{r+1,K}^2 \right)^{\frac{1}{2}} \left(\sum_{K\in\mathcal{T}} h_K^{2\min(\overline{r},l)+2} \|\underline{\tau}\|_{\overline{r}+1,K}^2 \right)^{\frac{1}{2}},$$

$$|b(\boldsymbol{\xi}_u, \underline{\xi}_\tau)| \leq C \left(\sum_{K\in\mathcal{T}} h_K^{2\min(s,k)} \|\boldsymbol{u}\|_{s+1,K}^2 \right)^{\frac{1}{2}} \left(\sum_{K\in\mathcal{T}} h_K^{2\min(\overline{r},l)+2} \|\underline{\tau}\|_{\overline{r}+1,K}^2 \right)^{\frac{1}{2}},$$

$$|c(\boldsymbol{\xi}_u, \boldsymbol{\xi}_v)| \leq C \left(\sum_{K\in\mathcal{T}} \overline{C}_{11}^{\partial K} h_K^{2\min(s,k)+1} \|\boldsymbol{u}\|_{s+1,K}^2 \right)^{\frac{1}{2}} \left(\sum_{K\in\mathcal{T}} \overline{C}_{11}^{\partial K} h_K^{2\min(\overline{s},k)+1} \|\boldsymbol{v}\|_{\overline{s}+1,K}^2 \right)^{\frac{1}{2}},$$

$$|d(\boldsymbol{\xi}_u, \xi_q)| \leq C \left(\sum_{K\in\mathcal{T}} h_K^{2\min(s,k)} \|\boldsymbol{u}\|_{s+1,K}^2 \right)^{\frac{1}{2}} \left(\sum_{K\in\mathcal{T}} h_K^{2\min(\overline{t},m)+2} \|q\|_{\overline{t}+1,K}^2 \right)^{\frac{1}{2}},$$

$$|e(\xi_p, \xi_q)| \leq C \left(\sum_{K\in\mathcal{T}} \overline{D}_{11}^{\partial K} h_K^{2\min(t,m)+1} \|p\|_{t+1,K}^2 \right)^{\frac{1}{2}} \left(\sum_{K\in\mathcal{T}} \overline{D}_{11}^{\partial K} h_K^{2\min(\overline{t},m)+1} \|q\|_{\overline{t}+1,K}^2 \right)^{\frac{1}{2}},$$

with constants C *independent of the meshsize.*

For the special form of C_{11} and D_{11} proposed in (2.21) and (2.22), respectively, we have as a consequence of Lemma 3.3 and (2.16) the following result.

COROLLARY 3.4. *Under the same assumptions as in Lemma* 3.3 *and for coefficients* C_{11} *and* D_{11} *of the form* (2.21) *and* (2.22), *respectively, we have*

$$\begin{aligned}
|a(\underline{\xi}_\sigma, \underline{\xi}_\tau)| &\leq C h^{\min(r,l)+\min(\overline{r},l)+2} \|\underline{\sigma}\|_{r+1} \|\underline{\tau}\|_{\overline{r}+1},\\
|b(\boldsymbol{\xi}_u, \underline{\xi}_\tau)| &\leq C h^{\min(s,k)+\min(\overline{r},l)+1} \|\boldsymbol{u}\|_{s+1} \|\underline{\tau}\|_{\overline{r}+1},\\
|c(\boldsymbol{\xi}_u, \boldsymbol{\xi}_v)| &\leq c_{11} C h^{\min(s,k)+\min(\overline{s},k)} \|\boldsymbol{u}\|_{s+1} \|\boldsymbol{v}\|_{\overline{s}+1},\\
|d(\boldsymbol{\xi}_u, \xi_q)| &\leq C h^{\min(s,k)+\min(\overline{t},m)+1} \|\boldsymbol{u}\|_{s+1} \|q\|_{\overline{t}+1},\\
|e(\xi_p, \xi_q)| &\leq d_{11} C h^{\min(t,m)+\min(\overline{t},m)+2} \|p\|_{t+1} \|q\|_{\overline{t}+1},
\end{aligned}$$

with constants C *independent of the meshsize.*

From Corollary 3.4 we immediately obtain a general expression for the functional $K_{\mathcal{A}}$ since

$$\begin{aligned}
\mathcal{A}(\underline{\xi}_\sigma, \boldsymbol{\xi}_u, \xi_p; \underline{\xi}_\tau, \boldsymbol{\xi}_v, \xi_q) &= a(\underline{\xi}_\sigma, \underline{\xi}_\tau) + b(\boldsymbol{\xi}_u, \underline{\xi}_\tau) - b(\boldsymbol{\xi}_v, \underline{\xi}_\sigma)\\
&\quad + c(\boldsymbol{\xi}_u, \boldsymbol{\xi}_v) + d(\boldsymbol{\xi}_v, \xi_p) - d(\boldsymbol{\xi}_u, \xi_q) + e(\xi_p, \xi_q).
\end{aligned} \tag{3.1}$$

In the situations encountered in Lemmas 2.4 and 2.7 we obtain the following results.

COROLLARY 3.5. *Assume* (2.15), (2.16), *and* (2.18) *with approximation orders* $k \geq 1$, $l, m \geq 0$. *Assume the coefficients* C_{11} *and* D_{11} *to be of the form* (2.21) *and* (2.22), *respectively. Let* $\underline{\Pi}$, $\boldsymbol{\Pi}$, *and* Π *be projection operators as in Lemma* 3.3. *Let* $\underline{\sigma} \in H^{l+1}(\Omega)^{d^2}$, $\boldsymbol{u} \in H^{k+1}(\Omega)^d$, *and* $p \in H^{m+1}(\Omega)$. *Then we have in Lemma* 2.4

$$K_{\mathcal{A}}(\underline{\sigma}, \boldsymbol{u}, p; \underline{\sigma}, \boldsymbol{u}, p) \leq C \Big[h^{2l+2} \|\underline{\sigma}\|_{l+1}^2 + h^{2k} \|\boldsymbol{u}\|_{k+1}^2 + h^{2m+2} \|p\|_{m+1}^2 \Big].$$

Furthermore, assume the elliptic regularity inequality (2.26) *and let* $(\boldsymbol{z}, q)$ *denote the solution of* (2.23)–(2.25) *with right-hand side* $\boldsymbol{\lambda} \in L^2(\Omega)^d$, $\underline{\zeta} = -\nabla \boldsymbol{z}$, $\widetilde{q} = -q$. *Then*

we have in Lemma 2.7

$$K_{\mathcal{A}}(\underline{\sigma}, \boldsymbol{u}, p; \underline{\zeta}, \boldsymbol{z}, \widetilde{q}) \leq C\Big[h^{2+l}\|\underline{\sigma}\|_{l+1} + h^{1+k}\|\boldsymbol{u}\|_{k+1} + h^{2+m}\|p\|_{m+1}\Big]\|\boldsymbol{\lambda}\|_0.$$

Proof. The assertions follow immediately from Corollary 3.4, the identity (3.1), the choice of the coefficients C_{11} and D_{11}, and from the elliptic regularity estimate (2.26) which yields $\|\underline{\zeta}\|_1 + \|\boldsymbol{u}\|_2 + \|\widetilde{q}\|_1 \leq C\|\boldsymbol{\lambda}\|_0$. ∎

3.3. The functional $K_{\mathcal{B}}$. In this subsection we determine the functional $K_{\mathcal{B}}$ reflecting the approximation properties in (2.29). We start by investigating the forms a, c, and d. Lemma 3.1 and Cauchy–Schwarz's inequality immediately give the following estimates.

LEMMA 3.6. *Assume* (2.15), (2.16), *and* (2.18). *Let* $\underline{\Pi}$, $\boldsymbol{\Pi}$, *and* Π *be projection operators satisfying (componentwise with* $\kappa = k$, $\kappa = l$, *and* $\kappa = m$, *respectively) the assumptions in Lemma* 3.1. *Let* $\underline{\sigma} \in H^{r+1}(\Omega)^{d^2}$, $\boldsymbol{u} \in H^{s+1}(\Omega)^d$, *and* $p \in H^{t+1}(\Omega)$ *for* r, s, $t \geq 0$. *Then we have*

$$\begin{aligned}
|a(\underline{\xi}_\sigma, \underline{\tau})| &\leq C\left(\sum_{K\in\mathcal{T}} h_K^{2\min(r,l)+2}\|\underline{\sigma}\|_{r+1,K}^2\right)^{\frac{1}{2}} \|\underline{\tau}\|_0 && \forall\ \underline{\tau} \in \underline{\Sigma},\\
|c(\boldsymbol{\xi}_u, \boldsymbol{v})| &\leq C\left(\sum_{K\in\mathcal{T}} \overline{C}_{11}^{\partial K} h_K^{2\min(s,k)+1}\|\boldsymbol{u}\|_{s+1,K}^2\right)^{\frac{1}{2}} \Theta(\boldsymbol{v}, 0) && \forall \boldsymbol{v} \in \boldsymbol{V},\\
|e(\xi_p, q)| &\leq C\left(\sum_{K\in\mathcal{T}} \overline{D}_{11}^{\partial K} h_K^{2\min(t,m)+1}\|p\|_{t+1,K}^2\right)^{\frac{1}{2}} \Theta(\boldsymbol{0}, q) && \forall q \in Q,
\end{aligned}$$

with constants C *independent of the meshsize.*

Next, we estimate the forms b and d in the case where $\underline{\Pi} : \underline{\Sigma} \to \underline{\Sigma}_N$, $\boldsymbol{\Pi} : \boldsymbol{V} \to \boldsymbol{V}_N$, and $\Pi : Q \to Q_N$ are chosen to be L^2-projections. Note that these projections clearly satisfy the assumptions of Lemma 3.1. It is also important to note that this is the *only* part of our analysis in which we actually use the inclusion properties (2.17).

LEMMA 3.7. *Assume* (2.15), (2.16) *and* (2.17), (2.18). *Let* $\underline{\Pi}$, $\boldsymbol{\Pi}$, *and* Π *be the (componentwise)* L^2*-projections onto the corresponding finite element spaces. Let* $\underline{\sigma} \in H^{r+1}(\Omega)^{d^2}$, $\boldsymbol{u} \in H^{s+1}(\Omega)^d$, *and* $p \in H^{t+1}(\Omega)$ *for* r, s, $t \geq 0$. *Then we have*

$$\begin{aligned}
|b(\boldsymbol{\xi}_u, \underline{\tau})| &\leq C\left(\sum_{K\in\mathcal{T}} h_K^{2\min(s,k)}\|\boldsymbol{u}\|_{s+1,K}^2\right)^{\frac{1}{2}} \|\underline{\tau}\|_0 && \forall\ \underline{\tau} \in \underline{\Sigma}_N,\\
|b(\boldsymbol{v}, \underline{\xi}_\sigma)| &\leq C\left(\sum_{K\in\mathcal{T}} \frac{1}{\underline{C}_{11}^{\partial K}} h_K^{2\min(r,l)+1}\|\underline{\sigma}\|_{r+1,K}^2\right)^{\frac{1}{2}} \Theta(\boldsymbol{v}, 0) && \forall \boldsymbol{v} \in \boldsymbol{V}_N,\\
|d(\boldsymbol{\xi}_u, q)| &\leq C\left(\sum_{K\in\mathcal{T}} \frac{1}{\underline{D}_{11}^{\partial K}} h_K^{2\min(s,k)+1}\|\boldsymbol{u}\|_{s+1,K}^2\right)^{\frac{1}{2}} \Theta(\boldsymbol{0}, q) && \forall q \in Q_N,\\
|d(\boldsymbol{v}, \xi_p)| &\leq C\left(\sum_{K\in\mathcal{T}} \frac{1}{\underline{C}_{11}^{\partial K}} h_K^{2\min(t,m)+1}\|p\|_{t+1,K}^2\right)^{\frac{1}{2}} \Theta(\boldsymbol{v}, 0) && \forall \boldsymbol{v} \in \boldsymbol{V}_N,
\end{aligned}$$

with constants C *independent of the meshsize.*

Proof. We start by proving the estimates for the form b. We note that $\int_K (\boldsymbol{u} - \boldsymbol{\Pi u}) \cdot \nabla \cdot \underline{\tau}\, d\boldsymbol{x} = 0$ due to the properties of the L^2-projection and the inclusion property $\partial_i \mathcal{S}(K) \subset \mathcal{V}(K)$ in (2.17). Therefore, using the fact that $\boldsymbol{C}_{12}$ is of order one, a repeated application of Cauchy–Schwarz's inequality gives

$$\begin{aligned}
|b(\boldsymbol{\xi}_u, \underline{\tau})| &= \left| \int_{\mathcal{E}_i} (\{\!\{\boldsymbol{\xi}_u\}\!\} + \underline{[\![\boldsymbol{\xi}_u]\!]} \cdot \boldsymbol{C}_{12}) \cdot [\![\underline{\tau}]\!]\, ds \right| \\
&\le C \left(\sum_{K \in \mathcal{T}} h_K^{-1} \|\boldsymbol{\xi}_u\|_{0,\partial K}^2 \right)^{\frac{1}{2}} \left(\sum_{K \in \mathcal{T}} \widehat{h}_K \|\underline{\tau}\|_{0,\partial K}^2 \right)^{\frac{1}{2}},
\end{aligned}$$

where $\widehat{h}_K = \sup\{h_{K'} : \langle K, K' \rangle \neq \emptyset\}$. Assumption (2.16) implies that $\widehat{h}_K \le \sigma_2^{-1} h_K$, and therefore, the desired estimate follows from Lemma 3.1 and the inverse inequality in Lemma 3.2.

Furthermore, we also note that $\int_K \nabla \boldsymbol{v} : (\underline{\sigma} - \underline{\Pi\sigma})\, d\boldsymbol{x} = 0$, since $\underline{\Pi}|_K$ is the L^2-projection into $\mathcal{S}(K)$ and $\partial_i \mathcal{V}(K) \subset \mathcal{S}(K)$ in (2.17). Thus, we obtain

$$\begin{aligned}
|b(\boldsymbol{v}, \underline{\xi}_\sigma)| &= \left| \int_{\mathcal{E}_i} (\{\!\{\underline{\xi}_\sigma\}\!\} - [\![\underline{\xi}_\sigma]\!] \otimes \boldsymbol{C}_{12}) : \underline{[\![\boldsymbol{v}]\!]}\, ds + \int_{\mathcal{E}_\mathcal{D}} \underline{\xi}_\sigma : (\boldsymbol{v} \otimes \boldsymbol{n})\, ds \right| \\
&\le \left(\int_{\mathcal{E}_i} \frac{1}{C_{11}} (\{\!\{\underline{\xi}_\sigma\}\!\} - [\![\underline{\xi}_\sigma]\!] \otimes \boldsymbol{C}_{12})^2\, ds + \int_{\mathcal{E}_\mathcal{D}} \frac{1}{C_{11}} \underline{\xi}_\sigma^2\, ds \right)^{\frac{1}{2}} \Theta(\boldsymbol{v}, 0). \\
&\le C \left(\sum_{K \in \mathcal{T}} \frac{1}{\underline{C}_{11}^{\partial K}} \|\underline{\xi}_\sigma\|_{0,\partial K}^2 \right)^{\frac{1}{2}} \Theta(\boldsymbol{v}, 0).
\end{aligned}$$

The second estimate for the form b follows from Lemma 3.1.

The estimates for d are obtained in a similar way from Lemma 3.1, observing again that $\boldsymbol{D}_{12}$ is of order one and that the volume terms vanish due to the properties of the L^2-projections and the inclusions in (2.17). Thus, using the inclusion $\partial_i \mathcal{Q}(K) \subset \mathcal{V}(K)$, we have

$$\begin{aligned}
|d(\boldsymbol{\xi}_u, q)| &= \left| \int_{\mathcal{E}_i} (\{\!\{\boldsymbol{\xi}_u\}\!\} + \boldsymbol{D}_{12} [\![\boldsymbol{\xi}_u]\!]) \cdot [\![q]\!]\, ds \right| \\
&\le \left(\int_{\mathcal{E}_i} \frac{1}{D_{11}} (\{\!\{\boldsymbol{\xi}_u\}\!\} + \boldsymbol{D}_{12} [\![\boldsymbol{\xi}_u]\!])^2\, ds \right)^{\frac{1}{2}} \Theta(\boldsymbol{0}, q) \\
&\le C \left(\sum_{K \in \mathcal{T}} \frac{1}{\underline{D}_{11}^{\partial K}} \|\boldsymbol{\xi}_u\|_{0,\partial K} \right)^{\frac{1}{2}} \Theta(\boldsymbol{0}, q),
\end{aligned}$$

and using the inclusion $\partial_i \mathcal{V}(K) \subset \mathcal{Q}(K)$,

$$\begin{aligned}
|d(\boldsymbol{v}, \xi_p)| &= \left| \int_{\mathcal{E}_i} (\{\!\{\xi_p\}\!\} - \boldsymbol{D}_{12} \cdot [\![\xi_p]\!]) [\![\boldsymbol{v}]\!]\, ds + \int_{\mathcal{E}_\mathcal{D}} \xi_p \boldsymbol{v} \cdot \boldsymbol{n}\, ds \right| \\
&\le C \left(\sum_{K \in \mathcal{T}} \frac{1}{\underline{C}_{11}^{\partial K}} \|\xi_p\|_{0,\partial K}^2 \right)^{\frac{1}{2}} \Theta(\boldsymbol{v}, 0).
\end{aligned}$$

The application of Lemma 3.1 completes the proof. ∎

For the special form of C_{11} and D_{11} proposed in (2.21) and (2.22), respectively, we have as a consequence of Lemma 3.6, Lemma 3.7, and (2.16) the following result.

COROLLARY 3.8. *Assume* (2.15), (2.16) *and* (2.17), (2.18). *Let the coefficients* C_{11} *and* D_{11} *be given by* (2.21), (2.22), *and let* $\underline{\Pi}$, $\mathbf{\Pi}$, *and* Π *be the (componentwise)* L^2*-projections onto the corresponding finite element spaces. Let* $\underline{\sigma} \in H^{r+1}(\Omega)^{d^2}$, $\boldsymbol{u} \in H^{s+1}(\Omega)^d$, *and* $p \in H^{t+1}(\Omega)$ *for* $r, s, t \geq 0$. *Then we have*

$$\begin{aligned}
|a(\underline{\xi}_\sigma, \underline{\tau})| &\leq Ch^{\min(r,l)+1}\|\underline{\sigma}\|_{r+1}\|\underline{\tau}\|_0 && \forall\ \underline{\tau} \in \underline{\Sigma},\\
|b(\boldsymbol{\xi}_u, \underline{\tau})| &\leq Ch^{\min(s,k)}\|\boldsymbol{u}\|_{s+1}\|\underline{\tau}\|_0 && \forall\ \underline{\tau} \in \underline{\Sigma}_N,\\
|b(\boldsymbol{v}, \underline{\xi}_\sigma)| &\leq c_{11}^{-\frac{1}{2}}Ch^{\min(r,l)+1}\|\underline{\sigma}\|_{r+1}\Theta(\boldsymbol{v}, 0) && \forall \boldsymbol{v} \in \boldsymbol{V}_N,\\
|c(\boldsymbol{\xi}_u, \boldsymbol{v})| &\leq c_{11}^{\frac{1}{2}}Ch^{\min(s,k)}\|\boldsymbol{u}\|_{s+1}\Theta(\boldsymbol{v}, 0) && \forall \boldsymbol{v} \in \boldsymbol{V},\\
|d(\boldsymbol{\xi}_u, q)| &\leq d_{11}^{-\frac{1}{2}}Ch^{\min(s,k)}\|\boldsymbol{u}\|_{s+1}\Theta(\mathbf{0}, q) && \forall q \in Q_N,\\
|d(\boldsymbol{v}, \xi_p)| &\leq c_{11}^{-\frac{1}{2}}Ch^{\min(t,m)+1}\|p\|_{t+1}\Theta(\boldsymbol{v}, 0) && \forall \boldsymbol{v} \in \boldsymbol{V}_N,\\
|e(\xi_p, q)| &\leq d_{11}^{\frac{1}{2}}Ch^{\min(t,m)+1}\|p\|_{t+1}\Theta(\mathbf{0}, q) && \forall q \in Q,
\end{aligned}$$

with constants C *independent of the meshsize.*

From Corollary 3.8 we are able to derive the following estimate for $K_{\mathcal{B}}$.

COROLLARY 3.9. *Assume* (2.15), (2.16) *and* (2.17), (2.18), *with approximation orders* $k \geq 1$, $l, m \geq 0$. *Let the coefficients* C_{11} *and* D_{11} *be given by* (2.21), (2.22), *and let* $\underline{\Pi}$, $\mathbf{\Pi}$, Π *denote* L^2*-projections. For* $\underline{\sigma} \in H^{l+1}(\Omega)^{d^2}$, $\boldsymbol{u} \in H^{k+1}(\Omega)^d$, *and* $p \in H^{m+1}(\Omega)$ *the error bound* (2.29) *is satisfied with*

$$K_{\mathcal{B}}(\underline{\sigma}, \boldsymbol{u}, p) \leq C\Big[h^{l+1}\|\underline{\sigma}\|_{l+1} + h^k\|\boldsymbol{u}\|_{k+1} + h^{m+1}\|p\|_{m+1}\Big].$$

Furthermore, assume the elliptic regularity (2.26) *and let* $(\boldsymbol{z}, q)$ *denote the solution of* (2.23)–(2.25) *with right-hand side* $\boldsymbol{\lambda} \in L^2(\Omega)^d$, $\underline{\zeta} = -\nabla\boldsymbol{z}$, $\widetilde{q} = -q$. *Then we have in Lemma* 2.7

$$K_{\mathcal{B}}(\underline{\zeta}, \boldsymbol{z}, \widetilde{q}) \leq Ch\|\underline{\lambda}\|_0.$$

Proof. The first assertion follows from the fact that

$$\begin{aligned}
\mathcal{A}(\underline{\xi}_\sigma, \pm\boldsymbol{\xi}_u, \xi_p; \underline{\tau}, \pm\boldsymbol{v}, q) = a(\underline{\xi}_\sigma, \underline{\tau}) \pm b(\boldsymbol{\xi}_u, \underline{\tau}) \mp b(\boldsymbol{v}, \underline{\xi}_\sigma) \pm c(\boldsymbol{\xi}_u, \boldsymbol{v})\\
\pm d(\boldsymbol{v}, \xi_p) \mp d(\boldsymbol{\xi}_u, q) + e(\xi_p, q),
\end{aligned}$$

from the definition of the $\mathcal{A}$-seminorm, and from Corollary 3.8.

The second assertion follows similarly from Corollary 3.8, substituting $(\underline{\sigma}, \boldsymbol{u}, p)$ by $(\underline{\zeta}, \boldsymbol{z}, \widetilde{q})$, observing the special form of C_{11} and D_{11}, and (2.26) which gives $\|\underline{\zeta}\|_1 + \|\boldsymbol{z}\|_2 + \|\widetilde{q}\|_1 \leq C\|\boldsymbol{\lambda}\|_0$. ∎

3.4. Proof of Proposition 2.5. We prove the stability result in Proposition 2.5. To do so, we fix $(\underline{\tau}, \boldsymbol{v}, q) \in \underline{\Sigma}_N \times \boldsymbol{V}_N \times Q_N$. Then, by the continuous inf-sup condition for the standard Stokes forms (see, e.g., [6, 24]) there is a velocity field $\boldsymbol{u} \in H_0^1(\Omega)^d = \{\boldsymbol{u} \in H^1(\Omega)^d : \boldsymbol{u}|_{\partial\Omega} = \mathbf{0}\}$ satisfying

$$-\int_\Omega q\,\nabla\cdot\boldsymbol{u}\,d\boldsymbol{x} \geq \kappa\|q\|_0^2, \qquad \|\boldsymbol{u}\|_1 \leq \|q\|_0, \tag{3.2}$$

with a constant $\kappa > 0$ just depending on Ω. Let $\mathbf{\Pi}\boldsymbol{u}$ be the L^2-projection of $\boldsymbol{u}$ onto the finite element space $\boldsymbol{V}_N$. By definition of $\mathcal{A}$, we have

$$\mathcal{A}(\underline{\tau}, \boldsymbol{v}, q; \underline{0}, \mathbf{\Pi}\boldsymbol{u}, 0) = -b(\mathbf{\Pi}\boldsymbol{u}, \underline{\tau}) + c(\boldsymbol{v}, \mathbf{\Pi}\boldsymbol{u}) + d(\Pi\boldsymbol{u}, q) =: T_1 + T_2 + T_3.$$

We set $\boldsymbol{\xi}_u := \boldsymbol{u} - \boldsymbol{\Pi}\boldsymbol{u}$ and estimate each of the terms T_1–T_3 separately.

For T_1 we have, by Corollary 3.8,

$$|T_1| \le |b(\boldsymbol{\xi}_u, \underline{\tau})| + |b(\boldsymbol{u}, \underline{\tau})| \le C\|\boldsymbol{u}\|_1\|\underline{\tau}\|_0 + \left|\int_\Omega \nabla\boldsymbol{u} : \underline{\tau}\, d\boldsymbol{x}\right| \le C\|\boldsymbol{u}\|_1\|\underline{\tau}\|_0,$$

and, by (3.2),

$$T_1 \ge -\frac{C_1}{\varepsilon_1}\|q\|_0^2 - C_1\varepsilon_1\|\underline{\tau}\|_0^2.$$

For the second term T_2 we have, analogously,

$$T_2 = c(\boldsymbol{v}, \boldsymbol{\Pi}\boldsymbol{u}) = c(\boldsymbol{v}, \boldsymbol{\xi}_u) \le c_{11}^{\frac{1}{2}} C\|\boldsymbol{u}\|_1 \Theta(\boldsymbol{v}, 0),$$

and hence

$$T_2 \ge -\frac{C_2 c_{11}}{\varepsilon_2}\|q\|_0^2 - C_2\varepsilon_2\Theta^2(\boldsymbol{v}, q).$$

For the third term, we write

$$T_3 = d(\boldsymbol{\Pi}\boldsymbol{u}, q) = d(\boldsymbol{u}, q) - d(\boldsymbol{\xi}_u, q).$$

Since, by Corollary 3.8 and (3.2)

$$|d(\boldsymbol{\xi}_u, q)| \le d_{11}^{-\frac{1}{2}} C\|\boldsymbol{u}\|_1 \Theta(\boldsymbol{0}, q) \le \frac{C d_{11}^{-1}}{\varepsilon_3}\|q\|_0^2 + C\varepsilon_3\Theta^2(\boldsymbol{v}, q),$$

and $d(\boldsymbol{u}, q) = -\int_\Omega q\nabla\cdot\boldsymbol{u}\, d\boldsymbol{x}$, we obtain

$$T_3 \ge \kappa\|q\|_0^2 - \frac{C_3 d_{11}^{-1}}{\varepsilon_3}\|q\|_0^2 - C_3\varepsilon_3\Theta^2(\boldsymbol{v}, q).$$

From the above estimates we conclude that

$$\begin{aligned}&\mathcal{A}(\underline{\tau}, \boldsymbol{v}, q; \underline{0}, \boldsymbol{\Pi}\boldsymbol{u}, 0)\\ &\quad\ge \Big(\kappa - \frac{C_1}{\varepsilon_1} - \frac{C_2 c_{11}}{\varepsilon_2} - \frac{C_3 d_{11}^{-1}}{\varepsilon_3}\Big)\|q\|_0^2 - C_1\varepsilon_1\|\underline{\tau}\|_0^2 - (C_2\varepsilon_2 + C_3\varepsilon_3)\Theta^2(\boldsymbol{v}, q).\end{aligned}$$

The parameters $\{\varepsilon_i\}_{i=1}^3$ can be chosen in such a way that

$$\mathcal{A}(\underline{\tau}, \boldsymbol{v}, q; \underline{0}, \boldsymbol{\Pi}\boldsymbol{u}, 0) \ge K_1\|q\|_0^2 - K_2|\,(\underline{\tau}, \boldsymbol{v}, q)\,|_{\mathcal{A}}^2,$$

with constants K_i independent of the meshsize.

Furthermore, we have by Corollary 3.4

$$|\,(\underline{0}, \boldsymbol{\Pi}\boldsymbol{u}, 0)\,|_{\mathcal{A}}^2 = c(\boldsymbol{\Pi}\boldsymbol{u}, \boldsymbol{\Pi}\boldsymbol{u}) = c(\boldsymbol{\xi}_u, \boldsymbol{\xi}_u) \le c_{11} C\|\boldsymbol{u}\|_1^2 \le K_3^2\|q\|_0^2.$$

The function $\boldsymbol{w} = \boldsymbol{\Pi}\boldsymbol{u}/K_3$ then satisfies the assertion in Proposition 2.5, with $\kappa_1 = K_1/K_3$ and $\kappa_2 = K_2/K_3$. This completes the proof.

3.5. Proof of the main results. Theorems 2.2 and 2.3 follow now immediately by choosing the projection operators $\underline{\Pi}$, $\boldsymbol{\Pi}$, and Π as L^2-projections, by combining Corollaries 3.5 and 3.9 with Lemmas 2.4, 2.6, and 2.7 and by taking into account the form of the coefficients C_{11} and D_{11}.

4. Numerical results. The numerical experiments we present in this section are devised to verify our theoretical error estimates. We also explore the effect of the use of several combinations of polynomial spaces on the efficiency of the resulting LDG methods. The numerical tests are carried out by using the finite element library `deal.II` by Bangerth and Kanschat [3].

We consider the Stokes system (1.1) with $\Omega = (-1,1)^2$ and right-hand side $\boldsymbol{f}$ and Dirichlet boundary condition $\boldsymbol{g}_{\mathcal{D}}$ chosen such that the exact solution is

$$\begin{aligned} u_1(x_1,x_2) &= -e^{x_1}(x_2\cos x_2 + \sin x_2),\\ u_2(x_1,x_2) &= e^{x_1}x_2\sin x_2,\\ p(x_1,x_2) &= 2e^{x_1}\sin x_2. \end{aligned}$$

In all our experiments, we use uniform triangulations made of squares; the grid whose squares have size $h = 2^{-\nu+1}$ is called a grid of level ν.

4.1. Verifying the sharpness of the theoretical error estimates. We begin by considering LDG methods with the same polynomial spaces for $\underline{\sigma}$, $\boldsymbol{u}$, and p and taking $C_{11} = h^{-1}$, $D_{11} = h$, $\boldsymbol{C}_{12} = \boldsymbol{0}$, and $\boldsymbol{D}_{12} = \boldsymbol{0}$. The results are shown in Tables 4.1 and 4.2 for P^k- and Q^k-elements, respectively. The tables confirm that the orders of convergence predicted by the theory are sharp since they are actually achieved. However, one exception needs to be pointed out: The pressure converges better than expected for linear and bilinear shape functions since superlinear convergence is observed. This phenomenon is particularly well accentuated in the case of bilinear functions for which the order of convergence of 3/2 can be clearly seen. The same order of convergence has recently been observed by Berrone [5] for the stabilized P^1-P^1 SUPG method.

4.2. The effect of the use of different polynomial spaces. To get an idea of what is the effect of the use of P^k- versus Q^k-spaces on quadrilateral elements, the errors of quadratic and biquadratic elements are compared in relation to the numerical effort in Figure 4.1. We use the number of nonzero elements in the stiffness matrix as a measure of the solution cost of a discretization. The graphs show that it is possible to compute the velocities $\boldsymbol{u}$ with the same accuracy and effort with P^2- and Q^2-shape functions; however, the pressures are computed more efficiently with P^2-elements.

Finally, since the theoretical results predict the same orders of convergence for all quantities if we take lower order P-elements for $\underline{\sigma}$ and p, we compare the efficiency of LDG methods obtained with several combinations of local spaces $\mathcal{S}(K)/\mathcal{V}(K)/\mathcal{Q}(K)$ in Figures 4.2 and 4.3.

	4	6.4e-4	2.00	1.6e-4	2.02	8.1e-6	3.00	1.2e-4	1.94
	5	1.6e-4	2.00	3.9e-5	2.00	1.0e-6	3.00	3.0e-5	1.97
3	2	6.1e-4	2.76	3.8e-4	2.37	1.9e-5	3.82	2.4e-4	2.24
	3	8.1e-5	2.92	6.4e-5	2.55	1.1e-6	4.12	3.8e-5	2.63
	4	1.0e-5	2.98	9.3e-6	2.80	6.0e-8	4.19	5.2e-6	2.88

We can see that all these LDG discretizations converge with the same order, as expected and proved for P-elements, and that, in most cases, it is more efficient to use the same local approximating spaces for all quantities. In fact, only the velocities in the Q^2-case are computed slightly more efficiently using a lower degree for the pressure. On the other hand, using lower-order polynomials for $\underline{\sigma}$ and/or p *increases* the error in p such that at least one additional refinement is necessary to recover the accuracy corresponding to an LDG method using the same local spaces.

5. Extensions and concluding remarks. In this paper, we have introduced LDG methods for the Stokes system and have carried out an a priori error analysis. We have shown that if polynomial approximations of degree $k-1$ are used for the pressure p and the stress tensor $\underline{\sigma}$ and polynomial approximations of degree k for the velocity $\boldsymbol{u}$, then optimal error estimates are obtained when the stabilization parameters C_{11} and D_{11} are taken to be of order h^{-1} and h, respectively. Future work will be devoted to the extension of the LDG method to the incompressible Navier–Stokes equations.

Extensions of our analysis to curvilinear elements and to (nonconvex) polygonal domains as well as to error estimates in negative-order norms for both the velocity and the pressure can easily be carried out; see [8] for details of the corresponding extensions for the Laplacian. Here, we simply must note that, to take into account the presence of the pressure, we have to consider the following modified adjoint problem:

$$\begin{aligned} -\Delta \boldsymbol{z} + \nabla q &= \boldsymbol{\lambda} && \text{in } \Omega, \\ \nabla \cdot \boldsymbol{z} &= g && \text{in } \Omega, \\ \boldsymbol{z} &= \boldsymbol{0} && \text{on } \partial\Omega, \end{aligned}$$

where g is in $H^1(\Omega)$. The elliptic regularity result we have used in (2.26) is a particular case of the above more general case; see, for example, Proposition 3.14 in [2] and the references therein.

The technique of the analysis employed is an extension of that used in [8] for the simpler case of the Laplacian. This same technique was then used in [13] to get improved convergence estimates for a special LDG method on Cartesian grids by changing some auxiliary projections used in the analysis. In a forthcoming paper, we shall carry out a similar study for the Stokes system. The numerical results in Table 5.1 already suggest an improvement similar to that obtained for the Laplacian.

Indeed, the use of these special fluxes with quadratic shape functions increases the order of convergence of the pressure by 1/2; moreover, they improve the order of

FAST COLLOCATION METHODS FOR SECOND KIND INTEGRAL EQUATIONS*

ZHONGYING CHEN†, CHARLES A. MICCHELLI‡, AND YUESHENG XU§

Dedicated to Professor Mike Powell
on the occasion of his sixty-fifth birthday with friendship and esteem

Abstract. In this paper we develop fast collocation methods for integral equations of the second kind with weakly singular kernels. For this purpose, we construct *multiscale interpolating functions* and *collocation functionals* having vanishing moments. Moreover, we propose a truncation strategy for the coefficient matrix of the corresponding discrete system which forms a basis for fast algorithms. An optimal order of convergence of the approximate solutions obtained from the fast algorithms is proved and the computational complexity of the algorithms is estimated. The stability of the numerical method and the condition number of the truncated coefficient matrix are analyzed.

Key words. fast collocation methods, Fredholm integral equations of the second kind, refinable sets, multiscale interpolation

1. Introduction.

The main purpose of this paper is to develop a fast collocation method for solving Fredholm integral equations of the second kind with weakly singular kernels. Among conventional numerical methods for solving integral equations, the collocation method receives more favorable attention from engineering applications due to lower computational cost in generating the coefficient matrix of the corresponding discrete equations. In comparison, the implementation of the Galerkin method requires much more computational effort for the evaluation of integrals (for example, see [At1, AC1, CX]). Nonetheless, it seems that most of the attention in wavelet methods for boundary integral equations has been paid to Galerkin methods or Petrov–Galerkin methods (see [BCR, CMX1, CMX3, DPS, MXZ, PS, PSS, R] and references cited therein). These methods are amenable to L_2 analysis and therefore the vanishing moments of the multiscale basis functions naturally lead to matrix truncation techniques.

For collocation methods, the appropriate context to work in is L_∞ and this provides challenging technical obstacles for the identification of good matrix truncation strategies. It is the goal of this paper to lay the foundations for fast collocation

methods for solving integral equations of the second kind with weakly singular kernels. This paper is divided into two main parts. In part one we develop and analyze a fast collocation method for solving general multidimensional integral equations under a sequence of hypotheses on the basis functions and collocation functionals. In part two, we present a construction of such functions and functionals when the domain of interest is an invariant set relative to a finite set of contractive affine mappings. This construction draws upon ideas developed in [CMX2, MSX1, MSX2].

The equations we consider in this paper are Fredholm integral equations of the second kind with weakly singular kernels defined on a bounded domain in $\mathbb{R}^d$ for $d \geq 1$. These types of equations cover many important applications including boundary integral equations [At1, At2] and the radiosity equations [ACr, AC2]. In practice, these equations are solved numerically by using piecewise polynomial collocation methods and, when the order of the full coefficient matrix is large, the computational cost for generating the matrix and then solving the corresponding linear system is huge. We introduce a matrix truncation strategy by making a careful choice of basis functions and collocation functionals, which leads to a fast algorithm for solving the integral equations.

We organize this paper as follows. In section 2, we describe the setting of the collocation methods, including the multiscale basis for the approximate solution space and the collocation functionals. In section 3, based on an estimate of the entries of the coefficient matrix of the collocation method, a fast collocation method is proposed, and in section 4, we analyze the matrix truncation algorithm including the order of convergence, stability, and computational complexity. The fast collocation methods that we develop and analyze in sections 3 and 4 are based on a set of hypotheses on the basis functions of the approximation space and the collocation functionals. In section 5 we present a concrete construction of multiscale bases on an invariant set in $\mathbb{R}^d$ and collocation functionals needed for fast collocation algorithms. This construction fulfills all the hypotheses imposed in sections 2–4.

2. The collocation scheme. In this section we describe a general setup for multiscale bases and collocation functionals for solving Fredholm integral equations of the second kind. We begin establishing our notational conventions. For a compact subset E of the d-dimensional Euclidean space $\mathbb{R}^d$, we let $\mathbb{X} = L^\infty(E)$, $\mathbb{V} = C(E)$ and denote the dual space of $\mathbb{V}$ by $\mathbb{V}^*$. For $\ell \in \mathbb{V}^*$ and $v \in \mathbb{X}$, we use $\langle \ell, v \rangle$ to denote the value of the linear functional ℓ evaluated at the function v and use $\|\ell\|$, $\|v\|_\infty$ for their respective norms. For any $s \in E$ we use δ_s to denote the linear functional in $\mathbb{V}^*$ defined for $v \in \mathbb{V}$ by the equation $\langle \delta_s, v \rangle = v(s)$. We shall need to evaluate δ_s on functions in $\mathbb{X}$. Therefore, as in [AGS] we take any norm preserving extension of δ_s to $\mathbb{X}$ and use the same notation for the extension. In particular, this convention allows us to evaluate piecewise polynomials *anywhere* on E.

For a set $A \subset \mathbb{R}^d$, $d(A)$ represents the diameter of A, i.e.,

$$d(A) := \sup\{|x - y| : x, y \in A\}, \tag{2.1}$$

where $|\cdot|$ denotes the Euclidean norm on the space $\mathbb{R}^d$. We use the index sets $\mathbb{Z}_n := \{0, 1, \ldots, n-1\}$, $\mathbb{Z} := \{\ldots, -1, 0, 1, \ldots\}$, $\mathbb{N} := \{1, 2, \ldots\}$, and $\mathbb{N}_0 := \{0, 1, \ldots\}$ throughout the paper. A vector x in $\mathbb{R}^d$ is written in the form $x = [x_i : i \in \mathbb{Z}_d]$ and a lattice point α is an element in $\mathbb{N}_0^d$ written as $\alpha := [\alpha_i \in \mathbb{N}_0 : i \in \mathbb{Z}_d]$. As is usually the case we set $|\alpha| := \sum_{i \in \mathbb{Z}_d} \alpha_i$ and denote the space of polynomials of total degree less than k by π_k.

A set in $\mathbb{R}^d$ is called star-shaped if it contains a point, called the center of the set, for which the line segment connecting this point and any other point in the set is contained in the set. As usual, for k a positive integer $W^{k,\infty}(E)$ will denote the set of all functions v on E such that $D^\alpha v \in \mathbb{X}$, where we use the standard multi-index notation for derivatives

$$D^\alpha v(x) = \frac{\partial^{|\alpha|} v(x)}{\partial x_0^{\alpha_0} \cdots \partial x_{d-1}^{\alpha_{d-1}}}, \quad x \in \mathbb{R}^d,$$

and the norm

$$\|v\|_{k,\infty} := \max\{\|D^\alpha v\|_\infty : |\alpha| \le k\}$$

on $W^{k,\infty}(E)$. For a star-shaped set E it is easy to estimate the distance of a function $v \in W^{k,\infty}(E)$ to the space π_k. Specifically, there is a positive constant c such that

$$\operatorname{dist}(v, \pi_k) \le c(d(E))^k \|v\|_{k,\infty}. \tag{2.2}$$

Throughout the paper c will always stand for a generic constant whose value will change with the context. Its meaning will be clear from the order of the qualifiers used to describe its role in our estimates.

There are several ingredients required in the development of the fast collocation algorithms for solving integral equations. First, we require a *multiscale* of finite dimensional subspaces of $\mathbb{X}$ denoted by $\mathbb{F}_n$ where $n \in \mathbb{N}_0$ in which we do our approximation. These spaces are required to have the property that

$$\mathbb{F}_n \subseteq \mathbb{F}_{n+1}, \quad n \in \mathbb{N}_0, \tag{2.3}$$

and

$$\mathbb{V} \subseteq \overline{\bigcup_{n \in \mathbb{N}_0} \mathbb{F}_n}. \tag{2.4}$$

For efficient computation relative to a scale of spaces we express them as a direct sum of subspaces

$$\mathbb{F}_n = \mathbb{W}_0 \bigoplus \mathbb{W}_1 \bigoplus \cdots \bigoplus \mathbb{W}_n. \tag{2.5}$$

These spaces serve as *multiscale* subspaces of $\mathbb{X}$ and later will be constructed as piecewise polynomial functions on E. We use the notation $w(n) := \dim \mathbb{W}_n$ and so we have that

$$f(n) := \dim \mathbb{F}_n = \sum_{r \in \mathbb{Z}_{n+1}} w(r).$$

We need a multiscale partition of the set E. It consists of a family of partitions $\{E_n : n \in \mathbb{N}_0\}$ of E such that for each scale $n \in \mathbb{N}_0$ the partition E_n consists of a family of subsets $\{E_{ni} : i \in \mathbb{Z}_{e(n)}\}$ of E with the properties that

$$\operatorname{meas}(E_{ni} \cap E_{ni'}) = 0, \quad i, i' \in \mathbb{Z}_{e(n)}, i \ne i', \tag{2.6}$$

and

$$\bigcup_{i \in \mathbb{Z}_{e(n)}} E_{ni} = E. \tag{2.7}$$

At the appropriate time later, we will adjust the number $e(n)$ of elements and the maximum diameter of the cells in the nth partition to be commensurate with $\dim \mathbb{W}_n$. The family of partitions $\{E_n : n \in \mathbb{N}_0\}$ is used in two ways. First, we demand that there is a basis $W_n := \{w_{nm} : m \in \mathbb{Z}_{w(n)}\}$ for the spaces

$$\mathbb{W}_n := \operatorname{span} W_n, \quad n \in \mathbb{N}_0,$$

having the following property.

(I) There exist positive integers ρ and h such that for every $n > h$ and $m \in \mathbb{Z}_{w(n)}$ written in the form $m = j\rho + s$ where $s \in \mathbb{Z}_\rho$ and $j \in \mathbb{N}_0$

$$w_{nm}(x) = 0, \quad x \notin E_{n-h,j}. \tag{2.8}$$

Hypothesis (I) ensures that the basis functions w_{nm} are locally supported and their supports are shrinking as level n increases. For $n > h$ we use the notation $S_{nm} := E_{n-h,j}$ so that the support of the functions w_{nm} is contained in the set S_{nm}. Note that the supports of the basis functions at the nth level are *not* disjoint. However, for every $n > h$ and every function w_{nm} there are at most ρ other functions at level n whose support overlaps the support of w_{nm}.

To define the collocation method we need a set of linear functionals in $\mathbb{V}^*$ given by

$$L_n := \{\ell_{nm} : m \in \mathbb{Z}_{w(n)}\}, \quad n \in \mathbb{N}_0.$$

The multiscale of partitions $\{E_n : n \in \mathbb{N}_0\}$ is also used to specify the supports of the linear functionals by the requirement that the linear functional ℓ_{nm} is a finite sum of point evaluations

$$\ell_{nm} = \sum_{s \in \hat{E}_{n-h,j}} c_s \delta_s, \tag{2.9}$$

where c_s are constants and $\hat{E}_{ni}$ is a finite subset of distinct points in E_{ni} with the cardinality bounded *independent* of $n \in \mathbb{N}$ and $i \in \mathbb{Z}_{w(n)}$. As with the functions we set $\hat{S}_{nm} := \hat{E}_{n-h,j}$ and consider it as the "support" of the functionals ℓ_{nm}.

The linear functionals and multiscale basis functions are tied together by the next requirement.

(II) For any $n, n' \in \mathbb{N}_0$

$$\langle \ell_{n'm'}, w_{nm} \rangle = \delta_{nn'}\delta_{mm'}, \quad (n,m),(n',m') \in \mathbb{U}, \quad n \le n', \tag{2.10}$$

where $\mathbb{U} := \{(i,j) : i \in \mathbb{N}_0, j \in \mathbb{Z}_{w(i)}\}$ and $\delta_{ii'}$ is the Kronecker delta and there exists a positive constant γ for which

$$\sum_{m \in \mathbb{Z}_{w(n)}} |\langle \ell_{n'm'}, w_{nm} \rangle| \le \gamma, \quad (n,m),(n'm') \in \mathbb{U}, \quad n > n'. \tag{2.11}$$

To include the commonly used piecewise polynomial collocation methods with a change of bases as our important special cases, we do not require the linear functionals and the multiscale basis functions to be biorthogonal. Instead, we require them to have a "semibiorthogonality" property imposed by condition (2.10) with a controllable perturbation from the biorthogonality, which is ensured by condition (2.11). Specifically, (2.10) means that the basis functions vanish when they are applied by

collocation functionals of higher levels. We denote by $\mathbf{E}$ the semi-infinite matrix with entries

$$\mathbf{E}_{n'm',nm} := \langle \ell_{n'm'}, w_{nm} \rangle, \quad (n',m'),(n,m) \in \mathbb{U}.$$

We note by condition (2.10) that the matrix $\mathbf{E}$ can be viewed as a block upper triangular matrix with the diagonal blocks equal to identity matrices. Consequently, the infinite matrix $\mathbf{E}$ has an inverse $\mathbf{E}^{-1}$ of the same type, that is,

$$(\mathbf{E}^{-1})_{n'm',nm} = \delta_{nn'}\delta_{mm'}, \quad n \le n', \quad m \in \mathbb{Z}_{w(n)}, \quad m' \in \mathbb{Z}_{w(n')}.$$

These conditions are more than is needed to introduce the collocation method for solving integral equations of the second kind. For this purpose, we suppose that K is a weakly singular kernel, that is, for every $s \in E$, $K(s,\cdot) \in L^1(E)$. Therefore, the operator $\mathcal{K} : \mathbb{X} \to \mathbb{V}$ defined by

$$(\mathcal{K}u)(s) := \int_E K(s,t)u(t)dt, \quad s \in E,$$

is compact in $\mathbb{X}$. We consider Fredholm integral equations of the second kind in the form

$$u - \mathcal{K}u = f, \tag{2.12}$$

where $f \in \mathbb{X}$ is a given function and $u \in \mathbb{X}$ is the unknown to be determined. When one is not an eigenvalue of $\mathcal{K}$, (2.12) has a unique solution in $\mathbb{X}$. The collocation scheme for solving (2.12) seeks a vector $\mathbf{u}_n := [u_{ij} : (i,j) \in \mathbb{U}_n]^T$, where $\mathbb{U}_n$ is the set of lattice points in $\mathbb{R}^2$ defined as $\{(i,j) : j \in \mathbb{Z}_{w(i)}, i \in \mathbb{Z}_{n+1}\}$, such that the function

$$u_n := \sum_{(i,j)\in\mathbb{U}_n} u_{ij}w_{ij}$$

in $\mathbb{F}_n$ has the property that

$$\langle \ell_{i'j'}, u_n - \mathcal{K}u_n \rangle = \langle \ell_{i'j'}, f \rangle, \quad (i',j') \in \mathbb{U}_n. \tag{2.13}$$

Equivalently, we obtain the linear system of equations

$$(\mathbf{E}_n - \mathbf{K}_n)\mathbf{u}_n = \mathbf{f}_n,$$

where

$$\mathbf{K}_n := [\langle \ell_{i'j'}, \mathcal{K}w_{ij} \rangle]_{f(n)\times f(n)},$$

$$\mathbf{E}_n := [\langle \ell_{i'j'}, w_{ij} \rangle]_{f(n)\times f(n)},$$

and

$$\mathbf{f}_n := [\langle \ell_{ij}, f \rangle : (i,j) \in \mathbb{U}_n]^T.$$

By definition, we have that $(\mathbf{E}_n)_{i'j',ij} = \mathbf{E}_{i'j',ij}$, for $(i',j'),(i,j) \in \mathbb{U}_n$ and by (2.10) we see that

$$(\mathbf{E}_n^{-1})_{i'j',ij} = (\mathbf{E}^{-1})_{i'j',ij}, \quad (i',j'),(i,j) \in \mathbb{U}_n. \tag{2.14}$$

The collocation scheme defined in (2.13) which has a multiscale structure is different from the traditional collocation scheme. However, it can be viewed as a scheme obtained from the traditional one by an appropriate change of bases for both approximate spaces and collocation functionals.

Let us use condition (II) to estimate the *inverse* of the matrix $\mathbf{E}_n$. To this end, we introduce a weighted norm on the vector $\mathbf{x} := [x_{ij} : (i,j) \in \mathbb{U}_n]^T$. We will find it convenient for our study of the multiscale collocation methods to define the weighted vector norms in a way that the weights differ from level to level. Specifically, for any $i \in \mathbb{Z}_{n+1}$ we set

$$\mathbf{x}_i := [x_{ij} : j \in \mathbb{Z}_{w(i)}]^T,$$

$$\|\mathbf{x}_i\|_\infty := \max\{|x_{ij}| : j \in \mathbb{Z}_{w(i)}\},$$

and whenever $\nu \in (0,1)$ we define

$$\|\mathbf{x}\|_\nu := \max\{\|\mathbf{x}_i\|_\infty \nu^{-i} : i \in \mathbb{Z}_{n+1}\}.$$

We also use the notation

$$\|\mathbf{x}\|_\infty := \max\{\|\mathbf{x}_i\|_\infty : i \in \mathbb{Z}_{n+1}\}$$

for the max norm of the vector $\mathbf{x}$.

LEMMA 2.1. *If condition* (II) *holds,* $0 < \nu < 1$ *and* $(1+\gamma)\nu < 1$, *then for any integer* $n \in \mathbb{N}_0$ *and vector* $\mathbf{x} \in \mathbb{R}^{f(n)}$ *there holds that*

$$\|\mathbf{x}\|_\nu \le \frac{1-\nu}{1-(1+\gamma)\nu} \|\mathbf{E}_n \mathbf{x}\|_\nu.$$

Proof. Let $\mathbf{y} := \mathbf{E}_n \mathbf{x}$ so that

$$y_{ij} = \sum_{(i',j') \in \mathbb{U}_n} \langle \ell_{ij}, w_{i'j'} \rangle \, x_{i'j'}.$$

In particular, for $i = n$, we have that $y_{ij} = x_{ij}$, while for $0 \le l \le n-1$ we have from (2.10) that

$$x_{n-l-1,j} = y_{n-l-1,j} - \sum_{n-l \le i' \le n, j' \in \mathbb{Z}_{w(i')}} \langle \ell_{n-l-1,j}, w_{i'j'} \rangle \, x_{i'j'}, \quad j \in \mathbb{Z}_{w(n-l-1)}.$$

Using condition (2.11), we conclude that

$$\|\mathbf{x}_{n-l-1}\|_\infty \le \|\mathbf{y}_{n-l-1}\|_\infty + \gamma \sum_{i=0}^{l} \|\mathbf{x}_{n-i}\|_\infty.$$

By induction on j, it readily follows that

$$\|\mathbf{x}_{n-j}\|_\infty \le \sum_{l=0}^{j-1} \gamma (1+\gamma)^l \|\mathbf{y}_{n-j+l+1}\|_\infty + \|\mathbf{y}_{n-j}\|_\infty.$$

Thus, we have that

$$\begin{aligned}\|\mathbf{x}_{n-j}\|_\infty \nu^{-(n-j)} &\le \gamma\nu \sum_{l=0}^{j-1} [(1+\gamma)\nu]^l \|\mathbf{y}_{n-j+l+1}\|_\infty \nu^{-(n-j+l+1)} + \|\mathbf{y}_{n-j}\|_\infty \nu^{-(n-j)} \\ &\le \left[1 + \gamma\nu \sum_{l=0}^{j-1} [(1+\gamma)\nu]^l\right] \|\mathbf{E}_n \mathbf{x}\|_\nu \\ &\le \frac{1-\nu}{1-(1+\gamma)\nu} \|\mathbf{E}_n \mathbf{x}\|_\nu,\end{aligned}$$

from which the result is proved. □

3. Estimates for matrix $\mathbf{K}_n$. In this section, our goal is to obtain estimates for the entries of the matrix $\mathbf{K}_n$. This requires conditions on the regularity of kernel $K(\cdot,\cdot)$, the support of the basis functions for $\mathbb{W}_n$, and vanishing moments for both the basis functions and the linear functionals. We describe these conditions next.

(III) There is a positive integer k such that for all $p \in \pi_k$

$$\langle \ell_{nm}, p\rangle = 0, \quad (w_{nm}, p) = 0, \quad (n,m) \in \mathbb{U}, \quad n \ge 1,$$

where $(\cdot,\cdot)$ denotes the inner product in $L^2(E)$.

Condition (III) is crucial for establishing the matrix compression scheme. The vanishing moment condition for the collocation functionals restricts them to being a certain type of divided difference functional.

(IV) There exists a positive constant θ_0 such that for all $(n,m) \in \mathbb{U}$ there holds that

$$\|\ell_{nm}\| + \|w_{nm}\|_\infty \le \theta_0,$$

where the norm of linear functionals is defined as in the beginning of section 2.

Condition (IV) is equivalent to saying that both basis functions and collocation functionals are uniformly bounded.

(V) For $s,t \in E$, $s \ne t$, the kernel K has continuous partial derivatives $D_s^\alpha D_t^\beta K(s,t)$ for $|\alpha| \le k$, $|\beta| \le k$. Moreover, there exists positive constants σ and θ_1 with $\sigma < d$ such that for $|\alpha| = |\beta| = k$ there holds

$$\left| D_s^\alpha D_t^\beta K(s,t) \right| \le \frac{\theta_1}{|s-t|^{\sigma+|\alpha|+|\beta|}}. \tag{3.1}$$

In the next lemma, we present an estimate of the entries of the matrix $\mathbf{K}_n$. A similar estimate for the matrix obtained from the Galerkin method was proved in [MXZ]. For estimates in a different form for the entries of wavelet Galerkin matrices, see [Al, BCR, DPS, PS, PSS]. Such an estimate forms the basis for a truncation strategy. In the statement of the next lemma we use the quantities

$$d_i := \max\{d(S_{ij}) : j \in \mathbb{Z}_{w(i)}\}, \quad i \in \mathbb{N}_0.$$

LEMMA 3.1. *If conditions* (I), (III)–(V) *hold and there is a constant* $r > 1$ *such that*

$$\operatorname{dist}(S_{ij}, S_{i'j'}) \ge r(d_i + d_{i'}), \tag{3.2}$$

then there exists a positive constant c such that

$$|K_{i'j',ij}| \le c(d_i d_{i'})^k \sum_{s\in\hat{S}_{i'j'}} \int_{S_{ij}} \frac{1}{|s-t|^{2k+\sigma}} dt.$$

Proof. Let s_0, t_0 be centers of the sets $S_{i'j'}$ and S_{ij}, respectively. Using the Taylor theorem with remainder we write

$$K = K_1 + K_2 + K_3,$$

where $K_1(s,\cdot)$ and $K_2(\cdot,t)$ are polynomials of total degree $\le k-1$ in t and in s, respectively,

$$|K_3(s,t)| \le d_i^k d_{i'}^k v(s,t), \quad s \in S_{i'j'},\ t \in S_{ij},$$

where

$$v(s,t) := \sum_{|\alpha|=k} \sum_{|\beta|=k} \frac{|r_{\alpha\beta}(s,t)|}{\alpha!\beta!} \tag{3.3}$$

and

$$r_{\alpha\beta}(s,t) = \int_0^1 \int_0^1 D_s^\alpha D_t^\beta K(s_0 + t_1(s-s_0), t_0 + t_2(t-t_0))(1-t_1)^{k-1}(1-t_2)^{k-1} dt_1 dt_2. \tag{3.4}$$

Applying the vanishing moment conditions yields the bound

$$|K_{i'j',ij}| \le \|\ell_{i'j'}\| \|w_{ij}\|_\infty d_i^k d_{i'}^k \sum_{s\in\hat{S}_{i'j'}} \int_{S_{ij}} |v(s,t)| dt. \tag{3.5}$$

It follows from the mean-value theorem and condition (V) that

$$|r_{\alpha\beta}(s,t)| = k^{-2} |D_s^\alpha D_t^\beta K(s',t')| \le \frac{\theta_1}{k^2 |s'-t'|^{2k+\sigma}}$$

holds for some $s' \in S_{i'j'},\ t' \in S_{ij}$. For $s \in \hat{S}_{i'j'} \sqsubseteq S_{i'j'}$, $t \in S_{ij}$ the assumption (3.2) yields

$$|s'-t'| \ge |s-t| - d_i - d_{i'} \ge (1-r^{-1})|s-t|,$$

from which it follows that

$$|r_{\alpha\beta}(s,t)| \le \frac{c_1}{|s-t|^{2k+\sigma}},$$

where

$$c_1 := \frac{\theta_1}{k^2(1-r^{-1})^{2k+\sigma}}.$$

Substituting the above inequality into (3.5) completes the proof with

$$c := \frac{\theta_1 \theta_0^2 e^{\frac{2d}{1-r^{-1}}}}{k^2(1-r^{-1})^\sigma}. \qquad \square$$

To present the truncation strategy we partition matrix $\mathbf{K}_n$ into a block matrix

$$\mathbf{K}_n = [\mathbf{K}_{i'i}]_{i',i\in\mathbb{Z}_{n+1}},$$

with

$$\mathbf{K}_{i'i} = [K_{i'j',ij}]_{j'\in\mathbb{Z}_{w(i')},j\in\mathbb{Z}_{w(i)}}.$$

We truncate the block $\mathbf{K}_{i'i}$ by using a given positive number ϵ to form a matrix

$$\mathbf{K}(\epsilon)_{i'i} = [K(\epsilon)_{i'j',ij}]_{j'\in\mathbb{Z}_{w(i')},j\in\mathbb{Z}_{w(i)}},$$

with

$$K(\epsilon)_{i'j',ij} = \begin{cases} K_{i'j',ij}, & \operatorname{dist}(S_{i'j'}, S_{ij}) \le \epsilon, \\ 0 & \text{otherwise,} \end{cases}$$

where ϵ is called the truncation parameters and it may depend on i', i, and n. In the next section, we will choose these truncation parameters so that the truncation scheme gives an optimal order of convergence and computational complexity up to a logarithmic factor. In the next lemma, we use the estimate for the entries of $\mathbf{K}_n$ presented in Lemma 3.1 to obtain estimates for the discrepancy between the blocks of $\mathbf{K}(\epsilon)$ and $\mathbf{K}_n$.

LEMMA 3.2. *If conditions* (I), (III)–(V) *hold, then given any constant* $r > 1$ *and* $0 \le \sigma' < \min\{2k, d-\sigma\}$ *there exists a positive constant* c *such that whenever* $\epsilon \ge r(d_i + d_{i'})$

$$\|\mathbf{K}_{i'i} - \mathbf{K}(\epsilon)_{i'i}\|_\infty \le c\epsilon^{-\eta}(d_i d_{i'})^k, \quad i', i \in \mathbb{Z}_{n+1},$$

where $\eta := 2k - \sigma'$.

Proof. We first note that

$$\|\mathbf{K}_{i'i} - \mathbf{K}(\epsilon)_{i'i}\|_\infty = \max_{j'\in\mathbb{Z}_{w(i')}} \sum_{j\in\mathbb{Z}_{i'j'}(\epsilon)} |K_{i'j',ij}|,$$

where

$$\mathbb{Z}_{i'j'}(\epsilon) := \{j : j \in \mathbb{Z}_{w(i)}, \operatorname{dist}(S_{ij}, S_{i'j'}) > \epsilon\}.$$

Therefore, by using Lemma 3.1 we have that

$$\|\mathbf{K}_{i'i} - \mathbf{K}(\epsilon)_{i'i}\|_\infty \le c(d_i d_{i'})^k \max_{j'\in\mathbb{Z}_{w(i')}} \sum_{s\in\hat{S}_{i'j'}} \sum_{j\in\mathbb{Z}_{i'j'}(\epsilon)} \int_{S_{ij}} \frac{1}{|s-t|^{2k+\sigma}} dt.$$

Although the sets S_{ij} are not disjoint we can use property (I) to conclude that

$$\sum_{j\in\mathbb{Z}_{i'j'}(\epsilon)} \int_{S_{ij}} \frac{1}{|s-t|^{2k+\sigma}} dt \le \rho\epsilon^{-\eta} \int_E \frac{1}{|s-t|^{\sigma+\sigma'}} dt.$$

Since $\sigma + \sigma' < d$ and E is a compact set, there holds that

$$\max_{s\in E} \int_E \frac{1}{|s-t|^{\sigma+\sigma'}} dt < \infty.$$

We conclude the above inequalities to obtain the desired estimate. ∎

4. Analysis of the truncation algorithm. In this section, we discuss the truncation strategy for the collocation method proposed in previous sections. We will analyze the order of convergence, stability, and computational complexity of the truncation algorithm. To this end, we let $\mathcal{P}_n$ be the projection operator from $\mathbb{X}$ onto $\mathbb{F}_n$ defined by the requirement that

$$\langle \ell_{ij}, \mathcal{P}_n x\rangle = \langle \ell_{ij}, x\rangle, \quad (i,j) \in \mathbb{U}_n.$$

It follows from (2.10) that $\mathcal{P}_n$ is well defined. We now introduce the operator from $\mathbb{F}_n$ into itself defined by the equation

$$\mathcal{K}_n := \mathcal{P}_n \mathcal{K}|_{\mathbb{F}_n}$$

and note that its matrix representation relative to the basis $\{w_{ij} : (i,j) \in \mathbb{U}_n\}$ is given by $\mathbf{E}_n^{-1}\mathbf{K}_n$. For each block $\mathbf{K}_{i'i}$, $i, i' \in \mathbb{Z}_{n+1}$ of $\mathbf{K}_n$, we shall specify later truncation parameters $\epsilon_{i'i}^n$ and reassemble the block to form a truncation matrix

$$\tilde{\mathbf{K}}_n = [\mathbf{K}(\epsilon_{i'i}^n)_{i'i}]_{i',i\in\mathbb{Z}_{n+1}}.$$

Using this truncation matrix, we let $\tilde{\mathcal{K}}_n : \mathbb{F}_n \to \mathbb{F}_n$ be the linear operator from $\mathbb{F}_n$ into itself relative to the basis $\{w_{ij} : (i,j) \in \mathbb{U}_n\}$ having the matrix representation $\mathbf{E}_n^{-1}\tilde{\mathbf{K}}_n$. Our goal is to provide an essential estimate for the difference of these two operators.

For $v \in L^\infty(E)$ we set

$$\mathcal{P}_n v = \sum_{(i,j)\in\mathbb{U}_n} v_{ij} w_{ij}$$

and note that the quantities v_{ij} are linear functionals of v. In the next lemma, we estimates these quantities under the following two additional requirements.

(VI) There exists a positive integer $\mu > 1$ and positive constants c_-, c_+ such that as $n \to \infty$

$$c_-\mu^n \le \dim\ \mathbb{F}_n \le c_+\mu^n,$$

$$c_-\mu^n \le \dim\ \mathbb{W}_n \le c_+\mu^n,$$

and

$$c_-\mu^{-n/d} \le d_n \le c_+\mu^{-n/d}.$$

Condition (VI) says that the dimension of spaces $\mathbb{F}_n$ and $\mathbb{W}_n$ grows exponentially in n and the diameters d_n decay exponentially in n. The next condition imposes an addition restriction on the constant γ appearing in (2.11).

(VII) The constant γ in hypothesis (II) satisfies the condition

$$(1+\gamma)\mu^{-k/d} < 1.$$

LEMMA 4.1. *Suppose that conditions* (I)–(IV), (VI), *and* (VII) *hold. If* $v \in W^{k,\infty}(E)$, *then there exists a positive constant* c *such that*

$$|v_{ij}| \le c\mu^{-ki/d}\|v\|_{k,\infty}, \quad (i,j) \in \mathbb{U}_n. \tag{4.1}$$

Proof. For $v \in W^{k,\infty}(E)$, we write

$$\mathcal{P}_n v = \sum_{(i,j)\in\mathbb{U}_n} v_{ij} w_{ij}$$

and denote $\mathbf{v} := [v_{ij} : (i,j) \in \mathbb{U}_n]$. By the definition of the projection $\mathcal{P}_n$, we have that

$$\mathbf{E}_n\mathbf{v} = \left[\left\langle \ell_{ij}, \sum_{(i',j')\in\mathbb{U}_n} v_{i'j'} w_{i'j'} \right\rangle : (i,j) \in \mathbb{U}_n\right] = [\langle \ell_{ij}, v\rangle : (i,j) \in \mathbb{U}_n].$$

Meanwhile, using Lemma 2.1 with $\nu := \mu^{-k/d}$ and condition (VII), we conclude that

$$\|\mathbf{v}\|_{\mu^{-k/d}} \le c\|\mathbf{E}_n\mathbf{v}\|_{\mu^{-k/d}},$$

where

$$c := \frac{1-\mu^{-k/d}}{1-(1+\gamma)\mu^{-k/d}} > 0$$

is a constant. Hence,

$$\|\mathbf{v}\|_{\mu^{-k/d}} \le c \max_{(i,j)\in\mathbb{U}_n} |\mu^{ik/d} \langle \ell_{ij}, v\rangle |. \tag{4.2}$$

On the other hand, recalling that the "support" of the functional ℓ_{ij} is the set $\hat{S}_{ij} \subseteq S_{ij}$, we use the Taylor theorem with remainder on the set S_{ij} for $v \in W^{k,\infty}(E)$ and conditions (III), (IV), and (VI) to conclude that there exists a positive constant c such that

$$| \langle \ell_{ij}, v\rangle | \le c d_i^k \|v\|_{k,\infty} \le c\mu^{-ki/d}\|v\|_{k,\infty}.$$

Combining this inequality with (4.2) we obtain the estimate

$$\|\mathbf{v}\|_{\mu^{-k/d}} \le c\|v\|_{k,\infty}.$$

Again, using the definition of the weighted norms, we have that

$$\|\mathbf{v}_i\|_\infty \le c\mu^{-ki/d}\|v\|_{k,\infty},$$

which proves the estimate of this lemma. □

Lemma 4.1 ensures that for a function $v \in W^{k,\infty}(E)$ the coefficients of its expansion in basis W_n and functionals L_n decay in order $\mathcal{O}(\mu^{-ik/d})$. This is an extension of a well-known result for orthogonal wavelets to the interpolating wavelets constructed in this paper.

For any real numbers α and β, we make use of the notation

$$\mu[\alpha,\beta;n] := \sum_{i\in\mathbb{Z}_{n+1}} \mu^{\alpha i/d} \sum_{i'\in\mathbb{Z}_{n+1}} \mu^{\beta i'/d}$$

to state the next lemma, which will play an important role in the analysis for the order of convergence and stability of the multiscale collocation method. To prove the

next lemma, we need to estimate the $L^\infty(E)$ norm of a typical element in $\mathbb{F}_n$ given by

$$v := \sum_{(i,j)\in\mathbb{U}_n} v_{ij} w_{ij} \tag{4.3}$$

by the norm $\|\mathbf{v}\|_\infty$ of its coefficients $\mathbf{v} := [v_{ij} : (i,j) \in \mathbb{U}_n]^T$. Specifically, we require the following condition.

(VIII) There exist positive constants θ_2 and θ_3 such that for all $n \in \mathbb{N}_0$ and v having form (4.3)

$$\theta_2 \|\mathbf{v}\|_\infty \le \|v\|_\infty \le \theta_3 (n+1) \|\mathbf{E}_n \mathbf{v}\|_\infty. \tag{4.4}$$

One way to satisfy this hypothesis is to consider the sequence of functions $\{\zeta_{ij} : (i,j) \in \mathbb{U}\}$ defined by the equation

$$\zeta_{ij} := \sum_{(i',j')\in\mathbb{U}} (\mathbf{E}^{-1})_{i'j',ij} w_{i'j'}, \quad (i,j) \in \mathbb{U}.$$

These functions are biorthogonal relative to the set of linear functionals $\{\ell_{ij} : j \in \mathbb{Z}_{w(i)}, i \in \mathbb{N}_0\}$, that is,

$$\langle \ell_{i'j'}, \zeta_{ij} \rangle = \delta_{ii'} \delta_{jj'}, \quad (i,j), (i',j') \in \mathbb{U}.$$

If in addition for all $i \in \mathbb{N}_0$

$$\sup_{t\in E} \sum_{j\in\mathbb{Z}_{w(i)}} |\zeta_{ij}(t)| \le \theta_3, \tag{4.5}$$

then the second inequality of (4.4) follows.

In the next lemma, we estimate the difference of operators $\mathcal{K}_n$ and $\tilde{\mathcal{K}}_n$ applying to $\mathcal{P}_n v$. It is an important step for both stability analysis and the convergence estimate.

LEMMA 4.2. *Suppose that conditions* (I)–(VIII) *hold,* $0 < \sigma' < \min\{2k, d - \sigma\}$, *and* $\eta := 2k - \sigma'$. *Let* b *and* b' *be real numbers, and let the truncation parameters* $\epsilon^n_{i'i}$, $i', i \in \mathbb{Z}_{n+1}$, *be chosen such that*

$$\epsilon^n_{i'i} \ge \max\{a\mu^{[-n+b(n-i)+b'(n-i')]/d}, r(d_i + d_{i'})\}, \quad i, i' \in \mathbb{Z}_{n+1},$$

for some constants $a > 0$ *and* $r > 1$. *Then there exists a positive constant* c *independent of* n *such that for any* $v \in W^{k,\infty}(E)$,

$$\|(\mathcal{K}_n - \tilde{\mathcal{K}}_n)\mathcal{P}_n v\|_\infty \le c\mu[2k - b\eta, k - b'\eta; n](n+1)\mu^{-(k+\sigma')n/d}\|v\|_{k,\infty} \tag{4.6}$$

and for $v \in L^\infty(E)$,

$$\|(\mathcal{K}_n - \tilde{\mathcal{K}}_n)\mathcal{P}_n v\|_\infty \le c\mu[k - b\eta, k - b'\eta; n](n+1)\mu^{-\sigma' n/d}\|v\|_\infty. \tag{4.7}$$

Proof. Since

$$\mathcal{P}_n v = \sum_{(i,j)\in\mathbb{U}_n} v_{ij} w_{ij},$$

we conclude that

$$(\mathcal{K}_n - \tilde{\mathcal{K}}_n)\mathcal{P}_n v = \sum_{(i,j)\in\mathbb{U}_n} h_{ij} w_{ij},$$

where

$$\mathbf{h} := \mathbf{E}_n^{-1}(\mathbf{K}_n - \tilde{\mathbf{K}}_n)\mathbf{v}.$$

Thus, by hypothesis (VIII), we conclude that

$$\|(\mathcal{K}_n - \tilde{\mathcal{K}}_n)\mathcal{P}_n v\|_\infty \le \theta_3(n+1)\|(\mathbf{K}_n - \tilde{\mathbf{K}}_n)\mathbf{v}\|_\infty. \tag{4.8}$$

We next estimate $\|(\mathbf{K}_n - \tilde{\mathbf{K}}_n)\mathbf{v}\|_\infty$. To this end, we introduce the matrix

$$\mathbf{\Delta}_n := [\Delta_{i'j',ij}]_{f(n)\times f(n)},$$

whose elements are given by

$$\Delta_{i'j',ij} := \nu\mu^{k(n-i)/d+\sigma' n/d}(K_{i'j',ij} - \tilde{K}_{i'j',ij}), \quad (i,j),(i',j') \in \mathbb{U}_n,$$

where $\nu = 1/\mu[2k - b\eta, k - b'\eta; n]$ and the vector

$$\mathbf{v}' := [v'_{ij} : (i,j) \in \mathbb{U}_n]$$

whose components are

$$v'_{ij} := \mu^{ki/d} v_{ij}, \quad (i,j) \in \mathbb{U}_n.$$

In this notation, we observe that

$$\|(\mathbf{K}_n - \tilde{\mathbf{K}}_n)\mathbf{v}\|_\infty \le \nu^{-1}\mu^{-(k+\sigma')n/d}\|\mathbf{\Delta}_n\|_\infty\|\mathbf{v}'\|_\infty. \tag{4.9}$$

By Lemma 4.1 we have that there exists a positive constant c such that for $v \in W^{k,\infty}(E)$,

$$\|\mathbf{v}'\|_\infty \le c\|v\|_{k,\infty}. \tag{4.10}$$

On the other hand, from Lemma 3.2, there exists a positive constant c such that

$$\begin{aligned}\sum_{(i,j)\in\mathbb{U}_n} \Delta_{i'j',ij} &\le \nu \sum_{i\in\mathbb{Z}_{n+1}} \mu^{k(n-i)/d+\sigma' n/d}\|\mathbf{K}_{i'i} - \tilde{\mathbf{K}}_{i'i}\|_\infty \\ &\le c\nu \sum_{i\in\mathbb{Z}_{n+1}} \mu^{k(n-i)/d+\sigma' n/d-k(i+i')/d}(\epsilon_{i'i}^n)^{-\eta}.\end{aligned}$$

Consequently, by the choice of $\epsilon_{i'i}$, we conclude that

$$\|\mathbf{\Delta}_n\|_\infty := \max_{(i',j')\in\mathbb{U}_n} \sum_{(i,j)\in\mathbb{U}_n} \Delta_{i'j',ij} \le c. \tag{4.11}$$

Combining (4.9)–(4.11) yields the first estimate.

To prove the second estimate, we proceed similarly and introduce the matrix

$$\mathbf{\Delta'}_n := [\Delta'_{i'j',ij}]_{f(n)\times f(n)},$$

whose entries are given by

$$\Delta'_{i'j',ij} := \nu' \mu^{\sigma' n/d}(K_{i'j',ij} - \tilde{K}_{i'j',ij}), \quad (i,j),(i',j') \in \mathbb{U}_n,$$

where $\nu' = 1/\mu[k - b\eta, k - b'\eta; n]$. With these quantities, we have the estimate

$$\|(\mathbf{K}_n - \tilde{\mathbf{K}}_n)\mathbf{v}\|_\infty \le (\nu')^{-1}\mu^{-\sigma' n/d}\|\mathbf{\Delta}'_n\|_\infty \|\mathbf{v}\|_\infty. \tag{4.12}$$

Condition (VIII) provides a positive constant c such that for $v \in L^\infty(E)$,

$$\|\mathbf{v}\|_\infty \le c\|v\|_\infty. \tag{4.13}$$

As before, Lemma 3.2 and the choice of $\epsilon_{i'i}$, $i, i' \in \mathbb{Z}_{n+1}$, ensure that there exists a positive constant c such that

$$\|\mathbf{\Delta}'_n\|_\infty \le c. \tag{4.14}$$

Combining this inequality with (4.12)–(4.13) yields the second estimate. □

We now turn our attention to the stability of the multiscale collocation method. For this purpose, we require the next hypothesis.

(IX) The operator $\mathcal{P}_n$ converges pointwise to the identity operator $\mathcal{I}$ in $L^\infty(E)$ as $n \to \infty$. In other words, for any $x \in L^\infty(E)$, there holds

$$\lim_{n\to\infty} \|\mathcal{P}_n x - x\|_\infty = 0.$$

Condition (IX) follows trivially if $\mathbb{F}_n$ is a space of piecewise polynomials. Because of this property and the fact that $\mathcal{K}$ is compact, we conclude for sufficiently large n that the operators $(\mathcal{I} - \mathcal{K}_n)^{-1}$ exist and are uniformly bounded in $L^\infty(E)$ (see, for example, [An, At2]). From this fact follows the stability estimate; that is, there exists a positive constant ρ and a positive integer m such that for $n \ge m$ and $x \in \mathbb{F}_n$ there holds that

$$\|(\mathcal{I} - \mathcal{K}_n)x\|_\infty \ge \rho\|x\|_\infty.$$

We shall establish a similar estimate for $\mathcal{I} - \tilde{\mathcal{K}}_n$.

THEOREM 4.3. *Suppose that* $0 < \sigma' < \min\{2k, d - \sigma\}$ *and* $\eta := 2k - \sigma'$. *If the conditions* (I)–(IX) *hold and* $\epsilon^n_{i'i}$, $i, i' \in \mathbb{Z}_{n+1}$, *are chosen as in Lemma* 4.2 *with*

$$b > \frac{k - \sigma'}{\eta}, \quad b' > \frac{k - \sigma'}{\eta}, \quad b + b' > 1,$$

then there exists a positive constant c *and a positive integer* m *such that when* $n \ge m$ *and* $x \in \mathbb{F}_n$,

$$\|(\mathcal{I} - \tilde{\mathcal{K}}_n)x\|_\infty \ge c\|x\|_\infty.$$

Proof. Note that for any real numbers α, β, and e,

$$\lim_{n\to\infty} \mu[\alpha, \beta; n](n+1)\mu^{-en/d} = 0$$

when $e > \max\{0, \alpha, \beta, \alpha+\beta\}$. Thus, our hypothesis ensures that there exists a positive integer m such that when $n \ge m$,

$$c\mu[k - b\eta, k - b'\eta; n](n+1)\mu^{-\sigma' n/d} < \rho/2, \tag{4.15}$$

where the constant c is the one appearing in (4.7). The stability of the collocation scheme and the second estimate in Lemma 4.2, together with (4.15), yield for $x \in \mathbb{F}_n$ that

$$\|(\mathcal{I} - \tilde{\mathcal{K}}_n)x\|_\infty \geq \|(\mathcal{I} - \mathcal{K}_n)x\|_\infty - \|(\mathcal{K}_n - \tilde{\mathcal{K}}_n)\mathcal{P}_n x\|_\infty \geq \frac{\rho}{2}\|x\|_\infty.$$

This completes the proof. □

In particular, this theorem ensures for $n \geq m$ that the equation

$$(\mathcal{I} - \tilde{\mathcal{K}}_n)\tilde{u}_n = \mathcal{P}_n f \tag{4.16}$$

has a unique solution given by

$$\tilde{u}_n := \sum_{(i,j)\in\mathbb{U}_n} \tilde{u}_{ij} w_{ij}.$$

This equation is equivalent to the matrix equation

$$(\mathbf{E}_n - \tilde{\mathbf{K}}_n)\tilde{\mathbf{u}}_n = \mathbf{f}_n,$$

where $\tilde{\mathbf{u}}_n = [\tilde{u}_{ij} : (i,j) \in \mathbb{U}_n]^T$. The next theorem provides error bounds for $\|u - \tilde{u}_n\|_\infty$. For this purpose, we introduce the next condition.

(X) There exists a positive constant c such that for $u \in W^{k,\infty}(E)$

$$\operatorname{dist}(u, \mathbb{F}_n) \leq c\mu^{-kn/d}\|u\|_{k,\infty}.$$

When $\mathbb{F}_n$ contains the piecewise polynomials of order k, the estimate in condition (X) follows directly from (2.2) and condition (VI).

THEOREM 4.4. *Suppose that conditions* (I)–(X) *hold and that* $0 < \sigma' < \min\{2k, d - \sigma\}$ *and* $\eta := 2k - \sigma'$. *Let* $\epsilon^n_{i'i}$, $i, i' \in \mathbb{Z}_{n+1}$, *be chosen as in Lemma* 4.2 *with* b *and* b' *satisfying one of the following three conditions:*

(i) $b > 1$, $b' > \frac{k-\sigma'}{\eta}$, $b + b' > 1 + \frac{k}{\eta}$.

(ii) $b = 1$, $b' > \frac{k-\sigma'}{\eta}$, $b + b' \geq 1 + \frac{k}{\eta}$; $b > 1$, $b' = \frac{k-\sigma'}{\eta}$, $b + b' > 1 + \frac{k}{\eta}$; *or* $b > 1$, $b' = \frac{k-\sigma'}{\eta}$, $b + b' = 1 + \frac{k}{\eta}$.

(iii) $b = 1$, $b' = \frac{k}{\eta}$; *or* $b = \frac{2k}{\eta}$, $b' = \frac{k-\sigma'}{\eta}$.

Then there exists a positive constant c *and positive integer* m *such that for all* $n \geq m$,

$$\|u - \tilde{u}_n\|_\infty \leq c f(n)^{-k/d}(\log f(n))^\tau \|u\|_{k,\infty},$$

where $\tau = 0$ *in case* (i), $\tau = 1$ *in case* (ii), *and* $\tau = 2$ *in case* (iii).

Proof. It follows from Theorem 4.3 that there exists a positive constant c such that

$$\|u - \tilde{u}_n\|_\infty \leq \|u - \mathcal{P}_n u\|_\infty + c\|(\mathcal{I} - \tilde{\mathcal{K}}_n)(\mathcal{P}_n u - \tilde{u}_n)\|_\infty. \tag{4.17}$$

Using the equation

$$\mathcal{P}_n(\mathcal{I} - \mathcal{K})u = (\mathcal{I} - \tilde{\mathcal{K}}_n)\tilde{u}_n,$$

we find that

$$(\mathcal{I} - \tilde{\mathcal{K}}_n)(\mathcal{P}_n u - \tilde{u}_n) = \mathcal{P}_n(\mathcal{I} - \mathcal{K})(\mathcal{P}_n u - u) + (\mathcal{K}_n - \tilde{\mathcal{K}}_n)\mathcal{P}_n u. \tag{4.18}$$

From (4.17), (4.18), hypothesis (IX), and Lemma 4.2, there exist positive constants c, p such that

$$\|u - \tilde{u}_n\|_\infty \le (1 + p\|\mathcal{I} - \mathcal{K}\|)\|\mathcal{P}_n u - u\|_\infty + c\mu' \mu^{-kn/d}\|u\|_{k,\infty},$$

where

$$\mu' := \mu[2k - b\eta, k - b'\eta; n](n+1)\mu^{-\sigma' n/d}.$$

We estimate each term separately. For the first term, we note that conditions (IX) and (X) provide a positive constant c such that

$$\|\mathcal{P}_n u - u\|_\infty \le c\mu^{-kn/d}\|u\|_{k,\infty}.$$

Now we turn our attention to estimating the quantity μ'. To this end, we observe for any real numbers α, β, and e with $e > 0$, the asymptotic order

$$\mu[\alpha, \beta; n](n+1)\mu^{-en/d} = \begin{cases} o(1) & \text{if } \ e > \max\{\alpha, \beta, \alpha + \beta\}, \\ \mathcal{O}(n) & \text{if } \ \alpha = e, \beta < e, \alpha + \beta < e \\ & \text{or if } \ \alpha < e, \beta = e, \alpha + \beta < e \\ & \text{or if } \ \alpha < e, \beta < e, \alpha + \beta = e, \\ \mathcal{O}(n^2) & \text{if } \ \alpha = 0, \beta = e \ \text{ or if } \ \alpha = e, \beta = 0, \end{cases}$$

as $n \to \infty$. Using this fact with $\alpha := 2k - b\eta$, $\beta := k - b'\eta$, and $e := \sigma'$, we conclude that

$$\mu' = \begin{cases} o(1) & \text{in case (i)}, \\ \mathcal{O}(n) & \text{in case (ii)}, \\ \mathcal{O}(n^2) & \text{in case (iii)}, \end{cases}$$

which establishes the result of this theorem by noting that $n = \log f(n)$. ∎

We see from this theorem that the convergence order of the approximate solution $\tilde{u}$ obtained from the truncated collocation method is almost optimal.

We next estimate the condition number of the matrix $\tilde{\mathbf{A}}_n := \mathbf{E}_n - \tilde{\mathbf{K}}_n$.

THEOREM 4.5. *If the conditions of Theorem* 4.3 *hold, then there exists a positive constant c such that the condition number of the matrix $\tilde{\mathbf{A}}_n$ satisfies the estimate*

$$\mathrm{cond}_\infty(\tilde{\mathbf{A}}_n) \le c \log^2(f(n)),$$

where $\mathrm{cond}_\infty(\mathbf{A})$ *denotes the condition number of a matrix* $\mathbf{A}$ *in the* ℓ^∞ *matrix norm.*

Proof. For any $\mathbf{v} := [v_{ij} : (i,j) \in \mathbb{U}_n]^T \in \mathbb{R}^{f(n)}$, we define the vector $\mathbf{g} := [g_{ij} : (i,j) \in \mathbb{U}_n]^T \in \mathbb{R}^{f(n)}$ by the equation

$$\tilde{\mathbf{A}}_n \mathbf{v} = \mathbf{g} \tag{4.19}$$

and the function

$$g := \sum_{(i,j) \in \mathbb{U}_n} g_{ij} \zeta_{ij}.$$

Therefore, we have that

$$g_{ij} = \langle \ell_{ij}, g \rangle = \langle \ell_{ij}, \mathcal{P}_n g \rangle, \quad (i,j) \in \mathbb{U}_n.$$

It follows from (IV) that

$$\|\tilde{\mathbf{A}}_n \mathbf{v}\|_\infty \le \theta_0 \|\mathcal{P}_n g\|_\infty. \tag{4.20}$$

Let

$$v := \sum_{(i,j)\in \mathbb{U}_n} v_{ij} w_{ij},$$

and observe the equation

$$(\mathcal{I} - \tilde{\mathcal{K}}_n) v = \mathcal{P}_n g. \tag{4.21}$$

We conclude from (4.20) and (4.21) that there exists a positive constant c such that

$$\begin{aligned} \|\tilde{\mathbf{A}}_n \mathbf{v}\|_\infty &\le \theta_0 \|(\mathcal{I} - \tilde{\mathcal{K}}_n) v\|_\infty \\ &\le \theta_0 (\|(\mathcal{I} - \mathcal{K}_n) v\|_\infty + \|(\mathcal{K}_n - \tilde{\mathcal{K}}_n) v\|_\infty) \\ &\le c \|v\|_\infty, \end{aligned}$$

where the last inequality holds because of (4.7) and (4.15). Next, appealing to hypotheses (I) and (IV), we observe for any $t \in E$ and $i \in \mathbb{Z}_{n+1}$ that

$$\left| \sum_{j \in \mathbb{Z}_{w(i)}} v_{ij} w_{ij}(t) \right| \le \rho \theta_0 \|\mathbf{v}\|_\infty,$$

because there are at most ρ value of $j \in \mathbb{Z}_{w(i)}$ such that functions $w_{ij}(t) \neq 0$. Therefore, we conclude that

$$\|v\|_\infty \le \rho \theta_0 (n+1) \|\mathbf{v}\|_\infty. \tag{4.22}$$

Consequently, there exists a positive constant c such that

$$\|\tilde{\mathbf{A}}_n\|_\infty \le c(n+1). \tag{4.23}$$

Conversely, for any $\mathbf{g} \in \mathbb{R}^{f(n)}$, there exists a vector $\mathbf{v} \in \mathbb{R}^{f(n)}$ such that (4.19) holds. Similar to (4.22), we argue that there exists a positive constant c such that

$$\|g\|_\infty \le c(n+1) \|\mathbf{g}\|_\infty.$$

Hence, we obtain from condition (VIII) the inequality

$$\|\mathbf{v}\|_\infty \le c\|v\|_\infty \le c\|(\mathcal{I} - \tilde{\mathcal{K}}_n) v\|_\infty = c\|g\|_\infty \le c(n+1)\|\mathbf{g}\|_\infty$$

from which it follows that there exists a positive constant c such that

$$\|\tilde{\mathbf{A}}_n^{-1}\|_\infty \le c(n+1). \tag{4.24}$$

Recalling hypothesis (VI) we combine the estimates (4.23) and (4.24) to obtain the desired result, namely

$$\mathrm{cond}_\infty(\tilde{\mathbf{A}}_n) = \mathcal{O}\left((n+1)^2\right) = \mathcal{O}\left(\log^2(f(n))\right), \quad n \to \infty. \qquad \square$$

In the remainder of this section, we will estimate the number of nonzero entries of matrix $\tilde{\mathbf{A}}_n$, which shows that the truncation strategy embodied in Lemma 4.2 can

lead to a fast numerical algorithm for solving (2.12) while preserving nearly optimal order of convergence. For any matrix $\mathbf{A}$, we denote by $\mathcal{N}(\mathbf{A})$ the number of nonzero entries in $\mathbf{A}$. The proof of the following theorem closely follows a similar result in [MXZ].

THEOREM 4.6. *Suppose that hypotheses* (I) *and* (VI) *hold. Let b and b' be real numbers not larger than one and the truncation parameters $\epsilon^n_{i'i}$, $i', i \in \mathbb{Z}_{n+1}$, be chosen such that*

$$\epsilon^n_{i'i} \le \max\{a\mu^{[-n+b(n-i)+b'(n-i')]/d}, r(d_i + d_{i'})\}, \quad i, i' \in \mathbb{Z}_{n+1},$$

for some constants $a > 0$ and $r > 1$. Then

$$\mathcal{N}(\tilde{\mathbf{A}}_n) = \mathcal{O}(f(n)\log^\tau f(n)),$$

where $\tau = 1$ except for $b = b' = 1$, in which case $\tau = 2$.

Proof. We first estimate the number $\mathcal{N}(\tilde{\mathbf{A}}_{i'i})$. For fixed i, i', and j', if $\tilde{A}_{i'j',ij} \neq 0$, then $\operatorname{dist}(S_{i'j'}, S_{ij}) \le \epsilon^n_{i'i}$, so that

$$S_{ij} \subseteq S(i,i') := \{v : v \in \mathbb{R}^d, |v - v_0| \le d_i + d_{i'} + \epsilon^n_{i'i}\},$$

where v_0 is an arbitrary point in the set $S_{i'j'}$. Let $\mathcal{N}_{i,i'j'}$ be the number of such sets which are contained in $S(i,i')$. Using condition (VI) we conclude that there exists a positive constant c such that

$$\mathcal{N}_{i,i'j'} \le \frac{\operatorname{meas}(S(i,i'))}{\min\{\operatorname{meas}(S_{ij}) : S_{ij} \subseteq S(i,i')\}} \le c\mu^i(d_i + d_{i'} + \epsilon^n_{i'i})^d.$$

Next, we invoke condition (I) to conclude that the number of functions w_{ij} having support contained in S_{ij} is bounded by ρ, and appealing to condition (VI) we have that $w(i') = \mathcal{O}(\mu^{i'})$, $i' \to \infty$. Consequently, there exists a positive constant c such that

$$\mathcal{N}(\tilde{\mathbf{A}}_{i'i}) \le \rho \sum_{j' \in \mathbb{Z}_{w(i')}} N_{i,i'j'} \le c\mu^{i+i'}(d_i + d_{i'} + \epsilon^n_{i'i})^d, \quad i, i' \in \mathbb{Z}_{n+1},$$

from which it follows that

$$\mathcal{N}(\tilde{\mathbf{A}}_n) \le c \sum_{i,i' \in \mathbb{Z}_{n+1}} \mu^{i+i'} \left[(d_i)^d + (d_{i'})^d + (\epsilon^n_{i'i})^d\right].$$

This inequality and conditions (I) imply that if the truncation parameters have the bound

$$\epsilon^n_{i'i} \le a\mu^{[-n+b(n-i)+b'(n-i')]/d},$$

then

$$\begin{aligned}
\mathcal{N}(\tilde{\mathbf{A}}_n) &\le c \sum_{i' \in \mathbb{Z}_{n+1}} \sum_{i \in \mathbb{Z}_{n+1}} \mu^{i+i'} \left(\mu^{-i} + \mu^{-i'} + a^d \mu^{-n+b(n-i)+b'(n-i')}\right) \\
&\le c \left[2(n+1) \sum_{i \in \mathbb{Z}_{n+1}} \mu^i + a^d \mu^n \left(\sum_{i \in \mathbb{Z}_{n+1}} \mu^{(b-1)(n-i)}\right)\left(\sum_{i' \in \mathbb{Z}_{n+1}} \mu^{(b'-1)(n-i')}\right)\right] \\
&= \mathcal{O}\left(\mu^n (n+1)^\tau\right) = \mathcal{O}\left(f(n)\log^\tau f(n)\right),
\end{aligned}$$

as $n \to \infty$. If $\epsilon^n_{i'i} \le r(d_i + d_{i'})$, a similar argument leads to

$$\mathcal{N}(\tilde{\mathbf{A}}_n) = \mathcal{O}\left(f(n)\log f(n)\right), \quad n \to \infty.$$

This completes the proof. □

It follows from Theorems 4.3–4.6 that for the truncation scheme to have *all* the desired properties of stability, convergence, and complexity, we have to choose the truncation parameters to satisfy the equation

$$\epsilon^n_{i'i} = \max\{a\mu^{[-n+b(n-i)+b'(n-i')]/d}, r(d_i + d_{i'})\}, \quad i, i' \in \mathbb{Z}_{n+1},$$

with $b = 1$, $b' > \frac{k-\sigma}{\eta}$, $b + b' \ge 1\frac{k}{\eta}$ or with $b = 1$, $b' = \frac{k}{\eta}$, $\sigma' < k$.

5. A concrete construction of multiscale functions and functionals. Whenever the basis $W := \{w_{ij} : (i,j) \in \mathbb{U}\}$ and the collocation functionals $L := \{\ell_{ij} : (i,j) \in \mathbb{U}\}$ satisfy hypotheses (I)–(IV) and (VI)–(X), the results of the last three sections present convergence, complexity, and stability estimates for the truncated collocation method. In this section, we illustrate by an example of practical importance multiscale functions and functionals which satisfy all these hypotheses. Our point of view here is based on the notion of iterated function systems which we have recently investigated in the context of the numerical solutions of integral equations [MX1, MX2, CMX2, MSX2]. In our example below, the solution spaces will be piecewise polynomials on a multiscale partition. Let us first describe the method we use to generate a multiscale partition of an invariant set E.

We start with a positive integer μ and a family $\Phi := \{\phi_e : e \in \mathbb{Z}_\mu\}$ of contractive affine mappings on $\mathbb{R}^d$. There exists a unique compact subset E of $\mathbb{R}^d$ such that

$$\Phi(E) = E, \tag{5.1}$$

where

$$\Phi(E) := \bigcup_{e \in \mathbb{Z}_\mu} \phi_e(E)$$

(see [H]). This set E is called the invariant set associated with the family of mappings Φ. Generally, it has a complex *fractal* structure. For example, there are choices of Φ for which E is the Cantor subset of $[0,1]$, the Sierpinski gasket contained in an equilateral triangle, or the twin dragons from wavelet analysis. We are interested in the cases when E has a simple structure which include, for example, the cube and simplex in $\mathbb{R}^d$. With these cases in mind, we make the following additional restriction on the family of mappings Φ.

(a) For every $e \in \mathbb{Z}_\mu$, the mapping ϕ_e has a continuous inverse on E.

(b) The set E has nonempty interior and

$$\text{meas}\,(\phi_e(E) \cap \phi_{e'}(E)) = 0, \quad e, e' \in \mathbb{Z}_\mu, e \ne e'.$$

We use Φ to obtain a multiscale partition $\{E_n : n \in \mathbb{N}_0\}$ of the set E in the following way. Given any $\mathbf{e} := (e_0, e_1, \ldots, e_{n-1}) \in \mathbb{Z}^n_\mu := \mathbb{Z}_\mu \times \cdots \times \mathbb{Z}_\mu$, n times, we define the mappings

$$\phi_{\mathbf{e}} := \phi_{e_0} \circ \phi_{e_1} \circ \cdots \circ \phi_{e_{n-1}}$$

and the number

$$\mu(\mathbf{e}) := \mu^{n-1}e_0 + \cdots + \mu e_{n-2} + e_{n-1}.$$

Note that every $i \in \mathbb{Z}_{\mu^n}$ can be uniquely written as $i = \mu(\mathbf{e})$ for some $\mathbf{e} \in \mathbb{Z}_\mu^n$. From (5.1) and conditions (a) and (b) it follows that the collection of sets

$$E_n := \{E_{n,\mathbf{e}} : E_{n,\mathbf{e}} = \phi_{\mathbf{e}}(E),\ \mathbf{e} \in \mathbb{Z}_\mu^n\}$$

forms a partition of E. We require that this partition has the following property:

(c) There exist positive constants c_-, c_+ such that for all $n \in \mathbb{N}_0$

$$c_- \mu^{-n/d} \le \max\{d(E_{n,\mathbf{e}}) : \mathbf{e} \in \mathbb{Z}_\mu^n\} \le c_+ \mu^{-n/d}. \tag{5.2}$$

This requirement is fulfilled when the Jacobi of the contractive affine mappings ϕ_e, $e \in \mathbb{Z}_\mu$, have the property that

$$J_{\phi_e} \sim \mathcal{O}(\mu^{-1}).$$

In fact, for any $s, t \in \phi_e(E)$, there exist $\hat{s}, \hat{t} \in E$ such that $s = \phi_e(\hat{s})$ and $t = \phi_e(\hat{t})$, and thus we have that

$$|s - t| \sim (J_{\phi_e})^{1/d} |\hat{s} - \hat{t}|.$$

This with the hypothesis on the Jacobi of the mappings ensures that for any $e \in \mathbb{Z}_\mu$

$$d(E_{1,e}) \sim \mathcal{O}(\mu^{-1/d}),$$

and by induction we find that for any $\mathbf{e} \in \mathbb{Z}_\mu^n$,

$$d(E_{n,\mathbf{e}}) \sim \mathcal{O}(\mu^{-n/d}).$$

On the partition E_n, we consider piecewise polynomials. Choose a positive integer k and let $\mathbb{F}_n$ be the spaces of all functions such that their restriction to any cell $E_{n,\mathbf{e}}$, $\mathbf{e} \in \mathbb{Z}_\mu^n$, is a polynomial of total degree $\le k - 1$. Here we use the convention that for $n = 0$ the set E is the only cell in the partition and so

$$m := \dim \mathbb{F}_0 = \begin{pmatrix} k + d - 1 \\ d \end{pmatrix}.$$

We must generate a suitable multiscale decomposition of $\mathbb{F}_n$. To this end, let

$$G_0 = \{t_j : j \in \mathbb{Z}_m\}$$

be a finite set of distinct points in E, which is refinable relative to the mappings Φ; that is, G_0 satisfies

$$G_0 \subseteq \Phi(G_0).$$

Set

$$G_1 := \Phi(G_0), \quad V_1 := G_1 \setminus G_0 = \{t_{m+j} : j \in \mathbb{Z}_r\}$$

with $r := (\mu - 1)m$. Now, we require that there exists a basis of elements in $\mathbb{F}_0$, denoted by $\psi_0, \psi_1, \ldots, \psi_{m-1}$ such that

$$\mathbb{F}_0 := \operatorname{span}\{\psi_j : j \in \mathbb{Z}_m\},$$

and they satisfy Lagrange interpolation conditions

$$\psi_i(t_j) = \delta_{i,j}, \quad i,j \in \mathbb{Z}_m. \tag{5.3}$$

A construction of refinable points $\{t_j : j \in \mathbb{Z}_m\} \in E$ that admits a unique d-dimensional Lagrange interpolation is presented in [MSX1].

With this basis of $\mathbb{F}_0$ at hand, we will generate a multiscale basis for $\mathbb{F}_0$ in the following way. For this purpose, we introduce linear operators $\mathcal{T}_e : \mathbb{X} \to \mathbb{X}$, $e \in \mathbb{Z}_\mu$, defined by

$$(\mathcal{T}_e x)(t) := x(\phi_e^{-1}(t))\chi_{\phi_e(E)}(t),$$

where χ_S denotes the characteristic function of some set S, and observe that $\|\mathcal{T}_e\| = 1$. Therefore, it follows that

$$\mathbb{F}_n = \bigoplus_{e \in \mathbb{Z}_\mu} \mathcal{T}_e \mathbb{F}_{n-1}, \quad n \in \mathbb{N},$$

where $\mathbb{A} \oplus \mathbb{B}$ denotes the direct sum of the spaces $\mathbb{A}$ and $\mathbb{B}$. The functions $\psi_{m+j} \in \mathbb{F}_1$, $j \in \mathbb{Z}_r$, satisfying

$$\psi_{m+j}(t_i) = 0, \quad i \in \mathbb{Z}_m, j \in \mathbb{Z}_r, \quad \psi_{m+j}(t_{m+j'}) = \delta_{jj'}, \quad j,j' \in \mathbb{Z}_r \tag{5.4}$$

with ψ_j, $j \in \mathbb{Z}_m$, defined by (5.3), form a basis for $\mathbb{F}_1$.

We require another basis for $\mathbb{F}_1$ consisting of functions with vanishing moments. To this end, we set

$$w_{0j} := \psi_j, \quad j \in \mathbb{Z}_m.$$

We set $q := m + r$ and for $j \in \mathbb{Z}_r$ find a vector $[c_{js} : s \in \mathbb{Z}_q]^T \in \mathbb{R}^q$ such that

$$w_{1j} := \sum_{s \in \mathbb{Z}_q} c_{js}\psi_s, \quad j \in \mathbb{Z}_r, \tag{5.5}$$

satisfies the equation

$$(w_{1j}, \psi_{j'}) = 0, \quad j' \in \mathbb{Z}_m, \ j \in \mathbb{Z}_r. \tag{5.6}$$

Since for each $j \in \mathbb{Z}_r$, (5.6) is a linear system of rank m with m equations and q unknowns, there exist r linearly independent solutions of this system which we denote by $w_{1j}, j \in \mathbb{Z}_r$. These functions form a basis for the space $\mathbb{W}_1$.

Let us now turn our attention to a construction of collocation functionals. We begin by defining

$$\ell_{0j} := \delta_{t_j}, \quad j \in \mathbb{Z}_m,$$

and for $j' \in \mathbb{Z}_r$, we find the vector $[c'_{j's} : s \in \mathbb{Z}_q]$ such that

$$\ell_{1j'} := \sum_{s \in \mathbb{Z}_q} c'_{j's}\delta_{t_s}, \quad j' \in \mathbb{Z}_r, \tag{5.7}$$

satisfies the equations

$$\langle \ell_{1j'}, w_{0j} \rangle = 0, \quad j \in \mathbb{Z}_m, \quad j' \in \mathbb{Z}_r, \tag{5.8}$$

and

$$\langle \ell_{1j'}, w_{1j} \rangle = \delta_{jj'}, \quad j \in \mathbb{Z}_r, \quad j' \in \mathbb{Z}_r. \tag{5.9}$$

For $j \in \mathbb{Z}_r$, the matrix of order q for this linear system of equations is

$$\mathbf{A} := [\langle \delta_{t_{i'j'}}, w_{ij} \rangle]_{(i,j),(i',j') \in \mathbb{U}_1}.$$

Let us prove that the matrix $\mathbf{A}$ is nonsingular. To this end, we assume that there are constants $a_{ij}, (i,j) \in \mathbb{U}_1$, such that

$$\sum_{(i,j) \in \mathbb{U}_1} a_{ij} \langle \delta_{t_{i'j'}}, w_{ij} \rangle = 0, \quad (i',j') \in \mathbb{U}_1,$$

that is,

$$\left\langle \delta_{t_{i'j'}}, \sum_{(i,j) \in \mathbb{U}_1} a_{ij} w_{ij} \right\rangle = 0, \quad (i',j') \in \mathbb{U}_1.$$

Since the set G_1 is Lagrange admissible relative to $(\Phi, \mathbb{F}_1)$ (cf. [CMX2]), we conclude that

$$\sum_{(i,j) \in \mathbb{U}_1} a_{ij} w_{ij} = 0,$$

and therefore $a_{ij} = 0$, $(i,j) \in \mathbb{U}_1$. This proves that $\mathbf{A}$ is nonsingular.

We find it convenient to write (5.8)–(5.9) in a matrix form. For this purpose, we introduce matrices

$$\tilde{\mathbf{B}} := [\langle \delta_{t_i}, \psi_j \rangle]_{i,j \in \mathbb{Z}_q}, \quad \mathbf{B} := [\langle \delta_{t_{m+i}}, \psi_j \rangle]_{i \in \mathbb{Z}_r, j \in \mathbb{Z}_m},$$

$$\mathbf{C}_1 := [c_{js}]_{j \in \mathbb{Z}_r, s \in \mathbb{Z}_m}, \quad \mathbf{C}_2 := [c_{j,m+s}]_{j \in \mathbb{Z}_r, s \in \mathbb{Z}_r},$$

$$\mathbf{C}'_1 = [c'_{js}]_{j \in \mathbb{Z}_r, s \in \mathbb{Z}_m}, \quad \mathbf{C}'_2 := [c'_{j,m+s}]_{j \in \mathbb{Z}_r, s \in \mathbb{Z}_r},$$

and

$$\mathbf{C} := [\mathbf{C}_1, \mathbf{C}_2], \quad \mathbf{C}' := [\mathbf{C}'_1, \mathbf{C}'_2].$$

The next lemma gives a relationship between the matrices $\mathbf{C}$ and $\mathbf{C}'$.

LEMMA 5.1.

$$\mathbf{C}'_1 = -\mathbf{C}'_2 \mathbf{B}, \quad \mathbf{C}'_2 = (\mathbf{C}_2^T)^{-1}.$$

Proof. It follows from (5.8) and (5.9) that

$$\mathbf{C}' \tilde{\mathbf{B}} [\mathbf{I}_m \mathbf{O}_{m \times r}]^T = \mathbf{O}_{r \times m},$$

and

$$\mathbf{C}' \tilde{\mathbf{B}} \mathbf{C}^T = \mathbf{I}_r,$$

where $\mathbf{O}_{m\times r}$ denotes the $m\times r$ zero matrix and $\mathbf{I}_m$ denotes the $m\times m$ identity matrix. The properties of basis $\{\psi_j : j\in\mathbb{Z}_q\}$ and the functionals $\{\delta_{t_j} : j\in\mathbb{Z}_q\}$ described above in (5.3) and (5.4) imply that

$$\tilde{\mathbf{B}} = \begin{bmatrix} \mathbf{I}_m & \mathbf{O}_{m\times r} \\ \mathbf{B} & \mathbf{I}_r \end{bmatrix},$$

$$\mathbf{C}_1' + \mathbf{C}_2'\mathbf{B} = \mathbf{O}_{r\times m},$$

and

$$(\mathbf{C}_1' + \mathbf{C}_2'\mathbf{B})\mathbf{C}_1^T + \mathbf{C}_2'\mathbf{C}_2^T = \mathbf{I}_r,$$

from which the result follows. □

We next describe the construction of a basis for $\mathbb{W}_i$, $i\in\mathbb{N}$. To this end, for $\mathbf{e} := (e_0,\dots,e_{n-1})\in\mathbb{Z}_\mu^n$ we introduce a composition operator $\mathcal{T}_\mathbf{e}$ by

$$\mathcal{T}_\mathbf{e} := \mathcal{T}_{e_0}\circ\cdots\circ\mathcal{T}_{e_{n-1}}.$$

For $i = 2,3,\dots,n$ we let

$$w_{ij} := \mathcal{T}_\mathbf{e} w_{1l},\quad j=\mu(\mathbf{e})r+l,\quad \mathbf{e}\in\mathbb{Z}_\mu^{i-1},\quad l\in\mathbb{Z}_r, \tag{5.10}$$

and

$$\mathbb{W}_i := \operatorname{span}\{w_{ij} : j\in\mathbb{Z}_{w(i)}\}.$$

Observe that the support of w_{ij} is contained in $S_{ij} := \phi_\mathbf{e}(E)$, $j\in\mathbb{Z}_{w(i)}$.

To generate multiscale collocation functionals, we introduce for any $e\in\mathbb{Z}_\mu$ a linear operator $\mathcal{L}_e : \mathbb{X}^*\to\mathbb{X}^*$ defined by the equation

$$\langle \mathcal{L}_e\ell, v\rangle = \langle \ell, v\circ\phi_e\rangle,\qquad v\in\mathbb{X},\ \ell\in\mathbb{X}^*,$$

and observe that $\|\mathcal{L}_e\| = 1$. Moreover, for $\mathbf{e} := (e_0,\dots,e_{n-1})\in\mathbb{Z}_\mu^n$, we define the composition operator

$$\mathcal{L}_\mathbf{e} := \mathcal{L}_{e_0}\circ\cdots\circ\mathcal{L}_{e_{n-1}}.$$

Consequently, for any $\mathbf{e},\mathbf{e}'\in\mathbb{Z}_\mu^i$, $w\in\mathbb{X}$, and $\ell\in\mathbb{X}^*$, we have that

$$\langle \mathcal{L}_\mathbf{e}\ell, \mathcal{T}_{\mathbf{e}'}w\rangle = \langle \ell, w\rangle\,\delta_{\mathbf{e}\mathbf{e}'}. \tag{5.11}$$

In addition, for $i>1$, $j=\mu(\mathbf{e})r+l$, $\mathbf{e}\in\mathbb{Z}_\mu^{i-1}$, $l\in\mathbb{Z}_r$, we define

$$\ell_{ij} := \mathcal{L}_\mathbf{e}\ell_{1l} \tag{5.12}$$

and observe that

$$\langle \ell_{ij}, v\rangle = \langle \ell_{1l}, v\circ\phi_\mathbf{e}\rangle = \sum_{s\in\mathbb{Z}_q} c_{ls}' v(\phi_\mathbf{e}(t_s)).$$

Note that the "support" of ℓ_{ij} is also contained in S_{ij}.

We partition the matrix $\mathbf{E}_n$ into a block matrix

$$\mathbf{E}_n := [\mathbf{E}_{i'i}]_{i',i\in\mathbb{Z}_{n+1}},$$

where

$$\mathbf{E}_{i'i} := [E_{i'j',ij}]_{j'\in\mathbb{Z}_{w(i')},j\in\mathbb{Z}_{w(i)}},$$

and in the next lemma relate the norm of the matrix $\mathbf{E}_{i'i}$ to that of $\mathbf{E}_{1,i-i'+1}$.

LEMMA 5.2. *If $i', i \in \mathbb{N}$ with $i > i'$, then*

$$\|\mathbf{E}_{i'i}\|_\infty = \|\mathbf{E}_{1,i-i'+1}\|_\infty. \tag{5.13}$$

Proof. From the definition of $\ell_{i'j'}$ and w_{ij}, for $(i',j'),(i,j) \in \mathbb{U}_n$ with $i > i'$, we obtain that there exist $\mathbf{e} \in \mathbb{Z}_\mu^{i-1}$, $\mathbf{e}' \in \mathbb{Z}_\mu^{i'-1}$, $l, l' \in \mathbb{Z}_r$, such that

$$\langle \ell_{i'j'}, w_{ij}\rangle = \langle \mathcal{L}_{\mathbf{e}'}\ell_{1l'}, \mathcal{T}_{\mathbf{e}}w_{1l}\rangle\,.$$

We introduce the vectors

$$\mathbf{e}_1 := (e_0,\dots,e_{i'-2}), \quad \mathbf{e}_2 := (e_{i'-1},\dots,e_{i-2})$$

and conclude from (5.11) that

$$\langle \ell_{i'j'}, w_{ij}\rangle = \langle \ell_{1l'}, \mathcal{T}_{\mathbf{e}_2}w_{1l}\rangle\,\delta_{\mathbf{e}'\mathbf{e}_1}.$$

Let $j_0 := \mu(\mathbf{e}_2)r + l$ and obtain that

$$\langle \ell_{i'j'}, w_{ij}\rangle = \langle \ell_{1l'}, w_{i-i'+1,j_0}\rangle\,\delta_{\mathbf{e}'\mathbf{e}_1}.$$

Consequently, we have that

$$\sum_{j\in\mathbb{Z}_{w(i)}} |\langle \ell_{i'j'}, w_{ij}\rangle| = \sum_{j\in\mathbb{Z}_{w(i-i'+1)}} |\langle \ell_{1l'}, w_{i-i'+1,j}\rangle|\,,$$

which proves the lemma. ∎

Let us use this lemma to estimate the constant γ appearing in condition (2.11).

LEMMA 5.3. *The condition* (2.11) *is satisfied with*

$$\gamma := \max\{\|\mathbf{C}_1\|_1, \|\mathbf{C}'\|_\infty\|\mathbf{C}_1\|_1\}.$$

Proof. By Lemma 5.2, it suffices to prove for $i \in \mathbb{N}$ that

$$\|\mathbf{E}_{0i}\|_\infty \le \|\mathbf{C}_1\|_1 \tag{5.14}$$

and

$$\|\mathbf{E}_{1,i+1}\|_\infty \le \|\mathbf{C}'\|_\infty\|\mathbf{C}_1\|_1. \tag{5.15}$$

Recall the definition

$$\mathbf{E}_{1,i+1} = [\langle \ell_{1l'}, w_{i+1,j}\rangle]_{l'\in\mathbb{Z}_r, j\in\mathbb{Z}_{w(i+1)}}\,.$$

We need to decompose this matrix. This is done by using (5.7) to write

$$\ell_{1l'} = \sum_{s'\in\mathbb{Z}_q} c'_{l's'}\delta_{t_{s'}}, \quad l' \in \mathbb{Z}_r.$$

Thus, it follows from (5.5) and (5.10) for any $j \in \mathbb{Z}_{w(i+1)}$ that there exists a unique pair $\mathbf{e}_j \in \mathbb{Z}_\mu^i$ and $l \in \mathbb{Z}_r$ such that

$$w_{i+1,j} = \sum_{s \in \mathbb{Z}_q} c_{ls} \mathcal{T}_{\mathbf{e}_j} \psi_s.$$

Since for any $s' \in \mathbb{Z}_q, \mathbf{e}_j \in \mathbb{Z}_\mu^i, i \in \mathbb{N}$, and $s = m, \ldots, q-1$,

$$\left\langle \delta_{t_{s'}}, \mathcal{T}_{\mathbf{e}_j} \psi_s \right\rangle = 0,$$

we conclude for $l' \in \mathbb{Z}_r$, $j = \mu(\mathbf{e}_j)r + l$, $\mathbf{e}_j \in \mathbb{Z}_\mu^i$, $l \in \mathbb{Z}_r$, that

$$\langle \ell_{1l'}, w_{i+1,j} \rangle = \sum_{s' \in \mathbb{Z}_q} \sum_{s \in \mathbb{Z}_m} c'_{l's'} c_{ls} \left\langle \delta_{t_{s'}}, \mathcal{T}_{\mathbf{e}_j} \psi_s \right\rangle.$$

We write this equation in matrix form by introducing for each $\mathbf{e} \in \mathbb{Z}_\mu^i$ matrix

$$\mathbf{D}_\mathbf{e} := \left[\left\langle \delta_{t_{s'}}, \mathcal{T}_\mathbf{e} \psi_s \right\rangle \right]_{s' \in \mathbb{Z}_q, s \in \mathbb{Z}_m}$$

and from these matrices build the matrix

$$\mathbf{D} := \left[\mathbf{D}_{\mathbf{e}_0}, \mathbf{D}_{\mathbf{e}_1}, \ldots, \mathbf{D}_{\mathbf{e}_{\mu^i - 1}} \right].$$

This notation allows us to write

$$\mathbf{E}_{1,i+1} = \mathbf{C}' \mathbf{D} \mathrm{diag}\{\mathbf{C}_1^T, \ldots, \mathbf{C}_1^T\},$$

where the rightmost matrix is a block diagonal matrix with μ^i identical blocks of $\mathbf{C}_1^T$. This formula will allow us to estimate the norm of the matrix $\mathbf{E}_{1,i+1}$.

Because the set G_0 is refinable relative to the contractive affine mappings Φ, we are assumed that for any $s' \in \mathbb{Z}_m$ there exist a unique $\mathbf{e}'' \in \mathbb{Z}_\mu^i$ and $s'' \in \mathbb{Z}_m$ such that $t_{s'} = \phi_{\mathbf{e}''}(t_{s''})$. Thus

$$\left\langle \delta_{t_{s'}}, \mathcal{T}_\mathbf{e} \psi_s \right\rangle = \left\langle \mathcal{L}_{\mathbf{e}''} \delta_{t_{s''}}, \mathcal{T}_\mathbf{e} \psi_s \right\rangle = \left\langle \delta_{t_{s''}}, \psi_s \right\rangle \delta_{\mathbf{e}''\mathbf{e}} = \delta_{ss''} \delta_{\mathbf{e}''\mathbf{e}},$$

which implies that $\|\mathbf{D}\|_\infty = 1$. Consequently, we conclude inequality (5.15). Similarly inequality (5.14) follows from

$$\mathbf{E}_{0i} = \left[\langle \ell_{0l'}, w_{ij} \rangle \right]_{l' \in \mathbb{Z}_m, j \in \mathbb{Z}_{w(i)}}.$$

This completes the proof of this lemma. □

We next show that the pair (W, L) of basis functions and collocation functionals constructed in this section satisfies hypotheses (I)–(IV) and (VI)–(X) described in the previous sections. This will be done in three propositions.

PROPOSITION 5.4. *The pair (W, L) satisfies hypotheses* (I)–(IV), (VI), (IX), *and* (X).

Proof. Hypothesis (I) is satisfied because for $(i, j) \in \mathbb{U}$, with $i > 1$, the support of w_{ij} is contained in $S_{ij} = \phi_\mathbf{e}(E) = E_{i-1,\mu(\mathbf{e})}$, where $j = \mu(\mathbf{e})r + l$, $l \in \mathbb{Z}_r$.

We now prove that the pair (W, L) satisfies hypothesis (II). For $(i, j) \in \mathbb{U}$, there exists a unique pair of $\mathbf{e} \in \mathbb{Z}_\mu^{i-1}$ and $l \in \mathbb{Z}_r$ such that $j = \mu(\mathbf{e})r + l$ and $w_{ij} = \mathcal{T}_\mathbf{e} w_{1l}$. Likewise, for $(i', j') \in \mathbb{U}$, there exists a unique pair of $\mathbf{e}' \in \mathbb{Z}_\mu^{i'-1}$ and $l' \in \mathbb{Z}_r$ such that $j' = \mu(\mathbf{e}')r + l'$ and $\ell_{i'j'} = \mathcal{L}_{\mathbf{e}'} \ell_{1l'}$. When $i = i'$, it follows from (5.11) and (5.9) that

$$\langle \ell_{i'j'}, w_{ij} \rangle = \langle \mathcal{L}_{\mathbf{e}'} \ell_{1l'}, \mathcal{T}_\mathbf{e} w_{1l} \rangle = \langle \ell_{1l'}, w_{1l} \rangle \delta_{\mathbf{e}'\mathbf{e}} = \delta_{l'l} \delta_{\mathbf{e}'\mathbf{e}} = \delta_{j'j}.$$

When $i < i'$, let $\mathbf{e}'_1 = (e'_0, \ldots, e'_{i-2}), \mathbf{e}'_2 = (e'_{i-1}, \ldots, e'_{i'-2})$; then

$$\langle \ell_{i'j'}, w_{ij} \rangle = \left\langle \mathcal{L}_{\mathbf{e}'_2} \ell_{1l'}, w_{1l} \right\rangle \delta_{\mathbf{e}'_1 \mathbf{e}} = \left\langle \ell_{1l'}, w_{1l} \circ \phi_{\mathbf{e}'_2} \right\rangle \delta_{\mathbf{e}'_1 \mathbf{e}}.$$

Since $\phi_{\mathbf{e}'_2} : E \to \phi_{\mathbf{e}'_2}(E)$ is an affine mapping, we conclude that $w_{1l} \circ \phi_{\mathbf{e}'_2}$ is a polynomial of total degree $\leq k-1$ in $\mathbb{F}_0$. By using (5.8), we have that

$$\langle \ell_{i'j'}, w_{ij} \rangle = 0, \quad (i,j), (i',j') \in \mathbb{U}, i < i'.$$

When $i > i'$, Lemma 5.3 ensures that condition (2.11) is satisfied. This proves hypothesis (II).

Next, we verify that hypothesis (III) is satisfied. Again, it follows from (5.8) that

$$\langle \ell_{i'j'}, \psi_j \rangle = \langle \ell_{1l'}, \psi_j \circ \phi_{\mathbf{e}'} \rangle = 0, \quad j \in \mathbb{Z}_m.$$

This proves the first equation of hypothesis (III). To prove the second equation, we consider $\mathcal{T}_{\mathbf{e}}$ as an operator from $L^2(E)$ to $L^2(E)$ and denote by $\mathcal{T}^*_{\mathbf{e}}$ the conjugate operator of $\mathcal{T}_{\mathbf{e}}$, which is defined by

$$(\mathcal{T}_{\mathbf{e}} x, y) = (x, \mathcal{T}^*_{\mathbf{e}} y), \quad x, y \in L^2(E).$$

It can be shown that for $y \in L^2(E)$

$$\mathcal{T}^*_{\mathbf{e}} y = J_{\phi_{\mathbf{e}}} y \circ \phi_{\mathbf{e}},$$

where $J_{\Phi_{\mathbf{e}}}$ is the Jacobi of mapping $\phi_{\mathbf{e}}$. Therefore, we have that

$$(w_{ij}, \psi_{j'}) = (\mathcal{T}_{\mathbf{e}} w_{1l}, \psi_{j'}) = (w_{1l}, \mathcal{T}^*_{\mathbf{e}} \psi_{j'}) = 0.$$

The last equality holds because $\mathcal{T}^*_{\mathbf{e}} \psi_{j'}$ is a polynomial of total degree $\leq k-1$ and w_{1l} satisfies condition (5.6).

From (5.12), (5.7), (5.10), and (5.5) we have that for $(i,j) \in \mathbb{U}, j = \mu(\mathbf{e})r + l$,

$$| \langle \ell_{ij}, v \rangle | = | \langle \ell_{1l}, v \circ \phi_{\mathbf{e}} \rangle | \leq \|\mathbf{C}'\|_\infty \|v\|_\infty$$

and

$$\|w_{ij}\|_\infty \leq \|w_{1l} \circ \phi^{-1}_{\mathbf{e}} \chi_{\phi_{\mathbf{e}}(E)}\|_\infty \leq \|\mathbf{C}\|_\infty \max_{j \in \mathbb{Z}_q} \|\psi_j\|_\infty,$$

which confirms hypothesis (IV).

By our construction, it is the case that

$$\dim \mathbb{F}_n = m\mu^n$$

and

$$\dim \mathbb{W}_n = m(\mu - 1)\mu^{n-1}.$$

These equations with (5.2) imply that hypothesis (VI) is satisfied.

The pointwise convergence of the interpolating projections $\mathcal{P}_n$ condition (IX) follows from a result of [AGS]. Finally, hypothesis (X) holds, since $\mathbb{F}_n$ are the spaces of piecewise polynomials of total degree $\leq k-1$. □

The next proposition regards hypothesis (VII).

PROPOSITION 5.5. *For any $k, d \in \mathbb{N}$, there exists an integer $\mu > 1$ such that hypothesis* (VII) *holds.*

Proof. We must show that there exists an integer $\mu > 1$ such that

$$1 + \gamma < \mu^{k/d},$$

where γ is defined in Lemma 5.3. This will be done by proving that γ is bounded from above independent of μ. For this purpose, we consider the matrices

$$\mathbf{H}_1 := [(\psi_i, \psi_j)]_{i\in\mathbb{Z}_m, j\in\mathbb{Z}_m}, \quad \mathbf{H}_2 := [(\psi_i, \psi_{m+j})]_{i\in\mathbb{Z}_m, j\in\mathbb{Z}_r}, \quad \mathbf{H} := [\mathbf{H}_1, \mathbf{H}_2].$$

Therefore, from (5.6) it follows that

$$\mathbf{C}\mathbf{H}^T = \mathbf{C}_1\mathbf{H}_1^T + \mathbf{C}_2\mathbf{H}_2^T = \mathbf{0},$$

where $\mathbf{C}_2$ is an arbitrary $r \times r$ nonsingular matrix. We choose $\mathbf{C}_2 := \mathbf{I}_r$, from which we have that

$$\mathbf{C}_1 = -\mathbf{H}_2^T(\mathbf{H}_1^T)^{-1}. \tag{5.16}$$

Moreover, from Lemma 5.1, we have that

$$\mathbf{C}' = [-\mathbf{B}, \mathbf{I}]$$

and thus

$$\|\mathbf{C}'\|_\infty = \|\mathbf{B}\|_\infty + 1. \tag{5.17}$$

For $j \in \mathbb{Z}_m$, the functions ψ_j are polynomials and therefore continuous, and thus, there exists a positive constant ρ such that

$$\max_{j\in\mathbb{Z}_m} \|\psi_j\|_\infty \le \rho.$$

Hence, recalling the definition of matrix $\mathbf{B}$ and (5.17) we have that

$$\|\mathbf{C}'\|_\infty = 1 + \max_{i\in\mathbb{Z}_r} \sum_{j\in\mathbb{Z}_m} |\psi_j(t_{m+i})| \le 1 + m \max_{j\in\mathbb{Z}_m} \|\psi_j\|_\infty \le 1 + m\rho.$$

On the other hand, we have by (5.16) that

$$\|\mathbf{C}_1\|_1 = \|\mathbf{H}_1^{-1}\mathbf{H}_2\|_\infty \le \|\mathbf{H}_1^{-1}\|_\infty \|\mathbf{H}_2\|_\infty.$$

Since $\|\mathbf{H}_1^{-1}\|_\infty$ is independent of μ, it remains to estimate $\|\mathbf{H}_2\|_\infty$ from above independent of μ. Therefore, we recall for $j \in \mathbb{Z}_r$ that

$$\psi_{m+j}(t) = \psi_l(\phi_e^{-1}(t))\chi_{\phi_e(E)}(t), \quad t \in E,$$

for some $l \in \mathbb{Z}_m$ and $e \in \mathbb{Z}_\mu$. Consequently, from (5.2) we conclude that there exists a positive constant c such that

$$|(\psi_i, \psi_{m+j})| \le \int_{\phi_e(E)} \left|\psi_i(t)\psi_l(\phi_e^{-1}(t))\right| dt \le \rho^2 \mathrm{meas}(\phi_e(E)) \le c\frac{\rho^2}{\mu}.$$

Noting that $r = (\mu - 1)m$, we obtain the desired estimate

$$\|\mathbf{H}_2\|_\infty = \max_{i \in \mathbb{Z}_m} \sum_{j \in \mathbb{Z}_r} |(\psi_i, \psi_{m+j})| \le c \frac{\rho^2}{\mu} (\mu - 1)m \le c\rho^2 m,$$

thereby proving the result. □

We have studied hypothesis (VII) in several cases of practical importance. We report below our finding for the cases when $d = 1$ and $E = [0, 1]$, as well as $d = 2$ and $E = \Delta$, where Δ is the triangle with vertices $(0, 0), (1, 0), (1, 0)$. When $d = 1$ and $E = [0, 1]$, hypothesis (VII) is satisfied for the following choices:

(1) $k = 2$, $\mu = 2$,

$$\phi_e(t) = \frac{t + e}{2}, \quad t \in E, \quad e = 0, 1,$$

and $t_i = (i + 1)/3$ for $i = 0, 1$;

(2) $k = 3$, $\mu = 2$,

$$\phi_e(t) = \frac{t + e}{2}, \quad t \in E, \quad e = 0, 1,$$

and $t_i = 2^i/7$ for $i = 0, 1, 2$;

(3) $k = 3$, $\mu = 3$,

$$\phi_e(t) = \frac{t + e}{3}, \quad t \in E, \quad e = 0, 1, 2,$$

and $t_i = (i + 1)/4$ for $i = 0, 1, 2$;

(4) $k = 4$, $\mu = 2$,

$$\phi_e(t) = \frac{t + e}{2}, \quad t \in E, \quad e = 0, 1,$$

and $t_i = (i + 1)/5$ for $i = 0, 1, 2, 3$.

In the other case hypothesis (VII) is also satisfied when $k = 2$, $\mu = 4$ for $(x, y) \in \Delta$

$$\phi_0(x, y) = \left(\frac{x}{2}, \frac{y}{2}\right), \quad \phi_1(x, y) = \left(\frac{x + 1}{2}, \frac{y}{2}\right),$$

$$\phi_2(x, y) = \left(\frac{x}{2}, \frac{y + 1}{2}\right), \quad \phi_3(x, y) = \left(\frac{1 - x}{2}, \frac{1 - y}{2}\right),$$

and $t_0 = (1/7, 4/7)$, $t_1 = (2/7, 1/7)$, $t_2 = (4/7, 2/7)$.

Finally, we turn our attention to hypothesis (VIII). We consider the sequence of functions $\{\zeta_{ij} : (i, j) \in \mathbb{U}\}$, biorthogonal to the linear functionals $\{\ell_{ij} : (i, j) \in \mathbb{U}\}$ and having property (4.5). Let

$$\zeta_{0j} := w_{0j}, \quad j \in \mathbb{Z}_m,$$

and observe that

$$\langle \ell_{0j}, \zeta_{0j'} \rangle = \delta_{jj'}, \quad j, j' \in \mathbb{Z}_m.$$

For each $j \in \mathbb{Z}_r$, we find vectors $\mathbf{c}_j'' := [c_{js}'' : s \in \mathbb{Z}_q]$ such that the function

$$\zeta_{1j} := \sum_{s \in \mathbb{Z}_q} c_{js}'' \psi_s$$

satisfies the system of linear equations

$$\langle \ell_{0j'}, \zeta_{1j} \rangle = 0, \quad j' \in \mathbb{Z}_m, \tag{5.18}$$

and

$$\langle \ell_{1j'}, \zeta_{1j} \rangle = \delta_{jj'}, \quad j' \in \mathbb{Z}_r. \tag{5.19}$$

Let us confirm $\mathbf{c}_j''$ exists and is unique. The coefficient matrix for (5.18) and (5.19) is

$$\tilde{\mathbf{A}} := [\langle \ell_{i'j'}, \psi_j \rangle]_{j \in \mathbb{Z}_q, (i',j') \in \mathbb{U}_1}. \tag{5.20}$$

Since $\{\psi_j : j \in \mathbb{Z}_q\}$ is a basis for the space $\mathbb{F}_1$, we conclude that matrix $\tilde{\mathbf{A}}$ is nonsingular since $\mathbf{A}$ is nonsingular. Thus, there exists a unique solution $\mathbf{c}''$ for equations (5.18) and (5.19). For $i > 1$, $j = \mu(\mathbf{e})r + l$, $\mathbf{e} \in \mathbb{Z}_\mu^{i-1}$, $l \in \mathbb{Z}_r$, we define functions

$$\zeta_{ij} := \mathcal{T}_{\mathbf{e}} \zeta_{1l}.$$

The functions constructed above will be used in the proof of the next result.

PROPOSITION 5.6. *The pair* (W, L) *satisfies hypothesis* (VIII).

Proof. We first verify that the sequences of functionals $\{\ell_{ij} : (i,j) \in \mathbb{U}\}$ and functions $\{\zeta_{ij} : (i,j) \in \mathbb{U}\}$ are biorthogonal, that is, they satisfy the condition

$$\langle \ell_{i'j'}, \zeta_{ij} \rangle = \delta_{ii'} \delta_{jj'}, \quad (i,j), (i',j') \in \mathbb{U}, \tag{5.21}$$

and, in addition, that there exists a positive constant θ_3 such that for any $i \in \mathbb{N}_0$ condition (4.5) is satisfied.

The proof of (5.21) for the case $i \le i'$ is similar to that for (II) in Proposition 5.4. Hence, we only present the proof for the case $i' < i$. In this case, we have

$$\langle \ell_{i'j'}, \zeta_{ij} \rangle = \langle \mathcal{L}_{\mathbf{e}'} \ell_{1l'}, \mathcal{T}_{\mathbf{e}} \zeta_{1l} \rangle = \langle \ell_{1l'}, \mathcal{T}_{\mathbf{e}_2} \zeta_{1l} \rangle \, \delta_{\mathbf{e}'\mathbf{e}_1},$$

where $j' = \mu(\mathbf{e}')r + l', j = \mu(\mathbf{e})r + l, \mathbf{e}_1 = (e_0, \ldots, e_{i'-2})$, and $\mathbf{e}_2 = (e_{i'-1}, \ldots, e_{i-2})$. From this, it follows that

$$\langle \ell_{i'j'}, \zeta_{ij} \rangle = 0$$

except for $\mathbf{e}' = \mathbf{e}_1$, in which case

$$\langle \ell_{i'j'}, \zeta_{ij} \rangle = \langle \ell_{1l'}, \zeta_{1l} \circ \phi_{\mathbf{e}_2}^{-1} \chi_{\phi_{\mathbf{e}_2}(E)} \rangle. \tag{5.22}$$

Since G_0 is a refinable set, we have that $\phi_e^{-1}(t) \in G_0$ when $t \in G_1 \cap \phi_e(E)$, $e \in \mathbb{Z}_\mu$, and thus

$$\phi_{\mathbf{e}_2}^{-1}(t_s) \in G_0 \ \text{ when } \ t_s \in \phi_{\mathbf{e}_2}(E), \ s \in \mathbb{Z}_q.$$

This observation with (5.18) yields the equation

$$\zeta_{1l}(\phi_{\mathbf{e}_2}^{-1}(t_s)) = \langle \delta_{\phi_{\mathbf{e}_2}^{-1}(t_s)}, \zeta_{1l} \rangle = 0 \tag{5.23}$$

whenever $t_s \in \phi_{\mathbf{e}_2}(E)$, $s \in \mathbb{Z}_q$. We appeal to (5.22) and (5.23) to conclude that $\langle \ell_{i'j'}, \zeta_{ij} \rangle = 0$.

Next, we show that condition (4.5) is satisfied. Without loss of generality, we consider only the case when $i \geq 1$. In this case the definition of ζ_{ij}, for $i \geq 1$, guarantees that

$$\begin{aligned}\sup_{t\in E} \sum_{j\in\mathbb{Z}_{w(i)}} |\zeta_{ij}(t)| &= \sup_{t\in E} \sum_{\mathbf{e}\in\mathbb{Z}_\mu^{i-1}} \sum_{l\in\mathbb{Z}_r} |\mathcal{T}_{\mathbf{e}}\zeta_{1l}(t)| \\ &= \sup_{t\in E} \sum_{\mathbf{e}\in\mathbb{Z}_\mu^{i-1}} \sum_{l\in\mathbb{Z}_r} |\zeta_{1l}(\phi_{\mathbf{e}}^{-1}(t))\chi_{\phi_{\mathbf{e}}(E)}(t)| \\ &\leq \sum_{l\in\mathbb{Z}_r} \|\zeta_{1l}\|_\infty,\end{aligned}$$

and therefore (4.5) holds with $\theta_3 := \sum_{l\in\mathbb{Z}_r} \|\zeta_{1l}\|_\infty$.

Finally, we verify the first inequality of (4.4) in condition (VIII). To this end, we note that for $v := \sum_{(i,j)\in\mathbb{U}_n} v_{i,j} w_{i,j}$ and $\mathbf{v} := [v_{ij} : (i,j) \in \mathbb{U}_n]^T$, there exists $(i_0, j_0) \in \mathbb{U}_n$ with $j_0 = \mu(\mathbf{e}_0)r + l_0, \mathbf{e}_0 \in \mathbb{Z}_\mu^{i_0-1}, l_0 \in \mathbb{Z}_r$, such that

$$\|\mathbf{v}\|_\infty = |v_{i_0 j_0}|. \tag{5.24}$$

For $l \in \mathbb{Z}_r$ we denote $\tilde{v}_l := v_{i_0 j}$ and $\tilde{w}_l := w_{i_0 j}$, where $j = \mu(\mathbf{e}_0)r + l$ and $\mathbf{e}_0 \in \mathbb{Z}_\mu^{i_0-1}$, and observe that

$$|v_{i_0 j_0}| \leq \left(\sum_{l\in\mathbb{Z}_r} |\tilde{v}_l|^2 \right)^{1/2}. \tag{5.25}$$

Recalling that $w_{i_0 j} = \mathcal{T}_{\mathbf{e}} w_{1l}$, $l \in \mathbb{Z}_r$, and that ϕ_e, $e \in \mathbb{Z}_\mu$, are affine, we conclude that

$$(\tilde{w}_{l'}, \tilde{w}_l) = J_{\phi_{\mathbf{e}_0}}(w_{1l'}, w_{1l}), \tag{5.26}$$

where J_{ϕ_e} denotes the Jacobi of the mapping ϕ_e. We introduce an $r \times r$ matrix

$$\mathbf{W} := [(w_{1l'}, w_{1l})]_{l',l\in\mathbb{Z}_r}$$

and note that it is the Gram matrix of the basis w_{1l}, $l \in \mathbb{Z}_r$, and thus it is positive definite. It follows that there exists a positive constant c_0 such that for $\tilde{v} := \sum_{l\in\mathbb{Z}_r} \tilde{v}_l \tilde{w}_l$ and $\tilde{\mathbf{v}} := [\tilde{v}_l : l \in \mathbb{Z}_r]^T$,

$$c_0 \sum_{l\in\mathbb{Z}_r} |\tilde{v}_l|^2 \leq \tilde{\mathbf{v}}^T \mathbf{W} \tilde{\mathbf{v}}. \tag{5.27}$$

By formula (5.26), we have that

$$\|\tilde{v}\|_2^2 = (\tilde{v}, \tilde{v}) = J_{\phi_{\mathbf{e}_0}} \tilde{\mathbf{v}}^T \mathbf{W} \tilde{\mathbf{v}}.$$

Combining this equation with (5.27) yields

$$\sum_{l\in\mathbb{Z}_r} |\tilde{v}_l|^2 \leq \frac{1}{c_0 J_{\phi_{\mathbf{e}_0}}} \|\tilde{v}\|_2^2. \tag{5.28}$$

Since the basis $\{w_{ij} : (i,j) \in \mathbb{U}_n\}$ that has been constructed in this section satisfies the conditions (III), we obtain that

$$\|\tilde{v}\|_2^2 = \int_{\phi_{\mathbf{e}}(E)} \tilde{v}(t)v(t)dt \le J_{\phi_{\mathbf{e}_0}} \|\tilde{v}\|_\infty \|v\|_\infty \le J_{\phi_{\mathbf{e}_0}} |v_{i_0 j_0}| \sum_{l \in \mathbb{Z}_r} \|\tilde{w}_l\|_\infty \|v\|_\infty.$$

Using condition (IV), we conclude that there exists a positive constant c_0 such that

$$\sum_{l \in \mathbb{Z}_r} \|\tilde{w}_l\|_\infty \le c,$$

which implies with the last inequality that

$$\|\tilde{v}\|_2^2 \le c J_{\phi_{\mathbf{e}_0}} \|\mathbf{v}\|_\infty \|v\|_\infty. \tag{5.29}$$

Combining (5.24), (5.25), (5.28), and (5.29) yields that there exists a positive constant c such that

$$\|\mathbf{v}\|_\infty \le c \|\mathbf{v}\|_\infty^{1/2} \|v\|_\infty^{1/2},$$

and thus

$$\|\mathbf{v}\|_\infty \le c \|v\|_\infty.$$

We have proved the first inequality of (4.4) with $\theta_2 := 1/c$. □

NUMERICAL TREATMENT OF DEFECTIVE BOUNDARY CONDITIONS FOR THE NAVIER–STOKES EQUATIONS*

L. FORMAGGIA†, J.-F. GERBEAU‡, F. NOBILE‡, AND A. QUARTERONI†§

Abstract. We present a formulation for accommodating defective boundary conditions for the incompressible Navier–Stokes equations where only averaged values are prescribed on measurable portions of the boundary. In particular we consider the case where the flow rate is imposed on several domain sections. This methodology has an interesting application in the numerical simulation of flow in blood vessels, when only a reduced set of boundary data are generally available for the upstream and downstream sections.

Key words. Navier–Stokes equations, boundary conditions, finite elements, Lagrange multipliers, fractional step methods, simulation of blood flow

Introduction. A necessary condition for the existence of the solution of the incompressible Navier–Stokes equations on a bounded domain Ω is that an appropriate set of boundary conditions is imposed on $\partial\Omega$. In a classical setting, at each point on the boundary one needs a number of conditions equal to the spatial dimension of the problem. Typically, one can prescribe the components of the velocity (Dirichlet boundary condition) or those of the Cauchy normal stress (Neumann boundary condition) or an appropriate combination of velocity and normal stress.

In this work, we will consider the specific situation occurring when one has at their disposal only averaged quantities on portions of the domain boundary, a priori insufficient to "close" the differential problem at hand. We will refer to this incomplete set as *defective* boundary conditions. An important applicative field where this situation occurs is the numerical simulation of blood flow in the human vascular system. If we aim at computing the blood flow field in an isolated portion of an artery—for instance, reconstructed from medical images—we immediately face the problem of which boundary conditions to impose at the artificial upstream and downstream sections. A possibility is to exploit data coming from measurements. Yet the most common techniques are normally able to measure only flow rates or average pressures and not complete fields as would be required for the numerical computations.

A similar situation occurs when one wants to simulate the cardiovascular system by multiscale approaches such those proposed in [8] and [6]. In that case, the boundary data for the Navier–Stokes equations do not come from measurements, but rather come as the output of simplified models of the global cardiovascular system.

These simple models, which are typically based on the solution of either a system of ordinary differential equations or of one-dimensional differential problems, normally provide the evolution of mean pressure and velocity inside the various regions of the cardiovascular system. If we want to use them to feed boundary data into a more detailed local model based on the solution of the Navier–Stokes equations, we need to have a way to "translate" these mean quantities in mathematically sound boundary conditions for the Navier–Stokes problem. This issue has been addressed in the cited references. Another interesting application of the technique proposed in this work is in the simulation of a free interface problem, when one wants to ensure that the numerical approximation satisfies mass conservation within machine precision. An example of a problem of this type is presented in the section dedicated to numerical experiments. Another applicative field is the simulation of flow in pipes, when measuring sensors provide only flow rate information.

A viable approach to handle the case of defective boundary conditions is provided by the so-called *do-nothing* boundary conditions proposed in [10].

In this paper we analyze another, somewhat more flexible, alternative based on the use of Lagrange multipliers. In particular, we will consider the case when given flow rates Q_i are to be prescribed on several sections of the domain boundary. The corresponding variational formulation, augmented by the Lagrange multipliers, is presented in all generality and analyzed for the case of a Stokes problem, where a well-posedness result is given. We present several approaches for the numerical solution of this problem in the context of fractional step schemes and compare their properties with respect to the effective fulfillment of the imposed flow rate constraint and computational efficiency. Several numerical experiments prove the effectiveness of this technique, which may be implemented in existing software with little efforts. This is an advantage with respect to the do-nothing approach, whose implementation for the prescribed flow rate problem is not straightforward, as it would require the construction of suitable (nonstandard) test functions.

We also discuss how to impose an average pressure (or normal stresses) on measurable parts of the domain. We show how the Lagrange multiplier technique may be successfully implemented in the case of slip boundary conditions for the velocity.

The technique developed here is targeted to applications where it is important to match the solution at the inflow and/or the outflow with known average data. In the present form it is not directly applicable for far-field conditions in unbounded domains and in particular for devising "nonabsorbing" boundary treatment for vortex flow. The reader interested in this particular aspect may, for instance, refer to [3, 4, 5].

In the first section of this work we address the problem in general terms and we introduce the functional setting for the analysis. We also give an overview of the do-nothing approach applied to problems where either the flow rate or the average normal stress is imposed on a portion of the computational domain boundary. In section 2 we introduce the alternative formulation given by a Lagrange multiplier approach and carry out its analysis. In section 3 we propose several algorithms that are suitable for its implementation in the context of the solution of the Navier–Stokes equations by algebraic fractional step techniques. Finally, section 4 presents numerical results illustrating the effectiveness of the proposed methodology.

1. Problem formulation and defective boundary conditions. Let Ω be a bounded domain of $\mathbb{R}^d$, $d = 2$ or 3, whose boundary $\partial\Omega$ is decomposed into the union of Γ and several disjoint sections S_0, $S_1, \ldots, S_n$, $n \geq 1$ (see Figure 1).

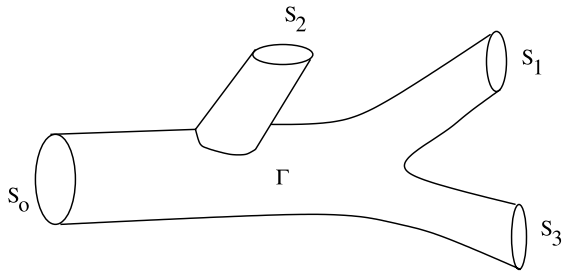

FIG. 1. *The partition of the boundary of the domain* Ω.

We are interested in solving the Navier–Stokes equations in Ω,

$$\begin{cases} \partial_t \mathbf{u} + \mathbf{u} \cdot \nabla \mathbf{u} + \nabla p - \nu \triangle \mathbf{u} = \mathbf{f}, & t > 0, \\ \operatorname{div} \mathbf{u} = 0, & t > 0, \\ \mathbf{u} = \mathbf{u}_0, & t = 0, \end{cases} \tag{1.1}$$

supplemented by homogeneous boundary conditions on Γ,

$$\mathbf{u}|_\Gamma = 0, \tag{1.2}$$

while two different kinds of boundary conditions will be considered on the sections S_i, $i = 0, \ldots, n$. Both are well suited for blood flow simulations [18, 6], where Ω would represent the portion of an artery, Γ the vessel wall, and S_i the artificial upstream and downstream sections. Even if for this specific problem the vessel wall should be considered moving with time because of the flexibility of the vessel wall structure, here we will address only the case where Γ is fixed.

The first condition we consider is the so-called *prescribed mean pressure problem* which requires that

$$\frac{1}{\operatorname{meas}(S_i)} \int_{S_i} p \, ds = P_i, \quad i = 0, \ldots, n, \tag{1.3}$$

where each P_i is a prescribed function of the time t, constant on S_i.

The second condition we wish to address is the *prescribed flow rate problem*

$$\int_{S_i} \mathbf{u} \cdot \mathbf{n} \, ds = Q_i \quad \text{for } i = 0, \ldots, n, \tag{1.4}$$

where the flow rates Q_i's (also called *velocity fluxes*) are assigned functions of time. Due to the fluid incompressibility fluid, a compatibility relation must exist among the fluxes Q_i, namely Q_0 must be equal to $-\sum_{i=1}^n Q_i$.

The initial-boundary value problem (1.1)–(1.2) with either (1.3) or (1.4) is not well-posed from a physical point of view, since its solution is not unique. Indeed, on every section S_i, we are prescribing just one scalar condition rather than d conditions at every point $\mathbf{x} \in S_i$, as it should be.

In [10] the do-nothing approach was advocated as a way of solving the two situations just presented. By this technique, a particular weak formulation is devised which allows to fulfill conditions (1.3) (resp., (1.4)) at some extent, giving rise to a well-posed problem. In fact, this formulation contains also "implicit" (Neumann-like) boundary conditions which select one particular solution among all the physical solutions of the original differential problem.

We will here give a brief presentation of this approach. Let us introduce the functional spaces

$$V = \left\{ \mathbf{v} \in \left[H^1(\Omega)\right]^d, \mathbf{v}|_\Gamma = 0 \right\} \qquad \text{and} \qquad M = L^2(\Omega).$$

We suppose that $\mathbf{f} \in V'$ and we introduce the functional $\phi_i \in V'$, $i = 0, \ldots, n$, which measures the flux of a vector function through the surface S_i. Precisely,

$$\langle \phi_i, \mathbf{v} \rangle = \int_{S_i} \mathbf{v} \cdot \mathbf{n} \, ds \quad \forall \mathbf{v} \in V,$$

where $\mathbf{n}$ is the outward unit normal vector on $\partial\Omega$. For this reason ϕ_i is called the *flux functional* on S_i.

Then, the do-nothing formulation for the *mean pressure problem* reads as follows: find $\mathbf{u} \in V$ and $p \in M$ such that, for all $\mathbf{v} \in V$ and $q \in M$,

$$\text{(1.5)} \qquad \begin{cases} (\partial_t \mathbf{u} + \mathbf{u} \cdot \nabla \mathbf{u}, \mathbf{v}) + \nu(\nabla \mathbf{u}, \nabla \mathbf{v}) - (p, \operatorname{div} \mathbf{v}) = \langle \mathbf{f}, \mathbf{v} \rangle - \displaystyle\sum_{i=0}^{n} P_i \langle \phi_i, \mathbf{v} \rangle, \\ (q, \operatorname{div} \mathbf{u}) = 0, \end{cases}$$

for all $t > 0$, with $\mathbf{u} = \mathbf{u}_0$ for $t = 0$.

It follows easily, by using the Green formula, that the solution of (1.5) satisfies

$$\left(p - \nu \frac{\partial u_n}{\partial \mathbf{n}} \right) \Big|_{S_i} = P_i, \qquad \frac{\partial \mathbf{u}_\tau}{\partial \mathbf{n}} \Big|_{S_i} = 0 \quad \text{for } i = 0, \ldots, n,$$

where we have set $u_n = \mathbf{u} \cdot \mathbf{n}$ and $\mathbf{u}_\tau = \mathbf{u} - u_n \mathbf{n}$.

Thus

$$\text{(1.6)} \qquad \frac{1}{\operatorname{meas}(S_i)} \int_{S_i} p \, ds = P_i + \frac{\nu}{\operatorname{meas}(S_i)} \int_{S_i} \frac{\partial u_n}{\partial \mathbf{n}} \, ds.$$

We conclude that the desired condition (1.3) is recovered exactly only in those cases where the last integral in (1.6) vanishes. This occurs, for instance, when S_i is a plane section perpendicular to a cylindrical pipe. Otherwise, P_i will be the mean value of the normal component of the normal stresses on S_i.

For the *prescribed flow rate problem*, the do-nothing approach is formulated as follows. Let us introduce the space

$$V^\star = \{ \mathbf{v} \in V, \langle \phi_i, \mathbf{v} \rangle = 0, i = 0, \ldots, n \}$$

and the vector functions $\mathbf{b}_i \in V$, $i = 1, \ldots, n$, (called *flux-carriers*) that satisfy

$$\operatorname{div} \mathbf{b}_i = 0, \quad \int_{S_0} \mathbf{b}_i \cdot \mathbf{n} \, ds = -1, \quad \int_{S_j} \mathbf{b}_i \cdot \mathbf{n} \, ds = \delta_{ij} \quad \text{for } i, j = 1, \ldots, n.$$

The weak formulation of problem (1.1), (1.2), (1.4) proposed in [10] reads as follows: Find $\mathbf{u} = \mathbf{w} + \sum_{i=1}^{n} Q_i \mathbf{b}_i$, with $\mathbf{w} \in V^\star$ and $p \in M \setminus \mathbb{R}$ such that for all $\mathbf{v} \in V^\star$ and $q \in M$

$$\text{(1.7)} \qquad \begin{cases} (\partial_t \mathbf{u} + \mathbf{u} \cdot \nabla \mathbf{u}, \mathbf{v}) + \nu(\nabla \mathbf{u}, \nabla \mathbf{v}) - (p, \operatorname{div} \mathbf{v}) = 0, \\ (q, \operatorname{div} \mathbf{u}) = 0 \end{cases}$$

for all $t > 0$, with $\mathbf{u} = \mathbf{u}_0$ for $t = 0$.

The corresponding solution satisfies

$$\left(p - \nu\frac{\partial u_n}{\partial \mathbf{n}}\right)|_{S_i} = P_i, \qquad \frac{\partial \mathbf{u}_\tau}{\partial \mathbf{n}}|_{S_i} = 0 \quad \text{for } i = 0, \dots, n, \tag{1.8}$$

where the P_i's are *a priori* unknown constants (in space).

The formulation of the *mean pressure problem* may be easily discretized as it can be regarded as a classical Navier–Stokes problem with Neumann boundary conditions. On the other hand, the definition of the functional space $V^\star$ makes the implementation of the *prescribed flow rate problem* less straightforward.

2. A Lagrange multiplier approach for flow rate boundary conditions. In this section, we propose a slightly different formulation of the prescribed flow rate problem presented above. We consider (1.1) and (1.2) and we prescribe the velocity flux on all but one section of $\partial\Omega$. More precisely, we aim at satisfying

$$\langle \phi_i, \mathbf{u}\rangle = \int_{S_i} \mathbf{u}\cdot\mathbf{n}\, ds = Q_i \quad \text{for } i = 1, \dots, n, \tag{2.1}$$

plus the following homogeneous Neumann boundary condition on S_0:

$$\left(-p\mathbf{n} + \frac{\partial \mathbf{u}}{\partial \mathbf{n}}\right)\Big|_{S_0} = 0. \tag{2.2}$$

The motivation of such an approach will be clarified in Remark 2.

Our goal is to formulate the initial-boundary value problem (1.1), (1.2), (2.1), (2.2) in a way that its numerical approximation be as simple as possible to implement. We look for $\mathbf{u} \in V$, $p \in M$, and $\lambda_1, \dots, \lambda_n \in \mathbb{R}$ such that, for all $\mathbf{v} \in V$ and $q \in M$,

$$\begin{cases} (\partial_t \mathbf{u} + \mathbf{u}\cdot\nabla\mathbf{u}, \mathbf{v}) + \nu(\nabla\mathbf{u}, \nabla\mathbf{v}) + \displaystyle\sum_{i=1}^{n} \lambda_i \langle \phi_i, \mathbf{v}\rangle - (p, \operatorname{div}\mathbf{v}) = \langle \mathbf{f}, \mathbf{v}\rangle, \\ (q, \operatorname{div}\mathbf{u}) = 0, \\ \langle \phi_i, \mathbf{u}\rangle = Q_i, \qquad i = 1, \dots, n, \end{cases} \tag{2.3}$$

for all $t > 0$, with $\mathbf{u} = \mathbf{u}_0$ for $t = 0$.

Note that now the test functions $\mathbf{v}$ are taken in V, a space which is more straightforward to discretize than $V^\star$.

PROPOSITION 2.1. *Any smooth solution of* (2.3) *satisfies the additional boundary conditions*

$$\left(p - \nu\frac{\partial u_n}{\partial \mathbf{n}}\right)|_{S_i} = \lambda_i \quad \textit{and} \quad \frac{\partial \mathbf{u}_\tau}{\partial \mathbf{n}}|_{S_i} = 0, \quad i = 1, \dots, n. \tag{2.4}$$

In particular, this yields that both $\frac{\partial \mathbf{u}_\tau}{\partial \mathbf{n}}$ *and* $p - \nu\frac{\partial u_n}{\partial \mathbf{n}}$ *are indeed constant over* S_i *for* $i = 1, \dots, n$. *Furthermore,* $(\mathbf{u}, p)$ *satisfies* (1.1), (1.2), (2.1), (2.2).

Proof. Conditions (1.2) and (2.1) are obviously satisfied. Integrating by parts the first equation of (2.3) yields for any $\mathbf{v} \in V$

$$\begin{aligned} \langle \partial_t \mathbf{u} + \mathbf{u}\cdot\nabla\mathbf{u} - \nu\triangle\mathbf{u} + \nabla p, \mathbf{v}\rangle + \int_{S_0} \left(\nu\frac{\partial \mathbf{u}}{\partial \mathbf{n}} - p\mathbf{n}\right)\cdot\mathbf{v}\, ds \\ + \sum_{i=1}^{n} \int_{S_i} \left(\nu\frac{\partial \mathbf{u}}{\partial \mathbf{n}} - p\mathbf{n} + \lambda_i\mathbf{n}\right)\cdot\mathbf{v}\, ds = \langle \mathbf{f}, \mathbf{v}\rangle. \end{aligned} \tag{2.5}$$

Now taking $\mathbf{v} \in \mathcal{D}(\Omega)$, we recover the momentum equation (1.1) in the sense of $\mathcal{D}'(\Omega)$. Consequently, from (2.5), it follows that

$$\int_{S_0} \left(\nu \frac{\partial \mathbf{u}}{\partial \mathbf{n}} - p\mathbf{n} \right) \cdot \mathbf{v}\, ds + \sum_{i=1}^{n} \int_{S_i} \left(\nu \frac{\partial \mathbf{u}}{\partial \mathbf{n}} - p\mathbf{n} + \lambda_i \mathbf{n} \right) \cdot \mathbf{v}\, ds = 0$$

for all $\mathbf{v} \in V$. Now using the splitting of the trace of u on $\partial\Omega$ in its normal and tangential component $\mathbf{u}|_{\partial\Omega} = u_n \mathbf{n} + \mathbf{u}_\tau$, we deduce relations (2.2) and (2.4). ∎

Remark 1. Among all possible solutions of (1.1), (1.2), (2.1), (2.2), problem (2.3) selects the one that satisfies the additional boundary condition (2.4).

Remark 2. In (2.3), we could have imposed a flux Q_0 on S_0, instead of the homogeneous Neumann condition (2.2). The corresponding problem would have been as follows: find $\mathbf{u} \in V$, $\tilde{p} \in M$, and $\tilde{\lambda}_0, \tilde{\lambda}_1, \ldots, \tilde{\lambda}_n \in \mathbb{R}$ such that, for all $\mathbf{v} \in V$ and $q \in M$,

$$\text{(2.6)} \qquad \begin{cases} (\partial_t \mathbf{u} + \mathbf{u} \cdot \nabla \mathbf{u}, \mathbf{v}) + \nu(\nabla \mathbf{u}, \nabla \mathbf{v}) + \displaystyle\sum_{i=0}^{n} \tilde{\lambda}_i \langle \phi_i, \mathbf{v} \rangle - (p, \operatorname{div} \mathbf{v}) = \langle \mathbf{f}, \mathbf{v} \rangle, \\ (q, \operatorname{div} \mathbf{u}) = 0, \\ \langle \phi_i, \mathbf{u} \rangle = Q_i, \qquad i = 0, \ldots, n, \end{cases}$$

for all $t > 0$, with $\mathbf{u} = \mathbf{u}_0$ for $t = 0$.

Due to the incompressibility of the fluid, the value of Q_0 must be equal to $-\sum_{i=1}^{n} Q_i$ (otherwise the problem has no solution). If $(\mathbf{u}, \tilde{p}, \tilde{\lambda}_0, \tilde{\lambda}_1, \ldots, \tilde{\lambda}_n)$ is a solution of (2.6), then, for any constant $C \in \mathbb{R}$, $(\mathbf{u}, \tilde{p} + C, \tilde{\lambda}_0 + C, \tilde{\lambda}_1 + C, \ldots, \tilde{\lambda}_n + C)$ is also a solution. The solution of (2.6) is thus defined up to an additive constant. Now, we set this constant C equal to $-\tilde{\lambda}_0$, and we denote $\tilde{p} + C$ and $\tilde{\lambda}_i + C$ by p and λ_i. Then, $(\mathbf{u}, p, \lambda_1, \ldots, \lambda_n)$ is the solution of (2.3) and, according to the "implicit" boundary condition (2.4), $\lambda_0 = 0$ yields simply the Neumann boundary condition (2.2). In other words, problem (2.3) (with the Neumann condition on S_0) and (2.6) (with the flux condition on S_0) are equivalent as soon as the "free" constant of problem (2.6) is well chosen.

Remark 3. From a theoretical viewpoint, our approach is very close to the do-nothing formulation recalled in the previous section. Comparing (1.8) and (2.4), we may note that the Lagrange multipliers corresponding to the constraints on the flux are in fact equal to the "a priori unknown" constants of the do-nothing formulation (1.8). Yet, our approach uses a standard functional space V which can be more straightforwardly discretized than the space V^*.

Now, for the sake of simplicity, we restrict ourselves to the analysis of the stationary Stokes problem (which embodies however all relevant difficulties of our Lagrange multiplier approach): find $(\mathbf{u}, p, \lambda_1, \ldots, \lambda_n) \in V \times M \times \mathbb{R}^n$ such that for all $(\mathbf{v}, q) \in V \times M$

$$\text{(2.7)} \qquad \begin{cases} \nu(\nabla \mathbf{u}, \nabla \mathbf{v}) + \displaystyle\sum_{i=1}^{n} \lambda_i \langle \phi_i, \mathbf{v} \rangle - (p, \operatorname{div} \mathbf{v}) = \langle \mathbf{f}, \mathbf{v} \rangle, \\ (q, \operatorname{div} \mathbf{u}) = 0, \\ \langle \phi_i, \mathbf{u} \rangle = Q_i, \ i = 1, \ldots, n. \end{cases}$$

The extension of the analysis to the complete time-dependent, nonlinear problem (2.3) can then be carried out by usual techniques (see, e.g., [20, 9, 19]).

PROPOSITION 2.2. *Problem* (2.7) *is well-posed.*

Proof. In order to prove existence, let us denote by $(\tilde{\mathbf{u}}, \tilde{p}) \in V \times M$ the solution of

$$\begin{cases} \nu(\nabla\tilde{\mathbf{u}}, \nabla\mathbf{v}) - (\tilde{p}, \operatorname{div}\mathbf{v}) = \langle \mathbf{f}, \mathbf{v}\rangle, \\ (q, \operatorname{div}\tilde{\mathbf{u}}) = 0 \end{cases} \tag{2.8}$$

for all $(\mathbf{v}, q) \in V \times M$. This is the weak formulation of the Stokes problem with homogeneous Dirichlet conditions on Γ and homogeneous Neumann conditions on $\partial\Omega \setminus \Gamma$.

Moreover, for $i = 1, \dots, n$, let $(\mathbf{w}_i, \pi_i) \in V \times M$ be the solution of the problem

$$\begin{cases} \nu(\nabla\mathbf{w}_i, \nabla\mathbf{v}) - (\pi_i, \operatorname{div}\mathbf{v}) = -\langle \phi_i, \mathbf{v}\rangle, \\ (q, \operatorname{div}\mathbf{w}_i) = 0, \end{cases} \tag{2.9}$$

for all $(\mathbf{v}, q) \in V \times M$.

Both systems (2.8) and (2.9) admit a unique solution. Note that the equations satisfied by $(\tilde{\mathbf{u}}, \tilde{p})$ are the unconstrained counterpart of (2.7) and that the solution $(\mathbf{w}_i, \pi_i)$ of (2.9) depends only on the geometry and not on the data of the Stokes problem. In some sense, the functions $\mathbf{w}_i$ are related to the flux-carriers $\mathbf{b}_i$ introduced in the do-nothing formulation (1.7).

We set, then, $\mathbf{u} = \tilde{\mathbf{u}} + \sum_{i=1}^n \lambda_i \mathbf{w}_i$ and $p = \tilde{p} + \sum_{i=1}^n \lambda_i \pi_i$. No matter how the λ_i, $i = 1, \dots, n$, are chosen, $(\mathbf{u}, p)$ satisfies the first two equations of (2.7). If we further require $\mathbf{u}$ to satisfy the third equation of (2.7), we obtain the following equations:

$$\langle \phi_i, \tilde{\mathbf{u}}\rangle + \sum_{j=1}^n \lambda_j \langle \phi_i, \mathbf{w}_j\rangle = Q_i, \quad i = 1, \dots, n,$$

whose compact form reads as

$$B\Lambda = Q - \tilde{Q}, \tag{2.10}$$

where $Q = (Q_1, \dots, Q_n) \in \mathbb{R}^n$, $\tilde{Q} = (\langle \phi_1, \tilde{\mathbf{u}}\rangle, \dots, \langle \phi_n, \tilde{\mathbf{u}}\rangle) \in \mathbb{R}^n$, $\Lambda = (\lambda_1, \dots, \lambda_n) \in \mathbb{R}^n$, and $B \in \mathbb{R}^{n\times n}$, $B_{ij} = \langle \phi_i, \mathbf{w}_j\rangle$. The matrix B is nonsingular (as will be proven in Lemma 2.3); thus, once the $\{\lambda_i\}$ are computed through relation (2.10), $(\mathbf{u}, p, \lambda_1, \dots, \lambda_n)$ will provide a solution of (2.7).

To prove uniqueness, let $(\mathbf{u}_1, p_1, \lambda_1^{(1)}, \dots, \lambda_n^{(1)})$ and $(\mathbf{u}_2, p_2, \lambda_1^{(2)}, \dots, \lambda_n^{(2)})$ be two solutions of (2.7). Then

$$\begin{cases} \nu(\nabla(\mathbf{u}_1 - \mathbf{u}_2), \nabla\mathbf{v}) + \displaystyle\sum_{i=1}^n (\lambda_i^{(1)} - \lambda_i^{(2)})\langle \phi_i, \mathbf{v}\rangle - (p_1 - p_2, \operatorname{div}\mathbf{v}) = 0, \\ (q, \operatorname{div}(\mathbf{u}_1 - \mathbf{u}_2)) = 0, \\ \langle \phi_i, \mathbf{u}_1 - \mathbf{u}_2\rangle = 0, \qquad i = 1, \dots, n, \end{cases} \tag{2.11}$$

for all $\mathbf{v} \in V$ and $q \in M$.

Taking $\mathbf{v} = \mathbf{u}_1 - \mathbf{u}_2$ in (2.11) we obtain $\nu\|\nabla(\mathbf{u}_1 - \mathbf{u}_2)\|_{L^2(\Omega)} = 0$, from which $\mathbf{u}_1 = \mathbf{u}_2$ a.e. in Ω. Consequently,

$$\sum_{i=1}^n (\lambda_i^{(1)} - \lambda_i^{(2)})\langle \phi_i, \mathbf{v}\rangle - (p_1 - p_2, \operatorname{div}\mathbf{v}) = 0 \qquad \forall \mathbf{v} \in V. \tag{2.12}$$

For all $i = 1, \dots, n$ we can construct $\mathbf{w}_i \in V$ which satisfy

$$\operatorname{div} \mathbf{w}_i = 0, \qquad \mathbf{w}_i|_{S_j} = 0,\ j = 1, \dots, n,\ j \neq i, \quad \text{and} \quad \langle \phi_i, \mathbf{w}_i \rangle = 1.$$

Note that $\langle \phi_0, \mathbf{w}_i \rangle = -1$ for all $i = 1, \dots, n$.

Taking in (2.12) $\mathbf{v} = \mathbf{w}_i$ we obtain

$$\lambda_i^{(1)} = \lambda_i^{(2)} \qquad \forall i = 1, \dots, n.$$

Finally, choosing $\mathbf{z} \in V$ such that

$$\operatorname{div} \mathbf{z} = p_1 - p_2, \qquad \mathbf{z}|_{S_i} = 0 \quad \forall i = 1, \dots, n,$$

(such a function exists; see, e.g., [9, 13]) and taking $\mathbf{v} = \mathbf{z}$ in (2.12), we obtain $\|p_1 - p_2\|_{L^2(\Omega)} = 0$. Henceforth $p_1 = p_2$ a.e. in Ω. ∎

LEMMA 2.3. *The matrix B introduced in* (2.10) *is nonsingular.*

Proof. Given an arbitrary vector $\boldsymbol{\alpha} \in \mathbb{R}^n$, for any $i = 1, \dots, n$ we can multiply each problem (2.9) by α_i and sum from $i = 1$ to n. Owing to the linearity of (2.9) we have

$$\begin{cases} \nu(\sum_{i=1}^n \alpha_i \nabla \mathbf{w}_i, \nabla \mathbf{v}) - (\sum_{i=1}^n \alpha_i \pi_i, \operatorname{div} \mathbf{v}) + \sum_{i=1}^n \alpha_i \langle \phi_i, \mathbf{v} \rangle = 0, \\ (q, \operatorname{div} \sum_{i=1}^n \alpha_i \mathbf{w}_i) = 0. \end{cases} \tag{2.13}$$

Now taking in $\mathbf{v} = \sum_{i=1}^n \alpha_i \mathbf{w}_i$, we obtain

$$\nu \left\| \nabla \left(\sum_{i=1}^n \alpha_i \mathbf{w}_i \right) \right\|^2_{L^2(\Omega)} + \sum_{i=1}^n \alpha_i \left\langle \phi_i, \sum_{j=1}^n \alpha_j \mathbf{w}_j \right\rangle = 0,$$

which implies, for all $\boldsymbol{\alpha} \in \mathbb{R}^n$, $\boldsymbol{\alpha} \neq \mathbf{0}$,

$$\boldsymbol{\alpha}^T B \boldsymbol{\alpha} = -\nu \left\| \nabla \left(\sum_{i=1}^n \alpha_i \mathbf{w}_i \right) \right\|^2_{L^2(\Omega)} \leq -\frac{\nu}{1 + C_p} \left\| \sum_{i=1}^n \alpha_i \mathbf{w}_i \right\|^2_{H^1(\Omega)} < 0. \tag{2.14}$$

In the last relation we have used the Poincaré inequality

$$\int_\Omega \mathbf{v}^2 \leq C_p \int_\Omega |\nabla \mathbf{v}|^2 \quad \forall \mathbf{v} \in V.$$

From (2.14) we infer that B is negative definite and then nonsingular. ∎

Remark 4. Let us point out a difficulty that may be encountered if one wants to impose on the sections S_i a mean value $P \in \mathbb{R}$ for the pressure (or, for the normal stresses) by following a route similar to that presented for the flow rate. The case where one wants to impose a pointwise value for the pressure on the boundary for the Stokes problem has been analyzed in [1]. For the sake of simplicity, we restrict ourselves to the Stokes problem. A possible formulation is as follows: find $(\mathbf{u}, p) \in V \times M$ and $\lambda_0, \dots, \lambda_n \in \mathbb{R}$ such that, for all $(\mathbf{v}, q) \in V \times M$,

$$\begin{cases} \nu(\nabla \mathbf{u}, \nabla \mathbf{v}) + (\nabla p, \mathbf{v}) = \langle \mathbf{f}, \mathbf{v} \rangle, \\ (\nabla q, \mathbf{u}) - \displaystyle\sum_{i=0}^n \lambda_i \int_{S_i} q \, ds = 0, \\ \displaystyle\int_{S_i} p \, ds = P_i \operatorname{meas}(S_i), \quad i = 0, \dots, n. \end{cases} \tag{2.15}$$

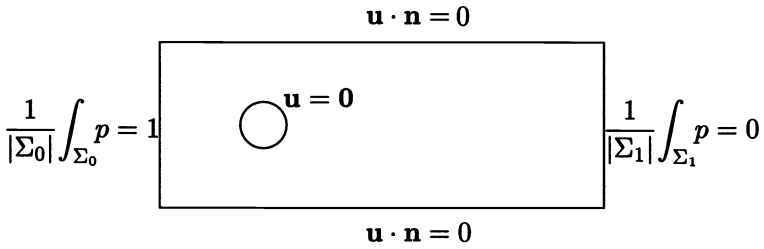

FIG. 2. *Boundary conditions for the Stokes flow around a cylinder.*

This formulation is, in some sense, the dual of the flux formulation as it imposes constraints on the dual problem (the pressure equation), whereas the flux boundary conditions yields a constraint on the primal problem (the velocity equations). Therefore, it can be regarded as the natural counterpart of our formulation for the flux problem. Unfortunately, it may be recognized that from (2.15) it follows that $\mathbf{u}\cdot\mathbf{n}|_{S_i} = \lambda_i$ on each S_i, whereas $\mathbf{u}\cdot\mathbf{n}|_{S_i}$ cannot be a constant different from 0 (since we assume no-slip boundary conditions on Γ). This formulation is therefore not unsuitable for the problem we are interested in. Nevertheless, it may be adopted in those cases where a slip boundary condition is imposed on the wall. In this case system (2.15) will effectively impose a mean value for p, thus differing from the do-nothing approach (1.5) which is instead equivalent to imposing the much stronger condition (1.6).

A numerical test is given hereafter to illustrate how the mean pressure formulation may be used when it is consistent with the velocity boundary conditions. We consider a Stokes flow around a cylinder between two flat plates. We have imposed a homogeneous Dirichlet boundary condition on the cylinder surface, a pure slip condition (i.e., $\mathbf{u}\cdot\mathbf{n} = 0$) on the plates. Moreover, we will prescribe the mean pressure at the inlet and the outlet (see Figure 2). In Figure 3 we show the pressure profile obtained at the inlet. It may be noted how it varies around the imposed mean value of 1.

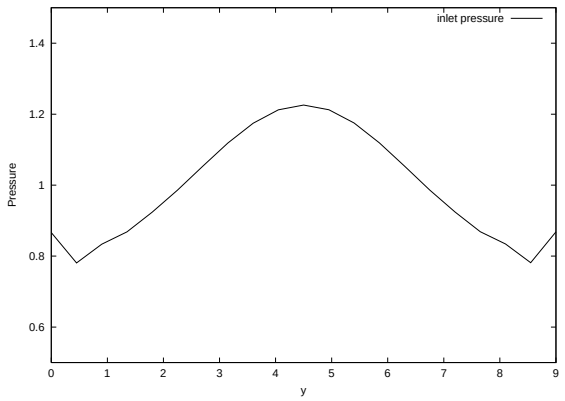

FIG. 3. *Inlet pressure distribution for the Stokes flow around a cylinder. It may be noted that the pressure is not uniform but is distributed around the imposed mean value of* 1.

3. The numerical solution of the Lagrange multipliers problem. In order to discretize formulation (2.7), we introduce a Galerkin approximation based on the finite-dimensional spaces $V_h \subset V$ and $M_h \subset M$, which we assume to satisfy the well-known LBB condition

$$\forall q_h \in M_h \quad \exists \mathbf{v}_h \in V_h,\ \mathbf{v}_h \neq 0 : \quad (q_h, \operatorname{div} \mathbf{v}_h) \geq \beta_h \|q_h\|_{L^2} \|\mathbf{v}_h\|_{H^1}. \tag{3.1}$$

Let $(\mathbf{u}_h, p_h, \lambda_{1h}, \dots, \lambda_{nh})$ be the solution of the discrete problem. We denote by $(u_i)_{i=1\dots dN}$ (resp., $(p_i)_{i=1\dots M}$) the components of $\mathbf{u}_h$ (resp., p_h) with respect to a basis $\{\mathbf{v}_i\}$ of V_h (resp., $\{q_i\}$ of M_h). Finally, we introduce the vectors $U = (u_1, \dots, u_{dN}) \in \mathbb{R}^{dN}$, $P = (p_1, \dots, p_M) \in \mathbb{R}^M$, and $\Lambda = (\lambda_{1h}, \dots, \lambda_{nh}) \in \mathbb{R}^n$.

Then the discrete counterpart of (2.7) gives rise to the following algebraic system of equations:

$$\begin{cases} AU + D^T P + \Phi^T \Lambda = F, \\ D\,U = 0, \\ \Phi\,U = Q, \end{cases} \tag{3.2}$$

where $A \in \mathbb{R}^{dN \times dN}$ is the stiffness matrix, $D \in \mathbb{R}^{M \times dN}$ is the matrix associated with the divergence operator, and Φ is the $n \times dN$ matrix whose lines are given by the vectors $\phi_i = (\int_{S_i} \mathbf{v}_1 \cdot \mathbf{n}\, ds, \dots, \int_{S_i} \mathbf{v}_{dN} \cdot \mathbf{n}\, ds)$, $i = 1, \dots, n$.

PROPOSITION 3.1. *System* (3.2) *admits a unique solution.*

Proof. The proof of the existence of the discrete solution $(\mathbf{u}_h, p_h, \lambda_{ih},\ i = 1, \dots, n)$ as well as that of the uniqueness of $\mathbf{u}_h$ and of the λ_{ih} follows the same lines of Proposition 2.2 by substituting V and M by their discrete counterpart. The uniqueness of p_h is assured by condition (3.1). □

If we discretize in time the Navier–Stokes system (2.3) by, for instance, a semi-implicit Euler scheme and then in space by the finite element method, we will produce an algebraic system analogous to (3.2), where the matrix A is now given by

$$A = \frac{1}{\delta t} M + B + K,$$

δt being the time step, M and B the mass and advection matrices, and K the stiffness matrix. Here and in the following it is assumed that the matrix A is positive definite, which is always the case if δt is chosen appropriately.

3.1. Solution algorithms. Here, we present and analyze four possible algorithms which may be adopted for the solution of system (3.2) and which are computationally more efficient than solving simultaneously for U, P, and Λ.

1. *Solution of additional Stokes problems.* If one wishes to introduce the proposed approach on a Navier–Stokes solver with as few modifications as possible to an existing code for Navier–Stokes equations with "classical" boundary conditions, a possibility is to follow the constructive proof of Proposition 2.2. As we have seen, the solution of the constrained problem can be obtained by combining the solutions of $n + 1$ unconstrained Stokes problems, given by (2.8) and (2.9). In particular, for a fixed geometry, the n solutions $\mathbf{w}_i$, $i = 1, \dots, n$, of problem (2.9) can be computed only once, so that the additional computational cost at each time step is just that of the solution of (2.8). The drawback is that the memory requirement to store the $\mathbf{w}_i$ may become prohibitive particularly in a three-dimensional computation and with a large number of Lagrange multipliers.

2. *Schur complement + Iterative solver.* An alternative algorithm is based on using an iterative solution of a Schur complement system. We rewrite (3.2) in the form

$$\begin{bmatrix} S & \tilde{\Phi}^T \\ \tilde{\Phi} & 0 \end{bmatrix} \cdot \begin{bmatrix} X \\ \Lambda \end{bmatrix} = \begin{bmatrix} G \\ Q \end{bmatrix}, \tag{3.3}$$

where $\tilde{\Phi} = [\Phi, 0] \in \mathbb{R}^{n \times (dN+M)}$, $X = [U, P]^T$, $G = [F, 0]^T$. The matrix

$$S = \begin{bmatrix} A & D^T \\ D & 0 \end{bmatrix}$$

has a standard Stokes form and, since the two discrete spaces V_h and M_h satisfy the LBB condition (3.1), S is nonsingular (see, e.g., [19, 2]). We can then eliminate the unknown X from (3.3), obtaining

$$\tilde{\Phi} S^{-1} \tilde{\Phi}^T \Lambda = \tilde{\Phi} S^{-1} G - Q, \tag{3.4}$$

which can be solved by an appropriate iterative method. Any matrix-vector multiplication will imply the solution of a Stokes problem with homogeneous Neumann conditions on the sections S_i.

If A is symmetric, then $R = \tilde{\Phi} S^{-1} \tilde{\Phi}^T$ is symmetric and positive definite (see Proposition 3.2 below). Consequently, the conjugate gradient (CG) algorithm may be used, which will converge to the exact solution in n iterations, n being the number of Lagrange multipliers (which coincides with the number of boundary sections S_i minus one). For instance, in the case of just one Lagrange multiplier, one iteration of the CG algorithm suffices to obtain the solution. (Note that in this case the linear system (3.4) reduces to just one scalar equation.)

Remark 5. The computational cost of the procedure depends on the number of matrix-vector multiplications required for every iteration of the chosen iterative solver and on the number of iterations necessary for convergence. For each matrix-vector multiplication we need to solve a Stokes problem. In the case of the CG algorithm, it is known that it converges to the exact solution in n steps. In addition, two extra Stokes problems have to be solved to obtain the initial residual (required to start up the procedure) and the final solution X. Therefore, if CG is adopted the computational cost would be equal to the solution of $n + 2$ Stokes problems (at each time step), which is higher than that of procedure 1. On the other hand, there is no need to store intermediate solutions.

PROPOSITION 3.2. *The matrix $R = \tilde{\Phi} S^{-1} \tilde{\Phi}^T$ is positive semidefinite; moreover, if A is symmetric, then R is symmetric and positive definite.*

Proof. System (3.3) (which is equivalent to system (3.2)) admits a unique solution, as shown in Proposition 3.1. Then, we necessarily have that $\ker(\tilde{\Phi}^T) = \{0\}$.

The matrix

$$S^* = \begin{bmatrix} A & D^T \\ -D & 0 \end{bmatrix}$$

is positive semidefinite (see, e.g., [19]), thus S^{*-1} and $R^* = \tilde{\Phi} S^{*-1} \tilde{\Phi}^T$ are also positive semidefinite.

On the other hand, $S = PS^*$, where

$$P = \begin{bmatrix} I & 0 \\ 0 & -I \end{bmatrix},$$

is such that $P^{-1} = P$. Then

$$R = \tilde{\Phi} S^{-1} \tilde{\Phi}^T = \tilde{\Phi} (P S^*)^{-1} \tilde{\Phi}^T = \tilde{\Phi} S^{*-1} P \tilde{\Phi}^T = \tilde{\Phi} S^{*-1} \tilde{\Phi}^T = R^*.$$

We conclude that also R is positive semidefinite. Moreover, if A is symmetric, R turns out to be symmetric, positive semidefinite, and nonsingular, so it is also positive definite. □

In the case where there is just one Lagrange multiplier (which occurs whenever we have just one input section and one output section), the CG algorithm reads as follows:

given $\lambda_0 \in \mathbb{R}$,

$$\begin{aligned}
&\text{(i)} && SX_1 = G - \tilde{\Phi}^T \lambda_0, \\
&\text{(ii)} && r_0 = \tilde{\Phi} X_1 - Q, \\
&\text{(iii)} && SX_2 = \tilde{\Phi}^T r_0, \\
&\text{(iv)} && \lambda = \lambda_0 + \frac{r_0^2}{r_0 \tilde{\Phi} X_2} r_0 = \lambda_0 + \frac{r_0^2}{\tilde{\Phi} X_2}, \\
&\text{(v)} && SX = G - \tilde{\Phi}^T \lambda.
\end{aligned}$$

Since in this case the CG method converges in one iteration, λ and X are the solutions of (3.3). This algorithm requires the solution of 3 Stokes problems at steps (i), (iii), and (v).

Remark 6. By a closer inspection, it can be noted that by taking $\lambda_0 = 0$, the CG algorithm just presented effectively reduces to procedure 1.

3. *Reordering + fractional step* I. We recall that any Stokes system of the form

$$\begin{bmatrix} A & D^T \\ D & 0 \end{bmatrix} \begin{bmatrix} U \\ P \end{bmatrix} = \begin{bmatrix} F \\ 0 \end{bmatrix}$$

can be solved exactly by the following three step algorithm:

(i) $AU_0 = F$,
(ii) $DA^{-1}D^T P = DU_0$,
(iii) $U = U_0 - A^{-1} D^T P$.

Let $H^{(1)}$ and $H^{(2)}$ denote two suitable approximations of A^{-1}. We can write an approximate factorization scheme as

(i) $AU_0 = F$,
(ii) $DH^{(1)}D^T P = DU_0$,
(iii) $U = U_0 - H^{(2)} D^T P$.

In this way we can recover many projection or quasi-compressibility methods for the Navier–Stokes equations (see [14, 17]). In particular, we will focus on the Yosida projection scheme [16], which consists of adopting $H^{(1)} = \delta t M^{-1}$ (while no approximation is made in step (iii), i.e., $H^{(2)} = A^{-1}$), and on the algebraic version of the Chorin–Temam scheme in which we have $H^{(1)} = H^{(2)} = \delta t M^{-1}$ [17].

System (3.2) can be reordered in a Stokes-like form as

$$\begin{bmatrix} \tilde{A} & \tilde{D}^T \\ \tilde{D} & 0 \end{bmatrix} \begin{bmatrix} \tilde{U} \\ P \end{bmatrix} = \begin{bmatrix} \tilde{F} \\ 0 \end{bmatrix}, \tag{3.5}$$

where

$$\tilde{A} = \begin{bmatrix} A & \Phi^T \\ \Phi & 0 \end{bmatrix} \in \mathbb{R}^{(dN+n)\times(dN+n)}, \qquad \tilde{D} = \begin{bmatrix} D & 0 \end{bmatrix} \in \mathbb{R}^{M\times(dN+n)},$$
$$\tilde{U} = \begin{bmatrix} U \\ \Lambda \end{bmatrix} \in \mathbb{R}^{dN+n}, \qquad \tilde{F} = \begin{bmatrix} F \\ Q \end{bmatrix} \in \mathbb{R}^{dN+n}.$$

We can then write an approximate factorization scheme as follows:

(i) $\tilde{A}\tilde{U}_0 = \tilde{F}$. Since A is positive definite and $\ker(\Phi^T) = \emptyset$, $\tilde{A}$ is nonsingular, too, and this system admits a unique solution. In particular, we have $\Phi U_0 = Q$.
(ii) $\tilde{D}\tilde{H}^{(1)}\tilde{D}^T P = \tilde{D}\tilde{U}_0$,
(iii) $\tilde{U} = \tilde{U}_0 - \tilde{H}^{(2)}\tilde{D}^T P$, where now $\tilde{H}^{(1)}$ and $\tilde{H}^{(2)}$ are possible approximations of $\tilde{A}^{-1}$.

We are now in the same setting of factorization schemes for the Stokes problem. We will then use the term *Yosida* scheme when $\tilde{A}^{-1}$ is approximated only in step (ii), while a scheme where $\tilde{H}^{(1)} = \tilde{H}^{(2)} \neq \tilde{A}^{-1}$ will be called a *Chorin–Temam* scheme.

We now detail a possible way to approximate $\tilde{A}^{-1}$. First, we note that if we write $\tilde{H}^{(1)}$ in the block form

$$\tilde{H}^{(1)} = \begin{bmatrix} H_{11}^{(1)} & H_{12}^{(1)} \\ H_{21}^{(1)} & H_{22}^{(1)} \end{bmatrix},$$

step (ii) of the algorithm is equivalent to

$$DH_{11}^{(1)}D^T P = DU_0,$$

where just the first diagonal block of $\tilde{H}^{(1)}$ is actually involved in the computation. Therefore, we need only look for an approximation $H_{11}^{(1)}$ of the corresponding term C_{11} of the following block decomposition of $\tilde{A}^{-1}$:

$$\tilde{A}^{-1} = \begin{bmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{bmatrix}.$$

The term C_{11} is equal to

$$C_{11} = A^{-1}\left(I - \Phi^T V^{-1}\Phi A^{-1}\right), \quad \text{where } V = \Phi A^{-1}\Phi^T.$$

A natural approximation of C_{11} is then

$$H_{11}^{(1)} = \delta t M^{-1}\left(I - \delta t \Phi^T V_{appr}^{-1}\Phi M^{-1}\right), \quad V_{appr} = \delta t \Phi M^{-1}\Phi^T, \tag{3.6}$$

and in particular we have $H_{11}^{(1)} = C_{11} + O(\delta t^2)$. The matrix V_{appr} is an $n \times n$ matrix. In general, the number n of Lagrange multipliers is very small so that V_{appr} can be easily inverted. Furthermore, if the lumped form of the mass matrix is used, V_{appr} is diagonal. In the case of just one Lagrange multiplier, V_{appr} reduces to a scalar.

The Yosida scheme then becomes

(i) $\tilde{A}\tilde{U}_0 = \tilde{F}$,
(ii) $DH_{11}^{(1)}D^T P = DU_0$, and
(iii) $\tilde{A}\tilde{U} = \tilde{A}\tilde{U}_0 - \tilde{D}^T P$.

We observe that, in this case, we recover exactly the constraints on the fluxes. Indeed, step (iii) implies $\Phi U = \Phi U_0 = Q$ in particular.

In the Chorin–Temam case, we note that step (iii) is equivalent to

$$U = U_0 - H_{11}^{(1)} D^T P, \tag{3.7}$$

$$\Lambda = \Lambda_0 - H_{21}^{(1)} D^T P. \tag{3.8}$$

Since we are interested only in the velocity field, we can neglect (3.8) and we need only compute the block $H_{11}^{(1)}$ as in (3.6). The algebraic Chorin–Temam scheme then becomes

(i) $\tilde{A}\tilde{U}_0 = \tilde{F}$,
(ii) $DH_{11}^{(1)} D^T P = DU_0$, and
(iii) $U = U_0 - H_{11}^{(1)} D^T P$.

We observe that, also in this case, the constraints on the fluxes are recovered exactly. Indeed, by multiplying step (iii) by Φ we have

$$\begin{aligned}\Phi U &= \Phi U_0 - \Phi H_{11}^{(1)} D^T P \\ &= \Phi U_0 - \left(\delta t \Phi M^{-1} - \delta t V_{appr} V_{appr}^{-1} \Phi M^{-1}\right) D^T P = \Phi U_0 = Q.\end{aligned}$$

4. *Reordering + fractional step* II. System (3.2) can also be reordered in a different manner as

$$\begin{bmatrix} A & \tilde{D}^T \\ \tilde{D} & 0 \end{bmatrix} \begin{bmatrix} U \\ \tilde{P} \end{bmatrix} = \begin{bmatrix} F \\ \tilde{Q} \end{bmatrix}, \tag{3.9}$$

where

$$\tilde{D} = \begin{bmatrix} D \\ \Phi \end{bmatrix} \in \mathbb{R}^{(M+n)\times dN}, \qquad \tilde{P} = \begin{bmatrix} P \\ \Lambda \end{bmatrix} \in \mathbb{R}^{M+n}, \qquad \tilde{Q} = \begin{bmatrix} 0 \\ Q \end{bmatrix} \in \mathbb{R}^{M+n}.$$

The three step algorithm then reads as

(i) $AU_0 = F$, which is unperturbed with respect to the Stokes system without constraints,
(ii) $\tilde{D} H^{(1)} \tilde{D}^T \tilde{P} = \tilde{D} U_0 - \tilde{Q}$,
(iii) $U = U_0 - H^{(2)} \tilde{D}^T \tilde{P}$.

Again, we consider the approximation $H^{(1)} = \delta t M^{-1}$ and either $H^{(2)} = A^{-1}$ (Yosida) or $H^{(2)} = \delta t M^{-1}$ (algebraic Chorin–Temam).

Remark 7. This algorithm can be easily implemented starting from an existing Navier–Stokes solver which uses factorization methods. It suffices to add to the matrix D the few lines of matrix Φ and apply the chosen factorization method.

Remark 8. Step (ii) is equivalent to

$$DH^{(1)}(D^T P + \Phi^T \Lambda) = DU_0, \tag{3.10}$$

$$\Phi H^{(1)}(D^T P + \Phi^T \Lambda) = \Phi U_0 - Q. \tag{3.11}$$

On the other hand, the third step gives

$$U = U_0 - H^{(2)}(D^T P + \Phi^T \Lambda),$$

from which we can infer that

$$\begin{aligned}\Phi U &= \Phi U_0 - \Phi H^{(2)}(D^T P + \Phi^T \Lambda) \\ &= \Phi U_0 - \Phi H^{(1)}(D^T P + \Phi^T \Lambda) + \Phi(H^{(1)} - H^{(2)})(D^T P + \Phi^T \Lambda).\end{aligned} \tag{3.12}$$

By exploiting (3.11), we finally have

$$\Phi U = Q + \Phi(H^{(1)} - H^{(2)})(D^T P + \Phi^T \Lambda). \tag{3.13}$$

Whenever $H^{(1)} = H^{(2)}$, like in the algebraic Chorin–Temam scheme, we recover the constraint on the fluxes exactly.

On the contrary, in the Yosida scheme, (3.13) becomes

$$\Phi U = Q + \Phi(\delta t M^{-1} - A^{-1})(D^T P + \Phi^T \Lambda) = Q + O(\delta t^2).$$

4. Numerical tests and algorithm assessment.

4.1. Womersley flow. In order to assess the proposed methodology, we consider a case where the analytical solution of the Navier–Stokes equations is known. More precisely, we consider the *Womersley* solution, which describes the transient flow in a cylindrical pipe associated to a time-periodic pressure gradient (see, e.g., [12]). As such, it may be considered as a transient counterpart of the Poiseuille solution.

If the pressure gradient is given by

$$\nabla p = \frac{dp}{dz}(t)\mathbf{e}_z = -\rho a \sin(\omega t)\mathbf{e}_z,$$

z being the pipe axial coordinate and ρ the fluid density, the velocity $\mathbf{u}$ reduces only to its axial component, i.e., $\mathbf{u} = u_z \mathbf{e}_z$, and the analytical expression for u_z is as follows:

- In the *two-dimensional* $(2D)$ *case* (flow between two infinite planes),

$$u_z(r,t) = \sum_0^\infty \gamma_{2k+1} \sin\left(\frac{(2k+1)\pi}{2r_0} r\right),$$

  where

$$\gamma_l = \frac{4a}{\pi l(l^4\sigma^2 + \omega^2)} \left(l^2\sigma \sin(\omega t) + \omega e^{-l^2\sigma t} - \omega \cos(\omega t)\right).$$

  Here $\sigma = \frac{\mu\pi^2}{4\rho r_0^2}$, r is the transverse coordinate, $2r_0$ the distance between the two planes, and μ the dynamic fluid viscosity.

- In the *three-dimensional* $(3D)$ *case* (flow in a cylindrical pipe),

$$u_z(r,t) = \mathrm{Re}\left\{ -\frac{a}{\omega}\left(1 - \frac{J_0\left(i^{3/2}\sqrt{\frac{\rho\omega}{\mu}} r\right)}{J_0\left(i^{3/2}\sqrt{\frac{\rho\omega}{\mu}} r_0\right)}\right) e^{i\omega t} \right\},$$

  where r is the radial coordinate, r_0 the cylinder radius, and J_0 the Bessel function of first kind and of order zero.

In both the 2D and 3D test cases, we have imposed homogeneous Neumann boundary conditions at the inflow, while at the outflow we have prescribed the flow rate associated to the Womersley solution. In Figure 4 we show the axial velocity field for the 2D case at two different times, together with the velocity profile at the inflow. The solution obtained agrees very well with the analytical Womersley solution. Therefore, a single condition on the flow rate at the outflow, imposed through a Lagrange multiplier, is sufficient to recover the Womersley flow.

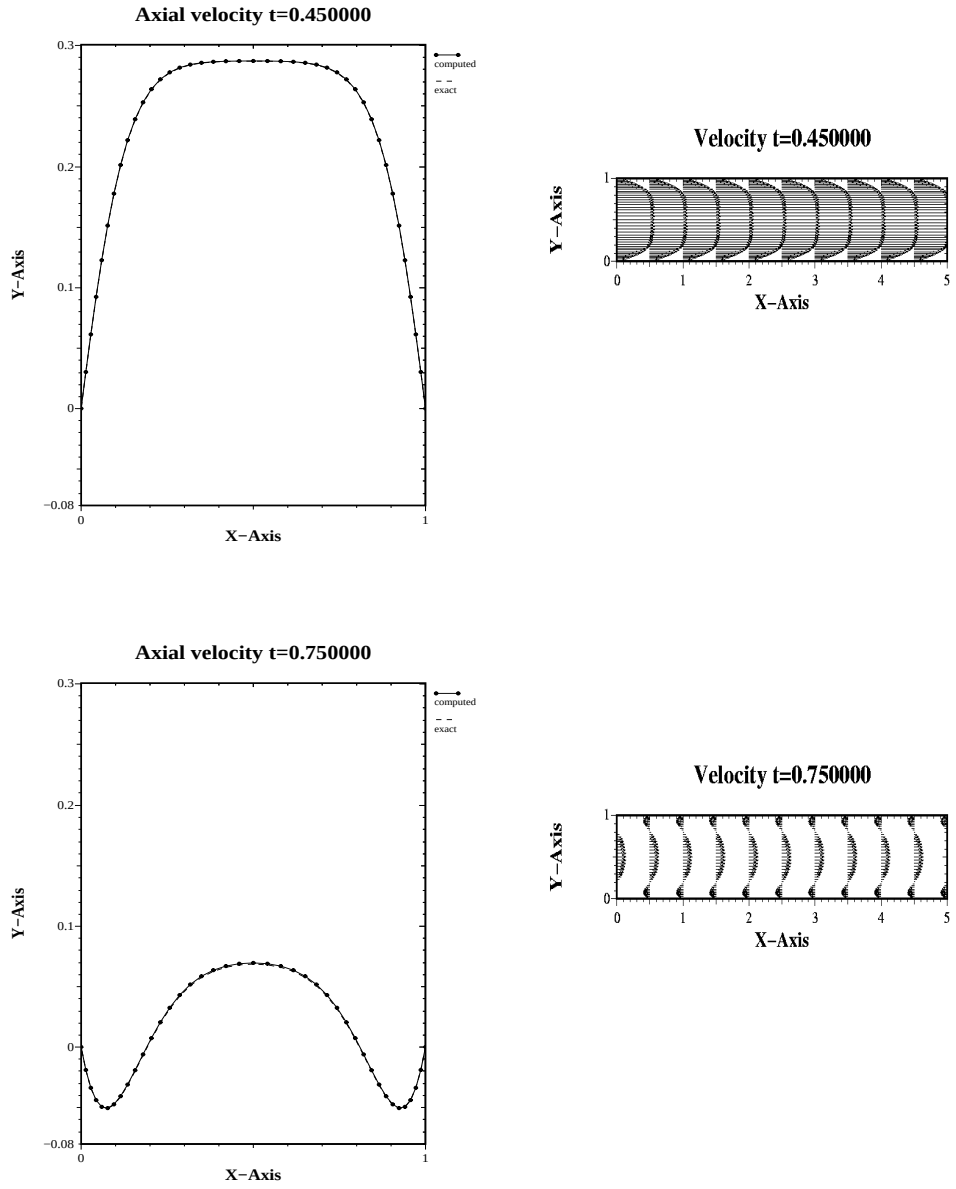

FIG. 4. *2D numerical solution obtained imposing the flux of the Womersley solution at the outflow section.*

The same experiment has been carried out in 3D and the result is shown in Figure 5. Here, the computed velocity field at three different times is illustrated, together with the corresponding axial velocity profile on the inflow section. Again, we outline the excellent agreement with the analytical solution.

Finally, we have carried out the same experiment in 2D using the numerical schemes "reordering + fractional step I" and "reordering + fractional step II" proposed in the previous section, both for the Yosida and the algebraic Chorin–Temam approximations, and we have evaluated the errors introduced on the fluxes. As expected, for the first scheme the difference between the flux we wish to impose and the one actually computed is of the order of the machine round-off error, both for the Yosida and the Chorin–Temam approximation.

For the latter scheme, this instead is true only when adopting the Chorin–Temam approximation. The behavior of the error on the fluxes for the Yosida approximation is shown in Figure 6. The error is decreasing with the time step size, with a convergence rate that appears to be even higher than quadratic.

4.2. Mass conservation in free interface simulations. We present here an application where it may be useful to impose the mass flow rate through a surface. We consider two immiscible and incompressible fluids, with the same viscosity, confined in a closed tank Ω and separated by a free interface (see Figure 7). We denote by $\Omega_i(t)$ and $\Sigma(t)$, for $i = 1, 2$, the domain occupied by the fluid i and the interface at time t, respectively. We adopt an arbitrary Lagrangian Eulerian (ALE) formulation [7] and we denote by $\mathbf{w}$ the domain velocity which satisfies $\mathbf{w} \cdot \mathbf{n} = \mathbf{u} \cdot \mathbf{n}$ on $\Sigma(t)$ and $\mathbf{w} \cdot \boldsymbol{\nu} = 0$ on $\partial\Omega$, where $\mathbf{n}$ denotes the normal to $\Sigma(t)$ directed from $\Omega_1(t)$ to $\Omega_2(t)$ and $\boldsymbol{\nu}$ is the outward normal on $\partial\Omega$. Because of the incompressibility and the immiscibility of the two fluids, the volume of $\Omega_1(t)$ (or equivalently $\Omega_2(t)$) must be preserved. At the continuous level, this property is satisfied. Indeed,

$$\begin{aligned} \operatorname{meas}(\Omega_1(t_2)) - \operatorname{meas}(\Omega_1(t_1)) &= \int_{t_1}^{t_2}\!\!\int_{\Sigma(t)} \mathbf{w} \cdot \mathbf{n}\, d\sigma = \int_{t_1}^{t_2}\!\!\int_{\Sigma(t)} \mathbf{u} \cdot \mathbf{n}\, d\sigma \\ &= \int_{t_1}^{t_2}\!\!\int_{\Omega_1(t)} \operatorname{div} \mathbf{u}\, dx = 0, \end{aligned} \tag{4.1}$$

since $\operatorname{div} \mathbf{u}$ vanishes almost everywhere in $\Omega_1(t)$.

At the discrete level, the relation $\int_{\Omega_1(t)} \operatorname{div} \mathbf{u}_h\, dx = 0$ is still verified if the pressure is discretized using *discontinuous* functions (as in the Q2/P1 or Q1/P0 finite elements) [2].

If instead the pressure is discretized using continuous functions, as in Taylor–Hood (P2/P1 or Q2/Q1), P1-isoP2, or Q1/Q1 stabilized finite elements [2, 9], there is no guarantee that (4.1) still holds at the discrete level. Numerical tests indeed confirm that those discretizations fail to conserve the measure of $\Omega_1(t)$. A possible strategy for the solution of this problem is to impose the condition

$$\int_{\Sigma(t)} \mathbf{u}_h \cdot \mathbf{n}_h\, d\sigma = 0$$

by a Lagrange multiplier, using the techniques presented in the previous section.

Let us show the results obtained on a 2D test case. In the following, all quantities are given in International System (IS) units. The two fluids are initially at rest and they are subjected to an oscillating body force $\mathbf{f} = (a\, g \sin(2\pi\nu\, t), -g)$ with $a = 0.05$,

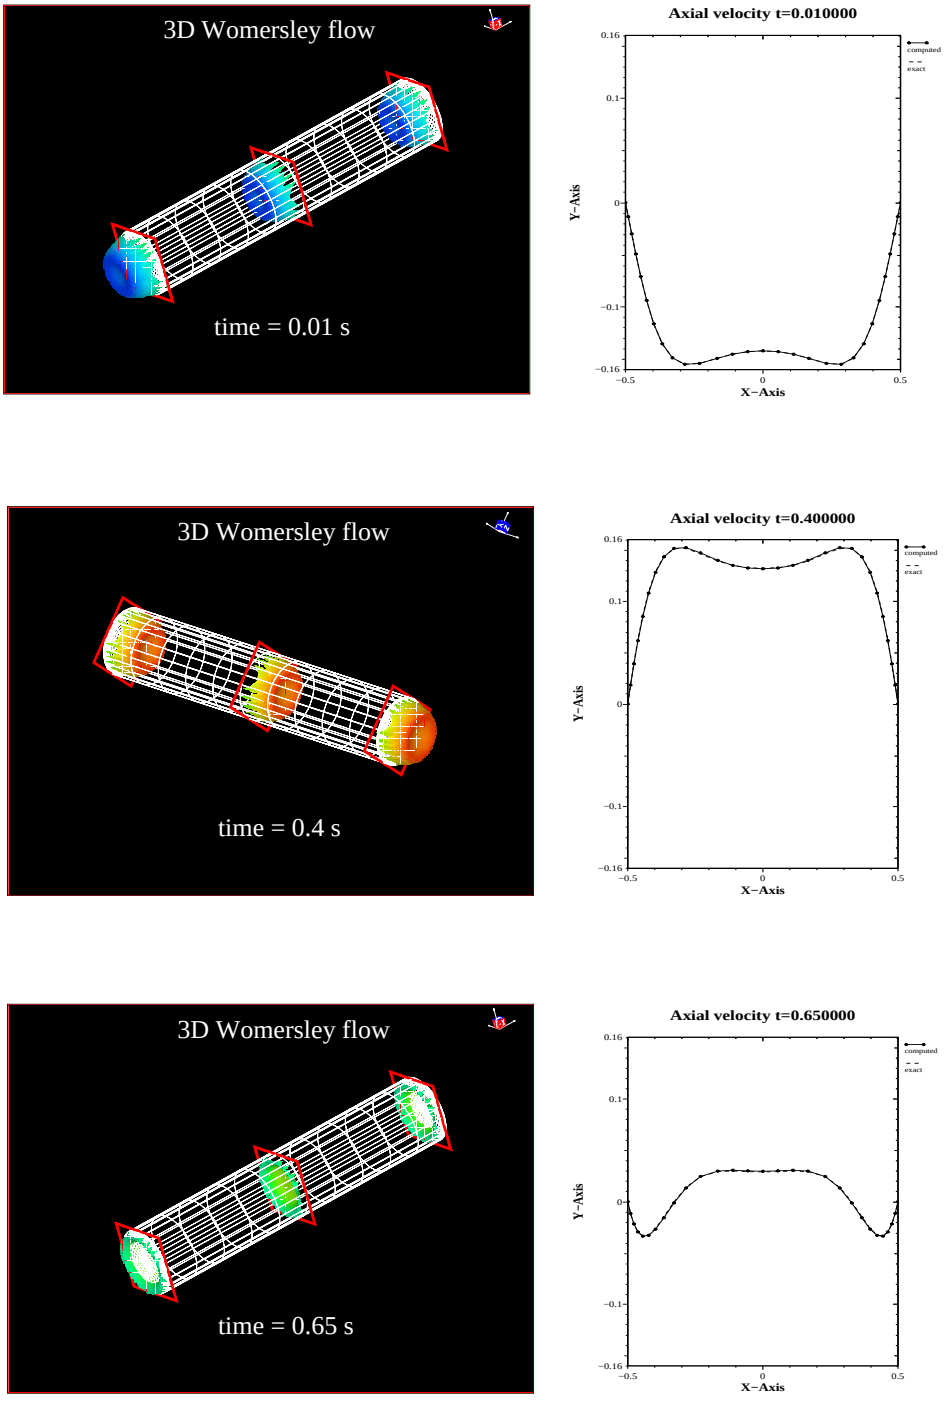

FIG. 5. *3D numerical solution obtained imposing the flux of the Womersley solution at the outflow section.*

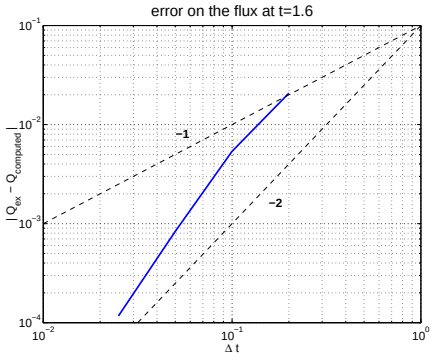

FIG. 6. *Behavior of the error on the flux for the scheme "reordering + fractional step* II*" with the Yosida approximation; the dotted lines are the reference lines for the error decrease rate.*

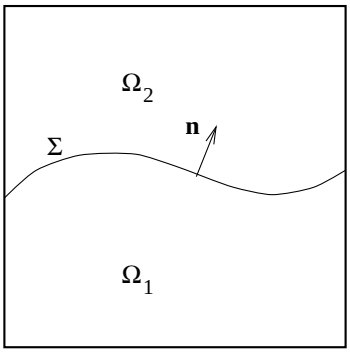

FIG. 7. *Two fluids separated by a free interface.*

$g = 10$, $\nu = 0.0625$. The kinematic viscosity of both fluids is taken to be $\nu = 0.005$, the density of the upper and the lower fluid is 0.91 and 1, respectively, $\text{meas}(\Omega_1) = \text{meas}(\Omega_2) = 4$ at $t = 0$. The mesh is allowed to move only along the vertical direction and the typical size of the mesh elements is $h = 0.1$. At time $t = 220$, if we use Q1/P0 or Q2/P1 elements, $\text{meas}(\Omega_1)$ is still equal to 4 (within machine precision), whereas it drops to approximately 3.9 when we adopt Q2/Q1 elements (see Figure 8). We have obtained analogous results with stabilized Q1/Q1 finite elements. Clearly, this lack of mass conservation decreases as h goes to zero, yet for many practical applications a mass loss is not acceptable and the use of an extremely fine mesh is not economical (or even not feasible).

Figure 8 shows that a perfect mass conservation is also obtained with Q2/Q1 elements if we impose a zero flow rate through Σ by the Lagrange multiplier technique. Finally, Figure 9 shows the elevation of a point on the interface obtained on the same mesh with the Q2/P1 elements and the Q2/Q1 elements with flux constraint. The difference is barely visible. The use of a Lagrange multiplier technique thus allows to adopt continuous pressure elements for this type of problem.

4.3. Multiscale domain decomposition. An application in which it is necessary to impose defective boundary conditions to a Navier–Stokes problem arises in the hemodynamics context when the cardiovascular system is simulated by a multiscale model. A multiscale technique couples detailed models, based on the solution

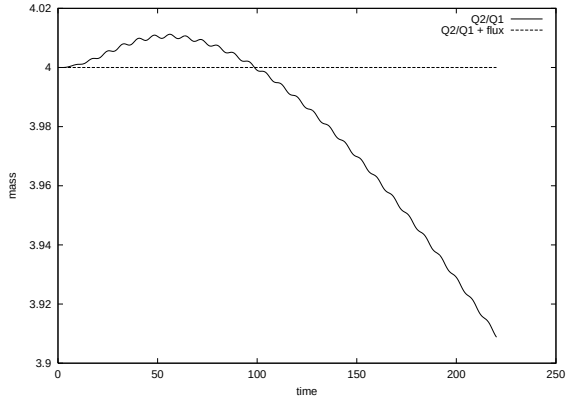

FIG. 8. *Mass conservation fails using $Q2/Q1$ elements, while it holds if we add a constraint on the velocity flux.*

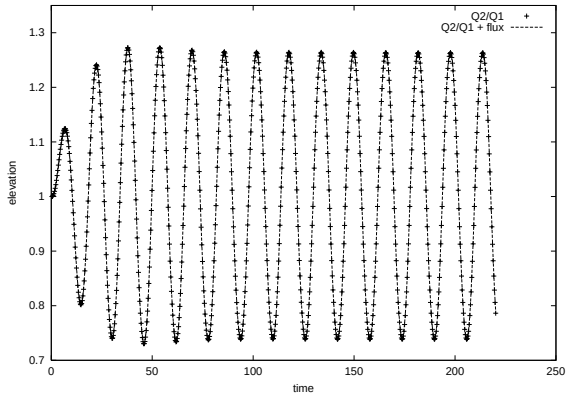

FIG. 9. *The time history of the elevation of a point of the interface. The results obtained with $Q2/P1$ elements are almost the same of that given by $Q2/Q1$ elements with flux constraint.*

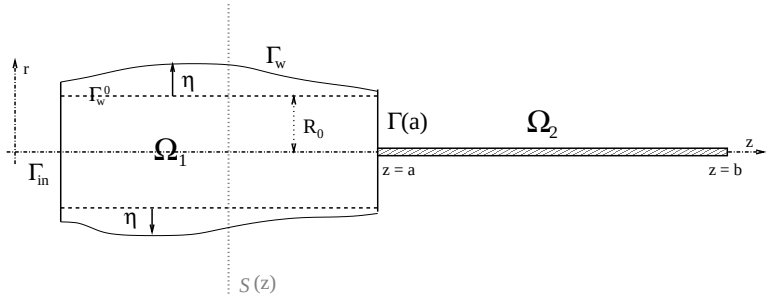

FIG. 10. *Coupled $2D$-$1D$ problem. On the left, the $2D$ model (Ω_1), where Γ_w represents the arterial wall and η the wall displacement with respect to the reference configuration Γ_w^0. On the right, the $1D$ model (Ω_2) defined on the interval $a \leq z \leq b$.*

of 2D or 3D fluid-structure interaction problems, with reduced models based on one-dimensional (1D) approximations or on systems of ordinary differential equations [8]. The simpler models normally provide the evolution of mean pressure and mean velocity in various regions of the cardiovascular system. The boundary data for the detailed model, which is based on the solution of the Navier–Stokes equations coupled with the vessel wall dynamics, must be obtained from these averaged quantities. This is a typical case of defective boundary conditions.

4.3.1. A 2D-1D coupling. Here we will give an illustrative example which consists in the coupling of a 2D and a 1D model. Let us consider the domain illustrated in Figure 10. In Ω_1 we define for $t > 0$ the fluid-structure model as

$$
\begin{cases}
\rho\partial_t \mathbf{u} + \rho\mathbf{u}\cdot\nabla\mathbf{u} + \nabla p - \mu\triangle\,\mathbf{u} = 0 & \text{in } \Omega_1,\\
\operatorname{div}\mathbf{u} = 0 & \text{in } \Omega_1,\\
\rho_w h\dfrac{\partial^2\eta}{\partial t^2} - kGh\dfrac{\partial^2\eta}{\partial z^2} + \dfrac{Eh}{1-\nu^2}\dfrac{\eta}{R_0^2} - \gamma\dfrac{\partial^3\eta}{\partial z^2\partial t} = f(t,z) & \text{on } \Gamma_w^0,\\
\partial_t\eta\,\mathbf{e}_r = \mathbf{u} & \text{on } \Gamma_w,\\
f(t,z) = \left(p\mathbf{n} - \mu\dfrac{\partial\mathbf{u}}{\partial\mathbf{n}}\right)\cdot\mathbf{e}_r\sqrt{1+\left(\dfrac{\partial\eta}{\partial z}\right)^2} & \text{on } \Gamma_w^0,
\end{cases}
\tag{4.2}
$$

where the unknowns are the fluid velocity $\mathbf{u}$, the fluid pressure p, and the wall displacement η. Here, ρ is the fluid density, h the vessel wall thickness, E the Young modulus, G the Timoshenko factor, and ρ_w the wall density. At $t = 0$ initial conditions $\mathbf{u}_0$, η_0, $\dot\eta_0$ are provided for the velocity, displacement, and displacement rate, respectively. We refer to [6] for a more detailed description and analysis of this problem. In Ω_2 we consider the following 1D problem for the velocity flux Q and the vessel section area A:

$$
\begin{cases}
\dfrac{\partial A}{\partial t} + \dfrac{\partial Q}{\partial z} = 0, & a < z < b,\ \ t > 0,\\
\dfrac{\partial Q}{\partial t} + \dfrac{\partial}{\partial z}\left(\alpha\dfrac{Q^2}{A}\right) + \dfrac{A}{\rho}\dfrac{\partial\bar p}{\partial z} + K_R\dfrac{Q}{A} = 0, & a < z < b,\ \ t > 0,
\end{cases}
\tag{4.3}
$$

with the algebraic relation $\bar p = \beta(A - A_0)$, A_0 being the reference area $A_0 = 2R_0$. The system is supplemented by initial conditions for A and Q at $t = 0$. This 1D reduced model is basically derived from (4.2), integrating the Navier–Stokes equations over each axial section $\mathcal{S}(z)$ and adopting a simplified version of the equation for the wall dynamics. A is the measure of $\mathcal{S}(z)$, the velocity flux is given by $Q(z) = \int_{\mathcal{S}(z)} u_z dr$, and $\bar p(z) = (\int_{\mathcal{S}(z)} p dr)/A(z)$; see [8] for more details.

System (4.2) has been discretized in space using P1-isoP2 finite elements for the fluid and P1 elements for the structure. For time discretization, we have adopted an ALE formulation to account for the domain movement with an implicit Euler discretization for the fluid equations and a Newmark scheme for the structure. On the other hand, system (4.3), which is hyperbolic, has been discretized using a second-order Taylor–Galerkin scheme with a characteristic treatment of the boundary.

At each time step t^n, we look for a solution of (4.2) and (4.3) which satisfies at $\Gamma(a)$ the coupling conditions

$$
\operatorname{meas}(\Gamma^n(a)) = A^n(a), \quad \int_{\Gamma^n(a)} u_z^n = Q^n(a), \quad \frac{1}{\operatorname{meas}(\Gamma^n(a))}\int_{\Gamma(a)} p^n = \bar p^n(a).
\tag{4.4}
$$

We have solved iteratively at each time step the two subproblems in Ω_1 and Ω_2. Given the approximate solution $\mathbf{u}^n$, p^n, η^n, Q^n, and A^n of the coupled problem at time $t = t^n$, we look for the solution $\mathbf{u}^{n+1}$, p^{n+1}, η^{n+1}, Q^{n+1}, and A^{n+1} using the following iterative algorithm:

We set $\mathbf{u}_{(0)} = \mathbf{u}^n$, $p_{(0)} = p^n$, and $\eta_{(0)} = \eta^n$, and for $k = 0, 1, \ldots$ we do the following:

1. We solve the 1D model (4.3) imposing at $z = a$

$$A_{(k+1)}(a) = A_0 + \frac{1}{\beta \,\mathrm{meas}(\Gamma_{(k)}(a))} \int_{\Gamma(a)} p_{(k)}$$

   and at $z = b$ absorbing boundary conditions based on characteristic analysis. We obtain $Q_{(k+1)}$ and $A_{(k+1)}$ in Ω_2.
2. We then solve the 2D problem imposing on $\Gamma(a)$ for the Navier–Stokes equations the defective condition

$$\int_{\Gamma(a)} \mathbf{u}_{(k+1)} \cdot \mathbf{e}_z = Q_{(k+1)}(a)$$

   and for the structure at $z = a$

$$\eta_{(k+1)}(a) = \frac{1}{2} A_{(k+1)}(a) - R_0.$$

   We obtain $\mathbf{u}_{(k+1)}$, $p_{(k+1)}$, $\eta_{(k+1)}$ in Ω_1.

We iterate until the coupling conditions are satisfied within a fixed tolerance and we finally set the solution at time t^{n+1} equal to the converged value. We may eventually add a relaxation step on the variable $A_{(k)}(a)$.

We observe that in step 2 of this algorithm we have to solve Navier–Stokes equations with flux boundary conditions on $\Gamma(a)$. A different algorithm for the same coupled 2D/1D problem, which allows us to impose a mean pressure condition on $\Gamma(a)$, has been proposed and analyzed in [6].

We present here the numerical results relative to the following test case: we have considered a fluid initially at rest and we have imposed a pressure of $15 mmHg$ ($2{\cdot}10^4\, dynes/cm^2$) at the inlet ($\Gamma_{in}$) for 0.005 seconds. For the fluid we have taken $\mu = 0.035\, poise$ and $\rho = 1\, g/cm^3$, while for the structure we have $E = 0.75{\cdot}10^6\, dynes/cm^2$, $\nu = 0.5$, $\rho_w = 1.1\, g/cm^3$, and $h = 0.1\, cm$. Figure 11 shows the fluid pressure and the domain deformation at different times. We may note how the "pressure wave" crosses the interface between the two models with little spurious reflections.

4.3.2. A two-dimensional–zero-dimensional coupling. This time, a by-pass anastomosis in a coronary, modeled by the incompressible Navier–Stokes equations in a fixed domain, is coupled with a lumped parameter model for the rest of the cardiovascular system. Lumped parameters models are well established tools [21] and able to provide an approximation of the time evolution of average pressure and flow rate in different compartments of the cardiovascular system. They are based on the solution of a system of algebraic-ordinary differential equations derived by using an analogue with an electrical circuit. In this analogy, electrical currents and voltage are interpreted as flow rate and mean pressure, respectively. The model here adopted is the one proposed in [11]. Its coupling with a 2D description of a coronary by-pass is shown in Figure 12.

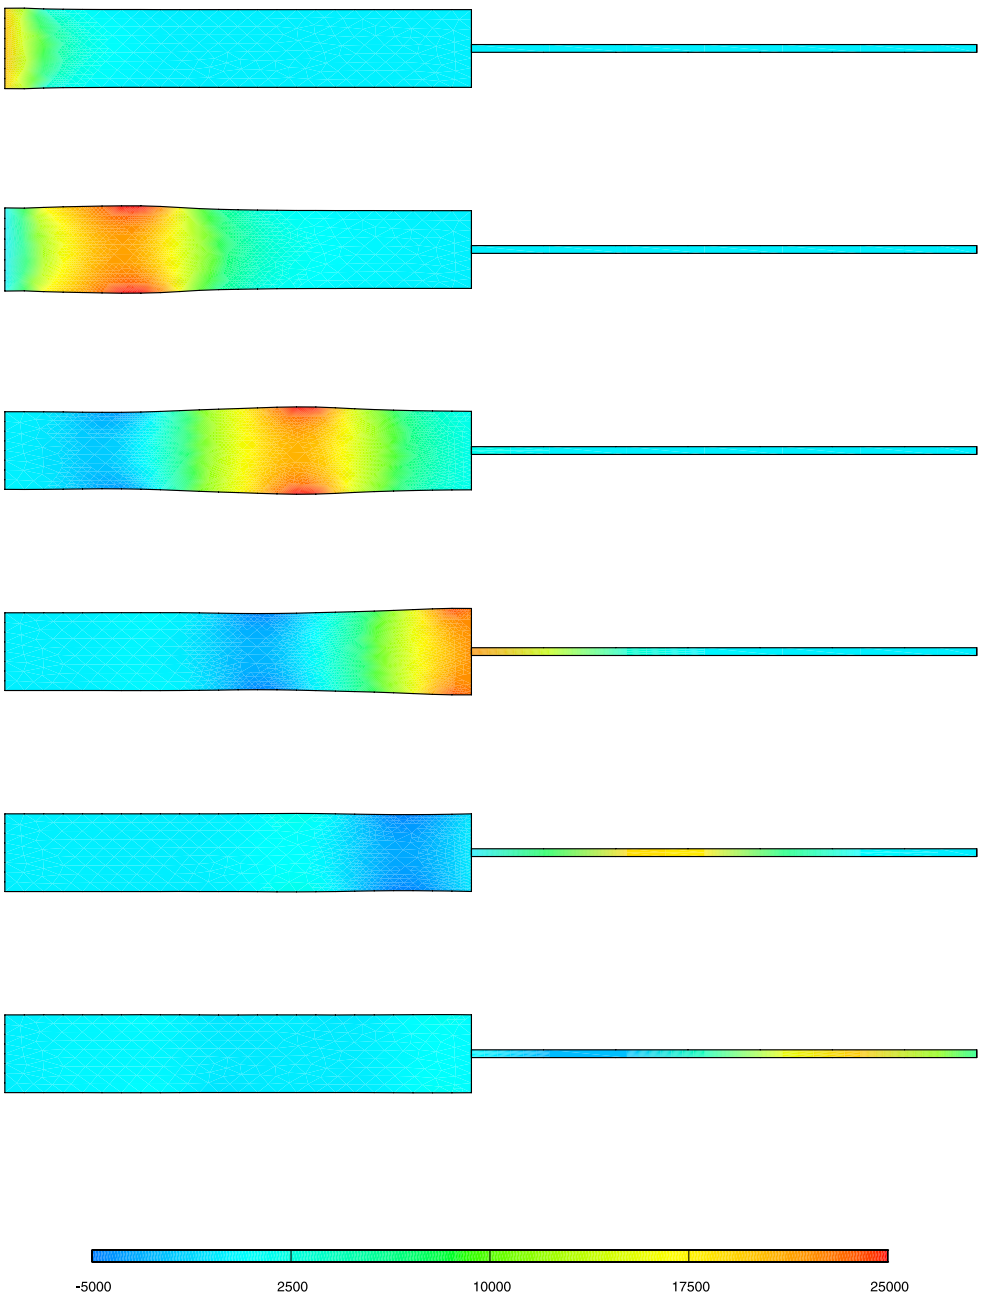

FIG. 11. *Coupling* $2D$ *simulation with the* $1D$ *reduced model; pressure distribution every* $5\,ms$*, starting from* $t = 1\,ms$.

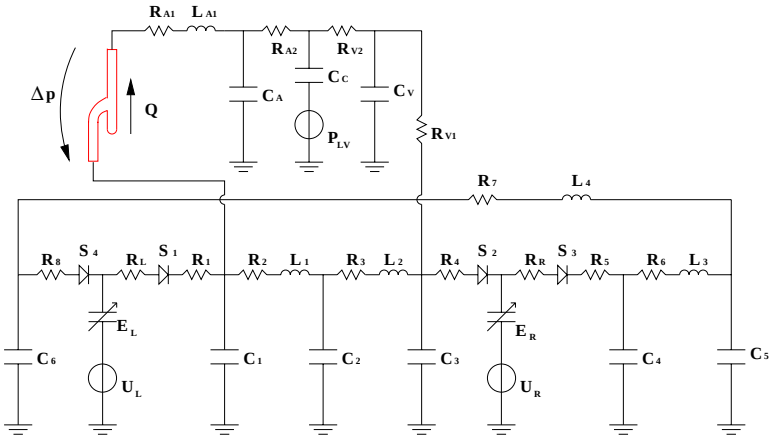

FIG. 12. *Lumped parameter model of the circulatory system coupled with a* 2*D description of a coronary by-pass.*

The interface condition we wish to impose between the two models are the continuity of flow rate and mean pressure. The numerical scheme employs a staggered algorithm where the pressure drop between inflow and outflow calculated by the Navier–Stokes model at a generic time step $t = t^k$ is imposed to the lumped parameter model which, in turn, is used to obtain the flow rate to advance the Navier–Stokes solution to $t = t^{k+1}$. We are therefore facing the case where we need to employ the technique presented in section 2. Since we are using a rigid wall model for the by-pass, the incoming and outgoing flow rates are equal, due to the incompressibility constraint. Actually, we have prescribed to the Navier–Stokes equations only the flow rate on the inflow section while homogeneous Neumann boundary conditions have been imposed on the outflow section. On the other hand, the pressure drop between inflow and outflow, needed to advance the lumped parameter model, is simply provided by the Lagrange multiplier.

An alternative coupling algorithm, based on imposing a mean pressure to the inflow and outflow sections of the Navier–Stokes problem while prescribing the flow rate to the lumped model, has been described in [15].

At the top of Figure 13 we show the flow rate and the pressure drop in the by-pass computed by the coupled system. The marks indicate the values at the times corresponding to the four snapshots of the fluid speed found in the lower part of the same figure.

5. Conclusions. In this work we have considered defective boundary conditions for Navier–Stokes equations. In particular, we have addressed the case where one wants to impose the flow rate on a measurable subset of the domain boundary. We have proposed a formulation based on a Lagrange multiplier technique and we have shown that it is well-posed for the Stokes and the linearized Navier–Stokes equations. Moreover, we have considered some numerical algorithms to effectively solve the mixed problem thus obtained. Finally, we have presented several applications in which the technique may be advantageously used and we have shown some numerical results illustrating its effectiveness.

FLUX RECOVERY FROM PRIMAL HYBRID FINITE ELEMENT METHODS*

SO-HSIANG CHOU†, DO Y. KWAK‡, AND KWANG Y. KIM‡

Abstract. A flux recovery technique is introduced and analyzed for the computed solution of the primal hybrid finite element method for second-order elliptic problems. The recovery is carried out over a single element at a time while ensuring the continuity of the flux across the interelement edges and the validity of the discrete conservation law at the element level. Our construction is general enough to cover all degrees of polynomials and grids of triangular or quadrilateral type. We illustrate the principle using the Raviart–Thomas spaces, but other well-known related function spaces such as the Brezzi–Douglas–Marini (BDM) or Brezzi–Douglas–Fortin–Marini (BDFM) space can be used as well. An extension of the technique to the nonlinear case is given. Numerical results are presented to confirm the theoretical results.

Key words. recovery technique, primal hybrid method, nonconforming method, conservative method

1. Introduction.

We consider the second-order elliptic boundary value problem

$$\begin{cases} -\operatorname{div}(\mathcal{K}\nabla u) = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where Ω is a bounded polygonal domain in $\mathbb{R}^2$ with the boundary $\partial\Omega$, and $\mathcal{K} = \mathcal{K}(\mathbf{x})$ is assumed to be symmetric and uniformly positive definite, i.e., there exist two positive constants c_1 and c_2 such that

$$c_1\xi^T\xi \le \xi^T\mathcal{K}(\mathbf{x})\xi \le c_2\xi^T\xi \qquad \forall \xi \in \mathbb{R}^2,\ \mathbf{x} \in \overline{\Omega}.$$

In many applications, it is more important to gain accurate approximation for the vector variable $\boldsymbol{\sigma} = -\mathcal{K}\nabla u$ (e.g., Darcy velocity) rather than the scalar variable u (e.g., pressure). A common way of achieving that goal is to use the mixed finite element methods, which have been a very active area of research since the late 1970s; see, for example, [4, 5, 6, 9, 20, 22]. All mixed methods have the further advantage of maintaining the discrete conservation law at the element level.

However, mixed methods lead to an indefinite symmetric algebraic system which may be hard to solve iteratively. An efficient way to solve for the mixed finite element method is to further introduce the Lagrange multipliers on the edges of the mesh to ensure the continuity of normal components of the velocity variable. This is sometimes called the mixed-hybrid method. In this fashion the velocity and the pressure finite element spaces have no continuity constraints at all, and thus both variables can be

eliminated to obtain a symmetric and positive definite matrix system which involves only the Lagrange multipliers. It can be shown that this matrix system is equivalent to some nonconforming finite element method for the original problem (1.1); see, for example, [1, 2, 7]. The nonconforming method for the pressure requires fewer degrees of freedom than the mixed finite element method, and moreover, its solution can be computed by a fast solver such as multigrid algorithms (cf. [3, 8, 10, 11]). By using this nonconforming solution, the vector approximation can be obtained through a simple formula, for example, as done in [17]. The rectangular case with piecewise constant diagonal tensor was considered in [8]. For the triangular case, see [1, 2, 7, 8, 17].

Our objective in this paper is to show that similar equivalence results can be derived through the primal hybrid finite element methods for the problem (1.1) which were analyzed in [21] as a general approach of constructing nonconforming finite element approximations. We first present a technique of recovering from the primal hybrid solution an optimal flux approximation $\boldsymbol{\sigma}_h$ based on the local Raviart–Thomas spaces. Although the construction is carried out in a local manner (over a single element at a time), it is ensured that $\boldsymbol{\sigma}_h$ is continuous across the interelement boundaries and that the discrete conservation law holds locally. Also, instead of the Raviart–Thomas spaces, other mixed finite element spaces such as the Brezzi–Douglas–Marini (BDM) spaces or the Brezzi–Douglas–Fortin–Marini (BDFM) spaces can be used as well.

The main advantage of our technique is that it is general enough to cover all degrees of polynomials and all types of grids, triangular or quadrilateral. In particular, our technique can be applied to any nonconforming finite element method which can be viewed as a primal hybrid finite element method.

As good examples of how the technique can be applied, we will derive simple formulas for $\boldsymbol{\sigma}_h$ in the lowest-order cases on triangular and quadrilateral grids, which lead to the $P1$ and the rotated $Q1$ nonconforming finite element methods, respectively (see [21] or section 4).

The rest of the paper is organized as follows. In the next section the primal finite element methods are introduced for the problem (1.1). In section 3, we present a technique of flux recovery from the primal hybrid finite element methods and establish optimal error estimates for the vector approximation thus obtained, and in section 4 a detailed description of how the technique can be applied for the lowest-order elements is given. In section 5, our results are extended to nonlinear problems. Finally, in section 6, some numerical results are presented to confirm the theoretical results.

2. Primal hybrid finite element methods. In this section we give a brief description of the primal hybrid finite element method for the problem (1.1). The reader can find much more detail on this subject in [21].

Let $\mathcal{T}_h$ be a partition of Ω into triangles or convex quadrilaterals which satisfies the usual regularity assumption

$$C_1 h_T^2 \le |T| \le C_2 h_T^2 \qquad \forall T \in \mathcal{T}_h,$$

where h_T denotes the diameter of T, $|T|$ is the area of T, and $h = \max_{T\in\mathcal{T}_h} h_T$.

Denote by $\hat{T}$ a standard reference element, i.e., the unit square or the unit triangle with the vertices $\hat{\mathbf{x}}_i$'s. Then there exists a unique bijective bilinear or linear transformation $F_T : \hat{T} \to T$ such that $\mathbf{x}_i = F_T(\hat{\mathbf{x}}_i)$ for all i. We set

$$\mathcal{J}_T = \text{ Jacobian matrix of } F_T, \qquad J_T = \det \mathcal{J}_T.$$

Based on the triangulation $\mathcal{T}_h$ we define the spaces

$$X = \{v \in L^2(\Omega) : v|_T \in H^1(T) \quad \forall T \in \mathcal{T}_h\} = \prod_{T\in\mathcal{T}_h} H^1(T),$$

$$M = \Big\{\mu \in \prod_{T\in\mathcal{T}_h} H^{-1/2}(\partial T) : \text{ there exists } \boldsymbol{\tau} \in \mathbf{H}(\mathrm{div},\Omega) \text{ such that } \boldsymbol{\tau}\cdot\mathbf{n}_T = \mu \text{ on } \partial T, \qquad \forall T \in \mathcal{T}_h\Big\},$$

where $\mathbf{n}_T$ is the unit outward normal along ∂T. Let $|\cdot|_{m,\Omega}$ and $\|\cdot\|_{m,\Omega}$ denote the usual seminorm and norm, respectively, on the Sobolev space $H^m(\Omega)$. We define the mesh-dependent norms

$$|||v|||_X = \left(\sum_{T\in\mathcal{T}_h} |||v|||_{1,T}^2\right)^{1/2}, \qquad v \in X,$$

$$\|\mu\|_h = \left(\sum_{T\in\mathcal{T}_h} h_T\|\mu\|_{0,\partial T}^2\right)^{1/2}, \qquad \mu \in \prod_{T\in\mathcal{T}_h} L^2(\partial T),$$

where

$$|||v|||_{1,T}^2 = |v|_{1,T}^2 + h_T^{-2}\|v\|_{0,T}^2.$$

Now the primal hybrid formulation for the problem (1.1) is given as follows: find a pair $(u,\lambda) \in X \times M$ such that

$$a(u,v) + b(v,\lambda) = (f,v) \qquad \forall v \in X, \tag{2.1a}$$

$$b(u,\mu) = 0 \qquad \forall \mu \in M, \tag{2.1b}$$

where

$$a(u,v) = \sum_{T\in\mathcal{T}_h} \int_T \mathcal{K}\nabla u\cdot\nabla v\,dx, \qquad b(v,\mu) = \sum_{T\in\mathcal{T}_h} \int_{\partial T} v\mu\,ds, \tag{2.2}$$

$$(f,v) = \int_\Omega fv\,dx. \tag{2.3}$$

It was shown in [21] that u belongs to $H_0^1(\Omega)$ and is the unique solution of the standard weak formulation

$$\int_\Omega \mathcal{K}\nabla u\cdot\nabla v\,dx = \int_\Omega fv\,dx, \qquad v \in H_0^1(\Omega),$$

and that

$$\lambda = -\mathcal{K}\nabla u\cdot\mathbf{n}_T \ \text{ on } \partial T \qquad \forall T \in \mathcal{T}_h. \tag{2.4}$$

We use the standard notation for the spaces of polynomials, i.e., $P_r(T)$ denotes the space of polynomials on T of total degrees at most r, and $Q_{r,s}(T)$ denotes the space of polynomials on T of degrees at most r and s in x and y, respectively. We also set $Q_r(T) = Q_{r,r}(T)$. On any element T we define

$$R_r(T) = \begin{cases} P_r(T) & \text{if } T \text{ is a triangle,} \\ Q_r(\hat{T})\circ F_T^{-1} & \text{if } T \text{ is a quadrilateral} \end{cases}$$

and

$$S_r(\partial T) = \{\mu \in L^2(\partial T) : \mu|_e \in P_r(e) \qquad \forall e \text{ edges of } T\}.$$

In order to discretize the primal hybrid formulation (2.1), we introduce a finite-dimensional subspace $\hat{X}$ of $H^1(\hat{T})$ such that $R_k(\hat{T}) \subset \hat{X}$ for some $k \geq 1$. Then we define a pair $X_h \times M_h$ of finite element spaces on $\mathcal{T}_h$ by

$$X_h = \{v \in X : v|_T \in X_h(T) \qquad \forall T \in \mathcal{T}_h\}, \tag{2.5}$$

$$M_h = \left\{ \mu \in \prod_{T \in \mathcal{T}_h} S_{k-1}(\partial T) : \mu|_{\partial T_1} + \mu|_{\partial T_2} = 0 \text{ on } \partial T_1 \cap \partial T_2 \right. \\ \left. \text{if } T_1 \text{ and } T_2 \text{ are adjacent elements} \right\}, \tag{2.6}$$

where we set $X_h(T) = \{\hat{v} \circ F_T^{-1} : \hat{v} \in \hat{X}\}$.

Now the primal hybrid finite element method is defined as follows: find a pair $(u_h, \lambda_h) \in X_h \times M_h$ such that

$$a(u_h, v) + b(v, \lambda_h) = (f, v) \qquad \forall v \in X_h, \tag{2.7a}$$

$$b(u_h, \mu) = 0 \qquad \forall \mu \in M_h. \tag{2.7b}$$

Examples for the space $\hat{X}$ are given in [21] for all $k \geq 1$ which ensures the existence and uniqueness of a solution (u_h, λ_h) for the system (2.7) and satisfy the following optimal error estimates (cf. [15, 21]).

THEOREM 2.1. *For $u \in H^{k+1}(\Omega)$ we have*

$$|\!|\!| u - u_h |\!|\!|_X + \|\lambda - \lambda_h\|_h \leq C h^k |u|_{k+1}.$$

The following observation is crucial to decouple the mixed system (2.7): u_h is the solution of the *nonconforming* finite element method

$$a(u_h, v) = (f, v), \qquad v \in V_h, \tag{2.8}$$

where

$$V_h = \{v \in X_h : b(v, \mu) = 0 \qquad \forall \mu \in M_h\}. \tag{2.9}$$

This implies that we may compute u_h directly from (2.8) and then compute λ_h from u_h locally by (2.7a), which reduces to

$$\int_{\partial T} v \lambda_h \, ds = \int_T f v \, dx - \int_T \mathcal{K} \nabla u_h \cdot \nabla v \, dx, \qquad v \in X_h(T). \tag{2.10}$$

Thus, the Lagrange multiplier λ_h may be interpreted as the (weak) *local residuals* of the nonconforming approximation u_h.

3. Flux recovery technique. To begin with, we define the Raviart–Thomas space of index $r \geq 0$ on $\mathcal{T}_h$ as follows:

$$RT_r = \{\boldsymbol{\tau} \in \mathbf{H}(\mathrm{div}, \Omega) : \boldsymbol{\tau}|_T \in RT_r(T)\},$$

where the local space $RT_r(T)$ is defined as

$$RT_r(T) = \{\mathcal{P}_T\hat{\boldsymbol{\tau}} : \hat{\boldsymbol{\tau}} \in (R_r(\hat{T}))^2 + (x,y)R_r(\hat{T})\},$$

and $\mathcal{P}_T\hat{\boldsymbol{\tau}} = J_T^{-1}\mathcal{J}_T\hat{\boldsymbol{\tau}} \circ F_T^{-1}$. We also set for $r \geq 1$

$$\boldsymbol{\Psi}_r(T) = \begin{cases} (P_{r-1}(T))^2 & \text{if } T \text{ is a triangle,} \\ \{\mathcal{J}_T^{-t}\hat{\boldsymbol{\tau}} \circ F_T^{-1} : \hat{\boldsymbol{\tau}} \in Q_{r-1,r}(\hat{T}) \times Q_{r,r-1}(\hat{T})\} & \text{if } T \text{ is a quadrilateral.} \end{cases}$$

Let us point out that if T is a rectangle, then

$$\boldsymbol{\Psi}_r(T) = Q_{r-1,r}(T) \times Q_{r,r-1}(T).$$

Now we present a technique of recovering an optimal vector approximation. Once the solution (u_h, λ_h) of the system (2.7) is computed, one can construct a unique $\boldsymbol{\sigma}_h \in RT_{k-1}(T)$ on each $T \in \mathcal{T}_h$:

$$\boldsymbol{\sigma}_h \cdot \mathbf{n}_T = \lambda_h \quad \text{on } \partial T, \tag{3.1a}$$

$$\int_T (\boldsymbol{\sigma}_h + \mathcal{K}\nabla u_h) \cdot \boldsymbol{\tau}\, dx = 0, \quad \boldsymbol{\tau} \in \boldsymbol{\Psi}_{k-1}(T) \quad (k \geq 2) \tag{3.1b}$$

(cf. [6, 20, 22]). By construction we immediately obtain the following two propositions.

PROPOSITION 3.1. *The normal components of $\boldsymbol{\sigma}_h$ are continuous across the interelement boundaries, i.e., we have $\boldsymbol{\sigma}_h \in RT_{k-1}$.*

Proof. This is a direct consequence of (3.1a). ∎

PROPOSITION 3.2. *We have for all $v \in R_{k-1}(T)$*

$$\int_T \operatorname{div} \boldsymbol{\sigma}_h\, v\, dx = \int_T f v\, dx.$$

This implies that the discrete conservation law holds locally.

Proof. By using (3.1a) and Green's theorem, (2.7a) becomes

$$\int_T (\boldsymbol{\sigma}_h + \mathcal{K}\nabla u_h) \cdot \nabla v\, dx + \int_T \operatorname{div} \boldsymbol{\sigma}_h\, v\, dx = \int_T f v\, dx \qquad \forall v \in X_h(T). \tag{3.2}$$

There is nothing to be done for $k = 1$, since $\nabla v = 0$ for $v \in R_0(T)$. For $k \geq 2$ we have $\nabla v \in \boldsymbol{\Psi}_{k-1}(T)$ for $v \in R_{k-1}(T)$, which proves the desired result by (3.1b). ∎

Remark 3.1. We could use other mixed finite elements instead of RT_{k-1}. For example, when one wants to use the $BDM_{k-1}(T)$ space on a triangle T ($k \geq 2$), (3.1) is replaced by

$$\boldsymbol{\sigma}_h \cdot \mathbf{n}_T = \lambda_h \quad \text{on } \partial T, \tag{3.3a}$$

$$\int_T (\boldsymbol{\sigma}_h + \mathcal{K}\nabla u_h) \cdot \nabla v\, dx = 0, \quad v \in P_{k-2}(T), \tag{3.3b}$$

$$\int_T (\boldsymbol{\sigma}_h + \mathcal{K}\nabla u_h) \cdot \operatorname{curl}(b_T v)\, dx = 0, \quad v \in P_{k-3}(T) \quad (k \geq 3), \tag{3.3c}$$

where b_T is the cubic bubble function on T. If the space $\hat{X}$ contains only $P_k(\hat{T})$ on a quadrilateral T, one may use the $BDFM_k(T)$ space, in which case (3.1) is replaced by

$$\boldsymbol{\sigma}_h \cdot \mathbf{n}_T = \lambda_h \quad \text{on } \partial T, \tag{3.4a}$$

$$\int_T (\boldsymbol{\sigma}_h + \mathcal{K}\nabla u_h) \cdot \boldsymbol{\tau}\, dx = 0, \quad \boldsymbol{\tau} \in \boldsymbol{\Psi}_{k-1}(T) \quad (k \geq 2), \tag{3.4b}$$

where we set

$$\boldsymbol{\Psi}_r(T) = \{\mathcal{J}_T^{-t}\hat{\boldsymbol{\tau}} \circ F_T^{-1} : \hat{\boldsymbol{\tau}} \in (P_{r-1}(\hat{T}))^2\}.$$

For a review of the degrees of freedom (3.3) and (3.4), we refer to [4, 5, 6].

Before going to an error estimate, we prove the following key lemma.

LEMMA 3.3. *Given $\beta \in L^2(\partial T)$ and $\mathbf{q} \in (L^2(T))^2$, let $\boldsymbol{\xi}_h \in RT_r(T)$ satisfy*

$$\int_{\partial T} \boldsymbol{\xi}_h \cdot \mathbf{n}_T\, \mu\, ds = \int_{\partial T} \beta\mu\, ds \qquad \forall \mu \in S_r(\partial T),$$
$$\int_T \boldsymbol{\xi}_h \cdot \boldsymbol{\tau}\, dx = \int_T \mathbf{q} \cdot \boldsymbol{\tau}\, dx \qquad \forall \boldsymbol{\tau} \in \boldsymbol{\Psi}_r(T) \quad (r \geq 1).$$

Then we obtain

$$\|\boldsymbol{\xi}_h\|_{0,T} \leq C(\|\mathbf{q}\|_{0,T} + h_T^{1/2}\|\beta\|_{0,\partial T}).$$

Proof. By considering the L^2 projections, we may assume that $\beta \in S_r(\partial T)$ and $\mathbf{q} \in RT_r(T)$. Then the proof is done by using a simple scaling argument [2, 6]. ∎

Now we derive an error estimate for the vector approximation $\boldsymbol{\sigma}_h$ constructed by (3.1). It is well known (see, e.g., [6, 20, 22, 23]) that the Raviart–Thomas projection $\Pi_h : (H^1(\Omega))^2 \to RT_r$ can be defined by

$$\int_{\partial T} \Pi_h\boldsymbol{\sigma} \cdot \mathbf{n}\, \mu\, ds = \int_{\partial T} \boldsymbol{\sigma} \cdot \mathbf{n}\, \mu\, ds, \qquad \mu \in S_r(\partial T), \tag{3.5}$$

$$\int_T \Pi_h\boldsymbol{\sigma} \cdot \boldsymbol{\tau}\, dx = \int_T \boldsymbol{\sigma} \cdot \boldsymbol{\tau}\, dx, \qquad \boldsymbol{\tau} \in \boldsymbol{\Psi}_r(T), \tag{3.6}$$

possessing the following approximation properties:

$$\|\boldsymbol{\sigma} - \Pi_h\boldsymbol{\sigma}\|_0 \leq Ch^l\, \|\boldsymbol{\sigma}\|_l, \qquad 1 \leq l \leq r+1,$$

for all $\boldsymbol{\sigma} \in (H^l(\Omega))^2$, and

$$\|\operatorname{div}(\boldsymbol{\sigma} - \Pi_h\boldsymbol{\sigma})\|_0 \leq Ch^l\, \|\operatorname{div}\boldsymbol{\sigma}\|_l, \qquad 0 \leq l \leq r+1,$$

for all $\boldsymbol{\sigma} \in (H^l(\Omega))^2$ with $\operatorname{div}\boldsymbol{\sigma} \in H^l(\Omega)$.

THEOREM 3.4. *Let $\boldsymbol{\sigma} = -\mathcal{K}\nabla u$. Then we have for $u \in H^{k+1}(\Omega)$*

$$\|\boldsymbol{\sigma} - \boldsymbol{\sigma}_h\|_0 \leq Ch^k(|\boldsymbol{\sigma}|_k + |u|_{k+1}).$$

Proof. It suffices to prove that

$$\|\Pi_h\boldsymbol{\sigma} - \boldsymbol{\sigma}_h\|_{0,T} \leq Ch^k(|\boldsymbol{\sigma}|_k + |u|_{k+1}).$$

From (3.5) and (3.6) it follows that

$$\int_{\partial T}(\Pi_h\boldsymbol{\sigma}-\boldsymbol{\sigma}_h)\cdot\mathbf{n}_T\,\mu\,ds=\int_{\partial T}(\lambda-\lambda_h)\mu\,ds,\quad \mu\in S_{k-1}(\partial T),$$
$$\int_T(\Pi_h\boldsymbol{\sigma}-\boldsymbol{\sigma}_h)\cdot\boldsymbol{\tau}\,dx=-\int_T\mathcal{K}\nabla(u-u_h)\cdot\boldsymbol{\tau}\,dx,\quad \boldsymbol{\tau}\in\boldsymbol{\Psi}_{k-1}(T)\quad (k\geq 2).$$

By applying Lemma 3.3 and then Theorem 2.1, we obtain

$$\begin{aligned}\|\Pi_h\boldsymbol{\sigma}-\boldsymbol{\sigma}_h\|_{0,T}&\leq C(|u-u_h|_{1,T}+h_T^{1/2}\|\lambda-\lambda_h\|_{0,\partial T})\\&\leq Ch^k(|\boldsymbol{\sigma}|_k+|u|_{k+1}).\end{aligned}$$

This completes the proof. ∎

4. Examples. In this section $\bar{f}$ indicates the piecewise constant average of f on $\mathcal{T}_h$, i.e.,

$$\bar{f}|_T=\frac{1}{|T|}\int_T f\,dx.$$

4.1. *P*1 nonconforming method. Let $\mathcal{T}_h$ be composed of triangles. We consider the lowest-order element, i.e., $k=1$:

$$X_h(T)=P_1(T),\qquad M_h=\prod_{T\in\mathcal{T}_h}S_0(\partial T)\bigcap M.$$

Then it is easy to see that V_h (defined by (2.9)) is the $P1$ nonconforming finite element space.

Let T be an arbitrary element of $\mathcal{T}_h$ with the edges e_1,e_2,e_3 and the barycenter $\mathbf{x}_T$, and let $\phi_i\in X_h(T)$ be the basis function associated with the edge e_i, namely, $\frac{1}{|e_i|}\int_{e_i}\phi_j\,ds=\delta_{ij}$. Then $\lambda_h|_{e_i}$ is given by (see (2.10))

$$\lambda_h|_{e_i}=\frac{1}{|e_i|}\left(\int_T f\phi_i\,dx-\int_T\mathcal{K}\nabla u_h\cdot\nabla\phi_i\,dx\right).$$

Using the formula $\nabla\phi_i=\frac{\mathbf{n}_i|e_i|}{|T|}$ results in

$$\lambda_h|_{e_i}=-\bar{\mathcal{K}}\nabla u_h\cdot\mathbf{n}_i+\frac{1}{|e_i|}\int_T f\phi_i\,dx.$$

By comparing the normal components $\boldsymbol{\sigma}_h\cdot\mathbf{n}_i$ for each i, one can show that the vector $\boldsymbol{\sigma}_h$ constructed by (3.1) is identical to the one given in [13]:

$$\boldsymbol{\sigma}_h=-\bar{\mathcal{K}}\nabla u_h+\frac{\bar{f}}{2}(\mathbf{x}-\mathbf{x}_T)+\mathbf{C}_T,\tag{4.1}$$

where $\mathbf{C}_T$ is determined by any two of the three equations

$$|e_i|\mathbf{n}_i\cdot\mathbf{C}_T=\int_T f\phi_i\,dx-\frac{|T|}{3}\bar{f},\qquad i=1,2,3.$$

In particular, when f is a constant on T, we obtain $\mathbf{C}_T=0$ and

$$\boldsymbol{\sigma}_h|_T=-\bar{\mathcal{K}}\nabla u_h|_T+\frac{f}{2}(\mathbf{x}-\mathbf{x}_T),\tag{4.2}$$

which is the formula obtained by Marini [17].

Remark 4.1. It is straightforward to extend the above results to higher-order elements of odd degrees $k \geq 3$:

$$X_h(T) = P_k(T), \qquad M_h = \prod_{T \in \mathcal{T}_h} S_{k-1}(\partial T) \bigcap M.$$

Once u_h is computed, λ_h can be computed at k Gauss–Legendre points on each edge by using the basis functions associated with these points.

Now let us consider the primal hybrid finite element method with the right-hand side f replaced by $\bar{f}$. By Proposition 3.2 we then have

$$\int_T \operatorname{div} \boldsymbol{\sigma}_h \, dx = \int_T \bar{f} \, dx, \tag{4.3a}$$

or $\operatorname{div} \boldsymbol{\sigma}_h = \bar{f}$. This, together with (3.2), implies that

$$\int_T (\boldsymbol{\sigma}_h + \mathcal{K} \nabla u_h) \, dx = 0. \tag{4.3b}$$

The equations (4.3a)–(4.3b) form the finite volume box method introduced by Courbet and Croisille [14]. Thus the primal hybrid finite element method along with our technique of flux recovery provide an alternative approach to the finite volume box method. A different approach is given in [13]; see also [12].

4.2. Rotated $Q1$ nonconforming method. Let $\mathcal{T}_h$ be composed of quadrilaterals, and

$$\hat{X} = \operatorname{span}\{1, \hat{x}, \hat{y}, \hat{x}^2 - \hat{y}^2\}, \qquad M_h = \prod_{T \in \mathcal{T}_h} S_0(\partial T) \bigcap M.$$

Then it is easy to see that V_h is the *parametric* rotated $Q1$ nonconforming finite element space introduced by Rannacher and Turek [19]. One could use the nonparametric version as well which, on rectangular grids, is given by

$$X_h(T) = \operatorname{span}\{1, x, y, x^2 - y^2\}, \qquad M_h = \prod_{T \in \mathcal{T}_h} S_0(\partial T) \bigcap M.$$

As in the $P1$ nonconforming method, $\lambda_h|_{e_i}$ is given by

$$\lambda_h|_{e_i} = \frac{1}{|e_i|} \left(\int_T f \phi_i \, dx - \int_T \nabla u_h \cdot \nabla \phi_i \, dx \right),$$

where $\phi_i \in X_h(T)$ is the basis function associated with the edge e_i.

Now we derive a simple formula for $\boldsymbol{\sigma}_h$ for the nonparametric version on rectangular grids. Suppose that f is piecewise constant. Then we obtain $\operatorname{div} \boldsymbol{\sigma}_h = f$ and

$$\int_T (\boldsymbol{\sigma}_h + \mathcal{K} \nabla u_h) \cdot \nabla v \, dx = 0 \qquad \forall v \in X_h(T). \tag{4.4}$$

Let us decompose $\boldsymbol{\sigma}_h|_T$ into

$$\boldsymbol{\sigma}_h|_T = \boldsymbol{\sigma}_{h,0}|_T + a_T(h_{T_y}^2 (x - x_T), h_{T_x}^2 (y - y_T)),$$

where $\boldsymbol{\sigma}_{h,0}|_T$ belongs to

$$\nabla X_h(T) = \{(a + bx, c - by) : a, b, c \in \mathbb{R}\},$$

and h_{T_x} and h_{T_y} are the width and the height of T, respectively. Since we have $\operatorname{div} \boldsymbol{\sigma}_{h,0}|_T = 0$, it follows that

$$a_T = \frac{f|_T}{h_{T_x}^2 + h_{T_y}^2}.$$

Now, by means of the orthogonality relation

$$\int_T (h_{T_y}^2(x - x_T), h_{T_x}^2(y - y_T)) \cdot \nabla v \, dx = 0, \qquad v \in X_h(T),$$

it is easy to see from (4.4) that

$$\boldsymbol{\sigma}_{h,0} = -P_0(\mathcal{K}\nabla u_h), \tag{4.5}$$

where P_0 is the L^2 projection which locally maps onto the space $\nabla X_h(T)$. Combining the results obtained thus far, we obtain

$$\boldsymbol{\sigma}_h|_T = -P_0(\mathcal{K}\nabla u_h)|_T + \frac{f|_T}{h_{T_x}^2 + h_{T_y}^2}(h_{T_y}^2(x - x_T), h_{T_x}^2(y - y_T)). \tag{4.6}$$

Remark 4.2. Similar results using the lowest-order rectangular Raviart–Thomas mixed finite element method can be found in [1, 8]. Our results show the primal hybrid approach provides a clear way of constructing the vector approximation from the Q_1 nonconforming solution.

5. Extension to nonlinear problems. The previous results can be extended to the nonlinear second-order elliptic boundary value problem

$$\begin{cases} -\operatorname{div} \mathbf{a}(u, \nabla u) = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{5.1}$$

The primal hybrid formulation is to find a pair $(u, \lambda) \in X \times M$ such that

$$a(u, v) + b(v, \lambda) = (f, v) \qquad \forall v \in X, \tag{5.2a}$$

$$b(u, v) = 0 \qquad \forall \mu \in M, \tag{5.2b}$$

where

$$a(u, v) = \sum_{T \in \mathcal{T}_h} \int_T \mathbf{a}(u, \nabla u) \cdot \nabla v \, dx. \tag{5.3}$$

Analysis of the primal hybrid finite element methods for this nonlinear problem is given in [18] for $k \geq 2$.

The previous technique of recovering a vector approximation can be applied as well. After computing the primal hybrid solution (u_h, λ_h), one constructs a unique $\boldsymbol{\sigma}_h \in RT_{k-1}(T)$ on each $T \in \mathcal{T}_h$ by

$$\boldsymbol{\sigma}_h \cdot \mathbf{n}_T = \lambda_h \quad \text{on } \partial T, \tag{5.4a}$$

$$\int_T [\boldsymbol{\sigma}_h + \mathbf{a}(u_h, \nabla u_h)] \cdot \boldsymbol{\tau} \, dx = 0, \quad \boldsymbol{\tau} \in \boldsymbol{\Psi}_{k-1}(T) \quad (k \geq 2). \tag{5.4b}$$

Setting $\boldsymbol{\sigma} = -\mathbf{a}(u, \nabla u)$, we can derive the bound for $\|\boldsymbol{\sigma} - \boldsymbol{\sigma}_h\|_0$ in the same way as before. By applying Lemma 3.3 to the error equations

$$\int_{\partial T} (\Pi_h \boldsymbol{\sigma} - \boldsymbol{\sigma}_h) \cdot \mathbf{n}_T \, \mu \, ds = \int_{\partial T} (\lambda - \lambda_h) \mu \, ds, \quad \mu \in S_{k-1}(\partial T),$$
$$\int_T (\Pi_h \boldsymbol{\sigma} - \boldsymbol{\sigma}_h) \cdot \boldsymbol{\tau} \, dx = -\int_T [\mathbf{a}(u, \nabla u) - \mathbf{a}(u_h, \nabla u_h)] \cdot \boldsymbol{\tau} \, dx,$$
$$\boldsymbol{\tau} \in \boldsymbol{\Psi}_{k-1}(T) \quad (k \geq 2),$$

we obtain

$$\|\Pi_h \boldsymbol{\sigma} - \boldsymbol{\sigma}_h\|_{0,T} \leq C(\|\mathbf{a}(u, \nabla u) - \mathbf{a}(u_h, \nabla u_h)\|_{0,T} + h_T^{1/2} \|\lambda - \lambda_h\|_{0,\partial T}).$$

Note that if $\mathbf{a}$ has bounded derivatives, then there exists a constant $C > 0$ independent of h such that

$$|\mathbf{a}(u, \nabla u) - \mathbf{a}(u_h, \nabla u_h)| \leq C(|u - u_h| + |\nabla(u - u_h)|),$$

which implies that

$$\|\mathbf{a}(u, \nabla u) - \mathbf{a}(u_h, \nabla u_h)\|_{0,T} \leq C \|u - u_h\|_{1,T}.$$

Thus it follows by Theorem 2.1 that

$$\|\Pi_h \boldsymbol{\sigma} - \boldsymbol{\sigma}_h\|_{0,T} \leq C h^k (|\boldsymbol{\sigma}|_k + |u|_{k+1}).$$

THEOREM 5.1. *We have for* $u \in H^{k+1}(\Omega)$

$$\|\boldsymbol{\sigma} - \boldsymbol{\sigma}_h\|_0 \leq C h^k (|\boldsymbol{\sigma}|_k + |u|_{k+1}).$$

6. Numerical results. To confirm the theoretical results established in the previous sections, numerical experiments are carried out on the unit square $\Omega = (0, 1)^2$ for three test problems. The first problem has a discontinuous tensor coefficient, and the second one has a smooth coefficient, but its solution has a very weak "layer" near the right boundary. Finally the third problem is taken from [16]. For numerical results on triangular grids, we refer to [13].

Errors for the velocity and the pressure approximations are computed in the discrete L^2 norms

$$\|\boldsymbol{\sigma} - \boldsymbol{\sigma}_h\|_{0,h}^2 = \sum_{T \in \mathcal{T}_h} \sum_{e \in \partial T} \left[\int_e (\boldsymbol{\sigma} - \boldsymbol{\sigma}_h) \cdot \mathbf{n} \, ds \right]^2, \tag{6.1}$$

$$\|u - u_h\|_{0,h}^2 = \sum_{T \in \mathcal{T}_h} \int_T (u - u_h)^2 \, dxdy, \tag{6.2}$$

where the integrals are evaluated by the midpoint rule, i.e., if S denotes an edge e or an area T, then we evaluate $\int_S g$ by $|S| \times g(\mathbf{x}_S)$, where $\mathbf{x}_S$ is the mass center of S. All the results below show second-order convergence in the velocity. They are tabulated as Tables 6.1–6.3.

ON THE NUMERICAL ANALYSIS OF THE IMPERFECT BIFURCATION OF CODIM ≤ 3*

KLAUS BÖHMER†, DÁŠA JANOVSKÁ‡, AND VLADIMÍR JANOVSKÝ§

Abstract. A postprocessing analysis of a previously computed bifurcation point of codim ≤ 3, corank $= 1$ is proposed. Some cases with codim > 3 also are included. Our aim is to predict quantitatively imperfect bifurcation phenomena. Our idea is to compute the differential of the diffeomorphism that links the state and parameter variables of the actual problem with its normal form.

Key words. bifurcation points, imperfect bifurcation diagrams, quantitative analysis

1. Introduction. This paper deals with unusual numerical techniques for the bifurcation analysis of steady states. The classical numerical methods for continuation of parameter dependent solutions are presented, e.g., in [25], [20], [26]; for their up-to-date versions, see, e.g., [12], [14], [13], [15], [27], [19], [31]. The latter in particular yield the following types of results. The bifurcation points (u^*, λ^*) in our notation below are detected along the solution curve, where solutions bifurcate or become singular. The numbers of bifurcating branches, their stability properties, and often their tangents, are determined (see, e.g., [31], [19], and here, in particular, section 7.8). The evaluation of the defining equations (see below) allows us to classify this type of singularity. Hence, the structure of the bifurcation scenario is known; see [17, Chap. III, Figs. 7.1, 7.2, 8.1 ff. and Chap. IV, Figs. 4.1 ff]. So, let (u^*, λ^*) for the original problem be classified, e.g., as a pitchfork or a winged cusp; see Figure 4.3 in [17, Chap. IV]. For the classified normal form, all details of the scenario are well known. However, it is not known where exactly in the neighborhood of the original (u^*, λ^*), e.g., the hysteresis effects really do occur. In the case of chemical processes, this is important information for the production process; see [28], [29].

To present this problem in more detail, we give a short outline. A unifying approach via a *generalized Liapunov–Schmidt reduction* was proposed and justified in [24]. Discretization methods for operator equations as elliptic PDEs, including Navier–Stokes operators, are applied here to the generalized Liapunov–Schmidt reductions. Their convergence was proved in [3], [10], [32], [2], [4], [5], [11]. Finally, the link between reduction techniques and *bordered matrices* was considered, e.g., in [18]. For some recent developments in this direction see [33], [1], [31], [19].

For bifurcation points we adopt the classification with one distinguished parameter; see [17], [24], [23], [31], [19].

The current state of the art of numerical bifurcation analysis (see, e.g., [24], [31], [19]) could be briefly described as follows: Going down the hierarchy of bifurcation points, find an *organizing center*. This is a singular point with the highest *codimension* locally available. In our approach it is codim = 3; it is a higher codim in other specific cases.

Going up the hierarchy, we start with the *postprocessing* of a previously discovered organizing center: in [19, section 7.8] this consists of finding tangents to specific curves of solutions passing through the organizing center by reducing the codim by one. In [30], [34], and [31, Chap. 6], scaling techniques are employed to determine, even for corank ≥ 1, the tangents of bifurcating solutions.

In our paper, we propose a much more complex postprocessing analysis based on the bifurcation equation. The technique presented will supply a first-order approximation to the complete bifurcation scenario in a neighborhood of the organizing center of the original problem. Hence, we (approximately) transform the scenario in a neighborhood of, e.g., a pitchfork from the normal form to the original situation. Golubitsky and Schaeffer in [17, pp. 146, 147; Figs. 7.1, 7.2] demonstrate the value of this normal form analysis. Our postprocessing allows us to transform this back to the original situation. This is important, e.g., for the chemical and pharmaceutical industries in connection with the continuously stirred tank reactor, in particular, with many different reactants, and also is important in other applications; see, e.g., [17], [28], [29].

Our immediate motivation is the theory for imperfect bifurcation; see [16] and [17]. It yields *qualitative information* concerning the behavior of the bifurcation when the problem is subjected to an arbitrary sufficiently small perturbation. In this context we use the well-known *unfolded normal forms* of the bifurcation scenarios. They are models of the actual bifurcation problems under perturbations. However, there exists no *quantitative* link between the models, i.e., the unfolded normal form and the actual computed bifurcation problem.

So, the main goal of our approach is to compute (or at least to approximate) a diffeomorphism that links the unfolded normal form to the real bifurcation problem. For the general case of codim ≤ 3, this is achieved for the first time in our Theorem 3.6. Its use, in combination with Tables 2–11 listed below, is demonstrated in Example 3.1. In the case studies [21] and [8] for simple and pitchfork bifurcations, resp., we have verified that the idea really works numerically.

The outline of the paper is as follows. In our preliminaries (section 2), we construct a kind of contact equivalence between the unfolded normal form and the actual (reduced) bifurcation problem (Lemma 2.1). Hence, the roots of the particular unfolded normal form are diffeomorphic to the solutions of the actual bifurcation problem. The differential of the diffeomorphism yields first-order approximations to every kind of bifurcation point in a neighborhood of the organizing center.

In section 3, we show how to compute this differential for all organizing centers with codim ≤ 3, corank $= 1$; see Theorem 3.6, Example 3.1, and Tables 2–11. For the extremely technical proofs of the necessary lemmas and the determination of the tables, we refer to [9]. We assume that a dimensional reduction has already been performed.

We conclude with a brief review of the generalized Liapunov–Schmidt reduction and computation of data for our a posteriori analysis (section 4). This is needed for

the final transformation of the reduced-to-the-original bifurcation scenario.

2. Preliminaries. We consider a smooth parameter dependent mapping $F : \mathbb{R}^N \times \mathbb{R}^n \to \mathbb{R}^N$, e.g., obtained by discretizing a PDE. Let $F = F(u, \beta)$, $\beta = (\lambda, \alpha) \in \mathbb{R}^1 \times \mathbb{R}^k$, $n = 1 + k$. In the bifurcation context [17], u is the state variable, and λ and α are the control and unfolding parameters.

Let $(u^*, \lambda^*, \alpha^*) \in \mathbb{R}^N \times \mathbb{R}^{1+k}$ be a bifurcation point of F with corank $= 1$, i.e.,

$$F(u^*, \lambda^*, \alpha^*) = 0, \qquad \dim \operatorname{Ker} F_u(u^*, \lambda^*, \alpha^*) = 1. \tag{2.1}$$

The point $(u^*, \lambda^*, \alpha^*)$ plays the role of an organizing center.

Note that here and in the following, subscripts of a mapping denote partial differentials of the mapping w.r.t. the variable indicated by the subscript.

We consider a *Liapunov–Schmidt reduction*

$$g : \mathbb{R}^1 \times \mathbb{R}^{1+k} \to \mathbb{R}^1, \quad g = g(x, y), \quad y = (t, z),$$

of F at the point $(u^*, \lambda^*, \alpha^*)$; see, e.g., [17, p. 25] and also [24], [31], [19] for a computational version of the reduction, which we shall outline later in section 4. As a consequence of the reduction, the solution sets $F(u, \lambda, \alpha) = 0$ and $g(x, t, z) = 0$ are locally one-to-one (isomorphic) in neighborhoods of $(u^*, \lambda^*, \alpha^*)$ and $0 \in \mathbb{R}^{2+k}$. This isomorphism is described in section 4. It also links the singular roots of F and g; see, e.g., [19, Prop. 6.2.7] and [31, Thm. 6.1.1].

Let $h : \mathbb{R}^2 \to \mathbb{R}^1$ be defined as the restriction $h(x, t) \equiv g(x, t, 0)$ so that $h(x, t) = 0$ defines the *perfect bifurcation scenario*. Note that for all singularities $h = h_x = 0$ at the origin.

The classification of g is realized by the classification of the perfect bifurcation scenario $h(x, t) = 0$. This can be achieved by algebraic/geometric means, namely, by linking the map h to a suitable *normal form* $h^* : \mathbb{R}^2 \to \mathbb{R}^1$. It guarantees the existence, but does not allow the computation of the diffeomorphism. The bifurcation scenario of the normal form is usually well understood.

The link is formally defined as a *contact equivalence*: there exist a smooth $M : \mathbb{R}^2 \to \mathbb{R}^1$ and a local diffeomorphism $\Psi : \mathbb{R}^2 \to \mathbb{R}^2$, $\Psi(x, t) = (\chi(x, t), \tau(t))$, such that

$$\chi = 0,\ M > 0,\ \chi_x > 0 \text{ at } 0 \in \mathbb{R}^2 \text{ and } \tau = 0,\ \tau_t > 0 \text{ at } 0 \in \mathbb{R}^1, \tag{2.2}$$

and

$$h = M h^* \circ \Psi \tag{2.3}$$

in a neighborhood of $0 \in \mathbb{R}^2$.

We shall abbreviate (2.2), (2.3) by saying $h \sim h^*$; the relation $\sim$ is a well-defined equivalence on germs of smooth functions $\mathbb{R}^2 \to \mathbb{R}^1$; see [17, p. 104].

In Table 1, we list the normal forms h^* considered in this paper: the relevant g^* is a *universal unfolding* and k is the codimension; see [17, p. 196].

The role of g^* becomes clear from the following lemma.

LEMMA 2.1. *Let $M : \mathbb{R}^2 \to \mathbb{R}^1$ and a local diffeomorphism $\Psi : \mathbb{R}^2 \to \mathbb{R}^2$ satisfy* (2.2) *and* (2.3) *in a neighborhood of $0 \in \mathbb{R}^2$. Let $g^* : \mathbb{R}^2 \times \mathbb{R}^k \to \mathbb{R}^1$ be a universal unfolding of h^*. Then there exist smooth extensions S, Φ of M, Ψ,*

$$S : \mathbb{R}^{2+k} \to \mathbb{R}^1, \quad \Phi : \mathbb{R}^{2+k} \to \mathbb{R}^{2+k}, \quad \Phi(x, t, z) = (X(x, t, z), T(t, z), Z(z)) \tag{2.4}$$

TABLE 1

Normal forms h^* and universal unfoldings g^* for codim $= k \leq 3$, corank $= 1$. Here, $|p| = |q| = 1$. For details see Tables 2–11 below, indicating the following cases $= 1, \ldots, 10$.

Case	Normal form h^*	k	Universal unfolding g^* of h^*
1	$px^2 + qt$	0	$px^2 + qt$
2	$px^2 + qt^2$	1	$px^2 + qt^2 + z_1$
3	$px^3 + qt$	1	$px^3 + qt + z_1$
4	$px^2 + qt^3$	2	$px^2 + qt^3 + z_1 + z_2 t$
5	$px^3 + qtx$	2	$px^3 + qtx + z_1 + z_2 x^2$
6	$px^4 + qt$	2	$px^4 + qt + z_1 x + z_2 x^2$
7	$px^2 + qt^4$	3	$px^2 + qt^4 + z_1 + z_2 t + z_3 t^2$
8	$px^3 + qt^2$	3	$px^3 + qt^2 + z_1 + z_2 x + z_3 tx$
9	$px^4 + qtx$	3	$px^4 + qtx + z_1 + z_2 t + z_3 x^2$
10	$px^5 + qt$	3	$px^5 + qt + z_1 x + z_2 x^2 + z_3 x^3$

such that

$$S(\cdot,\cdot,0) = M(\cdot,\cdot), \qquad \Phi(\cdot,\cdot,0) = \Psi(\cdot,\cdot) \tag{2.5}$$

satisfy (2.2) *and*

$$g = S\ g^* \circ \Phi \tag{2.6}$$

in a neighborhood of $0 \in \mathbb{R}^{2+k}$.

Proof. Let us extend $\Psi : \mathbb{R}^2 \to \mathbb{R}^2$ as $\bar{\Psi} : \mathbb{R}^{2+k} \to \mathbb{R}^{2+k}$, by the local bijection $\bar{\Psi}(x,t,z) = (\chi(x,t), \tau(t), z)$; see (2.2). We define $f : \mathbb{R}^{2+k} \to \mathbb{R}^1$ as

$$f(x,t,z) = \big(M \circ \Psi^{-1}(x,t)\big)^{-1}\, g \circ \bar{\Psi}^{-1}(x,t,z).$$

Then, $f(x,t,0) = h \circ \Psi^{-1}(x,t) / \big(M \circ \Psi^{-1}(x,t)\big) = h^*(x,t)$; i.e., $f = f(x,t,z)$ is a k-parameter unfolding of $h^* = h^*(x,t)$; see [17, p. 120]. Since we assume $g^* = g^*(x,t,z)$ to be a universal unfolding of $h^* = h^*(x,t)$, the f factors through g^* [17, p. 120, Def. 1.2], and hence there exist smooth $\widetilde{S} : \mathbb{R}^{2+k} \to \mathbb{R}^1$ and $\widetilde{\Phi} : \mathbb{R}^{2+k} \to \mathbb{R}^{2+k}$, $\widetilde{\Phi}(x,t,z) = (\widetilde{X}(x,t,z), \widetilde{T}(t,z), \widetilde{Z}(z))$ satisfying the following conditions:

$$\widetilde{\Phi}(x,t,0) = (x,t,0)\,, \quad \widetilde{S}(x,t,0) = 1\,, \quad f = \widetilde{S} g^* \circ \widetilde{\Phi}$$

in a neighborhood of $0 \in \mathbb{R}^{2+k}$. Then it is easy to verify that

$$S = M(x,t)\widetilde{S} \circ \bar{\Psi}(x,t,z)\,, \quad \Phi = \widetilde{\Phi} \circ \bar{\Psi}$$

satisfy (2.5) and (2.6). □

In the particular applications of Lemma 2.1 we have to assume that Φ is a diffeomorphism in a neighborhood of the origin; i.e., $D\Phi(0) \in \mathcal{L}(\mathbb{R}^{(2+k)}, \mathbb{R}^{(2+k)})$ is regular. In section 3 we will explicitly determine the Ψ and the Φ for the four families of singularities of codim ≤ 3.

REMARK 2.1. *The assumption concerning the regularity of $D\Phi(0)$ is equivalent to the assumption that the gradient of the defining conditions is regular at the origin; see* [9], [19]. *The mentioned gradients are listed in* [17, Table 3.2, p. 204]; *for the defining conditions, see* [17, Table 2.3, p. 198].

Following the discussion in [17, Chap. III, section 4], *the gradient of the defining conditions is regular if and only if g is a universal unfolding of $h \equiv g(x,t,0)$.*

In less formal language, we will assume that g depicts all quantitatively significant perturbations of h.

Hence, assume $\det D\Phi(0) \neq 0$. Due to Lemma 2.1, $g(x,t,z) = 0$ if and only if $g^*(X,T,Z) = 0$, where $\Phi(x,t,z) = (X(x,t,z), T(t,z), Z(z))$; the statement holds in the obvious local sense. Recall the canonical structure of the diffeomorphism Φ, namely, that $z \mapsto Z(z)$ and $(t,z) \mapsto (T(t,z), Z(z))$ are diffeomorphisms in a neighborhood of the origin.

These facts suggest the following solution of $g = 0$: Choose an imperfection $z \in \mathbb{R}^k$ and a control parameter $t \in \mathbb{R}^1$; map them as $z \mapsto Z(z)$, $(t,z) \mapsto T(t,z)$; solve $g^*(X, T(t,z), Z(z)) = 0$ for X, which amounts to finding roots of an algebraic equation; and define $\Phi^{-1}(X, T(t,z), Z(z))$ as (x,t,z). Then (x,t,z) solves $g = 0$.

The same applies to singular roots of g and g^* since Φ^{-1} provides a one-to-one link between stratified manifolds of singular points of g and those of g^*.

EXAMPLE 2.1. *Consider the classical pitchfork (case 5 in Table 1) as an example. Note that* ($g =$) $g_x = g_t = g_{xx} = 0$ *and* $g_{xxx} g_{xt} \neq 0$ *are the defining equations and nondegeneracy conditions, resp., and $z \in \mathbb{R}^2$ the unfolding parameters. Since, e.g., g^*_{tt} is none of the conditions, the $g^*_{tt} = 0$ in Table 1 does not imply $g_{tt} = 0$ in Table 6.*

The set of all singular points of g is stratified as $\mathcal{L} = \{(x,t,z) : g = g_x = 0\}$, $\mathcal{B} = \{(x,t,z) : g = g_x = g_t = 0\}$ and $\mathcal{H} = \{(x,t,z) : g = g_x = g_{xx} = 0\}$; these are called limit points, simple bifurcation points, and hysteresis points. Obviously, $\mathcal{L}$ is the image $\Phi^{-1}(\mathcal{L}^*)$, $\mathcal{L}^* = \{(x,t,z) : g^* = {g^*}_x = 0\}$. Similarly, $\mathcal{B} = \Phi^{-1}(\mathcal{B}^*)$ and $\mathcal{H} = \Phi^{-1}(\mathcal{H}^*)$. The sets $\mathcal{L}^*$, $\mathcal{B}^*$, and $\mathcal{H}^*$ can be constructed explicitly.

The diffeomorphism Φ is not available in general. The objective of this paper is to compute $D\Phi(0)$. With $\Phi(0) = 0$ this yields the natural first-order approximation for Φ. We will come back to this problem in section 3.

Regarding the solution of $g = 0$, the following (partially) linearized approximation procedure replaces the above nonlinear approach: Choose $z \in \mathbb{R}^k$ and $t \in \mathbb{R}^1$; map them as $z \mapsto Z_z\, z$ and $(t,z) \mapsto T_t\, t + T_z\, z$; solve the algebraic equation $g^*(X, T_t\, t + T_z\, z, Z_z\, z) = 0$ for X; and invert $D\Phi(0)$ and define the action of $(D\Phi(0))^{-1}$ at $(X, T_t\, t + T_z\, z, Z_z\, z) \in \mathbb{R}^{2+k}$ as (x,t,z). Then (x,t,z) are first-order approximations to the roots of $g = 0$. Similarly, all *singular* solutions of $g = 0$ in a neighborhood of the origin (e.g., limit points $\mathcal{L}$) can be approximated by the singular solutions of $g^* = 0$ (e.g., limit points $\mathcal{L}^*$).

The analysis of singular roots of g has to be lifted from a small dimensional $\mathbb{R}^{2+k}$ to the actual state space $\mathbb{R}^{N+1+k}$, where the roots of F live. This will be done in section 4.

In summary, by processing $D\Phi(0)$, we will obtain a sort of first-order predictor for all singular points in the neighborhood of $(u^*, \lambda^*, \alpha^*)$. The implementation of this idea was tested numerically in two case studies, where organizing centers 2 and 5 of Table 1 were considered; see [21] and [8].

3. Computing the differential $D\Phi(0)$. The crucial step towards computing $D\Phi(0)$ is an explicit solution of the recognition problem [17]. Note that the solution of the recognition problem in [17] is not constructive; see Chapter II, section 11. We need a solution based on the implicit function theorem. For motivation and discussion see both case studies [21] and [8].

We can give only a rough idea for the procedure: To obtain an equation for $D\,\Phi\,(0)$, we compute the partials in (2.6) w.r.t. x, t in a neighborhood of $0 \in \mathbb{R}^{k+2}$ to obtain the vector of defining conditions, e.g., $(g, g_x, g_t, g_{xx}) = 0$, for the pitchfork. With $g_{xxx} g_{tx} \neq 0$ this characterizes the origin $0 \in \mathbb{R}^{k+2}$ as an appropriate bifurcation

point of g and g^*. Next, we compute the gradients w.r.t. x, t, z of these vectors, e.g., $(g, g_x, g_t, g_{xx})^T$ for g [24], [23] and g^* [17]. They are collected to define $\mathbf{B}$ and $\mathbf{B}^*$. By [19], g and g^* represent a universal unfolding of h and h^* if and only if the corresponding matrix $\mathbf{B}$ and $\mathbf{B}^*$ is regular, respectively. Then we obtain for $D\,\Phi\,(0)$ the following equation:

$$\mathbf{B} \;=\; \mathbf{A}\,\mathbf{B}^*\,D\,\Phi\,(0); \tag{3.1}$$

in $\mathbf{A}$ we collect all other terms, e.g., products and sums of $S,\ S_x,\ S_t,\ X,\ X_x,\ X_t$, a.s.o., obtained in the above differentiation [9]. Note that the block structure of $D\Phi(0)$ reflects the canonical structure of Φ:

$$D\Phi(0) = \begin{pmatrix} X_x & X_t & X_z \\ 0 & T_t & T_z \\ 0 & 0 & Z_z \end{pmatrix} \in \mathcal{L}(\mathbb{R}^{(2+k)}, \mathbb{R}^{(2+k)})\,, \qquad Z_z \in \mathcal{L}(\mathbb{R}^k, \mathbb{R}^k)\,; \tag{3.2}$$

here and in (3.1) the required partial derivatives of $X(x,t,z)$, $T(t,z)$, and $Z(z)$ are evaluated at the origin. Now, the unknown terms in $\mathbf{A}, D\,\Phi\,(0)$ have to be determined by (3.1). For a naive approach this system usually has more unknowns than equations. So we need additional information.

Following [19], normal forms for singularities of codim$\leq$ 3 are organized in four families: pitchfork family (cases 5, 9 of Table 1), hysteresis family (cases 1, 3, 6, 10), asymmetric cusp family (cases 2, 4, 7), and a singleton winged cusp (case 8). For each family the structure of the $\chi(x,t), \tau(t)$ in (2.2) is described in detail in the following lemmas, finally allowing us to solve (3.1). We need the following conditions for the lemmas.

(3.3) Let $M = M(x,t),\ \chi = \chi(x,t),\ H = H(x),\ \omega = \omega(x), \psi = \psi(t),\ \tau = \tau(t),$ $a = a(t),\ b = b(t),\ c = c(t)$ be smooth real-valued functions in a neighborhood of the origin and $M(0,0) > 0$.

LEMMA 3.1. Pitchfork family. *Let* $h^* = px^n + qxt$, $n \geq 3$, $|p| = |q| = 1$. *Then* $h \sim h^*$ *if and only if* (*see* (3.3))

$$\begin{aligned} h(x,t) &= M \cdot \left(p\,\chi^k \,+\, q\,\chi\,\tau\right), \ \textit{where} \\ \tau(t) &= c\,t\,, \quad c > 0, \\ \chi(x,t) &= (x - \psi(t))\,H(x - \psi(t)) \ \textit{with}\ \psi(0) = 0,\ H(0) = 1. \end{aligned} \tag{3.4}$$

LEMMA 3.2. Hysteresis family. *Let* $h^* = px^n + qt$, $n \geq 2$, $|p| = |q| = 1$. *Then* $h \sim h^*$ *if and only if* (*see* (3.3))

$$\begin{aligned} h(x,t) &= M \cdot (p\,\chi^n \,+\, q\,\tau)\,, \ \textit{where} \\ \tau(t) &= c^n\,t\,, \quad c = \frac{1}{\omega(0)} > 0, \\ \chi(x,t) &= \chi(x) \,=\, cx\,\omega(x)\,. \end{aligned} \tag{3.5}$$

LEMMA 3.3. Asymmetric cusp family. *Let* $h^* = px^2 + qt^n$, $n \geq 2$, $|p| = |q| = 1$. *Then* $h \sim h^*$ *if and only if* (*see* (3.3))

$$h(x,t) = M \cdot \left(p\,\chi^2 \,+\, q\,\tau^n\right), \ \textit{where} \tag{3.6}$$

$$\tau(t) = (pqb(t))^{1/n}\,, \tag{3.7}$$

$$\chi(x,t) = x + a(t)\,, \tag{3.8}$$

with $a(0) = 0$ *and* $b(0) = b'(0) = 0$, $sgn(b''(0)) = pq$.

LEMMA 3.4. Winged cusp. *Let* $h^* = px^3 + qt^2$, $|p| = |q| = 1$. *Then* $h \sim h^*$ *if and only if* (*see* (3.3))

$$h(x,t) = M \cdot \left(p\,\chi^3 + q\,\tau^2\right), \text{ where} \tag{3.9}$$

$$\tau(t) = (pqc(t))^{1/2}, \tag{3.10}$$

$$\chi(x,t) = \left((x+a(t))((x+a(t))^2 + b(t))\right)^{1/3}, \tag{3.11}$$

with $a(0) = 0$, $b(0) = b'(0) = 0$ *and* $c(0) = c'(0) = 0$, $sgn(c''(0)) = pq$.

Proof. Lemma 3.1 follows from Lemma 2.7 in [16]. Lemmas 3.2–3.4 can be proved similarly; see [9]. □

For $h \sim h^*$, these lemmas yield sufficient information to construct a pair M, $\Psi = (\chi, \tau)$ such that (2.2), (2.3) hold. Note that the construction is certainly not unique: M/c, $c\Psi$ would be another pair, provided that $c \neq 0$. However, imposing the scaling condition $\chi_x(0) = 1$ makes the choice unique. Then Lemma 2.1 can be used to determine the $\Phi(x,t,z) = (X(x,t,z), T(t,z), Z(z))$ for the four families of singularities of codim ≤ 3.

DEFINITION 3.5. *Let* $h \sim h^*$; *i.e.,* (2.2), (2.3), *and* $\chi_x(0) = 1$ *hold. We say that* $M : \mathbb{R}^2 \to \mathbb{R}^1$, $\Psi(x,t) \equiv (\chi(x,t), \tau(t)) : \mathbb{R}^2 \to \mathbb{R}^2$ *are the scaled solutions of the recognition problem, provided that they are defined as suggested in Lemmas* 3.1–3.4, *respectively.*

Recall Lemma 2.1 and its assumptions. The scaled solution of the recognition problem is a legitimate candidate for a choice of M and Ψ.

THEOREM 3.6. *Consider a Liapunov–Schmidt reduction* g *of* F *at a singular point* $(u^*, \lambda^*, \alpha^*)$. *Let* $h \equiv g(x,t,0)$ *be equivalent to a normal form,* $h \sim h^*$, *from Table* 1. *Let* g *be a universal unfolding of* h. *Construct the diffeomorphism* Φ *in Lemma* 2.1, *employing the scaled solution of the recognition problem.*

Then for every family of singularities the $D\Phi(0)$ *is uniquely defined. In order to compute* $D\Phi(0)$, *the evaluation of a finite number of partial derivatives of* g *at the origin is needed.*

Proof. This is constructive. Tables 2–11 summarize the explicit relationship between data (selected partial derivatives of g at the origin) and entries of $D\Phi(0)$. Details are given in [9]. □

We demonstrate how to use Tables 2–11 in order to compute $D\Phi(0)$.

EXAMPLE 3.1. *We consider the pitchfork case* 5 *in Table* 1 *with* $g = g_x = g_t = g_{xx} = 0$, $g_{xxx}g_{xt} \neq 0$. *Table* 6 *is the table which is relevant to this case. The data represent* 16 *partial derivatives* g_{xxx}, g_{xt}, g_{tt}, g_{xtt}, g_{xxt}, g_{xxxx}, g_{xxxt}, $\partial^5 g/\partial x^5 \in \mathbb{R}^1$, $(g_z)^\top$, $(g_{xz})^\top$, $(g_{tz})^\top$, *and* $(g_{xxz})^\top \in \mathbb{R}^2$. *The claim is that the data define the matrix* $D\Phi(0) \in \mathcal{L}(\mathbb{R}^4, \mathbb{R}^4)$; *see* (3.2). *The entry* $X_x \equiv \chi_x(0)$ *is scaled to* 1. *Table* 6 *should be interpreted as a set of* 16 *nonlinear equations for*

- X_t, X_z, T_t, T_z, *and* Z_z *which are the entries of the scaled* $D\Phi(0)$. $X_t \in \mathbb{R}^1$, $(X_z)^\top \in \mathbb{R}^2$, $T_t \in \mathbb{R}^1$, $(T_z)^\top \in \mathbb{R}^2$, *and* $Z_z = ((Z_1)_z, (Z_2)_z) \in \mathcal{L}(\mathbb{R}^2, \mathbb{R}^2)$;
- S, S_x, S_t, S_{xx}, X_{xx}, $X_{xxx} \in \mathbb{R}^1$ *resulting from the chain rule and necessary to determine the above first partials;*

hence, 16 *equations for* 16 *unknowns altogether. This (and the other) system is solvable step by step in only linear subsystems of one or two equations with nonvanishing determinants. This is indicated in the last column of Table* 6 *starting with* S, T_t. *The pairs* S_x, X_{xx} *and* S_{xx}, X_{xxx} *are coupled linearly. To indicate that, we have introduced the horizontal lines in Tables* 6 *and* 10.

4. Remarks on implementation. Let us briefly review the Liapunov–Schmidt reduction via *bordered systems* following [19, section 7.4].

Consider $(u^*, \lambda^*, \alpha^*)$, satisfying (2.1). Let L and M be a pair of fixed vectors $M \in \mathbb{R}^N$, $L^\top \in \mathbb{R}^N$. Let the matrix

$$\mathcal{J}(u^*, \lambda^*, \alpha^*) \equiv \begin{pmatrix} F_u(u^*, \lambda^*, \alpha^*) & M \\ L & 0 \end{pmatrix} \in \mathcal{L}(\mathbb{R}^{(N+1)}, \mathbb{R}^{(N+1)})$$

be regular (which is the case for a generic choice of the *bordering* vectors M and L and necessary for the approach in [21], [7]. For appropriate choices of M, L in $\mathcal{J}$ with good condition numbers see [35], [34].) The nonlinear system

$$F\,(u^* + v, \lambda^* + t, \alpha^* + z) - M\,g\, = 0\,, \qquad L\,v\, =\, x \tag{4.1}$$

implicitly defines $g = g(x,t,z)$ and $v = v(x,t,z)$ as germs of smooth mappings $g : \mathbb{R}^1 \times \mathbb{R}^{1+k} \to \mathbb{R}^1$ and $v : \mathbb{R}^1 \times \mathbb{R}^{1+k} \to \mathbb{R}^N$ centered at the origin, i.e., satisfying $g(0) = 0$ and $v(0) = 0$. This particular definition of g is called Liapunov–Schmidt reduction.

Note that $F(u, \lambda, \alpha) = 0$ if and only if $g(x,t,z) = 0$, where $u = u^* + v(x,t,z)$, $\lambda = \lambda^* + t$, and $\alpha = \alpha^* + z$. In other words, there exists a local isomorphism between the roots of F and g. Hence, as a consequence of Lemma 2.1, the roots of F and g^* are in one-to-one correspondence. The same argument can be used regarding *singular* roots of F, g, and g^*.

Let $g(x,t,z) = 0$. Consider $(u, \lambda, \alpha) \in \mathbb{R}^{N+1+k}$,

$$u = u^* + v_x\, x + v_t\, t + v_z\, z\,, \quad \lambda = \lambda^* + t\,, \quad \alpha = \alpha^* + z, \tag{4.2}$$

where the partial differentials of v are evaluated at $(0,0,0) \in \mathbb{R}^{2+k}$. The point (u, λ, α) approximates a root of F. This approximation is to the first order.

At the end of section 2, we described a first-order approximation procedure for (possibly singular) roots of g. Hence, whatever root of g is *approximated*, the transformation (4.2) is adequate to lift its coordinates from $\mathbb{R}^{1+1+k}$ to the original state space $\mathbb{R}^{N+1+k}$.

As far as the proposed analysis is concerned, the main cost represents a computation of the partial derivatives of g which are required in Tables 2–11. All these derivatives are to be evaluated at the origin.

Note that the majority of these derivatives is contained in the gradient of the defining equations; see Remark 2.1. This gradient is obtained as a byproduct of the computation of $(u^*, \lambda^*, \alpha^*)$ by the Newton (or a Newton-like) method; see [19, section 7.4] and also the case study [8].

There are algorithms for a systematic computation of these partials; see [19, section 7.4]. They are computed by solving canonical linear systems. These systems have the same matrix, namely, $\mathcal{J}(u^*, \lambda^*, \alpha^*)$. Moreover, the partials of g are naturally computed with the relevant partial derivatives of v. So, by computing g_x we compute simultaneously v_x (from (4.2)), etc.

Having this fact in mind, one may ask why we have not used the higher derivatives of v (which we had computed anyway) for a higher order approximation in (4.2). Consider, say, the quadratic approximation. Observe that in Tables 2–11 the g_{zz} never shows up in the data, which means that we do not need g_{zz} for the first-order analysis of g. Therefore, computing v_{zz} would mean making an extra and "unsystematic" effort.

g_{xz}	$=$	$qST_z + S_x(Z_1)_z$	T_z
g_{xtt}	$=$	$2qT_t(SX_tX_{xx} + S_xX_t + S_t) + 6pSX_t^2$	S_t
g_{tz}	$=$	$qST_tX_z + qSX_tT_z + S_t(Z_1)_z$	X_z
g_{xxxt}	$=$	$qT_t(SX_{xxx} + 3S_xX_{xx} + 3S_{xx}) + 24pSX_t$	$S_{xx}\ X_{xxx}$
$\frac{\partial^6}{\partial x^6} g$	$=$	$5!p(3S_{xx} + 12S_xX_{xx} + 9SX_{xx}^2 + 4SX_{xxx})$	
g_{xxz}	$=$	$qST_zX_{xx} + 2qS_xT_z + (Z_1)_zS_{xx} + 2S(Z_2)_z$	$(Z_2)_z$
$\frac{\partial^5}{\partial x^4 \partial t} g$	$=$	$qT_t(4S_{xxx} + 6S_{xx}X_{xx} + 4S_xX_{xxx} + SX_{xxxx})$ $+4!pS_t + 2 \cdot 4!pX_t(2S_x + 5SX_{xx})$	$S_{xxx},\ \frac{\partial^4}{\partial x^4} X$
$\frac{\partial^7}{\partial x^7} g$	$=$	$7 \cdot 5!p(S_{xxx} + 6S_{xx}X_{xx} + 9S_xX_{xx}^2 + 4S_xX_{xxx}$ $+3SX_{xx}^3 + 6SX_{xx}X_{xxx} + SX_{xxxx})$	
g_{xxxz}	$=$	$qT_z(3S_{xx} + 3S_xX_{xx} + SX_{xxx}) + 4!pSX_z$ $+S_{xxx}(Z_1)_z + 6(Z_2)_z(S_x + SX_{xx}) + 6S(Z_3)_z$	$(Z_3)_z$

The required derivatives of g at the origin could be approximated by classical finite differences. Nevertheless, except for the origin where g is pinned to zero, the function $(x,t,z) \mapsto g(x,t,z) \in \mathbb{R}^1$ is not known, and its values have to be computed, as shown below.

Given (x,t,z), set $v^{(0)} = v_x\, x + v_t\, t + v_z\, z$ to be an initial approximation of $v(x,t,z)$; for v_x, v_t, and v_z, see (4.2). Consider the following iterations: Find $\delta v \in \mathbb{R}^N$ and $g^{(j+1)} \in \mathbb{R}^1$ as the solution of the linear system

$$\mathcal{J}\big(u^* + v^{(j)}, \lambda^* + t, \alpha^* + z\big) \begin{pmatrix} \delta v \\ -g^{(j+1)} \end{pmatrix} = \begin{pmatrix} -F(u^* + v^{(j)}, \lambda^* + t, \alpha^* + z) \\ 0 \end{pmatrix}$$

and update $v^{(j+1)} := v^{(j)} + \delta v$.

If (x,t,z) is sufficiently close to $0 \in \mathbb{R}^{2+k}$, then the iteration process is locally quadratically convergent. In particular, $v^{(j)} \to v(x,t,z)$ and $g^{(j)} \to g(x,t,z)$ as $j \to \infty$. For details see [22], [6], [7].

VARIANCE REDUCTION METHODS FOR SIMULATION OF DENSITIES ON WIENER SPACE*

ARTURO KOHATSU-HIGA† AND ROGER PETTERSSON‡

Abstract. We develop a general error analysis framework for the Monte Carlo simulation of densities for functionals in Wiener space. We also study variance reduction methods with the help of Malliavin derivatives. For this, we give some general heuristic principles which are applied to diffusion processes. A comparison with kernel density estimates is made.

Key words. stochastic differential equations, weak approximation, variance reduction, kernel density estimation

1. Introduction.

The Monte Carlo simulation method is used to estimate quantities of the type $E[f(X)]$, where f is a somewhat regular function and X is a random variable that can be simulated.

In this article, we are interested in the case when f is a generalized function such as the Dirac delta function δ_x or a discontinuous function such as an indicator function. In the first case the expectation will become the density of the random variable X and in the second the distribution function. If f is not regular, then the Monte Carlo method has to be slightly modified using $\frac{1}{n}\sum_{i=1}^{n} f_n(X^i)$, where f_n is a smooth function that approximates f and X^i are independent copies of X. This approximation converges to the desired quantity but a big error is produced due to the nonsmoothness of the general function f. In this framework it becomes important to devise methods for reducing the variance of the Monte Carlo estimation. This problem has been extensively studied by statisticians (although in a slightly different situation) in the theory of kernel density estimation; see, e.g., [12].

Here we propose to analyze the above problem using Malliavin calculus for Wiener space. More explicitly, using the integration by parts formula of Malliavin calculus one has that $E[f(X)] = E[F(X)H(X,1)]$, where $H(X,1)$ is an appropriate random variable and F is an antiderivative of f. In this way we gain smoothness in the function to be evaluated but the simulation of $H(X,1)$ is now required. The above formula can be explained as the integration by parts of $\int_{\mathbb{R}} f(x)p(x)dx = -\int_{\mathbb{R}} F(x)p'(x)dx$, where p is the density of X, i.e., $H(X,1) = -p'(X)/p(X)$. This looks simple as long as one knows the density of X. Here we deal with cases where p is not known explicitly. Still, we show that there are ways to simulate $H(X,1)$ and that some variance reduction is in fact achieved.

The typical example that we treat here is when X is the final value of a diffusion.

That is, $X = X_1$ where

$$X_t = x_0 + \int_0^t b(X_s)\mathrm{d}s + \int_0^t \sigma(X_s)\mathrm{d}W_s, \qquad t \in [0,1]. \tag{1.1}$$

Here $x_0 \in \mathbb{R}$ and b and σ are smooth functions. If the Hörmander hypothesis is satisfied, then the density of X_1 exists and is smooth. In [1] and [2] the approximation error for the density is studied when the random variable X_1 is replaced by the Euler–Maruyama approximation $\bar{X}$.

Obviously, the density of X is explicitly known only in particular cases and therefore the simulation of $H(X,1)$ is not a trivial matter. This is exactly the merit of Malliavin calculus. One can use this technique to develop an expression for $H(X,1)$ that can be simulated. In order to simulate $E[f(X)]$, our Monte Carlo method with variance reduction is to calculate $\frac{1}{n}\sum_{i=1}^n F(\bar{X}^i)H(\bar{X}^i,1)$, where $\bar{X}^i$ are independent Euler approximations of X. We concentrate on the particular case when f is the delta function which therefore generates the density of the diffusion process, but this methodology can be applied also when approximating the price of an option or its Greeks in mathematical finance. In fact, this idea appeared first in [5] applied to the calculation of Greeks called delta, vega, and gamma. Also in [6] a more careful study of the simulation of the density is carried out. An optimal variance reduction method is devised but it requires the knowledge of the density itself and is therefore not amenable to direct application.

In this article, we introduce a control variate method and a tuning method, similar to the ones used in kernel density estimation, that helps to reduce the variance substantially. The main difference with respect to kernel density estimation methods is that our tuning does not require that the window size goes to 0 as the sample size increases. Furthermore, the same simulated paths give good estimates for densities at any point. That is, one can compute the density over the whole real line with the same number of simulated paths.

We focus in the one-dimensional case just to avoid cumbersome notation. The results are also valid in multidimensions with appropriate modifications. The importance of these methods is obvious when the dimension is relatively large. See also [9] on variance reduction of smooth functions of diffusions, where methods of importance sampling and control variates are developed without the use of the integration by parts formula.

In section 2 after some preliminaries on Malliavin calculus we explain the general method and give a control variate method for variance reduction. In section 3 we estimate the error of the approximating expectations. The error is estimated when there is an Itô–Taylor expansion for the functional in the spirit of [8]. In section 4 we consider, as an application of section 3, the case of diffusion processes with a Hörmander condition. We also define the different approximations and give bounds on the approximation error. In section 5 we study the mean square error of the kernel density method. In section 6 a similar study for the integration by parts method is made and a comparison is made. In section 7 numerical implementations are described.

Throughout, let c denote a generic constant which may differ from line to line.

2. Malliavin derivative and density by duality. Let $W = \{W_t\}_{t\in[0,1]}$ be a standard one-dimensional Brownian motion defined on a complete probability space $(\Omega, \mathcal{F}, P)$. Assume $\mathcal{F} = \{\mathcal{F}_t\}_{t\in[0,1]}$ is generated by W. Let $\mathcal{S}$ be the space of random variables of the form $F = f(W_{t_1}, \dots, W_{t_n})$, where f is smooth. For $F \in \mathcal{S}$, $D_tF =$

$\sum_{i=1}^n \frac{\partial}{\partial x_i} f(W_{t_1}, \dots, W_{t_n}) 1_{[0,t_i]}(t)$. For $k \in \mathbb{Z}_+$, $p \geq 1$, let $\mathbb{D}^{k,p}$ be the completion of $\mathcal{S}$ with respect to the norm

$$\|F\|_{k,p} = \left(E[|F|^p] + E\left[\left(\sum_{j=1}^k \int_0^1 \dots \int_0^1 |D^j_{s_1,\dots,s_j} F|^2 ds_1 \dots ds_j \right)^{p/2} \right] \right)^{1/p},$$

where $D^j_{t_1,\dots,t_j} F = D_{t_1} \dots D_{t_j} F$. We let $\|F\|_{0,p} = (E[F^p])^{1/p} = \|F\|_p$ and $\mathbb{D}^\infty = \cap_{k,p} \mathbb{D}^{k,p}$. For processes $u = \{u_t\}_{t\in[0,1]}$ on $(\Omega, \mathcal{F}, P)$, $\mathbb{D}^{k,p}_{L^2([0,1])}$ is defined as $\mathbb{D}^{k,p}$ but with norm $\|u\|_{k,p,L^2([0,1])} = (E[\|u\|^p_{L^2([0,1])}] + E[(\sum_{j=1}^k \int_0^1 \dots \int_0^1 \|D^j_{s_1,\dots,s_j} u\|^2_{L^2([0,1])} ds_1 \dots ds_j)^{p/2}])^{1/p}$. For two-parameter processes $u = \{u_{s,t}\}_{s,t\in[0,1]}$, $\mathbb{D}^{k,p}_{L^2([0,1]^2)}$ is defined analogously. $\mathbb{D}^\infty_{L^2([0,1])}$ and $\mathbb{D}^\infty_{L^2([0,1]^2)}$ are defined similarly to $\mathbb{D}^\infty$.

We denote by $\delta(u)$ the Skorokhod integral, the dual operator of D. If u_t is $\mathcal{F}_t$ adapted, then $\delta(u) = \int_0^1 u_t dW_t$, the Itô integral of u; see, e.g., [11]. Here we write $\delta(u) = \int_0^1 u_t dW_t$, even if u_t is not $\mathcal{F}_t$ adapted. This integral satisfies that

$$\int_0^1 F u_t dW_t = F \int_0^1 u_t dW_t - \int_0^1 (D_t F) u_t dt \tag{2.1}$$

for $F \in \mathbb{D}^{1,2}$ and $E(F^2 \int_0^1 u_t^2 dt) < \infty$ (see, e.g., Nualart [11, (1.49), p. 40]) and

$$E\left[\int_0^1 (D_t F) u_t dt \right] = E[F\delta(u)]. \tag{2.2}$$

For F, G in $\mathbb{D}^{1,2}$ and h a stochastic process such that $E\int_0^1 h_t^2 dt < \infty$, we use the notation

$$H^h(F, G) = \int_0^1 \tilde{h}_t G dW_t, \tag{2.3}$$

where $\tilde{h}_t = h_t / \int_0^1 h_s D_s F ds$, whenever the integrand in (2.3) is Skorokhod integrable. The usefulness of $H^h(F, G)$ can be seen in the integration by parts formula of Malliavin calculus which can be expressed as

$$E[f'(F)G] = E[f(F)H^h(F, G)]. \tag{2.4}$$

We let $H(F, G) \equiv H^{DF}(F, G)$ (i.e., $h_t = D_t F$ in (2.3)). Arguments similar to those in [11, pp. 78, 97] give the following theorem.

THEOREM 2.1. *Assume $F \in \mathbb{D}^{1,2}$ and $E\int_0^1 h_t^2 dt < \infty$. Let φ be a function on $\mathbb{R}$ such that φ, $\frac{d}{dx}\varphi \in L^2(\mathbb{R})$, $\varphi(0) = 1$, and $c \in L^2(\mathbb{R})$. Let r be a positive number and assume that $\tilde{h}\varphi((F - x)/r)$ is Skorokhod integrable. Then the density of F, f exists, is continuous, and f has the representation $f(x) = E[\xi_{c,r}(x)]$, where $\xi_{c,r}(x) = (1_{\{F>x\}} - c(x))H^h(F, \varphi(\frac{F-x}{r}))$. Furthermore,*

$$H^h\left(F, \varphi\left(\frac{F-x}{r}\right)\right) = \varphi\left(\frac{F-x}{r}\right) H^h(F, 1) - \frac{1}{r}\varphi'\left(\frac{F-x}{r}\right). \tag{2.5}$$

Proof of Theorem 2.1. We first observe that taking $F = 1$ and $u_t = \varphi((F-x)/r)\tilde{h}_t$ in (2.2) yields

$$E\left[H^h\left(F, \varphi\left(\frac{F-x}{r}\right)\right)\right] = 0. \tag{2.6}$$

We now show the existence of the density of F. For this we assume that F and u are sufficiently smooth as well as φ. The general argument follows by a density argument. Taking $a < b$ and using (2.1), (2.2), and (2.6) we have that

$$\begin{aligned}
&\int_a^b E\left[(1_{\{F>x\}} - c(x))H^h\left(F, \varphi\left(\frac{F-x}{r}\right)\right)\right] dx \\
&= \int_a^b E\left[1_{\{F>x\}} \int_0^1 \tilde{h}_t \varphi\left(\frac{F-x}{r}\right) dW_t\right] dx \\
&= \int_a^b E\left[1_{\{F>x\}} \left(\varphi\left(\frac{F-x}{r}\right)\int_0^1 \tilde{h}_t dW_t - \int_0^1 \tilde{h}_t D_t \varphi\left(\frac{F-x}{r}\right) dt\right)\right] dx \\
&= E\left[\int_{-\infty}^F 1_{[a,b]}(x)\varphi\left(\frac{F-x}{r}\right) dx \int_0^1 \tilde{h}_t dW_t\right] \\
&\quad - \int_a^b E\left[\int_0^1 1_{\{F>x\}} \tilde{h}_t D_t \varphi\left(\frac{F-x}{r}\right) dt\right] dx \\
&= E\left[\int_0^1 D_t\left(\int_{-\infty}^F 1_{[a,b]}(x)\varphi\left(\frac{F-x}{r}\right)\right) dx \tilde{h}_t dt\right] \\
&\quad - \int_a^b E\left[\int_0^1 1_{\{F>x\}} \tilde{h}_t D_t \varphi\left(\frac{F-x}{r}\right) dt\right] dx \\
&= E\left[\int_0^1 1_{[a,b]}(F)\varphi(0)\tilde{h}_t D_t F dt\right] = E[1_{[a,b]}(F)],
\end{aligned}$$

which shows the absolute continuity of the law of F with respect to the Lebesgue measure. The right continuity of the density of F, f follows from the fact that $\frac{d}{dx}\varphi \in L^2([0,1])$ and the right continuity of the indicator function $1_{\{\cdot>x\}}$. Now f can also be written with $1_{\{F>x\}}$ replaced by $1_{\{F\geq x\}}$ from which the left continuity follows. Finally, taking $F = \varphi((F-x)/r)$ and $u_t = \tilde{h}_t$ in (2.1) the claim (2.5) follows. That is,

$$\begin{aligned}
&H^h\left(F, \varphi\left(\frac{F-x}{r}\right)\right) \\
&= \int_0^1 \varphi\left(\frac{F-x}{r}\right)\tilde{h}_t dW_t \\
&= \varphi\left(\frac{F-x}{r}\right)\int_0^t \tilde{h}_t dW_t - \int_0^1 D_t\left(\varphi\left(\frac{F-x}{r}\right)\right)\tilde{h}_t dt. \qquad \square
\end{aligned}$$

Taking $F = \varphi((F-x)/r)/\int_0^1 h_s D_s F ds$ and $u_t = h_t$ in (2.1) and assuming enough smoothness one obtains that

$$H^h(F,1) = \frac{\int_0^1 h_t dW_t}{\int_0^1 h_s D_s F ds} + \frac{\int_0^1\int_0^1 D_t(h_s D_s F)h_t ds dt}{(\int_0^1 h_s D_s F ds)^2}. \tag{2.7}$$

Note that the variance of $\xi_{c,r}(x)$ is finite under reasonable assumptions, while $\mathrm{var}(\delta_x(f)) = \infty$. The issue of the variance of $\xi_{c,r}(x)$ will be further discussed in section 5. The representation of the density f introduced in Theorem 2.1 has the additional benefit that it allows us to develop a control variate method for the reduction of variance; see also [5], [6], and [7] for related results.

REMARK 2.2 (control variate method). *Assume the same hypotheses as in Theorem* 2.1. *If* $f(x) > 0$, *then* $E[H^h(F, \varphi(\frac{F-x}{r}))^2] > 0$ *and, for fixed* φ *and* r, *the variance of* $\xi_{c,r}(x) = (1_{\{F \geq x\}} - c(x))H^h(F, \varphi(\frac{F-x}{r}))$ *is minimized by*

(2.8)
$$c(x) = c^h_{loc}(x) = E\left[1_{\{F\geq x\}} H^h\left(F, \varphi\left(\frac{F-x}{r}\right)\right)^2\right] \Big/ E\left[H^h\left(F, \varphi\left(\frac{F-x}{r}\right)\right)^2\right]. \qquad \square$$

The case of $f(x) = 0$ can also be dealt with using some extra changes. To simplify our discussion we will focus on the case when $f(x) > 0$.

3. Convergence of approximative functionals. In this section we present a general theory of approximation for random variables F on Wiener space that gives as a result rates of convergence to the density of F. This theory is based on Itô–Taylor expansions in the spirit of [8]. Later we consider as an application the case when F is the terminal value of the solution of a stochastic differential equation. Other examples that satisfy the following conditions will be treated in forthcoming publications. To simplify we use the notation $dW^1_s = dW_s$ and $dW^0_s = ds$.

CONDITION 3.1. (i) $\{F_n\}_{n\geq 0}$ *and* F *are in* $\mathbb{D}^\infty$ *and satisfy*

$$F - F_n = \sum_{i,j=0}^{1} \iint_{A_n^{i,j}} u_n^{i,j}(s_1, s_2) dW^i_{s_1} dW^j_{s_2},$$

where $A_n^{i,j}$ *are subsets of* $[0,1]^2$ *with mean area* $\sum_{i,j=0}^1 |A_n^{i,j}|/4 \leq a_n$ *for a sequence* $a_n \to 0$ *as* $n \to \infty$, *and* $\sup_n \sup_{s_1,s_2} \sum_{i,j=0}^1 \|u_n^{i,j}(s_1,s_2)\|_{k,p} < \infty$ *for all* $k \in \mathbb{Z}_+$, $p > 1$. *The processes* $u_n^{i,j}$ *are measurable, not necessarily adapted but with enough properties so that the above integrals are well defined.*

(ii) *For* $\alpha \in [0,1]$ *there exist processes* $h_n \equiv h_{n,\alpha}$ *in* $\mathbb{D}^\infty(L^2[0,1])$, *uniformly bounded in* n, *and a process* $h \in \mathbb{D}^\infty(L^2([0,1])$, *such that* $E[|\int_0^1 h(s)D_sFds|^{-p}] < \infty$ *for all* $p > 1$ *and* $E\|h_n - h\|^p_{L^2[0,1]} \leq e_n(p)$ *for a sequence* $e_n(p) \equiv e_{n,\alpha}(p) \to 0$, $n \to \infty$.

(iii) *For* $\alpha \in [0,1]$ *there exist positive random variables* d_n *and positive bounded constants* b_n *and* c *such that* $|b_n + \int_0^1 h(s)D_sFds| > c|\int_0^1 h(s)D_sFds|$ *and*

$$\left|b_n + \int_0^1 h_n(s)(\alpha D_sF_n + (1-\alpha)D_sF)ds\right| \geq d_n,$$

where for any $p > 1$ *there exists* $k(p) \equiv k(p,\alpha) \in \mathbb{Z}_+$ *such that* $\sup_n \sup_{\alpha\in[0,1]} E[d_n^{-p}] \times (a_n^{k(p)/2} + e_n(4k(p))^{1/2} + b_n^{2k(p)}) < \infty$.

Without loss of generality we assume that all the sequences a_n, b_n, e_n, and d_n are smaller than 1. Next we give the main approximation result in this section.

THEOREM 3.2. *Assume Condition* 3.1. *Then for any distribution* T,

$$|E[T(F) - T(F_n + Y_n)]| \leq c(a_n + b_n), \tag{3.1}$$

where Y_n *is an independent normal random variable with mean zero and variance* b_n. *Furthermore, if*

$$\sup_{n\geq 1}\sup_{0<\alpha<1} E\left[\left|\int_0^1 h_n(s)(\alpha D_s F_n + (1-\alpha)D_s F)ds\right|^{-p}\right] < \infty \tag{3.2}$$

for all $p > 1$, *then*

$$|E[T(F) - T(F_n)]| \leq ca_n. \tag{3.3}$$

We say that the approximation problem is *uniformly elliptic* when (3.2) is satisfied. If we instead only assume Condition 3.1, we will say that the approximation problem is of *Hörmander* type. See section 4 for more explanation about this terminology.

The above theorem will be usually applied to $T(y) = 1_{\{y\geq x\}}$ or $T(y) = \delta_x^{(k)}(y)$, the kth derivative of the Dirac delta measure. We will do the proof in the second case for $x = 0$, $k = 0$. The general case is proved similarly. The application of Theorem 3.2 to diffusion processes and its Euler approximation will be given in section 4. At the end of this section we also give a generalization of Theorem 3.2, where $F - F_n$ may be expressed as a sum of higher order stochastic multiple integrals.

We start with some technical results.

LEMMA 3.3. *Assume Condition* 3.1(i). *Then* $E\|D(F_n - F)\|^p_{L^2[0,1]} \leq ca_n^{p/4}$ *for any* $p > 4$.

The above rate is not optimal in most cases. But for our purposes it will suffice as a rate of convergence.

LEMMA 3.4. *Assume Condition* 3.1. *Then*

$$\sup_{n\geq 1}\sup_{0<\alpha<1} E\left[\left|b_n + \int_0^1 h_n(s)(\alpha D_s F_n + (1-\alpha)D_s F)ds\right|^{-p}\right] < \infty \quad \text{for all } p > 1.$$

Proof of Lemma 3.3. We consider one of the terms in Condition 3.1(i) ($i = 1$, $j = 1$). By Proposition 1.4.5 of [11, p. 69], which is a consequence of Meyer's inequality,

$$\begin{aligned}
&E\left\|D\iint_{A_n^{1,1}} u_n^{1,1}(s_1,s_2)dW_{s_1}^1 dW_{s_2}^1\right\|^p_{L^2([0,1])}\\
&\leq c_1\left\|\iint_{A_n^{1,1}} u_n^{1,1}(s_1,s_2)dW_{s_1}^1 dW_{s_2}^1\right\|^p_{1,p}\\
&\leq c_2\|1_{A_n^{1,1}}u_n^{1,1}\|^p_{3,p}\\
&= c_3\Bigg(E[\|1_{A_n^{1,1}}u_n^{1,1}\|^p_{L^2([0,1]^2)}]\\
&\qquad + E\left[\left(\sum_{j=1}^3\int_0^1\cdots\int_0^1 \|1_{A_n^{1,1}}D^j_{s_1,\ldots,s_j}u_n^{1,1}\|^2_{L^2([0,1]^2)}ds_1\ldots ds_j\right)^{p/2}\right]\Bigg)
\end{aligned}$$

$$\le E[\|1_{A_n^{1,1}} u_n^{1,1}\|^p_{L^2([0,1]^2)}]$$
$$+ E\left[\left(\|1_{A_n^{1,1}}\|^{1/2}_{L^2([0,1]^2)}\right.\right.$$
$$\left.\left.\times\left(\iint_{[0,1]^2}\left(\sum_{j=1}^{3}\int_0^1\cdots\int_0^1 (D^j_{s_1,\dots,s_j}u_n^{1,1}(t_1,t_2))^2 ds_1\dots ds_j\right)^2 dt_1 dt_2\right)^{1/2}\right)^{p/2}\right]$$
$$\le a_n^{p/4}\sup_{(t_1,t_2)\in[0,1]^2}\|u_n^{1,1}(t_1,t_2)\|^p_{3,p} \le c a_n^{p/4}. \qquad \square$$

Proof of Lemma 3.4. Define the set

$$A \equiv \left\{ \left|\int_0^1 (h_n(s)D_sF_n - h(s)D_sF)ds\right| \vee \left|\int_0^1 (h_n(s)-h(s))D_sF ds\right| \right.$$
$$\left. \vee\, b_n < \frac{1}{4}\left|\int_0^1 h(s)D_sF ds\right| \right\}.$$

On A, $|\int_0^1 h_n(s)(\alpha D_sF_n + (1-\alpha)D_sF)ds| \ge \frac{1}{2}|\int_0^1 h(s)D_sF ds|$; hence

$$E\left[\left|b_n + \int_0^1 h_n(s)(\alpha D_sF_n + (1-\alpha)D_sF)ds\right|^{-p}; A\right] \le 4^p E\left[\left|\int_0^1 h(s)D_sF ds\right|^{-p}\right].$$

By Chebyshev's inequality and Condition 3.1(iii), $E[\|b_n + \int_0^1 h_n(s)(\alpha D_sF_n + (1-\alpha)D_sF)ds\|^{-p}; A^c] \le c_p(E[d_{n,\alpha}^{-2p}]P(A^c))^{1/2}$. For any $k \in \mathbb{Z}_+$ so that $kp > 1$, we have by Condition 3.1(ii) and Lemma 3.3 that $P(A^c)$ is less than or equal to

$$4^{2kp}c_{k,p}E\left[\left|\int_0^1 h(s)D_sF ds\right|^{-2kp}\left(\|h_nDF_n - hDF\|^{2kp}_{L^1[0,1]}\right.\right.$$
$$\left.\left. + \|(h_n-h)DF\|^{2kp}_{L^1[0,1]} + b_n^{2kp}\right)\right]$$
$$\le c_{k,p}\left(E\left|\int_0^1 h(s)D_sF ds\right|^{-8kp}\right)^{1/4}\left\{\left(E\|D(F_n-F)\|^{4kp}_{L^2[0,1]}\right)^{1/2}\left(E\|h_n\|^{8kp}_{L^2[0,1]}\right)^{1/4}\right.$$
$$\left. + \left(E\|h_n-h\|^{4kp}_{L^2[0,1]}\right)^{1/2}\left(E\|DF\|^{8kp}_{L^2[0,1]}\right)^{1/4}\right\}$$
$$+ c_{k,p}E\left(\left|\int_0^1 h(s)D_sF ds\right|^{-2kp}\right)b_n^{2kp}$$
$$\le c_{k,p}\left(a_n^{kp/2} + e_n(4kp)^{1/2} + b_n^{2kp}\right).$$

The result follows by Condition 3.1(ii) and (iii). $\square$

Recall (2.3) and inductively define $H^{(n)}$ by $H^{(n)}(F,G) = H^h(F, H^{(n-1)}(F,G))$ and $H^{(0)}(F,G) = G$. We then have that for any $m \in \mathbb{Z}_+$ and $p > 1$,

$$\|H^{(m)}(F,G)\|_p$$
$$\le c\|G\|_{m+1,p_0}(\|F\|^{\alpha_1}_{m+1,p_1} + \|h\|^{\alpha_2}_{m,p_2})\left\|\left(\int_0^1 h(s)D_sF ds\right)^{-1}\right\|^{\alpha_3}_{p_3} \tag{3.4}$$

for a constant c and indices $\alpha_1,\ \alpha_2\ ,\ \alpha_3,\ p_0,\dots,p_3$ depending on m, p; see, e.g., [10, Proposition 3.3.2]. We consider the extended Wiener space $\mathcal{W}$ generated by $(W,\tilde{W})$, where $\tilde{W}$ is a Brownian motion independent of W. Let $Y_n=\sqrt{b_n}\tilde{W}_1$. For $G\in\mathbb{D}^{1,2}(\mathcal{W})$ (which has as a norm the natural extension for the product space $\mathbb{D}^{1,2}(W)\times\mathbb{D}^{1,2}(\tilde{W})$-norm) we deduce using (2.4) that

$$E[g'(Y_n+F)G]=E[g(Y_n+F)\bar{H}(F,G)], \tag{3.5}$$

where

$$\bar{H}(F,G)\equiv\bar{H}^h(F,G)=\int_0^1\frac{Gh(t)}{\int_0^1 h(s)D_sFds+b_n}dW_t+\int_0^1\frac{G\sqrt{b_n}}{\int_0^1 h(s)D_sFds+b_n}d\tilde{W}_t.$$

Similarly, define by induction $\bar{H}^{(k)}$ by $\bar{H}^{(k)}(F,G)=\bar{H}(F,\bar{H}^{(k-1)}(F,G))$, where $\bar{H}^{(0)}(F,G)=G$. Also if instead of h we use h_n in the definition of $\bar{H}$, then we use the notation $\bar{H}_n$. Using similar arguments as to those of the proof of (3.4) the following result is deduced.

LEMMA 3.5. *Assume $F\in\mathbb{D}^\infty(W)$ and $G\in\mathbb{D}^\infty(\mathcal{W})$. Then for $m\in\mathbb{Z}_+$ and $p>1$,*

$$\begin{aligned}\|\bar{H}^{(m)}(F,G)\|_p\le c\|G\|_{m+1,p_0}(\|F\|_{m+1,p_1}^{\alpha_1}+\|h\|_{m,p_2}^{\alpha_2}+b_n^{\alpha_3})\\ \times\left\|\left(\int_0^1 h(s)D_sFds+b_n\right)^{-1}\right\|_{p_4}^{\alpha_4}\end{aligned}$$

for a constant c and indices $p_0,p_1,p_2,p_4,\ \alpha_1,\dots,\alpha_4$, depending on m and p.

Proof of Lemma 3.5. We use induction. For $\bar{H}_k\equiv\bar{H}^{(k)}(F,G)$,

$$\bar{H}_k=\int_0^1\frac{\bar{H}_{k-1}h(t)}{\int_0^1 h(s)D_sFds+b_n}dW_t+\int_0^1\frac{\bar{H}_{k-1}\sqrt{b_n}}{\int_0^1 h(s)D_sFds+b_n}d\tilde{W}_t,$$

where $\bar{H}_0=G$. Applying Meyer's inequality (see, e.g., [11, p. 69]) and Hölder's inequality, for $k=0,\dots,m$, we have

$$\begin{aligned}&\|\bar{H}_k\|_{m-k,p}\\ &\le c\|\bar{H}_{k-1}\|_{m-k+1,\alpha p}(\|h\|_{m-k+1,\beta p}+\sqrt{b_n})\left\|\left(\int_0^1 h(s)D_sFds+b_n\right)^{-1}\right\|_{m-k+1,\gamma p},\end{aligned}$$

where $\alpha^{-1}+\beta^{-1}+\gamma^{-1}=1$. Furthermore, using the Cauchy–Schwarz inequality in the calculation of terms of the form $\int_{[0,1]^i}(D_{t_1,\dots,t_i}(\int_0^1 h(s)D_sFds+b_n)^{-1})^2dt_1\dots dt_i$ gives

$$\begin{aligned}&\left\|\left(\int_0^1 h(s)D_sFds+b_n\right)^{-1}\right\|_{m+1,\gamma p}\\ &\le c(\|F\|_{m+1,q_1}^{\beta_1}+\|h\|_{m,q_2}^{\beta_2}+b_n^{\beta_3})\left\|\left(\int_0^1 h(s)D_sFds+b_n\right)^{-1}\right\|_{q_4}^{\beta_4}\end{aligned}$$

for some indices $q_1,q_2,q_4,\beta_1,\dots,\beta_4$. The result follows by induction. □

Proof of Theorem 3.2. Let $f_n(x) = \phi_{\sqrt{b_n}}(x) = \exp(-x^2/2b_n)/\sqrt{2\pi b_n}$ and $G_n = \int_0^1 f_n'(Y_n+\alpha F_n+(1-\alpha)F)d\alpha$. Using the mean value theorem and the duality between the Skorokhod integral and the derivative operator (see, e.g., [11, equation (1.41), p. 35]) yields

(3.6)

$$
\begin{aligned}
&E[f_n(F+Y_n)-f_n(F_n+Y_n)]\\
&= E[G_n(F-F_n)] = \sum_{i,j=0}^{1} E\left[G_n \iint_{A_n^{i,j}} u_n^{i,j}(s_1,s_2)dW_{s_1}^i dW_{s_2}^j\right]\\
&= \iint_{A_n^{0,0}} E[G_n u_n^{0,0}(s_1,s_2)]ds_1ds_2 + \iint_{A_n^{0,1}} E[D_{s_2}(G_n)u_n^{0,1}(s_1,s_2)]ds_1ds_2\\
&\quad + \iint_{A_n^{1,0}} E[D_{s_1}(G_n)u_n^{1,0}(s_1,s_2)]ds_1ds_2 + \iint_{A_n^{1,1}} E[D^2_{s_1,s_2}(G_n)u_n^{1,1}(s_1,s_2)]ds_1ds_2.
\end{aligned}
$$

We will compute one of these terms as they are all similar. Using (3.5) three times, we get that $|E[D_{s_2}G_n u_n^{0,1}(s_1,s_2)]|$ equals

$$
\begin{aligned}
&\left|\int_0^1 E[f_n''(Y_n+\alpha F_n+(1-\alpha)F)(\alpha D_{s_2}F_n+(1-\alpha)D_{s_2}F)u_n^{0,1}(s_1,s_2)]d\alpha\right|\\
&= \left|\int_0^1 E[\Phi_n(Y_n+\alpha F_n+(1-\alpha)F)\bar{H}^{(3)}(\alpha F_n+(1-\alpha)F,\right.\\
&\qquad\qquad \left.(\alpha D_{s_2}F_n+(1-\alpha)D_{s_2}F)u_n^{0,1}(s_1,s_2))]d\alpha\right|\\
&\le \int_0^1 E|\bar{H}_n^{(3)}(\alpha D_{s_2}F_n+(1-\alpha)D_{s_2}F,(\alpha D_{s_2}F_n+(1-\alpha)D_{s_2}F)u_n^{0,1}(s_1,s_2))|d\alpha,
\end{aligned}
$$

where Φ_n is the distribution function associated with f_n. By Lemma 3.5,

$$
\begin{aligned}
&\sup_n \sup_{s_1,s_2} \sup_{0<\alpha<1} E|\bar{H}_n^{(3)}(\alpha F_n+(1-\alpha)F,(\alpha D_{s_2}F_n+(1-\alpha)D_{s_2}F)u_n^{0,1}(s_1,s_2))|\\
&\le c\sup_n \sup_{s_1,s_2} \sup_{0<\alpha<1} \|(\alpha D_{s_2}F_n+(1-\alpha)D_{s_2}F)u_n^{0,1}(s_1,s_2)\|_{4,p_0}\\
&\quad\times(\|\alpha F_n+(1-\alpha)F\|_{4,p_1}^{\alpha_1}+\|h_n\|_{3,p_2}^{\alpha_2}+b_n^{\alpha_3})\\
&\quad\times\left\|\left(b_n+\int_0^1 h_n(s)(\alpha D_sF_n+(1-\alpha)D_sF)ds\right)^{-1}\right\|_{p_4}^{\alpha_4},
\end{aligned}
$$

which is finite by Condition 3.1(i), (ii) and Lemma 3.4. Similar considerations lead to the conclusion that the other terms in (3.6) have a similar bound. In conclusion one has that $|E[f_n(F+Y_n)-f_n(F_n+Y_n)]| \le ca_n$.

Now consider $E[\delta_0(F)-f_n(F+Y_n)]$. Observe that

$$
\begin{aligned}
E[f_n(F+Y_n)] &= \int_{\mathbb{R}} E[f_n(F+y)]f_n(y)dy = E[\phi_{\sqrt{2b_n}}(F)]\\
&= E\int_{\mathbb{R}} \delta_0(F+z)\phi_{\sqrt{2b_n}}(z)dz = E\delta_0(F+\sqrt{2}Y_n).
\end{aligned}
$$

By Condition 3.1(ii) and Theorem 2.1, the densities of F and $F+\sqrt{2}Y_n$ are continuous and hence $E[\delta_0(F)-\delta_0(F+\sqrt{2}Y_n)] = \lim_{m\to\infty} E[f_m(F)-f_m(F+\sqrt{2}Y_n)]$. A Taylor

expansion of f_m around F yields

$$E[f_m(F) - f_m(F + \sqrt{2}Y_n)] = \sqrt{2}E[f_m'(F)Y_n] + 2E\left[\int_0^1 f_m''(F + \alpha\sqrt{2}Y_n)(1-\alpha)Y_n^2 d\alpha\right].$$

Clearly, $E[f_m'(F)Y_n] = 0$ by the independence of F and Y_n. By (2.4), (3.4), and Condition 3.1(ii),

$$\begin{aligned}|E[f_m''(F + \alpha\sqrt{2}Y_n)Y_n^2]| &= \left|\int E[f_m''(F + \alpha\sqrt{2}y)]y^2 f_n(y)dy\right| \\ &= \left|\int_{\mathbb{R}} E[\Phi_m(F + \alpha\sqrt{2}y)H^3(F,1)]y^2 f_n(y)dy\right| \\ &\le c\big(\|F\|_{4,p_1}^{\alpha_1} + \|h\|_{3,p_2}^{\alpha_2}\big)\left\|\left(\int_0^1 h(s)D_sF ds\right)^{-1}\right\|_{p_3}^{\alpha_3} E[Y_n^2] \le cb_n.\end{aligned}$$

Hence, $|E[\delta_0(F) - f_n(F + Y_n)]| \le cb_n$. Similarly, for an independent copy $\bar{Y}_n$ of Y_n, we obtain by Lemma 3.5

$$\begin{aligned}&|E[\delta_0(F_n + Y_n) - f_n(F_n + Y_n)]| \\ &= |E[\delta_0(F_n + Y_n) - \delta_0(F_n + Y_n + \sqrt{2}\bar{Y}_n)]| \\ &= 2\lim_{m\to\infty}\left|\int_0^1\int_{\mathbb{R}} E[f_m''(\alpha\sqrt{2}y + F_n + Y_n)]y^2 f_n(y)dy(1-\alpha)d\alpha\right| \\ &= 2\lim_{m\to\infty}\left|\int_0^1\int_{\mathbb{R}} E[\Phi_m(\alpha\sqrt{2}y + F_n + Y_n)\bar{H}_n^{(3)}(F_n,1)]y^2 f_n(y)dy(1-\alpha)d\alpha\right| \\ &\le c(\|F_n\|_{4,p_1}^{\alpha_1} + \|h_n\|_{3,p_2}^{\alpha_2} + b_n^{\alpha_3})\left\|\left(\int_0^1 h_n(s)D_sF_n ds + b_n\right)^{-1}\right\|_{p_4}^{\alpha_4} EY_n^2 \le cb_n.\end{aligned}$$

Furthermore, if (3.2) is satisfied, (3.3) follows as above but with $Y_n \equiv 0$. □

With the above technique and a further generalization of Condition 3.1(i) one can obtain a power expansion of the error.

THEOREM 3.6. *Assume Condition* 3.1 *but with* (i) *replaced by*

$$\begin{aligned}\text{(i)}' \qquad F - F_n = &\sum_{i=2}^{l}\sum_{j_1,\dots,j_i=0,1}\int_{A_n^{j_1,\dots,j_i}} u_{j_1,\dots,j_i}(s_1,\dots,s_i)dW_{s_1}^{j_1}\dots dW_{s_i}^{j_i} \\ &+ \sum_{j_1,\dots,j_{l+1}=0,1}\int_{R_n^{j_1,\dots,j_{l+1}}} u_n(s_1,\dots,s_{l+1})dW_{s_1}^{j_1}\dots dW_{s_{l+1}}^{j_{l+1}}\end{aligned}$$

for $l \ge 2$, where $A_n^{j_1,\dots,j_i}$ is a subset of $[0,1]^i$ with $\sum_{i=2}^{l}\sum_{j_1,\dots,j_i=0,1}|A_n^{j_1,\dots,j_i}|/[2(2^l - 2)] \le a_n \to 0$ as $n \to \infty$, $R_n^{j_1,\dots,j_{l+1}}$ is a subset of $[0,1]^{l+1}$, and $u_{j_1,\dots,j_i}$ as well as u_n are two measurable stochastic processes not necessarily adapted. Assume

$$\max_i \sup_{s_1,\dots,s_i}\|u_{j_1,\dots,j_i}(s_1,\dots,s_i)\|_{k,p} + \sup_n \sup_{s_1,\dots,s_{l+1}}\|u_n(s_1,\dots,s_{l+1})\|_{k,p} < \infty$$

for $k \in \mathbb{Z}_+$, $p > 1$. Let Y_n be an independent normal random variable with mean 0 and variance $b_n \le \sum_{i=2}^{l}\sum_{j_1,\dots,j_i=0,1}|A_n^{j_1,\dots,j_i}|/[2(2^l-2)]$. Then for any distribution

T, there exist deterministic functions $c_{j_1,\dots,j_i}$ and a constant c such that

$$\sup_n \Bigg| E[T(F) - T(F_n + Y_n)] - \sum_{i=2}^{l} \sum_{j_1,\dots,j_i=0,1} \int_{A_n^{j_1,\dots,j_i}} c_{j_1,\dots,j_i}(s_1,\dots,s_i)ds_1\dots ds_i \Bigg| \le c \sum_{j_1,\dots,j_{l+1}=0,1} |R_n^{j_1,\dots,j_{l+1}}| + o\left(\sum_{i=2}^{l} \sum_{j_1,\dots,j_i=0,1} |A_n^{j_1,\dots,j_i}| \right).$$

Furthermore, if (3.2) *is satisfied, then Y_n can be replaced by* 0.

Note that the second integral in Theorem 3.6 is interpreted as the anticipating multiple Skorokhod integral. In this theorem we have not used the coefficients a_n because this was just a bound for the sum of the areas of the sets $A_n^{i,j}$ (see also section 5).

COROLLARY 3.7. *If condition* (i)$'$ *in the above theorem is replaced by*

$$\text{(i)}'' \qquad F - F_n = \sum_{i=2}^{l} \sum_{j_1,\dots,j_i=0,1} \int_{A_n^{j_1,\dots,j_i}} u_{j_1,\dots,j_i}^n(s_1,\dots,s_i)dW_{s_1}^{j_1}\dots dW_{s_i}^{j_i},$$

where $\sup_n \max_i \sup_{s_1,\dots,s_i} \|u_{j_1,\dots,j_i}^n(s_1,\dots,s_i)\|_{k,p} \le c(k,p)$, *then for any distribution T,* $|E[T(F) - T(F_n + Y_n)]| \le c\sum_{i=2}^{l} \sum_{j_1,\dots,j_i=0,1} |A_n^{j_1,\dots,j_i}|$. *Furthermore, if* (3.2) *is valid, then Y_n can be replaced by* 0.

4. Application to diffusion processes. We assume for convenience throughout in this section that $b \in C_b^\infty(\mathbb{R})$ and $\sigma \in C_b^\infty(\mathbb{R})$. Consider the particular case when $F = X_1$ is given by (1.1) and $F_n = \bar{X}_1^n$ is given by its Euler approximation $\bar{X}_{t_i}^n = \bar{X}_{t_{i-1}}^n + b(\bar{X}_{t_{i-1}}^n)\Delta t_i + \sigma(\bar{X}_{t_{i-1}}^n)\Delta W_i$, where $\pi_n = \{0 = t_0 < t_1 < \cdots < t_n = 1\}$ is a partition of $[0,1]$ with mesh $m(\pi_n) = \max\{t_{i+1} - t_i : 0 \le i \le n-1\}$ and $\Delta W_i = W_{t_i} - W_{t_{i-1}}$. We interpolate $\bar{X}^n$ between the grid points by $\bar{X}_t^n = x_0 + \int_0^t b(\bar{X}_{\eta_s}^n)ds + \int_0^t \sigma(\bar{X}_{\eta_s}^n)dW_s$, where $\eta_s = \max\{t_i : t_i < s\}$. We first prove that Condition 3.1(i) is satisfied.

LEMMA 4.1. *Let $b \in C_b^\infty(\mathbb{R})$ and $\sigma \in C_b^\infty(\mathbb{R})$. Then Condition* 3.1(i) *is satisfied for $a_n = m(\pi_n)$.*

Proof.

$$X_t - \bar{X}_t^n = \int_0^t b'(\xi_s^0)(X_s - \bar{X}_s^n)ds + \int_0^t \sigma'(\xi_s^1)(X_s - \bar{X}_s^n)dW_s + \int_0^t b(\bar{X}_s^n) - b(\bar{X}_{\eta_s}^n)ds + \int_0^t \sigma(\bar{X}_s^n) - \sigma(\bar{X}_{\eta_s}^n)dW_s. \tag{4.1}$$

Here ξ_s^0 and ξ_s^1 are random points in the interval determined by X_s and $\bar{X}_s^n$. In particular we understand the expression $b'(\xi_s^0)$ in its integral form $b'(\xi_s^0) = \int_0^1 b'(\bar{X}_s^n + \lambda(X_s - \bar{X}_s^n))d\lambda$ and similarly for $\sigma'(\xi_s^1)$. Note that (4.1) is linear in $X - \bar{X}^n$. Therefore, if we define $\mathcal{E}$ as the unique solution to $\mathcal{E}_t = 1 + \int_0^t b'(\xi_s^0)\mathcal{E}_s ds + \int_0^t \sigma'(\xi_s^1)\mathcal{E}_s dW_s$, we

have

$$X_t - \bar{X}_t^n = \mathcal{E}_t \int_0^t \mathcal{E}_s^{-1}\sigma'(\epsilon_s^0)\{b(\bar{X}_{\eta_s}^n)(s-\eta_s) + \sigma(\bar{X}_{\eta_s}^n)(W_s - W_{\eta_s})\}ds$$
$$+\mathcal{E}_t \int_0^t \mathcal{E}_s^{-1}b'(\epsilon_s^1)\{b(\bar{X}_{\eta_s}^n)(s-\eta_s) + \sigma(\bar{X}_{\eta_s}^n)(W_s - W_{\eta_s})\}dW_s$$
$$- \mathcal{E}_t \int_0^t \mathcal{E}_s^{-1}\sigma'(\xi_s^1)\sigma'(\epsilon_s^0)\{b(\bar{X}_{\eta_s}^n)(s-\eta_s) + \sigma(\bar{X}_{\eta_s}^n)(W_s - W_{\eta_s})\}ds.$$

Here $b'(\epsilon_s^1) = \int_0^1 b'(\bar{X}_{\eta_s}^n + \lambda(\bar{X}_s^n - \bar{X}_{\eta_s}^n))d\lambda$, and similarly for $\sigma'(\epsilon_s^0)$. By using the integration by parts formula (see, e.g., [11, equation (1.49), p. 40])

$$X_t - \bar{X}_t^n = \sum_{i,j\in\{0,1\}} \int_0^t \int_{\eta_{s_2}}^{s_2} u_n^{i,j}(s_1,s_2)dW_{s_1}^i dW_{s_2}^j.$$

It is straightforward to show that $\|u_n^{i,j}(s_1,s_2)\|_{k,p}$ is uniformly bounded in (s_1,s_2) and n. Clearly $|A_n^{i,j}| = \int_0^1 \int_{\eta_s}^s duds \le m(\pi_n)$. Condition 3.1(i) is satisfied. □

Now we introduce sufficient conditions that ensure the smoothness of the density of X_t. This also explains the terminology introduced for Condition 3.1 and (3.2).

CONDITION 4.2 (Hörmander condition). *$|\sigma(x_0)| \ge \epsilon > 0$ or $|b(x_0)\sigma^{(k)}(x_0)| \ge \epsilon > 0$ for some $k \in \mathbb{N}$ and for some $\epsilon > 0$.*

CONDITION 4.3 (uniform ellipticity condition). *$|\sigma(x)| \ge \epsilon > 0$ for all $x \in \mathbb{R}$ and for some $\epsilon > 0$.*

LEMMA 4.4. (i) *If Condition 4.2 is satisfied, then Condition 3.1 is satisfied for $F = X_1$, $F_n = \bar{X}_1^n$ with $h_n(s) = h_{n,\alpha}(s) = \alpha D_s F_n + (1-\alpha)D_s F$, $h(s) = D_s F$, $e_n(p) = c_p a_n^{p/4}$ for some constant c_p, $b_n = d_n = a_n = m(\pi_n)$.*

(ii) *If Condition 4.3 is satisfied and $1 - t_{n-1} \ge cm(\pi_n)$ for some $c > 0$, then (3.2) is satisfied with the same choices for h_n and h as above.*

Results similar to Lemma 4.4 for h and F are well known; see, e.g., [11, p. 111].

Proof of Lemma 4.4. First we prove Lemma 4.4(i). Condition 3.1(i) is satisfied by Lemma 4.1. Condition 3.1(ii) is satisfied by Lemma 3.3. In fact,

$$E\,\|h_{n,\alpha} - h\|_{L^2[0,1]} = (1-\alpha)E\left\|D(\bar{X}_1^n - X_1)\right\|_{L^2[0,1]} \le c_p a_n^{p/4}.$$

Furthermore, by Condition 4.2 and the proof of [11, Theorem 2.3.2], $E[(\int_0^1 (D_s X_1)^2 ds)^{-p}] < \infty$ for all $p > 1$, and Condition 3.1(ii) follows.

To prove that Condition 3.1(iii) is satisfied we note that obviously $|a_n + \int_0^1 (D_s X_1)^2 ds| > |\int_0^1 (D_s X_1)^2 ds|$ and $|a_n + \int_0^1 (\alpha D_s \bar{X}_1^n + (1-\alpha)D_s X_1)^2 ds| \ge d_n \equiv a_n$. Clearly $\sup_n d_n^{-p}(a_n^{k(p)/2} + e_n(4k(p))^{1/2} + b_n^{2k(p)}) = 2a_n^{k(p)/2-p} + b_n^{2k(p)-p} < \infty$ if $2k(p) \ge p$.

Next we prove Lemma 4.4(ii). Similar to the proof of Lemma 3.4 we define the set $A \equiv \{\int_0^1 \left(D_s(\bar{X}_1^n - X_1)\right)^2 ds < \frac{1}{4}\int_0^1 (D_s X_1)^2 ds\}$, and we have that for any $p > 1$,

$$\sup_n \sup_\alpha E\left[\left|\int_0^1 (\alpha D_s \bar{X}_1^n + (1-\alpha)D_s X_1)^2 ds\right|^{-p}; A\right] \le 4^{-p} E\left[\left|\int_0^1 (D_s X_1)^2 ds\right|^{-p}\right] < \infty.$$

Next we find a similar bound for the expectation taken over the set A^c. Note that without loss of generality we can suppose that $\sigma(x) \ge \epsilon > 0$ for all $x \in \mathbb{R}$. Then

$D_sX_1 > \epsilon \exp(\int_s^1 \bar{b}'(X_u)du + \int_s^1 \sigma'(X_u)dW_u)$ (see (7.1)). Also notice that $D_s\bar{X}_1^n = \sigma(\bar{X}(t_{n-1}^n)) \geq \epsilon > 0$ for $t_{n-1} < s \leq 1$ (see (7.3) and (7.5)). Hence for $\alpha > 1/2$,

$$\left| \int_0^1 (\alpha D_s\bar{X}_1^n + (1-\alpha)D_sX_1)^2 ds \right| \geq \frac{1}{4}\epsilon^2(1-t_{n-1}).$$

For $\alpha \leq 1/2$ we use that

$$\begin{aligned} &\left| \int_0^1 (\alpha D_s\bar{X}_1^n + (1-\alpha)D_sX_1)^2 ds \right| \\ &\geq \frac{1}{4}\epsilon^2 \int_{t_{n-1}}^1 \exp\left(2\int_s^1 \bar{b}'(X_u)du + 2\int_s^1 \sigma'(X_u)dW_u\right) ds. \end{aligned}$$

In A^c the above estimates together with Chebyshev's inequality and Lemma 3.3 complete the proof as in the proof of Lemma 3.4. That is,

$$\begin{aligned} &\sup_n \sup_\alpha E\left[\left| \int_0^1 (\alpha D_s\bar{X}_1^n + (1-\alpha)D_sX_1)^2 ds \right|^{-p}; A^c \right] \\ &\leq 4^p\epsilon^{-2p}\Bigg((1-t_{n-1})^{-p}P(A^c) \\ &\quad + E\left[\left(\int_{t_{n-1}}^1 \exp\left(2\int_s^1 \bar{b}'(X_u)du + 2\int_s^1 \sigma'(X_u)dW_u\right) ds \right)^{-2p} \right]^{1/2} P(A^c)^{1/2} \Bigg) \\ &\leq cm(\pi_n)^{-p}(P(A^c) + P(A^c)^{1/2}). \end{aligned}$$

From here the result follows as $P(A^c) \leq c_k(m(\pi_n))^{k/2}$ for any $k > 1$. Taking k big enough finishes the proof of the lemma. □

Section 3 gives the rate of convergence of the Euler approximation. The same proof gives the following stronger result.

PROPOSITION 4.5. *Assume Condition* 4.2. *Then*

$$\sup_x |E\delta_x(X_1) - E\delta_x(\bar{X}_1^n + Y_n)| \leq cm(\pi_n),$$

where Y_n is an independent normal random variable with zero mean and variance $m(\pi_n)$. Furthermore, if Condition 4.3 *is valid and $1 - t_{n-1} \geq cm(\pi_n)$ for some $c > 0$, then*

$$\sup_x |E\delta_x(X_1) - E\delta_x(\bar{X}_1^n)| \leq cm(\pi_n).$$

This stronger version follows because the antiderivative of the delta function is the indicator function which is bounded in x. Applying Remark 2.2 to our current setting gives the following.

REMARK 4.6 (control variate method). (i) *Assume Condition* 4.2 *with the choices for h_n and h in Lemma* 4.4(i). *Let $\xi_{n,r}^{h_n}(x) = (1_{\{\bar{X}_1^n + Y_n > x\}} - c(x))H^{h_n}(\bar{X}_1^n + Y_n, \varphi(\frac{\bar{X}_1^n + Y_n - x}{r}))$. Then $E(\xi_{n,r}^{h_n}(x)) = E\delta_x(\bar{X}_1^n + Y_n)$ and $\sup_{x,n} E(\xi_{n,r}^{h_n}(x)^2) < \infty$. If $E\delta_x(\bar{X}_1^n + Y_n) > 0$, then $E[H^{h_n}(\bar{X}_1^n + Y_n, \varphi(\frac{\bar{X}_1^n - x}{r}))^2] > 0$ and, for fixed φ and r, the variance of $\xi_{n,r}^h(x)$ is minimized by*

$$c(x) = c_{n,r}^h(x) = \frac{E[1_{\{\bar{X}_1^n + Y_n > x\}} H^{h_n}(\bar{X}_1^n + Y_n, \varphi(\frac{\bar{X}_1^n + Y_n - x}{r}))^2]}{E[H^{h_n}(\bar{X}_1^n + Y_n, \varphi(\frac{\bar{X}_1^n + Y_n - x}{r}))^2]}.$$

(ii) *Assume Condition* 4.3 *with the choices for* h_n *and* h *in Lemma* 4.4(ii). *Then* Y_n *above can be replaced by* 0. *Furthermore* $E\delta_x(\bar{X}_1^n) > 0$. □

Results similar to Proposition 4.5 have already been obtained in [1] and [2]. The main difference with the results here is that the method of proof is somewhat different and that our Proposition 4.5 is the result of a general theory based on Itô–Taylor expansions which can also be applied to other situations. In fact, under further restrictions on the structure of the sets A_n, R_n, and the continuity of the processes u and u_n, one can improve Theorem 3.6 to obtain Taylor expansions of the errors. For example in the uniformly elliptic case we have

$$E[T(F_n) - T(F)] = c_1 a_n + c_2^{(n)} a_n^2$$

for any distribution T. In the general Hörmander case,

$$E[T(F_n + Y_n) - T(F)] = c_1 a_n + c_2 b_n + c_3^{(n)} a_n b_n + c_4^{(n)} a_n^2 + c_5^{(n)} b_n^2,$$

where Y_n is a mean zero normal random variable with variance b_n, independent of W, and $\sup_n |c_i^{(n)}| < \infty$, $i = 2, \dots, 5$. This result will be proven elsewhere.

5. Kernel density estimation method. So far we have given convergence results for the density approximation by integration by parts. In this section we discuss heuristically the "most natural" approach by kernel density estimates and compare the asymptotic variances.

The kernel density estimation technique is a very well known method used in statistics. The main difference between this and our situation is that in statistics the amount of data is limited while here the amount of simulations can be fixed by the user. Nevertheless, the same theory gives us some insight into the optimal use of this method for simulation of densities.

That is, let ϕ be a smooth positive even function with $\int_{\mathbb{R}} \phi(x)dx = 1$. Then the approximation of the density is obtained by computing $\sum_{i=1}^N \phi(\frac{F_n^i - x}{h})/(Nh)$. The error is measured through the $L^2(\mathbb{R})$-norm of the variance. Estimating this error requires the study of various errors.

The first error is the difference between the expectations of the simulated approximation and the limit random variable,

$$\frac{1}{h} E\left[\phi\left(\frac{F_n - x}{h}\right) - \phi\left(\frac{F - x}{h}\right)\right] = c_1(x) a_n + c_2^{(h,n)}(x) a_n^2, \tag{5.1}$$

where $\sup_{n,h} |c_2^{(h,n)}(x)| < \infty$. Here the constants obviously depend also on ϕ. To obtain this result it is enough to notice that

$$\frac{1}{h} E\left[\phi\left(\frac{F_n - x}{h}\right) - \phi\left(\frac{F - x}{h}\right)\right] = E[\delta_x(F_n + hY) - \delta_x(F + hY)],$$

where Y is a smooth random variable with density given by ϕ. This converts the estimation of the error into the uniformly elliptic case. Therefore the same method of proof as in Theorem 3.6 can be used.

The second error is the difference between the density to be approximated and the approximation with the kernel function (see, e.g., [12]):

$$\frac{1}{h} E\left[\phi\left(\frac{F - x}{h}\right) - \delta_x(F)\right] = \frac{1}{2} h^2 p''(x) \int u^2 \phi(u) du + O(h^4) p^{(4)}(x),$$

where p is the density of F. Similarly for the mean square error,

$$\begin{aligned}
&E\left[\left(\frac{1}{Nh}\sum_{i=1}^{N}\phi\left(\frac{F_n^i-x}{h}\right)-p(x)\right)^2\right]\\
&=\operatorname{Var}\left[\frac{1}{Nh}\sum_{i=1}^{N}\phi\left(\frac{F_n^i-x}{h}\right)\right]+\left(\frac{1}{h}E\left[\phi\left(\frac{F_n-x}{h}\right)-\phi\left(\frac{F-x}{h}\right)\right]\right)^2\\
&\quad+\left(E\left[\frac{1}{h}\phi\left(\frac{F-x}{h}\right)-p(x)\right]\right)^2\\
&\quad+2\frac{1}{h}E\left[\phi\left(\frac{F_n-x}{h}\right)-\phi\left(\frac{F-x}{h}\right)\right]E\left[\frac{1}{h}\phi\left(\frac{F-x}{h}\right)-p(x)\right]\\
&=p_n(x)\frac{1}{Nh}\int\phi^2(u)du+c_1(x)^2a_n^2+\frac{h^4}{4}\left(p''(x)\int u^2\phi(u)du\right)^2\\
&\quad+c_1(x)h^2a_np''(x)\int u^2\phi(u)du+\text{higher order terms},
\end{aligned}$$

where p_n is the density of F_n. If one considers as a minimization criterion the L^1-norm of the mean squared error, this gives the classical criterion of kernel density estimation. That is,

$$\begin{aligned}
&\int E\left[\left(\frac{1}{Nh}\sum_{i=1}^{N}\phi\left(\frac{F_n^i-x}{h}\right)-p(x)\right)^2\right]dx\\
&\quad\approx\frac{1}{Nh}\int\phi^2(u)du+c_1^2a_n^2+\frac{h^4}{4}\int p''(x)^2dx\left(\int u^2\phi(u)du\right)^2.
\end{aligned}$$

The optimum is therefore obtained when ϕ is the Epanechnikov kernel and $h\sim N^{-1/5}$ and $N\sim a_n^{-5/2}$.

6. Optimal choice for the integration by parts method. As in the previous section we will find heuristically an optimal choice of localization function φ and localization parameter r for the integration by parts method introduced in section 2. In order to do this we will find an asymptotical expression for the variance of the simulations.

Let $\varphi\in C_b^1$ with $\varphi(0)=1$. One criteria for optimality may be to choose φ and r so that they minimize

$$\int_{\mathbb{R}}E\left[1(F_n+Y_n\geq x)H^h\left(F_n+Y_n,\varphi\left(\frac{F_n+Y_n-x}{r}\right)\right)^2\right]dx \tag{6.1}$$

under the general Hörmander condition. This criteria can be studied but is cumbersome as the optimal choices will depend on n. Instead one may study the limit assuming that the error terms are small. Therefore for simplicity we consider for small r, under convenient smoothness and boundedness conditions, the asymptotic limit of (6.1) which, using (2.5), equals $\int_{\mathbb{R}}I(x)dx$, where

$$I(x)=E\left[1(F\geq x)\left(\varphi\left(\frac{F-x}{r}\right)H^h(F,1)-\frac{1}{r}\varphi'\left(\frac{F-x}{r}\right)\right)^2\right].$$

Let $H_i(x) = E[H^h(F,1)^i|F=x]$ for $i=1,2$, and let p be the density of F. Then

$$\begin{aligned} I(x) &= \int_x^\infty E\left[\left(\varphi\left(\frac{y-x}{r}\right)H^h(F,1) - \frac{1}{r}\varphi'\left(\frac{y-x}{r}\right)\right)^2 |F=y\right] p(y)dy \\ &= \int_x^\infty \left(\frac{1}{r^2}\varphi'\left(\frac{y-x}{r}\right)^2 - \frac{2}{r}\varphi\varphi'\left(\frac{y-x}{r}\right)H_1(y) + \varphi\left(\frac{y-x}{r}\right)^2 H_2(y)\right)p(y)dy \\ &= r\int_0^\infty \left(\frac{1}{r^2}\varphi'(z)^2 - \frac{2}{r}\varphi\varphi'(z)H_1(x+rz) + \varphi(x+rz)^2 H_2(x+rz)\right)p(x+rz)dz. \end{aligned}$$

Under smoothness and boundedness conditions of H_i, φ, and p, $I(x) = I_2(x) + O(r^2)$ for small r, where

$$\begin{aligned} I_2(x) = {} & \frac{1}{r}p(x)\int_0^\infty \varphi'(z)^2 dz + H_1(x)p(x)\int_0^\infty (\varphi'(z)^2 z p'(x) - 2\varphi\varphi'(z))dz \\ & + rp''(x)\int_0^\infty \frac{1}{2}\varphi'(z)^2 z^2 dz + H_2(x)p(x)\int_0^\infty \varphi^2(z)dz \\ & - 2(H_1(x)p'(x) + H_1'(x)p(x))\int_0^\infty \varphi\varphi'(z)z dz \end{aligned} \tag{6.2}$$

and

$$\int_{\mathbb{R}} I_2(x)dx = \frac{1}{r}\int_0^\infty \varphi'(z)^2 dz + r\int_0^\infty \varphi^2(z)dz \int_{\mathbb{R}} H_2(x)p(x)dx, \tag{6.3}$$

where $\int_{\mathbb{R}} H_2(x)p(x)dx = E[H^h(F,1)^2]$ and $\int_{\mathbb{R}} H_1(x)p(x)dx = E[H^h(F,1)] = 0$. An optimal value for r which minimizes (6.3) is given by

$$r = \left(\frac{\int_0^\infty \varphi'(z)^2 dz}{E[H^h(F,1)^2]\int_0^\infty \varphi(z)^2 dz}\right)^{1/2}.$$

Replacing this r in (6.3) yields

$$\int_{\mathbb{R}} I_2(x)dx = 2\left(E\left[H^h(F,1)^2\right]\int_0^\infty \varphi(z)^2 dz \int_0^\infty \varphi'(z)^2 dz\right)^{1/2},$$

which, by variational analysis, is minimized for φ solving

$$\varphi(z)\int_0^\infty \varphi'(z)^2 dz - \varphi''(z)\int_0^\infty \varphi(z)^2 dz = 0. \tag{6.4}$$

For any $\lambda > 0$, the function $\varphi(z) = e^{-\lambda|z|}$ is symmetric, solves (6.4), and satisfies $\varphi(0) = 1$. Hence we propose as a natural choice of r and φ

$$r = \left(\frac{\int_0^\infty \varphi'(z)^2 dz}{E[H^h(F,1)^2]\int_0^\infty \varphi(z)^2 dz}\right)^{1/2}, \qquad \varphi(x) = e^{-\lambda|x|}, \tag{6.5}$$

where $\lambda > 0$ may be arbitrarily chosen. Note that the main error term (6.3) with optimal φ is independent of the value of λ.

After the minimization in r and φ is done one can apply the control variate method introduced in Remark 4.6. Therefore the variance error for the integration by parts with control variates and localization is in the uniformly elliptic case

$$E\left[\left(\frac{1}{N}\sum_{i=1}^{N}(1(F_n^i \geq x) - c_n(x,r))\bar{H}_n\left(F_n^i, \varphi\left(\frac{F_n^i - x}{r}\right)\right) - p(x)\right)^2\right]$$
$$\approx C_1(x)^2 a_n^2 + \frac{\mathrm{Var}[(1(F_n \geq x) - c_n(x,r))\bar{H}_n(F_n, \varphi(\frac{F_n - x}{r}))]}{N}.$$

The optimal choice is therefore $N \sim a_n^{-2}$. For the general Hörmander case, $N \sim (a_n + b_n)^{-2}$.

6.1. Comparison of the kernel density estimate and the integration by parts method: Some conclusions and remarks. A first look at both methods shows that kernel density estimation has a square bias asymptotically equal to $h^4 p''(x)^2 \int u^2 \phi(u) du$ due to the fact of using ϕ, besides the square bias $c_1(x)^2 a_n^2 + c_2(x)^2 b_n^2$ from the approximation of F. If the first type of error is much smaller than the second one, then only the second one is important when comparing the two methods.

In order to compare both methods, suppose that $a_n = n^{-1}$. Then the optimal sample size for the integration by parts method is $N = n^2$, which is significantly less than the optimal sample size $N = n^{5/2}$ for the kernel density method. Furthermore, the kernel density method creates bias while the integration by parts does not, at least theoretically. Nevertheless, the amount of calculations in the integration by parts method is higher.

The optimal parameter $r_{n,N}$ does not go to 0 as n, N increase. In fact, r could remain constant throughout the calculations with little increase of the variance. It seems that $r_{n,N} \to r > 0$ in most of the cases. Numerical experiments indicate that the choice of r does not look to be sensitive. Kernel density estimation often requires a fine tuning of the bandwidth h.

There is no clear way to apply a control variate method to kernel density estimation methods.

In higher dimensions the kernel density estimate rate of convergence deteriorates typically to $N^{-\frac{4}{d+4}}$ while the integration by parts keeps the same rate.

Constants in the integration by parts methods increase in value as the degree of hypoellipticity increases.

Similar variance reductions could be studied on other environments where an integration by parts formula is available. For example, in the Poisson case one could use the same ideas as shown here; see, e.g., [3].

7. Numerical implementation. We consider the particular case when $F = X_1$ is given by (1.1) and F_n is its Euler approximation. We first note that

$$D_s X_t = \begin{cases} \sigma(X_s) e^{\int_s^t \bar{b}'(X_v)dv + \int_s^t \sigma'(X_v)dW_v}, & s \leq t, \\ 0, & s > t, \end{cases} \tag{7.1}$$

where $\bar{b}'(X_v) = b'(X_v) - \frac{1}{2}\sigma'(X_v)^2$; see, e.g., [11, p. 107]. Using (7.1), it follows that

(7.2)
$$D_s D_t X_1 = D_s[X_t]\sigma'(X_t) e^{\int_t^1 \bar{b}'(X_v)dv + \int_t^1 \sigma'(X_v)dW_v}$$

$$+\left[\sigma'(X_s)1_{\{t\le s\}}+\int_t^1 \bar{b}''(X_v)D_sX_v dv+\int_t^1 \sigma''(X_v)D_sX_v dW_v\right]D_tX_1.$$

Since

$$D_{t_j}\bar{X}^n_{t_k}=D_{t_j}\bar{X}^n_{t_{k-1}}+[b'(\bar{X}^n_{t_{k-1}})\Delta t+\sigma'(\bar{X}^n_{t_{k-1}})\Delta W_k]D_{t_j}\bar{X}^n_{t_{k-1}}\\ +\sigma(\bar{X}^n_{t_{k-1}})D_{t_j}\Delta W_k,$$

and $D_s\Delta W_{t_k}=1_{\{t_{k-1}<s\le t_k\}}$, it follows that $D_{t_k}\bar{X}^n_{t_k}=\sigma(\bar{X}^n_{t_{k-1}})$. By induction,

(7.3)
$$D_{t_j}\bar{X}^n_{t_k}=\begin{cases}0, & j=0,\\ \sigma(\bar{X}^n_{t_{k-1}}), & 1\le j=k,\\ \sigma(\bar{X}^n_{t_{j-1}})\Pi_{l=j}^{k-1}(1+b'(\bar{X}^n_{t_l})\Delta t_{l+1}+\sigma'(\bar{X}^n_{t_l})\Delta W_{l+1}), & 1\le j\le k-1,\\ 0, & j\ge k+1.\end{cases}$$

Note that (7.3) is a discrete version of (7.1) ($\Pi_j(1+\varepsilon_j)\approx e^{\sum_j(\epsilon_j-\epsilon_j^2/2)}$). Using similar arguments one obtains

(7.4)
$$D_{t_i}D_{t_j}\bar{X}^n_{t_k}=\begin{cases}0, & j=0,\\ 0, & j\ge k+1,\\ b'(\bar{X}^n_{t_{k-1}})D_{t_i}\bar{X}^n_{t_{k-1}}, & j=k,\\ D_{t_i}[\bar{X}^n_{t_{j-1}}]b'(\bar{X}^n_{t_{j-1}})\Pi_{l=j}^{k-1}(1+a'(\bar{X}^n_{t_l})\Delta t+b'(\bar{X}^n_{t_l})\Delta W_{l+1})\\ \quad+\Big(\sum_{l=j}^{k-1}\frac{[a''(\bar{X}^n_{t_l})\Delta t+b''(\bar{X}^n_{t_l})\Delta W_{l+1}]D_{t_i}\bar{X}^n_{t_l}}{1+a'(\bar{X}^n_{t_l})\Delta t+b'(\bar{X}^n_{t_l})\Delta W_{l+1}}\\ \quad+\frac{b'(\bar{X}^n_{t_{i-1}})1_{\{j\le i-1\le k-1\}}}{1+a'(\bar{X}^n_{t_{i-1}})\Delta t+b'(\bar{X}^n_{t_{i-1}})\Delta W_i}\Big)D_{t_j}\bar{X}^n_{t_k},\\ 2\le j\le k-1\end{cases}$$

which is a discrete version of (7.2).

To apply the above formulas to the integration by parts method we need to use that

$$D_s\bar{X}^n_{t_k}=D_{\eta_s^+}\bar{X}^n_{t_k},\tag{7.5}$$

where $\eta_s^+=\min\{t_i:t_i\ge s\}$. This follows because

$$D_s\bar{X}^n_{t_k}=D_s[\bar{X}^n_{t_{k-1}}+b(\bar{X}^n_{t_{k-1}})\Delta t_k+\sigma(\bar{X}^n_{t_{k-1}})\Delta W_k]\\ =[1+b'(\bar{X}^n_{t_{k-1}})\Delta t_k+\sigma'(\bar{X}^n_{t_{k-1}})\Delta W_k]D_s\bar{X}^n_{t_{k-1}}+\sigma(\bar{X}^n_{t_{k-1}})1_{\{t_{k-1}<s\le t_k\}}.$$

We then have that for $t_{k-1}<s<t_k$, $D_s\bar{X}^n_{t_k}=\sigma(\bar{X}^n_{t_{k-1}})=D_{t_k}\bar{X}^n_{t_k}$. By induction we have in general that for $t_{j-1}<s<t_j$, $D_s\bar{X}^n_{t_k}=D_{t_j}\bar{X}^n_{t_k}$ for $j=1,\dots,k$. We also have that

$$D_sD_t\bar{X}^n_{t_k}=D_{\eta_s^+}D_{\eta_t^+}\bar{X}^n_{t_k}.\tag{7.6}$$

Using (7.5), (7.6), and (2.7) gives

$$H^1(\bar{X}^n_1,1)=\frac{W_1}{\sum_1^n D_{t_i}\bar{X}^n_1\Delta t_i}+\frac{\sum_{i,j=1}^n D_{t_i}D_{t_j}\bar{X}^n_1\Delta t_i\Delta t_j}{(\sum_1^n D_{t_i}\bar{X}^n_1\Delta t_i)^2},$$

from which $H^1(\bar{X}_t^n, \varphi((\bar{X}_t^n - x)/r))$ can be computed by (2.5). An approximation to the density using the integration by parts formula can now be explicitly written. For example,

$$f^{n,N}(x) = \frac{1}{N}\sum_{i=1}^{N}(1_{\{\bar{X}_1^{n,i}\geq x\}} - \hat{c}_{loc}^1(x))H^1\left(\bar{X}_1^{n,i}, \varphi\left(\frac{\bar{X}_1^i - x}{r}\right)\right), \tag{7.7}$$

where

$$\hat{c}_{loc}^1(x) = \frac{\frac{1}{N}\sum_{i=1}^{N} 1_{\{\bar{X}_1^{n,i}\geq x\}} H^1\left(\bar{X}_1^{n,i}, \varphi\left(\frac{\bar{X}_1^{n,i}-x}{r}\right)\right)^2}{\frac{1}{N}\sum_{i=1}^{N} H^1\left(\bar{X}_1^{n,i}, \varphi\left(\frac{\bar{X}_1^{n,i}-x}{r}\right)\right)^2}$$

is a natural estimate of (2.9).

We perform the simulation (7.7) with optimal φ and r from (6.5) with $\lambda = 1$ and equidistant partition $m(\pi_n) = n^{-1}$ and compare with a locally optimal r (numerically obtained optimal r for fixed x) and the kernel density estimate; see Figure 1. We also compare the convergences in Figure 2. The computations are made in MATLAB.

CONVERGENCE ANALYSIS OF A TRANSMISSION ALGORITHM FOR CONVECTION-DIFFUSION PROBLEMS*

M. TIDRIRI†

Abstract. We prove the convergence of the transmission time marching algorithm for the β–monoscale-multimodel methods for hydrodynamics-type problems. Our analysis is based on the author's transmission multiplier method we introduced in [*C. R. Acad. Sci. Paris Sér.* I *Math.*, 328 (1999), pp. 637–642] and the local, global, and trace estimates we developed in [*J. Math. Anal. Appl.*, 229 (1999), pp. 137–157; *Abstr. Appl. Anal.*, 3 (2001), pp. 131–150].

Key words. boundary layers, compressible Navier–Stokes equations, convection-diffusion problems, Dirichlet–Dirichlet problems, Dirichlet–Neumann problems, local, global, and trace estimates, transmission multiplier method, transmission time marching algorithm, α–monoscale-multimodel method, β–monoscale-multimodel method

1. Introduction.

In this paper we prove the convergence of the transmission time marching algorithm (TTMA) for the β–monoscale-multimodel methods for hydrodynamics-type problems. The α– and β–monoscale-multimodel methods were introduced by the author [7, 8, 9] in order to separately handle local and global phenomena in the modeling of physical systems. These methods offer an easy way of supplementing and testing a large variety of boundary conditions. Moreover, in the local domain the model can be chosen to handle phenomena such as boundary layers and turbulence and can incorporate models of chemistry. We have already proved the validity of these methods and their superiority to classical methods in many (important) real life applications. More details about this type of methods can be found in [8, 9]. The TTMA [8, 9] is an algorithm that allows us to solve the multimodels obtained by applying the α– and β–monoscale-multimodel methods. In this paper we are interested in studying the convergence properties of the TTMA for the β–monoscale-multimodel methods for hydrodynamics-type problems.

Because of the practical importance of this algorithm, the establishment of its mathematical foundations is of crucial importance. The mathematical theory of such an algorithm started in [2, 3]. The analysis of the general TTMA for hydrodynamics-type applications remained open. We shall provide in this paper a complete analysis of such an algorithm. Our analysis is based on a general method we have introduced in [10]. Because of its practical importance we shall term it "the transmission multiplier method." We also use the local, global, and trace estimates we developed in [11, 12].

In section 2, we describe the α– and β–monoscale-multimodel methods for convection-diffusion problems and the TTMA that we propose for their solutions together with some applications in fluid mechanics. In section 3, we state the main local, global, and trace estimates of [11, 12] we shall need for the analysis of the TTMA. In

section 4, we study the convergence properties of the TTMA. We conclude this paper by some comments in section 5.

2. The α- and β-methods for convection-diffusion problems and the TTMA.

2.1. The convection-diffusion model. Let Ω be a connected bounded domain of $\mathbb{R}^n$, such that its boundary $\partial\Omega$ is Lipschitzian and Ω_l is a connected domain of $\mathbb{R}^n$ with $\Omega_l \subset \Omega$ (Figure 2.1). Let

$$\Gamma_b = \partial\Omega \cap \partial\Omega_l \quad \text{(internal boundary)},$$

$$\Gamma_i = \partial\Omega_l \cap \Omega \quad \text{(interface)},$$

$$\Gamma_\infty = \partial\Omega \backslash \Gamma_b \quad \text{(farfield boundary)}.$$

We denote by n the external unit normal vector to $\partial\Omega$ or $\partial\Omega_l$.

Let $v \in (L^\infty(\Omega))^n$ be a given velocity field of an inviscid incompressible flow such that

$$\begin{cases} \operatorname{div} v = 0 & \text{in} \quad \Omega, \\ v.n = 0 & \text{on} \quad \Gamma_b. \end{cases} \tag{2.1}$$

The model problem we want to solve is the following one:

$$\text{Find } \phi : \Omega \times (0,T) \to \mathbb{R} \text{ such that}$$

$$\begin{cases} \dfrac{\partial \phi}{\partial t} + \operatorname{div}(v\phi) - \nu\Delta\phi = 0 \ \text{ in } \ \Omega \times (0,T), \\ \phi = \phi^\infty \ \text{ on } \ \Gamma_\infty \times (0,T), \\ \phi = 0 \ \text{ on } \ \Gamma_b \times (0,T), \\ \phi(0) = \phi_0 \ \text{ in } \ \Omega, \end{cases} \tag{2.2}$$

where v is the velocity field given by (2.1) and ν is the diffusion coefficient. Assuming that $\phi_0 \in L^2(\Omega)$ and $\phi^\infty \in L^2(0,T; H^{1/2}(\Gamma_\infty))$, problem (2.2) has a unique solution $\phi \in L^2(0,T; H^1(\Omega))$. The corresponding stationary problem follows:

Find φ, a real valued function, defined on Ω and satisfying

$$\begin{cases} \operatorname{div}(v\varphi) - \nu\Delta\varphi = 0 \text{ in } \Omega, \\ \varphi = \varphi^\infty \text{ on } \Gamma_\infty, \\ \varphi = 0 \text{ on } \Gamma_b. \end{cases} \tag{2.3}$$

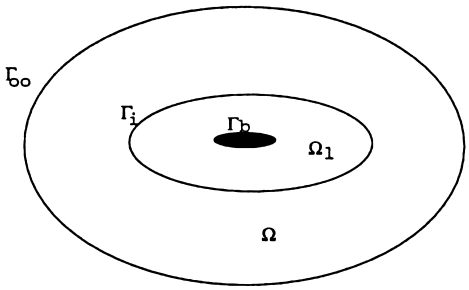

FIG. 2.1. *Description of the domain* Ω *and its splitting.*

2.2. The α- and β-methods for the convection-diffusion model. Let Ω_l be a domain of $\mathbb{R}^n$ such that $\Omega_l \subset \Omega$ (see Figure 2.1) and has as an external boundary Γ_i. The β–monoscale-multimodel method applied to the model problem consists in replacing the evolution problem (2.2) by the following evolution system:

Find ϕ (resp., ϕ_{loc}) : $\Omega \to \mathbb{R}$ (resp., $\Omega_l \to \mathbb{R}$) satisfying

$$\begin{cases} \dfrac{\partial \phi}{\partial t} + \operatorname{div}(v\phi) - \nu \Delta \phi = 0 \ \text{ in } \ \Omega \times (0,T), \\ \phi = \phi^{\infty} \ \text{ on } \ \Gamma_{\infty} \times (0,T), \\ \nu \dfrac{\partial \phi}{\partial n} = \nu \dfrac{\partial \phi_{loc}}{\partial n} \ \text{ on } \ \Gamma_b \times (0,T), \end{cases} \tag{2.4}$$

$$\begin{cases} \dfrac{\partial \phi_{loc}}{\partial t} + \operatorname{div}(v\phi_{loc}) - \nu \Delta \phi_{loc} = 0 \ \text{ in } \ \Omega_l \times (0,T), \\ \phi_{loc} = 0 \ \text{ on } \ \Gamma_b \times (0,T), \\ \phi_{loc} = \phi \ \text{ on } \ \Gamma_i \times (0,T), \end{cases} \tag{2.5}$$

$$\phi(0) = \phi_0 \ \text{ in } \ \Omega \ \ \phi_{loc}(0) = \phi_{0loc} \ \text{ in } \ \Omega_l. \tag{2.6}$$

The resulting coupled problem is referred to as the β–monoscale-multimodel problem for the convection-diffusion equations. We should notice here that this methodology yields coupled problems through transmission boundary conditions, which are obtained at the modeling level of the physical phenomena. Therefore this method *cannot and should not* be classified as a domain decomposition method.

REMARK 2.1. *The global problem has no no-slip boundary condition. This suppresses the boundary layer which appears at low viscosity and facilitates the numerical solution of this problem. The boundary layers are modeled by the local problem* (2.5), (2.6) *which are to be solved only on a small domain, with a very fine discretization if needed. This clearly indicates that our method here is not a domain decomposition method since the objective is to be able to handle phenomena such as boundary layers at the local level.*

REMARK 2.2. *The "Neumann" version of this method consists of replacing in* (2.5) *the boundary condition on* Γ_i *with the corresponding Neumann condition*

$$\frac{\partial \phi_{loc}}{\partial n} = \frac{\partial \phi}{\partial n} \ \text{ on } \ \Gamma_i.$$

REMARK 2.3. *If in* (2.4) *we replace* Ω *with* Ω_E *defined*

$$\Omega_E = \Omega \backslash \Omega_l$$

(in this case $\partial\Omega_E = \Gamma_\infty \cup \Gamma_i$*), we obtain the* α*–monoscale-multimodel problem for convection-diffusion equations.*

The asymptotic behavior of problems (2.4)–(2.6) for large time is given in the following theorem.

THEOREM 2.1. *The solution of the coupled problems* (2.4)–(2.6) *converges towards the solution of the stationary problem* (2.3) *as* t *goes to infinity.*

For the proof of this theorem we refer to [2].

REMARK 2.4. *Using the same method as in* [2] *we can prove similar theorems for the variant of our method mentioned in Remarks* 2.2 *and* 2.3.

2.3. TTMA and the main result. The TTMA is an algorithm that iterates back and forth between the local and global problem. For the β–monoscale-multimodel problem (2.4)–(2.6) this corresponds to a time integration scheme which yields the following semi-implicit algorithm:

- set $\phi^0_{loc} = \phi_0$ and $\phi^0 = \phi_0$;
- then, for $n \geq 0, \phi^n_{loc}$ and ϕ^n being known, solve successively

$$\text{(2.7)} \qquad \begin{cases} \dfrac{\phi^{n+1}_{loc} - \phi^n_{loc}}{\Delta t} + \operatorname{div}(v\phi^{n+1}_{loc}) - \nu\Delta\phi^{n+1}_{loc} = 0 \ \text{ in } \ \Omega_l, \\ \phi^{n+1}_{loc} = \phi^n \ \text{ on } \ \Gamma_i, \\ \phi^{n+1}_{loc} = 0 \ \text{ on } \ \Gamma_b, \end{cases}$$

$$\text{(2.8)} \qquad \begin{cases} \dfrac{\phi^{n+1} - \phi^n}{\Delta t} + \operatorname{div}(v\phi^{n+1}) - \nu\Delta\phi^{n+1} = 0 \ \text{ in } \ \Omega, \\ \phi^{n+1} = \phi^\infty \ \text{ on } \ \Gamma_\infty, \\ \nu\dfrac{\partial\phi^{n+1}}{\partial n} = \nu\dfrac{\partial\phi^{n+1}_{loc}}{\partial n} \ \text{ on } \ \Gamma_b. \end{cases}$$

REMARK 2.5. *We have a full decoupling between* (2.7) *and* (2.8)*. They can be solved by two independent solution techniques.*

REMARK 2.6. *The "Neumann" version of this method consists of replacing the Dirichlet boundary condition on* Γ_i *with the corresponding Neumann condition*

$$\frac{\partial\phi^{n+1}_{loc}}{\partial n} = \frac{\partial\phi^n}{\partial n} \ \text{ on } \ \Gamma_i.$$

The convergence properties of the resulting algorithm can be obtained using the same method developed in this paper.

REMARK 2.7. *The fully implicit version of this method consists of replacing the condition*

$$\phi^{n+1}_{loc} = \phi^n \ \text{ on } \ \Gamma_i$$

(resp., $\frac{\partial\phi^{n+1}_{loc}}{\partial n} = \frac{\partial\phi^n}{\partial n}$ *on* Γ_i*) with the condition*

$$\phi^{n+1}_{loc} = \phi^{n+1} \ \text{ on } \ \Gamma_i$$

(resp., $\frac{\partial \phi_{loc}^{n+1}}{\partial n} = \frac{\partial \phi^{n+1}}{\partial n}$ *on* Γ_i*). Since both coupling conditions are implicit we proposed applying a fixed-point iteration to each time step. The resulting algorithm has been studied in* [2, 3] *using the local, global, and trace estimates developed by the author in* [11]. *The semi-implicit algorithm studied here leads directly to uncoupled problems in each time step; see Remark* 2.5. *The analysis of the resulting algorithm is more technical and relies on the methods we introduced in* [10, 12].

REMARK 2.8. *If in* (2.8) *we replace* Ω *with* Ω_E *defined as*

$$\Omega_E = \Omega \backslash \Omega_l$$

(in this case $\partial\Omega_E = \Gamma_\infty \cup \Gamma_i$*), we obtain the TTMA for the* α*–monoscale-multimodel problem. The convergence properties of the resulting algorithm can be obtained using similar methods as those developed in this paper.*

We state now the main result of this paper.

THEOREM 2.2. *Assume that* $\phi^{(0)} \in L^n(\Omega) \cup L^\infty(\Omega)$ *and* $\phi_l^{(0)} \in L^n(\Omega_l) \cup L^\infty(\Omega_l)$. *For* τ *sufficiently small and for all choices of* Ω_l*, the solution of* (2.7)–(2.8) *converges linearly in* $H^1(\Omega)$ *to the solution of the stationary problem* (2.3).

Before we prove this theorem, we shall give in the next subsection some important applications of the α- and β-methods in fluid mechanics.

2.4. Applications to fluid mechanics. We describe in this subsection some important applications of the α- and β-methods in fluid mechanics. More details about these applications can be found in [8, 9].

Let us consider the compressible Navier–Stokes equations which we formally write either as

$$\frac{\partial W}{\partial t} + \operatorname{div}[F(W)] = 0 \quad \text{on} \quad \Omega \text{ (conservative form)}$$

or as

$$\frac{\partial U}{\partial t} + T(U) + D(U) = 0 \quad \text{on} \quad \Omega \text{ (nonconservative form)},$$

with $W = (\rho, \rho v, \rho E)$ and $U = (\rho, v, \theta)$ the conservative and nonconservative variables, $F = F_C + F_D$ the total flux (convective and viscous part), T and D the convective and viscous terms in the nonconservative form of the Navier–Stokes equations. The problem consists of computing a steady solution of these equations, with boundary conditions

$$\begin{gathered} \rho v, \rho E \text{ given on } \Gamma_\infty \text{ (exterior limit of the domain)}, \\ \rho \text{ given on } \Gamma_\infty \cap \{x, v(x) \cdot n \le 0\} \text{ (inflow)}, \\ v = 0 \text{ on the body } \Gamma_b \text{ (no-slip)}, \\ \theta = \theta_0 \text{ on the body } \Gamma_b. \end{gathered}$$

The global numerical treatment of these equations faces the following difficulties:

(i) In a conservative calculation, the numerical viscosity of the discretization scheme interferes with the physical viscosity and for a mesh of reasonable size leads to an overprediction of the boundary layer. Moreover, no-slip boundary conditions on the body are difficult to handle for many TVD schemes.

(ii) In a nonconservative calculation, the correct calculation of a shock requires locally a very fine grid if we want to satisfy the Rankine–Hugoniot conditions.

In this framework, our strategy is to couple a *global conservative scheme*, defined on the whole domain and based, for example, on a finite volume space discretization [1], and *a local approximation*, defined in the neighborhood of the body and based, for example, on a mixed finite element approximation of the nonconservative Navier–Stokes equations [6].

The coupling problem corresponds then to solving the following systems. In Ω, we solve the conservative Navier–Stokes equations

$$\frac{\partial W}{\partial t} + \operatorname{div}[F(W)] = 0 \text{ in } \Omega,$$
$$F(W)\cdot n = \begin{bmatrix} 0 \\ n\cdot\sigma(W)\cdot n \\ \tau\cdot\sigma(U_{loc})\cdot n \\ -q(U_{loc})\cdot n \end{bmatrix} \quad \text{on the wall,}$$
$$W = \text{given imposed value on } \Gamma_\infty.$$

In Ω_l, we solve the nonconservative Navier–Stokes equations

$$\frac{\partial U}{\partial t} + T(U) + D(U) = 0 \text{ in } \Omega,$$
$$U_{loc} = 0 \text{ on } \Gamma_b,$$
$$U_{loc} = W \text{ on } \Gamma_i.$$

Above, $n.\sigma.n$ and $\tau.\sigma.n$, respectively, denote the normal and the tangential forces exerted by the body on the flow, with n the unit normal vector to the wall oriented towards its interior. Notice that in the global conservative problem the matching conditions are of Neumann type as in (2.4), while for the local nonconservative problem these matching boundary conditions are of Dirichlet type as in (2.8) (but with an explicit boundary condition on Γ_i). From this, we see how it is possible to generalize algorithms (2.7)–(2.8) to a more complex system, such as the Navier–Stokes equations.

This coupling provides an efficient strategy to circumvent the difficulties mentioned in (i) and (ii) at the beginning of this subsection. These methods offer an easy way of supplementing and testing a large variety of boundary conditions. Moreover, in the local domain the model can be chosen to handle phenomena such as boundary layers and turbulence and can incorporate models of chemistry. We have already proved the validity of these methods and their superiority to classical methods in many (important) real life applications. More details about this type of coupling can be found in [8, 9].

3. Preliminary results. In this section we state local, global, and trace estimates for the solutions of elliptic equations. They are obtained by the author in [11, 12]. They play an important role in the proof of the main result of this paper. The first estimates are obtained for the solution of the following Dirichlet–Neumann problem:

$$\mathcal{L}u = -\nu\Delta u + v\cdot\nabla u + \frac{1}{\tau}u = \frac{1}{\tau}f \text{ in } \Omega, \tag{3.1}$$
$$u = 0 \text{ on } \Gamma_\infty, \tag{3.2}$$
$$\frac{\partial u}{\partial n} = g \text{ on } \Gamma_b, \tag{3.3}$$

where the function g is given in $H^{-1/2}(\Gamma_b)$, the coefficient τ is strictly positive, and ν is the diffusion coefficient. We assume that $f \in L^n(\Omega) \cap L^\infty(\Omega)$ and the coefficients ν and τ satisfy the relation

$$\nu\tau \le \frac{1}{2} \text{ and } \tau \le 1. \tag{3.4}$$

This hypothesis is neither necessary nor restrictive (see [11, 12]). Let $d > 0$ denote the distance between Γ_b and Γ_i. Let β be a real number such that $0 < \beta < 3\sqrt{\nu}/d$, and set $k = \beta/(\nu\sqrt{\tau})$. In the proof of Theorem 2.2 no additional restrictions on β were required. Thus, the inequality $d < 3\sqrt{\nu}/\beta$ relating the local domain Ω_l to the viscosity ν shows that all choices of Ω_l are possible. For small viscosity the domain Ω_l can be chosen small.

We have the following global H^1 estimate of the solution u of the Dirichlet–Neumann problem (3.1)–(3.3) in terms of the boundary data g and the data f.

LEMMA 3.1. *There exists a constant c_0 such that*

$$\|u\|_{1,\Omega} \le c_0\|g\|_{-1/2,\Gamma_b} + \frac{1}{\nu\tau}\|f\|_{0,\Omega}. \tag{3.5}$$

We now state the trace estimate.

THEOREM 3.1. *The solution u of the Dirichlet–Neumann problem* (3.1)–(3.3) *satisfies*

$$\|u\|_{1/2,\Gamma_i} \le C_1\sqrt{d}\left(d + \frac{\|v\|_\infty}{\nu}\right)^{1/2} \exp\left(-kd^2/36\right) \times \left[\|g\|_{-1/2,\Gamma_b} + \frac{1}{\nu\tau}\|f\|_{0,\Omega} + \frac{d}{\nu\tau}\|f\|_{L^n(\Omega)} + 2\|f\|_{\infty,\Omega}\right] + \frac{C_2}{\tau\sqrt{\nu}}\|f\|_{0,\Omega},$$

where C_1 and C_2 are constants, with C_1 depending only on n and $(\|V\|_\infty d/\nu)^2$ but not on τ.

We now consider the following Dirichlet–Dirichlet problem:

$$\mathcal{L}u_l = -\nu\Delta u_l + v \cdot \nabla u_l + \frac{1}{\tau}u_l = \frac{1}{\tau}f_l \text{ in } \Omega_l, \tag{3.6}$$

$$u_l = h \text{ on } \Gamma_i, \tag{3.7}$$

$$u_l = 0 \text{ on } \Gamma_b, \tag{3.8}$$

where the function h is given in $H^{1/2}(\Gamma_i)$, the coefficient τ is strictly positive, and ν is the diffusion coefficient. We assume that $f_l \in L^n(\Omega_l) \cap L^\infty(\Omega_l)$. The velocity field v is given by (2.1). Let Γ_V be the center surface of Ω_l defined as the surface whose distance from Γ_b and Γ_i is at least $d/2$. Let Ω_{il} be the subdomain of Ω_l of width $d/6$ centered at Γ_V (see Figure 3.1).

We have the following global and local estimate of the solution u_l of the Dirichlet–Dirichlet problem (3.6)–(3.8).

LEMMA 3.2. *The solution u_l of the Dirichlet–Dirichlet problem* (3.6)–(3.8) *satisfies*

$$\|u_l\|_{1,\Omega_l} \le \left[1 + \frac{c_1}{\nu}\|v\|_{\infty,\Omega_l} + \frac{1}{\nu\tau}\right]\|h\|_{1/2,\Gamma_i} + \frac{c_1}{\nu\tau}\|f_l\|_{0,\Omega_l}. \tag{3.9}$$

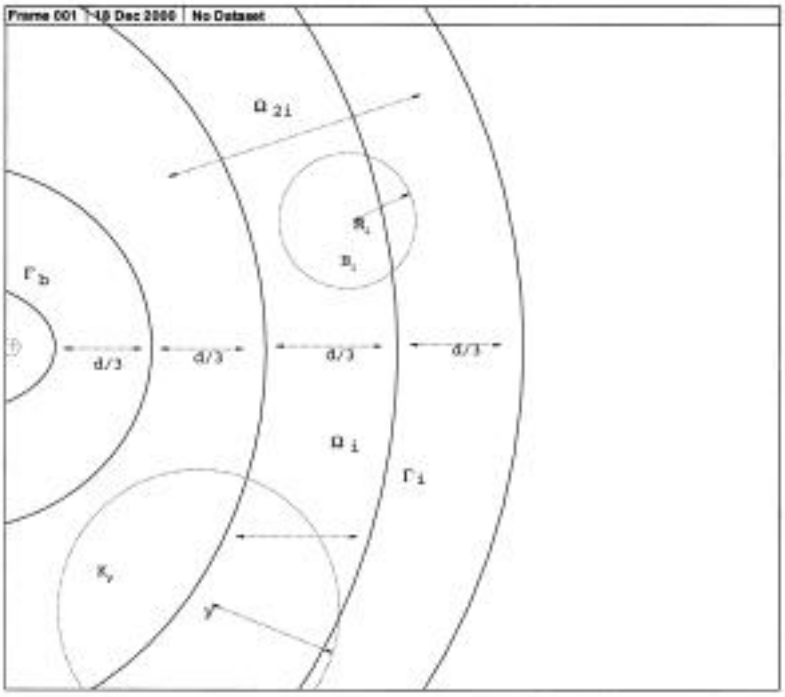

FIG. 3.1. *Description of the domain Ω_l and the splitting used in the majorization of the local solution.*

LEMMA 3.3. *There exists a constant c_2 such that*

$$\|u_l\|_{\infty,\Omega_{il}} \le c_2\|u_l\|_{0,\Omega_l} + c_2\frac{d}{\nu}\|f_l\|_{L^n(\Omega_l)}, \tag{3.10}$$

where c_2 depends only on n and $(\|V\|_\infty d/\nu)^2$.

We now state the trace estimate.

THEOREM 3.2. *The solution u_l of the Dirichlet–Dirichlet problem* (3.6)–(3.8) *satisfies*

$$\begin{aligned}\|\partial u_l/\partial n\|_{-1/2,\Gamma_b} \le{}& C_1\alpha_1^2\alpha_2\exp(-kd^2/36)\|h\|_{1/2,\Gamma_i}\\ &+ C_1\alpha_1\alpha_2\exp(-kd^2/36)\frac{d}{\nu\tau}\|f_l\|_{L^n(\Omega_l)}\\ &+ \alpha_1\left(C_1\alpha_2\exp(-kd^2/36)\frac{1}{\nu\tau} + C_2\frac{1}{\tau\sqrt{\nu}}\right)\|f_l\|_{0,\Omega_l}\\ &+ C_1\alpha_1\alpha_2\exp(-kd^2/36)\|f_l\|_{\infty,\Omega_{il}},\end{aligned}$$

where C_1 and C_2 are constants with C_1 depending only on n and $(n\|v\|_\infty d/\nu)^2$, $\alpha_1 = [1 + \frac{1}{\nu}\|v\|_{\infty,\Omega_l} + \frac{1}{\nu\tau}]$, and $\alpha_2 = \sqrt{d}(d + \frac{\|v\|_\infty}{\nu})^{1/2}$.

For the proof of these local, global, and trace estimates we refer to [12].

4. Proof of the main result. The proof of this theorem is based in a crucial manner on the method we have introduced in [10] and the local, global, and trace

estimates we developed in [12]. This proof is divided into four steps. In the first step we use the method we introduced in [10]. We then obtain a newly transformed problem. In the second step we give estimates of the boundary terms using the local, global, and trace estimates of the previous section. In the third step we study the transformed problem. In the last step we conclude the proof of our theorem.

Step 1. Use of the method of [10]. Without loss of generality, we may assume that $\phi_\infty = 0$ on Γ_∞. Setting $u = \phi^{n+1}$, $u_l = \phi_{loc}^{n+1}$, $f = \phi^n$, $f_l = \phi_{loc}^n$, $f_{lm} = \phi_{loc}^{n-1}$, $\tau = \Delta t$, and $a = \frac{1}{\tau}$ the algorithm in system (2.7)–(2.8) becomes the following:

For $n \geq 0$, f_l and f being known, solve

$$\begin{cases} a(u-f) + \operatorname{div}(vu) - \nu\Delta u = 0 \quad \text{in} \quad \Omega, \\ u = 0 \quad \text{on} \quad \Gamma_\infty, \\ \nu\dfrac{\partial u}{\partial n} = \nu\dfrac{\partial u_l}{\partial n} \quad \text{on} \quad \Gamma_b, \end{cases} \tag{4.1}$$

$$\begin{cases} a(u_l - f_l) + \operatorname{div}(vu_l) - \nu\Delta u_l = 0 \quad \text{in} \quad \Omega_l, \\ u_l = f \quad \text{on} \quad \Gamma_i, \\ u_l = 0 \quad \text{on} \quad \Gamma_b. \end{cases} \tag{4.2}$$

Let φ_1 and φ_2 be two positive functions defined, respectively, on Ω, Ω_l, to be precisely determined later. Multiplying the first equation in (4.1) by $\varphi_1 u$ and using Green's formula, we obtain

$$\int a(u-f)\varphi_1 u + \int \operatorname{div}(vu)\varphi_1 u - \nu\int \Delta u\varphi_1 u = 0. \tag{4.3}$$

Since the vector field v is given by (2.1), we have, using Green's formula,

$$\int \operatorname{div}(vu)\varphi_1 u = -\frac{1}{2}\int u^2 \nabla\varphi_1 \cdot v + \frac{1}{2}\int_\Gamma v\cdot n\varphi_1 u^2, \tag{4.4}$$

where $\Gamma = \partial\Omega$. We also have, using Green's formula,

$$\int \Delta u\varphi_1 u = -\int \nabla u\nabla\varphi_1 u - \int \varphi_1|\nabla u|^2 + \int_\Gamma \frac{\partial u}{\partial n}\varphi_1 u. \tag{4.5}$$

Combining (4.3), (4.4), and (4.5), we obtain

$$\begin{aligned} &\int \left(a\varphi_1 - \frac{1}{2}\nabla\varphi_1\cdot v\right)u^2 + \nu\int u\nabla u\cdot\nabla\varphi_1 + \nu\int \varphi_1|\nabla u|^2 \\ &+ \frac{1}{2}\int_\Gamma v\cdot n\varphi_1 u^2 - \nu\int_\Gamma \frac{\partial u}{\partial n}\varphi_1 u = a\int f\varphi_1 u. \end{aligned} \tag{4.6}$$

Similarly, we obtain

$$\begin{aligned} &\int \left(a\varphi_2 - \frac{1}{2}\nabla\varphi_2\cdot v\right)u_l^2 + \nu\int u_l\nabla u_l\cdot\nabla\varphi_2 + \int \varphi_2|\nabla u_l|^2 \\ &+ \frac{1}{2}\int_{\Gamma_l} v\cdot n\varphi_2 u_l^2 - \nu\int_{\Gamma_l}\frac{\partial u_l}{\partial n}\varphi_2 u_l = a\int f_l\varphi_2 u_l, \end{aligned} \tag{4.7}$$

where $\Gamma_l = \partial\Omega_l$.

Combining (4.6) and (4.7), we obtain

$$\begin{aligned}
&\int \left(a\varphi_1 - \frac{1}{2}\nabla\varphi_1 \cdot v\right) u^2 + \int \left(a\varphi_2 - \frac{1}{2}\nabla\varphi_2 \cdot v\right) u_l^2 \\
&+ \nu \int u\nabla u \cdot \nabla\varphi_1 + \nu \int \varphi_1 |\nabla u|^2 + \nu \int u_l \nabla u_l \cdot \nabla\varphi_2 + \nu \int \varphi_2 |\nabla u_l|^2 \\
&+ \frac{1}{2}\int_\Gamma v \cdot n\varphi_1 u^2 - \nu \int_\Gamma \frac{\partial u}{\partial n}\varphi_1 u + \frac{1}{2}\int_{\Gamma_l} v \cdot n\varphi_2 u_l^2 - \nu \int_{\Gamma_l} \frac{\partial u_l}{\partial n}\varphi_2 u_l \\
&= a\int f\varphi_1 u + a\int f_l \varphi_2 u_l. \qquad (4.8)
\end{aligned}$$

Using the coupling boundary conditions, we obtain

$$\begin{aligned}
&\frac{1}{2}\int_\Gamma v \cdot n\varphi_1 u^2 - \nu \int_\Gamma \frac{\partial u}{\partial n}\varphi_1 u + \frac{1}{2}\int_{\Gamma_l} v \cdot n\varphi_2 u_l^2 - \nu \int_{\Gamma_l} \frac{\partial u_l}{\partial n}\varphi_2 u_l \\
&\quad = \frac{1}{2}\int_{\Gamma_b} v \cdot n\varphi_1 u^2 - \nu \int_{\Gamma_b} \frac{\partial u}{\partial n}\varphi_1 u + \frac{1}{2}\int_{\Gamma_i} v \cdot n\varphi_2 u_l^2 - \nu \int_{\Gamma_i} \frac{\partial u_l}{\partial n}\varphi_2 u_l \\
&\quad = -\nu \int_{\Gamma_b} \frac{\partial u_l}{\partial n}\varphi_1 u + \frac{1}{2}\int_{\Gamma_i} v \cdot n\varphi_2 f^2 - \nu \int_{\Gamma_i} \frac{\partial u_l}{\partial n}\varphi_2 f \\
&\quad = BC_1 + BC_2 + BC_3. \qquad (4.9)
\end{aligned}$$

Combining (4.8) and (4.9) and using Cauchy–Schwarz inequality, we obtain

$$\begin{aligned}
&\int \left(\frac{a}{2}\varphi_1 - \frac{1}{2}\nabla\varphi_1 \cdot v\right) u^2 + \int \left(\frac{a}{2}\varphi_2 - \frac{1}{2}\nabla\varphi_2 \cdot v\right) u_l^2 + \nu \int u\nabla u \cdot \nabla\varphi_1 \\
&+ \nu \int \varphi_1 |\nabla u|^2 + \nu \int u_l \nabla u_l \cdot \nabla\varphi_2 + \nu \int \varphi_2 |\nabla u_l|^2 + \Sigma BC_i \\
&\leq \frac{a}{2}\int \varphi_1 f^2 + \frac{a}{2}\int \varphi_2 f_l^2. \qquad (4.10)
\end{aligned}$$

Using Green's formula we obtain

$$\int \nabla u \cdot \nabla\varphi_1 u = -\frac{1}{2}\int u^2 \Delta\varphi_1 + \frac{1}{2}\int_\Gamma u^2 \frac{\partial\varphi_1}{\partial n}. \qquad (4.11)$$

Similarly, we obtain

$$\int \nabla u_l \cdot \nabla\varphi_1 u_l = -\frac{1}{2}\int u_l^2 \Delta\varphi_1 + \frac{1}{2}\int_\Gamma u_l^2 \frac{\partial\varphi_1}{\partial n}. \qquad (4.12)$$

Equation (4.10) then becomes

$$\begin{aligned}
&\int \left(\frac{a}{2}\varphi_1 - \frac{1}{2}\nabla\varphi_1 \cdot v\right) u^2 + \int \left(\frac{a}{2}\varphi_2 - \frac{1}{2}\nabla\varphi_2 \cdot v\right) u_l^2 + \nu \int |\nabla u|^2 \varphi_1 \\
&- \frac{\nu}{2}\int u^2 \Delta\varphi_1 + \frac{\nu}{2}\int_\Gamma u^2 \frac{\partial\varphi_1}{\partial n} + \nu \int |\nabla u_l|^2 \varphi_2 \\
&- \frac{\nu}{2}\int u_l^2 \Delta\varphi_2 + \frac{\nu}{2}\int_{\Gamma_l} u_l^2 \frac{\partial\varphi_2}{\partial n} + \Sigma BC_i \\
&\leq \frac{a}{2}\int \varphi_1 f^2 + \frac{a}{2}\int \varphi_2 f_l^2. \qquad (4.13)
\end{aligned}$$

Using the boundary conditions, (4.13) becomes

$$\begin{aligned}&\frac{1}{2}\int(-\nu\Delta\varphi_1 - v\cdot\nabla\varphi_1 + a\varphi_1)u^2 + \frac{1}{2}\int(-\nu\Delta\varphi_2 - v\cdot\nabla\varphi_2 + a\varphi_2)u_l^2\\ &+\frac{\nu}{2}\int_{\Gamma_b} u^2\frac{\partial\varphi_1}{\partial n} + \frac{\nu}{2}\int_{\Gamma_i} u_l^2\frac{\partial\varphi_2}{\partial n} + \nu\int|\nabla u|^2\varphi_1 + \nu\int|\nabla u_l|^2\varphi_2 + \Sigma BC_i\\ &\qquad\le \frac{a}{2}\int\varphi_1 f^2 + \frac{a}{2}\int\varphi_2 f_l^2.\end{aligned}\tag{4.14}$$

Step 2. Use of the local, global, and trace estimates of [11, 12]. We shall give here estimates of the boundary terms in (4.8). These estimates are based on the local, global, and trace estimates we obtained in [11, 12].

Estimate of BC_1. Using the coupling boundary conditions and Cauchy–Schwarz inequality, we obtain

$$\begin{aligned}|BC_1| &= \nu\left|\int_{\Gamma_b}\frac{\partial u_l}{\partial n}\varphi_1 u\right|\\ &\le \nu\|\varphi_1|_{\Gamma_b}\|_\infty\|u\|_{\frac{1}{2},\Gamma_b}\left\|\frac{\partial u_l}{\partial n}\right\|_{-\frac{1}{2},\Gamma_b}\\ &\le \nu\|\varphi_1|_{\Gamma_b}\|_\infty\left(\|u\|^2_{\frac{1}{2},\Gamma_b} + \left\|\frac{\partial u_l}{\partial n}\right\|^2_{-\frac{1}{2},\Gamma_b}\right).\end{aligned}$$

Using the trace theorem and Lemma 3.1, we obtain

$$\begin{aligned}\|u\|_{1/2,\Gamma_b} &\le C(\Omega)\|u\|_{1,\Omega}\\ &\le c_0 C(\Omega)\left(\|g\|_{-1/2,\Gamma_b} + \frac{1}{\nu\tau}\|f\|_{0,\Omega}\right),\end{aligned}$$

where $g = \frac{\partial u}{\partial n}$. Using now the coupling boundary conditions in (4.1) and Theorem 3.2, we obtain

$$\begin{aligned}\|g\|_{-1/2,\Gamma_b} &= \|\partial u_l/\partial n\|_{-1/2,\Gamma_b}\\ &\le \beta_1\|h\|_{1/2,\Gamma_i} + \beta_2\|f_l\|_{0,\Omega_l} + \beta_3\|f_l\|_{L^n(\Omega_l)} + \beta_4\|f_l\|_{\infty,\Omega_{il}},\end{aligned}$$

where

$$\begin{aligned}\beta_1 &= C_1\alpha_1^2\alpha_2\exp(-kd^2/36),\\ \beta_2 &= C_1\alpha_1\alpha_2\exp(-kd^2/36)\frac{1}{\nu\tau} + C_2\alpha_1\frac{1}{\tau\sqrt{\nu}},\\ \beta_3 &= C_1\alpha_1\alpha_2\exp(-kd^2/36)\frac{d}{\nu\tau},\\ \beta_4 &= C_1\alpha_1\alpha_2\exp(-kd^2/36),\\ \alpha_1 &= 1 + \frac{1}{\nu}\|v\|_{\infty,\Omega_l} + \frac{1}{\nu\tau},\\ \alpha_2 &= \sqrt{d}\left(d + \frac{\|v\|_\infty}{\nu}\right)^{1/2}.\end{aligned}$$

Using now the fact that $h = u_l = f$ on Γ_i and the trace theorem, we obtain

$$\begin{aligned}\|\partial u_l/\partial n\|_{-1/2,\Gamma_b} &\le \beta_1\|f\|_{1/2,\Gamma_i} + \beta_2\|f_l\|_0 + \beta_3\|f_l\|_{L^n(\Omega_l)} + \beta_4\|f_l\|_{\infty,\Omega_i}\\ &\le C(\Omega)\beta_1\|f\|_{1,\Omega} + \beta_2\|f_l\|_{0,\Omega_l} + \beta_3\|f_l\|_{L^n(\Omega_l)} + \beta_4\|f_l\|_{\infty,\Omega_{il}}.\end{aligned}$$

Therefore, we have

$$
\begin{aligned}
|BC_1| &\le \nu\|\varphi_1|_{\Gamma_b}\|_\infty \left(\|u\|^2_{1/2,\Gamma_b} + \left\| \frac{\partial u_l}{\partial n} \right\|^2_{-1/2,\Gamma_b} \right) \\
&\le C(\Omega)\nu\|\varphi_1|_{\Gamma_b}\|_\infty \left(\|u\|^2_{1,\Omega} + \left\| \frac{\partial u_l}{\partial n} \right\|^2_{-1/2,\Gamma_b} \right) \\
&\le c_0 C(\Omega)\nu\|\varphi_1|_{\Gamma_b}\|_\infty \left(\|g\|^2_{-1/2,\Gamma_b} + \frac{1}{(\nu\tau)^2}\|f\|^2_{0,\Omega} + \left\| \frac{\partial u_l}{\partial n} \right\|^2_{-1/2,\Gamma_b} \right) \\
&\le C_{\varphi_1}\beta_1^2\|f\|^2_{1,\Omega} + C_{\varphi_1}\beta_2^2\|f_l\|^2_{0,\Omega_l} + C_{\varphi_1}\beta_3^2\|f_l\|^2_{L^n(\Omega_l)} + C_{\varphi_1}\beta_4^2\|f_l\|^2_{\infty,\Omega_{il}} \\
&\quad + C_{\varphi_1}\frac{1}{(\nu\tau)^2}\|f\|^2_{0,\Omega}, \qquad (4.15)
\end{aligned}
$$

where

$$
C_{\varphi_1} = c_0 C(\Omega)\nu\|\varphi_1|_{\Gamma_b}\|_\infty. \qquad (4.16)
$$

Estimate of BC_2. For the term BC_2 we have, using the fact that $u_l = f$ on Γ_i and the trace theorem,

$$
\begin{aligned}
|BC_2| &= \frac{1}{2}\left| \int_{\Gamma_i} v\cdot n\varphi_2 f^2 \right| \\
&\le \frac{1}{2}\|v\|_\infty\|\varphi_2|_{\Gamma_i}\|_\infty\|f\|^2_{\frac{1}{2},\Gamma_i} \\
&\le C(\Omega)\|v\|_\infty\|\varphi_2|_{\Gamma_i}\|_\infty\|f\|^2_{1,\Omega} \\
&\le C_v\|f\|^2_{1,\Omega}, \qquad (4.17)
\end{aligned}
$$

where

$$
C_v = C(\Omega)\|v\|_\infty\|\varphi_2|_{\Gamma_i}\|_\infty.
$$

Estimate of BC_3. Finally to get an estimate of BC_3 we proceed as follows:

$$
\begin{aligned}
|BC_3| &= \nu\left| \int_{\Gamma_i} \frac{\partial u_l}{\partial n}\varphi_2 f \right| \\
&\le \nu\|\varphi_2|_{\Gamma_i}\|_\infty\|f\|_{\frac{1}{2},\Gamma_i}\left\| \frac{\partial u_l}{\partial n} \right\|_{-\frac{1}{2},\Gamma_i}.
\end{aligned}
$$

The term $\|\partial u_l/\partial n\|_{-1/2,\Gamma_i}$ is estimated as follows. Using the weak formulation of problem (4.2), (2.1), and the boundary conditions in (4.2), we obtain

$$
\int_{\Gamma_i} \frac{\partial u_l}{\partial n} w = \int_{\Omega_l} \nabla u_l \nabla w + \frac{1}{\nu}\int_{\Omega_l} wv\cdot\nabla u_l - \frac{1}{\nu\tau}\int_{\Omega_l} f_l w + \frac{1}{\nu\tau}\int_{\Omega_l} u_l w,
$$

where $w \in H^1(\Omega_l)$ with $w = 0$ on Γ_b. Using the trace theorem and (2.1), we obtain

$$
\left| \int_{\Gamma_i} \frac{\partial u_l}{\partial n} w \right| \le \left(\left(1 + \frac{1}{\nu}\|v\|_{\infty,\Omega_l} \right)\|\nabla u_l\|_{0,\Omega_l} + \frac{1}{\nu\tau}\|f_l\|_{0,\Omega_l} + \frac{1}{\nu\tau}\|u_l\|_{0,\Omega_l} \right)\|w\|_{1,\Omega_l}.
$$

Therefore, we have

$$\left\|\frac{\partial u_l}{\partial n}\right\|_{-1/2,\Gamma_i} \le \left(1+\frac{1}{\nu}\|v\|_{\infty,\Omega_l}\right)\|\nabla u_l\|_{0,\Omega_l} + \frac{1}{\nu\tau}\|u_l\|_{0,\Omega_l} + \frac{1}{\nu\tau}\|f_l\|_{0,\Omega_l}$$

$$\le \alpha_1\|u_l\|_{1,\Omega_l} + \frac{1}{\nu\tau}\|f_l\|_{0,\Omega_l}. \tag{4.18}$$

Moreover, using Lemma 3.2 and the trace theorem, we obtain

$$\begin{aligned}\|u_l\|_{1,\Omega_l} &\le c_1\alpha_1\|h\|_{1/2,\Gamma_i} + \frac{c_1}{\nu\tau}\|f_l\|_{0,\Omega_l}\\ &\le c_1\alpha_1\|f\|_{1/2,\Gamma_i} + \frac{c_1}{\nu\tau}\|f_l\|_{0,\Omega_l}\\ &\le C(\Omega)c_1\alpha_1\|f\|_{1,\Omega} + \frac{c_1}{\nu\tau}\|f_l\|_{0,\Omega_l}.\end{aligned}$$

Hence we obtain

$$\begin{aligned}|BC_3| &\le C(\Omega)\nu\|\varphi_2|_{\Gamma_i}\|_\infty\alpha_1(\|u_l\|_{1,\Omega_l} + \|f_l\|_{0,\Omega_l})\|f\|_{1,\Omega}\\ &\le C(\Omega)\nu\|\varphi_2|_{\Gamma_i}\|_\infty\alpha_1^2c_1(\|f\|_{1,\Omega}^2 + \|f_l\|_{0,\Omega_l}^2)\\ &\le \alpha_3(\|f\|_{1,\Omega}^2 + \|f_l\|_{0,\Omega_l}^2),\end{aligned} \tag{4.19}$$

where

$$\alpha_3 = C(\Omega)\nu\|\varphi_2|_{\Gamma_i}\|_\infty\alpha_1^2c_1.$$

Estimate of $\Sigma|BC_i|$. Combining (4.15), (4.17), and (4.19), we obtain

$$\Sigma|BC_i| \le (C_{\varphi_1}\beta_1^2 + C_v + \alpha_3)\|f\|_{1,\Omega}^2 + (C_{\varphi_1}\beta_2^2 + \alpha_3)\|f_l\|_{0,\Omega_l}^2 + C_{\varphi_1}\beta_3^2\|f_l\|_{L^n(\Omega_l)}^2$$

$$+ C_{\varphi_1}\beta_4^2\|f_l\|_{\infty,\Omega_{il}}^2 + C_{\varphi_1}\frac{1}{(\nu\tau)^2}\|f\|_{0,\Omega}^2. \tag{4.20}$$

To proceed further we need to give an estimate of $\|f_l\|_{L^n(\Omega_l)}$ and $\|f_l\|_{\infty,\Omega_{il}}$. We use the Gagliardo–Nirenberg interpolation inequality (see, for example, [4] and references therein); we obtain for $n \ge 2$

$$\|f_l\|_{L^n(\Omega_l)} \le \epsilon_1\|f_l\|_{1,\Omega_l} + C_{\epsilon_1}\|f_l\|_{0,\Omega_l}. \tag{4.21}$$

Using now Lemma 3.3 and (4.21), we obtain

$$\begin{aligned}\|f_l\|_{\infty,\Omega_{il}} &\le c_2\|f_l\|_{0,\Omega_l} + c_2\frac{d}{\nu\tau}\|f_{lm}\|_{L^n(\Omega_l)}\\ &\le c_2\|f_l\|_{0,\Omega_l} + c_2\frac{d}{\nu\tau}(\epsilon_1\|f_{lm}\|_{1,\Omega_l} + C_{\epsilon_1}\|f_{lm}\|_{0,\Omega_l}).\end{aligned} \tag{4.22}$$

Combining (4.20), (4.21), and (4.22) we obtain

$$
\begin{aligned}
\Sigma|BC_i| &\le (C_{\varphi_1}\beta_1^2 + C_v + \alpha_3)\|f\|_{1,\Omega}^2 + (C_{\varphi_1}\beta_2^2 + \alpha_3)\|f_l\|_{0,\Omega_l}^2 \\
&\quad + C_{\varphi_1}\beta_3^2({\epsilon_1}^2\|f_l\|_{1,\Omega_l}^2 + C_{\epsilon_1}\|f_l\|_{0,\Omega_l}^2) \\
&\quad + c_2 C_{\varphi_1}\beta_4^2\left(\|f_l\|_{0,\Omega_l}^2 + \left(\frac{d}{\nu\tau}\right)^2({\epsilon_1}^2\|f_{lm}\|_{1,\Omega_l}^2 + C_{\epsilon_1}\|f_{lm}\|_{0,\Omega_l}^2)\right) \\
&\quad + C_{\varphi_1}\frac{1}{(\nu\tau)^2}\|f\|_{0,\Omega}^2 \\
&\le (C_{\varphi_1}\beta_1^2 + C_v + \alpha_3)\|\nabla f\|_{0,\Omega}^2 + \left[(C_{\varphi_1}\beta_1^2 + C_v + \alpha_3) + C_{\varphi_1}\frac{1}{(\nu\tau)^2}\right]\|f\|_{0,\Omega}^2 \\
&\quad + C_{\varphi_1}\beta_3^2{\epsilon_1}^2\|\nabla f_l\|_{0,\Omega_l}^2 + [C_{\varphi_1}\beta_3^2({\epsilon_1}^2 + C_{\epsilon_1}) + (C_{\varphi_1}\beta_2^2 + \alpha_3) + \alpha_2 C_{\varphi_1}\beta_4^2]\|f_l\|_{0,\Omega_l}^2 \\
&\quad + c_2 C_{\varphi_1}\beta_4^2\left(\frac{d}{\nu\tau}\right)^2{\epsilon_1}^2\|\nabla f_{lm}\|_{0,\Omega_l}^2 + c_2 C_{\varphi_1}\beta_4^2\left(\frac{d}{\nu\tau}\right)^2(\epsilon_1^2 + C_{\epsilon_1})\|f_{lm}\|_{0,\Omega_l}^2 \\
&\le \delta_1\|\nabla f\|_{0,\Omega}^2 + \delta_1'\|f\|_{0,\Omega}^2 + \delta_2\|\nabla f_l\|_{0,\Omega_l}^2 + \delta_3\|f_l\|_{0,\Omega_l}^2 + \delta_4\|f_{lm}\|_{0,\Omega_l}^2 \\
&\quad + \delta_5\|\nabla f_{lm}\|_{0,\Omega_l}^2, \qquad (4.23)
\end{aligned}
$$

where

$$
\begin{aligned}
\delta_1 &= C_{\varphi_1}\beta_1^2 + C_v + \alpha_3, \\
\delta_1' &= (C_{\varphi_1}\beta_1^2 + C_v + \alpha_3) + C_{\varphi_1}\frac{1}{(\nu\tau)^2}, \\
\delta_2 &= C_{\varphi_1}\beta_3^2{\epsilon_1}^2, \\
\delta_3 &= C_{\varphi_1}\beta_3^2({\epsilon_1}^2 + C_{\epsilon_1}) + (C_{\varphi_1}\beta_2^2 + \alpha_3) + \alpha_2 C_{\varphi_1}\beta_4^2, \\
\delta_4 &= c_2 C_{\varphi_1}\beta_4^2\left(\frac{d}{\nu\tau}\right)^2(\epsilon_1^2 + C_{\epsilon_1}), \\
\delta_5 &= c_2 C_{\varphi_1}\beta_4^2\left(\frac{d}{\nu\tau}\right)^2{\epsilon_1}^2. \qquad (4.24)
\end{aligned}
$$

Step 3. Study of the transformed problem and use of the method of [10]. Using (4.14) we obtain

$$
\begin{aligned}
&\frac{1}{2}\int(-\nu\Delta\varphi_1 - v\cdot\nabla\varphi_1 + a\varphi_1)u^2 + \frac{1}{2}\int(-\nu\Delta\varphi_2 - v\cdot\nabla\varphi_2 + a\varphi_2)u_l^2 \\
&+ \frac{\nu}{2}\int_{\Gamma_b} u^2\frac{\partial\varphi_1}{\partial n} + \frac{\nu}{2}\int_{\Gamma_i} u_l^2\frac{\partial\varphi_2}{\partial n} + \nu\int|\nabla u|^2\varphi_1 + \nu\int|\nabla u_l|^2\varphi_2 \\
&\qquad \le \frac{a}{2}\int\varphi_1 f^2 + \frac{a}{2}\int\varphi_2 f_l^2 + \Sigma|BC_i|. \qquad (4.25)
\end{aligned}
$$

Combining (4.23) and (4.25), we obtain

$$
\begin{aligned}
&\frac{1}{2}\int(-\nu\Delta\varphi_1 - v\cdot\nabla\varphi_1 + a\varphi_1)u^2 + \frac{1}{2}\int(-\nu\Delta\varphi_2 - v\cdot\nabla\varphi_2 + a\varphi_2)u_l^2 \\
&+\frac{\nu}{2}\int_{\Gamma_b} u^2\frac{\partial\varphi_1}{\partial n} + \frac{\nu}{2}\int_{\Gamma_i} u_l^2\frac{\partial\varphi_2}{\partial n} + \nu\int|\nabla u|^2\varphi_1 + \nu\int|\nabla u_l|^2\varphi_2 \\
&\qquad \le \int_\Omega\left(\frac{a}{2}\varphi_1 + \delta_1'\right)f^2 + \int_{\Omega_l}\left(\frac{a}{2}\varphi_2 + \delta_3\right)f_l^2 + \int_\Omega\delta_1|\nabla f|^2 \\
&\qquad\quad + \int_{\Omega_l}\delta_2|\nabla f_l|^2 + \int_{\Omega_l}\delta_4 f_{lm}^2 + \int_{\Omega_l}\delta_5|\nabla f_{lm}|^2. \qquad (4.26)
\end{aligned}
$$

We shall now construct φ_1 and φ_2 positive bounded below and above by positive constants such that we have

$$\begin{aligned}\frac{1}{2}(-\nu\Delta\varphi_1 - v\cdot\nabla\varphi_1 + a\varphi_1) &= \left(\frac{a}{2}\varphi_1 + \delta_1'\right)(1+\epsilon_2) + \delta_1'',\\ \frac{1}{2}(-\nu\Delta\varphi_2 - v\cdot\nabla\varphi_2 + a\varphi_2) &= \left(\frac{a}{2}\varphi_2 + \delta_3\right)(1+\epsilon_2) + \delta_3'',\end{aligned} \tag{4.27}$$

where ϵ_2, δ_1'', and δ_3'' are positive constants. This corresponds to

$$-\nu\Delta\varphi_1 - v\cdot\nabla\varphi_1 - a\epsilon_2\varphi_1 = 2\delta_1'(1+\epsilon_2) + 2\delta_1'', \tag{4.28}$$

$$-\nu\Delta\varphi_2 - v\cdot\nabla\varphi_2 - a\epsilon_2\varphi_2 = 2\delta_3(1+\epsilon_2) + 2\delta_3''. \tag{4.29}$$

For ϵ_2 small, we can use the generalized maximum principle [5]. We then can choose (see the appendix) $\varphi_{1|\Gamma_b} > 0$, $\varphi_{2|\Gamma_i} > 0$, $\delta_1'' > 0$, and $\delta_3'' > 0$, such that

$$\varphi_1 > 0, \quad \frac{\partial\varphi_1}{\partial n}_{|\Gamma_b} > 0, \quad \nu\varphi_1 > (1+\epsilon_2)\delta_1, \tag{4.30}$$

$$\varphi_2 > 0, \quad \frac{\partial\varphi_2}{\partial n}_{|\Gamma_i} > 0, \quad \nu\varphi_2 > (1+\epsilon_2)\delta_2. \tag{4.31}$$

We then obtain

$$\begin{aligned}&\int\left(\left(\frac{a}{2}\varphi_1 + \delta_1'\right)(1+\epsilon_2) + \delta_1''\right)u^2 + \int\left(\left(\frac{a}{2}\varphi_2 + \delta_3\right)(1+\epsilon_2) + \delta_3''\right)u_l^2\\ &\quad + \frac{\nu}{2}\int_{\Gamma_b} u^2\frac{\partial\varphi_1}{\partial n} + \frac{\nu}{2}\int_{\Gamma_i} u_l^2\frac{\partial\varphi_2}{\partial n} + \int(1+\epsilon_2)\delta_1|\nabla u|^2 + \int(1+\epsilon_2)\delta_2|\nabla u_l|^2\\ &\le \int_\Omega\left(\frac{a}{2}\varphi_1 + \delta_1'\right)f^2 + \int_{\Omega_l}\left(\frac{a}{2}\varphi_2 + \delta_3\right)f_l^2 + \int_\Omega\delta_1|\nabla f|^2 + \int_{\Omega_l}\delta_2|\nabla f_l|^2\\ &\quad + \int_{\Omega_l}\delta_4 f_{lm}^2 + \int_{\Omega_l}\delta_5|\nabla f_{lm}|^2.\end{aligned} \tag{4.32}$$

Step 4. Conclusions. From (4.32) we deduce

$$\begin{aligned}&\int\left(\left(\frac{a}{2}\varphi_1 + \delta_1'\right) + \frac{1}{1+\epsilon_2}\delta_1''\right)u^2 + \int\left(\left(\frac{a}{2}\varphi_2 + \delta_3\right) + \frac{1}{1+\epsilon_2}\delta_3''\right)u_l^2\\ &+ \frac{1}{1+\epsilon_2}\frac{\nu}{2}\int_{\Gamma_b} u^2\frac{\partial\varphi_1}{\partial n} + \frac{1}{1+\epsilon_2}\frac{\nu}{2}\int_{\Gamma_i} u_l^2\frac{\partial\varphi_2}{\partial n} + \int\delta_1|\nabla u|^2 + \int\delta_2|\nabla u_l|^2\\ &\quad\le \int_\Omega\frac{1}{1+\epsilon_2}\left(\frac{a}{2}\varphi_1 + \delta_1'\right)f^2 + \int_{\Omega_l}\frac{1}{1+\epsilon_2}\left(\frac{a}{2}\varphi_2 + \delta_3\right)f_l^2 + \int_\Omega\frac{1}{1+\epsilon_2}\delta_1|\nabla f|^2\\ &\qquad + \int_{\Omega_l}\frac{1}{1+\epsilon_2}\delta_2|\nabla f_l|^2 + \int_{\Omega_l}\frac{1}{1+\epsilon_2}\delta_4 f_{lm}^2 + \int_{\Omega_l}\frac{1}{1+\epsilon_2}\delta_5|\nabla f_{lm}|^2.\end{aligned} \tag{4.33}$$

Because of our special construction of the functions φ_1 and φ_2, we obtain

$$\int \left(\left(\frac{a}{2}\varphi_1 + \delta_1' \right) + \frac{1}{1+\epsilon_2}\delta_1'' \right) u^2 + \int \left(\left(\frac{a}{2}\varphi_2 + \delta_3 \right) + \frac{1}{1+\epsilon_2}\delta_3'' \right) u_l^2$$
$$+ \int \delta_1 |\nabla u|^2 + \int \delta_2 |\nabla u_l|^2$$
$$\leq \int_\Omega \frac{1}{1+\epsilon_2} \left(\frac{a}{2}\varphi_1 + \delta_1' \right) f^2 + \int_{\Omega_l} \frac{1}{1+\epsilon_2} \left(\frac{a}{2}\varphi_2 + \delta_3 \right) f_l^2$$
$$+ \int_\Omega \frac{1}{1+\epsilon_2}\delta_1 |\nabla f|^2 + \int_{\Omega_l} \frac{1}{1+\epsilon_2}\delta_2 |\nabla f_l|^2$$
$$+ \int_{\Omega_l} \frac{1}{1+\epsilon_2}\delta_4 f_{lm}^2 + \int_{\Omega_l} \frac{1}{1+\epsilon_2}\delta_5 |\nabla f_{lm}|^2. \tag{4.34}$$

Setting

$$a_{n+1} = \int \left(\left(\frac{a}{2}\varphi_1 + \delta_1' \right) + \frac{1}{1+\epsilon_2}\delta_1'' \right) u^2 + \int \delta_1 |\nabla u|^2$$
$$+ \int \left(\left(\frac{a}{2}\varphi_2 + \delta_3 \right) + \frac{1}{1+\epsilon_2}\delta_3'' \right) u_l^2 + \int \delta_2 |\nabla u_l|^2,$$

equation (4.34) then becomes

$$\begin{aligned} a_{n+1} &\leq s_1 a_n + s_2 a_{n-1}, \\ s_1 &= \frac{1}{1+\epsilon_2}, \\ s_2 &= \frac{1}{1+\epsilon_2}\max(\delta_4, \delta_5). \end{aligned} \tag{4.35}$$

Setting

$$b_n = \begin{pmatrix} a_n \\ a_{n-1} \end{pmatrix}$$

and

$$A = \begin{pmatrix} s_1 & s_2 \\ 1 & 0 \end{pmatrix},$$

we then obtain, using the Euclidean norm $\|.\|_2$,

$$\begin{aligned} \|b_n\|_2 \leq \|Ab_{n-1}\|_2 &= \sqrt{(s_1 a_{n-1} + s_2 a_{n-2})^2 + a_{n-1}^2} \\ &\leq \|A\|_2 \|b_{n-1}\|_2 \\ &\leq \|A\|_2^{n-1} \|b_1\|_2. \end{aligned}$$

Then the sequence a_n converges if the spectral radius of the matrix A is less than 1. This is true if

$$s_2 \leq 1 - \frac{1}{1+\epsilon_2} = \frac{\epsilon_2}{1+\epsilon_2}.$$

This last inequality is true if τ is taken to be sufficiently small. (See the definition of δ_4 and δ_5.) This concludes the proof of the theorem.

5. Conclusions. In this paper we proved the convergence of the TTMA for the case of transmission problems of hydrodynamics type. The proof is based in an essential way on the method we introduced in [10], and termed here "the transmission multiplier method," and the local, global, and trace estimates we developed in [11, 12]. We have described some applications of the TTMA to solving problems in fluid mechanics resulting from the applications of the α– and β–monoscale-multimodel methods. Our proof is obtained under a smallness condition on the time step only.

Appendix. Equation (4.28) can be written in the form

$$(L+h)\varphi_1 = f, \tag{A.1}$$

where

$$L\varphi_1 = \nu\Delta\varphi_1 + v\cdot\nabla\varphi_1,$$
$$h = a\epsilon_2, \quad f = -2\delta_1'(1+\epsilon_2) - 2\delta_1''.$$

Since Ω_l is bounded we can find a_1 and a_2, two real numbers such that Ω_l is contained in the slab $a_1 < x_1 < a_2$, where x_1 is the first coordinate of $x = (x_1, \ldots, x_n)$. Let

$$w(x) = 1 - \eta_2 e^{\eta_1(x_1 - a_1)}. \tag{A.2}$$

The numbers η_1 and η_2 are to be selected so that

$$w(x) > 0 \quad \text{on} \quad \Omega_l \cup \partial\Omega_l, \tag{A.3}$$
$$(L+h)w \le 0 \quad \text{in} \quad \Omega_l. \tag{A.4}$$

The operator $L+h$ applied to w yields

$$(L+h)w = -\eta_2(\eta_1^2\nu + \eta_1 v_1 + a\epsilon_2)e^{\eta_1(x_1-a_1)} + a\epsilon_2. \tag{A.5}$$

Let $m > 0$ be such that $v_1(x) \ge -m \ \ \forall x \in \Omega_l$. We may choose $m = \|v\|_{\infty,\Omega}$. We then choose η_1 and η_2 such that

$$\eta_1^2\nu - \eta_1 m + a\epsilon_2 > 0,$$
$$\eta_2 = \frac{a\epsilon_2}{\eta_1^2\nu - \eta_1 m + a\epsilon_2}.$$

This choice of η_1 and η_2 yields

$$(L+h)w \le 0 \quad \text{in} \quad \Omega_l. \tag{A.6}$$

Since we also want w to be positive on $\Omega_l \cup \partial\Omega_l$, we must have $\eta_2 e^{\eta_1(a_2-a_1)} < 1$. That is the inequality

$$\frac{a\epsilon_2}{\eta_1^2\nu - \eta_1 m + a\epsilon_2} < e^{-\eta_1(a_2-a_1)}. \tag{A.7}$$

This is satisfied if

$$\begin{aligned}\epsilon_2 &< \frac{1}{a}\eta_1 e^{-\eta_1(a_2-a_1)}\frac{(\eta_1\nu - m)}{1 - e^{-\eta_1(a_2-a_1)}} \\ &< \tau\eta_1 e^{-\eta_1(a_2-a_1)}\frac{(\eta_1\nu - m)}{1 - e^{-\eta_1(a_2-a_1)}},\end{aligned} \tag{A.8}$$

where we have used the definition of a. For ϵ_2 satisfying (A.8), the function w satisfies (A.3) and (A.4). Therefore [5] the solution of

$$(L+h)\varphi = -1 \text{ in } \Omega_l, \tag{A.9}$$

$$\frac{\partial \varphi}{\partial n} + \eta\varphi = 1 \text{ on } \Gamma_i, \tag{A.10}$$

$$\varphi = 1 \text{ on } \Gamma_b \tag{A.11}$$

with $\eta > 0$ satisfies $\varphi \geq w > 0$. By appropriate choice of $f = -2\delta_1'(1+\epsilon_2) - 2\delta_1'' \leq 0$, $g_1 > 0$, and $g_2 > 0$, the solution of

$$(L+h)\varphi = f \text{ in } \Omega_l, \tag{A.12}$$

$$\frac{\partial \varphi}{\partial n} + \eta\varphi = g_1 \text{ on } \Gamma_i, \tag{A.13}$$

$$\varphi = g_2 \text{ on } \Gamma_b \tag{A.14}$$

satisfies $\varphi > 0$ in $\Omega_l \cup \Gamma_i \cup \Gamma_b$ and $\frac{\partial \varphi}{\partial n} > 0$ on Γ_b. Thus $a_3\varphi_1$ with appropriate choice of $a_3 > 0$ satisfies the requirements in (4.30). Similar construction can be used to find φ_2 satisfying (4.31)

A NEW CLASS OF OPTIMAL HIGH-ORDER STRONG-STABILITY-PRESERVING TIME DISCRETIZATION METHODS*

RAYMOND J. SPITERI† AND STEVEN J. RUUTH‡

Abstract. Strong-stability-preserving (SSP) time discretization methods have a nonlinear stability property that makes them particularly suitable for the integration of hyperbolic conservation laws where discontinuous behavior is present. Optimal SSP schemes have been previously found for methods of order 1, 2, and 3, where the number of stages s equals the order p. An optimal low-storage SSP scheme with $s = p = 3$ is also known. In this paper, we present a new class of optimal high-order SSP and low-storage SSP Runge–Kutta schemes with $s > p$. We find that these schemes are ultimately more efficient than the known schemes with $s = p$ because the increase in the allowable time step more than offsets the added computational expense per step. We demonstrate these efficiencies on a set of scalar conservation laws.

Key words. strong stability preserving, total variation diminishing, Runge–Kutta methods, high-order accuracy, time discretization

1. Introduction.

The method of lines is a popular semidiscretization method for the solution of time-dependent partial differential equations (PDEs). The idea behind it is to first suitably discretize the spatial variables (e.g., by finite differences, finite volumes, finite elements, or spectral methods) to yield a set of ordinary differential equations (ODEs) in time. Then, this set of ODEs can be integrated using standard time-stepping techniques such as linear multistep or Runge–Kutta methods.

Standard stability analysis for the solvers of such systems generally focuses on linear stability. Indeed, such analysis is often adequate when the desired solutions are smooth. However, solutions to hyperbolic PDEs may not be smooth: shock waves or other discontinuous behavior can develop even from smooth initial data. In such cases, standard discretizations based on linear stability analysis suffer from poor performance due to the presence of spurious oscillations, overshoots, and progressive smearing. The numerical solutions obtained from these discretizations often exhibit a weak form of instability (called *nonlinear instability*) resulting in unphysical behavior. Accordingly, numerical methods based on a nonlinear stability requirement are very desirable. Such methods were originally referred to as *total variation diminishing* (TVD) [17]; see also the subsequent articles [18, 6]. However, following the more recent article [7], we refer to them in this paper as *strong-stability-preserving* (SSP) methods.

We are interested in the development, implementation, and analysis of a new class of optimal SSP Runge–Kutta (SSPRK) time-stepping schemes for the system of

ODEs

$$\dot{U} = L(U)$$

subject to suitable initial conditions, obtained from applying the method of lines to the hyperbolic conservation law

$$u_t + f(u)_x = 0. \tag{1.1}$$

Here, we assume that (1.1) has been suitably discretized in its spatial variables (e.g., using essentially nonoscillatory (ENO) schemes [10], TVD schemes [9], or monotonic upstream-centered schemes for conservation laws (MUSCL) methods [19]) and $U = U(t)$ is a vector of discretized variables; i.e., $[U(t)]_j = U_j(t) = u(x_j, t)$. In particular, if u_j^n is the numerical approximation to $u(x_j, t_n)$, then TVD discretizations have the property that the total variation

$$TV(U^n) = \sum_j |u_j^n - u_{j-1}^n| \tag{1.2}$$

of the numerical solution does not increase with time; i.e.,

$$TV(U^{n+1}) \leq TV(U^n).$$

When combined with a suitable SSP time-stepping scheme, the numerical solution obtained typically does not exhibit nonlinear instabilities. However, nonlinear instabilities can occur in a numerical solution obtained with, e.g., a TVD or MUSCL spatial discretization scheme, but with a standard (i.e., linearly stable) time-stepping scheme [6]. Hence, SSP time-stepping schemes are a critical part of the overall solution strategy to (1.1).

It has been known for some time from a result of Goodman and LeVeque [5] that any method that is TVD in two dimensions is at most first-order accurate. However, if we relax the strict requirement of TVD schemes, higher-order methods can be constructed that preserve stability in another suitable norm, such as the maximum norm. These schemes are what we call SSP, and their favorable properties are derived only from convexity arguments. In particular, if the forward Euler method is strongly stable with a certain CFL number, higher-order SSPRK methods with a modified CFL number can be constructed as convex combinations of forward Euler steps with various step sizes [18].

Optimal SSP schemes based on Runge–Kutta methods have been found for accuracy orders 1, 2, and 3, where the number of stages s is assumed to be equal to the order p. Gottlieb and Shu [6] recently proved that, unfortunately, no such four-stage, fourth-order SSPRK method exists involving just evaluations of $L(\cdot)$. Fourth-order accuracy has only been obtained at the additional expense of introducing two additional evaluations of a related operator $\tilde{L}(\cdot)$, leading to suboptimal efficiency both in terms of time-step restriction and memory usage (see section 2). This appears to be where the search for higher-order SSPRK methods has stopped, thus leaving researchers to focus on third-order accurate SSPRK methods.

In this paper, we derive a new class of optimal high-order SSPRK schemes where the restriction $s = p$ is lifted. For s-stage methods of orders 1 and 2, we provide proofs of optimality. The SSPRK scheme (4,3) is also proven to be optimal. The remaining schemes of order 3 and higher and the low-storage schemes are the results

of numerical optimization. We investigate the performance of our new schemes on a few test problems designed to capture solution features that pose particular difficulties to numerical methods. These features include contact discontinuities, expansion fans, compressive shocks, and sonic points. The results from these investigations indicate that both the standard and low-storage versions of our schemes offer significant advantages over methods currently available. In particular, our new schemes have significantly better stability restrictions than the best SSPRK schemes currently known. Thus, step-size selection can be based more on accuracy requirements rather than stability requirements, ultimately leading to more efficient integrators. Indeed, the results based on three important test cases indicate that our new fourth-order SSPRK scheme offers between 40% and 80% improvement in the effective time-step restriction over the most popular fourth-order schemes currently in use.

The remainder of this paper unfolds as follows. In section 2, we describe SSP schemes and motivate their use. In section 3, we determine optimal families of SSPRK schemes up to 5 stages and order 4. We also give optimal low-storage versions of these schemes. In section 4, we investigate the performance of our new SSPRK schemes on a set of scalar conservation laws having solutions that commonly cause numerical problems. The success of the new methods is measured relative to the most popular schemes currently in use. Finally, in section 5, we summarize our findings and offer plans for future work.

2. SSP schemes. The concept of strong stability is central to our discussion, so we begin with its definition.

DEFINITION 2.1. *A sequence* $\{U^n\}$ *is said to be* strongly stable *in a given norm* $||\cdot||$ *provided that* $||U^{n+1}|| \le ||U^n||$ *for all* $n \ge 0$.

We tacitly assume that U^n represents a vector of solution values on a mesh obtained from a method-of-lines approach to solving a PDE. The choice of norm is arbitrary,[1] with the TV-norm (1.2) and the infinity norm being two natural possibilities. Clearly, strong stability may not be relevant to the solution of an arbitrary PDE. However, the class of PDEs (1.1) forms a notable exception. Exact solutions for this class of problems have a range-diminishing property that forbids existing maxima from increasing, existing minima from decreasing, and new maxima or minima from forming. Although not precisely a discrete analogue to the range-diminishing property, the strong-stability property is a useful property to require of a numerical solution to (1.1): by imposing such a condition on the numerical solution, we can suppress the formation of spurious oscillations under a suitable restriction on the time step. Such oscillations are termed *nonlinear instabilities* and are often a precursor for the numerical solution itself to become completely unstable.

The authors in [7] prove the somewhat surprising result that, under rather general assumptions, high-order SSP methods must in fact be explicit. Fortunately, many researchers in fact prefer explicit time discretization methods in order to avoid the expense[2] of solving systems of nonlinear equations at each step. Accordingly, in this paper we will focus on the development of explicit Runge–Kutta methods. Consider an s-stage, explicit Runge–Kutta method written in the form

[1] Indeed, the results of this paper still apply if we replace the norm $||\cdot||$ by *any* convex function that maps into the nonnegative real line.

[2] Both in terms of computation time and software development.

$$U^{(0)} = U^n, \tag{2.1a}$$

$$U^{(i)} = \sum_{k=0}^{i-1} (\alpha_{ik} U^{(k)} + \Delta t \beta_{ik} L(U^{(k)})), \qquad i = 1, 2, \ldots, s, \tag{2.1b}$$

$$U^{n+1} = U^{(s)}, \tag{2.1c}$$

where all $\alpha_{ik} \geq 0$ and $\alpha_{ik} = 0$ only if $\beta_{ik} = 0$ [17]. This representation of a Runge–Kutta method can be converted to the standard Butcher array form (see, e.g., [8]) in a straightforward manner; see also [6]. However, the conversion from the Butcher array form to (2.1) is not unique. For example, the modified Euler scheme

$$\begin{array}{c|cc} 0 & 0 & 0 \\ 1 & 1 & 0 \\ \hline & \frac{1}{2} & \frac{1}{2} \end{array}$$

has a one-parameter family of representations of the form (2.1):

$$\alpha_{10} = 1,\ \alpha_{20} = 1 - \lambda,\ \alpha_{21} = \lambda, \qquad \beta_{10} = 1,\ \beta_{20} = \frac{1}{2} - \lambda,\ \beta_{21} = \frac{1}{2},$$

where $\lambda \in [0, 1]$. All of these representations are algebraically equivalent [18]; i.e., the only differences noticeable between stable implementations of any scheme would be due to round-off errors. However, different choices of λ may lend themselves more easily to implementation, memory management, or determination of stability restrictions. Throughout this article, we give representations that naturally allow stability restrictions to be read from the coefficients of the scheme. Standard Butcher array forms of the schemes presented are given in Appendix B.

For consistency, we must have that $\sum_{k=0}^{i-1} \alpha_{ik} = 1$, $i = 1, 2, \ldots, s$. Hence, if both sets of coefficients α_{ik}, β_{ik} are positive, then (2.1) is a convex combination of forward Euler steps with various step sizes $\frac{\beta ik}{\alpha_{ik}} \Delta t$. The Runge–Kutta scheme written in this form is particularly convenient to make use of the following result [18, 7].

THEOREM 2.2. *If the forward Euler method is strongly stable under the CFL restriction $\Delta t \leq \Delta t_{FE}$, then the Runge–Kutta method* (2.1) *with $\beta_{ik} \geq 0$ is SSP, provided*

$$\Delta t \leq c \Delta t_{FE},$$

where c is the CFL coefficient

$$c \equiv \min_{i,k} \frac{\alpha_{ik}}{\beta_{ik}}.$$

Thus, we can use the result of this theorem to provide a theoretical criterion according to which we can optimize a given SSPRK method.

SSPRK schemes with negative coefficients β_{ik} are also possible with the appropriate interpretation. Following the procedure first suggested in [17], whenever $\beta_{ik} < 0$, the operator $L(\cdot)$ is replaced with the related operator $\tilde{L}(\cdot)$, where $\tilde{L}(\cdot)$ is assumed to be strongly stable for Euler's method solved *backward* in time for a suitable time-step restriction. This allows the following generalization of Theorem 2.2.

THEOREM 2.3. *Let Euler's method solved forward in time combined with the spatial discretization $L(\cdot)$ be strongly stable under the CFL restriction $\Delta t \leq \Delta t_{FE}$.*

Let Euler's method solved backward in time combined with the spatial discretization $\tilde{L}(\cdot)$ *also be strongly stable under the same CFL restriction* $\Delta t \le \Delta t_{FE}$. *Then the Runge–Kutta method* (2.1) *is SSP, provided*

$$\Delta t \le c\Delta t_{FE},$$

where c *is the CFL coefficient*

$$c \equiv \min_{i,k} \frac{\alpha_{ik}}{|\beta_{ik}|},$$

where $\beta_{ik}L(\cdot)$ *is replaced by* $\beta_{ik}\tilde{L}(\cdot)$ *whenever* β_{ik} *is negative.*

Note. If both $L(U^{(i)})$ and $\tilde{L}(U^{(i)})$ are required, then the computational cost and storage requirements for that stage are typically doubled. Moreover, there is the added inconvenience of having to code the spatial discretization represented by $\tilde{L}(\cdot)$. These reasons provide the incentive for us to want to avoid negative β_{ik} as much as possible when searching for the most efficient SSPRK methods.

We also note that the quantity

$$\min_{i,k} \frac{\alpha_{ik}}{|\beta_{ik}|} \tag{2.2}$$

obviously depends on the particular representation (2.1) of a given Runge–Kutta scheme. Accordingly, the CFL restriction is determined by the choice of coefficients $\alpha_{ij},\ \beta_{ij}$ that maximizes (2.2); other choices render bounds that are not as sharp.

We will be comparing a new class of SSPRK methods with s stages and order p with $s > p$ to methods known in the literature where $s = p$ or some $\beta_{ik} < 0$. We note that if a method requires n_- extra evaluations of $\tilde{L}(\cdot)$, then the effective number of stages of that method is $m = s + n_-$. We find that the new SSPRK methods can have a significantly greater CFL coefficient (as given in Theorem 2.2) than the methods currently used in practice. However, we must make a fair comparison as to the computational cost of a step. This motivates the following definition.

Definition 2.4. *The* effective CFL coefficient *of an SSPRK method of order* p *is* cs^*/s, *where* c *is the CFL coefficient of the method,* s^* *is the minimum number of stages to theoretically achieve order* p, *and* s *is the number of stages required for one step of the method.*

It is well known (see, e.g., [8]) that a Runge–Kutta method having s stages can achieve order p for $s = p \le 4$. For $p > 4$, it is required that $s > p$. Because the cases we consider in this paper involve only $p \le 4$, we always take $s^* = p$ here.

As conjectured in Shu and Osher [18] and subsequently proven in Gottlieb and Shu [6], the optimal two-stage, order-2 SSPRK scheme is the modified Euler scheme

$$\begin{aligned} U^{(1)} &= U^n + \Delta t L(U^n), \\ U^{n+1} &= \frac{1}{2}U^n + \frac{1}{2}U^{(1)} + \frac{1}{2}\Delta t L(U^{(1)}). \end{aligned}$$

It has a CFL restriction $\Delta t \le \Delta t_{FE}$, which implies a CFL coefficient of 1. Henceforth, we will refer to this scheme as SSP(2,2). In general, we adopt the convention of referring to an s-stage, order-p SSPRK scheme as SSP(s,p).

Shu and Osher [18] also conjectured that the optimal three-stage, order-3 SSPRK scheme is

$$
\begin{aligned}
U^{(1)} &= U^n + \Delta t L(U^n),\\
U^{(2)} &= \frac{3}{4}U^n + \frac{1}{4}U^{(1)} + \frac{1}{4}\Delta t L(U^{(1)}),\\
U^{n+1} &= \frac{1}{3}U^n + \frac{2}{3}U^{(2)} + \frac{2}{3}\Delta t L(U^{(2)}),
\end{aligned}
$$

which has a CFL coefficient of 1 as well. The optimality of this scheme was later proved by Gottlieb and Shu [6]. This scheme is commonly called the *third-order TVD Runge–Kutta scheme*, but we will simply refer to it as SSP(3,3).

To achieve fourth order, Shu and Osher provide a four-stage method that contains two negative coefficients β_{ik} [18]. A slightly improved scheme (but also containing two negative coefficients β_{ik}) was proposed by Gottlieb and Shu [6]:

$$
\begin{aligned}
U^{(1)} &= U^n + \frac{1}{2}\Delta t L(U^n),\\
U^{(2)} &= \frac{649}{1600}U^n - \frac{10890423}{25193600}\Delta t \tilde{L}(U^n) + \frac{951}{1600}U^{(1)} + \frac{5000}{7873}\Delta t L(U^{(1)}),\\
U^{(3)} &= \frac{53989}{2500000}U^n - \frac{102261}{5000000}\Delta t \tilde{L}(U^n) + \frac{4806213}{20000000}U^{(1)}\\
&\quad - \frac{5121}{20000}\Delta t \tilde{L}(U^{(1)}) + \frac{23619}{32000}U^{(2)} + \frac{7873}{10000}\Delta t L(U^{(2)}),\\
U^{n+1} &= \frac{1}{5}U^n + \frac{1}{10}\Delta t L(U^n) + \frac{6127}{30000}U^{(1)} + \frac{1}{6}\Delta t L(U^{(1)})\\
&\quad + \frac{7873}{30000}U^{(2)} + \frac{1}{3}U^{(3)} + \frac{1}{6}\Delta t L(U^{(3)}).
\end{aligned}
$$

This scheme has a CFL coefficient of 0.936 and an effective CFL coefficient of $0.936 \times 4/6 = 0.624$ because 6 function evaluations are required per step. Because this seems to be the best four-stage, order-4 SSPRK scheme known, we will refer to it as SSP(4^{**},4), with the two asterisks meant to convey two negative coefficients β_{ik}. Gottlieb and Shu [6] subsequently proved that no four-stage, order-4 SSPRK scheme exists with positive coefficients.

Gottlieb and Shu [6] have also carried out an investigation of SSP time discretization methods for generalized Runge–Kutta methods (also known as pseudo-Runge–Kutta methods or hybrid methods [8]).[3] They report that they were unable to find effective SSP methods in this wider class of methods. It is from this point that we start our derivations of improved SSPRK schemes where generally $s > p$. The details of these derivations are provided in the next section.

3. Optimal SSP schemes. We now turn to the task of finding optimal SSPRK schemes. To begin, we seek to optimize an s-stage, order-p SSPRK scheme by maximizing its CFL coefficient according to Theorem 2.2. That is, we seek the global maximum of the nonlinear programming problem,

$$
\max_{(\alpha_{ik},\beta_{ik})} \min \frac{\alpha_{ik}}{\beta_{ik}}, \tag{3.1}
$$

where $\alpha_{ik},\ \beta_{ik}, k = 0, 1, \ldots, i-1,\ i = 1, 2, \ldots, s$, are real and nonnegative. The case $\alpha_{ik} = \beta_{ik} = 0$ is defined as `NaN` in the sense that it is not included in the minimization

[3] All of these methods also are special cases of methods known as *general linear methods.*

process if it occurs. Besides the nonnegativity constraints on the variables $\alpha_{ik},\ \beta_{ik}$, the objective function (3.1) is subject to the constraints

$$\sum_{k=0}^{i-1} \alpha_{ik} = 1, \qquad i = 1, 2, \ldots, s, \tag{3.2}$$

$$\sum_{j=1}^{s} b_j \Phi_j(t) = \frac{1}{\gamma(t)}, \quad t \in T_q, \quad q = 1, 2, \ldots, p. \tag{3.3}$$

Here, the functions $\Phi_j(t)$ are nonlinear constraints that are polynomial in $\alpha_{ik},\ \beta_{ik}$ and that correspond to the order conditions for a Runge–Kutta method to be of order p (see, e.g., [8]); i.e., T_q stands for the set of all rooted trees of order equal to q. The number of constraints represented by the Runge–Kutta order conditions is equal to

$$\sum_{q=1}^{p} \mathrm{card}(T_q),$$

where $\mathrm{card}(T_q)$ is the cardinality of T_q. Also, we use the notation b_j in the usual sense of the Butcher array representation of a Runge–Kutta method; again this would be a polynomial function of the coefficients α_{ik} and β_{ik}. It can be expected that the particular choice of coefficients $\alpha_{ik},\ \beta_{ik}$ that maximizes the quantity (2.2) for a given Runge–Kutta method will be naturally produced by the solution to this nonlinear programming problem; hence, the result will be a sharp estimate of the CFL coefficient.

In this form, the optimization problem does not lend itself easily to numerical solution. The difficulty due to the high degree of nonlinearity in the constraints is compounded by the following two considerations. First, the objective function (3.1) is nonsmooth and so an optimization strategy that uses gradient information will have difficulty obtaining reliable numerical estimates of the derivatives. Second, the $\min(\cdot)$ function can be quite insensitive to its arguments. This also contributes to the poor performance of optimization software on this problem. We found that even optimizers that do not rely on gradient information were unable to consistently converge to the same optimum with this formulation.

The performance of optimization software on this problem is greatly enhanced through the following standard reformulation. By introducing a dummy variable z, the nonlinear programming problem can be reformulated as

$$\max_{(\alpha_{ik},\beta_{ik})} z \tag{3.4a}$$

subject to

$$\alpha_{ik} \geq 0, \tag{3.4b}$$

$$\beta_{ik} \geq 0, \tag{3.4c}$$

$$\sum_{k=0}^{i-1} \alpha_{ik} = 1, \qquad i = 1, 2, \ldots, s, \tag{3.4d}$$

$$\sum_{j=1}^{s} b_j \Phi_j(t) = \frac{1}{\gamma(t)}, \quad t \in T_q, \quad q = 1, 2, \ldots, p, \tag{3.4e}$$

$$\alpha_{ik} - z\beta_{ik} \geq 0, \quad k = 0, 1, \ldots, i-1, \quad i = 1, 2, \ldots, s. \tag{3.4f}$$

It is easy to see that the dummy variable z corresponds to the CFL coefficient. This reformulation is a standard technique that is widely used in the context of linear programming problems with objective functions of the form $\max(\cdot)$ or $\min(\cdot)$ (see, e.g., [2]). It is also a common reformulation of the so-called *feasibility problem*, where any feasible solution to a set of equality or inequality constraints is desired (e.g., as in the first phase of a two-phase simplex algorithm for linear programming [3]).

The reformulated problem (3.4) was solved directly using the `fmincon` function from Matlab's Optimization Toolbox for $s = 1, 2, 3, 4, 5$ and $p = 1, 2, 3, 4$, and the results are shown below. Table 3.1 shows the optimal values for the CFL coefficients for given pairs (s, p). The * in the $(4, 4)$ position denotes the fact that no such SSPRK method exists with all coefficients $\alpha_{ik},\ \beta_{ik}$ positive.

TABLE 3.1
Optimal CFL coefficients for s-stage, order-p SSPRK methods.

	$s = 1$	$s = 2$	$s = 3$	$s = 4$	$s = 5$
$p = 1$	1	2	3	4	5
$p = 2$		1	2	3	4
$p = 3$			1	2	2.65
$p = 4$				*	1.51

Table 3.2 gives the theoretical efficiencies of these new schemes relative to the ones where $s = p$. We note that there is no efficiency gain for the first-order methods. For example, although the CFL coefficient of the (2,1) method is twice that of that (1,1) method (forward Euler), it also requires twice as much work. The percentages quoted refer to the theoretical increases in allowable step size of the new methods relative to the methods with $s = p$. For example, the (3,2) method has twice the allowable step size compared to the (2,2) method (the modified Euler method), but it requires 3/2 times more work. We thus report that the net effect is a relative increase in step size of $((2/1)/(3/2) - 1) \times 100\% = 33\%$. Equivalently, assuming the CFL coefficient is the exact bound on the time step, the new $(3, 2)$ scheme can produce a comparable second-order accurate answer with only 75% of the computational effort as the $(2, 2)$ scheme.

TABLE 3.2
Theoretical efficiency improvement over standard pth order SSPRK schemes.

	$s = 2$	$s = 3$	$s = 4$	$s = 5$
$p = 2$		33%	50%	60%
$p = 3$			50%	59%
$p = 4$				94%

We draw particular attention to the efficiency of the $(5, 4)$ scheme in Table 3.2. As mentioned earlier, a $(4, 4)$ SSPRK scheme does not exist for any positive CFL coefficient. The figure of 94% is measured relative to the $(4^{**}, 4)$ scheme reported in [6] as the best scheme of order 4 that could be found. Recall that this scheme had a CFL coefficient of 0.936 and effectively used 6 stages because it involved 2 coefficients β_{ik} that are negative (hence leading to a 50% increase of the storage requirement per step and the overhead of coding $\tilde{L}(\cdot)$). The new $(5, 4)$ scheme thus compares very favorably.

The first few optimal SSPRK schemes of orders 1 and 2 are given in Tables 3.3

TABLE 3.3
The first few optimal SSPRK schemes of order 1.

Stages	α_{ik}	β_{ik}	CFL coefficient
1	1	1	1
2	$\begin{matrix}1 & \\ 0 & 1\end{matrix}$	$\begin{matrix}\frac{1}{2} & \\ 0 & \frac{1}{2}\end{matrix}$	2
3	$\begin{matrix}1 & & \\ 0 & 1 & \\ 0 & 0 & 1\end{matrix}$	$\begin{matrix}\frac{1}{3} & & \\ 0 & \frac{1}{3} & \\ 0 & 0 & \frac{1}{3}\end{matrix}$	3

TABLE 3.4
The first few optimal SSPRK schemes of order 2.

Stages	α_{ik}	β_{ik}	CFL coefficient
2	$\begin{matrix}1 & \\ \frac{1}{2} & \frac{1}{2}\end{matrix}$	$\begin{matrix}1 & \\ 0 & \frac{1}{2}\end{matrix}$	1
3	$\begin{matrix}1 & & \\ 0 & 1 & \\ \frac{1}{3} & 0 & \frac{2}{3}\end{matrix}$	$\begin{matrix}\frac{1}{2} & & \\ 0 & \frac{1}{2} & \\ 0 & 0 & \frac{1}{3}\end{matrix}$	2
4	$\begin{matrix}1 & & & \\ 0 & 1 & & \\ 0 & 0 & 1 & \\ \frac{1}{4} & 0 & 0 & \frac{3}{4}\end{matrix}$	$\begin{matrix}\frac{1}{3} & & & \\ 0 & \frac{1}{3} & & \\ 0 & 0 & \frac{1}{3} & \\ 0 & 0 & 0 & \frac{1}{4}\end{matrix}$	3

and 3.4. Here we give the schemes in terms of the coefficients α_{ik}, β_{ik}; the Butcher form of these schemes is given in Appendix B. It is interesting to note that Gerisch and Weiner have independently proposed the SSP(3,2) scheme; see [4] for details.

From Tables 3.1, 3.3, and 3.4, we can conjecture the form of the optimal SSPRK methods with s stages and orders 1 and 2; namely, the optimal SSPRK method with s stages and order 1 has CFL coefficient s; and the optimal SSPRK method with s stages and order 2 has CFL coefficient $s-1$. Shu [17] has given a proof of the first-order result, and Gottlieb and Shu [6] have given a proof of the second-order result for $s=2$. We provide a new proof of the first-order result below as well as a proof of the second-order result for arbitrary s. These low-order methods with large CFL coefficients are useful when seeking a time-independent (steady-state) solution of (1.1), given that in such problems the accuracy considerations in time are typically less critical than those in space [17].

THEOREM 3.1. *For $s=1,2,3,\ldots$, the optimal s-stage SSPRK method of order 1 with $\beta_{ik}\geq 0$ has CFL coefficient s and can be represented in the form*

$$\alpha_{ik}=\begin{cases}1 & k=i-1,\\ 0 & \textit{otherwise.}\end{cases}\qquad \beta_{ik}=\begin{cases}\frac{1}{s} & k=i-1,\\ 0 & \textit{otherwise.}\end{cases}\qquad i=1,2,\ldots,s.$$

Before giving the proof of Theorem 3.1, we introduce the following notation and give a useful lemma. We find it convenient to write the general s-stage explicit Runge–Kutta method in the following form (cf. [6]):

$$U^{(0)}=U^n, \tag{3.5a}$$

$$U^{(i)}=U^{(0)}+\Delta t\sum_{k=0}^{i-1}c_{ik}L(U^{(k)}),\qquad i=1,2,\ldots,s, \tag{3.5b}$$

$$U^{n+1}=U^{(s)}. \tag{3.5c}$$

The coefficients c_{ik} are related to the coefficients $\alpha_{ik},\ \beta_{ik}$ recursively by

$$c_{ik} = \sum_{j=k+1}^{i-1} \alpha_{ij} c_{jk} + \beta_{ik}. \tag{3.6}$$

It is also easy to see that the coefficients c_{ik} are related to the Butcher array quantities $a_{ik},\ b_k$ by

$$\begin{aligned} a_{ik} &= c_{i-1,k-1}, \qquad k = 1, 2, \ldots, i-1, \quad i = 1, 2, \ldots, s-1, \\ b_k &= c_{s,k-1}, \qquad k = 1, 2, \ldots, s. \end{aligned}$$

LEMMA 3.2. *If a method of the form* (2.1) *with* $\alpha_{ik},\ \beta_{ik} \geq 0$ *has a CFL coefficient* $c > m > 0$, *then* $0 \leq c_{ik} < \frac{1}{m}$ *for all* $k = 0, 1, \ldots, i-1,\ i = 1, 2, \ldots, s$.

Proof. From Theorem 2.2, if $c > m > 0$, then $\alpha_{ik} > m\beta_{ik}$, or equivalently $\beta_{ik} < \frac{1}{m}\alpha_{ik}$, for all $i,\ k$ such that $\alpha_{ik} \neq 0$.

Now,

$$\alpha_{ik} \geq 0, \quad \sum_{k=0}^{i-1} \alpha_{ik} = 1, \quad i = 1, 2, \ldots, s, \quad \Rightarrow \quad \alpha_{ik} \leq 1$$

for all $i,\ k$. Hence, $\beta_{ik} < \frac{1}{m}$ for all $i,\ k$. In particular, $c_{10} = \beta_{10} < \frac{1}{m}$ for any valid SSPRK method.

We now proceed by induction on stage ℓ of an s-stage method. Assume $c_{ij} < \frac{1}{m}$ for $j = 0, 1, \ldots, \ell-1;\ i = 1, 2, \ldots, \ell$. (We have just shown that this result holds for $\ell = 1$.) Now consider stage $(\ell+1)$ of a valid SSPRK method; i.e., consider coefficients $c_{\ell+1,k}$ for $k = 0, 1, \ldots, \ell$ with

$$\sum_{k=0}^{\ell} \alpha_{\ell+1,k} = 1.$$

Then using (3.6),

$$\begin{aligned} c_{\ell+1,0} &= \sum_{k=1}^{\ell} \alpha_{\ell+1,k} c_{k0} + \beta_{\ell+1,0} \\ &< \frac{1}{m} \sum_{k=1}^{\ell} \alpha_{\ell+1,k} + \frac{1}{m}\alpha_{\ell+1,0} \\ &= \frac{1}{m}. \end{aligned}$$

Similar arguments can be used to show $c_{\ell+1,j} < \frac{1}{m}$ for $j = 1, 2, \ldots, \ell$. The lemma now follows by induction. ∎

Proof of Theorem 3.1. By contradiction, suppose there exists an s-stage, order-1 SSPRK method with CFL coefficient $c > s$. Because the method is order 1, we have

$$\sum_{k=0}^{s-1} c_{sk} = 1. \tag{3.7}$$

But from Lemma 3.2, we have

$$c_{ik} < \frac{1}{s}, \qquad k = 0, 1, \ldots, i-1, \quad i = 1, 2, \ldots, s.$$

Thus,

$$\sum_{k=0}^{s-1} c_{sk} < \sum_{k=0}^{s-1} \frac{1}{s} = 1,$$

contradicting (3.7). Thus, no s-stage, order-1 SSPRK method can exist with CFL coefficient $c > s$. Because the SSPRK methods proposed in Theorem 3.1 have $c = s$, they must be optimal representations. ∎

THEOREM 3.3. *For $s = 2, 3, 4, \ldots$, the optimal s-stage SSPRK method of order 2 with $\beta_{ik} \geq 0$ has CFL coefficient $s - 1$ and can be represented in the form*

$$\alpha_{ik} = \begin{cases} 1 & k = i-1, \\ 0 & \textit{otherwise.} \end{cases} \qquad \beta_{ik} = \begin{cases} \frac{1}{s-1} & k = i-1, \\ 0 & \textit{otherwise.} \end{cases} \qquad i = 1, 2, \ldots, s-1.$$

$$\alpha_{ik} = \begin{cases} \frac{1}{s} & k = 0, \\ \frac{s-1}{s} & k = s-1, \\ 0 & \textit{otherwise.} \end{cases} \qquad \beta_{ik} = \begin{cases} \frac{1}{s} & k = s-1, \\ 0 & \textit{otherwise.} \end{cases} \qquad i = s.$$

Proof. By contradiction, suppose there exists an s-stage, order-2 SSPRK method with CFL coefficient $c > s - 1$. Because it is order 2, the coefficients of the method must satisfy (3.7) and

$$\sum_{i=1}^{s-1} c_{si} \sum_{k=0}^{i-1} c_{ik} = \frac{1}{2}. \tag{3.8}$$

Also, using Lemma 3.2 with $c > s - 1$ implies that

$$c_{ik} < \frac{1}{s-1}, \qquad k = 0, 1, \ldots, i-1, \quad i = 1, 2, \ldots, s. \tag{3.9}$$

Using (3.9) in (3.8) for $k = 0, 1, \ldots, i-1,\ i = 1, 2, \ldots, s-1$, leads to

$$\sum_{i=1}^{s-1} \frac{i}{s-1} c_{si} > \frac{1}{2},$$

and using this result in (3.7) yields

$$\sum_{k=0}^{s-2} \frac{s-k-1}{s-1} c_{sk} < \frac{1}{2}.$$

Thus,

$$\begin{aligned} \frac{1}{2} &> \sum_{k=0}^{s-2} \frac{s-k-1}{s-1} c_{sk} \\ &= \sum_{k=0}^{s-2} \frac{s-k-1}{s-1} \left(\sum_{j=k+1}^{s-1} \alpha_{sj} c_{jk} + \beta_{sk} \right). \end{aligned}$$

Now we substitute recursively for c_{jk} using (3.6) in the right-hand side of the above equation and (3.8), and recalling that $\alpha_{ik} > (s-1)\beta_{ik}$ and $\alpha_{ik} \geq 0$ for $k = 0, 1, \ldots, i-1,\ i = 1, 2, \ldots, s$, we can use (3.8) to write

$$\frac{1}{2} > \frac{1}{2} + \sum_{j=1}^{s-2} j \sum_{l=s-j-1}^{s-1} \beta_{sl}\beta_{l,s-2-j} + \sum_{j=0}^{s-2} \frac{s-j-1}{s-1}\beta_{sj}.$$

This now contradicts the fact that $\beta_{ik} \geq 0$ for all $k = 0, 1, \ldots, i-1,\ i = 1, 2, \ldots, s$. Thus, no s-stage, order-2 SSPRK method can have CFL coefficient $c > s-1$. The proof is now completed by noting that because the schemes proposed have $c = s-1$, they must be optimal representations. □

In Tables A.1–A.2 in Appendix A, we give results for the coefficients of the optimal schemes of order $p = 3, 4$ in terms of their numerical values up to double precision.

A proof of optimality for the SSP(4,3) scheme follows easily from a result in [16], where it is proved that the optimal CFL coefficient of an s-stage SSPRK method of order p applied to a linear, constant-coefficient problem $\dot{U} = LU$ is $s - p + 1$. Thus if a nonlinear scheme can attain this optimal bound, then it must also be optimal. It is easy to see that SSP(4,3) is such a scheme.

We do not offer formal proofs of optimality in the remaining cases; however, these are the results of extensive numerical searches.

Finally, we describe our results for optimal low-storage SSPRK schemes. There are computational problems for which memory management considerations are at least as important as stability considerations when choosing a numerical time discretization method, e.g., direct numerical simulation of Navier–Stokes equations requiring high spatial resolution in three dimensions. In such cases, s-stage explicit Runge–Kutta methods that use less than the usual s units of storage are very desirable (see, e.g., [20]). We focus our discussion on SSPRK schemes that require only two units of storage per step,[4] although more general methods requiring more storage per step are possible. These schemes take the form

$$dU^{(i)} = A_i dU^{(i-1)} + \Delta t L(U^{(i-1)}), \tag{3.10a}$$

$$U^{(i)} = U^{(i-1)} + B_i dU^{(i-1)}, \qquad i = 1, 2, \ldots, s, \tag{3.10b}$$

where $U^{(0)} = U^n$, $U^{n+1} = U^{(s)}$, and $A_1 \equiv 0$. Again, we note that there is a relation between the coefficients $A_i,\ B_i$ and the coefficients $\alpha_{ik},\ \beta_{ik}$ or, equivalently, the usual quantities in the Butcher array. We denote the general s-stage, order-p low-storage SSPRK scheme simply by LS(s,p).

We have solved the corresponding nonlinear programming problems to optimize the CFL coefficient for the low-storage schemes defined by (3.10). The results for the coefficients $A_i,\ B_i$ are given in Tables 3.5–3.7 for up to 5 stages and order 3. Again, only numerical values of the coefficients are given to double precision. The Butcher array form of these schemes is given in Appendix C. Of course, a traditional implementation of any 2-stage scheme must be low-storage in the sense we are considering, so the optimal low-storage method with $s = p = 2$ corresponds to the optimal SSPRK scheme in Table 3.4. We note that the optimal 3-stage, order-3 low-storage method reported in Table 3.7 agrees with that reported in [6]. We also note that we were not successful in finding a 5-stage, order-4 scheme in this family, and we strongly suspect that such a method does not exist.

[4] We note that if some form of error control is envisaged, perhaps using an embedded [8] SSPRK scheme, then additional storage for the current solution vector is also required.

4. Numerical studies. In this section, we study the numerical behavior of our schemes and Shu–Osher SSP schemes for a few test problems designed to capture solution features that pose particular difficulties to numerical methods. Experiments for the classical fourth-order explicit Runge–Kutta method are also included because this method is commonly used in method-of-lines discretizations of hyperbolic conservation laws but is not SSP.

4.1. Test problems. There are a variety of solution features in computational fluid dynamics that commonly cause numerical problems. For example, many numerical methods produce significant errors near sonic points (points where the wavespeed equals zero). Upwind methods in particular are forced to give sonic points special consideration since the upwind direction changes at sonic points. Shock waves, contact discontinuities, and expansion fans may also lead to a variety of serious problems including oscillations, overshoots, and smearing that can spread discontinuities over several cells. In particular, contact discontinuities do not have any physical compression and thus smearing increases progressively with the number of time steps. Even when approximating smooth solutions, most numerical methods exhibit obvious flaws. For example, many stable numerical methods continuously erode the solution, leading to amplitude and dissipation errors [13].

To investigate the behavior of our time-stepping schemes, we consider three of Laney's five test problems [13]. These three problems involve all of the important flow features identified above: shocks, contacts, expansion fans, sonic points, and smooth solutions. Similar to Laney, we focus on the behavior of the numerical scheme for interior regions rather than boundaries and impose periodic boundary conditions on the domain $[-1, 1]$. It is known that sometimes a conventional (and intuitive!) treatment of the boundary data (especially in the case of inflow boundary conditions) within the stages of a Runge–Kutta method can lead to deterioration in the overall accuracy of the integration. We refer to [1] and references therein for a discussion of this problem and a method for its resolution. The spatial discretization and the results of the three test cases follow.

4.2. Spatial discretization. SSPRK schemes are natural candidates for any method-of-lines discretization involving nonsmooth solutions. Similar to the original paper on SSPRK methods [18], we choose finite-difference Shu–Osher methods (ENO) to spatially discretize the equations. These methods are derived using flux reconstruction and have a variety of desirable properties. For example, they naturally extend to an arbitrary order of accuracy in space, and they are independent of the time discretization, thus allowing experimentation with different time discretization methods. Moreover, educational codes are also freely available [13, 12], an attribute which is desirable for standardizing numerical studies. Our simulations are carried out with a discretization that has the same order of accuracy in Δx as the time discretization accuracy p. We further note that flux splitting is carried out according to

$$f^+(U) = \frac{1}{2}(f(U) + \alpha^n_{i+1/2}U),$$
$$f^-(U) = \frac{1}{2}(f(U) - \alpha^n_{i+1/2}U),$$

where $\alpha^n_{i+1/2} = \max\{|f'(U^n_{i+1})|, |f'(U^n_i)|\}$. For full details on the discretization as well as code, see [13, 12].

It is noteworthy that high-order, fully TVD spatial discretization schemes are also available; see Osher and Chakravarthy [15]. In these numerical studies, we

choose Shu–Osher spatial discretization schemes rather than TVD schemes since TVD schemes obtain only between first- and second-order accuracy at extrema and they have "been largely superseded by Shu and Osher's class of high-order ENO methods" [13].

It is also noteworthy that recent variations on Shu–Osher methods such as methods based on weighted essentially nonoscillatory (WENO) reconstructions (e.g., [14, 11]) also naturally combine with SSPRK schemes. See [13] for detailed discussions on these and other spatial discretizations appropriate for hyperbolic conservation laws.

4.3. Test Case 1: Linear advection of a sinusoid. In this test case, the smooth initial conditions

$$u(x,0) = -\sin(\pi x)$$

are evolved to time $t = 30$ according to the linear advection equation

$$\frac{\partial u}{\partial t} + \frac{\partial u}{\partial x} = 0$$

using a constant grid spacing of $\Delta x = 1/320$. Since this evolution causes the initial conditions to travel around the periodic domain $[-1, 1]$ exactly 15 times, it is clear that the exact solution is just $u(x, 30) = -\sin(\pi x)$. Test Case 1 effectively illustrates the evolution of a smooth solution with no sonic points and is useful for verifying convergence rates for high-order schemes. Moreover, even on completely smooth solutions most numerical methods designed for hyperbolic conservation laws exhibit obvious flaws [13]. This test case is quite helpful for understanding phase and amplitude errors but should not be used to study dispersion because only one frequency is present in the exact solution. It is also informative to contrast these results with those derived for problems involving shocks and other discontinuities.

To quantify the accuracy of the computed solution, we use the logarithm of the l_1 errors, i.e.,

$$\log_{10}\left(\frac{1}{N}\sum_{i=1}^{N}|U_i - u(x_i, 30)|\right),$$

where N is the number of grid points and x_i is the ith grid node. A plot of the error is given in Figure 4.1. To ensure a fair comparison for methods with a different number of stages, the error is plotted as a function of the effective CFL number[5] rather than the CFL number itself. This implies that for a particular plot, the total number of function evaluations at a particular abscissa value will be the same for each scheme. We start calculating errors for an effective CFL number of 0.6 and continue until the numerical method is so unstable that a value of `NaN` is returned; i.e., the scheme has become completely unstable.

In this smooth test example, the new second-order schemes give improved stability and accuracy over the original SSP(2,2). Also, SSP(5,3) gives improved stability over SSP(3,3) and SSP(4,3). Calculations for low-storage schemes show that LS(5,3) outperforms both LS(4,3) and LS(3,3). (For clarity, we use arrows to indicate the exact points at which SSP(3,3) and LS(3,3) go completely unstable.)

[5]Similar to the definition of an effective CFL coefficient, the *effective CFL number* of an SSPRK method of order p is $\frac{\Delta t}{\Delta x}\frac{s^*}{s}$, where s^* is the minimum number of stages to theoretically achieve order p, and s is the number of stages required for one step of the method.

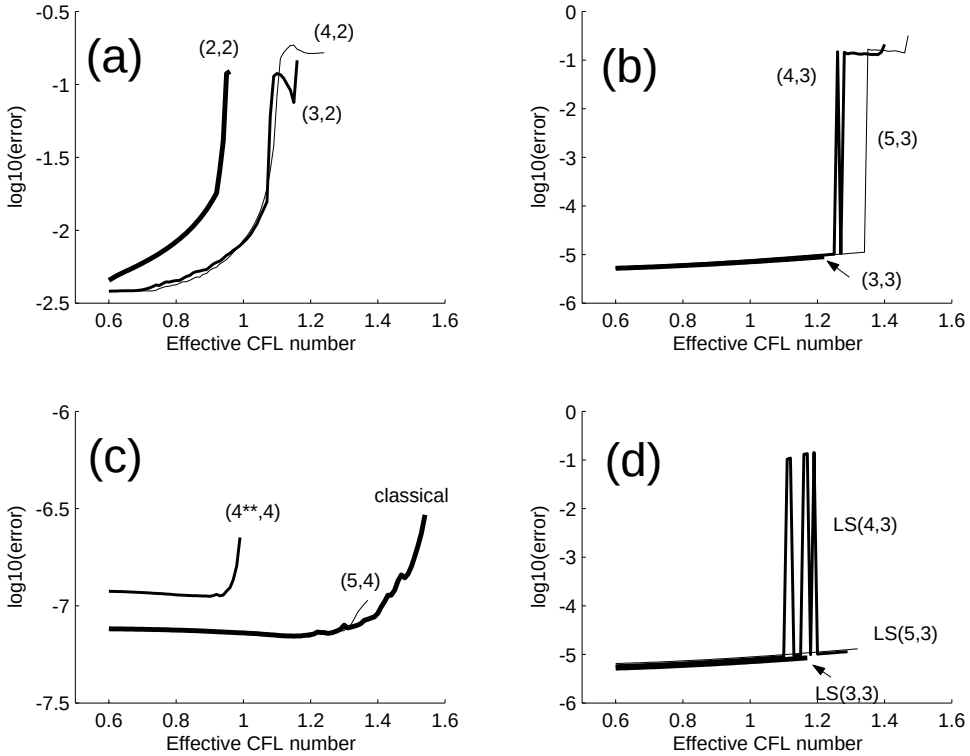

FIG. 4.1. l_1 *errors as a function of the effective CFL number.* (a) *Second-order schemes;* (b) *third-order schemes;* (c) *fourth-order schemes;* (d) *low-storage schemes.*

Based on these plots, we see that the second-order, third-order, and low-storage schemes all give stability restrictions that are within 20% of one another. This contrasts sharply with the results for fourth-order schemes (plot (c)). Here the new SSP(5,4) scheme gives more than a 40% improvement in the stability time-step restriction over the original SSP(4**,4). Moreover, it produces a marked reduction in the error, signifying a smaller error constant for this problem. It is noteworthy that in this case the classical fourth-order Runge-Kutta scheme outperforms even SSP(5,4): on *smooth* problems, schemes based purely on a linear stability analysis are expected to perform well. SSP schemes are designed to outperform on problems involving discontinuities in the solution or its derivatives, so in this case there is no reason to expect that schemes derived using nonlinear stability analysis will necessarily outperform classical schemes based on linear stability analysis.

4.4. Test Case 2: Linear advection of a square wave. In this test case, the discontinuous initial conditions

$$u(x,0) = \begin{cases} 1 & \text{for } |x| < 1/3, \\ 0 & \text{for } 1/3 < |x| \leq 1 \end{cases}$$

are evolved to time $t = 4$ according to the linear advection equation

$$\frac{\partial u}{\partial t} + \frac{\partial u}{\partial x} = 0$$

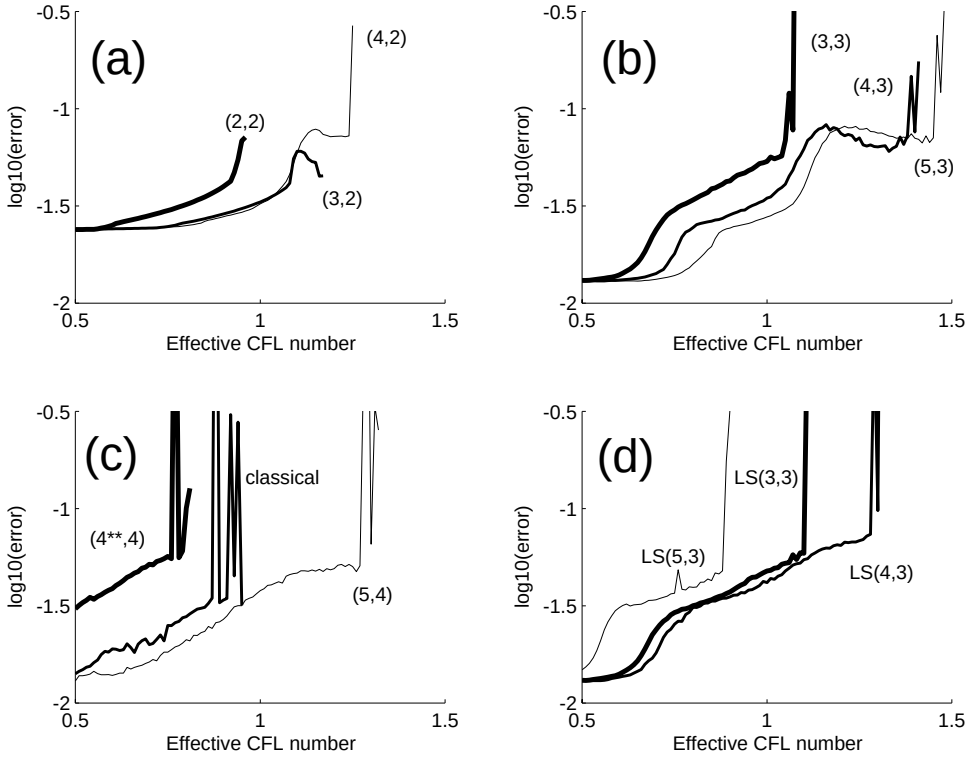

FIG. 4.2. *l_1 errors as a function of the effective CFL number.* (a) *Second-order schemes;* (b) *third-order schemes;* (c) *fourth-order schemes;* (d) *low-storage schemes.*

using a constant grid spacing of $\Delta x = 1/320$. Since this evolution causes the initial conditions to travel around the periodic domain $[-1, 1]$ exactly 2 times, it is clear that the exact solution at the final time is just $u(x, 4) = u(x, 0)$. Test Case 2 exhibits two jump discontinuities in the solution that correspond to contact discontinuities. This test case nicely illustrates progressive contact smearing and dispersion.

The log of the l_1 errors as a function of the effective CFL number is plotted in Figure 4.2. Based on these plots, it is immediately clear that a material improvement in both stability and accuracy is obtained using our new schemes.

For example, plot (a) shows that SSP(3,2) and SSP(4,2) allow about a 20–30% improvement in the time-step restriction over the original SSP(2,2). It is also clear that the new schemes also give a substantial improvement in stability and accuracy in the third-order case (b). Here we find that the optimal SSP(5,3) scheme gives about a 40% improvement in the stability time-step restriction over the usual SSP(3,3).

In the fourth-order case (c), even greater improvements are observed. SSP(5,4) gives more than a 60% improvement in the stability time-step restriction and requires only half the number of function evaluations to achieve an error of $10^{-1.5}$. Moreover, SSP(5,4) is clearly superior to the classical fourth-order Runge–Kutta scheme, with more than a 40% improvement in the observed time-step restriction. As conjectured, the best SSP schemes outperform classical (but generally non-SSP) schemes when discontinuities in the solution arise.

Out of the low-storage schemes (plot (d)), the new LS(4,3) gives the best

performance. It is interesting that the best-performing scheme LS(4,3) requires one-third less storage and is more CPU-efficient than the standard SSP(3,3) in this test example.

4.5. Test Case 3: Evolution of a square wave by Burgers's equation. In this test case, the discontinuous initial conditions

$$u(x,0) = \begin{cases} 1 & \text{for } |x| < 1/3, \\ -1 & \text{for } 1/3 < |x| \le 1 \end{cases}$$

are evolved to time $t = 0.3$ according to Burgers's equation

$$\frac{\partial u}{\partial t} + \frac{\partial}{\partial x}\left(\frac{1}{2}u^2\right) = 0$$

using a constant grid spacing of $\Delta x = 1/320$. In this example, the jump at $x = -1/3$ creates a simple centered expansion fan and the jump at $x = 1/3$ creates a steady shock. Until the shock and expansion fan intersect (at time $t = 2/3$), the exact solution is

$$u(x,t) = \begin{cases} -1 & \text{for } -\infty < x < b_1, \\ -1 + 2\frac{x-b_1}{b_2-b_1} & \text{for } b_1 < x < b_2, \\ 1 & \text{for } b_2 < x < b_{shock}, \\ -1 & \text{for } b_{shock} < x < \infty, \end{cases}$$

where $b_1 = -1/3 - t$, $b_2 = -1/3 + t$, and $b_{shock} = 1/3$ [13]. Test Case 3 is particularly interesting because it illustrates the behaviors near sonic points ($u = 0$) that correspond to an expansion fan and a compressive shock.

The log of the l_1 errors as a function of the effective CFL number is plotted in Figure 4.3. Based on these plots, it is clear that a marked improvement in both stability and accuracy is obtained in the second-, third-, and fourth-order cases using our new schemes.

Once again, plot (a) shows that SSP(3,2) and SSP(4,2) show about a 20–30% improvement in the time-step restriction over the original SSP(2,2). It is also clear that the new schemes also give a substantial improvement in stability and accuracy in the third-order case (b). Here we find that the optimal SSP(5,3) scheme gives about a 20% improvement in the stability time-step restriction over the usual SSP(3,3).

In the fourth-order case (c), even greater improvements are observed than in Test Case 2. SSP(5,4) gives an 80% improvement in the stability time-step restriction and requires only one-third the number of function evaluations to achieve an error of $10^{-2.6}$. Moreover, SSP(5,4) is clearly superior to the classical fourth-order Runge–Kutta scheme, with more than a 60% improvement in the observed time-step restriction. Similar to the previous example, SSP(5,4) outperforms classical (but generally non-SSP) schemes when discontinuities in the solution arise.

Out of the low-storage schemes (plot (d)), LS(3,3) and the new LS(4,3) give the best performance. In this test case, the best low-storage schemes are nearly as CPU-efficient as SSP(3,3) but require one-third less storage.

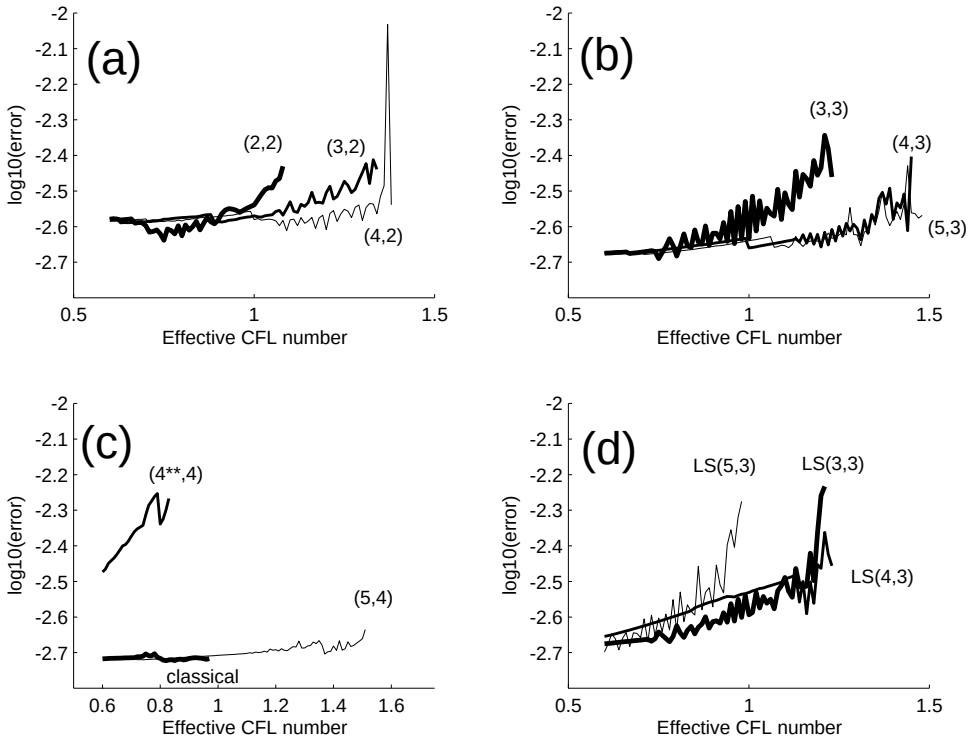

FIG. 4.3. l_1 *errors as a function of the effective CFL number.* (a) *Second-order schemes;* (b) *third-order schemes;* (c) *fourth-order schemes;* (d) *low-storage schemes.*

5. Summary and future work. We have presented new optimal SSPRK time discretization methods of orders 1 through 4 and stages 1 through 5. We find that, by allowing the number of stages to differ from the order of the method, it is possible to derive schemes with better, more effective CFL coefficients than those that are most commonly used. We have also performed a comparison of the new methods with Runge–Kutta methods (both SSP and non-SSP) most commonly used in practice on three problems involving scalar conservation laws. Our new methods compare favorably in terms of computational efficiency per time step, especially when the solution exhibits discontinuous behavior. The improvements are the greatest for the new fourth-order scheme with 5 stages (SSP(5,4)), where the allowable time step is significantly greater than the Shu–Osher fourth-order scheme and the classical fourth-order explicit Runge–Kutta scheme.

We also give results of a similar treatment of low-storage SSPRK schemes, where again we find significant improvements over the schemes most commonly used. The results are for orders 1 through 3 and stages 1 through 5. We were unable to find a low-storage scheme of order 4 having only 5 stages.

We have already examined the possibility of finding even more efficient SSPRK schemes by lifting the positivity constraint on the coefficients β_{ij}. Not surprisingly, improvements in the raw CFL coefficient are possible; however, the reduction in the effective CFL coefficient necessitated by the introduction of $\tilde{L}(\cdot)$ whenever $\beta_{ij} < 0$ causes these methods to be uncompetitive.

We are currently extending our investigation of optimal SSPRK methods to

methods having more than 5 stages and to orders 4 and 5. This work includes the study of low-storage SSPRK methods of order 4. We have also derived families of embedded SSPRK schemes for local error estimation and step-size control. We report on these findings elsewhere.

Appendix A. Optimal $(\alpha_{ik}, \beta_{ik})$ for $p = 3, 4$. Tables A.1 and A.2, respectively, give the optimal SSPRK methods of orders 3 and 4 and up to 5 stages in the representation (2.1).

GALERKIN PROPER ORTHOGONAL DECOMPOSITION METHODS FOR A GENERAL EQUATION IN FLUID DYNAMICS*

K. KUNISCH† AND S. VOLKWEIN†

Abstract. Error estimates for Galerkin proper orthogonal decomposition (POD) methods for nonlinear parabolic systems arising in fluid dynamics are proved. For the time integration the backward Euler scheme is considered. The asymptotic estimates involve the singular values of the POD snapshot set and the grid-structure of the time discretization as well as the snapshot locations.

Key words. proper orthogonal decomposition, evolution problems, Navier–Stokes equations, error estimates

1. Introduction.

Proper orthogonal decomposition (POD) provides a method for deriving low order models of dynamical systems. It can be thought of as a Galerkin approximation in the spatial variable, built from functions corresponding to the solution of the physical system at prespecified time instances. These are called the snapshots. Due to possible linear dependence or almost linear dependence, the snapshots themselves are not appropriate as a basis. Instead, a singular value decomposition is carried out and the leading generalized eigenfunctions are chosen as a basis, referred to as the POD basis.

POD was successfully used in a variety of fields including signal analysis and pattern recognition (see, e.g., [10]), fluid dynamics and coherent structures (see, e.g., [7, 22, 23, 24]), and more recently in control theory (see, e.g., [1, 3, 6, 15, 17, 18, 21]) and inverse problems (see [5]). Good approximation properties are reported for POD based schemes in several articles; see [8, 9, 14, 19], for example. Symmetry preserving properties of POD approximations are analyzed in [4].

As soon as one uses POD, questions concerning the quality of the approximation properties, convergence, and rate of convergence become relevant. It appears that, except for the work in [16], these issues have not been addressed. This may be due, in part, to the fact that for POD based approximation of partial differential equations one cannot rely on results clarifying the approximation properties of the POD-subspaces to elements in function spaces as, e.g., L^p or C. Such results are an essential building block for, e.g., finite element approximations to partial differential equations. In our work we propose a strategy to describe and analyze convergence and rate of convergence approximations based on POD approximation in space and backwards Euler discretization in time for a class of nonlinear evolutionary partial differential equations including the Navier–Stokes equation in two dimensions. Due to the lack of typical function space approximation results described above, these results are not a priori in the format that one is familiar with from finite difference, finite element, or spectral approximations, for example. While we believe that the estimates that we propose reflect well the properties of POD based approximations,

†Karl-Franzens-Universität Graz, Institut für Mathematik, Heinrichstraße 36, A-8010 Graz, Austria (karl.kunisch@uni-graz.at, stefan.volkwein@uni-graz.at).

they are certainly up for discussion and future improvement. Roughly, it will be shown that the approximation error can be decomposed in a contribution that arises due to the POD approximation in space, which is measured in terms of spectral properties specifying the POD basis, and in the usual approximation error due to the backwards Euler scheme with respect to time integration.

Concerning the availability of snapshots, two situations can be considered: in the first one the snapshots are obtained by an independent numerical method and then used within a POD approach for the sake of system reduction. In the second situation the snapshots could be obtained and digitalized from actual physical phenomena.

In this article we analyze the case in which snapshots are assumed to be available for the same system as that for which the approximation properties are analyzed. The value of this analysis is to understand and justify analytically the observed high approximation quality of POD schemes. Certainly the problem of quantifying the approximation properties of POD based schemes where the snapshots are taken from processes which are possibly "nearby," but different from the system under consideration, is of considerable interest. This situation can occur, for example, in the case of control and optimal control of systems: snapshots are taken from a system at a nominal control value, and a POD model reduction and subsequent optimal control step are performed. The dynamics of the optimally controlled system then differ from the original system. The analysis of these problems can be the focus of future research.

As already mentioned, the present work is a continuation of our efforts to approximation properties of POD based schemes. We extend our earlier results of [16] in three directions. First, the results of the present paper are asymptotic results in the sense that the constants appearing in the estimates do not depend on the snapshot set. Second, we now utilize two time discretizations, one for the set of snapshots and a second one for the numerical integration. The effect of the two grids on the convergence rate is kept separate in the estimates. Third, we focus in this paper on a different class of nonlinearities, including the Navier–Stokes equations in dimension two, which were not included in [16].

The paper is organized as follows. In section 2 the nonlinear evolution problem is introduced and necessary prerequisites are given. The POD method is reviewed in section 3. Convergence of the backward Euler scheme is studied in section 4. Technical proofs are deferred to appendices.

2. General equations in fluid dynamics. In this section we specify the abstract nonlinear evolution problem that will be considered in this paper and present an existence and uniqueness result.

Let V and H be real separable Hilbert spaces and suppose that V is dense in H with compact embedding. By $\langle \cdot\,, \cdot \rangle_H$ we denote the inner product in H. The inner product in V is given by a symmetric bounded, coercive, bilinear form $a : V \times V \to \mathbb{R}$:

$$\langle \varphi, \psi \rangle_V = a(\varphi, \psi) \quad \text{for all } \varphi, \psi \in V \tag{2.1}$$

with an associated norm given by $\| \cdot \|_V = \sqrt{a(\cdot\,, \cdot)}$. Since V is continuously injected into H, there exists a constant $c_V > 0$ such that

$$\|\varphi\|_H \le c_V \, \|\varphi\|_V \quad \text{for all } \varphi \in V. \tag{2.2}$$

We associate with a the linear operator A:

$$\langle A\varphi, \psi \rangle_{V',V} = a(\varphi, \psi) \quad \text{for all } \varphi, \psi \in V,$$

where $\langle \cdot, \cdot \rangle_{V',V}$ denotes the duality pairing between V and its dual. Then A is an isomorphism from V onto V'. Alternatively, A can be considered as a linear unbounded self-adjoint operator in H with domain

$$D(A) = \{\varphi \in V : A\varphi \in H\}.$$

By identifying H and its dual H' it follows that

$$D(A) \hookrightarrow V \hookrightarrow H = H' \hookrightarrow V',$$

each embedding being continuous and dense, when $D(A)$ is endowed with the graph norm of A.

We introduce the continuous operator $R : V \to V'$, which maps $D(A)$ into H and satisfies

$$\begin{aligned} \|R\varphi\|_H &\le c_R \, \|\varphi\|_V^{1-\delta_1} \|A\varphi\|_H^{\delta_1} \quad \text{for all } \varphi \in D(A), \\ |\langle R\varphi, \varphi \rangle_{V',V}| &\le c_R \, \|\varphi\|_V^{1+\delta_2} \|\varphi\|_H^{1-\delta_2} \quad \text{for all } \varphi \in V \end{aligned} \tag{2.3}$$

for a constant $c_R > 0$ and for $\delta_1, \delta_2 \in [0, 1)$. We also assume that $A + R$ is coercive on V; i.e., there exists a constant $\eta > 0$ such that

$$a(\varphi, \varphi) + \langle R\varphi, \varphi \rangle_{V',V} \ge \eta \, \|\varphi\|_V^2 \quad \text{for all } \varphi \in V. \tag{2.4}$$

Moreover, let $B : V \times V \to V'$ be a bilinear continuous operator mapping $D(A) \times D(A)$ into H such that there exist constants $c_B > 0$ and $\delta_3, \delta_4, \delta_5 \in [0, 1)$ satisfying

$$\begin{aligned} \langle B(\varphi, \psi), \psi \rangle_{V',V} &= 0, \\ \big|\langle B(\varphi, \psi), \phi \rangle_{V',V}\big| &\le c_B \, \|\varphi\|_H^{\delta_3} \|\varphi\|_V^{1-\delta_3} \|\psi\|_V \|\phi\|_V^{\delta_3} \|\phi\|_H^{1-\delta_3}, \\ \|B(\varphi, \chi)\|_H + \|B(\chi, \varphi)\|_H &\le c_B \, \|\varphi\|_V \|\chi\|_V^{1-\delta_4} \|A\chi\|_H^{\delta_4}, \\ \|B(\varphi, \chi)\|_H &\le c_B \, \|\varphi\|_H^{\delta_5} \|\varphi\|_V^{1-\delta_5} \|\chi\|_V^{1-\delta_5} \|A\chi\|_H^{\delta_5} \end{aligned} \tag{2.5}$$

for all $\varphi, \psi, \phi \in V$, for all $\chi \in D(A)$. To simplify the notation we set $B(\varphi) = B(\varphi, \varphi)$ for $\varphi \in V$.

For given $f \in L^2(0, T; H)$ and $y_0 \in V$ we consider the nonlinear evolution problem

$$\frac{d}{dt} \, \langle y(t), \varphi \rangle_H + a(y(t), \varphi) + \big\langle B(y(t)) + Ry(t), \varphi \big\rangle_{V',V} = \langle f(t), \varphi \rangle_H \tag{2.6a}$$

for all $\varphi \in V$ and $t \in (0, T]$ a.e. and

$$y(0) = y_0 \quad \text{in } H. \tag{2.6b}$$

The following theorem guarantees the existence of a unique solution to (2.6).

THEOREM 2.1. *Assume that* (2.3) *and* (2.5) *hold. Then for every* $f \in L^2(0, T; H)$ *and* $y_0 \in V$ *there exists a unique solution of* (2.6) *satisfying*

$$y \in C([0, T]; V) \cap L^2(0, T; D(A)) \cap H^1(0, T; H). \tag{2.7}$$

Proof. The proof is analogous to that of Theorem 2.1 in [25, p. 111], where the case with time-independent f was treated. □

Condition (2.4) will not be needed before section 4. Let us present an example for the nonlinear evolution system (2.6).

EXAMPLE 2.2. *Let Ω denote a bounded domain in $\mathbb{R}^2$ with boundary Γ and let $T > 0$. The two-dimensional Navier–Stokes equations are given by*

$$\varrho\left(u_t + (u\cdot\nabla)u\right) - \nu\Delta u + \nabla p = f \quad \text{in } Q = (0,T)\times\Omega, \tag{2.8a}$$

$$\operatorname{div} u = 0 \quad \text{in } Q, \tag{2.8b}$$

where $\varrho > 0$ is the density of the fluid, $\nu > 0$ is the kinematic viscosity, f represents volume forces, and

$$(u\cdot\nabla)u = \Big(u_1\frac{\partial u_1}{\partial x_1} + u_2\frac{\partial u_1}{\partial x_2}, u_1\frac{\partial u_2}{\partial x_1} + u_2\frac{\partial u_2}{\partial x_2}\Big)^{\mathsf{T}}.$$

The unknowns are the velocity field $u = (u_1, u_2)$ and the pressure p. Together with (2.8) *we consider nonslip boundary conditions*

$$u = u_d \quad \text{on } \Sigma = (0,T)\times\Gamma \tag{2.8c}$$

and the initial condition

$$u(0,\cdot) = u_0 \quad \text{in } \Omega. \tag{2.8d}$$

In [25, pp. 104–107, 116–117] *it was proved that* (2.8) *can be written in the form* (2.6).

Next we recall Young's inequality, which will frequently be used in our work. For a proof we refer to [2, p. 28], for instance.

LEMMA 2.3 (Young's inequality). *For all $a, b, \varepsilon > 0$ and for all $p \in (1,\infty)$ we have*

$$ab \le \frac{\varepsilon a^p}{p} + \frac{b^q}{q\varepsilon^{q/p}},$$

where $q = p/(p-1)$.

3. The POD method. This section is devoted to a discussion of the POD method for the nonlinear evolution problem (2.6). Throughout we denote by y the unique solution to (2.6) satisfying (2.7). Moreover, we suppose that $f \in C([0,T];H)$.

3.1. Computation of the POD basis. For given $n \in \mathbb{N}$ let

$$0 = t_0 < t_2 < \cdots < t_n \le T$$

denote a grid in the interval $[0,T]$ and set $\delta t_j = t_j - t_{j-1}$, $j = 1,\dots,n$. Define

$$\Delta t = \max\ (\delta t_1,\dots,\delta t_n) \quad \text{and} \quad \delta t = \min\ (\delta t_1,\dots,\delta t_n).$$

Suppose that the snapshots $y(t_j)$ of (2.6) at the given time instances t_j, $j = 0,\dots,n$, are known. We set

$$\mathcal{V} = \operatorname{span}\{y(t_0),\dots,y(t_n)\}$$

and refer to $\mathcal{V}$ as the ensemble consisting of the snapshots $\{y(t_j)\}_{j=0}^n$, at least one of which is assumed to be nonzero. Notice that $\mathcal{V} \subset V$ by construction. Throughout the remainder of this section we let X denote either the space V or H.

Let $\{\psi_i\}_{i=1}^d$ denote an orthonormal basis for $\mathcal{V}$ with $d = \dim \mathcal{V}$. Then each member of the ensemble can be expressed as

$$y(t_j) = \sum_{i=1}^{d} \langle y(t_j), \psi_i \rangle_X \psi_i \quad \text{for } j = 0, \dots, n. \tag{3.1}$$

The method of POD consists of choosing an orthonormal basis such that for every $\ell \in \{1, \dots, d\}$ the mean square error between the elements $y(t_j)$, $0 \le j \le n$, and the corresponding ℓth partial sum of (3.1) is minimized on average:

$$\begin{aligned} &\min_{\{\psi_i\}_{i=1}^{\ell}} \sum_{j=0}^{n} \alpha_j \left\| y(t_j) - \sum_{i=1}^{\ell} \langle y(t_j), \psi_i \rangle_X \psi_i \right\|_X^2 \\ &\text{subject to } \langle \psi_i, \psi_j \rangle_X = \delta_{ij} \quad \text{for } 1 \le i \le \ell, 1 \le j \le i. \end{aligned} \tag{3.2}$$

Here $\{\alpha_j\}_{j=0}^n$ are positive weights, which for our purposes are chosen to be

$$\alpha_0 = \frac{\delta t_1}{2}, \quad \alpha_j = \frac{\delta t_j + \delta t_{j+1}}{2} \text{ for } j = 1, \dots, n-1, \quad \text{and} \quad \alpha_n = \frac{\delta t_n}{2}.$$

A solution $\{\psi_i\}_{i=1}^{\ell}$ to (3.2) is called a POD basis of rank ℓ. The subspace spanned by the first ℓ POD basis functions is denoted by V^ℓ.

Remark 3.1. Note that

$$\mathcal{I}_n(y) = \sum_{j=0}^{n} \alpha_j \left\| y(t_j) - \sum_{i=1}^{\ell} \langle y(t_j), \psi_i \rangle_X \psi_i \right\|_X^2$$

is the trapezoidal approximation for the integral

$$\mathcal{I}(y) = \int_0^T \left\| y(t) - \sum_{i=1}^{\ell} \langle y(t), \psi_i \rangle_X \psi_i \right\|_X^2 dt.$$

For all $y \in C([0,T]; X)$ it follows that $\lim_{n\to\infty} \mathcal{I}_n(y) = \mathcal{I}(y)$.

The solution of (3.2) is characterized by the necessary optimality condition. For that purpose we endow $\mathbb{R}^{n+1}$ with the weighted inner product

$$\langle v, w \rangle_{\mathbb{R}^{n+1}} = \sum_{j=0}^{n} \alpha_j v_j w_j \quad \text{for } v = (v_0, \dots, v_n)^{\mathsf{T}},\ w = (w_0, \dots, w_n)^{\mathsf{T}} \in \mathbb{R}^{n+1}.$$

Let us introduce the bounded linear operator $\mathcal{Y}_n : \mathbb{R}^{n+1} \to X$ by

$$\mathcal{Y}_n v = \sum_{j=0}^{n} \alpha_j v_j y(t_j) \quad \text{for } v \in \mathbb{R}^{n+1}.$$

Then the adjoint $\mathcal{Y}_n^* : X \to \mathbb{R}^{n+1}$ is given by

$$\mathcal{Y}_n^* z = (\langle z, y(t_0) \rangle_X, \dots, \langle z, y(t_n) \rangle_X)^{\mathsf{T}} \quad \text{for } z \in X.$$

It follows that $\mathcal{R}_n = \mathcal{Y}_n \mathcal{Y}_n^* \in \mathcal{L}(X)$ and $\mathcal{K}_n = \mathcal{Y}_n^* \mathcal{Y}_n \in \mathbb{R}^{(n+1)\times(n+1)}$ are given by

$$\mathcal{R}_n z = \sum_{j=0}^{n} \alpha_j \langle z, y(t_j) \rangle_X y(t_j) \text{ for } z \in X \quad \text{and} \quad (\mathcal{K}_n)_{ij} = \langle y(t_j), y(t_i) \rangle_X,$$

respectively. Here $\mathcal{L}(X)$ denotes the Banach space of all bounded linear operators on X.

Using a Lagrangian framework we derive the following optimality conditions for the optimization problem (3.2):

$$\mathcal{R}_n\psi = \lambda\psi; \tag{3.3}$$

compare, e.g., [7, 26]. Note that $\mathcal{R}_n$ is a bounded, self-adjoint and nonnegative operator. Moreover, since the image of $\mathcal{R}_n$ has finite dimensions, $\mathcal{R}_n$ is also compact. By Hilbert–Schmidt theory (see, e.g., [20, p. 203]) there exist an orthonormal basis $\{\psi_i\}_{i\in\mathbb{N}}$ for X and a sequence $\{\lambda_i\}_{i\in\mathbb{N}}$ of nonnegative real numbers so that

$$\mathcal{R}_n\psi_i = \lambda_i\psi_i, \quad \lambda_1 \geq \cdots \geq \lambda_d > 0, \quad \text{and } \lambda_i = 0 \text{ for } i > d. \tag{3.4}$$

Moreover, $\mathcal{V} = \operatorname{span}\{\psi_i\}_{i=1}^d$.

Note that $\{\lambda_i\}_{i\in\mathbb{N}}$ as well as $\{\psi_i\}_{i\in\mathbb{N}}$ depend on n. Contents permitting the notation of this dependence are dropped.

Remark 3.2. Setting

$$v_i = \frac{1}{\sqrt{\lambda_i}}\,\mathcal{Y}_n^*\psi_i \quad \text{for } i = 1, \dots, d$$

we find $\mathcal{K}_n v_i = \lambda_i v_i$ and $\langle v_i, v_j\rangle_{\mathbb{R}^{n+1}} = \delta_{ij}$ for $1 \leq i, j \leq d$. Thus, $\{v_i\}_{i=1}^d$ is an orthonormal basis of eigenvectors of $\mathcal{K}_n$ for the image of $\mathcal{K}_n$. Conversely, if $\{v_i\}_{i=1}^d$ is a given orthonormal basis for the image of $\mathcal{K}_n$, then it follows that the first d eigenfunctions of $\mathcal{R}_n$ can be determined by

$$\psi_i = \frac{1}{\sqrt{\lambda_i}}\,\mathcal{Y}_n v_i \quad \text{for } i = 1, \dots, d.$$

The sequence $\{\psi_i\}_{i=1}^\ell$ solves the optimization problem (3.2). This fact as well as the error formula below were proved in [7, 26], for example.

PROPOSITION 3.3. *Let $\lambda_1 \geq \cdots \geq \lambda_d > 0$ denote the positive eigenvalues of $\mathcal{R}^n$ with the associated eigenvectors $\psi_1, \dots, \psi_d \in X$. Then, $\{\psi_i^n\}_{i=1}^\ell$ is a POD basis of rank $\ell \leq d$, and we have the error formula*

$$\sum_{j=0}^{n} \alpha_j \left\| y(t_j) - \sum_{i=1}^{\ell} \langle y(t_j), \psi_i\rangle_X \psi_i \right\|_X^2 = \sum_{i=\ell+1}^{d} \lambda_i. \tag{3.5}$$

3.2. Perturbation analysis for $\sum_{i=\ell+1}^{d} \lambda_i$. The eigenvalues $\{\lambda_i\}_{i\in\mathbb{N}}$ depend on the time instances $\{t_j\}_{j=0}^n$. Next we investigate $\sum_{i=\ell+1}^d \lambda_i$ as Δt tends to zero, i.e., $n \to \infty$. Let us define the bounded linear operator $\mathcal{Y} : L^2(0, T; \mathbb{R}) \to X$ by

$$\mathcal{Y}\varphi = \int_0^T \varphi(t) y(t)\, dt \quad \text{for } \varphi \in L^2(0, T; \mathbb{R}).$$

The adjoint $\mathcal{Y}^* : X \to L^2(0, T; \mathbb{R})$ is given by

$$\big(\mathcal{Y}^* z\big)(t) = \langle z, y(t)\rangle_X \quad \text{for } z \in X.$$

For $\mathcal{R} = \mathcal{Y}\mathcal{Y}^* \in \mathcal{L}(X)$ we find

$$\mathcal{R}z = \int_0^T \langle z\,, y(t)\rangle_X y(t)\, dt \quad \text{for } z \in X. \tag{3.6}$$

Notice that $\mathcal{R}_n\varphi$ is the trapezoidal approximation for the integral $\mathcal{R}\varphi$. If $y_t \in L^2(0,T;X)$, then we obtain

$$\lim_{\Delta t\to\infty} \|\mathcal{R}_n - \mathcal{R}\|_{\mathcal{L}(X)} = 0. \tag{3.7}$$

Let us mention that as far as the following analysis is concerned any other choice of positive weights α_j is possible provided that (3.7) holds.

We proceed to investigate the relationship between $\mathcal{R}_n$ and $\mathcal{R}$. Notice that $\mathcal{R}$ is self-adjoint and nonnegative. Since $y \in C([0,T];V)$, the Kolmogorov compactness criterion in $L^2(0,T;\mathbb{R})$ implies that $\mathcal{Y}^* : X \to L^2(0,T;X)$ is compact. Boundedness of $\mathcal{Y}$ implies that $\mathcal{R}$ is a compact operator as well. From the Hilbert–Schmidt theorem it follows that there exists a complete orthonormal basis $\{\psi_i^\infty\}_{i\in\mathbb{N}}$ for X and a sequence $\{\lambda_i^\infty\}_{i\in\mathbb{N}}$ of nonnegative real numbers so that

$$\mathcal{R}\psi_i^\infty = \lambda_i^\infty\psi_i^\infty, \quad \lambda_1^\infty \ge \lambda_2^\infty \ge \cdots, \quad \text{and } \lambda_i^\infty \to 0 \text{ as } i\to\infty. \tag{3.8}$$

Remark 3.4. Analogous to Remark 3.2 we set

$$v_i^\infty = \frac{1}{\sqrt{\lambda_i^\infty}}\,\mathcal{Y}^*\psi_i^\infty = \frac{1}{\sqrt{\lambda_i^\infty}}\,\langle\psi_i^\infty, y(t)\rangle_X\,dt \quad \text{for } i \in \{j\in\mathbb{N} : \lambda_j^\infty > 0\}.$$

Let $\mathcal{K} = \mathcal{Y}^*\mathcal{Y} \in \mathcal{L}(L^2(0,T;\mathbb{R}))$ be given by

$$\mathcal{K}\varphi = \int_0^T \langle y(s), y(t)\rangle_X \varphi(s)\,ds \quad \text{for } \varphi \in L^2(0,T;\mathbb{R}).$$

It follows that

$$\begin{aligned}
\big(\mathcal{K}v_i^\infty\big)(t) &= \int_0^T \langle y(s), y(t)\rangle_X v_i^\infty(s)\,ds \\
&= \frac{1}{\sqrt{\lambda_i^\infty}}\left\langle \int_0^T \langle\psi_i^\infty, y(s)\rangle_X y(s)\,ds, y(t)\right\rangle_X = \frac{1}{\sqrt{\lambda_i^\infty}}\,\langle\mathcal{R}\psi_i^\infty, y(t)\rangle_X \\
&= \frac{1}{\sqrt{\lambda_i^\infty}}\,\langle\mathcal{R}\psi_i^\infty, y(t)\rangle_X = \lambda_i^\infty v_i^\infty(t)
\end{aligned}$$

and, consequently, the v_i^∞'s are the eigenfunctions of $\mathcal{K}$ for $i\in\mathbb{N}$ with $\lambda_i^\infty > 0$.

The spectra of $\mathcal{R}$ and $\mathcal{R}_n$ are pure point spectra except for possibly 0. Each nonzero eigenvalue of $\mathcal{R}$ has finite multiplicity and 0 is the only possible accumulation point of the spectrum of $\mathcal{R}$; see [13, p. 185]. These facts together with (3.7) will allow us to draw important conclusions on the term $\sum_{i=\ell+1}^d \lambda_i^n$ in our estimates below. Henceforth we denote by $\{\lambda_i^n\}_{i=1}^{d(n)}$ the positive eigenvalues of $\mathcal{R}_n$ with associated eigenfunctions $\{\psi_i^n\}_{i=1}^{d(n)}$. Similarly $\{\lambda_i^\infty\}_{i\in\mathbb{N}}$ denotes the positive eigenvalues of $\mathcal{R}$ with associated eigenfunctions $\{\psi_i^\infty\}_{i\in\mathbb{N}}$. In each case the eigenvalues are considered according to their multiplicity. Let us note that

$$\int_0^T \|y(t)\|_X^2\,dt = \sum_{i=1}^\infty \lambda_i^\infty. \tag{3.9}$$

In fact,

$$\mathcal{R}\psi_i^\infty = \int_0^T \langle\psi_i^\infty, y(t)\rangle_X y(t)\,dt \quad \text{for every } i\in\mathbb{N}.$$

Taking the inner product with ψ_i^∞ and summing over i we arrive at

$$\sum_{i=1}^{\infty} \int_0^T \left| \langle \psi_i^\infty, y(t) \rangle_X \right|^2 dt = \sum_{i=1}^{\infty} \langle \mathcal{R}\psi_i^\infty, \psi_i^\infty \rangle_X = \sum_{i=1}^{\infty} \lambda_i^\infty.$$

Expanding $y(t) \in X$ in terms of $\{\psi_i^\infty\}_{i\in\mathbb{N}}$ we have

$$y(t) = \sum_{i=1}^{\infty} \langle \psi_i^\infty, y(t) \rangle_X \psi_i^\infty$$

and hence

$$\int_0^T \|y(t)\|_X^2 \, dt = \sum_{i=1}^{\infty} \int_0^T \left| \langle \psi_i^\infty, y(t) \rangle_X \right|^2 dt = \sum_{i=1}^{\infty} \lambda_i^\infty,$$

which is (3.9). From Proposition 3.3 and (3.4) we obtain

$$\sum_{j=0}^{n} \alpha_j \, \|y(t_j)\|_X^2 = \sum_{i=1}^{\infty} \lambda_i^n \quad \text{for every } n \in \mathbb{N}. \tag{3.10}$$

For convenience we do not indicate the dependence of α_j on n. Note that for $y \in C([0,T], X)$

$$\sum_{j=0}^{n} \alpha_j \, \|y(t_j)\|_X^2 \to \int_0^T \|y(t)\|_X^2 \, dt \quad \text{as } \Delta t \to 0.$$

Combining this fact with (3.9) and (3.10) we find

$$\sum_{i=1}^{\infty} \lambda_i^n \to \sum_{i=1}^{\infty} \lambda_i^\infty \quad \text{as } \Delta t \to 0. \tag{3.11}$$

Now choose and fix

$$\ell \quad \text{such that} \quad \lambda_\ell^\infty \neq \lambda_{\ell+1}^\infty. \tag{3.12}$$

Then by spectral analysis of compact operators [13, pp. 212–214] and (3.7) it follows that

$$\lambda_i^n \to \lambda_i^\infty \quad \text{for } 1 \le i \le \ell \text{ as } \Delta t \to 0. \tag{3.13}$$

Combining (3.11) and (3.13) there exists $\overline{\Delta t} > 0$ such that

$$\sum_{i=\ell+1}^{\infty} \lambda_i^n \le 2 \sum_{i=\ell+1}^{\infty} \lambda_i^\infty \quad \text{for all } \Delta t \le \overline{\Delta t} \tag{3.14}$$

if $\sum_{i=\ell+1}^{\infty} \lambda_i^\infty \neq 0$. Moreover, for ℓ as above, $\overline{\Delta t}$ can also be chosen such that

$$\sum_{i=\ell+1}^{d(n)} \left| \langle \psi_i^n, y_0 \rangle_X \right|^2 \le 2 \sum_{i=\ell+1}^{\infty} \left| \langle \psi_i^\infty, y_0 \rangle_X \right|^2 \quad \text{for all } \Delta \le \overline{\Delta t}, \tag{3.15}$$

provided that $\sum_{i=\ell+1}^{\infty} |\langle y_0, \psi_i^\infty \rangle_X|^2 \neq 0$. To verify (3.15) let us first note that $y_0 = y(0) \in \overline{\text{range } \mathcal{R}} = (\ker \mathcal{R})^\perp$. In fact, if $v \in \ker \mathcal{R}$, then $t \mapsto \langle v, y(t) \rangle_X$ is the zero function in $L^2(0,T;X)$. Since by assumption $y \in C([0,T];X)$ it follows that $\langle v, y(0) \rangle_X = 0$. But $v \in \ker \mathcal{R}$ was chosen arbitrarily and hence $y_0 \in (\ker \mathcal{R})^\perp$. As a consequence we have

$$\|y_0\|_X^2 = \sum_{i=1}^{\infty} \big|\langle y_0, \psi_i^\infty \rangle_X\big|^2. \tag{3.16}$$

Since $t_0 = 0$ holds, we have $y_0 \in \mathcal{V}^{(n)}$ for every n and

$$\|y_0\|_X^2 = \sum_{i=1}^{d(n)} \big|\langle y_0, \psi_i^n \rangle_X\big|^2. \tag{3.17}$$

Therefore, for $\ell < d(n)$ by (3.16) and (3.17)

$$\begin{aligned}\sum_{i=\ell+1}^{d(n)} \big|\langle y_0, \psi_i^n \rangle_X\big|^2 &= \sum_{i=1}^{d(n)} \big|\langle y_0, \psi_i^n \rangle_X\big|^2 - \sum_{i=1}^{\ell} \big|\langle y_0, \psi_i^n \rangle_X\big|^2 + \sum_{i=1}^{\ell} \big|\langle y_0, \psi_i^\infty \rangle_X\big|^2 \\ &\quad + \sum_{i=\ell+1}^{\infty} \big|\langle y_0, \psi_i^\infty \rangle_X\big|^2 - \sum_{i=1}^{\infty} \big|\langle y_0, \psi_i^\infty \rangle_X\big|^2 \\ &= \sum_{i=1}^{\ell} \Big(\big|\langle y_0, \psi_i^\infty \rangle_X\big|^2 - \big|\langle y_0, \psi_i^n \rangle_X\big|^2\Big) + \sum_{i=\ell+1}^{\infty} \big|\langle y_0, \psi_i^\infty \rangle_X\big|^2.\end{aligned}$$

As a consequence of (3.7) and (3.12) we have $\lim_{\Delta t \to 0} \psi_i^n = \psi_i^\infty$ for $i = 1, \dots, \ell$ and hence (3.15) follows.

4. Backward Euler Galerkin method. This section is devoted to error estimates for the Galerkin POD method applied to (2.6) combined with the backward Euler method for the time integration. Throughout, (2.3)–(2.5) are assumed to hold.

4.1. Case $X = V$. Let us choose $X = V$ in the context of section 3. To study the backward Euler Galerkin POD method for (2.6), we introduce the Ritz projection $P^\ell : V \to V^\ell$, $1 \leq \ell \leq d$, by

$$a(P^\ell \varphi, \psi) = a(\varphi, \psi) \quad \text{for all } \psi \in V^\ell, \tag{4.1}$$

where $\varphi \in V$. Since the Hilbert space V is endowed with the inner product (2.1), P^ℓ is the orthogonal projection of V on V^ℓ. In particular, this implies that P^ℓ has norm one.

LEMMA 4.1. *For every $\ell \in \{1, \dots, d\}$ the projection operators P^ℓ satisfy*

$$\sum_{j=0}^{n} \alpha_j \, \|y(t_j) - P^\ell y(t_j)\|_V^2 \leq \sum_{i=\ell+1}^{d} \lambda_i, \tag{4.2}$$

where λ_i denote the eigenvalues introduced in (3.4).

Proof. For arbitrary $\varphi \in V$ we deduce from (2.1) and (4.1) that

$$\|\varphi - P^\ell \varphi\|_V^2 = a(\varphi - P^\ell \varphi, \varphi - P^\ell \varphi) = a(\varphi - P^\ell \varphi, \varphi - \psi) \leq \|\varphi - P^\ell \varphi\|_V \|\varphi - \psi\|_V$$

for all $\psi \in V^\ell$ so that

$$\|\varphi - P^\ell \varphi\|_V \le \|\varphi - \psi\|_V \quad \text{for all } \psi \in V^\ell. \tag{4.3}$$

Using (4.3) and (3.5) we obtain

$$\sum_{j=0}^{n} \alpha_j \ \|y(t_j) - P^\ell y(t_j)\|_V^2 \le \sum_{j=0}^{n} \alpha_j \ \left\| y(t_j) - \sum_{i=1}^{\ell} a(y(t_j), \psi_i)\psi_i \right\|_V^2 = \sum_{i=\ell+1}^{d} \lambda_i,$$

which is estimate (4.2). □

The Galerkin POD method for (2.6) is described next. For $m \in \mathbb{N}$ we introduce the time grid

$$0 = \tau_0 < \tau_1 < \cdots < \tau_m = T, \qquad \delta\tau_j = \tau_j - \tau_{j-1} \text{ for } j = 1, \dots, m$$

and set

$$\delta\tau = \min\{\delta\tau_j : 1 \le j \le m\} \quad \text{and} \quad \Delta\tau = \max\{\delta\tau_j : 1 \le j \le m\}.$$

Throughout we assume that $\Delta\tau/\delta\tau$ is bounded uniformly with respect to m. To relate the two time discretizations $\{t_j\}_{j=0}^n$ and $\{\tau_j\}_{j=0}^m$ we set for every τ_k, $0 \le k \le m$, an associated index $\bar{k} = \operatorname{argmin}\{|\tau_k - t_j| : 0 \le j \le n\}$ and define $\sigma_n \in \{1, \dots, n\}$ as the maximum of the occurrence of the same value $t_{\bar{k}}$ as k ranges over $0 \le k \le m$.

The problem consists of finding a sequence $\{Y_k\}_{k=0}^m$ in V^ℓ satisfying

$$\langle Y_0, \psi \rangle_H = \langle y_0, \psi \rangle_H \quad \text{for all } \psi \in V^\ell \tag{4.4a}$$

and

$$\langle \overline{\partial}_\tau Y_k, \psi \rangle_H + a(Y_k, \psi) + \langle B(Y_k) + RY_k, \psi \rangle_{V',V} = \langle f(\tau_k), \psi \rangle_H \tag{4.4b}$$

for all $\psi \in V^\ell$ and $k = 1, \dots, m$, where we have set

$$\overline{\partial}_\tau Y_k = \frac{Y_k - Y_{k-1}}{\delta\tau_k}.$$

In the following theorem, existence and a priori estimates for the solution $\{Y_k\}_{k=0}^m$ are established. For the proof we refer to Appendix A.

THEOREM 4.2. *For every $k = 1, \dots, m$ there exists at least one solution Y_k of* (4.4b). *If $\Delta\tau$ is sufficiently small, the sequence $\{Y_k\}_{k=1}^m$ is uniquely determined. Moreover, the following estimates are satisfied:*

$$\|Y_k\|_H^2 \le (1 + \gamma\delta\tau)e^{-\gamma k\delta\tau} \ \|y_0\|_H^2 + \frac{1 - e^{-\gamma k\Delta\tau}}{\gamma} \ \|f\|_{C([0,T];H)}^2 \tag{4.5a}$$

for $k = 0, \dots, m$, where $\gamma = \eta/c_V^2$, c_V, η were introduced in (2.2) *and* (2.4), *respectively, and*

$$\sum_{k=1}^{m} \|Y_k - Y_{k-1}\|_H^2 + \eta \sum_{k=1}^{m} \delta\tau_k \ \|Y_k\|_V^2 \le \|y_0\|_H^2 + \frac{T}{\gamma} \ \|f\|_{C([0,T];H)}^2. \tag{4.5b}$$

Our next goal is to derive an error estimate for the expression

$$\sum_{k=0}^{m} \beta_k \ \|Y_k - y(\tau_k)\|_H^2,$$

where $y(\tau_k)$ is the solution of (2.6) at the time instances $t = \tau_k$, $k = 1, \dots, m$, and the positive weights β_j are given by

$$\beta_0 = \frac{\delta\tau_1}{2}, \quad \beta_j = \frac{\delta\tau_j + \delta\tau_{j+1}}{2} \text{ for } j = 1, \dots, m-1, \quad \text{and} \quad \beta_m = \frac{\delta\tau_m}{2}. \tag{4.6}$$

We make use of the following assumptions:

(A1) $y_t \in L^2(0,T;V)$ and $y_{tt} \in L^2(0,T;H)$.

(A2) There exists a normed linear space W continuously embedded in V and a constant $c_a > 0$ such that $y \in C([0,T];W)$ and

$$a(\varphi,\psi) \le c_a \ \|\varphi\|_H \|\psi\|_W \quad \text{for all } \varphi \in V \text{ and } \psi \in W. \tag{4.7}$$

(A3) $y \in W^{2,2}(0,T;V)$.

EXAMPLE 4.3. *For $V = H_0^1(\Omega)$, $H = L^2(\Omega)$, with Ω a bounded domain in $\mathbb{R}^l$ and*

$$a(\varphi,\psi) = \int_\Omega \nabla\varphi \cdot \nabla\psi \, dx \quad \textit{for all } \varphi,\psi \in H_0^1(\Omega),$$

choosing $W = H^2(\Omega) \cap H_0^1(\Omega)$ implies $a(\varphi,\psi) \le \|\varphi\|_W \|\psi\|_H$ for all $\varphi \in W$, $\psi \in V$, and (4.7) holds with $c_a = 1$.

Remark 4.4. Note that (A2) implies the existence of a constant $c_P > 0$ depending on ℓ and λ_ℓ such that

$$\|P^\ell\|_{\mathcal{L}(H)} \le c_P \quad \text{for all } 1 \le \ell \le d. \tag{4.8}$$

In fact, using (2.2) and (4.7) we find

$$\|P^\ell\varphi\|_H \le \sum_{i=1}^{\ell} |a(\psi_i,\varphi)| \ \|\psi_i\|_H \le c_a c_V \ \|\varphi\|_H \sum_{i=1}^{\ell} \|\psi_i\|_W.$$

Now we estimate the term $\|\psi_i\|_W$ for $i = 1, \dots, \ell$. Using $\sum_{j=0}^{n} \alpha_j = T$ and (3.4) we have

$$\begin{aligned} \|\psi_i\|_W = \frac{1}{\lambda_i} \ \|\mathcal{R}_n\psi_i\|_W &\le \frac{1}{\lambda_\ell} \sum_{j=0}^{n} \alpha_j \big|a(\psi_i, y(t_j))\big| \|y(t_j)\|_W \\ &\le \frac{1}{\lambda_\ell} \ \|y\|_{C([0,T];W)} \sum_{j=0}^{n} \alpha_j \|y(t_j)\|_V \le \frac{T}{\lambda_\ell} \ \|y\|_{C([0,T];W)} \|y\|_{C([0,T];V)}. \end{aligned}$$

This bound implies

$$\|P^\ell\varphi\|_H \le \frac{c\ell}{\lambda_\ell} \ \|\varphi\|_H \tag{4.9}$$

with $c = c_a c_V T \ \|y\|_{C([0,T];W)} \|y\|_{C([0,T];V)}$.

Throughout we shall use the decomposition

$$Y_k - y(\tau_k) = Y_k - P^\ell y(\tau_k) + P^\ell y(\tau_k) - y(\tau_k) = \vartheta_k + \varrho_k, \tag{4.10}$$

where $\vartheta_k = Y_k - P^\ell y(\tau_k)$ and $\varrho_k = P^\ell y(\tau_k) - y(\tau_k)$. The following lemma establishes an error estimate for ϑ_k. For the proof we refer to Appendix B.

LEMMA 4.5. *Assume that $\Delta\tau$ is sufficiently small and that* (A1), (A2) *hold. Then there exist constants $C_1, C_2 > 0$ independent of the grids $\{t_j\}_{j=0}^n$ and $\{\tau_j\}_{j=0}^m$ such that*

$$\begin{aligned} \|\vartheta_k\|_H^2 \;\le\; C_1 e^{C_2 k\delta\tau}\Bigg(& \|y_0 - P^\ell y_0\|_H^2 + \frac{\sigma_n}{\delta t}\Big(\frac{1}{\delta\tau} + \Delta\tau\Big)\sum_{i=\ell+1}^{d}\lambda_i \\ & + \sigma_n\Delta\tau\big(1 + c_P^2\big)(\Delta\tau + \Delta t)\|y_{tt}\|^2_{L^2(0,t_{\bar{k}+1};H)} \\ & + \sigma_n\Delta\tau\Delta t\ \|y_t\|^2_{L^2(0,t_{\bar{k}+1};V)}\Bigg) \end{aligned} \tag{4.11}$$

for each $1 \le k \le m$.

Remark 4.6. Since $y_0 \in \mathcal{V}$ we infer from (2.2) that

$$\|y_0 - P^\ell y_0\|_H^2 \le c_V^2 \sum_{i=\ell+1}^{d} \big|\langle \psi_i, y_0\rangle_V\big|^2.$$

We turn to the term $\|\varrho_k\|_H^2$. Observe that

$$\begin{aligned} \|\varrho_k\|_H^2 &= \|P^\ell y(\tau_k) - y(\tau_k)\|_H^2 \\ &\le 3\left(\|P^\ell y(\tau_k) - P^\ell y(t_{\bar{k}})\|_H^2 + \|P^\ell y(t_{\bar{k}}) - y(t_{\bar{k}})\|_H^2 + \|y(t_{\bar{k}}) - y(\tau_k)\|_H^2\right) \\ &\le 3\big(1 + c_P^2\big)\ \|y(t_{\bar{k}}) - y(\tau_k)\|_H^2 + 3\ \|P^\ell y(t_{\bar{k}}) - y(t_{\bar{k}})\|_H^2 \end{aligned} \tag{4.12}$$

and

$$\begin{aligned} \|y(t_{\bar{k}}) - y(\tau_k)\|_H^2 &\le \left(\int_{t_{\bar{k}-1}}^{t_{\bar{k}+1}} \|y_t(s)\|_H\, ds\right)^2 \\ &\le (\delta t_{\bar{k}} + \delta t_{\bar{k}+1})\ \|y_t\|^2_{L^2(t_{\bar{k}-1},t_{\bar{k}+1};H)}, \end{aligned} \tag{4.13}$$

where we set $t_{m+1} = T$ whenever $\bar{k} = m$. Using (4.13) and $\beta_k \le \Delta\tau$ we obtain

$$\sum_{k=0}^{m} \beta_k\ \|y(t_{\bar{k}}) - y(\tau_k)\|_H^2 \le 2\sigma_n\Delta\tau\Delta t\ \|y_t\|^2_{L^2(0,T;H)}.$$

From (2.2), $\beta_k \le \Delta\tau$, $\alpha_j \ge \delta t/2$, and Lemma 4.1 we infer that

$$\begin{aligned} \sum_{k=0}^{m} \beta_k\ \|P^\ell y(t_{\bar{k}}) - y(t_{\bar{k}})\|_H^2 &\le \frac{2c_V^2\sigma_n\Delta\tau}{\delta t}\sum_{j=0}^{n}\alpha_j\ \|P^\ell y(t_j) - y(t_j)\|_V^2 \\ &\le \frac{2c_V^2\sigma_n\Delta\tau}{\delta t}\sum_{i=\ell+1}^{d}\lambda_i. \end{aligned} \tag{4.14}$$

Combining the last two bounds and (4.12) it follows that

$$\sum_{k=0}^{m} \beta_k \, \|\varrho_k\|_H^2 \le 6\sigma_n(1+c_P^2)\Delta\tau\Delta t \, \|y_t\|^2_{L^2(0,T;H)} + \frac{6c_V^2\sigma_n\Delta\tau}{\delta t} \sum_{i=\ell+1}^{d} \lambda_i. \tag{4.15}$$

Note that $\sum_{k=0}^{m} \beta_k = T$ holds. By Lemma 4.5 we have

$$\begin{aligned} \sum_{k=0}^{m} \beta_k \, \|\vartheta_k\|_H^2 \quad &\le \quad C_3 \left(\|\vartheta_0\|_H^2 + \frac{\sigma_n}{\delta t}\Big(\frac{1}{\delta\tau} + \Delta\tau\Big) \sum_{i=\ell+1}^{d} \lambda_i \right) \\ &\quad + C_3\Delta\tau(1+c_P^2)(\Delta\tau + \sigma_n\Delta t)\|y_{tt}\|^2_{L^2(0,T;H)} \\ &\quad + C_3\sigma_n\Delta\tau\Delta t \, \|y_t\|^2_{L^2(0,T;V)}, \end{aligned} \tag{4.16}$$

where $C_3 = C_1 T e^{C_2 T}$. From (4.10), (4.15), (4.16), and Remark 4.4 we obtain the first part of the following theorem.

THEOREM 4.7.

(a) *Assume that* (A1), (A2) *hold and that* $\Delta\tau$ *is sufficiently small. Then there exists a constant* C *depending on* T*, but independent of the grids* $\{t_j\}_{j=0}^n$ *and* $\{\tau_j\}_{j=0}^m$*, such that*

(4.17)
$$\begin{aligned} &\sum_{k=0}^{m} \beta_k \, \|Y_k - y(\tau_k)\|_H^2 \\ &\le C \sum_{i=\ell+1}^{d} \left(\big|\langle \psi_i, y_0\rangle_V\big|^2 + \frac{\sigma_n}{\delta t}\Big(\frac{1}{\delta\tau} + \Delta\tau\Big)\lambda_i \right) + C\sigma_n\Delta\tau\Delta t \, \|y_t\|^2_{L^2(0,T;V)} \\ &\quad + C\sigma_n(1+c_P^2)\Delta\tau \left(\Delta t\|y_t\|^2_{L^2(0,T;H)} + (\Delta\tau + \Delta t)\|y_{tt}\|^2_{L^2(0,T;H)} \right). \end{aligned}$$

(b) *If* (A3) *is satisfied and* $\Delta\tau$ *sufficiently small, then there exists a constant* C *depending on* T*, but independent of the grids* $\{t_j\}_{j=0}^n$ *and* $\{\tau_j\}_{j=0}^m$*, such that*

(4.18)
$$\begin{aligned} &\sum_{k=0}^{m} \beta_k \, \|Y_k - y(\tau_k)\|_H^2 \le C\sigma_n\Delta\tau(\Delta\tau + \Delta t)\|y_{tt}\|^2_{L^2(0,T;V)} \\ &\quad + C \left(\sum_{i=\ell+1}^{d} \left(\big|\langle \psi_i, y_0\rangle_V\big|^2 + \frac{\sigma_n}{\delta t}\Big(\frac{1}{\delta\tau} + \Delta\tau\Big)\lambda_i \right) + \sigma_n\Delta\tau\Delta t\|y_t\|^2_{L^2(0,T;V)} \right). \end{aligned}$$

Proof. The proof of part (b) is obtained from that for (a) by utilizing (2.2) and $\|P^\ell\|_{\mathcal{L}(V)} = 1$ and by simple modifications of the estimates for the two terms $\sum_{k=0}^{m} \beta_k \|\vartheta_k\|_H^2$ and $\sum_{j=1}^{k} \delta\tau_j \|z_j\|_H^2$ in (B.16) of Appendix B. ∎

Compared to standard finite difference, finite element, or spectral element approximation results in the basic Galerkin POD backward Euler convergence, the result of Theorem 4.7 has an unusual format. This is due, in part, to the fact that one cannot rely on function space rate of convergence results, which are typically the basis for approximation theory of partial differential equations. The terms in the second line of (4.17) depend (through ψ_i, λ_i, d) on the way in which the snapshots are taken, on the number ℓ of basis elements, and on the relative locations of the snapshots and the

time discretization (through σ_n). In the remainder of this section we shall analyze these terms and show how they can be simplified if further assumptions are admitted.

Remark 4.8. In (4.17) and (4.18) the eigenvalues and eigenfunctions depend on n, i.e., $\lambda_i = \lambda_i^n$ and $\psi_i = \psi_i^n$. As proved in section 3, if ℓ satisfies (3.12) and $\sum_{i=\ell+1}^{\infty} \lambda_i^\infty \neq 0$ or $\sum_{i=\ell+1}^{\infty} |\langle \psi_i, y_0 \rangle_V|^2 \neq 0$, then by (3.14), (3.15) we have

$$\sum_{i=\ell+1}^{d} \Big(\big|\langle \psi_i, y_0 \rangle_V\big|^2 + \frac{\sigma_n}{\delta t}\Big(\frac{1}{\delta\tau} + \Delta\tau\Big)\lambda_i \Big) \leq 2 \sum_{i=\ell+1}^{\infty} \Big(\big|\langle \psi_i^\infty, y_0 \rangle_V\big|^2 + \frac{\sigma_n}{\delta t}\Big(\frac{1}{\delta\tau} + \Delta\tau\Big)\lambda_i^\infty \Big) \quad \text{for all } \Delta t \leq \overline{\Delta t},$$

and the dependence of the estimates of eigenvalues and eigenfunctions on n in (4.17) and (4.18) is thus eliminated.

Let us next derive some corollaries to the proof of Theorem 4.7. At first we consider the case in which the two grids coincide so that $n = m$ and $\tau_j = t_j$ for $j = 0, \ldots, m$.

COROLLARY 4.9. *Suppose that the assumptions of Theorem* 4.7(a) *hold. If the two time discretizations coincide, then there exists a constant $C > 0$ depending on T, but independent of the grid $\{\tau_j\}_{j=0}^m$, such that*

$$\begin{aligned} \sum_{k=0}^{m} \beta_k \, \|Y_k - y(\tau_k)\|_H^2 &\leq C(1 + c_P^2)\Delta\tau^2 \, \|y_{tt}\|_{L^2(0,T;H)}^2 \\ &\quad + C\left(\sum_{i=\ell+1}^{d} \Big(\big|\langle \psi_i, y_0 \rangle_V\big|^2 + \Big(\frac{1}{\delta\tau^2} + 1\Big)\lambda_i \Big) + \Delta\tau^2 \, \|y_t\|_{L^2(0,T;V)} \right). \end{aligned} \tag{4.19}$$

Proof. We proceed as in the proof of Theorem 4.2. Since the two time discretizations coincide, we obtain $n = m$, $\sigma_n = 1$, $\delta t = \delta\tau$, and $\alpha_j = \beta_j$ for $j = 0, \ldots, n$. In place of the estimate (4.15) we now have

$$\sum_{k=0}^{m} \beta_k \, \|\varrho_k\|_H^2 \leq c_V^2 \sum_{i=\ell+1}^{d} \lambda_i,$$

which gives the claim. ∎

Remark 4.10. Again, as in Theorem 4.7(b) compared to (a), the factor $1 + c_P^2$ can be avoided in (4.19) if in place of (A1), (A2) we assume (A3) and replace the term $\|y_{tt}\|_{L^2(0,T;H)}$ with $\|y_{tt}\|_{L^2(0,T;V)}$.

Let us briefly reflect on the behavior of the right-hand side of (4.17) and (4.18). First we note that if the number of POD elements for the Galerkin scheme coincides with the dimension of $\mathcal{V}$, then the first additive term on the right-hand side disappears. Second, if the number of snapshots is refined so that $\Delta t \to 0$, then the factor multiplying $\sum_{i=\ell+1}^{d} \lambda_i$ blows up. As noted above, the term $\sum_{i=\ell+1}^{d} \lambda_i$ itself changes as the snapshots are refined. While computations for many concrete situations show that $\sum_{i=\ell+1}^{d} \lambda_i$ is small compared to $\Delta\tau$, the question nevertheless arises of whether the term $1/(\delta\tau\delta t)$ can be avoided in the estimates. For this purpose we choose

$$\mathcal{V} = \text{span}\,\{y(t_0), \ldots, y(t_n), \overline{\partial}_t y(t_1), \ldots, \overline{\partial}_t y(t_n)\}, \tag{4.20}$$

where

$$\overline{\partial}_t y(t_j) = \frac{y(t_j) - y(t_{j-1})}{\delta t_j} \quad \text{for } j = 1, \dots, n.$$

Equation (3.5) must be replaced by

$$\sum_{j=0}^{n} \alpha_j \left\| y(t_j) - \sum_{i=1}^{\ell} \langle y(t_j), \hat{\psi}_i \rangle_V \hat{\psi}_i \right\|_V^2 + \sum_{j=1}^{n} \alpha_j \left\| \overline{\partial}_t y(t_j) - \sum_{i=1}^{\ell} \langle \overline{\partial}_t y(t_j), \hat{\psi}_i \rangle_V \hat{\psi}_i \right\|_V^2 = \sum_{i=\ell+1}^{d} \hat{\lambda}_i,$$

where $\{\hat{\lambda}_i\}_{i\in\mathbb{N}}$, $\{\hat{\psi}_i\}_{i\in\mathbb{N}}$ are the eigenvalues and eigenfunctions of $\hat{\mathcal{R}}_n \in \mathcal{L}(V)$ given by

$$\hat{\mathcal{R}}_n z = \sum_{j=0}^{n} \alpha_j \left(\langle z, y(t_j) \rangle_V y(t_j) + \langle z, \overline{\partial}_t y(t_j) \rangle_V \overline{\partial}_t y(t_j) \right)$$

and satisfying

$$\hat{\mathcal{R}}_n \hat{\psi}_i = \hat{\lambda}_i \hat{\psi}_i, \quad \hat{\lambda}_1 \geq \cdots \geq \hat{\lambda}_{d(n)} > 0, \quad \text{and } \lambda_i = 0 \text{ for } i > d(n).$$

As a consequence, estimate (B.16) in Appendix B can be replaced by

$$\sum_{j=1}^{k} \delta\tau_j \ \|z_j\|_H^2 \leq 14\sigma_n(1 + c_P^2)(\Delta\tau^2 + \Delta\tau\Delta t)\|y_{tt}\|^2_{L^2(0,t_{\bar{k}+1};H)} + \frac{14\sigma_n c_V^2 \Delta\tau}{\delta t} \sum_{i=\ell+1}^{d} \hat{\lambda}_i$$

in the case of (A1), (A2) holding, and by

$$\sum_{j=1}^{k} \delta\tau_j \ \|z_j\|_H^2 \leq 28\sigma_n(\Delta\tau^2 + \Delta\tau\Delta t)\|y_{tt}\|^2_{L^2(0,t_{\bar{k}+1};V)} + \frac{28\sigma_n c_V^2 \Delta\tau}{\delta t} \sum_{i=\ell+1}^{d} \hat{\lambda}_i$$

in the case of (A3). We obtain the following corollary.

COROLLARY 4.11. *If in addition to the assumptions of Theorem* 4.7(a) *the snapshots set is taken as in* (4.20)*, then*

$$\begin{aligned} &\sum_{k=0}^{m} \beta_k \ \|Y_k - y(\tau_k)\|_H^2 \\ &\leq C \sum_{i=\ell+1}^{d} \left(\left| \langle \hat{\psi}_i, y_0 \rangle_V \right|^2 + \frac{\sigma_n \Delta\tau}{\delta t} \hat{\lambda}_i \right) + C\sigma_n \Delta\tau\Delta t \ \|y_t\|^2_{L^2(0,T;V)} \\ &\quad + C(1 + c_P^2)\Delta\tau \big((\Delta\tau + \sigma_n \Delta t)\|y_{tt}\|^2_{L^2(0,T;H)} + \sigma_n \Delta t \|y_t\|^2_{L^2(0,T;H)} \big), \end{aligned} \tag{4.21}$$

where C has the same properties as in Theorem 4.7.

Remark 4.12. In [12] a laser surface hardening problem was considered. The numerical experiments show that the inclusion of the difference quotients into the snapshot set leads to better results.

In estimate (4.21) the term $1 + c_P^2$ can be avoided if (A3) in place of (A1), (A2) holds and $\|y_{tt}\|_{L^2(0,T;H)}$ is replaced by $\|y_{tt}\|_{L^2(0,T;V)}$. Note that the terms $\{\hat{\lambda}_i\}_{i\in\mathbb{N}}$,

$\{\hat{\psi}_i\}_{i\in\mathbb{N}}$, and σ_n depend on the time discretization of $[0,T]$ for the snapshots as well as the numerical integration. We address this dependence next.

If we suppose that

$$\Delta t = O(\delta\tau) \quad \text{and} \quad \Delta\tau = O(\delta t), \tag{4.22}$$

then there exists a constant $c_1 > 0$ independent of $\{t_j\}_{j=0}^n$ and $\{\tau_j\}_{j=0}^m$ such that

$$\max\left(\sigma_n, \frac{\sigma_n \Delta\tau}{\delta t}\right) \le c_1. \tag{4.23}$$

To obtain an estimate that is independent of the spectral values of a specific snapshot set $\{y(t_j)\}_{j=0}^n$ we follow the analysis of section 3.2. We assume that $y \in W^{2,2}(0,T;V)$, so that in particular (A3) holds, and introduce the operator $\hat{\mathcal{R}} \in \mathcal{L}(V)$ corresponding to $\mathcal{R}$ by

$$\hat{\mathcal{R}} z = \int_0^T \langle z, y(t)\rangle_V y(t) + \langle z, y_t(t)\rangle_V y_t(t)\, dt \quad \text{for } z \in V.$$

Note that $\hat{\mathcal{R}} = \hat{\mathcal{Y}}\hat{\mathcal{Y}}^*$, where $\hat{\mathcal{Y}}^* : V \to W^{1,2}(0,T;\mathbb{R})$ is given by

$$(\hat{\mathcal{Y}}^* z)(t) = \langle z, y(t)\rangle_V.$$

Since $y \in W^{2,2}(0,T;V)$ it is simple to argue that $\hat{\mathcal{Y}}^*$ is compact and hence $\hat{\mathcal{R}}$ is compact. Let us denote the positive eigenvalues and corresponding eigenfunctions of $\hat{\mathcal{R}}$ by $\{\hat{\lambda}_i^\infty\}_{i\in\mathbb{N}}$ and $\{\hat{\psi}_i^\infty\}_{i\in\mathbb{N}}$. Since $t_0 = 0$, we proceed as in section 3.2, that $y_0 \in \text{range } \hat{\mathcal{R}}_n$ for all n and $y_0 \in \overline{\text{range } \hat{\mathcal{R}}}$. The assumption $y \in W^{2,2}(0,T;V)$ allows us to argue that the analogue of (3.7), i.e.,

$$\lim_{\Delta t \to 0} \|\hat{\mathcal{R}}_n - \hat{\mathcal{R}}\|_{\mathcal{L}(V)} = 0,$$

holds. Let us choose and fix ℓ such that

$$\hat{\lambda}_\ell^\infty \ne \hat{\lambda}_{\ell+1}^\infty. \tag{4.24}$$

We can now proceed precisely as in section 3.2 to assert that there exists $\overline{\Delta t} > 0$ such that

$$\sum_{i=\ell+1}^{d(n)} \hat{\lambda}_i^n \le 2 \sum_{i=\ell+1}^{\infty} \hat{\lambda}_i^\infty \quad \text{and} \quad \sum_{i=\ell+1}^{d(n)} \left|\langle y_0, \hat{\psi}_i^n\rangle_V\right|^2 \le 2 \sum_{i=\ell+1}^{\infty} \left|\langle y_0, \hat{\psi}_i^\infty\rangle_V\right|^2 \tag{4.25}$$

for all $\Delta t \le \overline{\Delta t}$, provided, of course, that the terms on the right-hand side of (4.25) are different from zero. We summarize the above discussion in the following corollary.

COROLLARY 4.13. *Assume that $y \in W^{2,2}(0,T;V)$ and let the snapshots be chosen as in* (4.20). *If* (4.22) *holds and ℓ satisfies* (4.24), *then there exists a constant $C > 0$, independent of ℓ and the grids $\{t_j\}_{j=0}^n$ and $\{\tau_j\}_{j=0}^m$, and a $\overline{\Delta t} > 0$, depending on ℓ, such that*

$$\begin{aligned}\sum_{k=0}^{m} \beta_k \, \|Y_k - y(\tau_k)\|_H^2 \le C \sum_{i=\ell+1}^{\infty} \left(\left|\langle y_0, \hat{\psi}_i^\infty\rangle_V\right|^2 + \hat{\lambda}_i^\infty\right) \\ + C\left(\Delta\tau\Delta t \, \|y_t\|^2_{L^2(0,T;V)} + \Delta\tau(\Delta\tau + \Delta t) \, \|y_{tt}\|^2_{L^2(0,T;V)}\right)\end{aligned} \tag{4.26}$$

for all $\Delta t \le \overline{\Delta t}$.

Remark 4.14. In (4.26) the first term on the right-hand side of the inequality reflects the spatial approximation error of the Galerkin POD scheme and the second reflects the approximation error due to the temporal backward Euler scheme. If the latter is replaced by the Crank–Nicolson method, then, assuming $\Delta\tau = \Delta t$ and appropriate regularity on y, it can be shown with the techniques of this section that an estimate analogous to (4.26) holds with the first additive term on the right-hand side unchanged and the second one of fourth order in $\Delta\tau$.

4.2. Case $X = H$. Here we consider the case in which the POD basis is constructed with respect to the H-norm. Differently from the situation where the POD basis was constructed in V, the right-hand side of the estimate will involve the stiffness matrix

$$S = ((S_{ij})) \in \mathbb{R}^{d\times d} \quad \text{with} \quad S_{ij} = a(\psi_j, \psi_i).$$

We shall require the following lemma.

LEMMA 4.15. *For every* $\ell \in \{1, \dots, d\}$ *the projection operator* $P^\ell : V \to V^\ell$ *satisfies*

$$\sum_{j=0}^{n} \alpha_j \ \|y(t_j) - P^\ell y(t_j)\|_V^2 \le \|S\|_2 \sum_{i=\ell+1}^{d} \lambda_i, \tag{4.27}$$

where λ_i *denote the eigenvalues introduced in* (3.4) *and* $\|\cdot\|_2$ *stands for the spectral norm for symmetric matrices.*

Proof. Using the fact that $\|\varphi\|_V^2 \le \|S\|_2 \ \|\varphi\|_H^2$ for all $\varphi \in \mathcal{V}$ (see [16, Lemma 2]), we can proceed as in the proof of Lemma 4.1 and, utilizing (3.5) with $X = H$, we obtain the desired result. ∎

THEOREM 4.16. *Suppose that* (A3) *holds and that* $\Delta\tau$ *is sufficiently small. Then there exists a constant* $C > 0$ *depending on* T*, but independent of the grids* $\{t_j\}_{j=0}^n$ *and* $\{\tau_j\}_{j=0}^m$*, such that*

$$\begin{aligned}\sum_{k=0}^{m} \beta_k \ \|Y_k - y(\tau_k)\|_H^2 \le C \sum_{i=\ell+1}^{d} \|S\|_2 \Big(\big|\langle \psi_i, y_0\rangle_H\big|^2 + \frac{\sigma_n}{\delta t}\Big(\frac{1}{\delta\tau} + \Delta\tau\Big)\lambda_i\Big) \\ + C\sigma_n\Delta\tau\left((\Delta\tau + \Delta t)\|y_{tt}\|_{L^2(0,T;V)}^2 + \Delta t \ \|y_t\|_{L^2(0,T;V)}^2\right).\end{aligned} \tag{4.28}$$

Proof. We proceed as in the proofs of Lemma 4.5 and Theorem 4.7 and indicate only the necessary changes. Estimate (B.15) requires no change. For (B.16) we utilize $\|P^\ell\varphi\| \le c_V\|\varphi\|_V$ for $\varphi \in V$ and obtain, by applying Lemma 4.15,

$$\begin{aligned}\sum_{j=1}^{k} \delta\tau_j \ \|z_j\|_H^2 \quad &\le \quad 14\sigma_n(1 + c_V^2)(\Delta\tau^2 + \Delta\tau\Delta t)\|y_{tt}\|_{L^2(0,t_{k+1};V)}^2 \\ &\quad + \frac{56\sigma_n c_V^2\|S\|_2}{\delta t\delta\tau} \sum_{i=\ell+1}^{d} \lambda_i.\end{aligned} \tag{4.29}$$

The analogue of (B.17) is again obtained by Lemma 4.15. Summarizing the ϑ_k-terms we have

$$\begin{aligned}\sum_{j=1}^{k} \delta\tau_j \ \|\vartheta_k\|_H^2 \le C\left(\|\vartheta_0\|_H^2 + \frac{\sigma_n\|S\|_2}{\delta t}\Big(\frac{1}{\delta\tau} + \Delta\tau\Big)\sum_{i=\ell+1}^{d}\lambda_i\right) \\ + C\sigma_n(1 + c_V^2)\Delta\tau\big((\Delta\tau + \Delta t)\|y_{tt}\|_{L^2(0,T;V)}^2 + \Delta t \ \|y_t\|_{L^2(0,T;V)}^2\big).\end{aligned} \tag{4.30}$$

Turning to the ϱ_k-terms we find, following the estimates after (4.12),

$$\begin{aligned}
&\sum_{k=0}^{m} \beta_k \ \|\varrho_k\|_H^2 \\
&\quad \le 6\sigma_n(1+c_V^2)\Delta\tau\Delta t \ \|y_t\|^2_{L^2(0,T;V)} + 3\sum_{k=0}^{m} \beta_k \|P^\ell y(t_{\bar{k}}) - y(t_{\bar{k}})\|_H^2 \\
&\quad \le 6\sigma_n(1+c_V^2)\Delta\tau\Delta t \ \|y_t\|^2_{L^2(0,T;V)} + \frac{6c_V^2\sigma_n\Delta\tau}{\delta t} \sum_{j=0}^{n} \alpha_j \ \|P^\ell y(t_j) - y(t_j)\|_V^2.
\end{aligned}$$

Thus by Lemma 4.15

$$\sum_{k=0}^{m} \beta_k \ \|\varrho_k\|_H^2 \le 6\sigma_n(1+c_V^2)\Delta\tau\Delta t \ \|y_t\|^2_{L^2(0,T;V)} + \frac{6c_V^2\sigma_n\Delta\tau\|S\|_2}{\delta t} \sum_{i=\ell+1}^{d} \lambda_i. \tag{4.31}$$

Finally $\vartheta_0 = y_0 - P^\ell y_0$ can be estimated as follows:

$$\begin{aligned}
\|y_0 - P^\ell y_0\|_H \ &\le \ c_V \ \|y_0 - P^\ell y_0\|_V \le c_V \ \left\| y_0 - \sum_{i=1}^{\ell} \langle y_0, \psi_i\rangle_H \psi_i \right\|_V \\
&= \ c_V \left(\|S\|_2 \sum_{i=\ell+1}^{d} \left|\langle y_0, \psi\rangle_H\right|^2 \right)^{1/2}.
\end{aligned}$$

Combining the last estimate with (4.30)–(4.31) we obtain (4.28). ∎

Remark 4.17. Let us briefly discuss the asymptotic properties of the expression on the right-hand side of (4.28), which are restricted due to the appearance of $\delta t\delta\tau$ in the denominator and the terms σ_n and $\|S\|_2$. As in section 4.1 the factor $1/\delta\tau$ can be eliminated by adding the set $\{\overline{\partial} y(t_j)\}_{j=1}^n$ to the set of snapshots. Assuming that $\Delta t = O(\delta\tau)$ and $\Delta\tau = O(\delta t)$ implies (4.23), and consequently, σ_n and $\sigma_n\Delta\tau/\delta t$ are uniformly bounded with respect to refinement of the t- and τ-grids. The factor $\|S\|_2$, which tends to infinity as $m \to \infty$, appears to be unavoidable in case the POD basis is computed in H.

Appendix A. Proof of Theorem 4.2.

A.1. Existence. Existence of a solution $\{Y_k\}_{k=1}^m$ can be proved by using the Schauder fixed point theorem; see [11, p. 222], for instance. For that purpose we define $z = \mathcal{T}_k w$ via the mappings $\mathcal{T}_k : V^\ell \to V^\ell$, $k = 1, \dots, m$, as follows: $z \in V^\ell$ is the solution to

$$\langle z, \psi\rangle_H + \delta\tau_k\big(a(z,\psi) + \langle B(w,z) + Rz, \psi\rangle_{V',V}\big) = \langle \delta\tau_k f(\tau_k) + Y_{k-1}, \psi\rangle_H \tag{A.1}$$

for all $\psi \in V^\ell$. The bilinear form

$$\langle \cdot\,, \cdot\rangle_H + \delta\tau_k\big(a(\cdot\,,\cdot) + \langle B(w,\cdot) + R(\cdot), \cdot\rangle_{V',V}\big)$$

is continuous and coercive in $V^\ell \times V^\ell$ by (2.3)–(2.5). The existence and uniqueness of a solution to (A.1) can thus be shown by the Lax–Milgram theorem. The fixed points of $\mathcal{T}_k$ are the solutions of (4.4b). Taking $\psi = z$ in (A.1) above and using (2.2) and (2.4) we derive

$$\|z\|_V \le \frac{c_V}{\eta} \ \Big(\|f(\tau_k)\|_H + \frac{1}{\delta\tau_k} \ \|Y_{k-1}\|_H \Big). \tag{A.2}$$

Let us introduce the set

$$M_k = \Big\{ w \in V^\ell : \|w\|_V \le \frac{c_V}{\eta} \Big(\|f(\tau_k)\|_H + \frac{1}{\delta\tau_k} \|Y_{k-1}\|_H \Big) \Big\} \subset V^\ell.$$

From (A.2) we infer that $\mathcal{T}_k$ maps M_k into itself. Since M_k is a closed ball in V^ℓ, the set M_k is bounded, closed, and convex. Since the image of $\mathcal{T}_k$ is finite dimensional, $\mathcal{T}_k$ is compact. Thus, the existence of a fixed point Y_k follows from the Schauder fixed point theorem.

A.2. Uniqueness. To prove the uniqueness we assume that the two sequences $\{Y_k^1\}_{k=0}^m$, $\{Y_k^2\}_{k=0}^m$ in V^ℓ are solutions of (4.4b). Then $\delta Y_k = Y_k^1 - Y_k^2 \in V^\ell$ solves

$$\langle \delta Y_k, \psi \rangle_H + \delta\tau_k \big(a(\delta Y_k, \psi) + \langle R\delta Y_k, \psi \rangle_{V',V} \big) = \delta\tau_k \, \langle B(Y_k^2) - B(Y_k^1), \psi \rangle_{V',V}$$

for all $\psi \in V^\ell$. Setting $\psi = \delta Y_k$ and using (2.4), (2.5), and Young's inequality we obtain

$$\begin{aligned}
\|\delta Y_k\|_H^2 + \eta\delta\tau_k \, \|\delta Y_k\|_V^2 &\le \delta\tau_k \, \langle B(Y_k^2) - B(Y_k^1), \delta Y_k \rangle_{V',V} \\
&= -\delta\tau_k \, \langle B(\delta Y_k, Y_k^2) + B(Y_k^1, \delta Y_k), \delta Y_k \rangle_{V',V} \\
&= -\delta\tau_k \, \langle B(\delta Y_k, Y_k^2), \delta Y_k \rangle_{V',V} \\
&\le c_B \delta\tau_k \, \|Y_k^2\|_V \|\delta Y_k\|_H \|\delta Y_k\|_V \\
&\le \|\delta Y_k\|_H^2 + \frac{c_B^2 \delta\tau_k^2}{4} \, \|Y_k^2\|_V^2 \|\delta Y_k\|_V^2.
\end{aligned}$$

It follows that

$$\Big(1 - \frac{c_B^2 \delta\tau_k}{4\eta} \, \|Y_k^2\|_V^2 \Big) \, \|\delta Y_k\|_V^2 \le 0.$$

Let $c = \max\{\|Y_k^2\|_V : k = 1, \dots, m\}$. Then $\delta Y_k = 0$ and hence $Y_k^1 = Y_k^2$, provided that $\Delta\tau \le 4\eta/(c^2 c_B^2)$.

A.3. A priori estimates. To prove the estimates (4.5) we take $\psi = Y_k$ in (4.4b). Due to (2.3)–(2.5) and the identity

$$2 \, \langle \varphi - \psi, \varphi \rangle_H = \|\varphi\|_H^2 - \|\psi\|_H^2 + \|\varphi - \psi\|_H^2 \quad \text{for all } \varphi, \psi \in H \tag{A.3}$$

we obtain

$$\|Y_k\|_H^2 - \|Y_{k-1}\|_H^2 + \|Y_k - Y_{k-1}\|_H^2 + 2\eta\delta\tau_k \, \|Y_k\|_V^2 \le 2\delta\tau_k \, \|f(\tau_k)\|_H \|Y_k\|_H.$$

Using (2.2) and Young's inequality it follows that

$$\|Y_k\|_H^2 + \|Y_k - Y_{k-1}\|_H^2 + \eta\delta\tau_k \, \|Y_k\|_V^2 \le \|Y_{k-1}\|_H^2 + \frac{c_V^2 \delta\tau_k}{\eta} \, \|f(\tau_k)\|_H^2. \tag{A.4}$$

From (A.4) and (2.2) we infer that

$$(1 + \gamma\delta\tau_k) \, \|Y_k\|_H^2 \le \|Y_{k-1}\|_H^2 + \frac{\delta\tau_k}{\gamma} \, \|f(\tau_k)\|_H^2,$$

where $\gamma = \eta/c_V^2$, which yields

$$\|Y_k\|_H^2 \le \frac{1}{1 + \gamma\delta\tau} \, \|Y_{k-1}\|_H^2 + \frac{\delta\tau_k}{\gamma(1 + \gamma\delta\tau_k)} \, \|f(\tau_k)\|_H^2. \tag{A.5}$$

From

$$\frac{\delta\tau_k}{1+\gamma\delta\tau_k} = \frac{1}{\gamma}\Big(1-\frac{1}{1+\gamma\delta\tau_k}\Big) \le \frac{1}{\gamma}\Big(1-\frac{1}{1+\gamma\Delta\tau}\Big) = \frac{\Delta\tau}{1+\gamma\Delta\tau}$$

and (A.5) we infer upon summation that

$$\|Y_k\|_H^2 \le \Big(\frac{1}{1+\gamma\delta\tau}\Big)^k \|Y_0\|_H^2 + \frac{\Delta\tau}{\gamma}\,\|f\|^2_{C([0,T];H)} \sum_{j=1}^{k}\Big(\frac{1}{1+\gamma\Delta\tau}\Big)^j. \tag{A.6}$$

Recall that

$$\Big(\frac{1}{1+\gamma\delta\tau}\Big)^k \le (1+\gamma\delta\tau)e^{-\gamma k\delta\tau} \quad\text{and}\quad \Big(\frac{1}{1+\gamma\Delta\tau}\Big)^k \ge e^{-\gamma k\Delta\tau}. \tag{A.7}$$

Moreover, setting $\zeta = 1/(1+\gamma\Delta\tau)$ we find

$$\Delta\tau\sum_{j=1}^{k}\Big(\frac{1}{1+\gamma\Delta\tau}\Big)^j = \Delta\tau\,\frac{1-\zeta^k}{\zeta^{-1}-1} = \frac{1-\zeta^k}{\gamma} \le \frac{1-e^{-\gamma k\Delta\tau}}{\gamma}.$$

Inserting this estimate and (A.7) in (A.6) and utilizing the fact that $\|Y_0\|_H \le \|y_0\|_H$ yield (4.5a). Summing (A.4) over k we find

$$\|Y_m\|_H^2 + \sum_{k=1}^{m}\|Y_k - Y_{k-1}\|_H^2 + \eta\sum_{k=1}^{m}\delta\tau_k\|Y_k\|_V^2 \le \|Y_0\|_H^2 + \frac{c_V T}{\gamma}\|f\|^2_{C([0,T];H)},$$

which is estimate (4.5b).

Appendix B. Proof of Lemma 4.5. Using the notation $\overline{\partial}_\tau\vartheta_k = (\vartheta_k - \vartheta_{k-1})/\delta\tau_k$, $k = 1,\dots,m$, we obtain

$$\begin{aligned}&\langle\overline{\partial}_\tau\vartheta_k,\psi\rangle_H + a(\vartheta_k,\psi) + \langle R\vartheta_k,\psi\rangle_{V',V}\\ &\qquad = \langle v_k,\psi\rangle_H + \langle B(y(\tau_k)) - B(Y_k) + R(y(\tau_k) - P^\ell y(\tau_k)),\psi\rangle_{V',V},\end{aligned} \tag{B.1}$$

where

$$v_k = y_t(\tau_k) - \overline{\partial}_\tau P^\ell y(\tau_k) = y_t(\tau_k) - \overline{\partial}_\tau y(\tau_k) + \overline{\partial}_\tau y(\tau_k) - \overline{\partial}_\tau P^\ell y(\tau_k).$$

We put $w_k = y_t(\tau_k) - \overline{\partial}_\tau y(\tau_k)$ and $z_k = \overline{\partial}_\tau y(\tau_k) - \overline{\partial}_\tau P^\ell y(\tau_k)$. Choosing $\psi = \vartheta_k \in V^\ell$ in (B.1), using (2.4) and (A.3) we infer that

$$\begin{aligned}&\|\vartheta_k\|_H^2 - \|\vartheta_{k-1}\|_H^2 + \|\vartheta_k - \vartheta_{k-1}\|_H^2 + 2\eta\delta\tau_k\,\|\vartheta_k\|_V^2\\ &\le 2\delta\tau_k\big(\|v_k\|_H\|\vartheta_k\|_H + \big|\langle B(y(\tau_k)) - B(Y_k),\vartheta_k\rangle_{V',V}\big| + \|R\varrho_k\|_{V'}\|\vartheta_k\|_V\big).\end{aligned} \tag{B.2}$$

Applying Young's inequality it follows that

$$\|R\varrho_k\|_{V'}\|\vartheta_k\|_V \le \|R\|_{\mathcal{L}(V,V')}\|\varrho_k\|_V\|\vartheta_k\|_V \le \frac{\eta}{4}\,\|\vartheta_k\|_V^2 + c_0\,\|\varrho_k\|_V^2 \tag{B.3}$$

for a constant $c_0 > 0$ depending on $\|R\|_{\mathcal{L}(V,V')}$ and η. We proceed by estimating the nonlinear terms on the right-hand side of (B.2). Note that

$$\begin{aligned}&B(y(\tau_k)) - B(Y_k)\\ &\qquad = -B(y(\tau_k), Y_k - y(\tau_k)) - B(Y_k - y(\tau_k)) - B(Y_k - y(\tau_k), y(\tau_k)).\end{aligned} \tag{B.4}$$

Applying (2.5), (2.2), and Young's inequality we obtain the existence of two constants $c_1, c_2 > 0$ satisfying

$$\begin{aligned} &\big|\langle B(y(\tau_k), Y_k - y(\tau_k)), \vartheta_k\rangle_{V',V}\big| \\ &= \big|\langle B(y(\tau_k), \varrho_k), \vartheta_k\rangle_{V',V}\big| \le c_B c_V^{\delta_3}\, \|y\|_{C([0,T];V)} \|\varrho_k\|_V \|\vartheta_k\|_H^{1-\delta_3} \|\vartheta_k\|_V^{\delta_3} \\ &\le \frac{\eta}{4}\, \|\vartheta_k\|_V^2 + c_1\, \|\vartheta_k\|_H^2 + c_2\, \|\varrho_k\|_V^2. \end{aligned} \tag{B.5}$$

Again utilizing (2.5), Young's inequality, and (2.2) we find that there exist constants $c_3, c_4 > 0$ such that

$$\begin{aligned} &\big|\langle B(Y_k - y(\tau_k), y(\tau_k)), \vartheta_k\rangle_{V',V}\big| \\ &\quad = \big|\langle B(\vartheta_k, y(\tau_k)) + B(\varrho_k, y(\tau_k)), \vartheta_k\rangle_{V',V}\big| \\ &\quad \le c_B\, \|y\|_{C([0,T];V)} \Big(\|\vartheta_k\|_H \|\vartheta_k\|_V + c_V^{\delta_3} \|\varrho_k\|_V \|\vartheta_k\|_H^{1-\delta_3} \|\vartheta_k\|_V^{\delta_3}\Big) \\ &\quad \le \frac{\eta}{4}\, \|\vartheta_k\|_V^2 + c_3\, \|\vartheta_k\|_H^2 + c_4\, \|\varrho_k\|_V^2. \end{aligned} \tag{B.6}$$

From $y \in C([0,T];V)$ it follows that there exists a constant $c_5 > 0$ such that

$$\max_{1\le k\le m} \Big(\|\varrho_k\|_H^{\delta_3} \|\varrho_k\|_V^{1-\delta_3}, \|\varrho_k\|_V\Big) \le c_5. \tag{B.7}$$

Using (2.5) and (4.10) we conclude that

$$\langle B(Y_k - y(\tau_k)), \vartheta_k\rangle_{V',V} = \langle B(\vartheta_k, \varrho_k) + B(\varrho_k, \varrho_k), \vartheta_k\rangle_{V',V}. \tag{B.8}$$

Applying (2.5), (B.7), (B.8), and Young's inequality we find that

$$\begin{aligned} &\big|\langle B(Y_k - y(\tau_k)), \vartheta_k\rangle_{V',V}\big| \\ &\qquad \le c_B c_5 \Big(\|\vartheta_k\|_H \|\vartheta_k\|_V + \|\varrho_k\|_V \|\vartheta_k\|_H^{1-\delta_3} \|\vartheta_k\|_V^{\delta_3}\Big) \\ &\qquad \le \frac{\eta}{4}\, \|\vartheta_k\|_V^2 + c_6\, \|\vartheta_k\|_H^2 + c_7\, \|\varrho_k\|_V^2 \end{aligned} \tag{B.9}$$

for two constants $c_6, c_7 > 0$. From (B.2)–(B.9), Young's inequality, and $v_k = w_k + z_k$ we obtain

$$\|\vartheta_k\|_H^2 \le \|\vartheta_{k-1}\|_H^2 + \delta\tau_k\big(\|w_k\|_H^2 + \|z_k\|_H^2 + c_8\, \|\vartheta_k\|_H^2 + c_9\, \|\varrho_k\|_V^2\big), \tag{B.10}$$

where $c_8 = 2 + c_1 + c_3 + c_6$ and $c_9 = c_0 + c_2 + c_4 + c_7$. Suppose that

$$\Delta\tau \le \frac{1}{2c_8}. \tag{B.11}$$

With (B.11) holding we have $0 < 1 - c_8\delta\tau_k \le 1/2$ and

$$\frac{1}{1 - c_8\delta\tau_k} \le \frac{1}{1 - c_8\Delta\tau} \le 1 + 2c_8\Delta\tau. \tag{B.12}$$

From (B.10) and (B.12) we find that

$$\|\vartheta_k\|_H^2 \le (1 + 2c_8\Delta\tau)\big(\|\vartheta_{k-1}\|_H^2 + \delta\tau_k\big(\|w_k\|_H^2 + \|z_k\|_H^2 + c_9\, \|\varrho_k\|_V^2\big)\big) \tag{B.13}$$

holds. By summation on k we obtain

$$\begin{aligned}\|\vartheta_k\|_H^2 &\le \Big(1+\frac{2c_8\Delta\tau}{\delta\tau}\frac{k\delta\tau}{k}\Big)^k \\ &\quad\cdot\left(\|\vartheta_0\|_H^2+\sum_{j=1}^k\delta\tau_j\left(\|w_j\|_H^2+\|z_j\|_H^2+c_9\ \|\varrho_j\|_V^2\right)\right) \\ &\le e^{c_{10}k\delta\tau}\left(\|\vartheta_0\|_H^2+\sum_{j=1}^k\delta\tau_j\left(\|w_j\|_H^2+\|z_j\|_H^2+c_9\ \|\varrho_k\|_V^2\right)\right),\end{aligned}\tag{B.14}$$

where $c_{10}=2c_8\Delta\tau/\delta\tau$. Recall that by assumption, $\Delta\tau/\delta\tau$ is bounded uniformly with respect to m. We next estimate the terms involving w_j and z_j:

$$\begin{aligned}\sum_{j=1}^k\delta\tau_j\|w_j\|_H^2 &= \sum_{j=1}^k\delta\tau_j\ \|y_t(\tau_j)-\overline{\partial}_\tau y(\tau_j)\|_H^2 \\ &= \sum_{j=1}^k\frac{1}{\delta\tau_j}\ \|\delta\tau_j y_t(\tau_j)-(y(\tau_j)-y(\tau_{j-1}))\|_H^2 \\ &= \sum_{j=1}^k\frac{1}{\delta\tau_j}\left\|\int_{\tau_{j-1}}^{\tau_j}(s-\tau_{j-1})y_{tt}(s)\,ds\right\|_H^2 \\ &\le \sum_{j=1}^k\frac{1}{\delta\tau_j}\int_{\tau_{j-1}}^{\tau_j}(s-\tau_{j-1})^2\,ds\int_{\tau_{j-1}}^{\tau_j}\|y_{tt}(s)\|_H^2\,ds \\ &= \sum_{j=1}^k\frac{\delta\tau_j^2}{3}\ \|y_{tt}\|^2_{L^2(\tau_{j-1},\tau_j;H)}\le\frac{\Delta\tau^2}{3}\ \|y_{tt}\|^2_{L^2(0,\tau_k;H)}.\end{aligned}\tag{B.15}$$

The term $\|z_j\|_H^2$ can be estimated as follows:

$$\begin{aligned}\|z_j\|_H^2 &= \|\overline{\partial}_\tau y(\tau_j)-\overline{\partial}_\tau P^\ell y(\tau_j)\|_H^2 \\ &= \big\|\overline{\partial}_\tau y(\tau_j)-y_t(\tau_j)+y_t(\tau_j)-y_t(t_{\bar j})+y_t(t_{\bar j})-\overline{\partial}_\tau y(t_{\bar j}) \\ &\qquad+\overline{\partial}_\tau y(t_{\bar j})-\overline{\partial}_\tau P^\ell y(t_{\bar j})+\overline{\partial}_\tau P^\ell y(t_{\bar j})-P^\ell y_t(t_{\bar j}) \\ &\qquad+P^\ell y_t(t_{\bar j})-P^\ell y_t(\tau_j)+P^\ell y_t(\tau_j)-\overline{\partial}_\tau P^\ell y(\tau_j)\big\|_H^2 \\ &\le 7\big(1+\|P^\ell\|^2_{\mathcal{L}(H)}\big)\ \|\overline{\partial}_\tau y(\tau_j)-y_t(\tau_j)\|_H^2 \\ &\quad+7\ \big(1+\|P^\ell\|^2_{\mathcal{L}(H)}\big)\ \|y_t(t_{\bar j})-\overline{\partial}_\tau y(t_{\bar j})\|_H^2 \\ &\quad+7\big(1+\|P^\ell\|^2_{\mathcal{L}(H)}\big)\ \|y_t(\tau_j)-y_t(t_{\bar j})\|_H^2 \\ &\quad+7\ \|\overline{\partial}_\tau y(t_{\bar j})-\overline{\partial}_\tau P^\ell y(t_{\bar j})\|_H^2.\end{aligned}$$

Note that

$$\|\overline{\partial}_\tau y(\tau_j)-y_t(\tau_j)\|_H^2=\frac{1}{\delta\tau_j^2}\ \left\|\int_{\tau_{j-1}}^{\tau_j}(t-\tau_{j-1})y_{tt}(t)\,dt\right\|_H^2\le\frac{\delta\tau_j}{3}\ \|y_{tt}\|^2_{L^2(\tau_{j-1},\tau_j;H)}.$$

Analogously, we find

$$\|y_t(t_{\bar j})-\overline{\partial}_\tau y(t_{\bar j})\|_H^2\le\frac{\delta\tau_j}{3}\ \|y_{tt}\|^2_{L^2(t_{\bar j-1},t_{\bar j};H)}.$$

From

$$\|y_t(\tau_j) - y_t(t_{\bar{j}})\|_H^2 \le \left(\int_{t_{\bar{j}-1}}^{t_{\bar{j}+1}} \|y_{tt}(s)\|_H \, ds\right)^2 \le \big(\delta t_{\bar{j}} + \delta t_{\bar{j}+1}\big)\|y_{tt}\|^2_{L^2(t_{\bar{j}-1},t_{\bar{j}+1};H)}$$
$$\le 2\Delta t \, \|y_{tt}\|^2_{L^2(t_{\bar{j}-1},t_{\bar{j}+1};H)},$$

where we set $t_{m+1} = T$ whenever $j = m$, we find

$$\|z_j\|_H^2 \le \frac{7}{3}\big(1 + c_P^2\big)\delta\tau_j\big(\|y_{tt}\|^2_{L^2(\tau_{j-1},\tau_j;H)} + \|y_{tt}\|^2_{L^2(t_{\bar{j}-1},t_{\bar{j}};H)}\big)$$
$$+ 14\big(1 + c_P^2\big)\Delta t \, \|y_{tt}\|^2_{L^2(t_{\bar{j}-1},t_{\bar{j}+1};H)}$$
$$+ \frac{14}{\delta\tau_j^2}\, \big(\|y(t_{\bar{j}}) - P^\ell y(t_{\bar{j}})\|_H^2 + \|y(t_{\bar{j}-1}) - P^\ell y(t_{\bar{j}-1})\|_H^2\big),$$

where we set $t_{n+1} = T$. Note that $\alpha_j \ge \delta t/2$. Using (2.2) and Lemma 4.1 we estimate

$$\sum_{j=1}^k \frac{1}{\delta\tau_j} \, \|y(t_{\bar{j}}) - P^\ell y(t_{\bar{j}})\|_H^2 \le \frac{2\sigma_n}{\delta\tau\delta t} \sum_{j=0}^n \alpha_j \|y(t_j) - P^\ell y(t_j)\|_H^2 \le \frac{2\sigma_n c_V^2}{\delta\tau\delta t} \sum_{i=\ell+1}^d \lambda_i$$

and, analogously,

$$\sum_{j=1}^k \frac{1}{\delta\tau_j} \, \|y(t_{\bar{j}-1}) - P^\ell y(t_{\bar{j}-1})\|_H^2 \le \frac{2\sigma_n c_V^2}{\delta\tau\delta t} \sum_{i=\ell+1}^d \lambda_i.$$

Hence,

$$\sum_{j=1}^k \delta\tau_j \, \|z_j\|_H^2 \le 14\sigma_n(1 + c_P^2)(\Delta\tau^2 + \Delta\tau\Delta t)\|y_{tt}\|^2_{L^2(0,t_{\bar{k}+1};H)}$$
$$+ \frac{56\sigma_n c_V^2}{\delta t\delta\tau} \sum_{i=\ell+1}^d \lambda_i. \tag{B.16}$$

Using $\alpha_j \ge 2/\delta t$ and $\|P^\ell\|_{\mathcal{L}(V)} = 1$ we obtain for the terms $\|\varrho_k\|_V^2$

$$\|\varrho_j\|_V^2 = \|P^\ell y(\tau_j) - y(\tau_j)\|_V^2$$
$$= \|P^\ell y(\tau_j) - P^\ell y(t_{\bar{j}}) + P^\ell y(t_{\bar{j}}) - y(t_{\bar{j}}) + y(t_{\bar{j}}) - y(\tau_j)\|_V^2$$
$$\le 4 \, \|y(t_{\bar{j}}) - y(\tau_j)\|_V^2 + 2 \, \|P^\ell y(t_{\bar{j}}) - y(t_{\bar{j}})\|_V^2$$
$$\le 8\Delta t \, \|y_t\|^2_{L^2(t_{\bar{j}-1},t_{\bar{j}+1};V)} + \frac{4\alpha_{\bar{j}}}{\delta t} \, \|P^\ell y(t_{\bar{j}}) - y(t_{\bar{j}})\|_V^2.$$

Thus, we get

$$\sum_{j=1}^k \delta\tau_j \, \|\varrho_j\|_V^2 \le 4\sigma_n\Delta\tau\Delta t \, \|y_t\|^2_{L^2(0,t_{\bar{k}+1};V)} + \frac{4\sigma_n\Delta\tau}{\delta t} \sum_{i=\ell+1}^d \lambda_i. \tag{B.17}$$

Combining (B.14)–(B.17) the claim follows.

LYAPUNOV SPECTRAL INTERVALS: THEORY AND COMPUTATION*

LUCA DIECI† AND ERIK S. VAN VLECK‡

Abstract. Different definitions of spectra have been proposed over the years to characterize the asymptotic behavior of nonautonomous linear systems. Here, we consider the spectrum based on exponential dichotomy of Sacker and Sell [*J. Differential Equations,* 7 (1978), pp. 320–358] and the spectrum defined in terms of upper and lower Lyapunov exponents. A main goal of ours is to understand to what extent these spectra are computable. By using an orthogonal change of variables transforming the system to upper triangular form, and the assumption of integral separation for the diagonal of the new triangular system, we justify how popular numerical methods, the so-called continuous QR and SVD approaches, can be used to approximate these spectra. We further discuss how to verify the property of integral separation, and hence how to a posteriori infer stability of the attained spectral information. Finally, we discuss the algorithms we have used to approximate the Lyapunov and Sacker–Sell spectra and present some numerical results.

Key words. Lyapunov exponents, Sacker–Sell spectrum, integral separation, numerical computation

1. Introduction.

Lyapunov exponents, or Lyapunov characteristic numbers, characterize growth rates of time dependent linear differential equations and, by linearizing about trajectories, measure rates of convergence or divergence of nearby trajectories for nonlinear differential equations. For an n-dimensional problem, there are n Lyapunov exponents: these are the natural generalization to time dependent linear differential equations of the eigenvalues for autonomous linear systems. Although Lyapunov exponents are a set of n points, it is perhaps more natural to think of the spectrum of a linear nonautonomous system as possibly being a continuum. For example, consider the linear scalar differential equation $\dot{x} = (\sin(\ln(t)) + \cos(\ln(t)))x$ for $t \geq t_0 > 0$: the solution is $x(t) = \exp(t\sin(\ln(t)))\kappa_0$, $\kappa_0 = x(t_0)\exp(-t_0\sin(\ln(t_0)))$, so that all growth rates in the interval $[-1, +1]$ are attained.

This work is an attempt to blend the numerical techniques developed to approximate Lyapunov exponents with stability theory for Lyapunov exponents developed over 30 years ago. Characteristic exponents were developed by Lyapunov in his thesis [22] that was first published in 1892. Many of the ideas from Lyapunov's thesis and further developments on Lyapunov exponents are contained in the monograph of Adrianova [1] which serves as an excellent accessible introduction to the use of Lyapunov exponents in stability theory. Important results on stability of Lyapunov exponents that we use are due to Bylov [6], Bylov et al. [5], Bylov and Izobov [7], and Millionshchikov [24, 25]. An alternative to the spectrum of Lyapunov is based upon defining a spectrum in terms of exponential dichotomy. Important works are the book

of Coppel [9] on exponential dichotomy in stability theory, the work of Sacker and Sell [30] which defines a spectrum in terms of exponential dichotomy, and the work of Palmer [28] who showed that the structurally stable linear systems on the half-line are those with exponential dichotomy.

A contribution of this paper is to show, under certain natural conditions, the relationship between three definitions of spectra. The first spectrum is commonly referred to as the Sacker–Sell spectrum and its origin may be traced back to [30]. The second spectrum generalizes the original definition of Lyapunov [22] so that it may be viewed as a continuous spectrum. The third spectrum is motivated by computational considerations, since its definition is based upon the information one may be able to retrieve when using the so-called QR method to approximate Lyapunov exponents.

The assumption under which we are able to show the relationship between these three spectra is *integral separation*. It has been well known in the theoretical community (see the results summarized in [1]) that, for systems with distinct Lyapunov exponents, integral separation is a necessary and sufficient condition for stability of the exponents, i.e., for continuity of the exponents with respect to changes in the coefficient matrix. Thus, it is natural to assume such a condition if we are interested in numerical approximation of the Lyapunov exponents.

We will emphasize how integral separation can be characterized for the numerical techniques that have been proposed to approximate Lyapunov exponents.

1. The *continuous QR method* is based upon finding an orthogonal change of variables transforming the system to upper triangular form. Then, the Lyapunov exponents are determined from the diagonal elements of the new system. The approach can be made legitimate under the assumption of *regularity* of the system. However, in spite of being a strong assumption, regularity does not ensure stability of the exponents. This motivated us to consider integral separation of the diagonal of the upper triangular coefficient matrix: we prove that this is sufficient for stability of the Lyapunov exponents.
2. We also consider a method for finding Lyapunov exponents based upon decomposing a fundamental matrix solution via a smooth singular value decomposition, the *SVD approach*. If such decomposition is feasible,[1] then the system is transformed to diagonal form, and the Lyapunov exponents are extracted from time averages of the diagonal system. Again, this can be justified under the assumption of regularity. But, rather, we show that if the new diagonal system has an integrally separated diagonal, then the Lyapunov exponents can be found from the diagonal system and are stable.

In spite of their importance in the physical sciences, Lyapunov exponents have received little attention from the numerical community. This is certainly due to the inherent difficulties (and uncertainties) present in the task, but we believe that it is also due to the fact that stability theory for Lyapunov exponents is not as well known as it should be. For this reason, and also to make the present work self-contained, the first two sections of this paper present background information. Sections 2 and 3 summarize results from [1] on Lyapunov exponents and on equivalence between stability of distinct Lyapunov exponents and integral separation. Section 4 summarizes the three spectra we consider. Sections 5, 6, and 7 contain our main results: under assumptions of integral separation, we show some relationships between the three spectra. Further, we validate the QR and SVD techniques to find the Lyapunov spectra. In section 8, we detail numerical techniques based on the continuous QR method to approximate

[1] E.g., it is feasible if the singular values stay distinct for all times t.

the spectra, and we also discuss how we can attempt to verify integral separation of a system. Finally, we give some new results on the relation between integral separation and the Sacker–Sell spectrum and outline a computational procedure to approximate such a spectrum. In Section 9 we present numerical experiments. Section 10 contains conclusions.

2. Lyapunov exponents theory. The *characteristic exponent* of a (nonvanishing) function $f(t)$ is defined as

$$\chi(f) = \limsup_{t\to\infty} \frac{1}{t} \ln |f(t)|. \tag{2.1}$$

The following equalities relate the upper and lower characteristic exponents of f and $1/f$ and will be useful when relating the exponents of a linear system and of its adjoint:

$$\begin{array}{rcl} \limsup_{t\to\infty} \frac{1}{t} \ln |f(t)| & = & -\liminf_{t\to\infty} \frac{1}{t} \ln |1/f(t)|, \\ \liminf_{t\to\infty} \frac{1}{t} \ln |f(t)| & = & -\limsup_{t\to\infty} \frac{1}{t} \ln |1/f(t)|. \end{array} \tag{2.2}$$

We now summarize some results on properties of characteristic exponents.

THEOREM 2.1 ([1, Thms. 2.1.2 and 2.1.4]). *The characteristic exponent of a product does not exceed the sum of the characteristic exponents, i.e.,* $\chi(fg) \le \chi(f) + \chi(g)$. *Moreover, if* $\chi(f) + \chi(1/f) = 0$, *then* $\chi(fg) = \chi(f) + \chi(g)$.

DEFINITION 2.2. *The Lyapunov exponent of a vector valued function* $x : t \in \mathbb{R} \to \mathbb{R}^n$ *is defined as the Lyapunov exponent of the norm:* $\chi(x) = \chi(||x||)$.

In this work, we restrict our consideration to the 2-norm, $\|x(t)\|_2$, and similarly for matrix valued functions. The advantage is that these are invariant under orthogonal transformations, but similar results would hold for different norms.

Consider now an n-dimensional linear system

$$\dot{x} = A(t)x\,, \tag{2.3}$$

where A is continuous and bounded: $\sup_t \|A(t)\| < \infty$. Given a fundamental matrix solution X of (2.3), consider the quantities

$$\lambda_i = \limsup_{t\to\infty} \frac{1}{t} \ln ||X(t)e_i||, \qquad i = 1, \ldots, n, \tag{2.4}$$

where e_i denotes the ith standard unit vector. When $\sum_{i=1}^n \lambda_i$ is minimized with respect to all possible fundamental matrix solutions, then the λ_i are called the Lyapunov exponents, or Lyapunov characteristic numbers, and the corresponding fundamental matrix solution is called a *normal basis*. In general, the Lyapunov exponents satisfy

$$\sum_{i=1}^{n} \lambda_i \ge \limsup_{t\to\infty} \frac{1}{t} \int_0^t \mathrm{Tr}(A(s))ds, \tag{2.5}$$

where $\mathrm{Tr}(A(s))$ is the trace of the matrix $A(s)$.

Remark 2.1. The Lyapunov exponents are unaffected by what happens to X on a finite interval. For this reason, in (2.5) and elsewhere in this paper, one may replace 0 with any other (finite) value of t. With this in mind, we will continue using 0 as the lower limit of integration.

Along with (2.3), we will also need to consider the associated adjoint equation

$$\dot{y}(t) = -A^T(t)y(t). \tag{2.6}$$

Similarly to (2.4), one can define the Lyapunov exponents for (2.6); call them $\{-\mu_i\}_{i=1}^n$. We will henceforth restrict our consideration to the system (2.3) and the λ_i exponents only, but of course everything can be formulated also in terms of the adjoint system (2.6) and the μ_i's.

Given any fundamental matrix solution, Lyapunov showed how to construct a normal fundamental matrix solution.

THEOREM 2.3 (see Lyapunov's construction of a normal basis [22]). *Consider a matrix solution $Z(\cdot) = [Z_1, \ldots, Z_n]$ such that the Lyapunov exponents of the columns of Z are ordered as $\chi(Z_1) \geq \cdots \geq \chi(Z_n)$. Then, there exists a unit upper triangular matrix C such that $X(\cdot) = Z(\cdot)C$ is normal. Similarly, if the Lyapunov exponents of the columns of Z are ordered as $\chi(Z_1) \leq \cdots \leq \chi(Z_n)$, then there exists a unit lower triangular matrix C such that $X(\cdot) = Z(\cdot)C$ is normal.*

Remark 2.2. The assumption of ordered characteristic exponents for the columns of Z is not stringent, since it can be trivially achieved via column permutation of any matrix solution. In the original work of Lyapunov (see also [1]), the matrix C was taken as a unit lower triangular with the corresponding assumption that the growth rates of the columns of Z are ordered as $\chi(Z_1) \leq \cdots \leq \chi(Z_n)$. However, the ordering in which C is taken to be unit upper triangular is more natural for us, since often we end up working with upper triangular systems, and we should expect that the growth rates will be ordered from largest down to smallest. On the other hand, when working with the adjoint, it is the reverse ordering which is more natural; hence the use of a unit lower triangular C is more appropriate in this case. Indeed (see [1, Cor. 3.6.2]), if the basis X is normal for (2.3), then the basis X^{-T} is normal for the adjoint system; here and elsewhere in this work, X^{-T} is shorthand notation for $(X^{-1})^T$. Conceptually, then, we can always work with a normal basis and assume to have ordered Lyapunov exponents for a system and its adjoint:

$$\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n \quad \text{and} \quad -\mu_n \geq \cdots \geq -\mu_2 \geq -\mu_1 .$$

Indeed, we will henceforth assume that we are working with a normal matrix solution X.

A fundamental property of Lyapunov exponents is that they (and their stability properties) are preserved under *Lyapunov transformations*.

DEFINITION 2.4. *A smooth invertible change of variables $y \leftarrow T^{-1}x$ is called a Lyapunov transformation if T, T^{-1}, and $\dot{T}$ are bounded.*

Clearly, under a Lyapunov transformation, (2.3) is transformed into

$$\dot{y} = B(t)y, \qquad B = T^{-1}AT - \dot{T}T^{-1} . \tag{2.7}$$

For example, it has been known since Perron [29] and Diliberto [17] that there exists a Lyapunov, and orthogonal, change of variables for which B is upper triangular. To see this, write a fundamental matrix solution $X(t)$ as $Q(t)R(t)$, where Q is an orthogonal matrix valued function and R is an upper triangular matrix valued function with positive diagonal entries. Upon differentiating we have

$$AQR = Q\dot{R} + \dot{Q}R \quad \text{or} \quad \dot{Q} = AQ - QB. \tag{2.8}$$

Since $\dot{R} = BR$, then B is upper triangular. Since Q is orthogonal, if we let $S(Q) := Q^T\dot{Q} = Q^TAQ - B$, then the strict lower triangular piece of the skew symmetric

function S can be defined as the corresponding piece of Q^TAQ, and the rest of S is given by skew-symmetry.

Remark 2.3. In what follows, when considering upper triangular systems $\dot{R} = BR$, we will always assume that the diagonal entries of R are positive.

Linear systems for which the Lyapunov exponents exist as limits were called *regular* by Lyapunov.

DEFINITION 2.5. *A system is regular (Lyapunov) if the time average of the trace has a finite limit and equality holds in* (2.5).

Example 2.1. A simple example of a linear system where a strict inequality holds in (2.5) is

$$\begin{aligned}\dot{x} &= (\sin(\ln t) + \cos(\ln t))y,\\ \dot{y} &= (\sin(\ln t) + \cos(\ln t))x\end{aligned}$$

which has Lyapunov exponents $\lambda_1 = \lambda_2 = 1$, but $\limsup_{t\to\infty} \frac{1}{t}\int_0^t \operatorname{trace}(A(s))ds = 0$.

It was shown by Lyapunov that regularity is maintained under Lyapunov transformations and, in particular, for a regular triangular system $\dot{R} = B(t)R$ the Lyapunov exponents may be obtained as time averages of the diagonal elements of B:

$$\lambda_j = \lim_{t\to\infty} \frac{1}{t}\int_0^t B_{jj}(s)ds, \qquad j = 1,\dots,n. \tag{2.9}$$

Further, in this regular case, the μ_i exponents of the adjoint system equal the λ_i exponents.

3. Stability of Lyapunov exponents and integral separation. In this section we summarize results on the relation between stability of the exponents and the property of integral separation.

DEFINITION 3.1. *The characteristic exponents $\lambda_1 \geq \cdots \geq \lambda_n$ of system* (2.3) *are said to be stable if for any $\epsilon > 0$ there exists $\delta > 0$ such that $\sup_{t\in\mathbb{R}^+} ||E(t)|| < \delta$ implies*

$$|\lambda_i - \gamma_i| < \epsilon, \qquad i = 1,\dots,n, \tag{3.1}$$

where the γ_i's are the (ordered) Lyapunov exponents of the perturbed system $\dot{x} = [A(t) + E(t)]x$.

Naturally, since Lyapunov transformations preserve the exponents and the smallness of perturbations, stability of the characteristic exponents is invariant under Lyapunov transformations.

THEOREM 3.2 (see [1, Thm. 5.2.1]). *If the λ_i exponents of* (2.3) *are stable, and $E \to 0$ as $t \to \infty$, then the exponents of the perturbed system are also given by the λ_i's.*

DEFINITION 3.3 (see [1, Def. 5.3.2] and [6]). *Write a fundamental matrix solution columnwise $X(t) = [X_1(t),\dots,X_n(t)]$. Then, X is integrally separated if for $i = 1,\dots,n-1$ there exist $a > 0$ and $d > 0$ such that*

$$\frac{||X_i(t)||}{||X_i(s)||} \cdot \frac{||X_{i+1}(s)||}{||X_{i+1}(t)||} \geq de^{a(t-s)} \tag{3.2}$$

for all $t, s \ : \ t \geq s$.

Again, if a matrix solution X is integrally separated, and T is a Lyapunov transformation, then the matrix solution $Y \leftarrow T^{-1}X$ associated with (2.7) is also integrally separated; i.e., integral separation is kept under Lyapunov transformations.

THEOREM 3.4 (see [1, Props. 5.3.1 and 5.3.3]). *Integrally separated systems have distinct Lyapunov exponents.*

DEFINITION 3.5. *The functions g_i, $i = 1, \ldots, n$, are said to be integrally separated if for $i = 1, \ldots, n-1$,*

$$\int_s^t (g_i(\tau) - g_{i+1}(\tau))d\tau \geq a(t-s) - d, \qquad t \geq s,\ a > 0,\ d \in \mathbb{R}. \tag{3.3}$$

THEOREM 3.6 (see [1, Thm. 5.4.7] and [7]). *If the system* (2.3) *has distinct characteristic exponents $\lambda_1 > \cdots > \lambda_n$, then they are stable if and only if there exists a Lyapunov transformation $z \leftarrow T^{-1}x$ transforming* (2.3) *to the diagonal form*

$$\dot{z} = \operatorname{diag}[p_1(t), \ldots, p_n(t)]z, \tag{3.4}$$

where the diagonal elements, the p_i, are integrally separated functions.

THEOREM 3.7 (see [1, Thm. 5.4.8] and [7]). *If the system* (2.3) *has distinct characteristic exponents $\lambda_1 > \cdots > \lambda_n$, then they are stable if and only if there exists a fundamental matrix solution with integrally separated columns, as in Definition* 3.3.

Given the implications of integral separation, it is a comforting fact that it is a natural condition to have. This is because of a result of Palmer [28, p. 21]. Palmer considered the Banach space $\mathcal{B}$, of continuous bounded matrix valued functions A, with norm $||A|| = \sup_{t\geq 0} ||A(t)||$, and—using results from [24] and [5]—he showed that the systems with integral separation form an open and dense subset of $\mathcal{B}$. Therefore, integral separation is a generic property in $\mathcal{B}$.

Regularity (see Definition 2.5), however, is not enough to ensure stability and hence integral separation, as the following example from [1, p. 171] shows. Consider the regular system

$$\begin{aligned} \dot{x}_1 &= \left(1 + \frac{\pi}{2}\sin(\pi\sqrt{t})\right) x_1, \\ \dot{x}_2 &= 0, \end{aligned} \tag{3.5}$$

which has distinct Lyapunov exponents $\lambda_1 = 1$ and $\lambda_2 = 0$. Since for any $n \in \mathbb{N}$,

$$\int_{(2n-1)^2}^{(2n)^2} \left(1 + \frac{\pi}{2}\sin(\pi\sqrt{t})\right) d\tau = 0, \tag{3.6}$$

then the system (3.5) is not integrally separated and hence the Lyapunov exponents are not stable.

Remark 3.1. In all numerical works on approximation of Lyapunov exponents of which we are aware, it is assumed that system (2.3) is regular; e.g., see [2, 3, 12, 13, 18, 19, 20, 21]. This is justified on the grounds that regularity is a prevalent condition in a measure theoretic sense; see [27]. However, from the numerical point of view, we need to insist that the Lyapunov exponents be stable, and for this to be true we need integral separation, not regularity.

We now show that the adjoint system (2.6) has an integrally separated fundamental matrix solution if the original system (2.3) does.

LEMMA 3.8. *If* (2.3) *has a fundamental matrix solution with integrally separated columns, then the adjoint* (2.6) *has a fundamental matrix solution with integrally separated columns.*

Proof. Because of (2.7) and (2.8), we may consider, without loss of generality, an upper triangular system $\dot{R} = BR$ with an integrally separated fundamental matrix solution R. Then $S = R^{-T}$ satisfies $\dot{S} = -B^T S$. Since R has integrally separated columns, by Theorems 3.6 and 3.7, there exists a Lyapunov transformation L such that $D = \text{diag}(p_i) = L^{-1}BL - L^{-1}\dot{L}$ and the p_i are integrally separated, i.e., they satisfy (3.3). Let $Y = L^{-1}R$; then Y is integrally separated and $Y = \text{diag}(\exp(\int_0^t p_i(s)ds))$. Let $Z = (L^{-T})^{-1}S$ so that $Z = Y^{-T}$ and Z satisfies $\dot{Z} = -D^T Z = -DZ$. Then $Z_{ii}(t) = \exp(-\int_0^t p_i(s)ds)$ for $i = 1, \ldots, n$, and so

$$\frac{Z_{i,i}(t)}{Z_{i,i}(s)} \cdot \frac{Z_{i+1,i+1}(s)}{Z_{i+1,i+1}(t)} = \frac{Y_{i+1,i+1}(t)}{Y_{i+1,i+1}(s)} \cdot \frac{Y_{i,i}(s)}{Y_{i,i}(t)} \geq d\exp(a(t-s)),$$

$$a > 0,\ t \geq s,\ \ i = 1, \ldots, n-1.$$

Thus, by Theorems 3.6 and 3.7 the adjoint equation has an integrally separated fundamental matrix solution. ∎

4. Three definitions of spectra. Consider (2.3). It is well known that if $A(\cdot)$ is constant, then the asymptotic stability properties of the zero solution of (2.3) are determined by the real parts of the eigenvalues of A and the corresponding eigenvectors. In the case in which A is periodic in t, the Floquet theory effectively reduces the question of stability to the constant coefficient case. For the general case, we recall the next two classical concepts of stability, and we introduce a third related one.

4.1. Sacker–Sell spectrum. In [30], Sacker and Sell introduced a spectrum for (2.3) based upon exponential dichotomy: the Sacker–Sell spectrum is given by those values $\lambda \in \mathbb{R}$ such that the shifted system $\dot{x} = [A(t) - \lambda I]x$ does not have exponential dichotomy. We will indicate the Sacker–Sell spectrum with Σ_{ED}. Recall that the system (2.3) has *exponential dichotomy* if for a fundamental matrix solution X there exists a projection P and constants $\alpha, \beta > 0$ and $K, L \geq 1$, such that

$$\begin{array}{rcll} \|X(t)PX^{-1}(s)\| & \leq & Ke^{-\alpha(t-s)}, & t \geq s, \\ \|X(t)(I-P)X^{-1}(s)\| & \leq & Le^{\beta(t-s)}, & t \leq s. \end{array} \tag{4.1}$$

It is shown in [30] that Σ_{ED} is given by the union of at most n closed intervals. Thus, it can be written, for some k: $1 \leq k \leq n$, as

$$\Sigma_{\text{ED}} := [a_1, b_1] \cup \cdots \cup [a_k, b_k]. \tag{4.2}$$

4.2. Lyapunov spectrum. Another characterization of spectrum is based on the characteristic exponents of (2.3) and (2.6), the λ_i's and $-\mu_i$'s which we can consider as being ordered: $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n$ and $\mu_1 \geq \mu_2 \geq \cdots \geq \mu_n$. We define the Lyapunov spectrum, written Σ_{L}, as

$$\Sigma_{\text{L}} := \bigcup_{j=1}^{n} [\lambda_j^i, \lambda_j^s], \tag{4.3}$$

where $\lambda_j^i = \mu_j$ and $\lambda_j^s = \lambda_j$ and, in fact, $\lambda_j \geq \mu_j$ for $j = 1, \ldots, n$. The last statement is a consequence of the fact that the normal bases for (2.3) and (2.6) are X and X^{-T}, so, if $\lambda_j = \chi(Xe_j)$, then $-\mu_j = \chi(X^{-T}e_j)$. But obviously, $(X^{-T}e_j)^T(Xe_j) = 1$ for all t so that Theorem 2.1 gives $\lambda_j \geq \mu_j$.

Remark 4.1. Our definition of Lyapunov spectrum is strictly related to the *coefficient of irregularity* of Perron, who proved that a system is regular if and only if $\lambda_j = \mu_j$.

Remark 4.2. It must be appreciated that Σ_{L} and Σ_{ED} provide information on related, but different, questions. In particular, $\lambda \notin \Sigma_{\mathrm{L}}$ implies the existence of a bounded solution to the homogeneous problem $\dot{x} = (A(t) - \lambda I)x$, for some initial condition $x(0)$. Instead, $\lambda \notin \Sigma_{\mathrm{ED}}$ implies both the existence of a bounded solution to the homogeneous problem $\dot{x} = (A(t) - \lambda I)x$ for some $x(0)$ and the existence of a bounded solution to the nonhomogeneous problem $\dot{x} = (A(t) - \lambda I)x + f(t)$ for any (continuous and bounded) function $f(t)$, a condition which is not guaranteed by $\lambda \notin \Sigma_{\mathrm{L}}$. Obviously, both properties are quite important, and it depends on the particular application in which we are interested whether we need to know Σ_{ED} or whether knowledge of Σ_{L} is sufficient.

4.3. Computed Lyapunov spectrum. The third spectrum we consider is what we will call the *computed Lyapunov spectrum*, since it is close to what traditionally has been approximated. Its definition rests on the transformation of (2.3) to upper triangular form via an orthogonal change of variables; see (2.7) and (2.8). Consider the upper triangular system $\dot{R} = BR$. We define the computed Lyapunov spectrum, written Σ_{CL}, as

$$\Sigma_{\mathrm{CL}} := \bigcup_{j=1}^{n} [\lambda_{jj}^i, \lambda_{jj}^s], \quad \lambda_{jj}^i = \liminf_{t\to\infty} \frac{1}{t}\int_0^t B_{jj}(s)ds, \quad \lambda_{jj}^s = \limsup_{t\to\infty} \frac{1}{t}\int_0^t B_{jj}(s)ds. \tag{4.4}$$

5. The Lyapunov and computed Lyapunov spectra. In this section we prove that for upper triangular systems, integral separation of the diagonal elements implies that the Lyapunov spectrum, Σ_{L}, and the computed Lyapunov spectrum, Σ_{CL}, coincide. We prove this by constructing a bounded Lyapunov transformation that transforms the upper triangular system to a diagonal system given by the diagonal of the upper triangular system.

THEOREM 5.1. *For an upper triangular system $\dot{R} = BR$ with B smooth and bounded, integral separation of the diagonal of B implies $\Sigma_{\mathrm{L}} = \Sigma_{\mathrm{CL}}$.*

Proof. The proof is by induction. Write B in block form and define a transformation T_1 using the same blocking:

$$B = \begin{pmatrix} b_{11} & b_{12} & B_{13} \\ 0 & b_{22} & B_{23} \\ 0 & 0 & B_{33} \end{pmatrix} \quad \text{and} \quad T_1 = \begin{pmatrix} 1 & x & 0 \\ 0 & 1 & 0 \\ 0 & 0 & I \end{pmatrix}. \tag{5.1}$$

We want to take x such that

$$T_1^{-1}BT_1 - T_1^{-1}\dot{T}_1 = \begin{pmatrix} b_{11} & 0 & B_{13} - xB_{23} \\ 0 & b_{22} & B_{23} \\ 0 & 0 & B_{33} \end{pmatrix}. \tag{5.2}$$

To obtain this, we take x satisfying

$$\begin{cases} \dot{x} = b_{11}x - xb_{22} + b_{12}, \\ \lim\limits_{T\to\infty} x(T) = 0; \end{cases} \tag{5.3}$$

that is,

$$x(t) = -\lim_{T\to\infty} \int_t^T \exp\left(-\int_t^s (b_{11}(\tau) - b_{22}(\tau))d\tau\right) b_{12}(s)ds. \tag{5.4}$$

Since the diagonal elements of B are integrally separated (see (3.3)), we have

$$-\int_t^s (b_{11}(\tau) - b_{22}(\tau))d\tau \le -a(s-t) + d, \qquad a > 0,\ s \ge t, \tag{5.5}$$

which implies that x is bounded and the transformed coefficient matrix is bounded.

Now we assume that the matrix function B has been progressively diagonalized in its first p columns so that the transformed coefficient matrix has the form

$$B = \begin{pmatrix} B_{11} & B_{12} & B_{13} \\ 0 & b_{p+1,p+1} & B_{23} \\ 0 & 0 & B_{33} \end{pmatrix}, \tag{5.6}$$

where $B_{11} : t \to \mathbb{R}^{p\times p}$ is diagonal, and $B_{12} : t \to \mathbb{R}^{p\times 1}$, $B_{13} : t \to \mathbb{R}^{p\times(n-p-1)}$, $B_{23} : t \to \mathbb{R}^{1\times(n-p-1)}$ are all continuous and bounded. Consider the transformation T_p and transformed coefficient matrix of the form

$$T_p = \begin{pmatrix} I_p & x & 0 \\ 0 & 1 & 0 \\ 0 & 0 & I_{n-p-1} \end{pmatrix}, \qquad T_p^{-1}BT_p - T_p^{-1}\dot{T}_p = \begin{pmatrix} B_{11} & 0 & B_{13} - xB_{23} \\ 0 & b_{p+1,p+1} & B_{23} \\ 0 & 0 & B_{33} \end{pmatrix}, \tag{5.7}$$

where we require that x satisfies

$$\dot{x} = B_{11}x - xb_{p+1,p+1} + B_{12} = (B_{11} - b_{p+1,p+1}I)x + B_{12} \tag{5.8}$$

and $\lim_{T\to\infty} x(T) = 0$. Then, since B_{11} is diagonal,

$$x(t) = -\lim_{T\to\infty} \int_t^T \exp\left(-\int_t^s (B_{11}(\tau) - I \cdot b_{p+1,p+1}(\tau))d\tau\right) B_{12}(s)ds\,.$$

Since B_{12} is bounded and the diagonal of B is integrally separated, we have that x is bounded and T_p is Lyapunov. Since Lyapunov transformations preserve the Lyapunov spectrum, the result follows. ∎

The following corollary is an immediate consequence of the above proof and Theorems 3.6 and 3.7.

COROLLARY 5.1. *Given an upper triangular system $\dot{R} = BR$ with B smooth, bounded, and with integrally separated diagonal, then there exists an integrally separated fundamental matrix solution.*

As a partial converse to Theorem 5.1 we have the following.

THEOREM 5.2. *Suppose the system $\dot{R} = BR$, with B bounded, continuous and upper triangular, has an integrally separated fundamental matrix solution R. Then for all $\epsilon > 0$ there exists a permutation π such that $|\lambda^s_{\pi(i)} - \limsup_{t\to\infty} \frac{1}{t}\int_0^t B_{ii}(s)ds| < \epsilon$.*

Proof. Consider the system $\dot{D} = \mathrm{diag}(B)D$ and let $\lambda_i(D) = \limsup_{t\to\infty} \frac{1}{t}\int_0^t B_{ii}(s)ds$. Let L be the Lyapunov transformation defined by $L = \mathrm{diag}(\eta^{i-1}, i = 1,\dots,n)$ for $\eta \ge \eta_0 > 0$. Then $L^{-1}B(t)L - L^{-1}\dot{L} = \mathrm{diag}(B(t)) + E(t)$, where $E(t)$ is the strictly upper triangular function of entries $E_{ij}(t) = \eta^{j-i}B_{ij}(t)$, for $i = 1,\dots,n-1$ and $j = i+1,\dots,n$. Since L is Lyapunov, and stability of the exponents is preserved

under Lyapunov transformations, then, for $\epsilon > 0$ as given in the statement of the theorem, there exists $\delta = \delta(\epsilon)$ such that $\sup_t |E(t)| < \delta$ implies $|\lambda_i^s - \lambda_i'| < \epsilon$, where $\{\lambda_i'\}_{i=1}^n$ denote the Lyapunov exponents of $\dot{D} = \operatorname{diag}(B)D$.

We claim that there exists a permutation π such that $\lambda_i' = \lambda_{\pi(i)}(D)$. Let Π denote a permutation matrix such that $\hat{D} = \Pi D \Pi^T$ defines an ordering such that $\chi(\hat{D}_{11}) \geq \chi(\hat{D}_{22}) \geq \cdots \geq \chi(\hat{D}_{nn})$. Notice that $\hat{D}$ satisfies $\dot{\hat{D}} = \hat{B}_D \hat{D}$, where $\hat{B}_D = \Pi \operatorname{diag}(B) \Pi^T$ and $\chi(\hat{D}_{ii}) = \chi(\hat{D}e_i) = \chi(\Pi \operatorname{diag}(B)\Pi^T e_i) = \chi(\operatorname{diag}(B)e_{\pi(i)})$. To complete the claim, we need to show that the diagonal fundamental matrix solution $\hat{D}$ is normal. By the Lyapunov construction of a normal basis, there exists a unit upper triangular matrix C such that $\hat{D} \cdot C$ is normal, but since setting $C = I$ minimizes the sum of the characteristic exponents of the columns, we have that $\hat{D}$ is normal. ∎

Remark 5.1. The Lyapunov exponents of $\dot{D} = \operatorname{diag}(B)D$ are not necessarily stable. The ordering of the Lyapunov exponents is not necessarily preserved; hence the need for the permutation π.

6. Sacker–Sell spectrum and Lyapunov spectral intervals. In this section we state and prove results relating the Sacker–Sell spectrum, Σ_{ED}, the Lyapunov spectrum, Σ_{L}, and the computed Lyapunov spectrum, Σ_{CL}. The following lemma shows that if a system has exponential dichotomy, then the principal matrix solution and an orthogonal projection may be assumed.

LEMMA 6.1. *Suppose the linear system* (2.3) *admits an exponential dichotomy for some fundamental matrix solution. Then it also admits an exponential dichotomy for the principal matrix solution. Moreover, the projection P may be taken to be an orthogonal matrix.*

Proof. Assume that (2.3) admits an exponential dichotomy for a fundamental matrix solution $X(t) \equiv X(t; X_0)$ with $X(0) = X_0$. Then $X(t; X_0) = X(t, I)X_0$ and

$$\begin{aligned} X(t;X_0)PX^{-1}(s;X_0) &= X(t;I)(X_0PX_0^{-1})X^{-1}(s;I), \\ X(t;X_0)(I-P)X^{-1}(s;X_0) &= X(t;I)(X_0(I-P)X_0^{-1})X^{-1}(s;I). \end{aligned} \tag{6.1}$$

Let $\tilde{P} = X_0 P X_0^{-1}$ and observe that $\tilde{P}^2 = \tilde{P}$, so $\tilde{P}$ is a projection and hence we have that the principal matrix solution admits an exponential dichotomy.

Let $S = \operatorname{range}(\tilde{P})$ and let V denote an orthonormal basis for S so that $P_1 = VV^T$ is the unique orthogonal projection onto S. From [9, pp. 16–17], it follows that the principal matrix solution admits an exponential dichotomy with orthogonal projection P_1. ∎

The following is essentially in [30], but we give a different proof.

THEOREM 6.2. *The computed Lyapunov spectrum is contained within the Sacker–Sell spectrum.*

Proof. Consider $\dot{X} = A(t)X$ with principal matrix solution X and the shifted system $\dot{X}_\lambda = [A(t) - \lambda I]X_\lambda$ with fundamental matrix solution X_λ. Fix λ such that X_λ has exponential dichotomy. Then there exists a projection P, constants $\alpha, \beta > 0$ and $K, L \geq 1$ such that

$$\begin{aligned} \|X_\lambda(t)PX_\lambda^{-1}(s)\| &\leq Ke^{-\alpha(t-s)}, \qquad t \geq s, \\ \|X_\lambda(t)(I-P)X_\lambda^{-1}(s)\| &\leq Le^{\beta(t-s)}, \qquad t \leq s. \end{aligned} \tag{6.2}$$

By Lemma 6.1, the projection P can be chosen orthogonal and there exists an orthogonal matrix U such that $U^T P U = P_1$, where P_1 is a diagonal matrix with entries

either 0 or 1. Thus,

$$\begin{array}{rcll} \|X_\lambda(t)UP_1U^TX_\lambda^{-1}(s)\| & \leq & Ke^{-\alpha(t-s)}, & t\geq s,\\ \|X_\lambda(t)U(I-P_1)U^TX_\lambda^{-1}(s)\| & \leq & Le^{\beta(t-s)}, & t\leq s, \end{array} \tag{6.3}$$

or equivalently,

$$\begin{array}{rcll} e^{-\lambda(t-s)}\|W(t)P_1W^{-1}(s)\| & \leq & Ke^{-\alpha(t-s)}, & t\geq s,\\ e^{-\lambda(t-s)}\|W(t)(I-P_1)W^{-1}(s)\| & \leq & Le^{\beta(t-s)}, & t\leq s, \end{array} \tag{6.4}$$

where $W(t)=X(t)U$ satisfies $\dot W = A(t)W$. Let Π denote a column permutation such that $Z=W\Pi$ implies $\chi(Z_1)\geq\cdots\geq\chi(Z_n)$, where Z_i denotes the ith column of Z. Decompose Z as $Z(t)=Q(t)R(t)$, where $Q(0)=Z(0)=U\Pi$ and $R(0)=I$, and notice that $\chi(R_1)\geq\cdots\geq\chi(R_n)$. For this ordering of growth rates of the columns of R the Lyapunov construction of a normal basis (see Theorem 2.3) takes the form $R(t)\,C$, where C is a unit upper triangular matrix so the Lyapunov construction does not change the diagonal elements of R.

In terms of R, the exponential dichotomy relationship for the shifted system is

$$\begin{array}{rcll} \|R_\lambda(t)P_2R_\lambda^{-1}(s)\| & \leq & Ke^{-\alpha(t-s)}, & t\geq s,\\ \|R_\lambda(t)(I-P_2)R_\lambda^{-1}(s)\| & \leq & Le^{\beta(t-s)}, & t\leq s, \end{array} \tag{6.5}$$

where $P_2=\Pi^TP_1\Pi$. Recall that the computed Lyapunov spectrum is defined as $\bigcup_j[\lambda^i_{jj},\lambda^s_{jj}]$, where

$$\lambda^s_{jj}=\limsup_{t\to\infty}\frac{1}{t}\ln(R_{jj}(t)) \quad\text{and}\quad \lambda^i_{jj}=\liminf_{t\to\infty}\frac{1}{t}\ln(R_{jj}(t)). \tag{6.6}$$

Assume that rank of P, hence of P_1 and P_2, is m. In (6.5) set $s=0$ so we have $|R_\lambda(t)P_2|\leq Ke^{-\alpha t}$. Since P_2 is a permutation matrix (plus rows and columns of 0's), $R_\lambda(t)P_2$ is a matrix containing m columns of $R_\lambda(t)$ and $n-m$ zero columns. Thus, there must be m columns of R for which $\lambda^s_{jj}-\lambda=\chi(R_{jj})-\lambda\leq\chi(R_{\bullet,j})-\lambda\leq-\alpha$, while for $n-m$ rows of R^{-1} we have $-\lambda^i_{kk}+\lambda=\chi(R^{-1}_{kk})+\lambda\leq\chi(R^{-1}_{k,\bullet})+\lambda\leq-\beta$. Thus, for m indices j we have $\lambda^i_{jj}\leq\lambda^s_{jj}\leq\lambda-\alpha<\lambda$ and for $n-m$ indices k we have $\lambda<\lambda+\beta\leq\lambda^i_{kk}\leq\lambda^s_{kk}$. Hence, $\lambda\notin\bigcup_j[\lambda^i_{jj},\lambda^s_{jj}]$. ∎

THEOREM 6.3. *Assume that for a linear homogeneous n-dimensional system the Sacker–Sell spectrum is given by n disjoint intervals. Then there exists a fundamental matrix solution with integrally separated columns.*

Proof. Write the Sacker–Sell spectrum as $\bigcup_{i=1}^n[a_i,b_i]$, and for $i=1,\ldots,n-1$ choose $\lambda_i=(a_{i+1}+b_i)/2$. Obviously $\lambda_i\notin\Sigma_{\rm ED}$, and there exists a fundamental matrix solution X_{λ_i} that has exponential dichotomy. Using the argument from Theorem 6.2, there exists a projection P_i of the form $P_i=\left(\begin{smallmatrix}0&0\\0&I\end{smallmatrix}\right)$ and $K_i,L_i,\alpha_i,\beta_i>0$ such that

$$\begin{array}{rcl} K_ie^{-\alpha_i(t-s)} & \geq & ||X_{\lambda_i}(t)PX^{-1}_{\lambda_i}(s)||\geq\dfrac{|X_{\lambda_i}(t)PX^{-1}_{\lambda_i}(s)X_{\lambda_i}(s)Pc|}{|X_{\lambda_i}(s)Pc|}\\ & = & \dfrac{\|X_{\lambda_i}(t)Pc\|}{\|X_{\lambda_i}(s)Pc\|}=\dfrac{\|X_j(t)\|}{\|X_j(s)\|}\cdot e^{-\lambda_i(t-s)} \end{array} \tag{6.7}$$

for $t\geq s$, and $c=e_j$, $j=i+1,\ldots,n$, and

$$\begin{array}{rcl} L_ie^{\beta_i(t-s)} & \geq & ||X_{\lambda_i}(t)(I-P)X^{-1}_{\lambda_i}(s)||\geq\dfrac{\|X_{\lambda_i}(t)(I-P)X^{-1}_{\lambda_i}(s)X_{\lambda_i}(s)(I-P)c\|}{\|X_{\lambda_i}(s)(I-P)c\|}\\ & = & \dfrac{\|X_{\lambda_i}(t)(I-P)c\|}{\|X_{\lambda_i}(s)(I-P)c\|}=\dfrac{\|X_j(t)\|}{\|X_j(s)\|}\cdot e^{-\lambda_i(t-s)} \end{array} \tag{6.8}$$

for $t \le s$, and $c = e_j$, $j = 1, \ldots, i$. Then

$$\frac{\|X_i(t)\|}{\|X_i(s)\|} \cdot \frac{\|X_{i+1}(s)\|}{\|X_{i+1}(t)\|} \ge \frac{1}{L_i} e^{\beta_i (t-s)} \cdot \frac{1}{K_i} e^{\alpha_i (t-s)} = \frac{1}{L_i K_i} e^{(\alpha_i + \beta_i)(t-s)}. \tag{6.9}$$

Repeating for all $i = 1, \ldots, n-1$, and taking $a = \min_i\{\alpha_i + \beta_i\}$ and $d = \min_i\{\frac{1}{L_i K_i}\}$, completes the proof. □

Example 6.1. As a counterexample to a converse of Theorem 6.3, consider the diagonal system with $\dot{x}_1 = (\cos(\ln t) + \sin(\ln t))x_1$ and $\dot{x}_2 = (-1 + \cos(\ln t) + \sin(\ln t))x_2$ so that $\Sigma_{\mathrm{CL}} = \Sigma_{\mathrm{L}} = [-1, 1] \cup [0, 2]$. Then, because of Theorem 6.2, the Sacker–Sell intervals overlap, but

$$\frac{|x_1(t)|}{|x_1(s)|} \cdot \frac{|x_2(s)|}{|x_2(t)|} = e^{t-s}, \qquad t \ge s, \tag{6.10}$$

so that x_1 and x_2 are integrally separated. □

Even in the case of stable Lyapunov exponents, in general, the Lyapunov and computed Lyapunov spectra are contained in the Sacker–Sell spectrum (see [30]). The following example modeled after one of Perron (see [1, Ex. 4.4.1]) clarifies this fact and it will be important in order to understand how we may approximate Σ_{ED}.

Example 6.2. Consider the linear differential equation $\dot{x} = c(t)x$, $c(t) = \sin(\ln(t)) + \cos(\ln(t))$, for $t \ge t_0 > 0$. The exact solution is $x(t) = \exp(t \sin(\ln(t)))\kappa_0$, $\kappa_0 = x(t_0)\exp(-t_0 \sin(\ln(t_0)))$, and it is easily seen that the Lyapunov and computed Lyapunov spectra coincide and are given by the interval $[-1, +1]$. Since the problem is scalar, this Lyapunov spectrum is necessarily stable.

We will show that $[-1, 1] \subset \Sigma_{\mathrm{ED}}$, that is, that there are values of $\lambda > 1$, and $\lambda < -1$, for which the shifted system does not have exponential dichotomy. Consider $\lambda > 1$; the case $\lambda < -1$ is similar. Then, to have exponential dichotomy in the shifted system means that there exist constants $\alpha > 0$ and $K \ge 1$ such that

$$e^{-\lambda(t-s)} e^{\int_s^t c(r)dr} = x_\lambda(t) x_\lambda^{-1}(s) \le K e^{-\alpha(t-s)}, \qquad t \ge s \ge t_0,\ \lambda > 1\,. \tag{6.11}$$

We rewrite this in the equivalent form

$$\frac{e^{\lambda t}}{e^{\lambda s}} \, \frac{e^{\int_{t_0}^s c\,d\tau}}{e^{\int_{t_0}^t c\,d\tau}} \ge \frac{1}{K} e^{\alpha(t-s)} \tag{6.12}$$

and consider the diagonal system

$$\dot{X} = \begin{pmatrix} \lambda & 0 \\ 0 & c(t) \end{pmatrix} X\,. \tag{6.13}$$

Thus, to have exponential dichotomy is the same as asking that the principal matrix solution of this system be integrally separated with constants $\frac{1}{K} < 1$ and $\alpha > 0$. This is equivalent to the requirement that

$$\int_s^t (\lambda - c(\tau))d\tau \ge a(t-s) - d, \qquad t \ge s,\ a > 0\,,\ \ d \ge 0\,, \tag{6.14}$$

which, in general, is not true. Let $\lambda_M = \frac{e^{\pi/2} + e^{-\pi/2}}{e^{\pi/2} - e^{-\pi/2}} = \coth(\pi/2)$. If the functions λ and c were integrally separated, then we should have

$$\int_s^t (\lambda - \sin(\ln(\tau)) - \cos(\ln(\tau)))d\tau \ge a(t-s) - d\,,$$

or

$$\lambda(t-s) - (t\sin(\ln(t)) - s\sin(\ln(s))) \geq a(t-s) - d\,.$$

Now, consider the following sequences for t and s:

$$t_k = \exp(2k\pi + \pi/2), \qquad s_k = \exp(2k\pi - \pi/2). \tag{6.15}$$

Then, along these sequences we would need to have

$$\lambda e^{2k\pi}(e^{\pi/2} - e^{-\pi/2}) - e^{2k\pi}(e^{\pi/2} + e^{-\pi/2}) \geq a e^{2k\pi}(e^{\pi/2} - e^{-\pi/2}) - d$$

or

$$a(e^{\pi/2} - e^{-\pi/2}) \leq \lambda(e^{\pi/2} - e^{-\pi/2}) - (e^{\pi/2} + e^{-\pi/2}) + de^{-2k\pi}.$$

Thus, for $1 < \lambda < \lambda_M$ and k sufficiently large, $\lambda(e^{\pi/2} - e^{-\pi/2}) - (e^{\pi/2} + e^{-\pi/2}) + de^{-2k\pi} < 0$, and so no positive a exists and the system cannot have exponential dichotomy for $1 < \lambda < \lambda_M$, where $\lambda_M \geq 1.09$. A similar argument for $\lambda < -1$ leads us to consider the diagonal system

$$\dot{X} = \begin{pmatrix} c(t) & 0 \\ 0 & \lambda \end{pmatrix} X\,, \tag{6.16}$$

so that having exponential dichotomy is equivalent to integral separation of the principal matrix solution of (6.16) or (which is the same) to

$$\int_s^t (c(\tau) - \lambda)d\tau \geq a(t-s) - d, \qquad t \geq s\ ,\ a > 0\,,\ \ d \geq 0\,. \tag{6.17}$$

Similarly to the above, we now obtain that we cannot have exponential dichotomy for $-1.09 \leq \lambda < -1$. Therefore, $[-1.09, 1.09] \subseteq \Sigma_{\mathrm{ED}}$. This argument can be easily improved by replacing $\pi/2$ in the definition of t_k and s_k in (6.15) with $\omega \approx 1.25$ (find ω to maximize $\coth(\omega)\cdot\sin(\omega)$ so that ω is the positive root of $\cos(\omega)\cdot\sinh(\omega) - 2\sin(\omega) = 0$). This shows that $[-1.1187, 1.1187] \subseteq \Sigma_{\mathrm{ED}}$.

For the sake of completeness, we point out that in [16] we actually prove that—for this example—$\Sigma_{\mathrm{ED}} = [-\sqrt{2}, \sqrt{2}]$. We will use this fact in Example 9.1. ∎

7. The SVD. To approximate Lyapunov exponents, an alternative to QR-based techniques is based on the SVD of a fundamental matrix solution. This approach has been used in [19, 20, 23]. Here we explore the feasibility of this approach, in particular, the role of integral separation in this case. So, we will assume that we have an integrally separated fundamental matrix solution X with ordered growth rates: $\chi(X_1) > \cdots > \chi(X_n)$.

Techniques based on the SVD need to assume that X admits a smooth SVD for all $t \geq t_0$: $X(t) = U(t)\Sigma(t)V^T(t)$, where $U^TU = I, V^TV = I, \Sigma = \mathrm{diag}(\sigma_i,\ i = 1, \ldots, n)$ and U, V, Σ are all C^p functions, $p \geq 1$. Unlike the QR factorization of X, the existence of such a smooth SVD is not obvious except in the case where the singular values stay distinct. Still, some results are known: (i) If X is analytic, then the factors U, V, Σ exist and are analytic (see [4]); (ii) if $X \in C^p, p \geq 1$, then there exist smooth $U,\ V,\ \Sigma$ as long as the singular values do not coalesce with too high a degree of contact (in general, U and V lose some degree of differentiability, while Σ stays C^p; see [11] for a precise statement); (iii) generically (i.e., for a generic one-parameter family of

nonsingular C^p functions X), then U, V, Σ are C^p, and in fact the σ_i singular values are distinct for all t (see [11]).

To make some progress, let us henceforth assume that a smooth (at least C^1) SVD of X exists. Let $G = U^T A U$ for all t. We notice that since $X = U\Sigma V^T$ for all t, and all factors are smooth, then we must also have

$$\dot{X} = AU\Sigma V^T = \dot{U}\Sigma V^T + U\dot{\Sigma}V^T + U\Sigma\dot{V}^T\,,$$

so that by letting $H = U^T\dot{U}$ and $K = V^T\dot{V}$, and noticing that H and K must be skew-symmetric, one must have

$$\dot{\Sigma} = G\Sigma - H\Sigma + \Sigma K\,,$$

and so we must have

$$\dot{\sigma}_i \;=\; G_{ii}\sigma_i \to \sigma_i(t) = \sigma_i(s)e^{\int_s^t G_{ii}(\tau)d\tau}\,, \qquad i = 1, \ldots, n\,. \tag{7.1}$$

In [19, 20] under the assumption of distinct singular values, the authors derived differential equations for U and Σ, integrated these numerically, and then set[2]

$$\lambda_i = \limsup_{t\to\infty} \frac{1}{t}\ln(|\sigma_i(t)|)\,, \qquad i = 1, \ldots, n\,. \tag{7.2}$$

Under the assumption of distinct singular values, the differential equations describing the evolution of U, V, Σ have been derived many times before (e.g., see [32]) and are

$$\dot{U} = UH, \quad \dot{V}^T = -KV^T, \quad \dot{\Sigma} = D\Sigma, \tag{7.3}$$

where $D = \mathrm{diag}(G)$, $H^T = -H$, $K^T = -K$ and, for $i \neq j$,

$$H_{ij} = \frac{G_{ij}\sigma_j^2 + G_{ji}\sigma_i^2}{\sigma_j^2 - \sigma_i^2}, \qquad K_{ij} = \frac{(G_{ij} + G_{ji})\sigma_i\sigma_j}{\sigma_j^2 - \sigma_i^2}. \tag{7.4}$$

On the other hand, from the SVD of X the Lyapunov exponents may be obtained as

$$\chi(X_i) = \limsup_{t\to\infty} \frac{1}{t}\ln||\Sigma(t)V^T(t)e_i||\,. \tag{7.5}$$

Here, we explore the "equivalence" between (7.2) and (7.5) and at the same time validate the methods based upon differential equations for the U, V, and Σ factors. We will do this under the assumption that D, the diagonal of G, is integrally separated:

$$\int_s^t (G_{kk}(\tau) - G_{k+1,k+1}(\tau))d\tau \geq a(t-s) - d, \tag{7.6}$$

$$a > 0,\ d \in \mathbb{R},\ t \geq s,\ k = 1, 2, \ldots, n-1.$$

For some of the results here, we can assume also the following condition (simply (7.6) with $s = 0$) that is weaker and easier to verify than (7.6):

[2] In fact, in [19, 20], it was assumed that the λ_i's existed as limits.

$$\int_0^t (G_{k,k}(\tau) - G_{k+1,k+1}(\tau))d\tau \geq at - d, \tag{7.7}$$

$$a > 0,\ d \in \mathbb{R},\ t \geq 0,\ k = 1, \ldots, n-1.$$

LEMMA 7.1. *For all t, let $X = U\Sigma V^T$ be a C^p SVD of X, $p \geq 1$. Let $G = U^T AU$ satisfy* (7.7). *Then, for t sufficiently large, we eventually have*

$$\sigma_k(t) \ > \ \sigma_{k+1}(t), \qquad k = 1, \ldots, n-1. \tag{7.8}$$

Proof. Take $k = 1, \ldots, n-1$. From (7.1) and (7.7), we have

$$\begin{aligned}\sigma_k(t) &= \frac{\sigma_k(0)}{\sigma_{k+1}(0)}\ \sigma_{k+1}(0)e^{\int_0^t G_{kk}(\tau)d\tau} \\ &\geq \frac{\sigma_k(0)}{\sigma_{k+1}(0)}\ \sigma_{k+1}(0)e^{\int_0^t G_{k+1,k+1}(\tau)d\tau}\ e^{at}e^{-d}\,.\end{aligned}$$

That is,

$$\sigma_k(t) \geq \left[\frac{\sigma_k(0)}{\sigma_{k+1}(0)}e^{at}e^{-d}\right]\ \sigma_{k+1}(t), \qquad t \geq 0\,.$$

Now, let t_k be sufficiently large so that the term in brackets is greater than 1. Repeating the argument for all $k = 1, \ldots, n-1$ gives the result. ∎

Based upon Lemma 7.1, as long as (7.7) holds, we may as well assume that all singular values are distinct, and ordered, for all times $t \geq 0$. In particular, the differential equations (7.3) with H and K defined by (7.4) hold. Having done this, we now show the equivalence between (7.2) and (7.5).

THEOREM 7.2. *Under the assumption* (7.6), *we have* $\chi(X_i) = \limsup_{t\to\infty} \frac{1}{t}\ln(|\sigma_i(t)|)$.

Proof. Let $X = U\Sigma V^T$ be rewritten as $X = UP$, $P = \Sigma V^T$, so that

$$\dot{P} = (U^T AU - U^T\dot{U})P, \tag{7.9}$$

and since U is a Lyapunov transformation $\chi(P_i) = \chi(X_i)$. Consider also the system for Σ given in (7.3). We want to show that $\chi(\Sigma_{ii}) = \chi(P_i)$. If we rewrite the differential equations for P using the differential equations for Σ and V, then $\dot{P} = (D - \Sigma K\Sigma^{-1})P$.

Let $E = \Sigma K\Sigma^{-1}$, so for $i > j$, $E_{ij} = K_{ij}\frac{\sigma_i}{\sigma_j}$ and thus

$$E_{ij} = (G_{ij} + G_{ji})\frac{1}{\frac{\sigma_j^2}{\sigma_i^2} - 1}\,. \tag{7.10}$$

We have

$$\frac{\sigma_j^2}{\sigma_i^2} = \frac{\sigma_j^2(0)}{\sigma_i^2(0)}\exp\left(2\int_0^t (G_{jj}(\tau) - G_{ii}(\tau))\right)d\tau\,, \tag{7.11}$$

and since (7.6) holds, then $\frac{\sigma_j^2}{\sigma_i^2} \to \infty$ and thus $E_{ij} \to 0$ as $t \to \infty$ for $i > j$. Obviously, we also have $E_{ii} = 0$ for all i. Finally, for $j < i$, $E_{ji} = K_{ji}\frac{\sigma_j}{\sigma_i} = -K_{ij}\frac{\sigma_j}{\sigma_i}$. But

$$K_{ij}\frac{\sigma_j}{\sigma_i} = \frac{(G_{ij} + G_{ji})}{1 - \frac{\sigma_i^2}{\sigma_j^2}},$$

and now $1 - \frac{\sigma_i^2}{\sigma_j^2}$ does not go to ∞, and hence in general E_{ji} does not approach 0 as t approaches infinity. So, we write

$$E = \text{low}(E) + \text{upp}(E),$$

where $\text{upp}(E)$ is the strictly upper triangular part of E and $\text{low}(E)$ is the strictly lower triangular part of E, and consider the system

$$\dot{\overline{P}} = (D - \text{upp}(E))\overline{P}\,. \tag{7.12}$$

Since $\text{low}(E) \to 0$ as $t \to \infty$, and the exponents of the P system (7.9) are stable, then the Lyapunov exponents of the P system and of the $\overline{P}$ system (7.12) are the same by Theorem 3.2. In other words, $\chi(P_i) = \chi(\overline{P}_i)$ for $i = 1, \ldots, n$. Finally, with assumption (7.6) we can apply Theorem 5.1 to obtain

$$\chi(\overline{P}_i) = \chi(\overline{P}_{ii}) = \chi(\Sigma_{ii}), \qquad i = 1, \ldots, n. \tag{7.13}$$ □

Remark 7.1. From the proof of Theorem 7.2, it is apparent that for the Lyapunov exponents of the systems (7.9) and (7.12) to coincide it suffices to assume (7.7). However, the stronger condition (7.6) was needed to prove $\chi(\overline{P}_i) = \chi(\overline{P}_{ii})$.

When (7.7) holds, and a fortiori when (7.6) holds, we have the following result.

LEMMA 7.3. *Let* (7.7) *hold. Then, the orthogonal matrix function* $V(t) \to \overline{V}$*, as* $t \to \infty$*, where* $\overline{V}$ *is a constant orthogonal matrix.*

Proof. Recall that V satisfies $\dot{V}^T = -KV^T$, where K is defined in (7.4), $K_{ij} = (G_{ij} + G_{ji})\frac{\sigma_i\sigma_j}{\sigma_j^2 - \sigma_i^2}$ for $i \neq j$, and $K_{ii} = 0$ for all i. We claim that, under assumption (7.7), $K_{ij} \to 0$ exponentially fast as $t \to \infty$. For $i > j$, we have

$$\begin{aligned} K_{ij} &= (G_{ij} + G_{ji})\frac{\sigma_i(0)}{\sigma_j(0)}\frac{\exp(\int_0^t (G_{jj}(\tau) - G_{ii}(\tau))d\tau)}{\exp(2\int_0^t (G_{jj}(\tau) - G_{ii}(\tau))d\tau) - \frac{\sigma_i^2(0)}{\sigma_j^2(0)}} \\ &= (G_{ij} + G_{ji})\frac{\sigma_i(0)}{\sigma_j(0)}\left[\frac{1}{\exp(\int_0^t (G_{jj}(\tau) - G_{ii}(\tau))d\tau) + \frac{\sigma_i(0)}{\sigma_j(0)}}\right. \\ &\qquad \left. + \frac{\sigma_i(0)}{\sigma_j(0)}\frac{1}{\exp(2\int_0^t (G_{jj}(\tau) - G_{ii}(\tau))d\tau) - \frac{\sigma_i^2(0)}{\sigma_j^2(0)}}\right], \end{aligned} \tag{7.14}$$

and so by (7.7) we have that for $i > j$, $K_{ij} \to 0$ exponentially fast, as $t \to \infty$. By skew-symmetry, the same holds true also for $i < j$. The result now follows from [10, Thm. 2, p. 90].[3] □

Remark 7.2. Lemma 7.3 may be used indirectly to determine if (7.7) holds, a fact which was apparently used in [19].

The condition (7.6) is very similar to the condition (3.3) on the diagonal of the upper triangular coefficient matrix B obtained when finding the QR factorization of a

[3]Theorem 2 of [10] is concerned with the system $\dot{X} = (A + B(t))X$ when A is constant with simple eigenvalues λ_i and associated eigenvectors ξ_i, $i = 1, \ldots, n$, and B is continuous such that $\int_{t_0}^{\infty} \|B(t)\|dt < \infty$. In such a case, the cited theorem states that X converges to $\text{diag}(e^{\lambda_1 t}, \ldots, e^{\lambda_n t})[\xi_1, \ldots, \xi_n]C$, where C is a constant invertible matrix. However, the result and the proof in [10] hold true by just requiring that A is diagonalizable (not necessarily with distinct eigenvalues). We have used this fact with $A = 0$.

fundamental matrix solution. In fact, these two conditions lead to similar outcomes. The following is the QR analogue of Lemma 7.3.

LEMMA 7.4. *Consider the upper triangular system $\dot{R} = BR$, where B is bounded and continuous, and assume that the diagonal of B is integrally separated, as in* (3.5). *Then, $R \to \mathrm{diag}(R)\overline{Z}$ as $t \to \infty$, where $\overline{Z}$ is a constant upper triangular matrix with* 1*'s on the diagonal.*

Proof. Write $R = DZ$, where $Z = D^{-1}R$, and $D = \mathrm{diag}(R)$. Then D satisfies $\dot{D} = \mathrm{diag}(B)D$ and Z satisfies $\dot{Z} = EZ$, where $E = D^{-1}(B - \mathrm{diag}(B))D$. Then, $E_{ij} = B_{ij} \cdot \frac{R_{jj}}{R_{ii}}$ for $i < j$ and $E_{ij} = 0$ for $i \geq j$. Now,

$$\frac{R_{jj}}{R_{ii}} = \frac{R_{jj}}{R_{ii}}(0)\ e^{\int_0^t (B_{jj} - B_{ii})d\tau}\,.$$

Let $j = i + k$ for some $k = 1, \ldots$. The diagonal of B is integrally separated (see (3.5)), and so

$$\int_0^t (B_{jj} - B_{ii})d\tau \ \leq\ -k(at - d)\,,$$

from which $E_{ij} \to 0$ exponentially fast as $t \to \infty$, and the result follows. ∎

Remark 7.3. We notice that the assumption of integral separation (7.7) (or (7.6)) does not preclude singular values from coinciding at some (early) time t, in which case the computation of the factors U, V, Σ remains by and large unexplored territory. Indeed, if one chooses to use the SVD technique for approximating the Lyapunov exponents, even if (7.7) (or (7.6)) is satisfied, it is probably advisable to integrate for X for awhile prior to writing down and integrating the differential equations for the factors U, Σ, and V.

8. Numerical techniques. We only outline the continuous QR technique (see [8, 12, 13, 14, 21]), which is the one we used for the experiments in the next section.

Consider the linear homogeneous problem

$$\dot{x}(t) = A(t)x(t). \tag{8.1}$$

The key task is to find Q which transforms the upper left $p \times p$ ($p \leq n$) corner of A, $B = Q^T AQ - Q^T\dot{Q}$, to upper triangular form. From B, one can then approximate p Lyapunov exponents using (2.9) if the system is regular or the spectral intervals in the case where the system is not regular.

To find Q, one writes p columns of a fundamental matrix solution of (8.1) as $X = QR$, where Q is an $n \times p$ orthonormal function (i.e., for all $t \geq 0$: $Q^T(t)Q(t) = I_p$), and R is a $p \times p$ upper triangular function with positive entries on the diagonal. Upon differentiating $X = QR$, we have

$$AQR = \dot{X} = \dot{Q}R + Q\dot{R} \quad \text{or} \quad AQ = \dot{Q} + Q\dot{R}R^{-1}. \tag{8.2}$$

Let B denote the upper triangular function $\dot{R}R^{-1}$ and set $S(Q) = Q^T\dot{Q}$, which is skew symmetric. Then

$$Q^T AQ = S(Q) + B\,, \tag{8.3}$$

and since $S(Q)$ is skew symmetric and B is upper triangular, we have

$$S(Q)_{ij} = \begin{cases} (Q^T AQ)_{ij}, & i > j, \\ 0, & i = j, \\ -(Q^T AQ)_{ji}, & i < j. \end{cases} \tag{8.4}$$

Then, from (8.2), the equation for Q is

$$\dot{Q} = AQ - QB = AQ - Q(Q^T AQ - S(Q)) = (I - QQ^T)AQ + QS(Q). \tag{8.5}$$

Initial conditions for Q are obtained from a QR factorization of the initial conditions for X (and the most typical choice is to take $X(0) = \binom{I_p}{0}$).

To repeat this reasoning relative to a trajectory of a nonlinear problem, one must integrate

$$\dot{x} \;=\; f(x), \qquad x(0) = x_0\,, \tag{8.6}$$

and then use $A(t) = Df(x(t))$ in (8.2).

Once we have the triangular function B, we can compute the p Lyapunov exponents from (2.9) if the system is regular. Alternatively, one may (in principle) compute λ^s_{jj} (and λ^i_{jj}) in Σ_{CL}, $j = 1, \ldots, p$, from

$$\limsup_{t\to\infty} \frac{1}{t}\int_0^t B_{jj}(s)ds \quad \text{and} \quad \liminf_{t\to\infty} \frac{1}{t}\int_0^t B_{jj}(s)ds\ ,\ \ j = 1, \ldots, p\ . \tag{8.7}$$

Regardless of whether the B-system is regular, we found it convenient to work with the variables $\nu_j(t) = \int_0^t B_{jj}(s)ds$ so that we end up with the differential equations

$$\dot{\nu}_j = B_{jj}, \quad \nu_j(0) = 0, \quad j = 1, \ldots, p, \tag{8.8}$$

from which the exponents may be approximated as limits (or lim sups and lim infs) of

$$\frac{1}{t}\nu_j(t), \qquad j = 1, \ldots, p\,.$$

At this point, the skeleton of the method is clear: for nonlinear problems, integrate (8.6), (8.5), and (8.8); for linear problems, integrate just (8.5) and (8.8).

8.1. Numerical implementation. When approximating (8.5) numerically it is important to maintain Q orthonormal. Several choices are possible to achieve this; e.g., in [13, 3] techniques are discussed to directly integrate (8.5), whereas in [8, 21] a continuous Gram–Schmidt procedure is proposed. We have used the technique described in [14, 15]. The idea of this technique is to locally decompose Q in a way analogous to the numerical linear algebra context using elementary Givens rotations or Householder reflectors. Integration for these elementary factors can be done adaptively, and we refer to [15] for details.

So, in the end, the differential equations (8.6), (8.5), and (8.8) are all integrated with adaptive time stepping, controlled by the tolerance values `TOLX, TOLQ, TOLL`, respectively. The basic integrator in all cases is our implementation of the Dormand–Prince 4/5 embedded Runge–Kutta pair modeled after the pattern adopted in [15], to which we again refer for details.

8.2. Testing integral separation. It is clearly desirable to infer whether the system has integral separation. This is needed to gain some confidence in the answers one obtains (since it implies stable exponents), and also (see below) to obtain a computational procedure to approximate Σ_{ED}. We have used the following construction which is motivated by Steklov function considerations. Recall that, given a continuous

bounded function f, the Steklov function or Steklov average of f with step $H > 0$ is defined as (see [1, Def. 5.4.1] and [5])

$$f^H(t) = \frac{1}{H}\int_t^{t+H} f(\tau)d\tau. \tag{8.9}$$

Now, consider two bounded functions f_1 and f_2 (presently, think of them as diagonal elements of the upper triangular coefficient matrix B), and suppose we want to know if they are integrally separated:

$$\int_s^t (f_1(\tau) - f_2(\tau))d\tau \geq a(t-s) - d, \qquad a > 0,\, d \in \mathbb{R},\, t \geq s. \tag{8.10}$$

The importance of Steklov functions resides in the fact that (8.10) can be inferred from the Steklov average of the difference $f_1 - f_2$. This is the content of Lemma 5.4.1 in [1].

LEMMA 8.1. *Let f_1 and f_2 be two bounded functions. Then, f_1 and f_2 are integrally separated, i.e.,* (8.10) *holds if and only if for sufficiently large H their Steklov functions are separated, i.e.,*

$$f_1^H(t) - f_2^H(t) = \frac{1}{H}\int_t^{t+H} (f_1(\tau) - f_2(\tau))d\tau \geq a > 0, \qquad t \geq 0\,. \tag{8.11}$$

In practice, to check (8.11) will require a careful choice of H. We refer to Examples 9.1 and 9.2 for practical considerations.

8.3. Numerical computation of spectral intervals. In the case in which the system is not regular, it would be clearly desirable to approximate Σ_{CL} and/or Σ_{L}. Furthermore, it is clearly of interest to be able to approximate Σ_{ED} in the case in which the system does not have *point spectrum* (i.e., the Sacker–Sell intervals reduce to single points, the Lyapunov exponents of the system). As far as we know, the computational task of approximating spectral intervals has not been previously undertaken. This is most likely because in many problems the Lyapunov exponents appear to exist as limits (see Remark 3.1) and also because the numerical approximation of spectral intervals is an even more delicate task than approximation of Lyapunov exponents of regular systems. Naturally, this is due to the asymptotic nature of the quantities being computed. Further, for Σ_{CL}, there is the added difficulty that lim sups and lim infs must be approximated, which is more complicated than approximating limits. And, for Σ_{ED}, it is the uniformity (i.e., for all $t \geq s$) in the definition of exponential dichotomy which causes additional difficulties. These difficulties notwithstanding, below we present the strategies we have adopted to approximate spectral intervals. In what follows, we will restrict our attention to triangular systems: $\dot{R} = B(t)R$, where B is an upper triangular continuous and bounded function. As previously remarked, this restriction is no loss of generality. In order to further validate the results of the procedures to approximate the spectral intervals, we need to restrict our attention to triangular functions B whose diagonal is integrally separated.

8.3.1. Approximating Σ_{CL}. To approximate the lim inf and lim sup in the definition of Σ_{CL}, we reason as follows. Let $b(t)$ be a given diagonal element of the upper triangular transformed coefficient matrix B. Let $\lambda(t) = \frac{1}{t}\int_0^t b(s)ds$. Recall that

$$\lambda^+ = \lim_{\tau\to\infty} \sup_{t\geq\tau} \lambda(t) \quad \text{and} \quad \lambda^- = \lim_{\tau\to\infty} \inf_{t\geq\tau} \lambda(t)\,.$$

So, if we let

$$g(\tau) = \sup_{t\geq\tau} \frac{1}{t}\int_0^t b(s)ds \quad \text{and} \quad h(\tau) = \inf_{t\geq\tau} \frac{1}{t}\int_0^t b(s)ds\ ,$$

then for every $\epsilon > 0$ there exists $\tau(\epsilon)$ such that $\tau \geq \tau(\epsilon)$ implies $|g(\tau) - \lambda^+| < \epsilon$ and $|h(\tau) - \lambda^-| < \epsilon$. In our experiments, we mimic this definition on a finite interval. For given $T > 0$, we specify a value τ_0, $T > \tau_0 > 0$, and compute

$$g_f(T,\tau_0) = \sup_{T\geq t\geq\tau_0} \frac{1}{t}\int_0^t b(s)ds \quad \text{and} \quad h_f(T,\tau_0) = \inf_{T\geq t\geq\tau_0} \frac{1}{t}\int_0^t b(s)ds\,, \tag{8.12}$$

which will provide approximations to λ^+ and λ^-.

8.3.2. Approximating Σ_{ED}. Our approach to approximation of Σ_{ED} is motivated by the relationship between exponential dichotomy and integral separation as was seen in Example 6.2. We develop a procedure for approximating Σ_{ED} for diagonal systems, or for any system that is reducible to a diagonal system through a Lyapunov transformation. For example (see the proof of Theorem 5.1), our procedure applies to triangular systems whose diagonal is integrally separated.

So, consider $\dot{x} = D(t)x$, where $D = \mathrm{diag}(B_{jj}, j = 1,\dots,n)$ and where we may think of the B_{jj}'s as the diagonal entries of the upper triangular function B. For each $j = 1,\dots,n$, we consider the diagonal planar systems (cf. (6.13) and (6.16))

$$\dot{y}_j = \begin{pmatrix} \lambda & 0 \\ 0 & B_{jj}(t) \end{pmatrix} y_j \quad \text{and} \quad \dot{y}_j = \begin{pmatrix} B_{jj}(t) & 0 \\ 0 & \lambda \end{pmatrix} y_j. \tag{8.13}$$

Following the argument relating exponential dichotomy and integral separation in Example 6.2 (see (6.14) and (6.17)), we obtain the following result.

LEMMA 8.2. *Consider the diagonal system $\dot{x} = D(t)x$, $D = \mathrm{diag}(B_{jj}, j = 1,\dots,n)$. Then, for each $j = 1,\dots,n$, the Sacker–Sell spectrum corresponding to the jth diagonal element is given by the interval*

$$\Lambda_j = \{\lambda \in \mathbb{R} : (8.13) \textit{ are not integrally separated}\}\,. \tag{8.14}$$

As a consequence of Lemma 8.2, we have (cf. [16]) the following theorem.

THEOREM 8.3. *The Sacker–Sell spectrum of the diagonal system $\dot{x} = D(t)x$, $D = \mathrm{diag}(B_{jj}, j = 1,\dots,n)$, is given by*

$$\Sigma_{\mathrm{ED}} = \bigcup_{j=1}^{n} \Lambda_j\,, \tag{8.15}$$

where Λ_j is defined in (8.14)*, $j = 1,\dots,n$.*

To obtain a computational procedure for Σ_{ED} out of Theorem 8.3, we rely on Steklov functions. Indeed (recall Lemma 8.1), the systems in (8.13) are integrally separated if and only if for $H > 0$ sufficiently large the Steklov differences of λ and B_{jj}, respectively, B_{jj} and λ, are positive for all t.

Now, given any $H > 0$, for $j = 1,\dots,n$, consider

$$\alpha_j^H = \inf_t \frac{1}{H}\int_t^{t+H} B_{jj}(s)ds \quad \text{and} \quad \beta_j^H = \sup_t \frac{1}{H}\int_t^{t+H} B_{jj}(s)ds. \tag{8.16}$$

We will use $[\alpha_j^H, \beta_j^H]$ to approximate the jth spectral interval of Σ_{ED}, $j = 1, \ldots, n$. The following result justifies our approach on an infinite time interval.

THEOREM 8.4. *Consider $\dot{x} = D(t)x$, where $D = \text{diag}(B_{jj}, j = 1, \ldots, n)$. For $j = 1, \ldots, n$, let α_j^H and β_j^H be given as in* (8.16). *Let $H > 0$ be given. Then, for each $j = 1, \ldots, n$, $\Lambda_j \subseteq [\alpha_j^H, \beta_j^H]$. Moreover, for $H > 0$ sufficiently large, $[\alpha_j^H, \beta_j^H] \subseteq \Lambda_j$ and hence $[\alpha_j^H, \beta_j^H] = \Lambda_j$, $j = 1, \ldots, n$.*

Proof. First, assume that $H > 0$ is arbitrary and that $\lambda > \beta_j^H$ for some $j = 1, \ldots, n$. Then, there exists $a_j > 0$ such that

$$\int_t^{t+H} (\lambda - B_{jj}(\tau))d\tau \geq a_j H \quad \forall t\,. \tag{8.17}$$

We want to show that λ and B_{jj} are integrally separated functions. That is, we need to show that for all t, s, $t \geq s$, there exists $a > 0$ and $d \in \mathbb{R}$ such that

$$\int_s^t (\lambda - B_{jj}(\tau))d\tau \geq a(t-s) - d. \tag{8.18}$$

We will verify (8.18) with $a = a_j$ and $d = d_j := 2H(|\lambda| + \max_t |B_{jj}(t)|)$. Because of (8.17), (8.18) holds for all t and s with $t = s + H$. Consider the case of t, s, with $t < s + H$. Then, rewrite

$$\int_s^t (\lambda - B_{jj}(\tau))d\tau = \int_s^{s+H} (\lambda - B_{jj}(\tau))d\tau - \int_t^{s+H} (\lambda - B_{jj}(\tau))d\tau\,,$$

and thus $\int_t^{s+H}(\lambda - B_{jj}(\tau))d\tau \leq (|\lambda| + \max_t |B_{jj}(t)|)(s + H - t) \leq d_j$, so that

$$\int_s^t (\lambda - B_{jj}(\tau))d\tau \geq a_j H - d_j \geq a_j(t-s) - d_j\,.$$

Next, let t, s, with $t > s + H$. Then, for some integer $k > 1$, we have $t = s + kH + \sigma$, $\sigma \in [0, H)$. Therefore,

$$\int_s^t (\lambda - B_{jj}(\tau))d\tau = \sum_{j=0}^{k} \int_{s+jH}^{s+(j+1)H} (\lambda - B_{jj}(\tau))d\tau - \int_{s+kH+\sigma}^{s+(k+1)H} (\lambda - B_{jj}(\tau))d\tau\,,$$

and thus (using (8.17) and the previous argument used when $t < s + H$) we get

$$\int_s^t (\lambda - B_{jj}(\tau))d\tau \geq a_j(k+1)H - d_j \geq a_j(t-s) - d_j\,,$$

and (8.18) follows. Therefore, λ and $B_{jj}(t)$ are integrally separated, and so $\lambda \notin \Lambda_j$. A similar proof for $\lambda < \alpha_j^H$ establishes that $\Lambda_j \subseteq [\alpha_j^H, \beta_j^H]$ for any given $H > 0$.

Assume now that $\lambda \notin \Lambda_j$. Then λ and $B_{jj}(t)$ and/or $B_{jj}(t)$ and λ are integrally separated. Suppose that λ and $B_{jj}(t)$ are integrally separated; the argument for $B_{jj}(t)$ and λ integrally separated is similar. Then there exists $a > 0$ and $d \in \mathbb{R}$ such that for all t, s, with $t \geq s$, we have

$$\int_s^t (\lambda - B_{jj}(\tau))d\tau \geq a(t-s) - d. \tag{8.19}$$

Choose $H > 0$ large enough so that $a - d/H > a/2$. Thus, for all t,

$$\frac{1}{H}\int_t^{t+H} (\lambda - B_{jj}(s))ds \geq a - d/H > a/2, \tag{8.20}$$

and so $\lambda > \beta_j^H$. A similar proof for $B_{jj}(t)$ and λ integrally separated implies that $\lambda < \alpha_j^H$, and thus $\lambda \notin [\alpha_j^H, \beta_j^H]$. Therefore, for $H > 0$ sufficiently large, $[\alpha_j^H, \beta_j^H] = \Lambda_j$. □

On a finite time interval, our computational procedure to approximate Σ_{ED} mimics Theorem 8.4. Given $H > 0$, and $T > t_0 > 0$, we let $b(t)$ be a diagonal element $B_{jj}(t)$, for some $j = 1, \ldots, n$, of the triangular coefficient matrix B, defined on the time interval $[0, T]$. We compute the Steklov averages of b with respect to the given H: $b_H(t) := \frac{1}{H}\int_t^{t+H} b(\tau)d\tau$, for $T - H \geq t \geq t_0$. Next, we compute

$$\overline{b}_H = \sup_{T-H\geq t\geq t_0} b_H(t) \quad \text{and} \quad \underline{b}_H = \inf_{T-H\geq t\geq t_0} b_H(t) \tag{8.21}$$

and use these as approximations to $[\alpha_j^H, \beta_j^H]$ in (8.16).

9. Examples and numerical results. We first consider a linear example for which the Lyapunov exponents do not exist as limits; in this case, we approximate the spectral intervals. Then, we approximate the Lyapunov exponents for two nonlinear systems, i.e., the exponents associated with linearization about computed trajectories; in both cases considered, the Lyapunov exponents appear to exist as limits. Thus, we attempt verifying integral separation of the diagonal of the transformed triangular problem in order to infer stability of the Lyapunov exponents: in one case we are successful, in another we are not.

In all examples below, integration for Q is carried out with `QRINT` (see [15]) using Jacobi rotations (the so-called θ-method in `QRINT`).

Example 9.1. Consider a planar linear problem $\dot{x} = A(t)x$ with continuous spectrum, where $A(t)$ is defined by

$$\begin{aligned}
A_{11}(t) &= (2\sin(\tau(t)) + \alpha)\cos^2(\theta(t)) + \cos(\tau(t)) - \sin(\tau(t)) - \alpha - \beta\cos(\theta(t))\sin(\theta(t)),\\
A_{12}(t) &= (2\sin(\tau(t)) + \alpha)\cos(\theta(t))\sin(\theta(t)) - \dot{\theta}(t) + \beta\cos^2(\theta(t)),\\
A_{21}(t) &= (2\sin(\tau(t)) + \alpha)\cos(\theta(t))\sin(\theta(t)) + \dot{\theta}(t) - \beta\sin^2(\theta(t)),\\
A_{22}(t) &= -(2\sin(\tau(t)) + \alpha)\cos^2(\theta(t)) + \cos(\tau(t)) + \sin(\tau(t)) + \beta\cos(\theta(t))\sin(\theta(t)),
\end{aligned}$$

and $\tau(t) = \ln(t + 1)$. This problem is designed so that the orthogonal change of variables Q and the upper triangular coefficient matrix function B are

$$Q(t) = \begin{pmatrix} \cos(\theta(t)) & -\sin(\theta(t)) \\ \sin(\theta(t)) & \cos(\theta(t)) \end{pmatrix} \quad \text{and} \quad B(t) = \begin{pmatrix} B_{11}(t) & \beta \\ 0 & B_{22}(t) \end{pmatrix},$$

where $B_{11}(t) = \cos(\tau(t)) + \sin(\tau(t))$ and $B_{22}(t) = \cos(\tau(t)) - \sin(\tau(t)) - \alpha$. It is not hard to explicitly obtain the spectral intervals (recall the result for Example 6.2): we have $\Sigma_{\mathrm{L}} = [-1, 1] \cup [-\alpha - 1, -\alpha + 1]$ and $\Sigma_{\mathrm{ED}} = [-\sqrt{2}, \sqrt{2}] \cup [-\alpha - \sqrt{2}, -\alpha + \sqrt{2}]$. For our experiments we choose $\beta = 1$, $\theta(t) = \omega t$, and $\alpha = 4$. Integration for Q was done with local error tolerance 10^{-5}.

In Table 9.1, we report on results of experiments to approximate Σ_{L}. We approximate all integrals in (8.12) with the composite trapezoidal rule on data sampled at

integer times. In the table we specify the values T, τ_0, and report on the approximations (at 5 digits) for the two spectral intervals making up Σ_{L}. In spite of the crudeness of the quadrature rule, quite clearly Σ_{L} is approximated very well.

In Table 9.2 we report on calculations to approximate Σ_{ED}. In the table, we vary quantities in the procedure outlined in section 8.3; see (8.21). In particular, we vary the final time, T, and the length of the Steklov averages, H. The initial time for which the Steklov averages are maximized/minimized is fixed at $t_0 = 0$, and the approximations we obtain to $[\alpha_j^H, \beta_j^H]$ for $j = 1, 2$ are recorded to 5 digits. Our calculations are based upon data from the diagonal of B that we have sampled using a large step size of $h = 10$. The Steklov averages are approximated with the composite trapezoidal rule. The results point out the difficulty in finding an appropriate value for H: simultaneously, one would need H large enough so that the endpoints of the intervals in Σ_{ED} are approximated accurately, yet not so large with respect to the final time T that little data are sampled.

Example 9.2 (Lorenz equation). Our next example is the Lorenz equation

$$\begin{pmatrix} \dot{x} \\ \dot{y} \\ \dot{z} \end{pmatrix} = \begin{pmatrix} \sigma(y - x) \\ \rho x - xz - y \\ xy - \beta z \end{pmatrix}.$$

We consider the parameter values $\sigma = 16$, $\beta = 4.0$, and $\rho = 45.92$ and the initial condition $(x(0), y(0), z(0)) = (0, 1, 0)$. In Table 9.3, we summarize some results which are typical. Error control is done on the trajectory x, on Q, and on ν (see (8.8)). Apparently, the Lyapunov exponents exist as limits: the linearized problem appears to be regular.

Based upon the results in Table 9.3, we observe that (1) there is an obvious relation between the number of steps taken and the length of integration (recall that we are integrating with variable step size). This suggests that we are tracing "alike trajectories" on the Lorenz attractor; (2) with all the imperfections of finite precision arithmetic, the Lyapunov exponents are clearly converging towards $\lambda_1 \approx 1.5$, $\lambda_2 = 0$, and $\lambda_3 \approx -22.5$.

In order to infer stability of the exponents, we have verified if the linearized system enjoys integral separation. As far as we know, this is the first attempt of this type, on the Lorenz system or otherwise. We use the construction outlined in section 8.2 on the transformed, triangular problem. So, we have to check if the three functions

TABLE 9.3
Example 2. `TOLX=TOLQ=TOLL`$=1.E\text{-}6$.

t_{end}	`Steps`	λ_1	λ_2	λ_3
1.E2	8.6E3	1.415	3.E-2	-22.466
1.E3	8.6E4	1.4892	4.64E-3	-22.494
1.E4	8.6E5	1.499	4.64E-4	-22.499
1.E5	8.6E6	1.5027	4.07.E-5	-22.5027
1.E6	8.6E7	1.5024	7.6E-6	-22.5024

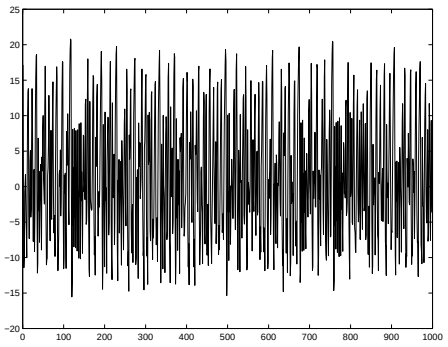

FIG. 9.1. $b_{11} - b_{22}$.

b_{11}, b_{22}, b_{33} are integrally separated. As it turns out, the first two functions are the hard ones (the third is more clearly integrally separated): Figure 9.1 shows $(b_{11} - b_{22})$ on $[0, 100]$, and clearly b_{11} and b_{22} are not separated. So, we check if (8.11) holds for H sufficiently large. In practice, to form b_{11}^H and b_{22}^H, we approximate the integral by the composite trapezoidal rule. We look for H in the range $[1, 20]$ and, for $t \in [0, 10000]$, the value $H = 20$ gave sufficient separation; see Figure 9.2. We conclude that, on the given interval, and subject to the limitations of finite precision computation, the diagonal of the transformed triangular system is integrally separated, and thus so is the linearized system, and the Lyapunov exponents are stable.

The next example highlights the difficulties in inferring integral separation of the diagonal of B for problems with close exponents, even when the Lyapunov exponents appear to exist as limits and to be stable.

Example 9.3. This example is adapted from one in [18] (used also in [13] and then [3]). We have a ring of oscillators with an external force proportional to the position component of the limit cycle of the van der Pol oscillator:

$$\begin{aligned} \ddot{y} + \alpha(y^2 - 1)\dot{y} + \omega^2 y &= 0, \\ \ddot{x}_i + d_i\dot{x}_i + \gamma[\Phi'(x_i - x_{i-1}) - \Phi'(x_{i+1} - x_i)] &= \sigma y \delta_{i1}\,, \qquad i = 1, \ldots, n\,. \end{aligned} \tag{9.1}$$

Above, $\Phi(x) = (x^2/2) + (x^4/4)$ is the single well Duffing potential, $\alpha, \omega, \gamma, \sigma$ are scalar parameters, x_i is the displacement of the ith particle, d_i is the damping coefficient, and we have periodic boundary conditions to be used in the expressions for Φ' ($x_0 = x_n$ and $x_{n+1} = x_1$). For our experiments, we set $n = 5$ and set $\alpha = 1$, $\omega = 1.82$, $\gamma = 1$, and $\sigma = 4$. We set $d_i = 0.25$ for i odd and $d_i = 0.15$ for i even. Initial conditions are taken as $y(0) = 0,\ \dot{y}(0) = -2,\ x_i(0) = \dot{x}_i(0) = 1,\ i = 1, \ldots, n$. Error control is performed on x, Q, and ν.

From the results summarized in Table 9.4, we observe good convergence for the four exponents on which we report. However, inferring integral separation, although

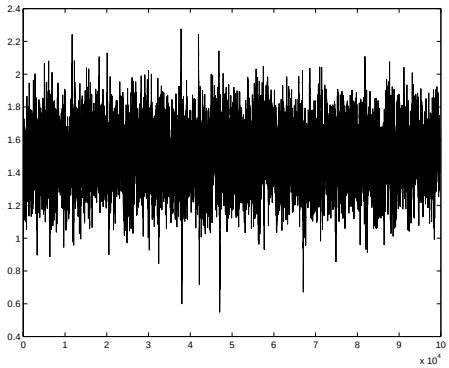

FIG. 9.2. $b^H_{11} - b^H_{22}$.

TABLE 9.4
Example 3. `TOLX=TOLQ=TOLL=TOL`.

t_{end}	`TOL`	`Steps`	λ_1	λ_2	λ_3	λ_4
1000	1.E-4	15214	1.8E-3	8.3E-4	-9.72E-2	-9.99E-2
5000	1.E-4	78599	4.9E-4	1.5E-4	-9.80E-2	-9.86E-2
10000	1.E-4	157372	2.1E-4	4.5E-5	-9.82E-2	-9.83E-2
1000	1.E-6	34911	1.7E-3	8.7E-4	-9.74E-2	-9.99E-2
5000	1.E-6	115135	4.2E-4	1.7E-4	-9.81E-2	-9.86E-2
10000	1.E-6	364206	1.4E-4	8.4E-5	-9.82E-2	-9.84E-2
1000	1.E-8	84584	1.7E-3	8.7E-4	-9.74E-2	-9.99E-2
5000	1.E-8	222556	4.2E-4	1.7E-4	-9.81E-2	-9.86E-2
10000	1.E-8	883292	1.4E-4	8.4E-5	-9.82E-2	-9.84E-2

perhaps possible, is quite difficult because of the clustering of the exponents. To illustrate, with $t_{\text{end}} = 1000$ and `TOL` $= 1.E-6$, at 2 digits the 12 approximate exponents are

$$\begin{array}{l} 1.7\text{E}-3,\ 8.7\text{E}-4,\ -9.7\text{E}-2,\ -1.0\text{E}-1,\ -1.0\text{E}-1,\ -1.0\text{E}-1, \\ -1.1\text{E}-1,\ -1.1\text{E}-1,\ -1.1\text{E}-1,\ -1.2\text{E}-1,\ -2.1\text{E}-1,\ -1.0\text{E}0. \end{array} \tag{9.2}$$

We attempted to verify if the linearized problem was integrally separated, but failed. To be precise, on the interval $[0, 1000]$, the value of $H = 100$ was sufficient to establish positivity of the Steklov differences $b^H_{22} - b^H_{33}$, $b^H_{10,10} - b^H_{11,11}$, and $b^H_{11,11} - b^H_{12,12}$, and hence integral separation of the respective diagonal entries of B, but all other Steklov differences were oscillating about 0 (even for larger values of H), therefore precluding us from inferring integral separation of the linearized problem. This highlights that, for a problem with close (or identical) exponents, it will be necessary to develop block analogues of QR techniques and associated criteria to infer integral separation (in a block sense).

10. Conclusions. In this paper we have blended theoretical studies on stability of Lyapunov exponents with computational techniques which target the Lyapunov exponents. Stability of the exponents is equivalent (in the case of distinct exponents) to having an integrally separated fundamental matrix solution. We have assumed that the system was integrally separated and further explored what conditions are needed to validate popular numerical methods, in particular those based on the QR and SVD of fundamental matrix solutions. We also explored the implications of integral

separation on approximation of three different spectra of linear systems: first, Σ_{ED}, of Sacker and Sell based upon exponential dichotomy; second, Σ_{L}, that naturally generalizes Lyapunov's upper and lower exponents to a spectrum; and third, Σ_{CL}, based on the diagonal elements of the upper triangular coefficient matrix B that is obtained through an orthogonal change of variables. In general, the Sacker–Sell spectrum is larger than the other two spectra, while under the assumption of integral separation of the diagonal of B we have that $\Sigma_{\mathrm{L}} = \Sigma_{\mathrm{CL}}$. We also showed how to approximate Σ_{ED} when the diagonal of B is integrally separated.

Future work will need to address several issues which we did not resolve in the present paper. In no particular order, we believe the following will be worthwhile investments:

1. Careful implementation and analysis of continuous SVD techniques.
2. Block analogues of QR and SVD techniques for the case of nondistinct exponents.
3. Refined implementation and study of techniques to approximate Σ_{ED} along the lines of the approach we laid down in section 8.3 and used in Example 9.1.
4. More thorough study of techniques to approximate Steklov averages, and further exploitation of the power of this tool.

MULTISCALE ASYMPTOTIC ANALYSIS AND NUMERICAL SIMULATION FOR THE SECOND ORDER HELMHOLTZ EQUATIONS WITH RAPIDLY OSCILLATING COEFFICIENTS OVER GENERAL CONVEX DOMAINS*

LI-QUN CAO†, JUN-ZHI CUI†, AND DE-CHAO ZHU‡

Abstract. The multiscale asymptotic analysis and numerical simulation for the second order Helmholtz equations with rapidly oscillating coefficients over general convex domains are discussed in this paper. A multiscale asymptotic analysis formulation for this problem is presented by constructing properly the boundary layer. A multiscale numerical algorithm and a postprocessing technique are given. Finally, numerical results show that the method presented in this paper is effective and reliable.

Key words. multiscale asymptotic analysis, second order Helmholtz equation, rapidly oscillating coefficients, finite element method, postprocessing technique

1. Introduction.

In this paper, we analyze the spectral properties of a second order elliptic operator corresponding to a composite medium with a periodic microstructure. More precisely, we consider the following Helmholtz problem:

$$\begin{cases} \mathcal{L}_\varepsilon u^\varepsilon(x) \equiv -\dfrac{\partial}{\partial x_i}\left(a_{ij}\left(\dfrac{x}{\varepsilon}\right)\dfrac{\partial u^\varepsilon(x)}{\partial x_j}\right) + b\left(\dfrac{x}{\varepsilon}\right)u^\varepsilon(x) = \lambda^\varepsilon \rho\left(\dfrac{x}{\varepsilon}\right)u^\varepsilon(x) \quad \text{in} \quad \Omega, \\ \mathcal{B}_\varepsilon(u^\varepsilon) = 0 \quad \text{on} \quad \partial\Omega, \end{cases} \tag{1.1}$$

where Ω is an arbitrary bounded convex Lipschitz domain, B_ε is a boundary operator, i.e., it is either Dirichlet's or Neumann's one.

Let us make assumptions as follows:

(A_1) Let $\xi = \varepsilon^{-1}x$, $a_{ij}(\xi)$, $b(\xi)$, and $\rho(\xi)$ are 1-periodic in ξ;

(A_2)

$$\gamma_0 \sum_{i=1}^{n} \eta_i^2 \le \sum_{i,j=1}^{n} a_{ij}\left(\frac{x}{\varepsilon}\right)\eta_i\eta_j \le \gamma_1 \sum_{i=1}^{n} \eta_i^2 \tag{1.2}$$

$\exists \gamma_0 > 0$, $\gamma_1 > 0$, $\forall (\eta_1, \dots \eta_n) \in R^n$;

(A_3) $a_{ij}(\frac{x}{\varepsilon}) = a_{ji}(\frac{x}{\varepsilon})$, $\rho(\frac{x}{\varepsilon}) \ge \rho_0 = \text{const} > 0$, $b(\frac{x}{\varepsilon}) \ge 0$;

(A_4) $a_{ij}(\frac{x}{\varepsilon})$, $\rho(\frac{x}{\varepsilon})$, $b(\frac{x}{\varepsilon}) \in L^\infty(\Omega)$.

It is well known that spectral theories have extensive applications in physics, chemistry, mechanics, and vibration engineering. For example, we analyze the stability of a structure through calculating the natural frequencies and natural vibration

modes. Also, in quantum physics, we investigate the electronic and magnetic properties of materials by computing eigenvalues and eigenfunctions of state Schrödinger equations associated with atomic structures. With the continuous emergence of some new materials such as composite materials, semiconductor superlattice, nanomaterials, and so forth, it is very necessary and pressing that the spectral properties of strongly heterogeneous materials are studied.

In mathematics, the above physical and mechanical problems can be represented as the Helmholtz equation of second order elliptic operator with rapidly oscillating coefficients in many cases. One of the main difficulties for analyzing these kinds of problems is that the computing amounts are too large to solve them numerically. For this purpose, a homogenization method was previously provided and analyzed; see [11, 13, 14, 16, 18]. The principal idea is to obtain the average field equation associated with the original problem by constructing a local smoothing operator and to discuss its convergence the on the basis of the compensated compactness theorem presented by L. Tartar (cf. [11]). Clearly, using classical numerical methods, we can numerically solve the homogenized Helmholtz equation in coarse meshes. Both theoretical analysis and numerical experiments show that the homogenization method is suitable for computing some macroscopic physical variables such as effective medium, natural frequencies, and so on. However, it is unable to accurately describe the local fluctuation of some physical variables such as natural vibration modes, stresses and strains, and temperature field, and so forth.

The crucial point of analyzing precisely the above problem is to find out the multiscale asymptotic expansion for the solution of considered problem (cf. [3, 4, 6]). Jikov, Zozlov, and Oleinik [11] and Oleinik, Shamaev, and Yosifian [18], investigated the Sturm–Liouville equation with oscillating coefficients in one dimension and obtained the complete asymptotic expansion of eigenvalues and eigenfunctions on the basis of analytic formulas of eigenvalues and eigenfunctions associated with the one-dimensional (1-D) Helmholtz problem with constant coefficients. Clearly, this method is not suitable for discussing the Helmholtz problems in higher-dimensional cases ($n \geq 2$). In [20], F. Santosa and M. Vogelius studied the first order corrections for a kind of eigenvalue problem associated with the vibration of periodic composite and analyzed the set of associated weak limit points in the case when Ω is a convex polygon, the sides of which all have a normal integer entries (the slopes are all rational or infinite).

S. Moskow and M. Vogelius (see [17]) gave a presentation formula for the set of first order corrections to a simple eigenvalue when the eigenvector is only in $H^{2+\omega}(\Omega)$ for some $\omega > 0$. In particular, this regularity assumption is sufficiently weak that it makes the representation formula valid when Ω is a convex, classical polygon. This is an important and excellent result.

T.Y. Hou, X.H. Wu, and Z. Cai [7] and T.Y. Hou and X.H. Wu [8] provided an interesting multiscale finite element method (FEM) based on the first order asymptotic expansion—the crucial idea is to find new finite element space; i.e., the set of basis functions consists of two parts, the first part being the set of piecewise polynomials and the second part the set of some oscillatory functions obtained by simultaneously solving locally partial differential equations in some subdomains.

Does there exist the multiscale asymptotic expansions of eigenvalues and eigenfunctions for second order Helmholtz equation with rapidly oscillating coefficients over general convex domains Ω in higher-dimensional cases ($n \geq 2$)? This is an interesting and difficult problem; refer to section 16 of [16]. One of the main results of this paper is that we answer the above problems in a sense and derive their rigorous verification.

The remainder of this paper is outlined as follows. In section 2 we introduce two examples associated with the themes of the paper derived from classical mechanics and Maxwell's equations. In section 3 the multiscale asymptotic analysis formulas of eigenvalues and eigenfunctions for the second order Helmholtz problem (1.1) with highly oscillatory coefficients over general convex domains are obtained, and the related regularity and error estimates are given. In section 4 the variation of eigenvalues and eigenfunctions is precisely analyzed due to the perturbation of the coefficients arising from numerically computing periodic solutions $N_{\alpha_1}(\xi),\ \alpha_1 = 1, 2, \dots n$. Section 5 is devoted to the finite element computations of the homogenized Helmholtz equation in the whole domain Ω and a boundary layer in a smaller computing scale. In section 6 the multiscale finite element algorithm and the postprocessing technique are presented, and the total error estimates are shown. Finally, some numerical results are reported, which provide a strong support for the effectiveness of the methods presented in this paper.

For convenience, we use throughout the paper the convention of summation upon repeated indices; C (with and without a subscript) denotes a generic positive constant, which is independent of ε.

2. The background of classical mechanics and Maxwell's equations. In this section, we concisely introduce some physical models of classical mechanics and Maxwell's equations associated with the themes of the paper.

2.1. Vibrations of the membrane with a periodic microstructure. As we know, the vibration of the membrane can be read as the following initial-boundary problem:

$$\begin{cases} \dfrac{\partial^2 V^\varepsilon(x,t)}{\partial t^2} - \dfrac{\partial}{\partial x_i}\left(a_{ij}\left(\dfrac{x}{\varepsilon}\right)\dfrac{\partial V^\varepsilon(x,t)}{\partial x_j}\right) = f(x,t) \quad \text{in} \quad \Omega \\ \text{subject to appropriate initial and boundary conditions,} \end{cases} \tag{2.1}$$

where $(a_{ij}(\frac{x}{\varepsilon}))$ is a symmetric, positive-definite matrix, and its elements are highly oscillatory coefficients with a small periodic parameter ε, and $f(x,t)$ is a given nonperiodic perturbation. Domain Ω and its basic configuration are shown in Figures 1 and 2.

By virtue of Fourier's transform, we know that

$$V^\varepsilon(x,t) = \frac{1}{(2\pi)^{1/2}} \int_{-\infty}^{+\infty} F(x,\omega)\chi^\varepsilon(x,\omega)e^{-i\omega t}d\omega, \tag{2.2}$$

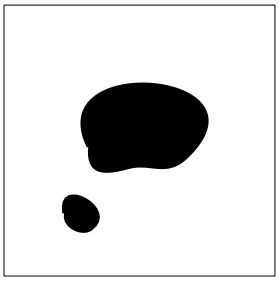

FIG. 2. *Basic configuration*

where

$$F(x,\omega) = \frac{1}{(2\pi)^{1/2}} \int_{-\infty}^{+\infty} f(x,t) e^{i\omega t} dt, \tag{2.3}$$

$$f(x,t) = \frac{1}{(2\pi)^{1/2}} \int_{-\infty}^{+\infty} F(x,\omega) e^{-i\omega t} d\omega, \tag{2.4}$$

and the admittance function

$$\chi^{\varepsilon}(x,\omega) = U^{\varepsilon}(x,\omega)/F(x,\omega), \tag{2.5}$$

where $U^{\varepsilon}(x,\omega)$ satisfies the following Helmholtz equation:

$$\begin{cases} -\dfrac{\partial}{\partial x_i}\left(a_{ij}\left(\dfrac{x}{\varepsilon}\right)\dfrac{U^{\varepsilon}(x,\omega)}{\partial x_j}\right) = \omega^2 U^{\varepsilon}(x,\omega) \\ \text{subject to appropriate boundary condition.} \end{cases} \tag{2.6}$$

2.2. Propagation in a waveguide partially filled with anisotropic dielectric material. Consider Maxwell's equation without sources:

$$\begin{cases} \nabla \times \underline{E} + \dfrac{\partial \underline{B}}{\partial t} = \underline{0}, \\ \nabla \times \underline{H} - \dfrac{\partial \underline{D}}{\partial t} = \underline{0}, \\ \nabla \cdot \underline{D} = 0, \\ \nabla \cdot \underline{B} = 0, \\ \underline{D} = \epsilon \underline{E}, \\ \underline{B} = \mu \underline{H}, \end{cases} \tag{2.7}$$

where $\underline{E} = (E_x, E_y, E_z)^T, \underline{D} = (D_x, D_y, D_z)^T, \underline{H} = (H_x, H_y, H_z)^T, \underline{B} = (B_x, B_y, B_z)^T$ are electric field intensity, electric flux density, magnetic field strength, and magnetic flux density, respectively. ϵ, μ are the dielectric constant tensor and the magnetic permeability tensor of anisotropic media.

Suppose that the propagation of a wave is in the z-axis; then

$$\underline{E}(t,x,y,z) = \underline{E}(x,y) e^{i(\omega t - k_z z)}, \tag{2.8a}$$

$$\underline{H}(t,x,y,z) = \underline{H}(x,y) e^{i(\omega t - k_z z)}, \tag{2.8b}$$

where $\sqrt{-1} = i$ and ω, k_z are the angular frequency and the propagation constant, respectively.

If $\epsilon = (\epsilon_{ij})_{3\times 3}$ is a symmetric tensor, then we can always change it into a diagonal tensor by using an orthogonal transformation. Therefore assume here that ϵ is a diagonal tensor without loss of generality, i.e., $\epsilon = diag(\epsilon_x, \epsilon_y, \epsilon_z)$, $\mu = diag(\mu_x, \mu_y, \mu_z)$.

Substituting (2.8a) and (2.8b) into (2.7), one can obtain

$$\begin{cases} \dfrac{\partial E_z}{\partial y} = -ik_z E_y - i\omega\mu_x H_x, \\ \dfrac{\partial E_z}{\partial x} = -ik_z E_x + i\omega\mu_y H_y, \\ \dfrac{\partial E_y}{\partial x} - \dfrac{\partial E_x}{\partial y} = -i\omega\mu_z H_z, \\ \dfrac{\partial H_z}{\partial y} = -ik_z H_y + i\omega\epsilon_x E_x, \\ \dfrac{\partial H_z}{\partial x} = -ik_z H_x - i\omega\epsilon_y E_y, \\ \dfrac{\partial H_y}{\partial x} - \dfrac{\partial H_x}{\partial y} = i\omega\epsilon_z E_z. \end{cases} \tag{2.9}$$

From (2.9), we can easily see that, once E_z, H_z are determined, other variables can be calculated.

One can directly verify that $\Phi = (E_z, H_z)$ satisfies the following governed equation:

$$T\Phi = k_0^2 M\Phi, \tag{2.10}$$

where

(2.11)

$$T = \begin{pmatrix} -\dfrac{\partial}{\partial x}\left(\dfrac{\epsilon_x}{\kappa_x^2}\dfrac{\partial}{\partial x}\right) - \dfrac{\partial}{\partial y}\left(\dfrac{\epsilon_y}{\kappa_y^2}\dfrac{\partial}{\partial y}\right) & \dfrac{k_z}{\omega}\left[\dfrac{\partial}{\partial y}\left(\dfrac{1}{\kappa_y^2}\dfrac{\partial}{\partial x}\right) - \dfrac{\partial}{\partial x}\left(\dfrac{1}{\kappa_x^2}\dfrac{\partial}{\partial y}\right)\right] \\ \dfrac{k_z}{\omega}\left[\dfrac{\partial}{\partial x}\left(\dfrac{1}{\kappa_y^2}\dfrac{\partial}{\partial y}\right) - \dfrac{\partial}{\partial y}\left(\dfrac{1}{\kappa_x^2}\dfrac{\partial}{\partial x}\right)\right] & -\dfrac{\partial}{\partial x}\left(\dfrac{\mu_x}{\kappa_x^2}\dfrac{\partial}{\partial x}\right) - \dfrac{\partial}{\partial y}\left(\dfrac{\mu_y}{\kappa_y^2}\dfrac{\partial}{\partial y}\right) \end{pmatrix},$$

$$M = \begin{pmatrix} \epsilon_z & 0 \\ 0 & \mu_z \end{pmatrix}. \tag{2.12}$$

3. Multiscale asymptotic analysis for the second order Helmholtz equation on general convex domains. As one of the main results of this section, we will obtain multiscale asymptotic analysis formulas of eigenvalues and eigenfunctions of the Helmholtz problem (1.1).

Formally, set

$$u^\varepsilon(x) \cong \sum_{l=0}^{+\infty} \varepsilon^l \sum_{\alpha_1,\cdots,\alpha_l=1}^{n} N_{\alpha_1\cdots\alpha_l}(\xi) D^\alpha u^0(x), \tag{3.1}$$

$$\lambda^\varepsilon \cong \sum_{i=0}^{+\infty} \varepsilon^i \lambda^{(i)}(\varepsilon). \tag{3.2}$$

In contrast to the usual expression, for the sake of convenience, we use here the following notation:

$$D^\alpha v = \frac{\partial^l v}{\partial x_{\alpha_1}\cdots\partial x_{\alpha_l}}, \qquad \alpha = \{\alpha_1, \cdots \alpha_l\},\ \langle\alpha\rangle = l, \tag{3.3}$$

α_i takes the values $1, 2, \dots n$.

Substituting (3.1), (3.2) into (1.1), and taking into account that $\frac{\partial}{\partial x_i} \to \frac{\partial}{\partial x_i} + \frac{1}{\varepsilon}\frac{\partial}{\partial \xi_i}$, one can write

(3.4)
$$\begin{aligned} 0 &= \mathcal{L}_\varepsilon u^\varepsilon(x) - \lambda^\varepsilon \rho(\tfrac{x}{\varepsilon}) u^\varepsilon(x) \\ &= -\sum_{l=0}^{+\infty} \varepsilon^{l-2} \sum_{\alpha_1,\dots,\alpha_l=1}^{n} H_{\alpha_1\cdots\alpha_l}(\xi) D^\alpha u^0(x) + \sum_{l=0}^{+\infty} \varepsilon^l \sum_{\alpha_1,\dots,\alpha_l=1}^{n} b(\xi) N_{\alpha_1\cdots\alpha_l}(\xi) D^\alpha u^0(x) \\ &\quad - \sum_{s=0}^{+\infty} \varepsilon^s \sum_{i=0}^{s} \lambda^{(i)} \sum_{\alpha_1,\dots,\alpha_{s-i}=1}^{n} \rho(\xi) N_{\alpha_1\cdots\alpha_{s-i}}(\xi) D^\alpha u^0(x), \end{aligned}$$

where

$$H_0(\xi) = \frac{\partial}{\partial \xi_i}\left(a_{ij}(\xi)\frac{\partial N_0(\xi)}{\partial \xi_j}\right), \tag{3.5}$$

$$H_{\alpha_1}(\xi) = \frac{\partial}{\partial \xi_i}\left(a_{ij}(\xi)\frac{\partial N_{\alpha_1}(\xi)}{\partial \xi_j}\right) + \frac{\partial}{\partial \xi_i}\left(a_{i\alpha_1}(\xi) N_0(\xi)\right) + a_{\alpha_1 j}(\xi)\frac{\partial N_0(\xi)}{\partial \xi_j}. \tag{3.6}$$

For $\langle\alpha\rangle = l \geq 2$

$$\begin{aligned} H_{\alpha_1\cdots\alpha_l}(\xi) &= \frac{\partial}{\partial \xi_i}\left(a_{ij}(\xi)\frac{\partial N_{\alpha_1\cdots\alpha_l}(\xi)}{\partial \xi_j}\right) + \frac{\partial}{\partial \xi_i}(a_{i\alpha_1}(\xi) N_{\alpha_2\cdots\alpha_l}(\xi)) \\ &\quad + a_{\alpha_1 j}(\xi)\frac{\partial N_{\alpha_2\cdots\alpha_l}(\xi)}{\partial \xi_j} + a_{\alpha_1\alpha_2}(\xi) N_{\alpha_3\cdots\alpha_l}(\xi). \end{aligned} \tag{3.7}$$

In order to compare the coefficients of powers $\varepsilon^{-2}, \varepsilon^{-1}, \varepsilon^0, \varepsilon^1, \dots$ on both sides of (3.4) and to ensure that (3.4) is an identity equation, we assume that

$$\begin{cases} H_0(\xi) = 0, \\ H_{\alpha_1}(\xi) = 0, \\ H_{\alpha_1\alpha_2}(\xi) = \hat{a}_{\alpha_1\alpha_2}, \\ H_{\alpha_1\alpha_2\alpha_3}(\xi) = N_{\alpha_1}(\xi)\hat{a}_{\alpha_2\alpha_3}, \\ \cdots \\ H_{\alpha_1\alpha_2\cdots\alpha_l}(\xi) = N_{\alpha_1\cdots\alpha_{l-2}}(\xi)\hat{a}_{\alpha_{l-1}\alpha_l}, \quad l \geq 4. \end{cases} \tag{3.8}$$

Notice that $\hat{a}_{\alpha_1\alpha_2}$, $N_{\alpha_1\cdots\alpha_j}(\xi)$, $\alpha_j = 1, 2, \dots n$, $j = 0, 1, 2, \dots$, will be defined below.

Substituting (3.8) into (3.4), one obtains

(3.9)
$$\begin{aligned} 0 = \sum_{l=0}^{+\infty} \varepsilon^l \Bigg\{ \sum_{\alpha_1,\cdots\alpha_l=1}^{n} N_{\alpha_1,\dots,\alpha_l}(\xi) \frac{\partial^l}{\partial x_{\alpha_1}\cdots\partial x_{\alpha_l}} \Bigg[- \sum_{\alpha_{l+1},\alpha_{l+2}=1}^{n} \hat{a}_{\alpha_{l+1}\alpha_{l+2}} \frac{\partial^2 u^0(x)}{\partial x_{\alpha_{l+1}}\partial x_{\alpha_{l+2}}} \\ + b(\xi) u^0(x) \Bigg] - \sum_{i=0}^{l} \lambda^{(i)} \sum_{\alpha_1,\cdots,\alpha_{l-i}=1}^{n} \rho(\xi) N_{\alpha_1\cdots\alpha_{l-i}}(\xi) D^\alpha u^0(x) \Bigg\}. \end{aligned}$$

To begin with, consider the first equation of (3.8), and conclude that

$$\begin{cases} \dfrac{\partial}{\partial \xi_i}\left(a_{ij}(\xi)\dfrac{\partial N_0(\xi)}{\partial \xi_j}\right) = 0 \quad \text{in} \quad R^n, \\ N_0(\xi) \quad \text{is} \quad \text{1-periodic} \quad \text{in} \quad \xi. \end{cases} \tag{3.10}$$

Let us remark that the equation

$$\begin{cases} \mathcal{L}_1\phi(\xi) \equiv \dfrac{\partial}{\partial \xi_i}\left(a_{ij}(\xi)\dfrac{\partial \phi(\xi)}{\partial \xi_j}\right) = F(\xi) \quad \text{in} \quad Q, \\ \phi(\xi) \quad \text{is 1-periodic in} \quad \xi \end{cases} \tag{3.11}$$

admits a unique solution (up to an additive constant) iff

$$\int_Q F(\xi)d\xi = 0,$$

where the unit cube $Q = \{\xi \in R^n,\ 0 < \xi_j < 1,\ j = 1, \dots n\}$.

Combining (3.10) with (3.11), it is easy to see that $N_0(\xi) \equiv C$; here set $C = 1$ without loss of generality.

From the second equation of (3.8), we define $N_{\alpha_1}(\xi)$ in the following way:

$$\begin{cases} \dfrac{\partial}{\partial \xi_i}\left(a_{ij}(\xi)\dfrac{\partial N_{\alpha_1}(\xi)}{\partial \xi_j}\right) = -\dfrac{\partial}{\partial \xi_i}(a_{i\alpha_1}(\xi)) \quad \text{in} \quad Q, \\ N_{\alpha_1}(\xi) = 0 \quad \text{on} \quad \partial Q. \end{cases} \tag{3.12}$$

Integrating on both sides of the third equation of (3.8) in ξ over the unit cell Q, and taking into account that $N_{\alpha_1}(\xi), N_{\alpha_1\alpha_2}(\xi)$ are 1-periodic functions in ξ, one can conclude that

$$\hat{a}_{\alpha_1\alpha_2} = \int_Q \left(a_{\alpha_1\alpha_2}(\xi) + a_{\alpha_1 j}(\xi)\frac{\partial N_{\alpha_2}(\xi)}{\partial \xi_j}\right) d\xi. \tag{3.13}$$

From (3.8), we next define $N_{\alpha_1\alpha_2}(\xi), \dots N_{\alpha_1\cdots\alpha_l}(\xi)$ in the following ways:

$$\begin{cases} \dfrac{\partial}{\partial \xi_i}\left(a_{ij}(\xi)\dfrac{\partial N_{\alpha_1\alpha_2}(\xi)}{\partial \xi_j}\right) = -\dfrac{\partial}{\partial \xi_i}(a_{i\alpha_1}(\xi)N_{\alpha_2}(\xi)) \\ \qquad - a_{\alpha_1 j}(\xi)\dfrac{\partial N_{\alpha_2}(\xi)}{\partial \xi_j} - a_{\alpha_1\alpha_2}(\xi) + \hat{a}_{\alpha_1\alpha_2} \quad \text{in } Q, \\ N_{\alpha_1\alpha_2}(\xi) = 0 \quad \text{on} \quad \partial Q. \end{cases} \tag{3.14}$$

For $\langle\alpha\rangle = l \geq 3$

$$\begin{cases} \dfrac{\partial}{\partial \xi_i}\left(a_{ij}(\xi)\dfrac{\partial N_{\alpha_1\cdots\alpha_l}(\xi)}{\partial \xi_j}\right) = -\dfrac{\partial}{\partial \xi_i}(a_{i\alpha_1}(\xi)N_{\alpha_2\cdots\alpha_l}(\xi)) \ - a_{\alpha_1 j}(\xi)\dfrac{\partial N_{\alpha_2\cdots\alpha_l}(\xi)}{\partial \xi_j} \\ \qquad - a_{\alpha_1\alpha_2}(\xi)N_{\alpha_3\cdots\alpha_l}(\xi) + N_{\alpha_1\cdots\alpha_{l-2}}(\xi)\hat{a}_{\alpha_{l-1}\alpha_l} \quad \text{in } Q, \\ N_{\alpha_1\cdots\alpha_l}(\xi) = 0 \quad \text{on} \quad \partial Q. \end{cases} \tag{3.15}$$

Remark 3.1. Existence and uniqueness of the solutions $N_{\alpha_1}(\xi), \ldots, N_{\alpha_1\cdots\alpha_l}(\xi)$ for problems (3.12), (3.14), and (3.15), respectively, can be easily established by induction with respect to l due to the uniform elliptic condition (A_2)–(A_4), Poincaré–Friedrichs' inequality, and Lax–Milgram's lemma. Then they are extended to the whole R^n by the 1-periodicity.

Remark 3.2. It is worthwhile to notice that the periodic solutions $N_{\alpha_1}(\xi)$, $\alpha_1 = 1, \ldots n$, defined in this paper, generally speaking, are different from $\tilde{N}_{\alpha_1}(\xi)$ defined in classical homogenization books (see [2, 11, 16, 18]) due to the different boundary conditions on ∂Q. But we can prove that their homogenized matrices are the same; see Appendix A.

Next, let us identify the coefficients of powers $\varepsilon^0, \varepsilon^1, \varepsilon^2, \ldots$ on the both sides of (3.9) for $l = 0$:

$$-\frac{\partial}{\partial x_{\alpha_1}}\left(\hat{a}_{\alpha_1\alpha_2}\frac{\partial u^0(x)}{\partial x_{\alpha_2}}\right) + b(\xi)u^0(x) = \lambda^{(0)}\rho(\xi)u^0(x), \quad \text{a.e.} \quad \xi \in R^n. \tag{3.16}$$

For $l = 1$

$$N_{\alpha_1}(\xi)\frac{\partial}{\partial x_{\alpha_1}}\left\{-\frac{\partial}{\partial x_{\alpha_2}}\left(\hat{a}_{\alpha_2\alpha_3}\frac{\partial u^0(x)}{\partial x_{\alpha_3}}\right) + b(\xi)u^0(x) - \lambda^{(0)}\rho(\xi)u^0(x)\right\} - \lambda^{(1)}\rho(\xi)u^0(x) = 0. \tag{3.17}$$

From (3.16), we know

$$\lambda^{(1)}\langle\rho\rangle u^0(x) = 0,$$

where $\langle f\rangle = \frac{1}{|Q|}\int_Q f(\xi)d\xi$, $|Q|$ denotes the Lebesgue measure of the unit cube Q.

Since $\langle\rho\rangle \neq 0$, $\|u^0\|_{L^2(\Omega)} = 1$, then $\lambda^{(1)} = 0$ holds. For $l = 2$

$$\begin{aligned} &N_{\alpha_1\alpha_2}(\xi)\frac{\partial^2}{\partial x_{\alpha_1}\partial x_{\alpha_2}}\left\{-\frac{\partial}{\partial x_{\alpha_3}}\left(\hat{a}_{\alpha_3\alpha_4}\frac{\partial u^0(x)}{\partial x_{\alpha_4}}\right) + b(\xi)u^0(x) - \lambda^{(0)}\rho(\xi)u^0(x)\right\} \\ &-\lambda^{(1)}\rho(\xi)N_{\alpha_1}(\xi)\frac{\partial u^0(x)}{\partial x_{\alpha_1}} - \lambda^{(2)}\rho(\xi)u^0(x) = 0. \end{aligned} \tag{3.18}$$

Analogously, we can infer that $\lambda^{(2)} = 0$.

The remainder shall similarly be proven, i.e., $\lambda^{(i)} = 0$, $i \geq 3$.

On the other hand, from (3.16), we know

$$-\frac{\partial}{\partial x_{\alpha_1}}\left(\hat{a}_{\alpha_1\alpha_2}\frac{\partial u^0(x)}{\partial x_{\alpha_2}}\right) = (\lambda^{(0)}\rho(\xi) - b(\xi))u^0(x).$$

Since $u^0(x) \not\equiv 0, x \in \Omega$, then there are some points $x \in \Omega$ such that $u^0(x) \neq 0$, and

$$-\frac{1}{u^0(x)}\frac{\partial}{\partial x_{\alpha_1}}\left(\hat{a}_{\alpha_1\alpha_2}\frac{\partial u^0(x)}{\partial x_{\alpha_2}}\right) = \lambda^{(0)}\rho(\xi) - b(\xi) \equiv C. \tag{3.19}$$

Integrating on the both sides of (3.19) in Q, we have

$$C = \lambda^{(0)}\langle\rho\rangle - \langle b\rangle. \tag{3.20}$$

Therefore we can prove that (3.16) and $\widehat{\mathcal{B}}(u^0) = 0$ on $\partial\Omega$ are equivalent to the following homogenized Helmholtz equation associated with problem (1.1):

$$\begin{cases} \widehat{\mathcal{L}}u^0(x) \equiv -\dfrac{\partial}{\partial x_i}\left(\hat{a}_{ij}\dfrac{\partial u^0(x)}{\partial x_j}\right) + \langle b\rangle u^0(x) = \lambda^{(0)}\langle\rho\rangle u^0(x) \quad \text{in} \quad \Omega, \\ \widehat{\mathcal{B}}(u^0) = 0 \quad \text{on} \quad \partial\Omega, \end{cases} \tag{3.21}$$

where $\hat{a}_{ij}$ is as shown in (3.13), and

$$\widehat{\mathcal{B}}(v) = \begin{cases} v & \text{for Dirichlet's boundary condition,} \\ \nu_i \hat{a}_{ij}\dfrac{\partial v}{\partial x_j} & \text{for Neumann's boundary condition.} \end{cases}$$

Remark 3.3. One can check that $\widehat{\mathcal{L}}$ is a linear symmetric positive-definite operator; see [2, 11, 16, 18].

For an integer $M \geq 2$, set

$$u_k^{\varepsilon,M}(x) = \sum_{l=0}^{M}\varepsilon^l \sum_{\alpha_1,\cdots,\alpha_l=1}^{n} N_{\alpha_1\cdots\alpha_l}(\xi)D^\alpha u_k^0(x), \tag{3.22}$$

$$\lambda_k^{\varepsilon,M} \equiv \lambda_k^{(0)}, \quad k = 1, 2, \ldots, \tag{3.23}$$

$$\begin{aligned} &\mathcal{L}_\varepsilon u_k^{\varepsilon,M}(x) - \lambda_k^{\varepsilon,M}\rho\left(\frac{x}{\varepsilon}\right)u_k^{\varepsilon,M}(x) = \sum_{l=0}^{M}\varepsilon^{l-2}\sum_{\alpha_1,\ldots,\alpha_l=1}^{n} H_{\alpha_1\cdots\alpha_l}(\xi)D^\alpha u_k^0(x) \\ &+ \sum_{l=0}^{M-2}\varepsilon^l \sum_{\alpha_1,\ldots,\alpha_l=1}^{n} b(\xi)N_{\alpha_1\cdots\alpha_l}(\xi)D^\alpha u_k^0(x) \\ &- \sum_{l=0}^{M-2}\varepsilon^l \sum_{\alpha_1,\ldots,\alpha_l=1}^{n} \lambda_k^{(0)}\rho(\xi)N_{\alpha_1\cdots\alpha_l}(\xi)D^\alpha u_k^0(x) + \varepsilon^{M-1}F_0(x,\varepsilon) \\ &= \sum_{l=0}^{M-2}\varepsilon^l \sum_{\alpha_1\cdots\alpha_l=1}^{n} N_{\alpha_1\cdots\alpha_l}(\xi)\frac{\partial^l}{\partial x_{\alpha_1}\cdots\partial x_{\alpha_l}}\left[\hat{a}_{\alpha_{l+1}\alpha_{l+2}}\frac{\partial^2 u_k^0(x)}{\partial x_{\alpha_{l+1}}\partial x_{\alpha_{l+2}}}\right. \\ &\left. + b(\xi)u_k^0(x) - \lambda_k^{(0)}\rho(\xi)u_k^0(x)\right] + \varepsilon^{M-1}F_0(x,\varepsilon) \\ &= \varepsilon^{M-1}F_0(x,\varepsilon), \end{aligned} \tag{3.24}$$

where $F_0(x,\varepsilon)$ is a sum of terms having the form $\varepsilon^i\psi(\xi)D^l u_k^0(x)$, $2 \leq M$, $i \geq 0$, $\psi(\xi)$ is a bounded function, and $\|F_0(x,\varepsilon)\|_{L^2(\Omega)} \leq C$, C is a constant independent of ε, x.

Let $\Omega_0 = \bigcup_{z\in\widehat{T}_\varepsilon}\varepsilon(z+Q) \subset \Omega$ as shown in Figure 3, where the index set $\widehat{T}_\varepsilon = \{z = (z_1,\ldots,z_n) \in Z^n,\ \varepsilon(z+Q) \subset \Omega\}$, and the unit cube $Q = \{\xi \in R^n : 0 < \xi_j < 1,\ j = 1, 2, \ldots, n\}$.

For simplicity, we assume that $\varepsilon/2 \leq dist(\partial\Omega_0, \partial\Omega) \leq 2\varepsilon$, $\Omega_1 = \Omega \setminus \bar{\Omega}_0$,$\Gamma^* = \partial\Omega_0 \cap \partial\Omega_1$ as shown in Figure 4.

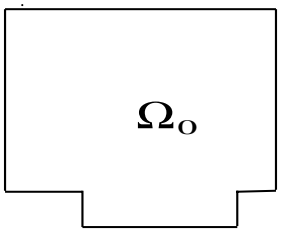

FIG. 3. *Subdomain* Ω_0.

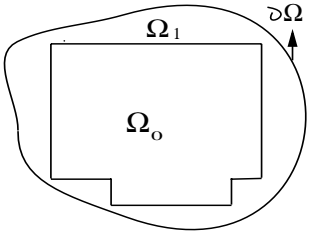

FIG. 4. *Boundary layer* Ω_1.

Now let us define the boundary layer in the following way:

$$\begin{cases} -\dfrac{\partial}{\partial x_i}\left(a_{ij}\left(\dfrac{x}{\varepsilon}\right)\dfrac{\partial W_k^\varepsilon(x)}{\partial x_j}\right)+\left(b\left(\dfrac{x}{\varepsilon}\right)-\lambda_k^{(0)}\rho\left(\dfrac{x}{\varepsilon}\right)\right)W_k^\varepsilon(x)=0, \quad x\in\Omega_1, \\ W_k^\varepsilon(x)=u_k^0(x), \quad x\in\partial\Omega_0, \\ \mathcal{B}_\varepsilon(W_k^\varepsilon)=0, \quad x\in\partial\Omega, \end{cases} \tag{3.25}$$

where $(\lambda_k^{(0)}, u_k^0(x))$, is the kth eigenpair of the homogenized Helmholtz problem (3.21), $k=1,2,\ldots$.

Remark 3.4. It is worthwhile to notice that $W_k^\varepsilon(x)$ is independent of ε along $\partial\Omega_0\cap\partial\Omega_1$. We will prove that it is correct in some cases later.

To begin with, let us discuss the corresponding homogeneous boundary value problem as follows:

$$\begin{cases} -\dfrac{\partial}{\partial x_i}\left(a_{ij}(\frac{x}{\varepsilon})\dfrac{\partial V_k^\varepsilon(x)}{\partial x_j}\right)+\left(b\left(\frac{x}{\varepsilon}\right)-\lambda_k^{(0)}\rho\left(\frac{x}{\varepsilon}\right)\right)V_k^\varepsilon(x)=0, \quad x\in\Omega_1, \\ V_k^\varepsilon(x)=0, \quad x\in\partial\Omega_0, \\ \mathcal{B}_\varepsilon(V_k^\varepsilon)=0, \quad x\in\partial\Omega. \end{cases} \tag{3.26}$$

Now we define the operator $\mathcal{K}_\varepsilon : L^2(\Omega_1)\to L^2(\Omega_1)$, set $\mathcal{K}_\varepsilon f^\varepsilon = v^\varepsilon$, where v^ε is the solution of the following problem:

$$\begin{cases} \mathcal{Q}_\varepsilon(v^\varepsilon)\equiv -\dfrac{\partial}{\partial x_i}\left(a_{ij}\left(\dfrac{x}{\varepsilon}\right)\dfrac{\partial v^\varepsilon}{\partial x_j}\right)+b\left(\dfrac{x}{\varepsilon}\right)v^\varepsilon=\rho\left(\dfrac{x}{\varepsilon}\right)f^\varepsilon \quad \text{in} \quad \Omega_1, \\ v^\varepsilon(x)=0 \quad \text{on} \quad \partial\Omega_0, \\ \mathcal{B}_\varepsilon(v^\varepsilon)=0 \quad \text{on} \quad \partial\Omega. \end{cases} \tag{3.27}$$

By virtue of conditions (A_2)–(A_3), we know that $\mathcal{Q}_\varepsilon : H^1(\Omega_1,\partial\Omega_0)\to L^2(\Omega_1)$ is a symmetric and positive-definite operator; therefore the inverse operator $\mathcal{K}_\varepsilon=\mathcal{Q}_\varepsilon^{-1}$: $L^2(\Omega_1)\to L^2(\Omega_1)$ is a bounded self-adjoint compact operator due to the compact imbedding $H^1(\Omega_1)\to L^2(\Omega_1)$. $\sigma_d(\mathcal{K}_\varepsilon)$ denotes the set of discrete spectra of operator $\mathcal{K}_\varepsilon$.

For simplicity, in this section we assume that

$$(\lambda_k^{(0)})^{-1}\notin\sigma_d(\mathcal{K}_\varepsilon). \tag{3.28}$$

Remark 3.5. We can prove that the first eigenvalue $(\lambda_1^{(0)})^{-1} \notin \sigma_d(\mathcal{K}_\varepsilon)$; see Appendix B.

It follows from Fredholm's alternative theorem that (3.26) admits a unique solution $V_k^\varepsilon(x) = 0$. Therefore (3.25) has one and only one solution.

For $M \geq 2$, set

(3.29)
$$U_k^{\varepsilon,M}(x) = \begin{cases} u_k^{\varepsilon,M}(x) = u_k^0(x) + \sum_{l=1}^{M} \varepsilon^l \sum_{\alpha_1,\ldots,\alpha_l=1}^{n} N_{\alpha_1\cdots\alpha_l}(\xi) D^\alpha u_k^0(x), & x \in \overline{\Omega}_0, \\ W_k^\varepsilon(x), \quad x \in \Omega_1 = \Omega \setminus \overline{\Omega}_0, \end{cases}$$

where $N_{\alpha_1\cdots\alpha_l}(\xi)$ is as defined in (3.12), (3.14), and (3.15).

Since $u_k^{\varepsilon,M}(x)|_{\partial\Omega_0\cap\partial\Omega_1} = u_k^0(x)|_{\partial\Omega_0\cap\partial\Omega_1} = W_k^\varepsilon(x)|_{\partial\Omega_0\cap\partial\Omega_1}$, then $U_k^{\varepsilon,M}(x) \in H^1(\Omega)$ holds. But, generally speaking, $[\frac{\partial U_k^{\varepsilon,M}}{\partial n}]|_{\partial\Omega_0\cap\partial\Omega_1} \neq 0$. To this end, we have to do it through some well-known regularizations.

At first, let us introduce a set of open covering $\{\mathcal{V}_l\}_{l=1}^3$ of the bounded closed set $\overline{\Omega} \subset R^n$:

(3.30)
$$\begin{aligned} \mathcal{V}_1 &= \left\{ x \in \Omega_0 : \quad dist(x, \partial\Omega_0) > \frac{\delta}{2} \right\}, \\ \mathcal{V}_2 &= \left\{ x \in (R^n \setminus \overline{\Omega}_0) : dist(x, \partial\Omega_0) > \frac{\delta}{2}, dist(x, \partial\Omega) < \delta \right\}, \\ \mathcal{V}_3 &= \{ x \in \Omega : \quad dist(x, \partial\Omega_0) < \delta \}, \end{aligned}$$

$\overline{\Omega} \subset \cup_{l=1}^3 \mathcal{V}_l$.

Using the partition of unity theorem, there exists a set of functions $\{\psi_l(x)\}_{l=1}^3$ such that

(1) $\psi_l(x) \in C_0^\infty(\mathcal{V}_l)$;

(2) $\sum_{l=1}^3 \psi_l(x) \equiv 1$, $\forall x \in \Omega$.

Set $\Omega_0'' = \Omega_0 \setminus \overline{\mathcal{V}}_3$, $\Omega_1'' = \Omega_1 \setminus \overline{\mathcal{V}}_3$, and choose a sufficiently small $\delta > 0$ such that $\delta \leq C \cdot \varepsilon^M$, $M \geq 2$.

Define

$$\tilde{U}_k^{\varepsilon,M}(x) = \psi_1(x) \cdot U_k^{\varepsilon,M}(x) + \psi_2(x) \cdot U_k^{\varepsilon,M}(x) + J_\delta * (\psi_3(x) \cdot U_k^{\varepsilon,M}(x)), \tag{3.31}$$

where the regularization $J_\delta * u$ is defined in section 2.17 of [1].

One can directly verify that $\tilde{U}_k^{\varepsilon,M}(x) \in H^1(\Omega)$ and $[\frac{\partial \tilde{U}_k^{\varepsilon,M}}{\partial n}]|_{\partial\Omega_0\cap\partial\Omega_1} = 0$.

LEMMA 3.1 (see [11, 18]). *Let A: $H \to H$ be a linear self-adjoint compact operator in a Hilbert space H. Let $\mu \in R^1$, and let $u \in H$ be such that $\|u\|_H = 1$ and*

$$\|Au - \mu u\|_H \leq \beta, \qquad \beta = \text{const} > 0. \tag{3.32}$$

Then there exists an eigenvalue μ_i of operator A such that

$$|\mu_i - \mu| \leq \beta. \tag{3.33}$$

Moreover, for any $d > \beta$ there exists a vector $\bar{u} \in H$ such that

$$\|u - \bar{u}\|_H \leq 2\beta d^{-1}, \qquad \|\bar{u}\|_H = 1, \tag{3.34}$$

and $\bar{u}(x)$ is a linear combination of the eigenvectors of operator A corresponding to the eigenvalues within the interval $[\mu - d, \mu + d]$.

THEOREM 3.1. *Let $(\lambda_k^\varepsilon, u_k^\varepsilon)$ be the kth eigenpair of the original Helmholtz problem* (1.1)*, set $\lambda_0^\varepsilon = 0$, and let $U_k^{\varepsilon,M}$, $\tilde{U}_k^{\varepsilon,M}$, $\lambda_k^{\varepsilon,M}$ be defined in the formulas* (3.29)*,* (3.31)*, and* (3.23)*, respectively. If $a_{ij}(\frac{x}{\varepsilon}) \in C(\overline{\Omega})$, $\nabla_\xi a_{ij}(\xi) \in L^\infty(\Omega)$, then it holds that*

$$|\lambda_k^\varepsilon - \lambda_k^{\varepsilon,M}| \le C_1(k)\varepsilon^{M-1}, \quad k = 1, 2, \ldots. \tag{3.35}$$

Moreover, if the multiplicity of the eigenvalues $\lambda_k^{(0)}$ is equal to t, i.e.,

$$\lambda_{k-1}^{(0)} < \lambda_k^{(0)} = \cdots = \lambda_{k+t-1}^{(0)} < \lambda_{k+t}^{(0)}, \quad \lambda_0^{(0)} = 0,$$

then

$$\|U_k^{\varepsilon,M} - \bar{u}_k^\varepsilon\|_{L^2(\Omega)} \le C_2(k)\varepsilon^{M-1}, \quad M \ge 2, \tag{3.36}$$

where $\bar{u}_k^\varepsilon$ is a linear combination of the eigenfunctions of problem (1.1) *corresponding to the eigenvalues $\lambda_k^\varepsilon \cdots \lambda_{k+t-1}^\varepsilon$.*

In particular, if $\lambda_k^{(0)}$ is a simple eigenvalue, then

$$\|U_k^{\varepsilon,M} - u_k^\varepsilon\|_{L^2(\Omega)} \le C_2(k)\varepsilon^{M-1}. \tag{3.37}$$

Proof. To begin, consider the auxiliary problem as follows:

$$\begin{cases} \mathcal{L}_\varepsilon w^\varepsilon(x) = f^\varepsilon(x) & \text{in } \Omega, \\ w^\varepsilon(x) = 0 & \text{on } \partial\Omega. \end{cases} \tag{3.38}$$

If $f^\varepsilon(x) \in L^2(\Omega)$, it follows from (A_2)–(A_4), Poincaré–Friedrichs' inequality, and Lax–Milgram's lemma that there exists a unique weak solution of problem (3.38). In other words, $\mathcal{L}_\varepsilon : H_0^1(\Omega) \to L^2(\Omega)$ is a homeomorphism mapping.

Set $\mathcal{N}_\varepsilon = \mathcal{L}_\varepsilon^{-1}$, one can check that $\mathcal{N}_\varepsilon : L^2(\Omega) \to L^2(\Omega)$ is a uniform bounded linear operator in ε, i.e., $\|\mathcal{N}_\varepsilon\|_{L^2(\Omega)\to L^2(\Omega)} \le C$, where C is a positive constant independent of ε.

If $x \in \overline{\Omega}_0$, from (3.24), then it holds in the sense of distributions that

$$\mathcal{L}_\varepsilon u_k^{\varepsilon,M}(x) - \lambda_k^{(0)}\rho\left(\frac{x}{\varepsilon}\right) u_k^{\varepsilon,M}(x) = \varepsilon^{M-1}F_0(x,\varepsilon). \tag{3.39}$$

If $x \in \Omega_1$, from (3.25), we have

$$\mathcal{L}_\varepsilon W_k^\varepsilon(x) - \lambda_k^{(0)}\rho\left(\frac{x}{\varepsilon}\right) W_k^\varepsilon(x) = 0. \tag{3.40}$$

From (3.39), (3.40), and (3.31), we obtain the following equation which holds in the sense of distributions:

$$\begin{cases} \mathcal{L}_\varepsilon \tilde{U}_k^{\varepsilon,M}(x) - \lambda_k^{\varepsilon,M}\rho\left(\frac{x}{\overline{\varepsilon}}\right)\tilde{U}_k^{\varepsilon,M}(x) = \tilde{F}_0(x,\varepsilon), \quad x \in \Omega, \\ \mathcal{B}_\varepsilon \tilde{U}_k^{\varepsilon,M}(x) = 0, \quad x \in \partial\Omega. \end{cases} \tag{3.41}$$

For any $v(x) \in L^2(\Omega)$, we obtain

(3.42)

$$\begin{aligned} (\tilde{F}_0, v)_\Omega &= \left(\mathcal{L}_\varepsilon \tilde{U}_k^{\varepsilon,M} - \lambda_k^{\varepsilon,M}\rho\left(\frac{x}{\varepsilon}\right)\tilde{U}_k^{\varepsilon,M}, v\right)_\Omega \\ &= \left(\mathcal{L}_\varepsilon u_k^{\varepsilon,M} - \lambda_k^{\varepsilon,M}\rho\left(\frac{x}{\varepsilon}\right) u_k^{\varepsilon,M}, v\right)_{\Omega_0''} + \left(\mathcal{L}_\varepsilon W_k^\varepsilon - \lambda_k^{\varepsilon,M}\rho\left(\frac{x}{\varepsilon}\right) W_k^\varepsilon, v\right)_{\Omega_1''} \\ &+ \left(\mathcal{L}_\varepsilon \tilde{U}_k^{\varepsilon,M} - \lambda_k^{\varepsilon,M}\rho\left(\frac{x}{\overline{\varepsilon}}\right)\tilde{U}_k^{\varepsilon,M}, v\right)_{\mathcal{V}_3\cap\Omega_0} + \left(\mathcal{L}_\varepsilon \tilde{U}_k^{\varepsilon,M} - \lambda_k^{\varepsilon,M}\rho\left(\frac{x}{\overline{\varepsilon}}\right)\tilde{U}_k^{\varepsilon,M}, v\right)_{\mathcal{V}_3\cap\Omega_1}. \end{aligned}$$

On the other hand, we know that

(3.43a)
$$\left(\mathcal{L}_\varepsilon \tilde{U}_k^{\varepsilon,M} - \lambda_k^{\varepsilon,M}\rho\left(\frac{x}{\varepsilon}\right)\tilde{U}_k^{\varepsilon,M}, v\right)_{\mathcal{V}_3\cap\Omega_0} = \left(\mathcal{L}_\varepsilon u_k^{\varepsilon,M} - \lambda_k^{\varepsilon,M}\rho\left(\frac{x}{\varepsilon}\right)u_k^{\varepsilon,M}, v\right)_{\mathcal{V}_3\cap\Omega_0} + \left(\mathcal{L}_\varepsilon \Lambda(x) - \lambda_k^{\varepsilon,M}\rho\left(\frac{x}{\varepsilon}\right)\Lambda(x), v\right)_{\mathcal{V}_3\cap\Omega_0},$$

where $\Lambda(x) = \psi_3(x)u_k^{\varepsilon,M}(x) - J_\delta * (\psi_3(x)u_k^{\varepsilon,M}(x))$.

Similarly, we have

(3.43b)
$$\left(\mathcal{L}_\varepsilon \tilde{U}_k^{\varepsilon,M} - \lambda_k^{\varepsilon,M}\rho\left(\frac{x}{\varepsilon}\right)\tilde{U}_k^{\varepsilon,M}, v\right)_{\mathcal{V}_3\cap\Omega_1} = \left(\mathcal{L}_\varepsilon W_k^{\varepsilon} - \lambda_k^{\varepsilon,M}\rho\left(\frac{x}{\varepsilon}\right)W_k^{\varepsilon}, v\right)_{\mathcal{V}_3\cap\Omega_1} + \left(\mathcal{L}_\varepsilon \Theta(x) - \lambda_k^{\varepsilon,M}\rho\left(\frac{x}{\varepsilon}\right)\Theta(x), v\right)_{\mathcal{V}_3\cap\Omega_1},$$

where $\Theta(x) = \psi_3(x)W_k^{\varepsilon}(x) - J_\delta * (\psi_3(x)W_k^{\varepsilon}(x))$.

Assume that Ω is a bounded convex Lipschitz domain and $a_{ij}(\frac{x}{\varepsilon}) \in C(\overline{\Omega})$, $\nabla_\xi a_{ij}(\xi) \in L^\infty(\Omega)$. By virtue of a priori estimates of PDEs (see [9, 10, 12]), we can prove that $u_k^\varepsilon(x) \in H^2(\Omega)$, $u_k^{\varepsilon,M}(x) \in H^2(\Omega_0)$, $W^\varepsilon(x) \in W^{2,p}(\Omega_1), 1 < p \le p_0 < +\infty$; also see Appendix C.

Using Theorem 3.16 of [1], we know that

$$\|\Lambda\|_{2,\mathcal{V}_3\cap\Omega_0} \le \delta, \quad \|\Theta\|_{2,p,\mathcal{V}_3\cap\Omega_1} \le \delta. \tag{3.44}$$

From (3.42), (3.43a), (3.43b), (3.44), (3.39), and (3.40), one can obtain

(3.45a)
$$\begin{aligned}
&\|\tilde{F}_0\|_{0,\Omega}^2 = (\tilde{F}_0, \tilde{F}_0)_\Omega \\
&\le C\left\{\varepsilon^{M-1}\|\tilde{F}_0\|_{0,\Omega_0} + \varepsilon^{-1}\cdot\|\Lambda\|_{2,\mathcal{V}_3\cap\Omega_0}\cdot\|\tilde{F}_0\|_{0,\mathcal{V}_3\cap\Omega_0} + \varepsilon^{-1}\cdot\|\Theta\|_{2,p,\mathcal{V}_3\cap\Omega_1}\cdot\|\tilde{F}_0\|_{0,p',\mathcal{V}_3\cap\Omega_1}\right\} \\
&\le C\left\{\varepsilon^{M-1}\|\tilde{F}_0\|_{0,\Omega_0} + \varepsilon^{-1}\cdot\delta\cdot\|\tilde{F}_0\|_{0,\Omega_0} + \varepsilon^{-1}\cdot\delta\cdot\|\tilde{F}_0\|_{0,p',\Omega_1}\right\} \\
&\le C\left\{\varepsilon^{M-1}\|\tilde{F}_0\|_{0,\Omega_0} + \varepsilon^{M-1}\|\tilde{F}_0\|_{0,p',\Omega_1}\right\},
\end{aligned}$$

where $p' = \frac{p}{p-1} > 2$. Let $p' = 2(1-\theta) + \theta\tilde{p}, \quad 2 < \tilde{p} < +\infty, \quad 0 \le \theta \le 1$.

Using the interpolation theorem (see Theorem 1.3.7 of [19]) we know that

$$\|\tilde{F}_0\|_{0,p',\Omega_1} \le C\|\tilde{F}_0\|_{0,\Omega_1}^{1-\theta}\cdot\|\tilde{F}_0\|_{0,\tilde{p},\Omega_1}^{\theta}. \tag{3.45b}$$

If we assume $\tilde{F}_0 \in L^{\tilde{p}}(\Omega_1)$, $\tilde{p} >> 2$, then we have $1-\theta \approx 1$. For convenience, we say that

$$\|\tilde{F}_0\|_{0,p',\Omega_1} \le C\cdot\|\tilde{F}_0\|_{0,\Omega_1}. \tag{3.45c}$$

Combining (3.45c) with (3.45a), one obtains

$$\|\tilde{F}_0\|_{0,\Omega} \le C\cdot\varepsilon^{M-1}. \tag{3.46}$$

From (3.41), we have

$$\tilde{U}_k^{\varepsilon,M}(x) - \lambda_k^{\varepsilon,M}\rho\left(\frac{x}{\varepsilon}\right)\mathcal{N}_\varepsilon(\tilde{U}_k^{\varepsilon,M}) = \mathcal{N}_\varepsilon(\tilde{F}_0(x,\varepsilon)).$$

Set $u = (\|\tilde{U}_k^{\varepsilon,M}\|_{0,\Omega})^{-1}\tilde{U}_k^{\varepsilon,M}$, $A = \mathcal{N}_\varepsilon$, $\lambda = \lambda_k^{\varepsilon,M} \equiv \lambda_k^{(0)}$, $\beta = -\|\mathcal{N}_\varepsilon(\tilde{F}_0)\|_{0,\Omega}(\|\tilde{U}_k^{\varepsilon,M}\|_{0,\Omega})^{-1}$, $H = L^2(\Omega)$.

It follows from Lemma 3.1 that there exists an eigenvalue $(\lambda_{n(k)}^\varepsilon)^{-1}$ of operator $\mathcal{N}_\varepsilon$ such that

$$|(\lambda_k^{\varepsilon,M})^{-1} - (\lambda_{n(k)}^\varepsilon)^{-1}| = |(\lambda_k^{(0)})^{-1} - (\lambda_{n(k)}^\varepsilon)^{-1}| \le C\varepsilon^{M-1}, \quad M \ge 2.$$

In accordance with the proof procedure of Theorem 2.1 in section 2.1, Chapter III of [18] (also see [11]), we know that $\lambda_k^\varepsilon \to \lambda_k^{(0)}$, $\varepsilon \to 0$. Hence, we can conclude that there is a small neighborhood of the point $\lambda_k^{(0)}$ which contains a eigenvalue λ_k^ε such that $\lambda_{n(k)}^\varepsilon = \lambda_k^\varepsilon$. Therefore

$$|\lambda_k^\varepsilon - \lambda_k^{\varepsilon,M}| \le C_1(k)\varepsilon^{M-1}.$$

Using Lemma 3.1 again, one obtains

$$\|\tilde{U}_k^{\varepsilon,M} - \bar{u}_k^\varepsilon\|_{0,\Omega} \le C_2(k)\varepsilon^{M-1}.$$

Especially if the eigenvalue $\lambda_k^{(0)}$ of problem (3.21) is simple, then one can choose $\bar{u}_k^\varepsilon = c_0 u_k^\varepsilon$, $c_0 = \text{const}$, such that

$$\|\tilde{U}_k^{\varepsilon,M} - u_k^\varepsilon\|_{0,\Omega} \le C_2(k)\varepsilon^{M-1}.$$

By using Theorem 3.16 of [1] again, it is easy to prove that

$$\|\tilde{U}_k^{\varepsilon,M} - U_k^{\varepsilon,M}\|_{0,\Omega} \le \delta \le C\cdot\varepsilon^M.$$

The proof of Theorem 3.1 is complete. □

Remark 3.6. One can directly verify that $\|U_k^{\varepsilon,M} - \bar{u}_k^\varepsilon\|_{1,\Omega} \le C\cdot\varepsilon^{\frac{(M-1)}{2}}$. Therefore, if $\lambda_k^{(0)}$ is simple, then $\|u_k^\varepsilon - W_k^\varepsilon\|_{0,\Omega_1} \le C|u_k^\varepsilon - u_k^0|_{1/2,\partial\Omega_0\cap\partial\Omega_1} \le C\|U_k^{\varepsilon,M} - u_k^\varepsilon\|_{1,\Omega} \le C\cdot\varepsilon^{\frac{(M-1)}{2}}$ on the basis of the trace theorem.

Next let us give some regularity results about $W_k^\varepsilon(x)$, which is of great use for error estimates of numerical computation.

THEOREM 3.2. *Let $W_k^\varepsilon(x)$ be the weak solution of problem* (3.25). *If $a_{ij}(\frac{x}{\varepsilon})$, $b(\frac{x}{\varepsilon})$, $\rho(\frac{x}{\varepsilon})$ satisfy conditions* (A_2)–(A_4), $(\lambda_k^{(0)})^{-1} \notin \sigma_d(\mathcal{K}_\varepsilon)$, *then it holds that*

$$\|W_k^\varepsilon\|_{1,\Omega_1} \le C\|u_k^0\|_{1,\Omega}, \quad k = 1,2,\ldots, \tag{3.47}$$

where C is independent of $\varepsilon, W_k^\varepsilon, u_k^0$.

The proof of Theorem 3.2 refers to section 3, Chapter I of [2].

THEOREM 3.3. *Let $\Omega_1 = \Omega \setminus \overline{\Omega}_0 \subset R^2$, and let $W^\varepsilon(x)$ be the weak solution of problem* (3.25). *For the sake of convenience, we do omit the subscript k. Under the hypotheses of Theorem* 3.2, *if $a_{ij}(\frac{x}{\varepsilon}) \in C(\overline{\Omega})$, $\nabla_\xi a_{ij}(\xi) \in L^\infty(\Omega)$, then there exists $1 < p_0 < +\infty$ such that*

$$W^\varepsilon(x) \in W^{2,p}(\Omega_1), \quad 1 < p \le p_0, \tag{3.48}$$

$$\|W^\varepsilon\|_{2,p,\Omega_1} \le C\varepsilon^{-2}\|u^0\|_{2,p,\Omega}. \tag{3.49}$$

The proof of Theorem 3.3 refers to Appendix C.

4. Finite element computations of periodic solutions $N_\alpha(\xi)$ and their related problems.

4.1. Finite element computations of periodic solutions $N_\alpha(\xi)$. For simplicity, we discuss only two-dimensional (2-D) problems without loss of generality.

Let $\mathcal{J}^{h_0} = \{K\}$ be a family of regular triangulations of the square Q, $h_0 = \max_K\{h_K\}$. Define a piecewise linear finite element space

$$V_{h_0} = \{v \in C(\bar{Q}) : v|_K \in P_1(K), \quad v|_{\partial Q} = 0\} \subset H_0^1(Q). \tag{4.1}$$

PROPOSITION 4.1. *Let $N_{\alpha_1\cdots\alpha_l}(\xi)$, $\alpha_j = 1, 2, \ldots, n$, $j = 1, \ldots, l$, be the weak solutions of problems* (3.12), (3.14), *and* (3.15), *respectively, and $N^{h_0}_{\alpha_1\cdots\alpha_l}(\xi)$ be the corresponding finite element solutions. If $N_{\alpha_1\cdots\alpha_j}(\xi) \in H^2(Q), j = 1, 2, \ldots, l$, then it holds that*

$$\|N_{\alpha_1\cdots\alpha_l} - N^{h_0}_{\alpha_1\cdots\alpha_l}\|_{1,Q} \le Ch_0 \left(\sum_{j=1}^{l} \|N_{\alpha_1\cdots\alpha_j}\|_{2,Q}\right), \tag{4.2}$$

where $C > 0$ is independent of $h_0, \varepsilon, N_{\alpha_1\cdots\alpha_j}, j = 1, \ldots, l$.

4.2. Perturbation bounds for eigenvalues and eigenfunctions of the modified homogenized Helmholtz equation. In practice, we need to solve the following modified homogenized Helmholtz equation associated with (3.21):

$$\begin{cases} \widehat{\mathcal{L}}_{h_0}\tilde{u}^0(x) \overset{\text{def}}{\equiv} -\dfrac{\partial}{\partial x_i}\left(\hat{a}^{h_0}_{ij}\dfrac{\partial \tilde{u}^0(x)}{\partial x_j}\right) + \langle b\rangle \tilde{u}^0(x) = \tilde{\lambda}^{(0)}\langle\rho\rangle\tilde{u}^0(x) \quad \text{in} \quad \Omega, \\ \widehat{\mathcal{B}}_{h_0}(\tilde{u}^0) = 0 \quad \text{on} \quad \partial\Omega, \end{cases} \tag{4.3}$$

where

$$\hat{a}^{h_0}_{ij} = \int_Q \left(a_{ij}(\xi) + a_{ik}(\xi)\frac{\partial N^{h_0}_j(\xi)}{\partial \xi_k}\right) d\xi. \tag{4.4}$$

$N^{h_0}_j(\xi)$ are the finite element approximate solution of $N_j(\xi)$ defined in (3.12).

$$\widehat{\mathcal{B}}_{h_0}(v) = \begin{cases} v \quad \text{for Dirichlet's boundary condition,} \\ \nu_i \hat{a}^{h_0}_{ij}\dfrac{\partial v}{\partial x_j} \quad \text{for Neumann's boundary condition.} \end{cases} \tag{4.5}$$

One can verify the following.

PROPOSITION 4.2. *The partial differential operator $\hat{\mathcal{L}}_{h_0}$ defined by* (4.3) *satisfies the following properties:*

$$(1) \quad \hat{a}^{h_0}_{ij} = \hat{a}^{h_0}_{ji}, \tag{4.6}$$

$$(2) \quad \bar{\mu}_1\eta_i\eta_i \le \hat{a}^{h_0}_{ij}\eta_i\eta_j \le \bar{\mu}_2\eta_i\eta_i \quad \forall(\eta_1\cdots\eta_n) \in R^n, \tag{4.7}$$

where $\bar{\mu}_1, \bar{\mu}_2 > 0$ are constants independent of the mesh size h_0.

Next we will precisely analyze the influence on the eigenvalues and the eigenfunctions because of the perturbation of the coefficients arising from computing numerically $N_{\alpha_1}(\xi)$, $\alpha_1 = 1, 2, \ldots, n$.

THEOREM 4.1. *Suppose that* $(\lambda_k^{(0)}, u_k^0)$ *and* $(\tilde{\lambda}_k^{(0)}, \tilde{u}_k^0)$ *are the kth eigenpairs of problems* (3.21) *and* (4.3)*, respectively. Then it holds that*

$$|\tilde{\lambda}_k^{(0)} - \lambda_k^{(0)}| \le C_k h_0^2 \|N_i\|_{2,Q}^2. \tag{4.8}$$

Moreover, if the multiplicity of the eigenvalue $\lambda_k^{(0)}$ *is equal to* t*, i.e.,*

$$\lambda_{k-1}^{(0)} < \lambda_k^{(0)} = \cdots = \lambda_{k+t-1}^{(0)} < \lambda_{k+t}^{(0)}, \quad \lambda_0^{(0)} = 0,$$

then

$$\|u_k^0 - \bar{u}_k^0\|_{L^2(\Omega)} \le C_k h_0^2 \|N_i\|_{2,Q}^2, \tag{4.9}$$

where $\bar{u}_k^0$ *is a linear combination of eigenfunctions of problem* (4.3) *corresponding to the eigenvalues* $\tilde{\lambda}_k^{(0)}, \ldots, \tilde{\lambda}_{k+t-1}^{(0)}$.

For the proof of Theorem 4.1, please refer to Appendix D.

COROLLARY 4.1. *Under the assumptions of Theorem* 4.1*, it then holds that*

$$\|u_k^0 - \bar{u}_k^0\|_{1,\Omega} \le C_k h_0 \|N_j\|_{2,Q}. \tag{4.10}$$

By virtue of interior regularity estimates of PDEs, one can directly prove the following.

THEOREM 4.2. *Suppose that* $(\lambda_k^{(0)}, u_k^{(0)}(x))$, $(\tilde{\lambda}_k^{(0)}, \tilde{u}_k^{(0)}(x))$ *are the kth eigenpairs of* (3.21) *and* (4.3)*, respectively,* $k = 1, 2, \ldots$, $\|u_k^0\|_{0,\Omega} = 1$, $\|\tilde{u}_k^0\|_{0,\Omega} = 1$, Ω_0 *as shown in Figure* 3*, and* $\Omega_0 \subset\subset \Omega' \subset\subset \Omega$*. If* $u^0(x) \in H^{M+2}(\Omega')$*, then it holds that*

$$\|u_k^0(x) - \tilde{u}_k^0(x)\|_{s,\Omega_0} \le C h_0^2 \|N_i\|_{2,Q}^2 \|u^0\|_{M+2,\Omega'}, \tag{4.11}$$

where $s = 0, 1, \ldots, M$, $k = 1, 2, \ldots$.

5. Solve approximately the homogenized Helmholtz equation and the boundary layer.

5.1. Finite element computation of the homogenized Helmholtz equation. For the sake of convenience, here we numerically solve the homogenized Helmholtz equation with the Dirichlet's boundary conditions over the whole domain Ω in a coarse mesh, and we assume that $\langle b \rangle \equiv 0$, $\langle \rho \rangle \equiv 1$.

For simplicity, suppose that $\Omega \subset R^2$ is a bounded smooth domain. Let $J^h = \{e\}$ be a family of regular subdivisions of $\Omega, h = \max_e h_e$, and satisfying the following properties:

(F_1) The elements are uniform rectangles in the interior domain $\Omega_0 \subset\subset \Omega$.

(F_2) The elements are regular triangles in region $\Omega_1 = \Omega \setminus \overline{\Omega}_0$, and the elements are (curved) triangles near the boundary $\partial\Omega$.

(F_3) Any face of any element e_1 is either a subset of the boundary $\partial\Omega$ or a face of another element e_2 in the subdivision.

Define a finite element space, $r \ge 1$,

$$S_0^h(\Omega) = \{v \in C(\overline{\Omega}) : \quad v|_e \in \overline{P}_r(e), \quad v|_{\partial\Omega} = 0\} \subset H_0^1(\Omega), \tag{5.1}$$

where

$$\overline{P}_r = \begin{cases} Q_r, & e \quad \text{is a rectangle,} \\ P_r, & e \quad \text{is a triangle.} \end{cases}$$

For simplicity, we give only the error estimates for the first eigenvalue problem without loss of generality.

The discrete variational form for the modified Helmholtz equation (4.3) is

$$A(\tilde{u}^0_{1,h}, v_h) = \tilde{\lambda}^{(0)}_{1,h}(\tilde{u}^0_{1,h}, v_h) \quad \forall v_h \in S^h_0(\Omega), \tag{5.2}$$

where the bilinear form

$$A(u, v) = \int_\Omega \hat{a}^{h_0}_{ij} \frac{\partial u}{\partial x_j} \frac{\partial v}{\partial x_i} dx. \tag{5.3}$$

At first, let us introduce some notation. Set $\|w\|^2_A = A(w, w)$, where $A(\cdot, \cdot)$ is as stated in (5.3). Define a Ritz–Galerkin projection operator $R_h : H^1_0(\Omega) \to S^h_0(\Omega)$ such that

$$A(u - R_h u, v_h) = 0, \quad u \in H^1_0(\Omega), \quad \forall v_h \in S^h_0(\Omega). \tag{5.4}$$

THEOREM 5.1. *Suppose that* $(\tilde{\lambda}^{(0)}_1, \tilde{u}^0_1)$ *and* $(\tilde{\lambda}^{(0)}_{1,h}, \tilde{u}^0_{1,h})$ *are the first eigenpairs of problems* (4.3), (5.2), *respectively; it then holds that*

$$0 \le \frac{A(w, w)}{(w, w)} - \tilde{\lambda}^0_1 \le \frac{\|w - \tilde{u}^0_1\|^2_A}{(w, w)} \quad \forall w \in H^1_0(\Omega), \tag{5.5}$$

$$0 < \tilde{\lambda}^{(0)}_1 \le \frac{A(\tilde{u}^0_{1,h}, \tilde{u}^0_{1,h})}{(\tilde{u}^0_{1,h}, \tilde{u}^0_{1,h})} = \tilde{\lambda}^{(0)}_{1,h} \le \frac{A(v, v)}{(v, v)} \quad \forall v \in S^h_0(\Omega), \tag{5.6}$$

and

$$0 \le \tilde{\lambda}^{(0)}_{1,h} - \tilde{\lambda}^{(0)}_1 \le \frac{A(R_h\tilde{u}^0_1, R_h\tilde{u}^0_1)}{(R_h\tilde{u}^0_1, R_h\tilde{u}^0_1)} - \tilde{\lambda}^{(0)}_1 \le \frac{\|R_h\tilde{u}^0_1 - \tilde{u}^0_1\|^2_A}{(R_h\tilde{u}^0_1, R_h\tilde{u}^0_1)}. \tag{5.7}$$

Proof. It is easy to see that (5.6) is true, so let us turn to the proof of (5.5). One can directly check that

$$\|w\|^2_A = \tilde{\lambda}^{(0)}_1 (w, \tilde{u}^0_1)^2 + \|w - (w, \tilde{u}^0_1)\tilde{u}^0_1\|^2_A. \tag{5.8}$$

It follows from (5.8) that

$$\tilde{\lambda}^{(0)}_1 = \min_{w \in H^1_0(\Omega),\ w \ne 0} \frac{\|w\|^2_A}{\|w\|^2_0} \le \frac{\|w\|^2_A}{\|w\|^2_0} \le \tilde{\lambda}^{(0)}_1 + \frac{\|w - (w, \tilde{u}^0_1)\tilde{u}^0_1\|^2_A}{\|w\|^2_0}. \tag{5.9}$$

On the other hand, one can show that

$$A(w - (w, \tilde{u}^0_1)\tilde{u}^0_1, \alpha\tilde{u}^0_1) = 0 \quad \forall \alpha \in R.$$

Hence

$$\begin{aligned} \|w - \tilde{u}^0_1\|^2_A &= \|w - (w, \tilde{u}^0_1)\tilde{u}^0_1\|^2_A + \|(w, \tilde{u}^0_1)\tilde{u}^0_1 - \tilde{u}^0_1\|^2_A \\ &\ge \|w - (w, \tilde{u}^0_1)\tilde{u}^0_1\|^2_A. \end{aligned}$$

From (5.9), we have

$$0 \le \frac{A(w, w)}{(w, w)} - \tilde{\lambda}^{(0)}_1 \le \frac{\|w - (w, \tilde{u}^0_1)\tilde{u}^0_1\|^2_A}{\|w\|^2_0} \le \frac{\|w - \tilde{u}^0_1\|^2_A}{\|w\|^2_0}.$$

Setting $w = R_h\tilde{u}_1^0$ in (5.5) and using (5.6), one can obtain

$$0 \le \tilde{\lambda}_{1,h}^{(0)} - \tilde{\lambda}_1^{(0)} \le \frac{\|R_h\tilde{u}_1^0 - \tilde{u}_1^0\|_A^2}{(R_h\tilde{u}_1^0, R_h\tilde{u}_1^0)}.$$

The proof of Theorem 5.1 is complete. □

THEOREM 5.2. *Let $(\tilde{\lambda}_1^{(0)}, \tilde{u}_1^0)$ and $(\tilde{\lambda}_{1,h}^{(0)}, \tilde{u}_{1,h}^0)$ be the first eigenpairs of problems* (4.3) *and* (5.2)*, respectively. If $\tilde{u}_1^0 \in H^{r+1}(\Omega)$, $S_0^h(\Omega)$ as indicated in* (5.1)*, then it holds that*

$$0 \le \tilde{\lambda}_{1,h}^{(0)} - \tilde{\lambda}_1^{(0)} \le Ch^{2r}. \tag{5.10}$$

Proof. It is well known that

$$\|R_h\tilde{u}_1^0 - \tilde{u}_1^0\|_0 \le Ch^2\|\tilde{u}_1^0\|_2,$$

$$\|R_h\tilde{u}_1^0 - \tilde{u}_1^0\|_A^2 \le Ch^{2r}\|\tilde{u}_1^0\|_{r+1}^2.$$

Choosing a sufficiently small $h > 0$ such that

$$\|R_h\tilde{u}_1^0\|_0 \ge \|\tilde{u}_1^0\|_0 - Ch^2\|\tilde{u}_1^0\|_2 \ge \frac{1}{2},$$

it follows from (5.7) that

$$0 \le \tilde{\lambda}_{1,h}^{(0)} - \tilde{\lambda}_1^{(0)} \le C \cdot h^{2r}\|\tilde{u}_1^0\|_{r+1}^2.$$

Now let us give some superconvergence estimates for the first eigenfunctions. For simplicity, set $\lambda = \tilde{\lambda}_1^{(0)}$, $\lambda_h = \tilde{\lambda}_{1,h}^{(0)}$, $u_h = \tilde{u}_{1,h}^0$; H_λ is the eigenspace of the operator $\widehat{\mathcal{L}}_{h_0}$ with respect to eigenvalue $\lambda = \tilde{\lambda}_1^{(0)}$. Define a projection operator $P : L^2(\Omega) \to H_\lambda$ such that

$$Pu = \sum_{i=1}^{l}(u, u_i)u_i, \tag{5.11}$$

where u_i, $i = 1, \ldots, l$, form a set of orthonormal basis of H_λ.

Let K be the inverse operator of $\widehat{\mathcal{L}}_{h_0}$; then K is a bounded self-adjoint compact operator due to Proposition 4.2.

LEMMA 5.1 (see [15]). *Let $R_h : H_0^1(\Omega) \to S_0^h(\Omega)$ be the Ritz–Galerkin projection operator, for $q_0 > 2$, $1 < q < q_0$; then it holds that*

$$\|\lambda_h R_h K - \lambda K\|_\infty \to 0 \quad as \quad h \to 0, \tag{5.12}$$

$$\|R_h K\|_\infty \le C. \tag{5.13}$$

LEMMA 5.2 (see [15]). *Let $u = Pu_h \in H_\lambda \subset W^{r+1,q}(\Omega)$, $q > 2$; then it holds that*

$$\|u\|_{r+1,q} \le C, \tag{5.14}$$

$$\|R_h K(I - R_h)u\|_\infty \le Ch^{r+2} \quad (r \ge 2). \tag{5.15}$$

THEOREM 5.3. *Let (λ, H_λ) be the solution of problem (4.3) and let (λ_h, V_λ) be the solution of problem (5.2), $V_\lambda \subset S_0^h(\Omega)$; if $H_\lambda \subset W^{r+1,q} \cap H_0^1(\Omega)$, $q > 2$, for any given $u_h \in V_\lambda$, then there exists $u \in H_\lambda$ such that*

$$\|R_h u - u_h\|_{0,\infty} \le Ch^{r+2} \quad (r \ge 2). \tag{5.16}$$

Proof. Set $u = Pu_h = \sum_{j=1}^{l}(u_h, u_i)u_i$, $\bar{u} = R_h u - u_h - P(R_h u - u_h)$. It is obvious that $(\bar{u}, u) = 0$ for any $u \in H_\lambda$, thus $\bar{u} \in H_\lambda^\perp$.

It follows from Fredholm's alternative theorem that the operator $(I - \lambda K)$ has a bounded inverse operator. Thus there exists a constant $\delta_0 > 0$ such that

$$\begin{aligned}
&\delta_0\|\bar{u}\|_{0,\infty} \le \|(I-\lambda K)\bar{u}\|_{0,\infty} = \|(I-\lambda K)(R_h u - u_h)\|_{0,\infty} \\
&= \|\lambda R_h K(I - R_h)u + (\lambda_h R_h K - \lambda K)(R_h u - u_h) \\
&\qquad + (\lambda - \lambda_h)R_h K R_h u\|_{0,\infty} \quad (\text{since } u_h = \lambda_h R_h K u_h, \quad u = \lambda K u) \\
&\le \lambda\|R_h K(I - R_h)u\|_{0,\infty} \\
&\quad + \|\lambda_h R_h K - \lambda K\|_\infty \|R_h u - u_h\|_{0,\infty} + Ch^{2r}.
\end{aligned} \tag{5.17}$$

Since $Pu - Pu_h = 0$,

$$\begin{aligned}
&\|P(R_h u - u_h)\|_{0,\infty} = \|P(R_h u - u)\|_{0,\infty} = \left\|\sum_{j=1}^{l}(R_h u - u, u_j)u_j\right\|_{0,\infty} \\
&\le \sum_{j=1}^{l}|(R_h u - u, u_j)|\|u_j\|_{0,\infty} = \sum_{j=1}^{l}\frac{1}{\lambda}|A(R_h u - u, u_j - u_j^I)|\|u_j\|_{0,\infty} \\
&\le Ch^{2r}\sum_{j=1}^{l}\|u\|_{r+1}\|u_j\|_{r+1}\|u_j\|_{0,\infty} \le Ch^{2r}\|u\|_{r+1}.
\end{aligned}$$

Using the triangle inequality, we have

$$\|R_h u - u_h\|_{0,\infty} \le \|\bar{u}\|_{0,\infty} + \|P(R_h u - u_h)\|_{0,\infty} \le \|\bar{u}\|_{0,\infty} + Ch^{2r}. \tag{5.18}$$

Substituting (5.17) into (5.18), one obtains

$$\begin{aligned}
&(1 - \tfrac{1}{\delta_0}\|\lambda_h R_h K - \lambda K\|_\infty)\|R_h u - u_h\|_{0,\infty} \\
&\le \tfrac{1}{\delta_0}\|R_h K(I - R_h)u\|_{0,\infty} + Ch^{2r}\|u\|_{r+1}.
\end{aligned}$$

Using Lemmas 5.1 and 5.2 and choosing a sufficiently small $h > 0$, we have

$$\frac{1}{2}\|R_h u - u_h\|_{0,\infty} \le Ch^{r+2}\|u\|_{r+1,q}. \qquad \square$$

Now we apply the above superconvergence results to implement the postprocessing technique of $D^\alpha \tilde{u}_k^0(x)$, where $\tilde{u}_k^0$ is the kth eigenfunction associated with problem (4.3), $k = 1, 2, \ldots$.

Using the nodal values of the bi-r-th finite element solution, we construct a bi-2r-th interpolation function at a new larger element with respect to a coarse mesh, which is called as the interpolated FEM refer to [15], as shown in Figures 5 and 6. Denote by $\mathcal{I}_{2h}^{(2r)}$ the bi-2r-th order interpolation operator.

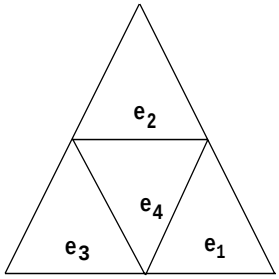

FIG. 5. *Triangular mesh.*

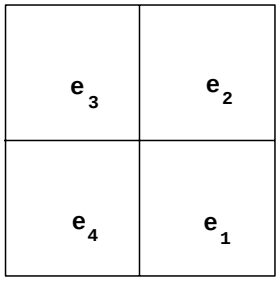

FIG. 6. *Rectangular mesh.*

LEMMA 5.3 (see [15]). *Let $\mathcal{I}_h : H^1(\Omega) \to S_0^h(\Omega)$ be a usual Lagrange interpolation operator; then the interpolation operators $\mathcal{I}_h$ and $\mathcal{I}_{2h}^{(2r)}$ satisfy the following properties:*

$$\|\mathcal{I}_{2h}^{(2r)}u\|_{m,p} \le C\|u\|_{m,p}, \quad 1 \le p \le \infty,\ m = 0, 1,\ \forall\, u \in S^h(\Omega_0), \tag{5.19}$$

where $C > 0$ does depend on r, p but does not depend on u, h;

$$(\mathcal{I}_{2h}^{(2r)})^2 = \mathcal{I}_{2h}^{(2r)}, \quad \mathcal{I}_{2h}^{(2r)}\mathcal{I}_h = \mathcal{I}_{2h}^{(2r)}, \quad \mathcal{I}_h\mathcal{I}_{2h}^{(2r)} = \mathcal{I}_h, \tag{5.20}$$

$$\forall\, P_i \in T_0^h,\ \mathcal{I}_{2h}^{(2r)}u(P_i) = \mathcal{I}_h u(P_i) = u(P_i), \quad u \in C(\bar{\Omega}_0), \tag{5.21}$$

where T_0^h is the set of nodal points of J^h restricted to $\overline{\Omega}_0$;

$$\|u - \mathcal{I}_{2h}^{(2r)}u\|_{m,p,E} \le Ch^{2r+1-m}\|u\|_{2r+1,p,E} \tag{5.22}$$

$$\forall u \in W^{2r+1,p}(E), \quad m = 0, 1,\ 1 \le p \le +\infty,\ \forall E \in J^{2h}|_{\Omega_0}.$$

THEOREM 5.4. *Assume that $(\tilde{\lambda}_k^{(0)}, \tilde{u}_k^0(x))$ is the kth eigenpair of problem (4.3) and $(\tilde{\lambda}_{k,h}^{(0)}, \tilde{u}_{k,h}^0(x))$ is its finite element approximate solution in $S_0^h(\Omega)$, and let $\Omega_0 \subset\subset \Omega' \subset\subset \Omega$ and let Ω' be covered by uniform rectangular meshes; then it holds that*

$$\|\tilde{u}_k^0(x) - \mathcal{I}_{2h}^{(2r)}\tilde{u}_{k,h}^0(x)\|_{0,\Omega_0} + h\|\tilde{u}_k^0(x) - \mathcal{I}_{2h}^{(2r)}\tilde{u}_{k,h}^0(x)\|_{1,\Omega_0} \le Ch^{r+2}, \tag{5.23}$$

where $C > 0$ is independent of $h, h_0, r \ge 2,\ k = 1, 2, \ldots$.

Proof. It follows from Lemma 5.3 that

$$\begin{aligned}
&\|\mathcal{I}_{2h}^{(2r)}\tilde{u}_k^0 - \mathcal{I}_{2h}^{(2r)}\tilde{u}_{k,h}^0\|_{1,\Omega_0} = \|\mathcal{I}_{2h}^{(2r)}(\mathcal{I}_h\tilde{u}_k^0 - \tilde{u}_{k,h}^0)\|_{1,\Omega_0} \\
&\le C\|\mathcal{I}_h\tilde{u}_k^0 - \tilde{u}_{k,h}^0\|_{1,\Omega_0} \le Ch^{r+1}\|\tilde{u}_k^0\|_{r+2,\Omega_0} \\
&+C\|\tilde{u}_k^0 - \tilde{u}_{k,h}^0\|_{-s,\Omega'} \le Ch^{r+1}\|\tilde{u}_k^0\|_{r+2,\Omega'}.
\end{aligned}$$

Thus

$$\|\tilde{u}_k^0 - \mathcal{I}_{2h}^{(2r)}\tilde{u}_{k,h}^0\|_{1,\Omega_0} \le \|\tilde{u}_k^0 - \mathcal{I}_{2h}^{(2r)}\tilde{u}_k^0\|_{1,\Omega_0} + \|\mathcal{I}_{2h}^{(2r)}\tilde{u}_k^0 - \mathcal{I}_{2h}^{(2r)}\tilde{u}_{k,h}^0\|_{1,\Omega_0} \le Ch^{r+1}\|\tilde{u}_k^0\|_{r+2,\Omega'}.$$

The remainder can similarly be proved. ∎

5.2. Finite element computation of the boundary layer. In practice, we need to solve the modified boundary layer as follows:

(5.24)
$$\begin{cases} \mathcal{L}_\varepsilon \tilde{W}_k^\varepsilon(x) \equiv -\dfrac{\partial}{\partial x_i}\left(a_{ij}\left(\dfrac{x}{\varepsilon}\right)\dfrac{\partial \tilde{W}_k^\varepsilon}{\partial x_j}\right) + \left(b\left(\dfrac{x}{\varepsilon}\right) - \tilde{\lambda}_{k,h}^{(0)}\rho\left(\dfrac{x}{\varepsilon}\right)\right)\tilde{W}_k^\varepsilon(x) = 0, \quad x \in \Omega_1, \\ \mathcal{B}_\varepsilon \tilde{W}_k^\varepsilon(x) = 0, \quad x \in \partial\Omega, \\ \tilde{W}_k^\varepsilon(x) = \tilde{u}_{k,h}^0(x), \quad x \in \partial\Omega_0, \end{cases}$$

where $(\tilde{\lambda}_{k,h}^{(0)}, \tilde{u}_{k,h}^0(x))$ is the finite element solution associated with $(\tilde{\lambda}_k^{(0)}, \tilde{u}_k^0(x))$ in $S_0^h(\Omega)$.

For the sake of simplicity, here assume that $\mathcal{B}_\varepsilon \equiv I$ is a Dirichlet boundary operator.

Let $\mathcal{F}^{h_1} = \{e\}$ be a family of regular triangulations of subdomain $\Omega_1 = \Omega \setminus \overline{\Omega}_0$ as shown in Figure 4. Let $h_1 = \max_{e\in\mathcal{F}^{h_1}}\{h_e\}$, $\frac{h_1}{\varepsilon^2} << 1$.

Define a piecewise linear finite element space as

$$S_{h_1}^\varepsilon(\Omega_1) = \{v \in C(\overline{\Omega}_1) : \quad v|_e \in P_1(e), \quad v|_{\partial\Omega\cup\partial\Omega_0} = 0\}. \tag{5.25}$$

From (3.25) and (5.24), one can easily check that

$$\begin{cases} -\dfrac{\partial}{\partial x_i}\left(a_{ij}\left(\dfrac{x}{\varepsilon}\right)\dfrac{\partial (W_k^\varepsilon - \tilde{W}_k^\varepsilon)}{\partial x_j}\right) + \left(b\left(\dfrac{x}{\varepsilon}\right) - \tilde{\lambda}_k^{(0)}\rho\left(\dfrac{x}{\varepsilon}\right)\right)(W_k^\varepsilon - \tilde{W}_k^\varepsilon)(x) \\ \qquad = \rho\left(\dfrac{x}{\varepsilon}\right)\left(\lambda_k^{(0)} - \tilde{\lambda}_{k,h}^{(0)}\right)\tilde{W}_k^\varepsilon, \quad x \in \Omega_1, \\ W_k^\varepsilon - \tilde{W}_k^\varepsilon(x) = 0, \quad x \in \partial\Omega, \\ W_k^\varepsilon - \tilde{W}_k^\varepsilon(x) = u_k^0(x) - \tilde{u}_{k,h}^0(x), \quad x \in \partial\Omega_0. \end{cases} \tag{5.26}$$

THEOREM 5.5. *Let $W_k^\varepsilon(x)$, $\tilde{W}_k^\varepsilon(x)$ be the weak solutions of problems* (3.25) *and* (5.24)*, respectively, and let $\tilde{W}_{k,h_1}^\varepsilon(x)$ be the finite element solution of $\tilde{W}_k^\varepsilon(x)$ in $S_{h_1}^\varepsilon(\Omega_1)$; then it holds that*

$$\|W_k^\varepsilon(x) - \tilde{W}_{k,h_1}^\varepsilon(x)\|_{1,p,\Omega_1} \le C\left\{\left(\frac{h_1}{\varepsilon^2}\right) + h_0 + h^r\right\}, \tag{5.27}$$

where C is a constant independent of ε, h_0, h, h_1, $1 < p \le p_0 < +\infty$, and h_0, h, h_1 are the mesh sizes associated with Q, Ω, Ω_1, respectively.

Proof. It follows from Theorem 3.3 and Theorem 5.2 that

$$\begin{aligned} &\|\tilde{W}_k^\varepsilon(x) - \tilde{W}_{k,h_1}^\varepsilon(x)\|_{1,p,\Omega_1} \le Ch_1\|\tilde{W}_k^\varepsilon\|_{2,p,\Omega_1} \\ &\le C\cdot\frac{h_1}{\varepsilon^2}\|\tilde{u}_{k,h}^0\|_{2,p,\Omega} \le C\cdot\frac{h_1}{\varepsilon^2}\|\tilde{u}_k^0\|_{2,p,\Omega_1}. \end{aligned} \tag{5.28}$$

On the other hand, it follows from (5.26), Theorem 4.1, Corollary 4.1, Theorem 5.2, and Theorem 5.3 that

$$\begin{aligned} \|W_k^\varepsilon(x) - \tilde{W}_k^\varepsilon(x)\|_{1,p,\Omega_1} &\le C\{\|u_k^0(x) - \tilde{u}_{k,h}^0(x)\|_{1,p,\Omega_1} \\ &+|\lambda_k^{(0)} - \tilde{\lambda}_{k,h}^{(0)}|\|\tilde{W}_k^\varepsilon(x)\|_{0,p,\Omega_1}\} \le C\{h^r + h_0\}. \end{aligned} \tag{5.29}$$

Combining (5.28) with (5.29) and using the triangle inequality, one can easily obtain (5.27).

6. Multiscale finite element algorithm and the postprocessing technique. To begin with, let us introduce the first order difference quotient as follows:

$$\delta_{x_i}\tilde{u}^0_{k,h}(N_p)=\frac{1}{\tau(N_p)}\sum_{e\in\sigma(N_p)}\left[\frac{\partial\tilde{u}^0_{k,h}}{\partial x_i}\right]_e(N_p), \tag{6.1}$$

where $\sigma(N_p)$ is the set of elements with node N_p, $\tau(N_p)$ is the number of elements of $\sigma(N_p)$, $\tilde{u}^0_{k,h}(x)$ is the finite element solution of $\tilde{u}^0_k(x)$ in $S^h_0(\Omega)$, and $[\frac{\partial\tilde{u}^0_{k,h}}{\partial x_i}]_e(N_p)$ is the value of the derivative $\frac{\partial\tilde{u}^0_{k,h}}{\partial x_i}$ at node N_p relative to element e.

Analogously, define any higher order difference quotients as follows:

$$\delta^l_{x_{\alpha_1}\cdots x_{\alpha_l}}\tilde{u}^0_{k,h}(N_p)=\frac{1}{\tau(N_p)}\sum_{e\in\sigma(N_p)}\left[\sum_{j=1}^{d}\delta^{l-1}_{x_{\alpha_1}\cdots x_{\alpha_{l-1}}}\tilde{u}^0_{k,h}(P_j)\frac{\partial\psi_j}{\partial x_{\alpha_l}}\right]_e(N_p), \tag{6.2}$$

where d is the number of nodes in e, P_j are the nodes of e, $\psi_j(x)$ are Lagrange's shape functions, $j=1,2,\ldots,d$.

Now let us give the multiscale finite element computing scheme:

$$U^{\varepsilon,h_0,h}_{k,M,h_1}(N_p)=\begin{cases}\tilde{u}^0_{k,h}(N_p)+\displaystyle\sum_{l=1}^{M}\varepsilon^l\sum_{\langle\alpha\rangle=l}N^{h_0}_{\alpha}(\xi(N_p))\delta^l_{x_{\alpha_1}\cdots x_{\alpha_l}}\tilde{u}^0_{k,h}(N_p), & N_p\in\overline{\Omega}_0,\\ W^{\varepsilon}_{k,h_1}(N_p), & N_p\in\Omega_1,\end{cases} \tag{6.3}$$

where the integer $M\geq 2$ and h_0,h,h_1 are the mesh parameters of Q, Ω, Ω_1, respectively.

The postprocessing computing scheme is presented for obtaining high accuracy:

$$\mathcal{P}U^{\varepsilon,h_0,h}_{k,M,h_1}(x)=\begin{cases}\mathcal{I}^{(2r)}_{2h}\tilde{u}^0_{k,h}(x)+\displaystyle\sum_{l=1}^{M}\varepsilon^l\sum_{\langle\alpha\rangle=l}N^{h_0}_{\alpha_1\cdots\alpha_l}(\xi)\delta^l_{x_{\alpha_1}\cdots x_{\alpha_l}}\mathcal{I}^{(2r)}_{2h}\tilde{u}^0_{k,h}(x), & x\in\overline{\Omega}_0,\\ \tilde{W}^{\varepsilon}_{k,h_1}(x), & x\in\Omega_1.\end{cases} \tag{6.4}$$

Finally, we will give the total error estimations.

THEOREM 6.1. *Let Ω be either a bounded smooth or a convex polygonal domain. With all assumptions as indicated above, it then holds that*

$$\|u^{\varepsilon}_k(x)-\mathcal{P}U^{\varepsilon,h_0,h}_{k,M,h_1}(x)\|_{0,\Omega_0}\leq C(\varepsilon^{M-1}+h_0^2+h^{2r-M}), \tag{6.5}$$

$$\|u^{\varepsilon}_k(x)-\tilde{W}^{\varepsilon}_{k,h_1}(x)\|_{0,p,\Omega_1}\leq C\left\{\varepsilon^{M-1}+h_0^2+h+\left(\frac{h_1}{\varepsilon^2}\right)\right\}, \tag{6.6}$$

where $C>0$ is a constant independent of ε, h_0, h, h_1; $\Omega_0\subset\subset\Omega$ is the union of periodic cells, $\Omega_1=\Omega\setminus\overline{\Omega}_0$; r denotes the degree of piecewise polynomials in $S^h_0(\Omega)$; h_0, h, h_1 are the mesh parameters of Q, Ω, Ω_1, respectively; and $M\geq 2$, $2r\geq M+1$, $0<h_1<<\varepsilon^2$, $1<p\leq p_0<+\infty$.

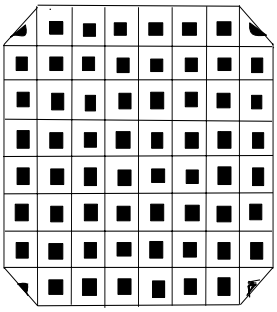

FIG. 7. *Domain* Ω.

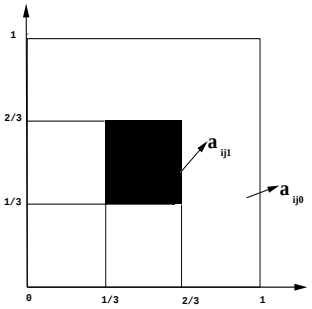

FIG. 8. *Unit cell* $Q = [0,1]^2$.

Proof. For $x \in \overline{\Omega}_0$, from (5.27), (3.25), (3.21), and (4.3), we obtain

$$u_k^\varepsilon(x) - \mathcal{P}U_{k,M,h_1}^{\varepsilon,h_0,h}(x) = u_k^\varepsilon(x) - u_k^{\varepsilon,M}(x) + u_k^{\varepsilon,M}(x) - \mathcal{P}U_{k,M,h_1}^{\varepsilon,h_0,h}(x)$$

$$= u_k^\varepsilon(x) - u_k^{\varepsilon,M}(x) + u_k^0(x) - \tilde{u}_k^0(x) + \tilde{u}_k^0(x) - \mathcal{I}_{2h}^{(2r)}\tilde{u}_{k,h}^0(x)$$

$$+ \sum_{l=1}^{M} \varepsilon^l \sum_{|\alpha|=l} (N_\alpha(\xi) - N_\alpha^{h_0}(\xi)) D^\alpha u_k^0(x) \tag{6.7}$$

$$+ \sum_{l=1}^{M} \varepsilon^l \sum_{|\alpha|=l} N_\alpha^{h_0}(\xi) D^\alpha (u_k^0(x) - \tilde{u}_k^0(x))$$

$$+ \textstyle\sum_{l=1}^{M} \varepsilon^l \sum_{|\alpha|=l} N_\alpha^{h_0}(\xi)(D^\alpha \tilde{u}_k^0(x) - \delta^l_{x_{\alpha_1}\cdots x_{\alpha_l}} \mathcal{I}_{2h}^{(2r)} \tilde{u}_{k,h}^0(x)).$$

It follows from Theorem 3.1, Theorem 4.1, Theorem 5.4, Proposition 4.1, and Theorem 4.2 that

$$\|u_k^\varepsilon(x) - \mathcal{P}U_{k,M,h_1}^{\varepsilon,h_0,h}(x)\|_{0,\Omega_0} \le C(\varepsilon^{M-1} + h_0^2 + h^{2r-M}).$$

On the other hand, for $x \in \Omega_1$, we have

$$u_k^\varepsilon(x) - \tilde{W}_{k,h_1}^\varepsilon(x) = u_k^\varepsilon(x) - W_k^\varepsilon(x) + W_k^\varepsilon(x) - \tilde{W}_{k,h_1}^\varepsilon(x). \tag{6.8}$$

It follows from Theorem 3.1 and Theorem 5.5 that

$$\|u_k^\varepsilon(x) - \tilde{W}_{k,h_1}^\varepsilon(x)\|_{0,p,\Omega_1} \le C\left\{\varepsilon^{M-1} + h_0^2 + h^r + \left(\frac{h_1}{\varepsilon^2}\right)\right\},$$

where $1 < p \le p_0 < +\infty$, $\Omega_1 = \Omega \setminus \overline{\Omega}_0$. ∎

7. Numerical results. In this section, we only consider the first eigenvalue and eigenfunction.

EXAMPLE 7.1. *We consider the following Helmholtz equation:*

$$\begin{cases} \mathcal{L}_\varepsilon u^\varepsilon \equiv -\dfrac{\partial}{\partial x_i}\left(a_{ij}\left(\dfrac{x}{\varepsilon}\right)\dfrac{\partial u^\varepsilon}{\partial x_j}\right) + b\left(\dfrac{x}{\varepsilon}\right)u^\varepsilon(x) = \lambda^\varepsilon \rho\left(\dfrac{x}{\varepsilon}\right)u^\varepsilon(x) \quad in \quad \Omega, \\ u^\varepsilon(x) = 0 \quad on \quad \partial\Omega, \end{cases} \tag{7.1}$$

where Ω *is as shown in Figure* 7*—note that* Ω *is not entire periodic domain. The unit cell* Q *is shown in Figure* 8, $\varepsilon = \frac{1}{8}$.

Case 1. $a_{ij0} = \delta_{ij}$, $a_{ij1} = 10.0\delta_{ij}$, $b(\frac{x}{\varepsilon}) = 30$, $\rho(\frac{x}{\varepsilon}) = 1$.
Case 2. $a_{ij0} = \delta_{ij}$, $a_{ij1} = \frac{1}{1000.0}\delta_{ij}$, $b(\frac{x}{\varepsilon}) = 30$, $\rho(\frac{x}{\varepsilon}) = 1$.
Case 3. $a_{ij0} = \delta_{ij}$, $a_{ij1} = \frac{1}{200.0}\delta_{ij}$, $b(\frac{x}{\varepsilon}) = 30$, $\rho(\frac{x}{\varepsilon}) = 1$.
Case 4. $a_{ij0} = \delta_{ij}$, $a_{ij1} = 200.0\delta_{ij}$, $b(\frac{x}{\varepsilon}) = 30$, $\rho(\frac{x}{\varepsilon}) = 1$.

Tables 1–3 show some numerical results. Where $e_0 = u^\varepsilon - u^0$, $e_1 = u^\varepsilon - U_1^\varepsilon$, $e_2 = u^\varepsilon - U_2^\varepsilon$, $u^0(x)$ is the finite element solution of the first eigenfunction for the homogenized Helmholtz equation, and $U_1^\varepsilon(x)$, $U_2^\varepsilon(x)$ are the first order and the second order multiscale finite element solutions calculated by multiscale finite element formulation (6.3), respectively. $u^\varepsilon(x)$, $U_2^\varepsilon(x)$, $U_1^\varepsilon(x)$, $e_2(x)$ are shown in Figure 9 and Figure 10.

Remark 7.1. It is worthwhile to notice that, in Case 1 and Case 4, errors e_2 for the second order method are larger than the error e_1 for the first order method, respectively. As we can judge, from the viewpoint of numerical computation, the reason is that if e_1 have had the better accuracy, then e_2 might become worse due to adding other items.

Concluding remarks. First of all, in this paper the main objectives are to obtain the multiscale asymptotic analysis formulas of eigenvalues and eigenfunctions of second order Helmholtz equation with rapidly oscillating coefficients over general bounded Lipschitz convex domains and to propose the multiscale finite element computing schemes and the postprocessing technique. Meanwhile, we derive their rigorous verifications.

Second, in solving the Helmholtz problems of composite media with a periodic structure by using multiscale numerical method, our work consists of the following parts:

(1) Compute the periodic solutions $N_{\alpha_1\cdots\alpha_l}(\xi)$, $l \geq 1$, in the unit cell Q.

(2) Solve the homogenized Helmholtz equation with constant coefficients over the whole domain Ω.

(3) Solve the boundary layer.

(4) Compute the higher order partial derivatives for eigenfunctions $u_k^0(x)$.

Third, from the viewpoint of mechanics, the work of this paper tell us some important facts:

(a) In the sense of given accuracy, the natural frequencies of the homogenized problem and the original linear problem are the same.

(b) According to the superposition priciple, the natural vibration modes consist of two parts: the natural vibration modes of the homogenized problem reflect the macroscopic behavior, and the periodic solutions $N_{\alpha_1\cdots\alpha_l}(\xi)$, $l \geq 1$, $\alpha_j = 1, \ldots, n$ describe the mesoscopic fluctuations of the natural vibration modes.

Finally, we would like to say that the method proposed in this paper can easily be extended into the elastic structures of composite materials with a small period. In the viewpoint of numerical computation, it is suitable for subdivided periodic structures and some random structures. We will discuss these problems in other papers.

Appendix A. The equivalence of two kinds of homogenization methods. In [2], we know that $\tilde{N}_{\alpha_1}(\xi)$ is defined in the following way:

$$\begin{cases} \dfrac{\partial}{\partial\xi_k}\left(a_{kj}(\xi)\dfrac{\partial\tilde{N}_{\alpha_1}(\xi)}{\partial\xi_j}\right) = -\dfrac{\partial}{\partial\xi_k}(a_{k\alpha_1}(\xi)) \quad \text{in} \quad R^n, \\ \tilde{N}_{\alpha_1}(\xi) \quad \text{is 1-periodic in } \xi, \\ \displaystyle\int_Q \tilde{N}_{\alpha_1}(\xi)d\xi = 0. \end{cases} \tag{A.1}$$

Define

$$V_{per} = \{v \in H^1(R^n) : \quad v(\xi) \quad \text{is 1-periodic in } \xi\}.$$

The variational form is the following:

$$\int_Q a_{kj}(\xi)\frac{\partial\tilde{N}_{\alpha_1}(\xi)}{\partial\xi_j}\frac{\partial\tilde{v}(\xi)}{\partial\xi_k}d\xi = -\int_Q a_{k\alpha_1}(\xi)\frac{\partial\tilde{v}(\xi)}{\partial\xi_k}d\xi,$$

i.e.,

$$\int_Q \left(a_{k\alpha_1}(\xi) + a_{kj}(\xi)\frac{\partial\tilde{N}_{\alpha_1}(\xi)}{\partial\xi_j}\right)\frac{\partial\tilde{v}(\xi)}{\partial\xi_k}d\xi = 0 \quad \forall \quad \tilde{v}(\xi) \in V_{per}. \tag{A.2}$$

On the other hand, from (3.12) we know that

$$\int_Q \left(a_{k\alpha_1}(\xi) + a_{kj}(\xi)\frac{\partial N_{\alpha_1}(\xi)}{\partial\xi_j}\right)\frac{\partial v(\xi)}{\partial\xi_k}d\xi = 0 \quad \forall \quad v(\xi) \in H_0^1(Q). \tag{A.3}$$

For the sake of simplicity, let $\tilde{v}(\xi) = e^{i2\pi m\cdot\xi}$ (in practice, we should choose $\tilde{v}(\xi) = \cos 2\pi m\cdot\xi, \sin 2\pi m\cdot\xi$), $v^{(k)}(\xi) = e^{i2\pi m\cdot\xi} - e^{i2\pi m\cdot\tilde{\xi}^{(k)}}$, where $m = (m_1, \ldots, m_k, \ldots, m_n) \in Z^n$, $\xi = (\xi_1, \ldots, \xi_k, \ldots, \xi_n)^T$, $\tilde{\xi}^{(k)} = (\xi_1, \ldots, \xi_{k-1}, 0, \xi_{k+1}, \ldots, \xi_n)^T$. One can directly check that $\tilde{v}(\xi) \in V_{per}$, $v^{(k)}(\xi) \in H_0^1(Q)$.

Set $\tilde{\Lambda}_{k\alpha_1}(\xi) = (a_{k\alpha_1}(\xi) + \sum_{j=1}^{n} a_{kj}(\xi)\frac{\partial \tilde{N}_{\alpha_1}(\xi)}{\partial \xi_j})$, $\Lambda_{k\alpha_1}(\xi) = (a_{k\alpha_1}(\xi) + \sum_{j=1}^{n} a_{kj}(\xi)\frac{\partial N_{\alpha_1}(\xi)}{\partial \xi_j}), \Theta_{k\alpha_1}(\xi) = \tilde{\Lambda}_{k\alpha_1}(\xi) - \Lambda_{k\alpha_1}(\xi)$.

Substituting $\tilde{v}(\xi), v^{(k)}(\xi)$ into (A.2), (A.3), respectively, one can obtain

$$\int_Q \tilde{\Lambda}_{k\alpha_1}(\xi) e^{i2\pi m\cdot\xi} d\xi = 0, \tag{A.4}$$

$$\int_Q \Lambda_{k\alpha_1}(\xi) e^{i2\pi m\cdot\xi} d\xi = 0, \tag{A.5}$$

i.e.,

$$\int_Q \Theta_{k\alpha_1}(\xi) e^{i2\pi m\cdot\xi} d\xi = 0 \quad \forall m \in Z^n. \tag{A.6}$$

Let

$$\Theta_{k\alpha_1}(\xi) = \sum_{q_1\cdots q_n=-\infty}^{+\infty} \widehat{\Theta}_{k\alpha_1}(q)\cdot e^{-i2\pi q\cdot\xi}. \tag{A.7}$$

Substituting (A.7) into (A.6), we obtain

$$\sum_{q_1,\cdots q_n=-\infty}^{+\infty} \widehat{\Theta}_{k\alpha_1}(q) \int_Q e^{-i2\pi(q-m)\cdot\xi} d\xi = 0. \tag{A.8}$$

Hence

$$\widehat{\Theta}_{k\alpha_1}(m) = 0 \quad \forall m \in Z^n.$$

This implies that

$$\Theta_{k\alpha_1}(\xi) = 0.$$

Therefore

$$\begin{aligned} \hat{a}_{k\alpha_1} &= \int_Q \left(a_{k\alpha_1}(\xi) + \sum_{j=1}^{n} a_{kj}(\xi)\frac{\partial N_{\alpha_1}(\xi)}{\partial \xi_j} \right) d\xi \\ &= \int_Q \left(a_{k\alpha_1}(\xi) + \sum_{j=1}^{n} a_{kj}(\xi)\frac{\partial \tilde{N}_{\alpha_1}(\xi)}{\partial \xi_j} \right) d\xi = \hat{\tilde{a}}_{k\alpha_1}, \quad k, \alpha_1 = 1, 2, \ldots, n. \end{aligned} \tag{A.9}$$

Appendix B. Two useful properties of the first eigenvalue and eigenfunction for the homogenized Helmholtz equation in some cases.

LEMMA B.1 (see [5]). *Assume that Ω is a bounded smooth domain, and let $(\lambda_1^{(0)}, u_1^0(x))$ be the first eigenpair of the homogenized Helmholtz problem (3.21); then it holds that $u_1^0(x)$ is a smooth function in Ω such that $u_1^0(x) \neq 0$ in Ω and $|\nabla u_1^0(x)| \neq 0$ in a neighborhood of $\partial\Omega$.*

PROPOSITION B.1. *Under the assumptions of Lemma B.1, one can prove that the first eigenvalue $\lambda_1^{(0)}$ of problem (3.21) is simple, and the corresponding eigenfunction $u_1^0(x)$ has a constant sign in Ω and is unique up to a constant factor.*

Proof. Set

$$V = \left\{ u \in H^1(\Omega), \langle \rho \rangle \int_\Omega |u(x)|^2 dx = 1 \right\},$$

$$D(u) = \int_\Omega \left(\hat{a}_{ij} \frac{\partial u}{\partial x_i} \frac{\partial u}{\partial x_j} + \langle b \rangle u^2 \right) dx. \tag{B.1}$$

Let $\lambda_1^{(0)} = \inf_{u \in V} D(u)$, $u_1^0(x)$ be a function giving the minimal value. Since $|u_1^{(0)}(x)| \in V$, if $u_1^0(x) \in V$, and $D(|u_1^0|) = D(u_1^0)$, then the function $|u_1^0(x)|$ is an eigenfunction corresponding to the eigenvalue $\lambda = \lambda_1^{(0)}$. It follows from Lemma B.1 that $|u_1^0(x)|$ does not vanish anywhere in Ω.

Next let $\bar{u}_1^0(x)$ be another eigenfunction corresponding to $\lambda_1^{(0)}$. Using Schmidt's technique and substituting $\bar{u}_1^0(x)$ by the function $\hat{u}_1^0(x) = \bar{u}_1^0(x) + \tau \cdot u_1^0(x)$, we can have that the function $\hat{u}_1^0(x)$ is orthogonal to $u_1^0(x)$; i.e., $\int_\Omega \hat{u}_1^0(x) \cdot u_1^0(x) dx = 0$ and $\langle \rho \rangle \int_\Omega |\hat{u}_1^0(x)|^2 dx = 1$. Since $u_1^0(x) > 0$ in Ω, the function $\hat{u}_1^0(x)$ changes its sign in Ω. However, $|\hat{u}_1^0(x)|$ is an eigenfunction with respect to $\lambda_1^{(0)}$, and $|\hat{u}_1^0(x)|$ vanishes at an inner point of Ω; it follows from Lemma B.1 that $\hat{u}_1^0(x) \equiv 0$.

The proof of Proposition B.1 is complete. ∎

PROPOSITION B.2. *Under the assumptions of Proposition* B.1*, if we consider the first eigenvalue* $\lambda_1^{(0)}$ *of* (3.21)*, then it holds that*

$$\left(\lambda_1^{(0)} \right)^{-1} \notin \sigma_d(\mathcal{K}_\varepsilon). \tag{B.2}$$

Proof. Given $\Omega_1 \subset\subset \Omega$ and $meas(\Omega \setminus \overline{\Omega}_1) = meas(\Omega_0) > 0$, denote by $\lambda_1^{(0)}(\Omega)$, $\tilde{\lambda}_1^{\varepsilon}(\Omega_1)$ the first eigenvalues associated with problem (3.21) and operator $\mathcal{Q}_\varepsilon$ of (3.27), respectively. The variational principle implies that $\lambda_1^{(0)}(\Omega) \le \tilde{\lambda}_1^{\varepsilon}(\Omega_1)$. Suppose that $\lambda_1^0(\Omega) = \tilde{\lambda}_1^{\varepsilon}(\Omega_1) = \lambda$. Then the eigenfunction corresponding to $\mathcal{Q}_\varepsilon$ with eigenvalue λ expanded by zero values on $\Omega \setminus \Omega_1$ is an eigenfunction in Ω. However, it vanishes at some points of Ω, contrary to the result of Lemma B.1.

The proof of Proposition B.2 is complete. ∎

Appendix C. Regularity results of the solution for the boundary layer. For the sake of simplicity, now we consider only 2-D problems; for the detailed discussion of three-dimensional problems, we refer to [10].

To begin with, consider the following boundary value problems over concave domain $\Omega_1 \subset R^2$, as shown in Figure 2:

$$\begin{cases} -\triangle u = f(x) & \text{in} \quad \Omega_1, \\ u(x) = 0 & \text{on} \quad \partial\Omega_1. \end{cases} \tag{C.1a}$$

Let $\{\sigma_j\}_{j=1}^N$ denote the angular points of Ω_1 and $\beta_j \pi$, $j = 1, \ldots, N$, are the corresponding internal angles, i.e.,

$$\beta_1 \le \beta_2 \le \cdots \le \beta_N, \quad \gamma_j = \frac{1}{\beta_j}.$$

It is obvious that $1 < \beta_N \le 2$, $\frac{1}{2} \le \gamma_N < 1$. Suppose that

$$V_j = \{x \in \Omega_1 : |x - \sigma_j| < r_j\}, \quad j = 1, \ldots, N, \tag{C.1b}$$

satisfy

$$V_i \cap V_j = \emptyset, \quad V_0 = \Omega_1 \setminus \cup_{j=1}^{N} \overline{V}_j. \tag{C.1c}$$

LEMMA C.1 (see [10]). *Suppose that u is the unique solution of problem* (C.1a); *if $f \in L^2(\Omega)$, then it holds that*

$$u(x) = \sum_{j=1}^{N} c_j(f) u_j + U(x), \tag{C.2}$$

where $U(x) \in H^2(\Omega_1) \cap H_0^1(\Omega_1)$, $\|U\|_2 \le C\|f\|_0$, and the constants $c_j(f)$ satisfy $|c_j(f)| \le C\|f\|_0$.

Note that u_j are some functions independent of f, u that satisfy the following conditions:

(B_1) *If $\gamma_j > 1$, then $u_j(x) \equiv 0$. In addition, $u_j(x) \equiv 0$ outside of V_j.*

(B_2) *If $\frac{1}{2} < \gamma_j < 1$, then there exists the following formula in a neighborhood of σ_j:*

$$u_j = \rho^{\gamma_j} \sin \gamma_j \theta \quad \text{if} \quad (\rho, \theta) \in V_j, \tag{C.3}$$

where $V_j = \{(\rho, \theta) : 0 < \rho < r_j, 0 < \theta < \beta_j \pi\}$.

Remark C.1. By virtue of (C.3), one can easily show that

$$|D^k u| \le C\rho^{\gamma_j - |k|} \tag{C.4}$$

in a neighborhood of σ_j.

Let us turn to the proof of Theorem 3.3. It follows from the finite covering theorem that there exist finite points $P_1, \ldots, P_s$ and the corresponding neighborhoods $\mathcal{O}_l$, $l = 1, \ldots, s$, such that

(i) $\cup_{l=1}^{s} \mathcal{O}_l \supset \overline{\Omega}_1$;

(ii) $diam(\mathcal{O}_l) \le \varepsilon R_0$, R_0 will be chosen later;

(iii) $\mathcal{I}_i = \{j : \mathcal{O}_j \cap \mathcal{O}_i \ne \emptyset, \}$, $\sigma(\mathcal{I}_i) \le s_0$, where $\sigma(\mathcal{I}_i)$ denote the number of elements in $\mathcal{I}_i$, $i = 1, \ldots, t$ and s_0 is a constant.

From the partition of unity theorem, there exist $\phi_l \in C_0^\infty(R^n)$, $l = 1, \ldots, s$, such that $0 \le \phi_l \le 1, \text{supp}\phi_l \subset \mathcal{O}_l$, and

$$\sum_{l=1}^{s} \phi_l \equiv 1 \quad \text{in} \quad \Omega_1.$$

Let $\mathcal{A}_\varepsilon \cdot = -\frac{\partial}{\partial x_i}(a_{ij}(\frac{x}{\varepsilon})\frac{\partial}{\partial x_j})\cdot$, $W^\varepsilon = \sum_{l=1}^{s} W_l^\varepsilon$, $W_l^\varepsilon = \phi_l \cdot W^\varepsilon$,

$$\mathcal{A}_\varepsilon W_l^\varepsilon = \phi_l \cdot \mathcal{A}_\varepsilon W^\varepsilon + \eta_l, \tag{C.5}$$

where

$$\begin{aligned} \eta_l = & -\frac{\partial \phi_l}{\partial x_j}\left[\frac{\partial}{\partial x_i}\left(a_{ij}\left(\frac{x}{\varepsilon}\right)\right) W^\varepsilon + a_{ij}\left(\frac{x}{\varepsilon}\right)\frac{\partial W^\varepsilon}{\partial x_j}\right] \\ & -a_{ij}\left(\frac{x}{\varepsilon}\right)\left[\frac{\partial \phi_l}{\partial x_i}\frac{\partial W^\varepsilon}{\partial x_j} + W^\varepsilon \frac{\partial^2 \phi_l}{\partial x_i \partial x_j}\right] \end{aligned} \tag{C.6}$$

and

$$\|\eta_l\|_{0,p,\mathcal{O}_l\cap\Omega_1} \le C\frac{1}{\varepsilon^2}\|W^\varepsilon\|_{1,p,\mathcal{O}_l\cap\Omega_1}. \tag{C.7}$$

$\forall R>0$, let

$$\omega_\varepsilon(R)=\max_{i,j}\max_{|x-x'|<\varepsilon R}\left|a_{ij}\left(\frac{x}{\varepsilon}\right)-a_{ij}\left(\frac{x'}{\varepsilon}\right)\right|,\quad x,x'\in\Omega_1.$$

For any fixed $x_0\in\mathcal{O}_l\cap\Omega_1$, set $A^\varepsilon=(a_{ij}(\frac{x_0}{\varepsilon}))$; it follows from (A_3) that there exists a orthogonal matrix T such that

$$TA^\varepsilon T'=\begin{pmatrix}\lambda_1 & 0\\ 0 & \lambda_2\end{pmatrix}=D,$$

where T' denotes the transpose of matrix T.

From (A_2), we know $\lambda_i\ge\sigma>0$, $i=1,2$, and let $B=\ D^{-1/2}T$; then $BA^\varepsilon B'=I$ and $\|B\|\le\sqrt{\|D^{-1}\|}\le\sqrt{\frac{1}{\sigma}}$,

$$\|B^{-1}\|=\|D^{1/2}\|\le\sum_{i=1}^{2}\lambda_i=\sum_i a_{ii}\left(\frac{x_0}{\varepsilon}\right)\le M_0,$$

where M_0 is a positive constant independent of ε.

If we let $\hat{\mathcal{O}}_l=B(\mathcal{O}_l\cap\Omega_1)$, then $\hat v(y)=v(B^{-1}y)\in W^{2,p}(\hat{\mathcal{O}}_l)$ for any $v\in W^{2,p}(\mathcal{O}_l\cap\Omega_1)$, where p will be stated below. We have that

$$C\|v\|_{2,p,\mathcal{O}_l\cap\Omega_1}\le\|\hat v\|_{2,p,\hat{\mathcal{O}}_l}\le C'\|v\|_{2,p,\mathcal{O}_l\cap\Omega_1}. \tag{C.8}$$

Let

$$\begin{aligned}g(x)&=-a_{ij}\left(\frac{x_0}{\varepsilon}\right)\frac{\partial^2 W_l^\varepsilon}{\partial x_i\partial x_j}=-\left(a_{ij}\left(\frac{x_0}{\varepsilon}\right)-a_{ij}\left(\frac{x}{\varepsilon}\right)\right)\frac{\partial^2 W_l^\varepsilon}{\partial x_i\partial x_j}-a_{ij}\left(\frac{x}{\varepsilon}\right)\frac{\partial^2 W_l^\varepsilon}{\partial x_i\partial x_j}\\ &=-\left(a_{ij}\left(\frac{x_0}{\varepsilon}\right)-a_{ij}\left(\frac{x}{\varepsilon}\right)\right)\frac{\partial^2 W_l^\varepsilon}{\partial x_i\partial x_j}+\phi_l(x)\left(\lambda^0\rho\left(\frac{x}{\varepsilon}\right)-b\left(\frac{x}{\varepsilon}\right)\right)\cdot W^\varepsilon(x)\\ &\quad+\eta_l(x)+\frac{\partial}{\partial x_i}\left(a_{ij}\left(\frac{x}{\varepsilon}\right)\right)\frac{\partial W_l^\varepsilon}{\partial x_j}.\end{aligned}$$

From (C.7), we obtain

$$\|g\|_{0,p,\mathcal{O}_l\cap\Omega_1}\le\omega_\varepsilon(R)\|W_l^\varepsilon\|_{2,p,\mathcal{O}_l\cap\Omega_1}+C\frac{1}{\varepsilon^2}\|W^\varepsilon\|_{1,p,\mathcal{O}_l\cap\Omega_1}. \tag{C.9}$$

On the other hand, set $\hat W_l^\varepsilon(y)=W_l^\varepsilon(B^{-1}y)$, $\quad\hat g(y)=g(B^{-1}y)$; then

$$a_{ij}\left(\frac{x_0}{\varepsilon}\right)\frac{\partial^2 W_l^\varepsilon}{\partial x_i\partial x_j}=\triangle\hat W_l^\varepsilon(y),\quad y=Bx.$$

Thus

$$\triangle\hat W_l^\varepsilon(y)=\hat g(y).$$

It follows from Lemma C.1 that

$$\|\hat{W}_l^\varepsilon\|_{2,p,\hat{\mathcal{O}}_l} \le C(p)\|\triangle \hat{W}_l^\varepsilon\|_{0,p,\hat{\mathcal{O}}_l} \le C(p)\|\hat{g}\|_{0,p,\hat{\mathcal{O}}_l}, \tag{C.10}$$

where $1 < p \le p_0 = \frac{2\beta_N}{2\beta_N - 1} < +\infty$ and β_N is the maximum internal angle of $B\Omega_1$.

From (C.8), (C.9), and (C.10), one obtains

$$\|W_l^\varepsilon\|_{2,p,\mathcal{O}_l\cap\Omega_1} \le C(p)\left\{\omega_\varepsilon(R)\|W_l^\varepsilon\|_{2,p,\mathcal{O}_l\cap\Omega_1} + \frac{1}{\varepsilon^2}\|W^\varepsilon\|_{1,p,\mathcal{O}_l\cap\Omega_1}\right\}.$$

Since $a_{ij}(\frac{x}{\varepsilon}) \in C(\overline{\Omega})$, $\nabla_\xi a_{ij}(\xi) \in L^\infty(\Omega)$; then there exists a constant $R_0 > 0$ such that

$$\omega_\varepsilon(R) < \frac{1}{3C(p)} \quad \text{for} \quad 0 < R < R_0.$$

Hence,

$$\begin{aligned}\|W_l^\varepsilon\|_{2,p,\mathcal{O}_l\cap\Omega_1} &\le C(p)\varepsilon^{-2}\{\|W_l^\varepsilon\|_{1,p,\mathcal{O}_l\cap\Omega_1} + \|u^0\|_{2,p,\mathcal{O}_l\cap\Omega_1}\}\\ &\le C(p)\varepsilon^{-2}\|u^0\|_{2,p,\mathcal{O}_l\cap\Omega_1}.\end{aligned}$$

Therefore

$$\begin{aligned}\|W^\varepsilon\|_{2,p,\Omega_1} &= \left\|\sum_{l=1}^s W_l^\varepsilon\right\|_{2,p,\Omega_1} \le \sum_{l=1}^s \|W_l^\varepsilon\|_{2,p,\mathcal{O}_l\cap\Omega_1}\\ &\le C(p)\varepsilon^{-2}\|u^0\|_{2,p,\Omega}.\end{aligned}$$

Appendix D. The difference between the eigenvalues and eigenfunctions of the homogenized Helmholtz equation (3.21) and those of the modified homogenized Helmholtz equation (4.3). Here we formulate some results in the spectral theory of linear abstract operators, which are useful for applications considered below.

Let $\mathcal{H}_\tau$, $0 < \tau \le 1$, be a family of Hilbert spaces with scalar products $(u, v)_{\mathcal{H}_\tau}$, and let $\mathcal{H}_0$ be a Hilbert space with a scalar product $(u, v)_{\mathcal{H}_0}$. Consider bounded linear operators $\mathcal{A}_\tau : \mathcal{H}_\tau \to \mathcal{H}_\tau$, $\mathcal{A}_0 : \mathcal{H}_0 \to \mathcal{H}_0$. We assume that spaces $\mathcal{H}_\tau$, $\mathcal{H}_0$ and operators $\mathcal{A}_\tau$, $\mathcal{A}_0$ are subject to the following conditions:

(I) There exist continuous linear operators $\mathcal{R}_\tau : \mathcal{H}_0 \to \mathcal{H}_\tau$ such that

$$\|\mathcal{R}_\tau u\|_{\mathcal{H}_\tau} \le c_0\|u\|_{\mathcal{H}_0} \quad \forall u \in \mathcal{H}_0, \tag{D.1}$$

where the constant c_0 is independent of τ; moreover,

$$\lim_{\tau\to 0}(u^\tau, v^\tau)_{\mathcal{H}_\tau} = (u^0, v^0)_{\mathcal{H}_0} \tag{D.2}$$

provided that

$$\lim_{\tau\to 0}\|u^\tau - \mathcal{R}_\tau u^0\|_{\mathcal{H}_\tau} = 0, \quad \lim_{\tau\to 0}\|v^\tau - \mathcal{R}_\tau v^0\|_{\mathcal{H}_\tau} = 0,$$

$$u^\tau, \quad v^\tau \in \mathcal{H}_\tau, \quad u^0, \quad v^0 \in \mathcal{H}_0.$$

(II) The operators $\mathcal{A}_\tau$, $\mathcal{A}_0$ are positive, compact, and self-adjoint, and the norms $\|\mathcal{A}_\tau\| = \|\mathcal{A}_\tau\|_{\mathcal{L}(\mathcal{H}_\tau)}$ are bounded by a constant independent of τ.

(III) If $f^\tau \in \mathcal{H}_\tau$, $f^0 \in \mathcal{H}_0$, and

$$\lim_{\tau\to 0} \|f^\tau - \mathcal{R}_\tau f^0\|_{\mathcal{H}_\tau} = 0, \tag{D.3}$$

then

$$\lim_{\tau\to 0} \|\mathcal{A}_\tau f^\varepsilon - \mathcal{R}_\tau \mathcal{A}_0 f^0\|_{\mathcal{H}_\tau} = 0. \tag{D.4}$$

(IV) For any sequence $f^\tau \in \mathcal{H}_\tau$ such that $\sup_\tau \|f^\tau\|_{\mathcal{H}_\tau} < \infty$, there exists a subsequence $f^{\tau'}$ and a vector $w^0 \in \mathcal{H}_0$ such that

$$\|\mathcal{A}_{\tau'} f^{\tau'} - \mathcal{R}_{\tau'} w^0\|_{\mathcal{H}_{\tau'}} \to 0 \quad \text{as} \quad \tau' \to 0. \tag{D.5}$$

Consider the spectral problems for the operators $\mathcal{A}_\tau$:

$$\begin{aligned} &u_\tau^k \in \mathcal{H}_\tau, \quad \mathcal{A}_\tau u_\tau^k = \mu_\tau^k u_\tau^k, \quad k = 1, 2, \dots, \\ &\mu_\tau^1 \ge \mu_\tau^2 \ge \cdots \ge \mu_\tau^k, \quad \mu_\tau^k > 0, \\ &(u_\tau^l, u_\tau^m) = \delta_{lm}, \end{aligned} \tag{D.6}$$

and consider the spectral problem for $\mathcal{A}_0$:

$$\begin{aligned} &u_0^k \in \mathcal{H}_0, \quad \mathcal{A}_0 u_0^k = \mu_0^k u_0^k, \quad k = 1, 2, \dots, \\ &\mu_0^1 \ge \mu_0^2 \ge \cdots \ge \mu_0^k, \quad \mu_0^k > 0, \\ &(u_0^l, u_0^m) = \delta_{lm}, \end{aligned} \tag{D.7}$$

where δ_{lm} is the Kronecker symbol.

LEMMA D.1 (see [11, 18]). *Let the space $\mathcal{H}_\tau, \mathcal{H}_0$ and operators $\mathcal{A}_\tau, \mathcal{A}_0$ satisfy conditions* (I)–(IV); *then for sufficiently small τ*

$$|\mu_\tau^k - \mu_0^k| \le 2 \sup_{u\in N(\mu_0^k, \mathcal{A}_0),\ \|u\|_{\mathcal{H}_0}=1} \|\mathcal{A}_\tau \mathcal{R}_\tau u - \mathcal{R}_\tau \mathcal{A}_0 u\|_{\mathcal{H}_\tau}, \quad k = 1, 2, \dots, \tag{D.8}$$

where μ_τ^k, μ_0^k are eigenvalues of problems (D.6) *and* (D.7), *respectively. $N(\mu_0^k, \mathcal{A}_0) = \{u \in \mathcal{H}_0, \mathcal{A}_0 u = \mu_0^k u\}$ is the eigenspace of operator $\mathcal{A}_0$ corresponding to the eigenvalue μ_0^k.*

LEMMA D.2 (see [11, 18]). *Assume that $k \ge 1$, $t \ge 1$ are integers, and*

$$\mu_0^{k-1} > \mu_0^k = \cdots = \mu_0^{k+t-1} > \mu_0^{k+t}, \tag{D.9}$$

i.e., the multiplicity of the eigenvalue μ_0^k is equal to t (here $\mu_0^0 = \infty$). Then for any $w \in N(\mu_0^k, \mathcal{A}_0)$, $\|w\|_{\mathcal{H}_0} = 1$, there exists a linear combination $\bar{u}_\tau$ of eigenvectors $u_\tau^k \cdots u_\tau^{k+t-1}$ of problem (D.6) *such that*

$$\|\bar{u}_\tau - \mathcal{R}_\tau w\|_{\mathcal{H}_\tau} \le M_k \|\mathcal{A}_\tau \mathcal{R}_\tau w - \mathcal{R}_\tau \mathcal{A}_0 w\|_{\mathcal{H}_\tau}, \tag{D.10}$$

where the constant M_k does not depend on τ.

Next let us turn to the proof of Theorem 4.1.

Proof. In Lemmas D.1 and D.2, choose $0 < \tau = h_0 << 1$, $\mathcal{H}_{h_0} = \mathcal{H}_0 = L^2(\Omega)$; $\mathcal{R}_{h_0} \equiv I$ is an identity operator.

For the sake of convenience, we prove that (4.8), (4.9) are valid for Dirichlet's boundary conditions, i.e., $\mathcal{B}_{h_0} \equiv I$.

Define the operators $\mathcal{A}_{h_0} : \mathcal{H}_{h_0} \to \mathcal{H}_{h_0}$ setting $\mathcal{A}_{h_0} f^{h_0} = w^{h_0}$, where w^{h_0} is the weak solution of the following problem:

$$\begin{cases} \widehat{\mathcal{L}}_{h_0} w^{h_0} = f^{h_0} & \text{in} \quad \Omega, \\ w^{h_0} = 0 & \text{on} \quad \partial\Omega, \end{cases} \tag{D.11}$$

where $w^{h_0} \in H^1(\Omega)$, $f^{h_0} \in L^2(\Omega)$.

It follows from Proposition 4.2 that the norm $\|\mathcal{A}_{h_0}\|$ is bounded. The compactness of the operator $\mathcal{A}_{h_0} : \mathcal{H}_{h_0} \to \mathcal{H}_{h_0}$ is due to the compact imbedding $H_0^1(\Omega) \subset L^2(\Omega)$. The fact that $\widehat{\mathcal{L}}_{h_0}$ is symmetric guarantees that $\mathcal{A}_{h_0}$ is a self-adjoint operator in $\mathcal{H}_{h_0}$, since

$$\begin{aligned} &(\mathcal{A}_{h_0} f^{h_0}, g^{h_0})_{\mathcal{H}_{h_0}} = (\mathcal{A}_{h_0} f^{h_0}, g^{h_0})_{L^2(\Omega)} = (w^{h_0}, g^{h_0})_{L^2(\Omega)} \\ &= (w^{h_0}, \widehat{\mathcal{L}}_{h_0} v^{h_0})_{L^2(\Omega)} = (\widehat{\mathcal{L}}_{h_0} w^{h_0}, v^{h_0})_{L^2(\Omega)} = (f^{h_0}, \mathcal{A}_{h_o} g^{h_0})_{L^2(\Omega)}, \end{aligned} \tag{D.12}$$

where $w^{h_0} = \mathcal{A}_{h_0} f^{h_0}$, $v^{h_0} = \mathcal{A}_{h_0} g^{h_0}$.

Below we need to verify that conditions (I)–(IV) are valid on purpose to use Lemmas D.1 and D.2.

It is easy to see that condition (I) is valid due to $\mathcal{R}_{h_0} \equiv I$.

In a similar way, we define the operator $\mathcal{A}_0 : \mathcal{H}_0 \to \mathcal{H}_0$ by $\mathcal{A}_0 f = w$, where w is the solution of the following Dirichlet problem:

$$\begin{cases} \widehat{\mathcal{L}} w = f & \text{in} \quad \Omega, \\ w = 0 & \text{on} \quad \partial\Omega, \end{cases} \tag{D.13}$$

where $w \in H_0^1(\Omega)$, $f \in L^2(\Omega)$.

Thus condition (II) has also been verified.

From (D.11) and (D.13), one obtains

$$-\frac{\partial}{\partial x_i}\left(\hat{a}_{ij}^{h_0} \frac{\partial (w^{h_0} - w)}{\partial x_j}\right) = -\frac{\partial}{\partial x_i}\left(\hat{r}_{ij} \frac{\partial w}{\partial x_j}\right) - \langle b \rangle (w^{h_0} - w) + f^{h_0}(x) - f(x), \tag{D.14}$$

where $\hat{r}_{ij} = \hat{a}_{ij}^{h_0} - \hat{a}_{ij}$.

Since $w^{h_0}(x) - w(x) \in H_0^1(\Omega)$, it follows from Proposition 4.2 and the Poincaré–Friedrichs inequality that

$$\begin{aligned} &\|w^{h_0} - w\|_{1,\Omega}^2 \le C a(w^{h_0} - w, w^{h_0} - w) \\ &\le C \int_\Omega \hat{r}_{ij} \frac{\partial w}{\partial x_j} \cdot \frac{\partial (w^{h_0} - w)}{\partial x_i} dx + C \int_\Omega (f^{h_0} - f) \cdot (w^{h_0} - w) dx \\ &\le C h_0^2 \|N_i\|_{2,Q} \|N_j\|_{2,Q} \|w\|_{1,\Omega} \|w^{h_0} - w\|_{1,\Omega} \\ &+ C \|f^{h_0} - f\|_{0,\Omega} \|w^{h_0} - w\|_{0,\Omega}. \end{aligned} \tag{D.15}$$

Thus

$$\|w^{h_0} - w\|_{1,\Omega} \le C h_0^2 \|N_i\|_{2,Q}^2 \|w\|_{1,\Omega} + C \|f^{h_0} - f\|_{0,\Omega}. \tag{D.16}$$

If $f^{h_0} \to f$ in $L^2(\Omega)$ as $h_0 \to 0$, by using (D.16) we have

$$w^{h_0} \to w \quad \text{in} \quad H_0^1(\Omega) \quad \text{as} \quad h_0 \to 0 \tag{D.17}$$

Therefore condition (III) holds, too.

Returning to condition (IV), for any sequence $f^{h_0} \in L^2(\Omega)$

$$\sup_{h_0} \|f^{h_0}\|_{L^2(\Omega)} < \infty.$$

Since $L^2(\Omega)$ is a reflexive Hilbert space, it follows from Eberlein's theorem that there exists a subsequence $f^{h_0'} \in L^2(\Omega)$ such that $f^{h_0'} \overset{w}{\rightharpoonup} f \in L^2(\Omega)$. Similarly to (D.15), one can obtain

$$\begin{aligned} &\|w^{h_0'} - w\|_{1,\Omega}^2 \le Ca(w^{h_0'} - w, w^{h_0'} - w) \\ &\le C \int_\Omega \hat{r}_{ij} \frac{\partial w}{\partial x_j} \frac{\partial (w^{h_0'} - w)}{\partial x_j} dx + C \int_\Omega (f^{h_0'} - f) \cdot (w^{h_0'} - w) dx \\ &= J_1 + J_2. \end{aligned} \tag{D.18}$$

$J_1 \to 0$ as $h_0 \to 0$ is due to the fact $\|\hat{r}_{ij}\|_F \le Ch_0^2 \|N_i\|_{2,Q} \|N_j\|_{2,Q}$. Since $f^{h_0'} \overset{w}{\rightharpoonup} f \in L^2(\Omega)$ as $h_0' \to 0$, then $J_2 \to 0$ as $h_0' \to 0$. Thus $w^{h_0'} \to w$ in $H^1(\Omega)$ as $h_0' \to 0$. Therefore condition (IV) is verified.

Setting $\mu_{h_0}^k = (\tilde{\lambda}_k^{(0)})^{-1}$, $\mu_0^k = (\lambda_k^{(0)})^{-1}$, it follows from Lemma D.2 that

$$|(\tilde{\lambda}_k^{(0)})^{-1} - (\lambda_k^{(0)})^{-1}| \le 2 \sup_{w \in N((\lambda_k^{(0)})^{-1}, \mathcal{A}_0), \quad \|w\|_{\mathcal{H}_0} = 1} \|\mathcal{A}_{h_0} w - \mathcal{A}_0 w\|_{\mathcal{H}_{h_0}}, \tag{D.19}$$

where $N((\lambda_k^{(0)})^{-1}, \mathcal{A}_0)$ as indicated in Lemma D.2.

For any $w \in N((\lambda_k^{(0)})^{-1}, \mathcal{A}_0)$, $\|w\|_{\mathcal{H}_0} = 1$, define

$$\begin{cases} \widehat{\mathcal{L}}_{h_0} v^{h_0} = w & \text{in} \quad \Omega, \\ v^{h_0} = 0 & \text{on} \quad \partial\Omega, \end{cases} \tag{D.20}$$

$$\begin{cases} \widehat{\mathcal{L}} v = w & \text{in} \quad \Omega, \\ v = 0 & \text{on} \quad \partial\Omega. \end{cases} \tag{D.21}$$

From the proof of Proposition 4.2, similarly, we can conclude that

$$\|v^{h_0} - v\|_{1,\Omega} \le Ch_0^2 \|N_i\|_{2,Q}^2. \tag{D.22}$$

Thus

$$\begin{aligned} &|(\tilde{\lambda}_k^{(0)})^{-1} - (\lambda_k^{(0)})^{-1}| \le 2 \sup_{w \in N((\lambda_k^{(0)})^{-1}, \mathcal{A}_0), \ \|w\|_{\mathcal{H}_0} = 1} \|\mathcal{A}_{h_0} w - \mathcal{A}_0 w\|_{\mathcal{H}_{h_0}} \\ &\le C \|v^{h_0} - v\|_{1,\Omega} \le Ch_0^2 \|N_i\|_{2,Q}^2, \end{aligned}$$

i.e.,

$$|\tilde{\lambda}_k^{(0)} - \lambda_k^{(0)}| \le C_k h_0^2 \|N_i\|_{2,Q}^2.$$

It follows from Lemma D.2 that

$$\|u_k^0 - \bar{u}_k^0\|_{0,\Omega} \le C_k h_0^2 \|N_i\|_{2,Q}^2. \qquad \square$$

NUMERICAL SCHUBERT CALCULUS BY THE PIERI HOMOTOPY ALGORITHM*

T. Y. LI†, XIAOSHEN WANG‡, AND MENGNIEN WU§

Abstract. Based on Pieri's formula on Schubert varieties, the Pieri homotopy algorithm was first proposed by Huber, Sottile, and Sturmfels [*J. Symbolic Comput.*, 26 (1998), pp. 767–788] for numerical Schubert calculus to enumerate all p-planes in $\mathbb{C}^{m+p}$ that meet n given planes in general position. The algorithm has been improved by Huber and Verschelde [*SIAM J. Control Optim.*, 38 (2000), pp. 1265–1287] to be more intuitive and more suitable for computer implementations.

A different approach of employing the Pieri homotopy algorithm for numerical Schubert calculus is presented in this paper. A major advantage of our method is that the polynomial equations in the process are all square systems admitting the same number of equations and unknowns. Moreover, the degree of each polynomial equation is always 2, which warrants much better numerical stability when the solutions are being solved. Numerical results for a big variety of examples illustrate that a considerable advance in speed as well as much smaller storage requirements have been achieved by the resulting algorithm.

1. Introduction.

With "l-planes" representing l dimensional linear subspaces, a general problem in enumerative geometry is

($\star$) Enumerate all p-planes in $\mathbb{C}^{m+p}$ that meet n given planes $L_1, \ldots, L_n$ in general position of dimension $m+1-k_i$ for $i = 1, \ldots, n$, with $k_1 + \cdots + k_n = mp$.

The condition that $k_1 + \cdots + k_n = mp$ guarantees a finite number of p-planes meeting those given planes.

Based on Pieri's formula, and following the new geometric proof of Pieri's formula established by Sottile [9], Huber, Sottile, and Sturmfels [3] proposed the *Pieri homotopy algorithm* to deal with this problem numerically. The homotopies in the algorithm have then been simplified by Huber and Verschelde [4] via the poset of localization patterns, making the algorithm more suitable for computer implementations.

In both of those works, each given plane L_i for $i = 1, \ldots, n$ with dimension $d_i = m + 1 - k_i$ is represented, as they were traditionally, by an $(m+p) \times d_i$ matrix consisting of d_i linearly independent vectors in $\mathbb{C}^{m+p}$. Let X be a p-plane that intersects all those given planes. Without loss, one may represent X by the $(m+p) \times p$

matrix

$$\begin{bmatrix} 1 & & 0 \\ x_{11} & \ddots & \\ \vdots & \ddots & 1 \\ x_{m1} & & x_{1p} \\ & \ddots & \vdots \\ 0 & & x_{mp} \end{bmatrix}.$$

For $i = 1, \ldots, n$, let $[\alpha]_i(x)$, where $x = (x_{11}, \ldots, x_{mp})$, denote the maximal minor of the $(m+p) \times (p+d_i)$ matrix $[X|L_i]$ with row indices $\alpha = (\alpha_1, \ldots, \alpha_{p+d_i})$. Then the intersection conditions in problem $(\star)$ become, for each $i = 1, \ldots, n$,

$$X \text{ meets } L_i \iff [\alpha]_i(x) = 0 \quad \forall \text{ possible row indices } \alpha = (\alpha_1, \ldots, \alpha_{p+d_i}).$$

The backbone of the Pieri homotopy algorithm [3, 4] is to solve k_i more variables in $x = (x_{11}, \ldots, x_{mp})$ one at a time for $i = 1, \ldots, n$ successively to satisfy the intersection conditions with $L_1, \ldots, L_i$:

$$[\alpha]_l(x) = 0 \ \forall \text{ possible row indices } \alpha = (\alpha_1, \ldots, \alpha_{p+d_l}), \text{ for } l = 1, \ldots, i. \tag{1}$$

To solve the above systems successively for $i = 1, \ldots, n$, different homotopies based on Pieri's formula on Schubert varieties are constructed at each stage where the solutions of the system at the current stage taken as the solutions of the target system of the current homotopy are the solutions of the start system of the homotopy at the next stage. In the process, if $k_i = 1$, then $d_i = m + 1 - 1 = m$, making $[X|L_i]$ a square matrix and resulting in the increment of one more equation in one more unknown in (1) from $(i-1)$th stage to ith stage. However, when $k_i > 1$, then $d_i = m + 1 - k_i < m$, and consequently the number of all possible maximal minors in the $(m+p) \times (p+d_i)$ matrix $[X|L_i]$ equals

$$\binom{p+m}{p+d_i} = \binom{p+m}{p+m+1-k_i} = \binom{p+m}{k_i - 1} > k_i$$

since $k_i = m+1-d_i < m$. When this occurs, the system in (1) admits more equations than unknowns and constitutes an overdetermined system.

Solving an overdetermined system by the homotopy continuation method as proposed in [8], a square system is constructed by using random linear combinations of all equations in (1). This reduction to a square system destroys the geometric structure and creates many excess solution paths to follow, which may lead to a considerable inefficiency of the algorithm since the solution sets of the new square system may properly contain the original ones.

In this paper, we present a different approach. Most importantly, we will represent each given plane L_i, $i = 1, \ldots, n$, in general position by a set of $m+p-d_i = p+k_i-1$ linear equations which defines L_i. The collection of the normals of those equations forms a $(p+k_i-1) \times (m+p)$ matrix, denoted by K_i, and X meets L_i if and only if

$$K_i X \Lambda_i = 0 \quad \text{for some } \Lambda_i \in \mathbb{P}^{p-1}.$$

Employing the same strategy as in [3, 4], we will solve k_i more variables in $x = (x_{11}, \ldots, x_{mp})$ one at a time from $i = 1$ to $i = n$ by solving for each i the system

$$K_l X \Lambda_l = 0 \ \ \Lambda_l \in \mathbb{P}^{p-1} \qquad \text{for } \ l = 1, \ldots, i. \tag{2}$$

And different homotopies are constructed, also based on Pieri's formula, at different stages to connect the solutions of the systems in (2) for consecutive i's. For each fixed i, the system in (2) has $(p+k_1-1)+\cdots+(p+k_i-1)=(p-1)i+k_1+\cdots+k_i$ equations. On the other hand, since $\Lambda_l \in \mathbb{P}^{p-1}$, it admits only $p-1$ variables for each l; together with $k_1+\cdots+k_i$ variables in $x=(x_{11},\ldots,x_{mp})$, the system has $(p+k_1-1)+\cdots+(p+k_i-1)=(p-1)i+k_1+\cdots+k_i$ variables. We therefore deal with square systems throughout the process even when $k_i>1$ occurs and never have to undertake the disadvantages of solving overdetermined systems. Moreover, another important advantage of our approach is that the degree of each polynomial equation in (2) is always 2 while polynomial equations in the previous approaches in [3, 4] may reach quite higher degrees in many situations, which may severely affect the numerical stability when solutions of the systems are being solved.

The computational experiences of the resulting algorithm are listed at the end of the paper to illustrate the remarkable speed up of our method has achieved over the existing algorithm in [4] for a big variety of examples, and our algorithm is particularly valuable for general cases when $k_i>1$ appears.

While, in this paper, we only deal with given planes in general position, the input data of planes for applications may not be so general. An approach common to practitioners of homotopies to solve a given problem is to deform the solutions of the general problem to those of the special problem by applying cheater's homotopy [5] or coefficient-parameter polynomial continuation [6, 7].

In [4], new homotopies were presented to compute p-plane producing curves intersecting m-planes at prescribed interpolation points. A future project would be to investigate whether the improvements proposed in this paper also apply to those new homotopies developed in [4].

2. Preliminaries.

DEFINITION 1. *Let $A_1 \subsetneq A_2 \subsetneq \cdots \subsetneq A_p$ be a set of planes in $\mathbb{C}^{m+p}$ with $\dim(A_i)=a_i$. The set*

$$\Omega(A_1,\ldots,A_p) := \{\ p\text{-planes } X \text{ in } \mathbb{C}^{m+p} |\ \dim(X \bigcap A_i) \geq i, i=1,\ldots,p\ \}$$

is called a Schubert variety.

For planes $A_1 \subsetneq \cdots \subsetneq A_p$ and $B_1 \subsetneq \cdots \subsetneq B_p$ with $\dim(B_i)=\dim(A_i)=a_i$, for $i=1,\ldots,p$, a nonsingular linear transformation in $\mathbb{C}^{m+p}$ can be constructed to transform A_i to B_i for $i=1,\ldots,p$, and the induced transformation transforms $\Omega(A_1,\ldots,A_p)$ onto $\Omega(B_1,\ldots,B_p)$. For this reason, the notation $\Omega(a_1,\ldots,a_p)$ is frequently used without specifying the planes A_i where $\dim(A_i)=a_i, i=1,\ldots,p$.

Now consider planes $A_1 \subsetneq A_2 \subsetneq \cdots \subsetneq A_p$ and $B_1 \subsetneq \cdots \subsetneq B_p$ with $\dim(A_i)=a_i$ and $\dim(B_i)=b_i$, $i=1,\ldots,p$. When they are all in general position, we may assume

$$A_i = \langle e_1,\ldots,e_{a_i}\rangle \ \text{ and } \ B_i = \langle e_{m+p+1-b_i},\ldots,e_{m+p}\rangle, \quad i=1,\ldots,p,$$

where e_j is the unit vector in $\mathbb{C}^{m+p}$ with unit at the jth entry. Here, and from here on, $\langle v_1,\ldots,v_l\rangle$ denotes the plane spanned by $v_1,\ldots,v_l$. If $X \in \Omega(A_1,\ldots,A_p) \bigcap \Omega(B_1,\ldots,B_p)$, then $\dim(X \bigcap A_{p+1-i}) \geq p+1-i$ and $\dim(X \bigcap B_i) \geq i$. Thus, since $\dim(X)=p$ and both $X \bigcap A_{p+1-i}$ and $X \bigcap B_i$ are planes in X,

$$\begin{aligned} \dim(A_{p+1-i} \bigcap B_i) &\geq \dim((X \bigcap A_{p+1-i}) \bigcap (X \bigcap B_i)) \\ &\geq \dim(X \bigcap A_{p+1-i}) + \dim(X \bigcap B_i) - \dim(X) \\ &\geq p+1-i+i-p = 1. \end{aligned}$$

So, $a_{p+1-i}+b_i \geq m+p+1$. Conversely, if $a_{p+1-i}+b_i \geq m+p+1$, then $a_{p+1-i} \geq m+p+1-b_i$. Thus $e_{m+p+1-b_i} \in B_i \bigcap A_{p+1-i}$. Let $X = \langle e_{m+p+1-b_p}, e_{m+p+1-b_{p-1}}, \ldots, e_{m+p+1-b_1}\rangle$. Obviously, $X \bigcap B_i = \langle e_{m+p+1-b_1}, e_{m+p+1-b_2}, \ldots, e_{m+p+1-b_i}\rangle$ and $\dim(X \bigcap B_i) = i$. Furthermore, $X \bigcap A_{p+1-i} \supseteq \langle e_{m+p+1-b_p}, \ldots, e_{m+p+1-b_i}\rangle$ and hence $\dim(X \bigcap A_{p+1-i}) \geq p+1-i$. Thus $X \in \Omega(A_1, \ldots, A_p) \bigcap \Omega(B_1, \ldots, B_p)$. Therefore, we have the following proposition.

PROPOSITION 1 (Theorem I, p. 327 [1]). *When $A_1 \subsetneq A_2 \subsetneq \cdots \subsetneq A_p$ and $B_1 \subsetneq \cdots \subsetneq B_p$ are planes in general position in $\mathbb{C}^{m+p}$ with $\dim(A_i) = a_i$ and $\dim(B_i) = b_i$ for $i = 1, \ldots, p$, then $\Omega(a_1, \ldots, a_p)$ and $\Omega(b_1, \ldots, b_p)$ intersect if and only if*

$$a_{p+1-i} + b_i \geq m+p+1 \qquad \text{for} \quad i = 1, \ldots, p.$$

As a corollary, we have the following proposition.

PROPOSITION 2 (Corollary, p. 328 [1]). *$\Omega(a_1, \ldots, a_p) \bigcap \Omega(m+p+1-a_p, \ldots, m+p+1-a_1)$ consists of a unique p-plane for given $1 \leq a_1 < \cdots < a_p \leq m+p$.*

EXAMPLE 1. *Let $m = p = 2$, $A_1 = \langle e_1, e_2\rangle$, $A_2 = \langle e_1, e_2, e_3\rangle$, $B_1 = \langle e_3, e_4\rangle$, and $B_2 = \langle e_2, e_3, e_4\rangle$. Then $\Omega(A_1, A_2) \bigcap \Omega(B_1, B_2) = \langle e_2, e_3\rangle$.*

In the rest of the paper, when we write $\mathbf{a} = (a_1, \ldots, a_p)$, those coordinates will satisfy $1 \leq a_1 < \cdots < a_p \leq m+p$. Because of the importance of Proposition 2, $\mathbf{a}^* = (m+p+1-a_p, \ldots, m+p+1-a_1)$ is called the *dual* of $\mathbf{a} = (a_1, \cdots, a_p)$.

For $0 \leq h \leq m$, let $\sigma_h := \Omega(m+1-h, m+2, \ldots, m+p)$, the set of p-planes that meet a given $(m+1-h)$-plane. Since every p-plane will meet any $(m+1)$-plane, σ_0 is the collection of all p-planes.

For $(a_1, \ldots, a_p)$ and $(b_1, \ldots, b_p)$ with $a_{p+1-i} \geq m+p+1-b_i$, for $i = 1, \ldots, p$, let $A_1 \subsetneq A_2 \subsetneq \cdots \subsetneq A_p$ and $B_1 \subsetneq \cdots \subsetneq B_p$ be planes in $\mathbb{C}^{m+p}$ with $\dim(A_i) = a_i$ and $\dim(B_i) = b_i$. If $X \in \Omega(a_1, \ldots, a_p) \bigcap \Omega(b_1, \ldots, b_p)$, then X meets $A_{p+1-i} \bigcap B_i$ for $i = 1, \ldots, p$. Let D be the smallest plane containing $A_p \bigcap B_1, \ldots, A_1 \bigcap B_p$. Then $X \subset D$ and

$$\begin{aligned} \dim(D) &\leq \dim(A_p \bigcap B_1) + \cdots + \dim(A_1 \bigcap B_p) \\ &= a_p + b_1 - (m+p) + \cdots + a + 1 + b_p - (m+p) \\ &= \textstyle\sum_{i=1}^{p} (a_i + b_i) - (m+p)p. \end{aligned}$$

Let $h = \sum a_i + \sum b_i - (m+p+1)p$. Clearly,

$$\dim(D) = h + p \Longleftrightarrow a_{p-i} < m+p+1-b_i \leq a_{p-i+1} \quad \forall i = 1, \ldots, p.$$

When $\dim(D) = h+p$, let G_h be a generic $(m+1-h)$-plane. Representing D and G_h by matrices consisting of independent vectors in $\mathbb{C}^{m+p}$, the rank of the $(m+p)\times(m+p+1)$ matrix $[D|G_h]$ is $m+p$. Thus, up to a scalar factor, there is a unique nonzero vector $g \in G_h$, where $g = v_1 + \cdots + v_p$ with $v_i \in A_{p+1-i} \bigcap B_i$ for $i = 1, \ldots, p$. Let $X = \langle v_1, \ldots, v_p\rangle$; then $X \in \Omega(A_1, \ldots, A_p) \bigcap \Omega(B_1, \ldots, B_p)$ and meets G_h.

PROPOSITION 3 (Theorem III, p. 333 [1]). *Let $1 \leq h \leq m$. For $(a_1, \ldots, a_p)$ and $(b_1, \ldots, b_p)$ satisfying*

$$a_{p-i} < m+p+1-b_i \leq a_{p+1-i}, \quad h = \textstyle\sum a_i + \sum b_i - (m+p+1)p, \tag{3}$$

the intersection $\Omega(a_1, \ldots, a_p) \bigcap \Omega(b_1, \ldots, b_p) \bigcap \sigma_h$ consists of a unique p-plane.

EXAMPLE 2. *Let $m = p = 2$, $A_1 = \langle e_1, e_2\rangle$, $A_2 = \langle e_1, e_2, e_3\rangle$, $B_1 = \langle e_3, e_4\rangle$, $B_2 = \langle e_1, e_2, e_3, e_4\rangle$, and $\sigma_1 = \Omega(D_1, D_2)$, where D_1 is a generic 2-plane and $D_2 = \mathbb{C}^4$. Then $A_1 \bigcap B_2 = A_1$ and $A_2 \bigcap B_1 = \langle e_3\rangle$. Denote the 1-plane $D_1 \bigcap \langle A_1, e_3\rangle$ by D_1'.*

Let $u = (u_1, u_2, u_3, u_4) \in D_1'$ *and* $f_1 = (u_1, u_2, 0, 0)$. *Then* $\Omega(2,3) \bigcap \Omega(2,4) \bigcap \sigma_1 = \langle f_1, e_3 \rangle$.

For $\Omega(a_1, \ldots, a_p)$ and $\Omega(b_1, \ldots, b_p)$, $\Omega(a_1, \ldots, a_p) + \Omega(b_1, \ldots, b_p)$ denotes the class of p-planes X, where for planes $A_1 \subsetneq A_2 \subsetneq \cdots \subsetneq A_p$ and $B_1 \subsetneq \cdots \subsetneq B_p$ with $\dim(A_i) = a_i$ and $\dim(B_i) = b_i$ for $i = 1, \ldots, p$, $\dim(X \bigcap A_i) \geq i$ (or $\dim(X \bigcap B_i) \geq i$) for all $i = 1, \ldots, p$. We abbreviate $\Omega(a_1, \ldots, a_p) + \Omega(a_1, \ldots, a_p)$ by $2\Omega(a_1, \ldots, a_p)$ and in general

$$\sum_{i=1}^{d} \Omega(a_1, \ldots, a_p) := d\,\Omega(a_1, \ldots, a_p).$$

Furthermore, $\Omega(a_1, \ldots, a_p) \bullet \Omega(b_1, \ldots, b_p)$ represents the class of p-planes X, where $\dim(X \bigcap A_i) \geq i$ *and* $\dim(X \bigcap B_i) \geq i$ for all $i = 1, \ldots, p$.

For sets of p-planes A and B, we write $A \bullet B$ for $A \bigcap B$. We say A is *equivalent* to B, denoted by $A \sim B$, if whenever

$$A \bullet \Omega(\mathbf{c}) = k\,\Omega(1, \ldots, p)$$

for some $\mathbf{c} = (c_1, \ldots, c_p)$, we also have

$$B \bullet \Omega(\mathbf{c}) = k\,\Omega(1, \ldots, p).$$

Note that $\Omega(1, \ldots, p)$ represents a general p-plane. The following property [1, 2, 3] will be used repeatedly for the establishment of our algorithm:

$$A \sim B \Longrightarrow A \bullet \sigma_h \sim B \bullet \sigma_h.$$

Following Proposition 3, for fixed $a_1, \ldots, a_p$ and h, any $\mathbf{b} = (b_1, \ldots, b_p)$ satisfying (3) yields

$$\Omega(a_1, \ldots, a_p) \bullet \sigma_h \bullet \Omega(b_1, \ldots, b_p) = \Omega(1, \ldots, p).$$

On the other hand, for the dual $\mathbf{b}^* = (b_1^*, \ldots, b_p^*) = (m+p+1-b_p, \ldots, m+p+1-b_1)$ of $\mathbf{b}$, by Proposition 2,

$$\Omega(b_1^*, \ldots, b_p^*) \bullet \Omega(b_1, \ldots, b_p) = \Omega(1, \ldots, p).$$

Moreover, for $\bar{\mathbf{b}} = (\bar{b}_1, \ldots, \bar{b}_p)$ satisfying (3), but $\bar{\mathbf{b}} \neq \mathbf{b}^*$,

$$\Omega(\bar{b}_1, \ldots, \bar{b}_p) \bullet \Omega(b_1, \ldots, b_p) = \emptyset.$$

These observations lead to the following important formula.

Proposition 4 (Pieri's formula, p. 354 [1]).

$$\Omega(a_1, \ldots, a_p) \bullet \sigma_h \sim \sum_{\mathbf{b}=(b_1,\ldots,b_p)} \Omega(b_1, \ldots, b_p), \ \textit{where}$$

$$0 < b_1 \leq a_1 < b_2 \leq a_2 < \cdots \leq a_{p-1} < b_p \leq a_p \ \textit{with} \ \sum b_j = \sum a_j - h. \tag{4}$$

When we fix $\mathbf{a} = (a_1, \ldots, a_p)$ and h, those $\mathbf{b} = (b_1, \ldots, b_p)$ satisfying (4) together with $\mathbf{a}$ are called the *Pieri nodes*; the nodes $\mathbf{b}$ are *induced* Pieri nodes of node $\mathbf{a}$.

From here on, we will use $[a_1, \ldots, a_p]$ to denote a Pieri node or its dual. Recall that for $i = 1, \ldots, n$, p-planes that meet plane L_i with $\dim(L_i) = m + 1 - k_i$ belong to $\Omega(m+1-k_i, m+2, \ldots, m+p) = \sigma_{k_i}$, and the condition $k_1 + \cdots + k_n = mp$ warrants

$$\sigma_{k_1} \bullet \sigma_{k_2} \bullet \cdots \bullet \sigma_{k_n} = d\,\Omega(1, \ldots, p). \tag{5}$$

Thus problem ($\star$) introduced in section 1 can now be interpreted as follows: finding all d specific p-planes in $\sigma_{k_1} \bullet \sigma_{k_2} \bullet \cdots \bullet \sigma_{k_n}$ for given planes $L_1, \ldots, L_n$ in general position. To calculate $\sigma_{k_1} \bullet \sigma_{k_2} \bullet \cdots \bullet \sigma_{k_n}$ in (5), Pieri's formula in Proposition 4 will be used as a main tool. The Pieri nodes derived in the process constitute a *Pieri poset*, and the number d is called the *Pieri root count*.

EXAMPLE 3. *For $m=2$, $p=2$ and given planes L_1, L_2, L_3, L_4 in general position with $\dim(L_i) = 2$ and $k_i = m + 1 - d_i = 1$ for all $i = 1, \ldots, 4$,*

$$\begin{aligned} & \sigma_{k_1} \bullet \sigma_{k_2} \bullet \sigma_{k_3} \bullet \sigma_{k_4} \\ = \;& \Omega(2,4) \bullet \sigma_{k_2} \bullet \sigma_{k_3} \bullet \sigma_{k_4} \\ \sim \;& (\Omega(1,4) + \Omega(2,3)) \bullet \sigma_{k_3} \bullet \sigma_{k_4} \\ \sim \;& 2\,\Omega(1,3) \bullet \sigma_{k_4} \\ \sim \;& 2\,\Omega(1,2). \end{aligned}$$

The Pieri poset of all the Pieri nodes and the poset that consists of their duals are shown in Figure 1.

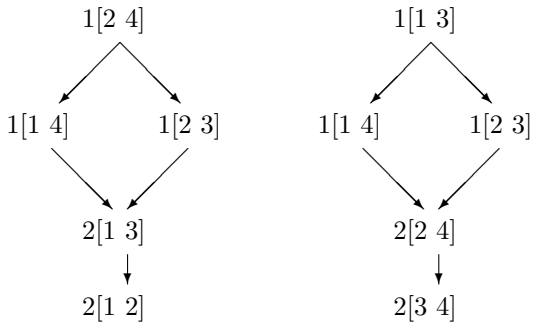

FIG. 1.

Now, any 2-plane X that meets L_1 must be in $\Omega(3,4) \bullet \sigma_1 \sim \Omega(2,4)$. Since $[2,4]^* = [1,3]$, there is a unique 2-plane in $\Omega(2,4) \bullet \Omega(1,3)$. So, if we let $A_1 = \langle e_1 \rangle$ and $A_2 = \langle e_1, e_2, e_3 \rangle$, there is a unique 2-plane in $\Omega(A_1, A_2)$ consisting of 2-planes of the form

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & u \\ 0 & 0 \end{bmatrix} := X_{[1,3]}$$

that meet L_1. We may determine this unique $X_{[1,3]}$ by finding u via its intersection condition with L_1.

Similarly, any 2-plane X that meets both L_1 and L_2 must lie in $\Omega(3,4) \bullet \sigma_1 \bullet \sigma_1 \sim \Omega(1,4) + \Omega(2,3)$ by Proposition 4. Since $[1,4]^* = [1,4]$ and $\Omega(2,3) \bullet \Omega(1,4) = \emptyset$, by

letting $A_1 = \langle e_1 \rangle$ *and* $A_2 = \langle e_1, e_2, e_3, e_4 \rangle$, *there is a unique* 2*-plane in* $\Omega(A_1, A_2)$ *consisting of* 2*-planes of the form*

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & v_1 \\ 0 & v_2 \end{bmatrix} := X_{[1,4]}$$

that meet both L_1 *and* L_2. *We may determine this unique* $X_{[1,4]}$ *by finding* v_1 *and* v_2 *via the intersection conditions of meeting* L_1 *and* L_2. *On the other hand, since* $[2,3]^* = [2,3]$ *and* $\Omega(1,4) \bullet \Omega(2,3) = \emptyset$, *there is a unique* 2*-plane in* $\Omega(A_1, A_2)$ *with* $A_1 = \langle e_1, e_2 \rangle$ *and* $A_2 = \langle e_1, e_2, e_3 \rangle$ *consisting of* 2*-planes of the form*

$$\begin{bmatrix} 1 & 0 \\ v_1' & 1 \\ 0 & v_2' \\ 0 & 0 \end{bmatrix} := X_{[2,3]}$$

that meet L_1 *and* L_2. *This* $X_{[2,3]}$ *is decided when* v_1' *and* v_2' *are found.*

Continuing the same pattern, since $\Omega(3,4) \bullet \sigma_1 \bullet \sigma_1 \bullet \sigma_1 \sim 2\Omega(1,3)$ *and* $[1,3]^* = [2,4]$, *there are two* 2*-planes in* $\Omega(A_1, A_2)$, *with* $A_1 = \langle e_1, e_2 \rangle$ *and* $A_2 = \langle e_1, e_2, e_3, e_4 \rangle$, *consisting of* 2*-planes of the form*

$$\begin{bmatrix} 1 & 0 \\ w_1 & 1 \\ 0 & w_2 \\ 0 & w_3 \end{bmatrix} := X_{[2,4]}$$

that meet L_1, L_2, *and* L_3. *And,* $\Omega(3,4) \bullet \sigma_1 \bullet \sigma_1 \bullet \sigma_1 \bullet \sigma_1 \sim 2\Omega(1,2)$ *as well as* $[1,2]^* = [3,4]$ *imply that the two* 2*-planes that meet all* $L_1, \ldots, L_4$ *can be found by solving two set of* y*'s of*

$$\begin{bmatrix} 1 & 0 \\ y_1 & 1 \\ y_3 & y_2 \\ 0 & y_4 \end{bmatrix} := X_{[3,4]}$$

in $\Omega(A_1, A_2)$ *with* $A_1 = \langle e_1, e_2, e_3 \rangle$ *and* $\langle e_1, e_2, e_3, e_4 \rangle$.

The theme of the so-called Pieri homotopy algorithm is as follows:

1. *Finding* u *in* $X_{[1,3]}$ *by the criteria of meeting* L_1.
2. (a) *Solving* $\{v_1, v_2\}$ *in* $X_{[1,4]}$ *by a homotopy with a starting point containing* $\{v_1 = u, v_2 = 0\}$.
   (b) *Solving* $\{v_1, v_2\}$ *in* $X_{[2,3]}$ *by a different homotopy with a starting point containing* $\{v_1' = 0, v_2' = u\}$.
3. *Solving two sets of* $\{w_1, w_2, w_3\}$ *in* $X_{[2,4]}$ *by a homotopy with two starting points containing* $\{w_1 = 0, w_2 = v_1, w_3 = v_2\}$ *and* $\{w_1 = v_1', w_2 = v_2' w_3 = 0\}$, *respectively.*
4. *Solving two sets of* $\{y_1, y_2, y_3, y_4\}$ *in* $X_{[3,4]}$ *by a homotopy with two starting points containing* $\{y_1 = w_1, y_2 = w_2, y_3 = w_3, y_4 = 0\}$ *with two sets of values of* $\{w_1, w_2, w_3\}$ *obtained at the last step.*

The details of those homotopies of our approach will be elaborated in the next section.

From the process in the above example, we solve the ultimate solutions in $X_{[3,4]}$ by following the cascade of solving

(6)
$$\begin{array}{ccc} & X_{[1\,3]} & \\ \swarrow & & \searrow \\ X_{[2\,3]} & & X_{[1\,4]} \\ \searrow & & \swarrow \\ & 2X_{[2\,4]} & \\ & \downarrow & \\ & 2X_{[3\,4]}. & \end{array}$$

For $\mathbf{a} = [a_1, \ldots, a_p]$, write

$$X_{\mathbf{a}} = X_{[a_1,\ldots,a_p]} := \begin{bmatrix} 1 & & 0 \\ x_{1,1} & \ddots & \\ \vdots & \ddots & 1 \\ x_{(a_1-1),1} & & x_{1,p} \\ & \ddots & \vdots \\ & & x_{(a_p-p),p} \\ & & 0 \\ 0 & & \vdots \\ & & 0 \end{bmatrix}.$$

Those $\mathbf{a}$'s in (6) actually follow the duals of the Pieri poset in Figure 1. For nodes $\mathbf{a}$ and $\mathbf{b}$,

$$\mathbf{a} \to \cdots \to \cdots \to \mathbf{b}$$

is called a *chain* joining $\mathbf{a}$ and $\mathbf{b}$. A chain joining $\mathbf{a} = [m+1, m+2, \ldots, m+p]$ and $\mathbf{b} = [1, \ldots, p]$ is called a *complete chain*. The Pieri homotopy algorithms in general are constructed based on the duals of the Pieri poset consisting of all the derived Pieri nodes.

3. Algorithms. For given planes $L_1, \ldots, L_n$ in $\mathbb{C}^{m+p}$ in general position with $\dim(L_i) = m + 1 - k_i$ for $i = 1, \ldots, n$, all derived Pieri nodes in

$$\sigma_{k_1} \bullet \sigma_{k_2} \bullet \cdots \bullet \sigma_{k_n}$$

form a poset. Unless otherwise indicated, we shall use the term "Pieri poset" for the poset of duals of all those Pieri nodes. As mentioned in the introduction, we shall represent each L_i by a $(p + k_i - 1) \times (m + p)$ matrix K_i whose rows consist of all the normals of the linear equations that define L_i.

(a) Hypersurface intersection conditions, where $k_i = 1$ for all $i = 1, \ldots, n$. Letting $\mathbf{a}^0 = [1, 2, \ldots, p]$ sit on top of the Pieri poset, we may write

$$\mathbf{a}^0 \;\to\; \mathbf{a}^1 \to \;\cdots\; \to \;\mathbf{a}^n \tag{7}$$

for a complete chain in the poset, and it is obvious that the coordinates of consecutive nodes $\mathbf{a}^j$ and $\mathbf{a}^{j+1}$ in the chain can differ by 1 on only one component. We shall use

$$\mathbf{a}^j \;\stackrel{\mu_{j+1}}{\longrightarrow}\; \mathbf{a}^{j+1}$$

to denote that the μ_{j+1}th component of $\mathbf{a}^j$ is increased by 1 to reach $\mathbf{a}^{j+1}$. We may therefore write

$$\mathbf{a}^0 \;\stackrel{\mu_1}{\longrightarrow}\; \mathbf{a}^1 \;\stackrel{\mu_2}{\longrightarrow}\; \cdots \;\stackrel{\mu_n}{\longrightarrow}\; \mathbf{a}^n$$

for a complete chain. Recall that for $\mathbf{a} = [a_1, \ldots, a_p]$

$$X_{\mathbf{a}} = \begin{bmatrix} 1 & & 0 \\ x_{1,1} & \ddots & \\ \vdots & \ddots & 1 \\ x_{(a_1-1),1} & & x_{1,p} \\ & \ddots & \vdots \\ & & x_{(a_p-p),p} \\ & & 0 \\ 0 & & \vdots \\ & & 0 \end{bmatrix}.$$

For $\mathbf{a}^0 \;\stackrel{\mu_1}{\longrightarrow}\; \mathbf{a}^1$, the only unknown in $X_{\mathbf{a}^1}$ can be determined by

$$K_1 X_{\mathbf{a}^1} \Lambda_1^1 = 0,$$

where $\Lambda_1^1 = e_{\mu_1} \in \mathbb{C}^p$. Now, suppose we have proceeded up to

$$\mathbf{a}^0 \;\stackrel{\mu_1}{\longrightarrow}\; \mathbf{a}^1 \;\stackrel{\mu_2}{\longrightarrow}\; \cdots \;\stackrel{\mu_j}{\longrightarrow}\; \mathbf{a}^j$$

in the chain. This means that we have solved all the variables in $X_{\mathbf{a}^j}$ and found $\Lambda_1^j, \ldots, \Lambda_j^j \in \mathbb{P}^{p-1}$ such that

$$K_l X_{\mathbf{a}^j} \Lambda_l^j = 0 \;\text{ for }\; l = 1, \ldots, j.$$

Namely, a p-plane in the form $X_{\mathbf{a}^j}$ that meets planes $L_1, \ldots, L_j$ has been determined. To proceed one step further in the chain, for

$$\mathbf{a}^j \;\stackrel{\mu_{j+1}}{\longrightarrow}\; \mathbf{a}^{j+1}, \quad \text{where } \mathbf{a}^{j+1} = [a_1^{(j+1)}, \ldots, a_p^{(j+1)}],$$

consider the homotopy

$$H(t, X_{\mathbf{a}^{j+1}}, \Lambda^{j+1}) = \begin{cases} K_1 X_{\mathbf{a}^{j+1}} \Lambda_1^{j+1} = 0, \\ \vdots \\ K_j X_{\mathbf{a}^{j+1}} \Lambda_j^{j+1} = 0, \\ [(1-t)\hat{K}_{\mathbf{a}^{j+1}} + tK_{j+1}] X_{\mathbf{a}^{j+1}} \Lambda_{j+1}^{j+1} = 0, \end{cases} \tag{8}$$

where the μ_lth component of Λ_l^{j+1} is 1 for $l = 1, \ldots, j+1$, and $\widehat{K}_{\mathbf{a}^{j+1}}$ is the matrix $[e_{a_1^{(j+1)}}, \ldots, e_{a_p^{(j+1)}}]^T$. For each $t \in [0,1]$, the system admits $p-1$ variables in Λ_l^{j+1} for each $l = 1, \ldots, j+1$ and $j+1$ variables in $X_{\mathbf{a}^{j+1}}$; it admits, in total, $(p-1)(j+1)+(j+1) = p(j+1)$ variables. It is clear that the total number of equations is also $p(j+1)$, making the system a square system. When $t = 0$,

$$\begin{array}{lcll} X_{\mathbf{a}^{j+1}} & = & X_{\mathbf{a}^j}, & \\ \Lambda_l^{j+1} & = & \Lambda_l^j, & l = 1, \ldots, j, \\ \Lambda_{j+1}^{j+1} & = & e_{\mu_{j+1}} (\in \mathbb{C}^p) & \end{array}$$

is a solution of the system $H(0, X_{\mathbf{a}^{j+1}}, \Lambda^{j+1}) = 0$ in (8). Following the homotopy path of $H(t, X_{\mathbf{a}^{j+1}}, \Lambda^{j+1}) = 0$ emanating from this solution, we obtain a solution of $X_{\mathbf{a}^{j+1}}$ and Λ_l^{j+1} for $l = 1, \ldots, j+1$ at $t = 1$ that satisfies

$$K_l X_{\mathbf{a}^{j+1}} \Lambda_l^{j+1} = 0 \quad \text{for } l = 1, \ldots, j+1.$$

A p-plane that meets $L_1, \ldots, L_{j+1}$ in the form of $X_{\mathbf{a}^{j+1}}$ is then found and the chain has been extended one step further; namely, we have proceeded along the chain up to

$$\mathbf{a}^0 \xrightarrow{\mu_1} \mathbf{a}^1 \xrightarrow{\mu_2} \cdots \xrightarrow{\mu_{j+1}} \mathbf{a}^{j+1}.$$

When we proceed further along the chain and arrive at $\mathbf{a}^n$, a p-plane that meets all L_i, $i = 1, \ldots, n$, becomes available.

EXAMPLE 4. *In Example* 3*, there are two chains in the dual poset:*

$$\textit{chain } 1\textit{:}\ [1\,2] \xrightarrow{2} [1\,3] \xrightarrow{2} [1\,4] \xrightarrow{1} [2\,4] \xrightarrow{1} [3\,4],$$
$$\textit{chain } 2\textit{:}\ [1\,2] \xrightarrow{2} [1\,3] \xrightarrow{1} [2\,3] \xrightarrow{2} [2\,4] \xrightarrow{1} [3\,4],$$

and the corresponding homotopies are

$$\begin{array}{l} [1\,2] \\ \downarrow \\ [1\,3]\text{:} \left[\begin{array}{l} K_1 X_{[1\,3]} \Lambda_1^1 = 0, \Lambda_1^1 = \left[\begin{array}{c} 0 \\ 1 \end{array} \right] \end{array} \right. \\ \downarrow \\ [1\,4]\text{:} \left[\begin{array}{r} K_1 X_{[1\,4]} \Lambda_1^2 = 0 \\ \{(1-t)\underline{[e_1, e_4]^T} + tK_2\} X_{[1\,4]} \Lambda_2^2 = 0 \end{array} \right. \\ \downarrow \\ [2\,4]\text{:} \left[\begin{array}{r} K_1 X_{[2\,4]} \Lambda_1^3 = 0 \\ K_2 X_{[2\,4]} \Lambda_2^3 = 0 \\ \{(1-t)[e_2, e_4]^T + tK_3\} X_{[2\,4]} \Lambda_3^3 = 0 \end{array} \right. \\ \downarrow \\ [3\,4]\text{:} \left[\begin{array}{r} K_1 X_{[3\,4]} \Lambda_1^4 = 0 \\ K_2 X_{[3\,4]} \Lambda_2^4 = 0 \\ K_3 X_{[3\,4]} \Lambda_3^4 = 0 \\ \{(1-t)[e_3, e_4]^T + tK_4\} X_{[3\,4]} \Lambda_4^4 = 0 \end{array} \right. \end{array} \qquad \begin{array}{l} [1\,2] \\ \downarrow \\ [1\,3]\text{:} \left[\begin{array}{l} K_1 X_{[1\,3]} \Lambda_1^1 = 0, \Lambda_1^1 = \left[\begin{array}{c} 0 \\ 1 \end{array} \right] \end{array} \right. \\ \downarrow \\ [2\,3]\text{:} \left[\begin{array}{r} K_1 X_{[2\,3]} \Lambda_1^2 = 0 \\ \{(1-t)\underline{[e_2, e_3]^T} + tK_2\} X_{[2\,3]} \Lambda_2^2 = 0 \end{array} \right. \\ \downarrow \\ [2\,4]\text{:} \left[\begin{array}{r} K_1 X_{[2\,4]} \Lambda_1^3 = 0 \\ K_2 X_{[2\,4]} \Lambda_2^3 = 0 \\ \{(1-t)[e_2, e_4]^T + tK_3\} X_{[2\,4]} \Lambda_3^3 = 0 \end{array} \right. \\ \downarrow \\ [3\,4]\text{:} \left[\begin{array}{r} K_1 X_{[3\,4]} \Lambda_1^4 = 0 \\ K_2 X_{[3\,4]} \Lambda_2^4 = 0 \\ K_3 X_{[3\,4]} \Lambda_3^4 = 0 \\ \{(1-t)[e_3, e_4]^T + tK_4\} X_{[3\,4]} \Lambda_4^4 = 0. \end{array} \right. \end{array}$$

For chain 1, $\Lambda_k^l = \left[\begin{smallmatrix} * \\ 1 \end{smallmatrix} \right]$, $k = 1, 2$, $l = 1, \ldots, k$, $\Lambda_k^l = \left[\begin{smallmatrix} 1 \\ * \end{smallmatrix} \right]$, $k = 3, 4$, $l = 1, \ldots, k$; *for chain* 2, $\Lambda_k^l = \left[\begin{smallmatrix} * \\ 1 \end{smallmatrix} \right]$, $k = 1, 3$, $l = 1, \ldots, k$, $\Lambda_k^l = \left[\begin{smallmatrix} 1 \\ * \end{smallmatrix} \right]$, $k = 2, 4$, $l = 1, \ldots, k$. *Between chain* 1 *and* 2*, the only distinct homotopies are* $[1\,3] \xrightarrow{2} [1\,4]$ *in chain* 1 *and* $[1\,3] \xrightarrow{1} [2\,3]$ *in chain* 2. □

EXAMPLE 5. *For* $m = 3$, $p = 2$, *let* $L_1, \ldots, L_6$ *be planes with* $\dim(L_i) = 3$ *for* $i = 1, \ldots, 6$. *The Pieri poset is shown in Figure* 2. *For the complete chain*

Remark 1. Let $\mathbf{a}$ be a node shared by k different complete chains

$$\mathbf{a}_l^0 \xrightarrow{\mu_{1l}} \mathbf{a}_l^1 \xrightarrow{\mu_{2l}} \cdots \xrightarrow{\mu_{nl}} \mathbf{a}_l^n, \quad l = 1, \ldots, k.$$

Say $\mathbf{a}_l^{j+1} = \mathbf{a}$, for $l = 1, \ldots, k$. This means $\sigma_{k_1} \bullet \sigma_{k_2} \bullet \cdots \bullet \sigma_{k_j} \bullet \Omega(\mathbf{a}) = k\,\Omega(1, \ldots, p)$, where $k_i = 1$ for $i = 1, \ldots, j$. In this situation, the homotopies for the extensions $\mathbf{a}_l^j \xrightarrow{\mu_{(j+1)l}} \mathbf{a}_l^{j+1} = \mathbf{a}$ in (8) are the same for all l. It is critically important that those

k paths that emanate from k different starting points

$$X_{\mathbf{a}} = X_{\mathbf{a}_l^j}, \quad \Lambda_{il}^{j+1} = \Lambda_{il}^j \text{ for } i = 1, \ldots, j, \quad \Lambda_{(j+1)l}^{j+1} = \begin{bmatrix} 0 \\ \vdots \\ 1 \\ \vdots \\ 0 \end{bmatrix} \leftarrow \mu_{(j+1)l}\text{th}$$

will reach different solutions at $t = 1$. This assertion is warranted by the following observations. Since for each $t \in [0,1]$, $(1-t)\widehat{K}_{\mathbf{a}} + tK_{j+1}$ represents an m-plane $L_{j+1}(t)$, and those m-planes $L_{j+1}(t)$ are in general position for $0 < t \leq 1$, it follows that for each $t \in (0,1]$ the system

$$\begin{aligned} K_1 X_{\mathbf{a}} \Lambda_1^{j+1} &= 0, \\ &\vdots \\ K_j X_{\mathbf{a}} \Lambda_j^{j+1} &= 0, \\ [(1-t)\widehat{K}_{\mathbf{a}} + tK_{j+1}] X_{\mathbf{a}} \Lambda_{j+1}^{j+1} &= 0 \end{aligned}$$

has k solutions and all of them are nonsingular. Since at $t = 0$ those k solutions are also nonsingular, those k different paths of the same homotopy will lead to k different solutions at $t = 1$.

(b) General intersection conditions, where $k_i > 1$ for certain $1 \leq i \leq n$. The Pieri poset in this case is somewhat more complicated. For $k_i > 1$, let $\mathbf{a}^i$ be a derived node of $\mathbf{a}^{i-1}$. The coordinates of nodes $\mathbf{a}^{i-1}$ and $\mathbf{a}^i$ may have several different components and their differences may not simply differ by just 1. Moreover, as the following example shows, not all the nodes can be proceeded to reach final node $\mathbf{a}^n$ to be part of a complete chain.

EXAMPLE 6. *For $m = 5$, $p = 3$, and given planes $L_1, \ldots, L_5$ in general position with $\dim(L_i) = 3$, for all $i = 1, \ldots, 5$, $\sum_{i=1}^5 k_i = 15 = mp$. Furthermore,*

$$\begin{aligned} & \sigma_0 \bullet \sigma_3 \bullet \sigma_3 \bullet \sigma_3 \bullet \sigma_3 \bullet \sigma_3 \\ \sim\ & [\Omega(6,7,8) \bullet \sigma_3] \bullet \sigma_3 \bullet \sigma_3 \bullet \sigma_3 \bullet \sigma_3 \\ \sim\ & [\Omega(3,7,8) \bullet \sigma_3] \bullet \sigma_3 \bullet \sigma_3 \bullet \sigma_3 \\ \sim\ & [\Omega(1,6,8) + \Omega(2,5,8) + \Omega(3,4,8)] \bullet \sigma_3 \bullet \sigma_3 \bullet \sigma_3 \\ \sim\ & [2\Omega(1,3,8) + 3\Omega(1,4,7) + 2\Omega(2,4,6) + \Omega(1,5,6) + \Omega(3,4,5)] \bullet \sigma_3 \bullet \sigma_3 \\ \sim\ & [7\Omega(1,3,5) + 6\Omega(1,2,6)] \bullet \sigma_3 \\ \sim\ & 6\Omega(1,2,3). \end{aligned}$$

The Pieri poset in this case is shown in Figure 3*, and the poset consisting of complete chains is shown in Figure* 4.

Of course, only complete chains in the Pieri poset are meaningful in computing our solutions. For $\mathbf{a}^0 = (1, \ldots, p)$, let

$$\mathbf{a}^0 \longrightarrow \mathbf{a}^1 \longrightarrow \cdots \longrightarrow \mathbf{a}^n$$

be a complete chain, where $\mathbf{a}^{j+1}$ is derived from $\mathbf{a}^j$ via $\sigma_{k_{j+1}}$ for $j = 1, \ldots, n-1$. Namely, $\Omega(\mathbf{a}^j) \subset \sigma_0 \bullet \sigma_{k_1} \bullet \cdots \sigma_{k_j}$ and $\Omega(\mathbf{a}^{j+1}) \subset \sigma_0 \bullet \sigma_{k_1} \bullet \cdots \sigma_{k_{j+1}}$. When $k_i > 1$ for certain $i \in \{1, \ldots, n\}$, we will insert artificial *intermediate* nodes between nodes $\mathbf{a}^{i-1}$ and $\mathbf{a}^i$ for our algorithm as follows:

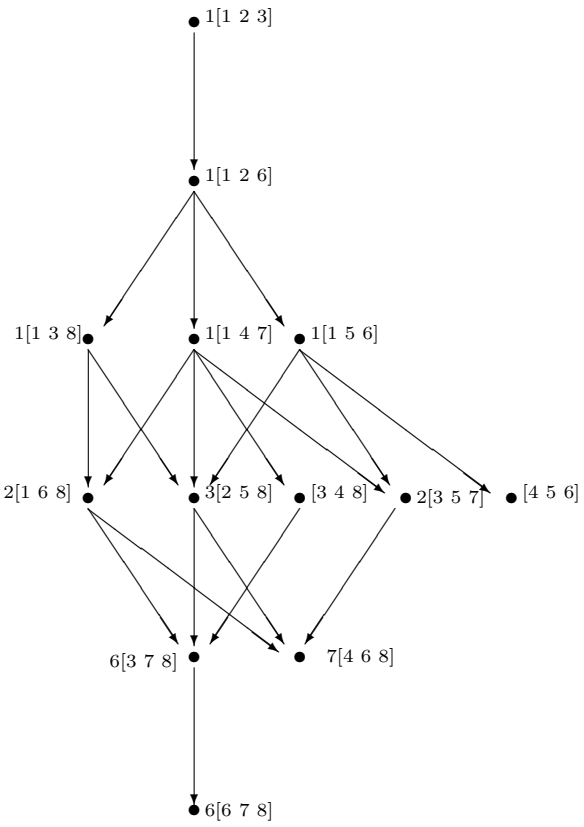

FIG. 3.

Writing

$$\mathbf{a}^{i-1} = [a_1^{(i-1)}, \ldots, a_p^{(i-1)}] \quad \text{and} \quad \mathbf{a}^{i} = [a_1^{(i)}, \ldots, a_p^{(i)}],$$

we let $l_1 = \min\{j \mid a_j^{(i-1)} < a_j^{(i)}\}$ and $\mathbf{b}^1 = (b_1^{(1)}, \ldots, b_p^{(1)})$, where

$$b_j^{(1)} = \begin{cases} a_j^{(i-1)} & \text{for } j = 1, \ldots, l_1 - 1, \\ a_{l_1}^{(i-1)} + 1 & \text{for } j = l_1 \\ a_j^{(i)} & \text{for } j = l_1 + 1, \ldots, p. \end{cases}$$

Inductively, when $\mathbf{b}^s = (b_1^{(s)}, \ldots, b_p^{(s)})$ is defined for $s < k_i - 1$, let $l_{s+1} = \min\{j \mid b_j^{(s)} < a_j^{(i)}\}$ and $\mathbf{b}^{s+1} = (b_1^{(s+1)}, \ldots, b_p^{(s+1)})$, where

$$b_j^{(s+1)} = \begin{cases} b_j^{(s)} & \text{for } j = 1, \ldots, l_{s+1} - 1, \\ b_{l_{s+1}}^{(s)} + 1 & \text{for } j = l_{s+1} \\ a_j^{(i)} & \text{for } j = l_{s+1} + 1, \ldots, p. \end{cases}$$

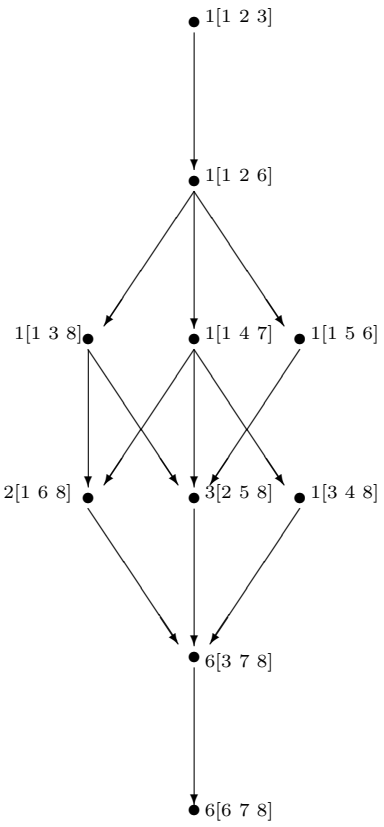

FIG. 4.

We insert those nodes $\mathbf{b}^1, \ldots, \mathbf{b}^{k_i-1}$ defined above between $\mathbf{a}^{i-1}$ and $\mathbf{a}^i$. Obviously, the coordinates of any two consecutive nodes among them can differ by 1 on only one coordinate. Therefore, we may write

$$\mathbf{a}^{i-1} := \mathbf{b}^0 \xrightarrow{\mu_1} \mathbf{b}^1 \xrightarrow{\mu_2} \cdots \xrightarrow{\mu_{k_i-1}} \mathbf{b}^{k_i} := \mathbf{a}^i,$$

where μ_j in $\mathbf{b}^{j-1} \xrightarrow{\mu_j} \mathbf{b}^j$ represents the coordinate where $\mathbf{b}^{j-1}$ and $\mathbf{b}^j$ differ.

EXAMPLE 7. *For instance, the node insertion between* [1 4 7] *and* [1 6 8] *on Figure* 4 *of Example* 6 *is*

$$[1\ 4\ 7] \xrightarrow{2} (1\ 5\ 7) \xrightarrow{2} (1\ 6\ 7) \xrightarrow{3} [1\ 6\ 8],$$

and when all intermediate nodes are inserted the poset with complete chains is shown in Figure 5.

For consecutive nodes $\mathbf{a}^{i-1}$ and $\mathbf{a}^i$ with $k_i > 1$ and the chain joining the intermediate nodes between them,

$$\mathbf{a}^{i-1} = \mathbf{b}^0 \xrightarrow{\mu_1} \mathbf{b}^1 \xrightarrow{\mu_2} \cdots \xrightarrow{\mu_{k_i-1}} \mathbf{b}^{k_i} = \mathbf{a}^i, \tag{9}$$

suppose we have solved all the variables in $X_{\mathbf{a}^{i-1}}$ as well as $\Lambda_l^{i-1} \in \mathbb{P}^{p-1}$ for $l = 1, \ldots, i-1$ for which

$$K_l X_{\mathbf{a}^{i-1}} \Lambda_l^{i-1} = 0 \qquad \text{for} \quad l = 1, \ldots, i-1. \tag{10}$$

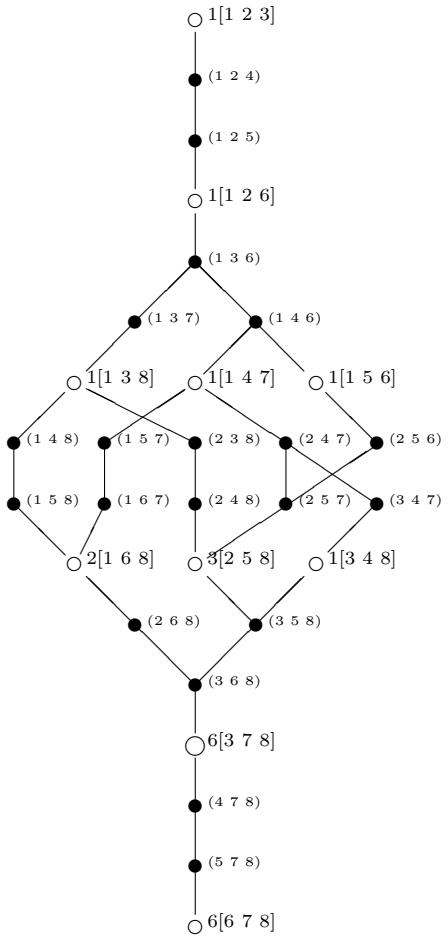

FIG. 5.

Recall that the $(p+k_j-1)\times(m+p)$ matrix K_l is a representation of the plane L_l. Let $K_i=[v_1,\ldots,v_{p+k_i-1}]^T$, where v_s for $s=1,\ldots,p+k_i-1$ are linearly independent vectors in $\mathbb{C}^{m+p}$. For

$$\mathbf{a}^{i-1}=\mathbf{b}^0 \ \xrightarrow{\mu_1}\ \mathbf{b}^1$$

consider the homotopy

$$\begin{aligned} K_1X_{\mathbf{b}^1}\Lambda_1^{i+k_i-1} &= 0,\\ &\vdots\\ K_{i-1}X_{\mathbf{b}^1}\Lambda_{i-1}^{i+k_i-1} &= 0,\\ [(1-t)\hat{K}_1^0+t\hat{K}_1^1]X_{\mathbf{b}^1}\Lambda_{i+k_i-1}^{i+k_i-1} &= 0, \end{aligned} \tag{11}$$

where for $\mathbf{b}^1=(b_1^{(1)},\ldots,b_p^{(1)})$

$$\begin{aligned} &\hat{K}_1^0:=[e_{b_1^{(1)}},\ldots,e_{b_p^{(1)}}]^T\\ \text{and}\quad &\hat{K}_1^1:=[e_{b_1^{(1)}},\ldots,e_{b_{\mu_1-1}^{(1)}},v_1,e_{b_{\mu_1+1}^{(1)}},\ldots,e_{b_p^{(1)}}]^T. \end{aligned}$$

Moreover, the μ_1th coordinate of $\Lambda_{i+k_i-1}^{i+k_i-1} \in \mathbb{P}^{p-1}$ is set to be 1, and for $l = 1, \ldots, i-1$ the coordinate of $\Lambda_l^{i+k_i-1} \in \mathbb{P}^{p-1}$ is set to be 1 if the same coordinate of $\Lambda_l^{i-1} \in \mathbb{P}^{p-1}$ is 1.

This homotopy is a deformation of square systems of size

$$p + \sum_{l=1}^{i-1}(p + k_l - 1).$$

Clearly, when $t = 0$ any solution $X_{\mathbf{a}^{i-1}}$, $\Lambda_l^{i+k_i-1}$ for $l = 1, \ldots, i-1$ of (10) coupled with $\Lambda_{i+k_i-1}^{i+k_i-1} = e_{\mu_1}$ is a solution of (11). The solutions we obtain at $t = 1$ by following the paths of the homotopy in (11) emanating from those solutions will be established as solutions of the start system of the homotopy constructed for the next step.

Inductively, write $\mathbf{b}^l = (b_1^{(l)}, \ldots, b_p^{(l)})$ for $l = 0, \ldots, k_i$ and suppose for $2 \le j \le k_i$ the system

$$\begin{aligned} K_1 X_{\mathbf{b}^{j-1}} \Lambda_1^{i+k_i-(j-1)} &= 0, \\ &\vdots \\ K_{i-1} X_{\mathbf{b}^{j-1}} \Lambda_{i-1}^{i+k_i-(j-1)} &= 0, \\ \hat{K}_{j-1}^1 X_{\mathbf{b}^{j-1}} \Lambda_{i+k_i-(j-1)}^{i+k_i-(j-1)} &= 0, \end{aligned} \tag{12}$$

where

$$\hat{K}_{j-1}^1 := [e_{b_1^{(j-1)}}, \ldots, e_{b_{\mu_{j-1}-1}^{(j-1)}}, v_{j-1}, e_{b_{\mu_{j-1}+1}^{(j-1)}}, \ldots, e_{b_p^{(j-1)}}, v_1, \ldots, v_{j-2}]^T$$

has been solved. For

$$\mathbf{b}^{j-1} \xrightarrow{\mu_j} \mathbf{b}^j$$

consider the homotopy

$$\begin{aligned} K_1 X_{\mathbf{b}^j} \Lambda_1^{i+k_i-j} &= 0, \\ &\vdots \\ K_{i-1} X_{\mathbf{b}^j} \Lambda_{i-1}^{i+k_i-j} &= 0, \\ [(1-t)\hat{K}_j^0 + t\hat{K}_j^1] X_{\mathbf{b}^j} \Lambda_{i+k_i-j}^{i+k_i-j} &= 0, \end{aligned} \tag{13}$$

where

$$\begin{aligned} &\hat{K}_1^0 = [e_{b_1^{(j)}}, \ldots, e_{b_p^{(j)}}, v_1, \ldots, v_{j-1}]^T \\ \text{and} \quad &\hat{K}_j^1 = [e_{b_1^{(j)}}, \ldots, e_{b_{\mu_j-1}^{(j)}}, v_j, e_{b_{\mu_j+1}^{(j)}}, \ldots, e_{b_p^{(j)}}, v_1, \ldots, v_{j-1}]^T. \end{aligned}$$

And, as in (11), the μ_jth coordinate of $\Lambda_{i+k_i-j}^{i+k_i-j} \in \mathbb{P}^{p-1}$ is set to be 1, and for $l = 1, \ldots, i-1$, the coordinate of $\Lambda_l^{i+k_i-j}$ is set to be 1 if the same coordinate of $\Lambda_l^{i+k_i-(j-1)}$ is 1.

This homotopy is a deformation of square system of size

$$p + j - 1 + \sum_{l=1}^{i-1}(p + k_l - 1),$$

and it is straightforward that any solution of the system in (12) induces a solution of (13) when $t = 0$. Those paths of the homotopy in (13) emanating from those solutions lead to, at $t = 1$, a set of solutions of

$$\begin{aligned} K_1 X_{\mathbf{b}^j} \Lambda_1^{i+k_i-j} &= 0, \\ &\vdots \\ K_{i-1} X_{\mathbf{b}^j} \Lambda_{i-1}^{i+k_i-j} &= 0, \\ \hat{K}_j^1 X_{\mathbf{b}^j} \Lambda_{i+k_i-j}^{i+k_i-j} &= 0. \end{aligned} \tag{14}$$

Continuing those steps successively from $j = 2$, when we reach $j = k_i$, the solutions at $t = 1$ provide a set of p-planes in the form $X_{\mathbf{a}^i}$ that meet $L_1, \ldots, L_i$.

EXAMPLE 8. *In Example* 7*, the homotopies of the chain*

$$\underbrace{[1\,2\,3] \xrightarrow{3} (1\,2\,4) \xrightarrow{3} (1\,2\,5) \xrightarrow{3} [1\,2\,6]}_{\text{level 1}}$$

$$\underbrace{\xrightarrow{2} (1\,3\,6) \xrightarrow{2} (1\,4\,6) \xrightarrow{3} [1\,4\,7]}_{\text{level 2}}$$

$$\underbrace{\xrightarrow{1} (2\,4\,7) \xrightarrow{2} (2\,5\,7) \xrightarrow{3} [2\,5\,8]}_{\text{level 3}} \longrightarrow \cdots$$

at the third level with $K_3 := [v_1, v_2, v_3, v_4, v_5]^T$ *are*

$$\begin{array}{l} [1\,4\,7] \\ \downarrow \\ (2\,4\,7) \\ \qquad : \left[\begin{array}{r} K_1 X_{(2,4,7)} \Lambda_1^5 = 0, \\ K_2 X_{(2,4,7)} \Lambda_2^5 = 0, \\ \{(1-t)[e_2, e_4, e_7]^T + t[e_2, v_5, e_7]^T\} X_{(2,4,7)} \Lambda_5^5 = 0, \end{array} \right. \\ \downarrow \\ (2\,5\,7) \\ \qquad : \left[\begin{array}{r} K_1 X_{(2,5,7)} \Lambda_1^4 = 0, \\ K_2 X_{(2,5,7)} \Lambda_2^4 = 0, \\ \{(1-t)[e_2, e_5, e_7, v_5]^T + t[e_2, e_5, v_4, v_5]^T\} X_{(2,5,7)} \Lambda_4^4 = 0, \end{array} \right. \\ \downarrow \\ [2\,5\,8] \\ \qquad : \left[\begin{array}{r} K_1 X_{[2,5,8]} \Lambda_1^3 = 0, \\ K_2 X_{[2,5,8]} \Lambda_2^3 = 0, \\ \{(1-t)[e_2, e_5, e_8, v_4, v_5] + t[v_1, v_2, v_3, v_4, v_5]\} X_{[2,5,8]} \Lambda_3^3 = 0, \end{array} \right. \end{array}$$

where

$$\Lambda_1^5, \Lambda_1^4, \Lambda_1^3 = \begin{bmatrix} * \\ * \\ 1 \end{bmatrix}, \quad \Lambda_2^5, \Lambda_2^4, \Lambda_2^3 = \begin{bmatrix} * \\ * \\ 1 \end{bmatrix},$$

$$\textit{and} \quad \Lambda_5^5 = \begin{bmatrix} 1 \\ * \\ * \end{bmatrix}, \quad \Lambda_4^4 = \begin{bmatrix} * \\ 1 \\ * \end{bmatrix}, \quad \Lambda_3^3 = \begin{bmatrix} * \\ * \\ 1 \end{bmatrix}.$$

Write $\widehat{K}_1^t = (1-t)[e_2, e_4, e_7]^T + t[e_2, v_5, e_7]^T$. *Then,*

$$\widehat{K}_1^t X_{(247)}\Lambda_5^5 = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ * & * & * & * & * & * & * & * \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ x_1 & 1 & 0 \\ & x_2 & 1 \\ & x_3 & x_4 \\ & & x_5 \\ 0 & & \\ & & x_6 \\ & & x_7 \\ & & 0 \end{bmatrix} \begin{bmatrix} \lambda_1 \\ \lambda_2 \\ \lambda_3 \end{bmatrix}$$

$$= \begin{bmatrix} x_1 & 1 & 0 \\ \star & \star & \star \\ 0 & 0 & x_7 \end{bmatrix} \begin{bmatrix} \lambda_1 \\ \lambda_2 \\ \lambda_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}.$$

Obviously, $\lambda_3 = 0$ *for all* $t \in [0,1]$, *and, as assigned,* $\lambda_1 = 1$ *for all* $t \in [0,1]$. *Let* $x_1^{(1)}, \ldots, x_7^{(1)}, \lambda_1^{(1)}(=1), \lambda_2^{(1)}, \lambda_3^{(1)}(=0)$ *be a solution of* $\widehat{K}_1^1 X_{(247)}\Lambda_5^5 = 0$. *Now, for* $\widehat{K}_2^t := (1-t)[e_2, e_5, e_7, v_5]^T + t[e_2, e_5, v_4, v_5]$ *at* $t = 0$,

$$\widehat{K}_2^0 X_{(257)}\Lambda_4^4 = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ * & * & * & * & * & * & * & * \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ x_1 & 1 & 0 \\ & x_2 & 1 \\ & x_3 & x_4 \\ & y & x_5 \\ 0 & & \\ & & x_6 \\ & & x_7 \\ & & 0 \end{bmatrix} \begin{bmatrix} \lambda_1 \\ \lambda_2 \\ \lambda_3 \end{bmatrix}$$

$$= \begin{bmatrix} x_1 & 1 & 0 \\ 0 & y & x_5 \\ 0 & 0 & x_7 \\ \star & \star & \star \end{bmatrix} \begin{bmatrix} \lambda_1 \\ \lambda_2 \\ \lambda_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}.$$

As assigned, $\lambda_2 = 1$ *and obviously* $\lambda_3 = 0$, *and the new variable* y *must be zero. And, since*

$$x_1\lambda_1 + 1 = 0,$$

$x_l = x_l^{(1)}$ *for* $l = 1, \ldots, 7$, *along with* $\lambda_1 = -\frac{1}{x_1^{(1)}}$, $\lambda_2 = 1$, $\lambda_3 = 0$, *is a solution of* $\widehat{K}_2^0 X_{(257)}\Lambda_4^4 = 0$. *Similarly, with* $\widehat{K}_2^1 = [e_2, e_5, v_4, v_5]^T$, *let* $x_1^{(2)}, \ldots, x_7^{(2)}, y^{(2)}, \lambda_1^{(2)}$,

$\lambda_2^{(2)}(=1), \lambda_3^{(2)}$ *be a solution of*

$$\widehat{K}_2^1 X_{(257)} \Lambda_4^4 = \begin{bmatrix} 0&1&0&0&0&0&0&0\\ 0&0&0&0&1&0&0&0\\ *&*&*&*&*&*&*&*\\ *&*&*&*&*&*&*&* \end{bmatrix} \begin{bmatrix} 1&0&0\\ x_1&1&0\\ &x_2&1\\ &x_3&x_4\\ 0&y&x_5\\ &&x_6\\ &&x_7\\ &&0 \end{bmatrix} \begin{bmatrix} \lambda_1\\ \lambda_2\\ \lambda_3 \end{bmatrix}$$

$$= \begin{bmatrix} x_1&1&0\\ 0&y&x_5\\ \star&\star&\star\\ \star&\star&\star \end{bmatrix} \begin{bmatrix} \lambda_1\\ \lambda_2\\ \lambda_3 \end{bmatrix} = \begin{bmatrix} 0\\0\\0\\0 \end{bmatrix}.$$

Then for $\widehat{K}_3^t := (1-t)[e_2, e_5, e_8, v_4, v_5]^T + t[v_1, v_2, v_3, v_4, v_5]$ *at* $t = 0$,

$$\widehat{K}_3^0 X_{[258]} \Lambda_3^3 = \begin{bmatrix} 0&1&0&0&0&0&0&0\\ 0&0&0&0&1&0&0&0\\ 0&0&0&0&0&0&0&1\\ *&*&*&*&*&*&*&*\\ *&*&*&*&*&*&*&* \end{bmatrix} \begin{bmatrix} 1&0&0\\ x_1&1&0\\ &x_2&1\\ &x_3&x_4\\ &y&x_5\\ 0&&x_6\\ &&x_7\\ &&z \end{bmatrix} \begin{bmatrix} \lambda_1\\ \lambda_2\\ \lambda_3 \end{bmatrix}$$

$$= \begin{bmatrix} x_1&1&0\\ 0&y&x_5\\ 0&0&z\\ \star&\star&\star\\ \star&\star&\star \end{bmatrix} \begin{bmatrix} \lambda_1\\ \lambda_2\\ \lambda_3 \end{bmatrix} = \begin{bmatrix} 0\\0\\0\\0\\0 \end{bmatrix}.$$

Then $\lambda_3 = 1$, *as assigned, implies* $z = 0$. *On the other hand, since*

$$y\lambda_2 + x_5 = 0 \text{ and } x_1\lambda_1 + \lambda_2 = 0,$$

$x_l = x_l^{(2)}$ *for* $l = 1, \ldots, 7$, $y = y^{(2)}$, $\lambda_2 = -\frac{x_5^{(2)}}{y^{(2)}}$, *and* $\lambda_1 = -\frac{\lambda_2}{x_1^{(2)}}$ *is a solution of* $\widehat{K}_3^0 X_{[258]} \Lambda_3^3 = 0$. ∎

Remark 2. In Example 8, $\widehat{K}_1^1$ defines a 5-plane L_3^1 containing L_3, $\widehat{K}_2^1$ defines a 4-plane L_3^2 containing L_3, and $\widehat{K}_3^1 = K_3$ represents L_3. So the strategy behind the homotopies we construct between intermediate nodes is the following. To find the 3-planes in the form of $X_{[258]}$ which meet L_1, L_2, L_3 (those $X_{[258]}$ are in $\sigma_3 \bullet \sigma_3 \bullet \sigma_3 \bullet \Omega(2,5,8)$), we first find the 3-planes $X_{(247)}$ which meet L_1, L_2, L_3^1 (those $X_{(247)}$ are in $\sigma_3 \bullet \sigma_3 \bullet \sigma_1 \bullet \Omega(2,4,7)$). Then we find the 3-planes $X_{(257)}$ which meet L_1, L_2, L_3^2 (those X's are in $\sigma_3 \bullet \sigma_3 \bullet \sigma_2 \bullet \Omega(2,5,7)$). Ultimately, we find the 3-planes $X_{[258]}$ which meet L_1, L_2, L_3.

4. Numerical results. An implementation of a previous version of the Pieri homotopy algorithm for numerical Schubert calculus [4] exists in the module of the extended version of PHCpack in [10] that also provides the SAGBI homotopy proposed in [3] for solving general problems in enumerative geometry numerically. In general, as reported in [4], the Pieri homotopy algorithms are much superior in speed as well as the range of applications than the SAGBI homotopies. We therefore compare only the results of the implementation of our algorithm with those of the code in PHCpack. All computations were carried out on a 400 MHz Intel Pentium II CPU with 256 MB of RAM, running on SunOS 5.6. In all the tables below #hty represents the total number of homotopies we followed in the corresponding cases, and **Wu** is the symbol representing our code.

1. **$k_i = 1$ for all i, as shown in Table 1.**

TABLE 1

m	p	**#soln**	#hty	**Wu**	**PHC**
3	2	**5**	21	220ms	720ms
4	2	**14**	63	1s270ms	5s50ms
3	3	**42**	183	13s420ms	41s480ms
5	2	**42**	195	8s870ms	39s870ms

7	2	**429**	1196	1m16s	8m14s
4	3	**462**	1110	1m58s	8m59s
8	2	**1,430**	4,056	7m44s	53m2s
9	2	**4,862**	13,988	38m11s	6h29m1s
5	3	**6,006**	14,683	57m59s	7h53m28s
6	3	**87,516**	217,276	28h44m13s	-

The code in PHCpack requires a much bigger RAM than our code in all of the cases. For instance, for $(m, p) = (4, 3)$ above, PHC needs more than 7,044KB whereas **Wu** only needs 996KB.

2. **$k_i > 1$ for certain i's, as shown in Tables 2–10.** The first column of each table shows the numbers of all those k_i's.

As we can see from the results above, our novel approach of employing the Pieri homotopy algorithm for the numerical Schubert calculus has made a considerable advance in speed. And, in all the cases we have tried, the storage requirement for our code is much smaller than that of the existing code. The algorithm is particularly valuable when $k_i > 1$ appears.

THE MORTAR ELEMENT METHOD WITH OVERLAPPING SUBDOMAINS*

YVES ACHDOU† AND YVON MADAY‡

Abstract. In this paper, we discuss an extension of the mortar element method to overlapping subdomains and nonmatching grids in the overlapped zones. We discuss in particular the case where more than two subdomains overlap. The method is described and analyzed, as are some preconditioned iterative methods for solving the linear systems arising from this discretization.

Key words. overlapping domain decomposition method, nonconforming method

1. Introduction. Mortar element methods were introduced in [4] for nonoverlapping domain decompositions in order to couple different variational approximations in different subdomains. In the finite element context, one important advantage of the mortar element methods is that they allow for using structured grids in subdomains and thus are fast solvers [1]. The resulting methods are nonconforming but still yield optimal approximations. The literature on the mortar element methods is growing numerous; see [2] and references therein.

In this paper, we shall discuss the case of overlapping subdomains, with meshes constructed in an independent manner in each subdomain. As pointed out by F. Hecht, J. L. Lions, and O. Pironneau [12] and J.-L. Lions and O. Pironneau [15], such a situation can occur if the domain of computation is a scene constructed by constructive solid geometry in image synthesis and virtual reality: each object of the scene is described by set operations on primitive shapes like cubes, cylinders, spheres, and cones. With VRML (the language of virtual reality), the objects may be described as unions of more elementary objects with primitive shapes, which are never intersected, so it is not possible to construct a global mesh. Each simple object must have its individual mesh. In [12, 15], many algorithms (including algorithms from control theory) for this situation are proposed and cover cases more general than overlapping subdomains (domain with holes, for example).

We also note that independent of the development of the mortar methods, overlapping domain decomposition with nonmatching grids has been used for finite difference discretizations in the engineering community: these methods are often referred to as the *chimera methods*; see [6, 18]. We refer to [16] and the references therein for the numerical analysis of these methods.

To our knowledge, mortar methods with overlapping subdomains have been proposed first by Y. Kuznetsov [13], who focused on iterative solvers with Lagrange multipliers. For two overlapping subdomains, the mortar method has been analyzed by X. C. Cai, M. Dryja, and M. Sarkis [5] in two dimensions. They have considered two subdomains, with nonmatching grids and piecewise linear Lagrange finite ele-

ments. In particular, they have considered the case when the overlapping parameter is 0 (two rectangular subdomains for an L shaped domain). They have also proposed iterative solvers and preconditioners for the linear systems arising from the mortar discretization.

In this paper, we generalize their method in two dimensions, with more than two subdomains. We shall see that technical difficulties arise when the boundaries of two subdomains cross each other. For simplicity, we consider the Laplace equation and rule out the case when the overlap may vanish. For such situations, one should mix the method described in [5] and the one below. Also, we deal with first order Lagrange elements, but, with some effort, the ideas below may be generalized to higher order finite elements.

The paper is organized as follows. In section 2, we propose some mortar discretizations, and we study the ellipticity of the discrete problems. Section 3 is devoted to an error analysis following the lines of [4]. In section 4, we propose an alternative matching condition. In section 5, we study additive Schwarz preconditioners (see [14, 17] for reviews) for the linear system arising from the mortar discretizations: we generalize one of the preconditioners proposed in [5] which is not optimal but fairly easy to implement, and we propose another optimal preconditioner.

2. The discretization.

2.1. First definitions. In all of what follows, c or C will stand for various positive constants, independent of the geometric parameters.

We consider a polygonal domain Ω of $\mathbb{R}^2$ and the model boundary value problem in Ω:

$$\begin{aligned} -\Delta u &= f \qquad \text{in } \Omega, \\ u &= 0 \qquad \text{on } \partial\Omega. \end{aligned} \tag{2.1}$$

We consider first a family of overlapping subdomains $(\Omega_k)_{k\in\{1,\dots,K\}}$ with polygonal shapes covering Ω:

$$\Omega = \bigcup_{k=1}^{K} \Omega_k. \tag{2.2}$$

We denote by $(\Gamma_k^l)_{1\le l\le E_k}$ the sides of the polygonal boundary $\partial\Omega_k$.

We denote by H_k the diameter of Ω_k and by H the maximal diameter $H = \max_{1\le k\le K} H_k$. We assume that there exists a constant c such that for any k, $1 \le k \le K$, $cH \le H_k \le H$. We also suppose that there exists a positive constant τ such that any subdomain Ω_k contains a ball of diameter greater than τH.

For any subdomain Ω_k, we denote by δ_k the minimum distance of overlap between Ω_k and $\cup_{i\neq k}\Omega_i$:

$$\delta_k = \inf_{x\in\Omega_k\setminus\cup_{i\neq k}\Omega_i} \inf_{y\in\cup_{i\neq k}\Omega_i\setminus\Omega_k} |x-y|.$$

We also define $\delta \equiv \min_k \delta_k$.

Assumption 1. We assume that the intersection of two subdomains' boundaries can only be isolated points, called crosspoints. We assume that there exists a constant α, $0 < \alpha \le \frac{\pi}{2}$, such that the angles (taken not greater than $\frac{\pi}{2}$) between two subdomains' boundaries crossing each other are all greater than α. For simplicity, we assume also that a given crosspoint is neither the intersection of more than two subdomains' boundaries nor the vertex of a subdomain.

Assumption 2. We assume that there exists a constant N_1 such that, for any ball B of diameter H, $B \cap \Omega$ is covered by at most N_1 subdomains.

This assumption yields two important consequences.

PROPERTY 1. *We denote by ω_k the union of the subdomains intersecting Ω_k and by $\mathcal{I}_k$ the set of the integers i such that $\Omega_i \subset \omega_k$. There exists a constant $n_1(N_1)$ such that, for any k, $1 \le k \le K$, cardinal$(\mathcal{I}_k) \le n_1(N_1)$.*

PROPERTY 2. *There exists a constant $n_2(N_1)$ such that the number of subdomains containing a given point in Ω is bounded by $n_2(N_1)$.*

We also make the following assumption.

Assumption 3. There exists a constant N_2 such that the number of sides E_k of a given subdomain Ω_k is smaller than N_2.

As a consequence, we have the following property.

PROPERTY 3. *The number of crosspoints lying on $\partial\Omega_k$ is bounded by a constant.*

On each subdomain Ω_k, we have a family of triangular meshes $\mathcal{T}_{k,h_k}$ whose triangles have maximal diameters h_k. The meshes are constructed in an independent manner. The mesh nodes on $\partial\Omega_k$ need not match with the mesh nodes in the adjacent subdomains. We assume that the families $(\mathcal{T}_{k,h_k})_{h_k}$ are shape regular and quasi uniform; see [7]. We agree to simplify the notations by replacing $\mathcal{T}_{k,h_k}$ with $\mathcal{T}_k$.

Assumption 4. We call $h = \max_k h_k$, and we assume that, for a positive constant C,

$$h < C\delta. \tag{2.3}$$

Associated with the mesh $\mathcal{T}_k$, we consider the spaces Z_k and X_k of piecewise linear Lagrange finite elements:

$$Z_k \equiv \left\{ \begin{array}{l} u_k \text{ is continuous in } \overline{\Omega}_k, \\ \forall t \in \mathcal{T}_k, u_k|_t \text{ is linear} \end{array} \right\}, \quad X_k \equiv \{u_k \in Z_k, u_k = 0 \text{ on } \partial\Omega \cap \partial\Omega_k\}.$$

Each space X_k and Z_k is supplied with its usual nodal basis functions. We define $X = \Pi_{k=0}^{K} X_k$. The vectors $u = (u_k)_{k\in\{1,\dots,K\}}$ of X are collections of functions defined in the subdomains, but no continuity constraint is imposed at the subdomains boundaries. The nodal basis of X can be found by taking the K-tuple of the nodal bases of the spaces X_k.

For a side Γ_k^l of $\partial\Omega_k$, we denote by Z_k^l the space of functions obtained by taking the trace on Γ_k^l of the functions of Z_k and by $\mathcal{T}_k^l$ the trace of the mesh $\mathcal{T}_k$ on Γ_k^l. Thus $\mathcal{T}_k^l$ is composed of elementary segments that are the sides of some triangles of $\mathcal{T}_k$. The space Z_k^l is the space of piecewise linear Lagrange finite elements on $\mathcal{T}_k^l$.

REMARK 1. *All the assumptions on the domain decomposition are not too stringent. Indeed, in the cases of interest described in the introduction, the decomposition is done a priori before constructing the mesh and therefore not through an automatic mesh partitioner. In addition, two other assumptions on the meshes will be made below.*

2.2. The matching condition. In order to discretize (2.1), we need to define a subspace Y of X by imposing weak continuity constraints at the subdomain boundaries $\partial\Omega_k$, $1 \le k \le K$.

For a side Γ_k^l of $\partial\Omega_k \backslash \partial\Omega$, we denote by $\widetilde{W_k^l}$ the subspace of Z_k^l of the functions whose restrictions to the extreme elementary segments (the first and the last) of $\mathcal{T}_k^l$ are constant; see Figure 2.1. Such spaces are used as mortar spaces for the nonoverlapping case (see [4]). Here, we will have to additionally modify them locally, near the crosspoints.

FIG. 2.1. *The nodal bases of the spaces Z_k^l and $\widetilde{W_k^l}$; here, the dimension of Z_k^l is five.*

Let $(j_i)_{i\in\{1,\dots,n_k^l\}}$ be the family of the indices such that $|\Gamma_k^l \cap \Omega_{j_i}| > 0$ and $j_i \neq k$. The number n_k^l is the number of subdomains covering Γ_k^l. Note that, from Property 1, n_k^l is bounded by $n_1(N_1)$. For $i \in \{1,\dots,n_k^l\}$, we define $\Gamma_k^{l,i} = \Gamma_k^l \cap \Omega_{j_i}$. From (2.2), we have the following overlapping decomposition:

$$\Gamma_k^l = \bigcup_{i=1}^{n_k^l} \Gamma_k^{l,i}.$$

Call $p_k^l(x)$ the piecewise constant counting function defined on Γ_k^l by

$$p_k^l(x) = \sum_{i=1}^{n_k^l} 1_{\Gamma_k^{l,i}}(x), \tag{2.4}$$

which represents the number of subdomains covering x. Here, $1_{\Gamma_k^{l,i}}$ is the characteristic function of $\Gamma_k^{l,i}$ (and is equal to one if $x \in \Gamma_k^{l,i}$ and is zero otherwise). From (2.2) and Property 2, p_k^l is greater than or equal to one and bounded from above by a constant.

Given W_k^l, a space of test functions defined on Γ_k^l, the first possible matching condition on Γ_k^l is of the form

$$\forall w \in W_k^l, \quad \int_{\Gamma_k^l} \frac{1}{p_k^l(x)+1} \left(u_k(x) - \frac{1}{p_k^l(x)} \sum_{i=1}^{n_k^l} 1_{\Gamma_k^{l,i}}(x) u_{j_i}(x) \right) w(x)dx = 0. \tag{2.5}$$

Basically, the space W_k^l will be a subspace of $\widetilde{W_k^l}$, and the spaces will differ essentially due to the presence of crosspoints.

It now remains to define the space W_k^l. Suppose that for $i \in \{1,\dots,n_k^l\}$, $\Gamma_k^l \cap \partial\Omega_{j_i} \neq \emptyset$.[1] Then, from Assumption 1, we know that the intersections do not take place at a vertex of $\partial\Omega_{j_i}$ and let $\Gamma_{j_i}^{l'}$ be the side of $\partial\Omega_{j_i}$ such that $\Gamma_k^l \cap \Gamma_{j_i}^{l'}$ is a point denoted by x^*. If no special care is taken for the choices of W_k^l and $W_{j_i}^{l'}$, then the matching condition (2.5) on Γ_k^l and $\Gamma_{j_i}^{l'}$ will strongly couple the degrees of freedom (d.o.f.) of u_k and u_{j_i} near the crosspoint x^*, and there might be cases when these conditions are too restrictive; i.e., the functions u_k and u_{j_i} must be constant—even zero—near x^*. To avoid such a situation, and also in order to get a solver with good parallel properties (see section 5), we have to relax the weak continuity condition near x^*.

We call $(x_m)_{m\in\{1,\dots,M_k^l\}}$ the nodes of $\mathcal{T}_k^l$ different from the endpoints of Γ_k^l and $(\phi_m)_{m\in\{1,\dots,M_k^l\}}$ (resp., $(\psi_m)_{m\in\{0,\dots,M_k^l+1\}}$) the nodal basis functions of $\widetilde{W_k^l}$ (resp., of Z_k^l). Note that $\phi_m = \psi_m$ for $2 \le m \le M_k^l - 1$ and $\phi_1 = \psi_0 + \psi_1$ and $\phi_{M_k^l} = \psi_{M_k^l} + \psi_{M_k^l+1}$.

[1] The situation $\Gamma_k^l \cap \partial\Omega_{j_i} = \emptyset$ corresponds to $\Gamma_k^l \subset \Omega_{j_i}$.

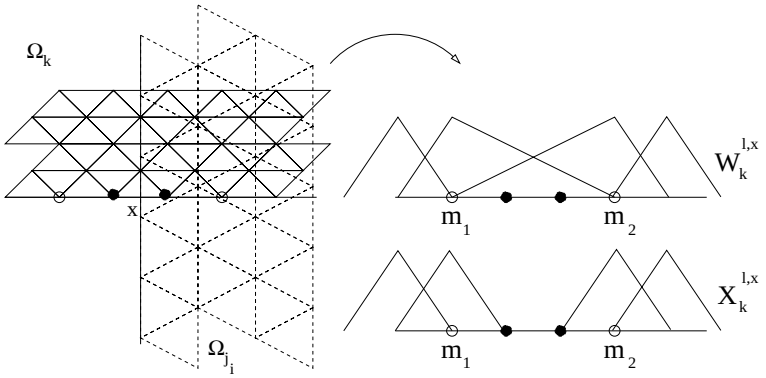

FIG. 2.2. *The nodal bases of the spaces W_k^{l,x^*} and X_k^{l,x^*}. (Only two subdomains have been represented.)*

We select the nodes of $\mathcal{T}_k^l$ for which the support of the associated basis function of X_k does not intersect $\Gamma_{j_i}^{l'}$: we obtain the set of nodes $(x_m)_{m\in\{1,\ldots,m_1\}\cup\{m_2,\ldots,M_k^l\}}$. We call $\widetilde{\phi}_{m_1}$ the continuous function vanishing outside (x_{m_1-1}, x_{m_2}), linear on (x_{m_1-1}, x_{m_1}) and on (x_{m_1}, x_{m_2}), such that $\widetilde{\phi}_{m_1}(x_{m_1}) = 1$. Likewise, $\widetilde{\phi}_{m_2}$ is the continuous function vanishing outside (x_{m_1}, x_{m_2+1}), linear on (x_{m_1}, x_{m_2}) and on (x_{m_2}, x_{m_2+1}), such that $\widetilde{\phi}_{m_2}(x_{m_2}) = 1$. The space W_k^{l,x^*} is defined by

$$W_k^{l,x^*} \equiv span(\phi_1, \ldots, \phi_{m_1-1}, \widetilde{\phi}_{m_1}, \widetilde{\phi}_{m_2}, \phi_{m_2+1}, \ldots, \phi_{M_k^l}). \tag{2.6}$$

The space W_k^{l,x^*} is displayed in Figure 2.2. For what follows, we also define the space

$$\begin{aligned} X_k^{l,x^*} &\equiv \{u \in Z_k^l, u = 0 \text{ at the endpoints of } \Gamma_k^l \text{ and } x_{m_1+1}, \ldots, x_{m_2-1}\} \\ &= span(\psi_1, \ldots, \psi_{m_1}, \psi_{m_2}, \ldots, \psi_{M_k^l}). \end{aligned} \tag{2.7}$$

DEFINITION 2.1. *For the crosspoint x^*, we define the* zone of influence *of x^* on Γ_k^l as the interval (x_{m_1-1}, x_{m_2+1}). We also define the* zone of influence *of a vertex x^* of Ω_k on Γ_k^l as the union of the two elements of $\mathcal{T}_k^l$ next to x^*. From Assumption* 1*, the zone of influence of a crosspoint has a size smaller than Ch.*

Assumption 5. The zones of influence of two crosspoints on Γ_k^l are disjoint. Moreover, the zones of influence on Γ_k^l of a crosspoint and a vertex of Ω_k are disjoint.

Finally, we define $\mathcal{X}_k^l$ as the set of crosspoints on Γ_k^l, and we set

$$W_k^l \equiv \bigcap_{x^*\in\mathcal{X}_k^l} W_k^{l,x^*} \tag{2.8}$$

and, likewise,

$$X_k^l \equiv \bigcap_{x^*\in\mathcal{X}_k^l} X_k^{l,x^*}, \tag{2.9}$$

and Y is the subspace of X defined by

$$Y \equiv \{u \in X;\ \forall k \in \{1, \ldots, K\},\ \forall l \in \{1, \ldots, E_k\}, u \text{ satisfies } (2.5)\} \tag{2.10}$$

for W_k^l defined by (2.8) and (2.6).

REMARK 2. *The functions in W_k^l will resemble those of $\widetilde{W_k^l}$ except at a few nodes near crosspoints. Furthermore, from Assumption* 5*, these exceptional regions around crosspoints are disjoint.*

REMARK 3. *The spaces W_k^l and X_k^l have the same dimension.*

Let $\mathcal{V}_k$ be the set of the nodes containing

1. the vertices of $\partial\Omega_k$,
2. all the other nodes of $\mathcal{T}_k$ on $\partial\Omega_k$ such that the support of the associated nodal basis function of X_k intersects another subdomain's boundary.

Let u be a function in $L^2(\Gamma_k^l)$. Under a technical but reasonable assumption on the mesh, the following problem is well posed: find $u_k^l \in Z_k^l$ such that

$$\begin{aligned} &u_k^l \text{ is given at the nodes of } \Gamma_k^l \cap \mathcal{V}_k, \\ &\forall w_k^l \in W_k^l, \quad \int_{\Gamma_k^l} \frac{1}{p_k^l(x)+1} u_k^l(x) w_k^l(x) dx = \int_{\Gamma_k^l} \frac{1}{p_k^l(x)+1} u(x) w_k^l(x) dx. \end{aligned} \tag{2.11}$$

This is a corollary of the following lemma.

LEMMA 2.2. *For a given crosspoint x^* on Γ_k^l, let $(x_m)_{m\in\{1,\dots,m_1\}\cup\{m_2,\dots,M_k^l\}}$ be the nodes of $\mathcal{T}_k^l$ involved in the above construction of W_k^{l,x^*}. Let δ^{--}, δ^-, δ^+, and δ^{++} be defined by $\delta^{--} = \frac{x_{m_1}-x_{m_1-1}}{x_{m_2}-x_{m_1}}$, $\delta^- = \frac{x_{m_1+1}-x_{m_1}}{x_{m_2}-x_{m_1}} < 1$, $\delta^+ = \frac{x_{m_2}-x_{m_2-1}}{x_{m_2}-x_{m_1}} < 1$, and $\delta^{++} = \frac{x_{m_2+1}-x_{m_2}}{x_{m_2}-x_{m_1}}$. Assume that there exists a constant c such that for all crosspoints x^*,*

$$\begin{aligned} &\tfrac{3}{2}\delta^- + \delta^{--} - (\delta^+)^2 \geq c, \\ &\tfrac{3}{2}\delta^+ + \delta^{++} - (\delta^-)^2 \geq c, \end{aligned} \tag{2.12}$$

and there exists a constant C independent of h such that

$$\inf_{u\in X_k^l} \sup_{\substack{w\in W_k^l \\ w\neq 0}} \frac{\int_{\Gamma_k^l} \frac{1}{p_k^l(x)+1} u(x) w(x) dx}{\|w\|_{L^2(\Gamma_k^l)}} \geq C \|u\|_{L^2(\Gamma_k^l)}. \tag{2.13}$$

Proof. If there is no crosspoint on Γ_k^l, then the result can be found in [2, Lemma 1] and its proof. In the opposite case, consider the tridiagonal matrix M of the bilinear form in the nodal bases of $X_k^l \times W_k^l$. We wish to prove that there exists a constant C such that the symmetrized matrix $\frac{1}{2}(M + M^T)$ has all its eigenvalues not smaller than Ch. This will be a consequence of the stronger property: for any i,

$$M_{i,i} - \frac{1}{2}(M_{i,i+1} + M_{i+1,i} + M_{i,i-1} + M_{i-1,i}) \geq Ch. \tag{2.14}$$

The estimate (2.14) is true if the node corresponding to the ith nodal basis function of X_k^l and W_k^l is not contained in the region of influence of a crosspoint; see the proof of [2, Lemma 1]. In the opposite case, there is exactly one crosspoint x^* in the support of the ith nodal basis function of W_k^l; assume with no restrictions that in the neighborhood of x^*, $p_k^l(s) = r+1$ for $s < x^*$, and $p_k^l(s) = r$ for $s > x^*$. We have $W_k^{l,x^*} = span(\phi_1, \dots, \phi_{m_1-1}, \widetilde{\phi}_{m_1}, \widetilde{\phi}_{m_2}, \phi_{m_2+1}, \dots, \phi_{M_k^l})$ and $X_k^{l,x^*} = span(\psi_1, \dots, \psi_{m_1}, \psi_{m_2}, \dots, \psi_{M_k^l})$. Without restriction, we can assume that

the ith (resp., $(i+1)$th) nodal basis function of W_k^l is $\widetilde{\phi}_{m_1}$ (resp., $\widetilde{\phi}_{m_2}$). We have

$$
\begin{aligned}
&M_{i,i-1} = M_{i-1,i} = \tfrac{x_{m_1}-x_{m_1-1}}{6(r+1)},\\
&M_{i,i} = \tfrac{x_{m_1}-x_{m_1-1}}{3(r+1)} + (x_{m_1+1}-x_{m_1})\left(\tfrac{1}{2(r+1)} - \tfrac{x_{m_1+1}-x_{m_1}}{6(r+1)(x_{m_2}-x_{m_1})}\right),\\
&M_{i,i+1} = \tfrac{1}{6r}\tfrac{(x_{m_2}-x_{m_2-1})^2}{x_{m_2}-x_{m_1}}
\end{aligned}
$$

and

$$
\begin{aligned}
&M_{i+1,i+2} = M_{i+2,i+1} = \tfrac{x_{m_2+1}-x_{m_2}}{6r},\\
&M_{i+1,i+1} = \tfrac{x_{m_2+1}-x_{m_2}}{3r} + (x_{m_2}-x_{m_2-1})\left(\tfrac{1}{2r} - \tfrac{x_{m_2}-x_{m_2-1}}{6r(x_{m_2}-x_{m_1})}\right),\\
&M_{i+1,i} = \tfrac{1}{6(r+1)}\tfrac{(x_{m_1+1}-x_{m_1})^2}{x_{m_2}-x_{m_1}}.
\end{aligned}
$$

Then (2.14) for i and $i+1$ is equivalent to

(2.15)
$$\frac{x_{m_1}-x_{m_1-1}}{6(r+1)} + \frac{x_{m_1+1}-x_{m_1}}{2(r+1)}\left(1-\frac{1}{2}\frac{x_{m_1+1}-x_{m_1}}{(x_{m_2}-x_{m_1})}\right) - \frac{1}{12r}\frac{(x_{m_2}-x_{m_2-1})^2}{x_{m_2}-x_{m_1}} \geq Ch$$

and

(2.16)
$$\frac{x_{m_2+1}-x_{m_2}}{6r} + \frac{x_{m_2}-x_{m_2-1}}{2r}\left(1-\frac{1}{2}\frac{x_{m_2}-x_{m_2-1}}{(x_{m_2}-x_{m_1})}\right) - \frac{1}{12(r+1)}\frac{(x_{m_1+1}-x_{m_1})^2}{x_{m_2}-x_{m_1}} \geq Ch.$$

From the quasi-uniformity assumption, and from Assumption 5, this is equivalent to

$$
\begin{aligned}
&\tfrac{\delta^{--}}{3} + \delta^-(1-\tfrac{1}{2}\delta^-) - \tfrac{r+1}{6r}(\delta^+)^2 \geq C,\\
&\tfrac{\delta^{++}}{3} + \delta^+(1-\tfrac{1}{2}\delta^+) - \tfrac{r}{6(r+1)}(\delta^-)^2 \geq C.
\end{aligned}
\tag{2.17}
$$

But (2.17) is a consequence of

$$
\begin{aligned}
&\tfrac{3}{2}\delta^- + \delta^{--} - (\delta^+)^2 \geq C,\\
&\tfrac{3}{2}\delta^+ + \delta^{++} - \tfrac{1}{2}(\delta^-)^2 \geq C,
\end{aligned}
\tag{2.18}
$$

because $r \geq 1$. Suppose now that assumption (2.12) is satisfied. Then, if (2.15) and (2.16) are satisfied and the matrix $\frac{1}{2}(M+M^T)$ is positive definite with its eigenvalues not less than Ch, for any vector U, $(MU,U) \geq Ch(U,U)$, which yields (2.13). □

REMARK 4. *From the proof of Lemma* 2.2, (2.11) *is a linear system with a square matrix* M *of size* $\dim(W_k^l)$, *nonsymmetric, but such that* $(MU,U) \geq ch(U,U)$. *In other words, the matrix* M *resembles a mass matrix.*

From the previous lemma, we deduce the following.

COROLLARY 2.3. *Under assumption* (2.12), *the problem* (2.11) *has a unique solution. Furthermore, if we impose that* $u_k^l = 0$ *at the nodes in* $\Gamma_k^l \cap \mathcal{V}_k$, *then we have*

$$\left\|u_k^l\right\|_{L^2(\Gamma_k^l)} \leq C\|u\|_{L^2(\Gamma_k^l)}. \tag{2.19}$$

Likewise, let x_i be a given node in $\Gamma_k^l \cap \mathcal{V}_k$. Under assumptions (2.12)*, the solution of the problem, find $\widetilde{\psi}_i \in Z_k^l$ such that*

$$\begin{aligned} &\widetilde{\psi}_i(x_i) = 1, \\ &\widetilde{\psi}_i = 0 \text{ at the other nodes of } \Gamma_k^l \cap \mathcal{V}_k, \\ &\forall w_k^l \in W_k^l, \quad \int_{\Gamma_k^l} \frac{1}{p_k^l(x)+1} \widetilde{\psi}_i(x) w_k^l(x) dx = 0, \end{aligned} \tag{2.20}$$

satisfies

$$\left\| \widetilde{\psi}_i \right\|_{L^2(\Gamma_k^l)} \leq C h^{\frac{1}{2}}. \tag{2.21}$$

REMARK 5. *Consider $u = (u_k)_k \in Y$. Then it is clear from* (2.5) *that all the nodal values of u_k located on $\Gamma_k^l \backslash \mathcal{V}_k$ can be found from the d.o.f. in the adjacent subdomains and from the d.o.f. on $\mathcal{V}_k$ by solving a system with a one-dimensional mass matrix. The nodal values of u_k located on $\partial\Omega_k \backslash \mathcal{V}_k$ can thus be seen as slave nodal values.*

2.3. The discrete problem. From now on, we shall assume that the conditions (2.12) are satisfied.

Let σ be the counting function $\sigma(x) = \sum_{k=1}^K 1_{\Omega_k}(x)$. The quantity $\sigma(x)$ represents the number of subdomains covering x. From Property 2, σ is bounded from above by a constant, and $\sigma \geq 1$. Consider the discrete problem: find $u \in Y$ such that for all $v \in Y$,

$$\sum_{k=1}^K \int_{\Omega_k} \frac{1}{\sigma} \nabla u_k \cdot \nabla v_k = \sum_{k=1}^K \int_{\Omega_k} \frac{1}{\sigma} f v_k. \tag{2.22}$$

Call a the symmetric bilinear form on Y:

$$a(u,v) = \sum_{k=1}^K \int_{\Omega_k} \frac{1}{\sigma} \nabla u_k \cdot \nabla v_k. \tag{2.23}$$

The following lemma allows us to state that problem (2.22) has a unique solution for Y defined by (2.10).

LEMMA 2.4. *The symmetric bilinear form a is positive definite.*

Proof. The bilinear form a is clearly positive semidefinite.

Let $u \in Y$ satisfy $a(u,u) = 0$. Then u_k is a constant ξ_k for $1 \leq k \leq K$. Let $\Xi = (\xi_1, \ldots, \xi_K)^T$. Taking $w = 1$ in (2.5) and summing up over all the sides of $\partial\Omega_k$, we obtain for each subdomain a linear equation for ξ. The system writes $S\Xi = 0$, where S is an irreducible $K \times K$ matrix such that

- for all $k \in \{1, \ldots, K\}$, $S_{kk} > 0$,
- for all $k \in \{1, \ldots, K\}$, for all $l \neq k$, $S_{kl} \leq 0$,
- for all $k \in \{1, \ldots, K\}$, $\sum_{l=1}^K S_{kl} = 0$.

From these properties, it is clear that there exists ξ such that all the ξ_k equal ξ. Now taking a subdomain Ω_k such that $meas(\partial\Omega_k \cap \partial\Omega) > 0$, we have that $u_k = 0$, which yields $\xi = 0$. ∎

Now, we wish to obtain an estimate on the ellipticity constant under typical but not necessarily optimal assumptions. For that, we recall that we have denoted by ω_k

the union of the subdomains intersecting Ω_k and by $\mathcal{I}_k$ the set of the integers i such that $\Omega_i \subset \omega_k$. Let us make the following assumption.

Assumption 6. Let Ω_k be a subdomain. We assume that for a positive constant C, for each $i \neq k \in \mathcal{I}_k$, there exists a side Γ_i^e and a subinterval γ_i of Γ_i^e such that

- $\gamma_i \subset \Omega_k$,
- $|\gamma_i| > CH$,
- γ_i is the union of elements of $\mathcal{T}_i^e$.

LEMMA 2.5. *Suppose that Assumptions* 1 *to* 6 *are satisfied. Then for* $\frac{h}{H}$ *small enough, there exists a constant* C *independent of* h, H, *and the overlap such that for any* u *in* Y,

$$\sum_{l\in\mathcal{I}_k}(\langle u_k\rangle - \langle u_l\rangle)^2 \leq C\sum_{l\in\mathcal{I}_k}\int_{\Omega_l}|\nabla u_l|^2, \tag{2.24}$$

where

$$\langle u_k\rangle = \frac{1}{|\Omega_k|}\int_{\Omega_k} u_k.$$

Proof. For $i \in \mathcal{I}_k$ and Γ_i^e as in Assumption 6, the subdomains intersecting Γ_i^e are (Ω_{j_m}), $j_m = 1, \ldots, n_i^e$. We wish to bound

$$\left|\int_{\gamma_i}\frac{1}{p_i^e(x)+1}\left(\langle u_i\rangle - \frac{1}{p_i^e(x)}\sum_{m=1}^{n_i^e} 1_{\Gamma_i^{e,m}}(x)\langle u_{j_m}\rangle\right)dx\right|$$

by using (2.5). The characteristic function 1_{γ_i} does not belong to W_i^e, so it is not a test function for (2.5). We thus take the test function in W_i^e supported in γ_i, equal to one at all the slave nodes of Ω_i whose related shape function is supported in γ_i. We call it w_i. We call $\overset{\circ}{\gamma}_i$ the region where $w_i = 1$. Clearly, from Property 3 and Assumption 1, the measure $meas(\gamma_i \setminus \overset{\circ}{\gamma}_i)$ is bounded by ch. From a scaled Poincaré–Wiertinger inequality, we have

$$\left|\int_{\gamma_i}\frac{w_i(x)}{p_i^e(x)+1}\left((\langle u_i\rangle - u_i(x)) - \frac{1}{p_i^e(x)}\sum_{m=1}^{n_i^e} 1_{\Gamma_i^{e,m}}(x)(\langle u_{j_m}\rangle - u_{j_m}(x))\right)dx\right|$$
$$\leq CH\left(\sum_{m\in\mathcal{I}_k}\int_{\Omega_m}|\nabla u_m|^2\right)^{\frac{1}{2}},$$

which yields, thanks to (2.5),

$$\left|\int_{\gamma_i}\frac{1}{p_i^e(x)+1}\left(\langle u_i\rangle - \frac{1}{p_i^e(x)}\sum_{m=1}^{n_i^e} 1_{\Gamma_i^{e,m}}(x)\langle u_{j_m}\rangle\right)w_i(x)dx\right|$$
$$\leq CH\left(\sum_{m\in\mathcal{I}_k}\int_{\Omega_m}|\nabla u_m|^2\right)^{\frac{1}{2}}.$$

Therefore,

$$\left| \int_{\gamma_i} \frac{1}{p_i^e(x)+1} \left(\langle u_i \rangle - \langle u_k \rangle - \frac{1}{p_i^e(x)} \sum_{m=1}^{n_i^e} 1_{\Gamma_i^{e,m}}(x)(\langle u_{j_m} \rangle - \langle u_k \rangle) \right) dx \right|$$
$$- \left| \int_{\gamma_i} \frac{1-w_i(x)}{p_i^e(x)+1} \left(\langle u_i \rangle - \langle u_k \rangle - \frac{1}{p_i^e(x)} \sum_{m=1}^{n_i^e} 1_{\Gamma_i^{e,m}}(x)(\langle u_{j_m} \rangle - \langle u_k \rangle) \right) \right|$$
$$\leq CH \left(\sum_{m \in \mathcal{I}_k} \int_{\Omega_m} |\nabla u_m|^2 \right)^{\frac{1}{2}}.$$

This yields the estimate

$$\left| \sum_{l \in \mathcal{I}_k} a_{li}(\langle u_l \rangle - \langle u_k \rangle) \right| - \frac{h_i}{H} \left| \sum_{l \in \mathcal{I}_k} b_{li}(\langle u_l \rangle - \langle u_k \rangle) \right| \leq C \left(\sum_{i \in \mathcal{I}_k} \int_{\Omega_i} |\nabla u_i|^2 \right)^{\frac{1}{2}}, \tag{2.25}$$

where it can be checked, thanks to Assumption 6, that

- $a_{ii} > C$, $|a_{ki}| > C$,
- $a_{li} \leq 0$ if $l \neq i$,
- $\sum_{l \in \mathcal{I}_k} a_{li} = 0$,
- $|b_{li}| < C$.

Thus, the matrix $(a_{ij})_{i \neq k, j \neq k}$ is a square M-matrix (in particular, $\sum_{k \neq l \in \mathcal{I}_k} a_{li} > C$). Therefore it is invertible and its inverse has a l^∞-norm bounded independently on h and H, and, thanks to Property 1, we have the desired result for h small enough. ∎

REMARK 6. *If Assumption* 6 *is not satisfied, then, thanks to the quasi-uniformity assumption on the grids inside the subdomains, we would obtain instead of* (2.24) *the estimate*

$$\sum_{l \in \mathcal{I}_k} (\langle u_k \rangle - \langle u_l \rangle)^2 \leq C \max_{l \in \mathcal{I}_k} \left(1 + \log \frac{H}{h_l} \right) \sum_{l \in \mathcal{I}_k} \int_{\Omega_l} |\nabla u_l|^2. \tag{2.26}$$

To prove this estimate, one has to take for each $i \neq k$ an index e such that $\Gamma_i^e \cap \Omega_k$ contains at least the support of a nodal basis function w_i of W_i^e. We have from the quasi-uniformity assumption the well-known estimate

$$\|u_m - \langle u_m \rangle\|_{L^\infty(\Omega_m)} \leq C \left(1 + \log \frac{H}{h_m} \right)^{\frac{1}{2}} \|\nabla u_m\|_{L^2(\Omega_m)}.$$

Thus

$$\left| \int_{\Gamma_i^e} \frac{w_i(x)}{p_i^e(x)+1} \left((\langle u_i \rangle - u_i(x)) - \frac{1}{p_i^e(x)} \sum_{m=1}^{n_i^e} 1_{\Gamma_i^{e,m}}(x)(\langle u_{j_m} \rangle - u_{j_m}(x)) \right) dx \right|$$
$$\leq Ch_i \left(\sum_{m \in \mathcal{I}_k} \left(1 + \log \frac{H}{h_m} \right) \int_{\Omega_m} |\nabla u_m|^2 \right)^{\frac{1}{2}},$$

which yields, thanks to (2.5),

$$\left| \int_{\Gamma_i^e} \frac{1}{p_i^e(x)+1} \left(\langle u_i \rangle - \frac{1}{p_i^e(x)} \sum_{m=1}^{n_i^e} 1_{\Gamma_i^{e,m}}(x) \langle u_{j_m} \rangle \right) w_i(x) dx \right|$$
$$\leq C h_i \left(\sum_{m \in \mathcal{I}_k} \left(1 + \log \frac{H}{h_m} \right) \int_{\Omega_m} |\nabla u_m|^2 \right)^{\frac{1}{2}}.$$

This yields the estimate

$$\left| \sum_{l \in \mathcal{I}_k} a_{li} (\langle u_l \rangle - \langle u_k \rangle) \right| \leq C \left(\sum_{i \in \mathcal{I}_k} \left(1 + \log \frac{H}{h_m} \right) \int_{\Omega_i} |\nabla u_i|^2 \right)^{\frac{1}{2}},$$

where $a_{ii} > C$, $|a_{ki}| > C$, $a_{li} \leq 0$ *if* $l \neq i$, $\sum_{l \in \mathcal{I}_k} a_{li} = 0$, *and therefore* (2.26).

REMARK 7. *Lemma* 2.5 *(or Remark* 6*) will be used both for the ellipticity analysis and for the consistency error analysis.*

LEMMA 2.6. *Under Assumptions* 1 *to* 6 *and* (2.12), *there exists a constant* C *such that for all* $u \in Y$,

$$\sum_{k=0}^{K} H^2 \langle u_k \rangle^2 \leq C \sum_{k=0}^{K} \int_{\Omega_k} |\nabla u_k|^2, \tag{2.27}$$

and there exists a constant C *independent of* h *and* H *such that for all* $u \in Y$,

$$\sum_{k=0}^{K} ||u_k||^2_{H^1(\Omega_k)} \leq C \sum_{k=0}^{K} \int_{\Omega_k} |\nabla u_k|^2. \tag{2.28}$$

Proof. Choose the coordinates so that Ω is contained in the square $(0, diam(\Omega))^2$. From the quasi-uniformity assumption on the subdomains, there exists a constant δ independent of h and H, $0 < \delta \leq 1$, such that the straight lines Δ_j of equations $x_2 = j\delta H$, $1 \leq j \leq J = \frac{diam(\Omega)}{\delta H}$, cross each subdomain Ω_k at least once. For a subdomain Ω_k, we denote by $\zeta_{k,j}$

$$\zeta_{k,j} = \sup_{x \in \Omega_k \cap \Delta_j} x_1 \text{ if } meas(\Omega_k \cap \Delta_j) > 0, \quad \zeta_{k,j} = -\infty \text{ if } meas(\Omega_k \cap \Delta_j) = 0.$$

Let $(k_i^j)_{1 \leq i \leq I_j}$ be the indices such that the line Δ_j crosses $\Omega_{k_i^j}$, numbered in such a way that $\zeta_{k_i^j,j}$ is an increasing sequence. Necessarily, we have $meas(\Omega_{k_i^j} \cap \Omega_{k_{i+1}^j}) > 0$. From Assumption 2, we know that there exists a constant C such that $I_j \leq \frac{C}{H}$. We

have

$$\sum_{i=1}^{I_j}\langle u_{k_i^j}\rangle^2 \le \sum_{i=1}^{I_j}\left(\langle u_{k_1^j}\rangle + \sum_{1\le l\le i-1}\langle u_{k_{l+1}^j}\rangle - \langle u_{k_l^j}\rangle\right)^2$$
$$\le \sum_{i=1}^{I_j}\left(2\langle u_{k_1^j}\rangle^2 + C(i-1)\sum_{1\le l\le i-1}\sum_{m\in\mathcal{I}_{k_l^j}}\int_{\Omega_m}|\nabla u_m|^2\right)$$
$$\le \frac{C}{H}\int_{\Omega_{k_1^j}}|\nabla u_{k_1^j}|^2 + \frac{C}{H^2}\sum_{i=1}^{I_j-1}\sum_{m\in\mathcal{I}_{k_i^j}}\int_{\Omega_m}|\nabla u_m|^2$$
$$\le \frac{C}{H^2}\sum_{i=0}^{I_j-1}\sum_{m\in\mathcal{I}_{k_i^j}}\int_{\Omega_m}|\nabla u_m|^2.$$

Finally, we obtain

$$\sum_{k=1}^{K}\langle u_k\rangle^2 \le \frac{C}{H^2}\sum_{j=1}^{J}\sum_{i=1}^{I_j-1}\sum_{m\in\mathcal{I}_{k_i^j}}\int_{\Omega_m}|\nabla u_m|^2$$
$$\le \frac{C}{H^2}\sum_{k=1}^{K}\int_{\Omega_k}|\nabla u_k|^2,$$

since each subdomain appears a finite number of times in the triple sum above.

Then (2.28) is a direct application of the Poincaré–Wiertinger inequality. ∎

REMARK 8. *In fact, for nonconforming methods, the ellipticity analysis can be postponed after the consistency analysis and simplified by using a clever duality argument* [9]. *However, this would not lead to an optimal result as in Lemma* 2.6 *because the consistency estimate would not be completely optimal. (There are, in any case, logarithmic factors in* h/H*.) Furthermore, we have seen in Remark* 7 *that the consistency error analysis uses* (2.26) *and Lemma* 2.5.

Finally, we obtain the following.

COROLLARY 2.7. *Under Assumptions* 1 *to* 6 *and* (2.12)*, there exists a constant* C_e *independent on the mesh parameters such that*

$$\forall u\in Y,\quad a(u,u)\ge C_e\sum_{k=1}^{K}\int_{\Omega_k}\left(|\nabla u_k|^2+u_k^2\right). \tag{2.29}$$

If only Assumptions 1 *to* 5 *and* (2.12) *are satisfied, we have* (2.29)*, but we know only that there exists a constant* C *independent on the mesh parameters such that*

$$C_e\le C\frac{1}{\max_l(1+\log\frac{H}{h_l})}. \tag{2.30}$$

3. Error analysis. Let us introduce the *broken* seminorm and norm on $\prod_{k=1}^{K}H^1(\Omega_k)$:

$$\forall u\in\prod_{k=1}^{K}H^1(\Omega_k),\quad |u|_*^2\equiv\sum_{k=1}^{K}\int_{\Omega_k}|\nabla u_k|^2,\quad \|u\|_*^2\equiv\sum_{k=1}^{K}\int_{\Omega_k}\left(|\nabla u_k|^2+u_k^2\right). \tag{3.1}$$

Let u^* be the solution of the continuous problem (2.1). With an abuse of notations, we still call u^* the vector of $\prod_{k=1}^K H^1(\Omega_k)$, defined by $u_k^* = u^*|_{\Omega_k}$. By the Berger–Scott–Strang lemma (see [3, 19]), we know that the error of the method is the sum of a consistency error and of a best approximation error:

$$\|u - u^*\|_* \leq \frac{1}{C_e}\left(\inf_{v\in Y}|u^* - v|_* + \sup_{0\neq v\in Y}\frac{|a(u^*,v) - \sum_{k=1}^K \int_{\Omega_k}\frac{1}{\sigma}fv_k|}{|v|_*}\right), \tag{3.2}$$

where C_e is the ellipticity constant. We have seen above that under Assumptions 1 to 6, C_e is bounded independently of the mesh parameters and the subdomains diameters.

3.1. Consistency error. For the consistency error, we first need to study a weighted L^2 projection operator: call $\tilde{\pi}_k^l$ the projection operator on W_k^l defined by

$$\forall w_k^l \in W_k^l, \quad \int_{\Gamma_k^l}\frac{1}{p_k^l(x)+1}(\tilde{\pi}_k^l u)(x)w_k^l(x)dx = \int_{\Gamma_k^l}\frac{1}{p_k^l(x)+1}u(x)w_k^l(x)dx. \tag{3.3}$$

It can be checked that the functional

$$|||u||| \equiv \sup_{0\neq v\in H^{\frac{1}{2}}(\Gamma_k^l)}\frac{\left|\int_{\Gamma_k^l}\frac{1}{p_k^l(x)+1}u(x)v(x)dx\right|}{\|v\|_{H^{\frac{1}{2}}(\Gamma_k^l)}}$$

defines a norm on $C^\infty(\Gamma_k^l)$. This is due in particular to the fact that $\frac{1}{p_k^l(x)+1}$ is a positive weight function in L^∞ bounded away from 0. We call $(H^{\frac{1}{2}})'(\Gamma_k^l)$ the completion of $C^\infty(\Gamma_k^l)$ for this norm. For $u \in (H^{\frac{1}{2}})'(\Gamma_k^l)$, we define $\|u\|_{(H^{\frac{1}{2}})'(\Gamma_k^l)} = |||u|||$.

The properties of the operator $\tilde{\pi}_k^l$ are given by the following lemma.

LEMMA 3.1. *For any real number r, $0 \leq r \leq 1$, we have the following estimate for any function $u \in H^r(\Gamma_k^l)$:*

$$\|u - \tilde{\pi}_k^l u\|_{L^2(\Gamma_k^l)} + h_k^{-\frac{1}{2}}\|u - \tilde{\pi}_k^l u\|_{(H^{\frac{1}{2}})'(\Gamma_k^l)} \leq Ch_k^r|u|_{H^r(\Gamma_k^l)}. \tag{3.4}$$

Proof. The proof is analogous to the one in [4]. ∎

LEMMA 3.2. *Assume that the solution u^* of (2.1) is such that $u^*|_{\Omega_k}$ belongs to $H^{\sigma_k}(\Omega_k)$ with $\sigma_k > \frac{3}{2}$. Then the consistency error is bounded by*

$$C\left(1 + \max_k \log\frac{H}{h_k}\right)\left(\sum_{k=1}^K \max_{i\in\mathcal{I}_k}\left(1 + \sqrt{\frac{h_i}{h_k}}\right)^2 h_k^{2(\sigma_k-1)}|u^*|^2_{H^{\sigma_k}(\Omega_k)}\right)^{\frac{1}{2}}.$$

Proof. We apply Green's formula in each subdomain and obtain that

$$\begin{aligned} &a(u^*,v) - \sum_{k=1}^K \int_{\Omega_k}\frac{1}{\sigma}fv_k \\ &= \sum_{k=1}^K \int_{\Omega_k}\frac{1}{\sigma}(-\Delta u^* - f)v_k + \sum_{k=1}^K \int_{\partial\Omega_k}\frac{1}{\sigma^-}\frac{\partial u^*}{\partial n_k}v_k - \sum_{k=1}^K\sum_{l=1}^{E_k}\sum_{i=1}^{n_k^l}\int_{\Gamma_k^{l,i}}\left[\frac{1}{\sigma}\right]\frac{\partial u^*}{\partial n_k}v_{j_i}, \end{aligned} \tag{3.5}$$

where n_k is the unit vector normal to $\partial\Omega_k$ outgoing from Ω_k and σ^- is the trace of $\sigma|_{\Omega_k}$ on $\partial\Omega_k$. We denote by σ^+ the trace of $\sigma|_{\Omega\setminus\Omega_k}$ on $\partial\Omega_k$. Note that $\sigma^+ = \sigma^- - 1$. The function $[\frac{1}{\sigma}]$ is the jump $\frac{1}{\sigma^+} - \frac{1}{\sigma^-} = \frac{1}{\sigma^-(\sigma^- - 1)}$.

Thus

$$a(u^*, v) - \sum_{k=1}^{K} \int_{\Omega_k} \frac{1}{\sigma} f v_k = \sum_{k=1}^{K} \sum_{l=1}^{E_k} \int_{\Gamma_k^l} \frac{1}{\sigma^-} \frac{\partial u^*}{\partial n_k} \left(v_k - \sum_{i=1}^{n_k^l} 1_{\Gamma_k^{l,i}} \frac{1}{\sigma^- - 1} v_{j_i} \right), \tag{3.6}$$

but on Γ_k^l we have that $p_k^l = \sigma^- - 1$, so by using (2.5),

$$\begin{aligned} a(u^*, v) - \sum_{k=1}^{K} \int_{\Omega_k} \frac{1}{\sigma} f v_k &= \sum_{k=1}^{K} \sum_{l=1}^{E_k} \int_{\Gamma_k^l} \frac{1}{p_k^l + 1} \frac{\partial u^*}{\partial n_k} \left(v_k - \sum_{i=1}^{n_k^l} 1_{\Gamma_k^{l,i}} \frac{1}{p_k^l} v_{j_i} \right) \\ &= \sum_{k=1}^{K} \sum_{l=1}^{E_k} \int_{\Gamma_k^l} \frac{1}{p_k^l + 1} \left(\frac{\partial u^*}{\partial n_k} - w_k^l \right) \left(v_k - \sum_{i=1}^{n_k^l} 1_{\Gamma_k^{l,i}} \frac{1}{p_k^l} v_{j_i} \right) \quad \forall w_k^l \in W_k^l. \end{aligned} \tag{3.7}$$

Therefore

$$\begin{aligned} &a(u^*, v) - \sum_{k=1}^{K} \int_{\Omega_k} \frac{1}{\sigma} f v_k \\ &= \sum_{k=1}^{K} \sum_{l=1}^{E_k} \int_{\Gamma_k^l} \frac{1}{p_k^l + 1} \left(\frac{\partial u^*}{\partial n_k} - w_k^l \right) \left(v_k - \langle v_k \rangle - \sum_{i=1}^{n_k^l} 1_{\Gamma_k^{l,i}} \frac{1}{p_k^l} (v_{j_i} - \langle v_k \rangle) \right) \\ &= \sum_{k=1}^{K} \sum_{l=1}^{E_k} \int_{\Gamma_k^l} \frac{1}{p_k^l + 1} \left(\frac{\partial u^*}{\partial n_k} - w_k^l \right) \left(\begin{array}{l} v_k - \langle v_k \rangle - \displaystyle\sum_{i=1}^{n_k^l} 1_{\Gamma_k^{l,i}} \frac{1}{p_k^l} (v_{j_i} - \langle v_{j_i} \rangle) \\ + \displaystyle\sum_{i=1}^{n_k^l} 1_{\Gamma_k^{l,i}} \frac{1}{p_k^l} (\langle v_k \rangle - \langle v_{j_i} \rangle) \end{array} \right). \end{aligned} \tag{3.8}$$

Let us introduce some useful tools before choosing w_k^l. Call $\widetilde{v_{j_i}}$ and $\overline{v_{j_i}}$ the piecewise linear and continuous functions on Ω_{j_i}, respectively, obtained from $v_{j_i} - \langle v_{j_i} \rangle$ and $\langle v_k \rangle - \langle v_{j_i} \rangle$ in the following way: $\widetilde{v_{j_i}} = v_{j_i} - \langle v_{j_i} \rangle$, $\overline{v_{j_i}} = \langle v_k \rangle - \langle v_{j_i} \rangle$ at all the nodes of $\mathcal{T}_{j_i}$, except those on $\partial\Omega_{j_i}$ or in the balls of radius h centered at the crosspoints, where $\widetilde{v_{j_i}} = \overline{v_{j_i}} = 0$; see Figure 3.1. Then it is possible to extend $\widetilde{v_{j_i}}|_{\Gamma_k^{l,i}}$ and $\overline{v_{j_i}}$ by 0 on Γ_k^l. We still call these extensions $\widetilde{v_{j_i}}$ and $\overline{v_{j_i}}$: these functions belong to $H^{\frac{1}{2}}(\Gamma_k^l)$. We have

$$|\widetilde{v_{j_i}}|^2_{H^{\frac{1}{2}}(\Gamma_k^l)} \leq C \left(1 + \log \frac{H}{h_{j_i}} \right) |v_{j_i}|^2_{H^1(\Omega_{j_i})},$$

$$\|\widetilde{v_{j_i}}\|^2_{L^\infty(\Gamma_k^l)} \leq \|v_{j_i} - \langle v_{j_i} \rangle\|^2_{L^\infty(\Omega_{j_i})} \leq C \left(1 + \log \frac{H}{h_{j_i}} \right) |v_{j_i}|^2_{H^1(\Omega_{j_i})},$$

and

$$\|\widetilde{v_{j_i}} - v_{j_i} + \langle v_{j_i} \rangle\|^2_{L^2(\Gamma_k^{l,i})} \leq C h_{j_i} \left(1 + \log \frac{H}{h_{j_i}} \right) |v_{j_i}|^2_{H^1(\Omega_{j_i})}.$$

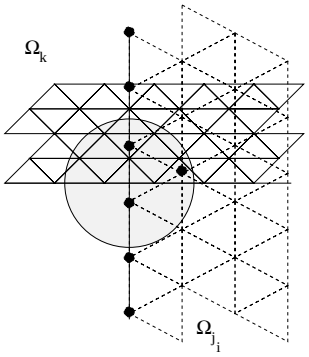

FIG. 3.1. *In black are the nodes where the functions* $\widetilde{v_{j_i}}$ *and* $\overline{v_{j_i}}$ *are set to* 0.

We also have that

$$|\overline{v_{j_i}}|^2_{H^{\frac{1}{2}}(\Gamma_k^l)} \leq C|\langle v_{j_i}\rangle - \langle v_k\rangle|^2$$

and

$$\|\overline{v_{j_i}} - (\langle v_{j_i}\rangle - \langle v_k\rangle)\|^2_{L^2(\Gamma_k^{l,i})} \leq Ch_{j_i}|\langle v_{j_i}\rangle - \langle v_k\rangle|^2.$$

Let us go back to the analysis of (3.8); we choose $w_k^l = \tilde{\pi}_k^l(\frac{\partial u^*}{\partial n_k})$. We decompose the integral

$$I_k^l = \int_{\Gamma_k^l} \frac{1}{p_k^l + 1}\left(\frac{\partial u^*}{\partial n_k} - \tilde{\pi}_k^l\left(\frac{\partial u^*}{\partial n_k}\right)\right)\left(1_{\Gamma_k^{l,i}}\frac{1}{p_k^l}(v_{j_i} - \langle v_{j_i}\rangle)\right)$$

into the sum

$$\int_{\Gamma_k^l} \frac{1}{p_k^l + 1}\left(\frac{\partial u^*}{\partial n_k} - \tilde{\pi}_k^l\left(\frac{\partial u^*}{\partial n_k}\right)\right)\left(1_{\Gamma_k^{l,i}}\frac{1}{p_k^l}\widetilde{v_{j_i}}\right)$$
$$+\int_{\Gamma_k^l} \frac{1}{p_k^l + 1}\left(\frac{\partial u^*}{\partial n_k} - \tilde{\pi}_k^l\left(\frac{\partial u^*}{\partial n_k}\right)\right)\left(1_{\Gamma_k^{l,i}}\frac{1}{p_k^l}(v_{j_i} - \langle v_{j_i}\rangle - \widetilde{v_{j_i}})\right).$$

The function $1_{\Gamma_k^{l,i}}\frac{1}{p_k^l}\widetilde{v_{j_i}} = \frac{1}{p_k^l}\widetilde{v_{j_i}}$ belongs to $H^{\frac{1}{2}}(\Gamma_k^l)$ because $\widetilde{v_{j_i}}$ vanishes near the points where p_k^l jumps, and its $H^{\frac{1}{2}}$-norm is bounded by

$$C\left(\left(1 + \log\frac{H}{h_{j_i}}\right)^{\frac{1}{2}}\|\widetilde{v_{j_i}}\|_{L^\infty(\Gamma_k^l)} + \|\widetilde{v_{j_i}}\|_{H^{\frac{1}{2}}(\Gamma_k^l)}\right).$$

From (3.4), we have

$$|I_k^l| \leq Ch_k^{\sigma_k - \frac{3}{2}}|u^*|_{H^{\sigma_k}(\Omega_k)}\left(\begin{array}{l} h_k^{\frac{1}{2}}\left(\left(1 + \log\frac{H}{h_{j_i}}\right)^{\frac{1}{2}}\|\widetilde{v_{j_i}}\|_{L^\infty(\Gamma_k^l)} + |\widetilde{v_{j_i}}|_{H^{\frac{1}{2}}(\Gamma_k^l)}\right) \\ + \|\widetilde{v_{j_i}} - v_{j_i}\|_{L^2(\Gamma_k^{l,i})}\end{array}\right)$$

$$\leq Ch_k^{\sigma_k - 1}|u^*|_{H^{\sigma_k}(\Omega_k)}\left(1 + \log\frac{H}{h_{j_i}}\right)\left(1 + \sqrt{\frac{h_{j_i}}{h_k}}\right)|v_{j_i}|_{H^1(\Omega_{j_i})}.$$

We decompose the integral

$$J_k^l = \int_{\Gamma_k^l} \frac{1}{p_k^l+1}\left(\frac{\partial u^*}{\partial n_k} - \tilde{\pi}_k^l\left(\frac{\partial u^*}{\partial n_k}\right)\right)\left(1_{\Gamma_k^{l,i}}\frac{1}{p_k^l}(\langle v_k\rangle - \langle v_{j_i}\rangle)\right)$$

into the sum

$$\int_{\Gamma_k^l} \frac{1}{p_k^l+1}\left(\frac{\partial u^*}{\partial n_k} - \tilde{\pi}_k^l\left(\frac{\partial u^*}{\partial n_k}\right)\right)\left(1_{\Gamma_k^{l,i}}\frac{1}{p_k^l}\overline{v_{j_i}}\right)$$
$$+\int_{\Gamma_k^l} \frac{1}{p_k^l+1}\left(\frac{\partial u^*}{\partial n_k} - \tilde{\pi}_k^l\left(\frac{\partial u^*}{\partial n_k}\right)\right)\left(1_{\Gamma_k^{l,i}}\frac{1}{p_k^l}(\langle v_k\rangle - \langle v_{j_i}\rangle - \overline{v_{j_i}})\right).$$

The function $1_{\Gamma_k^{l,i}}\frac{1}{p_k^l}\overline{v_{j_i}}$ belongs to $H^{\frac{1}{2}}(\Gamma_k^l)$, and its $H^{\frac{1}{2}}$-norm is bounded by

$$C\left(1+\log\frac{H}{h_{j_i}}\right)^{\frac{1}{2}}|\langle v_k\rangle - \langle v_{j_i}\rangle|.$$

Exactly as above, we obtain that

$$|J_k^l| \le Ch_k^{\sigma_k-1}|u^*|_{H^{\sigma_k}(\Omega_k)}\left(1+\log\frac{H}{h_{j_i}}\right)^{\frac{1}{2}}\left(1+\sqrt{\frac{h_{j_i}}{h_k}}\right)|\langle v_{j_i}\rangle - \langle v_k\rangle|.$$

We have seen in Remark 6 that, at worst,

$$|\langle v_{j_i}\rangle - \langle v_k\rangle|^2 \le C\left(1+\max_{j\in\mathcal{I}_k}\log\frac{H}{h_j}\right)\sum_{j\in\mathcal{I}_k}\int_{\Omega_j}|\nabla v_j|^2.$$

We conclude by summing up all the contributions. We get

$$\sup_{0\neq v\in Y}\frac{|a(u^*,v) - \sum_{k=1}^K\int_{\Omega_k}\frac{1}{\sigma}fv_k|}{|v|_*}$$
$$\le C\left(1+\max_k\log\frac{H}{h_k}\right)\left(\sum_{k=1}^K\max_{i\in\mathcal{I}_k}\left(1+\sqrt{\frac{h_i}{h_k}}\right)^2 h_k^{2(\sigma_k-1)}|u^*|^2_{H^{\sigma_k}(\Omega_k)}\right)^{\frac{1}{2}}. \qquad \square$$

REMARK 9. *It may be possible to prove a better result than Lemma* 3.2. *This question will be addressed in a forthcoming work.*

3.2. Best approximation error. Call i_k the interpolation operator onto X_k; we have for $u_k^* \in H^{1+\sigma_k}(\Omega_k)$, with $\sigma_k > 0$,

$$\sum_{k=1}^K h_k^2|u_k^* - i_ku_k^*|^2_{H^1(\Omega_k)} + \|u_k^* - i_ku_k^*\|^2_{L^2(\Omega_k)} \le C\sum_{k=1}^K h_k^{2+2\sigma_k}|u_k^*|^2_{H^{1+\sigma_k}(\Omega_k)}.$$

However, the vector $(i_ku_k^*)_{k=1,\dots,K}$ does not belong to Y, so we have to modify it in such a way that the matching conditions are satisfied at the subdomains' boundaries.

The function $i_ku_k^*$ will first be corrected on $\partial\Omega_k$; then the correction will be extended in the whole domain Ω_k by means of the trivial lifting operator L_k, which consists of setting the values at the nodes contained in Ω_k to 0. The properties of this standard lifting operator are given by the following lemma.

LEMMA 3.3. *There exists a constant $C > 0$ such that for any $u \in H^{\frac{1}{2}}(\partial\Omega_k)$, such that for all $l \in \{1, \ldots, E_k\}$, $u|_{\Gamma_k^l} \in X_k^l$, we have*

$$|L_k u|_{H^1(\Omega_k)} \leq C h_k^{-\frac{1}{2}} \|u\|_{L^2(\partial\Omega_k)} \tag{3.9}$$

and

$$\|L_k u\|_{L^2(\Omega_k)} \leq C h_k^{\frac{1}{2}} \|u\|_{L^2(\partial\Omega_k)}. \tag{3.10}$$

Proof. It is classical that

$$\|L_k u\|_{L^2(\Omega_k)} \leq C h_k^{\frac{1}{2}} \|u\|_{L^2(\partial\Omega_k)}.$$

Then (3.9) is obtained by an inverse inequality. ∎

Consider the side Γ_k^l, and let π^* be the operator from $\prod_{i=1}^{n_k^l} L^2(\Gamma_k^{l,i})$ into X_k^l defined by

$$\begin{aligned} \forall w_k^l \in W_k^l, \qquad & \int_{\Gamma_k^l} \frac{1}{p_k^l(x)+1} (\pi^*(u_{j_i})_{i=1,\ldots,n_k^l})(x) w_k^l(x) dx \\ & = \int_{\Gamma_k^l} \frac{1}{p_k^l(x)+1} \sum_{i=1}^{n_k^l} \frac{1}{p_k^l(x)} 1_{\Gamma_k^{l,i}}(x) u_{j_i}(x) w_k^l(x) dx; \end{aligned} \tag{3.11}$$

then we have the following lemma.

LEMMA 3.4. *There exists a constant $C > 0$ such that for any $(u_{j_i})_{i=1,\ldots,n_k^l} \in \prod_{i=1}^{n_k^l} L^2(\Gamma_k^{l,i})$,*

$$\|\pi^*(u_{j_i})_{i=1,\ldots,n_k^l}\|_{L^2(\Gamma_k^l)} \leq C \sum_{i=1}^{n_k^l} \|u_{j_i}\|_{L^2(\Gamma_k^{l,i})}. \tag{3.12}$$

Proof. Consider first the operator $\tilde{\pi}$ from $\prod_{i=1}^{n_k^l} L^2(\Gamma_k^{l,i})$ into W_k^l defined by

$$\begin{aligned} \forall w_k^l \in W_k^l, \qquad & \int_{\Gamma_k^l} \frac{1}{p_k^l(x)+1} (\tilde{\pi}(u_{j_i})_{i=1,\ldots,n_k^l})(x) w_k^l(x) dx \\ & = \int_{\Gamma_k^l} \frac{1}{p_k^l(x)+1} \sum_{i=1}^{n_k^l} \frac{1}{p_k^l(x)} 1_{\Gamma_k^{l,i}}(x) u_{j_i}(x) w_k^l(x) dx. \end{aligned} \tag{3.13}$$

Then it is clear that

$$\|\tilde{\pi}(u_{j_i})_{i=1,\ldots,n_k^l}\|_{L^2(\Gamma_k^l)} \leq C \sum_{i=1}^{n_k^l} \|u_{j_i}\|_{L^2(\Gamma_k^{l,i})}. \tag{3.14}$$

Now $\pi^*(u_i)_{i=1,\ldots,n_k^l}$ is obtained by correcting $\tilde{\pi}(u_i)_{i=1,\ldots,n_k^l}$ as in [4, Lemma 4.3] by using the functions defined in (2.20), and we obtain the desired estimate (3.12) from (2.21). ∎

We are now ready to establish a best approximation estimate.

We correct $i_k(u_k^*)$ in subdomain Ω_k in order to satisfy the matching condition on $\partial\Omega_k$. To do so, we add to $i_k(u_k^*)$ the function

$$e_k \equiv \sum_{l=1}^{E_k} L_k \left(\pi^*(i_{j_i}(u_{j_i}^*) - i_k(u_k^*))_{i=1,\ldots,n_k^l} \right).$$

The vector $(i_k(u_k^*)+e_k)_{1\le k\le K}$ belongs to Y. Indeed, $L_k(\pi^*(i_{j_i}(u_{j_i}^*)-i_k(u_k^*))_{i=1,\dots,n_k^l})$ vanishes in the triangles strictly embedded in Ω_k, so it does not play any role in the matching conditions on other subdomains' boundaries. The matching conditions have been designed for that.

We wish to estimate $|u_k^* - i_k(u_k^*) - e_k|_{H^1(\Omega_k)} \le |u_k^* - i_k(u_k^*)|_{H^1(\Omega_k)} + |e_k|_{H^1(\Omega_k)}$. From Lemma 3.3, we need to give a bound on $\|\pi^*(i_{j_i}(u_{j_i}^*) - i_k(u_k^*))_{i=1,\dots,n_k^l}\|_{L^2(\Gamma_k^l)}$. The bound is obtained from the stability of the operator π^* (see (3.12)) and from the estimate

$$\|i_{j_i}(u_{j_i}^*) - i_k(u_k^*)\|_{L^2(\Gamma_k^{l,i})} \le C(h^{\sigma_k-\frac{1}{2}}|u^*|_{H^{\sigma_k}(\Omega_k)} + h^{\sigma_{j_i}-\frac{1}{2}}|u^*|_{H^{\sigma_{j_i}}(\Omega_{j_i})}). \tag{3.15}$$

In the same manner, we can bound $\|u_k^* - i_k(u_k^*) - e_k\|_{L^2(\Omega_k)}$ so we obtain the best fit estimate.

LEMMA 3.5. *Let $u^* \in H^1(\Omega)$ be such that for $1 \le k \le K$, $u^*|_{\Omega_k} \in H^{\sigma_k}(\Omega_k)$ with $2 \ge \sigma_k > 1$. Then there exists $u \in Y$ such that*

$$\sum_{k=1}^K \frac{1}{h_k}\|u_k^* - u_k\|_{L^2(\Omega_k)} + |u_k^* - u_k|_{H^1(\Omega_k)} \le C\sum_{k=1}^K h_k^{\sigma_k-1}|u_k^*|_{H^{\sigma_k}(\Omega_k)}. \tag{3.16}$$

Then the error estimate is given by the following theorem.

THEOREM 3.6. *Assume that the solution u^* of (2.1) is such that for $1 \le k \le K$, $u^*|_{\Omega_k} \in H^{\sigma_k}(\Omega_k)$ with $2 \ge \sigma_k > \frac{3}{2}$. Then there exists a constant C such that, if $u \in Y$ is the solution of (2.22),*

$$\begin{aligned}&\sum_{k=1}^K \|u_k^* - u_k\|_{H^1(\Omega_k)}\\ &\le \frac{C}{C_e}\left(1+\max_k \log\frac{H}{h_k}\right)\left(\sum_{k=1}^K \max_{i\in\mathcal{I}_k}\left(1+\sqrt{\frac{h_i}{h_k}}\right)^2 h_k^{2(\sigma_k-1)}|u^*|^2_{H^{\sigma_k}(\Omega_k)}\right)^{\frac{1}{2}},\end{aligned} \tag{3.17}$$

where C_e is the ellipticity constant.

4. A strengthened matching condition. We give below an example of stronger matching conditions in the neighborhood of crosspoints.

4.1. An example of a strengthened matching condition. With the notations introduced in section 2.2, it is possible to strengthen the previous matching condition by supplementing the previous test function space $W_k^{l,0} \equiv W_k^l$ with Q supplementary spaces $(W_k^{l,q})_{1\le q\le Q}$ (to be defined below) such that $\dim(W_k^l) + \sum_{q=1}^Q \dim(W_k^{l,q}) \le \dim(\widetilde{W_k^l})$. Typically, each new space will correspond to a crosspoint on Γ_k^l. We define the direct sum as $\overline{W_k^l} = \bigoplus_{q=0}^Q W_k^{l,q}$, and we introduce a family of coefficients $\lambda_{0i} = 1$ for $1 \le i \le n_k^l$ and $\lambda_{qi} \in \{0,1\}$ for $1 \le q \le Q$ and $1 \le i \le n_k^l$ (these coefficients will be defined below), and we call p_q the function defined on Γ_k^l by

$$p_q(x) = \sum_{i=1}^{n_k^l} \lambda_{qi} 1_{\Gamma_k^{l,i}}(x). \tag{4.1}$$

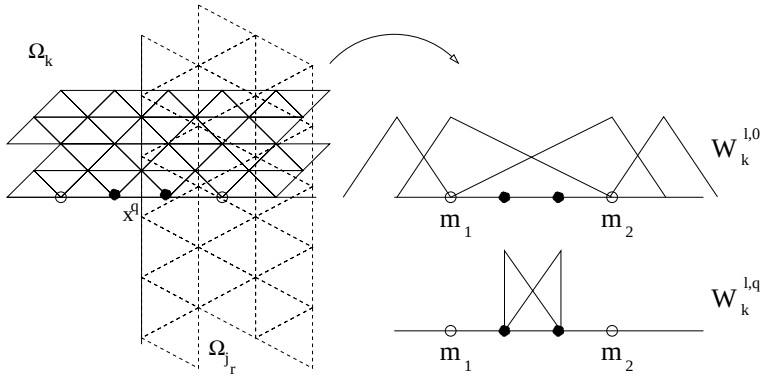

FIG. 4.1. *The spaces $W_k^{l,0}$ and $W_k^{l,q}$. (Only two subdomains have been represented.) In the case presented here, the dimension of $W_k^{l,q}$ is two.*

Then the strengthened matching condition reads as

$$\forall w \in W_k^{l,0}, \quad \int_{\Gamma_k^l} \frac{1}{p_k^l(x)+1} \left(u_k(x) - \frac{1}{p_0(x)} \sum_{i=1}^{n_k^l} 1_{\Gamma_k^{l,i}}(x) u_{j_i}(x) \right) w(x)dx = 0, \tag{4.2}$$

$$\forall q \in \{1,\dots,Q\},\ \forall w \in W_k^{l,q},$$
$$\int_{\Gamma_k^l} \left(u_k(x) - \frac{1}{p_q(x)} \sum_{i=1}^{n_k^l} \lambda_{qi} 1_{\Gamma_k^{l,i}}(x) u_{j_i}(x) \right) w(x)dx = 0. \tag{4.3}$$

REMARK 10. *Conditions* (4.2), (4.3) *are stronger than* (2.5), *since* $W_k^{l,0} = W_k^l$.

We have to specify the spaces $W_k^{l,q}$ for $q \geq 1$. Call $(x^q)_{1\leq q\leq Q}$ the crosspoints $x^q \in \mathcal{X}_k^l$. For a crosspoint x^q (assume that $\{x^q\} = \Gamma_k^l \cap \Gamma_{j_r}^{l'}$) (see Figure 4.1), we call $\{x_{m_1+1},\dots,x_{m_2-1}\}$ the nodes of $\mathcal{T}_k^l$ for which the support of the corresponding basis function of X_k intersects the side $\Gamma_{j_r}^{l'}$. We call $\widetilde{\phi}_{m_1+1}$ the piecewise linear and continuous (except at x_{m_1+1}) function, vanishing outside $[x_{m_1+1}, x_{m_1+2})$, linear on $[x_{m_1+1}, x_{m_1+2})$, and equal to 1 at x_{m_1+1} and 0 at x_{m_1+2}. Likewise, we call $\widetilde{\phi}_{m_2-1}$ the piecewise linear and continuous (except at x_{m_2-1}) function, vanishing outside $(x_{m_2-2}, x_{m_2-1}]$, linear on $(x_{m_2-2}, x_{m_2-1}]$, and equal to 1 at x_{m_2-1} and 0 at x_{m_2-2}.

We define $W_k^{l,q} \equiv span(\widetilde{\phi}_{m_1+1}, \phi_{m_1+2}, \dots, \phi_{m_2-2}, \widetilde{\phi}_{m_2-1})$. The spaces $W_k^{l,0}$ and $W_k^{l,q}$ are displayed on Figure 4.1. Note that with this choice of $W_k^{l,q}$, the supports of the functions in $W_k^{l,q}$ do not intersect the supports of the functions of X_k^{l,x_q}.

Obviously we have

$$\dim(\widetilde{W_k^l}) = \dim\left(\bigoplus_{q=0}^{Q} W_k^{l,q} \right).$$

Now we need to define the coefficients λ_{qi}. We set $\lambda_{0i} = 1$ for all $1 \leq i \leq n_k^l$. For $k \geq 1$, assume that $\{x_q\} = \Gamma_k^l \cap \Gamma_{j_r}^{l'}$. Then we set $\lambda_{qr} = 0$ and $\lambda_{qi} = 1$ for all $1 \leq i \leq n_k^l$, $i \neq r$.

Then Y is the subspace of X defined by

$$Y \equiv \{u \in X;\ \forall k \in \{1,\dots,K\},\ \forall l \in \{1,\dots,E_k\},\ u \text{ satisfies (4.2), (4.3)}\} \tag{4.4}$$

for $W_k^{l,q}$ and λ_{qi} defined as above.

REMARK 11. *Let $u = (u_k) \in Y$. Then it is very clear from* (4.2), (4.3) *that all the nodal values of u_k located on $\partial\Omega_k$, except at the vertices of $\partial\Omega_k$, can be found from the d.o.f. in the adjacent subdomains and from the d.o.f. located at the vertices of $\partial\Omega_k$. With this matching condition, all the nodal values located on $\partial\Omega_k$, except at the vertices of $\partial\Omega_k$, are slave nodal values.*

REMARK 12. *Finding the slave nodal values can be achieved in two steps:*

1. *Find the unknown located at the black nodes on Figure* 4.1 *by taking the test functions in the spaces $W_k^{l,q}, q > 0$. This corresponds to solving a small linear system with a mass matrix for each crosspoint on Γ_k^l.*
2. *Find the remaining nodal values (located on $\Gamma_k^l \backslash \mathcal{V}_k$) by solving a problem of the type* (2.11). *We have seen above that this problem has a unique solution under conditions* (2.12).

4.2. Error estimate. Since the space $\overline{W_k^l}$ contains the space W_k^l, and (2.5) is equivalent to (4.2), the consistency error is bounded from above by the consistency error studied in section 3.1. Therefore we have the following result.

LEMMA 4.1. *Assume that $u^*|_{\Omega_k}$ belongs to $H^{\sigma_k}(\Omega_k)$, with $\sigma_k > \frac{3}{2}$. Then the consistency error is bounded by*

$$C\left(1 + \max_k \log \frac{H}{h_k}\right)\left(\sum_{k=1}^{K} \max_{i \in \mathcal{I}_k}\left(1 + \sqrt{\frac{h_i}{h_k}}\right)^2 h_k^{2(\sigma_k - 1)} |u|^2_{H^{\sigma_k}(\Omega_k)}\right)^{\frac{1}{2}}.$$

For the best fit error, we proceed as above. We correct $i_k(u_k^*)$ in subdomain Ω_k in order to satisfy the matching conditions. The correction is done first on $\partial\Omega_k$; then the same lifting operator L_k as above is used to correct u_k in Ω_k. To correct the trace of u_k on $\partial\Omega_k$, we proceed in two steps.

First step. Let us focus on the side Γ_k^l and keep the notations used for the definition of the space $W_k^{l,q}$ in section 4.1. We call $Z_k^{l,q}$ the space spanned by $(\widetilde{\psi}_{m_1+1}, \dots, \widetilde{\psi}_{m_2-1})$, where $\widetilde{\psi}_i$ have been defined by (2.20).

REMARK 13. *From the geometric assumptions, the dimensions of $W_k^{l,q}$ and $Z_k^{l,q}$ are equal ($q \geq 1$) and bounded by a constant independent of h.*

For $q \geq 1$, call $\mathcal{I}_k^{l,q}$ the set of indices i, such that $\lambda_{qi} = 1$ (see section 4.1), and $\gamma_k^{l,q}$ the support of the functions in $W_k^{l,q}$. ($\gamma_k^{l,q}$ is the interval located between the two black nodes in Figure 4.1.) Consider the projector $\pi_k^{l,q}$ from $\prod_{i \in \mathcal{I}_k^{l,q}} L^2(\Gamma_k^{l,i})$ into $Z_k^{l,q}$ defined by

$$\forall w \in W_k^{l,q}, \quad \int_{\Gamma_k^l} \pi_k^{l,q}(u_i)_{i=1,\dots,n_k^l}(x) w(x) dx = \int_{\Gamma_k^l} \frac{1}{p_q(x)} \sum_{i=1}^{n_k^l} \lambda_{qi} 1_{\Gamma_k^{l,i}}(x) u_{j_i}(x) w(x) dx. \tag{4.5}$$

This projector has exactly the same matrix as the $L^2(\gamma_k^{l,q})$ projector on $W_k^{l,q}$. So we have the estimate

$$\|\pi_k^{l,q}(u_i)_{i=1,\dots,n_k^l}\|_{L^2(\gamma_k^{l,q})} \leq C \sum_{i \in \mathcal{I}_k^{l,q}} \|u_{j_i}\|_{L^2(\Gamma_k^{l,i})}. \tag{4.6}$$

However, from (2.21) and from Remark 13, if $z \in Z_k^{l,q}$, then

$$\|z\|_{L^2(\Gamma_k^l)} \leq Ch^{\frac{1}{2}} \|z\|_{L^\infty(\gamma_k^{l,q})} \leq C\|z\|_{L^2(\gamma_k^{l,q})}. \tag{4.7}$$

Thus we deduce from (4.6) and (4.7) that

$$\|\pi_k^{l,q}(u_i)_{i=1,\ldots,n_k^l}\|_{L^2(\Gamma_k^l)} \leq C \sum_{i \in \mathcal{I}_k^{l,q}} \|u_{j_i}\|_{L^2(\Gamma_k^{l,i})}. \tag{4.8}$$

Consider the function defined on Γ_k^l by $z_k^l = \sum_{q=1}^Q \pi_k^{l,q}(i_{j_i}(u_{j_i}^*) - i_k(u_k^*))$ and the function z_k defined on $\partial\Omega_k$ by assembling the functions z_k^l. Now we have to correct z_k in order to satisfy (4.2).

Second step. The second correction consists of taking the function $z_k + e_k$, where e_k is obtained by assembling $e_k^l \equiv (\pi^*(i_{j_i}(u_{j_i}^*) - i_k(u_k^*))_{i=1,\ldots,n_k^l})$. Finally we set

$$u_k \equiv i_k(u_k^*) + L_k(z_k + e_k).$$

The vector $(u_k)_{k=1,\ldots,K}$ belongs to Y.

It is possible to check the following estimate.

LEMMA 4.2. *Let $u^* \in H^1(\Omega)$ such that for $1 \leq k \leq K$, $u^*|_{\Omega_k} \in H^{\sigma_k}(\Omega_k)$ with $2 \geq \sigma_k > 1$. Then the vector $u \in Y$ constructed above satisfies*

$$\sum_{k=1}^K \frac{1}{h_k} |u_k^* - u_k|_{L^2(\Omega_k)} + |u_k^* - u_k|_{H^1(\Omega_k)} \leq C \sum_{k=1}^K h_k^{\sigma_k - 1} |u_k^*|_{H^{\sigma_k}(\Omega_k)}. \tag{4.9}$$

Finally, the conclusions of Theorem 3.6 hold for the strengthened matching condition.

5. Additive Schwarz preconditioners. The linear system corresponding to the solution of (2.22) is sparse, symmetric positive definite, and usually ill-conditioned. It is often mandatory to use a preconditioned iterative method to solve it. We propose hereafter two additive Schwarz preconditioners. These methods are based on finding a decomposition

$$Y = \sum_{k=0}^K Y_k,$$

where for $k = 1, \ldots, K$ the subspace Y_k will contain multivalued functions localized, roughly speaking, around the subdomain Ω_k, and the subspace Y_0 (called coarse space) will contain slowly varying functions, the latter space being chosen for the speed of convergence to be independent of K.

5.1. A coarse space Y_0. We assume that we can find a quasi-uniform triangular mesh $\mathcal{T}_H$ of Ω, whose elements have diameters of order H, and we define $\mathcal{N}_H$ as the set of the nodes of $\mathcal{T}_H$ lying inside Ω. We call $\hat{Y}_0$ the space of the continuous functions on $\overline{\Omega}$ vanishing on $\partial\Omega$ and whose restriction to any element of $\mathcal{T}_H$ is linear. For each node x in $\mathcal{N}_H$, let ζ_x be the nodal shape function corresponding to the node x.

The space $\hat{Y}_0$ is not a subspace of Y. However, for a given function $\hat{u}_0 \in \hat{Y}_0$, it is possible to obtain an element of Y by applying the same process to $\hat{u}_0$ as that used for the best approximation estimate, i.e.,

1. interpolate $\hat{u}_0$ in the subdomains,

2. correct on the boundary of subdomains by mortar projections,
3. add the trivial lifting of these corrections to the interpolated functions.

We call $I_0\hat{u}_0$ the element of Y obtained in this way. We have the following easy lemma.

LEMMA 5.1. *There exists a positive constant C independent of h and H, such that for $\hat{u}_0 \in Y_0$,*

$$|I_0\hat{u}_0|_* \leq C|\hat{u}_0|_{H^1(\Omega)}. \tag{5.1}$$

Proof. The result follows from (3.16) and from the inverse inequality

$$\forall \sigma,\ 1 < \sigma < \frac{3}{2}, \quad |\hat{u}_0|_{H^\sigma(\Omega)} \leq CH^{-\sigma+1}|\hat{u}_0|_{H^1(\Omega)}. \qquad \square$$

We define

$$Y_0 = I_0\hat{Y}_0. \tag{5.2}$$

We also define the bilinear form b_0 on $\hat{Y}_0$ by

$$b_0(\hat{u}_0, \hat{v}_0) = \int_\Omega \nabla\hat{u}_0 \cdot \nabla\hat{v}_0 \tag{5.3}$$

and the projection operator $\hat{T}_0$ from Y into $\hat{Y}_0$ by

$$\forall u \in Y, \quad \hat{T}_0 u \in \hat{Y}_0, \quad \text{and} \quad b_0(\hat{T}_0 u, \hat{v}_0) = a(u, I_0\hat{v}_0) \quad \forall \hat{v}_0 \in \hat{Y}_0. \tag{5.4}$$

The operator $\hat{T}_0$ is clearly continuous from Y into $\hat{Y}_0$. We also define the operator $T_0 = I_0 \circ \hat{T}_0$ from Y into Y_0.

For the following, we need to find a Clément-like interpolation operator (see [8]) from Y to $\hat{Y}_0$. For that, we associate with each node x in $\mathcal{N}_H$ a subdomain $\Omega_{k(x)}$ such that $x \in \Omega_{k(x)}$. For $u \in Y$, we define Ξu by

$$\Xi u = \sum_{x \in \mathcal{N}_H} \langle u_{k(x)} \rangle \zeta_x. \tag{5.5}$$

LEMMA 5.2. *Under Assumptions* 1 *to* 6, *there exists a constant C such that, for $u \in Y$,*

$$b_0(\Xi u, \Xi u) \leq Ca(u, u). \tag{5.6}$$

Proof. From the quasi uniformity of the mesh $\mathcal{T}_H$, there exists a constant C such that

$$\begin{aligned} b_0(\Xi u, \Xi u) &\leq C \sum_{t \in \mathcal{T}_H} \sum_{x,y \in \mathcal{N}_H, x,y \in \partial t} (\Xi u(x) - \Xi u(y))^2 \\ &= C \sum_{t \in \mathcal{T}_H} \sum_{x,y \in \mathcal{N}_H, x,y \in \partial t} (\langle u_{k(x)} \rangle - \langle u_{k(y)} \rangle)^2. \end{aligned}$$

The desired estimate is a consequence of Lemma 2.5. $\square$

LEMMA 5.3. *Under Assumptions* 1 *to* 6, *there exists a constant C such that for all $u \in Y$,*

$$\sum_{k=1}^K |(I_0\Xi u)_k|^2_{H^1(\Omega_k)} + \frac{1}{H^2} \sum_{k=1}^K \|u_k - (I_0\Xi u)_k\|^2_{L^2(\Omega_k)} \leq Ca(u, u). \tag{5.7}$$

Proof. We have

$$\int_{\Omega_k} |u_k - (I_0\Xi u)_k|^2$$
$$\leq 3\int_{\Omega_k} |u_k - \langle u_k\rangle|^2 + 3\int_{\Omega_k} |\langle u_k\rangle - \Xi u|^2 + 3\int_{\Omega_k} |(\Xi u - (I_0\Xi u)_k|^2.$$

We have from the Poincaré–Wiertinger inequality that

$$\int_{\Omega_k} |u_k - \langle u_k\rangle|^2 \leq CH^2 \int_{\Omega_k} |\nabla u_k|^2.$$

We also have that

$$\int_{\Omega_k} |\langle u_k\rangle - \Xi u|^2 \leq CH^2 \sum_{t\in\mathcal{T}_H, |t\cap\Omega_k|>0} \sum_{x \text{ vertex of } t} (\langle u_{k(x)}\rangle - \langle u_k\rangle)^2$$
$$\leq CH^2 \sum_{t\in\mathcal{T}_H, |t\cap\Omega_k|>0} \sum_{l:|\Omega_l\cap t|>0} \int_{\Omega_l} |\nabla u_l|^2,$$

as in the proof of Lemma 2.5. Finally, as in Lemma 3.5 and from the quasi uniformity of the coarse mesh $\mathcal{T}_H$, we have that

$$\int_{\Omega_k} |\Xi u - (I_0\Xi u)_k|^2 \leq CH^2 \int_{\omega_k} |\nabla \Xi u|^2.$$

Thanks to Lemma 5.2, summing over k yields the desired estimate on $\sum_{k=1}^K \|u_k - (I_0\Xi u)_k\|^2_{L^2(\Omega_k)}$. The estimate on $\sum_{k=1}^K |(I_0\Xi u)_k|^2_{H^1(\Omega_k)}$ comes from Lemma 5.2 and from the stability of I_0. ∎

5.2. A nonoptimal Schwarz preconditioner. The first Schwarz preconditioner is very much inspired from that proposed in [5] for the case of two subdomains. The idea is to define the spaces Y_k by means of the trivial lifting operators introduced above.

We call R_k the operator in X_k defined by the following: for any $v \in X_k$, the master d.o.f. of $R_k v$ are those of v and

$$\forall w \in W_k^l, \quad \int_{\Gamma_k^l} \frac{1}{p_k^l(x)+1} R_k v(x) w(x) dx = 0.$$

We have a similar result to Lemma 3.3.

LEMMA 5.4. *There exists a positive constant C such that, for any $u \in X_k$,*

$$\|u - R_k u\|_{L^2(\Omega_k)} + h_k |u - R_k u|_{H^1(\Omega_k)} \leq C h_k^{\frac{1}{2}} \|u\|_{L^2(\partial\Omega_k)}. \tag{5.8}$$

The range of R_k is called $\hat{Y}_k$. It is an easy matter to map any element of $\hat{Y}_k$ to an element of Y by setting all the extra master d.o.f. to zero. We call I_k this trivial extension operator and Y_k the range of I_k. We clearly have that $Y = \bigoplus_{k=1}^K Y_k$ because $u = \sum_{k=1}^K I_k R_k u_k$.

We also define the bilinear form b_k on $\hat{Y}_k$ by

$$b_k(\hat{u}_k, \hat{v}_k) = \left(1 + \max_{k\neq l\in\mathcal{I}_k} \frac{h_k}{h_l}\right) \int_{\Omega_k} \nabla\hat{u}_k \cdot \nabla\hat{v}_k + \sum_{l\in\mathcal{I}_k} \sum_{x\in\mathcal{M}_k^l} \frac{h_k}{h_l} \hat{u}_k(x)\hat{v}_k(x), \tag{5.9}$$

where $\mathcal{M}_k^l$ is the set of the nodes of $\mathcal{T}_k$ for which the related d.o.f. influence some slave nodal values at the nodes of $\mathcal{T}_l$, and the projection operator $\hat{T}_k$ from Y into $\hat{Y}_k$ by

$$\forall u \in Y, \quad \hat{T}_k u \in \hat{Y}_k \quad \text{and} \quad b_k(\hat{T}_k u, \hat{v}) = a(u, I_k \hat{v}) \quad \forall \hat{v} \in \hat{Y}_k. \tag{5.10}$$

We are now ready to construct the preconditioned operator: we define the operator $T : Y \to Y$ by

$$T = \sum_{k=0}^{K} T_k = \sum_{k=0}^{K} I_k \hat{T}_k. \tag{5.11}$$

The condition number of T is analyzed in a now classical way by following the abstract additive Schwarz method theory of [17, 14, 10, 11].

LEMMA 5.5. *Let us define three relevant parameters:*

1. *Let $C_0(H,h)$ be the minimum real number such that for all $u \in Y$ there exists a sum $u = \sum_{k=0}^{K} I_k \hat{u}_k$ with $\hat{u}_k \in \hat{Y}_k$, and*

$$\sum_{k=0}^{K} b_k(\hat{u}_k, \hat{u}_k) \leq C_0^2(H,h) a(u,u).$$

2. *For $k, l \in \{1, \ldots, K\}$, let $\mathcal{E}_{kl}$ be the best constants such that for $\hat{u}_k \in \hat{Y}_k$ and $\hat{u}_l \in \hat{Y}_l$,*

$$a(I_k \hat{u}_k, I_l \hat{u}_l) \leq \mathcal{E}_{kl} a(I_k \hat{u}_k, I_k \hat{u}_k)^{\frac{1}{2}} a(I_l \hat{u}_l, I_l \hat{u}_l)^{\frac{1}{2}}.$$

   This estimate is called the strengthened Cauchy–Schwarz inequality. Let $\rho(\mathcal{E})$ be the spectral radius of $\mathcal{E} = (\mathcal{E}_{kl})_{1 \leq k,l \leq K}$.

3. *Let ω be the minimum number such that for $k \in \{0, \ldots, K\}$, for $\hat{u}_k \in \hat{Y}_k$,*

$$a(I_k \hat{u}_k, I_k \hat{u}_k) \leq \omega b_k(\hat{u}_k, \hat{u}_k).$$

Then T is invertible and symmetric with respect to the scalar product $a(\cdot,\cdot)$, and, for $u \in Y$,

$$\frac{1}{C_0^2} a(u,u) \leq a(Tu,u) \leq \omega(1 + \rho(\mathcal{E})) a(u,u). \tag{5.12}$$

In the following lemma, we prove that C_0 can be chosen as $C \max_{1 \leq k \leq K} \frac{H}{h_k}$.

LEMMA 5.6. *Under Assumptions 1 to 6 there exists a constant C such that for $u \in Y$ there exists $(\hat{u}_k)_{k \in \{0,\ldots,K\}}$ such that $u = \sum_{k=0}^{K} I_k \hat{u}_k$ and*

$$\sum_{k=0}^{K} b_k(\hat{u}_k, \hat{u}_k) \leq C \max_{1 \leq k \leq K} \frac{H}{h_k} a(u,u). \tag{5.13}$$

Proof. We take $\hat{u}_0 = \Xi u$ and $\hat{u}_k = (R_k)((u - I_0 \hat{u}_0)|_k)$. From Lemma 5.2, we already have (5.6). Let us focus on $b_k(\hat{u}_k, \hat{u}_k)$ for $k > 0$. We have $b_k(\hat{u}_k, \hat{u}_k) = (1 + \max_{l \in \mathcal{I}_k} \frac{h_k}{h_l}) A_k + B_k$, where $A_k = \int_{\Omega_k} |\nabla \hat{u}_k|^2$ and $B_k = \sum_{l \in \mathcal{I}_k \setminus \{l\}} \sum_{x \in \mathcal{M}_k^l} \frac{h_k}{h_l} \hat{u}_k^2(x)$.

$$\begin{aligned} A_k &= \int_{\Omega_k} |\nabla (u - I_0 \hat{u}_0)|_k - \nabla (I - R_k)(u - I_0 \hat{u}_0)|_k|^2 \\ &\leq C \left(\int_{\Omega_k} |\nabla (u - I_0 \hat{u}_0)|_k|^2 + \frac{1}{h_k} \int_{\partial \Omega_k} |(u - I_0 \hat{u}_0)|_k|^2 \right) \end{aligned}$$

by Lemma 5.4. But a very crude argument and Lemmas 5.1 and 5.2 lead to

$$\sum_{k=1}^{K}\left(1+\max_{l\in\mathcal{I}_k}\frac{h_k}{h_l}\right)\int_{\Omega_k}|\nabla(I_0\hat{u}_0)|_k|^2\le C\max_k\frac{H}{h_k}\int_{\Omega}|\nabla\hat{u}_0|^2\le C\max_k\frac{H}{h_k}a(u,u).$$

It remains for us to study $\frac{1}{h_k}\int_{\partial\Omega_k}|(u-I_0\hat{u}_0)|_k|^2$, which can be bounded exactly as in the proof of Lemma 2.6. We have

$$\begin{aligned}&\int_{\partial\Omega_k}|u-I_0\hat{u}_0|_k|^2\\&\le 3\int_{\partial\Omega_k}|u_k-\langle u_k\rangle|^2+3\int_{\partial\Omega_k}|\langle u_k\rangle-\hat{u}_0|^2+3\int_{\partial\Omega_k}|(\hat{u}_0-I_0\hat{u}_0)|_k|^2.\end{aligned}$$

The estimate $\int_{\partial\Omega_k}|u_k-\langle u_k\rangle|^2\le CH\int_{\Omega_k}|\nabla u_k|^2$ is just a trace inequality. We have that

$$\begin{aligned}\int_{\partial\Omega_k}|\langle u_k\rangle-\hat{u}_0|^2&\le CH\sum_{t\in\mathcal{T}_H,|t\cap\Omega_k|>0}\ \sum_{x\text{ vertex of }t}(\langle u_{k(x)}\rangle-\langle u_k\rangle)^2\\&\le CH\sum_{t\in\mathcal{T}_H,|t\cap\Omega_k|>0}\ \sum_{l:|\Omega_l\cap t|>0}\int_{\Omega_l}|\nabla u_l|^2,\end{aligned}$$

as for the proof of Lemma 2.5. From the best-fit estimate (3.16) and the quasi uniformity of the coarse mesh, we obtain that

$$\begin{aligned}&\sum_{k=1}^{K}\left(1+\max_{l\in\mathcal{I}_k}\frac{h_k}{h_l}\right)\frac{1}{h_k}\int_{\partial\Omega_k}|(\hat{u}_0-I_0\hat{u}_0)|_k|^2\\&\le C\sum_{k=1}^{K}\left(1+\max_{l\in\mathcal{I}_k}\frac{h_k}{h_l}\right)\left(\frac{H}{h_k}\int_{\Omega_k}|\nabla(\hat{u}_0-I_0\hat{u}_0)|_k|^2+\frac{1}{Hh_k}\int_{\Omega_k}|(\hat{u}_0-I_0\hat{u}_0)|_k|^2\right)\\&\le C\max_k\frac{H}{h_k}\int_{\Omega}|\nabla\hat{u}_0|^2\le C\max_k\frac{H}{h_k}a(u,u).\end{aligned}$$

Thus we have proved that

$$\sum_{k=1}^{K}\left(1+\max_{l\in\mathcal{I}_k}\frac{h_k}{h_l}\right)A_k\le C\max_k\frac{H}{h_k}a(u,u). \tag{5.14}$$

It remains for us to study $\sum_{k=1}^{K}B_k$. We have that

$$\sum_{x\in\mathcal{M}_k^l}\frac{h_k}{h_l}|(u_k-I_0\hat{u}_0)|_k(x)|^2\le C\frac{1}{h_l}\left(H\int_{\Omega_k}|\nabla(u_k-I_0\hat{u}_0)|_k|^2+\frac{1}{H}\int_{\Omega_k}(u_k-I_0\hat{u}_0)|_k^2\right),$$

and we conclude the proof exactly as above. □

The constant ω in Lemma 5.5 can be chosen independently of the mesh and domain decomposition parameters, as stated in the following lemma.

LEMMA 5.7. *There exists a constant ω independent on the mesh parameters such that, for $k\in\{0,\dots,K\}$ for $\hat{u}_k\in\hat{Y}_k$,*

$$a(I_k\hat{u}_k,I_k\hat{u}_k)\le\omega b_k(\hat{u}_k,\hat{u}_k). \tag{5.15}$$

Proof. For $k=0$, (5.15) is obtained by using Lemma 5.1. For $k>0$, we have

$$\begin{aligned} a(I_k\hat{u}_k, I_k\hat{u}_k) &= \sum_{l\in\mathcal{I}_k}\int_{\Omega_l}|\nabla(I_k\hat{u}_k)_l|^2 \\ &= \int_{\Omega_k}|\nabla\hat{u}_k|^2 + \sum_{k\neq l\in\mathcal{I}_k}\int_{\Omega_l}|\nabla(I_k\hat{u}_k)_l|^2 \\ &\le \int_{\Omega_k}|\nabla\hat{u}_k|^2 + C\sum_{k\neq l\in\mathcal{I}_k}\frac{1}{h_l}\int_{\partial\Omega_l}(I_k\hat{u}_k)_l|^2_{\partial\Omega_l} \\ &\le \int_{\Omega_k}|\nabla\hat{u}_k|^2 + C\sum_{k\neq l\in\mathcal{I}_k}\frac{1}{h_l}\int_{\partial\Omega_l}\hat{u}_k|^2_{\partial\Omega_l} \\ &\le \int_{\Omega_k}|\nabla\hat{u}_k|^2 + C\sum_{k\neq l\in\mathcal{I}_k}\frac{h_k}{h_l}\sum_{x\in\mathcal{M}_k^l}\hat{u}_k(x)^2 \\ &\le \omega b_k(\hat{u}_k,\hat{u}_k). \qquad \square \end{aligned}$$

The strengthened Cauchy–Schwarz inequality comes from the fact that if $\mathcal{I}_l\cap\mathcal{I}_k=\emptyset$, then $a(I_k\hat{u}_k, I_l\hat{u}_l)=0$, from the Cauchy–Schwarz inequality and from Property 1. From the geometric assumptions, we have the following lemma.

LEMMA 5.8. *There exists a constant C such that $\rho(\mathcal{E})\le C$.*

Finally, we have the following result.

THEOREM 5.9. *Under Assumptions 1 to 6, there exists a constant C such that*

$$cond_a(T) \le C\max_k\frac{H}{h_k}. \tag{5.16}$$

REMARK 14. *Remember that the condition number of the original problem scales like* $\max_k \frac{1}{h_k^2}$.

REMARK 15. *It is also possible to generalize the first preconditioner proposed in* [5] *which is based on some harmonic lifting operator rather than trivial lifting operators. However, this preconditioner seems to be too difficult to implement and too costly. For that reason, we shall not discuss this method.*

5.3. An optimal Schwarz preconditioner. We introduce new spaces for an additive decomposition of Y. Let $\widetilde{Y}_k$ be the subspace of Y defined by

$$\widetilde{Y}_k = \left\{ \begin{array}{l} u\in Y; \\ \text{the d.o.f. of } u \\ \text{ associated with nodes not located in } \Omega_k \text{ are zero} \end{array} \right\}. \tag{5.17}$$

REMARK 16. *Note that if $|\Omega_k\cap\Omega_l|>0$, then an element of $\widetilde{Y}_k$ has d.o.f. corresponding to some mesh nodes of $\mathcal{T}_l$, which is not the case for the elements of $\hat{Y}_k$.*

REMARK 17. *An element of $\widetilde{Y}_k$ is not necessarily made of functions supported in Ω_k because the slave nodal values depend nonlocally on the d.o.f. However, the elements of $\widetilde{Y}_k$ are made of functions supported in ω_k.*

Now the mapping I_k is the canonical injection from $\widetilde{Y}_k$ into Y, and we define $b_k(\widetilde{u}_k,\widetilde{v}_k)=a(I_k\widetilde{u}_k, I_k\widetilde{v}_k)$. The projection operator $\widetilde{T}_k$ from Y onto $\widetilde{Y}_k$ is defined by

$$\forall u\in Y,\ \widetilde{T}_k u\in\widetilde{Y}_k,\quad b_k(\widetilde{T}_k u, v)=a(u, I_k v)\quad \forall v\in\widetilde{Y}_k, \tag{5.18}$$

and the preconditioned operator $T : Y \to Y$ is given by

$$T = \sum_{k=0}^{K} T_k = \sum_{k=0}^{K} I_k \widetilde{T_k}, \tag{5.19}$$

where $\widetilde{T_0} \equiv \hat{T}_0$ has been introduced in (5.4) and I_0 has been defined in section 5.1.

Again, this preconditioner is analyzed thanks to Lemma 5.5. The only noticeable difference from the previous preconditioner is the following lemma.

LEMMA 5.10. *Under Assumptions* 1 *to* 6, *there exists a constant* C *such that for* $u \in Y$ *there exists a sum* $u = \sum_{k=0}^{K} I_k \tilde{u}_k$, $\tilde{u}_k \in \widetilde{Y}_k$, *such that*

$$\sum_{k=0}^{K} b_k(\tilde{u}_k, \tilde{u}_k) \leq C \left(1 + \frac{H}{\delta}\right) a(u,u). \tag{5.20}$$

Proof. For the sake of brevity, we just give a sketch of the proof.

We take $\tilde{u}_0 = \Xi u$, where Ξu is defined in (5.5). For constructing $\tilde{u}_k$, we introduce a smooth partition of unity $(\theta_k)_{k\in\{1,\ldots,K\}}$ such that $\theta_k(x) = 0$ if $x \notin \Omega_k$ and $\|\nabla\theta_k\|_\infty \leq C\frac{1}{\delta}$. For $k \in \{1,\ldots,K\}$ and $u \in Y$, let $v^k \in X$ be given by $v_l^k = i_l(\theta_k u_l)$ and $\widetilde{v}^k \in Y$ be obtained by local correction of v^k on the boundary of the subdomains by mortar projections, as in the proof of the best approximation estimate. In fact, we have $\widetilde{v}^k \in \widetilde{Y}_k$, and it is possible to prove exactly as in [17, 14] that

$$\sum_{l\in\mathcal{I}_k} |\widetilde{v}_l^k|^2_{H^1(\Omega_l)} \leq C \sum_{l\in\mathcal{I}_k} \left(|u_l|^2_{H^1(\Omega_k)} + \frac{1}{\delta^2}\|u_l\|^2_{L^2(\Omega_k)} \right). \tag{5.21}$$

We call $\widetilde{R}_k$ the mapping from Y onto $\widetilde{Y}_k$: $\widetilde{R}_k(u) = \widetilde{v}^k$.

For $u \in Y$, we can check that $u = \sum_{k=1}^{K} \widetilde{R}_k(u)$, and therefore

$$u = I_0 \Xi u + \sum_{k=1}^{K} \widetilde{R}_k(u - I_0 \Xi u). \tag{5.22}$$

Thanks to (5.21) and Lemmas 5.2 and 5.3, we obtain the desired result. ∎

Finally, we have the following result.

THEOREM 5.11. *Under Assumptions* 1 *to* 6, *there exists a constant* C *such that*

$$cond_a(T) \leq C \left(1 + \frac{H}{\delta}\right). \tag{5.23}$$

ON STABILITY OF LMS METHODS AND CHARACTERISTIC ROOTS OF DELAY DIFFERENTIAL EQUATIONS*

K. ENGELBORGHS† AND D. ROOSE†

Abstract. We investigate the use of linear multistep (LMS) methods for computing characteristic roots of systems of (linear) delay differential equations (DDEs) with multiple fixed discrete delays. These roots are important in the context of stability and bifurcation analysis. We prove convergence orders for the characteristic root approximations and analyze under what condition for the steplength the discrete integration scheme retains certain delay-independent stability properties of the original equations. Unlike existing results, we concentrate on the recovery of both stability and instability. We illustrate our findings with a number of numerical test results.

Key words. delay differential equations, stability analysis, LMS methods

1. Introduction.

In this paper we study the (asymptotic) stability of the zero solution of a system of linear (or linearized) delay differential equations (DDEs),

$$\dot{x}(t) = A_0 x(t) + \sum_{i=1}^{m} A_i x(t-\tau_i), \quad \text{where } A_i \in \mathbb{R}^{n\times n},\ i = 0,\dots,m. \tag{1.1}$$

Using $\Delta(\lambda) := \lambda I - A_0 - \sum_{i=1}^{m} A_i \mathrm{e}^{-\lambda\tau_i}$, the characteristic equation for (1.1) reads

$$\det(\Delta(\lambda)) = 0. \tag{1.2}$$

The zero solution of (1.1) is (asymptotically) stable provided all the roots $\lambda \in \mathbb{C}$ of (1.2) have (strict) negative real parts. In correspondence with the infinite-dimensional nature of the DDE, there exists an infinite number of characteristic roots λ of (1.2). However, only a finite number have real parts greater than a given constant, $\Re(\lambda) > \gamma$, $\gamma \in \mathbb{R}$ [9, Lem. I.4.1]. Hence, a numerical method that automatically computes the rightmost roots of (1.2) would be of interest.

Equation (1.2) expresses a nonstandard, nonlinear eigenvalue problem, as the matrix Δ depends nonlinearly on λ. Individual roots can be computed efficiently using a Newton–Raphson iteration with a suitable starting value. However, even if a fine grid of starting values is used, there is no guarantee of finding all roots with a given property. For the purpose of bifurcation analysis, the rightmost roots, with leading real parts, are of interest in the determination of stability properties and in the detection of bifurcations.

In [4] a method is proposed to compute the rightmost characteristic roots based on an approximation of the time integration operator associated with the DDE. Indeed,

†Department of Computer Science, Katholieke Universiteit Leuven, Celestijnenlaan 200A, B-3001 Leuven, Belgium (koen.engelborghs@cs.kuleuven.ac.be, dirk.roose@cs.kuleuven.ac.be).

the characteristic roots of, e.g., a linear multistep (LMS) or Runge–Kutta approximation to (1.1), can be computed from a large (but standard) eigenvalue problem. Established and efficient numerical algorithms exist to compute selected (e.g., dominant or rightmost) eigenvalues of possibly very large matrices; see [23, 21].

Computational issues of this approach are discussed in [4]. In this paper we investigate the effect of the discretization on the stability. In particular, we investigate the correspondence between the characteristic roots of (1.1) and of the related discrete map obtained from an LMS method applied to (1.1). We prove convergence and investigate under what conditions the approximation retains certain delay-independent stability properties of the original equations. From these results we obtain a steplength heuristic that is used in the package DDE-BIFTOOL [3].

Part of our results were already obtained in the literature on time integration of DDEs; see, e.g., [27, 28, 10, 11]. All of these results concentrate on recovery of delay-independent stability. In the context of bifurcation analysis, the recovery of delay-independent instability, as we analyze here, is likewise important. Furthermore, we prove convergence orders for the characteristic root approximations and comment on the issue of stiffness in DDEs. A number of similar results were also proven for Runge–Kutta methods applied to DDEs using different types of interpolation for the past terms; see, e.g., [19, 14, 11, 12]. For a special type of delay equation (scalar pure-delay DDE with one delay), convergence of the roots of the characteristic equation of the forward Euler method to simple roots of the characteristic equation of the DDE is proven in [30]. Related results were also proven for Hopf bifurcations in the numerical approximation of DDEs; cf. [5, 29, 6].

The paper is structured as follows. First, we discuss stability properties of DDEs in section 3. Then we compare and extend this analysis to LMS methods applied to DDEs in section 4. We illustrate our findings with numerical results in section 5, comment on the issue of stiffness for DDEs in section 6, and conclude in section 7.

2. Illustrative example. Consider the scalar one-delay equation,

$$\dot{x}(t) = ax(t) + bx(t-\tau), \tag{2.1}$$

and its corresponding characteristic equation

$$\lambda = a + b\mathrm{e}^{-\lambda\tau}. \tag{2.2}$$

The right half-plane (RHP), $\Re(\lambda) \geq 0$, is mapped under the right-hand side of (2.2) onto a circle centered at a with radius $|b|$. If this circle lies completely in the open left half-plane (LHP), it is clear that (2.2) can have no solutions in the RHP, as the latter is mapped onto disjunct regions by the left- and right-hand sides of (2.2). This occurs whenever

$$\Re(a) + |b| < 0. \tag{2.3}$$

Hence (2.3) is a sufficient condition for stability of the zero solution of (2.1) which we could term RHP-stability of (2.1). In fact, this stability is independent of the delay τ (through (2.3)) and can be shown to be nearly equivalent to delay-independent stability (i.e., stability for all values of $\tau \geq 0$) [16].

When applying an LMS method to (2.1) it can similarly be proven that if the same circle, scaled with the steplength h of the LMS method (that is, the circle centered at ha with radius $|hb|$) is part of the stability region of the LMS method, then the zero solution of the difference equation defined by applying the LMS method to (2.1) is

stable. In other words, if h is small enough, the LMS method will capture the RHP-stability of the original DDE (2.1). As such, this condition is a direct generalization of the well-known result for ordinary differential equations (where $b = 0$ and ha should lie in the stability region of the LMS method).

The purpose of this paper is to generalize these properties to systems of equations with multiple delays. In this more general case, the RHP is mapped to more complicated regions than the circle considered above. We also consider RHP-instability. Namely, when the above circle lies completely in the RHP, this can be proven to be a sufficient condition for instability. Based on these results, our analysis leads to a steplength heuristic used to compute the correct stability and bifurcations of a given DDE system.

3. Sufficient conditions for DDE stability. Rewrite the characteristic equation (1.2) as

$$\lambda \in \sigma\left(A_0 + \sum_{i=1}^{m} A_i \mathrm{e}^{-\lambda\tau_i}\right), \tag{3.1}$$

where $\sigma(B)$ denotes the spectrum of a given matrix B. The key idea is to study the mapping of the RHP under the left- and right-hand sides of (3.1). If the right-hand side of (3.1) maps the closed RHP into the open LHP, then it is clear that there can be no solutions λ in the closed RHP, and hence there can be no unstable characteristic roots.

First we introduce some necessary notation. Let $\mathbb{C}_0^+$, $\mathbb{C}^+$ denote the open, respectively, closed, RHP,

$$\mathbb{C}_0^+ = \{\lambda \in \mathbb{C} \,|\, \Re(\lambda) > 0\} \quad \text{and} \quad \mathbb{C}^+ = \{\lambda \in \mathbb{C} \,|\, \Re(\lambda) \geq 0\},$$

and corresponding definitions for the open, respectively, closed, LHP, $\mathbb{C}_0^-$, respectively, $\mathbb{C}^-$. When studying the mapping of the right-hand side of (3.1) it is necessary, for reasons that will be clear later on, to avoid dependency on the delays. Therefore, we define the following set-valued function $\Sigma(\cdot)$ as

$$\Sigma(C) = \bigcup_{(\lambda_1,\ldots,\lambda_m)\in C\times C\times\cdots\times C} \sigma\left(A_0 + \sum_{i=1}^{m} A_i \mathrm{e}^{-\lambda_i}\right), \tag{3.2}$$

where $C \subset \mathbb{C}$. Note that we have replaced each $\lambda\tau_i$ in (3.1) by a separate λ_i in (3.2).

The mapping of the RHP under the right-hand side of (3.1) is included in the mapping of the RHP under Σ, that is,

$$\bigcup_{\lambda\in\mathbb{C}^+} \sigma\left(A_0 + \sum_{i=1}^{m} A_i \mathrm{e}^{-\lambda\tau_i}\right) \subseteq \Sigma(\mathbb{C}^+), \tag{3.3}$$

where the equality holds when there is only one nonzero delay. Note $\sigma(A_0+\sum_{i=1}^m A_i\mathrm{e}^{-\lambda_i})$; also note that the region (or regions) defined by $\Sigma(\mathbb{C}^+)$ form a bounded subset of $\mathbb{C}$ because

$$\begin{array}{rcl} \lambda \in \Sigma(\mathbb{C}^+) & \Rightarrow & |\lambda| \leq \|A_0 + \sum_{i=1}^m A_i \mathrm{e}^{-\lambda_i}\| \text{ with } \Re(\lambda_i) \geq 0, \\ & \Rightarrow & |\lambda| \leq \|A_0\| + \sum_{i=1}^m \|A_i\| |\mathrm{e}^{-\lambda_i}| \text{ with } \Re(\lambda_i) \geq 0, \\ & \Rightarrow & |\lambda| \leq \sum_{i=0}^m \|A_i\|. \end{array} \tag{3.4}$$

We distinguish three different cases, depending on the location of $\Sigma(\mathbb{C}^+)$.

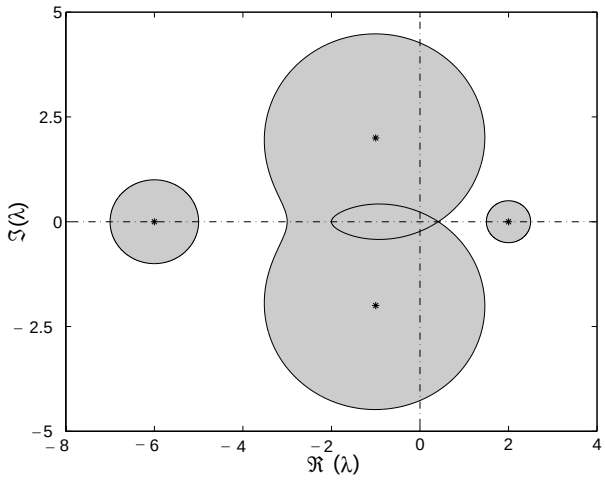

FIG. 3.1. *The mapping of the RHP under* Σ *(gray areas), the mapping of the imaginary axis under* Σ *(solid lines), and the eigenvalues of* A_0 $(*)$ *for the one-delay case with system matrices given by* (3.5).

DEFINITION 3.1. *Definition of stability of* Σ.

- *If* $\Sigma(\mathbb{C}^+) \subset \mathbb{C}_0^-$, *then we call* Σ *stable.*
- *If* $\Sigma(\mathbb{C}^+) \subset \mathbb{C}_0^+$, *then we call* Σ *unstable.*
- *If* $\exists \xi_0 \in \mathbb{R}_0 = \mathbb{R} \setminus \{0\} : \mathrm{i}\xi_0 \in \Sigma(\{\mathrm{i}\xi \,|\, \xi \in \mathbb{R}_0\})$, *then we call* Σ *Hopf-like.*

An illustration of this is given in Figure 3.1 using the matrices

$$A_0 = \begin{bmatrix} -1 & 2 & 0 & 0 \\ -2 & -1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & -6 \end{bmatrix} \text{ and } A_1 = \begin{bmatrix} 2 & 2 & 2 & 0 \\ -2 & 1 & 0 & 0 \\ 0 & 0 & -\frac{1}{2} & 0 \\ 1 & 1 & 1 & 1 \end{bmatrix}. \tag{3.5}$$

To check for stability of Σ it would be convenient if we could look only at the closed curve(s) described by $\Sigma(\{\mathrm{i}\xi \,|\, \xi \in \mathbb{R}\})$ (cf., the lines in Figure 3.1). Because of the periodicity of $\mathrm{e}^{-\mathrm{i}\xi}$, it suffices to examine the latter only for $\xi \in [0, 2\pi]$, i.e., $\Sigma(\{\mathrm{i}\xi \,|\, \xi \in \mathbb{R}\}) = \Sigma(\{\mathrm{i}\xi \,|\, \xi \in [0, 2\pi]\})$. For general matrices A_i, $i = 0, \ldots, m$, it is, however, not immediately clear whether these curves really form the boundary of $\Sigma(\mathbb{C}^+)$ in the complex plane. We now prove two theorems in this regard.

THEOREM 3.2. *The following statements hold:*

$$\begin{array}{c} \sigma(A_0 + A_1\mathrm{e}^{-\mathrm{i}\xi}) \subset \mathbb{C}_0^- \ \forall\, \xi \in [0, 2\pi], \\ \Updownarrow \\ \sigma(A_0 + A_1\mathrm{e}^{-\lambda}) \subset \mathbb{C}_0^- \ \forall\, \lambda \in \mathbb{C}^+, \end{array} \tag{3.6}$$

and

$$\begin{array}{c} \sigma(A_0 + A_1\mathrm{e}^{-\mathrm{i}\xi}) \subset \mathbb{C}_0^+ \ \forall\, \xi \in [0, 2\pi], \\ \Updownarrow \\ \sigma(A_0 + A_1\mathrm{e}^{-\lambda}) \subset \mathbb{C}_0^+ \ \forall\, \lambda \in \mathbb{C}^+. \end{array} \tag{3.7}$$

Proof. We prove only (3.6). The proof of (3.7) is analogous. It is clear that we need to prove only the downward implication.

We first treat the case of nonsingular A_1. We start from

$$\sigma(A_0 + A_1 \mathrm{e}^{-\mathrm{i}\xi}) \subset \mathbb{C}_0^-, \qquad \xi \in [0, 2\pi], \tag{3.8}$$

which we rewrite as

$$\det(\lambda I - A_0 - A_1 \mathrm{e}^{-\mathrm{i}\xi}) \neq 0,\ \xi \in [0, 2\pi],\ \Re(\lambda) \geq 0,$$

which, in turn, is equivalent to

$$\begin{array}{ll} \text{(a)} & \det(I - (\lambda I - A_0)^{-1} A_1 \mathrm{e}^{-\mathrm{i}\xi}) \neq 0,\ \xi \in [0, 2\pi],\ \Re(\lambda) \geq 0,\ \lambda \notin \sigma(A_0), \\ \text{(b)} & \det(\lambda I - A_0 - A_1 \mathrm{e}^{-\mathrm{i}\xi}) \neq 0,\ \xi \in [0, 2\pi],\ \Re(\lambda) \geq 0,\ \lambda \in \sigma(A_0). \end{array} \tag{3.9}$$

Part (a) of (3.9) is equivalent to saying that $(\lambda I - A_0)^{-1} A_1$ should have no eigenvalues on the unit circle,

$$|\sigma((\lambda I - A_0)^{-1} A_1)| \neq 1,\ \Re(\lambda) \geq 0,\ \lambda \notin \sigma(A_0),$$

(where the inequality holds over all elements of $\sigma(\cdot)$) and, because

$$\lim_{\Re(\lambda) \to +\infty} \|(\lambda I - A_0)^{-1} A_1\| = 0,$$

it is equivalent to

$$|\sigma((\lambda I - A_0)^{-1} A_1)| < 1,\ \Re(\lambda) \geq 0,\ \lambda \notin \sigma(A_0). \tag{3.10}$$

Suppose $\lambda_0 \in \sigma(A_0)$ with $\Re(\lambda_0) \geq 0$. For $\lambda \notin \sigma(A_0)$, we have that the matrix $A_1^{-1}(\lambda I - A_0)$ is regular and becomes singular in the limit $\lambda \to \lambda_0$, $\Re(\lambda) \geq 0$. By continuity of the eigenvalues, $A_1^{-1}(\lambda I - A_0)$ has an eigenvalue converging to zero and, correspondingly, $(\lambda I - A_0)^{-1} A_1$ has an eigenvalue converging to infinity (in modulus). The latter contradicts (3.10). Hence, from (3.9) it follows that $\sigma(A_0) \subset \mathbb{C}_0^-$. Therefore, we can conclude that (3.9), and thus also (3.8), is equivalent to

$$\sigma(A_0) \subset \mathbb{C}_0^-, \quad |\sigma((\lambda I - A_0)^{-1} A_1)| < 1,\ \Re(\lambda) \geq 0.$$

Note that the above equivalence still holds if A_1 is replaced by $A_1 \mathrm{e}^{-r}$ for some fixed $r \in \mathbb{R}^+$. Using this, we conclude that

$$\begin{array}{c} \sigma(A_0 + A_1 \mathrm{e}^{-\mathrm{i}\xi}) \subset \mathbb{C}_0^-,\ \xi \in [0, 2\pi], \\ \Updownarrow \\ \sigma(A_0) \subset \mathbb{C}_0^-, \quad |\sigma((\lambda I - A_0)^{-1} A_1)| < 1,\ \Re(\lambda) \geq 0, \\ \Downarrow \\ \sigma(A_0) \subset \mathbb{C}_0^-, \quad |\sigma((\lambda I - A_0)^{-1} A_1 \mathrm{e}^{-r})| < 1,\ \Re(\lambda) \geq 0,\ r \geq 0, \\ \Updownarrow \\ \sigma(A_0 + A_1 \mathrm{e}^{-(r+\mathrm{i}\xi)}) \subset \mathbb{C}_0^-,\ \xi \in [0, 2\pi],\ r \geq 0, \\ \Updownarrow \\ \sigma(A_0 + A_1 \mathrm{e}^{-\lambda}) \subset \mathbb{C}_0^-,\ \lambda \in \mathbb{C}^+. \end{array}$$

If A_1 is singular, then there exists an arbitrary small perturbation to a regular matrix. By continuity of the eigenvalues and the above statement, it follows that, in this case,

$$\begin{array}{c} \sigma(A_0 + A_1 \mathrm{e}^{-\mathrm{i}\xi}) \subset \mathbb{C}_0^-, \qquad \xi \in [0, 2\pi], \\ \Downarrow \\ \sigma(A_0 + A_1 \mathrm{e}^{-\lambda}) \subset \mathbb{C}^-, \qquad \lambda \in \mathbb{C}^+. \end{array}$$

However, since $\sigma(A_0 + A_1 e^{-i\xi}),\ \xi \in [0, 2\pi]$, forms a set of bounded and continuous curves, there exists an $s > 0$ such that the following holds:

$$\begin{gathered}
\sigma(A_0 + A_1 e^{-i\xi}) \subset \mathbb{C}_0^-,\ \xi \in [0, 2\pi], \\
\Downarrow \\
\exists s > 0,\ \sigma(A_0 + sI + A_1 e^{-i\xi}) \subset \mathbb{C}_0^-,\ \xi \in [0, 2\pi], \\
\Downarrow \\
\exists s > 0,\ \sigma(A_0 + sI + A_1 e^{-\lambda}) \subset \mathbb{C}^-,\ \lambda \in \mathbb{C}^+, \\
\Downarrow \\
\sigma(A_0 + A_1 e^{-\lambda}) \subset \mathbb{C}_0^-,\ \lambda \in \mathbb{C}^+,
\end{gathered}$$

which ends the proof. ∎

With the above proof for the one-delay case, it is rather straightforward to extend this result to the multiple delay situation. We will use the vector notation $\vec{\tau} = (\tau_1, \ldots, \tau_m)$, where inequalities hold componentwise, e.g., $\vec{\tau} \geq 0$, and we will use the notation C^m for $C \times C \times \cdots \times C$, where $C \subset \mathbb{C}$.

THEOREM 3.3. *The following statements hold:*

$$\begin{gathered}
\sigma\left(A_0 + \sum_{i=1}^{m} A_i e^{-i\xi_i}\right) \subset \mathbb{C}_0^-\ \forall \vec{\xi} \in [0, 2\pi]^m, \\
\Updownarrow \\
\sigma\left(A_0 + \sum_{i=1}^{m} A_i e^{-\lambda_i}\right) \subset \mathbb{C}_0^-\ \forall \vec{\lambda} \in (\mathbb{C}^+)^m,
\end{gathered} \tag{3.11}$$

and

$$\begin{gathered}
\sigma\left(A_0 + \sum_{i=1}^{m} A_i e^{-i\xi_i}\right) \subset \mathbb{C}_0^+\ \forall \vec{\xi} \in [0, 2\pi]^m, \\
\Updownarrow \\
\sigma\left(A_0 + \sum_{i=1}^{m} A_i e^{-\lambda_i}\right) \subset \mathbb{C}_0^+\ \forall \vec{\lambda} \in (\mathbb{C}^+)^m.
\end{gathered} \tag{3.12}$$

Proof. We prove the first statement. Applying Theorem 3.2, it follows that

$$\sigma\left(A_0 + \sum_{i=1}^{m} A_i e^{-i\xi_i}\right) \subset \mathbb{C}_0^-\ \forall \xi_1 \in [0, 2\pi]$$

is equivalent to

$$\sigma\left(A_0 + A_1 e^{-\lambda_1} + \sum_{i=2}^{m} A_i e^{-i\xi_i}\right) \subset \mathbb{C}_0^-\ \forall \lambda_1 \in \mathbb{C}^+$$

for fixed values of $\xi_2, \ldots, \xi_m$ (consider $A_0 + \sum_{i=2}^{m} A_i e^{-i\xi_i}$ as a new and fixed A_0 in Theorem 3.2). Applying Theorem 3.2 recursively on ξ_2 until ξ_m proves the above statement. ∎

Hence, for analyzing the stability of Σ, it suffices to examine the mapping of the imaginary axis under Σ. Note that the proof of Theorem 3.3 relies on the independent variation of the λ_i as introduced in the definition of Σ (3.2).

We are now ready to state the following theorem.

THEOREM 3.4 (relation of the stability of Σ to the stability of the zero solution of (1.1)).

(i) *If Σ is stable, then the zero solution of* (1.1) *is stable for all $\vec{\tau} \geq 0$.*

(ii) *If Σ is unstable, then the zero solution of* (1.1) *is unstable for all $\vec{\tau} \geq 0$.*

(iii) *The characteristic equation of* (1.1) *has a purely imaginary root $\lambda = \mathrm{i}\xi_0 \neq 0$ for some $\vec{\tau} \geq 0$ if and only if Σ's stability is Hopf-like.*

Proof.

(i) Since the mapping of the closed RHP under the right-hand side of the characteristic equation (3.1) is part of $\Sigma(\mathbb{C}^+)$ (cf., (3.3)), and the latter is, by assumption, mapped into the open LHP, then there can be no characteristic roots with $\Re(\lambda) \geq 0$. Since there exists only a finite number of roots with real part greater than any $\gamma < 0$, it follows that

$$\sup_{\det(\Delta(\lambda))=0} \Re(\lambda) < 0.$$

Because the stability of Σ does not depend on the values of $\vec{\tau}$, it follows that the zero solution of (1.1) is asymptotically stable for all $\vec{\tau} \geq 0$.

(ii) By continuity of the eigenvalues of $A_0 + \sum_{i=1}^m A_i \mathrm{e}^{-\lambda\tau_i}$ as a function of λ, it is possible to decompose $\sigma(A_0 + \sum_{i=1}^m A_i \mathrm{e}^{-\lambda\tau_i})$ into n continuous functions $\sigma_l(\lambda)$, $l = 1, \ldots, n$, such that

$$\sigma\left(A_0 + \sum_{i=1}^m A_i \mathrm{e}^{-\lambda\tau_i}\right) \equiv \{\sigma_1(\lambda), \ldots, \sigma_n(\lambda)\},$$

with correct multiplicity. Note that this decomposition may not be unique. Let G denote the closed convex hull of $\Sigma(\mathbb{C}^+)$. By assumption we have $G \subset \mathbb{C}_0^+$ and thus also

$$\bigcup_{\lambda\in G} \sigma_l(\lambda) \subset \bigcup_{\lambda\in\mathbb{C}^+} \sigma_l(\lambda) \subset \Sigma(\mathbb{C}^+) \subset G.$$

By Brouwer's fixed point theorem [13, Thm. VIII.1.1], this implies that $\sigma_l(\cdot)$ has a fixed point λ in G. This point is a solution of (3.1) with positive real part. Hence, since the stability of Σ does not depend on $\vec{\tau}$, the zero solution of (1.1) is unstable for all $\vec{\tau} \geq 0$.

(iii) From

$$\det\left(\mathrm{i}\xi_0 I - A_0 - \sum_{i=1}^m A_i \mathrm{e}^{-\mathrm{i}\xi_0\tau_i}\right) = 0$$

with $\xi_0 \neq 0$ it follows that $\mathrm{i}\xi_0 \in \Sigma(\{\mathrm{i}\xi \,|\, \xi \in \mathbb{R}_0\})$ by taking $\lambda_i = \mathrm{i}\xi_0\tau_i$ if $\tau_i > 0$ and $\lambda_i = \mathrm{i}2\pi$ otherwise. On the other hand, if $\mathrm{i}\xi_0 \in \Sigma(\{\mathrm{i}\xi \,|\, \xi \in \mathbb{R}_0\})$, then there exist $\lambda_i = \mathrm{i}\xi_i$, $\xi_i \neq 0$, such that $\mathrm{i}\xi_0 \in \sigma(A_0 + \sum_{i=1}^m \mathrm{e}^{-\lambda_i})$. Hence $\mathrm{i}\xi_0$ is a characteristic root for delays chosen such that $\tau_i = (\xi_i + 2\pi k)/\xi_0$, where $k \in \mathbb{Z}$ is chosen such that $\tau_i \geq 0$. ∎

As a result of this theorem we conclude that the stability of Σ is almost equivalent to delay-independent stability of the DDE (1.1). The "almost" refers to the fact that some cases are excluded from the definition of stability of Σ. Namely, as $\Sigma(\mathbb{C}^+)$ is not necessarily a connected region (rather, it consists of at most n connected components), it can map in both the RHP and the LHP without mapping onto the imaginary

axis. In this case, part (ii) of Theorem 3.4 still holds because one of the σ_l, $1 \leq l \leq n$ then maps into the open RHP (giving rise to a fixed point, and hence, to an unstable characteristic root). Thus, from all cases, only one degenerate case is excluded, namely, when $\Sigma(\mathbb{C}^+)$ maps onto the imaginary axis but only at the origin. This is in correspondence with the theorem on delay-independent stability given in [16] for the one-delay case.

In the next section we will see when an LMS method applied to (1.1) captures the stability properties of Σ.

4. LMS methods applied to DDEs. Consider the linear k-step formula [7]

$$\sum_{j=0}^{k} \alpha_j y_{s+j} = h \sum_{j=0}^{k} \beta_j f_{s+j} \tag{4.1}$$

applied to (1.1). Here, h is a (fixed) step size, $\alpha_k = 1$, and y_j and f_j present numerical approximations of $y(t)$, respectively, $A_0 y(t) + \sum_{i=1}^{m} A_i y(t - \tau_i)$, at the mesh point $t_j = jh$. During time integration, (4.1) is solved for y_{s+k} (for successive values of s) based on the previously computed mesh points y_{s+j}, $j < k$, and the initial condition.

The right-hand side approximation is chosen as

$$f_j := A_0 y_j + \sum_{i=1}^{m} A_i \tilde{y}(t_j - \tau_i), \tag{4.2}$$

where $\tilde{y}(t_j - \tau_i)$ presents an approximation for $y(t_j - \tau_i)$ obtained from the previously computed mesh points y_l, $l < j$. In particular, the use of so-called *Nordsieck interpolation* leads to

$$\tilde{y}(t_i + \epsilon h) = \sum_{l=-s_-}^{s_+} \psi_l(\epsilon) y_{i+l}, \qquad \epsilon \in [0, 1), \tag{4.3}$$

where the ψ_l are the Lagrange interpolation polynomials,

$$\psi_l(\epsilon) := \prod_{o=-s_-,\, o \neq l}^{s_+} \frac{\epsilon - o}{l - o}.$$

Applying (4.3) to (4.2) for the linear multiple delay DDE (1.1) we get

$$\sum_{j=0}^{k} \alpha_j y_{s+j} = h \sum_{j=0}^{k} \beta_j \left(A_0 y_{s+j} + \sum_{i=1}^{m} A_i \sum_{l=-s_-}^{s_+} \psi_l(\epsilon_i) y_{s+l+j-L_i} \right), \tag{4.4}$$

where $L_i := \lceil \tau_i / h \rceil$, $\epsilon_i := L_i - \tau_i / h \in [0, 1)$ (and $\lceil r \rceil$ is the smallest integer greater than or equal to $r \in \mathbb{R}$). In order to avoid the use of future mesh points while evaluating the past terms, we require that $L_i \geq s_+$ or, that,

$$\tau_i \geq (s_+ - \epsilon_i) h, \qquad i = 1, \ldots, m. \tag{4.5}$$

When there is only one delay or, more generally, when the delays are *commensurable*, that is, when all delays are an integer multiple of a single delay,

$$\tau_i = n_i \tau_0, \ n_i \in \mathbb{N}, \ i = 1, \ldots, m, \tag{4.6}$$

then, by choosing $h = \tau_0/L$, $L \in \mathbb{N}_0$, delayed mesh points are mapped onto mesh points in the past,

$$t_j - \tau_i = t_j - n_i L h = t_{j-n_i L}. \tag{4.7}$$

In this situation the mesh is called *constrained* and interpolation is no longer needed,

$$f_j = A_0 y_j + \sum_{i=1}^{m} A_i y_{j-n_i L}.$$

The LMS method is *explicit* whenever $\beta_k = 0$, and y_{s+k} can be directly computed from (4.1) by evaluating

$$y_{s+k} = -\sum_{j=0}^{k-1} \alpha_j y_{s+j} + h \sum_{j=0}^{k-1} \beta_j f_{s+j},$$

whose right-hand side depends only on y_{s+j}, $j < k$. Otherwise, the method is called *implicit*. Note that, if the (present) point y_{s+k} occurs due to a small delay, $\tau_i \le s_+ h$, $1 \le i \le n$, an explicit LMS method ($\beta_k = 0$) becomes implicit. The LMS method is of *order* p if

$$\sum_{j=0}^{k} \alpha_j = 0 \text{ and } \sum_{j=0}^{k} j^q \alpha_j = q \sum_{j=0}^{k} j^{q-1} \beta_j \text{ for } q = 1, \dots, p. \tag{4.8}$$

The method is called *consistent* if it is at least of order 1.

4.1. Stability of the LMS difference scheme. The stability of the difference scheme (4.4) can be obtained from a large but standard eigenvalue problem. In particular, the characteristic equation for the difference scheme (4.4) looks like

$$\det\left(\left(\sum_{j=0}^{k} \alpha_j \mu^{s+j}\right) I - h \left(\sum_{j=0}^{k} \beta_j \mu^{s+j}\right) \left(A_0 + \sum_{i=1}^{m} A_i \sum_{l=-s_-}^{s_+} \psi_l(\epsilon_i) \mu^{l-L_i}\right)\right) = 0. \tag{4.9}$$

To avoid spurious solutions μ (not influenced by the system matrices A_0, A_1) we require that the polynomials in ζ,

$$\sum_{j=0}^{k} \alpha_j \zeta^j \text{ and } \sum_{j=0}^{k} \beta_j \zeta^j, \tag{4.10}$$

have no roots in common. The corresponding LMS method is then called *irreducible* [7, section III.2.4]. To compare the roots μ with the solutions of the characteristic equation, we substitute μ for λ, using the relation

$$\mu = \exp(\lambda h). \tag{4.11}$$

Then, after dividing (4.9) by $h \sum_{j=0}^{k} \beta_j \mu^{s+j}$, we obtain

$$\det\left(\frac{1}{h}\left(\frac{\sum_{j=0}^{k} \alpha_j \mathrm{e}^{\lambda j h}}{\sum_{j=0}^{k} \beta_j \mathrm{e}^{\lambda j h}}\right) I - \left(A_0 + \sum_{i=1}^{m} A_i \sum_{l=-s_-}^{s_+} \psi_l(\epsilon_i) \mathrm{e}^{-\lambda(L_i - l)h}\right)\right) = 0. \tag{4.12}$$

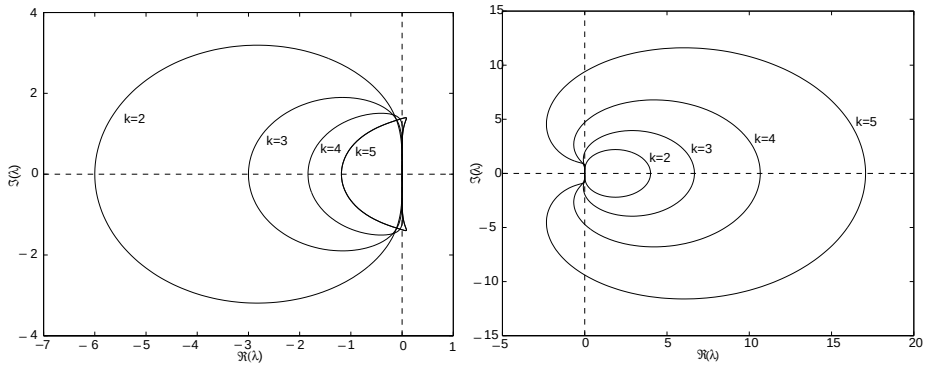

FIG. 4.1. *Boundaries of the stability regions for the Adams–Moulton (AM) (left), respectively, backwards-differentiation (BDF) (right) LMS methods of orders $k = 2, 3, 4, 5$. For the AM methods, the bounded stability region is the interior of curves depicted (left). For the BDF methods, the unbounded stability region is the exterior of the curves depicted (right).*

By the requirement of irreducibility and the fact that solutions $\mu = 0$ do not influence stability, it follows that the stability of the LMS method is now determined by the real parts of the (finite) solutions λ of (4.12) just as for the characteristic roots of (1.2).

To analyze the characteristic equation (4.12), set

$$\mathrm{LMS}(\lambda) := \frac{\sum_{j=0}^{k} \alpha_j \mathrm{e}^{\lambda j}}{\sum_{j=0}^{k} \beta_j \mathrm{e}^{\lambda j}}.$$

We will call the region $\mathbb{C} \setminus \mathrm{LMS}(\mathbb{C}^+)$ the *stability region* of the corresponding LMS method (for a more precise definition see [8, section V.1.1]). It is the region into which $\mathrm{LMS}(\cdot)$ does not map any unstable λ, $\Re(\lambda) \geq 0$. We further require that the *boundary locus curve* (which is the mapping of the imaginary axis under $\mathrm{LMS}(\cdot)$) describes the boundary of this region (this property is sometimes referred to as *property C* [8, section V.4.5]). A number of such regions are depicted in Figure 4.1.

The characteristic equation (4.12) is equivalent to

$$\frac{1}{h}\mathrm{LMS}(\lambda h) \in \sigma\left(A_0 + \sum_{i=1}^{m} A_i \mathrm{e}^{-\lambda\tau_i} \sum_{l=-s_-}^{s_+} \psi_l(\epsilon_i)\mathrm{e}^{\lambda(l-\epsilon_i)h}\right). \tag{4.13}$$

First we prove that the mapping of the RHP under the right-hand side of (4.13) is a subset of $\Sigma(\mathbb{C}^+)$. For this we need the following lemma.

LEMMA 4.1. *The polynomial in z,*

$$\sum_{l=-s_-}^{s_+} \psi_l(\epsilon) z^{s_+-l},$$

maps the (closed) unit circle into itself whenever $\epsilon \in [0, 1]$ and $s_- \leq s_+ \leq s_- + 2$. That is,

$$|z| \leq 1 \Rightarrow \left|\sum_{l=-s_-}^{s_+} \psi_l(\epsilon) z^{s_+-l}\right| \leq 1.$$

Proof. The proof of this lemma can be found in [17] and [26]. ∎

Under the conditions of this lemma, we obtain the following result.

LEMMA 4.2. *The mapping of the closed RHP under the right-hand side of* (4.13) *is a subset of* $\Sigma(\mathbb{C}^+)$.

Proof. For $\lambda \in \mathbb{C}^+$ we have

$$\begin{aligned} \mathrm{e}^{-\lambda\tau_i} \sum_{l=-s_-}^{s_+} \psi_l(\epsilon_i)\mathrm{e}^{\lambda(l-\epsilon_i)h} &= \mathrm{e}^{\lambda(-\tau_i-\epsilon_i h+s_+h)} \sum_{l=-s_-}^{s_+} \psi_l(\epsilon_i)\mathrm{e}^{-\lambda(s_+-l)h} \\ &= z_1 \sum_{l=-s_-}^{s_+} \psi_l(\epsilon_i) z_2^{s_+-l} \\ &= z_1 z_3, \end{aligned}$$

where $|z_1| \leq 1$ because $\Re(\lambda) \geq 0$ and due to (4.5), and where $|z_2| \leq 1$ because $\Re(\lambda) \geq 0$. Hence, by Lemma 4.1, $|z_3| \leq 1$. As a consequence, the above term can be replaced by an $\mathrm{e}^{-\lambda_i}$ with $\lambda_i \in \mathbb{C}^+$ which proves the lemma. ∎

The stability of the LMS method is related to the stability of Σ in the following way.

THEOREM 4.3 (dependence of the stability of the LMS-approximation on h and $\vec{\tau}$). *Suppose the LMS method is irreducible, consistent,* $\mathrm{LMS}(\mathbb{C}^+) \cap \mathrm{LMS}(\mathbb{C}_0^-) = \emptyset$, *and Nordsieck interpolation is used with* $s_- \leq s_+ \leq s_- + 2$. *Then the following statements hold:*

(i) *If* $h\Sigma(\mathbb{C}^+) \subset \mathrm{LMS}(\mathbb{C}_0^-)$ *for* $h \in (0, h^*]$, *then the zero solution of* (4.4) *is delay-independently stable* (*stable for all* $\vec{\tau} \geq 0$) *for* $h \in (0, h^*]$.

(ii) *If* $h\Sigma(\mathbb{C}^+) \subset \mathrm{LMS}(\mathbb{C}_0^+)$ *for* $h \in (0, h^*]$, *then the zero solution of* (4.4) *is delay-independently unstable* (*unstable for all* $\vec{\tau} \geq 0$) *for* $h \in (0, h^*]$.

(iii) *If the characteristic equation of* (1.1) *has a root* $\lambda \in \mathbb{C}$ *for some (fixed)* $\vec{\tau} \geq 0$ *with multiplicity* ν, *then there exists an* $h^* > 0$ *such that* (4.12) *has exactly* ν *roots* $\lambda_{h,i}$, $i = 1, \ldots, \nu$ *(taking into account multiplicities) with* $\max_{1\leq i\leq\nu} |\lambda - \lambda_{h,i}| = \mathcal{O}(h^{\frac{1}{\nu}\min\{p, s_-+s_++1\}})$ *for* $h \in (0, h^*]$ *and with* p *the order of the LMS method.*

Proof.

(i) By Lemma 4.2 we know that the mapping of the closed RHP under the right-hand side of the characteristic equation (4.13) maps into $\Sigma(\mathbb{C}^+)$, which, by assumption, maps into $\frac{1}{h}\mathrm{LMS}(\mathbb{C}_0^-)$. Hence, (4.13) can have no unstable roots because these are mapped into disjunct regions under the left- and right-hand sides of (4.13). This implies the asymptotic stability of the zero solution of the LMS method for $h \in (0, h^*]$ and for all $\vec{\tau} \geq 0$.

(ii) Formally rewrite (4.13) as

$$\lambda = \frac{1}{h}\mathrm{LMS}^{-1}\left(h\sigma_{h,l}\left(A_0 + \sum_{i=1}^{m} A_i \mathrm{e}^{-\lambda\tau_i} \sum_{q=-s_-}^{s_+} \psi_q(\epsilon_i)\mathrm{e}^{\lambda(q-\epsilon_i)h}\right)\right),$$

where $\sigma_{h,l}$ is similarly defined as in Theorem 3.4, part (ii). Now choose $0 < h < \hat{h} < h^*$ small enough such that the inverse LMS^{-1} uniquely exists for all arguments mapped onto by $h\sigma_{h,l}(\cdot)$ from $\lambda \in \mathbb{C}_0^+$. By the same reasoning as in the proof of Theorem 3.4, part (ii), this mapping has a fixed point $\lambda \in \mathbb{C}_0^+$ which is an unstable solution of (4.13). This root moves continuously in the function of h. For $h \in (0, h^*]$, (4.13) can have no pure imaginary

solutions λ (because $\Sigma(\{\mathrm{i}\xi \,|\, \xi \in \mathbb{R}\}) \subset \frac{1}{h}\mathrm{LMS}(\mathbb{C}_0^+)$). Hence for $h \in (0, h^*]$ this root cannot change sign and the zero solution of the LMS method is unstable for $h \in (0, h^*]$.

(iii) Denote the characteristic equation (4.9) after the substitution (4.11) by $P_h(\lambda) = 0$.

First, observe that

$$\sum_{l=-s_-}^{s_+} \psi_l(\epsilon)\mathrm{e}^{\lambda l h} = e^{\lambda\epsilon h} + \mathcal{O}(h^{s_-+s_++1})$$

uniformly in $\epsilon \in [0,1]$. We fix $\vec{\tau}$ and expand $\exp(\lambda h)$ into a Taylor series to obtain that

$$\begin{aligned} P_h(\lambda) \;=\; & \det\left(\lambda\left(\alpha_0 + \sum_{q=0}^{p}\sum_{j=1}^{k}\alpha_j\frac{(\lambda j h)^q}{q!}\right)I \right. \\ & - h\left(\beta_0 + \sum_{q=0}^{p-1}\sum_{j=1}^{k}\beta_j(\lambda j h)^q\right) \\ & \left.\cdot\left(A_0 + \sum_{i=1}^{m}A_i\mathrm{e}^{-\lambda\tau_i} + \mathcal{O}(h^{s_-+s_++1})\right) + \mathcal{O}(h^{p+1})\right). \end{aligned}$$

Using the order conditions (4.8), the latter simplifies to

$$\begin{aligned} P_h(\lambda) = \det & \left(h\left(\lambda I - \left(A_0 + \sum_{i=1}A_i\mathrm{e}^{-\lambda\tau_i} + \mathcal{O}(h^{s_-+s_++1})\right)\right)\right. \\ & \left.\cdot\left(\beta_0 + \sum_{q=0}^{p-1}\frac{(h\lambda)^q}{q!}\sum_{j=1}^{k}\beta_j j^q\right) + \mathcal{O}(h^{p+1})\right). \end{aligned}$$

From this it follows that

$$\frac{1}{h}P_h(\lambda) = P(\lambda)Q_h(\lambda) + \mathcal{O}(h^{\min\{p,s_-+s_++1\}}), \tag{4.14}$$

where $P(\lambda)$ denotes the characteristic equation (1.2) and

$$\lim_{h\to 0} Q_h(\lambda) = \left(\sum_{j=0}^{k}\beta_j\right)^n \neq 0, \tag{4.15}$$

where the latter inequality follows from the irreducibility (4.10) and the consistency (4.8). Moreover, it is clear that (4.14) holds uniform on bounded regions of λ in the complex plane.

The following statements follow the lines of proof of Hurwitz's theorem [2, section VII.2.5]. First, note that $P(\lambda)$ is an analytic function and that $P_h(\lambda)$ and $Q_h(\lambda)$ are analytic in bounded regions of the complex plane when h is small enough. Since λ^* is an isolated zero of $P(\lambda)$ of multiplicity ν, there exists an $R > 0$ and a $K_0 > 0$ such that

$$\inf_{\theta\in[0,2\pi]}\left|\left(\sum_{j=0}^{k}\beta_j\right)^n P(\lambda^* + r\mathrm{e}^{\mathrm{i}\theta})\right| > K_0 r^\nu \text{ for } r \in (0, R].$$

From (4.15), there exists an $h_0^* > 0$ and $0 < K_1 < 1$ such that

$$\inf_{|\lambda-\lambda^*|\le R} |Q_h(\lambda)| > K_1 \left| \sum_{j=0}^{k} \beta_j \right|^n \quad \text{for } h \in (0, h_0^*].$$

Hence,

$$\inf_{\theta\in[0,2\pi]} \left| Q_h(\lambda^* + re^{i\theta}) P(\lambda^* + re^{i\theta}) \right| > K_0 K_1 r^\nu \text{ for } r \in (0, R],\ h \in (0, h_0^*].$$

From (4.14), there exists a $0 < h_1^* < h_0^*$ and a $K_2 > 0$ such that (using $p^* = \min\{p, s_- + s_+ + 1\}$)

$$\sup_{|\lambda-\lambda^*|\le R} \left| \frac{1}{h} P_h(\lambda) - Q_h(\lambda) P(\lambda) \right| < K_2 h^{p^*} \text{ for } h \in (0, h_1^*].$$

Set $\kappa := (2\frac{K_2}{K_0 K_1})^{1/\nu}$; then, for each fixed $h < h^* := \min\{h_1^*, (R/\kappa)^{\nu/p^*}\}$ and corresponding $r = \kappa h^{p^*/\nu}$, we obtain

$$\begin{aligned} &\left| \frac{1}{h} P_h(\lambda^* + re^{i\theta}) - Q_h(\lambda^* + re^{i\theta}) P(\lambda^* + re^{i\theta}) \right| \\ &\qquad < K_2 h^{p^*} = K_2 \left(\frac{r}{\kappa}\right)^\nu = \frac{1}{2} K_0 K_1 r^\nu \\ &\qquad < \left| Q_h(\lambda^* + re^{i\theta}) P(\lambda^* + re^{i\theta}) \right| \end{aligned}$$

for $\theta \in [0, 2\pi]$. Hence, by Rouché's theorem [2, section V.3.8], $Q_h(\lambda)P(\lambda)$ and $P_h(\lambda)$, or, equivalently, $P(\lambda)$ and $\frac{1}{h}P_h(\lambda)$, have the same number of roots (counting multiplicities) in a circle of radius $r = \kappa h^{p^*/\nu}$ around λ^* for all $h \in (0, h^*]$. ∎

The above theorem provides conditions under which a given LMS method captures the stability properties of Σ, which, in turn, are related to the stability properties of the DDE. In the next section we exploit these results to obtain a steplength heuristic for h.

4.2. An LMS steplength heuristic. By comparing the first two parts of Theorems 3.4 and 4.3, it is clear that the stability region of the LMS method scaled with $1/h$ should mimic the LHP when compared to the regions $\Sigma(\mathbb{C}^+)$ in order to obtain a good correspondence between the stability of the LMS scheme and the original DDE (see also Figure 4.2 (right)).

For this reason we define a *safety radius* $\rho_{\mathrm{LMS},\epsilon}$ of the LMS stability region as follows:

$$\rho_{\mathrm{LMS},\epsilon} := \min\{\rho^-_{\mathrm{LMS},\epsilon}, \rho^+_{\mathrm{LMS},\epsilon}\}$$

with

$$\rho^-_{\mathrm{LMS},\epsilon} := \sup\{\rho > \epsilon \mid |\mathrm{LMS}(\lambda)| < \rho \text{ and } \Re(\mathrm{LMS}(\lambda)) < -\epsilon \Rightarrow \Re(\lambda) < 0\} \tag{4.16}$$

and

$$\rho^+_{\mathrm{LMS},\epsilon} := \sup\{\rho > \epsilon \mid |\mathrm{LMS}(\lambda)| < \rho \text{ and } \Re(\mathrm{LMS}(\lambda)) > \epsilon \Rightarrow \Re(\lambda) > 0\}, \tag{4.17}$$

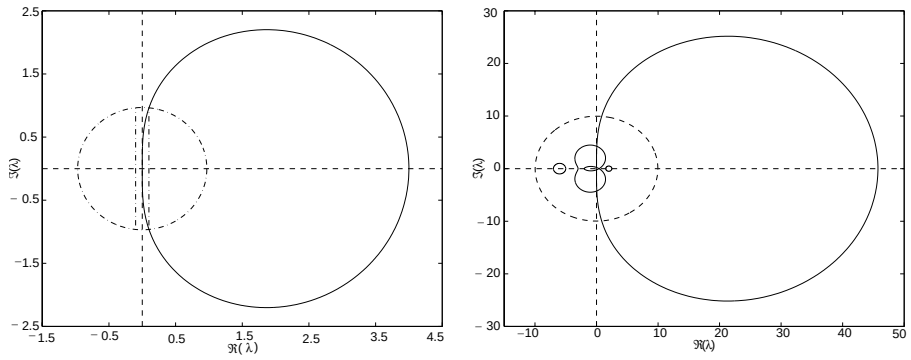

FIG. 4.2. *Left: Circle with radius $\rho_{\mathrm{LMS},0.1}$ for the stability region (—) of the second order BDF method. Right: Illustration of Heuristic* 4.2 *using $\rho_{\mathrm{LMS},0.1}$ shown left, $r = 0$, and the matrices* (3.5). *The $\Sigma(\mathbb{C}^+)$ regions of* (3.5) *are inside a circle with radius $\|A_0\| + \|A_1\|$ (−−). The stability region of the LMS method (−) is scaled with $1/h$, h obtained from* (4.21).

where we assume ϵ small enough such that the sets used in (4.16) and (4.17) are nonempty. In other words, the safety radius is the size of the circle in which the stability region of the LMS method mimics the LHP up to some accuracy ϵ (i.e., it has the correct stability except for a region of size 2ϵ around the imaginary axis; cf. Figure 4.2 (left)).

We can now use the safety radius $\rho_{\mathrm{LMS},\epsilon}$ and the bound on $\Sigma(\mathbb{C}^+)$ (see (3.4)) to obtain the following heuristic.

HEURISTIC 4.1. *The steplength h chosen as*

$$h = 0.9 \frac{\rho_{\mathrm{LMS},\epsilon}}{\sum_{i=0}^{m} \|A_i\|} \tag{4.18}$$

can be used to obtain an LMS scheme which approximates the (delay-independent) stability of the DDE up to some accuracy ϵ.

Indeed, if $\Sigma(\mathbb{C}^+)$ maps into $\Re(\lambda) < -\epsilon/h$, then there is delay-independent stability for the DDE, and this property is recovered by the LMS method (we assume ϵ is small enough such that $\epsilon/h \ll 1$). Similarly, if $\Sigma(\mathbb{C}^+)$ maps into $\Re(\lambda) > \epsilon/h$, then there is delay-independent instability for the DDE, and this property is recovered by the LMS method.

By virtue of the third parts of Theorems 3.4 and 4.3, we know that Hopf bifurcations as a function of the delay(s) (and hence delay-dependent stability) are associated with the crossings of the boundary of $\Sigma(\mathbb{C}^+)$ with the imaginary axis. These crossings are captured well when the boundary of the stability region of the LMS method mimics the imaginary axis when compared to $\Sigma(\mathbb{C}^+)$. This is the heuristic reason why the above steplength choice works well to capture the (more important) property of delay-dependent stability.

The previous analysis concentrates on recovering stability and hence on roots of the characteristic equations in their relation to the imaginary axis. The characteristic equation of (1.1) has a root $\lambda = r + \mathrm{i}\xi$ if and only if the system of DDEs,

$$\dot{x}(t) = (A_0 - rI)x(t) + \sum_{i=1}^{m} (A_i \mathrm{e}^{-r\tau_i})x(t - \tau_i), \tag{4.19}$$

has a root $\lambda = \mathrm{i}\xi$. Hence $\Sigma_r(\mathbb{C}^+)$ can be defined as before, in terms of the system matrices,

$$A_0^r = A_0 - rI \text{ and } A_i^r = A_i \mathrm{e}^{-r\tau_i},\ i = 1, \ldots, m, \tag{4.20}$$

to study the *r-stability* of the continuous problem and its dependency on the delay(s). This leads to the following adaptation of Heuristic 4.1.

HEURISTIC 4.2. *The heuristic choice of the steplength h,*

$$h = 0.9 \frac{\rho_{\mathrm{LMS},\epsilon}}{\|A_0\| + |r| + \sum_{i=1}^m \|A_i\| \mathrm{e}^{-r\tau_i}}, \tag{4.21}$$

can be used to approximate the roots with real parts greater than $r < 0$, $\Re(\lambda) \geq r$.

This heuristic choice of h is implemented in the package DDE-BIFTOOL [3], where it is applied to the original matrices $A_0, \ldots, A_m$ without the shift (4.20). The latter is done to avoid deterioration in the approximation to the most interesting part of the spectrum (near the imaginary axis).

Numerical results (see further) indicate that Heuristics 4.1 and 4.2 are quite effective.

5. Numerical results. In this section we illustrate our findings with numerical results.

In order to compute the characteristic roots of the LMS method (4.12) we compute the eigenvalues μ of the matrix M that maps $[y_{s-L}\ y_{s-L+1}\ \cdots\ y_{s+k-1}]$ onto $[y_{s-L+1}\ y_{s-L+2}\ \cdots\ y_{s+k}]$ using the LMS method for y_{s+k} and a shift for all other values (and where $L = \max_i L_i + s_-$). Then, we use the relation (4.11) to obtain

$$\Re(\lambda) = \frac{1}{h} \log(|\mu|)$$

and

$$\Im(\lambda) = \frac{1}{h} \arcsin\left(\frac{\Im(\mu)}{|\mu|}\right) \bmod \frac{\pi}{h}.$$

In our tests we use the explicit Adams–Bashforth (AB), implicit AM, and implicit BDF LMS methods with different number of steps k (see, e.g., [7, section III.1.1-2,6]).

Consider the well-known delayed logistic equation,

$$\dot{x}(t) = (\alpha - x(t-1))x(t), \tag{5.1}$$

cf., e.g., [18, section I.5.1] and [15]. The rightmost roots of the characteristic equation of the steady state solution $x^* = \alpha$ of (5.1) for $\alpha = 2$ are depicted in Figure 5.1 (left). The convergence towards the rightmost root by the corresponding root of the LMS method is shown in Figure 5.1 (right) for varying h. Here, the steplength h was chosen as an integer fraction of the delay, $h = 1/L$. Table 5.1 gives the numerical approximation of the orders of convergence based on a least squares approximation of the results for $L = 10, \ldots, 100$ using the AB, AM, and BDF methods with $k = 2, 3, 4, 5$ steps. The results for the AM method are shown in Figure 5.1 (right). The $\mathcal{O}(h^p)$ convergence, $p = k + 1$ for AM, $p = k$ for AB and BDF methods [7, Table III.2.1], is clearly apparent.

The following system of DDEs, taken from [24], models two coupled neurons with time delayed connections:

$$\begin{cases} \dot{x_1}(t) = -\kappa x_1(t) + \beta \tanh(x_1(t-\tau_s)) + a_{12} \tanh(x_2(t-\tau_2)), \\ \dot{x_2}(t) = -\kappa x_2(t) + \beta \tanh(x_2(t-\tau_s)) + a_{21} \tanh(x_1(t-\tau_1)). \end{cases} \tag{5.2}$$

We set $\kappa = 0.5$, $\beta = -1$, $a_{12} = 1$, $a_{21} = 2.34$, $\tau_1 = \tau_2 = 0.2$, and $\tau_s = 1.57$ and investigate the steady state solution $(x_1^*, x_2^*) = (0, 0)$. The convergence towards a rightmost root by the corresponding root of the LMS method is shown in Figure 5.2 (right) for varying h. Here, the steplength h is allowed to vary continuously, and appropriate interpolation is used for the past terms.

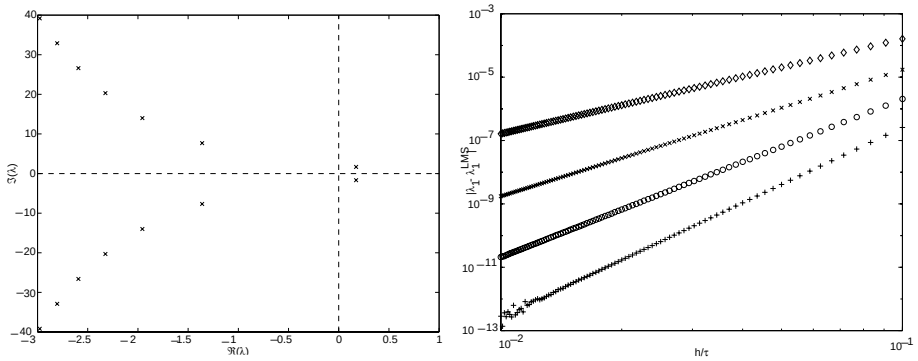

FIG. 5.1. *Left: The rightmost roots of the characteristic equation* (5.1) *for* $\alpha = 2$. *Right: Convergence of the corresponding LMS root to the rightmost root of* (5.1) *for* $\alpha = 2$, *for varying* $h = 1/L$, $L = 10, \ldots, 100$. *Here, AM methods were used with* $k = 2$ ($\diamond$), $k = 3$ ($\times$), $k = 4$ ($\circ$), *and* $k = 5$ ($+$).

The scalar DDE,

$$\dot{x}(t) = 2x(t) - \mathrm{e}x(t-1), \tag{5.3}$$

with $\mathrm{e} = \exp(1)$ has a double characteristic root at $\lambda = 1$. Table 5.2 gives the numerical approximation of the orders of convergence towards this root based on a least squares approximation of the results for $h = 1/L$, $L = 10, \ldots, 100$ using the AB, AM, and BDF methods with $k = 2, 3, 4, 5$ steps. The $\mathcal{O}(|h|^{p/\nu})$ convergence, $\nu = 2$, is clearly apparent.

Finally, Table 5.3 and Figure 5.3 illustrate the results, respectively, the effectiveness, of Heuristic 4.2 for different values of r.

6. On stiffness in DDEs. Stiffness in the numerical solution of initial-value problems has been used with quite different meanings by a number of authors. For an overview in the context of ordinary differential equations, see [25]. The situation for DDEs is even less clear. In [1] Dahlquist is quoted as follows:

> *A "stiff" problem is characterized by the property that there are processes in the physical system, described by a system of ordinary differential equations, with significantly different time scales ....*

When applying this definition to DDEs one might conclude, observing the existence of sequences of characteristic roots with decreasing real parts (see Figure 5.3), that all DDEs are stiff. This is contradicted by the fact that almost all existing software for simulation of DDEs is based on explicit Runge–Kutta methods. The latter gives rise to a more practical observation of stiffness. We quote from Hairer and Wanner [8] as follows:

> *Stiff equations are problems for which explicit methods don't work.*

We now illustrate how visualization of the regions $\Sigma(\mathbb{C}^+)$ allows us to distinguish between stiff and nonstiff problems in the latter sense.

In [22] a model is introduced to describe the flow of a viscoelastic fluid (i.e., a fluid with a fading memory). This models consists of a partial differential equation with an infinite, distributed delay term. The classical method used to study this integrodifferential equation is the conversion into a pair of coupled partial differential equations. In [20], however, the distributed delay is replaced by two point delays. Here, we study a one-delay version,

$$\frac{\partial u}{\partial t} = \frac{1-\delta}{\nu}(u_{xx}(x,t) + u_{xx}(x,t-\tau)) + \delta u_{xx}(x,t) + Ru(x,t) - u^3(x,t), \tag{6.1}$$

on $x \in [0,\pi]$ with boundary conditions $u(0,t) = u(\pi,t) = 0$. $u(x,t)$ is the velocity of the fluid and ν, δ, τ, and R are parameters of the problem.

We use a classical second order central difference scheme in space to approximate (6.1) by a system of n DDEs,

$$\begin{aligned}\frac{\mathrm{d}u_i}{\mathrm{d}t} &= \left(\frac{1-\delta}{\nu} + \delta\right)\left(\frac{u_{i-1}(t) - 2u_i(t) + u_{i+1}(t)}{\Delta x^2}\right) \\ &\quad + \frac{1-\delta}{\nu}\left(\frac{u_{i-1}(t-\tau) - 2u_i(t-\tau) + u_{i+1}(t-\tau)}{\Delta x^2}\right) + Ru_i(t) - u_i^3(t),\end{aligned} \tag{6.2}$$

$i = 1, \ldots, n,$

where $u_0(t) \equiv u_{n+1}(t) \equiv 0$, $\Delta x = \pi/(n+1)$. We fix $\nu = 2$, $\delta = 0.1$, $R = 0.08$, and $\tau = 3$.

The regions $\Sigma(\mathbb{C}^+)$ of the linearization of (6.2) around its zero steady state solution are shown in Figure 6.1 (left) for $n = 8$. The figure indicates that this example is in fact mildly stiff. Indeed, the regions $\Sigma(\mathbb{C}^+)$ are such that an implicit method with unbounded stability region can capture the stability for a smaller h more efficiently than an explicit method can. This is illustrated in Figure 6.2 using the scaled stability regions of the BDF, respectively, AM, methods using, for both methods, $k = 2$ and $h = 0.3$. Both methods capture the stability of the regions $\Sigma(\mathbb{C}^+)$ near the origin, but the AM method fails to capture the "tail" of the regions $\Sigma(\mathbb{C}^+)$ at its leftmost end.

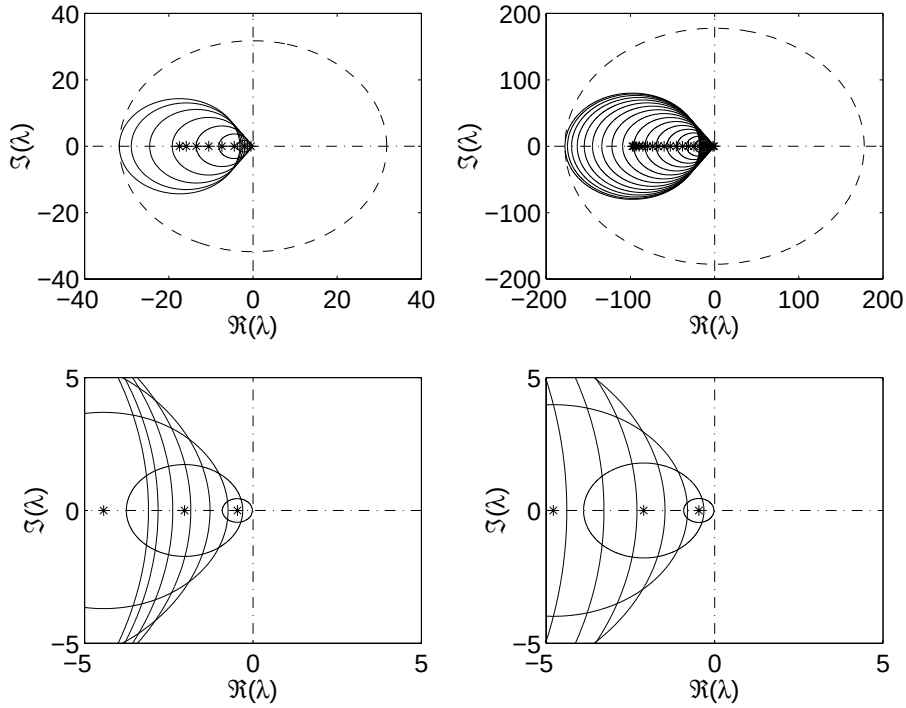

FIG. 6.1. *Stability regions of the zero steady state solution of* (6.2) *using* $n = 8$ *(left) and* $n = 20$ *(right). Full view (top) and a blow up near the origin (bottom).*

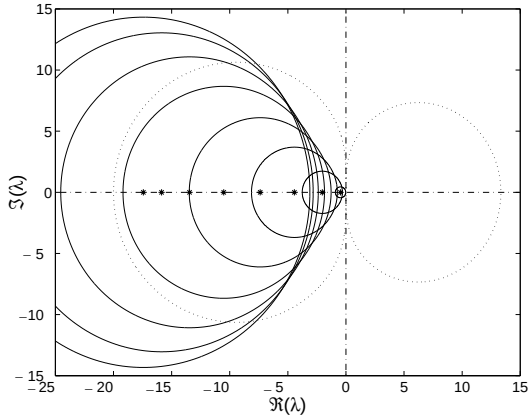

FIG. 6.2. *Stability regions of the zero steady state solution of* (6.2) *using* $n = 8$ *and stability regions of the BDF and AM methods for* $k = 2$ *scaled with* $1/h$ *using* $h = 0.3$.

The stability of the AM method for our case, $\tau_0 = 3$, is indeed wrong; see Figure 6.3 (upper right).

If system (6.2) is considered for a larger value of n, then stiffness increases and the situation is even more clear. Figure 6.1 shows the regions $\Sigma(\mathbb{C}^+)$ for a system of size $n = 20$. Taking a finer discretization enlarges the stability regions to the left, while the situation near the origin remains approximately the same. Hence, this effect is

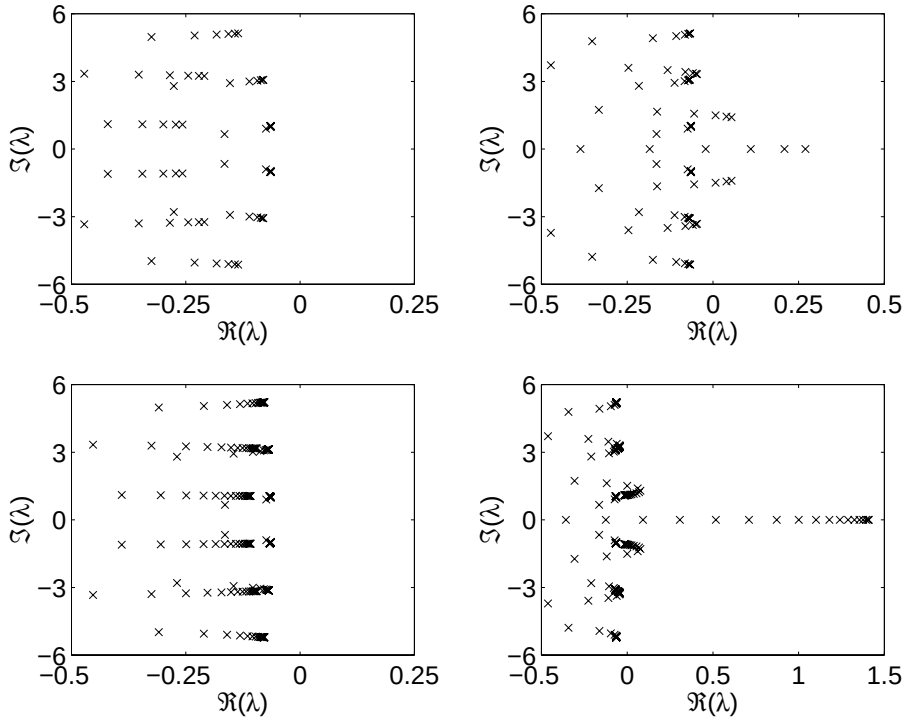

FIG. 6.3. *LMS approximations of the rightmost characteristic roots of the stable zero solution of* (6.2) *using* $h = 0.3$. *Left: BDF method,* $k = 2$. *Right: AM method,* $k = 2$. *Top:* $n = 8$. *Bottom:* $n = 20$. *Note that only some rightmost roots of the BDF method are close to actual correct roots of the system (not shown).*

not felt by the BDF method which produces (in contrast to the AM method) similar results for $n = 20$ using the same steplength $h = 0.3$; see Figure 6.3 (lower left).

As a last remark, we note that the above characterization of stiffness does not depend on the size of the delay. Hence one could say that a problem with the same system matrices but a larger delay is relatively more difficult (because the discretized state space grows with the size of the delay for fixed h) but is not more stiff.

7. Conclusion. DDEs are used to model systems with some form of memory or delayed feedback and arise in a growing number of applications.

The stability of a steady state solution of a DDE is governed by the roots of a characteristic equation which expresses a nonlinear, nonstandard eigenvalue problem. For stability and bifurcation analysis it is of interest to compute the stability determining, i.e., the rightmost characteristic, roots. Established numerical algorithms exist to compute selected eigenvalues of possibly very large matrices. Therefore, selected characteristic roots can be approximated by computing the eigenvalues of the map defined by a discrete numerical time integration approximation to the given DDE [4].

In this paper we investigate the correspondence between the characteristic roots of a DDE and the eigenvalues obtained from an LMS method approximation. In particular, we investigate under what conditions for the steplength the approximation retains certain delay-independent stability properties of the original system. We

concentrate on the recovery of both stability and instability and prove convergence orders of the approximate characteristic roots. This analysis allows us to obtain a steplength heuristic for the computation of the characteristic roots with real parts greater than a given constant, as used in the package DDE-BIFTOOL [3].

We illustrate the results using numerical experiments. In particular, the analysis of an example system of DDEs arising from a partial differential equation with delay discretized in space shows how the investigated stability issues allow us to interpret stiffness for DDEs.

Acknowledgment. The authors thank Professor J. Quaegebeur for helpful comments concerning Theorems 3.2 and 3.3.

VARIATIONAL BARRIER METHOD OF ADAPTIVE GRID GENERATION IN HYPERBOLIC PROBLEMS OF GAS DYNAMICS*

BORIS N. AZARENOK†

Abstract. Application of the harmonic mapping using a variational approach to generate moving adaptive grids in the hyperbolic problems of gas dynamics is considered. Using the example of a three-point model of adaptation, the possibility to generate an unfolded mesh with strong grid lines condensing in the vicinity of discontinuities of the control/(monitor) function is demonstrated. The algorithm of redistributing the boundary nodes is suggested and consists of using constrained minimization of the discrete harmonic functional when constraints define the boundary of the domain. In real computations due to mesh adaptation it is possible to reduce the errors, caused by shock waves smearing over the cells, by many factors of ten. Modeling of the two-dimensional (2-D) supersonic gas flow in the channel has shown that the same accuracy on the adaptive grid with the same structure as the quasi-uniform mesh can be acheived while requiring less CPU memory by a factor of 25 and less running time by a factor of 50 to 60. Computational tests of the steady transonic and supersonic flow over an airfoil demonstrate the ability of the method to control mesh sizes across shocks.

1. Introduction.

Moving adaptive grid technology has important applications in the problems of fluid dynamics. The essence of such an approach, referred to as r-refinement, is in adjusting redistribution of the grid nodes in such a manner to catch particularities in the solution of interest with fixed computer cost. The constructive way is that we try to position more grid nodes in the domains of sharp change in the solution being the regions of high gradients while the mesh retains the regular structure that makes the course of computation more simple. Examples of some r-refinement based methods can be found in Carey [10], Charakhch'yan and Ivanenko [12], Hawken, Gottlieb, and Hansen [21], Ivanenko [24], Jacquotte [26], Li, Tang, and Zhang [28], Tang and Tang [38], Thompson [39], and Zegeling [41]. In Liu, Ji, and Liao [30] the deformation method is suggested, where the grid velocities are determined by solving a scalar Poisson equation. An approach based on the moving mesh partial differential equations method has been considered in Cao, Huang, and Russell [8, 9] and Huang [22]. Here the Euler–Lagrange equations, both stationary and with the time dependent left part, to the variational functional are solved and mesh adaptation is performed using a class of monitor functions that are the symmetric positive definite matrices.

When constructing an adaptive moving grid the main difficulty is in maintaining its nondegeneracy. Probably, an approach should consist of extending the equidistribution principle, providing a one-to-one mapping of logic space onto the physical domain in a discrete approach, from the widely used one-dimensional (1-D) case to

the two-dimensional (2-D) one. Some ways to define equidistribution-like methods in 2 dimensions can be found in Baines [6], Cao, Huang, and Russell [8, 9], Dwyer, Sanders, and Raiszadek [14], Huang [22], and Zegeling [41]. In Ivanenko [25] it was suggested to use a variational functional depending on derivatives of the functions sought and on variable coefficients, which are the elements of some symmetric positive defined matrix, and in a discrete approach the following variational principle is proved: a mapping, minimizing that functional, is one-to-one.

One of the mesh generation techniques is in using a harmonic mapping, first applied in Winslow [40], and in particular a variational approach. Here, when minimizing the Dirichlet (or harmonic) functional of smoothness, we ensure the grid lines are as smooth as possible; see Brackbill and Saltzman [7]. To include adaptivity in this process it has been suggested to write the Dirichlet functional on the surface of the graph of the control/(monitor) function, which is the solution of the basic problem or somehow connected with it, and to perform an adaptation by solving the Euler–Lagrange equations to the harmonic functional; see Liseikin [31, 32]. Application of such monitor surfaces has also been considered in Dwyer, Sanders, and Raiszadek [14], Eisman [15], and Spekreijse [36]. Note that Dvinsky [13] was the first to use the harmonic mapping for mesh adaptation where the gradient of the monitor function is utilized to perform grid lines clustering.

Numerical solution of the discrete Euler–Lagrange equations cannot always provide generation of the unfolded mesh even in domains without adaptation; see examples of grids to the backstep in Knupp and Steinberg [27] and Ivanenko [24]. It means, though, in a continuous approach that there exists a unique harmonic mapping, being one-to-one, and when discretizing the one-to-one property of the mapping can be lost. The discrete mapping can also be nonunique; see Garanzha and Kaporin [18].

To provide a one-to-one harmonic mapping at a discrete level Charakhch'yan and Ivanenko [11] have suggested a variational barrier method of grid generation in a physical domain without adaptation when the mapping is constructed by minimizing the harmonic functional. The functional is approximated in such a manner that there is an infinite barrier ensuring all grid cells to be convex quadrilaterals. This approach has been extended to adaptive grid generation when the harmonic functional is written on the surface of the control function; see Ivanenko [23, 24], Charakhch'yan and Ivanenko [12]. In Azarenok [2] and Azarenok and Ivanenko [4, 5] this approach has been applied in 2-D unsteady problems of gas dynamics when as a control function it used one of the flow parameters or the superposition of several parameters.

The purpose of the present work is to show some theoretical aspects and practical possibilities of using the variational barrier method of constructing structured adaptive grids in hyperbolic problems of gas dynamics with discontinuous solutions. In the 1-D case based on solving the nonlinear advection equation it is shown that the regularized discrete functional is convex and its minimum is attained on the mesh, which can be strongly condensed in the vicinity of discontinuities of the control function; meanwhile, this functional keeps the infinite barrier preventing the grid cells from collapsing. In the 2-D case it is shown that at strong grid lines condensing the infinite barrier disappears; nevertheless, when using the iterative procedure of mesh generation, we can guarantee the grid to be unfolded. The algorithm of redistributing the boundary nodes, consisting of using constrained minimization of the functional when constraints define the boundary of the domain, is suggested. Such an approach allows us to perform consistent redistribution of grid nodes inside the domain and on its boundary that increases the reliability of grid generation and the modeling of

the flow problem. Modeling of the 2-D supersonic gas flow in the channel has shown that the same accuracy on the adaptive grid with the same structure as on the quasi-uniform mesh can be achieved while requiring less CPU memory by a factor of 25 and less running time by a factor of 50 to 60. Computational tests of the steady transonic and supersonic flow over an airfoil demonstrate the possibility to control mesh sizes across shocks.

2. Problem formulation. The theory of harmonic mappings is useful for formulating a well-posed variational grid generation problem. The energy of a mapping $\phi : (M, g) \to (N, h)$ between two n-dimensional Riemannian manifolds M and N with metric tensors g_{ij} and h_{ij} is the function $e(\phi) : M \to \mathcal{R}(\geq 0)$, defined in some local coordinates ξ^i, μ^i as

$$e(\phi) = \frac{1}{2} g^{ij}(\xi) \frac{\partial \mu^k}{\partial \xi^i} \frac{\partial \mu^l}{\partial \xi^j} h_{kl}(\mu),$$

where g^{ij} is the inverse metric. The energy functional (or total energy) of the mapping ϕ is defined as (see Eells and Lemaire [16] and Dvinsky [13])

$$E(\phi) = \int_M e(\phi) d\xi, \qquad \text{where } d\xi = \sqrt{\det(g)} d\xi^1 \cdots \xi^n. \tag{2.1}$$

A smooth mapping $\phi : (M, g) \to (N, h)$ is harmonic if it is a critical point of the energy functional E.

Sampson [34] and Schoen and Yau [35] have shown that the harmonic mapping $M \to N$ when $\dim N = 2$ is always a homeomorphism (one-to-one) provided that the curvature of N is nonpositive and the boundary ∂N is convex (with respect to the metric h_{ij}). But it is sometimes not true when $\dim N > 2$ [17].

Now we turn to the problem formulation of the surface grid generation utilized for constructing the adapted mesh [12, 24, 32]. Let a simply connected domain $\Omega \subset \Re^2$ with a smooth boundary in plane x-y be given. Consider the surface S^{r2} of the graph of the control/(monitor) function $z = f(x, y)$; see Figure 1. The surface S^{r2} can be presented in Euclidean space $\mathcal{R}^3$ by a parametrization $\boldsymbol{r}(\xi, \eta) = (x(\xi, \eta), y(\xi, \eta), f[x(\xi, \eta), y(\xi, \eta)])$, where ξ, η are the local coordinates on S^{r2}. We seek a mapping of the unit square in parametric plane ξ-η onto the domain Ω, when a mapping of the boundary of a square onto the boundary of Ω is given, so that the mapping of the surface S^{r2} onto the parametric square is harmonic. The conditions of the above Sampson, Shoen and Yau's statement are obviously satisfied for the mapping of the physical domain Ω onto the parametric domain Ω_p with Euclidean metric $h_{ij} = \delta_{ij}$ (here δ_{ij} is the Kronecker symbol), which is the square in the parametric plane ξ-η. Hence, the nondegenerate harmonic coordinates ξ, η may be constructed on the surface S^{r2}. The coordinate lines ξ, η are then projected on the physical domain Ω and the result is an adaptive-harmonic grid.

To construct the harmonic mapping we use the variational formulation of the Dirichlet functional, which is the measure of closeness of the mapping to conformal. The task at hand is to minimize the Dirichlet functional written on the surface S^{r2}. This functional of smoothness can be expressed through the invariants $\mathcal{I}_1$, $\mathcal{I}_2$ of the orthogonal transforms of the covariant metric tensor g_{ij} [31, 32], namely,

$$I = \int_{S^{r2}} \frac{\mathcal{I}_1}{\mathcal{I}_2} dS^{r2}.$$

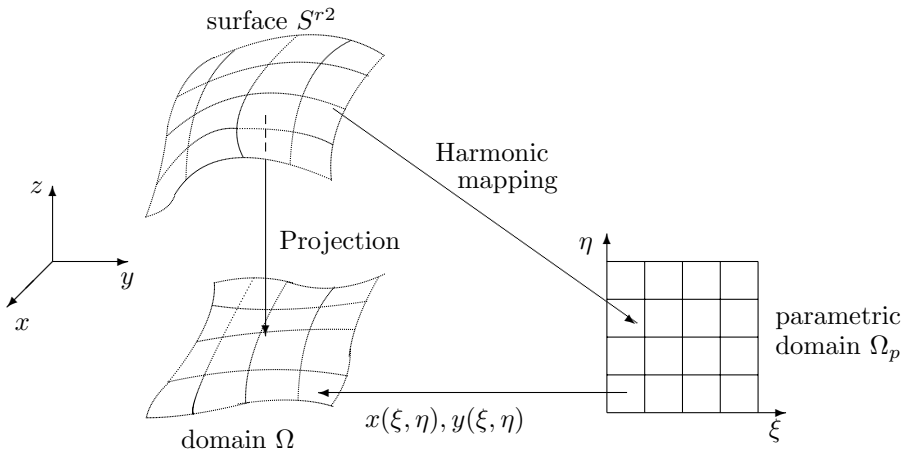

FIG. 1. *Adaptive grid generation.*

The invariant $\mathcal{I}_2 = \det(g_{ij}) = g_{11}g_{22} - (g_{12})^2$ and it equals the area squared of the cell on the surface S^{r2}; the invariant $\mathcal{I}_1 = g_{11} + g_{22}$ means the sum of the length squared of the cell sides. Noting that $dS^{r2} = \sqrt{g_{11}g_{22} - (g_{12})^2}d\xi d\eta$ we get

$$I = \int_0^1 \int_0^1 \frac{g_{11} + g_{22}}{\sqrt{g_{11}g_{22} - (g_{12})^2}} d\xi d\eta. \tag{2.2}$$

The components of the tensor g_{ij} are defined on the surface S^{r2} with the local coordinates ξ, η in Euclidean space $\mathcal{R}^3$ as follows:

$$g_{11} = \boldsymbol{r}_\xi^2 = x_\xi^2 + y_\xi^2 + f_\xi^2 = x_\xi^2 + y_\xi^2 + (f_x x_\xi + f_y y_\xi)^2,$$
$$g_{12} = (\boldsymbol{r}_\xi \cdot \boldsymbol{r}_\eta) = x_\xi x_\eta + y_\xi y_\eta + f_\xi f_\eta = x_\xi x_\eta + y_\xi y_\eta + (f_x x_\xi + f_y y_\xi)(f_x x_\eta + f_y y_\eta),$$
$$g_{22} = \boldsymbol{r}_\eta^2 = x_\eta^2 + y_\eta^2 + f_\eta^2 = x_\eta^2 + y_\eta^2 + (f_x x_\eta + f_y y_\eta)^2.$$

Substituting them in (2.2) we get the following form of the functional:

$$I = \int_0^1 \int_0^1 \frac{(x_\xi^2 + x_\eta^2)(1 + f_x^2) + (y_\xi^2 + y_\eta^2)(1 + f_y^2) + 2f_x f_y(x_\xi y_\xi + x_\eta y_\eta)}{(x_\xi y_\eta - x_\eta y_\xi)\sqrt{1 + f_x^2 + f_y^2}} d\xi d\eta. \tag{2.3}$$

This form of the harmonic functional has been derived in [12, 24] from the energy functional (2.1) (if multiplied by 2) written for the surface S^{r2}

$$E = \int_0^1 \int_0^1 Tr(g_{ij}^{-1})\sqrt{\det(g_{ij})} d\xi d\eta,$$

where $Tr(g_{ij}^{-1}) = g^{ii}$.

With the purpose of controlling the degree of coordinate lines condensing in the domains of high gradients, it is convenient to use $c_a f$ instead of the control function f, where c_a is a coefficient of adaptation [24] which can depend on variables x, y. Thus, we work with the control function multiplied by some coefficient c_a in order to increase or decrease adaptation.

In the 1-D case, to generate the inverse harmonic mapping of the graph of f onto the unit segment in parametric space ξ requires us to minimize the following

functional (see [31, 32]):

$$I = \int_0^1 \frac{1}{x_\xi \sqrt{1 + c_a^2 f_x^2}} d\xi. \tag{2.4}$$

Here at once we use $c_a f$ instead of f, and it means we seek the grid points arc-length equidistribution in the metric of the curve $c_a f$.

For the direct mapping of the unit segment in parametric space ξ to the curve $c_a f$, the Dirichlet functional has the form

$$I = \int_0^1 x_\xi^2 (1 + c_a^2 f_x^2) d\xi. \tag{2.5}$$

The Euler–Lagrange equations to the functionals (2.4) and (2.5) are similar, and

$$x_\xi \sqrt{1 + c_a^2 f_x^2} = \text{const}. \tag{2.6}$$

3. Approximation of a functional. We consider a piecewise bilinear mapping of the unit square $i \le \xi \le i+1$, $j \le \eta \le j+1$ in the parametric plane ξ-η onto a quadrilateral grid cell in plane x-y formed by nodes with coordinates $(x, y)_{i,j}$, $(x, y)_{i+1,j}$, $(x, y)_{i+1,j+1}$, $(x, y)_{i,j+1}$ numbered from 1 to 4 in an anticlockwise manner, where i, j are positive integers. The functional (2.3) is approximated in such a way that its minimum is attained on a grid of convex quadrilaterals, referred to as a convex grid [12, 24],

$$I^h = \sum_{i=1}^{i_{\max}} \sum_{k=1}^{4} \frac{1}{4} \left[F_k\right]_i, \tag{3.1}$$

where F_k is the integrand evaluated in the kth corner of the ith cell. If the set of convex meshes is not empty, the system of algebraic equations written to every interior node (here i is a global node number)

$$R_x = \frac{\partial I^h}{\partial x_i} = 0, \quad R_y = \frac{\partial I^h}{\partial y_i} = 0, \tag{3.2}$$

has at least one solution that is a convex mesh. To find it one should have an initial convex mesh and then use a method of unconstrained minimization [4, 12, 24]. It has been shown [11, 12, 24] when generating a curvilinear mesh without adaptation in an arbitrary simply connected domain Ω in plane x-y that the discrete functional (3.1) (if no adaptation, then in (2.3) we define $f_x = f_y = 0$) has an infinite barrier on the boundary of the set of convex grids; see Figure 2. This is caused by the condition of positiveness to the Jacobian of the mapping $J = x_\xi y_\eta - x_\eta y_\xi$ in (2.3). Should the vertexes of some cell be displaced so that the cell becomes nearly nonconvex (see Figure 2(b)), then one of four triangles, into which the cell is divided by its two diagonals, degenerates; its area, equal to $0.5J$, tends to zero and, therefore, $I^h \to \infty$. The infinite barrier holds in the case of adaptive grid generation as well as when the control function $f \in C^1(\Omega)$ since the values f_x, f_y under the square root in (2.3) are bounded everywhere in Ω. When starting from an initial convex mesh, due to the infinite barrier every step of the minimization procedure can be chosen so that the mesh always remains convex. However, if f is of the class of discontinuous functions, what we generally have in hyperbolic problems of gas dynamics, in the vicinity of a

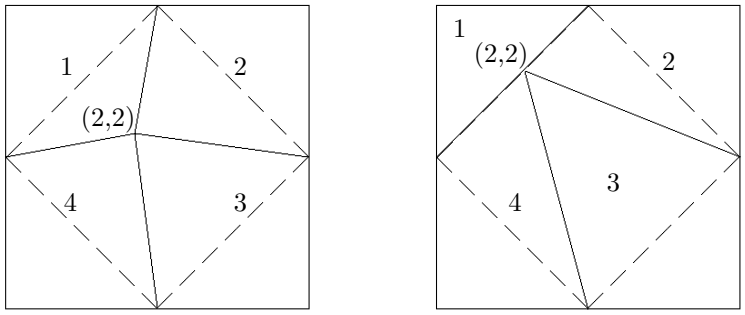

FIG. 2. *When minimizing the discrete functional I^h there is an infinite barrier preventing the cells from folding. The mesh shown consists of four cells. At minimization only the node $(2,2)$ moves. Dashed lines indicate the domain inside which the node $(2,2)$ shall be placed so that all four cells are convex* (a). *If this node approaches the dashed line* (b), *one* (*right*) *of two triangles, into which cell* 1 *is divided by the diagonal, degenerates, its area tends to zero, and, therefore, $I^h \to \infty$.*

discontinuity the derivatives f_x, f_y become unbounded, is that the the infinite barrier disappears and this causes some grid cells to fold and the modeling to break. In order to prevent grid lines overlapping, we use the procedure of regularization to the discrete functional described in section 5.

We make use of the rectangular rule to compute the 1-D functional (2.4)

$$I^h = \sum_{i=1}^{i_{\max}} \frac{\triangle\xi}{(x_\xi)_{i+1/2}\sqrt{1 + c_a^2 (f_x)_{i+1/2}^2}}, \tag{3.3}$$

where $i_{\max}$ is the number of spacings and the derivatives are computed via

$$(x_\xi)_{i+1/2} = (x_{i+1} - x_i)/\triangle\xi, \quad (f_x)_{i+1/2} = (f_{i+1} - f_i)/(x_{i+1} - x_i). \tag{3.4}$$

4. Three-point model of adaptation. In this section we demonstrate that when solving the Cauchy problem for the nonlinear advection equation under some conditions the values of the discrete function in the cells of the moving mesh remain invariable. Then the problem of constructing an adaptive mesh can be considered separately from the basic problem as if using an analytical control function. This allows us to analyze some properties of the discrete functional which also hold in the general case of computing a real flow with discontinuities.

Consider a 1-D adaptive mesh generation when solving the IVP to the nonlinear advection equation with discontinuous initial data when the shock moves from the left to the right:

$$\frac{\partial u}{\partial t} + u\frac{\partial u}{\partial x} = 0, \quad u(x,0) = \begin{cases} u_l & \text{if} \quad x < 0, \\ u_r & \text{if} \quad x \geq 0, \end{cases} \qquad u_l > u_r > 0. \tag{4.1}$$

We use the integral equation

$$\oint_C u\,dx - \frac{1}{2}u^2 dt = 0, \tag{4.2}$$

which in case of a smooth solution is equivalent to the above differential equation, and a discontinuous solution is governed by it as well. Here the contour C is the boundary of an arbitrary domain in plane x-t.

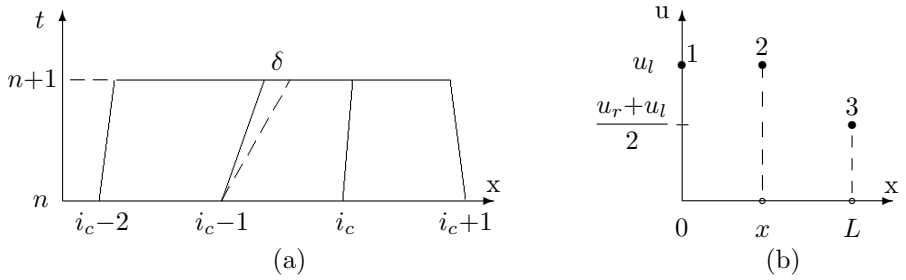

FIG. 3. *Moving grid* (a); i_c *is a center of the shock smeared. If the mesh moves with the speed of shock* $w = 0.5(u_r + u_l)$ *and the number of intervals* $i_{\max}$ *is even, then the updated value* $u^{i+1/2}$ *does not change. Three-point model of adaptation* (b); *in the coordinate system moving with the speed of shock* w, $x_1 = 0$ *and* $x_3 = L$ *are the coordinates of the fixed boundary nodes,* $x_2 = x$ *is a moving node.*

In plane x-t we introduce the moving grid (see Figure 3(a)) with spacings at the nth time level $h_{i+1/2} = x^n_{i+1} - x^n_i$ and at the $n+1$st level $h^{i+1/2} = x^{n+1}_{i+1} - x^{n+1}_i$ and time step $\triangle t = t^{n+1} - t^n$, where n, i are integers. Let at t^n the cell-average values of the discrete function $u_{i+1/2}$ be defined in the center of intervals. To update the values $u^{i+1/2}$ at time t^{n+1} we use the Godunov scheme on the moving grid [20, 19]. This scheme can be obtained if we integrate (4.2) along the contour C being the boundary of the computing cell

$$u^{i+1/2}h^{i+1/2} - u_{i+1/2}h_{i+1/2} - u_{i+1}h_{i+1} + h_i u_i + \frac{\triangle t}{2}\left[(u_{i+1})^2 - (u_i)^2\right] = 0, \tag{4.3}$$

where $h_i = x^{n+1}_i - x^n_i$. In order to determine a flux through the intercell boundary $[x^n_i, x^{n+1}_i]$ we need the value u_i on it, which is defined via the condition across the discontinuity

$$u_i = \begin{cases} u_{i-1/2} & \text{if } h_i/\triangle t < 0.5(u_{i-1/2} + u_{i+1/2}), \\ u_{i+1/2} & \text{otherwise.} \end{cases}$$

The above condition takes into account the inclinations of the straight-line characteristic $dx/dt = 0.5(u_{i-1/2} + u_{i+1/2})$ at the point x^n_i and the slanted boundary of the cell $[x^n_i, x^{n+1}_i]$ defined as $h_i/\triangle t$. If the ith node moves faster than perturbations from this node, then we set $u_i = u_{i+1/2}$, and if vice versa, then $u_i = u_{i-1/2}$.

From (4.3) we get the values at t^{n+1}

$$u^{i+1/2} = \frac{1}{h^{i+1/2}}\left\{u_{i+1/2}h_{i+1/2} - \frac{\triangle t}{2}\left[(u_{i+1})^2 - (u_i)^2\right] - u_i h_i + u_{i+1}h_{i+1}\right\}. \tag{4.4}$$

THEOREM 4.1. *Let, without adaptation, the grid nodes move with the speed of shock* $w = 0.5(u_r + u_l)$. *Suppose at time* t^n *the values* $u_{i+1/2} = u_l$ *if* $i < i_c$ *and* $u_{i+1/2} = u_r$ *if* $i \geq i_c$, *where* i_c *is a node that is the center of the shock smeared and the midmesh node, i.e.,* $i_c = 0.5i_{\max} + 1$, *where* $i_{\max}$ *is an even number of intervals. Then the updated values* $u^{i+1/2}$ *do not change.*

Proof. First, note that the problem is symmetrical about the i_cth node. This node moves with the velocity w. Consider the interval $(i_c - 1, i_c)$; see Figure 3(a). Let at time t^{n+1} the $i_c - 1$st node shift by δ from the position

$$x^{n+1}_{i_c-1} = x^n_{i_c-1} + w\triangle t,$$

where it would be if there were no adaptation. Denote $h_{i_c-1/2} = h$; then $h^{i_c-1/2} = h - \delta$. Observing that projections of the cell lateral edges onto x are $h_{i_c} = w\triangle t$, $h_{i_c-1} = w\triangle t + \delta$, and defining the intercell values from the condition across the discontinuity as $u_{i_c-1} = u_l$ and $u_{i_c} = u_r$, we get from (4.4) that

$$u^{i_c-1/2} = \frac{1}{h-\delta}\left[u_l h - \frac{\triangle t}{2}\left(u_r^2 - u_l^2\right) - (w\triangle t + \delta)u_l + u_r w\triangle t\right]$$
$$= \frac{1}{h-\delta}\left[u_l h - \frac{\triangle t}{2}\left(u_r + u_l\right)\left(u_r - u_l\right) + w\triangle t\left(u_r - u_l\right) - \delta u_l\right] = u_l.$$

A similar result holds if $u_{i_c} = u_l$. □

Consequently, when constructing the adaptive mesh we need not solve the IVP (4.1) and can merely set the values equal u_l in the cells to the left of the i_cth point and u_r to the right.

We shall construct the adaptive mesh minimizing the functional (3.3) and using u as a control function. We can simplify the model considering the left half of the mesh consisting of three points, i.e., when $i_c = 3$. Such an assumption does not change the mesh structure. The general case can be easily obtained from this three-point model. We pass into the new coordinate system moving with the velocity w so that $x_1 = 0$; see Figure 3(b). Then, when adapting, 1 and 3 are the fixed boundary nodes and $x_3 = L$, where $L = 2h$, h is a spacing of the initial uniform mesh, and coordinate x_2 is variable, referred to further as x. We also have $u_1 = u_2 = u_l$, $u_3 = (u_l + u_r)/2$.
